ENERGY ESTIMATES RELATING DIFFERENT LINEAR ELASTIC MODELS OF A THIN CYLINDRICAL SHELL I. THE MEMBRANE-DOMINATED CASE*

JYRKI PIILA† AND JUHANI PITKÄRANTA†

Abstract. Three different linear models describing the elastic deformation of a thin cylindrical shell are analyzed under a given smooth normal pressure distribution. A model problem with membrane-dominated state of deformation is considered. The models studied are (1) the standard three-dimensional model, (2) the classical shell model of Koiter–Sanders–Novozhilov, and (3) the asymptotic membrane theory of the shell. Estimates are derived relating the deformations fields according to different models in relative energy norm.

Key words. linear elasticity, energy estimates

AMS(MOS) subject classifications. 73C02, 73C20

1. Introduction. In this paper, which is the first part in a series of three papers, we compare three linear elastic models, describing the membrane-dominated deformation state of a finite, thin cylindrical shell. As a model problem we study a shell occupying, in Cartesian coordinates, the region

$$\Omega = \left\{ (x_1, x_2, x_3) \in R^3 \mid 0 < x_1 < H,\ R - \frac{t}{2} < \sqrt{x_2^2 + x_3^2} < R + \frac{t}{2} \right\}.$$

We will further choose $H = R = 1$ and assume that thickness t of the shell is small, i.e., $t << 1$. The shell is assumed to be loaded by a smoothly varying normal pressure distribution on the surface

$$\Gamma_+ = \left\{ (x_1, x_2, x_3) \in \overline{\Omega} \mid 0 < x_1 < 1,\ \sqrt{x_2^2 + x_3^2} = 1 + \frac{t}{2} \right\}.$$

The boundary at $x_1 = 0$ is assumed to be clamped, i.e., the displacements vanish at $x_1 = 0$, whereas the boundary at $x_1 = 1$ may be either clamped or free.

The three shell models to be considered are:

(1) The standard three-dimensional elastic model;

(2) The dimensionally reduced shell model of Koiter–Sanders–Novozhilov; and

(3) The asymptotic membrane theory of the shell.

We point out that shell problems fall, in general, into two categories depending on whether the membrane or bending deformations dominate. Here we concentrate on the membrane-dominated case. The bending-dominated case, closely related to the so-called inextensional shell theory, is the subject of Part II. In Part III we finally study another type of membrane-dominated situation referred to as the "soft" membrane case. In all three parts of the paper, the geometry of the shell is the same, and also the load is assumed to be of the same form as here, i.e., a smoothly varying normal pressure distribution. Thus only the boundary conditions and the shape of the load vary.

Here, in Part I, we take only the classical shell model of Koiter–Sanders–Novozhilov (as we have decided to call it; cf. [12], [20], [16]) as the representative of dimensionally reduced shell models. In Parts II and III we call this a model of Kirchhoff type and consider in addition what we call a model of Reissner–Mindlin type. The terminology here refers to the classical models of plate bending.

As is well known (cf. [14]), the displacement field $\underline{U}^{3D} = (U_1^{3D}, U_2^{3D}, U_3^{3D})$ minimizes the total energy

$$F^{3D}(\underline{U}) = \tfrac{1}{2}\mathcal{A}^{3D}(\underline{U},\underline{U}) - Q^{3D}(\underline{U}),$$

where the quadratic part $\mathcal{A}^{3D}(\underline{U},\underline{U})$ represents the deformation energy and the linear part $Q^{3D}(\underline{U})$ is the potential energy due to the external load. A dimensionally reduced shell model is obtained in this formulation by assuming that the displacements vary quadratically along directions normal to the midsurface of the shell. By dropping out certain "small" terms (see §3 below), the Koiter–Sanders–Novozhilov model is obtained. Finally, if the load is appropriately scaled in terms of t, we obtain a nontrivial and finite deformation state as $t \to 0$. In the present situation the limit state corresponds to the membrane theory of the shell, and it is obtained by letting the pressure distribution be proportional to t.

Let $\underline{U}^K$ stand for the displacement field corresponding to the shell model with positive thickness, and let $\underline{U}^0$ denote the membrane theory limit of $\underline{U}^K$. Our main results are estimates for $|||\underline{U}^{3D} - \underline{U}^K|||_{3D}$ and $|||\underline{U}^K - \underline{U}^0|||_{3D}$, where $|||\cdot|||_{3D}$ is the relative energy norm corresponding to the three-dimensional model. In particular, we show that in both the clamped-clamped and the clamped-free case

$$|||\underline{U}^{3D} - \underline{U}^K|||_{3D} = \mathcal{O}(t^{3/4} + \delta_\nu t^{1/2}), \tag{1.1a}$$

$$|||\underline{U}^K - \underline{U}^0|||_{3D} = \mathcal{O}(t^{1/4}), \tag{1.1b}$$

where ν, $0 \le \nu < \frac{1}{2}$, is the Poisson ratio of the material and

$$\delta_\nu = \begin{cases} 0 & \text{if } \nu = 0, \\ 1 & \text{otherwise.} \end{cases}$$

We also show that (1.1b) is the best possible estimate.

Estimates (1.1) are proved by splitting the displacement fields as $\underline{U}^{3D} = \underline{U}_A^{3D} + \underline{U}_B^{3D} + \underline{U}_C^{3D}$, and $\underline{U}^K = \underline{U}_A^K + \underline{U}_B^K$, where $\underline{U}_A^{3D}$ and $\underline{U}_A^K$ are both close to $\underline{U}^0$ and $\underline{U}_B^{3D}$, $\underline{U}_C^{3D}$ and $\underline{U}_B^K$ are residual fields arising because of the incompatibility of boundary conditions in different models. The residual fields satisfy homogeneous three-dimensional elastic/shell equations with certain inhomogeneous boundary conditions, see §4 below. In fact, we show that, with an appropriate splitting,

$$\begin{aligned} |||\underline{U}_A^{3D} - \underline{U}^0|||_{3D} &= \mathcal{O}(t), \\ |||\underline{U}_A^K - \underline{U}^0|||_{3D} &= \mathcal{O}(t), \\ |||\underline{U}_B^K|||_{3D} &= \mathcal{O}(t^{1/4}), \\ |||\underline{U}_B^{3D} - \underline{U}_B^K|||_{3D} &= \mathcal{O}(t^{3/4}), \\ |||\underline{U}_C^{3D}|||_{3D} &= \mathcal{O}(\delta_\nu t^{1/2}). \end{aligned}$$

The main difficulty in deriving energy estimates of the above type is to estimate the residual fields containing the (leading) boundary layer effects. So far we are only able to treat the simple geometry and boundary conditions considered. Yet, the results appear to be new even in this relatively simple case. For previous studies of the convergence of dimensionally reduced models for both plates and shells the reader is referred to [1]–[13], [15], [17]–[21]. Further references can be found, e.g., in [4], [6].

We point out that since $|||(\underline{U}_B^{3D}+\underline{U}_C^{3D})-\underline{U}_B^K|||_{3D}$ is asymptotically smaller than $|||\underline{U}_B^{3D}+\underline{U}_C^{3D}|||_{3D}$ in view of the estimates stated, this indicates that the (nonasymptotic) shell model does capture some of the leading boundary layers in the original three-dimensional formulation. This is in contrast to plate bending problems, where the Reissner–Mindlin model apparently does not exhibit such a superiority over the asymptotic Kirchhoff model [1], [2], [3].

Finally, let us mention that although the energy norm is certainly a "convenience norm" in our studies, the results are relevant from the numerical point of view since finite element approximations effectively generate best approximations in this norm; cf. [17], where the numerical aspects are discussed in the bending-dominated context.

The plan of the paper is as follows. Proceeding from the main notation in §2, we derive the dimensionally reduced shell models in §3 and also state some existence and convergence results of general nature. In §4 we prove convergence rate estimates (1.1) in the clamped-clamped case, and finally in §5 the clamped-free case is considered. In the Appendix we derive some regularity results for the displacement field $\underline{U}^K$ needed in estimating $|||\underline{U}^{3D}-\underline{U}^K|||_{3D}$. The need of such estimates is the main obstacle in extending the present results to more general situations.

Throughout the paper, the analysis is based on the energy principle or its variational form, i.e., we do not introduce the stresses at all. We depart here somewhat from the classical tradition where the stresses and the associated complementary energy principle usually play a vital role (cf. [13], [15], [21], [3], [11], [9]). In the subsequent Parts II and III we use the same analysis technique, except for one point in Part II where we still need the complementary energy principle.

2. Preliminaries. We summarize in this section the main notation to be used in the sequel. We work in a cylindrical coordinate system $(\alpha_1,\alpha_2,\alpha_3)$, where the shell occupies the region

$$\Omega=\left\{(\alpha_1,\alpha_2,\alpha_3)\in R^3 \mid (\alpha_1,\alpha_2)\in\omega,\ -\frac{t}{2}<\alpha_3<\frac{t}{2}\right\}.$$

Here (α_1,α_2) is a parametrization of the midsurface of the shell, with

$$\omega=\left\{(\alpha_1,\alpha_2)\in R^2 \mid 0<\alpha_1<1,\ -\pi<\alpha_2<\pi\right\}.$$

In the three-dimensional model of elasticity the strain tensor corresponding to a displacement field $\underline{V}$ is then defined as $\underline{\underline{e}}(\underline{V})=\{e_{ij}\}_{i,j=1}^3$, where (cf. [14])

$$\begin{aligned} e_{11}&=V_{1,1}, & e_{22}&=\chi(V_{2,2}+V_3),\\ e_{12}&=\tfrac12(\chi V_{1,2}+V_{2,1}), & e_{23}&=\tfrac12\big(V_{2,3}+\chi(V_{3,2}-V_2)\big),\\ e_{13}&=\tfrac12(V_{1,3}+V_{3,1}), & e_{33}&=V_{3,3}. \end{aligned}$$

Here the components V_i refer to the local orthonormal basis that corresponds to the curvilinear coordinate system; $V_{i,j}$ stands for $\partial V_i/\partial\alpha_j$ and $\chi=1/(1+\alpha_3)$. In the dimensionally reduced shell models the strain tensor is replaced by membrane strains

$\underline{\underline{\beta}} = \{\beta_{ij}\}_{i,j=1}^2$ and bending strains $\underline{\underline{\kappa}} = \{\kappa_{ij}\}_{i,j=1}^2$ depending only on (α_1, α_2). These have the expressions (cf. [16])

$$\begin{array}{lll} \beta_{11} = u_{,1}\,, & \beta_{12} = \tfrac{1}{2}(u_{,2} + v_{,1}\,), & \beta_{22} = v_{,2} + w, \\ \kappa_{11} = w_{,11}\,, & \kappa_{12} = w_{,12} - v_{,1}\,, & \kappa_{22} = w_{,22} - v_{,2}\,, \end{array}$$

where $\underline{u} = (u, v, w)$ is the displacement vector of the middle surface.

We introduce the bilinear forms

$$\begin{aligned} &\mathcal{A}^{3D}(\underline{U}, \underline{V}) \\ &\quad = D^{-1} \textstyle\int_\Omega \{\lambda\ tr\underline{\underline{e}}\ (\underline{U}) tr\underline{\underline{e}}(\underline{V}) + \mu \sum_{i,j=1}^3 e_{ij}(\underline{U}) e_{ij}(\underline{V})\} \chi^{-1}\, d\alpha_1\, d\alpha_2\, d\alpha_3, \\ &t^2 \mathcal{A}^K(\underline{u}, \underline{\tilde{v}}) + \mathcal{B}^K(\underline{u}, \underline{\tilde{v}}) \\ &\quad = t^2 \textstyle\int_\omega \{\nu\ tr\underline{\underline{\kappa}}\ tr\underline{\underline{\tilde{\kappa}}} + (1-\nu) \sum_{i,j=1}^2 \kappa_{ij}\ \tilde{\kappa}_{ij}\}\ d\alpha_1\ d\alpha_2 \\ &\qquad + 12 \textstyle\int_\omega \{\nu\ tr\underline{\underline{\beta}}\ tr\underline{\underline{\tilde{\beta}}} + (1-\nu) \sum_{i,j=1}^2 \beta_{ij}\ \tilde{\beta}_{ij}\}\ d\alpha_1\ d\alpha_2, \end{aligned}$$

corresponding to the three-dimensional and dimensionally reduced formulations, respectively. Here $tr\underline{\underline{e}} = e_{11} + e_{22} + e_{33}$, $tr\underline{\underline{\beta}} = \beta_{11} + \beta_{22}$, $tr\underline{\underline{\kappa}} = \kappa_{11} + \kappa_{22}$. Further, λ and μ are material parameters depending on the Young modulus $E > 0$ and the Poisson ratio ν, and D is a scaling factor. These are defined as

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)}, \qquad \mu = \frac{E}{1+\nu}, \qquad D = \frac{Et}{12(1-\nu^2)}.$$

In the above notation, the scaled total energy to be minimized according to the three-dimensional model takes the form (cf. [14])

$$\begin{aligned} F^{3D}(\underline{U}) &= \tfrac{1}{2}\mathcal{A}^{3D}(\underline{U}, \underline{U}) - Q^{3D}(\underline{U}), \quad \text{where} \\ Q^{3D}(\underline{U}) &= \int_\omega f(\alpha_1, \alpha_2) \cdot U_3\left(\alpha_1, \alpha_2, \frac{t}{2}\right)\left(1 + \frac{t}{2}\right)\, d\alpha_1\, d\alpha_2. \end{aligned}$$

Here $f = D^{-1}F$ is the scaled load. We assume below that the actual load F is proportional to t, so f is independent of t. We see as well that this scaling assures (in the present membrane-dominated case) the existence of a nontrivial and finite limit deformation state as $t \to 0$.

Similarly, in the shell model of Koiter–Sanders–Novozhilov [16], the total energy is expressed as

$$\begin{aligned} F^K(\underline{u}) &= \tfrac{1}{2}\{t^2 \mathcal{A}^K(\underline{u}, \underline{u}) + \mathcal{B}^K(\underline{u}, \underline{u})\} - q(\underline{u}), \quad \text{where} \\ q(\underline{u}) &= \int_\omega f w\ d\alpha_1\ d\alpha_2, \end{aligned}$$

and f is as before. By taking the limit as $t \to 0$ we get formally the energy according to the membrane theory of the shell. This is denoted by F^0:

$$F^0(\underline{u}) = \tfrac{1}{2}\mathcal{B}^K(\underline{u}, \underline{u}) - q(\underline{u}). \tag{2.1}$$

The energy norms in the above three models are denoted by $|||\cdot|||_{3D}$, $|||\cdot|||_{K,t}$, and $|||\cdot|||_0$, respectively:

$$|||\underline{U}|||_{3D} = \sqrt{\mathcal{A}^{3D}(\underline{U},\underline{U})},$$
$$|||\underline{u}|||_{K,t} = \sqrt{t^2\mathcal{A}^K(\underline{u},\underline{u}) + \mathcal{B}^K(\underline{u},\underline{u})},$$
$$|||\underline{u}|||_0 = \sqrt{\mathcal{B}^K(\underline{u},\underline{u})}.$$

The corresponding energy spaces are denoted similarly by $\mathcal{U}^{3D}$, $\mathcal{U}^K$, and $\mathcal{U}^0$. Here

$$\mathcal{U}^{3D} = \{\underline{U} \in [H^1(\Omega)]^3 \mid \underline{U}(\cdot,-\pi,\cdot) = \underline{U}(\cdot,\pi,\cdot),\ \underline{U}(\alpha_1,\cdot,\cdot) = 0$$
$$\text{at } \alpha_1 \in \{0,\ 1\} \text{ in the clamped-clamped case or}$$
$$\text{at } \alpha_1 = 0 \text{ in the clamped-free case}\},$$

and

$$\mathcal{U}^K = \Bigg\{ (u,v,w) \in H^1(\omega) \times H^1(\omega) \times H^2(\omega) \mid$$
$$(u,v,w)(\cdot,-\pi) = (u,v,w)(\cdot,\pi),\ \frac{\partial w}{\partial \alpha_2}(\cdot,-\pi) = \frac{\partial w}{\partial \alpha_2}(\cdot,\pi),$$
$$(u,v,w)(\alpha_1,\cdot) = \frac{\partial w}{\partial \alpha_1}(\alpha_1,\cdot) = 0$$
$$\text{at } \alpha_1 \in \{0,\ 1\} \text{ in the clamped-clamped case or}$$
$$\text{at } \alpha_1 = 0 \text{ in the clamped-free case} \Bigg\},$$

where $H^p(\Omega)$ and $H^p(\omega)$ stand for the usual Sobolev spaces. To define $\mathcal{U}^0$, we note that if $\underline{u}$ is any smooth function vanishing at $\alpha_1 = 0$, then $\beta_{ij}(\underline{u}) = 0$, $i,j = 1,2$, implies $\underline{u} = \underline{0}$. Hence $|||\cdot|||_0$ defines a norm over such a set of functions and accordingly $\mathcal{U}^0$ is well defined as the closure of $\mathcal{U}^K$ with respect to $|||\cdot|||_0$. A partial characterization of $\mathcal{U}^0$ is given in Lemma 3.3 below.

In the following analysis we assume throughout that f is a restriction to ω of a smooth function $\tilde{f} = \tilde{f}(\alpha_1,\alpha_2)$ defined on R^2 and 2π-periodic in α_2. The set of such functions is denoted by $C^\infty_{\text{per}}(\overline{\omega})$. It would in fact suffice to assume a finite, sufficiently high degree of smoothness.

By C or c we denote various constants taking different values on different usage. The constants are independent of parameter t except when indicated explicitly. Further, we use the abbreviation $\mathcal{O}(\phi(t))$ for a quantity whose absolute value is bounded by $c(p)\phi(t)\|f\|_{p,\omega}$ for some finite p, where now and in the sequel $\|\cdot\|_{p,\omega}$ stands for the norm of the Sobolev space $H^p(\omega)$. Finally, the inner product of $L^2(\Omega)$ is denoted by $(\cdot,\cdot)$.

3. The shell models. The shell models to be considered can be derived from the basic assumption that the displacement field, expressed in terms of the curvilinear coordinates $(\alpha_1,\alpha_2,\alpha_3)$, is a quadratic function of α_3 for each (α_1,α_2). In particular we assume that

$$\begin{aligned} U_1(\alpha_1,\alpha_2,\alpha_3) &= u(\alpha_1,\alpha_2) - \alpha_3\theta_1(\alpha_1,\alpha_2), \\ U_2(\alpha_1,\alpha_2,\alpha_3) &= v(\alpha_1,\alpha_2) - \alpha_3\theta_2(\alpha_1,\alpha_2), \\ U_3(\alpha_1,\alpha_2,\alpha_3) &= w(\alpha_1,\alpha_2) + \alpha_3\psi_1(\alpha_1,\alpha_2) + \tfrac{1}{2}\alpha_3^2\psi_2(\alpha_1,\alpha_2). \end{aligned} \tag{3.1}$$

Displacement fields of this type were apparently first considered in [12]. Here $\underline{u} = (u, v, w)$ may be interpreted as the displacements of the midsurface of the shell along the coordinate axes; (θ_1, θ_2) are the so-called rotations, and (ψ_1, ψ_2) are auxiliary functions. The second-order terms relating U_1 and U_2 are skipped because they don't have any influence on the term $e_{33}(\underline{U}^{3D} - \underline{U})$, which alone causes the error of order $\mathcal{O}(\delta_\nu t^{1/2})$. (See Theorem 4.3.)

Upon making ansatz (3.1) in F^{3D}, expanding $1/(1+\alpha_3)$ into a Taylor series, and integrating with respect to α_3, we obtain

$$
\begin{aligned}
F^{3D}(\underline{U}) =& \frac{t^2}{2}\int_\omega \left\{ \nu (tr\underline{\underline{\kappa}})^2 + (1-\nu)\sum_{i,j=1}^{2} \kappa_{ij}^2 \right\} d\alpha_1\, d\alpha_2 \\
& + 6\int_\omega \left\{ \nu (tr\underline{\underline{\beta}})^2 + (1-\nu)\sum_{i,j=1}^{2} \beta_{ij}^2 \right\} d\alpha_1\, d\alpha_2 \\
& - q(\underline{u}) + R(\underline{U}),
\end{aligned}
\tag{3.2}
$$

where β_{ij} and q are as in §2,

$$
\kappa_{11} = \theta_{1,1}, \qquad \kappa_{12} = \tfrac{1}{2}(\theta_{1,2} + \theta_{2,1} - v_{,1}\,), \qquad \kappa_{22} = \theta_{2,2},
$$

and the remainder $R(\underline{U})$ is expanded as $R(\underline{U}) = \sum_{i=0}^{\infty} t^i R_i(\underline{U})$, where

$$
\begin{aligned}
R_0(\underline{U}) =& 3(1-\nu)\int_\omega \left\{ \rho_1^2 + \rho_2^2 + \frac{2(1-\nu)}{1-2\nu}\left(\psi_1 + \frac{\nu}{1-\nu} tr\underline{\underline{\beta}}\right)^2 \right\} d\alpha_1\, d\alpha_2, \\
R_1(\underline{U}) =& -\frac{1}{2}\int_\omega f\cdot(w + \psi_1)\, d\alpha_1\, d\alpha_2, \\
R_2(\underline{U}) =& \frac{1-\nu}{4}\int_\omega \left\{ \psi_{1,1}^2 + \psi_{1,2}^2 + \frac{2(1-\nu)}{1-2\nu}\left(\psi_2 - \frac{\nu}{1-\nu} tr\underline{\underline{\kappa}}\right)^2 - \frac{1}{1-\nu} f\left(\psi_1 + \frac{1}{2}\psi_2\right) \right. \\
& + \sum_{i,j=1}^{2} \beta_{ij} \left\{ \sum_{k,h=1}^{2} \left(c_{ijkh}\beta_{kh} + \tilde{c}_{ijkh}\kappa_{kh}\right) + c_{ij}\psi_1 + \tilde{c}_{ij}\psi_2 \right\} \\
& + \psi_1 \left\{ \sum_{i,j=1}^{2} \left(C_{ij}\beta_{ij} + \tilde{C}_{ij}\kappa_{ij}\right) + c_1\psi_1 + c_2\psi_2 \right\} \\
& \left. + c\rho_1^2 + C\rho_2^2 + \sum_{i=1}^{2} \rho_i(\hat{c}_{1i}\psi_{1,i} + \hat{c}_{2i}\psi_{2,i}) \right\} d\alpha_1\, d\alpha_2,
\end{aligned}
$$

etc., where $\rho_1 = -\theta_1 + w_{,1}$ and $\rho_2 = -\theta_2 + w_{,2} - v$.

The Koiter–Sanders–Novozhilov model is now obtained formally as the following.

Step 1. With $\underline{u} = \underline{u}^K$ fixed (to be defined in Step 3), minimize $R(\underline{U})$ approximately with respect to (θ_1, θ_2) by imposing the so-called Kirchhoff–Love constraints $\rho_1 = \rho_2 = 0$, i.e.,

$$
\theta_1^K = \frac{\partial w^K}{\partial \alpha_1}, \qquad \theta_2^K = \frac{\partial w^K}{\partial \alpha_2} - v^K.
\tag{3.3}
$$

Step 2. Minimize $R(\underline{U})$ approximately with respect to (ψ_1, ψ_2). Our choice is

$$\psi_1^K = -\frac{\nu}{1-\nu} tr\underline{\underline{\beta}}^K, \qquad \psi_2^K = \frac{\nu}{1-\nu} tr\underline{\underline{\kappa}}^K. \tag{3.4}$$

Step 3. Drop $R(\underline{U})$ and define $\underline{u}^K$ as the minimizer of the remaining part of the energy under constraints (3.3). So, $\underline{u}^K$ minimizes $F^K(\underline{u})$ as defined in §2.

In the above formalism, the asymptotic membrane theory is obtained by setting $t = 0$ in (3.2) and minimizing what is left. Thus, $\underline{u}^0$ minimizes $F^0(\underline{u})$ as defined by (2.1), $\theta_1^0 = w,_1^0$, $\theta_2^0 = w,_2^0 - v^0$, and $\psi_1^0 = -\nu tr\underline{\underline{\beta}}^0/(1-\nu)$. In this case we may set $\psi_2^0 = 0$.

Remark 3.1. Suppose that we do not drop the residual term $R_1(\underline{U})$ above, so that $\underline{\tilde{u}}^K$ is the minimizer of

$$t^2\mathcal{A}^K(\underline{u},\underline{u}) + \mathcal{B}^K(\underline{u},\underline{u}) - 2\tilde{q}(\underline{u}), \quad \text{where}$$

$$\tilde{q}(\underline{u}) = \int_\omega f\left(w\left(1+\frac{t}{2}\right) - \frac{\nu t}{2(1-\nu)} tr\underline{\underline{\beta}}\right) d\alpha_1\, d\alpha_2.$$

It is easy to verify that $|||\underline{\tilde{U}}^K - \underline{U}^K|||_{3D} = \mathcal{O}(t)$, so that this change has no effect on the main results (1.1a) and (1.1b).

Regarding the solvability of the above dimensionally reduced problems, we note first that, due to the well-known Korn inequality,

$$t^2\mathcal{A}^K(\underline{u},\underline{u}) + \mathcal{B}^K(\underline{u},\underline{u}) \geq ct^2\left(||u||_{1,\omega}^2 + ||v||_{1,\omega}^2 + ||w||_{2,\omega}^2\right), \qquad \underline{u} \in \mathcal{U}^K,$$

the existence and uniqueness of $\underline{u}^K$ is guaranteed by the Riesz representation theorem. Also $\underline{u}^0$ exists and is unique by the same argument, for we have the following.

LEMMA 3.1. *For any $f \in C^\infty_{\text{per}}(\overline{\omega})$, q is a bounded linear functional on $\mathcal{U}^0$.*

Proof. Let $\underline{u} \in \mathcal{U}^K$. Integrating by parts, we get

$$|q(\underline{u})| = \left|\int_\omega \left(f\beta_{22} - 2I_1[f,_2]\beta_{12} + I_2[f,_{22}]\beta_{11}\right) d\alpha_1\, d\alpha_2\right| \leq C||f||_{2,\omega}|||\underline{u}|||_0,$$

where $I_n[g](\alpha_1,\alpha_2)$ is defined as

$$I_n[g](\alpha_1,\alpha_2) = \int_1^{\alpha_1}\int_1^{x_1}\cdots\int_1^{x_{n-1}} g(x_n,\alpha_2)\, dx_n\, dx_{n-1}\cdots dx_1.$$

Since $\mathcal{U}^K$ is dense in $\mathcal{U}^0$, the assertion follows. □

We can characterize $\underline{u}^0$ as follows.

LEMMA 3.2. *For any $f \in C^\infty_{\text{per}}(\overline{\omega})$, $\underline{u}^0 = (u^0, v^0, w^0) \in [C^\infty_{\text{per}}(\overline{\omega})]^3$ and $u^0 = v^0 = 0$ at the clamped ends of the cylinder.*

Note that since $(u,v,w) \to \left\{||u||_{1,\omega}^2 + ||v||_{1,\omega}^2 + ||w||_{L_2(\omega)}^2\right\}^{1/2}$ is a stronger norm than $|||\cdot|||_0$, we cannot impose any boundary conditions on w^0 at the clamped ends. In the proof of Lemma 3.2 we need the following characterization of the energy space $\mathcal{U}^0$.

LEMMA 3.3.

$$\mathcal{U}^0 \cap [C^\infty_{\text{per}}\ (\overline{\omega})]^3 = \{\underline{u} \in [C^\infty_{\text{per}}\ (\overline{\omega})]^3 \mid u = v = 0 \textit{ at the clamped ends of the cylinder}\}.$$

Proof. Let $\{\underline{u}_n\}_{n=1}^{\infty} = \{(u_n, v_n, w_n)\}_{n=1}^{\infty}$ be a sequence in $\mathcal{U}^0 \cap [C^{\infty}_{\text{per}}(\bar{\omega})]^3$ such that $\underline{u}_n \to \underline{u} \in \mathcal{U}^0 \cap [C^{\infty}_{\text{per}}(\bar{\omega})]^3$ in the norm $|||\cdot|||_0$ and such that $u_n = v_n = 0$ for all n at the clamped ends. Then, assuming a Fourier expansion of $\underline{u}_n$ with respect to α_2 as in the Appendix, it follows that each Fourier component of u_n and v_n converges to the corresponding component of u, respectively, v in $H^1(0,1)$. Accordingly, each Fourier component of u and v vanishes at the clamped ends and hence so do u and v. On the other hand, if $\underline{u} \in [C^{\infty}_{\text{per}}(\bar{\omega})]^3$ is given such that $u = v = 0$ at the clamped ends, then we can find a sequence $\{w_n\}_{n=1}^{\infty}$ of smooth functions such that $w_n = \partial w_n/\partial \alpha_1 = 0$ at the clamped ends and such that $w_n \to w$ in $L_2(\omega)$. Then $(u, v, w_n) \to (u, v, w)$ in the norm of $\mathcal{U}^0$, and accordingly, $\underline{u} \in \mathcal{U}^0$. □

Proof of Lemma 3.2. We simply solve $\underline{u}^0$ explicitly. First note that $\underline{u}^0$ must satisfy the Euler equations

$$\begin{aligned} \beta_{11,1} + \nu\beta_{22,1} + (1-\nu)\beta_{12,2} &= 0, \\ \nu\beta_{11,2} + \beta_{22,2} + (1-\nu)\beta_{12,1} &= 0, \\ 12\nu\beta_{11} + 12\beta_{22} &= f, \end{aligned}$$

and if the end at $\alpha_1 = 1$ is free, also the natural boundary conditions

$$\beta_{11} + \nu\beta_{22} = \beta_{12} = 0 \quad \text{at} \quad \alpha_1 = 1.$$

If $\underline{u}^0$ is smooth, we can impose the boundary condition $u^0(0,\cdot) = v^0(0,\cdot) = 0$ by Lemma 3.3. Then $\underline{u}^0$ must be of the form

$$\begin{aligned} u^0 &= \tilde{c}\{I_3[f_{,22}] - \nu I_1[f]\} - \alpha_1^2\xi' + \alpha_1\eta, \\ v^0 &= -\tilde{c}\{I_4[f_{,222}] + (2+\nu)I_2[f_{,2}]\} + \frac{\alpha_1^3}{3}\xi'' + 4(1+\nu)\alpha_1\xi - \frac{\alpha_1^2}{2}\eta', \\ w^0 &= -\nu u_{,1} - v_{,2} + \frac{f}{12}, \end{aligned}$$

where now $\tilde{c} = 1/\big(12(1-\nu^2)\big)$,

$$I_n[g](\alpha_1, \alpha_2) = \int_0^{\alpha_1}\int_0^{x_1}\cdots\int_0^{x_{n-1}} g(x_n, \alpha_2)\, dx_n\, dx_{n-1}\cdots dx_1,$$

and ξ and η are functions of α_2 only. In the clamped-clamped case ξ and η are determined by solving the system

$$\begin{aligned} &\xi' - \eta = g_1, \quad \tfrac{1}{3}\xi'' + 4(1+\nu)\xi - \tfrac{1}{2}\eta' = g_2, \quad \text{where} \\ &g_1 = \tilde{c}\{I_3[f_{,22}](1,\cdot) - \nu I_1[f](1,\cdot)\}, \\ &g_2 = \tilde{c}\{I_4[f_{,222}](1,\cdot) + (2+\nu)I_2[f_{,2}](1,\cdot)\}, \end{aligned}$$

under the boundary conditions $\xi(-\pi) = \xi(\pi)$, $\xi'(-\pi) = \xi'(\pi)$, $\eta(-\pi) = \eta(\pi)$. In the clamped-free case ξ and η are defined so as to satisfy the mentioned natural boundary conditions at $\alpha_1 = 1$. Obviously, ξ and η are in both cases restrictions to $[-\pi, \pi]$ of smooth 2π-periodic functions defined for all $\alpha_2 \in R$. We have thus found a solution of the desired type to the limit variational problem that is in $\mathcal{U}^0$ by Lemma 3.3. It follows from Lemma 3.1 that this solution is unique in the sense of the norm of $\mathcal{U}^0$. □

So far we have defined $\underline{u}^0$ only as a formal limit of $\underline{u}^K$ as $t \to 0$. We show next that $\underline{u}^K$ actually converges to $\underline{u}^0$ in the norm $|||\cdot|||_{K,t}$. The proof is a restatement of the classical regularization argument of Tihonov [22].

THEOREM 3.1. $|||\underline{u}^K - \underline{u}^0|||_{K,t} \to 0$ *as* $t \to 0$.

Proof. We note first that for all $\underline{u} \in \boldsymbol{\mathcal{U}}^K$,

$$F^K(\underline{u}) = F^0(\underline{u}) + \frac{t^2}{2}\mathcal{A}^K(\underline{u},\underline{u}) = \frac{1}{2}|||\underline{u} - \underline{u}^0|||_0^2 - \frac{1}{2}|||\underline{u}^0|||_0^2 + \frac{t^2}{2}\mathcal{A}^K(\underline{u},\underline{u}).$$

Let $\{\underline{u}_n\}_{n=1}^{\infty} \subset \boldsymbol{\mathcal{U}}^K$ be a sequence such that $|||\underline{u}_n - \underline{u}^0|||_0 \to 0$ as $n \to \infty$. Then since $F^K(\underline{u}^K) \leq F^K(\underline{u}_n)$ for all n, it follows that

$$|||\underline{u}^K - \underline{u}^0|||_0^2 + t^2\mathcal{A}^K(\underline{u}^K,\underline{u}^K) \leq |||\underline{u}_n - \underline{u}^0|||_0^2 + t^2\mathcal{A}^K(\underline{u}_n,\underline{u}_n).$$

We can now fix first n and then t so that the right-hand side is arbitrarily small and hence the assertion follows easily. □

4. Convergence rate estimates, the clamped-clamped case. We start by splitting the displacement fields $\underline{U}^K$ and $\underline{U}^{3D}$. First $\underline{U}^K$ is rewritten as $\underline{U}^K = \underline{U}_A^K + \underline{U}_B^K$, where $\underline{U}_A^K$ is defined in terms of $\underline{u}_A^K = (u_A^K,\ v_A^K,\ w_A^K)$ according to (3.1), (3.3), and (3.4), and further $\underline{u}_A^K$ minimizes F^K under periodic boundary condition at $\alpha_2 \in \{-\pi,\ \pi\}$ and under the inhomogeneous boundary conditions

$$\underline{u}(\alpha_1,\cdot) = \underline{u}^0(\alpha_1,\cdot), \qquad \frac{\partial w}{\partial \alpha_1}(\alpha_1,\cdot) = \frac{\partial w^0}{\partial \alpha_1}(\alpha_1,\cdot) \quad \text{at } \alpha_1 \in \{0,\ 1\}.$$

The remaining part $\underline{U}_B^K$ is then likewise defined in terms of $\underline{u}_B^K$ according to (3.1), (3.3), and (3.4), where $\underline{u}_B^K$ minimizes the homogeneous functional $\underline{u} \to \frac{1}{2}\{t^2\mathcal{A}^K(\underline{u},\underline{u}) + \mathcal{B}^K(\underline{u},\underline{u})\}$ under the periodic boundary condition at $\alpha_2 \in \{-\pi,\ \pi\}$ and under the boundary conditions

$$\underline{u}(\alpha_1,\cdot) = -\underline{u}^0(\alpha_1,\cdot), \qquad \frac{\partial w}{\partial \alpha_1}(\alpha_1,\cdot) = -\frac{\partial w^0}{\partial \alpha_1}(\alpha_1,\cdot) \quad \text{at } \alpha_1 \in \{0,\ 1\}.$$

Next, let $\gamma = 1 + \frac{t}{2}$. (This factor is needed essentially to compensate for the dissymmetry of the loading with respect to the shell midsurface; see the proof of Theorem 4.1 below.) We split the three-dimensional displacement field $\underline{U}^{3D}$ corresponding to a given load f as $\underline{U}^{3D} = \underline{U}_A^{3D} + \underline{U}_B^{3D} + \underline{U}_C^{3D}$, where $\underline{U}_A^{3D}$ minimizes F^{3D} under the periodic boundary condition at $\alpha_2 \in \{-\pi,\ \pi\}$ and under the inhomogeneous boundary conditions

$$\underline{U}(\alpha_1,\cdot,\cdot) = \gamma\underline{U}_A^K(\alpha_1,\cdot,\cdot), \qquad \alpha_1 \in \{0,\ 1\}.$$

The remaining parts $\underline{U}_B^{3D}$ and $\underline{U}_C^{3D}$ minimize the homogeneous functional $\underline{U} \to \frac{1}{2}\mathcal{A}^{3D}(\underline{U},\underline{U})$ under the boundary conditions

$$\underline{U}(\alpha_1,\cdot,\cdot) = \gamma\underline{U}_B^K(\alpha_1,\cdot,\cdot) \quad \text{and}$$

$$\underline{U}(\alpha_1,\cdot,\cdot) = \left(0,\ 0,\ \gamma\frac{\nu}{1-\nu}\left(\alpha_3 tr\underline{\underline{\beta}}(\underline{u}^K) - \frac{1}{2}\alpha_3^2 tr\underline{\underline{\kappa}}(\underline{u}^K)\right)\right)(\alpha_1,\cdot,\cdot),$$

respectively, at $\alpha_1 \in \{0,\ 1\}$.

Our aim is to prove that

$$|||\underline{U}_A^K - \underline{U}^0|||_{3D} = \mathcal{O}(t), \qquad |||\underline{u}_A^K - \underline{u}^0|||_{K,t} = \mathcal{O}(t^2), \tag{4.1}$$

$$|||\underline{U}_B^K|||_{3D} = \mathcal{O}(t^{1/4}), \qquad |||\underline{u}_B^K|||_{K,t} = \mathcal{O}(t^{1/4}), \tag{4.2}$$

$$|||\underline{U}_A^{3D} - \underline{U}_A^K|||_{3D} = \mathcal{O}(t), \tag{4.3}$$

$$|||\underline{U}_B^{3D} - \underline{U}_B^K|||_{3D} = \mathcal{O}(t^{3/4}), \tag{4.4}$$

$$|||\underline{U}_C^{3D}|||_{3D} = \mathcal{O}(\delta_\nu t^{1/2}). \tag{4.5}$$

The main results (1.1) are obviously consequences of these estimates. We will also prove that (4.2) and thus (1.1b) is the best possible estimate. Note that in view of (4.1)–(4.5), the leading irregularities of $\underline{U}^{3D}$ and $\underline{U}^K$ due to the clamped boundaries are contained in $\underline{U}_B^{3D} + \underline{U}_C^{3D}$ and $\underline{U}_B^K$, respectively. Moreover, we conclude that

$$\frac{|||(\underline{U}_B^{3D} + \underline{U}_C^{3D}) - \underline{U}_B^K|||_{3D}}{|||\underline{U}_B^{3D} + \underline{U}_C^{3D}|||_{3D}} = \mathcal{O}(t^{1/2} + \delta_\nu t^{1/4}),$$

so $\underline{U}_B^K$ is a "good" approximation of $\underline{U}_B^{3D} + \underline{U}_C^{3D}$ in the sense of relative energy norm.

Estimates (4.1) and (4.2) follow immediately from Lemmas A.1 and A.2 of the Appendix. Note that the second parts of (4.1) and (4.2) sharpen the result of Theorem 3.1. It thus suffices to prove (4.3) through (4.5). We start by proving (4.4). By Lemma A.2, $\underline{u}_B^K \in [C^\infty_{\text{per}}(\overline{\omega})]^3$, and for any multi-index $\tau = (\tau_1, \tau_2)$,

$$\begin{aligned} &\|D^\tau u_B^K\| = t^{-\sigma}\mathcal{O}(t^{1/4} + t^{(3-2\tau_1)/4}),\\ (4.6)\qquad &\|D^\tau v_B^K\| = t^{-\sigma}\mathcal{O}(t^{1/4} + t^{(5-2\tau_1)/4}),\\ &\|D^\tau w_B^K\| = t^{-\sigma}\mathcal{O}(t^{(1-2\tau_1)/4}), \end{aligned}$$

where $\sigma = 0$ if $\|\cdot\| = \|\cdot\|_{L_2(\omega)}$ and $\sigma = \frac{1}{4}$ if $\|\cdot\| = \|\cdot\|_{L_\infty(\omega)}$. Applying these regularity estimates we can prove the following.

THEOREM 4.1. $|||\underline{U}_B^{3D} - \underline{U}_B^K||| = \mathcal{O}(t^{3/4})$.

Proof. Let $\tilde{\underline{U}}_B^{3D}$ be the solution of the variational problem $\mathcal{A}^{3D}(\tilde{\underline{U}}_B^{3D}, \underline{V}) = 0$ for all $\underline{V} \in \boldsymbol{\mathcal{U}}^{3D}$ with boundary conditions $\tilde{\underline{U}}_B^{3D}(\alpha_1, \cdot, \cdot) = \underline{U}_B^K(\alpha_1, \cdot, \cdot)$ at $\alpha_1 \in \{0,\ 1\}$. Then by linearity $\underline{U}_B^{3D} = \gamma \tilde{\underline{U}}_B^{3D}$, and it follows from the triangle inequality that

$$|||\underline{U}_B^{3D} - \underline{U}_B^K|||_{3D} \le \gamma |||\tilde{\underline{U}}_B^{3D} - \underline{U}_B^K|||_{3D} + \frac{t}{2}|||\underline{U}_B^K|||_{3D}.$$

Since $|||\underline{U}_B^K|||_{3D} = \mathcal{O}(1)$ at most, it obviously suffices to prove the assertion with $\underline{U}_B^{3D}$ replaced by $\tilde{\underline{U}}_B^{3D}$. By a simple calculation,

$$\begin{aligned} e_{11}(\underline{U}_B^K) &= \beta_{11} - \alpha_3\kappa_{11}, & e_{12}(\underline{U}_B^K) &= \chi\beta_{12} - \chi^2\alpha_3\kappa_{12} + R_{12},\\ e_{13}(\underline{U}_B^K) &= R_{13}, & e_{22}(\underline{U}_B^K) &= \beta_{22} - \alpha_3\kappa_{22} + R_{22},\\ e_{23}(\underline{U}_B^K) &= R_{23}, & e_{33}(\underline{U}_B^K) &= -\frac{\nu}{1-\nu}\,(tr\underline{\underline{\beta}} - \alpha_3 tr\underline{\underline{\kappa}}), \end{aligned}$$

where throughout this proof $\beta_{ij} = \beta_{ij}(\underline{u}_B^K)$, $\kappa_{ij} = \kappa_{ij}(\underline{u}_B^K)$. Applying (4.6), the remainder terms $R_{ij} = R_{ij}(\underline{U}_B^K)$ can be easily estimated as

$$(4.7)\qquad \|R_{ij}\|_{L_2(\Omega)} = \mathcal{O}(t^{5/4}).$$

We note that since $\underline{u}_B^K$ minimizes $t^2\mathcal{A}^K(\underline{u}, \underline{u}) + \mathcal{B}^K(\underline{u}, \underline{u})$, we have the Euler equations

$$(4.8a)\qquad \beta_{11,1} + \nu\beta_{22,1} + (1-\nu)\beta_{12,2} = 0,$$

$$(4.8b)\qquad \nu\beta_{11,2} + \beta_{22,2} + (1-\nu)\beta_{12,1} - \frac{t^2}{12}\cdot K_1 = 0,$$

$$(4.8c)\qquad 12\nu\beta_{11} + 12\beta_{22} + t^2\cdot K_2 = 0,$$

where

$$K_1 = \nu\kappa_{11,2} + 2(1-\nu)\kappa_{12,1} + \kappa_{22,2},$$
$$K_2 = \kappa_{11,11} + \nu\kappa_{22,11} + 2(1-\nu)\kappa_{12,12} + \nu\kappa_{11,22} + \kappa_{22,22}.$$

Let $\underline{V} \in \mathcal{U}^{3D}$. Integrating by parts and applying (4.8a) and (4.8b), we have

(4.9)
$$\begin{aligned}\mathcal{A}^{3D}(\underline{U}_B^K, \underline{V}) = \frac{12}{t}\Big\{&(\nu\beta_{11} + \beta_{22}, V_3) - \big(\kappa_{11} + \nu\kappa_{22}, V_{1,1}(\alpha_3 + \alpha_3^2)\big) \\ &- \left((1-\nu)\kappa_{12}, \frac{\alpha_3 V_{1,2}}{(1+\alpha_3)^2} + \frac{\alpha_3 V_{2,1}}{1+\alpha_3}\right) \\ &- \big(\nu\kappa_{11} + \kappa_{22}, \alpha_3(V_{2,2} + V_3)\big)\Big\} \\ &- t(K_1, V_2) + R_1(\underline{V}), \qquad |R_1(\underline{V})| \le C(f)\cdot t^{3/4}\cdot |||\underline{V}|||_{3D},\end{aligned}$$

where the estimate follows from (4.6) and (4.7). Next, again integrating by parts and recalling (4.6), we find that

$$\begin{aligned}&\frac{12}{t}\int_\Omega (\nu\beta_{11} + \beta_{22}) V_3 \, d\alpha_1\, d\alpha_2 \,\partial_3\left(\alpha_3 + \frac{t}{2}\right) \\ &= \int_\omega (12\nu\beta_{11} + 12\beta_{22}) V_3\left(\cdot, \frac{t}{2}\right) d\alpha_1\, d\alpha_2 \;+ R_2(\underline{V}), \\ &|R_2(\underline{V})| \le C(f)\cdot t^{5/4}\cdot |||\underline{V}|||_{3D}.\end{aligned} \tag{4.10}$$

The remaining terms on the right side of (4.9) can be handled in a similar manner. As the details get here more complicated, we collect the required results first in the following.

LEMMA 4.1. *Let $\underline{V} \in \mathcal{U}^{3D}$. Then*

$$\begin{aligned}&-\frac{12}{t}\big(\kappa_{11} + \nu\kappa_{22}, V_{1,1}(\alpha_3 + \alpha_3^2)\big) \\ &= t^2\int_\omega (\kappa_{11,11} + \nu\kappa_{22,11}) V_3\left(\cdot, \frac{t}{2}\right) d\alpha_1\, d\alpha_2 + R_3(\underline{V}),\end{aligned} \tag{4.11}$$

$$\begin{aligned}&-\frac{12}{t}\left((1-\nu)\kappa_{12}, \frac{\alpha_3 V_{1,2}}{(1+\alpha_3)^2} + \frac{\alpha_3 V_{2,1}}{1+\alpha_3}\right) \\ &= t^2\int_\omega 2(1-\nu)\kappa_{12,12} V_3\left(\cdot, \frac{t}{2}\right) d\alpha_1\, d\alpha_2 + R_4(\underline{V}),\end{aligned} \tag{4.12}$$

$$\begin{aligned}&-\frac{12}{t}\big(\nu\kappa_{11} + \kappa_{22}, \alpha_3(V_{2,2} + V_3)\big) - t(K_1, V_2) \\ &= t^2\int_\omega (\nu\kappa_{11,22} + \kappa_{22,22}) V_3\left(\cdot, \frac{t}{2}\right) d\alpha_1\, d\alpha_2 + R_5(\underline{V}),\end{aligned} \tag{4.13}$$

where $|R_j(\underline{V})| \le C(f)\cdot t^{3/4}\cdot |||\underline{V}|||_{3D}, j = 3, 4, 5.$

End of the proof of Theorem 4.1. It follows from (4.8c) and (4.9)–(4.13) that for all $\underline{V} \in \mathcal{U}^{3D}$, $\mathcal{A}^{3D}(\underline{U}_B^K - \underline{\tilde{U}}_B^{3D}, \underline{V}) = \sum_{j=1}^5 R_j(\underline{V})$. By the above estimates, the assertion of Theorem 4.1 follows. □

Thus it suffices to prove Lemma 4.1.
Proof of (4.11).

$$\begin{aligned}
&-\frac{12}{t}(\kappa_{11}+\nu\kappa_{22}, V_{1,1}(\alpha_3+\alpha_3^2))\\
&\quad=\frac{12}{t}\int_\Omega(\kappa_{11,1}+\nu\kappa_{22,1})V_1\,d\alpha_1\,d\alpha_2\,\partial_3\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)+r_1\\
&\quad=-\frac{12}{t}\left(\kappa_{11,1}+\nu\kappa_{22,1},(2e_{13}(\underline{V})-V_{3,1})\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)+r_1\\
&\quad=-\frac{12}{t}\left(\kappa_{11,11}+\nu\kappa_{22,11},V_3\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)+r_1+r_2\\
&\quad=-\frac{12}{t}\int_\Omega(\kappa_{11,11}+\nu\kappa_{22,11})V_3\,d\alpha_1\,d\alpha_2\,\partial_3\left(\frac{\alpha_3^3}{6}-\frac{\alpha_3t^2}{8}-\frac{t^3}{24}\right)+r_1+r_2\\
&\quad=t^2\int_\omega(\kappa_{11,11}+\nu\kappa_{22,11})V_3\left(\cdot,\frac{t}{2}\right)\,d\alpha_1\,d\alpha_2+r_1+r_2+r_3.
\end{aligned}$$

By (4.6), $|R_3(\underline{V})|=\left|\sum_{i=1}^3 r_i(\underline{V})\right|\le C(f)\cdot t^{3/4}\cdot|||\underline{V}|||$ and the assertion follows.
Proof of (4.12).

$$\begin{aligned}
&-\frac{12(1-\nu)}{t}\left(\kappa_{12},\frac{\alpha_3V_{1,2}}{(1+\alpha_3)^2}+\frac{\alpha_3V_{2,1}}{1+\alpha_3}\right)\\
&=-\frac{12(1-\nu)}{t}\int_\Omega\kappa_{12}\left(\frac{V_{1,2}}{(1+\alpha_3)^2}+\frac{V_{2,1}}{1+\alpha_3}\right)\,d\alpha_1\,d\alpha_2\,\partial_3\left((1+\alpha_3)^2\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)+r_1\\
&=-\frac{12(1-\nu)}{t}\left(\kappa_{12,2}\left(V_{1,3}-\frac{2V_1}{1+\alpha_3}\right)+\kappa_{12,1}\left(V_{2,3}(1+\alpha_3)-V_2\right),\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)+r_1\\
&=I+II+r_1.
\end{aligned}$$

Taking into account that $V_{1,3}=2e_{13}-V_{3,1}$ and also that

$$||V_1||_{L_2(\Omega)}\le||e_{11}(\underline{V})||_{L_2(\Omega)},$$

we have integrating by parts;

$$\begin{aligned}
I&=-\frac{12(1-\nu)}{t}\left(\kappa_{12,12},V_3\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)+r_2\\
&=t^2\int_\omega(1-\nu)\kappa_{12,12}V_3\left(\cdot,\frac{t}{2}\right)\,d\alpha_1\,d\alpha_2+r_2+r_3,
\end{aligned}$$

where the last equality follows in the same way as in the previous proof. Similarly,

$$\begin{aligned}
II=&-\frac{12}{t}(1-\nu)\left(\kappa_{12,1},(2(1+\alpha_3)e_{23}(\underline{V})-V_{3,2})\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)\\
=&t^2\int_\omega(1-\nu)\kappa_{12,12}V_3\left(\cdot,\frac{t}{2}\right)\,d\alpha_1\,d\alpha_2+r_4.
\end{aligned}$$

By (4.6), $|R_4(\underline{V})|=\left|\sum_{i=1}^4 r_i(\underline{V})\right|\le C(f)\cdot t^{5/4}\cdot|||\underline{V}|||$, and also this part of the proof is complete.

Proof of (4.13).

$$
\begin{aligned}
&-\frac{12}{t}\left(\nu\kappa_{11}+\kappa_{22},\alpha_3(V_{2,2}+V_3)\right)\\
&\quad=-\frac{12}{t}\left(\nu\kappa_{11}+\kappa_{22},(V_{2,2}+V_3)\left(\alpha_3+2\alpha_3^2-\frac{t^2}{4}\right)\right)+r_1\\
&\quad=I+II+r_1,
\end{aligned}
$$

where

$$
\begin{aligned}
I=&-\frac{12}{t}\left(\nu\kappa_{11}+\kappa_{22},V_{2,2}\left(\alpha_3+2\alpha_3^2-\frac{t^2}{4}\right)\right)\\
=&\frac{12}{t}\int_\Omega(\nu\kappa_{11,2}+\kappa_{22,2})\frac{V_2}{1+\alpha_3}\;d\alpha_1\;d\alpha_2\;\partial_3\left((1+\alpha_3)^2\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}\right)\right)\\
=&t^2\int_\omega(\nu\kappa_{11,22}+\kappa_{22,22})V_3\left(\cdot,\frac{t}{2}\right)d\alpha_1\;d\alpha_2+r_2.
\end{aligned}
$$

Rewriting $-t(K_1,V_2)=-t(\nu\kappa_{11}+\kappa_{22},V_3)+r_3$, we have

$$
\begin{aligned}
II-t(K_1,V_2)=&-\frac{12}{t}\int_\Omega(\nu\kappa_{11}+\kappa_{22})V_3\;d\alpha_1\;d\alpha_2\;\partial_3\left(\frac{\alpha_3^2}{2}-\frac{t^2}{8}+\frac{2\alpha_3^3}{3}-\frac{t^2\alpha_3}{4}\right)\\
&-t\int_\Omega(\nu\kappa_{11}+\kappa_{22})V_3\;d\alpha_1\;d\alpha_2\;\partial_3(\alpha_3)+r_3=r_3+r_4.
\end{aligned}
$$

Defining $R_5(\underline{V})=\sum_{i=1}^4 r_i$, we again conclude from (4.6) that

$$
|R_5(\underline{V})|=\left|\sum_{i=1}^4 r_i(\underline{V})\right|\le C(f)\cdot t^{5/4}\cdot|||\underline{V}|||_{3D},
$$

and so, combining the above identities, the last part of Lemma 4.1 is proved. □

To prove (4.3) we cite first from Lemma A.1 that $\underline{u}_A^K\in[C^\infty_{\text{per}}(\overline{\omega})]^3$ and that

$$
||u_A^K||_{5,\omega}+||v_A^K||_{6,\omega}+||w_A^K||_{4,\omega}=\mathcal{O}(1). \tag{4.14}
$$

THEOREM 4.2. $|||\underline{U}_A^{3D}-\underline{U}_A^K|||_{3D}=\mathcal{O}(t)$.

Proof. First of all, we can replace $\underline{U}_A^{3D}$ by $\underline{\tilde{U}}_A^{3D}=\frac{1}{\gamma}\underline{U}_A^{3D}$ so that $\underline{\tilde{U}}_A^{3D}-\underline{U}_A^K$ is kinematically admissible. Proceeding then exactly in the same way as in the previous proof, we find that $\mathcal{A}^{3D}(\underline{U}_A^K-\underline{\tilde{U}}_A^{3D},\underline{V})=\delta(\underline{V})$ for all $\underline{V}\in\mathcal{U}^{3D}$. Using estimates (4.14) we can easily verify that in this case $|\delta(\underline{V})|\le C(f)\cdot t\cdot|||\underline{V}|||_{3D}$. Hence the assertion follows. □

THEOREM 4.3. $|||\underline{U}_C^{3D}|||_{3D}=\mathcal{O}(\delta_\nu t^{1/2})$.

Proof. Let $\underline{U}=(U_1,U_2,U_3)$, where $U_1=U_2=0$ and

$$
U_3=\gamma\frac{\nu}{1-\nu}\left(\alpha_3 tr\underline{\underline{\beta}}(\underline{u}^K)-\frac{1}{2}\alpha_3^2 tr\underline{\underline{\kappa}}(\underline{u}^K)\right)e^{-\alpha_1(1-\alpha_1)/t}.
$$

Then by the definition of $\underline{U}_C^{3D}$, and by (4.6) and (4.14),

$$
|||\underline{U}_C^{3D}|||_{3D}\le|||\underline{U}|||_{3D}=\mathcal{O}(\delta_\nu t^{1/2}).
$$

□

Remark 4.1. Let us show that (4.2), and thus (1.1b), is the best possible estimate. We assume that $f \equiv 1$. In that case the solution of (4.8) is of the form $\big(u_B^K(\alpha_1), 0, w_B^K(\alpha_1)\big)$. After a simple computation, we get

$$\begin{aligned} w_B^K = & C_0 + C_1 e^{-A\alpha_1}\cos A\alpha_1 + C_2 e^{-A\alpha_1}\sin A\alpha_1 \\ & + C_3 e^{A\alpha_1}\cos A\alpha_1 + C_4 e^{A\alpha_1}\sin A\alpha_1, \end{aligned} \tag{4.15}$$

where $A = \big(3(1-\nu)\big)^{1/4} t^{-1/2}$. Taking into account the desired boundary conditions and also the constraint

$$\int_0^1 \big(12 w_B^K + (w_B^K)^{(4)}\big)\, d\alpha_1 = 0,$$

which follows from (4.8c), we get five linearly independent equations for the coefficients C_i in (4.15). Using symbolic calculus (MATHEMATICA) we obtain the exact estimates

$$C_0 = \mathcal{O}(\delta_\nu t^{1/2}),\quad C_1 = \mathcal{O}(1),\quad C_2 = \mathcal{O}(1),\quad C_3 = \mathcal{O}(e^{-A}),\quad C_4 = \mathcal{O}(e^{-A}). \tag{4.16}$$

Further, u_B^K can be solved from (4.8a):

$$u_B^K = -\nu \int_0^{\alpha_1} w_B^K(\tau)\, d\tau + \nu\alpha_1 \int_0^1 w_B^K(\tau)\, d\tau. \tag{4.17}$$

By (4.15), (4.16), and (4.17),

$$\lim_{t\to 0} t^{-3/4} \|e_{22}(\underline{U}_B^K)\|_{L_2(\Omega)} \sim \lim_{t\to 0} t^{-1/4} \|\beta_{22}\|_{L_2(\omega)} \sim \mathcal{O}(1),$$

and hence (4.2) cannot be improved.

Next, let us define the interior domain of the cylinder,

$$\Omega_\delta := \big\{(\alpha_1, \alpha_2, \alpha_3) \in \Omega \mid \delta < \alpha_1 < 1 - \delta\,\big\},\qquad 0 < \delta < \tfrac{1}{2},$$

and also the corresponding energy norm

$$|||\underline{U}|||_\delta^2 = D^{-1} \int_{\Omega_\delta} \left\{ \lambda\big(tr\ \underline{\underline{e}}(\underline{U})\big)^2 + \mu \sum_{i,j} e_{ij}(\underline{U})^2 \right\} (1+\alpha_3)\, d\alpha_1\, d\alpha_2\, d\alpha_3.$$

It follows from (4.15), (4.16), and (4.17) that

$$|||\underline{U}_B^K|||_\delta = \mathcal{O}(t^{1/4} e^{-\delta t^{-1/2}} + \delta_\nu t^{1/2}). \tag{4.18}$$

This shows that $\underline{U}_B^K$ is a true bondary layer only if $\nu = 0$. Anyhow, it follows from (4.1)–(4.5) and (4.18) that

$$|||\underline{U}^K - \underline{U}^L|||_\delta \le C(f)(t + \delta_\nu t^{1/2}),\qquad \delta \ge t^{1/2}\ln(t^{-3/4}), \tag{4.19}$$

so the interior convergence rate is faster than the global one.

5. The clamped-free case. In this last section we consider the case where the boundary at $\alpha_1 = 1$ is free. The splitting of $\underline{U}^K$ and $\underline{U}^{3D}$ is otherwise similar to the previous chapter, but now the boundary values are only fixed at the clamped end.

We are going to prove that (4.1)–(4.5) still hold with one exception, namely, that the second part of (4.1) must be rewritten as

$$|||\underline{u}_A^K - \underline{u}^0|||_{K,t} = \mathcal{O}(t^{5/4}). \tag{4.1$'$}$$

Again (4.1′) and (4.2) are consequences of Lemmas A.1 and A.2, respectively. To prove the rest, we proceed exactly in the same way as in §4. Using the natural boundary conditions

$$\begin{aligned} &\beta_{11}^K + \nu\beta_{22}^K = 0, \quad && 6\beta_{12}^K - t^2\kappa_{12}^K = 0, \\ &\kappa_{11}^K + \nu\kappa_{22}^K = 0, \quad && \kappa_{11,1}^K + \nu\kappa_{22,1}^K + 2(1-\nu)\kappa_{12,2}^K = 0 \end{aligned} \tag{5.1}$$

at the free end, we find that

$$\mathcal{A}^{3D}(\underline{U}_X^K - \underline{\tilde{U}}_X^{3D}, \underline{V}) = \delta_X(\underline{V}) - \int_\Gamma \underline{g}^X \cdot \underline{V}(1,\cdot,\cdot)\, d\alpha_2\, d\alpha_3$$

for all $\underline{V} \in \boldsymbol{\mathcal{U}}^{3D}$, where X stands for either A or B, $\Gamma = \{(1, \alpha_2, \alpha_3) \in \overline{\Omega}\}$,

$$\underline{g}^X = \frac{12}{t}(1-\nu)\left\{0,\ \kappa_{12}^X(1,\alpha_2)\left(\alpha_3 + 2\alpha_3^2 - \frac{t^2}{4}\right),\ \kappa_{12,2}^X(1,\alpha_2)\left(\frac{\alpha_3^2}{2} - \frac{t^2}{8}\right)\right\},$$

and where $\delta_X(\underline{V}) = \sum_{j=1}^5 R_j(\underline{V})$ consists of the same residual terms as in the proofs of Theorems 4.1 and 4.2. It follows from Lemma A.1 that $\underline{u}_A^K \in [C_{\text{per}}^\infty(\overline{\omega})]^3$ and that

$$\begin{aligned} \|\, D^\tau u_A^K\|_{L_2(\omega)} &= \mathcal{O}(1 + t^{(7-2\tau_1)/4}), \\ \|\, D^\tau v_A^K\|_{L_2(\omega)} &= \mathcal{O}(1 + t^{(9-2\tau_1)/4}), \\ \|D^\tau w_A^K\|_{L_2(\omega)} &= \mathcal{O}(1 + t^{(5-2\tau_1)/4}) \end{aligned} \tag{5.2}$$

for every multi-index $\tau = (\tau_1, \tau_2)$. Using (5.2) and (4.6), which is valid also in the clamped-free case, we get, as in the previous section,

$$|\delta_A(\underline{V})| \le C(f)\cdot t \cdot |||\underline{V}|||_{3D}, \qquad |\delta_B(\underline{V})| \le C(f)\cdot t^{3/4}\cdot |||\underline{V}|||_{3D}. \tag{5.3}$$

We need finally an estimate for the displacement field $\underline{U}^X \in U^{3D}$ defined so that

$$\mathcal{A}^{3D}(\underline{U}^X, \underline{V}) = \int_\Gamma \underline{g}^X \cdot \underline{V}(1,\cdot,\cdot)\, d\alpha_2\, d\alpha_3, \quad \underline{V} \in \boldsymbol{\mathcal{U}}^{3D}. \tag{5.4}$$

In the Appendix (see Lemma A.4) we prove that

$$|||\underline{U}^X|||_{3D} = \mathcal{O}(t). \tag{5.5}$$

After these preliminaries, the main result of this chapter can be stated.

THEOREM 5.1. *Theorems* 4.1, 4.2, *and* 4.3 *hold also in the clamped-free case.*

Proof. Observing that

$$\mathcal{A}^{3D}(\underline{U}_X^K + \underline{U}^X - \underline{\tilde{U}}_X^{3D}, \underline{U}_X^K + \underline{U}^X - \underline{\tilde{U}}_X^{3D}) = \delta_X(\underline{U}_X^K + \underline{U}^X - \underline{\tilde{U}}_X^{3D}),$$

the assertions of Theorems 4.1 and 4.2 follow from (5.3), (5.5), and the triangle inequality. Theorem 4.3 can be proved in the same way as before. □

Remark 5.1. Let us assume that $f \equiv 1$ as we did in Remark 4.1. Solving (4.8) under the relevant natural boundary conditions at $\alpha_1 = 1$, we find that

$$u_B^K(\alpha_1) = -\nu \int_0^{\alpha_1} w_B^K(\tau)\, d\tau,$$

and w_B^K is of the form (4.15), where this time

$$C_0 = 0, \quad C_1 = \mathcal{O}(1), \quad C_2 = \mathcal{O}(1), \quad C_3 = \mathcal{O}(e^{-2A}), \quad C_4 = \mathcal{O}(e^{-2A}).$$

It turns out easily that (4.2) cannot be improved, but now $\underline{U}_B^K$ is a pure boundary layer. Estimate (4.19) can this time be rewritten as

$$|||\underline{U}^K - \underline{U}^0|||_\delta = \mathcal{O}(t), \qquad \delta \geq t^{1/2}\ln(t^{-3/4}),$$

where now $\Omega_\delta = \{\underline{\alpha} \in \Omega |\ \alpha_1 > \delta\}$ and $|||\cdot|||_\delta$ is the corresponding norm.

Appendix. Here we (1) study the regularity properties of the displacement field $\underline{u}^K$ as defined according to the Koiter–Sanders–Novozhilov shell model, and (2) prove estimate (5.5) related to the three-dimensional model. The analysis is based on Fourier expansions.

First consider the dimensionally reduced model. Here we expand the load and the displacement field as

$$f = \sum_{k=0}^{\infty} \big(f^{ck}(\alpha_1)\cos k\alpha_2 + f^{sk}(\alpha_1)\sin k\alpha_2\big),$$

$$(u,v,w) = \sum_{k=0}^{\infty} \big(u^{ck}(\alpha_1)\cos k\alpha_2,\ v^{ck}(\alpha_1)\sin k\alpha_2,\ w^{ck}(\alpha_1)\cos k\alpha_2\big)$$
$$+ \sum_{k=1}^{\infty} \big(u^{sk}(\alpha_1)\sin k\alpha_2, -v^{sk}(\alpha_1)\cos k\alpha_2,\ w^{sk}(\alpha_1)\sin k\alpha_2\big).$$

It is easy to check that the energy is then split orthogonally as

$$F^K(\underline{u}) = \sum_{k=0}^{\infty} c_k F_{ck}^K(u^{ck}, v^{ck}, w^{ck}) + \sum_{k=1}^{\infty} c_k F_{sk}^K(u^{sk}, v^{sk}, w^{sk}),$$

where $c_0 = 2\pi$, $c_k = \pi$ for $k \geq 1$, and

$$F_{ck}^K(\underline{u}) = \tfrac{1}{2}\{t^2\mathcal{A}_k^F(\underline{u},\underline{u}) + \mathcal{B}_k^F(\underline{u},\underline{u})\} - q_{ck}^F(\underline{u}),$$
$$F_{sk}^K(\underline{u}) = \tfrac{1}{2}\{t^2\mathcal{A}_k^F(\underline{u},\underline{u}) + \mathcal{B}_k^F(\underline{u},\underline{u})\} - q_{sk}^F(\underline{u}),$$

where further

$$q_{ck}^F(\underline{u}) = \int_0^1 f^{ck} w\, d\alpha_1, \qquad q_{sk}^F(\underline{u}) = \int_0^1 f^{sk} w\, d\alpha_1,$$

$$\mathcal{A}_k^F(\underline{u},\underline{u}) = \int_0^1 \left\{ \nu(tr\underline{\underline{\kappa}}^k)^2 + (1-\nu)\sum_{i,j=1}^{2}(\kappa_{ij}^k)^2 \right\} d\alpha_1,$$

$$\mathcal{B}_k^F(\underline{u},\underline{u}) = 12\int_0^1 \left\{ \nu(tr\underline{\underline{\beta}}^k)^2 + (1-\nu)\sum_{i,j=1}^{2}(\beta_{ij}^k)^2 \right\} d\alpha_1 \quad \text{with}$$

$$\beta_{11}^k = u', \quad \beta_{12}^k = \tfrac{1}{2}(-ku + v'), \quad \beta_{22}^k = kv + w,$$
$$\kappa_{11}^k = w'', \quad \kappa_{12}^k = -kw' - v', \quad \kappa_{22}^k = -k^2 w - kv.$$

Due to the orthogonality of the above, splitting it suffices to consider one Fourier component of $\underline{u}^K$ at a time in proving regularity estimates. Thus assume $f = g(\alpha_1)\cos k\alpha_2$ or $f = g(\alpha_1)\sin k\alpha_2$ define the energy space

$$\boldsymbol{\mathcal{U}} = \{\underline{u} \in [H^1(I)]^2 \times H^2(I) \mid \underline{u} = w' = 0 \text{ at the clamped endpoints}\},$$

where $\underline{u} = (u, v, w)$ and $I = (0,\ 1)$, and consider the variational problem.

Find $\underline{u}^k \in \boldsymbol{\mathcal{U}}$ such that

$$\text{(A.1)} \qquad t^2 \mathcal{A}_k^F(\underline{u}^k, \underline{\tilde{v}}) + \mathcal{B}_k^F(\underline{u}^k, \underline{\tilde{v}}) = \int_I g\tilde{w}\, d\alpha_1 \qquad \text{for all } \underline{\tilde{v}} \in \boldsymbol{\mathcal{U}}.$$

Below we denote by $|||\cdot|||_k$ the corresponding energy norm and by $||\cdot||_{s,I}$, $s \geq 0$, the norm of the Sobolev space $H^s(I)$.

Next, we denote by $\underline{u}_0^k$ the limit of $\underline{u}^k$ as $t \to 0$ and split then $\underline{u}^k$ as $\underline{u}^k = \underline{u}_A^k + \underline{u}_B^k$, where $\underline{u}_A^k$ satisfies (A.1) together with the inhomogeneous boundary conditions

$$u_A^k = u_0^k, \quad v_A^k = v_0^k, \quad w_A^k = w_0^k, \quad (w_A^k)' = (w_0^k)'$$

at the the clamped ends. Then $\underline{u}_B^k$ satisfies (A.1) with $g = 0$, together with the boundary conditions

$$u_B^k = -u_0^k, \quad v_B^k = -v_0^k, \quad w_B^k = -w_0^k, \quad (w_B^k)' = -(w_0^k)'$$

at the clamped ends.

In the four lemmas below we use the abbreviation $\mathcal{O}(\phi(t))$ for a quantity bounded by $c(p,k)\phi(t)||g||_{p,I}$ for some finite p, where the dependence on parameter k is algebraic, i.e., there exists $m = m(p) \in N$ such that, $c(p,k) \leq c(p)k^m$.

LEMMA A.1. *For any* $s \geq 0$,

$$\begin{aligned} ||u_A^k - u_0^k||_{s,I} &= t^{-\sigma}\mathcal{O}(t^2 + t^{(5-s)/2}), \\ ||v_A^k - v_0^k||_{s,I} &= t^{-\sigma}\mathcal{O}(t^2 + t^{(6-s)/2}), \\ ||w_A^k - w_0^k||_{s,I} &= t^{-\sigma}\mathcal{O}(t^{(4-s)/2}), \end{aligned}$$

where $\sigma = 0$ *in the clamped-clamped case and* $\sigma = \frac{3}{4}$ *in the clamped-free case.*

LEMMA A.2. *For any* $s \geq 0$,

$$\begin{aligned} ||u_B^k\ || &= t^{-\sigma}\mathcal{O}(t^{1/4} + t^{(3-2s)/4}), \\ ||v_B^k\ || &= t^{-\sigma}\mathcal{O}(t^{1/4} + t^{(5-2s)/4}), \\ ||w_B^k|| &= t^{-\sigma}\mathcal{O}(t^{(1-2s)/4}), \end{aligned}$$

where $\sigma = 0$ *if* $||\cdot|| = ||\cdot||_{s,I}$ *and* $\sigma = \frac{1}{4}$ *if* $||u|| = \sum_{m \leq s} ||D^m u||_{L_\infty(I)}$.

LEMMA A.3. *Assume the clamped-free case. Then for* $0 \leq m \leq 3$,

$$(u_B^k)^{(m)}(1) = \mathcal{O}(1), \quad (v_B^k)^{(m)}(1) = \mathcal{O}(1), \quad (w_B^k)^{(m)}(1) = \mathcal{O}(1).$$

Proof of Lemma A.1. Setting $\underline{u} = \underline{u}_A^k - \underline{u}_0^k \in \boldsymbol{\mathcal{U}}$, we have integrating by parts that

(A.2)

$$t^2\mathcal{A}_k^F(\underline{u},\underline{\tilde{v}}) + \mathcal{B}_k^F(\underline{u},\underline{\tilde{v}}) = t^2\left\{\int_I (h_1\tilde{v} + h_2\tilde{w})\,d\alpha_1 + \delta\big(A\tilde{w}'(1) + B\tilde{w}(1) + C\tilde{v}(1)\big)\right\}$$

for all $\underline{\tilde{v}} = (\tilde{u},\tilde{v},\tilde{w}) \in \boldsymbol{\mathcal{U}}$, where h_1 and h_2 are t–independent smooth functions, A, B, and C t-independent scalars and either $\delta = 0$ (clamped-clamped case) or $\delta = 1$ (clamped-free case). Noting that

$$\|\tilde{w}\|_{L_2(I)} \le ck^2|||\underline{\tilde{v}}|||_k, \tag{A.3a}$$

$$|\tilde{v}(1)| \le \|\tilde{v}\|_{1,I} \le ck|||\underline{\tilde{v}}|||_k \tag{A.3b}$$

for all $\underline{\tilde{v}} \in \boldsymbol{\mathcal{U}}$, we get the energy estimate

$$|||\underline{u}|||_k = \mathcal{O}(t^2) \quad \text{in the clamped-clamped case.} \tag{A.4}$$

Further,

$$\|\tilde{w}\|_{2,I} \le ct^{-1}|||\underline{\tilde{v}}|||_k, \tag{A.5a}$$

and thus by interpolation,

$$\|\tilde{w}\|_{1,I} \le ckt^{-1/2}|||\underline{\tilde{v}}|||_k. \tag{A.5b}$$

Next, writing

$$\tilde{w}^{(j)}(1) = \int_{1-\epsilon}^{1} \partial\left(\frac{\tau-1+\epsilon}{\epsilon}\tilde{w}^{(j)}(\tau)\right) = \int_{1-\epsilon}^{1}\left\{\frac{1}{\epsilon}\tilde{w}^{(j)}(\tau) + \frac{\tau-1+\epsilon}{\epsilon}\tilde{w}^{(j+1)}(\tau)\right\}\,d\tau$$

and using the Cauchy–Schwarz inequality, we get

$$|\tilde{w}^{(j)}(1)|^2 \le \frac{2}{\epsilon}\int_I [\tilde{w}^{(j)}(\tau)]^2\,d\tau + \frac{2\epsilon}{3}\int_I [\tilde{w}^{(j+1)}(\tau)]^2\,d\tau. \tag{A.6}$$

Substituting $\epsilon = t^{1/2}$ and recalling (A.3a), (A.5a), and (A.5b), we have

$$|\tilde{w}(1)| \le ck^2t^{-1/4}|||\underline{\tilde{v}}|||_k, \tag{A.7a}$$

$$|\tilde{w}'(1)| \le ckt^{-3/4}|||\underline{\tilde{v}}|||_k. \tag{A.7b}$$

By (A.2), (A.3a), (A.3b), (A.7a), and (A.7b) we get as a counterpart to (A.4),

$$|||\underline{u}|||_k = \mathcal{O}(t^{5/4}) \quad \text{in the clamped-free case.} \tag{A.8}$$

By (A.3), (A.4), (A.5), and (A.8) we further get the a priori estimates

$$\|u\|_{1,I} = \mathcal{O}(t^{2-\sigma}), \quad \|v\|_{1,I} = \mathcal{O}(t^{2-\sigma}), \quad \|w\|_{s,I} = \mathcal{O}(t^{(4-s-2\sigma)/2}), \quad 0 \le s \le 2,$$

with σ as in Lemma A.1. Applying these results in the Euler equations

$$u'' = \tfrac{1}{2}k^2(1-\nu)u - \tfrac{1}{2}k(1+\nu)v' - \nu w', \tag{A.9a}$$

$$v'' = c\left\{t^2h_1 - 6k\big((1+\nu)u' + 2(kv+w)\big) + kt^2\big((2-\nu)w'' - k^2w - kv\big)\right\}, \tag{A.9b}$$

$$w^{(4)} = h_2 + 2k^2w'' - k^4w + k(2-\nu)v'' - k^3v - 12t^{-2}(\nu u' + kv + w), \tag{A.9c}$$

where $c = -1/\big(2(1-\nu)(3+t^2)\big)$, we get the a posteriori estimates for $||u||_{2,I}$, $||v||_{2,I}$ and $||w||_{4,I}$. Finally, differentiating in (A.9), the proof is completed by induction and interpolation. □

Proof of Lemma A.2. Let $\underline{u} \in \boldsymbol{\mathcal{U}}$ be such that $u = v = 0$ and $w = -w_0^k(\alpha_1)\cdot\rho(\alpha_1)$, where in the clamped-clamped case

$$\rho(\alpha_1) = e^{-t^{-1/2}\alpha_1(1-\alpha_1)}\big(\cos t^{-1/2}\alpha_1(1-\alpha_1) + \sin t^{-1/2}\alpha_1(1-\alpha_1)\big),$$

and in the clamped-free case

$$\rho(\alpha_1) = e^{-t^{-1/2}\alpha_1}(\cos t^{-1/2}\alpha_1 + \sin t^{-1/2}\alpha_1).$$

Then $t^2\mathcal{A}_k^F(\underline{u},\underline{u}) + \mathcal{B}_k^F(\underline{u},\underline{u}) = \mathcal{O}(t^{1/2})$ and since $\underline{u}_B^k$ minimizes in $\boldsymbol{\mathcal{U}}$ this functional, we get the a priori estimates

$$||u_B^k||_{1,I} = \mathcal{O}(t^{1/4}), \quad ||v_B^k||_{1,I} = \mathcal{O}(t^{1/4}), \quad ||w_B^k||_{s,I} = \mathcal{O}(t^{(1-2s)/4}), \quad 0 \le s \le 2.$$

Applying these results in Euler equations (A.9), where now and in the sequel $h_1 = h_2 = 0$, the assertion with $||\cdot|| = ||\cdot||_{s,I}$ follows. Noting that (A.6) holds with 1 and $\tilde{w}$ replaced by any $\alpha_1 \in I$ and smooth function g, the second part of the assertion follows by recalling the Sobolev-norm estimates already obtained. □

Proof of Lemma A.3. In this proof we use the notation $(u,v,w) \leftarrow (u_B^k, v_B^k, w_B^k)$. Furthermore, we make change of variable $\alpha_1 \leftarrow 1-\alpha_1$ so as to switch the clamped and free ends.

By (A.6) and Lemma A.2, $w(0) = \mathcal{O}(1)$. By the same argument $u^{(j)}(0) = \mathcal{O}(1)$ for $j = 0,1$ and $v^{(j)}(0) = \mathcal{O}(1)$ for $j = 0,1,2$. Taking into account equations (A.9), the natural boundary conditions

$$\text{(A.10)} \qquad w''(0) = \nu\big(k^2w(0) + kv(0)\big), \qquad w^{(3)}(0) = (2-\nu)\big(k^2w'(0) + kv'(0)\big),$$

and the equation

$$u' = -\nu w - k(1-\nu)\int_0^{\alpha_1} \beta_{12}(\tau)\,d\tau - k\nu v$$

obtained from (A.9a) using the boundary condition $\beta_{11}(0) + \nu\beta_{22}(0) = 0$, it is enough to prove that $w'(0) = \mathcal{O}(1)$. Substituting the last equation into (A.9c), we get the equation of the form

$$\text{(A.11)} \qquad w^{(4)} + 4A^4w = g, \quad \text{where } A = \big(3(1-\nu^2)t^{-2} + \tfrac{1}{4}k^4\big)^{1/4} = \mathcal{O}(t^{-1/2})$$

and where by Lemma A.2, g satisfies the estimate;

$$\max_{\alpha_1\in[0,1]}\big\{|g(\alpha_1)| + |g'(\alpha_1)|\big\} = \mathcal{O}(t^{-2}).$$

By (A.11) and (A.10), we have

$$\begin{aligned}
\text{(A.12)} \qquad w(\alpha_1) &= a^{(3)}(\alpha_1)\cdot w(0) + a''(\alpha_1)\cdot w'(0) + b(\alpha_1), \quad \text{where}\\
a(\alpha_1) &= \frac{1}{4A^3}\big(\sin A\alpha_1\cdot\cosh A\alpha_1 - \cos A\alpha_1\cdot\sinh A\alpha_1\big),\\
b(\alpha_1) &= \int_0^{\alpha_1} g(\alpha_1-\tau)a(\tau)\,d\tau + a'(\alpha_1)\cdot w''(0) + a(\alpha_1)\cdot w'''(0).
\end{aligned}$$

By (A.10), $w''(0) = \mathcal{O}(1)$ and, also applying (A.6), $w'''(0) = \mathcal{O}(t^{-1/2})$ at most. Taking into account that $w(1) = -w_0^k(1)$ and $w'(1) = -(w_0^k)'(1)$, it follows from (A.12) that

$$\begin{bmatrix} w(0) \\ w'(0) \end{bmatrix} = -2\cosh^{-2} A \begin{bmatrix} a^{(3)}(1) & -a''(1) \\ -a^{(4)}(1) & a^{(3)}(1) \end{bmatrix} \cdot \begin{bmatrix} b(1) + w_0^k(1) \\ b'(1) + (w_0^k)'(1) \end{bmatrix}. \tag{A.13}$$

Noting that $a^{(4)}(\alpha_1) = -4A^4 a(\alpha_1)$ and also that $a^{(3)}(0) = 1$, we have, integrating by parts,

$$b(1) = -\frac{g(0)a^{(3)}(1)}{4A^4} + \mathcal{O}(t^{1/2}e^A).$$

On the other hand, $b'(1) = g(0)a(1) + \mathcal{O}(e^A)$, and thus

$$-a^{(4)}(1)b(1) + a^{(3)}(1)b'(1) = 4A^4 a(1)b(1) + a^{(3)}(1)b'(1) = \mathcal{O}(e^{2A}).$$

The assertion follows now from (A.13). □

We prove finally the energy estimate (5.5) for the solution of (5.4). In the same way as above, the solution of (5.4) can be expanded into Fourier series

$$\begin{aligned} \underline{U}^X = & \sum_{k=0}^{\infty} \big(U_1^{ck}(\alpha_1,\alpha_3)\cos k\alpha_2,\ U_2^{ck}(\alpha_1,\alpha_3)\sin k\alpha_2,\ U_3^{ck}(\alpha_1,\alpha_3)\cos k\alpha_2\big) \\ & + \sum_{k=1}^{\infty} \big(U_1^{sk}(\alpha_1,\alpha_3)\sin k\alpha_2,\ -U_2^{sk}(\alpha_1,\alpha_3)\cos k\alpha_2,\ U_3^{sk}(\alpha_1,\alpha_3)\sin k\alpha_2\big). \end{aligned}$$

Each component $(U_1^{\cdot k}, U_2^{\cdot k}, U_3^{\cdot k}) \in \mathcal{U}^{2D}$ satisfies the variational equation

$$\begin{aligned} & \mathcal{A}^{2D}(\underline{U}^X, \underline{V}) \\ & = D^{-1} \int_{\tilde\Omega} \left\{ \lambda\, tr\underline{\underline{e}}(\underline{U}^X) tr\underline{\underline{e}}(\underline{V}) + \mu \sum_{i,j=1}^{3} e_{ij}(\underline{U}^X) e_{ij}(\underline{V}) \right\} (1+\alpha_3)\, d\alpha_1\, d\alpha_3 \\ & = \int_{\tilde\Gamma} \underline{g}^X(\alpha_3) \cdot \underline{V}(1,\alpha_3)\, d\alpha_3, \qquad \underline{V} \in \mathcal{U}^{2D}, \end{aligned}$$

where $\tilde\Gamma = (-t/2, t/2)$, $\tilde\Omega = I \times \tilde\Gamma$, $\underline{\underline{e}}$ is the strain tensor corresponding to $\underline{V}$,

$$\begin{aligned} e_{11} &= V_{1,1}, & e_{22} &= \chi(kV_2 + V_3), \\ e_{12} &= \tfrac{1}{2}\,(-\chi k V_1 + V_{2,1}), & e_{23} &= \tfrac{1}{2}\,\big(V_{2,3} - \chi(kV_3 + V_2)\big), \\ e_{13} &= \tfrac{1}{2}\,(V_{1,3} + V_{3,1}), & e_{33} &= V_{3,3}, \end{aligned}$$

and finally

$$\underline{g}^X(\alpha_3) = \frac{12(1-\nu)\kappa_{12}^X(1)}{t} \left(0,\ \alpha_3 + 2\alpha_3^2 - \frac{t^2}{4},\ k\left(\frac{\alpha_3^2}{2} - \frac{t^2}{8}\right)\right).$$

Above, κ_{12}^X is the Fourier component of κ_{12}^X corresponding to $f^{\cdot k}$. Due to the orthogonality of the basis functions, (5.5) holds if we prove the following.

