WEAK CONVERGENCE OF INTEGRANDS AND THE YOUNG MEASURE REPRESENTATION*

DAVID KINDERLEHRER† AND PABLO PEDREGAL‡

Abstract. Validity of the Young measure representation is useful in the study of microstructure of ordered solids. Such a Young measure, generated by a minimizing sequence of gradients converging weakly in L^p, often needs to be evaluated on functions of the pth power polynomial growth. A sufficient condition for this evaluation is given in terms of the variational principle. The principal result, Theorem 2.1, concerns lower semicontinuity of functionals integrated over arbitrary sets. The question arose in the numerical analysis of equilibrium configurations of crystals with rapidly varying microstructure, whose specific application is treated elsewhere. Several applications are given. Of particular note, Young measure solutions of an evolution problem are found.

Key words. weak convergence, lower semicontinuity, Young measure, calculus of variations

1. Introduction.

For a lower semicontinuous functional of the form[1]

$$\Phi(v)=\int_\Omega \varphi(\nabla v)\,dx, \qquad v\in H^{1,p}(\Omega;\mathbb{R}^m),$$

the convergence property

$$\Phi(u^k)\to\Phi(u) \quad \text{and} \quad u^k\to u \quad \text{in } H^{1,p}(\Omega;\mathbb{R}^m) \text{ weakly}$$

for a particular sequence (u^k) does not by itself inform us of the behavior of the sequence $(\varphi(\nabla u^k))$. Here we show that if φ is nonnegative and has polynomial growth, then $(\varphi(\nabla u^k))$ is weakly convergent in $L^1(\Omega)$ to $\varphi(\nabla u)$. A consequence is that the Young measure generated by (∇u^k) represents the weak limit of a sequence $(\psi(\nabla u^k))$ when ψ is dominated by φ, which we explain below. Our interest in this question arose in the attempt to estimate convergence properties of numerical methods for functionals which are not lower semicontinuous, where φ plays the role of the relaxed density. Validity of the Young measure representation is useful knowledge in the study of the microstructure of ordered solids; cf. Ball and James [5], [6], Chipot and Kinderlehrer [10], Ericksen [18]-[29], Fonseca [31]-[34], James [35], James and Kinderlehrer [36], Kinderlehrer [37], Kinderlehrer and Pedregal [38], Matos [41], and Pedregal [45], [46]. We do not give any explicit applications to the numerical analysis in this paper except to say that our results confirm the validity of the Young measure representation for the limits of the approximations generated by finite element methods when the energy density has appropriate polynomial growth at infinity. We refer to [9], [11]-[14] for discussions of these developments.

The proof of this and related facts is based on a method of Acerbi and Fusco [1] and subsequent application of the Dunford and Pettis criterion for weak convergence

in L^1. Weak convergence of a sequence (f^k) in L^1 is sufficient but not necessary to give sense to the Young measure representation. Ball and Zhang [8] use the Chacon biting lemma to study this question under hypotheses weaker than ours.

The proofs of our results are in §§ 1-3. Three applications are given in §§ 4-6. The example of constraint management in § 4 is a generalization of a result of Müller [44]; cf. also Zhang [51]. In § 5 we give a discussion of the Young measure representation when surface energies are present in the system; cf. [39]. Both of these applications use the convergence property above, or (1.3) below, without assuming that the functional is being driven to a minimum. An application to an evolution problem is given in § 6, where it is shown how Young measure solutions may be found. This builds on some recent work of Slemrod [47]. Useful discussions of Young measures are given by Young [50] and Tartar [48], [49], and more recently by Ball [3] and Evans [30]. One consequence of our considerations is that they lead to a notion of Young measures generated by functions whose gradients are in L^p for finite p [45]. We begin with a description of our principal results. Below, $\mathbb{M}$ denotes the $m\times n$ matrices.

THEOREM 1.1. *Let φ be continuous and quasi-convex and satisfy*

$$0\leqq \varphi(A)\leqq C(1+|A|^p), \qquad A\in\mathbb{M}, \tag{1.1}$$

where $1\leqq p\leqq\infty$. Suppose that

$$u^k\to u \quad \textit{in } H^{1,p}(\Omega) \textit{ weakly and} \tag{1.2}$$

$$\int_\Omega \varphi(\nabla u)\,dx=\lim_{k\to\infty}\int_\Omega \varphi(\nabla u)\,dx. \tag{1.3}$$

Then there is a subsequence (not relabeled) of the (u^k) such that

$$\varphi(\nabla u^k)\to\varphi(\nabla u) \quad \textit{in } L^1(\Omega) \textit{ weakly.}$$

THEOREM 1.2. *Let φ be continuous and quasi-convex and satisfy*

$$0\leqq \varphi(A)\leqq C(1+|A|^p), \qquad A\in\mathbb{M},$$

where $1\leqq p\leqq\infty$. If $u^k\to u$ in $H^{1,p}(\Omega)$ weakly, then

$$\int_E \varphi(\nabla u)\,dx\leqq\liminf_{k\to\infty}\int_E \varphi(\nabla u^k)\,dx \tag{1.4}$$

for every (measurable) $E\subset\Omega$.

We wish to discuss Theorem 1.2 briefly, prior to giving the proof. We shall give a direct proof based on the method of Acerbi and Fusco [1]. This will provide both an efficient self-contained proof and will expose the limitations of the method.

The case of Theorem 1.2 with $p=\infty$ is automatic since $\{\varphi(\nabla u^k)\}$ are uniformly bounded in this case. Indeed, choose M with the property

$$\|\varphi(\nabla u^k)\|_{L^\infty(\Omega)}\leqq M \quad \text{for all } k.$$

Given E, let U be an open neighborhood of E with $|U-E|<\varepsilon$. Now U is the union of countably many cubes $\{D_j\}$ with disjoint interiors and for each D_j, (1.4) holds [15], [16], [45]. Hence

$$\begin{aligned}\int_U \varphi(\nabla u)\,dx&\leqq\sum\int_{D_j}\varphi(\nabla u)\,dx\\&\leqq\sum\liminf\int_{D_j}\varphi(\nabla u^k)\,dx\\&\leqq\liminf\int_U\varphi(\nabla u^k)\,dx.\end{aligned}$$

Finally, we have that

$$\int_E \varphi(\nabla u)\,dx \leqq \liminf \int_E \varphi(\nabla u^k)\,dx + 2M\varepsilon.$$

Thus, if $u_k \to u$ in $H^{1,\infty}(\Omega)$ weak*, then

$$\int_E \varphi(\nabla u)\,dx \leqq \liminf \int_E \varphi(\nabla u^k)\,dx \tag{1.5}$$

for any measurable $E \subset \Omega$.

The case $p=1$ for Theorems 1.1 and 1.2 is easy and will not be discussed.

To illustrate how the preceding results apply to the Young measure representation, let us recall this notion. Let $C_0(\mathbb{R}^m)$ denote the continuous functions on $\mathbb{R}^m$ vanishing at ∞. Given a sequence $f^k \in L^1(\Omega; \mathbb{R}^m)$, $k = 1, 2, 3, \cdots$, for any $\psi \in C_0(\mathbb{R}^m)$, the composed sequence $(\psi(f^k))$ admits a subsequence weak* convergent in $L^\infty(\Omega)$; namely, for some $\bar{\psi} \in L^\infty(\Omega)$,

$$\psi(f^{k'}) \to \bar{\psi} \quad \text{in } L^\infty(\Omega) \text{ weak*}.$$

The association of ψ to $\bar{\psi}$ is linear, which, after some argument (cf. [3]) employing the boundedness in L^1 of the sequence (f^k), permits us to assert the existence of a family $\nu = (\nu_x)_{x \in \Omega}$ of probability measures with the property that

$$\bar{\psi}(x) = \int_{\mathbb{R}^m} \psi(\lambda)\,d\nu_x(\lambda) \quad \text{in } \Omega \text{ a.e.}$$

For the validity of the representation it is sufficient that

$$\psi(f^{k'}) \to \bar{\psi} \quad \text{in } L^1(\Omega) \text{ weakly.} \tag{1.6}$$

The family ν is the Young measure or parametrized measure generated by $(f^{k'})$; cf. Young [50].

If $f^k \in L^p(\Omega; \mathbb{R}^m)$, $k = 1, 2, 3, \cdots$, satisfy

$$\|f^k\|_{L^p(\mathbb{R}^n)} \leqq C$$

and generate a Young measure $\nu = (\nu_x)_{x \in \Omega}$, it may be verified that whenever $\psi \in C(\mathbb{R}^m)$ satisfies

$$\lim_{|\lambda| \to \infty} \frac{|\psi(\lambda)|}{1 + |\lambda|^p} = 0,$$

the sequence $\psi(f^k)$ converges weakly in L^1 and the representation (1.6) is valid. When $f^k = \nabla u^k$ arises as a minimizing sequence in a variational principle for φ satisfying (1.7) or W satisfying (1.12) below, it is less than obvious that we are entitled to use the Young measure to evaluate the limit energy or other integrals of (∇u^k) with exactly pth power growth. Our results, Theorem 1.3 and Corollary 1.4, affirm the validity of the Young measure representation:

Introduce the Banach space, for $p \geqq 1$ fixed,

$$E = \left\{ \psi \in C(\mathbb{M}) \colon \sup_{\mathbb{M}} \frac{|\psi(A)|}{|A|^p + 1} < \infty \right\}.$$

THEOREM 1.3. *Let φ be quasi-convex and satisfy, for some constants $C \geqq c > 0$,*

$$\max\{c|A|^p - 1, 0\} \leqq \varphi(A) \leqq C(1 + |A|^p), \qquad A \in \mathbb{M}, \tag{1.7}$$

where $1 \leqq p < \infty$. *Suppose that*

$$u^k \to u \quad in\ H^{1,p}(\Omega)\ weakly\ and \tag{1.8}$$

$$\int_\Omega \varphi(\nabla u)\,dx = \lim_{k\to\infty} \int_\Omega \varphi(\nabla u^k)\,dx. \tag{1.9}$$

Let $\nu = (\nu_x)_{x\in\Omega}$ *be a Young measure generated by* (∇u^k). *Then for any* $\psi \in E$, *the sequence*

$$\psi(\nabla u^k) \to \bar{\psi} \quad in\ \sigma(L^1(\Omega), L^\infty(\Omega)),$$

where

$$\bar{\psi}(x) = \int_{\mathbb{M}} \psi(A)\,d\nu_x(A) \quad in\ \Omega\ a.e. \tag{1.10}$$

Further, consider $W \in C(\mathbb{M})$ satisfying

$$\max\{c|A|^p - 1, 0\} \leqq W(A) \leqq C(1+|A|^p), \qquad A \in \mathbb{M}, \tag{1.11}$$

for some $p \geqq 1$ and $0 < c \leqq C$. Let

$$A_\Omega(y_0) = \{v \in H^{1,p}(\Omega)\colon v = y_0 \text{ on } \partial\Omega\}, \quad \text{where } y_0 \in H^{1,p}(\Omega).$$

COROLLARY 1.4. *Let* W *satisfy* (1.11). *Suppose that* $(u^k) \subset A_\Omega(y_0)$ *satisfies*

$$\lim_{k\to\infty} \int_\Omega W(\nabla u^k)\,dx = \inf_{A_\Omega(y_0)} \int_\Omega W(\nabla v)\,dx, \tag{1.12a}$$

$$u^k \to u \quad in\ H^{1,p}(\Omega)\ weakly. \tag{1.12b}$$

Let $\nu = (\nu_x)_{x\in\Omega}$ *be a Young measure generated by* (u^k). *Then for any* $\psi \in E$, *the sequence*

$$\psi(\nabla u^k) \to \bar{\psi}\ in\ \sigma(L^1(\Omega), L^\infty(\Omega)),$$

where

$$\bar{\psi}(x) = \int_{\mathbb{M}} \psi(A)\,d\nu_x(A) \quad in\ \Omega\ a.e. \tag{1.13}$$

In particular, the $(W(\nabla u^k))$ *converges to a limit energy density* $\bar{W}$ *in* $\sigma(L^1(\Omega), L^\infty(\Omega))$ *where*

$$\bar{W}(x) = \int_{\mathbb{M}} W(A)\,d\nu_x(A) \quad in\ \Omega\ a.e. \tag{1.14}$$

Note above that if $p = 1$, we are not assured of a sequence (u^k) satisfying the hypothesis (1.12b). A version of Corollary 1.4 has also been proved independently by Matos [42] who obtains an improved class E by combining Ekeland's lemma with the reverse Hölder inequality, although the convergence is then restricted to $\sigma(L^1(\Omega'), L^\infty(\Omega'))$ for $\Omega' \subset\subset \Omega$.

Note that a particular consequence of Theorem 1.3 is that the sequence $\{|M \cdot \nabla u_k|^p\}$, for a constant matrix M, converges weakly in $L^1(\Omega)$, although not to $|M \cdot \nabla u|^p$. Another consequence concerns the relaxation of W, or its quasi convexification; cf. [7], [15], [16], for example. Assume that $p > 1$. The integrand

$$W^{\#}(F) = \inf_{H_0^{1,\infty}(\Omega)} \frac{1}{|\Omega|} \int_\Omega W(F + \nabla\zeta)\,dx \tag{1.15}$$

is quasi-convex and relaxes the variational principle (1.8) in the sense that

$$\inf_{A_\Omega(y_0)} \int_\Omega W(\nabla v)\,dx = \inf_{A_\Omega(y_0)} \int_\Omega W^{\#}(\nabla v)\,dx.$$

Obviously a minimizing sequence for (1.12) is also a minimizing sequence for the functional with the integrand $W^{\#}$. For a given F, the infimum in (1.15) may or may not be realized, but given a minimizing sequence $u^k(x) = Fx + \zeta^k(x) \in H^{1,p}(\Omega; \mathbb{R}^m)$,

$$W^{\#}(F)|\Omega| = \lim_{k\to\infty} \int_\Omega W(\nabla u^k)\, dx.$$

Let $\mu = (\mu_x)_{x\in\Omega}$ be a Young measure generated by (u^k). We may assume that μ_x is independent of $x \in \Omega$, although we pass over the details of that here. Applying Corollary 1.4, we obtain in particular that

$$W^{\#}(F) = \int_{\mathbb{M}} W(A)\, d\mu(A), \tag{1.16}$$

so the infimum is attained in a Young measure fashion. Moreover, the inequality $W^{\#} \leqq W$ ensures that

$$\operatorname{supp} \mu \subset \{A\colon W(A) = W^{\#}(A)\}.$$

Of course, if σ is any other Young measure generated by some sequence of the form $(v^k) \subset H^{1,p}(\Omega, \mathbb{R}^m)$ with $v^k = Fx$ on $\partial\Omega$, then

$$\int_{\mathbb{M}} W(A)\, d\mu(A) \leqq \int_{\mathbb{M}} W(A)\, d\sigma(A),$$

so μ satisfies an ersatz minimizing principle as well.

2. Proof of Theorem 1.2. Our aim is to give a proof of the second result. Theorem 1.1 will be a corollary of it. For this we adopt a technique of Acerbi and Fusco, which has an important ingredient from a paper of F.-C. Liu [40]. The technique uses these facts from Acerbi and Fusco.

LEMMA 2.1. *Let $G \subset \mathbb{R}^n$ have $|G| < \infty$. Assume that $\{M_k\}$ is a sequence of subsets of G such that for some $\varepsilon > 0$*

$$|M_k| > \varepsilon \quad \textit{for all } k.$$

Then there is a subsequence k_j for which

$$\bigcap M_{k_j} \neq \varnothing.$$

LEMMA 2.2. *Let $\{f_k\}$ be a sequence bounded in $L^1(\Omega)$. Then for each $\varepsilon > 0$, there is a triple $(A_\varepsilon, \delta, S)$, where $A_\varepsilon \subset \Omega$ with $|A_\varepsilon| < \varepsilon$, $\delta > 0$, and S is an infinite subset of the natural numbers, such that*

$$\int_D |f_k|\, dx < \varepsilon$$

whenever $D \cap A_\varepsilon = \varnothing$ and $|D| < \delta$ for all $k \in S$.

For any $v \in C_0^\infty(\mathbb{R}^n)$, we set

$$M^*v(x) = M(|v(x)|) + M(|\nabla v(x)|),$$

where

$$Mf(x) = \sup_{r>0} \frac{1}{|B_r|} \int_{B_r(x)} |f(z)|\, dz$$

is the maximal function of f. It is well known that if $v \in C_0^\infty(\mathbb{R}^n)$, then $M^*v \in C(\mathbb{R}^n)$ and

$$\|M^*v\|_{L^p(\mathbb{R}^n)} \leqq C(n, p)\|v\|_{H^{1,p}(\mathbb{R}^n)}, \qquad 1 < p \leqq \infty, \tag{2.1}$$

and, in particular, for any $\lambda > 0$,

$$|\{M^*v \geqq \lambda\}| \leqq C(n,p)\lambda^{-p}\|v\|^p_{H^{1,p}(\mathbb{R}^n)}, \qquad 1<p<\infty. \tag{2.2}$$

LEMMA 2.3. *Let* $v \in C_0^\infty(\mathbb{R}^n)$ *and* $\lambda > 0$. *Set* $H^\lambda = \{M^*v < \lambda\}$. *Then*

$$\frac{|v(x)-v(y)|}{|x-y|} \leqq C(n)\lambda, \qquad x, y \in H^\lambda, \tag{2.3}$$

where $C(n)$ *depends only on* n.

We shall also make use of the well-known fact that a Lipschitz function defined on a subset of $\mathbb{R}^n$ may be extended to all of $\mathbb{R}^n$ without increasing its Lipschitz constant.

Proof of Theorem 1.2. We regard u^k and u as extended to functions in $H^{1,p}(\mathbb{R}^n)$ with norms controlled by their $H^{1,p}(\Omega)$ norms. Let $\varepsilon > 0$.

Step 1. Since the functional of (1.4) is continuous in $H^{1,p}(\mathbb{R}^n)$ in the norm topology, because of the upper bound on φ, we may find $z, z^k \in C_0^\infty(\mathbb{R}^n)$ with

$$\int_{\mathbb{R}^n} |\varphi(\nabla u) - \varphi(\nabla z)|\, dx < \varepsilon, \tag{2.4}$$

$$\int_{\mathbb{R}^n} |\varphi(\nabla u^k) - \varphi(\nabla z + \nabla z^k)|\, dx < \varepsilon, \tag{2.5}$$

and

$$\|u - u^k - z^k\|_{H^{1,p}(\mathbb{R}^n)} < \frac{1}{k}.$$

Thus $z^k \to 0$ in $H^{1,p}(\mathbb{R}^n)$ weakly and

$$\|z^k\|_{H^{1,p}(\mathbb{R}^n)} \leqq M < \infty. \tag{2.6}$$

Set

$$H^\lambda = \{M^*z < \lambda\} \quad \text{and} \quad H_k^\lambda = \{M^*z^k < \lambda\}.$$

According to Lemma 2.3, we may find ζ^k, $\eta \in H^{1,\infty}(\mathbb{R}^n)$ such that $\zeta^k = z^k$ on H_k^λ and $\eta = z$ on H^λ with

$$\|\nabla \zeta^k\|_{L^\infty(\mathbb{R}^n)} \leqq \|\nabla z^k\|_{L^\infty(H_k^\lambda)} \leqq \lambda$$

and

$$\|\zeta^k\|_{H^{1,\infty}(\mathbb{R}^n)} \leqq C(n)\lambda,$$

and the same for η. After extraction of a subsequence we may suppose that

$$\zeta^k \to \zeta \quad \text{in } H^{1,\infty}(\mathbb{R}^n) \text{ weak*}.$$

We apply Lemma 2.2 to the sequence $\{M^*(z^k)^p\}$. By (1.2) and (2.1) these functions are bounded in $L^1(\Omega)$. So, given $\varepsilon' > 0$, there is a triple $(A_{\varepsilon'}, \delta, S)$ with $|A_{\varepsilon'}| < \varepsilon'$ and

$$\int_D M^*(z^k)^p\, dx < \varepsilon'$$

whenever $D \cap A_{\varepsilon'} = \varnothing$ with $|D| < \delta$ and $k \in S$.

Now let $G = \{\zeta \neq 0\}$. Since the $z^k \to 0$ in $L^p(\mathbb{R}^n)$ in norm, we may assume that $z^k \to 0$ pointwise almost everywhere in Ω. Thus if we set $G_0 = G \backslash \{x \in \Omega\colon z^k(x) \to 0\}$, then $|G_0| = |G|$. We write G_0 as a union,

$$G_0 = (G_0 \cap H_k^\lambda) \cup (G_0 \cap (\mathbb{R}^n - H_k^\lambda)).$$

By (2.2),

$$|G_0 \cap (\mathbb{R}^n - H_k^\lambda)| \leqq C\lambda^{-p}M^p \quad \text{for all } k. \tag{2.7}$$

This implies that

$$|G_0| = |G| \leqq 2C\lambda^{-p}M^p. \tag{2.8}$$

Otherwise, if

$$|G_0| > 2C\lambda^{-p}M^p,$$

then

$$|G_0 \cap H_k^\lambda| > C\lambda^{-p}M^p,$$

by (2.7). Applying Lemma 2.1, there would be a subsequence k_j such that

$$G_0 \cap \left(\bigcap H_{k_j}^\lambda\right) \neq \varnothing,$$

and for x in this intersection,

$$\zeta(x) = \lim \zeta^k(x) = \lim z^k(x) = 0,$$

which contradicts the definition of the set G. Hence (2.8) holds.

Step 2. Since $\varphi(\nabla u) \in L^1(\Omega)$, we may find $\sigma, 0 < \sigma < \varepsilon$, and λ large enough that

$$\int_{A_\sigma \cup (\Omega - H^\lambda) \cup G} \varphi(\nabla u)\, dx < \varepsilon; \tag{2.9}$$

cf. (2.8) above. Let $E \subset \Omega$ be measurable and assume a subsequence of the u^k chosen (but not relabeled) so that

$$\lim \int_E \varphi(\nabla u^k)\, dx = \liminf \int_E \varphi(\nabla u^k)\, dx.$$

Put

$$\alpha_k = \int_E \varphi(\nabla u^k)\, dx.$$

Since $\varphi \geqq 0$, by (2.5)

$$\begin{aligned} \alpha_k &\geqq \int_{E \cap H^\lambda \cap H^{\lambda,k} \cap (\Omega - A_\sigma)} \varphi(\nabla u^k)\, dx \\ &\geqq -\varepsilon + \int_{E \cap H^\lambda \cap H^{\lambda,k} \cap (\Omega - A_\sigma)} \varphi(\nabla z + \nabla z^k)\, dx. \end{aligned}$$

But $\nabla z = \nabla \eta$ and $\nabla z^k = \nabla \zeta^k$ in $H^\lambda \cap H^{\lambda,k}$ so that

$$\begin{aligned} \alpha_k &\geqq -\varepsilon + \int_{E \cap H^\lambda \cap H^{\lambda,k} \cap (\Omega - A_\sigma)} \varphi(\nabla \eta + \nabla \zeta^k)\, dx \\ &= -\varepsilon + \int_{E \cap H^\lambda \cap (\Omega - A_\sigma)} \varphi(\nabla \eta + \nabla \zeta^k)\, dx \\ &\quad - \int_{E \cap H^\lambda \cap (\Omega - H^{\lambda,k}) \cap (\Omega - A_\sigma)} \varphi(\nabla \eta + \nabla \zeta^k)\, dx \\ &= -\varepsilon + \beta_k - \gamma_k. \end{aligned}$$

Since $\nabla(\eta+\zeta^k)$ is uniformly bounded and φ is quasi-convex, by the remark (1.5) we have that for K sufficiently large

$$\beta_k+\varepsilon \geqq \int_{E\cap H^\lambda\cap(\Omega-A_\sigma)} \varphi(\nabla\eta+\nabla\zeta)\,dx.$$

We now inspect γ_k. Using the bounds on $\nabla\eta$ and $\nabla\zeta^k$, and choosing λ large enough,

$$\begin{aligned}\gamma_k &\leqq C(1+\lambda^p)|(\Omega-H^\lambda_k)\cap(\Omega-A_\sigma)|\\ &\leqq C|\Omega-H^\lambda_k|+\int_{(\Omega-H^{\lambda,k})\cap(\Omega-A_\sigma)} CM^*(z^k)^p\,dx\\ &\leqq C\varepsilon+C\sigma\leqq 2C\varepsilon.\end{aligned}$$

Consequently, for k sufficiently large,

$$\alpha_k\geqq -C\varepsilon+\int_{E\cap H^\lambda\cap(\Omega-A_\sigma)} \varphi(\nabla\eta+\nabla\zeta)\,dx. \tag{2.10}$$

Step 3. Again using the positivity of φ, from (2.10),

$$\alpha_k\geqq -C\varepsilon+\int_{E\cap H^\lambda\cap(\Omega-A_\sigma)\cap(\Omega-G)} \varphi(\nabla\eta+\nabla\zeta)\,dx.$$

Since $\zeta=0$ in $\Omega-G$, we have that $\nabla\zeta=0$ in $\Omega-G$, so, since $\eta=z$ in H^λ, we deduce that

$$\begin{aligned}\alpha_k &\geqq -C\varepsilon+\int_{E\cap H^\lambda\cap(\Omega-A_\sigma)\cap(\Omega-G)} \varphi(\nabla\eta)\,dx\\ &\geqq -C\varepsilon+\int_{E\cap H^\lambda\cap(\Omega-A_\sigma)\cap(\Omega-G)} \varphi(\nabla z)\,dx.\end{aligned}$$

By (2.4) and (2.9),

$$\begin{aligned}\alpha_k &\geqq -(1+C)\varepsilon+\int_{E\cap H^\lambda\cap(\Omega-A_\sigma)\cap(\Omega-G)} \varphi(\nabla u)\,dx\\ &\geqq -(1+C)\varepsilon+\int_E \varphi(\nabla u)\,dx-\int_{E\cap[A_\sigma\cup(\Omega-H^\lambda)\cup G]} \varphi(\nabla u)\,dx\\ &\geqq -(2+C)\varepsilon+\int_E \varphi(\nabla u)\,dx.\end{aligned}$$

Since $\varepsilon>0$ is arbitrary, the theorem is proved.

3. Proofs of the other results.

Proof of Theorem 1.1. This follows from the Dunford-Pettis criterion. Assume that the sequence $(\varphi(\nabla u^k))$ is not $\sigma(L^1, L^\infty)$ relatively compact. Then for some $\varepsilon>0$ and every $\delta>0$, there is an $A_\delta\subset\Omega$ and an integer k_δ such that $|A_\delta|<\delta$ and

$$\int_{A_\delta} \varphi(\nabla u^{k_\delta})\,dx>\varepsilon.$$

Since $\varphi(\nabla u)\in L^1(\Omega)$, there is a $\delta_0>0$ such that if $|E|<\delta_0$, then

$$\int_E \varphi(\nabla u)\,dx<\varepsilon. \tag{3.1}$$

Let us choose in particular $\delta_j = 2^{-j}\delta_0$. Then there is a sequence A_j, $|A_j| < \delta_j$, and k_j such that

$$\int_{A_j} \varphi(\nabla u^{k_j})\, dx > \varepsilon \quad \text{for all } j.$$

Let $E = \bigcup A_j$, so $|E| \leqq \delta_0$ and (3.1) holds. Thus

$$\varepsilon \leqq \int_E \varphi(\nabla u^{k_j})\, dx \leqq \int_\Omega \varphi(\nabla u^{k_j})\, dx - \int_{\Omega - E} \varphi(\nabla u^{k_j})\, dx.$$

Letting $k_j \to \infty$, we have by Theorem 1.2 and the hypothesis (1.3) that

$$\begin{aligned} \varepsilon &\leqq \int_\Omega \varphi(\nabla u)\, dx - \int_{\Omega - E} \varphi(\nabla u)\, dx \\ &= \int_E \varphi(\nabla u)\, dx < \varepsilon, \end{aligned}$$

a contradiction.

Proof of Theorem 1.3. The proof of Theorem 1.3 also follows by the Dunford–Pettis criterion, using Theorem 1.1.

Proof of Corollary 1.4. A minimizing sequence for the functional

$$\int_\Omega W(\nabla v)\, dx$$

is also a minimizing sequence for its relaxation

$$\int_\Omega W^{\#}(\nabla v)\, dx$$

whose integrand $W^{\#}$ is quasi-convex and satisfies (1.11). We apply Theorem 1.3 to $W^{\#}$.

4. Constraint management in a limit case. Certain variational principles in elasticity constrain the admissible variations $v \in H^{1,p}(\Omega; \mathbb{R}^n)$, where $\Omega \subset \mathbb{R}^n$, to satisfy

$$\det \nabla v > 0 \quad \text{in } \Omega \text{ a.e.}$$

In the limit case $p = n$, $\det \nabla v \in L^1(\Omega)$ for $v \in H^{1,n}(\Omega; \mathbb{R}^n)$ but it is not necessarily integrable to any higher power. Thus it is not automatic that if $u^k \to u$ in $H^{1,n}(\Omega; \mathbb{R}^n)$ weakly, that $\det \nabla u^k \to \det \nabla u$ in $L^1(\Omega)$ weakly. In fact, without additional requirements, this condition does not hold. The reader may refer to the counterexamples in Ball and Murat [7]. However, much is known about this situation, as we summarize below.

First of all, the determinant is a null Lagrangian, that is, if $u, v \in H^{1,n}(\Omega; \mathbb{R}^n)$ and $u|_{\partial\Omega} = v|_{\partial\Omega}$, then

$$\int_\Omega \det \nabla u\, dx = \int_\Omega \det \nabla v\, dx. \tag{4.1}$$

Assume that $u^k, u \in H^{1,n}(\Omega; \mathbb{R}^n)$ and

$$u^k \to u \quad \text{in } H^{1,n}(\Omega; \mathbb{R}^n) \text{ weakly.} \tag{4.2}$$

Then for a subsequence of the (u^k), not relabeled (cf., e.g., [2]),

$$\det \nabla u^k \to \det \nabla u \quad \text{in } D'(\Omega). \tag{4.3}$$

Very recently, Müller [44] showed that if (4.2) holds and $\det \nabla u^k \geqq 0$, then

$$\det \nabla u^k \to \det \nabla u \quad \text{in } L^1_{\text{loc}}(\Omega) \text{ weakly.} \tag{4.4}$$

We give a slight generalization of Müller's result, and also an independent proof of it. With it, alternate proofs of some results in elasticity may be given, for example, some of those in Zhang [51].

THEOREM 4.1. *Let* $u^k, u \in H^{1,n}(\Omega; \mathbb{R}^n)$ *satisfy*

$$u^k \to u \quad \text{in } H^{1,n}(\Omega; \mathbb{R}^n) \text{ weakly,} \tag{4.5}$$

$$\det \nabla u^k \geqq 0 \quad \text{in } \Omega \text{ a.e.,} \tag{4.6}$$

$$u^k|_{\partial\Omega} = u_0|_{\partial\Omega}, \tag{4.7}$$

where $u_0 \in H^{1,n}(\Omega; \mathbb{R}^n)$ *is fixed. Then*

$$\det \nabla u^k \to \det \nabla u \text{ in } L^1(\Omega) \text{ weakly} \tag{4.8}$$

Proof. First of all, $u = u_0$ on $\partial\Omega$. From (4.6), we deduce that

$$\int_\Omega \zeta \det \nabla u \, dx \geqq 0 \quad \text{whenever } 0 \leqq \zeta \in C_0^\infty(\mathbb{R}^n),$$

thus $\det \nabla u \geqq 0$ in Ω almost everywhere. By (4.1),

$$\int_\Omega \det \nabla u \, dx = \int_\Omega \det \nabla u^k \, dx = \int_\Omega \det \nabla u_0 \, dx, \quad \text{for all } k. \tag{4.9}$$

Now let

$$\varphi(A) = \max\{\det A, 0\}, \quad A \in \mathbb{M},$$

which is continuous, quasi-convex, and satisfies

$$0 \leqq \varphi(A) \leqq C(1 + |A|)^n, \qquad A \in \mathbb{M}.$$

Then $\varphi(\nabla u^k) = \det \nabla u^k$ and $\varphi(\nabla u) = \det \nabla u$, so, trivially, by (4.9),

$$\int_\Omega \varphi(\nabla u) \, dx = \lim_{k\to\infty} \int_\Omega \varphi(\nabla u^k) \, dx.$$

Consequently, by Theorem 1.1, possibly for a subsequence which we do not relabel,

$$\det \nabla u^k \to \det \nabla u \quad \text{in } L^1(\Omega) \text{ weakly.} \qquad \square$$

The idea of Theorem 4.1 is that the sequence (u^k) may arise as a minimizing sequence for some variational principle subject to (4.6). Additional information then follows from the theorem.

5. Application to functionals with surface energies. We consider a simple situation where cooperative bulk and surface energies are minimized. Let $\Omega \subset \mathbb{R}^n$ have smooth boundary Γ and set

$$E(v) = \int_\Omega W(\nabla v) \, dx + \int_\Gamma \tau(\nabla v, \nu) \, dS, \qquad v \in C^1(\bar{\Omega}; \mathbb{R}^m), \tag{5.1}$$

where ν denotes the exterior normal to Γ. The infimum of E over $C^1(\bar{\Omega}; \mathbb{R}^m)$ is not necessarily the sum of the infima of its two summands, so we envision an application of our results when (1.3) will hold for each of the two terms but where these quantities will not be the unrestricted infima of their portions of the functional.

Assume that W is continuous and satisfies, for some $p>1$ and $C \geqq c>0$,

$$\max\{c|A|^p-1,0\} \leqq W(A) \leqq C(1+|A|^p), \qquad A \in \mathbb{M}. \tag{5.2}$$

About τ we assume that it is continuous and, for some $s>1$,

$$\begin{aligned} &0 \leqq \tau(A,\nu), \\ &c(|A_{\tan}|^s-1) \leqq \tau(A,\nu) \leqq C(|A|^s+1), \end{aligned} \qquad A \in \mathbb{M}, \tag{5.3}$$

where $A_{\tan}=A(\mathbb{1}-\nu\otimes\nu)$ is the tangential part of A.

For a fixed $\nu \in \mathbb{S}^{n-1}$, let $D' \subset \{x\cdot\nu=0\}$ be a domain and let dx' denote the $(n-1)$-Lebesgue measure on D'. By $D'\times(-r,r)$, $r>0$, we abbreviate the name of the set

$$\{x \in \mathbb{R}^n \colon x'=(\mathbb{1}-\nu\otimes\nu)x \in D' \text{ and } |x\cdot\nu|<r\}.$$

Let $[E]$ denote the $(n-1)$-dimensional Lebesgue measure of E. We define

$$\begin{aligned} &\tau^{\#}(F,\nu)=\inf_{C'}\frac{1}{[D']}\int_{D'}\tau(F+\nabla\zeta,\nu)\,dx', \qquad (F,\nu)\in\mathbb{M}\times\mathbb{S}^{n-1}, \\ &C'=C_0^1(D'\times(-r,r)). \end{aligned} \tag{5.4}$$

We always suppose that $[\partial D']=0$. Clearly $\tau^{\#}\geqq 0$ and is independent of r. The relaxation of the functional E is given by

$$E^{\#}(v)=\int_\Omega W^{\#}(\nabla v)\,dx+\int_\Gamma \tau^{\#}(\nabla v,\nu)\,dS, \qquad v\in C^1(\bar{\Omega};\mathbb{R}^m), \tag{5.5}$$

where $W^{\#}(A)$ is the ordinary quasi convexification of W and $\tau^{\#}$ is defined by (5.4). A special property of $\tau^{\#}$ is that

$$\tau^{\#}(A,\nu)=\tau^{\#}(A_{\tan},\nu), \qquad A\in\mathbb{M},$$

which implies that

$$c(|A_{\tan}|^s-1)\leqq\tau^{\#}(A,\nu)\leqq C(|A|^s+1), \qquad A\in\mathbb{M}, \tag{5.6}$$

and that $\tau^{\#}$ is well defined on $H^{1,s}(\Gamma;\mathbb{R}^m)$. An easy generalization of [39] tells us that

$$\inf_{C^1(\bar{\Omega})}E(v)=\inf_V E^{\#}(v), \qquad V=H^{1,p}(\Omega;\mathbb{R}^m)\times H^{1,s}(\Gamma;\mathbb{R}^m). \tag{5.7}$$

Let $(u^k)\subset V$ be a minimizing sequence for E. Then (u^k) is a minimizing sequence for $E^{\#}$, which is bounded in V. Suppose that $u\in V$ and $u^k\to u$ in V weakly. By lower semicontinuity,

$$\begin{aligned} &E^{\#}(u)=\lim_{k\to\infty}E^{\#}(v)=\inf_{C^1(\bar{\Omega})}E(v)=\inf_V E^{\#}(v) \text{ and} \\ &\int_\Omega W^{\#}(\nabla u)\,dx=\lim_{k\to\infty}\int_\Omega W^{\#}(\nabla u^k)\,dx, \\ &\int_\Gamma \tau^{\#}(\nabla_{\tan}u,\nu)\,dS=\lim_{k\to\infty}\int_\Gamma\tau^{\#}(\nabla u^k,\nu)\,dS. \end{aligned} \tag{5.8}$$

We may apply Theorem 1.3, or a slight generalization of it in the case of $(\tau^{\#}(\nabla u^k,\nu))$, to deduce that

$$\begin{aligned} &W^{\#}(\nabla u^k)\to W^{\#}(\nabla u) \quad \text{in } L^1(\Omega) \text{ weakly}, \\ &\tau^{\#}(\nabla u^k,\nu)\to\tau^{\#}(\nabla_{\tan}u,\nu) \quad \text{in } L^1(\Gamma) \text{ weakly}. \end{aligned}$$

If $\mu=(\mu_x)_{x\in\Omega}$ denotes a Young measure generated by (∇u^k), we have the limit energy representations

$$\bar{W}(x)=W^{\#}(\nabla u(x))=\int_{\mathbb{M}} W(A)\,d\mu_x(A),\qquad x\in\Omega,$$

$$\bar{\tau}(x)=\tau^{\#}(\nabla_{\tan}u(x),\nu(x))=\int_{\Gamma}\tau^{\#}(A,\nu(x))\,d\mu_x(A),\qquad x\in\Gamma,$$

and

$$\int_\Omega \bar{W}(x)\,dx+\int_\Gamma \bar{\tau}(x)\,dS=\inf_{C^1(\bar{B})}E(v).$$

6. Measure valued solutions of an evolution problem. Some of our methods may be employed to study measure valued solutions of evolution problems. A more extensive treatment is given by Slemrod [47]; here we wish to explain merely how such solutions may come about. For further developments we refer to Demoulini [17]. To fix the ideas, we consider a scalar case. Suppose that $\varphi\in C^1(\mathbb{R}^n)$ satisfies

$$\begin{aligned}&\max(c|a|^2-1,0)\leqq\varphi(a)\leqq C(|a|^2+1),\\ &|\nabla\varphi(a)|\leqq C|a|,\end{aligned}\qquad a\in\mathbb{R}^n,\tag{6.1}$$

where $0<c\leqq C$. Let $q(a)=\nabla\varphi(a)$. Our interest is in solutions, possibly Young measures, which in some sense satisfy

$$-\operatorname{div}\bar{q}+\frac{\partial u}{\partial t}=0\quad\text{in }\Omega\times\mathbb{R}^+,\tag{6.2}$$

$\mathbb{R}^+=(0,\infty)$, subject to appropriate boundary conditions.

To render this more precise, let us agree that $\nu=(\nu_{x,t})_{(x,t)\in\Omega\times\mathbb{R}^+}$ is a Young measure solution of (6.2) provided that the following condition holds.

CONDITION 6.1. *ν is a family of probability measures and*

$$u\in L^\infty(\mathbb{R}^+;H_0^1(\Omega))\quad\textit{with }\frac{\partial u}{\partial t}\in L^2(\Omega\times\mathbb{R}^+)$$

which satisfy

$$-\operatorname{div}\bar{q}+\frac{\partial u}{\partial t}=0\quad\textit{in }H^{-1}(\Omega\times\mathbb{R}^+),\tag{6.3}$$

$$u|_{t=0}=u_0,\tag{6.4}$$

where

$$\begin{aligned}\bar{q}(x,t)&=\int_{\mathbb{R}^n}q(a)\,d\nu_{x,t}(a)\\ \nabla u(x,t)&=\int_{\mathbb{R}^n}a\,d\nu_{x,t}(a)\end{aligned}\qquad\textit{in }\Omega\times\mathbb{R}^+\textit{ a.e.}\tag{6.5}$$

Above, $u_0\in H_0^1(\Omega)$ is given. Moreover, we shall impose the condition that ν is a Young measure in the sense that it meets the following condition.

CONDITION 6.2. *ν is generated by a sequence (∇u^h), $h>0$, where*

$$u^h\in L^\infty(\mathbb{R}^+;H_0^1(\Omega)).\tag{6.6}$$

The equation (6.5) means that

$$\int_0^\infty \int_\Omega \left(\bar{q} \cdot \nabla \zeta + \frac{\partial u}{\partial t} \zeta \right) dx\, dt = 0 \quad \text{for } \zeta \in H_0^1(\Omega \times \mathbb{R}^+). \tag{6.7}$$

We shall give an outline of the proof of the following theorem.

THEOREM 6.1. *Assume* (6.1) *about* φ. *Then there exists a Young measure solution* $\nu = (\nu_{x,t})_{(x,t) \in \Omega \times \mathbb{R}^+}$ *of*

$$-\operatorname{div} \bar{q} + \frac{\partial u}{\partial t} = 0 \quad \textit{in } \Omega \times \mathbb{R}^+,$$

satisfying (6.3)-(6.6). *In addition,*

$$\operatorname{supp} \nu_{x,t} \subset \{a \in \mathbb{R}^n \colon \varphi(a) = \varphi^{**}(a)\} \quad \textit{in } \Omega \times \mathbb{R}^+ \ \textit{a.e.}, \tag{6.8}$$

where φ^{**} *is the convexification of* φ.

Recall that if $\varphi \in C^1(\mathbb{R}^n)$, then $\varphi^{**} \in C^1(\mathbb{R}^n)$, whence

$$q(a) = q^{**}(a) \quad \text{in } \{a \in \mathbb{R}^n \colon \varphi(a) = \varphi^{**}(a)\},$$

where $q^{**}(a) = \nabla \varphi^{**}(a)$. Note also that φ^{**} satisfies (6.1). Hence the following corollary.

COROLLARY 6.2. *Assume* (6.1) *about* φ *and let* $\nu = (\nu_{x,t})_{(x,t) \in \Omega \times \mathbb{R}^+}$ *be a Young measure solution satisfying* (6.8). *Then* ν *is a solution of the relaxed problem*

$$-\operatorname{div} \bar{q}^{**} + \frac{\partial u}{\partial t} = 0 \quad \textit{in } \Omega \times \mathbb{R}^+. \tag{6.9}$$

The constructed solution has some additional properties which we shall describe in the sequel.

Step 1. An equilibrium problem. Let $w \in H_0^1(\Omega)$ and $h > 0$ and consider

$$\Phi(v) = \Phi_h(v) = \int_\Omega \left(\varphi(\nabla v) + \frac{1}{2h} |v - w|^2 \right) dx, \qquad v \in H_0^1(\Omega), \tag{6.10}$$

$$\Phi^{**}(v) = \int_\Omega \left(\varphi^{**}(\nabla v) + \frac{1}{2h} |v - w|^2 \right) dx, \qquad v \in H_0^1(\Omega), \tag{6.11}$$

where φ^{**} is the convexification of φ. By a known relaxation theorem (cf. [16]),

$$I = \inf\nolimits_{H_0^1(\Omega)} \Phi(v) = \inf\nolimits_{H_0^1(\Omega)} \Phi^{**}(v). \tag{6.12}$$

Now let (v^k) be a minimizing sequence for $\Phi(v)$. We may assume there is a $u \in H_0^1(\Omega)$ such that

$$v^k \to u \quad \text{in } H_0^1(\Omega) \text{ weakly as } k \to \infty.$$

By lower semicontinuity,

$$\Phi(v^k) \to \Phi^{**}(u) \quad \text{as } k \to \infty,$$

and by the Rellich theorem,

$$\int_\Omega |v^k - w|^2\, dx \to \int_\Omega |u - w|^2\, dx \quad \text{as } k \to \infty.$$

Hence

$$\int_\Omega \varphi^{**}(\nabla u)\, dx = \lim\nolimits_{k \to \infty} \int_\Omega \varphi^{**}(\nabla v^k)\, dx = \lim\nolimits_{k \to \infty} \int_\Omega \varphi(\nabla v^k)\, dx.$$

Hence, by Theorem 1.1,

$$\varphi^{**}(\nabla v^k) \to \varphi^{**}(\nabla u) \quad \text{in } L^1(\Omega) \text{ weakly},$$
$$\varphi(\nabla v^k) \to \varphi^{**}(\nabla u) \quad \text{in } L^1(\Omega) \text{ weakly}.$$

Denoting by $\nu = (\nu_x)_{x \in \Omega}$ the Young measure generated by (∇v^k),

$$\begin{gathered} \operatorname{supp} \nu \subset \{a \in \mathbb{R}^n : \varphi(a) = \varphi^{**}(a)\}, \\ \varphi^{**}(\nabla u) = \bar{\varphi} = \bar{\varphi}^{**} \quad \text{and} \quad \bar{q} = \bar{q}^{**} \quad \text{in } \Omega \text{ a.e.}, \end{gathered} \tag{6.13}$$

where

$$\bar{\psi}(x) = \int_{\mathbb{R}^n} \psi(a)\, d\nu_x(a) \quad \text{in } \Omega \text{ a.e.}$$

In fact, the Young measure representation holds for any $\psi \in E$, where

$$E = \left\{ \psi \in C(\mathbb{R}^n \times \Omega) : \sup_{\mathbb{R}^n \times \Omega} \frac{|\psi(a, x)|}{|a|^2 + 1} < \infty \right\}.$$

We may now apply the technique developed in [10] to discuss stable Young measure minimizers of variational principles; cf. § 5. The idea here is to observe that

$$\psi_\varepsilon(a, x) = \varphi(a + \varepsilon \nabla \zeta(x)) \leqq C(1 + |a|^2), \qquad a \in \mathbb{R}^n,$$

when $\zeta \in C_0^\infty(\Omega)$, $-1 \leqq \varepsilon \leqq 1$. Hence $\psi_\varepsilon \in E$, so

$$\begin{aligned} \int_\Omega \bar{\varphi}\, dx &\leqq \lim_{k\to\infty} \int_\Omega \varphi(\nabla v^k + \varepsilon \nabla \zeta)\, dx \\ &= \int_\Omega \int_{\mathbb{R}^n} \varphi(a + \varepsilon \nabla \zeta(x))\, d\nu_x(a)\, dx. \end{aligned}$$

This equation may be differentiated with respect to ε. As a consequence, we may write an equilibrium equation

$$\int_\Omega \left(\bar{q} \cdot \nabla \zeta + \frac{1}{h}(u - w)\zeta \right) dx = 0 \quad \text{for } \zeta \in H_0^1(\Omega). \tag{6.14}$$

Finally, the Young measure representation provides us with an elementary estimate for $\bar{q}$. Indeed, using the estimates of (6.1) and (6.13),

$$\begin{aligned} \int_\Omega |\bar{q}|^2\, dx &\leqq \int_\Omega \int_{\mathbb{R}^n} |q(a)|^2\, d\nu_x(a)\, dx \\ &\leqq C \int_\Omega \int_{\mathbb{R}^n} |a|^2\, d\nu_x(a)\, dx \\ &\leqq C \int_\Omega \int_{\mathbb{R}^n} (\varphi(a) + 1)\, d\nu_x(a)\, dx \\ &= C \int_\Omega (\varphi^{**}(\nabla u) + 1)\, dx. \end{aligned} \tag{6.15}$$

Step 2. Approximate solution. Let $u_0 \in H_0^1(\Omega)$ be given and $h > 0$. We define a sequence of Young measure solutions $\nu^{h,j}$ and underlying functions $u^{h,j}$ by setting

$$\nu^{h,0} = \delta_{\nabla u_0} \quad \text{and} \quad u^{h,0} = u_0$$

and $\nu^{h,j+1}$ is the solution of (6.12) with $w=u^{h,j}$ and $u^{h,j+1}$ its underlying function. We are then in possession of the energy densities

$$\varphi^{**}(\nabla u^{h,j})=\langle \nu^{h,j},\varphi\rangle=\langle \nu^{h,j},\varphi^{**}\rangle \tag{6.16}$$

and the flux densities

$$\bar{q}^{h,j}=\langle \nu^{h,j},q\rangle=\langle \nu^{h,j},q^{**}\rangle. \tag{6.17}$$

Let $I^{h,j}=[hj,h(j+1))$, $\chi^{h,j}=\chi_{I^{h,j}}$, the characteristic function of $I^{h,j}$, and

$$\lambda^{h,j}(t)=\begin{cases}\dfrac{t}{h}-j, & hj\leqq t\leqq h(j+1),\\ 0, & \text{otherwise.}\end{cases}$$

Set

$$u^h(x,t)=\textstyle\sum_j \chi^{h,j}\{(1-\lambda^{h,j}(t))u^{h,j}(x)+\lambda^{h,j}(t)u^{h,j+1}(x)\}\in L^\infty(\mathbb{R}^+;H_0^1(\Omega)) \tag{6.18}$$

and

$$\nu_{x,t}^h=\textstyle\sum_j \chi^{h,j}(t)\nu_x^{h,j}\in E'. \tag{6.19}$$

Now from (6.18),

$$\frac{\partial u^h}{\partial t}=\frac{1}{h}(u^{h,j+1}-u^{h,j})\quad\text{and}\quad \bar{q}^h=\langle \nu^h,q\rangle=\textstyle\sum_j \bar{q}^{h,j}\chi^{h,j} \tag{6.20}$$

comprise a solution of

$$-\operatorname{div}\bar{q}^h+\frac{\partial u^h}{\partial t}=0\quad\text{in } H^{-1}(\Omega),\quad\text{for each } t,$$

from which it is elementary to check that

$$\int_0^\infty\int_\Omega\left(\bar{q}^h\cdot\nabla\zeta+\frac{\partial u^h}{\partial t}\zeta\right)dx\,dt=0\quad\text{for } \zeta\in H_0^1(\Omega\times\mathbb{R}^+). \tag{6.21}$$

Step 3 (Estimates). Uniform estimates are available for $u^h\in L^\infty(\mathbb{R}^+;H_0^1(\Omega))$ and $\partial u^h/\partial t\in L^2(\Omega\times\mathbb{R}^+)$. To begin, $u^{h,j}$ is admissible in the variational principle for $u^{h,j+1}$, so

$$\int_\Omega\left(\varphi^{**}(\nabla u^{h,j+1})+\frac{1}{2h}|u^{h,j+1}-u^{h,j}|^2\right)dx\leqq\int_\Omega\varphi^{**}(\nabla u^{h,j})\,dx.$$

Hence

$$\int_\Omega\varphi^{**}(\nabla u^{h,j})\,dx\leqq\int_\Omega\varphi^{**}(\nabla u_0)\,dx=M^2 \tag{6.22}$$

and

$$\frac{1}{2h}\textstyle\sum_j|u^{h,j+1}-u^{h,j}|^2\leqq\displaystyle\int_\Omega\varphi^{**}(\nabla u_0)\,dx=M^2. \tag{6.23}$$

Since φ^{**} satisfies (6.1), the inequality (6.22) tells us that

$$\|\nabla u^{h,j}\|_{L^2(\Omega)}\leqq M. \tag{6.24}$$

By convexity of the L^2 norm and (6.24) we have that

$$\|u^h\|_{L^\infty(\mathbb{R}^+;H_0^1(\Omega))} \leqq M. \tag{6.25}$$

Rearranging a little in (6.23) and noting (6.20),

$$\int_0^\infty \int_\Omega \left|\frac{\partial u^h}{\partial t}\right|^2 dx\,dt \leqq M^2. \tag{6.26}$$

Introduce the function

$$w^h(x,t) = \textstyle\sum_j u^{h,j}(x)\chi^{h,j}(t) \in L^\infty(\mathbb{R}^+; H_0^1(\Omega)). \tag{6.27}$$

Then (6.24) implies that

$$\|w^h\|_{L^\infty(\mathbb{R}^+;H_0^1(\Omega))} \leqq M. \tag{6.28}$$

Finally, we wish to estimate $\bar{q}^h$ using (6.15), which provides the estimate

$$\|\bar{q}^h\|_{L^\infty(\mathbb{R}^+;L^2(\Omega))} \leqq C \int_\Omega (\varphi^{**}(\nabla u^{h,j})+1)\,dx \leqq C(M^2+1). \tag{6.29}$$

Step 4 (Passage to the limit). We let $h \to 0$. From the estimates (6.25), (6.26), (6.28), and (6.29), we may extract a subsequence of h as $h \to 0$ and

$$\begin{aligned}
&\nu = (\nu_{x,t})_{(x,t)\in\Omega\times\mathbb{R}^+} \in E' && \text{with supp } \nu \subset \{\varphi(a) = \varphi^{**}(a)\} \text{ and } \nu \text{ is a Young measure,}\\
&w \in L^\infty(\mathbb{R}^+; H_0^1(\Omega)) && \text{with } \nabla w = \langle \nu, a\rangle,\\
&\bar{q} \in L^\infty(\mathbb{R}^+; L^2(\Omega)) && \text{with } \bar{q} = \langle \nu, q\rangle = \langle \nu, q^{**}\rangle,\\
&u \in L^\infty(\mathbb{R}^+; H_0^1(\Omega)) && \text{with } \frac{\partial u}{\partial t} \in L^2(\Omega\times\mathbb{R}^+),
\end{aligned}$$

which satisfy

$$\int_0^\infty \int_\Omega \left(\bar{q}\cdot\nabla\zeta + \frac{\partial u}{\partial t}\zeta\right) dx\,dt = 0 \quad \text{for } \zeta \in H_0^1(\Omega\times\mathbb{R}^+). \tag{6.30}$$

In fact, (6.30) above holds for $\zeta \in L^\infty(\mathbb{R}^+; H_0^1(\Omega))$. We remark that ν is a Young measure but it is not generated by the sequence (∇u^h) of (6.18), but rather by a diagonal subsequence of the functions which generate the (ν^h) of (6.19). Although $\nu \in E'$, we have not verified the Young measure representation for $\psi \in E$, although, as we mentioned in the introduction, under these circumstances, whenever $\psi \in C(\mathbb{R}^m)$ satisfies

$$\lim_{|a|\to\infty} \frac{|\psi(a)|}{1+|a|^2} = 0,$$

the sequence $\psi(\nabla v^k)$ converges weakly in L^1 and the representation is valid.

It remains to show that the Young measure ν and the limit function u are connected. We claim that $u = w$. In fact, we shall show that $\nabla u = \nabla w$ by means of an easy lemma.

LEMMA 6.3. *Let* $(f^{h,j}) \subset$ *bounded set of* $L^2(\Omega)$ *for* $h > 0$ *and* $j = 1, 2, 3, \cdots$, *and set*

$$f^h(x,t) = \textstyle\sum_j f^{h,j}(x)\chi^{h,j}(t),$$

$$g^h(x,t) = \textstyle\sum_j \chi^{h,j}\{(1-\lambda^{h,j}(t))f^{h,j}(x) + \lambda^{h,j}(t)f^{h,j+1}(x)\},$$

where $\chi^{h,j}$ is the characteristic function of $[hj, h(j+1))$ and

$$\lambda^{h,j}(t)=\begin{cases} t/h-j, & hj\leqq t\leqq h(j+1),\\ 0, & \text{otherwise.}\end{cases}$$

Suppose that

$$f^h\to f \quad \text{and} \quad g^h\to g \quad \text{in } L^2_{\text{loc}}(\Omega\times\mathbb{R}^+) \text{ weakly.}$$

Then $f=g$.

Proof. It suffices to show that

$$\int_0^\infty\int_\Omega f\zeta\,dx\,dt=\int_0^\infty\int_\Omega g\zeta\,dx\,dt$$

for $\zeta\in C_0^\infty(\Omega)$ of the form $\zeta(x,t)=w(x)z(t)$. Let $z^{h,j}=z(hj)$ and

$$\zeta^h(x,t)=w(x)\sum_j z^{h,j}\chi^{h,j}(t),$$
$$\xi^h(x,t)=w(x)\sum_j\chi^{h,j}(t)\{(1-\lambda^{h,j}(t))z^{h,j}+\lambda^{h,j}(t)z^{h,j-1}\}.$$

It is elementary to check that $\zeta^h\to\zeta$ and $\xi^h\to\zeta$ uniformly since z is smooth. Since

$$\int_0^\infty\int_\Omega f^h\xi^h\,dx\,dt=\int_0^\infty\int_\Omega g^h\zeta^h\,dx\,dt,$$

the lemma follows. □

From the lemma we may write a generalized Fourier law for the solution, which is really much weaker than the property that supp $\nu\subset\{\varphi(a)=\varphi^{**}(a)\}$. If $\varphi^{**}(0)=0$, then

$$\bar{q}^{**}\cdot\nabla u\geqq 0.$$

Acknowledgment. We are delighted to thank J. Matos and S. Demoulini for many helpful conversations. We also thank M. Gurtin and L. Tartar for their interest in this work.

REMARQUES SUR L'EXISTENCE GLOBALE POUR LE SYSTEME DE NAVIER-STOKES INCOMPRESSIBLE*

J. Y. CHEMIN†

Résumé. Le but de cet article est d'appliquer une estimation d'énergie à perte démontrée avec la technique du découpage dyadique de l'espace des fréquences à la démonstration de résultats d'existence globale de solutions suffisamment régulières des équations de Navier-Stokes avec un terme de force.

Abstract. The goal of this paper is the application of an energy estimate with loss of derivative, proved with the Littlewood-Paley theory, to prove some results of global existence of smooth enough solutions of the Navier-Stokes equations with an exterior force.

Mots-clefs. mécanique des fluides (visqueux), Littlewood-Paley (théorie de)

Codes matières AMS. 35L60, 76A02

Introduction. Nons nous intéressons dans ce travail au mouvement des particules d'un fluide incompressible visqueux. Ce mouvement est décrit par le système de Navier-Stokes relatif à un champ de vecteurs défini sur tout $\mathbf{R}^d$, d valant ici 2 ou 3, que nous rappelons:

$$(S_\varepsilon) \qquad \begin{aligned} &\partial_t v + v.\nabla v - \varepsilon\Delta v = -\nabla p + \nabla^\perp V,\\ &\operatorname{div} v(t,\cdot)=0 \quad \text{à tout instant } t \text{ positif ou nul},\\ &v|_{t=0}=v_0. \end{aligned}$$

Ici, $v(t,x)$ désigne la vitesse d'une particule située au point x à l'instant t, $p(t,x)$ la pression dans le fluide au point x à l'instant t, $V(t,x)$ le potentiel (ici une matrice antisymétrique), dont dérive la force extérieure au point x à l'instant t, $\nabla^\perp V$ le vecteur de jème coordonnée $\sum_i \partial_i V_j^i$, et ε la viscosité du fluide, qui est supposée être une constante strictement positive. Les données du problème sont bien sûr le potentiel V et le champ des vitesses v_0.

Le but de ce travail est de démontrer des résultats d'existence globale en regardant le système de Navier-Stokes, non pas comme un système parabolique, mais comme un système hyperbolique amélioré par le terme de viscosité. Ce point de vue permet de retrouver des résultats bien connus, comme par exemple le Théorème 0.1 relatif à la dimension deux et le Théorème général d'unicité 2.2, et d'en démontrer un nouveau, le Théorème 0.2. Dans cette optique, l'existence locale en temps pour des données régulières, par exemple, $v_0 \in H^s$ et $V \in L^1_{\text{loc}}[(0,+\infty[;H^{s+1})$, $s > d/2+1$, résulte de la théorie classique des systèmes hyperboliques (voir, par exemple, [1]), le terme de viscosité étant ignoré grâce à son signe. Cette théorie repose sur la démonstration d'estimations d'énergie. La première estimation d'énergie vérifiée par une solution assez régulière du système (S_ε) provient de l'identité suivante:

$$(0.1)\ (|v(t,\cdot)|_0)^2-(|v_0|_0)^2+2\varepsilon\int_{[0,t]}(|\nabla v(\tau,\cdot)|_0)^2\,dt = 2\int_{[0,t]}(\nabla^\perp V(\tau,\cdot)|v(\tau,\cdot))\,d\tau.$$

En utilisant le fait que $2(\nabla^\perp V(\tau,\cdot)|v(\tau,\cdot)) \leqq \varepsilon^{-1}(|V(\tau,\cdot)|_0)^2+\varepsilon(|\nabla v(\tau,\cdot)|_0)^2$, nous

* Received by the editors June 8, 1990; accepted for publication (in revised form) March 20, 1991.

† Centre de Mathematiques, Unité de Recherche Associée D 0169, Ecole Polytechnique, F-91128 Palaiseau Cedex, France.

obtenons trivialement l'estimation bien connue suivante:

$$(E) \qquad (|v(t,\cdot)|_0)^2+\varepsilon\int_{[0,t]}(|\nabla v(\tau,\cdot)|_0)^2\,d\tau \leqq (|v_0|_0)^2+\varepsilon^{-1}\int_{[0,t]}(|V(\tau,\cdot)|_0)^2\,d\tau.$$

L'idée de l'article est d'appliquer des méthodes d'énergies pour estimer l'évolution, non plus nécessairement de la norme L^2 du champ des vitesses v, mais de la norme H^s, pour un s assurant l'existence globale d'une solution suffisamment régulière pour être unique dans sa classe. L'outil permettant de réaliser ce programme est une estimation d'énergie avec perte dans les espaces de Sobolev homogènes sur le terme $(v.\nabla a|a)$. Cette estimation, ne mettant en jeu qu'un faible niveau de régularité du champ de vecteurs v, introduit des pertes de régularité que le terme de viscosité permet d'absorber.

La structure de l'article sera la suivante. Dans le premier paragraphe, on exposera la démonstration de l'inégalité d'énergie avec perte de régularité, démonstration qui repose sur la caractérisation en couronnes dyadiques des espaces de Sobolev homogènes et inhomogènes. Nous donnerons de plus une première application de ce résultat sous la forme d'une condition nécessaire de non-existence globale de solutions régulières. Dans le deuxième paragraphe, nous utiliserons cette estimation pour démontrer un lemme d'explosion, un théorème d'unicité et un lemme de convergence qui, appliqués au cas de la *dimension deux d'espace*, permettent de redémontrer fort aisément le théorème bien connu suivant.

THÉOREME 0.1. *Soit s un réel postif ou nul; si v_0 est un champ de vitesses de $\mathbf{R}^2$ à coefficients L^2, et V un potentiel-vecteur de $\mathbf{R}^2$ à coefficients $L^2_{\mathrm{loc}}([0,+\infty[;H^s)$; alors le système (S_ε) admet une unique solution dans l'espace $C([0,+\infty[;L^2)\cap C(]0,+\infty[;H^s)\cap L^2_{\mathrm{loc}}(]0,+\infty[;H^{s+1})$.*

Remarquons que ce théorème est tout-à-fait classique, voir, par exemple, [4].

Dans le troisième et dernier paragraphe, nous appliquerons ce qui précède au cas de la *dimension trois d'espace.* Désignons par H^s (respectivement, $\underline{H}^s$) l'espace de Sobolev (respectivement, homogène), et par $|u|_s$ (respectivement, $\|u|_s$) la quantité $\int(1+|\xi|^2)^s|\hat{u}(\xi)|^2\,d\xi$ (respectivement, $\int|\xi|^{2s}|\hat{u}(\xi)|^2\,d\xi$); nous démontrerons alors le théorème suivant.

THÉOREME 0.2. *Il existe un réel C_0 strictement postif tel que, si s est un réel supérieur ou égal à $\frac{1}{2}$, si les données v_0 et V sont telles que*

(i) $v_0\in H^{1/2}$ *et* $V\in L^2([0,+\infty[;H^{1/2})\cap L^2_{\mathrm{loc}}(]0,+\infty[;H^s)$,

(ii) $\|v_0|_{1/2}+\varepsilon^{-1/2}(\int_{[0,+\infty[}(\|V(t,\cdot)|_{1/2})^2\,dt)^{1/2}\leqq C_0\varepsilon$;

alors (S_ε) admet une unique solution dans $C([0,+\infty[;\,H^{1/2})\cap L^2([(0,+\infty[;\,H^{3/2})\cap C(]0,+\infty[;\,H^s)\cap L^2_{\mathrm{loc}}(]0,+\infty[;\,H^{s+1})$.

Remarques. Ce Théorème 0.1 a été démontré dans [3] par des méthodes de semi-groupes en supposant que V est une fonction Höldérienne de $[0,+\infty[$ à valeurs dans H^1 et en remplaçant, dans la condition (ii) du Théorème 0.2, la quantité $(\int_{[0,+\infty[}(\|V(t,\cdot)|_{1/2})^2\,dt)^{1/2}$ par $\mathrm{Sup}_{t\in[0,+\infty[}\,t^{3/4}\|V(t,\cdot)|_1$.

Enfin, observons que les quantités intervenant dans le membre de gauche de (ii) sont invariantes par changement d'échelle, ainsi que $\mathrm{Sup}_{t\in[0,+\infty[}\,t^{3/4}\|V(t,\cdot)|_1$.

Nous utiliserons dans tout ce travail les notations suivantes:

- Nous désignerons par ϕ une partition dyadique de l'unité, i.e., une fonction de $C_0^\infty(\mathbf{R}^d\backslash\{0\};[0,1])$ telle que, pour tout $\xi\in\mathbf{R}^d\backslash\{0\}$, on ait $1=\sum_{q\in\mathbf{Z}}\phi(2^{-q}\xi)$; de plus, on posera $\psi=1-\sum_{q\geqq 0}\phi(2^{-q}.)$; remarquons que ψ appartient à $C_0^\infty(\mathbf{R}^d)$. Nous désignerons par Δ_q l'opérateur $\phi(2^{-q}D)$, par S_q l'opérateur $\psi(2^{-q}D)$ et par $\underline{N}$ un entier tel que $0\notin\mathrm{Supp}\,\psi(2^{-\underline{N}}.)+\mathrm{Supp}\,\phi$;
- Si s est un réel, nous désignerons parΛ^s l'opérateur $(\mathrm{Id}-\Delta)^{s/2}$.

Enfin, nous allons rappeler la caractérisation des espaces de Sobolev homogènes et inhomogènes à l'aide du découpage dyadique de l'espace des fréquences. Il est clair que $C^{-1} \leqq \sum_{q \in \mathbf{Z}} (\phi(2^{-q}\xi))^2 \leqq C$ et que $C^{-1} \leqq (\psi(\xi))^2 + \sum_{q \geqq 0} (\phi(2^{-q}\xi))^2 \leqq C$; le fait que $C^{-1} \| \phi(2^{-q}D)u|_s \leqq 2^{qs} |\phi(2^{-q}D)u|_0 \leqq C \| \phi(2^{-q}D)u|_s$ assure

$$\begin{aligned} &C^{-1}(\|u|_s)^2 \leqq \sum_{q \in \mathbf{Z}} 2^{2qs}(|\phi(2^{-q}D)u|_0)^2 \leqq C(\|u|_s)^2, \\ (0.2) \qquad &C^{-1}(|u|_s)^2 \leqq \sum_{q \leqq 0} 2^{2qs}(|\phi(2^{-q}D)u|_0)^2 + (|\psi(D)u|_0)^2 \leqq C(|u|_s)^2. \end{aligned}$$

Pour des démonstrations complètes, nous renvoyons le lecteur à [1].

1. Inégalité d'énergie à perte; Application à la dimension deux d'espace. Nous allons énoncer et démontrer une inégalité d'énergie avec perte, en utilisant la décomposition de Bony d'un produit.

LEMME 1.1. *Soient v un champ de vecteurs à divergence nulle et s, r, r', r'' quatre réels tels que $r + r' + r'' = d/2 + 1 + 2s$, $r + r' > 0$ et $0 \leqq r < d/2 + 1$; alors il existe une constante C telle que*

(i) $(\Delta^{s/2}(v.\nabla a) | \Delta^{s/2}a) \leqq C|v|_r \|a|_{r'} \|a|_{r''} + |a|_r \|v|_{r'} \|a|_{r''}$,

(ii) $(\Lambda^s(v.\nabla a) | \Lambda^s a) \leqq C|v|_r |a|_{r'} a|_{r''} + |a|_r |v|_{r'} |a|_{r''}$.

Si, de plus $r' < d/2 + 1$, alors, nous avons,

(iii) $(\Lambda^s(v.\nabla a) | \Lambda^s a) \leqq C|v|_r |a|_{r'} |a|_{r''}$.

Démonstration. L'idée de base est d'écrire $(\Delta^{s/2}(v.\nabla a) | \Delta^{2/2}a)$ comme suit:

$$(1.1) \qquad (\Delta^{s/2}(v.\nabla a) | \Delta^{s/2}a) = \sum_{q,q',p,p;j} (\Delta^{s/2}\Delta_q(\Delta_p(v^j)\partial_j \Delta_{p'}(a)) | \Delta^{s/2}\Delta_{q'}(a)).$$

Il est bien clair, d'après la formule de Plancherel, qu'il existe un entier N tel que $|q - q'| \leqq N$. En utilisant la décomposition de Bony, il vient

$$\begin{aligned} &(\Delta^{s/2}(v.\nabla a) | \Delta^{s/2}a) = \sum_1^3 T^i, \quad \text{avec} \\ &T^1 = \sum_{q,q',p;j} (\Delta^{s/2}\Delta_q(S_{p-\underline{N}}(v^j)\partial_j \Delta_p(a)) | \Delta^{s/2}\Delta_{q'}(a)), \\ (1.2) \qquad &T^2 = \sum_{q,q',p;j} (\Delta^{s/2}\Delta_q(\Delta_p(v^j)\partial_j S_{p-\underline{N}}(a)) | \Delta^{s/2}\Delta_{q'}(a)), \\ &T^3 = \sum_{q,q',p,p',|p-p'| \leqq \underline{N};j} (\Delta^{s/2}\Delta_q(\Delta_p(v^j)\partial_j \Delta_{p'}(a)) | \Delta^{s/2}\Delta_{q'}(a)). \end{aligned}$$

Nous allons maintenant majorer chaque T^i. D'après la définition de T^1, des manipulations algébriques très simples et une intégration par parties assurent, grâce à la nullité de la divergence du champ de vecteurs v

$$\begin{aligned} &T^1 = \sum_{q,q',p;j} ([\Delta^{s/2}\Delta_q, S_{p-\underline{N}}(v^j)]\partial_j \Delta_p(a)) | \Delta^{s/2}\Delta_{q'}(a)) \\ (1.3) \qquad &+ \frac{1}{2} \sum_{q',p;j} ((S_{q'-\underline{N}} - S_{p-\underline{N}})(v^j)\partial_j \Delta^{s/2}\Delta_p(a)) | \Delta^{s/2}\Delta_{q'}(a)). \end{aligned}$$

Vu que $\|(S_{q'-\underline{N}} - S_{p-\underline{N}})(v^j)\|_{L^\infty} \leqq 2^{-p(r-d/2-1)}$, nous sommes donc ramenés à étudier la commutation entre l'opérateur de convolution $\Delta^{s/2}\Delta_q$ et la multiplication par $S_{p-\underline{N}}(v^j)$, ce qui se fait grâce à la formule suivante:

$$(1.4) \quad \Delta^{s/2}\Delta_q(S_{p-\underline{N}}(v^j)\partial_j \Delta_p(a)) = 2^{qd} \int h_s(2^q(x-y))(S_{p-\underline{N}}(v^j)\partial_j \Delta_p(a))(y)\, dy,$$

où h_s désigne la transformée inverse de Fourier de $|\xi|^s \phi(\xi)$.

Une formule de Taylor à l'ordre 1 avec reste intégral assure

$$
\begin{aligned}
\Delta^{s/2}\Delta_q(S_{p-\underline{N}}(v^j)\partial_j\Delta_p(a)) &= S_{p-\underline{N}}(v^j)\partial_j\Delta^{s/2}\Delta_q(\Delta_p(a)) \\
&\quad +2^{qd}\sum_{1\leqq i\leqq d}\int_{[0,1]}\int (x^i-y^i)h_s(2^q(x-y)) \\
&\quad \cdot S_{p-\underline{N}}(\partial_i v^j)(y+t(y-x))\partial_j\Delta_p(a)(y)\,dy\,dt.
\end{aligned}
\tag{1.5}
$$

Il ressort de la caractérisation des espaces H^s que, comme $r<d/2+1$, nous avons $\|S_{p-\underline{N}}(\partial_i v^j)\|_{L^\infty}\leqq C2^{-p(r-d/2-1)}|v|_r$. La définition de h et le fait que $|p-q|\leqq N'$ assure alors

$$
|[\Delta^{s/2}\Delta_q, S_{p-\underline{N}}(v^j)]\partial_j\Delta_p(a)|_0\leqq c_p 2^{-p(r+r'+d/2-1)}|v|_r|a|_{r'}\operatorname*{Sup}_{1\leqq i\leqq d}\|x^i h\|_{L^1},
\tag{1.6}
$$

avec $(c_p)_{p\in\mathbb{N}}\in 1^2(\mathbb{N})$. D'où $T^1\leqq C|v|_r\|a|_{r'}\|a|_{r''}$.

Comme $r<d/2+1$, $\|\partial_j S_{p-\underline{N}}(a)\|_{L^\infty}\leqq C2^{-p(r-d/2-1)}|a|_r$. Le fait que $T^2\leqq C|a|_r\|v|_{r'}\|a|_{r''}$ résulte alors simplement de l'existence d'un entier N' tel que $|p-q|$ et $|q-q'|$ soient majorés par N'.

La nullité de la divergence du champ de vecteurs v permet de se ramener à majorer $(\Delta_\mathrm{q}(\Delta_\mathrm{p}(\mathrm{v}^\mathrm{j})\Delta_{\mathrm{p}'}(\mathrm{a}))|\Delta_{\mathrm{q}'}(\mathrm{a}))$. Il est clair qu'il existe un entier N' tel que $|q-q'|$ soit majoré par N'; d'autre part, vu que $|p-p'|\leqq \underline{N}$, le support de la transformée de Fourier de $\Delta_p(v^j)\Delta_{p'}(a)$ est inclus dans une boule de rayon $\mathrm{C}2^\mathrm{p}$, il existe un entier $\underline{N}'$ tel que $p\geqq q-\underline{N}'$. Le fait que $|\Delta_p(v^j)\Delta_{p'}(a)|_0\leqq c_p c'_p 2^{-p(r+r'-d/2)}\|v|_r\|a|_{r'}$ et la relation entre r, r', r'' et s assurent alors

$$
T^3\leqq\sum_{p\geqq q-\underline{N}'} c_q 2^{(q-p)(r+r')}\|v|_r\|a|_{r'}\|a|_{r''},
\tag{1.7}
$$

où c_q est le terme général d'une série sommable; d'où le (i) du lemme, $r+r'$ étant supposé strictement postif.

La démonstration dans le cas des espaces de Sobolev inhomogènes, strictement analogue si l'on pose $\Delta_q=0$ si $q\leqq -2$ et $\Delta_q=\psi(D)$ si $q=-1$, est laissée au lecteur.

Remarque. Nous avons utilisé l'hypothèse de nullité de la divergence du champ de vecteurs v uniquement pour assurer le résultat lorsque $r+r'>0$. Il est clair, d'après la démonstration que le lemme est encore vrai sans hypothèse de nullité de la divergence du champ de vecteurs v en supposant alors $r+r'>1$.

LEMME 1.2. *Soit s un réel strictement supérieur à $d/2+1$, nous considèrons un potentiel-vecteur V dans $L^2_{\mathrm{loc}}([0,+\infty[;H^s)$ et v une solution du système (S_ε) qui soit dans $C([0,T^*[;H^s)$ pour un $s>d/2+1$, l'intervalle $[0,T^*[$ étant l'intervalle maximal de définition de la solution. Nous avons alors l'alternative suivante*:

$$
\textit{ou bien } T^*=+\infty,\quad \textit{ou bien } v\notin L^2([0,T^*[;H^{d/2}).
$$

Démonstration: Nous allons démontrer que, si la solution v appartient à $L^2([0,T^*[;H^{d/2})$; alors elle appartient à $L^\infty([0,T^*[;H^s)$, ce qui interdit à T^* d'être fini. En posant $g_s(t)=(\|v(t,\cdot)|_s)^2$, nous avons l'inégalité d'énergie

$$
\begin{aligned}
g'_s(t)+2\varepsilon(\|\nabla v(t,\cdot)|_s)^2 &= 2(\Delta^{s/2}v.\nabla v)(t,\cdot)|\Delta^{s/2}v(t,\cdot)) \\
&\quad +2(\Delta^{s/2}\nabla^\perp V(t,\cdot)|\Delta^{s/2}v(t,\cdot)).
\end{aligned}
\tag{1.8}
$$

En faisant une intégration par parties, il vient

$$
2(\Delta^{s/2}\nabla^\perp V(t,\cdot)|\Delta^{s/2}v(t,\cdot))\leqq 2\varepsilon^{-1}(\|V(t,\cdot)|_s)^2+\varepsilon/2(\|v(t,\cdot)|_{s+1})^2.
\tag{1.9}
$$

Puis, en appliquant le Lemme 1.1(i), avec $r=d/2$, $r'=s$ et $r''=s+1$, nous avons $2(\Delta^{s/2}v(t,\cdot))\leqq C(|v(t,\cdot)|_{d/2}\|v(t,\cdot)|_{s}\|v(t,\cdot)|_{s+1}$. Il vient alors

$$2(\Delta^{s/2}(v.\nabla v)(t,\cdot)|\Delta^{s/2}v(t,\cdot))\leqq(C^2/2\varepsilon)(|v(t,\cdot)|_{d/2})^2g_s(t)+\varepsilon(\|v(t,\cdot)|_{s+1})^2. \tag{1.10}$$

Il résulte alors de (1.9) que

$$g_s'(t)+\varepsilon(|v(t,\cdot)|_{s+1})^2\leqq((C^2/2\varepsilon)(|v(t,\cdot)|_{d/2})^2+\varepsilon/2)g_s+2\varepsilon^{-1}(\|V(t,\cdot)|_s)^2. \tag{1.11}$$

Une intégration standard entraine alors l'importante estimation d'énergie suivante:

$$\begin{aligned} g_s(t)\leqq g_s(0)\exp\left(\int_{[0,t]}((C^2/2\varepsilon)(|v(\tau,\cdot)|_{d/2})^2\,d\tau\right)\\ +2\varepsilon^{-1}\int_{[0,t]}(\|V(\tau,\cdot)|_s)^2\exp\left(\int_{[\tau,t]}((C^2/2\varepsilon)(|v(\dagger,\cdot)|_{d/2})^2\,d\dagger\right)d\tau. \end{aligned} \tag{1.12}$$

Cette estimation, jointe au fait que v appartienne à $L^2([0,T^*[;H^{d/2})$ et V à $L^2([0,T^*[;H^s)$ assure, avec l'aide de l'estimation (0.1), que v est dans $L^\infty([0,T^*[;H^s)$; d'où le lemme.

Remarques. Nous pouvons démontrer le même résultat en supposant que le potentiel-vecteur V appartient à $L^1_{\text{loc}}([0,+\infty[;H^{s+1})$.

L'estimation (1.12) ci-dessus est valable pour tout réel positif s.

2. Un lemme de produit; Application à un théorème d'unicité. Nous allons énoncer et démontrer un lemme de produit utilisant la décomposition de Bony d'un produit de deux distributions tempérées.

LEMME 2.1. (i) *Soit v un champ de vecteurs à divergence nulle, si r et r' sont deux réels tels que $r<d/2$, $r'<d/s+1$ et $r+r'\geqq d/2$; alors, nous avons*

$$|v.\nabla a|_{r+r'-d/2-1}\leqq C|v|_r|a|_{r'};$$

(ii) *Soit $r>1-d/2$, nous avons* $|ab|_{r-1}\leqq C(|a|_{d/2-1}|b|_r+|a|_r|b|_{d/2-1})$.

Démonstration. Nous utilisons la décomposition d'un produit en somme de deux paraproduits et d'un reste introduite par Bony dans [2]; c'est à dire que nous écrivons

$$\begin{aligned} v.\nabla a=\sum_{q\geqq 0;j}S_{q-N}(v^j)\partial_j\Delta_q(a)+\sum_{q\geqq 0;j}S_{q-N}(\partial_ja)\Delta_q(v^j)\\ +\sum_{q,q'\geqq 1,|q-q'|\leqq N;j}\Delta_{q'}(v^j)\partial_j\Delta_q(a). \end{aligned} \tag{2.1}$$

Le fait que la divergence du champ de vecteurs v soit nulle permet d'écrire

$$\begin{aligned} v.\nabla a=\sum_{q\geqq 0;j}S_{q-N}(v^j)\partial_j\Delta_q(a)+\sum_{q\geqq 0;j}S_{q-N}(\partial_ja)\Delta_q(v^j)\\ +\sum_{q,q'\geqq -1,|q-q'|\leqq N;j}\partial_j(\Delta_{q'}(v^j)\Delta_q(a)). \end{aligned} \tag{2.2}$$

La caractérisation des espaces de Sobolev inhomogènes donnée en (0.2) permet alors de conclure, une fois observé que, vue la localisation du support de la transformée de Fourier, nous avons $\|\Delta_q(a)\|_{L^\infty}\leqq C2^{qd/2}|\Delta_q(a)|_0$. La démonstration du point (ii) est analogue.

Nous pouvons maintenant énoncer et démontrer le théorème d'unicité suivant.

THÉORÈME 2.2. *Le système (S_ε) admet au plus une solution dans l'espace $L^\infty[(0,T[;H^{d/2-1})\cap L^2([(0,T[;H^{d/2})$.*

Démonstration. Nous procèdons de manière très classique en supposant l'existence de deux solutions v et w pour une même donnée initiale v_0 dans $H^{d/2-1}$, et nous estimons l'évolution en temps de la différence. Nous avons

$$\partial_t(v-w)+v.\nabla(v-w)=-\nabla p(v,w)+(v-w).\nabla w. \tag{2.3}$$

Posons $\delta_\lambda(t)=(|\psi(\lambda D)(v-w)(t,\cdot)|_{d/2-1})^2$, $\delta(t)=\operatorname{Sup}_{\tau\in[0,t]}(|(v-w)(t,\cdot)|_{d/2-1})^2$ et $\Delta(t)=\operatorname{Sup}_{\tau\in[0,t]}|v(\tau,\cdot)|_{d/2-1}$. Il résulte de (1.3), en appliquant l'opérateur $\psi(\lambda D)\Lambda^{d/2-1}$ et en faisant le produit scalaire avec $\psi(\lambda D)\Lambda^{d/2-1}(v-w)$ que

$$\begin{aligned}\delta'_\lambda(t)=&-2(\psi(\lambda D)\Lambda^{d/2-1}(v.\nabla(v-w))(t,\cdot)|\psi(\lambda D)\Lambda^{d/2-1}(v-w)(t,\cdot))\\&+2(\psi(\lambda D)\Lambda^{d/2-1}((v-w).\nabla w)(t,\cdot)|\psi(\lambda D)\Lambda^{d/2-1}(v-w)(t,\cdot))\\&-2\varepsilon(|\psi(\lambda D)\nabla(v-w)(t,\cdot)|_{d/2-1})^2.\end{aligned} \tag{2.4}$$

Le Lemme 1.1 appliqué avec $r=s=d/2$ et $r'=r''=d/2$ assure, pour presque-tout t,

$$\begin{aligned}&(\psi(\lambda D)\Lambda^{d/2-1}(v.\nabla(v-w))(t,\cdot)|\psi(\lambda D)\Lambda^{d/2-1}(v-w)(t,\cdot))\\&\leqq C|v(t,\cdot)|_{d/2}|(v-w)(t,\cdot)|_{d/2-1}|(v-w)(t,\cdot)|_{d/2}.\end{aligned} \tag{2.5}$$

D'après le Lemme de produit 2.1 (i), appliqué avec $r=d/2-1$ et $r'=d/2$, il vient

$$\begin{aligned}&(\psi(\lambda D)\Lambda^{d/2-1}((v-w).\nabla w)(t,\cdot)|\psi(\lambda D)\Lambda^{d/2-1}(v-w)(t,\cdot))\\&\leqq C|w(t,\cdot)|_{d/2}|(v-w)(t,\cdot)|_{d/2-1}|(v-w)(t,\cdot)|_{d/2}.\end{aligned} \tag{2.6}$$

Il résulte de (2.4-2.6) que nous avons, pour presque-tout t,

$$\begin{aligned}&\delta'_\lambda(t)+\varepsilon(|\psi(\lambda D)\nabla(v-w)(t,\cdot)|_{d/2-1})^2\\&\leqq C(|v(t,\cdot)|_{d/2}+|w(t,\cdot)|_{d/2})|(v-w)(t,\cdot)|_{d/2-1}|(v-w)(t,\cdot)|_{d/2}.\end{aligned} \tag{2.7}$$

Or, le fait que $|(v-w)(t,\cdot)|_{s+1}\leqq C(|\nabla(v-w)(t,\cdot)|_s+|(v-w)(t,\cdot)|_s)$ et que $2ab\leqq C^{-1}\varepsilon^{-1}a^2+C\varepsilon b^2$, assure que nous avons, pour presque-tout t,

$$\delta(t)\leqq((C^2/\varepsilon)\left(\int_{[0,t]}(|v(\tau,\cdot)_{,d/2})^2\,d\tau+\int_{[0,t]}(|w(\tau,\cdot|_{d/2})^2\,d\tau\right)+\varepsilon t)\,\delta(t). \tag{2.8}$$

Vu que v et w appartiennent à $L^2([0,T];H^{d/2})$, nous obtenons le résultat en prenant T assez petit.

On va maintenant aborder la démonstration du Théorème 0.1. Dans un premier temps, nous régularisons la donnée initiale v_0 et le potentiel-vecteur V en considérant une suite $(v_{0,n})_{n\in\mathrm{N}}$ (respectivement, $(V_n)_{n\in\mathrm{N}}$) de H^∞ (respectivement, de $L^2_{\mathrm{loc}}([0,+\infty[,H^\infty))$ telle que $v_{0,n}$ (respectivement, V_n) tende vers v_0 dans L^2 (respectivement, V dans $L^2_{\mathrm{loc}}([0,+\infty[,L^2))$.

Le théorème d'existence d'une solution locale en temps pour les systèmes hyperboliques symétriques s'appliquent ici. En effet, comme le terme de viscosité n'apparait pas grâce à son signe, l'estimation hyberbolique linéaire standard (voir, par exemple, [1]) assure, pour le linéarisé $L_vw=\partial_tw+v.\nabla w-\varepsilon\Delta w-\nabla\Delta^{-1}(\operatorname{tr}(dv\,dw))$, l'estimation suivante:

$$\begin{aligned}&\text{si }\lambda\geqq C_s\|v\|_{L^\infty([0,T],H^s)},\text{ pour tout }r>-s+d/2,\text{ si }w\text{ est assez régulière,}\\&\|e^{-\lambda t}w\|_{L^\infty([0,T],H^s)}\leqq|w(0)|_s+\|e^{-\lambda t}L_vw\|_{L^\infty([0,T],H^s)}.\end{aligned} \tag{2.9}$$

En suivant la démarche empruntée par Alinhac et Gérard dans [1], nous obtenons l'existence d'une solution dans $C([0,T];H^s)$ vérifiant l'estimation (2.9) pour le linéarisé. Nous utilisons alors un shéma itératif standard défini par $L_{v^n}v^{n+1}=\nabla^\perp V$ et

$v^{n+1}_{|t=0}=v_0$. L'estimation (2.9) entraine que, pour T assez petit, la suite $(v_n)_{n\in\mathbf{N}}$ est une suite bornée de $C([0, T]; H^s)$. En suivant toujours la démarche usuelle, nous observons que $L_{v^n}(v^{n+1}-v^n)=L_{v^n-v^{n+1}}v^{n+1}$, l'estimation (2.9) assurant alors que, pour t assez petit, la suite $(v_n)_{n\in\mathbf{N}}$ est une suite de Cauchy dans $C([0, T]; H^{s-1})$.

Nous disposons alors, pour tout n, d'une solution v_n définie a priori sur un intervalle de temps $[0, T_n[$. Le Lemme 1.2 assure que ces solutions existent globalement en temps; reste maintenant à démontrer, en s'inspirant de la démonstration du théorème d'unicité, que la suite $(v_n)_{n\in\mathbf{N}}$ est de Cauchy dans $L^\infty_{\text{loc}}([0, +\infty[;L^2)$. Cela va résulter du lemme suivant, valable en toute dimension.

LEMME 2.3. *Soient q un réel de l'intervalle $[d/2-1, +\infty[$, et T un réel strictement positif; si $(v_n)_{n\in\mathbf{N}}$ est une suite de solution du système (S_ε) sur l'intervalle $[0, T]$ pour les données $v_{0,n}$ et V_n telle que:*

(i) *la suite $(v_{0,n})_{n\in\mathbf{N}}$ soit de Cauchy dans l'espace H^q,*

(ii) *la suite $(V_n)_{n\in\mathbf{N}}$ soit de Cauchy dans l'espace $L^2([0, T];H^q)$,*

(iii) *la suite $(v_n)_{n\in\mathbf{N}}$ soit bornée dans l'espace $L^2([0, T];H^{d/2})$;*

alors, la suite $(v_n)_{n\in\mathbf{N}}$ est de Cauchy dans l'espace $C([0, T];H^q)$.

Démonstration. Nous allons étudier l'évolution en temps de $\delta_{n,m}(t)=(|v_n-v_m)(t,\cdot)|_q)^2$. Le système (S_ε) assure que

$$\begin{aligned}\delta'_{n,m}(t)=&-2(\Lambda^q(v_n.\nabla(v_n-v_m))(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &+2(\Lambda^q((v_n-v_m).\nabla v_m).\nabla v_m)(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &-2\varepsilon(|\nabla(v_n-v_m)(t,\cdot)|_q)^2+2(\Lambda^q\nabla^\perp(V_n-V_m)(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot)).\end{aligned}\tag{2.10}$$

En appliquant le Lemme 1.1 (ii) avec $r=d/2$, $r'=q+1$ et $s=r''=q$, il vient, comme $q\geqq d/2-1$,

$$\begin{aligned}&-2(\Lambda^q(v_n.\nabla(v_n-v_m))(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &\qquad\leqq C|v_n(t,\cdot)|_{q+1}|(v_n-v_m)(t,\cdot)|_{q+1}|(v_n-v_m)(t,\cdot)|_q.\end{aligned}\tag{2.11}$$

Comme

$$\begin{aligned}&2(\Lambda^q((v_n-v_m).\nabla v_m)(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &\qquad=2(\Lambda^{q-1}((v_n-v_m).\nabla v_m)(t,\cdot)|\Lambda^{q+1}(v_n-v_m)(t,\cdot)),\end{aligned}$$

l'application du Lemme de produit 2.1 (ii) avec $r=q$, il vient, grâce au fait que q est plus grand que $d/2-1$,

$$\begin{aligned}&2(\Lambda^q((v_n-v_m).\nabla v_m)(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &\qquad\leqq C|v_m(t,\cdot)|_{q+1}|(v_n-v_m)(t,\cdot)|_q|(v_n-v_m)(t,\cdot)|_{q+1}.\end{aligned}\tag{2.12}$$

Il s'agit donc maintenant, d'après (2.11) et (2.12), de majorer la quantité

$$\Delta_{n,m}(t)=C(|v_n(t,\cdot)|_{q+1}+|v_m(t,\cdot)|_{q+1})|(v_n-v_m)(t,\cdot)|_{q+1}|(v_n-v_m)(t,\cdot)|_q.\tag{2.13}$$

En utilisant le fait que $|(v_n-v_m)(t,\cdot)|_{q+1}\leqq|\nabla(v_n-v_m)(t,\cdot)|_q+|(v_n-v_m)(t,\cdot)|_q$, nous obtenons

$$\begin{aligned}\Delta_{n,m}(t)\leqq\;& C(|v_n(t,\cdot)|_{q+1}+|v_m(t,\cdot)|_{q+1})(\varepsilon^{-1}(|v_n(t,\cdot)|_{q+1}+|v_m(t,\cdot)|_{q+1})+1)\delta_{n,m}(t)\\ &+(\varepsilon/2)(|\nabla(v_n-v_m)(t,\cdot)|_q)^2.\end{aligned}\tag{2.14}$$

Enfin, une intégration par parties standard assure

$$\begin{aligned}&2(\Lambda^q\nabla^\perp(V_n-V_m)(t,\cdot)|\Lambda^q(v_n-v_m)(t,\cdot))\\ &\qquad\leqq\varepsilon^{-1}(|(V_n-V_m)(t,\cdot)|_q)^2+\varepsilon(|\nabla(v_n-v_m)(t,\cdot)|_q)^2.\end{aligned}\tag{2.15}$$

Il résulte alors de (2.11-2.15) que l'on a

$$
\begin{aligned}
&\delta_{n,m}(t)+(\varepsilon/2)\int_{[0,t]}(|\nabla(v_n-v_m)(\tau,\cdot)|_q)^2\,d\tau\\
&\leqq\delta_{n,m}(0)\exp C(\varepsilon,T)\int_{[0,T]}((|v_m(t,\cdot)|_{q+1})^2+(|v_n(t,\cdot)|_{q+1})^2+1)\,d\tau\\
(2.16)\qquad&+\int_{[0,t]}\varepsilon^{-1}(|V_n-V_m)(t,\cdot)|_q)^2\exp(C(\varepsilon,T)\\
&\cdot\int_{[\tau,t]}(|v_m(\dagger,\cdot)|_{q+1})^2+(|v_n(\dagger,\cdot)|_{q+1})^2+1)\,d\dagger)\,d\tau,
\end{aligned}
$$

d'où le lemme.

Revenons à la démonstration du Théorème 0.1. Comme, d'après l'identité d'énergie (E), la suite $(v_n)_{n\in\mathbf{N}}$ est bornée dans $L^2([0,T[;H^1)$, le Lemme 2.3 assure le Théorème 0.1 pour $s=0$.

Pour démontrer le Théorème 0.1 dans tout les cas, on va procéder par une récurrence très simple; supposons que la solution v soit telle que $v\in C([0,+\infty[;H^r)\cap L^2_{\text{loc}}([0,+\infty[;H^{r+1})$, pour $r<s$. Pour tout réel α strictement positif, il existe un réel t_0 de l'intervalle $]0,\alpha[$ tel que $v(t_0,\cdot)$ appartienne à H^{r+1}. Nous considérons alors une suite $(v_n)_{n\in\mathbf{N}}$ de solution régularisée construite comme au début de la démonstration du cas $s=0$. L'estimation d'énergie (1.12) assure que la suite $(v_n)_{n\in\mathbf{N}}$ est bornée dans $L^2_{\text{loc}}([t_0,+\infty[;H^{\text{Inf}(s,r+1)+1})$. Le Lemme 2.3 alors le résultat.

3. Existence globale en dimension 3. Le but de cette partie est la démonstration du Théorème 0.2. Observons le comportement du système (S_ε) par changement d'échelle. Si v est une solution du système (S_ε) avec données v_0 et f; alors, pour tout réel λ strictement postif, $v_\lambda(t,x)=\lambda v(\lambda^2t,\lambda x)$ est solution du systéme (S_ε) avec données $v_{0,\lambda}=\lambda v_0(\lambda x)$ et $V_\lambda(t,x)=\lambda^2V(\lambda^2t,\lambda x)$. Nous avons très facilement les égalités suivantes:

(3.1)

$$|v_{0,\lambda}|_0=\lambda^{-1/2}|v_0|_0\quad\text{et}\quad\left(\int_{[0,+\infty[}(|V_\lambda(t,\cdot)|_0)^2\,dt\right)^{1/2}=\lambda^{-1/2}\left(\int_{[0,+\infty[}(|V(t,\cdot)|_0)^2\,dt\right)^{1/2},$$

$$\|v_{0,\lambda}|_{1/2}=\|v_0|_{1/2}\quad\text{et}\quad\left(\int_{[0,+\infty[}(\|V_\lambda(t,\cdot)|_{1/2})^2\,dt\right)^{1/2}=\left(\int_{[0,+\infty[}(\|V(t,\cdot)|_{1/2})^2\,dt\right)^{1/2}.$$

Il en résulte qu'il suffit de démontrer le Théorème 0.2 en supposant

$$|v_0|_{1/2}+\varepsilon^{-1/2}\left(\int_{[0,+\infty[}(|V(t,\cdot)|_{1/2})^2\,dt\right)^{1/2}\leqq C_0\varepsilon. \tag{3.2}$$

Nous procèdons comme pour la démonstration du Théorème 0.1; nous commencons par régulariser les données v_0 et V en considérant une suite $(v_{0,n})_{n\in\mathbf{N}}$ de H^∞ (respectivement, $(V_n)_{n\in\mathbf{N}}$) telle que $v_{0,n}$ tende vers v_0 dans $H^{1/2}$ (respectivement, V_n tende vers V dans $L^2([0,+\infty[;H^{1/2}))$ et que

$$|v_{0,n}|_{1/2}+\varepsilon^{-1/2}\left(\int_{[0,+\infty[}(|V_n(t,\cdot)|_{1/2})^2\,dt\right)^{1/2}\leqq C_0\varepsilon.$$

L'étape essentielle consiste en la démonstration d'estimations a priori sur les solutions v_n du système (S_ε) pour les données initiales $v_{0,n}$ et V_n assurant que ces solutions existent globalement en temps; il suffit ensuite d'appliquer le Lemme 2.3.

Nous allons désigner par v une solution quelconque du système (S_ε) avec données v_0 et V vérifiant (3.2) telles que v_0 soit H^∞ et V soit $L^2_{\text{loc}}([0,+\infty[;H^\infty)$. La solution v est définie sur l'intervalle maximal $[0, T^*[$. Etudions la fonction $g(t)=(\|v(t,\cdot)|_{1/2})^2+(|v(t,\cdot)|_0)^2$; nous avons

$$\begin{aligned}g'(t)&\leqq 2(\Delta^{1/4}(v.\nabla v)|\Delta^{1/4}v)-2\varepsilon(\Delta^{1/4}\nabla v(t,\cdot)|\Delta^{1/4}\nabla v(t,\cdot))\\&\quad+2(\Delta^{1/4}\nabla^\perp V(t,\cdot)|\Delta^{1/4}v(t,\cdot))\\&\quad-2\varepsilon(\nabla v(t,\cdot)|\nabla v(t,\cdot))+2(\nabla^\perp V(t,\cdot)|v(t,\cdot)).\end{aligned}\tag{3.3}$$

D'après le Lemme 1.1(i), il existe une constante $C>0$ telle que l'on ait:

$$2(\Delta^{1/4}(v.\nabla v)(t,\cdot)|\Lambda^{1/4}v(t,\cdot))\leqq C|v(t,\cdot)|_{1/2}(\|v(t,\cdot)|_{3/2})^2.\tag{3.4}$$

De plus, $2(\nabla^\perp V(\tau,\cdot)|v(\tau,\cdot))\leqq\varepsilon^{-1}(|V(\tau,\cdot)|_0)^2+\varepsilon(\|v(t,\cdot)|_1)^2$; de même, nous avons $2(\Delta^{1/4}\nabla^\perp V(t,\cdot)|\Delta^{1/4}v(t,\cdot))\leqq\varepsilon^{-1}(\|V(t,\cdot)|_{1/2})^2+\varepsilon(\|v(t,\cdot)|_{3/2})^2$; nous obtenons alors

$$g'(t)+\varepsilon(\|v(t,\cdot)|_{3/2})^2\leqq(C|v(t,\cdot)|_{1/2}-2\varepsilon)(\|v(t,\cdot)|_{3/2})^2+\varepsilon^{-1}(|V(t,\cdot)|_{1/2})^2.\tag{3.5}$$

Il en résulte que, tant que $|v(t,\cdot)|_{1/2}$ reste inférieur à ε/C, nous avons

$$g'(t)+\varepsilon(\|v(t,\cdot)|_{3/2})^2\leqq\varepsilon^{-1}(|V(t,\cdot)|_{1/2})^2.\tag{3.6}$$

Il en résulte, par une intégration immédiate, que, tant que $|v(t,\cdot)|_{1/2}$ reste inférieur à ε/C,

$$(|v(t,\cdot)|_{1/2})^2+\varepsilon\int_{[0,t]}(\|v(\tau,\cdot)|_{3/2})^2\,d\tau\leqq(|v_0|_{1/2})^2+\varepsilon^{-1}\int_{[0,+\infty[}(|V(\tau,\cdot)|^2_{1/2}\,d\tau.\tag{3.7}$$

Donc, si $|v_0|_{1/2}+\varepsilon^{-1/2}\int_{[0,+\infty[}(|V(\tau,\cdot)|^2_{1/2}\,d\tau)^{1/2}\leqq\varepsilon/2C$, alors l'estimation (3.7) est vraie sur tout l'intervalle $[0,T^*[$. Le lemme d'explosion 1.2 assure alors que $T^*=+\infty$. L'estimation (3.7) est donc valable sur tout $\mathbf{R}^+$. En utilisant une récurrence strictement analogue à celle concluant la démonstration du Théorème 0.1, nous obtenons le Théorème 0.2 via le Lemme 2.3.

ON UNIFORM DIFFERENCE SCHEMES FOR SECOND-ORDER SINGULAR PERTURBATION PROBLEMS IN BANACH SPACES[*]

A. ASHYRALYEV[†] AND H. O. FATTORINI[‡]

Abstract. The paper considers finite difference approximations of arbitrary order $O(\tau^n)$ to certain nonhomogeneous singular perturbation problems involving a small coefficient ε^2 in the higher derivative, where τ is the length of the discretization step in t and n is an arbitrary integer fixed in advance. Approximation is uniform with respect to ε.

Key words. singular perturbation, finite difference schemes

AMS(MOS) subject classifications. 65N05, 35R99

1. Introduction. We consider in this paper four singular perturbation problems involving second-order differential equations in a Banach space E. The equations are

$$\varepsilon^2 u''(t; \varepsilon) = Au(t, \varepsilon) + f(t), \tag{1.1}$$

$$\varepsilon^2 u''(t, \varepsilon) + u'(t, \varepsilon) = Au(t, \varepsilon) + f(t), \tag{1.2}$$

$$\varepsilon^2 u''(t, \varepsilon) - iu'(t, \varepsilon) = Au(t, \varepsilon) + f(t), \tag{1.3}$$

$$\varepsilon^2 u''(t, \varepsilon) + u'(t, \varepsilon) = (\varepsilon^2 A + B)u(t, \varepsilon) + f(t), \tag{1.4}$$

where A, B are linear, generally unbounded operators in E. In each case, the usual initial conditions are given:

$$u(0) = u_0, \qquad u'(0) = u_1. \tag{1.5}$$

The *singular perturbation problem* related to these equations is that of showing that

$$u(t, \varepsilon) \to u(t), \tag{1.6}$$

where $u(t)$ is the solution of the *limit equation* obtained by setting $\varepsilon = 0$ in (1.1), (1.2), (1.3), (1.4). The corresponding limit equations are

$$Au(t) + f(t) = 0, \tag{1.7}$$

$$u'(t) = Au(t) + f(t), \tag{1.8}$$

$$u'(t) = iAu(t) + if(t), \tag{1.9}$$

$$u'(t) = Bu(t) + f(t). \tag{1.10}$$

Equations (1.8), (1.9), and (1.10) come with the initial condition

$$u(0) = u_0, \tag{1.11}$$

while (1.7) is not associated with any initial condition. The singular perturbation problem associated with (1.1) is called *elliptic* since in typical applications A is a

(linear) elliptic operator. The singular perturbation problem associated with (1.2) is called *parabolic* [11], [14]. The *Schrödinger* perturbation problem is associated with (1.3), ([12], [14]) and the *hyperbolic* problem corresponds to (1.4) ([13], [14]); a reason for the latter terminology is that one of the main applications of (1.4) is to the hyperbolic partial differential equation $\varepsilon^2(u_{tt}-a(x)u_{xx})+(u_t+b(x)u_x)=f(x,t)$, which appears in problems of traffic flow (see [13]). The parabolic singular perturbation problem appears in the study of oscillations in viscous media and the Schrödinger singular perturbation problem in the proof that the nonrelativistic limit of the Klein-Gordon equation is the Schrödinger equation. For further details and bibliography on these applications, see [14], especially Chapters VI and VIII.

Equations like (1.1) could be handled as first-order systems in a suitable "phase space" as in [14, Chap. III], or [18], thus reducing the problem to one involving first-order rather than second-order equations. However, the fact that the limit equations of the second-order equations are of first order makes it simpler and more efficient to deal directly with the equations rather than with the corresponding systems. The same comment applies to (1.2), (1.3), and (1.4). Moreover, the finite difference schemes obtained by reduction to first-order systems are different than those implemented in the second-order equation.

A (strong) solution of any of the equations (1.1)-(1.4) is a function twice continuously differentiable in the norm of E such that $u(t)\in D(A)$ and the equation is satisfied everywhere. A minimal assumption on the initial value problem for any of the equations (1.1)-(1.4) for fixed ε is *well posedness*: there exists a dense subspace D of E such that (a) for every $u_0, u_1\in D$ the initial value problem has a strong solution $u(t;\varepsilon)$ in $t\geqq 0$, and (b) arbitrary strong solutions $u(t;\varepsilon)$ depend continuously on their initial data u_0, u_1 uniformly on compact subsets. In each of the four cases the equation is reduced by elementary transformations to the equation

$$v''(t)=Av(t); \tag{1.12}$$

thus the well-posedness requirement will be transferred to (1.12). It is known [23], [8] that the well-posedness condition is satisfied if and only if A is the infinitesimal generator of a strongly continuous cosine function $\{C(t);\ -\infty<t<\infty\}$. The solution of the inhomogeneous equation

$$v''(t)=Av(t)+g(t) \tag{1.13}$$

is given by

$$v(t)=C(t)v(0)+S(t)v'(0)+\int_0^t S(t-s)g(s)\,ds, \tag{1.14}$$

where

$$S(t)u=\int_0^t C(s)u\,ds. \tag{1.15}$$

The operator valued functions $C(\cdot)$, $S(\cdot)$ are called the *solution operators* of (1.12). In general, $v(t)$ is a strong solution only under suitable assumptions on $v(0)$, $v'(0)$, and $g(s)$ (for example, $v(0)$, $v'(0)\in D(A)$, $g(\cdot)$ is twice continuously differentiable). For arbitrary $v(0)$, $v'(0)$, and locally integrable $g(\cdot)$ the (strongly continuous) function (1.14) satisfies the equation (1.13) and the second initial condition (1.5) only in the sense of distributions and is called a *weak solution* (or simply a *solution*) of (1.12). It follows from a uniqueness argument that every solution of (1.13) admits the representation (1.14).

The solution operators $C(\cdot)$, $S(\cdot)$ can be extended to all t setting $C(t)=C(-t)$, $S(t)=-S(-t)$; we have $C(0)=I$, $S(0)=0$,

$$(1.16)\qquad \begin{aligned} &(S(t)u)'=C(t) \qquad (u\in E),\\ &(C(t)u)'=AS(t)u=S(t)Au \qquad (u\in D(A)),\end{aligned}$$

$$(1.17)\qquad C(s+t)+C(s-t)=2C(s)C(t),$$

$$(1.18)\qquad S(s+t)+S(s-t)=2S(s)C(t)$$

for $-\infty<s,\ t<\infty$ (the last two equations are called the *cosine* and *sine* functional equation, respectively). Finally, $C(\cdot)$ and $S(\cdot)$ grow exponentially at infinity:

$$(1.19)\qquad \|C(t)\|,\ \|S(t)\|\leqq Me^{\omega|t|} \qquad (-\infty<t<\infty)$$

for suitable M, ω. The resolvent $R(\lambda^2;\ A)=(\lambda^2I-A)^{-1}$ exists for $\operatorname{Re}\lambda>\omega$. (For proof of these and other properties, see [23] or [14].)

We consider in this paper discretizations (that is, approximation by finite difference schemes) of the initial value problems (1.1)-(1.4), which yield approximations to the solution $u(t,\ \varepsilon)$ of arbitrarily high order in the discretization step τ, uniformly in ε for $\varepsilon>0$. These discretizations are based on reduction of each equation to (1.13) and on the simplest difference scheme for this equation (introduced in [21]), which is examined in detail in § 3 and can be considered a direct generalization of the Courant-Friedrichs-Lewy difference scheme for the one-dimensional wave equation in [4]. This difference scheme is directly applied to (1.13) via Taylor expansions of the right-hand side about mesh points $k\tau$. Other treatments of finite difference schemes for second-order equations are in [3], [16], [20], and [22]. A general study of discretization schemes for linear convolution equations (possibly more general than differential) is in [10], although without rates of convergence.

Uniform difference schemes for ordinary differential equations were considered by numerous authors: see [19] and especially [5] and bibliography there. See also [7], [1], and [2] for a related problem for a partial differential equation. In this connection, we note that there is another equally natural way to approximate the solution of singular perturbation problems as $\varepsilon\to 0$, which is first to use asymptotic expansions and then to discretize them, as done in [17] and [6]. For a treatment of asymptotic expansions for operator equations see [11], [14] for the parabolic problem and [13] for the hyperbolic problem.

Since the elliptic singular perturbation problem is not included in [14] (and has probably not been studied in this level of generality) we include in § 2 a few simple convergence results, although convergence of $u(t,\varepsilon)$ to the solution of (1.7) is not essential (uniform approximation holds even in cases where $u(t,\ \varepsilon)$ is not convergent). A treatment of convergence of $u(t,\ \varepsilon)$ for (1.2) and (1.3) (respectively, (1.4)) can be found in [14] (respectively, [13]).

2. The elliptic singular perturbation problem. The initial value problem is

$$(2.1)\qquad \varepsilon^2u''(t;\ \varepsilon)=Au(t;\ \varepsilon)+f(t),$$

$$(2.2)\qquad u(0;\ \varepsilon)=u_0, \qquad u'(0;\ \varepsilon)=u_1.$$

The assumptions on A have been stated in § 1. We assume in addition that 0 belongs to the resolvent set $\rho(A)$ of A, that is, that A^{-1} exists and is bounded (this can always be insured by a translation). In this case, the solution $u(t)$ of the limit equation (1.7) is given by

$$(2.3)\qquad u(t)=-A^{-1}f(t).$$

Set $v(t)=u(\varepsilon t;\ \varepsilon)$. Then $v(\cdot)$ satisfies the initial value problem

$$v''(t)=Av(t)+f(\varepsilon t), \tag{2.4}$$

$$v(0)=u_0, \qquad v'(0)=\varepsilon u_1. \tag{2.5}$$

Expressing $v(t)$ by means of (1.14) we obtain the formula

$$u(t;\ \varepsilon)=C(t/\varepsilon)u_0+\varepsilon S(t/\varepsilon)u_1+\varepsilon^{-1}\int_0^t S((t-s)/\varepsilon)f(s)\,ds. \tag{2.6}$$

In general, $u(t,\ \varepsilon)$ does not converge as $\varepsilon\to 0$.

Using formulas (1.16) and assuming that $f(t)$ is continuously differentiable as many times as necessary we obtain, integrating by parts repeatedly,

$$\begin{aligned}\int_a^b S((b-s)/\varepsilon)f(s)\,ds=&-\sum_{j=1}^{m}\varepsilon^{2j-1}\{C((b-s)/\varepsilon)A^{-j}f^{(2j-2)}(s)\}\Big|_a^b\\ &-\sum_{j=1}^{m-1}\varepsilon^{2j}\{S((b-s)/\varepsilon)A^{-j}f^{(2j-1)}(s)\}\Big|_a^b\\ &+\varepsilon^{2m-1}\int_a^b C((b-s)/\varepsilon)A^{-m}f^{(2m-1)}(s)\,ds.\end{aligned} \tag{2.7}$$

Integrating by parts once again,

$$\begin{aligned}\int_a^b S((b-s)/\varepsilon)f(s)\,ds=&-\sum_{j=1}^{m}\varepsilon^{2j-1}\{C((b-s)/\varepsilon))A^{-j}f^{(2j-2)}(s)\}\Big|_a^b\\ &-\sum_{j=1}^{m}\varepsilon^{2j}\{S((b-s)/\varepsilon)A^{-j}f^{(2j-1)}(s)\Big|_a^b\\ &+\varepsilon^{2m}\int_a^b S((b-s)/\varepsilon)A^{-m}f^{(2m)}(s)\,ds.\end{aligned} \tag{2.8}$$

We justify these formulas under minimal hypotheses on f. Let $f(\cdot)$ be an E-valued function defined in $a\leqq t\leqq b$. Denote by $H^{1,p}(a,b;\ E)$ the space of all functions $f(\cdot)$ such that there exists $g(\cdot)\in L^p(a,b;\ E)$ and $u\in E$ such that

$$f(t)=u+\int_a^t g(s)\,ds \qquad (a\leqq t\leqq b).$$

Obviously, $f(\cdot)$ is absolutely continuous and has a derivative $f'(t)=g(t)$ almost everywhere.

For $r=1,2,\cdots$ we denote by $H^{r,p}(a,b;\ E)$ the space of all E-valued $r-1$ times continuously differentiable functions $u(\cdot)$ such that $u^{(r-1)}(\cdot)\in H^{1,p}(a,b;\ E)$.

Let ω be the constant in (1.19). It is shown in [8], [14] that if $\lambda\geqq\omega$ then fractional powers $(\lambda^2I-A)^\alpha$ can be defined for all α, $-\infty<\alpha<\infty$. These fractional powers satisfy the additivity property $(\lambda^2I-A)^{\alpha+\beta}=(\lambda^2I-A)^\alpha(\lambda^2I-A)^\beta$. Moreover, $(\lambda^2I-A)^{-\alpha}$ is bounded for $\lambda>\omega$ and $\alpha>0$ and for arbitrary λ, $\mu\geqq\omega$, $-\infty<\alpha<\infty$, $D((\lambda^2I-A)^\alpha)=D(\mu^2I-A)^\alpha)$ and $(\lambda^2I-A)^\alpha-(\mu^2I-A)^\alpha$ is bounded.

LEMMA 2.1. *Let $f(\cdot)$ be an E-valued function defined in $a\leqq t\leqq b$ and let $\lambda\geqq\omega$, $0\leqq\alpha\leqq 1$, m, r be positive integers. Then the following statements are equivalent*:

$$(A^{-m}(\lambda^2I-A)^{-\alpha}f)(\cdot)\in H^{r,1}(a,b;\ E), \tag{2.9}$$

$$((\lambda^2I-A)^{-m-\alpha}f)(\cdot)\in H^{r,1}(a,b;\ E) \tag{2.10}$$

and independent of λ for $\lambda>\omega$.

That (2.9) and (2.10) are equivalent follows from the equalities

$$\begin{aligned} A^{-m}(\lambda^2I-A)^{-\alpha}-(\lambda^2I-A)^{-m-\alpha} &= (A^{-m}-(\lambda^2I-A)^{-m})(\lambda^2I-A)^{-\alpha} \\ &= (I-A^{m}(\lambda^2I-A)^{-m})A^{-m}(\lambda^2I-A)^{-\alpha} \\ &= -(I-(\lambda^2I-A)^{m}A^{-m})(\lambda^2I-A)^{-m-\alpha} \end{aligned}$$

with both $(I-A^m(\lambda^2I-A)^{-m})$ and $(I-(\lambda^2I-A)^mA^{-m})$ bounded. As for independence of λ, we note that, for $\beta>0$ and $\lambda>\omega$,

$$(\mu^2I-A)^{-\alpha}=((\mu^2I-A)^{-\alpha}(\lambda^2I-A)^{\alpha})(\lambda^2I-A)^{-\alpha}$$

with $(\mu^2I-A)^{-\alpha}(\lambda^2I-A)^{\alpha}$ bounded (see [14]).

It is known ([7], [14, Chap. III]) that if $\lambda\geqq\omega$ and $\alpha<\frac{1}{2}$ then $S(t)E\subset D(((\lambda^2I-A)^{\alpha})$ and

$$t\to(\lambda^2I-A)^{\alpha}S(t) \tag{2.11}$$

is a strongly continuous function for all t. This may not be true for $\alpha=\frac{1}{2}$; for instance, if E is the space $C_0(-\infty,\infty)$ of all continuous functions on the line that tend to zero at $\pm\infty$ and $A=d^2/dx^2$ with maximal domain, A is the infinitesimal generator of the cosine function

$$C(t)u(x)=\{u(x+t)+u(x-t)\}/2$$

and (2.11) is not bounded for $\alpha=\frac{1}{2}$ (see [14]). However, (2.11) is strongly continuous for $\alpha=\frac{1}{2}$ if $E=L^p(\Xi,\Sigma,\mu)$ for $1<p<\infty$, (Ξ,Σ,μ) a measure space, in particular, if E is a Hilbert space.

LEMMA 2.2. (a) *Let $r\geqq1$ be odd and let $f(\cdot)$ be an E-valued function such that, for some $\lambda\geqq\omega$ and $\alpha<\frac{1}{2}$,*

$$((\lambda^2I-A)^{-j-\alpha}f)(\cdot)\in H^{2j,1}(a,b;E)\qquad(1\leqq j\leqq(r-1)/2), \tag{2.12}$$

$$(A^{-j}f)(\cdot)\in H^{2j-1,1}(a,b;E)\qquad(1\leqq j\leqq(r+1)/2). \tag{2.13}$$

Then

$$\begin{aligned} &\int_a^b S((b-s)/\varepsilon)f(s)\,ds \\ &\quad=-\sum_{j=1}^{(r+1)/2}\varepsilon^{2j-1}\{(A^{-j}f)^{(2j-2)}(b)-C((b-a)/\varepsilon))(A^{-j}f)^{(2j-2)}(a)\} \\ &\qquad+\sum_{j=1}^{(r-1)/2}\varepsilon^{2j}S((b-a)/\varepsilon)(A^{-j}f)^{(2j-1)}(a) \\ &\qquad+\varepsilon^{r}\int_a^b C((b-s)/\varepsilon)(A^{-(r+1)/2}f)^{(r)}(s)\,ds \\ &\quad=I_r(a,b,\varepsilon;f)+\varepsilon^{r}\int_a^b C((b-s)/\varepsilon)(A^{-(r+1)/2}f)^{(r)}(s)\,ds \end{aligned} \tag{2.14}$$

(r odd).

(b) *Let $r\geqq2$ be even and $f(\cdot)$ be an E-valued function such that, for some $\lambda\geq\omega$ and $\alpha<\frac{1}{2}$,*

$$((\lambda^2I-A)^{-j-\alpha})f(\cdot)\in H^{2j,1}(a,b;E)\qquad(1\leqq j\leqq r/2), \tag{2.15}$$

$$(A^{-j}f)(\cdot)\in H^{2j-1,1}(a,b;E)\qquad(1\leqq j\leqq r/2). \tag{2.16}$$

Then

$$\begin{aligned}\int_a^b & S((b-s)/\varepsilon)f(s)\,ds \\ &= -\sum_{j=1}^{r/2} \varepsilon^{2j-1}\{(A^{-j}f)^{(2j-2)}(b) - C((b-a)/\varepsilon))(A^{-j}f)^{(2j-2)}(a)\} \\ &\quad + \sum_{j=1}^{r/2} \varepsilon^{2j} S((b-a)/\varepsilon)(A^{-j}f)^{(2j-1)}(a) \\ &\quad + \varepsilon^r \int_a^b S((b-s)/\varepsilon)(A^{-r/2})f^{(r)}(s)\,ds \\ &= I_r(a, b, \varepsilon; f) + \varepsilon^r \int_a^b S((b-s)/\varepsilon)(A^{-r/2})f^{(r)}(s)\,ds \end{aligned} \tag{2.17}$$

$(r\ even)$.

If $E = L^p(\Xi, \Sigma, \mu)$ $(1 < p < \infty)$, (Ξ, Σ, μ) a measure space, we may take $\alpha = \frac{1}{2}$ in (2.12) and (2.15).

Proof. We extend $f(\cdot)$ setting $f(t) = f(a)$ for $t \leqq a$ and $f(t) = f(b)$ for $t \geqq b$ and define $f_n = \phi_n * f$, where $\{\phi_n\}$ is a δ-sequence of scalar test functions. Since f_n is infinitely differentiable, (2.7) can be applied. To take limits in the first summation, we observe that $(A^{-j}f_n)^{(2j-1)}(\cdot) \to (A^{-j}f)^{(2j-1)}(\cdot)$ in $L^1(a, b; E)$, so that $(A^{-j}f_n)^{(2j-2)}(\cdot) \to (A^{-j}f)^{(2j-2)}(\cdot)$ uniformly and, in particular, $(A^{-j}f_n)^{(2j-2)}(a) \to (A^{-j}f)^{(2j-2)}(a)$. For the second summation, we note that

$$\begin{aligned} & S((b-a)/\varepsilon)(A^{-j}f_n)^{(2j)}(s) \\ &\quad = ((\lambda^2 I - A)^\alpha S((b-a)/\varepsilon))(A^{-j}(\lambda^2 I - A)^{-\alpha} f_n)^{(2j)}(s), \end{aligned} \tag{2.18}$$

deducing that $S((b-a)/\varepsilon)(A^{-j}f_n)^{(2j)}(\cdot) \to S((b-a)/\varepsilon)(A^{-j}f)^{(2j)}(\cdot)$ in $L^1(a, b; E)$. Finally, we can take limits in the integral since, due to the last condition (2.12), $(A^{-(r+1)/2}f_n)^{(r)}(\cdot) \to (A^{-(r+1)/2}f)^{(r)}(\cdot)$ in the space $L^1(a, b; E)$.

The proof of (b) is similar. The treatment of the boundary terms is exactly the same. As for the integral, we write

$$\begin{aligned} & S((b-s)/\varepsilon)(A^{-r/2}f_n)^{(r)}(s) \\ &\quad = ((\lambda^2 I - A)^\alpha S((b-s)/\varepsilon))(A^{-r/2}(\lambda^2 I - A)^{-\alpha} f_n)^{(r)}(s) \end{aligned} \tag{2.19}$$

and use the last condition (2.16).

Example 2.3. Let $E = L^2(0, \pi)$, $A = d^2/dx^2$ with maximal domain determined by the boundary conditions

$$u(0) = u(\pi) = 0.$$

The spectral decomposition of A is

$$Au(x) = A \sum_{n=1}^{\infty} c_n \sin nx = -\sum_{n=1}^{\infty} n^2 c_n \sin nx \tag{2.20}$$

and that of the cosine function $C(t)$ generated by A is

$$C(t)u(x) = \{u(x+t) + u(x-t)\}/2 = \sum_{n=1}^{\infty} c_n \cos nt \sin nx. \tag{2.21}$$

Since we are in a Hilbert space and $\omega = 0$, we may use conditions (2.12) or (2.15) for $\lambda = 0$ and $\alpha = \frac{1}{2}$. An E-valued function

$$f(t) = \sum_{n=1}^{\infty} c_n(t) \sin nx \tag{2.22}$$

satisfies (2.12) and (2.13) if and only if all the coefficients $c_n(t)$ are $r-1$ times continuously differentiable with $c_n^{(r-1)}(t)$ absolutely continuous and such that the functions

$$\{\Sigma \, |n^{-2j-1} c_n^{(2j)}(t)|^2\}^{1/2} \qquad (1 \leqq j \leqq (r-1)/2), \tag{2.23}$$

$$\{\sum |n^{-2j} c_n^{(2j-1)}(t)|^2\}^{1/2} \qquad (1 \leqq j \leqq (r+1)/2) \tag{2.24}$$

belong to $L^1(a, b; E)$ or, equivalently, if all the functions

$$\{\sum |n^{-j-1} c_n^{(j)}(t)|^2\}^{1/2} \qquad (1 \leqq j \leqq r) \tag{2.25}$$

belong to $L^1(a, b; E)$. Conditions (2.15) and (2.16) reduce also to (2.25).

Remark 2.4. The assumption that $f(\cdot)$ is an E-valued function in Lemma 2.2 can be weakened: it is enough that, for some $\alpha < \frac{1}{2}$, $f(\cdot)$ satisfy (2.12) or (2.15) for $j = 0$. If $E = L^p(\Xi, \Sigma, \mu)(1 < p < \infty)$, we may take $\alpha = \frac{1}{2}$. In Example 2.3, this amounts to abandoning the requirement that $\{\sum |c_n(t)|^2\}^{1/2}$ be summable and require only that (2.25) hold for $j = 0$ as well.

Formulas (2.14) and (2.17) (used for $a = 0$, $b = t$) provide asymptotic series up to any power of ε for the solution $u(t, \varepsilon)$ of (2.1). For instance, formula (2.17) for $r = 2$ yields

$$\begin{aligned} u(t, \varepsilon) = {} & -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) \\ & + \varepsilon S(t/\varepsilon)(u_1 + (A^{-1}f)'(0)) \\ & + \varepsilon \int_0^t S((t-s)/\varepsilon)(A^{-1}f)''(s)\, ds \end{aligned} \tag{2.26}$$

or, formula (2.14) with $r = 3$,

$$\begin{aligned} u(t, \varepsilon) = {} & -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) \\ & + \varepsilon S(t/\varepsilon)(u_1 + (A^{-1}f)'(0)) \\ & - \varepsilon^2 (A^{-2}f)''(t) + \varepsilon^2 C(t/\varepsilon)(A^{-2}f)''(0) \\ & + \varepsilon^2 \int_0^t C((t-s)/\varepsilon)(A^{-2}f)'''(s)\, ds. \end{aligned} \tag{2.27}$$

These two formulas are used in the following result.

THEOREM 2.5. *Assume that*

$$\|C(t)\|, \|S(t)\| \leqq M \qquad (-\infty < t < \infty). \tag{2.28}$$

(a) *Let* $f(\cdot)$ *satisfy*

$$((\lambda^2 I - A)^{-1-\alpha})f(\cdot) \in H^{2,1}(0, T; E), \qquad (A^{-1}f)(\cdot) \in H^{1,1}(0, T; E), \tag{2.29}$$

for some $\alpha < \frac{1}{2}$. *Then*

$$u(t, \varepsilon) = -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) + 0(\varepsilon) \qquad (\varepsilon \to 0) \tag{2.30}$$

uniformly in $0 \leqq t \leqq T$.

(b) *Let* (2.28) *hold, and assume in addition that*

$$(2.31)\qquad ((\lambda^2 I - A)^{-1-\alpha})f(\cdot) \in H^{2,1}(0, T; E), \qquad (A^{-2}f)(\cdot) \in H^{3,1}(0, T; E)$$

for some $\alpha < \frac{1}{2}$. *Then*

$$(2.32)\qquad \begin{aligned} u(t, \varepsilon) &= -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) \\ &\quad + \varepsilon S(t/\varepsilon)(u_1 + (A^{-1}f)'(0)) + 0(\varepsilon^2) \qquad (\varepsilon \to 0) \end{aligned}$$

uniformly in $0 \leqq t \leqq T$.

(c) *If* $E = L^p(\Xi, \Sigma, \mu)$ $(1 < p < \infty)$, *then* (2.32) *is true under the only assumption that* $\alpha = \frac{1}{2}$ *in* (2.31).

(d) *If E is a Hilbert space then* (2.31) *is true under the only assumption that* $\alpha = \frac{1}{2}$ *in* (2.31).

The proof of Theorem 2.5 (a) and (b) follows from (2.26) and (2.27), respectively; we use the fact that the (strongly continuous operator valued) function

$$(2.33)\qquad (\lambda^2 I - A)^{\alpha} S(\cdot)$$

is uniformly bounded in $-\infty < s < \infty$, which follows from an analogue of formula (6.18) in [14] for $\alpha < \frac{1}{2}$. To show (c) we note that if $E = L^p(\Xi, \Sigma, \mu)$ $(1 < p < \infty)$, then (2.33) is a strongly continuous operator valued function in $-\infty < s < \infty$ also for $\alpha = \frac{1}{2}$. However, the hypotheses that $E = L^p(\Xi, \Sigma, \mu)$ does not insure uniform boundedness of (2.33) [14, Chap. III]; thus (2.30) does not follow. However, if E is a Hilbert space, the first condition (2.28) implies that

$$C(t) = K \cosh(tB) K^{-1},$$

where B is self-adjoint with $B \leqq 0$ and K is self-adjoint and invertible [9], [14]. Moreover, the second condition (2.28) implies that $B \leqq -\rho I$ with $\rho > 0$ [14, Chap. IV]. Thus, uniform boundedness of (2.33) for $\alpha = \frac{1}{2}$ can be directly proved using the functional calculus.

COROLLARY 2.6. *Assume that* (2.28) *holds and that* $(A^{-1}f)(\cdot) \in H^{1,1}(0, T; E)$. *Then*

$$(2.34)\qquad u(t, \varepsilon) = -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) + 0(1) \qquad (\varepsilon \to 0)$$

uniformly in $0 \leqq t \leqq T$.

Proof. We use this time formula (2.14) for $r = 1$, which yields

$$(2.35)\qquad \begin{aligned} u(t, \varepsilon) &= -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) \\ &\quad + \varepsilon S(t/\varepsilon)u_1 + \int_0^t C((t-s)/\varepsilon)(A^{-1}f)'(s)\, ds \end{aligned}$$

if $(A^{-1}f)(\cdot) \in H^{1,1}(0, T; E)$. We construct a sequence $\{f_n(\cdot)\}$, each f_n satisfying the conditions of Theorem 2.5 (a) (or, for that matter, smooth as in the proof of Lemma 2.2) and such that

$$\int_0^T \|(A^{-1}f)(s) - (A^{-1}f_n)(s)\|\, ds \to 0 \qquad (n \to \infty).$$

Now, let $u_n(t, \varepsilon)$ denote the solution of (2.1)-(2.2) with $f = f_n$ and choose $\delta > 0$. We select n so large that $\|u(t, \varepsilon) - u_n(t, \varepsilon)\| \leqq \delta/2$ uniform with respect to ε, and then let $\varepsilon \to 0$ making use of Theorem 2.5 (a).

Remark 2.7. Formulas such as (2.14) and (2.17) can be extended to the case where A does not have an inverse (this will be useful in § 7). The formula corresponding to (2.14) is.

$$\begin{aligned}\int_a^b & S((b-s)/\varepsilon)A^{(r+1)/2}f(s)\,ds \\ &= -\sum_{j=1}^{(r+1)/2} \varepsilon^{2j-1}\{(A^{(r+1-2j)/2}f)^{(2j-2)}(b) \\ &\qquad\qquad -C((b-a)/\varepsilon))(A^{(r+1-2j)/2}f)^{(2j-2)}(a)\} \\ &\quad + \sum_{j=1}^{(r-1)/2} \varepsilon^{2j}S((b-a)/\varepsilon)(A^{(r+1-2j)/2}f)^{(2j-1)}(a) \\ &\quad +\varepsilon^r\int_a^b C((b-s)/\varepsilon)f^{(r)}(s)\,ds,\end{aligned}\tag{2.36}$$

which is valid for any $f(\cdot)$ such that

$$f(t)\in D(A^{(r+1)/2}) \quad \text{a.e. in } a\leqq t\leqq b,\tag{2.37}$$

$$(A^{(r+1-2j)/2}f)(\cdot)\in H^{2j,1}(a, b; E) \qquad (0\leqq j\leqq (r+1)/2).\tag{2.38}$$

A similar extension can be made of (2.17):

$$\begin{aligned}\int_a^b & S((b-s)/\varepsilon)A^{r/2}f(s)\,ds \\ &= -\sum_{j=1}^{r/2} \varepsilon^{2j-1}\{(A^{(r-2j)/2}f)^{(2j-2)}(b) \\ &\qquad\qquad -C((b-a)/\varepsilon))(A^{(r-2j)/2}f)^{(2j-2)}(a)\} \\ &\quad + \sum_{j=1}^{r/2} \varepsilon^{2j}S((b-a)/\varepsilon)(A^{(r-2j)/2}f)^{(2j-1)}(a) \\ &\quad +\varepsilon^r\int_a^b S((b-s)/\varepsilon)f^{(r)}(s)\,ds\end{aligned}\tag{2.39}$$

under the hypotheses that

$$f(t)\in D(A^{r/2}) \quad \text{a.e. in } a\leqq t\leqq b,\tag{2.40}$$

$$(A^{(r-2j)/2}f)(\cdot)\in H^{2j,1}(a, b; E) \qquad (0\leqq j\leqq r/2).\tag{2.41}$$

3. The difference equation. We use for (2.1) the difference scheme

$$\varepsilon^2\tau^{-2}(u_{k+1}-2u_k+u_{k-1}) = 2(\tau/\varepsilon)^{-2}(C(\tau/\varepsilon)-I)u_k+f_k \qquad (k=1, 2, \cdots, N-1)\tag{3.1}$$

on (the interior points of) the grid $0, \tau, 2\tau, \cdots, N\tau = T$. We first treat the homogeneous case ($f_k=0$) and take $\varepsilon=1$, so that the difference equation is

$$u_{k+1}+u_{k-1} = 2C(\tau)u_k \qquad (k=1, 2, \cdots, N-1).\tag{3.2}$$

Following Piskarev [21] we define two operator valued solutions $\{C_k(\tau)\}$, $\{S_k(\tau)\}$ ($k\geqq 0$) of (3.2) specifying the initial conditions

$$C_0(\tau)=C_1(\tau)=I, \quad S_0(\tau)=0, \quad S_1(\tau)=I.\tag{3.3}$$

These solutions (called the *solution operators* of (3.2)) are uniquely defined and can be explicitly computed (recursively).

If $\{u_k\}$ is the solution of (3.2) satisfying the initial conditions

$$u_0 = \tilde{u}_0, \qquad \tau^{-1}(u_1 - u_0) = \tilde{u}_1, \tag{3.4}$$

then

$$u_k = C_k(\tau)\tilde{u}_0 + \tau S_k(\tau)\tilde{u}_1 \qquad (k = 0, 1, \cdots, N). \tag{3.5}$$

We check inductively using the cosine functional equation (1.17) that the operators $\{C_k(\tau)\}$, $\{S_k(\tau)\}$ are given by the following formulas:

$$\begin{aligned} C_k(\tau) &= 2C((k-1)\tau) - 2C((k-2)\tau) + \cdots + 2(-1)^{k+2}C(\tau) + (-1)^{k+1}I \\ &= (-1)^{k+1}I + 2(-1)^{k+1}\sum_{j=1}^{k-1}(-1)^j C(j\tau) \qquad (k \geqq 2), \end{aligned} \tag{3.6}$$

$$\begin{aligned} S_k(\tau) &= 2C((k-1)\tau) + 2C((k-3)\tau) + \cdots + 2C(3\tau) + 2C(\tau) \\ &= 2\sum_{j=0}^{(k-2)/2} C((2j+1)\tau) \qquad (k \geqq 2 \text{ even}), \end{aligned} \tag{3.7}$$

$$\begin{aligned} S_k(\tau) &= 2C((k-1)\tau) + 2C((k-3)\tau) + \cdots + 2C(2\tau) + I \\ &= I + 2\sum_{j=1}^{(k-1)/2} C(2j\tau) \qquad (k \geqq 3 \text{ odd}). \end{aligned} \tag{3.8}$$

(Formula (3.7) for $k = 2$ is $S_2(\tau) = 2C(\tau)$.) Thus, the following two estimates result from (1.19):

$$\|C_k(\tau)\| \leqq Mk\, e^{k\omega\tau}, \quad \|S_k(\tau)\| \leqq Mk\, e^{k\omega\tau} \qquad (k = 0, 1, \cdots, N). \tag{3.9}$$

The estimate for $\|C_k(\tau)\|$ falls short of establishing stability in the strict sense for solutions of (3.2) since the only bound on k is $k \leqq N = T/\tau$ and the right-hand side will tend to infinity as $\tau \to 0$; the corresponding estimate for $\|S_k(\tau)\|$ is sufficient since only $\tau S_k(\tau)$ is used and $k\tau \leqq T$. However, the first estimate (3.9) establishes "stability" in a sense acceptable in numerical analysis; see [15, p. 32].

We show below that (3.9) cannot in general be improved.

Example 3.1. We consider the operator A in Example 2.5. Formula (3.6) translates into

$$C_k(\tau) \sum_{n=1}^{\infty} c_n \sin nx = \sum_{n=1}^{\infty} F_n(k, \tau) c_n \sin nx, \tag{3.10}$$

where the functions $F_n(k, \tau)$ are given by

$$\begin{aligned} F_n(k, \tau) &= (-1)^{k+1}\left(1 + 2\sum_{j=1}^{k-1}(-1)^j \cos(jn\tau)\right) \\ &= \cos(k - \tfrac{1}{2})n\tau / \cos(n\tau/2), \end{aligned} \tag{3.11}$$

(see [24]) which is only $O(k)$ if $n\tau \approx \pi$.

We note that, in view of the characterization (2.21) of the cosine function $C(t)$, the difference equation (3.2) is the classical Courant-Friedrichs-Lewy difference scheme

$$u(x, (k+1)\tau) + u(x, (k-1)\tau) = u(x+\tau, k\tau) + u(x-\tau, k\tau) \tag{3.12}$$

(see [4]). For a stability analysis of (3.12) confirming the estimates (3.9) in this particular case, see [15, p. 31].

Remark 3.2. Formulas (3.6)-(3.8) for $\{C_k(\tau)\}$, $\{S_k(\tau)\}$ are not especially transparent. They become much more obvious when there exists a strongly continuous group $\{U(t); -\infty < t < \infty\}$ such that

$$C(t) = (U(t) + U(-t))/2. \tag{3.13}$$

Proceeding formally, we try

$$C_k(\tau) = AU(k\tau) + BU(-k\tau), \tag{3.14}$$

where A, B are unknown operator coefficients. Using the initial conditions $C_k(0) = C_k(\tau) = I$ we obtain the formal expression

$$\begin{aligned} C_k(\tau) &= U(k\tau)(I + U(\tau))^{-1} + U(-k\tau)(I + U(\tau))^{-1} \\ &= \{U(k\tau) + U((1-k)\tau)\}(I + U(\tau))^{-1} \\ &= \sum_{j=1-k}^{k-1} (-1)^{k-1-j} U(j\tau). \end{aligned} \tag{3.15}$$

In the same way we obtain

$$S_k(\tau) = -\{U((k+1)\tau) - U((1-k)\tau)\}(I - U(2\tau))^{-1} = \sum_{j=1-k}^{k-1} U(j\tau). \tag{3.16}$$

The final expressions for $C_k(\tau)$ and $S_k(\tau)$ are easily obtained from (3.15) and (3.16) and can be checked directly in (3.2).

We deal next with the inhomogeneous equation (3.1) for $\varepsilon = 1$:

$$u_{k+1} + u_{k-1} = 2C(\tau)u_k + \tau^2 f_k \qquad (k = 1, 2, \cdots, N-1). \tag{3.17}$$

Obviously, we may define f_0, f_N arbitrarily, since these values of f_k do not play a role in (3.17). We define $f_0 = 0$ and define a sequence $\{u_k\}$ starting with $u_0 = 0$ and continuing with

$$u_k = \tau^2 \sum_{j=0}^{k-1} S_{k-j}(\tau) f_j \qquad (k = 1, \cdots, N). \tag{3.18}$$

Obviously, we have $u_0 = 0$, $u_1 = 0$. Moreover,

$$u_2 + u_0 = u_2 = \tau^2 S_2(\tau) f_0 + \tau^2 f_1 = \tau^2 f_1 = 2C(\tau)u_1 + \tau^2 f_1,$$

and, due to the sine functional equation (1.18),

$$\begin{aligned} u_{k+1} + u_{k-1} &= \tau^2 \sum_{j=0}^{k} S_{k+1-j}(\tau) f_j + \tau^2 \sum_{j=0}^{k-2} S_{k-1-j}(\tau) f_j \\ &= \tau^2 f_k + \tau^2 \sum_{j=0}^{k-1} (S_{k+1-j}(\tau) + S_{k-1-j}(\tau)) f_j \\ &= \tau^2 f_k + 2C(\tau)\left(\tau^2 \sum_{j=0}^{k-1} S_{k-j}(\tau) f_j\right) \\ &= 2C(\tau)u_k + \tau^2 f_k \qquad (k \geqq 2). \end{aligned}$$

THEOREM 3.3. *The solution of the inhomogeneous equation* (3.17) *with initial conditions* (3.4) *is given by* $u_0 = \tilde{u}_0$,

$$u_k = C_k(\tau)\tilde{u}_0 + \tau S_k(\tau)\tilde{u}_1 + \tau^2 \sum_{j=0}^{k-1} S_{k-j}(\tau) f_j \qquad (k = 1, 2, \cdots, N) \tag{3.19}$$

and

$$\begin{aligned} \|u_k\| &\leqq Mk\, e^{k\omega\tau} \|\tilde{u}_0\| + Mk\tau\, e^{k\omega\tau} \|\tilde{u}_1\| \\ &\quad + M(T(T+\tau)/2)\, e^{k\omega\tau} \max_{1 \leqq j \leqq k-1} \|f_j\| \qquad (k = 0, 1, \cdots, N). \end{aligned} \tag{3.20}$$

Proof. Formula (3.19) has already been established. We use the second formula (3.9) to estimate:

$$\begin{aligned} \left\| \tau^2 \sum_{j=0}^{k-1} S_{k-j}(\tau) f_j \right\| &\leqq M\tau^2 \sum_{j=0}^{k-1} (k-j)\, e^{(k-j)\omega\tau} \|f_j\| \\ &\leqq \left(M\, e^{k\omega\tau} \tau^2 \sum_{j=1}^{k} j \right) \max_{1 \leqq j \leqq k-1} \|f_j\| \\ &\leqq M\, e^{k\omega\tau} \tau k \tau (k+1)/2 \max_{1 \leqq j \leqq k-1} \|f_j\| \\ &\leqq M(T(T+\tau)/2)\, e^{k\omega\tau} \max_{1 \leqq j \leqq k-1} \|f_j\|. \end{aligned} \tag{3.21}$$

This ends the proof of Theorem 3.3.

Equation (3.1) is reduced to (3.17), writing it in the form

$$\tau^{-2}(u_{k+1} - 2u_k + u_{k-1}) = 2\tau^{-2}(C(\tau/\varepsilon) - I)u_k + \varepsilon^{-2} f_k$$

or, equivalently,

$$u_{k+1} + u_{k-1} = 2C(\tau/\varepsilon)u_k + \tau^2(\varepsilon^{-2} f_k) \qquad (k = 1, 2, \cdots, N-1). \tag{3.22}$$

Using Theorem 3.3

$$u_k = C_k(\tau/\varepsilon)\tilde{u}_0 + \tau S_k(\tau/\varepsilon)\tilde{u}_1 + \tau^2 \sum_{j=0}^{k-1} S_{k-j}(\tau/\varepsilon)(\varepsilon^{-2} f_j); \tag{3.23}$$

thus

$$\begin{aligned} \|u_k\| &\leqq Mk\, e^{k\omega\tau/\varepsilon} \|\tilde{u}_0\| + Mk\, e^{k\omega\tau/\varepsilon} \|\tilde{u}_1\| \\ &\quad + M(T(T+\tau)/2)\, e^{k\omega\tau/\varepsilon} \max_{0 \leqq j \leqq k-1} \|\varepsilon^{-2} f_j\|. \end{aligned} \tag{3.24}$$

We shall use (3.24) for $\omega = 0$ (that is, we assume that (2.28) holds). In this case we obtain

$$\|u_k\| \leqq Mk \|\tilde{u}_0\| + Mk\tau \|\tilde{u}_1\| + M((T^2+1)/2) \max_{0 \leqq j \leqq k-1} \|\varepsilon^{-2} f_j\| \tag{3.25}$$

for $\tau \leqq 1/T$.

Remark 3.4. Discretization of the second-order equation $u''(t) = Au(t)$ by means of the difference scheme (3.2) runs into problems absent in the case of the first-order equation $u'(t) = Au(t)$. For this equation the corresponding difference scheme is

$$\tau^{-1}(u_{k+1} - u_k) = \tau^{-1}(S(\tau) - I)u_k$$

or

$$u_{k+1} = S(\tau)u_k \qquad (k = 0, 1, \cdots, N-1), \tag{3.26}$$

where $S(t)$ is the semigroup generated by A. The solution operator of (3.26) is $S_k(\tau)=S(k\tau)$, thus the difference equation is just as stable as the differential equation: if

$$(3.27) \qquad \|S(t)\| \leqq Me^{\omega t} \qquad (t \geqq 0)$$

then

$$(3.28) \qquad \|S_k(\tau)\| \leqq Me^{\omega k\tau} \qquad (k=1,2,\cdots).$$

There is no exact analogue for the second-order equation; the first bound (1.19) for the solution operators of the differential equation results in the weaker estimate (3.9) for the discrete propagator $C_k(\tau)$. As shown in Example 3.1, this is unavoidable.

Remark 3.5. We note another discrepancy between the first- and second-order case. The first-order singularly perturbed initial value problem is

$$(3.29) \qquad \varepsilon u'(t;\varepsilon)=Au(t;\varepsilon)+f(t),$$

$$(3.30) \qquad u(t;\varepsilon)=u_0 \qquad (t \geqq 0),$$

whose explicit solution is

$$(3.31) \qquad u(t;\varepsilon)=S(t/\varepsilon)u_0+\varepsilon^{-1}\int_0^t S((t-s)/\varepsilon)f(s)\,ds \qquad (t\geqq 0),$$

where $S(t)$ is the semigroup generated by A. The corresponding discretization of (3.29) is

$$(3.32) \qquad u_{k+1}=S(\tau/\varepsilon)u_k+\tau(\varepsilon^{-1}f_k).$$

The solution of (3.32) corresponding to the initial condition u_0 is

$$(3.33) \quad u_k=S(k\tau/\varepsilon)u_0+\tau\sum_{j=0}^{k-1}S((k-j-1)\tau/\varepsilon)(\varepsilon^{-1}f_j) \qquad (k=0,1,\cdots,N).$$

Assume that the semigroup $S(t)$ has negative exponential growth

$$(3.34) \qquad \|S(t)\| \leqq Me^{-\omega t} \qquad (t\geqq 0)$$

with $\omega>0$. Then we obtain from (3.31) and the fact that

$$\varepsilon^{-1}\int_0^\infty e^{-\omega s/\varepsilon}\,ds=\omega^{-1}$$

the estimate

$$(3.35) \qquad \|u(t)\| \leqq M\|u_0\|+\omega^{-1}M\max_{0\leqq t\leqq T}\|f(t)\|.$$

On the other hand, (3.33) yields the estimate

$$(3.36) \qquad \|u_k\| \leqq M\|u_0\|+CM\max_{0\leqq j\leqq n}\|f_j\|,$$

where C is the maximum of the function

$$\sigma\sum_{k=0}^{\infty}e^{-k\omega\sigma}=\sigma/(1-e^{-\omega\sigma})$$

in $0\leqq\sigma\leqq\infty$. Hence the a priori bounds for the differential equation and the difference equation are of the same stability type. The situation is different for the second-order equation (2.1) and its discretization (3.1). Since there are no cosine functions of negative exponential growth, on the one hand we cannot get rid of the factor ε^{-1} estimating

(2.6); on the other hand, the estimate (3.15) corresponding to the difference equation contains a factor ε^{-2} on the right-hand side instead of the factor ε^{-1} resulting from (2.5). This determines that we should prefer the differential equation to the difference equation in estimates for approximate solutions.

4. Higher-order estimates. We study in this section the approximation of the solution of the differential equation (2.1) by that of the difference equation (3.1). We assume that $\omega = 0$, that is, that (2.28) holds.

The method used below (and in the next sections) can be outlined as follows. All estimations will be based on formula (2.35) for solutions of the initial value problem (2.1)-(2.2), that is,

$$\begin{aligned} u(t, \varepsilon) &= -A^{-1}f(t) + C(t/\varepsilon)(u_0 + A^{-1}f(0)) \\ &\quad + \varepsilon S(t/\varepsilon)u_1 + \int_0^t C((t-s)/\varepsilon)(A^{-1}f)'(s)\, ds \end{aligned} \tag{4.1}$$

with $(A^{-1}f)(\cdot) \in H^{1,1}(0, T; E)$. Assume that $f_{\tau,n}(\cdot)$ is a function such that $(A^{-1}f_{\tau,n})(\cdot) \in H^{1,1}(0, T; E)$ as well, and that

$$\int_0^T \|(A^{-1}f)'(s) - (A^{-1}f_{\tau,n})'(s)\|\, ds \leqq C\tau^n. \tag{4.2}$$

Then, if $u_{\tau,n}(t; \varepsilon)$ is the solution of the initial value problem (2.1)-(2.2), with the same initial conditions and $f = f_{\tau,n}$ we have

$$\|u(t; \varepsilon) - u_{\tau,n}(t; \varepsilon)\| \leqq C\tau^n \qquad (0 \leqq t \leqq T). \tag{4.3}$$

We shall take the approximants $f_{\tau,n}$ to be piecewise polynomial functions in the intervals of a grid $0, \tau, 2\tau, \cdots, (N-1)\tau$, $N\tau = T$. We use Taylor polynomials in each interval $k\tau \leqq t < (k+1)\tau$, although (see Remark 4.6) other approximations can be used, for instance, interpolation polynomials of Newton-Cotes type. The particular form of the $f_{\tau,n}$ will make possible to obtain $u_{\tau,n}(t, \varepsilon)$ at the gridpoints $k\tau$ by means of the difference equation (3.1) with a particular right-hand side $\{f_k(\varepsilon)\}$ and initial conditions $u_0(\varepsilon)$, $u_1(\varepsilon)$ involving the values of $f(\cdot)$ and of its derivatives at gridpoints.

We begin by deducing this difference equation for a solution of the initial value problem (2.1)-(2.2) with an arbitrary right-hand side $f(\cdot)$. Let $t_k = k\tau$ for $k = 1, 2, \cdots, N$, with $N\tau = T$. We compute $u(t, \varepsilon)$ using (4.1) and replace the sequence $\{u(t_k, \varepsilon)\}$ in the difference equation (3.1) (or, equivalently, (3.22)). It follows from the cosine functional equation (1.17) and the sine functional equation (1.18) that both $\{C(t_k/\varepsilon)u_0\}$ and $\{S(t_k/\varepsilon)u_1\}$ satisfy the homogeneous difference equation. Accordingly, $\{u(t_k, \varepsilon)\}$ satisfies

$$\begin{aligned} &u(t_{k+1}, \varepsilon) + u(t_{k-1}, \varepsilon) - 2C(\tau/\varepsilon)u(t_k, \varepsilon) \\ &\quad = -A^{-1}f((k+1)\tau) + 2C(\tau/\varepsilon)f(k\tau) - A^{-1}f((k-1)\tau) \\ &\quad\quad + \int_0^{k\tau} \{C(((k+1)\tau - s)/\varepsilon) + C(((k-1)\tau - s)/\varepsilon) \\ &\quad\quad\quad -2C(\tau/\varepsilon)C((k\tau - s)/\varepsilon)\}(A^{-1}f)'(s)\, ds \\ &\quad\quad + \int_{k\tau}^{(k+1)\tau} C(((k+1)\tau - s)/\varepsilon)(A^{-1}f)'(s)\, ds \\ &\quad\quad - \int_{(k-1)\tau}^{k\tau} C(((k-1)\tau - s)/\varepsilon)(A^{-1}f)'(s)\, ds \\ &\quad = \tau^2(\varepsilon^{-2}f_k(\varepsilon)) \qquad (k = 1, 2, \cdots, N-1). \end{aligned} \tag{4.4}$$

Since the first integral vanishes due to the sine functional equation (1.18), we have

$$\begin{aligned} f_k(\varepsilon) = &-\varepsilon^2\tau^{-2}\{A^{-1}f((k+1)\tau)+2C(\tau/\varepsilon)A^{-1}f(k\tau)-A^{-1}f((k-1)\tau)\} \\ &+\varepsilon^2\tau^{-2}\int_{k\tau}^{(k+1)\tau} C(((k+1)\tau-s)/\varepsilon)(A^{-1}f)'(s)\,ds \\ &-\varepsilon^2\tau^{-2}\int_{(k-1)\tau}^{k\tau} C(((k-1)\tau-s)/\varepsilon)(A^{-1}f)'(s)\,ds. \end{aligned} \tag{4.5}$$

This solution satisfies the initial conditions

$$u(0,\varepsilon)=\tilde{u}_0=u_0, \tag{4.6}$$

$$\begin{aligned} \tau^{-1}(u(\tau,\varepsilon)-u(0,\varepsilon)) = &-A^{-1}f(\tau)+A^{-1}f(0) \\ &+\tau^{-1}(C(\tau/\varepsilon)-I)(u_0+A^{-1}f(0))+\varepsilon\tau^{-1}S(\tau/\varepsilon)u_1 \\ &+\tau^{-1}\int_0^\tau C((\tau-s)/\varepsilon)(A^{-1}f)'(s)\,ds=\tilde{u}_1(\varepsilon), \end{aligned} \tag{4.7}$$

where u_0, u_1 are the initial values (2.2) for the differential initial value problem.

Denote by $B^n(a, b; E)$ the space of all E-valued functions $g(\cdot)$ having derivatives of order $\leqq n$ with $g^{(n)}(s)$ bounded. We approximate $g(\cdot)$ by its Taylor polynomial of order $n-1$ in each interval $k\tau \leqq t \leqq (k+1)\tau$,

$$\begin{gathered} g_{\tau,n}(t)=\sum_{r=1}^{n-1}\frac{1}{r!}(t-k\tau)^r g^{(r)}(k\tau) \\ (k\tau\leqq t<(k+1)\tau,\ k=0,1,\cdots,N-1). \end{gathered} \tag{4.8}$$

It follows from the remainder formula applied in each interval that

$$\|g(t)-g_{\tau,n}(t)\|\leqq C\tau^n \qquad (0\leqq t\leqq T). \tag{4.9}$$

These considerations will be applied to $g(\cdot)=A^{-1}f(\cdot)$, where $f(\cdot)$ is the function on the right-hand side of (2.1). Assuming that $A^{-1}f(\cdot)\in B^n(a, b; E)$, we will have

$$\|(A^{-1}f)(t)-(A^{-1}f)_{\tau,n}(t)\|\leqq C\tau^n \tag{4.10}$$

so that (4.2), a fortiori (4.3), will hold. To figure out explicitly the difference equation satisfied by $\{u_{\tau,n}(t_k,\varepsilon)\}$ it is enough to compute $f_k(\varepsilon)$ given by (4.4) and $\tilde{u}_1(\varepsilon)$ given by (4.7). This amounts to finding explicit expressions for the operators

$$P_{r,b}(a,b,\varepsilon)u=\int_a^b C((b-s)/\varepsilon)u(s-a)^r\,ds \tag{4.11}$$

and

$$P_{r,a}(a,b,\varepsilon)u=\int_a^b C((s-a)/\varepsilon)u(s-a)^r\,ds \tag{4.12}$$

for arbitrary a, b, ε. For related purposes, we shall also make use of the operators

$$Q_{r,b}(a,b,\varepsilon)u=\int_a^b S((b-s)/\varepsilon)u(s-a)^r\,ds, \tag{4.13}$$

$$Q_{r,a}(a,b,\varepsilon)u=\int_a^b S((s-a)/\varepsilon)u(s-a)^r\,ds. \tag{4.14}$$

To compute $Q_{r,b}(a, b, \varepsilon)$ we use Lemma 2.2 for $f(s) = (s-a)^r$; for r even we use (2.14) for $r+1$ (so that the integral term drops out) and for r odd we use (2.17) for $r+1$. To compute the $Q_{r,a}(a, b, \varepsilon)$ we switch a and b in (2.14) and (2.17) and use $f(s) = (s-b)^r$. The $P_{r,b}$ and $P_{r,a}$ are reduced to the $Q_{r,a}$ and the $Q_{r,b}$ by means of an integration by parts. The first few $P_{r,a}$, $P_{r,b}$, $Q_{r,a}$, $Q_{r,b}$ are

$$P_{0,a}(a, b, \varepsilon) = P_{0,b}(a, b, \varepsilon) = \varepsilon S((b-a)/\varepsilon), \tag{4.15}$$

$$Q_{0,a}(a, b, \varepsilon) = Q_{0,b}(a, b; \varepsilon) = \varepsilon A^{-1}C((b-a)/\varepsilon) - \varepsilon A^{-1}, \tag{4.16}$$

$$\begin{aligned} P_{1,a}(a, b, \varepsilon) &= \varepsilon(b-a)S((b-a)/\varepsilon) - \varepsilon^2 A^{-1}C((b-a)/\varepsilon) + \varepsilon^2 A^{-1}, \\ P_{1,b}(a, b, \varepsilon) &= \varepsilon^2 A^{-1}C((b-a)/\varepsilon) - \varepsilon^2 A^{-1}, \end{aligned} \tag{4.17}$$

$$\begin{aligned} Q_{1,a}(a, b, \varepsilon) &= \varepsilon A^{-1}C((b-a)/\varepsilon) - \varepsilon^2 A^{-1}S((b-a)/\varepsilon), \\ Q_{1,b}(a, b, \varepsilon) &= -\varepsilon A^{-1}(b-a) + \varepsilon^2 A^{-1}S((b-a)/\varepsilon). \end{aligned} \tag{4.18}$$

We note that the computation of the $P_{r,a}$ can be reduced to the computation of the $P_{r,b}$ by writing $(s-a)^r = ((s-b)+(b-a))^r$ and using the binomial formula. The same observation applies to the $Q_{r,a}$ and $Q_{r,b}$.

THEOREM 4.1. *Assume the boundedness condition* (2.28) *is satisfied, and let* $u(t, \varepsilon)$ *be the solution of* (2.1)-(2.2) *with* $A^{-1}f(\cdot)$ *continuously differentiable and*

$$(A^{-1}f(\cdot))' \in B^n(0, T; E) \tag{4.19}$$

$(n \geqq 1)$. *Then the solution* $\{u_k(\varepsilon)\}$ *of the difference equation* (3.22) *with right-hand side*

$$\begin{aligned} f_k(\varepsilon) = {} & -\varepsilon^2\tau^{-2}\{A^{-1}f((k+1)\tau) + 2C(\tau/\varepsilon)A^{-1}f(k\tau) - A^{-1}f((k-1)\tau)\} \\ & + \varepsilon^2\tau^{-2}\sum_{r=0}^{n-1}\frac{1}{r!}P_{r,(k+1)\tau}(k\tau, (k+1)\tau, \varepsilon)(A^{-1}f)^{(r+1)}(\kappa\tau) \\ & - \varepsilon^2\tau^{-2}\sum_{r=0}^{n-1}\frac{1}{r!}P_{r,(k-1)\tau}((k-1)\tau, k\tau, \varepsilon)(A^{-1}f)^{(r+1)}((k-1)\tau) \end{aligned} \tag{4.20}$$

and initial conditions

$$u_0(\varepsilon) = \tilde{u}_0 = u_0, \tag{4.21}$$

$$\begin{aligned} \tau^{-1}(u_1(\varepsilon) - u_0(\varepsilon)) = \tilde{u}_1 = {} & -A^{-1}f(\tau) + A^{-1}f(0) \\ & + \tau^{-1}(C(\tau/\varepsilon) - I)(u_0 + A^{-1}f(0)) \\ & + \varepsilon\tau^{-1}S(\tau/\varepsilon)u_1 \\ & + \tau^{-1}\sum_{r=0}^{n-1}\frac{1}{r!}P_{r,\tau}(0, \tau, \varepsilon)(A^{-1}f)^{(r+1)}(0) \end{aligned} \tag{4.22}$$

satisfies

$$\|u_k(\varepsilon) - u(t_k, \varepsilon)\| = 0(\tau^n) \qquad (k = 1, 2, \cdots, N) \tag{4.23}$$

as $\tau \to 0$, *uniformly with respect to* ε.

Remark 4.2. A number of variants of Theorem 4.1 can be established using the same methods. For instance, approximations that satisfy

$$\|u_k(\varepsilon) - u(t_k, \varepsilon)\| = 0(\varepsilon\tau^n) \tag{4.24}$$

can be obtained by starting with formula (2.26) and requiring that $(A^{-1}f)''(\cdot) \in B^n(0, T; E)$. In this case, the $P_{r,a}$, $P_{r,b}$ are replaced by the $Q_{r,a}$, $Q_{r,b}$.

Remark 4.3. Since the right-hand sides of (4.15) and (4.16) contain the operators A^{-1}, $C(\tau/\varepsilon)$, and $S(\tau/\varepsilon)$, the finite difference schemes proposed in this section are practical only if these can be explicitly computed. In general, A^{-1}, $C(\tau/\varepsilon)$, and $S(\tau/\varepsilon)$ will have to be replaced by suitable approximations (in the case of a hyperbolic equation, approximations to $C(\tau/\varepsilon)$ and $S(\tau/\varepsilon)$ may be constructed discretizing the space variables), and the resulting scheme will be independent of ε inasmuch as these approximations are independent of ε. Thus, Theorem 4.1 provides only a framework or "template" for construction of practical discretizations. (The same applies to the difference schemes proposed in §§ 6–8.)

Example 4.4. To illustrate the application of the results to a particular example, we consider a Banach space analogue of the operator in Example 2.3. Let $E = C(0, \pi)$ be the space of all continuous functions in the interval $0 \leqq x \leqq \pi$ satisfying

$$u(0) = u(\pi) = 0 \tag{4.25}$$

endowed with the supremum norm, and let $A = d^2/dx^2$ with maximal domain. Then A generates a cosine function $C(t)$ given by

$$C(t)u(x) = (u(x+t) + u(x-t))/2, \tag{4.26}$$

where $u(x)$ has been continued to $-\infty < x < +\infty$ as a 2π-periodic function odd about $x = 0$ and $x = \pi$. We have

$$S(t)u(x) = \frac{1}{2}\int_{x-t}^{x+t} u(\xi)\, d\xi, \tag{4.27}$$

$$A^{-1}u(x) = \int_0^x (x-\xi)u(\xi)\, d\xi - \frac{x}{\pi}\int_0^\pi (\pi-\xi)u(\xi)\, d\xi. \tag{4.28}$$

Assume we wish to construct an approximation of order $0(\tau^2)$ to the solution of the initial value problem (2.1)–(2.2) by means of the difference scheme (3.22). Theorem 4.1 will hold if $f(t)(x) = f(x, t)$ is three times differentiable with respect to t uniformly with respect to x in $0 \leqq x \leqq \pi$. Taking advantage of periodicity, the integral (4.27) can be approximated independently of ε, while (4.28) does not depend on ε. Approximation of sufficiently high degree will of course need smoothness assumptions with respect to x on $u_0(x)$, $u_1(x)$.

Remark 4.5. Theorem 4.1 actually holds under milder hypotheses; for instance, an approximation of order $0(\tau)$ can be obtained under the only assumption that $(Af)'(t)$ is Lipschitz continuous.

Remark 4.6. Approximations different from the piecewise Taylor polynomial (4.8) can also be employed, and may in fact be of easier application in practice. For instance, we may use in each interval $k\tau \leqq t \leqq (k+1)\tau$ polynomials interpolating $f(t)$ at $k\tau$, $(k+1)\tau$ and $n-1$ interior points as in Newton-Cotes integration formulas. The advantage of this method is that evaluation of derivatives of $f(\cdot)$ is unnecessary. The expressions on the right-hand side of the difference equation (3.22) are computed using the repeated integration-by-parts formulas (2.14) and (2.17).

5. The parabolic singular perturbation problem. The assumptions on the initial value problem

$$\varepsilon^2 u''(t, \varepsilon) + u'(t, \varepsilon) = Au(t, \varepsilon) + f(t), \tag{5.1}$$

$$u(0, \varepsilon) = u_0, \qquad u'(0, \varepsilon) = u_1 \tag{5.2}$$

are those in § 1. We study (5.1)-(5.2) by reducing it to the elliptic singular perturbation problem. If $u(t, \varepsilon)$ is a strong solution of (5.1)-(5.2) and

$$v(t;\, \varepsilon)=e^{t/2\varepsilon^2}u(t, \varepsilon), \tag{5.3}$$

then $v(\cdot;\, \varepsilon)$ satisfies the initial value problem

$$\varepsilon^2 v''(t;\, \varepsilon)=(A+(1/4\varepsilon^2)I)v(t;\, \varepsilon)+e^{t/2\varepsilon^2}f(t), \tag{5.4}$$

$$v(0;\, \varepsilon)=u_0, \qquad v'(0;\, \varepsilon)=(1/2\varepsilon^2)u_0+u_1. \tag{5.5}$$

We treat (5.4)-(5.5) using the techniques of the elliptic singular perturbation problem. Denoting by $C(t;\, \varepsilon)$ the cosine function generated by $A+(1/4\varepsilon^2)I$, the difference equation associated with the differential equation (5.4) is

$$v_{k+1}+v_{k-1}=2C(\tau/\varepsilon;\, \varepsilon)v_k+\tau^2(\varepsilon^{-2}f_k). \tag{5.6}$$

Hence, the difference equation for

$$\{u_k\}=\{e^{-k\tau/2\varepsilon^2}v_k\} \tag{5.7}$$

is

$$e^{(k+1)\tau/2\varepsilon^2}u_{k+1}+e^{(k-1)\tau/2\varepsilon^2}u_{k-1}=2C(\tau/\varepsilon;\, \varepsilon)\, e^{k\tau/\varepsilon^2}u_k+\tau^2\, e^{k\tau/2\varepsilon^2}(\varepsilon^{-2}f_k). \tag{5.8}$$

This equation can be written in the form

$$\begin{aligned} &\tau^{-2}(u_{k+1}-2u_k+u_{k-1})+\tau^{-1}(1-e^{-\tau/\varepsilon^2})\tau^{-1}(u_k-u_{k-1}) \\ &\qquad =\tau^{-2}(2C(\tau/\varepsilon;\, \varepsilon)\, e^{-\tau/2\varepsilon^2}-(1+e^{-\tau/\varepsilon^2})I)u_k+\varepsilon^{-2}\, e^{-\tau/2\varepsilon^2}f_k, \end{aligned} \tag{5.9}$$

which shows better its relation with (5.1). Initial conditions are

$$u_0=\tilde{u}_0, \qquad \tau^{-1}(e^{\tau/2\varepsilon^2}u_1-u_0)=\tilde{u}_1. \tag{5.10}$$

To obtain estimates for $\{u_k\}$ we use the explicit solution formula (3.19) for $\{v_k\}$, denoting by $C_k(t/\varepsilon;\, \varepsilon)$, $S_k(t/\varepsilon;\, \varepsilon)$ the discrete propagators of the difference equation (5.6). The result is

$$\begin{aligned} u_k&=e^{-k\tau/2\varepsilon^2}C_k(\tau/\varepsilon;\, \varepsilon)\tilde{u}_0+e^{-k\tau/2\varepsilon^2}\tau S_k(\tau/\varepsilon;\, \varepsilon)\tilde{u}_1 \\ &\quad +\tau^2\sum_{j=0}^{k-1} e^{-(k-j)\tau/2\varepsilon^2}S_{k-j}(\tau/\varepsilon;\, \varepsilon)(\varepsilon^{-2}f_j), \end{aligned} \tag{5.11}$$

where $\tilde{u}_0$, $\tilde{u}_1$ are the initial conditions (5.10). To estimate this expression we use the bound

$$\|C(t;\, \varepsilon)\|\leqq M\exp{(\omega^2+1/4\varepsilon^2)^{1/2}t} \tag{5.12}$$

(see [14, Chap. VI]). Since

$$(\omega^2+1/4\varepsilon^2)^{1/2}=(1/2\varepsilon)(1+4\omega^2\varepsilon^2)^{1/2}\leqq(1/2\varepsilon)(1+2\omega^2\varepsilon^2) \tag{5.13}$$

we obtain

$$\begin{aligned} e^{-k\tau/2\varepsilon^2}\|C_k(\tau/\varepsilon;\, \varepsilon)\|&\leqq Mk\, e^{k\tau\omega^2}, \\ e^{-k\tau/2\varepsilon^2}\|S_k(\tau/\varepsilon;\, \varepsilon)\|&\leqq Mk\, e^{k\tau\omega^2}. \end{aligned} \tag{5.14}$$

Accordingly,

$$\begin{aligned} \tau^2\sum_{j=0}^{k-1} e^{-j\tau/2\varepsilon^2}\varepsilon^{-2}\|S_{k-j}(\tau/\varepsilon;\, \varepsilon)\|&\leqq \varepsilon^{-2}M\, e^{k\tau\omega^2}\tau^2\sum_{j=0}^{k-1}(k-j) \\ &\leqq \varepsilon^{-2}M\, e^{k\tau\omega^2}\tau k\tau(k+1)/2, \end{aligned}$$

which yields

$$\begin{aligned}\|u_k\| &\leqq Mk\, e^{k\tau\omega^2}\|\tilde{u}_0\| + Mk\tau\, e^{k\tau\omega^2}\|\tilde{u}_1\| \\ &+M((T(T+\tau)/2)\, e^{k\tau\omega^2} \max_{1\leqq j\leqq k-1} \|\varepsilon^{-2}f_j\|.\end{aligned} \tag{5.15}$$

6. Higher-order estimates for the parabolic problem. We study the approximation of the solution of the differential equation (5.1) by that of the difference equation (5.8).

Using (2.6) we obtain

$$\begin{aligned}u(t;\,\varepsilon) &= e^{-t/2\varepsilon^2}C(t/\varepsilon;\,\varepsilon)u_0 + e^{-t/2\varepsilon^2}S(t/\varepsilon;\,\varepsilon)((1/2\varepsilon)u_0+\varepsilon u_1) \\ &+\varepsilon^{-1}\int_0^t S((t-s)/\varepsilon;\,\varepsilon)\, e^{-(t-s)/2\varepsilon^2}f(s)\, ds.\end{aligned} \tag{6.1}$$

Using (5.12) and (5.13) we obtain

$$\begin{aligned}\|S(t;\,\varepsilon)\| &\leqq M(\omega^2+1/4\varepsilon^2)^{-1/2}(\exp(\omega^2+1/4\varepsilon^2)^{1/2}t-1) \\ &\leqq 2\varepsilon M \exp(\omega^2+1/4\varepsilon^2)^{1/2}t \leqq 2\varepsilon M \exp(1/2\varepsilon+\omega^2\varepsilon)t.\end{aligned} \tag{6.2}$$

Hence we deduce from (6.1) that

$$\|u(t;\,\varepsilon)\| \leqq 2M e^{\omega^2 t}(\|u_0\|+\varepsilon^2\|u_1\|)+2M e^{\omega^2 T}\int_0^T \|f(t)\|\, dt. \tag{6.3}$$

A slightly better estimation (with a factor M instead of $2M$) can be obtained by different means (see [14, Chap. VI]).

The arguments in this section are very much the same as those in § 4. Assuming that $f(\cdot)\in L^1(0,\, T;\, E)$ and $f_{\tau,n}(\cdot)\in L^1(0,\, T;\, E)$ is a function such that

$$\int_0^T \|f(s)-f_{\tau,n}(s)\|\, ds \leqq C\tau^n, \tag{6.4}$$

if $u_{\tau,n}(t,\,\varepsilon)$ is the solution of the initial value problem (5.1)-(5.2) with the same initial conditions and $f=f_{\tau,n}$ it follows from (6.3) that

$$\|u(t,\,\varepsilon)-u_{\tau,n}(t,\,\varepsilon)\| \leqq C\tau^n \qquad (0\leqq t\leqq T). \tag{6.5}$$

We deduce the difference equation for a solution $u(t,\,\varepsilon)$ of the initial value problem (5.1)-(5.2) with an arbitrary right-hand side $f(\cdot)$. Taking into account that $v(t;\,\varepsilon)$, given by (5.3), satisfies the differential equation (5.4), a computation similar to that in (4.4) (and the fact that $S(-t)=-S(t)$) reveals that $\{u(t_k,\,\varepsilon)\}$ is a solution of the difference equation

$$\begin{aligned}&e^{(k+1)\tau/2\varepsilon^2}u(t_{k+1},\,\varepsilon)+e^{(k-1)\tau/2\varepsilon^2}u(t_{k-1},\,\varepsilon)-2C(\tau/\varepsilon;\,\varepsilon)\, e^{k\tau/2\varepsilon^2}u(t_k,\,\varepsilon) \\ &=\varepsilon^{-1}\, e^{(k+1)\tau/2\varepsilon^2}\int_{k\tau}^{(k+1)\tau} S(((k+1)\tau-s)/\varepsilon;\,\varepsilon)\, e^{-((k+1)\tau-s)/2\varepsilon^2}f(s)\, ds \\ &-\varepsilon^{-1}\, e^{(k-1)\tau/2\varepsilon^2}\int_{(k-1)\tau}^{k\tau} S(((k-1)\tau-s)/\varepsilon;\,\varepsilon)\, e^{-((k-1)\tau-s)/2\varepsilon^2}f(s)\, ds \\ &=\varepsilon^{-1}\, e^{(k+1)\tau/2\varepsilon^2}\int_{k\tau}^{(k+1)\tau} S(((k+1)\tau-s)/\varepsilon;\,\varepsilon)\, e^{-((k+1)\tau-s)/2\varepsilon^2}f(s)\, ds \\ &+\varepsilon^{-1}\, e^{(k-1)\tau/2\varepsilon^2}\int_{(k-1)\tau}^{k\tau} S((s-(k-1)\tau)/\varepsilon;\,\varepsilon)\, e^{(s-(k-1)\tau)/2\varepsilon^2}f(s)\, ds.\end{aligned} \tag{6.6}$$

Initial conditions must be given in the form (5.10):

$$u(0, \varepsilon) = \tilde{u}_0 = u_0, \tag{6.7}$$

$$\begin{aligned} &\tau^{-1}(e^{\tau/2\varepsilon^2}u(\tau, \varepsilon) - u(0, \varepsilon)) \\ &\quad = \tau^{-1}(C(\tau/\varepsilon; \varepsilon) - I)u_0 + \tau^{-1}S(\tau/\varepsilon; \varepsilon)((1/2\varepsilon)u_0 + \varepsilon u_1) \\ &\quad + (\varepsilon\tau)^{-1}\, e^{\tau/2\varepsilon^2} \int_0^\tau S((\tau - s)/\varepsilon; \varepsilon)\, e^{-(\tau-s)/2\varepsilon^2} f(s)\, ds = \tilde{u}_1. \end{aligned} \tag{6.8}$$

We assume that $f(\cdot)$ belongs to $B_n(a, b; E)$ and use a piecewise Taylor polynomial approximation $f_{\tau,n}(\cdot)$ as in § 4:

$$\begin{gathered} f_{\tau,n}(t) = \sum_{r=1}^{n-1} \frac{1}{r!}(t - k\tau)^r f^{(r)}(k\tau) \\ (k\tau \leqq t < (k+1)\tau,\ k = 0, 1, \cdots, N-1), \end{gathered} \tag{6.9}$$

which yields the approximation

$$\|f_{\tau,}(t) - f_{\tau,n}(t)\| \leqq C\tau^n \qquad (0 \leqq t \leqq T). \tag{6.10}$$

Let $u_{\tau,n}(t, \varepsilon)$ be the solution of the initial value problem (5.1)-(5.2) with $f = f_{\tau,n}$. The function $u_{\tau,n}(t, \varepsilon)$ is obtained at gridpoints $k\tau$ by means of the difference equation (6.6) with initial conditions (6.7)-(6.8), where $f(\cdot)$ is replaced by $f_{\tau,n}(\cdot)$. To figure out explicitly all coefficients in terms of the values of $f(\cdot)$ and its derivatives at gridpoints it is enough to find explicit expressions for the operators

$$Q^p_{r,a}(a, b; \varepsilon) = \int_a^b S((s-a)/\varepsilon; \varepsilon)\, e^{(s-a)/2\varepsilon^2}(s-a)^r\, ds, \tag{6.11}$$

$$Q^p_{r,b}(a, b; \varepsilon) = \int_a^b S((b-s)/\varepsilon; \varepsilon)\, e^{-(b-s)/2\varepsilon^2}(s-a)^r\, ds. \tag{6.12}$$

Just as in the case of the operators $P_{r,a}$, $Q_{r,a}$, $P_{r,b}$, $Q_{r,b}$ in § 4, the computation of $Q^p_{r,a}$ reduces to that of $Q^p_{r,b}$, writing $(s-a)^r = ((s-b)+b-a))^r$ and applying the binomial formula. Thus we limit ourselves to the latter; we explicitly calculate $Q^p_{0,b}(a, b, \varepsilon)$ and $Q^p_{1,b}(a, b, \varepsilon)$ and give a recursion formula from which each $Q^p_{r,b}(a, b; \varepsilon)$ can be computed. For $r = 0$ we use (2.17) for $r = 2$ and $f(s) = e^{-(b-s)/2\varepsilon^2}u$, keeping in mind that $A + (1/4\varepsilon^2)I$ is the infinitesimal generator of $C(t; \varepsilon)$:

$$\begin{aligned} &\int_a^b S((b-s)/\varepsilon; \varepsilon)\, e^{-(b-s)/2\varepsilon^2}\, ds \\ &\quad = -\varepsilon(A + (1/4\varepsilon^2)I)^{-1} + \varepsilon C((b-a)/\varepsilon; \varepsilon)(A + (1/4\varepsilon^2)I)^{-1}\, e^{-(b-a)/2\varepsilon^2} \\ &\quad + (1/2)S((b-a)/\varepsilon; \varepsilon)(A + (1/4\varepsilon^2)I)^{-1}\, e^{-(b-a)/2\varepsilon^2} \\ &\quad + (1/4\varepsilon^2) \int_a^b S((b-s)/\varepsilon; \varepsilon)(A + (1/4\varepsilon^2)I)^{-1}\, e^{(b-s)/2\varepsilon^2}\, ds. \end{aligned}$$

Applying $A + (1/4\varepsilon^2)I$ to both sides, putting integrals on the left-hand side and then applying A^{-1}, we obtain

$$\begin{aligned} Q^p_{0,b}(a, b; \varepsilon) &= \int_a^b S((b-s)/\varepsilon; \varepsilon)\, e^{-(b-s)/2\varepsilon^2}\, ds \\ &= -\varepsilon A^{-1} + \varepsilon C((b-a)/\varepsilon; \varepsilon)A^{-1}\, e^{-(b-a)/2\varepsilon^2} \\ &\quad + (1/2)S((b-a)/\varepsilon; \varepsilon)A^{-1}\, e^{-(b-a)/2\varepsilon^2}. \end{aligned} \tag{6.13}$$

The computation of $Q^p_{1,b}$ is similar, with $f(s)=e^{-(b-s)/2\varepsilon^2}(s-a)u$:

$$\begin{aligned}\int_a^b & S((b-s)/\varepsilon;\,\varepsilon)\, e^{-(b-s)/2\varepsilon^2}(s-a)\,ds \\ &= -\varepsilon(A+(1/4\varepsilon^2)I)^{-1}(b-a)+\varepsilon^2 S((b-a)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-a)/2\varepsilon^2} \\ &\quad +(1/4\varepsilon^2)\int_a^b S((b-s)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-s)/2\varepsilon^2}(s-a)\,ds \\ &\quad +\int_a^b S((b-s)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-s)/2\varepsilon^2}\,ds.\end{aligned}$$

This leads to the formula

$$Q^p_{1,b}(a,b,\varepsilon)=-\varepsilon A^{-1}(b-a)+\varepsilon^2 S((b-a)/\varepsilon)A^{-1}\,e^{-(b-a)/2\varepsilon^2}+A^{-1}Q^p_{0,b}(a,b,\varepsilon). \tag{6.14}$$

In the same way we obtain

$$\begin{aligned}\int_a^b & S((b-s)/\varepsilon;\,\varepsilon)\, e^{-(b-s)/2\varepsilon^2}(s-a)^r\,ds \\ &= -\varepsilon(A+(1/4\varepsilon^2)I)^{-1}(b-a)^r \\ &\quad +(1/4\varepsilon^2)\int_a^b S((b-s)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-s)/2\varepsilon^2}(s-a)^r\,ds \\ &\quad +r\int_a^b S((b-s)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-s)/2\varepsilon^2}(s-a)^{r-1}\,ds \\ &\quad +r(r-1)\varepsilon^2\int_a^b S((b-s)/\varepsilon;\,\varepsilon)(A+(1/4\varepsilon^2)I)^{-1}\,e^{-(b-s)/2\varepsilon^2}(s-a)^{r-2}\,ds.\end{aligned}$$

Hence

$$\begin{aligned}Q^p_{r,b}(a,b;\,\varepsilon)&=-\varepsilon A^{-1}(b-a)^r+rA^{-1}Q^p_{r-1,b}(a,b,\varepsilon) \\ &\quad +r(r-1)\varepsilon^2A^{-1}Q^p_{r-2,b}(a,b;\,\varepsilon),\end{aligned} \tag{6.15}$$

from which all the $Q^p_{r,b}$ can be calculated inductively.

THEOREM 6.1. *Let $u(t,\varepsilon)$ be the solution of* (5.1)-(5.2) *with $f(\cdot)\in B^n(a,b;E)$. Then, if $\{u_k(\varepsilon)\}$ is the solution of the difference equation* (5.8) *with right-hand side*

$$\begin{aligned}f_k(\varepsilon)&=\varepsilon\tau^{-2}\,e^{\tau/2\varepsilon^2}\sum_{r=0}^{n-1}\frac{1}{r!}\,Q^p_{r,(k+1)\tau}(k\tau,(k+1)\tau,\varepsilon)f^{(r)}(k\tau) \\ &\quad -\varepsilon\tau^{-2}\,e^{-\tau/2\varepsilon^2}\sum_{r=0}^{n-1}\frac{1}{r!}\,Q^p_{r,(k-1)\tau}((k-1)\tau,k\tau,\varepsilon)f^{(r)}((k-1)\tau)\end{aligned} \tag{6.16}$$

and initial conditions

$$u_0(\varepsilon)=u_0, \tag{6.17}$$

$$\begin{aligned}\tau^{-1}(e^{\tau/2\varepsilon^2}u_1(\varepsilon)-u_0(\varepsilon))&=\tau^{-1}(C(\tau/\varepsilon;\,\varepsilon)-I)u_0+\tau^{-1}S(\tau/\varepsilon;\,\varepsilon)((1/2\varepsilon)u_0+\varepsilon u_1) \\ &\quad +(\varepsilon\tau)^{-1}\,e^{\tau/2\varepsilon^2}\sum_{r=0}^{n-1}\frac{1}{r!}\,Q^p_{r,\tau}(0,\tau,\varepsilon)f^{(r)}(0).\end{aligned} \tag{6.18}$$

Then $\{u_k(\varepsilon)\}$ satisfies

$$\|u_k(\varepsilon)-u(t_k;\,\varepsilon)\|=0(\tau^n)\qquad(k=1,2,\cdots,N) \tag{6.19}$$

as $\tau\to 0$, uniformly with respect to ε.

7. The Schrödinger singular perturbation problem. The treatment of the initial value problem

$$\varepsilon^2 u''(t, \varepsilon) - iu'(t, \varepsilon) = Au(t, \varepsilon) + f(t), \tag{7.1}$$

$$u(0, \varepsilon) = u_0, \qquad u'(0, \varepsilon) = u_1 \tag{7.2}$$

is similar to that of (5.1)-(5.2). Formally, the initial value problem can be reduced to (5.1)-(5.2) as follows: if $u(t, \varepsilon)$ is a solution of (7.1)-(7.2), then the function $\tilde{u}(t, \varepsilon)$ "defined" by $\tilde{u}(t, \varepsilon) = u(-it, i\varepsilon)$ is a solution of the equation $\varepsilon^2 \tilde{u}''(t, \varepsilon) + \tilde{u}'(t, \varepsilon) = A\tilde{u}(t, \varepsilon) + f(-it)$ with initial conditions $u(0, \varepsilon) = u_0$, $\tilde{u}'(0, \varepsilon) = -iu_1$. Using this formal correspondence, all formulas in §§ 5 and 6 have analogues here: of course, independent proofs must be provided.

Assuming that $u(t, \varepsilon)$ is a solution of the initial value problem (7.1)-(7.2), we set

$$v(t; \varepsilon) = e^{-it/2\varepsilon^2} u(t, \varepsilon). \tag{7.3}$$

Then $v(\cdot; \varepsilon)$ satisfies the initial value problem

$$v''(t; \varepsilon) = (A - (1/4\varepsilon^2)I)v(t; \varepsilon) + e^{-it/2\varepsilon^2} f(t; \varepsilon), \tag{7.4}$$

$$v(0; \varepsilon) = u_0, \qquad v'(0; \varepsilon) = (-i/2\varepsilon^2)u_0 + u_1. \tag{7.5}$$

Denoting by $C(t; i\varepsilon)$ the cosine function generated by $A - (1/4\varepsilon^2)I$, the difference equation associated to (7.4) is

$$v_{k+1} + v_{k-1} = 2C(\tau/\varepsilon; i\varepsilon)v_k + \tau^2(\varepsilon^{-2} f_k).$$

Thus, the difference equation for $\{u_k\} = \{e^{ik\tau/2\varepsilon^2} v_k\}$ is

$$\begin{aligned} &e^{-i(k+1)\tau/2\varepsilon^2} u_{k+1} + e^{-i(k-1)\tau/2\varepsilon^2} u_{k-1} \\ &\quad = 2\tau^{-2} C(\tau/\varepsilon; i\varepsilon)\, e^{-ik\tau/\varepsilon^2} u_k + \tau^2\, e^{-ik\tau/2\varepsilon^2}(\varepsilon^{-2} f_k), \end{aligned} \tag{7.6}$$

which can be rewritten in the form

$$\begin{aligned} &\tau^{-2}(u_{k+1} - 2u_k + u_{k-1}) + \tau^{-1}(1 - e^{i\tau/\varepsilon^2})\tau^{-1}(u_k - u_{k-1}) \\ &\quad = \tau^{-2}(2C(\tau/\varepsilon; i\varepsilon)\, e^{i\tau/2\varepsilon^2} - (1 + e^{i\tau/\varepsilon^2})I) + \varepsilon^{-2}\, e^{i\tau/2\varepsilon^2} f_k, \end{aligned} \tag{7.7}$$

showing its direct relationship with (7.1). Initial conditions are

$$u_0 = \tilde{u}_0, \qquad \tau^{-1}(e^{-i\tau/2\varepsilon^2} u_1 - u_0) = \tilde{u}_1. \tag{7.8}$$

Estimates for the solution of (7.6)-(7.8) can be obtained directly from the explicit solution,

$$\begin{aligned} u_k = {} & e^{ik\tau/2\varepsilon^2} C_k(\tau/\varepsilon; i\varepsilon)\tilde{u}_0 + e^{ik\tau/2\varepsilon^2} \tau S_k(\tau/\varepsilon; i\varepsilon)\tilde{u}_1 \\ & + \tau^2 \sum_{j=0}^{k-1} e^{i(k-j)\tau/\varepsilon^2} S_{k-j}(\tau/\varepsilon; i\varepsilon)(\varepsilon^{-2} f_j). \end{aligned} \tag{7.9}$$

We shall estimate this expression in the setting used in [12] (see also [14, Chap. VII]) for treatment of the Schrödinger singular perturbation problem; we assume that E is a Hilbert space and that

$$A = A_0 + B, \tag{7.10}$$

where A_0 is a self-adjoint operator bounded above and B is a bounded operator. In this situation there exist constants M, ω such that

$$\|C(t; i\varepsilon)\| \leqq M e^{\omega\varepsilon|t|} \qquad (-\infty < t < \infty), \tag{7.11}$$

$$\|S(t; i\varepsilon)\| \leqq M\varepsilon\, e^{\omega\varepsilon|t|} \qquad (-\infty < t < \infty) \tag{7.12}$$

(see [12] or [14, p. 242]). Using (7.11) and formulas (3.6), (3.7), and (3.8) for the discrete propagators we obtain

$$\|C_k(\tau/\varepsilon;\, i\varepsilon)\| \leqq Mk\, e^{\omega k\tau}, \qquad \|S_k(\tau/\varepsilon;\, i\varepsilon)\| \leqq Mk\, e^{\omega k\tau} \tag{7.13}$$

and we estimate (7.9) in the same way as (5.11):

$$\|u_k\| \leqq Mk\, e^{k\tau\omega}\|\tilde{u}_0\| + Mk\tau\, e^{k\tau\omega}\|\tilde{u}_1\| + M(T(T+\tau)/2)\, e^{k\tau\omega} \max_{1\leq j\leq n} \|\varepsilon^{-2} f_j\|. \tag{7.14}$$

The estimates below are similar to those for the parabolic problem. We begin by writing the solution of (7.4) using (7.3) and (2.6):

$$\begin{aligned} u(t;\, \varepsilon) &= e^{it/2\varepsilon^2} C(t/\varepsilon;\, i\varepsilon)u_0 + e^{it/2\varepsilon^2} S(t/\varepsilon;\, i\varepsilon)((-i/2\varepsilon)u_0 + \varepsilon u_1) \\ &\quad + \varepsilon^{-1} \int_0^t S((t-s)/\varepsilon;\, i\varepsilon)\, e^{i(t-s)/2\varepsilon^2} f(s)\, ds. \end{aligned} \tag{7.15}$$

Using (7.11) and (7.12) we obtain the analogue of (6.3),

$$\|u(t;\, \varepsilon)\| \leqq 2M e^{\omega t}(\|u_0\| + \varepsilon^2\|u_1\|) + 2M e^{\omega T} \int_0^T \|f(t)\|\, dt. \tag{7.16}$$

We proceed exactly as in §§ 5 and 6. Assuming that $f(\cdot) \in L^1(0, T;\, E)$ and $f_{\tau,n}(\cdot) \in L^1(0, T;\, E)$ is a function such that (6.4) holds, then, if $u_{\tau,n}(t, \varepsilon)$ is the solution of the initial value problem (7.1)-(7.2) with the same initial conditions and $f = f_{\tau,n}$, it follows from (7.16) that (6.5) holds.

We deduce the difference equation for a solution $u(t, \varepsilon)$ of the initial value problem (7.1)-(7.2) with an arbitrary right-hand side $f(\cdot)$. Taking into account that $v(t, \varepsilon)$ given by (7.3) satisfies the differential equation (7.4), a computation similar to (6.6) shows that $\{u(t_k;\, \varepsilon)\}$ solves

$$\begin{aligned} & e^{-i(k+1)\tau/2\varepsilon^2} u(t_{k+1}, \varepsilon) + e^{-i(k-1)\tau/2\varepsilon^2} u(t_{k-1}, \varepsilon) - 2C(\tau/\varepsilon;\, i\varepsilon)\, e^{-ik\tau/\varepsilon^2} u(t_k, \varepsilon) \\ & + \varepsilon^{-1}\, e^{-i(k+1)\tau/2\varepsilon^2} \int_{k\tau}^{(k+1)\tau} S(((k+1)\tau - s)/\varepsilon;\, i\varepsilon)\, e^{i((k+1)\tau - s)/2\varepsilon^2} f(s)\, ds \\ & + \varepsilon^{-1}\, e^{-ik\tau/2\varepsilon^2} \int_{(k-1)\tau}^{k\tau} S(((k-1)\tau - s)/\varepsilon;\, i\varepsilon)\, e^{i(k\tau - s)/2\varepsilon^2} f(s)\, ds \end{aligned} \tag{7.17}$$

with initial conditions

$$u(0, \varepsilon) = \tilde{u}_0 = u_0, \tag{7.18}$$

$$\begin{aligned} & \tau^{-1}(e^{-i\tau/2\varepsilon^2} u(\tau, \varepsilon) - u(0, \varepsilon)) \\ & = \tau^{-1}(C(\tau/\varepsilon;\, i\varepsilon) - I)u_0 + \tau^{-1} S(\tau/\varepsilon;\, i\varepsilon)((-i/2\varepsilon)u_0 + \varepsilon u_1) \\ & \quad + (\varepsilon\tau)^{-1}\, e^{-i\tau/2\varepsilon^2} \int_0^\tau S((\tau - s)/\varepsilon;\, i\varepsilon)\, e^{i(\tau - s)/2\varepsilon^2} f(s)\, ds. \end{aligned} \tag{7.19}$$

We use the same piecewise Taylor polynomial approximation (6.9). To figure out explicitly all coefficients in terms of the values of $f(\cdot)$ and of its derivatives at gridpoints, we find explicit formulas for the operators

$$Q^s_{r,a}(a, b, \varepsilon) = \int_a^b S((s-a)/\varepsilon;\, i\varepsilon)\, e^{-i(s-a)/2\varepsilon^2} (s-a)^r\, ds, \tag{7.20}$$

$$Q^s_{r,b}(a, b, \varepsilon) = \int_a^b S((b-s)/\varepsilon;\, i\varepsilon)\, e^{i(b-s)/2\varepsilon^2} (s-a)^r\, ds. \tag{7.21}$$

The computation of $Q^s_{r,a}$ reduces to that of $Q^s_{r,b}$ in the same way as in the parabolic problem; also, as in § 6 we limit ourselves to computing $Q^s_{0,b}$ and $Q^s_{1,b}$ and to give a recursion formula from which each $Q^s_{r,b}$ can be computed. There is a difference, however, between the computations here and those in § 6: the infinitesimal generator of the cosine function $C(t;\, i\varepsilon)$ is $A-(1/4\varepsilon^2)I$, which may not have an inverse. Thus, rather than using formula (2.14) we use (2.36) with the function

$$f(t)=e^{i(b-s)/2\varepsilon^2}(s-a)^r u,$$

which satisfies the necessary assumptions for use of (2.36) if $u\in D(A^m)$ for sufficient large m. We omit the details and only state the final results:

$$\begin{aligned} Q^s_{0,b}(a,b,\varepsilon) &= \int_a^b S((b-s)/\varepsilon;\, i\varepsilon)\, e^{i(b-s)/2\varepsilon^2}\, ds \\ &= -\varepsilon A^{-1}+\varepsilon C((b-a)/\varepsilon;\, i\varepsilon)A^{-1}\, e^{i(b-a)/2\varepsilon^2} \\ &\quad -(1/2)S((b-a)/\varepsilon;\, \varepsilon)A^{-1}\, e^{i(b-a)/2\varepsilon^2}, \end{aligned} \tag{7.22}$$

$$\begin{aligned} Q^s_{1,b}(a,b,\varepsilon) &= \int_a^b S((b-s)/\varepsilon;\, \varepsilon)\, e^{i(b-s)/2\varepsilon^2}(s-a)\, ds \\ &= -\varepsilon A^{-1}(b-a)+\varepsilon^2 S((b-a)/\varepsilon;\, \varepsilon)A^{-1}\, e^{i(b-a)/2\varepsilon^2} \\ &\quad +A^{-1}Q^s_{0,b}(a,b,\varepsilon), \end{aligned} \tag{7.23}$$

$$\begin{aligned} Q^s_{r,b}(a,b,\varepsilon) &= \int_a^b S((b-s)/\varepsilon;\, \varepsilon)\, e^{i(b-s)/2\varepsilon^2}(s-a)^r\, ds \\ &= -\varepsilon A^{-1}(b-a)^r - irA^{-1}Q^s_{r-1,b}(a,b,\varepsilon) \\ &\quad +r(r-1)\varepsilon^2 A^{-1}Q^s_{r-2,b}(a,b;\,\varepsilon). \end{aligned} \tag{7.24}$$

THEOREM 7.1. *Let $u(t,\varepsilon)$ be the solution of* (7.1)-(7.2) *with $f(\cdot)\in B^n(a,b;\,E)$. Then the solution $\{u_k(\varepsilon)\}$ of the difference equation* (7.6) *with right-hand side*

$$\begin{aligned} f_k(\varepsilon) &= \varepsilon\tau^{-2}\, e^{-i\tau/2\varepsilon^2}\sum_{r=0}^{n-1}\frac{1}{r!}\, Q^s_{r,(k+1)\tau}(k\tau,(k+1)\tau,\varepsilon)f^{(r)}(k\tau) \\ &\quad +\varepsilon\tau^{-2}\, e^{i\tau/2\varepsilon^2}\sum_{r=0}^{n-1}\frac{1}{r!}\, Q^s_{r,(k-1)\tau}((k-1)\tau,k\tau,\varepsilon)f^{(r)}((k-1)\tau) \end{aligned} \tag{7.25}$$

and initial conditions

$$u_0(\varepsilon)=u_0, \tag{7.26}$$

$$\begin{aligned} \tau^{-1}(e^{-i\tau/2\varepsilon^2}u_1(\varepsilon)-u_0(\varepsilon)) &= \tau^{-1}(C(\tau/\varepsilon;\, i\varepsilon)-I)u_0+\tau^{-1}S(\tau/\varepsilon;\, i\varepsilon)((-i/2\varepsilon)u_0+\varepsilon u_1) \\ &\quad +(\varepsilon\tau)^{-1}\, e^{-i\tau/2\varepsilon^2}\sum_{r=1}^{n-1}\frac{1}{r!}\, Q^s_{r,\tau}(0,\tau,\varepsilon)f^{(r)}(0). \end{aligned} \tag{7.27}$$

Then $\{u_k(\varepsilon)\}$ satisfies

$$\|u_k(\varepsilon)-u(t_k;\,\varepsilon)\|=0(\tau^n)\qquad (k=1,2,\cdots,N) \tag{7.28}$$

as $\tau\to 0$, uniformly with respect to ε.

8. The hyperbolic singular perturbation problem. We can write the hyperbolic singular perturbation problem (1.4)-(1.5) as an "ε-dependent parabolic singular perturbation problem":

$$\varepsilon^2 u''(t;\,\varepsilon)+u'(t;\,\varepsilon)=A(\varepsilon)u(t,\varepsilon)+f(t), \tag{8.1}$$

$$u(0,\varepsilon)=u_0,\qquad u'(0,\varepsilon)=u_1, \tag{8.2}$$

where $A(\varepsilon)=\varepsilon^2A+B$. Accordingly, the treatment in §§ 5 and 6 can be extended with few modifications.

We state below the necessary information on (8.1), (8.2) from [14]. Assume that, for each $\varepsilon>0$ the function $A(\varepsilon)$ generates a cosine function and denote by $C(t;\varepsilon)$ the cosine function generated by $A(\varepsilon)+(1/4\varepsilon^2)I$ and by $S(t;\varepsilon)$ the corresponding sine function. All the basic estimates in § 6 can be extended if we assume the bounds

$$\|C(t;\varepsilon)\|\leqq M\exp(1/2\varepsilon+\omega\varepsilon)t \qquad (t\geqq 0), \tag{8.3}$$

$$\|S(t;\varepsilon)\|\leqq M\varepsilon\exp(1/2\varepsilon+\omega\varepsilon)t \qquad (t\geqq 0). \tag{8.4}$$

In fact, (8.3) implies

$$e^{-k\tau/2\varepsilon^2}\|C_k(\tau/\varepsilon;\varepsilon)\|\leqq Mk\,e^{k\tau\omega} \tag{8.5}$$

(see (5.14)) and the corresponding bound for the solution of the difference equation (5.8) with initial condition (5.10):

$$\|u_k\|\leqq 2Mk\,e^{k\tau\omega}\|\tilde{u}_0\|+2Mk\tau\,e^{k\tau\omega}\|\tilde{u}_1\|+M(T(T+\tau)/2)\,e^{k\tau\omega}\max_{1\leqq j\leqq n}\|\varepsilon^{-2}f_j\|. \tag{8.6}$$

The solution of the initial value problem (8.1)-(8.2) is given by (6.1), and we obtain on the basis of (8.3)-(8.4) the bound

$$\|u(t;\varepsilon)\|\leqq 2Me^{\omega t}(\|u_0\|+\varepsilon^2\|u_1\|)+2Me^{\omega T}\int_0^T\|f(t)\|\,dt \tag{8.7}$$

in the same way (6.3) is obtained. See [13] for more details on the hyperbolic singular perturbation problem. In particular, the key estimates (8.3) and (8.4) hold if E is a Hilbert space, A is a self-adjoint operator such that

$$(Au,u)\leqq-\kappa(u,u) \qquad (u\in D(A)), \tag{8.8}$$

and B is a closed, densely defined operator with adjoint B^* densely defined, satisfying $D(B)\supseteq D(Q)$, $D(B^*)\supseteq D(Q)$ (Q the unique positive square root of $(-A)^{1/2}$) and such that

$$\|Bu\|\leqq\|Qu\|,\quad \|B^*u\|\leqq\|Qu\| \qquad (u\in D(Q)), \tag{8.9}$$

$$\operatorname{Re}(Bu,u)\leqq\omega(u,u),\quad \operatorname{Re}(B^*u,u)\leqq\omega(u,u) \qquad (u\in D(Q)). \tag{8.10}$$

For other sets of hypotheses implying (8.3)-(8.4) see [13]. We assume that $A(\varepsilon)^{-1}$ exists and is bounded, which is the case for instance if $\omega<0$ in (8.10). The computations in § 6 for the operators $Q^p_{r,a}$, $Q^p_{r,b}$ apply without changes to the operators

$$Q^H_{r,a}(a,b;\varepsilon)=\int_a^b S((s-a)/\varepsilon;\varepsilon)\,e^{(s-a)/2\varepsilon^2}(s-a)^r\,ds,$$

$$Q^H_{r,b}(a,b;\varepsilon)=\int_a^b S((b-s)/\varepsilon;\varepsilon)\,e^{-(b-s)/2\varepsilon^2}(s-a)^r\,ds.$$

The result corresponding to Theorem 6.1 can be stated and proved in exactly the same way, thus we omit the details.

UNIQUE CONTINUATION FOR THE KORTEWEG-DE VRIES EQUATION*

BINGYU ZHANG†

Abstract. Unique continuation problems are considered for the Korteweg-de Vries (KdV) equation

$$u_t + uu_x + u_{xxx} = 0, \qquad -\infty < x, \quad t < +\infty.$$

By using the inverse scattering transform and some results from the Hardy function theory, it is proven that if $u \in L^\infty_{\mathrm{loc}}(R, H^s(R))(s > \frac{3}{2})$ is a solution of the KdV equation, then it cannot have compact support at two different moments unless it vanishes identically. In addition, it is shown under certain conditions that if u is a solution of the KdV equation, then u must vanish everywhere if it vanishes on two horizontal half lines in the x-t space. This implies that the solution u must vanish everywhere if it vanishes on an open subset in the x-t space. As a consequence of the Miura transformation, the above results for the KdV equation are also true for the modified Korteweg-de Vries equation

$$v_t - 6v^2 v_x + v_{xxx} = 0, \qquad -\infty < x, \quad t < +\infty.$$

Key words. unique continuation, Korteweg-de Vries equation, inverse scattering transform, Hardy function

AMS(MOS) subject classification. 35Q20

1. Introduction. Let L be an evolution operator acting on functions defined on some connected open set Ω of $R^{n+1} = R^n_x \times R_t$. L is said to have the unique continuation property if every solution u of $Lu = 0$ that vanishes on some nonempty open set $\Omega_1 \subset \Omega$ vanishes in the horizontal component of Ω_1 in Ω, i.e., in $\{(x, t) \in \Omega;\ \exists x_1, (x_1, t) \in \Omega_1\}$ (cf. [4], [8], and [13]).

Saut and Scheurer [12], [13] considered some dispersive operators in one space dimension of the type

$$L = iD_t + \alpha i^{2k+1} D^{2k+1} + R(x, t, D)$$

where $\alpha \neq 0$, $D = 1/i\, \partial/(\partial x)$, $D_t = 1/i\, \partial/(\partial t)$, and

$$R(x, t, D) = \sum_{j=0}^{2k} r_j(x, t) D^j, \qquad r_j \in L^\infty_{\mathrm{loc}}(R, L^2_{\mathrm{loc}}(R)).$$

They proved that if $u \in L^2_{\mathrm{loc}}(R, H^{2k+1}_{\mathrm{loc}}(R))$ is a solution of $Lu = 0$, which vanishes in some open set Ω_1 of $R_x \times R_t$, then u vanishes in the horizontal component of Ω_1.

As a consequence of uniqueness of the solution of the KdV equation in $L^\infty_{\mathrm{loc}}(R, H^3(R))$, their result immediately yields the following theorem.

THEOREM 1.1. *If $u \in L^\infty_{\mathrm{loc}}(R, H^3(R))$ is a solution of the* KdV *equation*

$$u_t + uu_x + u_{xxx} = 0$$

and vanishes on an open set of $R_x \times R_t$, then

$$u(x, t) = 0 \quad \textit{for } x \in R, \quad t \in R.$$

In this paper, we consider various unique continuation properties of the KdV equation. By using the inverse scattering transform we prove that a solution u of the KdV equation, which decays sufficiently fast at $\pm\infty$, vanishes everywhere if it vanishes on two different horizontal half lines in the x-t space. In addition, we prove that a class of generalized solution of the KdV equation or solutions of the KdV equation in

* Received by the editors January 9, 1990; accepted for publication (in revised form) March 8, 1991.

$L^{\infty}_{\text{loc}}(R;\, H^s(R))(s>\frac{3}{2})$ cannot have compact support at two different moments in the x-t space unless it vanishes identically. The methods we use are different from those of Saut and Scheurer. However, with a little stronger condition made on the solution u, our results recover Theorem 1.1 as a corollary.

The results obtained for the KdV equation are also true for the modified KdV equation

$$v_t - 6v^2 v_x + v_{xxx} = 0$$

as we see by applying the Miura transformation

$$u = -\tfrac{1}{6}(v^2 + v_x),$$

where v is a solution of the modified KdV equation and u is a solution of the KdV equation

$$u_t + uu_x + u_{xxx} = 0.$$

The paper is organized as follows: In § 2, we provide a sketch of the inverse scattering transform and cite some results from Deift and Trubowitz [3] which play important roles in the proof of our main results. In § 3, we prove some unique continuation properties for the linearized KdV equation (Airy equation) by using the Fourier transform. In § 4, we prove our main unique continuation results for the KdV equation. We will see that the inverse scattering transform in the nonlinear problem plays the same role as that of the Fourier transform in the linear problem.

2. The inverse scattering transform. We use the following notation to denote the Fourier and the inverse Fourier transform:

$$\hat{f}(y) = \frac{1}{\pi}\int_{-\infty}^{+\infty} e^{2ixy} f(x)\, dx$$

and

$$\check{f}(x) = \int_{-\infty}^{+\infty} e^{-2ixy} f(y)\, dy.$$

Let H^2_+ be the Hardy space of functions $h(k)$ analytic in $\operatorname{Im} k > 0$ with

$$\sup_{b>0} \int_{-\infty}^{+\infty} |h(a+ib)|^2\, da < \infty.$$

Such a function $h(k)$ assumes boundary values

$$h(a) = \lim_{\varepsilon \to 0} H(a + i\varepsilon)$$

in $L^2(R)$ and it is well known that

$$H^2_+ = \{h(k) \in L^2(R) \colon \operatorname{supp} \hat{h} \subset (-\infty, 0)\}.$$

Similarly, H^2_- denotes the Hardy space of functions analytic in $\operatorname{Im} k < 0$ with

$$\sup_{b<0} \int_{-\infty}^{+\infty} |h(a+ib)|^2\, da < \infty$$

and

$$H^2_- = \{h(k) \in L^2(R) \colon \operatorname{supp} \hat{h} \subset (0, \infty)\}.$$

Consider the Schrödinger operator

$$\mathcal{S}(f) = -f'' + qf - k^2 f, \tag{1}$$

where k is a complex number and q, called a potential of (1), is a real function of $x \in R$ satisfying

$$\int_{-\infty}^{+\infty} (1+|x|)|q(x)|\,dx < \infty. \tag{2}$$

Let f_1 and f_2 be two solutions of $\mathscr{S}(f)=0$ such that

$$f_1 \sim e^{ikx} \quad \text{as } x \to \infty,$$
$$f_2 \sim e^{-ikx} \quad \text{as } x \to -\infty.$$

Set

$$m_1 = e^{-ikx} f_1, \qquad m_2 = e^{ikx} f_2.$$

Then

$$m_1'' + 2ikm_1' = qm_1, \tag{3}$$
$$m_2'' - 2ikm_2' = qm_2 \tag{4}$$

with $m_1 \to 1$ as $x \to \infty$ and $m_2 \to 1$ as $x \to -\infty$.

Define (for all real $k \neq 0$)

$$\frac{1}{T(k)} = 1 - \frac{1}{2ik}\int_{-\infty}^{+\infty} q(t)m_1(t,k)\,dt, \tag{5}$$

$$\frac{R_1(k)}{T(k)} = \frac{1}{2ik}\int_{-\infty}^{+\infty} e^{-2ikt}q(t)m_2(t,k)\,dt, \tag{6}$$

$$\frac{R_2(k)}{T(k)} = \frac{1}{2ik}\int_{-\infty}^{+\infty} e^{2ikt}q(t)m_1(t,k)\,dt, \tag{7}$$

and

$$S(k) = \begin{pmatrix} T(k) & R_2(k) \\ R_1(k) & T(k) \end{pmatrix}.$$

Here $T(k)$ is called the *transmission coefficient* and $R_1(k)$ is called the *right reflection coefficient*. The operator $\mathscr{S}(f)$ has only finite many simple negative eigenvalues, listed as

$$-\beta_n^2 < -\beta_{n-1}^2 < \cdots < -\beta_1^2, \tag{8}$$

which are called *bound states* of the potential q for $\mathscr{S}(f)$. The corresponding eigenfunctions $\psi_n, \cdots, \psi_1$ are assumed to satisfy

$$\int_{-\infty}^{+\infty} |\psi_k|^2\,dx = 1, \qquad k = 1, 2, \cdots, n.$$

Let

$$c_j = \lim_{x\to\infty} e^{-\beta_j x}\psi_n(x), \qquad j = 1, 2, \cdots, n. \tag{9}$$

They are called *normalizing coefficients.*

The following propositions are cited from [3].

PROPOSITION 2.1. *There is a constant c independent of x and k such that*

$$|m_j(x,k) - 1| < e^{c/|k|}\frac{c}{|k|}, \qquad j = 1, 2$$

for $k \neq 0$ and $\operatorname{Im} k \geqq 0$.

PROPOSITION 2.2. *The transmission coefficient* $T(k)$ *is meromorphic in* $\operatorname{Im} k > 0$ *with a finite number of simple poles* $i\beta_1, \cdots, i\beta_n$, $\beta_j > 0$, $T(k)$ *is continuous in* $\operatorname{Im} k \geqq 0$, $k \neq 0$, $i\beta_1, \cdots, i\beta_n$, *and*

$$T(k) = 1 + O\left(\frac{1}{k}\right) \quad \textit{as } |k| \to \infty, \quad \operatorname{Im} k \geqq 0.$$

Moreover, if q *is supported on a half line, then* $T(k)$ *is meromorphic in the entire* k*-plane.*

PROPOSITION 2.3. *Let* q *be the potential of the Schrödinger operator* $\mathcal{S}$ *defined in* (1).

(i) *If* q *has* N*th-order derivatives which are in* $L^1(R)$, *then*

$$R_1(k) = O\left(\frac{1}{k^{N+1}}\right) \quad \textit{as } |k| \to \infty, \quad k \textit{ real.}$$

(ii) *If* q *is supported on a left half line, then* $R_1(k)$ *is meromorphic in the upper half plane.*

(iii) *If* q *has compact support, then* $R_1(k)$ *is meromorphic in the entire plane.*

PROPOSITION 2.4. (Removing all bound states). *Assume that* q *has* n *bound states, listed as*

$$-\beta_n^2 < -\beta_{n-1}^2 < \cdots < -\beta_1^2.$$

Define inductively

$$q(x, 0) = q(x),$$

$$q(x, -n) = q(x, -(m-1)) - 2\frac{d^2}{dx^2}\log f_1(x, i\beta_{n-m+1}; -(m-1))$$

for $1 \leqq m \leqq n$.

Then $q(x, -n)$ *has no bound states and its right reflection coefficient is*

$$R_1(k, -n) = (-1)^n\left(\prod_{j=1}^{n}\frac{k - i\beta_j}{k + i\beta_j}\right)R_1(k). \tag{10}$$

In addition, if $\operatorname{supp} q \subset (a, b)$, *then* $\operatorname{supp} q(x, -n) \subset (a, b)$ *where* a *is a finite number or* $-\infty$.

PROPOSITION 2.5. (Trace formula). *If* q *has no bound states, then*

$$q(x) = \frac{2i}{\pi}\int_{-\infty}^{+\infty} kR_1(k)\, e^{2ikx} m_1^2(x, k)\, dk. \tag{11}$$

PROPOSITION 2.6. *Assume that* q *has no bound states. If* q *has a support lying to the left of some point, then*

$$\sup\{\textit{support of } q\} = \inf\left\{x\colon \int_{-\infty}^{+\infty} kR_1(k)\, e^{2ikt}\, dk = 0 \textit{ for all } t > x\right\}.$$

Consider the initial value problem for the KdV equation

$$u_t + uu_x + u_{xxx} = 0, \qquad u(x, 0) = q(x), \tag{12}$$

for $x \in R$ and $t \geqq 0$ where $q \in H^4(R)$ and

$$\int_{-\infty}^{+\infty} (1 + |x|)|q(x)|\, dx < \infty.$$

It is well known that the initial value problem (12) can be solved by using the inverse scattering transform (cf. [2], [9], and [16] for more details). The basic steps of the solution method are as follows.

Step 1. With the initial data $u(x,0)=q(x)$ as a potential, solve

$$-f''+qf=\lambda f$$

to get the scattering data

$$\lambda_j(0)=-\beta_j^2, \qquad c_j(0)=c_j$$

and

$$R_1(k,0)=R_1(k), \qquad T(k,0)=T(k)$$

as in (8), (9), (6), and (5).

Step 2. Treat t as a parameter and consider $u(x,t)$, the solution of (12), as a potential to solve

$$-f''+u(x,t)f=\lambda f.$$

The remarkable fact is that we can obtain the scattering data corresponding to $u(x,t)$ without knowing what $u(x,t)$ is. In fact,

$$\lambda_j(t)=\lambda_j(0), \quad c_j(t)=c_j(0)\, e^{4\beta_j^3 t}, \qquad j=1,2,\cdots,n \tag{13}$$

and

$$R_1(k,t)=R_1(k,0)\, e^{8ik^3 t}, \qquad T(k,t)=T(k,0). \tag{14}$$

Step 3. Let

$$B(\xi,t)=\sum_{j=1}^{n} c_j^2(0)\, e^{8\beta_j^3 t-\beta_j\xi}+\frac{1}{2\pi}\int_{-\infty}^{+\infty} R_1(k,0)\, e^{i(8k^3t+k\xi)}\, dk \tag{15}$$

and use it to define the Gel'fand-Levitan equation

$$K(x,y;t)+B(x+y;t)+\int_x^{\infty} B(x+z;t)K(z,y;t)\, dz=0 \tag{16}$$

for all time t.

Step 4. Solve (16) to get $K(x,y;t)$. Then the desired solution of (12) is

$$u(x,t)=-2\frac{d}{dx}K(x,x;t).$$

3. The linear KdV equation. Consider the initial value problem for the linear KdV equation:

$$u_t+u_{xxx}=0, \qquad u(x,0)=q(x) \tag{17}$$

for $x\in R$, $t\in R$.

Formally, by using the Fourier transform, we obtain

$$u(x,t)=\frac{1}{\pi}\int_{-\infty}^{+\infty} e^{2ikx}\, e^{ik^3t}\tilde{q}(k)\, dk. \tag{18}$$

If $q\in L^2(R)$, the $u(x,t)$ defined in (18) belongs to $L^2(R)$ for any t and is called a mild solution of (17). Obviously, if q is smooth enough, then $u(x,t)$ is a classical solution of (17).

THEOREM 3.1. *Let $u(x, t)$ be a mild solution of* (17). *If there exist $t_1 < t_2$ such that*

$$\operatorname{supp} u(\cdot, t_j) \subset (-\infty, \alpha), \qquad j = 1, 2 \tag{19}$$

or

$$\operatorname{supp} u(\cdot, t_j) \subset (\alpha, \infty), \qquad j = 1, 2 \tag{20}$$

for some $\alpha \in R$, then

$$u(x, t) \equiv 0, \qquad -\infty < x, \quad t < +\infty.$$

To prove Theorem 2.1 we need the following lemma.

LEMMA 3.1. *Assume $0 \neq q \in L^2(R)$ and* $\operatorname{supp} q \subset (-\infty, 0)$. *Let*

$$H(b) = \int_{-\infty}^{0} e^{2bx} q(x)\, dx.$$

Then there exist $b_n > 0$ such that $b_n \to \infty$ as $n \to \infty$ and

$$|H(b_n)| \geqq \alpha_1 e^{-\beta_1 b_n}, \qquad n = 1, 2, \cdots \tag{21}$$

where α_1 and β_1 are positive constants independent of n.

Proof of Lemma 3.1. Let

$$F(z) = \int_{-\infty}^{\infty} e^{-2izx} q(x)\, dx \qquad (\operatorname{Im} z > 0)$$

and

$$f(z) = F\left(i \frac{1+z}{1-z}\right) \qquad (|z| < 1).$$

Then f belongs to the Hardy space H^2 in the unit disc and

$$H(b) = F(ib).$$

Consider the canonical factorization of f (cf. [10, Chap. 17]):

$$f(z) = B(z) S(z) Q(z)$$

where B is a Blaschke product,

$$B(z) = z^k \prod_n \frac{z_n - z}{1 - \bar{z}_n z} \frac{|z_n|}{z_n},$$

z_n are zeros of $H(z)$ in the unit disk,

$$S(z) = \exp\left\{ -\int_{-\pi}^{\pi} \frac{e^{i\psi} + z}{e^{i\psi} - z}\, d\mu(\psi) \right\}$$

is a singular inner function (μ is a positive singular measure, possibly zero), and

$$Q(z) = \exp\left\{ \frac{1}{2\pi} \int_{-\pi}^{\pi} \frac{e^{i\psi} + z}{e^{-\psi} - z} \log |f(e^{i\psi})|\, d\psi \right\}$$

is an outer function. If $z = r e^{i\theta}$, then

$$\operatorname{Re}\left[\frac{e^{i\psi} + z}{e^{i\psi} - z}\right] = P_r(\theta - \psi)$$

$$= \frac{1 - r^2}{1 - 2r \cos(\theta - \psi) + r^2},$$

the Poisson kernel, and

$$P_r(\theta-\psi)<\frac{1+r}{1-r} \qquad (0\leqq r<1).$$

Thus,

$$\log|S(r)|\geqq -\frac{1+r}{1-r}\|\mu\|$$

($\|\mu\|=\mu(-\pi,\pi)$) and

$$\log|Q(r)|\geqq -\frac{1+r}{1-r}\int_{-\pi}^{\pi}\log^-|f(e^{i\psi})|\,d\psi$$

where $\log=\log^+-\log^-$. So there exists $C<\infty$ such that

$$(1-r)\log|S(r)Q(r)\|\geqq -C \qquad (0<r<1).$$

As for the Blaschke product B, it is known that

$$\overline{\lim_{r\to 1_-}}\sup(1-r)\log|B(r)|=0$$

[14, Lemma 2.3]. Hence there exists $r_n\to 1_-$ as $n\to\infty$ such that

$$\lim_{n\to\infty}(1-r_n)\log|B(r_n)|=0$$

and

$$(1-r_n)\log|f(r_n)|\geqq -3C, \qquad n=1,2,\cdots.$$

Let

$$r_n=\frac{b_n-1}{b_n+1}.$$

Then

$$b_n=\frac{1+r_n}{1-r_n}, \qquad 1-r_n=\frac{2}{b_n+1},$$

and

$$\frac{2}{b_n+1}\log|F(ib_n)|=(1-r_n)\log|f(r_n)|\geqq -3C.$$

Thus

$$|F(ib_n)|\geqq e^{-3/2C(b_n+1)}$$

for all n.

Choosing $\alpha_1=e^{-3C/2}$ and $\beta_1=3C/2$, we have

$$|H(b_n)=|F(ib_n)|\geqq \alpha_1\,e^{-\beta_1 b_n}, \qquad n=1,2,\cdots.$$

The proof is completed. □

Proof of Theorem 3.1. Without loss of generality, assume that $\alpha=0$ and $t_1=0$. Then

$$u(x,t_1)=u(x,0)=q(x)$$

and

$$u(x, t) = \frac{1}{\pi} \int_{-\infty}^{+\infty} e^{2ikx}\, e^{8ik^3x} \check{q}(k)\, dk.$$

For the case in which u satisfies (19), we have

$$\int_{-\infty}^{+\infty} e^{2ikx}\, e^{8ik^3t_2} \check{q}(k)\, dk = 0 \quad \text{for } x > 0. \tag{22}$$

In addition, since $e^{8ik^3t_2}\check{q}(k) \in L^2(R)$, we have $e^{8ik^3t_2}\check{q}(k) \in H_+^2$. Thus, by the definition of the Hardy function,

$$\sup_{b>0} \int_{-\infty}^{+\infty} |e^{8i(a+ib)^3t_2} \check{q}(a+ib)|^2\, da < \infty. \tag{23}$$

On the other hand,

$$\begin{aligned} I(b) &\equiv \int_{-\infty}^{+\infty} |e^{8i(a+ib)^3t_2} \check{q}(a+ib)|^2\, da \\ &= e^{16b^3t_2} \int_{-\infty}^{+\infty} e^{-48a^2bt_2} |\check{q}(a+ib)|^2\, da \\ &\geqq e^{16b^3t_2} \int_0^1 e^{-48a^2bt_2} |\check{q}(a+ib)|^2\, da \\ &\geqq e^{16b^3t_2}\, e^{-48bt_2} \int_0^1 \left| \int_{-\infty}^0 e^{2bx}\, e^{-2iax} q(x)\, dx \right|^2 da \\ &\geqq e^{16b^3t_2}\, e^{-48bt_2} \left| \int_0^1 \int_{-\infty}^0 e^{2bx}\, e^{-2iax} q(x)\, dx\, da \right|^2 \\ &\geqq e^{16b^3t_2}\, e^{-48bt_2} \left| \int_{-\infty}^0 e^{2bx} \left(\int_0^1 e^{-2iax}\, da \right) q(x)\, dx \right|^2 \\ &= e^{16b^3t_2}\, e^{-48bt_2} \left| \int_{-\infty}^0 e^{2bx} h(x)\, dx \right|^2, \end{aligned}$$

where

$$h(x) = \frac{1 - e^{-2ix}}{2ix} q(x).$$

If q is not identical zero, by Lemma 2.1, there exist b_n such that

$$\left| \int_{-\infty}^0 e^{2b_nx} h(x)\, dx \right| \geqq \alpha_1\, e^{-\beta_1 b_n}, \qquad n = 1, 2, \cdots,$$

where $b_n \to \infty$ as $n \to \infty$. We have

$$I(b_n) \geqq \alpha_1^2\, e^{16b_n^3t_2}\, e^{-48b_nt_2}\, e^{-2\beta_1 b_n} \quad \text{for } n = 1, 2, \cdots$$

and

$$\lim_{n\to\infty} I(b_n) = \infty,$$

which is in contradiction with (23). Hence, we must have

$$q(x) = 0 \quad \text{for } x \in R$$

and

$$u(x, t) \equiv 0, \qquad -\infty < x, \quad t < +\infty.$$

The case where u satisfies assumption (20) reduces to the case that we have just treated if we let

$$t' = -t, \qquad x' = -x.$$

The proof is completed. □

COROLLARY 3.1. *Let u be a mild solution to* (17). *If u vanishes on an open subset in x-t space, then u vanishes everywhere.*

Proof. Without loss of generality, we assume that

$$u(x, t) = 0 \quad \text{for } \alpha < x < \beta, \quad t_1 < t < t_2,$$

for some $\alpha, \beta \in R$ and $t_1, t_2 \in R$. Define

$$u_1(x, t) = \begin{cases} u(x, t) & \text{for } x \leqq \gamma, \\ 0 & \text{for } x > \gamma \end{cases}$$

and

$$u_2(x, t) = \begin{cases} 0 & \text{for } x \leqq \gamma, \\ u(x, t) & \text{for } x > \gamma \end{cases}$$

where $\gamma = (\alpha + \beta)/2$.

Both u_1 and u_2 are mild solutions of the linear KdV equation for $t_1 < t < t_2$ and

$$\operatorname{supp} u_1(x, t) \subset (-\infty, \gamma), \qquad \operatorname{supp} u_2(x, t) \subset (\gamma, \infty)$$

for $t_1 < t < t_2$. Hence, by Theorem 2.1,

$$u_2(x, t) = u_1(x, t) = 0 \quad \text{for } x \in R, \quad t_1 < t < t_2,$$

which implies that u vanishes everywhere. The proof is completed. □

4. The Korteweg–de Vries equation. Consider the initial value problem for the KdV equation

$$(24) \qquad u_t + uu_x + u_{xxx} = 0, \qquad u(x, 0) = q(x).$$

It is known that if $q \in H^s(R)$ for $s > 2$, then (24) has a unique solution $u \in C(R; H^s(R))$ and for $\frac{3}{2} < s < 2$, equation (24) has a unique solution $u \in C(-T, T; H^s(R))$ where T depends on the initial value q (cf. [1], [5], and [11]).

For the solutions of (24), we have the following proposition.

PROPOSITION 4.1. *Assume that $u \in C(R; H^s(R))$, $s > \frac{3}{2}$, is a solution of the* KdV *equation and $u(x, 0) = q(x)$ satisfies that*

(i) $\int_{-\infty}^{+\infty} |q'(x)|\, dx < \infty$, $\int_{-\infty}^{+\infty} (1 + |x|) q(x)|\, dx < \infty$;

(ii) $\operatorname{supp} q \subset (-\infty, \alpha)$ *for some* $\alpha \in R$;

(iii) *q has no bound states if q is considered as a potential for* (1).

Then

$$u(x, t) = 0 \quad \textit{for } x \in R, \quad t \in R,$$

if there is a $t^* > 0$ such that

$$\operatorname{supp} u(\cdot, t^*) \subset (-\infty, \alpha).$$

Proof. Without loss of generality, we assume that $\alpha = 0$. According to the steps solving the KdV equation by the inverse scattering transform, $u(x, t^*)$ has no bound states if $q(x)$ has no bound states. Let $R_1(k)$ be the right reflection coefficient of q and $R_1(k, t^*)$ be the right reflection coefficient of $u(\cdot, t^*)$. Then by (14),

$$R_1(k, t^*) = R_1(k)\, e^{8ik^3t^*}.$$

From Proposition 2.3 and 2.6, we have

$$\int_{-\infty}^{+\infty} k^2 |R_1(k)|^2\, dk < \infty \tag{25}$$

and

$$\int_{-\infty}^{+\infty} kR_1(k)\, e^{2ikx}\, dx = 0 \quad \text{for } x \geqq 0. \tag{26}$$

Similarly, we have

$$\int_{-\infty}^{+\infty} k^2 |R_1(k, t^*)|^2\, dk = \int_{-\infty}^{+\infty} k^2 R_1(k)|^2\, dk < \infty \tag{27}$$

and

$$\int_{-\infty}^{+\infty} kR_1(k, t^*)\, e^{2ikx}\, dk = 0 \quad \text{for } x \geqq 0. \tag{28}$$

Thus,

$$kR_1(k) \in H_+^2, \qquad kR_1(k, t^*) \in H_+^2$$

and

$$\sup_{b>0} \int_{-\infty}^{+\infty} |a + ib|^2 |R_1(a + ib, t^*)|^2\, da < \infty. \tag{29}$$

On the other hand,

$$\begin{aligned} I(b) &\equiv \int_{-\infty}^{\infty} |a + ib|^2 |R_1(a + ib, t^*)|^2\, da \\ &= \left(\int_{-\infty}^{+\infty} (a^2 + b^2) |R_1(a + ib)|^2\, e^{-48a^2bt^*}\, da \right) e^{16b^3t^*} \\ &\geqq \left(\int_0^1 (a^2 + b^2) |R_1(a + ib)|^2\, e^{-48a^2bt^*}\, da \right) e^{16b^3t^*} \\ &\geqq \left(\int_0^1 (a^2 + b^2) |R_1(a + ib)|^2\, da \right) e^{16b^3t^* - 48bt^*}. \end{aligned}$$

Note that

$$R_1(k) = \frac{T(k)}{2ik} \int_{-\infty}^{+\infty} e^{-2ikt} q(t) m_2(t, k)\, dt.$$

By Propositions 2.1 and 2.2,

$$R_1(k) \sim \frac{1}{2ik} \int_{-\infty}^{+\infty} e^{-2ikt} q(t)\, dt$$

as $|k| \to \infty$, $\operatorname{Im} k \geqq 0$. Hence,

$$I(b) \geqq C e^{16b^3 t^* - 48bt^*} \int_0^1 |\check{q}(a+ib)|^2\, da,$$

where C is a constant independent of b.

If q is not identically zero, by Lemma 3.1 and the same argument as used in the proof of Theorem 3.1, there exist b_n with $b_n \to \infty$ such that

$$\lim_{n\to\infty} I(b_n) = \infty,$$

which is in contradiction with (29). Hence q must be identically zero which implies, by the uniqueness of the solution to (24), that

$$u(x,t) \equiv 0, \qquad -\infty < x, \quad t < +\infty.$$

The proof is completed. □

THEOREM 4.1. *Suppose $u \in C(R, H^s(R))$, $s > \frac{3}{2}$, is a solution of the* KdV *equation*

$$u_t + uu_x + u_{xxx} = 0.$$

If there exist $t_1, t_2 \in R$ with $t_1 < t_2$ such that

$$\text{(30)} \qquad \operatorname{supp} u(\cdot, t_j) \subset (-\infty, \alpha), \qquad j = 1, 2,$$

and

$$\text{(31)} \qquad \int_{-\infty}^{+\infty} (1+|x|)|u(x,t_1)|\, dx < \infty, \qquad \int_{-\infty}^{+\infty} |u_x(x,t_1)|\, dx < \infty,$$

or

$$\text{(32)} \qquad \operatorname{supp} u(\cdot, t_j) \subset (\alpha, \infty), \qquad j = 1, 2,$$

and

$$\text{(33)} \qquad \int_{-\infty}^{+\infty} (1+|x|)|u(x,t_2)|\, dx < \infty, \qquad \int_{-\infty}^{+\infty} |u_x(x,t_2)|\, dx < \infty,$$

then

$$u(x,t) = 0 \quad \textit{for } x \in R, \quad t \in R.$$

Proof. Without loss of generality, we assume that $t_1 = 0$. We only consider the case wherein u satisfies assumption (30) and (31). The other case will reduce to this case if we make transform

$$x' = -x, \qquad t' = -t.$$

Suppose $u(x,0) = q(x)$. If $q(x)$ has no bound states, then our assertion is Proposition 4.1, which we have proved. Hence we assume that q has n bound states

$$-\beta_n^2 < \cdots < -\beta_1^2.$$

Let

$$q(x,0) = q(x)$$

and

$$q(x, m) = q(x, -(m-1)) - 2\frac{d^2}{dx^2}\log f_1(x, i\beta_{n-m+1}; -(m-1)).$$

Inductively, we obtain $q(x, -n)$, which has no bound states. In addition,

$$\operatorname{supp} q(x, -n) \subset (-\infty, \alpha)$$

and the right reflection coefficient of $q(x, -n)$ is

$$R_1(k, -n) = (-1)^n \left(\prod_1^n \frac{k - i\beta_j}{k + i\beta_j} \right) R_1(k). \tag{34}$$

Let $v(x, t)$ be the solution of

$$v_t + vv_x + v_{xxx} = 0, \qquad v(x, 0) = q(x, -n). \tag{35}$$

Claim.

$$\operatorname{supp} v(\cdot, t_2) \subset (-\infty, \alpha). \tag{36}$$

If (36) is true, then from Proposition 3.1 we have

$$q(x, -n) = 0 \quad \text{for } x \in R.$$

It follows that

$$R_1(k, -n) = (-1)^n \left(\prod_{j=1}^n \frac{k - i\beta_j}{k + i\beta_j} \right) R_1(k) = 0.$$

Thus

$$R_1(k) = 0, \qquad k \text{ real}.$$

It implies that q has only bound states and has no continuous spectrum if we consider q as a potential of (1). Hence u is a pure n-soliton solution of the KdV equation. This is in contradiction with assumption (30) since a pure n-soliton solution of the KdV equation cannot have support on a half line for any $t \in R$. The contradiction implies, via the uniqueness of the solution of the KdV equation in $C(R, H^s(R))$, that

$$q(x) = 0, \qquad x \in R$$

and

$$u(x, t) = 0, \qquad x \in R, \quad t \in R.$$

The theorem will be established when we prove the claim.

Proof of the claim. As a potential for (1), $v(x, t_2)$ has no bound states since $v(x, 0) = q(x, -n)$ has no bound states. By (14) and (34), the right reflection coefficient corresponding to $v(x, t_2)$ is

$$R_1(k, v) = (-1)^n \prod_{j=1}^n \frac{k - i\beta_j}{k + i\beta_j} R_1(k)\, e^{8ik^3 t_2}. \tag{37}$$

Let $p(x) = u(x, t_2)$. Then $p(x)$ has n bound states

$$-\beta_n^2 < \cdots < -\beta_1^2.$$

Let $p(x, -n)$ be defined as in Proposition 2.4 such that $p(x, -n)$ has no bound states and its right reflection coefficient is

$$R_1(k, p(x, -n)) = (-1)^n \prod_{j=1}^{n} \frac{k - i\beta_j}{k + i\beta_j} R_1(k)\, e^{8ik^3 t_2}.$$

It is clear that

$$R_1(k, p(x, -n)) = R_1(k, v).$$

By assumption (30) and Proposition 2.4,

$$\operatorname{supp} p(\cdot\,, -n) \subset (-\infty, \alpha).$$

Proposition 2.6 implies that

$$\int_{-\infty}^{+\infty} kR_1(k, p(x, -n))\, e^{2ikt}\, dk = 0 \quad \text{for } t \geqq \alpha.$$

Hence

$$\int_{-\infty}^{+\infty} kR_1(k, v)\, e^{2ikt}\, dk = 0 \quad \text{for } t \geqq \alpha.$$

Using Proposition 2.6 again, we arrive at

$$\operatorname{supp} v(\cdot\,, t_2) \subset (-\infty, \alpha).$$

The proof is completed. □

Let $\sigma(x) = (1+|x|^2)^{1/2}$. For $r, s \in R$ we denote by $H_r^s(R)$ the completion of the Schwartz space $S(R)$ of rapidly decreasing infinitely differentiable functions on R, in the norm $\|u\|_{r,s} = |\sigma^r F^{-1} \sigma^s F u|_2$, where $|\cdot|_2$ denotes the standard norm of $L^2(R)$ and F^{-1}, F are the inverse Fourier transform and the Fourier transform, respectively. For $r \in R$ and $s \in N \cup \{0\}$, we denote by $W_r^s(R)$ the completion of the space $S(R)$ in the norm $\|u\|^* = (\sum_{|\alpha| \leqq s} |\sigma^r D^\alpha u|_2^2)^{1/2}$. For $s \in N \cup \{0\}$, $H_r^s(R) = W_r^s(R)$ (cf. [15]).

Let

$$S_r^s(R) = H^s(R) \cap H_r^0(R).$$

Then

$$S_r^s(R) \subset [H_r^0(R), H_0^r(R)]_\theta = H_{(1-\theta)r}^{\theta s}(R)$$

for any $0 < \theta < 1$ (cf. [15]). It has been proved by Tsutsumi [15] that if $q \in S_r^s$ with $r \geqq 0$ and $s \geqq \max\{2r, \frac{1}{2} + \varepsilon\}$, then the initial value problem (24) has a unique solution $u(x, t)$ in $L_{\text{loc}}^\infty(R; S_r^s(R))$. It is clear that if $q \in S_r^{2r}(R)$ with $r > \frac{3}{2}$, then $(1+|x|)q(x) \in L^1(R)$ and $q_x \in L^1(R)$. Hence, if $q \in S_r^{2r}$ with $r > \frac{3}{2}$, the solution u of (24) satisfies

$$\int_{-\infty}^{+\infty} (1+|x|)|u(x, t)|\, dx < \infty, \qquad \int_{-\infty}^{+\infty} |u_x(x, t)|\, dx < \infty$$

for any $t \in R$.

From Theorem 4.1 we have the following corollaries.

Corollary 4.1. *Assume that* $q \in S_r^{2r}$ *with* $r > \frac{3}{2}$. *If there exist* $t_1, t_2 \in R$ *such that for some* $\alpha \in R$,

$$\operatorname{supp} u(\cdot\,, t_j) \subset (-\infty, \alpha), \qquad j = 1, 2,$$

or

$$\operatorname{supp} u(\cdot\,, t_j) \subset (\alpha, \infty), \qquad j = 1, 2,$$

where u is the solution of (24), *then*

$$u(x,t)=0 \quad \textit{for } x\in R, \quad t\in R.$$

COROLLARY 4.2. *Assume that* $q\in S_r^{2r}$ *with* $r>\frac{3}{2}$. *If the solution of* (24) *vanishes on an open set of* $R_x\times R_t$, *then it vanishes everywhere.*

Corollary 4.1 is directly from Theorem 4.1. The proof of Corollary 4.2 is similar to the proof of Corollary 3.1.

COROLLARY 4.3. *Assume that* $q\in S_r^{2r}$ *with* $r>\frac{3}{2}$. *If the solution u of* (24) *satisfies*

$$u(\alpha,t)=0, \quad u_x(\alpha,t)=0, \quad u_{xx}(\alpha,t)=0$$

for some $\alpha\in R$ *and* $t\in(t_1,t_2)$, *then*

$$u(x,t)=0 \quad \textit{for } x\in R, \quad t\in R.$$

Proof. Let

$$u_1(x,t)=\begin{cases} u(x,t) & \text{for } x<\alpha, \\ 0 & \text{for } x\geqq\alpha \end{cases}$$

for $t\in(t_1,t_2)$ and

$$u_2(x,t)=\begin{cases} 0 & \text{for } x<\alpha, \\ u(x,t) & \text{for } x\geqq\alpha \end{cases}$$

for $t\in(t_1,t_2)$. Then both u_1 and u_2 are solutions of the KdV equation for $t\in(t_1,t_2)$. By Theorem 4.1,

$$u_1(x,t)=u_2(x,t)=0 \quad \text{for } x\in R, \quad t\in(t_1,t_2)$$

which implies that

$$u(x,t)=0 \quad \text{for } x\in R, \quad t\in R.$$

Remark. Corollaries 4.2 and 4.3 may also be derived from Saut and Scheurer's results in the same way as Theorem 1.1.

Now we consider a class of generalized solutions of the KdV equation.

DEFINITION. $u\in L^2_{\text{loc}}(R\times R)$ $(L^2_{\text{loc}}((0,T)\times R))$ is called a generalized solution of the KdV equation if for any $\phi\in C_0^\infty(R\times R)$ $(\phi\in C_0^\infty((0,T)\times R))$,

$$\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}\left(u\phi_t+\frac{1}{2}u^2\phi_x+u\phi_{xxx}\right)dx\,dt=0$$

$$\left(\int_0^T\int_{-\infty}^{+\infty}\left(u\phi_t+\frac{1}{2}u^2\phi_x+u\phi_{xxx}\right)dx\,dt=0\right).$$

S. N. Kruzhkov and A. V. Faminskii [7] have proved the following theorem.

THEOREM (Kruzhkov and Faminskii). *If* $q\in L^2(R)$ *and satisfies*

$$\int_0^\infty z^{3/2}q^2(x)\,dx<\infty,$$

then the KdV *equation has a unique generalized solution u satisfying*

$$\operatorname*{ess\,sup}_{t\in(0,T)}\left\{\int_{-\infty}^{+\infty}u^2(x,t)\,dx+\int_0^\infty x^{3/2}u^2(x,t)\,dx\right\}<\infty$$

and

$$\lim_{t\to0,t\in E_T}\int_{-\infty}^{+\infty}u(x,t)w(x)\,dx=\int_{-\infty}^{+\infty}q(x)w(x)\,dx$$

for any $w \in C_0^\infty(R)$, where $E_T = (0, T) \backslash \Omega$ and Ω is a subset of measure zero in $(0, T)$ such that for any $t \in E_T$ $u(x, t)$ is defined almost everywhere on R.

In addition, if for some $\varepsilon > 0$ and integer $p \geqq 0$ and $q \geqq 0$ such that

$$\int_0^\infty x^{3p+q+1/2+\varepsilon} q^2(x)\, dx < \infty,$$

then the solution u possesses continuous derivatives $\partial^{k+l} u(x, t)/\partial x^p \partial t^k$ for $0 \leqq k \leqq p$, $0 \leqq l \leqq q$.

THEOREM 4.2. *Let u be a generalized solution of the* KdV *equation on $R \times R$ and for any $T > 0$,*

$$\operatorname*{ess\ sup}_{t \in (-T, T)} \left\{ \int_{-\infty}^{+\infty} u^2(x, t)\, dx + \int_0^\infty x^{3/2} u^2(x, t)\, dx \right\} < \infty.$$

If there exist $t_1 < t_2$ such that for any $w(x) \in C_0^\infty(R)$,

$$\lim_{t \to t_1^+} \int_{-\infty}^{+\infty} u(x, t) w(x)\, dx = \int_{-\infty}^{+\infty} u(x, t) w(x)\, dx$$

and for some $-\infty < a < b < \infty$,

$$\operatorname{supp} u(x, t_j) \subset (a, b), \qquad j = 1, 2$$

then

$$u(x, t) = 0 \quad \textit{for } x \in R, \quad t \in R.$$

Proof. Let

$$q(x) = u(x, t_1), \qquad p(x) = u(x, t_2).$$

Choose $T > t_2$. Then u is a solution of

$$u_t + u u_x + u_{xxx} = 0, \qquad u(x, t_1) = q(x)$$

for $x \in R$ and $t \in (t_1, T)$. Using the compact support of q with the Kruzhkov and Faminskii Theorem, we have $u \in C^\infty((t_1, T) \times R)$. Especially, $u(\cdot, t_2) = p(x) \in C^\infty(R)$, which implies $p \in S(R)$ since p has compact support. According to [15], there exists a $v(x, t) \in S(R)$ for any $t \in R$, which solves the KdV equation and $v(x, t_2) = p(x)$. By uniqueness, we have

$$v(x, t) = u(x, t) \quad \text{for } x \in R, \quad t \in R.$$

Applying Theorem 4.1, we obtain

$$u(x, t) = 0 \quad \text{for } x \in R, \quad t \in R.$$

The proof is completed. □

Similarly, we have the following theorem.

THEOREM 4.3. *Let $u \in L^\infty_{\text{loc}}(R, H^s(R))$, $s > \frac{3}{2}$, be a solution of the* KdV *equation. If there exist $t_1 < t_2$ such that for some $a, b \in R$,*

$$\operatorname{supp} u(\cdot, t_j) \subset (a, b), \qquad j = 1, 2,$$

then

$$u(x, t) = 0 \quad \textit{for } x \in R, \quad t \in R.$$

Proof. Let $p(x) = u(x, t_2)$ and $q(x) = u(x, t_1)$. Then u solves

$$u_t + uu_x + u_{xxx} = 0, \qquad u(x, t_1) = q(x)$$

for $x \in R$, $t \in (t_1, \infty)$.

Since q has compact support,

$$\int_{-\infty}^{+\infty} q^2 e^{2bx}\, dx < \infty \quad \text{for some } b > 0.$$

Thus, by a result in [6], $u(x, t) \in C^\infty(R)$ for any $t > t_1$. In particular, $p(x) = u(x, t) \in C^\infty(R)$, which implies $p \in S(R)$ since $p(x)$ has compact support. Therefore, $u(x, t) \in S(R)$ for any $t \in R$ [15]. Then Theorem 4.1 yields

$$u(x, t) = 0, \qquad x \in R, \quad t \in R.$$

The proof is completed. □

Remark. Consider the modified KdV equation

$$v_t - 6v^2 v_x + v_{xxx} = 0.$$

Let

$$u = -\tfrac{1}{6}(v^2 + v_x). \tag{38}$$

Then u solves

$$u_t + uu_x + u_{xxx} = 0.$$

Equation (38) corresponds to the Miura transformation. Using this transformation, all the results we have obtained for the KdV equation are also true for the modified KdV equation. For instance, if v solves the modified KdV equation and has compact support at two different times, then

$$u = -\tfrac{1}{6}(v^2 + v_x)$$

solves the KdV equation and has compact support at two different times. By Theorem 4.2, u vanishes identically. Hence

$$v^2(x, t) + v_x(x, t) = 0 \quad \text{for any } x \text{ and } t,$$

which implies that v vanishes identically.

A FAMILY OF STABLE EQUILIBRIA IN BIFURCATION WITH SPHERICAL SYMMETRY*

E. BARANY†‡ AND I. MELBOURNE†§

Abstract. It is shown that asymptotically stable branches of equilibria may generically bifurcate from a spherically symmetric solution that loses stability to spherical harmonics of order l for any odd l. The problem is reduced to one of evaluation of certain Clebsch-Gordan coefficients. The evaluation uses methods from the quantum mechanical theory of angular momentum.

Key words. steady-state bifurcation, spherical symmetry, asymptotic stability, Clebsch-Gordan coefficients

AMS(MOS) subject classifications. 58F14, 34C35

Introduction. Steady-state bifurcation with spherical symmetry appears in several physical contexts; see Chossat, Lauterbach, and Melbourne [1990] and the references therein. Generically, the problem reduces to a bifurcation equation on a $(2l+1)$-dimensional space spanned by the spherical harmonics of order l (Ihrig and Golubitsky [1984]; Golubitsky, Stewart, and Schaeffer [1988]). The induced action of $O(3)$ is the natural action on the space of spherical harmonics.

In this paper we establish the existence of a family of stable equilibria occurring in generic steady-state bifurcation with $O(3)$ symmetry in the cases where l is odd, $l \geqq 3$. Previously, branches of stable equilibria had only been computed in the specific cases $l = 1, 3$, and 5 (see Chossat et al. [1990]). In the notation and terminology of the above references, the stable solutions have (maximal) isotropy D_{2l}^d.

Up to a point, the methods and results parallel those of Chossat and Lauterbach [1989], who demonstrated the *instability* of the so-called *axisymmetric* solutions for all odd $l \geqq 3$. (The axisymmetric solutions are also unstable for even l, as shown by Ihrig and Golubitsky [1984].) Using the group-theoretical techniques of the above references, it is possible to reduce questions of existence and stability of certain branches of equilibria to conditions on the Taylor coefficients of a vector field with $O(3)$-symmetry.

Where this paper differs from prior work in this area is in its emphasis on methods from the quantum mechanical theory of angular momentum; see, for example, Biedenharn and Louck [1981] or Wigner [1959]. In particular, we are able to obtain general expressions for the relevant Taylor coefficients by evaluating certain Clebsch-Gordan coefficients. We note that Chossat [1983] used similar techniques to establish his example of submaximal branching. See also Barany [1988].

It transpires that these techniques are more flexible and efficient than the algorithm of Sattinger [1979] which is used, for example, in Chossat and Lauterbach [1989] and Chossat et al. [1990]. The result proved in this paper was easy to conjecture on the basis of previous calculations (especially Chossat et al. [1990] for $l = 3$ and 5). We expect that the techniques used here will lead to a variety of new results for bifurcation with spherical symmetry, and this will be the subject of future work.

§ The research of this author was supported in part by National Science Foundation Defense Advanced Research Projects Agency grant DMS-8700897.

The remainder of this paper falls into two sections. In the first section we set up the equivariant bifurcation theory of Golubitsky, Stewart, and Schaeffer [1988] in the context of spherical symmetry, Ihrig and Golbitsky [1984] (see also Chossat et al. [1990]). In particular, we explain how the natural representations of $O(3)$ arise and define the family of branches of equilibria that will be proven stable. We also perform the calculations which reduce the computation of existence and stability to evaluation of certain cubic order Taylor coefficients. It is shown that the bifurcating equilibria are stable if the branching is supercritical (the equilibria exist to the right of the bifurcation point) and $l-1$ eigenvalues $\mu_0, \cdots, \mu_{l-2}$ are negative simultaneously.

In § 2 we compute the required Taylor coefficients by evaluating certain Clebsch-Gordan coefficients. It is known that there are $[l/3]+1$ independent cubic mappings with $O(3)$-symmetry. These mappings can be ordered with the first cubic being $|x|^2x$. The second mapping is the one that drives the stability result in the cases $l=3$ and 5 considered in Chossat et al. [1990]. It is natural to concentrate on this second mapping for general l. On setting the coefficients of the remaining $[l/3]-1$ terms equal to zero, we obtain the following expressions for the μ_m:

$$\mu_m = \beta(l^2-m^2), \qquad 0 \leqq m \leqq l-3,$$

$$\mu_{l-2} = \beta(4l-6),$$

where β is the coefficient of the second equivariant mapping. Thus the eigenvalues all have the same sign, sgn(β). Since the eigenvalues depend continuously on the coefficients of the equivariant mappings, we obtain stability of the equilibria for an open set of symmetric vector fields.

1. Steady-state bifurcation with $O(3)$-symmetry. In this section we begin by providing the necessary group-theoretic background for the analysis of steady-state bifurcation with $O(3)$-symmetry. See Golubitsky, Stewart and Schaeffer [1988] for the general context of bifurcation with symmetry, and Ihrig and Golubitsky [1984] and Chossat, Lauterbach, and Melbourne [1990] for more details in the specific case of this section. We then proceed to compute the existence and stability of equilibria with isotropy D_{2l}^d in terms of Taylor coefficients of a vector field with $O(3)$ symmetry. There are three topics which we discuss to the extent that they concern us in this paper: (i) reduction to an absolutely irreducible representation, (ii) existence of equilibria, and (iii) stability of equilibria.

(i) *Reduction.* Consider the ODE

$$\frac{dz}{dt} = F(z, \lambda)$$

where $F: \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ is $O(3)$-*equivariant*, that is,

$$F(\gamma z, \lambda) = \gamma F(z, \lambda) \quad \text{for all } \gamma \in O(3), \quad z \in \mathbb{R}^n, \quad \lambda \in \mathbb{R}.$$

Suppose that $F(0, \lambda) \equiv 0$ so that $z=0$ is a trivial solution. This solution is asymptotically stable if all eigenvalues of the linearization $L = (d_zF)_{0,0}$ have negative real part, and unstable if any eigenvalue has positive real part. We say that a *steady-state bifurcation* takes place at $(z, \lambda) = (0, 0)$ if the trivial solution loses stability by an eigenvalue crossing the imaginary axis at zero. A Lyapunov-Schmidt or center manifold reduction leads to reduced equations on $V = \ker(L)$. These reduction methods can also be applied to more complicated evolution equations on infinite-dimensional Banach spaces. From now on we assume that the reduction has been performed and that $\mathbb{R}^n = V$.

The theory for equivariant steady-state bifurcation established by Golubitsky et al. [1988] implies that generically $O(3)$ acts absolutely irreducibly on V (absolute irreducibility means that the only commuting matrices L: $V \to V$ are scalar multiples of the identity). For each positive integer l there are precisely two $(2l+1)$-dimensional absolutely irreducible representations of $O(3)$, which we now describe.

Write $O(3)=SO(3)\oplus\{\pm I\}$. For each l, there is a $(2l+1)$-dimensional irreducible representation of $SO(3)$ on the space V_l of spherical harmonics of order l. These are the only irreducible representations of $SO(3)$ and moreover they are absolutely irreducible. To each of these representations, there correspond two absolutely irreducible representations of $O(3)$, $-I$ acting either trivially or as minus the identity. The "natural" representation is the one on the space of spherical harmonics V_l, and it has $-I$ acting trivially when l is even and nontrivially when l is odd. It is the natural representation that typically occurs in physical applications.

A more concrete description of the representations of $O(3)$ can be found, for example, in Sattinger [1979] and Chossat et al. [1990], or in Beidenharn and Louck [1981]. Complexified coordinates are given by $\{z_{-l}, \cdots, z_0, \cdots, z_l\}$ with the *reality condition*

$$z_{-m}=(-1)^m \bar{z}_m. \tag{1.1}$$

We can only describe explicitly the action of one maximal torus in $SO(3)$, which we denote by $SO(2)$, and the corresponding copy of $O(2)$ (also in $SO(3)$). This copy of $O(2)$ contains rotations θ in a plane and a rotation κ which restricts to a reflection in the plane of rotation. The action of $O(2)$ is given by

$$\theta \cdot z_m = e^{im\theta} z_m, \tag{1.2a}$$

$$\kappa \cdot z_m = (-1)^{m+l} z_{-m} = (-1)^l \bar{z}_m. \tag{1.2b}$$

We also record the action of $-I$:

$$-I \cdot z_m = (-1)^l z_m. \tag{1.2c}$$

Finally, we comment on the structure of the $O(3)$-equivariant mapping up to cubic order in the case of l odd. Since the action of $O(3)$ is absolutely irreducible, the only commuting linear maps are scalar multiples of the identity. There is a steady-state bifurcation at $\lambda=0$, so after reparametrization we may assume that the linear term has the form λz. Since l is odd, $-I$ acts as minus the identity, and there are no equivariant mappings of even order.

We now turn to the cubic mappings. It is not difficult to determine the restrictions given by the maximal torus $SO(2)$ described above. If we write a general cubic equivariant C in components $(C_{-l}, \cdots, C_l)$, then

$$C_m(z)=\sum_{\substack{i\leqq j\leqq k\\ i+j+k=m}} (ijk) z_i z_j z_k. \tag{1.3}$$

The reality condition (1.1) gives

$$C_{-m}(z)=(-1)^m \overline{C_m(z)}.$$

The main problem lies in determining the restrictions placed on the coefficients (ijk) by the remaining two dimensions of $SO(3)$. In § 2 we find sufficiently many of the restrictions to prove our main result.

In what follows it suffices to truncate F at cubic order. Existence and stability of the equilibria with isotropy D^d_{2l} is determined by the truncated vector field $\lambda z + C(z)$.

(ii) *Existence.* Let $z \in V$ and define the *isotropy subgroup* of z to be

$$\Sigma_z = \{\gamma \in O(3) \mid \gamma z = z\}.$$

The *fixed-point subspace* Fix (Σ) of an isotropy subgroup is defined to be

$$\text{Fix}\,(\Sigma) = \{z \in V \mid \sigma z = z \text{ for all } \sigma \in \Sigma\}.$$

An $O(3)$-equivariant map $F\colon V \times \mathbb{R} \to V$ restricts to a map

$$F|_{\text{Fix}\,(\Sigma)\times\mathbb{R}}\colon \text{Fix}\,(\Sigma) \times \mathbb{R} \to \text{Fix}\,(\Sigma). \tag{1.4}$$

Thus the problem of finding solutions with isotropy Σ reduces to a problem in Fix (Σ). In particular, when dim Fix $(\Sigma) = 1$, the equivariant branching lemma guarantees the existence of a unique branch of equilibria with isotropy Σ.

In this paper, we restrict to the case of l odd and consider the isotropy subgroup D_{2l}^d which is generated by $-I\cdot(\pi/l)$ and κ where the first element is the composition of $-I$ and a rotation in $SO(2)$ through angle π/l. It follows from (1.2) that the action of D_{2l}^d on the complexified space of spherical harmonics is given by

$$-I\cdot(\pi/l)\cdot z_m = -e^{im\pi/l}\,z_m, \tag{1.5a}$$

$$\kappa \cdot z_m = -\bar{z}_m. \tag{1.5b}$$

If we write $z_m = x_m + iy_m$ then it is easy to check that

$$\text{Fix}\,(D_{2l}^d) = \{iy_l\}. \tag{1.6}$$

In particular, dim Fix $(D_{2l}^d) = 1$ and the equivariant branching lemma guarantees a unique branch of solutions in Fix (D_{2l}^d). For $l \geqq 3$, D_{2l}^d is the largest subgroup of $O(3)$ that fixes iy_l, and so it is an isotropy subgroup (Ihrig and Golubitsky [1984]). Hence there exist solutions with isotropy D_{2l}^d.

Restricting F as in (1.4) and using (1.6), we can compute the branching equation for equilibria with isotropy D_{2l}^d by solving $F_l(iy_l) = 0$. In the notation of (1.3) we obtain

$$\lambda = (-lll)y_l^2 + O(y_l^4). \tag{1.7}$$

(iii) *Stability.* The principle of (orbital) linearized stability implies that in order to establish asymptotic stability of a branch of solutions (z, λ) it is sufficient to show that the eigenvalues of the Jacobian $(dF)_{z,\lambda}$ all have negative real part (with the exception of eigenvalues that are forced to vanish by the action of the group).

The main group-theoretic tool for computing the eigenvalues of such a matrix is the *isotypic decomposition.* Recall that the equivariant vector field F satisfies

$$F(\gamma z, \lambda) = \gamma F(z, \lambda) \quad \text{for all } \gamma \in O(3), \quad z \in V, \quad \lambda \in \mathbb{R}.$$

Differentiation of this identity yields

$$(dF)_{\gamma z,\lambda}\gamma = \gamma(dF)_{z,\lambda}. \tag{1.8}$$

Taking $\gamma \in \Sigma$, we see that $(dF)_{z,\lambda}$ commutes with elements of Σ when $z \in \text{Fix}\,(\Sigma)$.

Now we can decompose the space of spherical harmonics into a direct sum:

$$\{iy_l\} \oplus \{x_l\} \oplus \{z_{l-1}, z_{-(l-1)}\} \oplus \cdots \oplus \{z_1, z_{-1}\} \oplus \{z_0\}. \tag{1.9}$$

Each of the summands is invariant under the action of D_{2l}^d. Moreover, using (1.5) it is easy to check that D_{2l}^d acts absolutely irreducibly and nonisomorphically on each factor. Thus (1.9) is the isotypic decomposition for D_{2l}^d and, by (1.8), $(dF)_{iy_l,\lambda}$ maps each summand (or isotypic component) into itself. It follows that the eigenvalues of $(dF)_{iy_l,\lambda}$ can be computed by restriction to each isotypic component.

General theory guarantees that the eigenvalue in $\{iy_l\}$ is -2λ where λ is as computed in (1.7). We call the corresponding eigenvalue the *branching eigenvalue.* This eigenvalue is stable if and only if the branch of equilibria bifurcates supercritically (that is, exists for positive λ). There are three eigenvalues that are forced to be zero by the group. These lie in $\{x_l\}$ and $\{z_{l-1}, z_{-(l-1)}\}$. It is easy to check the eigenvalues in $\{iy_l\}$ and $\{x_l\}$ by explicit computations.

It remains to compute the eigenvalues in $\{z_0\}$ and $\{z_m, z_{-m}\}$, $m=1,\cdots,l-2$. We will include the case $m=l-1$ since the structure of the calculations is identical. Since D^d_{2l} acts absolutely irreducibly on each $\{z_m, z_{-m}\}$ it follows that the corresponding eigenvalues are double. Hence we need only compute

$$\begin{aligned}\mu_m &= \frac{\partial F_m}{\partial z_m}(iy_l, \lambda), \qquad m=0,\cdots,l-1,\\ &= \lambda + (-lml)z_{-l}z_l + \cdots \big|_{z_l=iy_l}\\ &= [(-lll)-(-lml)]y_l^2 + O(y_l^4).\end{aligned}$$

Of course, we already have that $\mu_{l-1}=0$ and so $(-lll)=(-l, l-1, l)$. In § 2 we show that the expressions $[(-lll)-(-lml)]$, $0 \leqq m \leqq l-2$, are simultaneously negative for a nonempty open set of cubic equivariant mappings C.

2. Evaluation of the eigenvalues. Recall from § 1 that we must show that there is a cubic mapping for which the $l-1$ expressions

$$(2.1) \qquad \mu_m = (-lll)-(-lml), \qquad 0 \leqq m \leqq l-2$$

are simultaneously negative. Here, $(-lml)$ appears in the mth component of the bifurcation equations and is the coefficient of $z_{-l}z_m z_l$.

It is known that there are $r=[l/3]+1$ linearly independent equivariant cubic mappings $c_1, \cdots, c_r$ (see Lévy-Leblond and Lévy-Nahas [1965] and Chossat and Lauterbach [1989] for independent and different proofs of this fact). Hence we may write the general equivariant cubic as

$$C = \sum \alpha_i C_i, \qquad \alpha_1, \cdots, \alpha_r \in \mathbb{R}.$$

The first cubic C_1 can be taken to be $|x|^2x$ and appears for all l. The expressions μ_m in (2.1) are easily seen to be independent of C_1. When $l=3$ and 5, there is a second mapping C_2, and it transpires that the expressions in (2.1) are all positive multiples of α_2 (Chossat et al. [1990]). Hence the D^d_{2l} solutions are stable when $\alpha_2 < 0$.

Now, the C_i can be ordered, and we will show that, for all l, on setting $\alpha_i = 0$, $i \geqq 3$, the expressions in (2.1) are positive multiples of α_2. Hence we have stability when $\alpha_2 < 0$, $\alpha_i = 0$, $i \geqq 3$. By continuity, we have stability for an open set of equivariant cubics.

We now describe our techniques for computing nonlinear equivariant mappings. The space of pth order equivariant mappings can be identified with the space of p-linear maps that (a) transform like the lth representation of $O(3)$, and (b) are symmetric, that is, fixed by S_p, the symmetric group on p symbols. Hence the first step is to take the p-fold tensor product of the lth representation of $O(3)$ and reduce simultaneously to that representation and by S_p. The expansion coefficients appearing in the tensor products are called Clebsch-Gordan (CG) coefficients; see, for example, Biedenharn and Louck [1981], Miller [1972], or Sattinger [1979].

Where our methods differ from those of Sattinger is in the use of results from the theory of angular momentum in quantum mechanics to compute CG coefficients. The advantage of these methods is that it is possible to compute each coefficient individually, with each independent equivariant mapping taken one at a time. In physics there is a wealth of literature on these computations, and we shall quote many formulas. The reader is referred to Biedenharn and Louck [1981] or Wigner [1959] for a more detailed discussion and derivation of these formulas.

There is one possible cause of confusion that we wish to clear up from the outset. The results we quote apply to a conventionally normalized form of the CG coefficients. These may differ from other "CG coefficients" by a factor that depends only on the representation of $O(3)$ and the independent equivariant mapping being evaluated. This factor may be absorbed into α_2, and so does not affect the bifurcation theory.

The remainder of this section will fall into two subsections: (i) reduction of the three-fold tensor product, and (ii) evaluation of the required Clebsch–Gordan coefficients.

(i) Consider $z^{(L)} \in V_L$ in the basis of spherical harmonics of order L,

$$z^{(L)} = \sum_{m=-L}^{L} z_m^{(L)} Y_L^m. \tag{2.2}$$

If z is the direct sum $z = \oplus z^{(L)}$ over all nonnegative integers L, then

$$z_m^{(L)} = \int d\Omega\, \overline{Y_L^m} z$$

are the expansion coefficients. In order to compute the quadratic equivariant mappings, we wish to know how the expansion coefficients $(z^2)_m$ for the square of z will depend on the original z_m. We have the following integral over three spherical harmonics:

$$\int d\Omega\, \overline{Y_L^m} Y_{l_1}^{m_1} Y_{l_2}^{m_2} = \left(\frac{(2l_1+1)(2l_2+1)}{4\pi(2L+1)}\right)^{1/2} C_{0,\,0,\,0}^{l_1, l_2, L} C_{m_1, m_2, m}^{l_1,\ l_2,\ L}. \tag{2.3}$$

The $C_{m_1, m_2, m}^{l_1,\ l_2,\ L}$ are CG coefficients that satisfy the conventional choice of normalization of the highest-weight coefficients $C_{m_1, m_2, L}^{l_1,\ l_2,\ L}$ where $L = m_1 + m_2$; see Biedenharn and Louck [1981]. To simplify the notation, we define

$$N_{l_1 l_2}^L = \left(\frac{(2l_1+1)(2l_2+1)}{4\pi(2L+1)}\right)^{1/2} C_{0,\,0,\,0}^{l_1, l_2, L}. \tag{2.4}$$

Then from (2.2) and (2.3), we can write

$$Y_L^{m_1} Y_L^{m_2} = \sum_{L=0}^{2l} N_{ll}^L C_{m_1, m_2, m_1+m_2}^{l,\ \ l,\ \ L} Y_L^{m_1+m_2}. \tag{2.5}$$

In deriving (2.5) we have used two properties of the CG coefficients, namely, that the coefficient $C_{m_1, m_2, m}^{l_1,\ l_2,\ L}$ vanishes unless $m = m_1 + m_2$, and that L satisfies the "triangle inequality" $|l_1 - l_2| \leqq L \leqq l_1 + l_2$.

Now squaring (2.2) and using (2.5) we can identify the quadratic expansion coefficients from the lth representation that transform as in the Lth representation. Let $z_m^{(l);2;(L)}$ be shorthand for $(z^{(l)})_m^{2(L)}$. Then

$$z_m^{(l);2;(L)} = \sum_{m_1+m_2=m} N_{ll}^L C_{m_1, m_2, m}^{l,\ \ l,\ \ L} z_{m_1}^{(l)} z_{m_2}^{(l)}. \tag{2.6}$$

Taking $L = l$ in (2.6) gives the (unique) quadratic equivariant $z^{(l);2;(l)}$. This equivariant vanishes for odd l, as can be seen from the property

$$C_{m_1, m_2, m}^{l_1,\ l_2,\ l} = (-1)^{l_1+l_2-l} C_{m_2, m_1, m}^{l_2,\ l_1,\ l}. \tag{2.7}$$

In order to generate the cubic order equivariants we iterate the process and consider the three-fold tensor product $z^{(l);3;(l)}$ obtained from the product of $z^{(l)}$ with its square

$$z^{(l);2} = \sum_{L=0}^{2l} \sum_{m=-L}^{L} z_m^{(l);2;(L)} Y_L^m. \tag{2.8}$$

We must first reduce to the $(2l+1)$-dimensional representation of $O(3)$. Observe that several terms in this product transform like this representation: one for each of the $(2l+1)$ values of L in (2.8). It is possible to show that the first $[l/3]+1$ even values of L generate the independent equivariant cubics. Since this fact is not required to prove our main result, we defer the proof to a later paper.

Writing $z^{(l);3;(l)}(L)$ as the part of the cubic that transforms as l and comes from L, we get

$$z_m^{(l);3;(l)}(L) = N_{ll}^L N_{lL}^l \sum_{m_3+M=m} \sum_{m_1+m_2=M} C_{m_3,\, M,\, m}^{l,\ L,\ l} C_{m_1,\, m_2,\, M}^{l,\ l,\ L} z_{m_1}^{(l)} z_{m_2}^{(l)} z_{m_3}^{(l)}. \tag{2.9}$$

It follows from (2.7) that the sum in (2.9) vanishes when L is odd. From now on we assume that L is even (shortly we shall specialize to the case $L=2$). To obtain the (ijk) coefficients defined in § 1, we reduce by S_3; that is, we symmetrize (2.9) over the subscripts m_1, m_2, and m_3. There are three cases:

i, j, k all unequal:

$$\begin{aligned}(ijk)_L = 2N_{ll}^L N_{lL}^l (&C_{i,j+k,\,i+j+k}^{l,L,\ l} C_{j,\,k,j+k}^{l,l,\ L} + C_{j,\,i+k,\,i+j+k}^{l,L,\ l} C_{i,\,k,\,i+k}^{l,l,\ L}\\ &+ C_{k,\,i+j,\,i+j+k}^{l,\ L,\ l} C_{i,j,\,i+j}^{l,l,L}),\end{aligned} \tag{2.10a}$$

$i \neq j = k$:

$$(ijj)_L = N_{ll}^L N_{lL}^l (C_{i,2j,\,i+2j}^{l,L,\,l} C_{j,j,2j}^{l,l,L} + 2C_{j,\,i+j,\,i+2j}^{l,L,\ l} C_{i,j,\,i+j}^{l,l,L}), \tag{2.10b}$$

$i = j = k$:

$$(iii)_L = N_{ll}^L N_{lL}^l C_{i,2i,3i}^{l,L,\,l} C_{i,\,i,2i}^{l,l,L}. \tag{2.10c}$$

(ii) We now explicitly compute the coefficients $(-lml)_2$, $0 \leqq m \leqq l$, as required (in fact, there is some redundancy, as we already know that $(-l,l-1,l)=(-lll)$). The choice $L=2$ is motivated by the results for $l=3$ and 5, and simplifies the calculations due to the (obvious) property

$$C_{m_1,\, m_2,\, m}^{l_1,\ l_2,\ L} = 0 \quad \text{for } |m| > L. \tag{2.11}$$

In particular, if the common factor $2N_{ll}^2 N_{l2}^l$ is absorbed into the coefficient α_2 of the cubic equivariant, the equations in (2.10) become

$$\begin{aligned}(-lml)_2 &= C_{m,0,m}^{l,\ 2,l} C_{-l,l,0}^{l,\ \ l,2}, & 0 \leqq m \leqq l-3,\\ (-lml)_2 &= C_{m,0,m}^{l,\ 2,l} C_{-l,l,0}^{l,\ \ l,2} + C_{l,\,m-l,\,m}^{l,2,\ \ \ l} C_{-l,\,m,\,m-l}^{l,\ \ l,\ 2}, & m = l-2,\, l-1,\\ (-lll)_2 &= C_{l,0,l}^{l,2,l} C_{-l,l,0}^{l,\ \ l,2}.\end{aligned}$$

A further simplification can be obtained by transforming the CG coefficients using the following two properties:

$$C_{m_1,\, m_2,\, m}^{l_1,\ l_2,\ l} = (-1)^{l_1-m_1} \left(\frac{2l+1}{2l_2+1}\right)^{1/2} C_{m_1,\,-m,\,-m_2}^{l_1,\ l,\ \ l_2},$$

$$C_{m_1,\, m_2,\, m}^{l_1,\ l_1,\ L} = (-1)^L C_{-m_2,\,-m_1,\,-m}^{l_1,\ \ l_1,\ \ L}.$$

Absorbing the common square root (with $l_2=2$) into α_2, we have

$$(2.12)\qquad \begin{aligned} &(-lml)=(-1)^{m+1}C^{l,\,l,\,2}_{l,-l,0}C^{l,\,l,\,2}_{m,-m,0}, && 0\leqq m\leqq l-3,\\ &(-lml)=(C^{l,\,l,\,2}_{l,-m,l-m})^2+(-1)^{m+1}C^{l,\,l,\,2}_{l,-l,0}C^{l,\,l,\,2}_{m,-m,0}, && m=l-2,\,l-1,\\ &(-lll)=(C^{l,\,l,\,2}_{l,-l,0})^2. \end{aligned}$$

At this point, we have reduced the problem to the evaluation of two types of CG coefficients. In particular, it is sufficient to consider "Racah's first form"

$$(2.13)\qquad \begin{aligned} C^{l_1,\,l_2,\,l}_{m_1,m_2,m}&=\delta_{m,m_1+m_2}\left(\frac{(2l+1)(l_1+l_2-l)!(l_1-m_1)!(l_2-m_2)!(l-m)!(l+m)!}{(l_1+l_2+l+1)!(l+l_1-l_2)!(l-l_1+l_2)!(l_1+m_1)!(l_2+m_2)!}\right)^{1/2}\\ &\quad\cdot\sum_t(-1)^{l_1-m_1+t}\left(\frac{(l_1+m_1+t)!(l+l_2-m_1-t)!}{t!(l-m-t)!(l_1-m_1-t)!(l_2-l+m_1+t)!}\right) \end{aligned}$$

where summation is over those t for which all factorials are of nonnegative numbers. Specializing, we find that

$$(2.14a)\qquad C^{l,\,l,\,2}_{m,-m,0}=2(-1)^{m+1}\left(\frac{5(2l-2)!}{(2l+3)!}\right)^{1/2}(3m^2-l^2-l),$$

$$(2.14b)\qquad C^{l,\,l,\,2}_{l,-l+1,1}=\left(\frac{5(2l-2)!}{(2l+3)!}\right)^{1/2}\sqrt{12l}(2l-1),$$

$$(2.14c)\qquad C^{l,\,l,\,2}_{l,-l+2,2}=\left(\frac{5(2l-2)!}{(2l+3)!}\right)^{1/2}\sqrt{24l(2l-1)}.$$

The derivation of these formulas is straightforward. The only contributions from (2.13) in (2.14a) come from $t=0$, 1, and 2. For (2.14b, c) the only contributions come from $t=0$. On substituting the expressions in (2.14) into (2.12) and then into (2.1), we see that

$$\begin{aligned} &\mu_m=12l(2l-1)(l^2-m^2)\alpha_2, \qquad 0\leqq m\leqq l-3,\\ &\mu_{l-1}=12l(2l-1)(4l-6)\alpha_2. \end{aligned}$$

Hence the μ_m are positive multiples of α_2 as required. It is also easy to verify that $\mu_{l-1}=0$ as expected.

QUALITATIVE ANALYSIS OF MYELINATED NERVE FIBERS WITH POINT-NODE FITZHUGH–NAGUMO DYNAMIC SYSTEM*

PEI-LI CHEN[†]

Abstract. The equations for the membrane potentials in a point-node myelinated axon fibers model take the form

$$\begin{aligned}
&U_t = U_{xx} - GU, && x \in (0,1) \mod (1),\\
&W = 0, && x \in (0,1) \mod (1),\\
&U_t = M[U_x]_x + F(U) - W, && x = 0 \mod (1),\\
&W_t = \sigma U - \gamma W, && x = 0 \mod (1),\\
&[U]_x = 0, && x = 0 \mod (1),
\end{aligned}$$

where $U = (u_1, u_2, \cdots, u_n)^t$, $W = (w_1, w_2, \cdots, w_n)^t$, $M = \hat{\lambda} I - \alpha B$ and the model dynamics are of FitzHugh–Nagumo type. In this paper, two new results for this model are presented.

In the first result it is shown that this model has two nontrivial solutions and the contracting rectangle technique is used to show that one of these solutions is stable. The second result gives an existence proof for the Cauchy problem associated with this model.

1. Introduction.

Grindrod and Sleeman [9, p. 119] define a myelinated nerve axon as follows: "A myelinated nerve axon consists of axoplasm surrounded by a long cylindrical membrane which is in turn surrounded by a sheath of lipoprotein, called myelin, formed by condensation of Schwann cell membranes. The sheath, a fatty layered tissue, insulates the axon from the external ionic fluid." In each myelin segment, the potential $u(x,t)$ is governed by a diffusion equation of the form

$$u_t = u_{xx} - gu, \tag{1.1}$$

in which the spatial variable x is measured along the axon and the constant $g = 1/R$, where R represents the axoplasmic resistivity.

Again, quoting Grindrod and Sleeman [9, p. 119]: "At approximately millimeter intervals, there are small gaps called nodes of Ranvier. These nodes expose the extracellular fluid to the excitable axon membrane." At the nodes the axon membrane is selectively permeable to the charged ions within the axoplasm and outer ionic fluid. Here the potential $u(x,t)$ is governed by a nonlinear diffusion equation of the form

$$u_t = u_{xx} - J, \tag{1.2}$$

where J represents the ionic current through the membrane.

In the early 1950s, Hodgkin and Huxley published a series of papers on the unmyelinated axon model based on the giant squid axon. In [13] they proposed a system

*Received by the editors August 1, 1989; accepted for publication (in revised form) April 4, 1991. This work was done while the author was a Morrey Assistant Professor in the Department of Mathematics at the University of California at Berkeley, Berkeley, California 94720.

[†]Department of Mathematics, Southern Illinois University at Carbondale, Carbondale, Illinois 62901-4408.

of differential equations, each of which is in the general form of (1.2). Because of the analytic complexity of the Hodgkin–Huxley model, most work on the model, particularly on qualitative behavior of the solutions, has been numerical. To gain some insight into the mathematical phenomena involved in the nerve conduction process FitzHugh [6] and Nagumo, Arimoto, and Yoshizawa [15] introduced a simpler prototype system of the form

$$\begin{aligned} u_t &= u_{xx} + f(u) - w, \\ w_t &= \sigma u - \gamma w, \end{aligned} \tag{1.3}$$

where u is still the membrane potential and w represents a recovery process. The current-voltage relation $-f(u)$ is an "N-shaped" function, sketched in Fig. 1, and σ, γ are recovery constants.

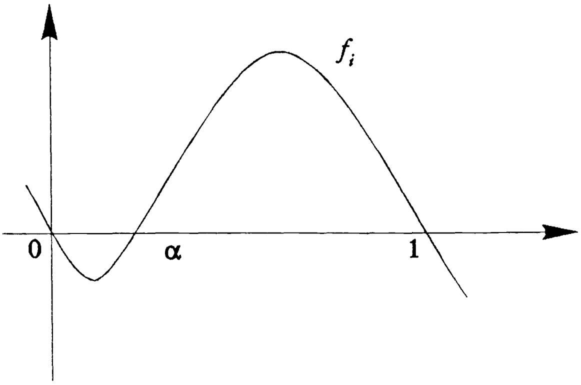

FIG. 1. *Each of $-f_i$ is an N-shaped function.*

Questions of existence and qualitative behavior of solutions to (1.3) have been pursued very actively by many mathematicians (see, for example, [8]–[12], [16], [17]). Grindrod and Sleeman [10] used a contracting rectangle technique (see [4] for a general reference) to give a qualitative analysis of unmyelinated nerve fibers.

Myelinated axons, especially myelinated axon fibers, which are more prevalent in human anatomy than unmyelinated axons, have also been modeled. However, fewer analytical results have been obtained for these models. Some asymptotic behavior was considered in simpler models (e.g., Bell [1], Bell and Cosner [2], Chen and Bell [3], and Grindrod and Sleeman [9]).

The main purpose of this paper is to consider questions related to the equations for the point-node myelinated axon fibers (see [2] and [3] for references). These equations are

$$U_t = U_{xx} - GU, \qquad x \in (0,1) \mod (1), \tag{1.4}$$

$$W = 0, \qquad x \in (0,1) \mod (1), \tag{1.5}$$

$$U_t = M[U_x]_x + F(U) - W, \qquad x = 0 \mod (1), \tag{1.6}$$

$$W_t = \sigma U - \gamma W, \qquad x = 0 \mod (1), \tag{1.7}$$

$$[U]_x = 0, \qquad x = 0 \mod (1), \tag{1.8}$$

where $U = (u_1, u_2, \cdots, u_n)^t \in C^1(\mathbb{R}^+ \times \mathbb{R}, \mathbb{R}^n)$, $W \in C^1(\mathbb{R}^+ \times \mathbb{Z}, \mathbb{R}^n)$, $F(U) = (f_1(u_1), \cdots, f_n(u_n))^t$, $[U_x]_x = U_x(x+, t) - U_x(x-, t)$, $G = \text{Diag}\{g_1, \cdots, g_n\}$ and $M = (\hat{\Lambda} I - \alpha B)$. Here each u_i is the potential of a membrane, each $-f_i$ is an N-shaped function as sketched in Fig. 1, each $g_i > 0$, $\hat{\Lambda}$ and α are positive constants satisfying $\hat{\Lambda} \gg \alpha > 0$, $\sigma = \text{Diag}\{\sigma_1, \sigma_2, \cdots, \sigma_n\}$, $\gamma = \text{Diag}\{\gamma_1, \gamma_2, \cdots, \gamma_n\}$, where σ_i, γ_i are positive constants $(i = 1, 2, \cdots, n)$, I is the $n \times n$ identity matrix, and B is the adjacency matrix for the graph, which is defined as follows.

Following [10] we define Γ to be a graph on n vertices (see Fig. 2) where the adjacency matrix $B = (b_{ij})$, $i, j = 1, \cdots, n$ is defined by

$$(1.9) \qquad b_{ij} = \begin{cases} 0 & \text{if } i = j, \\ 1 & \text{if } i \neq j \text{ and there is an edge} \\ & \qquad \text{in } \Gamma \text{ which connects } v_i \text{ and } v_j, \\ 0 & \text{otherwise.} \end{cases}$$

Thus B is a symmetric matrix and describes the geometry of the graph Γ. "This concept is often used by chemists where it is sometimes called the topology matrix and is used to describe and classify hydrocarbon molecules. By the previous construction, if Γ is the graph on n vertices, representing n-fibers, the adjacency matrix, B of Γ, describes the ability of separate fibers to interact." See [10, p. 6].

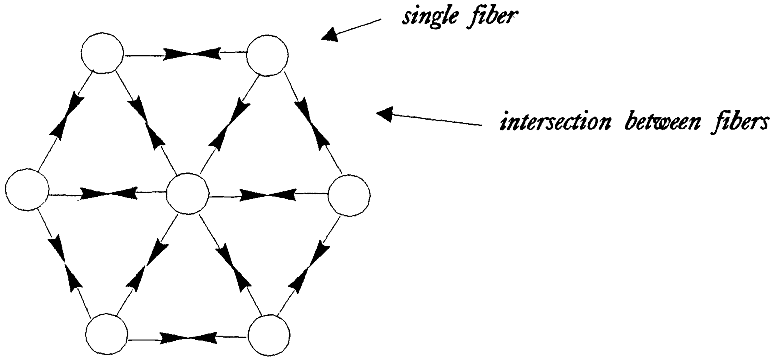

FIG. 2. *Configuration of parallel fibers in cross section.*

Since $\hat{\Lambda} \gg \alpha > 0$ the matrix M is positive definite. Let $\lambda_1, \cdots, \lambda_n$ denote its eigenvalues. It is obvious that $\lambda_i > 0$, $i = 1, \cdots, n$. Let C be the unitary matrix whose columns are the orthonormalized eigenvectors of M, that is, $M = C\Lambda C^t$, where $\Lambda = \text{Diag}\{\lambda_1, \cdots, \lambda_n\}$. Setting $V(x,t) = C^t U(x,t)$ and premultiplying the system (1.4)–(1.8) by C^t, V satisfies the following equations:

$$\begin{aligned}
&(1.10) && V_t = V_{xx} - GV, && x \in (0,1) \mod (1), \\
&(1.11) && V_t = \Lambda[V_x]_x + C^t F(CV) - C^t W, && x = 0 \mod (1), \\
&(1.12) && W_t = \sigma CV - \gamma W, && x = 0 \mod (1), \\
&(1.13) && [V]_x = 0, && x = 0 \mod (1).
\end{aligned}$$

We define the operator G_1 by

$$G_1\begin{pmatrix} V \\ W \end{pmatrix} = \begin{pmatrix} C^tF(CV) - C^tW \\ \sigma CV - \gamma W \end{pmatrix}, \qquad x = 0 \mod (1), \tag{1.14}$$

$$G_1\begin{pmatrix} V \\ W \end{pmatrix} = \begin{pmatrix} -GV \\ 0 \end{pmatrix}, \qquad x \in (0,1) \mod (1), \tag{1.15}$$

and the matrix P by

$$P = \begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix} \quad \text{if } x = 0 \mod (1),$$

$$P = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \quad \text{if } x \in (0,1) \mod (1).$$

System (1.10)–(1.13) can then be rewritten as

$$\begin{pmatrix} V \\ W \end{pmatrix}_t = P \cdot \begin{pmatrix} V \\ W \end{pmatrix}_{xx} + G_1\begin{pmatrix} V \\ W \end{pmatrix}, \qquad x \in (0,1) \mod (1) \tag{1.16}$$

$$\begin{pmatrix} V \\ W \end{pmatrix}_t = P \cdot \begin{pmatrix} [V_x]_x \\ 0 \end{pmatrix} + G_1\begin{pmatrix} V \\ W \end{pmatrix}, \qquad x = 0 \mod (1). \tag{1.17}$$

In §2, by using the Implicit Function Theorem, it is shown that for certain values of the parameters there exist nonzero steady state solutions to (1.16) and (1.17). In §3, we show that there exist contracting rectangles around some special steady state solutions. In §4, we use this result to prove that one of the steady state solutions is approximately stable. In §5, the existence proof of solutions of the system (1.4)–(1.8) is given for the Cauchy problem (see [5] and [3] for references).

2. Steady state solutions. Let (U, W) be the steady state solution of (1.4)–(1.8). In this case, U satisfies the equations

$$U_{xx} - GU = 0, \qquad x \in (0,1) \mod (1), \tag{2.1}$$

$$M[U_x]_x + F(U) - \sigma\gamma^{-1}U = 0, \qquad x = 0 \mod (1). \tag{2.2}$$

The general solution of (2.1) can be expressed as

$$u_i = \frac{[{}_{k+1}u_i \sinh\sqrt{g_i}(x-k) + {}_ku_i \sinh\sqrt{g_i}(k+1-x)]}{\sinh\sqrt{g_i}} \qquad \text{for } x \in (k, k+1),$$

where ${}_ku_i = u_i(k)$ for all $k \in \mathbb{Z}$. Obviously, $(U, W) = (0, 0)$ is a trivial steady state solution. The jump of the first derivative of u_i on each node $x = k$ is given by

$$[u_{ix}]_k = G_i({}_{k+1}u_i - 2\cosh\sqrt{g_i}\ {}_ku_i + {}_{k-1}u_i), \tag{2.3}$$

where $G_i = \sqrt{g_i}/\sinh\sqrt{g_i}$. Let $\hat{G} = \mathrm{Diag}\{G_1, G_2, \cdots, G_n\}$, $\mathrm{Chg} = \mathrm{Diag}\{\cosh\sqrt{g_1}, \cosh\sqrt{g_2}, \cdots, \cosh\sqrt{g_n}\}$, ${}_kU = ({}_ku_1, {}_ku_2, \cdots, {}_ku_n)^t$. Using this notation, (2.3) can be rewritten as

$$[U_x]_k = \hat{G}({}_{k+1}U - 2\mathrm{Chg}_kU + {}_{k-1}U). \tag{2.4}$$

Substituting (2.4) into (2.2), we see that U satisfies

$$\hat{G}({}_{k+1}U - 2\mathrm{Chg}_kU + {}_{k-1}U) + A_\lambda F({}_kU) - A_\lambda\sigma\gamma^{-1}{}_kU = 0, \tag{2.5}$$

$$x = k \in \mathbb{Z},$$

where the matrix $A_\lambda = C\Lambda^{-1}C^t = M^{-1}$. We will now look for a special solution of the form

$$ {}_kU = z \quad \text{for all } k \in \mathbb{Z}, $$

where $z = (z_1, z_2, \cdots, z_n)^t$. In this case, (2.5) is equivalent to

$$ 2\hat{G}(1 - \mathrm{Chg})z + A_\lambda F(z) - A_\lambda \sigma\gamma^{-1} z = 0. $$

In order to find a nonzero solution of the above equation, let us define the functions

$$ \begin{aligned} H_1(z; G, \sigma\gamma^{-1}) &= F(z) - I(z; G, \sigma\gamma^{-1}), \\ I(z; G, \sigma\gamma^{-1}) &= (A_\lambda^{-1} 2\hat{G}(\mathrm{Chg} - I) + \sigma\gamma^{-1})z, \end{aligned} \tag{2.6} $$

where $A_\lambda^{-1} = C\Lambda C^t = M$. Then

$$ D_z H_1(z; G, \sigma\gamma^{-1}) = \begin{pmatrix} f_1' & 0 & 0 & \cdots & 0 \\ 0 & f_2' & 0 & \cdots & 0 \\ 0 & 0 & f_3' & \cdots & 0 \\ & \cdots & & \cdots & \\ 0 & 0 & 0 & \cdots & f_n' \end{pmatrix} - \sigma\gamma^{-1} I - 2A_\lambda^{-1}\hat{G}(\mathrm{Chg} - I). \tag{2.7} $$

Let $\hat{f}_i(z_i) = f_i(z_i) - \sigma_i/\gamma_i z_i$ for $i = 1, 2, \cdots, n$. Then for σ_i/γ_i small there exists $\alpha_1^{(i)}, \alpha_2^{(i)}$ such that

$$ \hat{f}_i(\alpha_1^{(i)}) = \hat{f}_i(\alpha_2^{(i)}) = 0 $$

for $i = 1, 2, \cdots, n$ (cf. Fig. 3). This is equivalent to

$$ H_1(\alpha_1; 0, \sigma\gamma^{-1}) = H_1(\alpha_2; 0, \sigma\gamma^{-1}) = 0, \tag{2.8} $$

where $\sigma\gamma^{-1}$ is fixed and $\alpha_j = (\alpha_j^{(1)}, \alpha_j^{(2)}, \cdots, \alpha_j^{(n)})^t$, $j = 1, 2$. By the definition of $\hat{f}_i$ and $\hat{f}_i'$ at α_1 and α_2, there exists a $g^* > 0$ such that $D_z H_1(\alpha_1; G, \sigma\gamma^{-1})$ is positive definite for $0 < g_i < g^*$ and $D_z H_1(\alpha_2; G, \sigma\gamma^{-1})$ is negative definite for $0 < g_i < g^*$, $i = 1, 2, \cdots, n$. Using the Implicit Function Theorem there exist smooth manifolds $\alpha_1 = \alpha_1(G)$ and $\alpha_2 = \alpha_2(G)$ in a neighborhood $U_0 = \prod_1^n(-q, q)$ of $G = (0, 0, \cdots, 0)^t$ such that

$$ \begin{aligned} &H_1(\alpha_1(G), G, \sigma\gamma^{-1}) = 0, \\ &H_1(\alpha_2(G), G, \sigma\gamma^{-1}) = 0, \qquad G \in U_0. \end{aligned} $$

Hence the following theorem has been proved.

THEOREM 2.1. *The differential equations* (2.1)–(2.2) *have at least two superthreshold* (*nonzero*) *solutions, provided the positive constants* g_i *and* σ_i/γ_i *are small* ($i = 1, 2, \cdots, n$).

If we define $U_{\alpha_i}(x) = (u_{1\alpha_i^{(1)}}(x), u_{2\alpha_i^{(2)}}(x), \cdots, u_{n\alpha_i^{(n)}}(x))^t$ then U_{α_1} and U_{α_2} are two superthreshold solutions with $u_{j\alpha_i^{(j)}}(k) = \alpha_i^{(j)}$ for all $k \in \mathbb{Z}$, where $i = 1, 2$; $j = 1, 2, \cdots, n$.

3. Contracting rectangle. In this section and the next, the idea of "invariant region" or "contracting rectangle" (see [17] and [10]) will be used to reveal the behavior of solutions of (1.4)–(1.8) around the steady state solutions $(U, W) = (0, 0)$ and $(U, W) = (U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$. In fact, these two solutions are "attractors," that is, if any solution of (1.4)–(1.8) is close enough to one of the two steady states, then it must be attracted to the steady state solution.

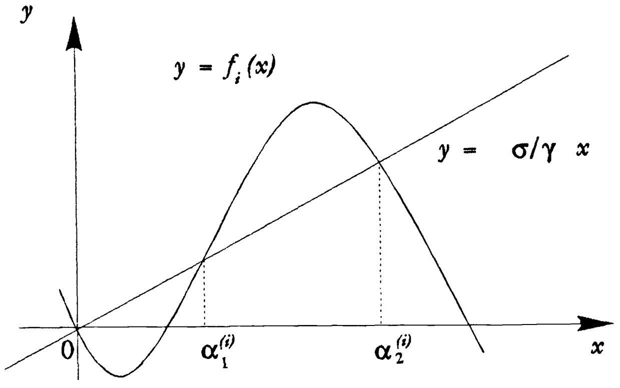

FIG. 3. $\hat{f}_i(\alpha_1^{(i)}) = \hat{f}_i(\alpha_2^{(i)}) = 0$.

DEFINITION 3.1. Let H denote a vector field over $\mathbb{R}^{2n}$ and let S be a bounded convex set in $\mathbb{R}^{2n}$, with boundary ∂S. S is contracting for H if, for every $w \in \partial S$ and the outward normal vector $n(w)$ of ∂S at w, we have

$$H(w) \cdot n(w) < 0.$$

If S is of the form

$$S = S_1 \times S_2, \tag{3.1}$$

where $S_1 = \pi_{j=1}^n[-\overline{u}_j, \overline{u}_j]$ and $S_2 = \pi_{j=1}^n[-\overline{z}_j, \overline{z}_j]$, then S is called a contracting rectangle.

The boundary of S consists of $4n$ "faces" which are denoted as follows.

$S \cap \{(U, W) : u_i = \overline{u}_i\}$ is the upper ith face,
$S \cap \{(U, W) : u_i = -\overline{u}_i\}$ is the lower ith face,
$S \cap \{(U, W) : z_i = \overline{z}_i\}$ is the upper $(n+i)$th face,
$S \cap \{(U, W) : z_i = -\overline{z}_i\}$ is the lower $(n+i)$th face.

3.1. Contracting rectangle around the trivial solution $(U, W) = (0, 0)$. Define $H(U, W) = G_1(U, W)$ as in (1.14) and (1.15). Then either $x \in \mathbb{Z}$ or $x \in \mathbb{R}\backslash\mathbb{Z}$.

3.1.1. Case for $x = 0$ mod(1). Fixing $x = n \in \mathbb{Z}$, the vector field $G_1 : \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ defined by (1.14) is the same as (1.1) of [10]; hence we can use the same results as in §1 of [10] where $C = (c_{ij})$ and we define $\hat{C} = (\hat{c}_{ij})$ where $\hat{c}_{ij} = |c_{ij}|$, for $i, j = 1, \cdots, n$.

THEOREM 3.2 (Grindrod and Sleeman [10]). *We assume that the functions f_i $(i = 1, 2, \cdots, n)$ satisfy the condition that*

$$\min_i\{a_i\} > r \max_i\{\sigma_i/\gamma_i\}, \tag{3.2}$$

where $a_i = -f_i'(0)$, $i = 1, \cdots, n$, and $r = \rho(\hat{C}^t\hat{C})$. Then there exists a rectangle S^* of the form (3.1) *and a constant $\kappa_1 > 0$ such that $G_1(U, W) \cdot n(U, W) < -\kappa_1\tau$ on $\partial(\tau S^*)$ for any outward normal $n(U, W)$ to $\partial(\tau S^*)$ at (U, W) and any $\tau \in (0, 1)$.*

3.1.2. Case for $x \in \mathbb{R}\backslash\mathbb{Z}$. Here $(U, 0)$ is on the ∂S if and only if there exists some $u_i = \overline{u}_i$ (or $u_i = -\overline{u}_i$). By (1.15),

$$G_1(U, W) = \begin{bmatrix} -GU \\ 0 \end{bmatrix}.$$

We only consider the case that $(U, 0)^t$ is on the upper ith face. In this case $n(U, 0) = (\ell_i, 0)^t$, where $\ell_i = (0, \cdots, 0, 1, 0, \cdots, 0)^t$ and $G_1(U, 0) \cdot n(U, 0) = -g_i\overline{u}_i$. We have now proved the following lemma.

LEMMA 3.3. *For any rectangle S given by* (3.1), *$\tau \in (0, 1)$, and $\kappa_2 = \min_i\{g_i\}$, we have that*

$$G_1(U, 0) \cdot n(U, 0) \leq -\kappa_2\tau \tag{3.3}$$

on $\partial(\tau S)$ for any outward normal vector $n(U, 0)$ to $\partial(\tau S)$ at $(U, 0)$.

3.2. Contracting rectangle near steady state solution. $(U_{\alpha_2}(x), \sigma\gamma^{-1}U_{\alpha_2}(x))$ Let (U, W) be a solution of (1.4)–(1.8) near the steady state solution $(U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$. Let us define the functions

$$V_1(x, t) = U(x, t) - U_{\alpha_2}(x), \qquad x \in (0, 1) \mod (1), \tag{3.4}$$

$$Z_1(n, t) = W(n, t) - \sigma\gamma^{-1}U_{\alpha_2}(n), \qquad n = 0 \mod (1). \tag{3.5}$$

These functions then satisfy the following differential equations

$$V_{1t} = V_{1xx} - GV_1, \qquad x \in (0, 1) \mod (1), \tag{3.6}$$

$$Z_1 = 0, \qquad x \in (0, 1) \mod (1), \tag{3.7}$$

$$V_{1t} = M[V_{1x}]_x + F(U_{\alpha_2} + V_1) - F(U_{\alpha_2}) - Z_1, \qquad x = 0 \mod (1), \tag{3.8}$$

$$Z_{1t} = \sigma V_1 - \gamma Z_1, \qquad x = 0 \mod (1), \tag{3.9}$$

$$[V_1]_x = 0, \qquad x = 0 \mod (1). \tag{3.10}$$

3.2.1. Case for $x = 0$ mod(1). Now $F(U) - F(U_{\alpha_2}) = DF(U_{\alpha_2} + \theta V_1)V_1$, where $0 < \theta < 1$. From before we have that

$$DF(U_{\alpha_2}) = \begin{bmatrix} f_1'(u_{1\alpha_2^{(1)}}) & 0 & \cdots & 0 \\ 0 & f_2'(u_{2\alpha_2^{(2)}}) & \cdots & 0 \\ 0 & 0 & \cdots & f_n'(u_{n\alpha_2^{(n)}}) \end{bmatrix} \tag{3.11}$$

is negative definite. In fact, we can find $\epsilon_1 > 0$ such that $f_i'(u_{i\alpha_2^i}(x)) < -\epsilon_1$ for all $x \in \mathbb{R}$. By the smoothness of the function $F(Y)$, there is a constant $\delta_0 > 0$ such that the matrix

$$DF(U_{\alpha_2}(x) + Y) \tag{3.12}$$

is negative definite for any $Y = (y_1, y_2, \cdots, y_n)^t \in S'$, where $S' = \prod_{i=1}^n[-\delta_0, \delta_0]$. In this case we can find $\eta_0 > 0$, such that

$$\eta_0 = \min_{\substack{1 \leq i \leq n \\ x \in \mathbb{R}, y \in S'}} \{\lambda_i(u_{i\alpha_2^i}(x) + y_i)\},$$

where $-\lambda_i$ $(i = 1, 2, \cdots, n)$ are eigenvalues of the matrix (3.12). Let

$$\hat{D}_0 = \begin{bmatrix} -\eta_0 & & \bigcirc \\ & -\eta_0 & \\ & & \ddots & \\ \bigcirc & & & -\eta_0 \end{bmatrix}, \tag{3.13}$$

$V = C^tV_1$, and $Z = Z_1$. The vector field near $(U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$ is then given by

$$G_1(V,Z) = \begin{bmatrix} C^t(F(U_{\alpha_2} + CV) - F(U_{\alpha_2})) - C^tZ \\ \sigma CV - \gamma Z \end{bmatrix}. \tag{3.14}$$

If we linearize this near $(U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$ we have that

$$\hat{G}_{1L}(V,Z) = \begin{bmatrix} -\hat{D}_0 & -C^t \\ \sigma C & -\gamma \end{bmatrix} \begin{bmatrix} V \\ Z \end{bmatrix}.$$

We use the same argument as in the contracting rectangle around $(U,W) = (0,0)$ and arrive at the following lemma.

LEMMA 3.4. *Let $-\eta_0 < -\hat{\gamma}\delta_1$, where $\hat{\gamma} = \rho(\hat{C}^t\hat{C})$, $\delta_1 = \max_i\{\sigma_i/\gamma_i\}$, and C is the orthogonal matrix with $MC = \Lambda C$ and $\hat{C} = (|C_{ij}|)_{n\times n}$. Then there exists a rectangle S^{**} and a constant κ_3 such that for $\tau \in (0,1)$*

$$G_1(V,Z)\cdot n(V,Z) < -\kappa_3\tau$$

for $(V,Z) \in \partial(\tau S^*)$.

3.2.2. Case for $x \in \mathbb{R}/\mathbb{Z}$. This is the same as in case 3.1.2.

4. Asymptotic stability.

Let us consider a more general system of the form

$$\begin{aligned}
&(4.1) && U_t = U_{xx} - GU, && x \in (0,1) \ \text{mod}\ (1),\\
&(4.2) && W \equiv 0, && x \in (0,1) \ \text{mod}\ (1),\\
&(4.3) && U_t = \Lambda[U_x]_x + F_1(U,W), && x = 0 \ \text{mod}\ (1),\\
&(4.4) && W_t = F_2(U,W), && x = 0 \ \text{mod}\ (1),\\
&(4.5) && [U]_n = 0, && x = 0 \ \text{mod}\ (1),
\end{aligned}$$

where $U \in C(\mathbb{R}^+ \times \mathbb{R}, \mathbb{R}^n)$, $W \in C(\mathbb{R}^+ \times \mathbb{Z}, \mathbb{R}^n)$. $F_i \in C^1(\mathbb{R}^{2n}, \mathbb{R}^n)$ $(i = 1,2)$; matrices Λ and G are the same as before.

The contracting rectangles allow us to define nonlinear functionals, which are decreasing functions of time [4], [10], [17] for some solutions of the differential equations (4.1)–(4.5). Here the functionals to be considered are those associated with the rectangles $S = S_1 \times S_2$ such that the origin is in the interior of S.

Let $|\cdot|_{S_1}$ be the norm on $\mathbb{R}^n$ defined by S_1 in the usual way:

$$|V|_{s_1} = \inf\{t \geq 0 : V \in tS_1\}. \tag{4.6}$$

Thus $|V|_{s_1}$ is the smallest multiple of S_1 containing V. Similarly, the norm $|Z|_{s_2}$ is defined in the obvious way:

$$|Z|_{s_2} = \inf\{t \geq 0 : Z \in tS_2\}. \tag{4.7}$$

If we now define the continuous functions $V_{s_i} : BC \to \mathbb{R}$ $(i = 1,2)$ by

$$V_{s_1}(V) = \sup_{x\in\mathbb{R}} |V(x)|_{s_1} \quad \text{and} \quad V_{s_2}(Z) = \sup_{n\in\mathbb{Z}} |Z(n)|_{s_2}, \tag{4.8}$$

then we can now state the following lemma.

LEMMA 4.1. *Let S be defined as in Definition* 3.1 (*or $S = S^* \cap S^{**}$ if necessary*). *Suppose that (U,W) is a solution of* (4.1)–(4.5) *for $|t - T| < \delta$, and that (U_0, W_0) is a steady state solution of* (4.1)–(4.5). *Let $V = U - U_0$, $Z = W - W_0$ with $V_{s_1}(V(T)) = \tau_1 < 1$, $V_{s_2}(Z(T)) = \tau_2 < 1$, $V \in C_0(\mathbb{R})$, and $Z \in c_0$. Suppose that there exist $\eta_1, \eta_2 > 0$ such that for any $V \in \partial(\tau_1 S_1)$ or $Z \in \partial(\tau_2 S_2)$ with $Z \neq 0$ and $\overline{n}(V,Z)$ normal to*

$\partial(\tau_1 S_1 \times \tau_2 S_2)$ at (V, Z), we have that $(F_1(U, W) - F_1(U_0, W_0)) \cdot \overline{n}(V, Z) < -\tau_1\eta_1$ or $(F_2(U, W) - F_2(U_0, W_0)) \cdot \overline{n}(V, Z) < -\tau_2\eta_2$; then

$$\overline{D}V_{s_1}(V(T)) \leq -(\eta/L)V_{s_1}(V(T)) \tag{4.9}$$

or

$$\overline{D}V_{s_2}(Z(T)) \leq -(\eta/L)V_{s_2}(Z(T)), \tag{4.10}$$

where L is the length of the shortest side of S, $\eta = \min\{\eta_1, \eta_2, \min_{1\leq j\leq n}\{g_j\overline{u}_j, g_j\overline{z}_j\}\}$.

Proof. Let S be defined as in Definition 3.1. If $V_{s_1}(V(T)) = \tau_1$, then by (4.6)

$$-\tau_1\overline{u}_j \leq v_j(T, x) \leq \tau_1\overline{u}_j \quad \text{for all } x \in \mathbb{R} \quad (j = 1, \cdots, n).$$

We say that $V(T, x)$ is in the jth upper face if $v_j(T, x) = \tau_1\overline{u}_j$, with an analogous definition for the lower face. Now, if $V(T, x) \in \partial\tau_1 S_1$, then there is a subset $J \subset \{1, \cdots, n\}$ such that $V(T, x)$ is on one of the jth faces if and only if $j \in J$. If $V(T, \overline{x})$ is in the jth upper face, then $v_j(T, x) \leq \tau_1\overline{u}_j$ for all x near $x = \overline{x}$. In this case, if $\overline{x} \in \mathbb{R}/\mathbb{Z}$, then $\partial_{xx}v_j(T, \overline{x}) \leq 0$ and

$$\partial_t v_j(T, \overline{x}) = \partial_{xx}v_j(T, \overline{x}) - g_j v_j(T, \overline{x}) \leq -g_j\tau_1\overline{u}_j;$$

if $\overline{x} = k \in \mathbb{Z}$, then $v_j(T, \overline{x})$ is the local maximum and $[v_x]_k \leq 0$. Therefore

$$\partial_t v_j(T, k) < -\eta_1\tau_1,$$

and in this case

$$v_j(T + h, \overline{x}) < \tau_1(\overline{u}_j - \eta_1 h) \quad \text{for small } h.$$

By the continuity of V, this holds for all x in a neighborhood of $\overline{x}$. A similar result holds for the lower faces.

Let $X = \{x : V(T, x) \in \partial\tau_1 S_1\}$. Since $V \in C_0(\mathbb{R})$ then X is a compact set in $\mathbb{R}$, and by the above computation there is an open set $\Omega \subset \mathbb{R}$ which contains X such that, for $\theta \in \Omega$, we have that for small h

$$V(T + h, \theta) \in (1 - h\eta_1 L^{-1})\tau_1 S_1,$$

where $L = \max_{1\leq j\leq n}\{\overline{u}_j, \overline{z}_j\}$. Now $V \in C\{(T - \delta, T + \delta)|C_0(\mathbb{R})\}$ and for $x \in \mathbb{R}\backslash\Omega$, $V(T, x) \subset \operatorname{int}(\tau_1 S_1)$. Thus there is an $h_0 > 0$ and a compact set $K_1 \subset \operatorname{int}(\tau_1 S_1)$ for which $V(T + h, x) \subset K_1$ for all $|h| < h_0$. Hence for sufficiently small h,

$$V_{s_1}(V(T + h)) \leq \tau_1(1 - h\eta_1/L),$$

so that

$$(V_{s_1}(V(T + h)) - V_{s_1}(V(T)))/h \leq -\eta/L \; V_{s_1}(V(T)),$$

and (4.9) has been proved.

Let us turn our attention to $Z(t, k)$. Now $V_{s_2}(Z(T, k)) = \tau_2$ so that if $Z(T, k) \in \partial(\tau_2 S_2)$, say in the $(n + j)$th upper face, then $z_j(T, k) = \tau_2\overline{z}_j$ for some k and

$$\partial_t z_j(T, k) = F_2(U(T, k), W(T, k)) - F_2(U_0(k), W_0(k)) < -\eta_2\tau_2.$$

This makes $z_j(T + h, k) < \tau_2(\overline{z}_j - \eta_2 h)$ for some h. Let $\overline{N} = \{k : Z(T, k) \in \partial\tau_2 S_2\}$. Since $Z \in c_0$, $\overline{N}$ is a bounded set in $\mathbb{Z}$ (provided $\overline{u}_j$ or $-\overline{z}_j$ are not the nonzero roots of F_1 and F_2; in fact, it is valid when $\overline{u}_j$ and $\overline{z}_j$ are small). We can then find a neighborhood $\pi \supset \overline{N}$ such that for $\theta \in \pi$,

$$Z(T + h, \theta) \subset (1 - h\eta_2/L)\tau_2 S_2 \quad \text{for small } h.$$

Let $k \in \mathbb{Z}/\pi$. Since $Z(T, k) \subset \operatorname{int}(\tau_2 S_2)$ and $Z \in C((T - \delta, T + \delta), c_0)$ there is an $h_0 > 0$ and a compact set $K_2 \subset \operatorname{int}(\tau_2 S_2)$ for which $Z(T + h, k) \subset K_2$ for all $|h| < h_0$. Thus for sufficiently small h, $Z(T + h, k) \subset (1 - h\eta_2/L)\tau_2 S_2$ for all $k \in \mathbb{Z}$. Hence

$$(V_{s_2}(Z(T + h)) - V_{s_2}(Z(T)))/h \leq -\eta/L \; V_{s_2}(Z(T)). \qquad \square$$

By Lemma 4.1, we can easily obtain the following result.

THEOREM 4.2. *The steady state solutions* $(U, W) = (0, 0)$ *and* $(U, W) = (U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$ *are attractors of* (1.4)–(1.8), *provided* (3.2) *is valid.*

Proof. By Lemma 4.1,

$$\begin{aligned} &V_{s_1}(U - Q)(t) \le e^{-\frac{\eta_3}{L}t}V_{s_1}(U - Q)(0), \\ &V_{s_2}(W - \sigma\gamma^{-1}Q)(t) \le e^{-\frac{\eta_3}{L}t}V_{s_2}(W - \sigma\gamma^{-1}Q)(0), \end{aligned}$$

where $\eta_3 = \min\{\eta, \kappa_1, \kappa_2, \kappa_3\}$, $(Q, \sigma\gamma^{-1}Q)$ is one of the steady states $(0, 0)$ or $(U_{\alpha_2}, \sigma\gamma^{-1}U_{\alpha_2})$ (note that $S = S^* \cap S^{**}$ is fixed and C is an orthogonal matrix). □

Remark 4.3. The above theorem tells us that if the initial values $(U(x, 0), W(k, 0))$ are close enough to one of the steady states with their difference belonging to $C_0(\mathbb{R})$, then the solution $(U(x, t), W(k, t))$ must approach the steady state uniformly in the norm of $L^\infty(\mathbb{R})$ as $t \to \infty$.

5. Existence. We will now give an existence proof for the problem defined by (1.4)–(1.8). We note that the standard literature deals with the existence of solutions (at least) in L^2. However, our steady state solutions $U_{\alpha_i(x)}$ are not in L^2. To overcome this problem we introduce a new function $(V, Z) = (U - Q, W - \sigma\gamma^{-1}Q)$ near $(Q, \sigma\gamma^{-1}Q)$ which is the nontrivial steady state solution of (1.4)–(1.8). We then prove the existence of a solution (V, Z) of (5.1)–(5.4) in some subspace of L^2. This result establishes the existence of the solution $(U, W) = (Q + V, \sigma\gamma^{-1}Q + Z)$ to (1.4)–(1.8), although neither U nor W belongs to L^2.

Let us start with the system (1.10)–(1.13). Suppose that $(Q, \sigma\gamma^{-1}Q)$ is a steady state solution of (1.10)–(1.13) and that $(\hat{U}, \hat{Z})$ satisfies (1.10)–(1.13). Using the above idea, we define new functions

$$\begin{array}{ll} u = \hat{U} - Q, & x \in (0,1) \mod (1), \\ v = \hat{U} - Q, & x = 0 \mod (1), \\ w = \hat{Z} - \sigma\gamma^{-1}Q, & x = 0 \mod (1). \end{array}$$

Then (u, v, w) satisfy the following equations:

$$\begin{array}{lll} (5.1) & u_t = u_{xx} - Gu, & x \in (0,1) \mod (1), \\ (5.2) & v_t = \Lambda[u_x]_x + C^t[F(C(Q + v)) & \\ & \qquad - F(CQ)] - C^t w, & x = 0 \mod (1), \\ (5.3) & w = \sigma Cv - \gamma w, & x = 0 \mod (1), \\ (5.4) & [u]_x = 0, & x = 0 \mod (1). \end{array}$$

Let

$$H = \{(p, q, r) : p \in L^2(\mathbb{R}, \mathbb{C}^n),\ q \in \ell^2(\mathbb{Z}, \mathbb{C}^n),\ r \in \ell^2(\mathbb{Z}, \mathbb{C}^n)\}$$

with the inner product given by

$$\langle (p_1, q_1, r_1), (p_2, q_2, r_2)\rangle_H = \int_{\mathbb{R}} \langle \Lambda p_1, p_2\rangle + \sum_{i \in \mathbb{Z}} (\langle q_1, q_2\rangle^i + \langle r_1, r_2\rangle^i),$$

where $\langle \Lambda p_1, p_2\rangle(x) = (\lambda_1 p_1^1 \bar{p}_2^1 + \lambda_2 p_1^2 \bar{p}_2^2 + \cdots + \lambda_n p_1^n \bar{p}_2^n)(x)$,

$\langle q_1, q_2\rangle^i = (q_1^1 \bar{q}_2^1 + q_1^2 \bar{q}_2^2 + \cdots + q_1^n \bar{q}_2^n)(i)$, for $i \in \mathbb{Z}$, $\Lambda = \mathrm{Diag}\{\lambda_1, \lambda_2, \ldots, \lambda_n\}$.

H is a complete Hilbert space. Let X be a subspace of H given by

$$X = \Big\{(p, q, r) \in H : p, p', p'' \in L^2(\mathbb{R}, \mathbb{C}^n), \{[p']_i\} \in \ell^2, \\ \lim_{x \to i} p(x) = q(i) \text{ for each } i \in \mathbb{Z}\Big\}.$$

Then X is dense in H. Let

$$Y = \{(p,q,r) \in H : p, p' \in L^2(\mathbb{R}, \mathbb{C}^n), \ \lim_{x \to i} p(x) = q(i)\}$$

with the inner product given by

$$\begin{aligned}\langle (p_1,q_1,r_1),(p_2,q_2,r_2)\rangle_Y = \int_{\mathbb{R}} &(\langle \Lambda p_1, p_2\rangle + \langle \Lambda p_1', p_2'\rangle) \\ &+ \sum_{i\in\mathbb{Z}} (\langle q_1, q_2\rangle^i + \langle r_1, r_2\rangle^i).\end{aligned}$$

Y is a complete space and, in fact, $Y = H^1 \times S \times \ell^2$, where

$$S = \{q \in \ell^2 : \text{ there exists a } p \in H^1 \text{ with } \lim_{x\to i} p(x) = q(i)\}.$$

Then the three spaces satisfy

$$X \subset Y \subset H \tag{5.5}$$

and

$$\|(u,v,w)\|_H \le \|(u,v,w)\|_Y \quad \text{for any } (u,v,w) \in Y. \tag{5.6}$$

Define the linear operator $A : X \to H$ by

$$A(u,v,w) = (-u_{xx} + u, \Lambda[-u_x]_x + v, w), \tag{5.7}$$

where $u(i,t) = v^i(t)$. It is easy to verify that $\langle A(u_1,v_1,w_1),(u_2,v_2,w_2)\rangle_H = \langle (u_1,v_1,w_1), A(u_2,v_2,w_2)\rangle_H$ for any $(u_i,v_i,w_i) \in X$ $(i = 1,2)$. That is, A is a self-adjoint operator. In order to prove existence, we will need the following lemmas.

LEMMA 5.1. *The operator A defined by* (5.7) *with* dom $(A) = X$ *is a closed operator from X to H with $A^{-1} : H \to H$ bounded.*

Proof. For any $(u,v,w) \in X$ we have, by the definition of A,

$$A(u,v,w) = (p,q,r) \in H.$$

To show that A has a bounded inverse, we need to find A^{-1}. Fix $(p,q,r) \in H$, then for any $(x,y,z) \in Y$ we have that

$$\begin{aligned}\langle (x,y,z),(p,q,r)\rangle_H &\le \|(x,y,z)\|_H \|(p,q,r)\|_H \\ &\le \|(x,y,z)\|_Y \|(p,q,r)\|_H.\end{aligned}$$

$\langle (x,y,z),(p,q,r)\rangle_H$ defines a bounded linear functional on Y. By the Riesz Representation Theorem, there exists a unique $(u,v,w) \in Y$ such that

$$\langle (x,y,z),(p,q,r)\rangle_H = \langle (x,y,z),(u,v,w)\rangle_Y \quad \text{for any } (x,y,z) \in Y. \tag{5.8}$$

Thus for any given $(p,q,r) \in H$, we can define $B : H \to Y$, where

$$B(p,q,r) = (u,v,w). \tag{5.9}$$

We need to show that $B = A^{-1}$ and B is bounded. This is equivalent to showing that

1°. $\|B\| < \infty$,

2°. $B(H) \subset X$,

3°. Equation (5.9) is valid if and only if $A(u,v,w) = (p,q,r) \in H$, that is, $B = A^{-1}$.

By (5.8) and (5.9),

$$\begin{aligned}\|B(p,q,r)\|_Y^2 &= \langle (u,v,w),(u,v,w)\rangle_Y = \langle (u,v,w),(p,q,r)\rangle_H \\ &\le \|(u,v,w)\|_H \|(p,q,r)\|_H \le \|B(p,q,r)\|_Y \|(p,q,r)\|_H.\end{aligned}$$

Therefore $\|B(p,q,r)\|_Y \leq \|(p,q,r)\|_H$. Hence B is a bounded operator with $\|B\| \leq 1$.

To show 2°, the conclusion of Lemma 15.5 of [7, §I.15] will be used. The bilinear form for the operator $Lw = -w''$ is given by $\beta[x,y] = \int_{[j-1,j]}\langle x', y'\rangle$. Thus Lemma 15.5 in [7] can be rewritten equivalently in the following way.

Assume that $u \in H^1(a,b)$ and that for all $\phi \in C_0^\infty(a,b)$,

$$|\beta[u,\phi]| \leq k_1\|\phi\|_{L^2}. \tag{5.10}$$

Then for any subdomain (a_1,b_1) of (a,b) with $[a_1,b_1] \subset (a,b)$, u' belongs to $H^1((a_1,b_1))$ and

$$(\|u'\|_{L^2} + \|u''\|_{L^2})|_{(a_1,b_1)} \leq K(c + \|u\|_{L^2} + \|u'\|_{L^2})|_{(a,b)},$$

where K is a constant depending only on c, (a_1,b_1), and (a,b).

To prove condition (5.10), we choose $\phi \in C_0^\infty(\mathbb{R},\mathbb{C}^n)$ with $\operatorname{supp}\phi \subset [a,b] \subset (j-1,j)$. Let $\psi = (\psi^k)$, $\eta = (\eta^k)$ be such that $\psi^k = \eta^k = 0$ for all $k \in \mathbb{Z}$; then

$$(\phi,\psi,\eta) \in Y$$

and (5.8) yields

$$\int_{(j-1,j)}\langle \phi', \Lambda u'\rangle = \int_{(j-1,j)}\langle \phi, \Lambda(p-u)\rangle. \tag{5.11}$$

By Holder's inequality,

$$\begin{aligned}\left|\int_{(j-1,j)}\langle\phi',u'\rangle\right| &\leq \frac{1}{\min\limits_{1\leq i\leq n}\lambda_i}(\|(u,v,w)\|_H + \|(p,q,r)\|_H)\|\phi\|_{L^2(j-1,j)}\\ &= \frac{1}{\min\limits_{1\leq i\leq n}\lambda_i}(\|B(p,q,r)\|_H + \|(p,q,r)\|_H)\|\phi\|_{L^2(j-1,j)}\\ &\leq \frac{1}{\min\limits_{1\leq i\leq n}\lambda_i}2\|(p,q,r)\|_H\|\phi\|^2_{L^2(j-1,j)}.\end{aligned}$$

This establishes (5.10). Therefore,

$$u''|_{(a,b)} \in L^2(a,b) \quad \text{for any } [a,b] \subset (j-1,j).$$

Taking the complex conjugate of (5.11),

$$-\int_{(a,b)}\langle u'', \Lambda\phi\rangle = \int_{(a,b)}\overline{\langle \Lambda\phi', u'\rangle} = \int_{(a,b)}\langle p-u, \Lambda\phi\rangle.$$

The above identity is true for any $\phi \in C_0^\infty((a,b),\mathbb{C}^n)$. By choosing suitable ϕ and by (5.8) we also can conclude that $u'', u' \in L^2(\mathbb{R})$. Thus 2° holds.

To show that 3° holds we will show that it holds for each component.

Since C_0^∞ is dense in L^2, for any $h \in L^2[(a,b),\mathbb{C}^n]$,

$$\int_{(a,b)}\langle -u'', h\rangle = \int_{(a,b)}\langle p-u, h\rangle.$$

Therefore $-u'' + u = p$ on (a,b); hence $-u'' + u = p$ on $(j-1,j)$. This is the first component in (5.7).

Now $L^2[(j-1,j)] \subset L^1[(j-1,j)]$, so that u' is absolutely continuous on $(j-1,j)$ and

$$u'(b) - u'(b) = \int_{(a,b)} u'' \quad \text{for any } (a,b) \subset (j-1,j).$$

Let $a \to j-1+$ or $b \to j-$; then $u'(j-1+)$ and $u'(j-)$ are well defined. Next, let us verify the last two components in (5.7).

Let $y^k_{j,i} = \delta_{jk} e_i$, where $e_i = (0, \cdots, 0, 1, 0, \cdots, 0)^t$ is the ith base vector in $\mathbb{R}^n$. We define the function

$$x_{j,i} = \begin{cases} \frac{x-j+h}{h} e_i, & x \in (j-h, j), \\ -\frac{x-j-h}{h} e_i, & x \in (j, j+h), \\ 0 & \text{otherwise}, \end{cases}$$

where $i = 1, 2, \cdots, n$. Then $(x_{j,k}, y_{j,i}, 0) \in Y$. Substituting this into (5.8) we see that

(5.12)
$$\begin{aligned} \frac{1}{h}\int_{(j-h,j)} \lambda_i u_i' + \frac{1}{h}\int_{(j-h,j)} \lambda_i (x-j+h) u_i - \frac{1}{h}\int_{(j,j+h)} \lambda_i u_i' \\ - \frac{1}{h}\int_{(j,j+h)} \lambda_i (x-j-h) u_i + v^j_i \\ = \frac{1}{h}\int_{(j-h,j)} \lambda_i (x-j+h) p_i - \frac{1}{h}\int_{(j,j+h)} \lambda_i (x-j-h) p_i + q^j_i, \end{aligned}$$

where $u = (u_1, \cdots, u_n)^t$, $p = (p_1, \cdots, p_n)^t$, etc.

Now

$$\frac{1}{h}\int_{(j-h,j)} \lambda_i u_i' = \frac{\lambda_i}{h}(u_i(j) - u_i(j-h)) \to \lambda_i u_i'(j-) \quad \text{as } h \to 0,$$
$$\frac{1}{h}\int_{(j,j+h)} \lambda_i u_i' \to \lambda_i u_i'(j+) \quad \text{as } h \to 0,$$

and $\left|\frac{1}{h}\int_{(j-h,j)} \lambda_i (x-j\pm h) k\right| \le \int_{(j-h,j)} \lambda_i |k| \to 0$ as $h \to 0$ for any $k \in L^2(\mathbb{R})$. Letting $h \to 0$ in (5.12) we see that

$$\lambda_i u_i'(j-) - \lambda_i u_i'(j+) + v^j_i = q^j_i, \qquad i = 1, 2, \cdots, n,$$

which is the second component of (5.7). Now choose $(0, 0, z_{j,i}) \in Y$ with $z^k_{j,i} = \delta_{jk} e_i$, where $z_{i,i}(k) = z^k_{j,i}$. Substituting this into (5.8), we have that

$$\langle (0, 0, z_{j,i}), (u, v, w) \rangle_H = \langle (0, 0, z_{j,i}), (p, q, r) \rangle_Y,$$

which implies that $w^i_j = r^i_j$, $i = 1, 2, \cdots, n$. Thus we have obtained the third component of (5.7). Therefore we have that if $B(p, q, r) = (u, v, w)$ then $(u, v, w) \in X$ and $A(u, v, w) = (p, q, r)$. We now need to show the converse. That is, if $A(u, v, w) = (p, q, r)$, then $B(p, q, r) = (u, v, w)$. Thus (5.8) is valid.

By the definition of A,

$$(p, q, r) = (-u_{xx} + u, \Lambda[-u_x] + v, w).$$

Choose any $(\hat{x},\hat{y},\hat{z}) \in Y$. Taking the inner product of the above expression with $(\hat{x},\hat{y},\hat{z})$ we arrive at

$$\begin{aligned}
\langle(\hat{x},\hat{y},\hat{z}),(p,q,r)\rangle_H &= \int \langle\Lambda\hat{x},p\rangle + \sum_{i\in\mathbb{Z}}(\langle\hat{y}^i,q^i\rangle + \langle\hat{z}^i,r^i\rangle) \\
&= \int (-\langle\hat{x},\Lambda u_{xx}\rangle + \langle\hat{x},\Lambda u\rangle) + \sum_{i\in\mathbb{Z}}\{-\langle\hat{y}^i,\Lambda[u_x^i]\rangle + \langle\hat{y}^i,v^i\rangle + \langle\hat{z}^i,w^i\rangle\} \\
&= \int (\langle\hat{x}_x,\Lambda u_x\rangle + \langle\hat{x},\Lambda u\rangle) \\
&\quad + \sum_{i\in\mathbb{Z}}\{\langle\hat{y}^i,\Lambda[u_x^i]\rangle - \langle\hat{y}^i,\Lambda[u_x^i]\rangle + \langle\hat{y}^i,v^i\rangle + \langle\hat{z}^i,w^i\rangle\} \\
&= \langle(\hat{x},\hat{y},\hat{z}),(u,v,w)\rangle_Y.
\end{aligned}$$

Here we used the fact that $\lim_{s\to i}\hat{x}(s) = \hat{y}^i$ and $u_x\big|_{i-}^{i+} = -u_x(i-) + u_x(i+)$. Thus condition 3° holds and the proof is complete. □

To apply semigroup theory to the nonlinear problem we need another lemma, which is a special case of Theorem V3.2 of [14]. Define

$$\begin{aligned}
\theta(A) &= \{\langle A(u,v,w),(u,v,w)\rangle_H | \\
&\qquad (u,v,w) \in \operatorname{dom} A \text{ with } \|(u,v,w)\|_H = 1\}, \\
\Gamma &= \operatorname{cl}(\theta(A)), \\
\Delta &= \mathbb{C}\backslash\Gamma.
\end{aligned}$$

LEMMA 5.2. *Suppose that A is closed and Δ is connected. For $\lambda \in \Delta$, $A-\lambda$ has nullity zero and constant deficiency. If the deficiency is zero, then Δ is contained in the resolvent set of A and*

$$\|(\lambda - A)^{-1}\| \le 1/\operatorname{dis}(\lambda,\Gamma) \qquad \textit{for } \operatorname{Re}\lambda \le 0. \tag{5.13}$$

Let us check the linear operator A to see if it satisfies the conditions in the lemma so that (5.13) is valid.

By Lemma 5.1 we know that A is closed. Choose any $(u,v,w) \in X$ with $\|(u,v,w)\|_H = 1$. Then

$$\begin{aligned}
\langle A(u,v,w),(u,v,w)\rangle_H &= \int_{\mathbb{R}} \langle -\Lambda u'' + \Lambda u, u\rangle \\
&\quad + \sum_{i\in\mathbb{Z}}\{\langle -\Lambda[u']_i + v^i, v^i\rangle + \langle w^i, w^i\rangle\} \\
&= \int_{\mathbb{R}} (\langle u',\Lambda u\rangle + \langle u,\Lambda u\rangle) + \{\|v\|_{\ell^2}^2 + \|w\|_{\ell^2}^2\} \\
&\quad + \sum_{j\in\mathbb{Z}}\{\langle\Lambda u'(j+1-),u(j)\rangle \\
&\quad - \langle\Lambda u'(j+),u(j)\rangle\} + \langle\Lambda[u']_j,u^j\rangle \\
&= \|(u,v,w)\|_Y \\
&\ge \|(u,v,w)\|_H = 1.
\end{aligned}$$

Hence $\theta(A) \subset [1,\infty)$, $\Gamma \subset [1,\infty)$, and $\Delta = \mathbb{C}/\Gamma$ is connected in $\mathbb{C}$.

By the definition of $\theta(A)$, we know that $A-\lambda$ has nullity zero for any $\lambda \in \Delta$. If $\operatorname{Re}\lambda \le 0$, it is very easy to check that

$$L_\pm = \ker(A^* - \overline{\lambda} \mp i) = \emptyset.$$

Hence (5.13) is valid.

To prove that the solution of (5.1)–(5.4) exists, rewrite (5.1)–(5.4) as follows:

$$\begin{aligned}&U_t - U_{xx} + U = (I-G)U, && x \in (0,1) \mod (1),\\ &V_t - \Lambda[U_x]_x + V = V + C^t(F(C(Q+V)) && \\ &\qquad\qquad\qquad\qquad - F(CQ)) - C^t W, && x = 0 \mod (1),\\ &W_t + W = \sigma CV + (I-\gamma)W, && x=0 \mod (1),\\ &[U]_x = 0, && x = 0 \mod (1),\end{aligned} \tag{5.14}$$

with initial conditions given by

$$(U,V,W)\big|_{t=0} = (\phi,\psi,\eta).$$

Let

$$\hat{F}(t,(U,V,W)) = \big((I-G)U, V + C^t\big(F(C(Q+V)) - F(CQ)\big) - C^t W,\\ \sigma CV + (I-\gamma)W\big)^t.$$

Then (5.14) can be simply written as

$$\frac{d}{dt}(U,V,W) + A(U,V,W) = \hat{F}(t,(U,V,W)), \tag{5.15}$$

with

$$(U,V,W)\big|_{t=0} = (\phi,\psi,\eta). \tag{5.16}$$

Next, we use the following lemma (due to Sobolevski's theorem; see [7, §11.16]) to prove that (5.15) and (5.16) have a solution.

LEMMA 5.3. *Let A be a closed linear operator on a Banach space E such that* (5.13) *holds. Suppose that $\hat{F}(t,p)$ is a function on $[0,T_0]\times E$ so that for some constants $\alpha, \eta \in (0,1)$ and for any $R > 0$ there exists a constant $C(R)$ for which*

$$\begin{aligned}&\|\hat{F}(t_1, A^{-\alpha}p_1) - \hat{F}(t_2, A^{-\alpha}p_2)\|_E\\ &\qquad \le C(R)(|t_1 - t_2|^\eta + \|p_1 - p_2\|_E),\end{aligned} \tag{5.17}$$

where $t_1, t_2 \in [0, t_0]$, $p_1, p_2 \in E$ with $\|p_1\|_E, \|p_2\|_E < R$. Then for any $p_0 \in dom\ A$ and each $R > \|A_0^\alpha p_0\|_E$, there exists a $t^* = t^*(R, \|A_0^\alpha p_0\|_E) > 0$ such that the initial value problem

$$\frac{dp}{dt} + Ap = \hat{F}(t,p), \qquad p(0) = p_0 \tag{5.18}$$

has a unique solution on $[0,t^*]$. Furthermore, if there exists a constant $R' > 0$ such that for any solution p of (5.18) *in $[0,T_1]$, $T_1 \le T_0$, we have that $\|Ap\|_E < R'$. Then we may choose $R > R'$ and thus apply the local existence assertion to $[0,t^*]$, $[t^*, 2t^*]$, and so on, until $[0,T_0]$ is exhausted.*

Since the operator A in (5.18) was shown to be closed in X and satisfies (5.13), we need only to establish (5.17) for the function $\hat{F}$ in (5.15) to conclude the local existence of a solution to (5.1)–(5.4).

Let $(X_k, Y_k, Z_k) = A^{-\alpha}(U_k, V_k, W_k)$ for $k = 1, 2$. Then

$$\begin{aligned}
&\|\hat{F}(t_1, A^{-\alpha}(U_1, V_1, W_1)) - \hat{F}(t_2, A^{-\alpha}(U_2, V_2, W_2))\|_H \\
&\quad = \|\hat{F}(t_1, (X_1, Y_1, Z_1)) - \hat{F}(t_2, (X_2, Y_2, Z_2))\|_H \\
&\quad = \|((I - G)(X_1 - X_2), \\
&\qquad\qquad Y_1^i - Y_2^i + C^t[F(C(Q^i + Y_1^i)) - F(C(Q^i + Y_2^i))] \\
&\qquad\qquad - C^t(Z_1^i - Z_2^i), \sigma C(Y_1^i - Y_2^i) + (I - \gamma)(Z_1^i - Z_2^i))\|_H \\
&\quad \leq \|(I - G)(X_1 - X_2), 0, 0)\|_H + \|(0, Y_1^i - Y_2^i + C^t[F(C(Q^i + Y_1^i)) \\
&\qquad - F(C(Q^i + Y_2^i))] - C^t(Z_1^i - Z_2^i), 0)\|_H \\
&\qquad + \|(0, 0, \sigma C(Y_1^i - Y_2^i) + (I - \gamma)(Z_1^i - Z_2^i))\|_H.
\end{aligned}$$

Now C is an orthogonal matrix so that

$$\begin{aligned}
&\|((I - G)(X_1 - X_2), 0, 0)\|_H \\
&\quad \leq \max_{1\leq i\leq n} |1 - g_i| \, \|(X_1 - X_2, Y_1 - Y_2, Z_1 - Z_2)\|_H, \\
&\|(0, 0, \sigma C(Y_1^i - Y_2^i) + (I - \gamma)(Z_1^i - Z_2^i))\|_H \\
&\quad \leq \big(\max_i\{\sigma_i\} + \max_i |1 - \gamma_i|\big)\|(X_1 - X_2, Y_1 - Y_2, Z_1 - Z_2)\|_H, \\
&\big\|\big(0, Y_1^i - Y_2^i + C^t[F(C(Q^i + Y_1^i)) - F(C(Q^i + Y_2^i))] - C^t(Z_1^i - Z_2^i), 0\big)\|_H \\
&\qquad\qquad \leq \|(0, Y_1^i - Y_2^i, 0)\|_H + \|(0, C^t(Z_1^i - Z_2^i), 0)\|_H \\
&\qquad\qquad\qquad + \|(0, C^t[F(CQ^i + CY_1^i) - F(CQ^i + CY_2^i)], 0)\|_H \\
&\qquad\qquad \leq (2 + \max_{\substack{1\leq i\leq n \\ y\in\mathbb{R}}} |f_i'(y)|)\|(X_1 - X_2, Y_1 - Y_2, Z_1 - Z_2)\|_H.
\end{aligned}$$

Therefore

$$\begin{aligned}
\|\hat{F}(t_1, A^{-\alpha}(U_1, V_1, W_1)) - \hat{F}(t_2, A^{-\alpha}(U_2, V_2, W_2))\|_H& \\
\leq C(R)\|(X_1 - X_2, Y_1 - Y_2, Z_1 - Z_2)\|_H&,
\end{aligned} \tag{5.19}$$

where

$$C(R) = \max_{1\leq i\leq n} |1 - g_i| + \max_{1\leq i\leq n} \sigma_i + \max_{1\leq i\leq n} |1 - \gamma_i| + 2 + \max_{\substack{1\leq i\leq n \\ y\in\mathbb{R}}} \{|f_i'(y)|\}.$$

Hence $\hat{F}$ satisfies condition (5.17), and the system (5.15)–(5.16) has unique solution $P = (U, V, W)$ with the initial value $P_0 = (U_0, V_0, W_0)$ at $t = 0$ satisfying $\|A^\alpha P_0\|_H \leq R$.

To prove global existence, we must show that $\|A(U, V, W)\|_H$ is bounded for any solution $P = (U, V, W)$. By (5.19),

$$\|\hat{F}(U, V, W)\|_H \leq C(R)\|(U, V, W)\|_H. \tag{5.20}$$

If $\|(U, V, W)\|_H$ and $\|(U_t, V_t, W_t)\|_H$ are bounded, then by (5.15)–(5.16), we can see that $\|A(U, V, W)\|_H$ is bounded.

Let

$$E(t) = (\|(U, V, W)\|_H^2 + \|(U, V, W)_t\|_H^2)/2.$$

Then $E(t)$ is a Lyapunov function and its derivative is given by

$$\begin{aligned}
E'(t) &= \int_{\mathbb{R}} \{(\langle U, \Lambda U_t\rangle + \langle U_t, \Lambda U_{tt}\rangle) \\
&\qquad + \sum_{\mathbb{Z}} (\langle V_t, V_{tt}\rangle + \langle V_t, V\rangle + \langle W, W_t\rangle + \langle W_t, W_{tt}\rangle)\} \\
&= \int_{\mathbb{R}} \{\langle U, \Lambda U_{xx} - \Lambda GU\rangle + \langle U_t, (\Lambda U_{xx} - \Lambda GU)_t\rangle\} \\
&\qquad + \sum_{i\in\mathbb{Z}} \{\langle V_t^i, \Lambda[V_{tx}]_i + C^t(DF)CV_t^i - C^tW_t^i\rangle \\
&\qquad\qquad + \langle V^i, \Lambda[U_x]_i + C^tDF(CQ^i + \theta CV^i)CV^i - C^tW^i\rangle \\
&\qquad\qquad + \langle W^i, \sigma CV^i - \gamma W^i\rangle + \langle W_t^i, \sigma CV_t^i - \gamma W_t^i\rangle\} \\
&= J_1(t) + J_2(t),
\end{aligned}$$

where

$$\begin{aligned}
J_1(t) &= -\int_{\mathbb{R}} \{\langle U, \Lambda GU\rangle + \langle U_t, \Lambda GU_t\rangle + \langle U_x, \Lambda U_x\rangle + \langle U_{xt}, \Lambda U_{xt}\rangle\}, \\
J_2(t) &= \sum_{i\in\mathbb{Z}} \{\langle V_t^i, C^t(DF)CV_t^i\rangle - \langle V_t^i, C^tW_t^i\rangle \\
&\qquad + \langle V^i, C^tDF(CQ^i + \theta CV^i)CV^i\rangle - \langle V^i, C^tW^i\rangle \\
&\qquad + \langle W^i, \sigma CV^i\rangle - \langle W^i, \gamma W^i\rangle + \langle W_t^i, \sigma CV_t^i\rangle - \langle W^i, \gamma W_t^i\rangle\}.
\end{aligned}$$

Notice that if $B(x) = (b_{ij}(x))_{n\times n}$ is any bounded matrix then for any vector $u \in \mathbb{R}^n$, $v \in \mathbb{R}^n$,

$$\langle u, Bv\rangle \le \frac{n^2}{2} \max_x |b_{ij}(x)|(\|u\|^2 + \|v\|^2).$$

DF is a bounded matrix. Thus we can find a constant $K_1 > 0$ such that

$$J_2(t) \le K_1 \sum_{i\in\mathbb{Z}} (\|V^i\|^2 + \|V_t^i\|^2 + \|W_t^i\|^2 + \|W^i\|)^2.$$

Letting $K_2 = 2\max\{K_1, \{\lambda_i g_i, \lambda_i : i = 1, 2, \cdots, n\}\}$, we have that

$$E'(t) \le K_2 E(t).$$

Therefore

$$E(t) \le E(0)e^{K_2 t} \le E(0)e^{K_2 T_0} \quad \text{for } 0 \le t \le T_0. \tag{5.21}$$

By the definition of $E(t)$, there is a constant $R_1(T_0)$, such that

$$\|(U, V, W)\|_H \le R_1(T_0) \text{ and } \|(U, V, W)_t\|_H \le R_1(T_0).$$

By (5.15) and (5.20), we can find an $R' > 0$ such that

$$\|A(U, V, W)\|_H < R'.$$

Combining this with Lemma 5.3 we have just proved the following theorem.

THEOREM 5.4. *If* $p_0 = (U, V, W)|_{t=0} \in X$ *and* $DF(u) = diag\{f_1'(u_1), f_2'(u_2), \cdots, f_n'(u_n)\}$ *is bounded, then the problem* (1.4)–(1.8) *has a unique solution* $(U, V, W) \in X$ *for all* $t > 0$.

STABILITY AND HOPF BIFURCATION OF STEADY STATE SOLUTIONS OF A SINGULARLY PERTURBED REACTION-DIFFUSION SYSTEM*

ROBERT GARDNER†

Abstract. This paper presents a stability analysis of steady state solutions of a singularly perturbed reaction-diffusion system which arises as a model for predator-prey interactions. This is the first illustration of the application of a topological invariant for systems of boundary value problems called the *stability index*, recently introduced by C. Jones and the author, which counts the multiplicity of unstable eigenvalues of the linearized equations. The main results are as follows:

(i) It is shown that the spectrum σ of the linearized operator is approximated by the spectrum σ_R of a certain reduced operator defined in the small parameter limit.

(ii) Under additional assumptions on the parameters σ_R is characterized in two cases. In the first case stability is obtained for all interval sizes L, while in the second case, countably many Hopf bifurcations occur as L is increased.

1. Introduction.

We will study the diffusive predator-prey system with Dirichlet conditions

$$(1.1)\qquad \begin{aligned} &u_t = u_{xx} + f(u, v), && u(\pm L, t) = 0,\\ &v_t = \varepsilon^2 v_{xx} + g(u, v), && v(\pm L, t) = 0, \end{aligned}$$

$$(1.2)\qquad \begin{aligned} &f(u, v) = h(u) - uv = u(b-u)(u-a) - uv,\\ &g(u, v) = m(u-\gamma)v - v^2. \end{aligned}$$

Here u and v are the population densities of prey and predator species, respectively. The parameters m, a, b, γ are all positive; we assume further that $0 < a < \gamma < b$. In the absence of diffusion and boundary conditions, the kinetic equations associated with (1.1) admit a stable rest point at the origin and interior to the positive quadrant, either a stable rest point or a stable limit cycle, depending on the values of m and γ.

The object of this paper is to discuss the stability of steady state solutions of (1.1), i.e., functions $(U(x), V(x))$ satisfying

$$(1.3)\qquad \begin{aligned} &\ddot{U} + f(U, V) = 0, && U(\pm L) = 0,\\ &\varepsilon^2 \ddot{V} + g(U, V) = 0, && V(\pm L) = 0, \end{aligned}$$

wherein both components are positive; such solutions will be called *positive solutions.* The existence of a global continuum of such solutions which bifurcates as ε decreases from a solution in which $v \equiv 0$ was proved by Conway, Gardner, and Smoller [2]; see also Li [11] and Li and Lloyd [12]. The asymptotic behavior and in certain cases the uniqueness of this branch as $\varepsilon \to 0$ was discussed by Dancer [3]. In brief, we show that if ε is sufficiently small and if the other parameters are suitably chosen, then in one case, such solutions are linearly stable for all interval sizes L for which positive solutions

exist, while in a second case, the positive solution undergoes countably many Hopf bifurcations as L increases. Thus we show that if $\mathscr{L}$ is the linearized operator about such a solution, then the spectrum of $\mathscr{L}$ either lies entirely in the stable half plane $\operatorname{Re}\lambda < 0$, or, as L is increased, pairs of complex conjugate eigenvalues cross the imaginary axis $\operatorname{Re}\lambda = 0$. A precise statement of the main results is given in § 5.

It is well known for this class of equations that nonlinear stability and bifurcation are correctly predicted by the linearized analysis (see Henry [10]). In regard to large amplitude solutions of systems such as (1.3), the difficult aspect of this procedure is to determine the number and location of any unstable eigenvalues of $\mathscr{L}$. Some new methods for analyzing this question for boundary value problems were recently introduced by Gardner and Jones [7]. Similar methods with applications were previously introduced by Alexander, Gardner, and Jones [1], and by Gardner and Jones [8], [9] for traveling waves; this paper presents the first illustration of how these methods work in the stability analysis of a specific boundary value problem. In either setting, the main constructions are a complex vector bundle $\mathscr{E}(K)$ over a real 2-sphere, and an analytic function $D(\lambda)$ of the eigenvalue parameter, called the Evans function. $D(\lambda)$ is essentially the Wronskian of certain distinguished solutions of the linearized equations; its roots, counting order, coincide with the eigenvalues of $\mathscr{L}$, counting multiplicity. The main result in [7] asserts that if $K \subset \mathbb{C}$ is a simple closed curve which is disjoint from the spectrum of $\mathscr{L}$, then a certain topological invariant $c_1(\mathscr{E}(K))$, called the first Chern number of $\mathscr{E}(K)$, is an integer which is equal to the number of eigenvalues of $\mathscr{L}$ inside K (counting multiplicity). In many situations, including the problem at hand, it is possible to show that all potentially unstable eigenvalues of $\mathscr{L}$ lie in some large but fixed contour K containing $\lambda = 0$ in its interior. For such K, the underlying solution will be stable (unstable) if this invariant is equal to (greater than) zero; we therefore call $c_1(\mathscr{E}(K))$ the *stability index*.

The main concern here is to illustrate the application of the stability index to the problem described above. However, we shall briefly describe some of the main points of the general theory. The principal observation is that the candidates for eigenfunctions are the solutions of the linearized equations (written as a first-order system) which satisfy the boundary conditions at $x = -L$. These solutions span certain n-dimensional subspaces $\Phi(x, \lambda)$ of $\mathbb{C}^{2n}$ which are parametrized both by $x \in [-L, L]$ and by the eigenvalue parameter λ. Another way to say this is that they form a vector bundle over the base space $[-L, L] \times \mathbb{C}$. If λ is restricted to lie in K, it turns out that the twisting of these vector spaces over $[-L, L] \times K$ determines the number of eigenvalues of $\mathscr{L}$ inside K. The actual construction of $\mathscr{E}(K)$ consists of taking certain algebraic quotients of vector spaces associated with $\Phi(x, \lambda)$, and then gluing on suitable fibers over the "caps," $\{\pm L\} \times K^\circ$, where K° is the interior of K. The result is a bundle $\mathscr{E}(K)$ over a base space B,

$$B = \{-L\} \times K^\circ \cup [-L, L] \times K \cup \{L\} \times K^\circ,$$

which is topologically a 2-sphere. The quotient and gluing procedures are performed in such a manner that c_1 of the resulting bundle $\mathscr{E}(K)$ coincides with the winding number of the curve $D(K)$, and therefore measures the number of eigenvalues of $\mathscr{L}$ inside K. These ideas were motivated and developed at length in [1], [7] and [8], and the interested reader is referred to these papers for additional details.

These tools are of particular significance when the underlying solution is constructed by a singular perturbation procedure. In this setting the vector spaces $\Phi(x, y)$, and hence, $\mathscr{E}(K)$, frequently admit a direct sum decomposition where the summands are related to certain fast or slow behavior of solutions of the linearized equations. In other words, $\mathscr{E}(K)$ admits a Whitney sum decomposition

$$\mathscr{E}(K)=\bigoplus_{\mathrm{i}=1}^{\mathrm{k}}\mathscr{E}_{\mathrm{i}}(\mathrm{K})$$

of subbundles $\mathscr{E}_i(K)$ of $\mathscr{E}(K)$. The additive property of c_1,

$$c_1(\mathscr{E}(K))=\sum_{i=1}^{k}c_1(\mathscr{E}_i(K)),$$

provides a mechanism for computing the stability index. In particular, the topological character of c_1 permits the passage to a limit as the small parameter, say ε, tends to zero. This permits us to identify certain reduced eigenvalue problems obtained directly from the equations with $\varepsilon=0$, which, working backwards, can then be used to predict the number and location of the eigenvalues of the perturbed problem with $\varepsilon>0$. In the problem at hand, the bundle $\mathscr{E}(K)$ is two-dimensional. A Whitney sum decomposition,

$$\mathscr{E}(K)=\mathscr{E}_1(K)\oplus\mathscr{E}_2(K),$$

will be obtained where $\mathscr{E}_1(K)$ and $\mathscr{E}_2(K)$ are complex line bundles over B, which correspond, respectively, to fast and slow behavior in the linearized equations. It turns out that $\mathscr{E}_1(K)$ is trivial, so that $c_1(\mathscr{E}_1(K))=0$. The bundle $\mathscr{E}_2(K)$ is more complicated to analyze. In the limit of the small parameter ε at $\varepsilon=0$, the reduced eigenvalue problem associated with $\mathscr{E}_2(K)$ is

$$\ddot{P}=\left[(\lambda-\bar{f})-\frac{\bar{f}_v\bar{g}_u}{\lambda-\bar{g}_v}\right]P,\qquad P(-L)=P(L)=0, \tag{1.4}$$

where the partials $\bar{f}_u, \bar{f}_v, \bar{g}_u, \bar{g}_v$ are evaluated at the singular limit

$$(\bar{U}(x),\ \bar{V}(x))=\lim_{\varepsilon\to0}(U(x,\varepsilon),\ V(x,\varepsilon)). \tag{1.5}$$

The second half of the paper is devoted to the spectral analysis of problem (1.4) and is independent of the previous material. Even though (1.4) is a scalar equation, it is complicated by the fact that the eigenvalue parameter λ enters into the potential in a nonlinear, nonstandard manner; this is because it is really an eigenvalue problem for a system. Furthermore, it has variable coefficients. This is therefore not a routine computation, and we found it necessary to make some additional assumptions about the parameters in order to characterize its spectrum. Our main hypothesis is that the parameter m, which is the slope of $g=0$ in Fig. 2.2, is large. The principal tool that is used is Sturm–Liouville theory; in particular, we analyze the associated projectivized problem on $\mathbb{C}P^1$ which, in the local coordinate $z=\dot{P}/P$, is just

$$\dot{z}=G(x,\lambda)-z^2,\qquad z(-L)=\infty, \tag{1.6}$$

where $G(x,\lambda)$ is the potential in (1.4). In the stable case we show that λ with $\operatorname{Re}\lambda\geqq0$ is not an eigenvalue by locating certain invariant regions for (1.6) which keep the solution of (1.6) away from the boundary conditions $z=\infty$ at $x=+L$. In the unstable case we employ a topological argument to prove the existence of pure imaginary eigenvalues for large L. The exact eigenvalue count is then obtained by proving that $\operatorname{Re}\lambda'(L)>0$ whenever $\lambda(L)$ is a pure imaginary eigenvalue. We remark that there is an advantage to using the stability index in bifurcation problems. In particular, since the Evans function $D^{\varepsilon}(\lambda)$ for the perturbed problem uniformly approximates the Evans function $D^*(\lambda)$ for the reduced problem, and since they are both analytic, the transverse crossing of eigenvalues for the reduced problem implies transversality for the perturbed problem. Indeed, this is how we prove transversality here when $\varepsilon > 0$. This idea was introduced by Terman [14] in his stability analysis of the combustion equations.

We finally remark that Dancer has concurrently presented a stability analysis of solutions of the same equations using quite different methods (see [4]). It is also likely that the singular limit eigenvalue problem (SLEP) method could be used as well; see [6].

2. Preliminaries.

2.1. Positive solutions. The equations

$$\ddot{U}+f(U,V)=0, \qquad \varepsilon^2\ddot{V}+g(U,V)=0 \tag{2.1}$$

admit branches of solutions with $V(x)\equiv 0$. The u-component then satisfies the scalar equation

$$\ddot{U}+h(U)=0, \qquad U(-L)=U(L)=0. \tag{2.2}$$

There is a critical interval size L_h such that (2.2) has only the zero solution $U\equiv 0$ for $L<L_h$, and three solutions $0<U_1(x)<U_2(x)$ for $L>L_h$ (see [13]). This is obtained through an analysis of the "time map" associated with (2.2),

$$T(p)=\int_0^{U(p)} \frac{du}{\sqrt{2H(u)-H(U(p))}}$$

where $T(p)$ becomes infinite as $p\to 0, \bar{p}$ and has a unique local minimum at some $p^*\in(0,\bar{p})$; thus $L_h=2T(p_*)$ (see Fig. 2.1). The zero solution and $U_2(x)$ are stable, while $U_1(x)$ is unstable relative to the evolution equation associated with (2.2).

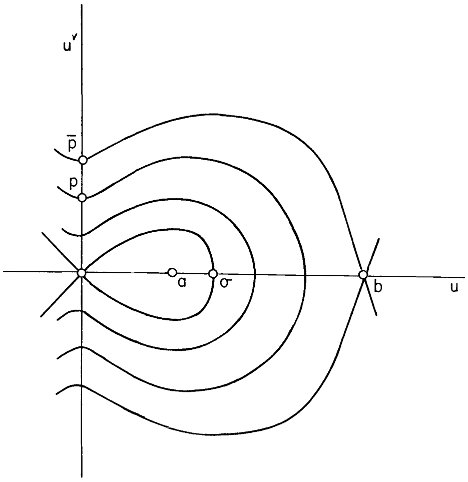

FIG. 2.1

In [2], Conway, Gardner, and Smoller show that if $L>L_h$ is fixed, then as a solution of (1.1) the solution $(U_2(x),0)$ is stable if ε is sufficiently large, but that as ε is decreased, a positive steady solution bifurcates from $(U_2(x),0)$, and stability is transferred to the bifurcating branch. However, the stability of the bifurcating branch far from the bifurcation point was left unresolved.

In a pair of papers, Dancer [3], [4] characterized several interesting properties of the branch of positive solutions of (2.1). In particular, he showed that the bifurcating

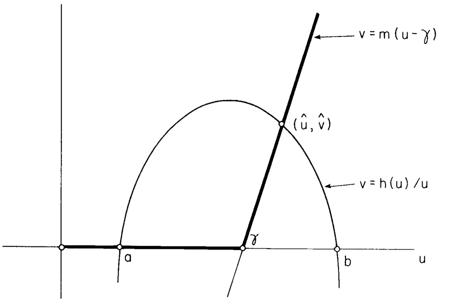

FIG. 2.2

branch $(U(x, \varepsilon), V(x, \varepsilon))$ continues globally as $\varepsilon \to 0$. Furthermore, he calculated the limit in (1.5), by showing that $(\bar{U}(x), \bar{V}(x))$ satisfies a certain reduced equation, which is obtained from (2.1) by setting $\varepsilon = 0$. The second equation $g = 0$ is then algebraic, and is satisfied whenever $v = 0$ or $v = m(u - \gamma)$. Let $p(u)$ denote the Lipschitz continuous function

$$p(u) = \begin{cases} 0 & \text{if } u \leqq \gamma, \\ m(u-\gamma) & \text{if } u \geqq \gamma. \end{cases}$$

The correct reduced equation for (2.1) when $\varepsilon = 0$ is then

$$\ddot{U} + r(U, m, \gamma) = 0, \qquad U(-L) = U(L) = 0, \tag{2.3}$$

where

$$r(U;\, m, \gamma) = (f(U), p(U)).$$

Since $a < \gamma < b$ it is easily seen that $r(U;\, m, \gamma)$ is qualitatively a cubic with roots at zero, a, and $\hat{u} \in (a, b)$, (see Fig. 2.2). In [2], the reduced problem (2.3) was studied by the time map procedure mentioned above in connection with (2.2). It was shown there that there is a unique $L_r > L_h$ such that (2.3) has exactly three solutions $0 < U_1(x;\, m, \gamma) < U_2(x;\, m, \gamma)$ for $L > L_r$ and only the zero solution for $L < L_r$. As in the case of (2.2), the zero solution and U_2 are (linearly) stable relative to the evolution equation associated with (2.3). Furthermore, branch $(U(x, \varepsilon), V(x, \varepsilon))$, which bifurcates from $U_2(x), 0)$ as ε decreases, tends to the limit

$$U_2(x;\, m, \gamma), p(U_2(x;\, m, \gamma))$$

as $\varepsilon \to 0$ (see Dancer [3]). This seems to suggest that $(U(x, \varepsilon), V(x, \varepsilon))$ is also an attractor. This, as it turns out, is not always the case. The reason for this is that the correct linearized eigenvalue problem for (2.1) when $\varepsilon = 0$ is (1.4), which is quite different from the equation obtained by linearizing (2.3) at $U_2(x;\, m, \gamma)$.

We summarize these results in the following theorem.

THEOREM 2.1. *There exists a positive branch of solutions* $(U(x, \varepsilon), V(x, \varepsilon))$ *of* (1.3) *for all* $\varepsilon \in (\varepsilon_0, 0)$ *for some* $\varepsilon_0 > 0$. *The limit* $(\bar{U}(x), \bar{V}(x))$ *as* $\varepsilon \to 0$ *of this branch exists. Furthermore,* $\bar{V}(x) = p(U_2(x;\, m, \gamma))$ *is Lipschitz continuous, and* $U_2(x;\, m, \gamma) = \bar{U}(x)$ *is the stable positive solution of* (2.3). *The limit is uniform in x.*

3. The linearized equations.

3.1. Notation. The linearization of (1.3) about $(U(x, \varepsilon), V(x, \varepsilon))$ yields a second-order linear operator $\mathscr{L}$ with domain $X = [H^2(-L, L) \cap H_0^1(-L, L)]^2$ given by

$$\mathscr{L}\begin{pmatrix} P \\ R \end{pmatrix} = \begin{pmatrix} \ddot{P} + f_u P + f_v R \\ \varepsilon^2 \ddot{R} + g_u P + g_v R \end{pmatrix}. \tag{3.1}$$

The partials f_u, f_v, g_u, and g_v are all evaluated at $(U(x, \varepsilon), V(x, \varepsilon))$. The stability of the solution is determined by the spectrum of $\mathscr{L}$; hence, we consider the eigenvalue problem

$$\mathscr{L}\begin{pmatrix} P \\ R \end{pmatrix} = \lambda \begin{pmatrix} P \\ R \end{pmatrix}, \quad \begin{pmatrix} P \\ R \end{pmatrix} \in X. \tag{3.2}$$

In order to implement the theory in [5] it is convenient to rewrite (3.2) as a first-order system:

$$\begin{aligned} \dot{P} &= Q, & \varepsilon \dot{R} &= S, \\ \dot{Q} &= (\lambda - f_u)P - f_v R, & \varepsilon \dot{S} &= -g_u P + (\lambda - g_v)R. \end{aligned} \tag*{$(3.3)_s$}$$

It will be desirable to express $(3.3)_s$ in vector form. To this end let $Y = (P, Q, R, S)^t \in \mathbb{C}^4$ and let $A(x, \lambda, \varepsilon)$ be the coefficient matrix obtained by multiplying the last two equations in $(3.3)_s$ by ε^{-1}; thus (3.3) can be expressed as

$$\dot{Y} = A(x, \lambda, \varepsilon) Y. \tag*{$(3.3)_s$}$$

In this scaling, the transition layer in the derivative of u when $u = \gamma$ is of width $\mathcal{O}(\varepsilon)$. Since this system focuses on the slow behavior for $u \neq \gamma$ we shall call $(3.3)_s$ the *slow system.*

It will also be convenient to rescale x by setting $\xi = \varepsilon^{-1} x$ and introducing fast variables,

$$p, q, r, s \text{ (at } \xi) = P, Q, R, S \text{ (at } \varepsilon\xi).$$

The equations for p, q, r, s are then easily seen to be

$$\begin{aligned} p' &= \varepsilon q, & r' &= s, \\ q' &= \varepsilon[(\lambda - f_u)p - f_v r], & s' &= -g_u p + (\lambda - g_v) r. \end{aligned} \tag*{$(3.3)_f$}$$

The partials are now evaluated at $(u(\xi, \varepsilon), v(\xi, \varepsilon)) = (U(\xi\varepsilon, \varepsilon), V(\xi\varepsilon, \varepsilon))$. Setting $y = (p, q, r, s)^t \in \mathbb{C}^4$ and $a(\xi, \lambda, \varepsilon)$ to be the coefficient matrix in $(3.3)_f$ we obtain the equivalent vector form

$$y' = a(\xi, \lambda, \varepsilon) y. \tag*{$(3.3)_f$}$$

The range of ξ is now the interval $|\xi| \leqq L_\varepsilon$ where $L_\varepsilon = L\varepsilon^{-1}$.

The boundary conditions for Y are that $P, R = 0$ at $x = \pm L$. Let U be the two-dimensional subspace of $\mathbb{C}^4$:

$$U = \{(0, Q, 0, S)^t \colon Q, S \in \mathbb{C}\}. \tag{3.4}$$

A geometric condition for λ to be an eigenvalue is that $Y(x) \in U$ at $x = \pm L$. In the fast scaling, the condition is that $y(\xi) \in U$ at $\xi = \pm L_\varepsilon$.

3.2. A crude estimate for $\sigma(\mathscr{L})$. Let $K \subset \mathbb{C}$ be the simple curve depicted in Fig. 3.1. More precisely K is the union of four segments $l_A \cup l_+ \cup l_* \cup l_-$, where l_* is the vertical segment connecting $\pm i\delta$ along the imaginary axis, l_A is the indicated portion of the circle $|\lambda| = A$, and l_+, l_- are segments connecting $i\delta, -i\delta$ to $|\lambda| = A$ which make an angle ϕ with the imaginary axis. Let $L_\pm$ be the ray with initial point at $\pm i\delta$ which coincides with $l_\pm$, and define

$$S_\phi = \{\lambda \in \mathbb{C} \colon \lambda \text{ lies to the right of } L_+ \cup l_* \cup L_-\}. \tag{3.5}$$

LEMMA 3.1. *There exists $\phi > 0$ sufficiently small and $A > 0$ sufficiently large such that if $\lambda \in S_\phi$ with $|\lambda| \geqq A$, then λ is* not *an eigenvalue of $\mathscr{L}$. The constants ϕ and A are independent of ε for $0 < \varepsilon \leqq \varepsilon_0$ for some $\varepsilon_0 > 0$.*

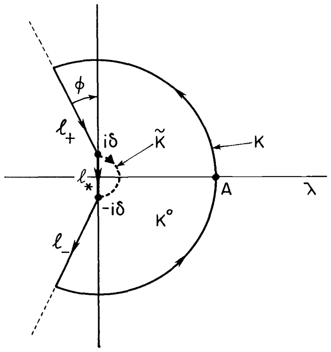

FIG. 3.1

We shall give only a brief sketch of the proof of this lemma since it follows with minor modifications from arguments in [1] and [8]. Let $\delta = |\lambda|^{-1/2}$ and $\psi = \arg \lambda$, and change scales in $(3.3)_s$ by setting $x = \delta z$. In suitably rescaled variables the equations are now

$$(3.6) \qquad \begin{aligned} \dot{P} &= Q, & \varepsilon \dot{R} &= S, \\ \dot{Q} &= (e^{i\psi} - \delta^2 f_u)P - \delta^2 f_v R, & \varepsilon \dot{S} &= -\delta^2 g_u P + (e^{i\psi} - \delta^2 g_v)R. \end{aligned}$$

If ψ is such that $\lambda \in S_\phi$, the coefficient matrix of (3.6) is uniformly hyperbolic as *both* ε and δ tend to zero. There is a pair of uniformly slow eigenvalues as $\delta \to 0$ that tend to $\pm e^{i\psi/2}$, and a pair of uniformly fast eigenvalues that tend to $\pm\varepsilon^{-1} e^{i\psi/2}$ as $\delta \to 0$. The crucial observation is that the fast eigenvalues remain uniformly separated from the slow eigenvalues as both ε and δ tend to zero. This is used to control the behavior of the two-dimensional subspace $\Phi(x, \lambda, \varepsilon)$ satisfying the boundary conditions at $x = -L$. This is accomplished by considering the flow induced by (3.6) on the space of complex lines in $\mathbb{C}^4$ or $\mathbb{C}P^3$ (see also § 5, below). The eigenvector e_f associated with the fast unstable eigenvalue $\varepsilon^{-1} e^{i\psi/2}$ of (3.6) represents a point in $\mathbb{C}P^3$ which is essentially an attracting rest point that is uniform in its attraction property as both ε and δ tend to zero. It turns out that Φ contains a one-dimensional subspace of solutions which is rapidly attracted to the span of e_f under the flow induced by (3.6) on $\mathbb{C}P^3$. This line of solutions therefore remains bounded away from the subspace U of boundary conditions for all $|x| \leqq L$.

The slow subspace of (3.6) is spanned by the two eigenvectors e_s and f_s associated with the eigenvalues tending, respectively, to $e^{i\psi/2}$ and $-e^{i\psi/2}$ as $\delta \to 0$. It follows from an invariant manifold theorem due to Fenichel (see [5]) applied to the projectivized flow on $\mathbb{C}P^3$ induced by (3.6) that there is a slow, two-dimensional subspace $\Psi(x, \lambda, \varepsilon)$ of solutions of the perturbed problem (3.6) that remains close to the slow subspace, Span$\{e_s, f_s\}$ for all x. More precisely, there is an invariant manifold $\hat{\mathcal{M}}$ for the projectivization of (3.6) that remains near the image of Span$\{e_s, f_s\}$ in $\mathbb{C}P^3$. The subspace Ψ is $\pi^{-1}\hat{\mathcal{M}}$ where $\pi : \mathbb{C}^4 \to \mathbb{C}P^3$ is the projection map. Since $\Phi(-L, \lambda) = U$ and U contains a slow direction, it follows that the intersection $\Phi \cap \Psi$ is one-dimensional. It follows that Φ contains a slow line of solutions that is rapidly attracted to the slow unstable direction spanned by e_s, since the latter is an attractor for the projectivized flow on $\mathbb{C}P^3$ relative to the flow in the invariant manifold $\hat{\mathcal{M}}$.

It follows that Φ contains two distinct solutions; the fast solution is attracted to the fast unstable direction e_f and the slow solution is attracted to the slow unstable direction e_s. In particular, Φ will lie near the space spanned by e_f and e_s at $x = L$. It is then immediate that $\Phi(L, \lambda, \epsilon)$ is transverse to the space U of boundary conditions for all small ε and δ. Additional details can be found in [1], [6], [7].

Remark. Lemma 3.1 shows that any potentially unstable eigenvalue λ of $\mathscr{L}$, i.e., any λ for which $\operatorname{Re}\lambda \geqq 0$, necessarily lies interior to the compact loop K, where K is independent of ε.

3.3. Construction of $\mathscr{E}$(K, ε). We can now describe the construction of the bundle $\mathscr{E}(K, \varepsilon)$. It will be convenient to use the slow system in $(3.3)_s$. Let

$$u_1 = (0, 0, 0, 1)^t, \qquad u_2(\gamma) = (0, 1, 0, \gamma)^t,$$

so that $U = \operatorname{Span}\{u_1, u_2(\gamma)\}$ is the subspace of $\mathbb{C}^4$ representing the boundary conditions. The parameter γ will need to be chosen carefully later. We will denote $u_2(0)$ simply by u_2. Let $V = U^{\perp}$, so that $V = \operatorname{Span}\{v_1, v_2\}$, where

$$v_1 = (0,0,1,0)^t, \qquad v_2 = (1, 0, 0, 0)^t.$$

The vector bundle $\mathscr{E}(K, \varepsilon)$ will be specified by a triple (E, B, π), where E is the total space, B is the base space, and $\pi : E \to B$ is the projection map. The base space B is homeomorphic to a real 2-sphere. It is defined as the union $B = B_l \cup B_* \cup B_r$, where

$$\begin{aligned} B_l &= \{-L\} \times \overline{K^\circ} && \text{(left cap)},\\ B_* &= [-L, L] \times K && \text{(sides)},\\ B_r &= \{+L\} \times \overline{K^\circ} && \text{(right cap)}. \end{aligned}$$

The total space E will be a certain subset of the trivial bundle $B \times [\mathbb{C}^4/V \times \mathbb{C}^4/U] \approx B \times \mathbb{C}^4$. The fibers over the caps are defined to be

$$E_l = B_l \times [\mathbb{C}^4/V \times \{\bar{0}\}], \qquad E_r = B_r \times [\{\bar{0}\} \times \mathbb{C}^4/U].$$

Here, $\bar{0}$ will be used to denote the zero element of either $\mathbb{C}^4/U$ or $\mathbb{C}^4/V$; which space is intended will be clear from the context.

It remains to define E over B_*. To this end, let $\Phi_i(x, \lambda, \varepsilon)$, $i = 1, 2$, be the solutions of $(3.3)_s$ satisfying

$$(3.7) \qquad \Phi_1(-L, \lambda, \varepsilon) = u_1, \qquad \Phi_2(-L, \lambda, \varepsilon) = u_2(\gamma).$$

Given $b = (x, \lambda) \in B$ let $x(b) = x$. We define sections $\chi_i : B_* \to B_* \times \mathbb{C}^4/V \times \mathbb{C}^4/U$ by

$$\chi_i(b, \varepsilon) = \left(\frac{L - x(b)}{2L}\Phi_i(b, \varepsilon) + V, \Phi_i(b, \varepsilon) + U\right).$$

The fibers of E over B_* are defined to be

$$E_* = \{(b, \operatorname{Span}\{\chi_1(b, \varepsilon), \chi_2(b, \varepsilon)\}) : b \in B_*\}.$$

Definition. The bundle $\mathscr{E} = \mathscr{E}(K, \varepsilon)$ is defined to be (E, B, π), where

$$E = E_l \cup E_* \cup E_r,$$

$$\pi^{-1}(b) = \begin{cases} \mathbb{C}^4/V \times \{\bar{0}\} & \text{if } b \in B_l,\\ \operatorname{Span}\{\chi_1(b, \varepsilon), \chi_2(b, \varepsilon)\} & \text{if } b \in B_*,\\ \{\bar{0}\} \times \mathbb{C}^4/U & \text{if } b \in B_r. \end{cases}$$

In order to check that this is indeed a bundle we need to check the local triviality condition where the caps fit onto the sides, i.e., over $\partial B_l \cap B_*$ and $\partial B_r \cap B_*$. This is clear for the former set by virtue of the definition of Φ_i, and hence, χ_i at $x = -L$. In particular, Φ_1 and Φ_2 span U at $x = -L$ and U complements V. At $x = +L$, Φ_1 and

Φ_2 may indeed fail to complement U; this occurs precisely when λ is an eigenvalue. Thus we see that if λ is *not* an eigenvalue of $\mathscr{L}$ for all $\lambda \in K$ then $\mathscr{E}(K, \varepsilon)$ forms a bundle over B (see [7] for further details). Although this is generally the case for most curves K, $\mathscr{E}$ depends on the parameter ε. Since we shall need to let $\varepsilon \to 0$ to compute $c_1(\mathscr{E}(K, \varepsilon))$, such a generic result would not be particularly useful. Thus we shall need to locate curves K as in Fig. 3.1 which are disjoint from the spectrum of $\mathscr{L}$ for all sufficiently small ε. It follows from Lemma 3.1 that if ϕ, A are suitably chosen then the portion of K along which $|\lambda| = A$ always satisfies this condition. It is the portion of K near the imaginary axis where all the action occurs. We shall check this condition in § 4 by using the reduced problem (1.4) defined at $\varepsilon = 0$ to obtain sufficient control over the solutions $\Phi_1(x, \lambda, \varepsilon)$ and $\Phi_2(x, \lambda, \varepsilon)$ used in the definition of $\mathscr{E}(K, \varepsilon)$ to approximate them at $x = L$. These solutions will also play an important role in obtaining the Whitney sum decomposition

$$\mathscr{E}(K, \varepsilon) = \mathscr{E}_1(K, \varepsilon) \oplus \mathscr{E}_2(K, \varepsilon),$$

which will be used later to compute $c_1(\mathscr{E}(K, \varepsilon))$.

3.4. Critical eigenvalues. A *critical eigenvalue* λ_ε of $\mathscr{L}$ is a branch of eigenvalues that tend to zero as $\varepsilon \to 0$. Such eigenvalues typically occur in the linearization about solutions with transition layers (see Fujii and Nishiura [6]). Here the singular limit $(\bar{U}(x), \bar{V}(x))$ is *continuous*, and it happens that there are no critical eigenvalues. More precisely, we have the following lemma, which generalizes a result of Dancer [3, Lemma 2].

LEMMA 3.2. *There exists* $\varepsilon_0 > 0$ *and* $\delta > 0$ *such that* $\{\lambda: \operatorname{Re} \lambda \geqq 0$ *and* $|\lambda| \leqq \delta\}$ *is in the resolvent set of* $\mathscr{L}$ *for all* $\varepsilon \in (0, \varepsilon_0]$.

Proof. Suppose to the contrary that there exists a sequence $\varepsilon_n \to 0$ for which there exist $\lambda_n \to 0$ with $\operatorname{Re} \lambda_n \geqq 0$ and an associated sequence of eigenfunctions (P_n, R_n) of $\mathscr{L}$ associated with the eigenvalues λ_n. We shall drop the subscript n and normalize the eigenfunction so that $\|P\|^2_{L^2} + \|R\|^2_{L^2} = 1$. The proof consists of showing that (i) (P, R) converges to a limit $(\bar{P}, \bar{R})$ in an appropriate sense, where $\bar{P}$ satisfies the variational equation obtained by linearizing (2.3) about $\bar{U}(x)$, and (ii) $\bar{P}$ does not vanish identically. Together, these imply that $\bar{U}(x)$ is a linearly degenerate solution of (2.3). However, from [2], it is known that $\bar{U}(x)$ is a linearly nondegenerate solution of [2.3], yielding the desired contradiction.

To prove (i) we note that from the first equation in (3.2), $\{P\}$ is uniformly bounded in $H^2 \cap H^1_0$ and therefore some subsequence converges weakly in H^2 and therefore strongly in H^1_0 to an H^2 limit $\bar{P}$. In particular, P converges to $\bar{P}$ uniformly on $[-L, L]$. Since $\{R\}$ is bounded in L^2 some further subsequence converges weakly in L^2 to a limit $\bar{R}$ with $\|\bar{R}\|_{L^2} \leqq 1$. From the second equation in (3.2) we have for all $\psi \in C^\infty_0(-L, L)$ that

$$\int_{-L}^{L} [\varepsilon^2 \ddot{\psi} R + \psi(g_u P + (g_v - \lambda))]\, dx = 0.$$

It follows that $(g_v - \lambda)R$ is weakly convergent in L^2 to both $\bar{g}_v \bar{R}$ and to $-\bar{g}_u \bar{P}$; it follows that $\bar{R} = -(\bar{g}_u / \bar{g}_v)\bar{P}$ whenever $\bar{g}_v \neq 0$. Since

$$\bar{g}_v = -m|\bar{U}(x) - \gamma|$$

is only zero at two values of x in $(-L, L)$ it follows that $\bar{R} = -(\bar{g}_u / \bar{g}_v)\bar{P}$ almost everywhere. Now take the weak formulation of the first equation in (3.2) and pass to the limit as $\varepsilon \to 0$; from the above, we have that

$$\int_{-L}^{L} \bar{P}\ddot{\psi} + \psi(\bar{f}_u - \bar{f}_v \bar{g}_u / \bar{g}_v)\bar{P}\, dx = 0$$

for all $\psi \in (_0^{-\infty}(-L, L))$. Note that the potential term is just dr/dU at $\bar{U}(x)$, where r is the nonlinear term in (2.3). It follows that $\bar{P} \in H^2 \cap H_0^1$ is a smooth solution of

$$\bar{P}^{\cdot\cdot} + r_U(\bar{U}(x)m, \gamma)\bar{P} = 0, \qquad \bar{P}(-L) = \bar{P}(L) = 0.$$

Next, we show that $\bar{P}$ is not identically zero. Let z^* denote the complex conjugate of z and let $\gamma = RR^*$. A simple computation shows that

$$\varepsilon^2 \ddot{\gamma} - 2\varepsilon^2 |\dot{R}|^2 = -2g_u \operatorname{Re} PR^* + 2 \operatorname{Re}(\lambda - g_v)\gamma.$$

Suppose that $\gamma(x)$ achieves a positive maximum at $x_* \in (-L, L)$. It follows that the left-hand side of the above is nonpositive at x_* so that

$$\operatorname{Re}(\lambda - g_r)\gamma \leqq g_u \operatorname{Re} PR^*.$$

We now use an estimate for g_v for small ε, namely, that

$$g_v = -2V(x, \varepsilon) + m(U(x, \varepsilon) - \gamma) \leqq -\tfrac{1}{2}V(x, \varepsilon)$$

for all $x \in [-L, L]$ (see Dancer [3, Lemma 1 and display (20)]). Since $\gamma \geqq 0$ and $\operatorname{Re} \lambda \geqq 0$, we have from the above that at x_*,

$$\tfrac{1}{2}V\gamma \leqq g_u \operatorname{Re} PR^*.$$

Since $g_u = mV$ it follows that

$$\gamma(x_*) \leqq 2m|P(x_*)|\gamma(x_*)^{1/2}$$

so that $\|R\|_\infty \leqq 2m\|P\|_{L^\infty}$. If $\bar{P}$ vanished identically, it would follow that $\|P\|_{L^\infty}$ converges to zero, since P converges to $\bar{P}$ uniformly. By the above this would imply that R converges to zero uniformly, contradicting our normalization $\|P\|_{L^2}^2 + \|R\|_{L^2}^2 = 1$.

As a consequence of Lemmas 3.1 and 3.2, it follows that K can only intersect $\sigma(\mathscr{L})$ along the segments l_- and l_+ in Fig. 3.1. We shall rule out this possibility later. Assuming this for the moment so that $\mathscr{E}(K, \varepsilon)$ is well defined, we see from Lemma 3.2 that the segment l_* of K can be deformed through a family of curves $l_*(\gamma)$, $0 \leqq \gamma \leqq 1$ lying inside the semicircle $\{\operatorname{Re} \lambda \geqq 0, |\lambda| = \delta\}$ with endpoints at $\lambda = \pm i\delta$ for all $\gamma \in [0, 1]$ in such a manner that (i) $l_* = l_*(0)$ and $\tilde{l} = l_*(1)$ is the semicircle $|\lambda| = \delta$, $\operatorname{Re} \lambda \geqq 0$, and (ii) $\sigma(\mathscr{L})$ does not intersect the curve K_γ obtained by replacing l_* with $l_*(\gamma)$. It follows that the bundles $\mathscr{E}(K_\gamma, \varepsilon)$ are all well defined and isomorphic so that $c_1(\mathscr{E}(K_\gamma, \varepsilon))$ is independent of $\gamma \in [0, 1]$. Thus if $\tilde{K} = K_1$ is the curve depicted in Fig. 3.1, then

$$c_1(\mathscr{E}(K, \varepsilon)) = c_1(\mathscr{E}(\tilde{K}, \varepsilon)).$$

In the following sections we shall work with $\mathscr{E}(\tilde{K}, \varepsilon)$ rather than the original bundle. This, as we shall see below, is essential because the fast-slow structure of $(3.3)_s$ breaks down near $\lambda = 0$. This splitting is used crucially in obtaining the Whitney sum decomposition of the bundle and in computing the stability index.

3.5. Projective space. One of our principal goals will be to characterize the behavior of the solutions $\Phi_i(x, \lambda, \varepsilon)$ of $(3.3)_s$ (see (3.7)) over the interval $[-L, L]$. More precisely, we need to characterize the behavior of the *span* of these solutions. An important tool for analyzing the behavior of one-dimensional subbundles of $\mathscr{E}$ is the flow induced by $(3.3)_s$ on the space of complex lines. In general, given a linear flow on $\mathbb{C}^n$ there is an induced flow on the space of complex lines in $\mathbb{C}^n$. The space of complex lines in $\mathbb{C}^n$ is called *complex projective space* and is denoted by $\mathbb{C}P^{n-1}$. $\mathbb{C}P^{n-1}$ is a compact manifold which is obtained from $\mathbb{C}^n$ by the equivalence relation $y_1 \sim y_2$ for $y_1, y_2 \in \mathbb{C}^n \backslash \{0\}$ if $y_1 = \alpha y_2$ for some $\alpha \in \mathbb{C} \backslash \{0\}$. If $\pi : \mathbb{C}^n \to \mathbb{C}P^{n-1}$ is the projection map we also use the notation $\hat{y}$ for the image $\pi(y)$ in $\mathbb{C}P^{n-1}$ of a point $y \in \mathbb{C}^n \backslash \{0\}$.

Given a linear system on $\mathbb{C}^n$,

$$y' = Ay,$$

there is an induced (nonlinear) flow on $\mathbb{C}P^{n-1}$, which we denote by

$$\hat{y}' = \hat{A}(\hat{y}).$$

It is easily checked that if e is an eigenvector of A then $\hat{e}$ is a critical point of the vector field $\hat{A}(\hat{y})$. Furthermore, if μ is the eigenvalue of A associated with e, then the eigenvalues of $d\hat{A}(\hat{e})$ are $\mu_i - \mu$, where $\{\mu_i\}$ are the remaining eigenvalues of A. In particular, if μ_1 is the eigenvalue of the largest real part and $Ae_1 = \mu_1, e_1$, then $\hat{e}_1$ is an *attracting* rest point of $\hat{A}(\hat{y})$. We shall frequently use this observation.

3.6. The spectrum of the coefficient matrix. In order to analyze the projectivization of $(3.3)_f$ we shall need to characterize the spectrum of its coefficient matrix, $a(\xi, \lambda, \varepsilon)$. We shall use the notation $\bar{f}_u(\xi)$, etc., to denote the partial derivatives of f and g at the singular limit $\bar{u}(\xi)$, $\bar{v}(\xi) = \bar{U}(x)$, $\bar{V}(x)$.

LEMMA 3.3. *For all $\lambda \in \tilde{K} \cup \tilde{K}^\circ$ and all sufficiently small ε the matrices $a(\xi, \lambda, \mu)$ have eigenvalues $\mu_i(\xi, \lambda, \varepsilon)$, $1 \leqq i \leqq 4$ with associated eigenvectors $e_i(\xi, \lambda, \varepsilon)$. For all $|\xi| \leqq L_\varepsilon$, μ_1 and μ_4 are $\mathcal{O}(1)$ as $\varepsilon \to 0$ and satisfy*

$$\operatorname{Re} \mu_4(\xi, \lambda, \varepsilon) < 0 < \operatorname{Re} \mu_1(\xi, \lambda, \varepsilon).$$

In particular, μ_1 and μ_4 tend to nonzero limits μ_{1*}, μ_{4*} as $\varepsilon \to 0$, where

$$\mu_{1*}(\xi, \lambda) = \sqrt{\lambda - \bar{g}_v(\xi)}, \qquad \mu_{4*}(\xi, \lambda) = -\sqrt{\lambda - \bar{g}_v(\xi)}. \tag{3.8}$$

The associated eigenvectors tend to limits $e_{i*}(\xi, \lambda)$ as $\varepsilon \to 0$, where

$$e_{1*}(\xi, \lambda) = (0, 0, 1, \mu_{1*}(\xi, \lambda))^t, \qquad e_{4*}(\xi, \lambda) = (0, 0, 1, \mu_{4*}(\xi, \lambda))^t. \tag{3.9}$$

The slow eigenvalues μ_2 and μ_3 are of order ε as $\varepsilon \to 0$. They may coalesce for some values of ξ; however, for ξ near $\pm L_\varepsilon$ (so that $\bar{u}(\xi)$, $\bar{v}(\xi)$ is near $(0, 0)$), they satisfy

$$\mu_2(\xi, \lambda, \varepsilon) = \sqrt{\bar{g}(\xi, \lambda)}\varepsilon + \mathcal{O}(\varepsilon^2), \qquad \mu_3(\xi, \lambda, \varepsilon) = -\sqrt{\bar{g}(\xi, \lambda)}\varepsilon + \mathcal{O}(\varepsilon^2) \tag{3.10}$$

where

$$\bar{g}(\xi, \lambda) = \lambda - \bar{f}_u(\xi) - \frac{\bar{f}_v(\xi)\bar{g}_u(\xi)}{\lambda - \bar{g}_v(\xi)}. \tag{3.11}$$

The associated eigenvectors tend to limits e_{2*}, e_{3*} as $\varepsilon \to 0$, where

$$\begin{aligned} e_{2*}(\xi, \lambda) &= \left(1, \sqrt{\bar{g}(\xi, \lambda)}, \frac{\bar{g}_u(\xi)}{\lambda - \bar{g}_v(\xi)}, 0\right)^t, \\ e_{3*}(\xi, \lambda) &= \left(1, -\sqrt{\bar{g}(\xi, \lambda)}, \frac{\bar{g}_u(\xi)}{\lambda - \bar{g}_v(\xi)}, 0\right)^t. \end{aligned} \tag{3.12}$$

The proof of a similar lemma for the same system (where ε occurs in the first rather than the second equation) can be found in [8], and will therefore be omitted. We remark that

$$\bar{g}_v(\xi) = -m|\bar{u}(\xi) - \gamma| \leqq 0;$$

hence for $\lambda \in K \cup K^\circ$, where $\tilde{K}$ is the curve depicted in Fig. 3.1 $|\arg(\lambda - \bar{g}_v(\xi))| \leqq (\pi/2) + \phi$. It follows that $\operatorname{Re}(\lambda - \bar{g}_v(\xi))^{1/2}$ is uniformly positive for all ξ and all such λ. This would not be true had we worked with the original K, since when $\bar{u} = \gamma$ and λ is real and nonpositive, $\operatorname{Re}(\lambda - \bar{g}_v(\xi)) \leqq 0$. Thus the fast-slow splitting breaks down here. The reason that this problem is controllable is that the singular limit is *continuous* at this point, so that the linearization of the reduced equation provides a good approximation for small λ. Problems where the singular limit has transition layers are much more delicate (e.g., see [8]).

3.7. The fast subbundle. We can now characterize the one-dimensional subbundle of $\mathscr{E}(K, \varepsilon)$ associated with the solution $\Phi_1(x, \lambda, \varepsilon)$ of $(3.3)_s$ which satisfies

$$\Phi_1(-L, \lambda, \varepsilon) = (0, 0, 0, 1)^t.$$

It will be convenient to change to the fast scaling by setting

$$\phi_i(\xi, \lambda, \varepsilon) = \Phi_i(\xi\varepsilon, \lambda, \varepsilon).$$

In this scaling the coefficient matrix $a(\xi, \lambda, \varepsilon)$ in $(3.3)_f$ has coefficients which depend on ξ through the presence of the partials f_u, f_v, g_u, g_v evaluated at $u(\xi, \varepsilon)$, $v(\xi, \varepsilon)$. We claim that $a_\xi = \mathcal{O}(\varepsilon)$; to this end we show that $u', v' = \mathcal{O}(\varepsilon)$. The equations for (u, v) in this scaling are

$$u' = \varepsilon w, \quad v' = z, \quad w' = -\varepsilon f(u, v), \quad z' = -g(u, v). \tag{3.13}$$

Since $w(\xi) = W(x) = U'(x)$ remains uniformly bounded, $|u'(\xi)|$ is uniformly of order ε for all ξ. Also, let $\gamma = v - p(u)$; the equation for γ is then

$$\gamma' = z - p'(u(\xi, \varepsilon))\varepsilon w(\xi, \varepsilon).$$

It follows that z remains of order ε. If this were not the case, say $|z(\xi_0)| > \delta > 0$ for some $\delta > 0$ independent of ε, the condition $|z(\xi)| > \delta/2$ would then hold on some uniform interval $|\xi - \xi_0| \leqq d$ about ξ_0, since $|z'| \leqq K$ for some $K > 0$ and all ξ. It would then follow that $|\gamma(\xi_0 + d)| \geqq \delta d/2 - \mathcal{O}(\varepsilon)$. This contradicts the fact that $\gamma(\xi, \varepsilon) \to 0$ as $\varepsilon \to 0$ uniformly in ε.

We summarize this in a lemma.

LEMMA 3.4. *There exists $M > 0$ independent of ε such that $|a_\xi(\xi, \lambda, \varepsilon)| \leqq M\varepsilon$ for all $|\xi| \leqq L_\varepsilon$, $\lambda \in \tilde{K} \cup \tilde{K}^\circ$, and $\varepsilon \in (0, \varepsilon_0]$.*

We now use this to control the solution $\phi_1(\xi, \lambda, \varepsilon)$ of $(3.3)_f$ and its projectivization $\hat{\phi}_1(\xi, \lambda, \varepsilon)$, satisfying

$$\hat{y}' = \hat{a}(\hat{y}; \xi, \lambda, \varepsilon), \tag{3.14}$$

together with the condition that $\phi_1 = u_1$ at $\xi = -L_\varepsilon$. In particular, we shall use the parametrized collection of frozen coefficient systems:

$$\hat{y}' = \hat{a}(\hat{y}; \eta, \lambda, \varepsilon). \tag*{$(3.15)_\eta$}$$

The basic idea is that the family $(3.15)_\eta$ admits a smooth curve of *attracting* rest points $\hat{e}_1(\eta, \lambda, \varepsilon)$. This follows from the remarks concerning projectivized flows in § 3.5 together with the limiting forms (3.8) and (3.9) of $\mu_1(\eta, \lambda, \varepsilon)$ and $e_1(\eta, \lambda, \varepsilon)$. In particular, these estimates imply that if $B(\eta, \lambda, \varepsilon)$ is the matrix $d\hat{a}(\hat{e}_1(\eta, \lambda, \varepsilon), \eta, \varepsilon)$ and μ is any eigenvalue of $B(\eta, \lambda, \varepsilon)$, then there exists $\sigma > 0$ independent of η and ε such that $\operatorname{Re} \mu < -\sigma$.

We can now use the "elephant trunk" lemma of [8]. The idea is to take $N(\eta, \lambda, \varepsilon)$ to be an attracting neighborhood of $\hat{e}_1(\eta, \lambda, \varepsilon)$ for $(3.15)_\eta$ and to form a tube $\Omega^+(\lambda, \varepsilon)$ in the augmented space $\mathbb{R}\times\mathbb{C}P^3$,

$$\Omega^+(\lambda, \varepsilon)=\{(\eta, \hat{y}): |\eta|\leqq L_\varepsilon \quad \text{and} \quad \hat{y}\in N(\eta, \lambda, \varepsilon)\}.$$

Using the uniform bound $\operatorname{Re} \sigma B(\eta, \lambda, \varepsilon)\leqq -\sigma$ on the spectrum of B, we see that the neighborhoods $N(\eta, \lambda, \varepsilon)$ can be chosen to contain a ball about $\hat{e}_1(\eta, \lambda, \varepsilon)$ of uniform radius $\delta>0$. (For definiteness, fix some metric ρ on $\mathbb{C}P^3$; δ can then be set relative to ρ and σ.)

We now have all the ingredients for the elephant trunk lemma in [8]. In particular, we have the following.

LEMMA 3.5. *There exists $\varepsilon_0>0$ such that for all $\varepsilon\in(0, \varepsilon_0]$, the set $\Omega^+(\lambda, \varepsilon)$ is positively invariant for the augmented flow*

$$\xi'=1, \qquad \hat{y}'=\hat{a}(y; \xi, \lambda, \varepsilon), \tag{3.16}$$

relative to the interval $|\xi|\leqq L_\varepsilon$, i.e., if $(\bar{\xi}, \hat{y}_0)\in\Omega^+(\lambda, \varepsilon)$, then the solution $(\xi, \hat{y}(\xi))$ with this data remains in $\Omega^+(\lambda, \varepsilon)$ for all $\xi\in[\bar{\xi}, L_\varepsilon]$.

This lemma is an immediate consequence of our Lemma 3.4 and Lemma 4.1 in [8]. We can now state the main result of this section.

THEOREM 3.6. *There exists $\varepsilon_0>0$ and $d>0$ independent of ε such that for all $\varepsilon\in(0, \varepsilon_0]$ and $\lambda\in\tilde{K}\cup\tilde{K}^\circ$, the solution $(\xi, \hat{\phi}_1(\xi, \lambda, \varepsilon))$ of* (3.16) *lies interior to $\Omega^+(\lambda, \varepsilon)$ for all $\xi\geqq -L_\varepsilon+d$.*

Proof. Note that from (3.8) and (3.9) we have that

$$\phi_1(-L_\varepsilon, \lambda, \varepsilon)=u_1=\tfrac{1}{2}(\lambda-\bar{g}(-L_\varepsilon))^{-1/2}[e_1(-L_\varepsilon, \lambda, \varepsilon)-e_4(-L_\varepsilon, \lambda, \varepsilon)]+\mathcal{O}(\varepsilon).$$

Thus at $\xi=-L_\varepsilon$, ϕ_1 is close to the fast subspace, i.e., the subspace spanned by e_1 and e_4. Furthermore, it has a nontrivial projection in the e_1 direction for all $\lambda\in\tilde{K}\cup\tilde{K}^\circ$ and for all $\varepsilon\in(0; \varepsilon_0]$. Let $y(\xi, \lambda, \varepsilon)$ denote the solution of the frozen system,

$$y'=a(-L_\varepsilon, \lambda, \varepsilon)y, \qquad y(-L_\varepsilon)=u_1,$$

so that $\hat{y}(\xi, \lambda, \varepsilon)$ is the associated solution of $(3.15)_{-L_\varepsilon}$. Since $\operatorname{Re}\mu_1(-L_\varepsilon, \lambda, \varepsilon)>\operatorname{Re}\mu_i(-L, \lambda, \varepsilon)$ for $i=2, 3, 4$, it follows that there exists $d>0$ depending only on $\operatorname{Re}\mu_1-\operatorname{Re}\mu_2=\mathcal{O}(1)$ such that $\hat{y}(-L_\varepsilon+d, \lambda, \varepsilon)\in N(-L_\varepsilon, \lambda, \varepsilon)$. By Lemma 3.4,

$$|e_1(\xi, \lambda, \varepsilon)-e_1(-L_\varepsilon, \lambda, \varepsilon)|\leqq K\varepsilon$$

for some $K>0$ and all $\xi\in[-L_\varepsilon, -L_\varepsilon+d]$. Hence $\hat{y}(-L_\varepsilon+d, \lambda, \varepsilon)$ lies interior to $N(-L_\varepsilon+d, \lambda, \varepsilon)$, too. Finally, it follows from Lemma 3.4 and Gronwall's inequality that

$$\rho(\hat{\phi}_1(\xi, \lambda, \varepsilon), \hat{y}(\xi, \lambda, \varepsilon))\leqq K\varepsilon$$

for some $K>0$, $\varepsilon\in(0, \varepsilon_0]$, and all $\xi\in[-L_\varepsilon, -L_\varepsilon+d]$. (Recall that ρ is a fixed metric on $\mathbb{C}P^3$.) Hence $\hat{\phi}_1(-L_\varepsilon+d, \lambda, \varepsilon)\in N(-L_\varepsilon+d, \lambda, \varepsilon)$ for sufficiently small ε_0, which, together with Lemma 3.5, proves the theorem.

We remark that Theorem 3.6 implies that $\hat{\phi}_1(L_\varepsilon, \lambda, \varepsilon)$ is near $\hat{e}_1(L_\varepsilon, \lambda, \varepsilon)$. Since $e_1(L_\varepsilon, \lambda, \varepsilon)$ is transverse to the boundary conditions U, this implies that $\phi_1(\xi, \lambda, \varepsilon)$ is *not* an eigenfunction of $\mathcal{L}$ for all $\lambda\in\tilde{K}\cup\tilde{K}^\circ$. Hence an eigenvalue λ of $\mathcal{L}$ only can arise through an eigenfunction $\phi_2(\xi, \lambda, \varepsilon)$ associated with slow behavior.

We also remark that a similar procedure can be used to determine the behavior of any solution $\hat{y}(\xi, \lambda, \varepsilon)$ of (3.14) that is near $\hat{e}_4(L_\varepsilon, \lambda, \varepsilon)$ when $\xi=L_\varepsilon$. The same considerations together with Lemmas 3.4 and 3.5 enable us to define a *negatively* invariant set $\Omega^-(\lambda, \varepsilon)$ in $[-L_\varepsilon, L_\varepsilon]\times\mathbb{C}P^3$ containing the curve $(\eta, \hat{e}_4(\eta, \lambda, \varepsilon))$ in its interior. The proof simply requires a time reversal.

Corollary 3.7. *For all* $\varepsilon \in (0, \varepsilon_0]$ *and* $\lambda \in K \cup K^\circ$, *there exists a negatively invariant neighborhood* $\Omega^-(\lambda, \varepsilon)$ *of* $(\eta, \hat{e}_4(\eta, \lambda, \varepsilon))$ *for the system* (3.16) *relative to the interval* $|\eta| \leqq L_\varepsilon$.

3.8. The slow subbundle. Next, we shall define and characterize the behavior of the slow solution $\Phi_2(x, \lambda, \varepsilon)$ of $(3.3)_s$. This will be accomplished by proving the existence of a certain two-dimensional space of solutions of $(3.3)_s$ which remains uniformly near the slow eigenspace of the coefficient matrix in $(3.3)_s$; for a precise definition, see § 3.9. Recall that Φ_2 is the solution of $(3.3)_s$ satisfying

$$\Phi_2(-L, \lambda, \varepsilon) = (0, 1, 0, \gamma)^t = u_2(\gamma),$$

where γ is a free parameter. Although an arbitrary choice of γ would suffice in defining the bundle $\mathscr{E}(\tilde{K}, \varepsilon)$ we shall require a judicious choice of γ in order that Φ_2 be uniformly approximated by the slow reduced equation (1.4) for all $x \in [-L, L]$. The reason for this is that the slow subspace is hyperbolic, so that most solutions near the slow subspace will be rapidly pushed into a fast direction in either forward or backward time.

To define Φ_2, let $\Phi_2^\circ(x, \lambda, \varepsilon)$ be the solution with $\gamma = 0$, and let $\Phi(x, \lambda, \varepsilon)$ be the span of $\Phi_1(x, \lambda, \varepsilon)$ and $\Phi_2^\circ(x, \lambda, \varepsilon)$, so that $\Phi(-L, \lambda, \varepsilon) = U$. Next, let $\Psi_i(x, \lambda, \varepsilon)$ be the solution of $(3.3)_s$ satisfying

$$\Psi_i(L, \lambda, \varepsilon) = E_i(L, \lambda, \varepsilon),$$

for $i = 2, 3, 4$, where $E_i(x, \lambda, \varepsilon) = e_i(\xi, \lambda, \varepsilon)$ are as in Lemma 3.3. Let $\Psi(x, \lambda, \varepsilon)$ be the span of the Ψ_i's, $i = 2, 3, 4$. Then Ψ is three-dimensional and Φ is two-dimensional. Furthermore, by Theorem 3.6, $\hat{\Phi}_1(L, \lambda, \varepsilon) = \hat{\phi}_1(L_\varepsilon, \lambda, \varepsilon) \in N(L_\varepsilon, \lambda, \varepsilon)$ and therefore lies near $\hat{E}_1(L, \lambda, \varepsilon)$ in $\mathbb{C}P^3$. It follows that $\Phi_1(L, \lambda, \varepsilon)$ is transverse to $\Psi(L, \lambda, \varepsilon) = \operatorname{span}\{E_i(L, \lambda, \varepsilon); i = 2, 3, 4\}$, and thus, that the subspaces $\Psi(L, \lambda, \varepsilon)$ and $\Phi(L, \lambda, \varepsilon)$ intersect transversely. Therefore, there is a unique choice of γ such that $\Phi_2 \in \Phi \cap \Psi$ for all $(x, \lambda, \varepsilon)$ for some $\Phi_2 \neq 0$. From the definition of Φ_2 we see that

$$\begin{aligned} &\Phi_2(-L, \lambda, \varepsilon) = u_2(\gamma) \in U, \\ (3.17)\qquad &\Phi_2(+L, \lambda, \varepsilon) \in \operatorname{Span}\{E_i(L, \lambda, \varepsilon)\colon i = 2, 3, 4\}. \end{aligned}$$

Note that $\gamma = \gamma(\varepsilon)$ must tend to zero as $\varepsilon \to 0$, since if this were not the case, $u_2(\gamma)$ would have a component in the E_1 direction, which is uniformly bounded away from zero as $\varepsilon \to 0$. By the next result, Lemma 3.8, this would contract the behavior of Φ_2 at $x = L$.

3.9. Hyperbolicity of the slow subbundle. The behavior of $\hat{\Phi}_2$ for all $x \in [-L, L]$ is determined by the conditions in (3.17). This can be seen by introducing the *slow subspace* $\Sigma_s(x, \lambda, \varepsilon)$ associated with $A(x, \lambda, \varepsilon)$. By Lemma 3.3, the fast eigenvectors E_1 and E_4 are simple, and hence well defined for all $x \in [-L, L]$. However, it is possible that the slow eigenvalues μ_2, μ_3 in (3.10) coalesce or become pure imaginary for certain $x \in [-L, L]$ so that the associated eigenvectors E_2 and E_3 may depend discontinuously on $(x, \lambda, \varepsilon)$. However, there is a well-defined two-dimensional (generalized) eigenspace $\Sigma_s(x, \lambda, \varepsilon)$ of $A(x, \lambda, \varepsilon)$ that does depend smoothly on the parameters $(x, \lambda, \varepsilon)$. Furthermore, there exists a basis, $E_2(x, \lambda, \varepsilon)$, $E_3(x, \lambda, \varepsilon)$ for $\Sigma_s(x, \lambda, \varepsilon)$ that depends smoothly on $(x, \lambda, \varepsilon)$. For parameter values such as $x = -L, L$ where μ_2 and μ_3 are simple, E_2 and E_3 can be taken to be eigenvectors. When μ_2 and μ_3 coincide it may be necessary to choose E_2 and E_3 to be vectors other than eigenvectors in order to make them continuous functions of $(x, \lambda, \varepsilon)$.

LEMMA 3.8. *Let $\eta > 0$ be given. There exists $\varepsilon_o > 0$ such that for all $x \in [-L, L]$, $\varepsilon \in (0, \varepsilon_o]$, $\lambda \in \tilde{K} \cup \tilde{K}^\circ$,*

$$\rho(\hat{\Phi}_2(x, \lambda, \varepsilon), \hat{\Sigma}_s(x, \lambda, \varepsilon)) < \eta. \tag{3.18}$$

Proof. Select $y \in \pi^{-1}\hat{\Phi}_2(x, \lambda, \varepsilon)$ with $\|y\| = 1$ in the Euclidean norm. Since the fast eigenvectors $E_1(x, \lambda, \varepsilon)$ and $E_4(x, \lambda, \varepsilon)$ are well defined for all $(x, \lambda, \varepsilon)$, we can express y in the form

$$y = c_1E_1 + c_4E_4 + E_s$$

for appropriate $E_s \in \Sigma_s(x, \lambda, \varepsilon)$. Since $\|y\| = 1$, there exists $d > 0$ depending only on η and the metric ρ such that if

$$|c_1|, |c_4| < d,$$

then (3.18) holds for all $(x, \lambda, \varepsilon)$. Suppose then that this condition fails to hold at some $(x_o, \lambda, \varepsilon)$, say, for example, $|c_1(x_o, \lambda, \varepsilon)| \geqq d$. Let $\xi_o = \varepsilon^{-1}x_o$ and consider the frozen system

$$y' = a(\xi_o, \lambda, \varepsilon)y, \qquad y(\xi_o) = y. \tag{3.19}$$

The eigenvalue of largest real part of the frozen system is $\mu_1(\xi_o, \lambda, \varepsilon)$; since $\operatorname{Re}(\mu_i - \mu_1)$, $i \neq 1$, is uniformly negative for all $(\xi, \lambda, \varepsilon)$, there exists $l > 0$ depending only on $\operatorname{Re}(\mu_i - \mu_1)$, $i = 2, 3, 4$ such that

$$(\xi_o + l, \hat{y}(\xi_o + l)) \in \Omega^+(\lambda, \varepsilon),$$

where $y(\xi)$ is the solution of (3.19) and $\Omega^+(\lambda, \varepsilon)$ is the positively invariant neighborhood of $(\xi, \hat{e}_1)$ constructed in Theorem 3.6. Let $\phi_2(\xi, \lambda, \varepsilon) = \Phi_2(\varepsilon\xi, \lambda, \varepsilon)$ be suitably renormalized so that $\phi_2 = y$ at $\xi = \xi_o$. It follows from standard continuous dependence theorems, together with Lemma 3.4, that $\hat{\phi}_2(\xi, \lambda, \varepsilon)$ is uniformly approximated by $\hat{y}(\xi)$ on the compact interval $[\xi_o, \xi_o + l]$, so that

$$(\xi_o + l, \hat{\phi}_2(\xi_o + l, \lambda, \varepsilon)) \in \Omega^+(\lambda, \varepsilon)$$

for sufficiently small ε. This contradicts the second statement in (3.17), provided that $\xi_o + l \leqq L_\varepsilon = \varepsilon^{-1}L$.

In the event that $|c_4| \geqq d$, we obtain $l < 0$ independent of ε such that

$$(\xi_o + l, \hat{\phi}_2(\xi_o + l, \lambda, \varepsilon)) \in \Omega^-(\lambda, \varepsilon),$$

where $\Omega^-(\lambda, \varepsilon)$ is the negatively invariant neighborhood of $(\xi, \hat{e}_4)$ of Corollary 3.7, provided that $\xi_o + l \geqq -L_\varepsilon$, the argument is the same as for $|c_1| \geqq d$ after a time reversal. This contradicts the first statement in (3.17) at $x = -L$.

It only remains to treat the case where $\xi_o + l$ is exterior to the interval $|\xi| \leqq L_\varepsilon$. Near each boundary we need only consider one case. For ξ_o near $-L_\varepsilon$ (respectively, $+L_\varepsilon$) the case that requires further discussion is the one where $|c_4| \geqq d$ (respectively, $|c_1| \geqq d$). For ξ_o near $-L_\varepsilon$ we still use the solution $y(\xi)$ of the frozen system (3.19) to approximate $\phi_2(\xi, \lambda, \varepsilon)$ in backward time. We can no longer conclude that $\hat{\phi}_2$ enters $\Omega^-(\lambda, \varepsilon)$ in backward time, since the interval $[\xi_o + l, \xi_o]$ may no longer be entirely contained in $|\xi| \leqq L_\varepsilon$. However, the E_4-component is the most rapidly growing component of the soution $y(\xi)$ in backward time; it therefore follows from the initial condition that the E_4-component of $y(\xi)/\|y\|$ remains uniformly bounded away from zero on $\{-L_\varepsilon \leqq \xi \leqq \xi_o\}$.

This implies that $\hat{y}(-L_\varepsilon)$ is uniformly bounded away from $\hat{\Sigma}_s(-L, \varepsilon, \lambda)$, and, in particular, $\hat{u}_2(\gamma)$, the initial value for $\hat{\phi}_2$ at $\xi = -L_\varepsilon$ in (3.17). By Lemma 3.4, $\hat{y}(\xi)$ uniformly approximates $\hat{\phi}_2$ on this interval; hence the first statement in (3.17) would be violated. The second case, where $|c_1| \geqq d$ for ξ_o near L_ε, is treated similarly.

3.10. Approximation by the slow reduced equation. We can now show that the slow solution $\hat{\Phi}_2$ is approximated by a certain solution of the slow reduced equation (1.4). To this end, rewrite (1.4) as a system

$$\dot{\Gamma}_* = B_*(x, \lambda)\Gamma_*, \tag{3.20}$$

where $\Gamma_* = (P_*, Q_*)^t$ and

$$B_*(x, \lambda) = \begin{pmatrix} 0 & 1 \\ \bar{g}(x, \lambda) & 0 \end{pmatrix};$$

here, $\bar{g}(x, \lambda)$ is as in (3.11). Since (3.20) is linear it induces a flow on $\mathbb{C}P^1$ which we denote by

$$\hat{\Gamma}^{\cdot}_* = \hat{B}_*(\hat{\Gamma}_*; x, \lambda). \tag{3.21}$$

It will be convenient to cover $\mathbb{C}P^1$ $(=S^2)$ with two coordinate patches: $w_* = P_*/Q_*$ and $z_* = Q_*/P_*$. The equations for w_* and z_* are easily seen to be

$$\dot{w}_* = 1 - \bar{g}(x, \lambda)w_*^2, \tag{3.22}$$

$$\dot{z}_* = \bar{g}(x, \lambda) - z_*^2. \tag{3.23}$$

The solution of (3.21) of interest is the solution $\hat{\Gamma}_*(x, \lambda)$ representing the boundary condition at $x = -L$, i.e., the solution satisfying the initial condition

$$\pi^{-1}\hat{\Gamma}_*(-L, \lambda) = \text{Span}\,(0, 1).$$

In terms of the coordinate w_* this condition is

$$w_*(-L, \lambda) = 0.$$

LEMMA 3.9. *Let*

$$\Phi_2(x, \lambda, \varepsilon) = (P, Q, R, S) \quad \textit{at } (x, \lambda, \varepsilon)$$

and let

$$\Gamma(x, \lambda, \varepsilon) = (P, Q)^t \quad \textit{at } (x, \lambda, \varepsilon).$$

Given $\sigma > 0$, there exists $\varepsilon_o > 0$ such that

$$\rho(\hat{\Gamma}(x, \lambda, \varepsilon), \hat{\Gamma}_*(x, \lambda)) < \sigma$$

for all $\lambda \in \tilde{K} \cup \tilde{K}^\circ$, $x \in (-L, L]$, and $\varepsilon \in (0, \varepsilon_o]$; here ρ is a fixed metric on $\mathbb{C}P^1$.

Proof. We will show that $\hat{\Gamma}(x, \lambda, \varepsilon)$ satisfies a system of the form

$$\hat{\Gamma}^{\cdot} = \hat{B}(\hat{\Gamma}; x, \lambda, \varepsilon),$$

where $\hat{B}(\hat{\Gamma}; x, \lambda, \varepsilon)$ is uniformly approximated by $\hat{B}_*(\hat{\Gamma}; x, \lambda)$ for all $\hat{\Gamma}$ in $\mathbb{C}P^1$, $x \in [-L, L]$, and $\lambda \in \tilde{K} \cup \tilde{K}_o$. The lemma then follows from standard continuous dependence theorems for flows.

The first task is to choose E_2 and E_3 so that they depend smoothly on $(x, \lambda, \varepsilon)$. The only difficulty occurs when $\mu_2 = \mu_3$. Since the eigenvectors of matrices with nonsimple eigenvalues can depend discontinuously on parameters, some care must be taken here. This possibility indeed arises for certain values of x. However, it is easily checked that when this occurs, the generalized null space of $A(x, \lambda, \varepsilon)$ is spanned by vectors of the form

$$E_2=(1,0,J(x,\lambda),0)^t+\mathcal{O}(\varepsilon), \qquad E_3=(0,1,0,0)^t+\mathcal{O}(\varepsilon), \tag{3.24}$$

where

$$J(x,\lambda)=\frac{\bar{g}_u(x)}{\lambda-\bar{g}_v(x)}.$$

The computation is straightforward though tedious and will be omitted. Note that if E_2 and E_3 are chosen as in (3.24) they span the same space as e_{2*}, e_{3*} in (3.12), modulo $\mathcal{O}(\varepsilon)$ terms. This is the required basis for $\Sigma_s(x, \lambda, \varepsilon)$.

Next, select

$$Y=(P,Q,R,S)^t \in \pi^{-1}\hat{\Phi}_2(x,\lambda,\varepsilon)$$

to be a vector of unit length. For some coefficients α_i we have that

$$Y=\sum_{i=1}^{4}\alpha_i E_i(x,\lambda,\varepsilon).$$

Let $d\in(0,1)$ be given. Since $\Sigma_s(x,\lambda,\varepsilon)$ is spanned by E_2, E_3 at (x,λ,ε), it follows that there exists $\varepsilon_o>0$, $\eta=\eta(d)$ such that (3.18) implies that $|\alpha_1|\leqq d$ and $|\alpha_4|\leqq d$ for $\lambda\in\tilde{K}\cup\tilde{K}^\circ$ and $\varepsilon\in(0,\varepsilon_o]$. It then follows from (3.24) that

$$\begin{aligned} P&=\alpha_2+\mathcal{O}(d), & Q&=\alpha_3+\mathcal{O}(d),\\ R&=\alpha_2 J(x,\lambda)+\mathcal{O}(d), & S&=\mathcal{O}(d). \end{aligned} \tag{3.25}$$

Since Y is a unit vector there exists $k>0$ depending only on $|J|$ and on d such that $\max\{|P|,|Q|\}\geqq k$. Suppose first that $|Q|\geqq k$. Then $(P/Q,\ R/Q,\ S/Q)$ provides a coordinate patch on $\mathbb{C}P^3$ at $\hat{Y}$. If $w=P/Q$, the equation for w is then

$$\dot{w}=1-(\lambda-f_u)w^2+f_vRP/Q^2.$$

From (3.25) and $|Q|\geqq k$ we have that

$$RP/Q^2=J(x,\lambda)w^2+\mathcal{O}(d).$$

Noting that

$$\begin{aligned}\bar{g}(x,\ )&=\lambda-\bar{f}_u-\frac{\bar{f}_v\bar{g}_u}{\lambda-\bar{g}_v}\\ &=\lambda-\bar{f}_u-\bar{f}_vJ(x,\lambda)\end{aligned}$$

and that f_u, f_v are uniformly approximated by $\bar{f}_u, \bar{f}_v$ for small ε, it follows from the above that

$$w'=1-\bar{g}(x,\lambda)w^2+\mathcal{O}(d).$$

Hence if $|Q|\geqq k$, $\hat{\Gamma}$ satisfies an equation which in the local coordinate w uniformly approximates the reduced equation for w_*, (3.22). In the event that $|P|\geqq k$, a similar computation leads to the equation

$$\dot{z}=\bar{g}(x,\lambda)-z^2+\mathcal{O}(d),$$

which uniformly approximates (3.24). Hence $\hat{\Gamma}(x,\lambda,\varepsilon)$ is uniformly approximated by $\hat{\Gamma}_*(x,\lambda)$ for $\varepsilon\in(0,\varepsilon_o]$ and $\lambda\in\tilde{K}\cup\tilde{K}^\circ$.

3.11. The reduced slow subbundle. Suppose for the moment that the eigenvalue problem in (1.4) is well understood. In particular, suppose that we can locate curves $\tilde{K}$ as in Fig. 3.1 that are disjoint from the spectrum of (1.4). Later, in § 4, we shall indicate how this can be done in certain situations. The results of the preceding section suggest defining a reduced line bundle $\mathscr{E}_{2*}(\tilde{K})$ whose fibers are defined via the reduced system (3.20). To this end let

$$\tilde{U}=\{(0,Q)\colon Q\in\mathbb{C}\},\qquad \tilde{V}=\{(P,0)\colon P\in\mathbb{C}\};$$

so that $\tilde{U}=\operatorname{Span}(0,1)^t$ represents the boundary conditions for (3.20) and $\mathbb{C}^2=\tilde{U}\oplus\tilde{V}$. Define a section $\xi_*\colon B_*\to B_*\times[\mathbb{C}^2/\tilde{V}\times\mathbb{C}^2/\tilde{U}]$ by

$$\tilde{\xi}_*(b)=\left(b,\frac{L-x(b)}{2L}\Gamma_*(b)+\hat{V},\Gamma_*(b)+\tilde{U}\right)$$

for all $b\in B_*$. Over the caps, put

$$\tilde{\xi}_l(b)=(b,(0,1)^t+\tilde{V}_o,\bar{0})\qquad(b\in B_L),$$
$$\tilde{\xi}_r(b)=(b,\bar{0},\tilde{E}_{2*}(L,\lambda)+\tilde{U}_o)\ (b\in B_R),$$

where $\tilde{E}_{2*}(L,\lambda)=(1,\sqrt{\bar{g}(L,\lambda)})$. Finally, define the fibers of $\tilde{\mathscr{E}}_{2*}(K)$ by

$$\pi^{-1}(b)=\begin{cases}\operatorname{Span}\tilde{\xi}_l(b), & b\in B_l,\\ \operatorname{Span}\tilde{\xi}_*(b), & b\in B_*,\\ \operatorname{Span}\tilde{\xi}_r(b), & b\in B_r.\end{cases}\tag{3.26}$$

Since we are assuming at this point that $\tilde{K}$ is disjoint from the eigenvalues of (1.4) it follows that $\tilde{\mathscr{E}}_{2*}(\tilde{K})$ is a line bundle over B.

Next we define another line bundle $\mathscr{E}_{2*}(\tilde{K})$ which turns out to be the limit of $\mathscr{E}_2(\tilde{K},\varepsilon)$ as $\varepsilon\to0$. To this end, embed the solution $\Gamma_*(x,\lambda)$ of (3.20) satisfying $\Gamma_*(-L,\lambda)=(0,1)^t$ into $\mathbb{C}^4$ by setting for $b\in B_*$

$$\Phi_{2*}(b)=(P_*(b),Q_*(b),J(b)P_*(b),0)^t.\tag{3.27}$$

Next define a map $\xi_*\colon B_*\to\mathbb{C}^4/V\times\mathbb{C}^4/U$ by setting

$$\chi_{2*}(b)=\left(\frac{L-x(b)}{2L}\Phi_{2*}(b)+V,\Phi_{2*}(b)+U\right).$$

Next, define $\xi_l(b)$, $\xi_r(b)$ over the caps by setting

$$\xi_l(b)=(u_2+V,\bar{0}),\qquad \xi_r(b)=(\bar{0},E_{2*}(b)+U).$$

The bundle $\mathscr{E}_{2*}(\tilde{K})$ is then the line bundle over B, $\pi\colon E\to B$, where

$$\pi^{-1}(b)=\begin{cases}(b,\operatorname{Span}\xi_l(b)), & b\in B,\\ (b,\operatorname{Span}\chi_{2*}(b)), & b\in B_*,\\ (b,\operatorname{Span}\xi_r(b), & b\in B_r.\end{cases}\tag{3.28}$$

It is easily seen that this indeed forms a bundle. The local triviality condition is immediate over $\bar{B}_l\cap B_*$. This condition is also satisfied over $\bar{B}_r\cap B_*$. This is seen by noting that $\mathbb{C}^4/U$ identifies vectors with the same first and third components. From (3.12) and (3.27) we see that

$$\Phi_{2*}(b)=P_*(b)E_{2*}(b)+(0,Q_*(b)-P_*(b)\sqrt{\bar{g}(b)},0,0)^t;$$

thus $\Phi_{2*}(b)$ is a scalar multiple of $E_{2*}(b)$ mod U.

Finally we note that the bundle $\tilde{\mathscr{E}}_{2*}(\tilde{K})$ is equivalent to $\mathscr{E}_{2*}(\tilde{K})$. This can be seen by noting that the sections $\tilde{\xi}_l, \tilde{\xi}_*, \tilde{\xi}_r$ and ξ_l, χ_{2*}, ξ_r can be used to construct an explicit bundle isomorphism by mapping $\tilde{\xi}_*(b)$ onto $\xi_*(b)$ and extending linearly. Since isomorphic bundles have the same Chern numbers we have proved the following result.

LEMMA 3.10. *The line bundles* $\tilde{\mathscr{E}}_{2*}(\tilde{K})$ *and* $\mathscr{E}_{2*}(\tilde{K})$ *defined, respectively, by* (3.26) *and* (3.28) *are isomorphic, and* $c_1(\tilde{\mathscr{E}}_{2*}(\tilde{K}))=c_1(\mathscr{E}_{2*}(\tilde{K}))$.

3.12. The Whitney sum decomposition. The Whitney sum decomposition

$$\mathscr{E}(\tilde{K},\varepsilon)=\mathscr{E}_1(\tilde{K},\varepsilon)\oplus\mathscr{E}_2(\tilde{K},\varepsilon) \tag{3.29}$$

can now be specified more precisely. Let

$$\bar{\Phi}_i(\lambda,\varepsilon)=\Phi_i(L,\lambda,\varepsilon)+U, \qquad i=1,2,$$

$$\bar{e}_i(\lambda,\varepsilon)=E_i(L,\lambda,\varepsilon)+U, \qquad i=1,2.$$

Then $\{\bar{\phi}_1,\bar{\phi}_2\}$ and $\{\bar{e}_1,\bar{e}_2\}$ both form bases for $\mathbb{C}^4/U$. It follows that there exists a nonsingular matrix $f^\varepsilon\in Gl(2;\mathbb{C})$ such that

$$\bar{\phi}_j(\lambda,\varepsilon)=f^\varepsilon_{j,1}(\lambda)\bar{e}_1(\lambda,\varepsilon)+f^\varepsilon_{j,2}(\lambda)\bar{e}_2(\lambda,\varepsilon) \tag{3.30}$$

for $j=1,2$. Theorem 3.6 and Lemma 3.8 provide certain information about $f^\varepsilon_{i,j}(\lambda)$ as $\varepsilon\to 0$, namely, there exists $k>0$ such that for all $\lambda\in\tilde{K}$ and $\varepsilon\in(0,\varepsilon_o]$,

$$\begin{aligned}&|f^\varepsilon_{1,1}(\lambda)|,\ |f^\varepsilon_{2,2}(\lambda)|\geqq k,\\ &\lim_{\varepsilon\to 0}f^\varepsilon_{1,2}(\lambda)=\lim_{\varepsilon\to 0}f^\varepsilon_{2,1}(\lambda)=0,\ \text{uniformly.}\end{aligned} \tag{3.31}$$

Now f^ε is only defined for λ near $\tilde{K}$. In order to obtain the Whitney sum decomposition in (3.29) we need to find a trivialization $B_R\times\{\bar{0}\}\times\mathbb{C}^4/U$ over the entire right cap that coincides with (3.30) over $\tilde{K}\times\{L\}$. Let

$$\bar{\gamma}_1(\lambda,\varepsilon)=\bar{e}_1(\lambda,\varepsilon)+\frac{f^\varepsilon_{1,2}(\lambda)}{f^\varepsilon_{1,1}(\lambda)}\bar{e}_2(\lambda,\varepsilon),$$

$$\bar{\gamma}_2(\lambda,\varepsilon)=\bar{e}_2(\lambda,\varepsilon)+\frac{f^\varepsilon_{2,1}(\lambda)}{f^\varepsilon_{2,2}(\lambda)}\bar{e}_1(\lambda,\varepsilon).$$

Then $\{\bar{\gamma}_1,\bar{\gamma}_2\}$ is a basis for $\mathbb{C}^4/U$ for $\lambda\in\tilde{K}$. By (3.31) the second term in each expression tends to zero uniformly as $\varepsilon\to 0$ for $\lambda\in\tilde{K}$. Let $K_1\subset\tilde{K}^\circ$ be a simple closed curve close enough to $\tilde{K}$ so that $f^\varepsilon(\lambda)$ is well defined in the region between K_1 and $\tilde{K}$ for $\varepsilon\in(0,\varepsilon_o]$. Let $\psi(\lambda)$ be a smooth function satisfying

$$\psi(\lambda)=\begin{cases}1 & \text{for } \lambda\in\tilde{K},\\ 0 & \text{for } \lambda \text{ inside } K_1.\end{cases}$$

Finally, let

$$\bar{g}_1(\lambda,\varepsilon)=\bar{e}_1(\lambda,\varepsilon)+\frac{f^\varepsilon_{1,2}(\lambda)}{f^\varepsilon_{11}(\lambda)}\bar{e}_2(\lambda,\varepsilon)\psi(\lambda),$$

$$\bar{g}_2(\lambda,\varepsilon)=\bar{e}_2(\lambda,\varepsilon)+\frac{f^\varepsilon_{21}(\lambda)}{f^\varepsilon_{22}(\lambda)}\bar{e}_1(\lambda,\varepsilon)\psi(\lambda);$$

then $\{\bar{g}_1(\lambda,\varepsilon),\bar{g}_2(\lambda,\varepsilon)\}$ is a basis for $\mathbb{C}^4/U$ for all $\lambda\in\tilde{K}\cup\tilde{K}^\circ$ and $\varepsilon\in(0,\varepsilon_o]$, which equals $\{\bar{\gamma}_1(\lambda,\varepsilon),\bar{\gamma}_2(\lambda,\varepsilon)\}$ when $\lambda\in\tilde{K}$.

Now let $\chi_1(b, \varepsilon)$ and $\chi_2(b, \varepsilon)$ be the sections of $\mathscr{E}(\tilde{K}, \varepsilon)$ restricted to the sides B_*, which were used to define $\mathscr{E}(\tilde{K}, \varepsilon)$. The summands $\mathscr{E}_i(\tilde{K}, \varepsilon)$ are triples (E_i, B, π_i), where

$$\pi_i^{-1}(b) = \begin{cases} \text{Span}\,\{(u_i + V, \bar{0})\} & \text{if } b \in B_l, \\ \text{Span}\,\chi_i(b, \varepsilon) & \text{if } b \in B_*, \\ \text{Span}\,\bar{g}_i(b, \varepsilon) & \text{if } b \in B_r, \end{cases} \tag{3.32}$$

where $u_2 = u_2(\gamma)$ is as in § 3.8. It follows from the above that $\mathscr{E}_i(\tilde{K}, \varepsilon)$ forms a line bundle $i = 1, 2$; by construction, we see that (3.29) holds.

We remark that the above construction of the summands is somewhat different than in the case of traveling waves in which the spatial domain is infinite. The difference between the two is that, in the latter case, the behavior of each $\hat{\phi}_i$ is precisely determined at $\xi = +\infty$ by the equations. In the case of boundary value problems, each $\hat{\phi}_i$ is only approximately determined at $x = +L$.

We also remark that the function $f^\varepsilon(\lambda)$, which is called the *gluing map* of $\mathscr{E}(\tilde{K}, \lambda)$, plays a central role in the general theory in [1] and [7] and, in particular, in characterizing the first Chern number of $\mathscr{E}(\tilde{K}, \lambda)$. Briefly, this is seen by noting that f^ε is a map from $\tilde{K} \approx S^1$ into $Gl(2; \mathbb{C})$, and so represents a class in $\pi_1(Gl(2; \mathbb{C})) \cong \mathbb{Z}$. It turns out that $c_1(\mathscr{E}(\tilde{K}))$ can be characterized explicitly as the winding number of the curve $\det f^\varepsilon(\tilde{K})$. Furthermore, the relation between $c_1(\mathscr{E}(\tilde{K}, \varepsilon))$ and the number of eigenvalues of $\mathscr{L}$ inside $\tilde{K}$ is obtained by proving that the Evans function $D(\lambda)$ is a nonzero, constant multiple of $\det f^\varepsilon$. See [7] for additional details.

3.13. Continuation to the reduced problem. We can now prove the main theorem of this section. We now return to our original notation wherein K denotes the curve in Fig. 3.1 passing through the origin and $\tilde{K}$ is the curve in the figure with the origin in its exterior. All results of the previous section were proved for the bundle $\mathscr{E}(\tilde{K}, \varepsilon)$.

THEOREM 3.11. *Suppose that $\lambda \in K$ in Fig.* 3.1 *is* not *an eigenvalue of* (1.4) *for all $\lambda \in K$. There exists ε_o such that for all $\varepsilon \in (0, \varepsilon_o]$ the number of eigenvalues inside K of the perturbed problems* (3.2) *counting multiplicity is equal to the number of eigenvalues inside K of the reduced problem* (1.4) *counting multiplicity.*

Proof. The main result in [7] asserts that the multiplicity of eigenvalues of (3.2) (respectively, (1.4)) inside K is equal to $c_1(\mathscr{E}(K, \varepsilon))$ (respectively, $c_1(\tilde{\mathscr{E}}_{2*}(K))$). The topological character of c_1 together with our previous approximation theorems will enable us to equate these two quantities.

To begin with, Lemma 3.2 in § 3.4 implies that (3.2) has no spectrum inside the semicircle, $\text{Re}\,\lambda \geqq 0$, $|\lambda| = \delta$, with δ independent of ε. The same statement is also valid for the spectum of (1.4); this is because $U(x)$ is a linearly nondegenerate solution of (2.3) and (1.4) is precisely the variational equation for (2.3) at $U(x)$ when $\lambda = 0$. Even though the potential in (1.4) is singular for $\lambda < 0$, the result follows from a similar but simpler limiting argument for sequences of eigenvalues $\lambda \to 0$ with $\text{Re}\,\lambda \geqq 0$ as that used in the proof of Lemma 3.2; it will therefore be omitted. We can therefore deform the curve K in Fig. 3.1 to $\tilde{K}$ via the homotopy K_γ to conclude that

$$c_1(\mathscr{E}(K, \varepsilon) = c_1(\mathscr{E}(\tilde{K}, \varepsilon)), \qquad c_1(\tilde{\mathscr{E}}_{2*}(K)) = c_1(\tilde{\mathscr{E}}_{2*}(\tilde{K})).$$

The additive property of c_1 together with (3.29) implies that

$$c_1(\mathscr{E}(\tilde{K}, \varepsilon)) = c_1(\mathscr{E}_1(\tilde{K}, \varepsilon)) + c_1(\mathscr{E}_2(\tilde{K}, \varepsilon)).$$

The proof will be complete if it can be shown that

(i) $c_1(\mathscr{E}_1(\tilde{K}, \varepsilon)) = 0$ for $\varepsilon \in (0, \varepsilon_o]$,

(ii) $c_1(\mathscr{E}_2(\tilde{K}, \varepsilon)) = c_1(\tilde{\mathscr{E}}_{2*}(\tilde{K}))$ for $\varepsilon \in (0, \varepsilon_o]$.

To prove (i) we show that $\mathscr{E}_1(\tilde{K}, \varepsilon)$ is a trivial bundle for all such ε. To this end we show that there is a global, nonvanishing section of $\mathscr{E}_1(\tilde{K}, \varepsilon)$. The existence of such a section is an immediate consequence of Theorem 3.6, which asserts that $\hat{\Phi}_1(L, \lambda, \varepsilon)$ lies near $\hat{E}_1(L, \lambda, \varepsilon)$ for all $\lambda \in \tilde{K} \cup \tilde{K}^\circ$. It follows that the entries $f^\varepsilon_{1,1}(\lambda)$ and $f^\varepsilon_{1,2}(\lambda)$ of the gluing map are well defined and continuous for *all* $\lambda \in \tilde{K} \cup \tilde{K}^\circ$. Thus the characterization (3.30) of $\bar{\phi}_1(\lambda, \varepsilon)$ is valid for all such λ, and we are justified in replacing $\bar{g}_1(b, \varepsilon)$ with $\bar{\phi}_1(b, \varepsilon)$ in (3.32) when $i = 1$. Since $\bar{\phi}_1$ continuously extends $\chi_1(b)$ to all of $\tilde{K} \cup \tilde{K}^\circ$, this provides the desired nonvanishing section.

To prove (ii) we need to show that $\mathscr{E}_2(\tilde{K}, \varepsilon)$ approaches $\mathscr{E}_{2*}(\tilde{K})$ as $\varepsilon \to 0$. Since c_1 is a homotopy invariant, these two bundles would then have to have the same first Chern number; (ii) then follows from Lemma 3.10.

In order to specify what it means for two line bundles to be close together, it is useful to introduce a certain map $\hat{e} : B \to \mathbb{C}P^{n-1}$ associated with a given line bundle (E, B, π) whose fibers are complex lines in $\mathbb{C}^n$. Given such a bundle, $\hat{e}(b)$ is the point in the compact metric space $\mathbb{C}P^{n-1}$ associated with the complex line $\pi^{-1}(b)$. Thus the notion of a complex line bundle over B is equivalent to the specification of a continuous map $\hat{e} : B \to \mathbb{C}P^{n-1}$. More precisely, let $\Gamma_1(\mathbb{C}^n)$ be the canonical bundle over $\mathbb{C}P^{n-1}$, i.e., the fiber in $\Gamma_1(\mathbb{C}^n)$ over a point $\hat{e} \in \mathbb{C}P^{n-1}$ is the complex line in $\mathbb{C}^n$ associated with $\hat{e}$. We then have the commutative diagram

$$\begin{tikzcd}
E \arrow[r, "\hat{e}^*"] \arrow[d, "\pi"] & \Gamma_1(\mathbb{C}^n) \arrow[d] \\
B \arrow[r, "\hat{e}"] & \mathbb{C}P^{n-1};
\end{tikzcd}$$

the pullback $\hat{e}^*\Gamma_1(\mathbb{C}^n)$ is then isomorphic to E. Thus two complex line bundles (E_i, B, π_i) over the same base space are close togeher if their associated maps $\hat{e}_i : B \to \mathbb{C}P^{n-1}$ are close in the topology of $\mathbb{C}P^{n-1}$.

Let $\hat{e}_2(b, \varepsilon)$ and $\hat{e}_{2*}(b)$ be the maps into $\mathbb{C}P^3$ associated with $\mathscr{E}_2(\tilde{K}, \varepsilon)$ and $\mathscr{E}_{2*}(\tilde{K})$, respectively. We need to show that $\hat{e}_2(b, \varepsilon) \to \hat{e}_{2*}(b)$ uniformly in $\mathbb{C}P^3$ for $b \in B$ as $\varepsilon \to 0$. Over the caps B_l and B_r this is immediate, since $u_2(\gamma) \to u_2(0) = u_2$ and $E_2(L, \lambda, \varepsilon) \to E_{2*}(L, \lambda)$ as $\varepsilon \to 0$. The convergence of $\hat{e}_2(b, \varepsilon)$ to $\hat{e}_{2*}(b)$ over the sides B_* will be established if it can be shown that $\hat{\Phi}_2(x, \lambda, \varepsilon)$ converges uniformly to $\hat{\Phi}_{2*}(x, \lambda)$, where Φ_{2*} is as in (3.27). This follows immediately from the form (3.27) for Φ_{2*}, Lemma 3.9, and the expression (3.25) for a unit vector $Y \in \pi^{-1}\hat{\Phi}_2(x, \lambda, \varepsilon)$. In particular, Lemma 3.9 states that if

$$Y = (P, Q, R, S) \in \pi^{-1}\hat{\Phi}_2(x, \lambda, \varepsilon),$$

$$Y_* = (P_*, Q_*, R_*, S_*) \in \pi^{-1}\hat{\Phi}_{2*}(x, \lambda),$$

then

$$(P, Q)^\wedge \to (P_*, Q_*)^\wedge \quad (\text{in } \mathbb{C}P^1).$$

Thus we may select the representatives Y and Y_* so that (P, Q) approaches (P_*, Q_*) in $\mathbb{C}^2$. Finally, (3.25) implies that

$$P = J(x, \lambda)R + \mathcal{O}(d), \qquad P_* = J(x, \lambda)R_*,$$

where the first equation holds for arbitrary d and sufficiently small ε depending on d. Thus $\hat{Y} \to \hat{Y}_*$ in $\mathbb{C}P^3$ uniformly for $x \in (-L, L]$.

4. Analysis of the reduced equation. We have now shown that the spectrum σ_ε of the perturbed operator $\mathscr{L}$ is approximated by the spectrum of the reduced problem (1.4), which we shall denote by σ_R. The spectral analysis of (1.4) is complicated by the fact that it has variable coefficients and that the eigenvalue parameter λ occurs in a nonstandard, nonlinear manner. In this section we shall present a detailed analysis of the spectrum of (1.4) in the special case that the parameter $\mu = \sqrt{m}$ is sufficiently large. In this case the line $v = m(u - \gamma)$ is almost vertical. In terms of the singular limit $(\bar{U}(x), \bar{V}(x))$ there is a transition layer when $|x| = x_\gamma$ is such that $\bar{U}(x_\gamma) = \gamma$; on the interval $|x| \leqq x_\gamma$ the solution remains close to the critical point $(\hat{u}, \hat{v})$ in Fig. 2.2. Hence the solution breaks up into two distinct parts, the outer layers, on the intervals $x_\gamma \leqq |x| \leqq L$, and the inner layer, on the $|x| \leqq x_\gamma$. It turns out that it is the inner layer that is critical in determining the spectrum of (1.4).

4.1. Asymptotics of $U(x; u)$ for large μ. Let $U(x, \mu)$ denote the maximal stationary solution $U_2(x, m, \gamma)$ of the singular limit equation (2.3), where $\mu^2 = m$ and γ is regarded as fixed. Thus $U(x, \mu)$ solves

$$\ddot{U} + r(U, \mu) = 0, \qquad U(\pm L) = 0, \tag{4.1}$$

where

$$r(U, \mu) = h(U) - \mu^2 U(U - \gamma)_+. \tag{4.2}$$

The function $r(U; \mu)$ is qualitatively a cubic which approaches $h(U)$ as $\mu \to 0$. As $\mu \to \infty$ the largest root of $h(U; \mu)$, which we denote by $\bar{u}(\mu)$, tends to γ, The phase plane in (4.1) with $U \geqq \gamma$ and large μ is indicated in Fig. 4.1. The stable and unstable manifolds of the rest point at $(\bar{u}(\mu), 0)$ have slope μ. Upon comparison with Fig. 2.1, which depicts the phase plane for (4.1) with $U \leqq \gamma$, we obtain a condition for the existence of $U(x, \mu)$ for all large μ, namely, that

$$\sigma < \gamma < b, \tag{4.3}$$

where σ is the equal area point of r,

$$\int_0^\sigma r(U; \mu)\, dU = 0;$$

hence if (4.3) holds, σ is independent of γ. A simple calculation shows that

$$\sigma = \frac{2}{3}(a+b) - \left[\frac{4}{9}(a+b)^2 - 2ab\right]^{1/2}. \tag{4.4}$$

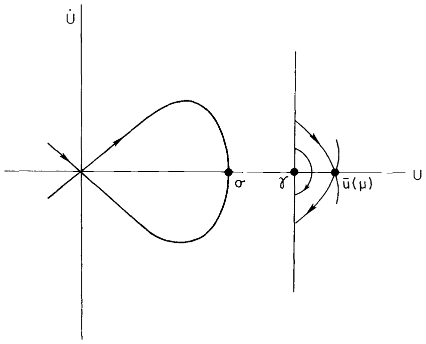

FIG. 4.1

Let $U(x, p, \mu)$ be the solution of (4.1) that satisfies

$$U(0, p, \mu) = 0, \qquad \dot{U}(0, p, \mu) = p, \tag{4.5}$$

so that $U(x, \mu) = U(x - L, p, \mu)$ for some $p = p(L)$. An important tool in our analysis of the asymptotics of $U(x, \mu)$ as $\mu \to \infty$ is the time map for solutions of (4.1):

$$T(p, \mu) = \int_0^{\hat{U}} \frac{dU}{\sqrt{2p^2 - 2R(U, \mu)}} = \int_0^{\hat{U}} \frac{dU}{\sqrt{2R(\hat{U}, \mu) - 2R(U, \mu)}},$$

where $\hat{U} = U(p, \mu)$ is the value of $U(x, p, \mu)$ when $\dot{U} = 0$, and

$$R(U, \mu) = \int_0^U r(s, \mu)\, ds.$$

Thus $T(p, \mu)$ is the time it takes $U(x, p, \mu)$ to hit $\dot{U} = 0$. The properties of the time map for this equation were discussed in [2, Appendix]. In particular, the graph of $T(p, \mu)$ is as indicated in Fig. 4.2: it has a unique local minimum L_o at some positive $p = p_o$, and it has vertical asymptotes at $p = 0$, $p = \bar{p}$. For $L > L_o$ the solution $U(x, \mu)$ is $U(x + L, p, \mu)$, where $U(x, p, \mu)$ is the solution for which $T(p, \mu) = L$ and $p \in (p_o, \bar{p})$. This uniquely determines $U(x, \mu)$ for each $L > L_o$.

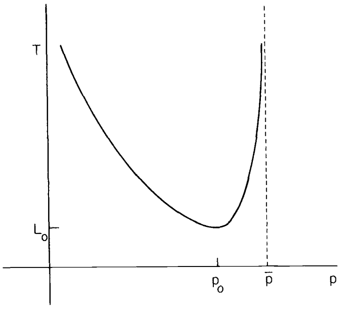

FIG. 4.2

We are interested in the asymptotics of T as $\mu \to \infty$. To this end it is useful to express T as

$$T(p, \mu) = \alpha(p) + \beta(p, \mu),$$

where $\alpha(p)$ is defined by the equation

$$U(\alpha(p), p, \mu) = \gamma,$$

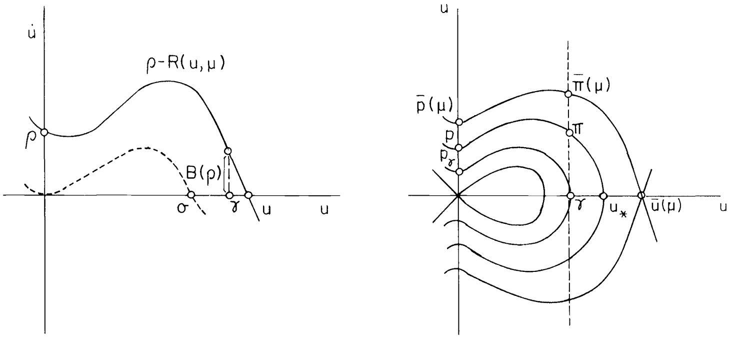
and $\beta = T - \alpha$. Note that since $r(U, \mu)$ is actually independent of μ when $U \leqq \gamma$, $\alpha(p)$ is also independent of μ. Thus $\alpha(p)$ is the time map for the portion of the solution where $0 \leqq U \leqq \gamma$, and β is the time map for the remainder $\gamma \leqq U \leqq \hat{U}(p, \mu)$.

Since β depends implicitly on p it is convenient to introduce another parameter,

$$\pi = \pi(p) = \dot{U}(\alpha(p), p, \mu).$$

Let $\rho = p^2$ and $B = \pi^2$; it can then be seen from Fig. 4.3(a) that $B = B(\rho)$ is monotone increasing in ρ, so that $\pi(p) = B(p^2)^{1/2}$ is monotone increasing in p. Let

$$\bar{p}(\mu) = \sqrt{2R(\bar{u}(\mu), \mu)}, \quad \bar{\pi}(\mu) = \pi(\bar{p}(\mu)), \quad p_\gamma = \sqrt{2R(\gamma, \mu)};$$



(a) (b)

FIG. 4.3

then $\bar{p}(\mu) > p_\gamma$ for all μ and $\bar{p}(\mu) \to p_\gamma$ as $\mu \to \infty$ since $\bar{u}(\mu)$ tends to γ for large μ. More precisely,

$$\bar{u}(\mu) - \gamma = \frac{k(\mu)}{\mu^2},$$

where $k(\mu)$ tends to some constant $k_o > 0$ as $\mu \to \infty$ (at the rate μ^{-2}). We also see from the figure that $0 \leqq \pi \leqq \bar{\pi}(\mu)$.

Now let $p = P(\pi)$ be the inverse function for $\pi = \pi(p)$. We can then express $T(p, \mu)$ as $\hat{T}(\pi, \mu)$, where

$$\hat{T}(\pi, \mu) = T(p, \mu) = T(P(\pi), \mu) = a(\pi) + b(\pi, \mu)$$

for $0 \leqq \pi \leqq \bar{\pi}(\mu)$, where the partial time maps are

$$a(\mu) = \alpha(P(\pi)), \qquad b(\pi, \mu) = \beta(P(\pi), \mu).$$

We now regard $L > L_o$ and γ as fixed and set

$$\Pi(\mu) = \dot{U}(-x_\gamma(\mu), \mu),$$

where $-x_\gamma(\mu) < 0$ is the negative value of x, where $U(x, \mu) = \gamma$, so that $x_\gamma(\mu) = \alpha(p)$ for some p. In order to characterize the behavior of $U(x, \mu)$ for large μ we shall need to estimate how close $\Pi(\mu)$ is to $\bar{\pi}(\mu)$. This will provide estimates for $|U(x, \mu) - \bar{u}(\mu)|$ for $|x| \leqq x_\gamma(\mu)$.

THEOREM 4.1. *Let p_γ be the value of p where the* maximum *value of $U(x, p, \mu)$ on $0 \leqq x \leqq T$ is γ (see Fig. 4.3b), and let $\alpha_o = \alpha(p_\gamma)$. Fix $L \geqq \alpha_o + \delta$ for $\delta > 0$, and let $q > 1$ be given. There exists $K = K(q, \delta) > 0$ such that*

$$(4.6) \qquad \begin{aligned} |U(x, \mu) - \bar{u}(\mu)| &\leqq K\mu^{-1(q+3)/2}, \\ |V(x, \mu) - \bar{v}(\mu)| &\leqq K\mu^{-(q-1)/2}, \end{aligned}$$

where $V(x, \mu) = \mu^2(U(x, \mu) - \gamma)_+$ uniformly on the interval

$$(4.7) \qquad \begin{cases} |x| \leqq x_*(\mu), \\ x_*(\mu) = x_\gamma(\mu) - K \log \mu/\mu. \end{cases}$$

Remark. Note that (4.6) implies that $V(x, \mu)$ has a transition layer at $|x| = x_\gamma(\mu)$ of width $\mathcal{O}(\log \mu/\mu)$. This also implies that $a(\Pi(\mu))$ tends to $\alpha_o < L$ as $\mu \to \infty$, so that for large μ, the amount of time $U(x, \mu)$ spends in the inner segment is approximately $2(L - \alpha_o)$.

Proof. Let $w = u - \bar{u}(\mu)$; for $u \geqq \gamma$ the equation for w is

$$\begin{aligned}\ddot{w} &= 2k\mu^2 w + 3l\mu^2 w^2 + 4\mu^{-2} w^3\\ &= \mu^2 g(w, \mu),\end{aligned}$$

where

$$\left.\begin{aligned}k &= k(\mu) \to k_o > 0\\ l &= l(\mu) \to l_0 > 0\end{aligned}\right. \quad \text{as } \mu \to \infty.$$

Let $w(x)$ be the solution of the above equation with initial conditions

$$w(0) = \gamma - \bar{u}(\mu) = -\frac{a}{\mu^2}, \qquad \dot{w}(0) = \pi_1 = \bar{\pi}(\mu) - \mu^{-q},$$

where $a = a(\mu)$ tends to $a_o > 0$ as $\mu \to \infty$. We estimate the first time $T = T(\pi_1)$ it takes for $w(x; \mu)$ to turn around, i.e., $\dot{w}(T(\pi_1), \mu) = 0$. Let $w_1 = w(T(\pi_1), \mu)$; then it follows that $w_1 < 0$ and that

$$\frac{\dot{w}^2}{2} = \mu^2 G(w, \mu) + A, \tag{4.8}$$

where

$$G(w, \mu) = \int_o^w g(s, \mu)\, ds.$$

Evaluating (4.8) at $x = 0$ gives

$$A = \frac{1}{2}(\bar{\pi}(\mu) - \mu^{-q})^2 - \mu^2 G\left(-\frac{a}{\mu^2}, \mu\right).$$

But $\bar{\pi}^2/2 = \mu^2 G(w(0), \mu)$ so that $\bar{\pi} = b\mu^{-1} + \mathcal{O}(\mu^{-2})$ where $b = a\sqrt{2k}$, and

$$A = -\mu^{-q}\bar{\pi} + \mathcal{O}(\mu^{-2q}).$$

We also have that at $x = T(\pi_1)$,

$$0 = \mu^2 G(w_1, \mu) + A, \tag{4.9}$$

so that

$$T(\pi_1) = \frac{1}{\mu\sqrt{2}} \int_{-a^2/\mu^2}^{w_1} \frac{dw}{[G(w, \mu) - G(w_1, \mu)]^{1/2}}.$$

In the following, K will denote a generic positive constant depending on q. Now from (4.9) we have that

$$\begin{aligned}G(w, \mu) &= kw_1^2 + lw_1^3 + \mu_1^{-4} w^4\\ &= A\mu^{-2}\\ &= \mu^{-q}\bar{\pi}(\mu)\mu^{-2} + \mathcal{O}(\mu^{-2q-2})\\ &= K\mu^{-(q+3)},\end{aligned}$$

so that

$$|w_1| \leqq K\mu^{-(q+3)/2}. \tag{4.10}$$

The time map $T(\pi_1)$ can be expressed as

$$T(\Pi_1)=\frac{1}{\mu\sqrt{2}}\int_{-a/\mu^2}^{w_1}\frac{dw}{[k(w^2-w_1^2)+l(w^3-w_1^3)+\mu^{-2}(w^4-w_1^4)]^{1/2}}$$

$$=\frac{1}{\mu\sqrt{2}}\int_{1}^{-a\mu^{-2}/w_1}\frac{ds}{[k(s^2-1)+lw_1(s^3-1)+\mu^{-2}w_1^2(s^4-1)]^{1/2}},$$

where $s=w/w_1$. Since $q>1$ we see from (4.10) that the upper limit s_* is positive and that

$$s_*=-a\mu^{-2}/w_1=\mathcal{O}(\mu^{(q-1)/3})\to+\infty$$

as $\mu\to\infty$. Thus $T(\pi_1)$ can be expressed as

$$T(\pi_1)=\frac{1}{\mu\sqrt{2}}\left(\int_1^2+\int_2^{s_*}\right).$$

The first integral is clearly bounded independently of μ and therefore contributes a term of order μ^{-1} to $T(q)$. Also, for $2\leqq s\leqq s_*$ we have that

$$|w_1 s|,\ w_1^2 s^2\leqq K\mu^{-2},$$

so that for such s,

$$[k(s^2-1)+lw_1(s^3-1)+w_1^2\mu^{-2}(s^4-1)^{-1/2}\leqq Ks^{-1}.$$

We therefore have that

$$T(\Pi_1)\leqq\frac{1}{\mu}\left[K+K\log\left|\frac{a}{\mu^2 w_1}\right|\right],$$

which together with (4.10) yields

$$T(\pi_1)\leqq K\frac{\log\mu}{\mu} \tag{4.11}$$

for some $K=K(q)$.

We have now proved that

$$\bar{\pi}(\mu)\geqq\Pi(\mu)\geqq\pi_1=\bar{\pi}(\mu)-\mu^{-q},$$

where $\Pi(\mu)=\dot{U}(-x_\gamma(\mu),\mu)$. For $\pi\in[\pi_1,\bar{\pi}(\mu)]$ let $w(x,\pi)$ be the solution of the differential equation satisfying

$$w(0,\pi)=-\frac{a}{\mu^2},\qquad \dot{w}(0,\pi)=\pi,$$

and let

$$T(\pi)=\frac{1}{\mu\sqrt{2}}\int_{-a/\mu^2}^{w_1}[G(w,\mu)-G(w_*(\pi),\mu]^{-1/2}\,dw,$$

where $w_*(\pi)$ is the solution of

$$0=G(w,\mu)+\left[\frac{\pi^2}{2}-G\left(-\frac{a}{\mu^2},\mu\right)\right].$$

$T(\pi)$ is therefore the time map for the portion of the solution $w(x,\pi)$ with values starting at $-a/\mu^2$ and ending at w_1. Since $\pi>\pi_1$ it follows that $w_*(\pi)>w_1$; thus the integrand in $T(\pi)$ is smooth on $[-a/\mu^2, w_1]$. We can therefore compute $T'(\pi)$ by differentiating under the integral sign to obtain

$$T'(\pi)=\frac{1}{\mu 2^{3/2}}\int_{-a/\mu^2}^{w_1} g(w_*(\pi))w'_*(\pi)[G(w,\mu)-G(w_*(\pi)),\mu]^{-3/2}\,dw.$$

Now $g(w,\mu)=kw+\mathcal{O}(w^2)$ so that $g(w_*(\pi))>0$. Also, it is easily seen from Fig. 4.3 that $w'_*(\pi)\geqq 0$, since $w_*(\pi)=u_*-\gamma$, where u_* is as in the figure. It follows that $T'(\pi)\leqq 0$, so that $T(\pi)\leqq T(\pi_1)$ for all $\pi\in[\pi_1,\bar{\pi}]$; by (4.11) we now have that

$$T(\Pi(\mu))\leqq K\frac{\log\mu}{\mu}. \tag{4.12}$$

Now let

$$\begin{aligned} W(x,\mu)&=w(x,\Pi(\mu))\\ &=U(x-x_\gamma(\mu),\mu)-\bar{u}(\gamma)\end{aligned}$$

be the solution of the boundary value problem with $L>\alpha_0+\delta$ translated so that $W=-a/\mu^2$ at $x=0$, and let $P(\mu)=P(\Pi(\mu))$ so that

$$L=\alpha(P(\mu))+\beta(P(\mu),\mu).$$

Since $x_\gamma(\mu)=\alpha(P(\mu))$ it follows that $W(x,\mu)$ is monotone increasing on the interval $0\leqq x\leqq\beta(P(\mu),\mu)$. Since $\Pi(\mu)\in[\pi_1,\bar{\pi}(\mu)]$ it follows that $\alpha(P(\mu))$ tends to α_o as $\mu\to\infty$. For $L>\alpha_o+\delta$ it therefore follows that $\beta(P(\mu),\mu)$ is bounded away from zero for large μ. Finally, let $\hat{x}=T(\Pi(\mu))$; it follows from (4.10) and (4.12) that $\hat{x}\leqq x_*$ in (4.7), and that

$$0\geqq W(\hat{x},\mu)=w_1\geqq -K^{-(q+3)/2}. \tag{4.13}$$

Furthermore, $W(x,\mu)$ is monotone increasing on the interval $[\hat{x},\beta(P(\mu),\mu)]$; thus (4.13) holds for all x in this interval. Since $U(x,\mu)=U(-x,\mu)$, this is equivalent to (4.6), (4.7).

4.2. The linearized singular limit equation. We can now analyze the reduced linearized equation

$$\ddot{P}=G(x,\lambda,\mu)P, \tag{4.14}$$

where

$$G(x,\lambda,\mu)=\lambda-\bar{f}_u-\frac{\bar{f}_v\bar{g}_u}{\lambda-\bar{g}_v},$$

and the partials are evaluated at the singular limit $\bar{U}(x,\mu)$, $\bar{V}(x,\mu)$ of Theorem 2.1. It will be convenient to express the variables in (4.14) in real and imaginary parts; thus let

$$\begin{cases} \lambda=\alpha+i\beta,\\ G(x,\lambda,\mu)=G_R(x,\lambda,\mu)+iG_I(x,\lambda,\mu),\\ G_R=\alpha-h'(U)+V+\dfrac{\mu^2UV(\alpha+V)}{(\alpha+V)^2+\beta^2},\\ G_I=\beta\left[1-\dfrac{\mu^2UV}{(\alpha+V)^2+\beta^2}\right],\end{cases} \tag{4.15}$$

where $(U,V)=(U(x,\mu),V(x,\mu))$. The values of G when the singular limit is near the rest point $(\bar{u}(\mu),\bar{v}(\mu))$ are of particular importance; thus let

$$\bar{G}(\lambda,\mu)=\bar{G}_R(\lambda,\mu)+i\bar{G}_I(\lambda,\mu) \tag{4.16}$$

denote the expressions in (4.15) wherein (U, V) are replaced by $(\bar{u}(\mu), \bar{v}(\mu))$. For simplicity we shall denote the latter by $(\bar{u}, \bar{v})$.

The existence of pure imaginary eigenvalues $\lambda = i\beta$ is of particular importance. Let

$$\bar{g}_R(\beta, \mu) = \bar{G}_R(i\beta, \mu), \qquad \bar{g}_I(\beta, \mu) = \bar{G}_I(i\beta, \mu); \tag{4.17}$$

the graphs of $\bar{g}_R$ and $\bar{g}_I$ as functions of β have a crucial role in determining when such eigenvalues exist. Since they must occur in conjugate pairs it suffices to consider $\beta \geqq 0$. Let

$$\beta_I(\mu) = [\mu^2\bar{u}\bar{v} - \bar{v}^2]^{1/2}; \tag{4.18}$$

then $\bar{g}_I(\beta, \mu) = 0$ for $\beta \geqq 0$ if and only if $\beta = 0$ or $\beta_I(\mu)$. Similarly, let $\Gamma_R = \bar{u}\bar{v}^2/(h'(\bar{u}) - \bar{v})$, and define

$$\beta_R(\mu) = [\Gamma_R\mu^2 - \bar{v}^2]^{1/2}, \tag{4.19}$$

so that $\bar{g}_R(\beta, \mu) = 0$ for $\beta \geqq 0$ only at $\beta = \beta_R(\mu)$. If β_R is infinite or imaginary, then g_R has no real roots. Typical graphs of $\bar{g}_R$ and $\bar{g}_I$ are depicted in Fig. 4.4.

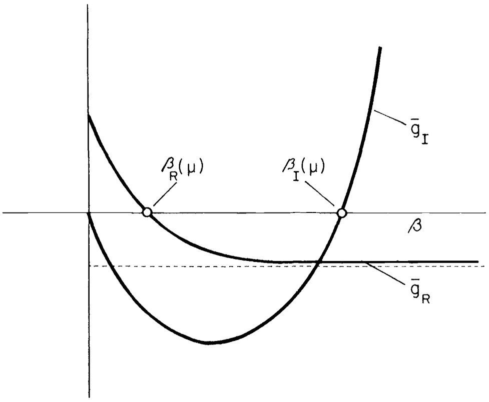


FIG. 4.4

Observe that $\beta_R(\mu)$ and $\beta_I(\mu)$ are both $\mathcal{O}(\mu)$ for large μ and that $\bar{g}_R(\beta, \mu)$ has a horizontal asymptote at the value $-h'(\bar{u}) + \bar{v}$.

It turns out that the potential for an instability depends on the relative position of $\beta_I(\mu)$ and $\beta_R(\mu)$. We therefore distinguish two cases:

Case S (stable case). $\beta_I(\mu) < \beta_R(\mu)$, or $\beta_R(\mu)$ is imaginary.

Case U (unstable case). $\beta_R(\mu) < \beta_I(\mu)$.

It can be seen from Fig. 4.4 that $\bar{g}_R(\beta, \mu) \lesseqgtr 0$ precisely when $\beta \gtreqless \beta_R(\mu)$. Thus if $g_R(\beta_I(\mu), \mu)$ is positive (negative) then we are in Case S (Case U). The transition from Case S to Case U therefore occurs when $\bar{g}_R(\beta_I(\mu), \mu) = 0$; this condition leads to the equation $-h'(\bar{u}) + 2\bar{v} = 0$. Recall that as $\mu \to \infty$, $(\bar{u}, \bar{v})$ tends to (γ, v_γ), where $v_\gamma = (b - \gamma)(\gamma - a)$. Since we are interested in the asymptotics as $\mu \to \infty$, the asymptotic critical condition is that $-h'(\gamma) + 2v_\gamma = 0$. This equation is easily solved for γ (see (1.2)); the solution is $\gamma = \gamma_0 = \sqrt{ab}$. We have now proved the following lemma.

LEMMA 4.2. *Suppose that* $\gamma_o = \sqrt{ab}$. *Then if* $\gamma > \gamma_o$ (*respectively,* $\gamma < \gamma_0$), *Case S* (*respectively, Case U*) *holds for all sufficiently large* μ.

Remark. The condition $\gamma < \sigma$ (see (4.3)) imposed previously on γ was needed to ensure the existence of the singular solution $U(x, \mu)$ of (4.1). If $\gamma_o < \sigma$ then Case S

necessarily occurs for all relevant γ. On the other hand, if $\gamma_o > \sigma$ then Case U occurs whenever $\sigma < \gamma < \gamma_o$. If we regard a as fixed and $b \gg a$ as a large parameter, then an inspection of the asymptotic behavior of the expression (4.4) for σ as $b \to \infty$ shows that σ remains uniformly bounded for large b. Since $\gamma_o = \mathcal{O}(b^{1/2})$ we see that $\sigma < \gamma_o$ whenever $a \ll b$.

Let $P(x, \lambda)$ denote the solution of (4.14) satisfying

$$P(-L, \lambda) = 0, \qquad \dot{P}(-L, \lambda) = 1. \tag{4.20}$$

Then λ is the spectrum σ_R of the slow reduced equation if and only if $P(L, \lambda) = 0$. The following lemma gives another characterization of σ_R.

LEMMA 4.3. *Let* $\bar{x} \in (0, L]$ *and let* $P(x, \lambda)$ *be the solution of* (4.14), (4.20). *Then* $\lambda \in \sigma_R$ *if and only if*

$$P(\bar{x}, \lambda) = -P(-\bar{x}, \lambda), \qquad \dot{P}(\bar{x}, \lambda) = P(-x, \lambda) \tag*{(4.21)$_-$}$$

or

$$P(\bar{x}, \lambda) = P(-\bar{x}, \lambda), \qquad \dot{P}(\bar{x}, \lambda) = -P(-\bar{x}, \lambda). \tag*{(4.21)$_+$}$$

Proof. Suppose first that $\lambda \in \sigma_R$ so that $P(x, \lambda)$ is an eigenfunction. We will first show that $P(x, \lambda) = \pm P(-x, \lambda)$. Since $U(x, \lambda) = U(-x, \lambda)$, $G(x, \lambda, \mu)$ inherits a similar symmetry, so that $P(\pm x, \lambda)$ are both eigenfunctions. It follows from the fact that $\dim P = 1$ that all eigenvalues are simple, whence $P(-x, \lambda) = cP(x, \lambda)$ for some constant c. Since $P(x, \lambda) \not\equiv 0$ it follows that

$$|P(0, \lambda)| + |\dot{P}(0, \lambda)| \neq 0.$$

If $P(0, \lambda) \neq 0$ then $c = 1$, while if $P(0, \lambda) = 0$, $\dot{P}(0, \lambda) \neq 0$, so that in this case $c = -1$. Thus precisely one of the relations $(4.21)_\pm$ hold for arbitrary $\bar{x} \in (0, L]$.

Now suppose that $(4.21)_-$ holds. Let $\tilde{P}(x, \lambda) = -P(-x, \lambda)$, and define

$$P_*(x, \lambda) = \begin{cases} P(x, \lambda) & \text{for } -L \leqq x \leqq \bar{x}, \\ \tilde{P}(x, \lambda) & \text{for } \bar{x} \leqq x \leqq L \end{cases}$$

by $(4.21)_-$ it follows that $P_*(x, \lambda)$ is a C^2 solution of (4.14) which satisfies the boundary conditions both at $x = -L$ and $x = L$, so that $\lambda \in \sigma_R$. The argument is similar in the event that $(4.21)_+$ holds.

In order to study the eigenvalue problem for (4.14) it will be convenient to projectivize (4.14) to get an equation on $\mathbb{C}P^1 = S^2$. To this end set $z = \dot{P}/P$ and $w = P/\dot{P}$ to obtain local coordinates covering $\mathbb{C}P^1$. The equations for z and w are then

$$\dot{z} = G(x, \lambda, \mu) - z^2 \tag{4.22}$$

and

$$\dot{w} = 1 - G(x, \lambda, \mu) w^2, \tag{4.23}$$

respectively. Let

$$z = \sigma + i\tau, \qquad w = s + it;$$

then (4.22) and (4.23) are equivalent to

$$\begin{aligned} \dot{\sigma} &= G_R(x, \lambda, \mu) - \sigma^2 + \tau^2, \\ \dot{\tau} &= G_I(x, \lambda, \mu) - 2\sigma\tau, \end{aligned} \tag{4.24}$$

and

$$\begin{aligned} \dot{s} &= 1 - G_R(x, \lambda, \mu)(s^2 - t^2) + 2G_I(x, \lambda, \mu)st, \\ \dot{t} &= -G_I(x, \lambda, \mu)(s^2 - t^2) - 2G_R(x, \lambda, \mu)st. \end{aligned} \tag{4.25}$$

Condition (4.20) is equivalent to $w=0$ or $z=\infty$ at $x=-L$. *In the following, $z(x, \lambda)$ will denote the solution of* (4.22) *satisfying $z=\infty$ at $x=-L$.* The dependence of z on the parameters μ and L will be suppressed for now. In the bifurcation analysis presented later, the dependence of z on L will be denoted explicitly by writing $z=z(x, \lambda, L)$. The two conditions $(4.21)_{\pm}$ can be incorporated into a single condition,

$$z(\bar{x}, \lambda)=-z(-\bar{x}, \lambda) \tag{4.26a}$$

or equivalently,

$$w(\bar{x}, \lambda)=-w(-\bar{x}, \lambda). \tag{4.26b}$$

By allowing $\bar{x}$ to approach zero in (4.26a) and (4.26b) we obtain the equivalent condition

$$\lambda \in \sigma_R \quad \text{if and only if } z(0, \lambda)=0 \quad \text{or} \quad z(0, \lambda)=\infty. \tag{4.27}$$

There are two distinct ideas that will be used in determining when λ is an eigenvalue. In order to show that λ *cannot* be an eigenvalue, we shall locate certain positively invariant sets for (4.24) that prevent the solution $z(x, \lambda, \mu)$ from satisfying (4.26). In the unstable case, we shall require a topological argument in the λ, z plane to demonstrate the existence of unstable eigenvalues. We first consider the stable case.

THEOREM 4.4. *Suppose that $\sigma<\gamma_o<\gamma$ and that $\mu=\sqrt{m}$ is sufficiently large. Then the solution $z(x, \lambda)$ of* (4.22) *satisfying $z(-L, \lambda)=\infty$ does not satisfy* (4.27) *for any $\lambda \in \mathbb{C}$ with* $\operatorname{Re} \lambda \geqq 0$.

Proof. Since eigenvalues occur in conjugate pairs it suffices to consider only $\beta=\operatorname{Im} \lambda \geqq 0$. We first need to determine the behavior of $z(x, \lambda)$ for x near $-L$. Since $w(-L, \lambda)=0$ it follows from (4.25) that

$$s(x)=(x+L)+\mathcal{O}(x+L)^2.$$

Now for $x \leqq -x_\gamma(\mu)$, $G_I(x, \lambda, \mu)=\beta \geqq 0$. Suppose first that $\beta>0$; the t equation in (4.25) together with the above yields

$$t(x, \lambda)=-\beta(x+L)^3+\mathcal{O}(x+L)^5,$$

so that $t(x)<0$ for x near $-L$ and $x+L>0$. Since $(\sigma+i\tau)=(s-it)(s^2+t^2)^{-1}$ it follows that $\sigma(x, \lambda)>0$ and $\tau(x, \lambda)>0$ for such x. Also, $\sigma(x, \lambda)=\mathcal{O}(x+L)^{-1}$ while $\tau(x, \lambda)=\mathcal{O}(x+L)$, so that $z=\sigma+i\tau$ is asymptotic to the positive σ-axis from above as x approaches $-L$ from above. If $\beta=0$ then $t\equiv\tau\equiv 0$ so that $z(x, \lambda)=\sigma(x, \lambda, \mu)=(x+L)^{-1}+\mathcal{O}(1)$ as $x \to -L^+$.

Let $\alpha_o \geqq 0$ satisfy

$$\alpha_0 \geqq \max\{h'(u)-v\colon 0 \leqq u \leqq b, 0 \leqq v \leqq (a+b)^2/4\};$$

we will consider the following four regions in the nonnegative λ plane separately:

$$\mathrm{I}=\{\lambda\colon \alpha>\alpha_0, \beta \geqq 0\},$$

$$\mathrm{II}=\{\lambda\colon 0 \leqq \alpha \leqq \alpha_0, \beta \geqq K\mu\},$$

$$\mathrm{III}=\{\lambda\colon 0 \leqq \alpha \leqq \alpha_0, \beta_o \leqq \beta \leqq K\mu\},$$

$$\mathrm{IV}=\{\lambda\colon 0 \leqq \alpha \leqq \alpha_o, 0 \leqq \beta \leqq \beta_o\},$$

where β_o and K are positive and independent of μ.

Suppose first that $\lambda \in I$ and let $\Sigma_+=\{z\colon \sigma>0\}$. We will show that $z(x, \lambda)$ remains finite and inside Σ_+ for all $x \in (-L, L]$. This has been demonstrated above for $-L<x$ and x near $-L$. Let $\bar{x} \in (-L, L]$ be the smallest value of x for which the assertion fails to be true. If $z(\bar{x}, \lambda)=\infty$ then $w(\bar{x}, \lambda)=0$. It then follows from (4.25) that

$$s(x, \lambda)=(x-\bar{x})+\mathcal{O}(x-\bar{x})^2,$$

so that $s(x, \lambda) < 0$ for $x < \bar{x}$; since s and σ have the same sign, this contradicts the minimality of $\bar{x}$. Suppose then that $\sigma(\bar{x}, \lambda) = 0$. It follows from (4.24) that $\dot{\sigma} = G_R(\bar{x}, \lambda, \mu) + \tau^2$; our condition that $\alpha > \alpha_0$ implies that G_R, and hence $\dot{\sigma}$ is positive at $x = \bar{x}$, again contradicting the minimality of $\bar{x}$. Hence $z(L, \lambda)$ is finite and nonzero, so that λ is not an eigenvalue.

Now suppose that $\lambda \in \mathrm{II}$. From (4.15) it is evident that if $\beta \geqq K\mu$ and if K is large then $G_{\mathrm{I}}(x, \lambda, \mu) > 0$ for all x and all sufficiently large μ. Let $T_+ = \{z\colon \tau > 0\}$; we claim that $z(x, \lambda)$ remains finite and inside T_+ for all $x \in (-L, L]$. By the expansion obtained earlier this clearly holds for $x > -L$ and x near $-L$. Let $\bar{x}$ be the smallest $x > -L$ such that either condition fails. If $z(\bar{x}, \lambda) = \infty$ then $w(\bar{x}, \lambda) = 0$. Since $G_{\mathrm{I}} > 0$ for all x and $\lambda \in \mathrm{II}$ it follows from (4.25) that $s(x, \lambda) = (x - \bar{x}) + \mathcal{O}(x - \bar{x})^2$ and that $t(x, \lambda) = -G_{\mathrm{I}}(\bar{x}, \lambda, \mu)(x - \bar{x})^3 + \mathcal{O}(x - \bar{x})^4$ so that $\tau = -t(s^2 + t^2)^{-1} < 0$ for $x < \bar{x}$, contradicting the minimality of $\bar{x}$. Finally, if $\tau(\bar{x}, \lambda) = 0$ then $\dot{\tau} = G_{\mathrm{I}}$ is positive at $\bar{x}$, again contradicting the minimality of $\bar{x}$. Thus $\lambda \in \mathrm{II}$ is not an eigenvalue.

Before proceeding to III, we shall need to give a finer estimate for K, namely, that

$$K\mu < \beta_R(\mu) \tag{4.28}$$

for large μ. Recall that K is chosen so that $G_I(x, \lambda, \mu) > 0$ for all x and $\beta \geqslant K\mu$. Since $(\bar{u}, \bar{v})$ are the maxima of (U, V) for $|x| \leqq L$, we see that

$$G_{\mathrm{I}}(x, \lambda, \mu) = \beta\left[1 - \frac{\mu^2 UV}{(\alpha + V)^2 + \beta^2}\right]$$
$$\geqq \beta\left[1 - \frac{\mu^2 \bar{u}\bar{v}}{V^2 + \beta^2}\right].$$

Hence the condition on G_{I} will hold if

$$\beta \geqslant \mu\sqrt{\bar{u}\bar{v} - V^2/\mu^2},$$

so that K can be any constant larger than $(\bar{u}\bar{v})^{1/2}$. Since we are in Case S we see from (4.18), (4.19) that

$$\beta_{\mathrm{I}}(\mu) = \sqrt{\mu^2\bar{u}\bar{v} - \bar{v}^2} < \sqrt{\Gamma_R\mu^2 - \bar{v}^2} = \beta_R(\mu)$$

for large μ, so that $\sqrt{\bar{u}\bar{v}} < \Gamma_R^{1/2}$. Thus if K is chosen so that

$$\sqrt{\bar{u}\bar{v}} < K < \Gamma_R^{1/2},$$

G_{I} will be positive for all x and $\beta \geqq K\mu$, and also (4.28) will be satisfied.

Now suppose that $\lambda \in \mathrm{III}$, so that $0 \leqq \alpha \leqq \alpha_0$ and $\beta_0 \leqq \beta \leqq K\mu$. We first consider the behavior of $z(x, \lambda)$ on the interval $-L \leqq x \leqq -x_\gamma(\mu)$. Since $V(x, \mu) \equiv 0$ on this interval we see from (4.15) that $G_R = \alpha - h'(U) + V$ is uniformly bounded and in fact, independent of β, while $G_{\mathrm{I}} \equiv \beta$. Thus (4.24) can be expressed as

$$\dot{\sigma} = G_R - \sigma^2 + \tau^2, \qquad \dot{\tau} = \beta - 2\sigma\tau.$$

If we regard β as a large parameter and G_R as $\mathcal{O}(1)$ then the phase plane for this system is as depicted in Fig. 4.5 for each $x \in [-L, -x_\gamma(\mu)]$. In particular, the vector field $(\dot{\sigma}, \dot{\tau})$ is nearly vertical in a uniform neighborhood of the origin for large β. Consider the region Σ depicted in the figure. The diagonal edge of Σ near the origin has slope -1; it is then easily seen that $(\dot{\sigma}, \dot{\tau})$ points strictly into Σ along $\partial\Sigma$ so that Σ is positively invariant for (4.24) relative to the interval $[-L, -x_\gamma(\mu)]$ provided that $\beta \geqq \beta_o$ and that β_o is sufficiently large. Note that this condition is independent of μ. Since the right edge of Σ can be extended arbitrarily close to $\sigma = +\infty$, it follows from our characterization of $z(x, \lambda)$ for x near $-L$ that $z(x, \lambda)$ lies in Σ for some $x \in (-L, -x_\gamma(\mu)]$.

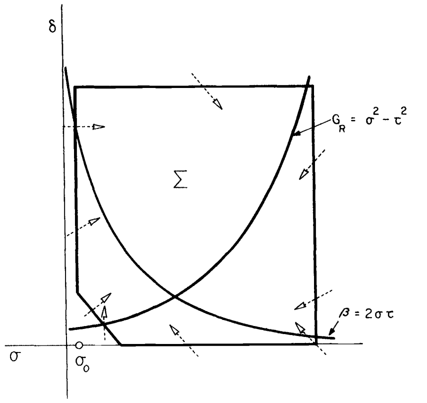

FIG. 4.5

At $x = -x_\gamma(\mu)$ we see that $\sigma(x, \lambda) \geqq \sigma_o > 0$ where $\sigma_o > 0$ is the lower bound for σ in Σ, which depends only on β_o. From Fig. 4.4, we see that $G_R(x, \lambda, \mu)$ is uniformly bounded from below for large μ, say

$$\min_{|x| \leqq L} G_R(x, \lambda, \mu) \geqq -A^2$$

for some $A > 0$ independent of λ and μ. Thus

$$\dot{\sigma} = G_R - \sigma^2 + \tau^2 \geqq -(A^2 + \sigma^2).$$

Thus for $x \geqq x_\gamma$ we obtain the estimate

$$\sigma(x, \lambda) \geqq A \tan\left[-A(x + x_\gamma) + \tan^{-1}(\sigma_o / A)\right]. \tag{4.29}$$

From the above, we see that there exists $x_1 \in (-x_\gamma, 0)$ and $\sigma_1 > 0$, both independent of μ, such that $\sigma(x_1, \lambda) \geqq \sigma_1$ for all $\lambda \in \mathrm{III}$ and all sufficiently large μ. We now use (4.6) and (4.7) of Theorem 4.1 to approximate $G(x_1, \lambda, \mu)$ by $\bar{G}(\lambda, \mu)$. For $\lambda \in \mathrm{III}$, the coefficients of U and V in the expressions (4.15) for G_R and G_I have factors of order at most μ^2. It therefore follows from Theorem 4.1 that

$$|G(x, \lambda, \mu) - \bar{G}(\lambda, \mu)| \leqq K\mu^{-(q-7)/2}$$

for all x satisfying (4.7). Fix $q > 7$ so that x_1 satisfies (4.7) for all large μ. We therefore have that $G(x, \lambda, \mu)$ is uniformly approximated by $\bar{G}(\lambda, \mu)$ on the interval $|x| \leqq |x_1|$. Since $\bar{G}(\lambda, \mu)$ is uniformly positive for $\lambda \in \mathrm{III}$, it follows that $G(x, \lambda, \mu) > 0$ for $|x| \leqq |x_1|$, for all $\lambda \in \mathrm{III}$ and all large μ. We can now use the same argument that was used for $\lambda \in \mathrm{I}$ to show that $z(x, \lambda)$ remains finite and inside the right half plane Σ_+ on the interval $|x| \leqq |x_1|$. This violates the condition (4.26) with $\bar{x} = |x_1|$, so that by Lemma 4.3, $\lambda \in \mathrm{III}$ is not an eigenvalue.

Finally, suppose that $\lambda \in \mathrm{IV}$. We can no longer construct the positively invariant region Σ as in case III. The first step will be to show that $\sigma(x, \lambda)$ remains bounded from below uniformly for $x \in [-L, -x_1]$ for some $x_1 \in (0, x_\gamma)$, $\lambda \in \mathrm{IV}$, and for all large μ. The second step will be to show that $z(x, \lambda)$ is rapidly attracted to a certain rest point of the interior layer equation

$$\dot{z} = \bar{G}(\lambda, \mu) - z^2$$

on the interval $|x| \leqq x_1$. This rest point has positive real part and is of order $\sqrt{\mu}$; thus $z(x, \lambda)$ violates the eigenvalue condition (4.26) with $\bar{x} = x_1$ for large μ.

We first consider the case $0<\beta \leqq \beta_o$. We will show that (σ, τ) remains finite and $\tau(x, \lambda)$ remains positive for all $x \in (-L, -x_\gamma(\mu)]$ and $\lambda \in \mathrm{IV}$. Since $G_I \equiv \beta$ on this interval it follows that τ remains positive for as long as (σ, τ) remains finite. However, by expanding (s, t) about a point $\bar{x}$ where $(s, t)=(0,0)$ it can be seen that $\tau(x, \lambda)$ must change sign from negative to positive as x crosses $\bar{x}$. Hence (σ, τ) remains finite with $\tau>0$ on this interval. Furthermore, a similar argument implies that (s, t) remains finite on this interval, since otherwise (σ, τ) would vanish at some $\bar{x}$. Since $\dot{\tau}=\beta$ at $\bar{x}$ it would again follow that τ changes from negative to positive as x crosses $\bar{x}$, providing a contradiction. It follows that (s, t) is uniformly bounded and continuous and uniformly bounded away from $(0,0)$ on compact subintervals of $(-L, -x_\gamma(\mu)]$. Since $\sigma(x, \lambda) \to +\infty$ as $x \to -L^+$ it follows that

$$\underline{\sigma} = \operatorname*{Min}_{\substack{\lambda \in \mathrm{IV} \\ -L \leqq x \leqq -x_\gamma(\mu)}} \sigma(x, \lambda)$$

is finite. Furthermore, since U, V are actually independent of μ for $x \leqq -x_\gamma(\mu)$ and $V(x, \mu) \equiv 0$ there, it can be seen from (4.15) that $G(x, \lambda, \mu)$—and hence $\sigma(x, \lambda)$—is independent of μ on this interval, so that $\underline{\sigma}$ is independent of μ. Finally, since $\dot{\tau}=\beta-2\sigma\tau$ it follows that

$$0 \leqq \tau \leqq \bar{\tau}$$

on $[-L, -x_\gamma(\mu)]$ where $\bar{\tau}$ depends only on $\underline{\sigma}$.

We next note that the lower bound $\underline{\sigma}$ for $\sigma(x, \lambda)$ can be extended to the interval $(-L, -x_1]$ for some $x_1<x_\gamma(\mu)$. In particular, the term in G_R which becomes significant for $x>-x_\gamma(\mu)$ is always positive (see (4.15)). Hence precisely the same estimate (4.29) as was used in case III to bound σ from below for $x \geqq -x_\gamma(\mu)$ applies here as well.

Now fix $x_1<x_\gamma(\mu)$ as above; for sufficiently large μ it follows that

$$x_1<x_\gamma(\mu)-\frac{K \log \mu}{\mu},$$

where K is as in Theorem 4.1. Thus for $|x| \leqq x_1$, $G(x, \lambda, \mu)$ is within $\mu^{-(q-7)/2}$ of $\bar{G}(\lambda, \mu)$. Since $0 \leqq \alpha \leqq \alpha_o$ and $0 \leqq \beta \leqq \beta_o$ where α_o, β_o are independent of μ, it follows that

$$\bar{G}_R(\lambda, \mu)>L^2\mu^2$$

for some $L>0$ and all large μ (see (4.15)). By the previous estimate it then follows that

$$G_R(x, \lambda, \mu)>L^2\mu^2$$

for $|x| \leqq x_1$. Thus $\sigma(x, \lambda)$ satisfies the differential inequality

$$\dot{\sigma} \geqq L^2\mu^2-\sigma^2$$

for $|x| \leqq x_1$. Furthermore, by our estimate of σ from below on $(-L, -x_1]$ it follows that

$$\sigma(x_1, \lambda)>\underline{\sigma}.$$

If $|\sigma| \leqq \mu L$ we can integrate the differential inequality to obtain

$$\sigma(x, \lambda) \geqq \mu L \frac{\Gamma-e^{-2\mu L(x+x_1)}}{\Gamma+e^{-2\mu L(x+x_1)}},$$

where

$$\Gamma=\frac{\mu L+\underline{\sigma}}{\mu L-\underline{\sigma}}.$$

Thus for $x>-x_1$, $\sigma(x,\lambda)$ rapidly becomes positive and of order μL. Since $\sigma(-x_1,\lambda)\geqq\underline{\sigma}$ it follows that $z(x,\lambda)$ cannot satisfy the eigenvalue condition (4.26) with $\bar{x}=x_1$. Thus $\lambda\in\mathrm{IV}$ is not an eigenvalue, completing the proof.

We next consider Case U, wherein the graphs of $\bar{g}_I$ and $\bar{g}_R$ have the aspect depicted in Fig. 4.6a.

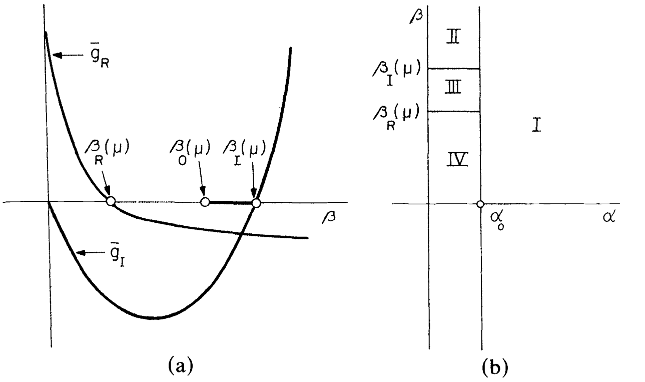

FIG. 4.6

The next theorem shows that for large L, σ_R contains pairs of complex conjugate eigenvalues with positive real part. The proof is somewhat lengthy; we therefore give a brief sketch of the main ideas first. The positive λ-quadrant is again divided into four distinct regions, as depicted in Fig. 4.6b. Here, region IV is defined by taking

$$\beta_0(\mu)=\beta_I(\mu)-p>\beta_R(\mu), \tag{4.30}$$

where $p>0$ is independent of μ, to be determined below. The first part of the proof, Lemma 4.6, shows that σ_R is disjoint from regions I, II, and III. The techniques here for the most part are the same as in Theorem 4.4.

The next step, Lemma 4.7, treats an approximate eigenvalue problem for pure imaginary eigenvalues on an interior interval $|x|\leqq l$ obtained by replacing $G(x,\lambda,\mu)$ by the constant potential $\bar{G}(\lambda,\mu)$. Thus we consider the problem

$$\dot{z}=\bar{G}(i\beta,\mu)-z^2,\qquad z(-l)=(1+i)\beta^{1/2}/2^{1/2}. \tag{4.31a}$$

The approximate eigenvalue problem consists of finding a solution of (4.31) that satisfies

$$z(0)=0\quad\text{or}\quad\infty. \tag{4.31b}$$

Problem (4.31) will have solutions at certain distinguished $\bar{l}_n^j$ and $\bar{\beta}_n^j$ with $j=0$ or ∞ and $n\geqq0$, satisfying

$$\begin{aligned}&\bar{\beta}_n^o<\bar{\beta}_n^\infty<\bar{\beta}_{n+1}^o, &&\bar{\beta}_n^j\in[\beta_o,\beta_I],\\ &\bar{l}_n^o<\bar{l}_n^\infty<\bar{l}_{n+1}^o, &&\bar{l}_n^j\to\infty\quad\text{as } n\to\infty.\end{aligned} \tag{4.32}$$

This determines branches $\bar{\lambda}(l)$ of approximate eigenvalues satisfying $\bar{\lambda}(\bar{l}_n^j)=i\beta_n^j$. It can be shown by direct computation that $\operatorname{Re}\bar{\lambda}'(\bar{l}_n^j)>0$. The transverse crossing of each eigenvalue shows that approximate problem (4.31) has precisely $2(2n+1)$ unstable eigenvalues for $\bar{l}_n^o<l<\bar{l}_n^\infty$ and $2(2n+2)$ unstable eigenvalues for $\bar{l}_n^\infty<l<\bar{l}_{n+1}^o$.

The last step consists of using (4.31) to approximate σ_R. To this end, we note that the interior interval $|x|\leqq x_\gamma(\mu)$ of the nonlinear problem is implicitly a function of L, which we denote by writing $x_\gamma = x_\gamma(\mu, L)$. This suggests the introduction of a parameter $l = x_\gamma(\mu, L)$ for the size of the interior interval. In order to obtain the uniform approximation of G by $\bar{G}$, we need to introduce

$$x_*(\mu, L) = x_\gamma(\mu, L) - K \log \mu/\mu,$$

where K is as in Theorem 4.1. It follows from the remarks preceding Theorem 4.1 that x_γ, and hence x_*, is a monotone function of L. We can therefore invert this relation by writing

$$L = X_*(\mu, l).$$

The proof is completed by showing that (4.31) provides a good approximation to (4.22) for λ along the portion of the imaginary axis satisfying (4.32). This provides a sequence of exact, purely imaginary eigenvalues $i\beta_n^j$ at intervals $L_n^j = X_*(\mu, l_n^j)$, where β_n^j and l_n^j are approximated by $\bar{\beta}_n^j$ and $\bar{l}_n^j$. Finally, we show that the eigenvalues of the exact problem cross the imaginary axis transversally too, with Re $\lambda'(L_n^j) > 0$. This provides an exact eigenvalue count in Re $\lambda \geqq 0$. We summarize this in the following theorem.

THEOREM 4.5. *Suppose that $\sigma < \gamma < \gamma_o$, so that Case U holds. There exist critical interval sizes L_n^j, $j = 0$ or ∞, $n \geqq 0$ with $L_n^{\circ} < L_n^{\infty} < L_{n+1}^{\circ}$, and there exists μ_o and $N(\mu_o)$ such that if $\mu > \mu_o$ then* (i) *$\sigma_R \cap \{$Re $\lambda \geqq 0\}$ is empty for $L < L_o^{\circ}$, and* (ii) *for $L_n^{\circ} < L < L_n^{\infty}$* (respectively, $L_n^{\infty} < L < L_{n+1}^{\circ}$). *$\sigma_R$ contains exactly* $(2n+1)$ (*respectively,* $(2n+2)$) *pairs of complex conjugate eigenvalues, for $0 \leqq n \leqq N-1$. If $\lambda(L)$ is the branch of eigenvalues with* Re $\lambda(L_n^j) = 0$, *then* Re $\lambda'(L_n^j) > 0$.

Proof. The proof will proceed in a sequence of lemmas, as outlined above.

LEMMA 4.6. *There exists $p > 0$ independent of μ such that if $\beta_o(\mu)$ is as in* (4.30), *then $\sigma_R \cap \{$I $\cup$ II $\cup$ III$\} = \varnothing$, where* I, II, III *are the regions depicted in Fig.* 4.6b.

Proof. The proof that I $\cap\, \sigma_R = \varnothing$ is the same as in Theorem 4.4. For $\lambda \in$ II, we claim that $G_{\rm I}(x, \lambda, \mu) > 0$ for $|x| \leqq L$ and all large μ; the proof then proceeds as in case II of the previous theorem. From (4.15), $G_{\rm I}$ will be positive if

$$\frac{\mu^2 UV}{(\alpha + V)^2 + \beta^2} < 1,$$

which will in turn be true if

$$\frac{\mu^2 UV}{(\alpha + V)^2 + \beta^2} < 1.$$

From (4.18), the latter inequality is equivalent to

$$\bar{v}(\mu)^2 - V^2 < \mu^2(\bar{u}(\mu)\bar{v}(\mu) - UV)$$

(recall that $\bar{u}$, $\bar{v}$ are the maxima of U, V). In order to establish this for large μ, note that for such μ we have that

$$\bar{v}(\mu) + V < \mu^2 \bar{u}(\mu).$$

Since $V \leqq \bar{v}(\mu)$ and $U \leqq \bar{u}(\mu)$, the previous inequality is easily seen to imply that the first inequality holds for $|x| \leqq L$.

Finally, suppose that $\lambda \in$ III. We shall split III into three regions:

$$A = \{\lambda\colon 0 \leqq \alpha \leqq \alpha_o, 0 \leqq \beta \leqq \beta_*\},$$

$$B = \{\lambda\colon 0 \leqq \alpha \leqq \alpha_o, \beta_* \leqq \beta \leqq \beta_R(\mu)\},$$

$$C = \{\lambda\colon 0 \leqq \alpha \leqq \alpha_o, \beta_R(\mu) \leqq \beta \leqq \beta_0(\mu)\},$$

where β_* is large, but independent of μ. For $\lambda \in A$ the argument is the same as in case IV of Theorem 4.4.

We next show that $\lambda \in B$ is not an eigenvalue. For the most part, this is proved as in case III of Theorem 4.4. In particular, the region Σ in Fig. 4.5 is positively invariant for $x \in [-L, -x_\gamma(\mu)]$, and a lower bound $\sigma(x, \mu) \geqq \sigma_o > 0$ for $-x_\gamma(\mu) \leqq x \leqq -x_1$ is obtained for $x_1 < x_\gamma(\mu)$ independent of μ, exactly as before. If $\bar{G}_R(\lambda, \mu) > 0$, then $G(x, \lambda, \mu)$ is uniformly positive for $|x| \leqq x_1$ and large μ, and the proof is completed as in the previous theorem. However, since $\bar{G}_R(i\beta_R(\mu), \mu) = 0$ it is no longer true that $\bar{G}_R(\lambda, \mu)$ will be uniformly positive for $\lambda \in B$, so that $G_R(x, \lambda, \mu)$ may in fact become negative for some $|x| \leqq x_1$. For $\lambda \in B$ near $i\beta_R(\mu)$ the important observation is that $\bar{G}_I(i\beta_R(\mu), \mu)$ is negative and of order μ, as can be seen from (4.19) and (4.15) so that $|G_I| \gg |G_R|$ for λ near $i\beta$. Thus the vector field $(\dot{\sigma}, \dot{\tau})$ is nearly vertical for (σ, τ) near the origin. Consider the region Γ depicted in Fig. 4.7 to the right of the union of line segments consisting of the two vertical rays connected by a line segment with fixed positive slope. By the above remarks, Γ will be positively invariant for $(\dot{\sigma}, \dot{\tau})$ for all $|x| \leqq x_1$ since $(\dot{\sigma}, \dot{\tau})$ is nearly vertical near the origin. Since $\sigma(-x_1, \lambda) > \sigma_o > 0$ it follows that $z(-x_1, \lambda) \in \Gamma$. The usual argument now shows that $z(x, \lambda)$ remains finite and inside Γ for $|x| \leqq x_1$. Finally, as in part IV of Theorem 4.4, $\sigma(-x_1, \lambda)$ is positive and of order $\mu^{1/2}$. It then follows from the above that for large μ, $-z(-x_1, \lambda) \notin \Gamma$, so that $z(x_1, \lambda) \neq -z(-x_1, \lambda)$. Thus $\lambda \in B$ is not an eigenvalue.

Next, suppose that $\lambda \in C$, so that

$$\beta_R(\mu) \leqq \beta \leqq \beta_I(\mu) - p. \tag{4.32}$$

For all λ with $0 \leqq \alpha \leqq \alpha_o$ and $\beta \leqq \beta_R(\mu)$, there exists M independent of μ such that $|G_R(x, \lambda, \mu)| \leqq M$ or all $|x| \leqq L$ (see (4.15)). Let

$$x_*(\mu) = x_\gamma(\mu) - K \log \mu/\mu, \tag{4.33}$$

where $K = K(q)$ is chosen as in Theorem 4.1 with $q > 7$. (For the moment, we shall suppress the dependence of x_* on L.) For $|x| \leqq x_*(\mu)$, $G(x, \lambda, \mu)$ is uniformly approximated by $\bar{G}(\lambda, \mu)$. Now $\bar{G}_I(\lambda, \mu)$ is large and negative for $\lambda \in C$. It is easily seen from (4.15) that, given $N > 0$, there exists $p > 0$ independent of μ such that $\bar{G}_I(\lambda, \mu) < -N$ for $\lambda \in C$ with p as in (4.32). Now, given the uniform bound M for $|G_R(\lambda, \mu)|$ for $\lambda \in C$, set $N = N(M)$ so that the region Γ in Fig. 4.7 is positively invariant for $\dot{z} = z^2 - \bar{G}(\lambda, \mu)$. In particular, choosing N large relative to M ensures that $(\dot{\sigma}, \dot{\tau})$ is nearly vertical near the origin. For $|x| \leqq x_*(\mu)$ it follows that Γ will also be positively invariant for (4.24) for large μ. The proof that $\lambda \notin \sigma_R$ is now obtained in the same

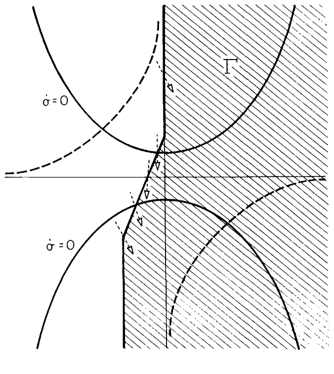

FIG. 4.7

manner as for $\lambda \in B$, by showing that $z(x_*(\lambda), \mu) \neq -z(-x_*(\mu), \lambda)$. The proof will then be complete if it can be shown that $z(-x_*(\mu), \lambda)$ lies in Γ. This fact will be proved in the next lemma, where a sharper estimate for z at $-x_*$ is obtained.

LEMMA 4.7. *For $\lambda \in \mathrm{IV} \cup C$ (see Fig. 4.6b), the solution $z(x, \lambda)$ of (4.22) satisfies*

$$|z(x_*(\mu), \lambda) - \Gamma\beta^{1/2}| \leqq C \log \mu,$$

where $\Gamma = (1+i)/\sqrt{2}$, $C > 0$ is independent of β and μ, and $x_*(\mu)$ is chosen as in (4.33).

Proof. The proof consists of two estimates; first, we approximate z on the outer layer $-L \leqq x \leqq -x_\gamma(\mu)$, and next, on the interval from $-x_\gamma$ to $-x_*$, which is of length $K \log \mu/\mu$. For λ in this range, α is $\mathcal{O}(1)$ and β is $\mathcal{O}(\mu)$, so that β and μ are of the same order of magnitude; in the following, we shall treat them as equivalent parameters.

Since $z = \infty$ at $-L$ it is convenient to work with $w = z^{-1}$, which satisfies (4.23) together with the condition $w = 0$ at $-L$. Let

$$\zeta(y) = \beta^{1/2} w(-L + \beta^{-1/2} y),$$

so that ζ satisfies

$$\dot{\zeta} = 1 - (G/\beta)\zeta^2, \qquad \zeta(0) = 0. \tag{4.34}$$

For $x \in [-L, x_\gamma(\mu)]$ and $\lambda \in \mathrm{III} \cup C$ we have that

$$G/\beta = i + \mathcal{O}(\beta^{-1}).$$

Dropping the $\mathcal{O}(\beta^{-1})$ terms in (4.34) we obtain an exact solution

$$\zeta_*(y) = \frac{1}{\Gamma} \frac{1 - e^{-2\Gamma y}}{1 + e^{-2\Gamma y}},$$

which for large $y > 0$ is exponentially close to Γ^{-1}. Let $\Delta(y) = \zeta(y) - \zeta_*(y)$; then Δ satisfies the equation

$$\dot{\Delta} = -(G/\beta)(\zeta + \zeta_*)\Delta + \mathcal{O}(\beta^{-1}), \qquad \Delta(0) = 0. \tag{4.35}$$

Let $c(y)$ be the coefficient of Δ on the right-hand side of (4.35), so that

$$c(y) = (-i + \mathcal{O}(\beta^{-1}))(\Delta + 2\zeta_*).$$

Since ζ_* is close to Γ^{-1} for large y and $\operatorname{Im} \Gamma^{-1} = -2^{-1/2}$ it follows that given $\gamma \in (0, \sqrt{2})$ there exists $\varepsilon > 0$ and $y_1 > 0$ such that for $|\Delta| \leqq \varepsilon$, $y \geqq y_1$, and large β, we have that $\operatorname{Re} c(y) < -\gamma$. Note that y_1 depends only on $\zeta_*(y)$ and hence is independent of β.

We first estimate $\Delta(y)$ on $0 \leqq y \leqq y_1$. To this end let $D(y)$ be the maximum of $|\Delta(t)|$ on $0 \leqq t \leqq y$. Then from (4.35) we obtain

$$D(y) \leqq K\beta^{-1} \int_o^y e^{tD(t)}\, dt$$

for some constant $K > 0$. We claim that $D(y) \leqq 1$ on $[0, y_1]$. Let $y_* \in [0, y_1]$ be the smallest $y > 0$ for which $D(y_*) = 1$. It then follows from the above that

$$D(y_*) \leqq K\beta^{-1}(e^{y_*} - 1);$$

since y_1 and y_* are bounded independently of β, the right-hand side can be made strictly less than 1 by choosing β large. Hence $y_* \geqq y_1$ and $D(y) \leqq \tilde{K}\beta^{-1}$ for $\tilde{K} = K(e^{y_1} - 1)$ on $[0, y_1]$. Thus for large β we will have that $D(y_1) < \varepsilon$, so that $\operatorname{Re} c(y_1) < -\gamma$.

Set β so large that $\tilde{K}(L+\gamma^{-1})\beta^{-1}<\varepsilon$ where $L=\int_0^{y_1}|\exp\int_t^{y_1}c(r)\,dr|\,dt$. For all $y\geqq y_1$ for which $\operatorname{Re} c(y)<-\gamma$ we have for $y_1\leqq t\leqq y$ that

$$\left|\exp\int_t^y c(r)\,dr\right|\leqq e^{-\gamma(y-t)}$$

for such y. It then follows that

$$\begin{aligned}|\Delta(y)|&\leqq K\beta^{-1}\int_0^y\left|\exp\int_t^y c(r)\,dr\right|dt\\ &\leqq K\beta^{-1}\int_0^{y_1}\left|\exp\int_t^{y_1}\operatorname{Re} c(r)\,dr\right|dt+K\beta^{-1}\int_{y_1}^y e^{-\gamma(y-t)}\,dt\\ &\leqq\tilde{K}\beta^{-1}(L+\gamma^{-1}).\end{aligned}$$

Thus $|\Delta(y)|<\varepsilon$ for such y. It follows that $|\Delta(y)|\leqq K\beta^{-1}\leqq\varepsilon$ for all $y\in[0,\beta^{1/2}(L-x_\gamma(\mu))]$ and some (new) $K>0$. We therefore have that

$$|\zeta(y)-\Gamma^{-1}|\leqq K\beta^{-1}+(e^{-2^{1/2}y}).$$

Returning to z it then follows that

$$z(x,\lambda,\mu)=\beta^{1/2}\Gamma+\mathcal{O}(\beta^{-1/2})$$

for $x\in[-L,-x_\gamma(\mu)]$.

We finally estimate z on the interval $[-x_\gamma,-x_*]$, where x_* is as in (4.33). On this interval, $G_I(x,\lambda,\mu)$ undergoes a rapid transition from β to $\bar{G}_{\mathrm{I}}(\lambda,\mu)$, which is negative and $\mathcal{O}(1)$, and $|G_R|$ remains uniformly $\mathcal{O}(1)$. Let $z_\gamma=z(x_\gamma,\lambda,\mu)$ and set $\Delta=z-z_\gamma$, so that $\Delta(x_\gamma)=0$ and

$$\dot{\Delta}=E(x)-2z_\gamma\Delta-\Delta^2,$$

where $E(x)=G-z_\gamma^2$ is of order β on $[-x_\gamma,-x_*]$. From the previous estimate, $\operatorname{Re} z_\gamma=\sigma_\gamma$ is close to $\beta^{1/2}/\sqrt{2}$, and so σ_γ is large and positive. We then obtain

$$|\Delta(x)|\leqq\int_{-x_\gamma}^x e^{-\sigma_\gamma(x-t)}|E(t)|\,dt+\int_{-x_\gamma}^x e^{-\sigma_\gamma(x-t)}\,|\Delta(t)|^2\,dt.$$

Let $D(x)$ be the maximum of $|\Delta(x)|$ on $[-x_\gamma,-x]$; we then have for some $C>0$ that $|E(x)|\leqq C\beta$, so that

$$D(x)\leqq C\beta\sigma_\gamma^{-1}[1-e^{-\sigma_\gamma(x+x_\gamma)}]+\sigma_\gamma^{-1}[1-e^{-\sigma_\gamma(x+x_\gamma)}]D(x)^2.$$

Since $\sigma_\gamma=\beta^{1/2}/\sqrt{2}+\mathcal{O}(\beta^{-1/2})$ it follows for some constant $C>0$ and $x\in[-x_\gamma,-x_*]$,

$$\begin{aligned}|1-e^{-\sigma_\gamma(x+x_\gamma)}|&\leqq C\sigma_\gamma\log\mu/\mu\\ &=C\log\mu/\mu^{1/2}\end{aligned}$$

since β and μ are of the same order. For large μ, we can therefore arrange that

$$0\leqq\sigma_\gamma^{-1}[1-e^{-\sigma_\gamma(x+x_\gamma)}]<C\log\mu/\mu$$

for $x\in[-x_\gamma,-x_*]$ and some $C>0$. From the above inequality for $D(x)$ we then obtain

$$D(x)<C\log\mu+[C\log\mu/\mu]D^2(x)\tag{4.36}$$

for some $C>0$ independent of μ and for $x\in[-x_\gamma,-x_*]$. Choose μ so large that $C^2\log^2\mu/\mu<1/4$. Since $D(x_\gamma)=0$ and (4.36) holds for $x\in[-x_\gamma,-x_*]$, it easily follows that $D(x) \leqq 2C \log \mu$ for all such x. Since z_γ and $\Gamma\beta^{1/2}$ differ by an error of order $\beta^{-1/2}$, the proof of Lemma 4.6 is complete.

We shall also require the following estimate for $z_\beta(x, \lambda)$ on the interval $[-L, -x_*]$.

LEMMA 4.8. *For $\lambda \in \mathrm{III}$ and $x \in [-L, -x_*]$, the solution $z(x, \lambda)$ of (4.22) satisfies $|z_\beta(x, \lambda)| \leqq C\beta^{-1/2}$.*

The proof, which uses the fact that $|G_\beta|$ is uniformly $\mathcal{O}(1)$ on this interval for all such λ, is similar to and simpler than that of Lemma 4.7, and will therefore be omitted.

Finally we describe $\sigma_R \cap \mathrm{IV}$. We have now determined $z(x, \lambda)$ on the interval $[-L, -x_*(\mu)]$; the crucial estimate is

$$z(-x_*(\mu), \lambda) = \Gamma\beta^{1/2} + \mathcal{O}(\log \mu).$$

On the interior interval $|x| \leqq x_*(\mu)$, the potential $G(x, \lambda, \mu)$ in (4.15) is uniformly approximated by the autonomous potential, $\bar{G}(\lambda, \mu)$ in (4.16). For $\lambda \in \mathrm{III}$, $\bar{G}(\lambda, \mu)$ is uniformly bounded for all μ. Thus the projectivized, nonautonomous flow on $\mathbb{C}P^1$ (as given by (4.22), (4.23) in local coordinates) is uniformly approximated by the autonomous projectivized flow, which in local coordinates is given by

$$\dot{z} = \bar{G}(\lambda, \mu) - z^2, \tag{4.37}$$

$$\dot{w} = 1 - \bar{G}(\lambda, \mu) w^2 \tag{4.38}$$

on the interval $|x| \leqq x_*(\mu)$. By the remark following Lemma 4.3 we have that $\lambda \in \sigma_R$ if and only if $z(0, \lambda) = 0$ or ∞ (see (4.27)). We therefore see that λ will be an approximate eigenvalue of (4.22) whenever there exists a solution $\bar{z}(x, \lambda)$ of (4.7) satisfying

$$\bar{z}(-x_*(\mu), \lambda) = z(-x_*(\mu), \lambda),$$
$$\bar{z}(0, \lambda) = 0 \quad \text{or} \quad \infty.$$

Since (4.37) is autonomous, this suggests introducing a new parameter l for the size of the interior interval. Ultimately, l will have to be related to the entire interval size L. Recall that x_* depends implicitly on L, which we have suppressed until now. The precise relation follows from the estimates in § 4.1, namely,

$$x_*(\mu; L) = L - \alpha(p_\gamma) + \mathcal{O}(\log \mu / \mu),$$

so that $x_*(\mu, L)$ and L essentially differ by a constant. Our strategy will be to first treat the autonomous eigenvalue problem consisting of (4.37) together with the condition

$$\begin{aligned} &\bar{z}(0, \lambda) = z(-x_*(\mu; L), \lambda), \\ &\bar{z}(l, \lambda) = 0 \quad \text{or} \quad \infty. \end{aligned} \tag{4.39}$$

The values $l = \bar{l}$ for which (4.37), (4.39) has a solution will then determine approximate eigenvalues of the exact equations provided that $\bar{L}$ is chosen so that $\bar{l} = x_*(\bar{L}, \mu)$. Exact eigenvalues will then be obtained by a transversality argument. This strategy is made feasible by Lemma 4.7, which estimates $z(-x_*(\mu; L), \lambda)$. In fact, even though this point depends on L, it is of the form

$$z(-x_*(\mu; L), \lambda) = \Gamma\beta^{1/2} + \mathcal{O}(\log \mu);$$

it follows that the error induced in the solution of (4.37) due to the $\log \mu$ term is of order $\log \mu / \mu^{1/2}$, which can be seen by explicitly solving the equation. It follows that the values $l = \bar{l}$ for which (4.37), (4.39) have solutions depending on L only up to an error of order $\log \mu / \mu^{1/2}$. Hence in locating approximate eigenvalues it is sufficient to drop the $\mathcal{O}(\log \mu)$ error terms in the above and treat z at $-x_*$ as essentially $\Gamma\beta^{1/2}$.

We first consider the existence of purely imaginary eigenvalues $\lambda = i\beta$. Let $\bar{z}(x, i\beta)$ be the solution of (4.37) with initial value $\bar{z}(0, \beta, \mu) = \Gamma\beta^{1/2}$. Let $\gamma = \sqrt{G(i\beta, \mu)}$, so that for $\beta < \beta_I(\mu)$, γ is a repeller and $-\gamma$ is an attractor for (4.37). It follows that the solution $\bar{z}(x, i\beta)$ must remain exterior to a neighborhood of γ for all $x \geqq 0$ and must eventually tend to $-\gamma$ as $x \to +\infty$. Since this is actually a flow on $\mathbb{C}P^1$, $\bar{z}$ may blow up in finite time; by using (4.38) in place of (4.37) at such a point $x = \bar{x}$, the usual argument applied to (4.25) shows that

$$\lim_{x \to \bar{x}^-} \operatorname{Re} \bar{z} = -\infty, \qquad \lim_{x \to \bar{x}^+} \operatorname{Re} \bar{z} = +\infty,$$

and that $\operatorname{Im} z$ tends to zero as $x \to \bar{x}$ through positive (respectively, negative) values as $x \to \bar{x}^-$ (respectively, $x \to \bar{x}^+$). Hence if $\bar{z}$ blows up at $\bar{x}$, it is asymptotic to the negative σ-axis from above for $x < \bar{x}$ and to the positive σ-axis from below for $x > \bar{x}$. We therefore see that since $\operatorname{Im} z \leqq 0$ is positively invariant for the flow induced by (4.37), (4.38) on the Riemann sphere, including the point at infinity, there exists a uniquely determined finite time $\bar{l}(\beta) > 0$ for which

$$\operatorname{Im} \bar{z}(\bar{l}(\beta), i\beta) = 0$$

(or where $\bar{z} = \infty$), provided that $\beta < \beta_I(\mu)$. Note that when $\beta = \beta_I(\mu)$, $\bar{G}_I = 0$ so that all solutions of (4.37) are periodic; the particular solution $\bar{z}$ never crosses $\operatorname{Im} z = 0$ and winds about the center γ infinitely often in the clockwise direction. Given $N > 0$ select $\beta_1(\mu) \in (\beta_o(\mu), \beta_I(\mu))$ such that $\bar{z}(x, \beta_1)$ winds about γ exactly N times on the interval $[0, \bar{l}(\beta_1)]$. (See Fig. 4.8.) (More precisely, if we connect the points $\bar{z}$ at $x = 0$ and $x = l(\beta_1)$ with a line segment, the resulting closed curve has winding number $-N$ with respect to γ.) Suppose that the interval $[\beta_o(\mu), \beta_1(\mu)]$ contains no eigenvalues. It follows from our previous estimates that $\operatorname{Re} \bar{z}(\bar{l}(\beta_o), i\beta) > 0$ since such λ also lie in region C. In view of our characterization of $\bar{z}$ near a point $\bar{x}$ where blowup occurs and our assumption that $\sigma_R \cap [i\beta_o i\beta_1] = \varnothing$, it follows that

$$0 < \operatorname{Re} \bar{z}(\bar{l}(\beta, \mu), \beta) < \infty$$

for all $\beta \in [\beta_o, \beta_1]$.

Let

$$D = \{(x, i\beta) \colon \beta_o(\mu) \leqq \beta \leqq \beta_1(\mu), 0 \leqq x \leqq \bar{l}(\beta)\}$$

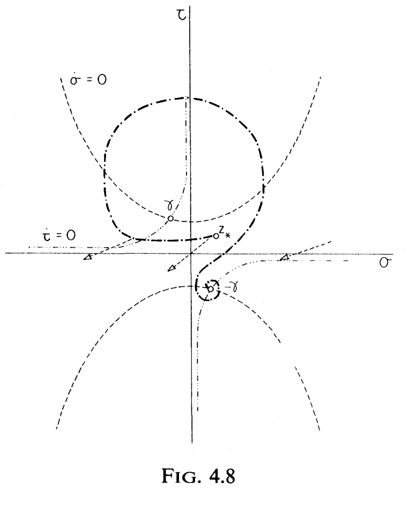

FIG. 4.8

so that D is a 2-cell. The solution $\bar z$ maps D into the hemisphere of $\mathbb{C}P^1$ corresponding to the $\operatorname{Im} z \geqq 0$; since $\bar z$ never hits the point γ for $(x, i\beta) \in D$ we may regard $\bar z$ as a map from D into the punctured disk in $\mathbb{C}P^1$ consisting of $\operatorname{Im} z \geqq 0$ minus the point γ. Furthermore, since we are assuming that $[\beta_o, \beta_1]$ contains no eigenvalues, the (real) curve $\bar z(\bar l(\beta, \mu), i\beta)$ remains in the ray $0 < \operatorname{Re} z < \infty$ for all $\beta \in [\beta_o, \beta_1]$. The behavior of the map $\bar z$ as a map from ∂D into the punctured disk is therefore as depicted in Fig. 4.9; in particular, our assumption that there are no eigenvalues imply that the image of the curve BC lies in the ray $\operatorname{Im} z = 0$, $\operatorname{Re} z > 0$, and therefore has zero winding with respect to the deleted point γ. Thus $\bar z(\partial D)$ represents a class $-N\bar 1$ in $\pi_1(S^1)$, where $\bar 1$ is an appropriate generator for $\pi_1(S^1)$ and $-N$ is the winding of segment (3) about γ, as defined earlier. This provides a contradiction, since $\bar z$ extends to a continuous map from $D^2 \to S^1$, so that $\bar z: \partial D \to S^1$ is homotopic to a constant map. Hence our assumption that $[\beta_o, \beta_1]$ contained no eigenvalues must have been false.

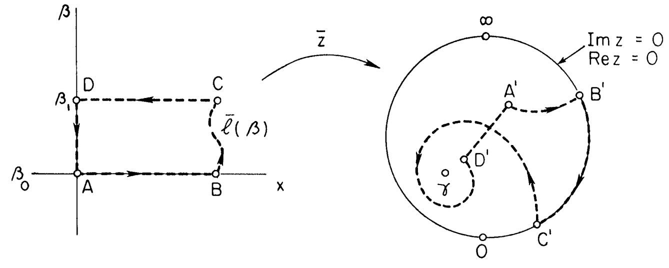

FIG. 4.9

The above argument actually shows that with N as above, $\bar z(\bar l(\beta), i\beta)$ must pass through *both* zero and ∞ at least N times. We shall see next that each crossing must be transverse in the counterclockwise direction in Fig. 4.9, so that the point C^1 must cross zero and ∞ in the counterclockwise direction as β is decreased from β_1 to β_o. Hence, there are *exactly* $2N$ values of β where approximate eigenvalues occur, which we denote by $\bar\beta_n^o, \bar\beta_n^\infty$, $n = 0, \cdots, N-1$. We shall also see below that the time $\bar l(\beta)$ is monotonically increasing with β, near each $\bar\beta_n^j$, and that the approximate eigenvalues occur at interior interval sizes

$$\bar l_n^o = \bar l(\bar\beta_n^o), \qquad \bar l_n^\infty = \bar l(\bar\beta_n^\infty),$$

with

$$\bar l_n^o < \bar l_n^\infty < \bar l_{n+1}^o. \tag{4.40}$$

Let $Z(\beta) = \bar z(l(\beta), i\beta)$, so that $Z(\beta)$ is real and $Z(\bar\beta_n^j) = j$ for $j = 0, \infty$. We first consider the case where β is near $\bar\beta_n^o$. The solution $\bar z(x, i\beta)$ of (4.37) with initial data $z_* = \Gamma\beta^{1/2}$ has the implicit form

$$\log\frac{\gamma+\bar z}{\gamma-\bar z} = 2\gamma\bar l + \log\frac{\gamma+z_*}{\gamma-z_*}, \tag{4.41}$$

$$z_* = z(-x_*(\mu, L), \beta, \mu);$$

however, some care must be used in specifying the branch of the log for β near β_n^j. To this end let $z = re^{i\phi}$ and define

$$\operatorname{Log} z = \log r + \phi i$$

with $-\pi < \phi \leqq \pi$. From Fig. 4.8 it is evident that for $x \leqq \bar{l}(\beta)$, $\bar{z}(x, \beta)$ remains in $\operatorname{Re} z \geqq 0$ and winds $n \geqq 0$ times about the rest point at γ in the *clockwise* direction. It follows that $(\gamma+\bar{z})/(\gamma-\bar{z})$ winds n times in the *counterclockwise* direction about zero, so that the angle of $(\gamma+\bar{z})/(\gamma-\bar{z})$ must increase by $2\pi n$ on $[0, \bar{l}(\beta)]$. Also, z_* is of order $\beta^{1/2}$, so that $(\gamma+z_*)/(\gamma-z_*) = -1+\mathcal{O}(\beta^{-1/2})$. We therefore obtain

$$\operatorname{Log} \frac{\gamma+\bar{z}}{\gamma-\bar{z}}\bigg|_{x=l(\beta)} = 2\gamma\bar{l} - (2n+1)\pi i + \mathcal{O}(\beta^{-1/2})$$

with $n \geqq 0$. Now for $\bar{z}$ near zero, we have that $(\gamma+\bar{z})/(\gamma-\bar{z}) = 1+2\bar{z}\gamma^{-1}+\mathcal{O}(\bar{z}^2)$; recalling that $\gamma^2 = \bar{G}$ we then have for such $\bar{z}$ that

$$\bar{z} = \bar{G}\bar{l} - (n+\tfrac{1}{2})\pi i\gamma + \mathcal{O}(\beta^{-1/2}) + \mathcal{O}(\beta-\beta_n^\circ)^2.$$

The defining condition for $\bar{l}(\beta)$ is that $\operatorname{Im} \bar{z}(\bar{l}, \beta) = 0$. Let $\gamma = \gamma_R + i\gamma_I$ and $\bar{Z}(\beta) = \bar{z}(\bar{l}(\beta), i\beta)$; we then obtain

$$\bar{l}(\beta) = (n+\tfrac{1}{2})\pi\gamma_R/\bar{G}_I + \mathcal{O}(\beta^{-1/2}) + \mathcal{O}(\beta-\beta_n^\circ)^2,$$

$$\bar{Z}(\beta) = \bar{G}_R\bar{l} + (n+\tfrac{1}{2})\pi\gamma_I + \mathcal{O}(\beta^{-1/2}) + \mathcal{O}(\beta-\beta_n^\circ)^2.$$

From Lemma 4.8 we have that $|z_{*\beta}| = \mathcal{O}(\beta^{-1/2})$; it therefore follows that

$$\bar{l}'(\bar{\beta}_n^\circ) = \left(n+\frac{1}{2}\right)\frac{\gamma_{R\beta}\bar{G}_I - \gamma_R\bar{G}_{I\beta}}{\bar{G}_I^2}.$$

It can be seen from (4.15) that $\bar{G}_{I\beta} > 0$ and is $\mathcal{O}(1)$ for $\beta \in [\beta_o, \beta_I]$; it is also easily seen that $|G_{R\beta}| = \mathcal{O}(\beta^{-1})$. Since $\gamma = \sqrt{G}$, $\gamma_R < 0$ and $\gamma_I > 0$, so that the second term in $\bar{l}'$ is positive. A simple computation shows that

$$\gamma_{R\beta} = \frac{\bar{G}_{I\beta}\gamma_I}{2|\gamma|^2} > 0, \qquad \gamma_{I\beta} = \frac{\bar{G}_{I\beta}\gamma_R}{2|\gamma|^2} < 0; \tag{4.42}$$

thus the first term in $\bar{l}'$ is negative. In order to determine the sign of $\bar{l}'$, let $\bar{G} = |\bar{G}|e^{i\phi}$, so that $\phi \in (\pi, 3\pi/2)$, and

$$\gamma = |\bar{G}|^{1/2}\left(-\sin\frac{\phi-\pi}{2} + i\cos\frac{\phi-\pi}{2}\right).$$

Let $a = |\bar{G}_R|/|\bar{G}|$ and $b = |\bar{G}_I|/|\bar{G}|$; we then have that

$$\gamma_R = -|\bar{G}|^{1/2}\left[\frac{1-a}{2}\right]^{1/2}, \qquad \gamma_I = |G|^{1/2}\left[\frac{1+a}{2}\right]^{1/2}. \tag{4.43}$$

Combining the above we obtain

$$\begin{aligned}\bar{l}'(\beta) &= \frac{(n+\frac{1}{2})\pi\bar{G}_{I\beta}|\bar{G}|^{1/2}}{\bar{G}_I^2}\left[\frac{\bar{G}_I\gamma_I}{2|\bar{G}|} - \gamma_R\right] \\ &= \frac{(n+\frac{1}{2})\pi\bar{G}_{I\beta}|\bar{G}|^{1/2}}{\bar{G}_I^2}\left[-\frac{b}{2}\sqrt{\frac{1+a}{2}} + \sqrt{\frac{1+a}{2}}\right].\end{aligned}$$

The sign of $\bar{l}'(\beta)$ is therefore determined by the quantity in brackets. Since $a^2+b^2=1$ and $0 \leqq a, b \leqq 1$, we have that the latter quantity is positive if and only if

$$1 > \frac{(1+a)^2}{4},$$

which clearly is valid for all $a \in (0, 1)$. We have therefore established that $\bar{l}'(\bar{\beta}_n^{\circ}) > 0$. We also have that

$$\bar{Z}'(\bar{\beta}_n^{\circ}) = \bar{G}_{R\beta}\bar{l} + \bar{G}_R\bar{l}' + (n+\tfrac{1}{2})\pi\gamma_{I\beta} + \mathcal{O}(\beta^{-1/2}),$$

since $G_{R\beta} = \mathcal{O}(\beta^{-1})$, so that from the above and (4.42), $\bar{Z}'(\bar{\beta}_n^{\circ}) < 0$.

Next, we characterize the behavior of $\bar{l}(\beta)$ and $\bar{z}(l, i\beta)$ for β near $\bar{\beta}_n^{\infty}$. To this end introduce the local coordinate $\zeta = \bar{G}/z$ on $\mathbb{C}P^1$; the equation for $\bar{\zeta}$ is then

$$\dot{\bar{\zeta}} = \bar{G} - \zeta^2, \qquad \bar{\zeta}(0, \beta) = \bar{G}/z_* = \zeta_*.$$

This is the same equation as for z; only the initial condition ζ_* is different. Here $\zeta_* = \mathcal{O}(\beta^{-1/2})$ is near zero. Since $\zeta(\bar{l}(\bar{\beta}_n^{\infty}), i\beta_n^{\infty}) = 0$, this suggests introducing the time $\hat{l}(\beta)$ (defined for β near $\bar{\beta}_n^{\infty}$) for which $\operatorname{Im} \zeta(\hat{l}, i\beta) = 0$. The formula for $\bar{\zeta}$ is therefore given implicitly by (4.40) with $\bar{z}$, z_*, and $\bar{l}$ replaced by $\bar{\zeta}$, ζ_*, and $\hat{l}$, respectively. The main difference is that $\bar{\zeta}$ and ζ_* are both near zero. Since $\bar{\zeta}$ must wind in the clockwise direction about γ it follows that $(\gamma+\zeta)/(\gamma-\zeta)$ must wind $(n+1)$ times about the origin in the counterclockwise direction as x increases from zero to $\hat{l}(\beta)$. It follows that the equation for $\bar{\zeta}$ and $\hat{l}$ is

$$\operatorname{Log}\frac{\gamma+\bar{\zeta}}{\gamma+\bar{\zeta}} = 2\gamma\hat{l} - 2\pi(n+1)i + \mathcal{O}(\beta^{-1/2}).$$

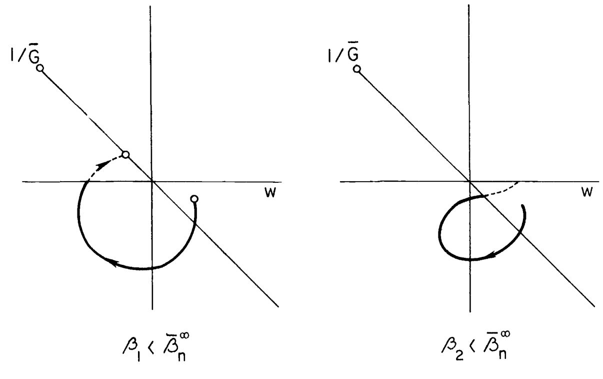
Let $\bar{\zeta}_R(\beta) = \bar{\zeta}(\hat{l}(\beta), \beta)$; we then obtain

$$\bar{\zeta}_R(\beta) = \bar{G}\hat{l} - \pi(n+1)\gamma i + \mathcal{O}(\beta^{-1/2}) + \mathcal{O}(\beta - \bar{\beta}_n^{\infty})^2.$$

The argument now proceeds exactly as before to show that $\hat{l}'(\bar{\beta}_n^{\infty}) > 0$ and that $\zeta'_R(\bar{\beta}_n^{\infty}) < 0$.

The behavior of $\bar{z}(x, \beta)$ can now be determined. Let $w = z^{-1}$ so that $w = \zeta/\bar{G}$. Since $\bar{\zeta}'_R(\bar{\beta}_n^{\infty}) < 0$ it follows that $w(\hat{l}(\beta), i\beta)$ lies along the span of $1/\bar{G}$; since $\bar{\zeta}_R(\bar{\beta}_n^{\infty}) < 0$, its behavior for $\beta_1 < \bar{\beta}_n^{\infty} < \beta_2$ is as depicted in Fig. 4.10. It is easily seen that this is equivalent to the point $\bar{z}(\hat{l}(\beta), i\beta)$ moving in the clockwise direction through the point at infinity in Fig. 4.9 as β increases through $\bar{\beta}_n^{\infty}$. From Fig. 4.10 it is evident that $\bar{z}(\bar{l}(\beta), i\beta)$ also moves in the clockwise direction about the equation $\operatorname{Im} z = 0$. Also from Fig. 4.10, we see that

$$\bar{l}(\beta_1) < \hat{l}(\beta_1), \qquad \bar{l}(\beta_2) > \hat{l}(\beta_2);$$



1/Ḡ
w
$\beta_1 < \bar{\beta}_n^{\infty}$
1/Ḡ
w
$\beta_2 < \bar{\beta}_n^{\infty}$

FIG. 4.10

hence

$$\hat{l}(\beta_2)-\hat{l}(\beta_1)<\bar{l}(\beta_2)-\bar{l}(\beta_1),$$

and since $\hat{l}'(\bar{\beta}_n^\infty)>0$ it follows that $\bar{l}(\beta)$ is strictly monotone increasing for β near β_n^∞.

We also need to show that the critical intervals $\bar{l}_n^j$ satisfy (4.40). This is easily established from our formulae for the $\bar{l}_n^j$, namely,

$$\bar{l}_n^o=\pi\left(n+\frac{1}{2}\right)\frac{\gamma_R}{\bar{G}_I}\bigg|_{\beta=\bar{\beta}_n^o}+\mathcal{O}(\beta^{-1/2}),$$

$$\bar{l}_n^\infty=n\pi\frac{\gamma_R}{\bar{G}_I}\bigg|_{\beta=\bar{\beta}_n^\infty}+\mathcal{O}(\beta^{-1/2}).$$

In order to establish (4.40) it suffices to show that the function $(\gamma_R/\bar{G}_I)$ is monotone increasing in β. This will be the case if $(\gamma_R\bar{G}_{I\beta}-\gamma_R\bar{G}_I)>0$; from (4.42), (4.43), and a bit of algebra, this is equivalent to

$$\left[-\frac{1}{2}\left(1+\frac{|\bar{G}_R|}{|\bar{G}|}\right)+1\right]\frac{|\bar{G}_I|}{|\bar{G}|}>0,$$

which, since $|\bar{G}_R|<|\bar{G}|$, is clearly valid.

Our analysis of (approximate) imaginary eigenvalues is now complete. It remains to describe the multiplicity of all unstable (or neutrally stable) approximate eigenvalues for a given l. To this end we take β near $\bar{\beta}_n^j$ and l near $\bar{l}_n^j$, and reverse their roles, i.e., we treat l as the independent variable. Our goal is to show that the purely imaginary eigenvalue $\bar{\lambda}_n^j=i\bar{\beta}_n^j$ lies along a branch of eigenvalues $\bar{\lambda}_n^j(l)$ for l near $\bar{l}_n^j$; in the following, we shall drop the sub- and superscripts. This is accomplished by the implicit function theorem. Moreover, we shall show that $\alpha'(\bar{l}_n^j)>0$, where $\alpha(l)=\operatorname{Re}\lambda(l)$. This implies that eigenvalues can only cross from the left (stable) half plane into the right (unstable) half plane, and that the crossing is transverse. Hence, the unstable eigenvalue count is

$$\begin{array}{ll}0 & \text{for } l<\bar{l}_o^o,\\ 2(2n+1) & \text{for } \bar{l}_n^o<l<\bar{l}_n^\infty,\\ 2(2n+2) & \text{for } \bar{l}_n^\infty<l<\bar{l}_{n+1}^\infty\end{array}$$

(counting complex conjugates).

The computation proceeds as follows for the case $j=0$. The case $j=\infty$ is treated similarly using the variable $\zeta=\bar{G}/z$, and will be omitted. Let $\bar{z}(x,\lambda)$ be the solution of (4.37) satisfying $\bar{z}(0,\lambda)=\Gamma\beta^{1/2}$, so that $\bar{z}(\bar{l}_n^o,i\bar{\beta}_n^o)=0$. Assume the existence of a curve $\bar{\lambda}(l)$ of eigenvalues with $\bar{\lambda}(\bar{l}_n^o)=i\bar{\beta}_n^o$, we see that $\lambda(l)$ must satisfy $\bar{z}(l,\lambda(l))=0$, so that at $l=\bar{l}_n^o$,

$$\bar{\lambda}'(l)=-\frac{\bar{z}_l}{\bar{z}_\lambda}.$$

These partials can be computed directly from (4.41), yielding $\bar{z}_\lambda=\frac{1}{2}\bar{G}_\lambda l$ and $\bar{z}_l=\bar{G}$ (modulo terms of order $\beta^{-1/2}$). From the display preceding (4.15) we see that $\bar{G}_\lambda=1+\mathcal{O}(\beta^{-2})$, so that $\bar{\lambda}'(l)=-2\bar{G}/l+\mathcal{O}(\beta^{-1/2})$. Since $\bar{G}=\lambda-\bar{f}_u+\mathcal{O}(\beta^{-2})$, by taking real parts we finally obtain $\bar{\alpha}'(\bar{l}_n^o)=2\bar{f}_u/l+\mathcal{O}(\beta^{-1/2})$, where the partial is evaluated at the rest point $(\bar{u},\bar{v})$. Since we are in Case U it turns out that $(\bar{u},\bar{v})$ must lie on the left branch of $v=(b-u)(u-a)$ in Fig. 2.2, so that $\bar{f}_u>0$. We have therefore proved that $\bar{\alpha}'(\bar{l}_n^o)>0$.

We now return to the exact equation (4.22). There are two issues that need to be addressed: (i) the outer interval size L must be determined in some manner by the inner interval size l, and (ii) the autonomous potential $\bar{G}$ must be replaced by $\bar{G}(x, \lambda, \mu)$ on the interval $|x| \leqq x_*(\mu; L)$. We first determine interval sizes $\bar{L}^j_n$ that determine approximate, purely imaginary eigenvalues on the full interval $|x| \leqq L$. To this end, note that the inner interval size $x_*(\mu, L) = x_\gamma(\mu, L) - K \log \mu/\mu$ of the underlying solution depends on L through $x_\gamma(\mu, L)$, and that by the time map estimates § 4.1, we have that

$$x_\gamma(\mu, L) = L - \alpha(p_\alpha) + \mathcal{O}(\mu^{-1}).$$

Furthermore, it also follows from the time map estimates of § 4.1 that $x_{*L} = x_{\gamma L} = 1 + \mathcal{O}(\mu^{-1})$. In particular, this is proved by differentiating $T = -x_\gamma + L$ in (4.5) with $\hat{U} = \gamma$ with respect to L and noting that the constant $R(\gamma, \mu) = \mu^{-2} g(\mu, L)$ where g_L is uniformly bounded. Thus $x_*(\mu, L)$ can be made to monotonically sweep through any desired range of values by suitably varying L.

Next, we explicitly denote the L dependence of the exact solution z by writing $z = z(x, \lambda, L)$ for the solution of (4.22) satisfying $z = -\infty$ at $x = -L$ and $w = w(x, \beta, L)$ for z^{-1}. We shall now approximate z and w by $\bar{z}$ and $\bar{w} = \bar{z}^{-1}$, respectively. Recall that the overlapping coordinate patches $|z| \leqq 2$ and $|w| \leqq 2$ cover the Riemann sphere $\mathbb{C}P^1$.

LEMMA 4.9. *There exists $K > 0$ depending only on L such that*

(i) $$|z(x, \lambda, L) - \bar{z}(x + x_*(\mu, L), \lambda)| \leqq K \log \mu/\mu$$

on $|x| \leqq x_*(\mu, L)$ whenever $|\bar{z}| \leqq 2$;

(ii) $$|w(x, \lambda, L) - \bar{w}(x + x_*(\mu, L), \lambda)| < K \log \mu/\mu$$

on $|x| \leqq x_*(\mu, L)$ whenever $|\bar{w}| \leqq 2$.

Proof. Since $\bar{w}$ and w are $\mathcal{O}(\beta^{-1/2})$ at $x = -x_*$ we begin with the w-estimate. Let $x_1 \in [-x_*, x_*]$ be the largest $x > x_*$ such that $|\bar{w}| \leqq 2$. Let $\Delta = w(x, \lambda, L) - \bar{w}(x + x_*, \lambda)$; by Lemma 4.7 we have that $|\Delta(-x_*)| = \mathcal{O}(\log \mu/\mu)$, so that

$$\dot{\Delta} = -(G - \bar{G})w^2 - \bar{G}(w + \bar{w})\Delta,$$

$$\Delta(-x_*) = \mathcal{O}(\log \mu/\mu).$$

Recall that G and $\bar{G}$ are uniformly bounded for $\lambda \in \mathrm{IV}$ of Fig. 4.6, so that for $|w|$, $|\bar{w}| \leqq 2$ the coefficient of Δ is uniformly bounded, by some constant $C > 0$. By Theorem 4.1 $|G - \bar{G}|$ is uniformly of order $\mu^{-(q-7)}$ for $|x| \leqq x_*$, so that for $q = 8$ this term is of order μ^{-1}. An application of Gronwall's inequality yields the estimate in (ii) where K depends only on $\exp[C(x_1 - x_*)]$.

At $x = x_1$, $\bar{w} = 2$ so that $|\bar{z}| \leqq \frac{1}{2}$. Let $x_2 \in [x_1, x_*]$ be the largest x such that $|\bar{z}(x_2, \lambda)| \leqq 2$. We apply a similar estimate to the equation satisfied by $z - \bar{z}$ to obtain estimate (i) on $[x_1, x_2]$. Continuing in this manner we obtain at least one of the estimates in (i) or (ii) for all $|x| \leqq x_*$.

Lemma 4.9 can be stated more compactly in terms of the projection $\pi: \mathbb{C}^2 \to \mathbb{C}P^1$. For $\Gamma \in \mathbb{C}^2 \backslash \{0\}$ let $\hat{\Gamma} = \pi(\Gamma) = \operatorname{span} \Gamma$ and with a slight abuse of notation let $\hat{z} = \pi(1, z)$ (respectively, $\hat{w} = \pi(w, 1)$), so that for $w = z^{-1}$, $\hat{z} = \hat{w}$. Also, let $\hat{0} = \pi((1, 0))$ and $\hat{\infty} = \pi(0, 1)$. If ρ is a fixed metric on $\mathbb{C}P^1$, then for $|x| \leqq x_*(\mu, L)$ we have that

$$\rho(\hat{z}(x, \lambda, L), \hat{\bar{z}}(x + x_*(\mu, L), \lambda)) \leqq K \log \mu/\mu.$$

Let L_o be determined by the equation $\bar{l}^{\infty}_{N-1} = x_*(\mu, L_o)$. We first determine $\delta > 0$ so that $\hat{\bar{\bar{Z}}}(\beta) = \hat{\bar{z}}(\bar{l}(\beta), i\beta)$ is uniformly bounded away from $\hat{0}$ and $\hat{\infty}$ for $|\beta - \bar{\beta}^j_n| \geqq \delta$,

$j=0, \infty$, and $n=0, \cdots, N-1$. For $j=0$ this follows from $\bar{Z}'(\bar{\beta}_n^\circ)<0$ and for $j=\infty$, from $\bar{W}'(\bar{\beta}_n^\infty)>0$ for $\bar{W}=\bar{Z}^{-1}$. For $|\beta-\bar{\beta}_n^\circ|\geqq\delta$ and $x\geqq 0$ there exists $\varepsilon>0$ such that

$$\rho(\bar{z}^{\wedge}(x, i\beta), \hat{0})>\varepsilon.$$

This is because $z(x, i\beta)$ crosses $\operatorname{Im} z=0$ exactly once, at $x=\bar{l}(\beta)$, at which point $\operatorname{Re}\bar{z}\neq 0$ by our condition on β. For x near zero, $\bar{z}^{\wedge}(x, i\beta)$ starts near $\hat{\infty}$, however, since $w'=1+\mathcal{O}(w^2)$ for w near zero, there exists a small $x_1>0$ such that $\rho(\bar{z}^{\wedge}(x_1, i\beta), \hat{\infty})>0$. Using our condition on β, we have that

$$\rho(\bar{z}^{\wedge}(x, i\beta\ ), \hat{\infty})\geqq\varepsilon$$

for $x\geqq x_1$. Now by Lemma 4.9, we have that

$$\rho(\hat{z}(0, i\beta, L), \bar{z}^{\wedge}(x_*(\mu, L), i\beta))\leqq K\log\mu/\mu.$$

For $\beta\leqq\bar{\beta}_{N-1}^\infty+\delta$ we then have that $\hat{z}(0, i\beta, L)\not\in\{\hat{0}, \hat{\infty}\}$ for all L. Finally, for $L\leqq L_o$ it follows that $\bar{l}_n^j>\bar{l}_{N-1}^\infty$ for all $n\geqq N$ and all j. We then have that the orbit segment $\bar{z}^{\wedge}(x, i\beta)$ on $x_1\leqq x\leqq x_*(\mu, L)$ lies uniformly in the region $\{\operatorname{Im} z\geqq\varepsilon\}^{\wedge}$ for some $\varepsilon>0$. It once again follows that $\hat{z}(0, i\beta, L)\not\in\{0, \hat{\infty}\}$ for large μ.

We next show that there is an exact imaginary eigenvalue $i\beta_n^j$ at an interval size L_n^j near $\bar{L}_n^j$, where $\bar{L}_n^j$ is determined by the equation $\bar{l}_n^j=x_*(\mu, \bar{L}_n^j)$. To this end, note that for fixed $\beta\in[\beta_n^\circ-\delta, \beta_n^\circ+\delta]$, $\dot{\bar{z}}(\bar{l}(\beta), i\beta)=\bar{G}+\mathcal{O}(z^2)$, so that $\bar{z}$ crosses $\operatorname{Im} z=0$ transversally at $x=\bar{l}(\beta)$. It follows from Lemma 4.9 that for such β there exists a unique $L=L(\beta)$ such that $\operatorname{Im} z(0, i\beta, L(\beta))=0$. Furthermore, we have by Lemma 4.9 that $|x_*(\mu, L(\beta))-\bar{l}(\beta)|\leqq K\log\mu/\mu$. Now let $\beta_\pm=\beta_n^\circ\pm\delta$; since $\bar{Z}'(\beta_n^\circ)<0$ we have that there exists $c>0$ such that

$$\bar{Z}(\beta_+)<-c\delta<c\delta<\bar{Z}(\beta_-). \tag{4.44}$$

For $\beta=\beta_-$ and β_+ we have that

$$|z(0, i\beta, L(\beta))-\bar{z}(x_*(\mu, L(\beta), i\beta))|<K\log\mu/\mu.$$

Since $x_*(\mu, L(\beta))=\bar{l}(\beta)+\mathcal{O}(\log\mu/\mu)$ we have from (4.44) that

$$\operatorname{Re}\bar{z}(x_*(\mu, L(\beta_+), i\beta_+))<0<\operatorname{Re}\bar{z}(x_*(\mu, L(\beta_-), i\beta_-)).$$

Combining the last two inequalities we see that $z(0, i\beta, L(\beta))$ is positive at $\beta=\beta_+$ and negative at $\beta=\beta_-$ for large μ. Thus there exists $\beta_n^\circ\in[\beta_-, \beta_+]$ such that $z(0, i\beta_n^\circ, L(\beta_n^\circ))=0$. The critical interval size is therefore $L_n^\circ=L(\beta_n^\circ)$. The argument for β near $\beta_n^{-\infty}$ is similar, only now we have to use the variable $\zeta=G/z$ rather than w in order to get the transverse crossing of $\operatorname{Im}\zeta=0$; with this modification, the proof is the same as for $\beta=\bar{\beta}_n^\circ$.

In order to complete the proof we need to show that $Z'(\beta_n^\circ)>0$ and that $W'(\beta_n^\infty)<0$; this will imply that $i\beta_n^j$ is the unique exact imaginary eigenvalue for $|\beta-\beta_n^{-j}|\leqq\delta$; combining this with our previous result that $i\beta$ is not an eigenvalue for $|\beta-\beta_n^j|\geqq\delta$, $n\leqq N-1$, and $L\leqq L_o$, we see that $i\beta_n^j$ are the only imaginary eigenvalues that occur for $L\leqq L_o$. Finally, we need to show that if $\lambda(L)$ is a branch of eigenvalues with $\lambda(L_n^j)=i\beta_n^j$, then $\operatorname{Re}\lambda'(L_n^j)>0$.

The crucial ingredient needed in proving the above assertions will be a description of the dependence of $z(x, \lambda, L)$ on the parameters λ and L. To this end, let

$$\Delta(x, \lambda, L)=z(x, \lambda, L)-\bar{z}(x+x_*(\mu, L), \lambda),$$

$$\delta(x, \lambda, L)=\zeta(x, \lambda, L)-\zeta(x+x_*(\mu, L), \lambda),$$

where $\zeta=\bar{G}/z$ and $\zeta=\bar{G}/\bar{z}$. We then have the following lemma.

LEMMA 4.10. *Given $q > 0$ sufficiently large in Theorem 4.1 there exists $p > 0$ and $K > 0$ such that for $\lambda \in \mathrm{IV}$,*

(i) $|\Delta_\lambda| \leqq K(\mu^{-p} + \mu^{-1/2})$ *for* $|x| \leqq x_*(\mu, L)$, *whenever* $|\bar{z}| \leqq 2$, *and* $|\delta_\lambda| \leqq K(\mu^{-p} + \mu^{-1/2})$ *for* $|x| \leqq x_*(\mu, L)$ *whenever* $|\zeta| \leqq 2$.

(ii) $|\Delta_L| \leqq K\mu^{-1/2}$ *for* $|x| \leqq x_*(\mu, L)$ *whenever* $|\bar{z}| \leqq 2$ *and* $|\delta_L| \leqq K\mu^{-1/2}$ *for* $|x| \leqq x_*(\mu, L)$ *whenever* $|\zeta| \leqq 2$.

Proof. (i) We extend $\bar{z}(0, \lambda)$ analytically by defining $\bar{z}(0, \lambda) = \sqrt{\lambda}$, since $\Gamma\beta^{1/2} = \sqrt{i\beta}$. Thus $\bar{z}\lambda = \lambda^{-1/2} = \mathcal{O}(\mu^{-1/2})$. Next, we estimate z_λ at $x = x_*$. Note that $G_\lambda = 1 + \mathcal{O}(\mu^{-2})$; the equation for w_λ is

$$\dot{w}_\lambda = -G_\lambda w^2 - Gww_\lambda, \qquad w_\lambda(-L, \lambda, L) \equiv 0.$$

Since G is approximately $i\beta$ and w is approximately $\bar{\Gamma}\beta^{-1/2}$ on $[-L, -x_\gamma]$, Re Gw is positive and of order $\beta^{1/2}$. It follows that $|w_\lambda| \leqq K\mu^{-3/2}$ on $[-L, -x_\gamma]$, so that $|z_\lambda| \leqq K\mu^{-1/2}$ for such x. On $[-x_\gamma, -x_*]$ the change in z_λ is of order $\log \mu/\mu$, so that $|z_\lambda| \leqq K\mu^{-1/2}$ at $-x_*$. We therefore have that $|\Delta_\lambda| \leqq K\mu^{-1/2}$ at $x = -x_*$. This also yields the estimate $|\delta_\lambda| \leqq K\mu^{-3/2}$ at $x = -x_*$.

In order to obtain the desired estimate on the interior layer $|x| \leqq x_*(\mu, L)$, we use the equation

$$\dot{\delta}_\lambda = G_\lambda - \bar{G}_\lambda - 2[\zeta\delta_\lambda + \bar{\zeta}_\lambda\delta]$$

for δ whenever $|\bar{\zeta}| \leqq 2$, and the equation

$$\dot{\Delta}_\lambda = G_\lambda - \bar{G}_\lambda - 2[z\Delta_\lambda + \bar{z}_\lambda\Delta]$$

whenever $|\bar{z}| \leqq 2$ is in the proof of Lemma 4.9. By Theorem 4.1 we have that $|G_\lambda - \bar{G}_\lambda| \leqq K\mu^{-(q-7)/2}\mu^{-2} = K\mu^{-(q-3)/2}$. Combining this with our initial estimate $|\delta_\lambda| \leqq K\mu^{-3/2}$ at $-x_*$, together with Lemma 4.9 to estimate δ itself, we obtain the desired estimate for Δ_λ and δ_λ as in Lemma 4.9.

(ii) We first need to estimate z_L on the outer layer $[-L, -x_\gamma]$. The equation for w_L is

$$\dot{w}_L = G_L - 2ww_L, \qquad w_L(-L, \lambda, L) = 0.$$

Clearly, G_L is determined by U_L and V_L (see (4.15)) and on $[-L, -x_\gamma]$, $V \equiv 0$, so that G_L is determined by U_L here. It is not difficult to check using the time map (4.5) that $U_L = \mathcal{O}(1)$ on $[-L, -x_\gamma]$. Now, by the outer estimate of Lemma 4.7, we have that $|w - \bar{\Gamma}\beta^{-1/2}| \leqq K\mu^{-3/2}$; using this to approximate w in the equation for w_L we obtain the estimate $|w| \leqq K\mu^{-3/2}$ by the usual Gronwall estimate. Since $z_L = -w_L/w^2$ we obtain $|z_L| \leqq K\mu^{-1/2}$.

In the interval $[-x, x_*]$ the partial $V_L = \mu^2 U_L$ also needs to be estimated. In order to estimate U_L here, we use the time map

$$x - x_\gamma = \int_\gamma^U [C - R(s, \mu)]^{-1/2}\, ds,$$

where $C = C(L) = R(\gamma, \mu) + \mu^{-2}g(L, \mu)$ and $|g_L|$ is bounded. Differentiation with respect to L yields

$$U_L = \frac{1}{2}[C - R(U, \mu)]^{1/2}\mu^{-2}g_L \int_\gamma^U [C - R(s, \mu)]^{-3/2}\, ds.$$

On the interval $[-x, -x_*]$, $|U - \gamma| \leqq K\mu^{-2}$; it then follows that

$$|C - R(U, \mu)| = \mathcal{O}(1)|\mu^{-2} + \mu^2(U - \gamma)|.$$

Using this in the above expression for U_L yields the estimate $|U_L| \leqq K\mu^{-3}$, so that $|V_L| \leqq K\mu^{-1}$ and $|G_L| \leqq K\mu^{-1}$.

Using the above estimate for $|G_L|$ in $[-x_\gamma, x_*]$ in the equation

$$\dot{z}_L = G_L - 2zz_L,$$

together with our previous estimate for z_L at x_γ and the estimate of Lemma 4.7 for z on $[-x_\gamma, -x_*]$, we obtain

$$\begin{aligned} |z_L(-x_*, \lambda, L)| &\leqq K\mu^{-1/2} + K \log \mu/\mu^2 \\ &= K\mu^{-1/2}. \end{aligned}$$

Now $\bar{z}(0, \lambda)$ is independent of L, so that the above estimate for z_L at $-x_*$ yields the estimate $|\Delta_L| \leqq K\mu^{-1/2}$ and $|\delta_L| \leqq K\mu^{-3/2}$ at $x = -x_*$.

The equations for Δ_L are

$$\begin{aligned} \dot{\Delta}_L &= G_L - 2z\Delta_L - 2\bar{z}_L\Delta, \\ \dot{\delta}_L &= G_L - 2\zeta\delta_L - 2\bar{\zeta}_L\delta, \end{aligned}$$

since $\bar{G}_L \equiv 0$. The estimates for $|\Delta_L|$ and $|\delta_L|$ on $|x| \leqq x_*(\mu, L)$ now follow from the estimate for δ_L at $x = -x_*(\mu, L)$ together with the estimates of Lemma 4.9 for Δ and $\delta = (w - \bar{w})/\bar{G}$. In particular, as in Lemma 4.9, we estimate $|\delta_L|$ when $|\bar{\zeta}| \leqq 2$ and $|\Delta_L|$ when $|\bar{z}| \leqq 2$. The details are similar to previous arguments and will be omitted.

We can now complete the proof of Theorem 4.5. We first note that for β near $\bar{\beta}_n^\circ$, evaluation of (i) of Lemma 4.9 at $x = 0$ and $L = L(\beta)$, together with the defining conditions

$$\operatorname{Im} \bar{z}(\bar{l}(\beta), i\beta) = 0, \qquad \operatorname{Im} z(0, i\beta, L(\beta)) = 0$$

for $\bar{l}(\beta)$ and $L(\beta)$ leads to the estimate

$$|\bar{l}(\beta) - x_*(\mu, L(\beta))| \leqq K \log \mu/\mu.$$

The estimate in (ii) of Lemma 4.9 leads to a similar estimate for β near $\bar{\beta}_n^\infty$. The equation for $L(\beta)$ leads to the formulae

$$L'(\beta) = -\operatorname{Im} iz_\beta/\operatorname{Im} z_L, \qquad \bar{l}'(\beta) = -\operatorname{Im} i\bar{z}_\beta/\operatorname{Im} \dot{\bar{z}}.$$

Lemma 4.10 provides the estimate

$$\begin{aligned} z_\beta(0, i\beta, L) &= \bar{z}_\beta(x_*(\mu, L), i\beta) + \mathcal{O}(\mu^{-1/2}), \\ z_L(0, i\beta, L) &= \dot{\bar{z}}(x_*(\mu, L), i\beta)x_{*L} + \mathcal{O}(\mu^{-1/2}). \end{aligned}$$

Since $x_{*L} = 1 + \mathcal{O}(\mu^{-1})$ we have from the above and our previous estimate for $|\bar{l} - x_*|$ that

$$\begin{aligned} z_\beta(0, i\beta, L) &= \bar{z}_\beta(\bar{l}(\beta), i\beta) + \mathcal{O}(\mu^{-1/2}), \\ z_L(0, i\beta, L) &= \dot{\bar{z}}(\bar{l}(\beta), i\beta) + \mathcal{O}(\mu^{-1/2}). \end{aligned}$$

Using these in the above we obtain the estimate

$$|L'(\beta) - \bar{l}'(\beta)| \leqq K\mu^{-1/2}.$$

We had previously shown that $\bar{l}'(\bar{\beta}_n^\circ) > 0$, from which we obtain $L'(\beta_n^\circ) > 0$. This finally leads to the estimate

$$\begin{aligned} \operatorname{Re}(iz_\beta + z_L L'(\beta)) &= \operatorname{Re}(i\bar{z}_\beta + \dot{\bar{z}}\bar{l}'(\beta)) + \mathcal{O}(\mu^{-1/2}) \\ &= \bar{Z}'(\beta) + \mathcal{O}(\mu^{-1/2}). \end{aligned}$$

We had shown earlier that $\bar{Z}'(\bar{\beta}_n^\circ)<0$; it then follows that $Z(\beta)=z(0, i\beta, L(\beta))$ has a negative derivative at $\beta=\beta_n^\circ$. The proof that $\zeta(0, i\beta, L(\beta))$ has a positive derivative near β_n^∞ is the same as the above for $\beta=\beta_n^\circ$. We have therefore established that the only purely imaginary eigenvalues that occur for $L\leqq L_o$ are $i\beta^j_n$, which occurs at a uniquely determined interval size $L=L_n^j$.

It only remains to show that there is a branch $\lambda(L)$ of eigenvalues for L near L_n^j with $\lambda(L_n^j)=i\beta_n^\circ$ for which $\operatorname{Re}\lambda'(L_n^j)>0$. We again provide the argument only for $j=0$; we therefore need to solve the equation $z(0, \lambda, L)=0$. We have that a solution exists for $(\lambda, L)=(i\beta_n^\circ, L_n^\circ)$, and that if $\lambda(L)$ is such a branch, then

$$z_\lambda\lambda'(L)+z_L=0;$$

by Lemma 4.10 we then obtain

$$\lambda'(L)=-z_L/z_\lambda=-\dot{\bar{z}}/\bar{z}_\lambda+\mathcal{O}(\mu^{-1/2})$$

where we have used that $z_L=\dot{\bar{z}}+\mathcal{O}(\mu^{-1})$. Since $\bar{z}_\lambda=\bar{G}_\lambda l/2\neq 0$, $\lambda(L)$ exists by the implicit function theorem. Moreover, we have already shown that

$$\operatorname{Re}(-\dot{\bar{z}}/\bar{z}_\lambda)>0,$$

which completes the proof of Theorem 4.5.

5. Concluding remarks. We conclude by combining the results of §§ 3 and 4 to obtain some rigorous results on the stability and Hopf bifurcation of the perturbed problem with $\varepsilon>0$. Recall that by Lemma 4.2, Case S (respectively, Case U) holds if $\gamma>\sqrt{ab}$ (respectively, $\gamma<\sqrt{ab}$) and μ is sufficiently large.

THEOREM 5.1. *Suppose that Case S holds and that μ is large. Then there exists $\varepsilon_o>0$ such that the perturbed solution $(U(x, \varepsilon), V(x, \varepsilon))$ of* (1.3) *is a stable solution of* (1.1) *for $0<\varepsilon<\varepsilon_0$ for all $L>L_h$.*

Proof. By Theorem 3.11 it suffices to show that (1.4) has no eigenvalues inside K in Fig. 3.1. Theorem 4.4 implies that (1.4) has no eigenvalues in $\operatorname{Re}\lambda\geqq 0$ in Case S. Since the spectrum of (1.4) is discrete, (1.4) will have no spectrum inside K if the angle ϕ in Fig. 3.1 is small enough.

THEOREM 5.2. *Suppose that Case U holds and that μ is large. Let the angle ϕ in Fig.* 3.1 *be $\phi=0$, so that $c_1(\mathscr{E}(K, \varepsilon))$ measures the number of eigenvalues of $\mathscr{L}$ in* $\operatorname{Re}\lambda\geqq 0$. *Then there exists $\varepsilon_o>0$ and interval sizes $L_n^j(\varepsilon)$ which approach L_n^j as $\varepsilon\to 0$ such that for $0<\varepsilon<\varepsilon_o$,*

(i) *$(U(x, \varepsilon), V(x, \varepsilon))$ is stable for $L<L_o^\circ(\varepsilon)$;*

(ii) *For L near $L_n^j(\varepsilon)$, the perturbed operator $\mathscr{L}$ admits a branch of eigenvalues $\lambda_\varepsilon(L)$ such that $\lambda_\varepsilon(L_n^j(\varepsilon))=i\beta_n^j(\varepsilon)$ for some $\beta_n^j(\varepsilon)$ near β_n^j, and* $\operatorname{Re}\lambda_\varepsilon'(L_n^j(\varepsilon))>0$. *Hence a Hopf bifurcation occurs as L crosses each $L_n^j(\varepsilon)$.*

(iii) *Let $N>0$ be given. The stability index $c_1(\mathscr{E}(K, \varepsilon))$ is* $2(2n+1)$ *for $L_n^\circ(\varepsilon)<L<L_n^\infty(\varepsilon)$ and* $2(2n+2)$ *for $L_n^\infty(\varepsilon)<L<L_{n+1}^\circ(\varepsilon)$, for all $n\leqq N$ and all sufficiently small $\varepsilon>0$.*

Proof. For $L<L_o^\circ(\varepsilon)$ the stability proof is the same as in Case S. In order to prove (ii) consider L near L_n^j and λ near $i\beta^j_n$. Let C be a small circle about $i\beta^j_n$, so that for L near L_n^j, C is disjoint from σ_R, and for each such L, there is a unique eigenvalue $\lambda_*(L)\in\sigma_R$ inside C, so that $\lambda_*(L_n^j)=i\beta_n^j$ and $\operatorname{Re}\lambda_*'(L_n^j)>0$. For such C we may therefore form the bundles $\mathscr{E}_{2*}(C)$ and $\tilde{\mathscr{E}}_{2*}(C)$ for the reduced problem as in § 3.11; for each L near L_n^j, $c_1(\mathscr{E}_{2*}(C))=c_1(\tilde{\mathscr{E}}_{2*}(C))=1$. Using the same procedure as was used to decompose $\mathscr{E}(K, \varepsilon)$, we form the perturbed bundle $\mathscr{E}(C, \varepsilon)$ and decompose it into a fast and slow summand

$$\mathscr{E}(C, \varepsilon)=\mathscr{E}_1(C, \varepsilon)\oplus\mathscr{E}_2(C, \varepsilon),$$

where, as in the case of K, $c_1(\mathscr{E}_1(C, \varepsilon))=0$, and the fibers of the slow summand $\mathscr{E}_2(C, \varepsilon)$ are uniformly near those of $\mathscr{E}_{2*}(C)$ over the whole base space. Now each bundle $\mathscr{E}_2(C, \varepsilon)$ and $\mathscr{E}_{2*}(C)$ depends on the parameter L; by rescaling x and introducing L as a parameter into the equations, it is easily seen that the solutions, and hence the bundles, depend analytically on L. This is seen by employing standard theorems on the analytic dependence of solutions of o.d.e.'s on parameters. Each bundle has its own Evans function, which we shall denote by $D^\varepsilon(\lambda, L)$ and $D^*(\lambda, L)$, respectively. By the previous remark, both D and D^* depend analytically on both λ and L. Since $\mathscr{E}_2$ is approximated by $\mathscr{E}_{2*}$, it follows that $D^\varepsilon(\lambda, L)$ approaches $D^*(\lambda, L)$ for fixed L and $\lambda \in C$. By the Cauchy integral formula, they are therefore also close over the interior of C. By Rouche's theorem it follows that D and D^* have the same number of roots inside C counting multiplicity, so that $D^\varepsilon(\lambda, L)$ has a simple root $\lambda_\varepsilon(L)$ for each L. Now $\operatorname{Re} \lambda'_*(L^j_n)>0$ so that $\operatorname{Re} \lambda_*(L)$ is positive (respectively, negative) for $L_+ > L^j_n + \delta$ (respectively, $L_- < L^j_n - \delta$) for fixed, small $\delta > 0$. Since $D^\varepsilon(\lambda, L)$ uniformly approximates $D^*(\lambda, L)$ for λ inside C, it follows that

$$\operatorname{Re} \lambda^\varepsilon(L_-) < 0 < \operatorname{Re} \lambda^\varepsilon(L_+)$$

so that $\lambda^\varepsilon(L) = i\beta^j_n(\varepsilon)$ at some $L = L^j_n(\varepsilon)$ near L^j_n. Again using the analyticity of D^ε and D^* in both λ and L, it follows from the Cauchy integral formula and the uniform approximation of D^ε by D^* that D^ε_λ and D^ε_L approach D^*_λ and D^*_L as $\varepsilon \to 0$. Hence

$$\begin{aligned}\lim_{\varepsilon\to 0} \operatorname{Re} \lambda'_\varepsilon(L^j_n(\varepsilon)) &= \lim_{\varepsilon\to 0} \operatorname{Re} -D^\varepsilon_\lambda / D^\varepsilon_L \\ &= \operatorname{Re} \lambda'_*(L^j_n) > 0,\end{aligned}$$

so that $\operatorname{Re} \lambda'_\varepsilon(L^j_n(\varepsilon)) > 0$ for small $\varepsilon > 0$.

We can now complete the proof. Let $\delta > 0$ be so small that $\operatorname{Re} \lambda_*(L^j_n \pm \delta) \neq 0$ for all n, j with $n \leqq N-1$. If L is such that $|L - L^j_n| \geqq \delta$ for all n, j then σ_R has no imaginary eigenvalues for this L. We therefore have by Theorem 3.11 that the eigenvalue count for the perturbed operator $\mathscr{L}$ inside K is given by that of the reduced problem (1.4), which, by Theorem 4.5, is as specified in (iii) of Theorem 5.2. Finally, for $|L - L^j_n| \leqq \delta$ we see from the previous paragraph concerning the behavior of the branch $\lambda_\varepsilon(L)$ inside C that the eigenvalue count inside K increases precisely by 2 as L crosses $L^j_n(\varepsilon)$. More precisely, we form the curve $K_1 = \partial(K^\circ \cup C^\circ \cup \bar{C}^\circ)$, where $\bar{C}^\circ$ is the complex conjugate of C°. By previous remarks, we may form the bundle $\mathscr{E}_2(K_1, \varepsilon)$, which will be well defined for L near L^j_n. If $K_2 = \partial(K^\circ \backslash (C^\circ \cup \bar{C}^\circ))$ then K_2 winds about all the eigenvalues with strictly positive real part, while C (respectively, $\bar{C}$) winds about $i\beta^j_n(\varepsilon)$ (respectively, $-i\beta^j_n(\varepsilon)$). We then have that

$$c_1(\mathscr{E}_2(K_1, \varepsilon)) = c_1(\mathscr{E}_2(K_2, \varepsilon)) + c_1(\mathscr{E}_2(C, \varepsilon)) + c_1(\mathscr{E}_2(\bar{C}, \varepsilon));$$

hence the eigenvalue count is precisely as specified in (iii) for all L.

We finally remark that the direction of bifurcation has not been determined. It seems likely, however, that the asymptotic methods of § 4 could be used to compute the higher-order asymptotics of the bifurcating solutions needed in such a computation. We conjecture that each Hopf bifurcation is supercritical, so that the first one at $L = L^\circ_o(\varepsilon)$ gives rise to a stable periodic solution.

MULTIPARAMETER BIFURCATION OF A PREDATOR-PREY SYSTEM*

J. HAINZL†

Abstract. For a two-dimensional predator-prey system, proposed by Bazykin and depending on several parameters, a complete local bifurcation analysis with respect to all parameters is achieved. The major part of the paper is devoted to the unfolding of a degenerate codimension-2 bifurcation occurring for a one-dimensional subset of parameters. The main problem here consists in studying parameter dependent integrals which are not algebraic.

Key words. predator-prey system, bifurcation, unfolding, stability, parameter dependent integral, limit cycle, homoclinic orbit

AMS(MOS) subject classifications. 34C05, 34C25

1. Introduction.

The starting point of this paper is the predator-prey system

$$
\begin{aligned}
\dot{x}_1 &= \alpha_1 x_1 - \frac{\alpha_{12} x_1 x_2}{1+\beta_1 x_1} - \alpha_{11} x_1^2, \\
\dot{x}_2 &= -\alpha_2 x_2 + \frac{\alpha_{21} x_1 x_2}{1+\beta_1 x_1} - \alpha_{22} x_2^2
\end{aligned}
\tag{1}
$$

with $x_1(t), x_2(t)$ the prey and predator populations, and positive parameters $\alpha_i, \alpha_{ij}, \beta_1$. This system was first proposed by Bazykin in [2], [3], where a detailed discussion concerning ecological motivation and possible behavior of solutions is presented. A rigorous treatment of (1) has been carried out in [9]. There, besides some results on Hopf bifurcation, we mainly aimed at basic questions such as the location and stability of equilibria and the existence of periodic orbits. In the present paper, this former investigation is supplemented by a fairly complete bifurcation analysis of (1) depending on all the parameters. Apart from a regular codimension-2 bifurcation which occurs in a two-dimensional parameter region, we are primarily concerned with the unfolding of a degenerate codimension-2 bifurcation occurring in a one-dimensional parameter region. This interesting bifurcation phenomenon can be observed at parameter values where three equilibria coalesce to a single one (cusp point).

The paper is organized as follows. In §2 we first summarize those facts from [9] that are needed in the present context. We introduce the manifold $\mathcal{M}$ in the parameter space, describing the set of equilibria of (1); it can be reduced to a cusp surface with two folds C_+, C_- and a cusp point C_0. Then we characterize those parameters for which codimension-2 bifurcation occurs on $C_+ \cup C_-$ (regular case) or at C_0 (degenerate case). A transformation defined in §3 shows that the corresponding linearization is of nilpotent type $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. In §4, the regular case is treated and, using known methods, a complete unfolding of this bifurcation problem is achieved. The subsequent §§5–12 are entirely devoted to the degenerate case. The main task here is to investigate the quotient of parameter dependent integrals which, contrary to the cases found in the literature, are not algebraic. Various analytical results, partly supported by numerical

*Received by the editors September 7, 1990; accepted for publication March 20, 1991.

†Fachbereich Mathematik, Universität Kassel, Heinrich-Plett-Straße 40, D-3500 Kassel, West Germany.

calculations, finally yield the complete unfolding of this degenerate bifurcation, which is presented in §12. Some remarks conclude the paper.

2. Preliminaries and auxiliary results. Let us first summarize some simplifications and results from [9]. By rescaling x_1, x_2, t suitably, the parameters α_1, α_{12}, and β_1 in (1) adopt the value 1, and without restriction, we may assume $\alpha_{21} > \alpha_2$. In [9] it turned out to be useful to introduce instead of $x_1, x_2, \alpha_2, \alpha_{11}, \alpha_{21}, \alpha_{22}$ the variables x, y and parameters $\alpha, \beta, \gamma, \delta$ defined by

$$(2)\qquad \begin{aligned} x &:= \alpha_{21}^{-1}(1+x_1), & y &:= \alpha_{21}^{-2}x_2\,, \\ \alpha &:= \alpha_{21}^{-1}, & \beta &:= (\alpha_{21}-\alpha_2)^{-1} \\ \gamma &:= \alpha_{11}^{-1}\alpha_{21}^{-1}(1+\alpha_{11}), & \delta &:= \alpha_{22}^{-1}\alpha_{21}^{-2}(\alpha_{21}-\alpha_2)\,. \end{aligned}$$

System (1) then turns into

$$(3)\qquad \begin{aligned} \dot{x} &= -(x-\alpha)\cdot\left[\frac{x-\gamma}{\gamma-\alpha}+\frac{y}{\alpha x}\right], \\ \dot{y} &= -\frac{y}{\beta\delta}\left(y-\delta+\frac{\beta\delta}{x}\right), \end{aligned} \qquad x \geq \alpha, y \geq 0$$

and, as justified in [9], the variation of the remaining four parameters may be restricted to

$$(4)\qquad 0<\alpha<\beta<\gamma\,, \qquad \delta>0\,.$$

The only equilibria of (3) are two trivial saddles (α,0) and (γ,0), which are ignored throughout the paper, and the intersection points of the two curves

$$(5)\qquad y=\frac{\alpha x(\gamma-x)}{\gamma-\alpha} \text{ (parabola) and } y=\delta-\frac{\beta\delta}{x} \text{ (hyperbola).}$$

Depending on the parameters there exist at least one and at most three such equilibria ($\overline{x}$,$\overline{y}$). Introducing the variable ζ instead of $\overline{x}$, the dependence of these equilibria

$$(6)\qquad (\overline{x},\overline{y}) = (\zeta\,, \alpha(\gamma-\alpha)^{-1}\zeta(\gamma-\zeta))$$

on the parameters is best characterized by identifying these equilibria with the points of a four-dimensional manifold $\mathcal{M}$ in $(\alpha,\beta,\gamma,\delta,\zeta)$-space, defined by the equation

$$(7)\qquad \delta=\alpha\zeta^2(\gamma-\zeta)(\gamma-\alpha)^{-1}(\zeta-\beta)^{-1}\,, \qquad 0<\alpha<\beta<\zeta<\gamma\,.$$

(Note that (7) cannot be solved for ζ uniquely. Thus, for convenience, we shall consider $(\alpha,\beta,\gamma,\zeta)$ instead of $(\alpha,\beta,\gamma,\delta)$ as parameters.) For any fixed (α,β), $\mathcal{M}$ reduces to a two-dimensional surface of cusp type in (γ,δ,ζ)- space, with upper fold C_+, lower fold C_-, and cusp point C_0. A qualitative picture of this surface is given in Fig. 1.

In [9] it was shown that

$$(8)\qquad C_0 = (\overline{\gamma},\overline{\delta},\overline{\zeta}) := (9\beta, 27\alpha\beta^2(9\beta-\alpha)^{-1}, 3\beta)\,;$$

moreover, for increasing $\gamma \in (9\beta,\infty)$, we have

(9) On wC_-, ζ is strictly decreasing from 3β to 2β,
(10) On wC_+, $\frac{\zeta}{\gamma}$ is strictly increasing from $\frac{1}{3}$ to $\frac{1}{2}$.

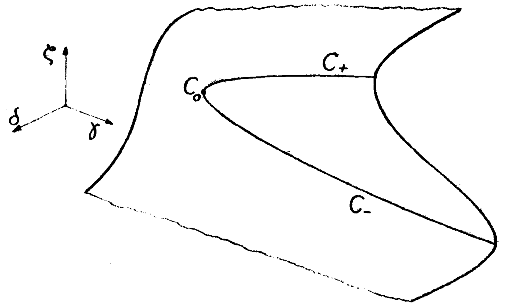

FIG. 1. *The surface $\mathcal{M}$.*

In [9], the stability of the equilibria represented by (7) has been investigated via linearization. Denoting the corresponding characteristic equation by

$$\lambda^2 + p\lambda + q = 0 , \tag{11}$$

we obtain for p, q the following functions on $\mathcal{M}$:

$$p = \frac{1}{\beta} - \frac{1}{\zeta} + \frac{\alpha}{\gamma - \alpha}\left(\frac{\gamma}{\zeta} + \frac{2\zeta}{\alpha} - \frac{\gamma}{\alpha} - 2\right) , \tag{12}$$

$$q = \frac{\alpha}{\gamma - \alpha}\left(\frac{1}{\beta} - \frac{1}{\zeta}\right)\left(\frac{\gamma}{\zeta} + \frac{2\zeta}{\alpha} - \frac{\gamma}{\alpha} - 2\right) + \left(\frac{1}{\alpha} - \frac{1}{\zeta}\right) \cdot \frac{\alpha(\gamma - \zeta)}{\zeta(\gamma - \alpha)} . \tag{13}$$

Furthermore, we know that $q = 0$ exactly on $C_- \cup C_0 \cup C_+, q < 0$ on the middle sheet of $\mathcal{M}$ (corresponding to saddles) and $q > 0$ on the remainder of $\mathcal{M}$. In the points of $C_+ \cup C_-$, saddle-node bifurcation occurs (with δ as the varying parameter). Moreover, the points on $\mathcal{M}$ yielding $p = 0, q > 0$ were investigated for Hopf bifurcation in [9].

In the present paper, we are interested in bifurcations occurring at points where both p and q vanish, corresponding to equilibria with double eigenvalue zero. Such points must be located on the curve

$$\mathcal{C} := C_- \cup C_0 \cup C_+ . \tag{14}$$

By virtue of (8)–(10), $\mathcal{C}$ can be parametrized by $\zeta \in (2\beta, \infty)$. Since $q = 0$ on $\mathcal{C}$, we obtain from (13) (see [9]):

$$2\zeta^2 = \zeta(\gamma + 3\beta) - 2\beta\gamma \text{ on } \mathcal{C}. \tag{15}$$

The following lemma shows that, in a neighborhood of any point on $\mathcal{C}$, we may regard (p, q) instead of (γ, ζ) as parameters of the surface $\mathcal{M}$.

LEMMA 1. *For any fixed $(\alpha, \beta), 0 < \alpha < \beta$, we have*

$$\Delta := p_\gamma q_\zeta - p_\zeta q_\gamma > 0 \quad on\ \mathcal{C} . \tag{16}$$

Proof. From (12), (13) we calculate the partial derivatives

$$\begin{aligned} p_\gamma &= -\zeta^{-1}(\gamma - \alpha)^{-2}(2\zeta - \alpha)(\zeta - \alpha) , \\ p_\zeta &= \zeta^{-2}(\gamma - \alpha)^{-1}(\gamma - \alpha - \alpha\gamma + 2\zeta^2) , \\ q_\gamma &= -\zeta^{-2}\beta^{-1}(\gamma - \alpha)^{-2}(\zeta - \alpha)\left[\zeta(2\zeta - 3\beta - \alpha) + 2\alpha\beta\right] , \\ q_\zeta &= \beta^{-1}\zeta^{-3}(\gamma - \alpha)^{-1}\left[2\zeta^3 - \zeta(\alpha\gamma + 3\alpha\beta + 2\beta\gamma) + 4\alpha\beta\gamma\right] . \end{aligned} \tag{17}$$

Then, using (15) repeatedly, a lengthy calculation yields

$$\Delta = \zeta^{-2}(\gamma-\alpha)^{-3}(\zeta-2\beta)^{-1}\{2(\zeta-\beta)^3 + (\beta-\alpha)\underbrace{[\zeta(6\zeta-6\beta-5\alpha)+2\beta^2+\alpha^2]}_{=:A}\}$$
$$+\beta^{-1}\zeta^{-4}(\gamma-\alpha)^{-2}\{2(\zeta-\beta)^3+(\beta-\alpha)\underbrace{[3\zeta^2-\zeta(6\beta+\alpha)+2\beta^2+2\alpha\beta]}_{=:B}\}.$$

Since $\zeta > 2\beta$ on C, we obviously obtain $A > 0$; B is a quadratic polynomial in ζ whose zeros are less than 2β, whence $B > 0$, too. This yields $\Delta > 0$. □

Using this lemma, we can prove the following.

LEMMA 2. *On the curve C, p is strictly increasing from $(2\beta)^{-1}(1+\alpha-2\beta)$ to β^{-1}, as ζ runs through the interval $(2\beta,\infty)$.*

Proof. From (15) we obtain

$$\gamma =: \gamma(\zeta) = \zeta(\zeta-2\beta)^{-1}(2\zeta-3\beta) \quad \text{on } C. \tag{18}$$

Since (α,β) is fixed, p and q in (12), (13) are functions of (γ,ζ) only. Eliminating γ by (18), we thus have

$$p = p(\gamma(\zeta),\zeta) =: \tilde{p}(\zeta), \qquad q = q(\gamma(\zeta),\zeta) \equiv 0 \quad \text{on } C.$$

Differentiation with respect to ζ yields $p_\gamma \cdot \gamma' + p_\zeta = \tilde{p}', q_\gamma \cdot \gamma' + q_\zeta = 0$. From this and Lemma 1 we obtain by Cramer's rule $\tilde{p}'q_\gamma = -\Delta < 0$, and since $q_\gamma < 0$ (see (17)), we finally get $\tilde{p}'(\zeta) > 0$ for each $\zeta \in (2\beta,\infty)$. The remaining assertion follows easily from (12) and (18). □

LEMMA 3. *Let $0 < \alpha < \beta$ be arbitrarily fixed.*

(a) *If $2\beta \le 1+\alpha$, we have $p > 0$ everywhere on C.*

(b) *If $2\beta > 1+\alpha$, there is just one point $P \in C$ satisfying $p = 0$. Moreover, we have*

$$P\begin{cases} \in C_- \\ = C_0 \\ \in C_+ \end{cases} \quad \text{if } T(\alpha,\beta) := 9\beta^2 - 3\beta(\alpha+6) + 2\alpha \begin{cases} <0 \\ =0 \\ >0 \end{cases}.$$

(*See Fig.* 2.)

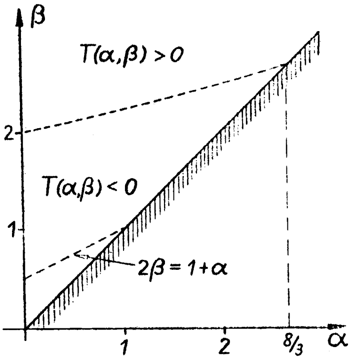

FIG. 2. *Illustration to Lemma* 3.

Proof. From (8), (12) we calculate

$$p = -\frac{1}{3\beta(9\beta-\alpha)}[9\beta^2 - 3\beta(\alpha+6)+2\alpha] \quad \text{in } C_0. \tag{19}$$

Now, all the assertions follow from Lemma 2. □

3. Another transformation. As was already mentioned above, we will consider only neighborhoods of points of $\mathcal{M}$ satisfying $p = q = 0$. By Lemma 3, such a point exists if and only if

$$2\beta > 1 + \alpha\,. \tag{20}$$

Therefore, in addition to the requirement $0 < \alpha < \beta$, we assume inequality (20) throughout the rest of the paper. Let $P = P(\alpha,\beta)$ denote the unique point of $\mathcal{M}$ yielding $p = q = 0$. Then the parameters (γ,ζ) corresponding to P satisfy equation (18) (from $q = 0$), and by exploiting $p = 0$, we obtain from (12) and (18) the additional condition

$$\alpha = \zeta\frac{N_2}{N_1} \quad \text{in } P = P(\alpha,\beta) \tag{21}$$

where

$$N_1 := \beta^2\zeta + 3\beta\zeta - \zeta^2 - 2\beta^2 = (\gamma-\alpha)^{-1}(\zeta-2\beta)^{-1}\zeta^2\beta^2(\zeta-\beta) > 0, \tag{22}$$

$$N_2 := \beta^2\zeta + 5\beta\zeta - 2\zeta^2 - 3\beta^2 > 0\,. \tag{23}$$

Now we consider parameters $(\alpha,\beta,\gamma,\zeta)$ such that (α,β) satisfies (20) and (γ,ζ) defines a point on the surface $\mathcal{M}$ which is sufficiently close to $P(\alpha,\beta)$. Then the parameter dependent affine transformation

$$x = \zeta + \left(\frac{1}{\alpha} - \frac{1}{\zeta}\right)X, \qquad y = \frac{\alpha\zeta(\gamma-\zeta)}{\gamma-\alpha} + \left(\frac{1}{\beta} - \frac{1}{\zeta} - p\right)X - Y \tag{24}$$

turns system (3) into the following system for $X(t), Y(t)$:

$$\dot{X} = Y + \Phi(X,Y)\,, \qquad \dot{Y} = -qX - pY + \Psi(X,Y)\,. \tag{25}$$

Here we calculate

$$\begin{aligned}\Phi(X,Y) &= \alpha\zeta(\zeta-\alpha)^{-1}[\Theta(x,y) - (\gamma-\alpha)^{-1}(x-\zeta)^2]\,,\\ \Psi(X,Y) &= \Theta(x,y)\cdot[1 + \alpha\beta^{-1}(\zeta-\alpha)^{-1}(\zeta-\beta) - \alpha\zeta(\zeta-\alpha)^{-1}p]\\ &\quad - \alpha(\zeta-\alpha)^{-1}(\gamma-\alpha)^{-1}[\beta^{-1}(\zeta-\beta) - \zeta p](x-\zeta)^2\\ &\quad + \alpha^{-1}\beta^{-1}\zeta^{-2}(\gamma-\zeta)^{-1}(\gamma-\alpha)(\zeta-\beta)\\ &\quad \times [y - \alpha\zeta(\gamma-\alpha)^{-1}(\gamma-\zeta)]^2\,,\end{aligned} \tag{26}$$

with

$$\Theta(x,y) := \zeta^{-1}(\gamma-\alpha)^{-1}x^{-1}(x-\zeta)[\alpha(\gamma-\zeta)(x-\zeta) - (\gamma-\alpha)y + \alpha\zeta(\gamma-\zeta)]\,.$$

On the right-hand side of (26), (x,y) has to be expressed in terms of (X,Y) according to (24). Φ and Ψ are at least quadratic with respect to (X,Y) and real-analytic (rational) functions of $X, Y, \alpha, \beta, \gamma, \zeta$; by virtue of Lemma 1 they are also real-analytic functions of $X, Y, \alpha, \beta, p, q$ for (p,q) sufficiently small.

The linearization of system (25) at the point $(X,Y,p,q) = (0{,}0{,}0{,}0)$ is $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. In what follows, we have to investigate (25) in a neighborhood of this point, which corresponds to $P(\alpha,\beta) \in \mathcal{M}$. For this purpose, we need the second and some higher-order derivatives of Φ,Ψ with respect to (X,Y), evaluated at $(X,Y,p,q) = (0{,}0{,}0{,}0)$. For simplicity, we do not explicitly express Φ,Ψ in terms of (p,q), but retain the parameters (γ,ζ) which then have to satisfy (18) and (21). In the following formulae,

γ and α have been eliminated by (18) and (21). The calculations yield (we omit the arguments)

$$\Psi_{XX} = -2N_2^{-1}\beta^{-3}\zeta^{-4}(\zeta-\beta)^4(\zeta-3\beta)\,, \tag{27}$$

$$\Psi_{XY} = -\beta^{-1}\zeta^{-3}N_2^{-1}(\zeta-\beta)[2(\zeta-\beta)^2-\beta^2\zeta]\,, \tag{28}$$

$$\Phi_{XX} = -2\beta^{-2}\zeta^{-3}N_2^{-1}(\zeta-\beta)^3(\zeta-2\beta)\,. \tag{29}$$

LEMMA 4. *Assume* (20), *and let* $P = P(\alpha,\beta)$ *be defined as above. Then we have* $\Phi_{XX} < 0$ *and* $\Psi_{XY} < 0$. *Moreover,* Ψ_{XX} *is* $> 0, = 0, < 0$, *whenever* $P \in C_-$, $P = C_0$, $P \in C_+$, *respectively.*

Proof. The assertions on Ψ_{XX} and Φ_{XX} follow from (8)–(10). It remains to show that $R := 2(\zeta-\beta)^2 - \beta^2\zeta$ is always positive. For $P = C_0$ we have $\zeta = 3\beta$; hence $R = \beta^2(8-3\beta)$. This is positive, since by (19)

$$\alpha = \frac{9\beta(\beta-2)}{3\beta-2} \quad \text{in the case where } P = C_0\,, \tag{30}$$

and thus, to obtain $0 < \alpha < \beta$, we necessarily have $2 < \beta < \frac{8}{3}$. Now, the admissible domain $0 < \alpha < \beta$, $1+\alpha < 2\beta$ in the (α,β)-plane is connected (see Fig. 2), hence it is enough to show that R is nowhere zero. Assuming $\beta^2\zeta = 2(\zeta-\beta)^2$ and inserting this into (21), we obtain $\alpha = \beta$, which is forbidden. □

Since $\Psi_{XX} \neq 0$ for $P \in C_- \cup C_+$, we shall not need any higher derivatives in this regular case. But the degeneracy $\Psi_{XX} = 0$ in case $P = C_0$ necessitates the calculation of some more and higher-order derivatives. Using (30) and $\zeta = 3\beta$ in (27)–(29) and also in calculating the additional derivatives written down below, we finally obtain the following derivatives.

Derivatives required in the degenerate case $P = C_0$:

$$\begin{aligned}
\Phi_{XX} &= -\frac{16}{81\beta^3(\beta-2)}, & \Phi_{XY} &= \frac{1}{9\beta^2}\,, \\
\Psi_{XY} &= -\frac{2(8-3\beta)}{81\beta^3(\beta-2)}, & \Psi_{YY} &= \frac{4}{27\beta^2(\beta-2)}\,, \\
\Phi_{XXX} &= -\frac{16}{3^5\beta^5(\beta-2)}, & \Psi_{XXX} &= -\frac{32(3\beta-4)}{3^7\beta^6(\beta-2)^2}\,, \\
\Psi_{XXY} &= -\frac{16(3\beta-4)}{3^7\beta^5(\beta-2)^2}, & \Psi_{XXXX} &= \frac{2^9(3\beta-4)}{3^{10}\beta^8(\beta-2)^3}\,,
\end{aligned} \qquad 2 < \beta < \tfrac{8}{3}\,. \tag{31}$$

4. The regular case $P \in C_- \cup C_+$**.** Throughout this section the parameters (α,β) are assumed to satisfy

$$0 < \alpha < \beta\,, \quad 1+\alpha < 2\beta\,, \quad \alpha \neq \frac{9\beta(\beta-2)}{3\beta-2} \tag{32}$$

(see Fig. 2) such that, by Lemma 3, the unique point $P = P(\alpha,\beta)$ is lying on $C_+ \cup C_-$. In a neighborhood of P, system (25) adopts the form

$$\begin{aligned}
\dot{X} &= Y + a_{11}X^2 + a_{12}XY + a_{22}Y^2 + \mathcal{O}_3\,, \\
\dot{Y} &= -qX - pY + b_{11}X^2 + b_{12}XY + b_{22}Y^2 + \mathcal{O}_3\,.
\end{aligned} \tag{33}$$

Here, the terms $\mathcal{O}_3$ are power series in (X, Y, p, q) with powers $X^iY^jp^kq^l$ satisfying $i+j+k+l \geq 3$ and $i+j \geq 2$, and with coefficients depending analytically on (α,β). a_{ij}, b_{ij} are given by Taylor's formula, e.g., $a_{11} = \frac{1}{2}\Phi_{XX}$, the derivatives being evaluated at $(X,Y,p,q) = (0,0,0,0)$. By Lemma 4, $b_{11} = \frac{1}{2}\Psi_{XX} \neq 0$; hence for $q \neq 0$ we may rescale in the following way:

$$\begin{aligned} &\varepsilon := |q b_{11}^{-1}|^{\frac{1}{2}}\,, \qquad p =: -|b_{11}|^{\frac{1}{2}}\varepsilon\tau\,, \\ &X =: \varepsilon^2 y_1\,, \qquad Y =: |b_{11}|^{\frac{1}{2}}\varepsilon^3 y_2\,, \\ &t =: |b_{11}|^{-\frac{1}{2}}\varepsilon^{-1}\widetilde{t}. \end{aligned} \tag{34}$$

For definiteness we now assume $q < 0$. (As for the case $q > 0$, see Remark 1 at the end of this section.) From (33), we then derive the following system for $y_1(\widetilde{t}), y_2(\widetilde{t})$ with small parameters ε, τ:

$$\begin{aligned} \dot{y}_1 &= y_2 + \varepsilon a_{11}|b_{11}|^{-\frac{1}{2}}y_1^2 + \mathcal{O}_4\,, \\ \dot{y}_2 &= y_1 + e y_1^2 + \tau y_2 + \varepsilon b_{12}|b_{11}|^{-\frac{1}{2}}y_1 y_2 + \mathcal{O}_4\,, \qquad e := \operatorname{sgn} b_{11}\,. \end{aligned} \tag{35}$$

Here, and in what follows, the terms $\mathcal{O}_4$ are analytic in all variables, at least of second order both with respect to (y_1, y_2) and (ε, τ). Such systems have been treated in the literature; see, e.g., [10]. To establish the standard situation we transform (y_1, y_2) into (U, V) in such a way that the two equilibria of (35), located at $(0,0)$ and near $(-e, 0)$, turn into $(U, V) = (0,0)$ and $(-e, 0)$ exactly. We can choose this transformation as follows:

$$\begin{aligned} U &= y_1 + e b_{12}|b_{11}|^{-\frac{1}{2}}\varepsilon y_1^2 y_2 + \mathcal{O}_4\,, \\ V &= y_2 + \varepsilon a_{11}|b_{11}|^{-\frac{1}{2}}y_1^2 + \mathcal{O}_4 \end{aligned} \tag{36}$$

and obtain the transformed system

$$\begin{aligned} \dot{U} &= V + \varepsilon e b_{12}|b_{11}|^{-\frac{1}{2}}U[2V^2 + U^2(1 + eU)] + \mathcal{O}_4\,, \\ \dot{V} &= U + eU^2 + \tau V + \varepsilon|b_{11}|^{-\frac{1}{2}}UV[2a_{11} + b_{12}(1 - eU - 2U^2)] + \mathcal{O}_4\,. \end{aligned} \tag{37}$$

The unperturbed system (37) with $\varepsilon = \tau = 0$

$$\dot{U} = V\,, \qquad \dot{V} = U + eU^2 \tag{38}$$

is Hamiltonian with the first integral

$$H(U,V) = \tfrac{1}{2}V^2 - \tfrac{1}{2}U^2 - \tfrac{1}{3}eU^3\,. \tag{39}$$

Thus for system (38), there exists a homoclinic orbit filled up with periodic orbits encircling $(-e, 0)$. To find out for which parameters (ε, τ) the perturbed system (37) still has periodic orbits or a homoclinic orbit, we use the method and results from [10]. Calculating the derivative $\dot{H}(U,V)$ of H along solutions of (37) we obtain

$$\begin{aligned} \dot{H}(U,V) = \tau V^2 + \varepsilon|b_{11}|^{-\frac{1}{2}}\{&(2a_{11} + b_{12})UV^2 - eb_{12} \\ &\times [(3U^2 + 4eU^3)V^2 + U^4(1 + eU)^2]\} + \mathcal{O}_4\,. \end{aligned} \tag{40}$$

Now, for $0 < b < 1$, let γ_b denote the half orbit of (38) in the upper half plane with initial point $(-eb, 0)$ and endpoint $(-ec, 0)$, where, owing to (39), $c = c(b) > 1$ is given by

$$c = \tfrac{1}{4}\left(3 - 2b + \sqrt{12b(1-b) + 9}\,\right). \tag{41}$$

Then it is known from [10] that the orbit of (37) through $(-eb, 0)$ is periodic if and only if

$$\tau = -\frac{B(b)}{A(b)}\varepsilon + \mathcal{O}(\varepsilon^2)\,, \tag{42}$$

where $A(b)$,$B(b)$ are the following integrals determined by $\dot{H}(U,V)$:

$$A(b) := \int_{\gamma_b} V\,dU\,,$$

$$(43)\qquad B(b) := |b_{11}|^{-1/2} \int_{\gamma_b} \{(2a_{11} + b_{12})UV^2 - eb_{12}[(3U^2 + 4eU^3)V^2 + U^4(1+eU)^2]\}\frac{dU}{V}\,.$$

To simplify $B(b)$, we apply partial integration, using $dV/dU = U(1+eU)/V$:

$$\int_{\gamma_b} U^4(1+eU)^2\frac{dU}{V} = \int_{\gamma_b} U^3(1+eU)\frac{dV}{dU}\,dU = -\int_{\gamma_b}(3U^2+4eU^3)V\,dU\,,$$

thus obtaining

$$(44)\qquad B(b) = |b_{11}|^{-\frac{1}{2}}(2a_{11}+b_{12})\int_{\gamma_b} UV\,dU\,.$$

Lemma 4 implies $2a_{11} = \Phi_{XX} < 0$, $b_{12} = \Psi_{XY} < 0$. Hence we get

$$(45)\qquad k := -|b_{11}|^{-\frac{1}{2}}(2a_{11}+b_{12}) > 0\,,$$

and introducing

$$(46)\qquad S(b,e) := \frac{\int_{\gamma_b} UV\,dU}{\int_{\gamma_b} V\,dU}\,,\qquad (e = \operatorname{sgn} b_{11})$$

we obtain

$$(47)\qquad -\frac{B(b)}{A(b)} = k\;S(b,e)\,.$$

Now, from [11] or [5] we gather that $S(b,-1)$ has positive derivative in $0 < b < 1$ and

$$(48)\qquad \lim_{b\to 0+} S(b,-1) = \frac{6}{7}\,,\qquad \lim_{b\to 1-} S(b,-1) = 1;$$

moreover, $S(b,1) = -S(b,-1)$. Via (42), this yields existence and uniqueness of periodic orbits for (37), if and only if the small parameters (ε,τ), $\varepsilon > 0$, approximately satisfy the sector condition $\frac{6}{7}k < \frac{\tau}{\varepsilon} < k$ in case $e=-1$, and $-k < \frac{\tau}{\varepsilon} < -\frac{6}{7}k$ in case $e = 1$. Beyond that, we now can state the following theorem.

THEOREM 1. (a) *Unfolding of the bifurcation at $P \in C_+$ (upper fold): Assume $0 < \alpha < \beta$ and $\alpha < 9\beta(\beta-2)(3\beta-2)^{-1}$. Then, in the (ε,τ) half plane $\varepsilon > 0$, a neighborhood $\mathcal{U}$ of the origin is subdivided by two curves*

$$(49)\qquad L_1 : \tau = \tfrac{6}{7}k\varepsilon + \mathcal{O}(\varepsilon^2),\qquad L_2 : \tau = k\varepsilon + \mathcal{O}(\varepsilon^2)$$

into sectors I, II, III *such that the local flow of the original system* (3) *with parameters corresponding to $(\varepsilon,\tau) \in \mathcal{U}$ is qualitatively given in Fig.* 3. *(Note that the third equilibrium, far away towards the "southwest," is not involved in this statement.) In particular, a periodic orbit only exists in sector* II; *it is unique and unstable. On L_1, there exists an unstable homoclinic orbit, and the points on L_2 are origins of subcritical Hopf bifurcation with respect to the parameter τ (ε fixed).*

(b) *Unfolding of the bifurcation at $P \in C_-$ (lower fold): Assume $0 < \alpha < \beta$, $1 + \alpha < 2\beta$ and $\alpha > 9\beta(\beta-2)(3\beta-2)^{-1}$ (see Fig.2). Then, in the (ε,τ) half plane $\varepsilon > 0$, a neighborhood $\mathcal{V}$ of the origin is subdivided by two curves*

$$(50)\qquad L_3 : \tau = -\tfrac{6}{7}k\varepsilon + \mathcal{O}(\varepsilon^2)\,,\qquad L_4 : \tau = -k\varepsilon + \mathcal{O}(\varepsilon^2)$$

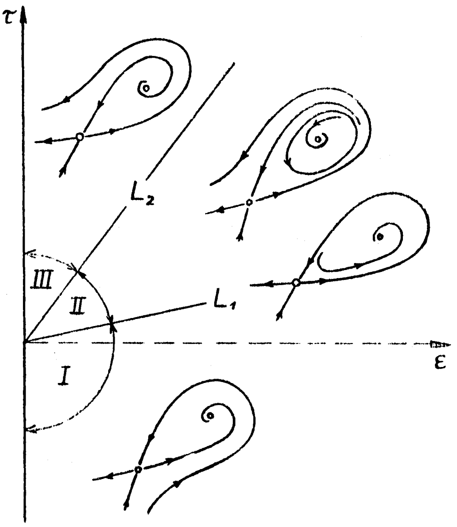

FIG. 3. *Unfolding at $P \in C_+$.*

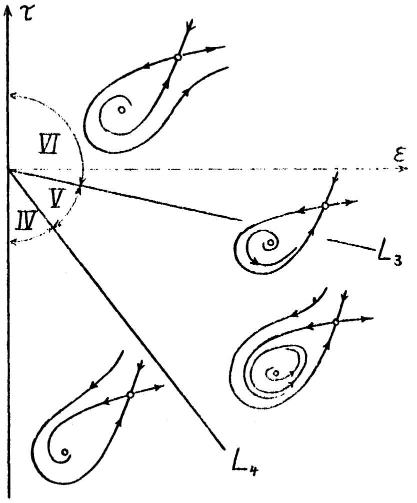

FIG. 4. *Unfolding at $P \in C_-$.*

into sectors IV, V, VI *such that the local flow of the original system* (3) *with parameters corresponding to* $(\varepsilon, \tau) \in \mathcal{V}$ *is qualitatively given in Fig.* 4. (*Again, the third equilibrium, now far away towards "northeast," is not involved.*) *In particular, a periodic orbit only exists in sector* V; *it is unique and asymptotically stable. On L_3, there exists a homoclinic orbit which is asymptotically stable* (*from inside*). *The points on L_4 are origins of supercritical Hopf bifurcation with respect to the parameter τ.*

Proof. Existence and uniqueness of periodic orbits has already been settled. The existence of a homoclinic orbit again is known from the literature [10], [4], [5]. The statements on Hopf bifurcation are easily verified. Thus, we still have to prove the assertions concerning stability. As for the homoclinic orbits, we apply [5, p. 357]. Since the linearized right-hand side of (37) has trace τ, the assertion follows from $\tau > 0$ on L_1 and $\tau < 0$ on L_3. To prove the stability results for the periodic orbits, we refer to [1, Thm. (23.9)]. (We note that [7, Thm. 4.1] could be applied, too.) Having set $\tau := k\varepsilon\, S(b,e) + \mathcal{O}(\varepsilon^2)$ in the right-hand side of (37) which will then be denoted by $f_\varepsilon(U,V)$, this system has a T-periodic orbit Γ through $(U,V) = (-eb, 0)$, described by $(U(t),V(t))$, $0 \le t \le T$. To calculate

$$D := \int_0^T \operatorname{div} f_\varepsilon(U(t),V(t))\,dt \tag{51}$$

we proceed similarly to the derivation of (44), obtaining

$$D = -2ke\,\varepsilon\left[S(b,e)\int_{\gamma_b} V^{-1}dU - \int_{\gamma_b} V^{-1}UdU\right] + \mathcal{O}(\varepsilon^2)\,. \tag{52}$$

Setting

$$C(b) := \int_{\gamma_b} UVdU$$

we calculate the derivatives with respect to b (see also [5])

$$C'(b) = (b^2 - b)\int_{\gamma_b} V^{-1}UdU\,, \qquad A'(b) = (b^2 - b)\int_{\gamma_b} V^{-1}dU\,.$$

Thus (52), (46) yield

$$\begin{aligned} D &= 2ke\varepsilon(b-b^2)^{-1}[S(b,e)A'(b) - C'(b)] + \mathcal{O}(\varepsilon^2) \\ &= -2ke\varepsilon(b-b^2)^{-1}\underbrace{A(b)S'(b,e)}_{>0} + \mathcal{O}(\varepsilon^2)\,. \end{aligned}$$

Hence, $D > 0$ if $e = -1$, and $D < 0$ if $e = 1$. In virtue of the theorem in [1] mentioned above, the statements on the stability of Γ are now proved. □

Remarks. (1) Before establishing equations (35) we assumed $q < 0$. This means that the origin $(U,V) = (0,0)$ of system (37) corresponds to a point on the middle sheet of the cusp surface $\mathcal{M}$. It is easy to see that the alternative assumption $q > 0$ would essentially amount to a translation by the vector $\binom{e}{0}$ in the (U,V)-plane. Then the origin $(U,V) = (0,0)$ would correspond to a point on the lower sheet of $\mathcal{M}$ (if $e = 1$), respectively, upper sheet (if $e = -1$); but no new insights would be attained.

(2) Returning to the parameters (p,q), $q < 0$, via (34), we get the relation

$$\frac{\tau}{\varepsilon} = |b_{11}|^{\frac{1}{2}}\frac{p}{q}\,, \tag{53}$$

but an admissible range of (ε, τ)

$$0 < \delta \le \delta_0, \qquad |\tau| \le \tau_0$$

corresponds to the admissible range $|p| \le \sqrt{|q|}\tau_0$, which is not the intersection of a full neighborhood of (0,0) with the lower half plane $q < 0$. This drawback could be overcome by a modified scaling similar to the one described in the degenerate case (see §11). We do not go into details here.

(3) The phase portraits illustrated in Figs. 3 and 4 may easily be carried over to the cusp surface $\mathcal{M}$ in the (δ,γ,ζ)-space. Using (53) and Lemma 2, we obtain a corresponding subdivision of the intersection of a neighborhood of $P = P(\alpha,\beta)$ with the middle sheet of $\mathcal{M}$. Figure 5, respectively, Fig. 6, shows this subdivision projected parallel to the negative δ-axis. Here, I' corresponds to I, etc., and the curves L_2', L_4' are just the projections parallel to the ζ-axis (onto the middle sheet of $\mathcal{M}$) of the curve $p = 0$, $q > 0$.

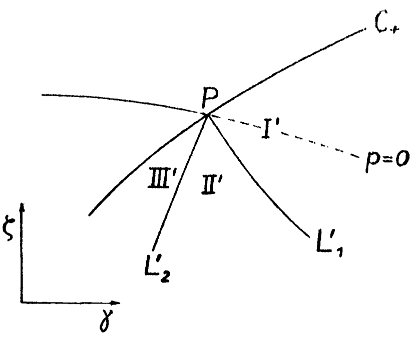

FIG. 5. *See Remark* (3).

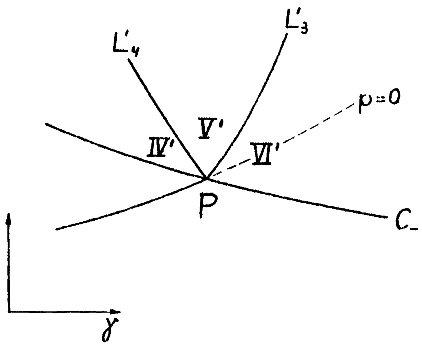

FIG. 6. *See Remark* (3).

5. The degenerate case $P = C_0$; Transformation to normal form. Beginning with the main objective of the paper, we henceforth assume

$$\alpha = 9\beta(\beta-2)(3\beta-2)^{-1}, \qquad 2 < \beta < \tfrac{8}{3}, \tag{54}$$

which means that the point $P = P(\alpha,\beta)$ yielding $p = q = 0$ is now the cusp point C_0. Lemma 4 yields $\Psi_{XX} = 0$; hence system (25) has to be expanded beyond quadratic terms. It turns out that the following expansion will suffice:

$$\begin{aligned}\dot X &= Y + a_{11}X^2 + a_{12}XY + a_{22}Y^2 + a_{111}X^3\\ &\quad + a_{112}X^2Y + a_{122}XY^2 + a_{222}Y^3 + \mathcal{O}_4,\\ \dot Y &= -qX - pY + b_1pX^2 + b_2qX^2 + b_{12}XY + b_{22}Y^2 + b_{111}X^3\\ &\quad + b_{112}X^2Y + b_{122}XY^2 + b_{222}Y^3 + b_{1111}X^4 + \mathcal{O}_4.\end{aligned} \tag{55}$$

Here, $\mathcal{O}_4$ means terms of at least fourth order with respect to (X,Y); the coefficients in (55), well defined by Taylor expansion of Φ,Ψ at $(X,Y) = (0,0)$, are real-analytic functions of the parameters (β,p,q), α being eliminated by (54). To transform (55) into normal form, we choose the near identity transformation

$$\begin{aligned} X &= w_1 + c_{11}w_1^2 + e_{111}w_1^3 + c_{112}w_1^2w_2 \,, \\ Y &= w_2 + d_{11}w_1^2 + d_{12}w_1w_2 + d_{111}w_1^3 \\ &\quad + d_{112}w_1^2w_2 + d_{122}w_1w_2^2 + d_{222}w_2^3 \,, \end{aligned} \tag{56}$$

where the coefficients are obtained from those in (55), evaluated at $(p,q) = (0,0)$. Writing $\widetilde{a}_{11} := a_{11}|_{p=q=0}$ etc., we have

$$\begin{aligned} c_{11} &= \tfrac{1}{2}(\widetilde{a}_{12} + \widetilde{b}_{22}) \,, \quad d_{11} = -\widetilde{a}_{11} \,, \quad d_{12} = \widetilde{b}_{22} \,, \\ c_{111} &= \tfrac{1}{6}\left(2\widetilde{b}_{22}^2 + 3\widetilde{a}_{12}\widetilde{b}_{22} + \widetilde{a}_{12}^2 + 2\widetilde{a}_{112} + \widetilde{b}_{122}\right) , \\ c_{112} &= \tfrac{1}{2}(\widetilde{a}_{122} + \widetilde{b}_{222}) \,, \quad d_{111} = -\widetilde{a}_{11}\widetilde{b}_{22} - \widetilde{a}_{111} \,, \\ d_{112} &= \widetilde{b}_{22}^2 + \tfrac{1}{2}\widetilde{b}_{122} \,, \quad d_{122} = \widetilde{b}_{222} \,, \quad d_{222} = -\widetilde{a}_{222} \,. \end{aligned} \tag{57}$$

We then obtain the normal form system for (w_1, w_2):

$$\begin{aligned} \dot{w}_1 &= w_2 + pg_{11} + qg_{12} + h_1 \,, \\ \dot{w}_2 &= -qw_1 - pw_2 + Aw_1w_2 + Bw_1^3 + Cw_1^2w_2 \\ &\quad + Dpw_1^2 + Eqw_1^2 + Fw_1^4 + pg_{21} + qg_{22} + h_2 \,. \end{aligned} \tag{58}$$

Here, g_{ij} and h_i are real-analytic functions of (w_1, w_2, p, q, β), with (w_1, w_2, p, q) in a neighborhood of $(0,0,0,0)$; moreover, with respect to (w_1, w_2), all terms of g_{ij} are at least of order 2 and all terms of h_i are at least of order 4, other than those already written down in (58) explicitly. As for the coefficients $A, \cdots, F$, a straightforward calculation using (57) yields

$$\begin{aligned} A &= 2\widetilde{a}_{11} + \widetilde{b}_{12}, \qquad B = -\widetilde{a}_{11}\widetilde{b}_{12} + \widetilde{b}_{111} \,, \\ C &= -\widetilde{a}_{11}\widetilde{b}_{22} + \tfrac{1}{2}\widetilde{a}_{12}\widetilde{b}_{12} + \tfrac{1}{2}\widetilde{b}_{12}\widetilde{b}_{22} + 3\widetilde{a}_{111} + \widetilde{b}_{112} \,, \\ D &= \widetilde{a}_{11} + \widetilde{b}_1, \qquad E = \tfrac{1}{2}(\widetilde{b}_{22} - \widetilde{a}_{12}) + \widetilde{b}_2 \,, \\ F &= -\tfrac{1}{2}\widetilde{a}_{11}\widetilde{b}_{12}(\widetilde{a}_{12} + \widetilde{b}_{22}) + \widetilde{a}_{11}^2\widetilde{b}_{22} - \widetilde{b}_{12}\widetilde{a}_{111} \\ &\quad + \tfrac{3}{2}\widetilde{a}_{12}\widetilde{b}_{111} + \tfrac{1}{2}\widetilde{b}_{22}\widetilde{b}_{111} - \widetilde{a}_{11}\widetilde{b}_{112} + \widetilde{b}_{1111} \,. \end{aligned} \tag{59}$$

While $\widetilde{a}_{ij}$, $\widetilde{b}_{ij}$,$\widetilde{a}_{111}$,$\widetilde{b}_{111}$, $\widetilde{b}_{112}$, and $\widetilde{b}_{1111}$ are determined by (31), $\widetilde{b}_i$ are calculated as follows:

$$\begin{aligned} \widetilde{b}_1 &= \tfrac{1}{2}\Psi_{XXp}|_{(X,Y,p,q)=(0,0,0,0)} = \tfrac{1}{2}(\Psi_{XX\gamma}\gamma_p + \Psi_{XX\zeta}\zeta_p) \,, \\ \widetilde{b}_2 &= \tfrac{1}{2}\Psi_{XXq}|_{(X,Y,p,q)=(0,0,0,0)} = \tfrac{1}{2}(\Psi_{XX\gamma}\gamma_q + \Psi_{XX\zeta}\zeta_q) \,. \end{aligned} \tag{60}$$

On the right-hand side, Ψ is considered as a function of (X, Y, γ, ζ), with derivatives to be evaluated at $(0, 0, 9\beta, 3\beta)$, and the derivatives $\gamma_p, \gamma_q, \zeta_p, \zeta_q$ are calculated by using (54), putting $\gamma = 9\beta$, $\zeta = 3\beta$ in (17), and then inverting the matrix

$$\begin{pmatrix} p_\gamma & p_\zeta \\ q_\gamma & q_\zeta \end{pmatrix} .$$

In this way we obtain

$$\gamma_p = 0 \,, \quad \gamma_q = -\tfrac{27}{2}\beta^3 \,, \quad \zeta_p = \tfrac{18\beta^2}{16-3\beta} \,, \quad \zeta_q = -\tfrac{9\beta^2(3\beta+2)}{16-3\beta} \,, \tag{61}$$

and from (26)

$$\Psi_{XX\gamma} = \frac{4(9\beta^2 - 16)}{3^7\beta^6(\beta - 2)}, \qquad \Psi_{XX\zeta} = \frac{2(9\beta^2 - 72\beta + 80)}{3^6\beta^5(\beta - 2)} \,. \tag{62}$$

From (59) we now compute

$$
(63)\quad \begin{aligned}
&A=-\frac{2(16-3\beta)}{81\beta^3(\beta-2)}<0, \qquad B=-\frac{2^6}{3^8\beta^6(\beta-2)^2}<0,\\
&C=\frac{1}{3^7\beta^5(\beta-2)^2}(9\beta^2-132\beta+224)<0,\\
&D=\frac{2(9\beta^2-60\beta+16)}{81\beta^3(\beta-2)(16-3\beta)}<0,\\
&E=\frac{9\beta^3-36\beta^2+32\beta+64}{54\beta^3(\beta-2)(16-3\beta)}>0, \qquad F=\frac{32(20-9\beta)}{3^{11}\beta^8(\beta-2)^3}.
\end{aligned}
$$

6. Scaling; an auxiliary "unperturbed" system. From now on we assume $q\neq 0$. Then, in system (58), the variables (w_1,w_2,t) and the parameters (p,q) may be rescaled as follows:

$$
(64)\quad \varepsilon=\sqrt{|q|}, \quad p=-\varepsilon\tau, \quad w_1=\varepsilon A^{-1}u, \quad w_2=\varepsilon^2A^{-1}v, \quad t=\varepsilon^{-1}\tilde{t}.
$$

This leads to the following system for $u(\tilde{t})$,$v(\tilde{t})$ with small parameters (ε,τ), $\varepsilon>0$ (henceforth we omit the tilde in $\tilde{t}$):

$$
(65)\quad \begin{aligned}
\dot{u}&=v+R_1(u,v,\varepsilon,\tau),\\
\dot{v}&=-fu+\tau v+uv-au^3+\varepsilon bu^2v+\tau cu^2-\varepsilon fdu^2\\
&\quad+\varepsilon eu^4+R_2(u,v,\varepsilon,\tau).
\end{aligned}
$$

Here we have the following: For any fixed $\beta\in(2,\frac{8}{3}), R_i$ are bounded functions for (u,v) in an arbitrary bounded domain and (ε,τ) in a sufficiently small neighborhood of (0,0); moreover, R_i are real-analytic functions of (u,v,ε,τ), whose lowest terms are at least quadratic both with respect to (u,v) and (ε,τ). Finally, $f:=\operatorname{sgn} q$, and the coefficients $a,\cdots,e$ are given by

$$
(66)\quad \begin{aligned}
&a=-\frac{B}{A^2}=\frac{16}{(16-3\beta)^2}>0, \qquad b=\frac{C}{A^2}=\frac{3\beta(9\beta^2-132\beta+224)}{4(16-3\beta)^2}<0,\\
&c=-\frac{D}{A}=\frac{9\beta^2-60\beta+16}{(16-3\beta)^2}<0,\\
&d=-\frac{E}{A}=\frac{3(9\beta^3-36\beta^2+32\beta+64)}{4(16-3\beta)^2}>0, \qquad e=\frac{F}{A^3}=\frac{12\beta(9\beta-20)}{(16-3\beta)^3}.
\end{aligned}
$$

We first investigate the unperturbed system for $U(t)$, $V(t)$, resulting from (65) by setting $(\varepsilon,\tau)=(0{,}0)$:

$$
(67)\quad \begin{aligned}
\dot{U}&=V,\\
\dot{V}&=-fU+UV-aU^3,
\end{aligned} \qquad f=\operatorname{sgn} q.
$$

This system is invariant under $(t,U,V)\mapsto(-t,-U,V)$, and it has the first integral $I(U,V)$ given by

$$
(68)\quad I(U,V):=\frac{1}{2}\ln N+\frac{1}{\sigma}\arctan\frac{4aV-(f+aU^2)}{\sigma(f+aU^2)},
$$

where

$$
(69)\quad \sigma:=\sqrt{8a-1}=\frac{1}{16-3\beta}(-9\beta^2+96\beta-128)^{\frac{1}{2}}>0,
$$

$$
(70)\quad \begin{aligned}
N=N(U,V)&:=2aV^2-V(f+aU^2)+(f+aU^2)^2\\
&=(8a)^{-1}\{(4aV-f-aU^2)^2+\sigma^2(f+aU^2)^2\}.
\end{aligned}
$$

We calculate

$$\frac{\partial I(U,V)}{\partial U} = \frac{2aU}{N}(-V+f+aU^2), \qquad \frac{\partial I(U,V)}{\partial V} = \frac{2aV}{N}. \tag{71}$$

Owing to $I(-U,V) = I(U,V)$, the phase portraits are symmetric with respect to the V-axis. In case $f = 1$ ($q > 0$), system (67) has the only equilibrium $(U,V) = (0,0)$, and we easily check that each orbit is periodic (see Fig. 7). For $f = -1$ ($q < 0$), there are three equilibria $(U,V) = (0,0)$ (hyperbolic saddle point) and $(\pm a^{-1/2}, 0)$ (source and sink), and the phase portrait is qualitatively shown in Fig. 8. In particular, there is a homoclinic orbit, and all orbits intersecting the positive V-axis are periodic.

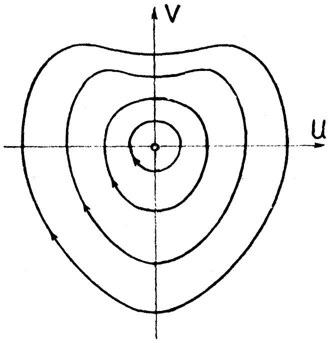

FIG. 7. *Phase portrait of system* (67), $f = 1$.

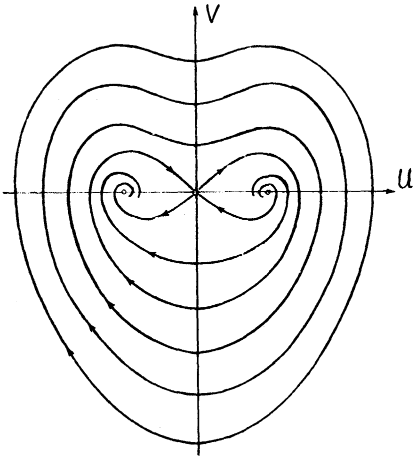

FIG. 8. *Phase portrait of system* (67), $f = -1$.

7. Looking for periodic orbits of system (65). Now, returning to the perturbed system (65), we have to investigate whether some of the periodic orbits of (67) or the homoclinic orbit in case $f = -1$ do survive for certain parameters $(\varepsilon, \tau) \neq (0,0)$.

Let $\dot{I}(u,v)$ denote the derivative of $I(u,v)$ along solutions of (65). Using (71), we obtain

$$\begin{aligned}\dot{I}(u,v) &= \frac{2av}{N(u,v)}\{\tau v + \varepsilon bu^2v + (\tau c - \varepsilon fd)u^2 + \varepsilon eu^4\} \\ &\quad + \frac{2a}{N(u,v)}\{u(-v + f + au^2)R_1(u,v,\varepsilon,\tau) + vR_2(u,v,\varepsilon,\tau)\}\,.\end{aligned} \tag{72}$$

For arbitrary $r > 0$, let $(U(t), V(t))$ be the (periodic) solution of (67) with $(U(0), V(0)) = (0, r)$ and $(U(\pm t_0),\ V(\pm t_0)) = (0, -r_0)$ for some $t_0 > 0$ and $r_0 > 0$ depending on r (t_0 minimal). Analogously, let $(u(t), v(t))$ denote the solution of (65) with $(u(0), v(0)) = (0, r)$, intersecting the negative v-axis for the first positive time t_1 at $(0, -r_1)$ and for the first negative time $-t_2$ at $(0, -r_2)$. Then we obtain

$$\begin{pmatrix}u(t)\\ v(t)\end{pmatrix} = \begin{pmatrix}U(t)\\ V(t)\end{pmatrix} + \mathcal{O}(\sqrt{\varepsilon^2+\tau^2}) \quad \text{uniformly in } |t| \le \max\{t_0, t_1, t_2\}\,,$$

and hence from (72), again uniformly in this t-interval:

$$\begin{aligned}\dot{I}(u(t), v(t)) = \frac{2aV(t)}{N(U(t), V(t)}&\{\tau V(t) + \varepsilon bU^2(t)V(t) \\ &\quad + (\tau c - \varepsilon fd)U^2(t) + \varepsilon eU^4(t)\} \\ + \mathcal{O}(\varepsilon^2 + \tau^2) &=: H(t) + \mathcal{O}(\varepsilon^2 + \tau^2)\,.\end{aligned} \tag{73}$$

Using (71), we see that $(u(t), v(t))$ is periodic if and only if

$$I(0, -r_1) = I(0, -r_2)\,. \tag{74}$$

Since $t_1 - t_0 = \mathcal{O}(\sqrt{\varepsilon^2 + \tau^2})$, we conclude

$$\begin{aligned}I(0, -r_1) - I(0, r) &= \int_0^{t_1} \dot{I}(u(t), v(t))\, dt \\ &= \int_0^{t_0} H(t)dt + \mathcal{O}(\varepsilon^2 + \tau^2)\,,\end{aligned} \tag{75}$$

and similarly,

$$I(0, -r_2) - I(0, r) = \int_0^{-t_0} H(t)\, dt + \mathcal{O}(\varepsilon^2 + \tau^2)\,. \tag{76}$$

The symmetry of (67) yields $U(-t) = -U(t)$, $V(-t) = V(t)$ and hence, $H(-t) = H(t)$, which again implies

$$\int_0^{-t_0} H(t)\, dt = -\int_0^{t_0} H(t)\, dt\,. \tag{77}$$

Thus, setting

$$K(r, \varepsilon, \tau) := I(0, -r_1) - I(0, -r_2) = 2\int_0^{t_0} H(t)\, dt + \mathcal{O}(\varepsilon^2 + \tau^2)\,, \tag{78}$$

(74) is equivalent to $K(r, \varepsilon, \tau) = 0$, or, by the implicit function theorem, to

$$\tau = -\frac{K_\varepsilon(r, 0, 0)}{K_\tau(r, 0, 0)}\,\varepsilon + \mathcal{O}(\varepsilon^2)\,, \tag{79}$$

whenever the denominator does not vanish. The quotient

$$Q(r) := -\frac{K_\varepsilon(r,0,0)}{K_\tau(r,0,0)} = -\frac{\int_0^{t_0} \frac{V(t)}{N(U(t),V(t))}[bU^2(t)V(t) - fdU^2(t) + eU^4(t)]dt}{\int_0^{t_0} \frac{V(t)}{N(U(t),V(t))}[V(t) + cU^2(t)]dt} \tag{80}$$

can be expressed by line integrals along the curve

$$\Gamma = \Gamma(r) := \{(U(t), V(t)) | 0 \leq t \leq t_0\}, \tag{81}$$

resulting in

$$Q(r) = -\frac{\int_\Gamma N^{-1}(U,V)[bU^2V - fdU^2 + eU^4]dU}{\int_\Gamma N^{-1}(U,V)[V + cU^2]dU}. \tag{82}$$

Moreover, in the case $f = -1$, let Γ_0 denote the homoclinic semi-orbit of (67) in the half plane $U \geq 0$ (see Fig. 8). Then, by arguments similar to the preceding ones (see [10], [4]), we find the condition for a homoclinic orbit of (65) to exist. Here, the role of $(u(t), v(t))$ above is played by those pieces of the local unstable, respectively, stable, manifold of the saddle (0,0) of (65), which start out into the upper half plane. We may summarize with the following lemma.

LEMMA 5. *Let r, $0 < r \leq \bar{r}$, be such that $Q(r)$ exists. Then the solution of* (65) *passing through* $(0, r)$ *is periodic if and only if $\tau = \tau(\varepsilon)$ is a well-defined real-analytic function*

$$\tau = Q(r)\varepsilon + \mathcal{O}(\varepsilon^2). \tag{83}$$

Moreover, in case $f = -1$, system (65) *has a homoclinic orbit joining the saddle* (0,0) *to itself, if and only if $\tau = \tau(\varepsilon)$ is a well-defined* (*real-analytic*) *function*

$$\tau = Q_0\varepsilon + \mathcal{O}(\varepsilon^2) \tag{84}$$

where

$$Q_0 := -\frac{\int_{\Gamma_0} N^{-1}(U,V)[bU^2V + dU^2 + eU^4]dU}{\int_{\Gamma_0} N^{-1}(U,V)[V + cU^2]dU} \tag{85}$$

and $N(U, V)$ is given by (70) *with $f = -1$.* □

Remark. As will be seen in §12, the denominator of Q_0 does not vanish.