LEMMA A.4. $|||\underline{U}^X|||_{2D} = \mathcal{O}(t)$.

Proof. It follows from Lemmas A.1 (in the spirit of (A.6)) and A.3 that independently of X,

$$(\text{A.14}) \qquad \|\hat{g}_2^X\|_{L_2(\tilde{\Gamma})} = \mathcal{O}(t^{1/2}), \qquad \|g_3^X\|_{L_2(\tilde{\Gamma})} = \mathcal{O}(t^{3/2}).$$

Further, we obtain easily the estimates

$$(\text{A.15a}) \qquad \|V_2\|_{L_2(\tilde{\Omega})} \le \|V_{2,1}\|_{L_2(\tilde{\Omega})} \le ckt^{1/2}|||\underline{V}|||_{2D},$$

$$(\text{A.15b}) \qquad \|V_3\|_{L_2(\tilde{\Omega})} \le ck^2t^{1/2}|||\underline{V}|||_{2D}$$

for all $\underline{V} \in \mathcal{U}^{2D}$. Then, if $\underline{V} \in \mathcal{U}^{2D}$, let

$$\hat{\underline{V}}(\alpha_1, \gamma_3) = \big(V_1(\alpha_1,\ t\gamma_3), tV_3(\alpha_1, t\gamma_3)\big), \qquad \gamma_3 \in (-\tfrac{1}{2},\ \tfrac{1}{2}) := J.$$

Using the Korn inequality, we get

$$\begin{aligned}
&\int_{\tilde{\Omega}} \left(V_{1,1}^2 + \frac{1}{2}(V_{1,3} + V_{3,1})^2 + V_{3,3}^2\right) d\alpha_1\, d\alpha_3 \\
&\quad = \int_{I\times J} \left(\hat{V}_{1,1}^2 + \frac{1}{2}t^{-2}(\hat{V}_{1,3} + \hat{V}_{3,1})^2 + t^{-4}\hat{V}_{3,3}^2\right) d\alpha_1\, d\gamma_3 \\
&\quad \ge ct\left(|\hat{V}_1|_{1,I\times J}^2 + |\hat{V}_3|_{1,I\times J}^2\right) \\
&\quad = c\int_{\tilde{\Omega}} \left(V_{1,1}^2 + t^2V_{1,3}^2 + t^2V_{3,1}^2 + t^4V_{3,3}^2\right) d\alpha_1\, d\alpha_3,
\end{aligned}$$

where c is independent of $\underline{V}$ and t. Thus,

$$(\text{A.16}) \qquad \|V_{3,1}\|_{L_2(\tilde{\Omega})} \le Ct^{-1/2}\ |||\underline{V}|||_{2D}, \qquad \underline{V} \in \mathcal{U}^{2D}.$$

Proceeding as in (A.6), we have

$$|V_i(1,\alpha_3)|^2 \le \frac{2}{\epsilon}\int_I |V_i(\tau,\alpha_3)|^2\, d\tau + \frac{2\epsilon}{3}\int_I |V_{i,1}(\tau,\alpha_3)|^2\, d\tau.$$

Then, integrating with respect to α_3, recalling (A.15) and (A.16) and substituting $\epsilon = 1$ if $i = 2$ and $\epsilon = t$ if $i = 3$, we obtain

$$\|V_2(1,\cdot)\|_{L_2(\tilde{\Gamma})} \le ckt^{1/2}|||\underline{V}|||_{2D}, \qquad \|V_3(1,\cdot)\|_{L_2(\tilde{\Gamma})} \le ck^2|||\underline{V}|||_{2D}$$

for all $\underline{V} \in \mathcal{U}^{2D}$. The assertion now follows from these inequalities, together with (A.14). □

WEAK SOLUTIONS OF SOME QUASILINEAR ELLIPTIC EQUATIONS WITH DATA MEASURES*

NOUR EDDINE ALAA† AND MICHEL PIERRE†

Abstract. Existence and uniqueness of weak solutions for some quasilinear elliptic equations with data measures and arbitrary growth with respect to the gradient are studied. Usual techniques based on a priori L^∞-bounds for the solutions and its gradient do not apply so that a new approach is needed. Various necessary or sufficient conditions are obtained on the data for existence. Relationship between existence of supersolutions and solutions is considered. Finally, sharp uniqueness results for weak solutions are given.

Key words. quasilinear equations, elliptic, convex nonlinearities, data measures, nonlinear capacities

AMS(MOS) subject classifications. 35J65, 35J25, 31C45

1. Introduction. This paper describes some results concerning existence and uniqueness of weak solutions for equations of the form

$$\alpha u - \Delta u = j(x, u, \nabla u) + \lambda f, \quad u \geqq 0 \quad \text{on } \Omega \tag{1.1}$$

$$u = 0 \quad \text{on } \delta\Omega, \tag{1.2}$$

where Ω is a bounded open set in $\mathbb{R}^N$, α, λ are nonnegative real numbers, j: $\Omega \times \mathbb{R} \times \mathbb{R}^N \to [0, \infty)$ measurable and continuous with respect to u and ∇u, and f: $\Omega \to [0, \infty)$ a nonnegative integrable function or, more generally a given finite nonnegative measure on Ω. We are particularly interested in situations where f is irregular and where the growth of j with respect to ∇u is arbitrary and, in particular, larger than $|\nabla u|^2$ for large $|\nabla u|$. The fact that f is not regular requires that one deals with "weak" solutions for which ∇u and even u itself are not bounded. As a consequence the techniques usually used to prove existence and based on a priori L^∞-estimates on u and ∇u fail. Let us make this more precise on a model problem like

$$\begin{gathered} u \in W_0^{1,p}(\Omega), \\ \alpha u - \Delta u = |\nabla u|^p + \lambda f \quad \text{on } \Omega, \end{gathered} \tag{1.3}$$

where $|\cdot|$ denotes the $\mathbb{R}^N$-euclidian norm and $p > 1$.

If $p \leqq 2$, the method of sub- and supersolutions can be used to prove existence in (1.3) if f is regular enough. For instance, if $\alpha > 0$ and $f \in L^\infty(\Omega)$, then (1.3) has a solution since $u_1 \equiv 0$ is a subsolution and $u_2 \equiv \|f\|_\infty/\alpha$ is a supersolution (see, e.g., [10], [4], [3]). The situation is quite different if $p > 2$: for instance a *size condition* is necessary on λf to have existence in (1.3) even if f is very regular. If $\alpha = 0$, the situation is even more different since the critical value is then $p = 1$. Indeed, as proved in next section, existence in (1.3) with $\alpha = 0$ and $p > 1$ requires that f be *small enough* and *regular enough.*

It is proved in Lions [12] that, if (1.3) has a nonnegative supersolution in $W_0^{1,\infty}(\Omega)$, then (1.3) has a solution (no matter the value of p). Note that here the supersolution is required to vanish at the boundary. This provides an a priori pointwise estimate for ∇u at the boundary. The boundedness on ∇u on the whole set Ω is then obtained by a maximum principle applied to the equation satisfied by $|\nabla u|^2$. The convexity of $r \to |r|^p$ is there an essential ingredient.

Obviously this approach fails to provide existence when f is not regular enough to expect $W^{1,\infty}$-solutions and new techniques have to be used. We describe some of them here.

Another difficulty is that uniqueness does not hold in general for weak solutions (although it does for regular solutions): if $f \equiv 0$ and Ω is a ball, (1.3) can have nonzero solutions (see § 3). Moreover, they are not regular: this proves that, even for good f, good a priori estimates can only be obtained for some of the solutions.

We prove in § 3 that uniqueness of solutions of (1.3) hold if and only if $p < N/(N-1)$ and that uniqueness of "strong" (i.e., in $W^{1,\infty}$) solutions hold. Section 2 is devoted to necessary conditions on the data to get existence of weak solutions in (1.1). Section 3 deals with uniqueness. Section 4 presents an existence result based on an isoperimetric inequality, for linear growth and any finite measure f. In the last section, we prove that existence of weak supersolutions implies existence of weak solutions in the case of (sub)quadratic growth. The difficulties in this section are similar to those in [8], and the techniques are of the same spirit.

2. Necessary conditions for existence. Throughout this paper, we denote by Ω a bounded open set in $\mathbb{R}^N$ with regular boundary. In this section, we are given

$$f \text{ a nonnegative finite measure on } \Omega \tag{2.1}$$

and

$$j\colon \Omega\times\mathbb{R}^N \to [0,\infty[\text{ such that}$$

$$j \text{ is measurable, a.e. } x,\ r \to j(x,r) \text{ is convex, continuous,} \tag{2.2}$$

$$\forall r \in \mathbb{R}^N \quad j(\cdot, r) \in L^1(\Omega), \tag{2.3}$$

$$j(x,0) = \min\{j(x,r),\, r\in\mathbb{R}^N\} = 0. \tag{2.4}$$

For $\lambda \in \mathbb{R}$, we consider the problem

$$\begin{aligned} &u \in W_0^{1,1}(\Omega), && j(\cdot, \nabla u) \in L^1_{\mathrm{loc}}(\Omega),\\ &-\Delta u \geqq j(\cdot,\nabla u) + \lambda f && \text{in } \mathscr{D}'(\Omega). \end{aligned} \tag{2.5}$$

We first state that, if $j(\cdot, r)$ is superlinear at infinity, then there exists $\lambda^* < \infty$ such that (2.5) does not have any solution for $\lambda > \lambda^*$. Moreover, f should also be regular enough. A rather sharp superlinearity condition on j is given next where the x-dependence is taken into account. We assume

(2.6) there exists ω open in Ω and $J\colon \mathbb{R}\to[0,\infty)$ convex, continuous with $J(0) = J'(0^+) = 0$

and

$$j(x,r) \geqq J(|r|) \quad \text{a.e. } x \in \omega, \tag{2.7}$$

$$\int^{+\infty} \frac{ds}{J(s)} < \infty, \tag{2.8}$$

$$\int_\omega f > 0. \tag{2.9}$$

THEOREM 2.1. *Assume* (2.1)-(2.4), (2.6)-(2.9) *hold. Then there exists* $\lambda^* < \infty$ *such that* (2.5) *does not have any solution for* $\lambda > \lambda^*$. *Moreover, when* (2.5) *has a solution,* *then for all nonnegative* φ *in* $C_0^\infty(\omega)$,

$$\lambda\int_\omega \varphi f \leqq \int_\omega \varphi J^*\left(\frac{|\nabla\varphi|}{\varphi}\right), \tag{2.10}$$

where J^* *is the convex conjugate function of* J.

Remarks. The growth condition (2.8) is sharp (see remarks in § 3). The introduction of ω allows the growth of $j(x, r)$ in r to depend on x. In particular, $j(x, r)$ can be sublinear for some x. However, it should be superlinear on some part of the support of f. Examples can be easily constructed in dimension 1, showing the necessity of (2.9) (see [2]).

The condition (2.10) is at the same time a size and a regularity condition on f. It is similar to those obtained in [6] for semilinear problems of the form "$-\Delta u = u^p + \lambda f$". We refer to [6], [1] for various discussions on the meaning of (2.10) (in particular for the power case) and for its relationship with nonlinear capacities.

Proof of Theorem 2.1. Assume u is a solution of (2.5). By (2.5)-(2.7), we have

$$-\Delta u \geqq J(|\nabla u|) + \lambda f \quad \text{in } \mathscr{D}'(\omega). \tag{2.11}$$

Let $\varphi \in C_0^\infty(\omega)$, $\varphi \geqq 0$. Multiply (2.11) by φ and integrate to obtain

$$\lambda\int_\omega \varphi f \leqq \int_\omega \nabla u \nabla\varphi - \varphi J(|\nabla u|) \leqq \int_\omega \varphi\left[|\nabla u|\frac{|\nabla\varphi|}{\varphi} - J(|\nabla u|)\right]. \tag{2.12}$$

If we recall that the conjugate function of J is defined by

$$\forall s \in \mathbb{R}^N, \qquad J^*(s) = \sup\{\alpha s - J(\alpha),\ \alpha \in \mathbb{R}\}, \tag{2.13}$$

we see that (2.12) implies

$$\forall\varphi \in C_0^\infty(\omega), \qquad \lambda\int_\omega \varphi f \leqq \int_\omega \varphi J^*\left(\frac{|\nabla\varphi|}{\varphi}\right). \tag{2.14}$$

This proves (2.10).

Let us now prove that this implies that λ is finite (whence the existence of λ^*). By density, (2.12) and (2.14) remain valid for $\varphi \in W_0^{1,\infty}(\omega)$. By (2.14) and (2.9), the existence of λ^* as in Theorem 2.1 will be proved if we can construct φ such that

$$\varphi \in W_0^{1,\infty}(\omega),\ \varphi > 0 \quad \text{on } \omega, \qquad \int_\omega \varphi J^*(|\nabla\varphi|/\varphi) < \infty. \tag{2.15}$$

Without loss of generality, it can be assumed that ω is a ball and, by translation, the ball $B(0, \varepsilon)$. We set

$$F(r) = \int_0^r \frac{ds}{J(s) + M},$$

where $M > 0$ is chosen large enough so that (see (2.8))

$$\eta = F(+\infty) \leqq \varepsilon.$$

We then introduce

$$\chi(r) = F^{-1}(r), \chi\colon [0, \eta) \to [0, \infty),$$

$$\varphi(x) = \begin{cases} \dfrac{1}{J(\chi(|x|)) + M} & 0 \leqq r \leqq \eta, \\ 0 & \eta \leqq r \leqq \varepsilon. \end{cases} \tag{2.16}$$

Writing $\varphi(x) = h(|x|)$, we check that

$$h'(r) = -h(r)J'(\chi(r))$$

$$I = \int_\omega \varphi J^*\left(\frac{|\nabla\varphi|}{\varphi}\right) = \omega_N \int_0^\eta r^{N-1}h(r)J^*(J'(\chi(r)))\,dr.$$

But, $J^*(J'(\chi(r))) = \chi(r)J'(\chi(r)) - J(\chi(r))$ so that

$$I \leqq \omega_N\eta^{N-1}\int_0^\eta -h'\chi - hJ(\chi) = \omega_N\eta^{N-1}\left\{[h\chi]_{r=\eta}^{r=0} + \int_0^\eta h(\chi' - J(\chi))\right\}.$$

Using (2.16), $\lim_{s\to\infty} s/J(s) = 0$, $\chi' = J(\chi) + M$, we deduce

$$I \leqq \omega_N\eta^{N-1}M\int_0^\eta h(r)\,dr < +\infty.$$

This proves (2.15) with $\omega = B(0, \varepsilon)$ and Theorem 2.1.

We now look at the problem (1.3) when $\alpha > 0$. As noticed in the introduction, if f is regular and $1 < p < 2$, then (1.3) has a solution. In other words, no size condition is required on f. However,

- a regularity condition is required on f as soon as $p > 1$,
- if, moreover, $p > 2$, then a size condition is also required.

This is the purpose of the two following results stated for data f, j satisfying (2.1)-(2.4) and

$$\text{(2.17)} \qquad \exists p > 1,\ C_1, C_2 > 0, \qquad j(x, r) \geqq C_1|r|^p - C_2.$$

We consider the following problem when $\alpha \geqq 0$:

$$\text{(2.18)} \qquad u \in W_0^{1,1}(\Omega), \qquad j(\,\cdot\,, \nabla u) \in L^1_{\mathrm{loc}}(\Omega)$$

$$\text{(2.19)} \qquad \alpha u - \Delta u \geqq j(\,\cdot\,, \nabla u) + \lambda f \quad \text{in } \mathscr{D}'(\Omega).$$

PROPOSITION 2.2. *Assume* (2.1)-(2.4), (2.17) *hold. Assume* (2.18), (2.19) *has a solution for some* $\lambda > 0$. *Then the measure* f *does not charge the sets of* $W^{1,p'}$*-capacity zero.*

Remark. We recall that a compact set $K \subset \Omega$ is of $W^{1,p'}$-capacity zero if there exists a sequence of C_0^∞-functions φ_n greater than 1 on K and converging to zero in $W^{1,p'}$. The above statement means that

$$\text{(2.20)} \qquad (K \text{ compact, } W^{1,p'}\text{-capacity } (K) = 0) \Rightarrow \int_K f = 0.$$

Obviously, this is not true for any measure f as soon as $N > p'$ or $p > N/(N-1)$ (see, e.g., [7] and the references there for more details).

PROPOSITION 2.3. *Assume* (2.1)-(2.4) *and* (2.17) *hold with* $p > 2$. *Then there exists* $\lambda^* < \infty$ *such that* (2.18), (2.19) *does not have any solution for* $\lambda > \lambda^*$.

Proof of Proposition 2.2. From (2.19), (2.17), we get the following inequality:

$$\text{(2.21)} \qquad \alpha u - \Delta u \geqq C_1|\nabla u|^p - C_2 + \lambda f.$$

Let K be a compact set of $W^{1,p'}$-capacity zero and φ_n on a sequence of C_0^∞-functions such that

$$\text{(2.22)} \qquad \varphi_n \geqq 1 \quad \text{on } K, \quad \|\varphi_n\|_{W^{1,p'}} \xrightarrow{n\to\infty} 0, \quad 0 \leqq \varphi_n \leqq 1.$$

Multiplying (2.21) by $\chi_n = \varphi_n^{p'}$ leads to

$$\lambda \int_\Omega f\chi_n + C_1 \int_\Omega \chi_n |\nabla u|^p \leqq C_2 \int_\Omega \chi_n + \alpha \int_\Omega u\chi_n + \int_\Omega \nabla u \nabla \chi_n. \tag{2.23}$$

We use $\nabla \chi_n = p' \varphi_n^{p'-1} \nabla \varphi_n$ and Young's inequality to treat the last integral above:

$$\int_\Omega \nabla u \nabla \chi_n \leqq \varepsilon \int_\Omega \chi_n |\nabla u|^p + C_\varepsilon \int_\Omega |\nabla \varphi_n|^{p'}. \tag{2.24}$$

Due to (2.22), passing to the limit in (2.23), (2.24) with ε small enough easily leads to

$$\lambda \int_K f \leqq 0. \tag{2.25}$$

Proof of Proposition 2.3. Let us consider a nonnegative function $\varphi \in W_0^{1,\infty}(\Omega)$ such that there are constants k_1, k_2 with

$$k_1\, d(x, \delta\Omega) \leqq \varphi(x) \leqq k_2\, d(x, \delta\Omega) \quad \forall x \in \Omega. \tag{2.26}$$

Let us also introduce the solution of

$$\begin{aligned} &\theta \in W_0^{1,\infty}(\Omega), \\ &-\Delta\theta = \varphi \quad \text{on } \Omega. \end{aligned} \tag{2.27}$$

Multiply inequality (2.21) by φ and integrate by parts to obtain

$$\begin{aligned} \lambda \int_\Omega f\varphi + C_1 \int_\Omega \varphi |\nabla u|^p &\leqq C_2 \int_\Omega \varphi + \int_\Omega \nabla u(\alpha \nabla\theta + \nabla\varphi) \\ &\leqq C_2 \int_\Omega \varphi + \varepsilon \int_\Omega \varphi |\nabla u|^p + C_2 \int_\Omega \varphi^{1-p'} |\alpha\nabla\theta + \nabla\varphi|^{p'}. \end{aligned}$$

Again we prove, as in Theorem 2.1, existence of λ^* by showing that the last integral is bounded. But due to (2.26), $\varphi^{1-p'}$ is integrable on Ω if $p'-1<1$ or $p>2$. On the other hand, $\nabla\theta$, $\nabla\varphi$ are in $L^\infty(\Omega)$.

Remark. A sharper result can be obtained in the same way for functions j satisfying $j(x, r) \geqq C_1 J(|r|) - C_2$, where J is a convex function such that $\int_\Omega \varphi J^*(C/\varphi) < \infty$ for C large.

3. An existence result for any finite measure.

THEOREM 3.1. *Let j satisfy* (2.2)-(2.4) *and assume there exist C_1 in $L^{N+\eta}(\Omega)$, $\eta > 0$ and C_2 in $L^1(\Omega)$ such that*

$$\text{p.p.}x \quad \forall r \quad j(x, r) \leqq C_1(x)|r| + C_2(x). \tag{3.1}$$

Then for all $\alpha \geqq 0$, all finite measure f and all $\lambda \in \mathbb{R}$, the problem (2.18), (2.19) *has a solution.*

The main ingredient in the proof is the isoperimetric inequality that we use under the following form (see, e.g., [13], [14] and the references there).

LEMMA 3.2. *Let $u \in W_0^{1,1}(\Omega)$. Then*

$$-\frac{d}{dt} \int_{[|u|>t]} |\nabla u| \geqq N\omega_N^{1/N} \mu(t)^{1-1/N}, \tag{3.2}$$

where ω_N is the measure of the unit ball and

$$\mu(t) = \text{measure } \{x \in \Omega : |u(x)| > t\}. \tag{3.3}$$

Proof of Theorem 3.1. We regularize the problem (2.18), (2.19) by taking regular functions f_ε converging to f in the sense of measures, $j_\varepsilon(x,\cdot)$ a regular approximation of $j(x,\cdot)$ satisfying (3.1) uniformly. Then, for all $\varepsilon>0$, there exists u_ε solution of

$$\text{(3.4)}\qquad \begin{aligned} &u_\varepsilon\in W_0^{1,\infty}(\Omega),\\ &(\alpha+\varepsilon)u_\varepsilon-\Delta u_\varepsilon=j_\varepsilon(x,\nabla u_\varepsilon)+\lambda f_\varepsilon \quad \text{in } \Omega. \end{aligned}$$

Indeed, the constant function $\lambda\|f_\varepsilon\|_{L^\infty(\Omega)}/(\alpha+\varepsilon)$ is a supersolution of (3.4), and a subsolution is given by w_ε solution of

$$\text{(3.5)}\qquad \begin{aligned} &w_\varepsilon\in W_0^{1,\infty}(\Omega),\\ &(\alpha+\varepsilon)w_\varepsilon-\Delta w_\varepsilon=\lambda f_\varepsilon \quad \text{in } \Omega, \end{aligned}$$

which satisfies $w_\varepsilon\leqq\lambda\|f_\varepsilon\|_{L^\infty(\Omega)}/(\alpha+\varepsilon)$. Since the growth of j_ε with respect to r is subquadratic, the classical theory applies (see [4]): there exists u_ε solution of (3.4).

We will prove the existence of M independent of ε such that

$$\text{(3.6)}\qquad \int_\Omega|\nabla u_\varepsilon|^q\leqq M,\qquad q=(N+\eta)'.$$

Let us first show how the existence of u solution of (2.18), (2.19) follows from (3.6) by passing to the limit in (3.4). From (3.6), since $u_\varepsilon=0$ on Ω, we first deduce

$$\|u_\varepsilon\|_{L^1}\leqq M_1,\quad \text{independent of } \varepsilon.$$

From (3.6) again and (3.4), (3.1), we obtain $\|\Delta u_\varepsilon\|\leqq M_1$. This yields compactness of u_ε in $W_0^{1,r}(\Omega)$ for all $r<N/(N-1)$ (this can be obtained by duality of the compactness of $h\to v$ from $L^r(\Omega)$ into $L^\infty(\Omega)$ for $r>N$, where v is the solution of

$$v\in W_0^{1,2}(\Omega),\qquad -\Delta v=h_{x_i}\quad\text{on } \Omega.$$

See, e.g., [11], [9]). We then pass to the limit in (3.4) to conclude.

We now drop the ε-dependence in (3.4) to make estimates on ∇u_ε and reach (3.6). For $0<t<t+h$, we introduce the function $z(\cdot)$ defined by

$$\text{(3.7)}\qquad z(r)=\begin{cases} 1 & r\geqq t+h,\\ (r-t)^+/h & t\leqq r\leqq t+h,\\ 0 & 0\leqq r\leqq t,\\ -z(-r) & r<0. \end{cases}$$

We multiply (3.4) by $z(u)$ and integrate by parts to obtain

$$(\alpha+\varepsilon)\int_\Omega uz(u)+\int_\Omega z'(u)|\nabla u|^2=\int_\Omega z(u)(j(\cdot,\nabla u)+\lambda f).$$

Using the growth assumption (3.1) and the definition of z, we deduce

$$\text{(3.8)}\quad \frac{1}{h}\int_{t<|u|<t+h}|\nabla u|^2\leqq\int_{|u|>t}C_1|\nabla u|+C_2+\lambda\|f\|_{L^1(\Omega)}\leqq C_q\left(\int_{|u|>t}|\nabla u|^q\right)^{1/q}+C_\lambda,$$

where $q=(N+\eta)'=N/(N-1)-\varepsilon(\eta)$, $\varepsilon(\eta)>0$, $C_q=\|C_1\|_{L^{N+\eta}}$ and $C_\lambda=\|C_2\|_{L^1(\Omega)}+\lambda\|f\|_{L^1(\Omega)}$. We now assume $N\geqq2$ so that $q<2$ and use that

$$\text{(3.9)}\quad \frac{1}{h}\int_{t<|u|<t+h}|\nabla u|^q\leqq\left(\frac{1}{h}\int_{t<|u|<t+h}|\nabla u|^2\right)^{q/2}\left(\frac{\mu(t)-\mu(t+h)}{h}\right)^{(2-q)/2},$$

$$\text{(3.10)}\quad \frac{1}{h}\int_{t<|u|<t+h}|\nabla u|\leqq\left(\frac{1}{h}\int_{t<|u|<t+h}|\nabla u|^q\right)^{1/q}\left(\frac{\mu(t)-\mu(t+h)}{h}\right)^{(q-1)/q},$$

where $\mu(t) = \text{measure } ([|u| > t])$. We take the qth power of (3.10), multiply by the square of (3.9) to obtain

$$\left(\frac{1}{h}\int_{t<|u|<t+h} |\nabla u|\right)^q \left(\frac{1}{h}\int_{t<|u|<t+h} |\nabla u|^q\right) \leqq \left(\frac{1}{h}\int_{t<|u|<t+h} |\nabla u|^2\right)^q \left(\frac{\mu(t)-\mu(t+h)}{h}\right).$$

We now plug (3.8) into the above inequality, and by letting h go to zero, we obtain a differential inequality for $g(t) = \int_{|u|>t} |\nabla u|^q$, namely,

$$\left(-\frac{d}{dt}\int_{|u|>t} |\nabla u|\right)^q (-g'(t)) \leqq (C_q g(t)^{1/q} + C_\lambda)^q (-\mu'(t)) \leqq (D_q g(t) + D_\lambda)(-\mu'(t)).$$

By the isoperimetric inequality (3.2), this also gives

$$-g'(t) + C_N g(t)\mu'(t)\mu(t)^{-q(1-1/N)} \leqq -\mu'(t)\mu(t)^{-q(1-1/N)}\lambda_N$$

with $C_N = D_q(N\omega_N^{1/N})^{-q}$, $\lambda_N = D_\lambda(N\omega_N^{1/N})^{-q}$. This can be rewritten as

$$-\frac{d}{dt}(e^{-k\mu(t)^\alpha} g(t)) \leqq \frac{d}{dt}[e^{-k\mu(t)^\alpha}]\frac{\lambda_N}{C_N}, \quad \alpha = 1 - q\frac{N-1}{N} > 0, \quad k\alpha = C_N.$$

Integrating from $t = 0$ to $t = \|u\|_\infty$ leads to (using $\mu(\|u\|_\infty) = 0$)

$$e^{-k\mu(0)^\alpha} g(0) \leqq \frac{\lambda_N}{C_N}.$$

Since $\mu(0) \leqq |\Omega|$, this yields

$$\int_\Omega |\nabla u|^q \leqq e^{k|\Omega|^\alpha}\frac{\lambda_N}{C_N},$$

which is (3.6). The adaptation is obvious if $N = 1$.

Remark. It is very likely that (3.1) can be replaced by a more general condition of the form

$$j(x, r) \leqq C_1 J(r) + C_2,$$

where $\int^\infty (ds/J(s)) = \infty$ (see (2.7), (2.8)). But adapting directly the above proof to that case does not seem straightforward.

4. About uniqueness of weak solutions. Although uniqueness and order-preserving hold for *regular* solutions (say, in $W_0^{1,\infty}$) of (2.19), they completely fail for solutions in the weaker sense (2.18), as proved by the following simple examples.

Example 4.1. Let $N > 2$, $\Omega = B(0, 1)$ and $u(x) = -(N-2)\ln|x|$. Then

$$\begin{aligned} &u \in W_0^{1,2}(\Omega), \\ &-\Delta u = |\nabla u|^2 \quad \text{in } \Omega, \end{aligned} \tag{4.1}$$

and $u \equiv 0$ is also solution of (4.1).

Example 4.2. Let $N > 1$, $\Omega = B(0, 1)$, $p > N/(N-1)$, $p \neq 2$, and

$$u(x) = C(1 - |x|^\alpha) \quad \text{with } \alpha = \frac{(p-2)}{(p-1)}, \quad \alpha C = N - 2 + \alpha (>0).$$

Then

$$u \in W_0^{1,p}(\Omega), -\Delta u = |\nabla u|^p \quad \text{in } \Omega. \tag{4.2}$$

Next, we make precise the class of solutions for which order-preserving and uniqueness hold. We consider the following problem where f, j are defined in (2.1)-(2.4) and $\alpha \geqq 0$:

$$u \in W_0^{1,1}(\Omega), \quad j(\cdot, \nabla u) \in L^1(\Omega), \tag{4.3}$$

$$\alpha u - \Delta u = j(\cdot, \nabla u) + f \quad \text{in } \mathscr{D}'(\Omega). \tag{4.4}$$

We call subsolution (respectively, supersolution) of (4.3), (4.4) a function u satisfying (4.3) and (4.4) with "$=$" replaced by "$\leqq$" (respectively, $\geqq$). We will say that u is a *regular* subsolution, supersolution, or solution of (4.3), (4.4) if, moreover,

$$\exists \varepsilon > 0, \quad \exists \vec{a} \in L^{N+\varepsilon}(\Omega, \mathbb{R}^N), \quad \vec{a}(x) \in \delta j(x, \nabla u(x)) \text{ a.e. } x \in \Omega, \tag{4.5}$$

where $\delta j(x, \cdot)$ is the subdifferential of $j(x, \cdot)$.

Theorem 4.3. *Let u be a supersolution of* (4.3), (4.4), *and let $\hat{u}$ be a* regular *subsolution of* (4.3), (4.4) *associated with $\hat{j}, \hat{f}$ satisfying* (2.1)-(2.4) *and $j \geqq \hat{j}, f \geqq \hat{f}$. Then $u \geqq \hat{u}$.*

Corollary 4.4. *Under assumptions* (2.1)-(2.4), *regular solutions of* (4.3), (4.4) *are unique. Moreover, the regular solution is the smallest solution when it exists.*

Corollary 4.5. *Assume* (2.1)-(2.4) *and*

$$\exists p < \frac{N}{(N-1)}, \, C_1, \, C_2 > 0, j(x, r) \leqq C_1 |r|^p + C_2. \tag{4.6}$$

Then solutions of (4.3), (4.4) *are unique.*

Remark. According to Examples 4.1, 4.2, the condition $p < N/(N-1)$ is sharp for the uniqueness of (weak) solutions of (4.3), (4.4). So is the assumption on $\vec{a}$ in the next lemma.

Lemma 4.6. *Let $\vec{a} \in L^{N+\varepsilon}(\Omega, \mathbb{R}^N)$, $\varepsilon > 0$, and w a solution of*

$$w \in W_0^{1,1}(\Omega), \qquad \Delta w \in L^1(\Omega), \tag{4.7}$$

$$\alpha w - \Delta w \leqq \vec{a} \cdot \nabla w \quad \textit{in } \mathscr{D}'(\Omega). \tag{4.8}$$

Then $w \leqq 0$.

Remark. Similar results can be found in [11] for $w \in W^{1,2}(\Omega)$ in a quite more general framework. However, the weaker assumption $w \in W^{1,1}$ makes a significant difference. Note that $w \in W_0^{1,1}$ and $\Delta w \in L^1$ imply that $w \in W_0^{1,p}$ for all $p \in [1, N/(N-1)[$ (see, e.g., [9]). It follows that $\vec{a} \cdot \nabla w$ is in $L^{1+\eta}$ for some $\eta > 0$.

Proof of Lemma 4.6. We give here a direct proof using the same isoperimetric inequality as in § 3. First, by elementary regularization argument, we prove $w^+ \in W_0^{1,1}(\Omega)$ and

$$\alpha w^+ - \Delta(w^+) \leqq \vec{a} \cdot \nabla(w^+) = \vec{a} \cdot \nabla w \cdot 1_{[w>0]} \quad \text{in } \mathscr{D}'(\Omega).$$

In other words, $w \geqq 0$ can be assumed in Lemma 4.6, without loss of generality.

Let f_n be a regular smooth approximation in $L^1(\Omega)$ of $\alpha w - \Delta w$. By classical results (see, e.g., [9]), the solution of

$$\begin{aligned} &w_n \in W_0^{1,\infty}(\Omega) \cap C^2(\Omega), \\ &\alpha w_n - \Delta w_n = f_n \end{aligned} \tag{4.9}$$

converges in $W_0^{1,p}$ to w for all $p \in [1, N/(N-1)]$ (note that this requires uniqueness for the Dirichlet problem in $W_0^{1,1}(\Omega)$). Multiplying (4.9) by $z(w_n)$, where z is defined as in (3.7) leads to

$$\frac{1}{h} \int_{t < w_n < t+h} |\nabla w_n|^2 \leqq \int z(w_n) f_n.$$

Passing to the limit, we obtain that $\nabla w \in L^2([t<w<t+h])$ and

$$(4.10)\qquad \frac{1}{h}\int_{t<w<t+h}|\nabla w|^2 \leqq \int_{w>t} z(w)(\alpha w-\Delta w) \leqq \int_{w>t}|\vec{a}||\nabla w| \leqq C_p\left(\int_{w>t}|\nabla w|\right)^{1/p},$$

where $p=(N+\varepsilon)'=N/(N-1)-\eta(\varepsilon)$, $\eta(\varepsilon)>0$ and $C_p=\|\vec{a}\|_{L^{N+\varepsilon}}$. We now assume $N \geqq 2$ and argue exactly like in the proof of Theorem 3.1 (see (3.9), (3.10)). We use

$$(4.11)\qquad \frac{1}{h}\int_{t<w<t+h}|\nabla w|^p \leqq \left(\frac{1}{h}\int_{t<w<t+h}|\nabla w|^2\right)^{p/2}\left(\frac{\mu(t)-\mu(t+h)}{h}\right)^{(2-p)/2}$$

$$(4.12)\qquad \frac{1}{h}\int_{t<w<t+h}|\nabla w| \leqq \left(\frac{1}{h}\int_{t<w<t+h}|\nabla w|^p\right)^{1/p}\left(\frac{\mu(t)-\mu(t+h)}{h}\right)^{(p-1)/p},$$

where $\mu(t)=$ measure $([w>t])$. We take the pth power of (4.12), multiply by the square of (4.11) and use (4.10) to obtain

$$\left(\frac{1}{h}\int_{t<w<t+h}|\nabla w|\right)^p\left(\frac{1}{h}\int_{t<w<t+h}|\nabla w|^p\right) \leqq C_p^p\int_{w>t}|\nabla w|^p\left(\frac{\mu(t)-\mu(t+h)}{h}\right).$$

By letting h go to zero, we obtain a differential inequality for $g(t)=\int_{w>t}|\nabla w|^p$, namely,

$$(4.13)\qquad \left(-\frac{d}{dt}\int_{w>t}|\nabla w|\right)^p(-g'(t)) \leqq C_p^p g(t)(-\mu'(t)).$$

By the isoperimetric inequality (3.2), this writes

$$-k_p g'(t)+C_p^p g(t)\mu'(t)\mu(t)^{-p(1-1/N)} \leqq 0, \qquad k_p=(N\omega_N^{1/N})^p$$

or

$$-\frac{d}{dt}(e^{-k\mu(t)^\alpha}g(t)) \leqq 0, \quad \alpha=1-p\frac{N-1}{N}>0, \quad k\alpha=C_p^p/k_p.$$

Since $\mu(\infty)=g(\infty)=0$, this implies $g(0)=0$, that is, $\nabla w=0$ and $w=0$ since $w \in W_0^{1,p}(\Omega)$. The adaptation is obvious if $N=1$.

Proof of Theorem 4.3. By difference between (4.3), (4.4) applied to u and $\hat{u}$, we have

$$(4.14)\qquad \alpha(\hat{u}-u)-\Delta(\hat{u}-u) \leqq \hat{j}(\cdot,\nabla\hat{u})-j(\cdot,\nabla u).$$

Since $\hat{u}$ is a regular solution and by the convexity of $j(x,\cdot)$, there exists $\hat{a} \in L^{N+\varepsilon}(\Omega,\mathbb{R}^N)$ such that

$$(4.15)\qquad \hat{j}(\cdot,\nabla u)-\hat{j}(\cdot,\nabla\hat{u}) \geqq \vec{a}\cdot\nabla(u-\hat{u}).$$

Since $j(\cdot,\nabla u) \geqq \hat{j}(\cdot,\nabla u)$, we obtain from (4.14), (4.15),

$$\alpha(\hat{u}-u)-\nabla(\hat{u}-u) \leqq \vec{a}\nabla(\hat{u}-u).$$

Therefore, $w=\hat{u}-u$ satisfies the assumptions of Lemma 4.6. The conclusion follows.

Proof of Corollary 4.4. It is a direct consequence of Theorem 4.3 and definition (4.5) of regular solutions.

Proof of Corollary 4.5. It is sufficient to prove that any solution is regular in the sense of (4.5). Since, for all $r, s \in \mathbb{R}^N$,

$$j(x,r+s)-j(x,r) \geqq \delta j(x,r)\cdot s,$$

we deduce from (4.6) that

$$\delta j(x,r)\cdot s \leqq C_1|r+s|^p+C_2$$

and

$$(4.16)\qquad |\delta j(x,r)| \leqq \hat{C}_1|r|^{p-1}+\hat{C}_2 \quad \text{for } |r|>1.$$

Now, if u is solution of (4.3), (4.4), then $\nabla u \in L^q(\Omega)$ for all $q \in [1, N/(N-1)[$. But from (4.16),

$$|\delta j(x, \nabla u)|^{N+\varepsilon} \leqq C_1' |\nabla u|^{(p-1)(N+\varepsilon)} + C_2'.$$

Since $p < N/(N-1)$, $(p-1)(N+\varepsilon) < N/(N-1)$ for ε small enough. This yields (4.5).

5. An existence result for (sub)quadratic growth. We consider here the more general problem

$$\text{(5.1)} \qquad u \in W_0^{1,1}(\Omega), \qquad j(\cdot, u, \nabla u) \in L^1_{\text{loc}}(\Omega),$$

$$\text{(5.2)} \qquad -\Delta u = j(\cdot, u, \nabla u) + f \quad \text{in } \mathscr{D}'(\Omega),$$

where f is as in (2.1) and j: $\Omega \times \mathbb{R} \times \mathbb{R}^N \to [0, \infty)$ satisfies

$$\text{(5.3)} \qquad j \text{ is measurable, a.e. } x, \ (s, r) \to j(x, s, r) \text{ is continuous,}$$

$$\text{(5.4)} \qquad j \text{ is nondecreasing in } s \text{ and convex in } r,$$

$$\text{(5.5)} \qquad j(x, s, 0) = \min \{ j(x, s, r), r \in \mathbb{R}^N \} = 0.$$

As proved in § 2, if j is superlinear in r, existence does not always hold since a size condition is required on f. A natural question is whether the existence of a nonnegative supersolution implies existence of a solution. This is well known in the "regular" case when moreover the growth of j is at most quadratic. However the proof relies on a priori $W^{1,\infty}$-estimates for the solution. This cannot be expected when f is only a measure. Therefore, a quite different technique has to be used. This is what we do next when j is at most quadratic. The same question remains open for superquadratic growth.

We will assume

$$\text{(5.6)} \qquad j(x, s, r) \leqq C_1(|s|)(|r|^2 + 1)$$

$$\text{(5.7)} \qquad C_1 : [0, \infty) \to [0, \infty) \quad \text{is nondecreasing.}$$

THEOREM 5.1. *Assume* (2.1), (5.3)-(5.7). *Assume there exists w in* $W_0^{1,2}(\Omega)$ *such that*

$$\text{(5.8)} \qquad -\Delta w \geqq j(\cdot, w, \nabla w) + f \quad \text{in } \mathscr{D}'(\Omega).$$

Then, there exists u solution of

$$\text{(5.9)} \qquad \begin{aligned} & u \in W_0^{1,2}(\Omega) \\ & -\Delta u = j(\cdot, u, \nabla u) + \lambda f \quad \text{in } \mathscr{D}'(\Omega) \end{aligned}$$

for all $\lambda \in [0, 1]$.

For the proof of Theorem 5.1, we introduce regularized versions of (5.9) with smaller j_n with linear growth. The corresponding solutions u_n—which exist by § 3—are such that

$$0 \leqq u_n \leqq u_{n+1} \leqq w.$$

For this, we use the monotonicity result of the previous section. The convergence of u_n to a solution of (5.9) will then follow from the next two lemmas.

LEMMA 5.2. *Let* $u \in W_0^{1,1}(\Omega)$, $v \in W_0^{1,2}(\Omega)$ *such that*

$$\text{(5.10)} \qquad 0 \leqq u \leqq v \quad \text{in } \Omega, \quad 0 \leqq -\Delta u.$$

Then, $u \in W_0^{1,2}(\Omega)$ *and*

$$\int_\Omega |\nabla u|^2 \leqq \int_\Omega |\nabla v|^2. \tag{5.11}$$

Remarks. If $v \in W_{\text{loc}}^{1,2}(\Omega)$ only, (5.11) can be replaced by local estimates.

Obviously Lemma 5.2 will provide $W^{1,2}$-estimates for the approximate solution u_n. But, we need a strong convergence in $W^{1,2}$ to pass to the limit in the nonlinear terms. It will be a consequence of the following lemma.

LEMMA 5.3. *Let* $u_n \in W_0^{1,2}(\Omega)$ *converging weakly in* $W_0^{1,2}(\Omega)$ *to* u *and such that*

$$0 \leqq u_n \leqq u, \; -\Delta u_n \geqq 0 \quad \textit{in } \mathscr{D}'(\Omega). \tag{5.12}$$

Then u_n *converges to* u *strongly in* $W_0^{1,2}(\Omega)$.

Proof of Lemma 5.2. Let u_n be a sequence of regular functions converging to u and such that $-\Delta u_n \geqq 0$. We write

$$\int_\Omega |\nabla u_n|^2 = \int_\Omega u_n(-\Delta u_n) \leqq \int_\Omega v(-\Delta u_n) = \int_\Omega \nabla v \nabla u_n \leqq \left(\int_\Omega |\nabla v|^2\right)^{1/2} \left(\int_\Omega |\nabla u_n|^2\right)^{1/2}.$$

The result follows.

Proof of Lemma 5.3. We write

$$\int_\Omega |\nabla(u-u_n)^2 = \int_\Omega \nabla u \nabla(u-u_n) - \int_\Omega \nabla u_n \nabla u + \int_\Omega |\nabla u_n|^2,$$

and we bound the last integral as follows:

$$\int_\Omega |\nabla u_n|^2 = \int_\Omega u_n(-\Delta u_n) \leqq \int_\Omega u(-\Delta u_n).$$

We now use the $W^{1,2}$-weak convergence of u_n towards u to conclude.

Proof of Theorem 5.1. For $n \geqq 1$, we introduce $\hat{j}_n(x, s, \cdot)$ the Yosida-approximation of $j(x, s, \cdot)$, which increases pointwise to $j(x, s, \cdot)$ as n tends to ∞ and satisfies

$$\hat{j}_n \leqq j, \qquad \|\hat{j}_{nt}(x, s, \cdot)\| \leqq n \tag{5.13}$$

where $\hat{j}_{nr}$ denotes a section of the subdifferential of $\hat{j}_n$ with respect to r. Then we set

$$j_n(x, s, r) = \hat{j}_n(x, s, r) \cdot 1_{[w<n]}, \tag{5.14}$$

where w is defined in (5.8). We check that j_n satisfies (5.3), (5.5), is convex in r, and

$$j_n \leqq j \cdot 1_{[w<n]}, \qquad j_n \leqq j_{n+1}. \tag{5.15}$$

We consider the sequence defined by

$$u_1 \in W_0^{1,1}(\Omega), -\Delta u_1 = \lambda f \cdot 1_{[w<1]}, \tag{5.16}$$

$$u_{n+1} \in W_0^{1,1}(\Omega), \; -\Delta u_{n+1} = j_n(\cdot, u_n, \nabla u_{n+1}) + \lambda f \cdot 1_{[w<n]}. \tag{5.17}$$

Let us prove by induction that

$$u_n \leqq \min(w, n) \quad \text{for all } n. \tag{5.18}$$

Indeed, if $w_n = \min(w, n)$, from (5.8) we easily deduce that

$$-\Delta w_n \geqq j(\cdot, w_n, \nabla w_n) \cdot 1_{[w<n]} + \lambda f 1_{[w<n]}. \tag{5.19}$$

For $n=1$, $-\Delta(w_1-u_1)\geqq 0 \Rightarrow u_1 \leqq w_1$. Let us assume $u_n \leqq w_n$. Then, from (5.19) and the monotonicity of j in s, we have

$$-\Delta w_n \geqq j(\cdot, u_n, \nabla w_n)\cdot 1_{[w<n]} + \lambda f \cdot 1_{[w<n]},$$

which by (5.13) implies

$$-\Delta w_n \geqq j_n(\cdot, u_n, \nabla w_n) + \lambda f \cdot 1_{[w<n]}. \tag{5.20}$$

Now, the monotonicity result of Theorem 4.3 can be applied with the function $J:(x,r)\to j_n(x,u_n(x),r)$, which satisfies (2.2)-(2.4). For this, we have to check that u_{n+1} is a regular solution of (5.17), that is, (see (4.3), (4.5))

$$J(\cdot, \nabla u_{n+1}) \in L^1(\Omega), \tag{5.21}$$

$$J_r(\cdot, \nabla u_{n+1}) \in L^{N+\varepsilon}(\Omega, \mathbb{R}^N). \tag{5.22}$$

Since J is linear at infinity by (5.13), (5.21) comes from $u_n \in W^{1,1}(\Omega)$. Now by definition of j_n,

$$\|J_r(\cdot, \nabla u_{n+1})\| \leqq C_n,$$

whence (5.22). Therefore, Theorem 4.3 applies and we deduce $w_n \geqq u_{n+1}$, which proves (5.18) by induction.

By Lemma 5.2 and estimate (5.18), u_n is bounded in $W_0^{1,2}(\Omega)$. Therefore, there exists u in $W_0^{1,2}(\Omega)$ such that (up to a subsequence)

$$u_n \to u \quad \text{strongly in } L^2, \quad \text{a.e. and weakly in } W_0^{1,2}. \tag{5.23}$$

By Lemma 5.3, the convergence holds strongly in $W_0^{1,2}$.

We will now pass to the limit in (5.17). We only have to prove that

$$j_n(\cdot, u_n, \nabla u_{n+1}) \xrightarrow{L^1(\Omega)} j(\cdot, u, \nabla u). \tag{5.24}$$

The convergence holds almost everywhere in (5.24) (up to a subsequence) by construction of j_n and by strong convergence of u_n and ∇u_n in $L^2(\Omega)$. Since

$$j_n(\cdot, u_n, \nabla u_{n+1}) \leqq C_1(|u_n|)(|\nabla u_{n+1}|^2+1)$$

for all $t>0$,

$$\int_{u_n<t} |j_n(\cdot, u_n, \nabla u_{n+1}) - j(\cdot, u, \nabla u)| \xrightarrow[n\to\infty]{} 0. \tag{5.25}$$

On the other hand, multiplying (5.17) by u_n leads to

$$\int_\Omega u_n j_n(\cdot, u_n, \nabla u_{n+1}) \leqq \int_\Omega \nabla u_n \nabla u_{n+1} \leqq C \quad \text{(independent of } n\text{)}.$$

Therefore, for $\varepsilon>0$ there exists t_ε (e.g., $t_\varepsilon = C/\varepsilon$) such that

$$\int_{u_n>t_\varepsilon} |j_n(\cdot, u_n, \nabla u_{n+1})| \leqq \varepsilon \quad \forall n. \tag{5.26}$$

By Fatou's lemma, we also have

$$\int_{u>t_\varepsilon} |j(\cdot, u, \nabla u)| \leqq \varepsilon. \tag{5.27}$$

But (5.25)-(5.27) imply (5.24). This finishes the proof.

Remark. A natural question is now the following. Let $p > 2$. Assume there exists a solution of

$$w \in W_0^{1,p}(\Omega), \qquad -\Delta w \geqq |\nabla w|^p + f. \tag{5.28}$$

Then, does there exist u solution of

$$u \in W_0^{1,p}(\Omega), \qquad -\Delta u = |\nabla u|^p + f? \tag{5.29}$$

Essentially, the approach above applies except for Lemma 5.3: we do not know whether it extends to $p > 2$. Therefore, strong convergence of u_n in $W^{1,p}$ is lacking. The limit u that is obtained is only a supersolution of the problem. The existence of such a supersolution is actually a very general fact, as proved in [5].

Remark. We refer to P. L. Lions [*Journal d'Analyse Mathématique*, 45 (1985), pp. 234-254] for results related to those in § 2.

EXISTENCE OF GLOBAL WEAK SOLUTIONS TO THE DYNAMICAL PROBLEM FOR A THREE-DIMENSIONAL ELASTIC BODY WITH SINGULAR MEMORY*

HAMID BELLOUT†, FREDERICK BLOOM†‡, AND JINDRICH NECAS§

Abstract. A three-dimensional elastic body with memory is considered, for which the memory term is generated by a singular but integrable kernel; the existence of a global weak solution to an associated initial-boundary value problem is established by constructing Galerkin approximations and deriving suitable energy estimates.

Key words. singular viscoelasticity, energy estimates

AMS(MOS) subject classifications. 35Q99, 45K05, 73F15

1. Introduction. In spite of intense efforts by many outstanding mathematicians, most questions concerning the global existence of both weak and classical solutions to the mixed problem, with large data, for the nonlinear wave equation governing the evolution of the displacement vector **u** in an elastic body, i.e.,

$$\rho\frac{\partial^2 u_i}{\partial t^2}-\frac{\partial}{\partial x_j}\left(\frac{\partial W}{\partial e_{ij}}\right)=\rho f_i, \qquad i=1,2,3, \tag{1.1}$$

remain open. Equations (1.1) are set in an open domain $\Omega\subseteq R^n$, $n\geqq 2$, with $e_{ij}=\frac{1}{2}((\partial u_i/\partial x_j)+(\partial u_j/\partial x_i))$ the components of the infinitesimal strain tensor. The evolution equation (1.1) reflects only the presence of an instantaneous elastic response governed by the stress tensor that applies in the case of small strains, namely,

$$\sigma_{ij}^I=\frac{\partial W}{\partial e_{ij}}, \tag{1.2}$$

where $W=W(e_{ij})$, the stored energy function, is supposed (as it will be in this paper) to be twice continuously differentiable, with bounded second derivatives, and positive definite, i.e., for some $\alpha>0$ and all symmetric $n\times n$ matrices,

$$\frac{\partial^2 W}{\partial e_{ij}\partial e_{kl}}\xi_{ij}\xi_{kl}\geqq \hat{\alpha}\|\xi\|^2. \tag{1.3}$$

We also suppose that $W(0)=0$ and $(\partial W/\partial e_{ij})(0)=0$.

For dynamic nonlinear elasticity problems of the type (1.1) in one-space dimension it is well known, e.g., Lax [16], Klainerman and Majda [17], that solutions develop singularities in finite time even for data that are small and compactly supported; existence of weak solutions for such problems follows from the recent work of DiPerna [18] and is based on compensated compactness arguments. For spatial dimension $n\geqq 2$ there are many partial results for the dynamic problem, e.g., local (in time) existence of classical solutions [19] and formation of singularities in finite time; excellent surveys of progress to date on problems involving but small and finite strain may be found, for example, in the expository paper [20] and the text [21].

§ Mathematical Institute, Charles University, Prague, Czechoslovakia. This author was on leave during Fall, 1989, at the Department of Mathematical Sciences, Northern Illinois University, DeKalb, Illinois 60115.

In this paper we consider an elastic material with memory for which the Cauchy stress has the form

$$\sigma_{ij}=\sigma^I_{ij}+\sigma^M_{ij}. \tag{1.4}$$

In (1.4), σ^I_{ij} is still given by (1.2), while

$$\sigma^M_{ij}=-\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\tau)-\mathbf{e}(t))\,d\tau, \tag{1.5}$$

with $V=V(\mathbf{e})$ an energy function possessing bounded second derivatives and positive definite, i.e., for some $\beta>0$

$$\frac{\partial^2 V}{\partial e_{ij}\partial e_{kl}}\xi_{ij}\xi_{kl}\geqq\beta\|\boldsymbol{\xi}\|^2 \tag{1.6}$$

for all symmetric $n\times n$ matrices $\boldsymbol{\xi}$; as was the case with the stored energy function W, we also assume that $V(0)=0$ and $(\partial V/\partial e_{ij})(0)=0$. The kernel $h(t)$ in (1.5) is singular but integrable and assumed to have (a nonlinear version of) a form due to Boltzman, namely, $h(t)=\lambda h_0(t)$ with $h_0(t)=t^{-\nu}a(t)+r(t), 0<\nu<\frac{1}{2}$, and $\lambda>0$. Both $a(t)$ and $r(t)$ are sufficiently smooth, decreasing, nonnegative functions on $[0,\infty)$ with $a(t)>0$ in some neighborhood of the origin. We suppose, additionally, that $\int_0^\infty h(\tau)\,d\tau<\infty$. Moreover we take the density $\rho\equiv 1$, which opens the door to the possibility of using a Galerkin approximation scheme, and we employ throughout the Langrangian description of the motion relative to the Cartesian coordinates x_i.

Elastic materials with singular memories of the type described by (1.5) have been considered in several recent pieces of work, e.g., Londen [1], Renardy [2], Hrusa and Renardy [3], Hannsgen and Wheeler [4], Hrusa and Renardy [5], Hrusa and Renardy [6], and Renardy [7]. In [1] the author establishes the existence of weak solutions to an abstract integrodifferential equation; the result applies to the one-dimensional viscoelastic model equation

$$u_{tt}=\phi(u_x)_x+\int_{-\infty}^t a'(t-\tau)\psi(u_x(x,\tau))_x\,d\tau+f(x,t), \tag{1.7}$$

provided $\phi=\psi$ and the memory function has a singularity that is stronger than logarithmic. In [2] it is shown that certain singular kernels do not permit the propagation of singularities and have a smoothing effect; these ideas were further expounded upon in [3], all within a one-dimensional framework. The authors in [4] consider the constant coefficient linear problem on a bounded domain and show that the evolution operator is compact for positive time if and only if the kernel of the integral operator is singular; results such as these, of course, point towards the fact that the models with singular kernels should have nicer existence properties than those with regular kernels. In [5] local and global existence in time (for small data) is established for the history-value problem associated with (1.7) when $a'(t)\sim -t^{-\alpha}, 0<\alpha<1$, as $t\to 0^+$; the equation (1.7) is approximated by equations with regular kernels, and energy estimates are used to prove convergence of the corresponding approximate solutions. The work in [6] differs from that in [5] in that $a(t)$ is allowed to have an integrable singularity at $t=0$, and local (but not global) existence of regular solutions for small data is established. In [7] the author provides an alternative existence proof based on coercive properties of the linearized problem; global existence for small data and local existence for large data (of smooth solutions) is proved for $a(t)$ having a singularity at $t=0$ at least as strong as a negative power of t. We note, in passing, that viscoelastic response, of the Boltzmann variety, governed by kernels that are singular at zero, has been noted by several investigators in the area of polymer physics, e.g., Doi and Edwards [8], Rouse [9], Zimm [10], and Laun [11].

The method that we use in the work reported here is very close in spirit to that employed recently by Milota, Nečas, and Šverák [12], where the scalar equation on $\Omega \subset R^n$,

$$u_{tt} - \frac{\partial}{\partial x_i}(a_i(\nabla u)) + \int_0^t h(t-\tau)\Delta u(\mathbf{x}, \tau)\, d\tau = f, \tag{1.8}$$

is studied, with $h(t) = e^{-\alpha t}t^{-\nu}$, $\alpha > 0$, $0 < \nu < 1$. After the work was completed we received a copy of a preprint of [13], where a model viscoelastic problem similar to the one considered here is treated for a scalar displacement u (as opposed to our vector $\mathbf{u}$). In [13] analogous results to those obtained here are produced by use of an entirely different approximation scheme, one that involves adding the term $\varepsilon\Delta u$ to the left-hand side of (2.2) and studying the limit of u^ε as $\varepsilon \to 0$ (i.e., by use of the viscosity method).

We note here that the work in [13] is somewhat flawed: from Lemma A.2 in [13], and the estimate $\|\mathbf{w}^n - \mathbf{v}^n\|_* \leqq \sqrt{\varepsilon_n}\, C$, therein, it follows only that $\|J_s\mathbf{v}^n - \mathbf{v}^n\|_* \leqq \omega(s) + \sqrt{\varepsilon_n}\, \tilde{C}$ for some $\tilde{C} > 0$ and not that $\|J_s\mathbf{v}^n - \mathbf{v}^n\|_* \leqq \omega(s)$, uniformly in n, for some ω: $[0, 1] \to [0, \infty)$, with $\omega(s) \downarrow 0$ as $\sigma \downarrow 0$, as stated by the author in equation (3.26) of [13]. The lemma following (3.27) is then correct, but vacuous, as one of the hypotheses, i.e., (3.26) of [13], is not satisfied. If (3.26) in [13] is replaced by the somewhat weaker statement alluded to above, a lemma corresponding to that which follows (3.27) in [13] may be stated in a manner sufficiently strong, so as to salvage the rest of the argument in § 3 of [13].

Remarks.

1. It is well known (e.g., Coleman [14]) that, for a viscoelastic body of the type under consideration here, the following condition must be satisfied: in an isothermal process starting from equilibrium, the integral of the stress power around a closed path in strain space must be nonnegative. In the present situation this condition is equivalent to the statement that

$$\int_{t_0}^{t_1} \sigma_{ij}\dot{e}_{ij}\, dt \geqq 0 \quad \forall e_{ij} \in C^1([t_0, t_1]), \quad e_{ij}(x, t_0) = e_{ij}(x, t_1), \tag{1.9}$$

where $x \in \Omega$. For such a closed strain path, of course, $\int_{t_0}^{t_1}(\partial W/\partial e_{ij})(\mathbf{e}(t))\dot{e}_{ij}(t)\, dt = W(\mathbf{e}(t))|_{t_0}^{t_1} = 0$; if we take a closed strain path $e_{ij} \in C^1([t_0, t_1])$ and extend it to the interval $[0, t_0)$ by setting $e_{ij}(x, t) = e_{ij}(x, t_0)$, for $0 \leqq t < t_0$, $x \in \Omega$, then we may compute that

$$\begin{aligned}
&\int_{t_0}^{t_1} \dot{e}_{ij}(t)\left(\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\tau) - \mathbf{e}(t))\, d\tau\right) dt \\
&\quad = \int_0^{t_1} \dot{e}_{ij}(t)\left(\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\tau) - \mathbf{e}(t))\, d\tau\right) dt \\
&\quad = \int_0^{t_1}\left(\int_0^t h(t-\tau)\frac{\partial}{\partial t} V(\mathbf{e}(\tau) - \mathbf{e}(t))\, d\tau\right) dt \\
&\quad = \int_0^{t_1} d\tau \int_\tau^{t_1} h(t-\tau)\frac{\partial}{\partial t} V(\mathbf{e}(\tau) - \mathbf{e}(t))\, dt \\
&\quad = \int_0^{t_1} h(t_1 - \tau) V(\mathbf{e}(\tau) - \mathbf{e}(t))\, d\tau \\
&\qquad - \int_0^{t_1} d\tau \int_\tau^{t_1} \frac{\partial h}{\partial t}(t-\tau) V(\mathbf{e}(\tau) - \mathbf{e}(t))\, dt \geqq 0,
\end{aligned} \tag{1.10}$$

and (1.9) is, therefore, satisfied.

2. We emphasize here that the operator $(\partial/\partial x_j)\sigma_{ij}^M$ is continuous in the same topology, i.e., in $L^2((0, T); W^{1,2}(\Omega; R^n))$ as $(\partial/\partial x_j)\sigma_{ij}^I$ and is even compact in time; this result will be established in the analysis that follows. A key point to be noted is that the memory part of the stress tensor σ_{ij}^M allows us to establish an estimate of the form

$$\|\mathbf{u}\|_{W^{\nu/2,2}((0,T);W^{1,2}(\Omega;R^n))} \leqq C(T), \tag{1.11}$$

for any $T > 0$, which, together with various energy estimates, and an interpolation lemma, yields an estimate of the type

$$\|\mathbf{u}\|_{W^{(1+\nu/2)\alpha,2}((0,T);W^{\alpha,2}(\Omega;R^n))} \leqq C'(T) \tag{1.12}$$

for $1/(1+\nu/2) < \alpha < 1$. The estimates (1.11), (1.12) are key ingredients in our global existence result.

2. Galerkin approximations and basic estimates. We assume in all that follows that Ω is a bounded domain, with Lipschitz continuous boundary $\partial\Omega$, and begin by choosing a basis $\{\mathbf{w}^i\}_{i=1}^{\infty}$ in the space $W_0^{1,2}(\Omega; R^n)$; a natural choice for such a basis would consist of the set of eigenfunctions for the problem

$$\frac{\partial}{\partial x_j}\left(\frac{\partial^2 W}{\partial e_{ij}\partial e_{kl}}(0)\frac{\partial u_k}{\partial x_l}\right) + \lambda u_i = 0 \quad \text{in } \Omega, \tag{2.1}$$
$$\mathbf{u} \in W_0^{1,2}(\Omega; R^n).$$

In any case we suppose that the basis chosen is orthonormal in the space $L^2(\Omega; R^n)$.

DEFINITION 2.1. A weak solution to the mixed problem

$$\ddot{u}_i - \frac{\partial}{\partial x_j}\sigma_{ij}^I - \frac{\partial}{\partial x_j}\sigma_{ij}^M = f_i \quad \text{in } Q = \Omega \times (0, \infty), \tag{2.2}$$

$$\mathbf{u} = 0 \quad \text{on } \partial\Omega \times (0, \infty), \tag{2.3}$$

$$\mathbf{u}(0, \cdot\,) = \mathbf{u}^0, \qquad \ddot{\mathbf{u}}(0, \cdot\,) = \mathbf{u}^1 \tag{2.4}$$

with $u^0 \in W_0^{1,2}(\Omega; \mathbb{R}^n)$, $\mathbf{u}^1 \in L^2(\Omega; \mathbb{R}^n)$, is a function $\mathbf{u} \in L^\infty((0, \infty); W_0^{1,2}(\Omega; \mathbb{R}^n))$, for which $\dot{\mathbf{u}} \in L^\infty((0, \infty); L^2(\Omega; R^n))$, $\ddot{u} \in L^\infty((0, \infty); W^{-1,2}(\Omega; R^n))$ and such that for almost all $T > 0$, and all $\mathbf{v} \in W_0^{1,2}(\Omega; R^n)$,

$$\int_{\Omega_r} \ddot{u}_i v_i \, d\mathbf{x} + \int_{\Omega T} \sigma_{ij}^I e_{ij}(\mathbf{v}) \, d\mathbf{x} + \int_{\Omega_T} \sigma_{ij}^M e_{ij}(\mathbf{v}) \, d\mathbf{x} = \int_{\Omega_T} f_i v_i \, d\mathbf{x}. \tag{2.5}$$

In (2.2), (2.5)

$$\mathbf{f} \in L^\infty((0, \infty); L^2(\Omega; \mathbb{R}^n)) \cap L^2((0, \infty); L^2(\Omega; R^n)), \tag{2.6}$$

while $\Omega_T = (0, T) \times \Omega$. For integer k, the $W^{k,2}$ are, of course, the Sobolev spaces of L^2 functions with square integrable derivatives up to order k, while the zero subscript denotes those functions with vanishing traces on $\partial\Omega$ up to order $k-1$; via duality $W^{-k,2} = (W_0^{k,2})^*$. Spaces of fractional derivatives will be introduced below.

If we construct Galerkin approximations of the solution of (2.2)-(2.4) of the form $\mathbf{u}^n = \sum_{k=1}^n e_i(t)\mathbf{w}^i(\mathbf{x})$, we then find that for all $\mathbf{w}^k$, $k = 1, 2, \ldots, n$ and all $t > 0$,

$$\begin{aligned} &\int_\Omega \ddot{u}_i^n w_i^k \, d\mathbf{x} + \int_n \frac{\partial W}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n))e_{ij}(\mathbf{w}^k) \, d\mathbf{x} \\ &\quad - \int_\Omega \left(\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(u^n(\tau)) - \mathbf{e}(u^n(t))) \, d\tau\right) e_{ij}(\mathbf{w}^k) \, d\mathbf{x} = \int_\Omega f_i w_i^k \, d\mathbf{x}, \end{aligned} \tag{2.7}$$

$$\int_{\Omega t} u_i^n(0,\cdot)w_i^k\,d\mathbf{x}=\int_{\Omega} u_i^0 w_i^k\,d\mathbf{x}, \tag{2.8}$$

$$\int_{\Omega} \dot{u}_i(0,\cdot)w_i^k\,d\mathbf{x}=\int_{\Omega} u_i^1 w_i^k\,d\mathbf{x}. \tag{2.9}$$

The problem (2.7)-(2.9) clearly possesses a unique solution on some interval $[0, t_0]$, and for this solution we may state the following.

LEMMA 2.1. *For any T, $0\leqq T<T_\infty$, T_∞ being the maximal time of existence of the solution of* (2.7)-(2.9), *the solution $\mathbf{u}^n$ satisfies, for some $c_1>0$,*

$$\begin{aligned}&\frac{1}{2}\int_{\Omega_T}\|\dot{\mathbf{u}}^n\|^2\,d\mathbf{x}+\int_{\Omega_T}W(\mathbf{e}(\mathbf{u}^n))\,d\mathbf{x}+c_1\int_{\Omega}\int_{M_{T,\delta}}\frac{\|\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t))\|^2}{|t-\tau|^{1+\nu}}\,d\mathbf{x}\,dt\,d\tau\\&\leqq\int_0^T\int_{\Omega}f_iu_i^n\,d\mathbf{x}\,dt+\frac{1}{2}\int_{\Omega}\|\dot{\mathbf{u}}^n\|^2d\mathbf{x}+\int_{\Omega}W(\mathbf{e}(\mathbf{u}^n))\,d\mathbf{x},\end{aligned}\tag{2.10}$$

where

$$M_{T,\delta}=\{(t,\tau)|0<t<T, 0<\tau<T, t-\delta<\tau<t+\delta, \delta>0\}.$$

Proof. We replace $\mathbf{w}^k$ in (2.7) by $\dot{\mathbf{u}}^n$ and then integrate the equation over $[0, T]$; there results

$$\begin{aligned}&\frac{1}{2}\int_{\Omega_T}\|\dot{\mathbf{u}}\|^2\,d\mathbf{x}-\frac{1}{2}\int_{\Omega}\|\dot{\mathbf{u}}^n(0)\|\,d\mathbf{x}+\int_{\Omega_T}W(\mathbf{e}(\mathbf{u}^n))\,d\mathbf{x}\\&\quad-\int_{\Omega}W(\mathbf{e}(\mathbf{u}^n(0)))\,d\mathbf{x}\\&\quad-\int_0^T dt\int_{\Omega}\left(\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t)))\,d\tau\right)\cdot\dot{e}_{ij}(\mathbf{u}^n(t))\,d\mathbf{x}\\&\quad=\int_0^t dt\int_{\Omega}f_i\dot{u}_i^n\,d\mathbf{x}\,dt.\end{aligned}\tag{2.11}$$

Denoting by $\nu=(\nu_t,\nu_\tau)$ the outer normal to ∂M_T, where

$$M_T=\{(t,\tau)|0<t<\tau, 0<t<\tau\},$$

we compute that for some $c_1>0$,

$$\begin{aligned}&-\int_{M_T}H(t-\tau)\frac{\partial}{\partial t}(e_{ij}(\mathbf{u}^n(t))-e_{ij}(\mathbf{u}^n(\tau)))\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(u^n(\tau)-\mathbf{e}(u^n(t)))\,dt\,d\tau\\&\quad=\int_{M_T}h(t-\tau)V(\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t)))\,dt\,d\tau\\&\quad=\int_{\partial M_T}h(t-\tau)\frac{\partial}{\partial t}V(\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t)))\nu_t\,ds\\&\quad\quad-\int_{M_T}h(t-\tau)V(\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t)))\,dt\,d\tau\\&\quad\geqq c_1\lambda\int_{M_{T,\delta}}\frac{\|\mathbf{e}(\mathbf{u}^n(\tau))-\mathbf{e}(\mathbf{u}^n(t))\|^2}{|t-\tau|^{1+\nu}}\,dt\,d\tau.\end{aligned}\tag{2.12}$$

Combining (2.11) with (2.12) we find the estimate (2.10). □

In what follows we will assume that besides (2.6), $\mathbf{f}$ satisfies the condition

$$\int_\Omega \int_0^\infty \int_0^\infty \frac{\|\mathbf{f}(\tau)-\mathbf{f}(t)\|^2}{|\tau-t|^{1+\nu}}\,dt\,d\tau\,d\mathbf{x}<\infty. \tag{2.13}$$

It follows from Lemma 2.1 that the Galerkin approximants $\mathbf{u}^n$ are defined on the entire interval $[0,\infty]$. We now make the following definition.

DEFINITION 2.2. Let B be a Banach space, $\mathbf{f}(t)\in B$, $0<t<T$, and $0<\mu<1$. Then we define

$$W^{\mu,2}((0,T);B)=\left\{\mathbf{f}\in L^2((0T);B)\,\middle|\,\int_0^T \|\mathbf{f}(t)\|_B^2\,dt+\int_0^T\int_0^T \frac{\|\mathbf{f}(t)-\mathbf{f}(\tau)\|_B^2}{|t-\tau|^{1+2\mu}} \equiv \|\mathbf{f}\|^2_{W^{\mu,2}}<\infty\right\}, \tag{2.14}$$

and we have the following.

LEMMA 2.2. *For each $T>0$, $\exists C^*(T)>0$ such that the Galerkin approximants $\mathbf{u}^n$ satisfy*

$$\|\dot{\mathbf{u}}^n\|_{W^{\nu/2,2}((0,T);W^{-1,2}(\Omega,R^n))}\leqq C^*(T). \tag{2.15}$$

Proof. Let $\boldsymbol{\phi}\in W_0^{1,2}(\Omega;\mathbb{R}^n)$, and let R_n be the projection operator mapping $W_0^{1,2}(\Omega;\mathbb{R}^n)$ to the subspace spanned by $(\mathbf{w}^1,\dots,\mathbf{w}^n)$. Then

$$\begin{aligned}\|\ddot{\mathbf{u}}(\tau)-\ddot{\mathbf{u}}^n(t)\|_{W^{-1,2}}&=\sup_{\|\boldsymbol{\phi}\|_{W^{1,2}}\leqq 1}\int_\Omega (\ddot{u}_i^n(\tau)-\ddot{u}_i(t))\phi_i\,d\mathbf{x}\\ &=\sup_{\|\boldsymbol{\phi}\|_{W^{1,2}}\leqq 1}\int_\Omega (\ddot{\mathbf{u}}_i^n(\tau)-\ddot{\mathbf{u}}_i(t))(R_n\boldsymbol{\phi})_i\,d\mathbf{x}.\end{aligned} \tag{2.16}$$

We now employ (2.7) so as to estimate the right-hand side of (2.16); it is sufficient to look at the term in (2.7) generated by the memory portion of the stress σ_{ij}^M, as the estimates for the other terms follow in a straightforward fashion. We have

$$\begin{aligned}&\sup_{\|\boldsymbol{\phi}\|_{W^{1,2},\leqq 1}}\left|\int_\Omega e_{ij}(R_n\boldsymbol{\phi})\,d\mathbf{x}\int_0^{t_1} h(t_1-\tau_1)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(\tau_1))-\mathbf{e}(\mathbf{u}^n(t_1)))\,d\tau_1\right.\\ &\qquad\left.-\int_\Omega e_{ij}(R_n\boldsymbol{\phi})\,d\mathbf{x}\int_0^{t_2} h\left((t_2-\tau_2)\frac{\partial V}{\partial e_{ij}}\right)\mathbf{e}(\mathbf{u}^n(\tau_2)-\mathbf{e}(\mathbf{u}^n(t_2)))\,d\tau_2\right|\\ &\leqq c_1\left\{\int_\Omega\sum_{i,j=1}^n\left[\int_0^{t_1} h(t_1-\tau_1)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(\tau_1))-\mathbf{e}(\mathbf{u}^n(t_1)))\,d\tau_1\right.\right.\\ &\qquad\left.\left.-\int_0^{t_2} h(t_2-\tau_2)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(\tau_2))-\mathbf{e}(\mathbf{u}^n(t_2)))\,d\tau_2\right]^2 d\mathbf{x}\right\}^{1/2}\end{aligned} \tag{2.17}$$

for some $c_1>0$. For $0<t_2<t_1<T$, we may write the terms within the square bracket, on the right-hand side of the above estimate, in the form

$$\begin{aligned}&\int_0^{t_2} h(s)\left[\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1)))-\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_2-s))-\mathbf{e}((\mathbf{u}^n(t_2)))\right]ds\\ &+\int_{t_2}^{t} h(s)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1)))\,ds.\end{aligned} \tag{2.18}$$

Using Schwarz's inequality on the first integral in this last expression we find that

$$\int_\Omega d\mathbf{x}\int_0^T dt_1\int_0^{t_1}\frac{dt_2}{|t_1-t_2|^{1+\nu}}\int_0^{t_2}\Big[\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1)))$$
$$-\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_2-s)-\mathbf{e}(\mathbf{u}^n(t_2-s)-\mathbf{e}(\mathbf{u}^n(t_2)))\Big]^2\,ds$$

$$\leqq c_2(T)\int_\Omega d\mathbf{x}\int_0^T dt_1\int_0^{t_1}\frac{dt_2}{|t_1-t_2|^{1+\nu}}\int_0^{t_2}[\|\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_2-s))\|^2 \tag{2.19}$$
$$+\|\mathbf{e}(\mathbf{u}^n(t_1))-\mathbf{e}(\mathbf{u}^n(t_2))\|^2]\,ds$$
$$\leqq c_3(T)\int_0^T\int_0^T\int_\Omega\frac{\|\mathbf{e}(\mathbf{u}^n(t_1))-\mathbf{e}(\mathbf{u}^n(t_2))\|^2}{|t_1-t_2|^{1+\nu}}\,dt_1\,dt_2\,d\mathbf{x},$$

while for the second integral in (2.18) we have the estimates

$$\left[\int_{t_2}^{t_1}h(s)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1)))\,ds\right]^2$$
$$\leqq c_4(T)\int_{t_2}^{t_1}h^2(s)\,ds\int_{t_2}^{t_1}\|\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1))\|^2\,ds \tag{2.20}$$
$$\leqq c_5(T)[(t_1-t_2)+(t_1-t_2)^{1-2\nu}]\int_{t_2}^{t_1}\|\mathbf{e}(\mathbf{u}^n(t_1-s)-\mathbf{e}(\mathbf{u}^n(t_1))\|^2\,ds.$$

However,

$$\int_\Omega d\mathbf{x}\int_0^T dt_1\int_0^{t_1}\frac{dt_2}{|t_1-t_2|^{1+\nu}}[(t_1-t_2)+(t_1-t_2)^{1-2\nu}]$$
$$\times\int_{t_2}^{t_1}\|\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1))\|^2\,ds \tag{2.21}$$
$$\leqq c_6(T)\sup_{0\leqq t\leqq T}\|\mathbf{u}^n(t)\|^2_{W^{1,2}}.$$

So for some $c_\eta(T)>0$,

$$\int_\Omega d\mathbf{x}\int_0^T dt_1\int_0^{t_1}\frac{dt_2}{|t_1-t_2|^{1+\nu}}\left[\int_{t_2}^{t_1}h(s)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^n(t_1-s))-\mathbf{e}(\mathbf{u}^n(t_1)))\,ds\right]^2 \tag{2.22}$$
$$\leqq c_\tau(T)\sup_{0\leqq t\leqq T}\|\mathbf{u}^n(t)\|^2_{W^{1,2}}.$$

Combining (2.16), (2.17), (2.18), (2.19), and (2.22), with the obvious estimates generated by the terms in (2.7), other than the one engendered by σ_{ij}^M, and using the definition (2.14), with $\mu=\nu/2$, we are led to (2.15).

3. An interpolation lemma. Let v^i be an orthonormal basis in $L^2(\Omega)$ formed by the eigenfunctions for the problem

$$\Delta v^i+\lambda v^i=0,\quad \text{in }\Omega;\qquad v^i\in W_0^{1,2}(\Omega). \tag{3.1}$$

Let $0\leqq\eta\leqq\frac{3}{2}$, $-1\leqq\theta\leqq 1$, and consider an element $v\in L^2((0,T);\ W^{-1,2}(\Omega))$, $T>0$. Then v may be expanded in a double Fourier series

$$v=\sum_{i=0}^{\infty}\sum_{j=1}^{\infty}C_{ij}h_i(t)v^i(x), \tag{3.2}$$

where $h_0(t)=1/\sqrt{T}$, $h_i(t)=\sqrt{2/T}\cos(i\pi/T)t$. We define

$$W^{\eta,2}((0,T);\,W_0^{\theta,2}(\Omega))$$

$$=\left\{u\in L^2((0,T);\,W^{-1,2}(\Omega))\,\middle|\,\sum_{i=0}^{\infty}\sum_{j=1}^{\infty}c_{ij}^2(1+i^2)^{\eta}\lambda_j^{\theta}\equiv\|\mathbf{u}\|_{\eta,\theta}^2<\infty\right\}. \tag{3.3}$$

For $1<\eta<\frac{3}{2}$, a norm equivalent to $\|\mathbf{u}\|_{\eta,\theta}$ is given by

$$\left[\|\mathbf{u}\|^2_{L^2((0,T);W^{-1,2}(\Omega))}+\int_0^T\int_0^T\frac{\|\dot{\mathbf{u}}(t)-\dot{\mathbf{u}}(\tau)\|^2_{W_0^{\theta,2}}}{|t-\tau|^{1+2(\eta-1)}}\,d\tau\,dt\right]^{1/2}. \tag{3.4}$$

For the spaces defined by (3.3) we may state the following.

LEMMA 3.1. *Let $0\leqq\alpha\leqq 1$, $0\leqq\eta<\frac{3}{2}$. Then there exists $C>0$ such that*

$$\|\mathbf{v}\|_{W^{\alpha\eta,2}((0,T);\,W^{-\alpha,2}(\Omega))}\leqq C\|\mathbf{v}\|^{1-\alpha}_{L^2((0,T);L^2(\Omega))}\|\mathbf{v}\|^{\alpha}_{W^{\eta,2}((0,T);W^{-1,2}(\Omega))}. \tag{3.5}$$

Proof. We compute directly that

$$\begin{aligned}&\|\mathbf{v}\|_{W^{\alpha\eta,2}((0,T);\,W^{-\alpha,2}(\Omega))}\\&=\sum_{i,j}c_{ij}^2(1+i^2)^{\alpha,\eta}\lambda_j^{-\alpha}\\&\leqq\sum_{i,j}c_{ij}^{2\alpha}(1+i^2)^{\alpha\eta}\lambda_j^{-\alpha}c_{ij}^{2(1-\alpha)}\\&\leqq\left(\sum_{i,j}c_{ij}^2(1+i^2)^{\eta}\lambda_j^{-1}\right)^{\alpha}\left(\sum_{i,j}c_{ij}^2\right)^{1-\alpha}.\end{aligned}$$

□

4. Existence of a weak solution. We begin by first proving that the operator $(\partial/\partial x_j)\sigma_{ij}^M$ is Lipschitz continuous, as indicated in the remarks of § 1; this result is the essential content of the following theorem.

THEOREM 4.1. *There exists $p>0$, independent of T, such that*

$$\begin{aligned}&\|\sigma_{ij}^M(\mathbf{u}^1)-\sigma_{ij}^M(\mathbf{u}^2)\|_{L^2((0,T);L^2(\Omega;R^{n^2}))}\\&\leqq\lambda p\|\mathbf{e}(\mathbf{u}^1)-\mathbf{e}(\mathbf{u}^2)\|_{L^2((0,T);L^2(\Omega;R^{n^2}))}.\end{aligned} \tag{4.1}$$

Proof. A direct computation yields the following series of estimates:

$$\begin{aligned}&\int_0^T dt\int_\Omega(\sigma_{ij}^M(\mathbf{u}^1))-(\sigma_{ij}^M(\mathbf{u}^2))^2\,d\mathbf{x}\\&\leqq d_1\int_0^T dt\int_\Omega\left[\int_0^t(h(t-\tau))[\|\mathbf{e}(\mathbf{u}^1(\tau))-\mathbf{e}(\mathbf{u}^2(\tau))\|+\|\mathbf{e}(\mathbf{u}^1(t))-\mathbf{e}(\mathbf{u}^2(t))\|]\,d\tau\right]^2d\mathbf{x}\\&\leqq d_2\int_0^T dt\int_\Omega\|\mathbf{e}(\mathbf{u}^1(t))-\mathbf{e}(\mathbf{u}^2(t))\|^2\,d\mathbf{x}\\&\qquad+d_3\int_0^T dt\int_\Omega\left(\int_0^t h(t-\tau)\,d\tau\right)\left(\int_0^t h(t+\tau)\|\mathbf{e}(\mathbf{u}^1(\tau))-\mathbf{e}(\mathbf{u}^2(\tau))\|^2\,d\tau\right)d\mathbf{x}\\&\leqq d_4\int_0^T dt\int_\Omega\|\mathbf{e}(\mathbf{u}^1(t))-\mathbf{e}(\mathbf{u}^2(t))\|^2\,d\mathbf{x}\\&\qquad+d_5\int_0^T d\tau\int_\Omega\|\mathbf{e}(\mathbf{u}^1(\tau))-\mathbf{e}(\mathbf{u}^2(\tau))\|^2\,d\mathbf{x}\int_\tau^T h(t-\tau)\,dt\\&\leqq d_6\int_0^T dt\int_\Omega\|\mathbf{e}(\mathbf{u}^1(t))-\mathbf{e}(\mathbf{u}^2(t))\|^2\,d\mathbf{x}.\end{aligned} \tag{4.2}$$

□

THEOREM 4.2 (Global existence of a weak solution). *The initial boundary value problem* (2.2)–(2.4) *possesses, under the conditions* (1.2)–(1.6), *with* $W(0)=V(0)=(\partial W/\partial e_{ij})(0)=(\partial V/\partial e_{ij})(0)=0$, $\mathbf{u}^0 \in W_0^{1,2}(\Omega;\, R^n)$, $\mathbf{u}^1 \in L^2(\Omega; \mathbb{R}^n)$, *and* (2.6), (2.13), *a weak solution on* $(0,\infty)$ *for* $\lambda p < \hat{\alpha}$ *and* $\nu < \frac{1}{2}$. *The solution* $\mathbf{u}$ *satisfies*

$$\text{(4.3a)} \qquad \text{(i)} \qquad \mathbf{u} \in L^\infty((0,\infty);\, W_0^{1,2}(\Omega;\, R^n)),$$

$$\text{(4.3b)} \qquad \text{(ii)} \qquad \dot{\mathbf{u}} \in L^\infty((0,\infty);\, L^2(\Omega; \mathbb{R}^n)),$$

$$\text{(4.3c)} \qquad \text{(iii)} \qquad \mathbf{u} \in W^{\nu/2,2}((0,\,T);\, W_0^{1,2}(\Omega;\, R^n)) \quad \forall T>0,$$

$$\text{(4.3d)} \qquad \text{(iv)} \qquad \begin{aligned} &\mathbf{u} \in W^{\nu/2,2}((0,\,T);\, W^{-1,2}(\Omega; \mathbb{R}^n)) \\ &\quad \cap L^2((0,\,T);\, W^{-1/(1+(\nu/2))}(\Omega; \mathbb{R}^n)) \quad \forall T>0. \end{aligned}$$

Remark. The condition $\lambda p < \hat{\alpha}$ yields the result that the operator $(\partial/\partial x_j)\sigma_{ij} = (\partial/\partial x_j)\sigma_{ij}^I + (\partial/\partial x_j)\sigma_{ij}^M$ is strongly monotone.