8. Manipulating the integrals involved in $Q(r)$. We now have to investigate $Q(r)$ as a function of $r > 0$. For this purpose, we first apply partial integration to the individual integrals in (82) in such a way that the boundary terms are zero. Using

$$\frac{dV}{dU} = U - \frac{U}{V}(f + aU^2), \quad \frac{dN}{dU} = \frac{UN}{V}, \quad \frac{dU}{V} = dt, \tag{86}$$

we calculate (all the integrals occurring subsequently do exist; we write $\int$ instead of $\int_\Gamma$)

$$\int \frac{U^2}{N}dU = -\frac{1}{3}\int U^3 \frac{d}{dU}\left(\frac{1}{N}\right) dU = \frac{1}{3}\int \frac{U^4 dU}{NV} > 0, \tag{87}$$

$$\begin{aligned} \int \frac{U^2V}{N}dU &= \int \frac{U^2V^2}{N}\frac{dU}{V} \\ &= -\frac{1}{3}\int U^3 \frac{d}{dU}\left(\frac{V}{N}\right)dU = \frac{1}{3}\int \frac{U^4}{NV}(f + aU^2)dU > 0, \end{aligned} \tag{88}$$

$$\int \frac{V}{N} dU = \int \frac{V^2}{N} \frac{dU}{V} = \int \frac{U^2}{VN}(f + aU^2) dU > 0, \tag{89}$$

$$\int \frac{U^4}{N} dU = \frac{1}{5} \int \frac{U^6}{NV} dU = \frac{3}{5a} \int \frac{U^2 V}{N} dU - \frac{f}{5a} \int \frac{U^4}{NV} dU > 0. \tag{90}$$

At this stage, it seems useful to introduce the following "polar" coordinates (ϱ, φ) in the (U, V)-plane:

$$f + aU^2 - 4aV = f\varrho \sin\varphi, \qquad \sigma(f + aU^2) = f\varrho\cos\varphi. \tag{91}$$

We calculate

$$N(U,V) = \frac{\varrho^2}{8a}, \qquad I(U,V) = \ln\frac{\varrho}{\sqrt{8a}} - \frac{\varphi}{\sigma}. \tag{92}$$

Defining, for convenience, the variable s by

$$r =: -fs, \qquad r > 0 \tag{93}$$

the integration curve $\Gamma = \Gamma(r)$, defined in (81) and also given by $I(U,V) = I(0,r)$, is described in terms of (ϱ, φ) as follows:

$$\varrho = \sqrt{8a} G(s) e^{\sigma^{-1}\varphi}, \qquad \varphi_0 \le \varphi \le \varphi_1 \quad \text{(logarithmic spiral)} \tag{94}$$

where

$$G(s) := \sqrt{2as^2 + s + 1}\exp(-\sigma^{-1}\arctan[\sigma^{-1}(4as + 1)])\,; \tag{95}$$

$$\varphi_0 = \varphi_0(s) := \arctan[\sigma^{-1}(4as + 1)] \tag{96}$$

and $\varphi_1 = \varphi_1(s)$ are consecutive zeros of the function

$$h^2(\varphi, s) := f(\sigma^{-1}\sqrt{8a}G(s)\cos\varphi e^{\sigma^{-1}\varphi} - 1) \tag{97}$$

which, for fixed s, is positive between φ_0 and $\varphi_1 > \varphi_0$ (for $f = -1$, see Fig. 9). Let $h(\varphi, s)$ denote the positive square root of $h^2(\varphi, s)$ in $\varphi_0 \le \varphi \le \varphi_1$. On $\Gamma = \Gamma(r)$, we then get

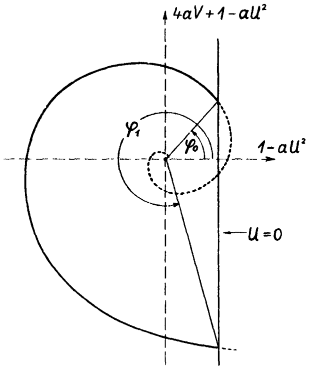

FIG. 9. *Illustrating* φ_0, φ_1 *in case* $f = -1$.

$$(98)\qquad \begin{aligned} &U = \frac{1}{\sqrt{a}}h(\varphi, s)\,, \qquad V = \frac{2f}{\sigma\sqrt{8a}}G(s)(\cos\varphi - \sigma\sin\varphi)e^{\sigma^{-1}\varphi}\,,\\ &dU = \frac{\sqrt{2}fG(s)}{\sigma^2 h(\varphi, s)}(\cos\varphi - \sigma\sin\varphi)e^{\sigma^{-1}\varphi}d\varphi\,,\\ &\frac{dU}{V} = \frac{2\sqrt{a}}{\sigma h(\varphi, s)}d\varphi\,. \end{aligned}$$

Together with (87)–(94), this yields

$$(99)\qquad \begin{aligned} \int_\Gamma \frac{U^2}{N}dU &= \frac{2}{3a^{3/2}\sigma G^2(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)e^{-2\sigma^{-1}\varphi}d\varphi > 0\,,\\ \int_\Gamma \frac{U^2V}{N}dU &= \frac{4\sqrt{2}}{3fa\sigma^2 G(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi > 0\,,\\ \int_\Gamma \frac{V}{N}dU &= \frac{4\sqrt{2}}{f\sigma^2 G(s)}\int_{\varphi_0}^{\varphi_1} h(\varphi, s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi > 0\,,\\ \int_\Gamma \frac{U^4}{N}dU &= \frac{4\sqrt{2}}{5fa^2\sigma^2 G(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi\\ &\quad - \frac{2}{5fa^{5/2}\sigma G^2(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)e^{-2\sigma^{-1}\varphi}d\varphi > 0\,. \end{aligned}$$

Now, let us introduce the variable

$$(100)\qquad \xi = \xi(s) := \ln G(s) + \sigma^{-1}\arctan\sigma^{-1}$$

yielding

$$(101)\qquad \begin{aligned} &\lim_{s\to 0}\xi(s) = 0\,,\ \lim_{s\to\pm\infty}|s|^{-1}e^{\xi} = \sqrt{2a}\exp[\sigma^{-1}(\arctan\sigma^{-1} \mp \tfrac{\pi}{2}]\,,\\ &\frac{d\xi}{ds} = \frac{2as}{2as^2 + s + 1}\,,\quad \xi(s) > 0 \quad \text{for } s \neq 0\,. \end{aligned}$$

Then the following functions $H_i(\xi)$, $i = 1, 2, 3$, are well defined:

$$(102)\qquad \begin{aligned} H_1(\xi) &:= \frac{f}{G(s)}\int_{\varphi_0}^{\varphi_1} h(\varphi, s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi\,,\\ H_2(\xi) &:= \frac{1}{G(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi\,,\\ H_3(\xi) &:= \frac{\sigma}{\sqrt{8a}G^2(s)}\int_{\varphi_0}^{\varphi_1} h^3(\varphi, s)e^{-2\sigma^{-1}\varphi}d\varphi\,. \end{aligned}$$

Obviously, from (99) we get

$$(103)\qquad H_1(\xi) > 0\,,\quad fH_2(\xi) > 0\,,\quad H_3(\xi) > 0 \quad \text{for all } \xi > 0\,.$$

Using (99) and (102), we obtain from (82)

$$(104)\qquad Q(r) = -f\frac{(5ab + 3e)H_2(\xi) - (5ad + 3e)H_3(\xi)}{15a^2H_1(\xi) + 5acH_3(\xi)}\,;$$

hence, by (66)

$$(105)\qquad Q(r) = \frac{3f}{5}\frac{\lambda H_2(\xi) + \mu H_3(\xi)}{48H_1(\xi) + \nu H_3(\xi)}$$

with coefficients

$$\begin{aligned}\lambda &:= \beta(9\beta^2+12\beta-40) > 0,\\ \mu &:= -9\beta^3+108\beta^2-200\beta+80 > 0, \qquad (106)\\ \nu &:= 9\beta^2-60\beta+16 < 0.\end{aligned}$$

Furthermore, we easily calculate

$$(107)\qquad f^{-1}(H_1(\xi)-H_3(\xi)) = \frac{\sigma}{\sqrt{8a}G^2(s)}\int_{\varphi_0}^{\varphi_1} h(\varphi,s)e^{-2\sigma^{-1}\varphi}d\varphi > 0,$$

$$(108)\qquad f^{-1}(H_1(\xi)+H_2(\xi)) = \frac{\sqrt{8a}}{\sigma}\int_{\varphi_0}^{\varphi_1} h(\varphi,s)\cos^2\varphi\, d\varphi > 0.$$

Owing to (107), the denominator in (105) may be written as

$$\begin{aligned}(109)\qquad \mathcal{D} &:= 48H_1(\xi)+\nu H_3(\xi)\\ &= (48+\nu)H_1(\xi) - \frac{\nu f\sigma}{\sqrt{8a}G^2(s)}\int_{\varphi_0}^{\varphi_1} h(\varphi,s)e^{-2\sigma^{-1}\varphi}d\varphi.\end{aligned}$$

Now, $\nu<0$ and

$$(110)\qquad 48+\nu = (3\beta-16)(3\beta-4) < 0 \quad \text{for } 2<\beta<\tfrac{8}{3};$$

hence

$$(111)\qquad \mathcal{D}<0 \quad \text{for } f=-1,\ \ \xi>0.$$

9. Differential equations and limit relations for $H_i(\xi)$. Next, we investigate the functions $H_i(\xi)$. As a first step, we derive a system of differential equations for these functions, which correspond to the Picard–Fuchs differential equations considered in [11].

From (100), (101) we obtain

$$(112)\qquad \frac{dG}{d\xi} = G, \qquad \frac{\partial h}{\partial s}\frac{ds}{d\xi} = \frac{f\sqrt{8a}G(s)\cos\varphi e^{\sigma^{-1}\varphi}}{2\sigma h(\varphi,s)}.$$

Moreover, it follows from (96), (97) that φ_0 and, by the implicit function theorem, also φ_1 are real-analytic functions of s satisfying $h(\varphi_0(s),s)\equiv h(\varphi_1(s),s)\equiv 0$. Using these properties, we can easily calculate the derivatives of the functions $H_i(\xi)$.

LEMMA 6. *Let us define the additional function*

$$(113)\qquad H_0(\xi) := \frac{\sqrt{8a}}{\sigma}\int_{\varphi_0}^{\varphi_1} h^{-1}(\varphi,s)\cos^2\varphi\, d\varphi.$$

Then H_1, H_2, H_3 satisfy the following linear system of differential equations:

$$\begin{aligned}H_1' &= -H_1+\tfrac{1}{2}H_0(\xi),\\ H_2' &= \tfrac{3}{2}H_1+\tfrac{1}{2}H_2, \qquad (114)\\ H_3' &= \tfrac{3}{2}H_1-2H_3.\end{aligned}$$

Proof. We shall only prove the second equation, the rest being similar. Using (102), (108), and (112) we obtain

$$\begin{aligned}H_2' &= -\frac{dG}{d\xi}\frac{1}{G^2}\int_{\varphi_0}^{\varphi_1} h^3(\varphi,s)\cos\varphi e^{-\sigma^{-1}\varphi}d\varphi + \tfrac{3}{2}\frac{f\sqrt{8a}}{\sigma}\int_{\varphi_0}^{\varphi_1} h(\varphi,s)\cos^2\varphi\, d\varphi\\ &= -H_2+\tfrac{3}{2}(H_1+H_2) = \tfrac{3}{2}H_1+\tfrac{1}{2}H_2.\end{aligned}$$ □

Next, we investigate the limits of $H_i(\xi)$ as ξ tends to ∞, respectively, to zero. By the way, recall the relation between r, s, and ξ given in (93) and (100).

LEMMA 7 (The limit $|s| \to \infty$).

(a) $\lim\limits_{r\to\infty} \sqrt{|s|}H_i(\xi(s)) = \frac{\sqrt{2}}{\sqrt{\sigma}}e^{-\frac{\pi}{4\sigma}} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \cos^{\frac{3}{2}} \varphi e^{-\frac{\varphi}{2\sigma}} d\varphi =: L_1, \qquad i = 0,1,3.$

(b) $\lim\limits_{r\to\infty} \frac{H_2(\xi(s))}{\sqrt{|s|}} = \frac{4\sqrt{2}af}{\sigma^{\frac{3}{2}}}e^{\frac{\pi}{4\sigma}} \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \cos^{\frac{5}{2}} \varphi e^{\frac{\varphi}{2\sigma}} d\varphi =: f\, L_2.$

Proof. From (95)–(97) we obtain for $r \to \infty$

$$\frac{\sigma h^2(\varphi, s)}{G(s)\sqrt{8a}e^{\sigma^{-1}\varphi}} \longrightarrow f\cos\varphi\,, \qquad \frac{G(s)}{|s|} \longrightarrow \sqrt{2a}\, e^{\frac{\pi}{2\sigma}}\,,$$

$$(\varphi_0, \varphi_1) \longrightarrow \left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \quad \text{in case } f = \ \ 1\,,$$

$$(\varphi_0, \varphi_1) \longrightarrow \left(\frac{\pi}{2}, \frac{3\pi}{2}\right) \quad \text{in case } f = -1\,.$$

If $f = 1$, the assertion for H_1,H_2,H_3 now follows easily from (102). For H_0, the integrand is unbounded, but a careful investigation also yields the assertion in case $f = 1$. The case $f = -1$ is treated similarly, and a final translation $\varphi = \psi + \pi$ then gives the desired result. □

LEMMA 8 (The limit $s \to 0$ ($\xi \to 0$)). *If $f = 1$, the interval $[\varphi_0, \varphi_1]$ shrinks to the point $\chi := \arctan\sigma^{-1}$. If $f = -1$, $[\varphi_0, \varphi_1]$ tends to the interval $[\chi, \vartheta]$, where $\vartheta > \chi$ is the zero next to χ of the function*

$$g(\varphi) := (1 - \sigma^{-1}\sqrt{8a}\cos\varphi e^{\sigma^{-1}(\varphi-\chi)})^{\frac{1}{2}} \geq 0\,. \tag{115}$$

The functions H_i satisfy the following limit relations:

(a) *Case* $f = 1$:

$$\lim_{\xi\to 0} H_0(\xi) = k := \frac{\pi\sigma^2}{4\sqrt{2a}}\,, \tag{116}$$

$$\lim_{\xi\to 0} \frac{H_1(\xi)}{\xi} = \frac{k}{2}\,, \tag{117}$$

$$\lim_{\xi\to 0} \frac{H_i(\xi)}{\xi^2} = \frac{3k}{8}\,, \qquad i = 2,3\,. \tag{118}$$

(b) *Case* $f = -1$:

$$\lim_{\xi\to 0} H_1(\xi) = -e^{\sigma^{-1}\chi} \int_{\chi}^{\vartheta} g(\varphi)\cos\varphi e^{-\sigma^{-1}\varphi} d\varphi =: l_1 > 0\,, \tag{119}$$

$$\lim_{\xi\to 0} H_2(\xi) = e^{\sigma^{-1}\chi} \int_{\chi}^{\vartheta} g^3(\varphi)\cos\varphi e^{-\sigma^{-1}\varphi} d\varphi =: l_2 < 0\,, \tag{120}$$

$$\lim_{\xi\to 0} H_3(\xi) = \frac{\sigma}{\sqrt{8a}} e^{2\sigma^{-1}\chi} \int_{\chi}^{\vartheta} g^3(\varphi) e^{-2\sigma^{-1}\varphi} d\varphi =: l_3 > 0\,, \tag{121}$$

$$\lim_{s\to 0} \frac{H_0(\xi(s))}{-\ln s} = \frac{\sigma^2}{4\sqrt{2a}}\,. \tag{122}$$

Proof. The assertions concerning the interval $[\varphi_0, \varphi_1]$ follow from (95)–(97), which show that $\tan\chi = \sigma^{-1}$, $G(0) = e^{-\sigma^{-1}\chi}$, and $h^2(\varphi, s)$ tends to $-fg^2(\varphi)$ if $\varphi \in [\varphi_0, \varphi_1]$. Then, using $h^2(\varphi_i(s), s) \equiv 0$, $i = 0, 1$, the expansion of

$$f_i(\psi, s) := h^2(\varphi_i(s) + \psi, s) \tag{123}$$

at $(\psi, s) = (0,0)$ yields

$$f_0(\psi, s) = -4af\sigma^{-2}\psi[\sigma s + \psi + \mathcal{O}(\psi^2 + s^2)] \tag{124}$$
$$=: 4af\sigma^{-2}\psi F(\psi, s),$$

$$f_1(\psi, s) = f\sigma^{-1}\psi\Big[1 - \sigma\tan\vartheta + \mathcal{O}(\sqrt{\psi^2 + s^2})\Big] \tag{125}$$

with $1 - \sigma\tan\vartheta < 0$. Let us now consider the case $f = 1$ $(s < 0)$. We obtain from (124) $\varphi_1(s) - \varphi_0(s) = -\sigma s + \mathcal{O}(s^2) =: \delta(s)$, and further, by the Weierstrass preparation theorem [5], $F(\psi, s) = (\delta(s) - \psi)/q(\psi, s)$, where the functions F, δ, and q are real-analytic, $q(\psi, s) = 1 + \mathcal{O}(\sqrt{\psi^2 + s^2})$. From (113) we now calculate

$$\begin{aligned} H_0(\xi) &= \sqrt{2}\int_0^{\delta(s)} \frac{\cos^2(\varphi_0(s) + \psi)}{\sqrt{\psi F(\psi, s)}} d\psi \\ &= \sqrt{2}\cos^2\chi \int_0^{\delta(s)} \frac{1 + \mathcal{O}(\sqrt{\psi^2 + s^2}\,)}{\sqrt{\psi(\delta(s) - \psi)}} d\psi \\ &= \frac{\sigma^2}{4\sqrt{2}a}\left(\underbrace{\int_0^{\delta(s)} \frac{d\psi}{\sqrt{\psi(\delta(s) - \psi)}}}_{=\pi} + \int_0^{\delta(s)} \frac{\mathcal{O}(\sqrt{\psi^2 + s^2}\,)}{\sqrt{\psi(\delta(s) - \psi)}} d\psi\right) \\ &= \ \frac{\pi\sigma^2}{4\sqrt{2}a} + \mathcal{O}(s)\,, \end{aligned}$$

which proves (116). Since, trivially, $H_i(\xi) \to 0$, $i = 1, 2, 3$, we can successively calculate the one-sided derivatives of $H_i(\xi)$ at $\xi = 0$ using (114):

$$\lim_{\xi \to 0} \frac{H_i(\xi)}{\xi} = H_i'(0) = \begin{cases} \frac{k}{2} & \text{if } i = 1, \\ 0 & \text{if } i = 2, 3\,, \end{cases}$$

which proves (117); then for $i = 2, 3$,

$$\lim_{\xi \to 0} \frac{H_i'(\xi)}{\xi} = H_i''(0) = \tfrac{3}{2}H_1'(0) = \frac{3k}{4}\,.$$

This obviously proves (118). Now consider the case $f = -1$ $(s > 0)$. Formulae (119)–(121) are simple consequences of the definition (102). Thus, we only have to prove (122). From (124), (125) we see that, as $s \to 0$, the integrand in H_0 becomes critical at the lower limit $\varphi_0(s)$ while it remains well behaved near the upper limit $\varphi_1(s)$. Therefore, we subdivide the interval $[\varphi_0(s), \varphi_1(s)]$ into $[\varphi_0(s), \varphi_0(s) + \eta]$ and $[\varphi_0(s) + \eta\,, \varphi_1(s)]$ with some $\eta > 0$, independent of s and sufficiently small. It is easy to show that the integral over $[\varphi_0(s) + \eta\,, \varphi_1(s)]$ is uniformly bounded with respect to s. Thus it suffices to investigate the integral over $[\varphi_0(s), \varphi_0(s) + \eta]$:

$$I := \frac{\sqrt{8a}}{\sigma}\int_{\varphi_0}^{\varphi_0 + \eta} h^{-1}(\varphi, s)\cos^2\varphi\, d\varphi = \sqrt{2}\int_0^{\eta} \frac{\cos^2(\varphi_0(s) + \psi)\, d\psi}{\sqrt{\psi[\sigma s + \psi + \mathcal{O}(\psi^2 + s^2)]}}\,.$$

Since, if $\psi \geq 0$, $s > 0$,

$$\begin{aligned} \sigma s + \psi + \mathcal{O}(\psi^2 + s^2) &= (\sigma s + \psi)(1 + \frac{\mathcal{O}(\psi^2 + s^2)}{\sigma s + \psi}) \\ &= (\sigma s + \psi)(1 + \mathcal{O}(\sqrt{\psi^2 + s^2}))\,, \end{aligned}$$

we obtain

$$I = \frac{\sigma^2}{4\sqrt{2}a} \int_0^{\eta} \frac{1 + \mathcal{O}(\sqrt{\psi^2 + s^2})}{\sqrt{\psi(\sigma s + \psi)}}\, d\psi\,.$$

Writing

$$I_1 := \int_0^{-\frac{1}{\ln s}} \frac{1 + \mathcal{O}(\sqrt{\psi^2 + s^2})}{\sqrt{\psi(\sigma s + \psi)}}\, d\psi\,,\quad I_2 := \int_{-\frac{1}{\ln s}}^{\eta} \frac{1 + \mathcal{O}(\sqrt{\psi^2 + s^2})}{\sqrt{\psi(\sigma s + \psi)}}\, d\psi\,,$$

we calculate

$$\begin{aligned} I_1 &= \left[1 + \mathcal{O}\left(\frac{1}{|\ln s|}\right)\right] \int_0^{-\frac{1}{\ln s}} \frac{d\psi}{\sqrt{\psi(\sigma s + \psi)}} \\ &= \left[1 + \mathcal{O}\left(\frac{1}{|\ln s|}\right)\right] \ln\left(\frac{2 + \sigma s|\ln s| + 2\sqrt{1 + \sigma s|\ln s|}}{\sigma s|\ln s|}\right); \end{aligned}$$

hence,

$$\lim_{s\to 0} \frac{I_1}{|\ln s|} = \lim_{s\to 0} \frac{\ln(s|\ln s|)}{\ln s} = 1\,.$$

Similarly, we obtain

$$\begin{aligned} I_2 &= \left[1 + \mathcal{O}(\sqrt{\eta^2 + s^2})\right] \ln \frac{(2\eta + \sigma s)\ln s + 2\ln s\sqrt{\eta^2 + \sigma s \eta}}{\sigma s \ln s - 2 - 2\sqrt{1 - \sigma s \ln s}} \\ &= \mathcal{O}(\ln|\ln s|) = o(|\ln s|)\,. \end{aligned}$$

This completes the proof of (122) and thus, of the whole lemma. □

10. Properties of $Q(r)$; Monotonicity in case $f = -1$. Let us now return to the quotient $Q = Q(r)$ in (105). Though inaccurate, we shall write $Q(r) = Q(s) = Q(\xi)$ for simplicity. Using the preceding lemmata and (103), (106), (110), we immediately obtain Lemma 9.

LEMMA 9. (a) *In the case $f = 1$, the numerator $\mathcal{N}$ of Q*

$$\mathcal{N} := \lambda H_2(\xi) + \mu H_3(\xi) \tag{126}$$

is positive for all $\xi > 0$, while the denominator $\mathcal{D}$, defined in (109), *satisfies the limit relations*

$$\lim_{\xi\to 0} \frac{\mathcal{D}}{\xi} = \frac{3\sqrt{2}\pi\sigma^2}{a}\,,\qquad \lim_{s\to -\infty} \sqrt{|s|}\mathcal{D} = (48 + \nu)L_1 < 0\,. \tag{127}$$

Thus, contrary to the case $f = -1$ (see (111)*), $\mathcal{D} = \mathcal{D}(\xi)$ has at least one zero in $0 < \xi < \infty$ with change of sign.*

(b) *For any $f = \pm 1$, the quotient Q satisfies*

$$\lim_{r\to\infty} \frac{Q}{|s|} = \frac{3\lambda}{5(48 + \nu)}\,\frac{L_2}{L_1} < 0\,. \tag{128}$$

(c) *In the case $f = 1$, we have*

$$\lim_{\xi\to 0} \frac{Q}{\xi} = \frac{3}{5} \cdot \frac{\lambda + \mu}{64} = \frac{3}{8}(3\beta^2 - 6\beta + 2) > 0\,. \tag{129}$$

(d) *In the case $f = -1$, we obtain from* (109) *$48l_1 + \nu l_3 < 0$, and hence*

$$\lim_{\xi\to 0} Q = -\frac{3}{5} \cdot \frac{\lambda l_2 + \mu l_3}{48 l_1 + \nu l_3}\,. \tag{130}$$

□

Remark. The quotient L_2/L_1 occurring in (128) can be expressed by the gamma function. From formula 19 in [6, p. 138] we calculate

$$\frac{L_2}{L_1} = \frac{20\pi^2\sigma(9\sigma^2+1)e^{\frac{\pi}{2\sigma}}}{(1+25\sigma^2)(1+2\sinh^2\frac{\pi}{4\sigma})}|\Gamma\left(\frac{1}{4}+\frac{i}{4\sigma}\right)|^{-4}. \qquad \square$$

From Lemma 9 we see that, for $f=1$, $Q(r)$ is unbounded at some point $r=r_0>0$. Further results on the behavior of Q can be received from the derivative $\frac{dQ}{d\xi}$. Using (114), a straightforward calculation yields

$$\begin{aligned} Z :=& \frac{5f}{3}(48H_1+\nu H_3)^2\frac{dQ}{d\xi} = 72(\lambda+\mu)H_1^2 + \lambda\left(72-\frac{3}{2}\nu\right)H_1H_2 \\ &- \left(48\mu-\frac{3}{2}\lambda\nu\right)H_1H_3 + \frac{5}{2}\lambda\nu H_2H_3 - 24H_0(\lambda H_2+\mu H_3). \end{aligned} \tag{131}$$

From this expression, combined with Lemmata 7 and 8, we obtain

$$\left.\begin{aligned} &(132) \qquad \lim_{\xi\to\infty} Z = f\lambda(48+\nu)L_1L_2 \\ &(133) \qquad \lim_{r\to\infty}\frac{1}{r}\frac{dQ}{d\xi} = \lim_{r\to\infty}\frac{dQ}{dr} = \frac{3\lambda}{5(48+\nu)}\frac{L_2}{L_1} < 0 \end{aligned}\right\} \text{ for } f=\pm1,$$

$$\lim_{\xi\to0}\frac{dQ}{d\xi} = \lim_{r\to0}\frac{1}{2ar}\frac{dQ}{dr} = \frac{3(\lambda+\mu)}{320} > 0 \quad \text{if } f=1, \tag{134}$$

$$\lim_{r\to0}\frac{1}{-r\ln r}\frac{dQ}{dr} = \frac{18\sqrt{2}\sigma^2}{5}\frac{\lambda l_2+\mu l_3}{(48l_1+\nu l_3)^2} \quad \text{if } f=-1. \tag{135}$$

Let us now investigate the case $f=-1$ more closely. The integrals involved in l_2, l_3 (see (120), (121)) can be calculated numerically, and it turns out that

$$\lambda l_2 + \mu l_3 < 0 \quad \text{for each } \beta \in (2, \tfrac{8}{3}). \tag{136}$$

Thus, by (135),

$$\lim_{\xi\to0}\frac{dQ}{d\xi} = -\infty \qquad (f=-1), \tag{137}$$

and the function Z, defined in (131), satisfies

$$\lim_{\xi\to0} Z = \infty, \quad \lim_{\xi\to\infty} Z = -\lambda(48+\nu)L_1L_2 > 0 \qquad (f=-1). \tag{138}$$

This suggests trying to show that $Z>0$, or equivalently, $dQ/d\xi<0$ for all $\xi>0$ and $f=-1$. For this purpose we look for positive constants c_1, c_2 such that

$$H_2(\xi)+c_1H_3(\xi) < 0, \quad c_2H_3(\xi)-H_1(\xi) < 0 \quad \text{for all } \xi>0 \; (f=-1). \tag{139}$$

Note that, from (107), we necessarily have $c_2<1$. Moreover, it seems useful to introduce

$$P_1 := \frac{\sigma}{\sqrt{8aG^2(s)}}\int_{\varphi_0}^{\varphi_1} h^{-1}(\varphi,s)e^{-2\sigma^{-1}\varphi}d\varphi > 0, \tag{140}$$

$$P_2 := \frac{\sigma}{\sqrt{8aG^2(s)}}\int_{\varphi_0}^{\varphi_1} h(\varphi,s)e^{-2\sigma^{-1}\varphi}d\varphi > 0. \tag{141}$$

Then (107) and a short calculation yield

$$H_3 - H_1 = P_2 \qquad (f=-1), \tag{142}$$

$$H_0 - 2H_1 + H_3 = P_1 \qquad (f=\pm1). \tag{143}$$

Now, eliminating H_0 from Z by (143), and using (142) and the inequalities

$$H_1^2 > c_2 H_1 H_3 \,, \quad -H_1 H_3 > c_1^{-1} H_1 H_2 \qquad (f = -1), \tag{144}$$

we obtain

$$\begin{aligned} Z =&72(\lambda + \mu)H_1^2 + 24\mu H_3^2 + (24\lambda - \tfrac{3}{2}\lambda\nu)H_1H_2 - (96\mu - \tfrac{3}{2}\lambda\nu)H_1H_3 \\ &+ \lambda(24 + \tfrac{5}{2}\nu)H_2H_3 - 24P_1(\lambda H_2 + \mu H_3) \\ >&[72c_2(\lambda + \mu) - 72\mu + \tfrac{3}{2}\lambda\nu]H_1H_3 + (48\lambda + \lambda\nu)H_1H_2 \\ &+ 24\mu H_3 P_2 + \lambda(24 + \tfrac{5}{2}\nu)H_2P_2 - 24P_1(\lambda h_2 + \mu H_3) \,. \end{aligned} \tag{145}$$

Since $c_2 < 1$, we have $72c_2(\lambda + \mu) - 72\mu + \frac{3}{2}\lambda\nu < \frac{3}{2}\lambda(48 + \nu) < 0$. Thus, by (144) we further obtain

$$Z > c_1^{-1}\lambda \underbrace{(48 + \nu)H_1H_2}_{>0} \cdot W(c_1, c_2) + R \,, \tag{146}$$

where

$$W(c_1, c_2) := c_1 - \frac{72(\lambda + \mu)}{\lambda(48 + \nu)}(c_2 - 1) - \tfrac{3}{2} \,, \tag{147}$$

$$R := \underbrace{24\mu H_3 P_2}_{>0} + \underbrace{\frac{\lambda}{2}(48 + 5\nu)H_2P_2}_{>0} - 24P_1(\lambda H_2 + \mu H_3) \,. \tag{148}$$

Before continuing here, we have to determine the constants c_1, c_2. For this purpose, we use the following lemma.

LEMMA 10. *Let l_1, l_2, l_3 be the integrals defined in* (119)–(121), *where $\beta \in (2, \frac{8}{3})$ is arbitrarily fixed.*

(a) *If $c_1 \geq \frac{3}{2}$ is such that $l_2 + c_1 l_3 < 0$, then*

$$H_2(\xi) + c_1 H_3(\xi) < 0 \quad \textit{for all } \xi > 0 \qquad (f = -1) \,.$$

(b) *If c_2 satisfies $\frac{1}{3} \leq c_2 < 1$ and $c_2 l_3 - l_1 < 0$, then*

$$c_2 H_3(\xi) - H_1(\xi) < 0 \quad \textit{for all } \xi > 0 \qquad (f = -1) \,.$$

Proof. (a) Setting $F(\xi) := e^{-\frac{\xi}{2}}(H_2(\xi) + c_1 H_3(\xi))$ and using (114), (142), we calculate

$$\begin{aligned} \frac{dF}{d\xi} &= \tfrac{1}{2}e^{-\frac{\xi}{2}}[3(1 + c_1)H_1(\xi) - 5c_1H_3(\xi)] \\ &< \tfrac{1}{2}e^{-\frac{\xi}{2}}(3 - 2c_1)H_3(\xi) \leq 0 \,. \end{aligned}$$

Since $\lim_{\xi \to 0+} F(\xi) = l_2 + c_1 l_3 < 0$, this implies $F(\xi) < 0$ for all $\xi > 0$ and thus proves the assertion.

(b) Using a similar trick, we set $\eta := 2 - 1/(2c_2)$ and $\widetilde{F}(\xi) := e^{\eta\xi}(c_2 H_3(\xi) - H_1(\xi))$. From (114) and (143) we obtain

$$\frac{d\widetilde{F}}{d\xi} = -\tfrac{1}{2}e^{\eta\xi}\left[P_1 + \frac{1}{c_2}\underbrace{(-3c_2^2 + 4c_2 - 1)}_{\geq 0}H_1\right] < 0 \,.$$

Now the assertion follows as in the proof of (a). □

Numerical calculations have shown $l_2 + 6l_3 < 0$ and $\frac{1}{2}l_3 - l_1 < 0$. Thus, by the preceding lemma, (139) holds for

$$c_1 = 6 \,, \qquad c_2 = \tfrac{1}{2} \,.$$

Now a simple estimation yields $W(6,\frac{1}{2}) > 0$. Moreover, from (106) we see that $\mu < 6\lambda$, which, together with $H_2 + 6H_3 < 0$, gives $\lambda H_2 + \mu H_3 < 0$. Thus $R > 0$, too, and hence $Z > 0$. We have proved the following lemma.

LEMMA 11. *In the case $f = -1$, $dQ/d\xi$ is negative for all $\xi > 0$ and arbitrarily fixed $\beta \in (2, \frac{8}{3})$. Moreover, $\lim_{s\to 0+} Q =: M < 0$.*

Let us now consider the case $f = 1$. It seems difficult to attain analytical results on the behavior of Q beyond those already stated in Lemma 9 and in (133), (134). But extensive numerical computations (carried out by Frank Rehrmann) produced the following results.

(149) *Numerical results for $f = 1$, $\beta \in (2, \frac{8}{3})$.* The denominator $\mathcal{D}$ of $Q(s)$ vanishes at exactly one point $s_0 < 0$. For $s_0 < s < 0$, $Q(s)$ is strictly decreasing from ∞ to 0. Moreover, $dQ(s)/ds$ vanishes at exactly one point $s_1 < s_0$; $Q(s)$ is strictly increasing in $(-\infty, s_1)$ from $-\infty$ to $m := Q(s_1) < 0$, and strictly decreasing in (s_1, s_0) from m to $-\infty$.

Figure 10 shows the graph of $Q(s)$ for $\beta = 2{,}3$ ($f = \pm 1$). For other values of β, $Q(s)$ behaves quite similarly: As β increases from 2 to $\frac{8}{3}$, s_0 ranges from $\approx -2{,}2$ to $\approx -1{,}9$, s_1 from $\approx -2{,}93$ to $\approx -2{,}95$, m from ≈ -41 to ≈ -34, and $M := \lim_{s\to 0+} Q(s)$ from $\approx -64{,}3$ to $\approx -18{,}8$.

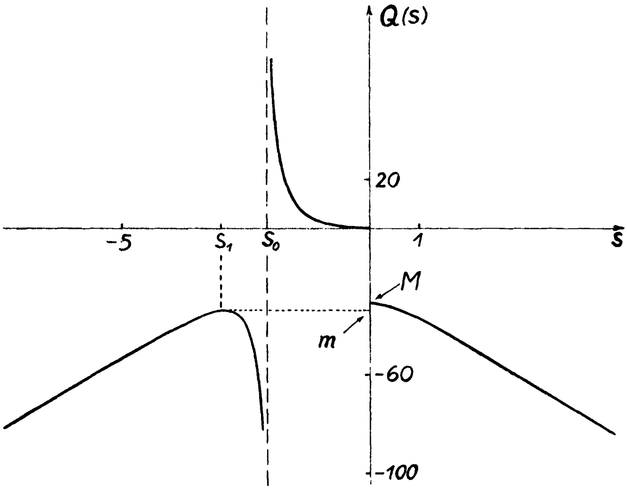

FIG. 10. *The quotient $Q(s)$ for $\beta = 2,3$.*

11. A modified scaling. Before pronouncing the main result on the unfolding of the degenerate bifurcation at the cusp point, we will briefly revisit the scaling chosen in (64). This scaling is unsatisfactory in a double sense. First, an admissible range of (ε, τ)

(150) $$0 < \varepsilon \le \varepsilon_0\,, \quad |\tau| \le \tau_0 \quad (\varepsilon_0, \tau_0 \text{ sufficiently small})$$

leads to an admissible range

(151) $$|p| \le \sqrt{|q|}\,\tau_0\,, \qquad 0 < |q| \le \varepsilon_0^2$$

in the (p,q)-plane which, obviously, is not just a full neighborhood of (0,0) with p-axis removed. The second drawback refers to the admissible range of (u,v) and, thus, of r. While the results of §§6 and 7 are valid only for (u,v) in a bounded domain and (ε,τ)

sufficiently small, Lemma 7 contains results for $r \to \infty$ and thus, for arbitrarily large v. To remedy this we follow the same procedure as in [4, p. 78]: In (64), we replace the scaling $\varepsilon = \sqrt{|q|}$ by

$$\varepsilon = \kappa^{-1}\sqrt{|q|}\,, \qquad 0 < \kappa \leq 1 \tag{152}$$

with a new parameter κ. Repeating the former calculations, it turns out that all the formulae and definitions in §§6–8 remain valid, if we simply replace f, where it occurs explicitly, by $f\kappa^2$. Moreover, in (65), the functions $R_i(u, v, \varepsilon, \tau)$ become real-analytic functions $R_i(u, v, \varepsilon, \tau, \kappa)$, at least quadratic both with respect to (u, v) and (ε, τ), which are again bounded for (u, v) in an arbitrary bounded domain, $0 < \kappa \leq 1$, and (ε, τ) as in (150). Now, the admissible range of (p, q) is

$$|p| \leq \kappa^{-1}\sqrt{|q|}\,\tau_0\,, \qquad 0 < |q| \leq \kappa^2\varepsilon_0^2\,. \tag{153}$$

Therefore, given $|q| \in (0, \varepsilon_0^2]$, if κ varies in $[\varepsilon_0^{-1}\sqrt{|q|}, 1]$, then p covers the interval $[0, \varepsilon_0\tau_0]$; hence, (p, q) covers a full neighborhood of (0,0) except $q = 0$. As for the second drawback mentioned above, we note that after the new scaling, all the former statements are again valid for any bounded region $\mathcal{B} : |u| < u_0, |v| < v_0$. In the original scaling, $\mathcal{B}$ corresponds to $|u| < \kappa^{-1}u_0, |v| < \kappa^{-2}v_0$, and since $\kappa \to 0$ is allowed, the original statements are valid for any $(u, v) \in \mathbb{R}^2$.

12. The unfolding in the cusp point.

From the results in the preceding sections we now derive the following theorem concerning the unfolding of the degenerate codimension-2 bifurcation in the cusp point. Recall that for this phenomenon to occur, the parameters (α, β) have to satisfy (54) and, given β, the parameters (γ, ζ) must be sufficiently close to $(9\beta, 3\beta)$, or equivalently, (p, q) must be sufficiently close to (0,0).

THEOREM 2. *In a neighborhood $\mathcal{U}$ of the origin in the (p, q)-parameter plane there exist curves*

$$\begin{aligned} L_1 &: p = Mq + \mathcal{O}(|q|^{\frac{3}{2}})\,, \quad q < 0 \\ L_2 &: p = -mq + \mathcal{O}(q^{\frac{3}{2}})\,, \quad q > 0 \end{aligned} \qquad (m, M \textit{ as in } (149) \textit{ and Lemma } 11)$$

and a subdivision of $\mathcal{U}$ into regions I–V *generated by L_1, L_2, the p-axis, and the positive q-axis* (see Fig. 11) *such that for system* (58) *the following statements hold locally, i.e., in a neighborhood of $(w_1, w_2) = (0,0)$ (for an illustration of these statements, see Fig.* 12):

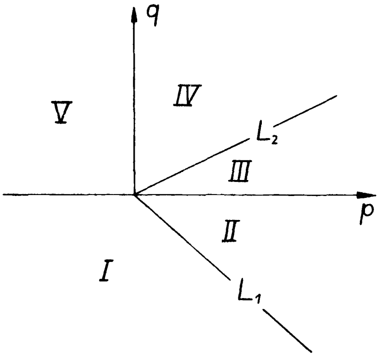

FIG. 11. *Subdivision of $\mathcal{U}$.*

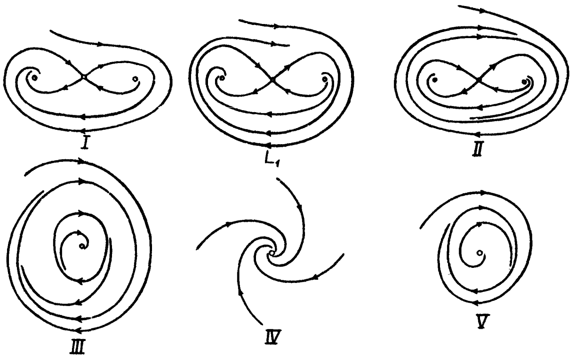

FIG. 12. *Phase portraits for the regions of Fig.* 11.

(a) $(p,q) \in$ I: *There is no periodic orbit, but there exist two heteroclinic orbits joining the saddle* (0,0) *to the sink in the left half plane.*

(b) $(p,q) \in L_1$: *There is a homoclinic orbit joining* (0,0) *to itself and surrounding the two other equilibria; it is asymptotically stable* (*from outside*).

(c) $(p,q) \in$ II: *There is exactly one periodic orbit; it encircles all three equilibria and is asymptotically stable. It approaches the homoclinic orbit just mentioned, if* (p,q) *tends to a point on* L_1. *Its size* (*e.g., its diameter*) *is of order* $\tilde{p}$ *as* (p,q) *tends to the point* $(\tilde{p},0)$. *Moreover, there exist two heteroclinic orbits joining the source in the right half plane to the saddle* (0,0).

(d) $(p,q) \in$ III: *There are exactly two periodic orbits; the outer one is asymptotically stable, while the inner one is unstable. As* (p,q) *tends to* $(\tilde{p},0)$, *the size of the outer periodic orbit is of order* $\tilde{p}$, *while the size of the inner one decreases to zero linearly with* q. *On the other hand, if* (p,q) *crosses the curve* L_2 *at* $(\tilde{p},\tilde{q})$, *the two periodic orbits first coalesce to a single periodic orbit—with size of order* $\tilde{q}$*—and then disappear.*

(e) $(p,q) \in$ IV: *No periodic orbit exists. As* (p,q) *approaches and crosses the positive* q*-axis transversely, supercritical Hopf bifurcation occurs.*

(f) $(p,q) \in$ V: *Exactly one periodic orbit exists; it is asymptotically stable. It shrinks down to a point as* (p,q) *tends either to* $(0,\tilde{q})$ *or to* $(\tilde{p},0)$, $(\tilde{q} > 0,\ \tilde{p} < 0)$. *More precisely, its size decreases like* $\sqrt{-p}$ *in the first limit, and like* q *in the second one.*

Proof. First we note that for $q \neq 0$, system (58) is equivalent to (65); hence we may use all the results on system (65) derived in the preceding sections. Moreover, by (64), the curves L_1, L_2 correspond to the curves $\tau = Q(s)\varepsilon + \mathcal{O}(\varepsilon^2)$ (see (83)) with $s \to 0+$ and $s = s_1$, respectively. We also note that any (nonconstant) periodic orbit of (65) must surround all three equilibria and, therefore, crosses the positive v-axis. The assertions on the precise number of period orbits now follow from Lemma 5 combined with Lemma 11 in case $q < 0$, while in case $q > 0$, the analytical results of Lemmata 5 and 9 do not suffice for their proof; we also need the numerical results (149). As for the size of the periodic orbits starting at $(w_1, w_2) = (0, A^{-1}|q|r)$, most statements are easy consequences of (64) and the limit relations (133), (134). But the two assertions concerning their shrinkage of order q again use the numerical results (149). The existence of a homoclinic orbit follows from Lemma 5, since Q_0 in (85) is easily seen to coincide with M. The fact that this homoclinic orbit is the limit of the periodic orbits in II if (p,q) tends to L_1 is proved along the same lines as analogous results in [10, p. 339] and [4, p. 70]. To prove the asymptotic stability of the homoclinic orbit we apply [5, p. 357]: Inserting $f = -1$ and $\tau = Q_0\varepsilon + \mathcal{O}(\varepsilon^2)$ into the right-hand side of (65), the trace of its linearization at $(u,v) = (0,0)$ is $Q_0\varepsilon + \mathcal{O}(\varepsilon^2)$, which is negative since $Q_0 = M < 0$ and $\varepsilon > 0$. Hence, the homoclinic orbit is asymptotically stable. Next we prove the stability assertions for the periodic orbit $\bar{\gamma}$ of system (65) starting at $(u,v) = (0,\bar{r})$, where $\bar{r} > 0$, $\varepsilon > 0$ are fixed and $\tau = Q(\bar{r})\varepsilon + \mathcal{O}(\varepsilon^2)$. Let $r > 0$ be sufficiently close to $\bar{r}$, and recall the definitions of $I(U,V)$, $N(U,V)$, $H(t)$, and $K = K(r,\varepsilon,\tau)$ in (68), (70), (73), (78). Obviously, $K(\bar{r},\varepsilon,\tau) = 0$, and from $\partial I(U,V)/\partial V = 2a\frac{V}{N} < 0$ for $V < 0$, we easily see that $\bar{\gamma}$ is asymptotically stable (respectively, unstable) if $(r-\bar{r})K < 0$ (respectively, > 0), or a fortiori if $dK/dr|_{r=\bar{r}} < 0$ (respectively, > 0). Now, using the previous notation we obtain

$$K(r,\varepsilon,\tau) = 4a\varepsilon\left\{ Q(\bar{r}) \underbrace{\int_{\Gamma} N^{-1}(V+cU^2)dU}_{=:\,J_1(r)} \right.$$
$$\left. + \underbrace{\int_{\Gamma} N^{-1}(bU^2V - fdU^2 + eU^4)dU}_{=:\,J_2(r)} \right\} + \mathcal{O}(\varepsilon^2)\,.$$

Owing to $Q(r) = -J_2(r)/J_1(r)$ (see (82)), we calculate

$$\frac{dK}{dr}|_{r=\bar{r}} = -4a\varepsilon J_1(\bar{r}) \cdot \frac{dQ}{dr}|_{r=\bar{r}} + \mathcal{O}(\varepsilon^2)\,.$$

The desired stability properties now follow from (111), Lemma 9, Lemma 11, and—in case $f = 1$—the supplementary numerical results (149). As for the heteroclinic orbits, we assume $(p,q) \in \mathrm{I} \cup \mathrm{II}$ and $r > 0$ arbitrarily fixed. By essentially repeating the preceding calculation, we obtain

$$K(r,\varepsilon,\tau) = 4a\underbrace{J_1(r)}_{<0}(\tau - \varepsilon Q(r)) + \mathcal{O}(\varepsilon^2 + \tau^2)\,.$$

Now, in case $(p,q) \in \mathrm{I}$, we have $\tau - \varepsilon Q(r) > 0$ and thus $K(r,\varepsilon,\tau) < 0$. If $(p,q) \in \mathrm{II}$, there exists $\tilde{r} > 0$ sufficiently small such that $\tau - \varepsilon Q(\tilde{r}) < 0$ (see Lemma 11); hence $K(\tilde{r},\varepsilon,\tau) > 0$. By (71), this implies the existence of a positively invariant compact region $\mathcal{P}$ in case $(p,q) \in \mathrm{I}$, and a negatively invariant compact region $\mathcal{N}$ in case $(p,q) \in \mathrm{II}$, as shown in Fig. 13. The existence of heteroclinic orbits as claimed in the theorem now easily follows by standard arguments using Poincaré–Bendixson theory, the hyperbolicity of the three equilibria, and the fact that $\mathcal{P}$, $\mathcal{N}$ contain no nonconstant periodic orbit. Hopf bifurcation of system (65) with $f = 1$ and parameter τ at $(u,v,\varepsilon,\tau) = (0,0,\varepsilon,0)$ is verified in the usual way (see [8]). Since we already know that it is supercritical with asymptotically stable Hopf cycles, we omit the details. Finally, to prove the phenomena claimed when (p,q) crosses L_2, we again rely on the computations (149). This ends the proof of Theorem 2. □

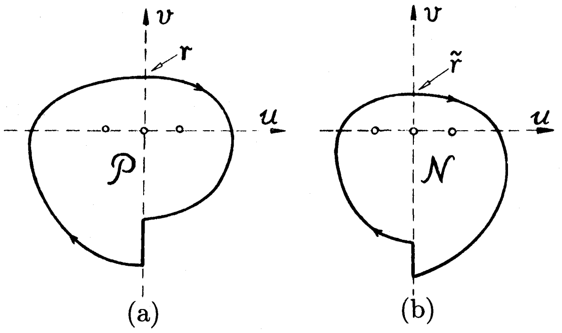

FIG. 13. *Illustrating the proof of Theorem* 2. (a) $(p,q) \in \mathrm{I}$, (b) $(p,q) \in \mathrm{II}$.

13. Concluding remarks. (1) The phenomenon described in Theorem 2, which occurs as (p,q) crosses the p-axis upwards, can be regarded as a counterpart to Hopf bifurcation: Three equilibria first coalesce to a single equilibrium, from which a family of periodic orbits then emanate. As we have seen, the growth of these periodic orbits is not of order $\sqrt{q}$ as in standard Hopf bifurcation, but only of order q.

(2) It is easily verified that, in addition to the heteroclinic orbits addressed in Theorem 2, system (58) has a continuum of heteroclinic orbits connecting the two equilibria $\neq$ (0,0); this is true for any (p,q) sufficiently small ($q \neq 0$).

(3) Returning to the surface $\mathcal{M}$ in (γ,δ,ζ)-space defined by (7), with (α,β) satisfying (54), the results of Theorem 2 and the phase portraits given in Fig. 12 may be carried over to a neighborhood $\mathcal{U}'$ of the cusp point C_0 of $\mathcal{M}$. Looking at $\mathcal{U}'$ parallel to the negative δ-axis, we obtain a subdivision of $\mathcal{U}'$ which is described qualitatively in Fig. 14. Here, the phase portraits in $\mathrm{I}', L_1', \cdots$ are equivalent to those in $\mathrm{I}, L_1, \cdots$. Moreover, Fig. 15 shows a vertical projection of $\mathcal{U}'$ onto the original parameter plane (γ,δ) with corresponding decomposition $\mathrm{I}'', L_1'', \cdots$. It is interesting to note that the restriction $|p| \leq \sqrt{|q|}\,\tau_0$, given in (151), is essential here for $q > 0$, since otherwise, there would exist parameters (p,q), $q > 0$—corresponding in Fig. 15 to the points of III$''$ and V$''$ between C_+ and C_-—for which system (58) has three equilibria, contrary to our previous results.

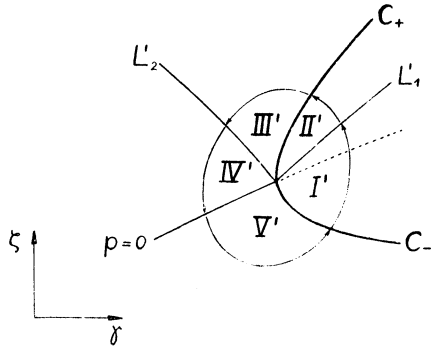

FIG. 14. *The neighborhood* $\mathcal{U}'$ *of* C_0.

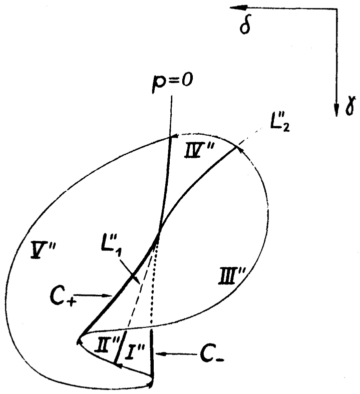

FIG. 15. *Vertical projection of* $\mathcal{U}'$.

(4) The local phase portraits of Fig. 12 could be translated back to the original (x, y)-plane, via the near identity transformation (56) and the orientation reversing transformation (24). Figures 16 and 17 show such phase portraits corresponding to regions II, respectively III. Note that all statements were of local nature such that, e.g., in Fig. 16, only the flow in a common neighborhood of the three inner equilibria is guaranteed.

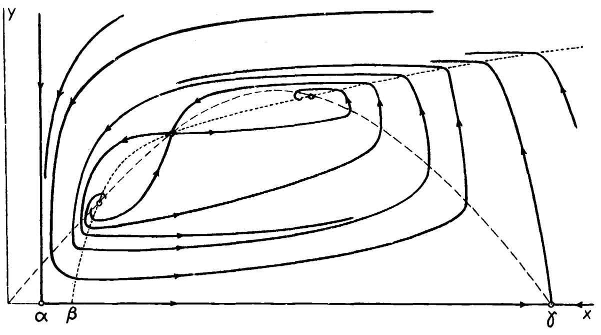

FIG. 16. *Phase portrait for region* II *in the* (x, y)*-plane. The curves* (5) *are indicated, too.*

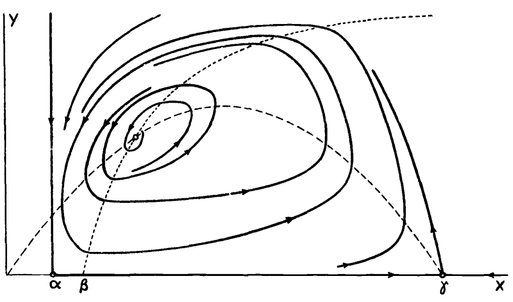

FIG. 17. *Phase portrait for region* III *in the* (x, y)*-plane.*

(5) The parts of this paper concerning the unfolding of the degenerate codimension-2 bifurcation in the cusp point can be treated in a more general setting. This has been done and will be published separately.

QUALITATIVE ANALYSIS OF ONE- OR TWO-SPECIES NEUTRAL DELAY POPULATION MODELS*

YANG KUANG†

Abstract. In this paper neutral delay models of single population growth, predator-prey, and competition interactions are introduced and investigated. These systems are more general than previous ones by allowing per capita growth rates to be nonlinear and delays to be of the general distributed type. Conditions are given for solutions of these systems to be bounded for proper initial functions. For neutral delay single population models, sufficient conditions for solutions tending to the positive steady states are also presented.

Key words. qualitative analysis, neutral delay equation, predator-prey system, competition system, distributed delay

1. Introduction.

The autonomous logistic delay differential equation

$$\dot{x}(t) = rx(t)[1 - x(t-\tau)/K], \tag{1.1}$$

where "$\cdot$"$= d/dt$, r, K, τ are positive constants, has been widely used as a model equation capable of showing oscillations of single-species population sizes in constant environments closed to both immigration and emigration (see Cushing [2], Gopalsamy and Zhang [10], Hale [13], Kuang and Feldstein [19], and Pielou [27]). It has been the object of intensive analysis by numerous authors (see the references cited in [10]). Indeed, it is a natural generalization of the following well-known logistic single-species population equation:

$$\dot{x}(t) = rx(t)[1 - x(t)/K]. \tag{1.2}$$

Here r is called the intrinsic growth rate of the species x, K is interpreted as the environment carrying capacity for x, and $r[1 - x(t)/K]$ is the per capita growth rate of x at time t. Based on his investigation on laboratory populations of Daphnia magna, F. E. Smith [28] argued that a growing population will use food faster than a saturated one; thus the per capita growth rate in (1.2) should be replaced by $r[1 - (x(t) + \rho\dot{x}(t))/K]$ (for details see Pielou [27, pp. 38–40]). This leads to the following equation:

$$\dot{x}(t) = rx(t)[1 - (x(t) + \rho\dot{x}(t))/K]. \tag{1.3}$$

We may think of x as a species grazing upon vegetation, which takes time τ to recover. In this case, it will be even more realistic to incorporate a single discrete delay τ in the per capita growth rate, which results in the following neutral delay logistic equation

$$\dot{x}(t) = rx(t)[1 - (x(t-\tau) + \rho\dot{x}(t-\tau))/K]. \tag{1.4}$$

This equation was first introduced and investigated by Gopalsamy and Zhang [10]. Subsequently, it was studied by Freedman and Kuang [6], and Kuang and Feldstein

[19]. The focus of these works was the qualitative behavior of the solutions, such as boundedness, asymptotic stability, and oscillation. In a recent paper Gopalsamy, He, and Wen [9] studied the existence and linear asymptotic stability of periodic solutions of equation (1.4), when r, ρ, and K are replaced by periodic functions of period ω, and $\tau = n\omega$ for some positive integer n.

Assume the population $x(t)$ described by (1.4) is a prey species, and suppose there exists a predatory species $y(t)$ that preys on species $x(t)$; then it is natural to propose the following mathematical model to describe their interaction:

$$\left\{\begin{aligned} \dot{x}(t) &= rx(t)[1 - (x(t-\tau) + \rho\dot{x}(t-\tau))/K] - y(t)p(x(t)), \\ \dot{y}(t) &= y(t)[-\alpha + \beta p(x(t-\sigma))]. \end{aligned}\right. \tag{1.5}$$

Here α, β, and σ are all positive constants, and $p(x)$ is the predator response function for the predator species y with respect to the prey species x. A slightly more general version of (1.5) was introduced and studied in Kuang [16], where the focus of the study was the local stability and oscillation analysis of system (1.5). An even more general version of (1.5) was proposed and studied in [18] where sufficient conditions were obtained for its solutions to be bounded.

Assume $x(t)$ described by (1.4) is the population of a species competing with another species with population $y(t)$ for a shared limited resource—space or a nutrient, for example; then the following system may model their interaction:

$$\left\{\begin{aligned} \dot{x}(t) &= r_1x(t)[1 - k_1x(t) - ax(t-\tau_1) - \beta\dot{x}(t-\tau_0) - c_1y(t-\tau_2)], \\ \dot{y}(t) &= r_2y(t)[1 - c_2x(t-\tau_3) - k_2y(t-\tau_4)]. \end{aligned}\right. \tag{1.6}$$

Here all parameters except β are assumed to be positive constants. We have included $k_1x(t)$ into the per capita growth rate of $x(t)$, which may reflect the possible instantaneous interference within species x. System (1.6) was first introduced and studied in Kuang [17]. Again the focus of that work was the local stability and oscillatory analysis of system (1.6). Sufficient conditions for solutions of (1.6) to be bounded can be found in [18].

Although extensive literature exists on functional differential equations and their applications (cf. [2], [3], [7], [13], [29]), works on global asymptotic stability and boundedness of solutions for nonlinear equations or systems are relatively few. Most of these existing results only apply to systems with special kernel in the distributed delays (cf. the references cited in [1], [2], [5], [20]), or with a strong nondelayed self-crowding effect (e.g., [8], [12], [22]–[25]). However, these requirements are rather artificial and restrictive, and very few real systems may satisfy them. Thus, there is an urgent need to study these questions for more general and realistic models. An effort along this line was documented in [11], [21].

As the reader may already be aware, many real systems are quite sensitive to sudden changes. This fact may suggest that proper mathematical models of the systems should consist of some neutral delay equations. Even though the delay lengths may be short, and the neutral terms relatively small, it is still necessary, for the sake of rigorousness, to justify that the neutral term effects are not important. Indeed, most of the time we may find that neutral term effects can be quite significant. This is largely due to the fact that neutral delay equations are not structurally stable in the sense that the introduction of neutral delay terms may destabilize an asymptotically stable equilibrium. For example, $3\dot{x} = -x$ has a globally asymptotically stable trivial solution, while the same solution in $\dot{x} + 2\dot{x}(t-\tau) = -x$ becomes unstable for any $\tau > 0$. This is because the corresponding characteristic equation of the neutral equation may have roots bifurcating from infinity [6], [13], a phenomenon that cannot occur in retarded equations. This indicates that it is important to deal with neutral delay equations in real mathematical models.

Although neutral delay equations have been studied extensively (see the references cited in Hale [13]), most of the existing works are related to fundamental questions such as existence, uniqueness, local stability analysis, etc. Recently, there seems to be a growing interest in the oscillation theory for neutral delay equations (cf. [7], [10], [16], [17]). The literature on global asymptotic stability for general nonlinear neutral delay equations is scarce. The main difficulty in this kind of analysis is probably the lack of compactness for bounded solutions (indeed, even the boundedness of solutions is usually hard to establish). Frankly speaking, the results to be presented in this paper are rather limited and primitive.

This paper is organized as follows: In the next section the system is described in detail and some preliminary results are presented. Section 3 deals with boundedness of solutions of a scalar neutral equation and §4 contains a discussion of domain of attractivity for the unique positive steady states. Section 5 considers the boundedness problem for the full system. The final section is devoted to discussion and presents some numerical simulations.

2. Preliminaries. In this paper we propose to study the following general neutral delay systems, which may model a two-species interaction (x and y) in a closed environment and include both systems (1.5) and (1.6) as special cases:

$$\begin{aligned}\dot{x}(t) =& x(t)\left[\int_{-\tau_1}^{0} g(x(t+s))d\mu_1(s) - \rho\int_{-\tau_2}^{0} \dot{x}(t+s)d\mu_2(s)\right.\\ &\left. - q(x(t))\int_{-\tau_3}^{0} y(t+s)d\mu_3(s)\right],\\ \dot{y}(t) =& y(t)\left[a + b\int_{-\tau_4}^{0} x(t+s)q(x(t+s))d\mu_4(s) - c\int_{-\tau_5}^{0} y(t+s)d\mu_5(s)\right],\end{aligned} \tag{2.1}$$

where τ_i, $i = 1, \cdots, 5$, ρ and c are nonnegative constants, and a and b are real numbers. We always assume the following:

(H1) $\mu_i(s)$ is nondecreasing and $\int_{-\tau_i}^{0} d\mu_i(s) = 1$, $i = 1, \cdots, 5$;

(H2) $g(x)$ is continuously differentiable such that $g(0) > 0$, $g'(x) < 0$ for $x \geq 0$, and $g(1) = 0$;

(H3) $p(x) = xq(x)$ is continuously differentiable, $p(0) = 0$, $p'(x) > 0$ for $x \geq 0$, and $\lim_{x\to+\infty} p(x) > |a/b|$.

Clearly, when $a < 0$, $b > 0$, $c = 0$, and $g(x) = r(1-x)$, then system (2.1) reduces to a slightly more general form of (1.5). We may refer to this resulting system as Gause-type neutral delay predator-prey system (cf. [16]). When $a > 0$, $b < 0$, we see (2.1) has (1.6) as a special case. System (2.1) is more general than the one considered in [18] in the following two aspects: (i) we allow the per capita growth rate of x to be nonlinear when y is absent, (ii) all delays are of the distributed type.

Let $\tau_0 = \max\{\tau_i : i = 1, 2, \cdots, 5\}$ and $R^+ = \{r : r \geq 0\}$. We always assume that the initial conditions for (2.1) are of the type

$$\begin{aligned} x(s) = \phi_1(s) \geq 0, s \in [-\tau_0, 0], \phi_1(0) > 0 \quad \text{and} \quad \phi_1 \in C^1([-\tau_0, 0], R^+),\\ y(s) = \phi_2(s) \geq 0, s \in [-\tau_0, 0], \phi_2(0) > 0 \quad \text{and} \quad \phi_2 \in C^1([-\tau_0, 0], R^+).\end{aligned} \tag{2.2}$$

We say $(x(t), y(t))$ is a solution of (2.1) on $[-\tau_0, \infty)$ if both $x(t)$ and $y(t)$ are positive continuously differentiable functions and satisfy both the above initial conditions and system (2.1).

We note that the first equation of system (2.1) can be rewritten as (provided $x(t) > 0$)

$$\left[\ln x(t) + \rho \int_{-\tau_2}^{0} x(t+s)d\mu_2(s)\right]' = \int_{-\tau_1}^{0} g(x(t+s))d\mu_1(s) - q(x(t)) \int_{-\tau_3}^{0} y(t+s)d\mu_3(s). \tag{2.3}$$

By letting $u(t) = \ln x(t)$, we can see that system (2.1) falls into the class of neutral systems considered in Hale [13, Chap. 12]. Thus, local existence, uniqueness, and continuous dependence of solutions are guaranteed [13, §12.2]. The following result ensures that the solution $(x(t), y(t))$ of (2.1) and (2.2) is positive and exists for all $t \geq 0$.

PROPOSITION 2.1. *Assume* (H1)–(H3) *in* (2.1). *Then the solution* $(x(t), y(t))$ *of* (2.1) *and* (2.2) *is positive and exists for all* $t > 0$. *Moreover, there exist positive constants* A *and* B (*depending on initial functions* ϕ_1 *and* ϕ_2), *such that* $x(t) < Ae^{Bt}$.

Proof. Suppose the maximal interval of existence for $x(t)$ and $y(t)$ is $[0, \omega)$. The positivity of $x(t)$ and $y(t)$ follows from the fact that the system is of Kolmogorov form. Assume first $\omega < +\infty$. Then equation (2.3) implies that, for $t \in [0, \omega)$,

$$\left[\ln x(t) + \rho \int_{-\tau_2}^{0} x(t+s)d\mu_2(s)\right]' < g(0),$$

which leads to

$$\ln x(t) + \rho \int_{-\tau_2}^{0} x(t+s)d\mu_2(s) < \ln x(0) + \rho \int_{-\tau_2}^{0} \phi_1(s)d\mu_2(s) + g(0)t.$$

Thus, for $t \in [0, \omega)$,

$$\ln x(t) < \ln x(0) + \rho \int_{-\tau_2}^{0} \phi_1(s)d\mu_2(s) + g(0)t. \tag{2.4}$$

Let $A = x(0)\exp\left(\rho \int_{-\tau_2}^{0} \phi_1(s)d\mu_2(s)\right)$, $B = g(0)$, then we see that (2.4) implies that for $t < \omega$,

$$x(t) < Ae^{Bt}. \tag{2.5}$$

Hence, $\lim_{t \to \omega} x(t) \leq Ae^{B\omega} < +\infty$. Clearly, (2.5) holds for all $t \in [0, \omega)$. The second equation of (2.1) implies that, for $t \in [0, \omega)$,

$$(\ln y(t))' \leq |a| + |b|p(Ae^{B\omega}),$$

which leads to

$$\lim_{t \to \omega} y(t) \leq y(0)\exp\left(\omega[|a| + |b|p(Ae^{B\omega})]\right) < +\infty. \tag{2.6}$$

By the well-known continuation theorem (Theorem 12.2.4 in [13]), we conclude that $\omega = +\infty$, proving the proposition. □

In the rest of this paper $\|\phi(s)\| = \max\{\phi(s), s \in [-\tau_0, 0]\}$ is denoted for any continuous function $\phi(s)$ defined on $[-\tau_0, 0]$.

3. Boundedness of $x(t)$. Our main object in this section is to obtain conditions under which $x(t)$ will be bounded. To this end, we will analyze the system independent of y. We need the following lemma. Its proof can be found in [18]. For convenience and completeness, we repeat its proof here.

LEMMA 3.1. *If $0 < \alpha \leq e^{-1}$, then there exists a $\lambda(\alpha)$, $1 < \lambda(\alpha) \leq e$ such that* $\exp(\alpha\lambda(\alpha)) = \lambda(\alpha)$ *and* $\exp(\alpha x) > x$ *for $x < \lambda(\alpha)$.*

Proof. If $\alpha = e^{-1}$, then we easily see that $e^{\alpha x} \geq x$ for all $x \in R$ and $e^{\alpha x} = x$ if and only if $x = e$. Clearly, for $x > 0$, $e^{\alpha x}$ is strictly increasing with respect to α. Thus, we see that if $0 < \alpha < e^{-1}$, $e^{\alpha x}$ will intersect with x at exactly two distinct points, say $x_1(\alpha)$ and $x_2(\alpha)$ and $x_1(\alpha) < x_2(\alpha)$. Then, we must have $1 < x_1(\alpha) < e < x_2(\alpha)$. Let $\lambda(\alpha) = x_1(\alpha)$; then the conclusion of the lemma holds. □

The following theorem is the main result of this section. It generalizes Theorem 3.1 in [18].

THEOREM 3.1. *Assume $\alpha \equiv g(0)\tau_1 + \rho \leq e^{-1}$, and let $\lambda(\alpha)$ be defined as in Lemma 3.1. Assume further that the initial function ϕ_1 for x satisfies $\|\phi_1\| < 1$. Then $x(t) < \lambda(\alpha)$ for $t \geq -\tau_0$.*

Proof. Since $x(t) > 0$, $y(t) > 0$, we have

$$\dot{x}(t) \leq x(t)\left[\int_{-\tau_1}^{0} g(x(t+s))d\mu_1(s) - p\int_{-\tau_2}^{0} \dot{x}(t+s)d\mu_2(s)\right]. \tag{3.1}$$

If $x(t)$ is not bounded by $\lambda(\alpha)$, then there must exist $t^* > t_0 > 0$ such that $x(t^*) = \lambda(\alpha)$, $x(t_0) = 1$, $1 < x(t) < \lambda(\alpha)$ for $t \in (t_0, t^*)$ and $x(t) < \lambda(\alpha)$ for $t \in [-\tau_0, t^*)$. It is easy to see that (3.1) implies that, for $t \geq t_0$,

$$\begin{aligned} x(t) \leq x(t_0)&\exp\left\{\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\right\} \\ &\cdot\exp\left\{-\rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s)\right)d\tau\right\}. \end{aligned} \tag{3.2}$$

Since $x(t) > 0$, for $t \geq -\tau_0$, we have

$$\begin{aligned} -\rho\int_{t_0}^{t^*}\left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s)\right)d\tau &= -\rho\int_{-\tau_2}^{0}\left(\int_{t_0}^{t^*} \dot{x}(\tau+s)d\tau\right)d\mu_2(s) \\ &= -\rho\int_{-\tau_2}^{0}[x(t^*+s) - x(t_0+s)]d\mu_2(s) < \rho\int_{-\tau_2}^{0} x(t_0+s)d\mu_2(s) \\ &< \rho\lambda(\alpha). \end{aligned} \tag{3.3}$$

If $t^* \leq t_0 + \tau_1$, then

$$\int_{t_0}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau < \int_{t_0}^{t^*} g(0)d\tau \leq g(0)\tau_1. \tag{3.4}$$

If $t^* > t_0 + \tau_1$, then $x(\tau+s) \geq 1$ for $s \in [-\tau_1, 0]$, $\tau \in [t_0 + \tau_1, t^*]$, which implies $g(x(\tau+s)) \leq 0$ by (H2). Thus

$$\int_{t_0+\tau_1}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau \leq 0. \tag{3.5}$$

Hence, we have

$$
\begin{aligned}
&\int_{t_0}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\\
&\quad=\int_{t_0}^{t_0+\tau_1}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\\
&\qquad+\int_{t_0+\tau_1}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\\
&\quad<\int_{t_0}^{t_0+\tau_1} g(0)d\tau = g(0)\tau_1.
\end{aligned}
\tag{3.6}
$$

That is, in both cases, we have

$$
\int_{t_0}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau < g(0)\tau_1. \tag{3.7}
$$

Therefore, (3.2) yields

$$
\lambda(\alpha) = x(t^*) < \exp(g(0)\tau_1 + \rho\lambda(\alpha)) < \exp(\alpha\lambda(\alpha)). \tag{3.8}
$$

Clearly, this is a contradiction to the definition of $\lambda(\alpha)$. Therefore, $x(t^*)$ must be less than $\lambda(\alpha)$, and the theorem is proved. □

We call a function $x(t)$ (defined on $[0, +\infty)$) *oscillatory about* x^* (see also [7], [10], [16], [17]) if there exists a sequence $\{t_n\} \to +\infty$ as $n \to +\infty$, such that $x(t_n) = x^*$, $n = 1, \cdots$. Otherwise, we call it *nonoscillatory about* x^*.

If $x(t)$ is unbounded, then the following theorem may roughly characterize its behavior.

THEOREM 3.2. *In system* (2.1), *if $x(t)$ is unbounded, then $x(t)$ is oscillatory about* 1.

Proof. Assume that $x(t)$ is unbounded and not oscillatory about 1, then there must exist a $t_0 > 0$ such that, for $t \geq t_0$, $x(t) > 1$. Let $t_1 = t_0 + \tau_1$; then we have for $t > t_1$,

$$
\int_{t_1}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau < 0,
$$

and

$$
\begin{aligned}
&-\rho\int_{t_1}^{t}\left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s)\right)d\tau\\
&\quad=-\rho\int_{-\tau_2}^{0}[x(t+s)-x(t_1+s)]d\mu_2(s)\\
&\quad<\rho\int_{-\tau_2}^{0} x(t_1+s)d\mu_2(s).
\end{aligned}
$$

Hence, from (3.2), we see that, for $t > t_1$,

$$
x(t) \leq x(t_1)\exp\left\{\rho\int_{-\tau_2}^{0} x(t_1+s)d\mu_2(s)\right\} < +\infty,
$$

which implies that $x(t)$ is bounded. This is a contradiction to our assumption, and the theorem is thus proved. □

4. Attractivity of the positive steady states in single population models. In this section we restrict our attention to the following neutral delay single population model, which results from (2.1) by taking $y(t) \equiv 0$:

$$\dot{x}(t) = x(t)\left[\int_{-\tau_1}^{0} g(x(t+s))d\mu_1(s) - \rho\int_{-\tau_2}^{0} \dot{x}(t+s)d\mu_2(s)\right]. \tag{4.1}$$

We always assume that the initial function of (4.1) satisfies the requirements stated in the first part of (2.2). Clearly, (4.1) has exactly two steady states. They are $x(t) \equiv 0$ and $x(t) \equiv 1$. The variational equation of (4.1) about $x(t) \equiv 0$ is $\dot{x}(t) = g(0)x(t)$. Thus, we see $x(t) \equiv 0$ is always unstable. In fact, we have the following stronger result.

PROPOSITION 4.1. *Let $x(t)$ be the solution of* (4.1); *then*

$$\limsup_{t\to+\infty} x(t) \geq 1.$$

Proof. Otherwise, there is $0 < \epsilon < 1$, $T > 0$, such that, for $t \geq T$, $x(t) \leq 1 - \epsilon$. Then for $t > t_0 \geq T + \tau_1 + \tau_2$,

$$\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau \geq \int_{t_0}^{t} g(1-\epsilon)d\tau = g(1-\epsilon)(t-t_0), \tag{4.2}$$

and

$$\begin{aligned} -\rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s)\right)d\tau &= -\rho\int_{-\tau_2}^{0}[x(t+s) - x(t_0+s)]d\mu_2(s) \\ &> -\rho\int_{-\tau_2}^{0} x(t+s)d\mu_2(s) \geq -(1-\epsilon)\rho. \end{aligned} \tag{4.3}$$

Therefore

$$\begin{aligned} x(t) &= x(t_0)\exp\left\{\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\right\} \\ &\quad\cdot\exp\left\{-\rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s)\right)d\tau\right\} \\ &\geq x(t_0)\exp\{g(1-\epsilon)(t-t_0) - (1-\epsilon)\rho\}, \end{aligned}$$

which implies that

$$\lim_{t\to+\infty} x(t) = +\infty,$$

a contradiction to the assumption that $x(t) \leq 1 - \epsilon$ for $t \geq T$. This proves the proposition. □

In order to prove our global stability result we need the following simple lemma.

LEMMA 4.1. *For $0 < r < 1$, there is a strictly decreasing function $h(r)$, such that $h(r) = \exp\{r(h(r)-1)\}$, $\lim_{r\to 0^+} h(r) = +\infty$, $\lim_{r\to 1^-} h(r) = 1$, and $x > \exp\{r(x-1)\}$ for $x \in (1, h(r))$.*

Proof. Clearly, for $0 < r < 1$, $e^{r(x-1)}$ always intersects with x at $x = 1$. $(d/dx)(e^{r(x-1)})|_{x=1} = r < (dx/dx)|_{x=1} = 1$, we see that $e^{r(x-1)}$ will intersect with x at another point, say $h(r)$. Clearly, this $h(r)$ has all those properties described in the lemma. □

As in Theorem 3.1, we denote

$$\alpha = g(0)\tau_1 + \rho,$$

and define $\lambda(\alpha)$ as in Lemma 3.1. Assuming $\alpha \leq e^{-1}$, we define

$$G(\alpha) = \max\{|g'(x)| : x \in [0, \lambda(\alpha)]\}.$$

We denote

$$\bar{\tau} = \max\{\tau_1, \tau_2\}.$$

Now we are ready to state and prove the main result of this section.

THEOREM 4.1. *In system* (4.1), *assume* $0 < \alpha < e^{-1}$, *and*

(i) $\lambda(\alpha)\rho < 1$,

(ii) $G(\alpha)\tau_1 + 2\rho \leq h^{-1}(\lambda(\alpha))$,

where $h^{-1}(\cdot)$ *is the inverse function of* $h(r)$ *defined in Lemma* 4.1. *Then we have that* $\lim_{t\to+\infty} x(t,\phi) = 1$, *provided that its initial function* $\phi(s)$ *satisfies that* $\phi(s) \in C^1([-\bar{\tau}, 0], R^+)$, $\phi(0) > 0$, *and* $\|\phi\| = \max\{|\phi(s)| : s \in [-\bar{\tau}, 0]\} < 1$.

Proof. By Theorem 3.1, we know that $x(t) < \lambda(\alpha)$, where $1 < \lambda(\alpha) \leq e$, and $\alpha \equiv g(0)\tau_1 + \rho \leq e^{-1}$. Denote

$$v = \limsup_{t\to+\infty} |x(t) - 1|; \tag{4.4}$$

then $0 \leq v \leq e - 1$. In the following, we assume $v > 0$. We claim that $x(t)$ must be oscillatory about 1. Otherwise, there is a $T > 0$ such that, for $t \geq T$, $x(t) > 1$ or $x(t) < 1$. We assume first that $x(t) > 1$ for $t \geq T$. Let $\bar{t} \geq T + \tau_1 + \tau_2$, such that

$$|\dot{x}(\bar{t})| = \max\{|\dot{x}(\bar{t} + s)| : s \in [-\tau_2, 0]\}.$$

If $\dot{x}(\bar{t}) \geq 0$, we have

$$\dot{x}(\bar{t}) + \rho x(\bar{t}) \int_{-\tau_2}^{0} \dot{x}(\bar{t} + s) d\mu_2(s) \geq (1 - \lambda(\alpha)\rho)\dot{x}(\bar{t}),$$

and

$$x(\bar{t}) \int_{-\tau_1}^{0} g(x(\bar{t} + s)) d\mu_1(s) < \lambda(\alpha) g(0),$$

which implies that (since $\lambda(\alpha)\rho < 1$)

$$\dot{x}(\bar{t}) < \frac{\lambda(\alpha)g(0)}{1 - \lambda(\alpha)\rho}.$$

If $\dot{x}(\bar{t}) < 0$, we have

$$\dot{x}(\bar{t}) + \rho x(\bar{t}) \int_{-\tau_2}^{0} \dot{x}(\bar{t} + s) d\mu_2(s) \leq (1 - \lambda(\alpha)\rho)\dot{x}(\bar{t}),$$

and

$$x(\bar{t}) \int_{-\tau_1}^{0} g(x(\bar{t} + s)) d\mu_1(s) > \lambda(\alpha) g(\lambda(\alpha)),$$

which implies that

$$\dot{x}(\bar{t}) > \frac{\lambda(\alpha)g(\lambda(\alpha))}{1 - \lambda(\alpha)\rho}.$$

Hence, for all $t \geq T + \tau_1 + \tau_2$,

$$|\dot{x}(t)| \leq \max\left\{\frac{\lambda(\alpha)g(0)}{1 - \lambda(\alpha)\rho}, \frac{-\lambda(\alpha)g(\lambda(\alpha))}{1 - \lambda(\alpha)\rho}\right\}. \tag{4.5}$$

This, together with the assumptions $v > 0$ and $x(t) > 1$ for $t \geq T$, implies that

$$\lim_{t\to+\infty} \max\left\{\int_{t_0}^{t} g(x(\tau + s)) d\tau : s \subset n[-\tau_1, 0]\right\} = -\infty.$$

Thus

$$\lim_{t\to+\infty}\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau$$
$$=\lim_{t\to+\infty}\int_{-\tau_1}^{0}\left(\int_{t_0}^{t} g(x(\tau+s))d\tau\right)d\mu_1(s)=-\infty.$$

Therefore, we have, for any $t_0\geq T$,

$$\lim_{t\to+\infty}x(t)=\lim_{t\to+\infty}x(t_0)\exp\left\{\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\right\}$$
$$\cdot\exp\left\{-\rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0}\dot{x}(\tau+s)d\mu_2(s)\right)d\tau\right\}=0,$$

since

$$\exp\left\{-\rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0}\dot{x}(\tau+s)d\mu_2(s)\right)d\tau\right\}$$
$$=\exp\left\{-\rho\int_{-\tau_2}^{0}[x(t+s)-x(t_0+s)]d\mu_2(s)\right\}$$
$$<\exp\{\rho\lambda(\alpha)\}<+\infty.$$

This clearly contradicts the assumption that $x(t)>1$ for $t\geq T$. The case of $x(t)<1$ for $t\geq T$ can be dealt with similarly. This proves the claim.

Now, since $x(t)$ is oscillatory about 1, we see that there is a sequence $\{T_i\}$, $i=1,\cdots$, such that $0<T_1<\cdots<T_i<T_{i+1}<\cdots$, $\lim_{i\to+\infty}T_i=+\infty$, and $x(T_i)=1$. Denote

$$u=\limsup_{t\to+\infty}x(t),$$
$$w=\liminf_{t\to+\infty}x(t).$$

Then, either $u=1+v$ or $w=1-v$. Assume first that $u=1+v$. Then, for any $0<\epsilon<v$, there is an $i(\epsilon)>1$ such that, for $t\geq T_i$, $1-v-\epsilon<x(t)<u+\epsilon$. Clearly, there is a $t^*=t^*(\epsilon)\geq T_i+\bar{\tau}$ such that $x(t^*)>u-\epsilon$, and $x(t^*)$ is the maximum in $[T_j,T_{j+1}]$ for some $j\geq i$. Without loss of generality, we may assume that $1<x(t)<x(t^*)$ for $t\in(T_j,t^*)$. We have

$$-\rho\int_{T_j}^{t^*}\left(\int_{-\tau_2}^{0}\dot{x}(\tau+s)d\mu_2(s)\right)d\tau=-\rho\int_{-\tau_2}^{0}[x(t^*+s)-x(T_j+s)]d\mu_2(s)$$
$$\leq\rho\int_{-\tau_2}^{0}(|x(t^*+s)-1|+|1-x(T_j+s)|)d\mu_2(s)$$
$$<2\rho(u+\epsilon-1).$$

If $t^*-T_j\leq\tau_1$, then

$$\int_{T_j}^{t^*}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\leq\int_{T_j}^{t^*}\left(\int_{-\tau_1}^{0} G(\alpha)(u+\epsilon-1)d\mu_1(s)\right)d\tau$$
$$\leq G(\alpha)\tau_1(u+\epsilon-1),$$

since

$$|g(x(\tau+s))|=|g(x(\tau+s))-g(1)|$$
$$=|g'(\theta x(\tau+s)+1-\theta)(x(\tau+s)-1)|$$
$$\leq G(\alpha)(v+\epsilon)=G(\alpha)(u+\epsilon-1),$$

where $\theta \in [0,1]$. If $t^* - T_j > \tau_1$, then

$$\int_{T_j+\tau_1}^{t^*} \left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s) \right) d\tau < 0,$$

and

$$\int_{T_j}^{T_j+\tau_1} \left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s) \right) d\tau \le G(\alpha)\tau_1(u+\epsilon-1).$$

Thus, in both cases we have

$$\begin{aligned} u-\epsilon < x(t^*) &= x(T_j)\exp\left\{ \int_{T_j}^{t^*} \left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s) \right) d\tau \right\} \\ &\quad \cdot \exp\left\{ -\rho \int_{T_j}^{t^*} \left(\int_{-\tau_2}^{0} \dot{x}(\tau+s)d\mu_2(s) \right) d\tau \right\} \\ &< \exp\{[G(\alpha)\tau_1 + 2\rho](u+\epsilon-1)\}. \end{aligned} \tag{4.6}$$

Since (4.6) is true for all $0 < \epsilon < v$, by letting $\epsilon \to 0$ we obtain

$$u \le \exp\{[G(\alpha)\tau_1 + 2\rho](u-1)\}. \tag{4.7}$$

This is a contradiction to assumption (ii), since if $G(\alpha)\tau_1 + 2\rho \le h^{-1}(\lambda(\alpha))$, then for $1 < x \le \lambda(\alpha)$,

$$x > \exp\{[G(\alpha)\tau_1 + 2\rho](x-1)\}.$$

This indicates that $u \ne 1+v$ if $v > 0$.

Now we assume $w = 1-v$. Then a similar argument as above yields that, for any $0 < \epsilon < v$,

$$1 - v + \epsilon > \exp\{-[G(\alpha)\tau_1 + 2\rho](v+\epsilon)\},$$

which implies that

$$1 - v \ge \exp\{-[G(\alpha)\tau_1 + 2\rho]v\}.$$

Thus,

$$w \ge \exp\{[G(\alpha)\tau_1 + 2\rho](w-1)\}.$$

This is impossible for $w < 1$ and $G(\alpha)\tau_1 + 2\rho \le h^{-1}(\lambda(\alpha))$, since $h^{-1}(\lambda(\alpha)) < 1$ by Lemma 4.1. This proves that $w \ne 1-v$ if $v > 0$. Hence, v must be zero, proving the theorem. □

In particular, for the equation

$$\dot{x}(t) = x(t)\left[\int_{-\tau_1}^{0} r[1 - x(t+s)]d\mu_1(s) - \rho \int_{-\tau_2}^{0} \dot{x}(t+s)d\mu_2(s) \right], \tag{4.8}$$

where $r > 0$, we have the following corollary.

COROLLARY 4.1. *In* (4.8) *let* $\alpha = r\tau_1 + \rho$. *Assume* $\alpha < e^{-1}$, $\lambda(\alpha)\rho < 1$ *and* $r\tau_1 + 2\rho \le h^{-1}(\lambda(\alpha))$. *Then the conclusion of Theorem* 4.1 *is valid for* (4.8).

Proof. We note in this case $g(x) = r(1-x)$. Thus $g(0) = r$ and $G(\alpha) = r$. The rest follows from Theorem 4.1. □

Remark 4.1. It should be mentioned here that assumption (ii) in Theorem 4.1 can be replaced by

(ii′) $G(\alpha)\tau_1 + 2\rho < (e-1)^{-1}$,

which is more restrictive, but easy to verify. This is because $1 < \lambda(\alpha) < e$ for $0 < \alpha < e^{-1}$; thus by Lemma 4.1 we have

$$h^{-1}(\lambda(\alpha)) > h^{-1}(e) = (e-1)^{-1}.$$

Remark 4.2. As mentioned in the Introduction, our results are rather limited and primitive. This can be seen by taking $\rho = 0$, i.e., when (4.1) is reduced to

$$\dot{x}(t) = x(t) \int_{-\tau_1}^{0} g(x(t+s))d\mu_1(s). \tag{4.9}$$

For (4.9) Theorem 3.2 in [15] implies that if $G\tau_1 \leq 1$, where G is any upper bound of $|g'(x)|$, $x \geq 0$, then $x \equiv 1$ is globally asymptotically stable with respect to initial function ϕ, $\phi \in C([-\bar{\tau}, 0], R^+)$, $\phi(0) > 0$. This is clearly much sharper than the conclusion implied by Theorem 4.1.

5. Boundedness results for system (2.1). We consider first the case when $c > 0$ in system (2.1). This will include the neutral competition system (1.6) as a special case. When $a < 0$, $b > 0$, system (2.1) can be used to model the predatory-prey interaction with self-crowding effect on predator. The following result generalizes Theorem 4.1 in [18].

THEOREM 5.1. *Assume $c > 0$, $\alpha = g(0)\tau_1 + \rho \leq e^{-1}$, $\lambda(\alpha)$ is defined as in Lemma 3.1, and $\|\phi_1\| < 1$. Then solutions of (2.1) are bounded. Moreover, if $x(t) < \lambda(\alpha)$, for $t \geq -\tau_0$, and*

(i) *If $a < 0$, $b > 0$, and $\beta = \max\{0, bp(\lambda(\alpha)) + a\}$, then*

$$\limsup_{t \to +\infty} y(t) \leq c^{-1}\beta e^{\beta\tau_5};$$

(ii) *If $a > 0$, $b < 0$, then*

$$\limsup_{t \to +\infty} y(t) \leq c^{-1}ae^{a\tau_5}.$$

Proof. The assertion on $x(t)$ follows from Theorem 3.1. Thus, in case (i) we have

$$\dot{y}(t) \leq y(t)\left[bp(\lambda(\alpha)) + a - c\int_{-\tau_5}^{0} y(t+s)d\mu_5(s)\right]. \tag{5.1}$$

It is thus clear that if $bp(\lambda(\alpha)) + a \leq 0$, then $\lim_{t \to +\infty} y(t) = 0$. Assume $bp(\lambda(\alpha)) + a = \beta > 0$, then (5.1) implies that $\dot{y}(t) \leq \beta y(t)$. Hence, for $t \geq t_0$, $y(t) \leq y(t_0)e^{\beta(t-t_0)}$, which leads to

$$y(t_0) \geq y(t)e^{-\beta(t-t_0)}.$$

Therefore,

$$\begin{aligned} -\int_{-\tau_5}^{0} y(t+s)d\mu_5(s) &\leq -\int_{-\tau_5}^{0} y(t)e^{\beta s}d\mu_5(s) \\ &\leq -e^{-\beta\tau_5}\int_{-\tau_5}^{0} y(t)d\mu_5(s) = -e^{-\beta\tau_5}y(t), \end{aligned} \tag{5.2}$$

since $y(t) > 0$ for $t \geq 0$. A substitution of (5.2) into (5.1) yields

$$\dot{y}(t) \leq y(t)(\beta - ce^{-\beta\tau_5}y(t)). \tag{5.3}$$

Clearly, solutions of

$$\dot{y}(t) = \beta y(t)(1 - c\beta^{-1}e^{-\beta\tau_5}y(t)) \tag{5.4}$$

satisfy

$$\lim_{t \to +\infty} y(t) = c^{-1}\beta e^{\beta\tau_5}. \tag{5.5}$$

Therefore, solutions of (5.3) must satisfy

$$\limsup_{t\to+\infty} y(t) \le c^{-1}\beta e^{\beta\tau_5}.$$

This proves case (i). For case (ii), we have

$$\dot{y}(t) \le y(t)\left[a - c\int_{-\tau_5}^{0} y(t+s)d\mu_2(s)\right]. \tag{5.6}$$

Thus $\dot{y}(t) \le ay(t)$, which implies that $y(t+s) \ge y(t)e^{as}$, for $s \le 0$. Therefore

$$\dot{y}(t) \le y(t)(a - ce^{-a\tau_5}y(t)).$$

Hence, by repeating the above argument, we can show that

$$\limsup_{t\to+\infty} y(t) \le c^{-1}ae^{a\tau_5}.$$

This completes the proof. □

In the rest of this section we assume $c = 0$, $a = -\delta < 0$, $b > 0$. System (2.1) thus reduces to

$$\begin{aligned}\dot{x}(t) = x(t)\Bigg[\int_{-\tau_1}^{0} & g(x(t+s))d\mu_1(s) - \rho\int_{-\tau_2}^{0}\dot{x}(t+s)d\mu_2(s)\\ & - q(x(t))\int_{-\tau_3}^{0} y(t+s)d\mu_3(s)\Bigg],\\ \dot{y}(t) = y(t)\Bigg[-\delta + b & \int_{-\tau_4}^{0} p(x(t+s))d\mu_4(s)\Bigg].\end{aligned} \tag{5.7}$$

When delays are absent from the above system, it reduces to the so-called Gause-type predator-prey system (cf., [4], [16]). For (5.7) we have the following boundedness result which generalizes Theorem 4.2 in [18].

THEOREM 5.2. *In* (5.7), *assume* $\alpha = g(0)\tau_1 + \rho \le e^{-1}$, $\lambda(\alpha)$ *is defined as in Lemma* 3.1, *and* $\|\phi_1\| < 1$. *Let* $\bar{x} > 0$ *be the unique solution of* $bp(x) = \delta$, $\gamma = \min\{q(x) : x \in [0, \lambda(\alpha)]\}$. *Denote* $\bar{y} = \gamma^{-1}[g(0) + \rho\lambda(\alpha) + \ln(\lambda(\alpha)/\bar{x})]$, $\tilde{y} = \max\{y(0), \bar{y}\}$, $\Delta = \tilde{y}\exp\{[bp(\lambda(\alpha)) - \delta](\tau_3 + \tau_4 + 1)\}$. *Then, for* $t \ge 0$, $x(t) < \lambda(\alpha)$, $y(t) < \Delta$. *Moreover, if* $\lambda(\alpha) < \bar{x}$, *then* $\limsup_{t\to\infty} y(t) = 0$; *and if* $\lambda(\alpha) \ge \bar{x}$, *then*

$$\limsup_{t\to+\infty} y(t) \le \bar{y}\exp\{[bp(\lambda(\alpha)) - \delta](\tau_3 + \tau_4 + 1)\}.$$

Proof. Again, the assertion on $x(t)$ follows from Theorem 3.1. In the following we assume $y(t)$ is not bounded by Δ. Clearly, in this case $\bar{x}$ must be less than $\lambda(\alpha)$, since if $\bar{x} > \lambda(\alpha)$, then $\dot{y}(t) < 0$; which implies that $y(t) \le y(0) < \Delta$.

The first equation in (5.7) gives us, for $t \ge t_0$,

$$\begin{aligned}x(t) = & x(t_0)\exp\left\{\int_{t_0}^{t}\left(\int_{-\tau_1}^{0} g(x(\tau+s))d\mu_1(s)\right)d\tau\right.\\ & \left. - \rho\int_{t_0}^{t}\left(\int_{-\tau_2}^{0}\dot{x}(\tau+s)d\mu_2(s)\right)d\tau\right\}\\ & \cdot\exp\left\{-\int_{t_0}^{t}\left(q(x(\tau))\int_{-\tau_3}^{0} y(\tau+s)d\mu_3(s)\right)d\tau\right\},\end{aligned}$$

which leads to

$$
\begin{aligned}
x(t) \le& \lambda(\alpha)\exp\{g(0)(t-t_0)+\rho\lambda(\alpha)\} \\
&\cdot\exp\left\{-\gamma\int_{-\tau_3}^{0}\left(\int_{t_0}^{t} y(\tau+s)d\tau\right)d\mu_3(s)\right\}.
\end{aligned} \tag{5.8}
$$

The second equation of (5.7) implies that

$$\dot{y}(t) < [bp(\lambda(\alpha))-\delta]y(t),$$

which leads to

$$y(t) < y(t_0)\exp\{[bp(\lambda(\alpha))-\delta](t-t_0)\}, \qquad t \ge t_0. \tag{5.9}$$

Since $y(t)$ is not bounded by Δ, there must be $t_2 > t_1 \ge 0$, such that $y(t_1)=\tilde{y}$, $y(t_2)=\Delta$, and $y(t)\ge\tilde{y}$ for $t\in[t_1,t_2]$. From (5.9) we see that $t_2-t_1>\tau_3+\tau_4+1$. In (5.8) we let $t_0=t_1+\tau_3$ and $t_0+1\le t\le t_2$, then $y(\tau+s)\ge\tilde{y}$ for $\tau\in[t_0,t]$, $s\in[-\tau_3,0]$. Thus,

$$
\begin{aligned}
x(t) \le&\lambda(\alpha)\exp\{g(0)(t-t_0)+\rho\lambda(\alpha)\}\exp\{-\gamma\tilde{y}(t-t_0)\} \\
\le&\lambda(\alpha)\exp\{g(0)(t-t_0)+\rho\lambda(\alpha)\} \\
&\cdot\exp\{-[g(0)+\rho\lambda(\alpha)+\ln(\lambda(\alpha)/\bar{x})](t-t_0)\} \\
\le&\lambda(\alpha)\exp\{-\ln(\lambda(\alpha)/\bar{x})\}\exp\{-[\rho\lambda(\alpha)+\ln(\lambda(\alpha)/\bar{x})](t-t_0-1)\} \\
=&\bar{x}\exp\{-[\rho\lambda(\alpha)+\ln(\lambda(\alpha)/\bar{x})](t-t_0-1)\}.
\end{aligned} \tag{5.10}
$$

Hence, for $t\in[t_0+1,t_2]$, $x(t)\le\bar{x}$. From the second equation of (5.7), we have

$$y(t)=y(t_0)\exp\left\{\int_{t_0}^{t}\left[-\delta+b\int_{-\tau_4}^{0}p(x(\tau+s))d\mu_4(s)\right]d\tau\right\}. \tag{5.11}$$

Let $t_0=t_1$ in (5.11), then for $t_1+\tau_3+\tau_4+1\le t\le t_2$,

$$
\begin{aligned}
y(t)=\tilde{y}&\exp\left\{\int_{t_1}^{t_1+\tau_3+\tau_4+1}\left[-\delta+b\int_{-\tau_4}^{0}p(x(\tau+s))d\mu_4(s)\right]d\tau\right\} \\
&\cdot\exp\left\{\int_{t_1+\tau_3+\tau_4+1}^{t}\left[-\delta+b\int_{-\tau_4}^{0}p(x(\tau+s))d\mu_4(s)\right]d\tau\right\}.
\end{aligned}
$$

Clearly $-\delta+b\int_{-\tau_4}^{0}p(x(t+s))d\mu_4(s)<bp(\lambda(\alpha))-\delta$. For $t_1+\tau_3+\tau_4+1\le t\le t_2$, $-\delta+b\int_{-\tau_4}^{0}p(x(t+s))d\mu_4(s)\le 0$. Therefore, for $t_1+\tau_3+\tau_4+1\le t\le t_2$,

$$y(t)<\tilde{y}\exp\{[bp(\lambda(\alpha))-\delta](\tau_3+\tau_4+1)\}=\Delta,$$

a contradiction to the assumption that $y(t_2)=\Delta$. This proves that $y(t)<\Delta$.

Next we prove the second part of the theorem.

Clearly, if $\lambda(\alpha)<\bar{x}$, then $\dot{y}(t)<0$, and $\limsup_{t\to+\infty}y(t)=0$. Assume now that $\lambda(\alpha)\ge\bar{x}$, and there is a $y(t)$, such that $\limsup_{t\to+\infty}y(t)>\bar{y}\exp\{[bp(\lambda(\alpha))-\delta](\tau_3+\tau_4+1)\}$. We claim that there exists a $\tilde{t}>0$ such that $y(\tilde{t})=\bar{y}$. Otherwise, for large t, $y(t)>\bar{y}$. From (5.10) we see $x(t)<\bar{x}$ for large t; indeed, in this case, $\lim_{t\to+\infty}x(t)=0$. This clearly implies that $\lim_{t\to+\infty}y(t)=0$, a contradiction. Obviously, for any $T>0$, there is a $\hat{t}\ge T$ such that $y(\hat{t})\ge\bar{y}\exp\{[bp(\lambda(\alpha))-\delta](\tau_3+\tau_4+1)\}$. Thus, for such a large $\hat{t}$, we can find a $\tilde{t}$, $\tilde{t}<\hat{t}$ such that $y(\tilde{t})=\bar{y}$ and $y(t)\ge\bar{y}$ for $t\in[\tilde{t},\hat{t}]$. Now we can repeat the previous argument (by letting $\tilde{t}=t_1$, $\hat{t}=t_2$) to derive a contradiction. The proof is thus complete. □

6. Discussion. In order to facilitate our discussion, we would like to present some numerical simulations of the neutral delay systems studied in the previous sections. Consider first the single-species neutral delay equation

$$\dot{x} = rx[1 - x(t-1) - c\dot{x}(t-1)]. \tag{6.1}$$

Figures 1a, 1b, and 1c depict three solutions of (6.1) when $r = 0.1$, $c = 5$. Clearly, we see that solutions of (6.1) seem to be very sensitive to initial functions. The solution with initial function as constant 0.2 seems to tend to a periodic solution with three peaks, while the solutions with initial function as $1.2 + 0.2t$ and 0.1 seem to approach the steady state $x(t) \equiv 1$ monotonically (for $t \geq 10$). This perhaps can explain (roughly) why our main results require initial functions to satisfy some conditions. However, such a drastic change of behaviors cannot happen if $c = 0$. (Indeed, all solutions tend to $x(t) \equiv 1$. See [30].)

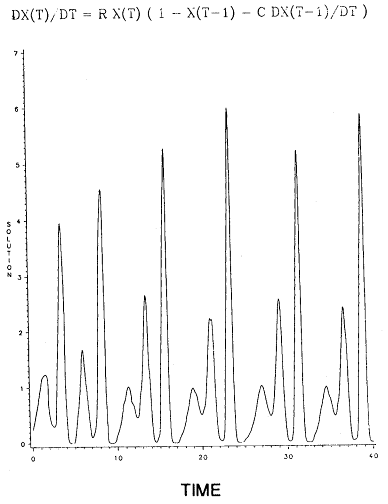

FIG. 1a. *Numerical solution of* (6.1) *with* $r = 0.1$, $c = 5$, *and* $x(t) = 0.2$, $t \leq 0$.

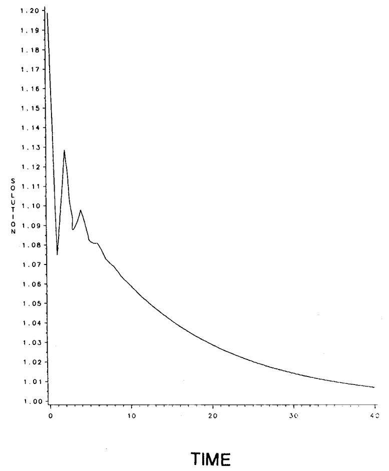

FIG. 1b. *Numerical solution of* (6.1) *with* $r = 0.1$, $c = 5$, *and* $x(t) = 1.2 + 0.2t$, $t \leq 0$.

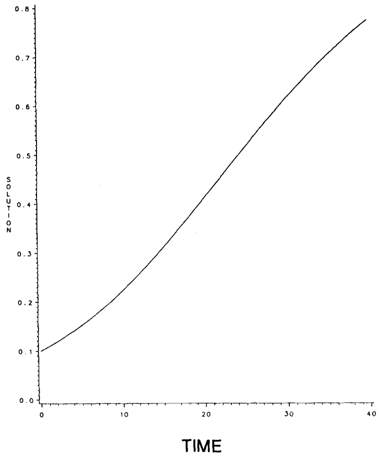

FIG. 1c. *Numerical solution of* (6.1) *with* $r = 0.1$, $c = 5$, *and* $x(t) = 0.1$, $t \leq 0$.

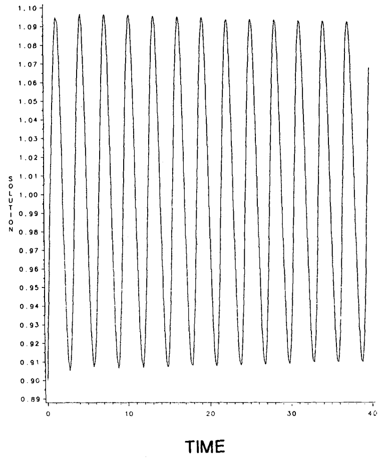

FIG. 2a. *Numerical solution of* (6.1) *with* $r = \pi/\sqrt{3}$, $c = \sqrt{3}/2\pi$, *and* $x(t) = 0.9$, $t \leq 0$.

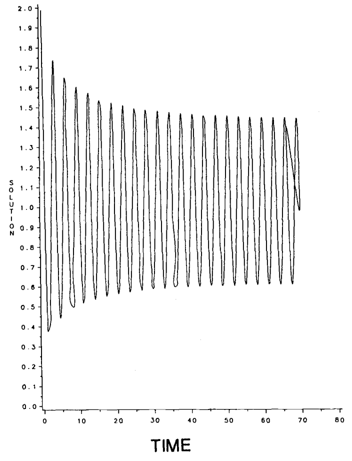

FIG. 2b. *Numerical solution of* (6.1) *with* $r = 0.05 + \pi/\sqrt{3} \approx 1.8638$, $c = \sqrt{3}/2\pi - 0.04$, $x(t) = 2.0 + t$, $t \leq 0$. $l(r, c) \approx 1.8197 < r$.

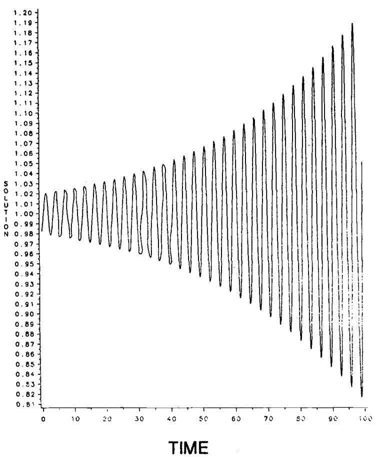

FIG. 2c. *Numerical solution of* (6.1) *with* $r = \pi/\sqrt{3} - 0.06$, $c = \sqrt{3}/2\pi + 0.02$, $x(t) = 0.98$, $t \leq 0$. $l(r,c) \approx 1.8103 > r \approx 1.7538$.

Denote

$$l(r,c) = \sqrt{1 - r^2c^2}\,\mathrm{arc}\cot[-rc(1 - r^2c^2)^{-1/2}]. \tag{6.2}$$

The following statements are proved in [6]:

(i) If $l(r,c) = r$, then the characteristic equation of (6.1) about $x(t) \equiv 1$ has roots $\pm i\omega$, $\omega > 0$.

(ii) If $l(r,c) < r$, then $x(t) \equiv 1$ is locally asymptotically stable.

(iii) If $l(r,c) > r$, then $x(t) \equiv 1$ is unstable.

Figures 2a, 2b, and 2c confirm these results. Clearly, these figures may suggest that a Hopf bifurcation takes place when the local stability of $x(t) \equiv 1$ changes from stable to unstable.

We consider next the following neutral delay predator-prey system:

$$\begin{cases} \dot{x}(t) = x(t)[1 - x(t-\tau) - \rho\dot{x}(t-\tau)] - y(t)\dfrac{x^2(t)}{x^2(t)+1}, \\ \dot{y}(t) = y(t)\left[-0.1 + \dfrac{x^2(t)}{x^2(t)+1}\right]. \end{cases} \tag{6.3}$$

When $\rho = 0$ (i.e., no neutral term), Figs. 3a and 3b indicate that solutions tend to the positive steady state $(\frac{1}{3}, \frac{20}{9})$ monotonically. Figures 4a and 4b seem to show that when ρ increased to 2.9, the solution $(x(t), y(t))$ with initial functions $x(t) = 0.35$, $y(t) = 2.21$, $t \leq 0$, tends to a periodic solution surrounding the positive steady state. Indeed, by a local stability analysis as presented in [16], we can show that the positive steady state is unstable when $\rho = 2.9$, $\tau = 1$. This may suggest that the existence of the neutral term resulted in a Hopf bifurcation, thus producing a stable periodic solution. Other numerical simulations of system (6.3) strongly suggest that solutions of (6.3) are oscillatory when $\rho \neq 0$, in contrast to the monotone behavior depicted in Figs. 3a and 3b when $\rho = 0$.

As pointed out in the beginning of this paper, one of the most useful features of delay equation in population dynamics is its ability to show oscillations of population sizes observed in real systems. Our numerical simulations seem to suggest that neutral delay models may serve better for this purpose.

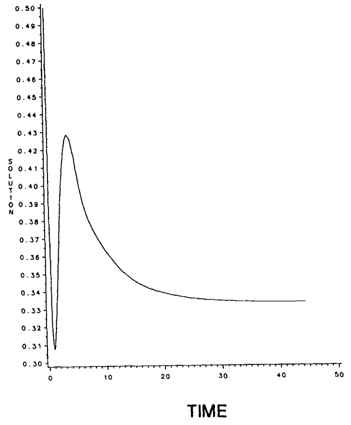

FIG. 3a. *Numerical solution of* $x(t)$ *of* (6.3) *with* $\rho = 0$, $\tau = 1$, *and* $(x(t), y(t)) = (0.5 - t, 1.5)$, $t \leq 0$.

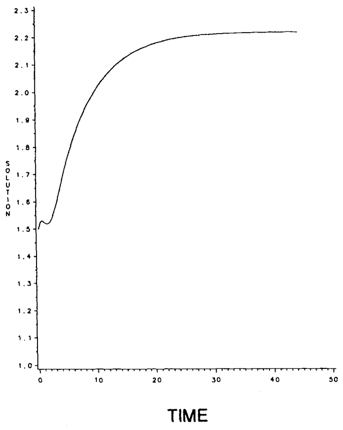

FIG. 3b. *Numerical solution of* $y(t)$ *of* (6.3) *with* $\rho = 0$, $\tau = 1$, *and* $(x(t), y(t)) = (0.5 - t, 1.5)$, $t \leq 0$.

It is well known that the dynamics of the simple-looking Wright's equation $\dot{x}(t) = rx(t)(1 - x(t - 1))$ is already very complicated (cf., [13], [14], [26], [30]). With the addition of a neutral term, we can only expect the dynamics to become even more complex. Numerical simulations depicted in Figs. 2a–2c, and Figs. 4a and 4b seem to suggest that periodic solutions exist and persist. These periodic solutions appear to be the outcome of a sequence of Hopf bifurcations as in the case of Wright's equation. Unfortunately, there seems to be no general Hopf bifurcation theory for nonlinear neutral systems to confirm this observation theoretically. A similar phenomenon is expected for system (2.1). This is an open problem left untouched in this paper. Another important question left unresolved is the domain of attractivity analysis for system (2.1). Indeed, this question is open even for system (2.1) when $\rho = 0$. These questions will be pursued in the future.

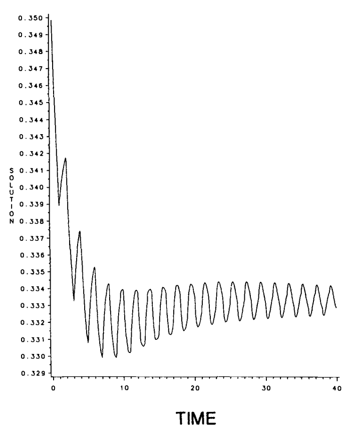

FIG. 4a. *Numerical solution of* $x(t)$ *of* (6.3) *with* $\rho = 2.9$, $\tau = 1$ *and* $(x(t), y(t)) = (0.35, 2.21)$, $t \leq 0$.

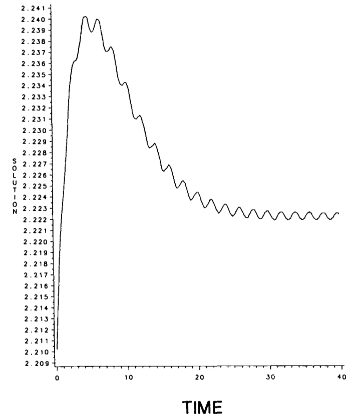

FIG. 4b. *Numerical solution of* $y(t)$ *of* (6.3) *with* $\rho = 2.9$, $\tau = 1$, *and* $(x(t), y(t)) = (0.35, 2.21)$, $t \leq 0$.

Our boundedness result in §3 indicates that if initial population is less than the carrying capacity of the environment (in our case, it is 1), and both the delay τ_1 and the neutral coefficient ρ are small, then the population stays bounded by $\lambda(\alpha)$, where $\lambda(\alpha)$ is between 1 and e, as defined in Lemma 3.1. Our global stability result in §4 suggests that, under slightly more restrictive conditions, the population approaches the environment carrying capacity as time goes by, a phenomenon observed for Wright's equation (for small delay) and logistic equations. This somehow partially justifies that the neutral delay effect can be ignored, provided that the delay length and neutral coefficient are expected to be small.

The results in §5 imply, to some extent, that the dissipativities of the considered systems are maintained for small delay τ_1 and small neutral coefficient ρ. They are certainly not surprising. However, for large τ_1 and ρ, the local stability analysis of [16] and [17] indicated that the neutral delay terms can be destabilizing.

Acknowledgments. The author is grateful to E. Lo for providing the numerical simulations displayed in the figures presented here, using the numerical schemes developed in [31].

The author also thanks the referees for their many valuable suggestions that improved the original manuscript.

A BOUNDARY VALUE PROBLEM WITH MULTIPLE SOLUTIONS FROM THE THEORY OF LAMINAR FLOW*

S. P. HASTINGS†, C. LU‡, AND A. D. MACGILLIVRAY§

Abstract. The equation considered is

$$f^{iv}+R(ff'''-f'f'')=0,$$

with boundary conditions

$$f(0)=f''(0)=0, \quad f(1)=1, \quad f'(1)=0.$$

It is shown that for all R there is at least one solution, and for sufficiently large R there are at least three solutions. The asymptotic behavior as $R \to -\infty$ is also studied. This equation arises in studying laminar flow in a porous channel.

Key words. boundary value problems, laminar flow

AMS(MOS) subject classification. 34B15

1. Introduction. In 1953 Berman [1] introduced and studied a mathematical model that describes the laminar flow of a viscous fluid between two porous walls through which fluid is injected or removed. This model arises in a number of applications, including transpiration cooling and the separation of U_{235} from U_{238} by gaseous diffusion.

Berman reduced the boundary value problem involving the steady-state Navier-Stokes equations to a boundary value problem involving a fourth-order nonlinear ordinary differential equation

$$f^{iv}+R(f'f''-ff''')=0, \tag{1}$$

with boundary conditions

$$f(0)=f''(0)=0, \tag{2}$$

$$f'(1)=0, \qquad f(1)=1, \tag{3}$$

where $f(\eta)$ is an unknown function related to the stream function, and η is the normalized transverse coordinate ($\eta=\pm 1$ are the walls).

$R=Vd/\mu$ is a Reynolds number based upon V, the normal outward velocity, μ, the viscosity, and d, where $2d$ is the distance between the walls. $V>0$ corresponds to suction (as in the process of isotope separation of uranium) and $V<0$ corresponds to injection (as in the process of transpiration cooling.) There have been many numerical studies and asymptotic analyses published; see [8] and the references listed there. R. M. Terrill studied the formal asymptotics of some solutions in [5] and [6]. In 1978 rigorous analytical results were obtained by Skalak and Wang [4], who showed that any solution must have one of three possible types of behavior and found each of these three types numerically. In 1987 Shih [3] proved the existence of solutions for $R<0$ using the Leray-Schauder fixed point theorem. Finally, in a preprint received after this paper was accepted for publication, Wang and Hwang gave a different proof of the existence of at least three solutions for large R [7], and they also proved the uniqueness of solutions for negative R.

The plan of this paper is as follows. We find it convenient to introduce $g = Rf$. First, in §§ 2 and 3, we give a simple proof of the existence of a concave down solution for $R > 0$. The method is a topological shooting argument based on a technique of Serrin and McLeod [2]. The uniqueness of this solution remains open. These solutions are increasing. In § 3 also we obtain a second family of increasing solutions, but these change concavity. They exist only for sufficiently large R. In § 4 we consider solutions such that g is initially decreasing. First we obtain a family of solutions with g decreasing on $[0, 1]$, so that $R < 0$. This result is not new, having been obtained by Shih [3], but we give a simpler proof. Finally, in § 5, we find a family of nonmonotone solutions, which also exist only for sufficiently large R. In the course of the proofs we obtain information about the asymptotic form of the solutions for large negative R. We will strengthen this result and discuss asymptotic behavior as $R \to +\infty$ in a second paper.

2. Statement of main result and first part of proof. Our main result in this paper is the following theorem.

THEOREM 1. *For each R, the boundary value problem* (1)-(3) *has at least one solution. For sufficiently large positive R,* (1)-(3) *has at least three solutions.*

Proof. With $g = Rf$, (1), (2), (3) become

$$g^{iv} + g'g'' - gg''' = 0, \tag{4}$$

$$g(0) = g''(0) = 0, \tag{5}$$

$$g'(1) = 0, \qquad g(1) = R. \tag{6}$$

Consider the initial value problem consisting of (4)-(5) and

$$g'(0) = \lambda, \qquad g'''(0) = \mu, \tag{7}$$

where λ and μ are to be found so that the solution $g = g_{\lambda,\mu}$ of (4), (5), (7) also satisfies (6). The dependence of g on (λ, μ) will usually be suppressed in our notation.

In the (λ, μ) plane define sets A and B as follows:

$$A = \{(\lambda, \mu) | g'(1) < 0 \text{ or } g(\eta) \text{ blows up before } \eta = 1\},$$

$$B = \{(\lambda, \mu) | g'(1) > 0\}.$$

It was shown in [4] that $g^{iv} < 0$ if $\mu \neq 0$ (see below), so solutions can only blow up by tending to $-\infty$. Since solutions of (4) depend continuously on initial conditions, A and B are open subsets of R^2. If a point (λ, μ) is not in A or B, then $g_{\lambda,\mu}$ solves (4)-(6) for some R. We shall first show how to find some continua in the (λ, μ) plane which lie in the complement of $A \cup B$, and then discuss the range of values of $g_{\lambda,\mu}(1)$ for points (λ, μ) in these continua.

Since $g_{\lambda,0}(\eta) \equiv \lambda\eta$, it is clear that the positive λ axis ($\lambda > 0$, $\mu = 0$) is contained in B, while the negative λ axis is contained in A.

3. Existence of solutions with $g'(0) \geqq 0$.

LEMMA 1. *For each $\lambda > 0$ there is a $\mu_-(\lambda) < 0$ such that if $\mu \leqq \mu_-(\lambda)$, then $(\lambda, \mu) \in A$.*

Proof. From (4), (5), and (7) it follows that $g^{iv}(0) = g^{vi}(0) = 0$, and

$$g^{v} = -g''^2 + gg^{iv}. \tag{8}$$

From this we have $g^{iv}(\eta) = -\int_0^\eta \exp \int_s^\eta g(r)\, dr\, g''(s)^2\, ds$, so that if $\mu \neq 0$, then $g^{iv} < 0$ as long as the solution is defined.

Hence g''' is decreasing, and if $\mu < 0$ and $|\mu|$ is sufficiently large (depending on λ), then $g'(\eta_0) < 0$ for some η_0 in $(0, 1)$, and $g'(\eta) < 0$ so long as the solution exists to the right of η_0. This proves Lemma 1.

Since A is open, $\mu_{-}(\lambda)$ can be assumed to be continuous in λ for $\lambda > 0$. For any $\lambda_2 > \lambda_1 > 0$, let

$$\Omega = \Omega_{\lambda_1, \lambda_2} = \{(\lambda, \mu) | \lambda_1 \leqq \lambda \leqq \lambda_2, \mu_{-}(\lambda) \leqq \mu \leqq 0\}.$$

Then B contains the top boundary ($\mu = 0$, $\lambda_1 \leqq \lambda \leqq \lambda_2$) of Ω and A contains the bottom boundary ($\mu = \mu_{-}(\lambda)$, $\lambda_1 \leqq \lambda \leqq \lambda_2$). By a result in [2], there is a continuum $\gamma_{\lambda_1, \lambda_2} \in \Omega_{\lambda_1, \lambda_2}$ connecting the left and right sides of Ω such that $\gamma_{\lambda_1, \lambda_2} \cap (A \cup B)$ is empty.

Since $g_{\lambda, \mu}$ is a continuous function of (λ, μ) on $\gamma_{\lambda_1, \lambda_2}$, the existence of a solution for any $R > 0$ is a consequence of showing that for sufficiently large λ_2 and small λ_1, with (λ_1, μ_1) and (λ_2, μ_2) in $\gamma_{\lambda_1, \lambda_2}$, λ_1 and λ_2 can be chosen so that $g_{\lambda_1, \mu_1}(1) < R$ and $g_{\lambda_2, \mu_2}(1) > R$.

Since we are dealing with solutions such that $g' > 0$ and $g'' < 0$, we have $g_{\lambda, \mu}(1) < \lambda$, so we simply choose λ_1 in $(0, R)$.

To choose λ_2 we integrate the inequality $g''' < \mu$ twice to show that for a solution of (4)-(7), $0 = g'(1) < \lambda + \mu/2$. Also, $g(1) > g(\frac{1}{4}) > \frac{1}{4} g'(\frac{1}{4}) > \frac{1}{4}(\lambda + \mu/4) > \frac{1}{8}\lambda$. Hence, to obtain $g_{\lambda_2, \mu_2}(1) > R$, we just pick $\lambda_2 > 8R$.

To obtain further solutions, we consider $\lambda \geqq 0$, $\mu > 0$.

LEMMA 2. *For each $\lambda \geqq 0$, there is a $\mu_{+}(\lambda) > 0$ such that if $\mu \geqq \mu_{+}(\lambda)$, then $(\lambda, \mu) \in A$.*

Proof. We first show that for sufficiently large μ (depending on λ, which for the moment is fixed), there is an η_μ in $(0, 1)$ with $g'''(\eta_\mu) = \mu/2$. Also, $\lim_{\mu \to \infty} \eta_\mu = 0$. To see this, use (7) and (8) to show that as long as $g''' \geqq \mu/2$,

$$g''' \leqq \mu - \frac{\mu^2 \eta^4}{48}.$$

Hence, $\eta_\mu \leqq (24/\mu)^{1/4}$. Furthermore, from (8), $g^v < 0$ in $(0, \eta_\mu)$, so g^{iv} is decreasing. By the mean value theorem applied to g''',

$$g^{iv}(\eta_\mu) \leqq -C\mu^{5/4}$$

for some $C > 0$ independent of μ.

Also, g^{iv} continues to decrease as long as $g > 0$, so beyond η_μ, as long as $g' > 0$, we have

$$g''' \leqq \frac{\mu}{2} - C\mu^{5/4}(\eta - \eta_\mu). \tag{9}$$

Integrating this twice and using the initial conditions shows that for sufficiently large μ, either $g(1)$ is not defined, or $g'(1) < 0$. In either case, $(\lambda, \mu) \in A$. This proves Lemma 2.

We now see that if $\lambda_2 > 0$, then there is a continuum δ_{0, λ_2} connecting $\lambda = 0$ with $\lambda = \lambda_2$ in the region $\mu \geqq 0$, and δ_{0, λ_2} is in the complement of $A \cup B$. In fact, since the positive λ-axis is contained in B, the continuum δ_{0, λ_2} lies in $\mu > 0$ except possibly at $\lambda = 0$. But just below, in Lemma 3, we shall show that in δ_{0, λ_2}, $\mu > 0$ when $\lambda = 0$. The corresponding solutions of (4)-(6) satisfy $g' > 0$ on $(0, 1)$, $g'' > 0$ on an initial interval $(0, \alpha)$, and $g'' < 0$ on $(\alpha, 1)$.

Also, $g(1)$ varies continuously on δ_{0, λ_2}. However it will be shown that $g(1)$ does not take on all positive values R.

LEMMA 3. $\inf \{g_{\lambda, \mu}(1) | \lambda \geqq 0, \mu > 0,$ *and* $g'_{(\lambda, \mu)}(1) = 0\} > 0$.

Proof of Lemma 3. Expand $g_{\lambda, \mu}(\eta)$ in a Taylor series in (λ, μ) around $(0, 0)$. The lowest order terms are

$$\phi(\eta)\mu + \psi(\eta)\lambda,$$

where ϕ and ψ satisfy

$$\phi'''=1,\ \phi(0)=\phi'(0)=\phi''(0)=0,$$
$$\psi'''=0,\ \psi(0)=\psi''(0)=0,\ \psi'(0)=1.$$

Here $\phi=\partial g/\partial\mu|_{(\lambda,\mu)=(0,0)}$, $\psi=\partial g/\partial\lambda|_{(\lambda,\mu)=(0,0)}$. Since $\phi'(1)>0$ and $\psi'(1)>0$, it follows that there is some $\rho>0$ such that, if $\mu\geqq 0$, $\lambda\geqq 0$, and $\rho>\mu^2+\lambda^2>0$, then $g'_{\lambda,\mu}(1)>0$ and $(\lambda,\mu)\in B$. Also, $g_{(\lambda,\mu)}(1)>0$ if $\lambda>0$, $\mu>0$ and $g'>0$ on $[0,1)$, while $g'_{(\lambda,\mu)}(1)<0$ for large μ. It follows that

$$\inf\{g_{(\lambda,\mu)}(1)|0\leqq\lambda\leqq\rho,\ \mu>0,\ g'_{(\lambda,\mu)}(1)=0\}>0.$$

We shall show later that for large λ, $g_{(\lambda,\mu)}(1)$ is large if $g'_{(\lambda,\mu)}(1)=0$, which will prove Lemma 3.

We now show that there is a solution of this type for any sufficiently large R. It is convenient to introduce another scaling. For $\lambda\neq 0$, let

$$h(\eta)=\frac{g(\eta)}{|\lambda|}.$$

Then

$$\varepsilon h^{iv}=-h'h''+hh''', \tag{10}$$

where $\varepsilon=1/|\lambda|$. Also,

$$h(0)=h''(0)=0,\quad h'(0)=1,\quad h'''(0)=\varepsilon\mu. \tag{11}$$

We have shown that for each $\varepsilon>0$ there are at least two values of μ, one negative and one positive, such that

$$h'(1)=0. \tag{12}$$

Let h_ε denote some solution of (10)-(12) with $\mu>0$. We must show that $\lim_{\varepsilon\to 0^+}(h_\varepsilon(1))/\varepsilon=\infty$. In fact, we show more.

LEMMA 4. $\liminf_{\varepsilon\to 0^+} h_\varepsilon(1)\geqq 1$.

Proof. Suppose, for some fixed $r<1$, that $h_{\varepsilon_j}(1)<r$ for some sequence of $\varepsilon_j\to 0$. Since $h'_\varepsilon>0$ on $[0,1)$, and h''' is decreasing, it follows that $h'_{\varepsilon_j}(r)<1$. Hence there is an $\eta_j<r$ such that $h''_{\varepsilon_j}(\eta_j)=0$, $h'_{\varepsilon_j}(\eta_j)>1$, and h''_{ε_j} decreases on $[\eta_j,1]$. We distinguish between two cases. Either $h''_{\varepsilon_j}((1+r)/2)\to 0$ or, for some subsequence if necessary, and some $\delta>0$, $h''_{\varepsilon_j}((1+r)/2)\leqq-\delta$. In the first case, $h''_{\varepsilon_j}\to 0$ uniformly on $[\eta_j,(1+r)/2]$. But this implies that $h_{\varepsilon_j}((1+r)/2)>r$ for large j, contradicting an earlier assumption. In the second case, $h''_{\varepsilon_j}\leqq-\delta$ on $[(1+r)/2,1]$, and since $h'_{\varepsilon_j}(r)<1$, we obtain a contradiction using (8). This proves Lemma 4 and establishes the existence of a second solution for large R.

4. Monotone solutions with $\lambda<0$. To obtain further solutions we now consider $\lambda<0$. If $\mu<0$, then g, g', g'', and g''' are all negative and decreasing on $(0,1)$. If $\mu=0$ then $g(\eta)=\lambda\eta$. For $\mu>0$, the following lemmas are useful.

LEMMA 5. *If $\lambda<0$, $\mu>0$, then $g'''>0$ as long as $g'\leqq 0$.*

Proof. We have seen that $g^{iv}<0$ if $\mu\neq 0$. But from (4) it is apparent that at the first zero of g''', where $g''>0$, sign $(g^{iv})=-\text{sign}(g')$. Hence $g'>0$ at this point.

LEMMA 6. *Let*

$$\phi(\eta)=\frac{\partial g_{\lambda,\mu}(\eta)}{\partial\mu}.$$

Then ϕ, ϕ', ϕ'' are all positive as long as $g'\leqq 0$.

Proof. Integrating (4) shows that

$$g''' = \lambda^2 + \mu - g'^2 + gg''. \tag{13}$$

Differentiating with respect to μ shows that

$$\phi''' = 1 - 2\phi' g' + \phi g'' + g\phi'',$$

with

$$\phi(0) = \phi'(0) = \phi''(0) = 0, \qquad \phi'''(0) = 1.$$

At the first zero, if any, of ϕ'', $\phi''' > 0$ if $g' \leqq 0$, a contradiction. This proves Lemma 6.

Still taking a fixed $\lambda < 0$, we consider the solutions for $\mu > 0$. If μ is small, then $g'(1) < 0$, and, by Lemma 5, $g'' > 0$ on $[0, 1]$. Lemma 6 then implies that $\phi'(1) > 0$.

LEMMA 7. *For sufficiently large μ, $g'(\eta) > 0$ for some η in $(0, 1)$.*

Proof. On an initial interval $g' < 0$, and as long as this inequality persists, we have

$$\lambda < g' < 0, \quad \lambda\eta \leqq g(\eta) < 0, \quad g'' > 0, \quad \text{and} \quad g^{iv} \geqq \lambda g'''.$$

Hence $g''' \geqq g'''(0)\, e^{\lambda\eta}$. For fixed λ, integrating two times shows that g' becomes positive at some $\eta < 1$, if $\mu = g'''(0)$ is sufficiently large, completing the proof.

Recall that $g'(1) < 0$ if $\mu = 0$, $\lambda < 0$. Lemmas 6 and 7 show that there is a unique $\mu = \mu_i(\lambda) > 0$ such that $g' < 0$ on $[0, 1]$ and $g'(1) = 0$. (Here "i" stands for "intermediate." The solution is unique because Lemma 6 shows that $g'(1)$ is strictly increasing in μ whenever $g' < 0$ on $[0, 1)$ and $g'(1) = 0$. Hence $g'(1)$ can only increase from negative to positive as μ increases, so long as g is negative.) The region $0 \leqq \mu < \mu_i(\lambda)$ is contained in A. Since $\partial g'_{\lambda,\mu}(1)/\partial\mu|_{\mu=\mu_i(\lambda)} > 0$ at $\eta = 1$, B contains an open set of the (λ, μ) plane with $\mu = \mu_i(\lambda)$ as its lower boundary for $\lambda < 0$.

An additional simple result clarifies the picture further.

LEMMA 8. *For $\mu > \mu_i(\lambda)$, g' has exactly one zero in the initial interval where $g < 0$.*

Proof. If not, then there is a point in $(0, 1)$ where

$$g' = 0, \quad g'' < 0, \quad g''' < 0, \quad g < 0.$$

However, from (13), g''' is positive if $g' = 0$, $gg'' > 0$. This proves Lemma 8.

The curve $\mu = \mu_i(\lambda)$, $\lambda < 0$, gives solutions for at least some negative values of R. Note that this curve is continuous, from the implicit function theorem, because $\mu_i(\lambda)$ can be viewed locally as a solution to the equation

$$g'_{\lambda,\mu}(1) = 0.$$

and from Lemma 6 we know that $\partial g'_{\lambda,\mu}(1)/\partial\mu \neq 0$. The existence of solutions for negative λ is not new, as it was shown in [3] that there is a solution to (1)-(3) for any $R < 0$. To obtain this from our arguments, we must show that if $\mu = \mu_i(\lambda)$, then $g(1) \to 0$ as $\lambda \to 0^-$, while $g(1) \to \infty$ as $\lambda \to -\infty$.

The first of these is trivial, since $g(1) \geqq \lambda$. For the second we again let $h(\eta) = g(\eta)/|\lambda|$, so that h satisfies (10), but with

$$h(0) = h''(0) = 0, \quad h'(0) = -1, \quad h'''(0) = \varepsilon\mu. \tag{14}$$

We now wish to use h_ε to denote the solution of (10), (12), (14) with $h' < 0$ on $[0, 1)$. The asymptotic form of h_ε is given by the following theorem.

THEOREM 2.

$$\lim_{\varepsilon \to 0^+} h_\varepsilon(\eta) = -\frac{2}{\pi} \sin\left(\frac{\pi}{2}\eta\right),$$

uniformly on $0 \leqq \eta \leqq 1$.

LEMMA 9. $\lim_{\varepsilon\to 0}\varepsilon^2\mu=0$.

Proof. Suppose, on the contrary, that there is a $\delta>0$ and a sequence of ε's tending to zero such that $\varepsilon^2\mu>\delta$, where $\mu=\mu_i(-1/\varepsilon)$. Thus $h_\varepsilon'''(0)=\varepsilon\mu\to\infty$. We have seen that for the solution under discussion, on $[0,1]$,

$$h'''>0,\quad h''>0,\quad -1<h'<0,$$

so

$$\varepsilon h'''\geqq\delta+hh''.$$

On some initial interval $[0,\alpha]$, $h''\leqq 2$. In this interval, $h'''\geqq(\delta+2h)/\varepsilon$. It follows easily that for sufficiently small ε, either $h'=0$ or $h''=2$, before $\eta=\frac{1}{2}$. But we are assuming that $h'<0$ on $[0,1)$. If $h''(\alpha)=2$, then $h''>2$ on $(\alpha,1]$, and $h'(1)>0$, which again is impossible. This proves Lemma 9.

Hence, there is a $\delta(\varepsilon)>0$ such that $\delta(\varepsilon)\to 0$ as $\varepsilon\to 0$ and $0<\varepsilon h'''\leqq\delta(\varepsilon)=\varepsilon^2\mu=\varepsilon h'''(0)$ on $[0,1]$. The equivalent of (13) for h is

$$\varepsilon h'''=1+\varepsilon^2\mu-h'^2+hh'', \tag{15}$$

so that on $[0,1]$,

$$-\delta(\varepsilon)\leqq 1-h'^2+hh''\leqq 0.$$

Since $h'<0$ on $[0,1)$, h' can be expressed as a function of h:

$$h'(\eta)=Q(h(\eta)).$$

Then $Q(0)=-1$, $-1<Q<0$ on $(h(1),0)$, and

$$Q^2-1-\delta\leqq hQQ'\leqq Q^2-1<0,$$

or

$$\frac{QQ'}{Q^2-1}\leqq\frac{1}{h}\leqq\frac{QQ'}{Q^2-1-\delta(\varepsilon)}.$$

These inequalities can be integrated from $h(1)$ to $h(\eta)$ (the resulting improper integral is convergent) giving, first,

$$1-\frac{h(\eta)^2}{h(1)^2}\leqq h'(\eta)^2\leqq 1+\delta-\frac{h(\eta)^2}{h(1)^2},$$

and then, integrating from zero to η,

$$-h(1)\sin\left(\frac{\sqrt{1+\delta}\,\eta}{h(1)}\right)\leqq h(\eta)\leqq -h(1)\sin\left(\frac{\eta}{h(1)}\right).$$

Since $h(\eta)$ is decreasing exactly on $[0,1]$, with $h'(1)=0$, the only possibility as $\varepsilon\to 0$ is that $h(1)\to -2/\pi$, and Theorem 2 follows.

5. Nonmonotone solutions for $\lambda<0$. As pointed out earlier, a region above $\mu=\mu_i(\lambda)$, $\lambda<0$ lies in the set B. Also, a neighborhood of the segment $\{\lambda=0, 0<\mu<\rho\lambda=0, 0\leqq\mu<\rho\}$, lies in B. We wish now to show that these regions overlap.

First we observe that $\lim_{\lambda\to 0^-}\mu_i(\lambda)=0$. This is apparent because $g'(1,0,\mu)>0$ if μ is positive and sufficiently small.

Again, let $\phi(\eta,\lambda,\mu)=(\partial g/\partial\mu)(\eta,\lambda,\mu)$. We have seen that $\phi'''(\eta,0,0)\equiv 1$, so $\phi'(1,0,0)=\frac{1}{2}$. Hence, $\phi'(1,\lambda,\mu)\geqq\frac{1}{4}$, for (λ,μ) in some neighborhood of $(0,0)$. Therefore there are $\mu_0>0$, $\lambda_0<0$ such that $\phi'(1,\lambda,\mu)>0$ for $0\leqq\mu\leqq\mu_0$, $\lambda_0\leqq\lambda\leqq 0$. Since

$g'(1, \lambda, \mu_i(\lambda)) = 0$, we see that $g'(1, \lambda, \mu) > 0$ if $|\lambda_0|$ is small enough to ensure that $\mu_i(\lambda_0) < \mu_0$, and $\lambda_0 \leqq \lambda < 0$, $\mu_i(\lambda) < \mu < \mu_0$. This proves that B contains an open set bounded below by $\mu = \mu_i(\lambda)$ for $\lambda \leqq 0$ and by $\mu = 0$ for $\lambda > 0$.

To obtain our final set of solutions we need Lemma 10.

LEMMA 10. *For each $\lambda < 0$ there is a $\mu_+(\lambda) > 0$ such that if $\mu \geqq \mu_+(\lambda)$, then $(\lambda, \mu) \in A$.*

Remark. After proving Lemma 10 we will have defined $\mu_+(\lambda)$ for all λ. The component of A containing the region $\mu \geqq \mu_+(\lambda)$ must be separated from B by a continuum γ which extends over the entire λ-axis. We have seen that in γ, $g(1) \to +\infty$ as $\lambda \to +\infty$. After proving Lemma 10, we will show that in γ, $g(1) \to +\infty$ as $\lambda \to -\infty$, as well. This will give three solutions for any sufficiently large positive R.

Proof. For large μ, as long as $g'' > 0$ and $g' \leqq \sqrt{\mu/2}$ we have, from (13),

$$\mu\eta \geqq g'' > 0, \quad g' > \lambda, \quad g > \lambda\eta,$$

and

$$g''' \geqq \frac{\mu}{2} + \lambda\mu\eta^2.$$

If $\eta < 1/(2\sqrt{|\lambda|})$, then $g''' \geqq \mu/4$, and integrating this three times, using the initial conditions on g, enables us to conclude that before $\eta = \sqrt{24|\lambda|/\mu}$, either $g = 0$ or $g' = \sqrt{\mu/2}$.

On the other hand, $g'' \leqq \mu\eta$, $g' \leqq \lambda + \mu\eta^2/2$, so $g'(\sqrt{24|\lambda|/\mu}) \leqq 11|\lambda| < \sqrt{\mu/2}$ for μ large. Hence we have shown that for large μ, $g = 0$ before $\eta = \sqrt{24|\lambda|/\mu}$. Furthermore, at $g = 0$, $g''' \geqq \lambda^2 - \mu/2 + \mu \geqq \mu/2$ and $0 \leqq g' \leqq 11|\lambda|$. From here the proof that $g'(1) < 0$ proceeds with estimates which are very similar to those in Lemma 2, and we omit the details. This proves Lemma 10.

The proof of Theorem 1 will be completed by showing that

$$\lim_{\substack{\lambda \to -\infty \\ g'_{(\lambda,\mu)}(0)=0}} g_{\lambda,\mu}(1) = \infty.$$

Once again, let $h = g/|\lambda|$, and consider (10), (12), (14). For small $\varepsilon > 0$, we assume $\mu > 0$ has been chosen so that $h'(\eta_1) = 0$ for some η_1 in $(0, 1)$ and also $h'(1) = 0$. We must show that $h_\varepsilon(1)/\varepsilon \to \infty$ (at least for some sequence of ε's tending to zero). Suppose this is not the case and there is an $M > 0$ such that $h_\varepsilon(1) \leqq M\varepsilon$ for all small ε. Equivalently, $h_\varepsilon(\eta) \leqq M\varepsilon$ for all η and small ε. For each ε the solution $h = h_\varepsilon$ has the following qualitative behavior.

$$\begin{aligned} h^{iv} &< 0 \quad \text{on } (0, 1], \\ h' &< 0 \quad \text{on some interval } [0, \eta_1),\ h' > 0 \quad \text{on } (\eta_1, 1], \\ h'' &> 0 \quad \text{on } [0, \eta_2],\ h'' < 0 \quad \text{on } (\eta_2, 1], \\ h''' &> 0 \quad \text{on } [0, \eta_3),\ h''' < 0 \quad \text{on } (\eta_3, 1], \\ h &< 0 \quad \text{on } (0, \eta_4),\ h > 0 \quad \text{on } (\eta_4, 1], \end{aligned}$$

where $0 < \eta_1 < \eta_3 < \eta_2$.

LEMMA 11. $\eta_2 > \eta_4$.

Proof. This is obvious if $\eta_3 \geqq \eta_4$. If $\eta_3 < \eta_4$, then

$$0 > \varepsilon h^{iv} = -h'h'' + hh''' \geqq -h'h''$$

on $[\eta_3, \eta_4]$, which implies that $h'' > 0$ on this interval, as desired.

LEMMA 12. $h'(\eta_2) > 1$.

Proof. Since $h'''(\eta_2) < 0$ and $h''(\eta_2) = 0$, the result follows from (15).

Continuing with the proof of Theorem 1, there is an $\eta_5 > \eta_2$ with $h'(\eta_5) = 1$. Also, $h'' < 0$ on $(\eta_2, \eta_5]$, so it is clear that $h(1) \geqq h(\eta_5) \geqq \eta_5 - \eta_2$, and thus $\eta_5 - \eta_2 \leqq M\varepsilon$. Also, h''' is decreasing, so

$$h'''(\eta_5) \leqq \frac{h''(\eta_5)}{(\eta_5 - \eta_2)} \leqq \frac{h''(\eta_5)}{M\varepsilon}.$$

However, since $h'(\eta_5) = 1$, we have from (15)

$$h'''(\eta_5) = \varepsilon\mu + \frac{h(\eta_5)}{\varepsilon} h''(\eta_5) \geqq Mh''(\eta_5).$$

These inequalities are inconsistent if $\varepsilon < 1/M^2$. We were using the assumption that $h(1)/\varepsilon \leqq M$, which therefore is impossible for small ε. This completes the proof of Theorem 1.

A NONLINEAR DIFFERENTIAL OPERATOR SERIES THAT COMMUTES WITH ANY FUNCTION*

PETER J. OLVER†

Abstract. A natural differential operator series is one that commutes with every function. The only linear examples are the formal series operators $e^{\alpha z D}$ representing translations. This paper discusses a surprising natural *nonlinear* "normally ordered" differential operator series, arising from the Lagrange inversion formula. The operator provides a wide range of new higher-order derivative identities and identities among Bell polynomials. These identities specialize to a large variety of interesting identities among binomial coefficients and classical orthogonal polynomials, a number of which are new.

Key words. natural differential operator series, normal ordering, Lagrange inversion, Bell polynomial, orthogonal polynomial

AMS(MOS) subject classifications. 26A24, 05A15, 05A19

1. Introduction. An operator $\mathcal{D}$ is called *natural* if it commutes with arbitrary functions, i.e.,

$$\Phi(\mathcal{D}u) = \mathcal{D}\Phi(u) \tag{1}$$

for all scalar functions Φ. In this paper we will take $u(t)$ to be a formal power series in the variable t, and $\mathcal{D}$ to be a formal series of differential operators. A simple example of a natural operator in this context is the exponential operator e^{zD}, where $D = d/dt$, which, by Taylor's theorem, coincides with the translation operator $e^{zD}u(t) = u(t+z)$. The proof that e^{zD} is natural is then elementary:

$$\Phi(e^{zD}u(t)) = \Phi(u(t+z)) = e^{zD}\Phi(u(t)). \tag{2}$$

In fact, it is not hard to show that the translation operators $e^{\alpha z D}$ are essentially the only linear natural differential operator series. It is therefore rather surprising that there exist nonlinear natural differential operator series! The main result of this paper is that the series operator

$$D^{-1} :e^{zDu}: D = 1 + \sum_{n=1}^{\infty} \frac{z^n}{n!} D^{n-1} \cdot u^n \cdot D \tag{3}$$

is natural, i.e., for any analytic function $\Phi(u)$, and any formal power series $u(t)$,

$$D^{-1} :e^{zDu}: D\Phi(u) = \Phi(D^{-1} :e^{zDu}: Du). \tag{4}$$

In (3) the colons mean that the operator is "normally ordered," meaning that all the multiplication terms appear after all the differentiations. This is reminiscent of the Wick ordering in quantum mechanics [4], although not quite the same. I do not know if the identity (4) has any bearing on this subject.

Two proofs of this identity will be discussed. The first is an application of the classical Lagrange inversion theorem [3], [7]. In fact, it will follow that the operator (3) formally represents the implicitly defined variable translation $x = t + zu(x)$, which explains its naturality. The second proof uses techniques from the Frobenius theory of partial differential equations, a method of independent interest, and appears in an

appendix. By choosing different elementary functions Φ in the identity (4), we are led to a large class of interesting new identities involving higher-order derivatives of scalar functions. Moreover, specializing the resulting derivative identities to various elementary types of functions $u(x)$, leads to, among others, the Hagen–Rothe binomial coefficient identity [5], the Abel identity [3], and a number of interesting identities among classical orthogonal polynomials, including Hermite, Legendre, and Jacobi polynomials, that I have not been able to find in the literature. In another direction, using the standard connection between higher-order derivatives of compositions of functions and the Bell polynomials [3], [10], these derivative identities are easily shown to be equivalent to a large collection of apparently new identities for Bell polynomials.

This work arose from an ongoing investigation into the canonical forms for bi-Hamiltonian systems [9], and applications of these results to the precise integrability of canonical bi-Hamiltonian systems can be found there.

2. Differential operators and normal ordering. We will be concerned with formal power series whose coefficients are differential operators. These in turn can be applied to analytic functions or formal power series, leading in turn to further formal series.

Let t be a scalar variable. We use D to denote the derivative operator d/dt. Let

$$F(z)=\sum_{n=0}^{\infty} c_n z^n \tag{5}$$

be a formal power series in the scalar variable z. We can form the operator series

$$F(zD)=\sum_{n=0}^{\infty} c_n z^n D^n$$

which, when applied to any analytic function $f(t)$ results in a formal power series

$$F(zD)f(t)=\sum_{n=0}^{\infty} c_n z^n f^{(n)}(t) \tag{6}$$

in the derivatives of $f^{(n)}=D^nf=d^nf/dt^n$ of f. For example, by Taylor's theorem, the exponential operator

$$e^{zD}f(t)=\sum_{n=0}^{\infty}\frac{1}{n!}z^nf^{(n)}(t)=f(t+z) \tag{7}$$

coincides with the operator of translation in z. If

$$f(t)=\sum_{i=0}^{\infty} f_i t^i$$

is itself a formal power series, then (6) is a formal power series in both z and t whose coefficients depend on the coefficients f_i of f. In particular, evaluating this identity at $t=0$ leads to the formal series

$$F(zD)f(t)|_{t=0}=\sum_{n=0}^{\infty} n!\,c_nf_nz^n. \tag{8}$$

Note that, under the natural identification of the coefficients of f with the derivatives of f at $t=0$, which is $f_n=(n!)^{-1}f^{(n)}(0)$, we recover the original equality (6). In fact, we can replace zero by any other value of t; hence we can use (8) to evaluate the series (6). This remark will be of use later on.

We now wish to extend our range of operators to certain types of nonlinear operators. By "nonlinear" we mean that the operator itself depends on an analytic function or a formal power series $u(t)$, so that the operator will, in general, be a nonlinear function of u. However, it still acts linearly when applied to other power series. The most elementary operators associated with a formal power series (5) are the nonlinear operators

$$F(zuD)=\sum_{n=0}^{\infty} c_n z^n (uD)^n \quad\text{and}\quad F(zDu)=\sum_{n=0}^{\infty} c_n z^n (D\cdot u)^n. \tag{9}$$

Note that since the operators of differentiation D and multiplication by u do not commute, these two operators are not the same; their commutator

$$[D,u]=D\cdot u-u\cdot D=u' \tag{10}$$

is the operator of multiplication by $u'=u^{(1)}$. For example,

$$\begin{aligned}e^{zuD}v&=\sum_{n=0}^{\infty}\frac{z^n}{n!}(uD)^n v\\&=v+zuv'+\frac{1}{2}z^2(u^2v''+uu'v')\\&\quad+\frac{1}{6}z^3(u^3v'''+3u^2u'v''+uu'^2v'+u^2u''v')+\cdots,\\e^{zDu}v&=\sum_{n=0}^{\infty}\frac{z^n}{n!}(D\cdot u)^n v\\&=v+z(uv'+u'v)+\frac{1}{2}z^2(u^2v''+3uu'v'+(uu''+u'^2)v)\\&\quad+\frac{1}{6}z^3(u^3v'''+6u^2u'v''+(4u^2u''+7uu'^2)v'\\&\qquad+(u^2u'''+4uu'u''+u'^3)v)+\cdots.\end{aligned}$$

A further type of operator is found by ordering the factors in the series in yet another way.

DEFINITION 1. Given a formal power series (5), the *normally ordered operator series* is defined to be

$$:F(zDu):=\sum_{n=0}^{\infty}c_nz^nD^n\cdot u^n. \tag{11}$$

Thus the action of $:F(zDu):$ on a function $f(t)$ is given by

$$:F(zDu):f=\sum_{n=0}^{\infty}c_nz^nD^n\{u^nf\}.$$

The colons in the notation (11) are to distinguish this operator from the more standard operator series (9). For example

$$\begin{aligned}:e^{zDu}:\,v&=\sum_{n=0}^{\infty}\frac{1}{n!}z^nD^n(u^nv)\\&=v+z(uv'+u'v)+\frac{1}{2}z^2(u^2v''+3uu'v'+2(uu''+u'^2)v)\\&\quad+\frac{1}{6}z^3(u^3v'''+9u^2u'v''+(9u^2u''+18uu'^2)v'\\&\qquad+(3u^2u'''+18uu'u''+6u'^3)v)+\cdots.\end{aligned}$$

The colon notation is borrowed from quantum mechanics. Indeed, these operators remind us of the Wick ordering used in quantum field theory [4], in which all the creation operators appear to the left of all the annihilation operators. (Indeed, the commutation relations (10) are also reminiscent of the standard commutation relations, but only coincide when $u = t$.) However, this is not really the ordering adopted here, since in the harmonic oscillator, the creation and annihilation operators are certain combinations of derivative and multiplication operators.

3. Natural operators. Certain formal series differential operators play a distinguished role, in that they commute with functional evaluation. We make the following definition.

DEFINITION 2. A series differential operator $\mathcal{D}$ is called *natural* if it commutes with all functions, i.e.,

$$\Phi(\mathcal{D}u) = \mathcal{D}\Phi(u) \tag{12}$$

for all scalar functions Φ and all formal series u.

A simple example is provided by the translation operator e^{zD}, as shown in the introduction. It is not hard to show that the following is essentially the only linear example.

PROPOSITION 3. *The operators $e^{\alpha zD}$, α a constant, are the only natural formal series linear differential operators of the form $\mathcal{D} = F(zD)$.*

Proof. Let

$$\mathcal{D} = F(zD) = \sum_{n=0}^{\infty} c_n z^n D^n.$$

First set $z = 0$ in (12), which gives $\Phi(c_0 u) = c_0 \Phi(u)$. For this to hold for all Φ, the leading term of $\mathcal{D}$ must be $c_0 = 1$. Now, assume by induction that we have shown that $c_j = \alpha^j/j!$, for $j \leqq n-1$, where $\alpha = c_1$, and $n \geqq 2$. Let $\Phi(u) = u^2$. Then the coefficient of z^n in (9) is

$$2c_0 c_n u u^{(n)} + 2c_1 c_{n-1} u' u^{(n-1)} + \cdots = c_n D^n(u^2).$$

This readily implies that $c_n = \alpha^n/n!$, completing the induction. (Note that in fact we only needed to check (12) for quadratic functions Φ to prove this result.)

The main result of this paper is the following example of a nonlinear natural differential operator.

THEOREM 4. *Let $u(t)$ be a formal power series and let $D = d/dt$. Then the series differential operator*

$$D^{-1} :e^{zDu}: D = 1 + \sum_{n=1}^{\infty} \frac{z^n}{n!} D^{n-1} \cdot u^n \cdot D \tag{13}$$

is natural, i.e., for any analytic function $\Phi(u)$,

$$D^{-1} :e^{zDu}: D\Phi(u) = \Phi(D^{-1} :e^{zDu}: Du). \tag{14}$$

Proof. This result follows as a direct consequence of the famous Lagrange inversion formula: cf. [3, p. 150] or [7, pp. 113, 114]. According to equation (5) of Melzak [7, p. 113], if $u(t)$ is any analytic function (or formal power series), and we define $x = \xi(z, t)$ implicitly by the formula

$$x = t + zu(x), \tag{15}$$

then, for any analytic function $f(t)$, we have the classical *Lagrange inversion formula*

$$(16)\qquad f(x)=f(t)+\sum_{n=1}^{\infty}\frac{z^n}{n!}\{D^{n-1}\cdot u(t)^n\cdot D\}f(t)=D^{-1}:e^{zDu}:Df(t).$$

Now set $f(t)=\Phi(u(t))$, so that (16) becomes

$$(17)\qquad \Phi(u(x))=D^{-1}:e^{zDu}:D\Phi(u(t)).$$

On the other hand, according to the formula at the bottom of page 144 of [7], for any analytic function $g(x)$, evaluated at (15),

$$\frac{\partial^n}{\partial z^n}g(\xi(z,t))|_{z=0}=D^{n-1}(u(t)^nDg(t)),\qquad n\geqq 1.$$

Therefore, taking $g=u$, we find the expansion

$$\begin{aligned}u(x)&=\sum_{n=0}^{\infty}\frac{z^n}{n!}\frac{\partial^n}{\partial z^n}u(\xi(z,t))|_{z=0}\\&=u(t)+\sum_{n=0}^{\infty}\frac{z^n}{n!}D^n(u(t)^nDu(t))\\&=D^{-1}:e^{zDu}:Du(t).\end{aligned}$$

Substituting this into (17) completes the proof of (13).

In view of the proof, then, it is no longer surprising that the operator series (13) is natural, since it corresponds to the variable translation (15) via Lagrange inversion. More generally, we can introduce the translation

$$(18)\qquad x=t+\Psi(z,u(x),u'(x),\cdots,u^{(n)}(x)),$$

which has a corresponding differential operator series, which will also clearly be natural. For example, the operators

$$D^{-1}:e^{zD\Psi(u,u',\cdots)}:D,$$

where Ψ is any analytic function of u and its derivatives, are also natural. An interesting problem that I have not tried to investigate is whether there exist other classes of natural differential operators, although it seems reasonable to conjecture that only the operators associated with such translations are natural.

4. Derivative identities. Just as generating function identities leads to combinatorial identities, so any natural differential operator leads to a large class of derivative identities, obtained by considering different functions Φ in the basic condition (14). Here we present some of the more elementary derivative identities to be found as a consequence of the main theorem. We first compute the basic formula

$$(19)\qquad \begin{aligned}\zeta(u)=D^{-1}:e^{zDu}:Du&=u+\sum_{n=1}^{\infty}\frac{z^n}{n!}D^{n-1}\{u^nu'\}\\&=\sum_{n=0}^{\infty}\frac{z^n}{(n+1)!}D^n(u^{n+1}).\end{aligned}$$

More generally, we find that, for $\Phi(u)=u^k$,

$$(20)\qquad D^{-1}:e^{zDu}:Du^k=\sum_{n=0}^{\infty}\frac{k}{n+k}\frac{z^n}{n!}D^n(u^{n+k}).$$

As long as k is not a negative integer, (20) is valid as it stands. It also remains correct when $k=-j$ is a negative integer, *provided* we interpret the term corresponding to $n=j$ in the summation according to the general "rule"

$$(21)\qquad \lim_{m\to 0}\frac{1}{m}D^n(u^m)=\lim_{m\to 0}D^{n-1}(u^{m-1}u')=D^n(\log u),\qquad n\geqq 1.$$

Note that if $n=0$, the term $(k/(n+k))D^n(u^{n+k})=u^k$ is not a problem. Now, according to Theorem 4, the series (20) is the kth power of the series (19). This implies certain unusual identities among higher-order derivatives of powers of u. For instance, taking the case $k=2$, the series identity

$$\sum_{n=0}^{\infty}\frac{2}{n+2}\frac{z^n}{n!}D^n(u^{n+2})=\left(\sum_{n=0}^{\infty}\frac{z^n}{(n+1)!}D^n(u^{n+1})\right)^2$$

implies the following derivative identities:

$$D^n(u^{n+2})=\sum_{i=0}^{n}\frac{n+2}{2(i+1)(n-i+1)}\binom{n}{i}D^i(u^{i+1})\cdot D^{n-i}(u^{n-i+1}).$$

More generally, if we apply the identities corresponding to $\Phi(u)$ being u^{k+l}, u^k, and u^l, then the series identity

$$\sum_{n=0}^{\infty}\frac{k+l}{n+k+l}\frac{z^n}{n!}D^n(u^{n+k+l})=\left(\sum_{n=0}^{\infty}\frac{k}{n+k}\frac{z^n}{n!}D^n(u^{n+k})\right)\left(\sum_{n=0}^{\infty}\frac{l}{n+l}\frac{z^n}{n!}D^n(u^{n+l})\right)$$

implies the additional derivative identities

$$(22)\qquad \begin{aligned}&\frac{k+l}{n+k+l}D^n(u^{n+k+l})\\&=\sum_{i=0}^{n}\frac{kl}{(i+k)(n-i+l)}\binom{n}{i}D^i(u^{i+k})\cdot D^{n-i}(u^{n-i+l}).\end{aligned}$$

These identities are valid for arbitrary (positive and negative) values of k, l, provided we use the rule (21) if either $n+k+l=0$, or any of the summation terms $i+k=0$ or $n-i+l=0$. For example, if we take $k=-1$, $l=1$, we find that the series

$$\eta(u)=\frac{1}{u}-z\frac{u'}{u}+\sum_{n=2}^{\infty}\frac{z^n}{(1-n)\cdot n!}D^n(u^{n-1})$$

is the series inverse for (19), i.e., $\eta(u)=1/\zeta(u)$, and hence we have the series identity

$$1=\left(\sum_{n=0}^{\infty}\frac{z^n}{(n+1)!}D^n(u^{n+1})\right)\cdot\left(\frac{1}{u}-z\frac{u'}{u}+\sum_{n=2}^{\infty}\frac{z^n}{(1-n)\cdot n!}D^n(u^{n-1})\right).$$

Rearranging the terms of degree n in z in this formula results in the derivative identity

$$(23)\quad D^n(u^{n+1})=(n+1)u'D^{n-1}(u^n)+\sum_{i=2}^{n}\frac{1}{i-1}\binom{n+1}{i}uD^i(u^{i-1})D^{n-i}(u^{n-i+1}),$$

valid for $n\geqq 1$. The identities (22), (23) appear to be related to, but interestingly not the same as, some derivative identities appearing in Adams and Hippisley [1, § 7.37, p. 160]. Many more examples can be deduced by choosing other types of elementary functions for $\Phi(u)$ in (14).

5. Binomial and orthogonal polynomial identities. We now specialize the above derivative identities for particular functions $u(t)$, and find that they reduce to a wide range of identities among binomial coefficients and orthogonal polynomials. Some are known, but the orthogonal polynomial identities are apparently new. (However, I have not attempted a completely exhaustive search of the literature.)

1. First consider the case

$$u(t)=t^{\alpha}, \quad \text{so } \frac{1}{n!}D^n u^m=\binom{m\alpha}{n}t^{m\alpha-n}.$$

Then (22) reduces to the identity

$$\frac{k+l}{n+k+l}\binom{(n+k+l)\alpha}{n}=\sum_{i=0}^{n}\frac{kl}{(i+k)(n-i+l)}\binom{(i+k)\alpha}{i}\binom{(n-i+l)\alpha}{n-i}. \tag{24}$$

This is equivalent to the Hagen-Rothe identity [5], [6, Eqn. 3.142], which generalizes the classical Vandermonde convolution identity for binomial coefficients,

$$\binom{r+s}{n}=\sum_{i=0}^{n}\binom{r}{i}\binom{s}{n-i},$$

which follows from (24) in the limit $\alpha\to 0$, $k\alpha\to r$, $l\alpha\to s$. In (24), we use the definition

$$\binom{\beta}{n}=\frac{\beta(\beta-1)\cdots(\beta-n+1)}{n!}$$

for the general binomial coefficients, so that

$$\frac{1}{\beta}\binom{\beta}{n}=\frac{(\beta-1)\cdots(\beta-n+1)}{n!}$$

is well defined even for $\beta=0$. As another example, the formula (23) in this case reduces to the identity

$$\frac{1}{n+1}\binom{(n+1)\alpha}{n}=\alpha\binom{n\alpha}{n-1}+\sum_{i=2}^{n}\frac{1}{(i-1)(n-i+1)}\binom{(i-1)\alpha}{i}\binom{(n-i+1)\alpha}{n-i},$$

which is similar to the Van der Corput identity; cf. [6, Eqn. 3.147].

2. Let

$$u=e^{\alpha t}, \quad \text{so } D^n u^m=m^n\alpha^n e^{\alpha t}.$$

Then (22) reduces to the identity

$$(n+k+l)^{n-1}=\sum_{i=0}^{n}\frac{kl}{k+l}\binom{n}{i}(i+k)^{i-1}(n-i+l)^{n-i-1}. \tag{25}$$

If we set $k=-x/z$, $l=-n-(y/z)$, we deduce

$$(x+y)^{n-1}=\sum_{i=0}^{n}\frac{x(y+nz)}{x+y+nz}\binom{n}{i}(x-iz)^{i-1}(y+iz)^{n-i-1}, \tag{26}$$

which is very similar to the Abel identity [3, p. 128],

$$(x+y)^n=\sum_{i=0}^{n}\binom{n}{i}x(x-iz)^{i-1}(y+iz)^{n-i}. \tag{27}$$

Indeed, they are essentially equivalent identities, since if we denote (27) by $A_n(x, y, z)$, and (26) by $B_{n-1}(x, y, z)$, then we easily verify the relation

$$A_n(x, y, z) + nzA_{n-1}(x, y, z) = B_n(x, y, z).$$

Consequently, we can use Theorem 4 to give yet another proof of the Abel identity.

3. Let

$$u = e^{-t^2}, \quad \text{so } D^n u^m = (-1)^n m^{n/2} H_n(\sqrt{m}\, t)\, e^{-mt^2},$$

where H_n denotes the usual Hermite polynomial [2, § 10.13]. In this case, (22) reduces to the identity

$$\begin{aligned}&(n+k+l)^{(n/2)-1}H_n(\sqrt{n+k+l}\, t)\\ &\quad = \sum_{i=0}^{n} \frac{kl}{k+l}\binom{n}{i}(i+k)^{(i/2)-1}(n-i+l)^{(n-i)/2-1}H_i(\sqrt{i+k}\, t)H_{n-i}(\sqrt{n-i+l}\, t),\end{aligned} \tag{28}$$

which we can interpret as an Abel-type identity for Hermite polynomials. It is not the same as the usual addition formula, since the arguments of the Hermite polynomials appearing in the summation depend on the summation index i. If either $n+k+l=0$, $i+k=0$, or $n-i+l=0$, then we view the corresponding term in (28) according to the rule

$$\lim_{m\to 0}(-1)^n m^{(n/2)-1}H_n(\sqrt{m}\, t) = \begin{cases} -2t, & n=1,\\ -2, & n=2,\\ 0, & n \geqq 3,\end{cases}$$

stemming from the rule (21).

4. Let

$$u = t^\alpha e^{-t}, \quad \text{so} \quad \frac{1}{n!}D^n u^m = t^{m\alpha-n}\, e^{-mt} L_n^{m\alpha-n}(mt),$$

where L_n^α are the generalized Laguerre polynomials [2, § 10.12]. Again (22) reduces to an Abel-type identity

$$\begin{aligned}&\frac{k+l}{n+k+l}L_n^{(n+k+l)\alpha-n}((n+k+l)t)\\ &\quad = \sum_{i=0}^{n}\frac{kl}{(i+k)(n-i+l)}L_i^{(i+k)\alpha-i}((i+k)t)L_{n-i}^{(n-i+l)\alpha-n+i}((n-i+l)t)\end{aligned} \tag{29}$$

for Laguerre polynomials. As in the previous example, we make the convention

$$\lim_{m\to 0}\frac{1}{m}L_n^{m\alpha-n}(mt) = \begin{cases}\alpha - t, & n=1,\\ [(-1)^{n-1}/n]\alpha, & n \geqq 2,\end{cases}$$

stemming from the rule (21), for any exceptional terms in (29).

5. Finally, consider the case

$$u = (1-t)^\alpha(1+t)^\beta.$$

Then

$$\frac{1}{n!}D^n u^m=(-2)^n(1-t)^{m\alpha-n}(1+t)^{m\beta-n}P_n^{(m\alpha-n,m\beta-n)}(t),$$

where $P_n^{(\alpha,\beta)}$ are the Jacobi polynomials [2, § 10.8]. In this case (22) reduces to the Hagen–Rothe type formula

$$\begin{aligned}&\frac{k+l}{n+k+l}P_n^{((n+k+l)\alpha-n,(n+k+l)\beta-n)}(t)\\ &=\sum_{i=0}^{n}\frac{kl}{(i+k)(n-i+l)}P_i^{((i+k)\alpha-i,(i+k)\beta-i)}(t)P_{n-i}^{((n-i+l)\alpha-n+i,(n-i+l)\beta-n+i)}(t),\end{aligned}\tag{30}$$

which again does not appear in the standard literature on Jacobi polynomials. Again, we need a rule

$$\lim_{m\to 0}\frac{1}{m}P_n^{(m\alpha-n,m\beta-n)}(t)=\frac{[\alpha(t+1)^n-\beta(t-1)^n]}{[n(-2)^n]},\qquad n\geqq 1,$$

for any exceptional terms in (30).

6. Bell polynomial identities. The Bell polynomials arise in the formula for the nth derivative of the composition of two functions [3], [10]. Specifically, we have

$$\frac{d^n}{dt^n}f\circ g=\sum_{i=1}^{n}(f^{(i)}\circ g)\cdot B_i^n(g),\tag{31}$$

where the B_i^n are polynomials in the derivatives $g^{(k)}$ of g. Thus, the above derivative identities can be rewritten as identities involving Bell polynomials. Surprisingly, these identities have not appeared in the literature.

First, according to (31) (see [10, Ex. 22, p. 46]),

$$\frac{d^n}{dt^n}u^m=\sum_{i=1}^{\min\{m,n\}}\frac{m!}{(m-i)!}u^{m-i}B_i^n(u).\tag{32}$$

Therefore, (19) can be rewritten as

$$\zeta(u)=u+\sum_{n=1}^{\infty}\sum_{i=1}^{n}\frac{z^n u^{n+1-i}}{(n+1-i)!}B_i^n(u).\tag{33}$$

Furthermore, according to (14), (19), for k a positive integer,

$$\zeta(u)^k=u^k+\sum_{n=1}^{\infty}\sum_{i=1}^{n}\frac{k(n+k-1)!}{n!(n+k-i)!}z^n u^{n+k-i}B_i^n(u).\tag{34}$$

For example, if $k=2$, then

$$\zeta(u)^2=u^2+\sum_{n=1}^{\infty}\sum_{i=1}^{n}\frac{2(n+1)}{(n+2-i)!}z^n u^{n+k-i}B_i^n(u).$$

If we compare this with the square of the series (33), we deduce that

$$\frac{2(n+1)}{(n+2-i)!}B_i^n(u)=\frac{2}{(n+1-i)!}B_i^n(u)+\sum_{\substack{p+q=n\\ r+s=i}}\frac{1}{(p+1-r)!(q+1-s)!}B_r^p(u)B_s^q(u),$$

which is equivalent to the identity

$$2(i-1)B_i^n(u)=\sum_{p,r}\binom{n+2-i}{p+1-r}B_r^p(u)B_{i-r}^{n-p}(u).\tag{35}$$

By way of contrast, consider the Bell polynomial identity coming from squaring the standard exponential series

$$e^{zu}=1+\sum_{n=1}^{\infty}\sum_{i=1}^{n}\frac{z^i t^n}{n!}B_i^n(u). \tag{36}$$

Equating $e^{2zu}=(e^{zu})^2$ and rearranging terms, we deduce

$$2(2^{i-1}-1)B_i^n(u)=\sum_{p,r}\binom{n}{p}B_r^p(u)B_{i-r}^{n-p}(u). \tag{37}$$

which is quite similar to (23), but, except in very special cases, a different identity. More generally, the equation $e^{(a+b)zu}=e^{azu}\,e^{bzu}$ leads to the further standard identities

$$((a+b)^i-a^i-b^i)B_i^n(u)=\sum_{p,r}\binom{n}{p}a^r b^{i-r}B_r^p(u)B_{i-r}^{n-p}(u), \tag{38}$$

valid for any a, b. On the other hand, the identity $\zeta(u)^{a+b}=\zeta(u)^a\zeta(u)^b$ leads to yet more complicated identities

$$\left[\frac{(a+b)(n+a+b-1)}{ab}-\frac{(n+a-1)\binom{n+a+b-i}{b}}{b\binom{n+a+b-i}{b}}-\frac{(n+b-1)\binom{n+a+b-i}{a}}{a\binom{n+a+b-i}{a}}\right]B_i^n(u)$$
$$=\sum_{p,r}\frac{\binom{n}{p}\binom{n+a+b-i}{p+a-r}}{\binom{n+a+b-2}{p+a-1}}B_r^p(u)B_{i-r}^{n-p}(u). \tag{39}$$

More identities can be constructed by using different functions $\Phi(u)$ in the fundamental theorem. The number of different identities satisfied by the Bell polynomials is remarkable!

Appendix: Alternative proof of the main theorem. An alternative proof of Theorem 4 is based on the properties of certain first-order partial differential operators or vector fields; cf. [8]. As such, this proof may be adapted to give an alternative proof of the Lagrange inversion formula. The mathematical methods have not been used in the subject before, and thus are of some interest, possibly being of use in other problems. Let

$$u=\sum_{n=0}^{\infty}u_n t^n$$

be a formal power series. We will also work with the associated formal series

$$v=\frac{1}{u}=\sum_{n=0}^{\infty}v_n t^n$$

and

$$w=\log\frac{u}{u_0}=\sum_{n=1}^{\infty}w_n t^n.$$

We will regard the coefficients of u and v, i.e., $u_0, u_1, u_2, \cdots$, and $v_0, v_1, v_2, \cdots$, as providing different local coordinates on the space of formal power series. They are connected by formulae of the form

$$u_n = R_n(v_0, v_1, \cdots, v_n), \qquad v_n = R_n(u_0, u_1, \cdots, u_n),$$

where the rational functions R_n can be explicitly expressed using determinants; cf. [10, Ex. 20, p. 45]. We can also use $u_0, w_1, w_2, \cdots$, as yet another set of coordinates, connected by formulae of the form

$$\text{(A1)} \qquad u_n = u_0 B_n(w_1, w_2, \cdots, w_n),$$

where B_n is a Bell polynomial coming from the relation $u = u_0\, e^w$. We now write out the basic series

$$\text{(A2)} \qquad \Psi(u) = D^{-1} :e^{zDu}: D\Phi(u) = \sum_{n=0}^{\infty} z^n \Psi_n,$$

where, according to (13),

$$\text{(A3)} \qquad \Psi_n = \frac{1}{n!} D^n \Xi_n(u)\bigg|_{t=0}, \qquad \Xi_n(u) = \int_0^u \tilde{u}^n \Phi'(\tilde{u})\, d\tilde{u}.$$

Note that we are using the identification between series coefficients and derivatives given in (8) in this formula. In particular, the coefficient Ψ_n depends on the first n coefficients $u_0, u_1, \cdots, u_n$ of u. We can also re-express Ψ_n in terms of the coefficients $v_0, v_1, \cdots, v_n$ of $v = 1/u$, or, alternatively, in terms of $u_0, w_1, w_2, \cdots, w_n$ using (A1). It will be very convenient to permit such changes of coordinates during the course of the proof.

The elementary first-order partial differential operators

$$\mathbf{u}_j = \frac{\partial}{\partial u_j}, \quad \mathbf{v}_j = \frac{\partial}{\partial v_j}, \quad \mathbf{w}_j = \frac{\partial}{\partial w_j},$$

will be regarded as vector fields acting on the functions of the coefficients of the formal power series u, and its associated power series $v = 1/u$, $w = \log(u/u_0)$. As such, they can all be re-expressed in any of our three coordinate systems. Note that

$$\text{(A4)} \qquad \mathbf{v}_j(u) = -\mathbf{v}_j\left(\frac{1}{v}\right) = -\frac{t^j}{v^2} = -t^j u^2, \qquad j = 0, 1, 2, \cdots,$$

$$\text{(A5)} \qquad \mathbf{w}_j(u) = \mathbf{w}_j(u_0\, e^w) = t^j u_0\, e^w = t^j u, \qquad j = 1, 2, 3, \cdots.$$

Using these and similar formulae, it is not too difficult to verify the following change of variables formulae for these vector fields:

$$\text{(A6)} \qquad \mathbf{v}_j = -\sum_{m,n=0}^{\infty} u_m u_n \frac{\partial}{\partial u_{m+n+j}} = -\sum_{n=0}^{\infty} u_n \frac{\partial}{\partial w_{n+j}}, \qquad j = 0, 1, 2, \cdots.$$

(In the second summation, we use (A1) to re-express the u's in terms of the w's.) Also

$$\text{(A7)} \qquad \mathbf{w}_j = \sum_{n=0}^{\infty} u_n \frac{\partial}{\partial u_{n+j}} = -\sum_{n=0}^{\infty} v_n \frac{\partial}{\partial v_{n+j}}, \qquad j = 1, 2, 3, \cdots.$$

Finally, we define the vector fields

$$\text{(A8)} \qquad \mathbf{y}_j = \mathbf{w}_j + z\mathbf{v}_{j-1}, \qquad j = 1, 2, 3, \cdots,$$

where z is a scalar parameter.

LEMMA A1. *The vector fields* $\mathbf{y}_j$ *all mutually commute*:

$$[\mathbf{y}_j, \mathbf{y}_k] = 0 \quad \textit{for all } j, k = 1, 2, 3, \cdots . \tag{A9}$$

The proof is simplest in the v coordinates. We just re-express $\mathbf{w}_j$ using the second formula in (A7), and do a simple direct computation.

LEMMA A2. *Let* $\Psi(u) = D^{-1} :e^{zDu}: D\Phi(u)$. *Then*

$$\mathbf{y}_j[\Psi(u)] = 0 \quad \textit{for all } j = 1, 2, 3, \cdots . \tag{A10}$$

Proof. Note that since we are now working with formal power series, the vector fields $\mathbf{v}_j, \mathbf{w}_j$ commute with the derivative operator $D = d/dt$. Using (A3), (A4), we compute

$$\begin{aligned}\mathbf{v}_j[\Psi(u)] &= \sum_{n=0}^{\infty} \frac{z^n}{n!} D^n \left\{ \frac{\partial \Xi_n(u)}{\partial u} \mathbf{v}_j(u) \right\} \bigg|_{t=0} \\ &= -\sum_{n=0}^{\infty} \frac{z^n}{n!} D^n \{ t^j u^{n+2} \Phi'(u) \} |_{t=0},\end{aligned}$$

whereas, using (A3), (A5), we find

$$\begin{aligned}\mathbf{w}_j[\Psi(u)] &= \sum_{n=0}^{\infty} \frac{z^n}{n!} D^n \left\{ \frac{\partial \Xi_n(u)}{\partial u} \mathbf{w}_j(u) \right\} \bigg|_{t=0} \\ &= \sum_{n=0}^{\infty} \frac{z^n}{n!} D^n \{ t^j u^{n+1} \Phi'(u) \} |_{t=0}.\end{aligned}$$

Note that

$$[D^n, t] = D^n \cdot t - t \cdot D^n = nD^{n-1};$$

hence, upon evaluation at $t = 0$,

$$D^n \cdot t|_{t=0} = nD^{n-1}|_{t=0}$$

Substituting this into the previous sum, we find (since $j \geqq 1$)

$$\begin{aligned}\mathbf{w}_j[\Psi(u)] &= \sum_{n=1}^{\infty} \frac{z^n}{(n-1)!} D^{n-1} \{ t^{j-1} u^{n+1} \Phi'(u) \} |_{t=0} \\ &= \sum_{n=0}^{\infty} \frac{z^{n+1}}{n!} D^n \{ t^{j-1} u^{n+2} \Phi'(u) \} |_{t=0}.\end{aligned}$$

Comparing with the previous summation, we deduce that

$$\mathbf{w}_j[\Psi(u)] = -z\mathbf{v}_{j-1}[\Psi(u)], \qquad j = 1, 2, 3, \cdots, \tag{A11}$$

which clearly implies the lemma.

If we write out the coefficient of z^n in the previous formula (A11), we find that

$$\mathbf{w}_j[\Psi_n(u)] = -\mathbf{v}_{j-1}[\Psi_{n-1}(u)], \qquad j, n = 1, 2, 3, \cdots . \tag{A12}$$

Since Ψ_n only depends on $u_0, u_1, \cdots, u_n$, only the first n of the equations in (A12) are nontrivial. We now regard (A12) as a system of first-order partial differential equations for the coefficients Ψ_n of the series (A2). The commutativity Lemma A1 will imply that the system is in involution in the sense of Frobenius [8], and hence can be uniquely solved using suitable initial data. In fact, since the w coordinates straighten out the vector fields $\mathbf{w}_j$, we can explicitly solve the system.

LEMMA A3. *Let Ψ_n, $n=0,1,2,\cdots$, be functions depending on the coefficients w_j of the formal series w which satisfy*

(i) $\Psi_n(u_0, w_1, w_2, \cdots, w_n)$ *depends only on the first n coefficients of w.*

(ii) $\Psi_n(u_0, 0, 0, \cdots, 0)=0$ *for $n>0$.*

(iii) $$\frac{\partial \Psi_n}{\partial w_j}=\mathbf{v}_{j-1}[\Psi_{n-1}], \qquad j=1,\cdots,n.$$

Then Ψ_n are uniquely determined by the function $\Psi_0(u_0)=\Phi(u_0)$.

Proof. According to Lemma A1, the integrability conditions for the elementary system of partial differential equations (iii) are satisfied. Therefore, the value of Ψ_n is uniquely determined by its noncharacteristic Cauchy data prescribed by condition (ii). This completes the proof.

Now, to complete the proof of Theorem 4, it suffices to notice that $\zeta(u)$, as defined by (A1), being a particular case of (A2), satisfies the three conditions of Lemma A3. But then the series $\Phi(\zeta(u))$ also satisfies them since, for example,

$$\mathbf{y}_j\Phi(\zeta(u))=\Phi'(\zeta(u))\mathbf{y}_j(\zeta(u))=0.$$

Also, the leading-order term of $\Phi(\zeta(u))$ is $\Phi(u_0)$, which agrees with that of $\Psi(u)$ as given by (A2). According to the uniqueness result in Lemma A3, the series must agree, i.e., $\Phi(\zeta(u))=\Psi(u)$. This completes the proof of the main theorem.

Acknowledgments. I would like to express my gratitude to two anonymous referees, one for observing how the main theorem easily follows from Lagrange inversion, and the other for encouraging me to investigate the consequences of the new derivative identities (22), (23) which are discussed in § 5.

AN ALGEBRAIC THEORY OF WAVELETS. I. OPERATIONAL CALCULUS AND COMPLEX STRUCTURE*

GERALD KAISER†

Abstract. In wavelet analysis, a function f is split into two parts at each iteration. The first part, Hf, represents a smoothed version of f, sampled half as frequently, while the second part, Gf, represents the detail lost by filtering through H. Although the operators H and G have very different interpretations, they exhibit a remarkable symmetry in their algebraic properties. We examine this symmetry by developing an effective, basis-independent operational calculus for wavelets and use it to show that the symmetry is due to the existence of a *complex structure*, i.e., a map J such that $J^2 = -I$ where I is the identity. This implies that the space V_α of (real) functions at the scale 2^α ($\alpha \in \mathbb{Z}$) may be regarded as a *complexification* $V_{\alpha+1}^c$ of the space $V_{\alpha+1}$ of functions at the next (coarser) scale. Roughly, the low-frequency parts Hf of the functions span the real part of $V_{\alpha+1}^c$ while their high-frequency parts Gf span the imaginary part. The map J mediates between the two and relates the corresponding operators H and G. Furthermore, at the scale $\alpha = -1$, J transforms the fundamental function ϕ associated with H into the "fundamental wavelet" ψ associated with G.

AMS(MOS) subject classifications. 16, 20, 41, 42

1. Operational calculus. In wavelet analysis (see Daubechies [1988], Mallat [1989], Meyer [1990], Strang [1990], and the references therein), one deals with the representation of a function ("signal") at different scales. We begin with a single real-valued function ϕ of one real variable which we take, for simplicity, to be continuous with compact support. It is assumed that for some $T > 0$, the translates $\phi_n(t) \equiv \phi(t - nT)$, $n \in \mathbb{Z}$, form an orthonormal set in $L^2(\mathbb{R})$ (such functions can be easily constructed). The closure of the span of the vectors ϕ_n in $L^2(\mathbb{R})$ forms a subspace V which can be identified with $\ell^2(\mathbb{Z})$, since for a real sequence $u \equiv \{u_n\}$ we have

$$\left\| \sum_n u_n \phi_n \right\|^2 = \sum_n u_n^2. \tag{1}$$

We introduce the shift operator

$$(Sf)(t) \equiv f(t - T), \tag{2}$$

which leaves V invariant and is an orthogonal operator on $L^2(\mathbb{R})$ (we shall be dealing with *real* spaces, unless otherwise stated). A general element of V can be written uniquely as

$$\sum_n u_n S^n \phi \equiv u(S)\phi, \tag{3}$$

*Received by the editors May 7, 1990; accepted for publication (in revised form) January 28, 1991.

†Mathematics Department, University of Massachusetts at Lowell, Lowell, Massachusetts 01854.

where $u(e^{i\xi T})$ is the square-integrable function on the unit circle ($|\xi| \leq \pi/T$) having $\{u_n\}$ as its Fourier coefficients and $u(S)$ is defined as an operator on "nice" functions (e.g., Schwartz test functions) $f(t)$ through the Fourier transform, i.e.,

$$[u(S)f]\,\hat{}(\xi) \equiv u(e^{i\xi T})\hat{f}(\xi). \tag{4}$$

For the purpose of developing our operational calculus, we shall consider operators $u(S)$ which are *polynomials* in S and S^{-1}. These form an abelian algebra $\mathcal{P}$ of operators on V. Moreover, it will suffice to restrict our attention to the dense subspace of finite combinations in V, i.e., to $\mathcal{P}\phi$, since our goal here is to produce an L^2 theory and this can be achieved by developing the algebraic (finite) theory and then completing in the L^2 norm. Note that the independence of the vectors ϕ_n means that $u(S)\phi = 0$ implies $u(S) = 0$. Our results could actually be extended to operators $u(S)$ with $\{u_n\} \in \ell^1(\mathbb{Z}) \subset \ell^2(\mathbb{Z})$, which also form an algebra since the product $u(S^{-1})w(S)$ corresponds to the convolution of the sequences $\{u_n\}$ and $\{w_n\}$. We resist the temptation.

Let us stop for a moment to discuss the "signal-processing" interpretation of $u(S)\phi$, since that is one of the motivations behind wavelet theory. It is natural to think of $u(S)\phi$ as an approximation to a function ("signal") $f(t)$ obtained by sampling f only at $t_n = nT$. Let f_0 denote the *band-limited* function obtained from f by cutting off all frequencies ξ with $|\xi| > \pi/T$. That is, $\hat{f}_0$ coincides with $\hat{f}$ for $|\xi| \leq \pi/T$ but vanishes outside this interval. The value of f_0 at t_n is then

$$f_0(nT) = \frac{1}{2\pi}\int_{-\pi/T}^{\pi/T} d\xi e^{-i\xi nT}\hat{f}(\xi), \tag{5}$$

which is just the Fourier coefficient of the periodic function

$$\hat{F}_0(\xi) \equiv \sum_n T f_0(nT)e^{i\xi nT} \tag{6}$$

obtained from $\hat{f}_0(\xi)$ by identifying $\xi + 2\pi/T$ with ξ. In the time domain,

$$F_0(t) = \sum_n T f_0(nT)\,\delta(t - nT). \tag{7}$$

This has the same form as $u(S)\phi$, if we set $u_n = Tf_0(nT)$ and $\phi(t) = \delta(t)$ where δ is the Dirac distribution. Hence the usual sampling theory may be regarded as the singular case $\phi = \delta$, and then $u(S)\phi$ characterizes the band-limited approximation f_0 of f. For square-integrable ϕ, the samples u_n are no longer the values at the sharp times t_n but are *smeared* over ϕ_n, since $u_n = \langle \phi_n, u(S)\phi \rangle$. In fact, ϕ acts as a *filter,* i.e., as a convolution operator, since $(u(S)\phi)\hat{}(\xi) = u(e^{i\xi T})\hat{\phi}(\xi)$. Roughly speaking, we may think of ϕ as giving the shape of a *pixel.*

Next, a scaled family of spaces $V_\alpha, \alpha \in \mathbb{Z}$, is constructed from V as follows. The dilation operator D, defined by

$$(Df)(t) = 2^{-1/2}f(t/2), \tag{8}$$

is orthogonal on $L^2(\mathbb{R})$. It stretches a function by a factor of 2 without altering its norm and is related to S by the commutation rules

$$(9) \qquad DS = S^2 D, \qquad D^{-1}S^2 = SD^{-1}.$$

Hence D "squares" S while D^{-1} takes its "square root." A repeated application of the above gives

$$(10) \qquad D^\alpha S = S^{2^\alpha} D^\alpha, \qquad \alpha \in \mathbb{Z}.$$

Define the spaces

$$(11) \qquad V_\alpha = D^\alpha V,$$

which are closed in $L^2(\mathbb{R})$ ($V_0 \equiv V$). An orthonormal basis for V_α is given by

$$(12) \qquad \phi_n^\alpha(t) \equiv D^\alpha S^n \phi(t) = 2^{-\alpha/2}\phi\left(2^{-\alpha}t - nT\right),$$

and V_α can also be identified with $\ell^2(\mathbb{Z})$. The motivation is that V_α will consist of functions containing detail only up to the scale of 2^α, which correspond to sequences $\{u_n^\alpha\}$ in $\ell^2(\mathbb{Z})$ representing samples at $t_n = 2^\alpha nT$. For this to work, we must have $V_{\alpha+1} \subset V_\alpha$ for all α. A *necessary* condition for this is that ϕ must satisfy a functional equation (taking $\alpha = -1$) of the form

$$(13) \qquad \phi = \sum_n h_n \phi_n^{-1} = D^{-1}\sum_n h_n S^n \phi \equiv D^{-1}h(S)\phi$$

for some (unique) set of coefficients h_n. Since we assume that ϕ has compact support, it follows that all but a finite number of the coefficients h_n vanish, so $h(S)$ is a polynomial in S and S^{-1}, i.e., $h(S) \in \mathcal{P}$. This operator *averages,* while D^{-1} *compresses.* Hence ϕ is a fixed point of this dual action of spreading and compression. $D\phi = h(S)\phi$, called a *dilation equation,* states that the dilated pixel $D\phi$ is a linear combination of undilated pixels ϕ_n. An integration with respect to t leads to

$$(14) \qquad \sum_n h_n = \sqrt{2} \quad \text{or} \quad h(I) = \sqrt{2}I,$$

giving a constraint on the coefficiants h_n (other constraints will emerge). Note that the singular case $\phi = \delta$ associated with sharp sampling satisfies the dilation equation with $h(S) = \sqrt{2}I$, where I denotes the identity operator on V. Since δ is not square-integrable, this solution does not fit into the L^2 theory considered here.

On the other hand, the coefficients h_n uniquely determine ϕ, up to a sign. For if we iterate $D^{-1}h(S) = h(S^{1/2})D^{-1}$, we obtain

$$(15) \qquad \phi = \left[D^{-1}h(S)\right]^N \phi = \prod_{\alpha=1}^{N} h\left(S^{2^{-\alpha}}\right) D^{-N}\phi.$$

Since the Fourier transform of $D^{-N}\phi$ satisfies

$$2^{N/2}(D^{-N}\phi)^{\wedge}(\xi) = \hat{\phi}(2^{-N}\xi) \to \hat{\phi}(0) \text{ as } N \to \infty, \tag{16}$$

we formally obtain

$$\phi = \hat{\phi}(0) \lim_{N\to\infty} \prod_{\alpha=1}^{N} \left[2^{-1/2} h\left(S^{2^{-\alpha}}\right)\right] \delta. \tag{17}$$

The normalization is determined up to a sign by $\|\phi\| = 1$. In general, the function ϕ determined by $h(S)$ is highly irregular. Daubechies [1988] has classified all $h(S) \in \mathcal{P}$ that give functions ϕ possessing some regularity. The simplest (and least regular) of these is related to the classical Haar basis. It will be used throughout the paper to illustrate the various operators as they are introduced. For the general case, the actions of these operators on bases are given in the appendix.

Example 1 (The Haar system). Let ϕ be the indicator function $\chi_{[0,1)}$ for the interval $[0, 1)$. Then

$$\begin{aligned} D\phi &= \frac{1}{\sqrt{2}}\chi_{[0,2)} = \frac{1}{\sqrt{2}}\left(\chi_{[0,1)} + \chi_{[1,2)}\right) \\ &= \frac{1}{\sqrt{2}}(I+S)\,\phi; \end{aligned} \tag{18}$$

hence ϕ satisfies the dilation equation with $h(S) = (I + S)/\sqrt{2}$.

The next step is to introduce a "multiscale analysis" based on the sequence of spaces V_α. We shall do this in a basis-independent fashion. Since shifts and dilations are related by $DS = S^2 D$, we have

$$D^{\alpha+1}u(S)\phi = D^{\alpha}u(S^2)D\phi = D^{\alpha}u(S^2)h(S)\phi. \tag{19}$$

This defines a map H_α^*: $V_{\alpha+1} \to V_\alpha$, given by

$$H_\alpha^* D^{\alpha+1}u(S)\phi = D^{\alpha}h(S)\,u(S^2)\phi. \tag{20}$$

Since the two sides of this equation are actually *identical* as functions or elements of $L^2(\mathbb{R})$, H_α^* is simply the *inclusion map* which establishes $V_{\alpha+1} \subset V_\alpha$. This shows that the relation $D\phi = h(S)\phi$ is not only necessary but also *sufficient* for $V_{\alpha+1} \subset V_\alpha$. Although a vector in $V_{\alpha+1}$ is identical with its image under H_α^* as an element of $L^2(\mathbb{R})$, it is useful to distinguish between them since this permits us to use operator theory to define other useful maps, such as the adjoint H_α: $V_\alpha \to V_{\alpha+1}$ of H_α^*. Since the norm on V_α is that of $L^2(\mathbb{R})$ and H_α^* is an inclusion, it follows that $H_\alpha H_\alpha^* = I_{\alpha+1}$, the identity on $V_{\alpha+1}$. In particular, H_α is *onto*; it is just the orthogonal projection from V_α to $V_{\alpha+1}$. H_α^* is interpreted as an operator that *interpolates* a vector in $V_{\alpha+1}$, representing it as the vector in V_α obtained by replacing the "pixel" ϕ with the linear combination of compressed pixels $D^{-1}h(S)\phi$. The adjoint H_α is sometimes called a "low-pass filter" because it *smooths out* the signal and resamples it at half the sampling rate, thus cutting the freqency range in half. However, it is *not* a filter in the traditional sense since it is not a convolution operator, as will be seen below. The kernel of H_α is denoted by $W_{\alpha+1}$. It is the orthogonal complement of the image of H_α^*, i.e., of $V_{\alpha+1}$, in V_α:

$$W_{\alpha+1} \equiv \ker H_\alpha = V_\alpha \ominus H_\alpha^* V_{\alpha+1} = V_\alpha \ominus V_{\alpha+1}. \tag{21}$$

Note that H_α^* is "natural" with respect to the scale gradation, i.e.,

$$H_\alpha^* D^{\alpha+1} = D^\alpha H_0^* D. \tag{22}$$

Our "home space" will be V. All our operators will enjoy the above naturality with respect to scale. Because of this property, it will generally be sufficient to work in V. Define the operator H^*: $V \to V$ by

$$H^* = H_0^* D. \tag{23}$$

We will refer to H^* as the "home version" of H_α^*. Home versions of operators will generally be denoted without subscripts. Note that while H_α^* preserves the scale (it is an inclusion map!), H^* involves a change in scale. It consists of a dilation (which spreads the sample points apart to a distance $2T$) followed by an interpolation (which restores the sampling interval to its original value T). Thus H^* is a *zoom-in operator*! Its adjoint

$$H = D^{-1} H_0 \tag{24}$$

consists of a "filtration" by H_0 (which cuts the density of sample points by a factor of 2 without changing the scale) followed by a compression (which restores it to its previous value). H is, therefore, a *zoom-out operator.* It is related to H_α by

$$H_\alpha D^\alpha = D^{\alpha+1} H. \tag{25}$$

The filtration performed by H (which will be detailed below) represents the (possible) loss of information due to zooming out.

The operators H and H^* are essentially identical with those used by Daubechies, except for the fact that hers act on the sequences $\{u_n\}$ rather than the functions $u(S)\phi$. They are especially useful when considering iterated decomposition and reconstruction algorithms (§3).

To find the action of H_α, it suffices to find the action of H. Note that $H^* u(S)\phi = h(S)u(S^2)\phi$, where $u(S^2)$ is *even* in S. This will be an important observation in what follows, hence we first study the decomposition of V into its even and odd subspaces.

An arbitary polynomial $u(S)$ in S, S^{-1} can be written uniquely as the sum of its even and odd parts,

$$\begin{aligned} u(S) &= \sum_n u_{2n} S^{2n} + \sum_n u_{2n+1} S^{2n+1} \\ &\equiv u_+(S^2) + S u_-(S^2). \end{aligned} \tag{26}$$

Define the operator E^* (for *even*) on V by

$$E^* S = S^2 E^*, \qquad E^* \phi = \phi. \tag{27}$$

Then

$$E^*u(S)\phi = u(S^2)\phi = \sum_n u_n\phi_{2n}. \tag{28}$$

Also define the operator O^* (for *odd*) by $O^* = SE^*$, so that

$$O^*u(S)\phi = Su(S^2)\phi = \sum_n u_n\phi_{2n+1}. \tag{29}$$

H^* is related to E^* by $H^* = h(S)E^*$. Hence to obtain H it suffices to find the adjoint E of E^*.

LEMMA 1. *Let $v(S) \in \mathcal{P}$ and denote the adjoints of E^* and O^* by E and O. Then*

(a)

$$\begin{aligned} EE^* &= OO^* = I, \\ OE^* &= EO^* = 0, \end{aligned} \tag{30}$$

(b)

$$\begin{aligned} Ev(S)\phi &= v_+(S)\phi = \sum_n v_{2n}\phi_n \\ Ov(S)\phi &= v_-(S)\phi = \sum_n v_{2n+1}\phi_n, \end{aligned} \tag{31}$$

(c)

$$\begin{aligned} Ev(S)E^* &= v_+(S) = \tfrac{1}{2}D^{-1}\left[v(S) + v(-S)\right] D, \\ Ov(S)O^* &= v_+(S), \\ Ov(S)E^* &= v_-(S) = \tfrac{1}{2}D^{-1}S^{-1}\left[v(S) - v(-S)\right] D \\ Ev(S)O^* &= Sv_-(S) \end{aligned} \tag{32}$$

(*note that* (a) *is a special case with* $v(S) = I$), *and*

(d)

$$E^*E + O^*O = I. \tag{33}$$

Proof. For $u(S), v(S) \in \mathcal{P}$, we have

$$\begin{aligned} \langle EE^*u(S)\phi, v(S)\phi \rangle &= \langle E^*u(S)\phi, E^*v(S)\phi \rangle \\ &= \langle u(S^2)\phi, v(S^2)\phi \rangle = \langle u(S)\phi, v(S)\phi \rangle, \end{aligned} \tag{34}$$

where the last equality follows from the invariance of the inner product under $S \mapsto S^2$, i.e.,

$$\langle S^{2n}\phi, S^{2m}\phi \rangle = \delta_{nm} = \langle S^n\phi, S^m\phi \rangle. \tag{35}$$

Hence $EE^* = I$, so $OO^* = ES^{-1}SE^* = I$. $EO^* = OE^* = 0$ follows from the orthogonality of even and odd functions of S (applied to ϕ). This proves (a). To show (b), note that due to the orthogonality of even and odd functions,

$$\begin{aligned} \langle E^*u(S)\phi, v(S)\phi \rangle &= \langle u(S^2)\phi, v(S)\phi \rangle = \langle u(S^2)\phi, v_+(S^2)\phi \rangle \\ &= \langle E^*u(S)\phi, E^*v_+(S)\phi \rangle = \langle u(S)\phi, v_+(S)\phi \rangle, \end{aligned} \tag{36}$$

where we have used (a). This proves the first equation in (b). The second follows from $O = ES^{-1}$ and $S^{-1}v(S) = v_-(S^2) + S^{-1}v_+(S^2)$. To prove (c), note that $u(S^2)E^* = E^*u(S)$ and $Su(S^2)E^* = O^*u(S)$; hence

$$\begin{aligned} Ev(S)E^* &= E(v_+(S^2) + Sv_-(S^2))E^* \\ &= EE^*v_+(S) + EO^*v_-(S) = v_+(S), \\ Ov(S)O^* &= ES^{-1}v(S)SE^* = v_+(S), \\ Ov(S)E^* &= O(v_+(S^2) + Sv_-(S^2))E^* \\ &= OE^*v_+(S) + EE^*v_-(S) = v_-(S), \\ Ev(S)O^* &= E(v_+(S^2) + Sv_-(S^2))SE^* \\ &= EO^*v_+(S) + EE^*Sv_-(S) = Sv_-(S). \end{aligned} \tag{37}$$

Lastly, (d) follows from

$$\begin{aligned} E^*Ev(S)\phi + O^*Ov(S)\phi &= E^*v_+(S)\phi + O^*v_-(S)\phi \\ &= v_+(S^2)\phi + Sv_-(S^2)\phi = v(S)\phi. \end{aligned} \tag{38}$$ □

Remark. The algebraic structure above is characteristic of orthogonal decompositions and will be met again in our discussion of low- and high-frequency filters. E^*E and O^*O are the projection operators to the subspaces of even and odd functions of S (applied to ϕ),

$$V^e \equiv \overline{\{v(S^2)\phi \mid v(S) \in \mathcal{P}\}}, \qquad V^o \equiv \overline{\{Sv(S^2)\phi \mid v(S) \in \mathcal{P}\}}, \tag{39}$$

and

$$V = V^e \oplus V^o. \tag{40}$$

This decomposition will play an important role in the sequel.

PROPOSITION 2. *The maps* $H\colon V \to V$ *and* $H_\alpha\colon V_\alpha \to V_{\alpha+1}$ *are given by*

$$\begin{aligned} Hu(S)\phi &= Eh(S^{-1})u(S)\phi \\ &= [h_+(S^{-1})u_+(S) + h_-(S^{-1})u_-(S)]\,\phi, \\ H_\alpha D^\alpha u(S)\phi &= D^{\alpha+1}E\,h(S^{-1})u(S)\phi \\ &= D^{\alpha+1}\,[h_+(S^{-1})u_+(S) + h_-(S^{-1})u_-(S)]\,\phi. \end{aligned} \tag{41}$$

Proof. Since $H^* = h(S)\,E^*$, it follows that $H = E\,h(S^{-1})$ and $H_\alpha D^\alpha = D^{\alpha+1}H = D^{\alpha+1}Eh(S^{-1})$. □

Example 2 (The Haar system, continued). For $h(S) = (I + S)/\sqrt{2}$ and $\phi = \chi_{[0,1)}$, we have $h_+(S) = h_-(S) = 1/\sqrt{2}$. Hence

$$\begin{aligned} H^*\phi_n &= h(S)\,\phi_{2n} = \frac{1}{\sqrt{2}}\,(\phi_{2n} + \phi_{2n+1}) \\ H\phi_n &= \frac{1}{\sqrt{2}}E\,(I + S^{-1})\;S^n\phi = \frac{1}{\sqrt{2}}E\,(S^n + S^{n-1})\,\phi \\ &= \frac{1}{\sqrt{2}}\begin{cases} S^{n/2}\,\phi, & n \text{ even}, \\ S^{(n-1)/2}\,\phi, & n \text{ odd} \end{cases} \\ &= \frac{1}{\sqrt{2}}\,\phi_{[n/2]}. \end{aligned} \tag{42}$$

2. Complex structure. Up to this point, it could be argued, nothing extraordinary has happened. We have a filter which, when applied repeatedly, gives rise to a nested sequence of subspaces V_α. However, the next step is quite surprising and underlies much of the interest wavelets have generated. It is desirable to record the information lost at each stage of filtering, i.e., that part of the signal residing in the orthogonal complement $W_{\alpha+1}$ of $V_{\alpha+1}$ in V_α. The orthogonal decomposition $V_\alpha = V_{\alpha+1} \oplus W_{\alpha+1}$ is described by filters H_α and G_α, where H_α is as above and G_α extracts high-frequency information. For this reason, H_α and G_α obey a set of algebraic relations similar to those satisfied by E and O above. What is quite remarkable is that there exists a vector ψ in V_{-1} that is related to the spaces W_α and the maps G_α in a way almost totally symmetric to the way ϕ is related to V_α and H_α. This is *not* merely a consequence of the orthogonal decomposition but is somehow related to the fact that $V_{\alpha+1}$ is "half" of V_α, due to the doubling of the sampling interval upon dilation, as expressed by the commutation relation $DS = S^2D$. However, the precise reason for this symmetry has not been entirely clear. The usual constructions are somewhat involved and do not appear to shed much light on this question. It was this puzzle which motivated the present work. As an answer, we propose the following new construction. Begin by defining a *complex structure* on V, i.e., a map $J\colon V \to V$ such that $J^2 = -I$. (To illustrate this concept, consider the complex plane $\mathbb{C}$ as the real space $\mathbb{R}^2$. Then multiplication by the unit imaginary i is represented by a real 2×2 matrix whose square is $-I$.) J is defined by giving its commutation rule with respect to the shift and its action on ϕ:

$$JS = -S^{-1}J, \qquad J\phi = \varepsilon(S)\,\phi, \tag{43}$$

where $\varepsilon(S)$ is an as yet undetermined function. It follows that for $u(S) \in \mathcal{P}$,

$$Ju(S)\phi = \varepsilon(S)u(-S^{-1})\phi. \tag{44}$$

We further require that J preserve the inner product, i.e., that $J^*J = I$. Combined with $J^2 = -I$, this gives $J^* = -J$. That is, J will behave like multiplication by i also with respect to the inner product, giving it an interpretation as a *Hermitian* inner product.

In order to study J, we first define two simpler operators C and M as follows.

$$\begin{aligned} CS &= S^{-1}C, \qquad & C\phi &= \phi, \\ MS &= -SM, \qquad & M\phi &= \phi. \end{aligned} \tag{45}$$

Note that $CM = MC$ and that $C^* = C$ and $M^* = M$, since

$$\begin{aligned} \langle Cu(S)\phi, v(S)\phi \rangle &= \langle u(S^{-1})\phi, v(S)\phi \rangle = \langle v(S)\phi, u(S^{-1})\phi \rangle \\ &= \langle u(S)\phi, v(S^{-1})\phi \rangle = \langle u(S)\phi, Cv(S)\phi \rangle, \end{aligned} \tag{46}$$

where we have used the symmetry of the inner product and $u(S)^* = u(S^{-1})$ (both of which depend on the reality of V), and

$$\begin{aligned} \langle Mu(S)\phi, v(S)\phi \rangle &= \langle u(-S)\phi, v(S)\phi \rangle = \langle u(S)\phi, v(-S)\phi \rangle \\ &= \langle u(S)\phi, Mv(S)\phi \rangle, \end{aligned} \tag{47}$$

where the invariance of the inner product under $S \mapsto -S$ was used. ($C^* = C$ could have been proved more simply by noting that the inner product is invariant under

$S \mapsto S^{-1}$, which follows from the orthogonality of the ϕ_n's; however, this orthogonality does not appear to be a fundamental feature of the theory, so we avoid it whenever possible.) Since C and M are also involutions, i.e.,

$$C^2 = M^2 = I, \tag{48}$$

it follows that they are orthogonal operators. Hence they represent *symmetries,* which makes them important in themselves, especially in the abstract context where we begin with an algebra and constructs a representation (see the remark at the end of §3). In fact, the orthogonal decomposition $V = V^e \oplus V^o$ is nothing but the spectral decomposition associated with M, since V^e and V^o are the eigenspaces of M with eigenvalues 1 and -1, respectively. C has a simple interpretation as a *conjugation operator,* since for $u(S) \in \mathcal{P}$,

$$Cu(S)C = u(S^{-1}) = u(S)^*. \tag{49}$$

In terms of C and M,

$$J = \varepsilon(S)CM. \tag{40}$$

PROPOSITION 3. *The conditions $J^* = -J$ and $J^2 = -I$ hold if and only if $\varepsilon(S)$ satisfies*

$$\varepsilon(-S) = -\varepsilon(S), \qquad \varepsilon(S^{-1})\varepsilon(S) = 1. \tag{51}$$

Proof. We have

$$J^* = MC\varepsilon(S^{-1}) = M\varepsilon(S)C = \varepsilon(-S)MC = \varepsilon(-S)CM; \tag{52}$$

hence $J^* = -J$ if and only if $\varepsilon(-S) = -\varepsilon(S)$. Assume this to be the case. Then

$$J^2 = \varepsilon(S)CM\varepsilon(S)CM = \varepsilon(S)\varepsilon(-S^{-1}) = -\varepsilon(S)\varepsilon(S^{-1}); \tag{53}$$

hence $J^2 = -I$ if and only if $\varepsilon(S^{-1})\varepsilon(S) = I$. □

Remarks. (1) J is determined only up to the orthogonal mapping $\varepsilon(S)$. This corresponds to a similar freedom in the standard approach to wavelet theory, where a factor $e^{i\lambda(\xi)}$ in Fourier space relates the functions $H(\xi)$ and $G(\xi)$ associated with the operators H and G (Daubechies [1988, p. 943], where $T = 1$). The relation between $\varepsilon(S)$ and $\lambda(\xi)$ is given in the Appendix.

(2) The simplest examples of a complex structure are given by choosing

$$\varepsilon(S) = \pm S^{2p+1}, \qquad p \in \mathbb{Z}. \tag{54}$$

More interesting examples can be obtained by enlarging $\mathcal{P}$ to a topological algebra, for example, allowing $u(S)$ with $\{u_n\} \in \ell^1(\mathbb{Z})$.

(3) The above proof used the symmetry of the inner product. Later we shall complexify our spaces and the inner product becomes Hermitian. However, this proof easily extends to the complex case (when transposing, also take the complex conjugate). C then becomes $\mathbb{C}$-*antilinear* and is interpreted as Hermitian conjugation.

At an arbitrary scale α, define maps $J_\alpha: V_\alpha \to V_\alpha$ by naturality, i.e.,

$$J_\alpha D^\alpha = D^\alpha J, \tag{55}$$

which implies that $J_\alpha^2 = -I_\alpha$ and $J_\alpha^* = -J_\alpha$. J_α is related to S by

$$\begin{aligned} S^{2^\alpha} J_\alpha D^\alpha &= S^{2^\alpha} D^\alpha J = D^\alpha SJ = -D^\alpha JS^{-1} \\ &= -J_\alpha D^\alpha S^{-1} = -J_\alpha S^{-2^\alpha} D^\alpha, \end{aligned} \tag{56}$$

showing that

$$S^{2^\alpha} J_\alpha = -J_\alpha S^{-2^\alpha}. \tag{57}$$

In particular, note that $S^{1/2}J_{-1} = -J_{-1}S^{-1/2}$; hence

$$SJ_{-1} = +J_{-1}S^{-1}. \tag{58}$$

We are now in a position to construct the basic wavelet ψ, the spaces W_α and an appropriate set of high-frequency filters in a way that will make the symmetry with ϕ, V_α, and H_α quite clear. Consider the *restriction* of J_α to the subspace $V_{\alpha+1}$ of V_α, i.e., the map K_α^*: $V_{\alpha+1} \to V_\alpha$ defined by

$$K_\alpha^* = J_\alpha H_\alpha^*. \tag{59}$$

K_α^* is natural with respect to the scale gradation, and its home version will, as usual, be denoted by $K^* \equiv K_0^* D = JH^*$. It will turn out that its adjoint K is essentially equivalent to the usual filter G (to be introduced below) but is more natural from the point of view of the complex structure. Define the vector $\psi \in V_{-1}$ by

$$\psi = K_{-1}^*\phi = J_{-1}D^{-1}h(S)\phi = D^{-1}Jh(S)\phi \equiv D^{-1}g(S)\phi, \tag{60}$$

where the function

$$g(S) = \varepsilon(S)h(-S^{-1}) \tag{61}$$

will play a similar role for the high-frequency components as does $h(S)$ for the low-frequency components. Namely, $g(S)$ is a "differencing operator," just as $h(S)$ is an averaging operator. (We will see below that for the Haar system, $g(S) = (I - S)/\sqrt{2}$.) For $w(S) \in \mathcal{P}$, we have

$$\begin{aligned} K^*w(S)\phi &= JH^*w(S)\phi = Jh(S)w(S^2)\phi \\ &= g(S)w(S^{-2})\phi = g(S)E^*Cw(S)\phi; \end{aligned} \tag{62}$$

hence

$$K^* = g(S)E^*C = g(S)CE^*. \tag{63}$$

PROPOSITION 4. *The adjoints of K^* and K_α^* are given by*

$$\begin{aligned} Kv(S)\phi &= ECg(S^{-1})v(S)\phi = Ev(S^{-1})D\psi, \\ K_\alpha D^\alpha v(S)\phi &= D^{\alpha+1}ECg(S^{-1})v(S)\phi = D^{\alpha+1}Ev(S^{-1})D\psi. \end{aligned} \tag{64}$$

Proof. Since $K = ECg(S^{-1})$ and $K_\alpha D^\alpha = D^{\alpha+1}K$, we have

$$Kv(S)\phi = ECg(S^{-1})v(S)\phi = Eg(S)v(S^{-1})\phi = Ev(S^{-1})D\psi \tag{65}$$

and

$$K_\alpha D^\alpha v(S)\phi = D^{\alpha+1}Eg(S^{-1})v(S)\phi = D^{\alpha+1}Ev(S^{-1})D\psi. \quad \square \tag{66}$$

Example 3 (The Haar system, continued). Returning to $h(S) = (I+S)/\sqrt{2}$ and choosing $\varepsilon(S) = -S$, we have

$$\begin{aligned}
J\,\phi_n &= -S\,(-S^{-1})^n\,\phi = (-1)^{1-n}\,\phi_{1-n},\\
g(S) &= -S\,\frac{1}{\sqrt{2}}\,(I - S^{-1}) = \frac{1}{\sqrt{2}}\,(I - S),\\
\psi &= D^{-1}\frac{1}{\sqrt{2}}(I - S)\,\phi = \frac{1}{\sqrt{2}}\left(\chi_{[0,1/2)} - \chi_{[1/2,1)}\right),\\
K^*\,\phi_n &= JH^*\,\phi_n = \frac{1}{\sqrt{2}}\,J\,(\phi_{2n} + \phi_{2n+1})\\
&= \frac{1}{\sqrt{2}}\,(\phi_{-2n} - \phi_{1-2n}),\\
K\,\phi_n &= E\,S^{-n}\,D\psi = \frac{1}{\sqrt{2}}\,E\,S^{-n}\,(I - S)\,\phi\\
&= \frac{1}{\sqrt{2}}\,E\,(S^{-n} - S^{1-n})\,\phi\\
&= \frac{1}{\sqrt{2}}\begin{cases} S^{-n/2}\,\phi, & n \text{ even},\\ S^{(1-n)/2}\,\phi, & n \text{ odd}\end{cases}\\
&= \frac{(-1)^n}{\sqrt{2}}\,\phi_{-[n/2]}.
\end{aligned} \tag{67}$$

It can be easily checked that the functions $\psi_n^\alpha \equiv D^\alpha S^n \psi$ $(\alpha, n \in \mathbb{Z})$ are mutually orthogonal. They form the *Haar basis* of $L^2(\mathbb{R})$.

Note. The "time-reversal" associated with K and K^* (i.e., $n \to -n$) is due to the presence of C in J. It is harmless, since ultimately it is only KK^* and K^*K that count. However, it can be removed by replacing K_α^* and K^* by

$$\begin{aligned}
K_\alpha'^* &\equiv J_\alpha H_\alpha^* C = K_\alpha^* C,\\
K'^* &\equiv K_0'^* D = K^* C.
\end{aligned} \tag{68}$$

For then

$$\begin{aligned}
K'K'^* &= I, &\quad K'^*K' &= K^*K,\\
K'H^* &= 0, &\quad HK'^* &= 0,
\end{aligned} \tag{69}$$

with similar formulas for H_α and K_α'. Hence H and K' lead to an orthogonal decomposition of V equivalent to that given by H and K. Furthermore, K' does not reverse time. For the Haar system,

$$\begin{aligned}
K'^*\phi_n &= K^*C\phi_n = K^*\phi_{-n} = \frac{1}{\sqrt{2}}\,(\phi_{2n} - \phi_{2n+1}),\\
K'\phi_n &= CK\phi_n = \frac{(-1)^n}{\sqrt{2}} C\,\phi_{-[n/2]}\\
&= \frac{(-1)^n}{\sqrt{2}}\,\phi_{[n/2]}.
\end{aligned} \tag{70}$$

We prefer K_α and K because they are "cleaner" with respect to the complex structure. For example, the complex decomposition and reconstruction algorithm given in §3 is less natural if K'_α and K' are used.

PROPOSITION 5. *The pairs of operators* $\{H, K\}$ *and* $\{H_\alpha, K_\alpha\}$ *satisfy*

$$\begin{aligned} HH^* &= Eh(S^{-1})h(S)E^* = I, \\ KK^* &= Eg(S^{-1})g(S)E^* = I, \\ HK^* &= Eh(S^{-1})g(S)E^*C = 0, \\ KH^* &= CEg(S^{-1})h(S)E^* = 0. \end{aligned} \tag{71}$$

and

$$H_\alpha H_\alpha^* = K_\alpha K_\alpha^* = I_{\alpha+1}, \qquad H_\alpha K_\alpha^* = K_\alpha H_\alpha^* = 0. \tag{72}$$

Proof. (Note that $H_\alpha H_\alpha^* = I_{\alpha+1}$ has already been shown; it is included here for completeness, since it belongs with the other identities.) The first equation follows from $H^* = H_0^* D$ and $H_0^* H_0 = I$. The second follows from the first and $K^* = JH^*$, since $J^*J = I$. The last two equations follow from Lemma 1, since $h(S^{-1})g(S)$ and $g(S^{-1})h(S)$ are odd functions hence their even parts vanish. This proves the identities for H and K. The other identities follow by naturality. □

PROPOSITION 6. *The pairs* $\{H, K\}$ *and* $\{H_\alpha, K_\alpha\}$ *give orthogonal decompositions of* V *and* V_α. *We have*

(a)

$$\begin{gathered} HV = KV = V, \\ H^*V = V_1, \qquad K^*V = W_1, \\ H^*H + K^*K = I, \end{gathered} \tag{73}$$

(b)

$$\begin{gathered} H_\alpha V_\alpha = K_\alpha V_\alpha = V_{\alpha+1}, \\ H_\alpha^* V_{\alpha+1} = V_{\alpha+1}, \qquad K_\alpha^* V_{\alpha+1} = W_{\alpha+1}, \\ H_\alpha^* H_\alpha + K_\alpha^* K_\alpha = I_\alpha. \end{gathered} \tag{74}$$

Proof. We have

$$HV = D^{-1}H_0 V = D^{-1}V_1 = V, \tag{75}$$

and since $K = -HJ$, it follows that $KV = HJV = HV = V$. Also

$$H^*V = H_0^* DV = H_0^* V_1 = V_1. \tag{76}$$

$KK^* = I$ and $HK^* = 0$ (Proposition 4) imply that K^* is injective and its range is orthogonal to that of H^*, i.e., to V_1. Hence $K^*V \subset W_1$. To show that $K^*V = W_1$, let $u(S) \in \mathcal{P}$. We need to find $v(S), w(S) \in \mathcal{P}$ such that

$$u(S)\phi = H^*v(S)\phi + K^*w(S)\phi = h(S)v(S^2)\phi + g(S)w(S^{-2})\phi \tag{77}$$

or, equivalently, dropping ϕ,

$$u(S) = h(S)v(S^2) + g(S)w(S^{-2}). \tag{78}$$

Use Lemma 1 to decompose this equation into its even and odd parts:

$$(79)\qquad \begin{aligned} u_+(S) &= Eu(S)E^* = E\left[h(S)v(S^2) + g(S)w(S^{-2})\right]E^* \\ &= h_+(S)v(S) + g_+(S)w(S^{-1}), \\ u_-(S) &= Ou(S)E^* = O\left[h(S)v(S^2) + g(S)w(S^{-2})\right]E^* \\ &= h_-(S)v(S) + g_-(S)w(S^{-1}), \end{aligned}$$

which can be written in matrix form as

$$(80)\qquad \begin{bmatrix} u_+(S) \\ u_-(S) \end{bmatrix} = \begin{bmatrix} h_+(S) & g_+(S) \\ h_-(S) & g_-(S) \end{bmatrix} \begin{bmatrix} v(S) \\ w(S^{-1}) \end{bmatrix} \equiv U(S) \begin{bmatrix} v(S) \\ w(S^{-1}) \end{bmatrix}.$$

But Proposition 5 is precisely the statement that the matrix $U(S)$ is *unitary*, i.e., $U(S)^*U(S) = I$. Multiplying by $U(S)^*$, we obtain the unique solution

$$(81)\qquad \begin{bmatrix} v(S) \\ w(S^{-1}) \end{bmatrix} = \begin{bmatrix} h_+(S^{-1}) & h_-(S^{-1}) \\ g_+(S^{-1}) & g_-(S^{-1}) \end{bmatrix} \begin{bmatrix} u_+(S) \\ u_-(S) \end{bmatrix},$$

which shows that $V \equiv V_1 \oplus W_1 = H^*V \oplus K^*V$. Applying H and K to (77) gives

$$(82)\qquad v(S)\phi = Hu(S)\phi, \qquad w(S)\phi = Ku(S)\phi,$$

which proves that $H^*H + K^*K = I$ as claimed. For the range of K_α^* we have $K_\alpha^* V_{\alpha+1} = K_\alpha^* D^{\alpha+1} V = D^\alpha K^* V = D^\alpha W_1 = W_{\alpha+1}$. Finally,

$$(83)\qquad H_\alpha^* H_\alpha + K_\alpha^* K_\alpha = D^\alpha(H^*H + K^*K)D^{-\alpha} = I_\alpha. \qquad \square$$

We now construct the usual "high-frequency filters" G_α. First note that elements in $W_1 \equiv K^*V$ can be written in the form

$$(84)\qquad K^*w(S)\phi = g(S)w(S^{-2})\phi = w(S^{-2})D\psi = Dw(S^{-1})\psi.$$

It follows that ψ is a "basic wavelet," i.e., that

$$(85)\qquad W_\alpha = \overline{D^\alpha \mathcal{P}\psi},$$

and the vectors

$$(86)\qquad \psi_n^\alpha \equiv D^\alpha S^n \psi = D^{\alpha-1}K^*S^{-n}\phi = D^{-1}K_\alpha^* \phi_{-n}^{\alpha+1}$$

form an orthonormal basis for W_α.

Since $K_0^*\colon V_1 \to V$ is injective and its range is W_1, it can be factored uniquely as

$$(87)\qquad K_0^* = G_0^* R_1^*,$$

where $R_1^*\colon V_1 \to W_1$ is an isomorphism and $G_0^*\colon W_1 \to V$ is the inclusion map. From

$$(88)\qquad K_0^* Dw(S)\phi = Dw(S^{-1})\psi = g(S)w(S^{-2})\phi$$

we read off

$$(89)\qquad \begin{aligned} R_1^* Dw(S)\phi &= Dw(S^{-1})\psi, \\ G_0^* Dw(S^{-1})\psi &= g(S)w(S^{-2})\phi. \end{aligned}$$

For the home versions, we have

$$K^* = G_0^* R_1^* D = G_0^* D R^* = G^* R^*, \tag{90}$$

where

$$R^*\colon V \equiv V_0 \to W \equiv W_0 \tag{91}$$

is an isomorphism and $G^*\colon W \to V$, though injective, is not an inclusion map. (This is the price for working with the home versions, which do not preserve the scale.) Note that $R^*R = I_W$ and $RR^* = I_V$; hence $K = RG$ implies that $G = R^*K$ and

$$\begin{aligned} GG^* &= R^*KK^*R = I_W, \\ GH^* &= R^*KH^* = 0, \\ G^*G &= K^*RR^*K = K^*K \end{aligned} \tag{92}$$

(hence $H^*H + G^*G = I$). Therefore H and G give an orthogonal decomposition of V which is equivalent to that given by H and K.

Defining $R_\alpha^*\colon V_\alpha \to W_\alpha$ and $G_\alpha^*\colon W_{\alpha+1} \to V_\alpha$ by $R_\alpha^* D^\alpha = D^\alpha R^*$ and $G_\alpha^* D^{\alpha+1} = D^\alpha G^*$, we get a graded family of filters G_α related to K_α by

$$K_\alpha^* = G_\alpha^* R_{\alpha+1}^*. \tag{93}$$

The operators G_α are, in fact, the usual high-frequency filters, for the latter are defined analogously to H_α, namely, by substituting $g(S)\phi$ for the dilated wavelet $D\psi$:

$$\begin{aligned} G_\alpha^* D^{\alpha+1} u(S)\psi &= G_\alpha^* D^\alpha u(S^2) D\psi \\ &= D^\alpha g(S) u(S^2)\phi = D^\alpha G^* u(S)\psi. \end{aligned} \tag{94}$$

The orthogonal decomposition of V given by H and G induces an orthogonal decomposition of V_α by H_α and G_α which is, in fact, the usual wavelet decomposition and is equivalent to the one given by H_α and K_α in Proposition 6.

Example 4 (The Haar system, final visit). For the Haar system, (87) and (90) give

$$\begin{aligned} R^*\,\phi_n &= D^{-1} R_1^* D\,\phi_n = S^{-n}\,\psi = \psi_{-n}, \\ G^*\,\psi_n &= G_0^* D\,\psi_n = \frac{1}{\sqrt{2}}(I - S)\,\phi_{2n} = \frac{1}{\sqrt{2}}\,(\phi_{2n} - \phi_{2n+1}), \\ G\,\phi_n &= R^* K\,\phi_n = \frac{(-1)^n}{\sqrt{2}}\,R^*\,\phi_{-[n/2]8} \\ &= \frac{(-1)^n}{\sqrt{2}}\,\psi_{[n/2]}. \end{aligned} \tag{95}$$

Remark. We have stated that K_α is more natural than G_α from the point of view of the symmetry associated with J_α. The reason is that both H_α and K_α map V_α to $V_{\alpha+1}$, whereas G_α maps V_α to $W_{\alpha+1}$. This symmetry is reflected by the simple relation $K_\alpha^* = J_\alpha H_\alpha^*$, whereas the relation

$$G_\alpha^* = J_\alpha H_\alpha^* R_{\alpha+1} \tag{96}$$

is somewhat more complicated. A more concrete divident of this symmetry will appear in the next section, where the complex combinations $H_\alpha^* \pm iK_\alpha^*$ will be considered. The corresponding combinations $H_\alpha^* \pm iG_\alpha^*$ do not make sense, as the two operators have different domains.

We now prove an identity which will be useful later.

PROPOSITION 7.

$$\begin{aligned} K^*H - H^*K &= J, \\ K_\alpha^* H_\alpha - H_\alpha^* K_\alpha &= J_\alpha. \end{aligned} \tag{97}$$

Proof. For $u(S)\phi = H^*v(S)\phi + K^*w(S)\phi \in V$, we have

$$\begin{aligned} (K^*H - H^*K)\,u(S)\phi &= K^*v(S)\phi - H^*w(S)\phi \\ &= JH^*v(S)\phi + JK^*w(S)\phi = Ju(S)\phi. \end{aligned} \tag{98}$$

The identity at arbitrary scale follows from naturality:

$$(K_\alpha^* H_\alpha - H_\alpha^* K_\alpha)D^\alpha = D^\alpha(K^*H - H^*K) = D^\alpha J = J_\alpha D^\alpha. \tag{99}$$ □

It is natural to wonder whether the complex structures J_α extend to define a "global" complex structure on $L^2(\mathbb{R})$. We now show that this is not the case.

PROPOSITION 8. *The complex structure J_α on V_α is not an extension of $J_{\alpha+1}$.*

Proof. The statement that J_α is an extension of $J_{\alpha+1}$ means that $J_{\alpha+1}$ is the restriction of J_α to $V_{\alpha+1}$, i.e.,

$$K_\alpha^* \equiv J_\alpha H_\alpha^* = H_\alpha^* J_{\alpha+1}. \tag{100}$$

If this were true, then left-multiplication by H_α would imply

$$0 = H_\alpha K_\alpha^* = H_\alpha H_\alpha^* J_{\alpha+1} = J_{\alpha+1}, \tag{101}$$

which contradicts $J_{\alpha+1}^2 = -I_{\alpha+1}$. □

3.1. Complex decomposition and reconstruction. The decomposition/reconstruction algorithm of the last section can be iterated, and when repeated indefinitely gives a unique representation of any function $f \in L^2(\mathbb{R})$ as an L^2-convergent infinite orthogonal sum of "detail" functions at finer and finer scales. We develop the algorithm formally in the home version, which will be seen to be much more convenient. For a rigorous treatment, see Daubechies [1988b]. Given any $D^\alpha v^\alpha(S)\phi \in V_\alpha$, write

$$v^\alpha \equiv v^\alpha(S)\phi \in V \tag{102}$$

for brevity. Since

$$\begin{aligned} I &= K^*K + H^*H = K^*K + H^*(K^*K + H^*H)H = \cdots \\ &= \sum_{\beta=1}^{N} (H^*)^{\beta-1} K^*KH^{\beta-1} + (H^*)^N H^N, \end{aligned} \tag{103}$$

we have

$$
\begin{aligned}
v^\alpha &= \sum_{\beta=1}^{N} (H^*)^{\beta-1} K^* K H^{\beta-1} v^\alpha + (H^*)^N H^N v^\alpha \\
&= \sum_{\beta=1}^{N} (H^*)^{\beta-1} K^* w^{\alpha+\beta} + (H^*)^N v^{\alpha+N},
\end{aligned} \tag{104}
$$

where

$$
\begin{aligned}
w^{\alpha+\beta} &\equiv K H^{\beta-1} v^\alpha, \\
v^{\alpha+N} &\equiv H^N v^\alpha.
\end{aligned} \tag{105}
$$

The vector $v^{\alpha+N}$ represents an N-fold smoothed version of v^α, while $w^{\alpha+\beta}$ represents the detail filtered out at the βth iteration. The terms in the above sum are orthogonal, since for $\gamma > \beta$ we have

$$
\begin{aligned}
&\langle (H^*)^{\beta-1} K^* w^{\alpha+\beta}, (H^*)^{\gamma-1} K^* w^{\alpha+\gamma} \rangle \\
&\qquad = \langle w^{\alpha+\beta}, K (H^*)^{\gamma-\beta} K^* w^{\alpha+\beta} \rangle = 0.
\end{aligned} \tag{106}
$$

To see what this expansion means in terms of the scale-preserving filters, apply D^α and use naturality (see Appendix):

$$
\begin{aligned}
D^\alpha v^\alpha = {} & \sum_{\beta=1}^{N} H^*_\alpha H^*_{\alpha+1} \cdots H^*_{\alpha+\beta-2} K^*_{\alpha+\beta-1} D^{\alpha+\beta} w^{\alpha+\beta} \\
& + H^*_\alpha H^*_{\alpha+1} \cdots H^*_{\alpha+N-1} D^{\alpha+N} v^{\alpha+N}.
\end{aligned} \tag{107}
$$

This formula shows the advantage of the home versions of the filters, which "zoom" in and out to get the detail at any desirable scale and can therefore be used repeatedly without changing operators.

It can be shown that $v^{\alpha+N} \to 0$ in $L^2(\mathbb{R})$ as $N \to \infty$, which gives the orthogonal decomposition

$$
D^\alpha v^\alpha = D^\alpha \sum_{\beta=1}^{\infty} (H^*)^{\beta-1} K^* w^{\alpha+\beta}. \tag{108}
$$

Since

$$
L^2(\mathbb{R}) = \overline{\bigcup_{\alpha \in \mathbb{Z}} V_\alpha}, \tag{109}
$$

any $L^2(\mathbb{R})$ function can be approximated as accurately as desired in the form of (108). We need only choose a "cut-off" scale α, which means that all detail finer than 2^α will be ignored. Moreover, since

$$
W_{\alpha+1} \subset V_\alpha \perp W_\alpha, \tag{110}
$$

the above gives the orthogonal decomposition

$$
L^2(\mathbb{R}) = \overline{\bigoplus_{\alpha \in \mathbb{Z}}} W_\alpha. \tag{111}
$$

Let us now look at the reconstruction and decomposition formulas in light of the complex structure. A single iteration gives

$$v^{\alpha} = H^{*}v^{\alpha+1} + K^{*}w^{\alpha+1} = H^{*}v^{\alpha+1} + JH^{*}w^{\alpha+1}, \tag{112}$$

where

$$v^{\alpha+1} = Hv^{\alpha}, \qquad w^{\alpha+1} = Kv^{\alpha} = -HJv^{\alpha}. \tag{113}$$

Since J is like multiplication by $\pm i$, let us define the complex conjugate pairs of vectors

$$\begin{aligned} \zeta^{\alpha} &= \frac{v^{\alpha} + iw^{\alpha}}{\sqrt{2}}, \\ \bar{\zeta}^{\alpha} &= \frac{v^{\alpha} - iw^{\alpha}}{\sqrt{2}}, \end{aligned} \tag{114}$$

where the $\sqrt{2}$ in the denominators is for later convenience. ζ^{α} and $\bar{\zeta}^{\alpha}$ belong to the *complexification* of V, i.e., to

$$V^{c} = V \oplus iV = \mathbb{C} \otimes V. \tag{115}$$

We endow V^{c} with the Hermitian inner product obtained from V by extending $\mathbb{C}$—linearly in the *second* factor and antilinearly in the first factor (this is the convention used in the physics literature). Note that under this inner product, iV is not orthogonal to V, and hence the direct sum $V \oplus iV$ is *not* an orthogonal decomposition. We now extend all operators on V to V^{c} by $\mathbb{C}$-linearity, denoting the extensions by the same symbols. Substituting

$$v^{\alpha+1} = \frac{\zeta^{\alpha+1} + \bar{\zeta}^{\alpha+1}}{\sqrt{2}}, \qquad w^{\alpha+1} = \frac{\zeta^{\alpha+1} - \bar{\zeta}^{\alpha+1}}{\sqrt{2}i} \tag{116}$$

into the reconstruction formula, we obtain

$$v^{\alpha} = Z^{*}\zeta^{\alpha+1} + \bar{Z}^{*}\bar{\zeta}^{\alpha+1} = 2\,\Re\left(Z^{*}\zeta^{\alpha+1}\right), \tag{117}$$

where the operators $Z^{*}, \bar{Z}^{*}$: $V^{c} \to V^{c}$ are defined by

$$Z^{*} = \frac{H^{*} - iK^{*}}{\sqrt{2}}, \qquad \bar{Z}^{*} = \frac{H^{*} + iK^{*}}{\sqrt{2}}. \tag{118}$$

Therefore

$$Z = \frac{H + iK}{\sqrt{2}} = \frac{H - iHJ}{\sqrt{2}} = H\left(\frac{I - iJ}{\sqrt{2}}\right). \tag{119}$$

The operators

$$P^{\pm} = \frac{I \mp iJ}{2} \tag{120}$$

are the orthogonal projections in V^{c} to the eigenspaces of J with eigenvalues $\pm i$, since

$$\begin{aligned} JP^{\pm} &= \pm iP^{\pm}, \\ (P^{\pm})^{*} &= P^{\pm} = (P^{\pm})^{2}. \end{aligned} \tag{121}$$

We have the orthogonal decomposition

$$V^c = V^+ \oplus V^-, \qquad V^\pm \equiv P^\pm V. \tag{122}$$

The above shows that the operator $Z\colon V^c \to V^c$ and its adjoint satisfy

$$Z = \sqrt{2}\,HP^+, \qquad Z^* = \sqrt{2}P^+H^*. \tag{123}$$

Since H^* is injective, it follows that the range of Z^* is V^+ and the kernel of Z is V^-. Similarly,

$$\bar{Z} = \sqrt{2}\,HP^-, \qquad \bar{Z}^* = \sqrt{2}P^-H^*, \tag{124}$$

so the range of $\bar{Z}^*$ is V^- and the kernel of $\bar{Z}$ is V^+.

PROPOSITION 9. *The operators Z and $\bar{Z}$ satisfy*

$$\begin{aligned} ZZ^* &= I, & \bar{Z}\bar{Z}^* &= I,\\ Z\bar{Z}^* &= 0, & \bar{Z}Z^* &= 0,\\ Z^*Z &= P^+, & \bar{Z}^*\bar{Z} &= P^-. \end{aligned} \tag{125}$$

Proof. By Proposition 5, we have

$$\begin{aligned} ZZ^* &= 2HP^+P^+H^* = 2HP^+H^*\\ &= H(I - iJ)H^* = HH^* - iHK^* = I, \end{aligned} \tag{126}$$

and

$$Z\bar{Z}^* = 2HP^+P^-H^* = 0. \tag{127}$$

Furthermore, by Propositions 6 and 7,

$$\begin{aligned} 2Z^*Z &= (H^* - iK^*)(H + iK)\\ &= (H^*H + K^*K) + i(H^*K - K^*H)\\ &= I - iJ = 2P^+. \end{aligned} \tag{128}$$

The other equalities follow from complex conjugation, which exchanges Z and $\bar{Z}$. □

Proposition 9 gives a new, *complex* decomposition and reconstruction algorithm. Given $\zeta^\alpha \in V^c$, define $\zeta^{\alpha+1}, \chi^{\alpha+1} \in V^c$ by

$$\begin{aligned} \zeta^{\alpha+1} &= Z\zeta^\alpha = \sqrt{2}HP^+\zeta^\alpha,\\ \chi^{\alpha+1} &= \bar{Z}\zeta^\alpha = \sqrt{2}HP^-\zeta^\alpha. \end{aligned} \tag{129}$$

Then ζ^α can be reconstructed using

$$\zeta^\alpha = Z^*\zeta^{\alpha+1} + \bar{Z}^*\chi^{\alpha+1}. \tag{130}$$

Like the real algorithm, this can be iterated. By Proposition 9,

$$\begin{aligned} I &= \bar{Z}^*\bar{Z} + Z^*Z = \bar{Z}^*\bar{Z} + Z^*(\bar{Z}^*\bar{Z} + Z^*Z)Z = \cdots \\ &= \sum_{\alpha=1}^{N} (Z^*)^{\alpha-1}\bar{Z}^*\bar{Z}Z^{\alpha-1} + (Z^*)^N Z^N. \end{aligned} \tag{131}$$

Hence for any $\zeta^0 \in V^c$ and $N \in \mathbb{N}$,

$$\begin{aligned} \zeta^0 &= \sum_{\alpha=1}^{N} (Z^*)^{\alpha-1}\bar{Z}^*\bar{Z}Z^{\alpha-1}\zeta^0 + (Z^*)^N Z^N \zeta^0 \\ &= \sum_{\alpha=1}^{N} (Z^*)^{\alpha-1}\bar{Z}^*\chi^\alpha + (Z^*)^N \zeta^N, \end{aligned} \tag{132}$$

where

$$\chi^\alpha \equiv \bar{Z}Z^{\alpha-1}\zeta^0, \qquad \zeta^N \equiv Z^N\zeta^0. \tag{133}$$

The convergence and significance (in relation to the usual frequency decomposition) of this algorithm will be studied elsewhere. Here we merely note that the terms in the above sum are mutually orthogonal, since for $\beta > \alpha$ Proposition 9 implies

$$\langle (Z^*)^{\alpha-1}\bar{Z}^*\chi^\alpha, (Z^*)^{\beta-1}\bar{Z}^*\chi^\beta \rangle = \langle \chi^\alpha, \bar{Z}(Z^*)^{\beta-\alpha}\bar{Z}^*\chi^\alpha \rangle = 0. \tag{134}$$

Just as the filters H and K have associated averaging- and "differencing" operators $h(S)$ and $g(S)$, there are operators associated with Z and $\bar{Z}$. If

$$\begin{aligned} Z^*\zeta(S)\phi &= 2^{-1/2}\left(h(S)\zeta(S^2) - ig(S)\zeta(S^{-2})\right)\phi \\ &= \left(\frac{h(S) - ig(S)C}{\sqrt{2}}\right) E^*\zeta(S)\phi; \end{aligned} \tag{135}$$

then $Z^* = z^*E^*$ and, similarly, $\bar{Z}^* = \bar{z}^*E^*$, where

$$z^* = \frac{h(S) - ig(S)C}{\sqrt{2}}, \qquad \bar{z}^* = \frac{h(S) + ig(S)C}{\sqrt{2}}. \tag{136}$$

Note, however, that these operators do not commute with S, since they contain C.

PROPOSITION 10. *The operators z and $\bar{z}$ satisfy*

$$zz^* = z^*z = \bar{z}\bar{z}^* = \bar{z}^*\bar{z} = I. \tag{137}$$

Proof. A straight computation gives

$$\begin{aligned} z^*z &= \frac{1}{2}\left(h(S) - ig(S)C\right)\left(h(S^{-1}) + iCg(S^{-1})\right) \\ &= \frac{1}{2}\left(h(S)h(S^{-1}) + g(S)g(S^{-1})\right) + \frac{i}{2}\left(h(S)g(S) - g(S)h(S)\right)C \\ &= \frac{1}{2}\left(h(S)h(S^{-1}) + h(-S)h(-S^{-1})\right) \\ &= DEh(S)h(S^{-1})E^*D^{-1} = I \end{aligned} \tag{138}$$

by Proposition 5, and the other identities are proved similarly. □

Furthermore, there is a natural complex function which stands in the same relation to z as do ϕ and ψ stand to $h(S)$ and $g(S)$, respectively. Consider the function $\bar{\chi} \in V_{-1}^{+}$ defined by

$$D\bar{\chi} \equiv Z^* \phi = z^* \phi = \frac{h(S) - ig(S)}{\sqrt{2}} \phi. \tag{139}$$

Using $D\phi = h(S)\phi$ and $D\psi = g(S)\phi$, we get

$$\bar{\chi} = \frac{\phi - i\psi}{\sqrt{2}}. \tag{140}$$

Similarly, we define $\chi \in V_{-1}^{-}$ by

$$\chi \equiv D^{-1} \bar{Z}^* \phi = \frac{\phi + i\psi}{\sqrt{2}}. \tag{141}$$

The functions ϕ and ψ are somewhat reminiscent of the cosine- and sine-function. By that analogy, χ and $\bar{\chi}$ correspond to *the complex exponentials*! It may be that χ and $\bar{\chi}$, which combine averaging and "differencing" in a complex way, play a similar role in wavelet analysis as do the complex exponentials in Fourier analysis.

Finally, note that the Hermitian inner product in V^c has the decomposition

$$\langle \zeta, \zeta' \rangle = \langle \zeta, P^+ \zeta \rangle + \langle \zeta, P^- \zeta' \rangle, \tag{142}$$

which is the sum of the inner products in V^+ and V^-. Now the restriction of P^+ to $V \subset V^c$ maps V one-to-one onto V^+, although it cannot preserve the inner product since V is real while V^+ is complex. In fact, for $\zeta \equiv P^+ u$ and $\zeta' \equiv P^+ u'$ in V^+, we have

$$\begin{aligned} \langle \zeta, \zeta' \rangle = \langle u, P^+ u' \rangle &= \frac{1}{2} \langle u, u' \rangle - \frac{i}{2} \langle u, Ju' \rangle \\ &\equiv \frac{1}{2} \langle u, u' \rangle - i\omega(u, u'), \end{aligned} \tag{143}$$

which states that imaginary part of the Hermitian inner product in V^+ is the skew-symmetric bilinear form ω. This form is known as the *symplectic structure* determined by the complex structure J together with the inner product on V. It plays a fundamental role in a broad variety of subjects, e.g., group representation theory, classical mechanics, and quantum mechanics (see Marsden [1981]). I do not know whether it has any significance for wavelet analysis, but that seems to me a question worth exploring.

Some final remarks. (1) Although no attempt has been made here to work in an *abstract* setting, the algebraic approach clearly lends itself to such generalizations. We have made use of just a few facts about our initial set-up, for example, that the inner product is invariant under S and D and also under C and M. This suggests that it is necessary to *begin* with an algebra whose generators include S and D and other operators such as C and M, subject to certain relations, and to look for *representations* of this algebra, i.e., for a vector space on which the elements of the algebra act as operators. In our case, the vector ϕ provides a representation on $L^2(\mathbb{R})$. ϕ is a *cyclic* vector because its orbit under the algebra spans $L^2(\mathbb{R})$, and the representation is *irreducible.* The representation is also *orthogonal* in the sense that the generators are represented by orthogonal operators. Solving the dilation equation $D\phi = h(S)\phi$ therefore amounts to constructing the entire representation!

(2) The complex combinations $H \pm iK$ are reminiscent of certain operators that occur in quantum mechanics in connection with *coherent states* and that are also associated with time-frequency localization. See Kaiser [1990], Kaiser and Streater [1991].

4. Appendix. Here we assemble various information for the reader's convenience. We begin with a summary of the operational calculus.

4.1. Operational calculus and basis representations. We list the actions of various operators in their "home versions," both intrinsically and on the orthonormal bases $\{\phi_n\}$ of $V \equiv V_0$ and $\{\psi_n\}$ of $W \equiv W_0$. (See Daubechies [1988b].) Since $\varepsilon(S)$ is odd, it may be written in the form $\varepsilon(S) = \sum_k \varepsilon_k \, S^{2k+1}$.

$$\begin{aligned}
H^*u(S)\phi &= h(S)u(S^2)\phi, & H^*\phi_k &= \sum_n h_{n-2k}\phi_n, \\
Hu(S)\phi &= Eh(S^{-1})u(S)\phi, & H\phi_n &= \sum_k h_{n-2k}\phi_k, \\
K^*u(S)\phi &= g(S)u(S^{-2})\phi, & K^*\phi_k &= \sum_n g_{n+2k}\phi_n, \\
Ku(S)\phi &= Eg(S)u(S^{-1})\phi, & K\phi_n &= \sum_k g_{n+2k}\phi_k, \\
G^*u(S)\psi &= g(S)u(S^2)\phi, & G^*\psi_k &= \sum_n g_{n-2k}\phi_n, \\
Gu(S)\phi &= Eg(S^{-1})u(S)\psi, & G\phi_n &= \sum_k g_{n-2k}\psi_k, \\
Ju(S)\phi &= \varepsilon(S)u(-S^{-1})\,\phi, & J\phi_n &= (-1)^n \sum_k \varepsilon_k \, \phi_{2k+1-n}.
\end{aligned}$$

4.2. Naturality. Naturality relates the scale-preserving filters $H_\alpha, K_\alpha, G_\alpha$, and Z_α to one another and to their home versions, which involve changes of scale. We give the relations for Z_α; the others are similar. The last two equations show the advantage of the home versions for iterated decomposition and reconstruction.

$$\begin{aligned}
&Z_\alpha D^\alpha = D^\alpha Z_0 = D^{\alpha+1} Z, \\
&Z_\alpha^* D^{\alpha+1} = D^\alpha Z_0^* D = D^\alpha Z^*, \\
&Z_{\alpha+N} Z_{\alpha+N-1} \cdots Z_\alpha D^\alpha = D^{\alpha+N+1} Z^{\alpha+N+1}, \\
&Z_\alpha^* Z_{\alpha+1}^* \cdots Z_{\alpha+N}^* D^{\alpha+N+1} = D^\alpha (Z^*)^{N+1}.
\end{aligned}$$

4.3. Relation to Daubechies' notation. Upon taking the Fourier transform, our operators $u(S)$ become functions $u(e^{i\xi T})$ on the unit circle. Their connections with those occuring in Daubechies' paper, where the sampling interval $T = 1$, are as follows: Write $\varepsilon(S) = S\varepsilon_-(S^2)$. Then

$$\begin{aligned} h(e^{i\xi}) &= H(\xi), & g(e^{i\xi}) &= G(\xi), \\ h_+(e^{i\xi}) &= \alpha(\xi), & g_+(e^{i\xi}) &= \gamma(\xi), \\ h_-(e^{i\xi}) &= \beta(\xi), & g_-(e^{i\xi}) &= \delta(\xi), \\ \varepsilon_-(e^{i\xi}) &= -e^{i\lambda(\xi)}, & U(e^{i\xi}) &= M(\xi). \end{aligned}$$

4.4. Analogy with complex numbers. We give a "pocket dictionary" of the correspondence between wavelet operations and operations on complex numbers. This is done for the relation $V_0 \approx V_1 \oplus iV_1$, although the same analogy holds at every scale.

$$\begin{aligned} V_1 &\longleftrightarrow \mathbb{R} \\ W_1 &\longleftrightarrow i\mathbb{R} \\ V_0 = V_1 \oplus JV_1 &\longleftrightarrow \mathbb{C} = \mathbb{R} \oplus i\mathbb{R} \\ u(S)\phi \mapsto H_0 u(S)\phi &\longleftrightarrow x + iy \mapsto \Re(x+iy) \\ u(S)\phi \mapsto K_0 u(S)\phi &\longleftrightarrow x + iy \mapsto \Im(x+iy) \\ u(S)\phi \mapsto Ju(S)\phi &\longleftrightarrow z \mapsto iz \\ Dv(S)\phi \mapsto H_0^* Dv(S)\phi &\longleftrightarrow x \mapsto x + i0 \\ Dw(S)\phi \mapsto K_0^* Dw(S)\phi &\longleftrightarrow y \mapsto 0 + iy \\ u(S)\phi = H_0^* Dv(S)\phi + JH_0^* Dw(S)\phi &\longleftrightarrow z = x + iy \\ Dw(S)\phi \mapsto R_1^* Dw(S)\phi &\longleftrightarrow y \in \mathbb{R} \mapsto iy \in i\mathbb{R}. \end{aligned}$$

Acknowledgment. The author thanks Yuli Makovoz for helpful discussions.

ITERATIVE RECONSTRUCTION OF MULTIVARIATE BAND-LIMITED FUNCTIONS FROM IRREGULAR SAMPLING VALUES*

HANS G. FEICHTINGER† AND KARLHEINZ GRÖCHENIG‡

Abstract. This paper describes a real analysis approach to the problem of complete reconstruction of a band-limited, multivariate function f from irregularly spaced sampling values $(f(x_i))_{i\in I}$. The required sampling density of the set $X=(x_i)_{i\in I}$ depends only on the spectrum Ω of f. The proposed reconstruction methods are iterative and stable and converge for a given function f with respect to any weighted L^p-norm $1\leqq p\leqq\infty$, for which f belongs to the corresponding Banach space $L^p_v(\mathbb{R}^m)$. It is also shown that any band-limited function f can be represented as a series of translates $L_{y_j}g$ (with complex coefficients) for a given integrable, band-limited function g if the Fourier transform satisfies $\hat{g}(t)\neq 0$ over Ω and the family $Y=(y_j)_{j\in J}$ is sufficiently dense. Moreover, the behavior of the coefficients (such as weighted p-summability) corresponds precisely to the global behavior of f (i.e., membership in the corresponding weighted L^p-space). The proofs are based on a careful analysis of convolution relations, spline approximation operators, and discretization operators (approximation of functions by discrete measures). In contrast to Hilbert space methods, the techniques used here yield pointwise estimates. Special cases of the algorithms presented provide a theoretical basis for methods suggested recently in the engineering literature. Numerical experiments have demonstrated the efficiency of these methods convincingly.

Key words. irregular sampling, iterative reconstruction, approximation of convolutions, multivariate band-limited functions, function spaces

1. Introduction.

According to the classical sampling theorem attributed to Whittaker, Shannon, Kotel'nikov, and several others, a band-limited function can be reconstructed from sampling values over any sufficiently fine lattice. Because of its great importance in information theory, electrical engineering, signal processing, and other applications, a lot of work has been carried out on improvements and extensions, e.g., to lattices in higher dimensions [PM], [Me], [DM]. Reviews and extensive references on these investigations are given in [Bu], [Je], [Hi2], [BERS], [BSS], and [Ma] (some of which mention the irregular sampling problem).

The regular sampling theorem is based on Fourier series and Poisson's formula. This limits the possible sampling sets to lattices, in other words, to discrete sets that arise from the standard lattice $\mathbb{Z}^m\subseteq\mathbb{R}^m$ through application of an invertible real $n\times n$ matrix (cf. [Co]). However, in many applications, e.g., optics, tomography, synthetic aperture radar, computer graphics, signal processing, meteorology, and geophysics it is necessary to deal with situations where sampling values are *not* available on a regular grid [SA], [Ce], [PK], [St], [So].

In this paper a new *iterative approach* to the irregular sampling problem is described which represents a *constructive* solution to this question. The proposed algorithms use only standard operations which are also well suited for numerical implementation.

1.1. The requirements for an irregular sampling theory.

As a simple model for sampling theory let us recall the regular sampling theorem: Given a band-limited function (of finite energy) $f\in L^2(\mathbb{R})$ with spectrum in $[-\pi W, \pi W]$, f can be represented as a cardinal series

$$f(t)=\sum_{k\in\mathbb{Z}} f(k/W)\,\mathrm{sinc}\,(\pi(Wt-k))$$

where sinc $(x) := x^{-1} \sin(x)$ for $x \neq 0$ and sinc $(0) = 1$; cf. [Bu], [BSS], [Pa]. The series is convergent in the L^2-sense and uniformly. In the case of oversampling, i.e., if sampling values $(f(\alpha k)_{k \in \mathbb{Z}})$ for some $\alpha < 1/W$ are known, the nonintegrable sinc-function can be replaced by other "windows" (cf. [Sch], [BERS]) with a more rapid decay. Then the series converges with respect to weighted L^p-norms as well, whenever f belongs to such a weighted L^p-space (cf. [F4, Thm. 2]). Such alternative windows with rapid decay are also required if band-limited tempered distributions must be reconstructed from their regular sampling values (cf. [Ca], [BERS], [Se]).

The regular sampling theorem combines *two aspects*:

(a) Any band-limited function can be *completely reconstructed* from its sampled values over a *sufficiently fine* lattice by means of a simple series expansion with the sampled values as coefficients.

(b) Any band-limited function can be *expanded into a series* with *translates of a single function* g as building blocks.

For the irregular sampling problem we will discuss these two aspects separately; see Theorems 3.1 and 3.2. Practical considerations impose the following requirements on an irregular sampling theory. They are satisfied in the case of regular sampling, at least for fast decaying kernels. The theory should be

(1) *Constructive*, i.e., a possibly iterative algorithm should allow numerical reconstruction;

(2) *Multidimensional*, so that it can be used in signal and image processing or for the interpolation of sequences of images;

(3) *Local*, so that the value of a band-limited function at a point is essentially determined by the adjacent sampling values, and more distant sampling values have no influence. Estimates with respect to weighted L^p-norms are a suitable tool to describe decay conditions and the locality properties of the reconstruction operators.

(4) *Stable*, so that small perturbations of the parameters cause only small errors in the reconstruction.

1.2. The real analysis approach of this paper. To achieve these objectives we choose a real variable approach. We start with the observation that a band-limited function satisfies a convolution equation of the form $f = f * g$, and then analyze this convolution equation carefully. The main tools are *pointwise estimates* (a) for spline type approximations of smooth functions and (b) for the approximation of a convolution by a weighted sum of translates, see Lemmas 4.1-4.4.

Iterative algorithms arise through repeated application of these approximation operators to the remainder term. The resulting sequence converges to the original signal at a geometric rate. These reconstruction methods satisfy all the requirements stated above.

In contrast to many previous papers on irregular sampling, we do not use methods from analytic function theory. This is one of the reasons why the results extend easily to multivariate irregular sampling. Our techniques allow for a treatment of irregular sampling in a very general class of Banach spaces.

Discretization operators which are dual to the spline operators lead to nonorthogonal series expansions of band-limited signals in terms of translates of a single function. The coefficients depend in a linear way on the expanded function, and the coefficient mapping is continuous with respect to any of the norms under consideration. Similar techniques can be used on nonabelian locally compact groups to derive very general results on atomic decompositions for function spaces [FG1], [FG2], [Gr1].

1.3. Review of the literature. Most papers concerning the irregular sampling theorem deal with signals of finite energy, i.e., work in the *Hilbert space* $L^2(\mathbb{R})$ [DS], [Be1,2], [Wi]. In general, such arguments are not applicable to the important class of almost periodic functions or even trigonometric polynomials. Unweighted L^p-spaces are treated in [Go] for regular sampling and in the important but nonconstructive paper by Beurling [B]. Only in a few cases [SA], [BH2], [PM] are two-dimensional problems discussed, however, with additional conditions on the sampling set.

In the mathematical literature very strong uniqueness theorems are found for band-limited functions, both in one dimension [BM], [Wa] and in higher dimensions [La], [B]. These results, which use complex analysis and operator theory, are of high theoretical interest, but they have had no practical implications because they are not constructive.

For small deviations from regular sampling the perturbation theory of orthonormal bases in Hilbert spaces yields irregular sampling theorems [Hi1], [Ye], [Ka], [Yo], [Ra1,2], [BH1,2]. In principle, these methods are constructive, but they seem to be too difficult to use for numerical computations. For instance, a reconstruction through a Lagrange type interpolation involves functions which are given as infinite products. A reconstruction by means of the biorthogonal system requires that these functions be computed first. Besides the computational complexity of this task, it is also known that the biorthogonal system depends on the sampling set in an unstable way, so that a small change of a single sampling point affects all functions of the biorthogonal system in an unpredictable way [Sp]. Moreover, sampling theorems of this kind are restricted to the Hilbert space $L^2(\mathbb{R}^m)$, and they cannot treat sampling sets with strong variations of the local density.

The results in [CPL], [So] are based on the idea of transforming the irregular sampling set into a regular one. They give exact reconstruction, but only for certain classes of functions which are not band-limited and which depend heavily on the sampling geometry in a nontransparent way.

For numerical computations *iterative methods* are most useful for recovering a band-limited function from irregularly sampled values [Wi], [SA], [MA]. They are all derived from the fundamental paper of Duffin and Shaeffer [DS] on nonharmonic Fourier series and a theorem in [Sa]. The convergence of these methods is known only for the Hilbert space L^2. The description of convergence therefore lacks the much desired locality.

The numerical implementation of [SA] is quite successful in image restoration, although for their third method no proof of convergence is known.

1.4. A short overview. The plan of this paper is as follows: Section 2 begins with a description of a family of Banach spaces of functions and measures on $\mathbb{R}^m$, which will allow us to describe convergence of the iterative methods with respect to a variety of norms. Together with these spaces, suitable operators such as spline type approximations and approximations through discrete measures are introduced. They are not well defined for L^p-spaces, but bounded on the auxiliary spaces introduced in this section. These concepts are also crucial in order to adapt the approach described in [F3] for L^1-spaces to $L^2(\mathbb{R}^m)$ or to weighted L^p-spaces. The main results of this paper are stated in § 3. In contrast to known results, we need not assume a positive minimal distance of the sampling points and can thus treat local variations of the density. For numerical applications this means that all information in regions of high sampling density can be used. For L^p-spaces and with positive minimal distance between the sampling points, the results allow a much simpler and more accessible formulation. Therefore we state them explicitly as corollaries. Section 4 contains the technical parts and the proof of the results. The underlying estimates are formulated in a series of lemmas.

2. Function spaces and operators. First let us fix some notation. We denote the space of all Radon measures (regular Borel measures on $\mathbb{R}^m$) by $R(\mathbb{R}^m)$. By the Riesz representation theorem we identify it with the topological dual of $\mathcal{K}(\mathbb{R}^m)$: $\mathcal{K}(\mathbb{R}^m):=\{k|k$ continuous, complex-valued, with compact support$\}$. A point measure δ_x is characterized by $\delta_x(f)=\int f(y)\,d\delta_x(y):=f(x)$. For the uniform norm we use the following symbol: $\|f\|_\infty:=\sup_{z\in\mathbb{R}^m}|f(z)|$.

Submultiplicative weight functions, i.e., continuous functions satisfying $w(x)\geqq 1$ for all $x\in\mathbb{R}^m$ and $w(x+y)\leqq w(x)w(y)$ for all $x,y\in\mathbb{R}^m$, are important because the weighted L^1-spaces $L^1_w(\mathbb{R}^m):=\{f|fw\in L^1(\mathbb{R}^m)\}$, with the norm $\|f\|_{1,w}:=\int_{\mathbb{R}^m}|f(x)|w(x)\,dx$, are Banach algebras under convolution (cf. [Rei], [F1] for details)

$$(2.1)\qquad f*g(x):=\int_{\mathbb{R}^m}f(x-y)g(y)\,dy \quad \text{for } f,g\in L^1_w(\mathbb{R}^m).$$

If $w=w_a:y\to(1+|y|)^a$, for some $a\geqq 0$ we write $L^1_a(\mathbb{R}^m)$ instead of $L^1_w(\mathbb{R}^m)$.

We shall describe our approach in the setting of solid BF-spaces (or Banach lattices). Formally we make the following general assumptions:

(B1) $(B,\|\ \|_B)\hookrightarrow L^1_{\text{loc}}(\mathbb{R}^m)$ is a Banach space of locally integrable functions on $\mathbb{R}^m$, and for any compact set $Q\subseteq\mathbb{R}^m$ there exists $C_Q>0$ such that

$$\int_Q|f(x)|\,dx\leqq C_Q\|f\|_B \quad \text{for all } f\in B.$$

(B2) $(B,\|\ \|_B)$ is a Banach module over $(C^0(\mathbb{R}^m),\|\ \|_\infty)$ with respect to pointwise multiplication, i.e., $hf\in B$ and $\|hf\|_B\leqq\|h\|_\infty\|f\|_B$ for $h\in C^0$ and $f\in B$.

(B3) $(B,\|\ \|_B)$ is translation invariant in the following sense: The translation operators L_y, $y\in\mathbb{R}^m$, given by $L_yf(x):=f(x-y)$, map B into itself and for some $a\geqq 0$ we have $\|L_yf\|_B\leqq C_B(1+|y|)^a\|f\|_B$ for all $f\in B$.

(B3′) $(B,\|\ \|_B)$ is a Banach convolution module over $L^1_a(\mathbb{R}^m)$, i.e., we assume that, for $f\in B$ and $g\in L^1_a$, $g*f\in B$ and $\|g*f\|_B\leqq C_B\|g\|_{1,a}\|f\|_B$.

Remark 2.1. It follows from (B3) that B is a space of tempered distributions, i.e., $(B,\|\ \|_B)\hookrightarrow\mathcal{S}'(\mathbb{R}^m)$. Consequently, the Fourier transform $\hat{f}$ and the spectrum $\operatorname{spec} f:=\operatorname{supp}\hat{f}$ (equals the support of $\hat{f}$) are well defined for $f\in B$. For any closed set $\Omega\subseteq\mathbb{R}^m$ the set

$$B^\Omega:=\{f\in B, \operatorname{spec} f\subseteq\Omega\}$$

is a closed subspace of B.

Examples. The most natural examples satisfying (B1)–(B3′) are the spaces

$$L^p_v:=\{f|fv\in L^p(\mathbb{R}^m)\},\quad \text{with norm } \|f\|_{v,p}:=\left(\int_{\mathbb{R}^m}|f(x)v(x)|^p\,dx\right)^{1/p}$$

for $1\leqq p<\infty$ (and a sup norm for $p=\infty$); cf. [F1]. The function v is assumed to be a continuous and positive function which is *moderate* with respect to the *weight function* w_a, i.e., it satisfies $v(x+y)\leqq C_1w_a(x)v(y)$ for all $x,y\in\mathbb{R}^m$. Note that obviously w_b is a moderate function (with respect to w_a) for any $b\in[-a,a]$. Our general approach also includes (weighted) mixed norm spaces in the sense of Benedek–Panzone, or weighted variants of rearrangement invariant Banach spaces such as Lorentz or Orlicz spaces [LT] or spaces of bounded p-mean [F5].

In order to extend the results stated in [F3] to L^p-spaces (with $p>1$) the Wiener type spaces $W(M, B)$ and $W(C^0, B)$ are an important tool [F2]. For $B=L^p$ they coincide with amalgam spaces in the sense of [FSt]. We shall describe them briefly, using the symbols MB and CB, and give a new simple proof of a convolution theorem.

DEFINITION 2.1. For a fixed open, bounded subset $Q\subseteq \mathbb{R}^m$ we define the *local maximal function* $x \mapsto f^{\#}(x)$ by $f^{\#}(x):=\sup_{z\in Q+x}|f(z)|$. Then

$$CB := \{f \mid f \text{ continuous}, f^{\#}\in B\}. \tag{2.2}$$

defines a Banach space with the norm

$$\|f\|_{CB} := \|f^{\#}\|_B. \tag{2.3}$$

We shall denote the space $CL^1_a(\mathbb{R}^m)$ by $C^1_a(\mathbb{R}^m)$. Note that the Schwartz space $\mathcal{S}(\mathbb{R}^m)$ is continuously embedded into these spaces: $\mathcal{S}(\mathbb{R}^m)\hookrightarrow C^1_a(\mathbb{R}^m)$ for any $a\in\mathbb{R}$. The second space associated with B in a natural way allows us to deal with discrete measures with a certain global behavior.

DEFINITION 2.2. For Q as above we set

$$MB = \{\mu\in R(\mathbb{R}^m), \text{with } q_\mu : x\mapsto |\mu|(x+Q)\in B\}, \tag{2.4}$$

$$\|\mu\|_{MB} := \|q_\mu\|_B. \tag{2.5}$$

For a discrete set $X=(x_i)_{i\in I}$ in $\mathbb{R}^m$ we shall write MB_X for the closed subspace $\{\mu=\sum_{i\in I}\lambda_i\delta_{x_i}, \mu\in MB\}$ of measures in MB supported on X.

In the last two definitions different bounded sets Q_1, Q_2 generate the same space and equivalent norms; hence $g\in CB$ if and only if $g^{\#\#}\in B$. For any positive $k\in\mathcal{K}(\mathbb{R}^m)$, $\||\mu|*k\|_B$ is also an equivalent norm for MB. These facts are used in the sequel (e.g., for (2.9) below) without notice.

Next we describe basic properties of these spaces.

THEOREM 2.1. *Let* $(B, \| \|_B)$ *satisfy the general assumptions* (B1)-(B3′). *Then the following hold*:

(i) *CB and MB are Banach spaces satisfying properties* (B1)-(B3′), *with the following continuous embeddings*:

$$CB \hookrightarrow B \hookrightarrow MB. \tag{2.6}$$

(ii) $MB * C^1_a \subseteq CB$, *and* $\|\mu*g\|_{CB}\leqq C_0\|\mu\|_{MB}\cdot\|g\|_{C^1_a}$ *for all* $\mu\in MB$ *and* $g\in C^1_a$.

(iii) *The spaces* MB^Ω, B^Ω, *and* CB^Ω *coincide, and the respective norms are equivalent for any compact subset* $\Omega\subseteq\mathbb{R}^m$, *i.e., any* $\mu\in MB^\Omega$ *is represented by a function* $f\in CB$, *and there exists a constant* $C_\Omega>0$ *such that* $\|f\|_{CB}\leqq C_\Omega\|f\|_B\leqq C_\Omega\|f\|_{MB}$ *for all* $f\in MB^\Omega$.

(iv) *If* $\mathcal{K}(\mathbb{R}^m)$ *is dense in B, then it is dense in CB.*

Remark 2.2. In view of the examples above we assume that (2.6) holds in the form

$$\|f\|_{MB}\leqq\|f\|_B\leqq\|f\|_{CB} \quad \text{for all } f\in CB.$$

Proof of Theorem 2.1. The verification of (i) and (iv) is left to the interested reader; cf. [F2]. For (ii) we have to verify $(\mu*f)^{\#}\in B$. By direct computation the following two pointwise estimates can be obtained:

$$(\mu*f)^{\#}\leqq|\mu|*f^{\#}, \tag{2.7}$$

and for any $k\in\mathcal{K}(\mathbb{R}^m)$, $k\geqq0$, with supp $k\subseteq Q=-Q$ and $\int_{\mathbb{R}^m}k(y)\,dy=1$,

$$h^{\#}*k\geqq|h|. \tag{2.8}$$

Combining these two estimates we obtain

$$(2.9) \qquad (\mu * g)^{\#} \leqq |\mu| * g^{\#} \leqq |\mu| * (k * g^{\#\#}) = (|\mu| * k) * g^{\#\#} \in B * L^1_a \subseteq B$$

whenever $\mu \in MB$ and $g^{\#\#} \in L^1_a$, i.e., $g \in C^1_a$, and the proof of (ii) is complete.

Since spec $\mu \subseteq \Omega$, $\mu = \mu * g$ holds for any $g \in C^1_a$ with $\hat{g}(t) \equiv 1$ on Ω. Consequently, $\mu = \mu * g \in MB * C^1_a \subseteq CB$ by (ii). This also gives the required estimate (cf. Remark 2.2)

$$(2.10) \quad \|\mu\|_{MB} \leqq \|\mu\|_B \leqq \|\mu\|_{CB} = \|\mu * g\|_{CB} \leqq \|(\mu * g)^{\#}\|_B \leqq C_B \|\mu\|_{MB} \|g^{\#}\|_{1,a}. \qquad \square$$

Besides these *convolution relations* two special types of *operators* on *CB* and *MB* are needed. Both involve so-called δ-PUs.

Definition 2.3. We call a family of nonnegative (measurable) functions $\Psi = (\psi_i)_{i \in I}$ a *δ-partition of unity* (δ-PU for short) if the following is satisfied: $\sum_{i \in I} \psi_i(x) \equiv 1$ on $\mathbb{R}^m$, and supp $\psi_i \subseteq K_\delta(x_i)$ for $i \in I$ for some discrete family $X = (x_i)_{i \in I}$ in $\mathbb{R}^m$. Here $K_\delta(x)$ denotes the open ball of radius δ centered at x. We shall use the symbol $|\Psi|$ for the infimum over all numbers δ such that Ψ is a δ-PU.

Note that X has to be *δ-dense* in $\mathbb{R}^m$, i.e., $\mathbb{R}^m = \bigcup_{i \in I} K_\delta(x_i)$ for any δ-PU Ψ.

Examples of δ-partitions of unity. (a) If X is any δ-dense family and $(P_i)_{i \in I}$ is a partition of $\mathbb{R}^m$ such that $P_i \subseteq K_\delta(x_i)$, then the family of indicator functions $(c_{P_i})_{i \in I}$ is a δ-PU. The use of Voronoi regions is most natural for our task (cf. [FG3]).

(b) If $\psi_0(x) = 1 - |x|/\delta$ for $|x| \leqq \delta$ and $\psi_0(x) = 0$ for $|x| > \delta$, then $L_{\delta n}\psi_0$, $n \in \mathbb{Z}$ is a continuous δ-partition for $\mathbb{R}$.

(c) For irregular sequences in $\mathbb{R}$ we can take triangular functions with $\psi_i(x_i) = 1$ and supported by $[x_{i-1}, x_{i+1}]$. The natural analogue for $\mathbb{R}^2$ can be described as follows. Starting with a triangulation induced from the set X, choose the functions to satisfy $\psi_i(x_i) = 1$ and to be piecewise linear over the triangles having x_i as a vertex; cf. [SA].

(d) For any δ-dense family X in $\mathbb{R}^m$ we can find smooth δ-PUs. In the regular case smooth PUs in $\mathbb{R}^m$ of the form $L_{\delta n}\psi_0$, $n \in \mathbb{Z}^m$, can be obtained using B-splines.

Remark 2.3. In many cases it is convenient to work with families $X = (x_i)_{i \in I}$ which are *well spread* in the following sense: X is δ-dense and *relatively separated* in $\mathbb{R}^m$, i.e., X is a *finite union* of subfamilies, such that $|x_i - x_j| \geqq \delta_0 > 0$ for all $i \neq j$ in the same subfamily, for some $\delta_0 > 0$. In this case the covering through the balls $K_\delta(x_i)$ is of finite height. Of course a sequence is relatively separated in $\mathbb{R}$ if $|x_n - n| \leqq C$ for all $n \in \mathbb{N}$ (cf. [BH2] for a two-dimensional version).

Remark 2.4. If the family Y is well spread and v is a moderate function, then $\mu = \sum_{j \in J} c_j \delta_{y_j} \in (ML^p_v)_Y$ if and only if $(\sum_{j \in J} |c_j|^p v(y_j)^p)^{1/p} < \infty$. For well-spread families it is also easy to check that $\sum_{j \in J} |f(y_j)|^p v(y_j)^p \leqq C^p_Y \|f\|^p_{CL^p_v}$ for all $f \in CL^p_v$. The estimate given in Theorem 2.1(iii) is thus a generalization of Nikolskij's inequality to general p and m dimensions (cf. [Ni, pp. 123–125], or [BH2, Thm. 1] for special cases with $p = 2$).

Using δ-PUs we define the following operators.

Definition 2.4. Given a δ-PU Ψ associated with a family X we denote by Sp_Ψ (actually we should write $Sp_{\Psi,X}$) the operator defined for continuous f:

$$(2.11) \qquad Sp_\Psi(f) := \sum_{i \in I} f(x_i)\psi_i.$$

We also use the same symbol Sp_Ψ in order to describe a related operator which maps sequences $\Lambda = (\lambda_i)_{i \in I}$ into functions on $\mathbb{R}^m$:

$$Sp_\Psi(\Lambda) := \sum_{i \in I} \lambda_i \psi_i.$$

Remark 2.5. Note that $\|Sp_\Psi(f)\|_\infty \leqq \|f\|_\infty$ for $f \in C^b(\mathbb{R}^m)$, and $Sp_\Psi(f) \in C^b(\mathbb{R}^m)$ if in addition Ψ consists of continuous functions. If Ψ consists of piecewise polynomials of fixed order, then $Sp_\Psi(f)$ is a spline approximation (or quasi interpolant) of f, which explains our notation. If Ψ is a system of triangular functions on $\mathbb{R}$, then $Sp_\Psi f$ is the piecewise linear interpolation of the sampling values of f at X. Basic properties of Sp_Ψ are collected in the following proposition.

Proposition 2.2. *Assume that* $(B, \| \|_B)$ *satisfies* (B1) *and* (B2).

(i) *There is a constant* $C_S > 0$ *such that* $\|Sp_\Psi f\|_B \leqq C_S \|f\|_{CB}$ *for all* $f \in CB$; *The family* Sp_Ψ *of all spline operators with continuous* Ψ *and* $|\Psi| \leqq 1$ *acts uniformly bounded on any space CB.*

(ii) supp $(Sp_\Psi f) \subseteq$ supp $(f) + K_1(0)$; *hence* $Sp_\Psi(\mathcal{K}(\mathbb{R}^m)) \subseteq \mathcal{K}(\mathbb{R}^m)$ *for* Ψ *in* $\mathcal{K}(\mathbb{R}^m)$.

(iii) $Sp_\Psi f \to f$ *with respect to* $\| \|_\infty$ *for* $|\Psi| \to 0$, *for any* $f \in \mathcal{K}(\mathbb{R}^m)$, *and consequently,* $Sp_\Psi f \to f$ *in CB for any* $f \in CB$, *whenever* $\mathcal{K}(\mathbb{R}^m)$ *is dense in B.*

(iv) *For fixed X the operator* Sp_Ψ *may be considered as a bounded operator from* MB_X *into B, i.e., we have*

$$\|Sp_\Psi(\Lambda)\|_B \leqq C \cdot \left\| \sum_{i \in I} \lambda_i \delta_{x_i} \right\|_{MB}.$$

Proof. (i) It is easily verified that $\sup_{z \in x+Q} |Sp_\Psi f(z)| \leqq \sup_{z \in x+Q_1} |f(z)|$ for $Q_1 := Q + K_1(0)$, because supp $\psi_i \subseteq K_1(x_i)$ for all $i \in I$. Taking the B-norm with respect to x on both sides proves both statements of (i). The simple proof of (ii) and (iii) is left to the interested reader. (iv) follows from

$$|Sp_\Psi(\Lambda)(x)| \leqq \sum_{i \in I} |\lambda_i| \psi_i(x) \leqq \sum_{\psi_i(x) \neq 0} |\lambda_i| \leqq q_\mu(x)$$

with $\mu = \sum_{i \in I} \lambda_i \delta_{x_i}$ and $Q := K_1(0)$, if $|\Psi| \leqq 1$, by taking the B-norm on both sides.

Next we introduce an operator which replaces a given function by a discrete measure. In order to avoid confusion with the PU Ψ used above we now write $\Phi = (\varphi_j)_{j \in J}$ for a PU associated with $Y = (y_j)_{j \in J}$ in $\mathbb{R}^m$.

DEFINITION 2.5. The discrete measure obtained from $f \in L^1_{\text{loc}}(\mathbb{R}^m)$ through concentration of mass by means of Φ is denoted by

$$D_\Phi f := \sum_{j \in J} \langle f, \varphi_j \rangle \delta_{y_j},$$

with $\langle f, \varphi_j \rangle = \int_{\mathbb{R}^m} \varphi_j(x) f(x)\, dx$.

The following properties of these operators are of interest to us.

PROPOSITION 2.3. *Assume that* $(B, \| \|_B)$ *satisfies* (B1)-(B3′).

(i) *There is a constant* $C_D > 0$ *such that for all* $f \in B$ *and all* Φ *with* $|\Phi| \leqq 1$,

$$\|D_\Phi f\|_{MB} \leqq C_D \|f\|_B;$$

(ii) *Assume that* $\mathcal{K}(\mathbb{R}^m)$ *is dense in B. Then* $D_\Phi f * h \to f * h$ *in CB, hence in B and uniformly over compact sets, for* $h \in C^1_a$, *as* $|\Phi| \to 0$.

Proof. In order to determine the norm of $D_\Phi f$ in MB we observe that

$$|D_\Phi f|(x+Q) = \sum_{\{j \mid y_j \in x+Q\}} |\langle f, \varphi_j \rangle|$$

$$\leqq \int_{\mathbb{R}^m} \left(\sum_{\{j \mid y_j \in x+Q\}} |f(y) \varphi_j(y)| \right) \leqq |f| * c_{Q_1}(x)$$

where c_{Q_1} is the indicator function of $Q_1 := Q + K_1(0)$. Since $|f| * c_{Q_1} \in B * L^1_a \subseteq B$ by (B3′) we obtain $\|D_\Phi f\|_{MB} \leqq C_1 \|\mu\|_{MB}$. The proof of (ii) is left to the interested reader.

Remark 2.6. Note that both Sp_Ψ and D_Φ are not bounded on B itself, and that the auxiliary spaces CB and MB are essential for our approach.

3. The main results. With the notations of § 2 we now describe the results about reconstruction and series expansions of irregularly sampled band-limited functions. The main theorems will contain two parts. The first part asserts the existence of a reconstruction operator. This formulation reveals the stability of the reconstruction and the correct norm estimates. The second part realizes the reconstruction operator as an iterative procedure. This form emphasizes the algorithmic aspect of the reconstruction. The corollaries make clear that for well-spread families the results can be described using natural Banach spaces of sequences instead of MB.

The first theorem deals with the complete reconstruction of band-limited functions from their sampling values.

THEOREM 3.1 (General sampling theorem for band-limited functions). *Let Ω be a compact subset of $\mathbb{R}^m$. Then there exist $\delta = \delta(\Omega) > 0$ and $C = C(\delta, \Omega) > 0$ such that for any δ-PU Ψ on $\mathbb{R}^m$ there is a bounded operator $\mathbf{B}: B \to B^\Omega$ with*

$$\|\mathbf{B}(\phi)\|_B \leqq C \cdot \|\phi\|_B, \tag{3.1}$$

which inverts Sp_Ψ on B^Ω, i.e., $f = \mathbf{B}(Sp_\Psi f)$ for all $f \in B^\Omega$. Consequently, f can be completely recovered from the sampling values $(f(x_i))_{i\in I}$.

The operator $\mathbf{B}$ can be realized by the following iterative algorithm: Fix a pair of band-limited functions $g, h \in L_a^1$ such that $\hat{g}(t) \equiv 1$ on Ω and $\hat{h}(t) \equiv 1$ on spec g. *Set*

$$\phi_0 := \phi \quad \textit{and} \quad \phi_{k+1} := \phi_k * h - Sp_\Psi(\phi_k * h); \tag{3.2}$$

Then

$$\mathbf{B}(\phi) = \left(\sum_{k=0}^{\infty} \phi_k\right) * g. \tag{3.3}$$

Formula (3.1) expresses the stability of the reconstruction. The algorithm satisfies all the other natural requirements discussed in the introduction. For more precise statements about the locality, see Theorem 3.4 and [FG4].

The operations involved can be easily implemented and our first numerical experiments have shown that the algorithm works efficiently. As has been shown in [Gr2], the required sampling density (at least for the one-dimensional case and a natural choice of Ψ) is just the Nyquist rate.

If $\Omega = [-1, 1]$, $g = h = \text{sinc}$, and Ψ is a system of triangular (or pyramid) type functions on $\mathbb{R}$ or $\mathbb{R}^2$, then the algorithm can be shown to be equivalent to method (2) suggested in [SA] (without proof for the irregular case there). Since $\text{sinc} \notin L^1$, our argument for the convergence of the algorithm cannot be applied directly, but the arguments given in § 4 are easily adjusted to this case.

COROLLARY A. *Given a compact set $\Omega \subseteq \mathbb{R}^m$ there exists $\delta = \delta(\Omega) > 0$ such that for* any *δ-dense, well-spread family X in $\mathbb{R}^m$ the following is true: There exists a bounded linear operator $\mathbf{R}$ from the sequence space $l_v^p := \{\Lambda | (\sum_{i\in I} |\lambda_i|^p v(x_i)^p)^{1/p} < \infty\}$ into $L_v^p(\mathbb{R}^m)$ such that $\mathbf{R}$ provides a complete reconstruction of f from its sampling values, i.e., $\mathbf{R}(f(x_i)_{i\in I}) = f$ for all $f \in (L_v^p)^\Omega$. For given Ω, X the same $\mathbf{R}$ and δ work for all a-moderate weights v and $1 \leqq p \leqq \infty$.*

A "dual" variant of Theorem 3.1 yields series expansions in terms of translates of a single function.

THEOREM 3.2 (Series expansions for band-limited functions). *For any $g \in L_a^1$ with $\hat{g}(s) \neq 0$ on a compact set $\Omega \subseteq \mathbb{R}^m$ there is a positive number $\gamma = \gamma(\Omega, g) > 0$ such that* *for any γ-dense family $Y=(y_j)_{j\in J}$ there is a bounded linear operator* $\mathbf{D}$ *from B^Ω into MB_Y satisfying*

$$f=D(f)*g \quad \text{for all } f\in B^\Omega.$$

Writing $\mathbf{D}(f)=\sum_{j\in J}c_j\delta_{y_j}$, *this means*

$$f=\sum_{j\in J}c_jL_{y_j}g. \tag{3.4}$$

The coefficients are obtained as $c_j:=\sum_{k=0}^\infty\langle\varphi_j,f_k\rangle$, where the sequence $(f_k)_{k=0}^\infty$ is given iteratively (using an auxiliary function g_1) by

$$f_0:=f*g_1 \quad \text{and} \quad f_{k+1}:=(f_k-D_\Phi f_k)*h, \tag{3.5}$$

Remark 3.1. Since the sampling sets in $\mathbb{R}^m$ do not have any natural order, we understand convergence of a series $h=\sum_{i\in I}h_i$ in the following sense: for any exhausting sequence $F_n\subseteq I$ of finite subsets of I, i.e., $F_n\subseteq F_{n+1}$ and $\bigcup_{n=1}^\infty F_n=I$, the sequence of partial sums $\sum_{i\in F_n}h_i$ converges to h. Consequently, these series converge unconditionally, i.e., they converge for any fixed enumeration of I. If $I=\mathbb{Z}^m$, the interpretation as a multiple iterated sum is also admissible.

COROLLARY B. *Under the assumptions of Theorem* 3.2 *for any η-dense family Y in $\mathbb{R}^m$ there is a bounded linear operator $\mathbf{C}:(L_v^p)^\Omega\to l_v^p$ such that $f(x)=\sum_{j\in J}(\mathbf{C}f)_jg(x-y_j)$ holds for every $f\in(L_v^p)^\Omega$. The series converges uniformly over compact sets and for $1\leqq p<\infty$ also in the norm of L^p.*

The next theorem offers an alternative reconstruction algorithm which is easier to implement numerically and computationally less intensive, but the required sampling density for this algorithm may be higher.

THEOREM 3.3 (Method of adaptive weights). *Given $\Omega\subseteq\mathbb{R}^m$ compact, $g\in L_a^1$ with $\hat g(t)\equiv1$ on Ω and $h\in L_a^1$ with $\hat h(t)\equiv1$ on* spec(g), *there exists $\eta=\eta(\Omega,g)>0$ such that $f\in B^\Omega$ can be reconstructed from its sampled values $(f(x_i)_{i\in I})$ on any η-dense family X by the following algorithm: Set $w_i=\int\psi_i(x)\,dx$ and*

$$\begin{aligned}\phi_0&=\sum_{i\in I}f(x_i)\cdot w_i\cdot\delta_{x_i}\in MB_X,\\ \phi_{k+1}&=\phi_k*h-\sum_{i\in I}\phi_k(x_i)\cdot w_i\cdot L_{x_i}h.\end{aligned}\tag{3.6}$$

Then $f=\sum_{n=0}^\infty\phi_n*g$ and the right side depends only on the sampling values $(f(x_i)_{i\in I})$.

Remark 3.2. The proof will show that the partial sums

$$f^{(n)}:=\sum_{i\in I}w_i\sum_{k=0}^n\phi_k(x_i)\cdot L_{x_i}g \tag{3.7}$$

are convergent to f at a geometric rate.

The following variant of Theorem 3.1 is of interest if many functions with the same spectrum are to be reconstructed from samples taken over the same family X or if X and Ω are given in advance.

THEOREM 3.4. *Under the conditions of Theorem* 3.1 *there is a family $(e_i)_{i\in I}$ in C_a^1 such that $f\in B^\Omega$ can be written as $f=\sum_{i\in I}f(x_i)e_i$. The series converges uniformly over compact sets and, if $\mathcal{K}(\mathbb{R}^m)$ is a-dense in B, in the norm of CB.*

Theorem 3.4 expresses the locality of the reconstruction. In contrast to the sinc-functions in the classical cardinal series the e_i's have much better decay properties. In applications the collection of functions $(e_i)_{i\in I}$ may be calculated in advance, using only the knowledge of Ω and the sampling set X. Given the sampling values $(f(x_i))_{i\in I}$, the reconstruction of f is then obtained quickly by ordinary summation.

Remark 3.3. The representation of f as a series in $(e_i)_{i\in I}$ is not unique. In contrast in Kadec's $\frac{1}{4}$-theorem the functions $(e_i)_{i\in I}$ are not linearly independent in general and thus do not constitute a basis. On the other hand, these series expansions work simultaneously for all p, $1\leqq p<\infty$. The nonuniqueness of the expansion is closely related to numerical stability.

In our last theorem we combine the two aspects of the regular sampling theorem and show how for a given family Y a suitable sequence of coefficients for a series expansion of the form (3.4) can be computed directly from the sampled values of f alone.

THEOREM 3.5 (Combined sampling and expansion). *Given $g\in L^1_a$ with $\hat{g}(x)\equiv 1$ on a compact set $\Omega\subseteq\mathbb{R}^m$, there exist two constants $\delta=\delta(\Omega, g)>0$ and $\gamma=\gamma(\Omega, g)>0$ such that for any two families $(x_i)_{i\in I}$ and $(y_j)_{j\in J}$ which are δ and γ-dense, respectively, there is a linear mapping* $\mathbf{M}$ *from the space of sampling values $\{(f(x_i)_{i\in I}), f\in B^{\Omega}\}$ into MB_Y satisfying*

$$f=\mathbf{M}(f(x_i))*g=\sum_{j\in J} c_jL_{y_j}g. \tag{3.8}$$

The coefficients can be obtained from a sequence defined iteratively by

$$f_0:=f, f_{k+1}:=f_k*h-(D_{\Phi}Sp_{\Psi}f_k)*h, \tag{3.9}$$

through

$$c_j:=\sum_{k=0}^{\infty}\langle\phi_j, Sp_{\Psi}f_k\rangle.$$

COROLLARY C. *If in the situation of Theorem 3.5 the sets X and Y are well spread, there exists a bounded linear operator* $\mathbf{N}$ *from $l^p_v(I)$ into $l^p_v(J)$ such that for $f\in(L^p_v)^{\Omega}$,*

$$f(x)=\sum_{j\in J}\mathbf{N}(f(x_i)_{i\in I})_j g(x-y_j),$$

with convergence in L^p_v for $1\leqq p<\infty$.

4. Proofs.

LEMMA 4.1. *For any compact subset $\Xi\subseteq\mathbb{R}^m$ there exists some constant $C^1_{\Xi}=C(\Xi, a)>0$ such that uniformly for all δ-PUs Ψ and spaces B satisfying* (B1)–(B3′)

$$\|f-Sp_{\Psi}f\|_B\leqq C^1_{\Xi}\cdot\|f\|_B\cdot\delta \quad \textit{for all } f\in B^{\Xi}.$$

Proof. We discuss the one-dimensional case first and check that the condition $\operatorname{spec} f\subseteq\Xi$ implies $f'\in CB$. Since $\hat{f'}(t)=2\pi it\hat{f}(t)$ for all $t\in\mathbb{R}$ it is sufficient to choose some $u\in\mathcal{S}(\mathbb{R})$ such that $\hat{u}$ is in $\mathcal{D}$ (infinitely differentiable with compact support) and satisfies $\hat{u}(t)=2\pi it$ on Ξ. Then $f'=f*u$, and since $\mathcal{S}(\mathbb{R}^m)\subseteq C^1_a$ this implies $f'\in CB$, and by Theorem 2.1(ii),

$$\|f'\|_{CB}\leqq C_0\|f\|_B\|u\|_{C^1_a}. \tag{4.1}$$

The mean value theorem implies

$$|f(x)-f(y)|\leqq\sup_{z\in K_\delta(x)}|f'(z)|\cdot\delta \quad \text{for } x, y\in\mathbb{R}^m \quad \text{with } |x-y|\leqq\delta.$$

It follows therefore that (note that $\operatorname{supp}\psi_i\subseteq K_\delta(x_i)$)

$$|(f(x)-f(x_i))\psi_i(x)|\leqq\delta\cdot\sup_{z\in K_\delta(x)}|f'(z)|\cdot\Psi_i(x). \tag{4.2}$$

By summation over $i \in I$, using the properties of a δ-PU we obtain

$$|(f - Sp_\Psi f)(x)| \leqq \sum_{i \in I} |(f(x) - f(x_i))\psi_i(x)| \leqq \delta \cdot \sup_{z \in K_\delta(x)} |f'(z)|,$$

and, after taking B-norms on both sides,

$$\|Sp_\Psi f - f\|_B \leqq \delta \cdot \|f'\|_{CB} \leqq \delta \cdot C^1_\Xi \|f\|_B, \tag{4.3}$$

for $C^1_\Xi := C_0 \cdot \|u\|_{C^1_a}$. This completes the proof in the one-dimensional case.

In the case $m \geqq 2$ we use that the partial derivatives on B^Ξ can be represented as convolution operators, i.e., $\partial f/\partial x_k = f * u_k$ for all $f \in B^\Xi$ if $u_k \in \mathscr{S}(\mathbb{R}^m)$ satisfies $\hat{u}_k(t) = 2\pi i t_k$ on Ξ. Thus

$$|\operatorname{grad} f(x)| = \left(\sum_{k=1}^m (\partial f/\partial x_k(x))^2 \right)^{1/2} \leqq \sum_{k=1}^m |\partial f/\partial x_k(x)| = \sum_{k=1}^m |f * u_k(x)|.$$

Setting $u(x) := \sum_{k=1}^m |u_k(x)|$, we have $u \in C^1_a$ and

$$|\operatorname{grad} f(x)| \leqq (|f| * u)(x) \quad \text{for all } x \in \mathbb{R}^m. \tag{4.4}$$

Invoking the mean value theorem we obtain for any $y \in B_\delta(x)$

$$|f(x) - f(y)| \leqq |x - y| \sup_{z \in K_\delta(x)} |\operatorname{grad} f(z)| \leqq \delta \cdot \sup_{z \in K_\delta(x)} (|f| * u)(z).$$

By Theorem 2.1(ii) we have $|f| * u \in CB$ and the same arguments as above apply (with f' being replaced by $|f| * u$). □

Remark 4.1. Observe that in the above situation we have the inequality

$$|\operatorname{grad} f|^\# \leqq |f| * u^\#. \tag{4.5}$$

Using (2.7) and (4.4) we therefore derive the estimate

$$\|\operatorname{grad} f\|_{CB} \leqq C^2_\Xi \cdot \|f\|_B \quad \text{for} f \in B^\Xi. \tag{4.6}$$

This result is a generalization of Bernstein's inequality from L^p to general function spaces B.

Proof of Theorem 3.1. Given $\Omega \subseteq \mathbb{R}^m$ compact, we fix a pair of band-limited functions $g, h \in L^1_a(\mathbb{R}^n)$ such that $\hat{g}(t) = 1$ on Ω, and $\hat{h}(t) = 1$ on spec g (any pair of Schwartz functions $\hat{g}, \hat{h} \in \mathscr{S}$ satisfying the condition will do). Consequently,

$$h * g = g, \qquad f * g = f = f * g * h \quad \text{for all } f \in B^\Omega. \tag{4.7}$$

In order to define the operator $\mathbf{B}$ on the Banach space $(B, \| \ \|_B)$ we define for $\phi \in B$ a sequence, starting with $\phi_0 = \phi$:

$$\phi_{k+1} := \phi_k * h - Sp_\Psi(\phi_k * h). \tag{4.8}$$

Since h is band-limited the functions $\phi_k * h$ are band-limited and Lemma 4.1 is applicable with $\Xi :=$ spec h. Hence (using (B3'))

$$\|\phi_{k+1}\|_B \leqq \delta \cdot C^1_\Xi \|\phi_k * h\|_B \leqq \delta \cdot C^1_\Xi \cdot C_B \|h\|_{1,a} \|\phi_k\|_B. \tag{4.9}$$

If $|\Psi| \leqq \delta$, such that $\delta \cdot C^1_\Xi C_B \|h\|_{1,a} =: \gamma < 1$, then

$$\|\phi_{k+1}\|_B \leqq \gamma \cdot \|\phi_k\|_B \leqq \gamma^{k+1} \|\phi\|_B \quad \text{for } k \geqq 0. \tag{4.10}$$

It follows that the operator $\mathbf{B}$ given as

$$\mathbf{B}(\phi) = \left(\sum_{n=0}^\infty \phi_n \right) * g \tag{4.11}$$

is well defined on B, with values in B^{Ξ}, and bounded due to the estimate

$$\begin{aligned}\|\mathbf{B}(\phi)\|_B &\leqq C_B\cdot\left\|\sum_{n=0}^{\infty}\phi_n\right\|_B\|g\|_{1,a}\\ &\leqq C_B\cdot\sum_{n=0}^{\infty}\|\phi_n\|_B\|g\|_{1,a}\leqq(1-\gamma)^{-1}C_B\|\phi\|_B\|g\|_{1,a}.\end{aligned}\tag{4.12}$$

In order to verify that $\mathbf{B}$ inverts the spline operator Sp_Ψ over B^Ω we have to consider the sequence $(\phi_k)_{k=0}^{\infty}$, now starting with $\phi_0:=Sp_\Psi f$, for $f\in B^\Omega$. We also use the sequence $(f_k)_{k=0}^{\infty}$, given by recursion (4.8), and starting with $f_0:=f$, because it satisfies the following identity:

$$f=f_{k+1}*g+\left(\sum_{n=0}^{k}Sp_\Psi(f_n*h)\right)*g.\tag{4.13}$$

Equation (4.13) is clear for $k=0$ by (4.8) and follows immediately by induction for $k>0$. Moreover, since $\|f_{k+1}*g\|_B\to 0$ at a geometric rate, (4.13) yields the following representation of f as an absolutely convergent series in B:

$$f=\left(\sum_{n=0}^{\infty}Sp_\Psi(f_n*h)\right)*g.\tag{4.14}$$

It will now be sufficient to verify that

$$Sp_\Psi(f_k*h)*g=\phi_k*g,\tag{4.15}$$

because then (4.14) implies the required identity

$$\mathbf{B}(Sp_\Psi f)=\left(\sum_{k=0}^{\infty}\phi_k\right)*g=\sum_{k=0}^{\infty}Sp_\Psi(f_k*h)*g=f\quad\text{for} f\in B^\Omega.\tag{4.16}$$

In order to verify (4.15) we show first that

$$f_{k+1}=f_k-\phi_k\quad\text{for } k\geqq 0.\tag{4.17}$$

This is clear for $k=0$ by (4.8) and follows for general $k\geqq 1$ by induction:

$$\begin{aligned}f_k-\phi_k&=f_{k-1}*h-Sp_\Psi(f_{k-1}*h)-\phi_{k-1}*h+Sp_\Psi(\phi_{k-1}*h)\\&=(f_{k-1}-\phi_{k-1})*h-Sp_\Psi((f_{k-1}-\phi_{k-1})*h)\\&=f_k*h-Sp_\Psi(f_k*h)=f_{k+1}.\end{aligned}$$

Equation (4.15) is true for $k=0$ and follows from (4.17) by induction for $k\geqq 1$, using (4.8):

$$\begin{aligned}Sp_\Psi(f_{k+1}*h)*g&=Sp_\Psi(f_k*h)*g-Sp_\Psi(\phi_k*h)*g\\&=\phi_k*h*g-Sp_\Psi(\phi_k*h)*g=\phi_{k+1}*g.\end{aligned}$$

The proof of Theorem 3.1 is thus complete. □

Remark 4.2. Note that both Lemma 4.1 and the proof of Theorem 3.1 work simultaneously for all function spaces B that are convolution modules over the same Beurling algebra L_a^1. Thus the same constants arise for all such spaces having the same constant C_B in (B3). This will be important for Theorem 3.4.

Proof of Corollary A. We define the reconstruction operator $\mathbf{R}$ from l_v^p into L_v^p as follows: For $\Lambda=(\lambda_i)_{i\in I}\in l_v^p$ we set $\mathbf{R}(\Lambda):=\mathbf{B}(Sp_\Psi(\Lambda))$, i.e., we form iteratively

$$\phi_0:=\sum_{i\in I}\lambda_i\psi_i\quad\text{and}\quad\phi_{k+1}:=\phi_k*h-Sp_\Psi(\phi_k*h)\quad\text{for } k\geqq 1.\tag{4.18}$$

Then $\mathbf{R}(\Lambda) = (\sum_{k=0}^{\infty} \phi_k) * g$, the series is well defined in L_v^p and $\operatorname{spec} \mathbf{R}(\Lambda) \subseteq \operatorname{spec} g$. A combination of Theorem 3.1, Remark 2.4, and Proposition 2.2(iv) then yields the boundedness of $\mathbf{R}$ as an operator from l_v^p into L_v^p. Evidently, $\mathbf{R}$ applied to the sequence $\Lambda = (f(x_i))_{i\in I}$ yields $\mathbf{R}(\Lambda) = \mathbf{B}(Sp_\Psi f) = f$. Thus $\mathbf{R}$ is indeed a reconstruction operator. □

The following result will play the same role in the proof of Theorem 3.2 as Lemma 4.1 in the proof of Theorem 3.1. The operator D_Φ is as in Proposition 2.3.

LEMMA 4.2 (Discretization of convolution). *For any compact subset $\Xi \subseteq \mathbb{R}^m$ there exists some constant $C_\Xi^3 = C(\Xi, a) > 0$ such that uniformly for all η-PUs Φ and all spaces B satisfying* (B1)-(B3′),

$$\|(f - D_\Phi f) * h\|_{CB} \leqq \eta \cdot C_\Xi^3 \cdot \|f\|_B \cdot \|h\|_{1,a} \tag{4.19}$$

for any band-limited $h \in L_a^1$ with $\operatorname{spec} h \subseteq \Xi$ and $f \in B$.

Proof. Given an η-PU $\Phi = (\varphi_j)_{j\in J}$ we consider for fixed $j \in J$

$$|(f\varphi_j - \langle f, \varphi_j\rangle \delta_{y_j}) * h| \leqq \int_{K_\eta(y_j)} |h(x-y) - h(x-y_j)|\,|f\varphi_j|(y)\,dy =: I. \tag{4.20}$$

Next we observe that the mean value theorem implies for fixed x, y, y_j:

$$|h(x-y) - h(x-y_j)| \leqq \eta \cdot |\operatorname{grad} h(\xi)|,$$

with ξ between $x-y$ and $x-y_j$; hence $\xi \in K_\eta(x-y)$, and we may continue the estimate by

$$I \leqq \int_{K_\eta(y_j)} \eta \cdot |\operatorname{grad} h|^{\#}(x-y)|f\varphi_j|(y)\,dy \leqq \eta \cdot |f\varphi_j| * (\operatorname{grad} h)^{\#}(x).$$

By summation over $j \in J$ we obtain from this the pointwise estimate

$$|(f - D_\Phi f) * h| \leqq \eta \cdot (|f| * (\operatorname{grad} h)^{\#}). \tag{4.21}$$

Since $\operatorname{spec}(f - D_\Phi f) * h \subseteq \operatorname{spec} h = \Xi$, the CB-norm is equivalent to its B-norm by Theorem 2.1(iii) for these functions. Using (B3′) we obtain as in (4.4) (cf. Remark 4.1):

$$\begin{aligned} \|(f - D_\Phi f) * h\|_{CB} &\leqq \|(f - D_\Phi f) * h\|_B \leqq \eta \|\,|f| * |\operatorname{grad} h|^{\#}\|_B \\ &\leqq \eta \cdot C_B \|f\|_B \,\|\,|\operatorname{grad} h|^{\#}\|_{1,a} \leqq \eta \cdot C_B C_\Xi^2 \cdot \|h\|_{1,a} \cdot \|f\|_B. \end{aligned} \tag{4.22}$$

Thus $C_\Xi^3 := C_B \cdot C_\Xi^2$ is an appropriate choice. □

Proof of Theorem 3.2. By the theorem of Wiener-Levy (cf. [Rei, Chaps. 1, 6.5]) there exists a band-limited function $g_1 \in L_a^1$ such that $\hat{g}_1(t) = 1/\hat{g}(t)$ on Ω. Next we choose a band-limited function $h \in \mathcal{S}(\mathbb{R}^m) \subseteq L_a^1$ with $\hat{h}(t) \equiv 1$ on $\operatorname{spec} g \cup \operatorname{spec} g_1$. Then

$$\begin{gathered} g * h = g, \qquad g_1 * h = g_1, \\ f * h = f * g_1 * g = f \quad \text{for all } f \in B^\Omega. \end{gathered} \tag{4.23}$$

We want to show that in the identity $f = (f * g_1) * g$ the factor $f * g_1$ can be replaced by a discrete measure. To this end we start an iteration procedure similar to that of Theorem 3.1, but with a different approximation of the convolution $f \mapsto f * h$. We define

$$f_0 := f * g_1, \qquad f_{k+1} := (f_k - D_\Phi f_k) * h, \tag{4.24}$$

with $D_\Phi\colon B \to MB$ as in Lemma 4.2. It follows by induction that

$$f = f_{k+1} * g + \left(\sum_{n=0}^{k} D_\Phi f_n\right) * g. \tag{4.25}$$

Substituting (4.24) and (4.23) into (4.25), we obtain for $k=0$

$$f_1 * g + (D_\Phi f_0) * g = f * g_1 * h * g - D_\Phi(f * g_1) * h * g$$
$$+ D_\Phi(f * g_1) * g = f.$$

The step from k to $k+1$ is also clear, if we again use $g * h = g$. If we now choose $\eta = \eta(\Omega, g) < 1/(C_\Xi^3 \cdot \|h\|_{1,a})$, or $\gamma := \eta \cdot C_\Xi^3 \|h\|_{1,a} < 1$, then Lemma 4.2 implies for any η-PU Φ

$$\|f_{k+1}\|_B \leqq \gamma \cdot \|f_k\|_B \leqq \gamma^{k+1} \|f_0\|_B \quad \text{for } k \geqq 0. \tag{4.26}$$

Taking the limit as $k \to \infty$ in (4.25) the series representation for f follows:

$$f = \left(\sum_{n=0}^{\infty} D_\Phi(f_n) \right) * g = D_\Phi\left(\sum_{n=0}^{\infty} f_n \right) * g. \tag{4.27}$$

The interchange of brackets is justified by the fact that the series $F := \sum_{n=0}^{\infty} f_n$ is absolutely convergent in B, by the continuity of D_Φ from B into MB, and by the continuity of convolution by $g \in C_a^1$ (Theorem 2.1(ii)). Thus

$$f = (D_\Phi F) * g = \sum_{j \in J} \langle \varphi_j, F \rangle L_{y_j} g \tag{4.28}$$

yields the desired expansion of f in terms of translates of g. The continuous dependence of the measure $D_\Phi F$ follows from Proposition 2.3(i) and (4.26):

$$\begin{aligned} \|D_\Phi F\|_{MB} &\leqq C_D \|F\|_{MB} \leqq C_D \|F\|_B \leqq C_D \cdot \sum_{k=0}^{\infty} \|f_k\|_B \\ &\leqq C_D \left(\sum_{k=0}^{\infty} \gamma^k \right) \|f_0\|_B \leqq C_D C_B (1-\gamma)^{-1} \|g_1\|_{1,a} \|f\|_B. \end{aligned} \tag{4.29}$$

Thus the operator $\mathbf{D}$ is given as $\mathbf{D}(f) := D_\Phi F$. □

Remark 4.3. If $\hat{g}(t) \equiv 1$ on Ω, the auxiliary function g_1 is not necessary and the reconstruction of f is much simpler. The iteration is then $f_0 = f$

$$f_{k+1} = f_k * h - (D_\Phi f_k) * h \tag{4.30}$$

where $\hat{h}(t) \equiv 1$ on spec g. The rest of the argument is the same.

Proof of Corollary B. It is no loss of generality to assume that X is well spread (by selecting a δ-dense and separated subfamily, and setting the coefficient equal to zero for the omitted points). Thus all we have to show is that in (4.29) $\|D_\Psi F\|_{ML_v^p}$ is equivalent to $(\sum_{i \in I} |\langle \psi_i, F \rangle|^p v(x_i))^{1/p}$. This follows from Remark 2.4. □

For the proof of Theorem 3.3 we have to use a different discretization operator (only valid on B^Ω but not defined on all of B), which will take the same role as D_Φ in the proof of Theorem 3.2. For $f \in CB$ we set

$$D_\Psi^+(f) := \sum_{i \in I} \left(\int \psi_i(y)\, dy \right) f(x_i) \delta_{x_i}. \tag{4.31}$$

These operators D_Ψ^+ combines the features of Sp_Ψ and D_Ψ. Since D_Ψ^+ maps CB into MB_X and uses sampling values of $f \in CB$ it can be used as an approximation operator in both Theorems 3.1 and 3.2. Lemma 4.3 provides the necessary estimate.

LEMMA 4.3. *Let* $(B, \| \|_B)$ *satisfy* (B1)-(B3) (*for some* $a > 0$). *Then there exists* $C_{D+} > 0$ (*depending only on* a) *such that for any* δ-PU Ψ,

$$\|D_\Psi(f) - D_\Psi^+(f)\|_{MB} \leqq \delta \cdot C_{D+} \|f\|_B \quad \textit{for all } f \in B^\Omega. \tag{4.32}$$

In particular, for any $\varepsilon > 0$ *there exists* $\delta_0 > 0$ *such that*

$$\|(D_\Psi^+ f) * h - f * h\|_{CB} \leqq \varepsilon \cdot \|f\|_B \tag{4.33}$$

for all $f \in B^\Omega$ *and all* δ-PU Ψ *with* $\delta \leqq \delta_0$.

In the proof we shall use the following a priori estimate.

Remark 4.4. Given complex-valued sequences $(c_i)_{i\in I}$ and $(d_i)_{i\in I}$ satisfying $|c_i|\leqq d_i$ for all $i\in I$ we have

$$\mu=\sum_{i\in I} d_i\delta_{x_i}\in MB \text{ implies } \nu:=\sum_{i\in I} c_i d_{x_i}\in MB \text{ and } \|\nu\|_{MB}\leqq\|\mu\|_{MB}. \tag{4.34}$$

Proof of Lemma 4.3. The mean-value theorem implies for $i\in I$:

$$\int |f(y)-f(x_i)|\psi_i(y)\,dy\leqq\delta\cdot\int |\operatorname{grad} f|^{\#}(y)\psi_i(y)\,dy. \tag{4.35}$$

After summation over $i\in I$ Remark 4.4 implies

$$\begin{aligned}\|D_\Psi f-D_\Psi^+ f\|_{MB}&\leqq\left\|\sum_{i\in I}\left(\int |f(y)-f(x_i)|\psi_i(y)\,dy\right)\delta_{x_i}\right\|_{MB}\\ &\leqq\delta\cdot\|D_\Psi|\operatorname{grad} f|^{\#}\|_{MB}.\end{aligned} \tag{4.36}$$

Applying Proposition 2.3(i) and Remark 4.1 we obtain

$$\begin{aligned}\|D_\Psi|\operatorname{grad} f|^{\#}\|_{MB}&\leqq C_D\cdot\|\,|\operatorname{grad} f|^{\#}\|_{MB}\leqq C_D\|\,|\operatorname{grad} f|^{\#}\|_B\\ &=C_D\|\operatorname{grad} f\|_{CB}\leqq(C_D C_0\|u\|_{C_a^1})\|f\|_B.\end{aligned} \tag{4.37}$$

Thus $\|D_\Psi f-D_\Psi^+ f\|_{MB}\leqq\delta\cdot C_3\|f\|_B$ for all $f\in B^\Omega$. Combining this fact with Lemma 4.2, the proof is complete if we choose $\delta_0\leqq\varepsilon\cdot\min(\frac{1}{2},\frac{1}{2}C_\Xi^2)$. □

Proof of Theorem 3.3. We refer to the proof of Theorem 3.2 for the iterative procedure, indicating only that D_Φ has to be replaced by D_Ψ^+. Furthermore, g_1 may be chosen to be identical to g (cf. Remark 4.3). By using Lemma 4.3 instead of Lemma 4.2 geometric convergence of the sequence $(f_n)_{n=0}^\infty$ can be verified for sufficiently small δ. In analogy to (4.27) we obtain

$$f=D_\Psi^+\left(\sum_{n=0}^\infty f_n\right)*g. \tag{4.38}$$

Proof of Theorem 3.4. We use the operator **B** from Theorem 3.1 in order to define

$$e_i:=\mathbf{B}(\psi_i). \tag{4.39}$$

Since $\psi_i\in L_a^1$, Theorem 3.1 implies $e_i\in L_a^1(\mathbb{R}^n)$ and $\operatorname{spec} e_i\subseteq\Xi$, thus $e_i\in C_a^1$ for $i\in I$ by Theorem 2.1(iii). If $\mathcal{K}(\mathbb{R}^m)$ is dense in B, then obviously

$$\lim_{n\to\infty}\sum_{i\in F_n} f(x_i)\psi_i=\sum_{i\in I} f(x_i)\psi_i$$

in B for any increasing sequence of finite subsets $F_n\subseteq I$, exhausting I. Therefore by the boundedness of **B**

$$\begin{aligned}f=\mathbf{B}(Sp_\Psi f)&=\mathbf{B}\left(\lim_{n\to\infty}\sum_{i\in F_n} f(x_i)\psi_i\right)\\ &=\lim_{n\to\infty}\sum_{i\in F_n} f(x_i)e_i=\sum_{i\in I} f(x_i)e_i,\end{aligned} \tag{4.40}$$

i.e., the series converges in B. Since the family $(e_i)_{i\in I}$ has joint spectrum we may apply Theorem 2.1(iii) to derive convergence in CB, hence uniform convergence over compact sets in $\mathbb{R}^m$. □

The direct method of obtaining suitable coefficients from the sampling values as described in Theorem 3.5 requires the following technical lemma.

LEMMA 4.4 (From sampling values to coefficients). *Given $\Xi\subseteq\mathbb{R}^m$, compact and $\rho>0$ there exist $\delta=\delta(\Xi)$ and $\gamma=\gamma(\Xi,h)>0$ such that*

$$\|f*h-(D_\Phi Sp_\Psi f)*h\|_B\leqq\rho\cdot\|f\|_B \quad \textit{for all } f\in B^\Xi \tag{4.41}$$

and uniformly for all δ-PUs Φ and all γ-PUs Φ.

Proof. We combine Lemmas 4.1 and 4.2 and obtain for $f \in B^{\Xi}$

$$\begin{aligned} &\|f * h - (D_\Phi Sp_\Psi f) * h\|_B \\ &\quad \leqq \|(f - D_\Phi f) * h\|_B + \|D_\Phi(f - Sp_\Psi f) * h\|_B && \text{(by Lemma 4.2)} \\ &\quad \leqq \gamma C_\Xi^3 \|h\|_{1,a} \|f\|_B + C_0 \|D_\Phi(f - Sp_\Psi f)\|_{MB} \cdot \|h\|_{C_a^1} && \text{(by Theorem 2.1(ii))} \\ &\quad \leqq \gamma C_\Xi^3 \|h\|_{1,a} \|f\|_B + C_D C_0 \|f - Sp_\Psi f\|_B \|h\|_{C_a^1} \\ &&& \text{(by Proposition 2.3 and Lemma 4.1)} \\ &\quad \leqq (\gamma C_\Xi^3 \|h\|_{1,a} + C_D C_0 C_\Xi^1 \delta \|h\|_{C_a^1}) \cdot \|f\|_B. \end{aligned}$$

Now choose γ, δ small enough so that the coefficient of $\|f\|_B$ is less than ρ. □

Proof of Theorem 3.5. The proof is similar to those of Theorems 3.1. and 3.2. We choose $h \in L_a^1$ band-limited with $\hat{h}(t) = 1$ on spec g and define

$$f_0 := f, \qquad f_{k+1} := f_k * h - (D_\Phi Sp_\Psi f_k) * h. \tag{4.42}$$

Then $f_k \in B^{\Xi}$ for all k, and if δ and γ are small enough, by Lemma 4.4

$$\|f_{k+1}\|_B \leqq \rho \cdot \|f_k\|_B \tag{4.43}$$

with $\rho < 1$. Since $f = f * g = f * h * g$ and $g = g * h$ we have for $n \geqq 0$

$$f = f * g = f_{n+1} * g + \sum_{k=0}^{n} D_\Phi(Sp_\Psi f_k) * g. \tag{4.44}$$

Since $\rho < 1$ it follows

$$f = \left(\sum_{k=0}^{\infty} D_\Phi(Sp_\Psi f_k) \right) * g. \tag{4.45}$$

Since the series of discrete measures $\sum_{k=0}^{\infty} D_\Phi(Sp_\Psi f_k) = D_\Phi(\sum_{k=0}^{\infty} Sp_\Psi f_k)$ is supported on $Y = (y_j)_{j \in J}$ and absolutely convergent in MB, the result can be written as $\sum_{j \in J} c_j \delta_{y_j}$, with $c_j := \langle \varphi_j, \sum_{k=0}^{\infty} Sp_\Psi f_k \rangle$. This sum is unconditionally convergent in MB, and norm convergent, if $\mathscr{K}(\mathbb{R}^m)$ is dense in B. It follows therefore that $f = \sum_{j \in J} c_j L_{y_j} g$, as was required.

As in (4.29) we verify that the coefficient mapping (it can be described by an infinite matrix) $\mathbf{M}$: $f \mapsto C = (c_j)_{j \in J}$, is continuous. Finally, we show as in the proof of Theorem 3.1 that the f_k's and therefore $(c_j)_{j \in J}$ depend only on the sampling values $(f(x_i))_{i \in I}$. □

Corollary C follows from Theorem 3.3 in the same way that Corollary B follows from Theorem 3.2.

Note added in proof. Since the submission of this manuscript we have obtained further results on the algorithms of Theorems 3.1–3.3: (a) [FG4] contains a detailed error analysis of these algorithms and shows their stability, again in the general function space setting. (b) The results of numerical experiments have been very convincing; see [FGH], [FCH], [FCS]. Particularly, the adaptive weights method described in Theorem 3.5 using the D_Ψ^+-operator has turned to be simple and extremely effective.