Proof. Let $1/(1+(\nu/2)) < \alpha < 1$. Then it follows from our interpolation Lemma 3.1, with $v = \dot{u}_i^n$, that $\dot{u}_i^n$ is a bounded sequence in $W^{(1+(\nu/2))\alpha,2}((0,\,T);\, W^{-\alpha,2}(\Omega))$, which, in turn, is compactly embedded in $W^{1,2}((0,\,T);\, W^{-1,2}(\Omega))$. Therefore, we may choose a subsequence $\mathbf{u}^{(n_k)}$, such that for each $T>0$, and some $\mathbf{u}$ satisfying (4.3a–d),

$$\text{(4.4a)} \qquad \mathbf{u}^{n_k} \to \mathbf{u}, \quad \text{in } L^2((0,\,T);\, W_0^{1,2}(\Omega; \mathbb{R}^n)),$$

$$\text{(4.4b)} \qquad \dot{\mathbf{u}}^{n_k} \to \dot{\mathbf{u}}, \quad \text{in } L^2((0,\,T);\, L^2(\Omega; \mathbb{R}^n)),$$

$$\text{(4.4c)} \qquad \mathbf{u}^{n_k} \to \mathbf{u}, \quad \text{in } W^{\nu/2,2}((0,\,T);\, W^{1,2}(\Omega; \mathbb{R}^n)),$$

$$\text{(4.4d)} \qquad \ddot{\mathbf{u}}^{n_k} \to \ddot{\mathbf{u}}, \quad \text{in } W^{\nu/2,2}((0,\,T);\, W^{-1,2}(\Omega; \mathbb{R}^n)),$$

$$\text{(4.4e)} \qquad \ddot{\mathbf{u}}^{n_k} \to \ddot{\mathbf{u}}, \quad \text{in } L^2((0,\,T);\, W^{-1,2}(\Omega;\, R^n)).$$

Now, let P_n be the projection operator from $L^2((0,\,T);\, W_0^{1,2}(\Omega; \mathbb{R}^n))$ to the space spanned by the vectors $c_j(t)\mathbf{w}^j(t)$, where, for $j=1,\dots,n$, the $c_j \in L^2((0,\,T))$. From (2.7) we obtain

$$\text{(4.5)} \qquad \begin{aligned} &\int_0^T \int_\Omega \ddot{u}_i^{n_k}((\ddot{u}_i^{n_k} - P_{n_k}\mathbf{u})_i)\, d\mathbf{x}\, dt \\ &\quad + \int_0^T \int_\Omega \frac{\partial W}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^{n_k}))e_{ij}(\mathbf{u}^{n_k} - P_{n_k}\mathbf{u})\, d\mathbf{x}\, dt \\ &\quad - \int_0^T \int_\Omega \left[\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(\mathbf{u}^{n_k}(\tau)) - \mathbf{e}(\mathbf{u}^{n_k}(t)))\, d\tau\right] \cdot e_{ij}(\mathbf{u}^{n_k} - P_{n_k}\mathbf{u})\, d\mathbf{x}\, dt \\ &= \int_0^T \int_\Omega f_i(u_i^{n_k} - (P_{n_k}\mathbf{u})_i)\, d\mathbf{x}\, dt. \end{aligned}$$

For $\mathbf{u} \in W_0^{1,2}(\Omega; \mathbb{R}^n)$, Korn's inequality, i.e.,

$$\text{(4.6)} \qquad \int_\Omega e_{ij}(\mathbf{u})e_{ij}(\mathbf{u})\, d\mathbf{x} \geqq \kappa \|\mathbf{u}\|^2_{W^{1,2}(\Omega;\mathbb{R}^n)},$$

holds for some $\kappa > 0$ (see, e.g., [15]). Now we know that as $n_k \to \infty$

$$\text{(4.7)} \qquad P_{n_k}\mathbf{u} - \mathbf{u}, \quad \text{in } L^2((0,\,T);\, W_0^{1,2}(\Omega;\, R^n)).$$

Therefore, both

$$\text{(4.8)} \qquad \int_0^T \int_\Omega \frac{\partial W}{\partial e_{ij}}(\mathbf{e}(P_{n_k}\mathbf{u}))e_{ij}(\mathbf{u}^{n_k} - P_{n_k}\mathbf{u})\, d\mathbf{x}\, dt \to 0$$

and

$$(4.9)\qquad \int_0^T \int_\Omega \left[\int_0^t h(t-\tau)\frac{\partial V}{\partial e_{ij}}(\mathbf{e}(P_{n_k}\mathbf{u})(\tau))-\mathbf{e}(P_{n_k}\mathbf{u}(t))\,d\tau\right] e_{ij}(\mathbf{u}^{n_k}-P_{n_k}\mathbf{u})\,d\mathbf{x}\,dt \to 0$$

as $n_k \to \infty$. By virtue, therefore, of (4.8), (4.9), (4.4e), and (4.1), with $\lambda p < \alpha$, we find that as $n_k \to \infty$

$$(4.10)\qquad \mathbf{u}^{n^k} \to \mathbf{u}, \text{in } L^2((0, T);\ W_0^{1,2}(\Omega; \mathbb{R}^n)),$$

and the existence of the required global weak solution follows as a direct consequence of (2.7). □

WEAK SOLUTION TO AN EVOLUTION PROBLEM WITH A NONLOCAL CONSTRAINT*

PETER SHI[†]

Abstract. A parabolic problem is considered with a nonlocal constraint in place of one of the standard boundary conditions. Well-posedness of the problem is proved in a weighted, fractional Sobolev space with the problem data proposed in related weighted spaces. This comes as an intrinsic requirement of the problem. The proof uses an interpolation inequality for norms of fractional Sobolev spaces and is based on an interesting choice of the test function.

Key words. nonlocal condition, weighted Sobolev space

AMS(MOS) subject classifications. primary 35K; secondary 35R

1. Introduction. In this paper, we are concerned with one-dimensional parabolic equations with a nonlocal condition—the so-called energy specification. This is a linear constraint having the form

$$\int_0^b \theta(\xi,t)d\xi = E(t), \tag{1.1}$$

where $b \in (0,1]$ is a constant and $E(\cdot)$ is a given function. Coupled with a one-dimensional parabolic equation, condition (1.1) is quite different from usual semilocal boundary conditions such as

$$-\theta_x = f(\theta)\cdot\theta \quad \text{on the boundary}, \tag{1.2}$$

where f is some nonlinear functional. The latter, though difficult to handle in its own right, can always be tied into weak formulations of the problem upon integration by parts, while condition (1.1) may not be the case using the stardard method. Our main tool used in this paper is an interpolation inequality (Lemma 3.1, §.3) combined with the basic methods described in Yurchuk [11] and in Ladyzhenskaya et al. [4, Chap. 3].

Evolution problems with linear constraint (1.1) have received attention in the last twenty years. Most of the work was directed to classical solutions, and these were carried out mostly by Cannon and his co-workers. We refer the reader to Cannon et al. [2] and references therein. We mention that a mathematical model with constraint (1.1) was recently derived in Shi and Shillor [8] in the context of thermoelasticity.

In contrast to previous work devoted to classical solution, we consider weak solutions. Let $\Omega_T = \Omega \times (0,T)$ with $T > 0$ and $\Omega = (0,1)$. We shall consider the problem

$$\theta_t - \theta_{xx} = f_1 + f_{2x}, \qquad (x,t) \in \Omega_T, \tag{1.3}$$

$$\theta_x(1,t) = 0, \qquad 0 < t < T, \tag{1.4}$$

$$\theta(x,0) = \varphi(x), \qquad 0 < x < 1, \tag{1.5}$$

*Received by the editors January 18, 1992; accepted for publication (in revised form) May 27, 1992.

[†]Department of Mathematical Sciences, Oakland University, Rochester, Michigan 48309-4401.

$$\int_0^b \theta(\xi,t)d\xi = E(t), \qquad 0 < t < T. \tag{1.6}$$

Our interest lies in the well-posedness of the problem (1.3)–(1.6) in a weighted fractional Sobolev space under compatible assumptions on data. In particular, we do not assume any classical differentibility of E. For other data φ, f_1, and f_2, we only assume their membership in certain weighted L^2-spaces. In order to keep the exposition from technical cumbersomeness, we restrict our discussion to linear equations with constant coefficients, although the method is not limited to this case by itself.

The first study of evolution problems involving energy specification goes back to Cannon [1] 1963. There the author considered the problem

$$\theta_t - \theta_{xx} = 0, \qquad x > 0, \quad t > 0, \tag{1.7}$$

$$\theta(x,0) = \varphi, \qquad x > 0, \tag{1.8}$$

$$\int_0^{x(t)} \theta(x,t)\,dx = E(t), \qquad t > 0, \tag{1.9}$$

where $x(t)$ is a given function. Introducing $f \equiv \theta(0,t)$ as the unknown, it is proved in [1] that (1.7)–(1.9) is equivalent to a Volterra integral equation of the second kind for f. The existence and uniqueness of the solution is proved with the aid of the integral equation. The author also proved that if the spacial domain is finite, then the problem reduces to an integral equation of Fredholm type whose kernel is generated by the Green's function for the heat equation. Recently, problems similar to (1.3)–(1.6) but involving nonlinearities in the equation have been treated in Lin [6] and Cannon et al. [2].

Along a different line, the problem was considered by Ionkin [3], Makarov and Kulyev [5], and Yurchuk [11]. The method in [11] is most innovative. The author established the existence of a weighted strong solution to the problem

$$\theta_t - \theta_{xx} = f, \qquad (x,t) \in \Omega_T, \tag{1.10}$$

$$\theta(1,t) = 0, \qquad 0 < t < T, \tag{1.11}$$

$$\theta(x,0) = \varphi(x), \qquad 0 < x < 1, \tag{1.12}$$

$$\int_0^1 \theta(\xi,t)d\xi = 0, \qquad 0 < t < T, \tag{1.13}$$

under certain assumptions on data. Unlike most cases where a weighted space appears either because of singular coefficients of the equation or because of an unbounded domain, here the weight comes to place for the annihilation of inconvenient terms during integration by parts. The result and the method in the present paper are further elaboration of those in [11].

We now introduce appropriate function spaces. Let $L^2(\Omega_T; x)$ be the weighted L^2-space with finite norm

$$\|f\|_{L^2_x} = \left(\int_{\Omega_T} x^2 f^2\,dx\,dt\right)^{1/2}. \tag{1.14}$$

Let $W^{1,0}(\Omega_T; x)$ be the subspace of $L^2(\Omega_T)$ with finite norm

$$\|u\|_{W^{1,0}_x} \equiv \left(\int_{\Omega_T} u^2\,dx\,dt\right)^{1/2} + \left(\int_{\Omega_T} x^2 u_x^2\,dx\,dt\right)^{1/2}. \tag{1.15}$$

$W^{2,1}(\Omega_T;x)$ is the subspace of $W^{1,0}(\Omega_T;x)$ whose elements satisfy u_t, $u_{xx} \in L^2(\Omega_T;x)$. In general, a function in the space $W^{k,h}(\Omega_T;x)$, with k, h nonnegative integers, possesses x-derivatives up to kth order in $L^2(\Omega_T;x)$, and t-devivatives up to hth order in $L^2(\Omega_T;x)$. In this paper, we also use weighted spaces on the interval $\Omega = (0,1)$ such as $L^2(\Omega;x)$ and $H^1(\Omega;x)$, whose definitions are analogous to the spaces on Ω_T. For example, $H^1(\Omega;x)$ is the subspace of $L^2(0,1)$ with the finite norm

$$\|\varphi\|_{H^1_x} \equiv \left(\int_0^1 \varphi^2 dx\right)^{1/2} + \left(\int_0^1 x^2\varphi_x^2 dx\right)^{1/2}. \tag{1.16}$$

The following theorem is proved in [11].

THEOREM 1.1. *Assume that* $\varphi \in H^1(\Omega;x)$ *and* $f \in L^2(\Omega_T;x)$. *Then problem* (1.10)–(1.13) *admits a solution in* $W^{2,1}(\Omega_T;x)$.

To state the result of the present paper, we require the definition of the fractional Sobolev space $W^{1,\alpha}(\Omega_T;x)$, $0<\alpha<1$, which is a subspace of $W^{1,0}(\Omega_T;x)$ having the finite integral

$$I_w(u) = \int_{-\infty}^{+\infty}\int_0^1 x^2|w^{\sim}|^2(x,s)(1+s^2)^{\alpha}\,dx\,ds$$

for each $w \in C_0^{\infty}(R^2)$ whose restriction to Ω_T equals u. Here and in the rest of the paper, the tilde sign $(\cdot)^{\sim}$ denotes the Fourier transform of the underlying function. The norm of $W^{1,\alpha}(\Omega_T;x)$ is given by

$$\|u\|_{W^{1,\alpha}(\Omega_T;x)} = \|u\|_{W^{1,0}(\Omega_T;x)} + \inf_w I_w(u). \tag{1.17}$$

The space $W^{0,\alpha}(\Omega_T;x)$ and $H^{\alpha}(0,T)$ are analagously defined. We refer the reader to [7] and [9] for more details on fractional Sobolev spaces.

We are now in a position to state the main result of this paper.

THEOREM 1.2. *Assume that* f_1, $f_2 \in L^2(\Omega_T;x)$ *with* f_2 *continuous in a neighborhood of* $x=1$, $\varphi \in L^2(\Omega;x)$, *and* $E \in H^{(1+\epsilon)/2}(0,T)$, *where* $\epsilon > 0$. *Then problem* (1.3)–(1.6) *admits a unique solution* θ *in* $W^{1,1/2}(\Omega_T;x)$, *provided that, in addition, one of the following conditions holds*:

(i) $b=1$;

(ii) $\varphi \in H^1(b-\sigma,1)$ *and* $f_{2x} \in L^2(b-\sigma,1)$ *for some small* $\sigma > 0$.

Moreover, we have the estimates

$$C\,\|\theta\|_{W_x^{1,1/2}} \le \begin{cases} \Sigma & \textit{if } b=1,\\ \Sigma + \|f_{2x}\|_{L^2(\Omega_{\sigma,T})} + \|\varphi\|_{H^1(b-\sigma,1)} & \textit{if } 0<b<1,\end{cases}$$

where $\Sigma = \|f_1\|_{L^2_x} + \|f_2\|_{L^2_x} + \|\varphi\|_{L^2_x} + \|E\|_{H^{\alpha}(0,T)}$, $\Omega_{\sigma,T} = (b-\sigma,1)\times(0,T)$, *and* $C>0$ *depends* ϵ, α, σ, b, *and* T *only.*

2. Weak formulation. In general, a $W^{1,1/2}(\Omega_T;x)$ solution to problem (1.3)–(1.6) can be understood in sense of distributions and traces, but we prefer a variational formulation in which the nonlocal constraint (1.6) does not explicitly appear. Following the idea of [11], we introduce the operators

$$J(v) \equiv \int_x^1 v(\xi,t)\,d\xi, \tag{2.1}$$

$$M(v) = x^2 v(x,t) + 2xJ(v). \tag{2.2}$$

For any function $v \in C^1(\overline{\Omega}_T)$, it is easy to check that the following holds:

$$J(v)(1,t) = 0, \qquad M(v)(0,t) = 0, \tag{2.3}$$

and

$$2\int_0^1 xvJ(v)\,dx = \int_0^1 |J(v)|^2\,dx \tag{2.4}$$

for all $t \in [0,T]$. These equalities can be extended to functions in $W^{1,0}(\Omega_T; x)$ by a density argument. Let $Lu = u_t - u_{xx}$. We next compute the integral $\int_{\Omega_T}(Lu)\cdot M(v)\,dx$. We first work with the special case, where

$$b = 1 \quad \text{and} \quad E(t) = 0 \quad \forall t \in (0,T). \tag{2.5}$$

Thus in the following computations we assume $u, v \in C^1(\overline{\Omega}_T)$, $u_x(1,t) = 0$, $u(x,0) = \varphi(x)$, and both u and v satisfy the homogeneous integral condition

$$\int_0^1 u(\xi,t)\,d\xi = \int_0^1 v(\xi,t)\,d\xi = 0. \tag{2.6}$$

In light of the above assumptions, we obtain

$$\begin{aligned} -\int_0^1 x^2 u_{xx} v\,dx &= -\left\{ x^2 v u_x \Big|_{x=0}^{x=1} - \int_0^1 u_x[2xv + x^2 v_x]\,dx \right\} \\ &= \int_0^1 2xvu_x\,dx + \int_0^1 x^2 u_x v_x\,dx, \end{aligned} \tag{2.7}$$

$$\begin{aligned} -2\int_0^1 u_{xx} xJ(v)\,dx &= -2\left\{ xJ(v)u_x \Big|_{x=0}^{x=1} - \int_0^1 u_x[J(v) - xv]\,dx \right\} \\ &= 2\int_0^1 u_x J(v)\,dx - 2\int_0^1 xvu_x\,dx \\ &= 2\left\{ J(v)u\Big|_{x=0}^{x=1} + \int_0^1 vu\,dx \right\} - 2\int_0^1 xvu_x\,dx \\ &= 2\int_0^1 uv\,dx - 2\int_0^1 xvu_x\,dx. \end{aligned} \tag{2.8}$$

It follows from (2.7) and (2.8) that

$$\int_0^1 -u_{xx}M(v)\,dx = \int_0^1 x^2 u_x v_x\,dx + 2\int_0^1 uv\,dx. \tag{2.9}$$

To compute the integral $u_t M(v)$, we assume in addition, $v(\cdot,T) = 0$. The standard integration by parts leads to

$$\int_0^T u_t M(v)\,dt = -\varphi(x)M\big(v(x,0)\big) - \int_0^T uM(v_t)\,dt. \tag{2.10}$$

Thus from (2.9) and (2.10) we obtain

$$\begin{aligned} &\int_{\Omega_T} (Lu)M(v)\,dx\,dt + \int_0^1 \varphi M\big(v(x,0)\big)\,dx \\ &= \int_{\Omega_T} [-uM(v_t) + x^2 u_x v_x + 2uv]\,dx\,dt. \end{aligned} \tag{2.11}$$

Returning to the general case, without assuming (2.5), we introduce the transform

$$u = \theta - E - \int_b^1 \theta\, d\xi, \tag{2.12}$$

where θ is a classical solution of (1.3)–(1.6). It is easy to check that u thus defined in (2.12) satisfies (2.6) and other conditions that lead to (2.11). Moreover, u satisfies the equation

$$Lu = f_1 + f_{2x} - \left(E + \textstyle\int_b^1 \theta\, d\xi\right)_t . \tag{2.13}$$

Substituting (2.12) and (2.13) into (2.11), after appropriate integration by parts, yields

$$\begin{aligned}\int_{\Omega_T} &\left[-\left(\theta - E - \textstyle\int_b^1 \theta\, d\xi\right) M(v_t) + x^2\theta_x v_x + 2\left(\theta - E - \textstyle\int_b^1 \theta\, d\xi\right) v\right] dx\, dt \\ &= \int_{\Omega_T} \left[f_1 M(v) + f_2\left(x^2 v_x + 2J(v)\right) + \left(E + \textstyle\int_b^1 \theta\, d\xi\right) M(v_t)\right] dx\, dt \\ &\quad + \int_0^1 \left[\varphi - E(0) - \textstyle\int_b^1 \varphi(\xi)\, d\xi\right] M(v(x,0))\, dx + \int_0^T f_2(1,t) v(1,t)\, dt,\end{aligned}$$

which in turn, by virtue of a straightforward simplification, gives

$$\begin{aligned}\int_{\Omega_T} &\left[-\theta M(v_t) + x^2\theta_x v_x + 2\left(\theta - E - \textstyle\int_b^1 \theta\, d\xi\right) v\right] dx\, dt \\ &= \int_{\Omega_T} \left[f_1 M(v) + f_2\left(x^2 v_x + 2J(v)\right)\right] dx\, dt \int_0^T f_2(1,t) v(1,t)\, dt \\ &\quad + \int_0^1 \left[\varphi - E(0) - \textstyle\int_b^1 \varphi(\xi)\, d\xi\right] M(v(x,0))\, dx.\end{aligned} \tag{2.14}$$

Definition 2.1. We say that $\theta \in W^{1,0}(\Omega_T)$ is a weak solution to problem (1.3)–(1.6) if (2.14) holds for all $v \in C^1(\overline{\Omega_T})$ such that

$$v(\cdot, T) = 0 \quad \text{and} \quad \int_0^1 v(\xi, \cdot)\, d\xi = 0. \tag{2.15}$$

The above computations leading to (2.14) have shown that any classical solution to (1.3)–(1.6) is also a weak solution. Reversing the steps above, we can also prove that a sufficiently smooth weak solution is a classical solution.

We remark that each term in (2.14) is well defined if the problem data satisfies the requirement of Theorem 1.2.

3. A priori estimates. In this section we derive estimates for classical solutions to problem (1.3)–(1.6) in the $W^{1,1/2}(\Omega_T; x)$ norm. The existence of a weak solution is obtained by subtracting a convergent subsequence, once a priori estimates are established. Regularity assumptions on problem data are not important for our purpose in this section since they can be approximated by smooth functions.

We use θ to denote the smooth solution to (1.3)–(1.6), and u is determined by the transform (2.12). These conventions will be in force throughout this section unless otherwise specified.

We first prove an interpolation inequality, which plays a crucial role in the subsequent estimates. The inequality may also be of interest by itself.

LEMMA 3.1. *For any $\frac{1}{2} < \alpha < 1$, there exists a constant $C_\alpha > 0$ such that for any $w, v \in C^1[0,T]$,*

$$\left|\int_0^T w'v\,dt\right| \le C_\alpha \|w\|_{H^\alpha(0,T)} \cdot \|v\|_{H^{1-\alpha}(0,T)}. \tag{3.1}$$

For any $0 < \beta < 1$ and $\delta > 0$, there exists $C_{\delta,\beta} > 0$ such that

$$\|v\|_{H^\beta(0,T)} \le \delta\|v\|_{H^1(0,T)} + C_{\delta,\beta}\|v\|_{L^2(0,T)} \quad \forall\ v \in H^1(0,T). \tag{3.1'}$$

Proof. A simple proof of (3.1′) can be made by contrapositive argument, using the fact of compact imbeddings

$$H^1(0,T) \hookrightarrow H^\beta(0,T) \hookrightarrow L^2(0,T).$$

Since (3.1′) is essentially known, we omit the proof.

To prove (3.1) we choose $f \in H^\alpha(R), g \in H^{1-\alpha}(R)$ such that $f|_{(0,T)} = w, g|_{(0,T)} = v$. Fix $\tau < T$. Then for all $h > 0$ sufficiently small, we get by the Plancherel theorem that

$$\begin{aligned} I_h &= \int_0^\tau \frac{w(t+h) - w(t)}{h} v(t)\,dt \\ &= \int_0^\tau \frac{f(t+h) - f(t)}{h} g(t)\,dt \\ &= \int_{-\infty}^\infty \frac{f(t+h) - f(t)}{h} (\chi_\tau g)(t)\,dt \\ &= \int_{-\infty}^\infty \frac{e^{ihs} - 1}{h} \tilde{f}(s)(\chi_\tau g)^\sim(s)\,ds, \end{aligned} \tag{3.2}$$

where χ_τ is the characteristic function of $(0,\tau)$. Now

$$\left|\frac{e^{ihs} - 1}{h}\right| \le 2|s| \quad \forall h > 0,$$

and

$$\lim_{h\to 0} \frac{e^{ihs} - 1}{h} = is \quad \forall s \in R.$$

Thus for all $h > 0$ the modulus of the integrand in the last integral in (3.2) is dominated by

$$k(s) = 2|s|\ |\tilde{f}(s)|\ |(\chi_\tau g)^\sim(s)|,$$

and $k \in L^1(R)$ since $f \in H^\alpha(R)$, $g \in H^{1-\alpha}(R)$. Hence by the dominated convergence theorem,

$$\begin{aligned} \left|\int_0^\tau u'v\,dt\right| &= \lim_{h\to 0} |I_h| \\ &= \left|\int_{-\infty}^\infty is\tilde{f}(s)(\chi_\tau g)^\sim(s)\,ds\right| \\ &\le \int_{-\infty}^\infty (1 + |s|^2)^{\alpha/2}|\tilde{f}(s)|\,(1 + |s|^2)^{(1-\alpha)/2}|(\chi_\tau g)^\sim(s)|\,ds \\ &\le \|f\|_{H^\alpha(R)} \cdot \|\chi_\tau g\|_{H^{1-\alpha}(R)} \\ &\le C\|f\|_{H^\alpha(R)} \cdot \|g\|_{H^{1-\alpha}(R)}, \end{aligned}$$

where the last inequality follows from the fact that multiplication by χ_τ is a bounded operator on $H^{1-\alpha}(R)$ with operator norm bounded by a constant $C > 0$ that does not depend on τ (Strichartz [9, Cor. II. 3.7]). Thus by definition of the norm in $H^\alpha(0,T)$ we get that

$$\left| \int_0^\tau w'v \, dt \right| \leq C \|w\|_{H^\alpha(0,T)} \|v\|_{H^{1-\alpha}(0,T)}.$$

The result follows by letting $\tau \to T$.

LEMMA 3.2. *For each $\frac{1}{2} < \alpha < 1, \epsilon > 0$, there exists a constant $C > 0$ that depends only on α and ϵ such that*

$$\|u\|_{W_x^{1,0}} \leq C \left\{ \|f_1\|_{L_x^2} + \|f_2\|_{L_x^2} + \|E\|_{H^\alpha(0,T)} + \|\varphi\|_{L_x^2} + \|\textstyle\int_b^1 \theta \, d\xi\|_{H^\alpha(0,T)} \right\}$$
$$+ \epsilon \|u\|_{W_x^{0,1-\alpha}}.$$

Proof. By virtue of (2.9) in which we set $v = u$, we obtain

$$\int_0^1 -u_{xx} M(u) \, dx = \int_0^1 x^2 u_x^2 \, dx + 2 \int_0^1 u^2 \, dx.$$

Adding to both sides of the above equality by $\int_0^1 u_t M(u) dx$ and integrating the result over $(0,T)$, give

$$\int_{\Omega_T} \left(u_t \, M(u) + x^2 u_x^2 + 2u^2 \right) dx \, dt = \int_{\Omega_T} Lu \cdot M(u) \; dx \, dt.$$

Invoking (2.12) and (2.13), and carrying out appropriate integration by parts, we obtain

$$\begin{aligned} &\int_{\Omega_T} \left(u_t \, M(u) + x^2 u_x^2 + 2u^2 \right) dx \, dt \\ &\quad = \int_{\Omega_T} \left[f_1 \, M(u) + f_2 \big(x^2 u_x + 2J(u) \big) + F_t M(u) \right] dx \, dt, \end{aligned} \tag{3.3}$$

where

$$F \equiv -E - \textstyle\int_b^1 \theta \, d\xi. \tag{3.4}$$

The first term of the integral on the left-hand side of (3.3) is controlled from below by the integral

$$\int_{\Omega_T} \left[2xu_t \int_x^1 u(\xi, t) \, d\xi \right] dx \, dt - \frac{1}{2} \int_0^1 x^2 \varphi^2 \; dx.$$

Therefore, using the definition for the $W^{1,0}(\Omega_T; x)$ norm, we infer from (3.3),

$$\begin{aligned} &\int_{\Omega_T} \left[2xu_t \int_x^1 u(\xi, t) \, d\xi \right] dx \, dt + C_1 \|u\|_{W_x^{1,0}}^2 \\ &\quad \leq C_2 \{ \|f_1\|_{L_x^2}^2 + \|f_2\|_{L_x^2}^2 + \|\varphi\|_{L_x^2}^2 \} + \left| \textstyle\int_{\Omega_T} F_t \, M(u) \, dx \, dt \right|, \end{aligned} \tag{3.5}$$

where $C_1 > 0$, $C_2 > 0$, are fixed constants. The calculations from (3.3) to (3.5) are straightforward but somewhat tedious. We only illustrate a typical step below.

$$\begin{aligned} 2\int_{\Omega_T} f_2 J(u)\,dx\,dt &= -2\int_0^T\int_0^1 J(u)\,dJ(f_2)\,dx\,dt \\ &= -2\int_0^T\int_0^1 uJ(f_2)\,dx\,dt \\ &\le \frac{1}{4\epsilon}\int_0^T\int_0^1 J^2(f_2)\,dx\,dt + \epsilon\int_{\Omega_T} u^2\,dx\,dt, \end{aligned}$$

where $\epsilon > 0$ is sufficient small. In light of the inequality

$$\int_0^1 J^2(f_2)\,dx \le 4\int_0^1 x^2 f_2^2\,dx,$$

the term $2\int_{\Omega_T} f_2 J(u)\,dx\,dt$ in (3.4) is then dominated by

$$\frac{1}{\epsilon}\int_{\Omega_T} x^2 f_2^2\,dx\,dt + \epsilon\int_{\Omega_T} u^2\,dx\,dt, \tag{3.6}$$

where the second term will be absorbed in the left-hand side of (3.3).

We now estimate the integrals on both sides of (3.5). In light of Lemma 3.1, we have

$$\left|\int_{\Omega_T} F_t M(u)\,dx\,dt\right| \le \frac{1}{4\epsilon}\|F\|^2_{H^\alpha(0,T)} + \epsilon\|u\|^2_{W_x^{0,1-\alpha}}, \tag{3.7}$$

where $\epsilon > 0$ is sufficiently small. The integral on the left-hand side of (3.5) can be estimated in virtue of the following identity:

$$\int_0^1 x\big[uJ(v) + vJ(u)\big]\,dx = \int_0^1 J(u)J(v)\,dx \quad \forall u, v \in C[0,1]. \tag{3.8}$$

For this, we assume, without loss of generality, $f_2(1,\cdot) = 0$. Indeed, replacing u by u_t, v by u, in (3.8), and integrating the result over $[0,T]$, yield

$$\begin{aligned} &\int_{\Omega_T}\left[2xu_t\int_x^1 u(\xi,t)\,d\xi\right]dx \\ &\quad= 2\int_{\Omega_T} J(u_t)J(u)\,dx\,dt - 2\int_{\Omega_T} xu\,J(u_t)\,dx\,dt \\ &\quad\ge -\int_0^1 J^2(\varphi)\,dx - 2\int_0^T\int_0^1 xu\left[\int_x^1 (u_{\xi\xi} + f_1 + f_{2\xi} + F_t)\,d\xi\right]dx\,dt \\ &\quad= -\int_0^1 J^2(\varphi)\,dx - 2\int_0^T\int_0^1 xu\left[-u_x + \int_x^1 f_1\,d\xi - f_2(x) + \int_x^1 F_t\,d\xi\right]dx\,dt \\ &\quad\ge -\int_0^1 J^2(\varphi)\,dx - C_3\left\{\|f_1\|^2_{L_x^2} + \|f_2\|^2_{L_x^2} + \frac{1}{4\epsilon}\|F\|^2_{H^\alpha(0,T)} + \epsilon\|u\|_{W_x^{0,1-\alpha}}\right\}. \end{aligned} \tag{3.9}$$

Substituting (3.7) and (3.9) into (3.3)–(3.5), we obtain the desired result.

The next lemma improves the estimates in Lemma 3.2.

LEMMA 3.3. *For each $\frac{1}{2} < \alpha < 1$ there exists a constant $C = C(\alpha) > 0$, such that*

$$(3.10)\quad \|u\|_{W_x^{1,1/2}} \le C\Big\{\|f_1\|_{L_x^2} + \|f_2\|_{L_x^2} + \|\varphi\|_{L_x^2} + \|E\|_{H^\alpha(0,T)} + \|\ \textstyle\int_b^1 \theta d\xi\ \|_{H^\alpha(0,T)}\Big\}.$$

Proof. Following the method in Ladyzhenskaya et al. [4, p. 161] we extend the domain of u first to $(0,1) \times (0,+\infty)$ such that u vanishes for sufficiently large t. Then we extend the function to $Q \equiv (0,1) \times (-\infty,+\infty)$ by reflection. More precisely, once u is extended to $(0,1) \times (0,\infty)$, we set

$$u_1 = \begin{cases} u(x,t), & t \ge 0, \\ u(x,-t), & t < 0. \end{cases}$$

For the derivative of u we introduce a similar extension, namely,

$$u_2 = \begin{cases} u_x(x,t), & t \ge 0, \\ -u_x(x,-t), & t < 0. \end{cases}$$

The minus sign is designated to coping with the differential equations. In the same way, the problem data are extended as follows.

$$f_1^* = \begin{cases} f_1(x,t), & t \ge 0, \\ -f_1(x,-t), & t < 0. \end{cases}$$
$$f_2^* = \begin{cases} f_{2x}(x,t), & t \ge 0, \\ -f_{2x}(x,-t), & t < 0. \end{cases}$$
$$F^* = \begin{cases} F(x,t), & t \ge 0, \\ F(x,-t), & t < 0. \end{cases}$$

With the above extensions, (2.13) reads

$$(3.11)\qquad u_{1t} - u_{2x} = f_1^* + f_2^* + F_t^* \quad \text{a.e. in } Q = (0,1) \times (-\infty + \infty).$$

Let $\delta > 0$ and choose any $w \in C^\infty(-\infty,+\infty)$ such that $w = 1$ on $[0,T]$ and $\operatorname{supp}(w) \subset [-\delta,\, T+\delta]$. Then (3.11) implies

$$\begin{aligned} (w\,u_1)_t &= w_t\,u_1 + w\,u_{1t} \\ (3.12)\qquad &= w_t u_1 + (wu_2)_x + wf_1^* + wf_2^* + (wF^*)_t - w_tF^*. \end{aligned}$$

We now let ψ be any function in $C^1[0,1]$, possibly complex valued, such that

$$(3.13)\qquad \psi_x(1) = 0, \qquad \int_0^1 \psi(x)\,dx = 0.$$

Multiplying on both sides of (3.12) by $M(\psi)$ and integrating each term over $[0,1]$ with respect to x, taking care of $\int_0^1 (wu_2)_x M(\psi) dx$ via integration by parts, yield

$$\begin{aligned} \int_0^1 (wu_1)_t\, M(\psi)\, dx &= \int_0^1 (w_tu_1)\, M(\psi)\, dx + \int_0^1 wu_2\big(x^2\psi_x + 2J(\psi)\big)\, dx \\ (3.14)\qquad &\quad + \int_0^1 f_1^* w\, M(\psi)\, dx + \int_0^1 f_2^* w\, M(\psi)\, dx \\ &\quad + \int_0^1 (wF^*)_t\, M(\psi)\, dx - \int_0^1 w_tF^*\, M(\psi). \end{aligned}$$

Applying the Fourier transform on both sides of (3.14), we obtain

$$\int_0^1 -is(wu_1)^\sim(x,s)\,M(\psi)\,dx = Z^\sim(s) + \int_0^1 -is(wF^*)^\sim(x,s)\,M(\psi)\,dx \tag{3.15}$$

where

$$\begin{aligned} Z^\sim(s) = &\int_0^1 \left(w_t u_1 + f_1^* w + f_2^* - w_t F^*\right)^\sim M(\psi)\,dx \\ &+ \int_0^1 (wu_2)^\sim(x,s)\left(x^2\psi_x + 2J(\psi)\right)dx. \end{aligned} \tag{3.16}$$

In (3.14), (3.15) we put

$$\psi(x) = \begin{cases} i \text{ complex conjugate of } (wu_1)^\sim(x,s), & \text{if } s \geq 0, \\ -i \text{ complex conjugate of } (wu_1)^\sim(x,s), & \text{if } s < 0. \end{cases} \tag{3.17}$$

Clearly such choice of ψ satisfies (3.13). We integrate the result with respect to s to obtain

$$\begin{aligned} &\int_Q |s|\,(wu_1)^\sim M\left[\overline{(wu_1)^\sim}\right] dx\,ds \\ &\quad = \int_{-\infty}^{+\infty} Z^\sim(s)\,ds + \int_Q |s|\,(wF^*)^\sim(x,s)\,M\left[\overline{(wu_1)^\sim}\right] dx\,ds. \end{aligned} \tag{3.18}$$

The integral on the left-hand side of (3.18) is equal to, by virtue of the identity (2.4) and the Plancherel theorem [10],

$$\int_Q |s|\,x^2|(wu_1)^\sim|^2\,dx\,ds + \int_Q |s|\;|J\left((wu_1)^\sim\right)|^2\,dx\,ds. \tag{3.19}$$

Using the Plancherel theorem again and integration by parts, as in the proof of Lemma 3.2, the first integral on the right-hand side of (3.18) can be estimated by a constant times

$$\int_Q |wu_1|^2\,dx\,dt + \int_Q |wu_2|^2\,dx\,dt + \|F\|_{L^2(0,T)} + N(f_1,f_2,\varphi), \tag{3.20}$$

where $N(f_1,f_2,\varphi)$ is bounded as long as $\{f_1,f_2,\varphi\}$ remain bounded in their $L^2(\Omega_T;x)$ and $L^2(\Omega;x)$ norms, respectively. It then follows from (3.18)–(3.20) that

$$\begin{aligned} &\int_Q |s|\,x^2|(wu_1)^\sim|^2\,dx\,dt \\ &\quad \leq C\int_Q \left(|wu_1|^2 + x^2|wu_2|^2\right)dx\,dt + \|F\|_{L^2(0,T)} + N(f_1,f_2,\varphi) \\ &\qquad + \left|\int_Q |s|\,(wF^*)^\sim(x,s)\,M\left[\overline{(wu_1)^\sim}\right] dx\,ds\right|, \end{aligned} \tag{3.21}$$

where $C > 0$ depends only on the choice of w. In light of the definitions for u_1 and u_2, the first integral on the right-hand side of (3.21) is controlled by $C\|u\|^2_{W^{1,0}(\Omega_T;x)}$

for some constant $C > 0$, depending only on w. The left-hand side of (3.21) is greater or equal to $\|u\|^2_{W^{1,1/2}(\Omega_T;x)}$ by the definition of the fractional Sobolev space. Based on these estimates, (3.21) implies

$$\begin{aligned} \|u\|^2_{W_x^{1,1/2}} \leq & C\|u\|^2_{W^{1,0}(\Omega_T;x)} + N(f_1, f_2, \varphi) \\ & + \left| \int_0^1 |s|\, x^2 |(wF^*)^\sim(x,s)\, M\left[\overline{(wu_1)^\sim}\right] dx\, ds \right| \end{aligned} \tag{3.22}$$

Finally, we estimate the right-hand side of (3.22) as follows:

$$\begin{aligned} & \left| \int_Q |s|\, (wF^*)^\sim(x,s)\, M\left[\overline{(wu_1)^\sim}\right] dx\, ds \right| \\ & \leq \left| \int_Q \left[(1+|s|^2)^{\alpha/2}(wF^*)^\sim\right](1+|s|^2)^{(1-\alpha)/2} M\left[\ \overline{(wu_1)^\sim}\ \right] dx\, ds \right| \\ & \leq \frac{1}{4\epsilon}\int_Q (1+s^2)^\alpha |(wF^*)^\sim|^2\, dx\, ds + \epsilon \int_Q (1+s^2)^{1-\alpha} \left|(wu_1)^\sim\right|^2 dx\, ds \\ & \leq \frac{1}{2\epsilon}\|F\|^2_{H^\alpha(0,T)} + 2\epsilon\|u\|^2_{W_x^{0,1-\alpha}} + N(f_1, f_2, \varphi), \end{aligned} \tag{3.23}$$

where in the last inequality it is necessary to choose w properly so that

$$\int_Q (1+s^2)^\alpha |(wF^*)^\sim|^2\, dx\, ds \leq 2\|F\|^2_{H^\alpha(0,T)} + N(f_1, f_2, \varphi).$$

We now conclude from (3.22), (3.23), and Lemma 3.2 that

$$\|u\|^2_{W_x^{1,1/2}} \leq N(f_1, f_2, \varphi) + \|F\|_{H^\alpha(0,T)} + \epsilon\|u\|^2_{W_x^{0,1-\alpha}}. \tag{3.24}$$

In view of (3.3), Lemma 3.3 follows by choosing $0 < \epsilon < 1$ in (3.24).

Proof of Theorem 1.2. The result of Theorem 1.2 follows almost immediately from Lemma 3.3. If $b = 1$, then (3.10) and (2.12) imply

$$\|\theta\|_{W_x^{1,1/2}} \leq C\left\{ \|f_1\|_{L_x^2} + \|f_2\|_{L_x^2} + \|\varphi\|_{L_x^2} + \|E\|_{H^\alpha(0,T)} \right\}. \tag{3.25}$$

Consequently, a weak solution in $W^{1,1/2}(\Omega_T; x)$ is obtained by extracting a convergent subsequence of these classical solutions and taking the limit in (2.14). Since the problem is linear, uniqueness of the solution follows from (3.25). The case when $0 < b < 1$ needs a bit more effort. Instead of (3.25), we have

$$\begin{aligned} \|\theta\|_{W_x^{1,1/2}} \leq C\Big\{ & \|f_1\|_{L_x^2} + \|f_2\|_{L_x^2} + \|\varphi\|_{L_x^2} + \|E\|_{H^\alpha(0,T)} \\ & + \|f_{2x}\|_{L^2(\Omega_{\sigma,T})} + \|\varphi\|_{H^1(b-\sigma,1)}. \Big\}, \end{aligned} \tag{3.26}$$

where $\Omega_{\sigma,T} = (b-\sigma, 1) \times (0,T)$. To derive (3.26) we employ cutoff functions. Let $w \in C^2[0,1]$ such that $w = 1$ on $[b,1]$ and $w = 0$ on $[0, b-\sigma]$. Let

$$\Theta = w(x)\theta(x,t)e^{-\lambda t}, \qquad \lambda > 0.$$

By straightforward computations using (1.3)–(1.6), we obtain

$$\Theta_t - \Theta_{xx} + \lambda\Theta = fe^{-\lambda t}, \qquad (x,t) \in \Omega_{\sigma,T}, \tag{3.27}$$

$$\Theta_x(1,t) = 0, \qquad 0 < t < T, \tag{3.28}$$

$$\Theta(b-\sigma,t) = 0, \qquad 0 < t < T, \tag{3.29}$$

$$\Theta(x,0) = w\varphi, \qquad b-\sigma < x < 1, \tag{3.30}$$

where

$$f = \big(f_1 + f_{2x}\big)w - \big(2\theta_x w_x + \theta w_{xx}\big).$$

Following standard $W^{2,1}(\Omega_{\sigma,T})$ estimates, squaring both sides of (3.27) and integrating by parts, we obtain

$$\|\Theta\|_{W^{2,1}(\Omega_{\sigma,T})} + \lambda^2\|\Theta\|_{L^2(\Omega_{\sigma,T})} \le C\|f\|_{L^2(\Omega_{\sigma,T})}, \tag{3.31}$$

where $C > 0$ is independent of f and λ. In light of Lemma 3.3, f can be further controlled by

$$\begin{aligned} \|f\|_{L^2(\Omega_{\sigma,T})} \le& \|f_1\|_{L^2(\Omega_{\sigma,T})} + \|f_{2x}\|_{L^2(\Omega_{\sigma,T})} \\ &+ \|\varphi\|_{H^1(b-\sigma,1)}\|E\|_{H^\alpha(0,T)} + C\left\|\int_b^1 \theta\, d\xi\right\|_{H^\alpha(0,T)}. \end{aligned} \tag{3.32}$$

Now applying (3.1′) of Lemma 3.1 to $\int_b^1 \theta(\xi,\cdot)\, d\xi$ yields

$$\begin{aligned} \left\|\int_b^1 \theta\, d\xi\right\|_{H^\alpha(0,T)} &\le \delta\left\|\int_0^1 \theta_t\, d\xi\right\|_{L^2(0,T)} + C_\delta\left\|\int_b^1 \theta\, d\xi\right\|_{L^2(0,T)} \\ &\le \delta\|\Theta\|_{W^{2,1}(\Omega_{\sigma,T})} + C_\delta\|\Theta\|_{L^2(\Omega_{\sigma,T})}, \end{aligned} \tag{3.33}$$

where $\delta > 0$ is arbitrary and $C_\delta > 0$. It follows from (3.31)–(3.33) that, by setting δ sufficiently small and λ sufficiently large,

$$\begin{aligned} &\|\Theta\|_{W^{2,1}(\Omega_{\sigma,T})} \\ &\le C\Big\{\|f_1\|_{L^2(\Omega_{\sigma,T})} + \|f_{2x}\|_{L^2(\Omega_{\sigma,T})} + \|\varphi\|_{H^1(b-\sigma,1)} + \|E\|_{H^\alpha(0,T)}\Big\}, \end{aligned} \tag{3.34}$$

where $C > 0$ is independent of problem data. Hence (3.26) follows from (3.34) and Lemma 3.3.

Remark. If (1.3) is replaced by

$$\theta_t - a(x,t)\theta_{xx} = f(x,t,u),$$

the existence of a solution can be proved by the same method, provided that $a \in C^1(\overline{\Omega_T})$ and f is continuous in its arguments and satisfies a growth condition such that

$$|f(x,t,u)| \le g(x,t) + C \cdot |u|.$$

By the aid of local estimates of the equation, the particular type of the boundary condition at $x = 1$ is not important for the method. Let us elaborate on this point a little more. Suppose a proper boundary condition for θ is given at $x = 1$. Then we have local estimates for θ in a neighborhood of $x = 1$. Once local estimates are established, it remains to give estimates on $(0, 1 - \epsilon) \times (0, T)$ for sufficiently small ϵ. This leads to the exact situation discussed in this paper once we consider the new function $\gamma = \theta\zeta$, where $\zeta = 0$ on $(1 - \epsilon, 1)$ and $\zeta = 1$ on $[0, 1 - 2\epsilon)$. This is also the viewpoint when we treat the case $0 < b < 1$ in the proof of Theorem 2.1.

Acknowledgment. The author would like to thank Professor John Cannon and Professor Yanping Lin for many helpful discussions and their generous supply of references.

ON THE RIEMANN PROBLEM FOR A COMBUSTION MODEL*

TONG LI†

Abstract. This paper studies the Riemann problem for a combustion model and proves that the solution exists globally and the solution converges uniformly, away from the shock, to a travelling wave solution as $t \to +\infty$. The results are obtained by using the method of characteristics, a maximum principle and that the equation is a nonlinear conservation law.

Key words. detonation, conservation law, characteristic, maximum principle, shock wave, travelling wave, asymptotic behavior

1. Introduction. We consider a combustion model

$$u_t + (\tfrac{1}{2}u^2 - q_0 z)_x = 0 \tag{1}$$

$$z_x = K\varphi(u)z. \tag{2}$$

introduced by Rosales and Majda [7]. The system can be considered as a simplified model for compressible Euler equations for reactive mixture if u is interpreted as a lumped variable with some features of pressure or temperature and z as the mass fraction of unburnt gas. In this interpretation, (1) and (2) describe a one-step irreversible chemical reaction, where $q_0 > 0$ is the amount of heat released by the reaction, K is the reaction rate, and $\varphi(u)$ has the ignition form

$$\varphi(u) = \begin{cases} 1 & u \geqq u_i \\ 0 & u < u_i \end{cases} \tag{3}$$

here the ignition temperature u_i satisfies $0 < u_i < \sqrt{2q_0}$.

The problem is well posed when the data are given by

$$u(x, 0) = u_0(x), \tag{4}$$

$$z(+\infty, t) = 1. \tag{5}$$

In this paper we consider the Riemann problem (1), (2), (5), and

$$u_0(x) = \begin{cases} u_0 & x \leqq 0, \\ 0 & x > 0. \end{cases} \tag{6}$$

Riemann problems are important because they are building blocks for solutions with general initial data and they also provide us a way to do numerical simulations.

One expects the solution of the Riemann problem to converge to a travelling wave (when it exists) as $t \to +\infty$. That is, the initial shock discontinuity triggers a detonation wave. In fact, the numerical results of Bourlioux [1] showed the convergence.

In this paper, we prove global existence of solutions to the Riemann problems and that the solutions converge to travelling wave solutions. The results are proved by using the method of characteristics, a maximum principle and the conservation property of (1). Independently, Levy obtained a similar result for a similar model in [4].

The main difficulty in the proof is that there is a shock discontinuity in the solution. One important aspect of the proof is to understand the evolution in time of the discontinuity.

The existence of the Riemann problem is established using a fixed point theorem based on an iteration procedure which is due to Ying and Teng [9]. Properties of the shock front $s(t)\in C^1[0,+\infty)$, namely that s' is bounded and s is convex, are obtained by employing a maximum principle and the method of characteristics. From these properties, we prove our a priori estimates for the solution which are needed for the convergence.

To prove that the solution of the Riemann problem converges to a shifted travelling wave, we use the conservation law (1) and the initial data to determine the shift. This technique was used before by Liu in the study of stability of shock waves [5]. It is used not only to identify the shift but also to obtain information which helps the convergence proof. The conservation laws and the comparison principle give us global L^1 control over the solution.

In § 2 we summarize results about travelling wave solutions for (1) and (2) by Rosales and Majda [7]. Section 3 is the proof of the global existence. Convergence is proved in § 4.

2. Travelling wave solutions. A travelling wave solution is a solution of the following form

$$(u(x,t),z(x,t))=(\psi(x-Dt),z(x-Dt)),$$

where D is the speed of the travelling wave solution. Let $\xi=x-Dt$. Plugging $(u(x,t), z(x,t))=(\psi(\xi),z(\xi))$ into (1) and (2), we have that $(\psi,z)(\xi)$ solves ordinary differential equations

$$-D\psi'+\psi\psi'=q_0z', \tag{7}$$

$$z'=K\varphi(\psi)z. \tag{8}$$

We impose boundary conditions

$$\lim_{\xi\to-\infty}(\psi,z)(\xi)=(u_0,0), \tag{9}$$

$$(\psi,z)(\xi)=(0,1),\qquad \xi\geqq 0. \tag{10}$$

Integrating (7) from $\xi<0$ to 0 and noticing that there is a shock discontinuity at $\xi=0$, we have

$$\psi(\xi)=D+(D^2-2q_0(1-z(\xi)))^{1/2},\qquad \xi<0. \tag{11}$$

Letting $\xi\to-\infty$ in the above equation and using (9), we get

$$D=D(u_0)=\frac{q_0}{u_0}+\frac{1}{2}u_0. \tag{12}$$

Integrating (8) and using (10), we have

$$z=e^{K\xi},\qquad \xi\leqq 0.$$

Inserting into (11), we get our travelling wave solution

$$(\psi(\xi),z(\xi))=\begin{cases}(0,1) & \xi\geqq 0\\ (D+(D^2-2q_0(1-e^{K\xi}))^{1/2},e^{K\xi}) & \xi<0.\end{cases}$$

It is easy to see that for the travelling wave to exist we have to require

$$u_0^2\geqq 2q_0. \tag{13}$$

We assume (13) throughout this paper. Corresponding to $u_0 = \sqrt{2q_0}$, we have $D = \sqrt{2q_0}$, which is the minimum travelling wave speed. The solution for the minimum value of D is called the Chapman-Jouguet (or CJ) detonation. A CJ detonation is characterized by being sonic with respect to the flow behind [2]. Because of this property, the CJ detonation plays a very special role in the stability theory. We will investigate this in a forthcoming paper.

From the explicit expression of the solution we see that the structure of a detonation wave is an ordinary nonreactive shock wave followed by a chemical reaction zone, which is the ZND (Zeldovich-Neumann-Doering) theory predicted.

3. Global existence. In this section we prove global existence and give global a priori estimates for solutions of the Riemann problem. We get the existence by means of a fixed point method based on an iteration procedure. A maximum principle and the method of characteristics enable us to get properties of the shock front. From these properties, we obtain our a priori estimates for the solution.

There is a shock discontinuity in the solution initiated from the Riemann initial data. Denote the shock wave position by $x = s(t)$. From the Rankine-Hugoniot condition and the initial condition, we have

$$\frac{ds}{dt} = \frac{1}{2} u(s(t), t), \tag{14}$$

$$s(0) = 0. \tag{15}$$

Writing (1) in characteristic form, we have

$$\frac{dx}{dt} = u(x, t),$$

$$\frac{du}{dt} = q_0 z_x.$$

Hence,

$$\frac{d^2x}{dt^2} = \frac{du}{dt} = q_0 z_x = q_0 K\varphi(u) z \geqq 0.$$

Therefore, every characteristic line $x = x(t)$ is convex in t and u increases along each characteristic line.

Let us simplify the problem by solving (2) in terms of the shock wave position.

For characteristic lines such that $x(t) \leqq s(t)$, it follows from the admissible conditions for shock waves [3] that $x(0) \leqq 0$. Furthermore, $u(x(t), t) \geqq u(x(0), 0) = u_0 > u_i$, $\varphi(u(x(t), t)) = 1$.

Similarly, for characteristic lines such that $x(t) > s(t)$, we have $x(0) > 0$. Furthermore, $u(x(t), t) = u(x(0), 0) = 0 < u_i$, $\varphi(u(x(t), t)) = 0$.

Plugging the value of φ into (2), we have that

$$z_x = \begin{cases} Kz & x \leqq s(t), \\ 0 & x > s(t). \end{cases}$$

Noticing that $\lim_{x \to +\infty} z(x, t) = 1$, z can be solved as

$$z(x, t) = \begin{cases} e^{K(x - s(t))} & x \leqq s(t), \\ 1 & x > s(t). \end{cases} \tag{16}$$

Plugging z into (1), the system is reduced to

$$u_t + uu_x = \begin{cases} q_0 K\, e^{K(x-s(t))} & x \leqq s(t), \\ 0 & x > s(t), \end{cases} \tag{17}$$

where $s(t)$ satisfies (14) and (15).

We now construct the solution by the iteration.

Consider first the following auxiliary problem.

$$u_t + uu_x = q_0 K\, e^{K(x-j(t))}, \tag{18}$$

$$u(x, 0) = u_0, \tag{19}$$

where $j \in E$, and

$$E = \{j : j \in C^1[0, T], j(0) = 0, j'(0) = \tfrac{1}{2}u_0, j'(t) \leqq D(u_0), j \text{ convex}\}.$$

Clearly, E is a closed bounded subset of $C^1[0, T]$.

We then iterate on j to find a fixed point of $s'(t) = \frac{1}{2}u(j(t), t)$ such that it is a solution of (14) and u is a solution of (17).

Lemma 3.1. *There exists a unique smooth solution u of problem* (18) *and* (19) *for all $t > 0$, which satisfies*

$$\frac{\partial u}{\partial x} \geqq 0, \tag{20}$$

$$\frac{d}{dt} u(j(t) + c, t) \geqq 0, \qquad c \leqq 0. \tag{21}$$

Proof. The classical solution of (18) and (19) can be constructed through its characteristic lines. Global solution exists if two characteristic lines never intersect.

Take any two characteristic lines $x_1(t)$ and $x_2(t)$ of $u(x, t)$, where $x_1(0) < x_2(0)$. We claim that the two characteristic lines $x_1(t)$ and $x_2(t)$ never intersect.

To prove the claim, suppose for the contrary that at time $t = t_0 > 0$ they intersect. We have $x_1(t_0) = x_2(t_0)$ and $x_1(t) < x_2(t)$, $0 \leqq t < t_0$. Hence, $d^2x_1/dt^2 < d^2x_2/dt^2$, $0 \leqq t < t_0$.

By Taylor expansion with remainder, there is some $\xi \in [0, t_0]$ such that

$$\begin{aligned} 0 &= x_1(t_0) - x_2(t_0) \\ &= (x_1 - x_2)(0) + \frac{d(x_1 - x_2)(0)}{dt} t_0 + \frac{1}{2} \frac{d^2(x_1 - x_2)(\xi)}{dt^2} t_0^2 \\ &\leqq (x_1 - x_2)(0) + (u(x_1(0), 0) - u(x_2(0), 0)) t_0 \\ &= (x_1 - x_2)(0) \\ &< 0, \end{aligned}$$

which is a contradiction. Thus $x_1(t)$ and $x_2(t)$ never intersect.

Given any two points (x_{10}, t_0) and (x_{20}, t_0), $t_0 > 0$ and $x_{10} < x_{20}$, draw characteristic lines $x_1(t)$ and $x_2(t)$ backwards in time. Since any two characteristic lines never intersect, we have

$$x_1(t) < x_2(t), \qquad 0 \leqq t \leqq t_0.$$

Integrating (18) along the characteristic lines, we have

$$u(x_1(t_0), t_0) < u(x_2(t_0), t_0).$$

Noticing that u is smooth, we have

$$\frac{\partial u}{\partial x} \geqq 0 \quad \text{for } t>0.$$

This proves (20).

To prove (21) we need a transformation

$$r=t,$$
$$y=x-j(t).$$

Then (18) becomes

$$u_r+(u-j')u_y=q_0K\,e^{Ky}.$$

Let $p=\partial u/\partial r$. Differentiating the above equation with respect to r, we have

$$\frac{dp}{dr}+\frac{\partial u}{\partial y}p=\frac{\partial u}{\partial y}j'',$$
$$p(y,0)=q_0K\,e^{Ky}>0,$$

where $d/dr=(\partial/\partial r)+(u-j')\,(\partial/\partial y)$ is derivative in the characteristic direction.

Assuming that j is smooth for the moment, we have $j''\geqq 0$. From (20), $\partial u/\partial y=\partial u/\partial x\geqq 0$. Now applying a maximum principle in the above equations for p, we have that $p(y,r)\geqq 0$ for any $r\geqq 0$ and any y. That is

$$p=\frac{\partial u}{\partial r}=\frac{\partial u}{\partial t}+j'\frac{\partial u}{\partial x}\geqq 0.$$

In particular, this holds at $y=c$, $c\leqq 0$, i.e., at $x=j(t)+c$, we have

$$\frac{\partial}{\partial t}u(j(t)+c,t)+j'(t)\frac{\partial}{\partial x}u(j(t)+c,t)\geqq 0.$$

That is,

$$\frac{d}{dt}u(j(t)+c,t)\geqq 0.$$

If j is not smooth enough, we arrive at our conclusion by approximating j by smooth functions and passing to the limit, since the result only involves the first derivative of j. □

We next prove a comparison principle for solutions of (1) and (2), which will be useful for qualitative study of the solutions.

In the following theorem the initial value has the following form:

$$u(x,0)=\begin{cases} u_0(x) & x\leqq s(0), \\ 0 & x>s(0), \end{cases}$$

where $u_0(x)\geqq 0$ is a nondecreasing function and $s(0)$ is the initial shock wave position.

THEOREM 3.2 (A comparison principle). *Suppose that $u_1(x,t)$ and $u_2(x,t)$ are solutions of* (1) *and* (2) *with nondecreasing initial data $u_{10}(x)$ and $u_{20}(x)$ and shock wave positions $s_1(t)$ and $s_2(t)$, respectively. If*

$$s_1(0)<s_2(0)$$

and

$$u_{10}(x)\geqq u_{20}(x), \qquad x\leqq s_1(0),$$

then there is some $T>0$ such that for $0<t<T$, we have

$$u_1(x,t)>u_2(x,t), \qquad x\leqq s_1(t).$$

Proof. Since $s_1(0) < s_2(0)$, there exists a $T > 0$ such that

$$s_1(t) < s_2(t), \qquad 0 < t < T.$$

From point (x, t_0), $0 < t_0 < T$, draw characteristic lines $x_1(t)$ and $x_2(t)$ of u_1 and u_2 backwards, respectively.

Step 1. Suppose that (x, t_0) is the first intersection point of the two characteristic lines. Then we claim $u_1(x, t_0) > u_2(x, t_0)$.

Suppose for the contrary that $u_1(x, t_0) \leqq u_2(x, t_0)$. Then, $x_1(t) > x_2(t)$, for $0 \leqq t < t_0$. We also know that $s_1(t) < s_2(t)$, for $0 \leqq t < t_0$. So, $x_1(t) - s_1(t) > x_2(t) - s_2(t)$. Integrating the equations for u_1 and u_2 along their characteristic lines $x_1(t)$ and $x_2(t)$, respectively, we have that

$$u_1(x, t_0) > u_2(x, t_0),$$

which contradicts our assumption that $u_1(x, t_0) \leqq u_2(x, t_0)$. Thus, $u_1(x, t_0) > u_2(x, t_0)$.

Step 2. We claim that any two characteristic lines of u_1 and u_2 intersect at most once. If two characteristic lines intersect at $t = t_0$, by Step 1, we have

$$\frac{dx_1}{dt} = u_1(x, t_0) > u_2(x, t_0) = \frac{dx_2}{dt},$$

$$x_1(t_0) = x_2(t_0).$$

We thus have

$$x_1(t) > x_2(t), \qquad t_0 < t < t_0 + \delta$$

for some $\delta > 0$.

Claim. $x_1(t) > x_2(t)$ for all $t > t_0$.

If this is not true, then there is a $t_1 > t_0$ such that $x_1(t_1) = x_2(t_1)$ and $x_1(t) > x_2(t)$, $t_0 < t < t_1$. It follows that $d^2x_1/dt^2 > d^2x_2/dt^2$, $t_0 < t < t_1$. By Taylor expansion with remainder, there is $t_0 < \xi < t_1$ such that

$$\begin{aligned} 0 &= x_1(t_1) - x_2(t_1) \\ &= x_1(t_0) - x_2(t_0) + \frac{d(x_1 - x_2)(t_0)}{dt}(t_1 - t_0) \\ &\quad + \frac{1}{2}\frac{d^2(x_1 - x_2)(\xi)}{dt^2}(t_1 - t_0)^2 > 0, \end{aligned}$$

a contradiction. Hence, no two characteristic lines of u_1 and u_2 intersect more than once.

By Step 1, we have

$$u_1(x, t_0) > u_2(x, t_0)$$

for all $x \leqq s_1(t_0)$, and $0 < t_0 < T$. □

Using the comparison principle, we get upper bound on the solution in the following lemma.

LEMMA 3.3.

$$\tfrac{1}{2}u(j(t), t) < D(u_0), \qquad t > 0. \tag{22}$$

Proof. From point $(j(t_0), t_0)$, draw a straight line with slope $D(u_0)$. Since $j'(t) \leqq D(u_0)$ (by the choice of j), we have

$$x(t) = j(t_0) + D(u_0)(t - t_0) < j(t) \quad \text{for } 0 \leqq t < t_0.$$

$x(t)=j(t_0)+D(u_0)(t-t_0)$ can be viewed as the shock wave position of the travelling wave $\psi(x-Dt+c)$, where $c=-j(t_0)+Dt_0>0$. Comparing initial data of $\psi(x-Dt+c)$ and $u(x,t)$, we have

$$\psi(x+c)\geqq u(x,0), \qquad x+c\leqq 0.$$

Applying the comparison principle in Theorem 3.2 to $\psi(x-Dt+c)$ and $u(x,t)$, we get

$$\psi(x-Dt+c)>u(x,t), \qquad x-Dt+c\leqq 0 \quad \text{for } 0\leqq t\leqq t_0.$$

In particular, at point $(j(t_0), t_0)$,

$$2D(u_0)=\psi(0)>u(j(t_0), t_0).$$

That proves the lemma. □

Let s be the solution of

$$s(0)=0,$$
$$s'(t)=\tfrac{1}{2}u(j(t), t).$$

By Lemma 3.3,

$$s'(t)<D(u_0).$$

By Lemma 3.1,

$$s''(t)=\frac{1}{2}\frac{d}{dt}u(j(t), t)\geqq 0.$$

Hence, $s\in E$ and is twice differentiable.

Define an operator $A: E\to C^1[0, T]$

$$s=Aj.$$

Clearly, $AE\subset E$, i.e., A maps E into itself.

LEMMA 3.4. *The mapping A has a fixed point.*

Proof. By the Arzela-Ascoli theorem, it is enough to prove that $s''=(Aj)''$ is bounded for all $j\in E$ (since then AE will be a bounded subset of $C^2[0, T]$, and hence, a compact subset of $E\subset C^1[0, T]$). This will assure the compactness necessary for the Schauder fixed point theorem.

By Lemma 3.3,

$$0\leqq j'(t)\leqq D.$$

A straightforward calculation from conditions (12) and (13) yields

$$u_0\geqq D.$$

Finally, using $u_x\geqq 0$ from Lemma 3.1, we have

$$\begin{aligned}0\leqq s''&=\frac{1}{2}\frac{d}{dt}u(j(t), t)\\&=\frac{1}{2}(u_t+j'(t)u_x)\\&=\frac{1}{2}(u_t+uu_x)+\frac{1}{2}(j'(t)-u)u_x\\&\leqq\frac{1}{2}q_0K+\frac{1}{2}(D-u_0)u_x\\&\leqq\frac{1}{2}q_0K,\end{aligned}$$

which is bounded uniformly with respect to $j \in E$. Hence, by the Schauder fixed point theorem A has a fixed point. □

Using this fixed point, we construct the following solution of Riemann problem (1), (2), (6), and (5):

$$u(x, t) = \begin{cases} u_j(x, t) & x \leqq s(t), \\ 0 & x > s(t), \end{cases} \tag{23}$$

$$z(x, t) = \begin{cases} e^{K(x - s(t))} & x \leqq s(t), \\ 1 & x > s(t), \end{cases} \tag{24}$$

where u_j is the solution of (18) and (19).

It is easy to check that (u, z) is a solution.

Next, we prove that the above-defined solution is unique. This allows us to extend the solution to $t = +\infty$.

LEMMA 3.5. *Solutions of form* (23) *and* (24) *are unique.*

Proof. Suppose that there are two solutions $u(x, t)$ and $v(x, t)$ with shock wave positions $s_1(t)$ and $s_2(t)$, respectively.

Because of the uniqueness of solutions of (18) and (19), we need only to show that $s_1(t) = s_2(t)$.

Translate s_2 along the x axis to the right of s_1 until they just touch. If the lowest touch point is $(s_1(t_0), t_0)$, then $t_0 = 0$.

Suppose for the contrary that $t_0 > 0$. Let $s_2 + \delta$ be the translation of s_2 such that $(s_1(t_0), t_0)$ is on $s_2 + \delta$. Then $\delta > 0$ and $s_1(t) < s_2(t) + \delta$ for $0 < t < t_0$.

Let

$$v_1(x, t) = v(x - \delta, t),$$
$$z_1(x, t) = z(x - \delta, t),$$

then (v_1, z_1) satisfies

$$v_{1t} + v_1 v_{1x} = q_0 z_{1x},$$
$$z_{1x} = q_0 \phi(v_1) z_1,$$
$$v_1(x, 0) = \begin{cases} u_0 & x \leqq \delta, \\ 0 & x > \delta, \end{cases}$$
$$z_1(x, 0) = 1.$$

In fact,

$$z_1(x, t) = \begin{cases} e^{K(x - (s_2(t) + \delta))} & x \leqq s_2(t) + \delta, \\ 1 & x > s_2(t) + \delta. \end{cases}$$

At time $t = 0$, we have

$$\int_{-\infty}^{+\infty} (u - v_1)(x, 0)\, dx = -\delta u_0 < 0. \tag{25}$$

It is easy to check that the conditions for the comparison principle hold. Applying the comparison principle in Theorem 3.2 to u and v_1, we have $u(x, t_0) > v_1(x, t_0)$ for $x \leqq s_1(t_0) = s_2(t_0) + \delta$. But this implies

$$\int_{-\infty}^{+\infty} (u - v_1)(x, t_0)\, dx = \int_{-\infty}^{s_1(t_0)} (u - v_1)(x, t_0)\, dx > 0,$$

which contradicts (25) since by the conservation law (1)

$$\int_{-\infty}^{+\infty} (u - v_1)(x, t)\, dx$$

is a constant independent of t.

Hence, $t_0 = 0$, which implies that $\delta = 0$. It follows that $s_1(t) \leqq s_2(t)$. Similarly, $s_2(t) \leqq s_1(t)$. Hence $s_2(t) = s_1(t)$. □

A nice property of the solution is given in the next lemma.

LEMMA 3.6. *The solution of the Riemann problem is convex in x, that is,*

$$\frac{\partial^2 u}{\partial x^2}(x, t) \geqq 0 \quad \textit{for } x \leqq s(t).$$

Proof. Differentiating equation (1) with respect to x twice, we have

$$u_{xxt} + u u_{xxx} + 3 u_x u_{xx} = q_0 z_{xxx}.$$

Rewriting the above equation in the characteristic form, we have

$$\frac{du_{xx}}{dt} + 3 u_x u_{xx} = q_0 K^3\, e^{K(x - s(t))} > 0.$$

Initially,

$$u_{xx}(x, 0) = 0 \quad \text{for } x \leqq 0.$$

Using a maximum principle along the characteristic direction, we have

$$u_{xx}(x, t) \geqq 0 \quad \text{for } x \leqq s(t). \qquad \square$$

Now we have the following theorem.

THEOREM 3.7. *Solution of* (1), (2), (6), *and* (5) *exists globally and satisfies*

$$0 \leqq u \leqq M, \quad 0 \leqq u_x \leqq M, \quad |u_t| \leqq M, \quad u_{xx} \geqq 0,$$

$$0 \leqq z \leqq 1, \quad 0 \leqq z_x \leqq K, \quad |z_t| \leqq M,$$

where M depends only on q_0, K, u_0. All the estimates involving derivatives are valid away from the shock curve $(s(t), t)$.

Furthermore, $s(t)$ satisfies

$$s'' \geqq 0$$

and

$$\lim_{t \to +\infty} s'(t)$$

exists.

Proof. From Lemmas 3.1 and 3.5, $u_j(x, t)$ and $s = s(t)$ are defined for all $t > 0$. Therefore, the solution of (1), (2), (6), and (5) exists for all $t > 0$ by the construction (23) and (24).

It follows from (20), $u_x \geqq 0$, that $u(x, t) \leqq u(s(t), t)$ for $x \leqq s(t)$. Furthermore, $u(s(t), t) \leqq 2D$ by Lemma 3.3. Hence, u is bounded.

Let $a = u_x$. Differentiating equation (1) with respect to x and writing the resulting equation in characteristic form, we get

$$\frac{da}{dt} + a^2 = q_0 K^2\, e^{K(x - s(t))}.$$

Integrating along the characteristic line $x=x(t)$ from 0 to t, we obtain

$$0 \leqq a(x(t),t) \leqq a(x(0),0)+\int_0^t q_0K^2\, e^{K(x(t)-s(t))}\, dt$$
$$=K(u(x(t),t)-u(x(0),0)) \leqq M.$$

Using (17),

$$u_t=q_0K\, e^{K(x-s(t))}-uu_x,$$

we can get the desired bound for u_t. From (24), clearly, z and z_x satisfy the above estimates. As for z_t, we have

$$z_t(x,t)=-Ks'(t)\, e^{K(x-s(t))}, \qquad x<s(t)$$

which is bounded.

By definition of s and Lemma 3.1, we have

$$s'(t)=\tfrac{1}{2}u(s(t),t) \leqq D(u_0),$$
$$s''(t) \geqq 0.$$

Hence, $\lim_{t\to+\infty} s'(t)$ exists. □

4. Convergence to travelling waves. In this section we prove that the solution of the Riemann problem (1), (2), (6), and (5) converges to a shifted travelling wave. The shift is determined from the initial data. This technique was used before by Liu [5]. We use it not only for identifying the shift but also for showing the convergence. The conservation laws and the comparison principle give us global L^1 control over the solution.

Let

$$x_0=-\frac{1}{u_0}\int_{-\infty}^{+\infty}\{u(x,0)-\psi(x)\}\, dx. \tag{26}$$

From the initial data, $x_0>0$.

Our final goal is to show that the solution $(u,z)\,(x,t)$ converges to $(\psi,z)\,(x-Dt+x_0)$ as $t\to+\infty$. This means that the final wave front is determined by its initial total mass. We note that the mass difference between any two solutions is a conserved quantity.

LEMMA 4.1. *If x_0 is determined as above, then*

$$\int_{-\infty}^{+\infty}(u(x,0)-\psi(x+x_0))\, dx=0. \tag{27}$$

Proof. First of all,

$$0>\int_{-\infty}^{+\infty}(u(x,0)-\psi(x))\, dx$$
$$=\int_{-\infty}^{0}(u_0-\psi(x))\, dx$$
$$=-\int_{-\infty}^{0}\frac{2q_0\, e^{Kx}}{(D^2-2q_0)^{1/2}+(D^2-2q_0(1-e^{Kx}))^{1/2}}\, dx$$
$$\geqq -\int_{-\infty}^{0}(2q_0\, e^{Kx})^{1/2}\, dx>-\infty.$$

Thus $u(x,0)-\psi(x)$ is integrable and so is $\psi(x+x_0)-\psi(x)$.

$$\begin{aligned}\int_{-\infty}^{+\infty}(\psi(x+x_0)-\psi(x))\,dx&=\left(\int_{-\infty}^{-x_0}+\int_{-x_0}^{+\infty}\right)(\psi(x+x_0)-\psi(x))\,dx\\&=\int_{-\infty}^{-x_0}(\psi(x+x_0)-u_0)+(u_0-\psi(x))\,dx+\int_{-x_0}^{0}[(u_0-\psi(x))-u_0]\,dx\\&=\int_{-\infty}^{-x_0}(\psi(x+x_0)-u_0)\,dx+\int_{-\infty}^{0}(u_0-\psi(x))\,dx-x_0u_0\\&=\int_{-\infty}^{0}(\psi(x)-u_0)\,dx+\int_{-\infty}^{0}(u_0-\psi(x))\,dx-x_0u_0\\&=-x_0u_0.\end{aligned}$$

The conclusion then follows easily from (26). □

For the travelling wave $(\psi, z)\ (x-Dt+x_0)$, its equations in characteristic form are

$$\frac{dx_1}{dt}=\psi,$$

$$\frac{d\psi}{dt}=q_0K\,e^{K(x_1(t)-s_1(t))},$$

where $s_1(t)=Dt-x_0$ is the shock wave position for the travelling wave. In the next lemma, we use the conservation law to estimate the lower bound of $s(t)$.

LEMMA 4.2. *Let $s_1(t)=Dt-x_0$ and $s(t)$ be the shock wave positions for $\psi(x-Dt+x_0)$ and $u(x,t)$, respectively.*

Then $s_1(t)<s(t)$ for $t>0$.

Proof. First, since $s_1(0)=-x_0<0=s(0)$, we have $s_1(t)<s(t)$ for $t<\delta$, where $\delta>0$.

Let $T=\sup\{t\,|\,s_1(\tau)<s(\tau)\text{for }\tau<t\}$. We want to prove $T=+\infty$. If this is not true, we have that $T=t_0<+\infty$. Hence

$$s_1(t_0)=s(t_0),$$
$$s_1(t)<s(t)\quad\text{for } t<t_0.$$

Applying the comparison principle Theorem 3.2 to ψ and u, we see that

$$\psi(x-Dt_0+x_0)>u(x,t_0)\quad\text{for } x\leqq s_1(t_0)=s(t_0),$$

and hence

$$\int_{-\infty}^{+\infty}[\psi(x-Dt_0+x_0)-u(x,t_0)]\,dx=\int_{-\infty}^{s_1(t_0)}[\psi(x-Dt_0+x_0)-u(x,t_0)]\,dx>0.$$

Using the conservation property of (1) and also the identity (27), we have

$$0<\int_{-\infty}^{\infty}[\psi(x-Dt_0+x_0)-u(x,t_0)]\,dx=\int_{-\infty}^{+\infty}[\psi(x+x_0)-u(x,0)]\,dx=0,$$

a contradiction. Therefore, $s_1(t)<s(t)$ for all $t>0$. □

LEMMA 4.3.

$$0<\psi(x-Dt+x_0)-u(x,t)<C\,e^{K(x-Dt+x_0)/2}$$

for $x-Dt+x_0<0$.

Proof. For $x-Dt+x_0<0$, we have $x<s_1(t)=Dt-x_0<s(t)$ by Lemma 4.2. Using the comparison principle Theorem 3.2, we have

$$\psi(x-Dt+x_0)>u(x,t)>u_0\quad\text{for } x<s_1(t).$$

Therefore,

$$\begin{aligned}0&<\psi(x-Dt+x_0)-u(x,t)\\&<\psi(x-Dt+x_0)-u_0\\&=\frac{2q_0\,e^{K(x-Dt+x_0)}}{(D^2-2q_0)^{1/2}+(D^2-2q_0(1-e^{K(x-Dt+x_0)}))^{1/2}}\\&\leqq\sqrt{2q_0}\,e^{K(x-Dt+x_0)/2}.\end{aligned}\qquad\square$$

This lemma implies that the difference between u and the travelling wave is integrable.

Next, we prove that $x=s(t)$ has an asymptotic line $x=Dt-\delta$ as $t\to+\infty$. Eventually we will show $\delta=x_0$.

LEMMA 4.4.

$$\lim_{t\to+\infty}(s(t)-Dt+\delta)=0,$$

$$\lim_{t\to+\infty}s'(t)=D(u_0)$$

for some δ, $0<\delta\leqq x_0$.

Proof. Let $E(t)=s(t)-Dt+x_0$. Then $E(t)>0$ and $E'(t)=s'(t)-D\leqq 0$ by Lemmas 4.2 and 3.3. Therefore, $\lim_{t\to+\infty}E(t)$ exists. Hence, there is some constant δ, with $0<\delta\leqq x_0$, such that

$$\lim_{t\to+\infty}s(t)-Dt+\delta=0.$$

By Theorem 3.7, $\lim_{t\to+\infty}s'(t)$ exists. Therefore,

$$\lim_{t\to+\infty}s'(t)=D.\qquad\square$$

Next, we prove that the solution to the Riemann problem are asymptotically functions of one variable $x-Dt+\delta$.

LEMMA 4.5. *There are Lipschitz functions* $u_\infty(\xi)$ *and* $z_\infty(\xi)$ *such that*

$$\lim_{t\to+\infty}\ \sup_{x-Dt+\delta\leqq 0}|(u,z)(x,t)-(u_\infty,z_\infty)(x-Dt+\delta)|=0.$$

Proof. Let

$$\xi=x-Dt+\delta,$$

$$u(x,t)=U(\xi,t),$$

$$z(x,t)=Z(\xi,t).$$

Let $E(t)=s(t)-Dt+\delta$. By Lemma 4.4, $E(t)$ decreases to zero and $s'(t)$ increases to D as $t\to+\infty$.

For any $\varepsilon>0$, there is a $T>0$, such that if t, t_1, $t_2>T$,

$$0<E(t)<\varepsilon,\qquad(28)$$

$$2|s'(t_1)-s'(t_2)|<\varepsilon,$$

$$1-\varepsilon<e^{-KE(t)}<1.\qquad(29)$$

Since $E(t)>0\geqq\xi$, we have $s(t)>x$. By (24),

$$Z(\xi,t)=z(x,t)=e^{K(x-s(t))}=e^{K\xi}\,e^{-KE(t)}.$$

Using (29),

$$(1-\varepsilon)\, e^{K\xi} < Z(\xi, t) < e^{K\xi}, \qquad \xi \leqq 0.$$

Letting

$$z_\infty(\xi) = e^{K\xi}, \qquad \xi \leqq 0,$$

we have

$$\lim_{t\to+\infty} \sup_{\xi\leqq 0} |Z(\xi, t) - z_\infty(\xi)| = 0.$$

We now look at the characteristic lines of $U(\xi, t)$ given by

$$\frac{d\xi}{dt} = \frac{dx}{dt} - D = U - D$$

and

$$\frac{d^2\xi}{dt^2} = \frac{d^2x}{dt^2} = \frac{du}{dt} = q_0 z_x = q_0 K\, e^{K\xi}\, e^{-KE(t)}.$$

Multiplying both sides of the above equality by $d\xi/dt$ and using inequality (29), we have

$$-\varepsilon q_0 K\, e^{K\xi} \frac{d\xi}{dt} < \frac{d\xi}{dt}\frac{d^2\xi}{dt^2} - q_0 K\, e^{K\xi}\frac{d\xi}{dt} < 0.$$

Integrating the above inequalities from t_1 to t_2 and using (29), we see that

$$-\varepsilon q_0\, e^{K\xi}\Big|_{t_1}^{t_2} < \frac{1}{2}\left(\frac{d\xi}{dt}\right)^2 - q_0\, e^{K\xi}\Big|_{t_1}^{t_2} < 0.$$

Noticing that $d\xi/dt = U - D$, we have

$$|\tfrac{1}{2}(U(\xi(t), t) - D)^2 - q_0\, e^{K\xi(t)}|\Big|_{t_1}^{t_2} < q_0\varepsilon. \tag{30}$$

Draw characteristic lines $\xi_1(t)$ and $\xi_2(t)$ from (ξ, t_1) and (ξ, t_2), respectively. Let t_1^* and t_2^* be the time at which $\xi_1(t)$ and $\xi_2(t)$ intersect $s(t)$, respectively. It follows from (28) that

$$\begin{aligned} &|U(\xi_2(t_2^*), t_2^*) - U(\xi_1(t_1^*), t_1^*)| \\ &\quad = |u(s(t_2^*), t_2^*) - u(s(t_1^*), t_1^*)| \\ &\quad = 2|s'(t_2^*) - s'(t_1^*)| < \varepsilon. \end{aligned} \tag{31}$$

We then estimate

$$\begin{aligned} &|\tfrac{1}{2}(U(\xi, t) - D)^2|_{t_1}^{t_2}| \\ &\quad \leqq |\tfrac{1}{2}(U(\xi_2(t_2), t_2) - D)^2 - q_0\, e^{K\xi_2(t_2)} - \tfrac{1}{2}(U(\xi_2(t_2^*), t_2^*) - D)^2 + q_0\, e^{K\xi_2(t_2^*)}| \\ &\qquad + |\tfrac{1}{2}(U(\xi_1(t_1), t_1) - D)^2 - q_0\, e^{K\xi_1(t_1)} - \tfrac{1}{2}(U(\xi_1(t_1^*), t_1^*) - D)^2 + q_0\, e^{K\xi_1(t_1^*)}| \\ &\qquad + |q_0\, e^{KE(t_1^*)} - q_0\, e^{KE(t_2^*)}| \\ &\qquad + |\tfrac{1}{2}(U(\xi_2(t_2^*), t_2^*) - D)^2 - \tfrac{1}{2}(U(\xi_1(t_1^*), t_1^*) - D)^2| \\ &\quad < c\varepsilon, \end{aligned}$$

where the last inequality follows from (30), (31), and (29).