Acknowledgment. We thank the referees for their valuable comments which helped to improve this paper.

ASYMPTOTICS OF THE SWALLOWTAIL INTEGRAL NEAR THE CUSP OF THE CAUSTIC*

D. KAMINSKI†

Abstract. The asymptotic behaviour of the "swallowtail integral" is examined, a generalized Airy function, given by

$$S(x,y,z) = \int_{-\infty}^{+\infty} \exp\{i(t^5/5 + xt^3/3 + yt^2/2 + zt)\}dt,$$

for large values of its parameters. In particular, its caustic is briefly discussed, and asymptotic expansions of S are obtained which are uniformly valid near cusps of the caustic as $|x|+|y|+|z| \to +\infty$.

In obtaining the asymptotics of S, the quartic transformation $f(t) = z^4/4 - \zeta z^2/2 + \eta z + \theta$ is used. Exact expressions for the parameters in this transformation are obtained, displaying ζ, η, and θ in terms of the known function f at its critical points.

1. Introduction.

The swallowtail integral is a function of three real variables defined by

$$S(x,y,z) = \int_{-\infty}^{+\infty} e^{i(t^5/5+xt^3/3+yt^2/2+zt)}dt. \tag{1.1}$$

By deforming the path of integration into the complex t-plane so that it begins at $\infty e^{9\pi i/10}$ and ends at $\infty e^{\pi i/10}$, we see that S can be extended to an entire function in $\mathbf{C}^3$. The swallowtail integral occupies important niches in several fields of mathematics and physics—in physics, S appears in both geometric optics and applications of catastrophe theory, paralleling the role played by Airy's integral (see [Gil]) and the Pearcey integral (see [Bri] and [Pea]).

The swallowtail integral arises when considering the large λ asymptotics of integrals of the form

$$G(\lambda;\alpha) = \int_{-\infty}^{+\infty} g(z;\alpha)e^{i\lambda f(z;\alpha)}dz, \tag{1.2}$$

where g and f are typically analytic, and $\alpha = (\alpha_1, \cdots, \alpha_n)$ is a collection of auxiliary parameters varying in some set A. If the saddle points of the integral (i.e., critical points of the phase function f) are all simple, then the asymptotics of (1.2) is given as a sum of terms each of order $\lambda^{-1/2}$. In the event that two simple saddles undergo confluence as $\alpha \to \alpha_0$, then the uniform asymptotic behaviour of (1.2) contains terms involving the Airy function and its derivative multiplied by powers of $\lambda^{-1/3}$. If three simple saddles coalesce as $\alpha \to \alpha_0$, then the uniform asymptotic behaviour of (1.2) can be described by terms containing the Pearcey function and its first-order derivatives,

each multiplied by powers of $\lambda^{-1/4}$, where the Pearcey function is given by

$$P(x,y) = \int_{-\infty}^{+\infty} e^{i(t^4/4+xt^2/2+yt)}dt. \tag{1.3}$$

The swallowtail integral enters the picture when four simple saddles of (1.2) undergo confluence as $\alpha \to \alpha_0$. In this case, the uniform asymptotic behaviour of (1.2) will be governed by terms involving S, S_x, S_y, and S_z, each multiplied by powers of $\lambda^{-1/5}$. Ursell, in [Urs], discussed the uniform asymptotic theory for integrals with several coalescing saddle points using an integral closely related to (1.1).

One factor serving to limit the utility of integrals of the type in (1.1) and (1.3) is the shortage of tables of values of these functions and a comparative lack of information regarding the large parameter behaviour of (1.1) and (1.2). The past few years have seen a growing body of work dedicated to resolving this difficulty. On the numerical side, Connor and his associates [Con1, Con2, Con3, Con4] have done significant work in developing tables for both P and S, but correspondingly little has been done in examining the large parameter behaviour of S (the Pearcey function has been analyzed in [Kam2, Par, Sta]).

In this work, we will develop asymptotic expansions of $S(x,y,z)$ which remain valid as three saddle points coalesce. The plan of the paper first involves a number of preliminary steps, collected in § 2, where a description of the so-called "caustic" associated with the swallowtail integral is presented. The type of asymptotic behaviour to be found for S near the caustic is briefly discussed, as is a detailed description of the behaviour of the saddle points of S.

The interesting case of large negative x behaviour of S, which serves as the focus of this paper, is taken up in § 3, with an examination of a quartic change of variables first used by Ursell in 1972; see [Urs]. In the process of developing the asymptotics of $S(x,y,z)$, we will provide the first "concrete" application of the Pearcey integral to uniform asymptotic theory.

Section 4 briefly examines the conformal mapping determined by the quartic transformation and shows why the attention we pay to the use of full steepest descent contours is important.

Section 5 examines the limiting forms of the uniform expansion obtained in § 3 and determines the values of the first three coefficients in the uniform expansion, at the caustic.

In the final portion of the paper, we present our results in the form of a theorem and show why restrictions imposed in earlier sections can be relaxed. A brief examination of the termwise differentiation of the uniform expansion is also undertaken.

2. Preliminaries.

2.1. Caustics. Let $F(t) = t^5/5+xt^3/3+yt^2/2+zt$ be the phase function of the integral (1.1). It is well known from stationary phase philosophy that the asymptotic behaviour of (1.1) is governed by the number and order of critical points of F, and in particular, by the number and order of those critical points that are real (if F has only complex critical points, S is of exponentially small order as $|x|+|y|+|z| \to \infty$).

For t_0 to be a zero of F' of order two or more requires that $F'(t) = t^4+xt^2+yt+z$ and $F''(t) = 4t^3+2xt+y$ both vanish simultaneously at $t = t_0$. If t_0 is a zero of order three, then we additionally must have $F'''(t) = 12t^2+2x$ equal to zero when $t = t_0$. Finally, we observe that zeros of F' of order four can occur only when $t_0 = 0$.

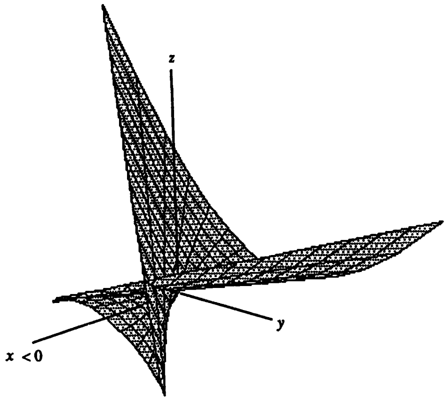

FIG. 1. *Locus of points (x, y, z) for which F' and F'' have simultaneous real zeros.*

From $F'''(t_0) = 0, t_0 = 0$ implies that x must be zero, and resubstituting these two values in $F'' = 0$ and $F' = 0$ shows that F' has a zero of order four only when $x = y = z = 0$. Therefore, in our problem of determining the large $|x| + |y| + |z|$ behaviour of S, we see that we never encounter a stationary point of order four.

Proceeding similarly for zeros of F' of order three shows that such zeros (for real t_0) can occur only when $x \leq 0$, as $F'''(t_0) = 12t_0^2 + 2x$ never vanishes for positive x. If x is positive, then S can have stationary points only of order ≤ 2. In the latter setting, the method of Chester, Friedman and Ursell [CFU] can be applied; this is briefly discussed in the last part of this section.

Interesting behaviour can therefore be expected for S when $x \leq 0$, and we shall find it convenient to characterize the saddle point structure of S after the fashion of Gilmore [Gil]. We accomplish this by plotting those parameter values of (x, y, z) for which F' has (real) zeros of order two or more. The result of this exercise is frequently referred to as a *caustic*, and is displayed in Fig. 1. We will examine this self-intersecting surface by taking plane slices $x =$ constant for $x > 0$, $x = 0$, and $x < 0$.

For $x > 0$, say $x = 1$, we have $F' = t^4 + t^2 + yt + z$ and $F'' = 4t^3 + 2t + y$ whence, if F' and F'' vanish simultaneously, $(y, z) = (-2t - 4t^3, t^2 + 3t^4)$. The resulting parametric curve in the yz-plane is the set of y and z values ($x = 1$) for which F has coalesced real critical points. Notice also that replacing t by $-t$ in the parametric forms for y and z results in only a change in sign of y.

The plane slice $x = 0$ results in a similarly shaped curve.

The negative $x =$ constant plane slice reveals a more complicated structure. For the purpose of illustration, we take $x = -1$. In this case, $F''' = 12t^2 - 2$, so that critical points of order three exist precisely when $t = \pm 1/\sqrt{6}$. The parametric equation of the curve in the yz-plane along which F has critical points of order two (or higher) is $(y, z) = (2t - 4t^3, -t^2 + 3t^4)$; see Fig. 2. Note the presence of two *cusps*, which correspond to those values of y and z for which F (with $x = -1$) has critical points of order three. Other points of the curve are associated with critical points of order two.

At points off the surface in Fig. 1, F has at most simple real zeros. The reader interested in a more detailed discussion of these plane sections is directed to [Gil, p. 62].

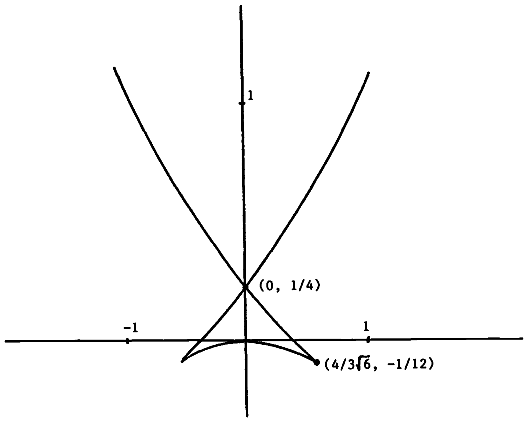

FIG. 2. *The plane slice $x = -1$ of Fig. 1. The bounded region contains those values (y, z) for which F' has exactly four distinct real zeros. Confluence of zeros of F' occurs only for (y, z) on the curve. Elsewhere, F' has either two distinct real zeros, or only complex conjugate pairs of zeros. This illustration is referenced later in the text, with y and z replaced by b and c, respectively.*

2.2. Reduction of S. Since the critical points of the phase function F of S can undergo a confluence only for points on the caustic, and since all such confluences involve only a pair of critical points except at the cusps, it suffices to restrict our attention only to the case of negative x. Elsewhere on the caustic, the method of Chester, Friedman, and Ursell (cf. [CFU]) can be applied to obtain the uniform asymptotic behaviour of S, as has been done in [Kam1].

Furthermore, we may, without loss of generality, assume that $y \geq 0$ in our treatment, as the case of $y < 0$ follows upon conjugation, since $S(x, -y, z)$ and $S(x, y, z)$ are complex conjugates. For notational convenience, we replace x by $-x$ and consider $S(-x, y, z)$ with $x > 0$.

If we introduce the change of variables $t = x^{1/2}u$, then $S(-x, y, z)$ has the integral representation

$$S(-x, y, z) = x^{1/2} \int_{\infty e^{9\pi i/10}}^{\infty e^{\pi i/10}} e^{ix^{5/2} f(u; yx^{-3/2}, zx^{-2})} du, \tag{2.1}$$

where

$$f(u; b, c) = \frac{u^5}{5} - \frac{u^3}{3} + b\frac{u^2}{2} + cu. \tag{2.2}$$

The uniform asymptotic behaviour of $S(-x, y, z)$ for large positive x can therefore be obtained from the uniform asymptotic behaviour of

$$I(\lambda) = \int_{\infty e^{9\pi i/10}}^{\infty e^{\pi i/10}} \exp\left[i\lambda f(t; b, c)\right] dt, \tag{2.3}$$

with $\lambda \to +\infty$. We shall work exclusively with this integral, recovering the desired behaviour of S at the end through the use of (2.1).

To proceed further requires detailed knowledge concerning the behaviour of the saddle points of $I(\lambda)$.

2.3. Zeros of quartic polynomials. It is well known that a solution of quartics by radicals is available, and several works in the theory of equations present formulae for this purpose. Regrettably, the form the zeros take is often unwieldy, due to the nested radicals that appear.

An elegant solution to the problem of extracting the roots of quartic polynomials can be found in the work of A. Greenhill [Gre1, Gre2], published in the late 19th century. Greenhill's approach involves the use of Weierstrass elliptic functions, and the expressions he obtains for the zeros of quartic polynomials reduce in short order to the more familiar forms provided by classical techniques, such as the use of Lagrange resolvents.

Let

$$U = x^4 + 6Cx^2 + 4Dx + E,$$

and set $g_2 = E + 3C^2$, $g_3 = CE - D^2 - C^3$. (Note that every quartic can be given the form possessed by U through the use of a linear change of variables.) Denote by $\wp(z; g_2, g_3)$ the Weierstrass elliptic function formed with the invariants g_2 and g_3. Let α (in the fundamental period parallelogram) be that number for which $\wp(2\alpha; g_2, g_3) = -C$, $\wp'(2\alpha; g_2, g_3) = -D$; for the existence of such α, see either [Gre1, p. 271–272] or [Gre2, p. 152–153]. Put

$$\mathcal{S} = 4s^3 - g_2 s - g_3$$

and let the discriminant of this cubic (called the *discriminating cubic* of the quartic U) be

$$\delta = g_2^3 - 27g_3^2.$$

Denote the zeros of $\mathcal{S}$ by $e_i, i = 1, 2, 3$, and those of U by $x_j, j = 0, 1, 2, 3$. Greenhill found that

$$\begin{aligned} x_0 &= \sqrt{\wp(2\alpha) - e_1} + \sqrt{\wp(2\alpha) - e_2} + \sqrt{\wp(2\alpha) - e_3}, \\ x_1 &= \sqrt{\wp(2\alpha) - e_1} - \sqrt{\wp(2\alpha) - e_2} - \sqrt{\wp(2\alpha) - e_3}, \\ x_2 &= -\sqrt{\wp(2\alpha) - e_1} + \sqrt{\wp(2\alpha) - e_2} - \sqrt{\wp(2\alpha) - e_3}, \\ x_3 &= -\sqrt{\wp(2\alpha) - e_1} - \sqrt{\wp(2\alpha) - e_2} + \sqrt{\wp(2\alpha) - e_3}. \end{aligned}$$

We note here that there is no ambiguity in the previous set of equations, as the square roots are chosen by

$$\sqrt{\wp(z) - e_i} = \frac{\sigma(z + \omega_i)}{\sigma(z) \cdot \sigma(\omega_i)} e^{-\eta_i z}.$$

In this equation, ω_i is an irreducible half-period, and the numbers η_i are determined by $\eta_i = \zeta(\omega_i)$. The functions ζ and σ are, respectively, the Weierstrass zeta and sigma functions. A number of well-known properties of $\wp$ and relations involving the constants ω_i, η_i, and e_i can be found in [Cop]. Of interest to us is the fact the square root determined in the previous equation is always ± the principal branch; see [Cop, p. 367].

This latter piece of information, together with the equation $\wp(2\alpha) = -C, \wp'(2\alpha) = -D$, give us the more familiar Lagrange form for the zeros of the quartic U, only with additional information regarding the branches of the square roots that appear. From this, we find that the zeros of $f'(t) = t^4 - t^2 + bt + c$ are given by

$$\begin{aligned} t_0 &= \sqrt{1/6 - e_1} + \sqrt{1/6 - e_2} - \sqrt{1/6 - e_3}, \\ t_1 &= \sqrt{1/6 - e_1} - \sqrt{1/6 - e_2} + \sqrt{1/6 - e_3}, \\ t_2 &= -\sqrt{1/6 - e_1} + \sqrt{1/6 - e_2} + \sqrt{1/6 - e_3}, \\ t_3 &= -\sqrt{1/6 - e_1} - \sqrt{1/6 - e_2} - \sqrt{1/6 - e_3}. \end{aligned} \tag{2.4}$$

Here, the e_i's are the roots of the discriminating polynomial, given by

$$\mathcal{S} = 4s^3 - \left(c + \frac{1}{12}\right)s + \left(\frac{c}{6} + \frac{b^2}{16} - \frac{1}{216}\right); \tag{2.5}$$

use of the trigonometric solution of cubics allows us to express the e_i's as

(2.6)

$$e_1 = \sqrt{\tfrac{c}{3} + \tfrac{1}{36}}\sin(\pi/3 - \psi), \quad e_2 = \sqrt{\tfrac{c}{3} + \tfrac{1}{36}}\sin\psi, \quad e_3 = -\sqrt{\tfrac{c}{3} + \tfrac{1}{36}}\sin(\pi/3 + \psi),$$

with the angle ψ given by

$$\sin 3\psi = \frac{c/6 + b^2/16 - 1/216}{(c/3 + 1/36)^{3/2}}. \tag{2.7}$$

Before proceeding with our discussion of the asymptotics of I, a few observations regarding the e_i should be recorded.

Along the caustic, we have

$$\left(\frac{c}{6} + \frac{b^2}{16} - \frac{1}{216}\right)^2 = \left(\frac{c}{3} + \frac{1}{36}\right)^3, \tag{2.8}$$

since the discriminating cubic must have repeated zeros when two or more t_i's coincide; thus, this equation gives the caustic in the bc-plane. This is precisely the $x = -1$ caustic of § 2.1, with y and z replaced by b and c (recall Fig. 2). The cusp points are easily found to have coordinates $(\pm 4/3\sqrt{6}, -1/12)$. As we pointed out in § 2.1, because of the symmetry in the caustic with respect to the vertical axis (in either y- or c- coordinates), we need only consider those values (b, c) with nonnegative ordinate.

Along the caustic, (2.7) must become $\sin 3\psi = \pm 1$ or $\psi = \pm\pi/6$. At the point $(b, c) = (0, 0)$, we find $\psi = -\pi/6$, and at $(b, c) = (0, 1/4)$, we have $\psi = \pi/6$. Thus, on the lower arch of the caustic (that segment joining $(0, 0)$ with $(4/3\sqrt{6}, -1/12)$), ψ must be $-\pi/6$, and on the middle segment of the caustic (that portion joining $(4/3\sqrt{6}, -1/12)$ to $(0, \frac{1}{4})$), we have $\psi = \pi/6$; see Fig. 2. By similar reasoning, we find that all level curves $\sin 3\psi = \tau$, with $-1 < \tau < 1$, must also pass through the cusp.

At the point $(b, c) = (0, 0)$, we find $t_0 = t_1 = 0$, $t_2 = 1$, and $t_3 = -1$ since $\psi = -\pi/6$, $e_1 = 1/6$, and $e_2 = e_3 = -1/12$. For $(b, c) = (0, \frac{1}{4})$, we have $\psi = \pi/6, e_1 = e_2 = 1/6$, and $e_3 = -1/3$ whence we find $t_0 = t_3 = -1/\sqrt{2}$, and $t_1 = t_2 = 1/\sqrt{2}$. Finally, at the cusp itself, where $(b, c) = (4/3\sqrt{6}, -1/12)$, all e_i's vanish since the discriminating cubic (2.5) reduces to $\mathcal{S} = 4s^3$. In this case, we have $t_0 = t_1 = t_2 = 1/\sqrt{6}$, and $t_3 = -3/\sqrt{6}$.

Piecing together these special values for the roots of $f' = 0$ shows that

$$t_3 \leq t_0 \leq t_1 \leq t_2. \tag{2.9}$$

Equality can occur only when (b, c) lies on the caustic. Hence, (2.9) is, in fact, strict inside the caustic. If we restrict (b, c) further so that $b \geq b_0 > 0$, then we find that the zero t_3 is isolated from the other three zeros.

With this restriction on the parameters b, c, we note the following. Inside the caustic, all four zeros of f' are real and distinct. On the lower arch, t_0 and t_1 coalesce and then separate into a complex conjugate pair as we pass below the caustic. On the upper arch (between the cusp and the point $(0, \frac{1}{4})$), t_1 and t_2 coincide, and then separate into a complex conjugate pair as we rise out of the caustic. t_3 remains real throughout this range of values of b and c.

The (nonuniform) asymptotic behaviour of I is readily available. For (b, c) inside the caustic, we have

$$I(\lambda; b, c) \sim \sum_{j=0}^{3} e^{\lambda i f(t_j; b,c) + \frac{\pi i}{4} \operatorname{sgn}(f''(t_j; b,c))} \sqrt{\frac{2\pi}{\lambda |f''(t_j; b, c)|}} \tag{2.10}$$

as $\lambda \to +\infty$, with (b, c) fixed. On the caustic (but not at the cusp), we have either $t_0 = t_1$ or $t_1 = t_2$. For the purpose of illustration, assume that $t_0 = t_1$. Then, for large λ and fixed (b, c), we have

$$\begin{aligned} I(\lambda; b, c) \sim & \sum_{j=2}^{3} e^{\lambda i f(t_j; b,c) + \frac{\pi i}{4} \operatorname{sgn}(f''(t_j; b,c))} \sqrt{\frac{2\pi}{\lambda |f''(t_j; b, c)|}} \\ & + \frac{2^{1/3} \Gamma(1/3) e^{\lambda i f(t_0; b,c)}}{3^{1/6} (\lambda f'''(t_0; b, c))^{1/3}}. \end{aligned} \tag{2.11}$$

In (2.11), notice that $f'''(t_0) \neq 0$ since we have fixed $(b, c) \neq (4/3\sqrt{6}, -1/12)$.

At the cusp, we have the triple zero $t_0 = t_1 = t_2 = 1/\sqrt{6}$ and the simple zero $t_3 = -3/\sqrt{6}$. Hence,

$$\begin{aligned} I(\lambda; \frac{4}{3\sqrt{6}}, \frac{-1}{12}) \sim & \frac{3^{1/8} \Gamma(1/4) e^{\pi i/8 - \lambda i/45\sqrt{6}}}{2^{7/8} \lambda^{1/4}} + \frac{3^{3/4}}{2^{7/4}} \sqrt{\frac{\pi}{\lambda}} e^{7\lambda i/5\sqrt{6} - \pi i/4} \\ & + \frac{2^{3/8} 3^{3/8} 63 \cdot \Gamma(3/4)}{32 \cdot 25 \lambda^{3/4}} e^{3\pi i/8 - \lambda i/45\sqrt{6}} \end{aligned} \tag{2.12}$$

as $\lambda \to +\infty$.

If (b, c) lies outside the caustic, then the asymptotic behaviour of $I(\lambda; b, c)$ is given by two terms from (2.10). One of these two terms arises from the real saddle t_3—the other stems from the remaining real saddle. The other two saddles, which now form a complex conjugate pair, provide only an exponentially negligible contribution to the value of I due to considerations of the topography of the saddles.

3. Uniform expansion of I.

3.1. The quartic transformation. Because the zeros t_0, t_1, and t_2 undergo various confluences, with all three zeros coinciding at the cusp, we introduce the quartic transformation first examined in [Urs]:

$$f(t; b, c) = \frac{z^4}{4} - \zeta \frac{z^2}{2} + \eta z + \theta. \tag{3.1}$$

This requires the determination of the parameters ζ, η, and θ as functions of b and c which provide for a (local) uniformly analytic, one-to-one transformation from t to z.

In particular, we shall require that the saddles of f correspond with the saddles of the right-hand side of (3.1). For notational convenience, we will denote the right-hand side of (3.1) by $g(z;\zeta,\eta,\theta)$; frequently, we will suppress the parameters ζ,η, and θ.

From the trigonometric solution of cubic equations, we have, as zeros of $g'(z;\zeta,\eta,\theta) = z^3-\zeta z+\eta$,

$$(3.2)\quad z_1 = 2\sqrt{\frac{\zeta}{3}}\sin(\pi/3-\phi),\quad z_2 = 2\sqrt{\frac{\zeta}{3}}\sin\phi,\quad z_3 = -2\sqrt{\frac{\zeta}{3}}\sin(\pi/3+\phi),$$

with the angle ϕ given by

$$(3.3)\qquad \sin 3\phi = \frac{3^{3/2}\eta}{2\zeta^{3/2}}.$$

An examination of the functions $\sin(\pi/3-\phi), \sin\phi$, and $-\sin(\pi/3+\phi)$ for $\phi \in\ ]-\pi/6,\pi/6[$ reveals that when the z_i are real, they satisfy the inequality

$$(3.4)\qquad z_3 < z_2 < z_1.$$

Note, too, that the quartic g must have $\zeta > 0$ in order to have three real saddles, and that these saddles z_i, for $i = 1,2,3$, coincide for $(\zeta,\eta) = (0,0)$.

The inequalities (2.9) and (3.4), together with the observation that t_3 remains isolated from t_0, t_1, and t_2 for $b \geq b_0 > 0$, strongly suggests that the correspondence

$$t_2 \leftrightarrow z_1,\quad t_1 \leftrightarrow z_2,\quad t_0 \leftrightarrow z_3$$

be made by the uniformly analytic, one-to-one solution of (3.1). How shall the parameters ζ,η, and θ be determined? The straightforward substitution of the t_i's and their associated z_j's into (3.1) rapidly leads to an unappealing system of nonlinear equations. A more elegant approach, adopted here, entails the use of some classical theory of equations.

For a polynomial $p(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0$ with zeros $x_1, x_2, \cdots, x_n$, it is well known that if we put $s_1 = \sum_{j=1}^n x_j$, $s_2 = \sum_{i<j} x_ix_j$, $s_3 = \sum_{i<j<k} x_ix_jx_k$, $\cdots$, $s_n = \prod_{j=1}^n x_j$, then the s_i's, the elementary symmetric functions of the roots of $p(x) = 0$, are related to the coefficients $a_0, a_1, \cdots, a_{n-1}$ via the formulae

$$(3.5)\quad a_0 = (-1)^n s_n,\quad a_1 = (-1)^{n+1}s_{n-1},\quad a_2 = (-1)^{n+2}s_{n-2},\quad \cdots,\quad a_{n-1} = -s_1.$$

We note that the saddles z_1, z_2, and z_3 are zeros of the polynomial $z^3 - \zeta z + \eta$. Hence, a straightforward application of (3.5) yields

$$(3.6)\qquad z_1+z_2+z_3 = 0,\quad z_1z_2+z_1z_3+z_2z_3 = -\zeta,\quad z_1z_2z_3 = -\eta.$$

If we form the functions

$$(3.7)\qquad \begin{aligned} \sigma_1 &= f(t_0)+f(t_1)+f(t_2),\\ \sigma_2 &= f(t_0)f(t_1)+f(t_0)f(t_2)+f(t_1)f(t_2),\\ \sigma_3 &= f(t_0)f(t_1)f(t_2), \end{aligned}$$

then use of the correspondence between the t_i's and the z_j's and equation (3.1) permits us to express the functions (3.7) as functions of the z_j's. Subsequent use of (3.6) then provides us with expressions for the σ_i's as functions of the parameters ζ,η, and θ.

These last expressions will prove solvable and will permit the computation of ζ, η, and θ in terms of the known roots t_0, t_1, and t_2.

Before proceeding with the computations, we note that this approach was implemented by Connor and his colleagues in [Con2]. However, the equations they used did not yield ζ, η, and θ as functions of the t_i's—the parameters were instead obtained by applying a numerical scheme to what will, in our treatment, appear as intermediate results. Furthermore, because of the extensive computation involved in solving for ζ, η, and θ as functions of the t_i's, we shall provide details only for one of the three equations we require; additional details regarding the equations we obtain can be found in the appendix of [Kam1].

We have, from (3.1) and the first equation of (3.7),

$$\sigma_1 = f(t_0) + f(t_1) + f(t_2) = \frac{1}{4}\sum_{i=1}^{3} z_i^4 - \frac{\zeta}{2}\sum_{i=1}^{3} z_i^2 + \eta \sum_{i=1}^{3} z_i + 3\theta.$$

By the first equation of (3.6), this reduces to

$$\sigma_1 = \frac{1}{4}(z_1^4 + z_2^4 + z_3^4) - \frac{\zeta}{2}(z_1^2 + z_2^2 + z_3^2) + 3\theta. \tag{3.8}$$

To calculate the sums of squares and of fourth powers, we proceed in the following fashion: squaring the first equation of (3.6) gives $(z_1 + z_2 + z_3)^2 = 0$ which reduces to $z_1^2 + z_2^2 + z_3^2 = 2\zeta$ in view of the second equation of (3.6). Equation (3.8) now becomes

$$\sigma_1 = \frac{1}{4}(z_1^4 + z_2^4 + z_3^4) - \zeta^2 + 3\theta. \tag{3.9}$$

Upon squaring the expression for the sum of squares, we find that $4\zeta^2 = (z_1^2 + z_2^2 + z_3^2)^2 = z_1^4 + z_2^4 + z_3^4 + 2(z_1^2 z_2^2 + z_1^2 z_3^2 + z_2^2 z_3^2)$. The latter term can be evaluated by squaring the second equation in (3.6). Thus, we have $\zeta^2 = (z_1 z_2 + z_1 z_3 + z_2 z_3)^2 = z_1^2 z_2^2 + z_1^2 z_3^2 + z_2^2 z_3^2$ since $z_1 + z_2 + z_3 = 0$. Therefore, $z_1^2 z_2^2 + z_1^2 z_3^2 + z_2^2 z_3^2 = \zeta^2$ so the expression for the sum of fourth powers becomes $4\zeta^2 = z_1^4 + z_2^4 + z_3^4 + 2\zeta^2$. Use of this in (3.9) gives

$$\sigma_1 = -\frac{\zeta^2}{2} + 3\theta. \tag{3.10}$$

Proceeding in a similar fashion gives

$$\sigma_2 = \frac{\zeta^4}{16} - \frac{9\eta^2\zeta}{8} - \theta\zeta^2 + 3\theta^2 \tag{3.11}$$

and

$$\sigma_3 = -\frac{27\eta^4}{64} + \frac{\eta^2\zeta^3}{32} + \frac{\theta\zeta^4}{16} - \frac{9\eta^2\theta\zeta}{8} - \frac{\theta^2\zeta^2}{2} + \theta^3. \tag{3.12}$$

It is with equations (3.10)–(3.12) that we shall obtain expressions for ζ, η, and θ.

From (3.11), we see that $\sigma_2\theta - 3\theta^3 + \theta^2\zeta^2/2 = \theta\zeta^4/16 - 9\eta^2\theta\zeta/8 - \theta^2\zeta^2/2$. Use of this in (3.12) gives

$$\sigma_3 = -\frac{27\eta^4}{64} + \frac{\eta^2\zeta^3}{32} + \sigma_2\theta + \frac{\theta^2\zeta^2}{2} - 2\theta^3. \tag{3.13}$$

From (3.10) we have

$$\theta = \frac{\sigma_1}{3} + \frac{\zeta^2}{6}, \tag{3.14}$$

and this in (3.11) gives

$$\eta^2 = -\frac{\zeta^3}{54} + \frac{8(\sigma_1^2 - 3\sigma_2)}{27\zeta}. \tag{3.15}$$

Equation (3.14) can be applied to (3.13) to eliminate all occurrences of θ. The result of doing this is:

$$\sigma_3 = -\frac{27\eta^4}{64} + \frac{\eta^2\zeta^3}{32} + \frac{1}{3}(\sigma_1\sigma_2 - \frac{2\sigma_1^3}{9}) - \frac{\zeta^2}{18}(\sigma_1^2 - 3\sigma_2) + \frac{\zeta^6}{216}. \tag{3.16}$$

If we replace every instance of η^2 by the right-hand side of (3.15) and multiply the resulting equation by $256\zeta^2$, we obtain

(3.17)
$$\zeta^8 - \frac{32}{3}(\sigma_1^2 - 3\sigma_2)\zeta^4 + \frac{256}{27}(9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3)\zeta^2 - \frac{256}{27}(\sigma_1^2 - 3\sigma_2)^2 = 0.$$

Note that

$$9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3 = \sigma_1^3 - 3\sigma_1(\sigma_1^2 - 3\sigma_2) - 27\sigma_3. \tag{3.18}$$

Equation (3.18) will prove to be of value in later discussion.

Put $Z = \zeta^2$ in the octic (3.17). The resulting quartic,

(3.19)
$$Z^4 - \frac{32}{3}(\sigma_1^2 - 3\sigma_2)Z^2 + \frac{256}{27}(9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3)Z - \frac{256}{27}(\sigma_1^2 - 3\sigma_2)^2 = 0,$$

can be solved using Greenhill's formulae (cf. § 2.3). To that end, we calculate the invariants of the required elliptic function.

From $g_2 = E + 3C^2$ and $g_3 = CE - D^2 - C^3$ in § 2.3, we have

$$\begin{aligned} g_2 &= -\tfrac{256}{27}(\sigma_1^2 - 3\sigma_2)^2 + 3[-\tfrac{16}{9}(\sigma_1^2 - 3\sigma_2)]^2 = 0, \\ g_3 &= \tfrac{4\cdot 16^3}{9^3}(\sigma_1^2 - 3\sigma_2)^3 - \tfrac{64^2}{27^2}(9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3)^2. \end{aligned} \tag{3.20}$$

The first of the two preceding equations represents a happy state of affairs, as the discriminating cubic takes the form $\mathcal{S} = 4s^3 - g_3$. Hence, the zeros of $\mathcal{S}$ are given by $\omega^j(g_3/4)^{1/3}, j = 0, 1, 2$, where ω is the cube root of unity $\omega = e^{2\pi i/3}$, and $(g_3/4)^{1/3}$ is taken with its principal value. Use of (3.20) permits us to write

$$\left(\frac{g_3}{4}\right)^{1/3} = \frac{16}{9}(\sigma_1^2 - 3\sigma_2)[1 - \mathcal{N}/\mathcal{D}]^{1/3}, \tag{3.21}$$

where we have set

$$\begin{aligned} \mathcal{N} &= (9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3)^2, \\ \mathcal{D} &= 4(\sigma_1^2 - 3\sigma_2)^3. \end{aligned} \tag{3.22}$$

Also, from $\wp(2\alpha) = -C$ (cf. § 2.3), we have $\wp(2\alpha) = \frac{16}{9}(\sigma_1^2 - 3\sigma_2)$.

For the sake of notational ease, let

$$\chi = \left[1 - \frac{\mathcal{N}}{\mathcal{D}}\right]^{1/3}; \tag{3.23}$$

upon applying Greenhill's formulae with the e_j's replaced by the $\omega^j(g_3/4)^{1/3}$, we obtain

$$\begin{aligned} Z_0 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\textstyle\sum_{j=0}^2 \sqrt{1-\omega^j\chi}, \\ Z_1 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left\{\sqrt{1-\chi} - \textstyle\sum_{j=1}^2 \sqrt{1-\omega^j\chi}\right\}, \\ Z_2 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left\{\sqrt{1-\omega\chi} - \textstyle\sum_{j=0,2} \sqrt{1-\omega^j\chi}\right\}, \\ Z_3 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left\{\sqrt{1-\omega^2\chi} - \textstyle\sum_{j=0}^1 \sqrt{1-\omega^j\chi}\right\}, \end{aligned} \tag{3.24}$$

where the first surd, $\sqrt{\sigma_1^2 - 3\sigma_2}$, is taken to have its principal value. The other surds must have their branches chosen with care although, from our discussion in § 2.3, we know the remaining square roots are ± the principal branch. To make the appropriate selection of these branches, we examine the Z_i's for values of (b, c) on the caustic.

On the caustic, the discriminating cubic associated with the quartic in Z has repeated roots. Hence, at least two t_i's coincide (whence at least two $f(t_i)$'s coincide) and from the discriminant $\delta = g_2^3 - 27g_3^2$ (recall § 2.3), we get $\delta = 0$ and

$$(\sigma_1^3 - 3\sigma_1(\sigma_1^2 - 3\sigma_2) - 27\sigma_3)^2 = 4(\sigma_1^2 - 3\sigma_2)^3; \tag{3.25}$$

for the sake of argument, assume that we have $t_0 = t_1 \neq t_2$, so that $f(t_0) = f(t_1) \neq f(t_2)$. Equation (3.7), together with some arithmetic, provides us with $9\sigma_1\sigma_2 - 2\sigma_1^3 - 27\sigma_3 = 2[f(t_0) - f(t_2)]^3$ and $\sigma_1^2 - 3\sigma_2 = [f(t_0) - f(t_2)]^2$. Use of these two equations, together with (3.18), establishes (3.25). Similarly, we can obtain (3.25) in the case $t_0 \neq t_1 = t_2$.

Equation (3.25) leads to the conclusion that $\mathcal{N} = \mathcal{D}$ on the caustic, whence the expressions for the Z_i's reduce to

$$\begin{aligned} Z_0 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}(\pm 1 \pm 1 \pm 1), & Z_1 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}(\pm 1 \mp 1 \mp 1), \\ Z_2 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}(\mp 1 \pm 1 \mp 1), & Z_3 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}(\mp 1 \mp 1 \pm 1), \end{aligned} \tag{3.26}$$

where in only the first row are the signs independently chosen, the choice of signs subsequently determined according to the pattern used for the x_j in terms of $\sqrt{\wp(2\alpha) - e_k}$ in § 2.3. With (3.25) and (3.19), the quartic in Z reduces to

$$Z^4 - \frac{32}{3}(\sigma_1^2 - 3\sigma_2)Z^2 + \frac{512}{27}(\sigma_1^2 - 3\sigma_2)^{3/2}Z - \frac{256}{27}(\sigma_1^2 - 3\sigma_2) = 0. \tag{3.27}$$

The form of the Z_i's in (3.26) strongly suggests putting $Z_i = \frac{4}{3}(\sigma_1^2 - 3\sigma_2)^{1/2}\epsilon_i$. In this event, (3.27) yields the reduced equation

$$\frac{\epsilon_i^4}{3} - 2\epsilon_i^2 + \frac{8\epsilon_i}{3} - 1 = 0. \tag{3.28}$$

Experiment is now easy and shows, for example, that if we choose the square roots appearing in the first equation of (3.24) to be all principal branch choices, then $\epsilon_0 = 3$ does not satisfy (3.28), but if we choose the square roots so the first two have their principal branch, the last one being the negative of the principal branch, then we have $\epsilon_0 = \epsilon_1 = \epsilon_2 = 1$ and $\epsilon_3 = -3$. This latter choice provides ϵ_i's, all of which satisfy (3.28). Hence, we make this latter selection of branches for the surds appearing in (3.24).

All other choices of branches for the surds in (3.24) amount to a reordering of the Z_i's under either of the two choices of branches discussed above. With our choice of branches, (3.24) becomes

$$\begin{aligned}
Z_0 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left[\sqrt{1-\chi} + \sqrt{1-\omega\chi} - \sqrt{1-\omega^2\chi}\right], \\
Z_1 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left[\sqrt{1-\chi} - \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi}\right], \\
Z_2 &= \tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left[-\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi}\right], \\
Z_3 &= -\tfrac{4}{3}\sqrt{\sigma_1^2 - 3\sigma_2}\left[\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi}\right],
\end{aligned} \tag{3.29}$$

where all surds are taken with their principal branch.

For our change of variables (3.1), we require $\zeta > 0$ (inside the caustic); recall that $Z = \zeta^2$. Hence, we must determine which of the Z_i's is real and nonnegative. With all square roots chosen to be the principal branch, we know that $\sqrt{\bar{z}}$ is the conjugate of $\sqrt{z}$, whence the observation that ω and ω^2 are complex conjugates implies that $\sqrt{1-\omega\chi}$ and $\sqrt{1-\omega^2\chi}$ are conjugates. Thus, of the Z_i's in (3.29), we see that only Z_2 and Z_3 can be real.

To determine which of Z_2 or Z_3 gives rise to real square roots, we examine the limiting behaviour of Z_2 and Z_3 as we approach the caustic. From (3.25), we know that for δ near zero, the ratio $\mathcal{N}/\mathcal{D}$ is approximately 1, in which case χ is tending to zero. Applying the binomial theorem to the expressions for Z_2 and Z_3 gives us

$$\begin{aligned}
-\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi} &= 1 + \chi + O(\chi^2), \\
\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi} &= 3 + O(\chi^2).
\end{aligned}$$

Thus, Z_2 is positive, Z_3 is negative, and so

$$\zeta = \pm\sqrt{\frac{4}{3}}\sqrt[4]{\sigma_1^2 - 3\sigma_2}\sqrt{-\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi}}.$$

Use of the fact that ζ must be positive inside the caustic yields

$$\zeta = \sqrt{\frac{4}{3}}\sqrt[4]{\sigma_1^2 - 3\sigma_2}\sqrt{-\sqrt{1-\chi} + \sqrt{1-\omega\chi} + \sqrt{1-\omega^2\chi}}. \tag{3.30}$$

This, together with (3.14) and (3.15), give computable expressions for the parameters ζ, η, and θ.

Before continuing with the development of the uniform expansion of I, we note that the term $\sigma_1^2 - 3\sigma_2 \geq 0$ inside and on the caustic, and is real outside the caustic (although it may be negative). Furthermore, in (3.15), when taking the square root to obtain η, it is chosen so that η is negative on the arc of the caustic joining $(0, 0)$ to

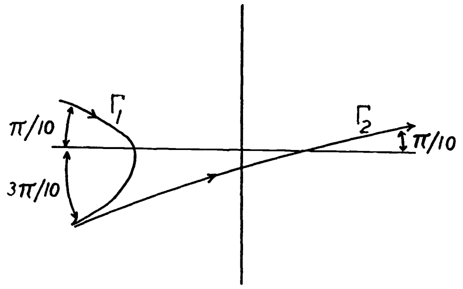

FIG. 3. *t-plane integration contours for the integrals $I_j(\lambda; b, c)$.*

$(4/3\sqrt{6}, -1/12)$, and positive on the arc joining $(4/3\sqrt{6}, -1/12)$ to $(0, \frac{1}{4})$. Additional details may be found in [Kam1, p. 84–85].

It is interesting to note that we have obtained closed form expressions for the parameters η, ζ and θ appearing in (3.1). Ursell, in examining the quartic transformation (3.1) remarks that these parameters can, in principle, be constructed from convergent power series (a consequence of using Levinson's theorem; see [Lev]), and that the power series approach is not practical computationally. He further states that the parameters can be obtained without explicit reference to the uniformly analytic one-to-one solution to (3.1), but does not go on to provide expressions for the parameters; cf. [Urs, p. 64–65]. This has been accomplished here.

With our transformation (3.1) completely determined, we can proceed to the uniform expansion of I.

3.2. The expansion of I. Since t_3 remains isolated from t_0, t_1, t_2 for $b > 0$, we rewrite $I(\lambda)$ as the sum of two path integrals:

$$I(\lambda; b, c) = \int_{\Gamma_1} e^{i\lambda f(t;b,c)} dt + \int_{\Gamma_2} e^{i\lambda f(t;b,c)} dt \equiv I_1(\lambda; b, c) + I_2(\lambda; b, c), \tag{3.31}$$

where $I_j(\lambda; b, c)$ denotes the integral of $e^{i\lambda f(t;b,c)}$ over the contour Γ_j, with the Γ_j as depicted in Fig. 3.

Γ_1 may be taken to be the steepest descent curve through t_3 beginning at $\infty e^{9\pi i/10}$ and ending at $\infty e^{13\pi i/10}$. Thus, I_1 has an asymptotic expansion of the form

$$I_1(\lambda; b, c) \sim e^{i\lambda f(t_3;b,c) - \pi i/4} \sum_{j=1}^{\infty} \frac{a_j(b,c)}{\lambda^{j/2}} \tag{3.32}$$

as $\lambda \to +\infty$. The leading term has the coefficient $a_1(b,c) = \sqrt{2\pi/(-f''(t_3; b, c))}$, which is well behaved for $b \geq b_0 > 0$. Note that $f''(t_3) < 0$ since t_3 gives a local maximum of the quintic f.

For the integral I_2, we invoke the quartic transformation (3.1) and introduce the function sequences $\{p_n\}, \{q_n\}, \{r_n\}, \{g_n\}$, and $\{h_n\}$, defined by

$$\begin{aligned} g_0(z; \zeta, \eta) &= p_0 + q_0 z + r_0 z^2 + (z^3 - \zeta z + \eta) h_0(z; \zeta, \eta), \\ \frac{\partial}{\partial z} h_k(z; \zeta, \eta) &= g_{k+1}(z; \zeta, \eta) \\ &= p_{k+1} + q_{k+1} z + r_{k+1} z^2 + (z^3 - \zeta z + \eta) h_{k+1}(z; \zeta, \eta), \end{aligned} \tag{3.33}$$

where $g_0(z;\zeta,\eta)=dt/dz$ (cf. eqn. (3.1)), and $k=0,1,\cdots$. The coefficients p_n, q_n and r_n are functions of ζ and η which, in view of our expressions for ζ,η, and θ in terms of b and c, in turn can be regarded as functions of b and c.

Through repeated substitution and partial integration, we obtain the expansion

$$(3.34)\quad I_2(\lambda;b,c)\sim e^{i\lambda\theta}\sum_{j=0}^{\infty}\left(\frac{i}{\lambda}\right)^j [p_jF_0(\lambda;\zeta,\eta)+q_jF_1(\lambda;\zeta,\eta)+r_jF_2(\lambda;\zeta,\eta)]$$

as $\lambda\to+\infty$, uniformly valid for (ζ,η) "near" the caustic $27\eta^2-4\zeta^3=0$; i.e., uniformly valid near the caustic in the bc-plane with $b\geq b_0>0$, and (b,c) within a band of fixed distance from the caustic.

The functions F_k appearing in the previous equation are given by the integrals

$$F_k=\int_C e^{i\lambda(z^4/4-\zeta z^2/2+\eta z)}z^k dz,$$

with $k=0,1,2$. C is a contour in the z-plane beginning at $\infty e^{9\pi i/8}$ and ending at $\infty e^{\pi i/8}$. With the change of variables $u=z/\lambda^{1/4}$, we find

$$\begin{aligned}F_0(\lambda;\zeta,\eta)&=\lambda^{-1/4}P(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta),\\ F_1(\lambda;\zeta,\eta)&=-i\lambda^{-1/2}P_y(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta),\\ F_2(\lambda;\zeta,\eta)&=-2i\lambda^{-3/4}P_x(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta),\end{aligned}$$

where the function $P(x,y)$ is the Pearcey function in (1.3), and the functions P_x and P_y are the first-order partial derivatives of $P(x,y)$ with respect to x and y, respectively. Use of the above expressions for the F_k in the expansion (3.34) yields the expansion

$$(3.35)\quad \begin{aligned}I_2(\lambda;b,c)\sim e^{i\lambda\theta}\sum_{j=0}^{\infty}\left(\frac{i}{\lambda}\right)^j&\left[\frac{p_j}{\lambda^{1/4}}P(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)\right.\\ &\left.-\frac{iq_j}{\lambda^{1/2}}P_y(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)-\frac{2ir_j}{\lambda^{3/4}}P_x(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)\right]\end{aligned}$$

as $\lambda\to+\infty$, uniformly valid for (b,c) in a band of fixed distance from the caustic with $b\geq b_0>0$ for some fixed b_0.

The expansion of I is therefore given by the sum of (3.32) and (3.35). In particular, we have the uniform approximation

$$(3.36)\quad \begin{aligned}I(\lambda;b,c)=&\,e^{i\lambda f(t_3;b,c)-\pi i/4}\sqrt{\frac{2\pi}{-\lambda f''(t_3;b,c)}}\left[1+O\left(\frac{1}{\sqrt{\lambda}}\right)\right]\\ &+e^{i\lambda\theta}\left[\frac{p_0}{\lambda^{1/4}}P(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)-\frac{iq_0}{\lambda^{1/2}}P_y(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)\right.\\ &\left.-\frac{2ir_0}{\lambda^{3/4}}P_x(-\lambda^{1/2}\zeta,\lambda^{3/4}\eta)\right]\cdot\left[1+O\left(\frac{1}{\lambda}\right)\right],\end{aligned}$$

where the O-symbols are independent of (b,c).

The expansion of $S(-x,y,z)$ now follows directly from $S(-x,y,z)=x^{1/2}\cdot I(x^{5/2}; yx^{-3/2},zx^{-2})$.

4. Conformal mapping. We shall devote the next few pages to an analysis of the conformal mapping determined by the "uniform change of variables" (3.1), for primarily two reasons: first, (3.1) is not as well known as the cubic transformation of [CFU]; second, we have been performing our computations under the assumption that (3.1) gives a solution that is uniformly analytic and one-to-one over an integration contour for I (more accurately, over the contour Γ_2 used in (3.31)).

The latter point is important, for if we use only the local properties of the transformation (3.1), we can still obtain the asymptotics of S in the case where three saddles coalesce, but at the cost of replacing the "=" signs in (3.32), (3.34), and (3.35) by "$\sim$" signs. This in turn means that if a theory of error bounds should emerge for uniform expansions developed through the use of (3.1), we can directly compute the errors in our asymptotic approximations. Without the use of the full steepest descent contour Γ_2, it is unlikely that we could obtain full precision in our expansions. Additional discussion on why full contours should be used in asymptotics can be found in [Olv].

A full treatment of the conformal mapping (3.1) would involve an analysis for each of the cases where there was no confluence of the t_i, two of the t_i coalesced, or three of the t_i coalesced (recall: at most three t_i can coalesce for the large parameter behaviour of S; see the discussion in § 2.1). For the purpose of illustration, we shall examine only one case; the reader will find a treatment of other saddle point configurations in [Kaml, pp. 90–100].

We begin by supposing that a point (b, c) lies inside the caustic (recall Fig. 2). Then there are four real saddles for the integral I, $t_3 < t_0 < t_1 < t_2$ (cf. (2.9)), of which only t_0, t_1, and t_2 are involved with confluence since we have taken $b \geq b_0 > 0$. We proceed by first determining the curves for which $\operatorname{Im} f(t; b, c) = 0$. It will prove to be convenient to introduce an intermediate variable Z in (3.1):

$$f(t; b, c) = Z = \frac{z^4}{4} - \zeta\frac{z^2}{2} + \eta z + \theta. \tag{4.1}$$

Clearly, the real t-axis is mapped to the real Z-axis in the following fashion:

$$\begin{aligned}]-\infty, t_3] &\rightarrow\,]-\infty, f(t_3)]\,, & [t_3, t_0] &\rightarrow [f(t_0), f(t_3)]\,, \\ [t_0, t_1] &\rightarrow [f(t_0), f(t_1)]\,, & [t_1, t_2] &\rightarrow [f(t_2), f(t_1)]\,, \\ [t_2, +\infty[&\rightarrow [f(t_2), +\infty[\,; \end{aligned}$$

we recall that f is a quintic with four relative extrema. The remaining curves in the t-plane sent by f to the real Z-axis can be found by solving the equation

$$\operatorname{Im} f(t) = 0 = \operatorname{Im}[f(t) - f(t_k)], \qquad (k = 0, 1, 2, 3), \tag{4.2}$$

since, in the present case, each of the t_k's real implies that $f(t_k)$ is real. We note that since the left-hand side of the (4.2) is independent of k, the solution curves arising from the right-hand side are the same for each k (in other words, we can select a convenient t_k without affecting the solution).

For each k, we develop f into its Taylor expansion centered at t_k; the right-hand side of (4.2) then has no constant terms. By use of changes of variables of the form $t - t_k = \sigma + i\tau$, where we have suppressed the dependence of σ on k, we obtain easily solved equations which express σ as a function of τ, or vice versa. Plotting these curves results in Fig. 4.

These curves, which include the real axis, partition the t-plane into several disjoint regions. We shall consider only those labelled $R_1, \cdots, R_4$, as our integration contour

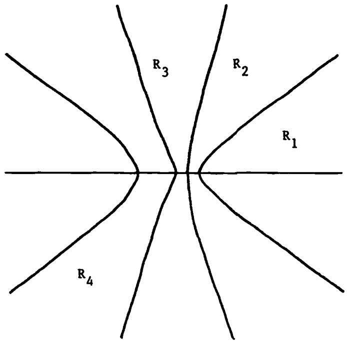

FIG. 4. *Curves in the complex t-plane for which* $\operatorname{Im} f(t; b, c) = 0$. *The real axis is included as such a curve.*

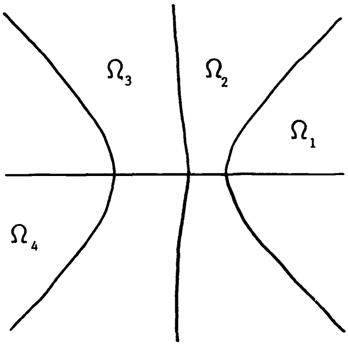

FIG. 5. *Curves in the complex z-plane for which* $\operatorname{Im} g(z) = 0$. *As in Fig.* 4, *the real axis is such a curve.*

for I_2 of equation (3.31), Γ_2, can be chosen to lie entirely within $R_1 \cup R_2 \cup R_3 \cup R_4$, or this union's closure.

We will see that the (local) uniformly analytic, one-to-one solution of (3.1) is indeed one-to-one on this union.

Since the saddles of $g(z; \zeta, \eta, \theta)$ under the tranformation (3.1) correspond with the t_i's in the fashion $t_2 \leftrightarrow z_1, t_1 \leftrightarrow z_2, t_0 \leftrightarrow z_3$, we have $z_3 < z_2 < z_1$ for (b, c) inside the caustic (this can also be seen from (3.2)). Hence, the z-plane curves for which $\operatorname{Im} g(z) = 0$ partition the z-plane into the disjoint regions displayed in Fig. 5. Again, the real axis is a curve for which $\operatorname{Im} g = 0$.

We will be concerned with the regions labelled $\Omega_1, \cdots, \Omega_4$.

Consider R_1 in the t-plane as depicted in Fig. 6. The arc BD is the steepest descent curve of if from t_2 to $\infty e^{\pi i/10}$. The arc BC is the upper extent of the region R_1. Under (4.1), the image of R_1 is the upper half of the Z-plane depicted in Fig. 6.

The map $z \to Z$ on Ω_1, defined by (4.1), produces a similar effect also displayed in Fig. 6. In the illustration, the curve BD is the steepest descent curve of $ig(z)$ beginning at z_1 and ending at $\infty e^{\pi i/8}$. BC is the upper extent of Ω_1. Under (4.1), Ω_1 maps to the half-plane depicted in Fig. 6.

Thus, under (4.1), the region R_1 maps to Ω_1.

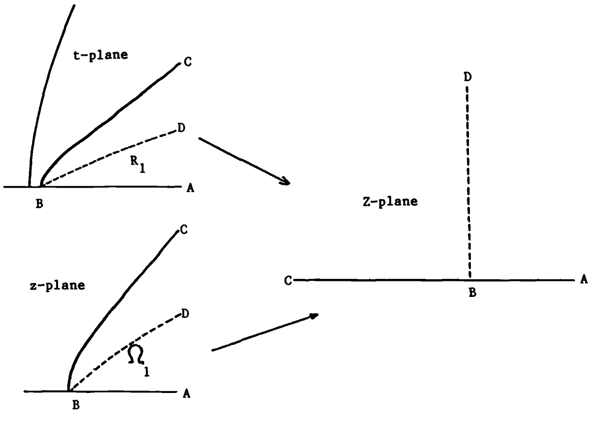

FIG. 6. *Effect of the mappings $t \longrightarrow Z$, $z \longrightarrow Z$ on the regions R_1 and Ω_1, respectively.*

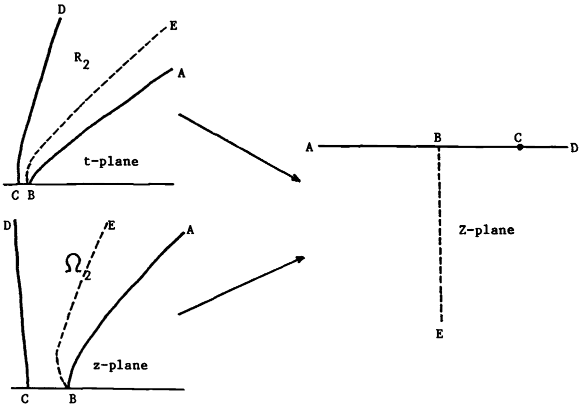

FIG. 7. *Effect of the mappings $t \longrightarrow Z$, $z \longrightarrow Z$ on the regions R_2 and Ω_2, respectively.*

We now direct our attention to R_2. In Fig. 7, the arcs CD and BA bound the region R_2; these are curves for which $\operatorname{Im} f = 0$. The arc BE is the steepest ascent curve for if from t_2 to $\infty e^{3\pi i/10}$. Under (4.1), the region maps to the half Z-plane as illustrated in Fig. 7.

It is easy to see that B, C reverse ordering upon application of the map $t \longrightarrow Z$ since t_1 is a local maximum of f, and t_2 is an adjacent local minimum.

Consider $z \longrightarrow Z$ acting on Ω_2; refer to Fig. 7. CD and BA are curves for which $\operatorname{Im} g(z) = 0$; these two arcs bound Ω_2 on two sides. BE is the steepest ascent curve of $ig(z)$ from z_1 to $\infty e^{3\pi i/8}$. Under (4.1), Ω_2 maps to the half Z-plane depicted in Fig. 7.

As was the case for R_1 and Ω_1, we see that $f(t) = g(z)$ provides us with a one-to-one map from R_2 onto Ω_2.

Similar analysis applies to the mapping from R_3 to Ω_3 (see Fig. 8).

Finally, we turn to $R_4 \longrightarrow \Omega_4$. In Fig. 9, CE is the steepest descent curve of if from t_0 to $\infty e^{13\pi i/10}$, and the corresponding curve in the z-plane is the steepest descent curve of ig from z_3 to $\infty e^{9\pi i/8}$.

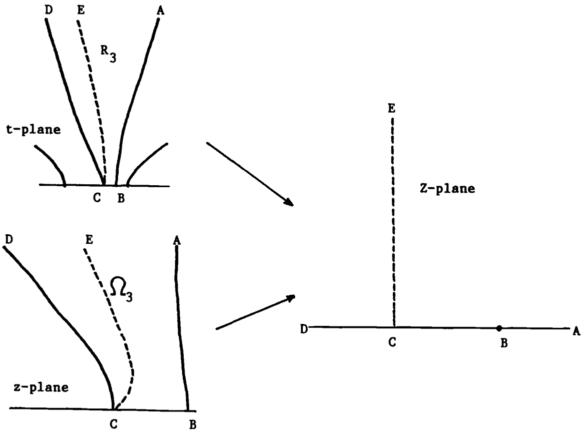

FIG. 8. *Effect of the mappings* $t \to Z$, $z \to Z$ *on the regions* R_3 *and* Ω_3, *respectively.*

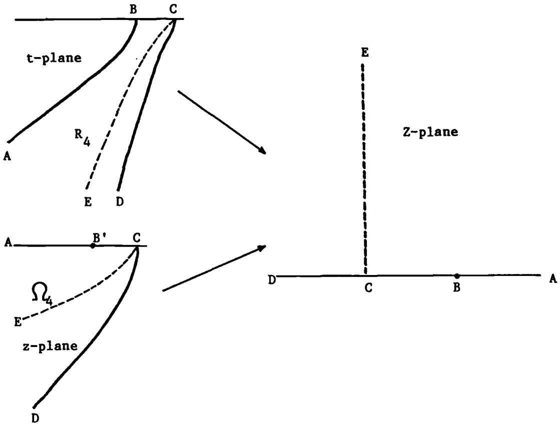

FIG. 9. *Effect of the mappings* $t \to Z$, $z \to Z$ *on the regions* R_4 *and* Ω_4, *respectively.*

We note here that f decreases steadily from $+\infty$ to $-\infty$ as t moves from $\mathrm{A} = \infty e^{6\pi i/5}$ to $\mathrm{B} = t_3$, to $\mathrm{C} = t_0$ and thence to $\mathrm{D} = \infty e^{7\pi i/5}$. Similarly, g decreases steadily from $+\infty$ to $-\infty$ as z moves from $\mathrm{A} = +\infty$ to $\mathrm{C} = z_3$ to $\mathrm{D} = \infty e^{5\pi i/4}$. Since $g(z_3) = f(t_0)$, this implies the existence of a point B' in the interval $]-\infty, z_3[$ such that $g(\mathrm{B}') = f(t_3)$. This is indicated in Fig. 9.

Thus, $R_4 \to \Omega_4$ in a one-to-one fashion. To obtain the mappings of the regions conjugate to the R_i to regions conjugate to the Ω_i, we merely "flip" all illustrations about the real t, z, and Z-axes, and replace "ascent" by "descent" and vice versa.

This concludes our look at the mapping (3.1) in the case where all t_i's are real and separated.

5. A limiting case. As an example of the use of the quartic transformation formulae developed in § 3, and as a check on the validity of our results, we determine the limiting form of the coefficients p_0, q_0, and r_0 in the approximation (3.36) when the parameters (b, c) tend to the cusp $(4/3\sqrt{6}, -1/12)$. This calculation showcases the determination of the parameters ζ, η, and θ, and makes explicit use of the formula for ζ presented as (3.30).

We begin by taking (b, c) to lie on the caustic. From the discussion leading to (2.9), it is readily seen that the $\psi = -\pi/6$ level curve in the bc-plane contains the lower arch of the caustic joining $(0,0)$ to $(4/3\sqrt{6}, -1/12)$, and the $\psi = \pi/6$ level curve contains the upper arch of the caustic joining $(4/3\sqrt{6}, -1/12)$ to $(0, \frac{1}{4})$; see Fig. 6. We will take (b, c) to lie on that part of the caustic joining $(0,0)$ to $(4/3\sqrt{6}, -1/12)$ so that $\psi = -\pi/6$ with $c \neq -1/12$ ($c = -1/12$ would place us at the cusp). With these choices for ψ and c, it is easy to see that (2.7) becomes

$$c/6 + b^2/16 - 1/216 = -(c/3 + 1/36)^{3/2},$$

a quadratic equation in b. We set $c = \Delta c - 1/12$. Use of this in the previous equation implies that $b^2 = \frac{8}{27}\left[1 - 9\Delta c - 54(\Delta c/3)^{3/2}\right]$, so if b is positive, we may write

$$b = \frac{4}{3\sqrt{6}}\left[1 - 9\Delta c - 54(\Delta c/3)^{3/2}\right]^{1/2} \tag{5.1}$$

for a point (b, c) on the arch of the caustic under examination. We will use (5.1) extensively to develop $\Delta c \to 0^+$ limits for a variety of quantities needed in the computation of p_0, q_0, and r_0 in (3.36). Before proceeding, we shall determine expressions for p_0, q_0, and r_0 on the caustic.

First, on the $\psi = -\pi/6$ portion of the caustic, we have $t_0 = t_1 < t_2$ so that $z_3 = z_2 < z_1$ in view of the correspondence $t_2 \leftrightarrow z_1, t_1 \leftrightarrow z_2, t_0 \leftrightarrow z_3$. Furthermore, from $\phi = -\pi/6$, we have $\eta = -2(\zeta/3)^{3/2}$ (cf. eqn. (3.3)), $z_1 = 2\sqrt{\zeta/3}$, and $z_2 = z_3 = -\sqrt{\zeta/3}$.

From the first equation of (3.33), we get

$$g_0(z) = \frac{dt}{dz} = p_0 + q_0 z + r_0 z^2 + (z^3 - \zeta z - 2(\zeta/3)^{3/2})h_0(z), \tag{5.2}$$

which implies

$$\begin{aligned} g_0(z_1) &= p_0 + 2\sqrt{\zeta/3}q_0 + 4\zeta r_0/3, \\ g_0(z_2) &= p_0 - \sqrt{\zeta/3}q_0 + \zeta r_0/3, \end{aligned} \tag{5.3}$$

in view of the fact that $(z^3 - \zeta z - 2(\zeta/3)^{3/2})h_0(z)$ vanishes at z_1 and z_2. As (5.3) forms a pair of linear equations in the three unknowns p_0, q_0, and r_0, (5.3) is insufficient for determining p_0, q_0, and r_0 uniquely. A third (linearly) independent equation can be found by differentiating (5.2) with respect to z, and then evaluating the result to obtain

$$g_0'(z_2) = q_0 - 2\sqrt{\frac{\zeta}{3}}r_0. \tag{5.4}$$

Thus, (5.3) and (5.4) determine p_0, q_0, and r_0. Upon forming the difference of the equations in (5.3), we find $g_0(z_1) - g_0(z_2) = 3\sqrt{\zeta/3}q_0 + \zeta r_0$, so that subsequent use of (5.4) yields

$$r_0 = \frac{1}{3\zeta}\left[g_0(z_1) - g_0(z_2) - 3\sqrt{\frac{\zeta}{3}}g_0'(z_2)\right]. \tag{5.5}$$

Use of this in (5.4) then provides us with

$$q_0 = \frac{g_0'(z_2)}{3} + \frac{2}{\sqrt{27\zeta}}[g_0(z_1) - g_0(z_2)]. \tag{5.6}$$

Finally, (5.5) and (5.6) together in (5.3) gives us

$$p_0 = \frac{g_0(z_1)}{9} + \frac{8g_0(z_2)}{9} + \frac{2}{3}\sqrt{\frac{\zeta}{3}}g_0'(z_2). \tag{5.7}$$

Thus, once we have determined $g_0(z_1), g_0(z_2)$, and $g_0'(z_2)$, equations (5.5)–(5.7) will provide us with values for our coefficients.

To calculate the $g_0(z_i)$ and $g_0'(z_2)$, we return to the mapping (3.1). If we differentiate (3.1) twice with respect to z (bearing in mind that $g_0(z) = dt/dz$), we obtain $f''(t)g_0^2(z) + f'(t)g_0'(z) = 3z^2 - \zeta$. Evaluation at $t = t_0 \leftrightarrow z = z_2$ yields no information (since $f'(t_0) = f''(t_0) = 0$ at the order two saddle t_0), while evaluation at $t = t_2 \leftrightarrow z = z_1$ yields $f''(t_2)g_0^2(z_1) = 3z_1^2 - \zeta = 3\zeta$, since $z_1 = 2\sqrt{\zeta/3}$, or $g_0(z_1) = \pm\sqrt{3\zeta/f''(t_2)}$. Now, $f''(t_2) > 0$ since t_2 is a local minimum of f; hence, the ratio inside the square root is positive. Because z must increase with t, the positive square root must be extracted and so we have

$$g_0(z_1) = \sqrt{\frac{3\zeta}{f''(t_2)}}. \tag{5.8}$$

To continue, we differentiate $f''(t)g_0^2(z) + f'(t)g_0'(z) = 3z^2 - \zeta$ again with respect to z and evaluate the result at $z = z_2 \leftrightarrow t = t_0$ to obtain

$$g_0(z_2) = \sqrt[3]{\frac{-6\sqrt{\zeta/3}}{f'''(t_0)}}. \tag{5.9}$$

If we repeat this process again, we find, after some arithmetic, that

$$g_0'(z_2) = \frac{6 - f''''(t_0)g_0^4(z_2)}{6f'''(t_0)g_0^2(z_2)}. \tag{5.10}$$

It is clear that $g_0(z_1), g_0(z_2)$, and $g_0'(z_2)$ can be expressed in terms of f, its derivatives, and ζ.

We turn to the calculation of these latter quantities. To begin, we apply the binomial theorem to (5.1) to find

$$\begin{aligned} b \ &= \ \frac{4}{3\sqrt{6}}\left[1 - \frac{9}{2}\Delta c - \frac{9}{\sqrt{3}}(\Delta c)^{3/2} - \frac{81}{8}(\Delta c)^2\right. \\ &\qquad \left. - \frac{81}{2\sqrt{3}}(\Delta c)^{5/2} - \frac{27\cdot 35}{16}(\Delta c)^3 + O(\Delta c)^{7/2}\right]. \end{aligned} \tag{5.11}$$

For the limiting forms of the saddles t_0 and t_2, we note that $\psi = -\pi/6$ implies, from (2.7), that $e_1 = \sqrt{\Delta c/3}$, $e_2 = e_3 = -\frac{1}{2}\sqrt{\Delta c/3}$; recall that we have set $c = \Delta c - 1/12$.
Use of these observations in (2.4) provides us with

$$t_0 = \frac{1}{\sqrt{6}}\sqrt{1 - 6\sqrt{\Delta c/3}}.$$

If we apply the binomial theorem to this expression for t_0, we find that

$$\begin{aligned} t_0 - \frac{1}{\sqrt{6}} &= \frac{-1}{\sqrt{6}} \Bigg[\sqrt{3}(\Delta c)^{1/2} + \frac{3}{2}(\Delta c) + \frac{9}{2\sqrt{3}}(\Delta c)^{3/2} + \frac{45}{8}(\Delta c)^2 \\ &\qquad + \frac{7 \cdot 27}{8\sqrt{3}}(\Delta c)^{5/2} + \frac{21 \cdot 27}{16}(\Delta c)^3 + O(\Delta c)^{7/2} \Bigg] \end{aligned}$$

as $\Delta c \to 0$, and in similar fashion for small Δc,

$$\begin{aligned} t_2 - \frac{1}{\sqrt{6}} &= \frac{1}{\sqrt{6}} \Bigg[2\sqrt{3}(\Delta c)^{1/2} + \frac{3}{4}(\Delta c) + \frac{15\sqrt{3}}{8}(\Delta c)^{3/2} + \frac{7 \cdot 45}{64}(\Delta c)^2 \\ &\qquad + \frac{17 \cdot 63\sqrt{3}}{128}(\Delta c)^{5/2} + \frac{21 \cdot 27 \cdot 31}{512}(\Delta c)^3 + O(\Delta c)^{7/2} \Bigg] . \end{aligned}$$

We are now in a position to calculate $f(t_0) - f(t_2)$, which we shall see is required in the calculation of ζ. We accomplish this by first writing f as its Taylor expansion about $t = 1/\sqrt{6}$. We replace b in the result of this computation by (5.11) and compute $f(1/\sqrt{6}), f'(1/\sqrt{6})$, and $f''(1/\sqrt{6})$; this results in approximations in terms of powers of $(\Delta c)^{1/2}$. Use of these approximations for f and its derivatives at $1/\sqrt{6}$, together with the preceding small Δc approximations for t_0 and t_2, in the Taylor series for f gives us small Δc approximations for $f(t_0)$ and $f(t_2)$. Upon taking the outcome of these two (involved) calculations and forming their difference, we find that

$$(5.12) \quad f(t_0) - f(t_2) = \frac{27}{4\sqrt{6}}(\Delta c)^2 \cdot \left[1 + \frac{6\sqrt{3}}{5}(\Delta c)^{1/2} + \frac{45}{8}(\Delta c) + O(\Delta c)^{3/2} \right] .$$

Since $\sigma_1^2 - 3\sigma_2 = (f(t_0) - f(t_2))^2$ on this portion of the caustic (see the discussion following (3.25)), we have $(\sigma_1^2 - 3\sigma_2)^{1/2} = f(t_0) - f(t_2)$.

We observe that (3.25) is equivalent to the expression $\mathcal{N} = \mathcal{D}$, where $\mathcal{N}$ and $\mathcal{D}$ are displayed in (3.22). This in turn implies that χ, in (3.23), is zero. Hence, (5.12) together with $\chi = 0$ and (3.30) yields

$$(5.13) \qquad \zeta = \frac{3^{3/4}}{2^{1/4}}(\Delta c) \left[1 + \frac{3\sqrt{3}}{5}(\Delta c)^{1/2} + \frac{9 \cdot 101}{400}(\Delta c) + O(\Delta c)^{3/2} \right] .$$

With ζ in hand, we can proceed to the calculation of $g_0(z_1), g_0(z_2)$, and $g_0'(z_2)$. We obtain $g_0(z_1)$ first. From the Taylor expansion of f centered at $t = 1/\sqrt{6}$, the small Δc approximation for t_2 and (5.11), we obtain

$$(5.14) \quad f''(t_2) = \frac{18}{\sqrt{6}} \left[(\Delta c) + \sqrt{3}(\Delta c)^{3/2} + \frac{45}{16}(\Delta c)^2 + \frac{33\sqrt{3}}{8}(\Delta c)^{5/2} + O(\Delta c)^3 \right] ,$$

and dividing this into 3ζ gives $3\zeta/f''(t_2) = (3^{1/4}/2^{3/4})[1 - \frac{2}{5}\sqrt{3}(\Delta c)^{1/2} + \frac{33}{50}(\Delta c) + O(\Delta c)^{3/2}]$, from which (5.8) yields

$$(5.15) \qquad g_0(z_1) = \frac{3^{1/8}}{2^{3/8}} \left[1 - \frac{\sqrt{3}}{5}(\Delta c)^{1/2} + \frac{27}{100}(\Delta c) + O(\Delta c)^{3/2} \right] .$$

To get $g_0(z_2)$ requires the limiting behaviour of $f'''(t_0)$ as $\Delta c \to 0$. The Taylor series for f centered at $1/\sqrt{6}$, the small Δc approximation of t_0 and (5.11) yield $f'''(t_0) = -4\sqrt{3}(\Delta c)^{1/2} + O(\Delta c)^{7/2}$; from this and (5.13), we find

$$g_0(z_2) = \frac{3^{1/8}}{2^{3/8}}\left[1 + \frac{\sqrt{3}}{10}(\Delta c)^{1/2} + \frac{3\cdot 81}{800}(\Delta c) + O(\Delta c)^{3/2}\right]. \tag{5.16}$$

To obtain $g_0'(z_2)$, we use the Taylor expansion for $f^{(iv)}$ centered at $t = 1/\sqrt{6}$ and put $t = t_0$. With the small Δc approximation for t_0, we have $f^{(iv)}(t_0) = (24/\sqrt{6})\left[1 - \sqrt{3}(\Delta c)^{1/2} - 3(\Delta c)/2 + O(\Delta c)^{3/2}\right]$. This and (5.10) gives us

$$g_0'(z_2) = -\frac{3^{3/4}}{2^{5/4}\cdot 5}\left[1 + \frac{21\sqrt{3}}{40}(\Delta c)^{1/2} + O(\Delta c)\right]. \tag{5.17}$$

With $g_0(z_1), g_0(z_2)$, and $g_0'(z_2)$ at our disposal, we are in a position to calculate the coefficients p_0, q_0, and r_0. Upon assembling the preceding approximations, and substituting into equations (5.5), (5.6), and (5.7), we find

$$r_0 = \frac{3^{3/8}63}{2^{1/8}32\cdot 25}[1 + O(\Delta c)^{1/2}], \tag{5.18}$$

$$q_0 = -\frac{3^{3/4}}{2^{5/4}5}[1 + O(\Delta c)^{1/2}], \tag{5.19}$$

and

$$p_0 = \frac{3^{1/8}}{2^{3/8}}[1 + O(\Delta c)^{1/2}]. \tag{5.20}$$

To compare the limit, as $\Delta c \to 0$, of (3.36) with the classically obtained result (2.12) requires the calculation of $P(0,0), P_x(0,0)$, and $P_y(0,0)$, where P is the Pearcey integral given in equation (1.3). Standard techniques give

$$P(0,0) = \frac{\Gamma(1/4)}{\sqrt{2}}e^{\pi i/8}; \quad P_x(0,0) = \frac{i\Gamma(3/4)}{\sqrt{2}}e^{3\pi i/8}; \quad P_y(0,0) = 0,$$

so that use of these values for the Pearcey function and its derivatives, along with (5.18)–(5.20), in (3.36) gives us

$$\begin{aligned}&\left[\frac{p_0(4/3\sqrt{6}, -1/12)}{\lambda^{1/4}}P(0,0) - \frac{i\cdot q_0(4/3\sqrt{6}, -1/12)}{\lambda^{1/2}}P_y(0,0)\right.\\ &\left.\quad - \frac{2i\cdot r_0(4/3\sqrt{6}, -1/12)}{\lambda^{3/4}}P_x(0,0)\right] e^{i\lambda f(1/\sqrt{6})}\\ &= \frac{3^{1/8}\Gamma(1/4)}{2^{7/8}\lambda^{1/4}}e^{\pi i/8 - i\lambda/(45\sqrt{6})} + \frac{2^{3/8}3^{3/8}63\Gamma(3/4)}{32\cdot 25\lambda^{3/4}}e^{3\pi i/8 - i\lambda/(45\sqrt{6})}.\end{aligned} \tag{5.21}$$

Equation (5.21), together with $f(-3/\sqrt{6}) = 7/5\sqrt{6}$ and $f''(-3/\sqrt{6}) = -32/3\sqrt{6}$ ($t_3 = -3/\sqrt{6}$ at the cusp), shows that (3.36) agrees with the classically obtained approximation given in (2.12).

6. Summary and closing remarks. Collecting the work of §§2–5, we have established the result:

Let S be the swallowtail integral defined in (1.1). *Then, for positive y and large positive x,*

$$\begin{aligned}\frac{S(-x,y,z)}{\sqrt{x}} &= e^{ix^{5/2}f(t_3;yx^{-3/2},zx^{-2})-\pi i/4}\sqrt{\frac{-2\pi}{x^{5/2}f''(t_3;yx^{-3/2},zx^{-2})}}\\ &\quad\cdot\left[1+O(x^{-5/4})\right]\\ &\quad+e^{ix^{5/2}\theta}\left[p_0P(-x^{5/4}\zeta,x^{15/8}\eta)x^{-5/8}-iq_0P_y(-x^{5/4}\zeta,x^{15/8}\eta)x^{-5/4}\right.\\ &\quad\left.-2ir_0P_x(-x^{5/4}\zeta,x^{15/8}\eta)x^{-15/8}\right]\cdot\left[1+O(x^{-5/2})\right],\end{aligned}$$

where $f(t;b,c)=t^5/5-t^3/3+bt^2/2+ct$, t_3 is the negative root of $t^4-t^2+yx^{-3/2}t+zx^{-2}=0$, and the functions ζ, η, and θ are given by equations (3.30), (3.15) *and* (3.14) *respectively* (*information about the branches that must be used in these formulae can be found in the discussion following equations* (3.29) *and* (3.30)). *The coefficients p_0, q_0, and r_0 are defined by equations* (3.33) *and satisfy, at the cusp of the caustic $4x^{3/2}=3\sqrt{6}\,y$, $z=-x^2/12$,*

$$p_0=3^{1/8}/2^{3/8};\quad q_0=-3^{3/4}/(2^{5/4}5);\quad r_0=3^{3/8}63/(2^{1/8}32\cdot 25)\ .$$

The function P is the Pearcey integral given as equation (1.3). *This asymptotic approximation of $S(-x,y,z)$ remains uniformly valid for large positive x, for y and z in a neighborhood of the cusp of the caustic, containing a disk of the form $(yx^{-3/2}-4/3\sqrt{6})^2+(zx^{-2}+1/12)^2\le\epsilon^2$ for some $\epsilon>0$.*

For negative y, the asymptotic behaviour can be obtained by forming the complex conjugate of the approximation for $S(-x,-y,z)$.

Uniform asymptotic expansions of the derivatives of $S(x,y,z)$ are also readily obtained from the expansions developed in this work. Because the integral I (cf. § 2.2) is analytic in *all* of its arguments (indeed, it is entire in the parameters b and c), the coefficients in the expansion of I are analytic in their parameters (b,c for the p_n, q_n and r_n). Thus, we need only differentiate our expansion termwise to obtain expansions of the derivatives of S; see [Urs, p. 52]. However, this requires the introduction of no new techniques, and so has been excluded from our (already lengthy) discussion.

We close this work by noting that, although the use of Greenhill's work was not necessary for the development of the expansion of I, it proved convenient at times. Further, it appears that elliptic functions provide a means of approaching the problem of expressing the zeros of higher degree polynomials (unsolvable by radicals for degree ≥ 5) as analytic functions of a polynomial's coefficients; see [Kie]. This consideration is of paramount importance for the development of uniform expansions of integrals such as

$$\int_{-\infty}^{+\infty}e^{i(t^6/6+wt^4/4+xt^3/3+yt^2/2+zt)}dt,$$

the next "canonical diffraction integral" in the suite of generalized Airy functions (termed the "butterfly" integral).

Acknowledgments. The author is grateful for the numerous improvements to [Kam1] suggested by Professors R. Wong, J. P. McClure, and F. W. J. Olver. The author is particularly indebted to Professor Wong for his guidance throughout this work.

ON THE OPTIMAL DESIGN OF COLUMNS AGAINST BUCKLING*

STEVEN J. COX† AND MICHAEL L. OVERTON‡

Abstract. The authors establish existence, derive necessary conditions, infer regularity, and construct and test an algorithm for the maximization of a column's Euler buckling load under a variety of boundary conditions over a general class of admissible designs. It is proven that symmetric clamped-clamped columns possess a positive first eigenfunction and a symmetric rearrangement is introduced that does not decrease the column's buckling load. The necessary conditions, expressed in the language of Clarke's generalized gradient [10], subsume those proposed by Olhoff and Rasmussen [25], Masur [22], and Seiranian [34]. The work of [25], [22], and [34] sought to correct the necessary conditions of Tadjbakhsh and Keller [37], who had not foreseen the presence of a multiple least eigenvalue. This remedy has been hampered by Tadjbakhsh and Keller's miscalculation of the buckling loads of their clamped-clamped and clamped-hinged columns. This issue is resolved in the appendix.

In the numerical treatment of the associated finite-dimensional optimization problem the authors build on the work of Overton [26] in devising an efficient means of extracting an ascent direction from the column's least eigenvalue. Owing to its possible multiplicity, this is indeed a nonsmooth problem and again the ideas of Clarke [10] are exploited.

1. Introduction. We recall Pearson's formulation [38, p. 66] of the following problem of Lagrange,

> To find the curve which by its revolution about an axis in its plane determines the column of greatest efficiency.

For columns of unit length and volume, efficiency here denotes the structure's resistance to buckling under axial compression. When λ is the magnitude of the axial load and u the resulting transverse displacement, we postulate the potential energy

$$\int_0^1 EI|u''|^2\,dx - \lambda\int_0^1 |u'|^2\,dx$$

with the two terms measuring bending and elongation respectively. Here I is the second moment of area of the column's cross section and E is its Young's modulus. For sufficiently small λ, the minimum of this potential energy, over all admissible displacements, is zero. The (Euler) buckling load of the column is the greatest λ, call it λ_1, for which this minimum is zero. That is,

$$\lambda_1 = \inf_{u\in V}\frac{\int_0^1 EI|u''|^2\,dx}{\int_0^1 |u'|^2\,dx}, \tag{1.1}$$

where V is a closed subspace of H^2, the space of L^2 functions on the interval $(0,1)$ with first and second distributional derivatives in L^2, distinguished by the choice of boundary conditions. The choice that has generated the greatest interest is the clamped-clamped condition $u(0) = u'(0) = u(1) = u'(1) = 0$. With the corresponding

V denoted by H_0^2, it is not difficult to show that the infimum in (1.1) is attained at some $u_1 \in H_0^2$. First order necessary conditions then require that u_1 satisfy

$$\int_0^1 EIu_1''v''\,dx = \lambda_1 \int_0^1 u_1'v'\,dx \quad \forall v \in H_0^2. \tag{1.2}$$

When I and E are smooth it follows from (1.2) that

$$-(EIu_1'')'' = \lambda_1 u_1'', \qquad u_1(0) = u_1'(0) = u_1(1) = u_1'(1) = 0. \tag{1.3}$$

With this we recognize (1.1) as Rayleigh's principle for the least eigenvalue of (1.3) and u_1 as an associated first eigenfunction. For the problem of Lagrange, the Young's modulus is assumed constant and, as the column is a solid of revolution, each cross section's second moment of area is simply a constant multiple of the square of its area, A, i.e., $I(x) = cA^2(x)$. Fixing our attention on columns of unit volume, we require

$$\int_0^1 A\,dx = 1. \tag{1.4}$$

We have reduced the problem of Lagrange to the search for that A which, subject to (1.4), maximizes the λ_1 of (1.1). This problem, with clamped-clamped boundary conditions, was first attacked in 1962 by Tadjbakhsh and Keller [37] in the continuation of work Keller [20] had begun at the suggestion of Clifford Truesdell. The work of [37] hinges on the necessary condition that the best A, and its corresponding eigenfunction u, satisfy

$$A^4|u''|^2 = A^3 \tag{1.5}$$

along the entire column. This was obtained on formally differentiating a second-order analogue (see eqn. (2.5)) of (1.3) with respect to A, subject to the integral constraint. Upon reconciling (1.3) and (1.5), Tadjbakhsh and Keller arrived at the representation

$$\begin{aligned} A(x) &= \tfrac{4}{3}\sin^2\theta(x), \qquad -\pi/2 \le \theta \le 3\pi/2, \\ \theta(x) - \tfrac{1}{2}\sin 2\theta(x) + \pi/2 &= 2\pi x, \qquad 0 \le x \le 1. \end{aligned} \tag{1.6}$$

The most striking aspect of this claim is that it requires the cross-sectional area to vanish at $\frac{1}{4}$ and $\frac{3}{4}$. This result should however come as no surprise, for implicit in (1.5) is the assumption that the optimal buckling load is simple, i.e., that the corresponding space of buckled configurations is one-dimensional. This requires the optimal column to buckle in much the same way as the uniform column ($A \equiv 1$), the first eigenfunction of which is $U(x) = 1 - \cos(2\pi x)$. The fact that A vanishes at the inflection points of U agrees then with the heuristic (suggested by (1.1)) that the optimal column need be thick only in regions where it bends, i.e., where the magnitude of the linearized curvature $|u''|$ is large.

Tadjbakhsh and Keller claimed $16\pi^2/3$ as the buckling load of the resulting column. It was not until 1977 that Olhoff and Rasmussen [25], observing that (1.3) does not exclude multiple eigenvalues, noted that as the least eigenvalue does not vary smoothly with A at points where its multiplicity exceeds one, the formal differentiation in [37] would be hard to justify. As evidence that Tadjbakhsh and Keller had indeed taken the wrong course, Olhoff and Rasmussen claimed, on the basis of numerical work, 30.51 for the buckling load of the column constructed according to (1.6). Unfortunately, they neglected to describe the means by which this value was arrived at. Indeed, the fact that A vanishes at $\frac{1}{4}$ and $\frac{3}{4}$ introduces computational difficulties. Although they did go on to suggest how $16\pi^2/3$ was incorrectly obtained, a number of workers have remained unconvinced, e.g., Myers and Spillers [24] and Barnes [4]. Upon fleshing out the relevant remarks of Olhoff and Rasmussen we shall see, in work relegated to an appendix, that the buckling load for the column proposed by Tadjbakhsh and Keller does not exceed $\pi^2/3$. These same arguments will serve to demonstrate that Tadjbakhsh and Keller's best clamped-hinged column also has a much lower buckling load than thought previously.

Having concluded that differentiating (1.3) would lead to less than optimal columns, Olhoff and Rasmussen presented a "bimodal formulation" of the problem of Lagrange, i.e., one that would accommodate double eigenvalues. Their subsequent necessary condition paired the best A with two corresponding linearly independent eigenfunctions u, v and a scalar $t \in [0,1]$ so that

$$A\left(t|u''|^2 + (1-t)|v''|^2\right) = 1 \tag{1.7}$$

along the entire column. On implementing an algorithm that enforced this optimality condition, Olhoff and Rasmussen arrived at a column whose cross sectional area was positive throughout and which could withstand loads up to 52.3563. Their methods were, however, no more rigorous than those of Tadjbakhsh and Keller, and moreover, solely on the basis of claims, the latter still had the stronger column, for $52.3563 < 16\pi^2/3$. Those persuaded by Olhoff and Rasmussen's criticism of the work of Tadjbakhsh and Keller then set out to put (1.7) on a solid foundation. Actually, they joined the discussion of the more general problem: What conditions are necessary for a multiple eigenvalue to attain its extremum? The greatest advances on this question have come in finite dimensions and lie in the apparently little-known work of Bratus and Seiranian [7]. These conditions, later discovered independently in a more general form by Overton [26], will be discussed in detail in §5. For now, we note that Bratus and Seiranian, upon applying their finite-dimensional arguments to the problem of Lagrange, arrived at the conclusion that the best A must, with two corresponding orthogonal eigenfunctions u, v, satisfy

$$A(\delta_1|u''|^2 + \delta_2|v''|^2 + \delta_3 u''v'') = 1, \quad \text{where } \delta_1\delta_2 \geq \frac{\delta_3^2}{4}. \tag{1.8}$$

This condition was also proposed by Masur [22] who, like Seiranian [34], went on to represent the best A via a system of transcendental equations. Their approximate solutions to these systems are in good agreement, with respective buckling loads of 52.3564 and 52.3565, with that proposed by Olhoff and Rasmussen [25]. Note that (1.7) and (1.8), with the introduction of a second buckling mode, possess mechanisms which, at least in principle, rule out the possibility of columns with vanishing cross sectional area.

Our main contribution to the problem of Lagrange is essentially twofold. We employ the generalized gradient of Clarke in (i) a rigorous derivation of the necessary conditions (1.8) and (ii) the construction of an efficient algorithm to solve the associated finite-dimensional optimization problem. Our initial focus on the clamped-clamped case will be extended in §5 to each of the boundary conditions considered by Tadjbakhsh and Keller.

In our discussion of the various optimality criteria something has been conspicuously lacking: the literature contains no proof of the existence of a best A for the problem of Lagrange. Before filling this gap we establish a number of preliminary results and look to a more general problem formulation.

2. The optimal design problem. The moment I is more precisely the second moment of area of the cross section about a line through its centroid normal to the plane of buckling. That is, denoting the cross section by $\Omega(x)$ with centroid at the origin, if η is a unit normal to the plane of buckling then

$$I(x) = \int_{\Omega(x)} |\eta^T y|^2 \, dy. \tag{2.1}$$

When Ω is a circle, in fact, when Ω is a regular polygon, this integral does not depend on η, and we find that I varies as the square of the cross-sectional area, A. On considering so called thin-walled columns we shall now see that I varies as an affine function of A. On the lateral surface of a cylinder with circular cross section of constant radius R we add a layer of variable thickness $\rho(x)$ with $\rho(x) \le \varepsilon R$, $\varepsilon \ll 1$. Neglecting powers of ρ greater than one we find $I(x) = \pi R^3 \rho(x) + \pi R^4$ and $A(x) = 2\pi R \rho(x) + \pi R^2$. Taking $\tilde{A}(x) = A(x) - \pi R^2/2$ for our design variable we find $I(x) = (R^2/2)\tilde{A}(x)$. The effect of this choice on the integral constraint is trivial. Of greater interest is that $\tilde{A}$, by construction, must satisfy the pointwise bounds

$$\frac{\pi R^2}{2} \le \tilde{A}(x) \le \frac{\pi R^2}{2} + 2\varepsilon\pi R^2. \tag{2.2}$$

It is not difficult to continue this line of reasoning and collect a number of examples where I varies as some power of A. We proceed then to consider the case where $EI = \sigma^p$ for some $p > 0$. Compelled by our examination of the previous special cases, we admit those σ in

$$ad = \left\{ \sigma \in L^\infty : 0 < \alpha \le \sigma(x) \le \beta, \ \int_0^1 \sigma(x)\, dx = 1 \right\}.$$

The weak formulation of the buckled column equation for $\sigma \in ad$ is

$$\int_0^1 \sigma^p u'' v'' \, dx = \lambda \int_0^1 u' v' \, dx \quad \forall v \in H_0^2. \tag{2.3}$$

As $\sigma \in L^\infty$ and $\alpha > 0$, (2.3) possesses the sequence of eigenvalues

$$0 < \lambda_1(\sigma) \le \lambda_2(\sigma) \le \cdots \uparrow \infty,$$

repeated according to their finite multiplicities and a corresponding sequence of eigenfunctions $\{u_k(\sigma)\}_{k=1}^\infty \subset H_0^2$, orthonormal in terms of the bilinear form associated with the right side of (2.3). As $H_0^2(0,1) \subset C^1([0,1])$ we find $u_k \in C^1([0,1])$. Upon integrating by parts on the right side of (2.3) we find that $\sigma^p u_k''$ differs from $-\lambda_k(\sigma) u_k$ by an affine function of x. Hence, $\sigma^p u_k'' \in C^1([0,1])$, and, in fact,

$$(\sigma^p u_k'')(x) = (\sigma^p u_k'')'(0)x + (\sigma^p u_k'')(0) - \lambda_k(\sigma) u_k(x). \tag{2.4}$$

We collect those eigenfunctions corresponding to $\lambda_1(\sigma)$ in

$$\mathcal{E}(\sigma) = \operatorname{span}\{u_k(\sigma); \ \lambda_k(\sigma) = \lambda_1(\sigma)\},$$

a subspace of H_0^2 with dimension equal to the multiplicity of $\lambda_1(\sigma)$. Implicit in Olhoff and Rasmussen's bimodal formulation is the assumption that this multiplicity is at most two. Seiranian [34], has confirmed this through Kamke's analysis of the second-order problem with nonseparated boundary conditions

$$w'' + \lambda\sigma^{-p} w = 0, \quad w(1) = w(0) + w'(0), \quad w'(1) = w'(0). \tag{2.5}$$

This is the strong version of (2.3) with $w = \sigma^p u''$ and was first considered in our context by Tadjbakhsh and Keller. Kamke, in [19, §4], proves that the multiplicity of each eigenvalue of (2.5) is no greater than two. Equation (2.4), however, suggests an approach that applies directly to the weak formulation.

If, corresponding to $\lambda_k(\sigma)$, there existed three linearly independent eigenfunctions u_1, u_2, u_3 then it would be possible to choose scalars a, b, c not all zero such that $v = au_1 + bu_2 + cu_3$ satisfies, in addition to $v(0) = v'(0) = v(1) = v'(1) = 0$, the two conditions $(\sigma^p v'')'(0) = 0$, and $(\sigma^p v'')(0) = 0$. From (2.4) we conclude that v satisfies the homogeneous linear second order equation with zero initial conditions

$$\sigma^p(x)v''(x) + \lambda_k(\sigma)v(x) = 0, \qquad v(0) = v'(0) = 0.$$

As the only solution to this equation is the identically zero function, we have established

LEMMA 2.1. *If $\sigma \in ad$ then the multiplicity of $\lambda_k(\sigma)$ is at most two.*

As the least eigenvalue of the uniform column is $4\pi^2$, we find, as a consequence of the monotonicity of the Rayleigh quotient, that

$$4\pi^2\alpha^p \le \lambda_1(\sigma) \le 4\pi^2\beta^p \quad \forall\, \sigma \in ad. \tag{2.6}$$

Corresponding to the least eigenvalue $\lambda_1(\sigma)$, a positive eigenfunction is expected. Indeed, this is the *only* type that Tadjbakhsh and Keller expected. To our knowledge, however, there is no proof that a positive first eigenfunction need exist. We remark that on this point the oscillation theory of Kamke is insufficient, for it concludes only that eigenfunctions corresponding to the least nonzero eigenvalue of (2.5) possess either three *or* two zeros. This translates into either one *or* no zero(s) for eigenfunctions corresponding to $\lambda_1(\sigma)$. We now improve on this situation in the case where σ is even (about 1/2), i.e., $\sigma(x) = \sigma(1-x)$.

THEOREM 2.2. *If $\sigma \in L^\infty$ is even and admits a positive lower bound, then there exists a positive even eigenfunction corresponding to $\lambda_1(\sigma)$.*

Proof 2.2. We exploit the essential idea in inverse iteration, a popular technique for computing the least eigenvalue and eigenvector of a symmetric matrix. In our context this idea amounts to approximating the least eigenfunction by the solution of a related nonhomogeneous boundary value problem. Given $v_0 \in H_0^2$ we consider its expansion in the complete set of eigenfunctions $\{u_k(\sigma)\}$,

$$v_0(x) = \overline{v}(x) + \sum_{k=m+1}^{\infty} a_k u_k(x),$$

where m is the least integer for which $\lambda_m(\sigma) < \lambda_{m+1}(\sigma)$ and $\overline{v}$ is an eigenfunction corresponding to $\lambda_1(\sigma)$. From v_0 we construct the sequence $\{v_j\} \subset H_0^2$ according to

$$\int_0^1 \sigma^p v_j'' \phi''\, dx = \lambda_1(\sigma) \int_0^1 v_{j-1}' \phi'\, dx \quad \forall\, \phi \in H_0^2.$$

On expanding v_j in $\{u_k(\sigma)\}$ we find

$$v_j(x) = \overline{v}(x) + \sum_{k=m+1}^{\infty} a_k \left(\frac{\lambda_1(\sigma)}{\lambda_k(\sigma)}\right)^j u_k(x).$$

As $\lambda_1(\sigma) < \lambda_k(\sigma)$ for all $k > m$, we find that v_j converges pointwise to $\overline{v}$ as $j \to \infty$. It remains then to produce a v_0 whose corresponding $\overline{v}$ is even and positive.

Our choice for v_0 is the first eigenfunction of the uniform column, i.e., $1-\cos(2\pi x)$, a positive even function with exactly two inflection points.

LEMMA 2.3. *Let f be an even member of L^∞ with a positive lower bound and v be a positive, even member of H_0^2 with precisely two inflection points. If $u \in H_0^2$ satisfies*

$$\int_0^1 f u'' \phi''\, dx = \int_0^1 v' \phi'\, dx \quad \forall \phi \in H_0^2, \tag{2.7}$$

then u is positive, even, and possesses precisely two inflection points.

Proof 2.3. Upon integrating by parts on the right of (2.7) we find that fu'' differs from v by an affine function. Dividing by f and integrating twice gives

$$u(x) = \int_0^x (x-y)(ay+b-v(y))g(y)\, dy, \tag{2.8}$$

where $g = 1/f$ and a and b are determined by $u(1) = 0$ and $u'(1) = 0$, i.e., by

$$a\int_0^1 xg(x)\, dx + b\int_0^1 g(x)\, dx = \int_0^1 v(x)g(x)\, dx, \tag{2.9}$$

$$a\int_0^1 x^2 g(x)\, dx + b\int_0^1 xg(x)\, dx = \int_0^1 xv(x)g(x)\, dx. \tag{2.10}$$

That these equations uniquely determine a and b follows from Hölder's inequality

$$\left(\int_0^1 xg(x)\, dx\right)^2 < \int_0^1 g(x)\, dx \int_0^1 x^2 g(x)\, dx.$$

Our hypotheses, in fact, allow us to conclude that

$$a = 0, \qquad b = \frac{\int_0^1 v(x)g(x)\, dx}{\int_0^1 g(x)\, dx}.$$

This obviously satisfies (2.9). Regarding (2.10), recall that every even function satisfies $\int_0^1 \phi(x)\, dx = 2\int_0^1 x\phi(x)\, dx$. Consequently,

$$b = \frac{\int_0^1 v(x)g(x)\, dx}{\int_0^1 g(x)\, dx} = \frac{2\int_0^1 xv(x)g(x)\, dx}{2\int_0^1 xg(x)\, dx} = \frac{\int_0^1 xv(x)g(x)\, dx}{\int_0^1 xg(x)\, dx}$$

satisfies (2.10) as well. Labeling $s(x) = (b - v(x))g(x)$, equation (2.8), $u(1) = 0$, and $u'(1) = 0$ take the form

$$u(x) = \int_0^x (x-y)s(y)\, dy, \qquad \int_0^1 s(y)\, dy = 0, \qquad \int_0^1 ys(y) = 0.$$

With this and the fact that s is even, we find

$$\begin{aligned} u(1-x) &= \int_0^{1-x} (1-x-y)s(y)\,dy \\ &= \int_0^1 (1-x-y)s(y)\,dy - \int_{1-x}^1 (1-x-y)s(y)\,dy \\ &= \int_0^x (x-y)s(y)\,dy = u(x). \end{aligned}$$

Regarding the convexity/concavity of u, we observe that $f(x)u''(x) = b - v(x)$. That $b - v(x)$ has at least two zeros follows from $b > 0$, $v(0) = v(1) = 0$, and $0 < b < \|v\|_\infty$. For $b - v(x)$ to possess more than two zeros v must admit a local minimum, a condition that requires of v no less then four inflection points. These zeros, say x_0 and $1 - x_0$, are the inflection points of u. As u vanishes at zero and is convex on $(0, x_0)$, it must be positive there, and, by symmetry, positive on $(1 - x_0, 1)$ as well. As u is positive at x_0 and $1 - x_0$ while concave between these points it must be positive on this interval as well. □

Proof 2.2. It now follows that $\{v_j\}$ is a sequence of positive even functions. Because the convergence of v_j to $\overline{v}$ is pointwise, we conclude that $\overline{v}$ is itself a positive even function. □

When σ is even and $\lambda_1(\sigma)$ is simple, we now have, up to a scalar multiple, a unique positive even first eigenfunction; call it u_1. When $\lambda_1(\sigma)$ is double, in addition to u_1, there exists a first eigenfunction u_2 for which $\int_0^1 u_1' u_2'\,dx = 0$. Consequently, u_2 is not even, and as u_1 and u_2 span $\mathcal{E}(\sigma)$ we may conclude that when σ is even, there exists, up to a scalar multiple, a unique positive even first eigenfunction.

Though Theorem 2.2 applies only to even functions, we shall see in the next result that this suffices for our purposes. Note that Lemma 2.3 states that the operator $(d^2/dx^2(f\,d^2/dx^2))^{-1}(-d^2/dx^2)$ leaves a subcone of the positive H_0^2 functions invariant when f is even. This cone is, however, too "thin" to allow one to invoke Krein–Rutman arguments. Regarding possible improvements of Lemma 2.3, we note that even the constant coefficient operator $(d^4/dx^4)^{-1}(-d^2/dx^2)$ does *not* leave the positive H_0^2 functions invariant. To see this, we solve for b in (2.9)–(2.10) with $g = 1$,

$$b = 4\int_0^1 v\,dx - 6\int_0^1 xv\,dx.$$

Taking for v any smooth positive function supported in $(\frac{2}{3}, 1)$ produces $b < 0$. As $u(0) = u'(0) = 0$ and $u''(0) = b$, we conclude that u is not positive.

THEOREM 2.4. *Given $\sigma \in ad$ there exists an even $\sigma_* \in ad$ for which $\lambda_1(\sigma) \leq \lambda_1(\sigma_*)$.*

Proof. There is a very simple argument when $0 < p \leq 1$. Given a function ϕ on $(0, 1)$, we denote its even part by $\phi_s(x) = \frac{1}{2}(\phi(x) + \phi(1-x))$. Consider the even function $\tilde{\sigma} \equiv ((\sigma^p)_s)^{1/p}$ and its corresponding even first eigenfunction $\tilde{u}$. With the normalization $\|\tilde{u}'\| = 1$, we find

$$\lambda_1(\sigma) \leq \int_0^1 \sigma^p |\tilde{u}''|^2\,dx = \int_0^1 (\sigma^p)_s |\tilde{u}''|^2\,dx = \int_0^1 \tilde{\sigma}^p |\tilde{u}''|^2\,dx = \lambda_1(\tilde{\sigma}). \tag{2.11}$$

As $t \mapsto t^{1/p}$ is convex, we observe that

$$\tilde{\sigma}(x) = \left(\frac{\sigma^p(x)}{2} + \frac{\sigma^p(1-x)}{2} \right)^{1/p} \leq \frac{\sigma(x)}{2} + \frac{\sigma(1-x)}{2} = \sigma_s(x). \tag{2.12}$$

Now $\sigma_s \in ad$ and (2.11)–(2.12) imply that $\lambda_1(\sigma) \leq \lambda_1(\sigma_s)$. Our attempts to argue in a similar fashion for $p > 1$ with $\tilde{\sigma} \equiv ((\sigma^{-p})_s)^{-1/p}$ and (2.5) have been thwarted by the fact that $\lambda_1(\sigma)$ corresponds to the *third* eigenvalue of (2.5). What is needed is a rearrangement of σ that echoes the curvature of its corresponding first eigenfunction. To make this precise, we first need the following extension of Lemma 2.3.

Recall that a function ϕ is said to be odd about the point $(x_0, \phi(x_0))$ on some interval containing x_0 when

$$\phi(x_0) - \phi(x_0 - x) = \phi(x_0 - x) - \phi(x_0)$$

for each x on the given interval. If, in addition to the original hypotheses of Lemma 2.3, we assume that f and v, when restricted to $(0, \frac{1}{2})$ are even about $\frac{1}{4}$ and odd about $(\frac{1}{4}, v(\frac{1}{4}))$, respectively, we conclude that u, when restricted to $(0, \frac{1}{2})$, is odd about $(\frac{1}{4}, u(\frac{1}{4}))$.

To see this we recall that $\int_0^1 u''\,dx = 0$ and u'' is even about $\frac{1}{2}$, hence $\int_0^{1/2} u''\,dx = 0$. For the remainder of this paragraph all functions will be restricted to $(0, \frac{1}{2})$. Recall as well that $u'' = (b - v)/f$, the quotient of a function odd about $(\frac{1}{4}, b - v(\frac{1}{4}))$ and a function even about $\frac{1}{4}$. Hence u'' is odd about $(\frac{1}{4}, b - v(\frac{1}{4}))$. The condition that $\int_0^{1/2} u''\,dx = 0$ now forces $b = v(\frac{1}{4})$. As u'' is now odd about $(\frac{1}{4}, 0)$ and $u(0) = u'(0) = 0$, we easily conclude that u is indeed odd about $(\frac{1}{4}, u(\frac{1}{4}))$.

If σ_* is now even about $\frac{1}{2}$ and even about $\frac{1}{4}$ when restricted to $(0, \frac{1}{2})$, then beginning the iteration of Theorem 2.2 with a v_0 that is even about $\frac{1}{2}$ and odd about $(\frac{1}{4}, v_0(\frac{1}{4}))$, e.g., $1 - \cos(2\pi x)$ will produce u_*, a positive eigenfunction corresponding to $\lambda_1(\sigma_*)$ that is even about $\frac{1}{2}$ and odd about $(\frac{1}{4}, u_*(\frac{1}{4}))$ on $(0, \frac{1}{2})$. We immediately note that σ_*^p and $|u_*''|^2$ are similarly ordered, i.e.,

$$(\sigma_*^p(x_1) - \sigma_*^p(x_2))(|u_*''(x_1)|^2 - |u_*''(x_2)|^2) \geq 0 \quad \forall x_1, x_2 \in (0,1). \tag{2.13}$$

Given $\sigma \in ad$ we now define its rearrangement σ_*.

$$\ell_c = \{x \in (0,1) : \sigma(x) \geq c\},$$

$$\ell_c^* = \begin{cases} \{x \in R : |x - \frac{1}{2}| \leq \frac{1}{4}|\ell_c|\} & \text{if } \ell_c \neq \emptyset, \\ \emptyset & \text{otherwise} \end{cases}$$

$$\sigma_*(x) = \begin{cases} \sigma_*(\frac{1}{2} - x), & \text{if } 0 \leq x \leq \frac{1}{4} \\ \sup\{c \in R : x \in \ell_c^*\}, & \text{if } \frac{1}{4} \leq x \leq \frac{3}{4} \\ \sigma_*(1 - x), & \text{if } \frac{3}{4} \leq x \leq 1. \end{cases}$$

In essence, this distributes half of σ's mass in a symmetrically decreasing fashion about $\frac{1}{2}$ on $(\frac{1}{4}, \frac{3}{4})$, completing the rest via symmetry. By construction, these two functions are equimeasurable, i.e.,

$$|\{x \in (0,1) : \sigma(x) \geq c\}| = |\{x \in (0,1) : \sigma_*(x) \geq c\}| \quad \forall c \in R,$$

and consequently, $\sigma_* \in ad$. We are now in position to apply the following result of Hardy, Littlewood, and Pólya; see Pólya and Szegö [31, p. 153].

If f and f_1 are equimeasurable, g and g_1 are equimeasurable, $f \in L^q$, $g \in L^{q'}$, and f_1 and g_1 are similarly ordered, then

$$\int_0^1 fg\,dx \leq \int_0^1 f_1 g_1\,dx. \tag{2.14}$$

Given $\sigma \in ad$ we now rearrange it as above into σ_* and consider its corresponding $u_* \in \mathcal{E}(\sigma_*)$. Upon normalizing $\|u_*'\| = 1$ we find

$$\lambda_1(\sigma) \leq \int_0^1 \sigma^p |u_*''|^2\,dx \leq \int_0^1 \sigma_*^p |u_*''|^2\,dx = \lambda_1(\sigma_*).$$

The first inequality is a consequence of Rayleigh's principle, the second, of (2.13)–(2.14). □

The stage now set, we address, in the next two sections, existence and necessary conditions for the generalized problem of Lagrange

$$\sup_{\sigma\in ad} \lambda_1(\sigma). \tag{2.15}$$

3. Existence. We adopt the direct method of the calculus of variations and neglect to relabel subsequences. Denote by $\hat{\lambda}_1$ the value of (2.15) and by $\{\sigma_n\} \subset ad$ an associated maximizing sequence, i.e., $\lambda_1(\sigma_n) \uparrow \hat{\lambda}_1$. Without loss, we may assume that each σ_n is even about 1/2. We abbreviate $\lambda_1(\sigma_n)$ to $\lambda_{1,n}$ and denote by $u_{1,n}$ a corresponding positive eigenfunction for which $\|u_{1,n}'\| = 1$ and $\int_0^1 \sigma_n^p |u_{1,n}''|^2\,dx = \lambda_{1,n}$, where $\|\cdot\|$ denotes the L^2 norm. These normalizations, in light of (2.6), impose a uniform H^2 bound on the sequence $\{u_{1,n}\}$. As a result, there exists a subsequence with weak H^2 limit $\overline{u} \in H_0^2$. The imbedding of H^2 in H^1 being compact, we find $\|\overline{u}'\| = 1$, and so $\overline{u}$ is not identically zero. The natural question is whether $\hat{\lambda}_1$ and $\overline{u}$ are indeed an eigenvalue and eigenfunction for some column with corresponding $\overline{\sigma} \in ad$. If so, then $\overline{\sigma}$ is necessarily the desired optimal design. This question was first addressed by Senatorov [35] in the context of a second-order problem. He discovered that weak convergence of the reciprocals of the coefficients of the highest order term must be considered. This observation continues to hold for fourth order problems, the details of which we now sketch.

Consider the weak formulation

$$\int_0^1 \sigma_n^p u_{1,n}'' v''\,dx = \lambda_{1,n} \int_0^1 u_{1,n}' v'\,dx \quad \forall v \in H_0^2. \tag{3.1}$$

Our previous remarks reveal that the right-hand side converges to $\hat{\lambda}_1 \int_0^1 \overline{u}'v'\,dx$ for each such v. Regarding the left side we define $\xi_n = \sigma_n^p u_{1,n}''$, and, as in (2.4), deduce from (3.1)

$$\xi_n(x) = (\sigma_n^p u_{1,n}'')(0) - \lambda_{1,n} u_{1,n}(x).$$

As the sequences $\{\xi_n\}$ and $\{u_{1,n}\}$ are uniformly bounded in L^2, so too must $\{(\sigma_n^p u_{1,n}'')(0)\}$. Consequently, ξ_n converges strongly in L^2 to some function $\overline{\xi}$. The left side of (3.1) therefore converges to $\int_0^1 \overline{\xi} v''\,dx$. It remains to characterize this $\overline{\xi}$. Recalling the pointwise bounds on the σ_n we may assume that σ_n^{-p} converges in the weak* topology of L^∞ to some function μ. Thus, $\xi_n \sigma_n^{-p}$ converges weakly in L^2 to $\mu\overline{\xi}$. But $\xi_n \sigma_n^{-p} = u_{1,n}''$, whose weak L^2 limit is $\overline{u}''$. Hence, $\overline{\xi} = \overline{u}''\mu^{-1}$. Defining $\overline{\sigma} = \mu^{-1/p}$, we may pass to the limit in (3.1) and obtain

$$\int_0^1 \overline{\sigma}^p \overline{u}'' v''\,dx = \hat{\lambda}_1 \int_0^1 \overline{u}' v'\,dx \quad \forall, v \in H_0^2. \tag{3.2}$$

As symmetry is preserved under weak $*$ convergence, we find $\overline{\sigma}$ to be even. In addition, the pointwise convergence of $u_{1,n}$ to $\overline{u}$ leaves $\overline{u}$ positive and even. Now (3.2) implies that $\hat{\lambda}_1 = \lambda_j(\overline{\sigma})$ for some j. That $j = 1$ follows from the existence of a positive even first eigenfunction for $\overline{\sigma}$ and the fact that $\overline{u}$ is itself positive and even. We need only determine whether $\overline{\sigma} \in ad$. We may verify the pointwise bounds without trouble. With respect to the integral constraint, we consider the convex function $f : R \to R$, $f(t) = t^{-1/p}$. The integral functional $\varphi \mapsto \int_0^1 f(\varphi(x))\,dx$ is then weak* lower semicontinuous on L^∞, see, e.g., Dacorogna [12, Thm. 1.1]. As $1/\sigma_n^p$ converges weak* to $1/\overline{\sigma}^p$, this allows us to conclude that

$$\int_0^1 \overline{\sigma}\,dx = \int_0^1 f(1/\overline{\sigma}^p)\,dx \le \liminf \int_0^1 f(1/\sigma_n^p)\,dx = \lim \int_0^1 \sigma_n\,dx = 1. \tag{3.3}$$

If indeed equality does not hold in (3.3), then there exists an even $\hat{\sigma} \in ad$ such that $\hat{\sigma}(x) \ge \overline{\sigma}(x)$ for almost every $x \in (0,1)$. From Rayleigh's principle we then easily deduce $\lambda_1(\hat{\sigma}) \ge \lambda_1(\overline{\sigma})$. We have now proven the following.

THEOREM 3.1. *There exists an even $\hat{\sigma} \in ad$ for which $\lambda_1(\sigma) \le \lambda_1(\hat{\sigma})$ for every $\sigma \in ad$.*

Our choice of *ad* was motivated by our interest in the "shape" of the strongest column. Theorem 3.1, however, may also be applied in the search for the "composition" of the strongest column. For example, consider the design problem where one must combine two materials in fixed proportion so as to maximize the buckling load of the resulting column. The set of admissible designs is then

$$\begin{aligned} ad_E = \{&\alpha\chi(x) + \beta(1-\chi(x)) : \chi \text{ is the characteristic} \\ &\text{function of a subset of (0,1) with measure } \gamma\}, \end{aligned}$$

where α and β are the Youngs moduli of the respective materials with γ the volume fraction of the first. In this context, Theorem 3.1 states that λ_1 attains its maximum on the weak* closure of ad_E, i.e., on

$$ad_E^* = \left\{ \alpha\theta(x) + \beta(1-\theta(x)) : 0 \le \theta(x) \le 1, \int_0^1 \theta\,dx = \gamma \right\}.$$

4. Necessary conditions.

We search now for a characterization of our optimal design, $\hat{\sigma}$. Typical of many such problems, two distinct approaches are possible. Taking advantage of the variational structure, the so called direct approach attempts to swap the order of the limits in

$$\hat{\lambda}_1 = \lambda_1(\hat{\sigma}) = \sup_{\sigma\in ad} \inf_{u\in H_0^2} \frac{\int_0^1 \sigma^p |u''|^2\,dx}{\int_0^1 |u'|^2\,dx},$$

inferring necessary conditions from the resulting saddle point. The indirect approach strives to determine $\hat{\sigma}$ through knowledge of the tangents to the graph of $\sigma \mapsto \lambda_1(\sigma)$

and the normals to *ad*. Our implementation of these two approaches intersect in their reliance on (i) recent work of Auchmuty [2] on dual variational principles and (ii) a lopsided minimax principle.

PROPOSITION 4.1.

$$\lambda_1^{-1}(\sigma) = \sup_{u\in H_0^2} \mathcal{A}(\sigma,u), \;\; \mathcal{A}(\sigma,u) = \sqrt{2}\|u'\| - \tfrac{1}{2}\int_0^1 \sigma^p |u''|^2\,dx.$$

$u \mapsto \mathcal{A}(\sigma,u)$ attains its maximum only on those $u \in \mathcal{E}(\sigma)$ for which $\|u'\| = \sqrt{2}\lambda_1^{-1}(\sigma)$.

Proof. In addition to being bounded above by $2\lambda_1^{-1}(\sigma)$, the map $u \mapsto \mathcal{A}(\sigma,u)$ is coercive and weakly upper semicontinuous on H_0^2 and therefore attains its maximum at some $\overline{u} \in H_0^2$. Necessarily, $\mathcal{D}_2\mathcal{A}(\sigma,\overline{u})$, the Gâteaux derivative of $u \mapsto \mathcal{A}(\sigma,u)$ at $\overline{u}$, must vanish. That is,

$$\int_0^1 \sigma^p \overline{u}'' v''\,dx = \sqrt{2}\|\overline{u}'\|^{-1}\int_0^1 \overline{u}' v'\,dx \quad \forall\, v \in H_0^2.$$

As a result, $\overline{u}$ is an eigenfunction corresponding to the eigenvalue $\sqrt{2}\|\overline{u}'\|^{-1}$. As $\overline{u}$ maximizes $u \mapsto \mathcal{A}(\sigma,u)$, this must be the least eigenvalue, $\lambda_1(\sigma)$. □

PROPOSITION 4.2. *Consider $F : X \times Y \to R$, where X and Y are topological vector spaces and assume that $x \mapsto F(x,y)$ is concave and upper semicontinuous while $y \mapsto F(x,y)$ is convex and lower semicontinuous. If there exists a $y_o \in Y$ and $c_o \in R$ such that $\{x \in X;\; F(x,y_o) \geq c_o\}$ is compact and $c_o < \inf_{y\in Y}\sup_{x\in X} F(x,y)$, then*

$$\sup_{x\in X}\inf_{y\in Y} F(x,y) = \inf_{y\in Y}\sup_{x\in X} F(x,y).$$

Proof. This is a weakening of Theorem 3.7, Chapter 2, in Barbu and Precupanu [3]. □

It is with the indirect approach that we shall meet with the greatest success. For prior attempts in this context see Haug and Rousselet [18] and Choi and Haug [9]. Our principal tool is the generalized gradient of Clarke [10].

For a real valued Lipschitz function F on a Banach space X we consider the generalized directional derivative of F at x in the direction v,

$$F^o(x;v) \equiv \limsup_{\substack{y \to x \\ t \downarrow 0}} \frac{F(y+tv) - F(y)}{t}.$$

Denoting the dual of X by X^* and $x^*(x)$ by $\langle x^*, x\rangle$ when $x^* \in X^*$ and $x \in X$, Clarke's generalized gradient of F at x is the nonempty, convex, weak* compact set

$$\partial F(x) \equiv \{\xi \in X^*;\; F^o(x;v) \geq \langle \xi, v\rangle \;\forall\, v \in X\}.$$

We demonstrate that $\sigma \mapsto \lambda_1^{-1}(\sigma)$ is Lipschitz on $\Sigma = \{\sigma \in L^\infty;\; \|\hat{\sigma} - \sigma\|_\infty < \alpha/2\}$. Choose $\sigma_1, \sigma_2 \in \Sigma$ such that $\lambda_1^{-1}(\sigma_1) > \lambda_1^{-1}(\sigma_2)$ and note that for $u_1 \in \operatorname{Argmax} \mathcal{A}(\sigma_1,\cdot)$, the set on which $u \mapsto \mathcal{A}(\sigma_1,u)$ attains its maximum,

$$\begin{aligned} |\lambda_1^{-1}(\sigma_1) - \lambda_1^{-1}(\sigma_2)| &\leq |\mathcal{A}(\sigma_1,u_1) - \mathcal{A}(\sigma_2,u_1)| \\ &\leq \int_0^1 |\sigma_1^p - \sigma_2^p||u_1''|^2\,dx \\ &\leq \|u_1''\|^2\|\sigma_1^p - \sigma_2^p\|_\infty \leq \alpha^{-2p}p|2\beta|^{p-1}\|\sigma_1 - \sigma_2\|_\infty. \end{aligned}$$

Without loss we assume that $\lambda_1(\hat{\sigma})$ is a double eigenvalue. Then $\mathcal{E}(\hat{\sigma})$ is two-dimensional and $\operatorname{Argmax} \mathcal{A}(\hat{\sigma}, \cdot)$ is the intersection of $\mathcal{E}(\hat{\sigma})$ with the sphere $\|u'\| = \sqrt{2}\hat{\lambda}_1^{-1}$. It will be convenient to choose a basis $\{\hat{u}_1, \hat{u}_2\}$ for $\mathcal{E}(\hat{\sigma})$ for which $\int_0^1 \hat{u}_i'\hat{u}_j'\, dx = 2\delta_{ij}\hat{\lambda}_1^{-2}$. For then,

$$\text{(4.1)} \qquad \operatorname{Argmax} \mathcal{A}(\hat{\sigma}, \cdot) = \{a\hat{u}_1 + b\hat{u}_2;\ a^2 + b^2 = 1\}.$$

Regarding the Gâteaux derivative of $\sigma \mapsto \mathcal{A}(\sigma, u)$ at $\hat{\sigma}$ in the direction η we have

$$\text{(4.2)} \qquad \langle \mathcal{D}_1 \mathcal{A}(\hat{\sigma}, u), \eta \rangle = -\tfrac{p}{2} \int_0^1 \eta \hat{\sigma}^{p-1} |u''|^2 \, dx.$$

Denoting convex hull by 'co,' the sense in which the gradient of a maximum is the maximum of the gradients is the following.

THEOREM 4.3. $\partial \lambda_1^{-1}(\hat{\sigma}) = \operatorname{co}\{-\tfrac{p}{2}\hat{\sigma}^{p-1}(a\hat{u}_1'' + b\hat{u}_2'')^2;\ a^2 + b^2 = 1\}$.

Proof. From (4.1) and (4.2) this set is precisely

$$\text{(4.3)} \qquad \operatorname{co}\{\mathcal{D}_1 \mathcal{A}(\hat{\sigma}, u);\ u \in \operatorname{Argmax} \mathcal{A}(\hat{\sigma}, \cdot)\}.$$

Our claim does not fit neatly into Clarke's result [10, Thm. 2.8.2] on the generalized gradient of a pointwise maximum. The contortions involved in fitting our problem to Clarke's hypotheses are no less difficult, and far less instructive, than an independent proof.

Let us denote the set in (4.3) by Ξ. We show that $\Xi \subset \partial \lambda_1^{-1}(\hat{\sigma})$. For $\xi \in \Xi$ and $\eta \in L^\infty$

$$\begin{aligned} \langle \xi, \eta \rangle &= \sum_{i=1}^n \mu_i \langle \mathcal{D}_1 \mathcal{A}(\hat{\sigma}, u_i), \eta \rangle \\ &= \sum_{i=1}^n \mu_i \lim_{t \downarrow 0} \frac{\mathcal{A}(\hat{\sigma} + t\eta, u_i) - \mathcal{A}(\hat{\sigma}, u_i)}{t} \\ &\le \sum_{i=1}^n \mu_i \limsup_{t \downarrow 0} \frac{\lambda_1^{-1}(\hat{\sigma} + t\eta) - \lambda_1^{-1}(\hat{\sigma})}{t} \\ &\le (\lambda_1^{-1})^o(\hat{\sigma}; \eta), \end{aligned}$$

hence $\xi \in \partial \lambda_1^{-1}(\hat{\sigma})$.

Regarding the reverse inclusion we define

$$g(\sigma; \eta) = \max_{\xi \in \Xi} \langle \xi, \eta \rangle, \qquad \sigma \in \Sigma,\ \eta \in L^\infty$$

and prove

$$(\lambda_1^{-1})^o(\sigma; \eta) \le g(\sigma; \eta).$$

Select $\sigma_n \to \sigma$ in L^∞ and $t_n \downarrow 0$ in R such that

$$q_n \equiv \frac{\lambda_1^{-1}(\sigma_n + t_n\eta) - \lambda_1^{-1}(\sigma_n)}{t_n}$$

converges to $(\lambda_1^{-1})^o(\sigma;\eta)$. Select $u_n \in$ Argmax $\mathcal{A}(\sigma_n + t_n\eta, \cdot)$ and note that

$$q_n \leq \frac{\mathcal{A}(\sigma_n + t_n\eta, u_n) - \mathcal{A}(\sigma_n, u_n)}{t_n}$$

with the right side equal to $\langle \mathcal{D}_1\mathcal{A}(\sigma_n + \bar{t}_n\eta, u_n), \eta\rangle$, for some $\bar{t}_n \in (0, t_n)$, by the Mean Value Theorem. As $\sigma_n + t_n\eta \to \sigma$ in L^∞ and $u_n \in$ Argmax $\mathcal{A}(\sigma_n + t_n\eta, \cdot)$, we recall from our work in Theorem 3.1 that $u_n \rightharpoonup u \in$ Argmax $\mathcal{A}(\sigma, \cdot)$ in H^2 and $(\sigma_n + t_n\eta)^p u_n'' \to \sigma^p u''$ in L^2, and hence $u_n'' \to u''$ in L^2, i.e., $u_n \to u$ in H^2. Recalling (4.2) this establishes

$$\langle \mathcal{D}_1\mathcal{A}(\sigma_n + \bar{t}_n\eta, u_n), \eta\rangle \to \langle \mathcal{D}_1\mathcal{A}(\sigma, u), \eta\rangle$$

with $u \in$ Argmax $\mathcal{A}(\sigma, \cdot)$. As a result,

$$(\lambda_1^{-1})^o(\sigma;\eta) = \lim_{n\to\infty} q_n \leq \langle \mathcal{D}_1\mathcal{A}(\sigma, u), \eta\rangle \leq g(\sigma;\eta).$$

If ζ is now an element of $\partial\lambda_1^{-1}(\hat{\sigma})$, then $g(\hat{\sigma};\eta) \geq \langle\zeta, \eta\rangle$ for each $\eta \in L^\infty$. Consequently,

$$0 = \min_{\eta\in L^\infty} \max_{\xi\in\Xi} \langle \xi - \zeta, \eta\rangle.$$

Noting that Ξ is closed and bounded in L^1 and finite dimensional (it lies in the span of $\{|\hat{u}_1''|^2, \hat{u}_1''\hat{u}_2'', |\hat{u}_2''|^2\}$), we find it compact in $(L^\infty)^*$. Invoking Proposition 4.2 yields a $\hat{\xi} \in \Xi$ for which

$$\langle \hat{\xi} - \zeta, \eta\rangle = 0 \quad \forall \eta \in L^\infty.$$

It follows that $\zeta = \hat{\xi}$ and so $\partial\lambda_1^{-1}(\hat{\sigma}) \subset \Xi$. □

This proof, though identical in outline to Clarke [10, Thm. 2.8.2], has exploited additional properties of λ_1 and $\mathcal{A}$ to make up for the missing hypotheses. Observe that when $\lambda_1(\hat{\sigma})$ is simple the generalized gradient reduces to the singleton

$$\partial\lambda_1^{-1}(\hat{\sigma}) = \{\mathcal{D}_1\mathcal{A}(\hat{\sigma}, \hat{u}_1)\}.$$

As zero is not a tangent direction to λ_1^{-1} at $\hat{\sigma}$, i.e., $0 \neq \partial\lambda_1^{-1}(\hat{\sigma})$, we are compelled to investigate the constraint set *ad*. Separating the equality from the inequality constraints brings

$$C \equiv \{\sigma \in L^\infty;\ \alpha \leq \sigma(x) \leq \beta\} \quad \text{and} \quad V(\sigma) \equiv \int_0^1 \sigma\, dx.$$

As $\hat{\sigma}$ minimizes $\sigma \mapsto \lambda_1^{-1}(\sigma)$ subject to $\sigma \in C$ and $V(\sigma) = 1$, we deduce from the Lagrange Multiplier Rule, [10, Thm. 6.1.1], that a nontrivial linear combination of elements in $\partial\lambda_1^{-1}(\hat{\sigma})$ and $\partial V(\hat{\sigma})$ is normal to C at $\hat{\sigma}$. In particular,

$$\left(\nu_1\partial\lambda_1^{-1}(\hat{\sigma}) + \nu_2\partial V(\hat{\sigma})\right) \cap N_C(\hat{\sigma}) \neq \emptyset,$$

where $\nu_1 \leq 0$, $\nu_1^2 + \nu_2^2 > 0$, and

$$N_C(\hat{\sigma}) = \left\{\zeta \in (L^\infty)^*;\ \int_0^1 (\hat{\sigma} - \sigma)\, d\zeta \geq 0,\ \forall \sigma \in C\right\}$$

is the cone of normals to C at $\hat{\sigma}$. In light of our previous calculations, and the fact that $\partial V(\hat{\sigma}) = 1 \in L^1$, there exists a $\hat{\xi} \in \partial\lambda_1^{-1}(\hat{\sigma})$ for which

$$\int_0^1 (\hat{\sigma} - \sigma)(\nu_1\hat{\xi} + \nu_2)\,dx \geq 0 \quad \forall\sigma \in C. \tag{4.4}$$

Observing that $\nu_1\hat{\xi} \geq 0$, we find that $\nu_2 \geq 0$ requires, through (4.4), that $\hat{\sigma} \equiv \beta$. This is an impossibility. Likewise, should $\nu_1 = 0$, (4.4) would require $\hat{\sigma} \equiv \alpha$ (since $\nu_2 < 0$). Taking $\ell^2 = \nu_2/\nu_1$, we arrive at

$$\int_0^1 (\hat{\sigma} - \sigma)(\hat{\xi} + \ell^2)\,dx \leq 0 \quad \forall\sigma \in C.$$

The subsequent reduction to pointwise optimality conditions follows a well-known course, see, e.g., Cea and Malanowski [8]. In particular,

$$\hat{\sigma}(x) = \alpha \quad\Rightarrow\quad -\hat{\xi}(x) \leq \ell^2, \tag{4.5}$$

$$\alpha < \hat{\sigma}(x) < \beta \quad\Rightarrow\quad -\hat{\xi}(x) = \ell^2, \tag{4.6}$$

$$\hat{\sigma}(x) = \beta \quad\Rightarrow\quad -\hat{\xi}(x) \geq \ell^2 \tag{4.7}$$

for almost every $x \in (0,1)$. To appreciate this result, we must recall that $\hat{\xi} \in \partial\lambda_1^{-1}(\hat{\sigma})$ means

$$-\hat{\xi}(x) = \frac{p}{2}\sum_{i=1}^{n} t_i\hat{\sigma}^{p-1}(x)(a_i\hat{u}_1''(x) + b_i\hat{u}_2''(x))^2,$$

where

$$t_i \geq 0, \quad \sum_{i=1}^{n} t_i = 1, \quad \text{and} \quad a_i^2 + b_i^2 = 1.$$

On expanding this sum of squares, (4.6) becomes

$$\hat{\sigma}^{p-1}\left(\delta_1|\hat{u}_1''|^2 + \delta_2|\hat{u}_2''|^2 + \delta_3\hat{u}_1''\hat{u}_2''\right) = 1, \tag{4.8}$$

where

$$\delta_1 = \frac{p}{2}\sum_{i=1}^{n} t_i a_i^2/\ell^2, \quad \delta_2 = \frac{p}{2}\sum_{i=1}^{n} t_i b_i^2/\ell^2, \quad \delta_3 = p\sum_{i=1}^{n} t_i a_i b_i/\ell^2.$$

Observing that $\delta_1\delta_2$ indeed dominates $\delta_3^2/4$, we have recovered (1.8), the necessary condition of Bratus and Seiranian [7] and Masur [22]. If in fact $\delta_1\delta_2 = \delta_3^2/4$, then for $\hat{u} \equiv \sqrt{\delta_1}\hat{u}_1 + \sqrt{\delta_2}\hat{u}_2$, equation (4.8) yields $\hat{\sigma}^{p-1}|\hat{u}''|^2 = 1$, the optimality condition of Tadjbakhsh and Keller. Since $\hat{u}$ is an eigenfunction and, therefore, admits at least two inflection points, the pointwise bounds must become active, i.e., $\hat{\sigma}^{p-1}|\hat{u}''|^2 = 1$ cannot hold on the entire interval. Ignoring any bound constraints, Masur [22] and Seiranian [34] found a σ and two orthogonal elements of $\mathcal{E}(\sigma)$ for which (4.8) holds with $p = 2$. This appears to be the design obtained by Olhoff and Rasmussen [25] and, by all indications, the one preferred by our algorithm as well (see §7, Fig. 1). It appears likely that in this case the bound constraints are inactive due to the fact that where $\hat{\sigma}$ is less than one, $\hat{\sigma}^2$ is much less than one. Since $\hat{\sigma}^2$ is the quantity that appears in the Rayleigh quotient, we expect it to be as large as possible. This suggests that $\hat{\sigma}$ is bounded away from zero, independent of α. This lower bound with the integral constraint supports the conjecture that $\hat{\sigma}$ is in fact bounded above as well. Hence, when α and β are, respectively, chosen below and above these 'natural' bounds, condition (4.8) is free to stand on its own. Clearly these natural bounds must depend on p. In fact, we shall provide numerical evidence in §7 in favor of the argument that the natural lower (upper) bound is an increasing (decreasing) function of p for $p > 1$.

Unfortunately, it is not known whether (4.8) is a sufficient condition for optimality. The proof of sufficiency offered by Tadjbakhsh and Keller [37] is incorrect. They proceed as if $\lambda_1(\sigma)$ corresponds to the least eigenvalue of (2.5) and, accordingly, admit all functions that satisfy the boundary conditions as test functions in a Rayleigh principle argument. In fact, (2.5) possesses a double zero eigenvalue, hence only those functions that are orthogonal to the first two eigenfunctions can be admitted. We remark that Ramm's claim [32], that Tadjbakhsh and Keller mistakenly applied Hölders inequality in their sufficiency proof, is incorrect, though [37, §6 (25)] is only valid for $n < 0$.

Though (4.8) need not hold over the entire length of the column, we now show that where it does hold it requires that $\hat{\sigma}$ be smooth.

THEOREM 4.4. *If* $\alpha < \hat{\sigma}(x) < \beta$ *for each* $x \in (a,b) \subset (0,1)$, *then* $\hat{\sigma} \in C^\infty(a,b)$.

Proof. We observed in (2.4) that

$$\hat{\sigma}^p \hat{u}_i'' = l_i - \hat{\lambda}_1 \hat{u}_i, \tag{4.9}$$

where l_i is an affine function of x. Now multiply (4.8) by $\hat{\sigma}^{p+1}$,

$$\delta_1(\hat{\sigma}^p \hat{u}_1'')^2 + \delta_2(\hat{\sigma}^p \hat{u}_2'')^2 + \delta_3(\hat{\sigma}^p \hat{u}_1'')(\hat{\sigma}^p \hat{u}_2'') = \hat{\sigma}^{p+1}. \tag{4.10}$$

From (4.9) we find, on recalling $H_0^2 \subset C^1$, that each term on the left of (4.10) is C^1, and hence, that $\hat{\sigma} \in C^1$. Writing (4.9) in the form

$$\hat{u}_i'' = \frac{l_i - \hat{\lambda}_1 \hat{u}_i}{\hat{\sigma}^p},$$

we conclude $\hat{u}_i'' \in C^1$, that is, $\hat{u}_i \in C^3$. Repeating this exact argument leads to $\hat{\sigma} \in C^3$ and $\hat{u}_i \in C^5$. The result then follows from continued repetitions. □

Having succeeded in pursuing the indirect approach, we now look to the possibility (and the implications) of exchanging the limits in the characterization

$$\hat{\lambda}_1^{-1} = \mathcal{A}(\hat{\sigma}, \hat{u}) = \inf_{\sigma \in ad} \sup_{u \in H_0^2} \mathcal{A}(\sigma, u).$$

Recalling Proposition 4.2, this will require convexity and lower semicontinuity of $\sigma \mapsto \mathcal{A}(\sigma, u)$, and concavity and upper semicontinuity of $u \mapsto \mathcal{A}(\sigma, u)$, as well as compactness of one of its upper level sets.

Remark 4.5. We noted the weak H^2 upper semicontinuity of $u \mapsto \mathcal{A}(\sigma, u)$ in Proposition 4.1. As $\{u \in H_0^2;\ \mathcal{A}(\sigma, u) \geq c\}$ is bounded it is also weakly compact (independent of $c \in R$ and $\sigma \in ad$). Convexity of $\sigma \mapsto \mathcal{A}(\sigma, u)$ follows on restricting $p \leq 1$.

The two remaining properties require more work. Note that $u \in$ Argmax $\mathcal{A}(\sigma, \cdot)$ implies $\mathcal{A}(\sigma, u) = \mathcal{A}(\sigma, -u) = \lambda_1^{-1}(\sigma)$ while $\mathcal{A}(\sigma, 0) = 0$. Hence, $u \mapsto \mathcal{A}(\sigma, u)$ is not concave on any set that contains Argmax $\mathcal{A}(\sigma,\cdot)$. This suggests that we examine the half-spaces exterior to $\{u \in H_0^2;\ \|u'\| \le \sqrt{2}\lambda_1^{-1}(\sigma)\}$. Unfortunately, this ball, and hence its support planes, depend on σ. Consequently, if we expect these half-spaces to vary continuously with σ, we must be careful in our choosing. This choice is greatly facilitated by the assumption that σ lies in ad_s, those functions in ad that are even about $\frac{1}{2}$. In this case, we may speak unambiguously of u_1, the positive even eigenfunction corresponding to $\lambda_1(\sigma)$. We normalize $\|u_1'\| = \sqrt{2}\lambda_1^{-1}(\sigma)$ and consider the associated half-space

$$\Pi_\sigma = \left\{ v \in H_0^2;\ \lambda_1^2(\sigma) \int_0^1 u_1' v'\, dx > 2 \right\}.$$

PROPOSITION 4.6. *For $\sigma \in ad_s$, $u \mapsto \mathcal{A}(\sigma, u)$ is concave on Π_σ.*

Proof. The quadratic form associated with the second Gâteaux derivative of $u \mapsto \mathcal{A}(\sigma,u)$ at $\overline{u} \in \Pi_\sigma$ satisfies

$$\begin{aligned}\langle \mathcal{D}_2^2 \mathcal{A}(\sigma,\overline{u})v,v\rangle &= \sqrt{2}\|\overline{u}'\|^{-1} \int_0^1 |v'|^2\,dx - \int_0^1 \sigma^p |v''|^2\,dx - \sqrt{2}^{-1}\|\overline{u}'\|^{-3}\left(\int_0^1 \overline{u}'v'\,dx\right)^2 \\ &\le (\sqrt{2}\|\overline{u}'\|^{-1} - \lambda_1(\sigma)) \int_0^1 |v'|^2\,dx \\ &\le 0 \quad \forall v \in H_0^2.\end{aligned}$$

□

This suggests that we penalize $\mathcal{A}$ with the indicator function of Π_σ,

$$\pi(\sigma,u) = \begin{cases} 0 & \text{if } u \in \Pi_\sigma; \\ \infty, & \text{otherwise.}\end{cases}$$

This not only guarantees concavity but also respects lower semicontinuity.

PROPOSITION 4.7. *$\sigma \mapsto \mathcal{A}(\sigma,u) - \pi(\sigma,u)$ is lower semicontinuous for the strong L^∞ topology on ad_s.*

Proof. Now $\sigma_n \to \sigma$ in L^∞ clearly implies $\mathcal{A}(\sigma_n,u) \to \mathcal{A}(\sigma,u)$ for each $u \in H_0^2$. Regarding $\limsup \pi(\sigma_n,u) \le \pi(\sigma,u)$, it suffices to show that

$$\pi(\sigma_n,u) \to 0 \quad \forall u \in \Pi_\sigma.$$

From the proof of Theorem 3.1 it is clear that $\lambda_1(\sigma_n) \to \lambda_1(\sigma)$ and $u_1(\sigma_n) \rightharpoonup u_1(\sigma)$ in H_0^2. Hence,

$$\lambda_1^2(\sigma_n) \int_0^1 u_1'(\sigma_n)u'\,dx \to \lambda_1^2(\sigma)\int_0^1 u_1(\sigma)u'\,dx > 2.$$

From this we conclude that u is eventually in each Π_{σ_n}, i.e., $\pi(\sigma_n,u) = 0$. □

We may now modify Proposition 4.2 (see Cox and McLaughlin [11, §7]) and conclude the following.

THEOREM 4.8. *If $p \le 1$, then $(\hat{\sigma}, u_1(\hat{\sigma}))$ is a saddle point for $\mathcal{A}$ over $ad_s \times H_0^2$. That is, denoting $u_1(\hat{\sigma})$ by $\hat{u}$,*

$$\mathcal{A}(\hat{\sigma},u) \le \mathcal{A}(\hat{\sigma},\hat{u}) \le \mathcal{A}(\sigma,\hat{u}) \quad \forall\,(\sigma,u) \in ad_s \times H_0^2.$$

The latter inequality yields the following maximum principle

$$\int_0^1 \sigma^p |\hat{u}''|^2 \, dx \leq \int_0^1 \hat{\sigma}^p |\hat{u}''|^2 \, dx \quad \forall \, \sigma \in ad_s.$$

The subsequent pointwise conditions call for an $\ell^2 > 0$ such that

$$\hat{\sigma}(x) = \alpha \;\Rightarrow\; \hat{\sigma}^{p-1}(x)|\hat{u}''(x)|^2 \leq \ell^2, \tag{4.11}$$

$$\alpha < \hat{\sigma}(x) < \beta \;\Rightarrow\; \hat{\sigma}^{p-1}(x)|\hat{u}''(x)|^2 = \ell^2, \tag{4.12}$$

$$\hat{\sigma}(x) = \beta \;\Rightarrow\; \hat{\sigma}^{p-1}(x)|\hat{u}''(x)|^2 \geq \ell^2 \tag{4.13}$$

for almost every $x \in (0,1)$. As $\sigma \mapsto \lambda_1^{-1}(\sigma)$ is convex when $p \leq 1$, these conditions are also sufficient. Hence, we see that where the direct method applies it gives more information. In particular, the necessary conditions (4.11)–(4.13) involve only a single buckling mode. Comparing these to the more general conditions in (4.5)–(4.7) suggests that $\lambda_1(\hat{\sigma})$ is indeed a simple eigenvalue when $p \leq 1$. We shall see numerical evidence of this in §7. The critical case, $p = 1$, where the optimal buckling load changes multiplicity, has received considerable attention. In this case, the right side of (4.11)–(4.13) is independent of $\hat{\sigma}$. In particular, a number of workers have claimed that

$$|\hat{u}''(x)| = \ell. \tag{4.14}$$

We remark, however, that in the absence of a second buckling mode the bound constraints must become active near the inflection points of $\hat{u}$, making (4.11) and (4.13) indeed necessary. Nonetheless, Seiranian [34], who deduced (4.14) from (1.8), proceeded to solve (4.14) in conjunction with (2.3), yielding

$$\hat{\sigma}(x) = \begin{cases} 3/2(1 - 16x^2) & \text{if } 0 \leq x \leq \frac{1}{4} \\ 3/2(16x - 16x^2 - 3) & \text{if } \frac{1}{4} \leq x \leq \frac{3}{4} \\ 3/2(32x - 16x^2 - 15) & \text{if } \frac{3}{4} \leq x \leq 1. \end{cases} \tag{4.15}$$

On evaluating the Rayleigh quotient with this $\hat{\sigma}$ and a specific C^1 test function, Seiranian arrived at a buckling load of 48. This design, like that of Tadjbakhsh and Keller for $p = 2$, vanishes at $\frac{1}{4}$ and $\frac{3}{4}$. Unlike the design of Tadjbakhsh and Keller, however, we are not able to show it to be suboptimal. We can only stress that, lacking an existence proof for $\alpha = 0$, $p = 1$, there is no reason to believe that (4.14) is a necessary condition for optimality.

5. Other boundary conditions. Intent on a clean exposition, we have to this point concentrated solely on the clamped-clamped boundary conditions $u(0) = u'(0) = u(1) = u'(1) = 0$. We now apply the work of the previous sections to the other standard sets of boundary conditions, in particular, hinged and free. A column is said to be free at a point when no conditions are prescribed, while it is hinged, or simply supported, when its displacement is required to vanish there. As a matter of notation, the weak formulation of the buckled column equation will read

$$\int_0^1 \sigma^p u'' v'' \, dx = \mu \int_0^1 u'v' \, dx \quad \forall \, v \in V_{i,j}, \tag{5.1}$$

where $V_{i,j}$ is a subspace of H^2, with i and j chosen from $\{0,1,2\}$ according to whether the respective end is either free, hinged, or clamped. For example,

$$V_{1,2} = \{u \in H^2;\ u(0) = 0,\ u(1) = u'(1) = 0\}$$

specifies the hinged-clamped column. We denote the least eigenvalue of (5.1) by $\mu_{i,j}(\sigma)$, and the corresponding space of eigenfunctions by $\mathcal{E}_{i,j}(\sigma)$. As before, $u \in \mathcal{E}_{i,j}(\sigma)$ implies that both u and $\sigma^p u''$ are elements of $C^1([0,1])$. In addition, such functions satisfy so called natural boundary conditions. In particular, if $i = 1$ then, in addition to $u(0) = 0$, we find

$$\sigma^p u''(0) = 0, \tag{5.2}$$

while if $i = 0$ we have, in addition to (5.2),

$$(\sigma^p u'')'(0) + \mu_{0,j}(\sigma)u'(0) = 0. \tag{5.3}$$

We shall consider only those $\mu_{i,j}(\sigma)$ for which $i+j \geq 2$, as otherwise $\mu_{i,j}(\sigma) = 0$. For comparison purposes, we record these eigenvalues in the case of the uniform column.

$$\mu_{0,2}(1) = \pi^2/4, \quad \mu_{1,1}(1) = \pi^2, \quad \mu_{1,2}(1) \approx 2.046\pi^2, \quad \mu_{2,2}(1) = 4\pi^2. \tag{5.4}$$

Clearly, $\mu_{i,j}(1) = \mu_{j,i}(1)$. Analogous to (2.5), for $i+j \geq 2$, (5.4) gives the uniform bounds

$$\pi^2\alpha^p/4 \leq \mu_{i,j}(\sigma) \leq 4\pi^2\beta^p \quad \forall\, \sigma \in ad. \tag{5.5}$$

As in §2, we address the multiplicity of $\mu_{i,j}(\sigma)$ and the presence of positive eigenfunctions.

LEMMA 5.1. *For $\sigma \in ad$,*
(a) *If $2 \leq i+j < 4$, then $\mu_{i,j}(\sigma)$ is simple and there exists a corresponding positive eigenfunction.*
(b) *$\mu_{0,2}(\sigma) < \mu_{1,2}(\sigma)$ and $\mu_{1,1}(\sigma) < \mu_{1,2}(\sigma) < \mu_{2,2}(\sigma)$.*

Proof. (a) Seiranian noted for these boundary conditions that (5.1) is equivalent, except for the presence of a simple zero eigenvalue when the product ij equals 2, to a second-order problem with *separated* boundary conditions. It now follows from the oscillation theory of Stürm, see, e.g., Atkinson [1], that each $\mu_{i,j}(\sigma)$ is simple and that for $ij \neq 2$, $\sigma^p u''$ is of one sign for each $u \in \mathcal{E}_{i,j}(\sigma)$. In case ij equals zero or 1, this yields, respectively, a positive convex or concave element of $\mathcal{E}_{i,j}(\sigma)$. When $ij = 2$ we find that $\sigma^p u''$ vanishes exactly once on $(0,1)$ for each $u \in \mathcal{E}_{i,j}(\sigma)$. Here we find an eigenfunction that is convex on $(0, x_0)$ and concave on $(x_0, 1)$ for some x_0. As this function must vanish at zero and 1, we conclude that it must be positive on $(0,1)$.

(b) As $V_{i+1,j} \subset V_{i,j}$ we find $\mu_{i,j}(\sigma) \leq \mu_{i+1,j}$. Should equality hold, we conclude $\mathcal{E}_{i+1,j}(\sigma) \subset \mathcal{E}_{i,j}(\sigma)$. As in (2.4), for $u \in \mathcal{E}_{i,j}(\sigma)$ we deduce from (5.1) that

$$(\sigma^p u'')(x) = ((\sigma^p u'')'(0) + \mu_{i,j}(\sigma)u'(0))\,x + \sigma^p u''(0) + \mu_{i,j}(\sigma)u(0) - \mu_{i,j}(\sigma)u(x). \tag{5.6}$$

If $\mu_{0,2}(\sigma) = \mu_{1,2}(\sigma)$, then for each $u \in \mathcal{E}_{1,2}(\sigma) \subset \mathcal{E}_{0,2}(\sigma)$ equation (5.6), in view of (5.3), reads

$$(\sigma^p u'')(x) = -\mu_{i,j}u(x). \tag{5.7}$$

On recalling that $u(1) = u'(1) = 0$, we see that u satisfies a linear homogeneous equation with zero terminal data, and hence, $u \equiv 0$.

If $\mu_{1,1}(\sigma) = \mu_{1,2}(\sigma)$, then for each $u \in \mathcal{E}_{1,2}(\sigma) \subset \mathcal{E}_{1,1}(\sigma)$ (5.6), in view of (5.2), reads

$$(\sigma^p u'')(x) = ((\sigma^p u'')'(0) + \mu_{i,j}(\sigma)u'(0))\,x - \mu_{i,j}(\sigma)u(x). \tag{5.8}$$

So $(\sigma^p u'')(1) = (\sigma^p u'')'(0) + \mu_{i,j}(\sigma)u'(0)$. But $(\sigma^p u'')(1) = 0$ so (5.8) reduces to (5.7) and again the clamped conditions at 1 imply that $u \equiv 0$.

If $\mu_{1,2}(\sigma) = \mu_{2,2}(\sigma)$, then for each $u \in \mathcal{E}_{2,2}(\sigma) \subset \mathcal{E}_{1,2}(\sigma)$ equation (5.6), in view of (5.2), reads

$$(\sigma^p u'')(x) = (\sigma^p u'')'(0)x - \mu_{i,j}(\sigma)u(x).$$

Hence, $(\sigma^p u'')(1) = (\sigma^p u'')'(0)$, from which we conclude that u is either identically zero or not of one sign. This excludes the positive element of $\mathcal{E}_{1,2}(\sigma)$ established in part (a). □

Thanks to the presence of positive first eigenfunctions, the existence theory of §3 applies directly to the problem of Lagrange

$$\sup_{\sigma \in ad} \mu_{i,j}(\sigma), \qquad 2 \le i + j \le 4. \tag{5.9}$$

We note that only for symmetric boundary conditions, i.e., $i = j$, should we expect an even optimal design. As $\mu_{i,j}(\sigma)$ is simple when $i+j < 4$, we deduce from Theorem 4.3 and conditions (4.5–4.7) that

$$\hat{\sigma}_{i,j}(x) = \alpha \quad \Rightarrow \quad \hat{\sigma}_{i,j}^{p-1}(x)|\hat{u}''(x)|^2 \le \ell^2, \tag{5.10}$$

$$\alpha < \hat{\sigma}_{i,j}(x) < \beta \quad \Rightarrow \quad \hat{\sigma}_{i,j}^{p-1}(x)|\hat{u}''(x)|^2 = \ell^2, \tag{5.11}$$

$$\hat{\sigma}_{i,j}(x) = \beta \quad \Rightarrow \quad \hat{\sigma}_{i,j}^{p-1}(x)|\hat{u}''(x)|^2 \ge \ell^2 \tag{5.12}$$

for almost every $x \in (0, 1)$, where $\hat{u} \in \mathcal{E}_{i,j}(\hat{\sigma}_{i,j})$. As before, $\hat{\sigma}_{i,j}$ is smooth where (5.11) holds.

The right side of (5.11) is the sole necessary condition offered by Keller [20] and Tadjbakhsh and Keller [37]. We now investigate the extent to which their claim is valid. Recall that their analysis of the clamped-clamped column erred in neglecting (a) double eigenvalues and (b) bounds on σ. As the previous lemma precludes the former phenomenon, we need only consider the latter. The observation to be made is that (5.10) and (5.12) are only needed near the zeros of $\hat{u}''$. As noted above, members of $\mathcal{E}_{1,1}(\sigma)$ and $\mathcal{E}_{2,0}(\sigma)$ have second derivatives of one sign. As such, in these cases, (5.11) stands on its own (with the minor adjustment that σ be allowed to vanish at zero and/or 1). In addition, as the related second-order problems are fully equivalent, i.e., there are no spurious eigenvalues, Tadjbakhsh and Keller's sufficiency proof is correct. In summary, Keller [20] has the correct necessary condition for the hinged-hinged column, Tadjbakhsh and Keller [37] have the correct necessary condition for the clamped-free column, and the proof of sufficiency in [37] holds for both. We now recall their analytical solutions to these problems.

Keller, in [20], with $p = 2$ and $i = j = 1$ reconciled (5.11) and (5.1) and found

$$\begin{aligned} \hat{\sigma}_{1,1}(x) &= \tfrac{4}{3}\sin^2\theta(x), \qquad 0 \le \theta \le \pi, \\ \theta(x) - \tfrac{1}{2}\sin 2\theta(x) &= \pi x, \qquad 0 \le x \le 1. \end{aligned} \tag{5.13}$$

We have observed that this is a shortened cycloid with parametrization

$$\begin{aligned} x(t) &= \tfrac{3}{4\pi}\left(\tfrac{2}{3}(t-\sin t)\right) \\ y(t) &= \tfrac{2}{3}(1-\cos t) \end{aligned} \qquad 0 \le t \le 2\pi.$$

This column buckles under an axial load of $4\pi^2/3$. In [37], Tadjbakhsh and Keller with $p = 2$ and $i = 2$, $j = 0$ reconciled (5.11) and (5.1) and found

$$\hat{\sigma}_{2,0}(x) = \tfrac{4}{3}\sin^2\theta(x), \qquad -\pi/2 \le \theta \le 0,$$

$$\theta(x) - \tfrac{1}{2}\sin 2\theta(x) + \pi/2 = \pi x/2, \qquad 0 \le x \le 1,$$

our parametrization being,

$$\begin{aligned} x(t) &= \tfrac{3}{2\pi}\left(\tfrac{2}{3}(t-\sin t)\right)+1 \\ y(t) &= \tfrac{2}{3}(1-\cos t) \end{aligned} \qquad -\pi \le t \le 0.$$

This column buckles under an axial load of $\pi^2/3$. Having argued in favor of the existing solutions to the clamped-free and hinged-hinged problems, we now turn to the clamped-hinged problem.

We saw in Lemma 5.1 that the second derivative of each function in $\mathcal{E}_{2,1}(\sigma)$ must change sign. The effect of this is that (5.11) forces $\hat{\sigma}_{2,1}$ to vanish at an interior point. In particular, when Tadjbakhsh and Keller reconciled (5.1) and (5.11) they found

$$\hat{\sigma}_{2,1}(x) = \frac{4\sin^2\theta(x)}{3\sin^2\theta(0)}, \qquad \theta(0) \le \theta \le \pi, \tag{5.14}$$

$$\theta(x) - \tfrac{1}{2}\sin 2\theta(x) + \tfrac{1}{2}\sin 2\theta(0) - \theta(0) = x(\pi + \tfrac{1}{2}\sin 2\theta(0) - \theta(0)), \qquad 0 \le x \le 1,$$

$$\tfrac{1}{2}\sin 2\theta(0) - \theta(0) = -\tfrac{2}{3}\sin^3\theta(0)\cos^{-1}\theta(0) - \pi.$$

Taking $a = \frac{1}{2}\sin 2\theta(0) - \theta(0)$, note that this $\hat{\sigma}_{2,1}(x)$ vanishes at $a/(\pi+a)$. Tadjbakhsh and Keller assert that the column built according to (5.14) will not buckle under loads less than approximately 27.22 in magnitude. We show in the appendix that this column cannot withstand loads exceeding $\pi^2/3$ – and so, in fact, is much weaker than the uniform column. In addition, as $\mu_{2,1}(\sigma)$ corresponds to the *second* eigenvalue of its associated second-order problem, the sufficiency proof of [37] is invalid. Hence, (5.14) is not an optimal design. In summary, (5.11) cannot stand alone in the clamped-hinged case, $\sigma(x) \ge \alpha$ is indeed an active constraint and (5.10) absolutely necessary. We suspect that there exists no solution to (5.9) when $ij = 2$ and $\alpha = 0$.

6. The finite-dimensional problem. We discretize the interval $[0, h, 2h, \cdots, (N-1)h = 1]$ and approximate $V_{i,j}$ by the finite-dimensional space $V_{i,j}^h$, the subspace of $V_{i,j}$ whose elements, when restricted to $[kh, (k+1)h]$, are cubic polynomials (see Strang and Fix [36]). As each member of $V_{i,j}^h$ is completely determined by the value of it and its derivative at each of the N mesh points, we identify $V_{i,j}^h$ with R^{2N-i-j}. We next approximate *ad* with the class of piecewise constant functions

$$ad^h \equiv \left\{ \sigma \in R^{N-1} : \alpha \le \sigma_k \le \beta, \sum_{k=1}^{N-1} \sigma_k = N-1 \right\}.$$

We have refrained from labeling elements of ad^h by σ^h to avoid confusion with powers of σ. In this context, the infinite-dimensional eigenvalue problem of (5.1) is now approximated by

$$B_h(\sigma)q_h = \mu K_h q_h, \quad \sigma \in ad^h, \quad q_h \in R^{2N-i-j}. \tag{6.1}$$

$B_h(\sigma)$ and K_h, the so-called bending and stiffness matrices, are each real, $(2N - i - j) \times (2N - i - j)$, symmetric, positive definite, and banded with half bandwidth of four. Our interest is, of course, in $\mu^h_{i,j}(\sigma)$, the least eigenvalue of (6.1). For, as $h \to 0$, one finds, e.g., in [36], that $\mu^h_{i,j}(\sigma) \to \mu_{i,j}(\sigma)$. The connection between the finite and infinite-dimensional problems now understood, we concentrate solely on (6.1). It should cause no confusion if, in our presentation of the finite-dimensional optimization problem, we suppress most dependence on h, i, and j. With this, (6.1) becomes

$$B(\sigma)q = \lambda K q, \quad \sigma \in ad^h, \quad q \in R^n, \tag{6.2}$$

and we denote its least eigenvalue by $\lambda_1(\sigma)$. Our finite-dimensional problem of Lagrange is now

$$\max_{\sigma \in ad^h} \lambda_1(\sigma). \tag{6.3}$$

The care that was taken in differentiating $\sigma \mapsto \lambda_1(\sigma)$ in §4 must also be exercised here. The occurrence of multiple eigenvalues is still possible. Clarke [10, Prop. 2.8.8] specifies the generalized gradient of the largest eigenvalue of a symmetric matrix in terms of a convex hull; see also [28] and [29]. Though such a characterization may suffice for an analytical description, as in §4, for computational purposes we have found it more useful to specify first-order conditions in terms of, less well-known, "dual matrices." We state the result in general terms. We shall need $\mathcal{S}^n$, the class of $n \times n$ real symmetric matrices, and the Frobenius matrix inner product, $\langle A, B \rangle = \operatorname{tr} A^T B$.

THEOREM 6.1. *Let $B : R^{N-1} \to \mathcal{S}^n$ be continuously Fréchet differentiable with $B_k(\sigma) = \partial B(\sigma)/\partial \sigma_k$ and let K be a fixed symmetric positive semidefinite matrix of the same order n. Assume $\sigma \in ad^h$ is such that $\lambda_1(\sigma)$ has multiplicity t, with corresponding eigenvectors given by the columns of a matrix $Q_1 \in R^{n \times t}$, normalized so that $Q_1^T K Q_1 = I$. Then a necessary condition for σ to solve* (6.3) *is that there exist a symmetric positive semidefinite matrix U of order t, with trace equal to 1, and Lagrange multipliers ν and γ_k, $k = 1, \cdots, N-1$, such that*

$$\langle U, Q_1^T B_k(\sigma) Q_1 \rangle = \nu + \gamma_k, \tag{6.4}$$

and

$$\sigma_k = \alpha \quad \Rightarrow \quad \gamma_k \le 0, \tag{6.5}$$

$$\alpha < \sigma_k < \beta \quad \Rightarrow \quad \gamma_k = 0, \tag{6.6}$$

$$\sigma_k = \beta \quad \Rightarrow \quad \gamma_k \ge 0 \tag{6.7}$$

for each k. Furthermore, this condition is also sufficient for optimality in the case that $\sigma \mapsto B(\sigma)$ is affine.

Proof. In the following we use the notation $U \ge 0$ to mean that a symmetric matrix U is positive semidefinite. Regarding $\lambda_1 : \mathcal{S}^n \to R$, we invoke Rayleigh's principle in

$$\lambda_1 = \min\{\langle q, Bq\rangle;\ q \in R^n,\ \langle q, Kq\rangle = 1\}$$
$$= \min\{\langle qq^T, B\rangle;\ q \in R^n,\ \langle q, Kq\rangle = 1\}.$$

Let $Q \in R^{n\times n}$ be any matrix satisfying

$$Q^T K Q = I. \tag{6.8}$$

It is easily shown that

$$\text{co}\{qq^T;\ q \in R^n,\ \langle q, Kq\rangle = 1\} = \{Q\hat{U}Q^T;\ \hat{U} \in \mathcal{S}^n,\ \text{tr}\,\hat{U} = 1,\ \hat{U} \geq 0\},$$

by using the spectral decomposition of $\hat{U}$, which by assumption has nonnegative eigenvalues adding to one, to obtain the requisite convex combination showing that the second set is contained in the first. It follows that

$$\lambda_1 = \min\{\langle Q\hat{U}Q^T, B\rangle;\ \hat{U} \in \mathcal{S}^n,\ \text{tr}\,\hat{U} = 1,\ \hat{U} \geq 0\}. \tag{6.9}$$

Now take Q to be a matrix whose columns are eigenvectors of (6.2), normalized so that (6.8) holds. The first t columns of Q are the columns of Q_1 and

$$Q^T B Q = \ \text{Diag}(\lambda_i),$$

where $\lambda_1 \leq \lambda_2 \leq \ldots$ are the eigenvalues of (6.2), repeated according to multiplicity. Therefore, the matrices achieving the minimization in (6.9) are those defined by

$$\hat{U} = Q\begin{pmatrix} U & 0 \\ 0 & 0 \end{pmatrix} Q^T = Q_1 U Q_1^T,$$

where $U \in \mathcal{S}^t$, with $\text{tr}\,U = 1$ and $U \geq 0$. Consequently, the generalized gradient of $B \mapsto -\lambda_1(B)$ is the set of such matrices $\hat{U}$ (see Rockafellar [33, pp. 29 and 35] or Clarke [10, §2.8]), no convex hull operation being required since the set of such $\hat{U}$ is convex.

With $\lambda_1(\sigma) = (\lambda_1 \circ B)(\sigma)$, the desired necessary conditions now follow from (i) the chain rule for generalized gradients [10, Thm. 2.3.10], (ii) the standard Lagrange multiplier rule [10, Thm. 6.1.1 and Thm. 6.4.4], and (iii) properties of the inner product. In particular,

$$\partial(-\lambda_1(\sigma)) = \{v \in R^{N-1};\ v_k = \langle U, Q_1^T B_k(\sigma) Q_1\rangle,\ U \in \mathcal{S}^t,\ U \geq 0, \text{tr}\,U = 1\}. \tag{6.10}$$

These necessary conditions are also sufficient in the case that $\sigma \mapsto B(\sigma)$ is affine because the composition of a concave function with an affine function is concave. □

Our attention to $\partial(-\lambda_1)$ in (6.10) and $\partial\lambda_1^{-1}$ in Theorem 4.3, rather than simply $\partial\lambda_1$, is merely an artifact of Clarke's concern with functions defined as pointwise maxima rather than minima. Here, it was convenient to characterize $-\lambda_1$ as the maximum of a Rayleigh quotient where, in §4, we found it more advantageous to maximize a functional of Auchmuty, and hence, to consider λ_1^{-1}.

A simpler version of this theorem (for the unconstrained case, with $K = I$ and $B(\sigma)$ an affine function) was given by Overton [26], following work of Fletcher [14]. The $n \times n$ matrix $\hat{U}$ is known as a "dual matrix" by analogy with "dual variables"

(Lagrange multipliers) familiar from mathematical programming. The $t \times t$ matrix U may be called a "reduced dual matrix," but since it is the one we shall need as a computational tool we shall also refer to it as simply the dual matrix. The distinction between $\hat{U}$ and U is analogous to the notational question of whether inactive constraints in a nonlinear program should be assigned zero Lagrange multipliers.

In the case that $t = 1$ and the bound constraints are inactive, the necessary condition reduces to the requirement that the gradient of $\lambda_1(\sigma)$, whose elements are $q_1^T B_k(\sigma) q_1$, has the constant value ν. (Here q_1 is the only column in Q_1, and U is the scalar one.) In the case that $t = 2$, let

$$U = \begin{pmatrix} \delta_1 & \delta_3/2 \\ \delta_3/2 & \delta_2 \end{pmatrix}. \tag{6.11}$$

Let the two columns of Q_1 be q_1 and q_2 and again assume that all bound constraints are inactive. The necessary condition then becomes

$$\delta_1 q_1^T B_k(\sigma) q_1 + \delta_2 q_1^T B_k(\sigma) q_2 + \delta_3 q_1^T B_k(\sigma) q_2 = \nu,$$

together with the trace and positive semidefinite constraints on U. Without loss of generality, δ_1 and δ_2 may be taken to have nonnegative sign, and the normalizing trace condition may be replaced by the assumption that $\nu = 1$. The positive semidefinite constraint is then simply

$$\delta_1 \delta_2 \geq \frac{\delta_3^2}{4}.$$

This is the same necessary condition given by Bratus and Seiranian [7] and Masur [22]. We note that the derivation given here not only applies for $t > 2$, but is much simpler than that given by [7] and [22] for the case $t = 2$. In a footnote, Masur conjectured that the positive semidefinite condition on U would also be the correct necessary condition for $t > 2$. Bratus [6] gave a discussion of necessary and sufficient conditions for general multiplicity t, but the given necessary condition concerns the necessary sign of the directional derivative of λ_1 for all feasible directions; the positive semidefinite condition on U was apparently not obtained.

Before discussing the algorithm that springs from Theorem 6.1, we will investigate the extent to which it suggests a new tack on the infinite-dimensional problem. Regarding the variational principle of (6.9), we consider $K^+(X)$, the space of positive compact linear operators on a real separable Hilbert space X. Each $T \in K^+(X)$ possesses a countable sequence of eigenvalues $\lambda_1(T) \geq \lambda_2(T) \geq \cdots \downarrow 0$ repeated according to multiplicity and a (possibly infinite) trace $\operatorname{tr} T = \sum_{i=1}^{\infty} \lambda_i$. In this context it is not difficult to show for symmetric $T \in K^+(X)$ that

$$\lambda_1(T) = \max \{\operatorname{tr} TU;\ U \in K^+(X),\ \operatorname{tr} U = 1\}.$$

Recall that $u \mapsto (\sigma^p u'')''$ and $u \mapsto -u''$ are positive symmetric isomorphisms of H_0^2 onto H^{-2} and H_0^1 onto H^{-1}, respectively. We denote these maps by A and B, remark that $B^{1/2}$ is a positive isomorphism of H_0^1 onto L^2, and denote by I the compact imbedding of H_0^2 in H_0^1. With $\phi = B^{1/2} J u$, and $*$ denoting adjoint, the buckled column equation receives the formulation

$$(1/\lambda)\phi = B^{1/2} I A^{-1} (B^{1/2} I)^* \phi.$$

By construction, $B^{1/2}IA^{-1}(B^{1/2}I)^*$ is a symmetric member of $K^+(L^2)$. Although we may now proceed to compute $\partial\lambda_1^{-1}$, as in the previous theorem, this representation suffers from its dependence on the unknown A^{-1} and $B^{1/2}$ in contrast to Theorem 4.3 which works directly with A and B.

We now turn to the question of how to solve the finite-dimensional optimization problem. Although there is a substantial literature on the generalization of gradient methods to nonsmooth problems (see the survey [28] by Polak), little attention has been given to applying nonsmooth optimization techniques to (6.3). One exception is [29], which describes an algorithm for maximizing the least eigenvalue of a variety of important structures, accounting for the presence of multiple eigenvalues. It focuses however on the clamped vibrating column, $(\sigma^p u'')'' = \lambda u$, $u \in H_0^2$, a problem which has long been known to admit only simple eigenvalues (see, e.g., Leighton and Nehari [21, Lemma 4.1]). Our algorithm differs from that of [29] in our attention to the added structure of the generalized gradient of λ_1 as revealed in the theorem above. We use an algorithm specifically designed to exploit this structure, which is based on Overton [26], but modified to be far more efficient for moderate to large mesh size N.

Given $\sigma \in ad^h$ with $\lambda_1(\sigma)$ and $\lambda_2(\sigma)$ the two least eigenvalues of (6.2), we normalize the corresponding eigenvectors q_1 and q_2 so that $Q_1 = [q_1\; q_2]$ satisfies $Q_1^T K Q_1 = I$, the 2×2 identity matrix. These eigenvalues and eigenvectors are computed by subspace iteration with a block size of two, with the necessary linear systems solved directly using the Cholesky factors of $B(\sigma)$ (see Bathe and Wilson [5] for details).

Define the approximate multiplicity t of λ_1 by $t = 2$ if

$$\lambda_2(\sigma) - \lambda_1(\sigma) \leq \tau\lambda_1(\sigma)$$

and $t = 1$ otherwise. Here τ is a positive tolerance which may be adjusted during the optimization process. A multiplicity higher than two is excluded (for sufficiently small h) by Lemmas 2.1 and 5.1. Now consider the following linear program (LP):

(LP0) $$\max_{d\in R^N} d_N$$

subject to

(LP1) $$Ed = e,$$

(LP2) $$Fd \leq f,$$

(LP3) $$d_k = 0, \qquad k \in J,$$

(LP4) $$\alpha - \sigma_k \leq d_k \leq \beta - \sigma_k, \qquad k = 1, \cdots N-1,$$

(LP5) $$|d_k| \leq \rho, \qquad k = 1, \cdots, N,$$

where

(i) The first $N-1$ components of d represent proposed changes to σ, while the last component approximates the corresponding change in $\lambda_1(\sigma)$. Let us write $d = [\eta^T \omega]^T$, with $\eta \in R^{N-1}$, $\omega \in R$;

(ii) ρ is a positive scalar, whose purpose is to ensure $\|d\|$ is not too large;

(iii) J is an index set, which effectively removes the corresponding variables from the linear program;

(iv) The first row of the matrix E is $[1, \cdots, 1, 0]$, and the first element of the right-hand side vector e is zero. This ensures that the changes to σ respect the integral constraint;

(v) The second row of E is

$$[-q_1^T B_1(\sigma) q_1, \cdots, -q_1^T B_{N-1}(\sigma) q_1, 1]$$

and the corresponding element of e is zero. If $t = 2$, then E contains an additional two rows,

$$[-q_2^T B_1(\sigma) q_2, \cdots, -q_2^T B_{N-1}(\sigma) q_2, 1] \quad \text{and} \quad [-q_1^T B_1(\sigma) q_2, \cdots, -q_1^T B_{N-1}(\sigma) q_2, 0],$$

with corresponding elements of e set to $\lambda_2(\sigma) - \lambda_1(\sigma)$ and zero, respectively;

(vi) If $t = 1$, F contains the single row

$$[-q_2^T B_1(\sigma) q_2, \cdots, -q_2^T B_{N-1}(\sigma) q_2, 1]$$

and f is the scalar $\lambda_2(\sigma) - \lambda_1(\sigma)$. If $t = 2$, F and f are empty, i.e., (LP2) may be removed.

We note that the given rows may be computed very efficiently, since the derivative matrices $B_k(\sigma)$ are extremely sparse.

The justification for (v) and (vi) is as follows. If $t = 1$, the second row of E imposes a linearization of the nonlinear equation $\lambda_1(\sigma + \eta) = \lambda_1(\sigma) + \omega$, while the only row in F imposes a linearization of the inequality $\lambda_2(\sigma + \eta) \geq \lambda_1(\sigma) + \omega$. Since ω is being maximized, the solution to the linear program yields the steepest ascent direction for $\lambda_1(\sigma)$, projected to satisfy the integral and bound constraints, with steplength required to be short enough that the linearized value for $\lambda_2(\sigma + \eta)$ does not drop below that for $\lambda_1(\sigma + \eta)$, and that the various bounds are satisfied. If $t = 2$, the second through fourth rows of E give a linearization of the appropriate set of three nonlinear equations, imposing the coalescence of $\lambda_1(\sigma + \eta)$ and $\lambda_2(\sigma + \eta)$, see [16]. The common linearized value, $\lambda_1(\sigma) + \omega$, is maximized, subject to the given constraints.

THEOREM 6.2. *Suppose that $\tau = 0$ so that the multiplicity estimate t is exact, and suppose that $\rho > 0$ and J is the empty set. Then $d = 0$ is a (nonunique) solution to the linear program given above if and only if* (6.4) *holds for some $U \in S^t$ with* $\operatorname{tr} U = 1$, *some $\nu \in R$ and some $\gamma \in R^{N-1}$ satisfying* (6.5)–(6.7).

Proof. By the usual Lagrange multiplier rule, the linear program admits the solution $d = 0$ if and only if there exist multipliers $\nu \in R$, $\delta \in R^{t(t+1)/2}$ and $\gamma \in R^{N-1}$ satisfying

$$E^T \begin{pmatrix} \nu \\ \delta \end{pmatrix} + \begin{pmatrix} \gamma \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

with γ subject to the standard sign condition. Setting $U = \delta_1 (= 1)$ if $t = 1$ and defining U by (6.11) if $t = 2$, we have (6.4)–(6.7) with $\operatorname{tr} U = 1$. The same argument holds in the reverse direction. □

Note two points: there is no positive semidefinite condition obtained on U, and the solution $d = 0$ is generally not at a vertex of the feasible region, so is not unique.

Our algorithm for solving (6.3) generates a sequence in ad^h. Each successive approximation is obtained from the previous one by consideration of a linear program

(LP) of the form given above. We first define a simple version of the algorithm, but one which is too costly for practical use. In this version, we obtain $\sigma+\eta$, a candidate replacement for σ, by solving the LP for $d=[\eta^T\omega]^T$. If $\lambda_1(\sigma+\eta)>\lambda_1(\sigma)$, σ is replaced by $\sigma+\eta$ and the process repeated. Otherwise, σ remains unchanged, the trust region radius ρ is decreased by a factor of two, and the revised LP is considered. This kind of trust region approach can be made very effective by modifying the size of ρ according to how well the actual increase in $\lambda_1(\sigma)$ agrees with the linear prediction ω, as discussed in Fletcher [14] in the context of general nonlinear programming. As recommended by Fletcher, we double ρ if the ratio of actual to predicted increase exceeds 0.75 and halve ρ if the ratio is less than 0.25. The process is terminated when $\|d\|\le\epsilon$, a convergence tolerance.

However, the expense of obtaining the optimal solution of each linear program is not justified. Although the "limit" LP defined by σ equal to a solution of (6.2)–(6.4) has an optimal solution which is not a vertex, generically, any LP solved during the successive approximation process can be expected to have a unique solution which must be at a vertex. Since only a few constraints involve all the variables, most of the constraints defining a vertex are simple bounds, and most of these may be trust radius bounds of the form (LP5). Since the only purpose of the trust radius bounds is to avoid taking steps too large for the linearizations to be accurate, there is little to be gained by finding the exact set of active bounds. We, therefore, partially solve the LP as follows. We first attempt to obtain a feasible point for the LP by setting d to the least norm solution of (LP1, LP3), contracting this step if necessary to satisfy the various inequalities. This contraction effectively scales the right-hand side of the only possible inhomogeneous equality constraint in the LP, that corresponding to the third row of E in the case $t=2$. The rationale here is that if the least norm step satisfying the equality constraints is not feasible, the underlying approximations are probably not good enough to justify the solution of the unmodified LP. We then start the LP solution process as in a projected gradient method, augmenting d by projected gradient steps with steplengths determined by the inequality constraints and bounds. The gradient being projected is that of the LP objective, i.e., the vector $[0,\cdots,0,1]$, while the constraints determining the projection are the equality constraints and any inequality constraint and bounds encountered during the process. This continues until either (a) a trust radius bound of the form (LP5) is encountered, or (b) the norm of the current projected gradient increment drops below the tolerance ϵ (unlikely to happen first). At this point the process of partially solving the LP is terminated. Anywhere from zero to many active bounds of the form (LP4) may be encountered by this process, as well as, possibly, the inequality (LP2) (in the case $t=1$). By adding any active bounds encountered to the set J, we avoid having to process these bounds again during the (partial) solution of subsequent LP's. However, the signs of the associated bound multipliers must be checked after the partial LP solution and bounds with the wrong sign removed from J if necessary. The entire process is very efficient, requiring QR factorizations of matrices with only two to four columns, with rows removed corresponding to active bounds. For complete details of the process, see [27].

In the case $t=2$, the LP partial solution process generates four multipliers corresponding to the rows of E, namely ν,δ_1,δ_2, and δ_3. If the corresponding dual matrix U, defined by (6.11), is not positive semidefinite, this is a clear indication that the multiplicity estimate t is incorrect, and so τ is reduced by a factor of ten. In principle, it might be necessary to use a more sophisticated technique to recover from a multiplicity estimate which is too large. For example, if the algorithm was started at a point where all the optimality conditions except $U \geq 0$ were satisfied, it would be necessary to split the multiple eigenvalue to obtain an ascent direction; this is explained further in [26] and [27]. However, this technique has not been required in our computational experiments for the Lagrange problem.

This completes our outline of the algorithm used to generate the numerical results given in the next section. For more algorithmic details, see [27]. We do not have any proof that the given algorithm will converge to a solution of (6.3), but given any approximate solution, we may verify the required signs of γ and the eigenvalues of the dual matrix U and compute the residual of the approximate equation (6.4). We have found the algorithm to be very effective in practice as the numerical results attest.

7. Computational results. The algorithm outlined in the previous section has been implemented in Fortran 77 and tested extensively. Subroutines from the Linpack [13] and Eispack [17] libraries were used to (a) perform the QR factorizations required during the partial LP solution process (for matrices with at most four columns), (b) obtain the Cholesky factorizations of $B(\sigma)$ needed for subspace iteration (these matrices have only seven nonzero diagonals), and (c) solve the reduced generalized eigenvalue problems required for subspace iteration (these have order two). Parameters were set as follows: τ, the relative multiplicity tolerance, was initialized to 0.1; ρ, the trust radius, was initialized to 5.0; ϵ, the convergence tolerance, was set to 10^{-3}. The initial σ was set to the constant one, corresponding to the uniform column. Runs were made for various values of N, the number of mesh points; p, the power of σ in the differential equation; α and β, the lower and upper bounds on σ, and the various homogeneous boundary conditions: clamped-clamped, clamped-hinged, clamped-free, and hinged-hinged.

The algorithm was found to be very efficient, typically invoking subspace iteration, in the computation of the two least eigenvalues of (6.2), about 50 times prior to reaching the convergence tolerance. At the final iterate, the residual of the approximate equation (6.4) was typically found to have norm about 10^{-3}. Smaller choices of ϵ required significantly more computation but did not produce a qualitatively improved solution. Other initial choices of ρ affected only the initial efficiency of the algorithm. The results were relatively insensitive to the initial choice of the multiplicity tolerance τ, although smaller choices delayed identification of the final multiplicity. There was usually no difficulty in determining the correct final multiplicity t, with corresponding positive semidefinite dual matrix U. In the cases where the final multiplicity t was two, the gap between λ_1 and λ_2 was typically reduced to 10^{-6}. The subspace iteration was itself very efficient, requiring only one or two steps on all but the first few steps of the optimization, reflecting the good separation of λ_2 from λ_3 and the availability of an excellent initial two-dimensional subspace, namely the span of the eigenvectors q_1 and q_2 computed at the previous optimization step. (The first subspace iteration was initialized using the first two columns of the identity matrix.) The initial σ in each case was that of the uniform column, $\sigma \equiv 1$. Symmetry was not imposed on the algorithm's subsequent choices of σ. A typical run for $N = 513$ required 1.5 hours on a Sparc station.

We begin our summary of the results with $p = 2$. Under the assumption that each transverse cross section of the column is circular, we recall that σ is proportional to the square of the cross section's radius. Plotting both $\pm\sqrt{\sigma}$ then gives a lengthwise cross section of the associated column. With this representation we may then view the corresponding buckling mode(s) simultaneously. Our figures, generated by Matlab

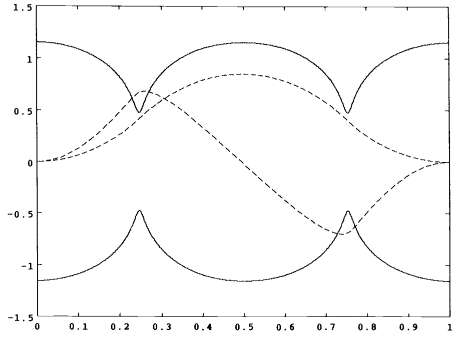

FIG. 1. *Strongest clamped-clamped column and first two buckling modes.* $p = 2$, $\alpha = 0$.

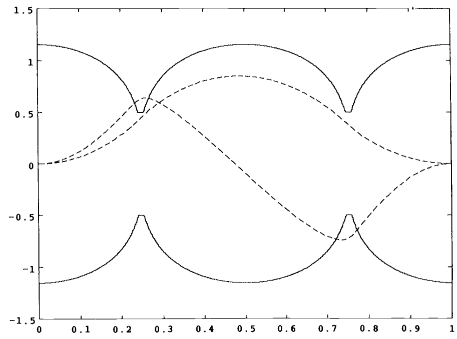

FIG. 2. *Strongest clamped-clamped column and first two buckling modes.* $p = 2$, $\alpha = .25$.

[23], portray the column in the piecewise fashion produced by the algorithm of §6, while using dashed curves(s) to indicate the buckling mode(s). We remark that for those optimal designs with double buckling loads the corresponding buckling modes depend on our initial choice of subspace, in subspace iteration, and σ.

Figure 1 gives our strongest clamped-clamped column and its first two buckling modes. Here $p = 2$, $\alpha = 0$, and $\beta = 10$, with a double buckling load of 52.3533. This value agrees to four figures with that obtained by Olhoff and Rasmussen [25], Masur [22], and Seiranian [34].

On increasing α or decreasing β, these bound(s) will eventually become active. Figure 2 gives our strongest clamped-clamped column and its first two buckling modes when $p = 2$, $\alpha = 0.25$, and $\beta = 10$. The least eigenvalue is still double, though now reduced to 52.3467.

As the uniform column has a simple first eigenvalue, we would expect that a sufficient increase in α would produce an optimal design with a simple first eigenvalue. Figure 3 gives our best strongest clamped-clamped column and its first buckling mode when $p = 2$, $\alpha = 0.5$, and $\beta = 10$. In this case the first two eigenvalues are 51.07086 and 62.3479.

Clearly there must exist (at least) one value of α between $\frac{1}{4}$ and $\frac{1}{2}$ at which the optimal buckling load switches multiplicity. Olhoff and Rasmussen [25] declare 0.28 to be the only such value. Our algorithm also indicates the presence of such a critical α in the vicinity of 0.28. We note that in addition to being able to approach 0.28 from above—proceeding until the gap between the least two eigenvalues vanishes—we

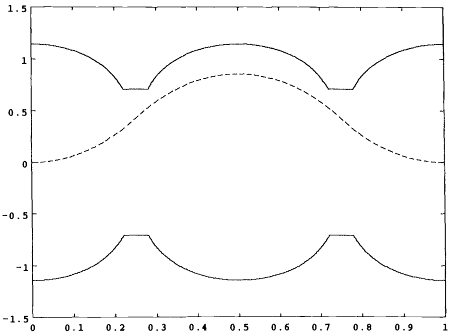

FIG. 3. *Strongest clamped-clamped column and first buckling mode. $p = 2$, $\alpha = .5$.*

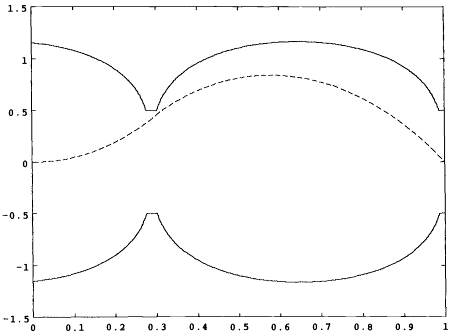

FIG. 4. *Strongest clamped-hinged column and first buckling mode. $p = 2$, $\alpha = .25$.*

have also approached from below, in this case proceeding until the least eigenvalue of the corresponding 2 by 2 dual matrix vanishes.

Figure 4 gives our strongest clamped-hinged column and its first buckling mode when $p = 2$, $\alpha = 0.25$, and $\beta = 10$. The buckling load of 27.0762 is, as expected, simple. Although decreasing α increases the buckling load, our designs converge, as $\alpha \to 0$, to the Tadjbakhsh and Keller solution, (5.13). As shown in the appendix, this column buckles at $\pi^2/3$, and so cannot possibly be optimal. The convergence of our algorithm to (5.13) only strengthens our belief that the problem, as stated by Tadjbakhsh and Keller, is without a solution. That is, $\sigma \mapsto \mu_{2,1}(\sigma)$ with $p = 2$, does *not* attain its maximum on *ad* when $\alpha = 0$.

Our numerical results also agree with Tadjbakhsh and Keller in the cases for which we have argued that they are correct. In particular, Fig. 5 gives our strongest clamped-free column and first buckling mode when $p = 2$, $\alpha = 0$, and $\beta = 10$. The buckling load, again simple, is 3.2897. Fig. 6 gives our strongest hinged-hinged column and first buckling mode when $p = 2$, $\alpha = 0$, and $\beta = 10$. Its simple buckling load is 13.1579.

We return to the clamped-clamped case and consider its dependence on p. Our analysis of (4.5–4.7) led us to believe that, for $p > 1$, the minimum (maximum) of the optimal design increases (decreases) with p. This is reinforced by Fig. 7, whose lower (upper) curve traces the minimum (maximum) of the optimal design as a function of p. As the buckling load is double for each of these designs, there must exist a curve, between the lower one and the curve that is constantly one, across which the

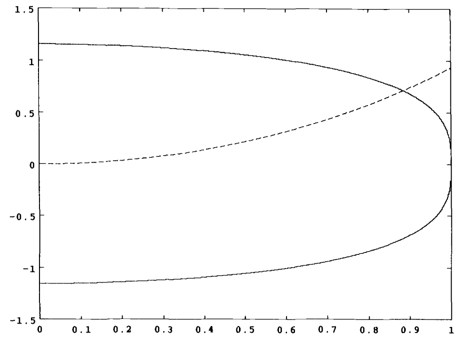

FIG. 5. *Strongest clamped-free column and first buckling mode.* $p = 2, \ \alpha = 0$.

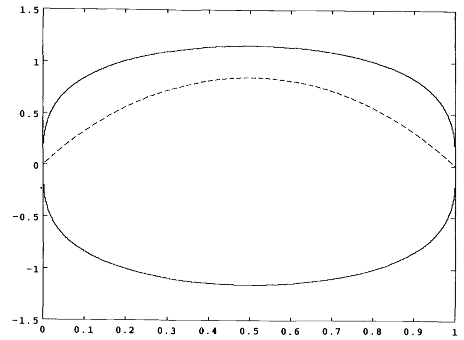

FIG. 6. *Strongest hinged-hinged column and first buckling mode.* $p = 2, \ \alpha = 0$.

optimal buckling load changes multiplicity. We have seen that $(2, 0.28)$ lies near such a curve. With respect to the range of p considered in Fig. 7, we have found that both the optimal buckling load and the least eigenvalue of its corresponding dual matrix increase with p. Regarding the behavior as p tends to 1 from above, we have found that the minimum of the optimal design tends to zero, and, though the optimal buckling load remains double, the least eigenvalue of the corresponding dual matrix tends to zero. Below $p = 1$ we found optimal designs with simple buckling loads regardless of our choice of α. Figure 8 gives our strongest clamped-clamped column when $p = 1, \ \alpha = 0$, and $\beta = 10$. The buckling load of 47.9898 and the design itself are very close to the analytical result of (4.15). Refining the mesh in neighborhoods of $\frac{1}{4}$ and $\frac{3}{4}$, and perhaps using piecewise linear elements for σ, would presumably bring us even closer to (4.15). We have not pursued this for two reasons. First, we argued in §4 that in the absence of an existence proof we cannot fully trust (4.15), and second, in both of the physical contexts where $p = 1$ has arisen, there is an a priori strictly positive lower bound on the admissible σ. Regarding the latter, we present in Fig. 9 our strongest clamped-clamped column when $p = 1, \ \alpha = 0.8$, and $\beta = 1.2$. Its simple buckling load is 43.4921.

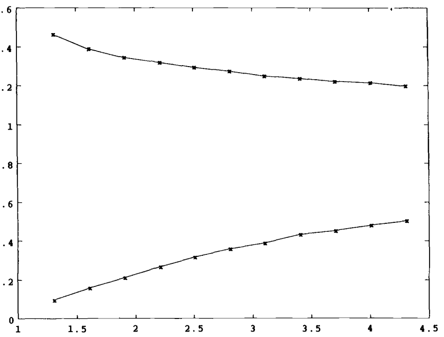

FIG. 7. *Maximum and minimum of* $\hat{\sigma}_{2,2}$ *vs. p.*

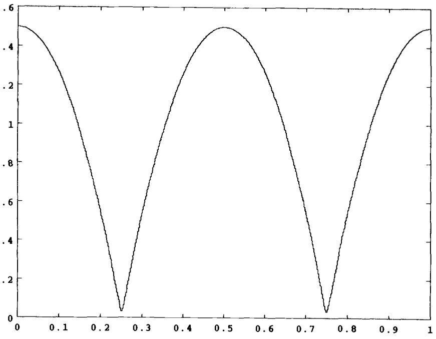

FIG. 8. $\hat{\sigma}_{2,2}$ *vs.* x. $p = 1$, $\alpha = 0$.

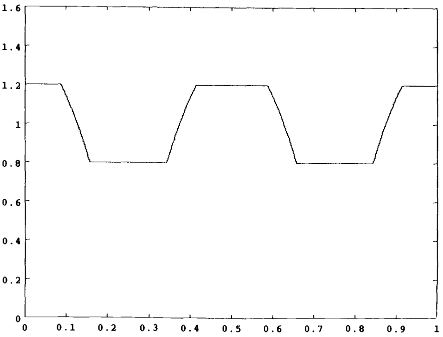

FIG. 9. $\hat{\sigma}_{2,2}$ *vs.* x. $p = 1$, $\alpha = 0.8$, $\beta = 1.2$.

Having addressed dependence on p and α at a particular level of discretization, we now fix $p = 2$, $\alpha = 0$, and $\beta = 10$ and with clamped-clamped boundary conditions demonstrate the convergence of several relevant parameters as N, the number of mesh points, becomes large. In particular, Table 1 lists $\hat{\mu}_{2,2}$ (the optimal buckling load), the least eigenvalue of the associated dual matrix U, and $\|\hat{\sigma}_N - \hat{\sigma}_{1025}\|_\infty$ (the greatest difference between the optimal design on a mesh of N points and the optimal design on a mesh of 1025 points) for values of N from 65 to 1025.

We close our study with a glance at the numerical range of the buckling load over

TABLE 1

N	$\hat{\mu}_{2,2}$	min ev(U)	$\|\hat{\sigma}_N - \hat{\sigma}_{1025}\|_\infty$
65	52.14944	0.023859	0.1066
129	52.31027	0.043317	0.0415
257	52.33615	0.047034	0.0424

1025	52.35548	0.046607	0.0000

ad. To this point we have concentrated on its maximization, and, though we may compare this value to that of the associated uniform column, it would be of interest to weigh it against the minimum buckling load. Clearly, α must now be strictly positive, for a buckling load of zero could be produced by prescribing that σ vanish on some interval. Regarding the existence of a minimizer for $\sigma \mapsto \mu_{i,j}(\sigma)$ over *ad*, we note that Theorem 3.1 is insufficient. Recall in (3.3) that the limit of the maximizing sequence integrated to less than one. This was not an obstacle, for adding mass could only increase the buckling load. As our goal now is to minimize this load, it appears that we must either relax the cost functional or construct the so called G-closure of *ad* to obtain a minimizing design. Instead of embarking on this, we modified the strongest column algorithm to minimize instead of maximize $\sigma \mapsto \mu_{i,j}(\sigma)$.

The modification to the algorithm is very simple, namely changing the sign of (LP0) and requiring a decrease instead of an increase in the smallest eigenvalue. The modified algorithm generated plausible weakest designs in *ad*, and, though we lack a proof of optimality, we shall content ourselves with a discussion of these numerical results. In all cases (independent of p and α) the minimum buckling load was simple; this is to be expected since the minimization should tend to separate the least eigenvalue from the remainder of the spectrum. In addition, we find that the generated designs have their mass concentrated near the inflection points of their associated positive buckling mode. This, too, is to be expected, making the opposite argument to that made in §2.

Figure 10 gives our weakest clamped-clamped column with $p = 2$, $\alpha = 0.25$, and $\beta = 10$. This column buckles under a simple axial load of 2.5658. The buckling load of our strongest column in this class (see Fig. 2) is 52.3467.

Figure 11 gives our weakest clamped-clamped column with $p = 1$, $\alpha = 0.8$, and $\beta = 1.2$. This column buckles under the simple axial load of 33.5631. The buckling load of our strongest column in this class (see Fig. 9) is 43.4921.

8. Concluding remarks. Having thoroughly discussed the work of Tadjbakhsh and Keller [37], we now take up two related issues, that, though broached by Keller in [20], have received little rigorous attention since.

The first involves the optimal design of cylindrical columns. Here, given again a fixed amount of material to be distributed over a column of fixed length, we seek the shape of the cross-section that, when used to generate a cylinder, produces a column with the greatest buckling load. We are not allowed to "taper" the column as we have in past sections. Keller quickly reduced this problem to the search for that planar domain of fixed area with the greatest least second moment of area. Recall that the

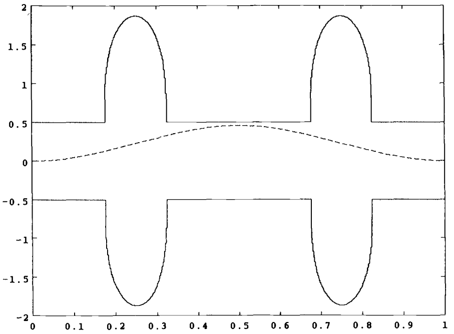

FIG. 10. *Weakest clamped-clamped column and first buckling mode.* $p = 2$, $\alpha = .25$.

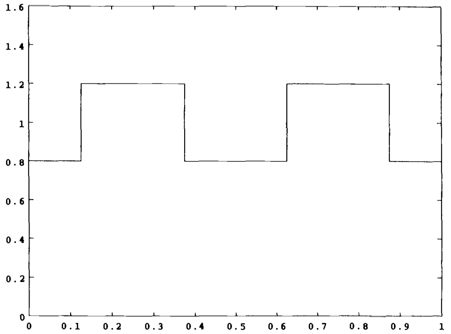

FIG. 11. *Weakest clamped-clamped design.* $p = 1$, $\alpha = 0.8$, $\beta = 1.2$.

second moment of area of the domain Ω with centroid at the origin in the direction η (with $|\eta| = 1$) is

$$I(\Omega, \eta) \equiv \int_{\Omega} |\eta^T y|^2 \, dy. \tag{8.1}$$

Denoting the unit circle by S, Keller's problem takes the form

$$\sup_{|\Omega|=A} \inf_{\eta \in S} I(\Omega, \eta). \tag{8.2}$$

Keller noted the existence of Ω for which this value is infinite. To exclude such Ω he restricted himself to convex domains. Within this smaller class he then argued, without proof, that the equilateral triangle possesses the greatest least second moment of area. Citing Pólya, Truesdell later observed that Keller's conjecture was indeed true. In particular, Pólya in [30] found that among convex sets the maximum of $4I_1 I_2 |\Omega|^{-4}$ occurs for triangles. Here I_1 and I_2 are the respective principal second moments of area, i.e., the min and max of (8.1). Keller's result follows, noting that only sets for which $I_1 = I_2$ need be considered, for if $I_1 < I_2$ we can simply redistribute the mass in such a way that I_1 increases while I_2 decreases.

This reduction to convex domains is too severe. It is not the lack of convexity that allows (8.2) to grow without bound but the possibility that Ω itself may be unbounded, though of finite area. To exclude this behavior, we may simply bound

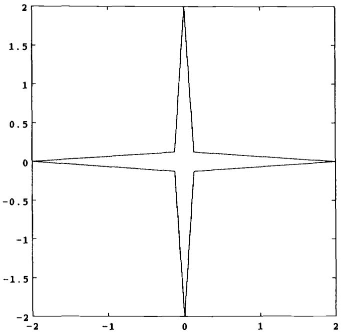

FIG. 12. *A domain whose second moment of area exceeds that of the equilateral triangle of the same area.*

$|\partial\Omega|$, the length of Ω's boundary. The fact that this does indeed bound $I(\Omega,\eta)$ follows from the isoperimetric inequality

$$2I_p(\Omega)/\pi \leq (|\partial\Omega|/2\pi)^4$$

of Pólya and Szegö [31, §1.5], where $I_p(\Omega)$ is the polar moment of inertia. As the second moment of area will be independent of η for the best Ω, its value will be one half that of its polar moment of inertia. We must now consider,

$$\sup_{\substack{|\Omega|=A \\ |\partial\Omega|\leq L}} \inf_{\eta\in S} I(\Omega,\eta). \tag{8.3}$$

For fixed A the value of (8.3) will grow as L is increased, suggesting that for sufficiently large L one may produce a domain whose second moment of area exceeds that of the equilateral triangle of the same area. We shall accomplish this with $A = 1$ and $L = 16$. To produce large values in (8.3), we need only consider domains that are symmetric about the coordinate axes, as well as the two diagonals that stretch out towards infinity. The symmetry will render $\eta \mapsto I(\Omega,\eta)$ constant, while the latter condition will ensure us that $I(\Omega,\eta)$ is large. The domain of Fig. 12 has an area of one, a boundary whose length does not exceed 16, and a second moment of area of $\frac{16}{45}+\frac{71}{8^3 90}$. This value is more than three times greater than $1/6\sqrt{3}$, the second moment of area of the equilateral triangle of the same area. Though we have not solved (8.2), this example demonstrates that (8.2) produces, through the designer's choice of L, columns with arbitrarily large buckling load.

The other issue we wish to resurrect from Keller [20] is that of post-buckling. Analysis of the buckled column must proceed from the nonlinear model. For example, in the hinged-hinged case we consider

$$(\sigma^p\phi')' + \lambda\sin\phi = 0, \quad \int_0^1 \sin\phi\, ds = 0, \quad \phi'(0) = \phi'(1) = 0, \tag{8.4}$$

where ϕ measures the angle between the column and a fixed axis in its plane of buckling. Equation (5.1) arises from linearizing $\sin\phi$ to ϕ, identifying $u' = \phi$, and differentiating the differential equation in (8.3). The least eigenvalue of (5.1), $\mu_{1,1}$, is indeed a bifurcation point for (8.3). Moreover, Keller showed that the direction of the solution branch emanating from $\mu_{1,1}$ was indeed rightward, i.e., that (8.3) admits only the trivial solution for $\lambda < \mu_{1,1}$. It remains to determine the nature of the nontrivial solution branch(es) for the other sets of boundary conditions. Here we would also like to understand the role of imperfections in the model and/or design. In particular, the splitting of the double eigenvalue in the optimal clamped-clamped column via an unfolding of the ideal bifurcation problem in a parameter that introduces material asymmetry would be of interest.

A.1. Appendix. We have argued throughout that the necessary and sufficient conditions proposed by Tadjbakhsh and Keller are incorrect. This does not in itself, however, invalidate their designs. Indeed, we argued that their solutions to the hinged-hinged and clamped-free problems are correct. This appendix serves to demonstrate that these are their only correct designs.

In particular, we show that Tadjbakhsh and Keller incorrectly calculated the buckling loads of their proposed solutions to the clamped-clamped and clamped-hinged problems. Recall their solution of the former,

$$\begin{aligned} A(x) &= \tfrac{4}{3}\sin^2\theta(x), \qquad -\pi/2 \le \theta \le 3\pi/2, \\ \theta(x) - \tfrac{1}{2}\sin 2\theta(x) + \pi/2 &= 2\pi x, \qquad 0 \le x \le 1. \end{aligned} \tag{A.1}$$

As Olhoff and Rasmussen [25] observed in their numerical work, the column constructed according to (A.1) tends to deform (under axial compression) on $(0, \frac{1}{4})$ and $(\frac{3}{4}, 1)$, with the center of the column experiencing only a rigid motion. To make this precise we recall from [37] that this A, when restricted to $(0, \frac{1}{4})$, is actually the optimal design of the clamped-free problem there, with a corresponding buckling load of $\pi^2/3$ (as the volume of this piece is also $1/4$) and first eigenfunction $u_{2,0}$. We normalize $u_{2,0}$ so that

$$\int_0^{1/4} |u_{2,0}'|^2\, dx = 1,$$

and use it to construct a sequence $\{\varphi_n\} \subset H_0^2$ on which

$$\frac{\int_0^1 A^2|\varphi_n''|^2\, dx}{\int_0^1 |\varphi_n'|^2\, dx} \to \frac{\pi^2}{3} \quad \text{as } n \to \infty. \tag{A.2}$$

First we build the continuous displacement

$$\tilde{u}(x) = \begin{cases} u_{2,0}(x), & \text{if } 0 \le x \le \frac{1}{4} \\ u_{2,0}(\frac{1}{4}), & \text{if } \frac{1}{4} \le x \le \frac{3}{4} \\ u_{2,0}(1-x), & \text{if } \frac{3}{4} \le x \le 1. \end{cases}$$

This function is not a member of H_0^2, but we shall see that it suffices to introduce the cubic perturbation

$$p_n(x) = a(x - 2nx^2 + n^2x^3), \quad \text{where } a = u_{2,0}'(\tfrac{1}{4}),$$

near its singularities. As $p_n(0) = p_n(1/n) = p_n'(1/n) = 0$, the function

$$\varphi_n(1-x) = \varphi_n(x) = \begin{cases} \tilde{u}(x), & \text{if } 0 \le x \le \frac{1}{4} \\ \tilde{u}(\frac{1}{4}) + p_n(x - \frac{1}{4}), & \text{if } \frac{1}{4} \le x \le \frac{1}{4} + \frac{1}{n} \\ \tilde{u}(\frac{1}{4}), & \text{if } \frac{1}{4} + \frac{1}{n} \le x \le \frac{1}{2} \end{cases}$$

possesses a continuous derivative. It remains to show that $\varphi_n'' \in L^2$. The only possible obstacle is the behavior of $u_{2,0}''$ near $\frac{1}{4}$. Returning to Tadjbakhsh and Keller [37,§3, (25)] we find

$$u_{2,0}''(x) = \frac{\sqrt{3}}{2 \sin \theta(x)}.$$

And, as (A.1) implies that $\theta(x) = O(|x - 1/4|^{1/3})$ as $x \to \frac{1}{4}$, we find $u_{2,0}''(x) = 0(|x - \frac{1}{4}|^{-1/3})$. This singularity is clearly square integrable, hence $\varphi_n \in H_0^2$, and we can consider the Rayleigh quotient

$$\text{(A.3)} \qquad \frac{\int_0^1 A^2 |\varphi_n''|^2\,dx}{\int_0^1 |\varphi_n'|^2\,dx} = \frac{2\int_0^{1/4} A^2 |u_{2,0}''|^2\,dx + 2\int_0^{1/n} A^2(x - 1/4)|p_n''|^2\,dx}{2\int_0^{1/4} |u_{2,0}'|^2\,dx + 2\int_0^{1/n} |p_n'|^2\,dx}.$$

By construction,

$$\int_0^{1/4} A^2 |u_{2,0}''|^2\,dx = \pi^2/3 \quad \text{and} \quad \int_0^{1/4} |u_{2,0}'|^2\,dx = 1.$$

It remains to show that the remaining terms in (A.3) tend to zero with increasing n. Beginning with the numerator, from $A(x) = O(|x - \frac{1}{4}|^{2/3})$ comes

$$\int_0^{1/n} A^2(x - 1/4)|p_n''(x)|^2\,dx = \int_0^{1/n} O(x^{4/3})|2an(3nx - 2)|^2\,dx = O(1/n^{1/3}),$$

while in the denominator

$$\int_0^{1/n} |p_n'(x)|^2\,dx = \int_0^{1/n} |a(1 - 4nx + 3n^2x^2)|^2\,dx = O(1/n).$$

As we have constructed a sequence of admissible displacements whose Rayleigh quotients tend to $\pi^2/3$, we conclude that the clamped-clamped column built according to (A.1) buckles at a load not exceeding $\pi^2/3$.

Now recall Tadjbakhsh and Keller's solution to the clamped-hinged problem,

$$\text{(A.4)} \qquad \hat{\sigma}_{2,1}(x) = \frac{4 \sin^2 \theta(x)}{3 \sin^2 \theta(0)}, \qquad \theta(0) \le \theta \le \pi,$$

$$\theta(x) - \tfrac{1}{2}\sin 2\theta(x) + \tfrac{1}{2}\sin 2\theta(0) - \theta(0) = x(\pi + \tfrac{1}{2}\sin 2\theta(0) - \theta(0)), \qquad 0 \le x \le 1,$$

$$\tfrac{1}{2}\sin 2\theta(0) - \theta(0) = -\tfrac{2}{3}\sin^3\theta(0)\cos^{-1}\theta(0) - \pi,$$

and the fact that it vanishes at $x_0 = y/(\pi+y)$, where $y = \frac{1}{2}\sin 2\theta(0) - \theta(0)$. Analogous to the above, this design is optimal for the clamped-free column on $(0, x_0)$. With the volume of this piece being x_0 as well, we find that it buckles at $\pi^2/3$. Denoting by $u_{2,0}$ the corresponding clamped-free eigenfunction on $(0, x_0)$ whose derivative has L^2 norm 1, we define,

$$\tilde{u}(x) = \begin{cases} u_{2,0}(x), & \text{if } 0 \le x \le x_0 \\ \frac{u_{2,0}(x_0)}{1-x_0}(1-x), & \text{if } x_0 \le x \le 1. \end{cases}$$

Here we introduce the perturbation

$$p_n(x) = bx - 2n(b+c)x^2 + n^2(b+c)x^3, \quad \text{where} \quad b = u_{2,0}(x_0),\ c = u_{2,0}'(x_0),$$

and the corresponding regularization

$$\varphi_n(x) = \begin{cases} \tilde{u}(x), & \text{if } 0 \le x \le x_0 \\ \tilde{u}(x_0) + p_n(x - x_0), & \text{if } x_0 \le x \le x_0 + 1/n \\ \tilde{u}(x), & \text{if } x_0 + 1/n \le x \le 1. \end{cases}$$

By construction, $\varphi_n \in C^1$, while, as in the clamped-clamped case, $u_{2,0}''$ behaves like $|x - x_0|^{-1/3}$ near x_0, and so $\varphi_n \in H_0^2$. Moreover, $\hat{\sigma}_{2,1}(x) = O(|x - x_0|^{2/3})$ implies, as above, that

$$\int_0^{1/n} \hat{\sigma}_{2,1}^2(x - x_0)|p_n''(x)|^2\,dx = O(1/n^{1/3}), \quad \text{and} \quad \int_0^{1/n} |p_n'|^2\,dx = O(1/n).$$

Consequently,

$$\frac{\int_0^1 \hat{\sigma}_{2,1}^2 |\varphi_n''|^2\,dx}{\int_0^1 |\varphi_n'|^2\,dx} \to \frac{\pi^2/3}{1 + u_{2,0}^2(x_0)/(1 - x_0)} \quad \text{as } n \to \infty,$$

i.e., the clamped-hinged column built according to (A.4) is even weaker than the clamped-clamped column of (A.1).

A.2. Acknowledgments. This work began during the first author's visit to the Courant Institute. The efforts of Bob Kohn and Cathleen Morawetz in this regard are greatly appreciated. We thank Andre Cherkaev for introducing us to the work of Bratus and Seiranian.

L^∞ ESTIMATE FOR SOME NONLINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS AND APPLICATION TO AN EXISTENCE RESULT*

L. BOCCARDO†, F. MURAT‡, AND J.-P. PUEL§

Abstract. Consider the nonlinear elliptic equation (E): $\mathcal{A}(u)+H(x,u,Du)=f(x)-\operatorname{div} g(x)$ where $\mathcal{A}(u)=-\operatorname{div}(a(x,u,Du))+a_0(x,u,Du)$ is a Leray-Lions operator defined on $W_0^{1,p}(\Omega)$ with $a_0(x,s,\xi)s\geqq \alpha_0|s|^p$, $\alpha_0>0$, and where H is a first-order term satisfying $|H(x,s,\xi)|\leqq C_0+C_1|\xi|^p$. The main goal of this paper is to prove an L^∞ estimate for the *bounded* solutions of (E) when f belongs to $L^q(\Omega)$ and g belongs to $(L^r(\Omega))^N$ with $r=p'q$ and $\max(1,N/p)<q\leqq+\infty$. In view of the method and results developed in the author's previous work, this implies the existence of a solution for equation (E).

Résumé. Considérons l'équation elliptique non linéaire (E): $\mathcal{A}(u)+H(x,u,Du)=f(x)-\operatorname{div} g(x)$ où $\mathcal{A}(u)=-\operatorname{div}(a(x,u,Du))+a_0(x,u,Du)$ est un opérateur de Leray-Lions défini sur $W_0^{1,p}(\Omega)$ avec $a_0(a(x,u,\xi)s\geqq\alpha_0|s|^p$, $\alpha_0>0$, et où H est un terme du premier ordre qui vérifie $|H(x,s,\xi)|\leqq C_0+C_1|\xi|^p$. Le résultat principal de ce travail est une estimation L^∞ pour les solutions *bornées* de (E) lorsque f appartient à $L^q(\Omega)$ et g appartient à $(L^r(\Omega))^N$ avec $r=p'q$ et $\max(1,N/p)<q\leqq+\infty$. A la lumière de la méthode et des résultats présentés dans nos précédents travaux, ceci implique l'existence d'une solution pour l'équation (E).

Key words. L^∞ estimate, nonlinear elliptic pde, natural growth with respect to Du

AMS(MOS) subject classifications. 35E, 35G

1. Introduction. Consider on a bounded open set $\Omega\subset R^N$ the nonlinear elliptic equation

$$\mathcal{A}(u)+H(x,u,Du)=f(x)-\operatorname{div} g(x) \quad \text{in } \Omega; \qquad u=0 \quad \text{on } \partial\Omega, \tag{1.1}$$

where

$$\mathcal{A}(u)=-\operatorname{div}(a(x,u,Du))+a_0(x,u,Du)$$

is a Leray-Lions operator from $W_0^{1,p}(\Omega)$ $(1<p<+\infty)$ into its dual $W^{-1,p'}(\Omega)$, $(1/p+1/p'=1)$, such that

$$\exists\alpha>0,\quad \text{for a.e. } x\in\Omega,\quad \forall s\in R,\quad \forall\xi\in R^N,\quad a(x,s,\xi)\xi\geqq\alpha|\xi|^p, \tag{1.2}$$

$$\exists\alpha_0>0,\quad \text{for a.e. } x\in\Omega,\quad \forall s\in R,\quad \forall\xi\in R^N,\quad a_0(x,s,\xi)s\geqq\alpha_0|s|^p, \tag{1.3}$$

and where H is a nonlinear first-order term defined through a Carathéodory function satisfying the "natural" growth condition with respect to ξ, i.e.,

$$\begin{gathered}\exists C_0>0,\quad \exists C_1>0,\quad \text{for a.e. } x\in\Omega,\quad \forall s\in R,\quad \forall\xi\in R^N,\\ |H(x,s,\xi)|\leqq C_0+C_1|\xi|^p.\end{gathered} \tag{1.4}$$

In [BMP1], [BMP2], [BMP3], and [BMP4] we have shown the existence of solutions for nonlinear elliptic equations analogous to (1.1) (in some cases without assuming

(1.3) but assuming existence of a sub- and a supersolution). We have also developed a method which essentially reduces the existence proof to the proof of an a priori L^∞ estimate for the solutions of a family of approximate equations.

The main goal of this paper is to prove an L^∞ estimate for the *bounded* solutions of (1.1): we assume that $f \in L^q(\Omega)$ and $g \in (L^r(\Omega))^N$ with $\max(1, N/p) < q \leqq \pm\infty$ and $r = p'q$ and we prove that any $u \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ that solves (1.1) satisfies

$$\|u\|_{L^\infty(\Omega)} \leqq \gamma, \tag{1.5}$$

where γ depends only on the data, i.e., Ω, N, p, q, α, α_0, C_0, C_1, $\|f\|_{L^q(\Omega)}$, $\|g\|_{(L^r(\Omega))^N}$. The main thrust of the result is thus to turn the *qualitative* information $u \in L^\infty(\Omega)$ into the *quantitative* estimate (1.5).

The a priori assumption that u belongs to $L^\infty(\Omega)$ is crucial to obtain (1.5) since there are examples satisfying all the above hypotheses where (1.1) possesses not only solutions in $W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ but also solutions in $W_0^{1,p}(\Omega)$ which do not belong to $L^\infty(\Omega)$ (see Remark 2.1 below).

The L^∞ estimate (1.5) generalizes to the case of nonlinear elliptic equations the results of De Giorgi [DG], Moser [M], and Stampacchia [S1], [S2] for the linear case. These are known to be optimal, in the sense that (for $p = 2$) the hypotheses $f \in L^q(\Omega)$, $q > N/2$ and $g \in (L^r(\Omega))^N$, $r = 2q$ are optimal. This indicates that our result for the nonlinear case is also optimal.

Our proof is an adaptation of the nonlinear context of (1.1) of Stampacchia's method, in the spirit of our previous work. Indeed the first step of Stampacchia's proof (see [S1], [S2]) consists of using in the linear equation the test function $G_k(u)$, where $G_k(s)$ is the function defined by $G_k(s) = 0$ if $|s| \leqq k$ and $G_k'(s) = 1$ if $|s| > k$ (see (2.9)). We adapt this first step to the nonlinear equation (1.1) by using here the nonlinear (with respect to $G_k(u)$) test function $\varphi(G_k(u))$, where $\varphi(s)$ is the odd function defined by $\varphi(s) = e^{\lambda s} - 1$ if $s \geqq 0$ (see (2.8)). Nonlinear test functions $\varphi(u)$, where $\varphi(s)$ has an exponential behaviour, are known to be well adapted to the study of (1.1) since they allow the absorption of the nonlinearity H by the coerciveness of the operator $\mathscr{A}$ (see, e.g., [BMP1], [BMP2], [BMP3], [BMP4]).

We mention that L^∞ bounds for similar problems have been recently proved in [MS] and [ALT] by different methods based on rearrangement techniques; see also the references added in proof.

Once the L^∞ estimate is obtained, the proof of existence of a solution for (1.1) that belongs to $W_0^{1,p}(\Omega) \cap L^\infty(\Omega)$ follows the method presented, for example, in [BMP4]. This will be done in § 3, where we also collect some comments about regularity of the solutions.

2. L^∞ estimate. We consider the nonlinear elliptic equation (1.1), and as we only look for bounded solutions, we rewrite it in the more precise way

$$\mathscr{A}(u) + H(x, u, Du) = f(x) - \operatorname{div} g(x) \text{ in } \mathscr{D}'(\Omega); \qquad u \in W_0^{1,p}(\Omega) \cap L^\infty(\Omega). \tag{2.1}$$

On the operator

$$\mathscr{A}(u) = -\operatorname{div}(a(x, u, Du)) + a_0(x, u, Du)$$

we assume that a and a_0 are Carathéodory functions defined on $\Omega \times R \times R^N$ with values in R^N and R, respectively, which satisfy (1.2), (1.3) and

$$\begin{aligned} &\exists \psi \in L^{p'}(\Omega), \quad \exists \beta > 0, \quad \text{for a.e. in } x \in \Omega, \quad \forall s \in R, \quad \forall \xi \in R^N, \\ &|a(x, s, \xi)| \leqq |\psi(x)| + \beta[|s|^{p-1} + |\xi|^{p-1}], \\ &|a_0(x, s, \xi)| \leqq |\psi(x)| + \beta[|s|^{p-1} + |\xi|^{p-1}]; \end{aligned} \tag{2.2}$$

$$\text{for a.e. } x\in\Omega,\quad \forall s\in R,\quad \forall\xi,\xi^*\in R^N,\quad \xi\neq\xi^*, \tag{2.3}$$
$$[a(x,s,\xi)-a(x,s,\xi^*)][\xi-\xi^*]>0.$$

These hypotheses ensure that $\mathscr{A}$ is a bounded, continuous, coercive, and pseudomonotone operator of Leray-Lions type from $W_0^{1,p}(\Omega)$ into its dual $W^{-1,p'}(\Omega)$ $(1/p+1/p'=1)$ (see [LL], [L]).

Furthermore, H is assumed to be a Carathéodory function defined on $\Omega\times R\times R^N$ with values in R, satisfying (1.4). Note that no extra requirement such as a Lipschitz continuity or a one-sided condition is imposed on H.

The operator $u\to\mathscr{A}(u)+H(x,u,Du)$ is then well defined, continuous, and bounded from $W_0^{1,p}(\Omega)$ into $W^{-1,p'}(\Omega)+L^1(\Omega)$, but it is neither pseudomonotone nor coercive.

We can now state the main result of this paper.

THEOREM 1. *Let us assume that* (1.2)-(1.4), (2.2) *hold true and that*

$$f\in L^q(\Omega),\ g\in(L^r(\Omega))^N \quad \textit{with } \max\left(1,\frac{N}{p}\right)<q\leqq+\infty,\quad r=p'q. \tag{2.4}$$

Then any solution u of (2.1) *satisfies the estimate*

$$\|u\|_{L^\infty(\Omega)}\leqq\gamma, \tag{2.5}$$

where γ is a constant which depends only on Ω, N, p, q, α, α_0, C_0, C_1, $\|f\|_{L^q(\Omega)}$, $\|g\|_{(L^r(\Omega))^N}$.

Remark 2.1. As mentioned in the Introduction, Theorem 1 provides an "explicit" estimate in $L^\infty(\Omega)$ for the solutions of (2.1) which are already known to belong to $W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$. This does not mean that every solution of (1.1) that belongs to $W_0^{1,p}(\Omega)$ also belongs to $L^\infty(\Omega)$. In fact, this last assertion is false, as is shown in Contre-exemple 3.2, § 3.7 of [BMP1].

Remark 2.2. Estimate (2.5) continues to hold if the right-hand side of (2.1) has the more general form

$$F(x,u,Du)-\operatorname{div}(G(x,u,Du)), \tag{2.6}$$

where F and G are Carathéodory functions from $\Omega\times R\times R^N$ into R and R^N, respectively, satisfying

$$\text{for a.e. } x\in\Omega,\quad \forall s\in R,\quad \forall\xi\in R^N,\quad |F(x,s,\xi)|\leqq|f(x)|,\quad |G(x,s,\xi)|\leqq|g(x)|,$$

where f and g satisfy (2.4). There is essentially no change in the proof of Theorem 1 given below, but the proof of the existence theorem given in § 3 does not work in this context. It would require that G be independent of Du.

Note also that (2.3) is not required to obtain Theorem 1. However, this hypothesis is needed for the existence result (see Theorem 2 below).

Proof of Theorem 1. Set

$$\lambda=\frac{p'C_1}{\alpha}+p', \tag{2.7}$$

and define for $k\in R^+$ the real functions $\varphi\in C^1(R)$ and $G_k\in W^{1,\infty}(R)$ by

$$\varphi(s)=\begin{cases}e^{\lambda s}-1 & \text{if } s\geqq0\\ -e^{-\lambda s}+1 & \text{if } s\leqq0,\end{cases} \tag{2.8}$$

$$G_k(s)=\begin{cases}s-k & \text{if } s\geqq k\\ 0 & \text{if } -k\leqq s\leqq k,\\ s+k & \text{if } s\leqq -k.\end{cases} \tag{2.9}$$

Let $A(k)$ be the set

$$A(k)=\{x\in\Omega, |u(x)|>k\}. \tag{2.10}$$

The functions $G_k(u)$ have been used in [S1] and [S2] as test functions to obtain the L^∞ estimate for linear equations. Adapting Stampacchia's method to the nonlinear case, we will use the test functions

$$v=\varphi(G_k(u)). \tag{2.11}$$

Since u belongs to $W_0^{1,p}(\Omega)\cap L^\infty(\Omega)$, so does v, and it is easy to show that

$$v=\varphi((|u|-k)^+)\chi_{A(k)}\operatorname{sign}(u), \tag{2.12}$$

$$Dv=\varphi'((|u|-k)^+)\chi_{A(k)}Du, \tag{2.13}$$

where $\chi_{A(k)}$ is the characteristic function of the set $A(k)$. The function v is then an admissible test function for (2.1). Using v in the weak formulation of (2.1) as well as (1.2)-(1.4) and Young's inequality, we obtain

$$\begin{aligned}\alpha\int_{A(k)}&|Du|^p\varphi'((|u|-k)^+)\,dx+\alpha_0\int_{A(k)}|u|^{p-1}\varphi((|u|-k)^+)\,dx\\ &\leqq\int_{A(k)}(C_0+C_1|Du|^p)\varphi((|u|-k)^+)\,dx\\ &+\int_{A(k)}|f|\varphi((|u|-k)^+)\,dx\\ &+\int_{A(k)}\varphi'((|u|-k)^+)\left(\frac{\alpha}{p}|Du|^p+\frac{1}{p'\alpha^{1/(p-1)}}|g|^{p'}\right)dx.\end{aligned} \tag{2.14}$$

From the choice (2.7) of λ we have for $s\geqq 0$,

$$\frac{\alpha}{p'}\varphi'(s)-C_1\varphi(s)\geqq\alpha\,e^{\lambda s}=\frac{\alpha}{\lambda^p}\left(\varphi'\left(\frac{s}{p}\right)\right)^p.$$

This implies

$$\begin{aligned}\frac{\alpha}{\lambda^p}\int_{A(k)}&\left|\varphi'\left(\frac{(|u|-k)^+}{p}\right)Du\right|^p dx+\alpha_0k^{p-1}\int_{A(k)}\varphi((|u|-k)^+)\,dx\\ &\leqq\int_{A(k)}(C_0+|f|)\varphi((|u|-k)^+)\,dx\\ &+\int_{A(k)}\frac{1}{p'\alpha^{1/(p-1)}}|g|^{p'}\varphi'((|u|-k)^+)\,dx.\end{aligned} \tag{2.15}$$

Let us define the function w_k by

$$w_k=\varphi\left(\frac{(|u|-k)^+}{p}\right). \tag{2.16}$$

Then w_k belongs to $W_0^{1,p}(\Omega)$ and

$$Dw_k=\frac{1}{p}\varphi'\left(\frac{(|u|-k)^+}{p}\right)\chi_{A(k)}\operatorname{sign}(u)\,Du.$$

One can easily show that

$$\forall s \geqq 0, \quad e^{\lambda s} - 1 \geqq (e^{\lambda s/p} - 1)^p,$$

$$\begin{cases} \exists C_2 > 0 \text{ (depending only on } \lambda \text{ and } p), \quad \forall s \geqq 1, \\ e^{\lambda s} - 1 \leqq C_2(e^{\lambda s/p} - 1)^p, \qquad \lambda\, e^{\lambda s} \leqq C_2 \lambda (e^{\lambda s/p} - 1)^p. \end{cases}$$

This implies

$$\varphi((|u| - k)^+) \geqq |w_k|^p \quad \text{a.e. on } \Omega,$$

$$\varphi((|u| - k)^+) \leqq C_2 |w_k|^p \quad \text{a.e. on } A(k+1),$$

$$\varphi'((|u| - k)^+) \leqq C_2 \lambda |w_k|^p \quad \text{a.e. on } A(k+1).$$

Combining these remarks with (2.15) yields

$$\begin{aligned} &\frac{\alpha p^p}{\lambda^p} \int_\Omega |Dw_k|^p \, dx + \alpha_0 k^{p-1} \int_\Omega |w_k|^p \, dx \\ &\leqq \int_{A(k+1)} C_2 \left((C_0 + |f|) + \frac{\lambda}{p' \alpha^{1/(p-1)}} |g|^{p'} \right) |w_k|^p \, dx \\ &\quad + \int_{A(k) - A(k+1)} \left((C_0 + |f|) \varphi((|u| - k)^+) \right. \\ &\qquad \left. + \frac{1}{p' \alpha^{1/(p-1)}} |g|^{p'} \varphi'((|u| - k)^+) \right) dx. \end{aligned} \tag{2.17}$$

Define

$$h = (C_0 + |f|) + \frac{\lambda}{p' \alpha^{1/(p-1)}} |g|^{p'}.$$

Since h belongs to $L^q(\Omega)$ and since

$$\varphi((|u| - k)^+) \leqq e^\lambda - 1, \qquad \varphi'((|u| - k)^+) \leqq \lambda\, e^\lambda \quad \text{on } A(k) - A(k+1),$$

we obtain

$$\begin{aligned} &\frac{\alpha p^p}{\lambda^p} \int_\Omega |Dw_k|^p \, dx + \alpha_0 k^{p-1} \int_\Omega |w_k|^p \, dx \\ &\leqq \int_{A(k+1)} C_2 h |w_k|^p \, dx + e^\lambda \int_{A(k) - A(k+1)} h \, dx. \end{aligned} \tag{2.18}$$

Sobolev's inequality asserts that for $p*$ defined by

$$\begin{cases} p^* = \dfrac{Np}{N-p} \quad \text{if } 1 < p < N, \\ p^* \text{ is any fixed real number such that } pq' < p^* < +\infty \quad \text{if } N \leqq p < +\infty, \end{cases} \tag{2.19}$$

there exists C^* which depends only on Ω, N, p, and $p*$ such that

$$\forall w \in W_0^{1,p}(\Omega), \quad C^* \|w\|_{L^{p^*}(\Omega)} \leqq \|Dw\|_{(L^p(\Omega))^N}. \tag{2.20}$$

Therefore, there exist strictly positive constants C_3 and C_4, depending only on Ω, N, p, q, $p*$, C_1, and α such that

$$\tag{2.21} \begin{aligned} C_3\left(\int_\Omega |w_k|^{p*}\,dx\right)^{p/p*} + C_4\alpha_0 k^{p-1}\int_\Omega |w_k|^p\,dx \\ \leqq \int_\Omega h|w_k|^p\,dx + \int_{A(k)} h\,dx. \end{aligned}$$

Because of (2.4) and (2.19) we have $p<pq'<p*$. From Hölder's inequality and an interpolation inequality, we get

$$\int_\Omega h|w_k|^p\,dx \leqq \|h\|_{L^q(\Omega)}\|w_k\|^p_{L^{pq'}(\Omega)} \leqq \|h\|_{L^q(\Omega)}\|w_k\|^{\theta p}_{L^p(\Omega)}\|w_k\|^{(1-\theta)p}_{L^{p*}(\Omega)},$$

where $\theta\in\,]0,1[$ is defined by

$$\frac{1}{pq'}=\frac{\theta}{p}+\frac{(1-\theta)}{p*}.$$

Using Young's inequality, we obtain for any $\eta, 0<\eta<+\infty$,

$$\int_\Omega h|w_k|^p\,dx \leqq (1-\theta)\eta^{1/(1-\theta)}\|w_k\|^p_{L^{p*}(\Omega)}+\theta\eta^{-1/\theta}\|h\|^{1/\theta}_{L^q(\Omega)}\|w_k\|^p_{L^p(\Omega)}.$$

Now choose η such that

$$(1-\theta)\eta^{1/(1-\theta)}=\frac{C_3}{2},$$

and then k_0 such that

$$C_4\alpha_0 k_0^{p-1}=\theta\eta^{-1/\theta}\|h\|^{1/\theta}_{L^q(\Omega)},$$

(this is the only place where the hypothesis $\alpha_0>0$ is used). We obtain from (2.21)

$$\forall k \geqq k_0,\quad \frac{C_3}{2}\left(\int_\Omega |w_k|^{p*}\,dx\right)^{p/p*} \leqq \int_{A(k)} h\,dx \leqq \|h\|_{L^q(\Omega)}|A(k)|^{1/q'},$$

where $|A(k)|$ denotes the Lebesgue measure of the set $A(k)$. We rewrite this inequality as

$$\tag{2.22} \forall k\geqq k_0,\quad \int_\Omega |w_k|^{p*}\,dx \leqq \left(\frac{2}{C_3}\|h\|_{L^q(\Omega)}\right)^{p*/p}|A(k)|^{p*/pq'}=C_5|A(k)|^{p*/pq'}.$$

Take $l>k\geqq k_0$ and observe that

$$|A(l)|\left(\lambda\left(\frac{l-k}{p}\right)\right)^{p*} \leqq |A(l)|\left|\varphi\left(\frac{l-k}{p}\right)\right|^{p*} \leqq \int_{A(l)}|w_k|^{p*}\,dx \leqq \int_\Omega |w_k|^{p*}\,dx.$$

Then

$$\tag{2.23} \forall l, k \text{ with } l>k\geqq k_0,\quad (l-k)^{p*}|A(l)| \leqq C_6|A(k)|^{p*/pq'},$$

where C_6 depends only on Ω, N, α, $\alpha_0, p, q, p*, C_0, C_1, \|f\|_{L^q(\Omega)}, \|g\|_{(L^r(\Omega))^N}$. Since $p*>0$ and $p*/pq'>1$, we can use a result of Stampacchia (cf. [S1, Lemma 4.1] or

[S2, Lemma 4.1]) which implies that there exists γ that depends only on C_6, k_0, p^* and p^*/pq' such that

$$A(k)=0, \quad \forall k \geqq \gamma.$$

This finishes the proof of Theorem 1.

3. Application to an existence result. In this section we will apply the method and results presented, for example, in [BMP4] and the L^∞ estimate of the previous section to a family of approximate equations for (2.1) in order to prove the existence of at least one solution of (2.1).

THEOREM 2. *Let us assume that* (1.2)-(1.4), *and* (2.2)-(2.4) *hold true. Then there exists at least one solution u of* (2.1).

Proof of Theorem 2. Let us define for $\varepsilon>0$ the approximation

$$H^\varepsilon(x, s, \xi)=\frac{H(x, s, \xi)}{1+\varepsilon|H(x, s, \xi)|}. \tag{3.1}$$

Note that H^ε satisfies (1.4). We consider the approximate problem

$$\begin{cases} -\operatorname{div}(a(x, u^\varepsilon, Du^\varepsilon))+a_0(x, u^\varepsilon, Du^\varepsilon) \\ \quad +H^\varepsilon(x, u^\varepsilon, Du^\varepsilon)=f(x)-\operatorname{div} g(x) \quad \text{in } \mathscr{D}'(\Omega), \\ u^\varepsilon \in W_0^{1,p}(\Omega). \end{cases} \tag{3.2}$$

For fixed $\varepsilon>0$, H^ε is uniformly bounded by $1/\varepsilon$. Therefore there exists at least one solution u^ε to (3.2) (see [LL], [L]). Using Stampacchia's method (see, e.g., [BG]) it can be proved that any solution u^ε of (3.2) belongs to $L^\infty(\Omega)$ (for fixed $\varepsilon>0$). We can now apply Theorem 1 which yields

$$\|u^\varepsilon\|_{L^\infty(\Omega)} \leqq \gamma,$$

where γ does not depend on ε.

Once the L^∞ estimate is obtained, we can apply Theorem 2.1 of [BMP4] (with a slight modification due to the term div g), or the remark at the end of § 3 of [BMP3], and obtain the relative compactness of the family (u^ε) in the strong topology of $W_0^{1,p}(\Omega)$. Then, by extracting a subsequence $(u^{\varepsilon'})$ which strongly converges in $W_0^{1,p}(\Omega)$ it is easy to pass to the limit when ε' tends to zero and to obtain Theorem 2.

Remark 3.1. (Regularity). We make the same hypotheses as in Theorem 1. Then, according to the results of [LU, Chap. 4, Thm. 1.1, p. 251], any solution of (2.1) actually belongs to $C^{0,\delta}(\Omega)$ for some δ, $0<\delta<1$, whenever $\partial\Omega$ is sufficiently smooth (otherwise one only obtains $C^{0,\delta}_{\text{loc}}(\Omega)$).

Moreover, if in (2.2) we assume that $\psi \in L^s(\Omega)$, with $s>p'$, a slight modification of Proposition 3.8 of [BMP2] (due to the term div g) (see also [GM], p. 156] when $p=2$) proves that u belongs to $W_0^{1,p+\delta}(\Omega)$ for some $\delta>0$ if $\partial\Omega$ is sufficiently smooth (otherwise one has only the local result).

Acknowledgments. A previous version of this work was presented by the first author at the Conference on Nonlinear Evolution Equations and Their Applications (Visegrad, Hungary, 1988). The authors are indebted to the organizers of this meeting for this invitation.

THE SURFACE EVAPORATION PROBLEM WITH SIGNORINI BOUNDARY CONDITION*

ZHIDA HUANG[†] AND MARIO PRIMICERIO[‡]

Abstract. The one-dimensional filtration of an incompressible liquid in a homogeneous, isotropic, rigid porous medium is considered. The bottom of the layer is impermeable, whereas on the top surface a Signorini-type boundary condition is imposed. Existence and uniqueness of the weak solution are proved under general conditions. Then some qualitative properties of the solution and its asymptotic behaviour are analyzed. In particular, the characterization of the set $D \equiv \{t: u(0, t)=0\}$ is discussed.

Key words. filtration, porous media, unilateral boundary conditions, evaporation, free boundary problem

AMS(MOS) subject classifications. 35K65, 35K85, 76S05, 35R35, 35B40

1. Introduction. In this paper we consider the flow of an incompressible liquid, say water, through a homogeneous isotropic and rigid porous medium. If θ represents water content, i.e., the mass of water per unit volume of the medium, and $\underset{\sim}{q}$ the discharge, the mass balance is expressed by

$$\theta_t + \operatorname{div} \rho \underset{\sim}{q} = 0, \tag{1.1}$$

where ρ is the density of water.

Equation (1.1) is completed by prescribing the dependence of θ upon the capillary pressure ψ (state equation) and a relationship between $\underset{\sim}{q}$ and the pressure gradient (law of motion).

It is generally agreed that when ψ exceeds a saturation value (say $\psi = 0$), θ is constant and equal to $\theta_* = \varepsilon\rho$,where ε is the porosity. In such situation Darcy's law holds

$$\underset{\sim}{q} = -K \text{ grad } [\psi/\rho g - x], \tag{1.2}$$

where g is the gravity acceleration, x is a vertical coordinate pointing downwards, and K is the hydraulic conductivity of the medium.

Law (1.2) is usually assumed to hold also in the unsaturated region ($\theta < \theta_*$ and $\psi < 0$) where the conductivity K is supposed to be experimentally determined as a function of θ or of ψ (see, e.g., [11], [12]).

When situations with low water content are to be dealt with, the situation becomes much more complicated; the notion of a "residual" water content θ_0 is introduced such that it cannot be further reduced by means of applied pressure gradients. It is reasonable to assume that, as θ approaches θ_0, the hydraulic conductivity falls to zero: actually, for $\theta = \theta_0$, the liquid phase is no longer connected and it is clearly understood that no pressure can be transmitted from one "pendular ring" of water to the others [12], [13].

Accordingly, we will assume shapes of $\theta - \psi$ and $K - \psi$ curves shown in Fig. 1.1 (see also [1], [14], [15]).

We will consider a one-dimensional case as a first approximation to practical problems in which a much more complicated situation can appear: essentially three-dimensional filtration (see [7], [17]), anisotropy, hysteresis phenomena, etc. This approximation is commonly adopted in most of the papers devoted to problems of

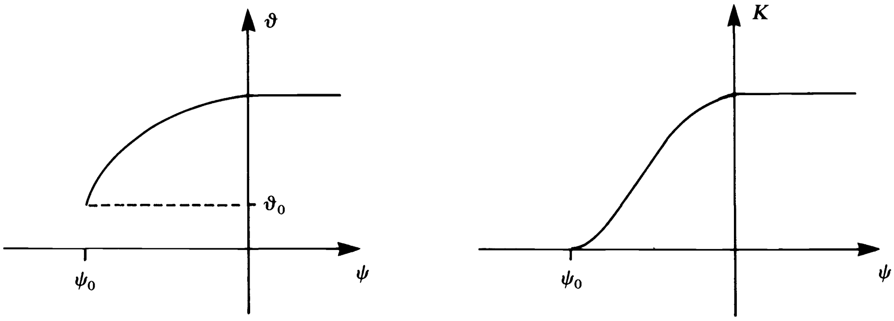

FIG. 1.1

this class and, from a mathematical point of view, makes it possible to use the Kirchhoff transformation

$$u(x, t) = \int_{\psi_0}^{\psi(x, t)} K(s)\, ds.$$

Denote

$$u_s = \int_{\psi_0}^{0} K(s)\, ds.$$

which means that the medium is saturated when $u \geqq u_s$. Then, when $u > 0$, $u(x, t)$ satisfies the equation

$$\theta(u)_t = u_{xx} - k(u)_x. \tag{1.3}$$

A sketch of $\theta(u)$ and $k(u)$ is given in Fig. 1.2.
In general, it is assumed in the literature (see [9], [10]) that $\theta'(u) \to +\infty$ as $u \to 0^+$ and $\theta'(u) \to 0$ as $u \to u_s$. Hence, (1.3) is degenerate when $u = 0$ and $u \geqq u_s$.

We will study (1.3) in a slab $0 < x < 1$, with initial condition

$$u(x, 0) = u_0(x), \qquad 0 < x < 1,$$

where u_0 has values in $(0, 1)$. We assume that the bottom of the slab is impervious, i.e.,

$$u_x(1, t) - k(u(1, t)) = 0,$$

and that evaporation takes place at the top surface $x = 0$. In previous papers (e.g., [5], [10], [16]) evaporation is modeled by prescribing a constant boundary flux; in particular, in [10] it is supposed that the medium can become dry not only on the surface

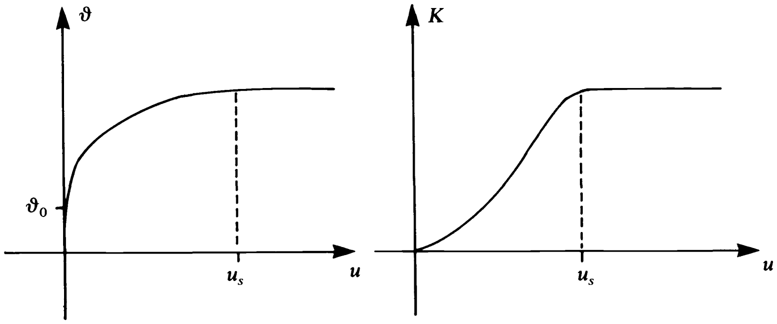

FIG. 1.2

but also below it and the rate of evaporation is a given function of the thickness of the dry part.

On the other hand, it seems reasonable and consistent with the model to assume that the flux becomes zero when the capillary piezometric head reaches the critical value ψ_0. In [8] a filtration problem is considered in which the boundary condition is $u_x(0,t)-k(u(0,t))=f(u(0,t))$ where $f(0)=0$ and f is a smooth function. Here we want to investigate the delicate case in which a discontinuity appears for $u=0$. Hence we will assume that the rate of evaporation is a given constant q if $u(0,t)>0$, whereas the flux is between 0 and q when $u(0,t)=0$. From a mathematical point of view, this is a unilateral or "Signorini type" boundary condition (see also [7]), which has the form

$$\begin{aligned} &u_x(0,t)-k(u(0,t))=q && \text{if } u(0,t)>0,\\ &0\leqq u_x(0,t)\leqq q && \text{if } u(0,t)=0,\end{aligned}$$

i.e.,

$$u_x(0,t)-k(u(0,t))\in qH(u(0,t)),$$

where

$$H(z)=\begin{cases}0, & z<0,\\ [0,1], & z=0,\\ 1, & z>0.\end{cases}$$

Summing up, the evaporation problem we will study is the following:

$$(\mathbb{P})\qquad \begin{aligned} &\theta(u)_t=u_{xx}-k(u)_x, \qquad (x,t)\in H_T=(0,1)x(0,T],\\ &u(x,0)=u_0(x), \qquad x\in[0,1],\\ &(u_x-k(u))|_{x=0}\in qH(u(0,t)), \qquad t\in(0,T],\\ &(u_x-k(u))|_{x=1}=0, \qquad t\in(0,T].\end{aligned}$$

The plan of this paper is as follows. In § 2, some assumptions on the problem ($\mathbb{P}$) and the definition of the weak solution of problem ($\mathbb{P}$) will be given. In § 3, using the parabolic regularization process, we prove the existence of a weak solution of ($\mathbb{P}$). In § 4, the uniqueness of weak solutions is proved. In § 5, we discuss the properties of the weak solution. We will see that $u(x,t)>0$ for any $x>0$ and finite t. Moreover we will consider the set $D=\{t\colon u(0,t)=0\}$, proving that there exists a T_0 such that $[T_0,+\infty)\subset D$ (but possibly $D\neq[T_0,+\infty)$); in other words, the surface will become eventually dry. Finally we prove that the weak solution tends to zero uniformly as $t\to+\infty$.

In § 6, we first consider the special case in which the initial condition satisfies

$$(1.4)\qquad 0\leqq u_0'(x)-k(u_0(x))\leqq q,$$

and we prove that the set D is connected, i.e., $D=[T_0,+\infty)$. Then, we pass to estimate the number of the "switching times," i.e., the number of times at which the Signorini boundary condition "switches" from a Neumann-type condition ($u_x-k(u)=q$) to a Dirichlet-type condition ($u=0$). We prove that this number is less than the number of zeros of the function $u_0'(x)-k(u_0(x))-q$.

2. Assumptions and weak solution. We assume that the functions $\theta(u)$, $k(u)$ and $u_0(x)$ satisfy the following conditions:

(A1) $\theta(u)$ is Lipschitz continuous in any closed subset of $\mathbb{R}^+$. $\theta(0)=\theta_0>0$; $\theta(u)\equiv\theta_s$ for $u\geqq u_s$; $\theta'(u)>0$ if $u\in[0, u_s)$; $\theta'(u)\in L^1(0, M_0)$, where M_0 is the upper bound of $u_0(x)$. It is permitted that $\theta'(u)\to\infty$ as $u\to 0^+$.

(A2) $k(u)\in C^{0+1}(\mathbb{R})$; $k(u)\equiv 0$ if $u\in(-\infty, 0]$; $k(u)\equiv K_s$ if $u\in[u_s, +\infty)$; $k'(u)>0$ when $u\in(0, u_s)$; there exists a constant $\sigma_0\in(0, u_s)$ such that $k(u)$ has a continuous first derivative in the interval $(-\infty, \sigma_0)$.

(A3) $\exists C>0$ s.t. $(k'(u))^2/\theta'(u)\leqq C$ in $[0, u_s]$.

(A4) $u_0(x)\in C^{0+1}([0, 1])$; there exists $x_0\in(0, 1)$ such that $m_0\leqq u_0(x)<u_s$ if $x\in[0, x_0)$ and $u_s\leqq u_0(x)\leqq M_0$ if $x\in[x_0, 1]$, where $m_0\in(0, u_s)$; $u_0'(0)-k(u_0(0))=q$; $u_0'(1)-k(u_0(1))=0$.

We define

$$C(u)=\int_0^u k^p(r)\theta'(r)\,dr, \tag{2.1}$$

where $p\geqq 1$ is a constant which can always be determined, as in [9], in such a way that

(C1) $C(r)\in C^{0+1}(\mathbb{R})$; $C(r)\equiv 0$ if $r\in(-\infty, 0]$; $C(r)\equiv C_s$ if $r\in[u_s, \infty)$; $C'(r)>0$ if $r\in(0, u_s)$; $C(r)$ has a continuous second derivative in $(-\infty, \sigma_0)$.

$$(k'(r))^2=0\left(\frac{C'(r)}{k^p(r)}\right) \quad\text{if } r\in(0, M_0);\quad \frac{C'(r)}{k^p(r)}\in L^1(0, M_0). \tag{C2}$$

Let

$$A(u)=\theta(u)-\theta_0 \tag{2.2}$$

and note that

$$A(u)=\int_0^u \frac{c'(s)}{k^p(s)}\,ds. \tag{2.2$'$}$$

Using transformations (2.1) and (2.2), equation (1.3) becomes

$$A(u)_t=u_{xx}-(k(u))_x. \tag{2.3}$$

Let G be a simply connected open region of the (x, t) plane. We will say that G belongs to the class U if $\exists t_0\leqq T$ such that $G\subset H_{t_0}$ and if $I=\partial G\cap\{t=t_0\}$ and $I_0=\partial G\cap\{x=0\}\equiv\{x=0, t_1\leqq t\leqq t_2\leqq t_0\}$ are nonempty. Moreover, the remainder of ∂G is piecewise smooth.

We will use class U in the definition of a weak solution where we will denote by $I_1=\partial G\cap\{x=1\}$ and by $I_c=\partial G\backslash(I\cup I_0\cup I_1)$.

Definition 2.1. A real, bounded, nonnegative, and measurable function $u(x, t)$ defined on $\bar{H}_T$ is called a weak solution to problem $(\mathbb{P})$, if $C(u)$ is continuous in $\bar{H}_T$ and smooth in $\{(x, t)\in H_T: 0<u(x, t)<u_s\}$, $u>0$ in H_T and if

$$\begin{aligned}\iint_G \{(u_x-k(u))\phi_x-A(u)\phi_t\}\,dx\,dt+q\int_{t_1}^{t_2} H(u(0, t))\phi(0, t)\,dt\\ =\int_{\mathrm{l}\overset{+}{\mathrm{c}}} A(u)\phi\,dx+\int_{\mathrm{l}\overset{+}{\mathrm{c}}}(u_x-k(u))\phi\,dt\end{aligned} \tag{2.4}$$

for any $G\in U$, where $\mathrm{l}\overset{+}{\mathrm{c}}$ means that the line integral is counterclockwise, and $\phi\in C^1(\bar{G})$ is an arbitrary test function which vanishes when $(x, t)\in I$. In addition, the mass conservation law is satisfied:

$$\int_0^1\{A(u(x, t))-A(u_0(x))\}\,dx+\int_0^t qH(u(0, t))\,dt=0 \quad\text{for any } t\in[0, T]. \tag{2.5}$$

3. The existence of a weak solution. As in [9], we construct function sequences $\{C_n(s)\}$, $\{k_n(s)\}$, $\{H_n(s)\}$, and $\{u_{0n}(x)\}$, which satisfy the following conditions:

(C_n): $C_n(s) \in C^2(\mathbb{R})$; $C_n(s) = (1/n)s + C(s)$ for $s \in (-\infty, \sigma_1)$, where $\sigma_1 \in (0, \sigma)$; $C_n(s) \to C(s)$ uniformly on any bounded subset of $\mathbb{R}$; $C_n'(s) \to C'(s)$ uniformly on any closed interval in $[0, u_s)$; $1/n \leqq C_n'(s) \leqq C_0$ for $n \geqq 1$ and $s \in \mathbb{R}$, where C_0 is a constant.

(k_n): $k_n(s) \in C^2(\mathbb{R})$; $k_n(s) = k(s)$ for $s \in (-\infty, \sigma_1)$; $k_n(s) \to k(s)$ uniformly on any bounded subset of $\mathbb{R}$; $0 \leqq k_n(s) \leqq k_0$, $0 \leqq k_n'(s) \leqq k_{01}$ for $n \geqq 1$ and $s \in \mathbb{R}$, where k_0 and k_{01} are constants.

(H_n): $H_n(s) \in C^1(\mathbb{R})$; $H_n(s) \equiv 0$ for $s \in (-\infty, 0]$; $H_n(s) \equiv 1$ for $s \in [1/n, \infty)$; $H_n'(s) \geqq 0$.

(u_{0n}): $u_{0n}(x) \in C^2([0, 1])$; $u_{0n}(x) \to u_0(x)$ uniformly on $[0, 1]$; $m_0 - (1/n) \leqq u_{0n}(x) < M_0 + (1/n)$. $|u_{0n}'(x)| \leqq M_{01}$.

At $x = 0$ or $x = 1$, $u_{0n}(x)$ satisfies the compatibility condition

$$u_{0n}''' = (A_n'(u_{0n}))^{-1} A_n''(u_{0n}) u_{0n}' u_{0n}'' + 2k_n'(u_{0n}) u_{0n}'' \\ + \{k_n''(u_{0n}) - (A_n'(u_{0n}))^{-1} A_n''(u_{0n}) k_n'(u_{0n})\}(u_{0n}')^2 - (k_n'(u_{0n}))^2 u_{0n}',$$

where $u_{0n} = k_n(u_{0n}) + qH_n(u_{0n})$ when $x = 0$ and $u_{0n} = k_n(u_{0n}) + k_n(\frac{1}{n})$ when $x = 1$, the function $A_n(s)$ is defined as

$$A_n(s) = \frac{1}{n} + \int_0^s \frac{C_n'(r)}{k_n^p(r) + (1/n)} \, dr.$$

Then, on the basis of [3], the problem

$$\begin{aligned} &(3.1) \qquad (A_n(u_n))_t = u_{nxx} - (k_n(u_n))_x, \qquad (x, t) \in H_T, \\ &(3.2) \qquad u_n(x, 0) = u_{0n}(x), \qquad 0 \leqq x \leqq 1, \\ &(3.3) \qquad u_{nx}(0, t) - k_n(u_n(0, t)) = qH_n(u_n(0, t)), \qquad 0 < t \leqq T, \\ &(3.4) \qquad u_{nx}(1, t) - k_n(u_n(1, t)) = k_n\left(\frac{1}{n}\right), \qquad 0 < t \leqq T, \end{aligned} \qquad (I_n)$$

has a unique solution $u_n(x, t) \in C^{2+\alpha, 1+(\alpha/2)}(\bar{H}_T)$, where $\alpha \in (0, 1)$.

The following lemmas can be proved by essentially standard methods.

LEMMA 3.1. *Let $u_n(x, t)$ be the solution of (I_n). Then there exists a constant M such that*

$$(3.5) \qquad 0 < u_n(x, t) \leqq M$$

for large n.

Proof. Let $U_0 = M_0 + (1/n)$ and define a function $U_n(x)$ by

$$x = \int_{U_0}^{U_n} \frac{ds}{k_n(s) + k_n(2/n)}.$$

Using the maximum principle it is easily proved that

$$0 < u_n(x, t) < U_n(x) \leqq M.$$

LEMMA 3.2. *There exists a constant $M_1 > 0$ such that*

$$(3.6) \qquad |u_{nx}(x, t)| \leqq M_1, \qquad (x, t) \in \bar{H}_T.$$

Proof. Let $V(x, t) = u_{nx}(x, t) - K_n(u_n)$. Then $V(x, t)$ satisfies

$$A_n'(u_n) V_t = V_{xx} - [(A_n'(u_n))^{-1} A_n''(u_n) u_{nx} + k_n(u_n)] V_x.$$

The maximum principle applied to V proves (3.6).

LEMMA 3.3. *There exists a constant $N>0$ such that $C_n(u_n(x,t))$ is uniformly Lipschitz continuous with respect to x and uniformly Hölder continuous (exponent $\frac{1}{2}$) with respect to t in $\bar{H}_T$ when $n>N$.*

Proof. The proof is obtained using condition (C_n), estimate (3.6) and Proposition 1 of [6].

Using the lemmas above, as in [9] we can select a subsequence from $\{u_n(x,t)\}$, which converges weakly in $L^2(H_T)$ to the weak solution $u(x,t)$ of $(\mathbb{P})$. The positivity of u in H_T will be proved in Theorem 5.1. Thus we have the following theorem.

THEOREM 3.1. *Problem $(\mathbb{P})$ has at least one weak solution.*

4. Uniqueness. To prove uniqueness we need the following lemmas.

LEMMA 4.1. *For any fixed constant $M>0$, there exists a constant $F_0>0$ such that*

$$[k(s_1)-k(s_2)]^2 \leqq F_0(s_1-s_2)[A(s_1)-A(s_2)] \tag{4.1}$$

for any $s_1, s_2 \in [0, M]$ if $(k'(s))^2 = 0(A'(s))$ in $(0, M]$.

Proof. See Lemma 1 of [4].

LEMMA 4.2. *Suppose $G \in H_T$ is a simply connected open region with continuous parabolic boundary $\partial_p G$, and u_1 and u_2 are weak solutions of (2.3) with the same boundary value: $u_1(x,t)=u_2(x,t)=f(x,t)$ or u_{1x} $(x,t)-k(u_1(x,t))=u_{2x}(x,t)-k(u_2(x,t))=h(x,t)$ on $\partial_p G$, where the definition of weak solution is usual (e.g., see [6], [9]), then $u_1(x,t)\equiv u_2(x,t)$ in $\bar{G}$.*

Proof. The proof is similar to that of Theorem 2 in [6] or Theorem 2 in [4] and we omit it.

LEMMA 4.3. *Suppose that $G \in U$ (defined in § 2), u_1 and u_2 are two weak solutions of $(\mathbb{P})$. If $C(u_1) \geqq C(u_2)$ in G and $C(u_1)=C(u_2)$ on I_c, then $u_1=u_2$ in G.*

Proof. Let $u_2(x,t)=u_1(x,t)$ when $(x,t)\in \bar{H}_T \backslash \bar{G}$, then the remainder of the proof is similar to that of Theorem 2 in [6] or Theorem 2 in [4] and we omit it.

THEOREM 4.1. *Problem $(\mathbb{P})$ has at most one weak solution.*

Proof. Suppose that u_1 and u_2 are two weak solutions of $(\mathbb{P})$. Then there will be a point $(x_0,t_0)\in H_T$ such that, e.g., $C(u_1(x_0,t_0))>C(u_2(x_0,t_0))$. Thus, let G_0 be the largest simply connected open subset of H_T such that $(x_0,t_0)\in G_0$ and $C(u_1)>C(u_2)$ when $(x,t)\in G_0$. Let G_1 be the intersection of the saturated regions of u_1 and u_2 (G_1 may be empty);

$$t^* = \inf\{t \mid (x,t)\in \partial G_0 \cap \partial G_1\};$$

$$G_2 = G_1 \cap \{(x,t) \mid t^* \leqq t \leqq t_0\};$$

$$I_c = \{(x,t)\in \partial(G_0 \cup G_2) \mid t=\inf\{t \mid (x,t)\in G_0\cup G_2\}\};$$

$$G = \{(x,t)\in H_T \mid \inf\{t \mid (x,t)\in G_0 \cup G_2\} < t < t_0\}.$$

Then, $G\in U$ (defined in § 2). By Lemmas 4.2 and 4.3, $C(u_1)\geqq C(u_2)$ when $(x,t)\in G$. Using the result of Lemma 4.3, we know that $u_1=u_2$ in G. This contradicts $C(u_1)>C(u_2)$ in G_0, and the proof is complete.

5. Some properties of the weak solution. In this section we first prove $u(x,t)>0$ in $\bar{H}_T \backslash \{(x,t) \mid x=0\}$ under the following assumption:

(A5) $\theta'(r)>C_0$ when $r\in[0,\frac{1}{2}u_s]$, where $C_0>0$ is a constant.

Then we prove that there exists a constant $T_0>0$ so that $u(0,t)\equiv 0$ when $t\geqq T_0$. Finally we prove $u(x,t)\to 0$ uniformly as $t\to\infty$.

THEOREM 5.1. *Let $u(x,t)$ be the weak solution of $(\mathbb{P})$. If assumption (A5) holds, then $u(x,t)>0$ in $\bar{H}_T\backslash\{(x,t)\mid x=0\}$.*

Proof. Suppose $u_n(x, t)$ is the solution of problem (I_n). With no loss of generality, we assume $0 \leqq u_n(x, t) \leqq \frac{1}{2}u_s$ so that $A'_n(u_n) \geqq C_0 > 0$ (by assumption (A5)).

For any fixed $x_0 \in (0, 1)$, let $B \in (0, 1)$ such that $\{x | (x - x_0) \leqq B\} \subset (0, 1)$. Then we construct a function

$$V(x, t) = \begin{cases} D\, e^{1/[(x-x_0)^2 - B^2] - \alpha t}, & |x - x_0| < B, \\ 0, & |x - x_0| \geqq B, \end{cases}$$

where D and α are positive constants to be determined later. Let

$$w(x, t) = u_n(x, t) - V(x, t).$$

Take D sufficiently small such that

$$u_{0n}(x) \geqq V(x, 0) \quad \text{for large } n.$$

We have

$$\begin{aligned} Lw &= w_{xx} - k'_n(u_n) w_x - A'_n(u_n) w_t \\ &= -V_{xx} + k'_n(u_n) V_x + A'_n(u_n) V_t \\ &= D\, e^{1/[(x-x_0)^2 - B^2] - \alpha t} \left\{ -\frac{6(x-x_0)^4 + 4(1-B^2)(x-x_0)^2 - 2B^4}{((x-x_0)^2 - B^2)^4} \right. \\ &\qquad \left. \cdot\, k'_n(u_n) \frac{2(x-x_0)}{((x-x_0)^2 - B^2)^2} - \alpha A'_n(u_n) \right\} \end{aligned}$$

in the region $Q = \{(x, t) |\, |x - x_0| < B, 0 < t < T\}$. Consider the sum of the first two terms in the above braces

$$\begin{aligned} S &= -\frac{6(x-x_0)^4 + 4(1-B^2)(x-x_0)^2 - 2B^4}{((x-x_0)^2 - B^2)^4} - \frac{2k'_n(u_n)(x-x_0)}{((x-x_0)^2 - B^2)^2} \\ &= -\frac{6(x-x_0)^4 + 4(1-B^2)(x-x_0)^2 - 2B^4 + 2k'_n(u_n)(x-x_0)((x-x_0)^2 - B^2)^2}{((x-x_0)^2 - B^2)^4}. \end{aligned}$$

Because $0 \leqq k'_n(u_n) \leqq k_{01}$ and

$$6(x-x_0)^4 + 4(1-B^2)(x-x_0)^2 - 2B^4 \to 4B^2 \quad \text{as } |x - x_0| \to B,$$

$$((x-x_0)^2 - B^2)^2 \to 0 \quad \text{as } |x - x_0| \to B,$$

we can choose an appropriate $B_0 \in (0, B)$ such that

$$S < 0 \quad \text{if } B_0 < |x - x_0| < B.$$

Thus we have

(5.1) $$Lw < 0 \quad \text{when } B_0 < |x - x_0| < B.$$

Since $A'_n(u_n) \geqq C_0 > 0$, we can select an appropriate α such that

(5.2) $$Lw < 0 \quad \text{if } 0 < |x - x_0| \leqq B_0.$$

Therefore, $w(x, t)$ cannot take its minimum in Q. Since $w(x, t) \geqq 0$ when $t = 0$ or $|x - x_0| = B$, it follows that

(5.3) $$w(x, t) = u_n(x, t) - V(x, t) \geqq 0 \quad \text{in } \bar{Q}.$$

By (5.3) and the arbitrariness of x_0, we conclude that $u(x, t) > 0$ in H_T.

It remains to prove $u(1, t) > 0$. For this purpose we choose constants B and x_0 such that

$$0 < 1 - x_0 < B < x_0 - B < 2x_0 - 1 < x_0 < 1.$$

Then, we construct a function

$$V(x, t) = \begin{cases} D\, e^{1/[(x-x_0)^2 - B^2] - \alpha t}, & x \in (x_0 - B, 1], \\ 0, & x \in [0, x_0 - B], \end{cases}$$

where D is sufficiently small such that

$$V(x, 0) \leqq u_{0n}(x) \quad \text{for large } n.$$

Let

$$w(x, t) = u_n(x, t) - V(x, t),$$
$$Q = \{(x, t) | x_0 - B < x < 1, t \in (0, T]\},$$
$$Lw = w_{xx} - k'_n(u_n) w_x - A'_n(u_n) w_t.$$

As we did above, we can take α large enough so that

$$Lw \leqq 0 \quad \text{in } Q.$$

Therefore $w(x, t)$ must take its minimum on $\partial_p Q$. Because $w \geqq 0$ when $t = 0$ or $x = x_0 - B$ and $w(1, 0) > 0$, $w(x, t) \geqq 0$ as long as $w(1, t) > 0$.

If there exists $t_1 = \min\{t | w(1, t) = 0\}$, we have $w(x, t) \geqq 0$ in $\bar{Q}_{t1} = \{[x, t) | x_0 - B \leqq x \leqq 1, 0 \leqq t \leqq t_1\}$. Thus,

$$u_{nx}(1, t_1) \leqq V_x(1, t_1). \tag{5.4}$$

But

$$V_x(1, t_1) = -\frac{2(1 - x_0)}{((1 - x_0)^2 - B^2)^2} V(1, t_1)$$
$$< 0 < k_n(u_n(1, t)) + k_n\left(\frac{1}{n}\right) = u_{nx}(1, t),$$

which contradicts (5.4). Thus,

$$w(1, t) > 0 \quad \text{for any } t \in [0, T].$$

This means $u(1, t) > 0$ for any $t \in [0, T]$ and Theorem 5.1 is proved.

THEOREM 5.2. *For the weak solution $u(x, t)$ of* ($\mathbb{P}$), *there exists a constant $T_0 > 0$ such that $u(0, t) \equiv 0$ when $t \geqq T_0$ (i.e., the surface will eventually become dry).*

Proof. Suppose (2.3) has a traveling wave solution $U(X) = U(x\text{-}mt)$, where m is a positive constant. Then $U(X)$ can be defined by

$$X = \int_{U_0}^{U(X)} \frac{ds}{k(s) - (mA(s) + B)}, \tag{5.5}$$

where U_0 and B are constants.

(i) We first prove that there exists a positive constant m_{01} which is small enough such that $q/2m_{01} > \max\{M_0, A(u_s)\}$, where $M_0 \geqq u_0(x)$, and

$$\int_{M_0}^{q/2m_{01}} \frac{ds}{k(s) - (m_{01}A(s) - (q/2))} > 1. \tag{5.6}$$

In fact, if we take

$$m_{01} \in \left(0, \min\left\{\frac{q}{2M_0}, \frac{q}{2A(u_s)}, \frac{q}{2k_s+q+2M_0}\right\}\right), \tag{5.7}$$

then

$$\int_{M_0}^{q/2m_{01}} \frac{ds}{k(s)-(m_{01}A(s)-(q/2))} > \int_{M_0}^{q/2m_{01}} \frac{ds}{k_s+(q/2)} = \left(\frac{q}{2m_{01}} - M_0\right)\left(\frac{1}{k_s+(q/2)}\right) > 1.$$

(ii) In (5.5), take $B = -q/2$, $m = m_{01}$ which satisfies (5.7). Thus, there exists a constant $U_0 \in (M_0, q/2m_{01})$ such that

$$X = \int_{M_0}^{q/2m_{01}} \frac{ds}{k(s)-(m_{01}A(s)-(q/2))} = 1. \tag{5.8}$$

The function $U(X)$, determined by

$$X = \int_{U_0}^{U(X)} \frac{ds}{k(s)-(m_{01}A(s)-(q/2))} \tag{5.9}$$

(where m_{01} and U_0 satisfy (5.7) and (5.8)), has the following properties:

(a) There exists a constant $a < 0$ such that $U(a) = 0$ and $U(\underset{\sim}{x})$ is monotonically increasing for $a \leqq X \leqq 1$.

(b) $U(0) = U_0 > M_0$, $U(1) = q/2M_{01}$.

Because $U(x - m_{01}t) > u(x, t)$ when $t = 0$, by Theorem 3.1 of [5], the first point $P_1 \equiv (x_1, t_1)$ such that $u(P_1) = U(P_1)$ and $u(x, t) < U(x - m_{01}t)$ for $t < t_1$, must belong to the boundaries $x = 0$ or $x = 1$.

If $x_1 = 1$, then $u_x(P_1) \geqq U_x(P_1)$. However,

$$u_x(P_1) = k(u(P_1)) < k(U(P_1)) - (m_{01}A(U(P_1)) - (q/2)) = U_x(P_1).$$

This is a contradiction.

If $x_1 = 0$, we have

$$u_x(P_1) \leqq U_x(P_1). \tag{5.10}$$

In this case, if $U(P_1) > 0$, then

$$\begin{aligned} U_x(P_1) &= k(U(P_1)) - (m_{01}A(U(P_1)) - (q/2)) \\ &= k(U(P_1)) + q - (m_{01}A(U(P_1)) + (q/2)) \\ &< k(U(P_1)) + q \\ &= u_x(P_1). \end{aligned}$$

This contradicts (5.10). Therefore, $U(x - m_{01}t)$ cannot take the same value of $u(x, t)$ before the time at which $U(0\text{-}m_{01}t) = 0$.

Because $U(x - m_{01}t)$ moves rightwards with the constant velocity m_{01}, the zero point of $U(X)$ must arrive at the boundary $x = 0$. In fact, we have $U(x - mt) = u(x, t) = 0$ when $t = -a/m_{01} \equiv T_0$ and $x = 0$.

It is quite evident that for any $\alpha > 0$, the function $U(x - m_{01}t + \alpha)$ possesses the same properties of $U(x - m_{01}t)$. This means that $u(0, t) \equiv 0$ when $t \geqq T_0$, as we had to prove.

THEOREM 5.3. *Suppose $u(x, t)$ is the weak solution of* ($\mathbb{P}$). *Then*

$$\lim_{t\to\infty} \sup_{x\in[0,1]} u(x, t) = 0. \tag{5.11}$$

Proof. On the basis of Theorem 5.2, there exists a constant t_0 such that $u(0, t) \equiv 0$ when $t \geqq t_0$. In the region $H_{t_0}^{+} = \{(x, t) | 0 < x < 1, t_0 < t < \infty\}$, we construct a dominant function $v(x, t)$ which is the usual weak solution of the problem

$$\begin{aligned} &A(V)_t = V_{xx} - k(V)_x, && (x, t) \in H_{t_0}^{+}, \\ &V(x, 0) = V_0(x), && 0 \leqq x \leqq 1, \\ &V(0, t) = h(t), && t_0 < t < \infty, \\ &V_x(1, t) - k(V(1, t)) = 0, && t_0 < t < \infty, \end{aligned}$$

where $V_0(x)$ is constructed by the relation

$$x = \int_{V(0)}^{V(x)} \frac{ds}{k(s)}$$

such that $V_0(x) > u(x, t_0)$, $h(t) \in C^1([t_0, \infty)) \cap C^{0+1}([0, \infty))$, $h'(t) \leqq 0$ and $\lim_{t \to \infty} h(t) = 0$.

There is no difficulty (see [1]) proving

$$\begin{aligned} &0 \leqq u(x, t) \leqq V(x, t) \quad \text{in } \bar{H}_{t_0}^{+}, \\ &V(x, t_2) \leqq V(x, t_1) \quad \text{if } t_2 > t_1, \\ &|V_x(x, t)| \leqq \text{constant}. \end{aligned} \tag{5.12}$$

Then, as in [1], we can prove

$$\lim_{t \to \infty} \sup_{x \in [0, 1]} V(x, t) = 0. \tag{5.13}$$

Consequently, (5.11) follows directly from (5.12) and (5.13).

6. The number of switching. In this section we consider the characterization of the set $D \equiv \{t: u(0, t) = 0\}$. This is an interesting question. For instance, we could look for conditions such that D is a (finite) union of intervals, so that solving the problem with the Signorini-type condition is equivalent to solving a sequence of problems in which the condition on $x = 0$ is $u_x - k(u) = q$ and $u = 0$, alternatively. First, we give here a sufficient condition that guarantees that D is connected, i.e., that once the surface becomes dry, it will not become wet again. We assume

$$0 \leqq u_0'(x) - k(u_0(x)) \leqq q, \tag{6.1}$$

and prove the following theorem.

THEOREM 6.1. *Suppose $u(x, t)$ is the weak solution of* ($\mathbb{P}$) *with assumption* (6.1) *and $t_0 = \inf\{t | u(0, t) = 0\}$, then $u(0, t) \equiv 0$ when $t \geqq t_0$.*

Proof. By (6.1), using the same method we used to prove Lemma 3.2, we can get

$$0 \leqq u_x(x, t) - k(u(x, t)) \leqq q \quad \text{in } \bar{H}_{t0}. \tag{6.2}$$

In the region $H_{t0T} = \{(x, t) | 0 < x < 1, t_0 < t \leqq T\}$ we construct a problem

$$\begin{aligned} &A(V)_t = V_{xx} - k(V)_x, && (x, t) \in H_{t0T}, \\ &V(x, t_0) = u(x, t_0), && 0 \leqq x \leqq 1, \\ &V(0, t) = 0, && t_0 < t \leqq T, \\ &V_x(1, t) - k(V(1, t)) = 0, && t_0 < t \leqq T. \end{aligned} \tag{6.3} \qquad (P_{t0})$$

Then, the problem (P_{t0}) has unique and usual weak solution $V(x, t)$. Using comparison techniques we can prove that

$$0 \leqq V_x(0, t) - k(V(0, t)) \leqq q. \tag{6.4}$$

Then, let

$$u(x, t) = \begin{cases} u(x, t), & (x, t) \in \bar{H}_{t0}, \\ V(x, t), & (x, t) \in \bar{H}_{t0T}. \end{cases} \tag{6.5}$$

It is easy to verify that the $u(x, t)$ is really a weak solution of $(\mathbb{P})$. Then, Theorem 6.1 follows from the uniqueness of the weak solution.

DEFINITION 6.1. We will say that $\bar{t}$ is a switching time for the Signorini condition if $u(0, \bar{t}) = 0$ and $\exists a > 0$ such that $u(0, t) > 0$ in $(\bar{t} - a, \bar{t})$ or in $(\bar{t}, \bar{t} + a)$.

Our aim is to estimate the number of switching times. We will show that it is controlled by the function

$$V_0(x) = u_0'(x) - k(u_0(x)) - q. \tag{6.6}$$

According to our assumptions it is

$$V_0(0) = 0, \qquad V_0(1) = -q. \tag{6.7}$$

To simplify the analysis below we will assume that V_0 has a finite number of zeros and (just to be specific) that $V_0(x) < 0$ in a neighborhood of $x = 0$.

Let u be the weak solution of $(\mathbb{P})$ and set

$$V(x, t) = u_x(x, t) - k(u(x, t)) - q \tag{6.8}$$

and note that $V(1, t) = -q$. We have the following lemma.

LEMMA 6.1. *Let $m \geqq 0$ be the (even) number of zeros of $V_0(x)$ in $(0, 1)$. For any $\tilde{t}$, $V(x, \tilde{t})$ has at most m zeros.*

Proof. The function $V(x, t)$ satisfies the degenerated parabolic equation

$$A'(u) V_t = V_{xx} - [(A'(u))^{-1} A''(u) u_x - k(u)] V_x$$

in H_T. From the maximum principle we have that the level curves $V = 0$ can only originate on $t = 0$. Of course, they can merge or they can end on $x = 0$ or on $t = T$ (the words "originate" and "end" have an obvious meaning in connection with the orientation of the t axis). This concludes the proof.

Next we have Lemma 6.2.

LEMMA 6.2. *Let $\varepsilon, x_1 > 0$ and $u(x, t)$ be the weak solution of the problem*

$$\begin{aligned} &A(u)_t = u_{xx} - k(u)_x, && 0 < x < x_1, \quad 0 < t < T, \\ &u(x, 0) = v_0(x), && 0 \leqq x \leqq x_1, \\ &u_x - k(u)|_{x=0} = q, && 0 < t < T, \\ &u_x - k(u)|_{x=x_1} = q + \varepsilon, && 0 < t < T. \end{aligned}$$

Assume that $v_0(x)$ satisfies assumptions (A4) where, apart from trivial modifications we substitute the last condition by $v_0' - k(v_0)|_{x=x_1} = q + \varepsilon$ and we add the condition $v_0' - k(v_0) > q$ in $(0, x_1]$. Then $u(x, t) > 0$ in $[0, x_1]x[0, T]$.

Proof. Define $U(x)$ by

$$x = \int_{v_0(0)}^{U(x)} \frac{ds}{k(s) + q}.$$

It is clear that $U(x)$ is a classical solution of (1.2). Using a comparison technique, we obtain

$$u(x, t) \geqq U(x) \geqq m_0 > 0,$$

where m_0 appears in the assumption (A4).

THEOREM 6.2. *Let $u(x, t)$ be the weak solution of* ($\mathbb{P}$). *Then the number of switching times cannot exceed $m+1$ where m is the number of zeros of $V_0(x)$ in* $(0, 1)$.

Proof. If the positivity set of V (call it Pos (V)) does not reach $x=0$ in finite time for $t>t_0$, where t_0 is the first switching time, then the argument of Theorem 6.1 still applies and no more switching times can appear.

After t_0 a new switching time t_1 can exist only if a level curve $V=0$ hits $x=0$ at $t=t_1$ and a segment $\{x=0, t \in (t_1, t_1+a)\}$ belongs to ∂ Pos (V). Afterwards, the argument of Lemma 6.2 applies unless a new line $V=0$ hits $x=0$, separating Pos (V) from the t axis. This concludes our proof.

TRANSIENT STIMULATED RAMAN SCATTERING*

CURTIS R. MENYUK[†] [‡] AND THOMAS I. SEIDMAN[†] [§]

Abstract. The system: $u_\xi = -zv$, $v_\xi = \bar{z}u$, $z_\tau = u\bar{v} - \gamma z$ with $z \to 0$ at $\tau \to -\infty$ and initial data for $\mathbf{u} = (u, v)$ at $\xi = 0$ are considered. Well posedness results are obtained for this and also for a version discretized in τ. Stability is considered as $\xi \to \infty$.

Key words. Raman scattering, well posed, partial differential equations, system, stability

AMS(MOS) subject classifications. 35B40, 35Q60, 78A60

1. Introduction. The Raman effect has played a conspicuous role in physics since its discovery in the 1920s [14], [11]. Specifically, the system of partial differential equations

$$\begin{cases} \text{(i)} \quad \partial u/\partial \xi = -zv, \\ \text{(ii)} \quad \partial v/\partial \xi = \bar{z}u, \\ \text{(iii)} \quad \partial z/\partial \tau = u\bar{v} - \gamma z, \end{cases} \tag{1.1}$$

was first derived to model the interaction of two laser beams with gases when the frequency difference between the beams corresponds to a resonance of the gas molecules [16], [1]. Here, u and v are unknown $\mathbb{C}$-valued functions on $\mathbb{R}_+ \times \mathbb{R}$ (i.e., functions of (ξ, τ) with $0 < \xi < \infty$; $-\infty < \tau < \infty$) which represent the two laser beams, usually referred to as the pump beam and the Stokes beam, respectively. Then the function $-iz$ corresponds to the off-diagonal density matrix element which describes the quantum mechanical state of the gas. The real parameter $\gamma \geq 0$ represents a de-excitation rate due to molecular collisions.

In recent years, these equations have been the focus of intense activity, both experimental and theoretical; some references to the relevant physical literature are provided in our bibliography. It has long been known that (1.1) has a Lax pair when $\gamma = 0$ and so has soliton solutions [2]. On the other hand, we note that it is physically reasonable to require that

$$z(\tau) \to 0 \quad \text{as } \tau \to -\infty \tag{1.2}$$

so that z should be "independent of the infinite past"; yet it was later shown that this physical boundary condition leads to special difficulties which require modification of the standard inverse scattering approach [8], [15], [9]. These modifications seriously complicate the theory, leading to results which are difficult to interpret [10]. We note that soliton-like pulses have been observed in experiments with laser beams whose durations are long compared to the collisional de-excitation time [3], [17] but,

surprisingly, soliton-like pulses are not observed in experiments with laser beams whose durations are short compared to the molecular de-excitation time [4], [5] — even though setting $\gamma = 0$ is presumably "more legitimate" for the latter case. Indeed, numerical experiments indicate that both u and z tend toward zero almost everywhere as $\xi \to \infty$ for a fairly broad set of initial data [13], [7]; compare §5. Following the somewhat less formal argument of [12], we show here that $z \to 0$ as $\xi \to \infty$. The more detailed asymptotic behavior of u and v as $\xi \to \infty$ remains an open question and, as will become evident in the course of this paper, a somewhat delicate one.

Clearly, there is a need for careful mathematical work. Remarkably, despite the importance of (1.1) in the physics literature, no one until now has even shown that these equations are well posed! The goal of this paper is to place the study of (1.1) on a firm mathematical foundation by demonstrating well posedness, obtaining a number of other simple results relating to the asymptotic behavior of these equations as $\xi \to \infty$, and outlining the remaining difficulties and some open problems. The key insights[1] will be that solutions satisfy the identities

$$(1.4) \qquad |\mathbf{u}(\xi,\tau)|^2 = |\mathbf{u}_0|^2 \quad \text{a.e. } \tau \in \mathbb{R} \quad \text{for all } \xi \geq 0$$

(where $|\mathbf{u}_0|^2 = |u_0(\tau)|^2 + |v_0(\tau)|^2$; see (2.1)) and, also pointwise in τ,

$$(1.5) \qquad \frac{d}{d\xi}\left(\int_{-\infty}^{\tau} |e^{-\gamma(\tau-\tilde{\tau})}u|^2\right) = -\frac{d}{d\xi}\left(\int_{-\infty}^{\tau} |e^{-\gamma(\tau-\tilde{\tau})}v|^2\right) = -|z(\tau)|^2.$$

2. Formulation.

We will use a subscript $_\xi$ (or simply $'$) for (partial) differentiation with respect to ξ and subscript $_\tau$ for differentiation with respect to τ, etc. We will consistently use the notation

$$\mathbf{u} := (u,v), \quad X := \begin{pmatrix} 0 & -z \\ \bar{z} & 0 \end{pmatrix}, \quad \mathbf{u}_0 := (u_0, v_0),$$

$$(2.1) \qquad K^2(\tau) := |\mathbf{u}_0(\tau)|^2 := [|u_0(\tau)|^2 + |v_0(\tau)|^2],$$

$$\sigma = \sigma(\tau) := \int_{-\infty}^{\tau} K^2(\tilde{\tau})\,d\tilde{\tau} \quad \text{so } K^2 d\tau =: d\sigma.$$

We will assume the initial data $\mathbf{u}(0) = \mathbf{u}_0$ is to be in $\mathcal{H}$ so

$$\kappa^2 := \|K\|^2 := \int_{-\infty}^{\infty} K^2\,d\tau < \infty.$$

We can solve (1.1.iii) as an ordinary differential equation in τ, temporarily ignoring the ξ dependence, to obtain

$$z(\tau) = e^{-\gamma(\tau-\tau_*)}z(\tau_*) + \int_{\tau_*}^{\tau} e^{-\gamma(\tau-\tilde{\tau})}u(\tilde{\tau})\overline{v(\tilde{\tau})}\,d\tilde{\tau}$$

[1] We note also that the system (1.1) is invariant under the action of the group $\mathcal{G} = \{g_\vartheta : \vartheta : \mathbb{R} \to \mathbb{R}\}$ of transformations

$$(1.3) \qquad g = g_\vartheta : (u,v) \mapsto (e^{i\vartheta}u, e^{i\vartheta}v)$$

for "arbitrary" real $\vartheta = \vartheta(\tau)$, independent of ξ. So far, however, we have not been able to exploit this insight effectively.

for arbitrary real τ_*, τ. Imposing (1.2), the first term on the right can be omitted "at $-\infty$" so the differential equation (1.1.iii) can replaced by

$$z(\tau) := \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})} u(\tilde{\tau})\overline{v(\tilde{\tau})}\, d\tilde{\tau} \tag{2.2}$$

as a *definition.* We note that a principal point of difference between our present treatment and most previous work is precisely this imposition of the boundary condition (1.2); compare Remark 4.4 below.

For (2.2) to be meaningful, we need $u\bar{v}$ to be integrable and we will therefore seek solutions in the L^2 space[2]

$$\mathcal{H} := \{\mathbf{u} = (u,v) : \mathbb{R} \to \mathbb{C}^2 : \|\mathbf{u}\|^2 := \int_{-\infty}^{\infty} |\mathbf{u}(\tau)|^2\, d\tau < \infty\}.$$

Along with $\mathcal{H}$, we introduce the spaces

$$\begin{aligned} \mathcal{H}_K &:= \{\mathbf{u} = (u,v) \in \mathcal{H} : |\mathbf{u}(\tau)| = K(\tau) \text{ a.e. } \tau \in \mathbb{R}\}, \\ \mathcal{Z} &:= \{z \in C((-\infty,\infty] \to \mathbb{C}) : z(-\infty) = 0\}, \\ \mathcal{X} &:= \left\{ X = \begin{pmatrix} 0 & -z \\ \overline{z} & 0 \end{pmatrix} : z \in \mathcal{Z} \right\}. \end{aligned}$$

Note that $\sup\{|z(\cdot)|\}$ just gives the norm of $X(\cdot) \in \mathcal{X}$ as an operator on $\mathcal{H}$ (or on any $\mathcal{H}_K \subset \mathcal{H}$), acting by pointwise multiplication. We will also introduce the linear space $\boldsymbol{\mathcal{U}}$ of functions $\mathbf{u}(\cdot) \in C(\mathbb{R}_+ \to \mathcal{H})$ for which the exponentially weighted norm

$$\|\mathbf{u}\|_\kappa := \sup_{\xi \ge 0}\{e^{-2\kappa^2\xi}\|\mathbf{u}(\xi,\cdot)\|_{\mathcal{H}}\} \tag{2.3}$$

is finite for some κ. Convergence in $\boldsymbol{\mathcal{U}}$ is given by convergence in $\|\cdot\|_\kappa$ for every large enough κ; $\boldsymbol{\mathcal{U}}$ is then metrizable and complete. We finally let $\boldsymbol{\mathcal{U}}_K$ be the subset of $\mathbf{u} \in \boldsymbol{\mathcal{U}}$ taking values almost everywhere in $\mathcal{H}_K$—topologized through $\|\cdot\|_\kappa$ with $\kappa := \|K\|$.

Finally, we introduce the map

$$\mathbf{X} : \mathbf{u} \mapsto X := \begin{pmatrix} 0 & -z \\ \overline{z} & 0 \end{pmatrix} \quad \text{for } \mathbf{u} = (u,v) \in \mathcal{H} \tag{2.4}$$

with $z = z(\cdot)$ defined by (2.2). Then (1.1.i, ii) can be written as an abstract ordinary differential equation with respect to ξ in the more succinct form

$$\mathbf{u}' = \mathbf{X}(\mathbf{u})\mathbf{u}, \qquad \mathbf{u}(0) = \mathbf{u}_0 \in \mathcal{H}. \tag{2.5}$$

[2] Clearly it would be sufficient to have this integrability only "to the left," i.e., on each semi-infinite interval $(-\infty, \tau]$ with τ finite, imposing no growth condition as $\tilde{\tau} \to +\infty$. The present formulation permits us to work with a Hilbert space formulation for $\mathbf{u} = (u,v)$ and the greater generality can be recovered—observing that, by setting everything equal to zero for $\tau > \tau^*$, we can always restrict the problem to $(-\infty, \tau^*]$ for each (arbitrary) finite τ^* to make the present formulation appropriate.

Note that although we use a $\mathbb{C}^2$ notation, thinking of $\mathcal{H}$ as a complex Hilbert space, it will later be convenient (cf., Thm. 3.4) to treat it also as a real Hilbert space, effectively identifying $\mathbb{C}^2$ with $\mathbb{R}^4$.

3. Well posedness. Our principal concern here is to show that the problem (2.5) has a unique solution, but we begin with a lemma about the map $\mathbf{u} \mapsto \mathbf{X}(\mathbf{u})$.

LEMMA 3.1. *The map* $\mathbf{X}$ *is well defined by* (2.2) *and* (2.4), *and is continuous from* $\mathcal{H}$ *to* $\mathcal{X}$. *For each* $\tilde{\mathcal{H}}_K := \cup\{\mathcal{H}_{\tilde{K}} : \tilde{K} \leq K\}$, *the set of functions* z *defined by* (2.2) *with* $\mathbf{u} \in \tilde{\mathcal{H}}_K$ *is precompact in* $\mathcal{Z}$ *and the map* $\mathbf{X}$ *is uniformly Lipschitzian on* $\tilde{\mathcal{H}}_K$ *with Lipschitz constant* $\kappa := \|K\|$.

Proof. Suppose $\mathbf{u} \in \mathcal{H}$ with $|\mathbf{u}(\tau)| \leq K(\tau)$ almost everywhere and obtain z from $\mathbf{u}$ as in (2.2). Noting that $e^{-\gamma(\tau-\tilde{\tau})} \leq 1$ and that $2|u\overline{v}| \leq K^2$, we then clearly have

$$|z(\tau) - z(\hat{\tau})| = \left|\int_{\hat{\tau}}^{\tau} e^{-\gamma(\tau-\tilde{\tau})} u\overline{v}\right| \leq \tfrac{1}{2}\int_{\hat{\tau}}^{\tau} K^2$$

which shows the continuity of z and, indeed, equicontinuity on $\tilde{\mathcal{H}}_K$; essentially the same computation shows that $\{z(\tau_n)\}$ is (uniformly on $\tilde{\mathcal{H}}_K$) always Cauchy as $\tau_n \to \infty$ so $z(\tau)$ always has a limit as $\tau \to \infty$. Similarly, there is a uniform bound: $|z(\tau)| \leq \frac{1}{2}\kappa^2$. By the Arzela–Ascoli Theorem, it follows that the relevant $\{z\}$ will be in a compact subset of $\mathcal{Z}$. Now let z_1, z_2 be obtained from $\mathbf{u}_1, \mathbf{u}_2$ and set $z := z_1 - z_2$, $\mathbf{u} := \mathbf{u}_1 - \mathbf{u}_2$ so, pointwise in τ, we have

$$\begin{aligned} &u_1\overline{v}_1 - u_2\overline{v}_2 = u_1\overline{v} + u\overline{v}_2 = u\overline{v}_1 + u_2\overline{v}, \\ &|u_1\overline{v}_1 - u_2\overline{v}_2| \leq \min\{[|u_1|^2 + |v_2|^2], [|v_1|^2 + |u_2|^2]\}^{1/2}|\mathbf{u}|. \end{aligned}$$

Note that this minimum is bounded by the average—which is bounded by $K(\tau)$ for $\mathbf{u}_1, \mathbf{u}_2 \in \mathcal{H}_K$. Thus,

$$|z(\tau)| \leq \int_{-\infty}^{\tau} K|\mathbf{u}| \leq \|K\|\|\mathbf{u}\|.$$

Since we are using $\sup\{|z(\cdot)|\}$ as our $\mathcal{X}$-norm, we then get for $\mathbf{X}(\cdot)$ the desired Lipschitz condition with constant $\kappa := \|K\|$. □

THEOREM 3.2. *Let* $\mathbf{u}_0 = (u_0, v_0)$ *be given in* $\mathcal{H}$. *Then there is a unique function* $\mathbf{u} = (u, v) : \mathbb{R}_+ \to \mathcal{H}$ *in* $\boldsymbol{\mathcal{U}}_K$ *satisfying the nonlinear equation* (2.5) *with the notation of* (2.1) *and* (2.4).

Before beginning the proof, we remark that an essentially identical argument works for the problem with ξ reversed (here and also in Theorem 3.3) so, in particular, we have *backward uniqueness* for the solution as well. We also remark that our definition of $\boldsymbol{\mathcal{U}}_K$ means that finding $\mathbf{u} \in \boldsymbol{\mathcal{U}}_K$ implicitly includes the assertion of (1.4).

Proof. Fix $\mathbf{u}_0 \in \mathcal{H}$, thus fixing $K := |\mathbf{u}| \in L^2_+(\mathbb{R})$ and the spaces $\mathcal{H}_K, \boldsymbol{\mathcal{U}}_K$ as above. There is no difficulty in defining a map $\mathbf{F} : \tilde{\mathbf{u}} \mapsto \mathbf{u}$ for $\tilde{\mathbf{u}} \in \boldsymbol{\mathcal{U}}_K$ by solving the linear ordinary differential equation

$$\mathbf{u}' = \mathbf{X}(\tilde{\mathbf{u}})\mathbf{u}, \qquad \mathbf{u}(0) = \mathbf{u}_0. \tag{3.1}$$

Indeed, we note from Lemma 3.1 that $\mathbf{X}(\tilde{\mathbf{u}})\mathbf{u}$ is continuous on $\mathbb{R}_+ \times \mathbb{R}$ so (3.1) can be interpreted pointwise in τ as a (finite-dimensional) ordinary differential equation in ξ—with an adequately defined initial condition for almost every τ. Note that, since $X := \mathbf{X}(\tilde{\mathbf{u}})$ is skew-adjoint, we have from (3.1) that

$$(|\mathbf{u}|^2)' = 2\langle \mathbf{u}, \mathbf{u}' \rangle = 2\langle \mathbf{u}, X\mathbf{u} \rangle \equiv 0$$

whence $|\mathbf{u}(\cdot,\tau)|$ is constant and we have (1.4) for solutions of (3.1), i.e., we have $\mathbf{u}(\cdot) \in \boldsymbol{\mathcal{U}}_K$. (Indeed, we need not even have $\tilde{\mathbf{u}} \in \boldsymbol{\mathcal{U}}_K$ to have $\mathbf{u} =: \mathbf{F}(\tilde{\mathbf{u}}) \in \boldsymbol{\mathcal{U}}_K$ and $\|\mathbf{u}(\xi,\cdot)\| \equiv \kappa$.)

A fixed point for $\mathbf{F}$ is a solution of (2.5) so it will be sufficient to show that $\mathbf{F}$ is a uniformly strict contraction from $\boldsymbol{\mathcal{U}}_K$ to itself. Given $\mathbf{u}_j := \mathbf{F}(\tilde{\mathbf{u}}_j)$ for $j = 1, 2$, set $\mathbf{u} := \mathbf{u}_1 - \mathbf{u}_2$, $\tilde{\mathbf{u}} := \tilde{\mathbf{u}}_1 - \tilde{\mathbf{u}}_2$ and let $\tilde{\nu}$ be the $\boldsymbol{\mathcal{U}}$-norm of $\tilde{\mathbf{u}}$. Then

$$\begin{aligned}(e^{-2\kappa^2\xi}\|\mathbf{u}\|^2)' &= e^{-2\kappa^2\xi}\left(-2\kappa^2\|\mathbf{u}\|^2 + 2\langle \mathbf{u}, [\mathbf{X}(\tilde{\mathbf{u}}_1) - \mathbf{X}(\tilde{\mathbf{u}}_2)]\,\mathbf{u}_2\rangle\right)\\ &\le e^{-2\kappa^2\xi}\left(-2\kappa^2\|\mathbf{u}\|^2 + 2\kappa\|\tilde{\mathbf{u}}\|\|\mathbf{u}_2\|\right)\\ &\le (\kappa^2/2)\, e^{-2\kappa^2\xi}\|\tilde{\mathbf{u}}\|^2.\end{aligned}$$

Since $\|\tilde{\mathbf{u}}(\xi)\|^2 \le \exp[4\kappa^2\xi]\tilde{\nu}^2$ and $\mathbf{u}(0) = 0$, integrating gives

$$e^{-2\kappa^2\xi}\|\mathbf{u}\|^2 \le \frac{\kappa^2}{2}\int_0^\xi e^{2\kappa^2\bar{\xi}} \le \tfrac{1}{4}e^{2\kappa^2\xi}\tilde{\nu}^2$$

and then

$$\left(e^{-2\kappa^2\xi}\|\mathbf{u}\|\right)^2 \le \tilde{\nu}^2/4$$

which shows that $\mathbf{F}$ is uniformly Lipschitzian on $\boldsymbol{\mathcal{U}}_K$ with Lipschitz constant $\frac{1}{2}$. The result then follows by the Contraction Mapping Theorem. □

We complete our treatment of well posedness by considering the continuous dependence of the solution on the initial data $\mathbf{u}_0$. It is clear that the estimate (3.2) gives continuous dependence of solutions on initial data in the sense of uniform convergence (with respect to the $\mathcal{H}$-norm) on bounded ξ-intervals but the estimate grows exponentially in ξ. Since we know that the solutions themselves are bounded uniformly in ξ, it might seem plausible that this could be improved to have convergence uniform on $\mathbb{R}_+$. That, however, is false; see Remark 6.4.

THEOREM 3.3. *Let* $\mathbf{u}_{j0} = (u_{j0}, v_{j0})$ *for* $j = 1, 2$ *be given in* $\mathcal{H}$ *with corresponding solutions* $\mathbf{u}_j : \mathbb{R}_+ \to \mathcal{H}$ *satisfying* (2.5). *Then*

$$\|\mathbf{u}_1(\xi,\cdot) - \mathbf{u}_2(\xi,\cdot)\| \le e^{(\kappa_+\kappa_-)\xi}\|\mathbf{u}_{10} - \mathbf{u}_{20}\| \tag{3.2}$$

where $\kappa_\pm := \|K_\pm\|$ *with* $K_\pm(\tau) := \max, \min\{|\tilde{\mathbf{u}}_0(\tau)|, |\hat{\mathbf{u}}_0(\tau)|\}$.

Proof. The argument is standard. Set $\mathbf{v} := \mathbf{u}_1 - \mathbf{u}_2$ and $X := X_1 - X_2$ with $X_j := \mathbf{X}(\mathbf{u}_j)$, etc. Pointwise in τ, we have $|\mathbf{v}|^2 = \langle \mathbf{v}, \mathbf{v}\rangle$ so

$$\begin{aligned}\partial|\mathbf{v}|^2/\partial\xi &= 2\mathrm{Re}[\langle \mathbf{v}, X_1\mathbf{v}\rangle + \langle \mathbf{v}, X\mathbf{u}_2\rangle]\\ &= 2\mathrm{Re}[\langle \mathbf{v}, X_2\mathbf{v}\rangle + \langle \mathbf{v}, X\mathbf{u}_1\rangle]\\ &= 2\mathrm{Re}\langle \mathbf{v}, X\mathbf{u}_2\rangle = 2\mathrm{Re}\langle \mathbf{v}, X\mathbf{u}_1\rangle\end{aligned}$$

by the skew symmetry of X_1, X_2. By Lemma 3.1, we have $|X(\tau)| \le \|K_+\|\,\|\mathbf{v}\|$ and (1.4) gives, pointwise in τ, $\min\{|\mathbf{u}_1|, |\mathbf{u}_2|\} \equiv K_-$. Thus,

$$\begin{aligned}\partial|\mathbf{v}|^2/\partial\xi &\le 2|\mathbf{v}(\tau)|\|K_+\|\|\mathbf{v}\|K_-(\tau),\\ d\|\mathbf{v}\|^2/d\xi &\le 2\|\mathbf{v}\|^2\|K_+\|\|K_-\|.\end{aligned}$$

The result now follows on applying the Gronwall inequality. □

Extending Theorem 3.3, we next wish to consider linearization of the system, i.e., differentiability of the dependence on initial data.

THEOREM 3.4. *The solution map* $\mathbf{S} : \mathcal{H} \to \boldsymbol{\mathcal{U}}$ *for* (2.5), *is "Fréchet differentiable" (in a sense to be made precise below). At each* $\mathbf{u}_0^* \in \mathcal{H}$ *and corresponding* $\mathbf{u}^* := \mathbf{S}(\mathbf{u}_0^*)$ *the derivative is the linear map:* $\mathcal{H} \to \boldsymbol{\mathcal{U}} : \mathbf{u}_0 = (u_0, v_0) \mapsto \mathbf{u}$ *defined by the linearized system:*

$$(3.3) \qquad \begin{cases} u' &= -z^*v - v^*z, \\ v' &= \overline{z}^*u + u^*\overline{z}, \end{cases} \qquad z := \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})}[\overline{v}^*u + u^*\overline{v}]\, d\tilde{\tau}$$

with $\mathbf{u}(0) = \mathbf{u}_0$. *In particular, for any* $\mathbf{u}_0^* \in \mathcal{H}$ *yielding* $\mathbf{u}^*$ *by* (2.5) *the equation* (3.3) *has a unique solution* $\mathbf{u}$ *for each initial* $\mathbf{u}_0 \in \mathcal{H}$ *and* $\mathbf{u}(\xi, \cdot)$ *will be bounded in* $\mathcal{H}$ *uniformly on bounded* ξ*-intervals.*

A word of caution is in order here since we have been working with complex spaces: *the solution map is not differentiable when complex differentiation is considered* since (2.5) involves conjugations. Instead, as noted earlier, although we have made no alteration in the notation, we are here considering $\mathcal{H} = L^2(\mathbb{R} \to \mathbb{C}^2)$ as isometrically equivalent to the *real* Hilbert space $L^2(\mathbb{R} \to \mathbb{R}^4)$, etc.

Proof. Now consider Theorem 3.3 with $\mathbf{u}_{20} = \mathbf{u}_0^*$ and, for $s \neq 0$, $\mathbf{u}_{10} = \mathbf{u}_0^* + s\mathbf{u}_0$; set $\mathbf{v} = \mathbf{v}(\xi, \tau; s) := [\mathbf{u}_1 - \mathbf{u}^*]/s$. Then (3.2) gives the uniform estimate $\|\mathbf{v}\| \leq e^{(\kappa_+ \kappa_-)\xi}\|\mathbf{u}_0\|$, where $\kappa_\pm = \kappa_\pm(s) \to \|\mathbf{u}_0^*\|^2$ as $s \to 0$. A standard argument then shows that $\mathbf{v}(\cdot; s)$ satisfies a system whose right-hand side tends to that of (3.3) as $s \to 0$ ($\mathcal{O}(s)$ difference in the coefficients) so $\|\mathbf{v}(\cdot; s) - \mathbf{u}\|_\kappa \to 0$ for any $\kappa > \|\mathbf{u}_0^*\|$. Temporarily fixing any such κ, we may treat (the relevant subspace of) $\boldsymbol{\mathcal{U}}$ as a Banach space with the norm $\|\cdot\|_\kappa$ and $\mathbf{u}$, given by (3.3), is the Gâteaux differential of $\mathbf{S}(\cdot)$ at $\mathbf{u}^*$ in the direction of $\mathbf{u}_0$. This is clearly linear in $\mathbf{u}_0$, so this gives a Gâteaux derivative. It is continuous in $\mathbf{u}_0^*$ (as long as we stay close enough to the original $\mathbf{u}_0^*$ so as not to disturb the choice of κ), so this is necessarily a Fréchet derivative, working with this $\|\cdot\|_\kappa$. [We do note that when considering bounded ξ-intervals, the choice of κ is irrelevant; in any case, (3.2) gives control of errors in the norm with $\kappa = \|\mathbf{u}_0^*\|$.] □

4. Some remarks.

Our first concern here is to verify (1.5).

LEMMA 4.1. *Let* $\mathbf{u}$ *be any solution of the system* (2.5) *with* $\mathbf{u}_0$ *in* L^2. *Then,*

$$(4.1) \qquad \begin{cases} \text{(i)} & \left(\int_{-\infty}^{\tau} |e^{-\gamma(\tau-\tilde{\tau})}u|^2\right)' = -|z|^2, \\ \text{(ii)} & \left(\int_{-\infty}^{\tau} |e^{-\gamma(\tau-\tilde{\tau})}v|^2\right)' = |z|^2, \\ \text{(iii)} & z'(\cdot,\tau) = \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})}\left(|u|^2 - |v|^2\right) z \end{cases}$$

for all $\xi > 0$ *and all* $\tau \in \mathbb{R}$.

Proof. From (1.1) we have $[e^{\gamma\tau}z]_\tau{}' = e^{\gamma\tau}\left(|u|^2 - |v|^2\right) z$ and, using (4.5), integrating this gives (4.1.iii). Similarly, we have

$$\overline{e^{\gamma\tau}z}(e^{\gamma\tau}z)_\tau = e^{2\gamma\tau}\overline{z}(u\overline{v}) = e^{2\gamma\tau}\overline{v}v_\xi = -e^{2\gamma\tau}u\overline{u_\xi}$$

and integrating this gives (4.1.i) and (4.1.ii). That these identities hold pointwise for *all* $\tau \in [0, 1]$ follows from the known continuity in τ of z and continuity of the indefinite integral in the third identity. □

COROLLARY 4.2. *If z is real (alternatively, if z is pure imaginary or if z vanishes identically) for $\tau \le \tau_*$ at $\xi = \xi_0$, then this holds for all $\xi \ge 0$. For the case in which $z \equiv 0$ on $\mathbb{R}_+ \times (-\infty, \tau_*)$, we have $\mathbf{u}$ stationary (independent of ξ) there and conversely.*

Proof. The first assertion follows immediately from (4.1.iii), viewing $e^{-\gamma(\tau-\tilde{\tau})}(|u|^2 - |v|^2)$ simply as an integrable real function and integrating this ODE forward or, as in the remark following the statement of Theorem 3.2, backward in ξ. The case of $z \equiv 0$ is obvious with the converse following by, e.g., (4.1.i). □

Remark 4.3. While the system (1.1) cannot give analyticity in its dependence on the initial data, we observe that we could consider the analytic system

$$(4.2) \qquad \begin{cases} u_1' = -z_1 v_1, \\ v_1' = \ \ z_2 u_1, \\ u_2' = -z_2 v_2, \\ v_2' = \ \ z_1 u_2, \end{cases} \qquad \begin{cases} z_1 := \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})} u_1 v_2, \\ z_2 := \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})} u_2 v_1, \end{cases}$$

and have

$$(4.3) \qquad [u_1, v_1, z_1] \equiv [u, v, z] \qquad [u_2, v_2, z_2] \equiv [\overline{u}, \overline{v}, \overline{z}]$$

for all real $\xi > 0$ if this holds initially, at $\xi = 0$.

Without (4.3), we do not have the estimate (1.4) and so it is not clear when solutions for (4.2) will exist globally. On any finite ξ-interval, however, we can get existence for initial data almost satisfying (4.3) and thus, analytic linearization, subject to (4.3), with (3.3) suitably extended to a complex neighborhood of $\mathbb{R}_+$. In particular, this shows that we can also obtain higher derivatives of the solution map with respect to the initial data.

Remark 4.4. For nonstationary solutions, it is interesting to consider the case in which $\gamma = 0$ and z is real on $\mathbb{R}$ — initially, at $\xi = 0$, and so for all $\xi \ge 0$ by Corollary 4.2.

For this we will first reduce the problem to a more convenient form, modifying our notation somewhat, without (at first) taking $\gamma = 0$. If we set $\mathbf{u} =: K\tilde{\mathbf{u}}$ pointwise in τ, then we have the identity

$$(4.4) \qquad |\tilde{\mathbf{u}}|^2 := |\tilde{u}|^2 + |\tilde{v}|^2 \equiv 1 \quad \text{pointwise in } \xi, \tau$$

in view of Theorem 3.2. It is easily seen that $\tilde{\mathbf{u}}$ also satisfies (2.5), provided we modify the definition of the operator $\mathbf{X}(\cdot)$ by replacing (2.2) with

$$(4.5) \qquad z(\tau) := \int_{-\infty}^{\tau} e^{-\gamma(\tau-\tilde{\tau})} u(\tilde{\tau}) \overline{v(\tilde{\tau})} K^2(\tilde{\tau})\, d\tilde{\tau}.$$

Of course, the initial data now must satisfy: $|\tilde{\mathbf{u}}_0| \equiv 1$, pointwise in τ.

That much reduction is available for all γ, but when $\gamma = 0$ we can conveniently use the variable σ of (2.1) to view $\tilde{\mathbf{u}}$ as a function of (ξ, σ), rather than of (ξ, τ). This further reduction will actually (σ—almost everywhere by Sard's Theorem) avoid any difficulty with the definition of $\tilde{u}$ when $K(\tau) = 0$. We note that it is possible to view z also as a function of (ξ, σ) since, while the function $\sigma(\cdot)$ may not be injective, this can happen only if K vanishes on some subinterval — in which case $\mathbf{u}$ (whence $u\overline{v} = z_\tau$)

also vanishes on this subinterval so z is constant there: the value of $z(\xi,\tau)$ depends only on (ξ,σ). In this case, the domain of σ is $[0,\kappa^2]$ and, henceforth omitting the $\tilde{}$, (4.5) becomes simply

$$z(\cdot,\sigma) := \int_0^\sigma u\bar{v}\,d\tilde{\sigma}. \tag{4.6}$$

Apart from the name of the variable ($\sigma \leftrightarrow \tau$), we observe that this is identical to the *original* problem for $\gamma = 0$ with initial data giving

$$K(\tau) = \{1 \text{ for } 0 \le \tau \le \kappa^2; 0 \text{ else}\}.$$

Note that use of (4.6) means that we have the boundary condition

$$z = 0 \quad \text{at } \sigma = 0, \tag{4.7}$$

corresponding to (1.2).

In view of (4.4), $\mathbf{u}$ must have the form

$$u = e^{i\vartheta}\cos\varphi, \qquad v = e^{i\vartheta}\sin\varphi \tag{4.8}$$

with ϑ,φ real. Assume ϑ is independent of ξ — first as an *ansatz*, but then confirmed by our subsequent calculations. We then see that (2.5), (4.6) are equivalent to the requirement that $z = \varphi_\xi$ and

$$\varphi_{\xi\sigma} = u\bar{v} = \tfrac{1}{2}\sin 2\varphi. \tag{4.9}$$

If we set $t := \sigma + \xi$ and $x := \sigma - \xi$, then (4.9) becomes

$$2\varphi_{tt} - 2\varphi_{xx} = \sin 2\varphi, \tag{4.10}$$

i.e., 2φ satisfies the sine-Gordon equation. Conversely, if $2\varphi = 2\varphi(t,x)$ is any real solution of the sine-Gordon equation, then, for arbitrary real $\vartheta(\sigma)$,

$$\begin{aligned} u(\xi,\sigma) &:= e^{i\vartheta(\sigma)}\cos\varphi(\sigma+\xi,\sigma-\xi),\\ v(\xi,\sigma) &:= e^{i\vartheta(\sigma)}\sin\varphi(\sigma+\xi,\sigma-\xi),\\ z &:= [\varphi_t - \varphi_x](\sigma+\xi,\sigma-\xi) \end{aligned}$$

gives a solution of (1.1) for $\gamma = 0$ with $z \equiv \varphi_\xi$ real.

For this to be consistent with the boundary conditions (4.7) we are imposing on z, it is necessary that 2φ be a solution of the sine-Gordon equation satisfying

$$\varphi_t(t,x) \equiv \varphi_x(t,x) \quad \text{along the line: } t + x = 0. \tag{4.11}$$

While the sine-Gordon equation has nontrivial traveling wave solutions, we emphasize that those are all excluded by this constraint (4.11)—corresponding to (4.7) and so to our original boundary condition (1.2) at $\tau \to -\infty$.

5. Discrete approximation. In this section we consider the "obvious" discretizations (with respect to τ) of the system (2.5). For convenience, we restrict our attention to the case $\gamma = 0$ and take the system reduced as in Remark 4.4 so that $|u_0|^2 + |v_0|^2 \equiv 1$ for $0 \le \sigma \le \kappa^2$ and

$$\begin{cases} u' &= -zv \\ v' &= \bar{z}u \end{cases} \qquad \text{with } z(\cdot,\sigma) := \int_0^\sigma u\bar{v}\,d\tilde{\sigma}. \tag{5.1}$$

While much of our analysis here directly parallels that for the partial differential equation system, for this finite-dimensional approximation we have the advantage of local compactness and will be able to obtain a more complete description of the asymptotic behavior of solutions as $\xi \to \infty$. This may be viewed both as a theoretical complement to the results observed in computational simulation and for comparison with our less complete asymptotic analysis in the next section, as an indication of goals and conjectures for future work.

For the remainder of this section, we adopt the notation that

$$\begin{aligned}
\mathcal{H} &:= (\mathbb{C}^2)^J,\\
\mathbf{u} &:= (\mathbf{u}_1, \cdots, \mathbf{u}_J) \in \mathcal{H}, \qquad [\mathbf{u}_j := (u_j, v_j) \in \mathbb{C}^2],\\
\mathcal{H}_1 &:= \{\mathbf{u} \in \mathcal{H} : |\mathbf{u}_j|^2 := |u_j|^2 + |v_j|^2 = 1\},\\
\mathcal{S} &:= \{\mathbf{u}^0 \in \mathcal{H}_1 : u_j^0 = 0 \text{ or } v_j^0 = 0 \quad \text{for each } j = 1, \cdots, J,\\
U_j &:= \delta\Sigma_1^j |u_k|^2,\\
\nu &:= \max\{U_j/j\delta : j = 1, \cdots, J\}.
\end{aligned}$$

In general, we have $U_j = U_j(\cdot)$ for some particular solution $\mathbf{u}(\cdot)$ of (5.3), below, and ν will similarly relate to this; we could write explicitly $\nu := \nu(\mathbf{u})$ for $\mathbf{u} \in \mathcal{H}_1$ or $\nu := \nu(\xi; \mathbf{u}^0) := \nu(\mathbf{u}(\xi))$, with $\mathbf{u}(\cdot)$ satisfying (5.3) with initial data $\mathbf{u}^0$.

Assuming the nodes are equally spaced with respect to σ, we can then define $z_j \approx z(j\delta)$ by a discretized approximation to the integral

$$z_j := \delta\Sigma_1^j u_k \overline{v_k} = \delta u_j \overline{v_j} + z_{j-1}, \qquad z_0 := 0, \tag{5.2}$$

for $j = 1, \cdots, J$. Thus, we consider here the system of ordinary differential equations

$$\begin{aligned}
u_j' &= -z_j v_j\\
v_j' &= \overline{z_j} u_j\\
\text{with}\, u_j(0) &= u_j^0, \quad v_j(0) = v_j^0
\end{aligned} \tag{5.3}$$

for each $j = 1, \cdots, J$, using (5.2). For the initial conditions we assume, as earlier, that

$$|u_j^0|^2 + |v_j^0|^2 = 1 \quad \text{for } j = 1, \cdots, J.$$

The factor δ could be removed by rescaling ξ, but we will retain $\delta := \kappa^2/J$ here to remind us of the correspondence: $u_j(\xi) \approx u(\xi, j\delta)$, etc. We note that (5.3) is equivalent to

$$\begin{aligned}
u_j' &= -\delta |v_j|^2 u_j - \delta\zeta_j v_j,\\
v_j' &= \delta |u_j|^2 v_j + \delta\zeta_j u_j
\end{aligned} \tag{5.4}$$

with $\delta\zeta_j := z_{j-1}$.

We begin by asserting the set of "background" results.

LEMMA 5.1. *For each* $\mathbf{u}^0 \in \mathcal{H}$ *there is a unique global solution* $\mathbf{u}(\cdot) = \mathbf{u}(\cdot; \mathbf{u}^0)$ *of* (5.3)*, depending on* $\mathbf{u}^0$ *uniformly on bounded* ξ*-intervals. The functions* $u_j, \overline{u}_j, \cdots, \overline{z}_j$ *are all real-analytic functions of* ξ. *For* $\mathbf{u}^0 \in \mathcal{H}_1$*, we have* $\mathbf{u}(\xi) \in \mathcal{H}_1$ *for all* $\xi \geq 0$.

Proof. The arguments are straightforward parallels of those given above for Theorems 3.2, 3.4, and Remark 4.3. Details are left to the reader. □

LEMMA 5.2. *For $j = 1, \cdots, J$ we have*

$$(5.5) \qquad \begin{cases} \text{(i)} & [u_j \bar{v}_j]' = z_j \left[|u_j|^2 - |v_j|^2 \right], \\ \text{(ii)} & z_j' = \delta \Sigma_1^j z_k \left[|u_k|^2 - |v_k|^2 \right], \\ \text{(iii)} & -U_j' = |z_j|^2 + \delta^2 \Sigma_1^j |u_k \bar{v}_k|^2. \end{cases}$$

If, for $k = 1, \cdots, j$, we have $z_k(0) = 0$, then this persists for all ξ, and u_k, v_k are then constant (independent of ξ).

Proof. The formulas (5.5.i, ii) are direct from (5.3) and the final assertion follows; compare Corollary 4.2. Also from (5.3), for each k we have

$$\begin{aligned} -\delta(|u_k|^2)' &= \delta[\bar{u}_k(z_k v_k) + u_k \overline{z_k v_k}] \\ &= \overline{(z_k - z_{k-1})} z_k + \bar{z}_k (z_k - z_{k-1}) \\ &= |z_k|^2 - |z_{k-1}|^2 + |z_k - z_{k-1}|^2, \end{aligned}$$

since $z_k - z_{k-1} = \delta u_k \bar{v}_k$. Summing over $k = 1, \cdots, j$ gives (5.5.iii). □

LEMMA 5.3. *If (for some k) z_k is not identically zero, then (for each $j \geq k$) z_j can vanish at most on a discrete set (with no finite limit points) and U_j is strictly decreasing on every ξ-interval.*

Proof. By the real-analyticity noted in Lemma 5.1, it is only possible for z_j to vanish on a set with a finite limit point if $z_j \equiv 0$; else $|z_j|^2 > 0$ almost everywhere and (5.5) implies U_j strictly decreasing. To have $z_j \equiv 0$ we must either have $u_j \equiv 0$ or $v_j \equiv 0$; suppose the former, so $|v_j| \equiv 1$. Since (5.4) would then give $0 \equiv u_j' = -z_{j-1} v_j$, this is only possible if also $z_{j-1} \equiv 0$. Similarly, $v_j \equiv 0$ would also require $z_{j-1} \equiv 0$. Induction on the index completes the proof. □

LEMMA 5.4. *For arbitrary initial data in $\mathcal{H}_1$, we have each $z_j \to 0$ and $\mathbf{u} \to \mathcal{S}$ as $\xi \to \infty$.*

Proof. Since U_J is nonincreasing by (5.5) and is obviously bounded below by zero, we must have $[|z_j|^2 + \delta^2 \Sigma_1^j |u_k \bar{v}_k|^2]$ integrable. As we know that u_j, v_j, z_j are bounded, this has a bounded derivative and so must go pointwise to zero. In particular, this immediately gives $z_j \to 0$. Each component of $\mathbf{u}$ lives in the (compact) unit sphere of $\mathbb{C}^2$ so, setting $\varphi(u, v) := |u\bar{v}|$, convergence $\varphi(u, v) \to 0$ implies that $(u, v) \to \varphi^{-1}(\{0\}) = \{(u, v) \in \mathcal{H}_1 : u = 0 \text{ or } v = 0\}$. Thus, $\mathbf{u} \to \mathcal{S} = \{\text{each } u_j = 0 \text{ or } v_j = 0\}$ as asserted. □

LEMMA 5.5. *Let $\mathbf{u}(\cdot)$ be a solution of (5.3) such that $U_J(\xi_*) < \delta$ for some $\xi_* \geq 0$. Then $\mathbf{u}(\tilde{\xi}) \in \mathcal{I}_0$ for each $\tilde{\xi} \geq 0$, where*

$$(5.6) \qquad \mathcal{I}_0 := \{\mathbf{u}^0 \in \mathcal{H}_1 : \text{ each } u_j \to 0 \text{ as } \xi \to \infty\}.$$

The set $\mathcal{I}_0$ is open in $\mathcal{H}_1$.

Proof. For each j, the assumption precludes having $|v_j| \to 0$ since U_J is nonincreasing and $|u_j| = 1$ implies $U_J \geq \delta$; by Lemma 5.4, this ensures $u_j \to 0$. By the definition, this gives $\mathbf{u}^0 \in \mathcal{I}_0$ and, of course, each $\mathbf{u}(\tilde{\xi} \in \mathcal{I}_0$. To see that $\mathcal{I}_0$ is open, consider any $\tilde{\mathbf{u}}^0 \in \mathcal{I}_0$ so each $\tilde{u}_j \to 0$. We may then find ξ_* such that $\tilde{U}_J(\xi_*) < \delta/2$. By Lemma 5.1 we have uniform continuity on bounded ξ-intervals for the dependence of solutions of (5.3) on the initial data, so there is a neighborhood of $\tilde{\mathbf{u}}^0$ giving $U_J(\xi_*) < \delta$. The first part of this proof then shows this neighborhood is in $\mathcal{I}_0$. □

THEOREM 5.6. *For arbitrary initial data in $\mathcal{H}_1$ we have convergence $\mathbf{u} \to \mathbf{u}^*$ (at an asymptotically exponential rate) as $\xi \to \infty$ for some steady state solution $\mathbf{u}^* \in \mathcal{S}$. Thus, for each $j = 1, \cdots, J$ we have either* Case 1: *$u_j \to 0$ and $v_j \to v_j^*$ (with $|v_j^*| = 1$) or* Case 2: *$v_j \to 0$ and $u_j \to u_j^*$ (with $|u_j^*| = 1$); in particular, we always have* Case 1 *for $j = 1$.*

Proof. We will proceed inductively in j, taking the system in the form (5.4) with the index j suppressed so

$$(5.7) \qquad \begin{cases} \text{(i)} \quad u' = -\delta(|v|^2 u + \zeta v), \\ \text{(ii)} \quad v' = \ \ \delta(|u|^2 v + \bar{\zeta} u), \end{cases}$$

and with the inductive assumption that we know

$$(5.8) \qquad |\zeta(\xi)| \le C e^{-\mu\delta\xi}$$

for $C = C_\mu$ and arbitrary $0 < \mu < 1$. By Lemma 5.4 we know that $u\bar{v} \to 0$ as $\xi \to \infty$, so we must be in one of the two possible cases—which we then consider separately to show the exponential decay rate for the appropriate component. With (4.4) and the inductive hypothesis on $\zeta = \zeta_j$, this completes the induction by giving the corresponding exponential decay for ζ_{j+1}. Returning to (5.3) with knowledge of exponential decay of z_j, integrability of the derivative gives existence of a specific limit for the nonvanishing component as well.

Case 1 $\boxed{u \to 0}$. Fix $\mu < 1$. Set $y := |u|^2$ so $y' = 2\,\mathrm{Re}\,\bar{u}u' = -2\delta[|v|^2 y + \mathrm{Re}\,\zeta\bar{u}v$, using (5.7.i) and note that $\mathrm{Re}\,\zeta\bar{u}v \le |\zeta||v|\sqrt{y} \le \varepsilon|v|^2 y + |\zeta|^2/4\varepsilon$. Now choose $0 < \varepsilon < 1 - \mu$ and use (5.8) with μ replaced by $\tilde{\mu} := \mu + \varepsilon < 1$. By (4.4), if $u \to 0$, then $|v| \to 1$ so (noting that $\mu/(1-\varepsilon) < 1$) there exists $\tilde{\xi}$ such that $(1-\varepsilon)|v(\xi)|^2 \ge \mu$ for $\xi \ge \tilde{\xi}$. Thus, we have

$$y'(\xi) \le -2\delta\mu y + (\delta C^2/2\varepsilon)e^{-2(\mu+\varepsilon)\delta\xi}$$

for $\xi \ge \tilde{\xi}$. The Gronwall inequality and some simple manipulation then give the desired estimate for $y = |u|^2$:

$$\begin{aligned} |u(\xi)|^2 &\le e^{-2\mu\delta(\xi-\tilde{\xi})}|u(\tilde{\xi})|^2 + \frac{\delta C^2}{2\varepsilon}\int_{\tilde{\xi}}^{\xi} e^{-2\mu\delta(\xi-\hat{\xi})}e^{-2(\mu+\varepsilon)\hat{\xi}}\,d\hat{\xi} \\ &\le \left[e^{2\mu\delta\tilde{\xi}}|u(\tilde{\xi})|^2 + \frac{\delta C^2}{2\varepsilon}\int_{\tilde{\xi}}^{\infty} e^{-2\varepsilon\hat{\xi}}\,d\hat{\xi}\right]e^{-2\mu\delta\xi} \\ &=: \tilde{C}^2 e^{-2\mu\delta\xi} \end{aligned}$$

for $\xi \ge \tilde{\xi}$; this also applies to all $\xi \ge 0$ with a modification of the $\tilde{C}$.

Case 2 $\boxed{v \to 0}$. Again, fix $\mu < 1$ and now set $y := |v|^2$ and choose $0 < 2\varepsilon < 1 - \mu$. Much as above, we get

$$y'(\xi) \ge 2\delta(\mu - \varepsilon)y - (\delta C^2/2\varepsilon)e^{-2\mu\delta\xi}$$

for ξ large enough ($\xi \ge \tilde{\xi}_0$) that $(1-\varepsilon)|u(\xi)|^2 \ge \mu - \varepsilon$. Applying the (reversed)

Gronwall inequality we then obtain, for any $\xi > \tilde{\xi} \geq \tilde{\xi}_0$,

$$\begin{aligned} y(\xi) &\geq e^{2(\mu-\varepsilon)\delta(\xi-\tilde{\xi})} y(\tilde{\xi}) - \frac{\delta C^2}{2\varepsilon} \int_{\tilde{\xi}}^{\xi} e^{2(\mu-\varepsilon)\delta(\xi-\hat{\xi})} e^{-2\mu\hat{\xi}}\, d\hat{\xi} \\ &= e^{2(\mu-\varepsilon)\delta(\xi-\tilde{\xi})} \left[y(\tilde{\xi}) - \left(\frac{\delta C^2}{2\varepsilon} \int_{\tilde{\xi}}^{\xi} e^{-2\varepsilon\delta(\hat{\xi}-\tilde{\xi})}\, d\hat{\xi} \right) e^{-2\mu\delta\tilde{\xi}} \right] \\ &\geq e^{2(\mu-\varepsilon)\delta(\xi-\tilde{\xi})} \left[y(\tilde{\xi}) - \frac{C^2}{4\varepsilon} e^{-2\mu\delta\tilde{\xi}} \right]. \end{aligned}$$

It follows that we must have $|v(\tilde{\xi})| \leq (C/2\varepsilon)e^{-\mu\delta\tilde{\xi}}$ for all $\tilde{\xi} \geq \tilde{\xi}_0$ (hence, for all $\tilde{\xi} \geq 0$ with a modified coefficient) or the Gronwall estimate would give $y(\xi) \to \infty$, contradicting the case that $v \to 0$.

In view of Lemmas 5.3, 5.4, and 5.5 and the experience with computational experimentation with a variety of sets of initial data, it is plausible to conjecture that one always has $u_j \to 0$ as $\xi \to \infty$ unless $z_k \equiv 0$ for each $k = 1, \cdots, j$. This is false!

THEOREM 5.7. *Let* $\mathbf{u}^*$ *be any stationary solution such that* $u_j = 0$ *for some* $j < J$. *Then there is a nonstationary solution* $\mathbf{u}$ *such that* $\mathbf{u}(\xi) \to \mathbf{u}^*$ *as* $\xi \to \infty$.

Proof. For each j we have either:

Case 1 $\boxed{u_j^* = 0 \text{ so } |v_j^*| = 1}$. Set

$$u_j = v_j^* \sin\alpha_j, \quad v_j = v_j^* \cos\alpha_j, \quad \chi_j := -1$$

so $(v_j^* \cos\alpha_j)\alpha_j' = u_j' = -z_j v_j^* \cos\alpha_j$ or:

Case 2 $\boxed{v_j^* = 0 \text{ so } |u_j^*| = 1}$. Set

$$u_j = u_j^* \cos\alpha_j, \quad v_j = u_j^* \sin\alpha_j, \quad \chi_j := +1$$

so $(u_j^* \cos\alpha_j)\alpha_j' = v_j' = \overline{z_j} u_j^* \cos\alpha_j$.

In either case, we have $u_j\overline{v_j} = \frac{1}{2}\sin 2\alpha_j$ whence, after scaling ξ for convenience to permit the omission of a factor δ from our definition of z_j, we must have

$$\text{(5.9)} \qquad \alpha_j' = \chi_j z_j, \qquad z_j = \Sigma_{k=1}^{j} \tfrac{1}{2} \sin 2\alpha_k$$

(provided $\cos 2\alpha_j \neq 0$) for $j = 1, \cdots, J$. Note that by restricting our attention here to the real case, we have isolated stationary solutions: each $\alpha_j = \pm\nu\pi$. Our notation ensures that any nonstationary solution $\alpha = [\alpha_1, \cdots, \alpha_J]$ of (5.9) for which $\alpha(\xi) \to 0$ corresponds to a nonstationary solution $\mathbf{u}$ of (5.4) for which $\mathbf{u} \to \mathbf{u}^*$ as $\xi \to \infty$. The linearization of (5.9) around $\alpha = 0$ is just

$$\text{(5.10)} \qquad \alpha' = \mathbf{A}\alpha \quad \text{with } \mathbf{A} := \begin{pmatrix} \chi_1 & 0 & 0 & \cdots \\ \chi_2 & \chi_2 & 0 & \cdots \\ \chi_3 & \chi_3 & \chi_3 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

Since $\mathbf{A}$ is lower triangular, we see that its eigenvalues (with multiplicity) are the diagonal elements $\{\chi_1, \cdots, \chi_J\}$ and if any of these is -1, we have a corresponding eigenvector giving an exponentially decaying solution. Since there are no purely imaginary eigenvalues, the linearized problem (5.10) gives the local splitting into stable and unstable manifolds whence the nonlinear problem (5.9) must also have an exponentially decaying solution near zero—asymptotically behaving precisely like the solution of (5.10). □

Remark 5.8. While we have carried through the analysis for the discretization corresponding to (5.2), we could equally well have considered a trapezoidal rule approximation to (4.6):

$$z_j := \delta\Sigma_1^j(u_{k-1}\overline{v_{k-1}} + u_k\overline{v_k})/2. \tag{5.11}$$

With trivial modification, we would then have obtained for that setting the same results obtained above. Indeed, (5.11) gives the *identical* system (5.4) if we were to scale ξ by 2 and set $\zeta_j := 2\sum_{k=1}^{j-1} u_k\overline{v_k}$, instead.

6. Stationary solutions. We now introduce the set $\mathcal{S}$ of all stationary solutions. Note that $\mathbf{u} \in \mathcal{S}$ means $\mathbf{u}' \equiv 0$ so $z \equiv 0$ on $\mathbb{R}$. By (2.2), this corresponds to having $u\overline{v} = 0$ almost everywhere; note from this that $\mathcal{S}$ is entirely independent of γ. It is easy to see that $\mathcal{S}$, $\mathcal{S}_0 := \{\mathbf{u} \in \mathcal{S} : u = u_0 \equiv 0\}$ and $\mathcal{S}\backslash\mathcal{S}_0 := \{\mathbf{u} \in \mathcal{S} : u_0 \not\equiv 0\}$ are each uncountable arc-wise connected sets in $\mathcal{H}_1$—even if we were to restrict attention to the "purely real" case, taking $\mathcal{H} := L^2(\mathbb{R} \to \mathbb{R}^2)$, or to factor out the action of the group $\mathcal{G} := \{g_\vartheta : \mathbf{u} \mapsto e^{i\vartheta(\tau)}\mathbf{u}\}$.

From the characterization $u\overline{v} \equiv 0$ we observe that, for each $\mathbf{u} \in \mathcal{S}$, we can partition[3] $\mathbb{R}$, independently of ξ in view of (1.4), as a disjoint union $\mathcal{A} \cup \mathcal{B}$ such that

$$\begin{cases} |u| = K,\ v = 0 & \text{on } \mathcal{A}, \\ u = 0,\ |v| = K & \text{on } \mathcal{B}. \end{cases} \tag{6.1}$$

We now wish to consider the linearization around a stationary solution $\mathbf{u}^* \in \mathcal{S}$ so that $z^* \equiv 0$ in (3.3). We fix $\mathcal{A}, \mathcal{B}$, and $K(\cdot)$ corresponding to $\mathbf{u}^*$ and note that (3.3) now gives

$$u' = -v^*z = \begin{cases} 0 & \text{on } \mathcal{A}, \\ -v^*z & \text{on } \mathcal{B}, \end{cases} \qquad \overline{v}' = \overline{u^*}z = \begin{cases} \overline{u^*}z & \text{on } \mathcal{A}, \\ 0 & \text{on } \mathcal{B}, \end{cases} \tag{6.2}$$

$$e^{\gamma\tau}z = \int_{-\infty}^{\tau} e^{\gamma\tilde{\tau}} \left\{ \begin{matrix} u^*\overline{v} & \text{on } \mathcal{A} \\ \overline{v^*}u & \text{on } \mathcal{B} \end{matrix} \right\} d\tilde{\tau}.$$

Now introduce

$$K^2 w := \begin{cases} -e^{\gamma\tau}u^*\overline{v} \quad (\text{so } v = -e^{-\gamma\tau}u^*\overline{w}) & \text{on } \mathcal{A}, \\ e^{\gamma\tau}\overline{v^*}u \quad (\text{so } u = e^{-\gamma\tau}\overline{v^*}w) & \text{on } \mathcal{B} \end{cases} \tag{6.3}$$

with w itself irrelevant, where $K = 0$; e.g., we may set $w := 0$ there. Then, noting that $\mathbf{u}^*$ is independent of ξ with $|v^*| = K$ on $\mathcal{A}$ and $|u^*| = K$ on $\mathcal{B}$, (6.2) gives (where $K \neq 0$)

[3] Any τ for which $K(\tau) = 0$ so $u = v = 0$ may arbitrarily be assigned either to $\mathcal{A}$ or to $\mathcal{B}$; the partition is unique to within $d\sigma$-nullsets.

$$(6.4)\qquad w' = \frac{1}{K^2}\left\{\begin{matrix}(-e^{\gamma\tau}u^*)(\overline{u^*}z) & \text{on } \mathcal{A}\\ (e^{\gamma\tau}\overline{v^*})(-v^*z) & \text{on } \mathcal{B}\end{matrix}\right\}$$

$$= -e^{\gamma\tau}z = \int_{-\infty}^{\tau}\left\{\begin{matrix}-e^{\gamma\tau}u^*\overline{v} & \text{on } \mathcal{A}\\ -e^{\gamma\tau}\overline{v^*}u & \text{on } \mathcal{B}\end{matrix}\right\}d\tilde{\tau}.$$

If we define $\chi : \mathbb{R} \to \{\pm 1\}$ by

$$(6.5)\qquad \chi := \{+1 \text{ on } \mathcal{A};\ -1 \text{ on } \mathcal{B}\}$$

and change variables to think of w as a function of (ξ, σ), using (2.1) so $K^2 d\tilde{\tau} = d\tilde{\sigma}$, then (6.4) takes the simple form

$$(6.6)\qquad w' = \int_0^{\sigma} \chi w \, d\tilde{\sigma}$$

or, equivalently,

$$(6.7)\qquad w_{\xi\sigma} = \chi w \quad \left(= \left[-e^{-\gamma\tau}z\right]_{\sigma}\right) \quad w(0,\cdot) = w_0 \in L^1_{d\sigma}.$$

Note that this formulation omits the irrelevant values of w for the set of τ where $K(\tau) = 0$, which disappears when we write things in terms of σ. Since the operator: $w \mapsto \int_0^{\sigma} \chi w \, d\tilde{\sigma}$ is certainly bounded, the solution operator $\mathbf{S}_{\xi} : w_0 \mapsto w(\xi, \cdot)$ for (6.6) forms a group on L^1. Alternatively, we might note that Theorem 3.4 ensures integrability of $K^2 w$ with respect to τ and so integrability of w with respect to σ.

We now restate the results of this discussion as a lemma without further proof.

LEMMA 6.1. *Let $\mathbf{u}^* \equiv \mathbf{u}_0^*$ be given in $\mathcal{S}$, determining $K(\cdot)$, $\sigma(\cdot)$ as in* (2.1) *and χ as in* (6.5); *let $\mathbf{u}$ be a linearized perturbation, obtained from* (3.3), *corresponding to a perturbation $\mathbf{u}_0 \in \mathcal{H}$ of the initial conditions $\mathbf{u}_0^*$. Then,*

$$(6.8)\qquad u = \left\{\begin{matrix}u_0,\\ e^{-\gamma\tau}v^*w,\end{matrix}\right. \qquad v = \left\{\begin{matrix}-e^{-\gamma\tau}u^*\overline{w} & \textit{on } \mathcal{A},\\ v_0 & \textit{on } \mathcal{B},\end{matrix}\right.$$

where w, viewed as a function of (ξ, σ), satisfies (6.7) *and has initial data w_0 at $\xi = 0$ given by*

$$K^2 w_0 := \left\{\begin{matrix}-e^{\gamma\tau}u^*\overline{v_0} & \textit{on } \mathcal{A},\\ e^{\gamma\tau}\overline{v^*}u_0 & \textit{on } \mathcal{B}.\end{matrix}\right.$$

Note that w_0 is necessarily integrable with respect to σ.

LEMMA 6.2. *When χ is constant $(\chi \equiv \pm 1)$, the solution of* (6.7) *is given explicitly by*

$$(6.9)\qquad w(\xi, \sigma) := w_0(\sigma) + \xi \int_0^{\sigma} w_0(\tilde{\sigma})\Psi'(r)\, d\tilde{\sigma},$$

where we set $r := \xi[\sigma - \tilde{\sigma}]$ and have

$$(6.10)\qquad \Psi(r) := \left\{\begin{matrix}J_0(2\sqrt{r}) & \textit{for } \chi \equiv -1 \ (\mathbf{u}^* \in \mathcal{S}_0),\\ I_0(2\sqrt{r}) & \textit{for } \chi \equiv +1,\end{matrix}\right.$$

where J_0 is the usual Bessel function of first kind and I_0 is the modified Bessel function: $I_0(s) := J_0(is)$.

Proof. We begin with the *ansatz* that $e^{-\gamma\tau}z$ can be obtained from w_0 by a convolution with respect to σ:

$$-e^{-\gamma\tau}z = \chi w_0 * \Psi(\xi\cdot) := \chi\int_0^\sigma w_0(\tilde\sigma)\Psi(r)\,d\tilde\sigma$$

with $r := \xi[\sigma - \tilde\sigma]$. Differentiating with respect to σ then gives[4] (6.9)—provided we require $\Psi(0) = 1$ so as to have the correct condition at $\xi = 0$. Next, differentiating first with respect to ξ and then with respect to σ gives

$$\begin{aligned} w_\xi &= \int_0^\sigma w_0(\tilde\sigma)\Psi'(r)\,d\tilde\sigma + \int_0^\sigma w_0(\tilde\sigma)[r\Psi''(r)]\,d\tilde\sigma \\ &= \int_0^\sigma w_0(\tilde\sigma)[r\Psi'(r)]'\,d\tilde\sigma, \\ w_{\xi\sigma} &= w_0(\sigma)[r\Psi'(r)]'\,|_{r=0} + \xi\int_0^\sigma w_0(\tilde\sigma)[r\Psi'(r)]''\,d\tilde\sigma \\ &= \chi\left[w_0(\sigma) + \xi\int_0^\sigma w_0(\tilde\sigma)\Psi'(r)\,d\tilde\sigma\right] \end{aligned}$$

with the final equality coming from (6.7). We obtain this last, provided that

$$[r\Psi'(r)]'\,|_{r=0} = \chi, \qquad [r\Psi'(r)]'' = \chi\Psi'(r).$$

The differential equation gives $([r\Psi'(r)]' - \chi\Psi(r)) =$ constant and evaluating at $r = 0$ shows this constant must be zero. If we now set $\Psi(r) =: \Phi(s)$ with $s := 2\sqrt{r}$, this gives

$$s^2\Phi'' + s\Phi' - \chi s^2\Phi = 0, \qquad \Phi(0) = 1.$$

For $\chi = -1$, this is Bessel's equation with parameter $a = 0$ and the normalization gives $\Phi(s) = J_0(s)$; for $\chi = +1$, we then get $\Phi(s) = J_0(is) =: I_0(s)$.

Note that $d\Psi(r)/dr = \Phi'(2\sqrt{r})/\sqrt{r}$ so, since

$$J_0'(s) = -J_1(s) \qquad I_0'(s) = iJ_0'(is) = -iJ_1(is) =: I_1(s),$$

we have

$$\Psi'(r) = \begin{cases} -J_1(2\sqrt{r})/\sqrt{r} & \text{for } \chi = -1, \\ I_1(2\sqrt{r})/\sqrt{r} & \text{for } \chi = +1 \end{cases} \tag{6.11}$$

for use in (6.9). Since $J_0(z)$ is an *even* analytic function of z, it is also analytic in $\sqrt{z}$ so Ψ is analytic (a fortiori bounded) near zero and so on any bounded interval. Thus, (6.9) makes sense for all $d\sigma$-integrable w_0. □

Remark 6.3. What information can we draw from this in the case of $\mathbf{u}^* \in \mathcal{S}_0$ (so $\chi \equiv -1$)? We observe, first, that the integral term in (6.9) is a convolution so, using L^1 norms,

$$\|w(\xi,\cdot)\| \le \|w_0\|\,[1 + \|\xi\Psi'\|]\,.$$

[4] It is at this point already that we need the assumption: $\chi \equiv$ constant.

Here we have, setting $s^2 = \xi\sigma$,

$$\|\xi\Psi'\| := \int_0^{\kappa^2} |\Psi'(\xi\sigma)|\,\xi d\sigma = 2\int_0^{\kappa\sqrt{\xi}} |J_1(2s)|\,ds,$$

and since $J_1(s)$ decays like $1/\sqrt{s}$, we see that we have $\|\xi\Psi'\| = \mathcal{O}(\xi^{1/4})$ so, at worst, we always have

$$\|w(\xi,\cdot)\|_{L^1} = \mathcal{O}(\xi^{1/4}) \quad \text{as } \xi \to \infty. \tag{6.12}$$

On the other hand, if we are considering perturbations for which $w_0 \in BV$ (bounded variation) so that it is justifiable to integrate by parts in (6.9), then we obtain

$$w(\xi,\sigma) = w_0(0)J_0(2\sqrt{\xi\sigma}) + \int_0^{\sigma} J_0(2\sqrt{\xi(\sigma-\tilde{\sigma})})\,dw_0(\tilde{\sigma}). \tag{6.13}$$

The integral term on the right can be estimated in the same way as for (6.12) to give $\mathcal{O}(\xi^{-1/4})$ decay. The first term goes to zero pointwise in σ as $\xi \to 0$ at a rate $\mathcal{O}(\xi^{-1/4})$. This is not uniform, but can certainly be integrated in σ to give a decay rate

$$\|w(\xi,\cdot)\|_{L^1} = \mathcal{O}(\xi^{-1/4}) \quad \text{as } \xi \to \infty \tag{6.14}$$

in this case.

Clearly, even as "linearized stability," this is far weaker than the results we have for the discretized setting, corresponding to Lemma 5.5 and Theorem 5.6. Nevertheless, it is as strong a result as we have been able to obtain here. That the result is weaker is certainly related to the fact that $\mathcal{S}_0$ is not isolated from other stationary solutions, but we might still hope to improve this. Indeed, if (6.12) could be improved to give boundedness as $\xi \to \infty$ for each initial $w_0 \in L^1(0,\kappa^2)$, then a simple argument would show decay for all w_0. So far we do not know whether this is true and, further, note that this linearized stability by itself would not show $\mathbf{u} \to \mathcal{S}_0$ (locally) for the nonlinear problem.

Remark 6.4. We next consider the case of $\mathbf{u}^* \in \mathcal{S}\backslash\mathcal{S}_0$ so $\mathcal{A}$ is nonempty. We are seeking here to demonstrate instability, so it is only necessary to construct special examples. Suppose $\mathcal{A}$ contains an interval $[\sigma_-,\sigma_+]$ and we take the perturbation $\mathbf{u}_0$ so $w_0 \equiv 1$ on this interval and vanishes otherwise. This effectively lets us take $\sigma_- = 0$ with no loss of generality. Thus, at least for σ in the interval, we are considering (6.7) with $\chi \equiv +1$ and Lemma 6.2 applies. Integrating by parts as for (6.13), we then have

$$w(\xi,\sigma) = I_0(2\sqrt{\xi\sigma}) \quad \text{for } 0 < \sigma < \sigma_+$$

and, since I_0 grows exponentially, we have instability: growth of $w(\xi,\cdot)$ which is exponential in $\xi^{1/2}$. We remark that this is consistent with having $\|w\| = \mathcal{O}(e^{\varepsilon\xi})$ for arbitrarily small $\varepsilon > 0$, as is suggested by the fact that the Volterra operator on the right of (6.6) has spectrum $\{0\}$.

What does this tell us for the nonlinear problem? Using the fact that, as observed in Remark 4.3, the solution map has a locally bounded second derivative we can show that *for arbitrarily large M and arbitrarily small $\varepsilon > 0$ there exist solutions of* (2.5) *which initially differ from $\mathbf{u}^*$ by less than ε but at a later time differ by more than $M\varepsilon$, assuming $M\varepsilon$ is not too big.*

Again, as in Remark 6.3, this is not very much. It certainly is enough, however, to guarantee that the exponential factor in (3.2) cannot be omitted to give the Lipschitz continuity uniform in ξ.

7. Asymptotic behavior. In this section we consider the asymptotic behavior of solutions of the system (2.5) as $\xi \to \infty$. We will assume that the reduction of §4 has been made, if necessary, so in (2.1) we have $K(\tau) \equiv 1$ for $\tau \in [0,1]$ with everything vanishing for $\tau \notin [0,1]$ whence we have (4.5) and (4.4). While we might conjecture for this context essentially the same results which we obtained for the discretized system in the previous section, we have so far not been able to carry out this program completely. Our results here are primarily the consequences of (4.1).

Remark 7.1.

DEFINITION. A function $\mathbf{v} : \mathbb{R}_+ \to \mathcal{X}$ will be called **recurrent** (for some ξ_0) if there is a sequence $\xi_n \to \infty$ for which $\|\mathbf{v}(\xi_n) - \mathbf{v}(\xi_0)\| \to 0$.

Clearly, every periodic function is recurrent for arbitrary ξ_0. Following Bohr, $\mathbf{v}$ is *almost periodic* on $\mathbb{R}_+$ if, for any $\varepsilon > 0$, there exists $\ell(\varepsilon)$ such that (with $\tilde{\xi}$ arbitrary) $\|\mathbf{v}(\xi) - \mathbf{v}(\xi_\varepsilon)\| \le \varepsilon$ for some $\tilde{\xi} < \xi_\varepsilon < \tilde{\xi} + \ell(\varepsilon)$ and all $\xi \in \mathbb{R}_+$; clearly, this also implies recurrence for arbitrary ξ_0. This would include sums of (incommensurately) periodic functions: if $\mathbf{v} := \sum_j \mathbf{v}_j$ (where each $\mathbf{v}_j$ is continuous with period ξ_j and $\sum_j \sup_\xi |\mathbf{v}_j|$ convergent); then it is easily seen to be almost periodic, using the number-theoretic result that we can always find positive integers q and $\{n_j\}$, making $|q - n_j\xi_j|$ arbitrarily small simultaneously for $j = 1, \cdots, J$ [6, Thm. 201] every "positive ray" $q[1/\xi_1, \cdots, 1/\xi_J]$ passes arbitrarily close to integer lattice points in $\mathbb{R}_+^J$ for infinitely many integers q].

Finally, we note that, for $\mathbf{v}$ satisfying an autononomous ODE, if we were to have $\|\mathbf{v}(\xi_n) - \mathbf{v}(\xi_0)\| \to 0$ for any sequence $\{\xi_n\}$ bounded away from ξ_0, then we would have recurrence at ξ_0. To see this when $\{\xi_n\}$ is bounded, extract a subsequence converging to some $\xi_1 \ne \xi_0$ and observe that continuity gives $\mathbf{v}(\xi_1) = \mathbf{v}(\xi_0)$ whence, assuming uniqueness for the ODE, $\mathbf{v}$ would necessarily be periodic with period $|\xi_1 - \xi_0|$.

THEOREM 7.2. *Under the hypotheses of Lemma* 4.1 *and taking the system reduced as in the previous section, if* $\mathbf{u}$ *is recurrent (for some* ξ_0*), then it is stationary:* $z \equiv 0$ *so* $\mathbf{u}$ *independent of* ξ.

Proof. By (4.1.ii), for each τ and for $\xi_n - \xi_0 \ge \delta > 0$ we have

$$\int_{\xi_0}^{\xi_0+\delta} |z(\cdot,\tau)|^2 \le \int_0^1 |v(\xi_n,\cdot)|^2 - \int_0^1 |v(\xi_0,\cdot)|^2 \le \sqrt{2\tau}\|\mathbf{u}(\xi_n,\cdot) - \mathbf{u}(\xi_0,\cdot)\| \to 0,$$

which gives $z \equiv 0$ on $[\xi_0, \xi_0 + \delta] \times [0,1]$ — and so everywhere, as in Corollary 4.2, giving stationarity of $\mathbf{u}$ as asserted. □

THEOREM 7.3. *Under the hypotheses of Lemma* 4.1 *and taking the system reduced as in the previous section, we always have* $z \in L^2(\mathbb{R}_+ \times [0,1])$ *and uniform convergence:* $z(\xi,\cdot) \to 0$ *as* $\xi \to \infty$.

Proof. It is convenient to set

$$U(\cdot,\tau) := \int_0^\tau |u|^2, \qquad V(\cdot,\tau) := \int_0^\tau |v|^2. \tag{7.1}$$

From (4.4) we see that $0 \le U, V \le \tau$ and, also using (4.1), we see that each is uniformly Lipschitzian (jointly in ξ, τ) with $U' = -|z|^2$, $V' = |z|^2$ so U is nonincreasing in ξ and V nondecreasing. For each (fixed) τ, we have

$$\begin{aligned}\int_\xi^{\tilde{\xi}} |z(\cdot,\tau)|^2 &= U(\xi,\tau) - U(\tilde{\xi},\tau) \le U(\xi,\tau) \le \tau \\ &= V(\tilde{\xi},\tau) - V(\xi,\tau) \le V(\tilde{\xi},\tau) \le \tau.\end{aligned}$$

So, taking $\xi = 0$ and letting $\tilde{\xi} \to \infty$, we see that we have $\|z(\cdot,\tau)\| \le \sqrt{\tau}$ (this is the $L^2(\mathbb{R}_+)$-norm) whence $\|z\| \le 1/\sqrt{2}$. (Here, this is the $L^2(\mathbb{R}_+ \times [0,1])$-norm.) Using the bounds $0 \le |u|^2, |v|^2 \le 1$ in (4.1.iii), we have $|z'| \le \sqrt{\tau}\|z\|$ so $\|z'\| \le \|z\|/\sqrt{2}$; thus

$$\left|\left(\|z\|^2\right)'\right| = 2\left|\operatorname{Re}\int_0^1 \bar{z}z'\right| \le \sqrt{2}\,\|z\|^2.$$

Then $(\|z\|^2)'$ is integrable on $\mathbb{R}_+$ whence $\|z\|^2$ has a limit as $\xi \to \infty$, necessarily zero almost everywhere in τ since $z \in L^2(\mathbb{R}_+ \times [0,1])$. This gives $z(\xi,\cdot) \to 0$ in $L^2(0,1)$-norm. Since $z(\xi,\cdot)$ stays in a compact subset of $C[0,1]$, as we have noted in the previous section, this is actually uniform convergence. □

Remark 7.4. Since the set $\mathcal{S}$ of stationary solutions is characterized by having $z \equiv 0$, it would be tempting to conclude, from the uniform convergence above, that it is a global attractor, i.e., that we must necessarily have $\mathbf{u} \to \mathcal{S}$; indeed, computation suggests the stronger conjecture that we have $\mathbf{u} \to \mathcal{S}_0$ $(u \to 0)$ as $\xi \to \infty$ for all $\mathbf{u}_0 \in \mathcal{U}_1$ — except, of course, $\mathcal{S}\backslash\mathcal{S}_0$. We do note, however, that this cannot follow simply from Theorem 7.3 since, e.g., there exist sequences like $\mathbf{u}_j(\tau) := (\cos j\pi\tau, \sin j\pi\tau)$ for which we have $|z_j(\tau)| \le 1/4\pi j \to 0$, but $\|\mathbf{u}_j - \mathcal{S}\| = 2\sqrt{\pi - 2} \not\to 0$. (Of course, this example has *not* been constructed by taking $\mathbf{u}_j := \mathbf{u}(\xi_j)$ with $\xi_j \to \infty$ for a solution $\mathbf{u}$ of (2.5).)

BUNSEN FLAMES AS STEADY SOLUTIONS OF THE KURAMOTO–SIVASHINSKY EQUATION*

DANIEL MICHELSON†

Abstract. Rotationally invariant steady solutions of the Kuramoto–Sivashinsky equation in two space dimensions are studied. Specifically, conical solutions, i.e., solutions which tend to a constant slope at infinity, are sought after. These solutions in combustion theory have a physical interpretation as the Bunsen flames. The technique of rigorous estimates by computer is used to prove the existence of such solutions for all physically reasonable values of the slopes.

Key words. Bunsen flames, Kuramoto–Sivashinsky equation, interval arithmetic, computer proofs

AMS(MOS) subject classifications. 34A34, 34A45, 35A50

1. Introduction.

The well-known Kuramoto–Sivashinsky equation is

$$u_t + \nabla^4 u + \nabla^2 u + \tfrac{1}{2}\,|\nabla u|^2 = 0, \qquad u = u(x,t). \tag{1.1}$$

In the context of the combustion theory, the function $u(x,t)$ represents the perturbation of the plane flame front that propagates in a fuel-oxygen mixture (e.g., see [6]).

In [5] we studied the steady solutions of this equation in one space dimension, i.e., solutions of the form

$$u(x,t) = -c^2 t + v(x), \qquad x \in R^1. \tag{1.2}$$

It was proved analytically that this equation has for small c periodic and quasi-periodic solutions and for large c a unique conical solution. For intermediate values of c it was shown numerically that besides the conical and periodic solutions there is, probably, a Cantor set of chaotic solutions. In this paper we consider equation (1.1) in the plane $x \in R^2$ and look for steady solutions of the form (1.2) with rotational symmetry, i.e., independent of the angle φ. The corresponding function $v(r)$ of the radius r satisfies the equation

$$\left(D^2 + \frac{1}{r}D\right)^2 v + \left(D^2 + \frac{1}{r}D\right) v = c^2 - \frac{1}{2}\left(Dv\right)^2, \qquad 0 \le r < \infty, \tag{1.3}$$

where D is the operator of differentiation with respect to r. With Dv denoted by y, the equation is reduced to a third-order nonautonomous ordinary differential equation (O.D.E.)

$$\left(D^2 + \frac{1}{r}D\right)\left(D + \frac{1}{r}\right) y + \left(D + \frac{1}{r}\right) y = c^2 - \frac{y^2}{2}, \qquad 0 \le r < \infty. \tag{1.4}$$

As $r \to \infty$ this equation approaches the one-dimensional limit

$$y''' + y' = c^2 - \frac{y^2}{2}, \quad y = y(x), \quad -\infty < x < +\infty. \tag{1.5}$$

Our ultimate goal is to study the set of all bounded solutions of (1.4). In this paper, however, we restrict ourselves only to so-called Bunsen flame profiles; namely, (1.1) with the right-hand side replaced by c^2 models a flame front generated by a circular gas burner. The constant c is proportional to the slope of the flame cone and is determined by the gas influx. A stationary radial solution of such a problem will obviously satisfy (1.4) with boundary condition

$$(1.6) \qquad y(0) = 0, \qquad \lim_{r \to +\infty} y(r) = -c\sqrt{2}.$$

The condition $y(0) = 0$ follows from the request that u is a weak solution of (1.1). Our numerical experiments with the partial differential equation (P.D.E.) (1.1) showed that the above stationary solutions of (1.1) are stable only for large values of c, namely, $c > 3$. For large c it is convenient to switch to the variables

$$(1.7) \qquad y_{\text{new}} = \frac{y_{\text{old}}}{(c\sqrt{2})}, \qquad r_{\text{new}} = \frac{r_{\text{old}} \cdot c^{1/3}}{2^{1/6}},$$

so that the new function $y(r)$ satisfies

$$(1.8) \qquad \left(D^2 + \frac{1}{r}D\right)\left(D + \frac{1}{r}\right)y + \alpha\left(D + \frac{1}{r}\right)y + y^2 - 1 = 0, \qquad 0 < r < \infty,$$

where

$$(1.9) \qquad \alpha = (\sqrt{2}/c)^{2/3}.$$

Our problem is now stated as follows: for small α prove the existence of bounded solutions of (1.8) that satisfy

$$(1.10) \qquad \lim_{r \to \infty} y(r) = -1.$$

On Fig. 1(a)–(c) one can see the graph of the solution $y(r)$ for $\alpha = 0$ in the planes yy', ry, and rv respectively. These graphs were obtained by a nonrigorous numerical experiment.

Unlike the autonomous equation (see [5]) the theoretical study of (1.8) runs into considerable difficulties. Because of the singularity at $r = 0$ the flow defined by (1.8) cannot be studied by topological methods. In addition, (1.8) does not possess a Lyapunov function even when $\alpha = 0$.

Lately a new approach of computer-assisted proofs in mathematics has come into being (e.g., see [1]–[4]). The idea is to do computations in interval arithmetic so that computer produces rigorous bounds of the true result. This idea could be used in solving O.D.E.'s on a bounded interval (e.g., see [3]). When the interval is unbounded, an asymptotic expansion should be constructed at infinity and bounds of the truncation error should be analytically derived. The main analytical difficulty is to maximize the domain of validity of the asymptotic expansion in order to reduce the finite interval on which the O.D.E. is solved numerically in interval arithmetic. Another problem is to stabilize the algorithm of numerical solution to prevent rapid exponential growth of the error.

Rewrite (1.8) as an autonomous system in R^4:

$$(1.11) \qquad d\bar{y}/dr = f(\bar{y}) = (y_2, y_3, 1 - y_1^2 - \alpha y_2 - 2y_3y_4 + y_2y_4^2 - y_1y_4^3, -y_4^2),$$

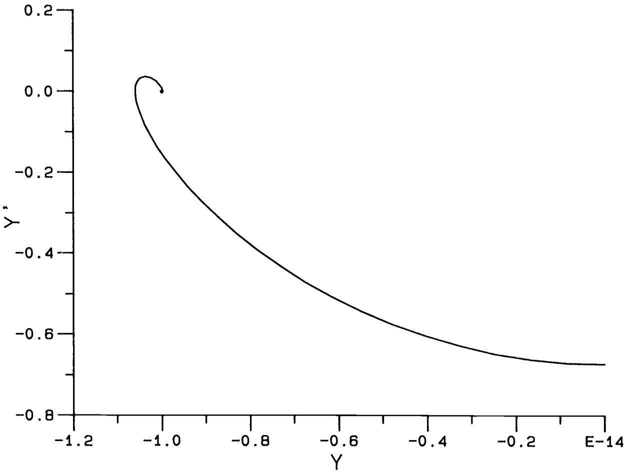

FIG. 1a. *The solution of* (1.8), (1.10) *with* $\alpha = 0$ *in the* yy' *plane.*

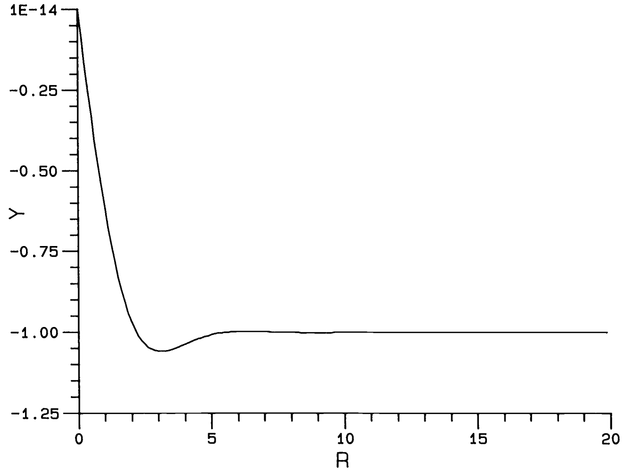

FIG. 1b. *The same curve in the ry plane.*

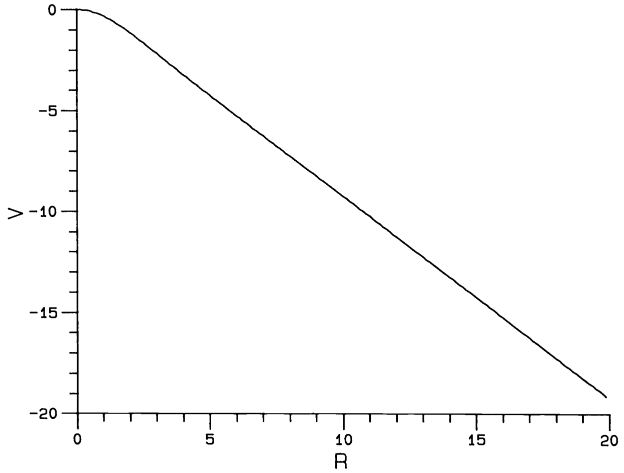

FIG. 1c. *The same curve in the rv plane.*

where

$$\bar{y} = (y_1, y_2, y_3, y_4) = (y, y', y'', r^{-1}). \tag{1.12}$$

The point $\bar{y}_0 = (-1, 0, 0, 0)$ is a critical point of the flow, and the differential $df(\bar{y}_0)$ besides the zero eigenvalue corresponding to the equation $y_4' = -y_4^2$ has a positive eigenvalue λ_1 and two eigenvalues $\lambda_2 = \bar{\lambda}_3$ with a negative real part. These eigenvalues are the roots of the characteristic equation

$$\lambda^3 + \alpha\lambda - 2 = 0. \tag{1.13}$$

Hence there exists a local three-dimensional central stable manifold M_{cs} of the flow that passes through the point $\bar{y}_0$. Since $y_4 = r^{-1} \to 0$ as $r \to \infty$, each point on M_{cs} that is sufficiently close to $\bar{y}_0$ is attracted by the flow to $\bar{y}_0$. Thus the surface M_{cs} replaces the asymptotic formula for large r. In a neighborhood of $r = 0$ the solution $y(r)$ of (1.8) could be expanded into converging power series

$$y(r) = \sum_{i=1}^{\infty} a_i r^{2i-1}, \tag{1.14}$$

where the slope

$$a_1 = y'(0) = s \tag{1.15}$$

is a free parameter which defines uniquely the rest of the coefficients a_i. We use this expansion to compute $\bar{y}(r_0)$, $r_0 = 1$. From that point, (1.8) is solved by the Taylor method with a small step $h = .125$ until the trajectory $\bar{y}(r)$ reaches the domain of existence of the manifold M_{cs}, say at $r = r_1$. Our algorithm described in §§2 and 4 takes into account the truncation and round-off errors. Thus, as we start with a point value of s, the final result $\bar{y}(r_1, s)$ is a small box in R^4. Suppose that for all $s \in I_{\Delta s} = [s_0 - \Delta s, s_0 + \Delta s]$:

$$\begin{aligned} &\text{(i) the boxes } \bar{y}(r_1, s) \text{ lie in the domain of existence of } M_{cs}, \\ &\text{(ii) the boxes } \bar{y}(r_1, s_0 - \Delta s) \text{ and } \bar{y}(r_1, s_0 + \Delta s) \text{ are separated by } M_{cs}. \end{aligned} \tag{1.16}$$

It follows then that there exists s in the interval $I_{\Delta s}$ such that $\bar{y}(r_1, s)$ belongs to M_{cs}, and hence $\bar{y}(r, s) \to \bar{y}_0$ as $r \to \infty$. The computation of $\bar{y}(r_1, s)$ for $s \in I_{\Delta s}$ is done by a single run of the program with s defined as the interval $I_{\Delta s}$. Since we want to prove the result for a continuum of α, we define α to be an interval $\alpha = I_{\Delta\alpha} = [\alpha_0 - \Delta\alpha, \alpha_0 + \Delta\alpha]$. The properties in (1.16) should then hold uniformly for α as above. Thus the idea of the proof is quite simple. However, its technical fulfillment is not trivial at all. The usual crude estimates of the domain of attraction for M_{cs} show that r_1 in the case where $\alpha = 0$ should be about 15. The roots of (1.13) are of absolute value $2^{1/3}$ so that the initial errors at $r = 0$ are amplified by the factor $\exp(15 \cdot 2^{1/3}) \approx 1.6 \cdot 10^8$. The domain of M_{cs} is of the order 10^{-2}. Thus, to satisfy (1.16) (i), Δs has to be of the order 10^{-10}. But then $\bar{y}(r_1, s_0 - \Delta s), \bar{y}(r_1, s_0 + \Delta s)$ are so close that they are not separated by M_{cs}. Besides, $\Delta\alpha$ also should be of the order 10^{-10}. Each run of the program takes about 10 seconds of computer time on Cyber 180/855. Thus, to cover an interval $\alpha \in [0, 1]$, we would need $\approx 2 \cdot 10^8$ hours of computer time. Instead, by a careful estimate of M_{cs} we reduced r_1 to about 5. The amplification factor thus was ≈ 500. Next, (1.8) was solved in characteristic variables. As a result, the solution $\bar{y}$ increased only in the direction normal to M_{cs}. Hence, smallness of $\bar{y}(r_n)-\bar{y}_0$ in the direction tangential to M_{cs} did not contradict the separability condition (1.16)(ii). Finally, the dependence of $\bar{y}(r)$ on the parameters s and α was expressed by a Taylor expansion of order 2. Thus, $\bar{y}(r)$ and the first derivatives with respect to s and α were computed at the central point (s_0, α_0) while only the second derivatives were computed in the domain $I_{\Delta s} \times I_{\Delta\alpha}$. As a result, we run the program successfully with $\Delta s = .0015$ and $\Delta\alpha = .005$ from $\alpha = 0$ through $\alpha = 2.39$ at the expense of 1 hour of CPU on Cyber 180/855. We could continue the proof for larger α with a smaller Δs, but for our purposes the interval $\alpha \in [0, 2.39]$ is more than enough.

Recall that the empirical stability domain of Bunsen flames extends only to $c = 3$, i.e., $\alpha = .31$. Our nonrigorous numerical experiments suggest that for $\alpha > 1.1$ problem (1.8), (1.10) has infinitely many solutions. The total picture is similar to that obtained in [5] for the antonomous (1.5). The branch followed by our program corresponds to the minimal slope $s = y'(0)$ of all the bounded solutions for given α. The values of s_0 corresponding to α_0 and the derivatives $ds_0/d\alpha_0$ were obtained by a nonrigorous preliminary program. In addition to conditions in (1.16) our interval arithmetic program verified the transversality of the intersection of the curve $\bar{y}(r_1, s)$ for $s \in I_{\Delta s}$ and the manifold M_{cs} and the negativeness of y. We summarize the results of all computations in the following theorem.

THEOREM 1. *Problem* (1.8), (1.10) *has a negative solution for all* $\alpha \in [0, 2.39]$, *i.e.,* $0.383 < c < \infty$. *This solution is formed by a transversal intersection of the curve* $\bar{y}(r_1, s), s \in {}^{I}\!_{\Delta s}$ *and the central stable manifold* M_{cs} *of the critical point* $\bar{y}_0 = (-1, 0, 0, 0)$. *The values of the slopes* $s = y'(0)$ *and the corresponding values of* α *appear in Table* 1.

Remark 1. Because of the lack of space we display in this article only the results for $\alpha = n \cdot 0.1$, $0 \le n \le 23$ and $\alpha = 2.39$. The complete Table 1 may be obtained from the author upon request.

The negativeness of $y(r)$ for all $r > 0$ means that the Bunsen-flame cone $v(r)$ is monotonically decreasing. We conjecture that the negativeness of $y(r)$ singles it out as the only bounded solution of (1.8) with $y(0) = 0$.

2. The power series expansion at $r = 0$. Let us substitute the formal expansion (1.14) into (1.8). We obtain the following recurrent relation:

$$a_{i+1} = -\left(\alpha a_i + \left(\sum_{j=1}^{i-1} a_j a_{i-j}\right)/(2i)\right)/(4i(i+1)), \qquad i \ge 2 \tag{2.1}$$

and

$$a_2 = \frac{1 - 2\alpha a_1}{16}, \tag{2.2}$$

where a_1 is a free parameter. For appropriate ρ_0 and ρ_1 the coefficients a_i are bounded by

$$|a_i| < \rho_1 \rho_0^{i-1}. \tag{2.3}$$

Indeed, for that purpose, ρ_1 and ρ_0 should satisfy

$$\rho_1 \ge |a_1|, \qquad \rho_1\rho_0 \ge \frac{|1 - 2\alpha a_1|}{16}. \tag{2.4}$$

From (2.1) we obtain

$$|a_{i+1}| \le \frac{\alpha\rho_1\rho_0^{i-1}}{4i(i+1)} + \frac{(i-1)\rho_1^2\rho_0^{i-2}}{8i^2(i+1)}. \tag{2.5}$$

Thus, to assure the bounds in (2.3) for $i \ge 2$, we impose

$$\frac{\alpha\rho_0}{4i(i+1)} + \frac{(i-1)\rho_1}{8i^2(i+1)} \le \rho_0^2, \qquad i \ge 2. \tag{2.6}$$

In particular,

$$\frac{\alpha\rho_0}{24} + \frac{\rho_1}{96} \le \rho_0^2. \tag{2.7}$$

The last inequality clearly implies all inequalities in (2.6). Since $\rho_0 > 0$, by (2.7)

$$\rho_0 \ge \frac{1}{48}\,(\alpha + (\alpha^2 + 24\rho_1)^{1/2}) = F_1(\rho_1), \tag{2.8}$$

while by (2.4)

$$\rho_0 \ge \frac{|1-2\alpha a_1|}{16\rho_1} = F_2(\rho_1). \tag{2.9}$$

Since $F_1(\rho)$ is increasing and $F_2(\rho)$ is a decreasing function there exists a unique ρ_1^* such that $F_1(\rho_1^*) = F_2(\rho_1^*)$. It is easy to see that this ρ_1^* satisfies the cubic equation

$$\rho_1^3 + \frac{\alpha(1-2\alpha a_1)}{4}\,\rho_1 - \frac{3}{8}\,(1-2\alpha a_1)^2 = 0. \tag{2.10}$$

Thus, the pair (ρ_0, ρ_1) with the smallest ρ_0 is given by the formula

$$\rho_1 = \max(\rho_1^*, |a_1|), \qquad \rho_0 = F_1(\rho_1). \tag{2.11}$$

The radius of convergence of the series is bounded from below by $R \ge \rho_0^{-1/2}$. For example, for $\alpha = 0$ the corresponding slope $a_1 = s = -.6739$. Since $F_1(|a_1|) = .0838$ is smaller than $F_2(|a_1|) = .0927$ it follows that $\rho_1 = \rho_1^* = .7211$ and $\rho_0 = .0867$, while $R > 3.39$. In computations we employ instead of y a finite sum

$$y_N = \sum_{i=1}^{N} a_i r^{2i-1}. \tag{2.12}$$

The remainder $E_N(r)$ is bounded by

$$|E_N(r)| \le \sum_{i=N+1}^{\infty} |a_i| r^{2i-1} \le \rho_1\rho_0^N r^{2N+1}(1-\rho_0 r^2)^{-1}. \tag{2.13}$$

In particular, for ρ_0, ρ_1 as above, and

$$N = 80, \qquad r = r_0 = 1, \tag{2.14}$$

we obtain $|E_N(r)| < 10^{-85}$. The derivatives $y'(r)$ and $y''(r)$ are approximated by the sums

$$y'_N = \sum_{i=1}^{N}(2i-1)a_i r^{2i-2}, \qquad y''_N = \sum_{i=1}^{N}(2i-1)(2i-2)a_i r^{2i-3}. \tag{2.15}$$

By (2.5)

$$(2i-1)(2i-2)|a_i| \le \alpha\rho_1\rho_0^{i-1} + \frac{\rho_1^2\rho_0^{i-2}}{2}, \tag{2.16}$$

and hence the remainder E''_N of y'' is bounded by

$$|E''_N(r)| \le \left(\alpha + \frac{\rho_1}{2\rho_0}\right)\rho_1\rho_0^N r^{2N-1}(1-\rho_0 r^2)^{-1}. \tag{2.17}$$

Clearly, for $r < 2N$ the terms in the sum for E'_N are smaller than the corresponding terms in $E''_N(r)$, and hence also $|E'_N(r)|$ is bounded by the right-hand side of (2.17). In addition to the function $y(r)$ we will have to compute its partial derivatives up to order 2 with respect to the parameters $y'(0) = s$ and α. More precisely, when differentiating with respect to α we assume that

$$s = s_0 + s_{\alpha_0}\cdot(\alpha-\alpha_0), \tag{2.18}$$

where s_0 and s_{α_0} are constants. In our computer program these constants are denoted by $S0$ and $SA0$. The coefficients of the expansion

$$\partial_p y(r) = \sum_{i=0}^{\infty}\partial_p a_i r^{2i-1}, \qquad p = s \text{ or } p = \alpha \tag{2.19}$$

satisfy for $i \ge 1$

$$\partial_p a_{i+1} = \left(\alpha\partial_p a_i + \partial_p\alpha\cdot a_i + 2\left(\sum_{j=1}^{i-1}\partial_p a_{i-j}\cdot a_j\right)/(2i)\right)/(4i(i+1)) \tag{2.20}$$

with the first coefficient

$$\partial_s a_1 = 1, \qquad \partial_\alpha a_1 = s_{\alpha_0}. \tag{2.21}$$

The corresponding formulas for the second derivatives are

$$\begin{aligned}\partial_{p_1}\partial_{p_2}a_{i+1} = \Bigg(&\alpha\partial_{p_1}\partial_{p_2}a_i + \partial_{p_1}\alpha\partial_{p_2}a_i + \partial_{p_2}\alpha\partial_{p_1}a_i\\ &+2\sum_{j=1}^{i-1}(\partial_{p_1}\partial_{p_2}a_{i-j}\cdot a_j + \partial_{p_1}a_{i-j}\cdot\partial_{p_2}a_j)/(2i)\Bigg)/(4i(i+1)),\end{aligned} \tag{2.22}$$

where p_1, p_2 are s or α. Clearly, only $\partial_\alpha\alpha = 1$ is nonzero. The first coefficient for all p_1, p_2 is

$$\partial_{p_1}\partial_{p_2}a_1 = 0. \tag{2.23}$$

We are looking for a common estimate

$$|\partial_s^{j_1}\partial_\alpha^{j_2}a_i| \le \rho_3\rho_2^{i-1}, \quad \rho_2 \ge \rho_0, \quad \rho_3 \ge \rho_1, \quad 0 \le j_1 + j_2 \le 2. \tag{2.24}$$

Then (2.20) implies

$$|\partial_p a_{i+1}| \le \frac{\alpha\rho_3\rho_2^{i-1} + \rho_1\rho_2^{i-1}}{4i(i+1)} + \frac{(i-1)\rho_3\rho_1\rho_2^{i-2}}{4i^2(i+1)} \tag{2.25}$$

and by (2.21) and (2.24)

$$\rho_3 = \max(1, |s_{\alpha_0}|, \rho_1). \tag{2.26}$$

From (2.22) we obtain the upper bound (in the case where $p_1 = p_2 = \alpha$)

$$\begin{aligned} |\partial_{p_1}\partial_{p_2}a_{i+1}| &\leq \frac{\alpha\rho_3\rho_2^{i-1} + 2\rho_3\rho_2^{i-1}}{4i(i+1)} + \frac{(i-1)(\rho_3\rho_1\rho_2^{i-2} + \rho_3^2\rho_2^{i-2})}{4i^2(i+1)} \\ &\leq \frac{(\alpha+2)\rho_3\rho_2^{i-1}}{4i(i+1)} + \frac{(i-1)\rho_3^2\rho_2^{i-2}}{2i^2(i+1)}. \end{aligned} \tag{2.27}$$

Clearly, the last bound is higher than that in (2.25). In order to satisfy (2.24) we have to request

$$\rho_2^2 \geq \frac{(\alpha+2)\rho_2}{4i(i+1)} + \frac{(i-1)\rho_3}{2i^2(i+1)}. \tag{2.28}$$

The strongest inequalities are attained in the cases $i = 1$, $i = 2$:

$$\rho_2^2 \geq \frac{(\alpha+2)\rho_2}{24} + \frac{\rho_3}{24}, \qquad \rho_2 \geq \frac{\alpha+2}{8}. \tag{2.29}$$

Hence we can define

$$\rho_2 = \max\left(\frac{1}{48}\,(\alpha+2+((\alpha+2)^2+96\rho_3)^{1/2}),\ \frac{\alpha+2}{8}\right). \tag{2.30}$$

Obviously, ρ_2 is greater than ρ_0 defined in (2.11). For example, for $\alpha = 0$ we obtain $\rho_3 = 1$ and $\rho_2 = .25$. The truncation error $\partial_s^{j_1}\partial_\alpha^{j_2}E_N$, $j_1 + j_2 \leq 2$ is estimated as in (2.13) with ρ_0, ρ_1 replaced by ρ_2 and ρ_3, respectively. For the second derivative $\partial_s^{j_1}\partial_\alpha^{j_2}E_N''$, instead of (2.16) we obtain

$$(2i-1)(2i-2)|\partial_s^{j_1}\partial_\alpha^{j_2}a_i| \leq (\alpha+2)\rho_3\rho_2^{i-1} + 2\rho_3^2\rho_2^{i-2}. \tag{2.31}$$

Hence, the common upper bound for the derivatives of E_N is

$$\begin{gathered} |\partial_s^{j_1}\partial_\alpha^{j_2}E_N^{(k)}| \leq (\alpha+2+2\rho_3/\rho_2)\rho_3\rho_2^N r^{2N-1}(1-\rho_2 r^2)^{-1}, \\ i_1 + i_2 \leq 2, \qquad k \leq 2. \end{gathered} \tag{2.32}$$

The above bound is denoted in the subroutine SERIES (see the Appendix) by $ERROR(2) = -ERROR(1)$. In the worst case of $\alpha = 2.39$, $s = -2.989$, and $s_{\alpha_0} = -1.55$ we obtain $\rho_1^* = 3.78 = \rho_1$, $\rho_0 = .254$, $\rho_3 = \rho_1$, $\rho_2 = \max(.50, .55) = .55$, and hence the bound in (2.32) for r and N as in (2.14) is $2.6 \cdot 10^{-19}$. This number, relative to the computed values of $\partial_s^{j_1}\partial_\alpha^{j_2}y_N^{(k)}(r)$, seems to be far below the maximal roundoff error of our computer. Still, to be sure, we add the interval ($ERROR(1)$, $ERROR(2)$) to the above derivatives of y_N. In subroutine SERIES we compute the derivatives $\partial_s^{j_1}\partial_\alpha^{j_2}y^{(k)}(r)$, $k \leq 2$ for $0 \leq j_1 + j_2 \leq 1$ at the central point s_0, α_0 and for $j_1 + j_2 = 2$ at the intervals $I_{\Delta s} = (s_0 - \Delta s, s_0 + \Delta s)$ and $I_{\Delta\alpha} = (\alpha_0 - \Delta\alpha, \alpha_0 + \Delta\alpha)$. In order to simplify notation we employ in our computer program the following general convention. For an interval variable f which depends on the parameters s and α we store the endpoints of the interval $\partial_s^{j_1}\partial_\alpha^{j_2}f$ at the vector

$$\partial_s^{j_1}\partial_\alpha^{j_2}f \to (f(j), f(j+1)), \qquad j = (j_1+j_2)(j_1+j_2+1) + 2j_2 + 1. \tag{2.33}$$

Thus, the index j varies from 1 through 11. The above derivatives for $j_1+j_2 \le 1$ are routinely computed at the central point (s_0, α_0), while the second-order derivatives are evaluated for the whole intervals $I_{\Delta s}$ and $I_{\Delta\alpha}$. In intermediate computations we sometimes need the values of f and its first derivatives at the above intervals. To distinguish between the central and interval functions, in the former case we modify the name f as $f0$. Note that the second derivatives are never evaluated at the central point. To allow a uniform treatment of the derivatives of f in majority of loops, we have abused the notation and denoted the second derivatives at the intervals of α and s by $f0$ instead of f. Thus, $f0(11), f0(12)$ is the derivative $\partial_\alpha^2 f$ at $I_{\Delta s} \times I_{\Delta s}$ while $f0(5) = \partial_\alpha f$ at (s_0, α_0). The values of f and the derivatives $\partial_s f$, $\partial_\alpha f$ at $I_{\Delta s} \times I_{\Delta\alpha}$ are computed by Taylor's formulas

$$\begin{aligned} f &= f0 + \partial_s f0 \cdot (s-s_0) + \partial_\alpha f0 \cdot (\alpha - \alpha_0) \\ &\quad + \tfrac{1}{2}\partial_s^2 f0 \cdot (s-s_0)^2 + \partial_s\partial_\alpha f0 \cdot (s-s_0)\cdot(\alpha-\alpha_0) + \tfrac{1}{2}\partial_\alpha^2 f0 \cdot (\alpha-\alpha_0)^2, \end{aligned} \tag{2.34}$$

$$\partial_s f = \partial_s f0 + \partial_s^2 f0 \cdot (s-s_0) + \partial_s\partial_\alpha f0 \cdot (\alpha-\alpha_0), \tag{2.35}$$

and similar expression for $\partial_\alpha f$. In actual computations we replace $(s-s_0)$, $(\alpha-\alpha_0)$, and their products by the intervals

$$\begin{aligned} &DP(3), DP(4) = -\Delta s, \Delta s; \qquad DP(5), DP(6) = -\Delta\alpha, \Delta\alpha, \\ &DP(7), DP(8) = -(\Delta s)^2, (\Delta s)^2; \qquad DP(9), DP(10) = -\Delta s\cdot\Delta\alpha,\ \Delta s \cdot \Delta\alpha, \\ &DP(11), DP(12) = -(\Delta\alpha)^2, (\Delta\alpha)^2. \end{aligned} \tag{2.36}$$

In our Fortran program formula (2.34) is written as

$$\begin{aligned} \text{I}\quad F(1) &= F0(1) + F0(3)^*DP(3) + F0(5)^*DP(5) \\ &\quad + 0.5^*F0(7)^*DP(7) + F0(9)^*DP(9) + 0.5^*F0(11)^*DP(11). \end{aligned} \tag{2.37}$$

Thus, interval variables are represented by the address of their left endpoints. The letter I in the first column of the instruction indicates that this is an interval statement. Our preprocessor COMPINT then translates this instruction into a sequence of CALL statements. This preprocessor and its output are described in more detail in §5.

Following the above convention we store the derivatives $\partial_s^{j_1}\partial_\alpha^{j_2} a_i$ in case $(s, \alpha) = I_{\Delta s} \times I_{\Delta\alpha}$ and $j_1 + j_2 \le 1$ at the locations $A(j,i)$, $A(j+1,i)$, where j is defined as in (2.31), while in all remaining cases they are stored in $A0(j,i)$, $A0(j+1,i)$. Formulas (2.1), (2.2) are used to compute $A0(1,i)$, $A0(2,i)$, formulas (2.20), (2.21) for $A0(3,i)$, $A0(4,i)$ and $A0(5,i)$, $A0(6,i)$, and formula (2.22) for $A0(j,i)$, $A0(j+1,i)$, where $j = 7, 9, 11$. In (2.22) the lower-order derivatives a_i, $\partial_s a_i$, and $\partial_\alpha a_i$ are replaced by the corresponding intervals $A(j,i)$, $A(j+1,i)$. The latter ones in turn are computed as in the example (2.37). The final series $\sum_{i=1}^N \partial_s^{j_1}\partial_\alpha^{j_2} a_i r^{2i-1}$ are summed up using the Horner method.

3. The central stable manifold. As mentioned in the Introduction, there exists a local three-dimensional central stable manifold M_{cs} of the flow (1.11) which passes through the point $\bar{y}_0 = (-1, 0, 0, 0)$. The neutral direction corresponds to the fourth equation $\dot{y}_4 = -y_4^2$. Hence the rate of convergence of $\bar{y}(r)$ to $\bar{y}_0$ is not exponential but of order $O(r^{-1})$. Note that (1.8) has a formal asymptotic solution

$$y = \sum_{i=0}^{\infty} b_i r^{-1}, \qquad b_0 = -1, \tag{3.1}$$

where the remaining coefficients are uniquely determined by b_0. Although the series in (3.1) is a diverging one, we will see below that the partial sums

$$y_N = \sum_{i=0}^{N} b_i r^{-i} \tag{3.2}$$

constitute the leading part of all solutions $y(r)$ that tend to the critical point $y = -1$ as $r \to \infty$. Let us pass to the variable

$$y_{\text{new}} = y_{\text{old}} - y_N. \tag{3.3}$$

In the new variable $y = y_{\text{new}}$ (1.8) becomes

$$\begin{aligned} y''' + \alpha y' - 2y &= f(y, r) \\ &= -2r^{-1}y'' + y'r^{-2} - yr^{-3} - y^2 - 2\Delta y_N \cdot y - p(r^{-1}), \end{aligned} \tag{3.4}$$

where

$$\Delta y_N = \sum_{i=2}^{N} b_i r^{-i} = O(r^{-2}) \tag{3.5}$$

and $p(r^{-1})$ is the result of substitution of y_N into (1.8):

$$p(r^{-1}) = \sum_{i=N+1}^{2N} p_i r^{-i} = O(r^{-N-1}). \tag{3.6}$$

Since $f(0, r) = O(r^{-N-1})$ and the roots of (1.13) are not imaginary, it follows easily that all solutions of (3.4) that tend to zero as $r \to \infty$ are of the order $O(r^{-N-1})$. We will need, however, an exact bound of y. For that purpose, let us pass to the characteristic variables $u = (u_1, u_2, u_3)$:

$$u_1 = \frac{(D - \lambda_2)(D - \lambda_3)y}{(\lambda_1 - \lambda_2)(\lambda_1 - \lambda_3)}, \quad u_2 = \frac{(D - \lambda_1)(D - \lambda_3)y}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)}, \quad u_3 = \bar{u}_2, \tag{3.7}$$

where $\lambda_1, \lambda_2 = \bar{\lambda}_3$ are the roots of (1.13) and $\lambda_1 > 0$. Equation (3.4) becomes

$$u_1' - \lambda_1 u_1 = \frac{f(u, r)}{(\lambda_1 - \lambda_2)(\lambda_1 - \lambda_3)}, \qquad u_2' - \lambda_2 u_2 = \frac{f(u, r)}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)}. \tag{3.8}$$

Assume for a moment that $f = f(r)$ is a given bounded function of r. Then solutions of (3.8) that are bounded on the interval (r_1, ∞) satisfy the estimate

$$\|u_1\|_\infty \le c_1 \|f\|_\infty, \qquad \|u_2\|_\infty \le c_2 \|f\|_\infty + |u_2(r_1)|, \tag{3.9}$$

where

$$c_1 = \frac{1}{\lambda_1|\lambda_1 - \lambda_2|^2}, \qquad c_2 = \frac{1}{|Re\ \lambda_2| \cdot |\lambda_2 - \lambda_1| \cdot |\lambda_2 - \lambda_3|} = \frac{1}{\lambda_1 \cdot |\lambda_2 - \lambda_1| \cdot |\mathrm{Im}\ \lambda_2|} \tag{3.10}$$

while $\|u\|_\infty = \sup_{r \geq r_1} |u(r)|$ is the usual maximum norm. The function y and its derivatives in terms of u_1, u_2 are

$$y = u_1 + 2\mathrm{Re}\ u_2, \quad y' = \lambda_1 u_1 + 2\mathrm{Re}(\lambda_2 u_2), \quad y'' = \lambda_1^2 u_1 + 2\mathrm{Re}(\lambda_2^2 u_2). \tag{3.11}$$

Now we recall that f depends on y, and with the aid of (3.9) we estimate

$$\begin{aligned}\|f\|_\infty &\leq 2r_1^{-1}(\lambda_1^2\|u_1\|_\infty + 2|\lambda_2|^2\|u_2\|_\infty) + r_1^{-2}(\lambda_1\|u_1\|_\infty + 2|\lambda_2|\ \|u_2\|_\infty) \\ &\quad + (r_1^{-3} + 2\|\Delta y_N\|_\infty)(\|u_1\|_\infty + 2\|u_2\|_\infty) \\ &\quad + (\|u_1\|_\infty + 2\|u_2\|_\infty)^2 + \|p\|_\infty \\ &\leq c_3\|f\|_\infty + c_4\|f\|_\infty^2 + c_5,\end{aligned} \tag{3.12}$$

where

$$\begin{aligned}c_3 &= 2r_1^{-1}(c_1\lambda_1^2 + 2c_2|\lambda_2|^2) + r_1^{-2}(c_1\lambda_1 + 2c_2|\lambda_2|) \\ &\quad + (r_1^{-3} + 2\|\Delta y_N\|_\infty + 4|u_2(r_1)|)(c_1 + 2c_2),\end{aligned} \tag{3.13}$$

$$c_4 = (c_1 + 2c_1)^2, \tag{3.14}$$

and

$$\begin{aligned}c_5 &= 2(2r_1^{-1}|\lambda_2|^2 + r_1^{-2}|\lambda_2| + r_1^{-3} + 2\|\Delta y_N\|_\infty)|u_2(r_1)| \\ &\quad + 4|u_2(r_1)|^2 + \sum_{i=N+1}^{2N} |p_i| r_1^{-i}.\end{aligned} \tag{3.15}$$

Given $u_2(r_1)$, system (3.8) is solved by iterations where $f = f_n = f(u^{(n)})$ is evaluated at $u^{(n)}$ and the corresponding bounded solution of the initial value problem with $u_2^{(n+1)}(r_1) = u_2(r_1)$ is denoted by $u^{(n+1)}$. The zero approximation $u^{(0)}$ is set to be zero. Now, inequality (3.12) is replaced by

$$\|f_{n+1}\|_\infty \leq c_3\|f_n\|_\infty + c_4\|f_n\|_\infty^2 + c_5. \tag{3.16}$$

Suppose that

$$c_3 < 1 \quad \text{and} \quad c_6 = (1 - c_3)^2 - 4c_4c_5 > 0. \tag{3.17}$$

Then (3.16) implies

$$\|f_{n+1}\|_\infty \leq c_7 = (1 - c_3 - \sqrt{c_6})/(2c_4), \tag{3.18}$$

since $\|f_0\|_\infty = \|p\|_\infty \leq c_5 \leq c_7$. Thus, there exists a subsequence $u^{(n_i)}$ that converges to the solution of the original nonlinear equation and has the prescribed value of

$u_2(r_1)$. The conditions in (3.17) restrict the size of r_1^{-1} and of $|u_2(r_1)|$. But once these conditions are met, the correspondence

$$r_1^{-1}, u_2(r_1) \rightarrow u_1(r_1) \tag{3.19}$$

defines the local central-stable manifold M_{cs}. The value of $u_1(r_1)$ is then bounded by

$$|u_1(r_1)| \leq c_1 c_7. \tag{3.20}$$

In our computation we set $N = 2$. Then

$$y_N = -1 + b_1 r^{-1} + b_2 r^{-2}, \qquad b_1 = \frac{-\alpha}{2}, \quad b_2 = \frac{\alpha^2}{8}, \tag{3.21}$$

$$\Delta y_N = b_2 r^{-2}, \tag{3.22}$$

and

$$\begin{aligned} p(r) &= p_3 r^{-3} + p_4 r^{-4} + p_5 r^{-5} \\ &= -(1 + \frac{\alpha^3}{4})r^{-3} + \frac{\alpha^4}{64} r^{-4} - \frac{9}{8}\alpha^2 r^{-4}. \end{aligned} \tag{3.23}$$

Since α varies in the interval $[\alpha_0 - \Delta\alpha, \alpha_0 + \Delta\alpha]$, we freeze the coefficient α in (3.4) at α_0 and instead modify f by

$$f \rightarrow f - (\alpha - \alpha_0)y'. \tag{3.24}$$

This effects the coefficients c_3 and c_5

$$c_3 \rightarrow c_3 + |\Delta\alpha|(c_1\lambda_1 + 2c_2|\lambda_2|), \qquad c_5 \rightarrow c_5 + 2|\Delta\alpha| \cdot |\lambda_2|\,|u_2(r_1)|. \tag{3.25}$$

The eigenvalues λ_i are roots of the equation

$$\lambda^3 + \alpha_0\lambda - 2 = 0. \tag{3.26}$$

Let us now look at Table 1. The numbers in the columns from left to right are as follows: $\alpha_0, s_0, s_{\alpha_0}, r_1$, the upper bound of $|z_2(r_1)|$ for $s, \alpha \in I_{\Delta s} \times I_{\Delta\alpha}$, the interval value of $z_1(r_1)$ for $s = s_0 - \Delta s$, $\alpha \in I_{\Delta\alpha}$, and the interval value of $z_1(r_1)$ for $s = s_0 + \Delta s$, $\alpha \in I_{\Delta\alpha}$. The increments $\Delta\alpha$ and Δs are fixed $\Delta\alpha = .005$, $\Delta s = .0015$. Because of the lack of space we display in this article only the results for $\alpha_1 = n \cdot 0.1$, $0 \leq n \leq 23$, and $\alpha = 2.39$. The complete Table 1 is on deposit with the author and may be obtained by the interested reader upon request. Let us check, for example, that for $\alpha_0 = 0$ the values r_1, $z_2(r_1)$ lie in the domain of existence of M_{cs} and $z_1(r_1)$ for $s = s_0 + \Delta s$ and $s_0 - \Delta s$ are separated by M_{cs}. The eigenvalues λ_i are

$$\lambda_1 = 2^{1/3} \approx 1.26, \qquad \lambda_2 = \frac{-\lambda_1 + i(3\lambda_1^2 + 4\alpha)^{1/2}}{2}. \tag{3.27}$$