Therefore, $\lim_{t\to+\infty}\frac{1}{2}(U(\xi,t)-D)^2$ exists and so does $\lim_{t\to+\infty}U(\xi,t)$. Denote this limit by $u_\infty(\xi)$. By Theorem 3.7, u, z, and their first derivatives are bounded. Hence $u_\infty(\xi)$, $z_\infty(\xi)$ are Lipschitz, and

$$\lim_{t\to+\infty}\sup_{\xi\leqq 0}|U(\xi,t)-u_\infty(\xi)|=0. \qquad \square$$

LEMMA 4.6.

$$\lim_{t\to+\infty}(U,Z)(\xi,t)=(0,1)=(u_\infty(\xi),z_\infty(\xi)),$$

where $\xi=x-Dt+\delta>0$.

Proof. If $\xi>0$, i.e., $x-Dt+\delta>0$, there is a $T>0$, such that for $t>T$,

$$0<E(t)=s(t)-Dt+\delta<x-Dt+\delta.$$

That is,

$$x-s(t)>0.$$

From (24) and (23), we have that

$$Z(\xi,t)=z(x,t)=1, \qquad U(\xi,t)=u(x,t)=0,$$

provided $t>T$.

Taking

$$(u_\infty,z_\infty)(\xi)=(0,1)$$

where $\xi>0$, the lemma is proved. $\square$

LEMMA 4.7. $(u_\infty,z_\infty)(\xi)$ *is a travelling wave solution* $(\psi,z)(\xi)$ *of* (1) *and* (2), *i.e.*,

$$(u_\infty,z_\infty)(\xi)=(\psi,z)(\xi), \quad \textit{where } \xi=x-Dt+\delta.$$

Proof. (u,z) is a weak solution of (1) and (2) if and only if

$$\iint \phi_t(x,t)u(x,t)+\phi_x(x,t)\left[\frac{1}{2}u^2(x,t)-q_0z(x,t)\right]dx\,dt=0$$

for any smooth function ϕ with compact support in $\{(x,t)|t>0\}$.

Taking $\phi(x-DT,t-T)$ as the test function in the above equation, then

$$\iint \phi_t(x-DT,t-T)u(x,t)+\phi_x(x-DT,t-T)\left[\frac{1}{2}u^2(x,t)-q_0z(x,t)\right]dx\,dt=0.$$

A change of variables in the above integral gives

$$\iint \phi_t(x,t)u(x+DT,t+T)$$
$$+\phi_x(x,t)\left[\frac{1}{2}u^2(x+DT,t+T)-q_0z(x+DT,t+T)\right]dx\,dt=0.$$

Hence

$$\iint \phi_t(x,t)U(x-Dt+\delta,t+T)$$
$$+\phi_x(x,t)\left[\frac{1}{2}U^2(x-Dt+\delta,t+T)-q_0Z(x-Dt+\delta,t+T)\right]dx\,dt=0.$$

Letting $T \to +\infty$,

$$\iint \phi_t(x,t)u_\infty(x-Dt+\delta)+\phi_x(x,t)\left[\frac{1}{2}u_\infty^2(x-Dt+\delta)-q_0z_\infty(x-Dt+\delta)\right]dx\,dt=0$$

for all ϕ.

Using Lemmas 4.5 and 4.6,

$$z_{\infty x}(x-Dt+\delta)=\begin{cases}Kz_\infty & x-Dt+\delta\leqq 0\\ 1 & x-Dt+\delta>0\end{cases}=K\varphi(u_\infty)z_\infty.$$

Thus, $(u_\infty, z_\infty)(x-Dt+\delta)$ is indeed a weak solution of (1) and (2).

We now show that $(u_\infty, z_\infty)(x-Dt+\delta)$ satisfies (7)-(10), which are equations for the travelling wave solution.

Clearly, $z_\infty(\xi)$ satisfies (8) and is smooth for $\xi\leqq 0$. By Lemma 4.5 $(u_\infty, z_\infty)(\xi)$ is Lipschitz for $\xi\leqq 0$, and hence absolutely continuous. Furthermore, (u_∞, z_∞) satisfies (7) almost everywhere. Using Lemma 4.6, we get

$$(u_\infty, z_\infty)(x-Dt+\delta)=(0,1)=(\psi,z)(x-Dt+\delta),\qquad x-Dt+\delta>0.$$

That is, (u_∞, z_∞) satisfies (10).

By Lemma 4.2,

$$u_0<u(x,t)<\psi(x-Dt+x_0),\qquad x-Dt+\delta<0.$$

Noticing that $\psi(-\infty)=u_0$, we get

$$\lim_{x-Dt+\delta\to-\infty} u_\infty(x-Dt+\delta)=u_0.$$

From Lemma 4.5,

$$\lim_{x-Dt+\delta\to-\infty} z_\infty(x-Dt+\delta)=0.$$

Hence (9) is satisfied.

Using the uniqueness of solution of (7)-(10),

$$(u_\infty, z_\infty)(x-Dt+\delta)=(\psi,z)(x-Dt+\delta),\qquad 0<\delta\leqq x_0.$$ □

LEMMA 4.8.

$$\delta=x_0.$$

That is, $(u, z)(x, t)$ *converges to the travelling wave* $(\psi, z)(x-Dt+x_0)$.

Proof. From Lemma 4.1, we have

$$\int_{-\infty}^{+\infty}[\psi(x+x_0)-u(x,0)]\,dx=0.$$

Using the conservation law and Lemma 4.3, we have that for any $t>0$,

$$\int_{-\infty}^{+\infty}(\psi(x-Dt+x_0)-u(x,t))\,dx=0.$$

Hence,

$$\int_{-\infty}^{+\infty}(\psi(x-Dt+x_0)-\psi(x-Dt+\delta))\,dx=0.$$

That is, $\delta=x_0$. □

We summarize our results in the following theorem.

THEOREM 4.9. *The solution of* (1), (2), (6), *and* (5) *converges uniformly to the travelling wave solution and the shock front is asymptotically linear*:

$$\lim_{t\to+\infty}\ \sup_{x-Dt+x_0\leqq 0}|(u,z)(x,t)-(\psi,z)(x-Dt+x_0)|=0,$$

$$\lim_{t\to+\infty}(u,z)(x,t)=(0,1)\quad \textit{for } x-Dt+x_0>0$$

and

$$\lim_{t\to+\infty}(s(t)-Dt+x_0)=0,$$

where x_0 *satisfies*

$$\int_{-\infty}^{\infty}[u(x,0)-\psi(x)]\,dx=-u_0x_0.$$

We also have the convergence result in L^p norm ($p\geqq 1$). This is a consequence of the conservation law and the above result.

COROLLARY 4.10.

$$\lim_{t\to+\infty}|(u,z)(x,t)-(\psi,z)(x-Dt+x_0)|_p=0,\qquad p\geqq 1.$$

Proof. We only prove the results for $p=1$. Results for $p>1$ are easy consequences of $p=1$ and Theorem 4.9.

Let $s_1(t)=Dt-x_0$. By Lemma 4.3 and the conservation law,

$$\int_{-\infty}^{s_1(t)}[\psi(x-Dt+x_0)-u(x,t)]\,dx=-\int_{s_1(t)}^{s(t)}[\psi(x-Dt+x_0)-u(x,t)]\,dx.$$

Therefore,

$$\begin{aligned}&|u(x,t)-\psi(x-Dt+x_0)|_1\\&=\int_{-\infty}^{s_1(t)}[\psi(x-Dt+x_0)-u(x,t)]\,dx+\int_{s_1(t)}^{s(t)}[u(x,t)-\psi(x-Dt+x_0)]\,dx\\&=2\int_{s_1(t)}^{s(t)}[u(x,t)-\psi(x-Dt+x_0)]\,dx\\&\leqq 2(s(t)-s_1(t))2D\to 0,\qquad t\to+\infty.\end{aligned}$$

A similar result for z directly follows from $s(t)-s_1(t)\to 0$. □

Acknowledgments. This is a part of my thesis. It is a pleasure to express my gratitude to my thesis advisor, Professor Tai-Ping Liu, for all his guidance and encouragement. Thanks are also due to A. Bourlioux for showing me her numerical results.

CLASSIFICATION OF THE RIEMANN PROBLEM FOR TWO-DIMENSIONAL GAS DYNAMICS*

CARSTEN W. SCHULZ-RINNE†

Abstract. The Riemann problem for two-dimensional gas dynamics with isentropic and polytropic gas is considered. The initial data is constant in each quadrant and chosen so that only a rarefaction wave, shock wave or slip line connects two neighboring constant initial states. With this restriction, the existence of sixteen (respectively, fifteen) genuinely different wave combinations for isentropic (respectively, polytropic) gas is proved. For each configuration the relations for the initial data and the symmetry properties of the solution are given. This paper corrects the conjectured classification presented in T. Zhang and Y. Zheng [*SIAM J. Math. Anal.*, 21 (1990), pp. 593–630].

Key words. Riemann problem, gas dynamics, initial data, compatibility conditions, self-similar solution

AMS(MOS) subject classifications. 35L65, 35L67, 76N15

1. Introduction. The study of the Riemann problem for gas dynamics has a long tradition, starting with the work of Riemann himself in the last century. In the last twenty years the Riemann problem for one-dimensional gas dynamics has been studied, and the results have been published in [6], [7], and [9] (they also contain further references). More recently the research was extended toward two-dimensional scalar conservation laws [2]–[4], [8], [10]. Riemann problems for two-dimensional gas dynamics were considered in [1] and [11].

Under certain assumptions, Zhang and Zheng [11] conjectured the existence of seventeen reasonable combinations of initial data (counting two subcases individually). Six of their configurations contain no slip lines. In this paper we analyze the same problem more thoroughly. We are able to prove that for isentropic gas one of these six configurations does not exist and one is centrally symmetric. For polytropic gas both cannot exist. Moreover, one of the remaining four configurations is always axially symmetric.

After exposing the problem in the following section, we classify the Riemann problem according to the combination of the elementary waves in §3. There it is shown that only sixteen (respectively, fifteen) genuinely different configurations for isentropic (respectively, polytropic) gas exist, compared to seventeen found by Zhang and Zheng [11]. These numbers are based on the same method of counting. In particular, those combinations which can be obtained by coordinate transformations are not counted.

Numerical solutions for each configuration have recently been computed by the author in joint work with Collins and Glaz. The wave structures are analyzed and illustrated by contour plots in [5].

2. Problem definition. The Euler equations of inviscid compressible isentropic flow consist of the continuity equations for the conservation of mass and momentum. For polytropic gas we have an additional equation for the conservation of energy.

*Received by the editors May 13, 1991; accepted for publication (in revised form) March 11, 1992.

The conservation form of these equations in Cartesian coordinates, together with the equation of state, is

$$U_t + F(U)_x + G(U)_y = 0, \tag{2.1}$$

where

$$U = \begin{pmatrix} \rho \\ \rho u \\ \rho v \end{pmatrix}, \quad F(U) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \end{pmatrix}, \quad G(U) = \begin{pmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \end{pmatrix}, \quad p = A\rho^\gamma$$

for isentropic gas and

$$U = \begin{pmatrix} \rho \\ \rho u \\ \rho v \\ \rho E \end{pmatrix}, \quad F(U) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \\ u(\rho E + p) \end{pmatrix}, \quad G(U) = \begin{pmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \\ v(\rho E + p) \end{pmatrix},$$

$$E = \frac{1}{(\gamma - 1)} \frac{p}{\rho} + \frac{u^2 + v^2}{2}$$

for polytropic gas. Here ρ is the density, u the x-velocity component, v the y-velocity component, p the pressure, E the energy, $\gamma > 1$ the ratio of specific heats of the gas, and $A > 0$ a constant.

The characteristic speeds of (2.1) in x- (or y-) direction, i.e., the eigenvalues of the Jacobian matrix $\nabla_U F$ (or $\nabla_U G$) are $\lambda_- = u - c$, $\lambda_0 = u$, and $\lambda_+ = u + c$ (or $\lambda_- = v - c$, $\lambda_0 = v$, and $\lambda_+ = v + c$). Here the sound speed c is defined by $c^2 = \gamma p/\rho$.

The Riemann problem in the (x, y)-plane is the initial value problem for (2.1) with initial data

$$(\rho, u, v)(x, y, 0) = (\rho_i, u_i, v_i), \qquad i = 1, \dots, 4 \tag{2.2}$$

for isentropic gas and

$$(p, \rho, u, v)(x, y, 0) = (p_i, \rho_i, u_i, v_i), \qquad i = 1, \dots, 4 \tag{2.2'}$$

for polytropic gas, where i denotes the ith quadrant.

The solution is a function of the similarity variables $\xi = x/t$ and $\eta = y/t$ and is called pseudostationary flow. Far enough away from the origin, the general solution consists of four planar waves, each parallel to one of the coordinate axes, between the four constant initial states. In general, a planar wave is formed by up to three elementary waves corresponding to the eigenvalues λ_-, λ_0, and λ_+: a backward rarefaction wave $\overleftarrow{R}$ or shock wave $\overleftarrow{S}$, a slip line (respectively, a contact discontinuity) for isentropic (respectively, polytropic) gas J, and a forward rarefaction wave $\overrightarrow{R}$ or shock wave $\overrightarrow{S}$. This study of the two-dimensional Riemann problem is restricted to situations where each planar wave consists of a single elementary wave. Thus the initial data has to be chosen so that only a rarefaction wave, shock wave or slip line[1] connects two neighboring constant initial states.

[1] From here on the use of the term *slip line* always denotes a slip line for isentropic gas and a contact discontinuity for polytropic gas.

Before we start with the classification of the two-dimensional Riemann problem, the formulas for the one-dimensional elementary waves between two constant states are briefly reviewed.

Across a backward (respectively, forward) rarefaction wave $\overleftarrow{R}$ (respectively, $\overrightarrow{R}$) the corresponding Riemann invariants are constant. They are $w + (2/(\gamma - 1))c$ (respectively, $w - (2/(\gamma - 1))c$) for isentropic gas and, additionally, the entropy s for polytropic gas, where w is the velocity. For a given left and right state (denoted by the indices l and r), we thus have

$$w_r - w_l = \frac{2\sqrt{\gamma}}{\gamma - 1}\left(\sqrt{\frac{p_l}{\rho_l}} - \sqrt{\frac{p_r}{\rho_r}}\right) =: \Phi_{lr} \qquad \text{(respectively, } w_l - w_r = \Phi_{lr}\text{)}$$

for $\overleftarrow{R}$ (respectively, $\overrightarrow{R}$). For polytropic gas we further find

$$\frac{p_l}{p_r} = \left(\frac{\rho_l}{\rho_r}\right)^{\gamma},$$

using the additional Riemann invariant s.

The Rankine–Hugoniot conditions for the system of equations (2.1) give the relations between the states on each side of a shock wave S. From these conditions we can derive

$$(w_l - w_r)^2 = \frac{(p_l - p_r)(\rho_l - \rho_r)}{\rho_l \rho_r} =: \Psi_{lr}^2 \qquad (\Psi_{lr} > 0)$$

and, additionally,

$$\frac{\rho_l}{\rho_r} = \left(\frac{p_l}{p_r} + \frac{(\gamma - 1)}{(\gamma + 1)}\right) \Bigg/ \left(1 + \frac{(\gamma - 1)}{(\gamma + 1)}\frac{p_l}{p_r}\right) =: \Pi_{lr}$$

for polytropic gas.

The type of elementary wave is determined by the pressure and the velocity inequalities:

$$\begin{array}{llcllc} p_l < p_r, & w_l < w_r : & \overrightarrow{R}, & p_l > p_r, & w_l < w_r : & \overleftarrow{R}, \\ p_l < p_r, & w_l > w_r : & \overleftarrow{S}, & p_l > p_r, & w_l > w_r : & \overrightarrow{S}. \end{array}$$

Across a contact discontinuity J the (normal) velocity and the pressure are constant, but the density can jump arbitrarily. For isentropic gas a slip line J only occurs in two-dimensional flow when the density and the normal velocity are constant and the tangential velocity is discontinuous.

3. Classification. In the following we assume that the initial data (2.2) or (2.2') are chosen so that only one elementary wave connects two neighboring constant states. First we consider all combinations that involve rarefaction and shock waves exclusively. Thereafter, all combinations involving slip lines are considered. For all possible configurations we give the relations that have to be satisfied by the initial data and the symmetry properties of the solution.

Configurations without slip lines. Here we consider the configurations that only involve rarefaction and shock waves. Then there exist only three distinct relations between the pressure values in the four quadrants:

$$\begin{array}{ccc} p_2 & < & p_1 \\ \vee & & \vee \\ p_3 & < & p_4 \end{array} \qquad \begin{array}{ccc} p_2 & < & p_1 \\ \wedge & & \vee \\ p_3 & > & p_4 \end{array} \qquad \begin{array}{ccc} p_2 & < & p_1 \\ \vee & & \vee \\ p_3 & > & p_4 \end{array}$$

The remaining relations can be derived from the above by coordinate transformations.

For the velocities four different relations are possible:

$$\begin{array}{cccc}
u_2 = u_3 < u_4 = u_1 & u_2 = u_3 > u_4 = u_1 & u_2 = u_3 < u_4 = u_1 & u_2 = u_3 > u_4 = u_1 \\
\text{and} & \text{and} & \text{and} & \text{and} \\
v_1 = v_2 > v_3 = v_4 & v_1 = v_2 < v_3 = v_4 & v_1 = v_2 < v_3 = v_4 & v_1 = v_2 > v_3 = v_4.
\end{array}$$

Altogether we get twelve configurations:

$p_1 > p_2,\ p_4 > p_3$:	$\overrightarrow{R}_{21}\overrightarrow{R}_{32}\overrightarrow{R}_{34}\overrightarrow{R}_{41}$	$\overleftarrow{S}_{21}\overleftarrow{S}_{32}\overleftarrow{S}_{34}\overleftarrow{S}_{41}$	$\overrightarrow{R}_{21}\overleftarrow{S}_{32}\overrightarrow{R}_{34}\overleftarrow{S}_{41}$	$\overleftarrow{S}_{21}\overrightarrow{R}_{32}\overleftarrow{S}_{34}\overrightarrow{R}_{41}$
$p_1 > p_2,\ p_4 < p_3$:	$\overrightarrow{R}_{21}\overleftarrow{R}_{32}\overleftarrow{R}_{34}\overrightarrow{R}_{41}$	$\overleftarrow{S}_{21}\overrightarrow{S}_{32}\overrightarrow{S}_{34}\overleftarrow{S}_{41}$	$\overrightarrow{R}_{21}\overrightarrow{S}_{32}\overleftarrow{R}_{34}\overleftarrow{S}_{41}$	$\overleftarrow{S}_{21}\overleftarrow{R}_{32}\overrightarrow{S}_{34}\overrightarrow{R}_{41}$
$p_1 > p_2 > p_3 > p_4$:	$\overrightarrow{R}_{21}\overrightarrow{R}_{32}\overleftarrow{R}_{34}\overrightarrow{R}_{41}$	$\overleftarrow{S}_{21}\overleftarrow{S}_{32}\overrightarrow{S}_{34}\overleftarrow{S}_{41}$	$\overrightarrow{R}_{21}\overleftarrow{S}_{32}\overleftarrow{R}_{34}\overleftarrow{S}_{41}$	$\overleftarrow{S}_{21}\overrightarrow{R}_{32}\overrightarrow{S}_{34}\overrightarrow{R}_{41}$

In this table and in the following E_{ij} with $E \in \{J, \overleftarrow{R}, \overrightarrow{R}, \overleftarrow{S}, \overrightarrow{S}\}$ and $i, j \in \{1, 2, 3, 4\}$ denotes an elementary wave E between the ith and jth quadrant.

Obviously, exchanging the axes in the right column gives the neighboring one. Examination of the configurations in the last row shows that they are impossible.

For $\overrightarrow{R}_{21}\overrightarrow{R}_{32}\overleftarrow{R}_{34}\overrightarrow{R}_{41}$ we have $v_4 - v_1 = \Phi_{41}$, $v_3 - v_2 = \Phi_{32}$, $v_2 = v_1$, $v_3 = v_4$. This implies $\sqrt{p_2/\rho_2} - \sqrt{p_1/\rho_1} = \sqrt{p_3/\rho_3} - \sqrt{p_4/\rho_4}$ in contradiction to the pressure inequality.

For $\overleftarrow{S}_{21}\overleftarrow{S}_{32}\overrightarrow{S}_{34}\overleftarrow{S}_{41}$ and $\overrightarrow{R}_{21}\overleftarrow{S}_{32}\overleftarrow{R}_{34}\overleftarrow{S}_{41}$ we have $v_4 - v_1 = \Psi_{41}$, $v_3 - v_2 = \Psi_{32}$, $v_2 = v_1$, $v_3 = v_4$ yielding $\Psi_{41} = \Psi_{32}$. Since the pressure inequality gives $p_4 - p_1 < p_3 - p_2$ and $1/\rho_1 - 1/\rho_4 < 1/\rho_2 - 1/\rho_3$, this is a contradiction, too.

At this point six configurations are remaining which are examined individually in the following.

Configuration 1. $\overrightarrow{R}_{21}\overrightarrow{R}_{32}\overrightarrow{R}_{34}\overrightarrow{R}_{41}$.

We have

$$p_1 > p_2,\ p_4 > p_3$$

and

$$\begin{array}{llll}
u_2 - u_1 = \Phi_{21}, & u_3 - u_4 = \Phi_{34}, & u_3 = u_2, & u_4 = u_1, \\
v_4 - v_1 = \Phi_{41}, & v_3 - v_2 = \Phi_{32}, & v_2 = v_1, & v_3 = v_4.
\end{array}$$

This gives the so-called compatibility condition $\Phi_{21} = \Phi_{34}$. For polytropic gas we have to include the following equations:

$$\frac{\rho_i}{\rho_j} = \left(\frac{p_i}{p_j}\right)^{1/\gamma} \quad \text{for } (i,j) \in \{(2,1),\ (3,4),\ (3,2),\ (4,1)\}.$$

Configuration 2. $\overrightarrow{R}_{21}\overleftarrow{R}_{32}\overleftarrow{R}_{34}\overrightarrow{R}_{41}$.

We have

$$p_1 > p_2,\ p_4 < p_3$$

and

$$\begin{array}{llll}
u_2 - u_1 = \Phi_{21}, & u_4 - u_3 = \Phi_{34}, & u_3 = u_2, & u_4 = u_1, \\
v_4 - v_1 = \Phi_{41}, & v_2 - v_3 = \Phi_{32}, & v_2 = v_1, & v_3 = v_4,
\end{array}$$

so that the compatibility conditions are $\Phi_{21} = -\Phi_{34}$ and $\Phi_{41} = -\Phi_{32}$. For polytropic gas we append the same equations as in Configuration 1.

Thus we must have $p_1 = p_3$ and $p_2 = p_4$ implying $u_1 - u_2 = v_1 - v_4$ and $u_4 - u_3 = v_2 - v_3$. Consequently, the solutions are symmetric to $\eta - \xi = v_1 - u_1$ and $\xi + \eta = u_2 + v_2$.

Configuration 3. $\overleftarrow{S}_{21}\overleftarrow{S}_{32}\overleftarrow{S}_{34}\overleftarrow{S}_{41}$.

We have

$$p_1 > p_2, p_4 > p_3 \tag{3.1}$$

and

$$\begin{aligned} u_2 - u_1 &= \Psi_{21}, & u_3 - u_4 &= \Psi_{34}, & u_3 &= u_2, & u_4 &= u_1, \\ v_4 - v_1 &= \Psi_{41}, & v_3 - v_2 &= \Psi_{32}, & v_2 &= v_1, & v_3 &= v_4. \end{aligned}$$

This gives the compatibility conditions

$$\Psi_{21} = \Psi_{34} \quad \text{and} \quad \Psi_{41} = \Psi_{32}. \tag{3.2}$$

For polytropic gas the following equations must be added:

$$\frac{\rho_i}{\rho_j} = \Pi_{ij} \quad \text{for } (i,j) \in \{(2,1),\ (3,4),\ (3,2),\ (4,1)\}. \tag{3.3}$$

Due to the compatibility conditions we have to choose $p_4 = p_2$ (which implies $\rho_4 = \rho_2$) according to the Theorem 1. Then the compatibility conditions (3.2) become a single equation, and we have $u_2 - u_1 = v_4 - v_1$. Consequently, the solutions are symmetric to $\eta - \xi = v_1 - u_1$.

THEOREM 1. *The inequality* (3.1), *the compatibility conditions* (3.2) *and the additional equations for polytropic gas* (3.3) *can only be satisfied if* $p_4 = p_2$. (*For polytropic gas it is assumed that* $1 < \gamma \leq 3$ *holds.*)

Proof. For isentropic gas we apply the equation of state to the compatibility conditions (3.2) and set

$$\rho_1 = x\rho_3, \quad \rho_2 = y\rho_3, \quad \text{and} \quad \rho_4 = z\rho_3,$$

getting

$$(x^\gamma - y^\gamma)\left(\frac{1}{y} - \frac{1}{x}\right) = (z^\gamma - 1)\left(1 - \frac{1}{z}\right), \qquad (x^\gamma - z^\gamma)\left(\frac{1}{z} - \frac{1}{x}\right) = (y^\gamma - 1)\left(1 - \frac{1}{y}\right).$$

We define $f(z, y)$ as the difference of the left- and right-hand side of the last equation (assuming x to be fixed). Now we have to prove that $f(y, z) = 0$ and $f(z, y) = 0$ for $x > y$, $z > 1$ only if $y = z$.

We find that

$$z\left(1 - \frac{z}{x}\right) f(y, z) + z(1 - z) f(z, y)$$

is a quadratic polynomial in z with the roots

$$z_1(y) = \frac{xy}{y(x+1) - x} \quad \text{and} \quad z_2(y) = \frac{x(x^\gamma - 1)}{y^\gamma(x-1) + x^\gamma - x}.$$

By construction, these roots are the only candidates for the roots of $f(y,z)$ and $f(z,y)$. After replacing z by z_1 in $f(y,z)$ and $f(z,y)$, we multiply both of them by a positive factor that has no influence on the roots of a function:

$$\begin{aligned} g_1(y) &= \frac{(y(x+1)-x)^\gamma}{y^\gamma(y^{-1}-x^{-1})} f(y,z_1) = \frac{(y(x+1)-x)^\gamma}{y^\gamma(1-y^{-1})} \cdot f(z_1,y) \\ &= \left(\frac{1+x^\gamma}{y^\gamma}-1\right)(y(x+1)-x)^\gamma - x^\gamma. \end{aligned}$$

Since $g_1(1) = g_1(x) = 0$ and $g_1(y)$ has its extremum for $y^{\gamma+1} = x(x^\gamma+1)/(x+1)$, there exists no root $y \in (1,x)$ of $g_1(y)$ and, consequently, of $f(y,z)$ or $f(z,y)$.

Now we define

$$\begin{aligned} g_2(y) &= (y^\gamma(x-1)+x^\gamma-x)^\gamma\,[f(y,z_2)+f(z_2,y)] \\ &= (y^\gamma(x-1)+x^\gamma-x)^\gamma\left(\frac{1}{y}(x^\gamma-1)-x^{\gamma-1}+1\right) - x^\gamma(x^\gamma-1)^\gamma\left(1-\frac{1}{x}\right). \end{aligned}$$

The common roots of $f(y,z_2)$ and $f(z_2,y)$ are a subset of the roots of $g_2(y)$. As before, we have $g_2(1) = g_2(x) = 0$, and we compute the first derivative of $g_2(y)$:

$$\begin{aligned} g_2'(y) =& \gamma^2 y^{\gamma-1}(x-1)(y^\gamma(x-1)+x^\gamma-x)^{\gamma-1}\left(\frac{1}{y}(x^\gamma-1)-x^{\gamma-1}+1\right) \\ &- (y^\gamma(x-1)+x^\gamma-x)^\gamma\frac{1}{y^2}(x^\gamma-1). \end{aligned}$$

In order to show that $g_2'(y)$ has at most two roots in $(1,x)$, we examine

$$\widehat{g_2}(y) = y^2(y^\gamma(x-1)+x^\gamma-x)^{1-\gamma}g_2'(y),$$

which has the same roots as $g_2'(y)$ in $(1,x)$. $\widehat{g_2}(y)$ is only extremal at $y = (1-\gamma^{-1})(x^\gamma - 1)/(x^{\gamma-1}-1)$. Thus $g_2'(y)$ has no more than two roots, and, consequently, $g_2(y)$ has at most one root in $(1,x)$.

On the other hand, $f(1,1)\,f(x,x) < 0$ and $f(y,y)$ is smooth, so that a root of $f(y,y)$ does exist in $(1,x)$. This must be the unique root of $g_2(y)$ in $(1,x)$, showing that $y = z$ is required as claimed. Moreover, for given x we can compute y by solving $y = z_2(y)$.

For polytropic gas we rewrite the compatibility conditions (3.2) to get

$$\begin{aligned} \frac{\rho_3}{\rho_2}(p_1-p_2)\left(1-\frac{\rho_2}{\rho_1}\right) &= (p_4-p_3)\left(1-\frac{\rho_3}{\rho_4}\right), \\ \frac{\rho_3}{\rho_4}(p_1-p_4)\left(1-\frac{\rho_4}{\rho_1}\right) &= (p_2-p_3)\left(1-\frac{\rho_3}{\rho_2}\right). \end{aligned}$$

Then we use the additional equations (3.3) to eliminate ρ_i, $i = 1,\dots,4$ in these equations. Setting

$$p_1 = xp_3, \quad p_2 = yp_3, \quad p_4 = zp_3 \quad \text{and} \quad \varepsilon = \frac{(\gamma-1)}{(\gamma+1)},$$

the compatibility conditions are equivalent to

$$(x-y)^2(1+\varepsilon y)(z+\varepsilon) = (z-1)^2(y+\varepsilon)(x+\varepsilon y),$$
$$(x-z)^2(1+\varepsilon z)(y+\varepsilon) = (y-1)^2(z+\varepsilon)(x+\varepsilon z).$$

We define $f(z,y)$ as the difference of the left- and right-hand side of the last equation (assuming x to be fixed). Now we have to prove that $f(y,z)=0$ and $f(z,y)=0$ for $x>y$, $z>1$ only if $y=z$.

The resultant $r(z)$ of $f(y,z)$ and $f(z,y)$ has the following roots:

$$z_0 = -\varepsilon, \quad z_1 = x, \quad z_2 = 1,$$
$$z_3^\pm = \frac{1}{2(1+2\varepsilon)}\left(\varepsilon(x+1) \pm \sqrt{\varepsilon^2(x+1)^2 + 4(1+2\varepsilon)x}\right),$$
$$z_4^\pm = \frac{1}{2\varepsilon(2\varepsilon^2+\varepsilon x - x)}\Bigl(-2\varepsilon^3 + (1+\varepsilon-6\varepsilon^2+2\varepsilon^3)x + (1-3\varepsilon+2\varepsilon^2)x^2$$
$$\pm\sqrt{x-1}\sqrt{2\varepsilon^3(x-1)+(1-\varepsilon-2\varepsilon^2)x}$$
$$\cdot\sqrt{-(1+3\varepsilon-2\varepsilon^2-2\varepsilon^3x^{-1})x-(1-\varepsilon)x^2}\Bigr).$$

By the definition of the resultant, the common roots of $f(y,z)$ and $f(z,y)$ are a subset of the roots of $r(z)$. Obviously, z_0, z_1, z_2 and z_3^- are not in the interval $(1,x)$. Under the assumption for γ, we have $0 < \varepsilon \leq \frac{1}{2}$. Then $z_4^\pm$ is well defined and its discriminant is negative because $x-1$ and $2\varepsilon^3(x-1)+(1-\varepsilon-2\varepsilon^2)x$ are positive and $-(1+3\varepsilon-2\varepsilon^2-2\varepsilon^3x^{-1})x-(1-\varepsilon)x^2$ is negative since

$$1+3\varepsilon-2\varepsilon^2-2\varepsilon^3x^{-1} \geq 1+3\varepsilon-2\varepsilon-2\varepsilon = 1-\varepsilon > 0.$$

Thus $z_4^\pm$ is complex, and z_3^+ is the only positive root of $r(z)$. It is easy to verify that $z_3^+ \in (1,x)$ and that $f(z_3^+, z_3^+) = 0$. □

Configuration 4. $\overleftarrow{S}_{21}\overrightarrow{S}_{32}\overrightarrow{S}_{34}\overleftarrow{S}_{41}$.

We have

$$p_1 > p_2, p_4 < p_3$$

and the same equations and compatibility conditions as in Configuration 3.

Necessarily we must have $p_1 = p_3$ and $p_2 = p_4$ (which implies $\rho_1 = \rho_3$ and $\rho_2 = \rho_4$) yielding $u_2 - u_1 = v_4 - v_1$ and $u_3 - u_4 = v_3 - v_2$. Consequently, the solutions are symmetric to $\eta - \xi = v_1 - u_1$ and $\xi + \eta = u_2 + v_2$.

Configuration 5. $\overrightarrow{R}_{21}\overleftarrow{S}_{32}\overrightarrow{R}_{34}\overleftarrow{S}_{41}$.

We have

$$p_1 > p_2,\ p_4 > p_3 \tag{3.4}$$

and

$$u_2 - u_1 = \Phi_{21}, \quad u_3 - u_4 = \Phi_{34}, \quad u_3 = u_2, \quad u_4 = u_1,$$
$$v_4 - v_1 = \Psi_{41}, \quad v_3 - v_2 = \Psi_{32}, \quad v_2 = v_1, \quad v_3 = v_4.$$

This gives the compatibility conditions

$$\Phi_{21} = \Phi_{34} \quad \text{and} \quad \Psi_{41} = \Psi_{32}. \tag{3.5}$$

For polytropic gas the equations

$$\frac{\rho_3}{\rho_2} = \Pi_{32}, \quad \frac{\rho_4}{\rho_1} = \Pi_{41}, \quad \frac{\rho_2}{\rho_1} = \left(\frac{p_2}{p_1}\right)^{1/\gamma}, \quad \text{and} \quad \frac{\rho_3}{\rho_4} = \left(\frac{p_3}{p_4}\right)^{1/\gamma} \tag{3.6}$$

are added.

We can prove that this configuration is impossible.

THEOREM 2. *There exist no p_i, $i = 1,\dots,4$ satisfying the inequality* (3.4), *the compatibility conditions* (3.5) *and the additional equations for polytropic gas* (3.6).

Proof. For isentropic gas we apply the equation of state to the compatibility conditions (3.5), getting

$$\sqrt{\rho_1^{\gamma-1}} - \sqrt{\rho_2^{\gamma-1}} = \sqrt{\rho_4^{\gamma-1}} - \sqrt{\rho_3^{\gamma-1}}, \qquad \frac{(\rho_1^\gamma - \rho_4^\gamma)(\rho_1 - \rho_4)}{\rho_1\rho_4} = \frac{(\rho_2^\gamma - \rho_3^\gamma)(\rho_2 - \rho_3)}{\rho_2\rho_3}.$$

Now we show that for any p_i, $i = 1,\dots,4$ satisfying the inequality (3.4) and the first compatibility condition, the second is violated. Defining

$$\delta = \frac{2}{(\gamma-1)} \quad \text{and} \quad R_i = \rho_i^{1/\delta}, \quad i = 1,\dots,4,$$

the first compatibility condition is equivalent to $R_1 - R_2 = R_4 - R_3$. Introducing $\Delta = R_1 - R_2 > 0$, we have

$$R_1 = R_2 + \Delta \quad \text{and} \quad R_4 = R_3 + \Delta. \tag{3.7}$$

Then the second compatibility condition can be written as

$$\frac{[(R_2+\Delta)^{\gamma\delta} - (R_3+\Delta)^{\gamma\delta}][(R_2+\Delta)^\delta - (R_3+\Delta)^\delta]}{(R_2+\Delta)^\delta (R_3+\Delta)^\delta} = \frac{[R_2^{\gamma\delta} - R_3^{\gamma\delta}][R_2^\delta - R_3^\delta]}{R_2^\delta R_3^\delta}.$$

We define $f(\Delta)$ as the difference of the left- and right-hand side of the last equation. Obviously, $f(0) = 0$. Now we have to prove that $f(\Delta)$ does not vanish for any positive R_2, R_3 and Δ. We differentiate f with respect to Δ. Using $\gamma\delta = \delta + 2$ and (3.7), this yields

$$\begin{aligned}\frac{\partial f}{\partial \Delta} = &\frac{1}{R_1^{\delta+1}R_4^{\delta+1}} \{(\delta+2)R_1R_4[R_1^{\delta+1} - R_4^{\delta+1}][R_1^\delta - R_4^\delta] \\ &- \delta[R_1^{\delta+2} - R_4^{\delta+2}][R_1^{\delta+1} - R_4^{\delta+1}]\}.\end{aligned}$$

Introducing $R = R_1/R_4 = (R_2 + \Delta)/(R_3 + \Delta) > 1$, this derivative becomes

$$\frac{\partial f}{\partial \Delta} = \frac{R_4}{R^{\delta+1}} (R^{\delta+1} - 1) \underbrace{\{(\delta+2)R(R^\delta - 1) - \delta(R^{\delta+2} - 1)\}}_{=h(R)}.$$

In order to show that $\partial f/\partial\Delta$ is negative for all positive R_2, R_3, and Δ, it is equivalent to show that the function $h(R)$ defined above is negative for all R strictly greater than one. Since $h(1) = 0$ we differentiate h with respect to R and get

$$h'(R) = (\delta+2)\{(\delta+1)R^\delta - 1 - \delta R^{\delta+1}\}.$$

Observing that $h'(1) = 0$, we compute $h''(R)$ to find

$$h''(R) = (\delta+2)(\delta+1)\delta R^{\delta-1}\{1 - R\}.$$

Obviously, $h''(R)$ is negative for R strictly greater than one. Thus we have proved that $f(\Delta)$ is negative for all positive R_2, R_3 and Δ.

For polytropic gas we use the additional equations (3.6) to derive the following equation, which is independent of ρ_i, $i = 1, \dots, 4$:

$$\left(\frac{p_2}{p_3}\right)^{1/\gamma} \Pi_{32} = \left(\frac{p_1}{p_4}\right)^{1/\gamma} \Pi_{41}.$$

Introducing

$$f(P) = \left(\frac{1}{P}\right)^{1/\gamma} \left(P + \frac{(\gamma-1)}{(\gamma+1)}\right) \Big/ \left(1 + \frac{(\gamma-1)}{(\gamma+1)} P\right),$$

this can be written as

$$f\left(\frac{p_3}{p_2}\right) = f\left(\frac{p_4}{p_1}\right).$$

Since $f(P)$ is strictly decreasing for $P \in (0, \infty)$, the last equation implies that

$$\text{(3.8)} \qquad \frac{p_3}{p_2} = \frac{p_4}{p_1}, \quad \text{which is equivalent to} \quad \frac{p_3}{p_4} = \frac{p_2}{p_1}.$$

Again using the additional equations, we eliminate ρ_i, $i = 1, \dots, 4$ in the first compatibility condition and get

$$\sqrt{\Pi_{41}} \left(1 - \left(\frac{p_2}{p_1}\right)^{(\gamma-1)/2\gamma}\right) = \sqrt{\frac{p_4}{p_1}} \left(1 - \left(\frac{p_3}{p_4}\right)^{(\gamma-1)/2\gamma}\right).$$

With our previous result (3.8), it follows that this is equivalent to $\Pi_{41} = p_4/p_1$. The only admissible solution $p_1 = p_4$ violates the inequality (3.4). □

Configuration 6. $\overrightarrow{R}_{21}\overrightarrow{S}_{32}\overleftarrow{R}_{34}\overleftarrow{S}_{41}$.

We have

$$\text{(3.9)} \qquad p_1 > p_2, \, p_4 < p_3$$

and

$$\begin{aligned} u_2 - u_1 &= \Phi_{21}, & u_4 - u_3 &= \Phi_{34}, & u_3 &= u_2, & u_4 &= u_1, \\ v_4 - v_1 &= \Psi_{41}, & v_3 - v_2 &= \Psi_{32}, & v_2 &= v_1, & v_3 &= v_4, \end{aligned}$$

so that the compatibility conditions are

$$\text{(3.10)} \qquad \Phi_{21} = -\Phi_{34} \quad \text{and} \quad \Psi_{41} = \Psi_{32}.$$

For polytropic gas we have the same additional equations as in Configuration 5, and this configuration is impossible, too.

THEOREM 3. *For polytropic gas there exist no p_i, $i = 1, \dots, 4$ satisfying the inequality* (3.9), *the compatibility conditions* (3.10), *and the additional equations for polytropic gas* (3.6).

Proof. As in the preceding proof, we use the additional equations (3.6) to derive that $p_3/p_2 = p_4/p_1$. This is in contradiction to the inequality (3.9), which implies that $p_3/p_2 > 1 > p_4/p_1$. □

For isentropic gas the following theorem states that we have to choose $p_3 = p_1$ and $p_4 = p_2$ (which implies $\rho_3 = \rho_1$ and $\rho_4 = \rho_2$). Thus the solutions are symmetric with respect to the point $(\xi, \eta) = \left(\frac{1}{2}(u_1 + u_2), \frac{1}{2}(v_1 + v_3)\right)$.

THEOREM 4. *For isentropic gas the inequality* (3.9) *and the compatibility conditions* (3.10) *can only be satisfied if* $p_3 = p_1$ *and* $p_4 = p_2$.

Proof. We apply the equation of state to the compatibility conditions (3.10), getting

$$\sqrt{\rho_1^{\gamma-1}} - \sqrt{\rho_2^{\gamma-1}} = \sqrt{\rho_3^{\gamma-1}} - \sqrt{\rho_4^{\gamma-1}}, \qquad \frac{(\rho_1^\gamma - \rho_4^\gamma)(\rho_1 - \rho_4)}{\rho_1\rho_4} = \frac{(\rho_3^\gamma - \rho_2^\gamma)(\rho_3 - \rho_2)}{\rho_3\rho_2}.$$

Defining

$$\delta = \frac{2}{(\gamma - 1)} \quad \text{and} \quad R_i = \rho_i^{1/\delta}, \quad i = 1, \ldots, 4,$$

the first compatibility condition becomes $R_1 - R_2 = R_3 - R_4$, which is equivalent to $R_1 - R_3 = R_2 - R_4$. Introducing $\Delta = R_1 - R_3$, we have $R_1 = R_3 + \Delta$ and $R_4 = R_2 - \Delta$. Then the second compatibility condition can be written as

$$\frac{[(R_3 + \Delta)^{\gamma\delta} - (R_2 - \Delta)^{\gamma\delta}][(R_3 + \Delta)^\delta - (R_2 - \Delta)^\delta]}{(R_3 + \Delta)^\delta (R_2 - \Delta)^\delta} = \frac{[R_3^{\gamma\delta} - R_2^{\gamma\delta}][R_3^\delta - R_2^\delta]}{R_3^\delta R_2^\delta}.$$

We define $f(\Delta)$ as the difference of the left- and right-hand side of the last equation. Obviously, $f(0) = 0$. Now we prove that $f(\Delta)$ is strictly increasing for any positive R_2, R_3 and $\Delta \in (-R_3, R_2)$. We differentiate f with respect to Δ. Using $\gamma\delta = \delta + 2$ and introducing $R = (R_3 + \Delta)/(R_2 - \Delta) = R_1/R_4 > 1$, this yields

$$\frac{\partial f}{\partial \Delta} = \frac{R_4}{R^{\delta+1}} (R^{\delta+1} + 1) \{(\delta + 2)R(R^\delta - 1) + \delta (R^{\delta+2} - 1)\} > 0.$$

Hence f is strictly increasing and $\Delta = 0$ is its unique root, i.e., $p_3 = p_1$ and $p_4 = p_2$ is necessary to satisfy the compatibility conditions. □

Configurations involving slip lines. Now we consider all combinations involving slip lines J. There are two genuinely different configurations with four J's, one where all the J's are moving clockwise and one where two J's are moving in the opposite direction.

Three J's imply $p_1 = p_2 = p_3 = p_4$ in contradiction to the pressure inequality of the fourth wave.

Two J's are either neighbors or not. In the first case we assume that the J's are between the third quadrant and its neighbors. Then we find the following eight configurations:

$$p_1 > p_2 = p_3 = p_4\colon \quad \overrightarrow{R}_{21}J_{32}J_{34}\overrightarrow{R}_{41} \quad \overleftarrow{S}_{21}J_{32}J_{34}\overleftarrow{S}_{41} \quad \overrightarrow{R}_{21}J_{32}J_{34}\overleftarrow{S}_{41} \quad \overleftarrow{S}_{21}J_{32}J_{34}\overrightarrow{R}_{41}$$

$$p_1 < p_2 = p_3 = p_4\colon \quad \overleftarrow{R}_{21}J_{32}J_{34}\overleftarrow{R}_{41} \quad \overrightarrow{S}_{21}J_{32}J_{34}\overrightarrow{S}_{41} \quad \overleftarrow{R}_{21}J_{32}J_{34}\overrightarrow{S}_{41} \quad \overrightarrow{S}_{21}J_{32}J_{34}\overleftarrow{R}_{41}.$$

As before, exchanging the axes in the right column gives the neighboring one.

In the case where the J's are not neighbors, three different combinations are possible:

$$p_1 = p_2 > p_3 = p_4\colon \quad J_{21}\overrightarrow{R}_{32}J_{34}\overrightarrow{R}_{41} \quad J_{21}\overleftarrow{S}_{32}J_{34}\overleftarrow{S}_{41} \quad J_{21}\overleftarrow{S}_{32}J_{34}\overrightarrow{R}_{41}.$$

A case with one J would imply $u_1 = u_2 = u_3 = u_4$ or $v_1 = v_2 = v_3 = v_4$ in contradiction to the existence of three shock and rarefaction waves.

In the following, these eleven configurations involving slip lines are listed with their relations for the initial data and their symmetry properties. For polytropic gas we have to include additional equations. Namely, for a rarefaction or a shock wave between the ith and jth quadrant (i, $j \in \{1, \ldots, 4\}$) we add

$$\frac{\rho_i}{\rho_j} = \left(\frac{p_i}{p_j}\right)^{1/\gamma} \quad \text{or} \quad \frac{\rho_i}{\rho_j} = \Pi_{ij},$$

respectively.

Configuration A. $\overleftrightarrow{J_{21}J_{32}J_{34}J_{41}}$ (motion in opposite directions).
We have $p_1 = p_2 = p_3 = p_4$ and

$$u_1 = u_2 < u_3 = u_4, \qquad v_1 = v_4 < v_3 = v_2.$$

The solutions are symmetric with respect to the point $(\xi, \eta) = \left(\frac{1}{2}(u_1 + u_3), \frac{1}{2}(v_1 + v_2)\right)$ for isentropic gas.

Configuration B. $\overrightarrow{J_{21}J_{32}J_{34}J_{41}}$ (clockwise motion).
We have $p_1 = p_2 = p_3 = p_4$ and

$$u_1 = u_2 > u_3 = u_4, \qquad v_1 = v_4 < v_3 = v_2.$$

The solutions have the same symmetry properties as in Configuration A.

Configuration C. $\overrightarrow{R}_{21}J_{32}J_{34}\overrightarrow{R}_{41}$.
We have $p_1 > p_2 = p_3 = p_4$ and

$$u_2 - u_1 = \Phi_{21}, \quad u_3 = u_4 = u_1, \quad v_4 - v_1 = \Phi_{41}, \quad v_3 = v_2 = v_1.$$

The solutions are symmetric to $\eta - \xi = v_1 - u_1$.

Configuration D. $\overleftarrow{R}_{21}J_{32}J_{34}\overleftarrow{R}_{41}$.
We have $p_1 < p_2 = p_3 = p_4$ and

$$u_1 - u_2 = \Phi_{21}, \quad u_3 = u_4 = u_1, \quad v_1 - v_4 = \Phi_{41}, \quad v_3 = v_2 = v_1.$$

The solutions are symmetric to $\eta - \xi = v_1 - u_1$.

Configuration E. $\overleftarrow{S}_{21}J_{32}J_{34}\overleftarrow{S}_{41}$.
We have $p_1 > p_2 = p_3 = p_4$ and

$$u_2 - u_1 = \Psi_{21}, \quad u_3 = u_4 = u_1, \quad v_4 - v_1 = \Psi_{41}, \quad v_3 = v_2 = v_1.$$

The solutions are symmetric to $\eta - \xi = v_1 - u_1$.

Configuration F. $\overrightarrow{S}_{21}J_{32}J_{34}\overrightarrow{S}_{41}$.
We have $p_1 < p_2 = p_3 = p_4$ and the same equations as in Configuration E.

Configuration G. $\overrightarrow{R}_{21}J_{32}J_{34}\overleftarrow{S}_{41}$.
We have $p_1 > p_2 = p_3 = p_4$ and

$$u_2 - u_1 = \Phi_{21}, \quad u_3 = u_4 = u_1, \quad v_4 - v_1 = \Psi_{41}, \quad v_3 = v_2 = v_1.$$

Configuration H. $\overleftarrow{R}_{21}J_{32}J_{34}\overrightarrow{S}_{41}$.
We have $p_1 < p_2 = p_3 = p_4$ and

$$u_1 - u_2 = \Phi_{21}, \quad u_3 = u_4 = u_1, \quad v_4 - v_1 = \Psi_{41}, \quad v_3 = v_2 = v_1.$$

Configuration I. $J_{21}\overrightarrow{R}_{32}J_{34}\overrightarrow{R}_{41}$.
We have $p_1 = p_2 > p_3 = p_4$ and

$$u_1 = u_2 = u_3 = u_4, \quad v_4 - v_1 = \Phi_{41}, \quad v_3 - v_2 = \Phi_{32}.$$

Configuration J. $J_{21}\overleftarrow{S}_{32}J_{34}\overleftarrow{S}_{41}$.
We have $p_1 = p_2 > p_3 = p_4$ and

$$u_1 = u_2 = u_3 = u_4, \quad v_4 - v_1 = \Psi_{41}, \quad v_3 - v_2 = \Psi_{32}.$$

Configuration K. $J_{21}\overleftarrow{S}_{32}J_{34}\overrightarrow{R}_{41}$.
We have $p_1 = p_2 > p_3 = p_4$ and

$$u_1 = u_2 = u_3 = u_4, \quad v_4 - v_1 = \Phi_{41}, \quad v_3 - v_2 = \Psi_{32}.$$

Conclusion. Combining the results of this section, we have sixteen (respectively, fifteen) different configurations for the Riemann problem for isentropic (respectively, polytropic) gas in two space dimensions:

$$\begin{array}{llll}
4R: & \overrightarrow{R}_{21}\overrightarrow{R}_{32}\overrightarrow{R}_{34}\overrightarrow{R}_{41} & \overrightarrow{R}_{21}\overleftarrow{R}_{32}\overleftarrow{R}_{34}\overrightarrow{R}_{41} & \\
4S: & \overleftarrow{S}_{21}\overleftarrow{S}_{32}\overleftarrow{S}_{34}\overleftarrow{S}_{41} & \overleftarrow{S}_{21}\overrightarrow{S}_{32}\overrightarrow{S}_{34}\overleftarrow{S}_{41} & \\
2R+2S: & & \overrightarrow{R}_{21}\overrightarrow{S}_{32}\overleftarrow{R}_{34}\overleftarrow{S}_{41} & \text{(only for isentropic gas)} \\
4J: & \overleftrightarrow{J_{21}\,J_{32}\,J_{34}\,J_{41}} & \overrightarrow{J_{21}\,J_{32}\,J_{34}\,J_{41}} & \\
2J+2R: & \overrightarrow{R}_{21}\,J_{32}\,J_{34}\overrightarrow{R}_{41} & \overleftarrow{R}_{21}\,J_{32}\,J_{34}\overleftarrow{R}_{41} & J_{21}\overrightarrow{R}_{32}\,J_{34}\overrightarrow{R}_{41} \\
2J+2S: & \overleftarrow{S}_{21}\,J_{32}\,J_{34}\overleftarrow{S}_{41} & \overrightarrow{S}_{21}\,J_{32}\,J_{34}\overrightarrow{S}_{41} & J_{21}\overleftarrow{S}_{32}\,J_{34}\overleftarrow{S}_{41} \\
2J+R+S: & \overrightarrow{R}_{21}\,J_{32}\,J_{34}\overleftarrow{S}_{41} & \overleftarrow{R}_{21}\,J_{32}\,J_{34}\overrightarrow{S}_{41} & J_{21}\overleftarrow{S}_{32}\,J_{34}\overrightarrow{R}_{41}.
\end{array}$$

THRESHOLD BEHAVIOR AND PROPAGATION FOR A DIFFERENTIAL-DIFFERENCE SYSTEM*

WEI-ZHENG GAO†

Abstract. This paper uses a comparison principle to study the long time behavior of a certain class of nonlinear difference-differential systems. These systems are motivated by certain models of heart tissue and myelinated axon. The main concern is to find steady state solutions, determine threshold properties, and study aspects of propagation. The theorems obtained are supported by numerical simulations.

Key words. threshold, comparison principle, myelinated axon, propagation

AMS(MOS) subject classifications. 34K25, 92A05

1. Introduction. Below we study a class of problems that are motivated by the structure of certain mathematical models, among them models of myelinated axon and heart tissue. The myelinated axon can be modeled by an electrical circuit. Based on current conservation from this circuit, we can set up the mathematical model to have the form

$$\frac{d}{dt}u_j = d(u_{j+1} - 2u_j + u_{j-1}) + f(u_j), \tag{1.1}$$

where u_j is the membrane potential at the jth node, $f(u)$ represents a current-voltage relation, and d is a constant [2], [3]. The simplest current-voltage relation is to let f be a cubic-shaped function. After appropriate scaling, we can assume

$$0 \leqq u_j \leqq 1 \quad \text{for all } j \in \mathbf{Z}.$$

Bell [2] studied this system. He proved that there exists a constant α, $0 < \alpha < 1$, such that if the initial condition $u_j(0) < \alpha$ holds for all j, then the solution $u_j(t) \to 0$ as $t \to \infty$ for all j. He calls this a subthreshold phenomenon. Under certain conditions, $u_j(t)$ does not go to zero as $t \to \infty$ for at least one j. This is called a superthreshold phenomenon. Under certain conditions on f, if $u_j(0)$ is greater than a particular value for at least one j, then $u_j(t) \to 1$ for all j as $t \to \infty$, and this process is in a form of propagating wave front. Keener [6] proved that propagation fails when the coupling is weak, i.e., when d is small. Zinner [8] proved that (1.1) has a traveling wavefront solution under certain conditions, and in [9] has shown that such a wavefront solution is globally stable.

To model a sheet of heart tissue, we need at least two spatial dimensions (Keener [7]). One possible mathematical model of a thin heart tissue is

$$\begin{aligned} \frac{d}{dt}u_{i,j} &= d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) \\ &\quad + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) + f(u_{i,j}), \end{aligned} \tag{1.2}$$

where $u_{i,j}(t)$ represents the potential in the (i, j) cell at time t.

In this paper, we study the threshold behavior and propagation of a more general semidiscrete dynamic system

$$\frac{d}{dt}u_\alpha(t) - \underset{d}{\Delta} u_\alpha(t) - f_\alpha(u_\alpha) = 0,$$

* Received by the editors January 21, 1991; accepted for publication (in revised form) May 5, 1992.

where

$$\underset{d}{\Delta} u_\alpha \equiv \sum_{\beta \in C_\alpha} d_{\beta-\alpha}(u_\beta - u_\alpha) \quad \text{for } \alpha \in \mathbf{K} \subseteq \mathbf{Z}^d,$$

$\mathbf{K}$ and C_α are defined in § 2. This system includes (1.1) and (1.2) as special cases. Various results obtained here are parallel to Bell's results [2].

(1) There exists some constant q such that if $0 < u_\alpha(0) \leqq q$ for all α, then $u_\alpha(t) \to 0$ as $t \to \infty$ for all $\alpha \in \mathbf{Z}^d$ (Theorem 4.2). This is a subthreshold result.

(2) Under certain conditions on f_α, there exists a constant b, such that $u_\alpha(0) \geqq 0$ for all α and $u_\gamma(0) \geqq b$ for some γ guarantee that $\lim_{t\to\infty} u_\alpha = 1$ for all $\alpha \in \mathbf{Z}^d$ (Theorem 4.5). This is a superthreshold result.

(3) Under the conditions stated in (2), $u_\alpha \to 1$ in a form of a traveling wavefront. This behavior is studied in § 5. Estimation of the lower bound $\underline{c}$ and the upper bound $\bar{c}$ of the propagation speed are obtained (Theorems 5.1 and 5.2).

The above theoretical results are supported by numerical simulations that are discussed in § 6.

2. Model and comparison theorem. Let $\mathbf{K} \subseteq \mathbf{Z}^d$. $\mathbf{K} \neq \Phi$. We define the boundary of $\mathbf{K}$ as

$$\partial\mathbf{K} = \{\alpha \in \mathbf{Z}^d \mid \exists \beta \in \mathbf{K} \text{ and } \exists \gamma \notin \mathbf{K} \text{ such that } \|\alpha - \beta\| = 1 \text{ and } \|\alpha - \gamma\| = 1\}.$$

We also assume that $\operatorname{Int}\mathbf{K} = \mathbf{K} \backslash \partial\mathbf{K} \neq \Phi$, where $\operatorname{Int}\mathbf{K}$ is the interior of $\mathbf{K}$. Furthermore, for any $\alpha \in \mathbf{Z}^d$ we define

$$C_\alpha \equiv \{\beta \in \mathbf{Z}^d \,\|\, |\alpha_i - \beta_i| = 0 \text{ or } 1, i = 1, \ldots, d, \beta \neq \alpha\},$$

where $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_d)$, $\beta = (\beta_1, \beta_2, \ldots, \beta_d)$. There are $N_d = 3^d - 1$ elements in C_α.

$$R^+ = \{t \mid 0 < t < \infty\},$$

$$R_0^+ = \{t \mid 0 \leqq t < \infty\},$$

$$X = \{\varphi \in C^1(R^+) \cap C(R_0^+) \mid \varphi'(0^+) \text{ exists}\}.$$

Consider the system

$$\frac{d}{dt} u_\alpha(t) - \underset{d}{\Delta} u_\alpha(t) - f_\alpha(u_\alpha) = 0, \tag{2.1}$$

where

$$\underset{d}{\Delta} u_\alpha \equiv \sum_{\beta \in C_\alpha} d_{\beta-\alpha}(u_\beta - u_\alpha) \quad \text{for } \alpha \in \mathbf{K}, \tag{2.2}$$

and the diffusion coefficients $d_\delta \geqq 0$, $\delta = \beta - \alpha$, with $\beta \in C_\alpha$, have the following properties:

(i) Symmetric with respect to α:

$$d_\delta = d_{-\delta}; \tag{2.3a}$$

(2.3b) (ii) $\sum_{\beta \in C_\alpha} d_\delta > 0;$

(2.3c) (iii) $d_\delta \equiv d_{\beta-\alpha}$ is independent of α.

Below, when we write $\sum_{\beta\in C_\alpha} d_\delta(u_\beta - u_\alpha)$, we will mean that $\delta = \beta - \alpha$. For a given dimension d, the operator Δ_d is uniquely determined by one particular set of d_δ's. We also suppose $f_\alpha \in C^1[0, 1]$ has the following properties:

(i) $f_\alpha(0) = f_\alpha(a_\alpha) = f_\alpha(1) = 0$, where $a_\alpha \in (0, 1)$,

(ii) $f_\alpha(u) < 0$ for $0 < u < a_\alpha$ and

(2.4) $f_\alpha(u) > 0$ for $a_\alpha < u < 1$,

where

$$0 < \underline{a} \leqq a_\alpha \leqq \bar{a} < 1, \quad \underline{a} = \inf_\alpha\{a_\alpha\}, \quad \bar{a} = \sup_\alpha\{a_\alpha\};$$

(iii) Assume

$$r_\alpha = \inf_s \left\{ 0 < s < a_\alpha \,\middle|\, f_\alpha(u) \leqq \frac{f_\alpha(p)}{p} u \quad \forall 0 < u \leqq p,\ s \leqq p \leqq a_\alpha \right\} < \underline{a}$$

for each α, $\bar{r} \equiv \sup_\alpha r_\alpha < \underline{a}$, and $\sup_{\alpha\in Z^d}\{f_\alpha(q)/q\} < 0$ for $q < \underline{a}$;

(iv) df_α/du is uniformly bounded over $0 \leqq u \leqq 1$.

The assumptions (i), (ii) on f_α may be dropped for some theorems and lemmas.

We first consider some examples of system (2.1).

Example 2.1. Special case of dimension $d = 1$.

Where α, β are scalar, let $\alpha \equiv i$; then $|\beta - \alpha| \leqq 1$ implies $\beta = i, i \pm 1$, so, $C_\alpha = \{i - 1, i + 1\}$. There are two diffusion coefficients, $d_{(i-1)-i} = d_{-1}$ and $d_{(i+1)-i} = d_1$. Equations (2.3a), (2.3b) imply that $d_{-1} = d_1 = d > 0$. Therefore, the operator $\Delta_d u_i$ is determined as

$$\begin{aligned} \underset{d}{\Delta} u_i &= d_1(u_{i+1} - u_i) + d_{-1}(u_{i-1} - u_i) \\ &= d(u_{i+1} - 2u_i + u_{i-1}), \end{aligned} \tag{2.5}$$

and (2.1) becomes

$$\frac{d}{dt} u_i = d(u_{i+1} - 2u_i + u_{i-1}) + f_i(u_i). \tag{2.6}$$

This is the prototypical example of system (2.1), and it has been studied extensively [2], [3].

Example 2.2. Special case of dimension $d = 2$.

In this case, $\mathbf{K} \subseteq \mathbf{Z}^2$; if $\alpha \equiv (i, j)$, then

$$C_{(i,j)} = \{(i \pm 1, j),\ (i, j \pm 1),\ (i \pm 1, j \pm 1)\}.$$

See Fig. 1(a). There are eight d_δ's: $d_{\pm 1,0}$, $d_{0,\pm 1}$, $d_{\pm 1,\pm 1}$. Different operators $\Delta_d u_{i,j}$ can be obtained by choosing different sets of d_δ's.

(1) For any $(i, j) \in \mathbf{Z}^2$, choosing

$$d_{1,0} = d_{-1,0} = d_1 > 0, \qquad d_{0,1} = d_{0,-1} = d_2 > 0,$$

$$d_{\pm 1,\pm 1} = 0; \quad \text{see Fig. 1(b)},$$

and with conditions (2.3a), (2.3b), and (2.3c) satisfied, we obtain

$$\underset{d}{\Delta} u_{i,j} = d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}), \tag{2.7}$$

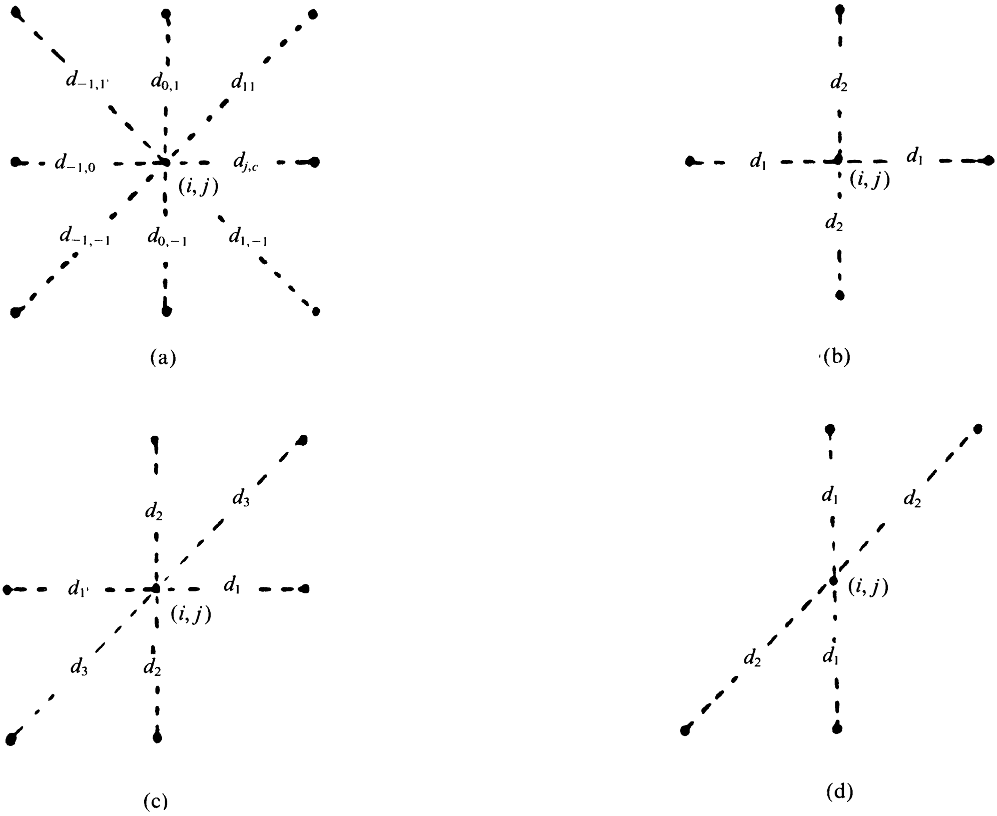

FIG 1. *Some examples of operator* $\underset{d}{\Delta}$ *for* $d=2$.

and (2.1) becomes

$$(2.8)\qquad \frac{d}{dt}u_{i,j}=d_1(u_{i+1,j}-2u_{i,j}+u_{i-1,j})+d_2(u_{i,j+1}-2u_{i,j}+u_{i,j-1})+f_{i,j}(u_{i,j}).$$

This is the standard two-dimensional analogue of (2.6).

(2) For any $(i,j)\in\mathbf{Z}^2$, choosing

$$d_{\pm1,0}=d_1>0,\quad d_{0,\pm1}=d_2>0,\quad d_{1,1}=d_{-1,-1}=d_3>0,$$
$$\text{and}\quad d_{1,-1}=d_{-1,1}=0$$

(see Fig. 1(c)), (2.3a) to (2.3c) are also satisfied, and (2.1) becomes

$$(2.9)\qquad \begin{aligned}\frac{d}{dt}u_{i,j}&=d_1(u_{i+1,j}-2u_{i,j}+u_{i-1,j})+d_2(u_{i,j+1}-2u_{i,j}+u_{i,j-1})\\&\quad+d_3(u_{i+1,j+1}-2u_{i,j}+u_{i-1,j-1})+f_{i,j}(u_{i,j}).\end{aligned}$$

(3) Similarly, if we choose

$$d_{0,\pm1}=d_1>0,\qquad d_{1,1}=d_{-1,-1}=d_2>0,$$
$$d_{\pm1,0}=0,\quad\text{and}\quad d_{1,-1}=d_{-1,1}=0$$

(see Fig. 1(d)), (2.1) becomes

$$\text{(2.10)}\qquad \frac{d}{dt}u_{i,j}=d_1(u_{i,j+1}-2u_{i,j}+u_{i,j-1})+d_2(u_{i+1,j+1}-2u_{i,j}+u_{i-1,j-1})+f_{i,j}(u_{i,j}).$$

Our main mathematical tool is the comparison theorem, which is stated as Lemma 2.2.

Let $\varphi_\alpha \in X$, f_α, $g_\alpha \in C^1(R^2)$; we define

$$\text{(2.11a)}\qquad P\varphi_\alpha(t)\equiv\frac{d}{dt}\varphi_\alpha(t)-\sum_{\beta\in C_\alpha} d_\delta(\varphi_\beta-k\varphi_\alpha)-f_\alpha(t,\varphi_\alpha),$$

$$\text{(2.11b)}\qquad \bar{P}\varphi_\alpha(t)\equiv\frac{d}{dt}\varphi_\alpha(t)-\sum_{\beta\in C_\alpha} d_\delta(\varphi_\beta-k\varphi_\alpha)-g_\alpha(t,\varphi_\alpha),$$

where $\alpha\in\mathbf{K}$, $k\in R$ is a constant, and the d_δ's satisfy (2.3).

LEMMA 2.1. *Assume* $\{u_\alpha(t)\}_{\alpha\in\mathbf{K}}$, $\{v_\alpha(t)\}_{\alpha\in\mathbf{K}}$ *with* u_α, $v_\alpha\in X$, f_α, $g_\alpha\in C^1(R^2)$, *and for all* $\alpha\in\mathbf{K}$ *the following conditions are satisfied*:

(2.12) (i) $Pu_\alpha \geqq \bar{P}v_\alpha$ *in* R^+, $\alpha\notin\partial\mathbf{K}$;

(2.13) (ii) $u_\alpha(0)\geqq v_\alpha(0)$;

(2.14) (iii) $f_\alpha(t,z)\geqq g_\alpha(t,z)$ *for* $t, z\in R$;

(iv) *If* $\mathbf{K}$ *has a boundary* $\partial\mathbf{K}$, *assume that*

$$\text{(2.15)}\qquad u_\gamma(t)\geqq v_\gamma(t)\quad\text{in } R_0^+\quad \forall\gamma\in\partial\mathbf{K};$$

(v) $\sup\{(\partial f_\alpha/\partial z)(t,z)\}=M<\infty$, *where the* sup *is taken over all* $z\in R$,

$$\alpha\in\mathbf{K},\quad\text{and}\quad t\geqq 0.$$

Then

$$u_\alpha(t)\geqq v_\alpha(t)\quad\text{in } R_0^+\quad\text{for all } \alpha\in\mathbf{K}.$$

Proof of this lemma is similar to the proof of Theorem 2.3 in [6]. The following comparison result is a special case of Lemma 2.1, where $k=1$, and $f_\alpha(t,z)=f_\alpha(z)$. This lemma is the main tool for studying system (2.1)-(2.4).

LEMMA 2.2. *Assume* $\{u_\alpha(t)\}_{\alpha\in\mathbf{K}}$, $\{v_\alpha(t)\}_{\alpha\in\mathbf{K}}$ *with* u_α, $v_\alpha\in X$, f_α, $g_\alpha\in C^1(R)$, *and for all* $\alpha\in\mathbf{K}$ *the following conditions are satisfied*:

(i) $\frac{d}{dt}u_\alpha-\underset{d}{\Delta}u_\alpha-f_\alpha(u_\alpha)\geqq\frac{d}{dt}v_\alpha-\underset{d}{\Delta}v_\alpha-g_\alpha(v_\alpha)$ *in* R^+, $\alpha\notin\partial\mathbf{K}$;

(ii) $f_\alpha(z)\geqq g_\alpha(z)$ *for* $z\in R$;

(iii) *For some* $M_1<\infty$, $\sup_{\alpha\in\mathbf{K}}\sup_{z\in R}\left\{\left|\frac{df_\alpha(z)}{dz}\right|\right\}\leqq M_1$,

(iv) $u_\alpha(0)\geqq v_\alpha(0)$,

(v) *Boundary condition* (2.15) *holds.*

Then

$$u_\alpha(t)\geqq v_\alpha(t)\quad\text{in } R_0^+\quad\text{for all } \alpha\in\mathbf{K}.$$

3. Steady state solutions. Before we go into the discussion of the threshold behavior, let us find some steady state solutions of (2.1)-(2.4) first, i.e., solutions to the system

$$\underset{d}{\Delta} u_\alpha + f_\alpha(u_\alpha) = 0,$$

or more explicitly,

$$\sum_{\beta \in C_\alpha} d_\delta(u_\beta - u_\alpha) + f_\alpha(u_\alpha) = 0. \tag{3.1}$$

3.1. Trivial steady state solutions. Trivial steady state solutions are $\{u_\alpha\} = \{0\}$, $\{1\}$ because $f_\alpha(0) = f_\alpha(1) = 0$ for all $\alpha \in \mathbf{Z}^d$. If $a_\alpha = a$ for all α, then $f_\alpha(a) = f_\alpha(a_\alpha) = 0$ for all α, which implies $\{u_\alpha\} = \{a\}$ is also a steady state solution.

We are interested in finding some nontrivial steady state solutions of system (2.1) with operator Δ_d given in (2.7). We consider the special case where $f_\alpha = f$ for all α, i.e.,

$$d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) + f(u_{i,j}) = 0, \tag{3.2}$$

where $d_1 > 0$, $d_2 > 0$, and $f(u_{i,j})$ satisfies (2.4). Function $f(u_{i,j})$ is shown in Fig. 2.

3.2. A particular class of nontrivial symmetric solutions of (3.2). Let us see an example first.

Example. Let p, q be constants satisfying

$$0 < p < a < q < 1 \quad (\text{so } f(p) < 0,\ f(q) > 0),$$

and

$$\begin{aligned} &2(q-p)(d_1 + d_2) + f(p) = 0, \\ &2(p-q)(d_1 + d_2) + f(q) = 0. \end{aligned} \tag{3.3}$$

Let

$$\begin{aligned} &q_{0,0} = p, \\ &q_{i,j} = \begin{cases} p & \text{if } |i| + |j| \text{ is even}, \\ q & \text{if } |i| + |j| \text{ is odd}. \end{cases} \end{aligned} \tag{3.4}$$

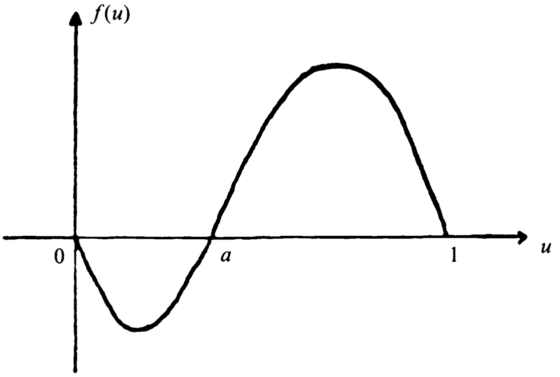

FIG. 2. *Typical form of $f(u)$.*

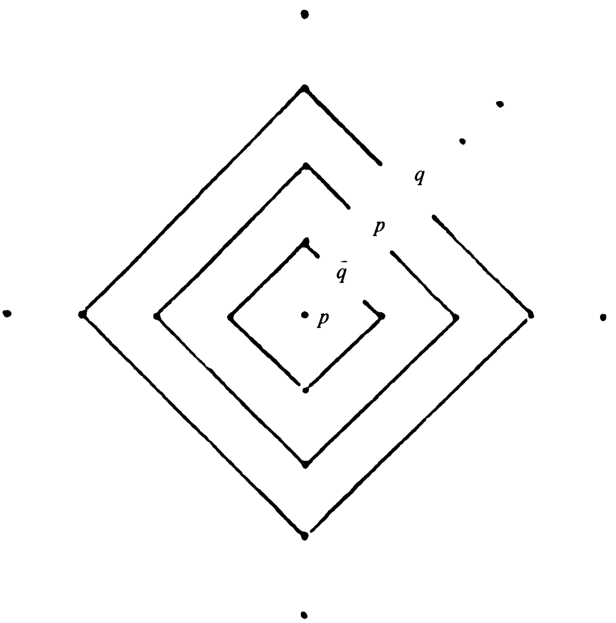

FIG. 3

Then $\{q_{i,j}\}$, defined by (3.4), is a (nontrivial) steady state solution of (2.1) and is given schematically in Fig. 3. This can be checked easily. For example, if for some $i, j \in \mathbf{Z}$ $|i|+|j|=$ even, then $|i\pm 1|+|j|$, $|i|+|j\pm 1|$ are both odd, so

$$q_{i,j}=p,\ q_{i+1,j}=q_{i-1,j}=q_{i,j+1}=q_{i,j-1}=q.$$

Therefore, by (3.3),

$$d_1(q_{i+1,j}-2q_{i,j}+q_{i-1,j})+d_2(q_{i,j+1}-2q_{i,j}+q_{i,j-1})+f(q_{i,j})=2(q-p)(d_1+d_2)+f(p)=0.$$

We now consider two particular cases.

(i) $f(u)=-(d_1+d_2)\sin(2\pi u)$, $d_1>0$, $d_2>0$ are arbitrary. f meets conditions of (2.4) with $a=\frac{1}{2}$. Let $p=\frac{1}{4}$, $q=\frac{3}{4}$, then

$$2(q-p)(d_1+d_2)+f(p)=(d_1+d_2)-(d_1+d_2)\sin\left(\frac{2\pi}{4}\right)=0,$$

$$2(p-q)(d_1+d_2)+f(q)=-(d_1+d_2)-(d_1+d_2)\sin\left(\frac{3\pi}{2}\right)=0,$$

so (3.3) is satisfied. From (3.4),

$$q_{i,j}=\begin{cases}\frac{1}{4} & \text{if } |i|+|j| \text{ is even (include 0)},\\ \frac{3}{4} & \text{if } |i|+|j| \text{ is odd},\end{cases}$$

so that $\{q_{i,j}\}$ is a nontrivial steady state solution.

(ii) $f(u)=0.5\cdot e^{5u}\sin[2\pi(1-u)^3]$, $\quad d_1=1, d_2=2.$

Here $a=1-2^{-1/3}\cong 0.2063$. This time p, q can be obtained by solving the nonlinear system that is represented in (3.3), namely,

$$6(q-p)+0.5\,e^{5p}\sin[2\pi(1-p)^3]=0,$$

$$6(p-q)+0.5\,e^{5q}\sin[2\pi(1-q)^3]=0.$$

The solution of this system is

$$p \cong 0.1117,$$

$$q \cong 0.2505.$$

Again, from (3.4) let

$$q_{i,j} = \begin{cases} p & \text{if } |i|+|j| \text{ is even (include 0),} \\ q & \text{if } |i|+|j| \text{ is odd,} \end{cases}$$

Then $\{q_{i,j}\}$ is a nontrivial steady state solution.

In the above example, the steady state $\{q_{i,j}\}$ is "diamond-symmetrically" distributed with respect to the "origin" $(i, j) = (0, 0)$, and attains values p and q alternatively. It is easy to prove that if the steady state solution $\{q_{i,j}\}$ has such a symmetric property and $d_1 \neq d_2$, then it must be obtained by the repeating of two values.

3.3. Some "special" steady state solutions of (2.1). There are some "special kinds" of steady state solutions of system (2.1). For example, let $\mathbf{K}$ be a bounded set centered at $\alpha = \mathbf{0}$, i.e., $\mathbf{K} = C_0 \cup \{\mathbf{0}\}$ (C_α is defined in § 2); therefore, (2.1) only holds at one point $\alpha = \mathbf{0}$, we can denote $f_\alpha = f$, and $a_\alpha = a$. Assume further that there exists b, such that

$$\sum_{\beta \in C_0} d_\beta b - f(b) = 0;$$

then $u_0(t) = b$, $u_\alpha(t) = 0$ for all $\alpha \in \partial\mathbf{K} \equiv C_0$ is a steady state solution. This follows from (3.1),

$$\begin{aligned} &\sum_{\beta \in C_0} d_\beta(u_\beta - u_0) + f(u_0) \\ &\quad = \sum_{\beta \in C_0} d_\beta(0 - u_0) + f(u_0) \\ &\quad = -\sum_{\beta \in C_0} d_\beta b + f(b) \\ &\quad = 0. \end{aligned}$$

This kind of steady state solution will be used when we discuss a superthreshold result.

4. Threshold results. We now investigate the sub- and superthreshold behavior of the system (2.1)-(2.4).

LEMMA 4.1. *Suppose* $\{u_\alpha(t)\}$, $\alpha \in \mathbf{Z}^d$ *is a solution to* (2.1)-(2.4) *with* $u_\alpha(0) \leqq q$ *for all* $\alpha \in \mathbf{Z}^d$. *If* $0 < q \leqq \underline{a}$, *then* $u_\alpha(t) \leqq q$ *for all* $\alpha \in \mathbf{Z}^d$, *and for all* $t \geqq 0$.

Proof. Let

$$w_\alpha(t) \equiv q \quad \forall \alpha \in \mathbf{Z}^d.$$

Then

$$\frac{d}{dt} w_\alpha - \underset{d}{\Delta} w_\alpha - f_\alpha(w_\alpha) = -f_\alpha(q) \geqq 0 = \frac{d}{dt} u_\alpha - \underset{d}{\Delta} u_\alpha - f_\alpha(u_\alpha)$$

$$w_\alpha(0) = q \geqq u_\alpha(0) \quad \forall \alpha.$$

By Lemma 2.2 $u_\alpha(t) \leqq w_\alpha(t) \equiv q$, for all $\alpha \in \mathbf{Z}^d$ and for all $t \geqq 0$. □

THEOREM 4.2. *Suppose* $\{u_\alpha(t)\}$ *is a solution to* (2.1)-(2.4) *with* $0 \leqq u_\alpha(0) \leqq q$ *for all* $\alpha \in \mathbf{Z}^d$. *If* $0 \leqq q < \underline{a}$, *then* $\lim_{t\to\infty} u_\alpha(t) = 0$ *uniformly for* $\alpha \in \mathbf{Z}^d$.

Proof. If $q = 0$, then $u_\alpha(t) \equiv 0$ for all α because zero is a steady state solution. We now assume $q > 0$, and $\bar{r} \leqq q < \underline{a}$ ($\bar{r}$ is defined in (2.4)). Let

$$\eta = \sup_{\alpha \in \mathbf{Z}^d} \left\{ \frac{f_\alpha(q)}{q} \right\} < 0 \quad ((\text{iii}) \text{ in } (2.4)), \tag{4.1}$$

$$w_\alpha(t) \equiv e^{\eta t}; \tag{4.2}$$

then $w_\alpha(0) = 1$ and

$$\begin{aligned} &\frac{d}{dt} w_\alpha - \underset{d}{\Delta} w_\alpha - \eta w_\alpha \\ &= \frac{d}{dt} w_\alpha - \sum_{\beta \in C_\alpha} d_\delta (w_\beta - w_\alpha) - \eta w_\alpha \\ &= \eta\, e^{\eta t} - 0 - \eta\, e^{\eta t} \\ &= 0. \end{aligned}$$

Suppose $u_\alpha(t)$ solves (2.1)-(2.4) with $0 \leqq u_\alpha(0) \leqq q$ for all α. Then,

$$\frac{d}{dt} u_\alpha - \underset{d}{\Delta} u_\alpha - f_\alpha(u_\alpha) = 0 = \frac{d}{dt} w_\alpha - \underset{d}{\Delta} w_\alpha - \eta w_\alpha,$$

$$0 \leqq u_\alpha(0) \leqq q \leqq 1 = w_\alpha(0).$$

Furthermore, $u_\alpha(0) \leqq q$ for all α, implies, by Lemma 4.1, $u_\alpha(t) \leqq q$ for all α, and for all $t \geqq 0$. For such $u_\alpha(t)$

$$f_\alpha(u_\alpha) \leqq \frac{f_\alpha(q)}{q} u_\alpha \leqq \eta u_\alpha.$$

The first inequality comes from the assumption that $q \geqq \bar{r}$. Therefore, the conditions of Lemma 2.2 are satisfied, so

$$0 \leqq u_\alpha(t) \leqq w_\alpha(t) \equiv e^{\eta t} \quad \forall t \geqq 0 \quad \text{and} \quad \forall \alpha \in \mathbf{Z}^d.$$

Finally, $\lim_{t\to\infty} e^{\eta t} = 0$ (since $\eta < 0$) implies $\lim_{t\to\infty} u_\alpha(t) = 0$ for all $\alpha \in \mathbf{Z}^d$.