Hence

$$\begin{aligned} &|\lambda_2| = (\lambda_1^2 + \alpha)^{1/2} \approx 1.26, \qquad |\lambda_1 - \lambda_2| = (3\lambda_1^2 + \alpha)^{1/2} \approx 2.18, \\ &|\text{Im } \lambda_2| = (3\lambda_1^2 + 4\alpha)^{1/2}/2 \approx 1.09. \end{aligned} \tag{3.28}$$

```

The constants

$$(3.29)\qquad \begin{aligned} c_1 &= \frac{1}{\lambda_1(3\lambda_1^2+\alpha)} = \frac{1}{6}, \\ c_2 &= \frac{2}{\lambda_1(3\lambda_1^2+\alpha)^{1/2}\cdot(3\lambda_1^2+4\alpha)^{1/2}} = \frac{1}{3}. \end{aligned}$$

For $r_1 = 5.375$ and $|u_2(r_1)| \le .012$ we have

$$(3.30)\qquad \|\Delta y_N(r)\|_\infty = |\alpha|^2/8\cdot r_1^{-2} \le |\Delta\alpha|^2/8\cdot r_1^{-2} = .11\cdot 10^{-6},$$

$$(3.31)\qquad \|p(r)\|_\infty \le \left(1+\frac{|\Delta\alpha|^3}{4}\right) r_1^{-3} + \frac{|\Delta\alpha|^4}{4} r_1^{-4} + \frac{9}{8}|\Delta\alpha|^2 r_1^{-4} \approx .6\cdot 10^{-2},$$

$$(3.32)\qquad c_3 \approx .58,\quad c_4 \approx .70,\quad c_5 \approx .022,\quad c_6 \approx .12,\quad c_7 \approx .058\ .$$

Thus r_1, $u_2(r_1)$ lie in the domain of M_{cs} and $|u(r_1)| \le c_1c_7 < .01$. The values $-.12$ and $.11$ of $u_1(r_1)$ for $s = s_0 \pm \Delta s$ are clearly separated by the strip $[-.01, .01]$. To verify the separability condition we wrote a computer program which appears as the SUBROUTINE ESTIM in the computer code in the Appendix. This subroutine is written also in interval arithmetic and the input values of all parameters are obtained from the main program. The trajectory $\bar{y}(r)$ is advanced in r with steps $h = .125$ until ESTIM gives a positive result, which constitutes a formal proof of the existence of solution. The final values of r_1 and $u(r_1)$ are printed only to make the claim more convincing.

In addition we checked the transversality of the intersection of the curve $\bar{y}(r_1; s)$ $s \in I_{\Delta s}$ with the manifold M_{cs}. Besides the values of $\bar{y}(r_1; s)$ and $u(r_1; s)$ our program computes the interval values of $\partial_s u(r_1; s)$ for $(s, \alpha) \in I_{\Delta s} \times I_{\Delta\alpha}$. Suppose that for some $s_1 \in I_{\Delta s}$, $u(r_1; s)$ lies in M_{cs} and $\partial_s u(r_1; s_1)$ is tangent to M_{cs}. Then the ratio $\partial_s u_1(r_1; s_1)/\partial_s u_2(r_1; s)$ should tend to zero as $r \to \infty$ since at the fixed point $\bar{y}_0$ the tangent plane to M_{cs} is just $u_1 = 0$. The values of $\partial_s u(r_1; s)$ computed by the program were such that $|\partial_s u_1(r_1; s)| \gg |\partial_s u_2(r_1; s)|$. We wish to prove that for these values of $\partial_s u(r_1; s_1)$ there exists a constant $c > 0$ such that

$$c|\partial_s u_1(r; s_1)|^2 - |\partial_s u_2(r; s_1)|^2 > 0 \quad \text{for all } r > r_1. \tag{3.33}$$

This clearly implies the transversality of the intersection. The function $u_s(r) = \partial_s u(r; s_1)$ satisfies the system

$$\begin{aligned} u'_{s1} &= \lambda_1 u_{s1} + \frac{1}{|\lambda_1 - \lambda_2|^2}\, df \cdot u_s, \\ u'_{s2} &= \lambda_2 u_{s2} + \frac{1}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)}\, df \cdot u_s, \qquad u_{s3} = \bar{u}_{s2}, \end{aligned} \tag{3.34}$$

where df is the differential of f with respect to u. From the explicit formulas of f in (3.4) and (3.24) and from the relations in (3.11) it follows that

$$|df \cdot u_s| \le a_1|u_{s1}| + a_2|u_{s2}|, \tag{3.35}$$

where

$$\begin{aligned} a_1 &= |\Delta\alpha|\lambda_1 + 2r_1^{-1}\lambda_1^2 + 2|b_2|r_1^{-2} + r_1^{-2}\lambda_1 + r_1^{-3} + 2\|y\|_\infty, \\ a_2 &= 2(|\Delta\alpha| \cdot |\lambda_2| + 2r_1^{-1}|\lambda_2|^2 + 2|b_2|r_1^{-2} + r_1^{-2}|\lambda_2| + r_1^{-3} + 2\|y\|_\infty), \end{aligned} \tag{3.36}$$

and

$$\|y\|_\infty \le \|u_1\|_\infty + 2\|u_2\|_\infty \le (c_1 + 2c_2)\|f\|_\infty + 2|u_2(r_1)|. \tag{3.37}$$

Multiplying the system in (3.34) by the vector $(cu_{s1}, -\bar{u}_{s2})$ and taking real parts yields

$$\begin{aligned} \frac{1}{2}(c|u_{s1}|^2 - |u_{s2}|^2)' &= c\lambda_1|u_{s1}|^2 - \operatorname{Re}\lambda_2|u_{s2}|^2 \\ &\quad + \frac{c}{|\lambda_1 - \lambda_2|^2}(df \cdot u_s)u_{s1} - \operatorname{Re}\left(\frac{(df \cdot u_s)\bar{u}_{s2}}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)}\right). \end{aligned} \tag{3.38}$$

We wish to show that the right-hand side of (3.38) is nonnegative. Recall that $-\operatorname{Re}\lambda_2 = \lambda_1/2 > 0$. In view of (3.35) it is enough to show that for some $c > 0$

$$c|u_{s1}|^2 + \frac{1}{2}|u_{s2}|^2 \ge (a_1|u_{s1}| + a_2|u_{s2}|)\left(cc_1|u_{s1}| + \frac{c_2}{2}|u_{s2}|\right), \tag{3.39}$$

where c_1 and c_2 are defined by (3.10). The last inequality of quadratic forms is equivalent to the inequalities of coefficients

$$a_1c_1 \le 1, \tag{3.40}$$

$$2d_1c \ge (d_2c + d_3)^2, \tag{3.41}$$

where

$$d_1 = (1 - a_1c_1)(1 - a_2c_2), \quad d_2 = c_1a_2, \quad \text{and} \quad d_3 = \frac{c_2a_1}{2}. \tag{3.42}$$

To satisfy (3.41) c should be

$$\begin{aligned} &\frac{d_4 - d_6}{d_2^2} \le c \le d_7 = \frac{d_4 + d_6}{d_2^2}, \qquad d_4 = d_1 - d_2d_3, \quad d_6 = \sqrt{d_5}, \\ &d_5 = d_4^2 - d_2^2d_3^2 = d_1(d_1 - 2d_2d_3). \end{aligned} \tag{3.43}$$

Finally, if the computed interval vector $\partial_s u(r_1; s), (s, \alpha) \in I_{\Delta s} \times I_{\Delta\alpha}$ satisfies

$$\frac{|\partial_s u_2(r_1; s)|^2}{|\partial_s u_1(r_1; s)|^2} < d_7, \tag{3.44}$$

we take $c = d_7$. This implies that $c|u_{s1}|^2 - |u_{s2}|^2 > 0$ for all $r > r_1$ and proves the tranvsersality. Our subroutine ESTIM also computed the above coefficients d_i and a_i and verified the inequalities (3.40) and (3.44). If transversality failed, the trajectory $y(r)$ was advanced in r until both the conditions of separation and of transversality were met. Thus the printout in Table 1 testifies both to the existence of the solution and the transversality of the intersection.

Let $M_{cs}(r_1^{-1}, \delta)$ be the restriction of M_{cs} to the domain $y_4 = r_1^{-1}$, $|u_2| < \delta$ with the parameter $\alpha \in I_{\Delta\alpha}$, where δ is the bound on $|u_2(r_1)|$ as it appears in the fourth column of Table 1. If du_1, du_2 is a tangent vector to $M_{cs}(r_1^{-1}, \delta)$ then our previous analysis shows that

$$\frac{|du_2|^2}{d_7} > |du_1|^2. \tag{3.45}$$

In view of (3.44) it follows that the curve $\bar{u}(r_1, s)$, $s \in I_{\Delta s}$ for each $\alpha \in I_{\Delta\alpha}$ has a unique intersection with $M_{cs}(r_1^{-1}, \delta)$. Note also that $M_{cs}(r_1^{-1}, \delta)$ is uniquely determined by the conditions

$$\|u_1\|_\infty \le c_1c_7, \quad \|u_2\|_\infty \le c_2c_7 + \delta, \quad \lim_{r \to \infty} u(r) = 0. \tag{3.46}$$

(Here the constants c_7 and δ replace the terms $\|f\|_\infty$ and $|u_2(r_1)|$ in (3.9).) Indeed, let $u(r), \tilde{u}(r)$ be two different solutions of (3.8) satisfying (3.46) such that $u_2(r_1) = \tilde{u}_2(r_1)$. In our analysis of the system (3.34) we can replace the function $u_s(r)$ by $\Delta u(r) = \tilde{u}(r) - u(r)$. Estimates of all constants a_i, d_i remain valid since the norm $\|y\|_\infty$ in (3.37) is replaced by the same bound

$$\tfrac{1}{2} \, \|y + \tilde{y}\|_\infty \le (c_1 + 2c_2)c_7 + 2\delta. \tag{3.47}$$

Clearly, $|\Delta u_2(r_1)|^2/|\Delta u_1(r_1)|^2 = 0 < d_7$, and hence for all $r > r_1$

$$|\Delta u_1(r)| > |\Delta u_2(r)|/d_7^{1/2}. \tag{3.48}$$

But for large r, $u(r)$ and $\tilde{u}(r)$ belong to a small neighborhood of zero where the central-stable manifold M_{cs} is unique and close to the tangent plane $u_1 = 0$. The last is contradicted by (3.48). Thus, the output in Table 1 shows that for each $\alpha \in I_{\Delta\alpha}$ there exists a unique $s^* \in I_{\Delta s}$ such that the corresponding solution of (1.8) in u coordinates satisfies conditions (3.46). This, however, does not mean that there are no other solutions with slopes s arbitrarily close to s^* that escape the neighborhood defined by (3.46) but ultimately converge to the point $\bar{y}_0$. In effect we demonstrated numerically in [5] that for $c \approx .835 \div 86$ and $c \approx .4845 - .4982$ equation (1.4) has homoclinic solutions, i.e., solutions which have the limits $y(\pm\infty) = -c\sqrt{2}$. Thus for corresponding values of α we may expect that (1.8) has infinitely many solutions with slopes $s_n = y'(0)$, $s_n \to s_0$ such that $\lim_{r\to\infty} y(r, s_n) \to -1$ and $y(r, s_0)$ is the negative solution established by Theorem 1.

4. Numerical solution of the O.D.E. in interval arithmetic. The power series expansion of §2 provides the box value of $\bar{y}$ and its partial derivatives with respect to s and α at $r = r_0 = 1$. On the other hand, the invariant manifold M_{cs} was estimated by us in §3 for $r \geq r_1 \approx 5 \div 7$. In order to connect between $r = r_0$ and $r = r_1$ equation (1.8) should be solved in the interval $[r_0, r_1]$ numerically. An O.D.E. could be solved in integral form as suggested by [2] or by an explicit Taylor method as in [3]. We prefer the second approach. Consider a general initial value problem for a system of differential equations

$$(4.1) \qquad y' = f(y), \quad y(r_0) = y_0, \quad y \in R^d.$$

Given $y(r)$ we compute $y(r+h)$ by the Taylor formula

$$(4.2) \qquad y(r+h) = y(r) + y'(r)h + \cdots + \frac{y^{(n)}(r)h^n}{n!} + E_n$$

with the remainder

$$(4.3) \qquad E_n = (E_{n1}, \cdots, E_{nd}), \qquad E_{ni} = \frac{y_i^{(n+1)}(r+\theta_i h)h^{n+1}}{(n+1)!},$$
$$0 < \theta_i < 1, \qquad 1 \leq i \leq d.$$

The coefficients $y^{(k)}(r)$, $1 \leq k \leq n$ are uniquely defined by $y(r)$ from (4.1). However, to obtain a rigorous estimate of $y(r+h)$ we must estimate the derivative $y^{(n+1)}$ in the interval $(r, r+h)$. Suppose we have a subroutine DERIV whose input consists of an interval value of r and a d-dimensional box value of $y(r)$, while the output consists of the box values of the derivatives $y^{(k)}(r)$, $1 \leq k \leq n+1$. Our algorithm below uses two calls to DERIV to compute $y(r+h)$. The algorithm could be split into the following 5 steps:

(1) Call DERIV with the input $r, y(r)$ and obtain the output $y^{(k)}(r), 1 \leq k \leq n$.

(2) Define the box

$$(4.4) \qquad y_{h0} = y(r) + FACT \cdot \sum_{k=1}^{m} y^{(k)}(r) \cdot [0, h]^k / k!, \qquad m \leq n,$$

where $FACT$ is a "safety" factor. We took $FACT = 1.5$, $m = 5$, and $n = 8$ or $n = 10$. The box y_{h0} is about to include all possible values of the vector $\{y_i(r_i)\}_{i=1}^d$, $r_i \in [r, r+h]$ corresponding to the true solution y.

(3) Call DERIV with the input $[r, r+h]$ instead of r and the box y_{h0} instead of $y(r)$. The resulting box values of the derivatives are denoted by $y_{h0}^{(k)}$, $1 \leq k \leq n+1$.

(4) Compute the box

$$y_h = \sum_{k=0}^{n} y^{(k)}(r)[0,h]^k/k! + y_{h0}^{(n+1)}[0,h]^{n+1}/(n+1)! \tag{4.5}$$

and check whether y_h lies in y_{h0}. If not, the program fails and the computation is stopped. If yes, go to Step 5.

(5) Compute $y(r+h)$ by

$$y(r+h) = \sum_{k=0}^{n} y^{(k)}(r)h^k/k! + y_{h0}^{(n+1)}h^{n+1}/(n+1)!. \tag{4.6}$$

The test in (4) proves that the remainder E_n in (4.3) is contained in the remainder of (4.6).

The main problem with interval computations is their exponential instability. Consider a linear system of O.D.E.'s with constant coefficients

$$y' = Ay. \tag{4.7}$$

If y is a d-dimensional symmetric box $[-\delta,\delta]^d$, then $Ay =$ abs$(A)y$, where abs$(A) = \{|a_{ij}|\}$. Hence the solutions of (4.7) when computed in interval arithmetic will grow exponentially even when the original matrix A has no positive eigenvalues. In the case of (3.4), if we disregard the term $f(y,r) = O(|\bar{y}|)\cdot O(r^{-1}+|\bar{y}|)$ then the resulting constant coefficients O.D.E. has positive eigenvalue λ_1 and complex eigenvalues λ_2, λ_3. If we turn to the characteristic variables u, the first component u_1 in (3.8) will grow with the rate $e^{\lambda_1 r}$, also in interval arithmetic, while the second component u_2 will grow as $e^{|\lambda_2|r}$, where really it is decreasing as $e^{\text{Re }\lambda_2 r} = e^{-\lambda_1 r/2}$. To prevent this exponential growth we switch to the real variables $z = (z_1, z_2, z_3)$,

$$z_1 = u_1, \qquad z_2 + iz_3 = e^{-i\text{Im }\lambda_2 r}u_2. \tag{4.8}$$

Then, instead of (3.8), variables z_2, z_3 will satisfy O.D.E.'s with the exponent Re λ_2. The precise transformation formulas from $\bar{y}$ to z are

$$u_1 = \sum_{j=0}^{2} c_{1j}y^{(j)}, \quad \text{Re } u_2 = \sum_{j=0}^{2} c_{2j}y^{(j)}, \quad \text{Im } u_2 = \sum_{j=0}^{2} c_{3j}y^{(j)}, \tag{4.9}$$

$$\begin{aligned} z_2 &= \cos\ \text{Im}\ \lambda_2 r \cdot \text{Re}\ u_2 + \sin\ \text{Im}\ \lambda_2 r \cdot \text{Im}\ u_2, \\ z_3 &= -\sin\ \text{Im}\ \lambda_2 r \cdot \text{Re}\ u_2 + \cos\ \text{Im}\ \lambda_2 r \cdot \text{Im}\ u_2 \end{aligned} \tag{4.10}$$

The variable y in (4.9) is, of course, the y_{new} of (3.4). In variable z equation (3.8) becomes

$$\begin{aligned} z_1' &= \lambda_1 z_1 + c_{13}f, \\ z_2' &= \text{Re}\ \lambda_2 \cdot z_2 + (c_{23}\cos\ \text{Im}\ \lambda_2 r + c_{33}\sin\ \text{Im}\ \lambda_2 r)f, \\ z_3' &= \text{Re}\ \lambda_2 \cdot z_3 + (c_{33}\cos\ \text{Im}\ \lambda_2 r - c_{23}\sin\ \text{Im}\ \lambda_2 r)f. \end{aligned} \tag{4.11}$$

The constants c_{ij} as follow from (3.7) are

$$
\begin{aligned}
&c_{11} = \frac{|\lambda_2|^2}{|\lambda_1 - \lambda_2|^2} = \frac{\lambda_1^2 + \alpha}{3\lambda_1^2 + \alpha}, \qquad c_{12} = \frac{-\lambda_2 - \lambda_3}{|\lambda_1 - \lambda_2|^2} = \frac{\lambda_1}{3\lambda_1^2 + \alpha},\\
&c_{13} = \frac{1}{3\lambda_1^2 + \alpha}, \qquad c_{21} = \operatorname{Re} \frac{\lambda_1 \lambda_3}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = \frac{\lambda_1^2}{3\lambda_1^2 + \alpha},\\
&c_{22} = -\operatorname{Re} \frac{\lambda_1 + \lambda_3}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = -\frac{\lambda_1}{2(3\lambda_1^2 + \alpha)},\\
(4.12)\quad &c_{23} = \operatorname{Re} \frac{1}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = -\frac{1}{2(3\lambda_1^2 + \alpha)},\\
&c_{31} = \operatorname{Im} \frac{\lambda_1 \lambda_3}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = \frac{\lambda_1 \alpha}{2(3\lambda_1^2 + \alpha)\operatorname{Im} \lambda_2},\\
&c_{32} = -\operatorname{Im} \frac{\lambda_1 + \lambda_3}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = -\frac{(3\lambda_1^2/2 + \alpha)}{2(\lambda_1^2 + \alpha) \operatorname{Im} \lambda_2},\\
&c_{33} = \operatorname{Im} \frac{1}{(\lambda_2 - \lambda_1)(\lambda_2 - \lambda_3)} = \frac{3\lambda_1/2}{2(\lambda_1^2 + \alpha)\operatorname{Im} \lambda_2}.
\end{aligned}
$$

The higher-order derivatives of z are computed by (4.11):

$$
\begin{aligned}
&z_1^{(i+1)} = \lambda_1 z_1^{(i)} + c_{13} f^{(i)},\\
(4.13)\quad &z_2^{(i+1)} = \operatorname{Re} \lambda_2 \cdot z_2^{(i)} + \sum_{j=0}^{i} \binom{i}{j} (c_{23} \cos^{(i-j)} \operatorname{Im} \lambda_2 r\\
&\qquad\qquad + c_{33} \sin^{(i-j)} \operatorname{Im} \lambda_2 r) f^{(j)}
\end{aligned}
$$

and similarly for z_3. It was more convenient to compute the derivatives of f by differentiating (3.4) instead of expressing f in terms of z. The differentiation formulas appear in the listing of the computer program in the subroutine DERIV. For the convenience of the reader we present them here in mathematical notation:

$$
(4.14)\qquad (y^2)^{(i)} = \sum_{j=0}^{i} \binom{i}{j} y^{(j)} y^{(i-j)},
$$

$$
\begin{aligned}
f^{(i)} &= -\sum_{j=0}^{i} \binom{i}{j} (2y^{(j+2)} (r^{-1})^{(i-j)} - 2b_2 y^{(j)} (r^{-1})^{(i-j+1)}\\
(4.15)\quad &+ y^{(j+1)} (r^{-1})^{(i+j+1)} + y^{(j)} (r^{-1})^{(i+j+2)}/2) - (y^2)^{(i)} - (\alpha - \alpha_0) y^{(i+1)}\\
&- q_3 (r^{-1})^{(i+2)} - q_4 (r^{-1})^{(i+3)} - q_5 (r^{-1})^{(i+4)},
\end{aligned}
$$

where $b_2 = \alpha^2/8$ as in (3.21) and q_i are related to p_i in (3.23) as

$$
(4.16)\qquad \begin{aligned}
&q_3 = p_3/2 = -(1 + \alpha^3/4)/2, \qquad q_4 = -p_4/6 = -\alpha^4/384,\\
&q_5 = p_5/24 = -3\alpha^2/64.
\end{aligned}
$$

Finally, by (3.4)

$$y^{(i+3)} = -\alpha_0 y^{(i+1)} + 2y^{(i)} + f^{(i)}. \tag{4.17}$$

Recall that the term $-(\alpha - \alpha_0)y^{(i+1)}$ is absorbed in $f^{(i)}$. Thus we compute first the derivatives $f^{(i)}$ and $y^{(i+3)}$ for $i = 1, \cdots, n$ and then the derivatives $z^{(i)}$, $i = 1, \cdots, n+1$. The value of $z(r+h)$ is then computed by formula (4.6) with y replaced by z. Recall that Re $\lambda_2 = -\lambda_1/2 < 0$. If $z_2 + hz_2'$ were added in interval arithmetic as

$$z_2 + h \text{ Re } \lambda_2 z_2 + O(f) \tag{4.18}$$

then, for a symmetric interval $z_2 = (-\delta, \delta)$, the result would be $z_2(1+h|\text{Re } \lambda_2|)+O(f)$. Instead we add it as

$$z_2 + hz_2' = z_2(1 + h \text{ Re } \lambda_2) + (c_{23} \cos \text{ Im } \lambda_2 r + c_{33} \sin \text{ Im } \lambda_2 r)f. \tag{4.19}$$

The remaining part of the Taylor formula is added in a straightforward manner by Horner's method. As r increases and z becomes small, $z_2(1 + h \text{ Re } \lambda_2)$ becomes a leading term in the Taylor formula. As a result z_2 decreases exponentially. The component z_1 grows, of course, but with the correct rate $e^{\lambda_1 r}$. Once $z(r+h)$ has been computed, $y(r+h)$ is expressed in terms of $z(r+h)$. The explicit inverse transformation formulas are

$$\begin{aligned} y &= u_1 + 2\text{Re } u_2, \\ y' &= \lambda_1 u_1 + 2(\text{Re } \lambda_2 \cdot \text{ Re } u_2 - \text{ Im } \lambda_2 \cdot \text{ Im } u_2), \\ y'' &= \lambda_1^2 u_1 + 2(\text{Re } \lambda_2^2 \cdot \text{ Re } u_2 - \text{ Im } \lambda_2^2 \cdot \text{ Im } u_2), \\ u_1 &= z_1, \qquad \text{Re } u_2 = z_2 \cos \text{ Im } \lambda_2 r - z_3 \sin \text{ Im } \lambda_2 r, \\ \text{Im } u_2 &= z_2 \sin \text{ Im } \lambda_2 r + z_3 \cos \text{ Im } \lambda_2 r. \end{aligned} \tag{4.20}$$

Despite the above stabilization procedure, the computations with reasonable intervals $\Delta\alpha = .005$ and $\Delta s = .0015$ exploded before reaching $r_1 \approx 6$. Therefore, instead of solving the differential equations (3.4), (4.11) with $\alpha = I_{\Delta\alpha}$, $s = I_{\Delta s}$ we evaluated the function $y(r,s,\alpha)$ and $z(r,s,\alpha)$ by the Taylor formula of order 2:

$$\begin{aligned} y(r,s,\alpha) &= y(r,s_0,\alpha_0) + \partial_s y(r,s_0,\alpha_0)(s-s_0) + \partial_\alpha y(r,s_0,\alpha_0)(\alpha-\alpha_0) \\ &\quad + \sum_{j_1+j_2=2} \frac{\partial_s^{j_i}\partial_\alpha^{j_2}}{j_1!j_2!} y(r,s,\alpha)(s-s_0)^{j_i}(\alpha-\alpha_0)^{j_2} \end{aligned} \tag{4.21}$$

and similarly for z. Hence $y(r,s_0,\alpha_0)$ and its first derivatives were computed for the point values of $s = s_0, \alpha = \alpha_0$ and only the second derivatives $\partial_s^{j_1}\partial_\alpha^{j_2}y$, $j_1 + j_2 = 2$ were computed for the original interval values of s and α. With Δs and $\Delta\alpha$, as above, $(s-s_0)^{j_1}(\alpha-\alpha_0)^{j_2} \approx 10^{-6}$, so we could afford second-order derivatives of a magnitude $10^3 - 10^4$. The equations for the derivatives with respect to s and α are obtained by differentiating (4.13)–(4.16). The eigenvalues λ_i and the coefficients c_{ij} in (4.13) are constant since they are computed at $\alpha = \alpha_0$; however, $b_2 = \alpha^2/8$ and q_i at (4.16) depend on α. When differentiating the nonlinear term y^2 in (4.14) we obtain

$$(\partial_s^2 y^2)^{(i)} = 2\sum_{j=0}^{i} \binom{i}{j} (\partial_s^2 y^{(j)} y^{(i-j)} + \partial_s y^{(j)} \partial_s y^{(i-j)}) \tag{4.22}$$

and similarly for the other second derivatives. Here we have to know the values of $y^{(i)}$ and $\partial_s y^{(i)}$ for $(s, \alpha) \in I_{\Delta s} \times I_{\Delta\alpha}$. The former ones are computed by (4.21) and the latter ones by

$$\begin{aligned}\partial_s y^{(i)}(r, s, \alpha) = \partial_s y^{(i)}(r, s_0, \alpha_0) + \partial_s^2 y^{(i)}(r, s, \alpha)(s - s_0) \\ + \partial_s \partial_\alpha y^{(i)}(r, s, \alpha)(\alpha - \alpha_0)\end{aligned} \tag{4.23}$$

and similarly for $\partial_\alpha y^{(i)}$. These interval values also appear when $b_2 y^{(j)}$ and $(\alpha - \alpha_0) y^{(i+1)}$ in (4.15) are differentiated twice with respect to α or in the mixed derivative $\partial_s \partial_\alpha$. The precise differentiation formulas appear in the listing of our computer code in the Appendix, in the subroutine DERIV. As already mentioned in §2, the derivatives $\partial_s^{j_1} \partial_\alpha^{j_2} f$ of a generic function f are stored in our program as shown in (2.33). The derivatives $\partial_s^{j_1} \partial_\alpha^{j_2}, 0 \le j_1 + j_2 \le 1$ computed at the central point (s_0, α_0) and the second-order derivatives in $I_{\Delta s} \times I_{\Delta\alpha}$ carry the name $f0$, while the derivatives up to order 1 in $I_{\Delta s} \times I_{\Delta\alpha}$ carry the original name f. More detailed comments that explain the purpose of each variable appear in the listing of the program in the Appendix. Now, with the Taylor expansion in $(s - s_0)$ and $(\alpha - \alpha_0)$, our program could advance the solution up to $r_1 \approx 6 \div 8$ (depending on α) with $\Delta\alpha$ and Δs as above. The step size h in r was constant $h = \frac{1}{8}$. The order n of the Taylor method was 8 for $0 \le \alpha \le 1.7$ and 10 for $1.7 < \alpha \le 2.4$. The slope s_0 corresponding to α_0 was computed by a preliminary nonrigorous program so that

$$z_1(\tilde{r}_1, s_0, \alpha_0) = 0, \tag{4.24}$$

where $\tilde{r}_1$ is the expected value of r_1 at which the subroutine ESTIM should succeed in proving the transversality of the intersection. As mentioned in (2.18), we assumed that when differentiating with respect to α, the slope s is a linear function of α. The derivative s_α in (2.18) is set by the preliminary program so that

$$\partial_\alpha z_1(\tilde{r}_1, s_0, \alpha_0) = 0. \tag{4.25}$$

As a result,

$$z_1(r_1, s, \alpha) \approx \partial_s z_1(r_1, s_0, \alpha_0) \cdot (s - s_0), \tag{4.26}$$

so that

$$z_1(r_1, s_0 \pm \Delta s, \alpha) = \pm\, \partial_s z_1(r_1, s_0, \alpha_0) \cdot \Delta s. \tag{4.27}$$

Because of the exponential growth, $\partial_s z_1(r_1, s_0, \alpha_0)$ is quite large, of the order $40 \div 70$. The interval values of $z_1(r_1, s_0 - \Delta s, \alpha)$ and $z_1(r_1, s_0 + \Delta s, \alpha)$ appear in the last four columns of Table 1. Indeed they are almost opposite to each other and well separated for all α by the plane $z_1 = 0$. The subroutine ESTIM testifies that they are also separated by the manifold M_{cs}.

5. The computer program. Below we will explain in general the structure of our computer code BUNSEN. The listing of the program appears in the Appendix. The program is written in Fortran and consists of the main part and of nine subroutines. The main part reads the input prepared by the preliminary program. This input consists of the values s_0, α_0, and s_{α_0} denoted correspondingly by $S0$, $ALF0$, and $SA0$. It also defines the vector DP as explained in (2.36), computes the coefficients $b_2 = B2$ and $q_i = Q(i)$ and their derivatives with respect to s and α, and computes the derivatives $RD(i) = (r^{-1})^{(i)}$ and other constants. It also calls various subroutines in the following order:

(1) Subroutine CONST, which computes the coefficients $COEF(i,j) = c_{ij}$ as defined in (4.12), the eigenvalues $LAM(1) = \lambda_1$, $LAM(2) = \operatorname{Re}\lambda_2$, $LAM(3) = \operatorname{Im}\lambda_2$, $LAM2(1) = \lambda_1^2$, $LAM2(2) = \operatorname{Re}(\lambda_2^2)$, $LAM2(3) = \operatorname{Im}(\lambda_2^2)$, $LAM2(4) = (\operatorname{Im}\lambda_2)^2$.

(2) Subroutine SERIES, which returns the vector $Y0$ defined as $(Y0(j,k),\ Y0(j+1,k)) = \partial_s^{j_1}\partial_\alpha^{j_2}y^{(k)}(r_0)$, with $0 \le k \le 2$, $j_1+j_2 \le 2$, and j as in (2.33). For $j_1+j_2 = 2$ the corresponding values are computed in $I_{\Delta s} \times I_{\Delta\alpha}$, otherwise at the central point (s_0, α_0).

(3) Next, the main program transforms the vector $Y0$ from the original y variables to the new variable $y_{\text{new}} = y_{\text{old}} - y_N$, where y_N is defined by (3.21). After that the subroutine TRANS computes the corresponding vector $z0$ as defined by (4.9), (4.10).

(4) The five step algorithm presented in §4 calls twice the subroutine DERIV and computes the derivatives $y^{(i)}(r)$, $z^{(i)}(r)$, and the truncation error E_n of the Taylor series. The derivatives $\partial_s^{j_1}\partial_\alpha^{j_2}y^{(i)}(r)$ are stored in the vector $YD0(j,i)$ and similarly for z. In the second call to DERIV the corresponding values for the interval $[r, r+h]$ are stored in the vectors $YDH0(j,i)$ and $ZDH0(j,i)$. Since for E_n we need to know only the derivatives of order $i = n+1$, in the second call to DERIV the derivatives $ZDH0(j, n+1)$ are computed from $YDH0(j,i)$, $i \le n+1$ by formulas (4.9)–(4.10) and not by (4.11). The last parameter $IFLAG$ in the calling sequence of DERIV controls the above-mentioned option of computing $ZDH0(j, n+1)$. The transformation from $YDH0$ to $ZDH0$ is carried out by the subroutine TRANSD. After the second call to DERIV the main program verifies that $y_h \subset y_{h_0}$ (see (4.5)) and computes the vector $Z0$ for $r = r+h$. The inverse transformation from z to y as defined by (4.20) is carried out by the subroutine TRANSIN.

(5) $z(r)$ for $\alpha = I_{\Delta\alpha}$ and $s = I_{\Delta s}$ or $s = s_0 \pm \Delta s$ is computed. The results are stored in vectors z and $z1$ correspondingly. Then subroutine ESTIM is called. It checks whether z lies in the domain of M_{cs} and whether $z1$ is separated by M_{cs}. The subroutine ESTIM also verifies the transversality of the intersection. Step (5) is executed if r becomes greater than $RMAX1 = 5$. If the result of ESTIM is positive, the program reads the new input for a higher value of α and repeats the whole procedure. If not, the trajectory is advanced in r. If r exceeds a fixed value $RMAX = 8$ the program stops.

As already mentioned in §2 our program is processed by a compiler which we called COMPINT. All statements indicated by the letter I in the first column are considered to be interval statements. All variables declared by the INTERVAL type statements preceded by the label ID in the first two columns are considered to be interval variables. Likewise, all variables assigned their values by the I statements are treated by COMPINT as interval variables. The interval variables are always pairs of real machine numbers $x(1), x(2), x(1) \le x(2)$. They are stored in the successive order and named by the address of the first number $x(1)$. Thus, all interval variables are defined in our program by the DIMENSION statement as arrays of length 2, and in case of vector variables we add the first dimension of length 2. The exception are the partial derivatives $\partial_s^{j_1}\partial_\alpha^{j_2}y$ and $\partial_s^{j_1}\partial_\alpha^{j_2}z$, which are stored as explained in (2.33). This was done in order to reduce the number of dimensions to 3, which is the maximal dimension allowed in Fortran.

The compiler COMPINT translates all I statements into a sequence of elementary operations +, −, *, and / and replaces them by a call to corresponding subroutines SUM, DIF, MUL, and DIV. The names of the subroutines carry two additional digits

1 or 2. For example, MUL21(A, B, C) computes the product of an interval variable A with a real scalar variable B. Thus the digit 1 stands for scalar variable and 2 for the interval one. In all cases the result C is an interval variable. When encountering the expression $C = A * B$ the compiler checks the type of the variables A and B and then sets in the corresponding name of the subroutine. The listing of the most involved elementary subroutine MUL22(A, B, MUL) appears in the Appendix. The resulting interval MUL satisfies

$$(5.1) \qquad D(1)(1-\varepsilon) < MUL(1) < D(1), \qquad D(2) < MUL(2) < D(2)(1+\varepsilon),$$

where

$$(5.2) \qquad D(1) = \min(A(i), B(j)), \quad D(2) = \max(A(i), B(j)), \quad i, j = 1, 2$$

and

$$(5.3) \qquad \varepsilon = 2^{-47} + 2^{-48}.$$

When computing $D(1)$ and $D(2)$, because of symmetric rounding we obtain instead numbers $C1$ and $C2$. Then $MUL(1)$ and $MUL(2)$ are defined by

$$(5.4) \qquad MUL(1) = C1 - 2^{e_1 - 48}, \qquad MUL(2) = C2 + 2^{e_2 - 48},$$

where e_1 and e_2 are the exponents of $C1$ and $C2$ in the binary floating point representation. The number 48 here stands for 48-digit binary mantissa in our computer. The rounding in (5.4) may cause a relative error up to 2^{-47} with an additional maximal relative error of 2^{-48} in the symmetric rounding. The constants $2^{e_1 - 48}$, $i = 1, 2$ are formed by logical operation at the level of binary words $C1$ and $C2$. To adjust this and other subroutines to a different word length we must change only two logical constants. Besides the above four operations our library named INTAR (interval arithmetic) includes two subroutines ISIN22(X, Y), ICOS22(X, Y), which for an interval X compute the interval Y such that $Y \supset \sin X$ and $Y \supset \cos X$, correspondingly. In order to give a correct result the length $x(2) - x(1)$ of X should in the worst case be less than 0.1. In our computation these programs were called with intervals $X = \operatorname{Re} \lambda_2 \cdot r$ of negligible length. The content of the library INTAR as well as the compiler COMPINT are not listed in this publication and can be obtained from the author by request. Two more interval arithmetic subroutines ISQRT22 and CUBEQ appear in the listing of our program BUNSEN. The first finds a square root of an interval and the second solves a cubic equation with interval coefficients. We need the latter to solve (1.13) and (2.10).

The parts of the program and the program as a whole were extensively checked. As a practical and most convincing test we should mention that (1.8) was solved independently by Taylor's method in the original variables y. In this case the algorithm is very simple and short. The results, however, agreed completely with the box values obtained by the program BUNSEN.

6. Conclusion. The Bunsen flame solutions are a particular though physically important case of two-dimensional structures described by the Kuramoto–Sivashinsky equation. In this paper we managed to prove the existence of these solutions for the physically relevant values of parameters. There are also other types of radial solutions which tend to periodic, quasi-periodic, or chaotic solutions of the O.D.E (1.5) as $r \to \infty$. A rigorous computer assisted proof of existence of such solutions seems to be a hard task even with modern supercomputers. Laboratory experiments have shown that Bunsen flames may rotate with a constant speed. The stationary solution we found is closely related to the leading term in the Fourier series expansion of the rotating flame with respect to the polar angle φ. It now seems possible to justify the existence of such rotating solutions, at least on the physical level of rigor.

7. Appendix. The computer program BUNSEN is not published here due to its length of 700 lines. It can be obtained from the author by electronic mail.

LARGE-TIME BEHAVIOR OF A TIME-PERIODIC COOPERATIVE SYSTEM OF REACTION-DIFFUSION EQUATIONS DEPENDING ON PARAMETERS*

PETER TAKÁČ†

Abstract. A kind of *structural stability* with respect to a parameter $\theta \in \Theta$ for a generic strongly monotone discrete-time dynamical system $\{T_\theta^n : X \longrightarrow X;\ n \in \mathbb{Z}_+\}$ is studied. Here, X and Θ are strongly ordered spaces, and the mapping $(x, \theta) \longmapsto T_\theta x$ from $\mathcal{X}$ into X is assumed to be continuous, strongly monotone and satisfying a compactness hypothesis. A classification of structurally stable points in $\mathcal{X}$ is introduced; the set of all such points is denoted by $\mathcal{S}$. *No* hyperbolicity hypothesis is assumed. If $\mathcal{X}$ is an open subset of a strongly ordered separable Banach space $\mathcal{V}$, it is proved that (1) $\mu(\mathcal{X} \setminus \mathcal{S}) = 0$ for every Gaussian measure μ on $\mathcal{V}$; (2) $(x, \theta) \in \mathcal{S}$ implies $\omega_\theta(x) \times \{\theta\} \subset \mathcal{S}$, where $\omega_\theta(x)$ denotes the ω-limit set of $x \in X$ under the semigroup $\{T_\theta^n : n \in \mathbb{Z}_+\}$; and (3) $\omega_\theta(x)$ is a "quasi cycle" for T_θ whenever $(x, \theta) \in \mathcal{S}$. These results are applied to a very general strictly cooperative time-periodic system of weakly coupled reaction-diffusion equations with (space- and/or time-dependent) parameters in both the reaction functions and Robin's boundary conditions. Here T_θ is the period map.

Key words. reaction-diffusion equation, strictly cooperative system, strongly monotone mapping, period map, structural stability, quasi cycle, ω-limit set

Introduction. This work deals with the large-time asymptotic behavior of a very general time-periodic system of reaction-diffusion equations which depend upon certain parameters. We restrict ourselves to those systems which have the following *monotonicity* property:

(M) The solution $u(t)$ (where $t \geq 0$ is the time variable) depends monotonically upon its initial value $u(0) = u_0$ and the parameter(s) θ.

More precisely, we assume that the solution $u(t) \equiv u(t, u_0, \theta)$ belongs to an ordered phase space $(X, \leq)$ and the parameter θ belongs to an ordered parameter space $(\Theta, \leq)$. Typically, X and Θ are suitable open subsets of ordered Banach spaces whose positive cone has nonempty interior (cf. Schaefer [23]). Then, given any $t \geq 0$, the mapping $u(t, \cdot, \cdot) \colon X \times \Theta \longrightarrow X$ is called *monotone* if

$$u_0 \leq u_0' \text{ in } X \quad \text{and} \quad \theta \leq \theta' \text{ in } \Theta \Longrightarrow u(t, u_0, \theta) \leq u(t, u_0', \theta') \quad \text{in } X.$$

We are interested in how the asymptotic behavior as $t \longrightarrow \infty$ of $u(t, u_0, \theta)$ depends upon u_0 and θ. In particular, we focus our study on (some sort of) *structural stability* of our monotone dynamical system with respect to the parameter θ. This problem can also be viewed as an *input-output* problem where (u_0, θ) represents the input, and $u(t, u_0, \theta)$ is the output, with the output depending monotonically and continuously upon the input, for each $t \geq 0$. Monotone dynamical systems without parameters have been studied recently by a number of authors, cf. Alikakos, Hess, and Matano [1], Chen and Matano [7], Hess [10], Hirsch [11]–[15], Matano and Mimura [17], Poláčik [21], Smith [25], Smith and Thieme [26], [27], Takáč [28]–[30], and others. Generically, autonomous monotone dynamical systems show convergence to an equilibrium (or a set of equilibria) for "almost every" relatively compact semiorbit. Under some additional restrictions the corresponding conclusion also holds for time-periodic

or discrete-time systems. However, until now the only work with parameters and monotonicity playing a crucial rôle is that of Thron [31], [32] who has studied simple input-output problems in pharmacokinetics by numerical simulations. In [31] a compartmental model deals with patients on a regular (time-independent) drug dosage schedule where drug dosage represents the input, and drug concentration (in a cell) is the output. It is conjectured that in such autonomous dynamical systems monotonicity with respect to certain parameters should prevent oscillatory (time-periodic) or chaotic large-time behavior in drug concentrations. The problem of stability of equilibria (steady states in drug concentrations) upon changes in drug dosage is mentioned as well. Our present article is the very beginning of rigorous analytical treatment of monotone dynamical systems depending (monotonically) upon parameters, with *no* hyperbolicity assumption of any kind.

The main objective of this article is to show that, in a very general time-periodic monotone dynamical system with parameters, "almost every" input $(u_0, \theta) \in X \times \Theta$ has the following two properties:

(1) Uniformly in time $t \in [0, \infty)$, the output $u(t, u_0, \theta)$ depends continuously upon the input varying near $(u_0, \theta) \in X \times \Theta$ (structural stability).

(2) The output $u(t, u_0, \theta)$ can be approximated by nearby periodic orbits, uniformly in time $t \in [t_0, \infty)$, where $t_0 \in [0, \infty)$ is sufficiently large (near periodic large-time behavior).

The kinds of applications of our results we have in mind include (a) chemical and biochemical reactions among diffusing substances in a vessel (e.g., a biochemical control circuit for enzymes metabolizing a drug in a cell) (cf. Othmer [19] and Thron [31]), (b) cooperative migrating populations with diffusive migration within a common region as studied in population biology, epidemiology, and ecology (cf. Fife [8] and Hirsch [12], [14]), and (c) two competing populations with diffusive migration within a region where they compete for resources, with competition, diffusion, and resource availability observing time-periodic seasonal oscillations (cf. Matano and Mimura [17]). Mathematical formulation of such models typically results in a time-periodic cooperative system of reaction-diffusion equations which may depend on certain parameters. A special case of such a system is a spatially homogeneous cooperative system of ordinary differential equations, a frequently used approximation. Below we present two problems, (**P**) and (**P′**), on which we can explain applications of our results.

Problem (**P**). We consider the following time-periodic, strictly cooperative system of reaction-diffusion equations with (spatially and/or temporally dependent) parameters in both the reaction-diffusion equations and the boundary conditions:

$$(\mathbf{P})\qquad \begin{aligned} &\frac{\partial u_k}{\partial t} - d_k(x,t)\Delta u_k = f_k(x,t,u_1,\cdots,u_n) + \sum_{\ell=1}^{n} \gamma_{k\ell}(x,t)u_\ell \quad \text{in } \Omega \times (0,\infty);\\ &\frac{\partial u_k}{\partial n} + \vartheta_k(x,t)u_k = 0 \qquad \text{on } \partial\Omega \times (0,\infty);\\ &\qquad u_k(x,0) = u_{k,0}(x) \qquad \text{in } \Omega. \end{aligned}$$

Here, $n \in \mathbb{N}$ is the number of equations indexed by $k = 1, 2, \cdots, n$, which are considered in an open bounded domain $\Omega \subset \mathbb{R}^N$ with the boundary $\partial\Omega$ of class C^3. The diffusion phenomenon is modelled by the N-dimensional Laplacian Δ with the diffusion coefficient $d_k(x,t) \geq d_k^* > 0$, $(x,t) \in \Omega \times (0,\infty)$. The systems of reaction functions f_k and $\gamma_{k\ell}$, $1 \leq k$, $\ell \leq n$, are assumed to be *cooperative* and *strictly* *cooperative*, respectively:

$$\frac{\partial f_k}{\partial u_l} \geq 0 \quad \text{and} \quad \gamma_{k\ell} > 0 \quad \text{whenever} \quad k \neq \ell.$$

We consider Robin's boundary conditions with $\vartheta_k(x,t) \geq \vartheta_k^* > 0$, $(x,t) \in \partial\Omega \times (0,\infty)$. All functions d_k, f_k, $\gamma_{k\ell}$, and ϑ_k are assumed to be *τ-periodic* in time $t \in \mathbb{R}^1_+$, where $\tau \in (0,\infty)$, and of class C^2 in their respective domains:

$$d_k : \overline{\Omega} \times \mathbb{R}^1_+ \longrightarrow [d_k^*, \infty), \qquad f_k : \overline{\Omega} \times \mathbb{R}^1_+ \times \mathbb{R}^n \longrightarrow \mathbb{R}^1,$$
$$\gamma_{k\ell} : \overline{\Omega} \times \mathbb{R}^1_+ \longrightarrow \mathbb{R}^1, \qquad \text{and} \qquad \vartheta_k : \partial\Omega \times \mathbb{R}^1_+ \longrightarrow [\vartheta_k^*, \infty).$$

The functions d_k and f_k are assumed to be fixed, whereas $\gamma \equiv (\gamma_{k\ell})_{k,\ell=1}^n$ and $\vartheta \equiv (\vartheta_k)_{k=1}^n$ are *parameters* varying in suitable open subsets of the Banach spaces

$$\tilde{V}_\gamma = C^2(\overline{\Omega} \times (\mathbb{R}^1/\tau\mathbb{Z}) \longrightarrow \mathbb{R}^{n\times n}) \quad \text{and} \quad \tilde{V}_\vartheta = C^2(\partial\Omega \times (\mathbb{R}^1/\tau\mathbb{Z}) \longrightarrow \mathbb{R}^n),$$

respectively. We denote all these parameters by $\theta = (\gamma, \vartheta) \in \Theta \subset \tilde{V}_\Theta = \tilde{V}_\gamma \times \tilde{V}_\vartheta$, where Θ is a suitable open subset of the strongly ordered Banach space $\tilde{V}_\Theta$. Of course, we consider the natural *pointwise* and *coordinatewise* ordering in all our function spaces. In particular, $\theta \leq \theta'$ in $\tilde{V}_\Theta$ is equivalent to: $\gamma_{k\ell} \leq \gamma'_{k\ell}$ in $\overline{\Omega} \times \mathbb{R}^1_+$ and $\vartheta_k \leq \vartheta'_k$ in $\partial\Omega \times \mathbb{R}^1_+$, where $\theta = (\gamma, \vartheta)$ and $\theta' = (\gamma', \vartheta')$ have coordinates indexed by k, $\ell = 1, \cdots, n$. The positive cone $(\tilde{V}_\Theta)_+ = \{\theta \in \tilde{V}_\Theta : \theta \geq 0\}$ in $\tilde{V}_\Theta$ has nonempty interior $\operatorname{Int}((\tilde{V}_\Theta)_+)$ which is equivalent to saying that $\tilde{V}_\Theta$ is *strongly ordered.*

Problem (**P**$'$). A particularly interesting example, which we owe to C. Dennis Thron [31], [32], of a (spatially homogeneous) time-periodic, strictly cooperative system of ordinary differential equations with (temporally dependent) parameters arises in pharmacology as a dynamical problem in drug metabolism:

$$(\mathbf{P}') \qquad \begin{aligned} &\frac{du_k}{dt} = f_k(t, u_1, \cdots, u_n, v_1, \cdots, v_{n'}) + \gamma_k(t) && \text{in } (0,\infty), \\ &\frac{dv_{k'}}{dt} = g_{k'}(t, u_1, \cdots, u_n, v_1, \cdots, v_{n'}) && \text{in } (0,\infty); \\ &u_k(0) = u_{k,0}, \\ &v_{k'}(0) = v_{k',0}. \end{aligned}$$

Here, $u_k : [0,\infty) \longrightarrow [0,\infty)$ denotes the (spatially homogeneous) concentration of the kth drug $(1 \leq k \leq n)$, $v_{k'} : [0,\infty) \longrightarrow [0,\infty)$ denotes the concentration of the k'th enzyme $(1 \leq k' \leq n')$, and $\gamma_k : [0,\infty) \longrightarrow [0,\infty)$ is the infusion rate of the kth drug. We are dealing with a compartmental model of a metabolic system of $(n + n')$ interacting drugs and enzymes occupying a single cell. Their interaction (e.g., induction of enzymes which metabolize drugs, synthesis of enzymes, etc.) is described by the system of (smooth) reaction functions $f_k : [0,\infty) \times \mathbb{R}^n \times \mathbb{R}^{n'} \longrightarrow \mathbb{R}$ and $g_{k'} : [0,\infty) \times \mathbb{R}^n \times \mathbb{R}^{n'} \longrightarrow \mathbb{R}$, which is assumed to be strictly cooperative by the biological nature of the interaction, i.e., all off-diagonal entries in the corresponding Jacobian matrix of the mapping $\left((f_k(t, \cdots))_{k=1}^n, (g_{k'}(t, \cdots))_{k'=1}^{n'}\right) : \mathbb{R}^n \times \mathbb{R}^{n'} \longrightarrow \mathbb{R}^n \times \mathbb{R}^{n'}$ in (**P**$'$) are > 0, for each $t \in [0,\infty)$. Particular forms of these reaction functions are obtained from intercompartmental fluxes and their dependence upon concentrations of drugs and enzymes; cf. Thron [31] for biological arguments. The drugs are injected in equal time-periods $\tau > 0$, and also all reaction functions are assumed to be τ-periodic in time t. For instance, we can consider the following simple *enzyme-substrate* system ($n = n' = 1$):

$$\begin{aligned} \frac{du}{dt} &= -c_1 u(E-v) + c_2 v + \gamma(t) \quad \text{for } t \in (0,\infty), \\ \frac{dv}{dt} &= c_1 u(E-v) - (c_2+c_3)v \quad \text{for } t \in (0,\infty). \end{aligned}$$

Here u, E, and v denote the (nonnegative) concentrations of substrate, total enzyme, and enzyme-substrate complex, respectively, and $\gamma(t)$ is the substrate influx rate which is considered to be τ-periodic. All constants E, c_1, c_2, and c_3 are assumed to be positive. (Of course, our results apply also to the case when E, c_1, c_2, and c_3 are known continuous τ-periodic functions of time t.) This system is strictly cooperative at any time $t \in [0,\infty)$ when its solution $\big(u(t), v(t)\big)$ satisfies $0 \le u(t) < \infty$ and $0 \le v(t) < E$.

Problem ($\mathbf{P}'$) poses an input-output problem in pharmacokinetics, where the infusion rates $\gamma \equiv (\gamma_k)_{k=1}^n$ are parameters representing time-periodic input, and the concentrations $(u,v) \equiv \big((u_k)_{k=1}^n, (v_k)_{k'=1}^{n'}\big)$ are solutions of ($\mathbf{P}'$) representing output. Of interest is the dependence of the output upon the input. Continuity of this dependence is closely related to structural stability of the dynamical system ($\mathbf{P}'$), with respect to the parameter γ varying in a suitable open subset Θ of the Banach space $\tilde{V}_\Theta = C(\mathbb{R}^1/\tau\mathbb{Z} \longrightarrow \mathbb{R}^n)$.

We now return to our first problem ($\mathbf{P}$); problem ($\mathbf{P}'$) can be treated analogously. We denote by $u \equiv (u_k)_{k=1}^n : \Omega \times \mathbb{R}_+^1 \longrightarrow \mathbb{R}^n$ the (unique) L_p-*solution* of our problem ($\mathbf{P}$) with the initial value $u_0 \equiv (u_{k,0})_{k=1}^n : \Omega \longrightarrow \mathbb{R}^n$, for a fixed $p \in (2N,\infty)$, cf. Amann [2], [3], [5]. The underlying space X for the solution $u(\,\cdot\,,t) \in X$, $t \in \mathbb{R}_+^1$, of ($\mathbf{P}$) is a suitably chosen open subset $X \subset \mathrm{Int}_V(V_+)$ of the interior of the positive cone V_+ in the strongly ordered Banach space $V = W_p^1(\Omega \longrightarrow \mathbb{R}^n)$, cf. Triebel [33]. This choice of X is justified by our applications, namely, u_k is the density of the kth component in chemical and biochemical reactions, population biology, epidemiology, ecology, etc., cf. Fife [8], Hirsch [12], [14], Matano and Mimura [17], and Othmer [19], and numerous references therein. If both X and Θ are suitably matched with the given system of reaction functions f_k, $1 \le k \le n$, then the solution $u(\,\cdot\,,t) \in X$ exists globally in time, i.e., for all $t \in \mathbb{R}_+^1$, whenever $u_0 \in X$ and $\theta \in \Theta$ are given. We set $\mathcal{X} = X \times \Theta$ and want to investigate the asymptotic behavior as $t \longrightarrow \infty$ of $u(\,\cdot\,,t) \equiv u(t) \in X$ depending upon $(u_0,\theta) \in \mathcal{X}$. Therefore, we write $u = u(t,u_0,\theta)$ to indicate this dependence.

We define the corresponding *period map* $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ by $\mathcal{T}(u_0,\theta) = \big(u(\tau,u_0,\theta),\theta\big)$ for all $(u_0,\theta) \in \mathcal{X}$. We will study the large-time asymptotic behavior of the solution u in terms of the asymptotic behavior of the iterates $\mathcal{T}^n$, $n \in \mathbb{Z}_+$, of $\mathcal{T}$ as $n \longrightarrow \infty$ applied to the points $(u_0,\theta) \in \mathcal{X}$. More precisely, we are interested in the ω-*limit sets* for the sequences $\mathcal{T}^n(u_0,\theta)$, $n \in \mathbb{Z}_+$, which are defined for every $(u_0,\theta) \in \mathcal{X}$ by

$$\begin{aligned} \omega(u_0,\theta) = \{(w,\theta) \in \mathcal{X} :\ & u(n_k\tau,u_0,\theta) \longrightarrow w \text{ in } X \ (k \longrightarrow \infty) \\ & \text{for some sequence } n_k \longrightarrow \infty \text{ in } \mathbb{Z}_+\}. \end{aligned}$$

To guarantee all the usual interesting properties of these ω-limit sets, e.g., $\omega(u_0,\theta)$ is nonempty, compact, and totally invariant under $\mathcal{T}$, we make use of the following two properties of the mapping $\mathcal{T}$ which can be derived from a number of results of Amann [5, Thm. 7.3] under appropriate hypotheses on f_k, X, and Θ:

(a) $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ is continuous;

(b) If $u_0 \in X$ and $\Sigma \subset \Theta$ is bounded in $\tilde{V}_\Theta$, then the closure in V of the set $u(\tau\mathbb{Z}_+, u_0, \Sigma) \equiv \{u(n\tau, u_0, \theta) : (n, \theta) \in \mathbb{Z}_+ \times \Sigma\}$ is compact in X.

In Example 4.1 we state the precise hypotheses under which both (a) and (b) are valid for the case of a single reaction-diffusion equation ($n = 1$). The reader can easily generalize these hypotheses to a system of n equations using Example 4.6.

To investigate the large-time asymptotic behavior of the solution $u(t, u_0, \theta)$ of $(\mathbf{P})$ we take advantage of the *strong monotonicity* of $u(t, \cdot, \cdot)$ with respect to $(u_0, \theta) \in \mathcal{X}$, for any fixed $t \in (0, \infty)$, which is a direct consequence of our choice of $X \subset \operatorname{Int}_V(V_+)$, $V \subset C(\overline{\Omega} \longrightarrow \mathbb{R}^n)$, and the strong maximum and boundary point principles for strictly cooperative (weakly coupled) parabolic systems, cf. Protter and Weinberger [22, Chap. 3, §8].

(c) If $u_0 \le u_0'$ in X and $\theta \le \theta'$ in Θ satisfy $(u_0, \theta) \ne (u_0', \theta')$, then

$$u(t, u_0', \theta') - u(t, u_0, \theta) \in \operatorname{Int}_V(V_+) \quad \text{holds for every} \quad t \in (0, \infty).$$

For v, $v' \in V$ we write $v \ll v'$ if and only if $v' - v \in \operatorname{Int}_V(V_+)$, and call the relation "$\ll$" the *strong ordering* in V. We use the same notation for the strong orderings in V_Θ and $\mathcal{V} = V \times V_\Theta$. Observe that each of the spaces V, V_Θ, and $\mathcal{V}$ is continuously imbedded into the space $C(K)$ of all continuous functions $\varphi : K \longrightarrow \mathbb{R}^1$ over a compact Hausdorff space K, endowed with the pointwise ordering "$\le$," and hence, for φ, $\varphi' \in C(K)$ we have $\varphi \ll \varphi'$ if and only if $\min_K(\varphi' - \varphi) > 0$.

Using properties (a), (b), and (c) of the mapping $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$, in §2 we define very essential *lower* and *upper stability* notions for an arbitrary point $(u_0, \theta) \in \mathcal{X}$ under the discrete-time semigroup $\{\mathcal{T}^n : n \in \mathbb{Z}_+\}$ acting on $\mathcal{X}$. In Lemma 2.3 we show that our stability notion is, in fact, equivalent to the classical notion of *Lyapunov stability*. This stability incorporates also continuous dependence of our discrete-time dynamical system $\{\mathcal{T}^n : \mathcal{X} \longrightarrow \mathcal{X};\ n \in \mathbb{Z}_+\}$ upon the parameter $\theta \in \Theta$, which reflects the *structural stability* of our system $(\mathbf{P})$ with respect to the parameter $\theta \in \Theta$. The set $\mathcal{S}$ of all stable points in $\mathcal{X}$ can be quite complicated even if we consider the dynamical system generated by a single autonomous ordinary differential equation with a scalar parameter, cf. Example 4.10. We would like to point out once again that *no* hyperbolicity of any kind is assumed in this article.

The most important parts of our main results, Theorems 3.3 and 3.4, can be stated for the problem $(\mathbf{P})$ as follows.

THEOREM 0.1. *Let $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ be the period τ map for the problem* $(\mathbf{P})$, *and assume it satisfies* (a), (b), *and* (c). *Then $\mathcal{U} \equiv \mathcal{X} \setminus \mathcal{S}$ is a Borel subset of $\mathcal{V} = V \times V_\Theta$, a strongly ordered separable Banach space, and $\mu(\mathcal{U}) = 0$ for every Gaussian measure μ on $\mathcal{V}$.*

If $(u_0, \theta) \in \mathcal{S}$ then also $\omega(u_0, \theta) \subset \mathcal{S}$, and $\omega(u_0, \theta)$ is a "quasi cycle" for $\mathcal{T}$ which can be approximated in $\mathcal{X}$ from below and from above, respectively, by monotone sequences of (*true*) *cycles $\omega(v_n, \theta)$ and $\omega(w_n, \theta)$ for $\mathcal{T}$, as $n \longrightarrow \infty$ in $\mathbb{N}$:*

$$v_n \le v_{n+1} \le w_{n+1} \le w_n \ \textit{in}\ X;$$

$$\mathcal{T}^{k_n}(v_n, \theta) = (v_n, \theta) \ \textit{and}\ \mathcal{T}^{\ell_n}(w_n, \theta) = (w_n, \theta) \quad \textit{for some}\ k_n,\ \ell_n \in \mathbb{N};$$

and

$$\omega(u_0,\theta) = \bigcap_{m=1}^{\infty} \mathrm{Cl} \bigcup_{n=m}^{\infty} \omega(v_n,\theta) = \bigcap_{m=1}^{\infty} \mathrm{Cl} \bigcup_{n=m}^{\infty} \omega(w_n,\theta)$$

with "Cl" *denoting the* (*compact*) *closures in* $\mathcal{X}$.

Loosely speaking, this theorem states that the ω-limit set $\omega(u_0,\theta)$ of almost every point $(u_0,\theta) \in \mathcal{X}$ is a stable *quasi cycle* for the period map $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$, meaning that $\omega(u_0,\theta)$ can be approximated by nearby ω-limit sets which are true cycles; see Definition 3.1. We prove this and other results by developing a suitable new theory for the large-time asymptotic behavior of very general discrete-time dynamical systems of the form $\{\mathcal{T}^n : \mathcal{X} \longrightarrow \mathcal{X};\ n \in \mathbb{Z}_+\}$, where $\mathcal{X} = X \times \Theta$, X and Θ are strongly ordered spaces, $\mathcal{T}(x,\theta) \equiv (T_\theta x, \theta)$ for $(x,\theta) \in \mathcal{X}$, and the mapping $(x,\theta) \longmapsto T_\theta x$ from $\mathcal{X}$ into X is continuous and strongly increasing. This theory generalizes a number of earlier results of the author [28], [30].

Without parameters, analogous results have been obtained for strongly increasing continuous-time semiflows by Hirsch [12], [14], Poláčik [21], Smith and Thieme [26], [27], and Takáč [30], and for time-periodic semilinear heat equations in one space dimension by Chen and Matano [7]. Structural stability of systems of weakly coupled reaction-diffusion equations with a single scalar parameter $\theta \in [0,\infty)$ in Robin's boundary conditions has been investigated by Hale and Rocha [9] who assumed large diffusivities d_k and hyperbolicity of all equilibrium solutions, but no cooperativeness hypothesis. They studied autonomous systems by showing the upper semicontinuity of their attractors with respect to d_k and θ, and then applying bifurcation methods. Although the importance of structural stability with respect to certain parameters is well known, we would like to emphasize another application of Theorem 0.1 and several other results in this article, namely, simple numerical simulations of the large-time asymptotic behavior of strongly increasing dynamical systems. Since roundoff computer errors may actually change the prescribed parameters, it is necessary to look for some kind of continuous dependence of the ω-limit sets or attractors upon these parameters to make sure that the computed results remain close to the true (precise) asymptotic behavior of the given system for *all* times.

This article is organized as follows. In §1 we generalize a number of basic preliminary results from Takáč [28], [30]. In §2 we introduce the lower and upper ω-limit sets which, in turn, play the key rôle in our definitions of lower and upper ω-stable points; these points form the sets $\mathcal{S}_-$ and $\mathcal{S}_+$, respectively. The equivalence of Ljapunov stability with ours is shown in Lemma 2.3. We describe some elementary properties of the sets $\mathcal{S}_-$, $\mathcal{S}_+$ and $\mathcal{U}_- = \mathcal{X} \setminus \mathcal{S}_-$, $\mathcal{U}_+ = \mathcal{X} \setminus \mathcal{S}_+$ in Theorems 2.4 and 2.5, respectively. In §3 we first define quasi cycles (Definition 3.1) and then state and prove our main results, Theorems 3.3, 3.4, and 3.6. Finally, in §4 we present three examples, Examples 4.1, 4.6, and 4.10, to which we apply our main results. The reader may find numerous additional applications of our results, for instance, to systems of delay equations or other functional differential equations; cf. Smith [25].

1. Families of semigroups: basic results. This section is devoted primarily to a generalization of the basic results from Takáč [28, §§1 and 2] and Takáč [30, §§1 and 2]. In these articles the author investigated a single strongly increasing continuous mapping $T : X \longrightarrow X$ in a strongly ordered space X, whereas in the present article a strongly increasing continuous family $\mathcal{T} \equiv \{T_\theta : \theta \in \Theta\}$ of such mappings is considered. Here Θ is a strongly ordered space of parameters. In particular, we are interested in the asymptotic behavior as $n \longrightarrow \infty$ of the discrete-time semigroups

$\{T_\theta^n : n \in \mathbb{Z}_+\}$ depending upon $\theta \in \Theta$, where $\mathbb{Z}_+ = \{0, 1, 2, \cdots\}$. Throughout the entire paper we assume the following hypotheses (X), (V), (Θ), (V_Θ), and $(\mathcal{T})$.

(X): X is a *strongly ordered space*, i.e., X is a metrizable topological space with a closed partial order relation "$\leq$" satisfying the following axiom, for every open subset U of X;

(SO1) If $x \in U$ then $a \ll x \ll b$ for some a, $b \in U$.

Here $x \ll y$ for x, $y \in X$ means that (x, y) belongs to the interior of the order relation in $X \times X$. We write $x < y$ if $x \leq y$, $x \neq y$. It is easy to see that for every open subset U of X, (SO1) implies the following.

(SO2) If a, $b \in U$ and $a \ll b$ then $a \ll x \ll b$ for some $x \in U$.

(V): V is a *strongly ordered vector space*, i.e., V is a metrizable topological vector space whose order relation is defined by a closed cone $V_+ = \{x \in V : x \geq 0\}$ with nonempty interior denoted by $\mathrm{Int}(V_+)$. (In some of our results we will assume that X is a nonempty open subset of V with closure $\mathrm{Cl}(X)$.)

(Θ): Θ is another strongly ordered space whose ordering is denoted by $\leq$ again.

(V_Θ): V_Θ is another strongly ordered vector space with the positive cone $(V_\Theta)_+ = \{\theta \in V_\Theta : \theta \geq 0\}$. (Again, $\Theta \subset V_\Theta$ nonempty and open will be assumed when needed.)

Observe that also the product space $\mathcal{X} = X \times \Theta$ is strongly ordered by $(x, \theta) \leq (y, \sigma) \overset{\text{def}}{\Longleftrightarrow} x \leq y$ (in X) and $\theta \leq \sigma$ (in Θ). Then $(x, \theta) \ll (y, \sigma)$ in $\mathcal{X}$ if and only if $x \ll y$ and $\theta \ll \sigma$. A similar statement is valid for $\mathcal{V} = V \times V_\Theta$. Our last hypothesis is as follows.

$(\mathcal{T})$: $\mathcal{T}_X$ is a continuous, strongly increasing mapping from $\mathcal{X}$ into X, i.e., $(x, \theta) < (y, \sigma)$ in $\mathcal{X}$ implies $\mathcal{T}_X(x, \theta) \ll \mathcal{T}_X(y, \sigma)$. Given any $\theta \in \Theta$, we define the mapping $T_\theta : X \longrightarrow X$ by $T_\theta x = \mathcal{T}_X(x, \theta)$, $x \in X$, and set $\mathcal{T}(x, \theta) \equiv (T_\theta x, \theta)$.

Clearly, $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ is continuous and increasing ($x \leq y$ in $\mathcal{X} \Longrightarrow \mathcal{T}x \leq \mathcal{T}y$), and it preserves also the strong ordering "$\ll$" in $\mathcal{X}$ ($x \ll y$ in $\mathcal{X} \Longrightarrow \mathcal{T}x \ll \mathcal{T}y$). We identify $\mathcal{T} \equiv \{T_\theta : \theta \in \Theta\}$ in a natural way.

For a fixed $\theta \in \Theta$, the *positive semiorbit under* T_θ (shortly, *θ-orbit*) of any $x \in X$ is defined by $\mathcal{O}_\theta^+(x) = \{T_\theta^n x : n \in \mathbb{Z}_+\}$, and the corresponding *ω-limit set* of x is defined by $\omega_\theta(x) = \{y \in X : T_\theta^{n_k} x \longrightarrow y \ (k \longrightarrow \infty)$ for some sequence $n_k \longrightarrow \infty$ in $\mathbb{Z}_+\}$. Obviously, $\omega_\theta(x) \neq \emptyset$ provided $\mathcal{O}_\theta^+(x)$ is relatively compact in X. A subset Y of X is called *positively invariant under* T_θ (shortly, *θ-invariant*) if $T_\theta(Y) \subset Y$, and *totally θ-invariant* if $T_\theta(Y) = Y$. For instance, every $\mathcal{O}_\theta^+(x)$ is θ-invariant, and if $\mathcal{O}_\theta^+(x)$ is relatively compact then $\omega_\theta(x)$ is totally θ-invariant. For the mapping $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ in place of T_θ we define analogous concepts and drop the subscript θ from the notation. Observe that $\mathcal{O}^+(x, \theta) = \mathcal{O}_\theta^+(x) \times \{\theta\}$ and $\omega(x, \theta) = \omega_\theta(x) \times \{\theta\}$. Clearly, a set $\mathcal{Y} \subset \mathcal{X}$ is invariant (totally invariant) if and only if, for each $\theta \in \Theta$, the set $Y_\theta = \{x \in X : (x, \theta) \in \mathcal{Y}\}$ is θ-invariant (totally θ-invariant).

Given a, $b \in X$, the set $[a, b] = \{x \in X : a \leq x \leq b\}$ is called a *closed order interval*, and $[[a, b]] = \{x \in X : a \ll x \ll b\}$ is called an *open order interval* in X. We write $[a, \infty]] = \{x \in X : x \geq a\}$, and proceed similarly for $[[-\infty, b]$, etc. A subset Y of X is called *order-convex* in X if $[a, b] \subset Y$ whenever a, $b \in Y$ and $a < b$; *lower closed* if $[[-\infty, b] \subset Y$ whenever $b \in Y$; and *upper closed* if $[a, \infty]] \subset Y$ whenever $a \in Y$. We denote closed order intervals in V by $[a, b]_V = \{x \in V : a \leq x \leq b\}$, and similarly, all other concepts in V will be marked by the subscript V in case confusion might arise.

Analogous concepts and notation as in X and V are introduced in Θ and V_Θ, and also in $\mathcal{X} = X \times \Theta$ and $\mathcal{V} = V \times V_\Theta$.

Now we are ready to introduce one of our basic concepts.

DEFINITION 1.1. A pair (A, B) of subsets A, B of $\mathcal{X}$ is called an *order decomposition* of $\mathcal{X}$ if it has the following five properties: (i) $A \neq \emptyset$ and $B \neq \emptyset$, (ii) A and B are closed, (iii) A is lower closed and B is upper closed, (iv) $A \cup B = \mathcal{X}$, and (v) $\mathrm{Int}(A \cap B) = \emptyset$.

An order decomposition (A, B) of $\mathcal{X}$ is called *invariant* if $\mathcal{T}(A) \subset A$ and $\mathcal{T}(B) \subset B$. The set $H = A \cap B$ (possibly empty) is called the *boundary* of the order decomposition (A, B) of $\mathcal{X}$. A *d-hypersurface* is any nonempty subset H of $\mathcal{X}$ such that $H = A \cap B$ for some order decomposition (A, B) of $\mathcal{X}$.

Notice that the boundary H of an order decomposition (A, B) of $\mathcal{X}$ satisfies $H = \partial A = \partial B$, where "$\partial$" is the boundary symbol in $\mathcal{X}$, and H is invariant whenever (A, B) is invariant. It is also easy to see that a d-hypersurface H never contains two strongly ordered points x, y (with $x \ll y$). Consequently, if H is invariant, then it contains no pair of points (x, θ), $(y, \sigma) \in \mathcal{X}$ satisfying $x \leq y$ and $\theta \ll \sigma$.

If X is a strongly ordered space, it turns out to be very useful to work with the *order topology* on X whose neighborhood base is generated by all open order intervals $[[a, b]]$ with $a \ll b$. If $Y \subset X$, we denote by $\hat{Y}$ the set Y endowed with the induced order topology. A subset Y of X is called *order open* (*order closed*, respectively) if it is open (closed, respectively) in $\hat{X}$. Notice that the identity mapping $\hat{\imath} : X \longrightarrow \hat{X}$ is continuous, but in general not homeomorphic. It is proved in Hirsch [13], [14] that if $f : X_1 \longrightarrow X_2$ is a continuous, increasing mapping between two strongly ordered spaces (i.e., $x \leq_{X_1} y$ implies $f(x) \leq_{X_2} f(y)$), then f is continuous also in the order topologies; that is, the induced mapping $\hat{f} : \hat{X}_1 \longrightarrow \hat{X}_2$ is continuous. It is easy to see that the order topology on V is induced by any *ordered norm* $|\cdot|_e$ on V defined by

$$|x|_e = \inf\{\lambda \in \mathbb{R}^1_+ : \ -\lambda e \leq x \leq \lambda e\}$$

for some $e \in \mathrm{Int}(V_+)$, where $\mathbb{R}^1_+ = [0, \infty)$.

Our first result deals with the existence of invariant d-hypersurfaces. We give a proof of existence which is much simpler than the original one in Takáč [28, Prop. 1.1] or [30, Prop. 1.2], even though our present hypotheses are slightly weaker.

PROPOSITION 1.2. *Let $\mathcal{X}$ be a strongly ordered space, and let $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ be continuous and preserving the strong ordering $\ll$ in $\mathcal{X}$ ($x \ll y$ in $\mathcal{X} \Longrightarrow \mathcal{T}x \ll \mathcal{T}y$). Assume that $G \subset \mathcal{X}$ is nonempty and invariant (under $\mathcal{T}$), and contains no pair of strongly ordered points x, y (with $x \ll y$). Then there exists an invariant order decomposition (A, B) of $\mathcal{X}$ such that $G \subset H = A \cap B$. In particular, we can define (A, B) in either of the following two ways.*

(i) *$A = \mathrm{Cl}(A^\circ)$ and $B = \mathcal{X} \setminus A^\circ$ where $A^\circ = \{x \in \mathcal{X} : \ \mathcal{T}^n x \ll y$ for some $n \in \mathbb{Z}_+$ and $y \in G\}$.*

(ii) *$A = \mathcal{X} \setminus B^\circ$ and $B = \mathrm{Cl}(B^\circ)$ where $B^\circ = \{x \in \mathcal{X} : \ \mathcal{T}^n x \gg y$ for some $n \in \mathbb{Z}_+$ and $y \in G\}$.*

For instance, if $\mathcal{X} = X \times \Theta$ and $\mathcal{T}$ satisfy (X), (Θ), and $(\mathcal{T})$, we may take $G = \omega(x, \theta)$ for any relatively compact $\mathcal{O}^+(x, \theta)$; cf. Proposition 1.5.

Proof. We prove only (i), the proof of (ii) being analogous. So let (A, B) be defined by (i). Clearly, A° is open since $\mathcal{T}$ is continuous, and A° is lower closed since $\mathcal{T}$ is increasing. It is easy to see that also $A = \mathrm{Cl}(A^\circ)$ is lower closed, whereas $B = \mathcal{X} \setminus A^\circ$ is upper closed, cf. Takáč [28, Lemma 2.1] or [30, Lemma 1.4]. Since G is invariant and contains no pair of strongly ordered points $x \ll y$, we have $A^\circ \cap G = \emptyset$. On the other hand, the fact that $\mathcal{X}$ is strongly ordered implies $G \subset \mathrm{Cl}\big(\cup_{y \in G}[[-\infty, y]]\big)$

and in particular $G \subset \mathrm{Cl}(A^\circ)$. Consequently, $G \subset \partial A^\circ \overset{\mathrm{def}}{=} \mathrm{Cl}(A^\circ) \setminus \mathrm{Int}(A^\circ) = A \cap B$ as desired. It is now obvious that the pair (A, B) satisfies properties (i)–(iv) in Definition 1.1. Suppose that (v) is false, i.e., there exists $b \in \mathrm{Int}(A \cap B) \neq \emptyset$. Then also $z \ll b \ll w$ for some $z, w \in \mathrm{Int}(A \cap B)$, since $\mathcal{X}$ is strongly ordered, and, consequently, $z' \ll b \ll w'$ for some $z' \in B$ and $w' \in A^\circ$. Hence $b \in [[z', w']] \subset A^\circ \cap B$ since A° is lower closed and B is upper closed. But then $A^\circ \cap B \neq \emptyset$ is a contradiction. We conclude that (A, B) is an order decomposition of $\mathcal{X}$.

Finally, making use of the fact that $\mathcal{T}$ preserves the strong ordering "$\ll$," we arrive at $\mathcal{T}(A^\circ) \subset A^\circ$ and $\mathcal{T}(\mathcal{X} \setminus A^\circ) \subset \mathcal{X} \setminus A^\circ$ which proves that (A, B) is invariant. □

In case $\mathcal{X} \subset \mathcal{V}$, our second result describes d-hypersurfaces as Lipschitz hypersurfaces in $\mathcal{V}$, cf. Takáč [28, Prop. 1.2] or [30, Prop. 1.3] for a proof. The first version of Part (i) was proved by Hirsch [15, Prop. 2.6] for the case $\dim(\mathcal{V}) < \infty$, the dimension of $\mathcal{V}$.

We recall that an everywhere defined linear mapping $L : V_1 \longrightarrow V_2$ between two ordered vector spaces is called *positive* (*strongly positive*, respectively) if $x < y$ in V_1 implies $Lx \leq Ly$ ($Lx \ll Ly$, respectively) in V_2. We set $I =$ identity mapping on $\mathcal{V}$, and $\mathbb{R}^1 = (-\infty, \infty)$.

PROPOSITION 1.3. *Let $\mathcal{X}$ be a nonempty open subset of $\mathcal{V}$, and let (A, B) be an order decomposition of $\mathcal{X}$ with the boundary $H = A \cap B$. Fix any vector $v \in \mathrm{Int}(\mathcal{V}_+)$, and denote by $R = \mathrm{lin}\{v\}$ the linear subspace of $\mathcal{V}$ spanned by v. Let Q be a positive continuous projection of $\mathcal{V}$ onto R, which always exists, and set $P = I - Q$ with $W = P(\mathcal{V})$, the range of P, so that $\mathcal{V} = W \oplus R$ is the direct algebraic and topological sum of W and R. Then we have the following statements.*

(i) *The restriction $P\big|_H$ of P to H is one-to-one, and both $P\big|_H$ and its inverse $\pi = (P\big|_H)^{-1} : P(H) \longrightarrow H$ are Lipschitz continuous in the ordered norm $|\cdot|_v$ with a common Lipschitz constant* 2.

(ii) *$P\big|_H$ is a homeomorphism of H onto $P(H)$ in the topologies induced by that on $\mathcal{V}$.*

(iii) *Furthermore, set*

$$H \oplus R = \{x \in \mathcal{V} : \ x = x_0 + \tau v \text{ for some } x_0 \in H \text{ and } \tau \in \mathbb{R}^1\},$$

where x_0 and τ are uniquely determined by $Px = Px_0$, and define a mapping $h : H \oplus R \longrightarrow \mathcal{V}$ by

$$h(x) = Px_0 + \tau v, \qquad x = x_0 + \tau v \in H \oplus R,$$

and similarly for $P(H) \oplus R$. Then also h and its inverse $h^{-1} : P(H) \oplus R \longrightarrow H \oplus R$ are Lipschitz continuous in the ordered norm $|\cdot|_v$ with a common Lipschitz constant 7, and h is a homeomorphism of $H \oplus R$ onto $P(H) \oplus R$ in the topologies induced by that on $\mathcal{V}$.

(iv) *If, in addition, $\mathcal{X}$ is order open in $\mathcal{V}$ (i.e., open in $\hat{\mathcal{V}}$), then $P(H)$ is order open in W, and $P(H) \oplus R$ is order open in $\mathcal{V}$.*

Let $\mathcal{X} = X \times \Theta$ and $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ satisfy (X), (Θ), and $(\mathcal{T})$. For a fixed $\theta \in \Theta$, we denote by $\mathcal{E}_\theta = \{x \in X : T_\theta x = x\}$ the set of all *equilibria* (i.e., *fixed points*) of T_θ. If $k \in \mathbb{N}$, the elements of $\mathcal{E}_\theta^k = \{x \in X : \ T_\theta^k x = x\}$ are called *k-periodic points* of T_θ, and their θ-orbits $\mathcal{O}_\theta^+(x)$ are called *k-cycles*. The following two elementary results were proved in Hirsch [13, Lemma 3.1] and Takáč [28, Lemma 2.2].

PROPOSITION 1.4. (Convergence criterion for strongly monotone semigroups.) *Assume that $(x, \theta) \in X \times \Theta$, $\mathcal{O}_\theta^+(x)$ is relatively compact, and either $T_\theta^k x > x$ or*

$T^k_\theta x < x$ *for some* $k \in \mathbb{N}$. *Then* $T^{nk+\ell}_\theta x \longrightarrow T^\ell_\theta p$ *as* $n \longrightarrow \infty$, $\ell = 0, 1, \cdots, k-1$, *for some* $p \in \mathcal{E}^k_\theta$, *and either* $p \gg x$ *or* $p \ll x$, *respectively. Moreover,* $\omega_\theta(x)$ *is a* k*-cycle.*

A set $Y \subset X$ is called *unordered* if no pair of points x, $y \in Y$ satisfies $x < y$.

PROPOSITION 1.5. (Nonordering of limit sets.) *Assume that* $(x, \theta) \in X \times \Theta$ *and* $\mathcal{O}^+_\theta(x)$ *is relatively compact. Then* $\omega_\theta(x)$ *is nonempty and unordered. If* $\mathrm{Cl}(\mathcal{O}^+_\theta(x))$ *is not unordered, then* $\omega_\theta(x)$ *is a cycle.*

From now on it is convenient to introduce the following ordering "$\preceq$" of unordered subsets of X: If F, $G \subset X$ are unordered, we write $F \preceq G$ if and only if

$$F \subset G_- = \cup\{[[-\infty, x] : x \in G\} \quad \text{and} \quad G \subset F_+ = \cup\{[x, \infty]] : x \in F\}.$$

We write $F \prec\!\!\prec G$ if and only if $F \subset \mathrm{Int}(G_-)$ and $G \subset \mathrm{Int}(F_+)$, while $F \prec G$ means $F \preceq G$, $F \neq G$.

We conclude this section with the following result.

PROPOSITION 1.6. *Let* x, $y \in X$ *and* σ, $\theta \in \Theta$ *be such that* $y \le x$ *and* $\sigma < \theta$. *Assume that both* $\mathcal{O}^+_\sigma(y)$ *and* $\mathcal{O}^+_\theta(x)$ *are relatively compact. Then* $\omega_\sigma(y) \prec\!\!\prec \omega_\theta(x)$. *If also* $w \in \omega_\theta(x)$ *is such that* $\mathcal{O}^+_\sigma(w)$ *is relatively compact, then* $\omega_\sigma(w)$ *is a cycle satisfying*

$$\omega_\sigma(y) \preceq \omega_\sigma(w) \prec\!\!\prec \omega_\theta(x).$$

Proof. By $(\mathcal{T})$ we have $T^n_\sigma y \ll T^n_\theta x$ for $n = 1, 2, \cdots$. Since $\mathcal{O}^+_\sigma(y)$ and $\mathcal{O}^+_\theta(x)$ are relatively compact, we obtain also $\omega_\sigma(y) \preceq \omega_\theta(x)$. Now take any $u \in \omega_\theta(x)$. Then $u = T_\theta u'$ for some $u' \in \omega_\theta(x)$, $v' \le u'$ for some $v' \in \omega_\sigma(y)$, and $v = T_\sigma v' \in \omega_\sigma(y)$ satisfies $v = T_\sigma v' \ll T_\theta u' = u$. Analogously, given any $v \in \omega_\sigma(y)$, we can find $u \in \omega_\theta(x)$ satisfying $v \ll u$. We have proved $\omega_\sigma(y) \prec\!\!\prec \omega_\theta(x)$.

Now fix any $w \in \omega_\theta(x)$ with $\mathcal{O}^+_\sigma(w)$ relatively compact. Then $\omega_\sigma(y) \prec\!\!\prec \omega_\theta(x)$ shows that $T^m_\sigma y \ll w$ for some $m \in \mathbb{Z}_+$ which, in turn, implies $\omega_\sigma(y) \preceq \omega_\sigma(w)$. Finally, from $T_\sigma w \ll T_\theta w \in \omega_\theta(x)$ we obtain $T_\sigma w \ll T^m_\theta x$ for some $m \in \mathbb{Z}_+$, and, consequently, $\omega_\sigma(w) = \omega_\sigma(T_\sigma w) \prec\!\!\prec \omega_\theta(T^m_\theta x) = \omega_\theta(x)$ as desired. In particular, $\omega_\sigma(w)$ is a cycle for T_σ, by Proposition 1.5., since $\mathcal{O}^+_\sigma(w)$ is not unordered. □

Remark. Observe that the cycle $C = \omega_\sigma(w)$ in Proposition 1.6 does *not* depend on a particular choice of $w \in \omega_\theta(x)$ with $\mathcal{O}^+_\sigma(w)$ relatively compact. Namely, if $\tilde{w} \in \omega_\theta(x)$ with $\mathcal{O}^+_\sigma(\tilde{w})$ relatively compact, then $\omega_\sigma(w) \prec\!\!\prec \omega_\theta(x)$ entails $\omega_\sigma(w) \preceq \omega_\sigma(\tilde{w})$, and, similarly, $\omega_\sigma(\tilde{w}) \preceq \omega_\sigma(w)$. We conclude that $\omega_\sigma(\tilde{w}) = \omega_\sigma(w)$ as desired.

2. Lower and upper ω-limit sets. In this section we introduce important stability concepts with respect to the varying parameter $\theta \in \Theta$. They are motivated by a number of results from Takáč [30, §3]. Throughout this entire section we assume that $\mathcal{X} = X \times \Theta$ and $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ satisfy (X), (Θ) and $(\mathcal{T})$. We say that the mapping $\mathcal{T}$ is *ω-compact* in a subset $\mathcal{Y}$ of $\mathcal{X}$ if $\mathcal{O}^+(x)$ is relatively compact for each $x \in \mathcal{Y}$, and also $\cup_{x \in \mathcal{Y}} \omega(x)$ is relatively compact in $\mathcal{X}$. Now let $x \in X$ and $\Sigma \subset \Theta$ be such that $\mathcal{T}$ is ω-compact in $\{x\} \times \Sigma$. We define the *lower* and *upper ω-limit sets* of $(x, \theta) \in \{x\} \times \Sigma$ *relative to* Σ by

$$\omega^\Sigma_{\theta-}(x) = \bigcap_{\substack{\sigma \in \Theta \\ \sigma \ll \theta}} \mathrm{Cl} \bigcup_{\substack{\varrho \in \Sigma \\ \sigma \le \varrho \ll \theta}} \omega_\sigma(x) \quad \text{and} \quad \omega^\Sigma_{\theta+}(x) = \bigcap_{\substack{\sigma \in \Theta \\ \sigma \gg \theta}} \mathrm{Cl} \bigcup_{\substack{\varrho \in \Sigma \\ \sigma \ge \varrho \gg \theta}} \omega_\sigma(x),$$

respectively. Observe that if there exists a sequence $\varrho_n \in \Sigma$, $\varrho_n \ll \theta$ ($\varrho_n \gg \theta$, respectively) and $\varrho_n \longrightarrow \theta$, then $\omega^\Sigma_{\theta-}(x) \neq \emptyset$ ($\omega^\Sigma_{\theta+}(x) \neq \emptyset$), by the ω-compactness of $\mathcal{T}$.

The lower and upper ω-limit sets satisfy the following analogue of Proposition 1.5.

PROPOSITION 2.1. (Nonordering of lower and upper limit sets.) *Assume that $x \in X$ and $\Sigma \subset \Theta$ are such that $\mathcal{T}$ is ω-compact in $\{x\} \times \Sigma$. Let $\theta \in \Sigma$. Then both $\omega^{\Sigma}_{\theta-}(x)$ and $\omega^{\Sigma}_{\theta+}(x)$ are compact, unordered, and totally θ-invariant.*

Proof. We consider only $\omega^{\Sigma}_{\theta-}(x)$. It is compact because $\mathcal{T}$ is ω-compact. Suppose it is not unordered, i.e., $a < b$ for some $a,\, b \in \omega^{\Sigma}_{\theta-}(x)$. Hence $T_\theta a \ll T_\theta b$, and there exist $u,\, v \in X$, and $\lambda \in \Theta$ such that $a \ll u$, $v \ll b$, $\lambda \ll \theta$, and $T_\sigma u \ll T_\sigma v$ whenever $\lambda \le \sigma \le \theta$. Next we find $\alpha,\, \beta \in \Sigma$ with $\lambda \le \beta \ll \alpha \ll \theta$ and $a' \in \omega_\alpha(x)$ and $b' \in \omega_\beta(x)$ so close to a and b, respectively, that $a' \ll u$ and $v \ll b'$. Hence, $T_\sigma a' \ll T_\sigma b'$ for all $\sigma \in \Theta$, $\lambda \le \sigma \le \theta$. By Proposition 1.6, we have $\omega_\beta(x) \ll \omega_\alpha(x)$. So $b' \ll a''$ for some $a'' \in \omega_\alpha(x)$. We obtain $T_\sigma a' \ll T_\sigma b' \ll T_\sigma a''$ for $\lambda \le \sigma \le \theta$. Taking $\sigma = \alpha$ we arrive at $T_\alpha a' \ll T_\alpha a''$ in $\omega_\alpha(x)$, a contradiction to $\omega_\alpha(x)$ is unordered. We have verified that $\omega^{\Sigma}_{\theta-}(x)$ is unordered.

To show that $\omega^{\Sigma}_{\theta-}(x)$ is totally θ-invariant, we may assume it is nonempty. If $\sigma \in \Sigma$, $\sigma \ll \theta$, then $\omega_\sigma(x) \preceq \omega^{\Sigma}_{\theta-}(x)$ and $\omega_\sigma(x) = T_\sigma \omega_\sigma(x) \preceq T_\theta \omega^{\Sigma}_{\theta-}(x)$, which entails $\omega^{\Sigma}_{\theta-}(x) \preceq T_\theta \omega^{\Sigma}_{\theta-}(x)$. On the other hand, if we fix $\lambda \in \Theta$, $\lambda \ll \theta$, and choose any $\sigma \in \Sigma$, $\lambda \le \sigma \ll \theta$, then $T_\lambda \omega_\sigma(x) \preceq T_\sigma \omega_\sigma(x) = \omega_\sigma(x) \preceq \omega^{\Sigma}_{\theta-}(x)$, and so $T_\lambda \omega^{\Sigma}_{\theta-}(x) \preceq \omega^{\Sigma}_{\theta-}(x)$. Using the compactness of $\omega^{\Sigma}_{\theta-}(x)$, we let $\lambda \longrightarrow \theta$ in Θ, thus obtaining $T_\theta \omega^{\Sigma}_{\theta-}(x) \preceq \omega^{\Sigma}_{\theta-}(x)$. Finally, $\omega^{\Sigma}_{\theta-}(x)$ is unordered forces $T_\theta \omega^{\Sigma}_{\theta-}(x) = \omega^{\Sigma}_{\theta-}(x)$ as desired. □

COROLLARY 2.2. *Let all hypotheses of* Proposition 2.1 *be satisfied. If $\varrho_n \longrightarrow \theta$ for some sequence $\varrho_n \in \Sigma$, $\varrho_n \ll \theta$, then*

$$\omega^{\Sigma}_{\theta-}(x) = \bigcap_{k=1}^{\infty} \operatorname{Cl} \bigcup_{n=k}^{\infty} \omega_{\varrho_n}(x)$$

and $\omega_\varrho(x) \prec\prec \omega^{\Sigma}_{\theta-}(x) \preceq \omega_\theta(x)$ for each $\varrho \in \Theta$, $\varrho \ll \theta$, and $\mathcal{O}^{+}_{\varrho}(x)$ relatively compact. A corresponding result holds for $\omega^{\Sigma}_{\theta+}(x)$.

Proof. Since $\{\varrho_n\}_{n=1}^{\infty}$ contains a strongly increasing subsequence (ordered by $\ll$), we may assume $\varrho_1 \ll \varrho_2 \ll \cdots \ll \theta$. Set $\Omega = \{\theta, \varrho_1, \varrho_2, \cdots\}$. If $\sigma \in \Sigma$, $\sigma \ll \theta$, and $m \in \mathbb{N}$ is so large that $\sigma \ll \varrho_m$, then $\omega_\sigma(x) \prec\prec \omega_{\varrho_m}(x) \preceq \omega^{\Omega}_{\theta-}(x)$. Hence, $\omega^{\Sigma}_{\theta-}(x) \preceq \omega^{\Omega}_{\theta-}(x)$. On the other hand, if $m \in \mathbb{N}$ is arbitrary and $\sigma_m \in \Sigma$, $\varrho_m \ll \sigma_m \ll \theta$, then $\omega_{\varrho_m}(x) \prec\prec \omega_{\sigma_m}(x) \preceq \omega^{\Sigma}_{\theta-}(x)$. Hence, $\omega^{\Omega}_{\theta-}(x) \preceq \omega^{\Sigma}_{\theta-}(x)$. But both $\omega^{\Sigma}_{\theta-}(x)$ and $\omega^{\Omega}_{\theta-}(x)$ are unordered, and, therefore,

$$\omega^{\Sigma}_{\theta-}(x) = \omega^{\Omega}_{\theta-}(x) = \bigcap_{k=1}^{\infty} \operatorname{Cl} \bigcup_{n=k}^{\infty} \omega_{\varrho_n}(x).$$

The remaining statements are obvious. □

Remark. It is clear from Corollary 2.2 that the set $\omega^{\Sigma}_{\theta-}(x)$ ($\omega^{\Sigma}_{\theta+}(x)$, respectively) is independent from the choice of $\Sigma \subset \Theta$ such that $\theta \in \Sigma$, $\varrho_n \longrightarrow \theta$ for some sequence $\varrho_n \in \Sigma$, $\varrho_n \ll \theta$ ($\varrho_n \gg \theta$), and $\mathcal{T}$ is ω-compact in $\{x\} \times \Sigma$. Therefore, we say that a point $(x, \theta) \in X \times \Theta$ is *lower* (*upper*, respectively) *approximable* if there exists a sequence $\varrho_n \in \Theta$, $\varrho_n \ll \theta$ ($\varrho_n \gg \theta$), satisfying $\varrho_n \longrightarrow \theta$ and $\mathcal{T}$ is ω-compact in $\{x\} \times \Omega$, where $\Omega = \{\theta, \varrho_1, \varrho_2, \cdots\}$. We define the *lower* (*upper*) *ω-limit set* of such (x, θ) by $\omega_{\theta-}(x) = \omega^{\Omega}_{\theta-}(x)$ ($\omega_{\theta+}(x) = \omega^{\Omega}_{\theta+}(x)$).

From this Remark we introduce the following stability classification of a lower (upper, respectively) approximable point $(x, \theta) \in X \times \Theta$.

We say that $(x, \theta) \in X \times \Theta$ is *lower* (*upper*, respectively) *ω-stable* if $\omega_{\theta-}(x) = \omega_\theta(x)$ ($\omega_{\theta+}(x) = \omega_\theta(x)$); otherwise, (x, θ) is *lower* (*upper*) *ω-unstable*. The set of all lower (upper) ω-stable points (x,θ) is denoted by $\mathcal{S}_-$ ($\mathcal{S}_+$), and the set of all lower (upper) ω-unstable points by $\mathcal{U}_-$ ($\mathcal{U}_+$). We denote $\mathcal{S}_{\theta-} = \{x \in X : (x,\theta) \in \mathcal{S}_-\}$ and $\mathcal{U}_{\theta-} = \{x \in X : (x,\theta) \in \mathcal{U}_-\}$ and, analogously, $\mathcal{S}_{\theta+}$ and $\mathcal{U}_{\theta+}$.

Observe that our stability notions are equivalent to the continuity properties of the set-valued mapping $\theta\ (\in \Theta) \longmapsto \omega_\theta(x)\ (\subset X)$, for $x \in X$ fixed.

Remark. Assume that $\hat{d}(x,y)$ is an *ordered metric* for $\hat{X}$, the space X with the order topology, i.e., $u \le a \le b \le v$ in X implies $\hat{d}(a,b) \le \hat{d}(u,v)$. Let $\hat{\delta}(\theta,\sigma)$ be an ordered metric for $\hat{\Theta}$, and define an ordered product metric

$$\hat{\mathcal{D}}\big((x,\theta),(y,\sigma)\big) = \max\{\hat{d}(x,y), \hat{\delta}(\theta,\sigma)\}$$

for $\hat{\mathcal{X}} = \hat{X} \times \hat{\Theta}$. For instance, if V is a strongly ordered vector space and $e \in \operatorname{Int}(V_+)$, then the ordered norm $|\cdot|_e$ on $\hat{V}$ defines an ordered metric $\hat{d}(x,y) = |x-y|_e$ for $\hat{V}$. The following lemma shows that our stability concept uses the metric $\hat{\mathcal{D}}$.

LEMMA 2.3. *Let $(x,\theta) \in X \times \Theta$ be lower approximable. Then $(x,\theta) \in \mathcal{S}_-$ if and only if the following statement holds.*

($*$) *For every $\epsilon > 0$ there exists $\delta > 0$ such that, for each $(y,\sigma) \in X \times \Theta$ with $(y,\sigma) \le (x,\theta)$ and $\mathcal{O}_\sigma^+(y)$ relatively compact, we have*

$$\hat{\mathcal{D}}\big((x,\theta),(y,\sigma)\big) \le \delta \Longrightarrow \hat{d}(T_\theta^n x, T_\sigma^n y) \le \epsilon \quad \textit{for all } n \in \mathbb{Z}_+.$$

Corresponding statements hold for (x,θ) upper approximable and $\mathcal{S}_+$.

Proof. We first deduce from $(\mathcal{T})$ that for every $\varrho \in \Theta$, $\varrho < \theta$, there exists $\delta > 0$ such that, for each $(y,\sigma) \in X \times \Theta$ with $(y,\sigma) < (x,\theta)$, we have

$$\hat{\mathcal{D}}\big((x,\theta),(y,\sigma)\big) \le \delta \Longrightarrow T_\varrho x \le T_\sigma y \ll T_\theta x.$$

We conclude that ($*$) is equivalent to the following.

$$(**) \qquad\qquad \text{Take } (y,\sigma) = (x,\varrho) \text{ in } (*).$$

Now assume $(x,\theta) \in \mathcal{S}_-$. Suppose ($**$) is not valid. Then, since $\hat{\mathcal{D}}$ and $\hat{d}$ are ordered metrics, there exist $\epsilon_0 > 0$ and sequences $\varrho_1 \ll \varrho_2 \ll \cdots \ll \theta$ in Θ and $n_1, n_2, \cdots$ in $\mathbb{Z}_+$ such that $\varrho_k \longrightarrow \theta$ in $\hat{\Theta}$ as $k \longrightarrow \infty$, $\mathcal{T}$ is ω-compact in $\{x\} \times \Omega$ where $\Omega = \{\theta, \varrho_1, \varrho_2, \cdots\}$, and

$$\hat{d}(T_\theta^{n_k} x, T_{\varrho_k}^{n_k} x) \ge \epsilon_0 \quad \text{for all } k \in \mathbb{N}.$$

The continuity of $\mathcal{T}$ forces $\{n_k\}$ to be unbounded. Passing to a subsequence, we may assume $n_1 < n_2 < \cdots$. Observe that $T_{\varrho_m}^{n_k} x \le T_{\varrho_k}^{n_k} x \le T_\theta^{n_k} x$ whenever $k \ge m \in \mathbb{N}$. Hence $\hat{d}(T_\theta^{n_k} x, T_{\varrho_m}^{n_k} x) \ge \epsilon_0$ for $k \ge m$, and letting $k \longrightarrow \infty$ we get $w \in \omega_\theta(x)$ and $u_m \in \omega_{\varrho_m}(x)$, satisfying $u_m \le w$ and $\hat{d}(w, u_m) \ge \epsilon_0$. Using the ω-compactness of $\mathcal{T}$ in $\{x\} \times \Omega$, we find a subsequence of $\{u_m\}$ convergent in X to some $u \in \omega_{\theta-}(x) = \omega_\theta(x)$. Consequently $u \le w$ and $\hat{d}(w,u) \ge \epsilon_0$, which means $u < w$ in an unordered set $\omega_\theta(x)$, a contradiction. We have proved that $(x,\theta) \in \mathcal{S}_- \Longrightarrow (**)$.

To prove the converse statement, we assume ($**$) is valid. We apply Corollary 2.2: Let $\varrho \ll \varrho_2 \ll \cdots \ll \theta$ be any sequence in Θ such that $\varrho_k \longrightarrow \theta$ and $\mathcal{T}$ is ω-compact in $\{x\} \times \Omega$ where $\Omega = \{\theta, \varrho_1, \varrho_2, \cdots\}$. Suppose $\omega_{\theta-}(x) \ne \omega_\theta(x)$. Then $u < v$ for some $u \in \omega_{\theta-}(x)$ and $v \in \omega_\theta(x)$. Making use of $\omega_{\varrho_1}(x) \mathrel{-\!\!\!\ll} \omega_{\varrho_2}(x) \mathrel{-\!\!\!\ll} \cdots \mathrel{-\!\!\!\ll} \omega_{\theta-}(x)$, we find a sequence $u_k \in \omega_{\varrho_k}(x)$ such that $u_k \ll u$ for all $k \in \mathbb{N}$. Consequently, there exists another sequence $n_1 < n_2 < \cdots$ in $\mathbb{Z}_+$ such that $T_{\varrho_k}^{n_k} x \le u$ and $T_\theta^{n_k} x \longrightarrow w \in \omega_\theta(x)$.

From $(**)$ we obtain $\hat{d}(T_\theta^{n_k}x, T_{\varrho_k}^{n_k}x) \longrightarrow 0$ as $k \longrightarrow \infty$, and, therefore, $w \leq u$. But then $w < v$ in $\omega_\theta(x)$ contradicts the fact that $\omega_\theta(x)$ is unordered. We have also verified $(**) \Longrightarrow (x,\theta) \in \mathcal{S}_-$. □

The structure of the ω-limit sets $\omega_\sigma(x)$ for $\sigma \ll \theta$ near θ, where $(x,\theta) \in X \times \Theta$ is lower ω-unstable, is very simple; and, similarly, for upper ω-unstable points we have the following.

THEOREM 2.4. *Let $(x,\theta) \in \mathcal{U}_-$. Assume there exists $\lambda_0 \in \Theta$, $\lambda_0 \ll \theta$, such that $\mathcal{O}_\sigma^+(y)$ is relatively compact for every $(y,\sigma) \in X \times \Theta$, satisfying $\lambda_0 \leq \sigma \leq \theta$ and $u \leq y \leq w$ for some $u \in \omega_{\lambda_0}(x)$ and $w \in \omega_\theta(x)$.*

Then there exists $\lambda \in \Theta$, $\lambda_0 \leq \lambda \ll \theta$, such that for every $\sigma \in \Theta$, $\lambda \leq \sigma \ll \theta$, the set $\omega_\sigma(x)$ is a k_σ-cycle for T_σ, satisfying $\omega_\sigma(w) = \omega_\sigma(x)$ for each $w \in \omega_\theta(x)$. In particular, if $u \in \omega_\sigma(x)$ then also $\omega_\theta(u)$ is a k_σ-cycle for T_θ, satisfying $\omega_\sigma(x) \prec\!\!\prec \omega_\theta(u) \preceq \omega_{\theta-}(x) \prec\!\!\prec \omega_\theta(x)$.

A corresponding result holds for $(x,\theta) \in \mathcal{U}_+$.

Proof. Since $\omega_{\theta-}(x) \prec \omega_\theta(x)$ and both $\omega_{\theta-}(x)$ and $\omega_\theta(x)$ are totally θ-invariant, there exist $\tilde{v} \in \omega_{\theta-}(x)$ and $\tilde{w} \in \omega_\theta(x)$ with $\tilde{v} \ll \tilde{w}$. Then $\tilde{v} \ll T_\theta^m x$ for some $m \in \mathbb{Z}_+$. Fix any $\lambda \in \Theta$, $\lambda_0 \leq \lambda \ll \theta$, so close to θ that $\tilde{v} \ll T_\lambda^m x$ holds. Now let $\sigma \in \Theta$, $\lambda \leq \sigma \ll \theta$. Then $v_\sigma \ll \tilde{v}$ for some $v_\sigma \in \omega_\sigma(x) \prec\!\!\prec \omega_{\theta-}(x)$, and, consequently, $T_\sigma^{m_\sigma}x \ll \tilde{v}$ for some $m_\sigma > m$ in $\mathbb{Z}_+$. Applying Proposition 1.4 to $T_\sigma^{m_\sigma}x \ll \tilde{v} \ll T_\lambda^m x \leq T_\sigma^m x$, we conclude that $\omega_\sigma(x)$ is a cycle. If $w \in \omega_\theta(x)$ then $T_\sigma w \ll T_\theta w \in \omega_\theta(x)$, and so $T_\sigma w \ll T_\theta^k x$ for some $k \in \mathbb{Z}_+$. We find $\varrho \in \Theta$, $\sigma \leq \varrho \ll \theta$, such that $T_\sigma w \ll T_\varrho^k x$, and, consequently, $\omega_\sigma(w) \preceq \omega_\varrho(x) \prec\!\!\prec \omega_{\theta-}(x)$. Hence, $T_\sigma^{n_\sigma}w \ll \tilde{v} \ll T_\sigma^m x$ for some $n_\sigma > m$ in $\mathbb{Z}_+$. It follows that $\omega_\sigma(w) \preceq \omega_\sigma(x)$. On the other hand, $\omega_\sigma(x) \prec\!\!\prec \omega_\theta(x)$ and $w \in \omega_\theta(x)$ force $\omega_\sigma(x) \preceq \omega_\sigma(w)$. Thus $\omega_\sigma(w) = \omega_\sigma(x)$ as desired. If $u \in \omega_\sigma(x)$ then $\omega_\sigma(x) \prec\!\!\prec \omega_\theta(u) \preceq \omega_{\theta-}(x)$ by Proposition 1.6, and if k_σ denotes the cardinality of the cycle $\omega_\sigma(x)$, then $u = T_\sigma^{k_\sigma}u \ll T_\theta^{k_\sigma}u$ entails that $\omega_\theta(u)$ is a k_σ-cycle by Proposition 1.4.

In order to verify $\omega_{\theta-}(x) \prec\!\!\prec \omega_\theta(x)$, we first recall that $\omega_{\theta-}(x) \prec \omega_\theta(x)$ and $\tilde{v} \ll \tilde{w}$ for some $\tilde{v} \in \omega_{\theta-}(x)$ and $\tilde{w} \in \omega_\theta(x)$. Since both $\omega_{\theta-}(x)$ and $\omega_\theta(x)$ are totally θ-invariant, it suffices to show $\omega_{\theta-}(x) \cap \omega_\theta(x) = \emptyset$. Then T_θ strongly increasing entails $\omega_{\theta-}(x) = T_\theta\omega_{\theta-}(x) \prec\!\!\prec T_\theta\omega_\theta(x) = \omega_\theta(x)$ as desired. Now suppose there exists $w^* \in \omega_{\theta-}(x) \cap \omega_\theta(x)$; hence, $\omega_\theta(w^*) \subset \omega_{\theta-}(x) \cap \omega_\theta(x)$. We have shown above that $\omega_\sigma(x) = \omega_\sigma(w^*) \prec\!\!\prec \omega_\theta(w^*)$ for all $\sigma \in \Theta$, $\lambda \leq \sigma \ll \theta$. From Corollary 2.2 we deduce $\omega_{\theta-}(x) \preceq \omega_\theta(w^*)$. But then $\omega_\theta(w^*) \subset \omega_{\theta-}(x)$ and $\omega_{\theta-}(x)$ unordered force $\omega_\theta(w^*) = \omega_{\theta-}(x)$. Similarly, we use $\omega_{\theta-}(x) \preceq \omega_\theta(x)$, $\omega_{\theta-}(x) \subset \omega_\theta(x)$, and $\omega_\theta(x)$ unordered to obtain $\omega_{\theta-}(x) = \omega_\theta(x)$, a contradiction to $(x,\theta) \in \mathcal{U}$. □

The last result in this section describes the structure of the ω-limit sets $\omega_\sigma(x)$ for $\sigma \ll \theta$ near θ, where $(x,\theta) \in X \times \Theta$ is lower ω-stable, and for upper ω-stable points as well.

THEOREM 2.5. *Let $(x,\theta) \in \mathcal{S}_-$. Assume there exists $\lambda_0 \in \Theta$, $\lambda_0 \ll \theta$, such that $\mathcal{O}_\sigma^+(y)$ is relatively compact for every $(y,\sigma) \in X \times \Theta$, satisfying $\lambda_0 \leq \sigma \leq \theta$ and $u \leq y \leq w$ for some $u \in \omega_{\lambda_0}(x)$ and $w \in \omega_\theta(x)$.*

Then for all $\sigma \in \Theta$, $\lambda_0 \leq \sigma \ll \theta$, and $w \in \omega_\theta(x)$, the set $\omega_\sigma(w)$ is a k_σ-cycle for T_σ independent from w and satisfies $\omega_\sigma(x) \preceq \omega_\sigma(w) \prec\!\!\prec \omega_\varrho(x)$ for some $\varrho \in \Theta$, $\sigma < \varrho \ll \theta$. In particular, if $u \in \omega_\sigma(w)$ then also $\omega_\theta(u)$ is a k_σ-cycle for T_θ satisfying $\omega_\sigma(w) \prec\!\!\prec \omega_\theta(u) \preceq \omega_\theta(x)$.

Finally, given arbitrary $v \in \omega_\theta(x)$ and $a \in X$, $a \ll v$, there exists $z \in X$, $a \ll z \ll v$, such that $z \ll T_\theta^k z$ for some $k \in \mathbb{N}$. In particular, for $\hat{U}_i = \omega_\theta(x) \cap [[T_\theta^i z, \infty]]$, $i \in \mathbb{Z}_+$, we have $T_\theta^k(\hat{U}_i) \subset \hat{U}_i$ and $\cup_{i=j}^{j+k-1}\hat{U}_i = \omega_\theta(x)$ for each $j \in \mathbb{Z}_+$. Also $\mathcal{O}_\theta^+(v)$ is dense in $\omega_\theta(x)$.

A corresponding result holds for $(x, \theta) \in \mathcal{S}_+$.

Proof. Let $\sigma \in \Theta$, $\lambda_0 \leq \sigma \ll \theta$, and $w \in \omega_\theta(x)$. Then $\omega_\sigma(w)$ is a k_σ-cycle for T_σ satisfying $\omega_\sigma(x) \preceq \omega_\sigma(w) \mathrel{-\!\!\!\prec\!\!\prec} \omega_\theta(x)$, by Proposition 1.6, which is independent from w, by the Remark after Proposition 1.6. Now observe $T_\sigma^m w \ll w$ for some $m \in \mathbb{N}$, and hence $T_\sigma^m w \ll T_\theta^\ell x$ for some $\ell \in \mathbb{N}$. Using the continuity of $\mathcal{T}$, we obtain $T_\sigma^m w \ll T_\varrho^\ell x$ for some $\varrho \in \Theta$, $\sigma < \varrho \ll \theta$, whence $\omega_\sigma(w) \mathrel{-\!\!\!\prec\!\!\prec} \omega_\varrho(x)$ because $\sigma < \varrho$. If $u \in \omega_\sigma(w)$ then $\omega_\sigma(w) \mathrel{-\!\!\!\prec\!\!\prec} \omega_\theta(u) \preceq \omega_\theta(x)$ by Proposition 1.6, and $u = T_\sigma^{k_\sigma} u \ll T_\theta^{k_\sigma} u$ shows that $\omega_\theta(u)$ is a k_σ-cycle by Proposition 1.4.

Fix arbitrary $v \in \omega_\theta(x)$ and $a \in X$, $a \ll v$. Then $\omega_\sigma(x) \preceq \omega_\sigma(v) \mathrel{-\!\!\!\prec\!\!\prec} \omega_\theta(x)$ whenever $\lambda_0 \leq \sigma \ll \theta$. Recalling $(x, \theta) \in \mathcal{S}_-$ and Corollary 2.2, we can find $\sigma \in \Theta$ so close to θ that $a \ll z \ll v$ for some $z \in \omega_\sigma(v)$. Hence, $z = T_\sigma^{k_\sigma} z \ll T_\theta^{k_\sigma} z$. Set $k = k_\sigma$ and $\hat{U}_i = \omega_\theta(x) \cap [[T_\theta^i z, \infty]]$, $i \in \mathbb{Z}_+$. Clearly, $T_\theta^i z \ll T_\theta^{k+i} z$ entails $T_\theta^k(\hat{U}_i) \subset \hat{U}_i$. From $\omega_\theta(z) \preceq \omega_\theta(x)$, we deduce $\cup_{i=j}^{j+k-1} \hat{U}_i = \omega_\theta(x)$ for each $j \in \mathbb{Z}_+$.

To show that $\mathcal{O}_\theta^+(v)$ is dense in $\omega_\theta(x)$ we first observe that the topologies from X and $\hat{X}$ coincide on $\omega_\theta(x)$, by compactness. Consequently, choose any $v' \in \omega_\theta(x)$ and $a' \in X$, $a' \ll v'$. Now take $\sigma \in \Theta$ above so close to θ that also $a' \ll z' \ll v'$ for some $z' \in \omega_\sigma(v) = \omega_\sigma(v')$. Hence, $z' = T_\sigma^\ell z$ for some $\ell \in \mathbb{Z}_+$, $0 \leq \ell \leq k_\sigma - 1$. We obtain $a' \ll z' = T_\sigma^\ell z \ll T_\theta^\ell v$. Letting $a' \longrightarrow v'$ in X we arrive at $v' \leq v^*$ for some $v^* \in \mathrm{Cl}(\mathcal{O}_\theta^+(v)) \subset \omega_\theta(x)$. Finally, $\omega_\theta(x)$ unordered forces $v' = v^*$. The proof is complete. □

3. Main results. We have seen in Theorems 2.4 and 2.5 that the set $\omega_{\theta-}(x)$ can be approximated from below by a sequence of cycles for T_θ, namely,

$$\omega_\theta(u_1) \preceq \omega_\theta(u_2) \preceq \cdots \preceq \omega_{\theta-}(x),$$

where $u_k \in \omega_{\sigma_k}(w)$ for any fixed $w \in \omega_\theta(x)$ and $\lambda_0 \leq \sigma_1 \ll \sigma_2 \ll \cdots \ll \theta$ in Θ with $\sigma_k \longrightarrow \theta$ as $k \longrightarrow \infty$. In particular, $\omega_{\theta-}(x)$ is approximated also by the sequence of cycles

$$\omega_{\sigma_1}(w) \mathrel{-\!\!\!\prec\!\!\prec} \omega_{\sigma_2}(w) \mathrel{-\!\!\!\prec\!\!\prec} \cdots \mathrel{-\!\!\!\prec\!\!\prec} \omega_{\sigma-}(x).$$

Similar approximation holds for $\omega_{\theta+}(x)$.

In our next theorem we will show that $\omega_{\theta-}(x)$ must be a quasi cycle for T_θ:

DEFINITION 3.1. *Given $\theta \in \Theta$, we say that a set $C \subset X$ is a quasi cycle for T_θ if C is nonempty, compact, and totally θ-invariant, and every open cover of C (by its relatively open subsets) possesses a refinement forming another finite open cover of C by the sets U_0, U_1, $\cdots$, U_{k-1} such that $T_\theta^j(U_i) \subset U_{i+j}$ for all i, $j \in \mathbb{Z}_+$, where $U_{\ell+k} \equiv U_\ell$, $\ell \in \mathbb{Z}_+$.*

We recall that if $\mathcal{C}$ and $\mathcal{C}'$ are two open covers of a topological space K, then $\mathcal{C}'$ is a *refinement* of $\mathcal{C}$ if for every $V \in \mathcal{C}'$ there exists $U \in \mathcal{C}$ such that $V \subset U$.

We start with the following technical lemma.

LEMMA 3.2. *Let G be a compact and unordered subset of X. Then the sets $U_a = G \cap [[a, \infty]]$, for all $a \in X$, form a base for a Hausdorff topology on G which is coarser than the topology from X restricted to G (and hence, both these topologies are identical).*

The same result is valid for the sets $U^b = G \cap [[-\infty, b]]$, $b \in X$.

Proof. Clearly every U_a, $a \in X$, is relatively open in $G \subset X$. If $x \in G$ and $x \in U_a \cap U_b$ for some a, $b \in X$, then there exists $c \in [[a, \infty]] \cap [[b, \infty]]$ with $c \ll x$;

hence, $x \in U_c \subset U_a \cap U_b$. It follows that $\{U_a : a \in X\}$ is a base for a topology on G which is coarser than the X-topology. Suppose the former one is not Hausdorff, i.e., there exist x, $y \in G$, $x \neq y$, such that for all a, $b \in X$ we have: $x \in U_a$, $y \in U_b$ $\Longrightarrow U_a \cap U_b \neq \emptyset$. So let $z_{ab} \in U_a \cap U_b$. Letting $(a,b) \longrightarrow (x,y)$ in $X \times X$, $a \ll x$, $b \ll y$, we obtain $x \leq z$ and $y \leq z$ for any limit point z of z_{ab} in $G \subset X$. But G unordered forces $x = z = y$, a contradiction. Thus, $\{U_a : a \in X\}$ is a base for a Hausdorff topology on G. □

Now we are ready to prove the following theorem.

THEOREM 3.3. *Let $(x,\theta) \in X \times \Theta$ be lower approximable. Assume there exists $\lambda_0 \in \Theta$, $\lambda_0 \ll \theta$, such that $\mathcal{O}_\sigma^+(y)$ is relatively compact for every $(y,\sigma) \in X \times \Theta$, satisfying $\lambda_0 \leq \sigma \leq \theta$ and $u \leq y \leq w$ for some $u \in \omega_{\lambda_0}(x)$ and $w \in \omega_\theta(x)$.*

Then $\omega_{\theta-}(x) \subset \mathcal{S}_{\theta-}$, and $\omega_{\theta-}(x)$ is a quasi cycle for T_θ. In particular $\omega_{\theta-}(x) = \mathrm{Cl}(\mathcal{O}_\theta^+(w))$ for every $w \in \omega_{\theta-}(x)$.

A corresponding result holds if $(x,\theta) \in X \times \Theta$ is upper approximable.

Proof. Set $C = \omega_{\theta-}(x)$. It follows from Theorems 2.4 and 2.5 that $(w,\theta) \in \mathcal{S}_-$ for every $w \in C$, i.e., $C \subset \mathcal{S}_{\theta-}$. To show that C is a quasi cycle for T_θ, we consider an arbitrary open cover $\mathcal{C}$ of C. Combining Lemma 3.2 with the compactness of C, we can find a finite set $M \subset X$ such that the sets $U_a = C \cap [[a,\infty]] \neq \emptyset$, $a \in M$, form a refinement of the cover $\mathcal{C}$ of C. Furthermore, observe that $\hat{N} = \cup_{a \in M}[[a,\infty]]$ is an order-open set in X with $C \subset \hat{N}$. Fix any $w \in C$. Thus, combining $\omega_\sigma(x) \preceq \omega_\sigma(w) \prec \prec C$ with Corollary 2.2 (and its proof) we can choose $\sigma \in \Theta$, $\lambda_0 \leq \sigma \ll \theta$, so close to θ that $\omega_\sigma(w) \subset \hat{N}$. Consequently, M can be replaced by $\omega_\sigma(w)$ which is a k-cycle for T_σ, and so $z \ll T_\theta^k z$ for $z \in \omega_\sigma(w)$. Fix any $z \in \omega_\sigma(w)$ and define $\hat{U}_i = C \cap [[T_\theta^i z, \infty]]$, $0 \leq i \leq k-1$, and $\hat{U}_{\ell+k} \equiv \hat{U}_\ell$, $\ell \in \mathbb{Z}_+$. Then $\hat{U}_i \subset U_a$ for some $a = a(i) \in M$ depending upon $i \in \mathbb{Z}$, $0 \leq i \leq k-1$. We conclude that $\{\hat{U}_i : 0 \leq i \leq k-1\}$ is a refinement of $\mathcal{C}$ having all properties required in Definition 3.1. So C is a quasi cycle. Finally, letting $\sigma \longrightarrow \theta$, we obtain $C = \mathrm{Cl}(\mathcal{O}_\theta^+(w))$ for $w \in C$. □

This theorem implies that the dynamics of T_θ on $\omega_{\theta-}(x)$ is not "very complicated"; it is very much cycle-like and stable in the sense of Definition 3.1. On the other hand, an example due to Smale [24] suggests that for $(x,\theta) \in \mathcal{U}_-$ the dynamics of T_θ on $\omega_\theta(x)$ can be rather "arbitrary." However, if $\mathcal{X} = X \times \Theta \subset V \times V_\Theta = \mathcal{V}$ with $\mathcal{V}$ separable, this case is very improbable because the set $\mathcal{U}_-$ has zero Gaussian measure as we state it more precisely in Theorem 3.4. This theorem is closely related to results in Hirsch [14, §7] and Takáč [30, Prop. 5.5 and Cor. 5.6]. A similar statement holds for $\mathcal{U}_+$. But first we need some additional notation.

Given $(x,\theta) \in X \times \Theta$, we set

$$\mathcal{X}_{(x,\theta)-} = \{(y,\sigma) \in X \times \Theta : \ \sigma \ll \theta \ \text{and} \ T_\sigma^n y \ll T_\theta^m x \ \text{for some} \ m,n \in \mathbb{Z}_+\}$$

and $\mathcal{X}'_{(x,\theta)-} = \partial\mathcal{X}_{(x,\theta)-} \cap \{(y,\sigma) \in X \times \Theta : \ \sigma \ll \theta\}$, where "$\partial$" stands for the boundary symbol in $\mathcal{X}$. The sets $\mathcal{X}_{(x,\theta)+}$ and $\mathcal{X}'_{(x,\theta)+}$ are defined analogously with the reversed ordering. Observe that if $\mathcal{X} = \mathcal{S}_- \cup \mathcal{U}_-$ then

$$\mathcal{X}_{(x,\theta)-} = \{(y,\sigma) \in \mathcal{X} : \ \sigma \ll \theta \ \text{and} \ \omega_\sigma(y) \prec\!\prec \omega_{\theta-}(x)\}.$$

We say that a subset $\mathcal{J}$ of $\mathcal{X}$ is *simply ordered* (*simply strongly ordered*, respectively) if x, $y \in \mathcal{J}$ and $x \neq y$ imply either $x < y$ or $x > y$ (either $x \ll y$ or $x \gg y$). The reader is referred to H-H. Kuo [16] for general facts about *Gaussian measures* in Banach spaces, and to Aronszajn [6] and Phelps [20] for descriptions of their null sets. Some additional details about null sets can be found in Hirsch [14, Lemma 7.7].

THEOREM 3.4. *Let X and Θ be nonempty open subsets of separable strongly ordered Banach spaces V and V_Θ, respectively. Assume that every point in $\mathcal{X} = X \times \Theta$ is lower approximable, i.e., $\mathcal{X} = \mathcal{S}_- \cup \mathcal{U}_-$. Then we have the following statements.*

(a) *If $\mathcal{J}$ is a simply strongly ordered subset of $\mathcal{X}$, then $\mathcal{U}_- \cap \mathcal{J}$ is at most countable.*

(b) *If μ is a Gaussian measure on $\mathcal{V} = V \times V_\Theta$, then $\mu(\mathcal{U}_-) = 0$. In particular, $\mathcal{U}_-$ is a Borel set in $\mathcal{V}$.*

(c) *If $(x,\theta) \in \mathcal{X}$, then the sets $A = \mathrm{Cl}(\mathcal{X}_{(x,\theta)-})$ and $B = \mathcal{X} \setminus \mathcal{X}_{(x,\theta)-}$ form an invariant order decomposition of $\mathcal{X}$. Its boundary $H = A \cap B = \partial\mathcal{X}_{(x,\theta)-}$ is an invariant Lipschitz hypersurface in $\hat{\mathcal{V}}$ as described in Proposition* 1.3, $(x,\theta) \in H$ *and* $\mathcal{X}'_{(x,\theta)-} \subset \mathcal{U}_- \cap H$.

Corresponding statements hold for $\mathcal{S}_+$ and $\mathcal{U}_+$.

Proof. (a) Let $\mathcal{J} \in \mathcal{X}$ be simply strongly ordered. Given $(x,\theta) \in \mathcal{U}_-$, we define

$$U_{\theta-}(x) = \cup\{[[v,w]] : \ v \in \omega_{\theta-}(x) \text{ and } w \in \omega_\theta(x)\}$$

which is a nonempty open subset of X. If $(x,\theta) \ll (y,\sigma)$ in $\mathcal{U}_- \cap \mathcal{J}$, it is obvious that $\omega_\theta(x) \mathrel{-\!\!\!\ll} \omega_{\sigma-}(y)$ whence $U_{\theta-}(x) \cap U_{\sigma-}(y) = \emptyset$. Since X is separable, we conclude that $\mathcal{U}_- \cap \mathcal{J}$ must be at most countable.

(b) First we show that $\mathcal{U}_-$ is a Borel set. We employ Lemma 2.3. If $e \in \mathrm{Int}(V_+)$ and $\eta \in \mathrm{Int}((V_\Theta)_+)$ are fixed, then $\hat{d}(x,y) = |x-y|_e$ and $\hat{\delta}(\theta,\sigma) = |\theta - \sigma|_\eta$ define ordered metrics in $\hat{V}$ and $\hat{V}_\Theta$, respectively. Given $\epsilon > 0$, $\delta > 0$, $n \in \mathbb{Z}_+$, and $(y,\sigma) \in \mathcal{X}$, we denote by $\mathcal{U}_-^{\epsilon,\delta,n}(y,\sigma)$ the set of all $(x,\theta) \in \mathcal{X}$ such that

$$(y,\sigma) \ll (x,\theta), \quad \hat{\mathcal{D}}\big((x,\theta),(y,\sigma)\big) < \delta \quad \text{and} \quad \hat{d}(T_\theta^n x, T_\sigma^n y) > \epsilon.$$

Obviously $\mathcal{U}_-^{\epsilon,\delta,n}(y,\sigma)$ is open in $\mathcal{V}$. From Lemma 2.3 we obtain

$$\mathcal{U}_- = \bigcup_{\epsilon}\bigcap_{\delta}\bigcup_{n}\bigcup_{(y,\sigma)} \mathcal{U}_-^{\epsilon,\delta,n}(y,\sigma),$$

where we take ϵ and δ rational and positive, $n \in \mathbb{Z}_+$, and (y,σ) from a dense countable subset of $\mathcal{X}$. Consequently, $\mathcal{U}_-$ is a Borel set in $\mathcal{V}$.

Now let μ be a Gaussian measure on $\mathcal{V}$. Fix any $v \in \mathrm{Int}(\mathcal{V}_+)$. Define the line $x + \mathbb{R}^1 v = \{x + rv \in \mathcal{V} : r \in \mathbb{R}^1\}$ for every $x \in \mathcal{V}$. By Part (a) the set $\mathcal{U}_- \cap (x + \mathbb{R}^1 v)$ is at most countable, and hence, it has Lebesgue measure zero. Since $\mathrm{Int}(\mathcal{V}_+) \neq \emptyset$, it is a straightforward matter to verify that $\mathcal{U}_-$ is an *exceptional set* in $\mathcal{V}$ in the sense of Aronszajn [6, Def. I.1.2]. Applying a result of Phelps [20, Prop. 5], we conclude that $\mu(\mathcal{U}_-) = 0$.

(c) Let $(x,\theta) \in \mathcal{X}$. Taking $G = \mathcal{O}^+(x,\theta)$ in Proposition 1.2(i) we observe that the sets $A = \mathrm{Cl}(\mathcal{X}_{(x,\theta)-})$ and $B = \mathcal{X} \setminus \mathcal{X}_{(x,\theta)-}$ form an invariant order decomposition (A,B) of $\mathcal{X}$ whose boundary $H = A \cap B = \partial\mathcal{X}_{(x,\theta)-}$ is described in Proposition 1.3. Obviously, $(x,\theta) \in G \subset H$.

It remains to show $\mathcal{X}'_{(x,\theta)-} \subset \mathcal{U}_-$. We take any $(z,\varrho) \in H$ with $\varrho \ll \theta$. Since A is lower closed in a strongly ordered space $\mathcal{X}$, we can find a sequence $z_1 \ll z_2 \ll \cdots \ll z$ in X with $z_k \longrightarrow z$, and another sequence $\varrho_1 \ll \varrho_2 \ll \cdots \ll \varrho$ in Θ with $\varrho_k \longrightarrow \varrho$. From our definition of $\mathcal{X}_{(x,\theta)-}$ and A we obtain $(z_k, \varrho_k) \in \mathcal{X}_{(x,\theta)-}$, whence

$$\omega_{\varrho_k}(z_k) \mathrel{-\!\!\!\ll} \omega_{\theta-}(x) \quad \text{for all } k \in \mathbb{N}. \tag{1}$$

We claim also

$$\omega_{\varrho-}(z) = \bigcap_{n=1}^{\infty} \mathrm{Cl} \bigcup_{k=n}^{\infty} \omega_{\varrho_k}(z_k). \tag{2}$$

Namely, it is easy to deduce from $(\mathcal{T})$ that for every $m \in \mathbb{N}$ there exists $k > m$ such that $T_{\varrho_m} z \ll T_{\varrho_k} z_k$, and hence, $\omega_{\varrho_m}(z_m) \preceq \omega_{\varrho_m}(z) \prec\!\prec \omega_{\varrho_k}(z_k) \preceq \omega_{\varrho_k}(z)$ by Proposition 1.6. Applying Corollary 2.2 to these inequalities, we arrive at (2). Next, we combine (1) and (2) with $\varrho \ll \theta$ to obtain

$$\omega_{\varrho-}(z) \prec\!\prec \omega_{\theta-}(x) \preceq \omega_\theta(x). \tag{3}$$

On the other hand, $(x,\theta) \in H$ and $(z,\varrho) \in H$ imply $\omega(x,\theta) = (\omega_\theta(x),\theta) \subset H$ and $\omega(z,\varrho) = (\omega_\varrho(z),\varrho) \subset H$.

Finally, suppose $(z,\varrho) \in \mathcal{S}_-$. Then $\omega_\varrho(z) = \omega_{\varrho-}(z) \prec\!\prec \omega_\theta(x)$ by (3), and $\varrho \ll \theta$ as well, and, consequently, H must contain a pair of points (a,ϱ) and (b,θ) satisfying $a \ll b$. But $(a,\varrho) \ll (b,\theta)$ is impossible by Definition 1.1. We have proved also $(z,\varrho) \in \mathcal{U}_-$. This completes our proof. □

In contrast with the results in Takáč [30, Props. 5.5 and 5.6] for $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ strongly increasing we are unable to obtain a similar complete characterization of the sets $\mathcal{U}_-$ and $\mathcal{U}_+$. We can prove only the following consequence of Theorem 3.4(c). Here we write $(X,\sigma) = X \times \{\sigma\} \subset \mathcal{X}$ whenever $\sigma \in \Theta$.

COROLLARY 3.5. *Let all hypotheses of Theorem* 3.4 *be satisfied, including* $\mathcal{X} = \mathcal{S}_- \cup \mathcal{U}_-$. *In addition, assume* X *is connected. Let* $(x,\theta) \in X \times \Theta$, $(z,\varrho) \in \mathcal{X}'_{(x,\theta)-}$ *and* $\sigma \in \Theta$ *with* $\varrho \le \sigma \ll \theta$. *Then* $(X,\sigma) \cap \mathcal{X}'_{(x,\theta)-} \neq \emptyset$.

Finally, set $A^{\sigma,0} = \{y \in X : (y,\sigma) \in \mathcal{X}_{(x,\theta)-}\}$, $A^\sigma = \mathrm{Cl}(A^{\sigma,0})$, $B^\sigma = X \setminus A^{\sigma,0}$ *and* $X^\sigma = \{y \in X : (y,\sigma) \in \mathcal{X}'_{(x,\theta)-}\}$ *for* $\sigma \in \Theta$, $\sigma \ll \theta$, *and denote by* Λ *the set of all such* σ *for which the interior of* X^σ *in* X *is nonempty. Then the following statements are valid.*

(i) *If* $B^\sigma \neq \emptyset$ *then* (A^σ, B^σ) *is a* σ*-invariant order decomposition of* X, *and* $A^\sigma \cup X^\sigma \subset A^{\lambda,0} = A^\lambda \setminus X^\lambda$ *whenever* $\lambda \ll \sigma \ll \theta$ *in* Θ. *If* $\lambda \ll \theta$ *then* $A^{\lambda,0} = \cup\{A^{\sigma,0} : \lambda \ll \sigma \ll \theta\}$.

(ii) *If* $\sigma \notin \Lambda$ *then* $X^\sigma = A^\sigma \cap B^\sigma$, *and, in particular, if also* $\varrho \le \sigma \ll \theta$ *then* X^σ *is a nonempty* σ*-invariant Lipschitz d-hypersurface in* $\hat{V}$.

(iii) *Every simply strongly ordered subset of* Λ *is at most countable, and if* μ *is a Gaussian measure on* V_Θ *then* $\mu(\Lambda) = 0$. *In particular,* Λ *is a Borel set in* V_Θ.

Analogous results hold for $\mathcal{X}_{(x,\theta)+}$ *and* $X'_{(x,\theta)+}$.

Proof. Suppose there exists $\sigma \in \Theta$, $\varrho \le \sigma \ll \theta$, such that $(X,\sigma) \cap \mathcal{X}'_{(x,\theta)-} = \emptyset$. Set $A^\circ = \mathcal{X}_{(x,\theta)-}$ (which is open and lower closed in $\mathcal{X}$), $A = \mathrm{Cl}(A^\circ)$, $B = \mathcal{X} \setminus \mathcal{X}_{(x,\theta)-}$, and $B^\circ = \mathrm{Int}(B)$ (which is open and upper closed in $\mathcal{X}$). By Theorem 3.4(c), (A,B) is an invariant order decomposition of $\mathcal{X}$ with the boundary $H = A \cap B$. Since X is connected and $(X,\sigma) \cap H = \emptyset$, we have either $(X,\sigma) \subset A^\circ$ or else $(X,\sigma) \subset B^\circ$. The former case forces $(X,\varrho) \subset A^\circ$ by $\varrho \le \sigma$, thus contradicting $(z,\varrho) \in H$. The latter one forces $(X,\theta) \subset B^\circ$ by $\sigma \ll \theta$, thus contradicting $(x,\theta) \in H$. Hence, we have proved $(X,\sigma) \cap \mathcal{X}'_{(x,\theta)-} \neq \emptyset$ as desired.

Proof of (i). Set $\tilde{B}^{\sigma,0} = \{y \in X : (y,\sigma) \in B^\circ\}$ for $\sigma \in \Theta$, $\sigma \ll \theta$, and observe that $X = A^{\sigma,0} \cup X^\sigma \cup \tilde{B}^{\sigma,0}$ is a disjoint union of σ-invariant sets, where $A^{\sigma,0}$ is open and lower closed and $\tilde{B}^{\sigma,0}$ is open and upper closed in X. Consequently, $B^\sigma = X^\sigma \cup \tilde{B}^{\sigma,0}$, and it is easy to see that (A^σ, B^σ) is a σ-invariant order decomposition of X provided $B^\sigma \neq \emptyset$. Now let $\lambda \ll \sigma \ll \theta$ in Θ. Obviously, $A^{\sigma,0} \subset A^{\lambda,0} = A^\lambda \setminus X^\lambda$. To show also $X^\sigma \subset A^{\lambda,0}$, we fix any $y \in X^\sigma$. Then $(y,\sigma) \in H$ and $\lambda \ll \theta$ imply $\mathcal{T}(y,\lambda) \ll \mathcal{T}(y,\sigma) \in H$, whence $(y,\lambda) \in A^\circ$, and we have shown $X^\sigma \subset A^{\lambda,0}$. We conclude that $A^\sigma \cup X^\sigma = A^{\sigma,0} \cup X^\sigma \subset A^{\lambda,0}$.

Finally, let $\lambda \ll \theta$ in Θ. We have already proved $\cup\{A^\sigma : \sigma \in [[\lambda,\theta]]\} \subset A^{\lambda,0}$. On the other hand, if $y \in A^{\lambda,0}$ then the fact that $(y,\lambda) \in A^\circ$ and A° is open in a strongly ordered space $\mathcal{X} = X \times \Theta$ shows that $(y, \sigma) \in A^\circ$ for any $\sigma \in \Theta$ close enough to λ, whence $y \in A^{\sigma,0}$ for some $\sigma \in [[\lambda, \theta]]$. It follows that $A^{\lambda,0} = \cup\{A^{\sigma,0} : \sigma \in [[\lambda, \theta]]\}$ as desired.

Proof of (ii). It follows immediately from the proof of (i) that $B^\sigma = \mathrm{Cl}(\tilde{B}^{\sigma,0})$ and $X^\sigma = A^\sigma \cap B^\sigma$ for every $\sigma \notin \Lambda$. If also $\varrho \le \sigma \ll \theta$ then X^σ is nonempty by $(X, \sigma) \cap \mathcal{X}'_{(x,\theta)-} \neq \emptyset$, and X^σ is a Lipschitz d-hypersurface in $\hat{V}$ by Proposition 1.3. The invariance of X^σ under T_σ has been proved in (i).

Proof of (iii). From (i) we obtain $X^\lambda \cap X^\sigma = \emptyset$ whenever $\lambda \ll \sigma \ll \theta$. Since X is separable, every simply strongly ordered subset of Λ can be only finite or countable. To show that Λ is a Borel set in V_Θ we fix any $\eta \in \mathrm{Int}((V_\Theta)_+)$. Given $u \ll v$ in X and $\delta \in (0, \infty)$, we define $U^{u,v,\delta}$ to be the union of all order intervals $[[\alpha, \beta]]$ in Θ such that $(v, \alpha) \in A^\circ$, $(u, \beta) \in B^\circ$ and $0 \ll \beta - \alpha \ll \delta\eta$. Clearly $\sigma \in \cap_{\delta>0} U^{u,v,\delta}$ if and only if $[[u, v]] \subset X^\sigma$ for $\sigma \in \Theta$, $\sigma \ll \theta$. Hence $\Lambda = \cup_{u \ll v} \cap_{\delta>0} U^{u,v,\delta}$ which remains valid even if we take u and v from a countable dense subset of X, $\delta > 0$ rational, and α and β from a countable dense subset of Θ. We conclude that Λ is a Borel set in V_Θ. If μ is a Gaussian measure on V_Θ, then $\mu(\Lambda) = 0$ by the same arguments as in the proof of Theorem 3.4(b). The proof is now complete. □

Remark. Loosely speaking, Corollary 3.5 contains the following results for a given $(x, \theta) \in X \times \Theta$: The set $\mathcal{X}'_{(x,\theta)-}$ forms the boundary of the set $\mathcal{X}_{(x,\theta)-}$ in $X \times [[-\infty, \theta]]$ of all $(y, \sigma) \in \mathcal{X}$ such that $\sigma \ll \theta$ and $\omega_\sigma(y) \prec\!\!\prec \omega_{\theta-}(x)$. This boundary is an invariant Lipschitz hypersurface in $\hat{\mathcal{V}}$ which can be expressed as the union of the sets (X^σ, σ) for $\sigma \ll \theta$. Except for a set Λ of Gaussian measure zero in Θ, every X^σ, $\sigma \notin \Lambda$, is a σ-invariant Lipschitz hypersurface in $\hat{V}$ which is strictly decreasing in σ, i.e., $A^\sigma \cup X^\sigma \subset A^\lambda \setminus X^\lambda$ provided $\lambda \ll \sigma \ll \theta$. If X is an open order interval in V, and λ, $\sigma \notin \Lambda$ are such that $\lambda \ll \sigma \ll \theta$ and $X^\lambda \neq \emptyset$, then $X^\sigma \prec\!\!\prec X^\lambda$.

Combining Theorems 3.3 and 3.4(b), we obtain the following analogue of well-known results due to Hirsch [14, Thm. 7.8 and 8.10(d)] for strongly increasing continuous-time semiflows.

THEOREM 3.6. *Let all hypotheses of Theorem* 3.4 *be satisfied, together with* $\mathcal{X} = \mathcal{S}_- \cup \mathcal{U}_- = \mathcal{S}_+ \cup \mathcal{U}_+$. *Let* $(x, \theta) \in \mathcal{X} = X \times \Theta$, *and let* μ *be any Gaussian measure on* $\mathcal{V} = V \times V_\Theta$. *If* $(x, \theta) \in \mathcal{S} \equiv \mathcal{S}_- \cap \mathcal{S}_+$ *then* $\omega_\theta(x)$ *is a quasi cycle for* T_θ *contained in* $\mathcal{S}_\theta \equiv \mathcal{S}_{\theta-} \cap \mathcal{S}_{\theta+}$; *otherwise,* $(x, \theta) \in \mathcal{U} \equiv \mathcal{U}_- \cup \mathcal{U}_+$ *where* $\mu(\mathcal{U}) = 0$.

4. Examples. In this section we present three examples to which our results from §3 can be applied. Our first, Example 4.1, is a single reaction-diffusion equation depending upon parameters in both the reaction function and Robin's boundary conditions. Our second, Example 4.6, is a strictly cooperative system of ordinary differential equations depending upon parameters in the reaction functions. It is easy to see that these two examples can be combined into a strictly cooperative system of weakly coupled reaction-diffusion equations or into a system of two reaction-diffusion equations for two competing species, cf. Matano and Mimura [17]. Our last example, Example 4.10, illustrates and clarifies our results for the sets $\mathcal{U}_-$ and $\mathcal{U}_+$ obtained in §3.

Example 4.1. We consider the initial-boundary value problem (IBVP) for the following reaction-diffusion equation:

$$\frac{\partial u}{\partial t} + A(x,t)u = f(x,t,u) + \gamma(x,t)u \quad \text{in } \Omega \times (0,\infty); \tag{1}$$

$$\frac{\partial u}{\partial n} + \vartheta(x,t)u = 0 \quad \text{on } \partial\Omega \times (0,\infty); \tag{1_b}$$

$$(1_i) \qquad u(x,0) = u_0(x) \quad \text{in } \Omega.$$

Here, Ω is a bounded open domain in $\mathbb{R}^N$ with the boundary $\partial\Omega$ of class C^3 and, with the outer unit normal $n = n(x)$ to $\partial\Omega$ at $x \in \partial\Omega$, $A(x,t)$ is a uniformly strongly elliptic operator of the form

$$A(x,t) \equiv -\sum_{i,j=1}^{N} a_{ij}(x,t)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{N} a_i(x,t)\frac{\partial}{\partial x_i}$$

whose coefficients satisfy a_{ij}, $a_i \in C^2(\overline{\Omega} \times \mathbb{R}^1_+)$, the reaction function f satisfies $f \in C^2(\overline{\Omega} \times \mathbb{R}^1_+ \times \mathbb{R}^1)$, and $\gamma \in C^2(\overline{\Omega} \times \mathbb{R}^1_+)$. In Robin's boundary conditions we assume $0 \le \vartheta \in C^2(\partial\Omega \times \mathbb{R}^1_+)$. Finally, $u : \Omega \times \mathbb{R}^1_+ \longrightarrow \mathbb{R}^1$ is the unknown function of (x,t) with a prescribed initial distribution $u_0 : \Omega \longrightarrow \mathbb{R}^1$. All functions a_{ij}, a_i, f, γ, and ϑ entering (IBVP) are assumed to be *τ-periodic* in time $t \in \mathbb{R}^1_+$ with a period $\tau \in (0,\infty)$. We will express the τ-periodicity in time of a function $\varphi : \mathbb{R}^1_+ \longrightarrow \mathbb{R}^1$ by writing $\varphi : \mathbb{R}^1/\tau\mathbb{Z} \longrightarrow \mathbb{R}^1$.

In order to guarantee global existence in time of an *L_p-solution* u (cf. Amann [2], [3], [5]) to (IBVP) for every sufficiently smooth initial distribution u_0 such that $0 \le u_0(x) \le M$ for all $x \in \Omega$, we make the following two hypotheses.

(f): $f(x,t,0) \ge 0$ for all $(x,t) \in \Omega \times \mathbb{R}^1_+$.

(γ): There exists a constant $M \in (0,\infty)$ such that $\gamma(x,t) \le -f(x,t,M)/M$ for all $(x,t) \in \Omega \times \mathbb{R}^1_+$.

In particular, then $\underline{u}(x,t) \equiv 0$ is a *subsolution* and $\overline{u}(x,t) \equiv M$ is a *supersolution* of (IBVP). Consequently, if u is a *classical solution* to (IBVP) in $\Omega \times [0,t_0)$, for some $t_0 \in (0,\infty]$, i.e., $u \in C(\overline{\Omega}\times[0,t_0)) \cap C^{1,0}(\overline{\Omega}\times(0,t_0)) \cap C^{2,1}(\Omega\times(0,t_0))$ satisfies (IBVP) in $\Omega \times [0,t_0)$, then we may apply the maximum and boundary point principles for parabolic equations (cf. Protter and Weinberger [22]) to conclude that

$$(2) \qquad 0 \le u(x,t) \le M \quad \text{for all } (x,t) \in \overline{\Omega} \times [0,t_0).$$

Now we are ready to employ existence, uniqueness, and regularity results due to Amann [2], [3], [5] to construct our mapping $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$.

We denote by $W^s_p = W^s_p(\Omega)$the Sobolev–Slobodeckii interpolation spaces for $1 < p < \infty$ and $0 \le s < \infty$, and, by $C^\mu = C^\mu(\overline{\Omega})$, the Hölder spaces for $0 \le \mu \le \infty$, cf. Triebel [33, Chap. 4]. If $\mu < s - (N/p)$ then $W^s_p \hookrightarrow C^\mu$ is a compact imbedding, and both W^s_p and C^μ are strongly ordered Banach spaces with the *pointwise ordering.* If u, $v : \Omega \longrightarrow \mathbb{R}^1$ are Lebesgue measurable functions, we write $u \le v$ if and only if $u(x) \le v(x)$ for almost everywhere $x \in \Omega$.

Next, we fix real numbers p and μ such that

$$(\mathrm{H}) \qquad 2 \le p < \infty \quad \text{and} \quad 0 < \mu < \frac{1}{2} - \frac{N}{p}.$$

Finally, we combine results of Amann [3, Thm. 2.1(i, ii) and Cor. 2.2] with our a priori estimate (2) to conclude that, given any $u_0 \in [0,M]_{W^1_p}$, where

$$[0,M]_{W^1_p} = \{\varphi \in W^1_p : \ 0 \le \varphi \le M\},$$

there exists a unique global *L_p-solution* $u : \mathbb{R}^1_+ \longrightarrow W^1_p$ of our (IBVP), cf. Amann [2, §15] or [3, §2] or [5, §7] for its definition. Moreover, u is also a classical solution of (IBVP) satisfying

$$(3) \qquad u \in C(\mathbb{R}^1_+ \longrightarrow C^\mu) \cap C^1((0,\infty) \longrightarrow C^\mu) \cap C((0,\infty) \longrightarrow C^{\mu+2}).$$

We set $V = W_p^1$, $\tilde{V}_\gamma = C^2(\overline{\Omega} \times (\mathbb{R}^1/\tau\mathbb{Z}))$, $\tilde{V}_\vartheta = C^2(\partial\Omega \times (\mathbb{R}^1/\tau\mathbb{Z}))$ and $\tilde{V}_\Theta = \tilde{V}_\gamma \times \tilde{V}_\vartheta$. From now on we assume that all a_{ij}, a_i, and f in (1) are fixed, and we also fix an arbitrary constant $M \in (0,\infty)$. We denote $\overline{X} = [0, M]_V$;

$\tilde{\Theta}_\gamma$ is the set of all $\gamma \in \tilde{V}_\gamma$ such that the hypothesis (γ) is satisfied for this M, i.e., $\gamma \le -f(\,\cdot\,, \cdot\,, M)/M$; and $\tilde{\Theta}_\vartheta = (\tilde{V}_\vartheta)_+$, the positive cone in $\tilde{V}_\vartheta$. Then $\overline{X}$ is a closed subset of V, and $\tilde{\Theta} = \tilde{\Theta}_\gamma \times \tilde{\Theta}_\vartheta$ is a closed subset of $\tilde{V}_\Theta$ whose elements are denoted by $\theta = (\gamma, \vartheta)$. All these spaces are endowed with the pointwise ordering.

Next we apply the strong maximum and boundary point principles (cf. Protter and Weinberger [22]) in a way very similar to Hirsch [14, Proof of Thm. 4.1] to derive the following strongly monotone dependence of the solution $u(t, u_0, \theta)$ to (IBVP) upon $u_0 \in \overline{X}$ and $\theta \in \tilde{\Theta}$ for each fixed $t \in (0,\infty)$.

PROPOSITION 4.2. (a) *If $u_0 < u_0'$ in $\overline{X}$, $\theta \in \tilde{\Theta}$ and $t \in (0,\infty)$, then we have*

$$u(t, u_0, \theta) \ll u(t, u_0', \theta) \quad \text{in } \overline{X}.$$

(b) *Let $0 \ll u_0 \le u_0'$ in $\overline{X}$, $\theta \le \theta'$ in $\tilde{\Theta}$, and $t \in (0,\infty)$, and assume $(u_0, \theta) \ne (u_0', \theta')$. Then we have*

$$0 \ll u(t, u_0, \theta) \ll u(t, u_0', \theta') \quad \text{in } \overline{X}.$$

Observe that $\varphi \ll \varphi'$ in $\overline{X}$ means $\min_{\overline{\Omega}}(\varphi' - \varphi) > 0$ for φ, $\varphi' \in \overline{X}$.

Amann [5, Thm. 7.3(i)] has shown that, when regarded as a mapping of $(t, u_0, \theta) \in \mathbb{R}_+^1 \times \overline{X} \times \tilde{\Theta} \subset \mathbb{R}_+^1 \times W_p^1 \times C^2(\partial\Omega \times (\mathbb{R}^1/\tau\mathbb{Z}))$ into $\overline{X} \subset W_p^1$, the solution $u(\,\cdot\,, \cdot\,, \cdot\,)$ of our (IBVP) is continuous and also Lipschitz continuous with respect to both u_0 and θ locally uniformly in $\mathbb{R}_+^1 \times \overline{X} \times \tilde{\Theta}$, i.e., the following result is valid.

PROPOSITION 4.3. *We have*

$$u \in C^{0,1-,1-}(\mathbb{R}_+^1 \times \overline{X} \times \tilde{\Theta} \longrightarrow \overline{X}).$$

From Amann [5, Thm. 7.3(v)] and (3) we easily obtain the following compactness properties of the mapping $u(\tau, \cdot\,, \cdot\,) : \overline{X} \times \tilde{\Theta} \subset W_p^1 \times \tilde{V}_\Theta \longrightarrow \overline{X} \subset W_p^1$:

PROPOSITION 4.4. *Let Σ be any subset of $\tilde{\Theta}$ which is bounded in $\tilde{V}_\Theta$. Then $u(\tau, \overline{X}, \Sigma)$, the image of $\overline{X} \times \Sigma$ under the mapping $u(\tau, \cdot\,, \cdot\,)$, is a subset of $\overline{X} \cap C^{\mu+2}$ which is bounded in $C^{\mu+2}$, and, in particular, it is relatively compact in W_p^1.*

Definition of $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$. We set $X = [[0, M]]_V$ in $V = W_p^1$, i.e., $X = \operatorname{Int}_V(\overline{X})$. We choose V_γ to be any closed linear subspace of $\tilde{V}_\gamma$ such that $V_\gamma \cap \operatorname{Int}((\tilde{V}_\gamma)_+) \ne \emptyset$ in $\tilde{V}_\gamma$, and V_ϑ to be any closed linear subspace of $\tilde{V}_\vartheta$ such that $V_\vartheta \cap \operatorname{Int}((\tilde{V}_\vartheta)_+) \ne \emptyset$ in $\tilde{V}_\vartheta$. Hence, $V_\Theta = V_\gamma \times V_\vartheta$ is a strongly ordered Banach space. The following three examples present the basic choices for V_γ, and similarly for V_ϑ: (i) $V_\gamma = \tilde{V}_\gamma = C^2(\overline{\Omega} \times (\mathbb{R}^1/\tau\mathbb{Z}))$, (ii) $V_\gamma = C^2(\overline{\Omega}) \subset \tilde{V}_\gamma$ (temporally independent functions), or (iii) $V_\gamma = \mathbb{R}^1 \subset \tilde{V}_\gamma$ (constant functions).

We may also choose one of the spaces V_γ or V_ϑ to be trivial, thus eliminating one of the parameters γ or ϑ. Next we choose Θ to be the set of all $\theta = (\gamma, \vartheta) \in V_\Theta$ such that $\gamma \ll -f(\,\cdot\,, \cdot\,, M)/M$ in V_γ and $\vartheta \gg 0$ in V_ϑ, i.e., $\Theta = \operatorname{Int}_{V_\Theta}(\tilde{\Theta} \cap V_\Theta)$ in V_Θ. Finally, we set $\mathcal{X} = X \times \Theta$ and $\mathcal{V} = V \times V_\Theta$, and define $\mathcal{T}$ by

$$\mathcal{T}(u_0, \theta) = \big(u(\tau, u_0, \theta), \theta\big) \quad \text{for all } (u_0, \theta) \in \mathcal{X}.$$

It follows from Propositions 4.2(b) and 4.3 that $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ satisfies hypothesis ($\mathcal{T}$) in §1. By Proposition 4.4, given any $\theta \in \Theta$, the θ-orbit $\mathcal{O}_\theta^+(u_0)$ of every $u_0 \in X$ is relatively compact in $\overline{X} \subset V$, whence $\omega_\theta(u_0) \subset \overline{X}$, and, more precisely, we have either $\omega_\theta(u_0) = \{0\}$ or $\omega_\theta(u_0) \subset X$ or $\omega_\theta(u_0) = \{M\}$ by Propositions 4.2(a) and 1.5. The case $\omega_\theta(u_0) = \{M\}$ cannot occur because $u(t, M, \theta) \ll M$ for $t > 0$, by the strong maximum and boundary point principles. The case $\omega_\theta(u_0) = \{0\}$ is easily excluded by strengthening hypothesis (f) to

$$(\mathrm{f}') : f(\,\cdot\,, \cdot\,, 0) \geq 0 \quad \text{in } \overline{\Omega} \times \mathbb{R}^1_+ \text{ and } f(x', t', 0) > 0 \quad \text{for some } (x', t') \in \overline{\Omega} \times \mathbb{R}^1_+.$$

From (f′) we derive $u(t, 0, \theta) \gg 0$ for $t > 0$. We conclude from Proposition 4.4 that every point in $\mathcal{X}$ is both lower and upper approximable, and, therefore, we can apply Theorems 2.5 and 3.6 to obtain the following theorem for our (IBVP).

THEOREM 4.5. *Assume that a_{ij}, a_i, and f satisfy the C^2-smoothness hypotheses stated above, together with the uniform strong ellipticity of $A(x, t)$ and with* (f'). *Then $\mathcal{U} = \mathcal{U}_- \cup \mathcal{U}_+$, the set of all ω-unstable points for $\mathcal{T}$, has zero Gaussian measure in $\mathcal{V}$.*

If $(u_0, \theta) \in \mathcal{S} = \mathcal{X} \setminus \mathcal{U}$ then $\omega_\theta(u_0)$ is a quasi cycle in $\mathcal{S}_\theta$ with the following three properties.

(i) *Let $w_0 \in \omega_\theta(u_0)$, and let $\theta_1, \theta_2 \in \Theta$ be such that $\theta_1 \ll \theta \ll \theta_2$. Then $\omega_{\theta_i}(w_0)$ is a k_i-cycle for T_{θ_i} independent from the choice of $w_0 \in \omega_\theta(u_0)$ for $i = 1, 2$. In particular, given any $w_i \in \omega_{\theta_i}(w_0)$ with $w_1 \leq w_2$, the function $u(\,\cdot\,, w_i, \theta_i) : \mathbb{R}^1_+ \longrightarrow W^1_p$ is a $k_i\tau$-periodic solution of* (IBVP) *with the parameter $\theta_i = (\gamma_i, \vartheta_i)$ and the initial distribution w_i.*

(ii) *Let w_0, θ_i, k_i, and w_i be as in* Part (i). *Then there exists $r \in \mathbb{R}^1_+$ such that*

$$u(s, w_1, \theta_1) \ll u(r + s, u_0, \theta) \ll u(s, w_2, \theta_2) \quad \textit{in } W^1_p \quad \textit{for all } s \in \mathbb{R}^1_+.$$

(iii) *If $\epsilon \in (0, \infty)$, one can choose $\theta_i \in \Theta$ in* Part (i) *so close to θ that for any choice of $w_0 \in \omega_\theta(u_0)$ and $w_i \in \omega_{\theta_i}(w_0)$ with $w_1 \leq w_2$ we have*

$$0 \ll u(\,\cdot\,, w_2, \theta_2) - u(\,\cdot\,, w_1, \theta_1) \leq \epsilon \quad \textit{in} \quad C(\overline{\Omega} \times \mathbb{R}^1_+).$$

Moreover, we can even choose θ_i so close to θ that there also exists $r_\epsilon \in \mathbb{R}^1_+$ such that

$$\|u(r_\epsilon + s, u_0, \theta) - u(s, w_i, \theta_i)\|_{W^1_p} \leq \epsilon \quad \textit{for all } s \in \mathbb{R}^1_+ \textit{ and } i = 1, 2.$$

Example 4.6. We consider the initial value problem (IVP) for the following system of n ordinary differential equations indexed by $k = 1, 2, \cdots, n$:

$$(4) \qquad \frac{du_k}{dt} = f_k(t, u_1, \cdots, u_n) + \sum_{\ell=1}^{n} \gamma_{k\ell}(t) u_\ell \quad \text{in } (0, \infty);$$

$$(4_i) \qquad u_k(0) = u_{k,0}.$$

Here, $u \equiv (u_1, \cdots, u_n) : \mathbb{R}^1_+ \longrightarrow \mathbb{R}^n$ denotes the unknown vector-valued function of time t with a prescribed initial vector $u_0 \equiv (u_{k,0}) \in \mathbb{R}^n$. We assume that the reaction functions f_k satisfy f_k, $\partial f_k/\partial u_\ell \in C(\mathbb{R}^1_+ \times \mathbb{R}^n)$, and $\gamma_{k\ell} \in C(\mathbb{R}^1_+)$. Let $\gamma = (\gamma_{k\ell})$ denote the matrix with the entries $\gamma_{k\ell}$, $1 \leq k$, $\ell \leq n$, and let $\gamma_k = (\gamma_{k\ell})_k$ denote its kth row. We assume that, for each $t \in \mathbb{R}^1_+$, the Jacobian matrix $((\partial f_k/\partial u_\ell) + \gamma_{k\ell})$ of the vector field $f(t,\cdot)+\gamma(t)=\big(f_k(t,\cdot)+\gamma_k(t)\big):\mathbb{R}^n\longrightarrow\mathbb{R}^n$ is *strictly cooperative* in $\mathbb{R}^n$.

(SC): If $k\neq\ell$ and $(t,u)\in\mathbb{R}^1_+\times\mathbb{R}^n$, then

$$\gamma_{k\ell}(t)>-\frac{\partial f_k}{\partial u_\ell}(t,u).$$

In order to guarantee global existence in time of a *classical solution* $u\in C^1(\mathbb{R}^1_+\longrightarrow\mathbb{R}^n)$ to (IVP) for every initial vector $u_0\in\mathbb{R}^n$ such that $0\le u_{k,0}\le M_k$ for $1\le k\le n$, we make the following two hypotheses.

(f): $f_k(t,0,\cdots,0)\ge 0$ for all $t\in\mathbb{R}^1_+$ and $k=1,\cdots,n$.

(γ): There exist constants $M_k\in(0,\infty)$, $1\le k\le n$, such that

$$\sum_{\ell=1}^{n}\gamma_{k\ell}(t)M_\ell\le -f_k(t,M_1,\cdots,M_k)\quad\text{for all } t\in\mathbb{R}^1_+.$$

In particular, then $0\le u_k(t)\le M_k$ for all $t\in\mathbb{R}^1_+$ provided $0\le u_{k,0}\le M_k$. All functions f_k and $\gamma_{k\ell}$ entering (IVP) are assumed to be *τ-periodic* in time $t\in\mathbb{R}^1_+$ with a period $\tau\in\mathbb{R}^1_+\setminus\{0\}$. The Euclidean space $\mathbb{R}^n$ is strongly ordered by the *coordinatewise ordering*: If $u=(u_k)\in\mathbb{R}^n$ and $v=(v_k)\in\mathbb{R}^n$, we write $u\le v$ if and only if $u_k\le v_k$ for $k=1,2,\cdots,n$.

We set $V=\mathbb{R}^n$ and $\tilde{V}_\Theta=C(\mathbb{R}^1/\tau\mathbb{Z}\longrightarrow\mathbb{R}^{n\times n})$. From now on we assume that all f_k in (4) are fixed, and we also fix an arbitrary vector $M=(M_k)\in\mathbb{R}^n$ with $M_k>0$ for $k=1,2,\cdots,n$. We denote $\overline{X}=[0,M]_V$; and $\tilde{\Theta}$ is the set of all $\gamma\in\tilde{V}_\Theta$ such that the hypotheses (SC) and (γ) are satisfied. The space $\tilde{V}_\Theta$ is endowed with the pointwise and coordinatewise ordering.

Next we apply the Müller–Kamke theorem (cf. Müller [18]) to derive the following strongly monotone dependence of the solution $u(t,u_0,\gamma)$ to (IVP) upon $u_0\in\overline{X}$ and $\gamma\in\tilde{\Theta}$, for each $t\in(0,\infty)$:

PROPOSITION 4.7. *All statements in Proposition* 4.2 *are valid also for* (IVP) *if we write $\theta=\gamma$.*

It is easy to prove also the following continuity properties of the solution u of our (IVP) with respect to t, u_0, and γ.

PROPOSITION 4.8. *We have*

$$u\in C^{1,1,1-}(\mathbb{R}^1_+\times\overline{X}\times\tilde{\Theta}\longrightarrow\overline{X}).$$

Definition of $\mathcal{T}:\mathcal{X}\longrightarrow\mathcal{X}$. We set $X=[[0,M]]_V$ in $V=\mathbb{R}^n$, i.e., $X=\mathrm{Int}_V(\overline{X})$. We choose V_Θ to be any closed linear subspace of $\tilde{V}_\Theta$ such that $V_\Theta\cap\mathrm{Int}((\tilde{V}_\Theta)_+)\neq\emptyset$ in $\tilde{V}_\Theta$. The following two examples present the basic choices for V_Θ: (i) $V_\Theta=\tilde{V}_\Theta=C(\mathbb{R}^1/\tau\mathbb{Z}\longrightarrow\mathbb{R}^{n\times n})$, or (ii) $V_\Theta=\mathbb{R}^{n\times n}\subset\tilde{V}_\Theta$ (matrices with constant entries).

Next, we choose Θ to be the set of all $\gamma\in V_\Theta$ such that

$$\gamma_{k\ell}(t)>-\inf_{u\in\mathbb{R}^n}\frac{\partial f_k}{\partial u_\ell}(t,u)\quad\text{for all } k\neq\ell \text{ and } t\in\mathbb{R}^1/\tau\mathbb{Z}$$

and

$$\gamma_{kk}(t)<-M_k^{-1}\left[f_k(t,M_1,\cdots,M_n)+\sum_{\substack{\ell=1\\ \ell\neq k}}^{n}\gamma_{k\ell}(t)M_\ell\right]\quad\text{for all } k \text{ and } t\in\mathbb{R}^1/\tau\mathbb{Z}.$$

Equivalently, $\Theta = \mathrm{Int}_{V_\Theta}(\tilde{\Theta} \cap V_\Theta)$ in V_Θ. Finally, we set $\mathcal{X} = X \times \Theta$ and $\mathcal{V} = V \times V_\Theta$ and define $\mathcal{T}$ by

$$\mathcal{T}(u_0, \gamma) = \big(u(\tau, u_0, \gamma), \gamma\big) \quad \text{for all } (u_0, \gamma) \in \mathcal{X}.$$

It follows from Propositions 4.7 and 4.8 that $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ satisfies hypothesis $(\mathcal{T})$ in §1. Since $\overline{X} = [0, M]_{\mathbb{R}^n}$ is compact, every point in $\mathcal{X}$ is both lower and upper approximable provided $\omega_\theta(u_0) \subset X$ for all $(u_0, \theta) \in \mathcal{X}$. Similarly, as in Example 4.1, we can achieve $\omega_\theta(u_0) \subset X$ by strengthening hypothesis (f) to

(f'): $f_k(t, 0, \cdots, 0) \geq 0$ for all $t \in \mathbb{R}^1_+$ and $k = 1, \cdots, n$, and $f_{k'}(t', 0, \cdots, 0) > 0$ for some $t' \in \mathbb{R}^1_+$ and k'.

Finally, we can apply Theorems 2.5 and 3.6 to obtain the following analogue of Theorem 4.5 for our (IVP).

THEOREM 4.9. *Assume that f_k satisfy $f_k, \partial f_k/\partial u_\ell \in C((\mathbb{R}^1/\tau\mathbb{Z}) \times \mathbb{R}^n)$, and* (f'). *Then $\mathcal{U} = \mathcal{U}_- \cup \mathcal{U}_+$ has zero Gaussian measure in $\mathcal{V}$. In particular, if* $\dim(V_\Theta) \equiv n_\theta < \infty$ *then also* $\dim(\mathcal{V}) = n + n_\Theta < \infty$*, and the $(n + n_\Theta)$-dimensional Lebesgue measure of $\mathcal{U}$ is zero.*

If $(u_0, \theta) \in \mathcal{S} = \mathcal{X} \setminus \mathcal{U}$ *then $\omega_\theta(u_0)$ is a quasi cycle in $\mathcal{S}_\theta$ having all properties* (i), (ii), *and* (iii) *from Theorem* 4.5 *with $\mathbb{R}^n$ in place of W^1_p.*

Remark. Problem $(\mathbf{P}')$ from the Introduction can be treated in the same way as Example 4.6. More generally, in both problems $(\mathbf{P})$ and $(\mathbf{P}')$, in place of $\sum_{\ell=1}^n \gamma_{k\ell}(x, t) u_\ell$ and $\gamma_k(t)$, respectively, we could consider any polynomial $p_k(u_1, \cdots, u_n)$ in the variables $u_1, \cdots, u_n \in [0, \infty)$ whose coefficients would play the rôle of (possibly space- and/or time-dependent) parameters. Naturally, condition (γ) from Examples 4.1 and 4.6 might then become more complicated.

Example 4.10. We consider the following single autonomous ordinary differential equation:

$$\frac{du}{dt} = \big(\theta - \varphi(u)\big) u \quad \text{for } t \in (0, \infty); \tag{5}$$

$$u(0) = u_0. \tag{5_i}$$

Here, $\varphi \in C^{1-}(\mathbb{R}^1_+)$, i.e., $\varphi : \mathbb{R}^1_+ \longrightarrow \mathbb{R}^1$ is locally Lipschitz continuous, and $\theta \in \mathbb{R}^1_+$ is a parameter. We assume that $\varphi(0) = 0$ and $\varphi(u) \longrightarrow \infty$ as $u \longrightarrow \infty$. The unknown function $u \in C^1(\mathbb{R}^1_+)$ exists globally in time for every initial value $u_0 \in \mathbb{R}^1_+$. Moreover, the limit $u(\infty) \equiv \lim_{t \to \infty} u(t)$ exists in $\mathbb{R}^1_+$ and satisfies

$$u(\infty) \in \{0\} \cup \varphi^{-1}(\theta),$$

where $\varphi^{-1}(\theta) = \{v \in \mathbb{R}^1_+ : \varphi(v) = \theta\}$ is closed in $\mathbb{R}^1_+$. Clearly, $u(\infty) > 0$ provided $u_0 > 0$ and $\theta > 0$. Again, we write $u(t, u_0, \theta)$ to indicate the dependence of the solution u of (5) upon t, u_0, and θ. We have

$$u \in C^{1,1-,1-}(\mathbb{R}^1_+ \times \mathbb{R}^1_+ \times \mathbb{R}^1_+ \longrightarrow \mathbb{R}^1_+),$$

and if $t \in (0, \infty)$, $u_0 \leq u_0'$, and $\theta \leq \theta'$ in $(0, \infty)$, and $(u_0, \theta) \neq (u_0', \theta')$, then also

$$0 < u(t, u_0, \theta) < u(t, u_0', \theta').$$

We set $V = V_\Theta = \mathbb{R}^1$ and $X = \Theta = (0, \infty)$ and fix any period $\tau \in (0, \infty)$. We define $\mathcal{T} : \mathcal{X} \longrightarrow \mathcal{X}$ by $\mathcal{T}(u_0, \theta) = \big(u(\tau, u_0, \theta), \theta\big)$ for $(u_0, \theta) \in \mathcal{X} = (0, \infty)^2$. Then $\mathcal{T}$

satisfies hypothesis $(\mathcal{T})$, and every point in $\mathcal{X}$ is both lower and upper approximable. It is evident from Lemma 2.3 that the sets $\mathcal{S}_-$ and $\mathcal{S}_+$, and thus $\mathcal{U}_- = \mathcal{X} \setminus \mathcal{S}_-$ and $\mathcal{U}_+ = \mathcal{X} \setminus \mathcal{S}_+$ as well, are independent from our choice of $\tau \in (0, \infty)$. They can be determined from the graph of φ as follows.

LEMMA 4.11. *Let $\theta \in (0,\infty)$ be fixed. Then $(0,\infty) \setminus \varphi^{-1}(\theta) = \cup_{n \in K}(a_n, b_n)$ is the union of at most countably many pairwise disjoint, nonempty open intervals (a_n, b_n), for $n \in K \subset \mathbb{N}$. Furthermore, given any $n \in K$ and $c_n \in (a_n, b_n)$, we have the following two alternatives.*

(i) *$\varphi(c_n) < \theta$ in which case $\varphi(x) < \theta$ and $u(\infty, x, \theta) = b_n \in \mathcal{S}_{\theta -}$ for all $x \in (a_n, b_n)$, and $a_n \in \mathcal{U}_{\theta +}$; in particular, we have $(a_n, b_n] \subset \mathcal{S}_{\theta -}$. Furthermore, either $(a_n, b_n] \subset \mathcal{S}_{\theta +}$ or else $(a_n, b_n] \subset \mathcal{U}_{\theta +}$.*

(ii) *$\varphi(c_n) > \theta$ in which case $\varphi(x) > \theta$ and $u(\infty, x, \theta) = a_n \in \mathcal{S}_{\theta +}$ for all $x \in (a_n, b_n)$, and $b_n \in \mathcal{U}_{\theta -}$; in particular, we have $[a_n, b_n) \subset \mathcal{S}_{\theta +}$. Furthermore, either $[a_n, b_n) \subset \mathcal{S}_{\theta -}$ or else $[a_n, b_n) \subset \mathcal{U}_{\theta -}$.*

LEMMA 4.12. *Let $\theta \in (0, \infty)$ and $x \in \varphi^{-1}(\theta)$ be fixed. Then $(x, \theta) \in \mathcal{S}_-$ if and only if there exists a sequence $x_1 < x_2 < \cdots < x$ in $(0,\infty)$ such that $x_n \longrightarrow x$ and $\varphi(x_n) < \theta$ for all $n \in \mathbb{N}$.*

An analogous statement holds for $\mathcal{S}_+$.

It follows from these two lemmas (whose proofs are simple exercises) that in order to determine the sets $\mathcal{S}_-$ and $\mathcal{S}_+$ we must first compute their intersections with the graph of φ by Lemma 4.12 and then $\mathcal{S}_-$ and $\mathcal{S}_+$ by Lemma 4.11. Roughly speaking, they can be as complicated as the graph of φ.

Acknowledgment. The author expresses his appreciation to C. Dennis Thron, M.D. (Dartmouth Medical School), for helpful discussions concerning applications of the results reported in this article to mathematical problems in pharmacology.

VECTOR-VALUED TAUBERIAN THEOREMS AND ASYMPTOTIC BEHAVIOR OF LINEAR VOLTERRA EQUATIONS*

WOLFGANG ARENDT† AND JAN PRÜSS‡

Abstract. The asymptotic behavior of the solutions of linear Volterra equations in a Banach space X of the form

$$(*)\qquad u(t) = f(t) + \int_0^t a(t-\tau)Au(\tau)d(\tau), \quad t \geq 0$$

is studied, in particular that of the resolvent $S(t)$ for $(*)$; here $a \in L^1_{\text{loc}}(\mathbb{R}_+)$ and A is a closed linear operator in X with dense domain. A complete characterization of the existence of $\lim_{t\to 0} S(t)x = Px$ for all $x \in X$ in the sense of Abel is obtained, and the nature of the ergodic limit P is studied. By means of vector-valued Tauberian theorems for the Laplace transform, a general result on convergence of $S(t)$ in the strong sense is derived. Several examples are given which illustrate this result, and also an application to the theory of linear viscoelasticity is presented.

Key words. Volterra equations, resolvents, asymptotic behavior, Laplace transform, ergodic limit, Abel-limit, Cesaro-limit, Tauberian theorems, C_0-semigroups, cosine families, viscoelasticity

1. Introduction. Let X be a Banach space, $a \in L^1_{\text{loc}}(\mathbb{R}_+)$, A a closed linear operator in X with dense domain $D(A)$, and consider the abstract linear Volterra equation in X

$$(1.1)\qquad u(t) = f(t) + \int_0^t a(t-\tau)Au(\tau)d\tau, \qquad t \geq 0,$$

where $f : \mathbb{R}_+ \to X$ is continuous, $\mathbb{R}_+ = [0, \infty)$. X_A denotes the Banach space $D(A)$ equipped with the graph norm $|.|_A$ of A. A function $u \in C(\mathbb{R}_+; X_A)$ satisfying (1.1) on $\mathbb{R}_+$ is called a *strong solution* of (1.1), while $u \in C(\mathbb{R}_+; X)$ is a *mild solution* of (1.1) if $a * u \in C(\mathbb{R}_+; X_A)$ holds and

$$(1.2)\qquad u(t) = f(t) + A\int_0^t a(t-\tau)u(\tau)d\tau, \qquad t \geq 0,$$

is satisfied on $\mathbb{R}_+$. A family $\{S(t)\}_{t\geq 0} \subset \mathcal{B}(X)$ of bounded linear operators in X is called a *resolvent* for (1.1) if $S(t)$ commutes with A and satisfies the *resolvent equation*

$$(1.3)\qquad S(t)x = x + \int_0^t a(t-\tau)AS(\tau)x d\tau, \qquad t \geq 0, \quad x \in D(A).$$

Once a resolvent $S(t)$ for (1.1) is known to exist, it is unique, and the solution of (1.1) is represented by the *variation of parameters formula*

$$(1.4)\qquad u(t) = \frac{d}{dt}\int_0^t S(t-\tau)f(\tau)d\tau, \qquad t \geq 0,$$

whenever u is a mild solution of (1.1), then $S * f \in C^1(\mathbb{R}_+; X)$ and u is represented by (1.4).

By now the question of existence of a resolvent for (1.1) has been settled for many different classes of pairs (a, A); for a general exposition of the theory, we refer to Prüss [33]. Here we always assume the existence of a resolvent $S(t)$ for (1.1) which is in addition of subexponential growth, i.e., which satisfies

$$\overline{\lim_{t\to\infty}} \frac{1}{t} \log |S(t)| \leq 0. \tag{1.5}$$

It is the purpose of this paper to study the asymptotic behavior of the solutions of (1.1), in particular that of the resolvent $S(t)$ itself. More precisely, the existence of the limits $\lim_{t\to\infty} u(t) = u(\infty)$ and $\lim_{t\to\infty} S(t) = P$ in various senses are investigated, and the nature of the limits $u(\infty)$ and P are discussed.

Our approach is based on the theory of vector-valued Laplace transforms. A well-known Abelian theorem shows that if $\lim_{t\to\infty} S(t)x = Px$ for all $x \in X$, then

$$H(\lambda) = \hat{S}(\lambda) = \int_0^\infty S(t)e^{-\lambda t}dt, \qquad \text{Re}\, \lambda > 0, \tag{1.6}$$

satisfies

$$A - \lim_{t\to\infty} S(t)x := \lim_{\lambda\to 0+} \lambda H(\lambda)x = Px \quad \text{for all } x \in X. \tag{1.7}$$

Therefore it is natural to study first the existence of the Abelian limit P of $S(t)$ as well as its properties. This will be done in §4, where we also apply some elementary vector-valued Tauberian theorems to deduce the convergence of $S(t)$ in the ordinary sense from existence of the ergodic limit $P \in \mathcal{B}(X)$; for that, several strong assumptions on $S(t)$ are needed. Once the Abelian limit $P \in \mathcal{B}(X)$ of $S(t)$ is known to exist, it follows easily that $A - \lim_{t\to\infty} u(t) = u(\infty)$ also exists whenever $f(t)$ admits an Abelian limit $f(\infty)$ and then $u(\infty) = Pf(\infty)$ holds.

The main result of this paper, the General Convergence Theorem stated and proved in §5, gives sufficient conditions for the strong convergence of $S(t)$ to its ergodic limit P as $t \to \infty$. For the special case $a(t) \equiv 1$ and A the generator of a bounded C_0-semigroup $T(t)$ in X, we have $S(t) = T(t)$ and the result reduces to a stability theorem for C_0-semigroups obtained recently by Arendt and Batty [2] and independently by Lyubich and Phong [28]; cf. also §7. The proof of the General Convergence Theorem relies on the complex Tauberian theory for the vector-valued Laplace transform. In fact, it is very much inspired by the proof of Arendt and Batty [2] for the semigroup case. However, due to the more complicated structure of the Laplace transform $H(\lambda)$ of the resolvent $S(t)$ for (1.1), i.e.,

$$H(\lambda) = \frac{1}{\lambda}(I - \hat{a}(\lambda)A)^{-1}, \qquad \text{Re}\, \lambda > 0, \tag{1.8}$$

the Tauberian arguments involved are more delicate and differ from those employed in the proof of Arendt and Batty [2].

Since Abelian and Tauberian theorems for the vector-valued Laplace transform are at the heart of our approach, and since there is no coherent presentation of this material available in the literature, we have included two sections on this matter. Section 2 contains the basic Abelian theorem, as well as the vector-valued extension of the classical real Tauberian theorems due to Hardy–Littlewood, Wiener, Pitt, and

Karamata; cf. Doetsch [15] and Widder [42] for their classical statements. Complex Tauberian theorems are presented in §3. Here a condition on the Laplace transform $\hat{f}$ of f is given which implies convergence of $f(t)$ $(t \to \infty)$. A first result of this type had been given in 1938 by Ingham [20], but recently a simple new technique of proof due to Newman [30] has led to considerable extensions; see Korevaar [25], Allan, O'Farrell, and Ransford [1], Arendt and Batty [2], Ransford [34], and Batty [3].

Section 6 is devoted to an elaboration of several examples and special cases of the theory developed in §§3–5. In particular, several classes of kernels are presented, for which the assumptions of the General Convergence Theorem reduce to boundedness of $S(t)$ (which is necessary for the existence of the strong limit of $S(t)$ anyway) and to a spectral condition that cannot be relaxed (and to some extent is also necessary). In §7, we apply our results to the theory of linear viscoelasticity. Here we show that if A generates a uniformly bounded cosine family and $a(t)$ is of the form

$$(1.9) \qquad a(t) = a_0 + a_\infty t + \int_0^t a_1(\tau)d\tau, \qquad t \geq 0$$

with $a_0, a_\infty \geq 0$, $a_1(t) \geq 0$ nonincreasing, $\log a_1(t)$ convex, and $\lim_{t\to\infty} a_1(t) = 0$, then $S(t)$ converges strongly as $t \to \infty$ if in addition $N(A)^\perp \cap N(A') = \{0\}$ and $a(t) \not\equiv a_\infty t$ hold. This result shows that any viscoelastic fluid in a smooth domain $\Omega \subset \mathbb{R}^n$ with compact boundary is asymptotically stable in the strong sense, whether Ω is bounded or not. It has been shown in Prüss [32] that viscoelastic fluids are uniformly asymptotically stable if and only if $A = P\Delta$ is invertible. This is always true for bounded domains Ω, but it is in general not the case for unbounded domains; cf. §7 for these concepts and further discussion.

2. Abelian and real Tauberian theorems. Throughout this section, $(X, |\ \ |)$ is a Banach space and $f \in L^1_{\text{loc}}([0,\infty), X)$ is such that

$$\hat{f}(\lambda) = \int_0^\infty e^{-\lambda t} f(t)dt := \lim_{b\to\infty} \int_0^b e^{-\lambda t} f(t)dt$$

exists for Re $\lambda > 0$ (this is equivalent to $\sup_{t\geq 0} e^{-\lambda t}|\int_0^t f(s)ds| < \infty$ for all $\lambda > 0$).

DEFINITION 2.1. Let $f_\infty \in X$. The function f converges to f_∞ in the sense of Cesaro $(t \to \infty)$ if $C - \lim_{t\to\infty} f(t) := \lim_{t\to\infty}(1/t)\int_0^t f(s)ds = f_\infty$, and f converges to f_∞ in the sense of Abel $(t \to \infty)$ if $A - \lim_{t\to\infty} f(t) := \lim_{\lambda\to 0+} \lambda\hat{f}(\lambda) = f_\infty$.

The following *Abelian theorem* is easy to prove (see [19, Thm. 18.2.1]). It will be convenient to introduce $F(t) = \int_0^t f(s)ds$ as an auxiliary function.

THEOREM 2.2. *Let* f_∞, $F_\infty \in X$.

(a) *If* $\lim_{t\to\infty} f(t) = f_\infty$, *then* $C - \lim_{t\to\infty} f(t) = f_\infty$.

(b) *If* $C - \lim_{t\to\infty} f(t) = f_\infty$, *then* $A - \lim_{t\to\infty} f(t) = f_\infty$.

(c) *If* $\lim_{t\to\infty} F(t) = F_\infty$, *then* $\lim_{\lambda\to 0+} \hat{f}(\lambda) = F_\infty$.

Note that (c) is a special case of (b) since $\hat{f}(\lambda) = (F')^\wedge(\lambda) = \lambda\hat{F}(\lambda) \quad (\lambda > 0)$.

A result if called a *Tauberian theorem* if a condition on f is given under which the converse implications of (a), (b), or (c) are valid. Such theorems are presented in sections A, B, C, D, and E respectively. Most of these results are well known at least in the numerical case. We include proofs here for the sake of completeness.

Our main objective is to find conditions under which Abelian convergence implies convergence (see §D).

A. Conditions under which $C-\lim_{t\to\infty} f(t) = f_\infty$ **implies** $\lim_{t\to\infty} f(t) = f_\infty$. A vector-valued function f is called *feebly oscillating* (when $t \to \infty$) if

$$\lim_{\substack{t,s\to\infty \\ t/s\to 1}} |f(t) - f(s)| = 0$$

(cf. [19, Def. 18.3.1], [43, Def. 8.4]).

Example 2.3. Assume that $t|f(t)| \leq M$ for $t \geq \tau$, where $\tau \geq 0$. Then F is feebly oscillating. In fact, $|F(t) - F(s)| \leq \int_s^t r|f(r)|(dr/r) \leq M\log(t/s)$ for $t \geq s \geq \tau$.

THEOREM 2.4. *Assume that f is feebly oscillating and let $f_\infty \in X$. If $C - \lim_{t\to\infty} f(t) = f_\infty$, then $\lim_{t\to\infty} f(t) = f_\infty$.*

Proof. We can suppose that $f_\infty = 0$. Let $\epsilon > 0$. There exist $\delta > 0$, $t_0 > 0$ such that $|f(s) - f(t)| < \epsilon$ whenever $s, t > t_0$, $s \in [t - \delta t, t + \delta t]$. Hence $|f(t) - (1/2\delta t)\int_{t(1-\delta)}^{t(1+\delta)} f(s)ds| = |(1/2\delta t)\int_{t(1-\delta)}^{t(1+\delta)} (f(t) - f(s))ds| \leq \epsilon$ if $t \geq t_0$. Since

$$\lim_{t\to\infty} \frac{1}{2\delta t}\int_{t(1-\delta)}^{t(1+\delta)} f(s)ds = 0,$$

we conclude $\lim_{t\to\infty} f(t) = 0$. □

B. Conditions under which $A-\lim_{t\to\infty} f(t) = f_\infty$ **implies** $C-\lim_{t\to\infty} f(t) = f_\infty$. The following result is a particular case of [19, Thms. 18.3.3, 18.3.2].

THEOREM 2.5. *Let $f_\infty \in X$. Assume that $f \in L^\infty([\tau,\infty); X)$ for some $\tau \geq 0$. If $A - \lim_{t\to\infty} f(t) = f_\infty$ then $C - \lim_{t\to\infty} f(t) = f_\infty$.*

Proof. 1. We first assume that $\tau = 0$. For $\beta > 0$ let $e_\beta(t) = \beta e^{-\beta t}(t > 0)$. Then span $\{e_\beta : \beta > 0\}$ is dense in $L^1[0,\infty)$ (in fact, if $g \in L^\infty[0,\infty)$ such that $0 = \langle e_\beta, g\rangle = \beta\hat{g}(\beta)$ for all $\beta > 0$, then $g = 0$ almost everywhere by uniqueness theorem for Laplace transforms). By hypothesis $\lim_{\alpha\to\infty}\int_0^\infty e^{-s}f(\alpha s)ds = \lim_{\lambda\to 0+}\int_0^\infty e^{-s}f(s/\lambda)ds = \lim_{\lambda\to 0+}\lambda\int_0^\infty e^{-\lambda s}f(s)ds = f_\infty$. Hence

$$\lim_{\alpha\to\infty}\langle e_\beta, f(\alpha\cdot)\rangle = \lim_{\alpha\to\infty}\beta\int_0^\infty e^{-s\beta}f(\alpha s)ds = \lim_{\alpha\to\infty}\int_0^\infty e^{-s}f(\frac{\alpha}{\beta}s)ds = f_\infty = \langle e_\beta, f_\infty\rangle$$

for all $\beta > 0$. It follows that $\lim_{\alpha\to\infty}\langle h, f(\alpha\cdot)\rangle = f_\infty\int_0^\infty h(t)dt$ for all $h \in L^1[0,\infty)$. Letting $h = X_{[0,1]}$ we obtain $\lim_{\alpha\to\infty} 1/\alpha\int_0^\alpha f(s)ds = \lim_{\alpha\to\infty}\int_0^1 f(\alpha s)ds = \lim_{\alpha\to\infty}\langle h, f(\alpha\cdot)\rangle = f_\infty$.

2. If $\tau > 0$ the result follows by applying 1. to $g(t) = f(t + \tau)$. □

Another result of this type involves an order condition. We assume in the following theorem that X is an ordered Banach space with normal cone X_+ (i.e., X_+ is a closed convex cone such that $X_+ \cap (-X_+) = \{0\}$ and $X'_+ - X'_+ = X'$ where X'_+ denotes the dual cone; see [5] for details). For example, X may be a Banach lattice.

THEOREM 2.6. *Assume that $f(t) \geq 0$ (i.e., $f(t) \in X_+$) for $t \geq 0$. If $A - \lim_{t\to\infty} f(t) = f_\infty$, then $C - \lim_{t\to\infty} f(t) = f_\infty$.*

Karamata's proof of this result (see [43, Thm. 8.5.3]) goes through in the vector-valued case described above. A very short and elegant proof in the scalar case is given by König [24].

C. Conditions under which $\lim_{\lambda\to 0+}\hat{f}(\lambda) = F_\infty$ **implies** $\lim_{t\to\infty} F(t) = F_\infty$. The following theorem is due to Hardy and Littlewood in the numerical case; see [43, Thm. 8.4.3].

THEOREM 2.7. *Let $F_\infty \in X$. Assume that for some $\tau \geq 0$*

$$M = \sup_{t\geq\tau} t|f(t)| < \infty. \tag{2.1}$$

If $\lim_{\lambda\to 0+}\hat{f}(\lambda) = F_\infty$, *then* $\lim_{t\to\infty} F(t) = F_\infty$.

Proof. 1. We first assume that $\tau = 0$. For $t > 0$ we have

$$\begin{aligned}|F(t) - \hat{f}(\frac{1}{t})| &= |\int_0^t f(s)[1 - e^{-s/t}]ds - \int_t^\infty f(s)e^{-s/t}ds| \\ &\leq M(\int_0^t [1 - e^{-s/t}]/s^{-1}ds + \int_t^\infty s^{-1}e^{-s/t}ds) \\ &\leq M[\sup_{0<s<t} t[1 - e^{-s/t}]/s + \int_1^\infty e^{-r}r^{-1}dr] \\ &\leq M[\sup_{0<x\leq 1}(1 - e^{-x})/x + \int_1^\infty e^{-r}r^{-1}dr] < \infty.\end{aligned}$$

Since $\lim_{t\to\infty}\hat{f}(1/t) = F_\infty$, it follows that F is bounded. But $A - \lim_{t\to\infty} F(t) = \lim_{\lambda\to 0+}\hat{f}(\lambda) = F_\infty$. So it follows from Theorem 2.5 that $C - \lim_{t\to\infty} F(t) = F_\infty$. The function F is slowly oscillating (see Example 2.3). Hence $\lim_{t\to\infty} F(t) = F_\infty$ by Theorem 2.4.

2. If $\tau > 0$ the result follows from 1. by considering $f(t+\tau)$ instead of $f(t)$. □

D. Conditions under which $A - \lim_{t\to\infty} f(t) = f_\infty$ implies $\lim_{t\to\infty} f(t) = f_\infty$. Since $\lambda\hat{F}(\lambda) = \hat{f}(\lambda)$, any Tauberian theorem of type D yields one of type C. Conversely, if $f \in C^1([\tau,\infty), X)$ we can apply a result of type C to the function $f'(t+\tau)$ and obtain a Tauberian theorem of type D.

Following an idea of Batty [3] we apply instead Tauberian theorems of type C to the function f_δ defined by

$$f_\delta(t) = (f(t+\delta) - f(t))/\delta \qquad (t \geq 0) \tag{2.2}$$

for some $\delta > 0$. The following implications hold.

LEMMA 2.8. *Let* $f_\infty \in X$, $\delta > 0$.

$$\begin{array}{ll}\text{(i)} & \lim_{t\to\infty} f(t) = f_\infty \\ & \Downarrow \\ \text{(ii)} & \lim_{t\to\infty}\int_t^{t+\delta} f(s)ds = f_\infty\delta \\ & \Updownarrow \\ \text{(iii)} & \lim_{t\to\infty}\int_0^t f_\delta(s)ds = f_\infty - \frac{1}{\delta}\int_0^\delta f(s)ds \\ & \Downarrow \\ \text{(iv)} & \lim_{\lambda\to 0+}\hat{f}_\delta(\lambda) = f_\infty - \frac{1}{\delta}\int_0^\delta f(s)ds \\ & \Updownarrow \\ \text{(v)} & A - \lim_{t\to\infty} f(t) = f_\infty.\end{array}$$

Proof. Since $|(1/\delta)\int_t^{t+\delta} f(s)ds - f_\infty| = |(1/\delta)\int_t^{t+\delta}(f(s) - f_\infty)ds| \leq \sup_{s\geq t}|f(s) - f_\infty|$, (i) implies (ii), and (ii) is equivalent to (iii) since $\int_0^t f_\delta(s)ds = (1/\delta)\int_t^{t+\delta} f(s)ds - (1/\delta)\int_0^\delta f(s)ds$.

By Theorem 2.2(c), (iii) implies (iv). Since

$$\hat{f}_\delta(\lambda) = \frac{1}{\delta\lambda}(e^{\lambda\delta} - 1)\lambda\hat{f}(\lambda) - \frac{e^{\lambda\delta}}{\delta}\int_0^\delta e^{-\lambda s}f(s)ds, \tag{2.3}$$

(iv) is equivalent to (v). □

Let $f_\infty \in X$. We say, f is *B-convergent* to f_∞, or simply write $B - \lim_{t\to\infty} f(t) = f_\infty$, if (ii) of Lemma 2.8 holds for all $\delta > 0$. A vector-valued function f is called *slowly oscillating* (when $t \to \infty$) if

$$\lim_{\substack{t,s\to\infty \\ t-s\to 0}} |f(t) - f(s)| = 0.$$

PROPOSITION 2.9. *Let $f_\infty \in X$.*

(a) *If $B - \lim_{t\to\infty} f(t) = f_\infty$, then $A - \lim_{t\to\infty} f(t) = f_\infty$.*

(b) *If $\lim_{t\to\infty} f(t) = f_\infty$, then $B - \lim_{t\to\infty} f(t) = f_\infty$.*

(c) *If f is slowly oscillating then $B - \lim_{t\to\infty} f(t) = f_\infty$ implies $\lim_{t\to\infty} f(t) = f_\infty$.*

Proof. (a) and (b) follow from Lemma 2.8. Assume that $B - \lim_{t\to\infty} f(t) = f_\infty$. Then

$$\begin{aligned}\overline{\lim_{t\to\infty}}|f(t) - f_\infty| &\le \overline{\lim_{t\to\infty}}|f(t) - \frac{1}{\delta}\int_t^{t+\delta} f(s)ds| \\ &= \overline{\lim_{t\to\infty}}|\frac{1}{\delta}\int_t^{t+\delta}(f(t) - f(s))ds| \le \overline{\lim_{t\to\infty}} \sup_{t\le s\le t+\delta}|f(t) - f(s)|.\end{aligned}$$

Hence if f is slowly oscillating, we obtain $\overline{\lim}_{t\to\infty}|f(t) - f_\infty| = 0$ by letting $\delta \downarrow 0$. □

Every feebly oscillating function is slowly oscillating (this is obvious from the definitions); moreover, f is slowly oscillating whenever there exists $\tau \ge 0$ such that $f = g + h$, where $g \in UC([\tau,\infty); X)$ (the space of all uniformly continuous functions on $[\tau,\infty)$ with values in X), and $h \in L^\infty([\tau,\infty); X)$ converges to zero as $t \to \infty$.

Remark. In order that $B - \lim_{t\to\infty} f(t) = f_\infty$ it suffices that (ii) holds for all $\delta \in (0,\delta_0)$ for some $\delta_0 > 0$. In fact, if (ii) holds for $\delta > 0$ and $\eta > 0$ it does so for $\delta + \eta$.

Now we are able to deduce from Theorem 2.7 the following Tauberian theorem of type D.

THEOREM 2.10. *Let $f_\infty \in X$. Assume that for some $\delta > 0$*

$$\overline{\lim_{t\to\infty}} \sup_{t\le s\le t+\delta} t|f(t) - f(s)| < \infty. \tag{2.4}$$

If $A - \lim_{t\to\infty} f(t) = f_\infty$ then $\lim_{t\to\infty} f(t) = f_\infty$.

Proof. Assumption (2.4) implies that f_δ satisfies (2.1) for $\delta > 0$ small enough and also that f is slowly oscillating. Since $A - \lim_{t\to\infty} f(t) = f_\infty$, it follows that (iv) of Lemma 2.8 is satisfied. We conclude (iii) from Theorem 2.7 so that $B - \lim_{t\to\infty} f(t) = f_\infty$. Hence $\lim_{t\to\infty} f(t) = f_\infty$ by Proposition 2.9. □

Note that (2.4) is satisfied whenever $f \in C^1([\tau,\infty), X)$ and $|tf'(t)| \le M$ for $t \ge \tau$; in fact, $|f(t) - f(s)| = |\int_t^s f'(r)dr| \le M\log(s/t) \le M(s-t)/t$ for $t < s$.

Applying Theorem 2.10 to F we obtain an improvement of Theorem 2.7.

COROLLARY 2.11. *Let $F_\infty \in X$. Assume that for some $\delta > \infty$*

$$\overline{\lim_{t\to\infty}} \int_t^{t+\delta} r|f(r)|dr < \infty. \tag{2.5}$$

If $\lim_{\lambda\to 0+} \hat{f}(\lambda) = F_\infty$, *then* $\lim_{t\to\infty} F(t) = F_\infty$.

Proof. We have

$$\begin{aligned}\overline{\lim_{t\to\infty}} \sup_{t\le s\le t+\delta} t|F(t) - F(s)| &\le \overline{\lim_{t\to\infty}} t \int_t^{t+\delta} |f(s)|ds \\ &\le \overline{\lim_{t\to\infty}} \int_t^{t+\delta} s|f(s)|ds < \infty.\end{aligned}$$

Hence F satisfies (2.4) and the conclusion follows from Theorem 2.10. □

E. Power series. Let $p(z) = \sum_{n=0}^\infty a_n z^n$ be a power series, where $a_n \in X$, which converges for $|z| < 1$. Defining $f \in L^1_{\mathrm{loc}}([0,\infty); X)$ by

$$f(t) = a_n \quad \text{if } t \in [n, n+1) \tag{2.6}$$

the preceding results yield Tauberian theorems for p. In fact,

$$\hat{f}(\lambda) = \left(\frac{1-e^{-\lambda}}{\lambda}\right) \sum_{n=0}^\infty a_n e^{-\lambda n} \qquad (\mathrm{Re}\,\lambda > 0). \tag{2.7}$$

From Theorem 2.7 Hardy's theorem can be obtained.

THEOREM 2.12. *Assume that* $\sup\{n|a_n| : n \in \mathbb{N}_0\} < \infty$, *and let* $b_\infty \in X$. *If* $\lim_{z\uparrow 1} p(z) = b_\infty$, *then* $\sum_{n=0}^\infty a_n = b_\infty$.

The special case when $\lim_{n\to\infty} na_n = 0$ had been proven by Tauber [38] (in the scalar case) and was the starting point of Tauberian theory.

In the case of power series, theorems of type C and D are equivalent. In fact, let $b_n = \sum_{k=0}^n a_k$, or equivalently, $a_0 = b_0$, $a_n = b_n - b_{n-1}$ $(n = 1, 2\cdots)$. Then $q(z) = \sum_{n=0}^\infty b_n z^n$ has the same radius of convergence as $p(z)$. The formula for the Cauchy product yields

$$\frac{1}{z-1} \sum_{k=0}^\infty a_k z^k = \sum_{k=0}^\infty z^k \cdot \sum_{k=0}^\infty a_k z^k = \sum_{k=0}^\infty b_k z^k \qquad (|z| < 1);$$

that is,

$$\sum_{k=0}^\infty a_k z^k = (1-z) \sum_{k=0}^\infty b_k z^k \qquad (|z| < 1).$$

Thus $A - \lim_{n\to\infty} b_n := \lim_{z\uparrow 1} (1-z) \sum_{k=0}^\infty b_k z^k = \lim_{z\uparrow 1} \sum_{k=0}^\infty a_k z^k$ whenever one of the limits exists. So we obtain the following.

COROLLARY 2.13. *Let $b_n \in X$ be such that* $\sup\{n|b_n - b_{n-1}| : n \in \mathbb{N}\} < \infty$. *If* $A - \lim_{n\to\infty} b_n = b_\infty$, *then* $\lim_{n\to\infty} b_n = b_\infty$.

3. Complex Tauberian theorems. We assume throughout this section that $f \in L^1_{\mathrm{loc}}([0,\infty); X)$ is such that

$$\hat{f}(\lambda) = \lim_{b\to\infty} \int_0^b e^{-\lambda t} f(t)dt =: \int_0^\infty e^{-\lambda t} f(t)dt$$

exists for Re $\lambda > 0$. In this section we consider conditions on $\hat{f}$ (rather than on f) in order to establish Tauberian theorems. The following theorem (of type C, see §2) is a variant of [2, Thm. 4.1].

THEOREM 3.1. *Let $f_\infty \in X$. Assume that $f \in L^\infty([\tau,\infty);X)$ for some $\tau \geq 0$ and that $(\hat{f}(\lambda) - F_\infty)/\lambda$ has a continuous extension to $\bar{\mathbb{C}}_+\backslash iE$, where $E \subset \mathbb{R}$ is a closed null set and $0 \notin E$. If for all $R > 0$*

$$M(R) := \sup_{\substack{\eta\in E \\ |\eta|\leq R}} \sup_{t\geq 0} \left| \int_0^t \exp(-i\eta s) f(s) ds \right| < \infty, \tag{3.1}$$

then $\lim_{t\to\infty} F(t) = F_\infty$.

Here and in the sequel we let $F(t) = \int_0^t f(s)ds$, $\mathbb{C}_+ = \{\lambda \in \mathbb{C} : \text{Re } \lambda > 0\}$, and $\bar{\mathbb{C}}_+$ the closure of $\mathbb{C}_+$. Note that the hypothesis implies that $\hat{f}(\lambda)$ has a continuous extension to $\bar{\mathbb{C}}_+\backslash iE$ and that $\hat{f}(0) = F_\infty$. In particular, $A - \lim_{t\to\infty} F(t) = F_\infty$.

The proof of [2, Thm. 4.1] works for Theorem 3.1 as well if the basic estimate Lemma 5.2 which will be proved in §5 is used instead of [2, Lemma 3.1].

For $E = \emptyset$ Theorem 3.1 is a version of a theorem due to Ingham [20]. A very short and elegant proof based on an ingenious contour argument due to Newman [30] is given by Korevaar [25]. In [2] the technique of Newman and Korevaar has been extended in order to treat singularities in $i\mathbb{R}$. Whereas in [2] it is assumed that $\hat{f}$ has a holomorphic extension to $\bar{\mathbb{C}}_+\backslash iE$, our slightly more general version is more natural in view of the applications to Volterra equations we have in mind (see §5).

We give several comments on Theorem 3.1, starting with the case when $E = \emptyset$.

Remark 3.2. *Quantitative estimates.* Korevaar's argument actually yields the following more precise result. Assume that $f \in L^\infty([\tau,\infty);X)$ for some $\tau > 0$ and that $F_\infty \in X$ such that $(\hat{f}(\lambda) - F_\infty)/\lambda$ has a continuous extension to $\mathbb{C}_+ \cup i[-R,R]$ where $R > 0$. Then

$$\overline{\lim_{t\to\infty}} |F(t) - F_\infty| \leq \frac{2}{R} \overline{\lim_{t\to\infty}} |f(t)|. \tag{3.2}$$

Proof. In fact, Korevaar shows (a special case of Lemma 5.2 below)

$$\overline{\lim_{t\to\infty}} |F(t) - F_\infty| \leq \frac{2}{R} \sup_{t\geq 0} |f(t)|. \tag{3.3}$$

Applying this to $g(t) = f(t+s)$ with $s \geq \tau$, we have $\hat{g}(\lambda) = e^{\lambda s}[\hat{f}(\lambda) - \int_0^s e^{-\lambda r} f(r)dr]$ (Re $\lambda > 0$) so that $(\hat{g}(\lambda) - G_\infty)/\lambda$ has a continuous extension to $\mathbb{C}_+ \cup i[-R,R]$ with $G_\infty = F_\infty - \int_0^s f(r)dr$. Hence, by (3.3)

$$\overline{\lim_{t\to\infty}} |F(t) - F_\infty| = \overline{\lim_{t\to\infty}} \left| \int_0^{t+s} f(r)dr - F_\infty \right| = \overline{\lim_{t\to\infty}} |G(t) - G_\infty| \leq \sup_{t\geq s} \frac{2}{R} |f(t)|.$$

Letting $s \to \infty$ yields (3.2). □

Quantitative estimates in the case $E \neq \emptyset$ are given in Batty [3].

Remark 3.3. *Convergence of the Laplace integral at regular points.* Assume that $\lim_{t\to\infty} |f(t)| = 0$. If $\hat{f}$ has a holomorphic extension to $\mathbb{C}_+ \cup U$, where U is a neighborhood of $i\eta \in i\mathbb{R}$, then

$$\hat{f}(i\eta) = \int_0^\infty e^{-i\eta s} f(s)ds = \lim_{t\to\infty} \int_0^t e^{-i\eta s} f(s)ds. \tag{3.4}$$

To see this, it suffices to replace $f(t)$ in (3.2) by $e^{-i\eta t}f(t)$.

Remark 3.4. *Riesz's theorem on power series* [40, Thm. 7.3]. Let $a_n \in X$ be such that $\lim_{n\to\infty}|a_n| = 0$ and let $p(z) = \sum_{n=0}^{\infty} a_n z^n$ ($|z| < 1$). If p has a holomorphic extension to $D \cup U$ ($D = \{z \in \mathbb{C} : |z| < 1\}$) where U is an open neighborhood of $z_0 \in \Gamma := \{z \in \mathbb{C} : |z| = 1\}$, then $p(z_0) = \lim_{N\to\infty}\sum_{n=0}^{N} a_n z_0^n$. This is obtained by applying (3.4) to the function f defined by (2.6).

Next we establish a complex Tauberian theorem of type D. The following is a variant of [3, Cor. 2.6].

THEOREM 3.5. *Assume that f is slowly oscillating, let $f_\infty \in X$, and suppose that $\hat{f}(\lambda) - (f_\infty/\lambda)$ has a continuous extension to $\bar{\mathbb{C}}_+\backslash iE$, where $E \subset \mathbb{R}$ is a closed null set such that $0 \notin E$. If for all $R > 0$,*

$$M(R) := \sup_{\eta\in E\cap[-R,R]}\sup_{t\geq 0}\left|\int_0^t \exp(-i\eta s)f(s)ds\right| < \infty, \tag{3.5}$$

then $\lim_{t\to\infty} f(t) = f_\infty$.

Remark. The assumption implies that $A - \lim_{t\to\infty} f(t) = f_\infty$.

Proof. The function f_δ defined by (2.2) is eventually bounded for $\delta > 0$ sufficiently small. Let $c := f_\infty - (1/\delta)\int_0^\delta f(s)ds$. Then by (2.3),

$$\begin{aligned}(\hat{f}_\delta(\lambda) - c)/\lambda &= \frac{1}{\delta\lambda}(e^{\lambda\delta} - 1)\hat{f}(\lambda) - \frac{e^{\lambda\delta}}{\lambda\delta}\int_0^\delta e^{\lambda s}f(s)ds - \frac{c}{\lambda}\\ &= \frac{1}{\delta\lambda}(e^{\lambda\delta} - 1)(\hat{f}(\lambda) - \frac{f_\infty}{\lambda}) + \left[\frac{1}{\delta\lambda}(e^{\lambda\delta} - 1) - 1\right]f_\infty/\lambda\\ &\qquad - \frac{e^{\lambda\delta}}{\delta}\int_0^\delta \frac{e^{-\lambda s} - 1}{\lambda}f(s)ds - \frac{e^{\lambda\delta} - 1}{\lambda\delta}\int_0^\delta f(s)ds.\end{aligned}$$

Since the functions $(1/\delta\lambda)(e^{\lambda\delta} - 1)$, $[(1/\delta\lambda)(e^{\lambda\delta} - 1) - 1]/\lambda$, and $(e^{-\lambda s} - 1)/\lambda$ are entire, it follows that $(\hat{f}_\delta(\lambda) - c)/\lambda$ has a continuous extension to $\bar{\mathbb{C}}_+\backslash iE$. Moreover,

$$\begin{aligned}\left|\int_0^t \exp(-i\eta s)f_\delta(s)ds\right| &= \left|\delta^{-1}\int_0^t \exp(-i\eta s)(f(s+\delta) - f(s)ds\right|\\ &= \delta^{-1}\left|\int_\delta^{\delta+t}\exp i\eta(\delta - s)f(s)ds - \int_0^t \exp(-i\eta s)f(s)ds\right|\\ &\leq 3\delta^{-1}M(R) \quad \text{for all } \eta \in E\cap[-R,R].\end{aligned}$$

It follows from Theorem 3.1 that $\lim_{t\to\infty}\int_0^t f_\delta(s)ds = c$. Hence $B-\lim_{t\to\infty} f(t) = f_\infty$ by Lemma 2.8. It follows from Proposition 2.9(c) that $\lim_{t\to\infty} f(t) = f_\infty$. □

Remark 3.6. (a) If in Theorem 3.5, instead of f slowly oscillating, we merely assume that $f_\delta \in L^\infty([\tau,\infty);X)$ for all $\delta > 0$, then we obtain $B - \lim_{t\to\infty} f(t) = f_\infty$

(b) However, if f is not slowly oscillating, then f does not converge in general, even if f is bounded. An example is the function $f(t) = T(t)y$ from [2, proof of Ex. 2.5]. The function f is bounded and $\hat{f}$ has a holomorphic extension to $\bar{\mathbb{C}}_+$. However, $f(t)$ does not converge for $t \to \infty$.

Next we consider the case where $0 \in E$. For simplicity we assume $f_\infty = 0$. We let $\mathrm{Lip}([\tau,\infty),X) = \{f : [\tau,\infty) \to X : f$ is Lipschitz continuous $\}$.

THEOREM 3.7. *Assume that* $f \in \mathrm{Lip}([\tau,\infty);X)$, *for some* $\tau \geq 0$. *Suppose that* $\hat{f}(\lambda)$ *has a continuous extension to* $\bar{\mathbb{C}}_+\backslash iE$, *where* E *is a closed null set,* $0 \in E$, *and that for each* $R \geq 0$

$$M(R) := \sup_{\eta\in E\cap[-R,R]} \sup_{t\geq 0} \left| \int_0^t \exp(-i\eta s) f(s)ds \right| < \infty. \tag{3.6}$$

Then $\lim_{t\to\infty} f(t) = 0$.

Remark. Since $0 \in E$, condition (3.6) implies that $C - \lim_{t\to\infty} f(t) = 0$.

Proof. We first show that $f \in L^\infty([\tau,\infty);X)$. There exists $L \geq 0$ such that $|f(t) - f(s)| \leq L|t-s|$ for all $s,t \geq \tau$. Let $\varphi \in X'$, $|\varphi| \leq 1$. Then, by the Taylor expansion for $F(t) = \int_0^t f(r)dr$ in $s \geq \tau$, we have

$$\langle F(s+1),\varphi\rangle = \langle F(s),\varphi\rangle + \langle f(s),\varphi\rangle + \int_s^{s+1} (s+1-r)\frac{d}{dr}\langle f(r),\varphi\rangle dr.$$

Hence

$$\begin{aligned}|\langle f(s),\varphi\rangle| &\leq |\langle F(s+1),\varphi\rangle| + |\langle F(s),\varphi\rangle| + \int_s^{s+1} (s+1-r)|\frac{d}{dr}\langle f(r),\varphi\rangle|dr \\ &\leq 2M(0) + L\int_s^{s+1}(s+1-r)dr \leq 2M(0) + \frac{L}{2}.\end{aligned}$$

Fix $\mu \in \mathbb{R}\backslash E$ and define $g(t) = e^{i\mu t}f(t)$. Then $g \in \mathrm{Lip}([\tau,\infty);X)$ and $\hat{g}(\lambda) = \hat{f}(\lambda - i\mu)(\mathrm{Re}\ \lambda > 0)$. Hence $\hat{g}(\lambda)$ has a continuous extension to $\bar{\mathbb{C}}_+\backslash iE'$ where $E' = E + \mu$. Moreover, for $\eta' = \eta + \mu \in E' \cap [-R,R]$ we have $|\int_0^t \exp(-i\eta' s)g(s)ds| = |\int_0^t \exp(-i\eta s)f(s)ds| \leq M(R + |\mu|)$ for all $t \geq 0$. Since $0 \notin E'$, the assertion follows from Theorem 3.5. □

Applying Theorem 3.5 to power series we obtain a variant of a result due to Allan, O'Farrell, and Ransford [1]. We let $\bar{D} = \{z \in \mathbb{C} : |z| \leq 1\}$, and $\Gamma = \{z \in \mathbb{C} : |z| = 1\}$.

THEOREM 3.8. *Let* $b_n \in X$ *be such that* $\sup\{|b_n| : n \in \mathbb{N}_0\} < \infty$ *and set* $p(z) = \sum_{n=0}^\infty b_n z^n$ *for* $|z| < 1$. *Assume that* p *has a continuous extension to* $\bar{D}\backslash F$, *where* $F \subset \Gamma$ *is a closed null set.*

If $\sup_{z\in F}\sup_{N\in\mathbb{N}} |\sum_{n=0}^N b_n z^n| < \infty$, *then* $\lim_{n\to\infty} b_n = 0$.

Remark. The hypothesis of the theorem directly implies $A - \lim_{n\to\infty} b_n = 0$ if $1 \notin F$ and $C - \lim_{n\to\infty} b_n = \lim_{n\to\infty} 1/n \sum_{k=0}^{n-1} b_k = 0$ if $1 \in F$.

Proof. Replacing b_n by $b_n w^{-n}$ for some $w \in \Gamma\backslash F$ if necessary, we may assume that $1 \notin F$. Let $f(t) = b_n$ for $t \in [n, n+1)$. Then $\hat{f}(\lambda) = [(1-e^{-\lambda})/\lambda]\sum_{n=0}^\infty b_n e^{-\lambda n}$ has a continuous extension to $\mathbb{C}_+\backslash iE$ where $E = \{\eta \in \mathbb{R} : e^{-i\eta} \in F\}$. Moreover, for $t \in [n, n+1)$ we have $\int_0^t \exp(-i\eta s)f(s)ds = \sum_{m=0}^n b_m \exp(-i\eta m)(1-\exp(-i\eta))/i\eta + b_n\exp(-i\eta n)(1-\exp(-i\eta(t-n)))/i\eta$, so that (3.5) is satisfied (since $0 \notin E$). It follows from Theorem 3.5 and Remark 3.6 that $\lim_{n\to\infty} b_n = \lim_{n\to\infty}\int_n^{n+1} f(s)ds = B - \lim_{t\to\infty} f(t) = 0$. □

It is implied by Riesz's theorem (Remark 3.4) that in the situation of Theorem 3.8 we have $p(z) = \sum_{n=0}^\infty b_n z^n$ for all regular $z \in \Gamma$ (and this is precisely what is shown in [1], assuming that p has a holomorphic extension to $\bar{D}\backslash F$).

An immediate consequence of Theorem 3.8 is the Katznelson–Tzafriri theorem (which actually was the motivation of the work by Allan, O'Farrell, and Ransford [1]).

THEOREM 3.9. (*Katznelson–Tzafrifi* [22].) *Let* $T \in \mathcal{L}(X)$ *such that* $\sup_{n\geq 0} |T^n| < \infty$ *and* $\sigma(T) \cap \Gamma \subset \{1\}$. *Then* $\lim_{n\to\infty} |(T-I)T^n| = 0$.

Proof. Let $p(z) = \sum_{n=0}^{\infty}(T-I)T^n z^n = (T-I)(I-zT)^{-1}, |z| < 1$. Since $\sup_{n\geq 0} |\sum_{n=0}^{N}(I-T)T^n| = \sup_{N\geq 0}|I - T^{N+1}| < \infty$, the hypotheses of Theorem 3.8 are satisfied for $b_n = (I-T)T^n$ and $F = \{1\}$. □

We are going to prove a continuous version of the Katznelson–Tzafriri theorem. Formally, it is expected that $(T^n)_{n\geq 0}$ has to be replaced by $(T(t))_{t\geq 0}$ and $T - I = (T(1) - I)/1$ by A, the generator of $(T(t))_{t\geq 0}$. We make this more precise. A C_0-semigroup $(T(t))_{t\geq 0}$ on X is called *eventually differentiable* if there exists $\tau > 0$ such that $T(\tau)X \subset D(A)$. Note that then $T(t)X \subset D(A)$ and $AT(t) \in \mathcal{L}(X)$ for all $t \geq \tau$.

THEOREM 3.10. *Let* $(T(t))_{t\geq 0}$ *be a bounded, eventually differentiable semigroup with generator* A. *The following are equivalent.*

(i) $\lim_{t\to\infty} |AT(t)| = 0$;

(ii) $\sigma(A) \cap i\mathbb{R} \subset \{0\}$.

Proof. Let $M = \sup_{t\geq 0} |T(t)|$. Assume that (ii) holds and that $\tau > 0$ such that $T(\tau)X \subset D(A)$. Then $T(t)X \subset D(A^2)$ for all $t \geq 2\tau$. Let $f : [0,\infty) \to \mathcal{L}(X)$ be given by $F(t) = AT(t + 2\tau)$. Then

$$\begin{aligned} |f(t) - f(s)| &= \left|\int_t^s \frac{d}{dr} f(r)dr\right| = \left|\int_t^s A^2 T(r + 2\tau)dr\right| \\ &= \left|\int_t^s T(r)A^2T(2\tau)dr\right| \leq M|A^2T(2\tau)||s-t|, \qquad s,t \geq 0, \end{aligned}$$

so that f is Lipschitz continuous. Moreover, $\hat{f}(\lambda) = R(\lambda, A)AT(2\tau)$ has a continuous extension to $\overline{\mathbb{C}}_+\backslash\{0\}$. Since $|\int_0^t f(s)ds| = |T(t+2\tau) - T(t)| \leq 2M \quad (t \geq 0)$, it follows from Theorem 3.7 that $\lim_{t\to\infty} |AT(t)| = \lim_{t\to\infty} |f(t)| = 0$.

Conversely, assume that (i) holds. (a) We show that $\lambda e^{t\lambda} \in \sigma(AT(t))$ for all $t \geq \tau$ whenever $\lambda \in \sigma(A) \cap i\mathbb{R}$. In fact, let $\lambda \in \sigma(A) \cap i\mathbb{R}$; then $\lambda \in \sigma_p(A) \cup \sigma_c(A)$ since λ is a boundary point of $\rho(A)$. Hence, there exist $x_n \in D(A)$, $|x_n| = 1$ such that $\lim_{t\to\infty} |(\lambda - A)x_n| = 0$. Consequently,

$$\begin{aligned} (\lambda e^{t\lambda} - AT(t))x_n &= \lambda(e^{\lambda t} - T(t))x_n + T(t)(\lambda - A)x_n \\ &= \lambda e^{\lambda t} \int_0^t e^{-\lambda s} T(s)(\lambda - A)x_n ds + T(t)(\lambda - A)x_n \to 0, \end{aligned}$$

as $n \to \infty$. Thus $\lambda e^{\lambda t} \in \sigma(AT(t))$ for $t \geq \tau$.

(b) Let $\eta \in \mathbb{R}$ be such that $i\eta \in \sigma(A)$. Then by (a), $i\eta e^{i\eta t} \in \sigma(AT(t))$ for $t \geq \tau$. Consequently, $|\eta| = |i\eta e^{i\eta t}| \leq |AT(t)| \to 0$ as $t \to \infty$, i.e., $\eta = 0$. □

As another application of Theorem 3.7 we obtain the following result which in some sense is complementary to Theorem 3.10.

THEOREM 3.11. *Let* $U(t)$ *be* C_0*-group with generator* A *and suppose that* $\sup_{t\geq 0} |U(t)x| < \infty$ *for all* $x \in D_\infty := \cap_{n\geq 0} D(A^n)$. *If* $\sigma(A) \cap i\mathbb{R} \subset \{0\}$, *then* $U(t) = I$ *for all* $t \in \mathbb{R}$.

Proof. Let $x \in D_\infty$ and $f(t) = AU(t)x = U(t)Ax$. Then f is Lipschitz continuous since $|f(t) - f(s)| = |\int_s^t (d/dr)U(r)Axdr| = |\int_s^t U(r)A^2xdr| \leq |t-s| \sup_{r\geq 0} |U(r)A^2x|$, and $|\int_0^t f(s)dr| = |U(t)x - x|$ is bounded for $t \geq 0$. For Re $\lambda > 0$ we have $\hat{f}(\lambda) \in D(A)$ and $(\lambda - A)\hat{f}(\lambda) = Ax$. Hence $\hat{f}(\lambda) = (\lambda - A)^{-1}Ax$ whenever $\lambda \in \varrho(A)$, Re $\lambda > 0$. This shows that $\hat{f}(\lambda)$ has a continuous extension to $\overline{\mathbb{C}}_+\backslash\{0\}$. It follows from Theorem 3.7 that $\lim_{t\to\infty} U(t)Ax = \lim_{t\to\infty} f(t) = 0$.

So far we have shown that $\lim_{t\to\infty} U(t)Ax = 0$ for all $x \in D_\infty$. We will deduce from this that $Ax = 0$ for all $x \in D_\infty$ and hence $A = 0$ since D_∞ is a core. In fact, D_∞ is a Fréchet space for the topology defined by the norms $p_n(x) = |x|+|Ax|+\cdots+|A^n x|$, $n \in \mathbb{N} \cup \{0\}$. We show that there exists $k \in \mathbb{N}$ such that

$$|U(t)x| \leq kp_k(x) \tag{3.7}$$

for all $x \in D_\infty$, $t \in \mathbb{R}$. If this is false, there exist $x_m \in D_\infty$, $t_m \in \mathbb{R}$ such that $p_m(x_m) = 1$ and $|U(t_m)x_m| \geq m$, $m \in \mathbb{N}$. Let $Y_k = \{x \in D_\infty : |U(t)x| \leq kp_k(x)$ for all $t \in \mathbb{R}\}$. Then Y_k is closed in D_∞ and $\cup_{k\geq 0} Y_k = D_\infty$. So by Baire's theorem there exists $k \in \mathbb{N}$ such that Y_k has a nonempty interior; i.e., we find $a \in D_\infty$, $\epsilon > 0$, $\ell \geq k$ such that $p_\ell(a-x) \leq \epsilon$ implies $|U(t)x| \leq kp_k(x)$ for all $t \in \mathbb{R}$. Consequently,

$$\begin{aligned} m\cdot \epsilon/p_\ell(x_m) - |U(t_m)a| &\leq \epsilon/p_\ell(x_m)|U(t_m)x_m| - |U(t_m)a| \leq |U(t_m)(a-\epsilon/p_\ell(x_m)x_m| \\ &\leq kp_k(a-(\epsilon/p_\ell(x_m))x_m) \leq k(p_k(a)+\epsilon p_k(x_m)/p_\ell(x_m)) \\ &\leq k(p_k(a)+\epsilon) \quad \text{since } \ell \geq k, \end{aligned}$$

hence,

$$\begin{aligned} \epsilon m &\leq p_\ell(x_m)[k(p_k(a)+\epsilon)+|U(t_m)a|] \leq p_m(x_m)[k(p_k(a)+\epsilon)+|U(t_m)a|] \\ &= [k(p_k(a)+\epsilon)+|U(t_m)a|] \quad \text{for all } m \geq \ell. \end{aligned}$$

But $(U(t_m)a)_{m\geq 0}$ is bounded in X, a contradiction. So (3.7) is proved.

Let $x \in D_\infty$. Then by (3.7)

$$\begin{aligned} |Ax| &= |U(-t)U(t)Ax| \leq kp_k(U(t)Ax) \\ &= k\{|U(t)Ax| + |U(t)A^2x| + \cdots + |U(t)A^{k+1}x|\} \to 0 \quad \text{as } t \to \infty. \end{aligned}$$

Hence $Ax = 0$ for all $x \in D_\infty$. □

4. Real ergodic theorems for Volterra equations. Throughout the remainder of the paper, we make the assumptions of the Introduction. In particular, $(S(t))_{t\geq 0}$ denotes the resolvent governing (1.1). Recall that we assume

$$\sup_{t\geq 0} |e^{-\lambda t}S(t)| < \infty$$

for all $\lambda > 0$. By $\hat{S}(\lambda) = \int_0^\infty e^{-\lambda t}S(t)dt$, Re $\lambda > 0$, we denote the Laplace transform of $S(t)$. In addition, we assume that the (complex-valued) kernel $a \in L^1_{\text{loc}}(\mathbb{R}_+)$ is Laplace transformable, i.e., there exists $\alpha \geq 0$ such that $\int_0^\infty e^{-\alpha t}|a(t)|dt < \infty$. We let $\hat{a}(\lambda) = \int_0^\infty e^{-\lambda t}a(t)dt$ (Re $\lambda \geq \alpha$). If (1.3) holds, then the closedness of A implies

$$\int_0^t a(t-s)S(s)x\,ds \in D(A) \quad \text{and} \quad S(t)x = x + A\int_0^t a(t-s)S(s)x\,ds \tag{4.1}$$

for all $x \in X$. Moreover, due to the assumptions above we have the following proposition.

PROPOSITION 4.1. (a) *$\hat{a}(\lambda)$ has a meromorphic extension to $\mathbb{C}_+$.*

(b) *$\hat{a}(\lambda) \neq 0$ on $\mathbb{C}_+$ if A is unbounded.*

(c) *$\lambda\hat{S}(\lambda) = (I - \hat{a}(\lambda)A)^{-1}$ for all $\lambda \in \mathbb{C}_+$ such that λ is not a pole of $\hat{a}$.*

We refer to [33] for the proof of (4.1) and Proposition 4.1.

COROLLARY 4.2. *If $\hat{a}$ has a pole in $\mathbb{C}_+$, then $R(A)$ is closed and $X = N(A) \oplus R(A)$.*

Remark. Here $R(A) := \{Ax : x \in D(A)\}$ denotes the *range* and $N(A) := \{x \in D(A) : Ax = 0\}$ the *kernel* of A.

Proof. Assume that $\lambda_0 \in \mathbb{C}_+$ is a pole of $\hat{a}$ of order n; then $1/\hat{a}(\lambda)$ maps a neighborhood of λ_0 onto a neighborhood of zero. It follows from Proposition 4.1(c) that there exists $\epsilon > 0$ such that $V := \{z \in \mathbb{C} : 0 < |z| < \epsilon\} \subset \varrho(A)$. Moreover, $|((1/\hat{a}(\lambda)) - A)^{-1}| = |\hat{a}(\lambda)\lambda\hat{S}(\lambda)| \leq$ const $|\hat{a}(\lambda)|$ near λ_0. Hence $|(z - A)^{-1}| \leq$ const$/|z|$ $(z \in V)$. Thus zero is at most a pole of order 1 of $(z - A)^{-1}$. Now the claim follows from [41, Chap. VIII.8]. □

In order to study the asymptotic behavior of the resolvent, we use the following terminology.

DEFINITION 4.3. The resolvent S is called (a) *uniformly* (*strongly, weakly*) *Abel-ergodic* if $\lim_{\lambda \to 0+} \lambda\hat{S}(\lambda) = P$ exists in the uniform (respectively, strong, weak) operator topology;

(b) *uniformly* (*strongly, weakly*) *Cesaro-ergodic* if $\lim_{t \to \infty} 1/t \int_0^t S(s)ds = P$ exists uniformly (respectively, strongly, weakly);

(c) *uniformly* (*strongly, weakly*) *ergodic* if $\lim_{t \to \infty} S(t) = P$ exists uniformly (respectively, strongly, weakly).

Notation. We shall use the abbreviation (i,J)-ergodic where i runs through the symbols u, s, w with obvious meaning, and J runs through A, C, E. Then the following implication scheme holds.

$$\begin{tikzcd}
(u,A) \arrow[d, Rightarrow] & (u,C) \arrow[l, Rightarrow] \arrow[d, Rightarrow] & (u,E) \arrow[l, Rightarrow] \arrow[d, Rightarrow] \\
(s,A) \arrow[d, Rightarrow] & (s,C) \arrow[l, Rightarrow] \arrow[d, Rightarrow] & (s,E) \arrow[l, Rightarrow] \arrow[d, Rightarrow] \\
(w,A) & (w,C) \arrow[l, Rightarrow] & (w,E) \arrow[l, Rightarrow]
\end{tikzcd}$$

Our goal is to characterize (i, J) ergodicity of $S(t)$ in terms of the operator A and the kernel a; or, at least, to find sufficient conditions. We need the following.

PROPOSITION 4.4. *Let B be a densely defined linear operator on X, $\mu_n \in \mathbb{C}$ such that* $\lim_{n \to \infty} |\mu_n| = \infty$, $1/\mu_n \in \varrho(B)$ *and* $\sup_{n \geq 0} |(I - \mu_n B)^{-1}| < \infty$. *Then*

(a) $N(B) \cap \overline{R(B)} = \{0\}$.

(b) *The following are equivalent.*

(i) $\lim_{n \to \infty}(I - \mu_n B)^{-1} = P$ *exists strongly*;

(ii) $\lim_{n \to \infty}(I - \mu_n B)^{-1} = P$ *exists weakly*;

(iii) $N(B) \oplus \overline{R(B)} = X$;

(iv) $N(B)^\perp \cap N(B') = \{0\}$.

If this is the case, then P is the projection onto $N(B)$ along $\overline{R(B)}$.

(c) *If X is reflexive, the equivalent conditions of* (b) *are automatically satisfied.*

(d) *Assume that the equivalent conditions of* (b) *hold. Then the following are equivalent.*

(i) $R(B)$ *is closed*;

(ii) $\lim_{n \to \infty}(I - \mu_n B)^{-1} = P$ *in* $\mathcal{L}(X)$;

(iii) $\lim_{n \to \infty}(I - \mu_n B)^{-2} = P$ *in* $\mathcal{L}(X)$.

This result is well known; we refer to [41, Chap. VIII.4] and [19, Chap. XVIII]. We add the analogous properties of $(I - \mu_n B)^{-1}$ at zero.

PROPOSITION 4.5. *Let B be an operator on X, $0 \neq \mu_n \in \mathbb{C}$ such that $1/\mu_n \in \varrho(B)$, $\lim_{n\to\infty} \mu_n = 0$ and $\sup_{n\geq 0} |(I - \mu_n B)^{-1}| < \infty$.*

(a) *The following are equivalent.*

(i) *$D(B)$ is dense in X;*

(ii) *$\lim_{n\to\infty}(I - \mu_n B)^{-1} = I$ strongly;*

(iii) *$\lim_{n\to\infty}(I - \mu_n B)^{-1} = I$ weakly.*

(b) *The following are equivalent.*

(i) *$D(B) = X$;*

(ii) *$\lim_{n\to\infty}(I - \mu_n B)^{-1} = I$ in $\mathcal{L}(X)$;*

(iii) *$\lim_{n\to\infty}(I - \mu_n B)^{-2} = I$ in $\mathcal{L}(X)$.*

For the proof we refer to [19, Chap. XVIII].

Strong and weak Abel ergodicity of the resolvent $S(T)$ of (1.1) are characterized as follows.

THEOREM 4.6. *The following are equivalent.*

(i) *$S(t)$ is strongly Abel ergodic.*

(ii) *$S(t)$ is weakly Abel ergodic.*

(iii) (a) *$|\lambda\hat{S}(\lambda)|$ is bounded on $(0,1]$;*

(b) *$\lim_{\lambda\to 0+} \hat{a}(\lambda) =: \hat{a}(0)$ exists in $\mathbb{C} \cup \{\infty\}$;*

(c) *$N(A)^\perp \cap N(A') = \{0\}$ if $\hat{a}(0) = \infty$.*

Moreover, if these equivalent conditions are satisfied, then $\lim_{\lambda\to 0} \lambda\hat{S}(\lambda) = (I - \hat{a}(0)A)^{-1}$ in $\mathcal{L}(X)$ if $0 \neq \hat{a}(0) \in \mathbb{C}$, $\lim_{\lambda\to 0+} \lambda\hat{S}(\lambda) = I$ strongly if $\hat{a}(0) = 0$, and $\lim_{\lambda\to 0} \lambda\hat{S}(\lambda) = P$ strongly if $\hat{a}(0) = \infty$, where P denotes the projection onto $N(A)$ along $\overline{R(A)}$. If X is reflexive, then (c) in (iii) can be omitted.

Proof. (ii) $\Rightarrow$ (iii). Assume that $w - \lim_{\lambda\to 0+} \lambda\hat{S}(\lambda)x = w - \lim_{\lambda\to 0+}(I - \hat{a}(\lambda)A)^{-1}x = Px$ for all $x \in X$. Then

$$\sup_{\lambda\in(0,1]} |(I - \hat{a}(\lambda)A)^{-1}| < \infty. \tag{4.2}$$

Choose a sequence $\lambda_n \to 0$ such that $\mu_n = \hat{a}(\lambda_n) \to \mu_\infty \in \mathbb{C} \cup \{\infty\}$. We distinguish three cases.

Case 1. $0 < |\mu_\infty| < \infty$.

Then, by (4.2), $\mu_\infty^{-1} \in \varrho(A)$ and $P = (I - \mu_\infty A)^{-1} = \lim_{n\to\infty}(I - \mu_n A)^{-1}$ in $\mathcal{L}(X)$.

Case 2. $\mu_\infty = 0$.

Then $\lim_{n\to\infty}(I - \mu_n A)^{-1} = I$ strongly by Proposition 4.5.

Case 3. $\mu_\infty = \infty$.

It follows from Proposition 4.4 and 4.5, that $(I - \mu_n A)^{-1} \to P$ strongly, where P is the projection onto $N(A)$ along $\overline{R(A)}$.

Now suppose that there exists another sequence $\lambda_n' \to 0$ such that $\hat{a}(\lambda_n') \to \mu_\infty' \neq \mu_\infty$, $\mu_\infty' \in \mathbb{C} \cup \{\infty\}$. Since $A \neq 0$, the limit operators P and P' are different. But this is impossible since $P = \lim_{\lambda\to 0+} \lambda\hat{S}(\lambda) = P'$. This shows that $\hat{a}(0) := \lim_{\lambda\to 0+} \hat{a}(\lambda)$ exists in $\mathbb{C} \cup \{\infty\}$. We have proved (iii). It follows from Propositions 4.4 and 4.5 that (iii) implies (i). □

From the preceding proof, we also obtain the following characterization of uniform Abel ergodicity.

THEOREM 4.7. *$S(t)$ is uniformly Abel ergodic if and only if the following four conditions hold.*

(a) *$|\lambda\hat{S}(\lambda)|$ is bounded on $(0,1]$;*

(b) *$\lim_{\lambda\to 0+} \hat{a}(\lambda) =: \hat{a}(0)$ exists in $\mathbb{C} \cup \{\infty\}$;*

(c) *if $\hat{a}(0) = \infty$ then $R(A)$ is closed and $X = N(A) \oplus R(A)$;*

(d) $\hat{a}(0) \neq 0$ *if* A *is unbounded.*

COROLLARY 4.8. *Suppose that* $(\lambda_0 - A)^{-1}$ *is compact for some* $\lambda_0 \in \varrho(A)$. *We assume that* $\hat{a}(0) \neq 0$ *if* A *is unbounded. If* $S(t)$ *is* (w, A)*-ergodic, then* $S(t)$ *is* (u, A)*-ergodic.*

Proof. This follows from Theorem 4.7 and Theorem 4.6 since $R(A)$ is closed because of the compactness of $(\lambda_0 - A)^{-1}$. □

It is instructive to classify Abel ergodicity by the limits of $\hat{a}(\lambda)$ as $\lambda \to 0+$. Assume that $\hat{a}(0) = \lim_{\lambda \to 0+} \hat{a}(\lambda) \in \mathbb{C} \cup \{\infty\}$ exists.

Case 1. $\hat{a}(0) = 0$. Then

(a) $S(t)$ is (u, A)-ergodic iff A is bounded; and

(b) $S(t)$ is (s, A)-ergodic iff $(I - \hat{a}(\lambda)A)^{-1}$ is bounded for $\lambda \to 0+$.

The ergodic limit then is $P = I$.

Case 2. $\hat{a}(0) \neq 0, \infty$. Then $S(t)$ is (u, A)-ergodic iff it is (s, A)-ergodic iff $(I - \hat{a}(\lambda)A)^{-1}$ is bounded for $\lambda \to 0+$ iff $\hat{a}(0)^{-1} \in \rho(A)$.

The ergodic limit then is $P = (I - \hat{a}(0)A)^{-1}$.

Case 3. $\hat{a}(0) = \infty$. Then

(a) $S(t)$ is (u, A)-ergodic iff $\overline{\lim}_{\lambda \to 0+} |(I - \hat{a}(\lambda)A)^{-1}| < \infty$, $N(A)^{\perp} \cap N(A') = \{0\}$ and $R(A)$ is closed;

(b) $S(t)$ is (s, A)-ergodic iff $\overline{\lim}_{\lambda \to 0+} |(I - \hat{a}(\lambda)A)^{-1}| < \infty$, and $N(A)^{\perp} \cap N(A') = \{0\}$.

The ergodic limit P is then the projection onto $N(A)$ along $\overline{R(A)}$.

In particular, we obtain the following necessary conditions.

COROLLARY 4.9. *If* $A - \lim_{t \to \infty} S(t) = 0$ *strongly, then* $\lim_{\lambda \to 0+} \hat{a}(\lambda) = \infty$ *and* $0 \notin \sigma_p(A) \cup \sigma_p(A')$.

Proof. For the second assertion observe that $Ax = 0$ implies $S(t)x = x$ $(t \geq 0)$ and so $x = 0$. This shows $N(A) = 0$. Hence $N(A') = N(A)^{\perp} \cap N(A') = \{0\}$. Thus $0 \notin \sigma_p(A) \cup \sigma_p(A')$. □

Next, we consider Cesaro ergodicity.

THEOREM 4.10. (a) *If* $S(t)$ *is bounded and* (w, A)*-ergodic, then* $S(t)$ *is* (s, C)*-ergodic.*

(b) *Suppose that* X *is an ordered Banach space with normal and generating cone. If* $S(t) \geq 0$ $(t \geq 0)$ *and* $S(t)$ *is* (w, A)*-ergodic, then* $S(t)$ *is* (s, C)*-ergodic.*

Proof. This follows from Theorem 2.5 and 2.6. □

Finally, we consider ergodicity of $S(t)$. We say that $S(t)$ is a *bounded analytic resolvent* if there exists a bounded, analytic extension of S to a sector $\Sigma(\theta) = \{z : |\arg z| < \theta\}$ for some $\theta \in (0, \pi/2)$.

Remark 4.11. Equation (1.1) is governed by a bounded analytic resolvent if and only if the following conditions are satisfied for some $\theta \in (0, \pi/2)$.

(a) $\hat{a}$ admits a meromorphic extension to $\Sigma(\theta + \pi/2)$.

(b) $\hat{a}(\lambda) \neq 0$ if A is unbounded and $1/\hat{a}(\lambda) \in \varrho(A)$ for all $\lambda \in \Sigma(\theta + \pi/2)$ with $\hat{a}(\lambda) \neq 0$.

(c) $|(I - \hat{a}(\lambda)A)^{-1}|$ is bounded on $\Sigma(\theta + \pi/2)$.

We refer to [33] for a proof.

In the semigroup case $(a(t) \equiv 1)$ the notion of bounded analytic resolvent coincides with that of a bounded analytic semigroup.

PROPOSITION 4.12. *Assume that* S *is a bounded analytic resolvent. Then there exists* $M \geq 0$ *such that*

$$t|S'(t)| \leq M \quad \textit{for all } t > 0$$

(see [33, Cor. 2.1] for a proof).

THEOREM 4.13. *Assume that $S(t)$ is a bounded analytic resolvent. If $S(t)$ is weakly Abel ergodic, then $S(t)$ is strongly ergodic. Moreover, $S(t)$ is even uniformly ergodic, if in addition $(\lambda_0 - A)^{-1}$ is compact for some $\lambda_0 \in \varrho(A)$.*

Proof. It follows from Theorem 4.6 that $S(t)$ is (s, A)-ergodic, and by Corollary 4.8 that S is (u, A)-ergodic if $(\lambda_0 - A)^{-1}$ is compact for some $\lambda_0 \in \varrho(A)$. Let $f(t) = S(t)$ $(t \geq 0)$. Then $f : (0, \infty) \to \mathcal{L}(X)$ is analytic and bounded, hence $f \in L^\infty([0, \infty); \mathcal{L}(X))$. Moreover, $\overline{\lim}_{t\to\infty} t|f'(t)| < \infty$ (by Proposition 4.12). So the claim follows from Theorem 2.10. □

Example 4.14. Consider the kernel $a(t) = t^{\alpha-1}/\Gamma(\alpha)$ where $\alpha \in (0, 2]$ and assume that (1.1) is well posed. For $\alpha = 1$ this means that A generates a C_0-semigroup, for $\alpha = 2$, that A generates a cosine function. We assume again that $\sup_{t\geq 0} |e^{-\lambda t} S(t)| < \infty$ for all $\lambda > 0$. Since $\hat{a}(\lambda) = \lambda^{-\alpha}$, it follows that $\Sigma(\alpha\frac{\pi}{2}) \subset \varrho(A)$. Moreover, $\lim_{\lambda\to 0+} \hat{a}(\lambda) = \infty$ and $\lambda\hat{S}(\lambda) = (I - \lambda^{-\alpha} A)^{-1} = \lambda^\alpha(\lambda^\alpha - A)^{-1}$. Thus Abel ergodicity is the same for all $\alpha \in (0, 2]$:

(a) $S(t)$ is (s, A)-ergodic iff $\sup_{\mu\in(0,1]} |\mu(\mu - A)^{-1}| < \infty$ and $N(A') \cap N(A)^\perp = \{0\}$.

(b) $S(t)$ is (u, A)-ergodic iff (a) holds and $R(A)$ is closed.

In order to characterize strong ergodicity we assume $\alpha < 2$ and $\Sigma(\theta) \subset \varrho(A)$, $|\mu(\mu - A)^{-1}| \leq M$ on $\Sigma(\theta)$ for some $\theta \in (\alpha, \pi/2, \pi)$. Then (1.1) is governed by a bounded analytic resolvent (Remark 4.11). If $N(A') \cap N(A)^\perp = \{0\}$, it follows from Theorem 4.13 that $\lim_{t\to\infty} S(t) = P$ strongly, where P is the projection onto $N(A)$ along $\overline{R(A)}$.

Finally, we consider Volterra equations on $L^\infty = L^\infty(\Omega, \Sigma, \mu)$, where (Ω, Σ, μ) denotes a positive measure space; this Banach space plays an exceptional role.

THEOREM 4.15. *If $X = L^\infty$, then the well-posedness of* (1.1) *implies that A is bounded.*

Remark. Conversely, if A is bounded, then (1.1) is well posed for every kernel.

Theorem 4.15 is due to Lotz [26] in the case $a(t) = 1$, where A is the generator of a C_0-semigroup (see also [29, A-II.3]); for the special case of contraction semigroups it was obtained independently by Coulhon [11]; and for positive semigroups it is due to Kishimoto and Robinson [23].

The reasons for the phenomenon expressed in Theorem 4.15 are two properties of $X = L^\infty$, namely,

$$\text{(DP)} \qquad x_n \to 0 \quad \text{in } (X, \sigma(X, X')) \quad \text{and} \quad x_n' \to 0 \quad \text{in } (X', \sigma(X', X'')) \\ \text{imply } \langle x_n, x_n' \rangle \to 0$$

and

$$\text{(G)} \qquad x_n' \to 0 \quad \text{in } (X', \sigma(X', X)) \quad \text{implies } x_n' \to 0 \quad \text{in } (X', \sigma(X', X''))$$

(see [36, Chaps. II.9.7 and II.10.4]). The first property is called the *Dunford–Pettis property*; a space satisfying the second is called a *Grothendieck space*. For further details on the background in geometry of Banach spaces, we refer to [26] (see also [27], [12]).

The key of the proof of Theorem 4.5 is the following result due to Lotz [26, Thm. 2].

LEMMA 4.16. *Let X satisfy* (G) *and* (DP). *Suppose $T_n \in \mathcal{L}(X)$ is such that $\lim_{n\to\infty} T_n = 0$ strongly and $\lim_{n\to\infty} T_n' = 0$ strongly. Then $\lim_{n\to\infty} |T_n^2| = 0$.*

Using this lemma we obtain the following general result which contains Theorem 4.15 as a special case.

THEOREM 4.17. *Assume that X satisfies* (G) *and* (DP). *Let B be an operator on X and (μ_n) be a sequence in $\mathbb{C}\backslash\{0\}$ such that $1/\mu_n \in \varrho(B)$, $\sup_{n\geq 0} |(I-\mu_n B)^{-1}| < \infty$ and $\lim_{n\to\infty} |\mu_n| = 0$. If $\overline{D(B)} = X$, then B is bounded.*

Proof. Let $J_n = (1-\mu_n B)^{-1}$. Then $\lim_{n\to\infty} J_n = I$ strongly by Proposition 4.5. Hence, $\sigma(X', X) - \lim_{n\to\infty} J_n' x' = x'$ and so by (G), $\sigma(X', X'') - \lim_{n\to\infty} J_n' x' = x'$ for all $x' \in X'$. It follows from Proposition 4.5 that $\lim_{n\to\infty} J_n' = I$ strongly. Now we deduce from Proposition 4.16 that $\lim_{n\to\infty} |(J_n - I)^2| = 0$ which implies $D(B) = X$ by Proposition 4.5. □

Next we consider ergodicity of (1.1) in L^∞.

THEOREM 4.18. *If $X = L^\infty$ and $S(t)$ is weakly Abel ergodic, then $S(t)$ is uniformly Abel ergodic.*

Remark. Since by our general assumption (1.1) is well posed, A is bounded in the situation of Theorem 4.18 (by Theorem 4.15).

We first show the following.

THEOREM 4.19. *Assume that X satisfies* (G) *and* (DP). *Let B be an operator on X such that $1/\mu_n \in \varrho(B)$ for a sequence $(\mu_n) \subset \mathbb{C}$ such that $\lim_{n\to\infty} |\mu_n| = \infty$. If $\lim_{n\to\infty}(I - \mu_n B)^{-1} = P$ weakly, then $\lim_{n\to\infty}(I - \mu_n B)^{-1} = P$ in $\mathcal{L}(X)$.*

Proof. By Proposition 4.4 we have $X = N(B) \oplus \overline{R(B)}$. We can assume $N(B) = 0$ and $P = 0$. Moreover, since $J_n := (I-\mu_n B)^{-1} \to 0$ strongly, it follows that $J_n' x' \to 0$ for $\sigma(X', X)$ and so by (G) for $\sigma(X', X'')$ for all $x' \in X'$. It follows from Proposition 4.4 that $\lim_{n\to\infty} J_n' = I$ strongly. Thus $\lim_{n\to\infty} |J_n^2| = 0$ by Lemma 4.16. This implies $R(B) = X$ by Proposition 4.4(d). □

Proof of Theorem 4.18. Assume that $S(t)$ is (w, A)-ergodic on L^∞. If $\hat{a}(0) \in \mathbb{C}$, then $S(t)$ is (u, A)-ergodic by Theorem 4.7 (note that A is bounded). If $\hat{a}(0) = \infty$, then S is (u, A)-ergodic by Theorem 4.19. □

Remark. Lotz [26] investigates ergodic properties of discrete semigroups $(T^n)_{n\geq 0}$ where T is a bounded linear operator on L^∞.

5. A general convergence theorem for Volterra equations.

This section contains the main theorem which is based on the complex methods introduced in §3.

We assume throughout that a is a kernel as described in §4, A is a linear closed densely defined operator and that the Volterra equation (1.1) is well posed and governed by the resolvent $S(t)$, which is bounded.

Then we know in particular that $\hat{a}$ has a meromorphic extension to $\mathbb{C}_+$. For later purposes (§§6 and 7) we set

$$\varrho(a) := \{i\mu : \mu \in \mathbb{R}, \hat{a} \text{ has a continuous extension to } \mathbb{C}_+ \cup i[\mu-\epsilon, \mu+\epsilon] \text{ with values in } \mathbb{C} \cup \{\infty\} \text{ for some } \epsilon > 0\} \tag{5.1}$$

and still denote by $\hat{a}$ the continuous extension of $\hat{a}$ to $\mathbb{C}_+ \cup \varrho(a)$.

In this section, though, we assume throughout that

$$\varrho(a) = i\mathbb{R}. \tag{5.2}$$

Moreover, we assume that $S(t)$ is strongly Abel ergodic, and set

$$\lim_{\lambda\to 0+} \lambda \hat{S}(\lambda) = Q \tag{5.3}$$

Remark. Since by assumption $S(t)$ is bounded, this is automatically satisfied if X is reflexive (see Thm. 4.4).

From Theorem 4.6, we know the following. If $\hat{a}(0) \in \mathbb{C}$, then $Q = (I - \hat{a}(0)A)^{-1}$; if $\hat{a}(0) = \infty$, then $X = N(A) \oplus \overline{R(A)}$ and $Q = P$, the projection onto $N(A)$ along $\overline{R(A)}$. The following "resolvent set $\varrho(a, A)$ of (a, A)" plays an important role.

$$\varrho(a, A) := \Big\{ i\eta \in i\mathbb{R} : \text{ there exists } \epsilon > 0 \text{ such that } \tfrac{1}{\lambda}[(1 - \hat{a}(\lambda)A)^{-1} - Q] \quad \text{has a strongly continuous extension to } \mathbb{C}_+ \cup i[\eta - \epsilon, \eta + \epsilon] \Big\}. \tag{5.4}$$

Now we are able to formulate the General Convergence Theorem. It is valid for arbitrary kernels (satisfying (5.2)). In the forthcoming sections it will be shown that, for many interesting classes of kernels, hypotheses (H2) and (H3) are automatically satisfied so that (H1) remains to be verified in order to conclude that $S(t)$ is strongly ergodic. Note that in the reflexive case (H1) reduces to a condition on the spectral behavior of (a, A) on $i\mathbb{R}$: the singular set iE has to be countable and $1/\hat{a}(i\eta) \notin \sigma_p(A')$ whenever $\eta \in E$ such that $\hat{a}(i\eta) \neq 0, \infty$ (by $\sigma_p(A')$ we denote the point spectrum of the adjoint A' of A).

THEOREM 5.1. *Assume* (5.2), (5.3), *and suppose the following three hypotheses are satisfied.*

(H1) *The singular set* $iE := i\mathbb{R} \backslash \varrho(a, A)$ *is countable and* $\mu \in E \backslash \{0\}$, $\hat{a}(i\mu) \neq 0, \infty$ *implies* $R(I - \hat{a}(i\mu)A) = X$; $\mu \in E \backslash \{0\}$, $\hat{a}(i\mu) = \infty$ *implies* $X = N(A) \oplus \overline{R(A)}$.

(H2) *For all* $\mu \in E$ *there exists* $C(\mu) \geq 1$ *such that* $|\int_0^t e^{-i\mu s}(a * S(s) - \hat{a}(i\mu)S(s))Ax\,ds| \leq C(\mu)|x|_A$ *for all* $x \in D(A)$ *if* $\hat{a}(i\mu) \in \mathbb{C}$, *and* $|\int_0^t e^{-i\mu s} S(s)Ax\,ds| \leq C(\mu)|x|_A$ *for all* $x \in D(A)$ *if* $\hat{a}(i\mu) = \infty$.

(H3) *There exist* $\tau \geq 0$, $M \geq 0$ *such that* $|S'(t)x| \leq M|x|_A$ $(x \in D(A),\ t \geq \tau)$, *and* $|S(t)| \leq M$ $(t \geq 0)$.

Then $\lim_{t\to\infty} S(t)x = Qx$ *for all* $x \in X$, *where* $Q = (I - \hat{a}(0)A)^{-1}$ *if* $\hat{a}(0) \in \mathbb{C}$, *and* Q *is the projection onto* $N(A)$ *along* $\overline{R(A)}$ *if* $\hat{a}(0) = \infty$.

We start with the following estimate which is a variant of [2, Lemma 3.1].

LEMMA 5.2. *Let* $f : [0, \infty) \to X$ *be measurable,* $|f(t)| \leq M_0$ $(t \geq 0)$. *Let* $R > 0$. *Assume that* $\hat{f}(\lambda)/\lambda$ (*which is defined for* Re $\lambda > 0$) *has a continuous extension to* $\mathbb{C}_+ \cup i([-R, R] \backslash \bigcup_{j=1}^n (\xi_j - \epsilon_j, \xi_j + \epsilon_j))$ *where* $\xi_j \in \mathbb{R}$, $\epsilon_j > 0$ *such that the intervals* $(\xi_j - \epsilon_j, \xi_j + \epsilon_j)$ $(j = 1 \cdots n)$ *are pairwise disjoint and* $0 \notin \bigcup_{j=1}^n [\xi_j - \epsilon_j, \xi_j + \epsilon_j] \subset (-R, R)$. *Furthermore, suppose that for* $j = 1, \cdots, n$ *there exist* $\eta_j \in (\xi_j - \epsilon_j, \xi_j + \epsilon_j)$ *such that*

$$M_j = \sup_{t \geq 0} \Big| \int_0^t \exp(-i\eta_j s) f(s) ds \Big| < \infty \qquad (j = 1 \cdots n).$$

Then,

$$\overline{\lim_{t\to\infty}} \Big| \int_0^t f(s) ds \Big| \leq \frac{2M_0}{R} \prod_{j=1}^n a_j + 12 \sum_{j=1}^n M_j \delta_j \prod_{\substack{k=1 \\ k \neq j}}^n b_{jk}, \tag{5.5}$$

where

$$
\begin{aligned}
&a_j = (1+\epsilon_j^2(R-|\xi_j|)^{-2})\xi_j^2(\xi_j^2-\epsilon_j^2)^{-1}; \\
(5.6) \qquad &b_{jk} = (1+\epsilon_k^2(|\xi_j-\xi_k|-\epsilon_j)^{-2})\xi_k^2(\xi_k^2-\epsilon_k^2)^{-1} \qquad (k \neq j); \\
&\delta_j = \epsilon_j\xi_j^2(|\xi_j|-\epsilon_j)^{-1}(\xi_j^2-\epsilon_j^2)^{-1}.
\end{aligned}
$$

Proof. We modify the proof of [2, Lemma 3.1] in the following way, keeping the notation used there (cf. also [25, 2.2]). The paths γ_j are replaced by straight lines on the imaginary axis ($j = 0, \cdots, n$). Applying (a slight extension of) Cauchy's theorem to $g(\lambda) = \hat{f}(\lambda)$, we have $0 = -(1/2\pi i)\int_\gamma h(z)(g(z)/z)e^{tz}dz$. Moreover, g_t being entire implies

$$\int_0^t f(s)ds = g_t(0) = \frac{1}{2\pi i}\int_{|z|=R} h(z)g_t(z)e^{tz}\frac{dz}{z}$$

and

$$0 = \sum_{j=1}^n \frac{1}{2\pi i}\int_{|z-i\eta_j|=\epsilon_j} h(z)g_t(z)e^{tz}\frac{dz}{z}.$$

Summing up, we obtain

$$
\begin{aligned}
\int_0^t f(s)ds = \frac{1}{2\pi i} &\int_{\substack{|z|=R \\ \mathrm{Re}z>0}} h(z)(g_t(z)-g(z))e^{tz}\frac{dz}{z} \\
&+\sum_{j=1}^n \frac{1}{2\pi i}\int_{\substack{|z-i\eta_j|=\epsilon_j \\ \mathrm{Re}z>0}} h(z)(g_t(z)-g(z))e^{tz}\frac{dz}{z} \\
&-\sum_{j=1}^n \frac{1}{2\pi i}\int_{\gamma_j} h(z)g(z)e^{tz}\frac{dz}{z} + \frac{1}{2\pi i}\int_{\substack{|z|=R \\ \mathrm{Re}z<0}} h(z)g_t(z)e^{tz}\frac{dz}{z} \\
&+\sum_{j=1}^n \frac{1}{2\pi i}\int_{\substack{\mathrm{Re}z<0 \\ |z-i\eta_j|=\epsilon_j}} h(z)g_t(z)e^{tz}\frac{dz}{z}
\end{aligned}
$$

Now the third term converges to zero ($t \to \infty$) by the Riemann–Lebesgue lemma; the other estimates are given in [2, Lemma 3.1]. □

We put Lemma 5.2 in a different form (corresponding to Tauberian theorems of type D) keeping the definition (5.6) throughout this section.

LEMMA 5.3. *Let $\varphi \in L^1_{\mathrm{loc}}([0,\infty), X) \cap C^1([\tau,\infty), X)$ where $\tau \geq 0$. Assume that $\hat{\varphi}(\lambda)$ has a continuous extension to $K := \mathbb{C}_+ \cup i([-R,R]\setminus\bigcup_{j=1}^n(\eta_j-\epsilon_j,\eta_j+\epsilon_j))$ where $\eta_j \in \mathbb{R}$, $\epsilon_j > 0$ such that the intervals $(\eta_j-\epsilon_j,\eta_j+\epsilon_j)$ are pairwise disjoint ($j = 1\cdots n$) and $0 \notin \bigcup_{j=1}^n[\eta_j-\epsilon_j,\eta_j+\epsilon_j] \subset (-R,R)$. Suppose that*

$$N_0 := \sup_{t\geq\tau}|\varphi'(t)| + |\varphi(\tau)| < \infty$$

and

$$N_j := \sup_{t\geq\tau}\left|\int_\tau^t e^{-i\eta_j s}\varphi'(s)ds\right| + |\varphi(\tau)| < \infty, \qquad \textit{for } j = 1,\cdots,n.$$

Then,

$$\overline{\lim_{t\to\infty}}|\varphi(t)| \le \frac{2N_0}{R}\prod_{j=1}^{n} a_j + 12\sum_{j=1}^{n} N_j\delta_j \prod_{\substack{k=1\\k\ne j}}^{n} b_{jk}.$$

Proof. (a) We assume that $\tau = 0$. Let $f(t) = \varphi'(t) + \varphi(0)\exp(-t)$. Then $\hat{f}(\lambda)/\lambda = \hat{\varphi}(\lambda) - \varphi(0)/(1+\lambda)$ has a continuous extension to K. Moreover, $|f(t)| \le |\varphi'(t)| + |\varphi(0)| \le N_0$ $(t \ge 0)$ and $|\int_0^t \exp(-i\eta_j s)f(s)ds| = |\int_0^t \exp(-i\eta_j s)\varphi'(s)ds + \varphi(0)\int_0^t \exp(-i\eta_j s)\exp(-s)ds| \le N_j$ $(t \ge 0)$, $j = 1\cdots n$. Since $\int_0^t f(s)ds = \varphi(t) - \varphi(0)\exp(-t)$ one has $\overline{\lim}_{t\to\infty}|\varphi(t)| = \overline{\lim}_{t\to\infty}|\int_0^t f(s)ds|$. So the claim follows from Lemma 5.2.

(b) If $\tau \ge 0$ is arbitrary we apply (a) to $\psi(t) = \varphi(t+\tau)$. □

Proof of Theorem 5.1. Since $S(t)x = x$ on $N(A)$ we can assume that $P = Q = 0$ in the case when $\hat{a}(0) = \infty$. Choose $\nu_0 \in \varrho(A)$ and let $L = (\nu_0 - A)^{-1}$. Let $0 \le \mu_0 \in \mathbb{R}\backslash E$ be fixed. Let $R > \mu_0$ such that $\pm R \notin E$. We set $E_0 = E \cap [\mu_0 - R, \mu_0 + R]$. For every ordinal α, we define inductively subsets E_α of E in the following way. Suppose that E_β has been defined for all $\beta < \alpha$. We let E_α be the set of all cluster points of $E_{\alpha-1}$, if α has a predecessor $\alpha - 1$, and $E_\alpha = \bigcap_{\beta<\alpha} E_\beta$ if not.

For $\mu \in E$, $\mu \ne 0$ we define

$$B(\mu) = \begin{cases} \dfrac{1-\hat{a}(i\mu)A}{C(\mu)} i\mu & \text{if } |\hat{a}(i\mu)| \le 1 \\ \left(\dfrac{1}{\hat{a}(i\mu)} - A\right) i\mu/C(\mu) & \text{if } |\hat{a}(i\mu)| > 1, \end{cases}$$

where $C(\mu)$ is the constant from hypothesis (H2), and

$$B(0) = \begin{cases} A & \text{if } \hat{a}(0) = \infty \\ 1 - \hat{a}(0)A & \text{if } \hat{a}(0) \in \mathbb{C}. \end{cases}$$

We shall prove the following.

Inductive statement. If $\mu_j \in E_\alpha$, $\epsilon_j > 0$ $(j = 1, \cdots, n)$ such that $(\mu_j - \epsilon_j, \mu_j + \epsilon_j)$ are pairwise disjoint,

$$E_\alpha \subset \bigcup_{j=1}^{n}(\mu_j - \epsilon_j, \mu_j + \epsilon_j) \quad \text{and } \mu_0 \notin \bigcup_{j=1}^{n}[\mu_j - \epsilon_j, \mu_j + \epsilon_j] \subset (\mu_0 - R, \mu_0 + R),$$

then

$$\overline{\lim_{t\to\infty}}|(S(t) - Q)LUx| \le \frac{2N_0|Ux|}{R}\prod_{j=1}^{n} a_j + 12\sum_{j=1}^{n} C_0|U_jx|\delta_j \prod_{\substack{k=1\\k\ne j}} b_{jk} \tag{5.7}$$

for all $x \in D(A^n)$, where

$$U = \prod_{j=1}^{n} B_j; \quad U_j = \prod_{\substack{k=1\\k\ne j}}^{n} B_k, \quad B_j = B(\mu_j);$$

the constants a_j, δ_j, b_{jk} are given by (5.6), and C_0, N_0 are constants which will be defined below and do not depend on μ_j, ϵ_j.

It is part of the inductive statement that

$$\overline{\lim_{t\to\infty}}|(S(t)-Q)Lx| \le \frac{2N_0}{R}|x| \tag{5.8}$$

for all $x \in X$ if $E_\alpha = \emptyset$ (which is (5.7) with the convention that the empty product is 1 and the empty sum zero).

Once the inductive statement has been established, the theorem is proved as follows. Since E_α is compact and countable, E_α is either empty or contains isolated points, so that $E_\alpha = \emptyset$ or $E_{\alpha+1} \neq E_\alpha$. Thus it follows that for some α (at most ω_1), $E_\alpha = \emptyset$. Hence, (5.8) holds. We can choose $0 < R \notin E \cup -E$ arbitrarily large. Thus $\lim_{t\to\infty}|(S(t)-Q)Lx| = 0$ for all $x \in X$. Since $R(L) = D(A)$ is dense in X and $S(t)$ is bounded the claim follows.

It remains to prove the inductive statement.

(1) $\alpha = 0$. Let $\mu_j \in E_0$, $\epsilon_j > 0$ such that

$$E_0 \subset \bigcup_{j=1}^{n}(\mu_j-\epsilon_j, \mu_j+\epsilon_j) \text{ and } \mu_0 \notin \bigcup_{j=1}^{n}[\mu_j-\epsilon_j, \mu_j+\epsilon_j] \subset (\mu_0-R, \mu_0+R),$$

according to the statement. Let $y \in X$ and set $\varphi(t) = e^{-i\mu_0 t}(S(t)-Q)Ly$ $(t \ge 0)$. We verify that φ satisfies the hypotheses of Lemma 5.3 (after specification of y).

For $\operatorname{Re}\lambda > 0$ we have

$$\hat{\varphi}(\lambda) = \hat{S}(\lambda+i\mu_0)Ly - \frac{1}{i\mu_0+\lambda}QLy = \frac{1}{\lambda+i\mu_0}((1-\hat{a}(\lambda+i\mu_0)A)^{-1}-Q)Ly.$$

Set $\eta_j = \mu_j - \mu_0$ $(j = 1, \cdots, n)$. Then $0 \notin \cup_{j=1}^{n}[\eta_j-\epsilon_j, \eta_j+\epsilon_j] \subset (-R, R)$ and $\hat{\varphi}(\lambda)$ has a continuous extension to $\mathbb{C}_+ \cup i([-R,R]\setminus\bigcup_{j=1}^{n}(\eta_j-\epsilon_j, \eta_j+\epsilon_j))$.

Setting $C_L = |L| + |AL|$ we have $|Ly|_A \le C_L|y|$. We have

$$\varphi'(t) = -i\mu_0\exp(-i\mu_0 t)(S(t)-Q)Ly + \exp(-i\mu_0 t)S'(t)Ly.$$

Using (H3), we obtain

$$|\varphi'(t)| + |\varphi(\tau)| \le N_0|y| \qquad (t \ge \tau) \tag{5.9}$$

with $N_0 = \mu_0(M+|Q|)|L| + MC_L + (M+|Q|)|L|$.

Now let $y = Ux = B_jU_jx$ where $x \in D(A^n)$, and observe that $|\eta_j| = |\mu_j-\mu_0| \le R$, hence $|\mu_j| \le R+\mu_0$. Moreover, since $C(\mu) \ge 1$, it follows from the definition of $B(\mu)$ that

$$|B(\mu)L| \le |\mu|C_L \qquad (0 \neq \mu \in E); \tag{5.10}$$

in particular,

$$|B_jL| \le (R+\mu_0)C_L \quad \text{if } \mu_j \neq 0. \tag{5.11}$$

Due to (1.1), hypothesis (H2) implies

$$\left|\int_0^t e^{-i\mu s}S(s)(1-\hat{a}(i\mu)A)x\,ds\right| \le C(\mu)|x|_A \qquad (x \in D(A))$$

if $\mu \in E\backslash\{0\}$ and $\hat{a}(i\mu) \in \mathbb{C}$. Consequently, it follows from (H2) that

$$\left|\int_0^t e^{-i\mu s} S(s)B(\mu)y\,ds\right| \leq |\mu||y|_A \quad (y \in D(A), \quad \mu \in E\backslash\{0\}). \tag{5.12}$$

We estimate $\int_\tau^t e^{-i\mu_j s}\varphi'(s)ds$.

Case 1. $\mu_j \neq 0$, i.e., $\eta_j = \mu_j - \mu_0 \neq -\mu_0$.

$$\begin{aligned}
&\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds \\
&\quad = -i\mu_0 \int_\tau^t \exp(-i\mu_j s)(S(s) - Q)Ly\,ds + \int_\tau^t \exp(-i\mu_j s)S'(s)Ly\,ds \\
&\quad = -i\mu_0 \int_\tau^t \exp(-i\mu_j s)(S(s) - Q)Ly\,ds + \exp(-i\mu_j t)S(t)Ly \\
&\qquad\qquad - \exp(-i\mu_j \tau)S(\tau)Ly + i\mu_j \int_\tau^t \exp(-i\mu_j s)S(s)Ly\,ds \\
&\quad = i(\mu_j - \mu_0) \int_0^t \exp(-i\mu_j s)S(s)Ly\,ds + \frac{\mu_0}{\mu_j}(\exp(-i\mu_j\tau) - \exp(-i\mu_j t))QLy \\
&\qquad\qquad + \exp(-i\mu_0 t)S(t)Ly - \exp(-i\mu_j\tau)S(\tau)Ly \\
&\qquad\qquad -i(\mu_j - \mu_0) \int_0^\tau \exp(-i\mu_j s)S(s)Ly\,ds.
\end{aligned}$$

Hence,

$$\begin{aligned}
&\left|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds\right| \\
&\quad \leq R\left|\int_0^t \exp(-i\mu_j s)S(s)B_j LU_j x\,ds\right| \\
&\qquad\qquad +2\frac{\mu_0}{|\mu_j|}|Q||B_j LU_j x| + 2M|B_j LU_j x| + R\tau M|B_j LU_j x| \\
&\quad \leq R|\mu_j|.|LU_j x|_A + 2\mu_0|Q|C_L|U_j x| + 2M(R + \mu_0)C_L|U_j x| \\
&\qquad\qquad +R\tau M(R + \mu_0)C_L|U_j x|,
\end{aligned}$$

by (5.12), (5.10), and (5.11). Setting

$$C_1 := R(R + \mu_0)C_L + 2\mu_0|Q|C_L + 2M(R + \mu_0)C_L + R\tau M(R + \mu_0)C_L,$$

we obtain

$$\left|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds\right| \leq C_1|U_j x|. \tag{5.13}$$

Case 2. $\mu_j = 0$; that is, $\eta_j = -\mu_0$. Then,

$$\begin{aligned}
\int_\tau^t e^{-i\eta_j s}\varphi'(s)ds &= -i\mu_0 \int_\tau^t (S(s) - Q)Ly\,ds + \int_\tau^t S'(s)Ly\,ds \\
&= -i\mu_0 \int_0^t (S(s) - Q)y\,ds + S(t)Ly - S(\tau)Ly + i\mu_0 \int_0^\tau (S(s) - Q)Ly\,ds.
\end{aligned}$$

We must distinguish two cases. (a) If $\hat{a}(0)=\infty$, then $Q=0$ and $B_j=A$, $y=AU_jx$. Then,

$$\begin{aligned}\left|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds\right| &\le \mu_0\left|\int_0^t S(s)ALU_jx\,ds\right| + 2M|ALU_jx| + \mu_0\tau M|ALU_jx| \\ &\le \mu_0 C(0)|LU_jx|_A + 2MC_L|U_jx| + \mu_0\tau MC_L|U_jx|\end{aligned}$$

by (H2). Hence, $|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds| \le C_2|U_jx|$ if we set $C_2 := (\mu_0 C(0)C_L + 2MC_L + \mu_0\tau MC_L)$ if $0\in E$ and $\hat{a}(0)=\infty$.

(b) If $\hat{a}(0)\in\mathbb{C}$, then $Q=(I-\hat{a}(0)A)^{-1}$, $B_j=Q^{-1}$, $y=Q^{-1}U_jx$ and so $(S(s)-Q)Ly=(S(s)Q^{-1}-I)LU_jx=(S(s)(I-\hat{a}(0)A)-I)LU_jx=S(s)LU_jx-LU_jx-\hat{a}(0)S(s)ALU_jx=A(a*S)(s)LU_jx-\hat{a}(0)S(s)ALU_jx$ by (4.1). Thus,

$$\begin{aligned}\left|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds\right| &\le \mu_0\left|\int_0^t ((a*S)(s)-\hat{a}(0)S(s))ALU_jx\,ds\right| + 2M|Q^{-1}LU_jx| \\ &\qquad + \mu_0\tau(M+|Q|)|Q^{-1}LU_jx|\end{aligned}$$

$$\le \mu_0 C(0)|LU_jx|_A + 2M|(I-\hat{a}(0)A)L||U_jx| + \mu_0\tau(M+|Q|)|(I-\hat{a}(0)A)L||U_jx|$$

by (H2). Hence, $|\int_\tau^t \exp(-i\eta_j s)\varphi'(s)ds| \le C_2|U_jx|$ $(t\ge\tau)$ if we set

$$C_2=\mu_0C(0)C_L+2M|(I-\hat{a}(0)A)L|+\mu_0\tau(M+|Q|)+\mu_0\tau(M+|Q|)|(I-\hat{a}(0)A)L|$$

in the case $0\in E$, $\hat{a}(0)\in\mathbb{C}$. So far, we have proved that

$$\left|\int_\tau^t \varphi'(s)\exp(-i\eta_j s)ds\right| \le C_3|U_jx|, \quad j=1,\cdots,n, \quad t\ge\tau$$

if we put $C_2:=0$ in the case where $0\notin E$ and $C_3=\max\{C_1,C_2\}$ (see (5.13)). Finally, we let

$$\begin{aligned} C_4 &= \begin{cases} MC_L & \text{if } 0\in E, \hat{a}(0)=\infty \\ (M+|Q|)(I-\hat{a}(0)A)L| & \text{if } 0\in E, \hat{a}(0)\in\mathbb{C} \\ 0 & \text{if } 0\notin E \end{cases} \\ C_5 &= (M+|Q|)(R+\mu_0)C_L \\ C_6 &= \max\{C_4,C_5\}. \end{aligned}$$

Then $|\varphi(\tau)|\le C_6|U_jx|$ $(j=1\cdots n)$. In fact, if $\mu_j\ne 0$, then

$$|\varphi(\tau)|\le(M+|Q|)|B_jLU_jx|\le C_5|U_jx|;$$

if $\mu_j=0$ and $\hat{a}(0)=\infty$, then $Q=0$, $B_j=A$, $y=AU_jx$, and so $|\varphi(\tau)|\le M|LAU_jx|\le MC_L|U_jx|=C_4|U_jx|$; if $\mu_j=0$ and $\hat{a}(0)\in\mathbb{C}$, then $Q=(I-\hat{a}(0)A)^{-1}$, $y=Q^{-1}U_jx$ and so

$$|\varphi(\tau)|\le(M+|Q|)|(I-\hat{a}(0)A)L||U_jx|=C_4|U_jx|.$$

Letting $C_0:=\max\{C_3,C_6\}$, we finally have

$$\left|\int_\tau^t \varphi'(s)\exp(-i\eta_j s)ds\right| + |\varphi(\tau)| \le C_0|U_jx|$$

$(j = 1, \cdots, n)$. In view of (5.9), now the claim (5.7) follows from Lemma 5.3. This proves the inductive statement for $\alpha = 0$.

(2) Let α be an ordinal greater than zero and assume that the inductive statement holds for all ordinals $\beta < \alpha$. We show the statement to hold for α. Let $(\mu_j - \epsilon_j, \mu_j + \epsilon_j)$ $(j = 1, \cdots, n)$ be disjoint intervals such that $\mu_0 \notin \cup_{j=1}^{n}[\mu_j - \epsilon_j, \mu_j + \epsilon_j] \subset (\mu_0 - R, \mu_0 + R)$ and $E_\alpha \subset \Omega := \cup_{j=1}^{n}(\mu_j - \epsilon_j, \mu_j + \epsilon_j)$.

Case 1. $\alpha - 1$ does not exist. Then $E_\alpha = \cap_{\beta<\alpha} E_\beta$. Since Ω is open and E_0 compact, it follows that $E_\beta \subset \Omega$ for some $\beta < \alpha$. So (5.7) follows trivially from the inductive hypothesis.

Case 2. $\alpha - 1$ exists. Since E_α is the set of all accumulation points of $E_{\alpha-1}$, $E_{\alpha-1} \backslash E_\alpha$ is finite, say $E_{\alpha-1} \backslash E_\alpha = \{\mu_{n+1}, \cdots, \mu_{n+p}\}$. Let $\epsilon_j > 0$, $j = n+1, \cdots, n+p$ be small enough so that $\mu_0 \notin \cup_{j=1}^{n+p}[\mu_j - \epsilon_j, \mu_j + \epsilon_j] \subset (\mu_0 - R, \mu_0 + R)$. Since $E_{\alpha-1} \subset \cup_{j=1}^{n+p}(\mu_j - \epsilon_j, \mu_j + \epsilon_j)$, we conclude from the inductive hypothesis for $\alpha - 1$ that

$$\overline{\lim_{t\to\infty}}|S(t) - Q)LVy| \le \frac{2N_0|Vy|}{R} \prod_{j=1}^{n+p} a_j + 12 \sum_{j=1}^{n+p} C_0 |V_j y| \delta_j \prod_{\substack{k=1 \\ k\neq j}}^{n+p} b_{jk}$$

for all $y \in D(A^{n+p})$, where

$$V = \prod_{j=1}^{n+p} B_j, \quad V_j = \prod_{\substack{k=1 \\ k\neq j}}^{n+p} B_k, \quad B_j = B(\mu_j) \quad (j = 1 \cdots n+p).$$

Letting $\epsilon_j \downarrow 0$ for $j = n+1, \cdots, n+p$, we obtain

$$\overline{\lim_{t\to\infty}}|(S(t) - Q)LVy| \le 2(N_0/R)|Vy| \prod_{j=1}^{n} a_j + 12 \sum_{j=1}^{n} C_0 |V_j y| \delta_j \prod_{\substack{k=1 \\ k\neq j}}^{n} b_{jk}. \tag{5.14}$$

Letting $W = \prod_{j=n+1}^{n+p} B_j$, $U = \prod_{j=1}^{n} B_j$, $U_j = \prod_{\substack{k=1 \\ k\neq j}}^{n} B_k$, we can rewrite (5.14) as

$$\begin{aligned} \overline{\lim_{t\to\infty}}|(S(t) - Q)LUWy| &\le 2(N_0/R)|UWy| \prod_{j=1}^{n} a_j \\ &\quad + 12 \sum_{j=1}^{n} C_0 |U_j W y| \delta_j \prod_{\substack{k=1 \\ k\neq j}}^{n} b_{jk} \qquad (y \in D(A^{n+p})). \end{aligned} \tag{5.15}$$

Now the operators $B_j (j = n+1, \cdots, n+p)$ commute and have dense range by (H1). This implies that $WD(A^{n+p})$ is dense in $(D(A^n); |\ |_{A^n})$, where $|x|_{A^n} := |x| + |Ax| + \cdots + |A^n x|$ for $x \in D(A^n)$. Thus, given $x \in D(A^n)$ we find $y_m \in D(A^{n+p})$ such that $\lim_{m\to\infty} |Wy_m - x|_{A^n} = 0$, hence $\lim_{m\to\infty} UWy_m = Ux$ in $(D(A), |\ |_A)$. Setting $y = y_m$ in (5.15), we obtain (5.7) by letting $m \to \infty$. This completes the proof of Theorem 5.1. □

6. Some examples and illustrations. In this section we want to discuss several examples of kernels $a(t)$ and operators A to which the General Convergence Theorem applies and also to present conditions on the kernel $a(t)$ such that assumptions (H2) and (H3) of Theorem 6.1 are satisfied.

We begin with the semigroup case $a(t) \equiv 1$, $t \geq 0$. Then the resolvent $S(t)$ satisfying

$$S(t) = I + A\int_0^t a(\tau)S(t-\tau)d\tau, \qquad t \geq 0, \tag{6.1}$$

is the semigroup generated by A, i.e., $S(t) = e^{At}$. Therefore the relation $S'(t)x = S(t)Ax$ shows that (H3) is trivially satisfied whenever the semigroup is bounded. To verify (H2), observe that $\hat{a}(\lambda) = 1/\lambda$; hence, $\hat{a}(0) = \infty$ and $\hat{a}(i\mu) \in \mathbb{C}$ otherwise. For $\mu = 0$ we obtain

$$\int_0^t S(\tau)Ax\,d\tau = \int_0^t S'(\tau)x\,d\tau = S(t)x - x, \qquad t > 0,$$

and so (H2) is valid for $\mu = 0$. If $\mu \neq 0$ we get, via an integration by parts,

$$\begin{aligned}\int_0^t e^{-i\mu\tau}((a*S)(\tau) - \hat{a}(i\mu)S(\tau))Ax\,d\tau &= \int_0^t e^{-i\mu\tau}\left(\int_0^\tau S(s)ds - \frac{1}{i\mu}S(\tau)\right)Ax\,d\tau \\ &= \frac{1}{i\mu}e^{-i\mu t}(x - S(t)x);\end{aligned}$$

hence, (H2) is valid for all $\mu \in \mathbb{R}$. Since $E = \sigma(A) \cap i\mathbb{R}$, (H1) becomes $(\sigma_p(A) \cup \sigma_p(A')) \cap i\mathbb{R} \subset \{0\}$ and $N(A)^\perp \cap N(A') = \{0\}$. Thus, the General Convergence Theorem reduces for the case $a(t) \equiv 1$ to the following version of the stability theorem of Arendt and Batty [2], and Lyubich and Phong [28].

COROLLARY 6.1. *Suppose A generates a bounded C_0-semigroup in X, let $\sigma(A) \cap i\mathbb{R}$ be countable, $\sigma_p(A') \cap i\mathbb{R} \subset \{0\}$, and assume $N(A)^\perp \cap N(A') = \{0\}$. Then $\lim_{t\to\infty} S(t)x = Px$ for each $x \in X$, where P denotes the projection onto $N(A)$ along $\overline{R(A)}$.*

Next we show that condition (H2) for $\mu \neq 0$ is satisfied for a large class of kernels, provided the resolvent $S(t)$ is known to be bounded. We denote by $BV(\mathbb{R}_+)$ the space of all functions $a : \mathbb{R} \to \mathbb{R}$ of bounded variation, which are left-continuous and such that $a(t) = 0$ for $t \leq 0$.

PROPOSITION 6.2. *Suppose that the resolvent $S(t)$ of* (1.1) *is bounded, let $a(t)$ be of the form*

$$a(t) = \sum_{k=0}^n a_k(t), \qquad t > 0, \tag{6.2}$$

where

$$a_0, ta_0 \in L^1(\mathbb{R}_+) \quad \textit{and} \quad \textit{for } k = 1, \cdots, n,$$

$$a_k \in W^{k-1,1}_{\text{loc}}(\mathbb{R}_+), \quad a_k^{(k-1)} \in BV(\mathbb{R}_+), \quad \int_0^\infty t|da_k^{(k-1)}(t)| < \infty. \tag{6.3}$$

Then $\varrho(a) \supset i\mathbb{R}\backslash\{0\}$, $\hat{a}(i\mu) \in \mathbb{C}$ for all $\mu \in \mathbb{R}\backslash\{0\}$, and for each $\mu \in \mathbb{R}\backslash\{0\}$ there is constant $c(\mu)$, such that

$$\left|\int_0^t e^{-i\mu s}[(a*S)(s) - \hat{a}(i\mu)S(s)]Ax\,dx\right| \leq c(\mu)|x|_A, \qquad x \in D(A). \tag{6.4}$$

If $n = 0$ the assertions also hold for $\mu = 0$.

Proof. Adding suitable constants to the functions of bounded variation $b_k(t) = a_k^{(k-1)}(t)$, we may assume $a_k^{(i)}(0) = 0$ for all $0 \le i \le k-2 \le n-2$. Let $b_0(t) = \int_0^t a_0(\tau)d\tau$. The familiar formula

$$\widehat{db}_k(\lambda) = (da_k^{(k-1)})^\wedge(\lambda) = \lambda^k \hat{a}_k(\lambda), \quad \operatorname{Re}\lambda > 0, \quad k = 1, \cdots, n,$$

by (6.2) yields the representation

$$\hat{a}(\lambda) = \sum_{k=0}^{n} \widehat{db}_k(\lambda)\lambda^{-k}, \qquad \operatorname{Re}\lambda > 0. \tag{6.5}$$

Since $b_k \in BV(\mathbb{R}_+)$, $k = 0, \cdots, n$, (6.5) shows that $\hat{a}(\lambda)$ admits a continuous extension at least to $\overline{\mathbb{C}}_+\backslash\{0\}$; hence, we obtain $\varrho(a) \supset i\mathbb{R}\backslash\{0\}$ and $\hat{a}(\lambda) \in \mathbb{C}$ for all $\lambda \in \overline{\mathbb{C}}_+\backslash\{0\}$. Integrating by parts k times leads to

$$\int_0^t e^{-i\mu\tau}(a_k * S)(\tau)d\tau = (i\mu)^{-k}\int_0^t e^{-i\mu\tau}(db_k * S)(\tau)d\tau - e^{-i\mu t}\sum_{j=0}^{k-1}(a_k^{(j)} * S)(t)(i\mu)^{-j-1};$$

hence, summation over k gives

$$\begin{aligned}
&\int_0^t e^{-i\mu\tau}[(a * S)(\tau) - \hat{a}(i\mu)S(\tau)]Ax\,d\tau \\
&= \sum_{k=0}^{n}(i\mu)^{-k}\int_0^t e^{-i\mu\tau}[(db_k * S)(\tau) - \widehat{db}_k(i\mu)S(\tau))]Ax\,d\tau \\
&\quad - e^{-i\mu t}\sum_{k=1}^{n}\sum_{j=0}^{k-1}(a_k^{(j)} * S)(t)(i\mu)^{-j-1}Ax \\
&= \sum_{k=0}^{n}(i\mu)^{-k}(T_k(t) - e^{-i\mu t}R_k(t))Ax,
\end{aligned} \tag{6.6}$$

where

$$T_k(t) = \int_0^t e^{-i\mu\tau}[(db_k * S)(\tau) - \widehat{db}_k(i\mu)S(\tau)]d\tau \tag{6.7}$$

and

$$R_k(t) = \sum_{j=k}^{n}(a_j^{(k-1)} * S)(t), \qquad R_0(t) = 0. \tag{6.8}$$

To estimate $T_k(t)$, we write

$$\begin{aligned}
T_k(t) &= \int_0^t e^{-i\mu\tau}\int_0^\tau db_k(\tau - s)S(s)d\tau - \int_0^t e^{-i\mu\tau}\widehat{db}_k(i\mu)S(\tau)d\tau \\
&= \int_0^t S(s)e^{-i\mu s}\left(\int_s^t db_k(\tau - s)e^{-i\mu(\tau - s)} - \widehat{db}_k(i\mu)\right)ds, \\
&= -\int_0^t S(s)e^{-i\mu s}\left(\int_{t-s}^\infty db_k(\tau)e^{-i\mu\tau}\right)ds.
\end{aligned}$$

Hence,

$$|T_k(t)| \le M \int_0^t \int_{t-s}^{\infty} |db_k(\tau)| ds = M \left(\int_t^{\infty} \int_0^t ds |db_k(\tau)| + \int_0^t \int_{t-\tau}^t ds |db_k(\tau)| \right)$$
$$= M \left(t \int_t^{\infty} |db_k(\tau)| + \int_0^t \tau |db_k(\tau)| \right) \le M \int_0^{\infty} \tau |db_k(\tau)| = M_k < \infty,$$

where $M = \sup_{\tau \ge 0} |S(\tau)|$. To derive a bound on the $R_k(t)$, we expand $(a_k * S)(t)$ into a Taylor series up to order k,

$$(a_k * S)(t+h) - (a_k * S)(t) = \sum_{j=0}^{k-1} (a_k^{(j)} * S)(t) \frac{h^j}{j!} + \int_t^{t+h} (db_k * S)(\tau) \frac{(t+h-\tau)^{k-1}}{(k-1)!} d\tau.$$

Summing over k, we obtain with (6.1)

$$S(t+h)x - S(t)x = \sum_{k=1}^{n} \sum_{j=1}^{k} (a_k^{(j-1)} * SAx)(t) \frac{h^{j-1}}{(j-1)!}$$
$$+ \sum_{k=0}^{n} \int_t^{t+h} (db_k * SAx)(\tau) \frac{(t+h-\tau)^{k-1}}{(k-1)!} d\tau.$$

Since $S(t)$ is bounded and $b_k \in BV(\mathbb{R}_+)$ the polynomials

$$P_t(h)x = \sum_{j=1}^{n} \frac{h^{j-1}}{(j-1)!} \left(\sum_{k=j}^{n} a_k^{(j-1)} * SAx \right) = \sum_{j=1}^{n} R_{j-1}(t) Ax \frac{h^{j-1}}{(j-1)!}$$

are bounded, uniformly for $0 \le h \le 1$, $t \ge 0$; but this implies the existence of a constant $C > 0$ such that

$$(6.9) \qquad |R_k(t)Ax| \le C|x|_A, \quad x \in D(A), \quad k = 1, \cdots, n.$$

The proof is now complete. □

A special case of Proposition 6.2 will be used in §7, namely, the following.

COROLLARY 6.3. *Suppose that the resolvent $S(t)$ for* (1.1) *is bounded; let $a(t)$ be of the form*

$$(6.10) \qquad a(t) = b_0 + b_\infty t + \int_0^t b_1(s) ds, \qquad t > 0,$$

where $b_0, b_\infty \ge 0$ are constants and $b_1 \in L^1_{\text{loc}}(\mathbb{R}_+)$ is nonnegative, nonincreasing, and convex. Then $\varrho(a) \supset i\mathbb{R}\backslash\{0\}$, $\hat{a}(i\mu) \in \mathbb{C}$ for all $\mu \in \mathbb{R}\backslash\{0\}$ and (6.4) *holds for each $\mu \in \mathbb{R}\backslash\{0\}$.*

Proof. We may assume $\lim_{t\to\infty} b_1(t) = 0$, changing b_∞ otherwise. Let $t_0 > 0$ and

$$c_1(t) = \begin{cases} b_1(t) - b_1(t_0) & \text{for } t \le t_0, \\ 0 & \text{for } t \ge t_0, \end{cases}$$
$$c_3(t) = \begin{cases} 0 & \text{for } t \le t_0, \\ b_1(t_0) - b_1(t) & \text{for } t > t_0, \end{cases}$$

and define $a_0(t) = 0$,

$$a_1(t) = b_0 + \int_0^t c_1(\tau)d\tau, \qquad t > 0,$$

$$a_2(t) = (b_\infty + b_1(t_0))t, \qquad t > 0,$$

$$a_3(t) = -\int_0^t c_3(\tau)d\tau, \qquad t > 0.$$

Obviously, $a(t) = a_1(t) + a_2(t) + a_3(t)$, $a_1 \in BV(\mathbb{R}_+)$ and $da_1 = b_0\delta + c_1(t)dt$ has all moments since its support is compact; $a_2 \in W^{1,1}_{\text{loc}}(\mathbb{R}_+)$, $\dot{a}_2 = b_\infty + b_1(t_0) \in BV(\mathbb{R}_+)$ and $d\dot{a}_2 = (b_\infty + b_1(t_0))\delta$ also has all moments. a_3 belongs to $W^{2,1}_{\text{loc}}(\mathbb{R}_+)$ since b_1 is nonincreasing and convex, and $\ddot{a}_3(t) = -\dot{c}_3(t)$ for $t > t_0$, $\ddot{a}_3(t) = 0$, for $t < t_0$; moreover, by convexity, $-\dot{c}_3(t)$ is nonincreasing for $t > t_0$ and nonnegative, hence $\ddot{a}_3 \in BV(\mathbb{R}_+) \cap L^1(\mathbb{R}_+)$ and in particular $d\ddot{a}_3$ admits a finite first moment, since $\ddot{a}_3(t)$ is nondecreasing, as integration by parts shows. □

The argument at the end of the proof of Proposition 6.2 also yields (H3), i.e., boundness of $S'(t)x$, whenever $S(t)$ is bounded and $a(t)$ is of the form (6.2), (6.3) with $a_0 = 0$. More precisely, we have the following.

PROPOSITION 6.4. *Suppose the resolvent $S(t)$ for* (1.1) *is bounded; let $a(t)$ be of the form*

$$a(t) = \sum_{k=1}^{n} a_k(t), \qquad t > 0, \tag{6.11}$$

where

$$a_k \in W^{k-1,1}_{\text{loc}}(\mathbb{R}_+), \quad a_k^{(k-1)} \in BV(\mathbb{R}_+), \quad k = 1, \cdots, n. \tag{6.12}$$

Then there is a constant $C > 0$, such that

$$|S'(t)x| \le C|x|_A \quad \textit{for all } x \in D(A), \quad t > 0. \tag{6.13}$$

Proof. Equation (6.1) yields for $x \in D(A)$

$$S'(t)x = \sum_{k=2}^{n} (\dot{a}_k * SAx)(t) + (da_1 * SAx)(t) = R_2(t)Ax + (da_1 * SAx)(t), \qquad t > 0,$$

where $R_2(t)$ is given by (6.8). Since $a_1 \in BV(\mathbb{R}_+)$, estimate (6.9) yields the assertion. Observe that for the proof of (6.9) no moment condition was used. □

For the applications in §7 we shall need the following special case of Proposition 6.4.

COROLLARY 6.5. *Suppose the resolvent $S(t)$ for* (6.1) *is bounded; let $a(t)$ be of the form*

$$a(t) = b_0 + b_\infty t + \int_0^t b_1(\tau)d\tau, \qquad t > 0, \tag{6.14}$$

where $b_0, b_\infty \ge 0$ and $b_1 \in L^1_{\text{loc}}(\mathbb{R}_+)$ is nonnegative and nonincreasing. Then there is a constant $C > 0$ such that

$$|S'(t)x| \le C|x|_A \quad \textit{for all } x \in D(A), \quad t > 0. \tag{6.15}$$

Proof. We may assume $\lim_{t\to\infty} b_1(t) = 0$. Define

$$a_1(t) = b_0 + \int_0^t c_1(\tau)d\tau, \qquad a_2(t) = (b_\infty + b_1(t_0))t - \int_0^t c_3(\tau)d\tau,$$

where $c_1(t)$ and $c_3(t)$ are defined as in the proof of Corollary 6.3. Then $a_1 \in BV(\mathbb{R}_+)$ and $\dot{a}_2 = b_\infty + b_1(t_0) - c_3(t) \in BV(\mathbb{R}_+)$; hence Proposition 6.4 applies and yields (6.15). □

Observe that in Proposition 6.4 we have to assume that the non-BV part of $a_0(t)$ of $a(t)$ in decomposition (6.2) is absent. This clearly restricts its applicability; however, in case $a_0 \neq 0$, Estimate (6.13) cannot be expected. In general, $S(t)x$ need not be differentiable at all. In this case, we must use the structure of $a_0(t)$ and A directly to obtain a bound on $S'(t)$.

The verification of (H2) for $\mu = 0$ is more difficult. If $n = 0$ in Proposition 6.2 then $\varrho(a) = i\mathbb{R}$, $\hat{a}(i\mu) \in \mathbb{C}$ for all $\mu \in \mathbb{R}$ and (6.4) remains valid for $\mu = 0$ as the proof given there shows (in fact, no integration by parts is needed). On the other hand, if $n \geq 1$ then generically $\hat{a}(0) = \infty$ as (6.5) shows (only one of the $\widehat{db_k}(0) = b_k(\infty)$, $k = 1, \cdots, n$ must be nonzero for $\hat{a}(0) = \infty$); then we have to prove that

$$U(t)Ax = \int_0^t S(\tau)Ax\, d\tau, \qquad t > 0, \tag{6.16}$$

is bounded by the graph norm $|x|_A$ of x. Since by (6.1) we obtain the relations

$$\hat{U}(\lambda)Ax = \frac{1}{\lambda\hat{a}(\lambda)}((S-I)x)^\wedge(\lambda) = \frac{1}{\lambda^2\hat{a}(\lambda)}(\dot{S})^\wedge(\lambda)x$$

for the Laplace transform of $U(t)Ax$, we see that $U(t)Ax$ will be bounded if there is $k \in BV(\mathbb{R}_+)$, such that $\widehat{dk}(\lambda) = (\lambda\hat{a}(\lambda))^{-1}$, or if there is $\ell \in BV(\mathbb{R}_+)$ such that $\widehat{d\ell}(\lambda) = (\lambda^2\hat{a}(\lambda))^{-1}$ and $S'(t)x$ is bounded. It should be clear that more information on the kernel $a(t)$ must be available in order to achieve this, rather than just an expansion of the form (6.2) and (6.3). In §7 it will be shown how this can be done. Let us summarize.

PROPOSITION 6.6. *Suppose that the resolvent $S(t)$ for* (1.1) *is bounded, and assume either of the following.* (a) *There is $k \in BV(\mathbb{R}_+)$ such that $(\lambda\hat{a}(\lambda))^{-1} = \widehat{dk}(\lambda)$, $\lambda > 0$, i.e.,*

$$(k * a)(t) \equiv t, \qquad t > 0.$$

(b) *There is $\ell \in BV(\mathbb{R}_+)$ such that $(\lambda^2\hat{a}(\lambda))^{-1} = \widehat{d\ell}(\lambda)$, $\lambda > 0$, i.e.,*

$$(\ell * a)(t) = t^2/2, \qquad t > 0,$$

and, in addition, suppose that (6.13) *holds.*

Then $0 \in \varrho(a)$, $\hat{a}(0) = \infty$, and there is a constant $C > 0$ such that

$$\left|\int_0^t S(\tau)Ax\, d\tau\right| \leq C|x|_A \quad \textit{for all } x \in D(A), \quad t \geq 0. \tag{6.17}$$

Consider now the cosine case, i.e., $a(t) \equiv t$ and A generating a bounded strongly continuous cosine family $C(t)$. Then we have $S(t) = C(t)$, $t \geq 0$, $a(t)$ is of the form (6.2), (6.3) and also of the form (6.11), (6.12). Since $\lambda^2\hat{a}(\lambda) = 1 = \widehat{d\ell}(\lambda)$ with $\ell(\lambda) = 1$ for $t > 0$, Propositions 6.2, 6.4, and 6.6 imply that (H2) and (H3) of the General Convergence Theorem are satisfied. Since $\sigma(A) \subset (-\infty, 0]$ (H1) becomes $\sigma(A)$ countable and $\sigma_p(A') \subset \{0\}$, $N(A)^\perp \cap N(A') = \{0\}$. Thus we have the following.

COROLLARY 6.7. *Suppose A generates a bounded, strongly continuous cosine family $C(t)$ in X, assume $\sigma(A)$ is at most countable, $\sigma_p(A') \subset \{0\}$ and $N(A)^\perp \cap N(A') = \{0\}$. Then $\lim_{t\to\infty} C(t)x = Px$ for all $x \in X$, where P denotes the projection onto $N(A)$ along $R(A)$.*

We conclude this section with an example which is such that none of the results of this section can be applied, although (H1), (H2), and (H3) hold, and so the General Convergence Theorem can still be used.

Example 6.8. Let X be a Hilbert space, A a dissipative operator in X such that $\varrho(A) \supset i\mathbb{R}$, and let $a(t) = \cos(t)$, $t > 0$. We claim that the resolvent $S(t)$ of (1.1) satisfies

$$\lim_{t\to\infty} S(t)x = x \quad \text{for all } x \in X. \tag{6.18}$$

To prove this we will apply the General Convergence Theorem of §5. Observe first that $\hat{a}(\lambda) = \lambda(\lambda^2+1)^{-1}$; hence $a(t)$ is not of the form (6.2), (6.3) in view of the poles $\lambda = \pm i$ of $\hat{a}(\lambda)$. For the Laplace transform of $S(t)$, we obtain

$$\lambda\hat{S}(\lambda) = (\lambda + 1/\lambda)(\lambda + 1/\lambda - A)^{-1}, \quad \operatorname{Re}\lambda \geq 0, \quad \lambda \neq 0, \tag{6.19}$$

which exists on $\overline{\mathbb{C}}_+\backslash\{0\}$, since A is dissipative and $\varrho(A) \supset i\mathbb{R}$, and the function $\varphi(\lambda) = \lambda + 1/\lambda$ maps $\overline{\mathbb{C}}_+\backslash\{0\}$ onto $\bar{\mathbb{C}}_+$. Furthermore, (6.19) yields

$$\lim_{\lambda\to 0+} \lambda\hat{S}(\lambda)x = \lim_{r\to\infty} r(r-A)^{-1}x = x \quad \text{for all } x \in X. \tag{6.20}$$

The set of singularities E of (a, A) consists only of the point zero and so we only have to prove that $S(t)$, $S'(t)A^{-1}$, and $V(t) = 1 * (a * S)(t)$ are bounded (existence of $S(t)$ follows, e.g., from the paper of Grimmer and Prüss [18] since $a(0+) > 0$ and $a(t)$ is smooth). Let $x \in D(A)$ and put $u(t) = V(t)x$; then it is easy to see that $u(t)$ satisfies

$$u'' = Au' - u + x, \qquad u(0) = u'(0) = 0. \tag{6.21}$$

Take the inner product of (6.21) with $u'(t)$ and integrate to the result

$$|u'(t)|^2 + |u(t) - x|^2 \leq |x|^2 + 2\int_0^t (Au'(s), u'(s))ds \leq |x|^2,$$

since A is dissipative and $u(0) = u'(0) = 0$. But this means

$$|(a * S)(t)x|^2 + |V(t)x - x|^2 \leq |x|^2, \qquad t > 0, \tag{6.22}$$

i.e., $V(t)$ and $(a*S)(t)$ are both bounded. Similarly, $u(t) = S(t)x$, $x \in D(A^2)$ satisfies (6.21) with initial values $u(0) = x$ and $u'(0) = Ax$; therefore, the same argument yields

$$|S'(t)x|^2 + |S(t)x - x|^2 \leq |Ax|^2, \qquad t > 0, \tag{6.23}$$

i.e., $S'(t)A^{-1}$ is bounded by 1 and so $S(t) = S'(t)A^{-1} + V(t)$ is bounded as well.

7. Applications to viscoelasticity. Let $\Omega \subset \mathbb{R}^n$ be a domain with compact and smooth boundary $\partial\Omega$ that is occupied by a linear incompressible viscoelastic fluid. Assuming the fluid at rest for $t \geq 0$, its velocity field $u(t,x)$ is governed for $t > 0$ by the following problem

$$(7.1)\quad \begin{cases} u_t(t,x) = \int_0^t \Delta u(t-\tau,x)da(\tau) - \nabla p(t,x) + g(t,x) & \\ (\nabla \circ u)(t,x) = 0 & \text{for } x \in \Omega, \quad t > 0, \\ u(t,x) = 0 & \text{for } x \in \partial\Omega, \quad t > 0, \\ u(0,x) = u_0(x) & \text{for } x \in \Omega. \end{cases}$$

Here $p(t,x)$ denotes the (also unknown) hydrostatic pressure; $g(t,x)$ a (given) external force field, $u_0(x)$ the (given) initial velocity field (induced by a δ-perturbation at time $t = 0$); $\Delta, \nabla, \nabla\circ$ designate the Laplacian, gradient, divergence with respect to the x-variables, respectively. The *stress relaxation modulus* $da(t)$ of a linear viscoelastic material is of the general form

$$(7.2)\qquad a(t) = a_0 + a_\infty t + \int_0^t a_1(s)ds, \qquad t \geq 0,$$

where $a_0, a_\infty \geq 0$ are constants, and $a_1(t) \geq 0$ is nonincreasing and of positive type, $\lim_{t\to\infty} a_1(t) = 0$; for a viscoelastic fluid we even have $a_\infty = 0$ and $a_1 \in L^1(\mathbb{R}_+)$.

For the derivation of (7.1), the properties of the kernel $da(t)$, and more on the physical background of viscoelasticity, we refer to the monographs of Christensen [9], Renardy, Hrusa, and Nohel [35], and Pipkin [31].

Equation (7.1) can be rewritten as an abstract Volterra equation in a Banach space X of the form (1.1), i.e.,

$$(7.3)\qquad u(t) = \int_0^t a(t-\tau)Au(\tau)d\tau + f(t), \qquad t \geq 0,$$

where A denotes a closed linear operator in X with dense domain $D(A)$ and $f \in C(\mathbb{R}_+, X)$. In fact, we may choose $X = L_0^2(\Omega;\mathbb{R}^n)$, the space of all divergence-free L^2-vector fields, $A = P\Delta$, the Stokes operator with $D(A) = W^{2,2}(\Omega;\mathbb{R}^n) \cap W_0^{1,2}(\Omega;\mathbb{R}^n) \cap X$ (P denotes the Helmholtz projection in $L^2(\Omega;\mathbb{R}^n)$) and $f : \mathbb{R}_+ \to X$ is defined by $f(t) = u_0 + \int_0^t g(s)ds$. It is well known that the Stokes operator is self-adjoint and negative semidefinite, and hence gives rise to a bounded cosine family in X.

For the Helmholtz projection and the properties of the Stokes operator mentioned above, as well as others, we refer to the paper by Giga and Sohr [17], and to the monograph of Temam [39].

Existence of the resolvent in the general case relevant for the theory of viscoelasticity was first obtained in a Hilbert space setting by Carr and Hannsgen [7].

PROPOSITION 7.1. *Let X be a Hilbert space, A self-adjoint and negative semidefinite and let $a(t)$ be of the form* (7.2) *with $a_0, a_\infty \geq 0$, $a_1(t) \geq 0$ nonincreasing and of positive type with $a_1 \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ and $\lim_{t\to\infty} a_1(t) = 0$. Then* (7.3) *admits a resolvent $S(t)$ such that $|S(t)| \leq 1$ on $\mathbb{R}_+$.*

Actually, Carr and Hannsgen assumed in addition that $a_1(t)$ is convex; however, for existence this is not needed. The proof of Proposition 7.1 relies on the spectral decomposition of self-adjoint operators in Hilbert spaces and estimates on the solutions

$s(t;\mu)$ of the scalar equations

$$s(t)+\mu\int_0^t a(t-\tau)s(\tau)d\tau = 1, \quad t\geq 0, \quad \mu \geq 0. \tag{7.4}$$

A different approach was introduced in Prüss [32].

PROPOSITION 7.2. *Let X be a Banach space, A the generator of a bounded cosine family $C(t)$ in X, $a(t)$ of the form* (7.2) *with $a_0, a_\infty \geq 0$, $a_1 \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$, $a_1(t)\geq 0$ nonincreasing and $\log a_1(t)$ convex, $\lim_{t\to\infty} a_1(t) = 0$. Then* (7.3) *is governed by a bounded resolvent $S(t)$.*

The proof of this result is based on the complete monotonicity of the functions $h(\lambda,\tau) = \exp(-\tau/\hat{a}(\lambda)^{1/2})/(\lambda\hat{a}(\lambda)^{1/2})$ with respect to $\lambda > 0$, for each fixed $\tau \geq 0$, on the representation formula

$$\hat{S}(\lambda) = \int_0^\infty C(\tau)h(\lambda,\tau)d\tau, \qquad \lambda > 0, \tag{7.5}$$

and on the generation theorem for resolvents due to Da Prato and Iannelli [13] and Grimmer and Prüss [18].

Here we are interested in the asymptotic behavior of the resolvent $S(t)$. Before we quote some known results, let us introduce the following definition.

DEFINITION 7.3. Suppose (7.3) admits a resolvent $S(t)$.

(i) Equation (7.3) is called *uniformly asymptotically stable* if there is $\varphi \in L^1(\mathbb{R}_+)\cap C_0(\mathbb{R}_+)$ such that $|S(t)| \leq \varphi(t)$ on $\mathbb{R}_+$.

(ii) Equation (7.3) is called *asymptotically stable* if $S(t)x \to 0$ as $t\to\infty$ for each $x\in X$.

Carr and Hannsgen [7] obtained the following result.

THEOREM 7.4. *Let the assumptions of Proposition* 7.1 *be satisfied, and assume in addition that $a_1 \in C^1(0,\infty)$ and that $-\dot{a}_1(t)$ is nonincreasing and convex. If A is invertible and $a(t) \not\equiv a_\infty t$, then* (7.3) *is uniformly asymptotically stable.*

Observe that A must necessarily be invertible if (7.3) is uniformly asymptotically stable. In fact, if $0\in\sigma(A)$, then $|\mu(\mu-A)^{-1}| \geq 1$ for each $\mu\in\varrho(A)$; on the other hand, $S(\cdot)x \in L^1(\mathbb{R}_+, X)$ for each $x\in X$ implies that $\hat{S}(\lambda) = (1/\lambda)(I-\hat{a}(\lambda)A)^{-1}$ is uniformly bounded for $\operatorname{Re}\lambda \geq 0$, i.e., $M \geq |\hat{S}(\lambda)| \geq 1/|\lambda|$ which is impossible. Also $a(t)\not\equiv a_\infty t$ is necessary for uniform asymptotic stability, since otherwise $S(t) = C(\sqrt{a_\infty}t)$ where $C(t)$ denotes the cosine family generated by A; but cosine families are never integrable.

There is a similar result for the situation of Proposition 7.2; see Prüss [32].

THEOREM 7.5. *Let the assumptions of Proposition* 7.2 *be satisfied. Then* (7.3) *is uniformly asymptotically stable if and only if $a(t)\not\equiv a_\infty t$ and A is invertible.*

In the case $A = P\Delta$, the Stokes operator in $L^2_0(\Omega;\mathbb{R}^n)$, A is invertible if the domain $\Omega\subset\mathbb{R}^n$ is bounded; thus Theorems 7.4 and 7.5 show that viscoelastic fluids with (sufficiently) convex stress relaxation moduli are always uniformly asymptotically stable, unless they are purely elastic, i.e., $da(t) = a_\infty dt$.

However, for unbounded domains Ω, the operator $A = P\Delta$ will in general not be invertible and so (7.3) is not uniformly asymptotically stable. As a consequence of our General Convergence Theorem and the results in §7, in this situation (7.3) will still be asymptotically stable, as the next theorems show.

THEOREM 7.6. *Let the assumption of Proposition* 7.2 *be satisfied, and assume in addition $a(t)\not\equiv a_\infty t$ and $N(A)^\perp \cap N(A') = \{0\}$. Then $\lim_{t\to\infty} S(t)x = Px$ for each $x\in X$, where P denotes the projection onto $N(A)$ along $\overline{R(A)}$.*

Proof. (a) By Proposition 7.2 there is a resolvent $S(t)$ for (7.3) which is bounded on $\mathbb{R}_+$. Since log-convex functions are convex, we see that Corollaries 6.3 and 6.5 apply; hence, $\varrho(a) \supset i\mathbb{R}\backslash\{0\}$ and (H2) holds for $\mu \neq 0$, and also (H3) is satisfied.

(b) We next compute the set E of singularities of $\hat{S}(\lambda)$. Since A generates a bounded cosine family, we have $\sigma(A) \subset (-\infty, 0]$. Convex functions are of positive type; hence, $\hat{a}(\lambda) \notin (-\infty, 0]$ for Re $\lambda > 0$. Therefore, $E \subset \{0\}$ will follow if we show that Im $\hat{a}(i\mu) \neq 0$ for $\mu \in \mathbb{R}$, $\mu \neq 0$. Since $ta_1(t) \leq \int_0^t a_1(\tau)d\tau \to 0$ as $t \to 0$, via an integration by parts, we obtain with $\mu > 0$,

$$(7.6) \qquad -\mu \mathrm{Im}\ \hat{a}(i\mu) = a_0 + \ \mathrm{Re}\ \hat{a}_1(i\mu) = a_0 + \mu^{-1}\int_0^\infty (-\dot{a}_1(t))\sin(\mu t)dt \geq 0,$$

since $a_1(t)$ is nondecreasing and convex (hence also absolutely continuous on $(0,\infty)$). Equality in (7.6) can only hold in case $a_0 = 0$, and $-\dot{a}_1(t)$ is constant on each of the intervals $(2k\pi\mu^{-1}; 2(k+1)\pi\mu^{-1})$; but this cannot happen since $a_1(t)$ is log-convex by assumption and is nontrivial, for otherwise, $a(t) \equiv a_\infty t$. Thus, $E \subset \{0\}$ holds.

(c) We next show $0 \in \varrho(a)$ and (H2) for $\mu = 0$. This will be done with the help of the following result.

LEMMA 7.7. *Let $a(t)$ satisfy the assumptions of Proposition* 7.2 *and define* $g(\lambda) = \hat{a}(\lambda)^{-1/2}$ *for* Re $\lambda \geq 0$. *Then there are* k, $\ell \in BV(\mathbb{R}_+)$ *such that*

$$(7.7) \qquad \widehat{dk}(\lambda) = \frac{g(\lambda)}{1+g(\lambda)}, \quad \widehat{d\ell}(\lambda) = \widehat{dk}(\lambda)g(\lambda)/\lambda, \quad \mathrm{Re}\ \lambda \geq 0.$$

The proof of Lemma 7.7 is based on Bernstein's theorem and the Wiener–Levy theorem; see Prüss [32, pp. 341–342].

Observe that Lemma 7.7 yields $0 \in \varrho(a)$ and $\hat{a}(0) = \infty$, since $\widehat{dk}(\lambda)$ is continuous on $\overline{\mathbb{C}}_+$, $\hat{a}(\lambda) = (1/\widehat{dk}(\lambda) - 1)^2$ and $\lim_{\lambda \to 0+} \hat{a}(\lambda) = \hat{a}(0) = \infty$.

Now let $U(t) = \int_0^t S(\tau)d\tau$; then for $x \in D(A)$, we have

$$(UAx)^\wedge(\lambda) = \lambda^{-1}\hat{S}(\lambda)Ax = \lambda^{-2}(I - \hat{a}(\lambda)A)^{-1}Ax = \lambda^{-2}g(\lambda)^2(g(\lambda)^2 - A)^{-1}Ax$$

and

$$(S-I)^\wedge(\lambda)x = \hat{a}(\lambda)A\lambda^{-1}(I - \hat{a}(\lambda)A)^{-1} = \lambda^{-1}A(g(\lambda)^2 - A)^{-1}x,$$

as well as

$$(S')^\wedge(\lambda)x = \lambda\hat{S}(\lambda)x - x = \hat{a}(\lambda)A(I - \hat{a}(\lambda)A)^{-1}x = A(g(\lambda)^2 - A)^{-1}x.$$

These relations and the identity

$$\lambda^{-2}g(\lambda)^2 = \lambda^{-1}\widehat{d\ell}(\lambda)(1 + \widehat{dk}(\lambda)) + \widehat{d\ell}(\lambda)^2, \qquad \mathrm{Re}\ \lambda \geq 0,$$

yield

$$\hat{U}(\lambda)Ax = \widehat{d\ell}(\lambda)^2(\hat{S}')^\wedge(\lambda)x + \widehat{d\ell}(\lambda)(1 + \widehat{dk}(\lambda))(S-I)^\wedge(\lambda)x;$$

hence,

$$U(t)Ax = (d\ell * d\ell * S')(t)x + (d\ell + d\ell * dk) * (S-I)(t)x.$$

Since the measures $d\ell$ and dk are bounded, we obtain from the boundedness of $S(t)$ and $S'(t)$ on $D(A)$ the desired bound on $U(t)Ax$, i.e., (H2) holds.

(d) Finally, the assumption $N(A)^{\perp} \cap N(A') = \{0\}$ implies $\lambda \hat{S}(\lambda) \to P$ strongly as $\lambda \to 0+$ by Theorem 4.6; hence, the General Convergence Theorem applies and the proof is complete. □

The proof of Theorem 7.6 shows that boundedness of $U(t)Ax$ is the difficult thing to prove. This turns out to be even more difficult in the situation of Proposition 7.1, where the assumptions on $a_1(t)$ are weaker so that, in general, Bernstein's theorem can no longer be employed. We want to discuss this case now in some detail. So suppose that X is a Hilbert space, A negative semidefinite, and let $a(t)$ be of the form (7.2) with $a_0, a_\infty \geq 0$, $a_1 \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ nonnegative, nonincreasing of positive type, and $\lim_{t\to\infty} a_1(t) = 0$; let us exclude the cosine case $a(t) \equiv a_\infty t$ which has already been discussed in §6.

Proposition 7.1 shows the existence and boundedness of the resolvent $S(t)$, Corollary 6.5 yields the boundedness of $S'(t)$ on $D(A)$. That is, (H3) holds, and since $\lim_{\lambda\to 0+} \hat{a}(\lambda) = \hat{a}(0) = \infty$, we obtain $\lim_{\lambda \to 0+} \lambda \hat{S}(\lambda)x = Px$ for all $x \in X$ where P denotes the orthogonal projection onto $N(A)$. By means of the decomposition $a_1(t) = a_2(t) + a_3(t)$, where

$$(7.8) \qquad a_2(t) = (a_1(t) - a_1(t_0))_+, \quad \text{and} \quad a_3(t) = \min(a_1(t), a_1(t_0))$$

for $t > 0$, $a_2(t) = a_3(t) = 0$ for $t \leq 0$ as before, we obtain

$$(7.9) \qquad \hat{a}(\lambda) = a_0/\lambda + a_\infty/\lambda^2 + \hat{a}_2(\lambda)/\lambda + \widehat{da_3}(\lambda)/\lambda^2, \qquad \mathrm{Re}\,\lambda \geq 0,$$

and therefore, $\varrho(a) \supset i\mathbb{R}\backslash\{0\}$, $\hat{a}(i\mu) \in \mathbb{C}$ for all $\mu \in \mathbb{R}$, $\mu \neq 0$.

Since $a_1(t)$ is nonincreasing, it follows that for $\mu \neq 0$

$$\mu^2 \mathrm{Re}\ \hat{a}(i\mu) = -a_\infty + \mu \mathrm{Im}\ \hat{a}_1(i\mu) \leq 0$$

and even strictly if $a_1(t)$ is also continuous on $(0, \infty)$ or in case $a_\infty > 0$. On the other hand, we have for $\mu \neq 0$

$$-\mu \mathrm{Im}\ \hat{a}(i\mu) = a_0 + \mathrm{Re}\ \hat{a}_1(i\mu) \geq 0,$$

since $a_1(t)$ is of positive type and even strictly if $a_0 > 0$. Therefore, we have

$$E_0 = E\backslash\{0\} = \{\mu \in \mathbb{R}\backslash\{0\} : \ \mathrm{Re}\ \hat{a}_1(i\mu) = -a_0, \hat{a}(i\mu)^{-1} \in \sigma(A) \text{ or } \hat{a}(i\mu) = 0\}$$

Thus, the spectral assumption (H1) reduces to

$$(7.10) \qquad E_0 \text{ is at most countable, and } \mu \in E_0 \text{ implies } \hat{a}(i\mu)^{-1} \notin \sigma_p(A).$$

Observe that $E_0 = \emptyset$ if $a_0 > 0$ or if $\mathrm{Re}\ \hat{a}_1(i\mu) \neq 0$ for all $\mu \neq 0$.

By Proposition 6.2 and Corollary 6.3, it is also not difficult to verify (H2) for $\mu \in E_0$; in fact, either $-\int_0^\infty t da_1(t) < \infty$ or a_1 convex will be sufficient; note, however, that the former is equivalent to $a_1 \in L^1(\mathbb{R}_+)$ since $a_1(t) \geq 0$ is nonincreasing.

We turn now to the question whether $0 \in \varrho(a)$ and whether $U(t)Ax = \int_0^t S(\tau)Ax\,d\tau$ is bounded on $D(A)$. The first two cases will be a consequence of Proposition 6.6.

Case 1. $a_\infty > 0$ (a "solid"). This one is easy. In fact, if $a_\infty > 0$, then $g_1(\lambda) = (\lambda^2 \hat{a}(\lambda))^{-1}$ is bounded and completely monotonic for $\lambda > 0$, since $a_1(t)$ is nonincreasing. Therefore, by Bernstein's theorem there is a function $\ell \in BV(\mathbb{R}_+)$

such that $g_1(\lambda) = \widehat{d\ell}(\lambda)$ for $t > 0$. Proposition 6.6 then implies $0 \in \varrho(a)$, $\hat{a}(0) = \infty$ and boundedness of $U(t)Ax$ on $D(A)$.

Case 2. $a_\infty = 0$, $a_0 > 0$, $a_1 \in L^1(\mathbb{R}_+)$ ("viscous fluid"). Here we use

$$g_2(\lambda) = \frac{1}{\lambda\hat{a}(\lambda)} = \frac{1}{a_0 + \hat{a}_1(\lambda)} = a_0^{-1}\left(1 - \frac{\hat{a}_1(\lambda)}{a_0 + \hat{a}_1(\lambda)}\right), \qquad \text{Re}\,\lambda \geq 0.$$

Since $a_1 \in L^1(\mathbb{R}_+)$ is of positive type, Re $\hat{a}_1(\lambda) \geq 0$ for Re $\lambda \geq 0$, and so $a_0 + \hat{a}_1(\lambda)$ does not vanish on $\overline{\mathbb{C}}_+$. By the Paley–Wiener theorem there is a function $r \in L^1(\mathbb{R}_+)$ such that

$$g_2(\lambda) = a_0^{-1}(1 - \hat{r}(\lambda)), \qquad \text{Re}\,\lambda \geq 0,$$

and so assumption (a) of Proposition 6.6 is satisfied; therefore, $0 \in \varrho(a)$, $\hat{a}(0) = \infty$, and $U(t)Ax$ is bounded on $D(A)$.

Case 3. $a_\infty = a_0 = 0$, $a_1 \in L^1(\mathbb{R}_+)$ (a "rigid fluid"). We assume in addition that a_1 is absolutely continuous on $(0, \infty)$ in this case. As before, decompose $a_1(t) = a_2(t) + a_3(t)$, where a_2, a_3 are as in (7.8) and $t_0 > 0$ is small enough for $\alpha = a_3(0+) = a_1(t_0) > 0$. Since

$$S(t)x - x = (a_1 * UAx)(t)$$

and

$$S'(t)x - (a_2 * SAx)(t) = (da_3 * UAx)(t) = \alpha U(t)Ax + (\dot{a}_3 * UAx)(t),$$

we obtain

$$\hat{U}(\lambda)Ax = (\alpha + \hat{a}_1(\lambda) + (\dot{a}_3)^\wedge(\lambda))^{-1}(S(t)x - x + S'(t)x - (a_2 * SAx)(t))^\wedge(\lambda).$$

By boundedness of $S(t)x$, $S'(t)x$, and $S(t)Ax$ on $D(A)$, and since $a_2 \in L^1(\mathbb{R}_+)$, it is sufficient to show that

$$g_3(\lambda) = (\alpha + \hat{a}_1(\lambda) + (\dot{a}_3)^\wedge(\lambda))^{-1} = (\alpha + \hat{b}(\lambda))^{-1} = \alpha^{-1}\left(1 - \frac{\hat{b}(\lambda)}{\alpha + \hat{b}(\lambda)}\right)$$

is the Laplace transform of a bounded measure.

By assumption, Re $\hat{a}_1(\lambda) \geq 0$ for Re $\lambda > 0$ and $\hat{a}_1(0) = \int_0^\infty a_1(t)dt > 0$; on the other hand, $|(\dot{a}_3)^\wedge(\lambda)| \leq a_3(0+) = \alpha$ since $\dot{a}_3(t) \leq 0$ on $(0, \infty)$, and equality only holds for $\lambda = 0$. Therefore, $\hat{b}(\lambda) = \hat{a}_1(\lambda) + (\dot{a}_3)^\wedge(\lambda) \neq -\alpha$ for Re $\lambda \geq 0$, and so by the Paley–Wiener theorem there is a function $r \in L^1(\mathbb{R}_+)$, such that

$$g_3(\lambda) = \alpha^{-1}(1 - \hat{r}(\lambda))) = \widehat{dk}(\lambda), \qquad \text{Re}\,\lambda \geq 0,$$

where $k(t) = \alpha^{-1}(1 - \int_0^t r(\tau)d\tau)$ belongs to $BV(\mathbb{R}_+)$. Thus, $U(t)Ax$ is bounded on $D(A)$, $0 \in \varrho(a)$, and $\hat{a}(0) = \infty$ follow in this case easily from (7.9).

Case 4. $a_\infty = 0$, $a_1 \notin L^1(\mathbb{R}_+)$. If a_1 is not integrable then we cannot apply the Paley–Wiener theorem directly to show that the functions $g_j(\lambda)$ in Case 2 and Case 3 above are Laplace transforms of bounded measures. However, it is enough to know that for every $\alpha > 0$ there is $r_\alpha \in L^1(\mathbb{R}_+)$ such that

$$\hat{r}_\alpha(\lambda) = \frac{\hat{a}_1(\lambda)}{\alpha + \hat{a}_1(\lambda)}, \qquad \text{Re}\,\lambda \geq 0,$$

holds. Obviously, this is enough in case $a_0 > 0$; put $\alpha = a_0$ to see this. If $a_0 = 0$, rewrite $g_3(\lambda)$ as

$$g_3(\lambda) = \alpha^{-1}\left(1 - \frac{\hat{r}_\alpha(\lambda) + (\dot{a}_3)^\wedge(\lambda)\hat{dk}_\alpha(\lambda)}{1 + (\dot{a}_3)^\wedge(\lambda)\hat{dk}_\alpha(\lambda)}\right)$$

where $\widehat{dk}_\alpha(\lambda) = (\alpha + \hat{a}_1(\lambda))^{-1} = \alpha^{-1}(1 - \hat{r}_\alpha(\lambda))$, and apply Paley–Wiener to this representation.

Shea and Wainger [37] have shown that if in addition $a_1(t)$ is convex such $r_\alpha \in L^1(\mathbb{R}_+)$ exist; see also Jordan, Staffans, and Wheeler [21]. It is clear that then we also have $0 \in \varrho(a)$.

We summarize this in the following theorem.

THEOREM 7.8. *Let the assumptions of Proposition* 7.1 *be satisfied. In addition we assume that one of the following conditions is satisfied:* (a) $a_\infty > 0$*;*

(b) $a_1 \in L^1(\mathbb{R}_+)$*, and either* a_1 *is absolutely continuous on* $(0, \infty)$ *or* $a_0 > 0$*;*

(c) $a_1(t)$ *is convex on* $(0, \infty)$*.*

Moreover, suppose that the spectral condition (7.10) *is satisfied. Then* $\lim_{t\to\infty} S(t)x = Px$ *for each* $x \in X$*, where* P *denotes the orthogonal projection onto* $N(A)$*.*

Finally, we want to mention that for a_1 convex, Re $\hat{a}_1(i\mu) = 0$ if $-\dot{a}_1(t)$ is constant on each of the intervals $(2k\pi\mu^{-1}, 2(k+1)\pi\mu^{-1})$; in particular, $E_0 = \emptyset$ if $-\dot{a}_1(t)$ is nonincreasing and continuous on $(0, \infty)$.

8. Acknowledgment. It is a pleasure for the second author to thank the Equipe de Mathématiques de Besançon for its kind hospitality during his visits.

RICCATI DIFFERENTIAL EQUATIONS WITH UNBOUNDED COEFFICIENTS AND NONSMOOTH TERMINAL CONDITION—THE CASE OF ANALYTIC SEMIGROUPS*

I. LASIECKA† AND R. TRIGGIANI†

Abstract. This paper provides, constructively, an explicit solution to the (operator) Differential Riccati Equation in Hilbert space with unbounded coefficients on a fixed time interval $[0, T)$, $T<\infty$, which arises in the optimal control problem with nonsmoothing terminal condition at $t=T$ for an abstract dynamics modeled by an analytic semigroup. The results are sharp as illustrated by counterexamples. Regularity properties of all the quantities involved are also given. Uniqueness of the solution is asserted under some additional assumptions on the terminal condition. Applications include parabolic equations with Dirichlet, or Neumann (Robin) boundary control, or else with point control, as well as plate-like equations with a high degree of damping, etc.

Key words. Riccati Differential Equations, analytic semigroups

AMS(MOS) subject classifications. 47, 35, 93

1. Introduction: statement of main results; literature. Consider the following abstract differential equation,

$$\dot{y}=Ay+Bu \quad \text{on, say, } [\mathscr{D}(A^*)]', \quad y(0)=y_0\in Y, \tag{1.1}$$

subject to the following assumptions to be maintained throughout the article.

(i) A is the infinitesimal generator of a strongly continuous analytic semigroup, denoted by e^{At} on the Hilbert space Y. Without loss of generality for the problem considered here, where the dynamics (1.1) is studied over a finite interval $[0, T]$, $T<\infty$, we may assume that A is boundedly invertible, i.e., $A^{-1}\in\mathscr{L}(Y)$. Then the fractional powers $(-A)^\theta$, $0<\theta<1$ are well defined.

(ii) B is a linear (generally unbounded from U to Y) but continuous operator: $U=\mathscr{D}(B)\to[\mathscr{D}(A^*)]'$, where U is another Hilbert space, such that

$$A^{-\gamma}B\in\mathscr{L}(U;Y) \quad \text{or} \quad \|A^{-\gamma}B\|_{\mathscr{L}(U;Y)}=\|B^*A^{*-\gamma}\|_{\mathscr{L}(Y;U)}\leqq c_\gamma \tag{1.2}$$
$$\text{for some fixed } \gamma, 0\leqq\gamma<1.$$

Generally, dependence on γ will not necessarily be explicitly noted in the sequel. In (1.1), A^* is the Y-adjoint of A, and $[\mathscr{D}(A^*)]'$ denotes the dual space of $\mathscr{D}(A^*)$ with respect to the Y-inner product, so that $|y|_{[\mathscr{D}(A^*)]'}=|A^{-1}y|_Y$.

Remark 1.1. It was pointed out in [L], [T], on the basis of preliminary work in [B1], [B2], [W], that in the case of a second-order parabolic equation defined on a bounded domain $\Omega\subset R^n$ the relevant values of the constant γ are as follows: $\gamma=\frac{3}{4}+\varepsilon$, $\forall\varepsilon>0$, for Dirichlet boundary control with $U=L_2(\Gamma)$, $Y=L_2(\Omega)$; or else, for Neumann boundary control with $U=L_2(\Gamma)$, $Y=H^1(\Omega)$; while $\gamma=\frac{1}{4}+\varepsilon$, for the Neumann boundary control with $U=L_2(\Gamma)$ and $Y=L_2(\Omega)$. For a more detailed discussion of these and other examples of partial differential equations with boundary-point control which fit into the present abstract theory, we refer to [L-T4].

With the dynamics (1.1), we associate the following quadratic functional cost over a preassigned fixed time interval $[0, T]$, $0<T<\infty$:

$$J(u,y)\equiv\int_0^T[|Ry(t)|_W^2+|u(t)|_U^2]\,dt+|Gy(T)|_Z^2, \tag{1.3}$$

where in (1.3), $y(t) = y(t; y_0)$, $R \in \mathscr{L}(Y; W)$, $G \in \mathscr{L}(Y; Z)$, and W, Z are other Hilbert spaces.

The corresponding optimal control problem is:

$$\begin{aligned} &\text{minimize } J(u, y) \text{ over all } u \in L_2(0, T; U), \\ &\text{where } y \text{ is the solution of (1.1) due to } u. \end{aligned} \tag{1.4}$$

The solution to (1.1) is

$$y(t) = e^{At}y_0 + (Lu)(t) \tag{1.5}$$

$$(Lu)(t) = \int_0^t e^{A(t-\tau)}Bu(\tau)\,d\tau \tag{1.6a}$$

$$: \text{continuous } L_2(0, T; U) \to L_2(0, T; \mathscr{D}((-A)^{1-\gamma})). \tag{1.6b}$$

The adjoint L^* of L: $(Lu, f)_{L_2(0,T;Y)} = (u, L^*f)_{L_2(0,T;U)}$ is given by

$$(L^*f)(t) = \int_t^T B^*\, e^{A^*(\tau-t)}f(\tau)\,d\tau \tag{1.7a}$$

$$: \text{continuous } L_2(0, T; [\mathscr{D}((-A)^{1-\gamma})]') \to L_2(0, T; U). \tag{1.7b}$$

Complementing (1.6*a*), we shall let L_T be the (unbounded) operator

$$L_T u = \int_0^Y e^{A(T-t)}Bu(t)\,dt \tag{1.8}$$

with densely defined domain $\mathscr{D}(L_T) = \{u \in L_2(0, T; U)\colon L_T u \in Y\}$, which describes the map (1.5) from the input u to the solution $y(T)$ of (1.1) at time $t = T$, with $y_0 = 0$. Its adjoint L_T^*, $(L_T u, y)_Y = (u, L_T^* y)_{L_2(0,T;Y)}$ is the closed operator

$$\{L_T^* y\}(t) = B^*\, e^{A^*(T-t)}y, \qquad 0 \leqq t \leqq T, \quad y \in Y. \tag{1.9}$$

1.1. Nonsmoothing case. Our main result is the following theorem.

THEOREM 1.1. *Let the* (*densely defined*) *operator GL_T be closed* (*or closeable*), *as an operator $L_2(0, T; U) \supset \mathscr{D}(GL_T) \to Z$. Then there exists a unique optimal pair $\{u^0(t, 0; y_0), y^0(t, 0; y_0)\}$ of problem* (1.1), (1.3), *with $T < \infty$, explicitly given by*

$$-u^0(t, 0; x) = \{\Lambda_{0T}^{-1}[L_T^* G^*\, e^{AT}x + L^*R^*R(e^{A\cdot}x)]\}(t), \tag{1.10}$$

$$y^0(t, 0; x) = e^{At}x + (Lu^0)(t), \tag{1.11}$$

$$\Lambda_{0T} = I + L^*R^*RL + L_T^* G^* GL_T, \tag{1.12}$$

with L, L^*, defined in (1.6), (1.7), *and L_T, L_T^* defined by* (1.8) *and* (1.9). *Moreover, there exists a nonnegative, self-adjoint operator $P(t) = P^*(t) \geqq 0$* (*see* (3.31) *of Proposition* 3.8), *defined explicitly in terms of the data in* (vii) = (1.19) *below, such that*

$$\text{(i)} \qquad P(\cdot) \in \mathscr{L}(Y; C([0, T]; Y)) \tag{1.13}$$

(*see* (2.27) *of Proposition* 2.2 *and comments in the proof thereof*);

(ii) *In fact, even more, for* $0 \leqq \theta < 1$,

$$|(-A^*)^\theta P(t)|_{\mathscr{L}(Y)} \leqq \frac{C_{T\gamma\theta}}{(T-t)^\theta}, \tag{1.14}$$

(*see* (3.26) *of Corollary* 3.7);

(iii) *For all* $0 < \varepsilon \leqq T$,

$$(-A^*)^\theta P(t) \in \mathscr{L}(Y; C([0, T-\varepsilon]; Y)), \qquad 0 \leqq \theta < 1, \tag{1.15}$$

(*see* (4.31) *of Proposition* 4.6);

$$\text{(iv)} \qquad |B^*P(t)|_{\mathscr{L}(Y;U)} \leqq \frac{C_{T\gamma}}{(T-t)^\gamma}, \qquad 0 \leqq t < T \tag{1.16}$$

(*see* (3.27) *of Corollary* 3.7);

(v) *For any* $0 < \varepsilon \leqq T$,

$$B^*P(\,\cdot\,) \in \mathscr{L}(Y; C([0, T-\varepsilon]; Y)) \tag{1.17}$$

(*see* (4.32) *of Proposition* 4.6).

(vi) *For each* $y_0 \in Y$, *the optimal control* $u^0(t, 0; y_0)$ *is given in pointwise feedback form by*

$$u^0(t, 0; y_0) = -B^*P(t)y^0(t, 0; y_0), \qquad 0 \leqq t < T \tag{1.18}$$

(*see* (2.28) *of Proposition* 2.2).

(vii) *The operator* $P(t)$ *is given* (*constructively*) *by*

$$P(t)x = \int_t^T e^{A^*(\tau - t)} R^*Ry^0(\tau, t; x)\,d\tau + e^{A^*(T-t)}G^*Gy^0(T, t; x). \tag{1.19}$$

(viii) *The optimal cost of the optimal control problem on* $[t, T]$ *initiating at time* t *at point* $x \in Y$ *is*

$$J(u^0(\,\cdot\,, t; x), \quad y^0(\,\cdot\,, t; x)) = (P(t)x, x)_Y \tag{1.20}$$

(*see* (3.32) *of Proposition* 3.8);

(ix) *For* $0 < t < T$, $P(t)$ *satisfies the following Differential Riccati Equation* (DRE), *for all* $x, y \in \mathscr{D}((-A)^\varepsilon)$, *for all* $\varepsilon > 0$ (*see Theorem* 4.5),

$$\begin{aligned}(\dot{P}(t)x, y)_Y = &-(R^*Rx, y)_Y - (P(t)x, Ay)_Y - (P(t)Ax, y)_Y \\ &+ (B^*P(t)x, B^*P(t)y)_U.\end{aligned} \tag{1.21}$$

(x) *The following regularity properties hold true for the optimal pair*

$$\|u^0(\,\cdot\,, s; x)\|_{L_2(s,T;U)} + \|y^0(\,\cdot\,, s; x)\|_{L_2(s,T;U)} \leqq c_T\|x\|_Y \tag{1.22}$$

(*see* (2.19), (2.20) *of Proposition* 2.1)

$$\|Gy^0(T, s; x)\|_Z \leqq c_T\|x\|_Y; \tag{1.23}$$

(*see* (2.21) *of Proposition* 2.1)

$$\|u^0(\,\cdot\,, s; x)\|_{C_\gamma([s,T];U)} \leqq c_{T\gamma}\|x\|_Y \tag{1.24}$$

(*see* (3.23) *of Theorem* 3.6)

$$\|y^0(\,\cdot\,, s; x)\|_{C([s,T];Y)} \leqq c_{T\gamma}\|x\|_Y \qquad \text{if } 0 \leqq \gamma < \tfrac{1}{2}; \tag{1.25a}$$

$$\|y^0(\,\cdot\,, s; x)\|_{C_{2\gamma-1+\varepsilon}([s,T];Y)} \leqq c_{T\gamma}\|x\|_Y \qquad \text{if } \tfrac{1}{2} \leqq \gamma < 1. \tag{1.25b}$$

(*see* (3.24) *of Theorem* 3.6).

In (1.24) *and* (1.25), *if* X *is a Hilbert space and* r *any real number*, $C_r([s, T]; X)$ *denotes the Banach space defined by*

$$\begin{aligned} C_r([s, T]; X) = \Big\{ & f(t) \in C([s, T); X): \\ & \|f\|_{C_r([s,T];X)} = \sup_{s \leqq t < T} (T-t)^r \|f(t)\|_X < \infty \Big\}. \end{aligned} \tag{1.26}$$

Moreover (*see Theorem* 4.1), *for* $x \in Y$ *and for each s fixed*, $0 \leqq s < T$, *the optimal control* $u^0(t, s; x)$ *and the optimal solution* $y^0(t, s; x)$ *are, respectively, U-valued and Y-valued functions that are differentiable in* $t \in (s, T)$ *with* $(\partial u^0/\partial t)(t, s; x) \in U$, $(\partial y^0/\partial t)(t, s; x) \in Y$. *In fact, these U-valued and Y-valued functions* $u^0(t, s; x)$ *and* $y^0(t, s; x)$ *are analytic in* $t \in (s, T)$ *if the operator A has compact resolvent in Y, or* $(-A)^p B$ *is compact, for some* $0 < p < 1$.

(xi) *If we define the evolution operator*

$$\Phi(t, \tau)x = y^0(t, \tau; x), \tag{1.27}$$

the following weak convergence results hold true (*see* (5.3) *and* (5.4) *of Proposition* 5.2):

$$\lim_{t \uparrow T} (G\Phi(T, t)x, z)_Z = (Gx, z) \quad \forall x \in X, \forall z \in Z; \tag{1.28}$$

$$\lim_{t \uparrow T} (P(t)x, y)_Y = (G^*Gx, y) \quad \forall x, y \in Y. \tag{1.29}$$

Remark 1.2. With reference to the assumption of Theorem 1.1, we have

(1.30) closed operator $(GL_T)^*$, written as $L_T^* G^*$, be *densely defined* as an operator $Z \supset \mathscr{D}((GL_T)^*) \rightarrow L_2(0, T; U)$ $\Leftrightarrow$ densely defined operator GL_T be *closeable* as an operator $L_2(0, T; U) \supset \mathscr{D}(GL_T) \rightarrow Z$

$$\Uparrow$$

(1.31) $(-A^*)^{\beta/2{}^*_G}$ be *densely defined* as an operator $Z \supset \mathscr{D}((-A^*)^{\beta/2} G^*) \rightarrow Y$ for some $\beta > 2\gamma - 1$

The equivalence is a standard result [K1, p. 168]. To see the sufficient condition, we compute from (1.9),

$$\begin{aligned} \{L_T^* G^* z\}(t) &= B^* e^{A^*(T-t)} G^* z \\ &= B^*(-A^*)^{-\gamma}(-A^*)^{\gamma-\beta/2} e^{A^*(T-t)}(-A^*)^{\beta/2} G^* z, \end{aligned} \tag{1.32}$$

use (1.2), and notice that $(-A^*)^{\gamma-\beta/2} e^{A^*(T-t)} \in \mathscr{L}(Y; L_2(0, T; Y))$ for $2\gamma - \beta < 1$.

We emphasize that condition (1.31) on $(-A^*)^{\beta/2} G^*$, which does not involve B, is *only sufficient* for the ultimate requirement that GL_T be closeable, which instead involves B. This will be seen in one example in § 7.2 below.

Remark 1.3. An example in § 7.1 will show that the assumption that GL_T be closed (closeable) cannot be dispensed with, for otherwise the optimal control may not exist.

1.2. The smoothing case. Next we shall assume that G is a smoothing operator in the sense that

$$(-A^*)^\beta G^* G \in \mathscr{L}(Y) \quad \text{for some } \beta > 2\gamma - 1 \tag{1.33}$$

(which is automatically satisfied with $\beta = 0$ if $0 \leqq \gamma < \frac{1}{2}$). Then, equation (1.33) implies that GL_T is, in fact, bounded: $GL_T \in \mathscr{L}(L_2(0, T; U), Z)$ (so that a fortiori the assumption of Theorem 1.1 is satisfied). To justify this claim, a useful result from [F1, Lemma 3.1] is invoked (which will be recalled in its entirety at the beginning of § 6), which says, in particular, that the operator $(-A^*)^{\beta/2} G^* G(-A)^{\beta/2-\varepsilon}$ admits a bounded extension in $\mathscr{L}(Y)$, $\varepsilon > 0$. Thus, $(-A^*)^{\beta/2-\varepsilon} G^* G(-A)^{\beta/2-\varepsilon}$ is self-adjoint and in $\mathscr{L}(Y)$. Then, $(-A^*)^{\beta/2-\varepsilon} G^* \in \mathscr{L}(Z, Y)$. Returning to (1.32) and the line below it, we see that $L_T^* G^*$ is bounded: $L_T^* G^* \in \mathscr{L}(Z, L_2(0, T; U))$), as desired, since $(-A^*)^{\gamma-\beta/2+\epsilon} e^{A^*(T-t)} \in \mathscr{L}(Y; L_2(0, T; Y))$.

Thus, if condition (1.33) is assumed, then, accordingly, stronger results follow; in particular, y^0 becomes continuous. Moreover, the solution of the DRE (1.21) given explicitly by (1.19), is unique and the limits (1.28) and (1.29) as $t \uparrow T$ of Theorem 1.1(xi) are strong. Thus, we recover results of [D-I], which were obtained via the "direct" method.

THEOREM 1.2 *Assume* (1.33). *Then*; *we have the following.*

(i) (*Regularity of optimal pair*). *For* $x \in Y$ *and any* $\varepsilon > 0$,

$$|u^0(\cdot, s; x)|_{C_{1-\gamma-\varepsilon}([s,T];U)} + |y^0(\cdot, s; x)|_{C([s,T];Y)} \leqq c_{T\gamma}|x|_Y, \tag{1.34}$$

$$y^0(T, \cdot\,; x) = \Phi(T, \cdot)x \in C([s, T]; Y), \tag{1.35}$$

(*see* (6.30) *and* (6.31) *of Corollary* 6.3) *from which, in particular,* (*see* (6.32))

$$\lim_{t\uparrow T} \Phi(T, t)x = x, \qquad x \in Y; \tag{1.36}$$

(ii) *For any* $0 \leqq \theta < 1$, $\varepsilon > 0$, $x \in Y$, *we have* $(-A^*)^\theta P(\cdot)x \in C_{\theta+1-2\gamma+\varepsilon}([0, T]; Y)$ (*see* (6.33) *of Corollary* 6.3)

$$|(-A^*)^\theta P(t)|_{\mathscr{L}(Y)} \leqq \frac{C_{T\gamma}}{1-\theta} \frac{1}{(T-t)^{\theta+1-2\gamma+\varepsilon}}, \tag{1.37}$$

(iii) $$B^*P(\cdot) \in \mathscr{L}(Y; C_{1-\gamma-\varepsilon}([0, T]; U));$$

that is,

$$|B^*P(t)x|_U \leqq \frac{C_T}{1-\gamma} \frac{1}{(T-t)^{1-\gamma-\varepsilon}} |x|_Y \tag{1.38}$$

(*see* (6.34) *of Corollary* 6.3);

(1.39) (iv) $$\lim_{t\uparrow T} P(t)x = G^*Gx, \qquad x \in Y$$

(*see* (6.35) *of Corollary* 6.3);

(v) (*uniqueness, see Theorem* 6.4) *the solution* $P(t)$, *given constructively by* (1.19), *of the DRE* (1.21) *and of the terminal condition* (1.39) *is unique within the class of self-adjoint operators* $\bar{P}(t)$ *such that*

$$\begin{array}{ll}(1.40) & \\ (1.41) & \end{array} \quad B^*\bar{P}(t)x \in \begin{cases} C_\gamma([0, T]; U) & \text{if } 0 \leqq \gamma < \frac{1}{2}, \quad \text{where } \beta = 0, \\ C_{1-\gamma-\varepsilon}([0, T]; U) & \text{if } \frac{1}{2} \leqq \gamma < 1, \end{cases}$$

If we assume further smoothing properties on G, we obtain, accordingly, more regular results. In particular, now u^0 becomes continuous as well. We recover results of [F.1], which were obtained via the "direct" approach.

THEOREM 1.3. *Under the assumption* (*which* a fortiori *implies that* $GL_T \in \mathscr{L}(L_2(0, T; U), Z)$)

$$(-A^*)^\gamma G^*G \in \mathscr{L}(Y), \tag{1.42}$$

which is stronger than assumption (1.33) *since* $2\gamma - 1 < \gamma$, *additional regularity results hold true, namely* (*see* (6.54))

(1.43) (i) $$|u^0(\cdot, s; x)|_{C([s,T];U)} \leqq c_T|x|_Y, \qquad x \in Y;$$

(ii) *For any* $0 \leqq \theta < 1$, $A^*P(\cdot) \in \mathscr{L}(Y; C_{\theta-\gamma}([0, T]; Y))$ (*see* (6.55)),

$$|(-A^*)^\theta P(t)|_{\mathscr{L}(Y)} \leqq \frac{C_T}{1-\theta} \frac{1}{(T-t)^{\theta-\gamma}}; \tag{1.44}$$

(1.45) (iii) $$B^*P(\cdot) \in \mathscr{L}(Y; C[0, T]; U) \qquad (\textit{see } (6.56)).$$

1.3. Literature. We shall concentrate here only on the case where e^{At} is analytic and where B is genuinely unbounded, particularly in the mathematically more demanding and physically more interesting range $\frac{1}{2}<\gamma<1$. (In the case $0<\gamma<\frac{1}{2}$, or even $\gamma=\frac{1}{2}$ if the generator A is, say, self-adjoint or normal, the analysis drastically simplifies and it technically reduces to the case $\gamma=0$ where B is then bounded, $B\in\mathscr{L}(U, Y)$: this is so, since then the operator L in (1.6) is continuous $L_2(0, T; U)\to C([0, T]; Y)$[DS], [L1, Appendix A]. This mildly unbounded case $\gamma<\frac{1}{2}$ where, moreover, G is very smoothing, essentially $(A^*)^{-1}$, is treated in [P−S]. A preliminary study via semigroup theory for a parabolic problem with $G=0$ was carried out in [B2]. The presence of the penalization operator G in (1.3) introduces additional genuine difficulties. Qualitatively, the analyticity of e^{At} tends "to compensate" the effects of the unboundedness of B on any interval of the type $[0, T-\varepsilon]$, $\forall\varepsilon>0$ small. Instead, the presence of a *non-smoothing* operator G produces a singularity at $t=T$ for $\{L_T^*G^*G\,e^{AT}x\}(t)=B^*\,e^{A^*(T-t)}G^*Ge^{AT}x$, which occurs in the explicit formula (1.10) for the optimal $u^0(t, 0; x)$. In [L-T1], the optimal control problem (1.4) was studied in several directions (from the regularity of the optimal pair to the synthesis thereof via a Riccati operator) in the case of a general second-order parabolic equation defined on a bounded domain Ω of R^n with Dirichlet boundary control, where the constant γ in (1.2) is $\gamma=\frac{3}{4}+\varepsilon$, $\varepsilon>0$[T], [L]. Moreover, in [L-T1], the operator G was taken to be the identity $G=I$ (with $Z=Y$), certainly a nonsmoothing case. The variational approach (from the optimal control problem to the Riccati equation) introduced in [L-T1] is explicit and constructive in the sense that: first, the optimal pair u^0, y^0 is characterized solely in terms of the data of the problem (see (1.10), (1.11)); next, an operator $P(t)$ is constructed (see (1.19)) in terms of original and optimal evolution, hence, ultimately in terms of the original data of the problem; finally, the operator $P(t)$ is shown to satisfy the DRE and its limiting condition as $t\uparrow T$.

Another approach, in a sense the converse of the first, so-called "direct" (as it proceeds in reverse from a direct study of the well-posedness of the Riccati Equation to the optimal control problem via dynamic programming) is proposed in [F1], [D-I], following [D]. Here, the operator G is taken to be "smoothing" for both the purposes of asserting a unique solution of the Riccati Equation (by local contraction argument and global a priori bound), as well as for the limiting condition as $t\uparrow T$. In these references, smoothing assumptions on G are (1.33) for [D-I] and (1.42) for [F1], in which cases existence and uniqueness of the solution to the DRE is asserted. In a more recent work [F2], the direct study of the Riccati Equation for existence (not for uniqueness) is carried out in the nonsmoothing case $G=$ Identity under the crucial assumption that A be dissipative, which then yields strong convergence of $P(t)$ to G^*G as $t\uparrow T$. An even more recent and almost contemporaneous work on the direct study of the Riccati Equation for existence (not for uniqueness) in the nonsmoothing case for G is [F4]. Instead of assuming that GL_T is closed (closeable)—a natural hypothesis on G in the variational approach of the present paper—[F4] makes the following assumption on G, say in the case $G\in\mathscr{L}(Y, Z)$:

There exists a sequence $G_n\in\mathscr{L}(Y, Z)$ of operators such that (a) there exists $\beta>2\gamma-1$ such that each G_n satisfies the assumption $G_n(-A)^{\beta/2}\in\mathscr{L}(Y, Z)$;

(b) $\{G_n^*G_n\}$ is a nondecreasing family of self-adjoint operators which converges monotonically to G^*G in the sense that as $n\to\infty$:

$$(G_n^*G_nx, x)_Y=\|G_nx\|^2\uparrow(G^*Gx, x)_Y=\|Gx\|_Z^2,\qquad\forall x\in Y. \tag{1.46}$$

Under this assumption (1.46), [F4, Thm. 3.2] shows existence of a solution $P(t)$ of the DRE (1.21) (with $d/dt(P(t)x, y)_Y$ on the left side), which satisfies the regularity properties (1.13) and (1.14), among others, as in Theorem 1.1 above. In addition, [F4] obtains also the strong convergence of $P(t) \to G^*G$ as $t \uparrow T$ (versus weak convergence in (1.29)), because of the postulated monotonic approximation property (b). We shall see in § 7.3 that assumption (1.46) in [F4]—which does not invoke B, only A and G—is stronger than the assumption GL_T closeable of our Theorem 1.1, which involves B.

The question was also raised as to whether the approach of [L-T1] could be extended to include a general nonsmoothing G, not just the identity. This paper is in response to this query.

The present contribution offers the most general treatment to date of the optimal control problem (1.4) for the dynamics (1.1) in the analytic case. This, in particular, includes the following.

(i) The relaxation of regularity assumptions on the (say, bounded) operator G of terminal state penalization (see also Remark 7.3 pointing out the applicability of our treatment—as well as that of [F4]—also to the case where G is unbounded, say $G \in \mathscr{L}(\mathscr{D}((-A)^\rho), Z)$, $\rho > 0$);

(ii) Sharpness of estimates on the behavior of the various relevant quantities u^0, y^0, $B^*P(t)$, $(-A^*)^\theta P(t)$, etc., in the neighborhood of T.

Moreover, the results of our Theorem 1.1—which are based only on the assumption that GL_T be closeable—are sharp: this is confirmed by the classes of counterexamples of § 7.3, where in fact, GL_T is not closeable and the optimal control does not exist.

In the process of restudying the optimal control problem (1.4) for the abstract equation (1.1) with a general G, we also dispense altogether with the assumption that the resolvent of A be compact (which was automatically satisfied and used in [L-T1], and likewise also in [F2]), thus incorporating in the treatment, in particular, Kelvin-Voigt models of plates, where the resolvent is not compact. Moreover, we recover through our variational approach the smoothing cases (1.33) and (1.42) of [D-I] and [F1], which were originally obtained by the direct approach.

We generally follow the variational approach of [L-T1] and incorporate an idea of [D-I] to quantitatively describe the singularity of the various quantities at $t = T$ via the Banach spaces defined in (1.26).

2. Preliminaries.

2.1. Explicit representation formulas for the optimal pair $\{u^0, y^0\}$. Following [L-T1] we shall collect here some preliminary results, culminating with the representation formulas of the optimal pair $\{u^0, y^0\}$. The solution to (1.1) with initial datum $y_s \in Y$ at initial time s, $0 \leqq s \leqq t \leqq T$, is given by (see (1.5), (1.6) for $s = 0$, where $L = L_0$)

$$(2.1)\qquad y(t, s; y_s) = e^{A(t-s)}y_s + (L_s u)(t),$$

$$(2.2)\qquad (L_s u)(t) = \int_s^t e^{A(t-\tau)}Bu(\tau)\, d\tau$$

(2.3a) : continuous $L_2(s, T; U) \to L_2(s, T; \mathscr{D}((-A)^{1-\gamma}))$ with operator norm uniform with respect to $s, 0 \leqq s \leqq T$;

that is

$$(2.3b)\qquad |L_s u|_{L_2(s,T;\mathscr{D}((-A)^{1-\gamma}))} \leqq K_{T\gamma}|u|_{L_2(s,T;U)},$$

where $K_{T\gamma}$ does not depend on s, $0 \leqq s \leqq T$. The continuity expressed by (2.3a, b) is a consequence of the basic assumption (1.2) on B, as well as of the standard result:

$$f \to \int_0^t A\, e^{A(t-\tau)}f(\tau)\, d\tau : L_2(0, T; Y) \to L_2(0, T; Y)$$

[DS], [L; Appendix A]. The adjoint operator $L_s^*:(L_s u, f)_{L_2(s,T;Y)}=(u, L_s^* f)_{L_2(s,T;U)}$ is given by (see (1.7) for $s=0$, where $L^*=L_0^*$)

$$(L_s^* f)(t)=\int_t^T B^* e^{A^*(\tau-t)} f(\tau)\, d\tau, \qquad s \leqq t \leqq T \tag{2.4}$$

(2.5a) : continuous $L_2(s, T; [\mathscr{D}((-A)^{1-\gamma})]') \to L_2(s, T; U)$ with operator norm uniform in $s: 0 \leqq s \leqq T$

(2.5b) : continuous $L_\infty(s, T; [\mathscr{D}((-A)^{\theta})]') \to C([s, T]; U)$ for $\gamma+\theta<1$, with operator norm uniform with respect to $s, 0 \leqq s \leqq T$;

that is,

$$|L_s^* f|_{C([s, T]; U)} \leqq K_{T\gamma} |f|_{L_\infty(s,T;[\mathscr{D}((-A)^\theta)]')}. \tag{2.5c}$$

Other regularity results for L_s and L_s^* will be given in Theorem 3.3 below. We shall also need the (unbounded) operator L_{sT} (see (1.8) for $s=0$, where $L_T=L_{0T}$)

$$L_{sT} u=(L_s u)(T)=\int_s^T e^{A(T-t)} B u(t)\, dt \tag{2.6}$$

with domain $\mathscr{D}(L_{sT})=\{u \in L_2(s, T; U): L_{sT} u \in Y\}$, and its adjoint $L_{sT}^*:(L_{sT} u, y)_Y=(u, L_{sT}^* y)_{L_2(s,T;U)}$ given by (see (1.9) for $s=0: L_T^*=L_{0T}^*$)

$$\{L_{sT}^* y\}(t)=B^* e^{A^*(T-t)} y, \qquad s \leqq t \leqq T, \tag{2.7}$$

which is unbounded from $Y \supset \mathscr{D}(L_{sT}^*)$ into $L_2(s, T; U)$. We note that $H^1(s, T; U) \subset \mathscr{D}(L_{sT})$, so that $\mathscr{D}(L_{sT})$ is dense in $L_2(s, T; U)$ and that L_{sT} is a closed operator. Next, by using the assumption that GL_T is closed (closeable), we shall convert $\mathscr{D}(GL_{sT})$ into a Hilbert space $V(s, T; U)$ equipped with the following inner product

$$(u, v)_{V(s,T;U)}=(u, v)_{L_2(s,T;U)}+(GL_{sT} u, GL_{sT} v)_Z \tag{2.8}$$

for $u, v \in \mathscr{D}(GL_{sT})$. Let $[V(s, T; U)]'$ denote the dual space of $V(s, T; U)$ with respect to $L_2(s, T; U)$ as pivot space:

$$V(s, T; U) \subset L_2(s, T; U) \subset [V(s, T; U)]' \tag{2.9a}$$

with continuous injections (from (2.8)),

$$|u|_{[V(s,T;U)]'} \leqq |u|_{L_2(s,T;U)} \leqq |u|_{V(s,T;U)} \tag{2.9b}$$

We now introduce the (unbounded) operator

$$\Lambda_{sT} \equiv I_s+L_s^* R^* R L_s+L_{sT}^* G^* G L_{sT} \tag{2.10a}$$

(2.10b) : continuous $L_2(s, T; U) \supset \mathscr{D}(\Lambda_{sT}) \to L_2(s, T; Y)$.

Using (2.3a) and (2.10), we readily verify via (2.8) that

$$|(\Lambda_{sT} u, v)_{L_2(s,T;U)}| \leqq M_{T\gamma} |u|_{V(s,T;U)} |v|_{V(s,T;U)}, \tag{2.11}$$

$$(\Lambda_{sT} u, u)_{L_2(s,T;U)} \geqq |u|_{V(s,T;U)}^2, \tag{2.12}$$

with constant $M_{T\gamma}$ independent on $s, 0 \leqq s \leqq T$, by (2.3a, b). Then, by (2.11) and (2.12), the Lax-Milgram theorem applies, and we can extend Λ_{sT} as

(2.13) Λ_{sT}: isomorphism $V(s, T; U)$ onto $[V(s, T; U)]'$

so that in particular,

$$|\Lambda_{sT}^{-1} v|_{V(s,T;U)} \leqq C_T |v|_{[V(s,T;U)]'} \tag{2.14}$$

with constant C_T independent of s, $0 \leqq s \leqq T$. From (2.8), we obtain

$$|GL_{sT}|_{\mathscr{L}(V(s,T;U);Z)} = |L_{sT}^* G^*|_{\mathscr{L}(Z;[V(s,T;U)]')} \leqq 1. \tag{2.15}$$

We now return to the optimal control problem (1.3), except that we shall consider it over the time interval $[s, T]$, with initial time $t = s$, rather than $t = 0$; $0 \leqq s < T$, and initial datum x. We shall call $\{u^0(\cdot, s; x)$ and $y^0(\cdot, s; x)\}$ the corresponding unique optimal pair. By standard minimization approaches (e.g., Lagrange multipliers, or direct computation, etc.), the following explicit characterization of the optimal pair can be derived [L-T1]:

$$-u^0(\cdot, s; x) = L_s^* R^* R y^0(\cdot, s; x) + L_{sT}^* G^* G y^0(T, s; x), \tag{2.16}$$

$$-u^0(\cdot, s; x) = \Lambda_{sT}^{-1}[L_{sT}^* G^* G\, e^{A(T-s)}x + L_s^* R^* R\, e^{A(\cdot - s)}x] \in V(s, T; U), \tag{2.17}$$

where we note that the element in the square bracket in (2.17) belongs, say, to $[V(s, T; U)]'$ so that (2.17) is well defined by (2.13). In going from (2.16) to (2.17) we have used the optimal dynamics

$$y^0(t, s; x) = e^{A(t-s)}x + \{L_s u^0(\cdot, s; x)\}(t) \tag{2.18}$$

for both $y^0(\cdot, s; x)$ and $y^0(T, s; x)$ in (2.16). Note that u^0 in (2.17), and hence y^0 in (2.18), are given explicitly in terms of the data of the problem.

2.2. L_2-estimates for $\{u^0, y^0\}$ and Z-estimate for $Gy^0(T; \cdot\,; x)$.

Proposition 2.1. *With reference to the optimal pair* $\{u^0(\cdot, s; x), y^0(\cdot, s; x)\}$, *we have*

$$\text{(i)} \quad |u^0(\cdot, s; x)|_{L_2(s,T;U)} \leqq |u^0(\cdot, s; x)|_{V(s,T;U)} \leqq C_T |x|_Y; \tag{2.19}$$

$$\text{(ii)} \quad |y^0(\cdot, s; x)|_{L_2(s,T;Y)} \leqq C_T |x|_Y; \tag{2.20}$$

$$\text{(iii)} \quad |Gy^0(T, s; x)|_Z \leqq C_T |x|_Y \tag{2.21}$$

with C_T a generic constant independent of s, $0 \leqq s \leqq T$.

Proof. (i) From (2.17) we compute via (2.9b), (2.14), (2.15), and (2.5a),

$$\begin{aligned}
|u^0(\cdot, s; x)|_{L_2(s,T;U)} &\leqq |u^0(\cdot, s; x)|_{V(s,T;U)} \\
&\leqq C_T |L_{sT}^* G^* G\, e^{A(T-s)}x + L_s^* R^* R\, e^{A(\cdot - s)}x|_{[V(s,T;U)]'} \qquad \text{(by (2.14))} \\
&\leqq C_T\{|G\, e^{A(T-s)}x|_Z + |L_s^* R^* R\, e^{A(\cdot - s)}x|_{L_2(s,T;U)}\} \qquad \text{(by (2.15), (2.9b))} \\
&\leqq C_T |x|_Y \qquad \text{(by (2.5a))}.
\end{aligned} \tag{2.22}$$

(ii) Inequality (2.20) follows then from the optimal dynamics (2.18) via (2.3) and inequality (2.19) established in (i).

(iii) From (2.18) we have for $t = T$ via (2.6),

$$Gy^0(T. s; x) = G\, e^{A(T-s)}x + GL_{sT}u^0(\cdot, s; x). \tag{2.23}$$

Then, inequality (2.21) follows from (2.23) via (2.15) (left) and (2.19) (right), with u^0 in $V(s, T; U)$. □

2.3. Definition of operator $P(t)$ and first properties. Following [L-T1], we next define the operator $P(t) \in \mathscr{L}(Y)$, $0 \leqq t < T$, by

$$P(t)x = \int_t^T e^{A^*(\tau - t)} R^* R y^0(\tau, t; x)\, d\tau + e^{A^*(T-t)} G^* G y^0(T, t; x). \tag{2.24}$$

$P(t)$ in (2.24) is defined explicitly in terms of the data of the problem, since y^0 is also, as remarked below (2.18).

It is convenient to introduce the (evolution) operator $\Phi(t, s)$,

$$\Phi(t, s)x = y^0(t, s; x), \quad x \in Y, \quad 0 \leqq s \leqq t \leqq T, \tag{2.25a}$$

which plainly satisfies

$$\Phi(t, t) = \text{Identity:} \quad \Phi(t, \tau)\Phi(\tau, s) = \Phi(t, s), \quad 0 \leqq s \leqq \tau \leqq t \leqq T. \tag{2.25b}$$

Further properties of $\Phi(\cdot, \cdot)$ will be collected in Lemma 4.3. We rewrite (2.24) via (2.25a) as

$$P(t)x = \int_t^T e^{A^*(\tau - t)} R^* R \Phi(\tau, t)x \, d\tau + e^{A^*(T-t)} G^* G \Phi(T, t)x. \tag{2.26}$$

PROPOSITION 2.2. *With reference to* (2.24), *we have*

$$\text{(i)} \qquad P(t) \in \mathscr{L}(Y; L_\infty(0, T; Y)) \tag{2.27}$$

$$\text{(ii)} \qquad -u^0(t, 0; x) = B^* P(t) y^0(t, 0; x), \quad 0 \leqq t < T; \quad x \in Y. \tag{2.28}$$

Proof. (i) Property (2.27) follows from (2.24) via the regularity properties (2.20) and (2.21) of Proposition 2.1. It may be boosted to $P(t) \in \mathscr{L}(Y; C([0, T]; Y))$, using the properties of Lemma 4.3(iii) (as done in the proof of Proposition 4.6).

(ii) As usual [L-T1], we rewrite (2.16) explicitly by virtue of (2.4), (2.7), and (2.25a),

$$\begin{aligned} -u^0(t, s; x) = \int_t^T & B^* \, e^{A^*(\tau - t)} R^* R \Phi(\tau, s)x \, d\tau \\ & + B^* \, e^{A^*(T-t)} G^* G \Phi(T, s)x. \end{aligned} \tag{2.29}$$

Choosing initial time s equal to t with corresponding initial datum $y^0(t, 0; x) = \Phi(t, 0)x$, we obtain (2.28) from (2.29) via (2.26) and (2.25b). □

We note that, by virtue of (2.28), the optimal dynamics (2.18) can be explicitly rewritten as

$$y^0(t, s; x) = e^{A(t-s)}x - \int_s^t e^{A(t-\tau)} BB^* y^0(\tau, s; x) \, d\tau; \tag{2.30a}$$

$$\Phi(t, s)x = e^{A(t-s)}x - \int_s^t e^{A(t-\tau)} BB^* \Phi(\tau, s)x \, d\tau. \tag{2.30b}$$

3. Pointwise estimates for $u^0(t, s; x)$, $y^0(t, s; x)$, and $P(t)$. Let X be a Hilbert space and let r be a real number. Following [D-I], we introduce the Banach space $C_r([s, T]; X)$ defined by

$$\begin{aligned} C_r([s, T]; X) = \Big\{ & f(t) \in C([s, T); X): \\ & |f|_{C_r([s, T]; X)} = \sup_{s \leqq t < T} (T - t)^r |f(t)|_X < \infty \Big\}. \end{aligned} \tag{3.1}$$

In the interesting case $r > 0$, r measures the singularity of $f(t)$ at $t \to T$. Note that $C_r([s, T]; X) \subset L_q(s, T; X)$ for $rq < 1$.

PROPOSITION 3.1. *With reference to the operators L_s and L_s^* of* (2.2) *and* (2.4), *we have*

(i) *For $r+\gamma<1$, L_s: continuous $C_r([s, T]; U) \to C([s, T]; Y)$:*

$$|L_s u|_{C([s,T];Y)} \leqq \frac{C_{T,\gamma}}{1-(\gamma+r)}(T-s)^{1-(\gamma+r)}|u|_{C_r([s,T];U)}, \tag{3.2}$$

so that the bound in (3.2) *may be made independent of s, $0 \leqq s \leqq T$;*

(ii) *For $r+\gamma \geqq 1$ and $\varepsilon>0$ arbitrary,*

$$L_s\text{: continuous } C_r([s, T]; U) \to C_{r+\gamma-1+\varepsilon}([s, T]; Y);$$

$$|L_s u|_{C_{r+\gamma-1+\varepsilon}([s,T];Y)} \leqq \frac{C_{T\gamma}}{\varepsilon}(T-s)^{\varepsilon}|u|_{C_r([s,T];U)}, \tag{3.3}$$

so that the bound in (3.3) *may be made independent of s, $0 \leqq s \leqq T$;*

(iii) *For $0 \leqq r < 1$,*

$$L_s^*\text{: continuous } C_r([s, T]; Y) \to C_{r+\gamma-1}([s, T]; U),$$

$$|L_s^* f|_{C_{r+\gamma-1}([s,T];U)} \leqq C_{T\gamma} 2^{r+\gamma-1} \max\left\{\frac{1}{1-r}, \frac{1}{1-\gamma}\right\}|f|_{C_r([s,T];Y)}, \tag{3.4}$$

so that the uniform norm is independent of s, $0 \leqq s \leqq T$.

Proof. We first note that $(L_s u)(t) \in C([s, T); Y)$ and $(L_s^* f)(t) \in C([s, T); U)$.

(i), (ii). By (2.2), assumption (1.2) on B, and the analyticity of e^{At},

$$\begin{aligned} |(L_s u)(t)|_Y &= \left|\int_s^t (-A)^\gamma e^{A(t-\tau)}(-A)^{-\gamma} B u(\tau)\, d\tau\right|_Y \\ &\leqq C_{T\gamma} \int_s^t \frac{|u(\tau)|_U (T-\tau)^r}{(t-\tau)^\gamma (T-\tau)^r}\, d\tau \\ &\leqq C_{T\gamma} |u|_{C_r([s,T];U)} \int_s^t \frac{d\tau}{(t-\tau)^\gamma (T-\tau)^r} \qquad \text{(by (3.1)).} \end{aligned} \tag{3.5}$$

For any $r \geqq 0$, we use $(T-\tau)^r \geqq (t-\tau)^r$ in the last integral in (3.5) so that

$$|(L_s u)(t)|_Y \leqq C_{T\gamma}|u|_{C_r([s,T];U)} \frac{(t-s)^{1-(\gamma+r)}}{1-(\gamma+r)}, \tag{3.6}$$

for $r+\gamma<1$ as assumed, and (3.6) yields (3.2) as desired.

For $r+\gamma \geqq 1$, we write using $(T-\tau)^{1-\gamma-\varepsilon} \geqq (t-\tau)^{1-\gamma-\varepsilon}$ and $(T-\tau)^{r+\gamma-1+\varepsilon} \geqq (T-t)^{r+\gamma-1+\varepsilon}$:

$$\begin{aligned} \int_s^t \frac{d\tau}{(t-\tau)^\gamma (T-\tau)^r} &= \int_s^t \frac{d\tau}{(t-\tau)^\gamma (T-\tau)^{1-\gamma-\varepsilon} (T-\tau)^{r+\gamma-1+\varepsilon}} \\ &\leqq \frac{1}{(T-t)^{r+\gamma-1+\varepsilon}} \int_s^t \frac{d\tau}{(t-\tau)^{1-\varepsilon}} \\ &= \frac{(t-s)^\varepsilon}{\varepsilon (T-t)^{r+\gamma-1+\varepsilon}}. \end{aligned} \tag{3.7}$$

Then (3.7) used in (3.5) yields (3.3) as desired, via (3.1).

(iii) By (2.4), assumption (1.2) on B, and analyticity,

$$|(L_s^*f)(t)|_U = \left| \int_t^T B^*(-A^*)^{-\gamma}(-A^*)^{\gamma} e^{A^*(\tau-t)} f(\tau)\, d\tau \right|_U$$

(by (3.1))
$$\leqq C_{T\gamma} \int_t^T \frac{|f(\tau)|_Y (T-\tau)^r}{(\tau-t)^{\gamma}(T-\tau)^r}\, d\tau$$

$$\leqq C_{T\gamma} |f|_{C_r([s,T];Y)}$$
$$\cdot \left\{ \int_t^{t+(T-t)/2} \frac{d\tau}{(\tau-t)^{\gamma}(T-\tau)^r} + \int_{t+(T-t)/2}^T \frac{d\tau}{(\tau-t)^{\gamma}(T-\tau)^r} \right\}$$

(using $T-\tau \geqq (T-t)/2$ in the first integral, and $(\tau-t) \geqq (T-t)/2$ in the second integral with $0 \leqq r < 1$),

$$\leqq C_{T\gamma} |f|_{C_r([s,T];Y)}$$
$$\cdot \left\{ \left(\frac{2}{T-t}\right)^r \left(\frac{T-t}{2}\right)^{1-\gamma} \frac{1}{1-\gamma} + \left(\frac{2}{T-t}\right)^{\gamma} \left(\frac{T-t}{2}\right)^{1-r} \frac{1}{1-r} \right\}$$

$$|(L_s^*f)(t)|_U \leqq C_{T\gamma} 2^{r+\gamma-1} \max\left\{\frac{1}{1-\gamma}, \frac{1}{1-r}\right\} \frac{1}{(T-t)^{r+\gamma-1}} |f|_{C_r([s,T];Y)}, \tag{3.8}$$

and (3.8) yields (3.4) via (3.1), as desired. □

Proposition 3.1 says that L_s and L_s^* are smoothing operators: L_s (respectively, L_s^*) reduces the order of the singularity from r to zero if $r+\gamma<1$, and from r to $r+(\gamma-1+\varepsilon)$ if $r+\gamma \geqq 1$ (respectively, to $r+(\gamma-1)$).

COROLLARY 3.2. *Given* $0<\gamma<1$, *there exists a positive integer* $n_0 = n_0(\gamma)$ *such that for all positive integers* $n \geqq n_0(\gamma)$ *we have*

$$(L_s^* R^* R L_s)^n\text{: continuous } C_{\gamma}([s, T]; U) \to C([s, T]; U) \tag{3.9}$$

$$(L_s^* R^* R L_s)^n v|_{C([s,T];U)} \leqq C_T |v|_{C_{\gamma}([s,T];U)}, \tag{3.10}$$

with uniform norm bound which may be taken independent of s, $0 \leqq s \leqq T$.

Proof. The results of Proposition 3.1 are applied, recursively, with R^* and R bounded. After n_0-iterations, a space $C_r([s,T];U)$ is obtained with $r \leqq 0$. Details are omitted. □

THEOREM 3.3. *With reference to the operators* L_s *and* L_s^* *in* (2.2), (2.4) *we have*:

(3.11) (i) L_s: *continuous* $L_2(s, T; U) \to L_r(s, T; Y)$,

where r is an arbitrary positive number satisfying $r<2/(2\gamma-1)$, *where* $2/(2\gamma-1)>2$ *for* $\frac{1}{2}<\gamma<1$; *for* $0 \leqq \gamma \leqq \frac{1}{2}$ *we may take* $r=\infty$;

(3.12) (ii) L_s^*: *continuous* $L_r(s, T; Y) \to L_{r'}(s, T; U)$,

where r is as in (i), *and* r' *is any positive number satisfying* $r'<2/(4\gamma-3)$, *where* $2/(4\gamma-3)>r$ *for* $\frac{3}{4}<\gamma<1$; *for* $0<\gamma \leqq \frac{3}{4}$, *we may take* $r'=\infty$;

(iii) *For* $p>1/(1-\gamma)$,

$$L_s\text{: continuous } L_p(s, T; U) \to C([s, T]; Y). \tag{3.13}$$

(iv) *Thus, a fortiori, there exists a positive integer* $n_1 = n_1(\gamma)$ *such that*

$$(L_s^* R^* R L_s)^{n_1}\text{: continuous } L_2(s, T; U) \to C([s, T]; U). \tag{3.14}$$

We may take $n_1=1$ *if* $\gamma \leqq \frac{3}{4}$; *and* $n_1=2$ *if* $\frac{3}{4}<\gamma<\frac{5}{6}$; *etc.*

In all cases the operator norm has a bound which may be taken not to depend on s, $0 \leqq s \leqq T$.

Proof. The proof uses Young's inequality. For a similar (but not identical) situation, see, e.g., [L-T2, Lemma 4.2] (or [L-T3, Thm. 2.5]). Details are omitted. □

THEOREM 3.4. *The operator* $[I_s+L_s^*R^*RL_s]$ *is boundedly invertible on the space* $C_\gamma([s, T; U)$ *defined by* (3.1):

$$[I_s+L_s^*R^*RL_s]^{-1}\in\mathcal{L}(C_\gamma([s,T];U)) \tag{3.15}$$

with uniform norm bound which depends on T and γ, *but may be taken not to depend on* s, $0\leqq s\leqq T$.

Proof. Let $h\in C_\gamma([s,T];U)$. We seek a unique $g\in C_\gamma([s,T];U)$ such that

$$g+L_s^*R^*RL_sg=h. \tag{3.16}$$

To simplify the notation, we may take $R=I$ in the argument below.

Step 1. Given such h, if $n_0=n_0(\gamma)$ is the positive integer of Corollary 3.2, equation (3.9), then there exists a unique $v\in L_2(s,T;U)$ such that

$$v+L_s^*L_sv=(L_s^*L_s)^{n_0}h\in C([s,T];U)\subset L_2(s,T;U), \tag{3.17}$$

since $I_s+L_s^*L_s$ is boundedly invertible on $L_2(s,T;U)$.

Step 2. We shall show that, in fact,

$$v\in C([s,T];U). \tag{3.18}$$

In fact, if $n_1=1$ (i.e., $0\leqq\gamma\leqq\frac{3}{4}$) in (3.14) of Theorem 3.3, then $L_s^*L_sv\in C([s,T];U)$ and (3.17) yields (3.18). In general, we write from (3.17), with $r=0,1,\cdots,n_1-1$:

$$(L_s^*L_s)^rv+(L_s^*L_s)^{r+1}v=(L_s^*L_s)^{n_0+r}h\in C([s,T];U), \tag{3.19}$$

where the regularity on the right of (3.19) is a consequence of (3.13) via (3.17) (right). Starting from $r=n_1-1$ in (3.19), we first obtain $(L_s^*L_s)^{r+1}v=(L_s^*L_s)^{n_1}v\in C([s,T];U)$ by (3.14); hence $(L_s^*L_s)^{n_1-1}v\in C([s,T];U)$ by (3.19). Next, using this latter information in (3.19), this time with $r=n_1-2$, leads to $(L_s^*L_s)^{n_1-2}v\in C([s,T];U)$. By repeating this procedure a finite number of times, we arrive at (3.18), as desired.

Step 3. Starting from the given h and the v obtained in (3.17), we shall finally define a finite sequence of vectors called $g_{n_0-1}, g_{n_0-2}, g_{n_0-3},\cdots,g_1, g$, whose last element g will be precisely the sought-after unique solution of (3.16). We define recursively

$$\begin{aligned}
&(3.20_{n_0-1}) &\quad g_{n_0-1}&=(L_s^*L_s)^{n_0-1}h-v &\quad &\in C_\gamma([s,T];U)\\
&(3.20_{n_0-2}) &\quad g_{n_0-2}&=(L_s^*L_s)^{n_0-2}h-g_{n_0-1} &\quad &\in C_\gamma([s,T];U)\\
& & &\ \ \vdots & &\\
& &\quad g_1&=(L_s^*L_s)h-g_2 &\quad &\in C_\gamma([s,T];U)\\
&(3.20_0) &\quad g&=h-g_1 &\quad &\in C_\gamma([s,T];U).
\end{aligned}$$

The regularity noted on the right of (3.20_{n_0-1}) is a consequence of Proposition 3.1 applied to h and of (3.18). Then, recursively, the other regularity statements follow. In particular, $g\in C_\gamma([s,T];U)$. It is now an easy matter to show that such g is the unique sought-after solution of (3.16). Moreover, the bound on the uniform norm in (3.15) may be taken not to depend on s, $0\leqq s\leqq T$, since this is the case for L_s and L_s^* in Proposition 3.1 and Theorem 3.3. Theorem 3.4 is proved. □

The above results are now used to obtain pointwise estimates.

LEMMA 3.5. *With reference to the last term in* (2.16), *we have*

$$|L_{sT}^*G^*Gy^0(T,s;x)|_{C_\gamma([s,T];U)}\leqq C_{T\gamma}|x|_Y, \tag{3.21}$$

where the constant $C_{T\gamma}$ *does not depend on* s, $0\leqq s\leqq T$.

Proof. From the definition (2.7) of L_{sT}^* and the assumption (1.2) on B, we readily obtain

$$
\begin{aligned}
|L_{sT}^* G^* G y^0(T, s; x)|_U &= |B^*(-A^*)^{-\gamma}(-A^*)^{\gamma} e^{A^*(T-t)} G^* G y^0(T, s; x)|_U \\
&\leqq \frac{C_{T,\gamma}}{(T-t)^{\gamma}} |Gy^0(T, s; x)|_Z \leqq \frac{C_{T,\gamma}}{(T-t)^{\gamma}} |x|_Y,
\end{aligned} \tag{3.22}
$$

where in the last step we have used (2.21). Then (3.22) yields (3.21) via the definition (3.1). □

The major result of this section is the following.

THEOREM 3.6. *For the optimal pair* $\{u^0, y^0\}$, *we have with constant* $C_{T\gamma}$ *independent of* s, $0 \leqq s \leqq T$:

(i)

$$|u^0(\cdot, s; x)|_{C_\gamma([s,T]; U)} \leqq C_{T\gamma} |x|_Y; \tag{3.23}$$

(ii) *If* $0 \leqq \gamma < \frac{1}{2}$,

$$|y^0(\cdot, s; x)|_{C([s,T]; Y)} \leqq C_{T\gamma} |x|_Y; \tag{3.24a}$$

(iii) *If* $\frac{1}{2} \leqq \gamma < 1$,

$$|y^0(\cdot, s; x)|_{C_{2\gamma-1+\varepsilon}([s,T]; Y)} \leqq C_{T\gamma} |x|_Y, \quad \forall \varepsilon > 0. \tag{3.24b}$$

Proof. (i) We return to (2.16) where we now substitute for the optimal $y^0(\cdot, s; x)$ from (2.18), thus obtaining

$$-u^0(\cdot, s; x) = [I_s + L_s^* R^* R L_s]^{-1} \{L_s^* R^* R\, e^{A(\cdot - s)} x + L_{sT}^* G^* G y^0(T, s; x)\}. \tag{3.25}$$

In fact, the expression in the bracket { } in (3.25) is a well-defined element of $C_\gamma([s, T]; U)$ for $x \in Y$: this is so by (3.21) for its second term and is plainly true (a fortiori) from (2.5) for its first term. Moreover, the inverse in (3.25) is well defined in $C_\gamma([s, T]; U)$ by Theorem 3.4. Indeed, these results collectively yield the bound (3.23), independent of s.

(ii) Estimates (3.24a, b) now follow from estimate (3.23), via the optimal dynamics (2.18), where we use property (3.2) with $r = \gamma$ and $r + \gamma < 1$ for (3.24a), and property (3.3) with $r = \gamma$ and $r + \gamma \geqq 1$ for (3.24b). □

COROLLARY 3.7. *With reference to the operator* $P(t)$ *introduced in* (2.24), *we have the following pointwise estimates for* $s \leqq t < T$;

(i) For $0 \leqq \theta < 1$,

$$|(-A^*)^{\theta} P(t) x| \leqq \frac{C_{T\gamma\theta}}{(T-t)^{\theta}} |x|_Y, \tag{3.26}$$

(ii)

$$|B^* P(t) x| \leqq \frac{C_{T\gamma}}{(T-t)^{\gamma}} |x|_Y, \tag{3.27}$$

where the constant C_T does not depend on s, $0 \leqq s \leqq T$.

Proof. (i) Recalling (2.24) we compute by analyticity

$$
\begin{aligned}
|(-A^*)^{\theta} P(t) x|_Y &= \left| \int_t^T (-A^*)^{\theta} e^{A^*(\tau - t)} R^* R y^0(\tau, t; x)\, d\tau \right. \\
&\qquad \left. + (-A^*)^{\theta} e^{A^*(T-t)} G^* G y^0(T, t; x) \right|_Y \\
&\leqq C_T \int_t^T \frac{1}{(\tau - t)^{\theta}} |y^0(\tau, t; x)|_Y\, d\tau + \frac{C_T}{(T-t)^{\theta}} |Gy^0(T, t; x)|_Z
\end{aligned} \tag{3.28}
$$

$$\leqq C_T\left\{\int_t^T \frac{1}{(\tau-t)^\theta}|y^0(\tau,t;x)|_Y\,d\tau+\frac{1}{(T-t)^\theta}|x|_Y\right\},$$

where in the last step we have used estimate (2.21) for the second term. We now distinguish two cases according to (3.24a, b). If $\gamma<\frac{1}{2}$, then (3.24a) applies in (3.28), and (3.28) yields (3.26). If, instead, $\frac{1}{2}\leqq\gamma<1$, then (3.24b) applies in (3.28), and we obtain for the right-hand side (R.H.S.) of (3.28),

$$\text{(3.29)}\qquad \text{R.H.S. of (3.28)}\leqq C_T\left\{\int_t^T \frac{d\tau}{(\tau-t)^\theta(T-\tau)^{2\gamma-1+\varepsilon}}+\frac{1}{(T-t)^\theta}\right\}|x|_Y.$$

But the integral in (3.29) is the same as the one that occurs when estimating L_s^* in the proof of Proposition 3.1(iii), which culminates with the bound in (3.8), with γ, r there replaced by θ, $2\gamma-1+\varepsilon$ now. Thus, we obtain by (3.28), (3.29), via (3.8),

$$\begin{aligned}&|(-A^*)^\theta P(t)x|_Y\\ \text{(3.29)}\qquad &\leqq C_{T\gamma\theta}\left\{\max\left\{\frac{1}{1-\theta},\frac{1}{1-2\gamma-\varepsilon}\right\}\frac{1}{(T-t)^{2(\gamma-1)+\theta+\varepsilon}}+\frac{1}{(T-t)^\theta}\right\}|x|_Y,\end{aligned}$$

from which (3.26) follows, since $\gamma-1<0$.

(ii) Estimate (3.27) now follows from estimate (3.26) with $\theta=\gamma>\theta+\gamma-1$, via hypothesis (1.2) on B. □

Further properties of $P(t)$ are obtained next, as a consequence of (3.27).

PROPOSITION 3.8.

(i) *For $0\leqq t<T$, the following identity, symmetric in $x, y\in Y$, holds,*

$$\begin{aligned}(P(t)x,y)_Y&=\int_t^T (R\Phi(\tau,t)x,R\Phi(\tau,t)y)_W\,d\tau+(G\Phi(T,t)x,G\Phi(T,t)y)_Z\\ \text{(3.30)}\qquad&\quad+\int_t^T (B^*P(\tau)\Phi(\tau,t)x,B^*P(\tau)\Phi(\tau,t)y)_U\,d\tau.\end{aligned}$$

(ii) *As a consequence,*

$$\text{(3.31)}\qquad P(t)=P^*(t)\geqq 0.$$

(iii) *The optimal cost of the optimal control problem on $[t,T]$ initiating at the point $x\in Y$ at the initial time t is*

$$\begin{aligned}J^0&=J(u^0(\cdot,t;x),y^0(\cdot,t;x))\\ &=\int_t^T |R\Phi(\tau,t)x|_W^2+|B^*P(\tau)\Phi(\tau,t)x|_U^2\,d\tau+|G\Phi(T,t)x|_Z^2\\ \text{(3.32)}\qquad&=(P(t)x,x)_Y.\end{aligned}$$

Proof. (i) As in [L-T1, Prop. 3.3(iii)] we substitute for $e^{A(\tau-t)}y$ and $e^{A(T-t)}y$ occurring in

$$(P(t)x,y)_Y=\int_t^T (R\Phi(\tau,t)x,R\,e^{A(\tau-t)}y)_W\,d\tau+(G\Phi(T,t)x,G\,e^{A(T-t)}y)_Z,$$

the expression obtained from (2.30). Interchanging the order of integration and using that $B^*P(t)$ is well defined for $t<T$, by (3.27), yields (3.30). Details are omitted, see, e.g., [L-T1, Prop. 3.3]. Then (ii) and (iii) follow at once. □

4. Derivation of the Riccati equation (1.13). In this section, our main goal is to show that the operator $P(t) \in \mathscr{L}(Y; L_\infty(0, T; Y))$ explicitly defined by (2.24) in terms of the data of the problem, is a Riccati operator; i.e., it satisfies the Riccati equation (1.13). To accomplish this, we need part (i) of the next theorem; part (ii) will not be invoked in the sequel and is listed here for completeness.

THEOREM 4.1 [L-T1]. (i) *For $x \in Y$ and for each s fixed, $0 \leqq s < T$, the optimal control $u^0(t, s; x)$ and the optimal solution $y^0(t, s; x)$ are respectively U-valued and Y-valued functions which are differentiable in $t \in (s, T)$ with $(\partial u^0/\partial t)(t, s; x) \in U$, $(\partial y^0/\partial t)(t, s; x) \in Y$; see* [L-T5] *for sharp regularity results.*

(ii) *In fact, these U-valued and Y-valued functions $u^0(t, s; x)$ and $y^0(t, s; x)$ are analytic in $t \in (s, T)$ if the operator A has compact resolvent in Y.*

Remark 4.1. Although paper [L-T1] deals specifically with the case of a parabolic equation with Dirichlet boundary control and with $G = I$, its proof of the result in Theorem 4.1 is general. To assert analyticity as in part (ii), the proof uses the analyticity of e^{At}, the representation formula (3.25) for u^0, and the compactness of the resolvent operator of A. The idea (similar to the idea behind the proof of Theorem 3.4) is to assert the invertibility of the operator $[I_s + L_s^* R^* R L_s]$ on the space of U-valued functions ($\mathscr{A}(\mathscr{F}, L_2(\Gamma))$ in the notation of [L-T1]), which are (i) analytic (holomorphic) on a suitable set $\mathscr{F}$ of the complex variable z which contains the interval $(0, T)$, and (ii) continuous on $\bar{\mathscr{F}}$. The proof in [L-T1] works essentially verbatim for the general case.

We next introduce the operator

$$A_P(t) = A - BB^*P(t): \qquad Y \supset \mathscr{D}(A_P(t)) \to Y, \tag{4.1}$$

where $P(t)$ is defined by (2.24) and show that

LEMMA 4.2. *With reference to* (4.1), *we have, for $s \leqq t < T$,*

$$\mathscr{D}(A_P(t)) \subset \mathscr{D}((-A)^{1-\gamma}). \tag{4.2}$$

Proof. Let $x \in \mathscr{D}(A_P(t))$, i.e., $z(t) = A_P(t)x = [A - BB^*P(t)]x \in Y$,

$$-(-A)^\gamma[(-A)^{1-\gamma} + (-A)^{-\gamma}BB^*P(t)]x = z(t) \in Y. \tag{4.3}$$

But $(-A)^{-\gamma}BB^*P(t)x \in Y$ for $t < T$ by assumption (1.2) on B and by property (3.27) of Corollary 3.7. From here and (4.3), we then obtain that

$$(-A)^{1-\gamma}x = -(-A)^{-\gamma}z(t) - (-A)^{-\gamma}BB^*P(t)x \in Y, \tag{4.4}$$

which means that $x \in \mathscr{D}((-A)^{1-\gamma})$, as desired. □

We next recall the operator $\Phi(t, s) \in \mathscr{L}(Y)$, $0 \leqq s \leqq t < T$,

$$\Phi(t, s)x = y^0(t, s; x), \qquad x \in Y, \tag{4.5}$$

which is defined via (2.18), (2.17), solely in terms of the data of the problem. All the preceding results on $y^0(t, s; x)$ can be expressed in terms of $\Phi(t, s)$ via (4.5). In particular, we recall that the optimal dynamics is rewritten (see (2.30)) as

$$\Phi(t, s)x = e^{A(t-s)}x + \int_s^t e^{A(t-\tau)}Bu^0(\tau, s; x)\, d\tau \tag{4.6a}$$

$$= e^{A(t-s)}x + \int_s^t e^{A(t-\tau)}BB^*P(\tau)\Phi(\tau, s)x\, d\tau. \tag{4.6b}$$

In the next two lemmas, we collect some properties of Φ, which in the case of the heat equation were proved in [L-T1].

LEMMA 4.3 [L-T1, Prop. 3.2].

(i) $\Phi(t, t) =$ *identity, and* $\Phi(t, \tau)\Phi(\tau, s) = \Phi(t, s)$ *for* $0 \leqq s \leqq \tau \leqq t < T$ (*transitivity*).

(ii) *For s fixed, the map* $t \to \Phi(t, s)x$ *is continuous in* Y, $s \leqq t < T$, $x \in Y$.

(iii) *For $t < T$ fixed, the map* $s \to \Phi(t, s)x$ *is continuous in* Y, $0 \leqq s \leqq t < T$, $x \in Y$.

(iv) *The map* $s \to G\Phi(T, s)x$ *is continuous in* Z, $0 \leqq s < T$, $x \in Y$.

(v) *For* $0 \leqq s < t < \tau < T$, *the following identity holds for* $x \in Y$:

$$\frac{\partial \Phi(\tau, t)}{\partial t} \Phi(t, s)x = -\Phi(\tau, t) \frac{\partial \Phi}{\partial t}(t, s)x \in Y. \tag{4.7}$$

(vi) *For* $0 \leqq s < t < T$, *the following identity holds for* $x \in Y$

$$\frac{\partial G(T, t)}{\partial t} \Phi(t, s)x = -G\Phi(T, t) \frac{\partial \Phi}{\partial t}(t, s)x \in Y. \tag{4.8}$$

(We note that (4.7), and (4.8) reduce the derivative of Φ and $G\Phi$ in the second argument, computed along the optimal trajectory, $\Phi(t, s)x$, in terms of the derivative of Φ in the first argument.)

(vii) *For* $0 \leqq s < t < T$ *and* $x \in Y$ *we have* $\Phi(t, s)x \in \mathscr{D}((-A)^\theta)$ *with* $\theta < 1 - \gamma$; *moreover, for* $x \in \mathscr{D}((-A)^\theta)$ *we have*

$$\lim_{s \uparrow t} (-A)^\theta \Phi(t, s)x = (-A)^\theta x. \tag{4.10}$$

Proof. (ii) This is a restatement of the result contained in (3.24) of Theorem 3.6 and a fortiori in Theorem 4.1(i).

(iii) For right continuity, we choose $h > 0$ such that $s < s + h \leqq t < T$;

$$\begin{aligned} |\Phi(t, s+h)x - \Phi(t, s)x| &= |\Phi(t, s+h)[x - \Phi(s+h, s)x]| \\ &\leqq \frac{C_T}{(T-t)^r} |\Phi(s+h, s)x - x| \to 0, \end{aligned} \tag{4.11}$$

where in the last step we have used (3.24) via (4.5) with $r = 2\gamma - 1 + \varepsilon$. Then the right-hand side of (4.11) goes to zero as $h \downarrow 0$ by (ii). As to the left continuity, we compute for $h > 0$, again by (3.24) via (4.5):

$$\begin{aligned} |\Phi(t, s-h)x - \Phi(t, s)x| &= |\Phi(t, s)[\Phi(s, s-h)x - x]| \\ &\leqq \frac{C_T}{(T-t)^r} |\Phi(s, s-h)x - x| \to 0, \end{aligned} \tag{4.12}$$

where the right-hand side of (4.12) goes to zero as $h \downarrow 0$ by

$$|\Phi(s, s-h)x - x| \leqq |e^{Ah}x - x| + \int_{s-h}^{s} |e^{A(s-\tau)}(-A)^\gamma A^{-\gamma} Bu^0(\tau, s-h; x)| \, d\tau, \tag{4.13}$$

which follows from (4.6) where (3.23) of Theorem 3.6 is used in (4.13).

(iv) The case $t = T$ is reduced to case (iii); for $|h|$ sufficiently small and $s + h < t < T$:

$$\begin{aligned} |G(\Phi(T, s+h)x - G\Phi(T, s)x| &= |G\Phi(T, t)[\Phi(t, s+h)x - \Phi(t, s)x]| \\ &\leqq C_T |\Phi(t, s+h)x - \Phi(t, s)x| \to 0, \end{aligned} \tag{4.14}$$

where we have used (2.21) of Proposition 2.1, and the right-hand side of (4.14) goes to zero as $h \to 0$ by part (iii).

(v) For $|h|$ sufficiently small so that $0 \leqq s < t+h < \tau < T$ and $s < t < \tau$, we compute for $x \in Y$,

$$\tag{4.15} \begin{aligned} &\frac{1}{h}[\Phi(\tau, t+h)\Phi(t, s)x - \Phi(\tau, t)\Phi(t, s)x] \\ &\qquad = \Phi(\tau, t+h)\frac{1}{h}[\Phi(t, s)x - \Phi(t+h, s)x]. \end{aligned}$$

But since $\partial\Phi(t, s)x/\partial t$ exists in Y by Theorem 4.1(i), we have for the right-hand side of (4.15),

$$\tag{4.16} \begin{aligned} &\Phi(\tau, t+h)\frac{1}{h}[\Phi(t+h, s)x - \Phi(t, s)x] - \Phi(\tau, t)\frac{\partial\Phi}{\partial t}(t, s)x \\ &\quad = \Phi(\tau, t+h)\left\{\frac{1}{h}[\Phi(t+h, s)x - \Phi(t, s)x] - \frac{\partial\Phi}{\partial t}(t, s)x\right\} \\ &\qquad + [\Phi(\tau, t+h) - \Phi(\tau, t)]\frac{\partial\Phi}{\partial t}(t, s)x \to 0 \quad \text{as } h \to 0. \end{aligned}$$

But $\Phi(\tau, t+h)$ is strongly continuous in h (property (iii)) and hence uniformly bounded in h in the $\mathscr{L}(Y)$-norm by the Principle of Uniform Boundedness: then the right-hand side of (4.16) goes to zero as $h \to 0$, and (4.7) is proved via (4.15).

(vi) The proof of (4.8) is similar to the one in (4.15) and (4.16) and uses the fact that $G\Phi(T, t+h)$ is strongly continuous in h for $t < T$ (property (iv)) and hence uniformly bounded in h in the $\mathscr{L}(Z)$-norm.

(vii) From (4.6) we have for $s < t < T$,

$$\tag{4.17} \begin{aligned} (-A)^\theta\Phi(t, s)x &= (-A)^\theta e^{A(t-s)}x \\ &\quad + \int_s^t (-A)^\theta e^{A(t-\tau)}(-A)^\gamma(-A)^{-\gamma}Bu^0(\tau, s; x)\, d\tau, \end{aligned}$$

and the integral in (4.17) is bounded in norm by the expression

$$\frac{C_T}{(T-t)^\gamma}\int_s^t \frac{d\tau}{(t-\tau)^{\theta+\gamma}}$$

(by virtue of property (1.2) on B and of property (3.23) of Theorem 3.6), which is well defined and converges to zero as $s \uparrow t$ if $\theta + \gamma < 1$. Equation (4.17) is well defined in Y, if $x \in Y$, $s < t$; or if $x \in \mathscr{D}((-A)^\theta)$, $s = t$. □

LEMMA 4.4.

(i) *For any $x \in Y$ and any t, $s < t < T$, we have with reference to the operator $A_P(t)$ in* (4.1),

$$\tag{4.18} \frac{\partial\Phi(t, s)x}{\partial t} = A_P(t)\Phi(t, s)x \in Y.$$

(ii) *For $0 \leqq s < t < \tau < T$ and $x \in Y$,*

$$\tag{4.19} \frac{\partial\Phi(\tau, t)}{\partial t}\Phi(t, s)x = -\Phi(\tau, t)A_P(t)\Phi(t, s)x \in Y.$$

(iii) *For $0 \leqq s < t < T$ and $x \in Y$,*

$$\tag{4.20} \frac{\partial G\Phi(T, t)}{\partial t}\Phi(t, s)x = -G\Phi(T, t)A_P(t)\Phi(t, s)x \in Y.$$

Proof. (i) As in [L-T1, Prop. 3.4], we start from (4.6b), differentiate in t (as guaranteed by Theorem 4.1(i)) after taking the Y-inner product with $y \in \mathscr{D}(A^*)$ and obtain for $s < t < T$,

$$\left(\frac{\partial \Phi(t,s)}{\partial t} x, y\right)_Y = (e^{A(t-s)}x, A^*y) - (A^{-1}BB^*P(t)\Phi(t,s)x, A^*y)$$

$$- \left(\int_s^t e^{A(t-\tau)}BB^*P(\tau)\Phi(\tau,s)x\,d\tau, A^*y\right)_Y$$

$$\text{(4.21)} \qquad \text{(by (4.6))} \qquad = ([I - A^{-1}BB^*P(t)]\Phi(t,s)x, A^*y), \qquad y \in \mathscr{D}(A^*),$$

where all the terms are well defined by property (1.2) on B and property (3.27) on $B^*P(t)$, $t < T$. By Theorem 4.1(i), the left-hand side of (4.21) is a well-defined Y-inner product $\forall x, y \in Y$, therefore, so is the right-hand side extended as a duality pairing. Thus, A^* can be moved to the left and (4.18) follows.

Properties (ii) and (iii) are a direct consequence of (4.7) and (4.8) of Lemma 4.3 via (4.18). □

The main result of this section is the following.

THEOREM 4.5. *The operator* $P(t)$ *defined by* (2.24) *satisfies the following Riccati equation for* $0 \leqq t < T$ *and* $x, y \in \mathscr{D}(A)$, *indeed for* $x, y \in \mathscr{D}((-A)^{\varepsilon})$, *for all* ε *with* $0 < \varepsilon < 1 - \gamma$,

$$\text{(4.22)} \qquad \begin{aligned}(\dot{P}(t)x, y)_Y = -(R^*Rx, y)_Y - (P(t)x, Ay)_Y - (P(t)Ax, y)_Y \\ + (B^*P(t)x, B^*P(t)y)_U,\end{aligned}$$

where $\dot{P}(t)$ *is a closed operator and* $(-A^*)^{-\varepsilon}\dot{P}(t)(-A)^{-\varepsilon}$ *can be extended to a bounded operator in* $\mathscr{L}(Y)$.

Proof. With, say, $x \in Y$, $y \in \mathscr{D}(A)$, and $0 \leqq s < t < T$, we differentiate in t (2.24), rewritten now via (4.5) as

$$\text{(4.23)} \qquad (P(t)x, y)_Y = \left(\int_t^T e^{A^*(\tau-t)}R^*R\Phi(\tau,t)x\,d\tau, y\right)_Y + (e^{A^*(T-t)}G^*G\Phi(T,t)x, y)_Y$$

to obtain after replacing x with $\Phi(t,s)x$ (all inner products are in Y),

$$(\dot{P}(t)\Phi(t,s)x, y) = -(R^*R\Phi(t,s)x, y)_Y - \left(\int_t^T e^{A^*(\tau-t)}R^*R\Phi(\tau,t)\Phi(t,s)x\,d\tau, Ay\right)$$

$$+ \left(\int_t^T e^{A^*(\tau-t)}R^*R\frac{\partial \Phi(\tau,t)}{\partial t}\Phi(t,s)x\,d\tau, y\right)$$

$$- (e^{A^*(T-t)}G^*G\Phi(T,t)\Phi(t,s)x, Ay)$$

$$\text{(4.24)} \qquad + (e^{A^*(T-t)}G^*\frac{\partial G\Phi(T,t)}{\partial t}\Phi(t,s)x, y\Big)$$

(using (4.23) with x replaced by $\Phi(t,s)x$ for the second and fourth terms in (4.24))

$$= -(R^*R\Phi(t,s)x, y)_Y - (P(t)\Phi(t,s)x, Ay)$$

$$+ \left(\int_t^T e^{A^*(\tau-t)}R^*R\frac{\partial \Phi(\tau,t)}{\partial t}\Phi(t,s)x\,d\tau, y\right)$$

$$+ \left(e^{A^*(T-t)}G^*\frac{\partial G\Phi(T,t)}{\partial t}\Phi(t,s)x\,d\tau, y\right)$$

(using identities (4.19) and (4.20))

$$= -(R^*R\Phi(t,s)x, y) - (P(t)\Phi(t,s)x, Ay)$$
$$-\left(\int_t^T e^{A^*(\tau-t)}R^*R\Phi(\tau,t)A_P(t)\Phi(t,s)x\,d\tau, y\right)$$
$$-(e^{A^*(T-t)}G^*G\Phi(T,t)A_P(t)\Phi(t,s)x, y)$$

(using again (4.23) with x replaced by $\Phi(t,s)x$)

$$= -(R^*R\Phi(t,s)x, y) - (P(t)\Phi(t,s)x, Ay) - (P(t)A_P(t)\Phi(t,s)x, y).$$

From here, recalling the definition of $A_P(t)$ in (4.1), we obtain

$$(4.25)\qquad (\dot{P}(t)\Phi(t,s)x, y) = -(R^*R\Phi(t,s)x, y) - (P(t)\Phi(t,s)x, Ay)$$
$$-(P(t)[A - BB^*P(t)]\Phi(t,s)x, y).$$

We now verify the following claim: The right-hand side of (4.25) is well defined with $s < t < T$ for all $x \in Y$ and all $y \in \mathscr{D}((-A)^\varepsilon)$, for all $\varepsilon > 0$.

In fact, we first note that from (3.27) of Corollary 3.7, we have for $t < T$,

$$(4.26)\qquad B^*P(t) \in \mathscr{L}(Y, U), \quad \text{and hence } P(t)BB^*P(t) \in \mathscr{L}(Y),$$

since $P(t)$ is self-adjoint (see (3.31) in Proposition 3.8(ii)). Moreover, for $t < T$, $(-A^*)^{1-\varepsilon}P(t) \in \mathscr{L}(Y)$, for all $\varepsilon > 0$, by (3.26) of Corollary 3.7, and likewise, since $P(t)$ is self-adjoint, $P(t)(-A)^{1-\varepsilon}$ can be extended to an operator in $\mathscr{L}(Y)$. Thus, we decompose the operator in the last term of (4.25) as

$$(4.27)\qquad P(t)[A - BB^*P(t)] = -P(t)(-A)^{1-\varepsilon}(-A)^\varepsilon - P(t)BB^*P(t),$$

so that (4.27) is well defined on $\mathscr{D}((-A)^\varepsilon)$, for all $\varepsilon > 0$, by (4.26). But, recalling Lemma 4.3(vii), we then see that $\Phi(t,s)x \in \mathscr{D}((-A)^\varepsilon)$ for all $0 < \varepsilon < 1 - \gamma$, $x \in Y$, $s < t < T$, so that the corresponding term $P(t)[A - BB^*P(t)]\Phi(t,s)x$ is well defined in Y. Thus, our claim has been verified.

We now restrict to $x \in \mathscr{D}((-A)^\varepsilon)$ and obtain from (4.10) with any $\varepsilon < 1 - \gamma$ and from Lemma 4.3(iii), $t < T$, recalling (4.26),

$$\lim_{s\uparrow t} P(t)[A - BB^*P(t)]\Phi(t,s)x = -P(t)(-A)^{1-\varepsilon}\lim_{s\uparrow t}(-A)^\varepsilon\Phi(t,s)x$$
$$-P(t)BB^*P(t)\lim_{s\uparrow t}\Phi(t,s)x$$
$$(4.28)\qquad = P(t)[A - BB^*P(t)]x, \qquad x \in \mathscr{D}((-A)^\varepsilon).$$

Thus, taking the limit of the right-hand side of (4.25) as $s \uparrow t$, $t < T$, and using (4.28) and Lemma 4.3(iii), we obtain the right-hand side of (4.22), well defined for all $x, y \in \mathscr{D}((-A)^\varepsilon)$, for all $\varepsilon > 0$, as desired.

As to the left-hand side of (4.25), we may consider the operator $\dot{P}(t)$ to be well-defined at least on the set $\mathscr{M}_t$ defined by

$$(4.29)\qquad \mathscr{M}_t \equiv \bigcup_{0 \leqq s < t} \mathscr{M}_{ts} \subset \mathscr{D}((-A)^\theta), \quad \text{where } \mathscr{M}_{ts} = \Phi(t,s)Y \subset \mathscr{D}((-A)^\theta)$$

for θ fixed, $\theta < 1 - \gamma$ (by Lemma 4.3(vii)) with $s < t < T$. By using the transitivity property of $\Phi(\cdot,\cdot)$, one then sees that $s_1 < s_2$ implies $\mathscr{M}_{s_1t} \subset \mathscr{M}_{s_2t}$ and that $\mathscr{M}_t$ is actually a subspace of Y, which is dense in Y by Lemma 4.3(ii), (iii). We next show that $\dot{P}(t)$ with domain $\mathscr{M}_t$ is *closeable*. In fact, let $\mathscr{M}_t \ni x_n = \Phi(t, s_n)y_n \to 0$, $s_n < t < T$, $y_n \in Y$, and let $\dot{P}(t)x_n \to v$ in Y. Then, $v = 0$. In fact, identity (4.25) with $\Phi(t,s)x$ replaced now by

$\Phi(t, s_n)y_n$ implies as $n\to\infty$ that $(v, y)=0$ for all $y\in\mathscr{D}((-A)^\varepsilon)$, hence for all $y\in Y$, and then $v=0$. We denote the *closure* of $\dot{P}(t)$ (smallest closed extension) still by $\dot{P}(t)$. Moreover, $\dot{P}(t)$ is also self-adjoint and thus, recalling Lemma 4.3(ii), we have $t<T$,

$$\lim_{s\uparrow t}(\dot{P}(t)\Phi(t, s)x, y)_Y=\lim_{s\uparrow t}(\Phi(t, s)x, \dot{P}(t)y)_Y \tag{4.30}$$
$$=(x, \dot{P}(t)y)_Y=(\dot{P}(t)x, y)_Y,$$

at least $\forall x\in Y$ and $\forall y\in\mathscr{M}_t$. Thus, at this point, we have that the DRE (4.22) holds true for all $x\in\mathscr{D}((-A)^\varepsilon)$, for all ε with $0<\varepsilon<1-\gamma$, and for all $y\in\mathscr{M}_t$. But, as seen above, the right-hand side of (4.22) is well defined also for all $y\in\mathscr{D}((-A)^\varepsilon)$. Moreover, $\mathscr{M}_t$ is dense in $\mathscr{D}((-A)^\varepsilon)$ in the $\mathscr{D}((-A)^\varepsilon)$-topology, as it follows a fortiori from (4.10) of Lemma 4.3. Then, the left-hand side of (4.22) can be extended likewise to all $y\in\mathscr{D}((-A)^\varepsilon)$. This implies that $(-A^*)^{-\varepsilon}\dot{P}(t)(-A)^{-\varepsilon}$ can be extended to a bounded operator in $\mathscr{L}(Y)$. Thus, the DRE (4.22) holds true for all $x, y\in\mathscr{D}((-A)^\varepsilon)$, as desired. The proof of Theorem 4.5 is complete. □

A final property of $P(t)$ which complements property (2.27) and property (3.26) is the following.

PROPOSITION 4.6. *For any $\varepsilon>0$ small we have*

$$(-A^*)^\theta P(t)\in\mathscr{L}(Y; C([0, T-\varepsilon]; Y)), \qquad 0\leqq\theta<1; \tag{4.31}$$

$$B^*P(t)\in\mathscr{L}(Y; C([0, T-\varepsilon]; Y)). \tag{4.32}$$

Proof. (i) From (2.26) with $x\in Y$, we have

$$(-A^*)^\theta P(t)x=\int_t^T(-A^*)^\theta e^{A^*(\tau-t)}R^*R\Phi(\tau, t)x\,d\tau \tag{4.33}$$
$$+(-A^*)^\theta e^{A^*(T-t)}G^*G\Phi(T, t)x,$$

and conclusion (4.31) follows from (4.33) using the properties of Lemma 4.3(ii) and (iv) with $t\leqq T-\varepsilon$.

(ii) Then (4.32) follows from (4.31) via assumption (1.2) on B. □

5. The issue of the limit of $P(t)$ as $t\uparrow T$. We rewrite (2.26) for convenience as

$$P(t)x=\int_t^T e^{A^*(\tau-t)}R^*R\Phi(\tau, t)x\,d\tau+e^{A^*(T-t)}G^*G\Phi(T, t)x, \tag{5.1}$$

and see that its first term satisfies the following result.

LEMMA 5.1.

$$\lim_{t\uparrow T}\int_t^T e^{A^*(\tau-t)}R^*R\Phi(\tau, t)x\,d\tau=0, \qquad x\in Y. \tag{5.2}$$

Proof. Conclusion (5.2) follows just by invoking the L_2-estimate (2.20) for $y^0(\tau, t; x)=\Phi(\tau, t)x$ and using the Schwarz inequality, or else by invoking the sharper estimate in (3.24). □

Lemma 5.1 reduces the strong (weak) convergence of $P(t)$ in (5.1) to the strong (weak) convergence of $G^*G\Phi(T, t)$. We begin with weak convergence results.

PROPOSITION 5.2. *Assume the standing hypothesis that $GL_T=GL_{0T}$ be closeable. Then*

$$\text{(i)}\qquad \lim_{t\uparrow T}(G\Phi(T, t)x, z)_Z=(Gx, z)_Z \qquad \forall x\in Y\quad \forall z\in Z; \tag{5.3}$$

$$\text{(ii)}\qquad \lim_{t\uparrow T}(P(t)x, y)_Y=(G^*Gx, y)_Y \quad \forall x, y\in Y. \tag{5.4}$$

Proof. (i) From the optimal dynamics (4.6a), we have

$$G\Phi(T,t)x = G\,e^{A(T-t)}x + \int_t^T G\,e^{A(T-\tau)}Bu^0(\tau,t;x)\,d\tau, \tag{5.5}$$

and thus (5.3) follows, as soon as we show that

$$\lim_{t\uparrow T}\left(\int_t^T G\,e^{A(T-\tau)}Bu^0(\tau,t;x)\,d\tau, z\right)_Z = 0 \quad \forall x\in Y \quad \forall x \in Z. \tag{5.6}$$

But the following uniform bound in $0\leqq t\leqq T$ holds true,

$$\begin{aligned}\left|\int_t^T G\,e^{A(T-\tau)}Bu^0(\tau,t;x)\,d\tau\right|_Z &= |G\Phi(T,t)x - G\,e^{A(T-t)}x|_Z \\ &\leqq C_T|x|_Y \quad \forall\, 0\leqq t\leqq T\end{aligned} \tag{5.7}$$

from (5.5), recalling (2.21) of Proposition 2.1 and (4.5). Thus, in view of (5.7), we see that the desired limit in (5.6) holds true, as soon as we prove that for all $x\in Y$, for all z in a dense set of Z

$$\lim_{t\uparrow T}\left(\int_t^T G\,e^{A(T-\tau)}Bu^0(\tau,t;x)\,d\tau, z\right)_Z = 0. \tag{5.8}$$

To prove (5.8) we choose $z\in\mathscr{D}((GL_T)^*)$, which is dense in Z by assumption via the equivalence of (1.30). We write $(GL_T)^*$ as usual as $L_T^*G^*$ (to denote, in effect, the extension) and note from (2.7) that $\mathscr{D}(L_{tT}^*G^*)\equiv\mathscr{D}(L_{0T}^*G^*)$, constant in t. Then, (5.8) follows from

$$\begin{aligned}&\left|\left(\int_t^T G\,e^{A(T-\tau)}Bu^0(\tau,t;x)\,d\tau, z\right)_Z\right| \\ &= \left|\int_t^T (u^0(\tau,t;x), B^*\,e^{A^*(T-\tau)}G^*z)_U\,d\tau\right| \\ &\leqq |u^0(\cdot,t;x)|_{L_2(t,T;U)}|L_{tT}^*G^*z|_{L_2(t,T;U)}\to 0 \quad \text{as } t\uparrow T. \quad \square\end{aligned} \tag{5.9}$$

COROLLARY 5.3. *Assume, in addition to GL_{0T} closeable, that G is compact. Then, the following strong convergence results hold*:

$$\text{(i)} \qquad \lim_{t\uparrow T} G^*G\Phi(T,t)x = G^*Gx, \qquad x\in Y; \tag{5.10}$$

$$\text{(ii)} \qquad \lim_{t\uparrow T} P(t)x = G^*Gx, \qquad x\in Y. \tag{5.11}$$

Proof. (i) Since G^* is compact, the weak convergence of $G\Phi(T,t)$ as in (5.3) becomes strong convergence as in (5.10).

(ii) Returning to (5.1) and recalling (5.2), we obtain (5.11) by (5.10). □

6. The smoothing case $(-A^*)^\beta G^*G\in\mathscr{L}(Y)$, $\beta>2\gamma-1$. In this section, we point out a more regular theory, which becomes available under the stronger assumption that

$$(-A^*)^\beta G^*G\in\mathscr{L}(Y), \qquad \beta>2\gamma-1, \tag{6.1}$$

i.e., when G^*G maps all of Y into $\mathscr{D}((-A^*)^\beta)$, so that (6.1) holds by the closed graph theorem. We first recall from [F1, Lemma 3.1] that as a consequence of (6.1), since $G^*G\in\mathscr{L}(Y)$ is self-adjoint, then the operator $(-A^*)^{\beta-\theta}G^*G(-A)^{\theta-\rho}$ admits a bounded extension in $L(Y)$, a condition which we write simply as

$$(-A^*)^{\beta-\theta}G^*G(-A)^{\theta-\rho}\in\mathscr{L}(Y) \quad \forall\, 0<\rho<\theta<\beta. \tag{6.2}$$

Next, we return to (2.17), rewritten here for convenience for $x \in Y$ as

$$-u^0(\cdot, s; x) = \Lambda_{sT}^{-1}[L_{sT}^* G^* G\, e^{A(T-s)}x + L_s^* R^* R\, e^{A(\cdot - s)}x], \tag{6.3a}$$

$$\Lambda_{sT} = I_s + L_s^* R^* R L_s + L_{sT}^* G^* G L_{sT}, \tag{6.3b}$$

which provides $u^0(\cdot, s, x)$ in terms of the data of the problem.

LEMMA 6.1. *Assume hypothesis* (6.1). *Then, for any $x \in Y$, the term in the square bracket of* (6.3a) *satisfies* (*recall* (3.1)),

$$L_{sT}^* G^* G\, e^{A(T-s)}x + L_s^* R^* R\, e^{A(\cdot - s)}x \in C_{\gamma-\beta}([s, T]; U). \tag{6.4}$$

Proof. Since $L_s^* R^* R\, e^{A(\cdot - s)}x \in C([s, T]; U)$ from (2.5a), and since $L_{sT}^* G^* G\, e^{A(T-s)}x \in C([s, T]; U)$ from (2.7), it remains to show that

$$|(L_{sT}^* G^* G\, e^{A(T-s)}x)(t)|_U \leqq \frac{C_{T\gamma}}{(T-t)^{\gamma-\beta}} |x|_Y. \tag{6.5}$$

But (6.5) follows readily via (2.7), (6.1), (1.2), and analyticity from

$$\begin{aligned} |(L_{sT}^* G^* G\, e^{A(T-s)}x)(t)|_U = |B^*(-A^*)^{-\gamma}\, e^{A^*(T-t)}(-A^*)^{\gamma-\beta} \\ \cdot (-A^*)^{\beta} G^* G\, e^{A(T-s)}x|_U. \end{aligned} \tag{6.6}$$ □

The crucial result of this section is the following theorem concerning Λ_{sT} in (6.3b).

THEOREM 6.2. *Assume hypothesis* (6.1). *Then the operator Λ_{sT} satisfies*

$$\Lambda_{sT}^{-1} = [I_s + L_s^* R^* R L_s + L_{sT}^* G^* G L_{sT}]^{-1} \in \mathscr{L}(C_{\gamma-\beta}([s, T]; U)) \tag{6.7}$$

with uniform bound which may be taken independent of s, $s \leqq t \leqq T$.

Proof. The proof will resemble the arguments of § 3 leading to Theorem 3.4. □

Step 1. *Claim.* Let $v_0 \in L_2(s, T; U)$; then

$$|(-A)^{-\sigma_0} L_{sT} v_0|_Y \leqq c_{T,\varepsilon_0}(T-s)^{\varepsilon_0} |v_0|_{L_2(s,T;U)}; \tag{6.8}$$

$$\forall \sigma_0 > \gamma - \tfrac{1}{2}, \quad \text{so that } \sigma_0 = \gamma - \tfrac{1}{2} + \varepsilon_0. \tag{6.9}$$

In fact, we compute from (2.6) via (1.2) and analyticity,

$$\begin{aligned} |(-A)^{-\sigma_0} L_{sT} v_0|_Y &= \left| (-A)^{-\sigma_0} \int_s^T (-A)^{\gamma} e^{A(T-\tau)}(-A)^{-\gamma} B v_0(\tau)\, d\tau \right|_Y \\ &\leqq C_T \int_s^T \frac{|v_0(\tau)|_U\, d\tau}{(T-\tau)^{\gamma-\sigma_0}} \\ &\leqq C_T \left\{ \int_s^T \frac{d\tau}{(T-\tau)^{2(\gamma-\sigma_0)}} \right\}^{1/2} |v_0|_{L_2(s,T;U)}, \end{aligned} \tag{6.10}$$

and for $2(\gamma - \sigma_0) < 1$, we obtain (6.8), as desired.

Step 2. *Claim.* Setting

$$v_1(t) = (L_{sT}^* G^* G L_{sT} v_0)(t), \tag{6.11}$$

we have, with $\beta > 2\sigma_0 = 2\gamma - 1 + 2\varepsilon_0$,

$$|v_1(t)|_U = |(L_{sT}^* G^* G L_{sT} v_0)(t)|_U \leqq \frac{C_T}{\sqrt{\varepsilon_0}} \frac{(T-s)^{\varepsilon_0}}{(T-t)^{1/2-\varepsilon_0}} |v_0|_{L_2(s,T;U)}, \tag{6.12}$$

so that a fortiori $L_{sT}^* G^* G L_{sT}$ is a smoothing operator:

$$L_{sT}^* G^* G L_{sT}: \text{continuous } L_2(s, T; U) \to L_{r_1}(s, T; U), \tag{6.13a}$$

$$2 < r_1 < \frac{1}{\gamma - \sigma_0} = \frac{2}{1 - 2\varepsilon_0}; \qquad r_1 - 2 < \frac{4\varepsilon_0}{1 - 2\varepsilon_0}. \tag{6.13b}$$

In fact, we compute from (2.7) and (2.6), via (1.2) and (6.2),

$$\begin{aligned}|(L_{sT}^*G^*GL_{sT}v_0)(t)|_U &= |B^*(-A^*)^{-\gamma}\, e^{A^*(T-t)}(-A^*)^{\gamma-\sigma_0} \\ &\quad \cdot (-A^*)^{\sigma_0}G^*G(-A)^{\sigma_0}(-A)^{-\sigma_0}L_{sT}v_0|_U \\ &\leqq C_T\frac{1}{(T-t)^{\gamma-\sigma_0}}|(-A)^{-\sigma_0}L_{sT}v_0|_Y,\end{aligned} \tag{6.14}$$

where in the last step we have used (6.2) for $(-A^*)^{\sigma_0}G^*G(-A)^{\sigma_0} \in \mathscr{L}(Y)$, which is legal since $\beta > 2\sigma_0 > 2\gamma - 1$ from (6.1) and (6.9). Then, (6.12) readily follows from (6.14) via (6.8), with $\gamma - \sigma_0 = \frac{1}{2} - \varepsilon_0$ from (6.9). In turn, (6.12) implies that $v_1 \in L_r(s, T; U)$ for all r such that $(\frac{1}{2} - \varepsilon_0)r = (\gamma - \sigma_0)r < 1$, i.e., in particular, for r_1 as in (6.13b).

Step 3. We reiterate the procedure of Steps 1-2 above. Since v_1 is more regular than the original v_0, we have the following claim.

Claim. We have

$$|(-A)^{-\sigma_1}L_{sT}v_1|_Y \leqq C_T(T-s_0)^{\varepsilon_0}|v_0|_{L_2(s,T;U)}; \tag{6.15}$$

$$\sigma_1 = \sigma_0 - \varepsilon_0 = \gamma - \tfrac{1}{2} < \sigma_0. \tag{6.16}$$

In fact, from (2.6) we compute via (1.2) and (6.12),

$$\begin{aligned}|(-A)^{-\sigma_1}L_{sT}v_1|_Y &= \left|(-A)^{-\sigma_1}\int_s^T (-A)^{\gamma}\, e^{A(T-\tau)}(-A)^{-\gamma}Bv_1(\tau)\, d\tau\right|_Y \\ &\leqq C_T\int_s^T\frac{|v_1(\tau)|_U\, d\tau}{(T-\tau)^{\gamma-\sigma_1}} \\ &\leqq C_T\left(\int_s^T\frac{d\tau}{(T-\tau)^{\gamma-\sigma_1+\gamma-\sigma_0}}\right)|v_0|_{L_2(s,T;U)},\end{aligned} \tag{6.17}$$

and (6.15) follows since $\gamma - \sigma_1 + \gamma - \sigma_0 = 1 - \varepsilon_0 < 1$ from (6.16) and (6.9).

Step 4. *Claim.* Setting

$$v_2(t) = (L_{sT}^*G^*GL_{sT}v_1)(t), \tag{6.18}$$

we have that

$$|v_2(t)|_U = |L_{sT}^*G^*GL_{sT}v_1)(t)|_U \leqq C_T\frac{(T-s)^{\varepsilon_0}}{(T-t)^{1/2-2\varepsilon_0}}|v_0|_{L_2(s,T;U)}, \tag{6.19}$$

so that a fortiori,

$$L_{sT}^*G^*GL_{sT}\text{: continuous } L_{r_1}(s, T; U) \to L_{r_2}(s, T; U); \tag{6.20a}$$

$$2 < r_1 < r_2 < \frac{1}{\gamma - \sigma_0 - \varepsilon_0} = \frac{2}{1 - 4\varepsilon_0}; \qquad r_2 - r_1 < r_2 - 2 < \frac{8\varepsilon_0}{1 - 4\varepsilon_0}. \tag{6.20a}$$

In fact, since $\sigma_1 = \sigma_0 - \varepsilon_0 < \sigma_0$, we rewrite the counterpart of (6.14) as

$$\begin{aligned}|(L_{sT}^*G^*GL_{sT}v_1)(t)|_U &= |B^*(-A^*)^{-\gamma}\, e^{A^*(T-t)}(-A^*)^{\gamma-(\sigma_0+\varepsilon_0)} \\ &\quad \cdot (-A^*)^{\sigma_0+\varepsilon_0}G^*G(-A)^{\sigma_0-\varepsilon_0}(-A)^{-\sigma_1}L_{sT}v_1|_U \\ &\leqq C_T\frac{1}{(T-t)^{\gamma-(\sigma_0+\varepsilon_0)}}|(-A)^{-\sigma_1}L_{sT}v_1|_Y,\end{aligned} \tag{6.21}$$

where in the last step we have used (6.2), for $(-A^*)^{\sigma_0+\varepsilon_0}G^*G(-A)^{\sigma_0-\varepsilon_0}\in\mathscr{L}(Y)$, which is legal since $\beta>(\sigma_0+\varepsilon_0)+(\sigma_0-\varepsilon_0)=2\sigma_0>2\gamma-1$ by (6.1) and (6.16). Then, (6.19) readily follows from (6.21) via (6.15) with $\gamma-(\sigma_0+\varepsilon_0)=\frac{1}{2}-2\varepsilon_0$ from (6.9). In turn, (6.19) implies that $v_2\in L_r(s, T; U)$ for all r such that $(\frac{1}{2}-2\varepsilon_0)r=[\gamma-(\sigma_0+\varepsilon_0)]r<1$; i.e., in particular, for r_2 as in (6.20b).

Step 5. The above procedure can be iterated a finite number of times yielding the following result: Let

$$v_n(t)=(L^*_{sT}G^*GL_{sT}v_{n-1})(t). \tag{6.22}$$

Then

$$|v_n(t)|_U=|(L^*_{sT}G^*GL_{sT}v_{n-1})(t)|_U\leqq C_T\frac{(T-s)^{\varepsilon_0}}{(T-t)^{1/2-n\varepsilon_0}}|v_0|_{L_2(s,T;U)}, \tag{6.23}$$

so that a fortiori

$$L^*_{sT}G^*GL_{sT}\text{: continuous } L_{r_{n-1}}(s, T; U)\to L_{r_n}(s, T; U); \tag{6.24a}$$

$$2<r_1<r_2<\cdots<r_n=\frac{1}{\gamma-\sigma_0-(n-1)\varepsilon_0}=\frac{2}{1-2n\varepsilon_0}; \tag{6.24b}$$

for $1-2n\varepsilon_0>0$.

Step 6. *Claim.* If $n>[\frac{1}{2}-(\gamma-\beta)]/\varepsilon_0$, then $v_n(t)$ in (6.22) satisfies

$$v_n(t)=(L^*_{sT}G^*GL_{sT}v_{n-1})(t)\in C_{\gamma-\beta}([s, T]; U), \tag{6.25}$$

as it readily follows from Step 5.

Step 7. Having obtained the results in (6.4) and (6.25), we return to identity (6.39) and apply a bootstrap argument (similar to the one carried out in Theorem 3.4). There is, to begin with, $u^0=u^0(\cdot, s; x)\in L_2(s, T; U)$ such that by (6.4) we have

$$u^0+L^*_sR^*RL_su^0+L^*_{sT}G^*GL_{sT}u^0=w\in C_{\gamma-\beta}([s, T]; U), \tag{6.26}$$

with $w=L^*_{sT}G^*G\,e^{A(T-s)}x+L^*_sR^*R\,e^{A(\cdot-s)}x$. Starting from (6.26) and proceeding as in Step 2 in the proof of Theorem 3.4, we then apply to (6.26) the operator $L^*_{sT}G^*GL_{sT}$ $n-1$ times, consecutively, thus obtaining $n-1$ additional identities, the last of which is

$$(L^*_{sT}G^*GL_{sT})^{n-1}u^0+(L^*_{sT}G^*GL_{sT})^nu^0=f_n\in C_{\gamma-\beta}([s, T]; U), \tag{6.27}$$

where $f_n=(L^*_{sT}G^*GL_{sT})^{n-1}[w-L^*_sR^*RL_su^0]$. Now, if n is chosen sufficiently large as in the claim of Step 6, then we obtain

$$(L^*_{sT}G^*GL_{sT})^nu^0\in C_{\gamma-\beta}([s, T]; U) \tag{6.28}$$

by (6.25). Then (6.28) and (6.27) imply that

$$(L^*_{sT}G^*GL_{sT})^{n-1}u^0\in C_{\gamma-\beta}([s, T]; U).$$

Proceeding backward along the remaining $n-2$ identities, we eventually obtain

$$u^0(\cdot, s; x)\in C_{\gamma-\beta}([s, T]; U), \tag{6.29}$$

and Theorem 6.2 is proved.

COROLLARY 6.3. *Assume hypothesis* (6.1) (*which is empty if* $0\leqq\gamma<\frac{1}{2}$), *where we set* $\beta=2\gamma-1+\varepsilon$. *Then, for* $x\in Y$,

(i)

$$u^0(\cdot, s; x)\in C_{1-\gamma-\varepsilon}([s, T]; U), \tag{6.30a}$$

and

$$\text{(6.30b)}\qquad |u^0(\cdot, s; x)|_{C_{1-\gamma-\varepsilon}([s,T];U)} \leqq C_{T\gamma}|x|_Y, \qquad \gamma-\beta = 1-\gamma-\varepsilon,$$

with bound which may be taken independent of s;

(ii)

$$\text{(6.31a)}\qquad y^0(\cdot, s; x) = \Phi(\cdot, s)x \in C([s, T]; Y),$$

and

$$\text{(6.31b)}\qquad |y^0(\cdot, s; x)|_{C([s,T];Y)} \leqq C_{T\gamma}|x|_Y,$$

with bound which may be taken independent of s;

(iii)

$$\text{(6.32a)}\qquad y^0(T, \cdot\,; x) = \Phi(T, \cdot)x \in C([s, T]; Y),$$

in particular.

$$\text{(6.32b)}\qquad \lim_{t\uparrow T} \Phi(T, t)x = x.$$

(iv) *For any* $0 \leqq \theta < 1$, *and* $\theta-\beta = \theta+1-2\gamma-\varepsilon$,

$$\text{(6.33a)}\qquad (-A^*)^\theta P(t)x \in C_{\theta-\beta}([0, T]; Y),$$

and

$$\text{(6.33b)}\qquad |(-A^*)^\theta P(t)x|_Y \leqq \frac{C_{T\gamma}}{1-\theta}\frac{1}{(T-t)^{\theta-\beta}}|x|_Y.$$

(v) *With* $\gamma-\beta = 1-\gamma-\varepsilon$,

$$\text{(6.34a)}\qquad B^*P(t)x \in C_{\gamma-\beta}([0, T]; U),$$

and

$$\text{(6.34b)}\qquad |B^*P(t)x|_U \leqq \frac{C_T}{1-\gamma}\frac{1}{(T-t)^{\gamma-\beta}}|x|_Y;$$

(vi)

$$\text{(6.35)}\qquad \lim_{t\uparrow T} P(t)x = \lim_{t\uparrow T} e^{A^*(T-t)}G^*G\Phi(T, t)x = G^*Gx.$$

Proof. (i) Conclusion (6.30) is a rewriting of (6.29); i.e., of Theorem 6.1.

(ii) Conclusion (6.31) follows from (6.30) via the optimal dynamics (2.18) and property (3.2) for the operator L_s with $r = 1-\gamma-\varepsilon$ so that $r+\gamma = 1-\varepsilon < 1$, as required.

(iii) Conclusion (6.32) follows from (2.18) with $t = T$, i.e., from (see (2.23)),

$$\text{(6.36)}\qquad y^0(T, t; x) = \Phi(T, t)x = e^{A(T-t)}x + L_{tT}u^0(\cdot, t; x),$$

where, by virtue of (2.6), (6.30), and (1.2), we obtain as desired,

$$\begin{aligned} |L_{tT}u^0(\cdot, t; x)|_Y &= \left|\int_t^T (-A)^\gamma e^{A(T-\tau)}(-A)^{-\gamma}Bu^0(\tau, t; x)\,d\tau\right|_Y \\ \text{(6.37)}\qquad &\leqq C_{T\gamma}\int_t^T \frac{d\tau}{(T-\tau)^\gamma(T-\tau)^{1-\gamma-\varepsilon}}|x|_Y \\ &= C_{T\gamma}(T-t)^\varepsilon|x|_Y. \end{aligned}$$

(iv) Recalling (2.24), we compute via (6.31), (6.32), and (6.1),

$$
\begin{aligned}
|(-A^*)^\theta P(t)x|_Y &= \bigg| \int_t^T (-A^*)^\theta e^{A^*(\tau-t)} R^*Ry^0(\tau, t; x)\, d\tau \\
&\qquad + (-A^*)^{\theta-\beta} e^{A^*(T-t)}(-A^*)^\beta G^*Gy^0(T, t; x)\bigg|_Y \\
&\leqq C_{T\gamma}\left\{\int_t^T \frac{d\tau}{(\tau-t)^\theta} + \frac{C_T}{(T-t)^{\theta-\beta}}\right\}|x|_Y, \qquad (6.38)
\end{aligned}
$$

and (6.33b) follows.

(v) By (6.33) with $\theta=\gamma$ and (1.2),

$$
|B^*P(t)x|_U = |B^*(-A^*)^{-\gamma}(-A^*)^\gamma P(t)x|_U = \frac{C_{T\gamma}}{1-\gamma}\frac{1}{(T-t)^{\gamma-\beta}}|x|_Y, \qquad (6.39)
$$

where $\gamma-\beta = 1-\gamma-\varepsilon$, as desired.

(vi) Conclusion (6.35) follows from (6.32b) via (5.1) and (5.2). □

THEOREM 6.4. (*Uniqueness of Riccati operator.*) *The operator $P(t)$ defined constructively in* (2.24) *in terms of the data of the problem is the unique solution to the* DRE (1.13) = (4.22) *and its terminal condition* (6.35) *within the class of self-adjoint operators $\bar{P}(t) \in \mathscr{L}(Y)$ such that,*

$$
\text{(i)} \qquad B^*\bar{P}(t)x \in C_\gamma([0, T]; Y), \qquad x \in Y, \qquad (6.40)
$$

if $0 \leqq \gamma < \frac{1}{2}$ (and no other assumption except the standing hypotheses specified below (1.1));

$$
\text{(ii)} \ B^*\bar{P}(t)x \in C_{\gamma-\beta}([0, T]; Y), \qquad x \in Y, \quad \gamma-\beta = 1-\gamma-\varepsilon, \qquad (6.41)
$$

if $\frac{1}{2} \leqq \gamma < 1$, provided that assumption (6.1) holds with $\beta = 2\gamma - 1 + \varepsilon$.

Proof. It suffices to show uniqueness within the specified class for the corresponding Riccati Integral Equation,

$$
\begin{aligned}
(P(t)x, y)_Y &= (G e^{A(T-t)}x, G e^{A(T-t)}y)_Z + \int_t^T (R e^{A(\tau-t)}x, R e^{A(\tau-t)}y)_W\, d\tau \\
&\quad - \int_t^T (B^*P(\tau) e^{A(\tau-t)}x, B^*P(\tau) e^{A(\tau-t)}y)_U\, d\tau, \qquad (6.42)
\end{aligned}
$$

$x, y \in Y$. Let $P_1(t)$ and $P_2(t)$ be two solutions within the specified class, and let $Q(t) = P_1(t) - P_2(t)$. Then $Q(t)$ satisfies for $x \in Y$,

$$
B^*Q(t)x \in \begin{cases} C_\gamma([0, T]; U) & \text{in case (i)}, \quad (6.43) \\ C_{1-\gamma-\varepsilon}([0, T]; U) & \text{in case (ii)}, \quad (6.44) \end{cases}
$$

as well as, for $0 < t < T$ and $x, y \in Y$,

$$
\begin{aligned}
(Q(t)x, y)_Y &= \int_t^T (B^*P_2(\tau) e^{A(\tau-t)}x, B^*Q(\tau) e^{A(\tau-t)}y)_U\, d\tau \\
&\quad - \int_t^T (B^*Q(\tau) e^{A(\tau-t)}x, B^*P_1(\tau) e^{A(\tau-t)}y)_U\, d\tau. \qquad (6.45)
\end{aligned}
$$

Set

$$
y = Bv, \ v \in U, \quad \text{and } B^*Q(t) = V(t), \qquad (6.46)
$$

so that $V(t)$ solves for $0 \leqq t < T$,

$$
\begin{aligned}
V(t)x = & \int_t^T B^*(-A^*)^{-\gamma}(-A^*)^{\gamma}\, e^{A^*(\tau-t)}\, V^*(\tau)B^*P_2(\tau)\, e^{A(\tau-t)}x\, d\tau \\
& - \int_t^T B^*(-A^*)^{-\gamma}(-A^*)^{\gamma}\, e^{A^*(\tau-t)}(B^*P_1(\tau))^*\, V(\tau)\, e^{A(\tau-t)}x\, d\tau.
\end{aligned} \tag{6.47}
$$

We seek to establish uniqueness of the solution $V(t)$ of (6.47) within the classes specified, respectively, in (6.43) and (6.44) for the two cases. We do this first locally, near T, and extend globally to all of $[0, T]$.

Case (i). $\gamma < \frac{1}{2}$. Multiplying (6.47) across for $(T-t)^{\gamma}$ we obtain after using (1.2), and $|B^*P_i(\tau)y|_U \leqq (C_T/(T-\tau)^{\gamma})|y|_Y$:

$$
\begin{aligned}
(T-t)^{\gamma}|V(t)x|_U & \leqq (T-t)^{\gamma}C_T \int_t^T \frac{(T-\tau)^{\gamma}|V^*(\tau)|\, d\tau}{(\tau-t)^{\gamma}(T-\tau)^{2\gamma}}|x|_Y \\
& \leqq (T-t)^{\gamma}C_T\left\{\int_t^T \frac{d\tau}{(\tau-t)^{\gamma}(T-\tau)^{2\gamma}}\right\}\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{\gamma}|V(\tau)|\right\}|x|_Y.
\end{aligned} \tag{6.48}
$$

Since $r = 2\gamma < 1$ in our case, the computations (of case (iii) in the proof of Proposition 3.1) leading to (3.8) can be applied to the integral in (6.48). We thus obtain

$$
\begin{aligned}
(T-t)^{\gamma}|V(t)x|_U & \leqq (T-t)^{\gamma}C_T\frac{1}{(T-t)^{\gamma+2\gamma-1}}\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{\gamma}|V(\tau)|\right\}|x|_Y \\
& \leqq C_T(T-t)^{1-2\gamma}\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{\gamma}|V(\tau)|\right\}|x|_Y,
\end{aligned} \tag{6.49}
$$

where $1-2\gamma>0$ in our case. Letting $t_0 \leqq t \leqq T$, we obtain from (6.49),

$$
\sup_{t_0\leqq t\leqq T}(T-t)^{\gamma}|V(t)| \leqq C_T(T-t_0)^{1-2\gamma}\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{\gamma}|V(\tau)|\right\}, \tag{6.50}
$$

and selecting $T-t_0$ sufficiently small, we obtain $C_T(T-t_0)^{1-2\gamma}<1$ and uniqueness on $[t_0, T]$ is established within the class $C_{\gamma}([t_0, T]; U)$.

Case (ii). $\frac{1}{2} \leqq \gamma < 1$. We now multiply (6.47) by $(T-t)^{1-\gamma-\varepsilon}$ and obtain after using $|B^*P_i(\tau)y|_U \leqq (C_T/(T-\tau)^{1-\gamma-\varepsilon})|y|_Y$,

$$
\begin{aligned}
(T-t)^{1-\gamma-\varepsilon}|V(t)x|_U \leqq & (T-t)^{1-\gamma-\varepsilon}C_T\left\{\int_t^T \frac{d\tau}{(\tau-t)^{\gamma}(T-\tau)^{2(1-\gamma-\varepsilon)}}\right\} \\
& \cdot\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{1-\gamma-\varepsilon}|V(\tau)|\right\}|x|_Y
\end{aligned} \tag{6.51}
$$

as a counterpart of (6.48). Since $r = 2(1-\gamma-\varepsilon)<1$ in our case the integral in (6.51) can be estimated again as in (3.8), and we obtain since $\gamma+[2(1-\gamma-\varepsilon)]-1 = 1-\gamma-2\varepsilon$,

$$
\begin{aligned}
(T-t)^{1-\gamma-\varepsilon}|V(t)x|_U & \leqq (T-t)^{1-\gamma-\varepsilon}C_T\frac{1}{(T-t)^{1-\gamma-2\varepsilon}}\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{1-\gamma-\varepsilon}|V(\tau)|\right\}|x|_Y \\
& \leqq (T-t)^{\varepsilon}C_T\left\{\sup_{t\leqq\tau\leqq T}(T-\tau)^{1-\gamma-\varepsilon}|V(\tau)|\right\}|x|_Y.
\end{aligned} \tag{6.52}
$$

The desired conclusion of uniqueness of $V(t)$ over $[t_0, T]$ with $T-t_0$ sufficiently small is obtained as in case (i), within the class $C_{1-\gamma-\varepsilon}([t_0, T]; U)$.

Finally, after a finite number of steps we obtain uniqueness of $V(t)$ on all of $[0, T]$, in each case, within its specified class. □

Remark 6.1. Under the assumption (as in [F1]),

$$(-A^*)^\gamma G^*G \in \mathscr{L}(Y), \tag{6.53}$$

which is stronger than assumption (6.1) since $2\gamma-1<\gamma$, additional regularity results hold true, namely,

(i)

$$u^0(\cdot, s; x) \in C([s, T]; U), \qquad x \in Y, \tag{6.54a}$$

$$\max_{s \leqq t \leqq T} |u^0(t, s; x)|_U \leqq C_T |x|_Y, \qquad x \in Y, \tag{6.54b}$$

with C_T independent of s;

(ii) For any $0 \leqq \theta < 1$,

$$(-A^*)^\theta P(t)x \in C_{\theta-\gamma}([0, T]; Y), \tag{6.55a}$$

$$|(-A^*)^\theta P(t)x|_Y \leqq \frac{C_T}{1-\theta} \frac{1}{(T-t)^{\theta-\gamma}} |x|_Y; \tag{6.55b}$$

(iii)

$$B^*P(t)x \in C([0, T]; U), \qquad x \in Y, \tag{6.56a}$$

$$\max_{0 \leqq t \leqq T} |B^*P(t)x| \leqq C_T |x|_Y, \qquad x \in Y. \tag{6.56b}$$

A sketch of the proof of the crucial property (6.54) is as follows. Under assumptions (6.53), we can show using (2.7), (2.6), [F1, Lemma 3.1] (as above in § 6) that

$$L_{sT}^* G^* G L_{sT}\text{: continuous } L_2(s, T; U) \to L_r(s, T; Y); \tag{6.57}$$

$$2 < r < \frac{2}{\gamma + 2\varepsilon} \quad \forall \varepsilon > 0,$$

with norm bounds which may be taken independent of s. Hence, by iteration, there exists a positive integer n_1 such that

$$(L_{sT}^* G^* G L_{sT})^{n_1}\text{: } L_2(s, T; U) \to C([s, T]; Y) \tag{6.58}$$

with norm bound which may be taken independent of s. Thus (6.58) lets us use a bootstrap argument (as in, say, Step 7 in the proof of Theorem 6.2) and obtain (6.54).

7. Counterexamples. It was independently noted in [F3] and in the first version of this paper that suitable one-dimensional range (finite range) operators G furnish examples which illustrate the sharpness or limitations of the theory presented.

7.1. Counterexample to the existence of the optimal control u^0 when GL_T is not closeable. The following example is proposed in [F3], but it is analyzed here from a different viewpoint (the example from [F3] is summarized in Remark 7.1). More precisely, in this example we shall see that the operator GL_T is not closeable and that the optimal control does not exist. This shows that our Theorem 1.1, more generally the treatment of this article, is sharp. Recall from § 2.1 that the assumption that GL_T be closeable is used to obtain a *complete* inner product space (Hilbert) $V(s, T; U)$ defined by (the extension of) $\mathscr{D}(GL_T)$ with respect to the inner product in (2.8), and that, moreover, the optimal control is characterized by (2.17), with Λ_{sT}^{-1} an isomorphism from $[V(s, T; U)]'$ onto $V(s, T; U)$.

The example. Consider, say the heat equation defined on a (smooth) bounded domain $\Omega \subset R^n$ with $L_2(0, T; L_2(\Gamma))$-control in the Dirichlet boundary conditions.

$$y_t = \Delta y \qquad \text{in } Q = (0, T] \times \Omega \tag{7.1a}$$

$$y(0, \cdot) = y_0 \qquad \text{in } \Omega \tag{7.1b}$$

$$y|_\Sigma = u \qquad \text{in } \Sigma = (0, T] \times \Gamma. \tag{7.1c}$$

Here $Y = L_2(\Omega)$, $U = L_2(\Gamma)$. There exists $\phi \in Y$, $|\phi| = 1$ such that

$$\int_0^T |B^* e^{A^*(T-t)}\phi|_U^2 \, dt = \infty; \tag{7.2}$$

for, otherwise, by transposition, the map $u \to y(T)$ (where $y_0 = 0$) would be continuous $L_2(0, T; L_2(\Gamma)) \to L_2(\Omega) = Y$, which is false even in the one-dimensional case, e.g., [Lio1, p. 217]. Following [F3], we consider the associated optimal control problem (1.3) with

$$R = 0; \quad Gy = (y, \phi)_Y \phi; \quad \phi \in Y; \quad G^* = G = G^*G. \tag{7.3}$$

Note that we have by (1.8) and (7.3),

$$GL_T u = \left(\int_0^T e^{A(T-t)} Bu(t) \, dt, \phi \right)_Y \phi = (u, B^* e^{A^*(T-\cdot)}\phi)_{L_2(0,T;U)} \phi \tag{7.4}$$

so that GL_T is finite rank and unbounded by (7.2), hence uncloseable [K1, p. 166].

Claim. There is no optimal control in this case. In fact, following § 2.1, if an optimal control $u^0(\cdot, 0; x) = u^0 \in L_2(0, T; U)$ exists, it satisfies the present version of (2.17) (or (1.10)), i.e., since $R = 0$,

$$-[u^0 + L_T^* G^* G L_T u^0] = L_T^* G^* G \, e^{AT} x = (e^{AT}x, \phi)_Y B^* e^{A^*(T-t)}\phi, \tag{7.5}$$

where we have used (7.3) on G^*G and (1.9) for L_T^*. Moreover, by (7.3) and (7.4),

$$L_T^* G^* G L_T u = L_T^* \{(L_T u, \phi)_Y \phi\} = \left(\int_0^T e^{A(T-t)} Bu(t) \, dt, \phi \right)_Y B^* e^{A^*(T-t)}\phi. \tag{7.6}$$

Using (7.6) in (7.5) yields

$$-u^0 = \{(u^0, B^* e^{A^*(T-\cdot)}\phi)_{L_2(0,T;U)} + (e^{AT}x, \phi)_Y\} B^* e^{A^*(T-t)}\phi. \tag{7.7}$$

Since $B^* e^{A^*(T-t)}\phi \notin L_2(0, T; U)$ by (7.2), then (7.7) yields that $u^0 \notin L_2(0, T; U)$, a contradiction.

Remark 7.1. It is argued in [F3] that, in the present case, it is *not possible* for the corresponding optimal problem (1.3), (7.3) to satisfy the following three desirable properties.

(i) That there exists a unique optimal control u^0;

(ii) That there exists $P(t)$, $0 \leqq t \leqq T$, nonnegative self-adjoint, such that identity (1.20) holds;

(iii) That for every $0 \leqq t < T$ and $x \in \mathscr{D}(A)$, $(P(t)x, x)$ is differentiable, $P(t)x \in \mathscr{D}((-A^*)^\gamma)$ and the DRE (1.21) is satisfied.

The analysis above shows, more fundamentally, that the optimal control does not exist in this case, with no need to involve the DRE.

Remark 7.2. We note that the choice (7.2) for ϕ implies that $\phi \notin \mathscr{D}((-A^*)^{\beta/2})$ for all $\beta > 2\gamma - 1$, and hence [F4, § 3.1], G in (7.3) does *not* satisfy assumption (1.46) of [F4]. In fact, if we had $\phi \in \mathscr{D}((-A^*)^{\beta/2})$ we would obtain that

$$B^* e^{A^*(T-t)}\phi = B^*(-A^*)^{-\gamma}(-A^*)^{\gamma-\beta/2} e^{A^*(T-t)}(-A^*)^{\beta/2}\phi \tag{7.8}$$

would belong to $L_2(0, T; U)$ by (1.3) and analyticity with $2\gamma-\beta<1$, thus contradicting (7.2). We note that in this case we have $\mathscr{D}((-A^*)^{\beta/2}G^*)=\{0\}$ for all $\beta>2\gamma-1$.

7.2. Assumption (1.31) is only sufficient for GL_T to be closed. We shall provide a class of examples where condition (1.31) is *violated*, yet GL_T is *closed*. This is not surprising as condition (1.31)—unlike GL_T—does not involve B. Let the generator A be negative, self-adjoint, say with compact resolvent. (We shall, however, maintain the notation A^*.) Let $\{e_n, n=1,2,\cdots\}$ be the corresponding orthonormal basis of eigenvectors of A on Y with eigenvalues $\{-\mu_n\}$, $\mu_n>0$. Let $\mathscr{S}_i$, $i=1,2$, be two infinite, disjoint sequences of positive integers that exhaust all of the positive integers $\mathbb{Z}$: $\mathscr{S}_1\cup\mathscr{S}_2=\mathbb{Z}$; $\mathscr{S}_1\cap\mathscr{S}_2=\emptyset$. For example, $\mathscr{S}_1=\{n=2,4,6,\cdots\}$, $\mathscr{S}_2=\{n=1,3,5,\cdots\}$. Consider the orthogonal decomposition of Y

$$Y=Y_1+Y_2,\quad Y_i=\overline{\operatorname{span}}\,\{e_n, n\in\mathscr{S}_i\},\quad i=1,2. \tag{7.9}$$

Let Π_i be the orthogonal projection of Y onto Y_i, so that Π_i commutes with A, hence with the semigroup e^{At} and Y_i are invariant under e^{At}. Define a vector $b\in Y_1$ by setting

$$(b, e_n)_Y=\begin{cases}\text{sequence in } n\in\mathscr{S}_1 \text{ such that } \sum\limits_{n\in\mathscr{S}_1}\mu_n^\beta|(b,e_n)_Y|^2=\infty\\ 0,\qquad n\in\mathscr{S}_2\end{cases} \tag{7.10}$$

for all $\beta>2\gamma-1$, so that

$$b\notin\mathscr{D}((-A^*)^{\beta/2})\quad\forall\beta>2\gamma-1. \tag{7.11}$$

Next, with $U=Y=W$, define the bounded operators G^*, G and the unbounded operators B^*, B by

$$G^*y=(y_1,a)_Yb+y_2;\quad Gy=(y_1,b)_Ya+y_2;\quad y_i=\Pi_iy\in Y_i;\quad a\in Y. \tag{7.12}$$

$$\begin{aligned}&By_1=0; &&B^*y_1=0; &&y_1=\Pi_1y\in Y_1;\\ &By_2=(-A)^\gamma y_2; &&B^*y_2=(-A^*)^\gamma y_2; &&y_2=\Pi_2y\in Y_2\cap\mathscr{D}((-A)^\gamma).\end{aligned} \tag{7.13}$$

We readily obtain by (7.12), (7.11) that

$$\begin{aligned}&\mathscr{D}((-A^*)^{\beta/2}G^*)=\mathscr{D}((-A^*)^{\beta/2})\cap Y_2;\\ &(-A^*)^{\beta/2}G^*y=(-A^*)^{\beta/2}y_2,\qquad y\in\mathscr{D}((-A^*)^{\beta/2}G^*).\end{aligned} \tag{7.14}$$

Thus, $\mathscr{D}((-A^*)^{\beta/2}G^*)$ is *not dense* in Y_2, and condition (1.31) is *violated.*

On the other hand, since $B\Pi_1u(t)\equiv0$ and Y_2 is invariant under A and e^{At}, we obtain by (1.8) and (7.12),

$$\begin{aligned}GL_Tu&=G\int_0^T e^{A(T-t)}Bu(t)\,dt\\ &=G\int_0^T e^{A(T-t)}\cancel{B\Pi_1}u(t)\,dt+G\int_0^T e^{A(T-t)}B\Pi_2u(t)\,dt\\ &=G\int_0^T e^{A(T-t)}(-A)^\gamma\Pi_2u(t)\,dt=(-A)^\gamma\int_0^T e^{A(T-t)}\Pi_2u(t)\,dt,\end{aligned} \tag{7.15}$$

where in the last step we have used (7.12) on G, with the integral term in Y_2. Thus, GL_T is a *closed* operator (being the product of a closed, boundedly invertible operator $(-A)^\gamma$ and of a bounded operator [K1, p. 164]). Our claim is proved. Note that, by (1.9), one likewise has $\{L_T^*G^*y\}(t)=(-A^*)^\gamma e^{A^*(T-t)}y_2$, $y_2=\Pi_2y\in Y_2$.

7.3. Variational versus direct approach: assumption (1.46) of the direct approach fails, yet GL_T is closed. We have already noted that assumption (1.46) for the direct approach of [F4; Thm. 3.2] in the case where G is nonsmoothing, involves only the operators A and G, not B. Instead, the assumption of the variational approach of the present paper in Theorem 1.1 that GL_T be closeable involves all the data of the problem: G, A, and B. Thus, not surprisingly, we provide new classes of examples where *assumption* (1.46) *fails*, yet GL_T is *closed*. Thus, [F4; Thm. 3.2] is not applicable, while our present Theorem 1.1 is; and more generally our present §§ 2-5 are applicable. We return to the example of § 7.2 and set

$$(7.16) \qquad G_1 y = (y_1, v)_{Y_1} v, \quad G_1^* = G_1 = G_1^* G_1, \quad v \in Y_1, \quad |v| = 1,$$

where we recall that the subspaces Y_i are invariant under A and e^{At}. It follows from an observation in [F4; § 3.1] that

$$(7.17) \qquad \begin{gathered} G_1 \text{ in (7.16) satisfies assumption (1.46)} \\ \Leftrightarrow v \in \mathscr{D}((-A^*)^{\beta/2}) \cap Y_1 \quad \text{for some } \beta > 2\gamma - 1. \end{gathered}$$

Next, choose $v = b$, with $b \in Y_1$ the (normalized) vector defined in (7.10), satisfying (7.11). Thus, the operator G_1,

$$(7.18) \qquad G_1 y = (y_1, b)_{Y_1} b \text{ does not satisfy (1.46) on } Y_1.$$

Since Y_i are invariant under A, it follows that the operator G,

$$(7.19) \qquad \begin{gathered} G = G_1 + I_2 \text{ does not satisfy (1.46) on } Y; \ G_1 \text{ as in (7.18);} \\ I_2 = \text{identity on } Y_2. \end{gathered}$$

Yet, as seen in § 7.2, GL_T is *closed.*

Remark 7.3. The variational approach of this article (as well as the direct approach of [F4]) can be readily extended to allow G to be unbounded, say $G \in \mathscr{L}(\mathscr{D}(-A)^\rho, Z)$, $\rho > 0$, or $G(-A)^{-\rho} \in \mathscr{L}(Y; Z)$. Recalling the explicit formula (1.10) for the optimal $u^0(t, 0; x)$, we write accordingly,

$$\{L_T^* G^* G e^{AT} x\}(t) = B^*(-A^*)^{-\gamma}(-A^*)^\gamma e^{A^*(T-t)}(-A^*)^\rho G^* G(-A)^{-\rho}(-A)^\rho e^{AT} x$$

with $(-A)^\rho e^{AT} x \in Y$ for $x \in Y$, whereby the original γ deteriorates to $\gamma + \rho$ in terms of singularity. This will not be pursued further here.

Remark 7.4. (a) We have seen in § 7.4 that the operator G in (7.3) with ϕ as in (7.2) neither satisfies assumption (1.46) of the direct approach of [F4] (see Remark 7.2) nor does it make GL_T closeable (see below (7.4)).

(b) Suppose that $G(-A)^{\beta/2}$ is closeable for some $\beta > 2\gamma - 1$ equivalently that $(-A^*)^{\beta/2} G^*$ is densely defined, see (1.31). Then the assumptions of both approaches are satisfied; i.e., (b_1) GL_T is closeable and (b_2) assumption (1.46) holds true.

Statement (b_2) is proved in [F4; § 3.4.1]. Statement (b_1) was already noted in (1.31): since then $GL_T = G(-A)^{\beta/2} V_T$ is the product of a closeable operator and of a *bounded* operator

$$V_T u = \int_0^T (-A)^p e^{A(T-t)}(-A)^{-\gamma} Bu(t)\, dt, \ p = \gamma - \beta/2 < \tfrac{1}{2},$$

so that $V_T \in \mathscr{L}(L_2(0, T; U), Y)$.

THE RECOVERY OF POTENTIALS FROM FINITE SPECTRAL DATA*

BRUCE D. LOWE[†], MICHAEL PILANT[†‡], AND WILLIAM RUNDELL[†‡]

Abstract. The reconstruction of a Sturm–Liouville potential from finite spectral data is considered. A numerical technique based on a shooting method determines a potential with the given spectral data. Convergence of reconstructed potentials is shown and numerical examples are considered.

Key words. inverse spectral theory, Sturm–Liouville problem

AMS(MOS) subject classification. 34B25

1. Introduction. The inverse Sturm–Liouville problem is one of the most celebrated of the class of inverse problems consisting of the determination of unknown coefficients in differential equations. The problem consists of recovering the potential function $q(x)$ in

$$-y'' + q(x)y = \lambda y, \tag{1.1}$$

$$y'(0) - hy(0) = 0, \tag{1.2}$$

$$y'(1) + Hy(1) = 0 \tag{1.3}$$

from a knowledge of spectral data. There are various versions of the problem depending on the exact nature of this data. However, in each of these, it is assumed that a complete spectrum, $\{\lambda_j\}_{j=1}^{\infty}$ for (1.1)–(1.3) is given. It is well known that this is, in itself, insufficient information for the recovery of q, and thus some additional information must be provided. There are exceptions to this, when, for example, the potential is known to be symmetric about the mid point and identical boundary conditions ($h = H$) are imposed at both ends. This is the so-called symmetric case. Some of the better known versions are described in the survey article [13] and the paper [18]. We shall briefly describe these in §5.

Questions of existence and uniqueness for the inverse spectral problem have been extensively studied over the past forty years and most of the fundamental questions answered. More recently the attention has shifted to the question of obtaining efficient reconstructive methods, and this paper continues the trend. In particular, we are interested in the question of obtaining approximations to $q(x)$ from limited data. For example, consider the symmetric case where the overposed data consists of the eigenvalues $\{\lambda_n\}$. In many physical problems of interest we are able to perform accurate measurements of only a relatively small number of the lowest eigenvalues, and the accuracy obtained degrades quite rapidly with higher modes. What if, instead of a complete set of eigenvalues, we are given only the first N eigenvalues $\{\lambda_n\}_{n=1}^{N}$? The answer to this question is known; uniqueness fails of course, but the difference between any two functions $q_1(x)$ and $q_2(x)$ that have $\{\lambda_n\}_{n=1}^{N}$ as their first N eigenvalues is a sum containing only the eigenfunctions of (1.1)–(1.3), $y(x; q_1, \lambda_n)$, and $y(x; q_2, \lambda_n)$ for $n > N$, [7], [9]. Since these eigenfunctions are quite "close to" the functions $\sin n\pi x$ (for Dirichlet conditions), the difference of q_1 and q_2 consists of functions

whose frequency is at least N. This means that from finite spectral data we should be able to recover all the low frequency modes of the potential $q(x)$, but none higher than the number of eigenvalues given. It also suggests that the goal of a recovery method might be to assume that $q(x)$ has a finite trigonometric expansion and attempt to recover the Fourier coefficients from the spectral data. Indeed, this has been a popular approach and is further exploited in this paper. Thus our goal is to obtain information about the function $q(x)$ from limited spectral data—typically less than the first ten eigenvalues, and we shall demonstrate that this is quite feasible for a wide class of potentials.

For certain problems it is often the case that we are able to say that, despite the large number of techniques used in the solution, all of them start from the same basic formula or use variations within a given family of methods. This is certainly not the situation for numerical solutions to the inverse spectral problem (1.1), where there has been a wide diversity of approaches. There are methods that, because they rely on a particular representation, are only applicable to a particular type of data; there are other methods that are applicable to most versions of the inverse Sturm–Liouville family. Some methods recover the value of q at discrete points $\{x_i\}_1^M$ and require M items of spectral data; other methods place no restriction on the number of output points for the potential. We can look at this in another light; some approaches place restrictions on the types of basis expansions allowed in the approximation of $q(x)$. Some algorithms are more naturally solved by a direct method, while others require an iterative solution.

Some of the early work on the reconstruction of the potential relied on replacing the original boundary problem for an ordinary differential equation with a discrete version of the problem. This leads to the question of recovering a matrix with unknown diagonal elements from knowledge of its eigenvalues. For a discussion of this approach, including the historical perspective, see [5]. For the symmetric case with Dirichlet boundary conditions, Hald [8] developed an algorithm based on the Rayleigh–Ritz formula. This reduces to finding a matrix of a certain form, an approximation to the Sturm–Liouville operator, whose eigenvalues are prescribed. There is some overlap in the methodology between this work and the present paper: in the present paper we generate a potential whose first N eigenvalues agree with the prescribed eigenvalues $\{\lambda_j\}_{j=1}^N$. We also show that our scheme is applicable to other inverse spectral problems.

In the original paper by Gel'fand and Levitan [6], a formula is developed that has been used to provide a numerical scheme. This requires solving the integral equation

$$K(x,t) + \int_0^x K(x,s)f(s,t)ds = f(x,t) \qquad 0 \le t \le x \tag{1.4}$$

for the function $K(x,t)$ at each fixed $x \in [0,1]$. Here the function $f(x,t)$ is obtained from data of the spectral function type. The potential is then recovered from $q(x) = 2(d/dx)K(x,x)$. The main difficulty with the method, and one that limits its effectiveness, is the sensitivity of the solution of the integral equation on the data function $f(x,t)$. This is given as the difference of two series in which, although the combination converges, each component is rapidly divergent. This leads to difficulties in accurate computation of f. In addition, the method has a relatively high operational count and, at least in the usual formulation, is restricted to spectral data consisting of eigenvalues and norming constants. Despite these drawbacks, the approach has provided a starting place for other techniques. McLaughlin and Handelman [12] have given a method of solution based on the Gel'fand–Levitan integral equation. Sacks [19] has given an iterative method (actually a quasi-Newton method) that is based on the mapping from $K(x,x)$ to $K_t(x,0)$. This significantly reduces the operational count from the original Gel'fand–Levitan formulation and provides an efficient reconstruction of $q(x)$ from eigenvalue plus norming constant data. Recently, Rundell and Sacks [18] gave an approach based on a representation theorem of Gel'fand and Levitan. This method translated the spectral data into Cauchy data for a certain hyperbolic equation which in turn converted the original Sturm–Liouville problem into an overposed problem for this wave equation, and this could be solved by an iterative procedure. This approach leads to a scheme with considerable flexibility in the type of overposed data it can handle and in the type of basis expansions for $q(x)$. The algorithm is extremely robust and has a very low operational count. Hald [7] showed that an algorithm, based on the work of Hochstadt [9], will always provide a solution of the inverse problem in the symmetric case. More recently, Andersson [1] has extended these techniques to the so called "impedance case," the recovery of the function $p(x)$ in $-(py')' = \lambda py$. There are extremely elegant characterizations of the isospectral sets corresponding to Dirichlet data, that is, the set of potentials $q(x)$ that have a given (Dirichlet) spectrum, [17]. These ideas can be used to provide constructive algorithms. Finally, Paine [16] has shown that a Newton type method can be used in the symmetric case. This relies on finding a solution of the potential to eigenvalue map, and there is some overlap with the ideas in the present paper. In all overposed problems, there is a certain latitude in deciding which items of data are "basic" to the problem and which are "additional." Put another way, the question is: what is considered to be the underlying direct problem; that is, the problem of recovering $y(x)$ in (1.1)–(1.3). It is more natural perhaps to consider the boundary conditions as "basic" and the eigenvalues to be the extra information used in the recovery of q. This was the approach taken by Paine. However, for a given $q(x)$ and eigenvalue sequence we can determine the eigenfunctions completely using only left endpoint data. This leaves the boundary condition imposed at the right endpoint to be used as the additional information for the recovery of q, and is the method of the present paper. At the start of this paragraph we mentioned the diversity of approaches to the problem. There is one thing that seems to be common to all of the above approaches—their restriction of applicability to one space variable. In most cases this is inherent in the method. For example, those methods based on the Gel'fand–Levitan representation are limited due to the fact that this only holds in one space dimension. The method of the present paper can, at least formally, be applied in higher dimensions, and this is one of the motivations for our study.

The plan of the paper is as follows. In the next section we will present our method for the symmetric case with Dirichlet boundary conditions. We shall show that our algorithm is always well defined and the associated iteration scheme converges to a function in a well-defined approximating set. In §3 we consider the two spectrum case for a general nonsymmetric potential. In §4 we consider the problem of the convergence of the approximations. Finally, in §5, we present some numerical results and discuss some of the other inverse Sturm–Liouville problems, indicating the minor modifications required to the algorithm.

2. Single spectrum case for a symmetric potential.

The operator

$$L \equiv -\frac{d^2}{dx^2} + q(x) \tag{2.1}$$

with unknown symmetric potential $q(x)$ on $[0,1]$ can be uniquely determined from the Dirichlet spectrum [3], or equivalently, the zeros of the entire function $u(1;q,\lambda)$, where $u(x;q,\lambda)$ satisfies

$$\begin{aligned} -u''(x;q,\lambda)+q(x)u(x;q,\lambda)&=\lambda u(x;q,\lambda),\\ u(0;q,\lambda)&=0,\\ u'(0;q,\lambda)&=1. \end{aligned} \tag{2.2}$$

Knowledge of the first N Dirichlet eigenvalues $\lambda_1,\cdots,\lambda_N$ will not uniquely determine the operator L. Indeed, expanding $q(x)$ into a Fourier cosine series

$$q(x)=q_0+\sum_{k=1}^{\infty} q_k\cos(2\pi kx),$$

we can at best hope to determine the first N coefficients $\{q_0,\cdots,q_{N-1}\}$. However, for N not too large, this should be adequate to approximate a sufficiently smooth $q(x)$. It is natural to seek an approximation

$$q^N(x)=q_N+\sum_{k=1}^{N-1} q_k\phi_k(x)$$

that lies in the space

$$\mathcal{S}_N\equiv \text{ span }\{1,\phi_k(x)=\cos(2\pi kx),k=1,\cdots,N-1\},$$

and for which $\lambda_1,\cdots,\lambda_N$ are zeros of $u(1;q^N(x),\lambda)$.

Let $\Lambda_N\equiv(\lambda_1,\cdots,\lambda_N)$ and define $F:\mathcal{R}^N\to\mathcal{R}^N$ by

$$F_j(\Lambda_N;q_1,\cdots,q_N)\equiv u_j(1;q_1,\cdots,q_N,\lambda_j)\equiv u\left(1;q_N+\sum_{i=1}^{N-1} q_i\cos(2\pi ix),\lambda_j\right). \tag{2.3}$$

We seek a vector $\vec{q}\equiv(q_1,\cdots,q_N)$ for which $F(\Lambda_N;q)=0$. When no ambiguity can occur, we drop the explicit vector notation. Theorem 1 shows that this is possible for $q(x)$ sufficiently close to zero.

The proof of Theorem 1 relies on the following result.

LEMMA 1. *Let $\Lambda_{N,0}=(\pi^2,4\pi^2,\cdots,N^2\pi^2)$ denote the first N Dirichlet eigenvalues corresponding to $q(x)=0$. The Jacobian $F_q(\Lambda;q)|_{\Lambda=\Lambda_{N,0},q=0}$ is upper triangular with elements*

$$\frac{\partial F_j}{\partial q_j}(\Lambda;q)|_{\Lambda=\Lambda_{N,0},q=0}=\frac{(-1)^j}{4\pi^2 j^2},\qquad j=1,\cdots,N-1,$$

$$\frac{\partial F_j}{\partial q_N}(\Lambda;q)|_{\Lambda=\Lambda_{N,0},q=0}=\frac{(-1)^{j+1}}{2\pi^2 j^2},\qquad j=1,\cdots,N$$

and with all the other elements zero.

As a direct consequence, the eigenvalues of $F_q(\Lambda_{N,0};0)$ are given by $(-1)^j/(4\pi^2j^2)$ for $j=1,\cdots,N-1$ and $(-1)^{N+1}/(2\pi^2N^2)$. The spectral condition number of $F_q(\Lambda_{N,0};0)$ is therefore

$$\mu\equiv\frac{|\lambda_{\max}|}{|\lambda_{\min}|}=\frac{N^2}{2}.$$

Proof. Using (2.2), it is easily verified that $u(x;0,\lambda_j) = \sin\sqrt{\lambda_j}x/\sqrt{\lambda_j}$. Furthermore, $w \equiv (\partial u_j/\partial q_k)(x;0,\lambda_j)$ satisfies the ordinary differential equation

$$\begin{aligned} -w'' &= \lambda_j w - \phi_k(x)u(x;0,\lambda_j), \\ w(0) &= 0 = w'(0) \end{aligned} \tag{2.4}$$

which has the solution

$$w(x) = \int_0^x u(x-t;0,\lambda_j)\phi_k(t)u(t;0,\lambda_j)dt. \tag{2.5}$$

Consequently, the jkth element of the Jacobian matrix is given by

$$\frac{\partial u_j}{\partial q_k}(1;0,\lambda_j) = \int_0^1 \frac{1}{\lambda_j}\sin(\sqrt{\lambda_j}(1-t))\sin(\sqrt{\lambda_j}t)\phi_k(t)dt, \tag{2.6}$$

where $\lambda_j = j^2\pi^2$. The result follows easily from a direct integration. □

The special structure of the Jacobian arises from the particular choice of the Fourier basis.

THEOREM 1. *For fixed N and $q(x) \in \mathcal{S}_N$ sufficiently small, $F(\Lambda_N, q)$ has a unique zero, denoted by $q^N(x)$.*

Proof. The Dirichlet eigenvalues of L depend continuously on L^∞ perturbations of the potential [17]. Consequently, for $q(x)$ near zero, Λ_N is a perturbation of $\Lambda_{N,0}$. Since $F(\Lambda_{N,0},0) = 0$, $F_q(\Lambda_{N,0},0)$ is nonsingular, and the function $F(\Lambda_N,q)$ depends smoothly on Λ_N and q, the result follows from the Implicit Function Theorem. □

Several comments are in order. First, the implicit function theorem is not constructive. Second, the theorem does not provide us with a uniform estimate on $q^N(x)$. We require such an estimate in order to obtain a convergence proof, and we derive this estimate in Lemma 4.

In order to actually determine the basis coefficients of $q^N(x)$, $(q_1^N, q_2^N, \cdots, q_N^N)$, we iterate using Newton's method, which yields the scheme

$$\begin{aligned} F_q(\Lambda_N; q^{(m)})\delta q^{(m)} &= -F(\Lambda_N; q^{(m)}), \\ q^{(m+1)} &= q^{(m)} + \delta q^{(m)}. \end{aligned} \tag{2.7}$$

If $q(x)$ is sufficiently close to zero, then $F_q(\Lambda_N; q_1^N, q_2^N, \cdots, q_N^N)$ is nonsingular and the scheme converges quadratically to $(q_1^N, q_2^N, \cdots, q_N^N)$ for all initial guesses which are sufficiently close. If instead of evaluating the Jacobian at $q^{(m)}$, we evaluate it at $q = 0$, we obtain a quasi-Newton scheme. This is more computationally efficient in practice.

Let us now consider the case where the mean of the potential is known. This can in fact be recovered from the spectral data, see [18]. When $\alpha \equiv \int_0^1 q(x)dx$, the problem reduces to finding $q^N(x) \in$ span $\{\cos(2\pi ix), i = 1, \cdots, N\}$ for which

$$u(1; q^N(x), \lambda_j - \alpha) = 0 \quad \text{for } j = 1, \cdots, N. \tag{2.8}$$

If we define $\bar{F} : \mathcal{R}^N \to \mathcal{R}^N$ by

$$\bar{F}_j(\Lambda_N, q_1, \cdots, q_N) = u\left(1; \sum_{r=1}^N q_r\cos(2\pi rx), \lambda_j\right), \qquad j = 1, \cdots, N$$

with

$$\Lambda_N = (\lambda_1 - \alpha, \cdots, \lambda_N - \alpha),$$

then the following lemma holds.

LEMMA 2.

$$\frac{\partial \bar{F}_j}{\partial q_k} = \frac{\partial u}{\partial q_k}(1; 0, \lambda_j) = \begin{cases} \dfrac{\sin\sqrt{\lambda_j}}{2\sqrt{\lambda_j}(\lambda_j - \pi^2 k^2)} & \textit{if } \dfrac{1}{\pi}\sqrt{\lambda_j} \neq \textit{ integer}, \\ 0 & \textit{if } \dfrac{1}{\pi}\sqrt{\lambda_j} = \textit{ integer } (\neq k), \\ \dfrac{(-1)^k}{4\pi^2 k^2} & \textit{if } \dfrac{1}{\pi}\sqrt{\lambda_j} = k. \end{cases}$$

Using the estimate $\lambda_j = \pi^2 j^2 + c_j$ where $c_j \in l^2(n)$ [17], the following theorem gives a sufficient condition for $\bar{F}_q(\Lambda_N, 0)$ to be nonsingular. This is particularly useful when employing the quasi-Newton method.

THEOREM 2. *If* $\Lambda_N = \{\lambda_j\}_{j=1}^{j=N}$, $\lambda_j = j^2\pi^2 + c_j$ *and* $|c_j| \leq \min\{C(j/\sqrt{\lambda_j}), \pi^2/4\}$, *then for* C *independent of* N *and sufficiently small*

$$\det \bar{F}_q(\Lambda_N, 0) \neq 0.$$

Proof. The proof of Theorem 2 follows from some simple inequalities which imply diagonal dominance.

Setting $a_j \equiv \sqrt{\lambda_j} - j\pi = \sqrt{\pi^2 j^2 + c_j} - \pi j$, a first-order MacLaurin expansion gives

$$|a_j| \leq \frac{c_j}{\sqrt{3}\pi j} \leq \frac{C}{\sqrt{3}\pi\sqrt{\lambda_j}}.$$

Summing the off-diagonal entries of the Jacobian matrix yields

$$\begin{aligned} \sum_{j\neq k} \left|\frac{\partial \bar{F}_j}{\partial q_k}(\Lambda_N, 0)\right| &= \sum_{j\neq k} \frac{|\sin\sqrt{\lambda_j}|}{2\sqrt{\lambda_j}|\lambda_j - \pi^2 k^2|} \\ &= \sum_{j\neq k} \frac{|\sin(a_j)|}{2\sqrt{\lambda_j}|\lambda_j - \pi^2 k^2|} \leq \sum_{j\neq k} \frac{|a_j|}{2\sqrt{\lambda_j}|\lambda_j - \pi^2 k^2|} \\ &\leq \frac{C}{2\sqrt{3}\pi} \sum_{j\neq k} \frac{1}{\lambda_j|\lambda_j - \pi^2 k^2|} \leq \frac{C}{2\sqrt{3}\pi^3 k^2}\left[\sum_{j\neq k} \frac{1}{\lambda_j} + \frac{1}{|\lambda_j - \pi^2 k^2|}\right]. \end{aligned}$$

With the estimates

$$\sum_{j\neq k} \frac{1}{\lambda_j} \leq \sum_{j\neq k} \frac{1}{\pi^2(j^2 - \frac{1}{4})} \leq \frac{1}{\pi^2}\sum_{j=1}^{\infty} \frac{2}{j^2} = \frac{1}{3}$$

and

$$\sum_{j\neq k} \frac{1}{|\pi^2 k^2 - \lambda_j|} \leq \sum_{j\neq k} \frac{1}{\pi^2|j^2 - k^2 - \frac{1}{4}|} \leq \frac{1}{3} + \frac{2(2+\sqrt{3})}{3\pi^2},$$

we obtain

$$\sum_{j\neq k} |\frac{\partial \bar{F}_j}{\partial q_k}(\Lambda_N, 0)| \leq \frac{C}{3\sqrt{3}\pi^3 k^2}\left[1+\frac{2+\sqrt{3}}{\pi^2}\right].$$

By a simple argument, we can show that the diagonal element satisfies

$$|\frac{\partial \bar{F}_i}{\partial q_i}(\Lambda_N, 0)| \geq \frac{1}{4\pi^2 i^2}\,\frac{96-24\sqrt{3}-4\sqrt{3}\pi}{97-12\sqrt{3}},$$

and the matrix will be diagonal dominant if

$$C < \frac{-54\pi^3+72\sqrt{3}\pi^3-9\pi^4}{158+73\sqrt{3}+97\pi^2-12\sqrt{3}\pi^2} \approx 1.26918.$$

We remark that the constant $C \approx 1$ corresponds to extremely large potentials.

3. Two spectrum case for a general potential. In the general case of a potential $q(x) \in L^2[0,1]$, we choose the $2N$ basis functions

$$\{\phi_k(x)\}|_{k=1}^{k=2N} = \{\sin 2\pi x, \cos 2\pi x, \cdots, \sin 2N\pi x, \cos 2N\pi x\}. \tag{3.1}$$

As in the previous section, we have assumed (by suitable renormalization) that the potential has zero mean.

In order to determine $q(x)$ uniquely, we must give two sets of spectra which, for purposes of this section, we suppose are Dirichlet–Dirichlet and Dirichlet–Neumann spectra:

$$\Lambda = \{\lambda_j, \mu_j\}|_{j=1}^{j=\infty},$$

where

$$-u'' + q(x)u = \lambda_j u, \quad u(0) = 0 = u(1), \quad u'(0) = 1$$

and

$$-v'' + q(x)v = \mu_j v, \quad v(0) = 0 = v'(1), \quad v'(0) = 1.$$

As before, we define u_j and v_j, respectively, as solutions of the initial value problems (for a given $q(x)$)

$$-u_j'' + q(x)u_j = \lambda_j u_j, \quad u_j(0) = 0, \quad u_j'(0) = 1$$

and

$$-v_j'' + q(x)v_j = \mu_j v_j, \quad v_j(0) = 0, \quad v_j'(0) = 1.$$

We have

$$\frac{\partial u}{\partial q_k}(1; 0, \lambda_j) = \int_0^1 u(1-t; 0, \lambda_j)\phi_k(t)u(t; 0, \lambda_j)dt,$$

$$\frac{\partial v}{\partial q_k}(1; 0, \lambda_j) = \int_0^1 v(1-t; 0, \lambda_j)\phi_k(t)v(t; 0, \lambda_j)dt,$$

which can be explicitly computed. An argument similar to that of Theorem 2 yields the following.

THEOREM 3. *If the Dirichlet–Dirichlet and Dirichlet–Neumann spectra for a potential of mean zero are sufficiently close to $q = 0$ spectra, in the sense that*

$$|\sqrt{\lambda_j} - j\pi| \leq C/\sqrt{\lambda_j}$$

and

$$|\sqrt{\mu_j} - \left(j - \frac{1}{2}\right)\pi| \leq C/\sqrt{\mu_j}$$

with C sufficiently small, and if ϕ_k is the Fourier basis for $L^2[0,1]$, then there is a unique $q^N \in$ span $\{\phi_k\}_{k=1}^{k=2N}$ with the prescribed spectra.

The coefficients of $q(x)$, with respect to the basis ϕ_k, can be recovered by either the Newton or quasi-Newton procedure given in §2.

4. A convergence theorem. The following heuristic argument justifies, in part, the excellent approximation properties of our algorithm. For a symmetric potential, the actual solution of (1.1)–(1.3) satisfies

$$(4.1) \qquad 0 = u_j(1; q, \Lambda_N), \qquad j = 1, 2, \cdots, N,$$

while the approximation $q^N \in S_N$ satisfies

$$(4.2) \qquad 0 = u_j(1; q^N, \Lambda_N), \qquad j = 1, 2, \cdots, N.$$

Expanding (4.1), we have

$$(4.3) \quad 0 = F(\Lambda_N, q) = F(\Lambda_N, q^N) + \frac{\partial F}{\partial q}(\Lambda_N, q^N) \cdot (q - q^N) + \mathcal{O}(|q - q^N|^2).$$

If $\det(\partial F/\partial q)(\Lambda_N, q^N) \neq 0$ and $0 = F(\Lambda_N, q^N)$, then we have to first order $q - q^N \notin S_N$. If we chose an orthonormal basis for S_N, we therefore have (to leading order) $q - q^N \perp S_N$; that is, q^N is very close to the best L^2 approximation to q in that space. This is in fact shown by the numerical computations given in §5. This also motivates the choice of the Fourier basis.

For the remainder to this section we shall assume that $q(x)$ is a symmetric L^2 potential with mean zero and spectrum $\{\lambda_j\}_{j=1}^{\infty}$, satisfying the following.

Assumption A. For some constants $\alpha, \beta > 0$ the eigenvalues of q satisfy $|\lambda_j - \pi^2 j^2| \leq \beta/(j^{1+\alpha})$.

We show that for β sufficiently small, $q^N(x)$ generated by the shooting method of §2 converges in L^2 to $q(x)$. Assumption A implies that $q(x) \in L^\infty$, [17, p. 39].

Consider the map $F : V_N \to \mathbf{R}^N$ given by

$$F_j(\Lambda_N, q) = 4(-1)^j \lambda_j u(1; q, \lambda_j), \qquad j = 1, \cdots, N,$$

where $\Lambda_N = (\lambda_1, \cdots, \lambda_N)$, $V_N = \{q \in \text{span}(\phi_k, k = 1, \cdots, N), \|\vec{q}\|_{L^1} \leq 1\}$, and $u(x; q, \lambda_j)$ solves (2.2). Here $\phi_k(t) = \cos 2\pi k t$. For β sufficiently small, we show that $q^N(x) \in V_N$ for all N. This readily follows once a Lipschitz bound independent of N is established for the Jacobian of F. This is given in Lemma 3, the proof of which can be found in the appendix. In what follows, C denotes a constant that is independent of k, β, and N.

LEMMA 3. *For $q^{(i)} \in V_N$ and all β sufficiently small*

$$\sum_{j=1}^{N}\left|\frac{\partial F_j}{\partial q_k}(\Lambda_N,q^{(1)}) - \frac{\partial F_j}{\partial q_k}(\Lambda_N,q^{(2)})\right| \le C\|q^{(1)} - q^{(2)}\|_{L^2}.$$

LEMMA 4. *If the eigenvalues λ_n satisfy* (A), *then for all β sufficiently small, $\|q^N\|_{L^2} \le 1$.*

Proof. By Lemma 3, $\|F'(\Lambda_N,q^{(2)}) - F'(\Lambda_N,q^{(1)})\|_{L^1} \le C\|q^{(1)}(\cdot) - q^{(2)}(\cdot)\|_{L^2} \le C\|\vec{q}^{(1)} - \vec{q}^{(2)}\|_{L^1}$ for $q^{(i)} \in V_N$, where C is independent of N. It is easy to show that $F'(\Lambda_N,0) = I - H_N$, where $\|H_N\|_{L^1} < \frac{1}{2}$ for β sufficiently small. Consequently, $\|F'(\Lambda_N,0)^{-1}\|_{L_1} < 2$ for all N and $\|F'(\Lambda_N,0)^{-1}F(\Lambda_N,0)\|_{L_1} \le 2\|F(\Lambda_N,0)\|_{L_1} \le 8\sum_{j=1}^{\infty}|\sqrt{\lambda_j}\sin\sqrt{\lambda_j}| \le C\beta\{\sum_{j=1}^{\infty}j^{-1-\alpha}\}$, which can be made arbitrarily small by choosing β appropriately. Using Newton's iteration, [4, p. 157], $\|\vec{q}^N\|_{L^1} \le 1$, giving $\|q^N\|_{L^\infty} \le 1$ and consequently $\|q^N\|_{L^2} \le 1$ for all N.

The convergence of $q^N(x)$ to $q(x)$ follows from the asymptotics of the eigenvalues of $q^N(x)$ and the continuity of the eigenvalue to potential map.

THEOREM 4. *If the eigenvalues λ_n satisfy* (A), *then for β sufficiently small q^N converges strongly to q in L^2.*

Proof. The eigenvalues $\lambda_k(q^N)$ satisfy the estimate

$$\left|\lambda_k(q^N) - \pi^2k^2 - \int_0^1(\cos 2\pi kx)q^N(x)dx\right| \le \frac{C}{k},$$

where C is independent of N [17, p. 35]. For N sufficiently large, $\lambda_k(q^N) = \lambda_k$ for $k = 1,\cdots,N$, by the counting lemma of [17, p. 28] and for $k \ge N+1$, $\langle q^N, \cos 2\pi kx\rangle_{L^2} = 0$, giving $|\lambda_k(q^N) - \pi^2k^2| \le C/k$. Now

$$\begin{aligned}\sum_{k=1}^{\infty}(\lambda_k(q^N) - \pi^2k^2)^2 &= \sum_{k=1}^{N}(\lambda_k - \pi^2k^2)^2 + \sum_{k=N+1}^{\infty}(\lambda_k(q^N) - \pi^2k^2)^2\\ &\le \sum_{k=1}^{\infty}(\lambda_k - \pi^2k^2)^2 + C\sum_{k=N+1}^{\infty}\frac{1}{k^2}\\ &\le \beta^2\sum_{k=1}^{\infty}\frac{1}{k^{2(1+\alpha)}} + C\sum_{k=N+1}^{\infty}\frac{1}{k^2}.\end{aligned}$$

For β sufficiently small and N sufficiently large, Hald's continuous dependence result [8] is applicable, giving

$$\begin{aligned}\|q^N - q\|_{L^2}^2 &\le C\sum_{k=1}^{\infty}(\lambda_k(q^N) - \lambda_k)^2 = C\sum_{k=N+1}^{\infty}(\lambda_k(q^N) - \lambda_k)^2\\ &\le C\left\{\sum_{k=N+1}^{\infty}(\lambda_k(q^N) - \pi^2k^2)^2 + \sum_{k=N+1}^{\infty}(\lambda_k - \pi^2k^2)^2\right\}\\ &\le C\left\{\sum_{k=N+1}^{\infty}\frac{1}{k^2} + \beta^2\sum_{k=N+1}^{\infty}\frac{1}{k^{2(1+\alpha)}}\right\}\\ &\le \frac{C}{N}.\end{aligned}$$

Clearly, $q^N \to q$ in L^2 with convergence rate of order half.

5. Numerical experiments. In this section we present some numerical experiments that we carried out to illustrate the performance of the algorithm. We will do so in three particular cases of the inverse Sturm–Liouville problem: symmetric $q(x)$; data consisting of two spectra; data consisting of the function $\lambda_j(H)$. We shall be able to point out some of the features of the method and be able to show its strengths as well as its weaknesses.

In order to construct data for the direct problem, that is, for given $q(x)$, the eigenvalues (and eigenfunctions if appropriate) we used the routine SLEIGN which is described in [2].

For the remainder of this section we will adopt the following notations. The function $u_j = u_j(x; q, \lambda)$ is the solution of the initial value problem

$$-u_j''(x) + q(x)u_j(x) = \lambda u_j(x), \qquad u_j(0) = 1, \quad u_j'(0) = h, \tag{5.1}$$

and the Frêchet derivative of u_j, with respect to q in the direction $\phi_k(x)$, we denote by $\hat{u}_{jk}(x)$. This satisfies

$$\begin{gathered} -\hat{u}_{jk}''(x) + q(x)\hat{u}_{jk}(x) = \lambda\hat{u}_{jk}(x) - \phi_k(x)u_j(x; q(x), \lambda), \\ \hat{u}_{jk}(0) = 0, \quad \hat{u}_{jk}'(0) = 0 \end{gathered} \tag{5.2}$$

with $\lambda = \lambda_j$ for $1 \leq j \leq N$ and $\phi_k(x)$ the kth element of the basis set, $1 \leq k \leq B$. If the boundary condition at the left endpoint is of Dirichlet type, then we modify the above in the obvious way, choosing $u_j(0) = 0$ and normalizing by $u_j'(0) = 1$. We denote by A_{jk} the $N \times B$ matrix with elements $\hat{u}_{jk}$. The boundary condition at $x = 1$ we shall denote by

$$\mathcal{B}[u] \equiv u'(1) + Hu(1) = 0 \tag{5.3}$$

and the resolution of the (finite-dimensional) inverse Sturm–Liouville problem requires that there be q such that $\mathcal{B}[u(\cdot; q; \lambda)] = 0$ for $\lambda = \lambda_j$, $1 \leq j \leq N$ for the given eigenvalues $\{\lambda_j\}$. Given the mth iterative approximation for $q(x)$, we update by

$$\mathcal{B}\left[u_j[q^{(m)}] + \frac{\partial u_j}{\partial q_k}[q^{(m)}].\delta q^{(m)}\right] = 0.$$

Since $\mathcal{B}$ is linear, we have

$$\mathcal{B}\left[\hat{u}_{jk}[q^{(m)}]\right].\delta q^{(m)} = -\mathcal{B}\left[u_j[q^{(m)}]\right]$$

as our update strategy. In each of the computations of $u_j(x)$ and $\hat{u}_{jk}(x)$, the current approximation $q^{(m)}$ is used. We used a Runge–Kutta–Fehlberg adaptive routine to perform the integration steps for the solutions of the initial value problems.

For the case of the recovery of a symmetric potential from the sequence of eigenvalues λ_j, $1 \leq j \leq N$, the algorithm is outlined in Fig. 1. Note that in the general symmetric case, symmetry is also required of the boundary data so that $\mathcal{B}[u] = u'(1) + hu(1)$.

Note that this algorithm does not require any separate input of the value of the mean $\int_0^1 q(s)ds$; the assumption of zero mean was only to simplify the analysis.

In all computations to be described we used the quasi-Newton version of the algorithm; in every example we tried, the differences in each iterate between the Newton