If $q < \bar{r}$, then, let $v_\alpha(t)$ be the solution of (2.1)-(2.4) with $\bar{r} \leqq v_\alpha(0) < \underline{a} - \varepsilon$ for some $\varepsilon > 0$. By Lemma 2.2, $u_\alpha(t) \leqq v_\alpha(t)$. But from the above discussion, $v_\alpha(t) \to 0$ as $t \to \infty$, for all α, therefore, again we have $\lim_{t\to\infty} u_\alpha(t) = 0$ for all $\alpha \in \mathbf{Z}^d$. This completes the proof. □

The following corollary gives us a superthreshold result.

COROLLARY 4.3. *Suppose* $\{u_\alpha(t)\}$ *is a solution to* (2.1)-(2.4) *with* $p \leqq u_\alpha(0) \leqq 1$ *for all* $\alpha \in \mathbf{Z}^d$. *If* $p > \bar{a}$, *then* $u_\alpha(t) \to 1$ *as* $t \to \infty$ *for all* $\alpha \in \mathbf{Z}^d$.

Proof. This is a direct result of Theorem 4.2. Suppose $\{u_\alpha(t)\}$ satisfies the above conditions. Define $w_\alpha(t) \equiv 1 - u_\alpha(t)$, $a_\alpha^* \equiv 1 - a_\alpha$, $q \equiv 1 - p$, and $F_\alpha(w) \equiv -f_\alpha(1-w)$; then $F_\alpha(w)$ satisfies (2.4) with a_α replaced by a_α^*. It can be checked easily. For example, $F_\alpha(0) = -f_\alpha(1-0) = -f_\alpha(1) = 0$, and $F_\alpha(a_\alpha^*) = F_\alpha(1 - a_\alpha) = -f_\alpha(a_\alpha) = 0$. Further, if $w \in (0, a_\alpha^*)$, then $0 < w < a_\alpha^* \equiv 1 - a_\alpha$, which implies $a_\alpha < 1 - w < 1$, so $F_\alpha(w) = -f_\alpha(1-w) < 0$. Similarly, it can be shown that $F_\alpha(w) > 0$ for $w \in (a_\alpha^*, 1)$. Furthermore, let $\underline{a}^* = \inf a_\alpha^*$;

then $\underline{a}^* = \inf(1-a_\alpha) = 1 - \sup a_\alpha = 1 - \bar{a}$. We also have

$$\begin{aligned}
&\frac{d}{dt} w_\alpha - \underset{d}{\Delta} w_\alpha - F_\alpha(w_\alpha)\\
&= \left[-\frac{d}{dt} u_\alpha \right] - [-\underset{d}{\Delta} u_\alpha] - [-f_\alpha(1-w_\alpha)]\\
&= -\left\{ \frac{d}{dt} u_\alpha - \underset{d}{\Delta} u_\alpha - f_\alpha(u_\alpha) \right\}\\
&= 0
\end{aligned}$$

and

$$w_\alpha(0) = 1 - u_\alpha(0) \leqq 1 - p < 1 - \bar{a} = \underline{a}^* \quad \text{for all } \alpha \in \mathbf{Z}^d.$$

Thus $\{w_\alpha(t)\}$ satisfies the conditions of Theorem 4.2 with $\underline{a}$ replaced by $\underline{a}^*$, by the theorem, $w_\alpha(t) \to 0$ as $t \to \infty$ for all $\alpha \in \mathbf{Z}^d$. The final result is obtained by considering $w_\alpha(t) = 1 - u_\alpha(t)$. □

Theorem 4.2 gives a subthreshold result. We now look for conditions that guarantee that $u_\alpha(t) \to 1$ as $t \to \infty$ for all $\alpha \in \mathbf{Z}^d$. A trivial condition is given in Corollary 4.3, that is assuming $u_\alpha(0) > \bar{a}$ for all $\alpha \in \mathbf{Z}^d$. Theorem 4.5 below tells us that under certain conditions, $u_\alpha(0) > b > a$ holding only at one node is enough to bump up the entire solution $\{u_\alpha(t)\}$ to $\{1\}$.

The steady state solution of (2.1) in the statement of Lemma 4.4 exists under certain conditions on f_α and **K** as discussed at the end of § 3. This lemma is a straight generalization of Lemma 2 in Bell and Cosner [2] and is similar to Proposition 2.2 in Aronson and Weinberger [1].

LEMMA 4.4. *Suppose for some domain* $\mathbf{K} \subset \mathbf{Z}^d$, *and* $\alpha \in \mathbf{K}$, $\{q_\alpha\}$ *satisfies* $0 \leqq q_\alpha \leqq 1$ *and*

$$\underset{d}{\Delta} q_\alpha + f_\alpha(q_\alpha) = 0. \tag{4.3}$$

If **K** *has boundary* $\partial\mathbf{K}$, *assume further* $q_\gamma \leqq 0$ *for all* $\gamma \in \partial\mathbf{K}$. *Let* $\{u_\alpha(t)\}$ *be a solution of* (2.1) *with* $u_\alpha(0) = q_\alpha$ *for* $\alpha \in \mathbf{K}$ *and* $u_\alpha(0) = 0$ *for all* $\alpha \in \mathbf{Z}^d \backslash \mathbf{K}$. *Then for each* α, $u_\alpha(t)$ *is a nondecreasing function of t with*

$$\lim_{t \to \infty} u_\alpha(t) = \tau_\alpha,$$

where $\{\tau_\alpha\}$ *is the smallest nonnegative solution to* (4.3) *valid for all* $\alpha \in \mathbf{Z}^d$, *which satisfies* $\tau_\alpha \geqq q_\alpha$ *for* $\alpha \in \mathbf{K}$.

In Theorem 4.5, we assume that $f_\alpha(u) = f(u)$ for all $\alpha \in \mathbf{Z}^d$, where f satisfies (2.4) with $a_\alpha = a$ fixed.

THEOREM 4.5. *Suppose* $f(u)$ *satisfies* (2.4). *Let* $M \equiv \sup_{0 \leqq u \leqq 1} f(u) > 0$, $m \equiv -\inf_{0 \leqq u \leqq 1} f(u) > 0$, *and suppose there exists constants* b, e *with* $a < b < e < 1$ *such that* (*see Fig.* 4)

$$\begin{aligned}
&2\left(\sum_{i=1}^{s} d_i \right) u - f(u) < 0 \quad \textit{for } u \in (b, e),\\
&2\left(\sum_{i=1}^{s} d_i \right) u - f(u) = 0 \quad \textit{at } u = b, e,
\end{aligned} \tag{4.4}$$

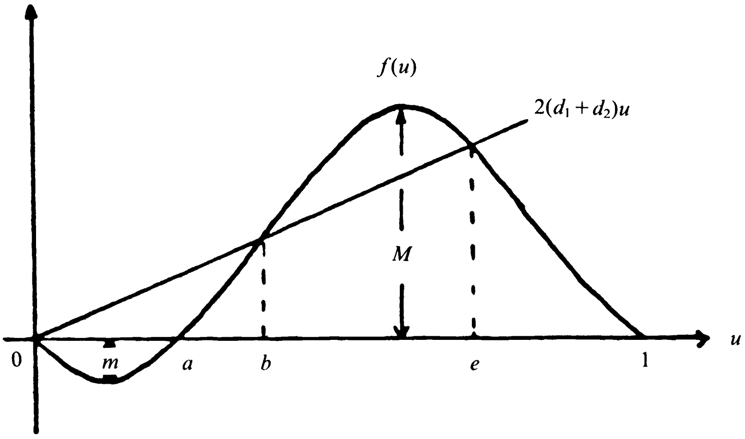

FIG. 4

where $d_i > 0$ for $i = 1, 2, \dots, 2s$, and s is to be defined such that $2s$ is the number of d_δ's that are >0. Suppose one of the following holds:

$$2\left(\sum_{i=1}^{s} d_i\right)b + m \leqq e\cdot\min(d_1, d_2, \dots, d_s) \tag{4.5}$$

$$2\left(\sum_{i=1}^{s} d_i\right) + M - (1-b)\min(d_1, d_2, \dots, d_s) \leqq 2\left(\sum_{i=1}^{s} d_i\right)e. \tag{4.6}$$

If $\{u_\alpha(t)\}$ is a solution of (2.1) *with $u_\alpha(0) \geqq 0$ for all α and $u_\gamma(0) \geqq b$ for some γ, then* $\lim_{t\to\infty} u_\alpha(t) = 1$ *for all $\alpha \in \mathbf{Z}^d$.*

The proof of the theorem is based on the following four lemmas. In order to reduce the bookkeeping work as much as possible, those lemmas are stated in the general form but proved in detail for $d = 2$, and for the particular operator $\Delta_d u_{i,j}$ given in (2.7):

$$\underset{d}{\Delta} u_{i,j} = d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}).$$

Throughout the next four lemmas, we assume that $f(u)$ satisfies the conditions in Theorem 4.5, (4.4) holds, and $\{q_\alpha\}$ is the smallest global nonnegative steady state solution to (2.1)-(2.4) with $q_\alpha \geqq b$ for some α.

LEMMA 4.6. *$q_\alpha \notin [b, e]$ for all $\alpha \in \mathbf{Z}^d$.*

Proof. Suppose there exists $\alpha = (i, j)$ with $b \leqq q_{i,j} \leqq e$. By (3.1),

$$\underset{d}{\Delta} q_{i,j} + f(q_{i,j}) = 0,$$

i.e.,

$$d_1(q_{i+1,j} - 2q_{i,j} + q_{i-1,j}) + d_2(q_{i,j+1} - 2q_{i,j} + q_{i,j-1}) + f(q_{i,j}) = 0,$$

or

$$\begin{aligned} d_1(q_{i+1,j} + q_{i-1,j}) + d_2(q_{i,j+1} + q_{i,j-1}) &= 2(d_1+d_2)q_{i,j} - f(q_{i,j}) \\ &\leqq 0 \quad (\text{by } (4.4)). \end{aligned}$$

So at least one of $q_{i+1,j}$, $q_{i-1,j}$, $q_{i,j+1}$, $q_{i,j-1}$ must be $\leqq 0$. For example, let $q_{i+1,j} \leqq 0$. If $q_{i+1,j} < 0$, then $\{q_{i,j}\}$ is not a global nonnegative steady state solution, with $q_{i+1,j} = 0$; we obtain,

$$d_1(q_{i+2,j} - 2q_{i+1,j} + q_{i,j}) + d_2(q_{i+1,j+1} - 2q_{i+1,j} + q_{i+1,j-1}) + f(q_{i+1,j}) = 0,$$

or

$$d_1 q_{i+2,j} + d_2(q_{i+1,j+1} + q_{i+1,j-1}) = -d_1 q_{i,j} < 0$$

$$(q_{i,j} > 0 \text{ because } q_{i,j} \in [b, e]).$$

Therefore, at least one of $q_{i+1,j}$, $q_{i-1,j}$, $q_{i,j+1}$, $q_{i,j-1}$ must be negative, so $\{q_{i,j}\}$ is not a nonnegative steady state. □

LEMMA 4.7. *Assume further that* (4.5) *holds. If there exists* $\alpha_\circ \in \mathbf{Z}^d$ *with* $q_{\alpha_\circ} \leqq b$, *then* $q_\alpha < b$ *for all* $\alpha \in \mathbf{Z}^d$.

Proof. Without loss of generality, let us assume $q_{0,0} < b$. From (3.1) and (4.5),

$$\begin{aligned} d_1(q_{1,0} + q_{-1,0}) + d_2(q_{0,1} + q_{0,-1}) \\ = 2(d_1 + d_2)q_{0,0} - f(q_{0,0}) \\ \leqq 2(d_1 + d_2)b + m \leqq e \cdot \min(d_1, d_2), \end{aligned}$$

i.e.,

$$d_1 q_{1,0} + d_1 q_{-1,0} + d_2 q_{0,1} + d_2 q_{0,-1} \leqq e \cdot \min(d_1, d_2).$$

So every term on the left-hand side is $\leqq e \cdot \min(d_1, d_2)$ because all d_1, d_2 and q's are nonnegative. But, $d_1 q_{1,0} \leqq e \cdot \min(d_1, d_2)$ implies $q_{1,0} \leqq e \cdot (\min(d_1, d_2)/d_1) \leqq e$. Similarly, $q_{-1,0} \leqq e$, $q_{0,1} \leqq e$, and $q_{0,-1} \leqq e$. Furthermore, by Lemma 4.6, $q_{i,j} \notin [b, e]$ implies $q_{1,0} < b$, $q_{-1,0} < b$, $q_{0,1} < b$, and $q_{0,-1} < b$.

It follows by induction that $q_{i,j} < b$ for all $i, j \in \mathbf{Z}$. □

LEMMA 4.8. *Assume further that* (4.6) *holds. If there exists* $\alpha_\circ \in \mathbf{Z}^d$ *with* $q_{\alpha_\circ} > e$, *then* $q_\alpha > e$ *for all* $\alpha \in \mathbf{Z}^d$.

Proof. Let us assume $q_{0,0} > e$. Define

$$\bar{q}_{i,j} \equiv 1 - q_{i,j}, \qquad F(\bar{q}_{i,j}) \equiv -f(1 - \bar{q}_{i,j});$$

then (3.1) can be rewritten as

$$d_1(\bar{q}_{i+1,j} - 2\bar{q}_{i,j} + \bar{q}_{i-1,j}) + d_2(\bar{q}_{i,j+1} - 2\bar{q}_{i,j} + \bar{q}_{i,j-1}) + F(\bar{q}_{i,j}) = 0. \tag{4.7}$$

We have

$$\sup_{0 \leqq u \leqq 1} (-F(u)) = \sup_{0 \leqq u \leqq 1} (f(1-u)) = M.$$

Notice that $q_{0,0} > e$ implies $\bar{q}_{0,0} < 1 - e$, and from (4.7), (4.6),

$$\begin{aligned} d_1\bar{q}_{1,0} + d_1\bar{q}_{-1,0} + d_2\bar{q}_{0,1} + d_2\bar{q}_{0,-1} &= 2(d_1 + d_2)\bar{q}_{0,0} - F(\bar{q}_{0,0}) \\ &< 2(d_1 + d_2)(1 - e) + M \\ &\leqq (1 - b) \cdot \min(d_1, d_2). \end{aligned}$$

Therefore, every term on the left-hand side is $<1-(b)\cdot\min(d_1, d_2)$. But $d_1\bar{q}_{1,0}<(1-b)\min(d_1, d_2)$ implies $\bar{q}_{1,0}<(1-b)[\min(d_1,d_2)/d_1]\leqq 1-b$, i.e., $q_{1,0}>b$, but $q_{i,j}\notin[b,e]$ by Lemma 4.6, thus $q_{1,0}>e$. Similarly, $q_{-1,0}>e$, $q_{0,1}>e$, and $q_{0,-1}>e$. By induction, $q_{i,j}>e$ for all $i,j\in\mathbf{Z}$. □

LEMMA 4.9. *Assume further that* (4.5) *or* (4.6) *holds; then* $q_\alpha\notin(e,1)$ *for all* $\alpha\in\mathbf{Z}^d$.

Proof. Suppose $q_{0,0}\in(e,1)$. First, let us construct a sequence $\{q_k\}$ out of $\{q_{i,j}\}$ such that $q_{0,0}\equiv q_0>q_1>q_2>\cdots>q_m>q_{m+1}$ with $q_m>e>a$ and $q_{m+1}\leqq e$, where $q_k\in\{q_{i,j}\}$ for $k=0,1,\ldots,m+1$ as follows.

Let $(i,j)=(0,0)$ in (3.1); define $q_0\equiv q_{0,0}$. We obtain

$$d_1(q_{1,0}-2q_{0,0}+q_{-1,0})+d_2(q_{0,1}-2q_{0,0}+q_{0,-1})+f(q_{0,0})=0$$

or

$$d_1(q_{1,0}-q_0)+d_1(q_{-1,0}-q_0)+d_2(q_{0,1}-q_0)+d_2(q_{0,-1}-q_0)=-f(q_0).$$

Assume without loss of generality that

$$q_{1,0}-q_0=\min(q_{1,0}-q_0, q_{-1,0}-q_0, q_{0,1}-q_0, q_{0,-1}-q_0).$$

Define $q_1\equiv q_{1,0}$ and

$$\varepsilon=\frac{1}{2(d_1+d_2)}\cdot\inf_{q\in[e,q_0]}\{f(q)\}>0.$$

We obtain

$$\begin{aligned}&2(d_1+d_2)(q_1-q_0)\\&\quad\leqq d_1(q_{1,0}-q_0)+d_1(q_{-1,0}-q_0)+d_2(q_{0,1}-q_0)+d_2(q_{0,-1}-q_0)\\&\quad=-f(q_0);\end{aligned}$$

therefore,

$$q_1-q_0\leqq\frac{-f(q_0)}{2(d_1+d_2)}\leqq-\varepsilon.$$

If $q_1\leqq e$, we are done ($m=0$).

Suppose $q_1>e$. Let $(i,j)=(1,0)$ in (3.1); we have

$$d_1(q_{2,0}-q_1)+d_1(q_{0,0}-q_1)+d_2(q_{1,1}-q_1)+d_2(q_{1,-1}-q_1)=-f(q_{1,0}).$$

Let q_2 be one of $q_{2,0}$, $q_{0,0}$, $q_{1,1}$, and $q_{1,-1}$, such that

$$q_2-q_1=\min(q_{2,0}-q_1, q_{0,0}-q_1, q_{1,1}-q_1, q_{1,-1}-q_1);$$

then

$$\begin{aligned}&2(d_1+d_2)(q_2-q_1)\\&\quad\leqq d_1(q_{2,0}-q_1)+d_1(q_{0,0}-q_1)+d_2(q_{1,1}-q_1)+d_2(q_{1,-1}-q_1)\\&\quad=-f(q_1);\end{aligned}$$

therefore,

$$q_2-q_1\leqq\frac{-f(q_1)}{2(d_1+d_2)}\leqq-\varepsilon.$$

Following the same procedure, we can construct a sequence $q_{0,0} \equiv q_0 > q_1 > q_2 > \cdots > q_k > q_{k+1}$, where

$$q_{k+1} - q_k \leqq -\varepsilon \quad \text{if } e < q_k \leqq q_0.$$

Therefore,

$$q_{k+1} \leqq q_k - \varepsilon \leqq q_{k-1} - 2\varepsilon \leqq \cdots \leqq q_0 - (k+1)\varepsilon.$$

This equation holds as long as $q_k > e$. It is easy to see that when k increases, q_{k+1} will eventually drop below e or be equal to it. This completes our construction of the sequence $\{q_k\}$.

The assumption we made so far is only (4.4). Now consider (4.5) and (4.6).

Case 1. Assume (4.5) holds. According to Lemma 4.6, $q_{m+1} \leqq e$ implies $q_{m+1} < b$. Therefore, $q_{i,j} < b$ for all i, j, by Lemma 4.7, which contradicts the assumption $q_{0,0} \in (e, 1)$.

Case 2. Assume (4.6) holds. By Lemma 4.8, $q_{0,0} > e$ implies $q_{i,j} > e$ for all i, j, which contradicts $q_{m+1} \leqq e$.

The contradictions are caused by the assumption $q_{0,0} \in (e, 1)$; therefore, $q_{i,j} \notin (e, 1)$ for all i, j. □

Now we can prove Theorem 4.5.

Proof of Theorem 4.5. First, from Lemmas 4.6 and 4.9, we conclude that the global nonnegative steady state solution $\{q_\alpha\}$ with $q_\alpha \geqq b$ for some α, under the assumptions of the theorem, must satisfy $q_\alpha \geqq 1$. But $q_\alpha \equiv 1$ is a steady state; therefore, the smallest such steady state is $q_\alpha \equiv 1$.

Let $\mathbf{0}$ be the d-dimensional zero vector. Suppose now $u_\alpha(0) \geqq 0$, and $u_{\mathbf{0}}(0) \geqq b$ (if $u_\alpha(0) \geqq b$ for some α, then simply make a translation in α). Let $\{v_\alpha(t)\}$ be the solution of (2.1) with initial data $v_\alpha(0) = 0$ for $\alpha \neq \mathbf{0}$ and $v_{\mathbf{0}} = b$. Since $q_\beta = 0$ for $\beta \in C_{\mathbf{0}} \backslash \{\mathbf{0}\}$, and $q_{\mathbf{0}} = b$ yields a solution of (4.3) at $\alpha = \mathbf{0}$ (where $2(\sum_{i=1}^{s} d_i)b - f(b) = 0$), we may apply Lemma 4.4 and conclude that for any α, $v_\alpha(t)$ is a monotone nondecreasing function of t. Hence $\lim_{t\to\infty} v_\alpha(t) = \tau_\alpha$, where $\{\tau_\alpha\}$ is the smallest global steady state for (2.1) with values lying above b. However, the only such steady state is $\{\tau_\alpha\} \equiv \{1\}$, so $\lim_{t\to\infty} v_\alpha(t) = 1$. Finally, $v_\alpha(0) \leqq u_\alpha(0) \leqq 1$ implies, by Lemma 2.2, $v_\alpha(t) \leqq u_\alpha(t) \leqq 1$ for all t, and all $\alpha \in \mathbf{Z}^d$; therefore, we obtain the conclusion that $\lim_{t\to\infty} u_\alpha(t) = 1$ for all $\alpha \in \mathbf{Z}^d$. □

THEOREM 4.10. *Suppose there are values* x_1, x_2, x_3, x_4 *with* $0 < x_1 < x_2 < x_3 < x_4 < 1$, *such that*

$$\text{(4.8)} \quad \text{(i)} \quad (1-x_1) + \frac{f(x_1)}{D} = 0, \qquad (1-x_2) + \frac{f(x_2)}{D} = 0, \quad \textit{and}$$
$$\frac{f(z)}{D} + (1-z) < 0 \quad \textit{for } 0 < x_1 < z < x_2,$$

$$\text{(4.9)} \quad \text{(ii)} \quad x_3 - \frac{f(x_3)}{D} = 0, \qquad x_4 - \frac{f(x_4)}{D} = 0, \quad \textit{and}$$
$$\frac{f(z)}{D} - z > 0 \quad \textit{for } x_3 < z < x_4 < 1,$$

where $D = \sum_{\beta \in C_\alpha} d_\delta$ (*independent of* α *by* (2.3c)). *See Fig.* 5. *Suppose* $0 \leqq u_\alpha(0) \leqq 1$ *for all* $\alpha \in \mathbf{Z}^d$. *Then for any* $\beta \in \mathbf{Z}^d$, *if* $u_\beta(0) \in [0, x_2)$, *then* $u_\beta(t) \in [0, x_2)$ *for all* $t > 0$. *If* $u_\beta(0) \in (x_3, 1]$, *then* $u_\beta(t) \in (x_3, 1]$ *for all* $t > 0$.

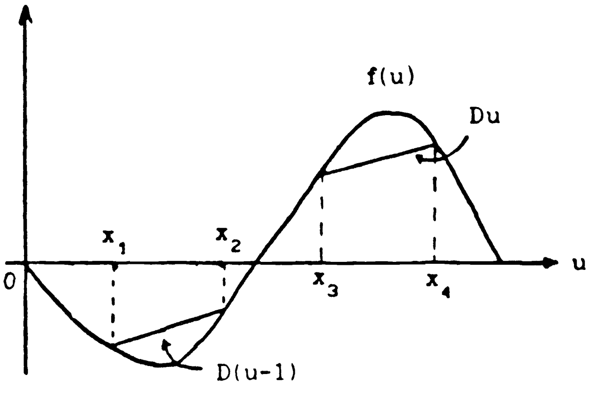

FIG. 5

Proof. First, $0 \leqq u_\alpha(0) \leqq 1$ for all $\alpha \in \mathbf{Z}^d$ implies $0 \leqq u_\alpha(t) \leqq 1$ for all $\alpha \in \mathbf{Z}^d$ and all $t \geqq 0$ by Lemma 2.2. Now suppose $u_\gamma(0) \in [0, x_2)$. If we can prove that whenever $u_\gamma(t)$ goes into region (x_1, x_2) it stops increasing, then $u_\gamma(t)$ will stay in the region $[0, x_2)$ for all t. This is true because if $u_\gamma(t) \in (x_1, x_2)$, then

$$\begin{aligned}\frac{d}{dt} u_\gamma(t) &= \sum_{\beta \in C_\gamma} d_\delta(u_\beta - u_\gamma) + f(u_\gamma) \\ &\leqq \sum_{\beta \in C_\gamma} d_\delta(1 - u_\gamma) + f(u_\gamma) \quad (\text{since } u_\beta \leqq 1 \text{ for all } \beta) \\ &= \left(\sum_{\beta \in C_\gamma} d_\delta\right)(1 - u_\gamma) + f(u_\gamma) \\ &< 0,\end{aligned}$$

by (4.8)).

The other part of the theorem can be proved in the analogous way.

5. Propagation. Throughout this section, we assume

$$\lim_{t \to \infty} u_\alpha(t) = 1 \quad \text{for all } \alpha \in \mathbf{Z}^d. \tag{5.1}$$

From Theorem 4.5 this is possible for some classes of f's. Below we use the notation

$$|\alpha| \equiv |(\alpha_1, \alpha_2, \ldots, \alpha_d)| = |\alpha_1| + |\alpha_2| + \cdots + |\alpha_d|,$$

and $[\cdot]$ means "integer part of."

THEOREM 5.1. *Assume*

(i) $\{u_\alpha(t)\}$ *is a solution to* (2.1)-(2.4) *satisfying* (5.1);

(ii) $u_\alpha(0) \in [0, 1]$ *for all* $\alpha \in \mathbf{Z}^d$,

$$u_\alpha(0) = 0 \quad \textit{for } |\alpha| > N \quad \textit{where } N < \infty. \tag{5.2}$$

Then there exists a $\bar{c} > 0$ *such that for each* $\alpha_0 \in \mathbf{Z}^d$, $\lim_{t \to \infty} u_\alpha(t) = 0$ *if* $|\alpha| = |\alpha_0| + [ct]$ *for* $c > \bar{c}$.

Proof. Define

$$\sigma = \sup_{\alpha \in \mathbf{Z}^d} \sup_{0 < u < 1} \left\{\frac{f_\alpha(u)}{u}\right\} > 0,$$

where $\sigma<\infty$ because of (2.4). Then

$$\begin{aligned}
\Lambda u_\alpha &\equiv \underset{d}{\Delta} u_\alpha+\sigma u_{\alpha'} \qquad (5.3)\\
&= \sum_{\beta\in C_\alpha} d_\delta(u_\beta-u_\alpha)+\sum_{\beta\in C_\alpha}\left(\frac{\sigma}{\sum_{\beta'\in C_\alpha} d_{\delta'}} d_\delta u_{\alpha'}\right)(\delta=\beta-\alpha,\ \delta'=\beta'-\alpha)\\
&= \sum_{\beta\in C_\alpha} d_\delta\left[u_\beta-\left(1-\frac{\sigma}{\sum_{\beta'\in C_\alpha} d_{\delta'}}\right)u_\alpha\right]\\
&= \sum_{\beta\in C_\alpha} d_\delta(u_\beta-ku_\alpha), \qquad (5.4)
\end{aligned}$$

where

$$k\equiv 1-\frac{\sigma}{\sum_{\beta'\in C_\alpha} d_{\delta'}}. \tag{5.5}$$

Equation (2.1) may be rewritten as

$$\frac{d}{dt}u_\alpha-\underset{d}{\Delta} u_\alpha-f_\alpha(u_\alpha)=\frac{d}{dt}u_\alpha-\Lambda u_\alpha+\sigma u_\alpha-f_\alpha(u_\alpha)=0,$$

or

$$\frac{d}{dt}u_\alpha-\Lambda u_\alpha=f_\alpha(u_\alpha)-\sigma u_\alpha\leqq 0. \tag{5.6}$$

The last inequality is obtained by using the fact that $u_\alpha(0)\in[0,1]$ implies, by Lemma 2.2, $u_\alpha(t)\in[0,1]$, and by using the definition of σ.

Define

$$w_\alpha(t)=Ap(t)\,e^{-\mu(|\alpha|-ct)}, \tag{5.7}$$

where positive constants μ, c, and A, and function $p(t)\geqq 0$ are to be determined. Then, by (5.4),

$$\begin{aligned}
\Lambda w_\alpha &= \sum_{\beta\in C_\alpha} d_\delta(w_\beta-kw_\alpha)\\
&= \sum_{\beta\in C_\alpha} d_\delta[Ap(t)\,e^{-\mu(|\beta|-ct)}-kAp(t)\,e^{-\mu(|\alpha|-ct)}]\\
&= Ap(t)\,e^{-\mu(|\alpha|-ct)}\sum_{\beta\in C_\alpha} d_\delta[e^{-\mu(|\beta|-|\alpha|)}-k] \qquad (5.8)\\
&= Ap(t)\,e^{-\mu(|\alpha|-ct)}\Gamma_\alpha(\mu|\underset{d}{\Delta}),
\end{aligned}$$

where

$$\Gamma_\alpha(\mu|\underset{d}{\Delta})\equiv\sum_{\beta\in C_\alpha} d_\delta[e^{-\mu(|\beta|-|\alpha|)}-k],\qquad \delta=\beta-\alpha. \tag{5.9}$$

$\Gamma_\alpha(\mu|\Delta_d)$ is a function of μ depending on α and the particular form of operator Δ_d. Explicit representations of $\Gamma_\alpha(\mu|\Delta_d)$ for a couple of particular Δ_d's are given in Examples 5.1 and 5.2. Furthermore, considering there are 3^d-1 elements in C_α and the definition of C_α, it is true that for any fixed μ, $-\mu(|\beta|-|\alpha|)$ is bounded above; i.e., there exists $M<\infty$ such that $-\mu(|\beta|-|\alpha|)<\mu M$. Therefore,

$$\Gamma_\alpha(\mu|\underset{d}{\Delta})\leqq[e^{\mu M}-k]\cdot\sum_{\beta\in C_\alpha} d_\delta\quad\forall\alpha\in\mathbf{K}.$$

Define

$$\Gamma\equiv\Gamma(\mu|\underset{d}{\Delta})=\sup_{\alpha\in\mathbf{K}}\Gamma_\alpha(\mu|\underset{d}{\Delta}); \tag{5.10}$$

then, for any fixed μ,

$$0<\Gamma<\infty. \tag{5.11}$$

It is not difficult to prove that $\Gamma(\mu)$ is a positive linear combination of $\cosh(k\mu)$, $k\in\mathbf{Z}^+$ by using the symmetry property (2.3a) and the definition of C_α. Therefore, $\Gamma(\mu)$ is even, monotonic increasing for $\mu>0$ and has a global minimum at $\mu=0$. It can also be proved that $\Gamma(0)=\sigma>0$, thus $\Gamma(\mu)$ can be represented as in Fig. 6. Examples 5.1 and 5.2 give the basic idea of the general discussion. Those results will be used later.

We now have

$$\begin{aligned}
&\frac{d}{dt}w_\alpha-\Lambda w_\alpha\\
&=A\frac{d}{dt}p(t)\,e^{-\mu(|\alpha|-ct)}+Ap(t)\,e^{-\mu(|\alpha|-ct)}\cdot\mu c-Ap(t)\,e^{-\mu(|\alpha|-ct)}\cdot\Gamma_\alpha\\
&=A\,e^{-\mu(|\alpha|-ct)}\left[\frac{d}{dt}p(t)+p(t)\mu c-\Gamma_\alpha p(t)\right]\\
&\geqq A\,e^{-\mu(|\alpha|-ct)}\left[\frac{d}{dt}p(t)+(\mu c-\Gamma)p(t)\right].
\end{aligned}$$

Let $p(t)$ be the solution of $(d/dt)p(t)+(\mu c-\Gamma)p(t)=0$; then

$$p(t)=e^{-\mu(c-\Gamma/\mu)t}. \tag{5.12}$$

So, by (5.6),

$$\frac{d}{dt}w_\alpha-\Lambda w_\alpha\geqq 0\geqq\frac{d}{dt}u_\alpha-\Lambda u_\alpha.$$

Furthermore, choose

$$A\equiv\sup_{\gamma\in\mathbf{Z}^d}\{e^{\mu|\gamma|}\cdot u_\gamma(0)\}. \tag{5.13}$$

A is finite because of the compact support assumption (5.2). Thus

$$\begin{aligned}
w_\alpha(0)&=Ap(0)\,e^{-\mu|\alpha|}\\
&=\sup_{\gamma\in\mathbf{Z}^d}\{e^{\mu|\gamma|}\cdot u_\gamma(0)\}\cdot 1\cdot e^{-\mu|\alpha|}\\
&\geqq u_\alpha(0).
\end{aligned}$$

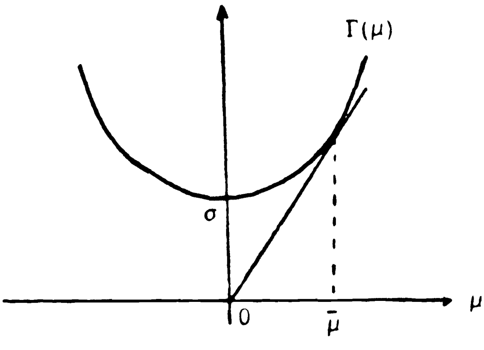

FIG. 6

This implies that $w_\alpha(t) \geqq u_\alpha(t)$ in R_o^+ for all $\alpha \in \mathbf{Z}^d$, because if choosing $f_\alpha \equiv 0$, $g_\alpha \equiv 0$, then all conditions of Lemma 2.1 are satisfied. From (5.7) and (5.12),

$$A\, e^{-\mu(|\alpha|-ct)} \cdot e^{-\mu(c-\Gamma/\mu)t} \geqq u_\alpha(t) \quad \text{in } R_o^+ \quad \text{for all } \alpha. \tag{5.14}$$

Now if μ and $\bar{c}$ are properly chosen, the left-hand side of (5.14) will go to zero if $c > \bar{c}$.

Let $\mu_o > 0$; the tangent line to $\Gamma(\mu)$, $\mu > 0$, at μ_o can be represented as

$$y(\mu) = \Gamma'(\mu_o)\mu + \Gamma(\mu_o) - \Gamma'(\mu_o)\mu_o .$$

Let $\bar{\mu} > 0$ be the value of μ_o such that the tangent line at $(\bar{\mu}, \Gamma(\bar{\mu}))$ passes through the origin (see Fig. 6). Then,

$$\Gamma(\bar{\mu}) = \Gamma'(\bar{\mu})\bar{\mu}. \tag{5.15}$$

The tangent line exists, because, as we discussed before, $\Gamma(\mu)$ is even, monotonic increasing for $\mu > 0$, and has a global minimum $\Gamma(0) = \sigma > 0$. Now choose

$$\bar{c} = \frac{\Gamma(\bar{\mu})}{\bar{\mu}} = \Gamma'(\bar{\mu}); \tag{5.16}$$

then $c > \Gamma(\bar{\mu})/\bar{\mu}$ if $c > \bar{c}$. But $\Gamma(\mu)/\mu$ is a continuous function of μ, so $c > \Gamma(\bar{\mu})/\bar{\mu}$ implies that there exists $\mu^+ > \bar{\mu}$ such that $c > \Gamma(\mu)/\mu$ for all μ with $\bar{\mu} \leqq \mu \leqq \mu^+$. Therefore, if $c > \bar{c}$ and μ is in the interval $(\bar{\mu}, \mu^+)$, then

$$\lim_{t\to\infty} e^{-\mu(c-\Gamma/\mu)t} = 0.$$

Furthermore, for any $\alpha_o \in \mathbf{Z}^d$, if $|\alpha| = |\alpha_o| + [ct]$, then the first factor in (5.14),

$$\begin{aligned} A\, e^{-\mu(|\alpha|-ct)} &= A\, e^{-\mu(|\alpha_o|+[ct]-ct)} \\ &\leqq A\, e^{-\mu(|\alpha_o|-1)}, \end{aligned}$$

is bounded.

Combining the results above, we obtain

$$\lim_{t\to\infty} A\, e^{-\mu(|\alpha|-ct)} \cdot e^{-\mu(c-\Gamma/\mu)t} = 0$$

if $|\alpha| = |\alpha_o| + [ct]$ for any $\alpha_o \in \mathbf{Z}^d$, $d > \bar{c}$ and $\mu \in (\bar{\mu}, \mu^+)$. The result of the theorem is obtained by considering the inequality given in (5.14) and $u_\alpha(t) \geqq 0$. □

Notice that there is no contradiction between our result and (5.1) because in (5.1) α is fixed, and in the result of Theorem 5.1, $\alpha = |\alpha_o| + [ct]$ is moving at a speed c.

Example 5.1. $d = 2$. Consider the Δ_d given in (2.7)

$$\underset{d}{\Delta} u_{i,j} = d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}).$$

Here we have

$$\alpha = (i, j),$$

$$d_{\pm 1,0} = d_1 > 0, \quad d_{0,\pm 1} = d_2 > 0, \quad d_{\pm 1,\pm 1} = 0,$$

and from (5.9),

$$\begin{aligned}\Gamma_\alpha(\mu) &= d_1[e^{-\mu(|(i+1,j)|-|(i,j)|)} - k] + d_1[e^{-\mu(|(i-1,j)|-|(i,j)|)} - k]\\ &\quad + d_2[e^{-\mu(|(i,j+1)|-|(i,j)|)} - k] + d_2[e^{-\mu(|(i,j-1)|-|(i,j)|)} - k]\\ &= d_1[\underbrace{e^{-\mu(|(i+1,j)|-|(i,j)|)} + e^{-\mu(|(i-1,j)|-|(i,j)|)} - 2k}_{(1)}]\\ &\quad + d_2[\underbrace{e^{-\mu(|(i,j+1)|-|(i,j)|)} + e^{-\mu(|(i,j-1)|-|(i,j)|)} - 2k}_{(2)}],\end{aligned}$$

where

$$k = 1 - \frac{\sigma}{2(d_1 + d_2)} \quad \text{from (5.5).}$$

If $i = 0$, and $j = 0$, then

$$\begin{aligned}(1) &= e^{-\mu(1-0)} + e^{-\mu(1-0)} - 2k = 2(e^{-\mu} - k)\\ (2) &= 2(e^{-\mu} - k).\end{aligned}$$

If $i \leqq -1$, j is arbitrary, then

$$\begin{aligned}|(i+1,j)| - |(i,j)| &\equiv |i+1| + |j| - |i| - |j| = |i+1| - |i|\\ &= -(i+1) - (-i) = -1,\\ |(i-1,j)| - |(i,j)| &= |i-1| - |i| = -(i-1) - (-i) = 1,\end{aligned}$$

so

$$(1) = e^{-\mu} + e^{\mu} - 2k.$$

If $i \geqq 1$, j is arbitrary, then

$$\begin{aligned}|(i+1,j)| - |(i,j)| &= |i+1| - |i| = i + 1 - i = 1,\\ |(i-1,j)| - |(i,j)| &= |i-1| - |i| = i - 1 - i = -1,\end{aligned}$$

so

$$(1) = e^{\mu} + e^{-\mu} - 2k.$$

Similarly, if $j \leqq -1$ or $j \geqq 1$, and i is arbitrary, we have

$$(2) = e^{\mu} + e^{-\mu} - 2k.$$

Therefore, we obtain

$$\Gamma_{i,j} = \Gamma_{i,j}(\mu) \equiv \begin{cases} 2(d_1 + d_2)(e^{-\mu} - k) & \text{if } i = j = 0,\\ (d_1 + d_2)(e^{-\mu} + e^{\mu} - 2k) & \text{otherwise,}\end{cases}$$

and

$$\begin{aligned}\Gamma &= (d_1 + d_2)(e^{-\mu} + e^{\mu} - 2k)\\ &= (d_1 + d_2)\left(e^{-\mu} + e^{\mu} - 2 + \frac{\sigma}{d_1 + d_2}\right).\end{aligned} \tag{5.17}$$

Notice that $\min \Gamma = \sigma > 0$. Now (5.15) becomes

$$e^{-\bar{\mu}} + e^{\bar{\mu}} - 2 + \frac{\sigma}{d_1 + d_2} = (-e^{-\bar{\mu}} + e^{\bar{\mu}})\bar{\mu},$$

or

$$\cosh(\bar{\mu}) - \bar{\mu}\sinh(\bar{\mu}) + \frac{\sigma}{2(d_1 + d_2)} - 1 = 0. \tag{5.18}$$

This equation has a positive solution for any $d_1, d_2 > 0$. Finally, by (5.16) and (5.17),

$$\bar{c} = 2(d_1 + d_2)\sinh(\bar{\mu}). \tag{5.19}$$

□

Example 5.2. Use the operator Δ_d defined in (2.9), namely,

$$\begin{aligned}\underset{d}{\Delta} u_{i,j} &= d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) \\ &\quad + d_3(u_{i+1,j+1} - 2u_{i,j} + u_{i-1,j-1}).\end{aligned}$$

Thus, from (5.9),

$$\begin{aligned}\Gamma_\alpha(\mu) = {} & \underbrace{d_1[e^{-\mu(|(i+1,j)|-|(i,j)|)} + e^{-\mu(|(i-1,j)|-|(i,j)|)} - 2k]}_{(1)} \\ & + \underbrace{d_2[e^{-\mu(|(i,j+1)|-|(i,j)|)} + e^{-\mu(|(i,j-1)|-|(i,j)|)} - 2k],}_{(2)} \\ & + \underbrace{d_3[e^{-\mu(|(i+1,j+1)|-|(i,j)|)} + e^{-\mu(|(i-1,j-1)|-|(i,j)|)} - 2k],}_{(3)}\end{aligned}$$

where

$$k = 1 - \frac{\sigma}{2(d_1 + d_2 + d_3)} \quad \text{from (5.5).}$$

As in Example 5.1, we have to go through various cases to determine (1), (2), and (3). From Example 5.1,

$$(1) = (2) = \begin{cases} 2(e^{-\mu} - k) & \text{if } i = j = 0, \\ e^{-\mu} + e^{\mu} - 2k & \text{otherwise.} \end{cases}$$

For (3) we have

$$(3) = \begin{cases} 2(e^{-2\mu} - k) & \text{if } i = j = 0, \\ e^{-2\mu} + e^{2\mu} - 2k & \text{if } i \geqq 1, j \geqq 1 \quad \text{or} \quad i \leqq -1, j \leqq -1, \\ 2(1 - k) & \text{if } i \geqq 1, j \leqq -1 \quad \text{or} \quad i \leqq -1, j \geqq 1. \end{cases}$$

Hence,

$$\Gamma_{i,j} = \begin{cases} 2(d_1 + d_2)(e^{-\mu} - k) + 2d_3(e^{-2\mu} - k) & i = j = 0, \\ (d_1 + d_2)(e^{-\mu} + e^{\mu} - 2k) + d_3(e^{-2\mu} + e^{2\mu} - 2k) & i \geqq 1, j \geqq 1 \quad \text{or} \\ & i \leqq -1, j \leqq -1, \\ (d_1 + d_2)(e^{-\mu} + e^{\mu} - 2k) + 2d_3(1 - k) & \text{otherwise.} \end{cases}$$

Since $\mu > 0$,

$$\begin{aligned}\Gamma(\mu) &= \sup_{(i,j) \in \mathbf{Z}^2} \Gamma_{i,j}(\mu) \\ &= (d_1 + d_2)(e^{-\mu} + e^{\mu} - 2k) + d_3(e^{-2\mu} + e^{2\mu} - 2k) \\ &= 2(d_1 + d_2)\cosh(\mu) + 2d_3\cosh(2\mu) - 2(d_1 + d_2 + d_3)k \\ &= 2[(d_1 + d_2)\cosh(\mu) + d_3\cosh(2\mu)] - 2(d_1 + d_2 + d_3) + \sigma,\end{aligned}$$

so that (5.15) becomes

$$\begin{aligned}2[(d_1+d_2)\cosh(\bar{\mu})+d_3\cosh(2\bar{\mu})]-2(d_1+d_2+d_3)+\sigma\\ =\bar{\mu}\{2(d_1+d_2)\cosh(\bar{\mu})+d_3\cosh(2\bar{\mu})\}.\end{aligned} \tag{5.20}$$

This equation has a positive solution $\bar{\mu}$. □

THEOREM 5.2. *Assume for* $\alpha\in\mathbf{Z}^d$,

(i) $\{q_\alpha\}$ *is not identical to* $\{0\}$ *and is a steady state solution to* (2.1)-(2.4) *with*

$$0\leqq q_\alpha<1 \quad \textit{for } |\alpha|<N<\infty, \quad q_\alpha\leqq 0 \quad \textit{for } |\alpha|=N;$$

(ii) *The only steady state* $\tau_\alpha\geqq 0$ for all $\alpha\in\mathbf{Z}^d$ *with* $\tau_\alpha\geqq q_\alpha$ *for* $|\alpha|<N$ *is* $\tau_\alpha=1$;

(iii) $\{u_\alpha(t)\}$ *is a solution to* (2.1)-(2.4), *and there exists* $\alpha_\circ\in\mathbf{Z}^d$, *such that*

$$u_{\alpha+\alpha_\circ}(0)\geqq q_\alpha \quad \textit{for } |\alpha|<N.$$

Then there exists $\underline{c}>0$, *such that for all* $c<\underline{c}$ *and* $\varepsilon>0$, *there exists* $T(\varepsilon,c)<\infty$, *with* $u_\alpha(t)\geqq 1-\varepsilon$ *for* $|\alpha|=|\alpha_\circ|+[ct]$ *and for* $t>T(\varepsilon,c)$.

Proof. We may assume that $\alpha_\circ=\mathbf{0}$, where $\mathbf{0}$ is the d-dimensional zero vector, and the general case can be obtained by a translation on α. The proof consists of the following.

(i) Let $\{w_\alpha(t)\}$ be the solution to (2.1) with $w_\alpha(0)=q_\alpha$ for $|\alpha|<N$, and $w_\alpha(0)=0$ for all α, $|\alpha|\geqq N$. By Lemma 4.4, $w_\alpha(t)\to 1$ monotonically for each α as $t\to\infty$. Thus, for each $\varepsilon>0$ there is a $t_1(\varepsilon)$, such that for $t\geqq t_1(\varepsilon)$,

$$w_{\mathbf{0}}(t)\geqq 1-\varepsilon. \tag{5.21}$$

(ii) Since there are only finitely many α's with $|\alpha|<N$, so that there exists $t_2<\infty$, such that for $t\geqq t_2$, and any α with $|\alpha|<N$, we have $w_{\alpha'}(t)\geqq w_\alpha(0)$, where $|\alpha'|=|\alpha|+1$. This is true because $w_\alpha(0)=q_\alpha<1$, and $w_{\alpha'}(t)\to 1$ as $t\to\infty$; therefore, for any α with $|\alpha|<N$ and any α' with $|\alpha'|=|\alpha|+1$, there exists $t'(\alpha,\alpha')$ such that $w_{\alpha'}(t)\geqq w_\alpha(0)$ for $t\geqq t'(\alpha,\alpha')$. Since there are only a finite number of $t'(\alpha,\alpha')$'s, we can choose

$$t_2=\max_{\alpha,\alpha'}\{t'(\alpha,\alpha')\}<\infty$$

$$\text{where } |\alpha|<N \quad\text{and}\quad |\alpha'|=|\alpha|+1.$$

Consider further that $w_\alpha(0)=0$ for $|\alpha|\geqq N$; we obtain

$$w_{\alpha'}(t)\geqq w_\alpha(0) \tag{5.22}$$

for all $\alpha\in\mathbf{Z}^d$, and all $\alpha'\in\mathbf{Z}^d$ with $|\alpha'|=|\alpha|+1$, as long as $t\geqq t_2$.

(iii) Equation (5.22) implies that

$$\begin{aligned}&w_\alpha(t+mt_2)\geqq w_{\mathbf{0}}(t)\\ &\text{for all } t>0 \quad\text{and}\quad m=|\alpha|\in\mathbf{Z}^+.\end{aligned} \tag{5.23}$$

In fact, from (5.22), $w_{\alpha'}(t_2)\geqq w_\alpha(0)$. By Lemma 2.2 (letting $\bar{w}_\alpha(0)\equiv w_{\alpha'}(t_2)$, etc.), we obtain

$$w_{\alpha'}(t+t_2)\geqq w_\alpha(t) \quad \text{for all } t\geqq 0. \tag{5.24}$$

Again, $w_{\alpha'}(2t_2)\geqq w_\alpha(t_2)$; so by Lemma 2.2,

$$w_{\alpha'}(t+2t_2)\geqq w_\alpha(t+t_2). \tag{5.25}$$

Let $\alpha=\mathbf{0}$; then from (5.24),

$$w_{\alpha'}(t+t_2)\geqq w_{\mathbf{0}}(t), \quad \text{where } |\alpha'|=|\mathbf{0}|+1=1. \tag{5.26}$$

In (5.25), letting $|\alpha|=1$, we obtain

$$w_{\alpha'}(t+2t_2) \geqq w_\alpha(t+t_2), \quad \text{where } |\alpha'|=|\alpha|+1=2,$$
$$\geqq w_0(t).$$

So (5.23) holds for $m=2$. Equation (5.23) can be obtained by using induction on m. Write (5.23) as

$$w_\alpha(t) \geqq w_0(t-mt_2) \quad \text{for } t \geqq mt_{2'} \quad \text{where } |\alpha|=m. \tag{5.27}$$

(iv) Let $\underline{c}=1/t_2$, and consider $w_\alpha(t)$ where $|\alpha|=[ct]$. If $c<\underline{c}$ then $1-ct_2=1-(c/\underline{c})>0$. Let $m=[ct]$ and $T(\varepsilon, c)=t_1(\varepsilon)/(1-ct_2)>0$ in (5.27); then for $t>T(\varepsilon, c)$,

$$w_\alpha(t) \geqq w_0(t-[ct]t_2) \geqq w_0(t(1-ct_2)) \geqq w_0(T(1-ct_2)) = w_0(t_1(\varepsilon))$$
$$\geqq 1-\varepsilon, \quad \text{where } |\alpha|=m=[ct].$$

Finally, the assumption $u_\alpha(0) \geqq q_\alpha = w_\alpha(0)$ implies, by Lemma 2.2, that $u_\alpha(t) \geqq w_\alpha(t)$ for all $t \geqq 0$, so $u_\alpha(t) \geqq 1-\varepsilon$ for $t>T(\varepsilon, c)$ and $c<\underline{c}$. □

Example 5.3. Returning to Example 5.1, let us calculate $\bar{c}$ and $\underline{c}$ for the system

$$\frac{d}{dt}u_{i,j} = d_1(u_{i+1,j}-2u_{i,j}+u_{i-1,j}) + d_2(u_{i,j+1}-2u_{i,j}+u_{i,j-1}) + f_{i,j}(u_{i,j}).$$

In order to simplify the calculations, let $f_{i,j}(u)=f(u)$, for all i, j, and let

$$f(u)=\begin{cases} -\frac{65}{62}u & u<\frac{62}{650} \\ \frac{65}{3}(u-0.1) & \frac{62}{650} \leqq u < \frac{71}{260} \\ 3.75 & \frac{71}{260} \leqq u < 0.75 \\ 15(1-u) & 0.75 \leqq u. \end{cases} \tag{5.28}$$

$f(u)$ is shown in Fig. 7. It can be treated as an approximation of some C^1 function.

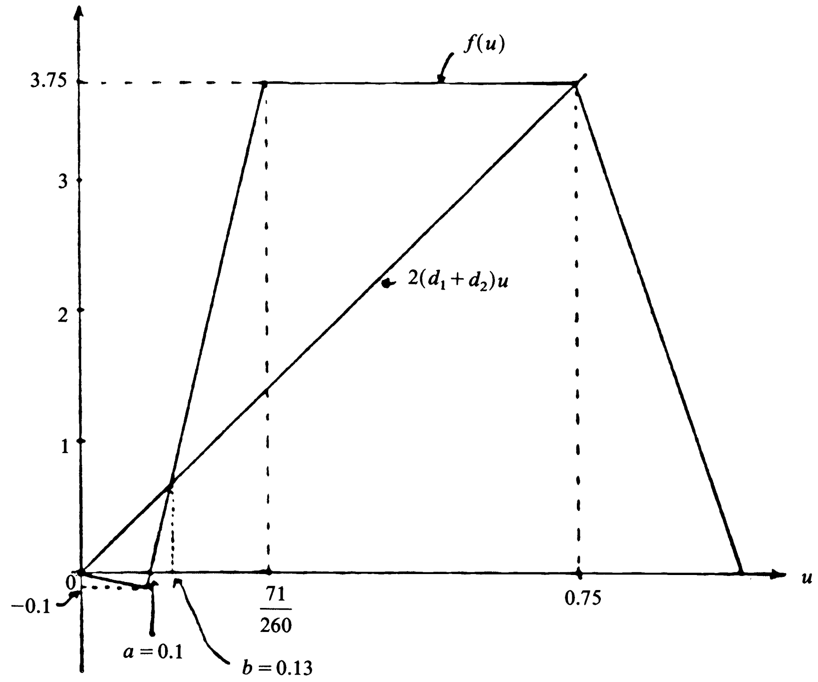

FIG. 7

Letting $d_1=1$, $d_2=1.5$, then (4.4), (4.5), and (4.6) are satisfied with $m=0.1$, $M=3.75$, $a=0.1$, $b=0.13$, and $e=0.75$. If we choose

$$u_{i,j}(0)=\begin{cases}0 & \text{if } i\neq 0,\ j\neq 0,\\ 0.13 & \text{if } i=j=0,\end{cases} \tag{5.29}$$

then by Theorem 4.5, $\lim_{t\to\infty} u_{i,j}(t)=1$.

The solution has been calculated numerically. We now calculate the upper bound and lower bound of the propagation speed.

(i) Calculation of the upper bound $\bar{c}$.

By (5.19), where $\bar{\mu}$ can be solved from (5.18),

$$\cosh(\bar{\mu})-\bar{\mu}\cdot\sinh(\bar{\mu})+\frac{\sigma}{2(d_1+d_2)}-1=0.$$

Now

$$\sigma_1=\sup_{0\leqq u<62/650}\left\{\frac{f(u)}{u}\right\}=\sup_{0\leqq u<62/650}\left\{-\left(\frac{\frac{65}{62}u}{u}\right)\right\}=-\frac{65}{62}.$$

Similarly, $\sigma_2=\sigma_3=975/71$, $\sigma_4=5$, so that

$$\sigma=\sup_{0\leqq u\leqq 1}\left\{\frac{f(u)}{u}\right\}$$
$$=\max\{\sigma_1,\sigma_2,\sigma_3,\sigma_4\}=\frac{975}{71}.$$

Hence $\cosh(\bar{\mu})-\bar{\mu}\cdot\sinh(\bar{\mu})+124/71=0$, which has the positive solution $\bar{\mu}\cong 1.715867$. Therefore, using values of d_j from Example 5.3, we have

$$\bar{c}=2(d_1+d_2)\sinh(\bar{\mu})\cong 5\sinh(1.715867)$$
$$\cong 13.454219.$$

(ii) Calculation of the lower bound $\underline{c}$.

$\underline{c}$ can be estimated by using the method used in the proof of Theorem 5.2.

We can choose $\underline{c}=1/t_2$, where $t_2=\max_{i,j,i'j'}\{t'(i,j,i',j')\}$ can be estimated as follows. From the given initial condition (5.28), we can see that $N=1$, $q_{0,0}=0.13$, and $q_{0,\pm 1}=q_{\pm 1,0}=0$, so that $w_{0,0}=0.13$, and $w_{i,j}=0$ if $i\neq 0$ and $j\neq 0$. From (2.1), letting $(i,j)=(0,1)$ and $t=0$, we obtain

$$\frac{d}{dt}w_{0,1}|_{t=0}=d_1(w_{1,1}-2w_{0,1}+w_{-1,1})+d_2(w_{0,2}-2w_{0,1}+w_{0,0})+f(w_{0,1})|_{t=0}$$
$$=d_2w_{0,0}(0)=1.5\times 0.13$$
$$=0.195.$$

If we assume that $w_{0,1}(t)$ is increasing linearly for small t (we do not know how small t must be, so this is only a rough approximation), then it will take $0.13/0.195\cong 0.667$ unit time to grow from 0 to 0.13. Similarly,

$$\frac{d}{dt}w_{1,0}|_{t=0}=d_1w_{0,0}(0)=0.13,$$

thus it will take 1 unit time for $w_{1,0}$ to grow from 0 to 0.13. Using the same calculation on $w_{-1,0}$, and $w_{0,-1}$, we obtain similar results. Therefore, $t_2 = \max(0.667, 1) = 1$, thus $\underline{c} = 1/t_2 = 1$.

6. Numerical simulations. Let us consider the system discussed in Examples 5.1 and 5.3, i.e.,

$$\frac{d}{dt} u_{i,j} = d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) + f(u_{i,j})$$

$$(i,j) \in \mathbf{Z}^2,$$

where $f(u)$ is given in (5.28). Let $d_1 = 1$, $d_2 = 1.5$; then (4.4), (4.5), and (4.6) are satisfied. We also set $u_{i,j}(t) \equiv 0$ on the boundary of the grid.

(1) Choosing initial condition

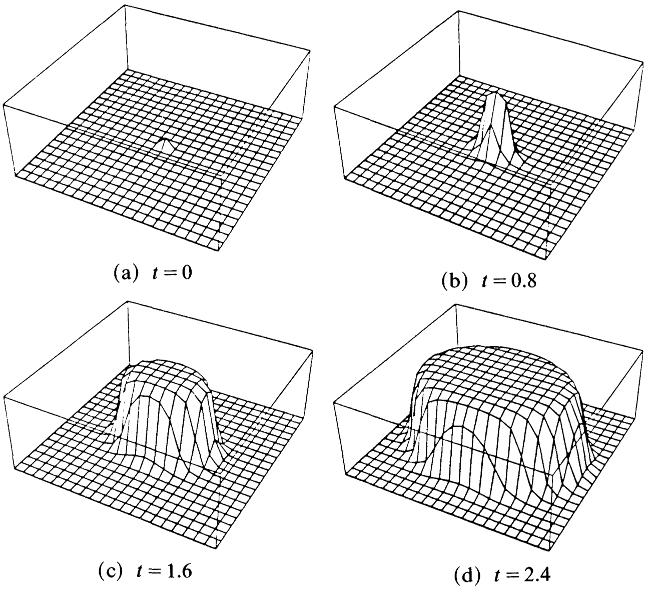
$$u_{i,j}(0) = 0.095 \quad \text{for all } i,j \text{ (not on the boundary).}$$

$u_{i,j}(0) < a$ for all i,j. From the numerical simulations, it is clear that $u_{i,j}(t) \to 0$ for all i,j when $t \to \infty$.

(2) Choosing

$$u_{i,j} = \begin{cases} 0 & \text{if } i \neq 0, j \neq 0, \\ 0.13 & \text{if } i = j = 0. \end{cases}$$

The result is shown in Fig. 8. From these graphs, we can see that $u_{i,j}(t) \to 1$ as $t \to \infty$, for all $i,j \in$ interior and $\notin$ boundary of the grid, which supports our superthreshold result, Theorem 4.5.



(a) $t = 0$

(b) $t = 0.8$

(c) $t = 1.6$

(d) $t = 2.4$

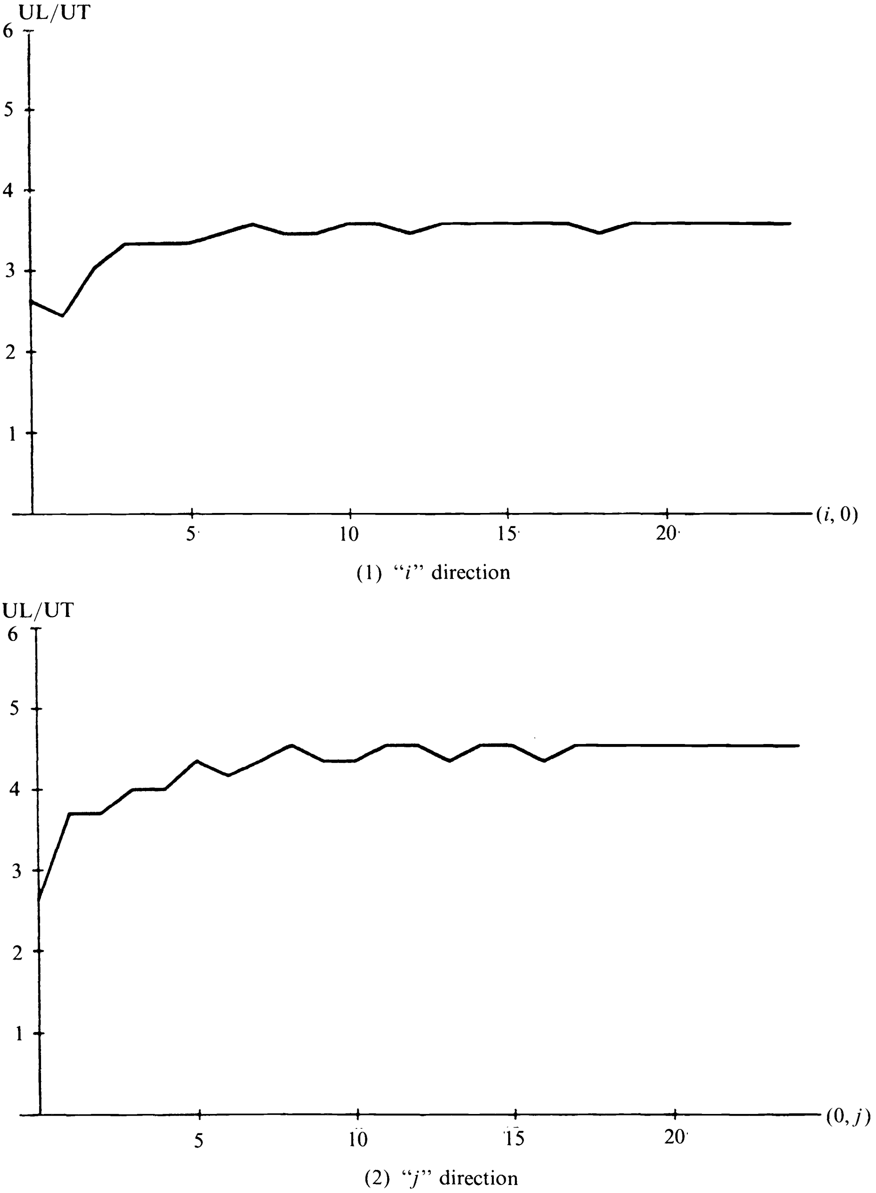
FIG. 8. *Superthreshold experiment for 2-D initial value problem.*

$$u_{i,j}(0) = \begin{cases} 0 & (i,j) \neq (0,0) \\ 0.13 & (i,j) = (0,0) \end{cases}, \qquad t_f = 2.4.$$

Propagation speed in two particular directions, the "i" direction (set $j \equiv 0$) and the "j" direction (set $i \equiv 0$), are shown in Fig. 9. From Fig. 9(1), along the "i" direction, after the node (5, 0), the propagation speed starts to stabilize at about 3.5 UL/UT (Unit Length/Unit Time). Along the "j" direction, from Fig. 9(2), the propagation speed starts to stabilize at about 4.5 UL/UT after the node (0, 7). In Example 2.3, we obtained $\underline{c} \approx 1$, $\bar{c} \approx 13.5$; therefore,

$$\underline{c} < c \text{ (both directions)} < \bar{c}.$$

The theoretical values of $\bar{c}$ and $\underline{c}$ are reasonable compared with the experimental result. It is seen that the comparison technique used gives rather conservative bounds. Here



(1) "i" direction

(2) "j" direction

FIG. 9. *Propagation speed.*

TABLE 1
Propagation tests.

$\mathbf{\Omega}$	$u_0(t)$	σ	Propagation
$\mathbf{\Omega}_1$	0.13	1.0	pass
	0.13	10.0	pass
$\mathbf{\Omega}_2$	0.13	0.05	not pass
	0.3	0.1	not pass
$\mathbf{\Omega}_3$	0.13	1.0	pass
	0.13	10.0	not pass

we choose $d_1 = 1.0$ ("i" direction), $d_2 = 1.5$ ("j" direction), the above calculation suggests that the larger d is, the higher the propagation speed in that corresponding direction.

We also considered propagation behavior of the inhomogeneous system

$$\frac{d}{dt} u_{i,j} = d_1(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + d_2(u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) + f_{i,j}(u_{i,j}),$$

with

$$f_{i,j}(u) = \begin{cases} f(u) & (i,j) \notin \mathbf{\Omega}, \\ -\sigma u & (i,j) \in \mathbf{\Omega}, \end{cases}$$

where $\mathbf{\Omega} \subset \mathbf{Z}^2$; $f(u)$ is given in (5.28) which satisfies the "propagation conditions."

The above function $f_{i,j}$ is motivated by considering the thin heart tissue model with the cells in region $\mathbf{\Omega}$ damaged. We want to study when propagation can pass through the damaged region. We choose $d_1 = 1.0$, $d_2 = 1.5$, grid size 70 × 70, and terminal time $t_f = 8.0$. The effects of initial conditions, σ, and shape of the damaged region on propagation was considered. The result is summarized as the following:

$$u_{i,j}(0) = \begin{cases} 0 & \text{if } i \neq 0, j \neq 0, \\ u_0 & \text{if } i = j = 0, \end{cases}$$

$$\mathbf{\Omega}_1 = \{(i,j) | 3 \leqq i \leqq 9, -3 \leqq j \leqq 3\} \qquad (3 \times 3 \text{ square centered at } (6,0)),$$

$$\mathbf{\Omega}_2 = \{(i,j) | 4 \leqq j \leqq 8\} \qquad (\text{a vertical band with width } 4),$$

$$\mathbf{\Omega}_3 = \{(i,j) | \{|i| \leqq 10 \cap |j| \leqq 10\} \backslash \{|i| \leqq 6 \cap |j| \leqq 6\}\}$$

(a rectangular ring centered at (0, 0) with center radius 8 and width 4).

The calculations were done using a fourth-order Runge-Kutta method on a VAX computer. Graphs were plotted using the package "Mathematical." Step size was a uniform .01 time units with grid size 70 × 70. For some calculation, in order to obtain a stable pattern, we need to increase the terminal time t_f; in such a case, to compensate the usage of CPU time, the grid size is reduced.

Acknowledgment. The author is grateful to Professor Jonathan Bell for many stimulating discussions and useful advice as well as the help in revising the manuscript.

GLOBAL ASYMPTOTIC STABILITY FOR A STATIONARY SOLUTION OF A SYSTEM OF INTEGRO-DIFFERENTIAL EQUATIONS DESCRIBING THE FORMATION OF LIVER ZONES*

KJELL HOLMÅKER†

Abstract. The formation of liver zones is modeled by a system of integro-differential equations. It has previously been proved that one particular stationary solution, characterized by a jump discontinuity at the zone boundary, is asymptotically stable with respect to sufficiently small perturbations of a special type. In this paper it is proved that this stationary solution is in fact globally asymptotically stable, that is, it is the limit (as time tends to infinity) of the solution of the integro-differential equations for arbitrary initial values.

Key words. integro-differential equations, global asymptotic stability, self-organization of cellular patterns

AMS(MOS) subject classifications. 45K05, 45M05, 92C15

1. Introduction.

1.1. Biological background.

The liver performs its metabolic functions with the aid of various enzymes fixed inside liver cells. These immobile cells line the many capillaries (hepatic sinusoids) through which the total hepatic blood flow is manifolded, whereby exchange of substances between blood and the cells is facilitated. The interplay of the unidirectional blood flow with local metabolism generates concentration gradients of blood-borne substances (such as oxygen) between the inlet and the outlet of the liver.

Several metabolic functions of the liver have been found to be organized in spatial zones arranged in relation to the direction of hepatic blood flow, in such a way that some enzymes act almost wholly upstream of others. We shall attribute such distributions of enzyme activities to distributions of cell-types. For the simplest case of two enzymes, let there be two corresponding cell-types, each containing only one of the enzymes; separate metabolic zones occur when all cells of the one type are located upstream of all cells of the other type. We shall suppose, furthermore, that each cell-type reproduces itself by division.

It has been shown recently that, for several kinds of enzyme kinetics, the observed zonal structure would result from the implementation of a certain physiologically desirable optimization principle [2], [3], [4], [5]. A mechanism by which that structure could develop in any one liver was considered in [1]. It is formulated in terms of competitive exclusion of the two cell-types in space and time and is an example of self-organization of gross cellular patterns. The mathematical model was discussed in [1], but for convenience the main steps in its derivation are repeated here.

As the many capillaries comprising the liver are similar and act essentially in parallel, we shall model a representative capillary lined with cells of two kinds. We put the x-axis along the blood flow, with inlet at $x=0$ and outlet at $x=\ell$. We define the density of cells of the first kind, $\rho_1(t,x)$, as a continuous representation of the number of cells of the first kind per unit length of capillary at time t at the position x. The density $\rho_2(t,x)$ of cells of the second kind is defined analogously. The total cell density $\rho_1+\rho_2$ cannot exceed some fixed maximum density σ of cell sites, as division of the cells is limited by the familiar phenomenon of contact inhibition.

The local rate of change $\partial\rho_1/\partial t$ of the density of cells of the first kind is assumed to consist of a growth-rate term proportional to ρ_1 (self-generation) and to the density of sites available, $\sigma-\rho_1-\rho_2$; and of a death-rate term proportional to ρ_1, with a coefficient $\beta_1(c)>0$ dependent on the local concentration c of a controlling blood-borne substance (we consider oxygen). We shall assume that $\beta_1(c)$ is of the form

$$\beta_1(c)=\mu_1-\nu_1(c-c_0),$$

where c_0 is the steady oxygen concentration at the inlet, and $\mu_1\geqq 0$, $\nu_1\geqq 0$ are constants. Then

$$\frac{\partial\rho_1}{\partial t}=k_1\rho_1(\sigma-\rho_1-\rho_2)-(\mu_1-\nu_1(c-c_0))\rho_1,$$

where $k_1>0$ is a constant. A similar equation is obtained for ρ_2. Oxygen is transported in the x-direction predominantly by convection with the blood and is used up by the two cell-types at the rates $\kappa_1\rho_1$ and $\kappa_2\rho_2$ (with positive constants κ_1 and κ_2). Changes in c caused by changes in ρ_1 and ρ_2 are quasi-steady. Therefore, c satisfies

$$f\frac{\partial c}{\partial x}=-\kappa_1\rho_1-\kappa_2\rho_2,$$

where f is the steady rate of blood flow. If this is integrated and c eliminated, we obtain the equations

$$\frac{\partial\rho_1}{\partial t}=\rho_1\left[k_1(\sigma-\rho_1-\rho_2)-\mu_1-\frac{\nu_1}{f}\int_0^x(\kappa_1\rho_1+\kappa_2\rho_2)\,d\xi\right],$$
$$\frac{\partial\rho_2}{\partial t}=\rho_2\left[k_2(\sigma-\rho_1-\rho_2)-\mu_2-\frac{\nu_2}{f}\int_0^x(\kappa_1\rho_1+\kappa_2\rho_2)\,d\xi\right].$$

If $k_1\sigma\leqq\mu_1$, then $\rho_1(t,x)\to 0$ as $t\to\infty$ for all x, and similarly for ρ_2. Therefore, we assume that $k_1\sigma>\mu_1$ and $k_2\sigma>\mu_2$. For similar reasons we also assume that at least one of ν_1 and ν_2 is positive (say ν_1).

To simplify the equations we introduce new variables

$$t'=(k_1\sigma-\mu_1)t,\quad x'=\frac{\nu_1\kappa_1}{fk_1}x,\quad v_i(t',x')=\frac{k_1}{c_1}\rho_i(t,x),\quad i=1,2,$$

and new parameters

$$\theta=\frac{\kappa_2}{\kappa_1},\quad \gamma=\frac{k_2}{k_1},\quad \lambda=\frac{k_1(k_2\sigma-\mu_2)}{k_2(k_1\sigma-\mu_1)},\quad \eta=\frac{\nu_2k_1}{\nu_1k_2}.$$

After dropping the primes we obtain

$$\begin{aligned}\frac{\partial v_1}{\partial t}(t,x)&=v_1(t,x)\left[1-v_1(t,x)-v_2(t,x)-\int_0^x[v_1(t,\xi)+\theta v_2(t,\xi)]\,d\xi\right],\\ \frac{\partial v_2}{\partial t}(t,x)&=\gamma v_2(t,x)\left[\lambda-v_1(t,x)-v_2(t,x)-\eta\int_0^x[v_1(t,\xi)+\theta v_2(t,\xi)]\,d\xi\right].\end{aligned}\tag{1.1}$$

This system is studied for $t\geqq 0$, $0\leqq x\leqq L$, where $L=\nu_1\kappa_1\ell/fk_1$, with given initial values

$$v_i(0,x)=v_i^0(x),\quad i=1,2,\quad 0\leqq x\leqq L.\tag{1.2}$$

The parameters satisfy

$$\theta>0,\quad \gamma>0,\quad \lambda>0,\quad \eta\geqq 0,\tag{1.3}$$

and the initial functions v_i^0 are nonnegative, bounded, and measurable functions.

1.2. The mathematical problem. In [1] it was shown that (1.1), (1.2) has a unique solution (v_1, v_2) such that the functions $v_i = v_i(t, x)$ are continuously differentiable in t for each x, measurable in x for each t, and satisfy (1.1), (1.2) for each (t, x). Furthermore, there is a constant $C \geqq 1$ such that

$$0 \leqq v_i(t, x) \leqq C \quad \text{for all } t \geqq 0, \quad x \in [0, L], \quad i = 1, 2. \tag{1.4}$$

The main question is what happens to the solution (v_1, v_2) as $t \to \infty$. One may guess that it tends to a stationary solution of (1.1), that is to a nonnegative solution of the system

$$\left.\begin{aligned} v_1\left[1 - v_1 - v_2 - \int_0^x (v_1 + \theta v_2)\, d\xi\right] &= 0, \\ v_2\left[\lambda - v_1 - v_2 - \eta \int_0^x (v_1 + \theta v_2)\, d\xi\right] &= 0, \end{aligned}\right\} \quad 0 \leqq x \leqq L.$$

It was shown in [1] that all stationary solutions are unstable except possibly one (see [1] for the definition of stability for this problem). In the most interesting case, where the parameters satisfy

$$\eta < \lambda < 1, \qquad 0 < x^* < L, \tag{1.5}$$

where

$$x^* = \ln \frac{1 - \eta}{\lambda - \eta}, \tag{1.6}$$

this stationary solution is

$$v_1^s(x) = \begin{cases} e^{-x} & \text{for } 0 \leqq x < x^*, \\ 0 & \text{for } x^* < x \leqq L, \end{cases} \tag{1.7}$$

$$v_2^s(x) = \begin{cases} 0 & \text{for } 0 \leqq x < x^*, \\ e^{-x^*} e^{-\eta\theta(x - x^*)} & \text{for } x^* < x \leqq L, \end{cases} \tag{1.8}$$

a solution that has the desired zonal structure. It was also shown in [1] that the stationary solution (v_1^s, v_2^s) is asymptotically stable with respect to a certain class of perturbations. Apart from being sufficiently small (uniformly in x) these perturbations had to go to zero at a certain rate as $x \to x^*$. In [1] the question of what happens for more general perturbations was left open, let alone the question of how the solution of (1.1), (1.2) behaves for initial functions (1.2) that are not necessarily close to the equilibrium solution (1.7), (1.8). We can now answer these questions in that we can show that $v_i(t, x) \to v_i^s(x)$ as $t \to \infty$ for $x \neq x^*$, $i = 1, 2$, for arbitrary initial functions v_i^0 (bounded away from zero). In other words we have the following theorem.

THEOREM 1. *Assume that the parameters satisfy* (1.3) *and* (1.5). *Let v_i^0 be bounded, measurable functions on* $[0, L]$ *such that*

$$v_i^0(x) \geqq \alpha_0 > 0 \quad \textit{for all } x \in [0, L], \quad i = 1, 2, \tag{1.9}$$

for some constant α_0. Then

$$v_i(t, x) \to v_i^s(x) \quad \textit{as } t \to \infty \quad \textit{for } x \neq x^*, \quad i = 1, 2, \tag{1.10}$$

where (v_1, v_2) is the solution of (1.1), (1.2), *and (v_1^s, v_2^s) is defined by* (1.7), (1.8). *The convergence in* (1.10) *is exponential for both v_1 and v_2 if $x < x^*$, and for v_1 if $x > x^*$.*

2. Proof of Theorem 1. The proof, which is rather long, is divided into three parts that are given as separate lemmas. In Lemma 2.1 we prove convergence for v_1 and v_2 if $x<x^*$, in Lemma 2.2 for v_1 if $x>x^*$, and in Lemma 2.3 for v_2 if $x>x^*$. In each lemma the proof is preceded by a comment where the main ideas of the proof are outlined.

LEMMA 2.1. *Let a, $0<a<x^*$, be fixed. Then there exist positive constants β and ω (depending on a) such that*

$$|v_1(t,x)-e^{-x}|\leqq \beta e^{-\omega t},\qquad v_2(t,x)\leqq \beta e^{-\omega t} \tag{2.1}$$

for $t\geqq 0$ and $x\in[0,a]$. If a is so close to x^* that $\nu(a)=\gamma[(1-\eta)e^{-a}+\eta-\lambda]<e^{-a}$, then ω can actually be taken as $\nu(a)$.

Comment. First, (2.1) can be obtained if x is sufficiently small. Using this result we can then extend (2.1) to a somewhat larger interval. Continuing in this fashion, it is possible to proceed step by step along the x-axis. Because of the positive difference x^*-a, we can reach the point a after a finite number of steps (the number depending on a). In each step the estimate for v_2 is obtained first. As for v_1, we must first prove that it remains bounded away from zero on the new interval. Then comes the crucial step of the proof, which is the introduction of a Lyapunov type function. From a differential inequality for this function a convergence result for v_1 in L_2-norm is obtained. Finally, another differential inequality, derived from the differential equation for v_1, gives the pointwise estimate in (2.1).

Proof of Lemma 2.1. Since $1-\lambda-(1-\eta)\int_0^{x^*}e^{-\xi}\,d\xi=0$, we have

$$\delta_1=1-\lambda-(1-\eta)\int_0^a e^{-\xi}\,d\xi>0. \tag{2.2}$$

Choose a $\delta>0$ such that

$$\delta\leqq\min\left[\frac{\delta_1}{2(1-\eta)(1+\theta)(x^*+C)},\frac{\lambda-\eta}{2(1-\eta)(1+(1+\theta)x^*+C)}\right], \tag{2.3}$$

where C is the constant from (1.4), and an integer N such that $N\delta=a$. Divide the interval $[0,a]$ onto N parts $[x_{k-1},x_k]$, $k=1,\dots,N$, where $x_k=k\delta$, and let

$$\omega'=\frac{\gamma\delta_1}{2}. \tag{2.4}$$

Suppose that for a certain $k-1$, $1\leqq k-1\leqq N-1$, we have found positive numbers β_{k-1} and ω_{k-1} such that

$$|v_1(t,x)-e^{-x}|\leqq\beta_{k-1}e^{-\omega_{k-1}t}, \tag{2.5}$$

$$v_2(t,x)\leqq\beta_{k-1}e^{-\omega' t} \tag{2.6}$$

for $t\geqq 0$, $x\in[0,x_{k-1}]$. We are going to show that for some $\beta_k\geqq\beta_{k-1}$ and $0<\omega_k\leqq\omega_{k-1}$ we have

$$|v_1(t,x)-e^{-x}|\leqq\beta_k e^{-\omega_k t}, \tag{2.7}$$

$$v_2(t,x)\leqq\beta_k e^{-\omega' t} \tag{2.8}$$

for $t\geqq 0$, $x\in[0,x_k]$. This will also be obtained for $k=1$ without any extra assumptions.

From (2.5) and (2.6) we see that there is a T_k such that

$$|v_1(t,x)-e^{-x}|\leqq\delta,\ v_2(t,x)\leqq\delta\quad\text{for } t\geqq T_k,\ x\in[0,x_{k-1}]. \tag{2.9}$$

On $(x_{k-1}, x_k]$ we get for $t \geqq T_k$ (if $k=1$ we consider $[0, x_1]$ and $t \geqq 0$),

(2.10)
$$\begin{aligned}
&1-\lambda-(1-\eta)\int_0^x (v_1+\theta v_2)\,d\xi \\
&\quad\geqq 1-\lambda-(1-\eta)\int_0^{x_{k-1}}(v_1+\theta v_2)\,d\xi-(1-\eta)\int_{x_{k-1}}^{x_k}(v_1+\theta v_2)\,d\xi \\
&\quad\geqq 1-\lambda-(1-\eta)\int_0^{x_{k-1}}(v_1-e^{-\xi}+\theta v_2)\,d\xi-(1-\eta)\int_0^{x_{k-1}}e^{-\xi}\,d\xi-(1-\eta)(1+\theta)C\delta \\
&\quad\geqq 1-\lambda-(1-\eta)(1+\theta)\delta x^*-(1-\eta)\int_0^a e^{-\xi}\,d\xi-(1-\eta)(1+\theta)C\delta \\
&\quad=\delta_1-(1-\eta)(1+\theta)(x^*+C)\delta \geqq \delta_1-\frac{\delta_1}{2}=\frac{\delta_1}{2},
\end{aligned}$$

where we have used (1.4), (2.9), (2.2), and (2.3). From (1.1), (1.2), and (1.9) it follows that $v_i > 0$, $i = 1, 2$, and

$$\frac{\partial}{\partial t}\ln\frac{v_2}{v_1^\gamma}=\gamma\left[\lambda-1+(1-\eta)\int_0^x (v_1+\theta v_2)\,d\xi\right],$$

so that

(2.11)
$$\frac{v_2(t,x)}{[v_1(t,x)]^\gamma}=\frac{v_2^0(x)}{[v_1^0(x)]^\gamma}\,e^{-\gamma\int_0^t[1-\lambda-(1-\eta)\int_0^x(v_1(\tau,\xi)+\theta v_2(\tau,\xi))\,d\xi]\,d\tau}.$$

From (1.4), (1.9), (2.10), (2.11), and (2.4) we see that

$$v_2(t,x) \leqq C\left(\frac{C}{\alpha_0}\right)^\gamma e^{\gamma[\lambda-1+(1-\eta)(1+\theta)Cx^*]T_k}\,e^{-\omega'(t-T_k)}$$

for $t \geqq T_k$, $x \in (x_{k-1}, x_k]$. But for $0 \leqq t \leqq T_k$ we have $v_2(t,x) \leqq C\,e^{\omega' T_k}\,e^{-\omega' t}$, so that there is a β'_k such that

(2.12)
$$v_2(t,x) \leqq \beta'_k\,e^{-\omega' t} \quad \text{for } t \geqq 0, \quad x \in (x_{k-1}, x_k].$$

Then choose $T'_k \geqq T_k$ so that $\beta'_k\,e^{-\omega' T'_k} \leqq \delta$. Thus

(2.13)
$$v_2(t,x) \leqq \delta \quad \text{for } t \geqq T'_k, \quad x \in [0, x_k].$$

As a first step towards proving (2.7) we want to show that $v_1(t,x) \geqq \alpha_k$ for $t \geqq T'_k$, $x \in (x_{k-1}, x_k]$, where

(2.14)
$$\alpha_k=\min\left[\frac{\lambda-\eta}{2(1-\eta)},\ \alpha_0\,e^{(1-2C-(1+\theta)Cx^*)T'_k}\right].$$

Assume on the contrary that $v_1(\bar t, \bar x) < \alpha_k$ for some $\bar t \geqq T'_k$ and $\bar x \in (x_{k-1}, x_k]$. As long as $v_1(t, \bar x) < \alpha_k$ (and $t \geqq T'_k$), we have, from (2.9), (2.13), (2.14), (1.6), and (2.3),

$$\begin{aligned}
&1-v_1-v_2-\int_0^{\bar x}(v_1+\theta v_2)\,d\xi \\
&\quad> 1-\alpha_k-\delta-\int_0^{x_{k-1}}(v_1-e^{-\xi})\,d\xi-\int_0^{x_{k-1}}e^{-\xi}\,d\xi-\int_{x_{k-1}}^{x_k}v_1\,d\xi-\int_0^{x_k}\theta v_2\,d\xi \\
&\quad> 1-\alpha_k-\delta-\delta x^*-\int_0^{x^*}e^{-\xi}\,d\xi-C\delta-\theta\delta x^* \\
&\quad=\frac{\lambda-\eta}{1-\eta}-(1+(1+\theta)x^*+C)\delta-\alpha_k \geqq \frac{\lambda-\eta}{1-\eta}-\frac{\lambda-\eta}{2(1-\eta)}-\alpha_k \geqq 0.
\end{aligned}$$

Therefore, $(\partial v_1/\partial t)(t, \bar{x}) > 0$ for these t. We have, from (1.1), (1.9), and (2.14),

$$v_1(t, x) \geqq \alpha_0 \, e^{[1-2C-(1+\theta)Cx^*]T_k'} \geqq \alpha_k$$

for $t \leqq T_k'$ and $x \in [0, x^*)$. In particular, $v_1(T_k', \bar{x}) \geqq \alpha_k$, and, therefore, there is an interval $[t', t'']$ with $t' \geqq T_k'$ such that $v_1(t', \bar{x}) = \alpha_k$, and $v_1(t, \bar{x}) < \alpha_k$ for $t \in (t', t'']$. But this is a contradiction, since $(\partial v_1/\partial t)(t, \bar{x}) > 0$ on $(t', t'']$. Thus $v_1(t, x) \geqq \alpha_k$ for all $t \geqq 0, x \in (x_{k-1}, x_k]$.