```
set $\mathcal{B}[u] = u'(1) + hu(1)$
set $q_0(x)$
do for $1 \le n \le max\ iterations$ {
    do for $1 \le j \le N$ {
        ode compute( $u_j$ )
        $b_j := \mathcal{B}[u_j]$
        do for $1 \le k \le B$ {
            ode compute( $\hat{u}_{jk}$ )
            $A_{jk} := \mathcal{B}[\hat{u}_{jk}]$
        }
    }
    svd matrix $A_{jk}$
    zero out small singular values
    solve $A_{jk} c_k = -b_j$
    $\delta q(x) := \sum c_k \phi_k(x)$
    $q_n(x) = q_{n-1}(x) + \delta q(x)$
}
```

FIG. 1. *Algorithm flowchart.*

and the quasi-Newton was within 1 percent. The difference in program running time was, of course, significant.

An initial approximation $q_0(x)$ is required, and we took this to be the zero function. Provided reasonable values were used, the algorithm was not sensitive to the choice of q_0.

We found that the number of iterations of the procedure before effective convergence of the functions q_n was obtained was always very small; most of the reconstruction coming in the first iteration, and the remainder in the next two.

The reason for the phenomena described in each of the three previous paragraphs is that the mapping from a given potential $q(x)$ to the spectral data is apparently very nearly linear. This observation was made in [18] where similar results were obtained.

The basis functions $\phi_k(x)$, $1 \le k \le B$ should be selected to match the expected functions $q(x)$. We used trigonometric functions, linear splines, and cubic splines. The algorithm allows the number of data items N to be different from the number of basis functions B. Usually one would choose $B = N$ to maximize the amount of information utilized. As the previous sections showed for the case of trigonometric basis functions and λ_j corresponding to the first N eigenvalues for the symmetric potential, we can simply invert the system $Ac = b$ in order to solve for the basis coefficients c_k of the function δq. The matrix remains well conditioned for all reasonable values of N. For other basis functions and spectral problems this is not always the case. In addition, we may have the situation where the spectral data is subject to measurement error and we wish to give additional data, that is, we have $N > B$. This is where the singular value decomposition is employed. We can use this to edit out the small singular values (those values σ_k with $\sigma_k < \sigma_{\max} TOL$) before back substituting to obtain the solution vector c_k. For general values of N and B we are therefore finding a least squares fit to this solution vector from the given data. All the runs shown below were made with TOL in the range $(10^{-6}, 10^{-4})$. In the case of the recovery problem with data consisting of the values of $\lambda_1(H_j)$ for N values of the parameter H, we were never able to recover functions with more than about six significant modes, and the use of the least squares approach becomes an essential feature of the method.

As we shall show, the algorithm outlined above can be extended to those spectral problems that consist entirely of eigenvalue data or eigenvalue data plus some pointwise information about the eigenfunction. For convenience we describe here those problems for which a uniqueness result for the inverse problem is known. In most of these cases the modification required to the algorithm consists simply of using the correct boundary operator $\mathcal{B}$ and perhaps a modification to the basis set.

Two spectrum case. Here we must recover the potential $q(x)$ from a double sequence of eigenvalues $\{\lambda_j^{(1)}, \lambda_j^{(2)}\}$, where we let $\{\lambda_j^{(1)}\}$ denote the eigenvalues corresponding to the boundary condition $u'(1) + H_1 u(1)$ and $\{\lambda_j^{(2)}\}$ denote the eigenvalues corresponding to the boundary condition $u'(1) + H_2 u(1)$. If there are $N/2$ eigenvalues from each set, and B basis functions, then A is again an $N \times B$ matrix whose entries are the values of $\mathcal{B}[\hat{u}_{jk}]$, where $H = H_1$ for $j \le N/2$ and $H = H_2$ for $N/2 < j \le N$.

Partially known q. If the function $q(x)$ is known on the interval $[0, \frac{1}{2}]$ and one complete spectrum is provided, then it is known that $q(x)$ can be uniquely determined over the remainder of the interval, [10]. To modify the basic algorithm we only need modify the basis set to consist of functions that span the interval $[\frac{1}{2}, 1]$.

Endpoint data. Here we let $\{\lambda_j\}$ denote the $N/2$ eigenvalues corresponding to the boundary condition $u'(1) + Hu(1)$. The data also includes the $N/2$ numbers k_j which are the values of the jth eigenfunction at $x = 1$, which, in view of the known boundary condition at the right-hand endpoint, also determines the values of $u_j'(1)$. Thus, in Fig. 1 we set the vector b_j to be

$$b_j = \begin{cases} u_j(1) - k_j & \text{if } j \le N/2, \\ u_j'(1) + Hk_j & \text{if } j > N/2. \end{cases}$$

Variable boundary condition data. In this version of the inverse Sturm–Liouville problem, we are given the value of $\lambda_M(H)$ as a function of H for some *fixed* eigenvalue number M, and where H runs over some interval. The algorithm is, thus, virtually identical to that depicted in Fig. 1. Suppose the data is of the form $\{H_j, \lambda_j\}$, where λ_j denotes the value of (say) the smallest eigenvalue of the problem when $H = H_j$. Then for each j we set $\mathcal{B}[u] = u_j'(1) + H_j u_j(1)$. Of course, the basis set must include both even and odd functions on the interval.

Figure 2a shows a reconstruction of the symmetric potential

$$q(x) = 1 - \exp(-20(x - 0.5)^2)$$

from Dirichlet eigenvalues and $B = N = 3$. The supremum norm difference between the reconstructed q and the actual q is 0.038.

With $B = N = 5$, this error is reduced to 0.004. In this and subsequent such graphs, the actual function is represented by a dashed line.

The asymptotic formula for the (Dirichlet) eigenvalues is given by $\lambda_n = n^2\pi^2 + \int_0^1 q(s)ds + c_n$, where c_n is in ℓ^2. As was shown in [14] and [18], the appropriate measure of accuracy for the data are the numbers c_n; we can expect to recover the potential from a reasonably small error in the c_n, but we can never expect to do so from even a few percent error in the eigenvalues themselves. We added 10 percent random

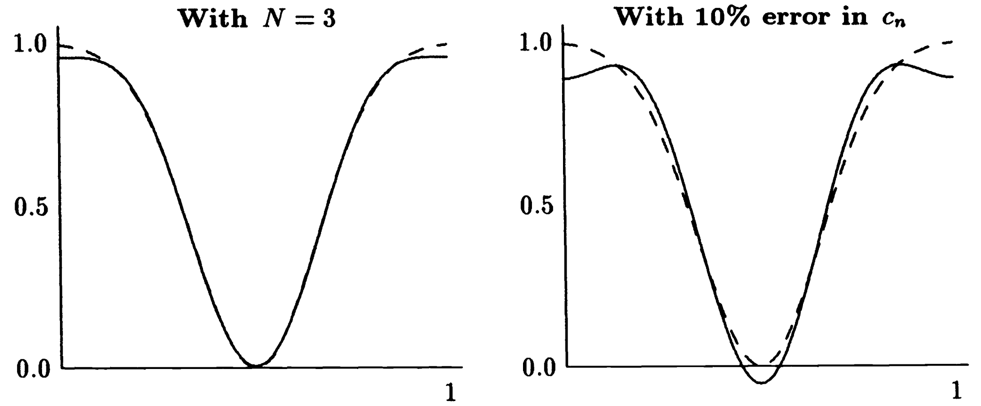

FIG. 2. *Reconstruction of a symmetric $q(x)$ from Dirichlet spectra.*

error to the numbers $\lambda_n - n^2\pi^2 - \int_0^1 q(s)ds$ and used the result in the recovery routine. Figure 2b shows a reconstruction under these conditions using the first five Dirichlet eigenvalues. Notice that in both these figures the reconstruction is much poorer at the endpoints of the interval. This is due to the fact that the actual potential is not a smooth periodic function on the real line, having discontinuities in the derivative at the points $x = 0, 1$, whereas any element in the span of the basis set is smooth. Similar effects can be expected in any method that uses a finite trigonometric basis, [18].

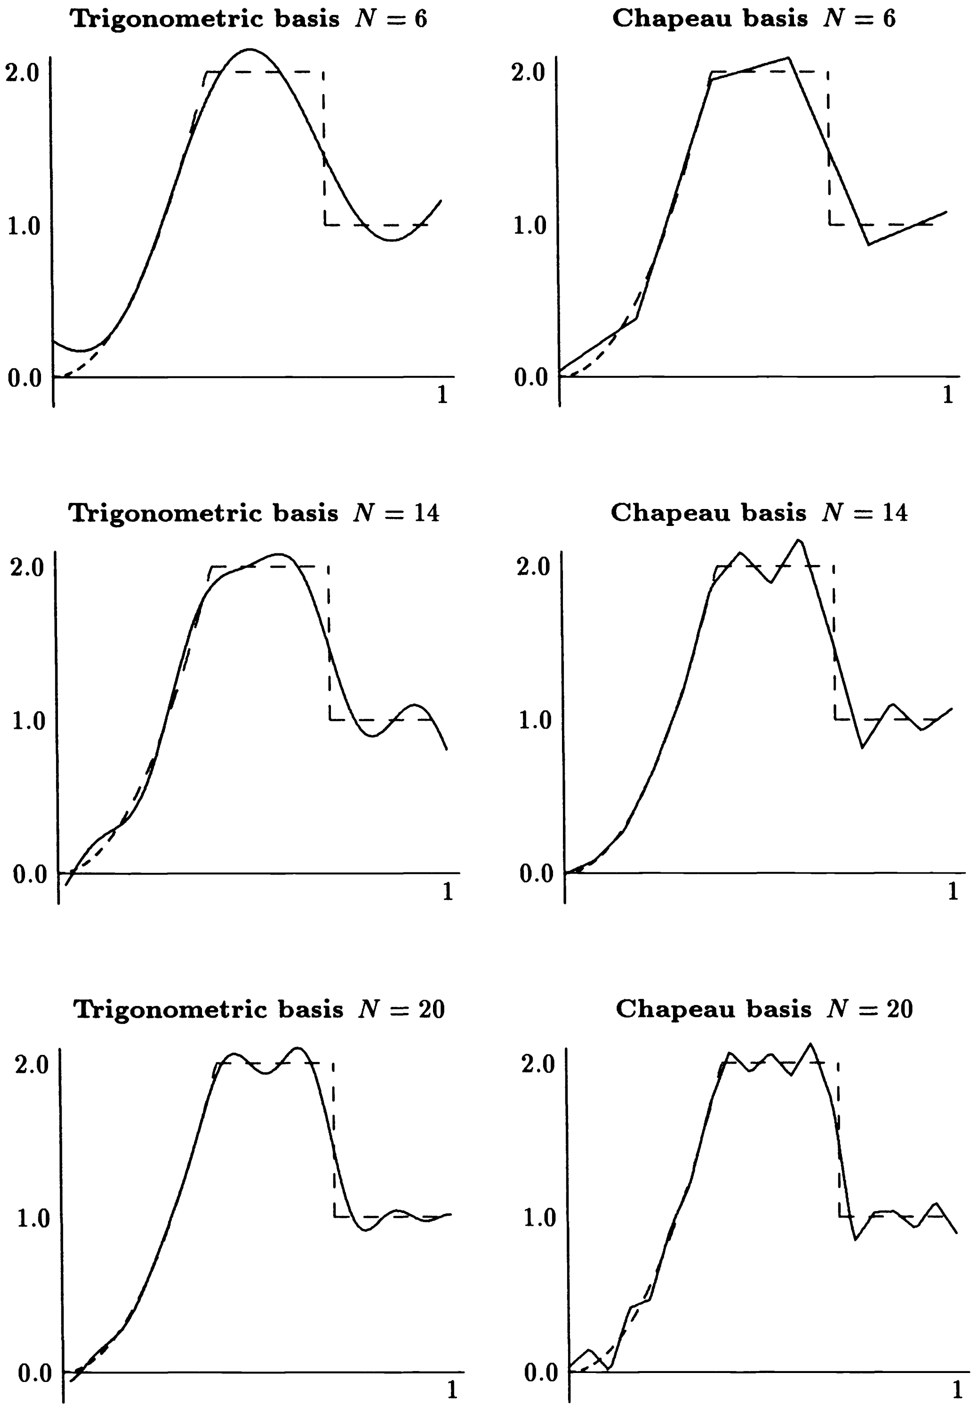
When the data consisted of two spectra we used as a test case the function

$$q(x) = \begin{cases} 12.5x^2 & \text{if } 0 \le x \le 0.4 \\ 2 & \text{if } 0.4 \le x \le 0.7 \\ 1 & \text{if } 0.7 \le x \le 1 \end{cases}$$

and provided both Dirichlet–Dirichlet ($h = H = \infty$) and Dirichlet–Neumann ($h = \infty$, $H = 0$) eigenvalues. Figure 3 shows the reconstructions for $N/2$ eigenvalues from each problem where $N = 6, 14, 20$. Both trigonometric $\{1, \cos(2\pi x), \sin(2\pi x), \cdots\}$ and linear spline (chapeau function) basis were used with $B = N$.

These computations were obtained by zeroing out some of the singular values. As a general rule we found that the further the function deviates from a smooth function when periodically extended, the larger the tolerance required to prevent overshoot at the endpoints. The case of $N = 20$ was run with TOL set to 10^{-4}; with this setting, only the first 14 trigonometric basis functions were retained. A lower value of TOL will result in the algorithm overemphasizing the higher modes in order to compensate for the discontinuity in the periodic function. This is already evident in the case of chapeau basis functions with $N = 20$, where a slightly larger value of TOL would have offered some improvements. This problem is not an issue with trigonometric basis functions in the symmetric case.

The problem of recovering the potential from spectral data consisting of the function $\lambda(H)$ for λ corresponding to some fixed eigenfunction number is a considerably more ill-posed problem than the other usual inverse Sturm–Liouville problems. The easiest proofs of uniqueness rely on analytic continuation, [15] and this has to be considered unreasonable as the basis of a numerical algorithm. The method of [18] was able to handle all the known inverse Sturm–Liouville problems, except this one.



Trigonometric basis $N = 6$

Chapeau basis $N = 6$

Trigonometric basis $N = 14$

Chapeau basis $N = 14$

Trigonometric basis $N = 20$

Chapeau basis $N = 20$

FIG. 3. *Reconstruction of a $q(x)$ from two spectra.*

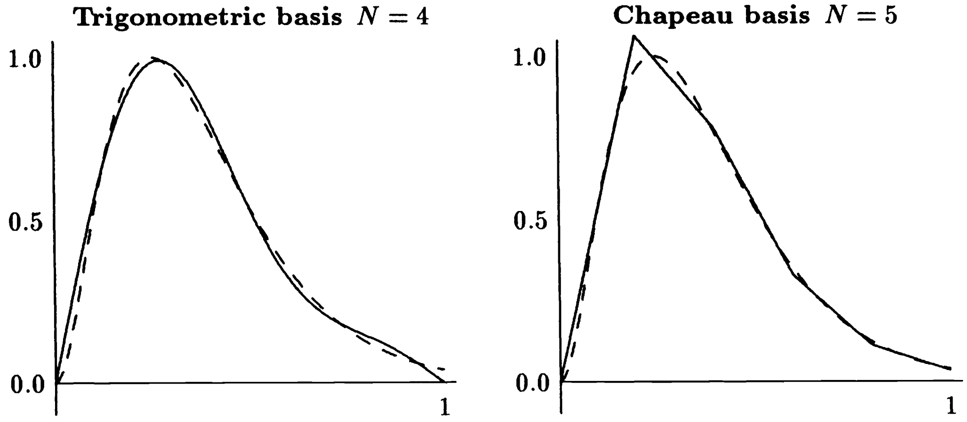


FIG. 4. *Reconstruction of $q(x)$ from $\lambda_1(H)$.*

The uniqueness theorem requires that the set of values H_j should have a finite accumulation point, and it is not known, at least to these authors, whether any finite data set can allow one to recover the lowest frequency modes of q as is the case when eigenvalue data are prescribed. To see the performance of the algorithm, consider the function $q(x) = 16x^2 \exp(-8x)$ which has been normalized to have a maximum value of one. This is a smooth function that has a very small discontinuity in its periodic extension. As such, the algorithm would recover it to within less than 1 percent error with spectral data consisting of 5 eigenvalues from each of two spectra, that is, $N = 10$. For the output of Fig. 4 we used as spectral data the value of $\lambda_1(H)$ for 10 values of H, namely $H = \{0, 1, 2, 3, 4, 5, 10, 20, 50, 100\}$. With the value of TOL set to 10^{-6} we were only able to keep about 5 or 6 modes with any of the basis functions we tried. Here, for good accuracy, we should keep the value of TOL small for best results and then delete any basis functions for which the corresponding singular value is less than the tolerance. The results are shown in Fig. 4.

The use of the singular value decomposition is essential for the functioning of this particular version of the algorithm. The number of values of H at which we computed λ_1 is not so crucial; much the same reconstructions would have resulted if we had used anywhere between 7 and 20 points, provided they were roughly equally spaced. This is due to the behavior of the analytic function $\lambda_1(H)$.

In terms of its numerical performance, how does this algorithm compare with some of the others mentioned in the introduction? The method of Paine is the closest in terms of methodology, although the implementation in [16] is only for the symmetric case, and in fact it is not clear how to implement the algorithm for noneigenvalue data. The mapping used is that between the potential and its eigenvalues. There is an additional disadvantage in this approach; the computation of the Frêchet derivative requires solving N^2 (where N is the number of points at which $q(x)$ is determined) Sturm–Liouville eigenvalue problems, and numerically this is an extremely expensive proposition. In contrast, our method requires $N \times B$ computations of an initial value problem and this requires considerably less computation. In addition, the quasi-Newton implementation means we have to compute this matrix only once. The method of Rundell and Sacks [18] is able to recover virtually the full family of inverse

Sturm–Liouville problems, the exception being the variable boundary condition data. This method leads to an extremely fast algorithm. Indeed, the computational time required to recover a potential from 10 or 20 items of spectral data is significantly less than the time taken to compute even *one* eigenvalue of the direct problem using the program SLEIGN. The method of this paper is unable, at least in the form presented here, to recover $q(x)$ from data consisting of eigenvalues and norming constants, but this is the only exception. In comparison with the Rundell–Sacks method the accuracy obtained is roughly the same, but the amount of computation required is considerably greater. Our Newton-type algorithm performs slightly better under noise in the spectral data, but this might be more a function of the particular implementations. One of the drawbacks to the method of [18] is that it is necessary to have an estimate of the mean of q, $\bar{q} = \int_0^1 q(s)ds$. For smooth functions, an adequate estimate can be obtained from the spectral data, but this ability degrades with rougher potentials. The method used here does not require the estimation of the mean. In addition, and this we believe to be the most important point, the ideas presented here can formally be extended to higher space dimensions, and this we intend to make the subject of future work.

Appendix: proofs of the lemmas. In what follows, C denotes a constant that is independent of k, β, and N.

LEMMA A1. *For $q \in V_N$ and $j \neq k$, $w(t) = \partial u_j(t; q, \lambda_j)/\partial q_k$ satisfies the estimate*

$$\left| w(t) + \frac{1}{4\pi k \lambda_j} \sin 2\pi k t \cos \sqrt{\lambda_j} t \right| \leq C \left(\frac{1}{\lambda_j |\sqrt{\lambda_j} - \pi k|} + \frac{1}{\lambda_j^{3/2}} \right).$$

Proof. w solves

$$\begin{gathered} -w'' + qw = \lambda_j w - \phi_k u_j[q], \\ w(0) = w'(0) = 0 \end{gathered}$$

which has the solution

$$w(t) = \int_0^t (y_1(s)y_2(t) - y_1(t)y_2(s))\phi_k(s)u_j[q](s)ds,$$

where y_1 and y_2 solve

$$\begin{gathered} -y_i'' + qy_i = \lambda_j y_i, \\ y_2(0) = y_1'(0) = 0, \\ y_2'(0) = y_1(0) = 1. \end{gathered}$$

Using the estimates [18, p. 13]

$$\left| y_1(s) - \cos \sqrt{\lambda_j} s \right| \leq \frac{1}{\sqrt{\lambda_j}} e^{\|q\|_{L^2}},$$

$$\left| y_2(s) - \frac{\sin \sqrt{\lambda_j} s}{\sqrt{\lambda_j}} \right| \leq \frac{1}{\lambda_j} e^{\|q\|_{L^2}},$$

we obtain

$$\begin{aligned}
|(y_1(s)y_2(t) - y_1(t)y_2(s)) - \frac{1}{\sqrt{\lambda_j}}\sin\sqrt{\lambda_j}(t-s)| &\le |y_1(s)|\left|y_2(t) - \frac{\sin\sqrt{\lambda_j}t}{\sqrt{\lambda_j}}\right| \\
&+|y_1(s) - \cos\sqrt{\lambda_j}s|\left|\frac{\sin\sqrt{\lambda_j}t}{\sqrt{\lambda_j}}\right| + |y_2(s)||y_1(t) - \cos\sqrt{\lambda_j}t| \\
&+\left|\cos\sqrt{\lambda_j}t\right|\left|y_2(s) - \frac{\sin\sqrt{\lambda_j}s}{\sqrt{\lambda_j}}\right| \\
&\le \frac{e^{\|q\|_{L^2}}}{2\lambda_j}\left(2 + \frac{1}{\sqrt{\lambda_j}}e^{\|q\|_{L^2}}\right).
\end{aligned}$$

Observing that $u_j[q] = y_2$ and using the estimate $|y_2(s) - (\sin\sqrt{\lambda_j}s/\sqrt{\lambda_j})| \le (e^{\|q\|_{L^2}}/\lambda_j)$ gives

$$\begin{aligned}
|w(t) &- \frac{1}{\lambda_j}\int_0^t \sin\sqrt{\lambda_j}(t-s)\phi_k(s)\sin\sqrt{\lambda_j}s\,ds| \\
&\le \left|\int_0^t \left\{y_1(s)y_2(t) - y_1(t)y_2(s) - \frac{1}{\sqrt{\lambda_j}}\sin\sqrt{\lambda_j}(t-s)\right\}\phi_k(s)y_2(s)ds\right| \\
&+\left|\int_0^t \frac{1}{\sqrt{\lambda_j}}\sin\sqrt{\lambda_j}(t-s)\phi_k(s)\left(y_2(s) - \frac{\sin\sqrt{\lambda_j}s}{\sqrt{\lambda_j}}\right)ds\right| \\
&\le \left\{1 + \frac{1}{2}\left(1 + \frac{e^{\|q\|_{L^2}}}{\sqrt{\lambda_j}}\right)\left(2 + \frac{e^{\|q\|_{L^2}}}{\sqrt{\lambda_j}}\right)\right\}\frac{\|\phi_k\|e^{\|q\|_{L^2}}}{\lambda_j^{3/2}}.
\end{aligned}$$

Now

$$\begin{aligned}
\int_0^t &\sin\sqrt{\lambda_j}(t-s)\phi_k(s)\sin\sqrt{\lambda_j}s\,ds \\
&= -\frac{\sin 2\pi kt\cos\sqrt{\lambda_j}t}{4\pi k} + \frac{\cos\sqrt{\lambda_j}t}{2}\int_0^t \cos 2\pi ks\cos 2\sqrt{\lambda_j}s\,ds \\
&\quad+\frac{\sin\sqrt{\lambda_j}t}{2}\int_0^t \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds,
\end{aligned}$$

$$\int_0^t \cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds = \frac{\sin 2(\sqrt{\lambda_j} - \pi k)t}{4(\sqrt{\lambda_j} - \pi k)} + \frac{\sin 2(\sqrt{\lambda_j} + \pi k)t}{4(\sqrt{\lambda_j} + \pi k)},$$

$$\int_0^t \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds = \frac{1 - \cos 2(\sqrt{\lambda_j} + \pi k)t}{4(\sqrt{\lambda_j} + \pi k)} + \frac{1 - \cos 2(\sqrt{\lambda_j} - \pi k)t}{4(\sqrt{\lambda_j} - \pi k)},$$

and the result follows using $\|\phi_k\|_{L^2} = 1/\sqrt{2}$ and $\lambda_j \ge 1$ for β sufficiently small.

LEMMA A2. $\left|\int_0^1 \sin\sqrt{\lambda_j}(1-t)\cos\sqrt{\lambda_j}t\sin 2\pi kt(q^{(1)} - q^{(2)})dt\right|$

$$\le \left(\frac{\sqrt{3}\beta}{2\pi}\right)\left(\frac{1}{j^{2+\alpha}}\right) + \frac{1}{2}\left|\int_0^1 \sin 2\pi jt\sin 2\pi kt(q^{(1)} - q^{(2)})dt\right|.$$

Proof. Since $q^{(i)} \in \operatorname{span}\{\cos 2\pi lx\}$, this gives

$$\begin{aligned}\int_0^1 &\sin\sqrt{\lambda_j}(1-t)\cos\sqrt{\lambda_j}t\sin 2\pi kt(q^{(1)}-q^{(2)})dt\\ &= \frac{\sin\sqrt{\lambda_j}}{2}\int_0^1 \cos 2\sqrt{\lambda_j}t\sin 2\pi kt[q^{(1)}-q^{(2)}]dt\\ &\quad -\frac{\cos\sqrt{\lambda_j}}{2}\int_0^1 \sin 2\sqrt{\lambda_j}t\sin 2\pi kt[q^{(1)}-q^{(2)}]dt.\end{aligned}$$

Using the inequalities $|\sin 2\sqrt{\lambda_j}t - \sin 2\pi jt| \le 2|\sqrt{\lambda_j}-\pi j||t| \le 2|t|\beta/\sqrt{3}\pi j^{2+\alpha}$ and $|\sin\sqrt{\lambda_j}| \le \beta/\sqrt{3}\pi j^{2+\alpha}$ gives the desired result.

LEMMA A3.

$$\sum_{j=1}^{\infty}\frac{1}{\sqrt{\lambda_j}}\left|\int_0^1 \sin 2\pi jt(\sin 2\pi kt(q^{(1)}-q^{(2)}))dt\right| \le \frac{1}{\sqrt{2}}\left(\sum_{j=1}^{\infty}\frac{1}{\lambda_j}\right)^{1/2}\|q^{(1)}-q^{(2)}\|_{L^2}.$$

Proof. $\int_0^1 \sin 2\pi jt\sin 2\pi kt[q^{(1)}-q^{(2)}]dt$ is the jth Fourier sine coefficient of $\sin 2\pi kt\cdot(q^{(1)}-q^{(2)})$. The result follows from the Cauchy–Schwarz inequality and Parseval's identity.

LEMMA A4. *For all β sufficiently small, $\sum_{\substack{j=1\\ j\neq k}}^{\infty}(1/\sqrt{\lambda_j}|\sqrt{\lambda_j}-\pi k|) \le C$.*

Proof. It is easily verified that

$$\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{1}{\sqrt{\lambda_j}|\sqrt{\lambda_j}-\pi k|} \le \frac{1}{\pi^2}\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{|\sqrt{\lambda_j}-\pi j|}{|j-k||\sqrt{\lambda_j}-\pi k|}+\frac{1}{\pi^2}\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{|\sqrt{\lambda_j}-\pi j|}{j\sqrt{\lambda_j}}+\frac{1}{\pi^2}\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{1}{j|j-k|}.$$

For β sufficiently small $\sqrt{\lambda_j} \ge 1$ and $|\sqrt{\lambda_j}-\pi k| \ge \frac{\pi}{2}$ for all $j \neq k$. The estimate

$$\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{1}{j|j-k|} \le \frac{3(1+\ln k)}{k} \le 3$$

and Assumption A gives the desired result.

LEMMA A5. *For $q^{(i)} \in V_N$ and β sufficiently small*

$$\begin{aligned}&\left|(u_j[q^{(1)}]-u_j[q^{(2)}])(t)-\frac{1}{\lambda_j}\int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s(q^{(1)}-q^{(2)})ds\right|\\ &\quad\le \frac{C\|q^{(1)}-q^{(2)}\|_{L^2}}{\lambda_j^{3/2}}.\end{aligned}$$

Proof. $u := u_j[q^{(1)}]-u_j[q^{(2)}]$ satisfies

$$\begin{gathered}-u'' = \lambda_j u - q^{(1)}u - (q^{(1)}-q^{(2)})u_j[q^{(2)}],\\ u(0)=u'(0)=0\end{gathered}$$

with solution

$$u(t) = \int_0^t \frac{\sin\sqrt{\lambda_j}(t-s)}{\sqrt{\lambda_j}}[q^{(1)}u + (q^{(1)}-q^{(2)})u_j[q^{(2)}]]ds.$$

An application of Gronwall's inequality gives

$$|u(t)| \le \sqrt{\frac{2}{\lambda_j}} e^{\frac{1}{\lambda_j}\|q^{(1)}\|^2_{L^2}} \|u_j[q^{(2)}]\|_{L^2} \|q^{(1)} - q^{(2)}\|_{L^2},$$

and from the estimate

$$\left| u_j[q^{(2)}] - \frac{\sin\sqrt{\lambda_j}s}{\sqrt{\lambda_j}} \right| \le \frac{1}{\lambda_j} e^{\|q^{(2)}\|_{L^2}}$$

we conclude that

$$\begin{aligned}&\left| u(t) - \frac{1}{\lambda_j}\int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s(q^{(1)} - q^{(2)})ds \right| \\ &\quad \le \left\{ e^{\|q^{(2)}\|_{L^2}} + \left(\sqrt{2}\|q^{(1)}\|_{L^2} e^{\frac{1}{\lambda_j}\|q^{(1)}\|^2_{L^2}} \left(1 + \frac{1}{\sqrt{\lambda_j}} e^{\|q^{(2)}\|_{L^2}} \right)\right)\right\} \frac{\|q^{(1)} - q^{(2)}\|_{L^2}}{\lambda_j^{3/2}}.\end{aligned}$$

The result follows from $\lambda_j \ge 1$ for β sufficiently small.

LEMMA A6. *For $j \ne k$ and all β sufficiently small*

$$\begin{aligned}&\left| \int_0^1 \sin\sqrt{\lambda_j}(1-t)\cos 2\pi kt \int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s[q^{(1)} - q^{(2)}]ds\,dt \right| \\ &\qquad \le C\left\{ \left(\frac{1}{j^{2+\alpha}} + \frac{1}{\sqrt{\lambda_j}} + \frac{1}{|\sqrt{\lambda_j} - \pi k|} \right) \|q^{(1)} - q^{(2)}\|_{L_2} \right. \\ &\qquad\qquad \left. + \left| \int_0^1 \sin 2\pi jt \sin 2\pi kt[q^{(1)} - q^{(2)}]dt \right| \right\}.\end{aligned}$$

Proof. An integration by parts gives

$$\begin{aligned}&\int_0^1 \sin\sqrt{\lambda_j}(1-t)\cos 2\pi kt \left\{ \int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s[q^{(1)} - q^{(2)}]ds \right\} dt \\ &= \frac{1}{2}\int_0^1 \left\{ \int_t^1 \sin\sqrt{\lambda_j}(1-s)\sin\sqrt{\lambda_j}s\cos 2\pi ks\,ds \right\} \sin 2\sqrt{\lambda_j}t[q^{(1)} - q^{(2)}]dt \\ &\quad - \int_0^1 \left\{ \int_t^1 \sin\sqrt{\lambda_j}(1-s)\cos\sqrt{\lambda_j}s\cos 2\pi ks\,ds \right\} \sin^2\sqrt{\lambda_j}t(q^{(1)} - q^{(2)})dt,\end{aligned}$$

where

$$\begin{aligned}&\int_t^1 \sin\sqrt{\lambda_j}(1-s)\sin\sqrt{\lambda_j}s\cos 2\pi ks\,ds \\ &\quad = \frac{\cos\sqrt{\lambda_j}\sin 2\pi kt}{4\pi k} + \frac{\sin\sqrt{\lambda_j}}{2}\int_t^1 \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds \\ &\quad + \frac{\cos\sqrt{\lambda_j}}{2}\int_t^1 \cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds,\end{aligned}$$

$$\begin{aligned}\int_t^1 &\sin\sqrt{\lambda_j}(1-s)\cos\sqrt{\lambda_j}s\cos 2\pi ks\,ds\\ &= -\frac{\sin\sqrt{\lambda_j}\sin 2\pi kt}{4\pi k}+\frac{\sin\sqrt{\lambda_j}}{2}\int_t^1\cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\\ &\quad -\frac{\cos\sqrt{\lambda_j}}{2}\int_t^1 \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds,\end{aligned}$$

$$\begin{aligned}\int_t^1 &\sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\\ &= \frac{\cos 2(\sqrt{\lambda_j}+\pi k)t-\cos 2(\sqrt{\lambda_j}+\pi k)}{4(\sqrt{\lambda_j}+\pi k)}\\ &\quad+\frac{\cos 2(\sqrt{\lambda_j}-\pi k)t-\cos 2(\sqrt{\lambda_j}-\pi k)}{4(\sqrt{\lambda_j}-\pi k)},\end{aligned}$$

$$\begin{aligned}\int_t^1 \cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds &= \frac{\sin 2(\sqrt{\lambda_j}-\pi k)-\sin 2(\sqrt{\lambda_j}-\pi k)t}{4(\sqrt{\lambda_j}-\pi k)}\\ &\quad+\frac{\sin 2(\sqrt{\lambda_j}+\pi k)-\sin 2(\sqrt{\lambda_j}+\pi k)t}{4(\sqrt{\lambda_j}+\pi k)}.\end{aligned}$$

A substitution gives

$$\begin{aligned}\int_0^1 &\sin\sqrt{\lambda_j}(1-t)\cos 2\pi kt\left\{\int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s[q^{(1)}-q^{(2)}]ds\right\}dt\\ &= \frac{\cos\sqrt{\lambda_j}}{8\pi k}\int_0^1 \sin 2\sqrt{\lambda_j}t\sin 2\pi kt[q^{(1)}-q^{(2)}]dt\\ &\quad+\frac{\cos\sqrt{\lambda_j}}{4}\int_0^1\left\{\int_t^1 \cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\right\}\sin 2\sqrt{\lambda_j}t[q^{(1)}-q^{(2)}]dt\\ &\quad+\frac{\sin\sqrt{\lambda_j}}{4\pi k}\int_0^1 \sin 2\pi kt\sin^2\sqrt{\lambda_j}t[q^{(1)}-q^{(2)}]dt\\ &\quad+\frac{\cos\sqrt{\lambda_j}}{2}\int_0^1\left\{\int_t^1 \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\right\}\sin^2\sqrt{\lambda_j}t[q^{(1)}-q^{(2)}]dt\\ &\quad+\frac{\sin\sqrt{\lambda_j}}{4}\int_0^1\left\{\int_t^1 \sin 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\right\}\sin 2\sqrt{\lambda_j}t[q^{(1)}-q^{(2)}]dt\\ &\quad-\frac{\sin\sqrt{\lambda_j}}{2}\int_0^1\left\{\int_t^1 \cos 2\sqrt{\lambda_j}s\cos 2\pi ks\,ds\right\}\sin^2\sqrt{\lambda_j}t[q^{(1)}-q^{(2)}]dt,\end{aligned}$$

and the result follows using $|\sin 2\sqrt{\lambda_j}t-\sin 2\pi jt|\le 2|t|\beta/\sqrt{3}\pi j^{2+\alpha}$, $|\sin\sqrt{\lambda_j}|\le\beta/\sqrt{3}\pi j^{2+\alpha}$, and $k\ge 1$.

LEMMA A7. *Let* $w(x)=w_1(x)-w_2(x)$ *where the functions* $w_1(x)=(\partial u_j/\partial q_k)\cdot(x;q^{(1)},\lambda_j)$ *and* $w_2(x)=(\partial u_j/\partial q_k)(x;q^{(2)},\lambda_j)$. *For* $q^{(i)}\in V_N$ *and all* j *and* k, $w(x)$

satisfies the estimate

$$|w|_{L^\infty} \leq \frac{C}{\lambda_j^{3/2}} \|q^{(1)} - q^{(2)}\|_{L^2}$$

for all β sufficiently small.

Proof. $w(x)$ solves

$$-w'' = \lambda_j w - q^{(1)} w - (q^{(1)} - q^{(2)}) w_2 - \phi_k (u_j[q^{(1)}] - u_j[q^{(2)}]),$$
$$w(0) = w'(0) = 0,$$

and this has the solution

$$w(x) = \int_0^x \frac{\sin\sqrt{\lambda_j}(x-t)}{\sqrt{\lambda_j}} [q^{(1)} w(t) + (q^{(1)} - q^{(2)}) w_2(t) + \phi_k (u_j[q^{(1)}] - u_j[q^{(2)}])] dt.$$

Using Gronwall's inequality, we have

$$|w(x)| \leq \sqrt{\frac{2}{\lambda_j}} \left[\|w_2\|_{L^2} \|q^{(1)} - q^{(2)}\|_{L^2} + \|\phi_k\|_{L^2} \|u_j[q^{(2)}] - u_j[q^{(1)}]\|_{L^2} \right] e^{\frac{1}{\lambda_j}\|q^{(1)}\|_{L^2}},$$

$$\|u_j[q^{(2)}] - u_j[q^{(1)}]\|_{L^2} \leq \sqrt{\frac{2}{\lambda_j}} e^{\frac{1}{\lambda_j}\|q^{(1)}\|_{L^2}^2} \|u_j[q^{(2)}]\|_{L^2} \|q^{(1)} - q^{(2)}\|_{L^2},$$

$$\|w_2\|_{L^2} \leq \sqrt{\frac{2}{\lambda_j}} e^{\frac{1}{\lambda_j}\|q^{(2)}\|_{L^2}^2} \|u_j[q^{(2)}]\|_{L^2} \|\phi_k\|_{L^2}.$$

The estimate now follows using $\left| u_j[q^{(2)}](s) - (\sin\sqrt{\lambda_j} s / \sqrt{\lambda_j}) \right| \leq \frac{1}{\lambda_j} e^{\|q^{(2)}\|_{L^2}}$ and $\lambda_j \geq 1$ for all β sufficiently small.

LEMMA A8. *For $q^{(i)} \in V_N$, $j \neq k$ and all β sufficiently small*

$$\left| \lambda_j \left(\frac{\partial u_j}{\partial q_k}(1; q^{(1)}, \lambda_j) - \frac{\partial u_j}{\partial q_k}(1; q^{(2)}, \lambda_j) \right) \right|$$
$$\leq C \left\{ \left(\frac{1}{\lambda_j} + \frac{1}{j^{1+\alpha}} + \frac{1}{\sqrt{\lambda_j}|\sqrt{\lambda_j} - \pi k|} \right) \|q^{(1)} - q^{(2)}\|_{L^2} \right.$$
$$\left. + \frac{1}{\sqrt{\lambda_j}} \left| \int_0^1 \sin 2\pi j t \sin 2\pi k t [q^{(1)} - q^{(2)}] dt \right| \right\}.$$

Proof. Let $w(x) = w_1(x) - w_2(x)$, where $w_1(x) = (\partial u_j / \partial q_k)(x; q^{(1)}, \lambda_j)$ and $w_2(x) = (\partial u_j / \partial q_k)(x; q^{(2)}, \lambda_j)$. Then

$$w(1) = \int_0^1 \frac{\sin\sqrt{\lambda_j}(1-t)}{\sqrt{\lambda_j}} [q^{(1)} w(t) + (q^{(1)} - q^{(2)}) w_2(t) + \phi_k (u_j[q^{(1)}] - u_j[q^{(2)}])] dt$$
$$= \int_0^1 \frac{\sin\sqrt{\lambda_j}(1-t)}{\sqrt{\lambda_j}} q^{(1)} w(t) dt$$

$$+\int_0^1 \frac{\sin\sqrt{\lambda_j}(1-t)}{\sqrt{\lambda_j}}\left[w_2(t)+\frac{\sin 2\pi kt\cos\sqrt{\lambda_j}t}{4\pi k\lambda_j}\right](q^{(1)}-q^{(2)})dt$$

$$+\frac{1}{4\pi k\lambda_j^{3/2}}\int_0^1 \sin\sqrt{\lambda_j}(1-t)\sin 2\pi kt\cos\sqrt{\lambda_j}t(q^{(1)}-q^{(2)})dt$$

$$+\int_0^1 \frac{\sin\sqrt{\lambda_j}(1-t)}{\sqrt{\lambda_j}}\phi_k\left\{u_j[q^{(1)}]-u_j[q^{(2)}]\right.$$

$$\left.-\frac{1}{\lambda_j}\int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s[q^{(1)}-q^{(2)}]ds\right\}dt$$

$$+\frac{1}{\lambda_j^{3/2}}\int_0^1 \sin\sqrt{\lambda_j}(1-t)\phi_k\left\{\int_0^t \sin\sqrt{\lambda_j}(t-s)\sin\sqrt{\lambda_j}s[q^{(1)}-q^{(2)}]ds\right\}dt.$$

Now $k \geq 1$ and $\|\phi_k\|_{L^2} = 1/\sqrt{2}$ for all k. The result follows from Lemmas A1, A2, A5, A6, and A7.

Proof of Lemma 3. By Lemma A8,

$$\sum_{\substack{j=1\\ j\neq k}}^{N}\left|\lambda_j\left(\frac{\partial u_j}{\partial q_k}(1;q^{(2)},\lambda_j)-\frac{\partial u_j}{\partial q_k}(1;q^{(1)},\lambda_j)\right)\right|$$

$$\leq C\left\{\sum_{j=1}^{\infty}\left(\frac{1}{\lambda_j}+\frac{1}{j^{1+\alpha}}\right)+\sum_{\substack{j=1\\ j\neq k}}^{\infty}\frac{1}{\sqrt{\lambda_j}|\sqrt{\lambda_j}-\pi k|}\right\}\|q^{(1)}-q^{(2)}\|_{L^2}$$

$$+\sum_{j=1}^{\infty}\frac{1}{\sqrt{\lambda_j}}\left|\int_0^1 \sin 2\pi jt\sin 2\pi kt[q^{(1)}-q^{(2)}]dt\right|.$$

By Lemma A7, when $j = k$, the remaining term is bounded by

$$\left|\lambda_k\left(\frac{\partial u_k}{\partial q_k}(1;q^{(2)},\lambda_k)-\frac{\partial u_k}{\partial q_k}(1;q^{(1)},\lambda_k)\right)\right| \leq \frac{C}{\sqrt{\lambda_k}}\|q^{(1)}-q^{(2)}\|_{L^2} \leq C\|q^{(1)}-q^{(2)}\|_{L^2}.$$

The result follows from Lemmas A3 and A4.

Acknowledgment. The authors thank Roger Knobel for several helpful discussions.

ERROR BOUNDS FOR THE ASYMPTOTIC EXPANSION OF THE RATIO OF TWO GAMMA FUNCTIONS WITH COMPLEX ARGUMENT*

C. L. FRENZEN†

Abstract. Error bounds are obtained for an asymptotic expansion of the ratio of two gamma functions $\Gamma(z+a)/\Gamma(z+b)$ when a and b are complex constants and $|z|$ is large. These bounds reduce to earlier bounds for the real case when a, b, and z are real. Properties of completely monotonic functions are used to provide error bounds in the complex case, as in the earlier real case.

Key words. error bound, asymptotic expansion, gamma function

AMS(MOS) subject classifications. primary 41A60; secondary 33A15

1. Introduction.

In [1], Fields showed that for all $n \geqq 1$,

$$\frac{\Gamma(z+a)}{\Gamma(z+b)} = \sum_{j=0}^{n-1} \frac{\Gamma(1-2\rho+2j)}{\Gamma(1-2\rho)(2j)!} B_{2j}^{(2\rho)}(\rho) w^{2\rho-1-2j} + O(w^{2\rho-1-2n}) \tag{1.1}$$

as $w \to \infty$ with $|\arg(w+\rho)| < \pi$, where a and b are fixed complex numbers, $2w = 2z+a+b-1$ and $2\rho = a-b+1$. The $B_{2j}^{(2\rho)}(\rho)$ are generalized Bernoulli polynomials, defined by

$$\left(\frac{t}{e^t-1}\right)^{2\rho} e^{\rho t} = \left(\frac{\sinh t/2}{t/2}\right)^{-2\rho} = \sum_{j=0}^{\infty} \frac{t^{2j}}{(2j)!} B_{2j}^{(2\rho)}(\rho), \tag{1.2}$$
$$B_0^{(2\rho)}(\rho) = 1 \qquad (|t| < 2\pi).$$

The first few of these polynomials are

$$B_2^{(2\rho)}(\rho) = -\frac{\rho}{6}, \quad B_4^{(2\rho)}(\rho) = \frac{\rho(5\rho+1)}{60}, \quad B_6^{(2\rho)}(\rho) = -\frac{\rho(35\rho^2+21\rho+4)}{504}. \tag{1.3}$$

A list of the $B_{2j}^{(2\rho)}(\rho)$ for $j = 1, 2, \cdots, 6$ and a recurrence formula can be found in [3].

In [2], it was shown that when a, b, and z are real, $z+a > 0$, $w > 0$, and $0 < 2\rho < 1$, the error made by truncating the asymptotic expansion in (1.1) is numerically less than and has the same sign as the first neglected term. The purpose of this paper is to indicate how, with a little more work, computable error bounds can be obtained for (1.1) when z, a, and b are complex. More specifically, we shall show that when $|\arg w| < 3\pi/4$ and a and b (and therefore ρ) are fixed complex constants such that $0 \leqq \operatorname{Re}(2\rho) < 1$, then

$$\frac{\Gamma(w+\rho)}{\Gamma(w-\rho+1)} = \sum_{j=0}^{n-1} \frac{\Gamma(1-2\rho+2j)}{\Gamma(1-2\rho)(2j)!} B_{2j}^{(2\rho)}(\rho) w^{2\rho-1-2j} + R_n(w,\rho), \tag{1.4}$$

where

$$|R_n(w,\rho)| \leqq \frac{\Gamma(1-\operatorname{Re}(2\rho)+2n)}{|\Gamma(1-2\rho)|(2n)!} |B_{2n}^{(|2\rho|)}(|\rho|)| \cdot (\operatorname{Re}(w e^{-i\beta}) - |\operatorname{Im}\rho||\sin\beta|)^{\operatorname{Re}(2\rho)-1-2n} e^{|\beta||\operatorname{Im}(2\rho)|}. \tag{1.5}$$

* Received by the editors August 13, 1990; accepted for publication (in revised form) June 21, 1991.

† Mathematics Department, Naval Postgraduate School, Monterey, California 93943.

In (1.5) β is any number in the interval $[-\pi/4, \pi/4]$. The bound (1.5) is valid when w lies in the annular sector

$$|\arg(w e^{-i\beta})| < \pi/2, \qquad \operatorname{Re}(w e^{-i\beta}) > |\operatorname{Im} \rho| |\sin \beta|. \tag{1.6}$$

In the conclusion of this paper we shall show that the bound in (1.5) may, for computational purposes, be replaced by

$$\begin{aligned}|R_n(w, \rho)| \leqq |1-2\rho|\, e^{\pi|\operatorname{Im} \rho|} |B_{2n}^{(|2\rho|)}(|\rho|)| (\operatorname{Re}(w e^{-i\beta}) \\ -|\operatorname{Im} \rho| |\sin \beta|)^{\operatorname{Re}(2\rho)-1-2n}\, e^{|\beta||\operatorname{Im}(2\rho)|}.\end{aligned} \tag{1.7}$$

For given values of w and ρ, the bound for $R_n(w, \rho)$ on the right side of (1.5) depends on the value given to β. A further discussion of this point will be given at the conclusion of this article.

2. Derivation of the error bound. As in [2], we shall assume that simple modifications to $\Gamma(w+\rho)/\Gamma(w-\rho+1)$ have been made using the functional equation for the gamma function $(z\Gamma(z) = \Gamma(z+1))$ so that $0 \leqq \operatorname{Re}(2\rho) < 1$. From [4, p. 119], we can write

$$\frac{\Gamma(w+\rho)}{\Gamma(w-\rho+1)} = \frac{1}{\Gamma(1-2\rho)} \int_0^\infty e^{-wt} t^{-2\rho} \left(\frac{\sinh t}{t/2}\right)^{-2\rho} dt, \tag{2.1}$$

assuming that $\operatorname{Re}(w+\rho) > 0$. All powers in (2.1) have their principal values. Note that if $\operatorname{Re} w < 0$, then the reflection formula for the gamma function can be used to write

$$\frac{\Gamma(w+\rho)}{\Gamma(w-\rho+1)} = \frac{-\sin \pi(w-\rho)}{\sin \pi(w+\rho)} \frac{\Gamma(-w+\rho)}{\Gamma(-w-\rho+1)}. \tag{2.2}$$

Without loss of generality, (2.2) allows us to assume $\operatorname{Re} w > 0$.

The function $((\sinh t/2)/t/2)^{-2\rho}$ is holomorphic within the sector $\mathscr{S}$: $|\arg t| \leqq \pi/2 - \delta$, where δ is any positive number satisfying $0 < \delta < \pi/4$. Putting $t = r + is$, it follows that

$$\begin{aligned}\frac{|r+is|^2}{|\sinh(r+is)|^2} &= \frac{r^2+s^2}{(\sinh r)^2 + (\sin s)^2} \\ &\leqq \left(\frac{r}{\sinh r}\right)^2 (1 + (\cot \delta)^2) \leqq (\csc \delta)^2,\end{aligned} \tag{2.3}$$

so that

$$\left|\left(\frac{\sinh t/2}{t/2}\right)^{-2\rho}\right| \leqq (\csc \delta)^{\operatorname{Re}(2\rho)}\, e^{\pi|\operatorname{Im}(2\rho)|} \tag{2.4}$$

within $\mathscr{S}$. Using the estimate in (2.4), we can rotate the path of integration in (2.1) (although $t^{-2\rho}$ is not analytic at $t=0$ the rotation is justified since $\operatorname{Re}(2\rho) < 1$). It is straightforward to show that (2.1) becomes, after rotating the path of integration,

$$\frac{\Gamma(w+\rho)}{\Gamma(w-\rho+1)} = \frac{1}{\Gamma(1-2\rho)} \int_0^{\infty e^{-i\beta}} e^{-wt} t^{-2\rho} \left(\frac{\sinh t/2}{t/2}\right)^{-2\rho} dt, \tag{2.5}$$

where β satisfies $-(\pi/2) < \beta < (\pi/2)$ and $|\arg(w e^{-i\beta})| < (\pi/2)$.

Using (1.2), we write

$$\left(\frac{\sinh t/2}{t/2}\right)^{-2\rho} = \sum_{j=0}^{n-1} \frac{t^{2j}}{(2j)!} B_{2j}^{(2\rho)}(\rho) + r_n(t, \rho). \tag{2.6}$$

Substituting (2.6) into (2.5) and integrating the sum termwise then gives (1.4) with

$$R_n(w,\rho)=\frac{1}{\Gamma(1-2\rho)}\int_0^{\infty e^{-i\beta}} e^{-wt}t^{-2\rho}r_n(t,\rho)\,dt, \tag{2.7}$$

where $|\beta|<\pi/2$ and $|\arg(we^{-i\beta})|<\pi/2$.

By letting $t=u^{1/2}e^{-i\beta}$ (for $u\in[0,\infty)$) and $w=|w|e^{i\alpha}$, (2.7) becomes, using (2.6),

$$\begin{aligned}R_n(w,\rho)=\frac{1}{2\Gamma(1-2\rho)}&\int_0^\infty e^{-u^{1/2}|w|\exp(i(\alpha-\beta))}u^{-\rho-1/2}\\ &\cdot e^{i\beta(2\rho-1)}\left[F(u)-\sum_{j=0}^{n-1}\frac{F^{(j)}(0)}{j!}u^j\right]du.\end{aligned}\tag{2.8}$$

In (2.8) the complex-valued function F of the real variable u is defined by

$$F(u)=(G(u))^{-2\rho} \tag{2.9}$$

where

$$G(u)=\frac{\sinh\sqrt{u\,e^{-2i\beta}/4}}{\sqrt{u\,e^{-2i\beta}/4}} \tag{2.10}$$

and

$$\frac{F^{(j)}(0)}{j!}=\frac{e^{-2i\beta j}}{(2j)!}B_{2j}^{(2\rho)}(\rho). \tag{2.11}$$

From (2.9) and (2.10) we can write

$$F(u)=\exp\left(-2\rho S\left(\frac{u\,e^{-2i\beta}}{4}\right)\right) \tag{2.12}$$

where

$$S(z)=\ln\frac{\sinh\sqrt{z}}{\sqrt{z}}. \tag{2.13}$$

Recall that a function f is completely monotonic on $[0,\infty)$ if $(-1)^nf^{(n)}(x)\geqq 0$ on $[0,\infty)$ for $n=0,1,2,\cdots$. If f is completely monotonic on $[0,\infty)$ then $|f^{(n)}(x)|\leqq|f^{(n)}(0)|$ for $x\in[0,\infty)$ and $n=0,1,2,\cdots$. Since

$$S^{(1)}(z)=\sum_{n=1}^{\infty}\frac{1}{z+(n\pi)^2},$$

it follows that $S^{(1)}$ is a completely monotonic function on $[0,\infty)$. In [2] we showed that the function

$$h_\gamma(x)=e^{-\gamma S(x)}=\left(\frac{\sinh x^{1/2}}{x^{1/2}}\right)^{-\gamma} \tag{2.14}$$

is completely monotonic on $[0,\infty)$ for $\gamma>0$.

To establish the bound for $R_n(w,\rho)$ in (2.8), we note that, by Taylor's theorem for vector-valued functions of a real variable, there exists a ξ between zero and u so that

$$\left|F(u)-\sum_{j=0}^{n-1}\frac{F^{(j)}(0)}{j!}u^j\right|\leqq\frac{|F^{(n)}(\xi)|}{n!}u^n. \tag{2.15}$$

To compute $F^{(n)}$, we apply the Faa di Bruno formula for the derivative of a composite function (see [5]):

$$[f(g(u))]^{(n)}=\sum_{k=1}^{n} f^{(k)}(g(u))A_{nk}\{g^{(1)}(u),\quad g^{(2)}(u),\cdots,g^{(n)}(u)\} \tag{2.16}$$

where

$$\begin{aligned} &A_{nk}\{g^{(1)}(u),g^{(2)}(u),\cdots,g^{(n)}(u)\}\\ &\quad=\sum\frac{n!}{m_1!\,m_2!\cdots m_n!}\left(\frac{g^{(1)}(u)}{1!}\right)^{m_1}\cdots\left(\frac{g^{(n)}(u)}{n!}\right)^{m_n}, \end{aligned} \tag{2.17}$$

and the sum in (2.17), for given values of n and k, ranges over all nonnegative integer solutions of the two equations

$$m_1+m_2+\cdots+m_n=k,\qquad m_1+2m_2+\cdots+nm_n=n. \tag{2.18}$$

From (2.12), we can write $F(u)=f(g(u))$, where $f(u)=e^{-2\rho u}$ and $g(u)=S(u\,e^{-2i\beta}/4)$. Applying (2.16), it follows that

$$F^{(n)}(u)=\left(\frac{e^{-2i\beta}}{4}\right)^{n}\sum_{k=1}^{n}(-2\rho)^k B_{nk}, \tag{2.19}$$

where

$$B_{nk}=\sum\frac{n!}{m_1!m_2!\cdots m_n!}\left(\frac{S^{(1)}(u\,e^{-2i\beta}/4}{1!}\right)^{m_1}\cdots\left(\frac{S^{(n)}(u\,e^{-2i\beta}/4)}{n!}\right)^{m_n}, \tag{2.20}$$

the sum in (2.20), again ranging over all nonnegative integer solutions of (2.18).

Because $S^{(1)}$ is completely monotonic on $[0,\infty)$, it follows that (see [7, p. 158])

$$|S^{(1)}(x+iy)|\leqq|S^{(1)}(x)|\leqq|S^{(1)}(0)|\qquad(0\leqq x<\infty,\ -\infty<y<\infty). \tag{2.21}$$

Indeed, we also have

$$|S^{(j)}(x+iy)|\leqq|S^{(j)}(x)|\leqq|S^{(j)}(0)|\qquad(0\leqq x<\infty,\ -\infty<y<\infty), \tag{2.22}$$

since $(-1)^{j+1}S^{(j)}$ is completely monotonic on $[0,\infty)$ for $j=2,3,\cdots$, when $S^{(1)}$ is. Therefore, when $\operatorname{Re}(u\,e^{-2i\beta}/4)\geqq 0$, i.e., when

$$-\frac{\pi}{4}\leqq\beta\leqq\frac{\pi}{4}. \tag{2.23}$$

equation (2.20), the triangle inequality, and (2.22) together imply

$$|B_{nk}|\leqq C_{nk}, \tag{2.24}$$

where

$$C_{nk}=\sum\frac{n!}{m_1!\,m_2!\cdots m_n!}\left(\frac{|S^{(1)}(0)|}{1!}\right)^{m_1}\cdots\left(\frac{|S^{(n)}(0)|}{n!}\right)^{m_n} \tag{2.25}$$

and the sum again is over all nonnegative integer solutions of (2.18). However, letting

$$h_{|2\rho|}(x)=e^{-|2\rho|S(x)}=\left(\frac{\sinh x^{1/2}}{x^{1/2}}\right)^{-|2\rho|},$$

where S is given in (2.13), it also follows from (1.2) and the complete monotonicity of both $S^{(1)}$ and $h_{|2\rho|}$ on $[0,\infty)$ (see (2.14)) that

$$(-1)^n h_{|2\rho|}^{(n)}(0)=\sum_{k=1}^{n}|2\rho|^k C_{nk}=\frac{n!4^n}{(2n)!}|B_{2n}^{(|2\rho|)}(|\rho|)|, \tag{2.26}$$

with C_{nk} given in (2.25). Consequently, (2.19), together with (2.24) and (2.26), then implies

$$|F^{(n)}(u)| \leqq \frac{n!}{(2n)!} |F(u)| |B_{2n}^{(|2\rho|)}(|\rho|)|. \tag{2.27}$$

To bound $|F(u)|$, from (2.9) and (2.10)

$$|F(u)| = |G(u)|^{-\mathrm{Re}\,(2\rho)}\, e^{\mathrm{Im}\,(2\rho) \arg G(u)} \leqq e^{\mathrm{Im}\,(2\rho) \arg G(u)}, \tag{2.28}$$

where we have used the complete monotonicity of $h_{\mathrm{Re}\,(2\rho)}(x)$ on $[0, \infty)$ (see (2.14), (2.21) and (2.23)). Since $|\arg G(u)| \leqq \pi$, one way to estimate $|F(u)|$ from (2.28) is

$$|F(u)| \leqq e^{\pi |\mathrm{Im}\,(2\rho)|}. \tag{2.29}$$

An alternative way to estimate $|F(u)|$ is to note that since $G(0) = 1$ and $\arg G(0) = 0$, for small positive u (2.10) implies

$$\arg G(u) = \beta + \arg \left(\sinh \left(\frac{u^{1/2}\, e^{-i\beta}}{2} \right) \right). \tag{2.30}$$

Noting that

$$\sinh \left(\frac{u^{1/2}\, e^{-i\beta}}{2} \right) = \exp \left(\frac{u^{1/2}\, e^{-i\beta}}{2} \right) \left(\frac{1 - \exp\,(-u^{1/2}\, e^{-i\beta})}{2} \right), \tag{2.31}$$

equation (2.30) implies, for small positive u,

$$\arg G(u) = \beta - \frac{u^{1/2}}{2} \sin \beta + \arg\,(1 - \exp\,(-u^{1/2}\, e^{-i\beta})). \tag{2.32}$$

The right-hand side of (2.32) represents $\arg G(u)$ for those u for which it is less than or equal to π in absolute value. When $u > 0$, $\mathrm{Re}\,(1 - \exp\,(-u^{1/2}\, e^{-i\beta})) > 0$, so that

$$\arg\,(1 - \exp\,(-u^{1/2}\, e^{-i\beta})) = \tan^{-1} \left(\frac{-e^{-u^{1/2} \cos \beta} \sin\,(u^{1/2} \sin \beta)}{1 - e^{-u^{1/2} \cos \beta} \cos\,(u^{1/2} \sin \beta)} \right). \tag{2.33}$$

Employing the inequalities

$$\frac{e^{-x}}{1 - e^{-x}} < \frac{1}{x} \quad (x > 0); \qquad \frac{\sin x}{x} < 1 \quad (x \neq 0)$$

we have, for $u > 0$,

$$\begin{aligned} \frac{e^{-u^{1/2} \cos \beta} |\sin\,(u^{1/2} \sin \beta)|}{1 - e^{-u^{1/2} \cos \beta} \cos\,(u^{1/2} \sin \beta)} &\leqq \frac{e^{-u^{1/2} \cos \beta} |\sin\,(u^{1/2} \sin \beta)|}{1 - e^{-u^{1/2} \cos \beta}} \\ &\leqq \frac{|\sin\,(u^{1/2} \sin \beta)|}{u^{1/2} \cos \beta} \\ &\leqq |\tan \beta|. \end{aligned} \tag{2.34}$$

Since $\tan^{-1}$ is an odd increasing function and $-(\pi/4) \leq \beta \leqq (\pi/4)$, (2.33) and (2.34) yield

$$|\arg\,(1 - e^{-u^{1/2} e^{-i\beta}})| \leqq |\beta| \qquad (u \geqq 0). \tag{2.35}$$

Equation (2.35) implies that

$$\mathrm{sgn}\,[\beta + \arg\,(1 - e^{-u^{1/2} e^{-i\beta}})] = \mathrm{sgn}\,\beta, \tag{2.36}$$

and, therefore, the absolute value of the right-hand side of (2.32) is less than π for all u satisfying $0<u^{1/2}|\sin\beta|/2<\pi$. For this range of u, the triangle inequality and (2.35) applied to (2.32) then imply

$$|\arg G(u)-\beta|\leqq\frac{u^{1/2}|\sin\beta|}{2}+|\beta|. \tag{2.37}$$

We now note that (2.37) holds for all u, for when $u^{1/2}|\sin\beta|/2\geqq\pi$ the inequality there is still satisfied because $|\arg G(u)-\beta|\leqq\pi+|\beta|$ for all u. Combining (2.15), (2.27), (2.28), and (2.8) then yields

$$\begin{aligned}|R_n(w,\rho)|\leqq|B_{2n}^{(|2\rho|)}(|\rho|)|\,&\frac{1}{2\Gamma(1-2\rho)}\\ &\cdot\int_0^\infty e^{-u^{1/2}(\operatorname{Re}(we^{-i\beta}))}u^{n-\operatorname{Re}\rho-\frac{1}{2}}\,e^{\operatorname{Im}(2\rho)(\arg G(u)-\beta)}\,du.\end{aligned} \tag{2.38}$$

From (2.37), it follows that

$$e^{\operatorname{Im}(2\rho)(\arg G(u)-\beta)}\leqq e^{|\operatorname{Im}(2\rho)|(u^{1/2}|\sin\beta|/2+|\beta|)} \tag{2.39}$$

Assuming now that the second inequality in (1.6) is satisfied, we use the inequality (2.39) in the integrand on the right side of (2.38), and, evaluating the resulting integral, we obtain the error bound in (1.5).

3. Discussion of the error bound and conclusion. For prescribed values of w and ρ the magnitude of the bound on the right-hand side of (1.5) depends on the value assigned to β. With $\arg w=\alpha$, the ratio of the absolute value of the first neglected term in the series (1.4) to the right side in (1.5) is

$$\begin{aligned}&\frac{|\Gamma(1-2\rho+2n)|}{|\Gamma(1-\operatorname{Re}(2\rho)+2n)|}\,\frac{|B_{2n}^{(2\rho)}(\rho)|}{|B_{2n}^{(|2\rho|)}(|\rho|)|}\,e^{-\alpha\operatorname{Im}(2\rho)-|\beta||\operatorname{Im}(2\rho)|}\\ &\quad\cdot\left(\cos(\alpha-\beta)-\frac{|\operatorname{Im}\rho||\sin\beta|}{|w|}\right)^{2n+1-\operatorname{Re}(2\rho)}.\end{aligned} \tag{3.1}$$

For large $|w|$ this ratio is approximately an $O(1)$ function of w,ρ, and β multiplied by $(\cos(\alpha-\beta))^{2n+1-\operatorname{Re}(2\rho)}$. When α lies in the interval $[-\pi/4,\pi/4]$ we can choose $\beta=\alpha$ so that $\cos(\alpha-\beta)=1$. Note that in this case the exponential term in (3.1) disappears when $\alpha\operatorname{Im}(2\rho)<0$. However, when α lies in $(\pi/4,3\pi/4)$ or $(-3\pi/4,-\pi/4)$ β must differ from α. As α approaches $3\pi/4$ or $-3\pi/4$ β must approach $\pi/4$ or $-\pi/4$, respectively, and the bound (1.5) starts to exceed the absolute value of the first neglected term by an increasingly large factor. In practice, however, (2.2) can and should be used to avoid this possibility. We stress that the restriction of β to $[-\pi/4,\pi/4]$ is necessary to obtain the error bound. A similar restriction is required to obtain one of the standard forms of error bound for Stirling's series for $\ln\Gamma(z)$ (see [6, p. 252]).

We can use

$$\begin{aligned}&\frac{\Gamma(1-\operatorname{Re}(2\rho)+2n)}{|\Gamma(1-2\rho)|(2n)!}\\ &\quad=\frac{(2n-\operatorname{Re}(2\rho))(2n-1-\operatorname{Re}(2\rho))\cdots(1-\operatorname{Re}(2\rho))\Gamma(1-\operatorname{Re}2\rho)}{(2n)!|\Gamma(1-2\rho)|},\end{aligned} \tag{3.2}$$

and (see [4, p. 38])

$$\begin{aligned}\frac{\Gamma(x)^2}{|\Gamma(x+iy)|^2}&=\left(1+\frac{y^2}{x^2}\right)\prod_{s=1}^{\infty}\left(1+\frac{y^2}{(x+s)^2}\right)\\&\leqq\left(1+\frac{y^2}{x^2}\right)\prod_{s=1}^{\infty}\left(1+\frac{y^2}{s^2}\right)\qquad(x>0),\end{aligned}\tag{3.3}$$

together with

$$\prod_{s=1}^{\infty}\left(1+\frac{y^2}{s^2}\right)=\frac{\sinh \pi y}{\pi y},\qquad \frac{\sinh \pi y}{\pi y}\leqq e^{\pi|y|}\tag{3.4}$$

to obtain from (3.2) the inequality

$$\frac{\Gamma(1-\operatorname{Re}2\rho+2n)}{|\Gamma(1-2\rho)|(2n)!}\leqq|1-2\rho|\,e^{\pi|\operatorname{Im}\rho|}.\tag{3.5}$$

Using (3.5) in (1.5) then gives the bound in (1.6).

To conclude, note that we could also have chosen the bound (2.29) for $|F(u)|$ instead of the bound used in (2.37). For large $\operatorname{Re}(w\,e^{-i\beta})$, the resulting difference in the error bound (1.5) is a factor of $e^{\pi|\operatorname{Im}(2\rho)|}$ instead of $e^{|\beta||\operatorname{Im}(2\rho)|}$. Since $|\beta|\leqq\pi/4$, the bound obtained from (2.37) is usually better. Finally, observe that the bound on the right side of (1.5) reduces to the absolute value of the first neglected term in the real case, for which $\operatorname{Im}(2\rho)=0$ and $\beta=0$. In fact, by the results in [2], the error in this case is numerically less than, and has the same sign as, the first neglected term.

FUNCTIONAL INEQUALITIES FOR HYPERGEOMETRIC FUNCTIONS AND COMPLETE ELLIPTIC INTEGRALS*

G. D. ANDERSON[†], M. K. VAMANAMURTHY,[‡] AND M. VUORINEN[§]

Abstract. The authors study monotoneity and convexity properties of the Gaussian hypergeometric function, particularly the special cases of complete elliptic integrals. They also prove functional inequalities for these functions and various combinations of them and present some conjectures about inequalities for these functions.

Key words. elliptic integral, hypergeometric function

AMS(MOS) subject classifications. primary 33E05, 33C05; secondary 33C75

1. Introduction. For real numbers a, b, c such that $c \neq -p, p = 0, 1, 2, 3, \cdots$, the Gaussian *hypergeometric function* is defined by

$$F(a,b;c;x) = \sum_{n=0}^{\infty} \frac{(a,n)(b,n)}{(c,n)} \frac{x^n}{n!} \tag{1.1}$$

for $-1 < x < 1$, where we have used the ascending factorial notation $(a,n) = a(a+1)\cdots(a+n-1)$ for $n = 1, 2, 3, \cdots$ and $(a,0) = 1$. In the exceptional case $c = -p$, $p = 0, 1, 2, \cdots$, $F(a,b;c;x)$ is defined also if $a = -j$ or $b = -j$, where $j = 0, 1, 2, \cdots$ and $j \leq p$. We shall study some properties of this function and of its special cases, namely, the complete elliptic integrals

$$\mathcal{K}(r) = \frac{\pi}{2} F\left(\frac{1}{2}, \frac{1}{2}; 1; r^2\right), \quad \mathcal{E}(r) = \frac{\pi}{2} F\left(-\frac{1}{2}, \frac{1}{2}; 1; r^2\right). \tag{1.2}$$

The basic properties of these functions can be found in [WW]. Numerous identities satisfied by these functions are given, for example, in [AS], [C2], [SO], and [PBM]. For a partial survey and bibliography of the hypergeometric function, see [A].

We now state some results of this paper.

THEOREM 1.1. *For $a \in I\!R$, $c > b > 0$, $x \in (-1, 1)$,*

(1) $F(a,b;c;x) \cdot F(-a,b;c;x) \geq 1$,

(2) $F(a,b;c;x) + F(-a,b;c;x) \geq 2$.

Moreover, (2) *also holds for $a, x \in (0,1)$ and $b, c \in (0, \infty)$. In particular,*

(3) $\mathcal{K}(x)\mathcal{E}(x) \geq \pi^2/4$, $\mathcal{K}(x) + \mathcal{E}(x) \geq \pi$ *for all $x \in [0, 1)$.*

In this paper, we denote $r' = \sqrt{1 - r^2}$ for any $r \in (0, 1)$. In [AVV2, Thm. 2.2(3)] it was shown that $r'\mathcal{K}(r)^2$ is strictly decreasing from $[0, 1)$ onto $(0, \pi^2/4]$. In this paper we extend this result and prove an analogous result for the other elliptic integral $\mathcal{E}$.

THEOREM 1.2. *For each $c \in [\frac{1}{2}, 2]$ the function $f(r) \equiv (r')^c \mathcal{K}(r)$ is decreasing and concave from $[0,1)$ onto $(0, \pi/2]$; the function $\sqrt{f}$ is also decreasing and concave.*

THEOREM 1.3. *The function $f(r) \equiv (r')^c \mathcal{E}(r)$ is increasing on $(0,1)$ if and only if $c \le -\frac{1}{2}$ and decreasing if and only if $c \ge 0$. Further, if $-2 \le c \le -1$, then f is convex.*

The elliptic integrals $\mathcal{K}(r)$ and $\mathcal{E}(r)$ are indispensable in many applications in mathematics as well as in physics and engineering. Some examples are: rectification of curves, quadrature of surfaces, and electromagnetic field computations [B], [L]. Carlson [C2], [C3] has found a unified approach for effective computation of many such integrals (see also [PT1]). Many generic classes of special funtions of mathematical physics, such as Chebyshev polynomials and Legendre functions, are special cases of the Gaussian hypergeometric function (1.1), while others, such as Bessel functions and parabolic cylinder functions, are limiting cases of (1.1). (For an extensive list of special cases see [SO, pp. 157–164], [AS], and [PBM].) Some generalized elliptic-type definite integrals that occur in radiation field problems are also special cases of the hypergeometric function (1.1) [KCH], [KLH].

The complete elliptic integrals also arise in a number of problems of geometric function theory [LV], [AVV1], [Vu]—our work was in part motivated by this fact. We also state some conjectures on the asymptotic behavior of $\mathcal{K}(r)$ near $r = 1$, refining the well-known asymptotic formulas in [BF].

2. The hypergeometric function.

In this section we study some monotoneity and convexity properties of the hypergeometric function and complete elliptic integrals. The evaluation of the hypergeometric function can be based on the numerical solution of the differential equation satisfied by this function (cf. [PT2]). A table of the values of $F(a,b;c;r)$ is given, e.g., in [CK].

THEOREM 2.1. (1) *Let $a, b, c \in (0, \infty)$. Then $f_1(x) \equiv F(a,b;c;x)$ is strictly increasing and convex on $[0,1)$. In particular, $g_1(x) \equiv \mathcal{K}(x)$ is strictly increasing and convex on $[0,1)$.*

(2) *Let $a \in (0,1), b, c \in (0,\infty)$. Then $f_2(x) \equiv F(-a,b;c;x)$ is strictly decreasing and concave on $[0,1)$. In particular, $g_2(x) \equiv \mathcal{E}(x)$ is strictly decreasing and concave on $[0,1)$.*

(3) *For $a \in (-1,1), b, c \in (0,\infty)$ the function $f_3(x) \equiv F(a,b;c;x) + F(-a,b;c;x)$ is strictly increasing and convex on $[0,1)$. In particular, the function $g_3(x) \equiv \mathcal{K}(x) + \mathcal{E}(x)$ is strictly increasing and convex on $[0,1)$.*

(4) *Let $a, b, c \in (0,\infty)$. Then $f_4(x) \equiv \frac{1}{x}(F(a,b;c;x) - 1)$ is strictly increasing and convex on $[0,1)$. In particular, the function $g_4(x) \equiv x^{-2}(\mathcal{K}(x) - \frac{\pi}{2})$ is strictly increasing and convex from $(0,1)$ onto $(\pi/8, \infty)$.*

(5) *Let $a \in (0,1), b, c \in (0,\infty), b < c$. Then $f_5(x) \equiv \frac{1}{x}(1 - F(-a,b;c;x))$ is strictly increasing and convex on $[0,1)$. In particular, $g_5(x) \equiv x^{-2}(\frac{\pi}{2} - \mathcal{E}(x))$ is strictly increasing and convex from $(0,1]$ onto $(\frac{\pi}{8}, \frac{\pi}{2} - 1]$.*

(6) *Let $a \in (0,1), b, c \in (0,\infty)$. Then $f_6(x) \equiv \frac{1}{x}(F(a,b;c;x) - F(-a,b;c;x))$ is strictly increasing and convex on $[0,1)$. In particular, $g_6(x) \equiv x^{-2}(\mathcal{K}(x) - \mathcal{E}(x))$ is strictly increasing and convex from $[0,1)$ onto $[\frac{\pi}{4}, \infty)$.*

(7) *Let $a \in [\frac{1}{2}, 1], b, c \in (0,\infty), a + b \le c$. Then*

$$f_7(x) \equiv \frac{1}{x}(F(-a,b;c;x) - (1-x)F(a,b;c;x))$$

is strictly increasing and convex from $(0,1)$ *onto* $(1-(2ab/c), B(b,a+c-b)/B(b,c-b))$. *In particular,* $g_7(x) \equiv x^{-2}(\mathcal{E}(x)-(1-x^2)\mathcal{K}(x))$ *is strictly increasing and convex from* $(0,1)$ *onto* $(\frac{\pi}{4},1)$.

Proof. The functions $f_1, 1-f_2, f_3, f_4, f_5$, and f_6 are represented by power series with nonnegative coefficients in the specified ranges of a,b,c,x. Moreover, $g_j(x) = (2/\pi)f_j(x^2)$ for $j=1,\cdots,7$, with $a=b=\frac{1}{2}, c=1$.

We shall give a proof for (7), since it is nontrivial. Using the series (1.1) we may write

$$f_7(x) = 1 - \frac{2ab}{c} + \sum_{n=1}^{\infty} C_n x^{2n},$$

where

$$C_n = \frac{(a,n)(b,n)}{(c,n)n!} - \frac{((a,n+1)-(-a,n+1))(b,n+1)}{(c,n+1)(n+1)!}.$$

Now

$$\begin{aligned} C_n &= \frac{(b,n)}{(c,n)(n+1)!} \\ &\quad \times \left[(n+1)(a,n) - \frac{b+n}{c+n}(a(a+1)\cdots(a+n)+a(-a+1)\cdots(-a+n))\right] \\ &> \frac{(b,n)}{(c,n)(n+1)!}[(n+1)(a,n)-(a,n)(a+n)-a(-a+1)\cdots(-a+n)] \\ &= \frac{a(b,n)(-a+1)}{(c,n)(n+1)!}[(a+1)\cdots(a+n-1)-(-a+2)\cdots(-a+n)], \end{aligned}$$

which is nonnegative since $a+m-1 \geq -a+m$ for $m=1,2,\cdots,n$ and $a \in [\frac{1}{2},1]$. Thus $f_7(x)$ is increasing and convex, and $f_7(0+) = 1-(2ab/c)$. The value of $f_7(1-)$ follows from [WW, §14.11, pp. 281–282]. Putting $a=b=\frac{1}{2}, c=1$ in the above theorem we see that $g_7(x)$ is strictly increasing and convex from $(0,1)$ on $(\frac{\pi}{4},1)$. □

Proof of Theorem 1.1. In (1), by a well-known integral representation [R, Thm. 16, p. 47],

$$(2.1) \quad \begin{cases} F(a,b;c;x) = \dfrac{1}{B(b,c-b)} \displaystyle\int_0^1 t^{b-1}(1-t)^{c-b-1}(1-xt)^{-a}dt, \\ F(-a,b;c;x) = \dfrac{1}{B(b,c-b)} \displaystyle\int_0^1 t^{b-1}(1-t)^{c-b-1}(1-xt)^{a}dt, \end{cases}$$

for $c > b > 0$ and $x \in (-1,1)$. Hence by Hölder's inequality [M],

$$F(a,b;c;x)\cdot F(-a,b;c;x) \geq \frac{1}{B(b,c-b)^2}\left(\int_0^1 t^{b-1}(1-t)^{c-b-1}dt\right)^2 = 1.$$

For (2), in the first case it is clear that both summands are positive; hence by (1) and the arithmetic-geometric mean inequality,

$$F(a,b;c;x)+F(-a,b;c;x) \geq 2[F(a,b;c;x)\cdot F(-a,b;c;x)]^{1/2} \geq 2.$$

In the second case the power series has constant term 2 and all coefficients positive, so that (2) follows immediately.

Finally, (3) follows from (1) and (2) if we take the special values $a = b = \frac{1}{2}$, $c = 1$. □

Remark 2.1. Theorem 1.1 (1) can also be derived from Carlson's logarithmic convexity results in [C1], as he has pointed out to us.

LEMMA 2.2. *Given* $a \in (0,1)$, $0 < b < c$, $(1+r)F(a,b;c;r^2) \geq F(a,b;c;r)$ *for* $r \in [0,1)$. *In particular,* $(1+r)\mathcal{K}(r) \geq \mathcal{K}(\sqrt{r})$ *for* $r \in [0,1)$.

Proof. This follows directly from the power series expansion for F. □

LEMMA 2.3. *For* $a,b,c,d > 0$ *and* $0 < r < 1$,

(1) $F(a,b;c;r) \leq F(a,b+d;c+d;r)$ *for* $c \geq b$,

(2) $F(a,b;c;r) \geq F(a,b+d;c+d;r)$ *for* $c \leq b$.

Proof. Since the proofs of the two cases are similar we prove only (1). Because both series in (1) have positive coefficients it is enough to show that the coefficients on the right side are larger, that is, $(a,n)(b,n)/(c,n) \leq (a,n)(b+d,n)/(c+d,n)$. But this holds if and only if $c \geq b$. □

Remark 2.2. The asymptotic relation

$$F(a,b;a+b;r) \sim -\frac{\log(1-r)}{B(a,b)} \quad \text{as } r \to 1 \tag{2.2}$$

is well known [WW, Ex. 18, p. 299], [Ch, pp. 266–7] (for a generalization see [SS] and the references there). See also [H].

We next prove an inequality relating the two functions in (2.2).

THEOREM 2.4. *Denote* $g(x) = (1/x)\log(1-x)$. *Then*

(1) *For* $a,b,x \in (0,1)$ *we have*

$$\frac{-g(x)}{B(a,b)} < F(a,b;a+b;x) < -g(x).$$

The lower estimate is sharp at $x = 1$ *and the upper estimate is sharp at* $x = 0$.

(2) *For* $a,b \in (1,\infty)$ *and* $x \in (0,1)$ *the inequalities in* (1) *are reversed.*

(3) *For* $a = b = 1$ *we have* $F(1,1;2;x) = -g(x)/B(1,1) = -g(x)$.

Proof. Part (3) follows by definition. The first part of (1) is proved by means of the integral representation (2.1). We observe that for $t \in (0,1)$ we have $t^{b-1} > 1$ and $[(1-t)/(1-xt)]^{a-1} > 1$, and the first inequality in (1) follows by simple integration. For the second inequality in (1) we compare the series expansions, noting that it is sufficient to prove that

$$\frac{(a,n)(b,n)}{(a+b,n)} < \frac{n!}{(n+1)} \tag{2.3}$$

for $n = 1,2,3,\cdots$. Inequality (2.3) follows by induction, as we now show. For $n = 1$, it reduces to $2ab < a+b$, which is true for $a,b \in (0,1)$ since $2ab \leq a^2+b^2 < a+b$. Next, assuming (2.3) for n, it is true for $n+1$ if and only if $n(ab-1)+2ab-a-b < 0$, which is true. The proof of (2) is similar. Sharpness at $x = 1$ follows from (2.2), while at $x = 0$ it is obvious. □

3. Complete elliptic integrals. In this section we continue the study of the integrals $\mathcal{K}$ and $\mathcal{E}$ begun in [AV2] and [AVV2]. In particular, we obtain some estimates for these integrals in terms of elementary functions and prove a monotoneity property for a function defined in terms of them. These inequalities supplement similar previously known inequalities that appear in many books on special functions, e.g. [AS, 17.3.33–36], [SO, 61:9:1–8]. Note, however, that our $\mathcal{K}(r)$ and $\mathcal{E}(r)$ defined in (1.2) are $\mathcal{K}(\sqrt{r})$ and $\mathcal{E}(\sqrt{r})$ in the notation of [AS, 17.3.9–10].

The complete elliptic integrals $\mathcal{K}(r)$ and $\mathcal{E}(r)$ of the first and second kind, respectively, are much better known than the hypergeometric function $F(a,b;c;r)$ of which they are special cases (cf. (1.1)). Thus algorithms for the computation of $\mathcal{K}(r)$ and $\mathcal{E}(r)$ are given in many program libraries and they are tabulated in many tables (e.g. [AS], [BF]). An algorithm for the computation of these functions can be based on Gauss' arithmetic-geometric mean iteration [AS, 17.6], which is adequate for most purposes. See also [BB] and [PT1].

For later reference we list two basic identities due to Landen [BF, 163.01, 164.02]; cf. [WW, p. 507]:

$$(3.1) \qquad \mathcal{K}\left(\frac{2\sqrt{r}}{1+r}\right) = (1+r)\mathcal{K}(r), \quad \mathcal{K}\left(\frac{1-r}{1+r}\right) = \frac{1}{2}(1+r)\mathcal{K}'(r).$$

In studying the convexity properties of $\mathcal{K}(r)$ and $\mathcal{E}(r)$ we shall need the following lemma.

LEMMA 3.1. *Let I, J be intervals in $I\!R$, $f : I \longrightarrow J$ be decreasing and concave, and $g : J \longrightarrow I\!R$ be increasing and concave. Then $h \equiv g \circ f : I \longrightarrow I\!R$ is decreasing and concave.*

Proof. For concavity let $a, b \in I$ and $t \in (0,1)$. Then

$$(g \circ f)((1-t)a + tb) \geq g((1-t)f(a) + tf(b)) \geq (1-t)(g \circ f)(a) + t(g \circ f)(b).$$

That $g \circ f$ is decreasing is obvious. □

Proof of Theorem 1.2. By [BF, 710.00], $f'(r) = -(r')^{c-2}g(r)$, where $g(r) \equiv cr\mathcal{K} - (\mathcal{E} - (r')^2\mathcal{K})/r$. For $c \geq 1/2$, differentiation [BF, 710.00, 710.04] gives

$$g'(r) = \frac{c\mathcal{E}}{(r')^2} + \frac{\mathcal{E} - \mathcal{K}}{r^2} \geq \frac{h(r)}{2r^2(r')^2},$$

where $h(r) \equiv (\mathcal{E} - (r')^2\mathcal{K}) - (r')^2(\mathcal{K} - \mathcal{E})$. But $h'(r) = 3r(\mathcal{K} - \mathcal{E}) > 0$, and it follows that $g(r) > g(0+) = 0$ for $0 < r < 1$. Hence f' is negative and decreasing, so that f is decreasing and concave on $(0,1)$. The limit $f(0+) = \pi/2$ is clear, while $f(1-) = 0$ follows from [AVV2, Thm. 2.2(2)]. Since $\sqrt{t}$ is concave and increasing on $(0,\infty)$, it follows from Lemma 3.1 that $\sqrt{f}$ is decreasing and concave on $(0,1)$. □

Proof of Theorem 1.3. By [BF, 710.02]

$$f'(r) = \frac{(r')^{c-2}}{r}[-cr^2\mathcal{E} - (r')^2(\mathcal{K} - \mathcal{E})],$$

which is nonnegative if and only if $-c \geq \sup\{g(r)h(r) : 0 < r < 1\}$, where

$$g(r) \equiv \frac{r'(\mathcal{K} - \mathcal{E})}{r^2}, \qquad h(r) \equiv \frac{r'}{\mathcal{E}}.$$

Now $h'(r) = -(\mathcal{E} - (r')^2\mathcal{K})/(rr'\mathcal{E}^2) < 0$, so that $h(r)$ is decreasing on $(0,1)$. Next, by [BF, 710.05],

$$r^4 g'(r) = \frac{r}{r'}\varphi(r), \qquad \varphi(r) \equiv (\mathcal{E} - (r')^2\mathcal{K}) - (\mathcal{K} - \mathcal{E}).$$

Since $\varphi(0) = 0$ and $\varphi'(r) = (r/(r')^2)((r')^2\mathcal{K} - \mathcal{E}) < 0$ for $0 < r < 1$ by [BF, 710.04, 710.05] and [AVV2, Thm. 2.2(7)], we have $g'(r) < 0$, so that $g(r)$ is decreasing on $(0,1)$. Hence $g(r)h(r)$ is decreasing on $(0,1)$. By l'Hôpital's rule and [BF, 710.05] we have

$$\lim_{r\to 0+} g(r)h(r) = \lim_{r\to 0+} \frac{2(\mathcal{K} - \mathcal{E})}{\pi r^2} = \lim_{r\to 0+} \frac{\mathcal{E}}{\pi(r')^2} = \frac{1}{2}.$$

Thus $\sup\{g(r)h(r) : 0 < r < 1\} = g(0+)h(0+) = 1/2$, so that $f'(r) \geq 0$ if and only if $c \leq -\frac{1}{2}$.

Next, $f'(r) \leq 0$ if and only if $c \geq -\inf\{g(r)h(r) : 0 < r < 1\} = -g(1-)h(1-) = 0$.

Finally, for $-2 \leq c \leq -1$, we write $f'(r)$ as $(r')^{c-2}\psi(r)$, where $\psi(r) \equiv -cr\mathcal{E} - ((r')^2/r)(\mathcal{K} - \mathcal{E})$. Then

$$\psi'(r) = (2 + c + (r')^2 r^{-2})(\mathcal{K} - \mathcal{E}) - (c+1)\mathcal{E} \geq 0 \text{ on } (0,1),$$

so that f is convex. □

THEOREM 3.2. (1) *The function* $f_1(r) \equiv r^{-4}((\pi/(2\sqrt{r'})) - \mathcal{K}(r))$ *is strictly increasing and convex from* $(0,1)$ *onto* $(\pi/128, \infty)$.

(2) *The function* $f_2(r) \equiv (\mathcal{E}(r') - 1)/(r^2 \log(1/r))$ *is increasing and convex from* $(0,1)$ *onto* $(\frac{1}{2}, \infty)$.

(3) *The function* $f_3(r) \equiv r^2\mathcal{K}(r) + c\log r'$ *is increasing if and only if* $c \leq 1$ *and decreasing if and only if* $c \geq \pi$. *In particular, for* $0 < r < 1$,

$$1 < \frac{r^2\mathcal{K}(r)}{\log(1/r')} < \pi.$$

The lower bound is sharp as $r \to 1-$, *and the upper bound is sharp as* $r \to 0+$.

Proof. The properties of f_1 follow if we subtract the series for $\mathcal{K}(r)$ from the series

$$\frac{\pi}{2\sqrt{r'}} = \frac{\pi}{2}(1 - r^2)^{-1/4} = \frac{\pi}{2}\left(1 + \frac{1}{4}r^2 + \frac{1\cdot 5}{4\cdot 8}r^4 + \frac{1\cdot 5\cdot 9}{4\cdot 8\cdot 12}r^6 + \cdots\right).$$

For (2) we use the series expansion

$$f_2(r) = \sum_{n=1}^{\infty} a_n \left(1 + \frac{(\log 4 - 2b_n) + \frac{1}{(2n-1)(2n)}}{\log(1/r)}\right) r^{2n-2},$$

where

$$a_1 = \frac{1}{2}, \qquad a_n = \left(\frac{1\cdot 3\cdots(2n-3)}{2\cdot 4\cdots(2n-2)}\right)^2 \frac{2n-1}{2n} \quad \text{for } n \geq 2,$$

and

$$b_n = \frac{1}{1\cdot 2} + \frac{1}{3\cdot 4} + \cdots + \frac{1}{(2n-1)(2n)}$$

[BB, (1.3.11)]. Since

$$b_n = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + \frac{1}{2n-1} - \frac{1}{2n} < \log 2$$

it follows that $f_2(r)$ is strictly increasing and convex. Clearly $f_2(0+) = a_1 = \frac{1}{2}$ and $f_2(1-) = \infty$.

In part (3) since $\mathcal{E}(r) + (r')^2\mathcal{K}(r)$ is decreasing from $[0,1]$ onto $[1,\pi]$ by [AVV2, Thm. 2.2(3)] it follows that

$$f_3'(r) = \frac{r}{(r')^2}[\mathcal{E}(r) + (r')^2\mathcal{K}(r) - c]$$

is nonnegative if and only if

$$c \leq \inf\{\mathcal{E}(r) + (r')^2\mathcal{K}(r) : 0 < r < 1\} = 1$$

and $f_3'(r) \leq 0$ if and only if

$$c \geq \sup\{\mathcal{E}(r) + (r')^2\mathcal{K}(r) : 0 < r < 1\} = \pi.$$

The bounds for $r^2\mathcal{K}(r)/\log(1/r')$ clearly follow, and they are sharp since $\mathcal{K}(0) = \pi/2$ and $\lim_{r\to 1-} \mathcal{K}(r)/\log(1/r') = 1$ [BF, 112.01]. □

COROLLARY 3.3. *For* $0 < r < 1$,

$$\frac{1+r}{4r}\log\left(\frac{1+r}{1-r}\right) < \mathcal{K}(r) < \pi\frac{1+r}{4r}\log\left(\frac{1+r}{1-r}\right).$$

Proof. Replace r by $2\sqrt{r}/(1+r)$ in the inequalities in Theorem 3.2(3) and use (3.1). □

Remark 3.1. The two lower bounds for $\mathcal{E}(r)$ in Theorem 2.1(5) and 3.2(2) are not comparable.

In the proof of our next theorem, which is close to the conjecture in [AVV2, §6], we need a technical lemma.

LEMMA 3.4. *For any natural number* n,

$$\frac{\pi}{2}\frac{(\frac{1}{2},n)^2}{(n!)^2}\left(1 + (8.5)\frac{(2n+1)^2}{(2n+2)^2}\right) > \frac{9}{2n+2}.$$

Proof. For $n = 1,2,3,4,5,6$, the lemma follows by direct calculation. If $n \geq 7$, by Wallis' inequalities [M, p. 192] it is sufficient to prove that

$$\frac{1}{2n+1}\left(1 + (8.5)\frac{(2n+1)^2}{(2n+2)^2}\right) > \frac{9}{2n+2},$$

which is equivalent to $2n^2 - 12n - 5.5 > 0$, true for $n \geq 7$. □

The upper bound in Theorem 3.5 below also follows from [CG, p. 1072, (1.1)], but our proof here is more direct. In connection with the lower bound see Conjecture 3.1(5) and Remark 3.3 below.

THEOREM 3.5. *For* $0 < r < 1$,

$$\frac{9}{8.5 + r^2} < \frac{\mathcal{K}(r)}{\log(4/r')} < \frac{4}{3 + r^2}.$$

Proof. By Wallis' inequalities [M, p. 192] the first inequality is equivalent to

$$(8.5+r^2)\frac{\pi}{2}\left(1+\sum_{n=1}^{\infty}\frac{(\frac{1}{2},n)^2}{(n!)^2}r^{2n}\right) > 9\log 4+\frac{9}{2}r^2+\frac{9}{2}\sum_{n=1}^{\infty}\frac{r^{2n+2}}{n+1}.$$

Comparing coefficients on both sides, for the constant term we have $(8.5)(\pi/2) > 9\log 4$ and for the coefficients of r^2 we have $(\pi/2)(1+\frac{1^2}{2^2}(8.5)) > 9/2$ by direct calculation, while Lemma 3.4 shows that the coefficient of r^{2n+2} on the left exceeds the corresponding one on the right.

For the second inequality, let

$$f(r)=(3+r^2)\mathcal{K}(r)-4\log\frac{4}{r'}.$$

Then $f(0)=3\pi/2-4\log 4<0$ and

$$f(1)=\lim_{r\to 1}[(3+r^2)(\mathcal{K}(r)-\log(4/r'))-(r')^2\log(4/r')]=0$$

by [BF, 112.01]. Thus it is sufficient to prove that f is increasing on $(0,1)$. Now writing

$$r(r')^2f'(r)=g(r)\equiv(3+r^2)(\mathcal{E}-(r')^2\mathcal{K})+2r^2(r')^2\mathcal{K}-4r^2,$$

we have $g(0)=0=g(1)$. It is sufficient to prove that $g(r)>0$ at each critical point in $(0,1)$. Now

$$g'(r)=rh(r),$$

where $h(r)\equiv 4\mathcal{E}+3(r')^2\mathcal{K}-8$ is strictly decreasing on $(0,1)$. Since $h(0)=7\pi/2-8>0$ and $h(1)=-4<0$, h has a unique zero $r_0\in(0,1)$, and we need only prove that $g(r_0)>0$. By numerical estimates we see that $h(0.74)<0<h(0.72)$, so that $0.72<r_0<0.74$. Then, since $(\mathcal{E}-(r')^2\mathcal{K})/r^2$ is increasing and $(r')^2\mathcal{K}$ is decreasing we find from standard tables (cf. [BF, p. 323]) that $g(r_0)/r_0^2>3.31$. □

For later reference we remark that the double inequalities

$$(3.2)\qquad r'<\frac{\mathcal{E}}{\mathcal{K}}<1-\frac{r^2}{2},\qquad \frac{\pi r^2}{4}<\mathcal{E}-(r')^2\mathcal{K}<r^2$$

for $0<r<1$, relating complete elliptic integrals of the first and second kind, were obtained in [AV1, (6)], [AV2, (1)], respectively. The first two inequalities are sharp at $r=0$, the third is asymptotically sharp as $r\to 0$, and the fourth as $r\to 1$. The inequality giving the upper estimate for $\mathcal{E}/\mathcal{K}$ in (3.2) can be written as

$$(3.3)\qquad \mathcal{E}-(r')^2\mathcal{K}<\frac{r^2\mathcal{K}}{2},\qquad 0<r<1.$$

In our next theorems we compare the quotient and product of the elliptic integrals $\mathcal{E}$ and $\mathcal{K}$ with elementary functions. A power series for $\mathcal{E}/\mathcal{K}$ is given in [AS, 17.3.23]. We let arth denote the inverse hyperbolic tangent function.

THEOREM 3.6. *For* $0<r<1$,

$$\frac{1}{2}\left((r')^2+\frac{r}{\operatorname{arth} r}\right)<\frac{\mathcal{E}(r)}{\mathcal{K}(r)}<\frac{r}{\operatorname{arth} r}.$$

Proof. The first inequality is equivalent to

$$f(r) \equiv \log\frac{1+r}{1-r} - \frac{2r\mathcal{K}}{2\mathcal{E}-(r')^2\mathcal{K}} > 0.$$

Since $f(0) = 0$, it is sufficient to prove that $f'(r) > 0$ for $0 < r < 1$. But by [BF, 710.00, 710.02, 710.04] and algebraic simplification we have

$$f'(r) = \frac{4\mathcal{E}(\mathcal{E}-(r')^2\mathcal{K})}{(r')^2(2\mathcal{E}-(r')^2\mathcal{K})^2} > 0.$$

Similarly, the second inequality is equivalent to

$$g(r) \equiv \log\frac{1+r}{1-r} - \frac{2r\mathcal{K}}{\mathcal{E}} < 0;$$

but $g(0) = 0$ and $g'(r) = 2\mathcal{K}(\mathcal{E}-\mathcal{K})/(r')^2\mathcal{E}^2 < 0$ for $0 < r < 1$. □

THEOREM 3.7. *Let* $f(r) = (\mathcal{E}-r'\mathcal{K})/(1-r')^2$, $0 < r < 1$, $f(0) = \pi/8$, $f(1) = 1$. *Then* f *is strictly increasing on* $[0,1]$. *In particular,*

$$\frac{\pi}{8}(1-r')^2 < \mathcal{E}(r) - r'\mathcal{K}(r) < (1-r')^2$$

for $0 < r < 1$. *The first inequality is sharp at* $r = 0$, *and the second inequality is sharp at both zero and* 1.

Proof. The limit $f(1-) = 1$ is clear, while by l'Hôpital's rule and [BF, 710.04, 710.05] we have

$$f(0+) = \lim_{r\to 0+}\frac{\mathcal{K}-\mathcal{E}}{2r^2} = \lim_{r\to 0+}\frac{\mathcal{E}}{4(r')^2} = \frac{\pi}{8}.$$

Next, for $0 < r < 1$, by differentiation [BF, 710.00, 710.02] and algebraic simplification,

$$rr'(1-r')^2 f'(r) = g(r),$$

where $g(r) \equiv (1-r')(\mathcal{K}-\mathcal{E}) - 2(1+r')(\mathcal{E}-r'\mathcal{K})$. Then $g(0) = 0$ and, for $0 < r < 1$, $(r')^2 g'(r) = r(1+2r')(\mathcal{E}-r'\mathcal{K})$, which is positive by the first inequality in (3.2). □

THEOREM 3.8. *Let* $f(r) \equiv \mathcal{E}(r)\mathcal{K}(r)$, $0 \le r < 1$. *Then* f *is strictly increasing and convex from* $[0,1)$ *onto* $[\pi^2/4, \infty)$ *and* $g(r) \equiv \sqrt{r'}f(r)$ *is strictly decreasing from* $[0,1)$ *onto* $(0, \pi^2/4]$. *In particular, for* $0 < r < 1$,

$$\frac{\pi^2}{4} < \mathcal{E}(r)\mathcal{K}(r) < \frac{\pi^2}{4\sqrt{r'}}.$$

Proof. By differentiation [BF, 710.00, 710.02] and algebraic manipulations,

$$f'(r) = \frac{\mathcal{E}^2-(r')^2\mathcal{K}^2}{r(r')^2} = \frac{\mathcal{E}-r'\mathcal{K}}{(1-r')^2}\cdot\left(\frac{\mathcal{E}}{r'}+\mathcal{K}\right)\cdot\frac{(1-r')^2}{r}\cdot\frac{1}{r'}.$$

By Theorems 3.7 and 1.3 the first two factors on the right are positive increasing functions, and it is easy to see that the last two factors are increasing. Hence f is increasing and convex. Next, by Theorem 1.4 and [AVV2, Thm. 2.2(3)] $g(r)$ is the product of two positive strictly decreasing functions $\sqrt{r'}\mathcal{K}(r)$ and $\mathcal{E}(r)$, hence is strictly decreasing. Finally, the limiting values and inequalities are clear. □

COROLLARY 3.9. *For* $0 < r < 1$,

$$\text{(1)} \qquad \frac{\pi}{2}\left(1 - \frac{r^2}{2}\right)^{-1/2} < \mathcal{K}(r) < \frac{\pi}{2}(r')^{-1/2},$$

$$\text{(2)} \qquad \frac{\pi}{2}\sqrt{r'} < \mathcal{E}(r) < \frac{\pi}{2}.$$

Proof. The lower estimates follow from (3.2) and Theorem 3.8. The upper estimate in (1) is a consequence of Theorem 1.2, and in (2) it follows from the fact that $\mathcal{E}$ is decreasing. □

It follows immediately from the definition (1.2) that $\mathcal{K}(r) \geq \pi/2$. We now obtain another pair of significant estimates for $\mathcal{K}(r)$ in terms of elementary functions.

THEOREM 3.10. *For* $0 < r < 1$, *define the functions* f, g *on* $[0,1)$ *by* $f(r) = r\mathcal{K}(r)^2/\log((1+r)/(1-r))$, $f(0) = \pi^2/8$, *and* $g(r) = f(r)/\mathcal{K}(r)$. *Then* f *is strictly increasing and* g *is strictly decreasing. In particular, for* $0 < r < 1$,

$$\left(\frac{\operatorname{arth} r}{r}\right)^{1/2} < \frac{2\mathcal{K}(r)}{\pi} < \frac{\operatorname{arth} r}{r}.$$

Both inequalities are sharp as $r \to 0$. *The second inequality is of the correct order as* $r \to 1$.

Proof. Since f and g are continuous at zero, it is sufficient to prove the monotoneity properties on $(0,1)$. Now

$$\begin{aligned}\left(\log\frac{1+r}{1-r}\right)^2 f'(r) &= \left(\mathcal{K}^2 + 2\mathcal{K}\frac{\mathcal{E} - (r')^2\mathcal{K}}{(r')^2}\right)\log\frac{1+r}{1-r} - \frac{2r\mathcal{K}^2}{(r')^2} \\ &= \frac{\mathcal{K}}{(r')^2}(2\mathcal{E} - (r')^2\mathcal{K})\left(\log\frac{1+r}{1-r} - \frac{2r\mathcal{K}}{2\mathcal{E} - (r')^2\mathcal{K}}\right),\end{aligned}$$

which is positive by Theorem 3.6.

Similarly,

$$\begin{aligned}\left(\log\frac{1+r}{1-r}\right)^2 g'(r) &= \left(\mathcal{K} + \frac{\mathcal{E} - (r')^2\mathcal{K}}{(r')^2}\right)\log\frac{1+r}{1-r} - \frac{2r\mathcal{K}}{(r')^2} \\ &= \frac{\mathcal{E}}{(r')^2}\left(\log\frac{1+r}{1-r} - \frac{2r\mathcal{K}}{\mathcal{E}}\right),\end{aligned}$$

which is negative by Theorem 3.6.

The lower estimate is sharp by continuity, and the upper estimate is of the correct order as $r \to 1$ since, by [BF, 112.01], $\mathcal{K}(r) \sim \operatorname{arth} r$ as $r \to 1$. □

Remark 3.2. The second inequality in Theorem 3.10 can be rewritten in terms of the hypergeometric function as $F(\frac{1}{2}, \frac{1}{2}; 1; r) \leq F(\frac{1}{2}, 1; \frac{3}{2}; r)$ [C2, p. 15], which is true by virtue of Lemma 2.3.

The next result improves an estimate in [AVV2, (1.8)].

THEOREM 3.11. *For* $0 < r < 1$,

$$1 < \sqrt[4]{1+r}\frac{\mathcal{K}(r)}{\mathcal{K}(\sqrt{r})} < \min\{\sqrt[4]{2}, (r')^{-1/2}\}.$$

Proof. Since $r < \sqrt{r} < 2\sqrt{r}/(1+r)$ it follows from [AVV2, Thm. 2.2(3)] and the first identity in (3.1) that

$$r'\mathcal{K}(r)^2 > \sqrt{1-r}\mathcal{K}(\sqrt{r})^2 > \frac{1-r}{1+r}((1+r)\mathcal{K}(r))^2 = (1-r^2)\mathcal{K}(r)^2.$$

Dividing by $\sqrt{1-r}$ and taking square roots we obtain

$$\sqrt{r'}\sqrt[4]{1+r}\mathcal{K}(r) < \mathcal{K}(\sqrt{r}) < \sqrt[4]{1+r}\mathcal{K}(r).$$

Finally, $\sqrt[4]{1+r}\mathcal{K}(r) < \sqrt[4]{2}\mathcal{K}(\sqrt{r})$ since $\mathcal{K}$ is increasing and $r < \sqrt{r}$. □

It is well known that $\mathcal{K}(r)+\log r'$ is strictly decreasing from $(0,1)$ onto $(\log 4, \pi/2)$ [AVV2, Thm. 2.2(1)]. The next result provides a dual of this fact.

THEOREM 3.12. *The function* $f(r) \equiv \sqrt{r}\mathcal{K}(r) + \log r'$ *is strictly increasing from* $(0,1)$ *onto* $(0, \log 4)$. *In particular, for* $0 < r < 1$,

$$\log\frac{1}{r'} < \sqrt{r}\mathcal{K}(r) < \log\frac{4}{r'}.$$

Proof. The limit $f(0+) = 0$ is obvious, while

$$f(1-) = \lim_{r\to 1-}[\sqrt{r}(\mathcal{K} + \log r') + (1-\sqrt{r})\log r'] = \log 4$$

by [BF, 112.01]. For the monotoneity we write $f'(r) = g(r)/(r^{1/2}(r')^2)$, where $g(r) \equiv \mathcal{E} - \frac{1}{2}(r')^2\mathcal{K} - r^{3/2}$ tends to zero as $r \to 1-$. Thus it is sufficient to prove that $g(r)$ decreases on $(0,1)$. But $g'(r) = h(r)/(2r)$, where $h(r) \equiv \mathcal{E} - (r')^2\mathcal{K} - 3r^{3/2}$, and by [AVV2, Thm. 2.2(7)], $h(r) \le r^2 - 3r^{3/2} < 0$ for $0 < r < 1$. □

V. I. Semenov [Se, (6)] has obtained the inequality

$$\frac{2}{\pi}r^2(1-r^2)\mathcal{K}(r)\mathcal{K}(r') \le \min\{h(r), h(r')\},\quad h(r) = r^2\log\frac{4}{r}. \tag{3.4}$$

The following corollary, which is precisely the second inequality of [AVV2, Thm. 4.2(5)], improves upon (3.4).

COROLLARY 3.13. *For* $0 < r < 1$,

$$\frac{2}{\pi}rr'\mathcal{K}(r)\mathcal{K}'(r) \le \min\left\{r\log\frac{4}{r}, r'\log\frac{4}{r'}\right\}.$$

Proof. By symmetry it is sufficient to prove one of these inequalities. By Theorem 3.12 and [AVV2, Thm. 2.2(3)] we have $\sqrt{r'}\mathcal{K}' \le \log(4/r)$ and $(2/\pi)\sqrt{r'}\mathcal{K} \le 1$. Multiplying, we obtain $(2/\pi)r'\mathcal{K}\mathcal{K}' \le \log(4/r)$, and the first inequality follows. □

Conjectures 3.1. Various generalizations of the classical relation (2.2) were obtained by S. Ramanujan [A] (see also [SS]). We here focus on the particular case

$a = b = \frac{1}{2}$ of (2.2). Our computational work supports the validity of the following conjectures, where $0 < r < 1$, $r' = (1-r^2)^{1/2}$:

(1) $\mathcal{K}(r) < \log(1+\frac{4}{r'}) - (\log 5 - \frac{\pi}{2})(1-r)$.

(2) The function $\sqrt[4]{1+r}\mathcal{K}(r)/\mathcal{K}(\sqrt{r})$ is increasing from $[0,1)$ onto $[1, \sqrt[4]{2})$.

(3) The function $(\mathcal{K}(r) - \log(4/r'))/((r')^2 \log(4/r'))$ is increasing from $(0,1)$ onto $((\pi/\log 16) - 1, \frac{1}{4})$.

(4) The function $(\mathcal{E}(r) - (r')^2\mathcal{K}(r))(\mathcal{E}(r)-1)/(r')^2(\mathcal{K}(r)-\mathcal{E}(r))$ is increasing from $(0,1)$ onto $(\frac{1}{2}, \frac{\pi}{2} - 1)$.

(5) (cf. [AVV2, 6.4(2)]) The inequality in Theorem 3.5 can be replaced by

$$9 < \frac{(8+r^2)\mathcal{K}(r)}{\log(4/r')} < 9.1.$$

(6) $(r')^2 \leq \dfrac{r'\exp(\mathcal{K}(r)) - 4}{\exp\left(\frac{\pi}{2}\right) - 4} \leq \dfrac{2\sqrt{1-r}}{2-r}$.

Remark 3.3. After this manuscript had been completed R. Kühnau kindly informed the authors about his work in [K] related to conjecture 3.1(5).

Acknowledgments. We are grateful to Professor B. C. Carlson and to the referees for their helpful comments.

SOME q-BETA AND MELLIN–BARNES INTEGRALS WITH MANY PARAMETERS ASSOCIATED TO THE CLASSICAL GROUPS*

ROBERT A. GUSTAFSON[†]

Abstract. Multidimensional generalizations of a q-beta integral of Nasrallah–Rahman and Barnes' second lemma are evaluated. These are integral analogues of Jackson, Dougall, and the Pfaff–Saalschütz summation theorem for hypergeometric series. These integrals can also be written as group integrals over the special unitary group, the compact symplectic groups or conjugation invariant integrals over the corresponding Lie algebras.

Key words. multivariate beta integrals, multivariate Mellin–Barnes integrals, q-beta integrals, the classical groups

AMS(MOS) subject classifications. 33A15, 33A30, 33A65, 33A75

1. Introduction. One of the foundations for the classical theory of hypergeometric series is Euler's beta integral and the Mellin–Barnes contour integrals (see Baily [4]). On the one hand, integral representations of hypergeometric series as well as orthogonal polynomials are obtained. On the other hand, an important tool for discovering and proving many important special function identities is found. More recently, multidimensional generalizations of Euler's beta integral and the Mellin–Barnes integral have been discovered in the setting of root systems or simple Lie groups. Some examples of these are Selberg's beta integral [22], the q-Dyson–Zeilberger–Bressoud theorem [1], [23], the Macdonald–Morris conjectures [15], [19], and some generalizations and analogues of the Askey–Wilson integral [3] for various compact Lie groups and Lie algebras [8], [9]. The connection of these integrals to multidimensional special functions is only beginning to be understood (e.g., see [10], [11], [16]). Another aspect of this circle of problems is to obtain group-theoretic interpretations for these fascinating multidimensional integrals and functions. Some progress has been made in one dimension in interpreting some of the basic (or q-analogue) special functions as spherical functions on quantum groups (e.g., see [12], [17]). In higher dimensions, there is the theory of zonal spherical polynomials (see, e.g., [7]), spherical functions for p-adic groups [14], and Macdonald's polynomials [16], which contain all of the above as special cases. It often appears that the discovery of new kinds of special function identities has given the impetus for the discovery of new group-theoretic interpretations of special functions.

Let q be a real number, $0 < q < 1$. For any complex number c, define

$$[c]_\infty = [c;q]_\infty = \prod_{k=0}^{\infty}(1 - cq^k)$$

and also

$$[c]_n = [c]_\infty/[cq^n]_\infty$$

for any integer n.

A one variable integral with many parameters generalizing Euler's beta integral was isolated by Rahman [21] (see [2]) and is a special case of an integral of Nasrallah–Rahman [20].

THEOREM 1.1. *Let $a_i \in C$, $1 \leq i \leq 5$, with $|a_i| < 1$, then*

$$\frac{1}{(2\pi i)} \int_T \frac{\left[z \prod_{i=1}^{5} a_i\right]_\infty \left[z^{-1} \prod_{i=1}^{5} a_i\right]_\infty [z^2]_\infty [z^{-2}]_\infty}{\prod_{i=1}^{5} [a_i z]_\infty [a_i z^{-1}]_\infty} \frac{dz}{z} = \frac{2 \prod_{k=1}^{5} \left[\prod_{\substack{i=1 \\ i \neq k}}^{5} a_i\right]_\infty}{[q]_\infty \prod_{1 \leq i < j \leq 5} [a_i a_j]_\infty}, \tag{1.2}$$

where the unit circle T taken in the positive direction.

If we set, for example, $a_1 = 0$, then identity (1.2) reduces to the important Askey–Wilson integral [3]. Identity (1.2) can be viewed as an integral analogue of Jackson's summation theorem for very well poised ${}_8\varphi_7$ hypergeometric series. The integrand in (1.2) is also the weight function for a very general family of biorthogonal rational functions [21], which include the Askey–Wilson polynomials [3] as a limiting case.

The purpose of this paper is to generalize integral (1.2) in the setting of the special unitary groups $SU(n)$ in §2 and the compact symplectic groups $Sp(n)$ in §4. In §5, we also evaluate some Mellin–Barnes integrals associated to the Lie algebras $su(n)$ and $sp(n)$ which generalize a Mellin–Barnes integral analogue of (1.2) due to Rahman [21]. Finally, in §3 we give a $u(n)$ (the Lie algebra of hermitian matrices) generalization of Barnes' second lemma [5], [4]. Barnes' second lemma is a Mellin–Barnes integral analogue of the important Pfaff–Saalschütz summation theorem for ${}_3F_2$ hypergeometric series. The integrals in this paper are given as multiple contour integrals, but can also be written as integrals over the corresponding Lie groups or Lie algebras. For details, see §10 of [9].

In future work [6], we plan to use the integrals evaluated here in order to derive a number of other special function identities, including Jackson-type, summation theorems for hypergeometric series associated to the classical groups and a generalization of the ${}_{10}\varphi_9$ transformation for $SU(n)$. We also hope to show that these integrals will be useful in constructing generating functions and reproducing kernels for multivariate orthogonal polynomials (see Nasrallah and Rahman [20]).

2. A generalization of Nasrallah–Rahman integral for $SU(n)$.

In this section we prove a generalization of the Nasrallah–Rahman integral (1.2) associated to the Lie groups $SU(n)$. The $SU(2)$ case is just the Nasrallah–Rahman integral (1.2). Briefly, the proof goes as follows. We first show that both sides of the integral identity (2.2) satisfy the same difference equation (2.8). This allows the proof of (2.2) to be reduced to a double induction, one parameter n measuring dimension and the other parameter k measuring the distance from an Askey–Wilson type integral for $SU(n)$ that has previously been evaluated [9]. An essential part of the induction proof is a technical multiple contour integral argument.

The main result is the following.

THEOREM 2.1. *For $n \geq 2$, let $a_i \in C$, $1 \leq i \leq n$, and $b_j \in C$, $1 \leq j \leq n+1$, with $|a_i|, |b_j| < 1$. Set $A = \prod_{i=1}^{n} a_i, B = \prod_{j=1}^{n+1} b_j$ and $C = AB$, then*

$$\frac{1}{(2\pi i)^{n-1}}\int_{T^{n-1}} \frac{\prod_{k=1}^{n} [Cz_k]_\infty \prod_{\substack{1\le i,j\le n\\ i\ne j}}[z_iz_j^{-1}]_\infty}{\prod_{k=1}^{n}\left\{\prod_{i=1}^{n} [a_iz_k^{-1}]_\infty \prod_{j=1}^{n+1}[b_jz_k]_\infty\right\}} \frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} = \frac{n!\prod_{j=1}^{n+1}[b_j^{-1}C]_\infty \prod_{i=1}^{n}[a_iB]_\infty}{[q]_\infty^{n-1}[A]_\infty \prod_{j=1}^{n+1}[b_j^{-1}B]_\infty \prod_{i=1}^{n}\prod_{j=1}^{n+1}[a_ib_j]_\infty},\tag{2.2}$$

where $\prod_{k=1}^{n} z_k = 1$, the integral in each variable $z_1,\cdots,z_{n-1}$ is over the unit circle T taken in the positive direction, and T^{n-1} is the $n-1$ fold direct product of T.

Proof. Observe that if we define the $n=1$ case of the integral on the left-hand side of (2.2) to be the evaluation of this integrand at $z_1 = 1$, then identity (2.2) is valid for $n = 1$. The $n = 2$ case of identity (2.2) is a restatement of integral (1.2). The general proof of Theorem 2.1 given here will include the $n = 2$ case, but for $n = 2$ our proof is related to an earlier proof of Askey [2], though Askey's simpler proof does not seem to generalize for $n > 2$.

To begin our proof of identity (2.2) for $n \ge 2$, we shall require that for any integer $\ell, b_i \ne b_jq^\ell$ for $1 \le i,j \le n+1, i \ne j$, and $b_j \ne Cq^\ell$ for $1 \le j \le n+1$. This restriction will be removed at the end of the proof of (2.2). We also remark that

$$b_k^{-1}C = \prod_{i=1}^{n} a_i \prod_{\substack{j=1\\ j\ne k}}^{n+1} b_j \quad\text{and}\quad b_k^{-1}C = \prod_{\substack{j=1\\ j\ne k}}^{n+1} b_j$$

both make sense when $b_k = 0$.

To prove (2.2), we first show that both sides of (2.2) satisfy the same q-difference equation in the parameters b_j, $1 \le j \le n+1$. We will need the following version of the partial fraction expansion.

LEMMA 2.3. (*Cf.* [18, *Lemma* 7.1].) *Let $\{x_1,\cdots,x_m\}$,, $\{y_1,\cdots,y_{m+1}\}$ and t be indeterminants with the y_i distinct. Then*

$$\sum_{\ell=1}^{m+1}\left\{\prod_{\substack{j=1\\ j\ne\ell}}^{m+1}\left(\frac{t-y_j}{y_\ell-y_j}\right)\prod_{k=1}^{m}(1-y_\ell x_k)\right\} = \prod_{k=1}^{m}(1-tx_k).\tag{2.4}$$

Proof. Identity (2.4) is equivalent to the $r < s$ case of Lemma 7.1 of [18] (see also [13]), which is a statement of the classical partial fractions expansion. To prove identity (2.4), divide both sides by $\prod_{j=1}^{m+1}(t - y_j)$ and obtain the following identity:

$$\sum_{\ell=1}^{m+1}\left\{(t-y_\ell)^{-1}\prod_{\substack{j=1\\ j\ne\ell}}^{m+1}(y_\ell-y_j)^{-1}\prod_{k=1}^{m}(1-y_\ell x_k)\right\} = \prod_{k=1}^{m}(1-tx_k)\prod_{j=1}^{m+1}(t-y_j)^{-1}.\tag{2.5}$$

Identity (2.5) is proved by observing that the left-hand side of (2.5) is simply the partial fraction expansion of the right-hand side of (2.5).

We now show that both sides of (2.2) satisfy the same q-difference equation.

DEFINITION 2.6. If f is a function involving the parameters b_ℓ and C, then define

$$R_\ell f(b_\ell, C) = f(b_\ell q, Cq).$$

LEMMA 2.7. *With notation as in Theorem* 2.1, *let f be either the left-hand side or right-hand side of* (2.2). *Assume that the parameters b_i are all distinct. Then*

$$\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1\\ j\neq\ell}}^{n+1} \left(\frac{C-b_j}{b_\ell - b_j} \right) \cdot (R_\ell f) \right\} = f. \tag{2.8}$$

Proof. Let I and Q denote, respectively, the left-hand side and right-hand side of equation (2.2). We have

$$R_\ell I = \frac{1}{(2\pi i)^{n-1}} \int_{T^{n-1}} \frac{\prod_{k=1}^{n} [Cz_k]_\infty \prod_{\substack{1\leq i,j\leq n\\ i\neq j}} [z_i z_j^{-1}]_\infty}{\prod_{k=1}^{n} \left\{ \prod_{i=1}^{n} [a_i z_k^{-1}]_\infty \prod_{j=1}^{n+1} [b_j z_k]_\infty \right\}} \tag{2.9}$$
$$\cdot \prod_{k=1}^{n} \left(\frac{1-b_\ell z_k}{1-Cz_k} \right) \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}}.$$

Substitute the expression on the right-hand side of (2.9) into the left-hand side of (2.8) and apply Lemma 2.3 with $m = n, t = C, x_i = z_i$ and $y_i = b_i$. This proves that I satisfies the q-difference equation (2.8).

Similarly, we have

$$R_\ell Q = \left\{ \prod_{\substack{j=1\\ j\neq\ell}}^{n+1} \left(\frac{1-b_j^{-1}B}{1-b_j^{-1}C} \right) \prod_{i=1}^{n} \left(\frac{1-a_i b_\ell}{1-a_i B} \right) \right\} Q. \tag{2.10}$$

To verify that Q satisfies the q-difference equation (2.8), we need to show that

$$\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1\\ j\neq\ell}}^{n+1} \left[\frac{(C-b_j)(1-b_j^{-1}B)}{(b_\ell - b_j)(1-b_j^{-1}C)} \right] \prod_{i=1}^{n} \left(\frac{1-a_i b_\ell}{1-a_i B} \right) \right\} = 1. \tag{2.11}$$

Simplifying, we are reduced to showing that

$$\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1\\ j\neq\ell}}^{n+1} \left(\frac{B-b_j}{b_\ell - b_j} \right) \prod_{i=1}^{n} (1-a_i b_\ell) \right\} = \prod_{i=1}^{n} (1-a_i B). \tag{2.12}$$

Identity (2.12) now follows from Lemma 2.3 upon setting $m = n, t = B, x_i = a_i$, and $y_i = b_i$ in identity (2.4). This completes the proof of Lemma 2.7.

We now prove Theorem 2.1 by induction on n. As mentioned above, the $n = 1$ case of identity (2.2) is trivially true. We will assume from now on that $n \geq 2$ and that the $n - 1$ case of identity (2.2) is valid.

We first prove identity (2.2) in the special case that $a_n = q^{k+1}C^{-1}$ and $b_{n+1} = q^{-k}C$, where k is a positive integer. This will proceed by induction on k, with the cases $k = 1$ and $k > 1$ handled differently.

Assume that $q^{k+1} < |C| < q^k$ and that $|q^kC^{-1}| < r^{-1}$ where r is a real number chosen as close to 1 as necessary. We will also assume that C^{n-1} is not a real number.

Let $R = r^{n-1}$. For $k > 1$, we let

$$a_i < R \quad \text{for } i = 1, \cdots, n-1 \tag{2.13a}$$

and

$$b_j < R^{n-1} \quad \text{for } j = 1, \cdots, n \tag{2.13b}$$

For $k = 1$, let $1 \geq t > 0$ be a real number so that

$$ta_i < R \quad \text{for } i = 1, \cdots, n-1 \tag{2.14a}$$

and

$$tb_j < R^{n-1} \quad \text{for } j = 1, \cdots, n. \tag{2.14b}$$

For $k > 1$, we will always let $t = 1$.

Let N be the contour which is the union of the circle of radius R centered at the origin, traversed in the positive direction, and the circle of radius ε centered at the point q^kC^{-1} traversed in the positive direction, where ε is a sufficiently small positive real number. We will now use the following notation:

$$H(m,t) = \frac{\prod_{\ell=1}^{n} [Cz_\ell]_\infty \prod_{\substack{1\leq i,j\leq n \\ i\neq j}} [z_iz_j^{-1}]_\infty}{\prod_{\ell=1}^{n} \left\{ [q^{m+1}C^{-1}z_\ell^{-1}]_\infty [q^{-m}Cz_\ell]_\infty \prod_{i=1}^{n-1} [a_itz_\ell^{-1}]_\infty \prod_{j=1}^{n} [b_jtz_\ell]_\infty \right\}} \tag{2.15a}$$

and

$$H(m) = H(m,1), \tag{2.15b}$$

where m is a nonnegative integer.

Rewriting the factors $\prod_{\ell=1}^n (1 - q^{-k}Cz_\ell)$ as $(-q^{-k}C)^n \prod_{\ell=1}^n (1 - q^kC^{-1}z_\ell^{-1})$, we find

$$\int\limits_{T^{n-1}} H(k,t)\frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}} = \frac{(-1)^n}{(q^{-k}C)^n} \int\limits_{T^{n-1}} H(k-1,t)\frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}}. \tag{2.16}$$

We also have

$$\begin{aligned} &\int\limits_{T^{n-1}} H(k-1,t)\frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}} \\ &= \int\limits_{T^{n-2}} \int\limits_{T-N} H(k-1,t)\frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}} \end{aligned} \tag{2.17}$$

$$+\int_{T^{n-3}}\int_{T-N}\int_{N} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}$$

$$+\int_{T^{n-4}}\int_{T-N}\int_{N^2} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}$$

$$+\cdots+\int_{N^{n-1}} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}.$$

Using Fubini's theorem and the symmetry of the integrands with respect to permutation of the variables $z_1,\cdots,z_{n-1}$, we find

$$\begin{aligned}\int_{T^{n-1}} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} &= \sum_{j=0}^{n-2}\int_{T^{n-2-j}}\int_{N^j}\int_{T-N} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}\\ &\quad+\int_{N^{n-1}} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}.\end{aligned}\tag{2.18}$$

With respect to the variable z_1, consider the poles of the integrand $H(k-1,t)\prod_{i=1}^{n-1} z_i^{-1}$ inside the region bounded by the contour $T-N$. The first pole is at $z_1 = C^{-1}q^k$ and the other pole is at $z_1 = Cq^{-k}z_2^{-1}\cdots z_n^{-1}$ (i.e., $z_n = C^{-1}q^k$). Notice that for the second pole to occur either $z_i \in T$ for all $i = 2,\cdots,n-1$ or at least one of the z_i, $i = 2,\cdots,n-1$ must lie on the circle of radius ε centered at q^kC^{-1}.

Let

$$J(k-1,t)=\frac{\prod_{j=2}^{n}\{(1-Cq^{-k}z_j)[Cz_j]_\infty\}}{[q]_{k-1}[q]_\infty\prod_{i=1}^{n-1}[a_itCq^{-k}]_\infty\prod_{j=1}^{n}[b_jtC^{-1}q^k]_\infty}\cdot\frac{\prod_{\substack{2\le i,j\le n\\ i\ne j}}[z_iz_j^{-1}]_\infty}{\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n-1}[a_itz_\ell^{-1}]_\infty\prod_{j=1}^{n}[b_jtz_\ell]_\infty\right\}},$$

where $\prod_{i=2}^{n} z_i = Cq^{-k}$. From identity (2.18) and the following remarks, it follows that

$$\begin{aligned}&\sum_{j=0}^{n-2}\frac{1}{(2\pi i)^{n-1}}\int_{T^{n-2-j}}\int_{N^j}\int_{T-N} H(k-1,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}\\ &= -\frac{2}{(2\pi i)^{n-2}}\int_{T^{n-2}} J(k-1,t)\frac{dz_2}{z_2}\cdots\frac{dz_{n-1}}{z_{n-1}}\\ &\quad-\sum_{j=1}^{n-2}\frac{1}{(2\pi i)^{n-2}}\int_{T^{n-2-j}}\int_{N^j} J(k-1,t)\frac{dz_2}{z_2}\cdots\frac{dz_{n-1}}{z_{n-1}}+\varepsilon M(t),\end{aligned}\tag{2.19}$$

where $M(t)$ is a number which is bounded independently of ε.

In the integrals on the right-hand side of (2.19) we can deform the contours N to the contour T by attaching the circle of radius R in N to the circle of radius ε by two parallel line segments in opposite directions and then separating the line segments. We can use Fubini's theorem repeatedly, crossing no poles of the integrand during the deformations. It follows that

$$(2.20) \qquad \int\limits_{T^{n-2-j}} \int\limits_{N^j} J(k-1,t)\frac{dz_2}{z_2}\cdots\frac{dz_{n-1}}{z_{n-1}} = \int\limits_{T^{n-2}} J(k-1,t)\frac{dz_2}{z_2}\cdots\frac{dz_{n-1}}{z_{n-1}}$$

for $0 \leq j \leq n-2$.

Now let

$$d = (q^k C^{-1})^{\frac{1}{n-1}}$$

for some choice of $(n-1)$th root of $q^k C^{-1}$. We make the change of variables

$$z_i' = z_i d \quad \text{for } i = 2, \cdots, n-1,$$

$$a_i' = a_i d \quad \text{for } i = 1, \cdots, n,$$

$$b_j' = b_j d^{-1} \quad \text{for } j = 1, \cdots, n,$$

and

$$C' = Cd^{-1}.$$

Note that $C' = q\prod_{i=1}^{n-1} a_i' \prod_{j=1}^{n} b_j'$.

In terms of the new variables we have

$$J(k-1,t) = \frac{\prod\limits_{j=2}^{n}\{(1-d^{-n}z_j')[C'z_j']_\infty\}}{[q]_{k-1}[q]_\infty \prod\limits_{i=1}^{n-1}[a_i'tC'q^{-k}]_\infty \prod\limits_{j=1}^{n}[b_j't(C')^{-1}q^k]_\infty}$$

$$\cdot \frac{\prod\limits_{\substack{2\leq i,j\leq n\\ i\neq j}} [z_i'(z_j')^{-1}]_\infty}{\prod\limits_{\ell=2}^{n}\left\{\prod\limits_{i=1}^{n-1}[a_i't(z_\ell')^{-1}]_\infty \prod\limits_{j=1}^{n}[b_j'tz_\ell']_\infty\right\}},$$

where $\prod_{i=2}^{n} z_i' = 1$. After making this change of variables and moving the contours of integration, we find

$$(2.21) \qquad \int\limits_{T^{n-2}} J(k-1,t)\frac{dz_2}{z_2}\cdots\frac{dz_{n-1}}{z_{n-1}} = \int\limits_{T^{n-2}} J(k-1,t)\frac{dz_2'}{z_2'}\cdots\frac{dz_{n-1}'}{z_{n-1}'}.$$

Consider the case $k=1$. Then

$$H(0,t) = \frac{\prod\limits_{1\leq i,j\leq n}[z_iz_j^{-1}]_\infty}{\prod\limits_{\ell=1}^{n}\left\{[qC^{-1}z_\ell^{-1}]_\infty \prod\limits_{i=1}^{n-1}[a_itz_\ell^{-1}]_\infty \prod\limits_{j=1}^{n}[b_jtz_\ell]_\infty\right\}}$$

and the integral $\int_{N^{n-1}} H(0,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}$ can be evaluated by means of the $SU(n)$ generalization of the Askey–Wilson integral [9, Thm. 6.1]. By a contour deformation argument similar to the above and by shifting the parameters a_it, $1 \le i \le n-1, b_jt$, $1 \le j \le n$, and $q^{-1}C$, it can be verified that the $SU(n)$ Askey–Wilson integral is also valid for the contour N and the parameters a_it, b_jt, and qC^{-1}. We find

$$\int\limits_{N^{n-1}} H(0,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} = \frac{(2\pi i)^{n-1}n![t^{2n-1}]_\infty}{[q]_\infty^{n-1}\left[qC^{-1}t^{n-1}\prod_{i=1}^{n-1}a_i\right]_\infty\left[t^n\prod_{j=1}^{n}b_j\right]_\infty} \cdot\prod_{j=1}^{n}\left\{[tqC^{-1}b_j]_\infty\prod_{i=1}^{n-1}[t^2a_ib_j]_\infty\right\}^{-1}. \tag{2.22}$$

Considering the limit as ε tends to zero, then from (2.18)–(2.22), it follows that

$$\begin{aligned}\frac{1}{(2\pi i)^{n-1}}\int\limits_{T^{n-1}} H(0,t)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} &= \frac{n![t^{2n-1}]_\infty}{[q]_\infty^{n-1}\left[qC^{-1}t^{n-1}\prod_{i=1}^{n-1}a_i\right]_\infty\left[t^n\prod_{j=1}^{n}b_j\right]_\infty}\\ &\quad\cdot\prod_{j=1}^{n}\left\{[tqC^{-1}b_j]_\infty\prod_{i=1}^{n-1}[t^2a_ib_j]_\infty\right\}^{-1}\\ &\quad-\frac{n}{(2\pi i)^{n-2}}\int\limits_{T^{n-2}} J(0,t)\frac{dz_2'}{z_2'}\cdots\frac{dz_{n-1}'}{z_{n-1}'}.\end{aligned} \tag{2.23}$$

Both sides of (2.23) are analytic functions of the parameters a_i, b_j, and t. If we choose the a_i and b_j appropriately and deform the contour T on the right-hand side of (2.23), then we can take the limit as $t \to 1$ on both sides of (2.23). We obtain

$$\frac{1}{(2\pi i)^{n-1}}\int\limits_{T^{n-1}} H(0)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} = -\frac{n}{(2\pi i)^{n-2}}\int\limits_{L^{n-2}} J(0,1)\frac{dz_2'}{z_2'}\cdots\frac{dz_{n-1}'}{z_{n-1}'}, \tag{2.24}$$

where L is an appropriate contour.

We have

$$J(0,1) = \frac{\prod_{j=2}^{n}[d^{-n}z_j']_\infty\prod_{\substack{2\le i,j\le n\\ i\ne j}}[z_i'(z_j')^{-1}]_\infty}{[q]_\infty\prod_{i=1}^{n-1}[a_i'C'q^{-1}]_\infty\prod_{j=1}^{n}[b_j'(C')^{-1}q]_\infty\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n-1}[a_i'(z_\ell')^{-1}]_\infty\prod_{j=1}^{n}[b_j'z_\ell']_\infty\right\}}.$$

Since $\prod_{i=1}^{n-1}a_i'\prod_{j=1}^{n}b_j' = d^{-n}$, then the integral on the right-hand side of equation (2.24) can be evaluated by the dimension $n-1$ case of identity (2.2), which we assume is valid by the induction hypothesis on the dimension n. From (2.16) and (2.24), we then obtain

$$\frac{1}{(2\pi i)^{n-1}} \int_{T^{n-1}} H(1)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}$$

$$(2.25) \qquad = \frac{(-1)^{n-1}n! \prod_{j=1}^{n} [(b'_j)^{-1}d^{-n}]_\infty \prod_{i=1}^{n-1} \left[a'_i \prod_{j=1}^{n} b'_j\right]_\infty}{(q^{-1}C)^n[q]_\infty^{n-1} \left[\prod_{i=1}^{n-1} a'_i\right]_\infty \prod_{j=1}^{n} \left[b_j'^{-1} \prod_{i=1}^{n} b'_i\right]_\infty}$$

$$\cdot \left\{ \prod_{i=1}^{n-1} \prod_{j=1}^{n} [a'_i b'_j]_\infty \prod_{i=1}^{n-1} [a'_i C' q^{-1}]_\infty \prod_{j=1}^{n} [b'_j (C')^{-1} q]_\infty \right\}^{-1}.$$

Now rewrite identity (2.25) in terms of the parameters a_i, b_j, and C. After some computation and using that $a_n = q^2C^{-1}$ and $b_{n+1} = q^{-1}C$, then identity (2.25) becomes the $k = 1$ dimension n case of identity (2.2). This completes the proof of the $k = 1$, dimension n case of identity (2.2).

We now consider the $k > 1$, dimension n case of identity (2.2). The $k - 1$, dimension n case is assumed to be valid. By a contour deformation argument similar to the above and by shifting the parameters a_i and b_j, it can be verified that the $k-1$ case of identity (2.2) is also valid for the contour N and the parameters a_i and b_j. We find

(2.26)

$$\int_{N^{n-1}} H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}} = \frac{(2\pi i)^{n-1}n! \prod_{j=1}^{n} [b_j^{-1}C]_\infty}{[q]_\infty^n \left[q^k C^{-1} \prod_{i=1}^{n-1} a_i\right]_\infty}$$

$$\cdot \frac{[q^{k-1}]_\infty \left[q \prod_{j=1}^{n} b_j\right]_\infty \prod_{i=1}^{n-1} \left[a_i q^{-k+1} C \prod_{j=1}^{n} b_j\right]_\infty}{\left[\prod_{j=1}^{n} b_j\right]_\infty \prod_{j=1}^{n} \left\{ \left[b_j^{-1} q^{-k+1} C \prod_{i=1}^{n} b_i\right]_\infty [q^k C^{-1} b_j]_\infty \prod_{i=1}^{n-1} [q_i b_j]_\infty \right\}}$$

$$\cdot \prod_{i=1}^{n-1} [q^{-k+1}Ca_i]_\infty^{-1} = \frac{(2\pi i)^{n-1}n! \prod_{j=1}^{n} [(b'_j)^{-1}C']_\infty \prod_{i=1}^{n-1} \left[q a'_i \prod_{j=1}^{n} b'_j\right]_\infty}{[q]_\infty^{n-1}[q]_{k-2} \left[\prod_{i=1}^{n-1} a'_i\right]_\infty \prod_{i=1}^{n-1} [q^{-k+1}C'a'_i]_\infty}$$

$$\cdot \prod_{j=1}^{n} \left\{ \left[q(b'_j)^{-1} \prod_{i=1}^{n} b'_i\right]_\infty [q^k (C')^{-1} b'_j]_\infty \prod_{i=1}^{n-1} [a'_i b'_j]_\infty \right\}^{-1}$$

$$\cdot \left(1 - d^n \prod_{j=1}^{n} b'_j\right)^{-1}.$$

In order to compute the integral of the function $J(k-1,1)$, we will define a related function $I(k-1)$ and a difference equation involving $I(k-1)$ and $J(k-1,1)$. Let

$$I(k-1) = \frac{\prod_{j=2}^{n}[C'z'_j]_\infty \prod_{\substack{2\le i,j\le n\\ i\ne j}} [z'_i(z'_j)^{-1}]_\infty}{\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n-1}[a'_i(z'_\ell)^{-1}]_\infty \prod_{j=1}^{n}[b'_j z'_\ell]_\infty\right\}}.$$

If $f(b'_\ell, C')$ is a function involving the parameters b'_ℓ and C', then we define the shift operator L_ℓ by

$$L_\ell f(b'_\ell, C') = f(b'_\ell q, C'),$$

i.e., which shifts b'_ℓ, but fixes C'. It then follows from Lemma 2.3 that

$$\begin{aligned} J(k-1,1) = {} & \left\{[q]_{k-1}[q]_\infty \prod_{i=1}^{n-1}[a'_i C' q^{-k}]_\infty \prod_{j=1}^{n}[b'_j(C')^{-1}q^k]_\infty\right\}^{-1} \\ & \cdot \sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\ j\ne\ell}}^{n}\left(\frac{d^{-n}-b'_j}{b'_\ell-b'_j}\right) L_\ell I(k-1)\right\}, \end{aligned} \tag{2.27}$$

where we require that the parameters b'_j, $1 \le j \le n$, are distinct.

Identity (2.27) shows that the integral of the function $J(k-1,1)$ can be computed in terms of the integrals of the functions $L_\ell I(k-1)$. Since $C' = q\prod_{i=1}^{n-1} a'_i \prod_{j=1}^{n} b'_j$, then the dimension $n-1$ case of identity (2.2) (which we assume is valid by the induction hypothesis) can be applied to evaluate the integrals of the $L_\ell I(k-1)$ functions. With a little simplification we have

$$\begin{aligned} & \frac{1}{(2\pi i)^{n-2}} \int_{T^{n-2}} J(k-1,1)\frac{dz'_2}{z'_2}\cdots\frac{dz'_n}{z'_n} \\ & = \frac{(n-1)!\prod_{j=1}^{n}[(b'_j)^{-1}C']_\infty \prod_{i=1}^{n-1}\left[qa'_i\prod_{j=1}^{n}b'_j\right]_\infty}{[q]_\infty^{n-1}[q]_{k-1}\prod_{i=1}^{n-1}[q'_i C' q^{-k}]_\infty \prod_{j=1}^{n}[b'_j(C')^{-1}q^k]_\infty} \\ & \cdot\left\{\left[\prod_{i=1}^{n-1}a'_i\right]_\infty \prod_{j=1}^{n}\left[q(b'_j)^{-1}\prod_{i=1}^{n}b'_i\right]_\infty \prod_{i=1}^{n-1}\prod_{j=1}^{n}[a'_i b'_j]_\infty\right\}^{-1} \\ & \cdot\sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\ j\ne\ell}}^{n}\left(\frac{d^{-n}-b'_j}{b'_\ell-b'_j}\right)\cdot\frac{(1-q^{-1}(b'_\ell)^{-1}C')\prod_{i=1}^{n-1}(1-a'_i b'_\ell)}{\left(1-\prod_{\substack{i=1\\ i\ne\ell}}^{n}b'_i\right)}\right\}. \end{aligned} \tag{2.28}$$

The expression inside the sum on the right-hand side of (2.28) can be rewritten as

$$\tag{2.29} \frac{(-q^{-1}C')}{\left(d^{-n}-\prod_{i=1}^{n} b'_i\right)} \sum_{\ell=1}^{n} \left\{ \prod_{\substack{j=1\\ j\neq\ell}}^{n} \left(\frac{d^{-n}-b'_j}{b'_\ell - b'_j}\right) \cdot \left(\frac{d^{-n}-\prod_{i=1}^{n} b'_i}{b'_\ell - \prod_{i=1}^{n} b'_i}\right) (1-q(C')^{-1}b'_\ell) \prod_{i=1}^{n-1}(1-a'_i b'_\ell) \right\}.$$

An application of Lemma 2.3 shows that (2.29) equals

$$\tag{2.30} \frac{(q^{-1}C')}{\left(d^{-n}-\prod_{i=1}^{n} b'_i\right)} \left\{ \prod_{j=1}^{n} \left(\frac{d^{-n}-b'_j}{\prod_{i=1}^{n}(b'_i)-b_j}\right) \cdot \left(1-q(C')^{-1}\prod_{i=1}^{n} b'_i\right) \prod_{i=1}^{n-1}\left(1-a'_i \prod_{j=1}^{n} b'_j\right) - (1-q(C')^{-1}d^{-n}) \prod_{i=1}^{n}(1-a'_i d^{-n}) \right\}.$$

Taking the limit as $\varepsilon \to 0$, then from (2.16)–(2.21) and (2.26)–(2.30), it follows that

$$\tag{2.31} \frac{1}{(2\pi i)^{n-1}} \int_{T^{n-1}} H(k) \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}} = \frac{n! \prod_{j=1}^{n} [(b'_j)^{-1}C']_\infty \prod_{i=1}^{n-1} \left[q a'_i \prod_{j=1}^{n} b'_j\right]_\infty}{[q]_\infty^{n-1}[q]_{k-1} \left[\prod_{i=1}^{n-1} a'_i\right]_\infty \prod_{i=1}^{n-1} [a'_i C' q^{-k}]_\infty} \cdot \prod_{j=1}^{n} \left\{ \left[q(b'_j)^{-1}\prod_{i=1}^{n} b'_i\right]_\infty [q^k b'_j (C')^{-1}]_\infty \prod_{i=1}^{n-1}[a'_i b'_j]_\infty \right\}^{-1} \cdot \frac{(-1)^n}{(q^{-k}C'd)^n} \left\{ \frac{(1-q^{k-1}) \prod_{i=1}^{n-1}(1-q^{-k}C'a'_i)}{\left(1-d^n \prod_{j=1}^{n} b'_j\right)} \right.$$

$$+\frac{(q^{-1}C')}{\left(d^{-n}-\prod_{i=1}^{n} b'_i\right)}(1-q(C')^{-1}d^{-n})\prod_{i=1}^{n-1}(1-a'_i d^{-n})$$

$$-\frac{(q^{-1}C')}{\left(d^{-1}-\prod_{i=1}^{n} b'_i\right)}\prod_{j=1}^{n}\left(\frac{d^{-n}-b'_j}{\prod_{i=1}^{n}(b'_i)-b'_j}\right)$$

$$\left.\cdot\left(1-q(C')^{-1}\prod_{i=1}^{n} b'_i\right)\cdot\prod_{i=1}^{n-1}\left(1-a'_i\prod_{j=1}^{n} b'_j\right)\right\}.$$

Since $d^{-n} = q^{-k}C'$, it follows that the first two terms cancel in the bracketed sum on the right-hand side of (2.31). After some further simplification, then the right-hand side of (2.31) reduces to

$$\begin{aligned}&\frac{n!\prod_{j=1}^{n}[b_j^{-1}C]_\infty\prod_{i=1}^{n-1}\left[a_i q^{-k}C\prod_{j=1}^{n} b_j\right]_\infty}{[q]_\infty^{n-1}[q]_{k-1}\left[q^{k+1}C^{-1}\prod_{i=1}^{n-1} a_i\right]_\infty\prod_{i=1}^{n-1}[a_i q^{-k}C]_\infty}\\ (2.32)\qquad&\cdot\prod_{j=1}^{n}\left\{\left[q^{-k}Cb_j^{-1}\prod_{i=1}^{n} b_i\right]_\infty[q^{k+1}C^{-1}b_j]_\infty\prod_{i=1}^{n-1}[a_i b_j]_\infty\right\}^{-1}\\ &\cdot\left(1-\prod_{i=1}^{n} b_j\right)^{-1}.\end{aligned}$$

Recalling that $a_n = q^{k+1}C^{-1}$ and $b_{n+1} = q^{-k}C$, this completes the proof of the $k > 1$, dimension n case of identity (2.2).

To complete the proof of the full dimension n case of identity (2.2), we begin by choosing an arbitrary complex number a_n such that $|q| < |a_n| < 1$ and setting $b_{n+1} = qa_n^{-1}$. Let $a_1, \cdots, a_{n-1}, b_1, \cdots, b_{n-1} \in C$ be fixed such that $|a_i|, |b_j| < 1$. Then set $b_n = q^k a_n^{-1}\prod_{i=1}^{n-1}(a_i b_i)^{-1}$, with $k > 0$ a sufficiently large integer so that $|b_n| < 1$. From (2.31) and (2.32) it then follows that identity (2.2) is valid for a set of values of b_n which includes the limit point $b_n = 0$. (The case $b_n = 0$ reduces to the $SU(n)$ generalization of the Askey–Wilson integral [9, Thm. 6.1].) By analytic continuation in the parameter b_n, we conclude that identity (2.2) is valid whenever $a_n b_{n+1} = q$.

This last condition can also be eliminated. With notation as in Lemma 2.7, we rewrite the q-difference equation (2.8) as

$$(2.33)\qquad R_{n+1}f = \prod_{j=1}^{n}\left(\frac{b_{n+1}-b_j}{C-b_j}\right)\left[f-\sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\ j\neq\ell}}^{n+1}\left(\frac{C-b_j}{b_\ell-b_j}\right)(R_\ell f)\right\}\right],$$

where f can be either the left or right-hand side of identity (2.2). Now suppose that identity (2.2) is valid whenever $b_{n+1} = q^\ell a_n^{-1}$ for some positive integer ℓ. If we choose the parameters on the left-hand side of (2.33) to satisfy $b_{n+1} = q^{\ell+1}a_n^{-1}$, then those on the right-hand side will satisfy $b_{n+1} = q^{\ell}a_n^{-1}$. It follows that identity (2.2) will also be valid for $b_{n+1} = q^{\ell+1}a_n^{-1}$. The set of points $b_{n+1} = q^{\ell}a_n^{-1}$ for $\ell = 1, 2, 3, \cdots$ has the limit point $b_{n+1} = 0$. Again, at $b_{n+1} = 0$, identity (2.2) reduces to the $SU(n)$ Askey–Wilson integral. By analytic continuation of the parameter b_{n+1}, we now conclude that identity (2.2) is valid for arbitrary b_{n+1}. Finally, by analytic continuation we drop the other restrictions on the values of the parameters b_j and C. This completes the proof of the dimension n case of identity (2.2). By induction, this proves Theorem 2.1.

3. A generalization of Barnes' second lemma for $u(n)$. In this section we prove a generalization of Barnes' second lemma associated to the Lie algebra $u(n)$ (of the Lie group $U(n)$). The $u(1)$ case is Barnes' second lemma [5]. The main result, Theorem 3.1, is proved analogously to Theorem 2.1. We again use a double induction on the dimension n and another parameter k.

The main result is the following.

THEOREM 3.1. *For $n \geq 1$, let $\alpha_i \in C$, $1 \leq i \leq n+1$, and $\beta_j \in C$, $1 \leq j \leq n+2$. Set $\gamma = \sum_{i=1}^{n+1} \alpha_i + \sum_{j=1}^{n+2} \beta_j$, then*

$$\begin{aligned}(3.2)\qquad &\frac{1}{(2\pi i)^n} \int_{-i\infty}^{i\infty} \cdots \int_{-i\infty}^{i\infty} \frac{\prod_{j=1}^{n} \left\{ \prod_{i=1}^{n+1} \Gamma(\alpha_i - z_j) \prod_{i=1}^{n+2} \Gamma(\beta_i + z_j) \right\}}{\prod_{j=1}^{n} \Gamma(\gamma + z_j) \prod_{\substack{1 \leq i,j \leq n \\ i \neq j}} \Gamma(z_i - z_j)} dz_1 \cdots, dz_n \\ &= \frac{n! \prod_{i=1}^{n+1} \prod_{j=1}^{n+2} \Gamma(\alpha_i + \beta_j)}{\prod_{i=1}^{n+2} \Gamma(\gamma - \beta_j)},\end{aligned}$$

where the contours of integration are deformed so as to separate the sequences of poles going to the right $\{\alpha_i + k \mid 1 \leq i \leq n+1, k = 0, 1, 2, \cdots\}$ from the sequences of poles going to the left $\{-\beta_i - k \mid 1 \leq i \leq n+2, k = 0, 1, 2, \cdots\}$.

Proof. If we define the $n = 0$ case of the integral on the left-hand side of (3.2) to be 1, then identity (3.2) is valid for $n = 0$. The $n = 1$ case of identity (3.2) is Barnes' second lemma [5].

We begin our proof of identity (3.2) for $n \geq 1$ by requiring that for any integer $\ell, \beta_i \neq \beta_j + \ell$ for $1 \leq i, j \leq n+2, i \neq j$, and $\beta_j \neq \gamma + \ell$ for $1 \leq j \leq n+2$. This restriction will be removed at the end of the proof of (3.2).

We will first show that both sides of (3.2) satisfy the same difference equation in the parameters β_j and γ. We will need the following version of the partial fractions expansion.

LEMMA 3.3. *Let $s \leq m$ and let $\{x_1, \cdots, x_s\}, \{y_1, \cdots, y_{m+1}\}$ and t be indeterminants with the y_i distinct. Then*

$$(3.4)\qquad \sum_{\ell=1}^{m+1} \left\{ \prod_{\substack{j=1 \\ j \neq \ell}}^{m+1} \left(\frac{t - y_j}{y_\ell - y_j} \right) \prod_{k=1}^{s} (y_\ell - x_k) \right\} = \prod_{k=1}^{s} (t - x_k).$$

Proof. The proof is very similar to that of Lemma 2.3. If we divide both sides of identity (3.4) by $\prod_{j=1}^{m+1}(t - y_j)$, then we obtain an obvious partial fractions expansion.

We now show that both sides of (3.2) satisfy the same difference equation.

DEFINITION 3.5. If f is a function involving the parameters β_ℓ and γ, then define

$$\rho_\ell f(\beta_\ell,\gamma) = f(\beta_\ell+1,\gamma+1).$$

LEMMA 3.6. *With notation as in Theorem* 3.1, *let f be either the left-hand side or the right-hand side of* (3.2). *Then*

$$\sum_{\ell=1}^{n+2}\left\{\prod_{\substack{j=1\\ j\neq\ell}}^{n+2}\left(\frac{\gamma-\beta_j}{\beta_\ell-\beta_j}\right)\cdot(\rho_\ell f)\right\} = f. \tag{3.7}$$

Proof. The proof of identity (3.7) is quite similar to that of identity (2.8). A simple application of (3.4) shows that the left-hand side of (3.2) satisfies identity (3.7). Another application of a special case of (3.4) (i.e., equating the t^m term on both sides of (3.4) when $s = m$) shows that the right-hand side of (3.2) also satisfies identity (3.7).

We now prove Theorem 3.1 by induction on n. As mentioned above, by defining the left-hand side of (3.2) to be 1, the $n = 0$ case of identity (3.2) is trivially true. We will assume from now on that $n \geq 1$ and that the $n-1$ case of identity (3.2) is valid.

Similarly to §2, we first prove identity (3.2) in the special case that $\alpha_{n+1} = k+1-\gamma$ and $\beta_{n+2} = \gamma - k$, where k is a positive integer. We will proceed by induction on k, with the cases $k = 1$ and $k > 1$ handled slightly differently.

Assume that $k+1 > \mathrm{Re}(\gamma) > k$ and that $\mathrm{Re}(\gamma - k) < r$, where r is a positive real number chosen as small as necessary. For $k \geq 1$ we let $\mathrm{Re}(\alpha_i) > r$ and $\mathrm{Re}(\beta_j) > r$ for $1 \leq i \leq n$ and $1 \leq j \leq n+1$. Let C be the circle of radius ε centered at the point $\kappa - \gamma$ and traversed in the negative direction, where ε is a sufficiently small positive real number. Let T be the imaginary axis tranversed from $-i\infty$ to $i\infty$, and let N be the union of C and T. We will use the following notation

$$H(m) = \frac{\displaystyle\prod_{\ell=1}^{n}\left\{\Gamma(m+1-\gamma-z_\ell)\Gamma(\gamma-m+z_\ell)\prod_{i=1}^{n}\Gamma(\alpha_i-z_\ell)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_\ell)\right\}}{\displaystyle\prod_{\ell=1}^{n}\Gamma(\gamma+z_\ell)\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}\Gamma(z_i-z_j)},$$

where m is a nonnegative integer.

We have

$$\int_{T^n} H(k)dz_1\cdots dz_n = (-1)^n\int_{T^n} H(k-1)dz_1\cdots dz_n. \tag{3.8}$$

Similarly to §2, we find that

$$\begin{aligned}&\int_{T^n} H(k-1)dz_1\cdots dz_n\\ &\quad= \int_{N^n} H(k-1)dz_1\cdots dz_n - \sum_{j=0}^{n-1}\int_{T^{n-1-j}}\int_{N^j}\int_{C} H(k-1)dz_1\cdots dz_n.\end{aligned} \tag{3.9}$$

Let

$$J(k-1)=\frac{\prod_{i=1}^{n}\Gamma(\alpha_i+\gamma-k)\prod_{j=1}^{n+1}\Gamma(\beta_j+k-\gamma)\prod_{\ell=2}^{n}(z_\ell-k+\gamma)}{(k-1)!\prod_{\ell=2}^{n}\Gamma(\gamma+z_\ell)\prod_{\substack{2\le i,j\le n\\ i\ne j}}\Gamma(z_i-z_j)}$$
$$\cdot\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n}\Gamma(\alpha_i-z_\ell)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_\ell)\right\}.$$

It follows that

$$\begin{aligned}(3.10)\qquad &\sum_{j=0}^{n-1}\frac{1}{(2\pi i)^n}\int_{T^{n-1-j}}\int_{N^j}\int_{C}H(k-1)dz_1\cdots dz_n\\ &=\sum_{j=0}^{n-1}\frac{1}{(2\pi i)^{n-1}}\int_{T^{n-1-j}}\int_{N^j}J(k-1)dz_2\cdots dz_n\\ &=\sum_{j=0}^{n-1}\frac{1}{(2\pi i)^{n-1}}\int_{T^{n-1}}J(k-1)dz_2\cdots dz_n\\ &=\frac{n}{(2\pi i)^{n-1}}\int_{T^{n-1}}J(k-1)dz_2\cdots dz_n,\end{aligned}$$

since the function $J(k-1)$ in the variable z_j, $2\le j\le n$, has no poles in the disk bounded by the contour C.

Consider the case $k=1$. Then

$$H(0)=\frac{\prod_{\ell=1}^{n}\left\{\Gamma(1-\gamma-z_\ell)\prod_{i=1}^{n}\Gamma(\alpha_i-z_\ell)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_\ell)\right\}}{\prod_{\substack{1\le i,j\le n\\ i\ne j}}\Gamma(z_i-z_j)}$$

and the integral $\int_{N^n}H(0)dz_1\cdots,dz_n$ can be evaluated by means of the $u(n)$ generalization of Barnes' first lemma [9, Thm. 5.1]. We find

$$(3.11)\qquad \int_{N^n}H(0)dz_1\cdots dz_n=0.$$

Applying identities (3.9)–(3.11), we obtain

$$(3.12)\qquad \frac{1}{(2\pi i)^n}\int_{T^n}H(0)dz_1\cdots dz_n=-\frac{n}{(2\pi i)^{n-1}}\int_{T^{n-1}}J(0)dz_2\cdots dz_n.$$

We have

$$J(0)=\prod_{i=1}^{n}\Gamma(\alpha_i+\gamma-1)\prod_{j=1}^{n+1}\Gamma(\beta_j+1-\gamma)\cdot\frac{\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n}\Gamma(\alpha_i-z_\ell)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_\ell)\right\}}{\prod_{\ell=2}^{n}\Gamma(\gamma-1+z_\ell)\prod_{\substack{2\le i,j\le n\\ i\ne j}}\Gamma(z_i-z_j)}.$$

Therefore, the integral on the right-hand side of equation (3.12) can be evaluated by the dimension $n-1$ case of identity (3.2), which we assume is valid by the induction hypothesis on the dimension n. From (3.8) and (3.12), we obtain, after simplification,

$$\begin{aligned}&\frac{1}{(2\pi i)^n}\int_{T^n} H(1)dz_1\cdots dz_n\\ (3.13)\qquad &= \frac{\prod_{i=1}^{n}\Gamma(\alpha_i+\gamma-1)\prod_{j=1}^{n+1}\Gamma(\beta_j+2-\gamma)\prod_{i=1}^{n}\prod_{j=1}^{n+1}\Gamma(\alpha_i+\beta_j)}{\prod_{i=1}^{n+1}\Gamma(\gamma-\beta_j)}.\end{aligned}$$

Since identity (3.13) is equivalent to the $k=1$ case of identity (3.2), this completes the $k=1$, dimension n case of identity (3.2).

We now consider the $k>1$, dimension n case of identity (3.2). The $k-1$, dimension n case is assumed to be valid. We have

$$\begin{aligned}\int_{N^n} H(k-1)dz_1\cdots dz_n &= \frac{(2\pi i)^n n!\prod_{i=1}^{n}\prod_{j=1}^{n+1}\Gamma(\alpha_i+\beta_j)}{(k-2)!\prod_{j=1}^{n+1}\Gamma(\gamma-\beta_j)}\\ (3.14)\qquad &\quad\cdot\prod_{j=1}^{n+1}\Gamma(k-\gamma+\beta_j)\prod_{i=1}^{n}\Gamma(\alpha_i+\gamma+1-k).\end{aligned}$$

Similarly to §2, to compute the integral of the function $J(k-1)$ we will define a related function $I(k-1)$ and a difference equation involving $I(k-1)$ and $J(k-1)$. Let

$$I(k-1)=\frac{\prod_{\ell=2}^{n}\left\{\prod_{i=1}^{n}\Gamma(\alpha_i-z_\ell)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_\ell)\right\}}{\prod_{\ell=2}^{n}\Gamma(\gamma+z_\ell)\prod_{\substack{2\le i,j\le n\\ i\neq j}}\Gamma(z_i-z_j)}.$$

If $f(\beta_\ell,\gamma)$ is a function involving the parameters β_ℓ and γ, then we define the shift operator Λ_ℓ by

$$\Lambda_\ell f(\beta_\ell,\gamma)=f(\beta_\ell+1,\gamma),$$

i.e., which shifts β_ℓ, but fixes γ. It then follows from Lemma 3.3 that

$$\begin{aligned}J(k-1)&=\frac{\prod_{i=1}^{n}\Gamma(\alpha_i+\gamma-k)\prod_{j=1}^{n+1}\Gamma(\beta_j+k-\gamma)}{(k-1)!}\\ (3.15)\qquad &\quad\cdot\sum_{\ell=1}^{n+1}\left\{\prod_{\substack{j=1\\ j\neq\ell}}^{n+1}\frac{(\gamma-k-\beta_j)}{(\beta_\ell-\beta_j)}\Lambda_\ell I(k-1)\right\}.\end{aligned}$$

Since $\gamma = 1 + \sum_{i=1}^{n} \alpha_i + \sum_{j=1}^{n+1} \beta_j$, then the dimension $n-1$ case of identity (3.2) (which we assume is valid by the induction hypothesis) can be used to evaluate the integrals of the $\Lambda_\ell I(k-1)$ functions. Identity (3.15) then allows us to evaluate the integral of $J(k-1)$. We find

$$\begin{aligned}\frac{1}{(2\pi i)^{n-1}} \int\limits_{T^{n-1}} J(k-1) dz_2 \cdots dz_n \\ (3.16) \qquad = \frac{(n-1)! \prod_{i=1}^{n} \Gamma(\alpha_i + \gamma - k) \prod_{j=1}^{n+1} \Gamma(\beta_j + k - \gamma) \prod_{i=1}^{n} \prod_{j=1}^{n+1} \Gamma(\alpha_i + \beta_j)}{(k-1)! \prod_{j=1}^{n+1} \Gamma(\gamma - \beta_j)} \\ \cdot \sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1 \\ j \neq \ell}}^{n+1} \frac{(\gamma - k - \beta_j)}{(\beta_\ell - \beta_j)} (\gamma - 1 - \beta_\ell) \prod_{i=1}^{n} (\alpha_i + \beta_\ell) \right\}.\end{aligned}$$

A simple extension of Lemma 3.3 (to the case $s = m+1$ in the notation of Lemma 3.3) can be used to evaluate the sum on the right-hand side of (3.16). We have

$$\begin{aligned}-\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1 \\ j \neq \ell}}^{n+1} \frac{(\gamma - k - \beta_j)}{(\beta_\ell - \beta_j)} (1 - \gamma + \beta_\ell) \prod_{i=1}^{n} (\alpha_i + \beta_\ell) \right\} \\ (3.17) \qquad = \prod_{j=1}^{n+1} (\gamma - k - \beta_j) - (\gamma - k + 1 - \gamma) \prod_{i=1}^{n} (\gamma - k + \alpha_i).\end{aligned}$$

Substituting (3.17) into the right-hand side of (3.16) and applying identities (3.8)–(3.10), (3.14), and (3.16), we find

$$\begin{aligned}(3.18) \qquad \frac{1}{(2\pi i)^n} \int\limits_{T^n} H(k) dz_1 \cdots dz_n = \frac{n! \prod_{i=1}^{n} \Gamma(\alpha_i + \gamma - k)}{\Gamma(k) \prod_{j=1}^{n+1} \Gamma(\gamma - \beta_j)} \\ \cdot \prod_{j=1}^{n+1} \Gamma(\beta_j + 1 + k - \gamma) \prod_{i=1}^{n} \prod_{j=1}^{n+1} \Gamma(\alpha_i + \beta_j).\end{aligned}$$

Recalling that $\alpha_{n+1} = k + 1 - \gamma$ and $\beta_{n+2} = \gamma - k$ completes the proof of the $k > 1$, dimension n case of identity (3.2).

To complete the proof of the full dimension n case of identity (3.2), we begin by choosing an arbitrary complex number α_{n+1} such that $0 < \mathrm{Re}(\alpha_{n+1}) < 1$ and setting $\beta_{n+2} = 1 - \alpha_{n+1}$. Let $\alpha_1, \cdots, \alpha_n, \beta_1, \cdots, \beta_n \in C$ be fixed such that $\mathrm{Re}(\alpha_i)$, $\mathrm{Re}(\beta_j) > 0$. Then set $\beta_{n+1} = 1 + s - \alpha_n - \sum_{i=1}^{n} (\alpha_i + \beta_i)$ with $s \in C$ such that $\mathrm{Re}(s) \geq 0$ and $\mathrm{Re}(\beta_{n+1}) > 0$. From (3.18) it follows that (3.2) is valid for $s = 0, 1, 2, \cdots$. Using Stirling's formula to estimate the growth the left-hand side and right-hand side of (3.2) as a function of s, it can be seen that the growth conditions for Carlson's theorem [4, p. 39] are satisfied. Carlson's theorem now shows that identity (3.2) is valid for all $s \in C$ (subject to the restriction $\mathrm{Re}(\alpha_1), \cdots, \mathrm{Re}(\alpha_{n+1}), \mathrm{Re}(\beta_1), \cdots, \mathrm{Re}(\beta_{n+2}) > 0$). In other words, identity (3.2) is valid whenever $\alpha_{n+1} + \beta_{n+2} = 1$.

This last condition can also be eliminated. With notation as in Lemma 3.7, we rewrite the difference equation (3.8) as

$$\rho_{n+2}f = \prod_{j=1}^{n+1}\left(\frac{\beta_{n+2}-\beta_j}{\gamma-\beta_j}\right)\left[f - \sum_{\ell=1}^{n+1}\left\{\prod_{\substack{j=1\\ j\neq\ell}}^{n+2}\left(\frac{\gamma-\beta_j}{\beta_\ell-\beta_j}\right)(\rho_\ell f)\right\}\right], \tag{3.19}$$

where f can be either the left or right-hand side of identity (3.2). As in §2, suppose now that identity (3.2) is valid when $\beta_{n+2} = \ell - \alpha_{n+1}$ for some positive integer ℓ. If we choose the parameters on the left-hand side of (3.19) to satisfy $\beta_{n+2} = \ell + 1 - \alpha_{n+1}$, then those on the right-hand side will satisfy $\beta_{n+2} = \ell - \alpha_{n+1}$. It follows that identity (3.2) will also be valid for $\beta_{n+2} = \ell + 1 - \alpha_{n+1}$. An application of Carlson's theorem similar to the above now shows that identity (3.2) is valid for arbitrary $\beta_{n+2} \in \mathcal{C}$ with $\mathrm{Re}(\beta_{n+2}) > 0$. Finally, by analytic continuation, we drop the restriction on the values of the parameters α_i, β_j, and γ. This completes the proof of the dimension n case of identity (3.2). By induction, this proves Theorem 3.1.

4. A generalization of the Nasrallah–Rahman integral for the symplectic groups. In this section we prove a generalization of the Nasrallah–Rahman integral (1.2) associated to the compact symplectic groups $Sp(n)$. The $Sp(1) \approx SU(2)$ case is just the Nasrallah–Rahman integral. The proof of the general integral identity is very similar to that discussed in §2. The main result is the following.

THEOREM 4.1. *For $n \geq 1$, let $a_i \in \mathcal{C}$, $1 \leq i \leq 2n+3$, with $|a_i| < 1$. Set $C = \prod_{i=1}^{2n+3} a_i$, then*

$$\begin{aligned}\frac{1}{(2\pi i)^n}\int_{T^n} &\frac{\prod_{1\leq i<j\leq n}[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty}{\prod_{i=1}^{2n+3}\prod_{j=1}^{n}[a_iz_j]_\infty[a_iz_j^{-1}]_\infty}\\ &\cdot\prod_{j=1}^{n}\left\{[z_j^2]_\infty[z_j^{-2}]_\infty[Cz_j]_\infty[Cz_j^{-1}]_\infty\frac{dz_j}{z_j}\right\}\\ &= \frac{n!2^n\prod_{j=1}^{2n+3}[Ca_j^{-1}]_\infty}{[q]_\infty^n\prod_{1\leq i<j\leq 2n+3}[a_ia_j]_\infty},\end{aligned}\tag{4.2}$$

where the integral in each variable z_j is over the unit circle T taken in the positive direction.

Proof. Note that if the contour T is allowed to be shifted, then the restriction $|a_i| < 1$, $1 \leq i \leq 2n+3$, may be eliminated. Also observe that the $n = 1$ case of the integral on the left-hand side of (4.2) is just the Nasrallah–Rahman integral (1.2).

To begin the proof of identity (4.2), we require that for any integer $\ell, a_i^{\pm 1} \neq a_jq^\ell$ for $1 \leq i,j \leq 2n+3, i \neq j$. This restriction will be removed at the end of the proof of (4.2).

As in §2, we first show that both sides of (4.2) satisfy the same q-difference equation in the parameters a_i, $1 \leq i \leq 2n+3$. We will need another version of the partial fractions expansion.

LEMMA 4.3. *Let $\{x_1, \cdots, x_m\}, \{y_1, \cdots, y_{m+1}\}$ and t be indeterminants with $y_i \neq y_j$ and $y_i y_j \neq 1$ for $1 \leq i, j \leq s, i \neq j$. Then*

$$\sum_{\ell=1}^{m+1} \left\{ \prod_{\substack{j=1 \\ j\neq\ell}}^{m+1} \frac{(t-y_j)(ty_j-1)}{(y_\ell - y_j)(y_\ell y_j - 1)} \prod_{k=1}^{m} (1-y_\ell x_k)(1-y_\ell x_k^{-1}) \right\} \tag{4.4}$$

$$= \prod_{k=1}^{m} (1-tx_k)(1-tx_k^{-1}).$$

Proof. Divide both sides of (4.4) by $\prod_{j=1}^{m+1}(t-y_j)(ty_j-1)$ and compute residues with respect to the poles y_ℓ and y_ℓ^{-1}, $1 \leq \ell \leq m+1$.

We now show that both sides of (4.2) satisfy the same q-difference equation.

DEFINITION 4.5. If f is a function involving the parameters a_ℓ and C, then define

$$R_\ell f(a_\ell, C) = f(a_\ell q, Cq).$$

LEMMA 4.6. *With notation as in Theorem 4.1, let f be either the left-hand side or right-hand side of (4.2). Then*

$$\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{j=1 \\ j\neq\ell}}^{n+1} \left(\frac{C-a_j}{a_\ell - a_j}\right)\left(\frac{Ca_j - 1}{a_\ell a_j - 1}\right) \cdot (R_\ell f) \right\} = f. \tag{4.7}$$

Proof. Let I and Q denote, respectively, the left-hand side and right-hand side of (4.2). Using (4.4), it is easily checked that I satisfies identity (4.7). To show that Q satisfies the q-difference equation (4.7) is equivalent to verifying the following identity:

$$\sum_{\ell=1}^{n+1} \left\{ \prod_{\substack{i=1 \\ i\neq\ell}}^{2n+3} a_i \prod_{\substack{j=1 \\ j\neq\ell}}^{n+1} \left(\frac{Ca_j - 1}{a_\ell - a_j}\right) \prod_{k=n+2}^{2n+3} \left(\frac{a_\ell a_k - 1}{C - a_k}\right) \right\} = 1. \tag{4.8}$$

We can rewrite the left-hand side of identity (4.8) as

(4.9)
$$\prod_{k=n+2}^{2n+3} \frac{a_k}{C-a_k} \prod_{j=1}^{n+1}(Ca_j - 1) \sum_{\ell=1}^{n+1} \left\{ \left(\frac{C^{-1}}{a_\ell - C^{-1}}\right) \prod_{j=1}^{n+1} \left(\frac{a_j}{a_\ell - a_j}\right) \prod_{k=n+2}^{2n+3} (a_\ell a_k - 1) \right\}.$$

Letting t be an indeterminant, then we have the following identity (which comes from an extension of (2.4)):

$$\sum_{\ell=1}^{n+1}\left\{\left(\frac{t-C^{-1}}{a_\ell-C^{-1}}\right)\prod_{\substack{j=1\\ j\neq\ell}}^{n+1}\left(\frac{t-a_j}{a_\ell-a_j}\right)\prod_{k=n+2}^{2n+3}(a_\ell a_k-1)\right\}$$

$$(4.10)\qquad =\prod_{k=n+2}^{2n+3}(ta_k-1)-(t-C^{-1})\prod_{j=1}^{n+1}(t-a_j)\prod_{k=n+2}^{2n+3}a_k$$

$$-\prod_{j=1}^{n+1}\left(\frac{t-a_j}{C^{-1}-a_j}\right)\prod_{k=n+2}^{2n+3}(C^{-1}a_k-1).$$

Identity (4.10) can be verified by dividing both sides of (4.10) by $(t-C^{-1})\prod_{j=1}^{n+1}(t-a_j)$ and then doing a partial fractions expansion of the right-hand side of (4.10) with respect to the indeterminant t. Setting $t=0$ in identity (4.10) and substituting into (4.9), we then prove (4.8). This completes the proof of Lemma 4.6.

The proof of Theorem 4.1 proceeds by induction on n, similarly to the proof of Theorem 2.1. If we define the left-hand side of (4.2) to be identically 1 for $n=0$, then the $n=0$ case of identity (4.2) is trivially true. We will assume from now on that $n\geq 1$ and that the $n-1$ case of identity (4.2) is valid. We first prove identity (4.2) in the case that $a_{2n+2}=q^{k+1}C^{-1}$ and $a_{2n+3}=q^{-k}C$, where k is a positive integer. As before, for fixed n we will prove identity (4.2) by induction with respect to k, with the cases $k=1$ and $k>1$ handled differently.

Assume that $q^{k+1}<|C|<q^k$ and that $|q^kC^{-1}|<r^{-1}$, where r is a real number chosen as close to 1 as necessary. We also assume that $|a_i|<r$ for $1\leq i\leq 2n+2$.

Let N be the contour which is the union of the circle of radius r centered at the origin, traversed in the positive direction, and the circle of radius ε centered at the point of q^kC^{-1}, traversed in the positive direction, where ε is a sufficiently small positive real number. We will use the notation

$$H(m)=$$

$$\frac{\prod_{\ell=1}^{n}\{[Cz_\ell]_\infty[Cz_\ell^{-1}]_\infty[z_\ell^2]_\infty[z_\ell^{-2}]_\infty\}\prod_{1\leq i<j\leq n}\{[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty\}}{\prod_{\ell=1}^{n}\{[q^{m+1}C^{-1}z_\ell]_\infty[q^{m+1}C^{-1}z_\ell^{-1}]_\infty[q^{-m}Cz_\ell]_\infty[q^{-m}Cz_\ell^{-1}]_\infty\}}$$

$$\cdot\left\{\prod_{\ell=1}^{n}\prod_{i=1}^{2n+1}[a_iz_\ell]_\infty[a_iz_\ell^{-1}]_\infty\right\}^{-1},$$

where m is a nonnegative integer.

As in §2, we find

$$(4.11)\qquad \int_{T^n}H(k)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}=(q^kC^{-1})^{2n}\int_{T^n}H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}.$$

We also have

$$\begin{aligned}(4.12)\qquad \int_{T^{n-1}} H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n} &= \sum_{j=0}^{n-1}\int_{T^{n-1-j}}\int_{N^j}\int_{T-N} H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}\\ &\quad+\int_{N^{n-1}} H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}.\end{aligned}$$

With respect to the variable z_1, the poles of the integrand $H(k-1)\prod_{i=1}^n z_i^{-1}$ inside the region bounded by the contour $T-N$ are at $z_1 = C^{-1}q^k$ and at $z_1 = Cq^{-k}$. It follows that

$$\begin{aligned}(4.13)\qquad &\sum_{j=0}^{n-1}\frac{1}{(2\pi i)^n}\int_{T^{n-1-j}}\int_{N^j}\int_{T-N} H(k-1)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n}\\ &=\sum_{j=0}^{n-1}-\frac{2}{(2\pi i)^{n-1}}\int_{T^{n-1-j}}\int_{N^j} J(k-1)\frac{dz_2}{z_2}\cdots\frac{dz_n}{z_n},\end{aligned}$$

where

$$\begin{aligned}J(k-1) = {}&\frac{(1-q^{-2k}C^2)[C^2q^{-k}]_\infty}{[q]_{k-1}[q]_\infty}\\ &\cdot\frac{\prod_{j=2}^{n}\{(1-Cq^{-k}z_j)(1-Cq^{-k}z_j^{-1})[Cz_j]_\infty[Cz_j^{-1}]_\infty[z_j^2]_\infty[z_j^{-2}]_\infty\}}{\prod_{i=1}^{2n+1}\{[a_iC^{-1}q^k]_\infty[a_iCq^{-k}]_\infty\prod_{j=2}^{n}[a_iz_j]_\infty[a_iz_j^{-1}]_\infty\}}\\ &\cdot\prod_{2\le i<j\le n}\{[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty\}.\end{aligned}$$

As in §2, we can deform the contour N into the contour T and show that

$$(4.14)\qquad \int_{T^{n-1-j}}\int_{N^j} J(k-1)\frac{dz_2}{z_2}\cdots\frac{dz_n}{z_n} = \int_{T^{n-2}} J(k-1)\frac{dz_2}{z_2}\cdots\frac{dz_n}{z_n}$$

for $0\le j\le n-1$.

Consider the case $k=1$. Then

$$H(0) = \frac{\prod_{\ell=1}^{n}[z_\ell^2]_\infty[z_\ell^{-2}]_\infty\prod_{1\le i<j\le n}[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty}{\prod_{\ell=1}^{n}\left\{[qC^{-1}z_\ell]_\infty[qC^{-1}z_\ell^{-1}]_\infty\prod_{i=1}^{2n+1}[a_iz_\ell]_\infty[a_iz_\ell^{-1}]_\infty\right\}}$$

and the integral $\int_{N^n} H(0)dz_1/z_1\cdots dz_n/z_n$ can be evaluated by means of the $Sp(n)$ generalization of the Askey–Wilson integral [9, Thm. 7.1]. We find

$$(4.15)\qquad \int_{N^n} H(0)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n} = 0.$$

We also have

$$J(0) = \frac{[C^2q^{-2}]_\infty}{[q]_\infty} \cdot \frac{\prod_{j=2}^{n} \{[Cq^{-1}z_j]_\infty [Cq^{-1}z_j^{-1}]_\infty [z_j^2]_\infty [z_j^{-2}]_\infty\}}{\prod_{i=1}^{2n+1} \left\{ [a_iC^{-1}q]_\infty [a_iCq^{-1}]_\infty \prod_{j=2}^{n} [a_iz_j]_\infty [a_iz_j^{-1}]_\infty \right\}}$$
$$\cdot \prod_{2\le i<j\le n} [z_iz_j]_\infty [z_i^{-1}z_j^{-1}]_\infty [z_iz_j^{-1}]_\infty [z_i^{-1}z_j]_\infty .$$

The integral of $J(0)$ can be evaluated by the dimension $n-1$ case of identity (4.2), which we assume is valid by the induction hypothesis on the dimension n. From (4.11)–(4.14) and (4.2), we find

$$\frac{1}{(2\pi i)^n} \int H(1) \frac{dz_1}{z_1} \cdots \frac{dz_n}{z_n}$$
$$= -\frac{2^n n! q^{2n} [C^2q^{-2}]_\infty \prod_{i=1}^{2n+1} [Cq^{-1}a_i^{-1}]_\infty}{C^{2n} [q]_\infty^n \prod_{i=1}^{2n+1} [a_iC^{-1}q]_\infty [a_iCq^{-1}]_\infty} \tag{4.16}$$
$$\cdot \left\{ \prod_{1\le i<j\le 2n+1} [a_ia_j]_\infty \right\}^{-1}$$
$$= \frac{2^n n! [C^2q^{-2}]_\infty \prod_{i=1}^{2n+1} [Ca_i^{-1}]_\infty}{[q]_\infty^n \prod_{i=1}^{2n+1} [a_iC^{-1}q^2]_\infty [a_iCq^{-1}]_\infty \prod_{1\le i<j\le 2n+1} [a_ia_j]_\infty}.$$

This completes the proof of the $k=1$, dimension n case of identity (4.2).

We now consider the $k>1$, dimension n case of identity (4.2). By the induction hypothesis for $k-1$, we have

$$\frac{1}{(2\pi i)^n} \int_{N^n} H(k-1) \frac{dz_1}{z_1} \cdots \frac{dz_n}{z_n}$$
$$= n! 2^n \cdot \frac{[q^{k-1}]_\infty [q^{-k}C^2]_\infty \prod_{i=1}^{2n+1} [Ca_i^{-1}]_\infty}{[q]_\infty^{n+1} \prod_{i=1}^{2n+1} [q^kC^{-1}a_i]_\infty [q^{-k+1}Ca_i]_\infty \prod_{1\le i<j\le 2n+1} [a_ia_j]_\infty}. \tag{4.17}$$

As in §2, we define a function $I(k-1)$, to be used in computing the integral of $J(k-1)$. Let

$$I(k-1)=\frac{\prod_{j=2}^{n}\{[Cz_j]_\infty[Cz_j^{-1}]_\infty[z_j^2]_\infty[z_j^{-2}]_\infty\}}{\prod_{\ell=2}^{n}\prod_{i=1}^{2n+1}[a_iz_\ell]_\infty[a_iz_\ell^{-1}]_\infty}\cdot\prod_{2\leq i<j\leq n}[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty .$$

If $f(a_\ell, c)$ is a function involving the parameters a_ℓ and c, then we define the shift operator

$$L_\ell f(b,c)=f(b_\ell q,c).$$

It follows from Lemma 4.3 that

$$\begin{aligned}J(k-1)={}&\frac{(1-q^{-2k}C^2)[C^2q^{-k}]_\infty}{[q]_{k-1}[q]_\infty\prod_{i=1}^{2n+1}\{[a_iC^{-1}q^k]_\infty[a_iCq^{-k}]_\infty\}}\\&\cdot\sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\j\neq\ell}}^{n}\frac{(Cq^{-k}-a_j)(Cq^{-k}a_j-1)}{(a_\ell-a_j)(a_\ell a_j-1)}L_\ell I(k-1)\right\}.\end{aligned}\tag{4.18}$$

Identity (4.18) allows us to compute the integral of the function $J(k-1)$ in terms of the integrals of the functions $L_\ell I(k-1)$. We have

$$\begin{aligned}&\frac{1}{(2\pi i)^{n-1}}\int\limits_{T^{n-1}}J(k-1)\frac{dz_2}{z_2}\cdots\frac{dz_n}{z_n}\\&=\frac{(n-1)!2^{n-1}(1-q^{-2k}C^2)[C^2q^{-k}]_\infty\prod_{i=1}^{2n+1}[Ca_i^{-1}]_\infty}{[q]_\infty^n[q]_{k-1}\prod_{1\leq i<j\leq 2n+1}[a_ia_j]_\infty\prod_{i=1}^{2n+1}\{[a_iC^{-1}q^k]_\infty[a_iCq^{-k}]_\infty\}}\\&\quad\cdot\sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\j\neq\ell}}^{n}\frac{(Cq^{-k}-a_j)(Cq^{-k}a_j-1)}{(a_\ell-a_j)(a_\ell a_j-1)}\right.\\&\qquad\left.\cdot(1-q^{-1}Ca_\ell^{-1})\prod_{\substack{i=1\\i\neq\ell}}^{2n+1}(1-a_ia_\ell)\right\}.\end{aligned}\tag{4.19}$$

To evaluate the sum on the right-hand side of (4.19), we will use the special case of identity (2.4) where we equate the t^m terms on both sides of (2.4). This special case of identity (2.4) is due to Louck and Biedenharn [13]. We have

$$\begin{aligned}
&\sum_{\ell=1}^{n}\left\{\prod_{\substack{j=1\\ j\neq\ell}}^{n}\frac{(Cq^{-k}-a_j)(Cq^{-k}a_j-1)}{(a_\ell-a_j)(a_\ell a_j-1)}\right.\\
&\qquad\qquad\left.\cdot(1-q^{-1}Ca_\ell^{-1})\prod_{\substack{i=1\\ i\neq\ell}}^{2n+1}(1-a_ia_\ell)\right\}\\
&\quad=q^{k-1}\prod_{j=1}^{n}(q^{-k}C-a_j)(q^{-k}Ca_j-1)\\
&\qquad\qquad\cdot\sum_{\ell=1}^{n}\left\{\frac{(1-qC^{-1}a_\ell)}{a_\ell(a_\ell-q^kC^{-1})}\cdot\frac{\prod_{i=n+1}^{2n+1}(a_ia_\ell-1)}{(a_\ell-q^{-k}C)\prod_{\substack{j=1\\ j\neq\ell}}^{n}(a_\ell-a_j)}\right\}\\
&=q^{k-1}\prod_{j=1}^{n}(q^{-k}C-a_j)(q^{-k}Ca_j-1)\left\{-qC^{-1}\prod_{i=n+1}^{2n+1}a_i-\frac{(-1)^{n+1}}{\prod_{j=1}^{n}(-a_j)}\right.\\
&\qquad\qquad-\frac{(1-qC^{-1}q^kC^{-1})\prod_{i=n+1}^{2n+1}(a_iq^kC^{-1}-1)}{q^kC^{-1}(q^kC^{-1}-q^{-k}C)\prod_{j=1}^{n}(q^kC^{-1}-a_j)}\\
&\qquad\qquad\left.-\frac{(1-qC^{-1}q^{-k}C)\prod_{i=n+1}^{2n+1}(a_iq^{-k}C-1)}{q^{-k}C(q^{-k}C-q^kC^{-1})\prod_{j=1}^{n}(q^{-k}C-a_j)}\right\}\\
&=-\frac{(q^{-k}C)^{2n}(1-q^{-k-1}C^2)\prod_{i=1}^{2n+1}(1-a_iq^kC^{-1})}{(1-q^{-2k}C^2)}\\
&\qquad\qquad+\frac{(1-q^{k-1})\prod_{i=1}^{2n+1}(1-a_iq^{-k}C)}{(1-q^{-2k}C^2)},
\end{aligned}\tag{4.20}$$

where we have used the identity $q^{-1}C=\prod_{j=1}^{2n+1}a_j$. Substituting (4.20) into the right-hand side of (4.19) and using identities (4.11)–(4.14) and (4.17), we find

$$\frac{1}{(2\pi i)^n}\int\limits_{T^n} H(k)\frac{dz_1}{z_1}\cdots\frac{dz_n}{z_n} = \frac{2^n n![C^2q^{-k-1}]_\infty \prod\limits_{i=1}^{2n+1}[Ca_i^{-1}]_\infty}{[q]_\infty^n[q]_{k-1}\prod\limits_{1\le i<j\le 2n+1}[a_ia_j]_\infty \prod\limits_{i=1}^{2n+1}[a_iC^{-1}q^{k+1}]_\infty[a_iCq^{-k}]_\infty}. \tag{4.21}$$

This completes the proof of the $k > 1$, dimension n case of identity (4.2).

The proof of the general dimension n case of identity (4.2) is completed similarly to §2. Let a_{2n+3} be an arbitrary complex number such that $|q| < |a_{2n+3}| < 1$ and set $a_{2n+2} = qa_{2n+3}^{-1}$. Let $a_1, \cdots, a_{2n+1} \in C$ be fixed so that $|a_i| < 1$ for $1 \le i \le 2n+1$. Set $a_{2n+1} = q^k a_{2n+3}^{-1}\prod_{i=1}^{2n} a_i^{-1}$, with $k > 0$ a sufficiently large integer so that $|a_{2n+1}| < 1$. From (4.21) it follows that identity (2.2) is valid for a set of values of a_{2n+1} which includes the limit point $a_{2n+1} = 0$. (The case $a_{2n+1} = 0$ reduces to the $Sp(n)$ generalization of the Askey–Wilson integral [9, Thm. 7.1].) By analytic continuation in the parameters a_{2n+1}, we conclude that identity (4.2) is valid whenever $a_{2n+1}a_{2n+3} = q$.

We use Lemma 4.6 to eliminate this last condition. With notation as in Lemma 4.6, we rewrite the q-difference equation (4.7) as

$$\begin{aligned} R_{2n+2}f = &\prod_{j=n+2}^{2n+1}\left(\frac{a_{2n+2}-a_j}{C-a_j}\right)\left(\frac{a_{2n+2}a_j-1}{Ca_j-1)}\right) \\ &\cdot\left[f-\sum_{\ell=n+2}^{2n+1}\left\{\prod_{\substack{j=n+2\\ j\neq\ell}}^{2n+2}\left(\frac{C-a_j}{a_\ell-a_j}\right)\left(\frac{Ca_j-1}{a_\ell a_j-1}\right)(R_\ell f)\right\}\right], \end{aligned} \tag{4.22}$$

where f can be either the left or right-hand side of identity (4.2). Now suppose that identity (4.2) is valid whenever $a_{2n+2} = q^\ell a_{2n+3}^{-1}$ for some positive integer ℓ. If we choose the parameters on the left-hand side of (4.22) to satisfy $a_{2n+2} = q^{\ell+1}a_{2n+3}^{-1}$, then those on the right-hand side will satisfy $a_{2n+2} = q^\ell a_{2n+3}^{-1}$. It follows that identity (4.2) will also be valid for $a_{2n+2} = q^{\ell+1}a_{2n+3}^{-1}$. Just as above, we conclude by analytic continuation that identity (4.2) is valid for arbitrary a_{2n+2}. Finally, by analytic continuation we also drop the other restrictions on the values of the parameters a_j and C. This completes the proof of the dimension n case of identity (4.2) and the proof of Theorem 4.1.

5. Some multidimensional Mellin–Barnes integrals.

In this section we give analogues of Nasrallah–Rahman integrals associated to the Lie algebras $su(n)$ and $sp(n)$. The integrals below can be viewed as limiting cases as $q \to 1^-$ of Theorems 2.1 and 4.1. The proofs are very similar to that of Theorem 3.1. The $n = 2$ case of Theorem 5.1 and the $n = 1$ case of Theorem 5.3 below (which are equivalent) are due to Rahman [21].

The first result is an analogue of Theorem 2.1.

THEOREM 5.1. *For $n \ge 2$, let $\alpha_i \in C$, $1 \le i \le n$, and $\beta_j \in C$, $1 \le j \le n+1$,* *with* $\mathrm{Re}(\alpha_i)$, $\mathrm{Re}(\beta_j) > 0$. *Set* $A = \sum_{i=1}^{n} \alpha_i, B = \sum_{j=1}^{n+1} \beta_j$ *and* $\gamma = A + B$, *then*

$$\int_{-i\infty}^{i\infty}\cdots\int_{-i\infty}^{i\infty} \frac{\prod_{k=1}^{n} \left\{\prod_{i=1}^{n} \Gamma(\alpha_i - z_k)\prod_{j=1}^{n+1}\Gamma(\beta_j+z_k)\right\} dz_1\cdots dz_{n-1}}{\prod_{k=1}^{n}\Gamma(\gamma+z_k)\prod_{\substack{1\le i,j\le n\\ i\neq j}}\Gamma(z_i-z_j)} = \frac{n!\Gamma(A)\prod_{j=1}^{n+1}\Gamma(B-\beta_j)\prod_{i=1}^{n}\prod_{j=1}^{n+1}\Gamma(\alpha_i+\beta_j)}{\prod_{j=1}^{n+1}\Gamma(\gamma-\beta_j)\prod_{i=1}^{n}\Gamma(\alpha_i+B)}, \tag{5.2}$$

where $\sum_{k=1}^{n} z_k = 0$.

Proof. The proof follows exactly the same lines as the proof of Theorem 3.1. The only modification needed is that in the $k = 1$ case of the induction on k, the parameters α_i and β_j should be modified by adding on an additional parameter t with $\mathrm{Re}(t) > 0$. Thus the $k = 1$ case exactly parallels the proof in §2. Finally, an application of Stirling's formula and Carlson's theorem, just as in §3, allows us to complete the proof of identity (5.2) for general values of the parameters.

We also prove the following analogue of Theorem 4.1 in an entirely similar way.

THEOREM 5.3. *For* $n \geq 1$, *let* $\alpha_i \in C$, $1 \leq i \leq 2n+3$. *Set* $\gamma = \sum_{i=1}^{2n+3} \alpha_i$, *then*

$$\frac{1}{(2\pi i)^n}\int_{-i\infty}^{i\infty}\cdots\int_{-i\infty}^{i\infty} \frac{\prod_{i=1}^{2n+3}\prod_{j=1}^{n}\Gamma(\alpha_i+z_j)\Gamma(\alpha_i-z_j)}{\prod_{1\le i<j\le n}\Gamma(z_i+z_j)\Gamma(-z_i-z_j)\Gamma(z_i-z_j)\Gamma(z_j-z_i)} \cdot\prod_{j=1}^{n}\frac{dz_j}{\Gamma(2z_j)\Gamma(-2z_j)\Gamma(\gamma+z_j)\Gamma(\gamma-z_j)} = \frac{n!2^n\prod_{1\le i<j\le 2n+3}\Gamma(\alpha_i+\alpha_j)}{\prod_{i=1}^{2n+3}\Gamma(\gamma-\alpha_i)}, \tag{5.4}$$

where the contours of integration are deformed so as to separate the sequences of poles going to the right $\{\alpha_i + k \mid 1 \leq i \leq 2n+3, k = 0, 1, 2, \cdots\}$ *from the sequences of poles going to the left* $\{-\alpha_i - k \mid 1 \leq i \leq 2n+3, k = 0, 1, 2, \cdots\}$.

AN $SU(n)$ q-BETA INTEGRAL TRANSFORMATION AND MULTIPLE HYPERGEOMETRIC SERIES IDENTITIES*

R. Y. DENIS† AND R. A. GUSTAFSON‡

Abstract. A multidimensional integral transformation is proved which is an $SU(n)$ integral analogue of Bailey's classical very well poised ${}_{10}\varphi_9$ hypergeometric series transformation. By applying Cauchy's theorem and specializing parameters, an $SU(n)$ ${}_{10}\varphi_9$ hypergeometric series transformation is then deduced. An $Sp(n)$ generalization of Jackson's very well poised ${}_8\varphi_7$ summation theorem is also proved.

Key words. q-beta integrals, integral transformation, hypergeometric series very well poised on Lie algebras, multiple hypergeometric series, Jackson's theorem

AMS(MOS) subject classifications. 33A15, 33A30, 33A65, 33A75

1. Introduction. In previous papers [4]–[6], the connection between summation theorems for hypergeometric series very well poised on semisimple Lie algebras and corresponding evaluations of multidimensional Mellin–Barnes and q-beta integrals on Lie groups and Lie algebras was developed. In particular, integral analogues of Gauss's sum, the Pfaff–Saalschütz sum, and Dougall's and Jackson's sum on various Lie groups and Lie algebras were found. These integrals generalize important one-dimensional integrals such as Barnes' first and second lemmas [3], the Askey–Wilson integral [1], the Nasrallah–Rahman integral [14], [15], and others. At the most basic level, the proofs of the simplest of these multidimensional integral identities depend on a use of Cauchy's theorem to express the integrals as sums of multiple series and then evaluation of these multiple series using a multidimensional form of the bilateralized Gauss's (${}_1H_1$) sum or a ${}_6\psi_6$ sum. At this point, the series depart from the scene and other methods such as difference equations are used to prove the integral identities. Just as with classical hypergeometric series, there is a hierarchy in the integral identities: a $u(n)$ Barnes' first lemma [5] is used to prove a $u(n)$ Barnes' second lemma [6]; the generalizations of the Askey–Wilson integral [5] are used to prove the corresponding generalization of the Nasrallah–Rahman integral [6].

In this paper we will come full circle, in the sense that integral identities will now be used to prove series identities. In §2 we will prove an integral analogue of the $SU(n)$ ${}_{10}\varphi_9$ transformation and then, in §3, we use this integral to deduce the corresponding $SU(n)$ ${}_{10}\varphi_9$ series identity. In §4 we use an $Sp(n)$ integral analogue of Jackson's ${}_8\varphi_7$ sum found in [6] to prove the corresponding $Sp(n)$ series identity. The methods used in this paper clearly have a wider application and could likely be used to give alternative proofs of the $u(n)$ Pfaff–Saalschütz series identities [7], the $SU(n)$ Jackson series identities [12], and other identities. It should be mentioned that the $SU(n)$ ${}_{10}\varphi_9$ series transformation found in §3 is probably equivalent to results of Milne [13], though the method of proof here is completely different.

One application of the integral and series identities, such as Theorems 2.1, 3.1, and 4.1, would be in the theory of orthogonal polynomials in several variables. It

is possible that they will be useful in finding generating functions and reproducing kernels for some of Macdonald's polynomials [11]. For example, in the one-dimensional case, see Nasrallah and Rahman [14]. Another possible application is to look for finite field or p-adic analogues of Theorem 2.1 or the previous integral identities in [4]–[6]. For some beautiful one-dimensional finite field and p-adic analogues of Barnes' first lemma see [9]–[10]. These papers also give some clue to the group representation theoretic significance of these integral identities.

2. A multivariate integral transformation. In this section we prove an integral analogue of the $SU(n)$ ${}_{10}\varphi_9$ hypergeometric series transformation. The proof involves a double $SU(n)$ integral. Applying Fubini's theorem and the $SU(n)$ generalization of the Nasrallah–Rahman integral [15, eqn. (2.4)], the double integral can be partially evaluated in two different ways. The resulting identity is the desired transformation.

THEOREM 2.1. *For $n \geq 2$ let $a, b_i, c_j \in \boldsymbol{C}$ for $1 \leq i \leq n+1$ and $1 \leq j \leq n+1$, with $|a|, |b_i|, |c_j| < 1$. Set $B = \prod_{i=1}^{n+1} b_i$ and $C = \prod_{j=1}^{n+1} c_j$, then*

$$(2.2)\qquad \prod_{i=1}^{n+1} \frac{[a^n c_i^{-1} C]_\infty}{[c_i^{-1} C]_\infty} \int_{T^{n-1}} \frac{\prod_{j=1}^{n} \{[aCz_j^{-1}]_\infty [a^n B z_j]_\infty\} \prod_{\substack{1\leq i,j\leq n\\ i\neq j}} [z_i z_j^{-1}]_\infty}{\prod_{i=1}^{n+1} \prod_{j=1}^{n} \{[ac_i z_j^{-1}]_\infty [b_i z_j]_\infty\}} \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}}$$

$$= \prod_{i=1}^{n+1} \frac{[a^n b_i^{-1} B]_\infty}{[b_i^{-1} B]_\infty} \int_{T^{n-1}} \frac{\prod_{j=1}^{n} \{[aBz_j^{-1}]_\infty [a^n C z_j]_\infty\} \prod_{\substack{1\leq i,j\leq n\\ i\neq j}} [z_i z_j^{-1}]_\infty}{\prod_{i=1}^{n+1} \prod_{j=1}^{n} \{[ab_i z_j^{-1}]_\infty [c_i z_j]_\infty\}} \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}},$$

where $\prod_{k=1}^{n} z_k = 1$, and the integral in each variable $z_1, \cdots, z_{n-1}$ is over the unit circle T taken in the positive direction.

Proof. Consider the following integral:

$$(2.3)\qquad \frac{1}{(2\pi i)^{n-1}} \int_{T^{n-1}} \int_{T^{n-1}} \frac{\prod_{k=1}^{n} \{[a^n B z_k]_\infty [a^n C u_k^{-1}]_\infty\} \prod_{\substack{1\leq i,j\leq n\\ i\neq j}} \{[z_i z_j^{-1}]_\infty [u_i u_j^{-1}]_\infty\}}{\prod_{k=1}^{n} \prod_{j=1}^{n+1} \{[b_j z_k]_\infty [c_j u_k^{-1}]_\infty\} \prod_{i,k=1}^{n} [a z_k^{-1} u_i]_\infty}$$

$$\cdot \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}} \frac{du_1}{u_1} \cdots \frac{du_{n-1}}{u_{n-1}},$$

where $\prod_{k=1}^{n} z_k = \prod_{k=1}^{n} u_k = 1$. If we evaluate the integral (2.3) with respect to the variables z_i, $1 \leq i \leq n$, or with respect to the variables u_i, $1 \leq i \leq n$, by means of the $SU(n)$ Nasrallah–Rahman integral [6, Thm. 2.1], we obtain the following identity:

(2.4)
$$\frac{n!\prod_{j=1}^{n+1}[a^nb_j^{-1}B]_\infty}{[q]_\infty^{n-1}[a^n]_\infty\prod_{j=1}^{n+1}[b_j^{-1}B]_\infty}\int_{T^{n-1}}\frac{\prod_{k=1}^{n}\{[aBu_k]_\infty[a^nCu_k^{-1}]_\infty\}}{\prod_{k=1}^{n}\prod_{j=1}^{n+1}\{[ab_ju_k]_\infty[c_ju_k^{-1}]_\infty\}}$$
$$\cdot\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}[u_iu_j^{-1}]_\infty\frac{du_1}{u_1}\cdots\frac{du_{n-1}}{u_{n-1}}$$
$$=\frac{n!\prod_{j=1}^{n+1}[a^nc_j^{-1}C]_\infty}{[q]_\infty^{n-1}[a^n]_\infty\prod_{j=1}^{n+1}[c_j^{-1}C]_\infty}\int_{T^{n-1}}\frac{\prod_{k=1}^{n}\{[aCz_k^{-1}]_\infty[a^nBz_k]_\infty\}}{\prod_{k=1}^{n}\prod_{j=1}^{n+1}\{[ac_jz_k^{-1}]_\infty[b_jz_k]_\infty\}}$$
$$\cdot\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}[z_iz_j^{-1}]_\infty\frac{dz_1}{z_1}\cdots\frac{dz_{n-1}}{z_{n-1}}.$$

Simplifying (2.4) and replacing the variables u_k by z_k^{-1}, $1\leq k\leq n$, on the left-hand side of (2.4), we obtain identity (2.2).

3. An $SU(n)$ ${}_{10}\varphi_9$ transformation. In this section we will prove an $SU(n)$ very well poised hypergeometric series transformation which correspronds to Theorem 2.1. The proof consists of writing both sides of identity (2.2) as sums of multiple series of residues and then specializing the parameters to make the series terminate. The $SU(2)$ case of this series transformation (3.2) is due to Bailey [2] (see Remark 3.7 below) and is one of the most powerful classical basic hypergeometric series identities. At the end of this section we will also state the limit $q\to 1^-$ of identity (3.2). We begin with the following theorem.

THEOREM 3.1. *For $n\geq 2$ let $a, b_j, c_j\in C$ for $1\leq j\leq n+1$, with $ab_ic_i=q^{-m_i}$ for some nonnegative integers m_i for $1\leq i\leq n-1$. Let $\gamma_i=ac_i$ and $w_i=ab_i$ for $1\leq i\leq n-1$, and $\gamma_n=\prod_{i=1}^{n-1}\gamma_i^{-1}$ and $w_n=\prod_{i=1}^{n-1}w_i^{-1}$. Set $B=\prod_{j=1}^{n+1}b_j$ and $C=\prod_{j=1}^{n+1}c_j$, then*

(3.2)
$$\prod_{i=1}^{n+1}\frac{[a^nc_i^{-1}C]_\infty}{[c_i^{-1}C]_\infty}\frac{\prod_{j=1}^{n}\{[aC\gamma_j^{-1}]_\infty[a^nB\gamma_j]_\infty]\}}{\prod_{i=1}^{n+1}\prod_{\substack{j=1\\ i\neq j}}^{n-1}\{[ac_i\gamma_j^{-1}]_\infty[b_i\gamma_j]_\infty\}}$$
$$\cdot\frac{\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}[\gamma_i\gamma_j^{-1}]_\infty}{\prod_{i=1}^{n+1}\{[ac_i\gamma_n^{-1}]_\infty[b_i\gamma_n]_\infty\}}\sum_{\substack{y_1\geq 0,\cdots,y_{n-1}\geq 0\\ y_1+\cdots+y_n=0}}\left\{\prod_{1\leq i<j\leq n}\left(\frac{\gamma_iq^{y_i}-\gamma_jq^{y_j}}{\gamma_i-\gamma_j}\right)\right.$$
$$\left.\cdot\prod_{j=1}^{n}\frac{[q\gamma_j/aC]_{y_j}\prod_{i=1}^{n+1}[b_i\gamma_j]_{y_j}}{[a^nB\gamma_j]_{y_j}\prod_{i=1}^{n+1}[q\gamma_j/ac_i]_{y_j}}\right\}$$

$$= \prod_{i=1}^{n+1} \frac{[a^n b_i^{-1} B]_\infty}{[b_i^{-1} B]_\infty} \frac{\prod\limits_{j=1}^{n} \{[aBw_j^{-1}]_\infty [a^n C w_j]_\infty\}}{\prod\limits_{i=1}^{n+1} \prod\limits_{\substack{j=1 \\ i\neq j}}^{n-1} \{[ab_i w_j^{-1}]_\infty [c_i w_j]_\infty\}}$$

$$\cdot \frac{\prod\limits_{\substack{1\leq i,j\leq n \\ i\neq j}} [w_i w_j^{-1}]_\infty}{\prod\limits_{i=1}^{n+1} \{[ab_i w_n^{-1}]_\infty [c_i w_n]_\infty\}} \sum_{\substack{y_1\geq 0,\cdots,y_{n-1}\geq 0 \\ y_1+\cdots+y_n=0}} \Bigg\{ \prod_{1\leq i<j\leq n} \left(\frac{w_i q^{y_i} - w_j q^{y_j}}{w_i - w_j}\right)$$

$$\cdot \prod_{j=1}^{n} \frac{[qw_j/aB]_{y_j} \prod\limits_{i=1}^{n+1} [c_i w_j]_{y_j}}{[a^n C w_j]_{y_j} \prod\limits_{i=1}^{n+1} [qw_j/ab_i]_{y_j}} \Bigg\}.$$

Proof. Let $a\alpha = \{ac_1, ac_2, \cdots, ac_{n+1}\}$, $\alpha^{-1} = \{c_1^{-1}, c_2^{-1}, \cdots, c_{n+1}^{-1}\}$, $a\beta = \{ab_1, \cdots, ab_{n+1}\}$, and $\beta^{-1} = \{b_1^{-1}, \cdots, b_{n+1}^{-1}\}$. Let Δ be the set of all $\delta = (u_1, \cdots, u_n)$, where for some j, $0 \leq j \leq n-1$,

$$\begin{aligned} &\{u_1, \cdots, u_j\} \subset a\alpha, \\ &\{u_{j+1}, \cdots, u_{n-1}\} \subset \beta^{-1}, \\ &u_n = \prod_{i=1}^{n-1} u_i^{-1}, \end{aligned}$$

and

$$u_i \neq u_k \quad \text{for all} \quad i \neq k,\ 1 \leq i, k \leq n.$$

Similarly, let Δ' be the set of all $\delta' = (v_1, \cdots, v_n)$, where for some j, $0 \leq j \leq n-1$,

$$\begin{aligned} &\{v_1, \cdots, v_j\} \subset a\beta, \\ &\{v_{j+1}, \cdots, v_{n-1}\} \subset \alpha^{-1}, \\ &v_n = \prod_{i=1}^{n-1} v_i^{-1}, \end{aligned}$$

and

$$v_i \neq v_k \quad \text{for all} \quad i \neq k,\ 1 \leq i, k \leq n.$$

We will temporarily assume that $|a|, |b_i|, |c_i| < 1$ for all i, $1 \leq i \leq n+1$. Following the argument in [5, §6], upon expanding identity (2.2) in a series of residues and cancelling various terms, we obtain

(3.3)

$$\sum_{\delta\in\Delta}\left\{\prod_{i=1}^{n+1}\frac{[a^nc_i^{-1}C]_\infty}{[c_i^{-1}C]_\infty}\,\frac{\prod\limits_{j=1}^{n}[aCu_j^{-1}]_\infty[a^nBu_j]_\infty}{\prod\limits_{i=1}^{n+1}\prod\limits_{j=1}^{n}{}'[ac_iu_j^{-1}]_\infty[b_iu_j]_\infty}\right.$$

$$\cdot\prod_{\substack{1\le i,j\le n\\ i\neq j}}[u_iu_j^{-1}]_\infty\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty}\left\{\prod_{1\le i<j\le n}\left(\frac{u_iq^{y_i}-u_jq^{y_j}}{u_i-u_j}\right)\right.$$

$$\left.\left.\cdot\prod_{j=1}^{n}\frac{[qu_j/aC]_{y_j}\prod\limits_{i=1}^{n+1}[b_iu_j]_{y_j}}{[a^nBu_j]_{y_j}\prod\limits_{i=1}^{n+1}[qu_j/ac_i]_{y_j}}\right\}\right\}$$

$$=\sum_{\delta'\in\Delta'}\left\{\prod_{i=1}^{n+1}\frac{[a^nb_i^{-1}B]_\infty}{[b_i^{-1}B]_\infty}\,\frac{\prod\limits_{j=1}^{n}[aBv_j^{-1}]_\infty[a^nCv_j]_\infty}{\prod\limits_{i=1}^{n+1}\prod\limits_{j=1}^{n}{}'[ab_iv_j^{-1}]_\infty[c_iv_j]_\infty}\right.$$

$$\cdot\prod_{\substack{1\le i,j\le n\\ i\neq j}}[v_iv_j^{-1}]_\infty\cdot\sum_{\substack{y_1,\cdots,y_n=-\infty\\ y_1+\cdots+y_n=0}}^{\infty}\left\{\prod_{1\le i<j\le n}\left(\frac{v_iq^{y_i}-v_jq^{y_j}}{v_i-v_j}\right)\right.$$

$$\left.\left.\cdot\prod_{j=1}^{n}\frac{[qv_j/aB]_{y_j}\prod\limits_{i=1}^{n+1}[c_iv_j]_{y_j}}{[a^nCv_j]_{y_j}\prod\limits_{i=1}^{n+1}[qv_j/ab_i]_{y_j}}\right\}\right\},$$

where $\prod'$ means the usual product except that if $c=q^{-\ell}$ for some nonnegative integer ℓ, then the factor $[c]_\infty$ in the product is replaced by $[q^{-\ell}]_\ell[q]_\infty$. Now multiply both sides of equation (3.3) by $\prod_{i=1}^{n-1}[ab_ic_i]_\infty$ and set $ab_ic_i=q^{-m_i}$, $1\le i\le n-1$, as in the statement of Theorem 3.1. The only terms not vanishing on the left-hand side of (3.3) will be when $\delta=(u_1,\cdots,u_n)$ satisfies

$$\{u_1,\cdots,u_j\}\subset\{ac_1,\cdots,ac_{n-1}\},$$
$$\{u_{j+1},\cdots,u_{n-1}\}\subset\{b_1^{-1},\cdots,b_{n-1}^{-1}\},$$

and

$$u_iu_j^{-1}\neq ac_\ell b_\ell\quad\text{for } 1\le i,j,\ell\le n-1.$$

Similarly, the only terms not vanishing on the right-hand side of (3.3) will be when $\delta'=(v_1,\cdots,v_n)$ satisfies

$$\{v_1,\cdots v_j\}\subset\{ab_1,\cdots,ab_{n-1}\},$$
$$\{v_{j+1},\cdots,v_{n-1}\}\subset\{c_1^{-1},\cdots,c_{n-1}^{-1}\},$$

and

$$v_iv_j^{-1}\neq ac_\ell b_\ell\quad\text{for } 1\le i,j,\ell\le n-1.$$

We now claim that all of the nonvanishing series on the left-hand side of (3.3) are equal. This can be proved by simply reversing the appropriate summations. For example, consider the series on the left-hand side of (3.3), where $\delta = (u_1, \cdots, u_n)$ and for some j, $0 \leq j \leq n-1$, we have $u_i = ac_i$ for $1 \leq i \leq j$ and $u_i = b_i^{-1}$ for $j < i \leq n-1$. Then we find

$$
\begin{aligned}
(3.4)\qquad & \prod_{i=1}^{n+1} \frac{[a^n c_i^{-1} C]_\infty}{[c_i^{-1} C]_\infty} \sum_{y_1=0}^{m_1} \cdots \sum_{y_j=0}^{m_j} \sum_{y_{j+1}=-m_{j+1}}^{0} \cdots \sum_{y_{n-1}=-m_{n-1}}^{0} \\
& \left\{ \prod_{\ell=1}^{j} \frac{[ab_\ell c_\ell]_{y_\ell}}{[q]_\infty [q^{-y_\ell}]_{y_\ell}} \prod_{\ell=j+1}^{n-1} \frac{[ab_\ell c_\ell]_{-y_\ell}}{[q]_\infty [q^{y_\ell}]_{-y_\ell}} \cdot \prod_{\substack{1 \leq i,\ell \leq n \\ i \neq \ell}} [u_i u_\ell^{-1}]_\infty \right. \\
& \left. \cdot \frac{\prod_{\ell=1}^{n} [aCu_\ell^{-1} q^{-y_\ell}]_\infty [a^n B u_\ell q^{y_\ell}]_\infty}{\prod_{\substack{i=1 \\ i \neq \ell}}^{n+1} \ \prod_{\substack{\ell=1 \\ \text{for } 1 \leq \ell \leq n-1}}^{n} [ac_i u_\ell^{-1} q^{-y_\ell}]_\infty [b_i u_\ell q^{y_\ell}]_\infty} \right\} \\
& = \prod_{i=1}^{n+1} \frac{[a^n c_i^{-1} C]_\infty}{[c_i^{-1} C]_\infty} \sum_{y_1=0}^{m_1} \cdots \sum_{y_{n-1}=0}^{m_{n-1}} \\
& \left\{ \prod_{\ell=1}^{n-1} \frac{[ab_\ell c_\ell]_{y_\ell}}{[q]_\infty [q^{-y_\ell}]_{y_\ell}} \cdot \prod_{\substack{1 \leq i,\ell \leq n \\ i \neq \ell}} [\gamma_i \gamma_\ell^{-1}]_\infty \right. \\
& \left. \cdot \frac{\prod_{\ell=1}^{n} [aC\gamma_\ell q^{-y_\ell}]_\infty [a^n B \gamma_\ell q^{y_\ell}]_\infty}{\prod_{\substack{i=1 \\ i \neq \ell}}^{n+1} \ \prod_{\substack{\ell=1 \\ \text{for } 1 \leq \ell \leq n-1}}^{n} [ac_i \gamma_\ell^{-1} q^{-y_\ell}]_\infty [b_i \gamma_\ell q^{y_\ell}]_\infty} \right\},
\end{aligned}
$$

where $y_1 + \cdots + y_n = 0, \gamma_i = ac_i$ for $1 \leq i \leq n-1$ and $\gamma_n = \prod_{i=1}^{n-1} \gamma_i^{-1}$. Similarly, we show that all of the nonvanishing series on the right-hand side of (3.3) are equal. Putting this together, we obtain identity (3.2). This completes the proof of Theorem 3.1.

Let $q \to 1^-$ in identity (3.2). We then obtain the following.

THEOREM 3.5. *For $n \geq 2$ let $a, b_j, c_j \in C$ for $1 \leq j \leq n+1$, with $a+b_i+c_i = -m_i$ for some nonnegative integer m_i for $1 \leq i \leq n-1$. Let $\gamma_i = a + c_i$ and $w_i = a + b_i$ for $1 \leq i \leq n-1$, and $\gamma_n = -\sum_{i=1}^{n-1} \gamma_i$ and $w_n = -\sum_{i=1}^{n-1} w_i$. Set $B = \sum_{j=1}^{n+1} b_j$ and $C = \sum_{j=1}^{n+1} c_j$, then*

(3.6)

$$\prod_{i=1}^{n+1}\frac{\Gamma(C-c_i)}{\Gamma(C-c_i+na)}\,\frac{\prod_{i=1}^{n+1}\prod_{\substack{j=1\\ i\neq j}}^{n-1}\{\Gamma(a+c_i-\gamma_j)\Gamma(b_i+\gamma_j)\}}{\prod_{j=1}^{n}\{\Gamma(a+C-\gamma_j)\Gamma(na+B+\gamma_j)\}}$$

$$\cdot\frac{\prod_{i=1}^{n+1}\{\Gamma(a+c_i-\gamma_n)\Gamma(b_i+\gamma_n)\}}{\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}\Gamma(\gamma_i-\gamma_j)}$$

$$\cdot\sum_{\substack{y_1\geq 0,\cdots,y_{n-1}\geq 0\\ y_1+\cdots+y_n=0}}\left\{\prod_{1\leq i<j\leq n}\left(\frac{\gamma_i+y_i-\gamma_j-y_j}{\gamma_i-\gamma_j}\right)\right.$$

$$\left.\cdot\prod_{j=1}^{n}\frac{(1+\gamma_j-a-C)_{y_j}}{(na+B+\gamma_j)_{y_j}}\,\frac{\prod_{i=1}^{n+1}(b_i+\gamma_j)_{y_j}}{\prod_{i=1}^{n+1}(1+\gamma_j-a-c_j)_{y_j}}\right\}$$

$$=\prod_{i=1}^{n+1}\frac{\Gamma(B-b_i)}{\Gamma(na+B-b_i)}\,\frac{\prod_{i=1}^{n+1}\prod_{\substack{j=1\\ i\neq j}}^{n-1}\{\Gamma(a+b_i-w_j)\Gamma(c_i+w_j)\}}{\prod_{j=1}^{n}\{\Gamma(a+B-w_j)\Gamma(na+C+w_j)\}}$$

$$\cdot\frac{\prod_{i=1}^{n+1}\{\Gamma(a+b_i-w_n)\Gamma(c_i+w_n)\}}{\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}\Gamma(w_i-w_j)}$$

$$\cdot\sum_{\substack{y_1\geq 0,\cdots,y_{n-1}\geq 0\\ y_1+\cdots+y_n=0}}\left\{\prod_{1\leq i<j\leq n}\left(\frac{w_i+y_i-w_j-y_j}{w_i-w_j}\right)\right.$$

$$\left.\cdot\prod_{j=1}^{n}\frac{(1+w_j-a-B)_{y_j}\prod_{i=1}^{n+1}(c_i+w_j)_{y_j}}{(na+C+w_j)_{y_j}\prod_{i=1}^{n+1}(1+w_j-a-b_i)_{y_j}}\right\}.$$

Remark 3.7 To show that the $n=2$ case of identity (3.2) is equivalent to Bailey's very well poised ${}_{10}\varphi_9$ transformation ([3], p. 68), set $ab_1c_1=q^{-m}$ in (3.2) and reverse the series on the right-hand side of (3.2). Set a in Bailey's notation equal to $a^2c_1^2$ here, and $c=a^2c_2c_1$, $d=a^2c_3c_1$, $e=qc_2^{-1}c_3^{-1}$, $f=ab_1c_1=q^{-m}$, $g=ab_2c_1$, $h=ab_3c_1$, $j=qa^{-1}B^{-1}c_1$, and $k=c_1^2$, where the notation on the left-hand side of each equality is Bailey's and on the right-hand side is that of (3.2) here. From (3.2), we then obtain the following transformation in Bailey's notation:

$$
\begin{aligned}
(3.8)\qquad & {}_{10}\varphi_9\left[\begin{matrix} a, & q\sqrt{a}, & -q\sqrt{a}, & c, & d, & e, \\ & \sqrt{a}, & -\sqrt{a}, & aq/c, & aq/d, & aq/e, \end{matrix}\right. \\
& \qquad \left.\begin{matrix} f, & g, & h, & j; & q \\ aq/f, & aq/g, & aq/h, & aq/j & \end{matrix}\right] \\
& = \frac{[f/a]_\infty, [g/a]_\infty [fgh/a]_\infty [h/a]_\infty}{[a^{-1}]_\infty [fg/a]_\infty [gh/a]_\infty [fh/a]_\infty} \\
& \cdot \frac{[qa/fj]_\infty [qa/gj]_\infty [qa/hj]_\infty [qa/fghj]_\infty}{[qa/j]_\infty [qa/ghj]_\infty [qa/hjf]_\infty [qa/jfg]_\infty} \\
& \cdot {}_{10}\varphi_9\left[\begin{matrix} k, & q\sqrt{k}, & -q\sqrt{k}, & kc/a, & kd/a, & ke/a, \\ & \sqrt{k}, & -\sqrt{k}, & aq/c, & aq/d, & aq/e, \end{matrix}\right. \\
& \qquad \left.\begin{matrix} f, & g, & h, & j; & q \\ kq/f, & kq/g, & kq/h, & kq/j & \end{matrix}\right],
\end{aligned}
$$

where $k = a^2q/cde$, $cdefghj = a^3q^2$, and $f = q^{-m}$ for some nonnegative integer m. Since $f = q^{-m}$, observe that

$$
\begin{aligned}
(3.9)\qquad & \frac{[f/a]_\infty [g/a]_\infty [fgh/a]_\infty [h/a]_\infty}{[a^{-1}]_\infty [fg/a]_\infty [gh/a]_\infty [fh/a]_\infty} \\
& = \frac{[a^{-1}q^{-m}]_m [gha^{-1}q^{-m}]_m}{[ga^{-1}q^{-m}]_m [ha^{-1}q^{-m}]_m} = \frac{[qa]_m [qa/gh]_m}{[qa/g]_m [qa/h]_m} \\
& = \frac{[qa]_\infty [qa/fg]_\infty [aq/fh]_\infty [qa/gh]_\infty}{[qa/f]_\infty [qa/g]_\infty [qa/h]_\infty [qa/fgh]_\infty}.
\end{aligned}
$$

Using identity (3.9) to substitute for the first part of the product on the it right-hand side of (3.8), we obtain Bailey's ${}_{10}\varphi_9$ transformation [3, p. 68].

4. A Jackson summation theorem for hypergeometric series on $Sp(n)$. In this section we generalize Jackson's summation theorem [8] for very well poised ${}_8\varphi_7$ hypergeometric series to the setting of basic hypergeometric series very well poised on $Sp(n)$. The $Sp(1)$ case reduces to the classical Jackson sum. The proof is very similar to that in §3, except that the starting point is the $Sp(n)$ integral identity [6, Thm. 4.1].

THEOREM 4.1. *For $n \geq 1$, let $a_i \in C$ for $1 \leq i \leq 2n+3$, with $a_j a_{n+j} = q^{-m_j}$ for some nonnegative integers m_j for $1 \leq j \leq n$. Set $C = \prod_{i=1}^{2n+3} a_i$. Then*

$$
\begin{aligned}
(4.2)\qquad \sum_{y_1\geq 0,\cdots,y_n\geq 0} \Bigg\{ & q^{-\sum_{i=1}^{n}(n+1-i)y_i} \prod_{j=1}^{n} \frac{(1-a_j^2 q^{2y_j})}{(1-a_j^2)} \\
& \cdot \prod_{1\leq i<j\leq n} \frac{(1-a_i a_j^{-1} q^{y_i-y_j})(1-a_i a_j q^{y_i+y_j})}{(1-a_i a_j^{-1})(1-a_i a_j)}
\end{aligned}
$$

$$\left.\cdot\prod_{j=1}^{n}\frac{\prod\limits_{i=n+2}^{2n+3}[a_ia_j]_{y_j}[a_ia_j^{-1}]_{-y_j}}{[Ca_j]_{y_j}[Ca_j^{-1}]_{-y_j}\prod\limits_{i=1}^{n+1}[qa_i^{-1}a_j]_{y_j}[qa_i^{-1}a_j^{-1}]_{-y_j}}\right\}$$

$$=\frac{\prod\limits_{i=n+1}^{2n+3}\{[Ca_i^{-1}]_\infty\prod\limits_{j=1}^{n}[a_ia_j^{-1}]_\infty\}}{\prod\limits_{n+1\leq i<j\leq 2n+3}[a_ia_j]_\infty\prod\limits_{1\leq i\leq j\leq n}[a_i^{-1}a_j^{-1}]_\infty\prod\limits_{i=1}^{n}[Ca_i]_\infty}.$$

Proof. Let us temporarily assume that $|a_i| < 1$ for $1 \leq i \leq 2n+3$. From [6, Thm. 4.1] we have the following identity:

$$\frac{1}{(2\pi i)^n}\int_{T^n}\frac{\prod\limits_{1\leq i<j\leq n}[z_iz_j]_\infty[z_i^{-1}z_j^{-1}]_\infty[z_iz_j^{-1}]_\infty[z_i^{-1}z_j]_\infty}{\prod\limits_{i=1}^{2n+3}\prod\limits_{j=1}^{n}[a_iz_j]_\infty[a_iz_j^{-1}]_\infty}$$

$$\cdot\prod_{j=1}^{n}\left\{[z_j^2]_\infty[z_j^{-2}]_\infty[Cz_j]_\infty[Cz_j^{-1}]_\infty\frac{dz_j}{z_j}\right\}=\frac{n!2^n\prod\limits_{j=1}^{2n+3}[Ca_j^{-1}]_\infty}{[q]_\infty^n\prod\limits_{1\leq i<j\leq 2n+3}[a_ia_j]_\infty},\tag{4.3}$$

where the integral in each variable z_j is over the unit circle T taken in the positive direction.

Let S be the set of all injective mappings π: $\{1,2,\cdots,n\}\to\{1,2,\cdots,2n+3\}$. Using Cauchy's theorem and following the argument in §7 of [5], we can rewrite (4.3) as

$$\sum_{\pi\in S}\sum_{y_1,\cdots,y_n=0}^{\infty}\left\{\frac{\prod\limits_{1\leq i\leq j\leq n}[a_{\pi(i)}a_{\pi(j)}q^{y_i+y_j}]_\infty[a_{\pi(i)}^{-1}a_{\pi(j)}^{-1}q^{-y_i-y_j}]_\infty}{\prod\limits_{i=1}^{2n+3}\prod\limits_{j=1}^{n}{}'[a_ia_{\pi(j)}q^{y_j}]_\infty[a_ia_{\pi(j)}^{-1}q^{-y_j}]_\infty}\right.$$

$$\left.\cdot\prod_{\substack{1\leq i,j\leq n\\ i\neq j}}[a_{\pi(i)}a_{\pi(j)}^{-1}q^{y_i-y_j}]_\infty\prod_{j=1}^{n}[Ca_{\pi(j)}q^{y_j}]_\infty[Ca_{\pi(j)}^{-1}q^{-y_j}]_\infty\right\}\tag{4.4}$$

$$=\frac{n!2^n\prod\limits_{j=1}^{2n+3}[Ca_j^{-1}]_\infty}{[q]_\infty^n\prod\limits_{1\leq i<j\leq 2n+3}[a_ia_j]_\infty},$$

where $\prod'$ is defined as in (3.3). Now multiply both sides of equation (4.4) by $\prod_{j=1}^{n}[a_ja_{n+j}]_\infty$ and set $a_ja_{n+j}=q^{-m_j}$. The only terms not vanishing on the left-hand side of (4.4) will be when the image of $\pi\subset\{1,\cdots,2n\}$, and if $j\in$ image of π, then $n+j\notin$ image of π for all j, $1\leq j\leq n$. An argument similar to that in §3 shows that on the left-hand side of (4.4), the corresponding series in $y_1,\cdots y_n$ for all such π are equal. Identity (4.2) and Theorem 4.1 now follow from (4.4) after simplification.

We also have the following result when $q \to 1^-$ in (4.2).

THEOREM 4.5. *For $n \geq 1$, let $a_i \in C$ for $1 \leq i \leq 2n+3$, with $a_j + a_{n+j} = -m_j$ for some nonnegative integers m_j for $1 \leq j \leq n$. Set $C = \sum_{i=1}^{2n+3} a_i$. Then*

(4.6)

$$\sum_{y_1\geq 0,\cdots,y_n\geq 0}\left\{\prod_{j=1}^{n}\left(\frac{a_j+y_j}{a_j}\right)\cdot\prod_{1\leq i<j\leq n}\frac{(a_i+y_i-a_j-y_j)(a_i+y_i+a_j+y_j)}{(a_i-a_j)(a_i+a_j)}\right.$$

$$\left.\cdot\prod_{j=1}^{n}\frac{\prod\limits_{i=n+2}^{2n+3}(a_i+a_j)_{y_j}(a_i-a_j)_{-y_j}}{(C+a_j)_{y_j}(C-a_j)_{-y_j}\prod\limits_{i=1}^{n+1}(1-a_i+a_j)_{y_j}(1-a_i-a_j)_{-y_j}}\right\}$$

$$=\frac{\prod\limits_{n+1\leq i<j\leq 2n+3}\Gamma(a_i+a_j)\prod\limits_{1\leq i\leq j\leq n}\Gamma(-a_i-a_j)\prod\limits_{i=1}^{n}\Gamma(C+a_i)}{\prod\limits_{i=n+1}^{2n+3}\left\{\Gamma(C-a_i)\prod\limits_{j=1}^{n}\Gamma(a_i-a_j)\right\}}.$$

SOME FORMULAS OF RAMANUJAN, REVISITED*

EMILIO MONTALDI† AND GIUSEPPE ZUCCHELLI‡

Abstract. An alternative form of a famous result of Ramanujan is given, which is quoted as Entry 29(b) in Chapter 10 of Berndt's [*Ramanujan's Notebooks*, Part II, Springer-Verlag, New York, 1988]. Other results of a similar kind are reconsidered and generalized.

Key words. elliptic integrals, hypergeometric functions

AMS(MOS) subject classifications. 33A25, 33A30

1. In his first letter to Hardy, dated January 16, 1913, Ramanujan [1] communicated the formula

$$\frac{1}{n+1}\,{}_3F_2\left[\begin{matrix}\frac12, & \frac12, n+1\\ 1, & n+2\end{matrix}\right]=\frac{(n!)^2}{\Gamma^2(n+\frac32)}\sum_{r=0}^{n}\frac{(\frac12)_r^2}{(r!)^2} \tag{1.1}$$

which, together with certain generalizations, gave rise to a flurry of papers in the years 1929–1931. This result is quoted as Entry 29(b) in Chapter 10 of Berndt's [2] second book, where the related formulas

$$\frac{\pi^2}{4}\varphi\left(n+\frac12\right)=2G+\sum_{r=0}^{n-1}\frac{(r!)^2}{(\frac32)_r^2} \tag{1.2}$$

and

$$2\varphi\left(n+\frac14\right)=1+\frac{16\Gamma^4(\frac34)}{\pi^3}\sum_{r=0}^{n-1}\frac{(\frac34)_r^2}{(\frac54)_r^2} \tag{1.3}$$

are also discussed. In (1.2) and (1.3), $\varphi(z)$ is defined by

$$\varphi(z)=\frac{\Gamma^2(z+\frac12)}{\Gamma(z)\Gamma(z+1)}\,{}_3F_2\left[\begin{matrix}\frac12, & \frac12, z\\ 1, & z+1\end{matrix}\right] \tag{1.4}$$

for all complex z; moreover,

$$G=\sum_{r=0}^{\infty}\frac{(-1)^r}{(2r+1)^2} \tag{1.5}$$

is Catalan's constant.

As far as we know, the most recent proof of (1.1) and (1.2) is due to Dutka [3], who performed two distinct evaluations of the integral $\int_0^1 x^m\,{}_2F_1(\frac12,\frac12;1;x^2)\,dx$, m being a nonnegative integer.

In this note, we first derive an alternative expression for the finite sum on the right side of (1.1). This is done in § 2. In § 3, we generalize Dutka's procedure and obtain some (perhaps new) formulas for ${}_3F_2$ and ${}_4F_3$.

2. Let us consider the integral

$$\begin{aligned}
I_n(\alpha) &\equiv \frac{1}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\int_0^1 t^{\alpha+n-(1/2)}(1-t)^{-1/2}\,dt\int_0^1 x^n(1-tx)^{-1/2}\,dx\\
&= \frac{1}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\int_0^1 t^{\alpha-(1/2)}(1-t)^{-1/2}\,dt\int_0^1 (1-tx)^{-1/2}\sum_{r=0}^{n}(-1)^r\binom{n}{r}(1-xt)^r\,dx\\
&= \frac{1}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\int_0^1 t^{\alpha-(3/2)}\sum_{r=0}^{n}(-1)^r\binom{n}{r}\frac{(1-t)^{-1/2}-(1-t)^r}{r+\frac{1}{2}}\,dt\\
&= \frac{1}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\Gamma\left(\alpha-\frac{1}{2}\right)\sum_{r=0}^{n}(-1)^r\frac{\binom{n}{r}}{r+\frac{1}{2}}\left[\frac{\pi^{1/2}}{\Gamma(\alpha)}-\frac{r!}{\Gamma(\alpha+r+\frac{1}{2})}\right].
\end{aligned}\tag{2.1}$$

By putting $\alpha=-n$, we get

$$\frac{\pi}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\int_0^1 x^n\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right)dx=\frac{(\frac{3}{2})_n}{n!}\sum_{r=0}^{n}\frac{(\frac{1}{2})_r}{r!}\frac{1}{2(n-r)+1}.\tag{2.2}$$

Now, by recalling Ramanujan's formula (1.1),

$$\begin{aligned}
\frac{\pi}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\int_0^1 x^n\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right)dx &= \frac{\pi}{4}\frac{(\frac{3}{2})_n^2}{(n!)^2}\frac{1}{n+1}\,{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, n+1\\ 1, & n+2\end{matrix}\right]\\
&= \sum_{r=0}^{n}\frac{(\frac{1}{2})_r^2}{(r!)^2}.
\end{aligned}\tag{2.3}$$

Hence, by comparing (2.2) and (2.3), we obtain the identity

$$\frac{(\frac{3}{2})_n}{n!}\sum_{r=0}^{n}\frac{(\frac{1}{2})_r}{r!}\frac{1}{2(n-r)+1}=\sum_{r=0}^{n}\frac{(\frac{1}{2})_r^2}{(r!)^2}.\tag{2.4}$$

An alternative proof of (2.4) may be of some interest. To this aim, we start from

$$(1-x)^{-1/2}={}_2F_1\left(1,\frac{1}{2};1;x\right)=\frac{1}{\pi}\int_0^1 t^{-1/2}(1-t)^{-1/2}(1-xt)^{-1}\,dt,$$

i.e.,

$$\frac{d}{dx}\frac{1}{2}\log\frac{1+\sqrt{x}}{1-\sqrt{x}}=\frac{1}{\pi}\int_0^1 t^{-1/2}(1-t)^{-1}\frac{\partial}{\partial x}\tan^{-1}\left(\sqrt{\frac{x(1-t)}{1-x}}\right)dt,$$

whence

$$\frac{1}{2}\log\frac{1+\sqrt{x}}{1-\sqrt{x}}=\frac{1}{\pi}\int_0^1 t^{-1/2}(1-t)^{-1}\tan^{-1}\left(\sqrt{\frac{x(1-t)}{1-x}}\right)dt.\tag{2.5}$$

By observing that

$$\begin{aligned}
&\int_0^1 (1-xu)^{-1}(1-u)^{-1/2}(1-xtu)^{-1/2}\,du\\
&\qquad=2[x(1-x)(1-t)]^{-1/2}\tan^{-1}\left(\sqrt{\frac{x(1-t)}{1-x}}\right),
\end{aligned}$$

(2.5) becomes

$$
\begin{aligned}
&x^{-1/2}(1-x)^{-1/2}\log\frac{1+\sqrt{x}}{1-\sqrt{x}}\\
&\quad=\frac{1}{\pi}\int_0^1 t^{-1/2}(1-t)^{-1/2}\,dt\\
&\qquad\cdot\int_0^1 (1-xu)^{-1}(1-u)^{-1/2}(1-xtu)^{-1/2}\,du\\
&\quad=\int_0^1 (1-u)^{-1/2}(1-xu)^{-1}\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;xu\right)du,
\end{aligned}
\tag{2.6}
$$

and, by comparing the coefficients of x^n on both sides, the required identity (2.4) follows at once. Incidentally, this derivation of (2.4) gives, together with (2.2), another proof of Ramanujan identity (1.1).

It may be noted that, with $\delta=x(d/dx)$, (2.6) is equivalent to

$$x^{-1/2}(1-x)^{-1/2}\log\frac{1+\sqrt{x}}{1-\sqrt{x}}=B\left(\delta+1,\frac{1}{2}\right)(1-x)^{-1}\,{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right). \tag{2.7}$$

This follows from the fact that $u^{x(d/dx)}=u^\delta$ has the operational property $u^\delta f(x)=f(ux)$, $f(x)$ being analytic in a neighborhood of $x=0$. By using

$$\frac{\Gamma(\delta+\frac{3}{2})}{\Gamma(\delta+1)\sqrt{\pi}}=\frac{1}{2\pi}\int_0^1 t^{-1/2}(1-t)^{-3/2}(1-t^{1+\delta})\,dt, \tag{2.8}$$

(2.7) is formally inverted to give (with $u(x)=x^{-1/2}(1-x)^{-1/2}\log(1+\sqrt{x}/1-\sqrt{x})$

$${}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right)=\frac{1-x}{\pi}\int_0^1 t^{-1/2}(1-t)^{-3/2}[u(x)-tu(xt)]\,dt. \tag{2.9}$$

This is a rather unusual expression for the complete elliptic integral of the first kind.

Equation (2.9) can also be proven directly from (2.4) and (2.8). Indeed, by observing that

$$
\begin{aligned}
&u(x)=2\sum_{n=0}^{\infty}x^n\sum_{r=0}^{n}\frac{(\frac{1}{2})_r}{r!}\frac{1}{2(n-r)+1}=2\sum_{n=0}^{\infty}x^n\frac{n!}{(\frac{3}{2})_n}c_n,\\
&c_n=\sum_{r=0}^{n}\frac{(\frac{1}{2})_r^2}{(r!)^2},
\end{aligned}
\tag{2.10}
$$

the right side is

$$
\begin{aligned}
&\frac{1-x}{\pi}\sum_{n=0}^{\infty}x^n\frac{n!}{(\frac{3}{2})_n}c_n\int_0^1 dt\,t^{-1/2}(1-t)^{-3/2}(1-t^{n+1})\\
&\quad=(1-x)\sum_{n=0}^{\infty}c_nx^n\\
&\quad=1+\sum_{n=0}^{\infty}(c_{n+1}-c_n)x^{n+1}={}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right),
\end{aligned}
$$

since

$$c_{n+1}-c_n=\left(\frac{(\frac{1}{2})_{n+1}}{(n+1)!}\right)^2.$$

This gives another reason why (2.4) is a useful formula.

3. Let us consider

$$A_\alpha \equiv \int_0^1 x^\alpha K(x)\,dx, \tag{3.1}$$

$$B_\alpha \equiv \int_0^1 x^\alpha E(x)\,dx, \tag{3.2}$$

where

$$K(x) = \int_0^1 (1-t^2)^{-1/2}(1-x^2t^2)^{-1/2}\,dt, \tag{3.3}$$

$$E(x) = \int_0^1 (1-t^2)^{-1/2}(1-x^2t^2)^{1/2}\,dt \tag{3.4}$$

are the complete elliptic integrals of the first and second kind, respectively.

From the well-known formulas [4]

$$x(1-x^2)K'(x) = E(x)-(1-x^2)K(x), \tag{3.5}$$

$$xE'(x) = E(x)-K(x), \tag{3.6}$$

we easily obtain

$$\begin{aligned} B_\alpha-(A_\alpha-A_{\alpha+2}) &= \int_0^1 x^{\alpha+1}(1-x^2)K'(x)\,dx \\ &= -\int_0^1 K(x)[(\alpha+1)x^\alpha-(\alpha+3)x^{\alpha+2}]\,dx \\ &= -(\alpha+1)A_\alpha+(\alpha+3)A_{\alpha+2}, \end{aligned}$$

i.e.,

$$(\alpha+2)A_{\alpha+2}-\alpha A_\alpha = B_\alpha \tag{3.7}$$

and

$$\begin{aligned} B_\alpha - A_\alpha &= \int_0^1 x^{\alpha+1}E'(x)\,dt = 1-(\alpha+1)\int_0^1 x^\alpha E(x)\,dx \\ &= 1-(\alpha+1)B_\alpha, \end{aligned}$$

i.e.,

$$(\alpha+2)B_\alpha = 1+A_\alpha. \tag{3.8}$$

Equations (3.7) and (3.8) imply

$$(\alpha+2)^2A_{\alpha+2}-(\alpha+1)^2A_\alpha = 1, \tag{3.9}$$

$$(\alpha+2)(\alpha+4)B_{\alpha+2}-(\alpha+1)^2B_\alpha = 2. \tag{3.10}$$

By introducing

$$C_\alpha \equiv \left[\frac{\Gamma(\alpha+1)}{\Gamma(\alpha+\frac{1}{2})}\right]^2 A_{2\alpha} = \frac{\pi}{4}\frac{\Gamma^2(\alpha+1)}{\Gamma(\alpha+\frac{1}{2})\Gamma(\alpha+\frac{3}{2})}\,{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, \alpha+\frac{1}{2} \\ 1, & \alpha+\frac{3}{2}\end{matrix}\right] \tag{3.11}$$

and

$$\begin{aligned} D_\alpha &\equiv \frac{\Gamma(\alpha+1)\Gamma(\alpha+2)}{\Gamma^2(\alpha+\frac{1}{2})} B_{2\alpha} \\ &= \frac{\pi}{4} \frac{\Gamma(\alpha+1)\Gamma(\alpha+2)}{\Gamma(\alpha+\frac{1}{2})\Gamma(\alpha+\frac{3}{2})} {}_3F_2\left[\begin{matrix} -\frac{1}{2}, & \frac{1}{2}, \alpha+\frac{1}{2} \\ 1, & \alpha+\frac{3}{2} \end{matrix}\right], \end{aligned} \tag{3.12}$$

it follows that

$$C_{\alpha+1} - C_\alpha = \frac{1}{4}\left[\frac{\Gamma(\alpha+1)}{\Gamma(\alpha+\frac{3}{2})}\right]^2 \tag{3.13}$$

and

$$D_{\alpha+1} - D_\alpha = \frac{1}{2} \frac{\Gamma(\alpha+1)\Gamma(\alpha+2)}{\Gamma^2(\alpha+\frac{3}{2})}, \tag{3.14}$$

whence ($n = 0, 1, 2, \cdots$)

$$C_{\alpha+n} = C_\alpha + \frac{1}{4}\sum_{r=0}^{n-1}\left[\frac{\Gamma(\alpha+r+1)}{\Gamma(\alpha+r+\frac{3}{2})}\right]^2 \tag{3.15}$$

and

$$D_{\alpha+n} = D_\alpha + \frac{1}{2}\sum_{r=0}^{n-1} \frac{\Gamma(\alpha+r+1)\Gamma(\alpha+r+2)}{\Gamma^2(\alpha+r+\frac{3}{2})}. \tag{3.16}$$

By observing that [5]

$$C_{1/2} = \frac{\pi}{4}, \quad C_0 = \frac{2G}{\pi}, \quad C_{-1/4} = \frac{\pi}{8}, \tag{3.17}$$

it is easy to obtain (1.1), (1.2), and (1.3) from (3.15). Our results (3.15) and (3.16) are an interesting generalization of Ramanujan's formulas.

With $\alpha = 1/2$, (3.16) becomes

$$D_{n+(1/2)} = \frac{\pi}{4}\sum_{r=0}^{n} \frac{(\frac{1}{2})_r(\frac{3}{2})_r}{(r!)^2}. \tag{3.18}$$

On the other hand, we have (cf. the derivation of (2.1))

$$\begin{aligned} D_{n+(1/2)} &= \frac{1}{4} \frac{\Gamma(n+\frac{3}{2})\Gamma(n+\frac{5}{2})}{(n!)^2} \lim_{\alpha\to -n} \int_0^1 t^{\alpha-(1/2)}(1-t)^{-1/2}\,dt \int_0^1 (tx)^n(1-tx)^{1/2}\,dx \\ &= \frac{3\pi}{8} \frac{(\frac{5}{2})_n}{n!} \sum_{r=0}^{n} \frac{1}{(n-r)!} \frac{r+1}{r+\frac{3}{2}} \left(-\frac{1}{2}\right)_{n-r}. \end{aligned} \tag{3.19}$$

Hence, we get the identity

$$\sum_{r=0}^{n} \frac{(\frac{1}{2})_r(\frac{3}{2})_r}{(r!)^2} = \frac{3}{2} \frac{(\frac{5}{2})_n}{n!} \sum_{r=0}^{n} \frac{1}{(n-r)!} \frac{r+1}{r+\frac{3}{2}} \left(-\frac{1}{2}\right)_{n-r}, \tag{3.20}$$

equivalent to the integral formula

$$\begin{aligned} &\frac{1}{x}(1-x)^{-1/2} - \frac{1}{2} x^{-3/2}(1-x)^{1/2} \log\frac{1+\sqrt{x}}{1-\sqrt{x}} \\ &= \int_0^1 (1-t)^{1/2}(1-xt)^{-2} {}_2F_1\left(-\frac{1}{2}, \frac{1}{2}; 1; xt\right) dt \\ &= B\left(\delta+1, \frac{3}{2}\right)(1-x)^{-2} {}_2F_1\left(-\frac{1}{2}, \frac{1}{2}; 1; x\right), \end{aligned} \tag{3.21}$$

which, by using

$$\frac{\Gamma(\delta+\frac{5}{2})}{\Gamma(\delta+1)\Gamma(\frac{3}{2})}=\frac{3}{2\pi}\int_0^1 t^{1/2}(1-t)^{-5/2}\left[t^{1+\delta}-1+(1+\delta)\frac{1-t}{t}\right]dt, \tag{3.22}$$

can be formally inverted to give

$$\begin{aligned}{}_2F_1\left(-\frac{1}{2},\frac{1}{2};1;x\right)&=\frac{3}{2\pi}(1-x)^2\int_0^1 t^{1/2}(1-t)^{-5/2}\\&\quad\cdot\left[tw(xt)-w(x)+\frac{1-t}{t}\left(1+x\frac{d}{dx}\right)w(x)\right]dt,\end{aligned} \tag{3.23}$$

$$\left(w(x)=\frac{1}{x}(1-x)^{-1/2}-\frac{1}{2}x^{-3/2}(1-x)^{1/2}\log\left(\frac{1+\sqrt{x}}{1-\sqrt{x}}\right)\right).$$

Some final remarks are in order. First, we note that

$${}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, \alpha+n\\ 1, & \alpha+n+1\end{matrix}\right]=\frac{1}{\pi}\int_0^1 x^{-1/2}(1-x)^{-1/2}{}_2F_1\left(\frac{1}{2},\alpha+n;\alpha+n+1;x\right)dx.$$

Now [6, (25)]

$$\begin{aligned}{}_2F_1\left(\frac{1}{2},\alpha+n;\alpha+n+1;x\right)&=\frac{(\alpha+1)_n}{(\alpha+\frac{1}{2})_n}\sum_{r=0}^n(-1)^r\binom{n}{r}\frac{(\frac{1}{2})_r}{(\alpha+1)_r}(1-x)^r\\&\quad\cdot{}_2F_1\left(\alpha+r,\frac{1}{2}+r;\alpha+r+1;x\right),\end{aligned} \tag{3.24}$$

and thus

$$\begin{aligned}{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, \alpha+n\\ 1, & \alpha+n+1\end{matrix}\right]&=\frac{(\alpha+1)_n}{(\alpha+\frac{1}{2})_n}\sum_{r=0}^n(-1)^r\binom{n}{r}\frac{(\frac{1}{2})_r}{(\alpha+1)_r r!}\\&\quad\cdot{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}+r, \alpha+r\\ r+1, & \alpha+r+1\end{matrix}\right].\end{aligned} \tag{3.25}$$

This formula—which, for $\alpha=1$, reduces to (2.4)—enables us to express

$${}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}+n, \alpha+n\\ n+1, & \alpha+n+1\end{matrix}\right]$$

in terms of $C_{\alpha+r-(1/2)}$, $r=0,1,\cdots,n$.

Next, we have

$$\begin{aligned}\int_0^1 x^{\alpha-1}{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right)dx&=\frac{1}{\pi}\int_0^1 t^{(1/2)-\alpha}(1-t)^{-1/2}\,dt\int_0^1(tx)^{\alpha-1}(1-tx)^{-1/2}\,dx\\&=\frac{1}{\pi}\int_0^1 t^{-(1/2)-\alpha}(1-t)^{-1/2}\,dt\int_0^t x^{\alpha-1}(1-x)^{-1/2}\,dx\\&=\frac{1}{\pi}\int_0^1 x^{\alpha-1}(1-x)^{-1/2}\,dx\\&\quad\cdot\left[\int_0^1 t^{-(1/2)-\alpha}(1-t)^{-1/2}\,dt-\int_0^x t^{-(1/2)-\alpha}(1-t)^{-1/2}\,dt\right],\end{aligned}$$

that is, by expanding $(1-t)^{-1/2}$ in a binomial series, and integrating term by term [7, (2)],

$$\frac{1}{\alpha}\,{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, \alpha\\ 1, & \alpha+1\end{matrix}\right]=\frac{\Gamma(\alpha)\Gamma(\frac{1}{2}-\alpha)}{\Gamma(1-\alpha)\Gamma(\frac{1}{2}+\alpha)}-\sum_{r=0}^{\infty}\frac{(\frac{1}{2})_r^2}{(r!)^2}\frac{1}{r-\alpha+\frac{1}{2}}. \tag{3.26}$$

Let us put $\alpha=n+(1/2)$, $n=0,1,2,\cdots$. A straightforward calculation shows that (as usual, $\Psi(z)=(d/dz)\log\Gamma(z)$)

$$\lim_{\alpha\to n+1/2}\left[\frac{\Gamma(\alpha)\Gamma(\frac{1}{2}-\alpha)}{\Gamma(1-\alpha)\Gamma(\frac{1}{2}+\alpha)}-\frac{(\frac{1}{2})_n^2}{(n!)^2}\frac{1}{n-\alpha+\frac{1}{2}}\right]=2\frac{(\frac{1}{2})_n^2}{(n!)^2}\left[\Psi(n+1)-\Psi\left(n+\frac{1}{2}\right)\right]$$

and thus

$$\frac{1}{n+\frac{1}{2}}\,{}_3F_2\left[\begin{matrix}\frac{1}{2}, & \frac{1}{2}, n+\frac{1}{2}\\ 1, & n+\frac{3}{2}\end{matrix}\right]=-\sum_{r=0}^{\infty}{}'\,\frac{(\frac{1}{2})_r^2}{(r!)^2}\frac{1}{r-n}+2\frac{(\frac{1}{2})_r^2}{(n!)^2}\left[\Psi(n+1)-\Psi\left(n+\frac{1}{2}\right)\right], \tag{3.27}$$

$\sum'$ having an obvious meaning. Since

$$\sum_{r=0}^{\infty}{}'\,\frac{(\frac{1}{2})_r^2}{(r!)^2}\frac{1}{r-n}=\sum_{r=0}^{n-1}\frac{(\frac{1}{2})_r^2}{(r!)^2}\frac{1}{r-n}+\left[\frac{(\frac{1}{2})_{n+1}}{(n+1)!}\right]^2{}_4F_3\left[\begin{matrix}1, & 1, n+\frac{3}{2}, n+\frac{3}{2}\\ 2, & n+2, n+2\end{matrix}\right], \tag{3.28}$$

(3.27) gives

$${}_4F_3\left[\begin{matrix}1, & 1, n+\frac{3}{2}, n+\frac{3}{2}\\ 2, & n+2, n+2\end{matrix}\right]$$

in terms of C_n.

We have explicitly checked (3.27), for $n=0,1,2,3$, by writing

$$\begin{aligned}\sum_{r=n+1}^{\infty}\frac{(\frac{1}{2})_r^2}{(r!)^2}\frac{1}{r-n}&=\int_0^1 x^{-(n+1)}\left[{}_2F_1\left(\frac{1}{2},\frac{1}{2};1;x\right)-\sum_{r=0}^{n}\frac{(\frac{1}{2})_r^2}{(r!)^2}x^r\right]dx\\ &=\frac{1}{\pi}\int_0^1 t^{-1/2}(1-t)^{-1/2}\,dt\int_0^1 x^{-(n+1)}\\ &\quad\cdot\left[(1-tx)^{-1/2}-\sum_{r=0}^{n}\frac{(\frac{1}{2})_r}{r!}(tx)^r\right]dx,\end{aligned}$$

and by using the formula

$$\begin{aligned}H_n(t)&\equiv\int_0^1 x^{-(n+1)}\left[(1-tx)^{-1/2}-\sum_{r=0}^{n}\frac{(\frac{1}{2})_r}{r!}(tx)^r\right]dx\\ &=-\frac{1}{n}\varphi_{n,0}(t)-\frac{1}{2}\frac{t}{n(n-1)}\varphi_{n-1,1}(t)\\ &\quad-\frac{1\cdot 3}{2^2}\frac{t^2}{n(n-1)(n-2)}\varphi_{n-2,2}(t)\\ &\quad-\cdots+\frac{1\cdot 3\cdots(2n-1)}{2^n n!}t^nL_n(t),\end{aligned} \tag{3.29}$$

where

$$\varphi_{n,r}(t)\equiv(1-t)^{-(r+(1/2))}-\sum_{j=0}^{n}\frac{(r+\frac{1}{2})_j}{j!}t^j \tag{3.30}$$

and

$$L_n(t) \equiv \int_0^1 \frac{1}{x}[(1-tx)^{-(n+(1/2))}-1]\,dx. \tag{3.31}$$

Explicitly, we have

$$L_0(t) = -2\log\left(\frac{1+\sqrt{1-t}}{2}\right); \tag{3.32}$$

furthermore, it is easy to show that

$$L_{n+1}(t) = L_n(t) + \frac{1}{n+\frac{1}{2}}[(1-t)^{-(n+(1/2))}-1]. \tag{3.33}$$

For the sake of completeness, we also quote the recurrence relation

$$M_{n+1} = \frac{2n+1}{2n+2}M_n - \frac{1}{(n+1)(2n+1)} + \frac{\pi}{4}\frac{(\frac{1}{2})_n}{(n+1)(n+1)!}, \tag{3.34}$$

where

$$\begin{aligned} M_n &\equiv \int_0^1 t^{n-(1/2)}(1-t)^{-1/2}\log\left(\frac{1+\sqrt{1-t}}{2}\right) dt \\ &= 2\int_0^{\pi/2} \sin^{2n}\Theta \log\left(\frac{1+\cos\Theta}{2}\right) d\Theta. \end{aligned} \tag{3.35}$$

Last, we recall that

$$M_0 = -2\pi\log 2 + 4G. \tag{3.36}$$

This result follows from (3.35) by using

$$\log\left(\frac{1+\cos\Theta}{2}\right) = 2\sum_{r=0}^{\infty}\frac{(-1)^r}{r+1}\cos(r+1)\Theta - 2\log 2.$$

The proof of (3.29)-(3.34) is left as an exercise to the reader.

Acknowledgment. We express our sincere gratitude to Professor B. C. Berndt for his kind encouragement.

ON TWO CONJECTURES CONCERNING THE MULTIPLICITY OF SOLUTIONS OF A DIRICHLET PROBLEM*

HANS G. KAPER† AND MAN KAM KWONG†

Abstract. It is shown that there exist two strictly convex functions, both denoted by f on $(-\infty, \infty)$, the first satisfying the conditions $f'(-\infty) < 1$ and $n^2 < f'(\infty) < (n+1)^2$ and the second satisfying the conditions $(n-1)^2 < f'(-\infty) < n^2 < f'(\infty) < (n+1)^2$, such that the Dirichlet problem for the second-order nonlinear differential equation $u'' + f(u) = h(x)$ on $[0, \pi]$ has at least $2(n+1)$ and five solutions, respectively. This settles in the negative two questions raised by Lazer and McKenna [*SIAM Review,* 32 (1990), pp. 537–578].

Key words. nonlinear boundary value problem, multiplicity of solutions, variation index, topological degree

1. The conjectures.

Recently, Lazer and McKenna [1] proposed a modified mathematical model for the onset of large-amplitude oscillations in suspension bridges forced by winds with specific velocities. Their study was motivated by the inadequacy of older theories' explanation of the collapse of the Tacoma Narrows Bridge of Seattle in 1941.

In the Lazer and McKenna model, the motion of the bridge is, as usual, governed by a system of differential equations, the complexity of which depends on the degree of approximation and the simplifications one is willing to accept. One of the new ideas introduced by Lazer and McKenna concerned the asymmetry of the restoring force that a cable exerts under expansion and compression. The authors' basic assumption is that the cable "strongly resists expansion, but does not resist compression." The study leads to boundary value problems of semilinear elliptic equations with Dirichlet conditions or second-order ordinary differential equations with periodic boundary conditions.

The study of semilinear elliptic equations with nonlinear restoring-force terms is a worthwhile subject, still largely unexplored. In their article [1], the authors collected several interesting open problems, some of which have not been answered even in the one-dimensional case, when the elliptic equation reduces to a second-order nonlinear ordinary differential equation.

In this article, we take up two of these open problems, namely problems 4 and 3. The problems concern the Dirichlet boundary value problem

$$u'' + f(u) = h(x), \qquad 0 < x < \pi, \tag{1.1}$$

$$u(0) = u(\pi) = 0, \tag{1.2}$$

where f is a genuinely nonlinear Lipschitz continuous function on $(-\infty, \infty)$ and h is any continuous function on $[0, \pi]$. The main objective is to determine upper and lower

† Mathematics and Computer Science Division, Argonne National Laboratory, Argonne, Illinois 60439-4801.

bounds for the number of distinct solutions of (1.1)–(1.2), when f is strictly convex and satisfies one of the following growth conditions:

$$f'(-\infty) < 1, \qquad n^2 < f'(\infty) < (n+1)^2, \tag{1.3}$$

$$(n-1)^2 < f'(-\infty) < n^2 < f'(\infty) < (n+1)^2. \tag{1.4}$$

Strict convexity is imposed to exclude certain degenerate cases. For example, when $f(u) = n^2 u$ for $u \in [-A, A]$, while f' still satisfies the inequalities in (1.3), the choice $h(x) = 0$ gives a continuum of solutions, namely, $u = a\sin(nx)$ for any $a < A$. However, when we construct our counterexamples in §5, we first work under less restrictive conditions on f; we subsequently use a perturbation argument to meet the full requirement.

In the following, we shall refer to a solution of (1.1)–(1.2) as a *D-solution* and reserve the simpler term *solution* for one that satisfies (1.1), but not necessarily the Dirichlet boundary conditions (1.2).

Lazer and McKenna proposed the following two conjectures:

CONJECTURE 1. *If f satisfies the conditions* (1.3), *then the boundary value problem* (1.1)–(1.2) *has at most* $2n$ *solutions for any given* h.

CONJECTURE 2. *If f satisfies the conditions* (1.4), *then the boundary value problem* (1.1)–(1.2) *has at most* 3 *solutions for any given* h.

In this article we show that there exist a constant-valued function h and a function f, which satisfy conditions (1.3), such that the boundary value problem (1.1)–(1.2) has at least $2(n+1)$ solutions. A slight modification of this counterexample will give a function which satisfies the conditions (1.4), such that the corresponding boundary value problem has at least five solutions. These results refute both conjectures of Lazer and McKenna.

Although all it takes to disprove a conjecture is one counterexample, augmented by convincing numerical data, we prefer to discuss in more depth the theoretical reasoning that led us to the discovery of the example. Such analytical considerations give a better understanding of the structure of the solution space and shed light on similar open problems.

We use the familiar shooting method. In §2 we sketch the simple concept of the variation index of a solution and its use in tracking the number of solutions. Although the index does not precisely indicate what must happen, it does show what may happen and, in our case, suggests that something can go wrong if we start with a solution having an undesirable index.

In §3 we present the analytical reasoning that led us to the counterexample. Our discussion pertains only to the particular case $n = 2$; extension to general n is obvious. In §4 we present a serendipitous result about the number of solutions of the Dirichlet problem (1.1)–(1.2) when the function h is even. In §5 we present the counterexamples along with some numerical results.

2. The variation index. Proofs in this section are only sketched, since all are elementary; in fact, some are quite well known. We consider the general inhomogeneous case (1.1) and the Dirichlet conditions (1.2).

The shooting method is intuitive. We replace the boundary value problem with an initial value problem, where, instead of (1.2), we impose the conditions

$$u(0) = 0, \qquad u'(0) = \alpha. \tag{2.1}$$

Here, $\alpha \in (-\infty, \infty)$ serves as a parameter. The solution of the initial value problem is a continuous function of both x and α; we denote its values by $u(x, \alpha)$. If, for some choice of α, $u(\pi, \alpha) = 0$, we have obtained a D-solution. Thus, by keeping tabs on how often $u(\pi, \alpha)$ changes sign as α varies from $-\infty$ to ∞, we can determine the total number of D-solutions. The job is often done by analyzing the upward/downward movement of the "tail end" of the solution trajectory.

Another technique, suitable for $h(x) = 0$, is to carefully follow the zeros of $u(x, \alpha)$, that is, the intersections of the graph of u with the x axis. Since a solution is never tangent to the x axis, the zeros of $u(x, \alpha)$ can only slide along the x axis and appear or disappear through the right endpoint π. More generally, and especially for inhomogeneous equations, we can follow the intersections of $u(x, \alpha)$ with a fixed D-solution, $u(x, \beta)$ say, for a suitable β. By the uniqueness theorem for initial value problems, no two distinct solutions $u(x, \alpha)$ and $u(x, \beta)$ of (1.1) can be tangent to each other at any $x \in [0, \pi]$. Thus, as α varies continuously, the intersection points of $u(x, \alpha)$ with $u(x, \beta)$ can only slide along the graph of the latter. The intersection number of the two solutions is an elementary interpretation of the abstract concept of topological degree. If a decrease in the number of intersections is noticed as α varies from one value to another, the lost intersection point must have slipped away through the right endpoint at some intermediate value of α. That value corresponds to a D-solution.

The intersection number of a solution $u(x, \beta)$, with a neighboring solution $u(x, \alpha)$, $\alpha \approx \beta$, can be approximated by studying the function w,

$$w(x) = w(x, \beta) = \partial u(x, \alpha)/\partial \alpha|_{\alpha=\beta}, \tag{2.2}$$

which satisfies the variational equation

$$w''(x) + f'(u)w(x) = 0, \qquad x > 0, \tag{2.3}$$

with initial conditions

$$w(0) = 0, \qquad w'(0) = 1. \tag{2.4}$$

In (2.3) we substitute the solution $u(x, \beta)$ into the expression $f'(u)$ as if it is a known function, and we regard (2.3) as a linear differential equation of w with the known coefficient $f'(u(x, \beta))$. The number of times that $w(x)$ changes sign in $[0, \pi]$ gives valuable information. The fact that w satisfies a linear differential equation makes it possible to apply the classical Sturm comparison technique.

We say that the *variation index* of $u(x, \beta)$ is k if the corresponding function w has k zeros in $(0, \pi]$. Note that $x = 0$ is always a zero, but it is not counted. If, furthermore, $w(\pi) \neq 0$, we say that the variation index is k^+. For simplicity, we shall use the abbreviated term *index*.

The use of the variational equation to study multiplicity of solutions has a long history, usually associated with bifurcation theory. In particular we note its use by Coffman [3], and subsequently by McLeod and Serrin [4], Ni and Nussbaum [5], and Kwong et al. [6]–[9] in the study of the uniqueness and nonuniqueness of the ground state of semilinear elliptic equations. The concept of the index is used throughout these works, even though it is not identified by name. A definition of the variation index was given recently by Clemons [10].

What is the significance of the sign of $w(x)$ at a given point x? The sign tells us whether $u(x, \alpha)$ increases or decreases as α is slightly increased from β. What about the index itself? If the index is k^+, there is sequence of $k + 1$ points

$$0 < x_1 < x_2 < \cdots < x_{k+1} < \pi, \tag{2.5}$$

such that

$$(2.6)\quad \left.\frac{\partial u(x_1,\alpha)}{\partial\alpha}\right|_{\alpha=\beta} > 0,\ -\left.\frac{\partial u(x_2,\alpha)}{\partial\alpha}\right|_{\alpha=\beta} > 0, \ldots, (-1)^k \left.\frac{\partial u(x_{k+1},\alpha)}{\partial\alpha}\right|_{\alpha=\beta} > 0.$$

Thus, there exists a small enough $\epsilon > 0$ such that for all $\alpha \in (\beta, \beta+\epsilon)$,

$$(2.7)\qquad u(x_1,\alpha) > u(x_1,\beta),\ u(x_2,\alpha) < u(x_2,\beta),\ \cdots$$

It follows that $u(x,\alpha)$ intersects $u(x,\beta)$ at least k times. The same is true for $\alpha \in (\beta-\epsilon,\beta)$. Note that in the degenerate case, when the index is k but not k^+, we can assert only the existence of $k-1$ intersection points.

Let us consider an example to see how the index can be used to deduce multiplicity results. Under the assumption $f'(-\infty) < 1$, it is easy to see that, given any β, we can find an α sufficiently negative that $u(x,\alpha)$ does not intersect $u(x,\beta)$ at all. On the other hand, under the additional assumption that $f'(\infty) > 1$, it can be shown that there exists a δ sufficiently large that $u(x,\delta)$ intersects $u(x,\beta)$ exactly once. Suppose now that $u(x,\beta)$ is actually a D-solution and that its index is known to be k^+. Let us decrease α from β to γ. Initially, when α is sufficiently close to β, $u(x,\alpha)$ has k intersection points with $u(x,\beta)$. As α reaches γ, all of these are lost. We thus conclude that at least k intermediate values of α give rise to D-solutions. Likewise, if we increase α from β to δ, $k-1$ intersection points are lost, adding $k-1$ more D-solutions. Including $u(x,\beta)$, there is a total of $2k$ D-solutions.

In [2], Lazer and McKenna studied the equation (1.1) with $h(x) = s\sin(x) + h_1(x)$ for large s. They constructed a large, almost linear solution, which can be shown to have index n^+. Starting with this D-solution, we can use the above arguments to obtain the main theorem of [2], namely, that there exist at least $2n$ D-solutions. The proof we sketched here is, of course, only a paraphrase of that in [2], with the role of the index underscored.

3. Toward the counterexamples. In this section, we confine ourselves mainly to Conjecture 1 described in §1, assuming that (1.3) holds. Some of the observations below, indicated by the presence of the modifiers *generic* or *generically*, are meant to be intuitive and nonrigorous.

If there exist an infinite number of D-solutions, then the conjecture is obviously false. So we henceforth assume that there are a finite number of D-solutions.

We order the D-solutions according to the magnitude of the corresponding parameter α and refer to the D-solution with the smallest (largest) α as the *first* (*last*) D-solution. We know from the discussion in the preceding section that the index of the first solution is zero or at most 1 (but not 1^+). Intuitively, we know that a degenerate index is nongeneric and occurs rarely. In any case, a small perturbation can bump it into a nondegenerate index. Thus, generically the first solution has index zero.

Using the comparison principle and the convexity assumption of f, it can easily be shown that from the third D-solution onward, the index cannot be zero. The discussion in the preceding section also shows that the index of the last D-solution is at most 2. Hence, if more than two D-solutions exists, the last one generically has index 1^+.

The first solution cannot intersect any other solution in $(0,\pi)$; otherwise, a continuity argument involving decreasing α will give an extra solution before the first one. On the other hand, we claim that any two other solutions must intersect.

We prove the claim by contradiction. Let u_1 denote the first solution and u_2, u_3 two other solutions. If $u_2 \leq u_3$ (they do not intersect), then both $u_2 - u_1$ and $u_3 - u_1$ are nonnegative functions satisfying a second-order differential equation of the form

$$(3.1) \qquad (u_i - u_1)'' + \frac{f(u_i) - f(u_1)}{u_i - u_1}(u_i - u_1) = 0, \qquad i = 2, 3.$$

The convexity of f, however, implies that the coefficient in the equation for $i = 3$ is larger than that in the equation for $i = 2$. Hence, by the Sturm comparison theorem, $u_3 - u_1$ oscillates faster than $u_2 - u_1$, a contradiction.

We now restrict ourselves to the case $n = 2$ and assume that h is symmetric,

$$(3.2) \qquad h(x) = h(\pi - x), \qquad 0 < x < \pi.$$

By (1.3), the coefficient $f'(u)$ in (2.3) is less than 9. By the Sturm comparison theorem, $w(x)$ cannot change sign more than twice. Thus the index of any $u(x, \alpha)$ is at most 2^+. Ignoring the degenerate cases, we therefore have three choices: 0, 1^+, and 2^+. The Sturm comparison theorem also tells us that no two solutions can intersect more than twice in $(0, \pi]$. It follows that no two D-solutions can intersect more than once in the interior $(0, \pi)$.

The first D-solution, denoted by $u(x, \beta)$, has index zero; hence, as we increase α from β, the tail of the graph, $u(\pi, \alpha)$, initially moves upward. Thus $u(\pi, \alpha) > 0$ for α greater than but close to β. In order to produce the next solution, $u(x, \gamma)$, the tail must start to move downward for some value of α before γ and continue to do so until γ is reached. Such movement of the tail can happen only if the index of $u(x, \gamma)$ is odd (again ignoring the degenerate case); thus, the only choice is 1^+. If $u(x, \gamma)$ is not the last D-solution, we can continue this argument to conclude that, generically, adjacent D-solutions have indices of opposite parity. The argument also shows that generically we expect an even number of D-solutions, an expectation that is confirmed in the symmetric case below by Theorem 1. A degeneracy may occur when the tail of the graph moves towards zero and then bounces back in the opposite direction, in which case we have a degenerate index. With all these observations, we conclude that the possible generic configurations of indices are $0, 0$ or $0, 1^+$ for two D-solutions and $0, 1^+, 2^+, 1^+$ for four D-solutions.

What additional properties are imposed by the symmetry of h? The first D-solution must be symmetric; otherwise it intersects its reflection, contradicting our assertion that the first solution does not intersect any other solutions. If more than two D-solutions exists, the last one cannot be symmetric. Indeed, it must intersect the second D-solution exactly once in $(0, \pi)$. Reflecting the second D-solution will then give another D-solution having a larger α than the last D-solution, a contradiction. Now that we know the last D-solution is not symmetric, its reflection must be a different D-solution and must have the same index 1^+. The only way this situation can happen in the four D-solution case is, therefore, that the second and fourth D-solutions are reflections of each other, and this forces the third to be symmetric with index 2^+ (recall that the first D-solution must be symmetric).

Although intuitive, these observations provide us enough clues for the search for a counterexample. Suppose we start with an equation that has a symmetric D-solution with index 1^+. We have just seen that this is incompatible with the case with four D-solutions. Hence, either we have only two D-solutions or the conjecture is false. We pick an example in which the index of the symmetric D-solution is 1^+ but very close to 2. Let the maximum of the D-solution be M. We still have freedom to modify

$f(u)$ for $u > M$. A small decrease in α brings part of the solution above M, and this enables us to manipulate $f(u)$, for $u > M$, so that the solution will bend down fast enough to give one more D-solution—thus excluding the case with two D-solutions.

Once a concrete example has been constructed, it is not difficult to furnish a rigorous proof.

We can argue in a similar way to obtain a counterexample to Conjecture 2. It so happened that almost the same nonlinear function $f(u)$ worked for both conjectures.

4. Interlude. Before proceeding with the actual construction of a counterexample, we digress for a moment to give a serendipitous result on the evenness of the number of D-solutions for symmetric equations, which follows from the arguments used in the preceding section.

THEOREM 1. *Suppose that* (1.3) *and* (3.2) *hold. Then* (1.1)–(1.2) *has either exactly one D-solution or an even number of D-solutions. In the latter case, there is a pair of distinct symmetric D-solutions.*

Proof. As seen before, the first D-solution is symmetric. If there is a nonsymmetric D-solution $u(x,\beta)$, its reflection $u(x,\gamma) = u(\pi - x, \beta)$ is also a D-solution. At the midpoint of the interval, $u'(\pi/2,\beta) = -u'(\pi/2,\gamma) \neq 0$. A shooting argument shows that at some intermediate α between β and γ, $u'(\pi/2,\alpha) = 0$, and this will give a second symmetric D-solution. There cannot be a third symmetric D-solution; otherwise it will intersect the second symmetric D-solution at some point different from $\pi/2$. By symmetry the two D-solutions will have more than two intersection points in $(0,\pi)$, contrary to the upper bound imposed on $f(u)$. The conclusion now follows from the fact that the remaining nonsymmetric D-solutions must occur in pairs. □

5. The counterexamples. Let us, for the time being, overlook the requirement of strict convexity on f and choose for f a non-C^1 function. This will simplify the analysis and the programming for our numerical computation. For the first counterexample, let

$$f(u) = \begin{cases} 8u - 439/100, & u \in [1,\infty), \\ 361u/100, & u \in [-C,1), \\ -361C/100, & u \in (-\infty,-C), \end{cases} \tag{5.1}$$

where C is some suitable large positive number. For the second counterexample, we simply let C be ∞ in the second line of (5.1) and eliminate the third line. We choose a constant forcing term on the right-hand side of (1.1),

$$h(x) = \frac{361}{100}\left(\frac{1+\cos\frac{\pi}{20}}{\cos\frac{\pi}{20}}\right), \tag{5.2}$$

which is determined so that the function

$$u(x,\beta) = \frac{1}{1+\cos\frac{\pi}{20}}\cos\left(\frac{19}{10}\left(x-\frac{\pi}{2}\right)\right) + \frac{1+\cos\frac{\pi}{20}}{\cos\frac{\pi}{20}} \tag{5.3}$$

is a D-solution of (1.1), where $\beta = u'(0,\beta)$.

The existence of at least six D-solutions, for large C, and at least five D-solutions, for $C = \infty$, is confirmed numerically. We start our computation by shooting solutions from $x = 0$ with initial slope between -10 and 10 at increments of 0.1. For the integration we use a fourth/fifth-order Runge–Kutta method from MATLAB, with an error tolerance of 10^{-6}. More accurate computations carried out near the D-solution, by using smaller tolerances and increments of the initial slope, confirm our conclusion.

The data given in Figs. 1 and 2 belong to the choice $C = 1$.

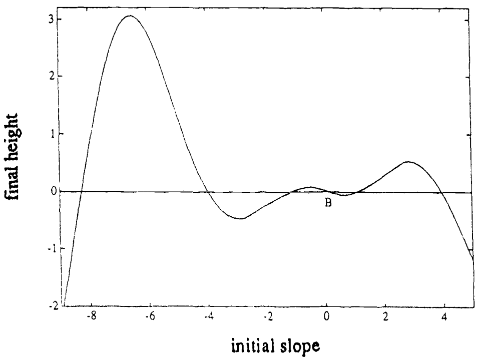

FIG. 1. *Final height $u(\pi, \alpha)$ vs. initial slope α.*

Figure 1 shows the graph of the final height $u(\pi, \alpha)$ as a function of the initial slope $\alpha = u'(0, \alpha)$ for $\alpha \in [-9, 5]$. Each intersection of the graph with the α axis gives a D-solution. Six D-solutions are clearly identifiable. No other solutions turn up when a wider range of α is used. For the second counterexample, with $C = \infty$, the corresponding graph is almost the same, except that the part where the initial slope is less than -5 is entirely above the axis; hence, there are five D-solutions.

Figure 2 shows the graphs of three shooting solutions $x \mapsto u(x, \alpha)$ for different values of the initial slope α.

Note that the graph in Fig. 1 is nowhere tangent to the α axis, indicating that none of the D-solutions is degenerate. It follows that a sufficiently small perturbation will not alter the total number of D-solutions. Thus, if we replace our choice (5.1) of f by a strictly convex smooth function, all six D-solutions will be preserved.

A theoretical proof of the existence of more than four D-solutions can be given along the line of reasoning set forth in §3. The computations, which are straightforward, are omitted.

The D-solution (5.3) is represented by the point B in Fig. 1 and by the graph labeled u(x,b) in Fig. 2. It has index 1^+, since the variational equation is

$$w''(x) + \frac{361}{100} w(x) = 0, \quad w(0) = 0, \quad w'(0) = 1, \tag{5.4}$$

whose solution $w(x) = \sin(19x/10)$ has only one zero in $(0, \pi)$. As shown in §2, this means that if α decreases from β, the final height $u(\pi, \alpha)$ moves upward, at least for a while. This property is confirmed in Fig. 1, as the part of the graph to the immediate left of B is above the α axis. In Fig. 2, the same property is manifested by the fact that the solution labeled u(x,a) intersects u(x,b) once and remains above it afterwards.

We continue to decrease α to γ; the corresponding solution $u(x, \gamma)$ is labeled u(x,c) in Fig. 2. All these solutions can be computed analytically because the equations are linear in each of the two disjoint regions $u < 1$ and $u > 1$. Indeed, the difference $u(x, \beta) - u(x, \gamma)$ is simply a multiple of $\sin(19x/20)$, as long as $u(x, \alpha)$ remains less than one. The portion of the solution above the dotted line $u = 1$ is now subjected to a much larger "restoring force," as the coefficient of the linear term

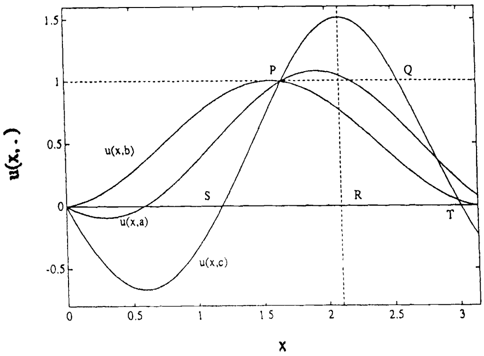

FIG. 2. *Shooting solutions for three different initial slopes.*

has jumped from 361/100 to 8. It is not hard to show that the duration for which the solution can remain above $u = 1$, i.e., the length PQ in Fig. 2, cannot be more than $\pi/\sqrt{8}$. The horizontal distance between the point S, where u(x,c) crosses the x axis, and the point P diminishes as γ decreases and can be arranged to be arbitrarily small if C is chosen sufficiently large. The symmetry of u(x,c) about the point R, halfway between P and Q, implies that the graph must intersect the x axis again at some point T, with $SR = RT$. If S is sufficiently close to P, then T falls within $(0, \pi)$, as shown. The change of sign from $u(\pi, \alpha)$ to $u(\pi, \gamma)$ implies the existence of a D-solution between α and γ. There are two intersection points between $u(x, \beta)$ and $u(x, \gamma)$. As the initial slope is further decreased below γ, two more D-solutions must occur before both of the intersection points are completely lost. Of these three extra solutions, one may be the first D-solution and so is symmetric. The other two will give two more D-solutions upon reflection.

It is easy to see how the construction can be extended to values of $n > 2$. We need to start with a symmetric D-solution having index $(n-1)^+$, which can be perturbed slightly to give a symmetric D-solution with index n^+. We leave it to the readers to supply the details.

VARIATIONAL FORMULATIONS FOR THE DETERMINATION OF RESONANT STATES IN SCATTERING PROBLEMS*

M. LENOIR†, M. VULLIERME-LEDARD†, AND C. HAZARD†

Abstract. Consider the scattering of an acoustic wave by a rigid obstacle. The poles of the analytical continuation of the resolvent operator are called scattering frequencies. On their localization depend the time-decay of the solution and the location of the energy peaks of the steady-state solution.

Two methods are proposed to construct explicitly the analytical continuation of the resolvent: the localized finite element method or the coupling between variational formulation and integral representation, which both rely upon the reduction of the exterior Helmholtz problem to a bounded domain. The determination of the scattering frequencies then amounts to solving a nonlinear eigenvalue problem for a completely continuous operator.

Then, the expansion of the approximate steady-state solution in the vicinity of a scattering frequency is computed. Numerical results for a simple one-dimensional problem are presented.

Key words. scattering frequencies, localized finite element method, integral representation

1. Introduction.

1.1. Motivation.

One of the most important questions in the study of coupled vibrations of an elastic solid and a compressible fluid is the determination of the energy transfer between the solid and the fluid. The question of determining the values of the excitation frequency of the structure which makes maximum the radiated acoustic pressure is usually denoted a "radiation problem" (see [7]); these frequencies are referred to as "resonant frequencies." In the case of the scattering of a plane monochromatic acoustic wave, they are the frequencies for which the response of the system shows maxima of amplitude. A similar problem arises in naval hydrodynamics in the study of periodic motions of a ship under the influence of a monochromatic swell; the question is now to compute the frequencies inducing motions of maximum amplitude.

The purpose of this work is to describe a *practical method of computation* of these frequencies together with the associated values of the response of the system. The direct determination of the resonant frequencies appears to be difficult; the study of the singularities of the scattering matrix (the so-called "scattering frequencies" which occur for complex values of the frequency) is, however, easier and provides valuable information about the resonant frequencies which stay along the real axis in the vicinity of these scattering frequencies (see Fig. 1). Recall that the scattering matrix is the operator connecting the asymptotic behaviour of the scattered wave to the incident plane monochromatic wave.

For the wave equation in the exterior of a rigid obstacle, Shenk and Thoe [10] have shown that the scattering frequencies are nothing but the poles of the analytical continuation of the resolvent of the Helmholtz operator. The method we propose relies on this result.

1.2. A brief description of the principle.

The method of coupling between variational formulation and integral representation [5] or the localized finite element method [6] allows us to reduce the exterior Helmholtz problem to a problem set in a

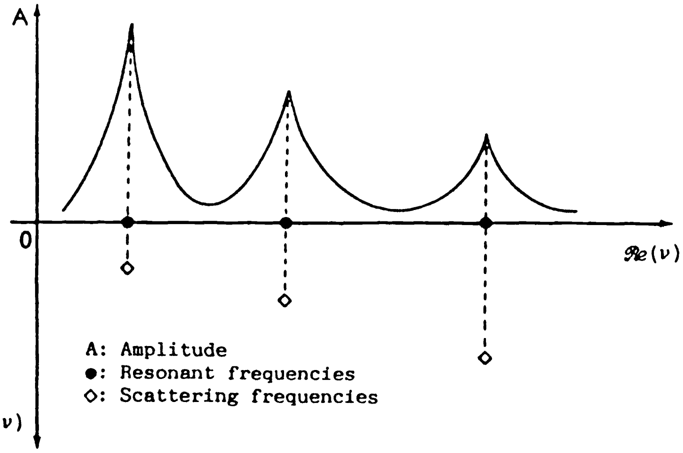

FIG. 1

bounded domain and to exhibit the analytical continuation of the resolvent. The determination of the scattering frequencies reduces then to the solution of a nonlinear eigenvalue problem for a completely continuous operator. This approach is similar to that of Shenk and Thoe [9], which relies upon an integral equation method; it is, however, easier to handle, due to its variational character and due to the fact that no volume potential is needed to remove fictitious singularities of the analytical continuation of the resolvent. The next step consists in expanding the solution in the vicinity of a scattering frequency in order to compute the location of the resonance and the associated amplitude of the solution.

The practical efficiency of our method has been tested in the case of the coupling between a vibrating string and a beam through a density of springs; it is the simplest model for fluid-structure interaction. In this paper we shall only describe the method in the simple case of the wave equation; the application to naval hydrodynamics will be accounted for in a forthcoming paper.

1.3. Some other procedures. Other procedures have been designed for the computation of resonant frequencies. The method of Wei, Majda and Strauss described by Wei [13] relies upon the transient theory of scattering of Lax and Phillips [4]; the solution of the wave equation is actually subject to an asymptotic expansion with respect to time in the following form:

$$u(t)=\sum_{j\in\mathbb{N}} \varphi_j(x)\, e^{-i\nu_j t},$$

where the ν_j are the scattering frequencies. The numerical computation of the longtime solution of the wave equation then allows the identification of the ν_j. The advantage of our procedure is to rely upon the stationary theory of scattering and, therefore, to apply to situations which are not relevant to Lax and Phillips theory, for example, the sea-keeping problem [12]. Also worth mentioning is the work of Ohayon and Sanchez-Palencia [8], which is about the coupling between a structure and a slightly compressible fluid. They first investigate the convergence of the scattering frequencies to the eigenfrequencies of the limit problem associated to an incompressible fluid. Then, they determine the resonant frequencies by expanding the solution with respect to the compressibility in the vicinity of the eigenfrequencies.

2. The resolvent. By Ω we denote the exterior of a compact set in $\mathbb{R}^n$; its boundary is denoted by Γ. The function $\Phi(x, t)$ is the solution of the wave equation

$$\frac{\partial^2\Phi}{\partial t^2}-c^2\Delta\Phi=0 \quad \text{in } \Omega,$$

$$\frac{\partial\Phi}{\partial n}=\operatorname{Re}\,(f(x)\,e^{-i\omega t}) \quad \text{on } \Gamma, f \text{ and } \omega \text{ being given},$$

$$\left(\Phi(x,0), \frac{\partial\Phi}{\partial t}(x,0)\right)=(\Phi_1(x), \Phi_2(x)), \quad \text{given.}$$

The limiting amplitude principle (Eidus [2]) shows that, as $t\to+\infty$, $\frac{1}{2}e^{i\omega t}(\Phi(x,t)+i\Phi(x,t+(\pi/2\omega)))$ tends to $\varphi(x)$ in the energy norm on compact sets, where φ is the solution of the reduced wave equation

$$\Delta\varphi+\nu_0\varphi=0 \quad \text{in } \Omega, \quad \text{with } \nu_0=\frac{\omega^2}{c^2},$$

$$(P_{\nu_0}) \qquad \frac{\partial\varphi}{\partial n}=f(x) \quad \text{on } \Gamma,$$

$$\left(\frac{\partial\varphi}{\partial R}-i\sqrt{\nu_0}\,\varphi\right)=o(R^{-(n-1)/2}) \quad (\textit{outgoing} \text{ radiation condition}).$$

If ν is any complex number of *positive imaginary part*, then problem

$$\Delta\varphi+\nu\varphi=0 \quad \text{in } \Omega,$$

$$(Q_\nu) \qquad \frac{\partial\varphi}{\partial n}=f \quad \text{on } \Gamma$$

has a unique solution in $H^1(\Omega)$. In variational form (Q_ν) reads:

$$\int_\Omega \nabla\varphi\,\nabla\bar\psi\,d\omega-\nu\int_\Omega \varphi\bar\psi\,d\omega=\int_\Gamma f\bar\psi\,ds \quad \forall\psi\in H^1(\Omega), \text{ i.e.,}$$

$$(I+S(\nu))\varphi=F(f) \quad \text{in } H^1(\Omega), \text{ where}$$

$$(S(\nu)\varphi\,|\,\psi)_{H^1(\Omega)}=-(1+\nu)\int_\Omega \varphi\bar\psi\,d\omega \quad \text{and} \quad (F(f)\,|\,\psi)_{H^1(\Omega)}=\int_\Gamma f\bar\psi\,ds.$$

By $R(\nu)$ (resolvent) we shall denote the operator $(I+S(\nu))^{-1}$: $H^1(\Omega)\to H^1(\Omega)$.

As $\nu\to\nu_0\in\mathbb{R}^+$, with $\operatorname{Im}(\nu)>0$, by the *limiting absorption principle* the solution φ of (Q_ν) tends to the solution of (P_{ν_0}) (Wilcox [14]). In the sequel we shall show that $R(\nu)$, defined for values of ν such that $\operatorname{Im}(\nu)>0$, actually extends to $\mathbb{C}\backslash\mathbb{R}^-$ as a meromorphic function of ν; the poles are, of course, located in the half-plane of complex numbers satisfying $\operatorname{Im}(\nu)<0$.

Remark 1. When the same limiting procedure is applied to the solution of problem (Q_ν) with $\operatorname{Im}(\nu)<0$, it no longer leads to the solution of problem (P_{ν_0}), but to a function satisfying the incoming radiation condition

$$\left(\frac{\partial\varphi}{\partial R}+i\sqrt{\nu_0}\,\varphi\right)=o(R^{-(n-1)/2}).$$

3. Coupling between variational formulation and integral representation.

3.1. Reduction to a bounded domain. The main difficulty we face in studying the way $R(\nu)$ depends on ν lies in the fact that the limit of $R(\nu)F(f)$ no longer belongs to $H^1(\Omega)$ when ν tends to the positive real axis. We shall thus be led to give another formulation of (Q_ν) allowing a precise control of the behaviour of $R(\nu)F(f)$ at infinity. For the time being we shall assume that $\text{Im}(\nu)>0$.

By $G_\nu(x)$ we shall denote the fundamental solution of $\Delta+\nu I$; for instance:

$$G_\nu(x)=\frac{1}{4i}H_0^{(1)}(\sqrt{\nu}\,\|x\|) \quad \text{in two dimensions} \tag{1}$$

$$G_\nu(x)=\frac{-1}{4\pi}\frac{e^{i\sqrt{\nu}\|x\|}}{\|x\|} \quad \text{in three dimensions,} \tag{2}$$

where $\sqrt{\nu}=\sqrt{\rho}\,e^{i\theta/2}$ for $\nu=\rho\,e^{i\theta}$ and $\theta\in]-\pi,+\pi]$.

The following representation formula holds for the solution φ of (Q_ν):

$$\varphi(y)=\int_\Gamma\left\{\varphi(x)\frac{\partial}{\partial n_x}G_\nu(x-y)-\frac{\partial\varphi}{\partial n}(x)G_\nu(x-y)\right\}ds_x.$$

It follows that on any boundary Σ surrounding Γ, we have

$$D_\lambda\varphi(y)=\int_\Gamma\left\{\varphi(x)\frac{\partial}{\partial n_x}\gamma_\nu(x,y)-\frac{\partial\varphi}{\partial n}(x)\gamma_\nu(x,y)\right\}ds_x,$$

with $D_\lambda\chi=((\partial\chi/\partial n)+\lambda\chi)_{|\Sigma}$ and $\gamma_\nu(x,y)=-(D_\lambda G_\nu)(x-y)$.

We are thus led to set the following problem in the bounded domain $\tilde{\Omega}$ limited by Γ and Σ (see Fig. 2):

$$(\tilde{Q}_\nu)\qquad \begin{aligned}&\Delta\tilde{\varphi}+\nu\tilde{\varphi}=0 \quad \text{in } \tilde{\Omega},\\ &\frac{\partial\tilde{\varphi}}{\partial n}=f \quad \text{on } \Gamma,\\ &D_\lambda\tilde{\varphi}(\cdot)=\int_\Gamma\left\{\tilde{\varphi}(x)\frac{\partial}{\partial n_x}\gamma_\nu(x,\cdot)-\frac{\partial\tilde{\varphi}}{\partial n}(x)\gamma_\nu(x,\cdot)\right\}ds_x.\end{aligned}$$

By $V(\Sigma,\lambda)$ we shall denote the denumerable set of the eigenvalues of the following associated problem:

$$(Z_\lambda)\qquad \begin{aligned}&\Delta\psi+\nu\psi=0 \quad \text{in } \Omega',\\ &D_\lambda\psi=0 \quad \text{on } \Sigma,\end{aligned}$$

where Ω' is the bounded domain with boundary Σ (see Fig. 3).

Remark 2. When $\text{Im}(\lambda)=0$ (respectively, $\text{Im}(\lambda)<0$, respectively, $\text{Im}(\lambda)>0$), then $V(\Sigma,\lambda)$ is included into $\mathbb{R}$ (respectively, into $\{\nu\,|\,\text{Im}(\nu)<0\}$, respectively, into $\{\nu\,|\,\text{Im}(\nu)>0\}$). □

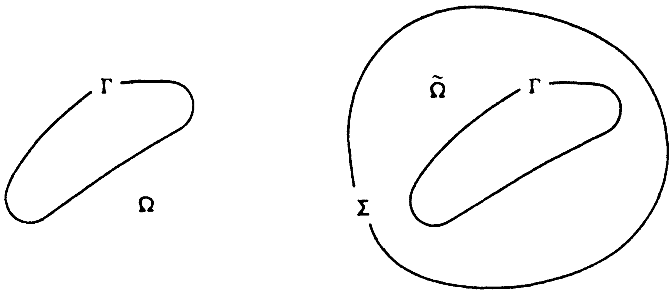

FIG. 2

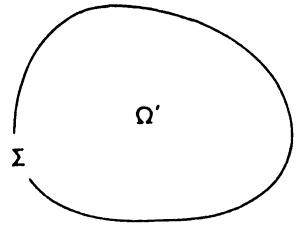

FIG. 3

PROPOSITION 1. *For* $\operatorname{Im}(\nu)>0$ *and* $\nu\notin V(\Sigma,\lambda)$, *problem* $(\tilde{Q}_\nu)$ *is well posed and its solution* $\tilde{\varphi}$ *is nothing but the restriction to* $\tilde{\Omega}$ *of the solution* φ *of* (Q_ν).

Proof. From Green's formula, we have, for $y\in\tilde{\Omega}$,

$$\tilde{\varphi}(y)=\int_{\Gamma\cup\Sigma}\left\{\tilde{\varphi}(x)\frac{\partial}{\partial n_x}G_\nu(x-y)-\frac{\partial\tilde{\varphi}}{\partial n}(x)G_\nu(x-y)\right\}ds_x.$$

Put

$$\psi(y)=\int_{\Sigma}\left\{\tilde{\varphi}(x)\frac{\partial}{\partial n_x}G_\nu(x-y)-\frac{\partial\tilde{\varphi}}{\partial n}(x)G_\nu(x-y)\right\}ds_x;$$

clearly, ψ extends to the whole Ω' as a solution of (Z_λ). If $\nu\notin V(\Sigma,\lambda)$, then

$$\tilde{\varphi}(y)=\int_{\Gamma}\left\{\tilde{\varphi}(x)\frac{\partial}{\partial n_x}G_\nu(x-y)-\frac{\partial\tilde{\varphi}}{\partial n}(x)G_\nu(x-y)\right\}ds_x,$$

from which we deduce that $\tilde{\varphi}$ extends to the whole Ω as a solution of (P_ν). The conclusion follows then by uniqueness of (P_ν). □

Under variational form, problem $(\tilde{Q}_\nu)$ writes as

$$(I+\tilde{S}(\nu))\tilde{\varphi}=\tilde{F}(f,\nu)\quad\text{in } H^1(\tilde{\Omega}),\quad\text{with}$$

$$(3)\qquad \begin{aligned}(\tilde{S}(\nu)\tilde{\varphi}\,|\,\tilde{\psi})_{H^1(\tilde{\Omega})}&=-(1+\nu)\int_{\tilde{\Omega}}\tilde{\varphi}\bar{\tilde{\psi}}\,d\omega+\lambda\int_{\Sigma}\tilde{\varphi}\bar{\tilde{\psi}}\,ds\\&\quad-\int_{\Sigma}\bar{\tilde{\psi}}(y)\int_{\Gamma}\tilde{\varphi}(x)\frac{\partial\gamma_\nu(x,y)}{\partial n_x}\,ds_x\,ds_y,\end{aligned}$$

and

$$(\tilde{F}(f,\nu)\,|\,\tilde{\psi})_{H^1(\tilde{\Omega})}=\int_{\Gamma}f\bar{\tilde{\psi}}\,ds-\int_{\Sigma}\bar{\tilde{\psi}}(y)\int_{\Gamma}f(x)\gamma_\nu(x,y)\,ds_x\,ds_y.$$

3.2. Analytical continuation of the resolvent. Formulas (1) and (2) extend analytically to $\mathbb{C}\backslash\mathbb{R}^-$; the continuation of $\tilde{S}(\nu)$ follows.

PROPOSITION 2. *The operator* $\tilde{S}(\nu)$ *is completely continuous on* $H^1(\tilde{\Omega})$; *moreover, function* $\tilde{S}$: $\nu\mapsto\tilde{S}(\nu)$, $\mathbb{C}\backslash\mathbb{R}^-\to\mathscr{L}(H^1(\tilde{\Omega}),H^1(\tilde{\Omega}))$ *is holomorphic.*

Proof. (i) We have

$$\begin{aligned}\|\tilde{S}(\nu)\tilde{\varphi}\|_{H^1(\tilde{\Omega})}\leqq\operatorname*{Sup}_{\tilde{\psi}\in H^1(\tilde{\Omega})}\frac{1}{\|\tilde{\psi}\|_{H^1(\tilde{\Omega})}}\Bigg(&|1+\nu|\,\|\tilde{\varphi}\|_{L^2(\tilde{\Omega})}\|\tilde{\psi}\|_{L^2(\tilde{\Omega})}+|\lambda|\,\|\tilde{\varphi}\|_{L^2(\Sigma)}\|\tilde{\psi}\|_{L^2(\Sigma)}\\&+\|\tilde{\varphi}\|_{L^2(\Gamma)}\|\tilde{\psi}\|_{L^2(\Sigma)}\int_{\Gamma}\left\|\frac{\partial\gamma_\nu(x,\cdot)}{\partial n_x}\right\|_{L^2(\Sigma)}ds_x\Bigg),\end{aligned}$$

and as a consequence,

$$\|\tilde{S}(\nu)\tilde{\varphi}\|_{H^1(\tilde{\Omega})} \leqq C_1\|\tilde{\varphi}\|_{L^2(\tilde{\Omega})} + C_2\|\tilde{\varphi}\|_{L^2(\Sigma)} + C_3\|\tilde{\varphi}\|_{L^2(\Gamma)};$$

the compactness of $\tilde{S}(\nu)$: $H^1(\tilde{\Omega}) \to H^1(\tilde{\Omega})$ follows.

(ii) The holomorphic dependence of $\tilde{S}(\nu)$ on ν is a straightforward consequence of that of G_ν. □

From now on, we shall denote $(I+\tilde{S}(\nu))^{-1}$ by $\tilde{R}(\nu)$.

COROLLARY 1. *Function $\tilde{R}(\nu)$ extends meromorphically to $\mathbb{C}\backslash\mathbb{R}^-$.*

Proof. From Proposition 1, $I+\tilde{S}(\nu)$ is invertible for $\operatorname{Im}(\nu)>0$ and $\nu \notin V(\Sigma, \lambda)$; the conclusion follows then from Proposition 2 and from Steinberg's theorem [11]. □

Proposition 1 shows that $V(\Sigma, \lambda)$ is included in the set $\tilde{E}$ of the poles of $\tilde{R}(\nu)$. The construction we carried out thus seems not to be intrinsic: it depends on Σ and λ. We shall, however, show below that it provides the analytical continuation of the resolvent $R(\nu)$. Let us recall that $\nu \to \psi(\nu)$ is holomorphic on D if, for each open bounded set U included in Ω, $\nu \mapsto \psi(\nu)_{|U}$ is itself holomorphic on D; notice that the uniqueness of the analytical continuation remains valid for functions with values in $H^1_{\mathrm{loc}}(\Omega)$.

COROLLARY 2. *The poles of the analytical continuation of $\nu \mapsto R(\nu)F(f, \nu)$ and those of $\nu \mapsto \tilde{R}(\nu)\tilde{F}(f, \nu)$ are the same.*

Proof. (i) For fixed λ and Σ, we put $\tilde{\varphi}_\nu = \tilde{R}(\nu)\tilde{F}(f, \nu)$ and by φ_ν we denote the function equal to $\tilde{\varphi}_\nu$ in $\tilde{\Omega}$ and to

$$\int_\Gamma \left\{\tilde{\varphi}_\nu(x)\frac{\partial}{\partial n_x}G_\nu(x,\cdot) - f(x)G_\nu(x,\cdot)\right\} ds_x \quad \text{in } \Omega\backslash\tilde{\Omega}. \tag{4}$$

For $\operatorname{Im}(\nu)>0$ and $\nu \notin V(\Sigma, \lambda)$, Proposition 1 shows that this function is nothing but $R(\nu)F(f)$; formula (4) together with the holomorphic properties of G_ν show that $\nu \mapsto \varphi_\nu$ is holomorphic for $\nu \in \mathbb{C}\backslash(\mathbb{R}^- \cup \tilde{E})$. It follows that φ_ν defines the analytical continuation of $R(\nu)F(f)$.

(ii) If $\tilde{R}(\nu)\tilde{F}(f, \nu)$ is holomorphic in the vicinity of $\hat{\nu}$, then by formula (4), φ_ν is also holomorphic; each pole of the analytical continuation of $R(\nu)F(f)$ is thus a pole of $\tilde{R}(\nu)\tilde{F}(f, \nu)$.

(iii) Assume on the other hand that the analytical continuation φ_ν of $R(\nu)F(f)$ is holomorphic in the vicinity of $\hat{\nu}$; as $\varphi_{\nu|\tilde{\Omega}} = \tilde{R}(\nu)\tilde{F}(f, \nu)$ $\forall \nu \notin \tilde{E}$, then $\tilde{R}(\nu)\tilde{F}(f, \nu)$ is holomorphic in the vicinity of $\hat{\nu}$. It follows that each pole of $\tilde{R}(\nu)\tilde{F}(f, \nu)$ is a pole of the analytical continuation of $R(\nu)F(f)$. □

We shall now show that a relevant choice of parameter λ allows the determination of the poles of $R(\nu)F(f)$ from those of $\tilde{R}(\nu)$.

This result is especially meaningful because it is much easier to compute the poles of $\tilde{R}(\nu)$ than those of $R(\nu)F(f)$. They are the values of ν for which -1 is an eigenvalue of $\tilde{S}(\nu)$; in other words, they are the solutions of the following nonlinear eigenvalue problem:

$$\int_{\tilde{\Omega}} \nabla\tilde{\varphi}\,\nabla\bar{\tilde{\psi}}\,d\omega + \lambda\int_\Sigma \tilde{\varphi}\bar{\tilde{\psi}}\,ds - \int_\Sigma \bar{\tilde{\psi}}(y)\int_\Gamma \tilde{\varphi}(x)\frac{\partial}{\partial n_x}\gamma_\nu(x, y)\,ds_x\,ds_y = \nu\int_{\tilde{\Omega}} \tilde{\varphi}\bar{\tilde{\psi}}\,d\omega. \tag{E_λ}$$

In the sequel, we shall devise a numerical method for its solution.

THEOREM 1. *For* $\operatorname{Im}(\lambda)>0$ *and* $\operatorname{Im}(\nu_*)<0$, *the following assertions are equivalent*:

(i) *ν_* is a pole of $\nu \mapsto \tilde{R}(\nu)$,*

(ii) *$\exists f \in L^2(\Gamma)$ such that ν_* is a pole of $\nu \mapsto R(\nu)F(f)$.*

Proof of (ii)-(i). We shall show that, if ν_* is a pole of $\tilde{R}(\nu)$, then $\tilde{F}(f, \nu_*)$ cannot belong to Im $(I+\tilde{S}(\nu_*))$ for all $f \in L^2(\Gamma)$. The proof is by contradiction: let us assume that

$$\forall f \in L^2(\Gamma),\ \tilde{F}(f, \nu_*) \in \operatorname{Im}(I+\tilde{S}(\nu_*)) = (\operatorname{Ker}(I+\tilde{S}^*(\nu_*))^{\perp}.$$

From formula (3), we have

$$(\tilde{S}^*(\nu_*)\tilde{\varphi} \,|\, \psi)_{H^1(\tilde{\Omega})} = -(1+\overline{\nu_*}) \int_{\tilde{\Omega}} \tilde{\varphi}\bar{\psi}\, d\omega + \bar{\lambda} \int_{\Sigma} \tilde{\varphi}\bar{\psi}\, ds \tag{5}$$
$$- \int_{\Sigma} \tilde{\varphi}(y) \int_{\Gamma} \bar{\psi}(x) \frac{\partial}{\partial n_x} \overline{\gamma_{\nu_*}}(x, y)\, ds_x\, ds_y.$$

Assume that $\tilde{\varphi}$ belongs to Ker $(I+\tilde{S}^*(\nu_*))$, then $\forall f \in L^2(\Gamma)$,

$$\int_{\Gamma} f\bar{\tilde{\varphi}}\, ds - \int_{\Sigma} \bar{\tilde{\varphi}}(y) \int_{\Gamma} f(x)\gamma_{\nu_*}(x, y)\, ds_x\, ds_y = 0, \quad \text{i.e.,}$$

$$\int_{\Gamma} f(x) \left\{ \bar{\tilde{\varphi}}(x) - \int_{\Sigma} \bar{\tilde{\varphi}}(y)\gamma_{\nu_*}(x, y)\, ds_y \right\} ds_x = 0;$$

thus

$$\tilde{\varphi}(x) = \int_{\Sigma} \tilde{\varphi}(y)\overline{\gamma_{\nu_*}}(x, y)\, ds_y \quad \text{on } \Gamma. \tag{6}$$

On the other hand, by formula (5), $\tilde{\varphi}$ is a solution of the following problem:

$$\Delta\tilde{\varphi} + \overline{\nu_*}\tilde{\varphi} = 0 \quad \text{in } \tilde{\Omega},$$
$$\frac{\partial\tilde{\varphi}}{\partial n} = \frac{\partial}{\partial n}\left(\int_{\Sigma} \tilde{\varphi}(y)\overline{\gamma_{\nu_*}}(\cdot, y)\, ds_y \right) \quad \text{on } \Gamma,$$
$$\frac{\partial\tilde{\varphi}}{\partial n} + \bar{\lambda}\tilde{\varphi} = 0 \quad \text{on } \Sigma.$$

Function $\int_{\Sigma} \tilde{\varphi}(y)\overline{\gamma_{\nu_*}}(\cdot, y)\, ds_y$ extends to the whole Ω'; it agrees with $\tilde{\varphi}$ in $\tilde{\Omega}$, since they both are solutions of $\Delta\psi + \overline{\nu_*}\psi = 0$ on $\tilde{\Omega}$, with the same Dirichlet and Neumann boundary conditions on Γ. As a consequence, by formula (6), $\tilde{\varphi}$ extends to Ω' and satisfies:

$$\Delta\tilde{\varphi} + \overline{\nu_*}\tilde{\varphi} = 0 \quad \text{in } \Omega',$$
$$\frac{\partial\tilde{\varphi}}{\partial n} + \bar{\lambda}\tilde{\varphi} = 0 \quad \text{on } \Sigma.$$

By Remark 2, it follows that $\tilde{\varphi} = 0$, and consequently Ker $(I+\tilde{S}^*(\nu_*)) = \{0\}$, which is inconsistent with (i). We thus proved the existence of f in $L^2(\Gamma)$ such that $\tilde{F}(f, \nu_*) \notin$ Im $(I+\tilde{S}(\nu_*))$, therefore, ν_* is a pole of $\tilde{R}(\nu)\tilde{F}(f, \nu)$; as a consequence by Corollary 2, it is a pole of $R(\nu)F(f)$.

(ii)-(i) Conversely, if ν_* is a pole of $R(\nu)F(f)$, then by Corollary 2, ν_* is a pole of $\tilde{R}(\nu)\tilde{F}(f, \nu)$; it is thus a pole of $\tilde{R}(\nu)$, since $\tilde{F}(f, \nu)$ depends holomorphically on ν. □

4. The localized finite element method.

4.1. Reduction to a bounded domain. We shall describe below an alternative way for the reduction of (P_ν) to a bounded domain. For the sake of definiteness, we shall choose the space dimension equal to 2; the method actually applies to any space dimension. For the time being we assume that Im $(\nu) > 0$.

Let Σ be a circle of radius r surrounding Γ, $\tilde{\Omega}$ the domain bounded by Γ and Σ, and $\check{\Omega}$ the domain exterior to Σ (see Fig. 4).

As before, we must find boundary conditions on Σ such that the solution $\tilde{u}$ of the problem set in $\tilde{\Omega}$ is the restriction to $\tilde{\Omega}$ of the solution of (Q_ν).

Let $\chi \in H^{1/2}(\Sigma)$, and consider the following auxiliary problem:

$$\text{(7)} \qquad \begin{aligned} &\Delta\check{u} + \nu\check{u} = 0 \quad \text{in } \check{\Omega}, \\ &\check{u} = \chi \quad \text{on } \Sigma. \end{aligned}$$

By $\mathcal{T}_\nu$ we denote the Calderon operator associated to problem (7), i.e., the continuous function $\mathcal{T}_\nu$:

$$\chi \mapsto \mathcal{T}_\nu(\chi) = \frac{\partial\check{u}}{\partial n}_{|\Sigma} \quad \text{from } H^{1/2}(\Sigma) \quad \text{to } H^{-1/2}(\Sigma).$$

Assume that $\tilde{u}$, defined on $\tilde{\Omega}$, satisfies the reduced wave equation; we can easily prove that condition:

$$\text{(8)} \qquad \frac{\partial\tilde{u}}{\partial n}_{|\Sigma} = -\mathcal{T}_\nu(\tilde{u}_{|\Sigma})$$

implies the analytical matching between $\tilde{u}$ and the solution $\mathcal{S}(\tilde{u}_{|\Sigma})$ of problem (7), with the Dirichlet datum $\chi = \tilde{u}_{|\Sigma}$. We are thus led to the following problem, set in the bounded domain $\tilde{\Omega}$:

$$(\tilde{\Pi}_\nu) \qquad \begin{aligned} &\text{Find } \tilde{u} \in H^1(\tilde{\Omega}), \quad \text{such that} \\ &\Delta\tilde{u} + \nu\tilde{u} = 0 \quad \text{in } \tilde{\Omega}, \\ &\frac{\partial\tilde{u}}{\partial n} = f \quad \text{on } \Gamma, \\ &\frac{\partial\tilde{u}}{\partial n} = -\mathcal{T}_\nu(\tilde{u}_{|\Sigma}) \quad \text{on } \Sigma. \end{aligned}$$

PROPOSITION 3. *Problem $(\tilde{\Pi}_\nu)$ has a unique solution $\tilde{u}$, which is nothing but the restriction to $\tilde{\Omega}$ of the solution u of (Q_ν).*

Proof. The restriction to $\tilde{\Omega}$ of the solution u of (Q_ν) is a solution of $(\tilde{\Pi}_\nu)$. Conversely, if $\tilde{u}$ is a solution of $(\tilde{\Pi}_\nu)$, then the function whose restriction to $\tilde{\Omega}$ is equal to $\tilde{u}$ and whose restriction to $\check{\Omega}$ is equal to $\mathcal{S}(\tilde{u}_{|\Sigma})$ is the solution of (Q_ν). □

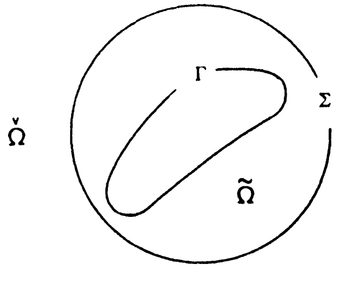

FIG. 4

An explicit formula for $\mathcal{T}_\nu$ can be obtained through diagonalization: we perform a Fourier expansion of the solution in the exterior domain. Let $\Phi_n = 1/\sqrt{2\pi}\, e^{in\theta}$, $n \in \mathbb{Z}$, and τ_n be the orthogonal projection on Φ_n in $L^2(-\pi, +\pi)$:

$$\tau_n(\chi) = \int_{-\pi}^{\pi} \chi \overline{\Phi_n}\, d\theta;$$

we have

$$\chi = \sum_{n\in\mathbb{Z}} \tau_n(\chi)\Phi_n \quad \forall \chi \in L^2(-\pi, +\pi) \quad \text{and}$$

(9)

$$\mathcal{T}_\nu(\chi) = -\sqrt{\nu} \sum_{n\in\mathbb{Z}} \tau_n(\chi) \frac{(H_n^{(1)})'(\sqrt{\nu}\, r)}{H_n^{(1)}(\sqrt{\nu}\, r)} \Phi_n.$$

The definition of the Hankel function $H_n^{(1)}$ is taken from [1]. A variational formulation of problem $(\tilde{\Pi}_\nu)$ then leads to

$$(I + \tilde{T}(\nu))\tilde{u} = \tilde{M}(f),$$

where

$$(\tilde{T}(\nu)\tilde{u}\,|\,v)_{H^1(\tilde{\Omega})} = -(\nu+1) \int_{\tilde{\Omega}} \tilde{u}\bar{v}\, d\omega - \sqrt{\nu} \sum_{n\in\mathbb{Z}} \tau_n(\tilde{u}_{|\Sigma}) \frac{(H_n^{(1)})'(\sqrt{\nu}\, r)}{H_n^{(1)}(\sqrt{\nu}\, r)} \overline{\tau_n(v_{|\Sigma})}, \quad \text{and}$$

(10)

$$(\tilde{M}(f)\,|\,v)_{H^1(\tilde{\Omega})} = \int_\Gamma f\bar{v}\, ds.$$

4.2. Analytical continuation of the resolvent. By Z_n we denote the set of the zeros of $H_n^{(1)}(\sqrt{\nu}\, r)$, and we set $Z = \bigcup_{n\in\mathbb{Z}} Z_n$.

PROPOSITION 4. *Formula* (10) *actually defines the analytical continuation of* $\nu \mapsto T(\nu)$ *to* $\mathbb{C}\backslash\{\mathbb{R}^- \cup Z\}$ *as an holomorphic function with values in* $\mathcal{L}(H^1(\tilde{\Omega}), H^1(\tilde{\Omega}))$.

Proof. The following formula holds:

$$\langle \mathcal{T}_\nu u, \bar{v}\rangle_{H^{-1/2}(\Sigma), H^{1/2}(\Sigma)} = -\sqrt{\nu} \sum_{n\in\mathbb{Z}} \tau_n(u)\overline{\tau_n(v)} \frac{(H_n^{(1)})'(\sqrt{\nu}\, r)}{H_n^{(1)}(\sqrt{\nu}\, r)}.$$

Let $z = \sqrt{\nu}\, r$; we have

$$\frac{(H_n^{(1)})'(z)}{H_n^{(1)}(z)} = \frac{(H_m^{(1)})'(z)}{H_m^{(1)}(z)} = \frac{-H_{m'}^{(1)}(z) + (m/z)H_m^{(1)}(z)}{H_m^{(1)}(z)} = -\frac{H_{m'}^{(1)}(z)}{H_m^{(1)}(z)} + \frac{m}{z},$$

with $m = |n|$, and $m' = |n| + 1$. From [1], we have

$$\frac{H_{m'}^{(1)}(z)}{H_m^{(1)}(z)} \sim 2\frac{m}{z} \quad \text{for } m \to \infty.$$

It follows that

(11)

$$\frac{(H_n^{(1)})'(z)}{H_n^{(1)}(z)} \sim -\frac{|n|}{z}, \quad \text{for } |n| \to \infty,$$

and consequently,

$$\begin{aligned} &|\langle \mathcal{T}_\nu u, \bar{v}\rangle_{H^{-1/2}(\Sigma), H^{1/2}(\Sigma)}| \\ &\leqq \sqrt{|\nu|} \left(\sum_{n\in\mathbb{Z}} |\tau_n(u)|^2 \frac{1}{|n|} \left| \frac{(H_n^{(1)})'(\sqrt{\nu}\, r)}{H_n^{(1)}(\sqrt{\nu}\, r)} \right|^2 \right)^{1/2} \left(\sum_{n\in\mathbb{Z}} |\tau_n(v)|^2 |n| \right)^{1/2}, \\ &\leqq C(r) \|u\|_{H^{1/2}(\Sigma)} \|v\|_{H^{1/2}(\Sigma)}. \end{aligned}$$

As a consequence, the series expansion of $\mathcal{T}_\nu u$ converges uniformly over any compact subset of $\mathbb{C}\backslash\mathbb{R}^-$, and the continuation of $\mathcal{T}_\nu$ that it defines is continuous from $H^{1/2}(\Sigma)$ into $H^{-1/2}(\Sigma)$. The statement of the proposition follows. □

As operator $\tilde{T}(\nu)$ is not completely continuous, Steinberg's theorem no longer applies; the following results hold, however.

PROPOSITION 5. *$I+\tilde{T}(\nu)$ is a Fredholm operator of index* 0 *in* $H^1(\tilde{\Omega})$.

Proof. We shall prove that $\tilde{T}(\nu)$ is the sum of a completely continuous operator and of an operator whose real part is positive. Clearly, it is enough to prove this result for operator $U(\nu)$ defined by

$$(U(\nu)u\,|\,v)_{H^1(\tilde{\Omega})}=\langle \mathcal{T}_\nu u,\,\bar{v}\rangle_{H^{-1/2}(\Sigma),H^{1/2}(\Sigma)}.$$

Formula (11) shows that $\operatorname{Re}((H_n^{(1)})'(\sqrt{\nu}\,r)/H_n^{(1)}(\sqrt{\nu}\,r))$ is negative beyond some rank N; since

$$(U(\nu)u\,|\,u)_{H^1(\tilde{\Omega})}=-\sqrt{\nu}\left(\sum_{n=-N+1}^{N-1}|\tau_n(u)|^2\frac{(H_n^{(1)})'(\sqrt{\nu}\,r)}{H_n^{(1)}(\sqrt{\nu}\,r)}+\sum_{|n|\geqq N}|\tau_n(u)|^2\frac{(H_n^{(1)})'(\sqrt{\nu}\,r)}{H_n^{(1)}(\sqrt{\nu}\,r)}\right),$$

the statement of the proposition follows. □

From now on we shall denote $(I+\tilde{T}(\nu))^{-1}$ by $\tilde{\mathcal{R}}(\nu)$.

PROPOSITION 6. *For all $f\in L^2(\Gamma)$, function $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$ extends meromorphically to $\mathbb{C}\backslash\mathbb{R}^-$; moreover each pole of $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$ is a pole of $\tilde{R}(\nu)$.*

Proof. (i) From Propositions 1 and 3, the following identity holds for any $\nu\notin V(\Sigma,\lambda)$ with $\operatorname{Im}(\nu)>0$:

$$\tilde{R}(\nu)\tilde{F}(f,\nu)=\tilde{\mathcal{R}}(\nu)\tilde{M}(f),\qquad \forall f\in L^2(\Gamma).$$

This identity actually defines the analytical continuation of $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$ to $\mathbb{C}\backslash\mathbb{R}^-$, for all $f\in L^2(\Gamma)$.

(ii) The last assertion of the Proposition follows then from Theorem 1. □

THEOREM 2. (i) *$\tilde{\mathcal{R}}(\nu)$ extends meromorphically to $\mathbb{C}\backslash\mathbb{R}^-$.*

(ii) *For* $\operatorname{Im}(\nu_*)<0$, *the two following statements are equivalent: ν_* is a pole of $\tilde{\mathcal{R}}(\nu)$, and $\exists f\in L^2(\Gamma)$ such that ν_* is a pole of $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$.*

(iii) *For* $\operatorname{Im}(\nu_*)<0$ *and* $\operatorname{Im}(\lambda)>0$, *$\tilde{\mathcal{R}}(\nu)$ has the same poles as $\tilde{R}(\nu)$.*

Proof. (i) If ν_* is a singular value of $\tilde{\mathcal{R}}(\nu)$, then $\exists f\in L^2(\Omega)$ such that ν_* is a pole of $\tilde{\mathcal{R}}(\nu)M(f)$. As in the proof of Theorem 1, we shall assume that $\forall f\in L^2(\Gamma)$, $\tilde{M}(f)\in\operatorname{Im}(I+\tilde{T}(\nu_*))=(\operatorname{Ker}(I+\tilde{T}^*(\nu_*)))^\perp$. From formula (10), we get

$$(12)\quad (\tilde{T}^*(\nu_*)\tilde{u}\,|\,v)_{H^1(\tilde{\Omega})}=-(\mu_*+1)\int_{\tilde{\Omega}}\tilde{u}\bar{v}\,d\omega-\sqrt{\mu_*}\sum_{n\in\mathbb{Z}}\tau_n(\tilde{u}_{|\Sigma})\frac{(H_n^{(2)})'(\sqrt{\mu_*}\,r)}{H_n^{(2)}(\sqrt{\mu_*}\,r)}\overline{\tau_n(v_{|\Sigma})},$$

with $\mu_*=\overline{\nu_*}$. Moreover, if $\tilde{u}\in\operatorname{Ker}(I+\tilde{T}^*(\nu_*))$, then

$$\forall f\in L^2(\Gamma),\qquad (\tilde{M}(f)\,|\,\tilde{u})_{H^1(\tilde{\Omega})}=0,\quad \text{i.e.,}$$

$$\int_\Gamma f\tilde{u}\,ds=0.$$

It follows that $\tilde{u}_{|\Gamma}=0$. From (12), we deduce that $\tilde{u}$ is a solution of the following problem:

$$(13)\qquad \begin{aligned}&\Delta\tilde{u}+\mu_*\tilde{u}=0\quad\text{in }\tilde{\Omega},\\&\tilde{u}_{|\Gamma}=0,\\&\frac{\partial\tilde{u}}{\partial n}=-\mathcal{T}^2_{\mu_*}(\tilde{u}_{|\Sigma})\quad\text{on }\Sigma,\end{aligned}$$

where

$$\mathcal{T}^2_{\mu_*}(\chi)=-\sqrt{\mu_*}\sum_{n\in\mathbb{Z}}\tau_n(\chi)\frac{(H_n^{(2)})'(\sqrt{\mu_*}\,r)}{H_n^{(2)}(\sqrt{\mu_*}\,r)}\Phi_n.$$

Since $\operatorname{Im}(\mu_*) > 0$, the functions $H_n^{(2)}(\sqrt{\mu_*}\, r)$ decrease exponentially at infinity; therefore, $\mathcal{T}^2_{\mu_*}$ is nothing the Calderon operator associated with the problem

$$\text{Find } \check{u} \in H^1(\check{\Omega}), \quad \text{such that}$$

$$\Delta \check{u} + \mu_* \check{u} = 0 \quad \text{in } \check{\Omega},$$

$$\check{u} = \chi \quad \text{on } \Sigma,$$

and thus $\tilde{u}$ is the restriction to $\tilde{\Omega}$ of the solution of the following coercive problem:

$$\text{Find } u \in H^1(\Omega), \quad \text{such that}$$

$$\Delta u + \mu_* u = 0 \quad \text{in } \Omega,$$

$$u_{|\Gamma} = 0.$$

As a consequence, u, and thus $\tilde{u}$, vanish. We actually proved that $\operatorname{Ker}(I + \tilde{T}^*(\nu_*)) = \{0\}$, which is inconsistent with the hypothesis.

(ii) From Theorem 1 and Proposition 6, we infer that the poles of $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$ are poles of $\tilde{R}(\nu)$; as a consequence, $\tilde{\mathcal{R}}(\nu)$ has only isolated singularities which are poles of $\tilde{\mathrm{R}}(\nu)$. Moreover, if ν_* is a singular value of $\tilde{\mathcal{R}}(\nu)$, then -1 is an eigenvalue of $\tilde{T}(\nu)$, of finite multiplicity by Proposition 5. It follows (Kato [3, p. 574]) that $\tilde{\mathcal{R}}(\nu)$ is meromorphic in the vicinity of ν_*, and consequently on $\mathbb{C}\backslash\mathbb{R}^-$.

(iii) Finally it is clear that, if ν_* is a pole of $\tilde{\mathcal{R}}(\nu)\tilde{M}(f)$ for some $f \in L^2(\Omega)$, it is thus a pole of $\tilde{\mathcal{R}}(\nu)$. □

Remark 3. What we just proved is that the scattering frequencies are also the solutions of the following nonlinear eigenvalue problem:

$$\text{(E)} \qquad \int_{\tilde{\Omega}} \nabla \tilde{u}\, \nabla \bar{\tilde{v}}\, d\omega - \sum_{n \in \mathbb{Z}} \tau_n(\tilde{u}_{|\Sigma}) \frac{(H_n^{(1)})'(\sqrt{\nu}\, r)}{H_n^{(1)}(\sqrt{\nu}\, r)} \overline{\tau_n(\tilde{v}_{|\Sigma})} = \nu \int_{\tilde{\Omega}} \tilde{u} \bar{\tilde{v}}\, d\omega.$$

This is an alternative formulation to Problem (E_λ), a condition for this last formulation to hold is that Σ be a circle.

4.3. The set of the zeros of the Hankel functions. Up to now, $\tilde{T}(\nu)$ has only been defined outside the set Z of the zeros of the Hankel functions; it is thus necessary to know whether these zeros are scattering frequencies or not. Let V_n be the operator defined by

$$(V_n u \mid v)_{H^1(\tilde{\Omega})} = \tau_n(u)\overline{\tau_n(v)}.$$

PROPOSITION 7. *Operator* V_n *is of rank* 1.

Proof. By Riesz' theorem, there exists a unique e'_n in $H^1(\tilde{\Omega})$ such that

$$(e'_n \mid v)_{H^1(\tilde{\Omega})} = \int_\Sigma \Phi_n \bar{v}\, ds.$$

It follows that

$$(V_n u \mid v)_{H^1(\tilde{\Omega})} = \left(\int_\Sigma u \overline{\Phi_n}\, ds\right)\left(\int_\Sigma \Phi_n \bar{v}\, ds\right) = \left(\left(\int_\Sigma u \overline{\Phi_n}\, ds\right) e'_n \,\middle|\, v\right)_{H^1(\tilde{\Omega})}, \quad \text{i.e.,}$$

$$V_n u = \left(\int_\Sigma u \overline{\Phi_n}\, ds\right) e'_n. \qquad □$$

Remark 4. The function e'_n exhibited in the proof of the preceding proposition is actually the solution of the following coercive problem:

$$(14)\qquad \begin{aligned} &-\Delta e'_n + e'_n = 0 \quad \text{in } \tilde{\Omega},\\ &\frac{\partial e'_n}{\partial \nu} = \Phi_n \quad \text{on } \Sigma,\\ &\frac{\partial e'_n}{\partial \nu} = 0 \quad \text{on } \Gamma. \end{aligned}$$

From now on we shall scale e'_n in $H^1(\tilde{\Omega})$ and set $e_n = e'_n/\|e'_n\|_{H^1(\tilde{\Omega})}$.

Let E_n be the orthogonal supplementary to $\{e_n\}$ in $H^1(\tilde{\Omega})$:

$$H^1(\tilde{\Omega}) = \{e_n\} \overset{\perp}{\oplus} E_n,$$

and accordingly the matrix decomposition of operator $(I + \tilde{T}(\nu))$:

$$\begin{pmatrix} A_n(\nu) & B_n(\nu) \\ C_n(\nu) & D_n(\nu) \end{pmatrix}.$$

By ν^* we denote a zero of $H_n^{(1)}(\sqrt{\nu}\, r)$; from formula (10) we infer that $A_n(\nu)$ expands as

$$A_n(\nu) = A'_n(\nu) + \frac{V_n}{\varepsilon_n(\nu)}, \quad \text{where } \varepsilon_n(\nu) = \frac{H_n^{(1)}(\sqrt{\nu}\, r)}{(H_n^{(1)})'(\sqrt{\nu}\, r)}$$

tends to zero when $\nu \to \nu^*$, and $A'_n(\nu)$ depends continuously on ν in the vicinity of ν^*. Similarly, operators $B_n(\nu)$, $C_n(\nu)$, and $D_n(\nu)$ depend continuously on ν.

THEOREM 3. *A zero ν^* of $H_n^{(1)}(\sqrt{\nu}\, r)$ is a pole of $\tilde{\mathcal{R}}(\nu)$ if and only if operator $D_n(\nu)$ is not invertible at $\nu = \nu^*$.*

Proof. Since Z and the set $\tilde{E}$ of the poles of $\tilde{\mathcal{R}}(\nu)$ are discrete sets in $\mathbb{C}\backslash\mathbb{R}^-$, there exists a neighborhood $\mathcal{V}$ of ν^* which does not contain any other point of $Z \cup \tilde{E}$.

(i) Assume that $D_n(\nu^*)$ is invertible; in $\mathcal{V}\backslash\{\nu^*\}$, $(I + \tilde{T}(\nu))$ is also invertible and the matrix decomposition of its inverse has the following form:

$$\begin{pmatrix} \mathcal{A}_n(\nu) & \mathcal{B}_n(\nu) \\ \mathcal{C}_n(\nu) & \mathcal{D}_n(\nu) \end{pmatrix}, \quad \text{with}$$

$$\begin{aligned} &\mathcal{A}_n(\nu) = (A_n(\nu) - B_n(\nu) D_n(\nu)^{-1} C_n(\nu))^{-1},\\ &\mathcal{B}_n(\nu) = -\mathcal{A}_n(\nu) B_n(\nu) D_n(\nu)^{-1},\\ &\mathcal{C}_n(\nu) = -\mathcal{A}_n(\nu) D_n(\nu)^{-1} C_n(\nu), \quad \text{and}\\ &\mathcal{D}_n(\nu) = -A_n(\nu)(C_n(\nu) B_n(\nu) - A_n(\nu) D_n(\nu))^{-1}, \end{aligned}$$

according to the fact that $\mathcal{A}_n(\nu)$, which is a multiplication operator, interchanges with any other. When ν tends to ν^*, then $\mathcal{A}_n(\nu)$, $\mathcal{B}_n(\nu)$, and $\mathcal{C}_n(\nu)$ vanish; moreover,

$$\mathcal{D}_n(\nu) = -(\varepsilon_n(\nu) A'_n(\nu) + V_n)(\varepsilon_n(\nu) C_n(\nu) B_n(\nu) - (\varepsilon_n(\nu) A'_n(\nu) + V_n) D_n(\nu))^{-1}$$

tends to $D_n(\nu^*)^{-1}$ when $\nu \to \nu^*$. It follows that $\tilde{\mathcal{R}}(\nu)$ can be continuously extended at point ν^* as

$$\tilde{\mathcal{R}}(\nu) = \begin{pmatrix} 0 & 0 \\ 0 & D_n(\nu^*)^{-1} \end{pmatrix}.$$

(ii) Conversely, assume that $\nu^* \notin \tilde{E}$, then there exists $\mathscr{B}_n(\nu)$, $\mathscr{C}_n(\nu)$, and $\mathscr{D}_n(\nu)$ such that

$$\left(A_n'(\nu)+\frac{V_n}{\varepsilon_n(\nu)}\right)\mathscr{B}_n(\nu)+B_n(\nu)\mathscr{D}_n(\nu)=0. \tag{15}$$

$$C_n(\nu)\mathscr{B}_n(\nu)+D_n(\nu)\mathscr{D}_n(\nu)=I_{|E_n}. \tag{16}$$

When $\nu \to \nu^*$, $\mathscr{B}_n(\nu)$ vanishes by formula (15), and consequently (16) implies:

$$D_n(\nu^*)\mathscr{D}_n(\nu^*)=I_{|E_n},$$

showing that $D_n(\nu^*)$ is invertible. □

Remark 5. For practical purposes it is worthwhile to give an explicit expression for operator

$$\begin{pmatrix} 0 & 0 \\ 0 & D_n(\nu) \end{pmatrix},$$

which we shall now simply denote by $D_n(\nu)$. Assume u and v belong to $H^1(\tilde{\Omega})$, then

$$\begin{aligned}(D_n(\nu)u\,|\,v)_{H^1(\tilde{\Omega})} &= ((I+\tilde{T}(\nu))u\,|\,v)_{H^1(\tilde{\Omega})}-((I+\tilde{T}(\nu))u\,|\,e_n)_{H^1(\tilde{\Omega})}(e_n\,|\,v)_{H^1(\tilde{\Omega})} \\ &= \int_{\tilde{\Omega}} \nabla u\,\nabla\bar{v}\,d\omega-\nu\int_{\tilde{\Omega}} u\bar{v}\,d\omega-\sum_{k\in\mathbb{Z}}\frac{\tau_k(u)\overline{\tau_k(v)}}{\varepsilon_k(\nu)} \\ &\quad -\left(\int_{\tilde{\Omega}}\nabla u\,\nabla\overline{e_n}\,d\omega-\nu\int_{\tilde{\Omega}} u\overline{e_n}\,d\omega-\sum_{k\in\mathbb{Z}}\frac{\tau_k(u)\overline{\tau_k(e_n)}}{\varepsilon_k(\nu)}\right)\overline{\tau_n(v)}.\end{aligned}$$

As $\tau_k(e_n)=\delta_{kn}$, we obtain

$$\begin{aligned}(D_n(\nu)u\,|\,v)_{H^1(\tilde{\Omega})} &= \int_{\tilde{\Omega}} \nabla u\,\nabla\bar{v}\,d\omega-\nu\int_{\tilde{\Omega}} u\bar{v}\,d\omega-\sum_{k\neq n}\frac{\tau_k(u)\overline{\tau_k(v)}}{\varepsilon_k(\nu)} \\ &\quad -\frac{\tau_n(u)\overline{\tau_n(v)}}{\|e_n'\|}+(\nu+1)\left(\int_{\tilde{\Omega}} u\overline{e_n}\,d\omega\right)\overline{\tau_n(v)}.\end{aligned} \tag{17}$$ □

5. Approximation of the scattering frequencies and of the associated resonant states. In the preceding sections, we described two different methods for reducing the determination of the scattering frequencies to a nonlinear eigenvalue problem, for a compact operator. We introduce at first, the internal approximation of this problem, then we perform an asymptotic expansion of the resolvent in the vicinity of a scattering frequency; the approximate location of the resonant frequencies and of the associated maxima of the response of the system follow.

5.1. Discretisation of the nonlinear eigenvalue problem. By V_h we denote a finite-dimensional subspace of $H^1(\Omega)$, following, for example, from a finite element discretization. If $(\cdot|\cdot)_h$ denotes the scalar product in V_h, we define $\mathbb{J}_h$ and $\mathbb{S}_h(\nu)$ by the following formulas:

$$(\mathbb{J}_h\varphi_h\,|\,\psi_h)_h=\int_\Omega \nabla\varphi_h\,\nabla\overline{\psi_h}\,d\omega+\int_\Omega \varphi_h\overline{\psi_h}\,d\omega, \tag{18}$$

$$\begin{aligned}(\mathbb{S}_h(\nu)\varphi_h\,|\,\psi_h)_h &= -(1+\nu)\int_\Omega \varphi_h\overline{\psi_h}\,d\omega+\lambda\int_\Sigma \varphi_h\overline{\psi_h}\,ds \\ &\quad -\int_\Sigma \overline{\psi_h}(y)\int_\Gamma \varphi_h(x)\frac{\partial\gamma_\nu}{\partial n_x}(x,y)\,ds_x\,ds_y \quad \forall\varphi_h,\psi_h\in V_h.\end{aligned} \tag{19}$$

The approximate determination of the scattering frequencies by the method of coupling between variational formulation and integral representation consists in solving the set of equations:

$$\mu_h(\nu_{h*}) = -1, \tag{20}$$

where the $\mu_h(\nu)$ are the solutions of the following generalized eigenvalue problem:

$$\mathbb{S}_h(\nu)e_h(\nu) = \mu_h(\nu)\mathbb{J}_h e_h(\nu).$$

Remark 6. Using the localized finite element method consists in replacing $\mathbb{S}_h(\nu)$ defined at formula (19) by

$$(\mathbb{S}_h(\nu)\varphi_h \mid \psi_h)_h = -(1+\nu)\int_\Omega \varphi_h\overline{\psi_h}\,d\omega - \sum_{n\in\mathbb{Z}} \tau_n(\varphi_{h|\Sigma})\frac{(H_n^{(1)}(\sqrt{\nu}\mathrm{r}))'}{H_n^{(1)}(\sqrt{\nu}\mathrm{r})}\overline{\tau_n(\psi_{h|\Sigma})}. \tag{21}$$

The solution of (20) by Newton's method requires the derivative $\mu_h'(\nu)$ of $\mu_h(\nu)$. Assume, for example, that $\mu_h(\nu)$ is a simple eigenvalue of $\mathbb{J}_h^{-1}\mathbb{S}_h(\nu)$, then

$$\mu_h'(\nu) = (\mathbb{S}_h'(\nu)e_h(\nu) \mid g_h(\nu))_h,$$

where $g_h(\nu)$ is the associated eigenvector of the adjoint operator, i.e., satisfying:

$$\mathbb{S}_h^*(\nu)g_h(\nu) = \overline{\mu_h}(\nu)\mathbb{J}_h g_h(\nu), \quad \text{and}$$

$$(\mathbb{J}_h e_h(\nu) \mid g_h(\nu))_h = 1.$$

In the sequel, we shall give expressions for the evaluation of $\mu_h'(\nu)$ in more complicated situations.

The next step will consist of expanding the solution of the diffraction problem in the vicinity of a scattering frequency. Let

$$(F_h(f,\nu) \mid \psi_h)_h = \int_\Gamma f\overline{\psi_h}\,ds - \int_\Sigma \overline{\psi_h}(y)\int_\Gamma f(x)\frac{\partial\gamma_\nu}{\partial n_x}(x,y)\,ds_x\,ds_y; \tag{22}$$

the use of the coupling method between variational formulation and integral representation leads then to expand the solution $\varphi_h(\nu)$ of problem

$$(\mathbb{J}_h + \mathbb{S}_h(\nu))\varphi_h(\nu) = F_h(f,\nu). \tag{23}$$

Remark 7. When using the localized finite element method, we replace $F_h(f,\nu)$ by $F_h(f)$, defined by

$$(F_h(f) \mid \psi_h)_h = \int_\Gamma f\overline{\psi_h}\,ds. \tag{24}$$

In the sequel, we shall only consider the *approximate problem*, consequently we shall omit index "h"; ν_* will denote the approximate scattering frequency under consideration. We shall first construct the Laurent expansion of the approximate resolvent $\mathbb{R}(\nu) = [\mathbb{J} + \mathbb{S}(\nu)]^{-1}$ in the vicinity of ν_*: this is an application of the perturbation theory of Kato [3]. An explicit calculation of the expansion of the solution of problem (23) will then be produced, which will provide an approximation of the resonant frequency.

5.2. Canonical form of the resolvent. Let us begin with some notations. The following expansion holds in the vicinity of ν_*:

$$\mathbb{S}(\nu) = \mathbb{S} + \sum_{n=1}^{\infty}(\nu-\nu_*)^n\mathbb{S}^{(n)};$$

or, equivalently,

$$\mathbb{U}(\nu)=\mathbb{U}+\sum_{n=1}^{\infty}(\nu-\nu_*)^n\mathbb{U}^{(n)},\quad\text{with}$$
(25)
$$\mathbb{U}(\nu)=\mathbb{J}^{-1}\mathbb{S}(\nu),\quad \mathbb{U}=\mathbb{J}^{-1}\mathbb{S}\quad\text{and}\quad \mathbb{U}^{(n)}=\mathbb{J}^{-1}\mathbb{S}^{(n)}\quad \forall n>0.$$

Since $\mathbb{U}(\nu)$ is a holomorphic function of ν, the number of distinct eigenvalues of $\mathbb{U}(\nu)$ is a constant independent of ν, apart from isolated values of ν which are called exceptional points (ν_* may be such an exceptional point). Let $\mu_k(\nu)$, $k=1, K$ (respectively, μ_i, $i=1, I$ where $I\leqq K$) denote the eigenvalues of $\mathbb{U}(\nu)$ for $\nu\neq\nu_*$ (respectively, of $\mathbb{U}$), and $\mathbb{P}_k(\nu)$ (respectively, $\mathbb{P}_i$) the associated eigenprojections. The spectrum of $\mathbb{U}(\nu)$ for $\nu\neq\nu_*$ can be divided into I "μ_i-groups" $\{\mu_k(\nu), k\in\mathcal{J}_i\}$ such that:

$$\mu_k(\nu)\rightarrow\mu_i\quad\text{as } \nu\rightarrow\nu_*,\quad k\in\mathcal{J}_i,\quad i=1, I.$$

A scattering frequency ν_* makes -1 an eigenvalue of $\mathbb{U}$; we can choose, for example, $\mu_1=-1$ and $\mathcal{J}_1=\{1,\cdots,s\}$. $\mathbb{P}=\mathbb{P}_1$ denotes the eigenprojection for the eigenvalue -1. The "(-1)-group" is then defined by

$$\mu_k(\nu)\rightarrow -1\quad\text{as } \nu\rightarrow\nu_*,\quad k=1, s.$$

From now on we shall assume that $\mathbb{U}(\nu)$ is diagonalizable in the vicinity of ν_*. The canonical form of the resolvent is thus written:

$$\mathbb{R}(\nu)=\mathbb{R}_S(\nu)+\mathbb{R}_R(\nu),\quad \nu\neq\nu_*,\quad\text{where}$$
(26)
$$\mathbb{R}_S(\nu)=\sum_{k=1}^{s}\frac{\mathbb{P}_k(\nu)\mathbb{J}^{-1}}{1+\mu_k(\nu)}\quad\text{and}\quad \mathbb{R}_R(\nu)=\sum_{k=s+1}^{K}\frac{\mathbb{P}_k(\nu)\mathbb{J}^{-1}}{1+\mu_k(\nu)}.$$

$\mathbb{R}_S(\nu)$ is the singular part of the resolvent and $\mathbb{R}_{\text{R}}(\nu)$ the reduced resolvent, which is holomorphic near $\nu=\nu_*$. As a matter of fact

(27) $$\mathbb{R}_R(\nu)=\mathbb{Q}\mathbb{J}^{-1}+0(\nu-\nu_*),\quad\text{where } \mathbb{Q}=\sum_{i=2}^{I}\frac{\mathbb{P}_i}{1+\mu_i}.$$

Notice that $\mathbb{Q}$ is the operator which associates to a given G the only solution X of