Let

$$V_k(t) = \int_{x_{k-1}}^{x_k} [v_1(t, x) - e^{-x} - e^{-x} \ln v_1(t, x) - x\, e^{-x}] \, dx,$$

$$w_1(t, x) = v_1(t, x) - e^{-x},$$

and

$$\psi(t, x) = \int_0^x [v_1(t, \xi) + \theta v_2(t, \xi)] \, d\xi.$$

Since the function $f(v, v_0) = (v - v_0 - v_0 \ln (v/v_0))/(v - v_0)^2$, $v > 0$, $v_0 > 0$, is decreasing in v for fixed v_0 and decreasing in v_0 for fixed v, and since $\alpha_k < e^{-x^*} = (\lambda - \eta)/(1 - \eta)$, there is a constant c_1 (depending only on C) such that

$$c_1 \int_{x_{k-1}}^{x_k} [w_1(t, x)]^2 \, dx \leqq V_k(t) \leqq \frac{1}{2\alpha_k} \int_{x_{k-1}}^{x_k} [w_1(t, x)]^2 \, dx. \tag{2.15}$$

We have

$$\dot{V}_k = \frac{dV_k}{dt} = \int_{x_{k-1}}^{x_k} (v_1 - e^{-x})(1 - v_1 - v_2 - \psi) \, dx$$

$$= -\int_{x_{k-1}}^{x_k} [w_1^2 + w_1(e^{-x} - 1 + \psi) + w_1 v_2] \, dx.$$

Here

$$e^{-x} - 1 + \psi = \int_0^x (v_1 - e^{-\xi} + \theta v_2) \, d\xi = \int_0^{x_{k-1}} (w_1 + \theta v_2) \, d\xi + \int_{x_{k-1}}^x (w_1 + \theta v_2) \, d\xi,$$

so that

$$w_1(e^{-x} - 1 + \psi) = (w_1 + \theta v_2) \int_{x_{k-1}}^x (w_1 + \theta v_2) \, d\xi - \theta v_2 \int_{x_{k-1}}^x (w_1 + \theta v_2) \, d\xi$$

$$+ w_1 \int_0^{x_{k-1}} (w_1 + \theta v_2) \, d\xi.$$

Since

$$\int_{x_{k-1}}^{x_k} (w_1 + \theta v_2) \left[\int_{x_{k-1}}^x (w_1 + \theta v_2) \, d\xi \right] dx = \frac{1}{2} \left[\int_{x_{k-1}}^{x_k} (w_1 + \theta v_2) \, d\xi \right]^2 \geqq 0,$$

we get for $t \geqq 0$ (using (2.5), (2.6), (2.12), and (2.15)),

$$\dot{V}_k \leqq -\int_{x_{k-1}}^{x_k} w_1^2 \, dx + \int_{x_{k-1}}^{x_k} \left[\theta v_2 \int_{x_{k-1}}^x (w_1 + \theta v_2) \, d\xi - w_1 \int_0^{x_{k-1}} (w_1 + \theta v_2) \, d\xi - w_1 v_2 \right] dx$$

$$\leqq -2\alpha_k V_k + \beta_k' \, e^{-\omega' t}[\theta(C + 1 + \theta C)\delta + C + 1]\delta + (C + 1)x^* \beta_{k-1}(e^{-\omega_{k-1} t} + \theta \, e^{-\omega' t})\delta.$$

Thus there are constants γ_k and ω'_k, where $0<\omega'_k<\min(2\alpha_k, \omega', \omega_{k-1})$, such that

$$V_k(t) \leqq \gamma_k e^{-\omega'_k t} \quad \text{for } t \geqq 0.$$

Thus, by (2.15),

$$\int_{x_{k-1}}^{x_k} |w_1(t, x)|\, dx \leqq \sqrt{\delta}\left[\int_{x_{k-1}}^{x_k} [w_1(t, x)]^2\, dx\right]^{1/2} \leqq \sqrt{\delta}\left(\frac{\gamma_k}{c_1}\right)^{1/2} e^{-(\omega'_k/2)t}.$$

For w_1 we have the equation

$$\frac{\partial w_1}{\partial t} = -v_1\left[w_1 + v_2 + \int_0^x (w_1 + \theta v_2)\, d\xi\right].$$

For $t \geqq 0$ and $x \in (x_{k-1}, x_k]$ we obtain

$$\begin{aligned} \frac{\partial w_1^2}{\partial t} &= 2w_1 \frac{\partial w_1}{\partial t} \\ &= -2v_1 w_1^2 - 2v_1 w_1\left[v_2 + \int_0^{x_{k-1}} w_1\, d\xi + \int_{x_{k-1}}^x w_1\, d\xi + \int_0^{x_{k-1}} \theta v_2\, d\xi + \int_{x_{k-1}}^x \theta v_2\, d\xi\right] \\ &\leqq -2\alpha_k w_1^2 + 2C(C+1)\Bigg[\beta'_k(1+\theta\delta)\, e^{-\omega' t} + \beta_{k-1} x^*(e^{-\omega_{k-1} t} + \theta\, e^{-\omega' t}) \\ &\qquad + \left(\frac{\delta\gamma_k}{c_1}\right)^{1/2} e^{-(\omega'_k/2)t}\Bigg]. \end{aligned}$$

There are constants β''_k and $\omega_k = \omega'_k/4$ such that

$$[w_1(t, x)]^2 \leqq (\beta''_k)^2\, e^{-2\omega_k t} \quad \text{for } t \geqq 0, x \in (x_{k-1}, x_k).$$

In the case $k=1$ this is obtained for $x=0$ also. In view of (2.12) we have thus proved (2.7), (2.8) with $\beta_k = \max(\beta_{k-1}, \beta'_k, \beta''_k)$.

After N steps we obtain

$$|v_1(t, x) - e^{-x}| \leqq \beta_N\, e^{-\omega_N t}, \qquad v_2(t, x) \leqq \beta_N\, e^{-\omega' t} \tag{2.16}$$

for $t \geqq 0$ and $x \in [0, a]$, which proves (2.1).

If T_0 is chosen so large that $\beta_N\, e^{-\omega_N T_0}$ and $\beta_N\, e^{-\omega' T_0}$ are small enough, it follows from the estimates in [1] (see in particular Remark 5.1; note a misprint at the beginning of the fourth row of Remark 5.1, where one should read $\sup_{\xi \in [0,x]} |w_i(t, \xi)|$) that

$$|v_1(t, x) - e^{-x}| \leqq \beta_0\, e^{-\nu(a)t}, \qquad v_2(t, x) \leqq \beta_0\, e^{-\nu(a)t}$$

for $t \geqq T_0, x \in [0, a]$ for a certain constant β_0, if $\nu(a) < e^{-a}$.

LEMMA 2.2. *For each $x' > x^*$ there are positive constants K and κ such that*

$$v_1(t, x) \leqq K\, e^{-\kappa t} \quad \textit{for } t \geqq 0, \quad x \in [x', L]. \tag{2.17}$$

Comment. It is first shown that $v_1 + v_2$ is bounded away from zero when x is close to x^*, and this together with Lemma 2.1 suffices to show (2.17).

Proof of Lemma 2.2. Let

$$\varphi(t) = \int_0^{x^*} [v_1(t, x) - e^{-x} + \theta v_2(t, x)]\, dx, \tag{2.18}$$

and

$$\psi_1(t, x) = \int_{x^*}^x [v_1(t, \xi) + \theta v_2(t, \xi)]\, d\xi \quad \text{for } x > x^*. \tag{2.19}$$

It follows from Lemma 2.1 (since $a<x^*$ is arbitrary) that $\varphi(t)\to 0$ as $t\to\infty$. The equations (1.1) can for $x>x^*$ be written

$$\begin{aligned}\frac{\partial v_1}{\partial t}&=v_1\left[\frac{\lambda-\eta}{1-\eta}-v_1-v_2-\varphi(t)-\psi_1(t,x)\right],\\ \frac{\partial v_2}{\partial t}&=\gamma v_2\left[\frac{\lambda-\eta}{1-\eta}-v_1-v_2-\eta\varphi(t)-\eta\psi_1(t,x)\right].\end{aligned}\tag{2.20}$$

Therefore (cf. (2.11)),

$$\frac{v_1(t,x)}{[v_2(t,x)]^{1/\gamma}}=\frac{v_1^0(x)}{[v_2^0(x)]^{1/\gamma}}\,e^{-(1-\eta)\int_0^t[\varphi(\tau)+\psi_1(\tau,x)]\,d\tau}.\tag{2.21}$$

Since $\varphi(t)\to 0$ as $t\to\infty$, we can choose T such that

$$|\varphi(t)|\leqq\frac{\lambda-\eta}{3(1-\eta)}\quad\text{for } t\geqq T.\tag{2.22}$$

Let

$$\delta_0=\frac{\lambda-\eta}{3(1-\eta)(1+\theta)C},\qquad b=x^*+\delta_0,\tag{2.23}$$

and

$$\alpha=\min\left[\alpha_0\,e^{(1-2C-(1+\theta)Cb)T},\alpha_0\,e^{\gamma(\lambda-2C-\eta(1+\theta)Cb)T},\frac{\lambda-\eta}{6(1-\eta)}\right].\tag{2.24}$$

Then it follows from (1.1) that

$$v_i(T,x)\geqq\alpha\quad\text{for } x\in(x^*,b],\quad i=1,2.$$

Suppose that $v_1(\bar t,\bar x)+v_2(\bar t,\bar x)<2\alpha$ for some $\bar t>T$ and $\bar x\in(x^*,b]$. Then there is an interval $[t',t'']$ with $t'>T$ such that $v_1(t',\bar x)+v_2(t',\bar x)=2\alpha$, and $v_1(t,\bar x)+v_2(t,\bar x)<2\alpha$ on $(t',t'']$. For $t\in(t',t'']$ and $x=\bar x$, we have, by (2.22)-(2.24),

$$\frac{\lambda-\eta}{1-\eta}-v_1-v_2-\varphi-\psi_1>\frac{\lambda-\eta}{1-\eta}-2\alpha-\frac{\lambda-\eta}{3(1-\eta)}-(1+\theta)C\delta_0\geqq 0,$$

and then (2.20) shows that $(\partial v_1/\partial t)(t,\bar x)>0$ and $(\partial v_2/\partial t)(t,\bar x)>0$ on $(t',t'']$. But this gives a contradiction, and, therefore,

$$v_1(t,x)+v_2(t,x)\geqq 2\alpha\quad\text{for all } t\geqq T,\quad x\in(x^*,b].\tag{2.25}$$

Thus

$$\psi_1(t,x)\geqq\min(1,\theta)2\alpha(x-x^*)\quad\text{for } t\geqq T,\quad x\in(x^*,b],\tag{2.26}$$

and since $\varphi(t)\to 0$ as $t\to\infty$,

$$\int_0^t[\varphi(\tau)+\psi_1(\tau,x)]\,d\tau\to\infty\quad\text{as } t\to\infty\quad\text{for } x\in(x^*,b].$$

Then we see from (2.21) that $v_1(t,x)\to 0$ as $t\to\infty$ for every $x\in(x^*,b]$. Since ψ_1 is increasing in x, (2.21) and (2.26) give an estimate of the form (2.17).

LEMMA 2.3. *For $x\in(x^*,L]$ we have that*

$$v_2(t,x)\to v_2^s(x)=e^{-x^*}\,e^{-\eta\theta(x-x^*)}\quad\textit{as } t\to\infty$$

with uniform convergence on closed subintervals of $(x^*,L]$.

Comment. First we show that $\int_{x^*}^b [v_2(t,x)-v_2^s(x)]^2\,dx \to 0$ as $t\to\infty$ for a suitable b. This is done by dividing the integral into two parts, where the first part is small because the interval is short. The other part is shown to go to zero by means of a Lyapunov type function (as in Lemma 2.1). There we use that $v_1\to 0$ and v_2 is bounded away from zero, when a neighbourhood of x^* is avoided (which follows from Lemma 2.2). After that pointwise convergence on $(x^*, b]$ is also obtained. Once we have passed the critical point x^*, we can proceed in small steps as in Lemma 2.1 and prove convergence on successively larger intervals. It may be noted that we do not obtain exponential convergence for v_2 if $x>x^*$. Indeed, experience from the linearized equation indicates that we should not expect a better rate of convergence than $1/t$.

Proof of Lemma 2.3. Let b and α be as in (2.23) and (2.24), and let $\varepsilon>0$ be given. Choose $x'\in(x^*, b)$ such that

$$(2.27)\qquad (C+e^{-x^*})^2(x'-x^*)<\frac{\varepsilon}{2}\quad\text{and}\quad \eta\theta(C+e^{-x^*})^2(b-x')(x'-x^*)<\frac{\alpha\varepsilon c_1}{4},$$

where c_1 is the constant in (2.15). Consider the function

$$V(t)=\int_{x'}^b\left[v_2(t,x)-v_2^s(x)-v_2^s(x)\ln\frac{v_2(t,x)}{v_2^s(x)}\right]dx,$$

where $v_2^s(x)$ is given by (1.8). Since $v_1(t,x)\to 0$ as $t\to\infty$ uniformly on $[x', b]$ (Lemma 2.2), it follows from (2.25) that there is a t_1 (depending on x', hence on ε) such that

$$v_2(t,x)\geqq\alpha\quad\text{for } t\geqq t_1,\quad x\in[x', b].$$

From the properties of the function $(v-v_0-v_0\ln(v/v_0))/(v-v_0)^2$ we find as in (2.15) (since $v_2^s(b)>\alpha$) that

$$(2.28)\qquad c_1\int_{x'}^b[w_2(t,x)]^2\,dx\leqq V(t)\leqq\frac{1}{2\alpha}\int_{x'}^b[w_2(t,x)]^2\,dx\quad\text{for } t\geqq t_1,$$

where

$$w_2(t,x)=v_2(t,x)-v_2^s(x).$$

The derivative of V is

$$\begin{aligned}\dot V&=\int_{x'}^b\gamma(v_2-v_2^s)\left(e^{-x^*}-v_1-v_2-\eta\varphi-\eta\int_{x^*}^x v_1\,d\xi-\eta\theta\int_{x^*}^x v_2\,d\xi\right)dx\\&=\gamma\int_{x'}^b w_2\left(-w_2-\eta\theta\int_{x^*}^x w_2\,d\xi-\varphi_1\right)dx,\end{aligned}$$

where φ is defined in (2.18), and

$$\varphi_1(t,x)=v_1(t,x)+\eta\varphi(t)+\eta\int_{x^*}^x v_1(t,\xi)\,d\xi,$$

so that $\varphi_1(t,x)\to 0$ as $t\to\infty$, uniformly on $[x', b]$. Since

$$\int_{x'}^b w_2(t,x)\left[\int_{x'}^x w_2(t,\xi)\,d\xi\right]dx=\frac{1}{2}\left[\int_{x'}^b w_2(t,\xi)\,d\xi\right]^2\geqq 0,$$

we have

$$\dot V(t)\leqq-\gamma\int_{x'}^b[w_2(t,x)]^2\,dx-\gamma\int_{x'}^b w_2(t,x)\left[\eta\theta\int_{x^*}^{x'}w_2(t,\xi)\,d\xi+\varphi_1(t,x)\right]dx.$$

There is a $t_2 \geqq t_1$ such that

$$|\varphi_1(t, x)| < \frac{\alpha\varepsilon c_1}{4(C+e^{-x^*})(b-x')} \quad \text{for } t \geqq t_2 \quad \text{and} \quad x \in [x', b].$$

For $t \geqq t_2$ we get, from (2.28) and (2.27),

$$\dot{V}(t) \leqq -2\alpha\gamma V(t) + \gamma(C+e^{-x^*})\left[\eta\theta(C+e^{-x^*})(x'-x^*) + \frac{\alpha\varepsilon c_1}{4(C+e^{-x^*})(b-x')}\right](b-x')$$

$$\leqq -2\alpha\gamma V(t) + \frac{1}{2}\gamma\alpha\varepsilon c_1.$$

Thus

$$V(t) \leqq V(t_2)\, e^{-2\alpha\gamma(t-t_2)} + \tfrac{1}{4}\varepsilon c_1 \quad \text{for } t \geqq t_2,$$

and there is a $t_3 \geqq t_2$ such that

$$V(t) \leqq \tfrac{1}{2}\varepsilon c_1 \quad \text{for } t \geqq t_3.$$

Consequently, by (2.27) and (2.28),

$$\int_{x^*}^{b} [w_2(t, x)]^2\, dx = \int_{x^*}^{x'} w_2^2\, dx + \int_{x'}^{b} w_2^2\, dx < (C+e^{-x^*})^2(x'-x^*) + \frac{1}{c_1} V(t)$$

$$\leqq \frac{1}{2}\varepsilon + \frac{1}{2}\varepsilon = \varepsilon \quad \text{for } t \geqq t_3 = t_3(\varepsilon).$$

This proves that

$$\int_{x^*}^{b} [w_2(t, x)]^2\, dx \to 0 \quad \text{as } t \to \infty,$$

and by Cauchy-Schwarz's inequality,

$$\text{(2.29)} \qquad \int_{x^*}^{b} |w_2(t, x)|\, dx \to 0 \quad \text{as } t \to \infty.$$

Fix $x \in (x^*, b]$. Again it follows from (2.25) that there is a t_4 such that $v_2(t, x) \geqq \alpha$ for $t \geqq t_4$. For $t \geqq t_4$ we have

$$\frac{\partial w_2^2}{\partial t} = 2w_2 \frac{\partial w_2}{\partial t} = -2\gamma w_2 v_2 \left(w_2 + \eta\theta \int_{x^*}^{x} w_2\, d\xi + \varphi_1 \right)$$

$$\leqq -2\alpha\gamma w_2^2 + \varphi_2,$$

where

$$\varphi_2(t, x) = -2\gamma v_2(t, x) w_2(t, x)\left[\eta\theta \int_{x^*}^{x} w_2(t, \xi)\, d\xi + \varphi_1(t, x)\right],$$

and it follows from (2.29) that $\varphi_2(t, x) \to 0$ as $t \to \infty$. Thus

$$[w_2(t, x)]^2 \leqq [w_2(t_4, x)]^2\, e^{-2\alpha\gamma(t-t_4)} + \int_{t_4}^{t} e^{-2\alpha\gamma(t-\tau)}\, \varphi_2(\tau, x)\, d\tau \quad \text{for } t \geqq t_4,$$

so that $w_2(t, x) \to 0$ as $t \to \infty$. The convergence is uniform on closed subintervals of $(x^*, b]$.

For the last part of the proof we divide $[b, L]$ into N intervals $[x_{k-1}, x_k]$, $k = 1, \dots, N$, of length

$$x_k - x_{k-1} \leqq \frac{v_2^s(L)}{4\eta\theta C}.$$

Assume that it is proved that $w_2(t, x) \to 0$ as $t \to \infty$ for $x \in (x^*, x_{k-1}]$ (this is the case for $k = 1$). Choose T_k such that

$$|\varphi_1(t, x)| \leqq \tfrac{1}{4}\, v_2^s(L) \quad \text{for } x \in (x_{k-1}, x_k], \quad t \geqq T_k,$$

and

$$\eta\theta \int_{x^*}^{x_{k-1}} |w_2(t, \xi)|\, d\xi \leqq \frac{1}{4}\, v_2^s(L) \quad \text{for } t \geqq T_k.$$

Let

$$\alpha_k = \min\,[\tfrac{1}{4}\, v_2^s(L), \alpha_0\, e^{\gamma(\lambda - 2C - \eta(1+\theta)CL)T_k}].$$

(Note that x_k, T_k, and α_k are not the same as in Lemma 2.1, although the usage is similar.) For $t \geqq T_k$ and $x \in (x_{k-1}, x_k]$, we have

$$\begin{aligned} &e^{-x^*} - v_1(t, x) - v_2(t, x) - \eta\varphi(t) - \eta\psi_1(t, x) \\ &= v_2^s(x_{k-1}) - \varphi_1(t, x) - v_2(t, x) - \eta\theta \int_{x^*}^{x_{k-1}} w_2(t, \xi)\, d\xi - \eta\theta \int_{x_{k-1}}^{x} v_2(t, \xi)\, d\xi \\ &\geqq v_2^s(L) - \frac{3}{4}\, v_2^s(L) - v_2(t, x) = \frac{1}{4}\, v_2^s(L) - v_2(t, x), \end{aligned}$$

so that $(\partial v_2/\partial t)(t, x) \geqq 0$, if $v_2(t, x) \leqq \alpha_k$. Since $v_2(T_k, x) \geqq \alpha_k$, this implies that $v_2(t, x) \geqq \alpha_k$ for all $t \geqq T_k$, $x \in (x_{k-1}, x_k]$. By means of the function

$$V_k(t) = \int_{x_{k-1}}^{x_k} \left[v_2(t, x) - v_2^s(x) - v_2^s(x) \ln \frac{v_2(t, x)}{v_2^s(x)} \right] dx,$$

we obtain just as before (when we used $V(t)$ to show that $w_2(t, x) \to 0$ as $t \to \infty$ for $x \in (x^*, b]$) that $\int_{x_{k-1}}^{x_k} |w_2(t, x)| dx \to 0$ as $t \to \infty$, and then $w_2(t, x) \to 0$ as $t \to \infty$ for $x \in (x_{k-1}, x_k]$. In this way we obtain after N steps that $w_2(t, x) \to 0$ as $t \to \infty$ for all $x \in (x^*, L]$. The convergence is uniform on closed subintervals of $(x^*, L]$.

By this, Theorem 1 is proved.

3. Some concluding remarks. Let us remark what happens for parameter values that do not satisfy (1.5), (1.6). If $\eta < \lambda < 1$, but $x^* \geqq L$, then there is only one zone, and convergence follows from Lemma 2.1. If $\lambda < 1$ and $\eta \geqq \lambda$, then there is no critical point x^*, and again there is only one zone. We can apply Lemma 2.1 with $a = L$; we replace x^* by L and $(\lambda - \eta)/(1 - \eta)$ by e^{-L}. If $\lambda = 1$ and $\eta < 1$, then we can prove Lemmas 2.2 and 2.3 with $x^* = 0$. If $\eta > \lambda > 1$, or $\lambda > 1$ and $0 < \eta \leqq \lambda$, or $\lambda = 1$ and $\eta > 1$, then the result follows by symmetry. Indeed, if we make the substitutions $\bar{t} = \lambda\gamma t$, $\bar{x} = \eta\theta x$, $\bar{v}_i = v_i/\lambda$, $\bar{\lambda} = 1/\lambda$, $\bar{\gamma} = 1/\gamma$, $\bar{\eta} = 1/\eta$, and $\bar{\theta} = 1/\theta$, then we obtain the equations (1.1) with all quantities barred and with indices 1 and 2 interchanged, and we can apply the previous results. The case $\eta = 0$ is also easily treated.

The case $\lambda=\eta=1$ is exceptional, as is indicated in [1], and requires a special treatment. Following [1] we define $v_1=F(x,u)\geqq 0$ as the solution of

$$v_1+\zeta(x)v_1^\gamma=u, \qquad u\geqq 0,$$

where $\zeta(x)=v_2^0(x)/[v_1^0(x)]^\gamma$. Define $G(x,u)=u-F(x,u)$, $F_\gamma(x,u)=F(x,u)+\gamma G(x,u)$, and $F_\theta(x,u)$ analogously. Then, as is shown in [1], the system (1.1) with $\lambda=\eta=1$ is equivalent to the single equation

$$\frac{\partial u}{\partial t}=F_\gamma(x,u)\left[1-u-\int_0^x F_\theta(\xi,u)\,d\xi\right], \tag{3.1}$$

with $v_1(t,x)=F(x,u(t,x))$ and $v_2(t,x)=G(x,u(t,x))$, or $u(t,x)=v_1(t,x)+v_2(t,x)$. It is shown in [1] that

$$1-u(x)-\int_0^x F_\theta(\xi,u(\xi))\,d\xi=0 \tag{3.2}$$

has a unique solution $u^s(x)$, and we can now prove that $u(t,x)\to u^s(x)$ as $t\to\infty$ with exponential convergence. We omit the details and only indicate the main steps of the proof.

Divide $[0,L]$ into N intervals $[x_{k-1},x_k]$ of length δ, where δ is sufficiently small. Let $w(t,x)=u(t,x)-u^s(x)$, and assume that

$$|w(t,x)|\leqq \beta_{k-1}\,e^{-\omega_{k-1}t}, \qquad t\geqq 0, x\in[0,x_{k-1}] \tag{3.3}$$

for some positive constants β_{k-1} and ω_{k-1}. Much as in Lemma 2.1 we can show that

$$u(t,x)\geqq \alpha_k>0, \quad t\geqq 0, \quad x\in(x_{k-1},x_k]. \tag{3.4}$$

Introduce the function

$$V_k(t)=\int_{x_{k-1}}^{x_k}\int_{u^s(x)}^{u(t,x)}\frac{F_\theta(x,\bar u)-F_\theta(x,u^s(x))}{F_\gamma(x,\bar u)}\,d\bar u\,dx. \tag{3.5}$$

From the properties of $F(x,u)$ and (3.4) we obtain

$$a_k\int_{x_{k-1}}^{x_k}[w(t,x)]^2\,dx\leqq V_k(t)\leqq b_k\int_{x_{k-1}}^{x_k}[w(t,x)]^2\,dx \tag{3.6}$$

for certain positive constants a_k and b_k. From (3.1) and (3.2) we get

$$\frac{\partial w}{\partial t}=F_\gamma(x,u)\left[-w-\int_0^x \Delta(t,\xi)\,d\xi\right], \tag{3.7}$$

where

$$\Delta(t,x)=F_\theta(x,u(t,x))-F_\theta(x,u^s(x)), \tag{3.8}$$

so that

$$\Delta(t,x)w(t,x)\geqq c_k[w(t,x)]^2, \quad t\geqq 0, \quad x\in(x_{k-1},x_k] \tag{3.9}$$

for some positive constant c_k. Then

$$\dot V_k(t)=\int_{x_{k-1}}^{x_k}\frac{\Delta(t,x)}{F_\gamma(x,u)}\frac{\partial w}{\partial t}\,dx=-\int_{x_{k-1}}^{x_k}\Delta(t,x)w(t,x)\,dx$$
$$-\int_{x_{k-1}}^{x_k}\Delta(t,x)\int_0^{x_{k-1}}\Delta(t,\xi)\,d\xi\,dx-\int_{x_{k-1}}^{x_k}\Delta(t,x)\int_{x_{k-1}}^{x}\Delta(t,\xi)\,d\xi\,dx.$$

The important thing is that the last term can be estimated:

$$\int_{x_{k-1}}^{x_k} \Delta(t, x) \int_{x_{k-1}}^{x} \Delta(t, \xi)\, d\xi\, dx = \frac{1}{2}\left(\int_{x_{k-1}}^{x_k} \Delta(t, x)\, dx\right)^2 \geqq 0.$$

The first term can be estimated in terms of $V_k(t)$ by (3.6) and (3.9), and the middle term tends exponentially to zero as $t \to \infty$, according to (3.3) (since $|\Delta| \leqq (1+\theta)|w|$). Thus $V_k(t)$, and hence $\int_{x_{k-1}}^{x_k} [w(t, x)]^2\, dx$, tends exponentially to zero. Finally, a pointwise estimate for $[w(t, x)]^2$, if $t \geqq 0$, $x \in (x_{k-1}, x_k]$, is obtained from (3.7) as in the proof of Lemma 2.1.

In this way we know the asymptotic behaviour of the solution of (1.1) for all values of the parameters.

Acknowledgment. The author wishes to thank L. Bass, A. M. Fink, and A. McNabb for many helpful discussions on this problem.

REMARKS ON PERIODS OF PLANAR HAMILTONIAN SYSTEMS*

FRANZ ROTHE[†]

In memoriam of Professor Peter Henrici for all his help.

Abstract. Criteria for monotonicity of the periods of planar Hamiltonian systems from various authors are logically related. From the more restrictive criteria, not only monotonicity is proved, but even a further convexity property of the energy-period function. This implies estimates for the canonical partition function—which is the Laplace transform of the energy-period function—and some averages from the canonical ensemble of thermodynamics. For the standard system of classical mechanics with quadratic kinetic energy and symmetric potential energy, the Laplace transform technique allows one to solve the inverse problem to determine the potential energy function from given periods. Several examples are discussed.

Key words. energy-period function, monotonicity, Laplace transform

AMS(MOS) subject classifications. 34C25, 34A25, 34A55

1. Introduction. In [17], Waldvogel proves that the oscillation periods of the well-known Volterra–Lotka system

$$\begin{aligned} \frac{du}{dt} &= \lambda u\,(1-v)\,, \\ \frac{dv}{dt} &= -\mu v\,(1-u) \end{aligned} \tag{1}$$

increase monotonically with the amplitude of the oscillations. A different variant of the proof based on the canonical ensemble from classical equilibrium thermodynamics is given by Rothe [12].

Introducing the variables (p,q) via $u = e^p$ and $v = e^q$ and exchanging the two equations transforms (1) into the Hamiltonian system,

$$\frac{dq}{dt} = \frac{\partial H}{\partial p}\,, \qquad \frac{dp}{dt} = -\frac{\partial H}{\partial q} \tag{2}$$

with the Hamiltonian

$$H(p,q) = \lambda\,(e^q - q - 1) + \mu\,(e^p - p - 1)\,. \tag{3}$$

In this note, we generalize the Hamiltonian (3) from the Volterra–Lotka system and treat the case of arbitrary Hamiltonians with separated variables

$$H(p,q) = \lambda F(q) + \mu G(p). \tag{4}$$

For the functions $F = F(q)$ and $G = G(p)$, we assume throughout that

- $(F0)$ $F \in C^4(\mathbb{R},\mathbb{R})$ is at least four times continuously differentiable, $F(0) = 0$; and
- $(f0)$ The derivative $f = F'$ satisfies $f(0) = 0$, $f'(0) > 0$, and $qf(q) > 0$ for all $q \neq 0$

*Received by the editors March 8, 1991; accepted for publication (in revised form) March 11, 1992.

[†]Mathematics Department, University of North Carolina, Charlotte, North Carolina 28223.

and similarly for the function $G = G(q)$ and its derivative $g = G'$. Thus we treat a system

$$\frac{dq}{dt} = \mu g(p), \qquad \frac{dp}{dt} = -\lambda f(q), \tag{5}$$

with $\lambda > 0$ and $\mu > 0$ and $(f0)$ holding for both functions f and g. Especially, our class of systems includes the standard example from classical mechanics

$$\frac{dq}{dt} = p, \qquad \frac{dp}{dt} = -f(q), \tag{6}$$

which results from (5) by setting $\lambda = \mu = 1$, $G(p) = \frac{1}{2}p^2$ for the kinetic energy and keeping only the one potential $F = F(q)$.

Systems (5) and (6) have a unique center at $(p, q) = (0, 0)$, which is surrounded by periodic orbits $(t, E, \lambda, \mu) \in \mathrm{IR}\times[0, \infty)\times(0, \infty)^2 \mapsto (p, q) = (p, q)(t, E, \lambda, \mu) \in \mathrm{IR}^2$. We are interested in estimates for the *energy-period function* $(E, \lambda, \mu) \in [0, \infty)\times(0, \infty)^2 \mapsto T = T(t, E, \lambda, \mu) \in (0, \infty)$, where T is the primitive period of the oscillations of system (5) given by

$$\begin{aligned} p(t + T(E, \lambda, \mu), E, \lambda, \mu) &= p(t, E, \lambda, \mu), \\ q(t + T(E, \lambda, \mu), E, \lambda, \mu) &= q(t, E, \lambda, \mu), \\ H(p(t, E, \lambda, \mu), q(t, E, \lambda, \mu)) &= E \\ \text{for all } t \in \mathrm{IR},\ E \in [0, \infty),\ &\lambda, \mu \in (0, \infty). \end{aligned} \tag{7}$$

In this introduction, we quote a typical new result of this note. Then we explain the application to Hamiltonian systems of several degress of freedom. Next, we indicate the connection with equilibrium thermodynamics. Finally, we comment on the application to bifurcation of two point boundary value problems.

Assume that both functions f and g satisfy

$$\begin{aligned} f'(q) > 0 &\text{ for all } q \in \mathrm{IR}, \\ q\left[f''(q) - \frac{f''(0)}{f'^2(0)}\left(f'^2(q) - \frac{1}{3}f(q)f''(q)\right)\right] < 0 &\text{ for all } q \neq 0. \end{aligned} \tag{8}$$

Then the energy-period function $T = T(E, \lambda, \mu)$ is a strictly increasing function of the energy E. The apparently much simpler assumption $qf''(q) < 0$ for all $q \neq 0$ is sufficient for (8) to hold. But since it implies $f''(0) = 0$, it is often too restrictive.

The following remark is based on work of Arnold [1]. In the theory of Hamiltonian dynamics, it is a basic problem to study the effects introduced by a weak coupling into systems of several independent oscillators. As the simplest, really hard example, take a system of two degrees of freedom with Hamiltonian

$$H = H_0 + \varepsilon H_1, \tag{9}$$

where H_0 is the Hamiltonian of the uncoupled system, H_1 is the coupling, and ε is a small coupling constant. Suppose that the unperturbed system is completely integrable and its Hamiltonian is

$$H_0 = H_{01}(J_1) + H_{02}(J_2), \tag{10}$$

where J_1 and J_2 are the action variables for the first and second degree of freedom.

Arnold's celebrated result from [1] states that under the appropriate *nondegeneracy assumption,* in the weak coupling limit $\varepsilon \to 0$ a part of the phase space Γ of nearly full Lesbesgue-measure is filled with nonresonant KAM-TORI. Indeed, Arnold gives results in two different settings, for which the relevant phase space Γ is

(a) $\Gamma = \{ (p_1, q_1, p_2, q_2) \} = \mathbb{R}^4$, the entire four-dimensional space;

(b) $\Gamma = \{ (p_1, q_1, p_2, q_2) \mid H(p_1, q_1, p_2, q_2) = E \}$, a three-dimensional surface with specified total energy E.

The nondegeneracy assumptions appropriate for case (a) and (b) are

$$\text{(11a)} \qquad \frac{\partial^2 H_{01}}{\partial J_1^2} \frac{\partial^2 H_{02}}{\partial J_2^2} \neq 0,$$

$$\text{(11b)} \qquad \frac{\partial^2 H_{01}}{\partial J_1^2} \left(\frac{\partial H_{02}}{\partial J_2} \right)^2 + \frac{\partial^2 H_{02}}{\partial J_2^2} \left(\frac{\partial H_{01}}{\partial J_1} \right)^2 \neq 0.$$

Assumptions (11a) and (11b) can be expressed in terms of the energy-period function instead of the action-angle variables. We consider the Hamiltonian system (2) with one degree of freedom dropping the index 1 or 2. The solutions of that system as specified by (7) give rise to a mapping $(t, E) \mapsto (p, q)$. We substitute $(p, q) = (p, q)(t, E)$ into the integral for the area $A(E)$ enclosed by the orbit $(p, q)(t, E)$. The determinant of the Jacobian of this mapping is equal to one, and hence $dp\,dq = dtdE$. Thus we get

$$\text{(12)} \qquad A(E) = \int_{\{(p,q) | H(p,q) \leq E\}} dp\,dq = \int_0^E T(\widetilde{E})\, d\widetilde{E},$$

and hence $dA/dE = T$. In action-angle variables (J, ϕ), the Hamiltonian $H = H(J)$ depends only on the action J, and the equations of motion are

$$\text{(13)} \qquad \frac{dJ}{dt} = 0, \qquad \frac{d\phi}{dt} = \frac{dH}{dJ}.$$

From the obvious solution $\phi(t) = (dH/dJ)\, t + \text{const}$, we see that $dH/dJ = 2\pi/T(H)$ for the orbit with $H = E$. Hence

$$\text{(14)} \qquad \frac{dH}{dJ} T = \frac{dH}{dJ} \frac{dA}{dH} = 2\pi,$$

which shows that the Hamiltonian $H = H(J)$ has the inverse function $J = A(H)/(2\pi)$. Calculating the second derivative for an inverse function, we get

$$\text{(15)} \qquad \frac{d^2 H}{dJ^2} = -\frac{d^2 J}{dH^2} \left(\frac{dJ}{dH} \right)^{-3} = -\frac{4\pi^2}{T^3} \frac{dT}{dH}.$$

Hence the nondegeneracy assumptions can be expressed in terms of the energy-period function $T = T(E)$ as

$$\text{(16a)} \qquad \frac{dT(E_1)}{dE} \frac{dT(E - E_1)}{dE} \neq 0,$$

$$\text{(16b)} \qquad \frac{d \log T(E_1)}{dE} + \frac{d \log T(E - E_1)}{dE} \neq 0.$$

For the nondegeneracy assumption (16a) to hold for all E and E_1, it is obviously necessary that the energy-period function is strictly increasing or decreasing. For many examples, this can be checked by means of the criteria from this note. The isoenergetical nondegeneracy assumption states that for fixed total energy $E = E_1 + E_2$, the frequency ratio $T(E_1)/T(E - E_1)$ of the two uncoupled subsystems with index 1 and 2 has a nonvanishing derivative with respect to E_1.

Our second remark takes the point of view of classical equilibrium thermodynamics. Assume that system (2) is coupled to a large heat bath with inverse absolute temperature β. All quantities of equilibrium thermodynamics can be derived from the *canonical partition function* $Z(\beta)$ defined as

$$Z(\beta) = \int \exp\left(-\beta H(p,q)\right)\, dp\, dq. \tag{17}$$

For example, the mean value and variance of the energy $H(p,q)$ are

$$\langle H\rangle_{\text{can}} = -\frac{\partial \log Z(\beta)}{\partial \beta} \quad \text{and} \quad \text{Var}_{\text{can}} H = \frac{\partial^2 \log Z(\beta)}{\partial \beta^2}, \tag{18}$$

and the specific heat is $\beta^2 \text{Var}_{\text{can}} H$. (See, e.g., Becker [2, p. 127].)

We substitute the solutions $(p,q) = (p,q)(t,E)$ of system (2) into definition (17). Because the mapping $(t,E) \mapsto (p,q)$ is area preserving, we get

$$Z(\beta,\lambda,\mu) = \int_0^\infty e^{-\beta E} T(E,\lambda,\mu)\, dE, \tag{19}$$

which shows that the canonical partition function is the Laplace transform of the energy-period function. This connection allows us to get bounds for the mean energy and the specific heat as well. We quote a typical result: If assumption (8) holds for both functions f and g, then the mean energy is bounded below by $\langle H\rangle_{\text{can}} > \beta^{-1}$. This lower bound is the actual value for the harmonic oscillator.

Several authors (see Schaaf [15] for a survey and an extensive biography) have considered the energy-period function in order to find or exclude bending points in the bifurcation diagram of two point boundary value problems. The most simple example is the nonlinear elliptic Dirichlet boundary value problem

$$\begin{aligned} &u_{xx} + f(u) = 0 \quad \text{for all } x \in [0,T], \\ &u(0) = u(T) = 0. \end{aligned} \tag{20}$$

In the bifurcation diagram, the bifurcation parameter T is plotted against a norm of u. The differential equation in (20) is equivalent to a Hamiltonian system with the variables $q = u$ and $p = u_x$. The energy $E = u_x^2/2 + F(u)$ serves as a norm of u.

The *second* branch in the bifurcation diagram—corresponding to solutions of (20) with one sign change for $x \in (0,T)$—is just the plot of the energy-period function $T = T(E)$ with the axes interchanged. The part of the *first* branch corresponding to positive solutions of (20) comes from the plot of the energy-halfperiod function $T = T^+(E)$, defined via

(21)

$$\begin{aligned} q(T^+(E),E) = q(0,E) &= 0, \\ q(u,E) \geq 0 \quad \text{and} \quad \tfrac{1}{2}p^2(u,E) + F(q(u,E))) &= E \\ &\text{for all } E \in [0,\infty) \quad \text{and} \quad u \in [0,T^+(E)]. \end{aligned}$$

The other part of the first branch corresponds to negative solutions, for which we define $T^- = T^-(E)$ by reversing the sign of q in (21).

Satisfactory monotonicity criteria for the first branch are given by Chafee [5], Opial [11], Schaaf [15], and others. We mention them briefly in Proposition 4 below. The situation is much more complicated for the second branch. It is not always possible to conclude monotonicity of the second branch by applying the same criteria as for the first branch. Indeed, for many nonsymmetric systems with $f(-u) \neq -f(u)$, as, e.g., (20) with $f(u) = e^u - 1$, monotonicity of the period $T = T^+(E) + T^-(E)$ results after the cancelling of an increasing halfperiod T^- and a decreasing halfperiod T^+.

In this note, we give several criteria for monotonicity of the entire period $T = T(E)$. This corresponds to the second bifurcation branch of (20), which brings in additional difficulties. Different critera deal with them in different manners. We can aim at estimates for the second derivative $T''(E)$ as Schaaf in [14] and a variety of results in [15], and Chicone [3] have done. Or we can try to eliminate or reduce the asymmetry by substraction of suitable terms (e.g., linear terms of the force). This is the approach of Chow and Wang [4] and several new criteria in this note.

The present note assembles these results and states implications among them. Thus we prove that our new monotonicity criteria $f \in \mathfrak{f}_4^\pm$ or $F \in \mathfrak{F}_4^\pm$ are more general than Schaaf's criterion $f \in \mathfrak{f}_1^\pm$. But in concrete examples, the latter turns out to be the most useful criterion. Fortunately, we get some new results from the more stringent criteria involving the second derivative, too: new convexity properties of the energy-period functions and estimates of thermodynamic averages.

2. Notation and main results. We define some sets of functions appearing as right-hand sides of system (5) and as primitive functions of them, respectively.

DEFINITION 1. By $\mathfrak{f} \subset C^3(\mathbb{R}, \mathbb{R})$ we denote the set of all functions satisfying

$$(f0) \qquad f(0) = 0,\ f'(0) > 0 \ \text{ and } \ qf(q) > 0 \quad \text{for all } \ q \neq 0.$$

By $\mathfrak{n} \subset \mathfrak{f}$ we denote the set of all functions for which there exist $q_1 \in [-\infty, 0)$, $q_2 \in (0, \infty]$ such that

$$(n) \qquad \begin{aligned} f'(q) > 0 &\quad \text{for all } \ q \in (q_1, q_2)\,, \\ f'(q) < 0 &\quad \text{for all } \ q \in \mathbb{R} \setminus [q_1, q_2]\,. \end{aligned}$$

By $\mathfrak{m} \subset \mathfrak{n}$ we denote the set of all functions satisfying

$$(m) \qquad f(0) = 0 \ \text{ and } \ f'(q) > 0 \quad \text{for all } \ q \neq 0.$$

By $\mathfrak{F} \subset C^4(\mathbb{R}, \mathbb{R})$ we denote the set of all functions satisfying

$$(F0) \qquad F(0) = 0 \ \text{ and } \ F' \in \mathfrak{f}\,.$$

By $\mathfrak{M} \subset \mathfrak{F}$ we denote the set of all functions satisfying

$$(M) \qquad F(0) = 0 \ \text{ and } \ F' \in \mathfrak{m}\,.$$

We denote the differentiation operator by D. Obviously, $\mathfrak{m} \subset \mathfrak{n} \subset \mathfrak{f} = D\mathfrak{F}$ and $\mathfrak{m} = D\mathfrak{M}$. Next we define some sets of functions f and g giving rise to a monotonic energy-period function. We need the following functions:

$$(22) \qquad \begin{aligned} f_1 &\equiv 5f''^2 - 3f'f''', \\ f_4 &\equiv q\,[f_0''\,(3f'^2 - ff'') \, - 3f_0'^2 f''] \,, \end{aligned}$$

corresponding to the function f. The index zero denotes values at $q = 0$.

Definition 2. We define classes of functions related to increasing periods. By $\mathfrak{f}_1^+ \subset \mathfrak{m}$ we denote the set of all functions satisfying

$$(f1)^+ \qquad f'(q) > 0 \text{ and } f_1(q) > 0 \quad \text{for all } q \in \mathbb{R}.$$

By $\mathfrak{f}_2^+ \subset \mathfrak{n}$ we denote the set of all functions satisfying

$$(f2)^+ \qquad \begin{aligned} &f'(q) > 0 \text{ and } f_1(q) > 0 && \text{for all } q \in (q_1, q_2)\,, \\ &f'(q) < 0 \text{ and } f_4(q) > 0 && \text{for all } q \in \mathbb{R} \setminus [q_1, q_2]\,. \end{aligned}$$

By $\mathfrak{f}_3^+ \subset \mathfrak{n}$ we denote the set of all functions satisfying

$$(f3)^+ \qquad \begin{aligned} &f'(q) > 0 \text{ and } f_1(q) > 0 && \text{for all } q \in (q_1, q_2)\,, \\ &f'(q) < 0 && \text{for all } q \in \mathbb{R} \setminus [q_1, q_2]\,. \end{aligned}$$

By $\mathfrak{f}_4^+ \subset \mathfrak{n}$ we denote the set of all functions satisfying

$$(f4)^+ \qquad \begin{aligned} &f'(q) > 0 \text{ and } f_4(q) > 0 && \text{for all } q \in (q_1, 0) \cup (0, q_2)\,, \\ &f'(q) < 0 && \text{for all } q \in \mathbb{R} \setminus [q_1, q_2]\,. \end{aligned}$$

The classes $(\overline{f1})^+$ through $(\overline{f4})^+$ of functions corresponding to nondecreasing periods are defined by replacing in $(f1)^+$ through $(f4)^+$ the assumptions $f_1(q) > 0$ and $f_4(q) > 0$ by $f_1(q) \geq 0$ and $f_4(q) \geq 0$.

Definition 3. We define the following classes of functions related to decreasing periods. For $i = 1$ and $i = 4$ we denote by $\mathfrak{f}_i^- \subset \mathfrak{m}$ the set of all functions satisfying

$$(fi)^- \qquad f'(q) > 0 \quad \text{for all } q \in \mathbb{R} \text{ and } f_i(q) < 0 \quad \text{for all } q \neq 0.$$

For $i = 1$ and $i = 4$ we denote by $\bar{\mathfrak{f}}_i^- \subset \mathfrak{m}$ the set of all functions satisfying

$$(\overline{fi})^- \qquad f'(q) > 0 \quad \text{for all } q \in \mathbb{R} \text{ and } f_i(q) \leq 0 \quad \text{for all } q \in \mathbb{R}.$$

Corresponding to the potential F, we define the functions

$$\begin{aligned} F_1 &\equiv 2F\,(3f'^2 - ff'') \,-\, 3f^2 f'\,, \\ F_2 &\equiv \left[1 + \tfrac{1}{3} f_0'' f_0'^{-2} f\right] \left[F\,(3f'^2 - ff'') \,-\, f^2 f'\right] \,-\, F f'^2\,, \\ F_3 &\equiv f_0'^{-1/2} \,-\, (2F)^{3/2} f^{-3} f'\,, \\ F_4 &\equiv 3 f_0'^2\,(f^2 - 2Ff') \,+\, f_0'' f^3\,, \\ F_5 &\equiv f_0'^2 f^6 f' F_4 + (2F)^{3/2} F_1\,. \end{aligned} \tag{23}$$

Definition 4. The following classes of potentials $F = F(q)$ correspond to monotonic periods. For $i = 1, 2, 3, 4$, we denote by $\mathfrak{F}_i^+ \subset \mathfrak{F}$ the set of all functions satisfying

$$(Fi)^+ \qquad F_i(q) > 0 \quad \text{for all } q \neq 0\,.$$

By $\mathfrak{F}_5^+ \subset \mathfrak{F}$ we denote the set of all functions for which there exist $q_1 \in [-\infty, 0)$, $q_2 \in (0, \infty]$ such that $f = F'$ satisfies

$$(F5)^+ \qquad \begin{aligned} &f'(q) > 0 \text{ and } F_5(q) > 0 && \text{for all } q \in (q_1, 0) \cup (0, q_2)\,, \\ &f'(q) < 0 && \text{for all } q \in \mathbb{R} \setminus [q_1, q_2]\,. \end{aligned}$$

For $i = 1, 2, 3, 4$, we denote by $\mathfrak{F}_i^- \subset \mathfrak{F}$ the set of all functions satisfying

$$(Fi)^- \qquad F_i(q) < 0 \quad \text{for all } q \neq 0\,.$$

The classes $(\overline{Fi})^-$ for $i = 1, 2, 3, 4$ are defined by including the equality sign in the assumptions for $F_i(q)$.

DEFINITION 5. The following classes of functions are related to increasing half-periods. By $\mathfrak{h}_1^+ \subset \mathfrak{f}$ we denote the set of all functions in $\mathfrak{f}$ such that

$$(h1)^+ \qquad qf''(q) < 0 \quad \text{for all } q \neq 0 .$$

By $\mathfrak{H}_1^+ \subset \mathfrak{F}$ we denote the set of all functions in $\mathfrak{F}$ such that

$$(H1)^+ \qquad f^2 - 2Ff' > 0 \quad \text{for all } q \neq 0 .$$

By $\mathfrak{h}_2^+ \subset \mathfrak{f}$ we denote the set of all functions in $\mathfrak{f}$ such that

$$(h2)^+ \qquad q\frac{d}{dq}\frac{f(q)}{q} < 0 \quad \text{for all } q \neq 0 .$$

Finally, let

$$(h3)^+ \qquad \mathfrak{h}_3^+ \equiv D\mathfrak{H}_1^+ .$$

Remark. Some of the classes $\mathfrak{F}_i$, $\mathfrak{f}_i$, and $\mathfrak{h}_i$ have been introduced by a variety of different authors; some seem to be new.

(1) In the investigation of the bifurcation for the nonlinear Dirichlet boundary value problem (20), the class $\mathfrak{h}_1^+$ was introduced by Chafee [5] and Hale [6] and the class $\mathfrak{h}_2^\pm$ by Opial [11];

(2) For all functions in the class $\mathfrak{h}_1^+$ and C^2-functions in the class $\mathfrak{h}_3^+$, necessarily $f''(0) = 0$ holds. This rather severe restriction does not hold for typical asymmetric systems as (20) with $f(u) = e^u - 1$ below;

(3) The functional f_1 was introduced by Schaaf already in [14];

(4) The functional F_1 is used by Chicone [3] in the form $F_1 = f^4\,(F\,f^{-2})''$;

(5) The functional F_4 is introduced by Chow and Wang [4].

THEOREM 1. *The following inclusions hold among the sets of functions from Definitions* 2 *and* 4:

$$\begin{gathered}
\mathfrak{f}_i^+ \subset D\mathfrak{F}_i^+ \qquad \textit{for } i = 1,2,3,4 \\
\mathfrak{f}_1^+ \subset \mathfrak{f}_3^+ \subset \mathfrak{f}_4^+ \supset \mathfrak{f}_2^+ \supset \mathfrak{f}_1^+ \\
\mathfrak{F}_1^+ \subset \mathfrak{F}_3^+ \subset \mathfrak{F}_4^+ \supset \mathfrak{F}_2^+ \supset \mathfrak{F}_1^+ \cap \mathfrak{M} \\
\mathfrak{F}_5^+ \subset \mathfrak{F}_4^+ \\
\mathfrak{h}_1^+ \subset \mathfrak{f}_4^+ \cap \{\, f \mid f''(0) = 0 \,\} \\
\mathfrak{H}_1^+ \subset \mathfrak{F}_4^+ \cap \{\, f \mid f''(0) = 0 \,\}.
\end{gathered}$$

Assume for system (5) *that both functions f and g are contained in $D\mathfrak{F}_4^+$ and $\lambda, \mu > 0$.*

Then the energy-period function $T = T(E, \lambda, \mu)$ is increasing in E and satisfies $\partial T/\partial E > 0$ for all $E > 0$. The mean energy for the canonical ensemble given by (18) *is bounded below by $\langle H\rangle_{\text{can}} > \beta^{-1}$ for all inverse temperatures $\beta > 0$. If the functions f and g are contained in $D\overline{\mathfrak{F}}_4^+$, then the corresponding inequalities including equality hold.*

Remarks. (1) One way to set up a system with constant periods is to look for the borderline case of a potential $F \in \mathfrak{F}$ and force $f = F'$ such that either one of the six assumptions $F_i(q) = 0$ for $i = 1,2,3,4$ or $f_1(q) = 0$ or $f_4(q) = 0$ holds identically for all $q \in \mathbb{R}$. Solving the corresponding ordinary differential equations yields an explicit expression for the function F. From all six assumptions we get

$$F(q) = 9f'^3(0)f''^{-2}(0)\left[1 - \tfrac{1}{3}f''(0)f'^{-1}(0)\,q - \sqrt{1 - \tfrac{2}{3}f''(0)f'^{-1}(0)\,q}\right] \tag{24a}$$

in case $f''(0) \neq 0$ and

$$F(q) = \tfrac{1}{2}f'(0)q^2 \tag{24b}$$

in case $f''(0) = 0$. In the limit $f''(0) \to 0$, $F(q)$ of formula (24a) approaches (24b).

(2) Of course, there exist other systems with a center that has constant periods of oscillation. Loud [8] solves this problem for quadratic systems. Obi [10] gives a criterion for constant periods for system (6).

(3) The first terms of the Taylor expansion of the energy-period function in terms of the variable E can be calculated using normal forms, methods from bifurcation theory or the Laplace transform technique introduced below. We get

$$T(0, \lambda, \mu) = 2\pi\,(\lambda\mu f'(0)g'(0))^{-1/2} \tag{25a}$$

$$\begin{aligned} T'(0, \lambda, \mu) &= \frac{T(0, \lambda, \mu)}{24\lambda\mu}\left[\frac{5f''^2(0) - 3f'(0)f'''(0)}{f'^3(0)} + \frac{5g''^2(0) - 3g'(0)g'''(0)}{g'^3(0)}\right] \\ &= \frac{T(0, \lambda, \mu)}{24\lambda\mu}\left[\frac{f_1(0)}{f'^3(0)} + \frac{g_1(0)}{g'^3(0)}\right], \end{aligned} \tag{25b}$$

which gives the motivation to consider the quantity f_1.

(4) As a simple specific example, we get the expansion of the energy-period function for *Duffing's equation*

$$\frac{d^2x}{dt^2} + x + \beta x = 0. \tag{26}$$

It is equivalent to a Hamiltonian system (6) with $f(q) = q + \beta q^3$. Since $f'(0) = g'(0) = 1$, $g_1(p) \equiv 0$ and $f_1(q) \equiv -18\beta$, (25a) and (25b) yield the expansion

$$T(E) = 2\pi - \frac{3\pi}{2}\beta E + o(E). \tag{27}$$

This was derived by Loud [8] with a different approach.

THEOREM 2. *For the sets of functions from Definitions* 3 *and* 4, *the following inclusions hold*:

$$\mathfrak{f}_i^- \subset D\mathfrak{F}_i^- \quad \textit{for } i = 1 \textit{ and } 4,$$

$$\mathfrak{F}_1^- \subset \mathfrak{F}_3^- \subset \mathfrak{F}_4^- \supset \mathfrak{F}_2^- .$$

Assume for system (5) *that both functions f and g are contained in $D\mathfrak{F}_4^-$ and $\lambda, \mu > 0$.*

Then the energy-period function $T = T(E, \lambda, \mu)$ is decreasing in E and satisfies $\partial T/\partial E < 0$ for all $E > 0$. The mean energy for the canonical ensemble given by (18) *is bounded above by $\langle H \rangle_{\text{can}} < \beta^{-1}$ for all inverse temperatures $\beta > 0$. If the functions f and g are contained in $D\overline{\mathfrak{F}}_4^-$, then the corresponding inequalities including equality hold.*

The following theorem, based on more restrictive assumptions, deals with the dependence of the energy-period function and other quantities on the parameters λ and μ. It generalizes the results for the Volterra system from Rothe [13]. The indefinite integral of the energy-period function is denoted by

$$A(E, \lambda, \mu) = \int_0^E T(\widetilde{E}, \lambda, \mu)\, d\widetilde{E}. \tag{28}$$

It is equal to the area enclosed by the orbit $(p, q)(t, E, \lambda, \mu)$ in the (p, q)-plane.

THEOREM 3. *Assume for system* (5) *that both functions* f *and* g *are contained in* $D\mathfrak{F}_2^+$ *and* $\lambda, \mu > 0$. *Then the energy-period function* $T = T(E, \lambda, \mu)$ *and its integral* $A(E, \lambda, \mu)$ *have the following qualitative properties*:

$$\frac{\partial T}{\partial E} > 0 \quad \text{for all } E > 0, \tag{29}$$

$$\frac{\partial}{\partial E}\left(\frac{E}{T}\frac{\partial T}{\partial E}\right) > 0 \quad \text{for all } E > 0. \tag{30}$$

The functions

$$(\log(E/\lambda), \log(E/\mu)) \mapsto \log\left[ET(E, \lambda, \mu)\right], \tag{31}$$

$$(\log(E/\lambda), \log(E/\mu)) \mapsto \log A(E, \lambda, \mu) \tag{32}$$

are well defined and strictly convex on their entire domain of definition $\mathbb{R}^2$. *For the canonical ensemble with any inverse temperatures* $\beta > 0$, *the mean energy* $\langle H\rangle_{\text{can}}$ *and the specific heat* $\beta^2\text{Var}_{\text{can}}H$ *are bounded below by*

$$\beta^2\text{Var}_{\text{can}}H > \beta\langle H\rangle_{\text{can}} > 1. \tag{33}$$

Assume, furthermore, that $f'(q) > 0$ *for all* $q \in \mathbb{R}$ *and* $g'(q) > 0$ *for all* $q \in \mathbb{R}$. *Then for all* $\lambda, \mu > 0$ *and* $E \geq 0$, *we get further conclusions*:

$$\frac{\partial T}{\partial E} < \frac{T}{E}. \tag{34}$$

The limit $\lim_{E\to\infty} T'(E, \lambda, \mu) = T'(\infty, \lambda, \mu)$ *exists and*

$$ET'(\infty, \lambda, \mu) < T(E, \lambda, \mu) < T(0, \lambda, \mu) + ET'(\infty, \lambda, \mu) + o(E, \lambda, \mu), \tag{35}$$

where $\lim_{E\to\infty} o(E, \lambda, \mu) = 0$.

The orbital averages of the two summands of the Hamiltonian

$$\langle F(q)\rangle_{H=E} \equiv \frac{1}{T}\int_0^T F(q(t, E, \lambda, \mu))\, dt, \tag{36}$$

$$\langle G(p)\rangle_{H=E} \equiv \frac{1}{T}\int_0^T G(p(t, E, \lambda, \mu))\, dt \tag{37}$$

have a ratio in the range $[\frac{1}{2}, 2]$.

Remarks.

(1) For the harmonic oscillator with $f(q) = q$ and $g(p) = p$, formula (33) holds with equality signs.

(2) In the examples of classical mechanics (36) and (37) are the mean potential and kinetic energy. Hence we have shown equipartition of energy up to the factor of 2.

(3) A result similar to (30) is given by Theorem 1.4.2 of Schaaf [15] for the Dirichlet boundary value problem (20). Schaaf considers the period T as a function of the independent variable $p = \sqrt{2E}$. Under the assumption that f is an A-B-functions

(which holds for $f \in f_1{}^+$), Schaaf proves $d^2T/dp^2 > 0$ for all p. Conversion to the independent variable E via $d^2T/dp^2 = 2ET''(E) + T'(E)$ yields

$$\text{(S)} \qquad \frac{ET''}{T'} > -\frac{1}{2},$$

whereas (30) from above is equivalent to

$$\text{(R)} \qquad \frac{ET''}{T'} > \frac{ET'}{T} - 1.$$

We want to compare (R) and (S). In general, neither one implies the other. Indeed, take (20) and let $f(u) = e^u - 1$. For $E \to 0$, the right-hand side of (R) tends to -1, and hence (S) is stronger than (R). For $E \to \infty$, (34) and (35) imply that the right-hand side of (R) tends to zero. Hence (R) is stronger than (S).

PROPOSITION 4. *The following inclusions hold among the sets of functions from Definition* 5:

$$\mathfrak{h}_1^+ \cup \mathfrak{h}_3^+ \subset \mathfrak{h}_2^+.$$

Proof. The inclusion $\mathfrak{h}_1^+ \subset \mathfrak{h}_2^+$ is straightforward to prove using $(uf' - f)' = uf''$. We give the detailed proof that $\mathfrak{h}_3^+ \subset \mathfrak{h}_2^+$. Let $f \in \mathfrak{h}_3^+$ be given. The function $g = \sqrt{F}$ has the first derivative $g' = f/(2\sqrt{F})$ and the second derivative $g'' = (2Ff' - f^2)/(4\sqrt{F}^3) < 0$, which is negative since $f \in \mathfrak{h}_2^+$. Hence

$$(38) \qquad (uf' - f) = 2ugg'' + 2g'(ug' - g).$$

From l'Hôpital's rule, we calculate

$$(39) \qquad \lim_{u\to 0}(ug' - g) = \lim_{u\to 0} \frac{uf - 2F}{2\sqrt{F}} = \lim_{u\to 0} \frac{uf' - f}{(f/\sqrt{F})} = 0,$$

and hence

$$(40) \qquad (ug' - g) = \int_0^u sg''(s)\,ds.$$

Finally, (38), (39), and (40) imply the result, since

$$(41) \qquad (uf' - f) = 2ug'' + 2g' \int_0^u sg''(s)\,ds < 0.$$

3. Proof of Theorems 1 and 2. We define the functions $q = q_f(x)$ and $p = q_g(y)$ such that in the (noncanonical) coordinates (x, y), the orbits of system (5) are transformed into ellipses. The relevant transformation $q = q_f(x)$ depends only on the function f. The corresponding transformation $p = q_g(y)$ depending on the function g defines the second coordinate y.

The function $x \mapsto q_f(x)$ is uniquely defined by the requirements

$$(42) \qquad F(q_f(x)) = \tfrac{1}{2}x^2 \quad \text{and} \quad xq_f(x) \geq 0 \quad \text{for all } x \in \mathbb{R}.$$

Obviously $(F0)$ implies that $q_f(x) > 0$ is equivalent to $x > 0$, $q_f(x) = 0$ is equivalent to $x = 0$, and $q_f(x) < 0$ is equivalent to $x < 0$.

Furthermore, we introduce the functions $t_f(x)$ and $s_f(x)$ defined by

$$t_f(x) = \frac{dq_f(x)}{dx} \quad \text{and} \quad s_f(x) = \frac{t_f(x) + t_f(-x)}{2}, \tag{43}$$

as well as the analogous functions $t_g(y)$ and $s_g(y)$.

Differentiating (42) by x and solving for the derivatives of the function t_f yields the identities

$$f\left(q_f(8x)\right) t_f(x) = x, \tag{44}$$

$$f^3\left(q_f(x)\right) \frac{d t_f(x)}{dx} = f^2\left(q(x)\right) - 2F\left(q(x)\right) f'\left(q(x)\right), \tag{45}$$

$$\frac{f^5\left(q_f(x)\right)}{x} \frac{d^2 t_f(x)}{dx^2} = F_1\left(q(x)\right). \tag{46}$$

Especially $(f0)$ and (44) imply $t_f(x) > 0$ for all $x \neq 0$. Hence the function $q = q_f(x)$ is strictly increasing and the new coordinates (x, y) are well defined. Indeed $f'(0) > 0$ and (58) below imply that $t_f(0) > 0$ holds, too.

LEMMA 1. *In the new coordinates, system* (5) *is transformed to*

$$\begin{aligned} \frac{dx}{dt} &= \frac{\mu}{t_f(x) t_g(y)} y, \\ \frac{dy}{dt} &= -\frac{\lambda}{t_f(x) t_g(y)} x. \end{aligned} \tag{47}$$

The Hamiltonian given by (4) is a constant of motion which we call *energy* and denote by E. Transformed to the (x, y)-coordinates it is

$$E = H(p, q) = \lambda F(q) + \mu G(p) = \lambda \tfrac{1}{2} x^2 + \mu \tfrac{1}{2} y^2, \tag{48}$$

from which we see that the orbits of (47) are ellipses. In the (x, y)-plane, we use polar coordinates (E, φ) defined by

$$x = \sqrt{\frac{2E}{\lambda}} \cos\varphi, \qquad y = \sqrt{\frac{2E}{\mu}} \sin\varphi. \tag{49}$$

The equations of motion (47) transform to

$$\frac{d\varphi}{dt} = -\frac{\sqrt{\lambda\mu}}{t_f\left(\sqrt{2E/\lambda} \cos\varphi\right) t_g\left(\sqrt{2E/\mu} \sin\varphi\right)}, \tag{50}$$

which yields the following lemma, going back to Waldvogel [17] and Schaaf [14].

LEMMA 2. *The energy-period function of system* (5) *is*

$$T(E, \lambda, \mu) = (\lambda\mu)^{-1/2} \int_0^{2\pi} t_f\left(\sqrt{\frac{2E}{\lambda}} \cos\varphi\right) t_g\left(\sqrt{\frac{2E}{\mu}} \sin\varphi\right) d\varphi. \tag{51}$$

Remark. Formula (51) contains rather detailed information about the temporal structure of the oscillations. We divide the (p, q)-plane into the four quadrants $\{ q >$

$0, p > 0\}$, $\{q > 0, p < 0\}$, $\{q < 0, p < 0\}$, and $\{q < 0, p > 0\}$ and denote by T^{++}, T^{+-}, T^{--}, and T^{-+}, the parts of the period for which the orbits is in the four quadrants. With the same integrand a as in (51), we get

$$T^{++}(E,\lambda,\mu) = \int_0^{\pi/2} a\,d\varphi, \qquad T^{-+}(E,\lambda,\mu) = \int_{\pi/2}^{\pi} a\,d\varphi, \tag{52}$$

$$T^{--}(E,\lambda,\mu) = \int_{\pi}^{3\pi/2} a\,d\varphi, \qquad T^{+-}(E,\lambda,\mu) = \int_{3\pi/2}^{2\pi} a\,d\varphi. \tag{53}$$

For system (5) with nonsymmetric force f or g—as for example the Volterra system (1)—it may well happen that the energy-period function $T(E)$ is monotone increasing although some of the functions T^{++}, T^{+-}, T^{-+}, or T^{--} are not.

In (43) we have already introduced the function $s_f(x)$ in terms of which (51) can be rewritten as

$$T(E,\lambda,\mu) = 4\,(\lambda\mu)^{-1/2} \int_0^{\pi/2} s_f\left(\sqrt{\frac{2E}{\lambda}}\cos\varphi\right) s_g\left(\sqrt{\frac{2E}{\mu}}\sin\varphi\right) d\varphi. \tag{54}$$

Differentiating formula (54) by E yields the following.

LEMMA 3. *The derivative of the energy-period function is*

$$\frac{\partial T(E,\lambda,\mu)}{\partial E} = 4\,(\lambda\mu)^{-1/2} \int_0^{\pi/2} b\,d\varphi \quad \textit{with} \tag{55}$$

$$b = \frac{s_f{}'\left(\sqrt{\frac{2E}{\lambda}}\cos\varphi\right)}{\sqrt{\frac{2E}{\lambda}}\cos\varphi}\, s_g\left(\sqrt{\frac{2E}{\mu}}\sin\varphi\right)\cos^2\varphi + s_f\left(\sqrt{\frac{2E}{\lambda}}\cos\varphi\right) \frac{s_g'\left(\sqrt{\frac{2E}{\mu}}\sin\varphi\right)}{\sqrt{\frac{2E}{\mu}}\sin\varphi}\,\sin^2\varphi.$$

Formula (55) is the main tool of our proof. To begin with, we consider the special case $E = 0$ for which formulas (54) and (55) imply

$$T(0,\lambda,\mu) = 2\pi\,(\lambda\mu)^{-1/2}\, s_f(0)s_g(0), \tag{56}$$

$$\frac{\partial T(0,\lambda,\mu)}{\partial E} = \pi\,(\lambda\mu)^{-1/2}\left[s_f{}''(0)s_g(0) + s_f(0)s_g''(0)\right], \tag{57}$$

where we have used l'Hôpital's rule to get $\lim_{x\to 0+}(s_f(x))/x = s_f{}''(0)$. To express $s_f(0), s_f{}''(0)$ and $t_f(0), t_f{}'(0), t_f{}''(0)$ in terms of the function f and its derivatives, we solve formulas (44), (45), and (46) by the latter quantities and apply l'Hôpital's rule several times. For example,

$$t_f(0) = \lim_{x\to 0+} t_f(x) = \lim_{x\to 0+} \frac{x}{f\left(q_f(x)\right)}.$$

For this $\frac{0}{0}$-limit, l'Hôpital's rule gives

$$= \lim_{x\to 0+} \frac{1}{f'(q_f(x))\,q_f{}'(x)} = \frac{1}{f'(0)q_f{}'(0)}.$$

Since $t_f = q_f{}'$ by definition, we can solve for $t_f(0)$. Similar, but even longer calculations yield the derivatives $t_f{}'(0)$ and $t_f{}''(0)$. Finally, we end up with

$$t_f(0) = \frac{1}{\sqrt{f'(0)}}, \tag{58}$$

$$t_f{}'(0) = -\frac{f''(0)}{3f'^2(0)}, \tag{59}$$

$$t_f{}''(0) = \frac{5f''^2(0) - 3f'(0)f'''(0)}{12f'^{7/2}(0)} = \frac{f_1(0)}{12f'^{7/2}(0)}. \tag{60}$$

Plugging (58) and (60) into the formulas (56) for $T(0,\lambda,\mu)$ and (57) for $\partial T(0,\lambda,\mu)/\partial E$ yields (25a) and (25b).

We come to the main part of the proof based on (55) for $E > 0$. The monotonicity results all rely on the property

$$s_f{}'(x) > 0 \quad \text{for all} \quad x > 0, \tag{$(s)^+$}$$

which we shall conclude from the primary assumptions of Theorem 1. Obviously, if $(s)^+$ holds for both functions f and g, then the energy-period function $T = T(E,\lambda,\mu)$ satisfies $(\partial T/\partial E) > 0$ for all $E > 0$, and hence is increasing in E. The further discussion involves the following assumptions for the functions t_f or t_g:

$$t_f(x) - xt_f{}'(x) > 0 \quad \text{for all } x \in \mathbb{R}, \tag{$(t0)$}$$

$$t_f{}''(x) > 0 \quad \text{for all } x \neq 0, \tag{$(t1)^+$}$$

$$x\frac{d}{dx}\frac{xt_f{}'(x) - xt_f{}'(0)}{t_f(x) - xt_f{}'(0)} > 0 \quad \text{for all } x \neq 0, \tag{$(t2)^+$}$$

$$t_f(x) - xt_f{}'(x) < t_f(0) \quad \text{for all } x \neq 0, \tag{$(t3)^+$}$$

$$xt_f{}'(x) - xt_f{}'(0) > 0 \quad \text{for all } x \neq 0, \tag{$(t4)^+$}$$

$$\begin{gathered} t_f(x) - xt_f{}'(x) > 0 \quad \text{and} \quad x \neq 0 \quad \text{imply} \\ 3x(t_f'(x) - t_f'(0))\,(t_f(x) - xt_f{}'(x)) + x^2 t_f(x)t_f{}''(x) > 0. \end{gathered} \tag{$(t5)^+$}$$

Assumptions $(t1)^-$, $(t2)^-$, $(t3)^-$, and $(t4)^-$ are defined by the reversed inequalities, whereas $(si)^+$ and $(si)^-$ with $i = 0, 1, 2, 3, 4, 5$ denote the corresponding assumptions for the function s_f.

LEMMA 4. *Take a function $f \in \mathfrak{f}$. Then the following implications hold:*

$$(t1)^+ \implies (t3)^+ \implies (t4)^+ \implies (s)^+, \tag{61}$$

$$(t2)^+ \implies (t4)^+ \implies (s)^+, \tag{62}$$

$$(t1)^+ \quad \text{and} \quad (t0) \implies (t2)^+. \tag{63}$$

Proof of Lemma 4. We begin proving (61). The implication $(t1)^+ \Rightarrow (t3)^+$ is easy to get from $(t_f(x) - xt_f(x)')' = -xt_f(x)''$.

To prove $(t3)^+ \Rightarrow (t4)^+$, we use $x^2\ [(t_f(x) - t_f(0))/x]\ ' = t_f(0) - [t_f(x) - xt_f(x)']$. Indeed, $(t3)^+$ implies that the function $x \in (0,\infty) \mapsto (t_f(x) - t_f(0))/x$ is strictly increasing, and hence $t_f{}'(0) = \lim_{y\to 0}[(t_f(y) - t_f(0))/y] < [(t_f(x) - t_f(0))/x]$ for all $x > 0$. Together with a similar reasoning for $x < 0$, this yields $(t4)^+$.

The final implication $(t4)^+ \Rightarrow (s)^+$ arises by adding $(t4)^+$ to the corresponding inequality with x replaced by $-x$. Thus (61) is proved. We omit the more straightforward proof of (62).

To show (63), we assume that both $(t1)^+$and $(t0)$ hold. We define $\bar t_f(x) = t_f(x) - xt_f(0)$ and use the identity

$$x\bar t_f^2 \frac{d}{dx}\left(\frac{x\bar t_f{}'}{\bar t_f}\right) = x^2\,\bar t_f\bar t_f{}'' + x\bar t_f{}'\left(\bar t_f - x\bar t_f{}'\right). \tag{64}$$

We show that the right-hand side of (64) is positive for all $x > 0$. Indeed, $\bar t_f{}'' = t_f{}'' > 0$ by assumption $(t1)^+$, and hence $\bar t_f(x) > t_f(0)$ for all $x \neq 0$. Further on, $\bar t_f - x\bar t_f{}' = t_f - xt_f{}' > 0$ by assumption $(t0)$ and $x\bar t_f{}'(x) > 0$ for all $x \neq 0$ because of $(t4)^+$. Thus the right-hand side of (64) is positive for all $x > 0$, and hence the identity (64) implies $(t2)^+$ with $x > 0$. A similar reasoning applies to the case $x < 0$. □

LEMMA 5. *Assume* $f \in \mathfrak{n}$. *Then* $(t5)^+$ *implies* $(t4)^+$.

Proof. Since $f \in \mathfrak{n}$, there exist $q_1 \in [-\infty, 0)$ and $q_2 \in (0,\infty]$ such that

$$\begin{aligned} &f'(q) > 0 \quad \text{for all } q \in (q_1, q_2),\\ &f'(q) < 0 \quad \text{for all } q \in \mathbb{R} \setminus [q_1, q_2]. \end{aligned} \tag{n}$$

Let $x_1 \in [-\infty, 0)$ and $x_2 \in (0, \infty]$ correspond to q_1 and q_2 from assumption (n) via $q_f(x_i) = q_i$ for $i = 1, 2$. In the following argument we distinguish the cases

(a) $x \in [x_1, 0) \cup (0, x_2]$,

(b) $x \in (-\infty, x_1) \cup (x_2, \infty)$.

For $x \in [x_1, 0) \cup (0, x_2]$, the assumption $f \in \mathfrak{n}$ yields

$$\bar t_f - x\bar t_f{}' = t_t - xt_f{}' = (2F)^{3/2} f^{-3} f' > 0;$$

hence

$$\frac{1}{x}\frac{d}{dx}\left(\frac{x^3\,\bar t_f{}'}{\bar t_f - x\bar t_f{}'}\right) = \frac{x^2\,\bar t_f\bar t_f{}'' + 3x\bar t_f{}'\left(\bar t_f - x\bar t_f{}'\right)}{\left(\bar t_f - x\bar t_f{}'\right)^2} > 0, \tag{65}$$

and finally

$$x\bar t_f{}'(x) > 0 \quad \text{for all} \quad x \in [x_1, 0) \cup (0, x_2]. \tag{66}$$

Especially, $x_i\bar t_f{}'(x_i) = \bar t_f(x_i) > \bar t_f(0) > 0$ for $i = 1$ and $i = 2$. Now we turn to the case $x \in (-\infty, x_1) \cup (x_2, \infty)$. From (n) we get

$$x^2 \frac{d}{dx}\left(\frac{\bar t_f}{x}\right) = \bar t_f - x\bar t_f{}' = t_t - xt_f{}' = (2F)^{3/2} f^{-3} f' < 0, \tag{67}$$

implying

$$x\bar t_f{}'(x) > \bar t_f(x) > x\bar t_f(x_i)/x_i > 0 \quad \text{for all } x \in (-\infty, x_1) \cup (x_2, \infty). \tag{68}$$

Together, formula (66) and (68) imply

$$x\bar t_f{}'(x) = x\left(t_f{}'(x) - t_f{}'(0)\right) > 0$$

for all $x \neq 0$ proving $(t4)^+$. □

LEMMA 6. *Take a function $f \in \mathfrak{f}$. Then the following implications hold:*

$$(t1)^- \Longrightarrow (t3)^- \Longrightarrow (t4)^- \Longrightarrow (s)^-, \tag{69}$$

$$(t1)^- \Longrightarrow (s1)^- \Longrightarrow (s2)^- \Longrightarrow (s3)^- \Longrightarrow (s)^-. \tag{70}$$

We omit the proof, which is analogous to Lemma 4. Note that in each of the assumptions (ti) with $i = 1, 2, 3, 4$, equality for all $x \in \mathbb{R}$ holds if and only if we have the linear function $t_f(x) = t_f(0) + xt_f{}'(0)$.

The next step is to restate assumptions (ti) with $i = 1, 2, 3, 4$ in terms of the original function f and its primitive F.

LEMMA 7. *Take any $F \in \mathfrak{F}$, and let $f = F'$. Then*

(1) *$(t0)$ holds if and only if $f \in \mathfrak{m}$;*

(2) *For $i = 1, 2, 3, 4, 5$ assumption $(ti)^+$ holds if and only if $F \in \mathfrak{F}_i^+$ and the corresponding assumption including equality holds if and only if $F \in \overline{\mathfrak{F}}_i^{+}$;*

(3) *For $i = 1, 2, 3, 4$ assumption $(ti)^-$ holds if and only if $F \in \mathfrak{F}_i^-$ and the corresponding assumption including equality holds if and only if $F \in \overline{\mathfrak{F}}_i^{-}$.*

Proof. Recall $\bar{t}_f(x) = t_f(x) - xt_f(0)$, and let $q = q_f(x)$. Some lengthy calculations involving relations (44), (45), (46) and (58), (59), (60) yield the identities

$$t_f(x) - xt_f{}'(x) = (2F(q))^{3/2} f(q)^{-3} f'(q), \tag{$tF0$}$$

$$t_f{}''(x) = (2F(q))^{1/2} f(q)^{-5} F_1(q), \tag{$tF1$}$$

$$x\bar{t}_f^2 \frac{d}{dx}\left(\frac{x\bar{t}_f{}'}{\bar{t}_f}\right) = x^2 \bar{t}_f \bar{t}_f{}'' + x\bar{t}_f{}' \left(\bar{t}_f - x\bar{t}_f{}'\right) = 8F^2(q) f^{-6}(q) F_2(q), \tag{$tF2$}$$

$$t_f(0) - t_f(x) + xt_f{}'(x) = F_3(q), \tag{$tF3$}$$

$$x\bar{t}_f{}'(x) = xt_f{}'(x) - xt_f{}'(0) = \tfrac{1}{3} f'^2(0) f^3(q) F_4(q), \tag{$tF4$}$$

from which the lemma can be read off. □

LEMMA 8. *Let $F \in \mathfrak{F}$, $f = F'$, and $i = 1, 2, 3, 4$. Under that general assumption, $f \in \mathfrak{f}_i^+$ implies $(ti)^+$, and hence $F \in \mathfrak{F}_i^+$.*

Proof. We need the identities

$$\frac{d}{dq}\left(\frac{F_1(q)}{f'^{\,5/3}(q)}\right) = \frac{2F(q)f(q)}{3f'^{\,8/3}(q)} f_1(q), \tag{71}$$

$$\frac{d}{dq}\left(\frac{F_4(q)}{f'(q)}\right) = \frac{f^2(q)}{f'^2(q)} f_4(q). \tag{72}$$

To begin with, we give the proof for the case $i = 4$. Assume that $f \in \mathfrak{f}_4^+$. By Definition 2, there exist $q_1 \in [-\infty, 0)$ and $q_2 \in (0, \infty]$ such that

(a) $f'(q) > 0$ and $f_4(q) > 0$ for all $q \in (q_1, 0) \cup (0, q_2)$;

(b) $f'(q) < 0$ for all $q \in \mathbb{R} \setminus [q_1, q_2]$.

Let $x_1 \in [-\infty, 0)$ and $x_2 \in (0, \infty]$ correspond to q_1 and q_2 via $q_f(x_i) = q_i$ for $i = 1, 2$. At first, we consider item (a). From the identity (72) we get $F_4(q) > 0$ for all $q \in (q_1, 0) \cup (0, q_2)$, and hence identity $(tF4)$ implies

$$x\bar{t}_f{}'(x) > 0 \quad \text{for all} \quad x \in (x_1, 0) \cup (0, x_2). \tag{73}$$

Now consider item (b). From $(tF0)$ we conclude $\bar{t}_f(x) - x\bar{t}_f{}'(x) < 0$, and hence

$$x\bar{t}_f{}'(x) > \bar{t}_f(x) > 0 \quad \text{for all} \quad x \in (-\infty, x_1) \cup (x_2, \infty). \tag{74}$$

Since $x\bar{t}_f{}'(x) = xt_f{}'(x) - xt_f{}'(0)$, (73), (74) imply $(t4)^+$.

To give the proof for the case $i = 3$, assume that $f \in \mathfrak{f}_3^+$. By Definition 2, there exist $q_1 \in [-\infty, 0)$ and $q_2 \in (0, \infty]$ such that

(a) $f'(q) > 0$ and $f_1(q) > 0$ for all $q \in (q_1, 0) \cup (0, q_2)$;

(b) $f'(q) < 0$ for all $q \in \mathbb{R} \setminus [q_1, q_2]$.