$$(\mathbb{I}+\mathbb{U})X=(\mathbb{I}-\mathbb{P})G\quad\text{and}\quad \mathbb{P}X=0.$$

5.3. Expansion of the eigenvalues and eigenprojections of the (−1)-group. The question is now to compute the expansion of the singular part of the resolvent. Let us first assume that the (-1)-group has only one element $\mu_1(\nu)$ (i.e., $s=1$). In this simple case, the eigenvalue $\mu_1(\nu)$ and the eigenprojection $\mathbb{P}_1(\nu)$ are holomorphic near $\nu=\nu_*$:

(28) $$\begin{cases}\mu_1(\nu)=-1+(\nu-\nu_*)\mu^{(1)}+(\nu-\nu_*)^2\mu^{(2)}+0(\nu-\nu_*)^3,\\ \mathbb{P}_1(\nu)=\mathbb{P}+(\nu-\nu_*)\mathbb{P}^{(1)}+0(\nu-\nu_*)^2,\end{cases}$$

with

$$\mu^{(1)}=\frac{1}{M}\operatorname{tr}[\mathbb{U}^{(1)}\mathbb{P}],\qquad \mu^{(2)}=\frac{1}{M}\operatorname{tr}[\mathbb{U}^{(2)}\mathbb{P}-\mathbb{U}^{(1)}\mathbb{Q}\mathbb{U}^{(1)}\mathbb{P}],$$
(29)
$$\mathbb{P}^{(1)}=-\mathbb{P}\mathbb{U}^{(1)}\mathbb{Q}-\mathbb{Q}\mathbb{U}^{(1)}\mathbb{P},$$

where M is the multiplicity of the eigenvalue -1 of $\mathbb{U}$ (which agrees here with the multiplicity of the eigenvalue $\mu_1(\nu)$ of $\mathbb{U}(\nu)$). If $\mu^{(1)}$ is different from zero, the expansion of the singular part of the resolvent writes

(30) $$\mathbb{R}_S(\nu)=\frac{1}{(\nu-\nu_*)}\left[\frac{\mathbb{P}}{\mu^{(1)}}\right]\mathbb{J}^{-1}+\left[\frac{\mathbb{P}^{(1)}}{\mu^{(1)}}-\frac{\mu^{(2)}\mathbb{P}}{\mu^{(1)2}}\right]\mathbb{J}^{-1}+0(\nu-\nu_*).$$

If $\mu^{(1)}=0$, we have to find the order l of the first nonvanishing term in the expansion (28) of $\mu_1(\nu)$. An expansion similar to (30), beginning, however, at order $(\nu-\nu_*)^{-l}$ holds.

Let us now study the case where the (-1)-group has several elements (i.e., $s>1$). By $\mathbb{P}'(\nu)$ we denote the total projection associated with the (-1)-group:

$$\mathbb{P}'(\nu)=\sum_{k=1}^{s}\mathbb{P}_k(\nu), \qquad \nu\neq\nu_*.$$

As we assumed that $\mathbb{U}$ is diagonalizable, -1 is a semisimple eigenvalue of $\mathbb{U}$, and we can assert that the operator

$$\dot{\mathbb{U}}(\nu)=\frac{1}{\nu-\nu_*}(\mathbb{I}+\mathbb{U}(\nu))\mathbb{P}'(\nu)$$

is holomorphic near $\nu=\nu_*$:

$$\dot{\mathbb{U}}(\nu)=\dot{\mathbb{U}}+\sum_{n=1}^{\infty}(\nu-\nu_*)^n\dot{\mathbb{U}}^{(n)}, \quad \text{with}$$

(31) $\dot{\mathbb{U}}=\mathbb{P}\mathbb{U}^{(1)}\mathbb{P}$, and

(32) $\dot{\mathbb{U}}^{(1)}=\mathbb{P}\mathbb{U}^{(2)}\mathbb{P}-\mathbb{P}\mathbb{U}^{(1)}\mathbb{P}\mathbb{U}^{(1)}\mathbb{Q}-\mathbb{P}\mathbb{U}^{(1)}\mathbb{Q}\mathbb{U}^{(1)}\mathbb{P}-\mathbb{Q}\mathbb{U}^{(1)}\mathbb{P}\mathbb{U}^{(1)}\mathbb{P}.$

Let $\dot\mu_k(\nu)$, $k=1,s$ be the eigenvalues of $\dot{\mathbb{U}}(\nu)$ for $\nu\neq\nu_*$, and $\dot{\mathbb{P}}_k(\nu)$ the associated eigenprojections. We obviously have:

(33) $\mu_k(\nu)=-1+(\nu-\nu_*)\dot\mu_k(\nu)$ and $\dot{\mathbb{P}}_k(\nu)=\mathbb{P}_k(\nu)$, $\nu\neq\nu_*$, $k=1,s$.

These eigenvalues can be divided into several "$\dot\mu_j$-groups" where the $\dot\mu_j$ are the eigenvalues of $\dot{\mathbb{U}}$, their number being less or equal to s. For the sake of simplicity, we shall assume that ν_* is not an exceptional point for $\dot{\mathbb{U}}(\nu)$, i.e., that $\dot{\mathbb{U}}$ has exactly s eigenvalues. Consequently, the $\dot\mu_k(\nu)$ and $\dot{\mathbb{P}}_k(\nu)$ are holomorphic near $\nu=\nu_*$ and can be expanded as (28):

$$(34)\qquad \begin{cases}\dot\mu_k(\nu)=\dot\mu_k+(\nu-\nu_*)\dot\mu_k^{(1)}+0(\nu-\nu_*)^2,\\ \dot{\mathbb{P}}_k(\nu)=\dot{\mathbb{P}}_k+(\nu-\nu_*)\dot{\mathbb{P}}_k^{(1)}+0(\nu-\nu_*)^2,\end{cases}$$

with

$$(35)\qquad \begin{cases}\dot\mu_k^{(1)}=\dfrac{1}{M_k}\operatorname{tr}[\dot{\mathbb{U}}^{(1)}\dot{\mathbb{P}}_k],\\ \dot{\mathbb{P}}_k^{(1)}=-\dot{\mathbb{P}}_k\dot{\mathbb{U}}^{(1)}\dot{\mathbb{Q}}_k-\dot{\mathbb{Q}}_k\dot{\mathbb{U}}^{(1)}\dot{\mathbb{P}}_k,\end{cases}$$

where $\dot{\mathbb{P}}_k$ is the eigenprojection for the eigenvalue $\dot\mu_k$ of $\dot{\mathbb{U}}$, M_k its multiplicity (which is equal to the multiplicity of the eigenvalue $\mu_k(\nu)$ of $\mathbb{U}(\nu)$), and the $\dot{\mathbb{Q}}_k$ are given by:

$$\dot{\mathbb{Q}}_k=\sum_{\substack{j=1\\ j\neq k}}^{s}\frac{\dot{\mathbb{P}}_j}{\dot\mu_j-\dot\mu_k}, \qquad k=1,s.$$

If all the eigenvalues $\dot\mu_k$ are different from 0, $\mathbb{R}_S(\nu)$ thus writes:

$$(36)\qquad R_S(\nu)=\frac{1}{\nu-\nu_*}\left\{\sum_{k=1}^{s}\frac{\dot{\mathbb{P}}_k\mathbb{J}^{-1}}{\dot\mu_k}\right\}+\left\{\sum_{k=1}^{s}\left[\frac{\dot{\mathbb{P}}_k^{(1)}}{\dot\mu_k}-\frac{\dot\mu_k^{(1)}\dot{\mathbb{P}}_k}{\dot\mu_k^2}\right]\mathbb{J}^{-1}\right\}+0(\nu-\nu_*).$$

Otherwise a similar expansion beginning at order $-l=-\mathrm{Max}_{k=1,s}\,l(k)$, where $l(k)$ denotes the order of the first nonvanishing term in the expansion (34) of $\dot\mu_k(\nu)$, can be obtained.

We have thus studied the case where ν_* is an exceptional point for the eigenvalue -1 of $\mathbb{U}$ but not for the reduced operator $\dot{\mathbb{U}}(\nu)$. If ν_* is an exceptional point for at least one eigenvalue μ_j of $\dot{\mathbb{U}}$, this reduction process can go further on provided that $\dot{\mathbb{U}}$ is diagonalizable, and so on, as many times (but in finite number) as necessary.

5.4. Expansion of the solution in the vicinity of ν_*. We now come back to problem (23) for obtaining the expansion of the solution $\varphi(\nu)$ in the vicinity of ν_*. The expansion of the right-hand side is straightforward:

$$F(f,\nu)=\sum_{n=0}^{\infty}(\nu-\nu_*)^n F^{(n)}.$$

Since $\varphi(\nu)$ simply writes $\mathbb{R}(\nu)F(f,\nu)$, its expansion follows from the one of the resolvent $\mathbb{R}(\nu)$:

$$\mathbb{R}(\nu)=\sum_{n=-l}^{\infty}(\nu-\nu_*)\mathbb{R}^{(n)}.$$

We have

$$\varphi(\nu)=\sum_{n=-l}^{\infty}(\nu-\nu_*)^n\varphi^{(n)},\quad \text{with} \tag{37}$$

$$\varphi^{(-l)}=\mathbb{R}^{(-l)}F^{(0)}\quad\text{and}\quad \varphi^{(1-l)}=\mathbb{R}^{(1-l)}F^{(0)}+\mathbb{R}^{(-l)}F^{(1)}. \tag{38}$$

We shall give here the explicit calculation of the first two terms of this expansion; we shall restrict ourselves to the simple case where ν_* is not an exceptional point and $\mu^{(1)}$ (in (28)) differs from zero (formula (30)). Further cases can be treated exactly in the same way by using the proper expression of the expansion of $\mathbb{R}(\nu)$.

Let $e_m(=e_{1m})$, $m=1, M$ (respectively, e_{ij}, $j=1, M(i)$, $i=2, I$) be a basis of the eigenspace associated with the eigenvalue -1 (respectively, μ_i, $i=2, I$) of $\mathbb{U}$:

$$\mathbb{S}e_m=-\mathbb{J}e_m,\quad m=1,M\quad\text{and}\quad \mathbb{S}e_{ij}=\mu_i\mathbb{J}e_{ij},\quad j=1,M(i),\quad i=2,I,$$

and g_m (respectively, g_{ij}) the associated eigenvectors of the adjoint chosen such that:

$$(\mathbb{J}e_{ij}\,|\,g_{i'j'})=\delta_{ii'}\delta_{jj'},\quad j=1,M(i),\quad j'=1,M(i'),\quad i,i'=1,I.$$

The eigenprojections $\mathbb{P}$ and $\mathbb{P}_i$, $i=2, I$ can then be expressed in this basis:

$$\mathbb{P}X=\sum_{m=1}^{M}(\mathbb{J}X\,|\,g_m)e_m\quad\text{and}\quad \mathbb{P}_iX=\sum_{j=1}^{M(i)}(\mathbb{J}X\,|\,g_{ij})e_{ij},\quad i=2,I,$$

and $\mathbb{Q}$ (defined by (27)) writes:

$$\mathbb{Q}X=\sum_{i=2}^{I}\frac{1}{1+\mu_i}\sum_{j=1}^{M(i)}(\mathbb{J}X\,|\,g_{ij})e_{ij},$$

whence we infer the expression of the coefficients of the expansion of $\mu_1(\nu)$ (given by formula (29)):

$$\mu^{(1)}=\frac{1}{M}\sum_{m=1}^{M}(\mathbb{S}^{(1)}e_m\,|\,g_m);$$

$$\mu^{(2)}=\frac{1}{M}\sum_{m=1}^{M}\left[(\mathbb{S}^{(2)}e_m\,|\,g_m)-\sum_{i=2}^{I}\frac{1}{1+\mu_i}\sum_{j=1}^{M(i)}(\mathbb{S}^{(1)}e_m\,|\,g_{ij})(\mathbb{S}^{(1)}e_{ij}\,|\,g_m)\right].$$

From formulas (27) and (30) follow $\mathbb{R}^{(-1)}$ and $\mathbb{R}^{(0)}$, and finally the first two terms of the expansion of the solution:

$$\varphi^{(-1)}=\frac{1}{\mu^{(1)}}\sum_{m=1}^{M}(F^{(0)}|g_m)e_m \quad \text{and} \tag{39}$$

$$\begin{aligned}\varphi^{(0)}=&\frac{1}{\mu^{(1)}}\sum_{m=1}^{M}\left[\!\left[(F^{(1)}|g_m)-\frac{\mu^{(2)}}{\mu^{(1)}}(\mathrm{F}^{(0)}|g_m)-\sum_{i=2}^{I}\frac{1}{1+\mu_i}\sum_{j=1}^{M(i)}(F^{(0)}|g_{ij})(\mathbb{S}^{(1)}e_{ij}|g_m)\right]\!\right]e_m\\&+\sum_{i=2}^{I}\frac{1}{1+\mu_i}\sum_{j=1}^{M(i)}\left[\!\left[(F^{(0)}|g_{ij})-\frac{1}{\mu^{(1)}}\sum_{m=1}^{M}(F^{(0)}|g_m)(\mathbb{S}^{(1)}e_m|g_{ij})\right]\!\right]e_{ij}\end{aligned}\tag{40}$$

There is a simpler way for obtaining, in some respects, more general formulas, provided the existence of expansion (37) is assumed from the beginning; it will be worked out in the appendix.

5.5. Approximation of the resonant frequencies. The expansion (37) of the solution $\varphi(\nu)$ we obtained in the preceding paragraph makes it possible to compute an approximation of the (real) value ν_0 of the frequency where the maximum of $\|\varphi(\nu)\|$ is reached.

As a first approximation, we have

$$\varphi(\nu)\sim\frac{1}{(\nu-\nu_*)^l}(\varphi^{(-l)}+(\nu-\nu_*)\varphi^{(1-l)});$$

thus,

$$\|\varphi(\nu)\|^2\sim\frac{1}{(\alpha^2+\beta^2)^l}(\|X\|^2+2\alpha\ \mathrm{Re}\,(X\,|\,Y)+2\beta\ \mathrm{Im}\,(X\,|\,Y))=A(\alpha),$$

where $\nu-\nu_*=\alpha+i\beta$, $\varphi^{(-l)}=X$ and $\varphi^{(1-l)}=Y$.

The maximum of $A(\alpha)$ is reached when α is a solution of

$$\alpha^2(1-2l)\ \mathrm{Re}\,(X\,|\,Y)-\alpha(\|x\|^2+2\beta\ \mathrm{Im}\,(X\,|\,Y))+\beta^2\ \mathrm{Re}\,(X\,|\,Y)=0,$$

i.e., as a first approximation for

$$\alpha=\frac{\beta^2\ \mathrm{Re}\,(X\,|\,Y)}{l(\|X\|^2+2\beta\ \mathrm{Im}\,(X\,|\,Y))};$$

it follows that

$$\nu_0\sim\mathrm{Re}\,(\nu_*)+\frac{\mathrm{Re}\,(\varphi^{(-l)}\,|\,\varphi^{(1-l)})(\mathrm{Im}\,(\nu_*))^2}{l(\|\varphi^{(-l)}\|^2-2\ \mathrm{Im}\,(\nu_*)\ \mathrm{Im}\,(\varphi^{(-l)}|\varphi^{(1-l)}))}.\tag{41}$$

6. Some numerical results. In this section, we shall deal with a generalization of the previous problem: the coupling between an elastic structure and an unbounded acoustic fluid; numerical results will be presented, which show the efficiency of the method.

6.1. A simple coupled problem. The problem under consideration is the coupling between an infinite vibrating string and an elastic beam; the connection is realized through a density of springs (see Fig. 5). When the system is at rest, the beam is assumed rectilinear and parallel to the string; only simple bending motions will be

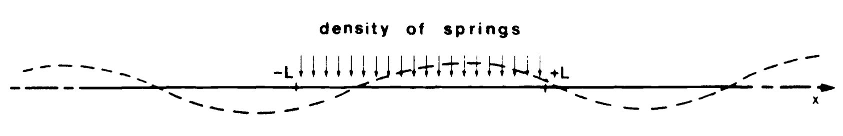

FIG. 5

considered. By $U(x, t)$ and $Y(x, t)$ we denote, respectively, the vertical displacement of a point on the string and the displacement of a point on the beam.

The system will be subject to a monochromatic incident wave of pulsation ω:

$$U_I(x, t) = \operatorname{Re}(u_I(x)\, e^{-i\omega t}), \quad \text{with } u_I(x) = e^{i(\omega/c)x};$$

it is a time-harmonic solution of

$$\frac{1}{c^2}\frac{\partial^2 U_I}{\partial t^2} - \frac{\partial^2 U_I}{\partial x^2} = 0 \quad \text{on } \mathbb{R}.$$

The following linearized equations hold then for the perturbation displacements of the string and of the beam:

$$(\mathcal{P}_t)\quad \begin{aligned}
&\frac{1}{c^2}\frac{\partial^2 U}{\partial t^2} - \frac{\partial^2 U}{\partial x^2} + K(x)(U - Y) = -K(x)U_I \quad \text{on } \mathbb{R},\\
&\rho(x)\frac{\partial^2 Y}{\partial t^2} + \frac{\partial^2}{\partial x^2}\left(E(x)I(x)\frac{\partial^2 Y}{\partial x^2}\right) - K(x)(U - Y) = K(x)U_I \quad \text{on }]-L, +L[,\\
&\frac{\partial^2 Y}{\partial x^2}(\pm L) = \frac{\partial}{\partial x}\left(E(x)I(x)\frac{\partial^2 Y}{\partial x^2}\right)(\pm L) = 0, \quad \text{where}
\end{aligned}$$

c is the velocity of the waves in the string (assumed constant), $\rho(x)$ the mass of the beam per unit length, $E(x)$ its Young modulus, and $I(x)$ the geometrical inertia of one section. By $K(x)$ we denote the stiffness per unit length of the springs; it vanishes outside the segment $]-L, +L[$. The first two equations in $(\mathcal{P}_t)$ model, respectively, the propagation of waves in the string, and the bending motion of the beam; notice the additional coupling terms, taking into account the action of the springs. The last equations are the free-conditions at the ends of the beam. The study of the behaviour of the longtime solution leads to the following problem:

$$(\mathcal{P}_{\omega^2})\quad \begin{aligned}
&-\frac{\omega^2}{c^2}u - \frac{d^2 u}{dx^2} + K(x)(u - y) = f_u \quad \text{on } \mathbb{R},\\
&-\omega^2\rho(x)y + \frac{d^2}{dx^2}\left(E(x)I(x)\frac{d^2 y}{dx^2}\right) - K(x)(u - y) = f_y \quad \text{on }]-L, +L[,\\
&\frac{d^2 y}{dx^2}(\pm L) = \frac{d}{dx}\left(E(x)I(x)\frac{d^2 y}{dx^2}\right)(\pm L) = 0,\\
&\left|\frac{du}{d|x|} - i\frac{\omega}{c}u\right| \xrightarrow[|x|\to\infty]{} 0 \quad \text{radiation condition,}
\end{aligned}$$

where $f_u = -f_y = -K(x)u_I$.

6.2. Analytical continuation of the resolvent. We consider now the extension of problem $(\mathcal{P}_{\omega^2})$ to complex ν values of ω^2; for the time being ν is assumed to be of strictly positive imaginary part:

Find (u, y) in $\mathcal{H} = H^1(\mathbb{R}) \times H^2(]-L, +L[)$ such that

$$(\mathcal{P}_\nu)\quad \begin{aligned}
&-\frac{\nu}{c^2}u - \frac{d^2 u}{dx^2} + K(x)(u - y) = f_u \quad \text{on } \mathbb{R},\\
&-\nu\rho(x)y + \frac{d^2}{dx^2}\left(E(x)I(x)\frac{d^2 y}{dx^2}\right) - K(x)(u - y) = f_y \quad \text{on }]-L, +L[,\\
&\frac{d^2 y}{dx^2}(\pm L) = \frac{d}{dx}\left(E(x)I(x)\frac{d^2 y}{dx^2}\right)(\pm L) = 0.
\end{aligned}$$

Under variational form, problem $(\mathcal{P}_\nu)$ writes as

$$\text{find } (u,y) \text{ in } \mathcal{H}, \quad \text{such that } \forall (v,z) \in \mathcal{H},$$
$$a_\nu((u,y),(v,z)) = \int_{\mathbb{R}} f_u \bar{v}\,dx + \int_{-L}^{+L} f_y \bar{z}\,dx,$$

where

$$a_\nu((u,y),(v,z)) = \int_{\mathbb{R}} \frac{du}{dx}\frac{d\bar{v}}{dx}\,dx + \int_{-L}^{+L} E(x)I(x)\frac{d^2y}{dx^2}\frac{d^2\bar{z}}{dx^2}\,dx$$
$$-\nu\left[\frac{1}{c^2}\int_{\mathbb{R}} u\bar{v}\,dx + \int_{-L}^{+L}\rho(x)y\bar{z}\,dx\right] + \int_{-L}^{+L} K(x)(u-y)(\bar{v}-\bar{z})\,dx.$$

PROPOSITION 8. *The bilinear form a_ν is continuous and coercive on $\mathcal{H}$.*

Proof. From Young's inequality we infer that

$$|a_\nu((u,y),(u,y))|^2$$
$$\geqq \left(1-\frac{1}{\eta}\right)\left[\int_{\mathbb{R}}\left|\frac{du}{dx}\right|^2 dx + \int_{-L}^{+L} E(x)I(x)\left|\frac{d^2y}{dx^2}\right|^2 dx + \int_{-L}^{+L} K(x)|u-y|^2\,dx\right]^2$$
$$+[(1-\eta)(\mathrm{Re}\,(\nu))^2 + (\mathrm{Im}\,(\nu))^2]\left[\frac{1}{c^2}\int_{\mathbb{R}}|u|^2\,dx + \int_{-L}^{+L}\rho(x)|y|^2\,dx\right]^2,$$

for each $\eta \geqq 0$. Now let $\eta = 1+\frac{1}{2}(\mathrm{Im}\,(\nu)/\mathrm{Re}\,(\nu))^2$; from the previous inequality we deduce that

$$|a_\nu((u,y),(u,y))| \geqq M(\nu)\left[\frac{1}{c^2}\int_{\mathbb{R}}|u|^2\,dx + \int_{\mathbb{R}}\left|\frac{du}{dx}\right|^2 dx\right.$$
$$\left. + \int_{-L}^{+L}\rho(x)|y|^2\,dx + \int_{-L}^{+L}E(x)I(x)\left|\frac{d^2y}{dx^2}\right|^2 dx\right],$$

and by Lion's lemma the coerciveness of a_ν. □

By A_ν we denote the operator on $\mathcal{H}$ associated with the bilinear form a_ν:

$$(A_\nu(u,y),(v,z))_{\mathcal{H}} = a_\nu((u,y),(v,z)),$$

the resolvent thus being $R(\nu) = (A_\nu)^{-1}$.

The explicit continuation of $R(\nu)$ to $\mathbb{C}\backslash\mathbb{R}^-$ is performed along the same lines as in § 4, which is quite easy for one-dimensional problems. Let $d \geqq L$ and $\mathrm{Im}\,(\nu) > 0$; problem $(\tilde{\mathcal{P}}_\nu)$ is then well posed. Its solution is the restriction to $]-d, +d[$ of the solution (u,y) of problem $(\mathcal{P}_\nu)$:

$$\text{Find } (\tilde{u},\tilde{y}) \text{ in } \tilde{\mathcal{H}} = H^1(]-d,+d[) \times H^2(]-L,+L[) \quad \text{such that,}$$

$$(\tilde{\mathcal{P}}_\nu)\quad \begin{aligned} &-\frac{\nu}{c^2}\tilde{u} - \frac{d^2\tilde{u}}{dx^2} + K(x)(\tilde{u}-\tilde{y}) = f_u \quad \text{on } \mathbb{R}, \\ &-\nu\rho(x)\tilde{y} + \frac{d^2}{dx^2}\left(E(x)I(x)\frac{d^2\tilde{y}}{dx^2}\right) - K(x)(\tilde{u}-\tilde{y}) = f_y \quad \text{on }]-L,+L[, \\ &\frac{d^2\tilde{y}}{dx^2}(\pm L) = \frac{d}{dx}\left(E(x)I(x)\frac{d^2\tilde{y}}{dx^2}\right)(\pm L) = 0. \end{aligned}$$

A variational form of this problem in $\tilde{\mathcal{H}}$ is as follows:

$$(I+\tilde{S}(\nu))(\tilde{u},\tilde{y})=\tilde{F},\quad \text{where}$$

$$\begin{aligned}(\tilde{S}(\nu))(\tilde{u},\tilde{y})\,|\,(\tilde{v},\tilde{z}))_{\tilde{\mathcal{H}}}=&-(1+\nu)\left[\frac{1}{c^2}\int_{-d}^{+d}\tilde{u}\bar{\tilde{v}}\,dx+\int_{-L}^{+L}\tilde{y}\bar{\tilde{z}}\,dx\right]\\&+\int_{-L}^{+L}K(x)(\tilde{u}-\tilde{y})(\bar{\tilde{v}}-\bar{\tilde{z}})\,dx\\&+\frac{i\sqrt{\nu}}{c}(\tilde{u}(+d)\bar{\tilde{v}}(+d)+\tilde{u}(-d)\bar{\tilde{v}}(-d)),\end{aligned}$$

and

$$(\tilde{F},(\tilde{v},\tilde{z}))_{\tilde{\mathcal{H}}}=\int_{-d}^{+d}f_u\bar{\tilde{v}}\,dx+\int_{-L}^{+L}f_y\bar{\tilde{z}}\,dx.$$

Notice that $\tilde{\mathcal{H}}$ has been equipped with the following scalar product:

$$\begin{aligned}((\tilde{u},\tilde{y}),(\tilde{v},\tilde{z}))_{\tilde{\mathcal{H}}}=&\frac{1}{c^2}\int_{-d}^{+d}\tilde{u}\bar{\tilde{v}}\,dx+\int_{-L}^{+L}\rho(x)\tilde{y}\bar{\tilde{z}}\,dx\\&+\int_{-d}^{+d}\frac{d\tilde{u}}{dx}\frac{d\bar{\tilde{v}}}{dx}\,dx+\int_{-L}^{+L}E(x)I(x)\frac{d^2\tilde{y}}{dx^2}\frac{d^2\bar{\tilde{z}}}{dx^2}\,dx.\end{aligned}$$

We easily check that $\tilde{S}(\nu)$ defines a holomorphic family of compact operators; as $(I+\tilde{S}(\nu))$ is invertible for $\mathrm{Im}\,(\nu)>0$,

$$\tilde{R}(\nu)=(I+\tilde{S}(\nu))^{-1}$$

extends meromorphically to $\mathbb{C}\backslash\mathbb{R}^-$ (Steinberg [11]). The poles of $\tilde{R}(\nu)$ located in the half-plane $\mathrm{Im}\,(\nu)\leqq 0$ are exactly those of the analytical extension of $R(\nu)$; i.e., the scattering frequencies of the coupled problem or, equivalently, the solutions of the following nonlinear eigenvalue problem:

$$\begin{aligned}&\int_{-d}^{+d}\frac{d\tilde{u}}{dx}\frac{d\bar{\tilde{v}}}{dx}\,dx+\int_{-L}^{+L}E(x)I(x)\frac{d^2\tilde{y}}{dx^2}\frac{d^2\bar{\tilde{z}}}{dx^2}\,dx+\int_{-L}^{+L}K(x)(\tilde{u}-\tilde{y})(\bar{\tilde{v}}-\bar{\tilde{z}})\,dx\\&+\frac{i\sqrt{\nu}}{c}(\tilde{u}(+d)\bar{\tilde{v}}(+d)+\tilde{u}(-d)\bar{\tilde{v}}(-d))=\nu\left[\frac{1}{c^2}\int_{-d}^{+d}\tilde{u}\bar{\tilde{v}}\,dx+\int_{-L}^{+L}\rho(x)\tilde{y}\bar{\tilde{z}}\,dx\right].\end{aligned}\tag{42}$$

6.3. Numerical implementation. The discretization of the problem by the finite element method is carried out as follows. Let us consider a subdivision $S_N=\{x_k, k=-N, N\}$ of $[-L,+L]$ (where $x_k<x_{k+1}$ and $x_{\pm N}=\pm L$) and $S_{N+P}=\{x_k, k=-N-P, N+P\}$ a subdivision of $[-d,+d]$, which contains S_N. We denote by

$$\mathcal{H}_h\subset C^0([-d,+d])\times C^1([-L,+L])$$

the finite-dimensional subspace of $\tilde{\mathcal{H}}$ defined by the pairs (u_h, y_h) such that u_h (respectively, y_h) is a polynomial of order 1 (respectively, 3) on each interval $[x_k, x_{k+1}]$ of S_{N+P} (respectively, S_N). For the sake of simplicity, the mechanical data $E(x)$, $I(x)$, $\rho(x)$, and $K(x)$ are assumed constant. Let $(\cdot,\cdot)_h$ be the scalar product in $\mathcal{H}_h$; we define the matrices $\mathbb{M}_h$, $\mathbb{K}_h$, and $\mathbb{C}_h$ (respectively, the "mass," "stiffness," and "coupling" matrices of the system) by:

$$(\mathbb{M}_h(u_h, y_h), (v_h, z_h))_h = \frac{1}{c^2}\int_{-d}^{+d} u_h\overline{v_h}\, dx + \int_{-L}^{+L} \rho y_h\overline{z_h}\, dx,$$

$$(\mathbb{K}_h(u_h, y_h), (v_h, z_h))_h = \int_{-d}^{+d} \frac{du_h}{dx}\frac{d\overline{v_h}}{dx}\, dx + \int_{-L}^{+L} EI\frac{d^2y_h}{dx^2}\frac{d^2\overline{z_h}}{dx^2}\, dx$$
$$+ \int_{-L}^{+L} K(u_h - y_h)\overline{(v_h - z_h)}\, dx,$$

$$(\mathbb{C}_h(u_h, y_h), (v_h, z_h))_h = \frac{i}{c}\,(u_h(+d)\overline{v_h(+d)} + u_h(-d)\overline{v_h(-d)}).$$

These matrices are computed classically by assembling the associated elementary matrices of each element. One can easily check that $\mathbb{M}_h$ and $\mathbb{K}_h$ (but not $\mathbb{C}_h$) are hermitian matrices, $\mathbb{M}_h$ is positive, and $\mathbb{K}_h$ is nonnegative. Notice that the same matrices could be obtained by a standard difference scheme.

Let us first consider the initial problem $(\mathcal{P}_{\omega^2})$, i.e., when the system is subject to a monochromatic incident wave of frequency ω:

$$u_I(x) = e^{i(\omega/c)x}.$$

The approximate response of the system is thus the solution of the following linear problem:

$$(43)\qquad \mathbb{A}_h(\omega^2)(u_h, y_h) = F_h, \quad \text{where } \mathbb{A}_h(\omega^2) = [-\omega^2\mathbb{M}_h + \mathbb{K}_h + \omega\mathbb{C}_h],$$

and the second member $F_h \in \mathcal{H}_h$ is defined by:

$$(F_h, (v_h, z_h))_h = \int_{-L}^{+L} Ku_I\overline{(z_h - v_h)}\, dx.$$

This system is solved by the elementary method of Gaussian elimination. Once the solution has been computed, we can then calculate the total energy of the beam, which is given by:

$$(44)\qquad E_b(\omega) = \tfrac{1}{2}([\omega^2\mathbb{M}_h + \mathbb{K}_h](0, y_h), (0, y_h))_h.$$

The determination of this quantity for each ω over a given frequency range leads us to the "response curve" of the beam whose maxima show the resonant states associated with the beam.

On the other hand, let us consider the matrix nonlinear eigenvalue problem deduced from (42):

$$(45)\qquad [\mathbb{K}_h + \sqrt{\nu}\,\mathbb{C}_h](u_h, y_h) = \nu\mathbb{M}_h(u_h, y_h),$$

whose solutions are the approximate scattering elements. By $\lambda_k(\nu)$ we denote any of the eigenvalues of the problem:

$$(46)\qquad [\mathbb{K}_h + \sqrt{\nu}\,\mathbb{C}_h](u_h, y_h) = \lambda_k(\nu)\mathbb{M}_h(u_h, y_h),$$

which actually are branches of analytic functions of ν with only algebraic singularities (Kato [3]). An approximate scattering frequency is thus a solution of the fixed-point equation $\lambda_k(\nu) = \nu$. The application of the iterative Newton method consists in computing, for a given initial value ν_0 and a given k, the sequence:

$$\nu_{j+1} = \nu_j - (\lambda_k(\nu_j) - \nu_j)\bigg/\left(\frac{d\lambda_k}{d\nu}(\nu_j) - 1\right),$$

where the iterations will be terminated if $|\nu_{j+1}-\nu_j|$ becomes less than the expected error ε. However, from a numerical point of view, the algorithm cannot be implemented in this form, for we cannot a priori know at each iteration which eigenvalue of problem (46) (with $\nu=\nu_j$) corresponds to the chosen branch $\lambda_k(\nu)$, even if all the eigenvalues of (46) are computed. This leads us to modify the previous relation as follows:

$$\nu_{j+1}=\nu_j-(\lambda(\nu_j)-\nu_j)\Big/\left(\frac{d\lambda}{d\nu}(\nu_j)-1\right),$$

where $\lambda(\nu_j)$ is now the closest eigenvalue to the given initial value ν_0. In this case, the sequence (ν_j) will converge (if it actually does) to the closest scattering frequency to ν_0. Let us notice again that nothing can ensure that, for two successive iterations, $\lambda(\nu_j)$ and $\lambda(\nu_{j+1})$ are points of the same branch: in particular, the algorithm will probably fail if ν_0 is chosen in the vicinity of a branch point.

The eigenvalue $\lambda(\nu_j)$ and the corresponding eigenvector are computed by the inverse iteration method [15] (assuming that $\lambda(\nu_j)$ is simple); it consists in the determination of a sequence (u_h^r, y_h^r) defined by:

$$[\mathbb{K}_h+\sqrt{\nu_j}\,\mathbb{C}_h-\nu_0\mathbb{M}_h](u_h^{r+1}, y_h^{r+1})=m^r\mathbb{M}_h(u_h^r, y_h^r),$$

where m^r is such that $\|(u_h^{r+1}, y_h^{r+1})\|_h=1$ and (u_h^0, y_h^0) is an arbitrary unit vector. Of course, the termination criterion (see [15]) must be chosen so that the precision on $\lambda(\nu_j)$ is better than the expected precision ε of the Newton algorithm.

Since $\lambda(\nu_j)$ has been assumed simple (and thus ν_j cannot be a branch point), its derivative $d\lambda/d\nu$ is obtained quite easily. Let (u_h, y_h) be an eigenvector associated with the eigenvalue $\lambda(\nu_j)$, and (v_h, z_h) a left eigenvector (i.e., an eigenvector of the adjoint problem) chosen so that $(\mathbb{M}_h(u_h, y_h), (v_h, z_h))_h=1$; we have:

$$\frac{d\lambda}{d\nu}(\nu_j)=\left(\frac{1}{2\sqrt{\nu_j}}\mathbb{C}_h(u_h, y_h), (v_h, z_h)\right)_h.$$

In our case, the left eigenvectors are simply given by $\alpha\,\overline{(u_h, y_h)}$ (where α is a nonzero complex number), for $[\mathbb{K}_h+\sqrt{\nu_j}\,\mathbb{C}_h]$ is a symmetric (but not hermitian) matrix.

For a scattering frequency ν_* which is close enough to the positive real axis, the expansion of the solution of problem (43) in the vicinity of ν_* can be performed as described in § 5 with:

$$\mathbb{S}_h(\nu)=\mathbb{K}_h+\sqrt{\nu}\,\mathbb{C}_h+(1-\nu)\mathbb{M}_h \quad\text{and}\quad \mathbb{J}_h=\mathbb{M}_h.$$

This expansion is:

$$(47)\qquad (u_h, y_h)=(\omega^2-\nu_*)^{-1}X^{(-1)}+X^{(0)}+0(\omega^2-\nu_*),$$

where $X^{(-1)}$ and $X^{(0)}$ are given by formulas (39) and (40) (with $M=1$). The computation of the former is obvious; the latter requires the calculation of all the eigenvalues and corresponding right and left eigenvectors of problem (46) for $\nu=\nu_*$: they are obtained by the classical "QR" method [15]. The expansion of the total energy of the beam (44) follows directly from (47): it thus provides an approximation of the response curve in the vicinity of the real part of a scattering frequency.

6.4. Numerical results. We report in this last paragraph the outcome of one typical numerical application. It is related to the following data:

$$c=1,\quad K=1.4,\quad \rho=0.5,\quad EI=0.1,\quad L=1.$$

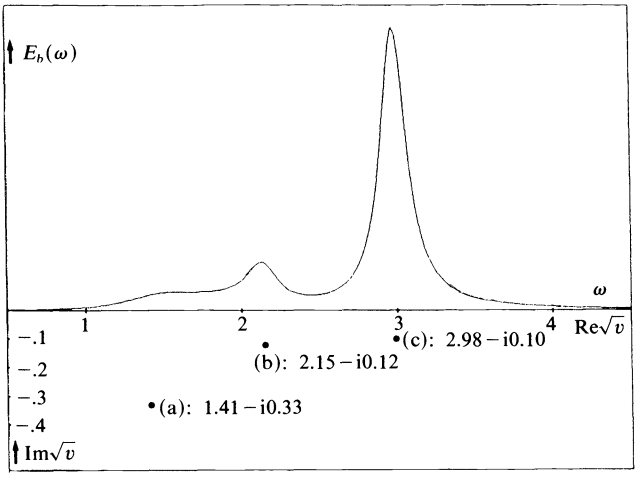

FIG. 6. *Response curve and location of scattering frequencies.*

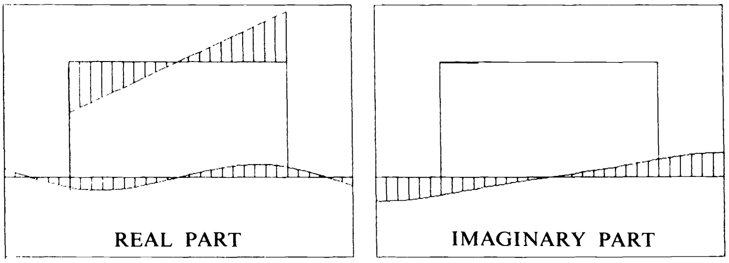

FIG. 7a. *Scattering mode—Case* (a).

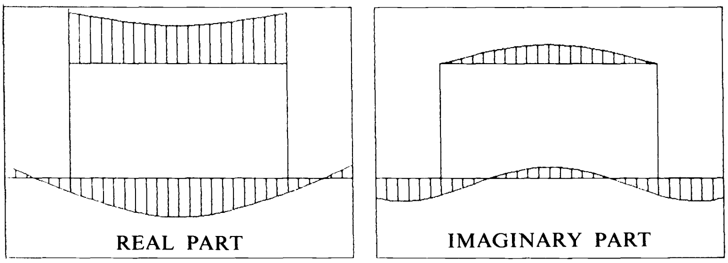

FIG. 7b. *Scattering mode—Case* (b).

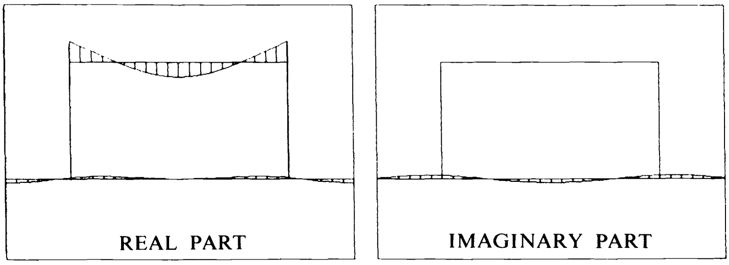

FIG. 7c. *Scattering mode—Case* (c).

The discretisation is shown in Fig. 7: 20 elements for the beam and $20+2\times 6$ elements for the string (75 degrees of freedom). For the computation of the scattering frequencies, the expected precision is 10^{-2} for the Newton algorithm and 10^{-4} for the inverse iteration method. The considered frequency range is $[0.5, 4.5]$.

The numerical experiments have shown that the choice of the initial value ν_0 is of the highest importance for the convergence of the Newton iterations. First, if ν_0 is of small modulus (say $|\nu_0|<1.$), the sequence (ν_j) generally does not converge: this is probably due to the fact that 0 is a branch point of the matrix $[\mathbb{K}_h+\sqrt{\nu}\,\mathbb{C}_h]$ in (46). When ν_0 is chosen in the vicinity of the positive real axis (say $\text{Im}\,(\nu_0)>-0.5$) and is not of small modulus, two situations occur. On one hand, if ν_0 is close enough to a scattering frequency (which is of course a priori unknown), the sequence (ν_j) converges to it (generally in less than 10 iterations); on the other hand, if ν_0 is unfortunately chosen about the middle of the gap between two scattering frequencies, the sequence may oscillate between them: actually, the computed eigenvalues $\lambda(\nu_j)$ result from two different but neighbouring branches $\lambda_k(\nu)$ of (46). At last, if the imaginary part of ν_0 increases, no convergence will be obtained.

The upper part of Fig. 6 is the response curve of the beam in the frequency range $[0.5, 4.5]$, i.e., the total energy (44) of the beam obtained by solving problem (43). The lower part of the same figure shows the location in the complex plane of the computed scattering frequencies (solutions of problem (46)). Notice that their real parts coincide approximately with the resonant frequencies, i.e., the locations of the maxima of the response.

Figure 7 shows, for each scattering frequency, the real and imaginary parts of the associated eigenvector: the upper and lower parts of each figure represent, respectively, the vertical displacement of the points on the beam and on the vibrating string. These "scattering modes" show what kind of motion is "excited":

(a) is a "roll" motion of the beam with very little bending strain;

(b) is a "heave" motion coupled with a bending mode of the beam;

(c) is a pure bending motion.

Figures 8 and 9 show the estimation of the response in the vicinity of the scattering frequencies (a), (b), and (c) using, respectively, the first term (order -1) and the two first terms (order -1 and 0) of the expansion (47) (the dotted curve reproduces the

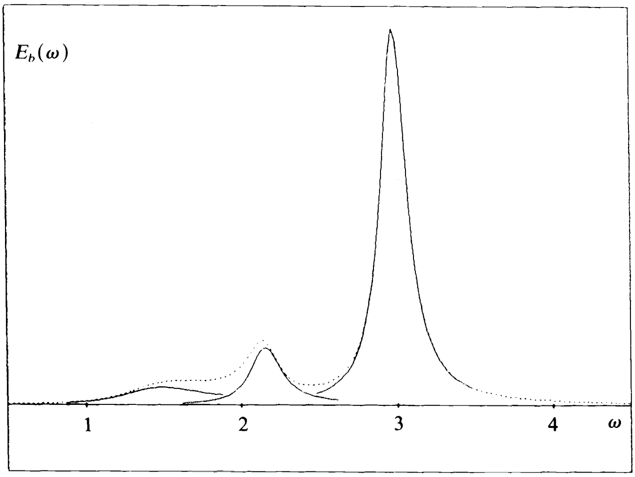

FIG. 8. *Approximation of the response at order* -1.

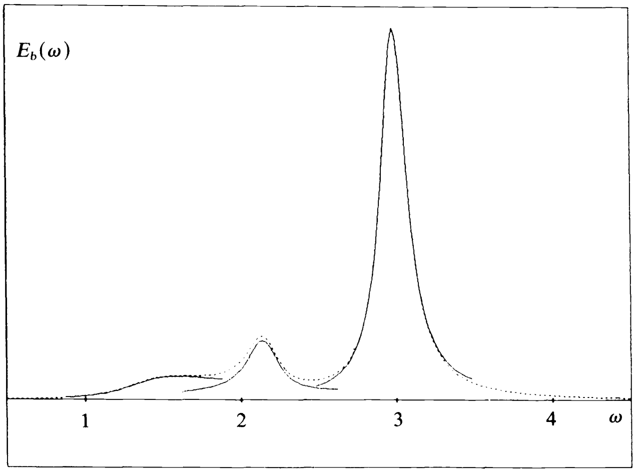

FIG. 9. *Approximation of the response at order* 0.

response curve of Fig. 6). In case (c), the first term provides a good approximation of the response and no significant improvement is given by including the second term (order zero) of the expansion. But in cases (a) and (b), this second term becomes necessary; in particular, it provides an approximation of the difference between the real part of the scattering frequency and the resonant frequency (see formula (41)): notice that although the imaginary parts of the scattering frequencies (b) and (c) have the same order of magnitude, this difference is negligible only in case (c).

7. Conclusion. The numerical results we obtained show the efficiency of our method: the knowledge of the scattering frequencies and of the associated scattering modes not only allows us to locate the resonant frequencies without computing the whole response curve, but also provides an approximation of the solution of the steady-state problem in the vicinity of these frequencies. However, as regards the numerical computation of the scattering frequencies, there still remains the question of which is worth studying: we actually need a priori bounds to provide good initial guesses for the iterative algorithm which solves the nonlinear eigenvalue problem.

In a forthcoming paper, we will show how the method can be extended to a more complicated fluid-structure interaction problem: the "sea-keeping" problem, i.e., the study of the motions of a floating body on the sea.

Appendix. A direct way of expanding the solution. In this section, we shall assume that the solution $\varphi(\nu)$ of (23) is subject to an expansion similar to (37): in the vicinity of ν_*, for some integer $\rho \geqq 0$, we have

$$\varphi(\nu) = \sum_{r \geqq -\rho} (\nu - \nu_*)^r \varphi^{(r)}. \tag{48}$$

The expansion of the right-hand side member $F(f, \nu)$ and of operator $\mathbb{S}(\nu)$ are straightforward:

$$F(f, \nu) = \sum_{n=0}^{\infty} (\nu - \nu_*)^n F^{(n)} \quad \text{and} \quad \mathbb{S}(\nu) = \sum_{n=0}^{\infty} (\nu - \nu_*)^n \mathbb{S}^{(n)}.$$

By replacing the different terms by their expansion in (23), we obtain the following relations between the coefficients:

$$\sum_{r=-p}^{q-1} \mathbb{S}^{(q-r)}\varphi^{(r)}+(\mathbb{J}+\mathbb{S}^{(0)})\varphi^{(q)}=F^{(q)}, \quad q \geqq -p. \tag{49}$$

In the sequel we shall give explicit expressions for the solution of system (49); the difficulty originates from the fact that the diagonal element $(\mathbb{J}+\mathbb{S}^{(0)})$ is singular.

Some definitions. We will use the same notations as defined in § 5. Moreover, for $m=1, M$, we set

$$h_m^{(0)}=e_m \quad \text{and, recursively}$$

$$H_m^{(\sigma)}=\sum_{s=0}^{\sigma} \mathbb{S}^{(\sigma+1-s)}h_m^{(s)} \quad \text{with} \tag{50}$$

$$h_m^{(\sigma+1)}=-\mathbb{Q}\mathbb{J}^{-1}H_m^{(\sigma)} \quad \sigma \geqq 0,$$

and

$$Z^{(\sigma)}=\sum_{s=-p}^{\sigma-1} \mathbb{S}^{(\sigma-s)}z^{(s)} \quad \sigma \geqq -p \quad \text{with}$$

$$z^{(s)}=\mathbb{Q}\mathbb{J}^{-1}(F^{(s)}-Z^{(s)}). \tag{51}$$

Notice that $Z^{(\sigma)}=0$ for $\sigma \leqq 0$ and $z^{(\sigma)}=0$ for $\sigma<0$, since $F^{(n)}=0$ for $n<0$; it follows that

$$Z^{(\sigma)}=\sum_{s=0}^{\sigma-1} \mathbb{S}^{(\sigma-s)}z^{(s)}.$$

Finally, by $\mathcal{H}^{(\sigma)}$ we denote the following matrix:

$$\mathcal{H}_{m'm}^{(\sigma)}=(H_m^{(\sigma)}|g_{m'}), \quad m, m'=1, M, \quad \sigma \geqq 0,$$

and by $\mathcal{S}^{(q)}$ the following vector:

$$\mathcal{S}_{m'}^{(q)}=(F^{(q+1)}-Z^{(q+1)}|g_{m'}).$$

Notice that $\mathcal{S}^{(q)}=0$ when $q<-1$.

PROPOSITION 9. *Provided that expansion* (48) *holds in the vicinity of* ν_*, *we have*

$$\text{(i)} \qquad \varphi^{(q)}=\sum_{m=1}^{M}\sum_{\sigma=-p}^{q} \varphi_m^{(\sigma)}h_m^{(q-\sigma)}+z^{(q)};$$

moreover, if $\psi^{(\sigma)}$ *denotes the vector of the* $\varphi_m^{(\sigma)}$, $m=1, M$,

$$\text{(ii)} \qquad \sum_{\sigma=-p}^{q} \mathcal{H}^{(q-\sigma)}\psi^{(\sigma)}=\mathcal{S}^{(q)}, \qquad q \geqq -p.$$

Proof. The proof is recursive; the first step consists in proving formula (i) for $q=-p$. By formula (49) we have

$$(\mathbb{J}+\mathbb{S}^{(0)})\varphi^{(-p)}=F^{(-p)}; \quad \text{consequently}$$

$$\mathbb{P}\mathbb{J}^{-1}F^{(-p)}=0 \quad \text{and thus}$$

$$\varphi^{(-p)}=\sum_{m=1}^{M} \varphi_m^{(-p)}e_m+\mathbb{Q}\mathbb{J}^{-1}F^{(-p)}.$$

(ii) We assume formula (i) is satisfied at ranks $q=-\rho$, Q, and we prove it at rank $Q+1$. By (49)

$$\sum_{r=-\rho}^{Q} \mathbb{S}^{(Q+1-r)}\left[\sum_{m=1}^{M} \sum_{\sigma=-\rho}^{r} \varphi_m^{(\sigma)} h_m^{(r-\sigma)} + z^{(r)}\right] + (\mathbb{J}+\mathbb{S}^{(0)})\varphi^{(Q+1)} = F^{(Q+1)},$$

which is nothing but

$$(\mathbb{J}+\mathbb{S}^{(0)})\varphi^{(Q+1)} + \sum_{m=1}^{M} \sum_{\sigma=-\rho}^{Q} \varphi_m^{(\sigma)} \sum_{r=\sigma}^{Q} \mathbb{S}^{(Q+1-r)} h_m^{(r-\sigma)} + \sum_{r=-\rho}^{Q} \mathbb{S}^{(Q+1-r)} z^{(r)} = F^{(Q+1)};$$

or, equivalently,

$$(\mathbb{J}+\mathbb{S}^{(0)})\varphi^{(Q+1)} + \sum_{m=1}^{M} \sum_{\sigma=-\rho}^{Q} \varphi_m^{(\sigma)} H_m^{(Q-\sigma)} = F^{(Q+1)} - Z^{(Q+1)}.$$

It follows that

$$\text{(52)} \qquad \begin{aligned} &\mathbb{P}\mathbb{J}^{-1}(F^{(Q+1)} - Z^{(Q+1)}) - \sum_{m=1}^{M} \sum_{\sigma=-\rho}^{Q} \varphi_m^{(\sigma)} \mathbb{P}\mathbb{J}^{-1} H_m^{(Q-\sigma)} = 0, \\ &\varphi^{(Q+1)} = \sum_{m=1}^{M} \varphi_m^{(Q+1)} e_m + \sum_{m=1}^{M} \varphi_m^{(\sigma)} h_m^{(Q+1-\sigma)} + z^{(Q+1)}. \end{aligned}$$

(iii) From formula (52), we infer that

$$\sum_{m=1}^{M} \sum_{\sigma=-\rho}^{Q} \varphi_m^{(\sigma)} (H_m^{(Q-\sigma)} \,|\, g_{m'}) = (F^{(Q+1)} - Z^{(Q+1)} \,|\, g_{m'}) \quad \forall m'=1, M, \forall Q \geqq -\rho, \quad \text{i.e.,}$$

$$\sum_{\sigma=-\rho}^{Q} \mathcal{H}^{(Q-\sigma)} \psi^{(\sigma)} = \mathcal{S}^{(Q)} \quad \forall Q \geqq -\rho. \qquad \square$$

This proposition allows the determination of the $\varphi_m^{(\sigma)}$. Three situations occur:

(i) If $\mathcal{H}^{(0)}=0$, then

$$\sum_{\sigma=-\rho}^{q-1} \mathcal{H}^{(q-\sigma)} \psi^{(\sigma)} = \mathcal{S}^{(q)}, \qquad q \geqq -\rho,$$

which is similar to formula (ii) of Proposition 9, with $\mathcal{H}^{(0)}$ replaced by $\mathcal{H}^{(1)}$. We are thus brought back to the initial situation.

(ii) If $\mathcal{H}^{(0)}$ is invertible, then

$$\text{(53)} \qquad \psi^{(\sigma)} = (\mathcal{H}^{(0)})^{-1}\left[\mathcal{S}^{(\sigma)} - \sum_{r=-\rho}^{\sigma-1} \mathcal{H}^{(\sigma-r)} \psi^{(r)}\right], \quad \text{for } \sigma \geqq -\rho;$$

notice that $\psi^{(\sigma)}$ vanishes for $\sigma < -1$.

(iii) If $\mathcal{H}^{(0)}$ is not invertible, and if we assume that its eigenvalue zero is semisimple, then the solution of (ii) of Proposition 9 is a similar problem to solving (49), where $\mathcal{H}^{(0)}$ replaces $(\mathbb{J}+\mathbb{S}^{(0)})$ and $\mathcal{H}^{(q)}$ replaces $\mathbb{S}^{(q)}$, $q>0$.

In the simple case where $M=1$, this discussion becomes straightforward: by l we denote the lowest integer such that $\mathcal{H}^{(l)} \neq 0$, and we obtain

$$\psi^{(q-l)} = \frac{1}{\mathcal{H}^{(l)}}\left[\mathcal{S}^{(q)} - \sum_{\sigma=-\rho}^{q+1-l} \mathcal{H}^{(q-\sigma)} \psi^{(\sigma)}\right];$$

it follows that $\psi^{(\sigma)}$ vanishes for $\sigma < -1 - l$.

Remark 8. The following quantities are needed in the preceding formulas:

$$h_m^{(\sigma+1)} = -\mathbb{Q}\mathbb{J}^{-1}H_m^{(\sigma)} \quad \text{and} \quad z^{(\sigma)} = \mathbb{Q}\mathbb{J}^{-1}(F^{(\sigma)} - Z^{(\sigma)});$$

we are thus led to the solution of singular systems:

$$(54) \qquad \begin{aligned} &(\mathbb{J} + \mathbb{S}^{(0)})h_m^{(\sigma+1)} = -\left[H_m^{(\sigma)} - \sum_{m'=1}^{M} (H_m^{(\sigma)} | g_{m'})\mathbb{J}e_{m'}\right] \\ &(\mathbb{J}h_m^{(\sigma+1)} | g_{m'}) = 0, \qquad m' = 1, M, \end{aligned}$$

and

$$(55) \qquad \begin{aligned} &(\mathbb{J} + \mathbb{S}^{(0)})z^{(\sigma)} = F^{(\sigma)} - Z^{(\sigma)} - \sum_{m'=1}^{M} (F^{(\sigma)} - Z^{(\sigma)} | g_{m'})\mathbb{J}e_{m'} \\ &(\mathbb{J}z^{(\sigma)} | g_{m'}) = 0, \qquad m' = 1, M. \end{aligned}$$

A special case. We now give some details about the case where $\mathscr{H}^{(0)}$ has only one eigenvalue, different from zero; moreover, assume that $\mathscr{H}^{(0)}$ is diagonalizable, then it is diagonal and eventually a multiple of the identity

$$\mathscr{H}^{(0)} = \frac{1}{M}\sum_{m=1}^{M} (H_m^{(0)} | g_m)\mathbb{I} = (H_{m'}^{(0)} | g_{m'})\mathbb{I} \quad \forall m'.$$

Furthermore, if $\mathbb{U}^{(0)}$ is assumed diagonalizable, an explicit expression of the operator $\mathbb{Q}$ is available:

$$\mathbb{Q}G = \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (\mathbb{J}G | g_{ij})e_{ij}.$$

As $\psi^{(\sigma)} = 0$ for $\sigma < -1$, it is enough to choose $\rho = 1$; as a consequence:

$$H_m^{(0)} = \mathbb{S}^{(1)}e_m,$$

$$h_m^{(1)} = -\sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (\mathbb{S}^{(1)}e_m | g_{ij})e_{ij},$$

$$H_m^{(1)} = \mathbb{S}^{(2)}e_m - \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (\mathbb{S}^{(1)}e_m | g_{ij})\mathbb{S}^{(1)}e_{ij},$$

and

$$z^{(0)} = \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (F^{(0)} | g_{ij})e_{ij},$$

$$Z^{(1)} = \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (F^{(0)} | g_{ij})\mathbb{S}^{(1)}e_{ij}.$$

It follows that

$$\mathscr{S}_m^{(-1)} = (F^{(0)} | g_m),$$

$$\mathscr{S}_m^{(0)} = (F^{(1)} | g_m) - \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (F^{(0)} | g_{ij})(\mathbb{S}^{(1)}e_{ij} | g_m),$$

and thus,

$$\varphi_m^{(-1)} = \frac{M(F^{(0)}|g_m)}{\sum_{m'=1}^{M} (\mathbb{S}^{(1)}e_{m'}|g_{m'})},$$

$$\begin{aligned}\varphi_m^{(0)} = \frac{M}{\sum_{m'=1}^{M} (\mathbb{S}^{(1)}e_{m'}|g_{m'})} \Bigg[& (F^{(1)}|g_m) - \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (F^{(0)}|g_{ij})(\mathbb{S}^{(1)}e_{ij}|g_m) \\ & - \frac{M}{\sum_{m'=1}^{M} (\mathbb{S}^{(1)}e_{m'}|g_{m'})} \sum_{m'=1}^{M} (F^{(0)}|g_{m'}) \\ & \cdot \Bigg[\!\!\Bigg[(\mathbb{S}^{(2)}e_{m'}|g_m) - \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (\mathbb{S}^{(1)}e_{m'}|g_{ij})(\mathbb{S}^{(1)}e_{ij}|g_m) \Bigg]\!\!\Bigg]\Bigg].\end{aligned}$$

Finally, we obtain

$$\varphi^{(-1)} = M \frac{\sum_{m=1}^{M} (F^{(0)}|g_m)e_m}{\sum_{m=1}^{M} (\mathbb{S}^{(1)}e_m|g_m)}, \quad \text{and}$$

$$\varphi^{(0)} = -\sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} \sum_{m=1}^{M} \varphi_m^{(-1)}(\mathbb{S}^{(1)}e_m|g_{ij})e_{ij} + \sum_{m=1}^{M} \varphi_m^{(0)}e_m + \sum_{i=2}^{I} \frac{1}{1+\mu_i} \sum_{j=1}^{M(i)} (F^{(0)}|g_{ij})e_{ij}.$$

Remark 9. It is worth noticing that these formulas agree with (39) and (40) if $\mathcal{H}^{(1)}$ is assumed diagonal.

GLOBAL SOLUTIONS TO THE COMPRESSIBLE NAVIER–STOKES EQUATIONS FOR A REACTING MIXTURE*

GUI-QIANG CHEN†

Abstract. Existence theorems are established for global generalized solutions to the compressible Navier–Stokes equations for a reacting mixture with discontinuous Arrhenius functions, which describe dynamic combustion. Equivalence of the Navier–Stokes equations in the Euler coordinates and the Lagrange coordinates for the generalized solutions is verified. The asymptotic behavior of the generalized solutions with different boundary conditions is identified and proved.

Key words. global generalized solutions, asymptotic behavior, equivalence, combustion, discontinuous Arrhenius functions, a priori estimates, Navier–Stokes equations

AMS(MOS) subject classifications. 35B40, 35D05, 76V05, 35B45

1. Introduction. We are concerned with the existence and asymptotic behavior of global solutions to the compressible Navier–Stokes equations for a reacting mixture with discontinuous reacting rate functions, which describe dynamic combustion. These equations in the Euler coordinates are of the following form (cf. [1]–[3]):

$$\tag{1.1} \begin{cases} \rho_t + (\rho u)_x = 0, \\ (\rho u)_t + (\rho u^2 + p)_x = (\mu u_x)_x, \\ (\rho E)_t + (u(\rho E + p))_x = (\mu u u_x)_x + (\nu T_x)_x + (q d \rho Z_x)_x, \\ (\rho Z)_t + (\rho u Z)_x = -K\phi(T)\rho Z + (d\rho Z_x)_x, \end{cases}$$

where ρ, u, E, and Z are the density, the fluid velocity, the total specific energy, and the mass fraction of the reactant, respectively; the constants μ, ν, d, and K are the coefficients of bulk viscosity, heat conduction, species diffusion, and rate of reactant, respectively; and T is the temperature.

The total specific energy has the form

$$\tag{1.2} E = e + \frac{u^2}{2} + qZ,$$

where e is the specific internal energy and q is the difference in the heats of formation of the reactant and the product.

For an ideal gas mixture with the same γ-gas laws, the internal energy e and the temperature T are often given via thermodynamics through the following equations of state:

$$\tag{1.3} \begin{cases} e = pv/(\gamma - 1), \\ T = pv/a. \end{cases}$$

Here, $v = \frac{1}{\rho}$ (the specific volume) and $a = RM > 0$, where R is the Boltzmann's gas constant and M is the molecular weight.

The rate function $\phi(T)$ is typically determined by the Arrhenius law:

$$\phi(T) = \begin{cases} T^\alpha e^{-A/T}, & T > T_i > 0, \\ 0, & T < T_i, \end{cases} \tag{1.4}$$

which is generally a uniformly bounded and discontinuous function, where T_i is the ignition temperature and A is the activation energy.

We begin with a bounded region with impermeably insulated boundaries. We assume that the distribution of ρ, u, T, and Z is known at the initial instant $t = 0$. By scaling, we can form the following initial boundary value conditions:

$$(\rho, u, T, Z)|_{t=0} = (\rho_0(x), u_0(x), T_0(x), Z_0(x)), \quad 0 \le x \le 1, \tag{1.5}$$

$$\begin{cases} u(t,i) = 0, \\ T_x(t,i) = 0, \qquad i = 0,1, \quad t \ge 0, \\ Z_x(t,i) = 0, \end{cases} \tag{1.6}$$

$$0 < m_0 \le \rho_0(x), T_0(x) \le M_0 < \infty, \quad 0 \le Z_0(x) \le 1, \tag{1.7}$$

with the compatibility conditions:

$$\begin{cases} u_0(i) = T_{0x}(i) = Z_{0x}(i) = 0, \\ (a\rho_0 T_0 - (\mu u_{0x})_x)|_{x=i} = 0, \end{cases} \quad i = 0,1. \tag{1.8}$$

In addition to the impermeably insulated boundaries, we consider the source boundaries. In particular, we are concerned with the following inhomogeneous initial boundary value conditions:

$$(\rho, u, T, Z)|_{t=0} = (\rho_0(x), u_0(x), T_0(x), Z_0(x)), \quad 0 \le x \le 1, \tag{1.9}$$

$$\begin{cases} u(t,i) = 0, \\ T(t,i) = q_i(t), \qquad i = 0,1, \quad t \ge 0, \\ Z(t,i) = r_i(t), \end{cases} \tag{1.10}$$

$$0 < m_0 \le \rho_0(x), T_0(x) \le M_0 < \infty, \quad 0 \le Z_0(x) \le 1, \tag{1.11}$$

with

$$\begin{cases} u_0(i) = 0, \\ T_0(i) = q_i(0), \\ Z_0(i) = r_i(0), \qquad i = 0,1, \\ 0 < m_0 \le q_i(t) \le M_0 < \infty, \\ 0 \le r_i(t) \le 1. \end{cases} \tag{1.12}$$

Assume that the region filled with the reacting gas is the whole space, and that the distribution of ρ, u, T, and Z is known at the initial instant. For this case we can form the following initial conditions:

$$(\rho,u,T,Z)|_{t=0}=(\rho_0(x),u_0(x),T_0(x),Z_0(x)),\quad -\infty<x<\infty, \tag{1.13}$$

$$\begin{cases} \lim\limits_{|x|\to\infty}(\rho_0(x),u_0(x),T_0(x),Z_0(x))=(1,0,1,0), \\ 0<m_0\le\rho_0(x),T_0(x)\le M_0<\infty,\quad |u_0(x)|\le M_0,\quad 0\le Z_0(x)\le 1. \end{cases} \tag{1.14}$$

As a result of the ignition phenomena in combustion problems, the rate function $\phi(T)$ is generally a discontinuous function in the solution space, and we must consider nonclassical solutions. We denote $\Omega=(0,1)$ or $(-\infty,\infty)$. A function (ρ,u,T,Z) is called a generalized solution to the system (1.1) in $(0,L)\times\Omega$, with the initial boundary value conditions (1.5)–(1.8), or (1.9)–(1.12), or the initial conditions (1.13)–(1.14), if

$$\begin{cases} \rho-1\in L^\infty(0,L;H^1(\Omega)),\qquad \rho_t\in L^2(0,L;L^2(\Omega)), \\ (u,T-1,Z)\in L^\infty(0,L;H^1(\Omega))\cap L^2(0,L;H^2(\Omega)), \\ (u_t,T_t,Z_t)\in L^2(0,L;L^2(\Omega)), \end{cases}$$

and if the function satisfies the system (1.1) almost everywhere in $(0,L)\times\Omega$ and the prescribed initial boundary value in the trace sense of the function belonging to the above classes (see Adams [4]).

It is well known that there are two coordinate systems to describe the flow of fluid in fluid dynamics: the Euler coordinates and the Lagrange coordinates [5]. The Euler coordinates represent a coordinate system imposed on the physical space, while the Lagrange coordinates represent a coordinate system imposed on the flow field. A different choice of independent space coordinates will lead to a different system of partial differential equations. In §2 we introduce the Lagrange coordinates and translate the preceding initial boundary value problems and the Cauchy problem in the Euler coordinates into corresponding problems in the Lagrange coordinates. A calculation using the product rule and chain rule shows that these corresponding problems are equivalent for classical solutions (when such solutions exist). While the discontinuity of the reacting rate function precludes the use of the product rule and chain rule in the classical sense, we verify the equivalence of these corresponding problems in the two coordinates for the corresponding generalized solutions.

In §3 we first establish the existence of global classical solutions of typical initial boundary value problems for the compressible Navier–Stokes equations with a smooth reacting rate function in the Lagrange coordinates. The local solution is based on the Banach theorem as a result of contractivity of the operator, which is equivalent to the solution constructed by linearization of the problems on a small time interval. The global existence theorem is established by extending the local solution with respect to time, based on a priori global estimates. These estimates are obtained by using the maximal principle and the techniques of energy estimates. To deal with the discontinuous rate function ϕ, we concentrate our attention to the dependence of the a priori estimate constants for ϕ. The main finding of our analysis is the crucial independence of the a priori estimates in H^1 on the bounds of the derivative functions of ϕ. By smoothing ϕ and taking the limit, we finally obtain a global generalized solution for the initial boundary value problems with the discontinuous Arrhenius function (1.4).

Different smoothing approaches generate different forms of the discontinuous Arrhenius function near $T = T_i$. We also transform the general initial boundary value problems (cf. (1.9)–(1.10)) to typical ones and similarly establish a global existence theorem.

Our results show that there are global solutions for the initial boundary value problems in spite of the fact that the Arrhenius function is discontinuous. In fact, our analysis indicates that the H^1 norm of the solutions is independent of the bounds of the derivative functions of the Arrhenius function. This finding should be useful in the related problems in the combustion theory.

Our further objective is to study properties of the solutions with the discontinuous Arrhenius functions (1.4). In §4 we focus on the asymptotic behavior of the solutions as $t \to \infty$. We compare the asymptotic behavior of the solutions with two different boundary conditions: the impermeably insulated boundaries and the thermal source boundaries. We conclude that the asymptotic behavior of the solutions with the discontinuous Arrhenius functions (1.4) for the first case is determined not only by the initial data, but also by the Arrhenius functions and the amount of heat released by the given chemical reaction. However, for the second case, the asymptotic behavior of the solutions with the Arrhenius functions (1.4) is completely determined by the boundary data and the initial density, and is independent of the initial velocity, temperature, and mass fraction as well as the scale of the Arrhenius functions and the amount of heat released by the given chemical reaction. We remark that the discontinuous Arrhenius functions (1.4) can have different forms near the ignition temperature $T = T_i$. These results show that the asymptotic behavior of the solutions is independent of those different forms near $T = T_i$ for ϕ. From the difference between the two cases, we can also find a difference in the asymptotic behavior between a reacting mixture and a nonreacting gas [6].

Finally, in §5 we establish an existence theorem of global generalized solutions for the Cauchy problem of the compressible Navier–Stokes equations for the reacting mixture.

In connection with earlier work, we recall that Gardner [7] and Wagner [8] studied the existence and behavior of steady plane wave solutions to the compressible Navier–Stokes equations for a reacting gas and confirmed some phenomena observed in numerical calculations and predicted by the ZND theory, which had been developed independently by Zeldovich, von Neumann, and Döring (see [1] for details). Several theoretical and computational properties regarding the structure and stability of reacting shock waves of the system (1.1) are documented and analyzed in [9] and the references cited therein. For recent developments and strategies in the mathematical theory of combustion, we refer the reader to [2], [3], [10] and the references cited therein.

The existence of global solutions to the one-dimensional nonsteady equations of a viscous compressible gas was first studied in [11]–[12] for simple models. Kazhikhov and Shelukhin [6], [13] established the unique solvability and decay of the solutions for the initial boundary value problems of the viscous heat-conducting perfect gas with large initial data. For a systematic study of existence and decay of the solutions to the system of equations of a viscous compressible gas for small initial data, we refer the reader to [14]–[17] and the references cited therein. We also refer the reader to [18]–[19] for global well-posedness of the Cauchy problem for the nonreacting compressible flow with discontinuous initial data.

2. Equivalence of the Navier–Stokes equations in the Euler and Lagrange coordinates for generalized solutions. The relation between the Euler coordinates (t, x) and the Lagrange coordinates (t, y) is given by

$$P : (t, x) \to (t, y), \qquad y = \int_{x(t)}^{x} \rho(t, s) ds, \tag{2.1}$$

where $x(t)$ is a well-defined particle path satisfying $x'(t) = u(x(t), t)$. Using this transformation, we obtain the compressible Navier–Stokes equations for the reacting gas in the Lagrange coordinates from (1.1):

$$\begin{cases} v_t - u_y = 0, \\ u_t + \widetilde{p}_y = \left(\frac{\mu u_y}{v}\right)_y, \\ \widetilde{E}_t + (\widetilde{p}u)_y = \left(\frac{\mu u u_y}{v} + \frac{\nu T_y}{v} + \frac{q d Z_y}{v^2}\right)_y, \\ Z_t + K\phi(T)Z = \left(\frac{dZ_y}{v^2}\right)_y, \end{cases} \tag{2.2}$$

where $\widetilde{p}(v, T) = p\left(\frac{1}{\rho}, T\right)$, and $\widetilde{E}(u, v, T) = E\left(u, \frac{1}{\rho}, T\right)$.

The initial boundary value conditions (1.5)–(1.8) can be translated into similar conditions:

$$(v, u, T, Z)|_{t=0} = (v_0(y), u_0(y), T_0(y), Z_0(y)), \qquad 0 \le y \le 1, \tag{2.3}$$

$$\begin{cases} u(t, i) = 0, \\ T_y(t, i) = 0, \qquad i = 0, 1, \quad t \ge 0, \\ Z_y(t, i) = 0, \end{cases} \tag{2.4}$$

$$0 < m_0 \le v_0(y), T_0(y) \le M_0 < \infty, \qquad 0 \le Z_0(y) \le 1, \tag{2.5}$$

with the compatibility conditions:

$$\begin{cases} u_0(i) = 0, \\ T_{0y}(i) = 0, \\ Z_{0y}(i) = 0, \qquad i = 0, 1, \\ \left(\frac{aT_0}{v_0} - \left(\frac{\mu u_{0y}}{v_0}\right)_y\right)|_{y=i} = 0. \end{cases} \tag{2.6}$$

Here we take $x(t) = 0$ in (2.1) and, for simplicity, assume that $\int_0^1 \rho_0(x)dx = 1$.

Similarly, the boundary conditions (1.9) can be transformed into the following form:

$$\begin{cases} u(t, i) = 0, \\ T(t, i) = q_i(t), \qquad i = 0, 1, \quad t \ge 0, \\ Z(t, i) = r_i(t). \end{cases} \tag{2.7}$$

More general boundary conditions can be expressed by

$$(2.8)\qquad \begin{cases} u(t,i) = p_i(t), \\ T(t,i) = q_i(t), \qquad i = 0,1, \quad t \geq 0, \\ Z(t,i) = r_i(t), \end{cases}$$

with

$$(2.9)\qquad \begin{cases} u_0(i) = p_i(0), \quad T_0(i) = q_i(0), \quad Z_0(i) = r_i(0), \\ |p_i(t)| \leq M_0 < \infty, \quad 0 \leq r_i(t) \leq 1, \\ 0 < m_0 \leq q_i(t) \leq M_0 < \infty, \\ l(t) = \int_0^1 v_0(y)dy + \int_0^t (p_1(\tau) - p_0(\tau))d\tau \geq \delta > 0. \end{cases}$$

The initial conditions (1.13)–(1.14) can be written into the same form:

$$(2.10)\qquad (v,u,T,Z)|_{t=0} = (v_0(y), u_0(y), T_0(y), Z_0(y)), \qquad -\infty < y < \infty,$$

with

$$(2.11)\qquad \begin{cases} \lim_{|y|\to\infty} (v_0(y), u_0(y), T_0(y), Z_0(y)) = (1,0,1,0), \\ |u_0(y)| \leq M_0 < \infty, \qquad 0 \leq Z_0(y) \leq 1, \\ 0 < m_0 \leq v_0(y), \ T_0(y) \leq M_0 < \infty. \end{cases}$$

We have the following theorem.

THEOREM 1. *The coordinate transformation P given by* (2.1) *induces a one-to-one correspondence between the generalized solutions of* (1.1) *satisfying* $0 < \alpha \leq \rho(t,x) \leq M < \infty$, *almost everywhere for some α and M, and the generalized solutions of* (2.2) *satisfying* $0 < \beta \leq v(t,y) \leq N < \infty$, *almost everywhere for some β and N. In addition, there is a one-to-one correspondence between the corresponding prescribed boundary conditions and initial conditions for the corresponding generalized solutions.*

Proof. We first notice that the transformation $y = \int_{x(t)}^{x} \rho(t,s)ds$ is actually a classical formula for the solution to the gradient system:

$$\frac{\partial y}{\partial x} = \rho(t,x), \qquad \frac{\partial y}{\partial t} = -(\rho u)(t,x),$$

which is consistent because of $\rho_t = -(\rho u)_x$, and P is a bi-C^1 homeomorphism from $(0,L) \times \Omega$ onto itself because $0 < \alpha \leq \rho(t,x) \leq M < \infty$ and $(\rho, u) \in H^1((0,L) \times \Omega)$.

Similar to Wagner [20], we make the transformation P by using the change of variables for integrals with the Jacobian ρ for the generalized solutions (ρ, u, T, Z) to the system (1.1). We write the system (1.1) as

$$U_t + F(U)_x = (DU_x)_x + H(U),$$

with initial data $U(0,x) = U_0(x)$. Then

$$(2.12)\qquad \iint\limits_{(0,L)\times\Omega} (\phi_t U + \phi_x(F - DU_x) + \phi H)dxdt + \int\limits_{\Omega} \phi U_0|_{t=0}dx = 0$$

for all C^1 test functions ϕ with supp $\phi \subset\subset [0,L) \times \Omega$.

Using the transformation P for integrals, we obtain from (2.12)

$$\begin{aligned}
0 = \iint\limits_{(0,L)\times\Omega} &\{(\phi_t \circ P^{-1})(U \circ P^{-1}) + (\phi_x \circ P^{-1})(F \circ P^{-1} - (D \circ P^{-1})(U_x \circ P^{-1})) \\
&+ (\phi \circ P^{-1})(H \circ P^{-1})\} \frac{1}{(\rho \circ P^{-1})} dy\, dt \\
&+ \int_\Omega (\phi \circ P^{-1})(U_0 \circ P^{-1}) \frac{1}{(\rho_0 \circ P^{-1})}|_{t=0} dy \\
= \iint\limits_{(0,L)\times\Omega} &\{(\widetilde{\phi}_t - (\widetilde{\rho}\widetilde{u})\widetilde{\phi}_y)\widetilde{U} + (\widetilde{\phi}_y\widetilde{\rho})(\widetilde{F} - \widetilde{D}(\widetilde{U}_y\widetilde{\rho})) + \widetilde{\phi}\widetilde{H}\} \frac{1}{\widetilde{\rho}} dy\, dt + \int_\Omega \widetilde{\phi}\widetilde{U}_0 \frac{1}{\widetilde{\rho}_0} dy.
\end{aligned}$$

Note that P is a bi-C^1 homeomorphism of $[0,L) \times \Omega$ onto itself and that the induced map $\phi \mapsto \phi \circ P^{-1} = \widetilde{\phi}$ is a bijection on the set of test functions on $[0,L) \times \Omega$. We have

$$\begin{cases} \left(\frac{\widetilde{U}}{\widetilde{\rho}}\right)_t + (\widetilde{F} - \widetilde{u}\widetilde{U})_y = (\widetilde{\rho}\widetilde{D}\widetilde{U}_y)_y + \frac{\widetilde{H}}{\widetilde{\rho}}, \\ \frac{\widetilde{U}}{\widetilde{\rho}}|_{t=0} = \frac{\widetilde{U}_0}{\widetilde{\rho}_0}. \end{cases}$$

Thus the system (1.1) is transformed into the following form:

$$\begin{aligned}
1_t + 0_y &= 0, \\
u_t + \widetilde{p}(v,T)_y &= \left(\frac{\mu u_y}{v}\right)_y, \\
\widetilde{E}_t + (\widetilde{p}u)_y &= \left(\frac{\mu u u_y}{v} + \frac{\nu T_y}{v} + \frac{q d Z_y}{v^2}\right)_y, \\
Z_t + K\phi(T)Z &= \left(\frac{dZ_y}{v^2}\right)_y.
\end{aligned}$$

Moreover, from the conservation of volume, $1_t + 0_x = 0$, we have

$$\left(\frac{1}{\rho}\right)_t - u_y = 0,$$

that is,

$$v_t - u_y = 0.$$

Conversely, we can deduce the system (1.1) from the system (2.2) by checking the process step by step.

Furthermore, we can similarly prove the one-to-one correspondence between the corresponding prescribed boundary conditions for the generalized solutions, in the trace sense of the solution functions belonging to the corresponding classes. This completes the proof of Theorem 1.

In the following sections we restrict our attention to the existence and asymptotic behavior of the global generalized solutions to the compressible Navier–Stokes equations in the Lagrange coordinates. The results can be completely translated into the corresponding results for the compressible Navier–Stokes equations in the Euler coordinates. For instance, the existence theorems for the problems (2.2)–(2.3) and

(2.8)–(2.9) can be translated into existence theorems for the problems (1.1) and (1.5) with free boundary conditions of the following form.

Given $p_i(t) \in H^1(0,L)$, $i=0,1$, there exist unique C^1 functions $x_0(t)$ and $x_1(t)$ such that $x_i'(t) = p_i(t)$ and

$$\int_{x_0(t)}^{x_1(t)} \frac{1}{v(t,s)}ds = 1.$$

The boundary conditions are

$$\begin{cases} u(t,x_i(t)) = p_i(t), & \\ T(t,x_i(t)) = q_i(t), & i=0,1, \quad t \geq 0. \\ Z(t,x_i(t)) = r_i(t). & \end{cases}$$

In particular, if $p_i(t)=0$, $i=0,1$, and $\int_0^1 v_0(y)dy = 1$, then the existence theorems of the system (2.2) with the boundary conditions (2.3)–(2.6) and (2.8)–(2.9) are simply the existence theorems of the system (1.1) with the boundary conditions (1.5)–(1.8) and (1.9)–(1.12).

Now we introduce some notations for the subsequent development.

$$\begin{aligned} Q_L &= (0,L)\times\Omega, \\ B^{\sigma/2,\sigma}(Q_L) &= \left\{ u \in C(Q_L) : \sup_{Q_L}|u| + \sup_{\substack{t\neq s\\ x\neq y}} \frac{|u(t,x)-u(s,y)|}{|t-s|^{\sigma/2}+|x-y|^{\sigma}} < \infty \right\} \\ B^{1+\sigma}(Q_L) &= \{u \in B^{\sigma/2,\sigma}(Q_L) : u_t, u_y \in B^{\sigma/2,\sigma}(Q_L)\}, \\ B^{2+\sigma}(Q_L) &= \{u \in B^{s/2,\sigma}(Q_L) : u_t, u_y, u_{yy} \in B^{\sigma/2,\sigma}(Q_L)\}, \\ \|\cdot\|_{k+\sigma} &= \|\cdot\|_{B^{k+\sigma}}, \qquad k=1,2, \\ \|\cdot\| &= \|\cdot\|_{L^2}. \end{aligned}$$

3. Existence of global solutions of the initial boundary value problems. Scaling the variables, we can write the system (2.2) into the following form:

$$v_t - u_y = 0, \tag{3.1}$$

$$u_t + \left(\frac{aT}{v}\right)_y = \left(\frac{\mu u_y}{v}\right)_y, \tag{3.2}$$

$$\left(T + \frac{u^2}{2}\right)_t + \left(\frac{auT}{v}\right)_y = \left(\frac{\mu u u_y}{v} + \frac{\nu T_y}{v}\right)_y + qK\phi(T)Z, \tag{3.3}$$

$$Z_t + K\phi(T)Z = \left(\frac{d}{v^2}Z_y\right)_y. \tag{3.4}$$

For concreteness, we are concerned with the typical initial boundary value problems:

$$(v,u,T,Z)|_{t=0} = (v_0(y), u_0(y), T_0(y), Z_0(y)), \qquad 0 \leq y \leq 1, \tag{3.5}$$

$$\begin{cases} u(t,i) &= 0, & & \\ T_y(t,i) &= 0, & \text{or} \quad T(t,i)=1, & i=0,1, \quad t\geq 0, \\ Z_y(t,i) &= 0, & \text{or} \quad Z(t,i)=0, & \end{cases} \tag{3.6}$$

$$\begin{cases} 0 < m_0 \leq v_0(y), T_0(y) \leq M_0 < \infty, \quad 0 \leq Z_0(y) \leq 1, \\ \int_0^1 v_0(y)dy = 1, \end{cases} \tag{3.7}$$

with the compatibility conditions:

$$\begin{cases} u_0(i) = 0, & \\ T_{0y}(i) = 0, \quad \text{or} \quad T_0(i) = 1, \\ Z_{0y}(i) = 0, \quad \text{or} \quad Z_0(i) = 0, \\ \left(\frac{aT_0}{v_0} - \left(\frac{\mu u_{0y}}{v_0} \right)_y \right) |_{y=i} = 0. \end{cases} \tag{3.8}$$

At first, we assume that the reacting rate function $\phi(T)$ is a C^1 function and that

$$\begin{cases} ||\phi||_{C^1} & \leq \frac{1}{\epsilon} < \infty, \qquad 0 \leq \phi(T) \leq M < \infty, \\ \phi(T) & = 0 \quad \text{as } T \leq T_i, \end{cases} \tag{3.9}$$

where the constants ϵ and T_i are positive, and the constant M is independent of ϵ. Then we have the following theorem.

THEOREM 2 (Local solutions). *Suppose that there exists a constant $M_0 > 0$ such that*

$$\begin{aligned} &M_0^{-1} \leq \min(v_0, T_0), \quad \max(v_0, T_0) \leq M_0 < \infty, \quad 0 \leq Z_0(y) \leq 1, \\ &||v_0||_{1+\sigma}, \quad ||u_0, T_0, Z_0||_{2+\sigma} \leq M_0 < \infty, \end{aligned}$$

and that the conditions (3.8) *and* (3.9) *hold. Then, for any $M > M_0$, there exist constants $L_0 = L_0(M)$, $N = N(M, \epsilon) \geq M_0$ such that there exists a unique solution (v, u, T, Z) for every initial boundary value problem in* (3.1)–(3.9) *on Q_{L_0} that satisfies*

$$\begin{cases} v \in B^{1+\sigma}(Q_{L_0}), \qquad (u, T, Z) \in B^{2+\sigma}(Q_{L_0}), \\ M^{-1} \leq v \leq M, \qquad N^{-1} \leq T \leq M, \\ ||v||_{1+\sigma, L_0}, \ ||u, T, Z||_{2+\sigma, L_0} \leq N. \end{cases}$$

The proof of Theorem 2 is based on the Banach theorem and the contractivity of the operator:

$$\begin{gathered} B^{1+\sigma}(Q_{L_0}) \times (B^{2+\sigma}(Q_{L_0}))^3 \mapsto B^{1+\sigma}(Q_{L_0}) \times (B^{2+\sigma}(Q_{L_0}))^3, \\ (v, u, T, Z) \mapsto (\overline{v}, \overline{u}, \overline{T}, \overline{Z}), \end{gathered}$$

defined by the following linearization of the problems:

$$\begin{cases} \overline{v}(t, y) = v_0(y) + \displaystyle\int_0^t u_y(\tau, y)d\tau, \\ \overline{u}_t(t, y) = \dfrac{\mu}{v}\overline{u}_{yy} - \dfrac{\mu}{v^2}v_y\overline{u}_y - \dfrac{a}{v}\overline{T}_y + \dfrac{aT}{v^2}v_y, \\ \overline{T}_t(t, y) = \dfrac{\nu}{v}\overline{T}_{yy} - \dfrac{\nu}{v^2}v_y\overline{T}_y - \dfrac{au_y}{v}\overline{T} + \dfrac{\mu}{v}u_y^2 + qK\phi(T)Z, \\ \overline{Z}_t(t, y) = \dfrac{d}{v^2}\overline{Z}_{yy} - \dfrac{2d}{v^3}v_y\overline{Z}_y - K\phi(T)\overline{Z}, \end{cases}$$

with the initial boundary value conditions:

$$\begin{cases} (\overline{v},\overline{u},\overline{T},\overline{Z})|_{t=0} = (v_0(y),u_0(y),T_0(y),Z_0(y)), \\ \overline{u}|_{y=i} = 0, \\ \overline{T}_y|_{y=i} = 0 \quad \text{or} \quad \overline{T}|_{y=i} = 1, \quad i = 0,1, \quad t \geq 0, \\ \overline{Z}_y|_{y=i} = 0 \quad \text{or} \quad \overline{Z}|_{y=i} = 0, \end{cases}$$

on a small time interval $[0, L_0]$. We omit the details of the proof.

Based on the local solvability and the a priori estimates below, we can extend the local solutions in Theorem 2 and obtain the following existence theorem of global solutions.

THEOREM 3 (Classical solutions). *Let the initial data satisfy the conditions* (3.7)–(3.8), *and*

$$v_0 \in C^{1+\alpha}(0,1), \qquad (u_0,T_0,Z_0) \in C^{2+\alpha}(0,1),$$
$$||u_0,T_0,Z_0||_{H^1} \leq M_0,$$

and let the reacting rate function $\phi(T)$ satisfy the condition (3.9). *Then there exists a unique classical solution (v,u,T,Z) for every initial boundary value problem in* (3.1)–(3.9) *such that, for any $L>0$, there exist constants $M(M_0)$ (independent of ϵ and L), $N(M_0,\epsilon,L)>0$ and the following estimates hold on Q_L:*

$$(3.10) \quad \begin{cases} M^{-1} \leq v \leq M, \quad 0 < N^{-1} \leq T \leq M, \quad |u| \leq M, \quad 0 \leq Z(t,y) \leq 1, \\ ||v_t,v_y||^2(t) + \int_0^t ||v_t,v_y||^2(\tau)d\tau \leq M, \\ ||u_y,T_y,Z_y||^2(t) + \int_0^t ||u_{yy},T_{yy},Z_{yy},u_y,T_y,Z_y,u_t,T_t,Z_t||^2(\tau)d\tau \leq M, \\ ||v||_{1+\sigma,L}, \ ||u,T,Z||_{2+\sigma,L} \leq N. \end{cases}$$

Now we make these a priori estimates. The main insight from our analysis is the crucial independence of the a priori estimates on the parameter ϵ. For simplicity, we use M to denote all positive constants that depend only on α_0, M_0, and $||\phi||_\infty$, and are independent of ϵ, L, $||v_0||_{1+\sigma}$, $||u_0,T_0,Z_0||_{2+\sigma}$, and use N to denote the universal constant that specially depends on ϵ and L.

For concreteness, we first deal with the impermeably insulated boundaries.

We have from (3.2) and (3.3)

$$(3.11) \qquad T_t + \frac{aT}{v}u_y = \left(\frac{\nu T_y}{v}\right)_y + \frac{\mu u_y^2}{v} + qK\phi(T)Z.$$

We can immediately conclude the following lemma from (3.1)–(3.4) and (2.3)–(2.6).

LEMMA 1.

$$(3.12) \qquad \int_0^1 v(t,y)dy = \int_0^1 v_0(y)dy = 1,$$

$$(3.13) \qquad \int_0^1 Z(t,y)dy + \int_0^t \int_0^1 K\phi(T)Z\,dy\,d\tau = \int_0^1 Z_0(y)dy,$$

$$\int_0^1 \left(T + \frac{u^2}{2} + qZ\right) dy = \int_0^1 \left(T_0 + \frac{u_0^2}{2} + qZ_0\right) dy, \tag{3.14}$$

$$\begin{aligned} U(t) &+ \int_0^t (V(\tau) + W(\tau))d\tau \\ &= \int_0^1 \left[a(v_0 - 1 - \ln v_0) + \frac{u_0^2}{2} + (T_0 - 1 - \ln T_0)\right] dy \equiv E_0 < \infty, \end{aligned} \tag{3.15}$$

where

$$\begin{cases} U(t) = \displaystyle\int_0^1 \left[a(v - 1 - \ln v) + \frac{u^2}{2} + (T - 1 - \ln T)\right] dy, \\ V(t) = \displaystyle\int_0^1 \left(\frac{\mu u_y^2}{vT} + \frac{\nu T_y^2}{vT^2}\right) dy, \\ W(t) = -q \displaystyle\int_0^1 \frac{T-1}{T} K\phi(T) Z dy. \end{cases}$$

LEMMA 2. $0 \le Z(t,y) \le 1$.

Proof. Set $Y = Ze^{-\beta t}$, $\beta > 0$ constant. Then $Y(t,y)$ satisfies

$$\begin{cases} Y_t + (\beta + K\phi(T))Y = \left(\dfrac{d}{v^2} Y_y\right)_y, \\ Y_y|_{y=0,1} = 0, \\ Y|_{t=0} = Z_0(y). \end{cases}$$

We claim that

$$Y(t,y) \ge 0.$$

On the contrary, there exists $(t_0, y_0) \in [0, L] \times [0,1]$ such that

$$Y(t_0, y_0) = \min_{Q_L} Y(t,y) < 0.$$

Then

$$Y_y(t_0,y_0) = 0, \quad Y_t(t_0,y_0) \le 0, \quad Y_{yy}(t_0,y_0) \ge 0.$$

We have

$$\left(\frac{d}{v^2} Y_y\right)_y (t_0, y_0) \ge 0.$$

However,

$$(Y_t + (\beta + K\phi(T))Y)(t_0, y_0) < 0.$$

This is a contradiction. It follows that

$$Z(t,y) = Y(t,y)e^{\beta t} \ge 0.$$

On the other hand, if we multiply both sides of (3.4) by pZ^{p-1}, $p \ge 2$, then we have

$$(Z^p)_t = \left(\frac{pdZ^{p-1}Z_y}{v^2}\right)_y - p\left(K\phi(T)Z^p + (p-1)Z^{p-2}\frac{dZ_y^2}{v^2}\right) \le \left(\frac{dpZ^{p-1}Z_y}{v^2}\right)_y.$$

Integrating this inequality from zero to 1, we obtain

$$\frac{d}{dt}||Z||_{L^p}(t) \leq 0.$$

This means that

$$||Z||_{L^p}(t) \leq ||Z_0||_{L^p}.$$

Let $p \to +\infty$. We obtain

$$Z(t,y) \leq ||Z_0||_{L^\infty} \leq 1.$$

LEMMA 3. $M^{-1} \leq v(t,y) \leq M$.

Proof. We know from Kazhikov [6], and Kazhikov and Shelukhin [13] that $v(t,y)$ and $T(t,y)$ satisfy the following equalities and estimates using (3.1)–(3.2) and the boundary conditions $(u(t,x),T(t,y))|_{x=0,1} = (0,1)$:

(1) For any $t \geq 0$, there exists $y_1(t) \in [0,1]$ such that

(3.16)
$$\begin{aligned} v(t,y) =&D(t,y)\mathrm{exp}\left(-\frac{1}{\mu}\int_0^t\int_0^1(u^2+aT)d\xi d\tau\right) \\ &\cdot\left\{1+\frac{a}{\mu}\int_0^t\frac{T(\tau,y)}{D(\tau,y)}\mathrm{exp}\left(\frac{1}{\mu}\int_0^\theta au\int_0^1(u^2+aT)d\xi ds\right)d\tau\right\},\end{aligned}$$

where

$$\begin{aligned} D(t,y) =&v_0(y)\mathrm{exp}\left\{\frac{1}{\mu}\left(\int_{y_1(t)}^y u(t,\xi)d\ xi - \int_0^y u_0(\xi)d\xi\right.\right. \\ &\left.\left.+\int_0^1 v_0(\eta)\left(\int_0^\eta u_0(\xi)d\xi\right)d\eta\right)\right\}. \end{aligned} \tag{3.17}$$

(2) For any $t \geq 0$, there exists $y_2(t) \in [0,1]$ such that

$$v(t,y) = \frac{1+\int_0^t \frac{a}{\mu}T(\tau,y)P(\tau)Q(\tau,y)d\tau}{P(t)Q(t,y)}. \tag{3.18}$$

Here

$$\begin{cases} P(t) = v_0(y_2(t))\mathrm{exp}\left\{\displaystyle\int_0^t \frac{a}{\mu}\frac{T}{v}(\tau,y_2(t))d\tau\right\}, \\ Q(t,y) = \dfrac{1}{v_0(y)v(t,y_2(t))}\mathrm{exp}\left\{\dfrac{1}{\mu}\displaystyle\int_{y_2(t)}^y(u_0(\xi)-u(t,\xi))d\xi\right\}, \end{cases} \tag{3.19}$$

and

$$\alpha_0 \leq v(t,y_2(t)),T(t,y_2(t)) \leq \beta_0, \tag{3.20}$$

where the positive constants α_0 and β_0 are roots of

$$y-1-\mathrm{ln}y = E_1 \equiv \frac{1}{\min\{1,a\}}\left(E_0+q\int_0^1 Z_0(y)dy\right).$$

(3) $T(t,y)$ satisfies

$$\alpha_0 \le \int_0^1 T(t,y)dy \le \beta_0. \tag{3.21}$$

The estimate (3.21) is a direct corollary of the Jensen inequality and the convexity of the function $T - 1 - \ln T$. In fact, we have

$$\int_0^1 T(t,y)dy - 1 - \ln \int_0^1 T(t,y)dy \le \int_0^1 (T(t,y) - 1 - \ln T(t,y))dy \le E_1 < +\infty,$$

by using (3.13) and (3.15).

Set

$$\begin{cases} m_v(t) = \min\limits_{y\in[0,1]} v(t,y), & M_v(t) = \max\limits_{y\in[0,1]} v(t,y), \\ m_T(t) = \min\limits_{y\in[0,1]} T(t,y), & M_T(t) = \max\limits_{y\in[0,1]} T(t,y). \end{cases}$$

Using (3.15), we conclude that there exists a constant $M > 0$, which is independent of t, such that

$$M^{-1} \le D(t,y), Q(t,y) \le M < \infty. \tag{3.22}$$

Furthermore, we observe that

$$0 < a_1 \le \int_0^1 (u(t,y)^2 + aT(t,y))dy \le a_2 < +\infty, \tag{3.23}$$

by using (3.13), (3.15), and (3.21), where

$$\begin{cases} a_1 = \alpha_0 a, \\ a_2 = \beta_0 a + 2(E_0 + q\int_0^1 Z_0(y)dy). \end{cases}$$

Therefore, we have from (3.16) and (3.23) that

$$v(t,y) \le M\exp(-a_1 t)\left\{1 + \frac{a}{\mu}\int_0^t M_T(\tau)\exp(a_1\tau)d\tau\right\}.$$

Thus

$$M_v(t) \le M\exp(-a_1 t)\left\{1 + \frac{a}{\mu}\int_0^t M_T(\tau)\exp(a_1\tau)d\tau\right\}. \tag{3.24}$$

Moreover, for $y_2(t) \in [0,1]$ satisfying (3.20), we have

$$\begin{aligned} T(t,y)^{1/2} &= T(t,y_2(t))^{1/2} + \int_{y_2(t)}^{y} \frac{T_y}{2T^{1/2}}dy \\ &\le T(t,y_2(t))^{1/2} + \left(\frac{1}{4\nu}V(t)M_v(t)\int_0^1 Tdy\right)^{1/2} \\ &\le T(t,y_2(t))^{1/2} + \left(\frac{\beta_0}{4\nu}V(t)M_v(t)\right)^{1/2}. \end{aligned}$$

Similarly, we have

$$T(t,y)^{1/2} \geq T(t,y_2(t))^{1/2} - \left(\frac{\beta_0}{2\nu}V(t)M_v(t)\right)^{1/2}.$$

Therefore,

$$\left\{\begin{array}{l} M_T(t) \leq M(1+M_v(t)V(t)), \\ m_T(t) \geq M^{-1}(1-M_v(t)V(t)). \end{array}\right. \tag{3.25}$$

Using (3.24) and (3.25), we have

$$M_v(t) \leq M\left\{1+\int_0^t \exp(-a_1(t-\tau))V(\tau)M_v(\tau)d\tau\right\},$$

and

$$M_v(t) \leq M\exp\left(M\int_0^\infty V(\tau)d\tau\right)\{1+\exp(-a_1 t)\} \leq M. \tag{3.26}$$

Furthermore, we have

$$m_v(t) \geq M^{-1}\exp(-a_2 t)\left\{1+\frac{a}{\mu}\int_0^t m_T(\tau)\exp(a_2\tau)d\tau\right\}. \tag{3.27}$$

Substitute (3.25) into (3.27). We obtain

$$m_T(t) \geq M^{-1}\left\{1-M\int_0^t \exp(-a_2(t-\tau))V(\tau)d\tau\right\}.$$

Notice that

$$\lim_{t\to+\infty}\int_0^t \exp(-a_2(t-\tau))V(\tau)d\tau = 0.$$

Therefore, there exists an $L_0 > 0$ such that

$$m_v(t) \geq \frac{M^{-1}}{2} \quad \text{when } t > L_0. \tag{3.28}$$

On the other hand, we have from (3.12), (3.18), and (3.22) that

$$\begin{aligned} P(t) &= \int_0^1 P(t)v(t,y)dy \\ &= \int_0^1 \frac{1+\int_0^t \frac{a}{\mu}T(\tau,y)P(\tau)Q(\tau,y)d\tau}{Q(t,y)}dy \\ &\leq M\left(1+\int_0^t P(\tau)d\tau\int_0^1 T(\tau,y)dy\right) \\ &\leq M\left(1+\int_0^t P(\tau)d\tau\right). \end{aligned}$$

This means that

$$P(t) \leq Me^{Mt},$$

that is,

$$m_v(t) \geq P(t)^{-1}Q(t,y)^{-1} \geq M^{-1}e^{-ML_0} > 0 \quad \text{when} \quad 0 \leq t \leq L_0. \tag{3.29}$$

Combining (3.28) with (3.29), we have

$$m_v(t) \geq M^{-1} > 0.$$

This completes the proof of Lemma 3.

LEMMA 4. $T(t,y) \geq N^{-1} > 0$.

Proof. Set $\theta = T^{-1}$. Multiplying (3.11) by T^{-2}, we obtain

$$\theta_t = \left(\nu \frac{\theta_y}{v}\right)_y + \frac{a^2}{4\mu}\frac{1}{v} - \frac{qK\phi(T)}{T^2}Z - \left\{\frac{2\nu T}{v}\theta_y^2 + \frac{\mu\theta^2}{v}\left(u_y - \frac{aT}{\mu}\right)^2\right\}. \tag{3.30}$$

Multiplying (3.30) by $2l\theta^{2l-1}, l = 1,2,3,\cdots$, we have

$$\begin{aligned}(\theta^{2l})_t &\leq \frac{a^2}{4\mu}\frac{2l\theta^{2l-1}}{v} - 2l(2l-1)\theta^{2l-2}\frac{\theta_y^2}{v} + \left(\frac{\nu(\theta^{2l})_y}{v}\right)_y \\ &\leq \frac{a^2}{4\mu}\frac{2l\theta^{2l-1}}{v} + \left(\frac{\nu(\theta^{2l})_y}{v}\right)_y.\end{aligned}$$

Therefore, we obtain

$$\begin{aligned}(\|\theta\|_{L^{2l}}(t))^{2l-1}\frac{d}{dt}\|\theta\|_{L^{2l}}(t) &\leq \frac{a^2}{4\mu}\int_0^1 \frac{\theta^{2l-1}}{v}dy \\ &\leq (\|\theta\|_{L^{2l}}(t))^{2l-1}\frac{a^2}{4\mu}\left\|\frac{1}{v}\right\| L^{2l}(t).\end{aligned}$$

Using the Hölder's inequality, we have

$$\begin{aligned}\|\theta\|_{L^{2l}}(t) &\leq \|\theta\|_{L^{2l}}(0) + \frac{a^2}{4\mu}\int_0^t \|\frac{1}{v}\|_{L^{2l}}(\tau)d\tau \\ &\leq \|\theta\|_{L^{2l}}(0) + \frac{a^2}{4\mu}\int_0^t \frac{1}{m_v(\tau)}d\tau \\ &\leq \|\theta\|_{L^{2l}}(0) + Mt.\end{aligned}$$

Set $l \to +\infty$. We obtain

$$m_T(t)^{-1} \leq M(1+t),$$

that is,

$$m_T(t) \geq M^{-1}(1+t)^{-1} \geq N^{-1} > 0.$$

LEMMA 5.

$$\|v_y, u, T-1, Z\|^2(t) + \int_0^t \|v_y, u_y, T_y, Z_y\|^2(\tau)d\tau + \int_0^t\int_0^1 K\phi(T)Z^2 dy\, d\tau \leq M.$$

Proof. Set $w = T + \frac{u^2}{2} - 1$. Then

$$w_t = \left(\frac{\nu T_y}{v}\right)_y + \left(\frac{\mu u u_y}{v}\right)_y - \left(\frac{auT}{v}\right)_y + qK\phi(T)Z.$$

We multiply both sides of the above equality and (3.2) by w and u^3, respectively. We then integrate them with respect to y from zero to one and use the interpolation formula. We obtain

$$
\begin{aligned}
&\int_0^1 (w^2+u^4)dy + \int_0^t\int_0^1 (T_y^2+u^2u_y^2)dy\,d\tau \\
\le& M\left\{\int_0^1 (w_0(y)^2+u_0(y)^4)dy \right.\\
&\left. + \int_0^t\int_0^1 (u^2T^2+K^2\phi(T)^2Z^2+K\phi(T)Z)dy\,d\tau\right\} \\
\le& M\left\{1+\int_0^t\int_0^1 u^2(w^2+u^4)dy\,d\tau \right.\\
&\left. + \int_0^t\int_0^1 u^2(u^2+1)dy\,d\tau + \int_0^t\int_0^1 K\phi(T)Z dy\,d\tau\right\} \\
\le& M\left(1+\int_0^t \max_y u(\tau,y)^2\int_0^1 (w^2+u^4)dy\,d\tau \right.\\
&\left. + \int_0^t \max_y u(\tau,y)^2\int_0^1 (u^2+1)dy\,d\tau\right) \\
\le& M\left(1+\int_0^t \max_y u(\tau,y)^2 d\tau \right.\\
&\left. + \int_0^t \max_y u(\tau,y)^2\int_0^1 (w^2+u^4)dy\,d\tau\right)
\end{aligned}
$$

by using the estimate

$$\left(T+\frac{u^2}{2}-\int_0^1 T(t,y)dy\right)^2 \le \int_0^1 (T_y^2+u^2u_y^2)dy.$$

Notice that

$$u^2(t,y) \le \left(\int_0^y u_y^2 dy\right)^2 \le \int_0^1 \frac{u_y^2}{vT}dy\int_0^1 vTdy \le MV(t),$$

and $V(t)$ is uniformly integrable. We have

$$||T-1||^2(t) + \int_0^t ||T_y||(\tau)d\tau \le M$$

by using the Gronwall's inequality.

Furthermore, we have

$$u_t + a\frac{T_y}{v} = \frac{aT}{v}\frac{v_y}{v} + \mu\left(\frac{v_y}{v}\right)_t$$

from (3.1) and (3.2). We multiply both sides of the above formula and (3.2) by v_y/v and u, respectively, and then integrate them. We obtain

$$\mu\int_0^1\left(\frac{v_y}{v}\right)^2 dy + \int_0^t\int_0^1\left(\frac{a}{v}T\left(\frac{v_y}{v}\right)^2+\mu\frac{u_y^2}{v}\right)dy\,d\tau \le M.$$

Notice that there exists $0 < \beta < 1$ such that

$$\frac{\int_0^1 \frac{u^2}{2} dy}{\int_0^1 (T + \frac{u^2}{2}) dy} < \beta$$

from (3.21). We have

$$\begin{aligned}
\int_0^1 v_y^2 dy &= \left(\int_0^1 \left(T + \frac{u^2}{2}\right) dy\right)^{-1} \int_0^1 \left(\int_0^1 T + \frac{u^2}{2} dy\right) v_y^2 dy \\
&= \left(\int_0^1 \left(T + \frac{u^2}{2}\right) dy\right)^{-1} \left(\int_0^1 \left(\int_0^1 T dy - T\right) v_y^2 dy + \int_0^1 T v_y^2 dy \right. \\
&\qquad \left. + \int_0^1 \frac{u^2}{2} dy \int_0^1 v_y^2 dy\right) \\
&\le \frac{1+\beta}{2} \int_0^1 v_y^2 dy + M \left(\int_0^1 \left(\int_0^1 T dy - T\right)^2 v_y^2 dy + \int_0^1 T v_y^2 dy\right).
\end{aligned}$$

Therefore,

$$\int_0^1 v_y^2 dy \le M \left(\int_0^1 T_y^2 dy \int_0^1 v_y^2 dy + \int_0^1 T v_y^2 dy\right).$$

Notice that

$$\int_0^t \int_0^1 (T_y^2 + T v_y^2) dy\, dt \le M.$$

We immediately conclude that

$$\int_0^t \int_0^1 v_y^2 dy\, d\tau \le M.$$

Finally, we multiply (3.4) by Z and obtain

$$\left(\frac{Z^2}{2}\right)_t + \frac{d}{v^2} Z_y^2 + K\phi(T) Z^2 = \left(\frac{dZZ_y}{v^2}\right)_y.$$

Therefore, we have

$$\int_0^1 Z^2 dy + \int_0^t \int_0^1 (Z_y^2 + K\phi(T) Z^2) dy\, d\tau \le M.$$

This completes the proof of Lemma 5.

LEMMA 6.

$$||v_t, u_y, T_y, Z_y||^2(t) + \int_0^t ||v_{yt}, u_{yy}, T_{yy}, Z_{yy}, u_t, T_t, Z_t||^2(\tau) d\tau \le M.$$

Proof. We multiply both sides of (3.2) by u_{yy} and use the interpolation inequalities:

$$\begin{cases} \max\limits_y u_y^2 \le \delta \int_0^1 u_{yy}^2 dx + C_\delta \int_0^1 u_y^2 dy, \\ \max\limits_y T^2 \le 2 \int_0^1 T_y^2 dy + 2 \left(\int_0^1 T dy\right)^2. \end{cases}$$

We deduce that

$$||u_y||^2(t) + \int_0^t ||u_{yy}||^2(\tau)d\tau \le M$$

by using Lemma 5.

Next, we multiply both sides of (3.11) by T_{yy} and integrate it. We have

$$\left(\int_0^1 \frac{T_y^2}{2}dy\right)_t + \nu\int_0^1 \frac{T_{yy}^2}{v}dy = \int_0^1 \left(\frac{aT}{v}u_y - \frac{\mu u_y^2}{v} - qK\phi(T)Z\right)T_{yy}dy,$$

and then

$$\left(\int_0^1 \frac{T_y^2}{2}dy\right)_t + \int_0^1 T_{yy}^2dy \le M\int_0^1 (T^2u_y^2 + u_y^2 + q^2K^2\phi(T)^2Z^2)dy.$$

Notice that

$$\int_0^1 u_y^4dy \le \left(\delta\int_0^1 u_{yy}^2dy + C_\delta\int_0^1 u_y^2dy\right)\int_0^1 u_y^2dy,$$

$$\int_0^1 T^2u_y^2dy \le 2\left(\int_0^1 T_y^2dy + \left(\int_0^1 Tdy\right)^2\right)\int_0^1 v_y^2dy,$$

$$\int_0^t\int_0^1 K^2\phi(T)^2Z^2dy\,d\tau \le M\int_0^t\int_0^1 K\phi(T)Z^2dy\,d\tau \le M.$$

We obtain

$$||T_y||^2(t) + \int_0^t ||T_{yy}||^2(\tau)d\tau \le M.$$

Finally, multiplying (3.4) by Z_{yy}, we have

$$\int_0^1 \frac{Z_y^2}{2}dy + \int_0^t\int_0^1 \frac{d}{v^2}Z_{yy}^2dy\,d\tau = \int_0^t\int_0^1 \left(K\phi(T)ZZ_{yy} + \frac{2dv_y}{v^3}Z_yZ_{yy}\right)dy\,d\tau$$
$$\le M\int_0^t\int_0^1 (K\phi(T)Z^2 + Z_y^2)dy\,d\tau \le M$$

by using $\int_0^1 v_y^2dy \le M$ and the interpolation inequality

$$\max_y Z_y^2 \le \delta\int_0^1 Z_{yy}^2dx + C_\delta\int_0^1 Z_y^2dy.$$

This completes the proof of Lemma 6 by using (3.1).

LEMMA 7. $|u| \le M,\ 0 < N^{-1} \le T \le M < \infty$.

Proof. Notice that

$$u^2 \le \int_0^y (u^2)_ydy \le 2\left(\int_0^1 u^2dy\right)^{1/2}\left(\int_0^1 u_y^2dy\right)^{1/2} \le M.$$

We define an auxiliary function f by

$$f(T) = \int_0^T \sqrt{T - 1 - \ln T}dT.$$

Then

$$f(T) \to +\infty \quad \text{as } T \to +\infty.$$

However,

$$\begin{aligned}|f(T)| &\le \int_0^y \sqrt{T-1-\ln T}|T_y|dy\\ &\le \left(\int_0^1 (T-1-\ln T)dy\right)^{1/2}\left(\int_0^1 T_y^2 dy\right)^{1/2} \le M.\end{aligned}$$

Therefore,

$$0 < N^{-1} \le T \le M < \infty.$$

This proves Lemma 7.

With these a priori estimates and $\phi(T) \in C^1$, we obtain the following estimates by using the standard method (cf. [11]–[12]) and the Schauder estimates (cf. [21]).

LEMMA 8. $||v||_{1+\sigma,L}$, $||u,T,Z||_{2+\sigma,L} \le N$.

This proves Theorem 3 for the impermeably insulated boundary conditions.

For the Dirichlet-type boundary conditions, we must use other techniques to arrive at the result.

Notice that the equalities (3.12) and (3.15) still hold by using (3.1) and (3.2), and the boundary conditions $(u(t,y),T(t,y))|_{y=0,1} = (0,1)$. Now we consider (3.4) with the initial boundary value conditions:

$$\left\{\begin{array}{l} Z|_{y=0,1} = 0,\\ Z|_{t=0} = Z_0(x) \ge 0.\end{array}\right. \tag{3.31}$$

Then we have the following lemma.

LEMMA 9. *The solution* $Z(t,y)$ *of* (3.4) *and* (3.31) *satisfies*

$$\left\{\begin{array}{l} 0 \le Z(t,y) \le 1,\\ \int_0^1 Z(t,y)dy + K\int_0^t\int_0^1 \phi(T)Z dy\,d\tau \le \int_0^1 Z_0(y)dy.\end{array}\right. \tag{3.32}$$

Proof. Similarly to the proof of Lemma 2, we first conclude that

$$Z(t,y) \ge 0.$$

The estimate

$$Z(t,y) \le 1$$

is a direct corollary of the maximal principle.

We multiply (3.4) by $\beta Z^{\beta-1}, \beta \in (1,2)$. Then we have

$$(Z^\beta)_t + \beta K\phi(T)Z^\beta = \beta Z^{\beta-1}\left(\frac{d}{v^2}Z_y\right)_y.$$

Thus

$$\int_0^1 Z(t,y)^\beta dy + \beta\int_0^t\int_0^1 K\phi(T)Z^\beta dy\,d\tau \le \int_0^1 Z_0^\beta(y)dy.$$

Notice that, for any fixed point $(\tau, y) \in (0, t] \times (0, 1)$,

$$\begin{cases} Z(\tau, y)^{\beta} \longrightarrow Z(\tau, y), \\ Z_0(y)^{\beta} \longrightarrow Z_0(y), \end{cases}$$

when $\beta \longrightarrow 1$ and

$$|Z^{\beta}(\tau, y)| \leq 1.$$

Using the dominated convergence theorem, we obtain

$$\int_0^1 Z(t, y)dy + K \int_0^t \int_0^1 \phi(T) Z dy d\tau \leq \int_0^1 Z_0(y)dy.$$

This completes the proof of Lemma 9.

LEMMA 10.

$$T \geq N^{-1} > 0.$$

Proof. Set $X = Te^{-\beta t}, \beta = \max_{Q_L} |\frac{au_y}{v}|$. Then $X(t, y)$ satisfies

$$\begin{cases} X_t + (\beta + \frac{au_y}{v})X = \left(\frac{\nu X_y}{v}\right)_y + \frac{\mu u_y^2}{v} e^{-\beta t} + qK\phi(Xe^{\beta t})Ze^{-\beta t}, \\ X|_{y=0,1} = e^{-\beta t}, \\ X|_{t=0} = T_0(x). \end{cases}$$

We conclude that

$$X(t, y) \geq \min(e^{-\beta L}, \min_{y \in [0,1]} T_0(y)) > 0$$

by using the maximal principle, which means that

$$T(t, y) \geq N^{-1} > 0.$$

Using Lemma 9, we can obtain the uniform bound of $v(t, y)$, which is independent of t and ϵ.

LEMMA 11. $M^{-1} \leq v(t, y) \leq M$.

In fact, using Lemma 9 and (3.15), we can obtain the estimate (3.23). Following the proof of Lemma 3, we then can complete the proof of Lemma 11.

The remaining arguments are the same as those discussed for the insulated problem. For the mixed problems, we can arrive at the result in the same fashion. This completes the proof of the theorem.

We know that the reacting rate function $\phi(T)$ is typically of the form (1.4) because of the ignition phenomenon in the combustion process. We modify $\phi(T)$ as follows:

$$\begin{cases} \phi_\epsilon(T) = \begin{cases} T^{\alpha} e^{-A/T}, & T \geq T_i + \epsilon, \\ 0, & T \leq T_i - \epsilon, \end{cases} \\ ||\phi_\epsilon||_{C^1} \leq \frac{1}{\epsilon} < \infty. \end{cases}$$

Then we follow the scheme given above and obtain global solutions $(v^\epsilon, u^\epsilon, T^\epsilon, Z^\epsilon)$ such that

$$v^\epsilon \in B^{1+\sigma}(Q_L), \qquad (u^\epsilon, T^\epsilon, Z^\epsilon) \in B^{2+\sigma}(Q_L),$$

and

$$(3.33)\quad \begin{cases} M^{-1} \le v^\epsilon \le M, \quad N^{-1} \le T^\epsilon \le M, \quad |u^\epsilon| \le M, \quad 0 \le Z^\epsilon(t,y) \le 1, \\ ||v^\epsilon_t, v^\epsilon_y||^2(t) + \int_0^t ||v^\epsilon_t, v^\epsilon_y||^2(\tau)d\tau \le M, \\ ||u^\epsilon_y, T^\epsilon_y, Z^\epsilon_y||^2(t) + \int_0^t ||v^\epsilon_{yt}, u^\epsilon_{yy}, T^\epsilon_{yy}, Z^\epsilon_{yy}, u^\epsilon_y, T^\epsilon_y, Z^\epsilon_y, Z^\epsilon_y, u^\epsilon_t, T^\epsilon_t, Z^\epsilon_t||^2(\tau)d\tau \le M, \end{cases}$$

where M is the constant independent of ϵ.

Using this fact, we can obtain the following theorem.

THEOREM 4 (Generalized solution). *Let the initial data satisfy* (3.7)–(3.8), *and*

$$(v_0(y), u_0(y), T_0(y), Z_0(y)) \in H^1(0,1).$$

Then there exists a generalized solution (v, u, T, Z) *for every initial boundary value problem in* (3.1)–(3.8) *with the discontinuous Arrhenius function* (1.4) *satisfying the same estimates as* (3.33).

In fact, we can immediately assert from (3.2) that there exists a subsequence converging in the strong topology of L^2 such that

$$(v^\epsilon, u^\epsilon, T^\epsilon, Z^\epsilon) \to (v, u, T, Z) \in H^1,$$

where (v, u, T, Z) is a generalized solution for the corresponding problem.

Remark. These existence arguments can be generalized to general initial boundary value problems. As an example, we consider the problem (3.1), (2.3), and (2.8)–(2.9).

Construct function $(u_1(t,y), T_1(t,y), Z_1(t,y))$ as follows:

$$u_1(t,y) = \frac{k(t)}{l(t)} \int_0^y v(t,\xi)d\xi + p_0(t),$$

where $k(t) = p_1(t) - p_0(t)$.

$T_1(t,y)$ and $Z_1(t,y)$ are solutions of the following linear problems:

$$\begin{cases} \dfrac{\partial T_1}{\partial t} = \dfrac{\partial}{\partial y}\left(\dfrac{\nu}{v}\dfrac{\partial T_1}{\partial y}\right), \quad 0 < y < 1, \quad 0 < t < L, \\ T_1|_{y=i} = q_i(t), \quad i = 0, 1, \quad t \ge 0, \\ T_1|_{t=0} = T_0(y), \end{cases}$$

and

$$\begin{cases} \dfrac{\partial Z_1}{\partial t} = \dfrac{\partial}{\partial y}\left(\dfrac{d}{v^2}\dfrac{\partial Z_1}{\partial y}\right), \quad 0 < y < 1, \quad 0 < t < L, \\ Z_1|_{y=i} = r_i(t), \quad i = 0, 1, \quad t \ge 0, \\ Z_1|_{t=0} = Z_0(y), \end{cases}$$

respectively.

Using the functions and mapping

$$(u, T, Z) \to (w, X, Y)$$

by

$$\begin{cases} w(t,y) = u(t,y) - u_1(t,y), \\ X(t,y) = \dfrac{T(t,y)}{T_1(t,y)}, \\ Y(t,y) = Z(t,y) - Z_1(t,y), \end{cases}$$

we transform (3.1)–(3.4), (2.3), and (2.8)–(2.9) into the following problem:

$$\begin{cases} v_t = w_y + \dfrac{k}{l}v, \\ w_t = \left(\dfrac{\mu}{v}w_y\right)_y - \left(\dfrac{aT_1\theta}{v}\right)_y - u_{1t}, \\ X_t = \left(\dfrac{\nu X_y}{v}\right)_y + \dfrac{2\nu}{v}\dfrac{T_{1y}}{T_1}X_y + \dfrac{\mu u_y^2}{vT_1} - a\dfrac{X}{v}u_y + K\dfrac{\phi(T_1X)}{T_1}Z, \\ Y_t = \left(\dfrac{d}{v^2}Y_y\right)_y - K\phi(T_1X)(Y+Z_1), \end{cases} \tag{3.34}$$

$$\begin{cases} w|_{y=0,1} = 0, \\ X|_{y=0,1} = 1, \qquad t \geq 0, \\ Y|_{y=0,1} = 0, \end{cases} \tag{3.35}$$

and

$$(v,w,X,Y)|_{t=0} = \left(v_0(y), u_0(y) - \frac{k(0)}{l(0)}\int_0^y v_0(\xi)d\xi - p_0(0), 1, 0\right). \tag{3.36}$$

In the same manner we can solve the problem (3.34)–(3.36) and obtain similar estimates of the solutions to (3.21) for $0 \leq t \leq L < +\infty$.

4. Asymptotic behavior of the solutions for the initial boundary value problems. For concreteness, in this section we restrict our attention to the two typical boundary conditions:

$$(\mathrm{I})\begin{cases} u(t,i) = 0, \\ T_y(t,i) = 0, \qquad i = 0,1, \quad t \geq 0, \\ Z_y(t,i) = 0, \end{cases}$$

and

$$(\mathrm{II})\begin{cases} u(t,i) = 0, \\ T(t,i) = 1, \qquad i = 0,1, \quad t \geq 0, \\ Z(t,i) = 0. \end{cases}$$

We compare the asymptotic behavior of the solutions to the system (3.1)–(3.4), satisfying the boundary conditions (I) and (II) with the initial condition (3.5) and discontinuous Arrhenius functions (1.4). We have the following theorem.

THEOREM 5. *Let the initial data satisfy the conditions of Theorem 4, and let the reacting rate function be of the form* (1.4). *Then*

(A) *Any generalized solution* (v,u,T,Z) *to the system* (3.1)–(3.4) *with the boundary conditions* (I) *satisfies*

$$||v - \int_0^1 v_0(y)dy, u, T - T_\infty, Z - Z_\infty||_{H^1(0,1)}(t) \to 0 \quad \text{as } t \to \infty, \tag{4.1}$$

where the constants T_∞ *and* Z_∞ *satisfy*

$$\begin{cases} T_\infty + qZ_\infty = \displaystyle\int_0^1 \left(T_0(y) + qZ_0(y) + \frac{u_0^2(y)}{2}\right) dy, \\ \phi(T_\infty)Z_\infty = 0. \end{cases}$$

(B) *Any generalized solution* (v,u,T,Z) *to the system* (3.1)–(3.4) *with the boundary conditions* (II) *satisfies*

$$||v - \int_0^1 v_0(y)dy, u, T - 1, Z||_{H^1(0,1)}(t) \to 0 \quad \text{as } t \to \infty. \tag{4.2}$$

Proof. The generalized solutions of the two problems satisfy the estimate

$$\int_0^\infty ||v_y, u_y, T_y, Z_y, v_t, u_t, T_t, Z_t, v_{yt}, u_{yy}, T_{yy}, Z_{yy}||^2(t)dt \le M < \infty$$

from Theorem 4. Therefore, we have

$$\int_0^\infty \left(\left|\frac{d}{dt}||v_y||^2(t)\right| + \left|\frac{d}{dt}||u_y||^2(t)\right| + \left|\frac{d}{dt}||T_y||^2(t)\right| \right. \\ \left. + \left|\frac{d}{dt}||Z_y||^2(t)\right| \right) dt \le M$$

and

$$\int_0^\infty (||v_y||^2(t) + ||u_y||^2(t) + ||T_y||^2(t) + ||Z_y||^2(t))\, dt \le M.$$

This means that

$$||v_y, u_y, T_y, Z_y||(t) \to 0 \quad \text{as } t \to \infty. \tag{4.3}$$

For (A), we have

(4.4)
$$\begin{cases} \left(v - \displaystyle\int_0^1 v_0(y)dy\right)^2 = \left(v - \displaystyle\int_0^1 v(t,y)dy\right)^2 \le \displaystyle\int_0^1 v_y^2 dy = ||v_y||^2(t) \to 0, \\ u^2 = \left(\displaystyle\int_0^y u_y dy\right)^2 \le \displaystyle\int_0^1 u_y^2 dy = ||u_y||^2(t) \to 0, \qquad t \to \infty, \\ (T + qZ - (T_\infty + qZ_\infty))^2 \le \left(T + qZ + \dfrac{u^2}{2} - \displaystyle\int_0^1 (T + qZ + \frac{u^2}{2})dy\right)^2 + Mu^2 \\ \quad \le ||T_y||^2(t) + q^2||Z_y||^2(t) + M||u_y||^2(t) \to 0 \end{cases}$$

by using (3.12) and (3.14).

Furthermore, since

$$\int_0^\infty \int_0^1 \phi(T) Z \, dy \, dt \leq M < \infty,$$

we deduce that

$$\phi(T_\infty) Z_\infty = 0.$$

This gives us (4.1).

For (B), we have

$$\left\{ \begin{array}{l} \left(v - \int_0^1 v_0(y) dy\right)^2 = \left(v - \int_0^1 v(t,y) dy\right)^2 \leq ||v_y||^2(t) \rightarrow 0, \\ u^2 = \left(\int_0^y u_y dy\right)^2 \leq ||u_y||^2(t) \rightarrow 0, \\ (T-1)^2 = \left(\int_0^y T_y dy\right)^2 \leq \int_0^1 T_y^2 dy = ||T_y||^2(t) \rightarrow 0, \\ Z^2 = \left(\int_0^y Z_y dy\right)^2 \leq \int_0^1 Z_y^2 dy = ||Z_y||^2(t) \rightarrow 0 \end{array} \right. \qquad t \rightarrow \infty, \tag{4.5}$$

by using the boundary conditions (II) and (3.12). This completes the proof of Theorem 5.

The boundary conditions (I) correspond to the impermeably insulated boundaries. Theorem 5(A) shows that the asymptotic state of the solutions of the problem is determined by the initial data and the Arrhenius functions. In particular,

(i) If the initial data satisfy

$$\int_0^1 \left(T_0(y) + qZ_0(y) + \frac{u_0(y)}{2}\right) dy > T_i + q, \tag{4.6}$$

then $Z_\infty = 0$, that is,

$$||Z||_{H^1(0,1)}(t) \rightarrow 0 \quad \text{as } t \rightarrow \infty;$$

(ii) If the initial data satisfy

$$\int_0^1 \left(T_0(y) + qZ_0(y) + \frac{u_0(y)}{2}\right) dy < T_i, \tag{4.7}$$

then

$$T_\infty \leq T_i.$$

Thus, in the impermeably insulated container, five factors determine whether the reacting process completes: the ignition temperature, the amount of heat released by the given chemical reaction, the initial temperature, the velocity, and the mass fraction of the reacting mixture after a sufficiently long time. In particular, if the initial temperature is appropriately high, and/or the initial velocity appropriately fast, and/or the initial mass fraction of the reacting mixture appropriately large such that (4.6) holds, then the reacting process will certainly complete, and all unburnt gas will be burnt out after a sufficiently long time. If the initial temperature is appropriately low, and the initial velocity appropriately slow, and the initial mass fraction of the reacting mixture appropriately small such that (4.7) holds, then the reacting process will certainly stop after a sufficiently long time.

In contrast, the boundary conditions (II) correspond to the thermal source boundaries. Theorem 5(B) shows that the asymptotic state of the temperature T and the mass fraction Z of the problem are completely determined by the boundary data instead of the initial data, the scale of the reacting rate functions, and the amount of heat released. This reacting process will certainly complete, and all unburnt gas will be burnt out after a sufficiently long time.

These arguments may be generalized to more general boundary conditions.

5. Existence of generalized solutions of the Cauchy problem. We now establish an existence theorem of global generalized solutions of the Cauchy problem.

THEOREM 6. *Let the initial data satisfy the condition* (2.11), *and let*

$$(v_0(y)-1, u_0(y), T_0(y)-1, Z_0(y)) \in H^1(-\infty,\infty).$$

Then there exists a generalized solution (v,u,T,Z) *of the problem* (3.1)–(3.4) *and* (2.10) *satisfying*

$$v(t,y), T(t,y) > 0, \qquad 0 \le Z(t,y) \le 1.$$

The proof of Theorem 6 is based on the same arguments as in §3 and the localization lemma of Kazhikhov [6].

LOCALIZATION LEMMA. *For each interval* $I_n = [n, n+1)$, *there is a point* $y_n(t) \in I_n$ *such that*

$$\begin{cases} \alpha_0 \le v(t,y_n(t)) \le \beta_0, \\ \alpha_0 \le T(t,y_n(t)) \le \beta_0, \\ \alpha_0 \le \int_{I_n} v(t,y)dy, \int_{I_n} T(t,y)dy \le \beta_0, \end{cases}$$

where the positive constants α_0 *and* β_0 *are two roots of the equation*

$$y-1-\ln y = \frac{1}{\min\{a,1\}}\left\{\int_0^\infty \left(\frac{u_0^2}{2} + a(v_0-1-\ln v_0) + (T_0-1-\ln T_0)\right)dy + q\int_{-\infty}^\infty Z_0(y)dy\right\}.$$

We omit the details of the proof of this theorem.

SOLUTION OF THE CAUCHY PROBLEM FOR A CONSERVATION LAW WITH A DISCONTINUOUS FLUX FUNCTION*

TORE GIMSE AND NILS HENRIK RISEBRO

Abstract. The Cauchy problem is solved for a conservation law arising in oil reservoir simulation where the flux function may depend discontinuously on the space variable. To do this front tracking is used as a method of analysis.

Key words. conservation laws, discontinuous coefficients, two-phase flow

AMS(MOS) subject classifications. 35A05, 35L65, 35R05, 76T05

Introduction. In this paper we study the Cauchy problem for two phase flow through a one-dimensional porous medium. Darcy's law together with the equations of mass balance gives

$$s_t + \Big\{f_0(s)\big(v - g(x)k(s)\big)\Big\}_x = 0, \tag{0.1}$$

where $s = s(x,t)$ denotes the saturation of one of the phases, f_0 is the fractional flow function, v is the total Darcy velocity, and $k(s)$ is the relative permeability of the phase not denoted by s. The gravitational term $g(x)$ includes the density differences between the phases as well as the absolute permeability of the rock and the angle of dip of the reservoir. This term is, therefore, not necessarily a continuous function of x. Equation (0.1) is an example of a conservation law

$$\begin{aligned} u_t + f(u,x)_x &= 0, \\ u(x,0) &= u_0(x), \end{aligned} \tag{0.2}$$

where u may be either a vector or a scalar variable. Such conservation laws do not in general possess continuous solutions, and by a solution of (0.2) we mean a solution in the distributional sense, such that for each $\phi \in C_0^1$

$$\int_{-\infty}^{\infty}\int_0^{\infty} \big(u\phi_t + f(u,x)\phi_x\big)\,dt\,dx + \int_{-\infty}^{\infty} \phi(x,0)u_0\,dx = 0. \tag{0.3}$$

The solution u is then called a *weak solution* of (0.2). Krushkov proved the existence of a weak solution to (0.2) for a scalar u under the assumption that $\partial f/\partial x$ was bounded [10]. This assumption does not hold for (0.1) since the geology often varies discontinuously in a porous medium. The analysis of Isaacson and Temple [9] shows that equations of the type (0.2) under reasonable restrictions on f, in general, possess a unique weak solution of the Riemann problem provided the initial states are close.

Here we are interested in the initial value problem for (0.1), and we prove the following theorem.

THEOREM. *If $g(x)$ has bounded total variation,* (0.1) *possesses a weak solution $s(x,t)$ for arbitrary initial data $s_0(x)$ of bounded total variation.*

This theorem is proved through construction of a sequence of approximate solutions. These solutions are constructed by the method of front tracking introduced by

*Received by the editors October 22, 1990; accepted for publication (in revised form) June 14, 1991.

Dafermos [1] and developed by Holden et al. [4]. This front tracking method is based on the solution of the Riemann problem for (0.1) which was studied by the authors in [3], and here we give a brief review of its solution. The solution of the Riemann problem for (0.1) is similar to the solution of the Riemann problem for the oil-polymer system studied by Isaacson [6]. This similarity is sufficient for us to use some of the ideas developed by Temple [12] for the oil-polymer system, most notably, the construction of a mapping Ψ from (s, g) to (z, g) such that the total variation of the approximate solutions remains bounded in (z, g). We will define a functional $F = F(u_\delta)$ where u_δ is our approximate solution generated by the front tracking scheme. Then F is shown to be nonincreasing in time, and this enables us to show that the sequence of approximations is well defined in the sense that each approximate solution can be defined at any time. Furthermore, we show that each approximate solution is constant on a finite number of polygons in $x - t$ space. Via a standard compactness argument, we can now show that a subsequence of the approximate solutions converges. The approximate solutions are constructed in such a way that they are weak solutions of equations which are close to (0.1). This makes it straightforward to prove that the limit is a weak solution.

In §1 of this paper we give some of the "physics" of the problem which leads to (0.1). In §2 we review the solution of the Riemann problem. In §3 we present the front tracking scheme and introduce the mapping Ψ and the functional F. We then show that F is nonincreasing and that this implies that the approximations are well defined. In §4 we prove that a subsequence of the approximate solutions converges towards a weak solution. Finally we make a remark on the applicability of this method of analysis to the oil-polymer system.

1. Physical motivation. We want to study two-phase flow in porous media, assuming for each phase Darcy's law:

$$v = -\lambda(\nabla P - \rho G),$$

where v is the Darcy speed, λ is the mobility, P the phase pressure, ρ is the density, and G a gravitational term. Combining Darcy's law with the source-free equation of mass conservation for each phase

$$\rho_t + \nabla(v\rho) = 0,$$

we find (for a more detailed treatment of these equations see [11]):

$$\alpha(\phi\rho_w s_w)_t + (\alpha\rho_w F_w)_x = 0 \tag{1.1}$$

which is the one-dimensional saturation equation, ignoring capillary effects (diffusion). Here α is the one-dimensional cross-sectional area, ϕ is the rock porosity, ρ_w is the density of water, and s_w is the saturation of the water at position x at time t. Lower indices x and t indicate derivatives with respect to space and time, respectively. F_w is the flow function of water:

$$F_w = f_w\big(v - K\lambda_o(\rho_w - \rho_o)g\big), \tag{1.2}$$

where f_w is the fractional flow function of water, $f_w = \lambda_w/(\lambda_w + \lambda_o)$, λ_w and λ_o being the phase mobilities of water and oil, v is the total Darcy velocity, K is the absolute rock permeability, and g is the component of gravity along the reservoir. Even if α, ϕ, and ρ are constants, so that (1.1) simplifies to read:

$$(s_w)_t + \frac{1}{\phi}(F_w)_x = 0, \tag{1.3}$$

F_w may be a function of *position* as well as saturation, $F_w = F_w(s_w, x)$. Heterogeneities like a varying reservoir angle (and thereby changing g), or changes in the rock permeability, K, along the reservoir, may both affect the flow function. This positional dependence of F_w may be smooth, when the parameters vary continuously along the reservoir, or discontinuous. The latter is probably very important and perhaps more common, since the rock is usually layered to some extent throughout the reservoir. Between such layers, introducing abrupt changes in rock permeability, $K = K(x)$ should be modeled discontinuously.

In general, the phase mobility curves $\lambda = \lambda(s_w)$ are assumed to be convex functions, typically shaped as indicated in Fig. 1.1. This gives an s-shaped, increasing fractional flow function $f_w = f_w(s_w)$, as shown in Fig. 1.2. In general, with increasing gravity or permeability, f decreases, so that two different flow functions typically look like Fig. 1.3. We will be interested in the Cauchy problem for (1.3).

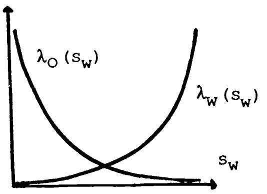

FIG. 1.1

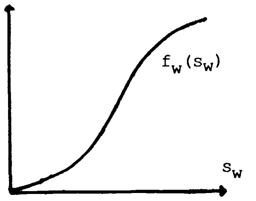

FIG. 1.2

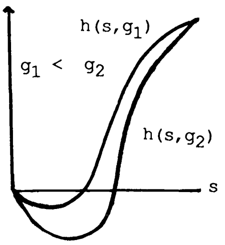

FIG. 1.3

2. The Riemann problem. We let s denote the saturation variable, introduce a variable $g = g(x)$ representing the geology, and let $u = (s, g)$, so that (1.3) may be written as a so-called triangular system ([2], [5]):

$$\begin{aligned} u_t + f(u)_x &= 0, \\ u(x,0) &= u_0(x). \end{aligned} \tag{2.1}$$

Here $f(u) = \big(h(s,g), 0\big)$ with

$$h(s,g) = f_0(s)\big(1 - gk(s)\big),$$

$f_0 = f_0(s)$ being a Lipschitz continuous, increasing function with one point of inflection (s-shaped) with $f_0(0) = 0$ and $f_0(1) = 1$ as in Fig. 1.2. The relative permeability $k(s)$ is usually assumed to be a decreasing, convex function of the saturation such that $k(0) = 1$ and $k(1) = 0$, cf. Fig. 1.1. Note that this implies that $h(1,g) = 1$ for all g. Also, each $h(\cdot, g)$ is Lipschitz continuous and has (possibly) one minimum and two points of inflection within the interval of definition, and finally $\partial h/\partial g \leq 0$, cf. Fig. 1.3. The Riemann problem for (1.3) or (2.1), which is the initial-value problem with initial constant states, denoted by $u_L = (s_l, g_l)$ and $u_R = (s_r, g_r)$, separated by a single geological discontinuity, has been studied by the authors in [3], where existence and uniqueness results are proved. Here we will need to know the solution of Riemann problems, so before proceeding with a more general treatment of (2.1), we will briefly summarize the main results of [3].

The one-dimensional Riemann problem for (2.1) may be written in the form

$$s_t + f_l(s)_x = 0 \quad \text{for } x < 0, \qquad s_t + f_r(s)_x = 0 \quad \text{for } x > 0, \tag{2.2}$$

with initial data

$$s(x,0) = \begin{cases} s_l & \text{if } x < 0, \\ s_r & \text{if } x > 0. \end{cases}$$

In the above notation, $f_l(s) = f_0(s)(1 - g_l k(s))$ and $f_r(s) = f_0(s)(1 - g_r k(s))$. Thus, to the left of the origin the flow function is f_l and to the right f_r. The saturation variable s is in the range $0 \leq s \leq 1$. We define s_- and s_+ to be the limits of the solution $s(x,t)$ as x approaches zero from below and above, respectively. Note that if the solution to (2.2) is unique, these values are independent of t. The Hugoniot relation at $x = 0$ gives

$$f_l(s_-) = f_r(s_+). \tag{2.3}$$

The procedure for determining possible values for s_- and s_+ is explained in full detail in [3], where it is proved that two such points always exist, and by introducing an additional entropy condition for the shock at $x = 0$, s_- and s_+ are uniquely determined. This entropy condition says that the jump $|s_- - s_+|$ at $x = 0$ should be the smallest possible jump here satisfying (2.3). This minimal jump condition is proved to be equivalent to the viscous profile entropy condition for an enlarged system of equations, in some extent equivalent to (2.2). The reader is referred to [3] for further details. We will now turn our attention to the two different waves involved in the solution of (2.1). First, s-waves are defined to be waves of constant g. Thus, in (s, g) phase space, these are found along horizontal lines. The other kind of waves are g-waves, which according to (2.3) have constant flow value, $f = const.$ Hence, it is useful to draw the level curves of f in the (s, g) diagram. This is done in Fig. 2.1. The bold curve labeled T in the figure is the transition curve, where $f_s = 0$. Solving the Riemann problem now consists of finding a sequence of s- and g-waves that go from u_L to u_R. The solution to the Riemann problem may now be found in the (s, g) phase space by the procedure indicated in Figs. 2.2 and 2.3 (use Fig. 2.2 for u_L to the left of T, and Fig. 2.3 for u_L to the right of T). Follow arrows that continuously connect u_L to u_R. Then find the solution by graphing the corresponding waves in the (x, t)-plane in the direction of the arrows. Note that any Riemann problem gives a solution consisting of at most three waves, an s-wave, a g-wave, and another s-wave. We write this composite solution wave as $[u_L u_R] = sgs'$. We close this section by displaying an example of how a Riemann problem like (2.2) is solved by the method indicated above. Given a Riemann problem as indicated in Fig. 2.4, in the (s, f) plane the solution looks like Fig. 2.5: Starting with a shock moving backwards along f_l from s_l (s-wave), crossing from s_- over to s_+ at f_r (minimal jump, g-wave), and finally continuing from s_+ to s_r with a rarefaction along f_r (another s-wave). In Fig. 2.6 we have indicated this solution in the (s, g) phase space, and finally in Fig. 2.7 the solution in the (x, t) plane is shown.

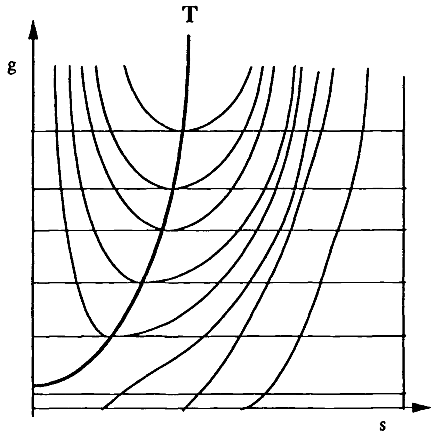

FIG. 3.1.

3. The front tracking scheme.

In this section we present the scheme we will use to generate a sequence of approximate solutions to (2.1). This scheme is a generalization of Dafermos' [1] scheme for the scalar conservation law. The basic idea of this scheme is to generate a sequence of exact solutions to approximate equations obtained by taking a piecewise linear approximation of the flux function. Via a standard compactness argument, we then show that this sequence possesses a convergent subsequence and furthermore that this converges towards a weak solution of (2.1).

In order to define our approximation we first have to define the approximate flux functions. Roughly speaking, these will be defined for a fixed g to be piecewise linear continuous in s. Assume that $g_0(x)$ is a function taking values in the interval $[0,G]$. We make a partition of this interval by choosing equally spaced points $\{\tilde{g}_i\}_1^{\tilde{n}}$ such that $\frac{1}{\tilde{n}} = \delta$ for some fixed δ. Let

$$s_T(g) = \min_s f(s,g) \tag{3.1}$$

and define $\tilde{f}_i = f\left(s_T(\tilde{g}_i), \tilde{g}_i\right)$. We choose $\{\hat{f}_i\}_1^{\hat{m}}$ to be an equally spaced partition of the interval $[f(s_T(G),G),1]$ such that $\hat{m} = \lceil\frac{1}{\delta}\rceil+1$, where $\lceil x\rceil$ = the largest integer smaller than or equal to x. Let

$$g_T(c) = \min_{f(s,g)=c} g \tag{3.2}$$

and define $\hat{g}_i = g_T(\hat{f}_i)$. Now we define

$$\{g_j\}_1^N = \{\tilde{g}_j\} \cup \{\hat{g}_j\} \qquad \{f_j\}_1^M = \{\tilde{f}_j\} \cup \{\hat{f}_j\}. \tag{3.3}$$

This defines a "mesh" in the (s,g) plane (cf. Fig. 3.1), and we see that the solution to a Riemann problem defined by two points in the mesh will have intermediate states that are in the mesh. We wish to simplify the solution to the Riemann problem further still by requiring that the s-waves consist only of states that are part of the mesh. This we do by approximating $f(s,g_i)$ by a piecewise linear function for each g_i. More precisely let

$$s_0(g) = 0 \quad \text{and} \quad s_{i+1}(g) = \min\left\{s > s_i(g) \mid f(s,g) \in \{f_i\}_1^M\right\} \tag{3.4}$$

for $i = 1, \cdots, n(g)$; note that $s_{n(g)}(g) = 1$. Let $s_{i,j}$ denote $s_i(g_j)$ and $f_{i,j}$ denote $f(s_{i,j}, g_j)$. We have that the intersections in the mesh have coordinates $(s_{i,j}, g_j)$, cf. Fig. 3.1. Finally we can define the approximate flux functions

$$(3.5)\qquad \begin{aligned} h_\delta(s,g_j) &= f_{i,j} + s\frac{f_{i+1,j}-f_{i,j}}{s_{i+1,j}-s_{i,j}},\\ f_\delta(s,g_j) &= \big(h_\delta(s,g_j),0\big)\end{aligned}$$

for $s \in [s_{i,j}, s_{i+1,j}]$ and for $j = 1,\cdots,N$.

The solution of the Riemann problem defined by

$$(3.6)\qquad \begin{aligned} &s_t{+}h_\delta(s,g_j)_x = 0,\\ &s_0(x) = \begin{cases} s_L & \text{if } x<0,\\ s_R & \text{if } x\ge 0\end{cases}\end{aligned}$$

consists of a number of constant states separated by discontinuities moving apart. Furthermore these constant states are a subset of $\{s_{i,j}\}_{i=1}^{n(g_j)}$. For a complete discussion of the Riemann problem for piecewise linear flux functions, see, e.g., [4].

In the following we let u denote the pair (s,g) and $u_{i,j}$ denote $(s_{i,j},g_j)$. Assume $u_0(x)$ to be a function taking values in the rectangle $[0,1]\times[0,G]$. We can construct an approximation to u_0, which we call $u_{0,\delta}(x)$, such that for each x; $u_{0,\delta}(x)\in\{u_{i,j}\}$ and

$$(3.7)\qquad \lim_{\delta\to 0}||u_0-u_{0,\delta}||_{L_1} = 0.$$

Condition (3.7) can be achieved since $g_j - g_{j-1}\le\delta$ and $s_{i,j}-s_{i-1,j} = O(\sqrt{\delta})$, where the right-hand side of the last equation depends on $\partial^2 f/\partial s^2$ on the T-curve.

We will now generate a weak solution $u_\delta(x,t)$ to the initial value problem

$$(3.8)\qquad u_{\delta t} + f_\delta(u_\delta)_x = 0,\qquad u_\delta(x,0) = u_{0,\delta}(x).$$

The initial function $u_{0,\delta}$ defines a series of finitely many Riemann problems, and by construction the solution to these problems are constant states (which are included in the set $\{u_{i,j}\}$) separated by discontinuities. We can track these discontinuities and thereby propagate the solution forward in time, until two of them collide. At this point we have a situation similar to what we had initially, namely a sequence of Riemann problems. Therefore we can solve these and propagate the solution until the next collision. Note that by construction u_δ is a weak solution of (3.8). We call this process front tracking, and it is clear that it can be repeated an arbitrary number of times. We do, however, need to justify that we can propagate the solution in this manner up to any given time by a finite number of operations. But in order to do this we first define a certain functional F which is nonincreasing for each collision of fronts.

We may think of a wave of u_δ either as a discontinuity in the (x,t) plane or as a directed path in (s,g) space. If the wave is an s-wave, this path is just the straight line from the state to the left of the discontinuity to the state to the right of the discontinuity. If the wave is a g-wave the path is the curve $f =$ const. from the left state to the right state. Thus u_δ can be thought of as a finite sequence of connected waves in the (s,g) plane, representing the discontinuities in u_δ as we move from left to right in the (x,t) plane. We will call any finite sequence of connected s- or g-waves in the (s,g) plane an I curve, where by connected we mean that the left state of a wave in the sequence is the right state of its predecessor, and we say that an I curve connects u_L to u_R if the left state of the first wave is u_L and the right state of the final wave is u_R. We will use the techniques developed for the oil-polymer system by Temple [12] and construct a certain $1-1$ mapping Ψ from (s,g) to (z,g), and a functional $F(I)$ such that $F(u_\delta)$ dominates the total variation of $\Psi\circ u_\delta$. We then prove that $F(u_\delta)$ is nonincreasing for each collision, and that this implies, first, that the approximation procedure can be continued to any time by finitely many operations, and, second, that a subsequence of the approximate solutions converges in L_1.

The mapping Ψ is similar to the mapping used by Temple in [12], and it involves the intersections of the T-curve with the level sets of f. Since f does not take all values on T, we must extend both T and the level sets outside $[0,1]\times[0,G]$. Assume for the moment that this is done in such a manner that for each point (s,g) in $[0,1]\times[0,G]$ we can find a unique point (s',g') on T such that $f(s',g')=f(s,g)$. Then z is defined as follows:

$$\begin{gathered}|z|=|g-g'|\\ \operatorname{sign} z=\begin{cases}-1 & \text{if } (s,g) \text{ is to the left of } T \text{ or above } T,\\ 1 & \text{if } (s,g) \text{ is to the right of } T \text{ or below } T.\end{cases}\end{gathered}\tag{3.9}$$

We have two cases of how to define the point (s',g') when f does not take the value $f(s,g)$ on T, depending on whether T intersects the s-axis or the g-axis. Assume first that T intersects the s-axis. Then we can extend T and the level curves of f in a smooth manner such that they intersect T at their minimum, cf. Fig. 3.2. If T intersects the g axis we make a smooth decreasing extension $g'(s)$ of T defined for negative s. If f does not take the value $f(s,g)$ on T, then f will take this value on the line $g=0$ at some point $\tilde{s}$. We then define $(s',g')=\bigl(-\tilde{s},g'(-\tilde{s})\bigr)$. Since the line $s=0$ is a level set for f, this mapping will be continuous and smooth, cf. Fig. 3.3. As in [12] we have that Ψ is $1-1$ and regular everywhere except on T. In the following we let $w=\Psi(u)$.

Now we can define the functional F. We define the strength of an s-wave to be

$$|s|=|\Delta z|\tag{3.10}$$

and the strength of a g-wave

$$|g|=\begin{cases}2|\Delta g| & \begin{cases}\text{if } g \text{ is to the right of } T \text{ and } g_L<g_R,\\ \text{or } g \text{ is to the left of } T \text{ and } g_L>g_R,\end{cases}\\ 4|\Delta g| & \begin{cases}\text{if } g \text{ is to the right of } T \text{ and } g_L>g_R,\\ \text{or } g \text{ is to the left of } T \text{ and } g_L<g_R.\end{cases}\end{cases}\tag{3.11}$$

We can write u_δ as $b_1,\cdots,b_n=I$, where b_i is either an s-wave or a g-wave, and we define

$$F(I)=\sum_i |b_i|.\tag{3.12}$$

Here follows the main lemma regarding F.

LEMMA 3.1. *Let J be any I curve connecting u_L to u_R, and let $[u_Lu_R]$ be the I curve that solves the Riemann problem defined by u_L and u_R. Then $F\bigl([u_Lu_R]\bigr)\le F(J)$.*

The proof of this lemma is analogous to the proof of the corresponding lemma (Lemma 5.1) in [12], and since it involves the study of a number of cases, it is presented in an appendix.

Now let F_0 denote $F\bigl(u_\delta(\cdot,t)\bigr)$, where t is taken to be so small that no collision has yet occured. The main theorem of this section then follows immediately from Lemma 3.1.

THEOREM 3.1. *Assume that F_0 is finite, and let $t_1\le t_2$, then*

$$F\bigl(u_\delta(\cdot,t_1)\bigr)\ge F\bigl(u_\delta(\cdot,t_2)\bigr).\tag{3.13}$$

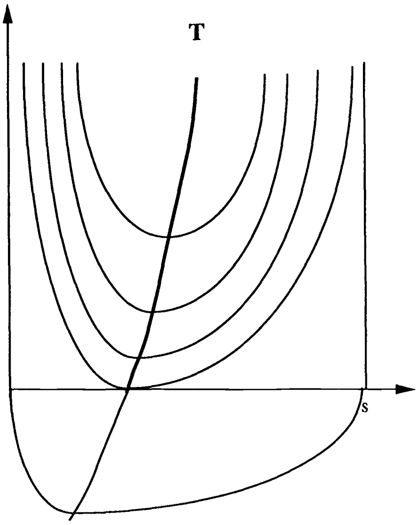

FIG. 3.2

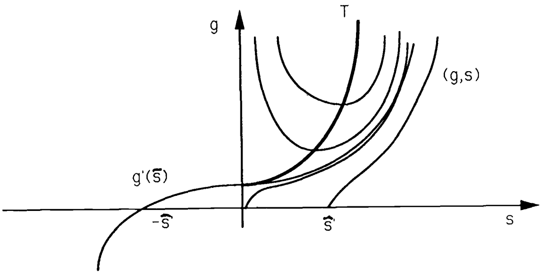

FIG. 3.3

Proof. It is clear that F only changes value when we have a collision of discontinuities in u_δ. At any one time we can have only finitely many collisions, and the change in F is a sum of the changes in F at each collision point. Consider, therefore, two discontinuities that collide, the one on the left separating states u_L and u_M, the one on the right separating states u_M and u_R. The theorem now follows, since by Lemma 3.1 $F\big([u_L u_M][u_M u_R]\big) \geq F\big([u_L u_R]\big)$. □

It is clear that F at each collision of u_δ either remains constant or changes by at least Δ, where Δ is the minimum distance between the states of which u_δ may consist, i.e.,

$$\Delta = \min_{(i,j)\neq(k,l)} |w_{i,j} - w_{k,l}|. \tag{3.14}$$

We wish to investigate those collisions which are possible if F remains constant for all time. Let s^+ (s^-) denote those s-waves over which s is increasing (decreasing), and let s_R (s_L) denote an s-wave with left and right state to the right (left) of T.

LEMMA 3.2. *Assume that $F(u_\delta)$ is constant and that u_δ contains the wave sequence gs_R^+ ($s_L^- g$). Then no s-wave will collide from the right (left) with g.*

Proof. Let the s_R^+ wave separate states $s_l < s_r$. Since F is constant it can only collide with s-waves that separate states $s_r < s'$. The result of this collision is a single s_R^+ wave separating states $s_l < s'$. If the s-wave collides with a g-wave the result of the collision must be gs_R^+ since F is constant. Since all s_R waves have positive speeds, the lemma follows. An analogous argument takes care of the case $s_L^- g$. □

LEMMA 3.3. *Assume that $F(u_\delta)$ is constant, then only three types of collisions can occur*:

(1) *An s-wave separating states $s_l \lessgtr s_m$, colliding with another s-wave separating states $s_m \lessgtr s_r$, giving as a result a single s-wave separating $s_l \lessgtr s_r$.*

(2) *An s-wave colliding with a g-wave from the right (left), giving sg (gs) as result ("an s-wave passing through a g-wave").*

(3) *An s-wave colliding with a g-wave, giving $s_L^- g s_R^+$ as a result.*

The proof of this lemma consists of checking a number of cases of Riemann solutions in the Figs. 2.2 and 2.3. It is straightforward and is, therefore, omitted. Combining the last two lemmas, we see that if F is constant; our approximation u_δ is well defined. However, Theorem 3.1 implies that after some finite number of collisions, F will change by an amount less than Δ for all subsequent collisions, i.e., F will remain constant for all collisions thereafter. Therefore, the approximation u_δ is well defined and u_δ is constant on a finite number of regions in $\mathbb{R} \times \mathbb{R}^+$. These regions are separated by a finite number of straight lines.

4. Convergence. Let $\mathrm{Var}_{ab}\, u$ denote the total variation of u with respect to the variables a and b. By construction, $F(I) \geq \mathrm{Var}_{zg}\, J$ for any I-curve J. Hence, by Theorem 3.1, we may find a uniform bound on $\mathrm{Var}_{zg}\, u_\delta(\cdot, t)$, provided F_0 is bounded. We show this by applying Temple's argument [12]: Let $S(\epsilon)$ be a strip of width ϵ around the T-curve. If u_L or u_R are outside the strip , the Riemann problem solution $[u_L u_R]$ has a finite number of waves, each globally bounded, and the waves intersect transversally in the (z, g) plane. Thus, $\mathrm{Var}_{zg}[u_L u_R] = O(1)|w_R - w_L|$ if $w_R = (z_R, g_R)$ and $w_L = (z_L, g_L)$ are the images of u_R and u_L under Ψ. Secondly, if u_L and u_R are in $S(\epsilon)$, $\mathrm{Var}_{zg} < 5|w_L - w_R|$ by construction, for ϵ sufficiently small. Therefore, for any Riemann problem, $\mathrm{Var}_{zg}\, I = O(1)|w_L - w_R|$. Let $\{J_i\}$ denote the solutions of the initial Riemann problems. This gives

$$\begin{aligned} F_0 &\leq 4 \sum_i \mathrm{Var}_{zg}\, J_i \\ &\leq O(1) \sum |w_L - w_R| \\ &\leq O(1)\, \mathrm{Var}_{zg}\, u_{0,\delta}, \end{aligned} \tag{4.1}$$

proving that $\mathrm{Var}_{zg}\, u_\delta(\cdot, t)$ is bounded for each fixed t.

Having proved boundedness in space for each time t, we want to prove Lipschitz continuity in t.

LEMMA 4.1.

$$\int_{-\infty}^{\infty} |w_\delta(x, t_2) - w_\delta(x, t_1)|\, dx \leq O(1)|t_2 - t_1|\, \mathrm{Var}_{zg}\, u_{0,\delta}.$$

Proof. Let M be the maximum speed at which a wave may propagate. M is given by the maximum slope of any $f_\delta(\cdot, g_j)$. Thus, if $t_1 < t_2$, $|w_\delta(x, t_2) - w_\delta(x, t_1)|$ is bounded by the spatial variation of $w_\delta(y, t_1)$, where $x - M|t_2 - t_1| < y < x + M|t_2 - t_1|$. However, as pointed out above, $w_\delta(\cdot, t)$ is of bounded variation, so that we may write:

$$\int_{-\infty}^{\infty} |w_\delta(x, t_2) - w_\delta(x, t_1)|\, dx = O(1) \int_{-\infty}^{\infty} \int_{x - M|t_2 - t_1|}^{x + M|t_2 - t_1|} \left| \frac{dw_\delta}{dy} \right| dx\, dy.$$

Here, $|dw_\delta/dy|\, dx\, dy$ is a measure of mass $\mathrm{Var}_{zg}\, w_\delta(x, t)$, and by changing the order of integration we have:

$$\begin{aligned}\int_{-\infty}^{\infty} |w_\delta(x,t_2) - w_\delta(x,t_1)|\,dx &= O(1)M|t_2 - t_1]\operatorname{Var}_{zg} w_\delta(x,t)\\ &\leq O(1)M|t_2 - t_1]\operatorname{Var}_{zg} u_{0,\delta}(x),\end{aligned}$$

the last inequality holds since

$$O(1)\operatorname{Var}_{zg} u_\delta(\cdot,t) = F\big(u_\delta(\cdot,t)\big) \leq F_0 \leq O(1)\operatorname{Var}_{zg} u_{0,\delta}. \qquad \square$$

It remains to prove the convergence of the sequence $\{u_\delta\}$.

THEOREM 4.1. *Let $w_0 = \Psi u_0$ be any initial data such that $\operatorname{Var}_{zg} w_0 < \infty$. Then for any sequence $\{\delta\}$, such that $\delta \to 0$, there exists a subsequence δ_j and a function u, such that for any finite time T, $u_{\delta_j}(\cdot,t)$ converges uniformly to $u(\cdot,t)$ in $L^1_{\text{loc}}(x)$ for any $t \leq T$.*

Proof. We have demonstrated that $w_\delta(\cdot,t)$ has uniformly bounded variation for each t, and so it follows from Helly's theorem, that a subsequence converges in $L^1_{\text{loc}}(x)$. By a diagonalization argument, such convergence is achieved on a countable dense set of t-values, t_j, $0 \leq t_j \leq T$. Let w_{δ_j} be this subsequence. By a further diagonalization argument, we may find a subsequence of $\{w_{\delta_j}\}$; w_μ, which converges uniformly in $L_1[-M,M]$ at a fixed t_j. Thus, for this sequence:

$$\begin{aligned}\int_{-M}^{M} |w_{\mu_1}(x,t) - w_{\mu_2}(x,t)|\,dx \leq &\int_{-M}^{M} |w_{\mu_1}(x,t) - w_{\mu_1}(x,t_j)|\,dx\\ &+ \int_{-M}^{M} |w_{\mu_1}(x,t_j) - w_{\mu_2}(x,t_j)|\,dx\\ &+ \int_{-M}^{M} |w_{\mu_2}(x,t_j) - w_{\mu_2}(x,t)|\,dx.\end{aligned}$$

Here the first and third term approach zero by Lemma 4.1, and the second term is small by the boundedness of $w_\mu(\cdot,t)$. Therefore, w_μ converges uniformly in $L_1[-M,M]$. This argument may now be applied a countable number of times, concluding the existence of a sequence, which we, for convenience, also label $\{w_\delta\}$, such that for any $t > 0$, $w_\delta(\cdot,t) \to w(\cdot,t)$ uniformly. The uniform continuity of Ψ^{-1} gives the theorem for $u_\delta = \Psi^{-1}w_\delta$ and $u = \Psi^{-1}w$. $\square$

Finally, we want to show that the limit obtained above is indeed a weak solution to the problem (2.1). For $T < \infty$ we define:

$$W(u) = \int_{-\infty}^{\infty}\int_0^T \big(\phi_t u + \phi_x f(u)\big)\,dx\,dt + \int_{-\infty}^{\infty} \phi u_o\,dx$$

for $\phi = \phi(x,t)$ an arbitrary function in C^1_0. For $u = \lim_{\delta\to 0} u_\delta$ we want to show that $W(u) = 0$. Since u_δ is a weak solution of (3.8):

$$\int_{-\infty}^{\infty}\int_0^T \big(\phi_t u_\delta + \phi_x f_\delta(u_\delta)\big)\,dx\,dt + \int_{-\infty}^{\infty} \phi u_{0,\delta}\,dx = 0,$$

which gives:

$$W(u) = \int_{-\infty}^{\infty}\int_0^T \Big(\phi_t(u - u_\delta) + \phi_x\big(f(u) - f_\delta(u_\delta)\big)\Big)\,dx\,dt + \int_{-\infty}^{\infty} \phi(u_0 - u_{0,\delta})\,dx$$

for all δ. Thus,

$$|W(u)| \leq \|\phi_t\|_\infty \|u - u_\delta\|_1 + \|\phi_x\|_\infty \|f(u) - f_\delta(u_\delta)\|_1 + \|\phi\|_\infty \|u_0 - u_{0,\delta}\|_1$$

$$\leq \|\phi_t\|_\infty \|u - u_\delta\|_1 \tag{4.2a}$$

$$+ \|\phi_x\|_\infty \|f(u) - f_\delta(u)\|_1 \tag{4.2b}$$

$$+ \|\phi_x\|_\infty \|f_\delta(u) - f_\delta(u_\delta)\|_1 \tag{4.2c}$$

$$+ \|\phi\|_\infty \|u_0 - u_{0,\delta}\|_1. \tag{4.2d}$$

Here, by Lipschitz continuity of f and f_δ, the terms (4.2b) and (4.2c) above are small. Furthermore, (4.2a) is small by the construction of u as the L_1 limit of u_δ, and (4.2d) is small by the construction of $u_{0,\delta}$. Hence, for any given $\epsilon > 0$, we may choose δ so that $|W(u)| < \epsilon$, concluding that $W(u) = 0$, and the limit u is a weak solution of (2.1). □

Remark. The system of conservation laws modeling polymer flow in porous media

$$\begin{aligned} s_t + \big(g(s,b)s\big)_x &= 0, \\ b_t + \big(g(s,b)b\big)_x &= 0 \end{aligned} \tag{4.3}$$

studied by Temple [12], and Temple and Isaacson [7], [8], has a structure of the solution to the Riemann problem that is remarkably similar to the Riemann solution used in this paper (Compare Figs. 8 and 9 in [12] with Figs. 2.2–2.3.). It is this similarity that enabled us to use essentially the same techniques as [12] to show that the functional F was nonincreasing and to obtain the estimates on $\mathrm{Var}_{zg}\, w_\delta$. This in turn guaranteed that our approximation u_δ was well defined and that the sequence $\{u_\delta\}$ possessed a subsequence which converged towards a weak solution of (2.1). We could have defined an analogue of u_δ, (s_δ, b_δ) as an approximation to the solution of (4.3). Since the whole subsequent argument hinges on the fact that F is nonincreasing, it applies equally well to (s_δ, b_δ) as to u_δ. Therefore, the front tracking method presented here gives an alternative proof of the existence of a solution to the Cauchy problem for (4.3).

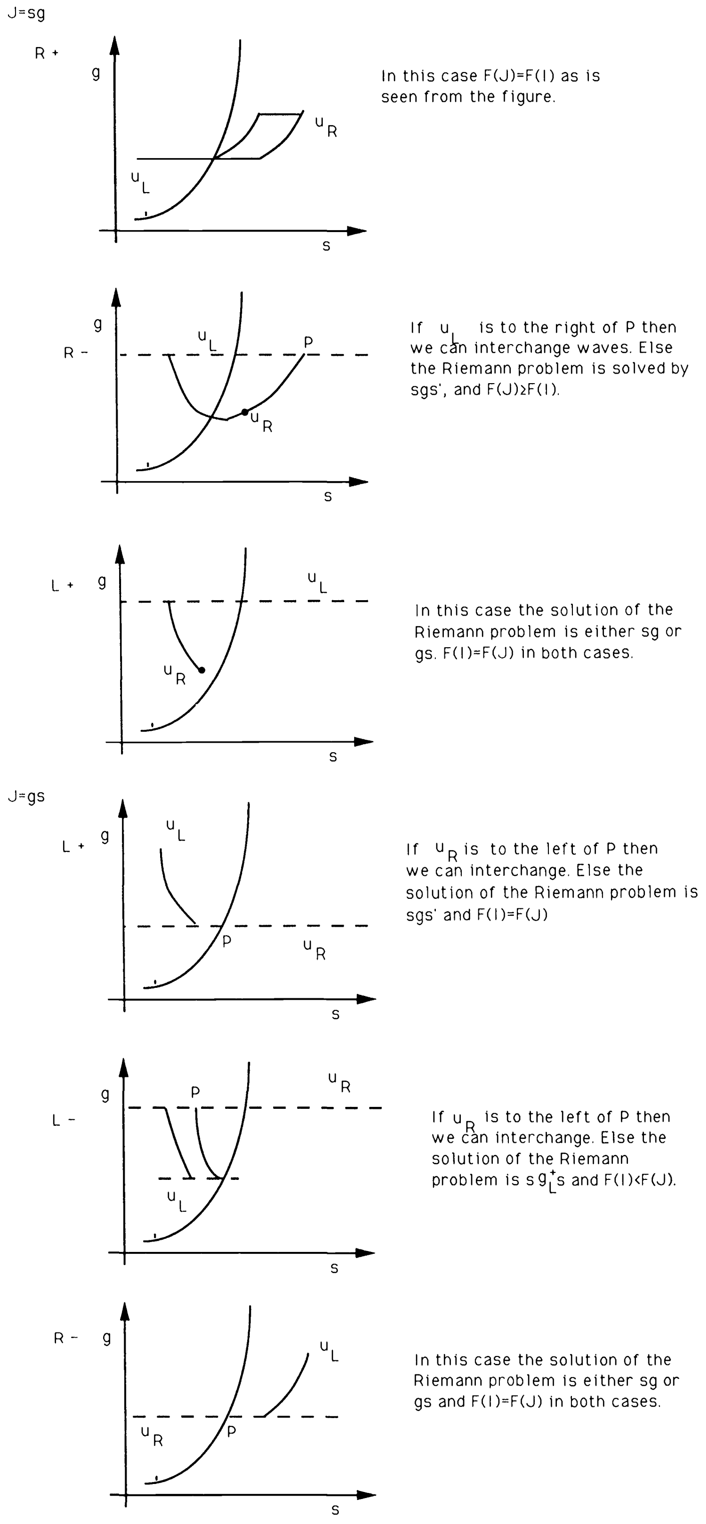
5. Appendix. Here we present the proof of Lemma 3.1.

LEMMA 3.1. *Let J be any I curve connecting u_L to u_R, and let $[u_L u_R]$ be the I curve that solves the Riemann problem defined by u_L and u_R. Then $F\big([u_L u_R]\big) \leq F(J)$.*

Since the structure of the solution of the Riemann problem is similar to the structure of the solution of the Riemann problem for the polymer system studied by Temple [12], Lemma 3.1 is proved by essentially the same arguments as the corresponding lemma in [12]. We first prove three lemmas; Lemma 3.1 will then follow from these.

Let g^+ (g^-) denote a g wave over which s is increasing (decreasing), and let g_R (g_L) denote a g-wave to the right (left) of T. We can now define the "addition" of waves; the addition of s_1 and s_2 is the s-wave that goes from the left state of s_1 to the right state of s_2. If g_1 and g_2 are both g_L or g_R waves then the addition of g_1 and g_2 is the combined g-wave. If two g-waves are of different type and $g(u_L) < g(u_R)$ $(g(u_L) > g(u_R))$ then their addition is the unique wave gs (sg) that goes from u_L to u_R.

Assume now that $J = sg$ $(J = gs)$ connects u_L to u_R. If u_L and u_R are on the same side of T and a "parallelogram" of s and g waves can be drawn with u_L and u_R as diagonally opposed corners, the interchange of J; $\bar{J}$ is defined to be the unique I curve $\bar{g}\bar{s}$ $(\bar{s}\bar{g})$ that connects u_L to u_R. If u_L and u_R are on different sides of T we can only define $\bar{J}$ if $J = sg_L^-$ or $J = g_R^+ s$. The interchange of sg_L^- is the unique I curve



In this case F(J)=F(I) as is seen from the figure.

If u_L is to the right of P then we can interchange waves. Else the Riemann problem is solved by sgs', and F(J)≥F(I).

In this case the solution of the Riemann problem is either sg or gs. F(I)=F(J) in both cases.

If u_R is to the left of P then we can interchange. Else the solution of the Riemann problem is sgs' and F(I)=F(J)

If u_R is to the left of P then we can interchange. Else the solution of the Riemann problem is sg_L^+s and F(I)<F(J).

In this case the solution of the Riemann problem is either sg or gs and F(I)=F(J) in both cases.

FIG. A1

$\bar{g}_R^+\bar{s}$ that connects the same endpoints. Other I-curves do not have an interchange. As in [12] it is easy to show that if J is the addition of b_1 and b_2 then $F(b_1b_2) \geq F(J)$, and if $\bar{J}$ is the interchange of J then $F(J) = F(\bar{J})$. Furthermore, if J connects u_L to u_R and J has an interchange $\bar{J}$, then $[u_Lu_R] = J$ or $[u_Lu_R] = \bar{J}$.

LEMMA A1. *If J connects u_L to u_R and $J = gs$ or $J = sg$ then $F(J) \geq F\big([u_Lu_R]\big)$.*

Proof. If J has an interchange then the lemma holds. Assuming that J does not have an interchange, we have eight cases to check: $J = sg$ or gs, $g = g_R$ or g_L, $g = g^+$ or g^-. But if $J = g_R^+s$ or sg_L^- then J has an interchange. This leaves six cases which are checked in Fig. A1. □

LEMMA A2. *If J connects u_L to u_R and $J = sgs'$ then $F(J) \geq F\big([u_Lu_R]\big)$.*

Proof. If gs or sg' can be interchanged, we can interchange and add waves so that Lemma A1 applies. Assume, therefore, that neither can be interchanged. This implies that s and s' both cross T and that $g = g_L^+$ or g_R^-. This leaves two cases to check as an exercise for the reader. □

LEMMA A3. *If J connects u_L to u_R and $J = gsg'$ then $F(J) \geq F\big([u_Lu_R]\big)$.*

Proof. We can assume that s crosses T and that $g \neq g_R^+$ and $g' \neq g_L^-$. Also if the variable g is increasing over g and decreasing over g' (or vice versa) it is easy to show that $F(J) \geq F(\tilde{s}\tilde{g})$ or $F(\tilde{g}\tilde{s})$, where $\tilde{s}\tilde{g}$ or $\tilde{g}\tilde{s}$ connects u_L to u_R. In this case, we can now use Lemma A1. Now s can cross from left to right or right to left, i.e., $gsg' = g_L^+sg_R^-$ or $g_R^-sg_L^+$. In both of these cases J contains a "strong" g-wave, whereas $[u_Lu_R] = sg^+s'$, i.e., the Riemann solution has a "weak" g-wave. The presence of this strong wave makes the lemma hold. □

Proof of Lemma 3.1. Once Lemmas A2 and A3 are established, the proof of this lemma carries over literally from the proof of Lemma 5.1 in [12] if "c-waves" are substituted with "g-waves." □

LINEARIZED STABILITY AND IRREDUCIBILITY FOR A FUNCTIONAL DIFFERENTIAL EQUATION*

MARY E. PARROTT†

Abstract. A principle of linearized stability is given for the abstract functional differential equation $\dot{u}(t)=Bu(t)+Ku_t$, $t \geqq 0$, $u_0=f$, where B generates a strongly continuous semigroup of bounded linear operators on a Banach space X, and $K: E=C([-r_0, 0], X) \rightarrow X$ is a nonlinear, continuously Fréchet-differentiable operator. The strong positivity property of irreducibility is also investigated for the semigroup associated with solutions of the linearized equation. The theory is applied to the stability analysis of an equation from population dynamics.

Key words. linearized stability, functional differential equation, positive semigroup, irreducibility

AMS(MOS) subject classifications. 34K20, 34K30

1. Introduction. In a recent paper [11] a result of Desch and Schappacher [2] was used to develop a principle of linearized stability for the abstract functional differential equation

$$(\mathrm{FDE}_1) \qquad \begin{aligned} \dot{u}(t) &= Bu(t)+\phi u_t, \qquad t \geqq 0, \\ u_0 &= f, \end{aligned}$$

where B generates a strongly continuous semigroup of bounded linear operators on a Banach space X, ϕ is a nonlinear Lipschitz continuous operator from $E=C([-r_0, 0], X)$ to X, and the functional $u_t \in E$ is defined by $u_t(s)=u(t+s)$ for $s \in [-r_0, 0]$. As a consequence, recent results from positive semigroup theory can be used to study the stability of (FDE_1), as indicated in [11].

In the present work we are motivated by a widely used equation (see, for example, [7], [1], [5], [14]) which describes the growth of a spatially distributed population with delay in the birth process:

$$(\mathrm{E}) \qquad \begin{aligned} \frac{\partial u}{\partial t}(x, t) &= d \frac{\partial^2 u}{\partial x^2}(x, t)+a u(x, t) \\ &\quad \cdot\left[1-b u(x, t)-\int_{-1}^{0} u(x, t+r(s))\, d\eta(s)\right], \\ &\qquad x \in[0, \pi], \qquad t \geqq 0. \end{aligned}$$

In [7] positive semigroup theory is used to study the stability of the solution semigroup corresponding to the (abstract) linearization of (E) at a stationary solution. However, no conclusions regarding the stability of (E) could be drawn from this analysis. The connection between the stability of equilibria of the nonlinear functional differential equation (E) and the stability of the zero equilibrium of the corresponding linearized equation will be established in the present paper as a consequence of our abstract results. Because of the nature of the nonlinearity which appears in (E), this equation cannot be modeled by an abstract equation of the form (FDE_1). Our goal here is to

develop a principle of linearized stability for abstract functional differential equations of the form

$$(\mathrm{FDE}_2)\qquad \begin{aligned} \dot{u}(t) &= Bu(t)+Ku_t, \qquad t\geqq 0,\\ u_0 &= f, \end{aligned}$$

where B generates a strongly continuous semigroup of bounded linear operators on a Banach space X and $K: E=C([-r_0,0],X)\to X$ is a nonlinear, continuously Fréchet-differentiable operator. (These assumptions are made more precise below.) This principle will be applied to (E) and, using the results of [7], we will be able to conclude an asymptotic stability result for an equilibrium of (E).

A second purpose of the present paper is to further examine the role of positive semigroup theory in the stability study of the linearizations of (FDE_1) and (FDE_2). More specifically, we will consider the consequences of the strong positivity property of irreducibility for the solution semigroup corresponding to the linear functional differential equation

$$\begin{aligned} \dot{u}(t) &= Bu(t)+\psi u_t, \qquad t\geqq 0,\\ u_0 &= f, \end{aligned}$$

where B generates a strongly continuous semigroup of bounded linear operators on X, and ψ is a bounded linear operator from E to X. The applicability of this theory to the study of the linearization of (E) is also given.

2. Stability result for (FDE_2). For $x\in X$, a Banach space, $\|x\|$ denotes the norm of x. For $f\in E=C([-r_0,0],X)$, where r_0 is a fixed positive constant, the norm of f, $\|f\|_E$, is defined by $\|f\|_E=\sup_{\theta\in[-r_0,0]}\|f(\theta)\|$. We use $|\cdot|$ to denote the norm of a bounded linear operator.

We consider the equation (FDE_2), where we assume the following hypotheses hold:

(H1) B generates a strongly continuous linear semigroup $T(t)$, $t\geqq 0$, on X.

(H2) $K: E=C([-r_0,0],X)\to X$ is a nonlinear, continuously Fréchet-differentiable operator at each $\hat{f}\in E$, that is,

$$K(f)=K(\hat{f})+K'(\hat{f})(f-\hat{f})+\circ(f-\hat{f})$$

for all $f\in E$, where $K'(\hat{f})$ is a bounded linear operator from E to X, $\circ$ is a continuous function from E to X, and b is a continuous increasing function from $[0,\infty)$ to $[0,\infty)$ such that $b(0)=0$ and $\|\circ(f)\|\leqq b(r)\|f\|_E$ for all $f\in E$ such that $\|f\|_E\leqq r$. In addition

$$|K'(f_1)-K'(f_2)|\leqq d(r)\|f_1-f_2\|_E$$

for all $f_1,f_2\in E$ such that $\|f_1\|_E$, $\|f_2\|_E\leqq r$, where d is a continuous increasing function from $[0,\infty)$ to $[0,\infty)$.

In the three lemmas that follow we show the existence of a unique local solution of (FDE_2). The method of proof is similar to that of Webb [16, Chap. 4], adapted for delay equations, and is therefore omitted. Basic existence and stability results for abstract semilinear functional differential equations (under various hypotheses) have also been obtained by other authors, including Fitzgibbon [3], Lightbourne [8], Rankin [12], Travis and Webb [15], Webb [17], and Martin and Smith [9].

LEMMA 2.1. *Assume that* (H1) *and* (H2) *are satisfied. Then for each $f\in E$ there exists a maximal interval of existence $[-r_0,T_f)$ and a unique continuous function*

$t \to u(t;f)$ from $[-r_0, T_f)$ to X such that

$$(1)\quad \begin{aligned} u(t;f) &= T(t)f(0) + \int_0^t T(t-s)Ku_s\,ds, \qquad t \in [0, T_f), \\ u(t;f) &= f(t), \qquad t \in [-r_0, 0], \end{aligned}$$

and either $T_f = \infty$ or $\lim_{t \to T_f^-} \sup \|u(t;f)\| = \infty$.

LEMMA 2.2. *Assume that* (H1) *and* (H2) *are satisfied. Then the function $u(t;f)$ of Lemma* 2.1 *is a continuous function of f in the sense that if $f \in E$ and $0 \leqq t < T_f$, there exist positive constants C and ε such that if $\hat{f} \in E$ and $\|f - \hat{f}\|_E < \varepsilon$, then $t < T_{\hat{f}}$ and $\|u(s;f) - u(s;\hat{f})\| \leqq C\|f - \hat{f}\|_E$ for all $-r_0 \leqq s \leqq t$.*

LEMMA 2.3. *Assume that* (H1) *and* (H2) *are satisfied. For $f \in E$ let $u(t;f)$ be the function given by Lemma* 2.1. *If $f(0) \in D(B), f' \in E$, and $f'^{-}(0) = Bf(0) + Kf$, then $u(t;f) \in D(B)$ for $0 \leqq t < T_f$, the function $t \to u(t;f)$ is continuously differentiable and satisfies $d/dt\, u(t;f) = Bu(t;f) + Ku_t$ on $[0, T_f)$, and $u_0 = f$.*

After the following definition we state a principle of linearized stability for (FDE_2).

DEFINITION 2.1. The *growth bound* ω of a linear semigroup $U(t)$, $t \geqq 0$, is defined by

$$\omega(U(t)) = \inf\{w \in R\text{: There exists } M \text{ such that } |U(t)| \leqq M e^{wt} \text{ for all } t \geqq 0\}.$$

THEOREM 2.1. *Let B and K satisfy* (H1) *and* (H2). *For each $f \in E$ let $u(t;f)$ be the solution of the integral equation* (1) *on the maximal interval of existence $[-r_0, T_f)$. Let $\hat{x} \in X$ satisfy $B\hat{x} + K\hat{f} = 0$, where $\hat{f} \in E$ is defined by $\hat{f}(s) = \hat{x}$ for all $s \in [-r_0, 0]$. Let $\hat{T}(t)$, $t \geqq 0$, be the strongly continuous semigroup of bounded linear operators in E with generator $\hat{A}$ defined by $\hat{A}f = f'$,*

$$D(\hat{A}) = \{f \in C^1([-r_0, 0], X) : f(0) \in D(B), f'(0) = Bf(0) + K'(\hat{f})f\}.$$

If $\omega(\hat{T}(t)) < 0$ then $\hat{f}$ is a locally exponentially stable equilibrium in the following sense: There exist $\varepsilon > 0$, $\tilde{M} \geqq 1$, and $\gamma < 0$ such that if $f \in E$ and $\|f - \hat{f}\|_E \leqq \varepsilon$, then $T_f = \infty$ and

$$\|u(t;f) - \hat{x}\| \leqq \tilde{M} e^{\gamma t} \|f - \hat{f}\|_E \quad \textit{for all } t \geqq 0.$$

Proof. If $\hat{x} \in X$ satisfies $B\hat{x} + K\hat{f} = 0$, then $u(t;\hat{f}) = \hat{x}$ for all $t \geqq 0$ by Lemmas 2.1 and 2.3. The fact that $\hat{A}$ generates a strongly continuous linear semigroup $\hat{T}(t)$, $t \geqq 0$, in E is proved in [10, B−IV, Thm. 3.1]. Also, $\hat{T}(t)$ is a translation semigroup, that is

$$(2)\quad \hat{T}(t)f(s) = \begin{cases} f(t+s) & \text{if } t+s \leqq 0, \\ \hat{T}(t+s)f(0) & \text{if } t+s \geqq 0, \end{cases}$$

and $\hat{T}(t)f(0)$ $(=(\hat{T}(t)f)(0))$ has the representation

$$\hat{T}(t)f(0) = T(t)f(0) + \int_0^t T(t-s)K'(\hat{f})(\hat{T}(s)f)\,ds, \qquad f \in E, \quad t \geqq 0.$$

In analogy to Webb [16, (4.100), p. 199] we claim the following fact:

(3) Let $\tilde{f} \in E$ and $t_1 > 0$. Let $h : [-r_0, t_1] \to X$ be continuous. Let $b : [-r_0, t_1] \to X$ satisfy

$$\begin{aligned} b(t) &= T(t)\tilde{f}(0) + \int_0^t T(t-s)(K'(\hat{f})b_s + h(s))\,ds, \qquad 0 \leqq t \leqq t_1 \\ b(t) &= \tilde{f}(0), \qquad -r_0 \leqq t \leqq 0. \end{aligned}$$

Then

$$b(t)=\hat{T}(t)\tilde{f}(0)+\int_0^t \hat{T}(t-s)h_s(0)\,ds, \qquad 0\leqq t\leqq t_1.$$

To prove (3), let $g:[0,t_1]\to E$ be defined by

$$g(t)(\theta)=\begin{cases}\left[\hat{T}(t)\tilde{f}+\displaystyle\int_0^{t+\theta}\hat{T}(t-s)h_s\,ds\right](\theta) & \text{if } t+\theta\geqq 0,\\ \tilde{f}(0) & \text{if } t+\theta\leqq 0,\end{cases}$$

and let $g_1:[0,t_1]\to E$ be defined by

$$g_1(t)(\theta)=\left[\hat{T}(t)\tilde{f}+\int_0^t \hat{T}(t-s)h_s\,ds\right](\theta), \qquad -r_0\leqq\theta\leqq 0.$$

If $\tilde{f}\in D(\hat{A})$ and h is continuously differentiable on $[-r_0,t_1]$, then by [6, p. 486],

$$\frac{d}{dt}g_1(t)=\hat{A}g_1(t)+h_t.$$

It can readily be verified that for $\hat{f}$ and h as above, and for every $\theta\in[-r_0,0]$ and $t\in[0,t_1]$ such that $t+\theta\geqq 0$, the function

$$\hat{T}(t)\tilde{f}+\int_0^{t+\theta}\hat{T}(t-s)h_s\,ds\in D(\hat{A}) \quad\text{and}\quad \hat{A}g(t)(0)=\hat{A}g_1(t)(0).$$

Thus,

$$\begin{aligned}\frac{d}{dt}g_1(t)(0)&=\hat{A}g(t)(0)+h_t(0)\\ &=Bg(t)(0)+K'(\hat{f})g(t)+h(t).\end{aligned}$$

Let

$$b_1(t)=\begin{cases}T(t)\tilde{f}(0)+\displaystyle\int_0^t T(t-s)(K'(\hat{f})g(s)+h(s))\,ds, & 0\leqq t\leqq t_1\\ \tilde{f}(0), \quad -r_0\leqq t\leqq 0.\end{cases}$$

Since

$$\begin{aligned}&g_1(t)(0)=\hat{T}(t)\tilde{f}(0)+\int_0^t\hat{T}(t-s)h_s(0)\,ds,\\ &g_1(0)(0)=\tilde{f}(0),\\ &\frac{d}{dt}g_1(t)(0)=Bg_1(t)(0)+K'(\hat{f})g(t)+h(t), \qquad 0\leqq t\leqq t_1,\end{aligned}$$

this implies, again by [6, p. 486],

$$g_1(t)(0)=g(t)(0)=b_1(t), \qquad 0\leqq t\leqq t_1.$$

For $\theta\in[-r_0,0]$, $t\in[0,t_1]$ such that $t+\theta\geqq 0$, $g(t)(\theta)=g(t+\theta)(0)=b_1(t+\theta)$ by the translation property (2).

For, θ, t such that $t+\theta\leqq 0$, $g(t)(\theta)=\tilde{f}(0)=b_1(t+\theta)$. Therefore, $g(t)=b_{1_t}$ and $b_1(t)=b(t)$, $0\leqq t\leqq t_1$. The fact (3) is thus proved for the case where $\tilde{f}\in D(\hat{A})$ and h is continuously differentiable. If $\tilde{f}\notin D(\hat{A})$ and h is not continuously differentiable, the argument of [16, p. 199] can be modified and applied to yield the conclusion again that $g(t)=b_t$, $0\leqq t\leqq t_1$.

Let $\bar\omega \in (\omega(\hat T(t)), 0)$. Then we can choose $M \geqq 1$ such that $|\hat T(t)| \leqq M e^{\bar\omega t}$ for $t \geqq 0$. Let $c_{\bar\omega} = e^{-2\bar\omega r_0}$, and let $r > 0$ such that $\|\circ(g)\| \leqq (-\bar\omega/2Mc_{\bar\omega})\|g\|_E$ for all $g \in E$ such that $\|g\|_E < r$. Let $\varepsilon = r/Mc_{\bar\omega}(=r/M e^{2\bar\omega r_0})$. Let $f \in E$ such that $\|f - \hat f\|_E < \varepsilon$, and let $t_1 \leqq \infty$ be the largest extended real number such that $\|u(t;f) - \hat x\| \leqq r$ for $0 \leqq t < t_1$. By (1) and (H2) we have for $0 \leqq t < t_1$,

$$\begin{aligned} u(t;f) &= T(t)f(0) + \int_0^t T(t-s)Ku_s\, ds \\ &= T(t)f(0) + \int_0^t T(t-s) \\ &\quad \cdot [K\hat f + K'(\hat f)(u_s - \hat f) + \circ(u_s - \hat f)]\, ds. \end{aligned} \tag{4}$$

We also have

$$\hat x = u(t;\hat f) = T(t)\hat x + \int_0^t T(t-s)K\hat f\, ds. \tag{5}$$

From (4) and (5) we have

$$u(t;f) - \hat x = T(t)(f(0) - \hat x) + \int_0^t T(t-s)[K'(\hat f)(u_s - \hat f) + \circ(u_s - \hat f)]\, ds.$$

Applying the fact (3) we obtain

$$u(t,f) - \hat x = \hat T(t)(f - \hat f)(0) + \int_0^t \hat T(t-s)h_s(0)\, ds,$$

where

$$h(s) := \begin{cases} \circ(u_s - \hat f), & s \in [0,t] \quad (t < t_1), \\ \circ(u_0 - \hat f), & s \in [-r_0, 0]. \end{cases}$$

Thus,

$$\|u(t;f) - \hat x\| \leqq \|\hat T(t)(f - \hat f)\|_E + \int_0^t \|\hat T(t-s)h_s\|_E\, ds. \tag{6}$$

For $s \in [0,t]$, $t < t_1$, $\|\hat T(t-s)h_s\|_E \leqq |\hat T(t-s)|\,\|h_s\|_E$.

Since

$$h(s+\theta) = \begin{cases} \circ(u_{s+\theta} - \hat f), & s+\theta \in [0,t], \\ \circ(u_0 - \hat f), & s+\theta \in [-r_0, 0], \end{cases}$$

$$\|h_s\|_E = \sup_{\theta \in [-r_0, 0]} \|h(s+\theta)\| \leqq \left(\frac{-\bar\omega}{2Mc_{\bar\omega}}\right)\|u_{\bar s} - \hat f\|_E$$

for some $\bar s \in [0, s]$. Let $\bar s = s + s_1$, $s_1 \in [-r_0, 0]$. If $s \geqq r_0$, then $s + \theta \in [-r_0, s]$ for $\theta \in [-2r_0, 0]$, and

$$\begin{aligned} \|u_{\bar s} - \hat f\|_E &= \sup_{\eta \in [-r_0, 0]} \|u(s + s_1 + \eta) - \hat f(\eta)\| \\ &\leqq \sup_{\theta \in [-2r_0, 0]} \|u(s+\theta) - \hat x\|. \end{aligned}$$

If $s < r_0$,

$$\begin{aligned} \|u_{\bar s} - \hat f\|_E &= \sup_{\eta \in [-r_0, 0]} \|u(s + s_1 + \eta) - \hat f(\eta)\| \\ &\leqq \sup_{\theta \in [-r_0 - s, 0]} \|u(s+\theta) - \hat x\|. \end{aligned}$$

For $s\in[0,t]$, $t<t_1$, we define a continuous function $\tilde{u}_s:[-2r_0,0]\to X$ by

$$\tilde{u}_s(\theta)=\tilde{u}(s+\theta;f)=\begin{cases}u(s+\theta;f) & \text{if } s+\theta\in[-r_0,s],\\ f(-r_0) & \text{if } s+\theta\in[-2r_0,-r_0].\end{cases}$$

Then for all $s\in[0,t]$, $t<t_1$,

$$\|u_{\bar{s}}-\hat{f}\|_E\leqq \sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta)-\hat{x}\|,$$

and hence

$$\|h_s\|_E\leqq\left(\frac{-\bar{\omega}}{2Mc_{\bar{\omega}}}\right)\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta)-\hat{x}\|. \tag{7}$$

From (6) and (7) we obtain for $0\leqq t<t_1$,

$$\|u(t;f)-\hat{x}\|\leqq Me^{\bar{\omega}t}\|f-\hat{f}\|_E+\left(\frac{-\bar{\omega}}{2c_{\bar{\omega}}}\right)$$
$$\cdot\int_0^t e^{\bar{\omega}(t-s)}\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta)-\hat{x}\|\,ds.$$

If $t\in[0,t_1)$, $\theta\in[-2r_0,0]$ such that $0\leqq t+\theta\leqq t<t_1$, then replacing t by $t+\theta$ in the above we have

$$\begin{aligned}\|u&(t+\theta;f)-\hat{x}\|\\ &=\|\tilde{u}(t+\theta;f)-\hat{x}\|\\ &\leqq Me^{\bar{\omega}(t+\theta)}\|f-\hat{f}\|_E+\left(\frac{-\bar{\omega}}{2c_{\bar{\omega}}}\right)\int_0^{t+\theta}e^{\bar{\omega}(t+\theta-s)}\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta)-\hat{x}\|\,ds\\ &\leqq Me^{-2\bar{\omega}r_0}e^{\bar{\omega}t}\|f-\hat{f}\|_E+\left(\frac{-\bar{\omega}}{2c_{\bar{\omega}}}\right)\int_0^t e^{\bar{\omega}(t-s)}e^{-2\bar{\omega}r_0}\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta)-\hat{x}\|\,ds\\ &\leqq Me^{-2\bar{\omega}r_0}e^{\bar{\omega}t}\|f-\hat{f}\|_E+\left(\frac{-\bar{\omega}}{2}\right)e^{\bar{\omega}t}\int_0^t e^{-\bar{\omega}s}\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta;f)-\hat{x}\|\,ds.\end{aligned} \tag{8}$$

If $t\in[0,t_1)$, $\theta\in[-2r_0,0]$ such that $-r_0\leqq t+\theta<0$, then

$$\begin{aligned}\|\tilde{u}(t+\theta;f)-\hat{x}\|&=\|u(t+\theta;f)-\hat{x}\|\\ &=\|f(t+\theta)-\hat{f}(t+\theta)\|\\ &\leqq\|f-\hat{f}\|_E\\ &\leqq Me^{\bar{\omega}(t-2r_0)}\|f-\hat{f}\|_E.\end{aligned} \tag{9}$$

If $t\in[0,t_1)$, $\theta\in[-2r_0,0]$ such that $t+\theta\in[-2r_0,-r_0]$,

$$\begin{aligned}\|\tilde{u}(t+\theta;f)-\hat{x}\|&=\|f(-r_0)-\hat{x}\|\\ &=\|f(-r_0)-\hat{f}(-r_0)\|\\ &\leqq\|f-\hat{f}\|_E\\ &\leqq Me^{\bar{\omega}(t-2r_0)}\|f-\hat{f}\|_E.\end{aligned} \tag{10}$$

From (8)-(10) we can conclude that

$$\begin{aligned}e^{-\bar{\omega}t}&\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(t+\theta;f)-\hat{x}\|\\ &\leqq Me^{-2\bar{\omega}r_0}\|f-\hat{f}\|_E+\left(\frac{-\bar{\omega}}{2}\right)\int_0^t e^{-\bar{\omega}s}\sup_{\theta\in[-2r_0,0]}\|\tilde{u}(s+\theta;f)-\hat{x}\|\,ds.\end{aligned}$$

Applying Gronwall's inequality we have

$$e^{-\bar{\omega}t} \sup_{\theta\in[-2r_0,0]} \|\tilde{u}(t+\theta;f)-\hat{x}\| \leqq M e^{-2\bar{\omega}r_0} \|f-\hat{f}\|_E e^{-(\bar{\omega}/2)t}$$

$$< \varepsilon M e^{-2\bar{\omega}r_0} e^{-(\bar{\omega}/2)t}.$$

Thus, for all $t\in[0, t_1)$

$$\|u(t;f)-\hat{x}\| < \varepsilon M e^{-2\bar{\omega}r_0} e^{(\bar{\omega}/2)t} \leqq r.$$

By Lemma 2.1, $t_1=\infty$ and we have shown that

$$\|u(t;f)-\hat{x}\| \leqq \tilde{M} e^{\gamma t} \|f-\hat{f}\|_E,$$

where $\tilde{M}=M e^{-2\bar{\omega}r_0}$ and $\gamma=\bar{\omega}/2$.

3. Positivity and the linearizations of (FDE$_1$) or (FDE$_2$). We consider the linearized abstract functional differential equation

$$\text{(FDE)}_\text{L} \qquad \begin{aligned} \dot{u}(t) &= Bu(t)+\psi u_t, \qquad t\geqq 0,\\ u_0 &= f, \end{aligned}$$

where we assume that B satisfies (H1) and ψ satisfies

(H2)′ $\psi\in\mathscr{L}(E, X)$ (that is, $\psi: E\to X$ is a bounded linear operator).

Let X be a Banach lattice. (The reader can refer to [10] or [13] for basic facts about Banach lattices and positive semigroups.) Then $E=C([-r_0,0],X)$ is also a Banach lattice with the natural pointwise order and the supremum norm. Let X_+ be the positive cone of X (that is, $X_+=\{x\in X: x\geqslant 0\}$, and let E_+ be the positive cone of E.

DEFINITION 3.1. An operator B with domain and range contained in a Banach lattice X is a *positive operator* on X if $Bx\in X_+$ whenever $x\in X_+$. A semigroup $T(t)$, $t\geqq 0$, on X is a *positive semigroup* if $T(t)x\in X_+$ whenever $x\in X_+$ and $t\in R_+$.

DEFINITION 3.2. Let A be the generator of a strongly continuous linear semigroup, $T(t)$, $t\geqq 0$, on a Banach space X. The *spectral bound* of A, $s(A)$, is defined by

$$s(A)=\sup\{\text{Re }\lambda: \lambda\in\sigma(A)\}.$$

(Here $\sigma(A)$ denotes the spectrum of A.)

If X is finite-dimensional, $s(A)=\omega(T(t))$, the growth bound of the semigroup (defined by Definition 2.1), and hence we obtain the classical Lyapunov stability theorem. It is well known that in general $s(A)\leqq\omega(T(t))<+\infty$, but strict inequality may occur. However, for positive linear semigroups, we can often conclude the uniform exponential stability of the zero equilibrium of the semigroup whenever $s(A)<0$. We state below some of the known important consequences of positivity for the stability study of (FDE)$_\text{L}$.

DEFINITION 3.3. A strongly continuous linear semigroup $T(t)$, $t\geqq 0$, on a Banach space X, with generator A, is called

(i) *exponentially stable* if there exists $\gamma>0$ such that $\lim_{t\to\infty} e^{\gamma t}\|T(t)f\|=0$ for every $f\in D(A)$.

(ii) *uniformly exponentially stable* if there exists $\gamma>0$ such that $\lim_{t\to\infty} e^{\gamma t}|T(t)|=0$.

We note that if $\omega(T(t))<0$, the semigroup $T(t)$ is uniformly exponentially stable.

PROPOSITION 3.1 [10, C-IV, Thms. 1.1 and 1.3]. *Let A be the generator of a positive linear semigroup $T(t)$, $t\geqq 0$, on a Banach lattice X. Then the following properties are equivalent*:

(a) *The semigroup $T(t)$ is exponentially stable.*

(b) *The spectral bound $s(A)$ is less than zero.*

If, in addition, X is a space $C(K)$, K compact, $C_0(Y)$, Y locally compact, or $L^1(Y, \mu)$ or $L^2(Y, \mu)$ for some measure space (Y, μ), then the above properties are equivalent to

(c) *The semigroup $T(t)$ is uniformly exponentially stable.*

PROPOSITION 3.2 [10, C-III, Cor. 1.4]. *Let $T(t)$, $t \geqq 0$, be a positive linear semigroup defined on a Banach lattice X, and let A be its generator. Then $s(A) \in \sigma(A)$ unless $s(A) = -\infty$.*

DEFINITION 3.4. For $\lambda \in \mathbb{C}$, $x \in X$, $g \in E = C([-r_0, 0], X)$, define the following operators:

(i) $\varepsilon_\lambda \otimes x \in E$ by $(\varepsilon_\lambda \otimes x)(s) = e^{\lambda s} \cdot x$, $s \in [-r_0, 0]$;

(ii) $H_\lambda \in \mathscr{L}(E)$ by $H_\lambda g(t) = \int_t^0 e^{\lambda(t-s)} g(s)\, ds$, $t \in [-r_0, 0]$;

(iii) $\psi_\lambda \in \mathscr{L}(X)$ by $\psi_\lambda(x) = \psi(\varepsilon_\lambda \otimes x)$.

PROPOSITION 3.3 [10, B-IV, Prop. 35 and Thm. 3.7]. *Let X be a Banach lattice. Assume, in addition to (H1) and (H2)$'$, that B generates a positive semigroup and ψ is a positive operator. Let $\hat{T}(t)$, $t \geqq 0$, be the strongly continuous semigroup of bounded linear operators in $E = C([-r_0, 0], X)$ with generator $\hat{A}$ defined by*

$$\hat{A}f = f',$$

$$D(\hat{A}) = \{f \in C^1([-r_0, 0], X) : f(0) \in D(B), f'(0) = Bf(0) + \psi f\}.$$

Then the semigroup $\hat{T}(t)$ is positive. For the generator $\hat{A}$ of $\hat{T}(t)$ and $\lambda \in R$ the following statements hold:

(a) *If $s(B + \psi_\lambda) < \lambda$, then $s(A) < \lambda$;*

(b) *If $s(B + \psi_\lambda) = \lambda$, then $s(A) = \lambda$;*

(c) *Suppose that B has compact resolvent and there exists $\mu \in R$ with $\sigma(B + \psi_\mu) \neq \varnothing$. Then*

$$s(B + \psi_\lambda) \leqq \lambda \text{ if and only if } s(\hat{A}) \leqq \lambda.$$

(*In particular, $s(B + \psi_0) < 0$ if and only if $s(\hat{A}) < 0$.*)

DEFINITION 3.5. A continuous map $r : [-1, 0] \to R_-$ satisfying $\min_{-1 \leqq s \leqq 0} r(s) = -r_0$ is called a *delay function* on $[-r_0, 0]$. If ψ is a bounded linear operator from $C([-1, 0], X)$ into X, the *delayed operator* $\psi_r \in \mathscr{L}(E, X)$ is defined by $\psi_r f = \psi(f \circ r)$, $f \in E$.

PROPOSITION 3.4 [7, Thm. 4.3]. *Let X be a Banach lattice. Assume that B satisfies (H1) and generates a positive semigroup on X, and ψ is a positive bounded linear operator from $C([-1, 0], X)$ to X. Let $\hat{T}_{B,\psi_r}(t)$, $t \geqq 0$, be the strongly continuous semigroup of bounded linear operators in E with generator $\hat{A}_{B,\psi_r}$ defined by $\hat{A}_{B,\psi_r} f = f'$,*

$$D(\hat{A}_{B,\psi_r}) = \{f \in C^1([-r_0, 0], X) : f(0) \in D(B), f'(0) = Bf(0) + \psi_r f\}.$$

If $s(B + \psi_0) < 0$ then $s(\hat{A}_{B,\psi_r}) < 0$ for every delay function r.

DEFINITION 3.6. If $\psi_1, \psi_2 \in \mathscr{L}(E, X)$ then ψ_1 is said to *dominate* ψ_2 if $|\psi_2 f| \leqq \psi_1 |f|$ for all $f \in E$. (Here $|f| = \sup(f, -f)$.) If $T_1(t)$, $T_2(t)$, $t \geqq 0$, are semigroups on E, $T_1(t)$ is said to *dominate* $T_2(t)$ if $|T_2(t) f| \leqq T_1(t)|f|$ for every $f \in E$, $t \geqq 0$.

PROPOSITION 3.5 [7, Cor. 4.4]. *Let X be a Banach lattice. Let B be the generator of a linear semigroup $T(t)$, $t \geqq 0$, on X, and let $\psi \in \mathscr{L}(C([-1, 0], X), X)$. Assume that there exists a semigroup $\tilde{T}(t)$, $t \geqq 0$, on X with generator $\tilde{B}$ which dominates $T(t)$, and an operator $\tilde{\psi}$ which dominates ψ. Then the linear semigroup $\hat{T}_{B,\psi_r}(t)$ (described in Proposition 3.4) is uniformly exponentially stable for all delay functions r if the spectral bound $s(\tilde{B} + \tilde{\psi}_0) < 0$ and one of the following conditions is satisfied:*

(a) *$X = C(K)$, K compact;*

(b) *$\tilde{T}(t)$ is norm continuous for $t > 0$ (that is, the function $t \to \tilde{T}(t)$ from $(0, \infty)$ into $\mathscr{L}(X)$ is norm continuous).*

We now examine the consequences of the strong positivity property of irreducibility for the stability study of $(\mathrm{FDE})_{\mathrm{L}}$.

DEFINITION 3.7. An operator B on a Banach lattice X is *strictly positive* if $x \in X_+$, $x \neq 0$ implies $Bx \in X_+$, $Bx \neq 0$. A linear semigroup $T(t)$, $t \geqq 0$, on X is *irreducible* if given $x \in X_+$, $x \neq 0$, $x^* \in X_+^*$, $x^* \neq 0$, there exists $t_0 > 0$ such that $\langle T(t_0)x, x^*\rangle > 0$. (For $y \in X$, $y^* \in X^*$, $\langle y, y^*\rangle = y^*(y)$.) A bounded operator T on X is *irreducible* if the semigroup $\{T^n\colon n \in N\}$ is irreducible.

It is well known that the eigenvalues of irreducible square matrices have special properties (see, for example, [13]). Likewise, positive irreducible semigroups possess special properties which are useful in the stability study of certain equations (see, for example, [10]).

We first give sufficient conditions which insure that the semigroup $T(t)$ corresponding to $(\mathrm{FDE})_{\mathrm{L}}$ (in the sense described in Proposition 3.3) is irreducible. A corresponding result for the functional equation $u(t) = \Phi u_t$, $t \geqq 0$, $u_0 = f$, was obtained in a recent paper by Grabosch [4, Prop. 3.7]. In that paper $E = L^1((-\infty, 0], F, e^{\eta s}\, ds)$ and F is a Banach lattice. The method of proof of the proposition below was motivated by the proof of [4, Prop. 3.7].

PROPOSITION 3.6. *Let X be a Banach lattice. Assume that B and ψ satisfy* (H1) *and* (H2)′. *In addition, assume that B generates a positive irreducible semigroup and ψ is strictly positive. Then the semigroup $\hat{T}(t)$, $t \geqq 0$, of Proposition* 3.3 *is irreducible.*

For the proof we will use the following two lemmas.

LEMMA 3.1 [10, C-III, Def. 3.1]. *Let E be a Banach lattice and $\hat{T}(t)$, $t \geqslant 0$, be a strongly continuous linear semigroup on E with generator $\hat{A}$. The following assertions are equivalent*:

(i) *$\hat{T}(t)$ is irreducible.*

(ii) *For some* (*every*) *$\lambda > s(\hat{A})$ the resolvent $R(\lambda, \hat{A})$ is irreducible.*

(iii) *For some* (*every*) *$\lambda > s(\hat{A})$, $R(\lambda, \hat{A})f$ is a quasi-interior point of E_+ whenever $f > 0$* (*that is, for all $\phi \in E^*$, $\phi > 0$, $\langle R(\lambda, \hat{A})f, \phi\rangle > 0$*).

LEMMA 3.2. *Let $\hat{x}$ be a quasi-interior point of X_+. Then $\varepsilon_\lambda \otimes \hat{x}$* (*as defined by Definition* 3.4) *is a quasi-interior point of E_+.*

Proof of Lemma 3.2. Let $\hat{x}$ be a quasi-interior point of X_+. Then the ideal $I_{\hat{x}}$ which is generated by $\hat{x}$ is dense in X (see [13, II, Def. 6.1]). Since ε_λ is a quasi-interior point of $C([-r_0, 0])_+$ [10, C-I, p. 238] the ideal I_{ε_λ} is dense in $C([-r_0, 0])$. Hence $I_{\varepsilon_\lambda} \otimes I_{\hat{x}}$ is dense in $C([-r_0, 0])\, \tilde{\otimes}_{\varepsilon} X$, which is isomorphic to $E = C([-r_0, 0], X)$ [13, p. 237]. (We are using here the tensor product notation from [13].) But $I_{\varepsilon_\lambda \otimes \hat{x}} \supseteq I_{\varepsilon_\lambda} \otimes I_{\hat{x}}$ implies that $I_{\varepsilon_\lambda \otimes \hat{x}}$ is dense in E, and hence that $\varepsilon_\lambda \otimes \hat{x}$ is a quasi-interior point of E_+.

Proof of Proposition 3.6. From [10, B-IV, Prop. 3.4] we have $\lambda \in \rho(B + \psi_\lambda)$ if and only if $\lambda \in \rho(\hat{A})$, and

(11) $R(\lambda, \hat{A})g = \varepsilon_\lambda \otimes [R(\lambda, B + \psi_\lambda)(g(0) + \psi H_\lambda g)] + H_\lambda g$, $g \in E$, where $\psi_\lambda \in \mathscr{L}(X)$ and $H_\lambda \in \mathscr{L}(E)$ are defined in Definition 3.4.

We will first show that

(12) $R(\lambda, B + \psi_\lambda)(g(0) + \psi H_\lambda g)$ is a quasi-interior point of X_+ (for sufficiently large λ) whenever $g \in E$, $g > 0$.

We note that if $g > 0$, then $g(0) \geqq 0$. Also, $H_\lambda g > 0$ if $g > 0$. Thus, due to the strict positivity of ψ, we have $\psi H_\lambda g > 0$ if $g > 0$. Therefore, if $g > 0$ then $g(0) + \psi H_\lambda g > 0$. So, if we show that $R(\lambda, B + \psi_\lambda)f$ is a quasi-interior point of X_+ whenever $f \in X$, $f > 0$, then this will establish (12). From [10, (1.12), p. 44] there exists $\lambda_0 \in R$ such that

$$R(\lambda, B + \psi_\lambda) = R(\lambda, B)(I - \psi_\lambda R(\lambda, B))^{-1} \quad \text{for } \lambda \geqq \lambda_0. \tag{13}$$

Since we are assuming that B generates an irreducible semigroup on X, this implies by Lemma 3.1 that $R(\lambda, B)\bar{f}$ is a quasi-interior point of X_+ whenever $\bar{f}\in X$, $\bar{f}>0$. Thus, if we show that $\bar{f}:=(I-\psi_\lambda R(\lambda, B))^{-1}f>0>0$ when $f>0$, then, by (13), $R(\lambda, B+\psi_\lambda)f$ is a quasi-interior point of X_+ when $f>0$. Since $1\in\rho(\psi_\lambda R(\lambda, B))$ for $\lambda\geqq\lambda_0$ and we know that $R(\lambda, B)$ is irreducible (hence strictly positive) and ψ_λ is strictly positive (since ψ is strictly positive), we have for $f>0$

$$(I-\psi_\lambda R(\lambda, B))^{-1}f=R(1, \psi_\lambda R(\lambda, B))f=\sum_{n=1}^{\infty}(\psi_\lambda R(\lambda, B))^n f>0.$$

Thus, $R(\lambda, B+\psi_\lambda)f$ is a quasi-interior point of X_+ when $f>0$. By Lemma 3.2, $\varepsilon_\lambda\otimes[R(\lambda, B+\psi_\lambda)(g(0)+\psi H_\lambda g)]$ is a quasi-interior point of E_+. Since $H_\lambda g>0$ for $g\in E$, $g>0$, $\varepsilon_\lambda\otimes[R(\lambda, B+\psi_\lambda)(g(0)+\psi H_\lambda g)]+H_\lambda g$ is a quasi-interior point of E_+ as well. Thus by (11) and Lemma 3.1, $R(\lambda, \hat{A})$ is irreducible and $\hat{T}(t)$ is irreducible.

Using Proposition 3.6 along with known facts from positive semigroup theory we obtain our main result for this section.

THEOREM 3.1. *Let X be a Banach lattice. Assume that B and ψ satisfy* (H1) *and* (H2)′. *In addition assume that B generates a positive irreducible semigroup $T(t)$, $t\geqq 0$, which is compact for each $t>0$, and ψ is strictly positive. Let $\hat{T}(t)$, $t\geqq 0$, be the strongly continuous semigroup in E with generator $\hat{A}$, as defined in Proposition* 3.3. *Then the following assertions hold*:

(i) *There exists a unique real number $\lambda_0=s(\hat{A})=\omega(\hat{T}(t))$ and a rank* 1 *projection P such that*

$$\|e^{-\lambda_0 t}\,\hat{T}(t)-P\|\leqq M e^{-\delta t}$$

for suitable constants $\delta>0$, $M\geqq 1$, and all $t\geqq 0$. The projection P has the form $P=\phi\otimes h$, where h is a quasi-interior point of E_+, and ϕ is a strictly positive linear form on E.

(ii) *λ_0 is the unique solution of the equation $\lambda=s(B+\psi_\lambda)$.*

Remark. Assertion (i) of Theorem 3.1 says that under the given conditions, solutions of $(\mathrm{FDE})_\mathrm{L}$ have *asynchronous exponential growth.* The constant λ_0 is called the *Malthusian parameter* and P is called the *exponential steady state.*

Proof of Theorem 3.1. The hypotheses that B generates a positive irreducible semigroup and ψ is strictly positive, along with (H1) and (H2)′, imply by Proposition 3.6 that $\hat{T}(t)$ is irreducible. The assumption that $T(t)$ is compact for each $t>0$ guarantees that $\hat{T}(t)$ is eventually compact (that is, compact for $t>r_0$) [15, Prop. 2.4]. By [10, C-III, Thm. 3.7(c)], $\sigma(\hat{A})\neq\varnothing$. Assertion (i) follows from [10, C-IV, Thm. 2.1 and Remarks 2.2(d), (e)]. Noting that $\sigma(B)\neq\varnothing$ (which again follows from [10, C-III, Thm. 3.7(c)], we have $-\infty<s(B)\leqq s(B+\psi_\lambda)$ for all $\lambda\in R$, which implies that $\sigma(B+\psi_\lambda)\neq\varnothing$. Thus assertion (ii) follows from [10, B-IV, Prop. 3.6].

If, in Theorem 3.1, ψ is not strictly positive but is dominated by a strictly positive bounded linear operator, then we have the following result.

COROLLARY 3.1. *Let X be a Banach lattice. Assume that B and ψ satisfy* (H1) *and* (H2)′. *Assume that B generates a positive irreducible semigroup $T(t)$, $t\geqq 0$, which is compact for each $t>0$. Assume there is a strictly positive linear operator $\tilde{\psi}\in\mathscr{L}(E, X)$ such that $|\psi f|\leqq\tilde{\psi}|f|$ for all $f\in E$. Let $\hat{T}(t)$, $t\geqq 0$, be the strongly continuous semigroup in E with generator $\hat{A}$, as defined in Proposition* 3.3. *Then there exists a unique real number $\lambda_0=s(\hat{A}_{\tilde{\psi}})=\omega(\hat{T}_{\tilde{\psi}}(t))$ and a positive constant M such that for $t\geqq 0$ and each $f\in E$,*

$$\|\hat{T}(t)f\|\leqq M e^{\lambda_0 t}\|f\|+o(e^{\lambda_0 t}).$$

(*Here $\hat{T}_{\tilde{\psi}}(t)$, $t\geqq 0$, is the linear semigroup, with generator $\hat{A}_{\tilde{\psi}}$, defined in a fashion analogous to $\hat{T}(t)$ and $\hat{A}$ except with $\tilde{\psi}$ replacing ψ* (*cf. Proposition* 3.3).)

Proof. By [7, Prop. 3.2] we know that $|\hat{T}(t)f| \leqq \hat{T}_{\tilde{\psi}}(t)|f|$. Since B and $\tilde{\psi}$ satisfy the hypotheses of Theorem 3.1, assertion (i) of that theorem holds for $\hat{T}_{\tilde{\psi}}(t)$. This assertion can also be formulated as follows: There exists $\phi \in E_+^*$, $\phi \neq 0$, and a quasi-interior element h of E_+ such that for $t \geqq 0$ and each $f \in E$,

$$\hat{T}_{\tilde{\psi}}(t)f = \phi(f)\, e^{\lambda_0 t}\, h + \circ(e^{\lambda_0 t}).$$

Thus,

$$\begin{aligned} \lim_{t\to\infty} \|e^{-\lambda_0 t}\, \hat{T}(t)f\| &\leqq \lim_{t\to\infty} \|e^{-\lambda_0 t}\, \hat{T}_{\tilde{\psi}}(t)|f|\| \\ &\leqq \|\phi(|f|)h\| \leqq M\|f\|, \end{aligned}$$

or, equivalently,

$$\|\hat{T}(t)f\| \leqq M e^{\lambda_0 t}\|f\| + \circ(e^{\lambda_0 t}).$$

4. Example. We now apply some of our results to the motivating population equation

$$\text{(E)}' \qquad \begin{aligned} \frac{\partial u}{\partial t}(x,t) &= d\Delta u(x,t) + au(x,t) \\ &\cdot\left[1 - bu(x,t) - \int_{-1}^{0} u(x, t + r(s))\, d\eta(s)\right], \end{aligned}$$

where $x \in [0, \pi]$, $t \geqq 0$, $\Delta = \partial^2/\partial x^2$ with Dirichlet boundary conditions, a, b, d are positive constants, η is a strictly positive measure on $[-1, 0]$ such that $b + \|\eta\| = 1$, and r is a delay function on $[-r_0, 0]$. If $a > d$ then it is known that there exists a stationary solution $h \in C^2[0, \pi]$ of (E) which is strictly positive on $(0, \pi)$ (see [14]). Thus $dh'' + ah(1-h) = 0$.

Let $X = \{f \in C[0, \pi]\colon f(0) = f(\pi) = 0\}$ and

$$B_0 = \frac{d^2}{dx^2} \quad \text{with maximal domain in } X.$$

As an abstract equation in X, (E)$'$ can be written as

$$\begin{aligned} \dot{u}(t) &= dB_0\, u(t) + au(t)\left[1 - bu(t) - \int_{-1}^{0} (u_t \circ r)(s)\, d\eta(s)\right] \\ &= dB_0\, u(t) + au(t) - abu_t^2(0) - au_t(0)\int_{-1}^{0} (u_t \circ r)(s)\, d\eta(s). \end{aligned}$$

Thus we have

$$\text{(14)} \qquad \dot{u}(t) = Bu(t) + Ku_t, \qquad t \geqq 0,$$

where $Bu = dB_0 u + au$, and for $g \in E = C([-r_0, 0], X)$,

$$\text{(15)} \qquad Kg = -abg^2(0) - ag(0)\int_{-1}^{0} (g \circ r)(s)\, d\eta(s).$$

It is well known that B_0 generates a contraction semigroup on X and B generates a strongly continuous semigroup on X. It is easy to check that K is continuously Fréchet-differentiable in the sense of (H2). Thus if we let $u_0 = f$, then (E)$'$ has the abstract form of (FDE$_2$). From Lemmas 2.1–2.3 we have the existence of a unique local solution of (14) for each $f \in E$. From Theorem 2.1 we know that the linearization of (14) at the stationary solution has the form

$$\dot{u}(t) = Bu(t) + \psi u_t, \qquad t \geqq 0, \tag{16}$$

where $\psi = K'(\hat{f})$, and $\hat{f}$ is the constant function in E defined by $\hat{f}(s) = h$ for all $s \in [-r_0, 0]$. We see from (15) that

$$\begin{aligned} \psi u_t &= K'(\hat{f})u_t \\ &= -2abhu(t) - au(t)\int_{-1}^{0} h\, d\eta(s) - ah\int_{-1}^{0} (u_t \circ r)(s)\, d\eta(s) \\ &= -abhu(t) - ahu(t)(b + \|\eta\|) - ah\int_{-1}^{0} (u_t \circ r)(s)\, d\eta(s) \\ &= (-ah - abh)u(t) - ah\int_{-1}^{0} (u_t \circ r)(s)\, d\eta(s). \end{aligned} \tag{17}$$

In [7], Kerscher and Nagel show that if $a > d$ and $b > \|\eta\|$ then the linear solution semigroup corresponding to (16), or the abstract equation in E, $v'(t) = \hat{A}v(t)$, is uniformly exponentially stable independent of the delay function r. From Theorem 2.1 we can conclude the following.

PROPOSITION 4.1. *If in* (E)$'$, $a > d$ *and* $b > \|\eta\|$, *then the equilibrium* $\hat{f} \in E$, *where* $\hat{f}(s) = h$, $s \in [-r_0, 0]$, *is locally exponentially stable in the sense of Theorem* 2.1, *independent of the delay function r.*

Proof. For completeness, and to illustrate the use of positivity in obtaining stability information for linear semigroups, we sketch the proof from [7, Prop., p. 48] that, under the given hypotheses, the linear solution semigroup corresponding to (16) is uniformly exponentially stable independent of the delay function.

It is well known that the operator B_0 generates a positive irreducible semigroup on X which is compact for $t > 0$ (see [10, B-III, § 3]). Let M_g denote the bounded multiplication operator with the function $g \in X$. Then the same properties hold for the semigroup generated by $B_0 + M_g$ (see [10, A-II, Thm. 1.30 and B-III, Prop. 3.3]). Since the function h is strictly positive and $dh'' + a(1-h)h = 0$, this implies that zero is an eigenvalue of $B_1 := dB_0 + M_{a(1-h)}$, which admits a strictly positive eigenfunction. It follows that the spectral bound of B_1 is zero (see [10, B-III, § 3]). Equation (16), with ψ as given in (17), is equivalent to the equation

$$\dot{u}(t) = \tilde{B}u(t) + \phi_r u_t, \qquad t \geqq 0, \tag{18}$$

where $\tilde{B} := dB_0 + M_{a(1-h-bh)}$, and $\phi_r f := -ah\int_{-1}^{0} (f \circ r)(s)\, d\eta(s)$ for $f \in E$. Let $B_2 := \tilde{B} + |\phi|_0$. Since $\phi_0(x) = \phi(1 \otimes x)$ for $x \in X$, where $\phi f := -ah\int_{-1}^{0} f(s)\, d\eta(s)$, $\phi_0(x) = -M_{ah}\|\eta\|x$. This implies $|\phi|_0 = M_{ah}\|\eta\|$. Thus,

$$\begin{aligned} B_2 &= dB_0 + M_{a(1-h-bh)} + M_{ah}\|\eta\| \\ &= dB_0 + M_{a(1-h)} - M_{ah(b-\|\eta\|)} \leqq B_1, \end{aligned}$$

by the assumption that $b > \|\eta\|$. Hence $s(B_2) \leqq s(B_1) = 0$. Assume that $s(B_2) = 0$. Then there exists a strictly positive fixed function $g \in X$ for $S_2(t)$, $t \geqq 0$, the semigroup generated by B_2; i.e., $S_2(t)g = g$ for $t \geqq 0$ (see [10, B-IV, § 2]). Thus, $S_1(t)g \geqq S_2(t)g = g$, $t \geqq 0$, for the semigroup $S_1(t)$, $t \geqq 0$, generated by B_1. But $S_1(t)$ possesses a strictly positive invariant linear form (see [10, B-II, § 3 and B-III, Prop. 1.5 and Thm. 1.6]). Hence $S_1(t)g = g$ and $B_1 g = 0 = B_2 g$, which is impossible since $M_{ah(b-\|\eta\|)} \neq 0$. We therefore conclude that $s(B_2)<0$. By Proposition 3.5, the solution semigroup corresponding to (18), and hence (16), is uniformly exponentially stable independent of the delay function r. The conclusion of the proposition follows from Theorem 2.1.

We can observe from the proof of Proposition 4.1 that the operator B in (16) generates a positive irreducible semigroup that is compact for each $t>0$. Also ψ, as given by (17), is dominated by the strictly positive operator $\tilde{\psi}$ defined by $\tilde{\psi}f=a(1+b)hf(0)+ah\int_{-1}^{0} f(r(s))\,d\eta(s)$ for $f\in E$. Therefore we can apply Corollary 3.1 to obtain the estimate

$$\|\hat{T}(t)f\| \leqq M e^{\lambda_0 t}\|f\| + \circ(e^{\lambda_0 t}) \tag{19}$$

for the linear semigroup $\hat{T}(t)$ corresponding to (16). From the analysis of [7] given in the proof of Proposition 4.1, the conclusion that

$$s(B_2)=s(\tilde{B}+|\phi|_0)<0$$

allows us to conclude that

$$\lambda_0=s(\hat{A}_{\tilde{\psi}})=\omega(\hat{T}_{\tilde{\psi}}(t))<0.$$

Thus the conclusion of uniform exponential stability of $\hat{T}(t)$ is also obtained here by using the estimate (19).

ANALYTICAL AND NUMERICAL RESULTS FOR THE AGE-STRUCTURED S-I-S EPIDEMIC MODEL WITH MIXED INTER-INTRACOHORT TRANSMISSION*

M. IANNELLI[†], F. A. MILNER[‡], AND A. PUGLIESE[†]

Abstract. A model which describes the dynamics of an $S \to I \to S$ epidemic in an age-structured population at the steady state is considered. The model consists of a nonlinear and nonlocal system of equations of hyperbolic type and has already been partly analyzed by other authors. Here, a special form for the force of infection is considered. Explicitly computable threshold conditions are given, and some regularity results for the solutions are proven. An implicit finite difference method of characteristics to approximate the solutions is used. Optimal error estimates are derived and results from numerical simulations are presented. The discrete dynamical system arising from the numerical algorithm, is also analyzed, showing that it shares many properties of the continuous model.

Key words. age structure, epidemic models, numerical method, discrete dynamical system

1. Introduction.

The importance of age structure in epidemic models has been recently stressed by many authors who have considered models for many different situations. Recently, Busenberg et al. [4], [5] have provided a complete analysis of a fairly general SIS model with age structure, showing existence of a threshold for endemic states. Our aim, in this paper, is to further develop this model by considering a special form for the force of infection, and to provide a numerical algorithm to approximate the solutions.

Since the model concerns diseases which do not impart immunity, it does not have many applications. Nonetheless, our results have a theoretical interest, and can be viewed as a preliminary step towards the study and simulations of more complex models such as the SIR models, which are used in the description of most childhood diseases. A significant advantage in the SIS case studied here is that the asymptotic behaviour of the model is completely known theoretically.

Let $p(a,t)$ be the age distribution of a population that is contaminated in part by a disease which does not impart immunity or affect the death rate. Within this population we distinguish the subpopulation of infected individuals and that of susceptibles. Let $i(a,t)$ and $s(a,t)$ denote, respectively, the age distributions of infected and susceptible individuals. The fact that the disease does not impart immunity means that

$$p(a,t) = i(a,t) + s(a,t). \tag{1.1}$$

We shall assume that infected and susceptible individuals interact with each other freely and uniformly. Thus, we shall assume that i and s are solutions of the following

coupled system of equations:

$$(1.2)\qquad \begin{cases} \dfrac{\partial i}{\partial t}+\dfrac{\partial i}{\partial a}=-\mu i+\lambda s-\gamma i, & a>0,\quad t>0,\\[2mm] i(0,t)=B_i(t)=q\displaystyle\int_0^\infty \beta(a)i(a,t)da, & t\ge 0,\\[2mm] i(a,0)=i^0(a), \quad a\ge 0, \end{cases}$$

$$(1.3)\qquad \begin{cases} \dfrac{\partial s}{\partial t}+\dfrac{\partial s}{\partial a}=-\mu s-\lambda s+\gamma i, & a>0,\quad t>0,\\[2mm] s(0,t)=B_s(t)=\displaystyle\int_0^\infty \beta(a)\big[s(a,t)+(1-q)i(a,t)\big]da, & t\ge 0,\\[2mm] s(a,0)=s^0(a), \quad a\ge 0, \end{cases}$$

where $\mu=\mu(a)$ is the age-specific death-rate, $\lambda=\lambda(a,i)$ is the age-specific force of infection, $\beta=\beta(a)$ is the age-specific birth-rate, and $\gamma=\gamma(a)$ is the age-specific recovery rate. The constant q is the probability that the disease be transmitted vertically. When there is no vertical transmission $q=0$ and thus $B_i\equiv 0$, that is, all newborns are susceptible. Adding (1.2) and (1.3) we arrive at the well-known McKendrick–von Foerster equation for p:

$$(1.4)\qquad \begin{cases} \dfrac{\partial p}{\partial t}+\dfrac{\partial p}{\partial a}=-\mu p, & a>0,\quad t>0,\\[2mm] p(0,t)=B(t)=\displaystyle\int_0^\infty \beta(a)p(a,t)da, & t\ge 0,\\[2mm] p(a,0)=p^0(a), \quad a\ge 0. \end{cases}$$

On the demographic functions we make the hypothesis that there exists a maximum age $a_\dagger$ for the population so that we can restrict our attention to the age interval $[0,a_\dagger]$. We also assume

(1.5) $\beta(a)$ is a nonnegative continuous function on $[0,a_\dagger]$ and $\mu(a)$ is a nonnegative continuous function on $[0,a_\dagger$.

Under assumption (1.5), a steady state solution of (1.4) exists if and only if the *net reproduction rate* is equal to unity:

$$R=\int_0^{a_\dagger}\beta(a)e^{-\int_0^a\mu(\alpha)d\alpha}da=1.$$

In this case the steady state solutions are

$$(1.6)\qquad p(a,t)=p^\infty(a)=b^0e^{-\int_0^a\mu(\alpha)d\alpha},\qquad a\in[0,a_\dagger],$$

where b^0 is an arbitrary constant, representing the number of newborns.

Throughout the paper we shall assume that $R=1$ and that the population has reached its steady state, i.e., $p^0(a)=p^\infty(a)$. It should be noted that this restriction is a severe one in general, and one which is not satisfied by most animal species in our world. A further analysis for time dependent populations will be carried out elsewhere. However, for diseases that have a fairly rapid spread, it is not inadequate to assume the population at a steady state.

Note that in the case we consider here, since (1.6) is the known explicit solution of (1.4), we see from (1.1) that the unknown s can be eliminated in (1.2) to yield a single equation for the infective subpopulation. In this case (1.3) in unnecessary since, once we have solved (1.2) for i, we find s directly from (1.1) and (1.6).

As for the form of the force of infection, Busenberg et al. [3] considered

$$\lambda = \lambda\big(a; i(\cdot, t)\big) = \begin{cases} \kappa(a) i(a,t) & \text{(intracohort)}, \\ \kappa(a) I(t) & \text{(intercohort)}, \end{cases} \tag{1.7}$$

where $I(t) = \int_0^{a_\dagger} i(a,t)da$. They found that in either case there exists a threshold parameter T (the reproductive number of the epidemic) such that for $T \leq 1$ all nonnegative solutions of (1.2) tend to zero as t goes to infinity; for $T > 1$ there exists a unique positive stationary solution of (1.2) (an endemic state for the disease) which is locally asymptotically stable.

Recently, Busenberg et al. [4], [5] have analyzed the more general case

$$\lambda\big(a; i(\cdot,t)\big) = \kappa_0(a) i(a,t) + \int_0^{a_\dagger} \kappa(a,a') i(a',t)\, da'.$$

They proved that, under mild assumptions on $\kappa(a,a')$, the threshold phenomenon always holds. More precisely, they rewrote the equation (1.2) using as variable the fraction of infected individuals in the population

$$u(a,t) = \frac{i(a,t)}{p^\infty(a)}, \quad t \geq 0, \quad a \in [0, a_\dagger]. \tag{1.8}$$

It follows from (1.1), (1.2) (1.6), and (1.8) that u is a solution of the following initial-boundary value problem:

$$\begin{aligned} &\frac{\partial u}{\partial t} + \frac{\partial u}{\partial a} + \gamma u = \lambda(1-u), \quad t > 0, \quad a \in [0, a_\dagger], \\ &u(0,t) = \frac{q}{b^0} \int_0^{a_\dagger} \beta(a) p^\infty(a) u(a,t)\, da, \qquad t \geq 0, \\ &u(a,0) = u^0(a) = i^0(a)/p^\infty(a), \qquad a \in [0, a_\dagger]. \end{aligned} \tag{1.9}$$

Note that $0 \leq u^0(a) \leq 1$, $a \geq 0$, and (1.9) ensure that $0 \leq u(a,t) \leq 1$ for $a, t > 0$, as the model requires. The advantage of the formulation for the fraction of infected individuals (1.8) over (1.2)–(1.3) is that the death rate μ does not appear explicitly and, when there is no vertical transmission ($q = 0$), neither does the birth rate β appear in (1.9). On the other hand, (1.6) says that the death rate is given in terms of the population age-density function $p^\infty(a)$ by the relation $\mu(a) = \frac{d}{da}\log\big(b^0/p^\infty(a)\big)$, and thus we see that, both with or without vertical transmission, (1.9) really does involve μ.

In [5] (1.9) was formulated as an abstract semilinear equation in the space $E = L^1(0, a_\dagger)$. Let A and F be defined by

(1.10)
$$\begin{cases} D(A) = \left\{ f \in E \, : \, f \text{ is abs. continuous}, \, f(0) = \dfrac{q}{b^0} \displaystyle\int_0^{a_\dagger} \beta(a) p^\infty(a) f(a) \, da \right\}, \\ Af = -f' \end{cases}$$

and by

$$[F(f)](a) = \lambda(a, f(\cdot))(1 - f(a)) - \gamma(a) f(a). \tag{1.11}$$

If we define

$$C = \{ f \in E : 0 \le f(a) \le 1 \text{ a.e.} \} \tag{1.12}$$

then (1.9) can be written as the following Cauchy problem in the closed convex set C:

$$\begin{cases} \dfrac{d}{dt} u(t) = Au(t) + F(u(t)), \\ u(0) = u_0, \end{cases} \tag{1.13}$$

where $u(t) \equiv u(\cdot, t)$ and $u_0 \equiv u^0(\cdot)$.

Concerning this abstract problem, if we assume the following general conditions,

(1.14) $A \, : \, D_A \subset E \to E$ is the infinitesimal generator of a strongly continuous semigroup e^{tA} such that $e^{tA} C \subset C$.

(1.15) $F : C \to E$ is a Lipschitz continuous function, and there exists $\alpha \in (0,1)$ such that $(I + \alpha F) C \subset C$.

Then, for any $u_0 \in C$, problem (1.13) has a unique mild solution (see [12]), i.e., a solution $u \in C([0,T]; C)$ of the integral equation:

$$u(t) = e^{tA} u_0 + \int_0^t e^{(t-s)A} F(u(s)) \, ds. \tag{1.16}$$

In [4], [5] Busenberg et al. prove that A, F, and C, as defined in (1.10)–(1.12), do satisfy conditions (1.14)–(1.15) (see [4], [5] for the precise assumptions on the functions $\kappa_0(a)$ and $\kappa(a, a')$). Therefore, letting $S(t)u_0$ be the mild solution of (1.13), they prove the following asymptotic result.

THEOREM 1.1. *Let*

$$G = (I - \alpha A)^{-1} (I + \alpha F),$$

where $\alpha \in (0,1)$ is a constant chosen so that $(I + \alpha F)$ is positive. Let ρ be the spectral radius of $DG(0)$, the Gateaux derivative of G at zero with respect to C. Then, if $\rho \le 1$, for each $u_0 \in C$, $S(t)u_0 \to 0$ as $t \to \infty$. If $\rho > 1$, there exists a unique $u_\infty \in C$, $u_\infty \not\equiv 0$ such that $Gu_\infty = u_\infty$; moreover, for each nontrivial u_0, $S(t)u_0 \to u_\infty$ as $t \to \infty$.

Remark 1.2. The theorem does not provide an explicit calculation of ρ. In the next section we give, for a particular choice of $\kappa(a, a')$, a computable threshold condition equivalent to $\rho \le 1$.

2. The inter-intracohort case. Here, we shall restrict ourselves to a combination of the inter- and intracohort cases (1.7). Specifically, we assume

$$\lambda\big(a, i(\cdot,t)\big) = c^1(a)i(a,t) + c^2(a)I(t), \tag{2.1}$$

where

$$I(t) = \int_0^{a_\dagger} i(a,t)\,da$$

and

(2.2) $c^1(a)$ and $c^2(a)$ are nonnegative, continuous functions on $[0, a_\dagger]$.

Busenberg et al. [3] have established an explicit threshold condition for both the intracohort case and the intercohort case without vertical transmission. Here we compute the threshold for the inter-intracohort case with vertical transmission. The result is somewhat analogous to the threshold established in [2] and [7] for epidemics in a heterogeneous but not age-structured population.

THEOREM 2.1. *Let $c^2 \not\equiv 0$. The solution $u \equiv 0$ of* (1.9) *is globally stable if and only if*

$$T_1 = \frac{q}{b^0}\int_0^{a_\dagger} \beta(a)p^\infty(a)\exp\left\{\int_0^a [c^1(\sigma)p^\infty(\sigma) - \gamma(\sigma)]\,d\sigma\right\} da < 1 \tag{2.3}$$

and

$$\begin{aligned} T_2 = {} & \frac{q\int_0^{a_\dagger}\beta(a)p^\infty(a)\int_0^a \exp\{\int_\sigma^a [c^1(\tau)p^\infty(\tau) - \gamma(\tau)]\,d\tau\}c^2(\sigma)\,d\sigma\,da}{b^0 - q\int_0^{a_\dagger}\beta(a)p^\infty(a)\exp\{\int_0^a[c^1(\sigma)p^\infty(\sigma) - \gamma(\sigma)]\,d\sigma\}\,da} \\ & \times \int_0^{a_\dagger} p^\infty(a)\exp\left\{\int_0^a [c^1(\sigma)p^\infty(\sigma) - \gamma(\sigma)]\,d\sigma\right\} da \\ & + \int_0^{a_\dagger} p^\infty(a)\int_0^a \exp\left\{\int_\sigma^a [c^1(\tau)p^\infty(\tau) - \gamma(\tau)]\,d\tau\right\} c^2(\sigma)\,d\sigma\,da \le 1. \end{aligned} \tag{2.4}$$

If the previous condition does not hold, then there exists a unique positive stationary solution of (1.9), *which attracts all nontrivial initial data.*

The case $c^2 \equiv 0$ was studied in [3]. In that case $T_2 = 0$, and the condition for the global stability of $u \equiv 0$ becomes $T_1 \le 1$. When $c^1 \equiv 0$, (2.3) is automatically satisfied as long as $\gamma \not\equiv 0$ or $q < 1$; if $c^1 \equiv 0$ and $q = 0$, (2.4) reduces to the condition given in [3].

Note that the denominator of the first addendum in T_2 is $b^0(1 - T_1)$. Therefore, when $T_1 \ge 1$, T_2 is negative or undefined. In this case we consider T_2 to be undefined, since the condition $T_1 \ge 1$ is enough for establishing the existence of a stationary positive solution.

Proof. Because of Theorem 1.1, it is enough to study ρ, the spectral radius of $DG(0)$. Since $DG(0)$ is linear, completely continuous, and leaves invariant the cone of nonnegative functions, by Krein–Rutman's theorem, there exists an eigenvector $v \ge 0$ with eigenvalue ρ. By definition, v solves the problem

$$\left\{\begin{aligned} & \alpha\rho\frac{d}{da}v(a) = [\alpha\,(c^1(a)p^\infty(a) - \gamma(a)) + (1-\rho)]\,v(a) + \alpha c^2(a)\int_0^{a_\dagger} p^\infty(\tau)v(\tau)\,d\tau, \\ & v(0) = \frac{q}{b^0}\int_0^{a_\dagger} \beta(\tau)p^\infty(\tau)v(\tau)\,d\tau. \end{aligned}\right. \tag{2.5}$$

Let $\eta = \int_0^{a_\dagger} p^\infty(\tau)v(\tau)\,d\tau$. Then (2.5) can be solved explicitly. If we define

$$P(x,y,z) = \exp\left\{\int_y^x \frac{c^1(\tau)p^\infty(\tau)-\gamma(\tau)}{z}\,d\tau + \frac{1}{\alpha}\left(\frac{1}{z}-1\right)(x-y)\right\} \tag{2.6}$$

for $x \geq y \geq 0$ and $z > 0$, then, by integrating the first equation of (2.5), we obtain

$$v(a) = v(0)P(a,0,\rho) + \eta\int_0^a P(a,\sigma,\rho)\frac{c^2(\sigma)}{\rho}\,d\sigma. \tag{2.7}$$

The second equation of (2.5) then implies

$$v(0) = \frac{q}{b^0}v(0)Z(\rho) + \frac{q}{b^0}\eta W(\rho), \tag{2.8}$$

where we set, for $z > 0$,

$$W(z) = \int_0^{a_\dagger} \beta(\tau)p^\infty(\tau)\int_0^\tau P(\tau,\sigma,z)\frac{c^2(\sigma)}{z}\,d\sigma\,d\tau,$$
$$Z(z) = \int_0^{a_\dagger} \beta(\tau)p^\infty(\tau)P(\tau,0,z)\,d\tau.$$

Concerning these functions, we note that, if α is small enough (as it was to ensure the positivity of $I+\alpha F$), we can have $\partial/\partial z P(a,\sigma,z) < 0$ for all $a, z > 0$, $0 \leq \sigma < a$; therefore,

$$\begin{cases} W(z) \quad \text{and} \quad Z(z) \quad \text{are strictly decreasing in } z, \\ \lim_{z\to 0+} Z(z) = +\infty. \end{cases} \tag{2.9}$$

In the following we assume that α is chosen so that (2.9) holds. Since v must be nonnegative, (2.8) implies that ρ must be such that

$$\frac{q}{b^0}Z(\rho) < 1. \tag{2.10}$$

If $q > 0$, let z^* be the solution of $qZ(z^*) = b^0$, which is unique because of (2.9). If $q = 0$ we let $z^* = 0$. Because of (2.10), we have that

$$\rho > z^*.$$

Using (2.8), we finally obtain

$$v(a) = \eta\left[\frac{qW(\rho)}{b^0 - qZ(\rho)}P(a,0,\rho) + \int_0^a P(a,\sigma,\rho)\frac{c^2(\sigma)}{\rho}\,d\sigma\right], \tag{2.11}$$

and, by multiplying both sides of (2.11) by $p^\infty(a)$, integrating from 0 to $a_\dagger$, and using the definition of η, we get:

$$H_\alpha(\rho) = 1, \tag{2.12}$$

where we have defined, for $z > z^*$,

$$H_\alpha(z) = \frac{qW(z)}{b^0 - qZ(z)} \int_0^{a_\dagger} p^\infty(a)P(a,0,z)\,da + \int_0^{a_\dagger} p^\infty(a) \int_0^{a} P(a,\sigma,z)\frac{c^2(\sigma)}{z}\,d\sigma.$$

Therefore, ρ can be found as a solution in $(z^*, +\infty)$ of the scalar equation (2.12). As for the subscript α, we remind that $P(a,\sigma,\rho)$, and therefore ρ, depend on α. It is clear that $H_\alpha(z)$ is a decreasing function of z on $(z^*, +\infty)$, that $\lim_{z\to(z^*)^+} H_\alpha(z) = +\infty$ and $\lim_{z\to+\infty} H_\alpha(z) = 0$. Therefore, we obtain from (2.9), (2.10) and (2.12),

$$\rho \leq 1 \quad \text{if and only if} \quad \frac{q}{b^0}Z(1) < 1 \quad \text{and} \quad H_\alpha(1) \leq 1.$$

This is just the thesis. □

Remark 2.2. Note that, although ρ in general will depend on α, $Z(1)$ and $H_\alpha(1)$ do not depend on it; that is, the threshold condition is, as expected, independent of α.

3. Regularity of solutions. Here we prove some regularity results that we will use in the analysis of the numerical algorithm. A standard assumption that guarantees regularity of the solutions of (1.16) is $F \in C^1(E,E)$. Unfortunately, this assumption does not hold in this case. The restriction of F to $C \cap L^\infty$ is indeed in $C^1(L^\infty, L^\infty)$, but A is not the generator of a C^0-semigroup in L^∞. Our proof of the regularity rests upon another regularity theorem concerning equation (1.16).

THEOREM 3.1. *Let* (1.14) *and* (1.15) *hold. Assume that there exists a space* Y *densely embedded in* E *such that:*

(3.1) $C \subset Y$, *C is closed in* Y.

(3.2) $(I - \epsilon A)^{-1} \in L(Y)$ $\forall\, \epsilon > 0$ *small enough.*

(3.3) $F(C) \subset Y$ *and* F *can be extended to a mapping* $F : Y \to Y$ *such that* $F \in C^1(Y,Y)$.

(3.4) $\forall\, x \in Y$ $DF[x] : Y \to Y$ *can be extended to a linear bounded mapping* $DF[x] \in L(E)$.

(3.5) *The mapping* $x \to DF[x] : C \subset E \to L(E)$ *is strongly continuous in* E. *There exists* $M > 0$ *such that*

$$||DF[x]||_{L(E)} \leq M \quad \forall x \in C.$$

Then, if $u_0 \in D_A \cap C$ *and* $Au_0 \in Y$ *we have:*

$$u(\cdot) \in C^1(0,T;E) \cap C(0,T;D_A),$$
$$u'(t) = Au(t) + F(u(t))$$

Let us first point out the following.

LEMMA 3.2. *Let* (1.14) *hold. Let*

$$A_n = A\left(I - \frac{1}{n}A\right)^{-1} = -nI + n\left(I - \frac{1}{n}A\right)^{-1} \tag{3.6}$$

be the Yosida approximants of A. *Then, for* n *large enough,*

$$e^{tA_n}C \subset C\,.$$

Proof. We first note that, if A is the generator of a C^0-semigroup, the condition

$$e^{tA}C \subset C \quad \text{for all } t > 0$$

is equivalent to the following:

$$(I - \alpha A)^{-1}C \subset C \quad \text{for } \alpha > 0 \text{ small enough.}$$

Take in fact $x \in C$, and recall that

$$(I - \alpha A)^{-1}x = \frac{1}{\alpha}\int_0^\infty e^{-\frac{1}{\alpha}t}e^{tA}x\,dt\,.$$

Since $\frac{1}{\alpha}\int_0^\infty e^{-\frac{1}{\alpha}t}\,dt = 1$, if $e^{tA}x \in C$ for all $t > 0$, $(I - \alpha A)^{-1}x \in C$ also.

Conversely, we have

$$e^{tA}x = \lim_{n\to\infty}(I - \frac{t}{n}A)^{-n}x \quad \forall\, x \in E.$$

Thus if $(I - \alpha A)^{-1}C \subset C$, then also $e^{tA}C \subset C$.

Using this observation, we consider $(I - \alpha A_n)^{-1}x$ for $x \in C$. We have the identity:

$$\begin{aligned}(I - \alpha A_n)^{-1}x &= \frac{(n-A)}{n}\left(I - \frac{\alpha n + 1}{n}A\right)^{-1} x\\ &= \frac{1}{\alpha n + 1}x + \left(1 - \frac{1}{\alpha n + 1}\right)\left(I - \frac{\alpha n + 1}{n}A\right)^{-1} x.\end{aligned}$$

Thus $(I - \alpha A_n)^{-1}x$, being the convex combination of two elements of C (for n large enough), belongs to C. □

Proof of Theorem 3.1. Consider the problem

$$u_n(t) = e^{tA_n}u_0 + \int_0^t e^{(t-s)A_n}F(u_n(s))\,ds. \tag{3.7}$$

Since $A_n \in L(E)$, (3.7) has a solution $u_n(t) \in C^1(0,T;E)$; moreover, $u_n(t) \in C \quad \forall\, t \in [0,T]$, and

$$u_n \to u \quad \text{in } C(0,T;E).$$

Now, by (3.2), A_n can be restricted to a bounded linear operator in $L(Y)$, so that, by (3.1)–(3.3), problem (3.7) can be viewed as a problem in Y. Since $F \in C^1(Y,Y)$, we have

$$u_n(\cdot) \in C^1(0,T;Y).$$

Thus, setting $v_n(t) = u_n'(t)$, (3.7) yields

$$v_n(t) = e^{tA_n}(A_n u_0 + F(u_0)) + \int_0^t e^{(t-s)A_n}DF[u_n(s)]v_n(s)\,ds.$$

Now consider the limit problem in E (see (3.4)):

$$v(t) = e^{tA}(Au_0 + F(u_0)) + \int_0^t e^{(t-s)A}DF[u(s)]v(s)\,ds\,; \tag{3.8}$$

(3.8) has a unique solution $v \in C(0,T;E)$ that can be found, thanks to (3.5), as the limit in $C(0,T;E)$ of the iterates w_n defined by:

$$(3.9) \qquad \begin{cases} w^0(t) = e^{At}(Au_0 + F(u_0)), \\ w^{n+1}(t) = e^{At}(Au_0 + F(u_0)) + \displaystyle\int_0^t e^{A(t-s)}F'(u(s))w^n(s)\,ds. \end{cases}$$

It is easy to show, using (3.4)–(3.5), that

$$v_n \rightarrow v \quad \text{in } C(0,T;E),$$

proving that $u \in C^1(0,T;E)$ and $u'(t) = v(t)$.

Finally, differentiating (3.7) we get

$$u_n'(t) = A_n u_n(t) + F(u_n(t))$$

so that

$$A_n u_n(t) \rightarrow u'(t) - F(u(t)) \quad \text{in } C(0,T;E).$$

Using (3.6), since

$$\left(I - \frac{1}{n}A\right)^{-1} u_n(t) \rightarrow u(t) \quad \text{in } C(0,T;E)$$

and A is a closed operator, this implies

$$u \in C(0,T;D_A); \qquad u'(t) = Au(t) + F(u(t)). \qquad \square$$

We shall make the following assumption on the parameters:

$$(3.10) \qquad \begin{aligned} &\beta(a), \gamma(a), c^0(a), c^1(a), \text{ and } c^2(a) \text{ are Lipschitz functions on } [0,a_\dagger]; \\ &\mu(a)\exp\left\{-\int_0^a \mu(\sigma)\,d\sigma\right\} \text{ is bounded on } [0,a_\dagger). \end{aligned}$$

The first regularity result is the following.

PROPOSITION 3.3. *Let* (1.5), (2.2), *and* (3.10) *hold. Let* u_0 *be a Lipschitz function on* $[0,a_\dagger]$ *such that*

$$u_0(0) = \frac{q}{b^0}\int_0^{a_\dagger} \beta(a)p^\infty(a)u_0(a)\,da.$$

Then, for any $T > 0$,

$$(3.11) \qquad u(t) \in C^1([0,T];L^1(0,a_\dagger)) \cap C([0,T];D(A)),$$

$$(3.12) \qquad u'(t) \in L^\infty(0,a_\dagger), \quad a.e.\ t \in [0,T],$$

and there exists $K > 0$ *such that*

$$(3.13) \qquad \|u'(t)\|_\infty \le K, \quad a.e.\ t \in [0,T].$$

Proof. Equation (3.11) follows from Theorem 3.1. In fact, our assumptions imply that (3.1)–(3.5) are fulfilled with $Y = L^\infty(0, a_\dagger)$. In particular, (3.2) follows easily from the following formula for the operator $(I - \epsilon A)^{-1}$ (see (3.11) in [5]):

$$((I - \epsilon A)^{-1} f)(a) = q \frac{\int_0^{a_\dagger} \beta(a) p^\infty(a) \int_0^a e^{-\frac{1}{\epsilon}(a-s)} f(s)\, ds\, da}{\epsilon \left(b^0 - q \int_0^{a_\dagger} \beta(a) p^\infty(a) e^{-\frac{1}{\epsilon} a}\, da \right)} + \frac{1}{\epsilon} \int_0^a e^{-\frac{1}{\epsilon}(a-s)} f(s)\, ds.$$

To obtain (3.5), start from the expression

$$(DF[f]g)(a) = \lambda(a, g(\cdot))(1 - f(a)) - \lambda(a, f(\cdot)) g(a) - \gamma(a) g(a).$$

We want to prove that, if $f_n \in C$, $f_n \to f$ in $L^1(0, a_\dagger)$, then, for each $g \in L^1(0, a_\dagger)$, we have

$$DF[f_n]g \to DF[f]g \quad \text{in } L^1(0, a_\dagger). \tag{3.14}$$

To obtain (3.14) we compute

$$\begin{aligned} &(DF[f_n]g - DF[f]g)(a) \\ &\quad = 2c^1(a) p^\infty(a) g(a) (f(a) - f_n(a)) \\ &\quad + \int_0^{a_\dagger} c^2(\sigma) p^\infty(\sigma) g(\sigma)\, d\sigma (f(a) - f_n(a)) \\ &\quad + \int_0^{a_\dagger} c^2(\sigma) p^\infty(\sigma) (f(\sigma) - f_n(\sigma))\, d\sigma\, g(a). \end{aligned} \tag{3.15}$$

The L^1 norm of the last two terms is bounded by

$$b^0 ||c^2||_\infty ||g||_1 ||f - f_n||_1$$

As for the other term in the right-hand side of (3.15), suppose that it does not converge to zero in L^1. Then there would exist a constant $c > 0$ and a subsequence $\{f_{n_k}\}$ such that

$$\int_0^{a_\dagger} c^1(a) p^\infty(a) |g(a)| |f(a) - f_{n_k}(a)|\, da \to c$$

as k goes to ∞. Since $f_{n_k} - f$ converges to zero in L^1, there exists a subsequence, still denoted by the same name, such that $f_{n_k} - f$ converges to zero almost everywhere Then we have

$$c^1 p^\infty |g| |f - f_{n_k}| \to 0 \quad \text{a.e.}$$

and

$$c^1 p^\infty |g| |f - f_{n_k}| \le 2b^0 ||c^1||_\infty |g|$$

since f and f_n are in C. Lebesgue's theorem then implies that $c^1 p^\infty |g| |f - f_{n_k}|$ converges to 0 in L^1.

Next, $v(t) = u'(t)$ satisfies the integral equation (3.8) and can be obtained as the limit in $C(0, T; L^1(0, a_\dagger))$ of the iterates w^n defined in (3.9). We want to prove that these iterates satisfy the relations

$$\begin{cases} w^n(t) \in L^\infty(0, a_\dagger), & t \in [0, T], \\ ||w^n(t)||_\infty \le M e^{\omega t}, & \text{a.e. } t \in [0, T], \end{cases} \tag{3.16}$$

where M and ω are suitable positive constants depending on A, F, u_0, and G.

Once (3.16) is proven, (3.12) and (3.13) follow because a closed ball of $L^\infty(0, a_\dagger)$ is closed in $L^1(0, a_\dagger)$. In order to prove (3.16) we need two lemmas.

LEMMA 3.4. *If* $u_0 \in L^\infty(0,a_\dagger)$, *then* $e^{At}u_0 \in L^\infty(0,a_\dagger)$ *and*

$$\|e^{At}u_0\|_\infty \le e^{\bar\beta t}\|u_0\|_\infty,$$

where $\bar\beta = \max_{a\in[0,a_\dagger]}\{\beta(a)\}$.

Proof. The explicit representation of e^{At} is

$$(e^{At}u_0)(a) = \begin{cases} u_0(a-t), & a>t, \\ B(t-a)[u_0], & a<t, \end{cases}$$

where $B(t)[u_0]$ is the solution of the integral equation

$$B(t) = J(t) + \int_0^t K(t-s)B(s)\,ds,$$

with

$$J(t) = \frac{q}{b^0}\int_t^{a_\dagger} \beta(a)p^\infty(a)u_0(a-t)\,da,$$

and

$$K(t) = \frac{q}{b^0}\beta(t)p^\infty(t).$$

Since $|J(t)| \le q\|u_0\|_\infty$ and $|K(t)| \le \bar\beta$, Gronwall's lemma yields

$$|B(t)[u_0]| \le qe^{\bar\beta t}\|u_0\|_\infty.$$

Finally, as $\sup_{a>t}\{|u_0(a-t)|\} \le \|u_0\|_\infty$, the lemma follows. □

LEMMA 3.5. *Let S be any measure space and let $f \in C([a,b];L^1(S))$ be such that*

$$\begin{cases} f(t) \in L^\infty(S), & t\in[a,b], \\ \|f(t)\|_\infty \le g(t), & a.e.\ t\in[a,b], \end{cases}$$

where $g(t)$ is a continuous real function in $[a,b]$. Then,

$$\int_a^b f(t)\,dt \in L^\infty(S), \quad and \quad \left\|\int_a^b f(t)\,dt\right\|_\infty \le \int_a^b g(t)\,dt.$$

Proof. Since $f(t) \in L^1([a,b];L^1(S))$, there exists $\tilde f \in L^1([a,b]\times S)$ such that $f(t) \equiv \tilde f(t,\cdot)$; moreover, $\int_a^b f(t)\,dt \equiv \int_a^b \tilde f(t,\cdot)\,dt$, and the thesis follows easily. □

Now we are ready to prove (3.16). Observing that, by our assumptions, $Au_0 + F(u_0)$ lies in $L^\infty(0,a_\dagger)$, we set

$$M = e^{\bar\beta T}\|Au_0 + F(u_0)\|_\infty, \qquad \omega = e^{\bar\beta T}\sup_{t\in[0,T]}\|F'(u(t))\|_{L(Y)},$$

where C is the convex set defined before. Now (3.16) is clearly true for $n=0$; assuming that it holds for n, Lemmas 3.4 and 3.5 yield

$$\|w^{n+1}(t)\|_\infty \le M + \int_0^t \omega Me^{\omega s}\,ds = Me^{\omega t},$$

and (3.16) is proven. □

As far as the solution of (1.9) is concerned, since $u(t) \equiv u(\cdot,t)$, $u'(t) \equiv u_t(\cdot,t)$, $Au(t) \equiv -u_a(\cdot,t)$, the previous result states that

$$u_t \in L^\infty([0,a_\dagger]\times[0,T]).$$

Consequently, since $u_a = -u_t + \gamma u + \lambda(1-u)$, we also have

$$u_a \in L^\infty\big([0,a_\dagger]\times[0,T]\big).$$

This leads to the following result.

PROPOSITION 3.6. *Under the same assumptions as in Proposition* 3.3, $u(a,t)$ *has bounded derivatives through second order in the characteristic direction* $\tau = \frac{1}{\sqrt{2}}(1,1)$.

Proof. For a and t fixed, set

$$g(s) = u(a+s, t+s).$$

This function has a distributional derivative satisfying

$$g'(s) = A(s)g^2(s) + B(s)g(s) + C(s),$$

where

$$\begin{aligned}A(s) &= -c^1(a+s),\\ B(s) &= c^1(a+s) - c^0(a+s) - c^2(a+s)I(t+s) - \gamma(a+s),\\ C(s) &= c^0(a+s) + c^2(a+s)I(t+s).\end{aligned}$$

Since A, B and C are differentiable, then $g(s)$ is two times differentiable; moreover, since $A(0)$, $B(0)$, $C(0)$, $A'(0)$, $B'(0)$, and $C'(0)$ belong to $L^\infty([0,a_\dagger] \times [0,T])$, so do $g'(0) = \partial u/\partial\tau$ and $g''(0) = \partial^2 u/\partial\tau^2$, and the proof is complete. □

4. A numerical algorithm. We shall now describe an algorithm for the approximation of the solution of (1.9), based on a first-order implicit finite difference method along the characteristics. Higher-order methods that require more regularity of the solution (hence, more compatibility conditions on the data: see [11]) need a more sophisticated analysis, which we intend to carry out in the future. The scheme analyzed here has a special interest because it preserves, for any time step of the discretization, many properties of the continuous system, as discussed in §5.

Let $\Delta t > 0$ be the age-time discretization parameter. We shall find an approximation U_j^n of $u(j\Delta t, n\Delta t)$, $n \geq 0$, $0 \leq j \leq A_\dagger = \left[\frac{a_\dagger}{\Delta t} + 0.5\right]$ by the finite difference method of characteristics as follows:

$$\begin{aligned}&\frac{U_j^n - U_{j-1}^{n-1}}{\Delta t} + \gamma_j U_j^n = \Lambda_{j-1}^{n-1}(1-U_j^n), \qquad n \geq 1,\ 1 \leq j \leq A_\dagger,\\ &U_0^n = \frac{q}{B_0}\sum_{j=1}^{A_\dagger} \beta_j p_j^\infty U_j^{n-1}\Delta t, \qquad n > 0,\\ &U_j^0 = u_j^0, \qquad 0 \leq j \leq A_\dagger,\end{aligned} \tag{4.1}$$

where we have used the notation $f_j = f(j\Delta t)$ for any function $f = f(a)$, and where

$$\Lambda_j^n = c_j^0 + c_j^1 p_j^\infty U_j^n + c_j^2 \sum_{k=1}^{A_\dagger} p_k^\infty U_k^n \Delta t \tag{4.2}$$

is the discrete transmission rate, and

$$B_0 = \sum_{k=1}^{A_\dagger} \beta_k p_k^\infty \Delta t \tag{4.3}$$

is the discrete analogue of the newborn count

$$b^0 = p^\infty(0) = \int_0^{a_\dagger} \beta(a) p^\infty(a) da.$$

This algorithm is an adaptation of the one used in [8].

We can prove that, without any restrictions on Δt, if the initial datum is between zero and one, the numerical solution (just as the real solution) stays between zero and one. Since u represents a ratio, this is a necessary constraint for the model to make sense.

PROPOSITION 4.1. *If $0 \le u_0(a) \le 1$, then, there exists $K > 0$ such that, for all $\Delta t > 0$ and all $n \ge 0$, $0 \le j \le A_\dagger$, we have*

$$0 \le U_j^n \le 1, \tag{4.4}$$

and

$$0 \le \Lambda_j^n \le K. \tag{4.5}$$

Proof. Note that (4.1) defines U_j^n explicitly, for $j \ge 1$, as

$$U_j^n = \left(\Lambda_{j-1}^{n-1} \Delta t + U_{j-1}^{n-1}\right) / \left[1 + \Delta t(\gamma_j + \Lambda_{j-1}^{n-1})\right]. \tag{4.6}$$

Hence, $0 \le U_{j-1}^{n-1} \le 1$ implies that $0 \le U_j^n \le 1$ for $j \ge 1$ because $\gamma \ge 0$. Moreover, $0 \le U_j^{n-1} \le 1$ for all $j \ge 1$, by (4.3), implies that $0 \le U_0^n \le 1$. This proves (4.4) inductively. Finally, (4.5) follows immediately, with

$$K = \max_{0 \le k \le 2;\, j \ge 0} \{c_j^k\} \left[2 + \int_0^\infty p^\infty(a)\, da\right],$$

since $p^\infty(a) = b^0 \exp\{-\int_0^a \mu(\sigma)\, d\sigma\}$ is a nonincreasing function. □

Using the regularity results obtained in §3, we can prove that the discrete function U defined by (4.1)–(4.3) converges uniformly to the solution u of (1.8) at a first-order rate.

THEOREM 4.2. *Let* (1.5), (2.2), *and* (3.1) *hold. Then, for each $T > 0$, there exists a constant K, independent of Δt, such that, for $u_j^n = u(j\Delta t, n\Delta t)$, $0 \le j \le A_\dagger$, $0 \le n \le N = \left[\frac{T}{\Delta t}\right]$,*

$$|u_j^n - U_j^n| \le K\Delta t.$$

Proof. Note that Taylor's theorem implies that

$$\begin{aligned} \frac{u_j^n - u_{j-1}^{n-1}}{\Delta t} &= \sqrt{2}\left(\frac{\partial u}{\partial \tau}\right)_j^n + O\left(\Delta t \left\|\frac{\partial^2 u}{\partial \tau^2}\right\|_{L^\infty\left([0,a_\dagger]\times[0,T]\right)}\right) \\ &= \frac{\partial u}{\partial t}(j\Delta t, n\Delta t) + \frac{\partial u}{\partial a}(j\Delta t, n\Delta t) + O(\Delta t). \end{aligned} \tag{4.7}$$

If we set

$$\zeta_j^n = u_j^n - U_j^n, \qquad 0 \le j \le A_\dagger,\ 0 \le n, \tag{4.8}$$

we have, from (4.6)–(4.8), the error equations

$$\frac{\zeta_j^n - \zeta_{j-1}^{n-1}}{\Delta t} + \gamma_j \zeta_j^n = -\Lambda_{j-1}^{n-1}\zeta_j^n + \left(\lambda_j^n - \Lambda_{j-1}^{n-1}\right)(1 - u_j^n) + O(\Delta t), \qquad 1 \le j \le A_\dagger, 1 \le n, \tag{4.9}$$

$$\begin{aligned} \zeta_0^n &= \frac{q}{b_0}\left[\int_0^{a_\dagger} \beta(a)p^\infty(a)u(a,n\Delta t)\,da - \sum_{j=1}^{A_\dagger} \beta_j p_j^\infty U_j^{n-1}\Delta t\right] \\ &\quad + \frac{q(B_0 - b_0)}{b_0 B_0}\sum_{j=1}^{A_\dagger} \beta_j p_j^\infty U_j^{n-1}\Delta t, \qquad n > 0. \end{aligned} \tag{4.10}$$

It is also clear that, if f is a Lipschitz function,

$$\left|\int_0^{a_\dagger} f(a)\,da - \sum_{j=1}^{A_\dagger} f_j\,\Delta t\right| \le M\Delta t, \tag{4.11}$$

where M is the Lipschitz constant of f. Using (4.11) in the integral in (4.10) and in the definition of b_0, we obtain

$$\begin{aligned} \zeta_0^n &= \frac{q}{b_0}\sum_{j=1}^{A_\dagger} \beta_j p_j^\infty \zeta_j^{n-1}\Delta t + \sum_{j=1}^{A_\dagger} \beta_j p_j^\infty \left[u_j^n - u_j^{n-1}\right]\Delta t + O(\Delta t) \\ &= \frac{q}{b_0}\sum_{j=1}^{A_\dagger} \beta_j p_j^\infty \zeta_j^{n-1}\Delta t + O(\Delta t) \\ &\le C\left(\|\zeta^{n-1}\|_{l^1} + \Delta t\right), \end{aligned} \tag{4.12}$$

where $\|\zeta^n\|_{l^1} = \sum_{j=0}^{A_\dagger} |\zeta_j^n|\Delta t$, and the constant C depends on the Lipschitz constants of β and p^∞ and on the bounds for $|u_t|$ and $|u_a|$. Using (4.11) again, we see that

$$|\lambda_j^n - \Lambda_{j-1}^{n-1}| \le \tilde{C}\left(\|\zeta^{n-1}\|_{l^1} + |\zeta_{j-1}^{n-1}| + \Delta t\right), \tag{4.13}$$

where $\tilde{C}$ depends on the Lipschitz constants of c^0, c^1, c^2, and p^∞ and on the bounds for $|u_t|$ and $|u_a|$.

Using (4.9) and (4.13), we have that, modifying perhaps the constant $\tilde{C}$,

$$\begin{aligned} |\zeta_j^n| &\le |\zeta_j^n|\left(1 + (\gamma_j + \Lambda_{j-1}^{n-1})\Delta t\right) \\ &\le (1 + \tilde{C}\Delta t)|\zeta_{j-1}^{n-1}| + \tilde{C}\Delta t\|\zeta^{n-1}\|_{l^1} + \tilde{C}(\Delta t)^2, \quad 1 \le j \le A_\dagger, \quad 1 \le n. \end{aligned} \tag{4.14}$$

Multiplying (4.14) by Δt and summing on j, and adding to the resulting relation (4.12) multiplied by Δt, we obtain

$$\|\zeta^n\|_{l^1} \le (1 + K\Delta t)\|\zeta^{n-1}\|_{l^1} + K(\Delta t)^2, \tag{4.15}$$

for some constant $K > 0$. Gronwall's lemma applied to (4.15), together with $\zeta_j^0 = 0$, then imply that

$$\|\zeta^n\|_{l^1} \leq (e^{nK\Delta t} - 1)\,\Delta t,$$

and, therefore, for any $T > 0$, there exists $\tilde{K}$ such that

$$\|\zeta^n\|_{l^1} \leq \tilde{K}\Delta t \tag{4.16}$$

for all $n \leq T/\Delta t$.

Using (4.16) in (4.12), we directly obtain

$$|\zeta_0^n| \leq \tilde{K}\Delta t. \tag{4.17}$$

Substituting (4.16) in (4.14) we have

$$|\zeta_j^n| \leq (1 + \tilde{K}\Delta t)|\zeta_{j-1}^{n-1}| + \tilde{K}(\Delta t)^2, \qquad 1 \leq j \leq A_\dagger\ , 1 \leq n. \tag{4.18}$$

Applying Gronwall's lemma to (4.18), we have

$$|\zeta_j^n| \leq \begin{cases} e^{jc\Delta t}|\zeta_0^{n-j}| + (e^{jc\Delta t} - 1)\,\Delta t, & n \geq j, \\ e^{nc\Delta t}|\zeta_{j-n}^0| + (e^{nc\Delta t} - 1)\,\Delta t, & n \leq j. \end{cases} \tag{4.19}$$

Using (4.17) and $\zeta_j^0 = 0$ in (4.19), we have the thesis. □

5. The discrete dynamical system. Here we want to point out that the algorithm illustrated in the previous section itself defines a (discrete) dynamical system that inherits the behaviour of the originating continuous flow.

To this purpose, and in view of (4.1) we consider the mapping

$$F : \mathbf{R}^{A_\dagger + 1} \to \mathbf{R}^{A_\dagger + 1},$$

defined (denoting $x \in \mathbf{R}^{A_\dagger+1}$ as $x \equiv (x_0, x_1, \cdots, x_{A_\dagger})$) as follows

$$\begin{cases} F_0(x) = \dfrac{q}{B_0} \displaystyle\sum_{i=1}^{A_\dagger} \beta_i p_i^\infty x_i \Delta t \\ F_i(x) = \dfrac{x_{i-1} + \Lambda_{i-1}(x)\Delta t}{1 + (\gamma_i + \Lambda_{i-1}(x))\Delta t} \qquad i = 1, \ldots A_\dagger, \end{cases} \tag{5.1}$$

where B_0 is defined in (4.3) and

$$\Lambda_i(x) = c_i^1 p_i^\infty x_i + c_i^2 \sum_{k=1}^{A_\dagger} p_k^\infty x_k \Delta t. \tag{5.2}$$

We shall assume

(H) $q > 0$, and there exists $i = 0 \ldots A_\dagger - 1$ such that $c_i^1 + c_i^2 > 0$.

Also recall that β_i cannot vanish for all index $i > 0$ because the net reproduction rate is equal to 1.

We restrict F to the compact set

$$C = \left\{ x \in \mathbf{R}^{A_\dagger+1} : 0 \leq x_i \leq 1, \quad i = 0, 1, \dots A_\dagger \right\}.$$

In fact, C is left invariant by F; is essentially proven in Proposition 4.1.

We now enumerate several properties of F to be used later in the section.

First note that F is continuous in C and hence also bounded. Moreover, $F(0) = 0$. Next note that F is monotone nondecreasing, with respect to the usual componentwise partial ordering of $\mathbf{R}^{A_\dagger+1}$. Indeed, for $0 \leq j \leq A_\dagger$ and $0 < i \leq A_\dagger$ we have:

$$\frac{\partial}{\partial x_j} F_0(x) = (1 - \delta_{0,j}) \frac{q}{B_0} \beta_j p_j^\infty \Delta t,$$

$$\frac{\partial}{\partial x_j} F_i(x)$$

$$= \frac{\delta_{i-1,j}}{1 + (\gamma_i + \Lambda_{i-1}(x))\Delta t} + \frac{(1 + \Delta t \gamma_i - x_{i-1}) \left[c_{i-1}^1 \delta_{i-1,j} + c_{i-1}^2 (1 - \delta_{0,j}) p_j^\infty \Delta t \right] \Delta t}{\left[1 + (\gamma_i + \Lambda_{i-1}(x))\Delta t \right]^2},$$

both of which are nonnegative for $x \in C$.

We finally consider the Jacobian matrix $F'(0) \equiv (\alpha_{ij})$:

$$\alpha_{0,j} = (1 - \delta_{0,j}) \frac{q}{B_0} \beta_j p_j^\infty \Delta t, \tag{5.3}$$

$$\alpha_{i,j} = \frac{(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t) \delta_{i-1,j} + p_j^\infty (1 - \delta_{0,j}) c_{i-1}^2 (\Delta t)^2}{(1 + \gamma_i \Delta t)}, \tag{5.4}$$

$(1 \leq i \leq A_\dagger,\ 0 \leq j \leq A_\dagger)$ and discuss its irreducibility.

For this purpose, we will write $P_i \longrightarrow P_j$ if $\alpha_{i,j} > 0$; then, a path from i to j is a sequence of indices $(i_0 = i, i_1, \cdots, i_n = j)$ such that $P_{i_k} \longrightarrow P_{i_{k+1}}$ for all $k = 0 \cdots n-1$. We remind the reader that the irreducibility of $F'(0)$ can be stated as the existence of a path from i to j for all couples (i,j). Now note that for $i = 1 \cdots A_\dagger$ we have $\alpha_{i,i-1} > 0$. Consequently, the connectivity graph of the matrix α contains at least the path

$$P_{A_\dagger} \longrightarrow \cdots \longrightarrow P_1 \longrightarrow P_0. \tag{5.5}$$

It follows that, in order to have $F'(0)$ irreducible, it is necessary and sufficient that there exists a path from P_0 to $P_{A_\dagger}$. It is then necessary to have $q > 0$ and $\beta_i > 0$ for some index i, as assumed in (H). To have a sufficient condition, consider

$$m = \max\{i = 1 \dots A_\dagger : \beta_i > 0\}$$

(the largest reproductive age); it is then enough to have:

(5.6) There exists $h < m$ such that $c_h^2 > 0$.

In fact, since $\beta_m > 0$, we have $\alpha_{0,m} > 0$ and, in view of (5.4), $\alpha_{h+1,A_\dagger} > 0$; then (5.6) means that we have the path:

$$P_0 \longrightarrow P_m \longrightarrow \cdots P_{h+1} \longrightarrow P_{A_\dagger}. \tag{5.7}$$

Equations (5.5) and (5.7) yield the irreducibility of $F'(0)$.

Condition (5.6) means that some age class below the maximum fertility age can be infected through intercohort transmission. Note that this corresponds exactly to the restriction imposed in [5] for the continuous case.

Furthermore, note that neither the case without vertical transmission nor the case of pure intracohort transmission result in an irreducible $F'(0)$, as F is defined in (5.1). However, in the case without vertical transmission, we may define

$$F \equiv (F_1, \cdots, F_{A_\dagger}) : \mathbf{R}^{A_\dagger} \to \mathbf{R}^{A_\dagger}.$$

In the pure intracohort case, we may define

$$F \equiv (F_0, \cdots, F_m) : \mathbf{R}^{m+1} \to \mathbf{R}^{m+1},$$

where m is, as above, the maximum reproductive age. In fact, it is clear that ages beyond m do not contribute to disease transmission to ages below m.

All the following considerations can be easily adjusted to these cases. For the sake of simplicity we will instead assume (H) and (5.6) for the rest of the section.

Now we define on C the discrete dynamical system:

$$\left\{\begin{array}{l} U^{n+1} = F(U^n) \\ U^0 \in C \end{array}\right. \tag{5.8}$$

for which the following holds.

THEOREM 5.1. *Let F be defined in* (5.1), *and let* (H) *and* (5.6) *hold. Then:*

(i) *If $\rho(F'(0)) \leq 1$, F has no nontrivial fixed points in C and $U^n \overset{n\to\infty}{\longrightarrow} 0$, for all $U^0 \in C$;*

(ii) *If $\rho(F'(0)) > 1$, F has one nontrivial fixed point $U^\infty \in C$; U^∞ is strictly positive, and we have $U^n \overset{n\to\infty}{\longrightarrow} U^\infty$ for all $U^0 \in C$, $U^0 \not\equiv 0$.*

The proof of this theorem is, for the main part, contained in Theorem 2.1 of [9]; however, we cannot rely completely upon that theorem because our mapping F does not satisfy a strict sublinearity condition needed there to prove uniqueness of the positive fixed point. Thus, to prove Theorem 5.1, we preliminarily prove uniqueness in an independent way.

PROPOSITION 5.2. *Under the assumptions of Theorem* 5.1, *F has at most one positive fixed point.*

Proof. Let $\bar{x} \neq \bar{y}$ be two positive fixed points of F. Without loss of generality we can assume $\bar{y} \not\geq \bar{x}$, so that, since $\bar{x}$ and $\bar{y}$ are strictly positive, it is possible to find the maximal $\xi \in (0,1)$ such that $\bar{y} \geq \xi\bar{x}$. Let

$$k = \max\{i = 0 \ldots A_\dagger : \bar{y}_i = \xi\bar{x}_i\}. \tag{5.9}$$

We will consider three cases, showing that each gives rise to a contradiction:

(a) $k > 0$ and $c^1_{k-1} + c^2_{k-1} > 0$.

(b) $k > 0$ and there exists h, $0 < h < k$ such that $c^1_{h-1} + c^2_{h-1} > 0$ and $c^1_i + c^2_i = 0$ for all $i = h \ldots k-1$.

(c) $k \geq 0$ and $c^1_{i-1} + c^2_{i-1} = 0$ for all i, $1 \leq i \leq k$.

Assume case (a). Then we have $\Lambda_{k-1}(\bar{x}) > 0$. The inequality $F_k(\bar{y}) \geq F_k(\xi\bar{x})$ gives:

$$\bar{y}_k \geq \frac{\xi\bar{x}_{k-1} + \xi\Lambda_{k-1}(\bar{x})\Delta t}{1 + (\gamma_k + \xi\Lambda_{k-1}(\bar{x}))\Delta t},$$

that is,

$$[1+(\gamma_k+\Lambda_{k-1}(\bar{x}))\Delta t]\,\bar{y}_k \geq \xi(\bar{x}_{k-1}+\Lambda_{k-1}(\bar{x})\Delta t)+(1-\xi)\bar{y}_k\Lambda_{k-1}(\bar{x})\Delta t.$$

Hence,

$$\bar{y}_k \geq \xi F_k(\bar{x})+\xi\bar{x}_k\frac{(1-\xi)\Lambda_{k-1}(\bar{x})\Delta t}{1+(\gamma_k+\xi\Lambda_{k-1}(\bar{x}))\Delta t},$$

and so,

$$\bar{y}_k \geq \xi\bar{x}_k\left[1+\frac{\Lambda_{k-1}(\bar{x})\Delta t}{1+(\gamma_k+\xi\Lambda_{k-1}(\bar{x}))\Delta t}\right] > \xi\bar{x}_k$$

in contradiction with (5.9).

In case (b), we note that it implies, for $h \leq i < k$, $\Lambda_i(x)=0\ \forall\ x \in C$; consequently, if $\bar{y}_{i+1}=\xi\bar{x}_{i+1}$, from

$$\text{(5.10)}\qquad \begin{cases} \bar{y}_{i+1}=F_{i+1}(\bar{y})=\dfrac{\bar{y}_i}{1+\gamma_{i+1}\Delta t} \\ \xi\bar{x}_{i+1}=\xi F_{i+1}(\bar{y})=\xi\dfrac{\bar{x}_i}{1+\gamma_{i+1}\Delta t} \end{cases}$$

we obtain

$$\text{(5.11)}\qquad \bar{y}_i=\xi\bar{x}_i$$

Applying this iteratively for $i=k-1\ldots h$, since $\bar{y}_k=\xi\bar{x}_k$, one gets:

$$\bar{y}_h=\xi\bar{x}_h \quad\text{and}\quad c^1_{h-1}+c^2_{h-1}>0.$$

We can therefore apply the argument of case (a).

In case (c), we have $\Lambda_i(x)=0$ for all $i=0\cdots k-1$; therefore, we can apply (5.10) iteratively for $i=k-1$ to $i=0$ to obtain

$$\text{(5.12)}\qquad \bar{y}_0=\xi\bar{x}_0.$$

Moreover, comparing (5.6) with (c), we see that $k<m$, that is,

$$\text{(5.13)}\qquad \bar{y}_m>\xi\bar{x}_m.$$

Then, we have

$$\text{(5.14)}\qquad \bar{y}_0=F_0(\bar{y})=\frac{q}{B_0}\sum_{i=1}^{A_\dagger}\beta_i p_i^\infty\bar{y}_i\Delta t>\frac{q}{B_0}\sum_{i=1}^{A_\dagger}\beta_i p_i^\infty\xi\bar{x}_i\Delta t=\xi F_0(\bar{x})=\xi\bar{x}_0,$$

contradicting (5.12). The strict inequality in (5.14) comes from (5.13), since $\beta_m>0$. □

Once uniqueness is proved, we use the following reduced version of Theorem 2.1 of [9].

THEOREM 5.3. *Let $\Phi(x)$ be a continuous, monotone, nondecreasing function that maps $[0,1]^n$ into itself. Assume that $\Phi(0) = 0$ and $\Phi'(0)$ exists and is irreducible. Suppose also that Φ is sublinear, i.e., if $x \in [0,1]^n$, then*

$$\Phi(\xi x) \geq \xi \Phi(x) \quad \forall\, \xi \in (0,1). \tag{5.15}$$

Then any nonzero fixed point of Φ is strictly positive. Moreover, if $\rho(\Phi'(0)) > 1$, Φ has a positive fixed point. Vice versa, if Φ has a positive fixed point, $\rho(\Phi'(0)) \geq 1$; if $\bar{x}$ is a positive fixed point and $\rho(\Phi'(0)) = 1$, then

$$\Phi'(0)\bar{x} = \bar{x}\,. \tag{5.16}$$

Proof. The proof of this theorem is essentially the same as that of Theorem 2.1 in [9]: here condition (5.15) replaces strict sublinearity.

The proof of existence does not require sublinearity. In order to take care of the fact that our domain is $[0,1]^n$ instead of $\mathbf{R}^n_+$, we have to note that, if $x \in [0,1]^n$ is such that $x_i = 1$, then $\Phi_i(x) \leq x_i$.

Finally, if Φ has a positive fixed point $\bar{x}$, we can apply the argument of Hethcote and Thieme to $\bar{x}$ and obtain

$$\Phi'(0)\bar{x} \geq \bar{x}. \tag{5.17}$$

Since $\bar{x}$ is positive, (5.17) implies, by Perron–Frobenius theory, that $\rho(\Phi'(0)) \geq 1$. If $\rho(\Phi'(0)) = 1$ (5.17) implies that $\bar{x}$ is an eigenvector of $\Phi'(0)$, i.e., (5.16). □

To apply this theorem to the proof of Theorem 5.1, we need to check that F satisfies (5.15), the other properties having already been established. From (5.1) we have

$$F_0(\xi \bar{x}) = \xi \frac{q}{B_0} \sum_{i=1}^{A_\dagger} \beta_i p_i^\infty \bar{x}_i \Delta t = \xi F_0(\bar{x}),$$

and, for $1 \leq i \leq A_\dagger$,

$$F_i(\xi \bar{x}) = \frac{\xi \bar{x}_{i-1} + \xi \Lambda_{i-1}(\bar{x})\Delta t}{1 + (\gamma_i + \xi \Lambda_{i-1}(\bar{x}))\Delta t} \geq \xi \frac{\bar{x}_{i-1} + \Lambda_{i-1}(\bar{x})\Delta t}{1 + (\gamma_i + \Lambda_{i-1}(\bar{x}))\Delta t} = \xi F_i(\bar{x}). \tag{5.18}$$

To exclude the case that there exists a positive fixed point $\bar{x}$ of (5.1) if $\rho(F'(0)) = 1$, we note that in this case (5.16) would hold, i.e., $F(\bar{x}) = F'(0)\bar{x}$. This means (see (5.3)–(5.4))

$$\frac{\bar{x}_{i-1} + \Lambda_{i-1}(\bar{x})\Delta t}{1 + (\gamma_i + \Lambda_{i-1}(\bar{x}))\Delta t} = \frac{\bar{x}_{i-1} + \Lambda_{i-1}(\bar{x})\Delta t}{1 + \gamma_i \Delta t} \tag{5.19}$$

for all $i = 1 \cdots A_\dagger$. Since $\bar{x}_i > 0$, (5.19) implies $\Lambda_{i-1}(\bar{x}) = 0$ for all $i = 1 \cdots A_\dagger$. Assumption (H) then yields $\bar{x} = 0$, in contradiction with its being positive.

Finally, as for the asymptotic behaviour of U^n, we note that it follows from Krasnoselskii's theory (Theorem 6.6 in [10]; see also [9]) that any $U^0 \in C$, $U^0 \neq 0$, will converge to the positive fixed point (when it exists), as long as there exists $N \geq 0$ such that $F^N(U^0)$ is strictly positive. This condition comes immediately from (5.1) and (5.6). □

Proceeding exactly as in §2, we can compute the threshold condition. More precisely, we have the following.

PROPOSITION 5.4. *The equilibrium $U \equiv 0$ is globally stable if and only if*

$$T_1(\Delta t) = \frac{q}{B_0} \sum_{i=1}^{A_\dagger} \beta_i p_i^\infty P_{i,0} \Delta t < 1, \tag{5.20}$$

and

$$T_2(\Delta t) = \sum_{i=1}^{A_\dagger} \left(\frac{qA\beta_i}{B_0(1 - T_1)} + 1 \right) p_i^\infty \left(\sum_{j=0}^{i-1} \frac{c_j^2 \Delta t}{1 + \gamma_{j+1}\Delta t} P_{i,j+1} \right) \Delta t \leq 1, \tag{5.21}$$

where

$$P_{i,j} = \prod_{k=j}^{i-1} \frac{1 + c_k^1 p_k^\infty \Delta t}{1 + \gamma_{k+1}\Delta t}$$

and

$$A = \sum_{i=1}^{A_\dagger} p_i^\infty P_{i,0} \Delta t.$$

Comparing Proposition 5.4 with Theorem 2.1, we realize that the threshold condition for the discrete dynamical system approaches that of the original continuous one as the time step tends to zero.

COROLLARY 5.5. *If Δt is small enough, there exists $C > 0$ such that*

$$|T_1(\Delta t) - T_1|, \qquad |T_2(\Delta t) - T_2| \leq C\Delta t. \tag{5.22}$$

Proof. It follows from the expressions (5.20)–(5.21) and (2.3)–(2.4), noting that, if $f \in L^\infty(0,a)$, $f \geq 0$, we have

$$0 \leq \exp\left\{ \sum_{k=j}^{i-1} f_k \Delta t \right\} - \prod_{k=j}^{i-1} (1 + f_k \Delta t) \leq \exp\left\{ \sum_{k=j}^{i-1} f_k \Delta t \right\} \left(e^{\|f\|_\infty^2 (\Delta t)^2} - 1 \right). \tag{5.23}$$

Equation (5.22) then follows from (5.23) and the approximation of integrals with Riemann sums. □

We finally prove that the endemic equilibrium U^∞ of the discrete dynamical system approaches the endemic equilibrium u^∞ of the continuous system as the time step Δt goes to zero.

For $h = \Delta t$, let

$$u_h^\infty(a) = \left(\left[\frac{a+h}{h} \right] - \frac{a}{h} \right) U_{\left[\frac{a}{h}\right]}^\infty + \left(\frac{a}{h} - \left[\frac{a}{h} \right] \right) U_{\left[\frac{a+h}{h}\right]}^\infty$$

i.e., u_h^∞ is the linear spline through U^∞.

PROPOSITION 5.5. *If $T_1 \geq 1$, or $T_2 > 1$, u_h^∞ converges to u^∞ uniformly in $[0, a_\dagger]$.*

Proof. We first note that u_h^∞ are everywhere differentiable from the right and from the left with

(5.24)

$$D^+ u_h^\infty(a) = \left[c^1 \left(\left[\frac{a}{h}\right] h \right) p^\infty \left(\left[\frac{a}{h}\right] h \right) u_h^\infty \left(\left[\frac{a}{h}\right] h \right) + c^2 \left(\left[\frac{a}{h}\right] h \right) \sum_{k=1}^{A_\dagger} p^\infty(kh) u_h^\infty(kh) h \right]$$
$$\times \left(1 - u_h^\infty \left(\left[\frac{a+h}{h} \right] h \right)\right) - \gamma \left(\left[\frac{a+h}{h} \right] h \right) u_h^\infty \left(\left[\frac{a+h}{h} \right] h \right)$$

and $D^-u_h^\infty(a)$ equal to $D^+u_h^\infty(a)$, except when $a/h \in \mathbf{N}$, in which case we substitute a/h in (5.24) with $(a-h)/h$, and $(a+h)/h$ with a/h.

From (5.24) it also comes out that u_h are Lipschitzian with common Lipschitz constant

$$L = \max\left\{ b^0\|c^1\|_\infty + \|c^2\|_\infty \int_0^{a_\dagger} p^\infty(a)\,da\,,\ \|\gamma\|_\infty \right\}.$$

Take a sequence $\{h_n\}$, $h_n \overset{n\to\infty}{\longrightarrow} 0$. Since $\{u_{h_n}^\infty\}$ are equi-Lipschitz (and so equicontinuous) and uniformly bounded, by Ascoli–Arzelà theorem, there exists a subsequence, still denoted by the same name, uniformly converging to $\bar{u}$.

Then, from (5.24), we see that both $D^+u_{h_n}^\infty$ and $D^-u_{h_n}^\infty$ converge uniformly (see Assumption 3.8) to

$$\left[c^1(a)p^\infty(a)\bar{u}(a) + c^2(a)\int_0^{a_\dagger} p^\infty(\sigma)\bar{u}(\sigma)\,d\sigma\right](1-\bar{u}(a)) - \gamma(a)\bar{u}(a), \tag{5.25}$$

and therefore $\bar{u}$ is differentiable, and its derivative is equal to (5.25).

Considering also the conditions on $u_h^\infty(0)$, we obtain that $G\bar{u} = \bar{u}$, with G as in Theorem 1.1. By Theorem 1.1 there exists a unique positive function u^∞ such that $Gu^\infty = u^\infty$. The only other possibility would be to have $\bar{u} = 0$, but this will be excluded below.

We have therefore proved that, from any sequence $\{h_n\}$, $h_n \overset{n\to\infty}{\longrightarrow} 0$, we can extract a subsequence uniformly converging to u^∞, proving, therefore, the convergence as h goes to zero.

We have still to exclude the case that there exists a sequence $\{h_n\}$, $h_n \overset{n\to\infty}{\longrightarrow} 0$, and $u_{h_n}^\infty \overset{n\to\infty}{\longrightarrow} 0$.

We find a lower bound, when Δt is sufficiently small, for U^∞ yielded by Theorem 5.1, using the fact, arising from the Proof of Theorem 2.1 of [9], that, if $\bar{v}$ is such that $F(\bar{v}) \geq \bar{v}$, then $U^\infty \geq \bar{v}$.

If $T_1 > 1$, there exists $z < 1$ and $h_0 > 0$ such that, for $\Delta t < h_0$,

$$T_{1,z}(\Delta t) = \frac{q}{B_0}\sum_{i=1}^{A_\dagger} \beta_i p_i^\infty P_{i,0} z^i \Delta t > 1,$$

with $P_{i,0}$ as in Proposition 5.4.

Now take $\bar{v}_0 = \epsilon$, $\bar{v}_i = \epsilon P_{i,0} z^i$, with ϵ such that $z\Lambda_{i-1}(\bar{v})\Delta t < 1 - z$ for all $i = 1 \ldots A_\dagger$.

Then, we have

$$F_0(\bar{v}) - \bar{v}_0 = \epsilon\left[\frac{q}{B_0}\sum_{i=1}^{A_\dagger} \beta_i p_i^\infty P_{i,0} z^i \Delta t - 1\right] > 0,$$

$$\begin{aligned}F_i(\bar{v}) - \bar{v}_i =& \frac{\bar{v}_{i-1}(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t) + c_{i-1}^2 \Delta t \sum_{j=1}^{A_\dagger} p_j^\infty \bar{v}_j \Delta t}{1 + \gamma_i \Delta t + \Lambda_{i-1}(\bar{v})\Delta t} - z\frac{1 + c_{i-1}^1 p_{i-1}^\infty \Delta t}{1 + \gamma_i \Delta t}\bar{v}_{i-1} \\ =& \frac{\bar{v}_{i-1}(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t)\left[(1+\gamma_i\Delta t)(1-z) - z\Lambda_{i-1}(\bar{v})\Delta t\right]}{(1 + \gamma_i\Delta t + \Lambda_{i-1}(\bar{v})\Delta t)(1+\gamma_i\Delta t)} \\ &+ \frac{c_{i-1}^2 \Delta t \sum_{j=1}^{A_\dagger} p_j^\infty \bar{v}_j \Delta t}{1 + \gamma_i\Delta t + \Lambda_{i-1}(\bar{v})\Delta t}.\end{aligned}$$

Therefore, we have $F(\bar{v}) \geq \bar{v}$ and so $U_0^\infty \geq \epsilon$, and $u_h^\infty(0) \geq \epsilon$ for all $h < h_0$.

Now suppose $T_1 = 1$, or $T_1 < 1$ and $T_2 > 1$. Then there exists $z < 1$ and $h_0 > 0$, such that for $\Delta t < h_0$,

$$T_{1,z}(\Delta t) < 1/z,$$

$$T_{2,z}(\Delta t) = \frac{A}{1/z - T_{1,z}} B + \sum_{i=1}^{A_\dagger} p_i^\infty D_i \Delta t > 1,$$

where

$$D_i = \sum_{j=0}^{i-1} \frac{c_j^2 \Delta t}{1 + \gamma_{j+1}\Delta t} P_{i,j+1} z^{i-j},$$

$$A = \sum_{i=1}^{A_\dagger} p_i^\infty P_{i,0} z^i \Delta t,$$

$$B = \frac{q}{B^0} \sum_{i=1}^{A_\dagger} \beta_i p_i^\infty D_i \Delta t.$$

Now take

$$\bar{v}_0 = \frac{\epsilon B}{1/z - T_{1,z}},$$

$$\bar{v}_i = P_{i,0} z^i \bar{v}_0 + \epsilon D_i, \qquad i \geq 1,$$

with ϵ as above.

Note that

$$\eta = \sum_{i=1}^{A_\dagger} p_i^\infty \bar{v}_i \Delta t = \frac{\epsilon B}{1/z - T_{1,z}} \sum_{i=1}^{A_\dagger} p_i^\infty P_{i,0} z^i \Delta t + \epsilon \sum_{i=1}^{A_\dagger} p_i^\infty D_i \Delta t \tag{5.26}$$
$$= \epsilon T_{2,z}(\Delta t).$$

We have

$$\begin{aligned}
F_0(\bar{v}) - \bar{v}_0 &= \frac{q}{B_0} \sum_{i=1}^{A_\dagger} \beta_i p_i^\infty P_{i,0} z^i \Delta t \bar{v}_0 + \epsilon \frac{q}{B_0} \sum_{i=1}^{A_\dagger} \beta_i p_i^\infty D_i \Delta t - \bar{v}_0 \\
&= \epsilon B \frac{1-z}{1 = zT_1} > 0 \\
F_i(\bar{v}) - \bar{v}_i &= \frac{\bar{v}_{i-1}(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t) + c_{i-1}^2 \Delta t \sum_{j=1}^{A_\dagger} p_j^\infty \bar{v}_j \Delta t}{1 + \gamma_i \Delta t + \Lambda_{i-1}(\bar{v})\Delta t} \\
&\quad - z \frac{1 + c_{i-1}^1 p_{i-1}^\infty \Delta t}{1 + \gamma_i \Delta t} \bar{v}_{i-1} \\
&\quad - z \frac{c_{i-1}^2 \Delta t}{1 + \gamma_i \Delta t} \epsilon \\
&= \frac{\bar{v}_{i-1}(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t)\left[(1 + \gamma_i \Delta t)(1-z) - z\Lambda_{i-1}(\bar{v})\Delta t\right]}{(1 + \gamma_i \Delta t + \Lambda_{i-1}(\bar{v})\Delta t)(1 + \gamma_i \Delta t)} \\
&\quad + \frac{\epsilon c_{i-1}^2 \Delta t \left((1 + \gamma_i \Delta t)(T_{2,z} - z) - z\Lambda_{i-1}(\bar{v})\Delta t\right)}{(1 + \gamma_i \Delta t + \Lambda_{i-1}(\bar{v})\Delta t)(1 + \gamma_i \Delta t)} \\
&> (1 - z - z\Lambda_{i-1}(\bar{v})\Delta t) \frac{\bar{v}_{i-1}(1 + c_{i-1}^1 p_{i-1}^\infty \Delta t) + \epsilon c_{i-1}^2 \Delta t}{(1 + \gamma_i \Delta t + \Lambda_{i-1}(\bar{v})\Delta t)(1 + \gamma_i \Delta t)} > 0.
\end{aligned}$$

Therefore we have $U^\infty \geq \bar{v}$, in particular, using (5.26) and $T_{2,z} > 1$,

$$\sum_{i=1}^{A_\dagger} p_i^\infty U_i^\infty \Delta t \geq \eta > \epsilon \tag{5.27}$$

for all $\Delta t < h_0$. Since the left-hand side of (5.27) are Riemann sums for u_h^∞, any limit function $\bar{u}$ must satisfy $\int_0^{a_\dagger} p^\infty(a)\bar{u}(a)\,da \geq \epsilon$. □

Note that, in contrast to the other results of this paper, through Proposition 5.5, we do not state anything about the order of convergence of u_h^∞ to u^∞.

6. Numerical experiments. The form of the force of infection λ we chose in (2.1) is $\lambda(a; i(\cdot, t)) = \chi_{[1,+\infty)}(a)\ \left[k_0 + k_1 T(a) i(a,t) + k_2 l(a) I(t)/P\right]$, where k_j, $0 \leq j \leq 2$ are nonnegative constants, and $l(a)$ and $T(a)$ are continuous piecewise linear functions given by

$$T(a) = \begin{cases} 0, & a \leq 1, \\ a/5, & 1 < a \leq 5, \\ 1, & 5 < a \leq 10, \\ 1 - (a-10)/5, & 10 < a \leq 15, \\ 0, & 15 < a, \end{cases}$$

and

$$l(a) = \begin{cases} 0, & a \leq 0, \\ a/15, & 0 < a \leq 15, \\ 1, & 15 < a. \end{cases}$$

The choice of these shapes is only indicative; they are a complication of the "catalytic logistic curve" introduced by Collins [6] and used more recently by Anderson and May [1].

We used the algorithm described above for the analysis of the asymptotic behavior of the subpopulation of infected individuals, and to see whether the convergence to the steady state is monotone or not. For the tests we took a steady state age distribution defined by (1.6) where $\mu(a)$ was the actual mortality rate of the population of the United States in 1980. For the sake of simplicity, the fertility function $\beta(a)$ was chosen as a sinusoidal centered at the age of 30 years, and with support between 15 and 45 years. Tests were run with and without vertical transmission. The cure rate γ was taken to be uniform in age, and such that the mean infective period is of 8 months.

We first studied the dependence of the threshold quantities on the coefficients of transmission k_1 and k_2. It is clear that T_1 is independent of k_2, while T_2 depends linearly on it. The dependence of T_1 and T_2 on k_1 is shown in Fig. 1. It appears that T_1 grows exponentially with k_1 (notice the logarithmic scale in the figure), while (when $k_2 > 0$) T_2 starts almost linearly, and then approaches an exponential. Notice also that, even for rather small values of k_2, the first quantity to pass the threshold is T_2. Finally note that, when $k_2 > 0$, a change from $q = 0$ to $q > 0$ increases T_2 by a very small amount.

We then performed several simulations of various cases (intracohort, intercohort, and mixed), with and without vertical transmission, below and above the threshold. The algorithm generally behaved in agreement with theoretical expectations: the total

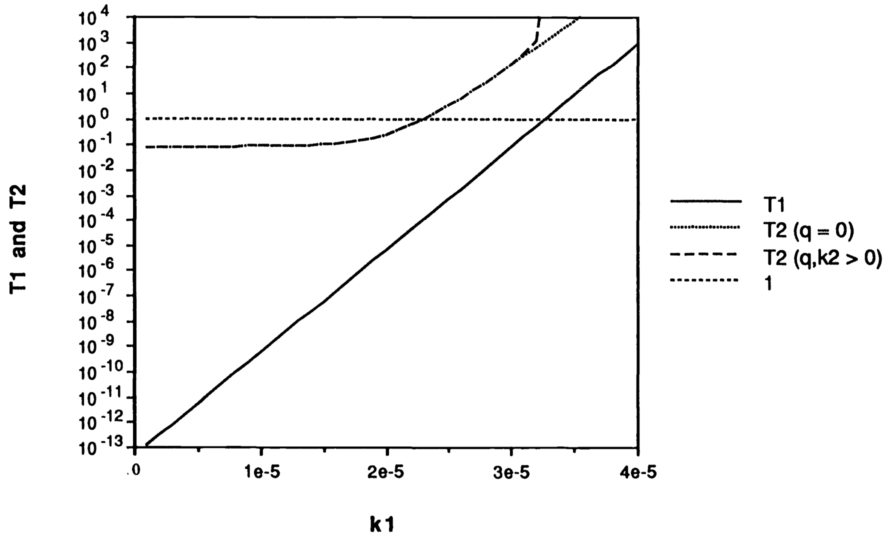

FIG. 1. *On the* y-*axis the threshold parameters* T_1 *and* T_2*; on the* x-*axis* k_1*. In all graphs* $\gamma = 1.5$*. The solid line represents* T_1*, computed with* $q = 0.111111$*;* T_2 *is computed with* $k_2 = 0.1$*, and either* $q = 0$*, or* $q = 0.111111$ *(these are the two dashed lines). Finally the threshold value* 1 *is shown in the figure.*

number of infectives converged to a positive equilibrium above the threshold, and to zero below the threshold; and the same was true for all age classes. Some plots of the total number of infectives vs. time are shown in Fig. 2; the solid lines corresponds to cases below the threshold, the dashed lines—above the threshold.

Note that in the intracohort case, it is not clear whether the lower simulation approaches zero or a positive equilibrium, despite a value of T_1 noticeably lower than one. In this case we have $T_1(\Delta t) < T_1$; therefore, theoretically, the discrete algorithm should also converge to zero. The lack of convergence to zero must thus be due to error accumulation.

In general, it seems that the intercohort case is much more well-behaved than the intracohort case; in the former case, changing the time step from 1/16 to 1/128 did not change the results noticeably, while in the intracohort case this caused differences of the order of 20% in certain cases at certain times. In this respect, the mixed case resembles the intercohort; a small amount of intercohort transmission is enough to stabilize the simulations. Probably, for the purely intracohort case, it should be worthwhile using a higher order method for integration along the characteristic lines; in order to do this a method where age discretization is kept distinct from time discretization should be used, such as the method introduced by de Roos [13].

From our simulations it appears also that, in the intercohort case, the convergence to the equilibrium is monotone (the same was true for all age classes, reaching at most something like a critically damped oscillation), while in the intracohort it can be oscillatory. The mixed case is intermediate in this respect.

Finally, in Fig. 3 we show the age distributions of the infectives at various times; we used rather high infectivities, in order to make these distributions visible. Clearly they are centered at the ages where the possibility of getting infected is highest: between the ages of 5 and 15 for the intracohort case; at later ages for the intercohort case. Notice that the addition of a small amount of intercohort transmission is enough

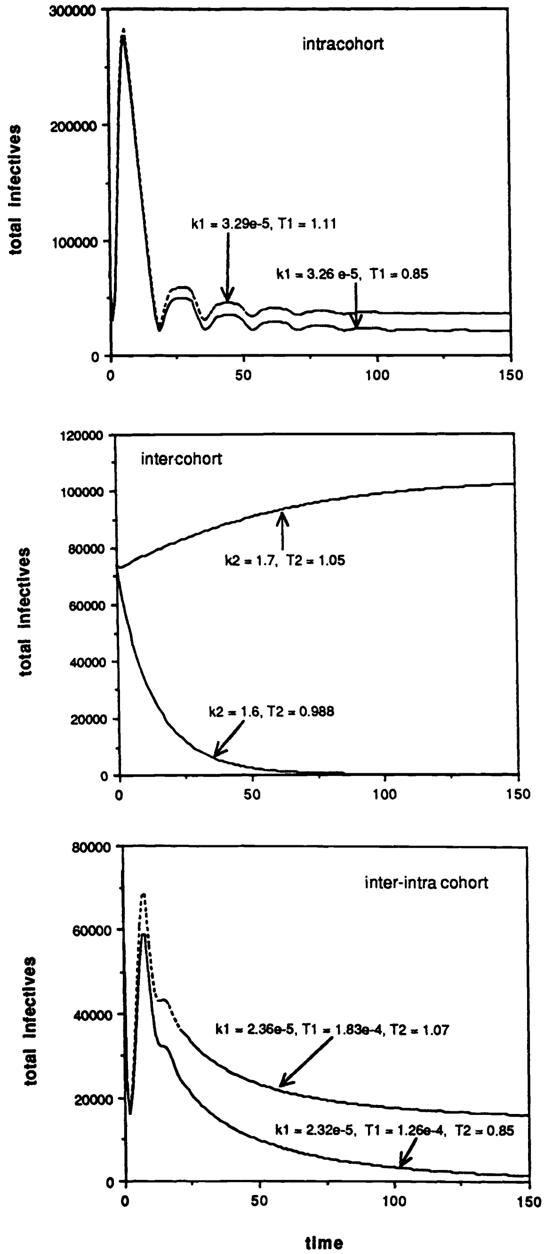

FIG. 2. *On the* y-*axis the total number of infectives; on the* x-*axis time. The three graphs correspond (from high to low) to the intracohort case* $(k_2 = 0)$, *intercohort* $(k_1 = 0)$, *inter-intracohort* $(k_1, k_2 > 0)$. *The two lines in each graph correspond to different values of a specified parameter. Other parameter values are* $\gamma = 1.5$, $q = 0.111111$.

for a very quick convergence to the equilibrium, but the age distribution remains similar to the intracohort case.

Acknowledgments. We thank an anonymous referee for several comments and suggestions that greatly improved the paper.

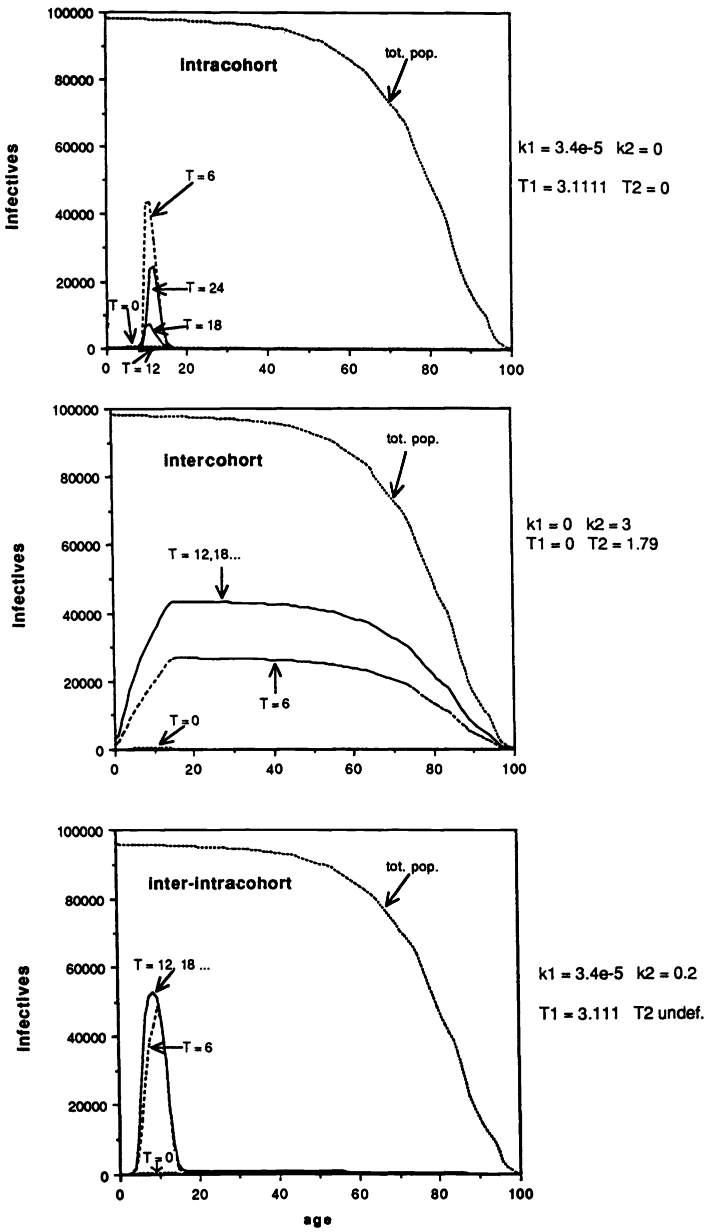

FIG. 3. *On the* x*-axis age, on the* y*-axis number of infectives. The three graphs are as in Fig. 2; the lines in each graph represent infective number at various times, starting with a given age distribution at* $T = 0$*. The stationary population distribution is also shown in the graphs. Some parameter values are specified; others are as above.*

PERIODIC SOLUTIONS OF SINGLE-SPECIES MODELS WITH PERIODIC DELAY*

H. I. FREEDMAN† AND JIANHONG WU‡

Abstract. A single-species population growth model is considered, where the growth rate response to changes in its density has a periodic delay. It is shown that if the self-inhibition rate is sufficiently large compared to the reproduction rate, then the model equation has a globally asymptotically stable positive periodic solution.

Key words. single-species, population growth, oscillations, periodic solutions, delay equations, global stability, fixed point theorems

AMS(MOS) subject classifications. 92A17, 34K20

1. Introduction.

The main focus of this paper is on a model of single-species population growth which incorporates a periodic time delay in the birth process. In particular, we show the existence of a stable periodic solution of a retarded functional differential equation to be given later which has the feature of periodicity right in the time delay. To the best of our knowledge, this is the first time equations with such delays have been considered in the literature.

This paper is motivated by the laboratory work of the group led by U. Halbach (see [4], [21]-[24], [40], [44] and the references therein) on rotifers. They noticed that in laboratory populations, periodic phenomena due to time delays in gestation occurred, and that the length of delay was a function of the controlled temperature. These periodic variations in population numbers also occurred when the temperature itself was varied periodically (thereby inducing a periodic delay) on a daily basis. This led us to a conjecture that periodic solutions should exist for single species delay models with periodic delay.

Previous work has shown that periodic oscillations could occur in autonomous delay differential equations [5], [6], [10], [13], [15], [16], [20], [25], [29]-[31], [35], [37], [40], [43], [45], as well as delay equations for population growth in fluctuating environments [2], [9], [11], [12], [14], [19], [28], [32]-[34], [39], [45]. However, periodic oscillations are not automatic in single-species models with delay as shown in [3], [7], [8], [18].

In the case where the delay in growth rate is a constant, the mechanism causing oscillation is for the delay to be so significant in terms of the time length of the delay or the magnitude of the delayed effects that the positive equilibrium point (carrying capacity) loses its stability. For details, we refer to [13] and the references therein.

The technique used in the analysis of our model is to first show that due to the periodicity of the growth rate and of the delay, there exists a positive periodic carrying capacity which is not a solution, but yields a globally stable periodic oscillation in the species density. In contrast with the aforementioned research for the constant delay case, we find that the periodicity in various growth rates and in the delay can cause stable oscillation of the species density about the carrying capacity even when the delay is small.

The idea here is to then treat the periodic oscillation as being generated from the periodic carrying capacity by proving the existence of an attracting region containing the carrying capacity.

The organization of this paper is as follows. Model equations and our major results are described in § 2. We will state our results for the linear growth rate case in detail and briefly indicate the possible extension to the nonlinear growth rate case. The proofs of the theorems are contained in § 3. Under the assumption of the existence of a periodic carrying capacity, we construct a Lyapunov function about the carrying capacity and employ the Lyapunov-Razumikhin technique to obtain an attracting region. Section 4 contains a brief discussion of our results and some related open problems.

2. Model equations and main results.

2.1. Linear growth rates. We first consider the following single-species model involving a discrete periodic delay

$$\dot{x}(t)=x(t)[a(t)-b(t)x(t)+c(t)x(t-\tau(t))], \tag{2.1}$$

where the net birth rate $a(t)$, the self-inhibition rate $b(t)$, the reproduction rate $c(t)$, and the delay $\tau(t)$ are continuously differentiable, ω-periodic functions, and $a(t)>0$, $b(t)>0$, $c(t)\geqq 0$, $\tau(t)\geqq 0$ for $t\in R=(-\infty,+\infty)$. This model represents the case that when the population size is small, growth is proportional to the size, and when the population size is not so small, the positive feedback is $a(t)+c(t)x(t-\tau(t))$ while the negative feedback is $b(t)x(t)$. Such circumstances can arise when the resources are plentiful and the reproduction at time t is by individuals of at least age $\tau(t)$ units of time.

The above model, with constant coefficient and delay, and its variants, has been utilized by many authors as a model of single species growth (see [18] and the references therein). The delay in the term $c(t)x(t)x(t-\tau(t))$ is a delay due to gestation. Thinking of small animals such as rotifers (as in the work of Halbach and co-workers mentioned in the introduction), there is a small delay in the time between final feeding before reproduction and reproduction. Hence, the reproduction rate has a component which is proportional to those animals present a short time earlier and those animals currently present (random mating).

Let $\tau^*=\max_{t\in[0,\omega]}\tau(t)$. It is a well-known fact that for any given $\varphi\in C([-\tau^*,0]; R)$, there exist $\alpha\in(0,\infty)$ and a unique solution $x(t)=x(t;\varphi)$ of (2.1) on $[-\tau^*,\alpha)$; that is, $x(t)$ is continuous on $[-\tau^*,\alpha)$, continuously differentiable, and satisfies (2.1) on $(0,\alpha)$ and $x(\theta)=\varphi(\theta)$ on $[-\tau^*,0]$. Moreover, if $\varphi(t)\geqq 0$ on $[-\tau^*,0]$, then $x(t)$ remains nonnegative for all $t\in[0,\alpha)$, and if x is noncontinuable past α and $\alpha<+\infty$, then $|x(t)|\to\infty$ as $t\to\alpha^-$.

The following theorem sets forth the principal result of this paper.

THEOREM 2.1. *Suppose that the equation*

$$a(t)-b(t)K(t)+c(t)K(t-\tau(t))=0$$

has a positive, ω-periodic, continuously differentiable solution $K(t)$. Then the model equation (2.1) *has a positive ω-periodic solution $Q(t)$. Moreover, if $b(t)>c(t)Q(t-\tau(t))/Q(t)$ for all $t\in[0,\omega]$, then $Q(t)$ is globally asymptotically stable with respect to positive solutions of* (2.1).

Remark 2.1. $K(t)$ represents the carrying capacity of the environment. If all of the growth rates a, b, and c are constant in time, then $K=a/b-c$. In the case where τ is also a constant, it is shown in [18] that the condition $b>c$ guarantees the global asymptotic stability of the carrying capacity. Our result here indicates that such a global asymptotic stability holds even when τ is not a constant.

Remark 2.2. In the case where $a(t)/(b(t)-c(t))$ is not a constant, the carrying capacity $K(t)$ must be an ω-periodic function, and the periodic solution $Q(t)$ obtained in our results is nonconstant.

Remark 2.3. In the case where $b(t)>c(t)$ for $t\in[0,\omega]$, by iterating the equation $K(t)=a(t)/b(t)+c(t)/b(t)K(t-\tau(t))$, we can get an explicit expression for $K(t)$

$$K(t)=\frac{a(t)}{b(t)}+\sum_{j=0}^{\infty}\prod_{i=0}^{j}\frac{c\circ m^i(t)}{b\circ m^i(t)}\frac{a\circ m^{j+1}(t)}{b\circ m^{j+1}(t)}, \tag{2.2}$$

where $m^0(t)=t$, $m^1(t)=t-\tau(t)$, $m^i(t)=m\circ m^{i-1}(t)$ for $t\in R$ and $i\geqq 1$. It is easy to see from the formula (2.2) that if $a(t)/b(t)-c(t)$ is not a constant, then the major role of the periodicity of the delay is to cause a periodic fluctuation of the corresponding carrying capacity about the carrying capacity which occurs when τ is a constant.

Remark 2.4. In applications, it is useful to have an estimate for the location of the periodic solution $Q(t)$. The proof of this theorem in the next section will provide a rough estimate of the constants ε and $M>0$ such that

$$\varepsilon\leqq\frac{Q(t)}{K(t)}\leqq M \quad \text{for } t\in[0,\omega].$$

This inequality also indicates that we can regard the periodic oscillation as being generated from the carrying capacity, in contrast to Cushing's result [14], where the periodic oscillation bifurcates from the trivial solution.

There is some experimental evidence [9] which indicates that continuously distributed delays are more realistic and more accurate than those with instantaneous time delays. Inspired by this evidence, we consider the following Volterra integro-differential equation

$$\dot{x}(t)=x(t)\left[a(t)-b(t)x(t)+\int_{-\infty}^{t}p(t,s)x(s)\,ds\right], \tag{2.3}$$

where $p(t,s)$ is a nonnegative continuous function satisfying $p(t+\omega,s+\omega)=p(t,s)$ for $-\infty<s\leqq t<+\infty$, and there exists a constant $\gamma>0$ such that

$$\int_{-\infty}^{0}p(t,t+\theta)\,e^{-\gamma\theta}\,d\theta<\infty \quad \text{for } t\in[0,\omega]. \tag{2.4}$$

The above assumptions are motivated and satisfied by the following special delay kernel

$$k(t,s)=\frac{1}{\tau^2(t)}\cdot(t-s)\cdot\exp\left[-\frac{1}{\tau(t)}(t-s)\right], \tag{2.5}$$

which attains its maximum at $s=t-\tau(t)$ for any fixed t. Therefore, (2.3) represents a continuously distributed delay analog of the difference-differential equation (2.1) with periodic discrete delay.

Let

$$C_\gamma=\left\{\varphi\in C((-\infty,0];R);\ \lim_{\theta\to-\infty}e^{\gamma\theta}\varphi(\theta)\text{ exists}\right\}$$

with

$$|\varphi|_{C_\gamma}=\sup_{-\infty<\theta\leqq 0}e^{\gamma\theta}|\varphi(\theta)|, \qquad \varphi\in C_\gamma,$$

and define $F: R\times C_\gamma\to R$ by

$$F(t,\varphi)=\varphi(0)\left[a(t)-b(t)\varphi(0)+\int_{-\infty}^{0}p(t,t+\theta)\varphi(\theta)\,d\theta\right], \qquad (t,\varphi)\in R\times C_\gamma.$$

Then $(C_\gamma, |\cdot|_{C_\gamma})$ is a Banach space which satisfies all of the fundamental axioms described in [26], and F is a continuous functional which is Lipschitz in $\varphi \in C_\gamma$. We notice that (2.3) can be reformulated as $\dot{x}(t) = F(t, x_t)$. Therefore, by Theorems 2.1-2.5 of [26], for each $\varphi \in C_\gamma$ there exists $\alpha := \alpha(\varphi) > 0$ and a unique solution $x(t; \varphi)$ of (2.3) defined on $(-\infty, \alpha)$ with $x_0 = \varphi$, and the mapping $(t, \varphi) \in (0, \alpha(\varphi)) \times C_\gamma \subseteq R \times C_\gamma \to x_t(\varphi) \in C_\gamma$ is continuous. Moreover, if $x(t; \varphi)$ is noncontinuable past $\alpha(\varphi)$ and $\alpha(\varphi) < \infty$, then $\lim_{t\to\alpha^-} |x(t; \varphi)| = \infty$.

The following result represents an analog of Theorem 2.1 in the case of distributed delay.

THEOREM 2.2. *Assume that there exists a continuously differentiable positive ω-periodic function $K(t)$ satisfying*

$$a(t) - b(t)K(t) + \int_{-\infty}^{t} p(t, s)K(s)\,ds = 0, \qquad t \in R;$$

then the model equation (2.3) *has a positive ω-periodic solution $Q(t)$. Moreover, if*

$$b(t) > \int_{-\infty}^{t} p(t, s)\frac{Q(s)}{Q(t)}\,ds, \qquad t \in R,$$

then $Q(t)$ is globally asymptotically stable with respect to positive solutions of (2.3) *in the state space C_γ.*

2.2. Nonlinear growth rates. In this part, we indicate a possible extension of our previous results to nonlinear growth rates. We consider the following model

$$\dot{x}(t) = x(t)[-D(t, x(t)) + B(t, x_t)], \tag{2.6}$$

where the death rate $D(t, x)$ is continuous in $(t, x) \in R^2$, ω-periodic in t, increasing and continuously differentiable in x; the birth rate $B(t, \varphi)$ is continuous in $(t, \varphi) \in R \times C([-\tau, 0]; R)$ (τ is a constant), continuously differentiable in $\varphi \in C([-\tau, 0]; R)$, and is ω-periodic in t in the following sense.

(H1) For any continuous ω-periodic function $x: R \to R$, $B(t, x_t)$ is ω-periodic as a function of t.

This model represents the case where there is a delay in the per capita birth rate, whereas the death rate is instantaneous [3], [5]. We assume that all positive feedbacks are included in the birth processes and any negative feedback is included in the death rate. Our crucial assumption is the following.

(H2) There exists a positive ω-periodic continuously differentiable function $K(t)$ such that $D(t, K(t)) = B(t, K_t)$ for $t \in R$.

With this assumption, Theorem 2.1 can be modified so as to apply to our nonlinear case.

THEOREM 2.3. *Suppose that*

(i) (H1)-(H2) *are satisfied.*

(ii) *For all $t \in [0, \omega]$, we have*

$$\inf_{x\in R^+} D_x(t, x) - \sup_{\varphi\in C} \|B_\varphi(t, \varphi)\| \cdot \frac{\max_{\theta\in[0,\omega]} K(\theta)}{K(t)} > 0, \tag{H3}$$

where $\|B_\varphi(t, \varphi)\|$ denotes the operator norm of the bounded linear operator $B_\varphi(t, \varphi)$: $C \to C$.

(iii) *There exists a constant $\delta > 0$ such that for every $\delta_0 \in (0, \delta)$, and for any $\varphi \in C$ with $\varphi(s) \geqq \varphi(0) = \delta_0$, we have $B(t, \varphi) - D(t, \varphi(0)) \geqq 0$.*

Then the model equation (2.6) *has a positive ω-periodic solution $Q(t)$. Moreover, if*

$$\inf_{x\in R^+} D_x(t,x)-\sup_{\varphi\in C}\|B_\varphi(t,\varphi)\|\frac{\max_{\theta\in[0,\omega]}Q(\theta)}{Q(t)}>0$$

for all $t\in[0,\omega]$, then $Q(t)$ is globally asymptotically stable with respect to positive solutions of (2.6).

3. Proofs of theorems. In this section, we give detailed proofs for Theorems 2.1 and 2.2 and briefly indicate how to modify these proofs to the nonlinear case.

Let $C=C([-\tau^*,0];R)$ denote the Banach space of all continuous functions with the sup-norm

$$\|\varphi\|=\sup_{\theta\in[-\tau^*,0]}|\varphi(\theta)|\quad\text{for } \varphi\in C.$$

C^+ denotes a subset of C consisting of all nonnegative functions, $x(t;\varphi)$, $t\geqq-\tau^*$, $\varphi\in C^+$, denotes the unique solution of equation (2.1) satisfying $x(t;\varphi)=\varphi(t)$ on $[-\tau^*,0]$, and $x_t(\varphi)\in C$ is defined as $x_t(\varphi)(s)=x(t+s;\varphi)$ for all $s\in[-\tau^*,0]$.

LEMMA 3.1. *There exists a constant $\delta>0$ such that for every $\delta_0\in(0,\delta)$, the set*

$$B^C_{\delta_0}=\{\varphi\in C^+\colon \varphi(\theta)\geqq\delta_0\quad \textit{for } \theta\in[-\tau^*,0]\}$$

is invariant, that is, $\varphi\in B^C_{\delta_0}$ implies $x_t(\varphi)\in B^C_{\delta_0}$ for all $t\geqq0$.

Proof. We select a constant $\delta>0$ such that

$$\inf_{t\in[0,\omega]}\{a(t)-b(t)\delta\}>0.$$

Let $\delta_0\in(0,\delta)$ and $\varphi\in B^C_{\delta_0}$ be given. We consider the solution $x(t)=x(t;\varphi)$ of (2.1). If at an instant $t\geqq0$ we have $x^2(s)\geqq x^2(t)=\delta_0^2$ for $s\in[t-\tau^*,t]$, then $[x^2(t)]'\leqq0$. However, from (2.1) we have

$$\begin{aligned}[x^2(t)]'&=2x^2(t)[a(t)-b(t)x(t)+c(t)x(t-\tau(t))]\\&\geqq2x^2(t)[a(t)-b(t)\delta_0]\\&>0.\end{aligned}$$

This contradiction indicates that $\min\{\min_{\theta\in[-\tau^*,0]}x^2(t+\theta),\delta_0^2\}$ is nondecreasing, and therefore

$$\min\left\{\min_{\theta\in[-\tau^*,0]}x^2(t+\theta),\delta_0^2\right\}\geqq\min\left\{\min_{\theta\in[-\tau^*,0]}\varphi^2(\theta),\delta_0^2\right\}=\delta_0^2$$

for all $t\geqq0$. This completes the proof.

LEMMA 3.2. *For any $\rho>1$, we have*

$$\rho x-\ln(\rho x)\geqq\beta[x-\ln x]\quad \textit{for all } x\geqq1$$

where $\beta=\rho-\ln\rho$.

Proof. Let $G(x)=\rho\ln x-\ln(\rho x)+(1/x)\ln\rho$. Then $G(1)=0$, $G(\infty)=\infty$, and

$$G'(x)=\frac{1}{x^2}[(\rho-1)x-\ln\rho]$$

from which we know that $G'(x)>0$ for $x>\ln\rho/(\rho-1)$ and $G'(x)<0$ for $x<\ln\rho/(\rho-1)$. Therefore there exists a unique $x^*>1$ such that $G(x^*)=\rho-1$, $G(x)>1$ if $x>x^*$ and $G(x)<\rho-1$ for $x<x^*$.

Consider now $f(x)=(\rho x-\ln(\rho x))/(x-\ln x)$. Then

$$f'(x)=\frac{\rho-1-\rho\ln x+\ln(\rho x)-(\ln\rho)/x}{(x-\ln x)^2}$$
$$=\frac{\rho-1-G(x)}{(x-\ln x)^2}$$

which implies that $f'(x)>0$ if $x<x^*$, and $f'(x)<0$ if $x>x^*$. Therefore

$$f(x)\geqq\min\{f(1),f(\infty)\}=\min\{\rho-\ln\rho,\rho\}=\rho-\ln\rho$$

for all $x\geqq 1$. This completes the proof.

The following result describes a dissipative property of the equation, where the existence of an attracting region is essential for our main results.

LEMMA 3.3. *Assume that*

$$\frac{c(t)}{K(t)}K(t-\tau(t))<b(t)\quad \textit{on } [0,\omega].$$

Then

(i) *For any $\xi\geqq\delta$, there exists a constant $d:=d(\xi)>0$ such that for any $\varphi\in C$ with $\delta\leqq\varphi(\theta)\leqq\xi$ on $[-\tau^*,0]$, we have $\delta\leqq x(t;\varphi)\leqq d(\xi)$ for all $t\geqq 0$;*

(ii) *There exists a constant $M\geqq\delta$ such that for any $\beta\geqq\delta$ there is a constant $T=T(\beta)>0$ such that for any $\varphi\in C$ with $\delta\leqq\varphi(\theta)\leqq\beta$ on $[-\tau^*,0]$ we have $\delta\leqq x(t;\varphi)\leqq M$ for all $t\geqq T(\beta)$.*

Proof. According to the assumptions, we can find a constant $\rho>1$ such that

$$\min_{t\in[0,\omega]}\left\{b(t)-\rho\cdot\frac{c(t)}{K(t)}\cdot K(t-\tau(t))\right\}=\delta_1>0.$$

For such $\gamma>1$, define

$$M^*=\frac{2}{\delta_1}\max_{0\leqq t\leqq\omega}\left\{(\rho-1)c(t)\max_{\theta\in[0,\omega]}K(\theta)+\frac{|\dot K(t)|}{K(t)}\right\}+\max_{\theta\in[0,\omega]}K(\theta).$$

Define a continuous map $V: R\times(0,\infty)\to R$ by

$$V(t,x)=\frac{x}{K(t)}-\ln\frac{x}{K(t)}\quad\text{for } (t,x)\in R\times(0,\infty).$$

Suppose $x(t)=x(t;\varphi)$ is a solution of (2.1) with $\min_{\theta\in[-\tau^*,0]}\varphi(\theta)\geqq\delta$. By Lemma 3.1, $x(t)\geqq\delta$ for all $t\geqq 0$, and therefore $V(t,x(t))$ is well defined and differentiable for $t\geqq 0$. Moreover, we have

$$\frac{d}{dt}V(t,x(t))=\left[1-\frac{K(t)}{x(t)}\right]\left\{\frac{x(t)}{K(t)}[a(t)-b(t)x(t)+c(t)x(t-\tau(t))]-\frac{\dot K(t)}{K^2(t)}x(t)\right\}$$
$$=\frac{x(t)-K(t)}{K(t)}\left\{a(t)-b(t)x(t)+c(t)x(t-\tau(t))-\frac{\dot K(t)}{K(t)}\right\}$$
$$=-\frac{x(t)-K(t)}{K(t)}\left\{b(t)[x(t)-K(t)]\right.$$
$$\left.-c(t)[x(t-\tau(t))-K(t-\tau(t))]-\frac{\dot K(t)}{K(t)}\right\}.$$

Suppose at some $t \geqq 0$, we have

$$V(t+s, x(t+s)) \leqq (\rho - \ln \rho) V(t, x(t)) \quad \text{for } s \in [-\tau^*, 0]$$

and $x(t) \geqq M^*$. Then by Lemma 3.2, we have

$$\frac{x(t+s)}{K(t+s)} - \ln \frac{x(t+s)}{K(t+s)} \leqq \frac{\rho x(t)}{K(t)} - \ln \left(\frac{\rho x(t)}{K(t)} \right)$$

for all $s \in [-\tau^*, 0]$. From the choice of M^*, it follows that

$$\frac{x(t)}{K(t)} \geqq \frac{M^*}{K(t)} \geqq 1,$$

and therefore by the increasing property of the function $u - \ln u$ for $u \geqq 1$, we get

$$\frac{x(t+s)}{K(t+s)} \leqq \frac{\rho x(t)}{K(t)} \quad \text{for } s \in [-\tau^*, 0].$$

Hence

$$x(t+s) - K(t+s) \leqq \frac{K(t+s)}{K(t)} \rho [x(t) - K(t)] + (\rho - 1) K(t+s)$$

for all $s \in [-\tau^*, 0]$. This implies that

$$\begin{aligned}
-K(t) \frac{d}{dt} V(t, x(t)) &= b(t)[x(t) - K(t)]^2 - c(t)[x(t) - K(t)][x(t - \tau(t)) - K(t - \tau(t))] \\
&\quad - \frac{\dot{K}(t)}{K(t)} [x(t) - K(t)] \\
&\geqq b(t)[x(t) - K(t)]^2 - c(t) \cdot \frac{K(t - \tau(t))}{K(t)} [x(t) - K(t)]^2 \rho \\
&\quad -(\rho - 1) c(t) K(t - \tau(t)) |x(t) - K(t)| - \frac{\dot{K}(t)}{K(t)} [x(t) - K(t)] \\
&\geqq \left[b(t) - \rho \frac{c(t)}{K(t)} \cdot K(t - \tau(t)) \right] [x(t) - K(t)]^2 \\
&\quad - \left[(\rho - 1) c(t) \max_{\theta \in [0, \omega]} K(\theta) + \frac{|\dot{K}(t)|}{K(t)} \right] |x(t) - K(t)| \\
&\geqq \delta_1 [x(t) - K(t)]^2 \\
&\quad - \left[(\rho - 1) c(t) \max_{\theta \in [0, \omega]} K(\theta) + \frac{|\dot{K}(t)|}{K(t)} \right] |x(t) - K(t)| \\
&\geqq \frac{1}{2} \delta_1 |x(t) - K(t)|^2.
\end{aligned}$$

That is,

$$\frac{d}{dt} V(t, x(t)) \leqq - \frac{\delta_1}{2 \max_{\theta \in [0, \omega]} K(\theta)} |x(t) - K(t)|^2$$

whenever $V(t+s, x(t+s)) \leqq (\gamma - \ln \gamma) V(t, x(t))$ for $s \in [-\tau^*, 0]$ and $x(t) \geqq M^*$. Therefore, employing a variation of the standard argument of the uniform boundedness and uniform ultimate boundedness theorem of Lyapunov-Razumikhim type [25], we can prove the conclusion with any given constant $M > M^*$.

The following result from [27] is our major tool used in guaranteeing the existence of a ω-periodic solution.

LEMMA 3.4 (Horn's fixed-point theorem). *Let $S_0 \subset S_1 \subset S_2$ be convex subsets of the Banach space X, with S_0 and S_2 compact and S_1 open relative to S_2. Let $P: S_2 \to X$ be a continuous mapping such that, for some integer $m > 0$,*

(a) $P^j(S_1) \subseteq S_2$, $1 \leqq j \leqq m-1$,

and

(b) $P^j(S_1) \subseteq S_0$, $m \leqq j \leqq 2m-1$.

Then P has a fixed point in S_0.

Now we are in a position to prove our major results.