At first, we consider item (a). From (60) we get $t_f{}''(0) > 0$. Since $F_1(0) = 0$, the identity (71)and the assumption $f_1(q) > 0$ imply $F_1(q) > 0$ for all $q \in (q_1, 0) \cup (0, q_2)$. Hence $(tF1)$ yields $t_f{}''(x) > 0$, and hence

$$t_f(x) - xt_f{}'(x) < t_f(0) \quad \text{for all} \quad x \in [x_1, 0) \cup (0, x_2]. \tag{75}$$

Now consider item (b). From $f'(q) < 0$ and $(tF0)$ we conclude that

$$t_f(x) - xt_f{}'(x) < 0 \quad \text{for all} \quad x \in (-\infty, x_1) \cup (x_2, \infty). \tag{76}$$

Finally, (75), (76) imply $(t3)^+$.

For the proof of case $i = 2$, assume $f \in \mathfrak{f}_2^+$. Clearly $\mathfrak{f}_2^+ \subset \mathfrak{f}_3^+$, and hence (73)–(76) and $(t3)^+$, $(t4)^+$ all hold. Furthermore, by Definition 2, there exist $q_1 \in [-\infty, 0)$ and $q_2 \in (0, \infty]$ such that

(a) $f'(q) > 0$ and $f_1(q) > 0$ for all $q \in (q_1, q_2)$;

(b) $f'(q) < 0$ and $f_4(q) > 0$ for all $q \in \mathbb{R} \setminus [q_1, q_2]$.

Consider item (a) first. From $f'(q) > 0$ and $(tF0)$ we conclude that $\bar{t}_f - x\bar{t}_f{}' = t_f(x) - xt_f{}'(x) > 0$. Hence (64), (75) imply

$$x\,\bar{t}_f^{-2} \frac{d}{dx}\left(\frac{x\bar{t}_f{}'}{\bar{t}_f}\right) = x^2\,\bar{t}_f\bar{t}_f{}'' + x\bar{t}_f{}'\left(\bar{t}_f - x\bar{t}_f{}'\right) > 0 \tag{77}$$

for all $x \in (x_1, 0) \cup (0, x_2)$. Now turn to item (b). Because of the identity

$$f^2(q)f'^{-2}(q)\,f_4(q) = 3f'^2(0)x\,t_f^{-1}(x)\left(t_f(x) - xt_f{}'(x)\right)^{-2}\ B$$
$$\text{with}\ \ B = x\,\bar{t}_f^{-2}\frac{d}{dx}\left(\frac{x\bar{t}_f{}'}{\bar{t}_f}\right) + 2x\bar{t}_f{}'\left(\bar{t}_f - x\bar{t}_f{}'\right),$$

we can conclude from $f_4(q) > 0$ that $B > 0$. Now $F'(q) < 0$ implies $\bar{t}_f - x\bar{t}_f < 0$, and hence

$$x\,\bar{t}_f^{-2}\frac{d}{dx}\left(\frac{x\bar{t}_f{}'}{\bar{t}_f}\right) > 0 \quad \text{for all } x \in (-\infty, x_1) \cup (x_2, \infty). \tag{78}$$

Together, (77) and (78) imply $(t2)^+$.

Finally, to consider the case $i = 1$, we assume $f \in \mathfrak{f}_1^+$. Note that $f \in \mathfrak{f}_2^+$ holds and $q_1 = -\infty, q_2 = +\infty$. Hence we argue as in case $i = 2$ with $x_1 = -\infty, x_2 = +\infty$. □

LEMMA 9. *Again we need the general assumption $F \in \mathfrak{F}$, $f = F'$. Then $f \in \mathfrak{f}_i^-$ implies $(ti)^-$ for $i = 1$ and $i = 4$.*

We skip the proof, which is similar to that of Lemma 8. Lemmas 4–9 prove the inclusions of the various function classes in Theorem 1 and 2. The monotonicity of the energy-period function follows from Lemma 3 and the monotonicity of the functions s_f and s_g. To prove the estimate of $\langle H \rangle_{\text{can}}$, we use (18) and (19) and a partial integration to get

$$\beta\,\langle H \rangle_{\text{can}} - 1 = \frac{1}{Z}\int_0^\infty e^{-\beta E} E \frac{dT}{dE}\, dE.$$

This completes the proofs of Theorems 1 and 2.

4. Proof of Theorem 3. Recall formula (43), defining $s_f(x) = \frac{1}{2}(t_f(x) + t_f(-x))$. Let $E = \frac{1}{2}x^2$, and, as in Rothe [12], introduce the function

$$\tau_f(E) = \sqrt{\tfrac{2}{E}}\, s_f(\sqrt{2E}). \tag{79}$$

The *convolution* of two functions $E \in [0, \infty) \mapsto u(E)$ and $E \in [0, \infty) \mapsto v(E)$ is defined as

$$(u * v)(E) = \int_0^E u(a)v(E-a)\, da. \tag{80}$$

We use the shorthand notation $\{u(E/\mu)\}$ for the function $E \mapsto u(E/\mu)$, where $\mu \in \mathbb{R}$ is a parameter. These definitions allow us to rewrite the formula (51) for the period as

(81)
$$T(E,\lambda,\mu) = (\lambda\mu)^{-1} \int_0^E \tau_f\left(\frac{a}{\lambda}\right) \tau_g\left(\frac{E-a}{\mu}\right) da = (\lambda\mu)^{-1} \left\{\tau_f\left(\frac{E}{\lambda}\right)\right\} * \left\{\tau_g\left(\frac{E}{\mu}\right)\right\}.$$

As formula (19) from the introduction shows, the canonical partition function $Z(\beta, \lambda, \mu)$ is the Laplace transform of the energy-period function $T(E, \lambda, \mu)$. For Laplace correspondences like (19) we introduce the symbolic notation $T(E, \lambda, \mu) \;\bullet\!\!-\!\!\circ\; Z(\beta, \lambda, \mu)$. Here β denotes the independent variable of the Laplace transformed function. It has the physical meaning of an inverse absolute temperature. For a given function $F \in \mathfrak{f}$ and $f = F'$ in system (5), we define

$$z_f(\beta) = \int_0^\infty \exp\left(-\beta F(q)\right) dq. \tag{82}$$

We assemble some useful Laplace correspondences.

Lemma 10. *The following functions are Laplace transforms of each other.*

$$\tau_f(E) \;\bullet\!\!-\!\!\circ\; z_f(\beta), \tag{83}$$

$$\sqrt{\tfrac{2}{E}} \;\bullet\!\!-\!\!\circ\; \sqrt{2\pi/\beta}, \tag{84}$$

$$\tau_f\left(\frac{E}{\lambda}\right) \;\bullet\!\!-\!\!\circ\; \lambda z_f(\lambda\beta), \tag{85}$$

$$T(E, \lambda, \mu) \;\bullet\!\!-\!\!\circ\; Z(\beta, \lambda, \mu). \tag{86}$$

Proof. Substituting $E = F(p)$ into (82) yields

$$z_f(\beta) = \int_0^\infty \exp\left(-\beta E\right) \tilde{\tau}_f(E)\, dE, \tag{87}$$

with $\tilde{\tau}_f(E) = \sum\{\,|F'(q)|^{-1} \mid F(q) = E\,\} = \tau_f(E)$. This proves (83) from which (85) follows. The correspondence (84) is elementary. Alternatively, it follows from (83) for the harmonic oscillator case $f(q) = q$ and $F(q) = \frac{1}{2}q^2$. Formula (86) was already proved in the introduction. □

Since the Laplace transformation takes convolutions into products, applying (85) to both functions f and g yields

$$\left\{\tau_f\left(E/\lambda\right)\right\} * \left\{\tau_g\left(E/\mu\right)\right\} \;\bullet\!\!-\!\!\circ\; \lambda\mu z_f(\lambda\beta) z_g(\mu\beta). \tag{88}$$

Because the Hamiltonian is assumed to be the sum (4), the canonical partition function defined by (17) factors into a product and we get

$$Z(\beta,\lambda,\mu)=z_f(\lambda\beta)z_g(\mu\beta). \tag{89}$$

From (86)–(89), we get an independent proof of the energy-period formula (81).

After these more general considerations, we are ready to begin the proof. In Theorem 3, we make the assumption that $f\in D\mathfrak{F}_2^+$ and $g\in D\mathfrak{F}_2^+$. Consider the function f. By Lemma 7, the inequality $(t2)^+$ holds, which asserts that both functions $\log x\mapsto\log\left(t_f(x)-xt_f{}'(0)\right)$ and $\log x\mapsto\log\left(t_f(-x)+xt_f{}'(0)\right)$ are strictly convex on their whole domain $\mathbb{R}\ni x$. From Rothe [13], we need the following.

LEMMA 11. *Let $f=f(x)$ and $g=g(x)$ be smooth positive functions defined for all $x\in(0,\infty)$. If the two functions $\log x\mapsto\log f(x)$ and $\log x\mapsto\log g(x)$ are both strictly convex on their domain $\mathbb{R}$, then the following functions are strictly convex on their entire domains*:

$$\log x\in\mathbb{R}\mapsto\log\left(f(x)+g(x)\right), \tag{90}$$

$$\log x\in\mathbb{R}\mapsto\log\left(f(x)g(x)\right), \tag{91}$$

$$(\log x,\log y)\in\mathbb{R}^2\mapsto\log\left[\int_0^1 f(sx)g((1-s)y)\,ds\right], \tag{92}$$

$$(\log(E/\mu),\log(E/\lambda))\in\mathbb{R}^2\mapsto\log\left[(\lambda\mu)^{-1/2}\{f(E/\lambda)\}*\{g(E/\mu)\}\right]. \tag{93}$$

Item (93)—not contained in Rothe [13]—is a consequence of (92). Note that the factor $(\lambda\mu)^{-1/2}$ makes the function in formula (93) well defined. By means of (90) in Lemma 11, we conclude that the function $\log x\in\mathbb{R}\mapsto\log s_f(x)$ is strictly convex. Now it is straightforward from (79) that both functions

$$\log\left(\frac{E}{\lambda}\right)\mapsto\log\tau_f\left(\frac{E}{\lambda}\right)\quad\text{and}\quad\log\left(\frac{E}{\mu}\right)\mapsto\log\tau_g\left(\frac{E}{\mu}\right) \tag{94}$$

are strictly convex, and finally (92) in Lemma 11 implies that the function

$$\left(\log\left(\frac{E}{\mu}\right),\log\left(\frac{E}{\lambda}\right)\right)\mapsto\log[(\lambda\mu)^{-1/2}T(E,\lambda,\mu)]$$

is strictly convex on its domain $\mathbb{R}^2$, which proves (31).

Next we prove estimate (32) for the area enclosed by the orbits of system (5). Define

$$T_f(E)=\int_0^\infty\sqrt{\tfrac{2}{a}}\,\tau_f(E-a)\,da=\left\{\sqrt{\tfrac{2}{E}}\right\}*\{\tau_f(E)\}, \tag{95}$$

and similarly T_g corresponding to g. Indeed, T_f is the energy-period function of the system

$$\begin{aligned}\frac{dq}{dt}&=p,\\ \frac{dp}{dt}&=-f(q),\end{aligned} \tag{96a}$$

and T_g is the energy-period function of the system

$$\begin{aligned} \frac{dq}{dt} &= g(p), \\ \frac{dp}{dt} &= -q. \end{aligned} \tag{96b}$$

A formula for the enclosed area A as a convolution can be found by means of Laplace transforms. From $A(E,\lambda,\mu) = \int_0^\infty T(E,\lambda,\mu)\,dE$ and elementary properties of the Laplace transformation, we get the correspondence

$$A(E,\lambda,\mu) \;\bullet\!\!-\!\!\circ\; \beta^{-1}Z(\beta,\lambda,\mu). \tag{97}$$

On the other hand, taking the convolution of (84) and (85) yields $\{\sqrt{2/E}\}*\{\tau_f(E)\} = T_f(E) \;\bullet\!\!-\!\!\circ\; \sqrt{2\pi/\beta}\,z_f(\beta)$, and hence

$$T_f\left(\frac{E}{\lambda}\right) \;\bullet\!\!-\!\!\circ\; \lambda\sqrt{2\pi/\lambda\beta}\,z_f(\lambda\beta) \quad\text{and}\quad T_g\left(\frac{E}{\mu}\right) \;\bullet\!\!-\!\!\circ\; \mu\sqrt{2\pi/\mu\beta}\,z_g(\mu\beta).$$

Taking the convolution of these two formulas yields

$$\begin{aligned} \{T_f\,(E/\lambda)\} * \{T_g\,(E/\mu)\} \;\bullet\!\!-\!\!\circ\; & 2\pi\lambda\mu\,\frac{z_f(\lambda\beta)}{\sqrt{\lambda\beta}}\,\frac{z_g(\mu\beta)}{\sqrt{\mu\beta}} \\ &= 2\pi\sqrt{\lambda\mu}\,\beta^{-1}Z(\beta,\lambda,\mu). \end{aligned} \tag{98}$$

Now comparison of (97) and (98) yields

$$A(E,\lambda,\mu) = \frac{1}{2\pi\sqrt{\lambda\mu}}\left\{T_f\left(\frac{E}{\lambda}\right)\right\} * \left\{T_g\left(\frac{E}{\mu}\right)\right\}. \tag{99}$$

Applying formula (31), which we have already proved above to the systems (96a) and (96b), we conclude that both functions

$$\log\left(\frac{E}{\lambda}\right) \mapsto \log T_f\left(\frac{E}{\lambda}\right) \quad\text{and}\quad \log\left(\frac{E}{\mu}\right) \mapsto \log T_g\left(\frac{E}{\mu}\right)$$

are strictly convex. Now (93) from Lemma 11 yields convexity for the convolution. Because of (99), we get that the function

$$\left(\log\left(\frac{E}{\mu}\right), \log\left(\frac{E}{\lambda}\right)\right) \mapsto \log A(E,\lambda,\mu)$$

is strictly convex on its domain $\mathbb{R}^2$, which proves (32).

The results about the canonical ensemble rely on the following lemma proved in [13, p. 676].

LEMMA 12. *Assume that the function* $\log E \in \mathbb{R} \mapsto \log\tau(E)$ *is strictly convex on* $\mathbb{R}$. *Taking the Laplace transform* $z(\beta) = \int_0^\infty e^{-\beta\tau(E)}\,dE$, *we get the function* $\log\beta \mapsto \log z(\beta)$, *which is strictly convex on* $\mathbb{R}$.

By this Lemma, the functions $\log\beta \mapsto \log z_f(\beta)$ and $\log\beta \mapsto \log z_g(\beta)$ are strictly convex. Since $Z(\beta,\lambda,\mu) = z_f(\lambda\beta)z_g(\mu\beta)$, by Lemma 12, the function $\log\beta \mapsto \log Z(\beta,\lambda,\mu)$ is strictly convex, too. Using (18) we conclude

$$0 < \beta\frac{\partial}{\partial\beta}\left(\beta\frac{\partial}{\partial\beta}\log Z\right) = \beta^2\mathrm{Var}_{\mathrm{can}}H - \beta\,\langle H\rangle_{\mathrm{can}}$$

for all $\beta > 0$. Since $\lim_{\beta\to 0}\beta\,\langle H\rangle_{\text{can}} = 1$, we get assertion (13).

We come to the second part of Theorem 3, relying on the additional assumption $f'(q) > 0$ and $g'(p) > 0$ for all $p, q \in \mathbb{R}$ as well as $f, g \in D\mathfrak{F}_2^+$ as before. Let s_f be the function defined by (43). Under the assumptions just stated, the function $x \in (0,\infty) \mapsto x s_f{}'(x)/s_f(x)$ is increasing and bounded above by the constant 1 because of $(tF0)$. Hence the function $x \in (0,\infty) \mapsto s_f(x)/x$ is positive and decreasing and finally $\lim_{x\to\infty} s_f{}'(x) = \lim_{x\to\infty} s_f\,(x)/x = s'_\infty$ exists. For all $\delta > 0$ there exists K_δ such that

$$xs'_\infty < s_f(x) < (1+\delta)xs'_\infty + K_\delta \quad \text{for all } x > 0. \tag{100}$$

Inserting this estimate into the basic period formula (54) yields the estimate

$$\begin{aligned}\left(\frac{4E^2}{\lambda\mu}\right) s'_{f\infty}s'_{g\infty} &< ET(E,\lambda,\mu)\\ &<(1+\delta)\left(\frac{4E^2}{\lambda\mu}\right) s'_{f\infty}s'_{g\infty}\\ &\quad + K'_\delta\left(1+\left(\frac{E}{\lambda}\right)^{3/2}+\left(\frac{E}{\mu}\right)^{3/2}\right).\end{aligned} \tag{101}$$

For the proof of the last claim in Theorem 3 we need the following.

LEMMA 13. *The orbital averages of F and G are*

$$\begin{aligned}\langle F(q)\rangle_{H=E} &\equiv \frac{1}{T}\int_0^T F(q(t,E))\,dt = -\frac{1}{T}\frac{\partial A(E,\lambda,\mu)}{\partial\lambda},\\ \langle G(p)\rangle_{H=E} &\equiv \frac{1}{T}\int_0^T G(p(t,E))\,dt = -\frac{1}{T}\frac{\partial A(E,\lambda,\mu)}{\partial\mu},\end{aligned} \tag{103}$$

or, in terms of the phase angle,

$$\begin{aligned}\langle F(q)\rangle_{H=E} &= \frac{4E}{T\lambda\sqrt{\lambda\mu}}\int_0^{\pi/2} s_f\left(\sqrt{\frac{2E}{\lambda}}\cos\varphi\right) s_g\left(\sqrt{\frac{2E}{\mu}}\sin\varphi\right)\cos^2\varphi\,d\varphi,\\ \langle G(p)\rangle_{H=E} &= \frac{4E}{T\mu\sqrt{\lambda\mu}}\int_0^{\pi/2} s_f\left(\sqrt{\frac{2E}{\lambda}}\cos\varphi\right) s_g\left(\sqrt{\frac{2E}{\mu}}\sin\varphi\right)\sin^2\varphi\,d\varphi.\end{aligned} \tag{104}$$

Proof. Differentiating the partition function $Z(\beta,\lambda,\mu)$ in (17) by the parameter λ and substituting the independent variables (t, E) yields

$$-\frac{1}{\beta}\frac{\partial Z(\beta,\lambda,\mu)}{\partial\lambda} = \int_0^\infty e^{-\beta E}\left(\int_0^{T(E,\lambda,\mu)} F(q(t,E,\lambda,\mu))dt\right)dE, \tag{105}$$

which is the Laplace correspondence $-T(E,\lambda,\mu)\,\langle F(q)\rangle_{H=E}$ •—○ $\beta^{-1}\partial Z/\partial\lambda$. On the other hand, differentiating the correspondence (97) by λ yields $\partial A(E,\lambda,\mu)/\partial\lambda$ •—○ $\beta^{-1}\partial Z/\partial\lambda$. Comparison of the last two formulas proves (103).

To show (104), we use (50) to substitute the phase angle φ into the definition (103) of $\langle F(q)\rangle$ and plug in $F(q) = \frac{1}{2}x^2 = (E/\lambda)\cos^2\varphi$, resulting from (42) and (49). □

To complete the proof of Theorem 3, we show (35) through (37). As further consequences of (100),

(106)
$$\left(\frac{2E^2}{\lambda\mu}\right) s'_{f\infty} s'_{g\infty} < X < (1+\delta)\left(\frac{2E^2}{\lambda\mu}\right) s'_{f\infty} s'_{g\infty} + K''_\delta\left(1+\left(\frac{E}{\lambda}\right)^{3/2}+\left(\frac{E}{\mu}\right)^{3/2}\right)$$

holds for all $(E/\lambda) > 0, (E/\mu) > 0$ uniformly—with the three choices $X = A(E,\lambda,\mu)$ as well as $X = \lambda ET\,\langle F(q)\rangle_{H=E}$ and $X = \mu ET\,\langle G(p)\rangle_{H=E}$. The first choice results from integrating (101) over the interval $[0,E]$; the two others use (104). Together, (101) and (106) imply

$$\lim_{E\to\infty}\frac{\lambda T}{A}\,\langle F(q)\rangle_{H=E} < 1 \quad\text{and}\quad \lim_{E\to\infty}\frac{\mu T}{A}\,\langle G(p)\rangle_{H=E} < 1. \tag{107}$$

On the other hand, elementary considerations show that

$$\lim_{E\to 0}\frac{\lambda T}{A}\,\langle F(q)\rangle_{H=E} = \frac{1}{2} \quad\text{and}\quad \lim_{E\to\infty}\frac{\mu T}{A}\,\langle G(p)\rangle_{H=E} = \frac{1}{2}. \tag{108}$$

Finally, we combine this information about the limits $E \to \infty$ and $E \to 0$ with the convexity from (32) and (103),

$$\frac{\partial}{\partial\lambda}\frac{\lambda}{A}\frac{\partial A}{\partial\lambda} = -\frac{\partial}{\partial\lambda}\frac{\lambda T}{A}\,\langle F(q)\rangle > 0 \quad\text{and}\quad \frac{\partial}{\partial\mu}\frac{\mu}{A}\frac{\partial A}{\partial\mu} = -\frac{\partial}{\partial\mu}\frac{\mu T}{A}\,\langle G(p)\rangle > 0,$$

to conclude that

$$\frac{\lambda T}{A}\,\langle F(q)\rangle_{H=E} \quad\text{and}\quad \frac{\mu T}{A}\,\langle G(p)\rangle_{H=E} \in (1/2,1) \quad\text{for all}\quad E,\lambda,\mu > 0, \tag{109}$$

proving (36) and (37) in Theorem 3.

A similar reasoning, combining convexity and limits for $E \to \infty$, applies to derivatives by E. Because of (30), the function $E \mapsto (E/T)(dT/dE)$ is increasing. Because of (101) we get $\lim_{E\to\infty}(E/T)(dT/dE) \leq 1$. Hence $\lim_{E\to\infty} T(E)/E = \lim_{E\to\infty} dT/dE = T'_\infty$ exists, and estimate (35) follows.

5. Examples.

(A) *The pendulum.* The frictionless pendulum is a Hamiltonian system (2) with

$$H(p,q) = \tfrac{1}{2}p^2 + 1 - \cos q. \tag{A.1}$$

In the (p,q) phase plane, there exist closed orbits surrounding the center at $(0,0)$ with $H(0,0) = 0$. We restrict the discussion to these oscillations and disregard the librations occuring at energies $H > 2$. The closed oscillatory orbits lie inside the bounded region $\mathcal{R}$ bounded by the two heteroclinic orbits connecting the saddle points S_1 at $(p,q) = (0,-\pi)$ with S_2 at $(p,q) = (0,\pi)$. At the saddle points and on the connecting heteroclinic orbits, the Hamiltonian assumes the value $H(p,q) = 2$. Hence the restriction to the region $\mathcal{R}$ implies $E \in [0,2)$ for the range of values of the Hamiltonian and $q \in (-\pi,\pi)$ for the phase angle in the potential $F(q) = 1 - \cos q$ and the force $f(q) = \sin q$.

Referring to Definition 1–4, we check that $f \in \mathfrak{n}$ but $f \notin \mathfrak{m}$, $f \in \mathfrak{h}_1^+$, and $f \in \mathfrak{f}_2^+$. (Hence even $f \in \mathfrak{f}_3^+$ and $f \in \mathfrak{f}_4^+$.) Therefore, Theorem 1 shows that the energy-period function $T = T(E)$ is strictly increasing. Since even $f \in \mathfrak{f}_2^+$ does hold, we apply Theorem 3 to get the stronger conclusion that

$$\frac{\partial}{\partial E}\left(\frac{E}{T}\frac{\partial T}{\partial E}\right) > 0 \quad \text{for all} \quad E \in [0,2).$$

Because of $f \notin \mathfrak{m}$, the second part of Theorem 3 leading to (34)–(37) does not apply. Indeed (34) and (35) do not hold for the pendulum. This is easy to see because the slow motion near the saddle points S_1 and S_2 implies $\lim_{E\to 2} T(E) = \infty$.

(B) *The "battle of sexes" model.* See, e.g., Maynard-Smith and Hofbauer [9] for the biological background of the "battle of sexes" model. Let the variables $u, v \in [0,1]$ give the parts of the male and female population with different mating behavior. Taking into account the effects of behavior on the numbers of offspring, Maynard-Smith derives the differential equations

$$\text{(B.1)} \qquad \begin{aligned} \frac{du}{dt} &= \lambda u\,(1-v)\left(1-\frac{v}{B}\right), \\ \frac{dv}{dt} &= -\mu v\,(1-u)\left(1-\frac{u}{A}\right) \end{aligned}$$

with parameters $\lambda, \mu > 0$ and $A, B \in [0,1)$. A transformation to a Hamiltonian system (2) is achieved by introducing the variables p and q via

$$\text{(B.2)} \qquad u = \frac{A}{A + (1-A)e^{-p}} \quad \text{and} \quad v = \frac{B}{B+(1-B)e^{-q}}.$$

(B.2) transforms (B.1) into the system (2)—or equivalently (5). The relevant Hamiltonian has the form (4) of a sum with separated variables. Indeed, $H(p,q) = \lambda F(q) + \mu G(p)$ with

(B.3)

$$F(q) = -q + A^{-1}\log\left[1 + A(e^q - 1)\right] \quad \text{and} \quad G(p) = -p + B^{-1}\log\left[1 + B(e^p-1)\right].$$

For the function $f(q) = F'(q) = -(A-1)(e^q-1)/[1+A(e^q-1)]$, we have to check that $f_1 = 5f''^2 - 3f'f''' \geq 0$. This leads to a rather lengthy calculation, unless we use the Schwarzian derivative

$$\mathcal{S}f \equiv \frac{f'''}{f'} - \frac{3}{2}\left(\frac{f''}{f'}\right)^2$$

for a shortcut. Indeed, since $f(q) = -(A-1)U/[1+AU] \equiv T(U)$ with $U(q) = e^q - 1$, the function f is the composition $f = T \circ U$, where T is a linear fractional transformation, for which the Schwarzian derivative vanishes. Hence we get for the Schwarzian of the composition,

$$\mathcal{S}f = \mathcal{S}(T\circ U) = [\mathcal{S}T \circ U]U'^2 + \mathcal{S}U = \mathcal{S}U = -\tfrac{1}{2},$$

and finally $f_1 = (f''^2/2) - 3f'^2\mathcal{S}f = (f''^2 + 3f'^2)/2 > 0$ for all $q \neq 0$. (Indeed, $f_1 = 2A^{-2}(1-A)^{-2}W^2(1+W+W^2)(1+W)^{-6} > 0$, where $W = A(1-A)^{-1}e^q$.) Since $f, g \in \mathfrak{m}$, we have confirmed that $f, g \in \mathfrak{f}_1^+$. Thus all parts of Theorem 3 do apply. As a final remark, note that the limiting case $A = B = 0$ leads back to the original Volterra model (1).

(C) *The power law.* Take the Hamiltonian

$$H(p,q) = \lambda \frac{|q|^\sigma}{\sigma} + \mu \frac{|p|^\rho}{\rho} \tag{C.1}$$

of the form (4) with the power law potentials $F(q) = |q|^\sigma/\sigma$ and $G(p) = |p|^\rho/\rho$. This example shows the advantage gained from the partition function (17) to achieve an easy calculation of the energy-period function. At first we use (82) to get

$$z_f(\gamma) = \int_0^\infty \exp\left(-\gamma F(q)\right)\, dq \; = \; 2\sigma^{-1+1/\sigma}\Gamma(\sigma^{-1})\gamma^{-1/\sigma},$$

where Γ is the Euler gamma function. Now formula (88) yields

$$\begin{aligned} Z(\beta,\lambda,\mu) &= z_f(\lambda\beta)z_g(\mu\beta) \\ &= 4\sigma^{-1+1/\sigma}\rho^{-1+1/\rho}\Gamma(\sigma^{-1})\Gamma(\rho^{-1})\;(\lambda\beta)^{-1/\sigma}\,(\mu\beta)^{-1/\rho}. \end{aligned} \tag{C.2}$$

Now we use the Laplace correspondence $T(E,\lambda,\mu)$ •—∘ $Z(\beta,\lambda,\mu)$ from (19) to transform (C.2) back and get

$$ET(E,\lambda,\mu) = 4\sigma^{-1+1/\sigma}\rho^{-1+1/\rho}\Gamma(\sigma^{-1})\Gamma(\rho^{-1})\Gamma(\sigma^{-1}+\rho^{-1})\left(\frac{E}{\lambda}\right)^{1/\sigma}\left(\frac{E}{\mu}\right)^{1/\rho}.$$

Integration over the interval $[0,E]$ and formula (103) yields

$$A = \frac{ET}{\sigma^{-1}+\rho^{-1}} \quad \text{and} \quad \lambda\sigma\left\langle F(q)\right\rangle_{H=E} = \mu\rho\left\langle G(q)\right\rangle_{H=E} = \frac{E}{\sigma^{-1}+\rho^{-1}}.$$

In the case $\sigma,\rho \in (1,2)$, Theorem 1 and the first part of Theorem 3 apply. In the case $\sigma,\rho \in (2,\infty)$, Theorem 2 applies.

(D) *An unsymmetric system with constant periods and its perturbation.* Constant periods arise for the potential (24a). For simplicity, let $f'(0) = 1$, $f''(0) = -3$, and take the kinetic energy $G(p) = \frac{1}{2}p^2$ with $\mu = 1$. We get the Hamiltonian

$$H_0(p,q) = \tfrac{1}{2}p^2 + \lambda\left(1 + q - \sqrt{1+2q}\right). \tag{D.1}$$

System (2) with the Hamiltonian (D.1) leads to oscillations in the range $q \in [-\frac{1}{2}, \frac{3}{2}]$, since the potential $F(q) = \lambda(1 + q - \sqrt{1+2q})$ is no longer well defined for $q < -\frac{1}{2}$ and $F(-\frac{1}{2}) = F(\frac{3}{2}) = \lambda/2$.

To solve the system (2) with Hamiltonian function (D.1), we use the same variables x and y as in the proof of Theorem 2. These variables are defined by

$$\begin{aligned} F(q(x)) &= \tfrac{1}{2}x^2 \text{ and } xq_f(x) \geq 0 \quad \text{for all} \quad x \in \mathbb{R}, \\ G(p(y)) &= \tfrac{1}{2}y^2 \text{ and } yq_g(y) \geq 0 \quad \text{for all} \quad y \in \mathbb{R}, \end{aligned}$$

as required by (42). We can check that $y = p$ and $x = \sqrt{1+2q} - 1$. Solving for q yields $q = q_f(x) = x + \frac{1}{2}x^2$, and hence (43) gives $t_f(x) = q_f{}'(x) = 1 + x$ and $t_g(y) = q_g{}'(y) = 1$.

System (50) for the phase angle in the (x, y)-plane takes the form

$$\frac{d\varphi}{dt} = -\frac{\sqrt{\lambda}}{1+\sqrt{2E}\cos\varphi}. \tag{D.2}$$

Integrating (D.3) over the range $\varphi \in [-\pi/2, \pi/2]$ gives the positive half period

$$T^{+} = T^{++} + T^{+-} = \frac{1}{\sqrt{\lambda}} \int_{-\pi/2}^{\pi/2} \left(1 + \sqrt{\frac{2E}{\lambda}} \cos\varphi\right) d\varphi = \frac{1}{\sqrt{\lambda}} \left(\pi + 2\sqrt{\frac{2E}{\lambda}}\right). \tag{D.3}$$

A similar integral over the range $\varphi \in [\pi/2, 3\pi/2]$ gives the negative half period

$$T^{-} = \frac{1}{\sqrt{\lambda}} \left(\pi - 2\sqrt{\frac{2E}{\lambda}}\right). \tag{D.4}$$

We see that both half periods depend on the energy E, but the total period $T = T^{+}(E) + T^{-}(E)$ is independent of E.

Now consider the energy-period function in case of the perturbed Hamiltonian

$$H(p, q) = H_0(p, q) - \varepsilon \frac{q^{n+1}}{n+1}$$

for a small perturbation parameter $\varepsilon > 0$. In the case $n \geq 3$, we get $f_1(0) = 0$, and hence (25b) implies $T'(0) = 0$. A numerical calculation for the example $\varepsilon = 0.1$ and $n = 3$ shows that $F_4(q) \geq 0$ holds for all $q \in [-0.3, \infty)$, but $f_1(q) \geq 0$ holds only for all $q \in [-0.2, \infty)$ and no longer for all $q \in [-0.3, -0.2]$. Hence we see—as follows from Theorem 1 as well—that Chow's functional F_4 implies increasing periods in a bit larger range of oscillation amplitudes than Schaaf's functional f_1.

6. The inverse problem. The following theorem considers the inverse problem to calculate the potential $F = F(q) \in \mathfrak{F}$ from a given energy-period function. To get a managable problem for which uniqueness is reasonable, we restrict ourselves to the system (6) with only one unknown potential $F = F(q)$. The inverse problem has been treated by Keller [7], too. It leads to an Abel integral equation, which can easily be solved by means of Laplace transformation already set up in this note. Hence we find it convenient to include this part. Beyond that, we get additional insights, as nessecary conditions for monotonicity of the energy-period function.

For given $E > 0$, let $q_- < 0 < q_+$ be the two solutions of $F(q_\pm) = E$, and define the function $v(E) = q_+ - q_-$. From (42), (43), and (79) we conclude

$$\frac{dv}{dE} = \frac{dv}{dx}\frac{dx}{dE} = 2s_f(x)\frac{dx}{dE} = 2\frac{s_f(\sqrt{2E})}{\sqrt{2E}} = \tau_f(E). \tag{110}$$

From now on, we omit the index f because we consider only one force function. Define the Abel integral operator $\mathfrak{A} : \tau \mapsto T$ by

$$T(E) = \int_0^\infty \sqrt{\tfrac{2}{a}}\, \tau(E-a)\, da = \left\{\sqrt{\tfrac{2}{E}}\right\} * \{\tau(E)\}. \tag{111}$$

In this operational notation, formula (95) for the energy-period function is simply $T = \mathfrak{A}\tau$ or $\{T(E)\} = \mathfrak{A}\{\tau(a)\}$.

THEOREM 4. *For the system (6), the energy-period function $T = T(E)$, the area $A = A(E)$ enclosed by orbits, and the Lagrangian $L = A - ET$ satisfy*

$$\begin{aligned} \{A(E)\} &= \mathfrak{A}\{2v(a)\}, & \{T(E)\} &= \mathfrak{A}\{\tau(a)\}, \\ \{ET(E) - \tfrac{1}{2}A(E)\} &= \mathfrak{A}\{a\tau(a)\}, & \{L(E)\} &= \mathfrak{A}\{v(a) - a\tau(a)\}, \\ \{T'(E)\} &= \mathfrak{A}\left\{\tfrac{d}{da}\left[\tau(a) - \sqrt{\tfrac{2}{f'(0)a}}\right]\right\} & \{ET'(E)\} &= \mathfrak{A}\{s'(\sqrt{2a})\}. \end{aligned}$$

Conversely, we can calculate the functions $v = v(a)$ and $v' = \tau$ from a given energy-period function by means of

$$\begin{aligned} \{v(a)\} &= \tfrac{1}{2\pi}\mathfrak{A}\{T(E)\}, \\ \left\{\tau(a) - \tfrac{1}{2\pi}T(0)\sqrt{\tfrac{2}{a}}\right\} &= \tfrac{1}{2\pi}\mathfrak{A}\{T'(E)\}, \\ \{a\tau(a) - \tfrac{1}{2}v(a)\} &= \tfrac{1}{2\pi}\mathfrak{A}\{ET'(E)\}, \\ \{a\tau'(a) + \tfrac{1}{2}\tau(a)\} &= \tfrac{1}{2\pi}\mathfrak{A}\{ET''(E) + T'(E)\}. \end{aligned} \tag{112}$$

By taking the Laplace transforms, these claims are rather straightforward to check. We leave the details to the reader.

Remarks.

(1) Obi [10] gives a criterion for constant periods of system (6), which we can derive from (113), too. Introducing Obi's function

$$E_{\mathrm{obi}}(x) = E_{\mathrm{obi}}(-x) = \frac{(q_+(x^2/2) + q_-(x^2/2))}{2} \quad \text{for } x \geq 0,$$

we get $q_+ + q_- = 2E_{\mathrm{obi}}\left(\sqrt{2F(q_+)}\right) = 2E_{\mathrm{obi}}\left(\sqrt{2F(q_-)}\right)$.

Constant periods $T(E) = 2\pi$ for all E occur if and only if $v(E) = 2\sqrt{2E}$, which is equivalent to $q_+ - q_- = 2\sqrt{2F(q_+)}$. Using Obi's function to eliminate either q_+ or q_-, we see that constant periods 2π occur if and only if Obi's condition

$$2F(q) = \left(q - E_{\mathrm{obi}}\left(\sqrt{2F(q)}\right)\right)^2$$

holds for all $q \in \mathbb{R}$.

(2) Under the additional symmetry assumption $F(q) = F(-q)$, formula (113) enables us to determine the potential from the given energy-period function, since the function $q^+ = \frac{1}{2}(q^+ - q^-) = \frac{1}{2}v(E)$ is the inverse of the potential $E = F(q^+)$.

(3) We get the following chain of implications among properties of the system (6). Roughly speaking, each step corresponds to a half-order integration achieved by the operator $\mathfrak{A}$.

$$\begin{aligned} &\frac{d}{dE}\left(\frac{E}{T}\frac{dT}{dE}\right) > 0 \quad \text{for all} \quad E > 0 \Longrightarrow \frac{ds}{da} > 0 \quad \text{for all} \quad a > 0 \Longrightarrow \\ &\qquad \frac{dT}{dE} > 0 \quad \text{for all} \quad E > 0 \Longrightarrow a\tau(a) - v(a) > 0 \quad \text{for all} \quad a > 0 \Longrightarrow \\ &\qquad L(E) > 0 \quad \text{for all} \quad E > 0. \end{aligned}$$

7. Acknowledgment. The author wants to thank the anonymous referees for useful suggestions, helping to clarify the connection to the bifurcation for two point boundary value problems, and a more complete list of references.

SOLUTIONS OF THIRD-ORDER DIFFERENTIAL EQUATIONS RELEVANT TO DRAINING AND COATING FLOWS*

WILLIAM C. TROY[†]

Abstract. The behavior of solutions of two differential equations is investigated. The first is a model for a viscous fluid draining over a wet surface. The second equation is derived from the first as a result of an inner expansion as a parameter δ tends to zero. The existence of the appropriate solution is proved for both equations.

Key words. differential equations, nonlinear, fluid mechanics, draining

AMS(MOS) subject classifications. 34B15, 34E05, 76O99

1. Introduction.

We investigate the behavior of solutions of two third-order differential equations, namely,

$$y''' = -1 + (1+\delta+\delta^2)\,y^{-2} - (\delta+\delta^2)\,y^{-3}, \qquad 0<\delta<1 \tag{1.1}$$

and

$$y''' = y^{-2} - y^{-3}. \tag{1.2}$$

Equation (1.1) arises in modeling draining or coating fluid flow problems. The function y represents the thickness of a thin film of viscous fluid draining over a wet solid surface in an unsteady manner. Equation (1.2) is the so-called "small δ limit" of (1.1), or inner expansion of (1.1) valid for $x \approx x_0$, obtained by setting $x = x_0 + \delta X, y = \delta Y$, followed by the formal limit $\delta \longrightarrow 0$.

In a recent article Tuck and Schwartz [3] present an extensive numerical study of the behavior of solutions of (1.1) and (1.2). The reader is referred to their paper for a more complete derivation of (1.1) and (1.2).

The physically important solution of (1.1) satisfies $(y, y', y'') \longrightarrow (\delta, 0, 0)$ as $x \longrightarrow \infty$, and $(y, y', y'') \longrightarrow (1, 0, 0)$ as $x \longrightarrow -\infty$. The numerical results of Tuck and Schwartz predict the existence of exactly one such solution, up to translation. We give a rigorous proof for the existence of at least one such solution in the first of our two main results (see Fig. 1).

THEOREM 1. *Let* $0 < \delta < 1$. *There is at least one solution* (*up to translation*) *of* (1.1) *satisfying* $\lim_{x\to\infty}(y, y', y'') = (\delta, 0, 0)$ *and* $\lim_{x\to-\infty}(y, y', y'') = (1, 0, 0)$.

Next we investigate the behavior of solutions of (1.2). Tuck and Schwartz show that the appropriate conditions to be satisfied by a solution of (1.2) are

$$y > 0 \quad \text{for all } x \in (-\infty, \infty)\,, \tag{1.3}$$

$$\lim_{x\to\infty}(y, y', y'') = (1, 0, 0)\,, \tag{1.4}$$

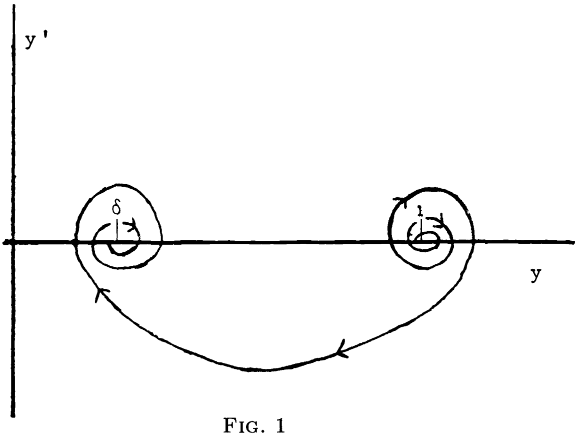

FIG. 1

and

$$\lim_{x \to -\infty} (y, y', y'') = (\infty, -\infty, 0). \tag{1.5}$$

Tuck and Schwartz also claim that any solution of (1.2)–(1.5) satisfies the asymptotic behavior

$$y \sim 3^{1/3}|x| \log^{1/3}(|x|) \quad \text{as } x \longrightarrow -\infty. \tag{1.6}$$

We confirm these properties in our second result (see Fig. 2).

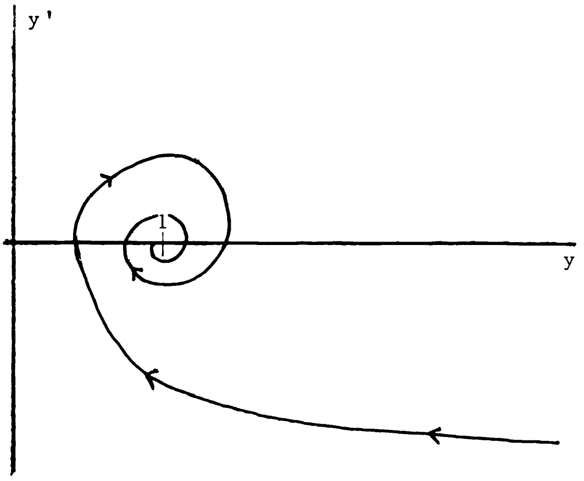

FIG. 2

THEOREM 2. *There exists a solution of* (1.2) *satisfying* (1.3)–(1.6).

2. Proof of Theorem 1. The proof uses a two-dimensional shooting argument. That is, we analyze the behavior of solutions of the initial value problem

$$y''' = -1 + (1+\delta+\delta^2)\,y^{-2} - (\delta+\delta^2)\,y^{-3}, \tag{2.1}$$

$$y(0) = \alpha, \quad y'(0) = \beta, \quad y''(0) = 0, \tag{2.2}$$

where $(\alpha,\beta) \in E \equiv \{(\alpha,\beta)\,|\delta \le \alpha \le 1 \text{ and } \beta \le 0\}$. For each $(\alpha,\beta) \in E$, let $[0,\bar{x})\,, \bar{x} = \bar{x}\,(\alpha,\beta)$ denote the maximal interval of existence of the solution of (2.1), (2.2) in $[0,\infty)$. Likewise, let $(\tilde{x},0]\,, \tilde{x} = \tilde{x}\,(\alpha,\beta)$ denote the maximal interval of existence of the solution in $(-\infty,0]$. It is possible that $\tilde{x}$ or $\bar{x}$ may be finite or infinite.

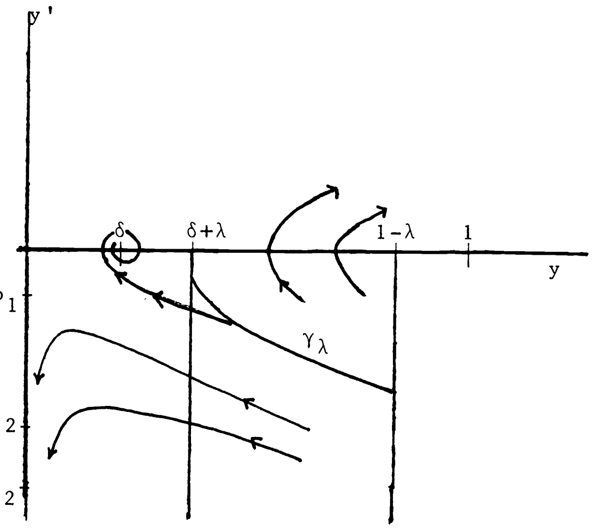

FIG. 3

In the first part of our proof we determine the behavior of solutions over $[0,\bar{x})$ for appropriately chosen values of α and β (see Fig. 3). In particular, for $\delta < \alpha \le 1$ and small $\beta < 0$, we find (Lemmas 1 and 3) that y' has a first zero on $[0,\bar{x})$, and $y(x_0) = \alpha$ for some first $x_0 > 0$. Next, in Lemmas 2 and 4 we show that if $\delta \le \alpha \le 1$ and $\beta < 0$ is large, then y' cannot have a zero and the solution enters an invariant set K_1 in which y' and y'' must remain negative. We then appeal to a topological result of McLeod and Serrin (Theorem 3) and show in Lemma 5 that there is a continuum γ_λ contained in $\{\delta + \lambda \le \alpha \le 1 - \lambda,\ \beta < 0\}$ for small $\lambda > 0$, which joins the lines $\alpha = \delta + \lambda$ and $\alpha = 1 - \lambda$, and such that if $(\alpha,\beta) \in \gamma_\lambda$, then $\lim_{x\to\infty}(y,y',y'') = (\delta,0,0)$. Next, we perform a similar analysis that determines the behavior of solutions on $(\tilde{x},0]$ (Lemmas 6–11).

We construct a second continuum, Γ_λ, joining the same lines as γ_λ such that if $(\alpha,\beta) \in \Gamma_\lambda$, then $\lim_{x\to-\infty}(y,y',y'') = (1,0,0)$ (see Fig. 4). For small $\lambda > 0$ we show that $\gamma_\lambda \cap \Gamma_\lambda \ne \phi$. Thus, if $(\bar{\alpha},\bar{\beta}) \in \gamma_\lambda \cap \Gamma_\lambda$ for small $\lambda > 0$, then Theorem 1 follows.

One of the main tools in our analysis is the energy functional

$$Q = y'y'' + y + \frac{(1+\delta+\delta^2)}{y} - \frac{(\delta+\delta^2)}{(2y^2)}, \tag{2.3}$$

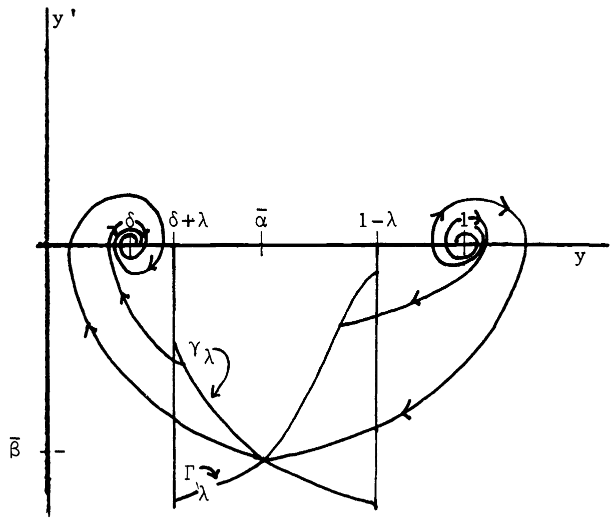

FIG. 4

which satisfies

$$Q' = (y'')^2. \tag{2.4}$$

We use Q to obtain our first technical result. Lemma 1 will play a key role in the construction of one of our shooting sets.

LEMMA 1. *Let $\delta < \alpha \le 1$ and $\beta < 0$. If there is a first $x_0 \in (0, \bar{x})$ for which $y(x_0) = \alpha$, then $y'(x_0) > 0$.*

Proof. Since $\beta < 0$, the definition of x_0 implies that $y'(x_0) \ge 0$. We assume, for the sake of contradiction, that $y'(x_0) = 0$. This and (2.3) lead to

$$Q(x_0) = Q(0). \tag{2.5}$$

For $\delta < \alpha < 1$, (2.1) gives $y'''(0) > 0$. Therefore, $y'' > 0$ on a small interval $(0, \epsilon)$, and an integration of (2.4) shows that

$$Q(x_0) = Q(0) + \int_0^{x_0} (y'')^2 dt \ge Q(0) + \int_0^{\epsilon} (y'')^2 dt > Q(0),$$

contradicting (2.5). If $\alpha = 1$, then $y'''(0) = 0$ and $y''''(0) = \beta(\delta^2 + \delta - 2) > 0$. Again $y''' > 0$ and $y'' > 0$ on a small interval $(0, \epsilon)$, and the same contradiction occurs. Thus we must conclude that $y'(x_0) > 0$.

Before defining our two shooting sets we need to determine the properties of a second type of solution, one which intersects the subset of R^3 given by

$$K_1 = \{(y, y', y'') \in R^3 | 0 < y < \delta, y' < 0, y'' < 0\}. \tag{2.6}$$

LEMMA 2. *If a solution of* (2.1), (2.2) *satisfies $(y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_1$ for some $\hat{x} \in [0, \bar{x})$, then $(y(x), y'(x), y''(x)) \in K_1$ for all $x \in [\hat{x}, \bar{x})$.*

Proof. It follows from (2.1) that $y'''(x) < 0, y'' < 0, y' < 0$, and $y > 0$, for all $x \in [\hat{x}, \bar{x})$.

We are now prepared to define our topological shooting sets by the following:

$A = \{(\alpha,\beta) \in E | y(x_0) = \alpha$ for some first $x_0 > 0$ and $0 < y(x) < \alpha$ on $(0,x_0)\}$;

$B = \{(\alpha,\beta) \in E | (y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_1$ for some $\hat{x} > 0$, and $0 < y(x) < \alpha$ for $0 < x < \hat{x}]\}$.

Remarks. We observe that $(y,y',y'') \equiv (\delta,0,0)$ and $(y,y',y'') \equiv (1,0,0)$ are solutions of (1.1). Thus, if $(\alpha,\beta) \in A \cup B$, then $(\alpha,\beta) \neq (\delta,0), (\alpha,\beta) \neq (1,0)$. Furthermore, if $(\alpha,\beta) = (\delta,\beta)$ and $\beta < 0$, then $y'''(0) = 0, y^{(4)}(0) < 0$, and (y,y',y'') immediately enters K_1. Thus $(\delta,\beta) \in B$ if $\beta < 0$.

It follows from Lemmas 1 and 2 and continuity that A and B are relatively open, disjoint subsets of E. We need to show that $A \neq \phi$ and $B \neq \phi$. For this we have the next two lemmas (see Fig. 3).

LEMMA 3. *For each $\alpha \in (\delta, 1]$ there exists $\beta_\alpha < 0$ such that if $\beta_\alpha < \beta < 0$, then $y(x_0) = \alpha$ for some first $x_0 > 0$.*

Proof. If $\alpha \in (\delta, 1)$ and $-\beta > 0$ is sufficiently small, then $y''' > 0$ for $x > 0$ until $y = 1$. This and continuity imply the result. If $\alpha = 1$ and $-\beta > 0$ is sufficiently small, then a linearization shows that (y,y') spirals around $(1,0)$ in the (y,y') plane, and the lemma follows.

It follows from Lemma 3 that $(\alpha,\beta) \in A$ if $\delta < \alpha \leq 1, \beta_\alpha < \beta < 0$.

LEMMA 4. *There exists $\tilde{\beta} \leq 0$ such that if $\delta \leq \alpha \leq 1$ and $\beta \leq \tilde{\beta}$, then $(y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_1$ for some $\hat{x} \in (0, \bar{x})$, and $y' < 0$ for $0 \leq x \leq \hat{x}$.*

Proof. Equation (2.1) shows that $|y'''|$ is bounded while $\delta/2 \leq y \leq 1$. Therefore, for large $-\beta > 0$, and $\delta \leq \alpha \leq 1$, there must be a first $x_1 \in (0, \bar{x})$ for which $y(x_1) = \delta/2$, and $y' < \beta + 1 << -2, y'' < 1$ for all $x \in (0, x_1]$. If $y''(x_1) \leq 0$, then $y'''(x_1) < 0$, and Lemma 2 shows that $(y,y',y'') \in K_1$ for all $x \in (x_1, \bar{x})$. We assume, for the sake of contradiction, that $y'' > 0$ for $x > x_1$ as long as $y' \leq 0$ and $y > 0$. Since (2.1) is autonomous, we may take $x_1 = 0$ so that

$$y(0) = \frac{\delta}{2}, \quad \beta < y'(0) < \beta + 1, \quad 0 < y''(0) < 1. \tag{2.7}$$

For $x > 0$, as long as $y' \leq 0$ and $y > 0$ we see that $y < \delta/2$ so that $y''' \leq -5$,

$$y'' \leq 1 - 5x, \quad \text{and} \quad y' \leq (\beta + 1) + x - \tfrac{5}{2}x^2. \tag{2.8}$$

Suppose for large $-\beta > 0$, that $y > 0$ over $[0, \frac{1}{5}]$ as long as $y'' > 0$. Then (2.8) shows that there is a first $\hat{x} \in \left(0, \frac{1}{5}\right]$ for which $y''(\hat{x}) = 0$, and $y' < 0$ on $[0, \hat{x})$. But then (y,y',y'') enters K_1 at $\hat{x}$. Thus the only possibility that remains is that $y(b) = 0$ for some first $b \in \left(0, \frac{1}{5}\right)$, and $y'' > 0, y' < 0$ on $[0, b)$. Let $0 < \epsilon < \delta/2$ be arbitrarily chosen, and let $a_2 > a_1 > 0$ satisfy $y(a_1) = \epsilon$ and $y(a_2) = \epsilon/2$. Then $y' > \beta$ over $[a_1, a_2]$ so that $a_2 - a_1 \geq -\epsilon/2\beta$. Also, over $[a_1, a_2]$ (2.1) gives $y''' < -(\delta + \delta^2)/2\epsilon^3$ for small $\epsilon > 0$. Therefore, $y'' < 1 - ((\delta + \delta^2)/2\epsilon^3)(x - a_1)$ over $a_1 < x < a_2$. In particular, we see that $y''(a_2) < 1 + ((\delta + \delta^2)/4\epsilon^2\beta) < 0$ for small $\epsilon > 0$, a contradiction. This completes the proof.

It follows from Lemma 4 that $(\alpha,\beta) \in B$ if $\delta \leq \alpha \leq 1$ and $\beta \leq \tilde{\beta}$. In order to complete the first part of our proof of Theorem 1 we need a topological result proved by McLeod and Serrin [1].

THEOREM 3 (see [1]). *Let I be the closed unit square $\{0 \leq x \leq 1, 0 \leq y \leq 1\}$ in the (x,y) plane, and let S^- and S^+ be disjoint relatively open subsets of I, respectively,* *containing the lines $y = 0$ and $y = 1$. Then the complement D of S^+ and S^- in I contains a continuum joining the lines $x = 0$ and $x = 1$.*

The McLeod–Serrin result applies to any closed rectangle in the plane. We need to apply this result to a subset of our set E in the (α, β) plane. For each small $\lambda > 0$ we define the subset E_λ of E by

$$E_\lambda = \{(\alpha,\beta) \in E | \delta + \lambda \leq \alpha \leq 1 - \lambda \text{ and } \tilde{\beta} \leq \beta \leq 0\}.$$

We define $S_\lambda^+ = A \cap E_\lambda$, $S_\lambda^- = B \cap E_\lambda$. Since A and B are relatively open in E, then S_λ^+ and S_λ^- are relatively open subsets of E_λ. Furthermore, Lemma 3 and continuity imply that the set $\delta + \lambda \leq \alpha \leq 1 - \lambda$, $\beta_\alpha < \beta < 0$ is contained in S_λ^+. Lemma 4 and continuity imply that the line segment $\beta = \tilde{\beta}$, $\delta + \lambda \leq \alpha \leq 1 - \lambda$ is contained in S_λ^-. Also, $S_\lambda^+ \cap S_\lambda^- = \phi$ since $A \cap B = \phi$. Thus, by Theorem 3 there is a continuum γ_λ contained in the complement $D_\lambda = E_\lambda - (S_\lambda^+ \cup S_\lambda^-)$ and which joins the lines $\alpha = \delta + \lambda, \tilde{\beta} < \beta < \beta_{\delta+\lambda}$ and $\alpha = 1 - \lambda$, $\tilde{\beta} < \beta < \beta_{1-\lambda}$. Recall that the entire line segment $\alpha = \delta$, $\tilde{\beta} < \beta < 0$ is contained in B. Similarly, by Lemma 3 the entire line segment $\alpha = 1$, $\beta_1 < \beta < 0$, is contained in A. The "endpoints" of γ_λ consist of the two sets

$$G_\lambda = \{(\delta + \lambda, \beta) |\ (\delta + \lambda, \beta) \in \gamma_\lambda\},$$

$$H_\lambda = \{(1 - \lambda, \beta) |\ (1 - \lambda, \beta) \in \gamma_\lambda\}.$$

Set $b_1(\lambda) \equiv \inf G_\lambda$ and $b_2(\lambda) \equiv \sup H_\lambda$. From these definitions, continuity, and our preceding discussion it follows that $b_1(\lambda) \longrightarrow 0$ as $\lambda \longrightarrow 0^+$, and $b_2(\lambda) \leq \beta_1/2 < 0$ for all small $\lambda > 0$. (See Fig. 3.) Next, we determine the behavior of solutions that satisfy $(\alpha, \beta) \in \gamma_\lambda$, where $\delta + \lambda < 1 - \lambda$.

LEMMA 5. *Let $(\alpha, \beta) \in \gamma_\lambda$. Then*

(i) $0 < \inf\{y(\zeta) | 0 < \zeta < \bar{x}\} \leq y(x) < \alpha$ *for* $0 < x < \bar{x}$;

(ii) $\bar{x} = \infty$;

(iii) $\lim_{x\to\infty} (y, y', y'') = (\delta, 0, 0)$.

Remarks. In the (y, y') plane a linearization shows that the solution spirals to $(\delta, 0)$ as $x \to \infty$. This and (i) imply that all relative minima of y remain bounded away from zero, while the relative maxima of y are less than α.

Proof. Suppose that $y(x_0) = \alpha$ for some first $x_0 > 0$. Then $(\alpha, \beta) \in A$, a contradiction. Next, we assume, for the sake of contradiction, that $\inf_{0<\zeta<\bar{x}}\{y(\zeta)\} = 0$. If, in fact, $\lim_{x\to\bar{x}} y(x) = 0$, then there is an $x_1 \in (0, \bar{x})$ with $y(x_1) = \delta/2$, and $y \in (0, \delta/2)$ for all $x \in (x_1, \bar{x})$. It then follows exactly as in the last part of the proof of Lemma 4 that (y, y', y'') eventually enters K_1. Thus $(\alpha, \beta) \in B$, again a contradiction. The remaining alternative is that $0 = \underline{\lim}_{x\to\bar{x}}\, y(x) < \overline{\lim}_{x\to\bar{x}}\, y(x)$. Then there exists an increasing sequence $\{x_N\}_N$ of positive numbers with $\lim_{N\longrightarrow\infty} x_N = \bar{x}, y'(x_N) = 0$ for all N, and $\lim_{N\to\infty} y(x_N) = 0$. This and (2.3) imply that $Q(x_N) \longrightarrow -\infty$ as $N \longrightarrow \infty$, a contradiction since $Q(0) > -\infty$ and $Q' \geq 0$ for all $x \in [0, \bar{x})$. Thus we must conclude that $\inf\{y(\zeta) | 0 < \zeta < \bar{x}\} > 0$, and (i) is proved. With y bounded below away from zero and bounded above by α, it follows from (2.1) that

$$|y'''| < M \quad \text{for } 0 < x < \bar{x} \tag{2.9}$$

for some $M > 0$. An integration of (2.9) shows that y' and y'' are bounded over any finite interval. Therefore, (y', y'') cannot become unbounded at any finite value, and

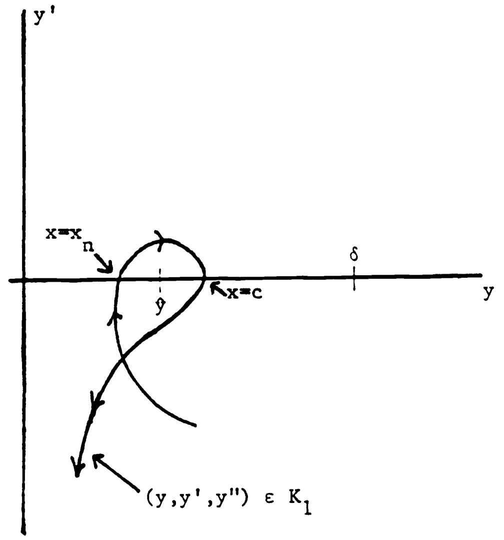

FIG. 5

it must be the case that $\bar{x} = \infty$ so that (ii) is proved. It remains to be shown that $\lim_{x\to\infty}(y, y', y'') = (\delta, 0, 0)$. First we show that Q is bounded above. If, in fact, $Q \longrightarrow \infty$ as $x \longrightarrow \infty$, it must be the case that $\lim_{x\to\infty} y'y'' = \infty$ since y is bounded away from zero. This leads either to $y \longrightarrow \infty$ or $y \longrightarrow -\infty$, which, by part (i), cannot be true. Therefore, $\lim_{x\to\infty} Q(x) = \bar{Q} < \infty$. Suppose that $\underline{\lim}_{x\to\infty} y'' = -\mu < 0$. Since y is bounded, it must be the case that $\overline{\lim}_{x\to\infty} y'' \geq 0$. Therefore, there is an unbounded increasing sequence $\{x_N\}_N$ such that $y''(x_N) = -\mu/2$ and $y'''(x_N) \geq 0$ for all N. Choose N such that

$$Q(x_N) > \bar{Q} - \frac{\mu^3}{64M}. \tag{2.10}$$

Let $a = x_N$, and let $b > a$ the succeeding point for which $y(b) = -\mu/4$. Then $y''' \leq M$ on (a, b) so that $b - a \geq \mu/(4M)$. This and (2.4), (2.10) lead to $Q(b) \geq Q(a) + \mu^3/64M > \bar{Q}$, a contradiction. It follows that $\underline{\lim}_{x\to\infty} y'' \geq 0$. Similarly, $\lim_{x\to\infty} y'' \leq 0$ so that $\lim_{x\to\infty} y'' = 0$. Next, suppose that $\overline{\lim}_{x\to\infty} y(x) \neq \delta$. There are two possibilities. First, suppose that $\lim_{x\to\infty} y(x) = \bar{y}$ exists with $\bar{y} \in (0, \delta) \cup (\delta, \alpha]$. Then $\lim_{x\to\infty} y''' = \gamma \neq 0$, and an integration leads to $y''(\infty) \neq 0$, a contradiction. The other possibility is that $\underline{\lim}_{x\to\infty} y(x) < \overline{\lim}_{x\to\infty} y(x)$. First, suppose that $\underline{\lim}_{x\to\infty} y(x) = \hat{y} < \delta$. Let $\{x_N\}_N$ be an increasing unbounded sequence with $y'(x_N) = 0$ for all N, and $\lim_{N\to\infty} y(x_N) = \hat{y}$. Also, $\lim_{N\to\infty} y''(x_N) = 0$. From (2.1) there is an $\eta > 0$ such that $y''' \leq -\eta$ when $y \leq (\hat{y} + \delta)/2$. Thus, if $y''(x_n) > 0$, an integration of (2.1) from x_N to x shows that for large $N, y' = 0$ and $y'' \leq 0$ at some first $x = c > x_N$ before $y = \hat{y}/2$ (Fig. 5). Thus (y, y', y'') enters K_1 at $x = c$ so that $(\alpha, \beta) \in B$, a contradiction. Similarly, (y, y', y'') enters K_1 at x_N if $y''(x_N) < 0$. Therefore, $\underline{\lim}_{x\to\infty} y(x) \geq \delta$. If we assume that $\overline{\lim}_{x\to\infty} y(x) > \delta$, then similar reasoning shows that y exceeds α, again a contradiction. Therefore, $\lim_{x\to\infty} y(x) = \delta$. Finally, it remains to prove that $\lim_{x\to\infty} y' = 0$. If $\underline{\lim}_{x\to\infty} y' < 0$, then it easily follows from the fact that $y'' \to 0$ and an integration that $\underline{\lim}_{x\to\infty} y(x) < \delta$, a contradiction. Thus $\underline{\lim}_{x\to\infty} y' \geq 0$. Likewise, $\overline{\lim}_{x\to\infty} y' \leq 0$. Therefore, $\lim_{x\to\infty}(y, y', y'') = (\delta, 0, 0)$, and (iii) is proved.

We now proceed with the second part of our shooting argument in which we follow solutions backwards from zero. Again, let $\lambda > 0$ satisfy $\delta + \lambda < 1 - \lambda$. For each such λ, our goal is to prove that there is a second continuum $\Gamma_\lambda \subseteq E_\lambda$ that joins the lines $\alpha = \delta + \lambda, \beta < 0$, and $\alpha = 1 - \lambda, \beta < 0$ and has the following additional properties. (Refer to Fig. 4.)

LEMMA 6. *Let* $(\alpha, \beta) \in \Gamma_\lambda$;

(i) $\alpha < y(x)$ *for* $\tilde{x} < x < 0$;

(ii) $\tilde{x} = -\infty$;

(iii) $\lim_{x \to -\infty}(y, y', y'') = (1, 0, 0)$.

Furthermore, if $b_3 \equiv \sup\{\beta < 0 | (\delta + \lambda, \beta) \in \Gamma_\lambda\}$ *and* $b_4 \equiv \inf\{\beta < 0 | (1 - \lambda, \beta) \in \Gamma_\lambda\}$, *then* b_3 *is bounded away from zero for small* λ, *and* $b_4 \to 0$ *as* $\lambda \to 0$.

We postpone the proof of Lemma 6 in order to see its consequences (Fig. 4). It follows from the properties of γ_λ and Γ_λ given above that $\gamma_\lambda \cap \Gamma_\lambda \neq \phi$ for small $\lambda > 0$. Let $(\bar{\alpha}, \bar{\beta}) \in \gamma_\lambda \cap \Gamma_\lambda$. Lemmas 5 and 6 imply that the solution with $y(0) = \bar{\alpha}, y'(0) = \bar{\beta}, y''(0) = 0$ must exist for all $x \in (-\infty, \infty)$, that $\lim_{x \to -\infty}(y, y', y'') = (1, 0, 0)$ and $\lim_{x \to \infty}(y, y', y'') = (\delta, 0, 0)$. Theorem 1 follows. Thus it remains to prove the existence of Γ_λ. For this we find it convenient to set $t = -x$ so that the problem (2.1), (2.2) becomes

$$y''' = 1 - \frac{(1 + \delta + \delta^2)}{y^2} + \frac{(\delta + \delta^2)}{y^3} \tag{2.11}$$

with initial condition

$$y(0) = \alpha, \quad y'(0) = -\beta > 0, \quad y''(0) = 0, \tag{2.12}$$

where $' \equiv d/dt$. Also, we set $\tilde{t} = -\tilde{x}$. It is evident that Lemma 6 is equivalent to the following.

LEMMA 7. *Let* $(\alpha, \beta) \in \Gamma_\lambda$. *Then*

(i) $\alpha < y(t)$ *for* $0 < t < \tilde{t}$;

(ii) $\tilde{t} = \infty$;

(iii) $\lim_{t \to \infty}(y, y', y'') = (1, 0, 0)$.

The existence of Γ_λ follows from a two-dimensional shooting argument that is similar to that used to prove the existence of γ_λ. Again, the first step is to define an energy functional analogous to Q, namely,

$$P \equiv y'y'' - y - \frac{(1 + \delta + \delta^2)}{y} + \frac{(\delta + \delta^2)}{2y^2}, \tag{2.13}$$

which satisfies

$$P' = (y'')^2. \tag{2.14}$$

The existence of Γ_λ and the proof of Lemma 7 requires the next four lemmas, which are analogous to Lemmas 1–4.

LEMMA 8. *Let* $\delta < \alpha \leq 1$ *and* $-\beta > 0$. *If there is a first* $t_0 > 0$ *for which* $y(t_0) = \alpha$, *then* $y'(t_0) < 0$.

Proof. $y'(t_0) \leq 0$ by definition of t_0. Suppose that $y'(t_0) = 0$. Then (2.13) implies that

$$P(t_0) = P(0). \tag{2.15}$$

However, $-\beta > 0$ and $\delta < \alpha \leq 1$ so that (2.11), (2.12) imply that $y'' \neq 0$ on an interval $(0, \epsilon)$. Therefore, an integration of (2.14) gives $P(t_0) > P(0)$, contradicting (2.15).

For our next result, we define the set

$$(2.16) \qquad H_1 = \{(y, y', y'') \in R^3 | y > 1, y' > 0, y'' > 0\}.$$

The set H_1 will play a role similar to that of the set K_1 defined in (2.6). In Lemma 2 we described the crucial properties of K_2, and we now describe the key properties of H_1 in our next result.

LEMMA 9. *If* $\left(y\left(\hat{t}\right), y'\left(\hat{t}\right), y''\left(\hat{t}\right)\right) \in H_1$ *for some* $\hat{t}$, *then* $(y(t), y'(t), y''(t)) \in H_1$ *for all* $t \in \left(\hat{t}, \tilde{t}\right)$.

Proof. It follows from (2.11) that $y''' > 0, y'' > 0, y' > 0$, and $y > 1$ for all $t \in \left(\hat{t}, \tilde{t}\right)$.

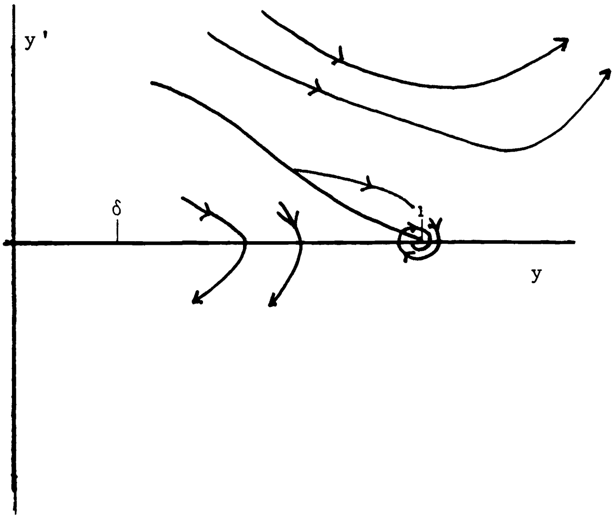

FIG. 6

We now define our topological shooting sets by (see Fig. 6)

$$C = \{(\alpha, \beta) \in E | \text{ there exists a first } t_0 > 0 \text{ with } y(t_0) = \alpha \text{ and } y > \alpha \text{ on } (0, t_0)\},$$
$$D = \{(\alpha, \beta) \in E | \left(y\left(\hat{t}\right), y''\left(\hat{t}\right), y''\left(\hat{t}\right)\right) \in H_1 \text{ for some } \hat{t} > 0,$$
$$\text{and } y > \alpha \text{ for all } t \in \left(0, \hat{t}\right]\}.$$

Remarks. It follows from the definitions of the sets C and D so that $(\alpha, \beta) \notin C \cup B$ if $(\alpha, \beta) = (\delta, 0)$ or $(\alpha, \beta) = (1, 0)$. Furthermore, if $(\alpha, \beta) = (1, \beta)$ and $\beta < 0$, then it follows from (2.11) that $y'''(0) = y''(0) = 0, y'(0) = -\beta > 0$ and $y^{(4)}(0) > 0$. Thus (y, y', y'') enters H_1 as t increases from zero, and we conclude that $(1, \beta) \in D$ for all $\beta < 0$.

It follows from Lemmas 8, 9, and continuity that C and D are both open in E, and $C \cap D = \phi$. In order to see that C and D are nonempty, we need the next two results. (See Fig. 6.) These are similar to Lemmas 3 and 4.

LEMMA 10. *For each $\alpha \in [\delta, 1)$ there exists $\beta^{\alpha} < 0$ such that if $-\beta^{\alpha} > -\beta > 0$, then $y(t_0) = \alpha$ for some first $t_0 > 0$.*

Proof. If $\alpha \in (\delta, 1)$ and $-\beta > 0$ is sufficiently small, then (2.11) implies that $y''' < 0$ for $t > 0$ until $y < \delta$. This and continuity imply the result. If $\alpha = \delta$ and $-\beta > 0$ is small, then a linearization of (2.11) around the constant solution $(y, y', y'') \equiv (\delta, 0, 0)$ shows that (y, y') spirals around $(\delta, 0)$ in the (y, y') plane, and the existence of t_0 is assured.

LEMMA 11. *There exists $\bar{\beta} < 0$ such that if $-\beta \geq -\bar{\beta}$ and $\delta \leq \alpha \leq 1$, then*

$$(y(\hat{t}), y'(\hat{t}), y''(\hat{t})) \in H_1 \quad \textit{for some } \hat{t} > 0, \quad \textit{and} \quad y'(t) > 0 \quad \textit{for all } t \in [0, \hat{t}].$$

Proof. Equation (2.11) shows that $|y'''|$ is bounded while $y \geq \alpha$. Thus, for large $-\beta > 0$ there is a first $t_1 \in (0, \bar{t})$ independent of $\alpha \in [\delta, 1]$ such that $y(t_1) = 2$, and $y' > -\beta - 1 > 2, y'' > -1$ for $0 \leq t \leq t_1$. If $y''(t_1) \geq 0$, then $y'''(t_1) > 0$; it follows from (2.11) that $(y, y', y'') \in H_1$ for $t > t_1$. We assume, for the sake of contradiction, that $y'' < 0$ for $t > t_1$ as long as $y' > 0$. Since (2.11) is autonomous, we may set $t_1 = 0$ and consider the initial values

$$y(0) = 2, \quad 2 < -\beta - 1 < y'(0) < -\beta, \quad -1 < y''(0) < 0. \tag{2.17}$$

For $t > 0$, as long as $y' > 0$, equation (2.11) implies that $y''' \geq \frac{1}{2}$,

$$y'' \geq -1 + \frac{t}{2}, \qquad y' \geq 2 - t + \frac{t^2}{4}. \tag{2.18}$$

It easily follows from (2.18) that, if $-\beta > 0$ is sufficiently large, $y'' = 0$ at some $\bar{t} \in (0, 2]$, and $y' > 0$ for all $t \in [0, \bar{t}]$. But then $y'''(\bar{t}) \geq \frac{1}{2}$; hence (y, y', y'') enters H_1 at $\bar{t}$.

We define $U_{\lambda}^{+} = C \cap E_{\lambda}$ and $U_{\lambda}^{-} = D \cap E_{\lambda}$, where, once again, $\lambda > 0$ satisfies $\delta + \lambda < 1 - \lambda$.

It follows from Lemma 10 that $(\alpha, \beta) \in U_{\lambda}^{+}$ if $\delta \leq \alpha < 1$ and $\beta^{\alpha} < \beta < 0$. Lemma 11 shows that $(\alpha, \beta) \in U_{\lambda}^{-}$ if $\delta \leq \alpha \leq 1$ and $|\beta - \bar{\beta}|$ is small. Also, $U_{\lambda}^{+} \cap U_{\lambda}^{-} = \phi$ since $C \cap D = \phi$. Thus, as before, we conclude from the result of McLeod and Serrin that there is a continuum $\Gamma_{\lambda} \subseteq E_{\lambda} - (U_{\lambda}^{+} \cup U_{\lambda}^{-})$ that joins the line segment $\alpha = \delta + \lambda, \bar{\beta} < \beta < 0$ with the line segment $\alpha = 1 - \lambda, \bar{\beta} < \beta < 0$. As with γ_{λ}, we investigate the endpoints of Γ_{λ}, which consist of the sets

$$J_{\lambda} = \{(\delta + \lambda, \beta) |\ (\delta + \lambda, \beta) \in \Gamma_{\lambda}\},$$
$$K_{\lambda} = \{(1 - \lambda, \beta) |\ (1 - \lambda, \beta) \in \Gamma_{\lambda}\}.$$

From continuity and the fact that the line segment $(1, \beta) \in D$ for $\beta < 0$ it follows that $\lim_{\lambda \to 0} \Gamma_{\lambda} \cap \{\alpha = 1 - \lambda\} = (1, 0)$. Furthermore, $(\delta, \beta) \in C$ for $\beta_{\delta} < \beta < 0$ so that $\sup J_{\lambda} < \beta_{\delta}/2$ for all small $\lambda > 0$. This, together with the properties of γ_{λ} described earlier, imply that $\gamma_{\lambda} \cap \Gamma_{\lambda} \neq \phi$ for sufficiently small $\lambda > 0$. Let $(\bar{\alpha}, \bar{\beta}) \in \gamma_{\lambda} \cap \Gamma_{\lambda}$ for small $\lambda > 0$. Then Lemmas 5 and 6 imply Theorem 1.

It remains to prove Lemma 7, which in turn implies Lemma 6. The proof of Lemma 7 uses the same arguments as the proof of Lemma 5. The main difference is that the functional P replaces the functional Q. For the sake of brevity, we omit a repetition of the details.

3. Proof of Theorem 2. Once again, we employ a two-dimensional shooting argument. Here the appropriate initial value problem is

$$y''' = y^{-2} - y^{-3}, \tag{3.1}$$

$$y(0) = \alpha, \quad y'(0) = \beta, \quad y''(0) = 0, \tag{3.2}$$

where $(\alpha, \beta) \in G \equiv \{(\alpha,\beta) | \frac{1}{2} \le \alpha \le 1, \beta \ge 0\}$. Let $[0, \bar{x})$ and $(\tilde{x}, 0]$ denote the maximal positive and negative intervals of existence of the solution of (3.1), (3.2). As in the previous section, we will make use of an energy functional, namely,

$$R = y'y'' + y^{-1} - \frac{y^{-2}}{2}, \tag{3.3}$$

which satisfies

$$R' = (y'')^2 \quad \text{for } \tilde{x} < x < \bar{x} \tag{3.4}$$

and

$$0 \le R(0) \le \tfrac{1}{2} \quad \text{for all } (\alpha, \beta) \in G. \tag{3.5}$$

As in §2 we need two technical lemmas before defining our shooting sets.

LEMMA 12. *For each $\alpha \in \left[\frac{1}{2}, 1\right)$ there exists $\beta_1(\alpha) > 0$ such that if $0 < \beta < \beta_1(\alpha)$, then $y(x_0) = \alpha$ for some first $x_0 > 0$, and $y'(x_0) < 0$.*

Proof. If $\beta = 0$, then $y'(0) = y''(0) = 0$ and $y'''(0) < 0$. This and continuity give the existence of x_0 for small $\beta > 0$. The definition of x_0 implies that $y'(x_0) \le 0$. It follows from (3.3) and (3.4) that $R(x_0) > R(0)$ so that $y'(x_0) < 0$.

Next, we define the subset K_2 of the phase space R^3 by

$$K_2 = \{(y, y', y'') \in R^3 | y > 1, y' > 0, y'' > 0\}. \tag{3.6}$$

LEMMA 13. *If $(y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_2$ for some $\hat{x} > 0$, then $(y(x), y'(x), y''(x)) \in K_2$ for all $x \in [\hat{x}, \bar{x})$.*

Proof. Equation (3.1) and the definition of K_2 imply that $y''' > 0, y'' > 0, y' > 0, y > 1$ for all $x \in [\hat{x}, \bar{x})$, and the lemma immediately follows.

We define our topological shooting (Fig. 6) sets by

$$\begin{aligned} X =& \{(\alpha, \beta) \in G | y(x_0) = \alpha \text{ for some first } x_0 > 0, \text{ and } y > \alpha \text{ for } 0 < x < x_0\}, \\ Y =& \{(\alpha, \beta) \in G | (y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_2 \text{ for some } \hat{x} > 0, \\ & \text{and } y(x) > \alpha \text{ for } 0 < x < \hat{x}\}. \end{aligned} \tag{3.7}$$

It follows from Lemma 12 and continuity that $X \ne \phi$ and X is open in G. Also, continuity implies that Y is open in G. Lemma 13 and the definitions of X and Y imply that $X \cap Y = \phi$. Finally, we show that $Y \ne \phi$ in the following lemma.

LEMMA 14. *There exists $\beta^{**} > 0$ such that if $\frac{1}{2} \leq \alpha \leq 1$ and $\beta \geq \beta^{**}$, then $(y(\hat{x}), y'(\hat{x}), y''(\hat{x})) \in K_2$ for some $\hat{x} \in (0, \bar{x})$, and $y' > 0$ for $0 \leq x < \bar{x}$.*

Proof. Equation (3.1) implies that $|y'''|$ is bounded as long as $y' > 0$. Thus, if $\beta >> 1$ and $\frac{1}{2} \leq \alpha \leq 1$, there is a first $x_1 = x_1(\alpha, \beta) \in (0,1)$ such that $y(x_1) = 2, y'(x) \geq \beta - 1 > 0$ and $y''(x) \geq -1$ over $[0, x_1]$. If $y''(x_1) \geq 0$, then $y'''(x_1) = \frac{1}{8}$, and it follows from Lemma 13 that $(y, y', y'') \in K_2$ for $x_1 < x < \bar{x}$. Suppose, however, that $y''(x) < 0$ for $0 < x < \bar{x}$ as long as $y' > 0$. In order to obtain a contradiction, we need a lower bound on $R(x_1)$. If $\frac{3}{4} \leq y(0) \leq 1$, then $R(0) \geq 12/27$. Thus, by (3.4), $R(x_1) \geq 12/27$. If $\frac{1}{2} \leq y(0) \leq \frac{3}{4}$, we let $0 < a_1 < a_2 < x_1$ satisfy $y(a_1) = \frac{3}{4}$ and $y(a_2) = \frac{7}{8}$. Then $y' < \beta$ and an integration over $[a_1, a_2]$ leads to $a_2 - a_1 \geq 1/(8\beta)$. Also, over $[0, a_2]$ it follows from (3.1) that $y''' \leq -64/343$. Thus $y'' \leq -64_x/343$, and we conclude from (3.43) that $R' \geq (64/343)^2 x^2$ and $R(x) \geq (64/343)^2 x^3/3$. At $x = x_1$, we obtain $R(x_1) \geq R(a_1) \geq 8/(3(343)^2\beta^3)$. Since our system is autonomous we may set $x_1 = 0$ and consider the initial value problem

$$(3.8) \qquad y(0) = 2, \quad \beta - 1 < y'(0) < \beta, \quad -1 \leq y''(0) < 0, \quad R(0) > \frac{8}{3(343)^2\beta^2}.$$

Suppose that $y' > 0$ for all $x \geq 0$. Then $y(\infty)$ exists with $2 < y(\infty) \leq \infty$. If $y(\infty) < \infty$, then $y''' \geq k \equiv (1/(y(\infty))^2) - (1/(y(\infty))^3) > 0$ on $[0, \infty)$. An integration shows that $y'' = 0$ at some first $x_1 > 0$. At $x_1, y(x_1) > 2, y'(x_1) > 0, y''(x_1) = 0$, and $y'''(x_1) > k > 0$ so that (y, y', y'') enters K_2 at x_1. Otherwise, if $y(\infty) = \infty$, then $R(\infty) > 0$, and we conclude from the definition of R that $y'y'' > 0$ for large x. Thus, once again, $y''(x_1) = 0$ at some first $x_1 > 0$ so that (y, y', y'') again enters K_2 at x_1. Finally, we must consider the possibility that $y'(a) = 0$ at some first $a > 0$. Since $y' > 0$ and $R > 0$ on(o, a),then $y'(y'y'' + (1/y) - (1/2y^2)) > 0$, and an integration gives $((y')^3/3 + \ln(y) + (1/2y) > \beta^3/4$ for large β. In particular, since $y(a) > 2$, then at $x = a$ we obtain $\ln(y(a)) > \beta^3/6$ for large β. That is, $y(a) > e^{\beta^3/6}$ for $\beta >> 1$. But then $R(a) \leq e^{-\beta^3/6} < 8/(3(343)^2\beta^3)$ for large β, contradicting (3.8). Thus a cannot exist for large β and the lemma is proved.

The next step in our analysis is to once again apply the McLeod–Serrin result. Let $\lambda > 0$ such that $\frac{1}{2} < 1 - \lambda$. Then, by Lemmas 12–14 and Theorem 3, there is a continuum g_λ contained in the set $\frac{1}{2} \leq \alpha \leq 1 - \lambda, \beta > 0$, which joins the line segments $\alpha = \frac{1}{2}, 0 < \beta < \beta^{**}$ and $\alpha = 1 - \lambda, 0 < \beta < \beta^{**}$ and such that $g_\lambda \cap (X \cup Y) = \phi$. Furthermore, since the line $\alpha = 1, \beta > 0$ is contained in the set Y, then we conclude that $\lim_{\lambda \to 0^+} g_\lambda \cap \{\alpha = 1 - \lambda\} = (1, 0)$. In order to complete the proof of Theorem 2 we need to prove two further results. First, we show in Lemma 15 that if $(\alpha, \beta) \in g_\lambda$, then $(y, y', y'') \longrightarrow (1, 0, 0,)$ as $x \longrightarrow \infty$. Following that, the rest of the proof is devoted to showing that there is a point $(\hat{\alpha}, \hat{\beta}) \in g_\lambda$ for which (1.5) and (1.6) hold.

LEMMA 15. *Let $(\alpha, \beta) \in g_\lambda$. Then*

(i) $\bar{x} = \infty$;

(ii) $\alpha < y(x) < \sup\{y(\zeta) | 0 \leq \zeta < \infty\} < \infty$;

(iii) $\lim_{x \to \infty}(y, y', y'') = (1, 0, 0)$.

Proof. If there were a first $x_0 > 0$ for which $y(x_0) = \alpha$, then Lemma 12 gives $y'(x_0) < 0$ so that $(\alpha, \beta) \in X$. This is a contradiction since $g_\lambda \cap (X \cup Y) = \phi$. Thus $y(x) > \alpha$ for all $x \in (0, \bar{x})$. Equation (3.1) shows that $|y'''|$ is bounded for all $x \in (0, \bar{x})$. Therefore, neither y' nor y'' can become unbounded at finite x. Also, since $y > \alpha$ for all $x \in (0, \bar{x})$, our conclusion must be that $\bar{x} = \infty$. This proves (i) and the first part of (ii). Next, suppose that $\sup\{y(\zeta) | 0 \leq \zeta < \infty\} = \infty$. Then $R(\infty) > 0$. If

y oscillates infinitely often as $x \longrightarrow \infty$, there is an unbounded, increasing sequence $\{x_i\}_i$ with $y(x_i) \longrightarrow \infty$ as $i \longrightarrow \infty$, and $y'(x_i) = 0$, all i. Then $\lim_{i\to\infty} R(x_i) = 0$, a contradiction. Thus it must be the case that $y' > 0$ and $y'' < 0$ for large x, and $y(x) \longrightarrow \infty$ as $x \longrightarrow \infty$. Again, $\lim_{x\to\infty} R(x) > 0$ so that $\lim_{x\to\infty} y'y'' > 0$. But then $y'' > 0, y' > 0, y > 1$ for large x and $(y, y', y'') \in K_2$, a contradiction. Therefore, $\sup\{y(\zeta)|0 \le \zeta < \infty\} < \infty$ and (ii) is proved. Part (iii) now easily follows from energy arguments similar to those used in Lemma 4. We omit the details for the sake of brevity.

Since (1.5) and (1.6) describe the behavior of the required solution as $x \longrightarrow -\infty$, we find it mathematically convenient to "turn the problem around" by setting $t = -x$. Then the appropriate initial value problem is

$$y''' = y^{-3} - y^{-2}, \tag{3.9}$$

$$y(0) = \alpha, \quad y'(0) = -\beta, \quad y''(0) = 0, \tag{3.10}$$

where $(\alpha, \beta) \in G$ and $' \equiv d/dt$. We need to determine the behavior of the solution of (3.9), (3.10) for $t \ge 0$, where $(\alpha, \beta) \in g_\lambda$. First we prove the following result for solutions satisfying $(\alpha, \beta) \approx (1, 0)$.

LEMMA 16. *There are values $\alpha_* \in (\frac{1}{2}, 1)$ and $\beta_* > 0$ such that if $\alpha_* < \alpha < 1$ and $0 \le \beta < \beta_*$, then $y''(t_0) = 0$ at some first $t_0 > 0$. Furthermore, $y''(t) > 0$ over $(0, t_0), y(t_0) > 1, y'(t_0) > 0$ and $y'''(t_0) < 0$.*

Proof. A linearization of (3.9) around the constant solution $y \equiv 1$ shows that the solution must spiral around $(1, 0)$ in the (y, y') plane if $1 - \alpha > 0$ and $\beta \ge 0$ are sufficiently small. In particular, since $\alpha < 1$, (3.19) implies that $y''' > 0$ for $t \ge 0$ until $y = 1$ at some first $\hat{t} > 0$. Here $y'(\hat{t}) > 0$ and $y''(\hat{t}) > 0$. Thus $y(t_0) > 1$, and it follows from (3.9) that $y'''(t_0) < 0$. This proves the lemma.

Remark. Recall that $\lim_{\lambda\to 0} g_\lambda \cap \{\alpha = 1 - \lambda\} = (1, 0)$. This and Lemma 16 immediately imply the following.

LEMMA 17. *If $\lambda > 0$ is small and $(1 - \lambda, \beta) \in g_\lambda$ for some $\beta > 0$, then there is a first $t_0 > 0$ such that $y''(t_0) = 0$. Furthermore, $y(t_0) > 1, y'(t_0) > 0, y'''(t_0) < 0$.*

We are now prepared to finish the proof of Theorem 2. Since g_λ is a continuum, we conclude that there is a continuous function $f : [\frac{1}{2}, 1 - \lambda] \longrightarrow (0, \infty)$ such that $(\alpha, f(\alpha)) \in g_\lambda$ for all $\alpha \in [\frac{1}{2}, 1 - \lambda]$. Furthermore, we assume that $\lambda > 0$ is sufficiently small so that Lemma 17 holds. We need to determine the behavior of the solution of $(3.9), (3.10)$, where $\beta = f(\alpha)$ as α increases from $\frac{1}{2}$ to $1 - \lambda$. That is, $y(0) = \alpha$ and $(dy/dt)(0) = -f(\alpha)$. (See Fig. 7.) We will use the functional

$$S \equiv y'y'' + \frac{y^{-2}}{2} - y^{-1}, \tag{3.11}$$

which satisfies

$$S' = (y'')^2 \tag{3.12}$$

and

$$-\tfrac{1}{2} \le S(0) \le 0 \quad \textit{for } (\alpha, \beta) \in g_\lambda. \tag{3.13}$$

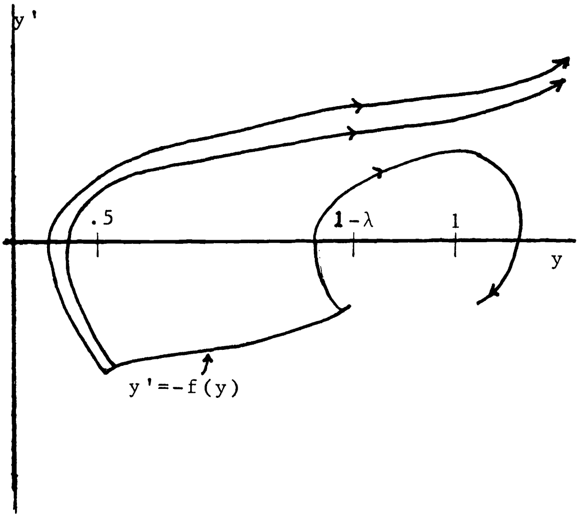

FIG. 7

The functional S plays a key role in proving the next pivotal result.

LEMMA 18. *Let $\frac{1}{2} \leq \alpha \leq 1-\lambda$ and $(y(0),(dy/dt)(0)) = (\alpha, -f(\alpha))$. If there is a value $\hat{t} > 0$ such that $S(\hat{t}) \geq 0$ and $y'' > 0$ for $0 < t \leq \hat{t}$, then $y'' > 0$ for all $t \in (0, \tilde{t})$.*

Proof. If $y''(t_0) = 0$ at some first $t_0 \in (\hat{t}, \tilde{t})$, then $y'''(t_0) \leq 0$ so that $y(t_0) \geq 1$. Thus, by (3.11), $S(t_0) \leq 0$. However, since $y'' > 0$ over $(\hat{t}, t_0)$, (3.12) and the condition $S(\hat{t}) \geq 0$ imply that $S(t_0) > 0$, a contradiction.

LEMMA 19. *If $\alpha - \frac{1}{2} \geq 0$ is sufficiently small and $(y(0),(dy/dt)(0)) = (\alpha, -f(\alpha))$, then there exists $\hat{t} = \hat{t}(\alpha) > 0$ such that $S(\hat{t}) > 0$, and $y'' > 0$ over $(0, \hat{t}]$.*

Proof. First we assume that $\alpha = \frac{1}{2}$ so that $y(0) = \frac{1}{2}, (dy/dt)(0) = -f(\frac{1}{2}) \leq 0$ and $(d^2y/dt^2)(0) = 0$. Then $y'''(0) > 0$ and $S(0) = 0$. Thus $y'' > 0$ and $S > 0$ on an interval $(0, \epsilon)$. This, continuity, and Lemma 18 prove the result.

Lemmas 17–19 will be used to help complete the first part of the proof of Theorem 2. For this we define the set $J = \{\hat{\alpha} \in (\frac{1}{2}, 1) |$ if $\frac{1}{2} < \alpha < \hat{\alpha}$ and $(y(0), y'(0), y''(0)) = (\alpha, -f(\alpha), 0)$, then there exists $\hat{t} > 0$ such that $y'' > 0$ for $0 < t \leq \hat{t}$ and $S(\hat{t}) > 0\}$. Continuity and Lemma 19 imply that J is open and nonempty.

Let $\alpha^* \equiv \sup J$. It follows from Lemma 17 that $\alpha^* < 1 - \lambda$. We consider the special solution of (3.10) for which $(y(0), (dy/dt)(0), (d^2y/dt^2)(0)) = (\alpha^*, -f(\alpha^*), 0)$.

We need to prove that

$$\lim_{t\to\infty} \left(y(t), \frac{dy}{dt}, \frac{d^2y}{dt^2} \right) = (\infty, \infty, 0). \tag{3.14}$$

First, since $y(0) = \alpha^* < 1$, then (3.9) implies that $y'' > 0$ for $t > 0$ at least until $y(t_1) = 1$ at some first $t_1 > 0$. Also, since $y(0) < 1$, $y'(0) \leq 0$ and $y'' > 0$ over $(0, t_1)$, it must be the case that $y'(t_1) > 0$. Thus we have $y(t_1) = 1, y'(t_1) > 0$, and $y''(t_1) > 0$. If there were a first $t_0 > t_1$ for which $y''(t_0) = 0$, then $y(t_0) > 1, y'''(t_0) < 0$, and $S(t_0) < 0$. It follows from (3.12) that $S < 0$ for $0 < t \leq t_0$. From this and continuity we see that $\alpha \notin J$ if $\alpha^* - \alpha \geq 0$ is sufficiently small, contradicting the definition of α^*. Thus it must be the case that $y'' > 0, y > 1, y' > y'(t_1) > 0,$ and $y''' < 0$ over (t_1, ∞). From this we conclude that $y(\infty) = \infty$ and $y''(\infty)$ must exist. If $y''(\infty) > 0$, then $S(\infty) = \infty$. Therefore, $S(\hat{t}) > 0$ for some $\hat{t} > 0$ and $y'' > 0$ over $(0, \hat{t}]$. But then continuity implies that $\alpha \in J$ if $\alpha - \alpha^* > 0$ is sufficiently small, again contradicting the definition of α^*. Therefore, $y''(\infty) = 0$. Finally, suppose that $y'(\infty) = K$ for some $K \in (0, \infty)$. Then, for large t it must be the case that $Kt < y < 2Kt$ and $y''' \le -1/(8K^2t^2)$. Then $y''(t) > \int_t^\infty (1/(8K^2u^2))du = 1/(8k^2t)$. One more integration shows that y' exceeds K at some finite t, a contradiction of the definition of K unless $K = \infty$. Thus we conclude that $\lim_{t\to\infty} y'(t) = \infty$.

To finish the proof of the first part of Theorem 2 we recall that $t = -x$ and conclude from the properties given above that $\lim_{x\to-\infty}(y(x), dy/dx, d^2y/dx^2) = (\infty, -\infty, 0)$.

The final step in proving Theorem 2 is to show that

$$\lim_{t\to\infty} \frac{y(t)}{(3^{1/3}t \log^{1/3}(t))} = 1 \tag{3.15}$$

and

$$\lim_{t\to\infty} \frac{y'(t)}{(3^{1/3} \log^{1/3}(t))} = 1. \tag{3.16}$$

At several points in the derivation of (3.15) and (3.16) we will make use of the following version of l'Hôpital's Rule.

L'Hôpital's Rule [2, pp. 384–385]. Suppose that f and g are differentiable and $g'(t) \neq 0$ on an open interval (d, ∞). Suppose that

$$\lim_{t\to\infty} f(t) = \lim_{t\to\infty} g(t) = 0 \quad \text{or that}$$
$$\lim_{t\to\infty} f(t) = \pm\infty \quad \text{and} \quad \lim_{t\to\infty} g(t) = \pm\infty.$$

If $\lim_{t\to\infty} f'(t)/g'(t)$ exists, then $\lim_{t\to\infty} f(t)/g(t) = \lim_{t\to\infty} f'(t)/g'(t)$.

We need one last technical result for the proof of (3.15) and (3.18), namely, the following.

LEMMA 20. *Let* $(y(0), (dy/dt)(0), (d^2y/dt^2)(0)) = (\alpha^*, -f(\alpha^*), 0)$. *Then*

(i) $\lim_{t\to\infty} S(t) = 0$;
(ii) $\lim_{t\to\infty} t/y = \lim_{t\to\infty} ty'' = \lim_{t\to\infty} yy'' = 0$;
(iii) $\lim_{t\to\infty} yy'y'' = 1$;
(iv) $\lim_{t\to\infty}((y')^3/\log(y)) = 3$;
(v) $\lim_{t\to\infty}(\log(y)/\log(t)) = 1$.

Proof. (i) Recall that $S = y'y'' - 1/y + 1/(2y^2)$ and $y(\infty) = \infty$. Thus we only need to prove that $y'y'' \longrightarrow 0$ as $t \longrightarrow \infty$. If $S(\hat{t}) > 0$ at some $\hat{t} > 0$, then continuity again implies that $\alpha^* \neq \sup J$. Therefore, $S(t) < 0$ on $(0, \infty)$, and it follows that $\lim_{t\to\infty} y'y'' \le 0$. However, $y' > 0$ and $y'' > 0$ for large $t > 0$. Thus $\lim_{t\to\infty} y'y'' = 0$, and (i) is proved.

(ii) From l'Hôpital's Rule we see that $\lim_{t\to\infty} t/y = \lim_{t\to\infty} 1/y' = 0$. An integration of (3.9) leads to

$$y''(t) = \int_t^\infty (y^{-2} - y^{-3})d\mu. \tag{3.17}$$

From (3.17) and an application of l'Hôpital's Rule we obtain

$$\lim_{t\to\infty} ty'' = \lim_{t\to\infty} \left(\int_t^\infty (y^{-2} - y^{-3})d\mu\right) \Big/ \left(\frac{1}{t}\right) = \lim_{t\to\infty} \left(\frac{t}{y}\right)^2 \left(1 - \frac{1}{y}\right) = 0.$$

Similarly, $\lim_{t\to\infty} yy'' = \lim_{t\to\infty}(1-(1/y))(1/y') = 0$.

(iii) Next, we integrate $S' = (y'')^2$ from t to ∞ and obtain

$$y'y'' = \frac{1}{y} - \frac{1}{2y^2} - \int_t^\infty (y'')^2 d\mu. \tag{3.18}$$

Multiplication of (3.18) by y gives

$$yy'y'' = 1 - \frac{1}{2y} - y\int_t^\infty (y'')^2 d\mu. \tag{3.19}$$

We need to show that the last term in (3.19) tends to zero as $t \longrightarrow \infty$. Again, by l'Hôpital's Rule, we obtain

$$\lim_{t\to\infty} y\int_t^\infty (y'')^2 d\mu = \lim_{t\to\infty} \frac{(yy'')^2}{y'} = 0.$$

(iv) From l'Hôpital's Rule, and (iii), it follows that

$$\lim_{t\to\infty} \frac{(y')^3}{\log(y)} = \lim_{t\to\infty} 3\, yy'y'' = 3.$$

(v) From (ii) and l'Hôpital's Rule, we obtain

$$\lim_{t\to\infty} \frac{\log(y)}{\log(t)} = \lim_{t\to\infty} \frac{ty'}{y} = \lim_{t\to\infty} \left(1 + \frac{ty''}{y'}\right) = 1.$$

We are now prepared to complete the derivation of (3.15) and (3.16). Multiply (3.18) by y', integrate from zero to t, and it follows that

$$\frac{(y')^3}{3} = \log(y) + \frac{1}{2y} - \int_0^t y'(\mu)\int_\mu^\infty (y''(s))^2 ds\, d\mu + W, \tag{3.20}$$

where $W = -[(f(\alpha^*))^3/3 + \log(\alpha^*) + 1/\alpha^*]$.

We divide (3.20) by $\log(t)$, use (v) of Lemma 20 and l'Hôpital's Rule to obtain

$$\lim_{t\to\infty} \frac{(y'(t))^3}{3\log(t)} = 1 + \lim_{t\to\infty}\left(-ty'\int_t^\infty (y''(s))^2 ds\right). \tag{3.21}$$

We need to show that the last term in (3.21) tends to zero as $t \to \infty$. First, since $y' > 0$ for large $t > 0$, then (3.21) implies that $y' \le 2[3^{1/3}\log^{1/3}(t)]$ for large $t > 0$. Thus

$$ty'(t)\int_t^\infty (y''(s))^2 ds \le 2t3^{1/3}\log^{1/3}(t)\int_t^\infty (y''(s))^2 ds. \tag{3.22}$$

From l'Hôpital's Rule we conclude that

$$\begin{aligned} &\lim_{t\to\infty} \int_t^\infty \frac{(y''(s))^2 ds}{(t^{-1}\log^{-1/3}(t))} \\ &= \lim_{t\to\infty} \frac{t^2(y''(t))^2\log^{1/3}(t)}{(1+3^{-1}\log^{-1}(t))}. \end{aligned} \tag{3.23}$$

It follows from parts (iii), (iv), and (v) of Lemma 20 that for large $t > 0$,

$$\lim_{t\to\infty} ty''(t)\log^{1/6}(t) = \lim_{t\to\infty}\left(\frac{t}{y}\right)(yy'y'')\left(\frac{\log(t)}{\log(y)}\right)^{1/6}\frac{\log^{1/6}(y)}{y'} = 0.$$

This and (3.23) imply that the right-hand side of (3.22) tends to zero as $t \longrightarrow \infty$. Thus, from (3.21) it follows that $\lim_{t\to\infty}(y'(t))^3/3\log(t) = 1$. Finally, this last limit, and l'Hôpital's Rule, leads to

$$\lim_{t\to\infty}\frac{y(t)}{(3^{1/3}t\log^{1/3}(t))}$$
$$= \lim_{t\to\infty}\frac{y'}{(3^{1/3}\log^{1/3}(t) + 3^{-2/3}\log^{-2/3}(t))} = 1.$$

This implies (3.16).

ASYMPTOTIC BEHAVIOR OF SOLUTIONS OF SDE FOR RELAXATION OSCILLATIONS*

K. NARITA†

Abstract. A stochastic Liénard equation with a small parameter $\varepsilon > 0$ multiplying the highest derivative is formulated by a two-dimensional stochastic differential equation (SDE). Here fast and slow variables appear. In order to investigate the asymptotic behavior of the fast variable in such a system as $\varepsilon \to 0$, a stochastic process $X^\varepsilon(t)$ as a good approximation for all $t \geqq 0$ is derived by the methods of matched and composite expansions for relaxation oscillations. Then the limit of $X^\varepsilon(t)$ is identified, so that $X^\varepsilon(t)$ converges weakly as $\varepsilon \to 0$ to a solution of a one-dimensional stochastic differential equation. This yields the weak convergence of the slow variable as $\varepsilon \to 0$.

Key words. Liénard equation, stochastic differential equation, composite expansion, relaxation oscillation, relative compactness, weak convergence

AMS(MOS) subject classifications. 60H10, 60H20, 60J60, 34F05

1. Matched and composite asymptotic expansions. We consider the influence of random perturbations upon the Liénard oscillator:

$$\varepsilon \frac{d^2x}{dt^2} + \kappa \frac{dx}{dt} + g(x) = \delta \frac{dw}{dt}$$

with a family $\{\varepsilon, \kappa, \delta\}$ of positive constants, where d/dt denotes the symbolic derivative and dw/dt is the so-called white noise. Here and hereafter ε is a small parameter such that $0 < \varepsilon \ll 1$, and $g(x)$ is a scalar function on $x \in R^1 = (-\infty, \infty)$. Putting $y = \varepsilon(dx/dt) + \kappa x$, we get an equivalent system:

$$\varepsilon \frac{dx}{dt} = y - \kappa x, \qquad \frac{dy}{dt} = -g(x) + \delta \frac{dw}{dt}.$$

The object of interest is the asymptotic behavior of the solution

$$(x(t), y(t)), \quad 0 \leqq t \leqq T (T < \infty) \quad \text{as } \varepsilon \downarrow 0.$$

The above equation follows from the formal oscillator:

$$\frac{d^2x}{d\tau^2} + \nu\kappa \frac{dx}{d\tau} + g(x) = \sqrt{\nu}\, \delta \frac{db}{d\tau}$$

with a large parameter $\nu \gg 1$ and a white noise $db/d\tau$, under consideration that

$$\varepsilon = \frac{1}{\nu^2} \ll 1, \qquad t = \frac{\tau}{\nu}$$

and a Brownian motion process $w(t) = (1/\sqrt{\nu})b(\nu t)$.

When $\delta = 0$, this equation of the Liénard type is connected with explaining the *relaxation oscillations*, which is named after van der Pol [8].

While an equation takes the form

$$\frac{d^2x}{dt^2} + g(x) = \varepsilon f\left(x, \frac{dx}{dt}\right) + \sqrt{\varepsilon}\, \delta \frac{dw}{dt}, \qquad 0 < \varepsilon \ll 1$$

* Received by the editors June 10, 1991; accepted for publication (in revised form) May 5, 1992.

† Department of Mathematics, Faculty of Technology, Kanagawa University, Rokkakubashi Kanagawa-ku, Yokohama 221, Japan.

for which the *averaging principle* of Papanicolaou [5] applies, our oscillator is of the type

$$\varepsilon\frac{d^2x}{dt^2}=f\left(x,\frac{dx}{dt}\right)+\delta\frac{dw}{dt},\qquad 0<\varepsilon\ll 1.$$

So we adopt another method.

Let $(\Omega, \mathbf{F}, P)$ be a probability space with an increasing family $\{\mathbf{F}_t; t\geqq 0\}$ of sub-σ-algebras of $\mathbf{F}$, and let $w(t)$ be a one-dimensional Brownian motion process adapted to $\mathbf{F}_t$. Then as the response of the above oscillator we take the solution of the following two-dimensional stochastic differential equation:

$$\begin{aligned}\varepsilon\, dx(t)&=[y(t)-\kappa x(t)]\,dt,\\ dy(t)&=-g(x(t))\,dt+\delta\,dw(t).\end{aligned}\tag{1.1}$$

Let $\phi=(\xi, \eta)$ be a two-dimensional random vector independent of the two-dimensional Brownian motion process. Then we consider (1.1) under the following initial condition:

$$x(0)=\xi,\qquad y(0)=\eta.\tag{1.2}$$

For $\varepsilon=0$ we obtain the *reduced system*:

$$0=y_0-\kappa x_0,\qquad dy_0=-g(x_0)\,dt+\delta\,dw(t).$$

Namely,

$$\begin{aligned}dx_0(t)&=-\frac{1}{\kappa}g(x_0(t))\,dt+\frac{\delta}{\kappa}\,dw(t),\\ y_0(t)&=\kappa x_0(t)\end{aligned}\tag{1.3}$$

with the initial state $(x_0(0), y_0(0))=(C_0, \kappa C_0)$, where the value C_0 is still undetermined. Since the derivative of $x(t)$ is of order $O(1/\varepsilon)$ formally, $x(t)$ is rapidly varying until the line $y=\kappa x$ is reached. During this short period of time, $y(t)$ seems to remain almost unchanged. Thus it is plausible that in the limit $\varepsilon\to 0$ the solution jumps at $t=0$ from the initial state (ξ, η) to the state$(\eta/\kappa, \eta)$. This enables us to determine C_0 in approximate solution (1.3) valid for $t>0$: $C_0=\eta/\kappa$. Obviously, this approximate solution $x_0(t)$ with the initial state $x_0(0)=C_0=\eta/\kappa$ does not satisfy the initial condition (1.2). In order to obtain a good approximation in both the time intervals such that

$$\text{near } t=0,\quad \text{away from } t=0,$$

we adopt the methods of *matched and composite expansions* in Grasman [1, Chap. 1] and Nayfeh [3, Chap. 4].

In § 1 we derive a good approximation for (1.1) in *all time intervals.* In § 2 we identify the limit, so that such an approximation converges weakly as $\varepsilon\to 0$ to a diffusion process governed by (1.3). In §§ 3 and 4 we prepare some estimates for the moment of the solution of (1.1), and in § 5 we give the proof of the identification of the limit. In the following, without being concerned for the moment with mathematical rigor, we present some preliminary considerations.

Since ε is small, we naively look for a *regular perturbation solution* (Taylor series in ε) of the form

$$\begin{aligned}x(t;\varepsilon)&=x_0(t)+\varepsilon x_1(t)+\cdots,\\ y(t;\varepsilon)&=y_0(t)+\varepsilon y_1(t)+\cdots.\end{aligned}\tag{1.4}$$

This is called the *outer expansion*. Substituting (1.4) into (1.1) and systematically equating the coefficients of powers of ε we get the following equations:

$$\begin{aligned} 0 &= y_0 - \kappa x_0, \\ dy_0 &= -g(x_0)\,dt + \delta\,dw(t), \end{aligned} \tag{1.5}$$

$$\begin{aligned} dx_{n-1} &= [y_n - \kappa x_n]\,dt, \\ dy_n &= -g_n(x_0, x_1, \dots, x_n)\,dt, \qquad n = 1, 2, \dots . \end{aligned} \tag{1.6}$$

Here we assume that

$$g(x_0 + \varepsilon x_1 + \varepsilon^2 x_2 + \cdots) = \sum_{n=0}^{\infty} g_n(x_0, x_1, x_2, \dots, x_n)\varepsilon^n$$

with $g_0(x_0) = g(x_0)$ and

$$g_n(x_0, x_1, x_2, \dots, x_n) = \sum_{\substack{n_1+n_2+\cdots+n_k=n \\ 1\leqq k\leqq n}} \frac{x_{n_1}\cdot x_{n_2}\cdots x_{n_k}}{k!}\left[\frac{d^k g(s)}{ds^k}\right]_{s=x_0}. \tag{1.7}$$

Equation (1.5) is just the same with the reduced system (1.3). We impose the initial condition on (1.5) as follows:

$$(x_0(0), y_0(0)) = (C_0, \kappa C_0).$$

Next we introduce the time scale:

$$\tau = \frac{t}{\varepsilon}.$$

Let $(x(t), y(t))$ be the solution of (1.1) with the initial state (1.2), and set

$$x(\tau;\,\varepsilon) = x(\tau\varepsilon), \qquad y(\tau;\,\varepsilon) = y(\tau\varepsilon).$$

Then $x(\tau;\,\varepsilon)$ and $y(\tau;\,\varepsilon)$ satisfy the following equations:

$$\begin{aligned} dx(\tau;\,\varepsilon) &= [y(\tau;\,\varepsilon) - \kappa x(\tau;\,\varepsilon)]\,d\tau, \\ dy(\tau;\,\varepsilon) &= -\varepsilon g(x(\tau;\,\varepsilon))\,d\tau + \sqrt{\varepsilon}\,\delta\,d\tilde{w}(\tau), \\ x(0;\,\varepsilon) &= \xi, \qquad y(0;\,\varepsilon) = \eta, \end{aligned} \tag{1.8}$$

where $\tilde{w}(\tau)$ is a Brownian motion process defined by $\tilde{w}(\tau) = (1/\sqrt{\varepsilon})w(\tau\varepsilon)$. It is assumed that the solution of (1.8) can be expanded in a power series of $\sqrt{\varepsilon}$:

$$\begin{aligned} x(\tau;\,\varepsilon) &= u_0(\tau) + \sqrt{\varepsilon}\,u_1(\tau) + \varepsilon u_2(\tau) + \cdots, \\ y(\tau;\,\varepsilon) &= v_0(\tau) + \sqrt{\varepsilon}\,v_1(\tau) + \varepsilon v_2(\tau) + \cdots . \end{aligned} \tag{1.9}$$

This is called the *inner expansion*. Substituting (1.9) into (1.8) and equating the coefficients of powers of $\sqrt{\varepsilon}$, we obtain the following equations:

$$\begin{aligned} &\frac{du_0}{d\tau} = v_0 - \kappa u_0, \qquad u_0(0) = \xi, \\ &v_0(\tau) = \eta, \end{aligned} \tag{1.10}$$

$$\begin{aligned} &\frac{du_1}{d\tau} = v_1 - \kappa u_1, \qquad u_1(0) = 0, \\ &v_1(\tau) = \delta\tilde{w}(\tau), \qquad v_1(0) = 0, \end{aligned} \tag{1.11}$$

$$(1.12)\qquad \begin{aligned} &\frac{du_n}{d\tau}=v_n-\kappa u_n, \qquad u_n(0)=0,\\ &\frac{dv_n}{d\tau}=-g_{n-2}(u_0,u_1,\ldots,u_{n-2}), \qquad v_n(0)=0,\\ &n=2,3,\ldots, \end{aligned}$$

where $g(u_0+\sqrt{\varepsilon}\,u_1+\varepsilon u_2+\cdots)$ is assumed to be expanded as

$$g(u_0+\sqrt{\varepsilon}\,u_1+\varepsilon u_2+\cdots)=\sum_{n=0}^{\infty} g_n(u_0,u_1,u_2,\ldots,u_n)(\sqrt{\varepsilon})^n$$

with $g_0(u_0)=g(u_0)$ and $g_n(u_0,u_1,u_2,\ldots,u_n)$ as in (1.7). The solution of (1.10) is given by

$$(1.13)\qquad u_0(\tau)=\xi\exp[-\kappa\tau]+\frac{\eta}{\kappa}[1-\exp[-\kappa\tau]], \qquad v_0(\tau)=\eta.$$

We must determine the value $x_0(0)=C_0$ in the outer expansion (1.4) and (1.5) so that both expansions (1.4) and (1.9) should have a limited time interval over which they are valid. Since τ must be large and t small, we substitute $t=\varepsilon\tau$ in (1.4) and require the identical asymptotic behavior of both expansions for τ large. Namely, by (1.4), we have

$$\begin{aligned} x&=x_0(\tau\varepsilon)+\varepsilon x_1(\tau\varepsilon)+\cdots,\\ y&=y_0(\tau\varepsilon)+\varepsilon y_1(\tau\varepsilon)+\cdots, \end{aligned}$$

and so

$$\begin{aligned} x&=\left[C_0-\frac{1}{\kappa}\int_0^{\tau\varepsilon} g(x_0(s))\,ds+\frac{\delta}{\kappa}\,w(\tau\varepsilon)\right]+\varepsilon x_1(\tau\varepsilon)+\cdots,\\ y&=\left[\kappa C_0-\int_0^{\tau\varepsilon} g(x_0(s))\,ds+\delta w(\tau\varepsilon)\right]+\varepsilon y_1(\tau\varepsilon)+\cdots. \end{aligned}$$

On the other hand, for large τ,

$$(1.14)\qquad u_0\approx\frac{\eta}{\kappa}, \qquad v_0\approx\eta.$$

Thus it is necessary that

$$C_0=\frac{\eta}{\kappa}.$$

Add the two expansions (1.4) and (1.9) and subtract the matching terms (1.14). Then we get the following expansion, which may be valid in both time intervals:

$$(1.15)\qquad \begin{aligned} x(t;\varepsilon)&=\left[x_0(t)+u_0\left(\frac{t}{\varepsilon}\right)-\frac{\eta}{\kappa}\right]+O(\varepsilon),\\ y(t;\varepsilon)&=\left[y_0(t)+v_0\left(\frac{t}{\varepsilon}\right)-\eta\right]+O(\varepsilon). \end{aligned}$$

This corresponds to the so-called *composite expansion.*

Let $(x^\varepsilon(t), y^\varepsilon(t))$ be the solution of (1.1) with the initial state (1.2). Then, being motivated by the formal expansion (1.15), we take account of the following processes:

$$X^\varepsilon(t)=x^\varepsilon(t)-\left[u_0\left(\frac{t}{\varepsilon}\right)-\frac{\eta}{\kappa}\right], \qquad Y^\varepsilon(t)=y^\varepsilon(t)-\kappa X^\varepsilon(t).$$

Then, in § 2 we give a theorem on the weak convergence of $X^\varepsilon(t)$ and $y^\varepsilon(t)$ as $\varepsilon \to 0$ to the diffusion processes $x_0(t)$ and $y_0(t)$ governed by SDE (1.3), respectively. The proof of the theorem is given in § 5 by using the following estimates:

Section 3: uniform boundedness for the moment of $(x^\varepsilon(t), y^\varepsilon(t))$ with respect to ε;

Section 4: relative compactness for $X^\varepsilon(t)$ and $y^\varepsilon(t)$;

Section 6: appendix (a priori bounds of the solution of the Langevin equation with a drift multiplied by $1/\varepsilon$).

2. Theorem on weak convergence for $\varepsilon \to 0$. Let $(x^\varepsilon(t), y^\varepsilon(t))$ be the solution of (1.1) with the initial state (1.2). Then we define a pair $(X^\varepsilon(t), Y^\varepsilon(t))$ of random processes by

$$X^\varepsilon(t)=x^\varepsilon(t)-\left[u_0\left(\frac{t}{\varepsilon}\right)-\frac{\eta}{\kappa}\right], \tag{2.1}$$
$$Y^\varepsilon(t)=y^\varepsilon(t)-\kappa X^\varepsilon(t),$$

where $u_0(\tau)$ is given by (1.13). We notice that

$$X^\varepsilon(t)=x^\varepsilon(t)-\left(\xi-\frac{\eta}{\kappa}\right)\exp\left[-\frac{\kappa}{\varepsilon}t\right], \qquad X^\varepsilon(0)=\frac{\eta}{\kappa}, \tag{2.1)'$$
$$Y^\varepsilon(t)=[y^\varepsilon(t)-\kappa x^\varepsilon(t)]-(\eta-\kappa\xi)\exp\left[-\frac{\kappa}{\varepsilon}t\right], \qquad Y^\varepsilon(0)=0.$$

We shall need the following definition and assumptions.

DEFINITION 2.1. For the continuous function $g(x)$, set $G(x)=\int_0^x g(s)\,ds$ and assume that there exists a constant $\beta \geqq 0$ such that $G(x)+\beta \geqq 0$ for all $x \in R^1$. Then, for each $0<\varepsilon \leqq 1$ and $(x, y) \in R^2=R^1 \times R^1$, we define the functions $V_\varepsilon(x, y)$ and $V(x, y)$ by

$$V_\varepsilon(x, y)=\varepsilon[G(x)+\beta]+\frac{y^2}{2}, \qquad V(x, y)=[G(x)+\beta]+\frac{y^2}{2}.$$

Assumption 2.1. The scalar function $g(x)$ is once continuously differentiable with respect to $x \in R^1$, and there exists a constant $c>0$ such that

$$|g(x)|+|g'(x)| \leqq c(1+|x|^p) \quad \text{for all } x \in R^1$$

with an integer $p \geqq 1$.

Assumption 2.2. The function $g(x)$ satisfies the following conditions:

(i) There exists a constant $\alpha>0$ such that

$$-xg(x) \leqq \alpha \quad \text{for all } x \in R^1;$$

(ii) $G(x) \to \infty$ as $|x| \to \infty$, where $G(x)$ is as in Definition 2.1;

(iii) Let $\beta \geqq 0$ be a constant such that $G(x)+\beta \geqq 0$ for all $x \in R^1$. Then there exists a constant $l>0$ such that

$$x^2+y^2 \leqq lV(x, y) \quad \text{for all } (x, y) \in R^2,$$

where $V(x, y)$ is as in Definition 2.1.

Assumption 2.3. Let $\phi=(\xi, \eta)$ be a two-dimensional random vector independent of the two-dimensional Brownian motion process, such that

$$E[V(\phi)^{mq}]<\infty \quad \text{for an integer } m \geqq 2,\ q=\max\{2p, 2\},$$

where p is as in Assumption 2.1 and V is as in Definition 2.1.

Example 2.1. Consider the following functions.

(i) $g(x)=\sum_{k=0}^{n}(2k+2)\alpha_{2k+2}x^{2k+1}$ with a family $\{\alpha_{2k+2}\}$ of positive constants;

(ii) $g(x)=rx^3-sx$ with constants $r>0$ and $s>0$.

In case (i), Assumptions 2.1 and 2.2 hold for $g(x)$ with the following choice of constants:

$$c=\sum_{k=0}^{n}(2k+2)^2\alpha_{2k+2}, \qquad p=2n+1,$$

$$\alpha>0, \quad \beta\geqq 0, \quad l\geqq \max\{2, \alpha_2^{-1}\}.$$

In case (ii), Assumptions 2.1 and 2.2 hold for $g(x)$ with the following choice of constants:

$$c=4r+2s, \qquad p=3,$$

$$\alpha=\frac{s^2}{4r^2}, \qquad \beta>\frac{s^2}{4r^2}, \qquad l\geqq \max\left\{2, \left(\sqrt{r\beta}-\frac{s}{2}\right)^{-1}\right\}.$$

Hereafter, $C([0, T]; R^1)$ is the space of continuous paths ω: $\to R^1$.

THEOREM 2.1. *Suppose that Assumptions* 2.1, 2.2, *and* 2.3 *hold. For the solution* $(x^\varepsilon(t), y^\varepsilon(t))$ *of* SDE (1.1) *with the initial state* (1.2), *let* $(X^\varepsilon(t), Y^\varepsilon(t))$ *be the process defined by* (2.1). *Then* $X^\varepsilon(t)$, $t\geqq 0$, *with the initial state* $X^\varepsilon(0)=\eta/\kappa$, *converges weakly in* $C([0, T]; R^1)$, $T<\infty$, *but arbitrary, as* $\varepsilon\to 0$ *to the solution* $X(t)$ *of the following one-dimensional* SDE:

$$dX(t)=-\frac{1}{\kappa}g(X(t))\,dt+\frac{\delta}{\kappa}d\tilde{w}(t), \qquad X(0)=\frac{\eta}{\kappa}, \tag{2.2}$$

where $\tilde{w}(t)$ *is a one-dimensional Brownian motion process. Moreover,* $E[\sup_{0\leqq t\leqq T}|Y^\varepsilon(t)|^{2m}]\to 0$ *as* $\varepsilon\to 0$ *for every* $T<\infty$ *with the same exponent m as in Assumption* 2.3. *In particular,* $y^\varepsilon(t)$, $t\geqq 0$, *with the initial state* $y^\varepsilon(0)=\eta$, *converges weakly in* $C([0, T]; R^1)$, $T<\infty$, *but arbitrary, as* $\varepsilon\to 0$ *to the process* $\kappa X(t)$.

3. Uniform boundedness for the moment. Let $z^\varepsilon(t)=(x^\varepsilon(t), y^\varepsilon(t))$ be the solution of SDE (1.1) with the initial state (1.2): $z^\varepsilon(0)=\phi$. Hereafter, ϕ is a two-dimensional random vector independent of the two-dimensional Brownian motion process, and V_ε and V are the functions given by Definition 2.1. Then, for the proof of Theorem 2.1 we estimate the moment of $z^\varepsilon(t)$ from above uniformly in ε.

LEMMA 3.1. *Suppose that* $g(x)$ *satisfies the conditions* (i) *and* (ii) *of Assumption* 2.2. *Suppose that* ϕ *satisfies the following moment condition*:

$$E[V(\phi)^m]<\infty \quad \textit{for an integer } m\geqq 1.$$

Then there exists a pathwise unique solution $z^\varepsilon(t)=(x^\varepsilon(t), y^\varepsilon(t))$ *of* (1.1) *with the initial state* $z^\varepsilon(0)=\phi$. *For each* $0<\varepsilon\leqq 1$, *set* $U_\varepsilon(t)=V_\varepsilon(z^\varepsilon(t))$. *Then*

$$E[(1+U_\varepsilon(t))^m]\leqq E[(1+V(\phi))^m]\exp[c_m t], \tag{3.1}$$

where $c_m=m[\alpha\kappa+\delta^2(m-\frac{1}{2})]$.

Proof. Denote by L^ε the differential generator associated with (1.1). Namely, for $(x, y)\in R^2$,

$$L^\varepsilon=\frac{1}{\varepsilon}(y-\kappa x)\frac{\partial}{\partial x}-g(x)\frac{\partial}{\partial y}+\frac{1}{2}\delta^2\frac{\partial^2}{\partial y^2}.$$

Then, by condition (i) of Assumption 2.2, V_ε satisfies

$$L^\varepsilon V_\varepsilon(x, y)=-\kappa x g(x)+\tfrac{1}{2}\delta^2\leqq \alpha\kappa+\tfrac{1}{2}\delta^2 \quad \text{for all } (x, y)\in R^2.$$

By the condition (ii) of Assumption 2.2, V_ε is radially unbounded: $V_\varepsilon(x, y) \to \infty$ as $(x^2+y^2)^{1/2} \to \infty$. Notice that $E[V_\varepsilon(\phi)] \leqq E[V(\phi)] < \infty$. So, according to nonexplosion criteria in Hasminskii [2] and Narita [4], any solution of SDE (1.1) with the initial state (1.2) such that $E[V_\varepsilon(\phi)] < \infty$ cannot explode, which implies the pathwise uniqueness for the solution. Moreover,

$$L^\varepsilon[(1+V_\varepsilon)^m] \leqq c_m(1+V_\varepsilon)^m \tag{3.2}$$

with the constant $c_m = m[\alpha\kappa + \delta^2(m-\frac{1}{2})]$. Apply the Ito formula to $(1+U_\varepsilon(t))^m$ and take expectation. Then, by (3.2) and the Gronwall lemma, we get (3.1). Hence the proof is complete.

LEMMA 3.2. *Under the same assumptions as in Lemma* 3.1, *suppose that the moment condition on ϕ is replaced by the following condition*:

$$E[V(\phi)^{2m}] < \infty \quad \textit{for an integer } m \geqq 1.$$

For each $0 < \varepsilon \leqq 1$, *set* $U_\varepsilon(t) = V_\varepsilon(z^\varepsilon(t))$. *Then*

$$E\left[\sup_{0 \leqq t \leqq T} (1+U_\varepsilon(t))^m\right] \leqq A_m(T) \exp[c_m T] \tag{3.3}$$

for every $T < \infty$, *where*

$$A_m(T) = E[(1+V(\phi))^m] + B_m \exp\left[\frac{c_{2m}T}{2}\right],$$

$$B_m = 2\delta m(2c_{2m}^{-1})^{1/2}(E[(1+V(\phi))^{2m}])^{1/2},$$

and c_{2m} *is the constant obtained by* c_m *in* (3.1) *with m replaced by* 2*m*.

Proof. For each $T < \infty$, set $S_\varepsilon(T) = \sup_{0 \leqq t \leqq T}(1+U_\varepsilon(t))^m$, where $U_\varepsilon(t) = V_\varepsilon(x^\varepsilon(t), y^\varepsilon(t))$. Then (3.2) yields

$$S_\varepsilon(T) \leqq S_\varepsilon(0) + c_m \int_0^T S_\varepsilon(t)\,dt + \sup_{0 \leqq t \leqq T} M_\varepsilon(t), \tag{3.4}$$

where $M_\varepsilon(t) = \int_0^t m(1+U_\varepsilon(s))^{m-1}\delta y^\varepsilon(s)\,dw(s)$. Put $e_N = \inf\{t; |z^\varepsilon(t)| \geqq N\}$. Then Lemma 3.1 implies that $e_N \to \infty$ with probability 1 as $N \to \infty$. Since $y^2 \leqq 2V_\varepsilon(z)$ for $z = (x, y) \in R^2$, $M_\varepsilon(t)$ satisfies

$$E[M_\varepsilon(t \wedge e_N)^2] \leqq 2\delta^2 m^2 \int_0^t E[(1+U_\varepsilon(s \wedge e_N))^{2m}]\,ds,$$

where $a \wedge b$ is the smaller of a and b. Notice that $E[V(\phi)^{2m}] < \infty$, so that the estimate (3.1) of Lemma 3.1 holds with m replaced by $2m$. Thus

$$E[M_\varepsilon(t)^2] = \lim_{N \to \infty} E[M_\varepsilon(t \wedge e_N)^2] < \infty.$$

Namely, $\{M_\varepsilon(t);\ t \geqq 0\}$ is a square integrable martingale satisfying

$$E[M_\varepsilon(t)^2] \leqq 2\delta^2 m^2 E[(1+V(\phi))^{2m}] \int_0^t \exp[c_{2m}s]\,ds,$$

where c_{2m} is the constant obtained by c_m in (3.1) with m replaced by $2m$. Thus the martingale inequality yields

$$\begin{aligned} E\left[\sup_{0 \leqq t \leqq T} |M_\varepsilon(t)|\right] &\leqq \left(E\left[\left\{\sup_{0 \leqq t \leqq T} M_\varepsilon(t)\right\}^2\right]\right)^{1/2} \\ &\leqq (4E[M_\varepsilon(T)^2])^{1/2} \\ &\leqq 2(2\delta^2 m^2 E[(1+V(\phi))^{2m}])^{1/2} \\ &\quad \times (c_{2m}^{-1}[\exp[c_{2m}T]-1])^{1/2}. \end{aligned}$$

Take expectation on (3.4), so that

$$E[S_\varepsilon(T)] \leqq E[S_\varepsilon(0)] + c_m \int_0^T E[S_\varepsilon(t)]\,dt + E\left[\sup_{0\leqq t\leqq T} |M_\varepsilon(t)|\right].$$

Further, notice that

$$E[S_\varepsilon(0)] \leqq E[(1+V(\phi))^m] \leqq (E[(1+V(\phi))^{2m}])^{1/2} < \infty$$

and that $(\exp[xT]-1)^{1/2} \leqq \exp[xT/2]$ for $x \geqq 0$. Then by the Gronwall lemma we get (3.3). Hence the proof is complete.

LEMMA 3.3. *Let the same assumptions as in Lemma* 3.2 *hold. Then*

$$E\left[\sup_{0\leqq t\leqq T} |y^\varepsilon(t)|^{2m}\right] \leqq 2^m A_m(T) \exp[c_m T] \quad \textit{for every } T<\infty, \tag{3.5}$$

where c_m and $A_m(T)$ are the same constants as in (3.1) *and* (3.3), *respectively.*

Proof. By Definition 2.1, since $y^2/2 \leqq V_\varepsilon(x, y)$ for $(x, y) \in R^2$, we see that $(\frac{1}{2})^m y^{2m} \leqq (1+V_\varepsilon(x, y))^m$. Thus (3.5) follows from (3.3) of Lemma 3.2, and hence the proof is complete.

LEMMA 3.4. *Suppose that $g(x)$ satisfies all conditions of Assumption* 2.2 *and that ϕ satisfies the following moment condition*:

$$E[V(\phi)^{2m}] < \infty \quad \textit{for an integer } m \geqq 1.$$

Then

$$E\left[\sup_{0\leqq t\leqq T} |x^\varepsilon(t)|^{2m}\right] \leqq K_m(T) \quad \textit{for every } T<\infty, \tag{3.6}$$

where

$$K_m(T) = 2^{2m-1}[l^m E[V(\phi)^m] + \kappa^{-2m} 2^m A_m(T) \exp[c_m T]]$$

with the same constants c_m and $A_m(T)$ as in (3.1) *and* (3.3), *respectively.*

Proof. By SDE (1.1), $x^\varepsilon(t)$ satisfies the linear ordinary differential equation of first order:

$$\frac{d}{dt} x^\varepsilon(t) = \frac{1}{\varepsilon}[y^\varepsilon(t) - \kappa x^\varepsilon(t)], \qquad x^\varepsilon(0) = \xi.$$

Namely,

$$x^\varepsilon(t) = \xi \exp\left[\frac{-\kappa t}{\varepsilon}\right] + \frac{1}{\varepsilon} \exp\left[\frac{-\kappa t}{\varepsilon}\right] \int_0^t y^\varepsilon(s) \exp\left[\frac{\kappa s}{\varepsilon}\right] ds,$$

and so, for $0 \leqq t \leqq T$,

$$|x^\varepsilon(t)| \leqq |\xi| \exp\left[\frac{-\kappa t}{\varepsilon}\right] + \sup_{0\leqq t\leqq T} |y^\varepsilon(t)| \frac{1}{\kappa}\left[1 - \exp\left[\frac{-\kappa t}{\varepsilon}\right]\right].$$

Use the following inequalities:

$$(a+b)^{2m} \leqq 2^{2m-1}(a^{2m} + b^{2m}) \quad \text{for } a \geqq 0 \quad \text{and} \quad b \geqq 0,$$

$$0 \leqq \exp[-x] \leqq 1 \quad \text{and} \quad 0 \leqq 1 - \exp[-x] \leqq 1 \quad \text{for } x \geqq 0.$$

Then, for each $T > 0$,

$$\sup_{0\leqq t\leqq T} |x^\varepsilon(t)|^{2m} \leqq 2^{2m-1}\left[|\xi|^{2m} + \kappa^{-2m} \sup_{0\leqq t\leqq T} |y^\varepsilon(t)|^{2m}\right]. \tag{3.7}$$

By condition (iii) of Assumption 2.2, since $\phi=(\xi, \eta)$ satisfies

$$|\xi|^{2m} \leqq |\phi|^{2m} \leqq [lV(\phi)]^m,$$

the moment condition on ϕ implies

$$E[|\xi|^{2m}] \leqq l^m E[V(\phi)^m] \leqq l^m (E[V(\phi)^{2m}])^{1/2} < \infty.$$

Therefore, taking expectation on (3.7), by (3.5) of Lemma 3.3 we obtain (3.6). Hence the proof is complete.

4. Relative compactness for $X^\varepsilon(t)$ $y^\varepsilon(t)$. Hereafter let $(x^\varepsilon(t), y^\varepsilon(t))$ denote the solution of (1.1) with the initial state (1.2), i.e., $(x^\varepsilon(0), y^\varepsilon(0)) = \phi = (\xi, \eta)$, where ϕ is a two-dimensional random vector independent of the two-dimensional Brownian motion process. Throughout this section, let V be the function given by Definition 2.1.

LEMMA 4.1. *Suppose that there exists a constant $c>0$ such that*

$$|g(x)| \leqq c(1+|x|^p) \quad \textit{for all } x \in R^1 \textit{ with an integer } p \geqq 1,$$

and suppose that Assumption 2.2 *holds. Let ϕ be a random vector such that*

$$E[V(\phi)^{2q}] < \infty, \qquad q = \max\{2p, 2\},$$

where p is as in the hypothesis. Let $T<\infty$ be arbitrary and fixed. Then

$$\sup_{0<\varepsilon\leqq 1} E[|y^\varepsilon(t)-y^\varepsilon(s)|^4] \leqq D(t-s)^2 \quad \textit{for } 0 \leqq s \leqq t \leqq T \tag{4.1}$$

with a constant $D>0$ independent of ε.

Proof. According to the second equation of SDE (1.1) and the Schwarz inequality, $y^\varepsilon(t)$ satisfies

$$(y^\varepsilon(t)-y^\varepsilon(s))^4 \leqq 2^3\left[(t-s)^3 \int_s^t |g(x^\varepsilon(u))|^4\,du + \left(\int_s^t \delta\,dw(u)\right)^4\right] \tag{4.2}$$

for $0 \leqq s \leqq t \leqq T.$

The growth restriction on $g(x)$ implies

$$|g(x)|^4 \leqq c^4 2^3 (1+|x|^{4p}) \quad \text{for all } x \in R^1.$$

Put $m=2p$. Then, by virtue of the moment condition on ϕ we notice that

$$E[V(\phi)^{2m}] \leqq (E[V(\phi)^{2q}])^{2p/q} < \infty \quad \text{with } q = \max\{2p, 2\}.$$

So the estimate (3.6) of Lemma 3.4 holds with $m=2p$. Namely,

$$E\left[\sup_{0\leqq t\leqq T} |x^\varepsilon(t)|^{4p}\right] \leqq K_{2p}(T),$$

where $K_{2p}(T)$ is the constant obtained by $K_m(T)$ in (3.6) with $m=2p$.

On the other hand,

$$E\left[\left(\int_s^t \delta\,dw(u)\right)^4\right] \leqq \delta^4 36(t-s)^2 \quad \text{for } 0 \leqq s \leqq t \leqq T.$$

Taking expectation on (4.2), we get (4.1). Hence the proof is complete.

LEMMA 4.2. *Under the same assumptions as in Lemma* 4.1, *suppose that the moment condition on ϕ is replaced by the following condition*:

$$E[V(\phi)^{mq}] < \infty \quad \textit{for an integer } m \geqq 2, \qquad q = \max\{2p, 2\},$$

where p is as in the hypothesis of Lemma 4.1. *Let* $Y^\varepsilon(t)$ *be the process defined by* (2.1). *Then*

$$E\left[\sup_{0\leqq t\leqq T}|Y^\varepsilon(t)|^{2m}\right]\leqq F_m(T)(\varepsilon+\sqrt{\varepsilon})\quad \textit{for every } T<\infty, \tag{4.3}$$

where $F_m(T)$ *is a positive constant independent of* ε *such that* $F_m(T)$ *is a continuous and increasing function of T. Moreover, for every* $T<\infty$,

$$\sup_{0<\varepsilon\leqq 1} E[|Y^\varepsilon(t)-Y^\varepsilon(s)|^4]\leqq \tilde{D}(t-s)^2 \quad \textit{for } 0\leqq s\leqq t\leqq T \tag*{(4.3)$'$}$$

with a constant $\tilde{D}>0$ *independent of* ε.

Proof. First we show (4.3). According to (2.1)$'$, $Y^\varepsilon(t)$ has the following form:

$$Y^\varepsilon(t)=\Delta^\varepsilon(t)-(\eta-\kappa\xi)\exp\left[\frac{-\kappa t}{\varepsilon}\right],$$

$$\Delta^\varepsilon(t)=y^\varepsilon(t)-\kappa x^\varepsilon(t).$$

Since $(x^\varepsilon(t), y^\varepsilon(t))$ satisfies SDE (1.1) with the initial state $(x^\varepsilon(0), y^\varepsilon(0))=(\xi,\eta)=\phi$, $\Delta^\varepsilon(t)$ satisfies the following linear stochastic differential equation:

$$d\Delta^\varepsilon(t)=\left[-\frac{\kappa}{\varepsilon}\Delta^\varepsilon(t)-g(x^\varepsilon(t))\right]dt+\delta\, dw(t),$$

$$\Delta^\varepsilon(0)=\eta-\kappa\xi.$$

Therefore, the solution $\Delta^\varepsilon(t)$ can be written in the form

$$\Delta^\varepsilon(t)=I_1^\varepsilon(t)-I_2^\varepsilon(t)+I_3^\varepsilon(t),$$

where

$$I_1^\varepsilon(t)=\Delta^\varepsilon(0)\exp\left[\frac{-\kappa t}{\varepsilon}\right]=(\eta-\kappa\xi)\exp\left[\frac{-\kappa t}{\varepsilon}\right],$$

$$I_2^\varepsilon(t)=\exp\left[\frac{-\kappa t}{\varepsilon}\right]\int_0^t \exp\left[\frac{\kappa s}{\varepsilon}\right]g(x^\varepsilon(s))\,ds,$$

$$I_3^\varepsilon(t)=\exp\left[\frac{-\kappa t}{\varepsilon}\right]\int_0^t \exp\left[\frac{\kappa s}{\varepsilon}\right]\delta\, dw(s).$$

Accordingly, we have

$$Y^\varepsilon(t)=-I_2^\varepsilon(t)+I_3^\varepsilon(t)\quad \text{for all } t\geqq 0.$$

In the following, let $m\geqq 1$ be any integer and fixed. Then, for each $T<\infty$,

$$\sup_{0\leqq t\leqq T}|Y^\varepsilon(t)|^{2m}\leqq 2^{2m-1}\left[\sup_{0\leqq t\leqq T}|I_2^\varepsilon(t)|^{2m}+\sup_{0\leqq t\leqq T}|I_3^\varepsilon(t)|^{2m}\right]. \tag{4.4}$$

First we evaluate $|I_2^\varepsilon(t)|^{2m}$. Consider the growth restriction on $g(x)$, so that

$$|g(x)|^{2m}\leqq c^{2m}2^{2m-1}(1+|x|^{2mp})\quad \text{for all } x\in R^1.$$

Then the Schwarz inequality yields

$$\begin{aligned}|I_2^\varepsilon(t)|^{2m} &\leqq t^{2m-1}\exp\left[\frac{-2m\kappa t}{\varepsilon}\right]\\ &\quad\times\int_0^t \exp\left[\frac{2m\kappa s}{\varepsilon}\right]c^{2m}2^{2m-1}(1+|x^\varepsilon(s)|^{2mp})\,ds\\ &\leqq t^{2m-1}c^{2m}2^{2m-1}\left[1+\sup_{0\leqq s\leqq t}|x^\varepsilon(s)|^{2mp}\right]\\ &\quad\times\exp\left[\frac{-2m\kappa t}{\varepsilon}\right]\int_0^t\exp\left[\frac{2m\kappa s}{\varepsilon}\right]ds\\ &= t^{2m-1}c^{2m}2^{2m-1}\left[1+\sup_{0\leqq s\leqq t}|x^\varepsilon(s)|^{2mp}\right]\\ &\quad\times\frac{\varepsilon}{2m\kappa}\left[1-\exp\left[\frac{-2m\kappa t}{\varepsilon}\right]\right].\end{aligned}$$

By the moment condition on ϕ we notice that

$$E[V(\phi)^{2mp}]\leqq(E[V(\phi)^{mq}])^{2p/q}<\infty \quad \text{for } m\geqq 2.$$

Thus the estimate (3.6) of Lemma 3.4 holds with m replaced by mp. So

$$\begin{aligned}E\left[\sup_{0\leqq t\leqq T}|I_2^\varepsilon(t)|^{2m}\right]&\leqq c^{2m}2^{2m-1}T^{2m-1}[1+K_{mp}(T)]\\ &\quad\times\frac{\varepsilon}{2m\kappa}\left[1-\exp\left[\frac{-2m\kappa T}{\varepsilon}\right]\right],\end{aligned}\tag{4.5}$$

where $K_{mp}(T)$ is the constant obtained by $K_m(T)$ in (3.6) with m replaced by mp.

Next we evaluate $|I_3^\varepsilon(t)|^{2m}$. Use the inequality that

$$E\left[\left(\int_0^t h(u)\,dw(u)\right)^{2m}\right]\leqq[m(2m-1)]^m t^{m-1}\int_0^t E[h(u)^{2m}]\,du$$

for a nonanticipating Brownian functional $h(u)$. Then

$$E[|I_3^\varepsilon(t)|^{2m}]\leqq J_m^\varepsilon(t)\quad\text{for all } t\geqq 0,\tag{4.6}$$

where

$$J_m^\varepsilon(t)=\delta^{2m}[m(2m-1)]^m t^{m-1}\frac{\varepsilon}{2m\kappa}\left[1-\exp\left[\frac{-2m\kappa t}{\varepsilon}\right]\right].$$

Notice that $I_3^\varepsilon(t)$ is the pathwise unique solution of the following Langevin equation:

$$dI(t)=-\frac{\kappa}{\varepsilon}I(t)\,dt+\delta\,dw(t),\qquad I(0)=0.$$

Put

$$M(t)=|I(t)|^{2m}+\frac{2m\kappa}{\varepsilon}\int_0^t|I(s)|^{2m}\,ds.$$

Then the Ito formula applies to the stochastic differential $d[|I(t)|^{2m}]$ with the following result:

$$M(t)=\int_0^t \delta^2 m(2m-1)|I(s)|^{2m-2}\,ds+2m\delta\int_0^t |I(s)|^{2m-1}\,dw(s).$$

Namely, $M(t)$ is a nonnegative submartingale, which yields

$$E\left[\sup_{0\leqq t\leqq T}|I(t)|^{2m}\right]\leqq E\left[\sup_{0\leqq t\leqq T}M(t)\right]\leqq 2(E[M(T)^2])^{1/2}.$$

Here, by the definition of $M(t)$ we see

$$E[M(T)^2]\leqq 2\left[\delta^4[m(2m-1)]^2T\int_0^T E[|I(s)|^{4m-4}]\,ds\right.$$
$$\left.+\delta^2[2m]^2\int_0^T E[|I(s)|^{4m-2}]\,ds\right].$$

Let m be such that $m\geqq 2$. Then, by the definition of $J^{\varepsilon}_m(t)$ in (4.6), both $J^{\varepsilon}_{2m-2}(t)$ and $J^{\varepsilon}_{2m-1}(t)$ are well defined. Further,

$$J^{\varepsilon}_{2m-2}(t)\leqq J^{\varepsilon}_{2m-2}(T)\quad\text{for all } t\leqq T,$$
$$J^{\varepsilon}_{2m-1}(t)\leqq J^{\varepsilon}_{2m-1}(T)\quad\text{for all } t\leqq T.$$

So the estimate (4.6) yields

$$E\left[\sup_{0\leqq t\leqq T}|I(t)|^{2m}\right]\leqq 2\sqrt{2}[\delta^2 m(2m-1)T(J^{\varepsilon}_{2m-2}(T))^{1/2}\tag{4.7}$$
$$+\delta 2m(TJ^{\varepsilon}_{2m-1}(T))^{1/2}],$$

since $(a+b)^{1/2}\leqq a^{1/2}+b^{1/2}$ for $a\geqq 0$ and $b\geqq 0$. Observe that for $n\geqq 1$

$$J^{\varepsilon}_n(t)^{1/2}\leqq \delta^n[n(2n-1)]^{n/2}T^{(n-1)/2}\left(\frac{\varepsilon}{2n\kappa}\right)^{1/2}.$$

Take expectation on (4.4). Then, by (4.5) and (4.7), we get (4.3) as follows:

$$E\left[\sup_{0\leqq t\leqq T}|Y^{\varepsilon}(t)|^{2m}\right]$$
$$\leqq 2^{2m-1}\left[c^{2m}2^{2m-1}T^{2m-1}[1+K_{mp}(T)]\left(\frac{1}{2m\kappa}\right)\varepsilon+H_m\delta^{2m}T^{m-1/2}\left(\frac{1}{2m\kappa}\right)^{1/2}\sqrt{\varepsilon}\right],$$

where

$$H_m=2\sqrt{2}[m(2m-1)[(2m-2)(4m-5)]^{m-1}+2m[(2m-1)(4m-3)]^{m-1/2}].$$

Now we show (4.3)′. Since $Y^{\varepsilon}(t)=-I^{\varepsilon}_2(t)+I^{\varepsilon}_3(t)$, we see that for $t\geqq s$,

$$Y^{\varepsilon}(t)-Y^{\varepsilon}(s)=-(I^{\varepsilon}_2(t)-I^{\varepsilon}_2(s))+(I^{\varepsilon}_3(t)-I^{\varepsilon}_3(s)),$$

and so

$$E[|Y^{\varepsilon}(t)-Y^{\varepsilon}(s)|^4]\leqq 2^3[E[|I^{\varepsilon}_2(t)-I^{\varepsilon}_2(s)|^4]+E[|I^{\varepsilon}_3(t)-I^{\varepsilon}_3(s)|^4]].$$

Here the estimate (6.2) of Lemma 6.1 in § 6 is applied to $I^{\varepsilon}_3(t)$:

$$\sup_{0<\varepsilon\leqq 1}E[|I^{\varepsilon}_3(t)-I^{\varepsilon}_3(s)|^4]\leqq 15\delta^4(t-s)^2\quad\text{for } 0\leqq s\leqq t.$$

Thus, in order to prove (4.3)′ we have only to show

$$\sup_{0<\varepsilon\leqq 1} E[|I_2^\varepsilon(t)-I_2^\varepsilon(s)|^4]\leqq K(t-s)^2 \quad \text{for } 0\leqq s\leqq t\leqq T$$

with a constant $K>0$ independent of ε.

By the assumption, since $|g(x)|\leqq c(1+|x|^p)$ for $x\in R^1$, we see that for $0\leqq u\leqq T$,

$$\begin{aligned}|I_2^\varepsilon(u)| &= \left|\exp\left[\frac{-\kappa u}{\varepsilon}\right]\int_0^u \exp\left[\frac{\kappa v}{\varepsilon}\right] g(x^\varepsilon(v))\,dv\right| \\ &\leqq c\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right)\exp\left[\frac{-\kappa u}{\varepsilon}\right]\int_0^u \exp\left[\frac{\kappa v}{\varepsilon}\right]dv \\ &\leqq \varepsilon\left(\frac{c}{\kappa}\right)\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right).\end{aligned}$$

On the other hand, $I_2^\varepsilon(t)$ satisfies the linear ordinary differential equation of first order:

$$\frac{d}{dt}I_2^\varepsilon(t)=-\frac{\kappa}{\varepsilon}I_2^\varepsilon(t)+g(x^\varepsilon(t)) \quad \text{with } I_2^\varepsilon(0)=0.$$

So, for $0\leqq s\leqq t\leqq T$,

$$I_2^\varepsilon(t)-I_2^\varepsilon(s)=-\frac{\kappa}{\varepsilon}\int_s^t I_2^\varepsilon(u)\,du+\int_s^t g(x^\varepsilon(u))\,du$$

and

$$\begin{aligned}|I_2^\varepsilon(t)-I_2^\varepsilon(s)| &\leqq \frac{\kappa}{\varepsilon}\int_s^t |I_2^\varepsilon(u)|\,du+\int_s^t |g(x^\varepsilon(u))|\,du \\ &\leqq \frac{\kappa}{\varepsilon}\times\varepsilon\left(\frac{c}{\kappa}\right)\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right)(t-s) \\ &\quad +c\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right)(t-s) \\ &=2c\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right)(t-s).\end{aligned}$$

Under the assumption, the estimate (3.6) holds with $m=2p$, that is,

$$E\left[\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^{4p}\right]\leqq K_{2p}(T).$$

Therefore,

$$\begin{aligned}E[|I_2^\varepsilon(t)-I_2^\varepsilon(s)|^4] &\leqq 2^4c^4E\left[\left(1+\sup_{0\leqq v\leqq T}|x^\varepsilon(v)|^p\right)^4\right](t-s)^4 \\ &\leqq K(t-s)^2 \quad \text{for } 0\leqq s\leqq t\leqq T\end{aligned}$$

with a constant $K>0$ independent of ε. This inequality together with Lemma 6.1 imply (4.3)′. Hence the proof is complete.

LEMMA 4.3. *Under the same assumptions as in Lemma* 4.2, *let* $X^\varepsilon(t)$ *be the process defined by* (2.1). *Let* $T<\infty$ *be arbitrary and fixed. Then*

$$\sup_{0<\varepsilon\leqq 1} E[|X^\varepsilon(t)-X^\varepsilon(s)|^4]\leqq D'(t-s)^2 \tag{4.8}$$

for $0\leqq s\leqq t\leqq T$ *with a constant* $D'>0$ *independent of* ε.

Proof. By (2.1)′, $(X^\varepsilon(t),\ Y^\varepsilon(t))$ satisfies

$$\kappa(X^\varepsilon(t)-X^\varepsilon(s))=(y^\varepsilon(t)-y^\varepsilon(s))-(Y^\varepsilon(t)-Y^\varepsilon(s))$$

for $0\leqq s\leqq t\leqq T$, and hence

$$\kappa^4|X^\varepsilon(t)-X^\varepsilon(s)|^4\leqq 2^3[|y^\varepsilon(t)-y^\varepsilon(s)|^4+|Y^\varepsilon(t)-Y^\varepsilon(s)|^4]$$

for $0\leqq s\leqq t\leqq T$. Take expectation on both sides of the above equation and apply the estimates (4.1) of Lemma 4.1 and (4.3)′ of Lemma 4.2. Then we obtain (4.8). Hence the proof is complete.

Remark 4.1. Lemmas 4.1 and 4.3, as follows from Prokhorov [6], assure the relative compactness of the families of probability measures induced by $y^\varepsilon=\{y^\varepsilon(t)\}$ and $X^\varepsilon=\{X^\varepsilon(t)\}$. By the representation theorem of Skorokhod [7], without loss of generality, we can assume that there exist a subsequence $\{\varepsilon_j\}_{j=1,2,\dots}$ of $\{\varepsilon\}$ and random processes $\tilde{y}(t)$ and $\tilde{X}(t)$, such that

$$y^{\varepsilon_j}(t)\to\tilde{y}(t)\quad\text{and}\quad X^{\varepsilon_j}(t)\to\tilde{X}(t)\quad\text{with probability 1}$$

uniformly for each finite time interval as $j\to\infty$.

LEMMA 4.4. *Under the same assumptions as in Lemma* 4.2, *let* $\{\varepsilon_j\}_{j=1,2,\dots}$ *and* $\tilde{X}(t)$ *be a subsequence and a process for which Remark* 4.1 *holds. For the sake of simplicity, let us consider that* $\{\varepsilon_j\}_{j=1,2,\dots}=\{\varepsilon\}$. *Then, for each* $T<\infty$ *there exists a constant* $\tilde{C}>0$ *independent of* ε, *satisfying the following estimates*:

$$E\left[\sup_{0\leqq t\leqq T}|X^\varepsilon(t)|^{mq}\right]\leqq\tilde{C},\qquad q=\max\{2p,2\}, \tag{4.9}$$

$$E\left[\sup_{0\leqq t\leqq T}|g(X^\varepsilon(t))|^{2m}\right]\leqq\tilde{C}, \tag*{(4.9)′}$$

$$E\left[\sup_{0\leqq t\leqq T}|g(\tilde{X}(t))|^{2m}\right]\leqq\tilde{C}, \tag*{(4.9)″}$$

where $m\geqq 2$ *and* $p\geqq 1$ *are as in the hypothesis of Lemma* 4.2.

Proof. We shall denote various positive constants independent of ε by the same symbol $\tilde{C}$. By the assumption, since $|g(x)|\leqq c(1+|x|^p)$ for all $x\in R^1$, $g(x)$ satisfies

$$|g(x)|^{2m}\leqq\tilde{C}(1+|x|^{mq})\quad\text{for all } x\in R^1\quad\text{and}\quad m\geqq 1 \tag{4.10}$$

with $q=\max\{2p,2\}$. Recall (2.1), so that

$$\begin{aligned}|X^\varepsilon(t)|^{mq}&=\left|x^\varepsilon(t)-\left(\xi-\frac{\eta}{\kappa}\right)\exp\left[\frac{-\kappa t}{\varepsilon}\right]\right|^{mq}\\&\leqq\tilde{C}[|x^\varepsilon(t)|^{mq}+|\phi|^{mq}],\end{aligned}$$

where $\phi=(\xi,\eta)$ is the initial vector in the hypothesis. Thus

$$\sup_{0\leqq t\leqq T}|X^\varepsilon(t)|^{mq}\leqq\tilde{C}\left[\sup_{0\leqq t\leqq T}|x^\varepsilon(t)|^{mq}+|\phi|^{mq}\right]. \tag{4.11}$$

The condition (iii) of Assumption 2.2 and the moment condition on ϕ imply

$$E[|\phi|^{mq}] \leqq (E[|\phi|^{2mq}])^{1/2} \leqq l^{mq/2}(E[V(\phi)^{mq}])^{1/2} < \infty, \tag{4.12}$$

where $m \geqq 2$. Therefore, the estimate (3.6) of Lemma 3.4 holds with m replaced by $mq/2$. Namely,

$$E\left[\sup_{0 \leqq t \leqq T} |x^{\varepsilon}(t)|^{mq}\right] \leqq \tilde{C}. \tag{4.13}$$

Take expectation on (4.11). Then, by (4.12) and (4.13) we get (4.9). So, by (4.9) and (4.10) we get (4.9)'. Consider that

$$g(X^{\varepsilon}(t)) \to g(\tilde{X}(t)) \quad \text{with probability 1} \quad \text{as } \varepsilon \to 0.$$

Then, by (4.9)' and the Fatou lemma we obtain (4.9)''. Hence the proof is complete.

5. Proof of Theorem 2.1. First of all we consider the one-dimensional SDE (2.2).

LEMMA 5.1. *Suppose that $g(x)$ is a once continuously differentiable function satisfying*

$$-xg(x) \leqq \alpha \quad \textit{for all } x \in R^1 \quad \textit{with a constant } \alpha > 0.$$

Let $\phi = (\xi, \eta)$ be a two-dimensional random vector independent of the two-dimensional Brownian motion process, such that

$$E[|\phi|^2] < \infty.$$

Then there exists a pathwise unique solution $X(t)$ of (2.2) with the initial state $X(0) = \eta/\kappa$. Moreover, suppose that $g(x)$ satisfies all conditions of Assumption 2.2 and that

$$E[V(\phi)^{2m}] < \infty \quad \textit{for an integer } m \geqq 1.$$

Then

$$E[(1+\tfrac{1}{2}|X(t)|^2)^{2m}] \leqq E[(1+\tfrac{1}{2}|X(0)|^2)^{2m}] \exp[b_m t], \tag{5.1}$$

where

$$b_m = 2m\left[\frac{\alpha}{\kappa} + \left(2m - \frac{1}{2}\right)\left(\frac{\delta}{\kappa}\right)^2\right].$$

Proof. Denote by L the differential generator associated with SDE (2.2):

$$L = -\frac{1}{\kappa} g(x) \frac{d}{dx} + \frac{1}{2}\left(\frac{\delta}{\kappa}\right)^2 \frac{d^2}{dx^2}, \qquad x \in R^1.$$

Then, the assumption on $g(x)$ implies

$$L\left[\frac{1}{2}x^2\right] = -\frac{1}{\kappa} xg(x) + \frac{1}{2}\left(\frac{\delta}{\kappa}\right)^2 \leqq \frac{\alpha}{\kappa} + \frac{1}{2}\left(\frac{\delta}{\kappa}\right)^2$$

for all $x \in R^1$. Moreover,

$$\frac{1}{2}x^2 \to \infty \quad \text{as } |x| \to \infty.$$

So, any solution $X(t)$ of (2.2) with the initial state $X(0) = \eta/\kappa$ such that $E[|\eta|^2] < \infty$, as follows from Hasminskii [2] and Narita [4], cannot explode. Hence the pathwise uniqueness holds for the solution of (2.2).

Next it is easy to see that

$$L[(1+\tfrac{1}{2}x^2)^{2m}] \leqq b_m(1+\tfrac{1}{2}x^2)^{2m} \quad \text{for all } x \in R^1$$

with the constant

$$b_m = 2m\left[\frac{\alpha}{\kappa} + \left(2m - \frac{1}{2}\right)\left(\frac{\delta}{\kappa}\right)^2\right].$$

Recall the condition (iii) of Assumption 2.2 and the moment condition on ϕ, so that

$$E\left[\left(\frac{1}{2}|X(0)|^2\right)^{2m}\right] \leqq E\left[\left(\frac{|\phi|^2}{2\kappa^2}\right)^{2m}\right] \leqq \left(\frac{l}{2\kappa^2}\right)^{2m} E[V(\phi)^{2m}] < \infty.$$

Then, evaluating $E[(1+\frac{1}{2}|X(t)|^2)^{2m}]$ by the Ito formula and the Gronwall inequality we obtain (5.1). Hence the proof is complete.

Proof of Theorem 2.1. Let m be the integer for which Assumption 2.3 holds:

$$E[V(\phi)^{mq}] < \infty, \qquad q = \max\{2p, 2\}, \quad m \geqq 2.$$

Then the initial vector ϕ satisfies all moment conditions in the hypotheses of Lemmas 3.1, 3.4, 4.1, 4.4, and 5.1 automatically. Under Assumptions 2.1 and 2.2, the function $g(x)$ satisfies all growth conditions in the hypotheses of Lemmas 3.1, 3.4, 4.1, 4.4, and 5.1. Therefore, the family $\{y^\varepsilon(t), x^\varepsilon(t), Y^\varepsilon(t), X^\varepsilon(t), X(t)\}$ of processes satisfies the family $\{(3.5), (3.6), (4.3), (4.9), (5.1)\}$ of estimates, respectively.

Denote by $\{\varepsilon_j\}_{j=1,2,\ldots}$ a subsequence of $\{\varepsilon\}$ for which Remark 4.1 holds. For simplicity of the notation, let us consider that $\{\varepsilon_j\} = \{\varepsilon\}$. Let $\tilde{y}(t)$ and $\tilde{X}(t)$ be the random processes for which Remark 4.1 holds. Then we proceed to the proof by showing the following results.

Step 1. $\tilde{y}(t) = \kappa\tilde{X}(t)$ for all $t \geqq 0$ with probability 1.

Step 2. There exists a one-dimensional Brownian motion process $\tilde{w}(t)$ such that

$$\tilde{y}(t) = \eta - \int_0^t g(\tilde{X}(s))\,ds + \delta\tilde{w}(t) \quad \text{for all } t \geqq 0$$

with probability 1.

Step 3. $$\tilde{X}(t) = \frac{\eta}{\kappa} - \frac{1}{\kappa}\int_0^t g(\tilde{X}(s))\,ds + \frac{\delta}{\kappa}\tilde{w}(t) \quad \text{for all } t \geqq 0$$

with probability 1.

Step 4. $X^\varepsilon(t)$ converges weakly in $C([0, T]; R^1)$, $T < \infty$, but arbitrary, as $\varepsilon \to 0$ to the solution $X(t)$ governed by SDE (2.2) with the initial state $X(0) = \eta/\kappa$.

Proof of Step 1. Observe that

$$\begin{aligned} E[|\tilde{y}(t) - \kappa\tilde{X}(t)|] \leqq{} & E[|\tilde{y}(t) - y^\varepsilon(t)|] + E[|Y^\varepsilon(t)|] \\ & + \kappa E[|X^\varepsilon(t) - \tilde{X}(t)|], \end{aligned} \tag{5.2}$$

where $Y^\varepsilon(t) = y^\varepsilon(t) - \kappa X^\varepsilon(t)$. Since the estimates (3.5) of Lemma 3.3 and (4.9) of Lemma 4.4 hold for $y^\varepsilon(t)$ and $X^\varepsilon(t)$ with $m \geqq 2$, both $\{y^\varepsilon(t)\}$ and $\{X^\varepsilon(t)\}$ are equi-integrable with respect to ε, while $y^\varepsilon(t) \to \tilde{y}(t)$ and $X^\varepsilon(t) \to \tilde{X}(t)$ with probability 1 as $\varepsilon \to 0$. Thus the L^1-convergence of $y^\varepsilon(t)$ and $X^\varepsilon(t)$ to $\tilde{y}(t)$ and $\tilde{X}(t)$ holds, respectively. On the other hand, the estimate (4.3) of Lemma 4.2 implies the L^{2m}-convergence of $Y^\varepsilon(t)$ to zero as $\varepsilon \to 0$. Thus, letting $\varepsilon \to 0$ in (5.2), we have

$$E[|\tilde{y}(t) - \kappa\tilde{X}(t)|] = 0,$$

and hence

$$P(\tilde{y}(t)=\kappa\tilde{X}(t))=1 \quad \text{for each } t\geqq 0.$$

Since $\tilde{y}(t)$ and $\tilde{X}(t)$ are continuous with probability 1, the result of Step 1 holds.

Proof of Step 2. Put

$$\Delta(t)=\tilde{y}(t)-\left[\eta-\int_0^t g(\tilde{X}(s))\,ds\right].$$

Rewrite $\Delta(t)$ as

$$\Delta(t)=[\tilde{y}(t)-y^\varepsilon(t)]+\left[y^\varepsilon(t)-\left(\eta-\int_0^t g(\tilde{X}(s))\,ds\right)\right].$$

Then, since $y^\varepsilon(t)=\eta-\int_0^t g(x^\varepsilon(s))\,ds+\delta w(t)$, we see

$$\Delta(t)=\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t)+\delta w(t), \tag{5.3}$$

where

$$\Delta_1^\varepsilon(t)=\tilde{y}(t)-y^\varepsilon(t) \quad\text{and}\quad \Delta_2^\varepsilon(t)=\int_0^t [g(x^\varepsilon(s))-g(\tilde{X}(s))]\,ds.$$

Since the estimate (3.5) of Lemma 3.3 holds with $m\geqq 2$, $\{|y^\varepsilon(t)|^2\}$ is equi-integrable with respect to ε, while $y^\varepsilon(t)\to\tilde{y}(t)$ with probability 1 as $\varepsilon\to 0$. Thus

$$E[|\Delta_1^\varepsilon(t)|^2]\to 0 \quad\text{as } \varepsilon\to 0. \tag{5.4}$$

On the other hand, the Schwarz inequality yields

$$|\Delta_2^\varepsilon(t)|^2\leqq t\int_0^t |g(x^\varepsilon(s))-g(\tilde{X}(s))|^2\,ds.$$

For a moment suppose that the following result holds:

$$E\left[\int_0^t |g(x^\varepsilon(s))-g(\tilde{X}(s))|^2\,ds\right]\to 0 \quad\text{as } \varepsilon\to 0. \tag{5.5}$$

Then we get

$$E[|\Delta_2^\varepsilon(t)|^2]\to 0 \quad\text{as } \varepsilon\to 0. \tag{5.6}$$

So, taking expectation on (5.3), by (5.4) and (5.6) we have

$$|E[\Delta(t)]|\leqq|E[\Delta_1^\varepsilon(t)]|+|E[\Delta_2^\varepsilon(t)]|\to 0 \quad\text{as } \varepsilon\to 0,$$

and hence

$$E[\Delta(t)]=0.$$

Further, it follows from (5.3) that

$$\Delta(t)^2=(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))^2+2\delta(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))w(t)+\delta^2 w(t)^2. \tag{5.7}$$

Here (5.4) and (5.6) imply

$$E[(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))^2]\leqq 2[E[|\Delta_1^\varepsilon(t)|^2]+E[|\Delta_2^\varepsilon(t)|^2]]$$

$$\to 0 \quad \text{as } \varepsilon\to 0,$$

$$|E[(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))w(t)]|\leqq (E[(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))^2])^{1/2}t^{1/2}$$

$$\to 0 \quad \text{as } \varepsilon\to 0.$$

Hence, taking expectation on (5.7) we get

$$\begin{aligned}E[\Delta(t)^2]&=E[(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))^2]\\&\quad+2\delta E[(\Delta_1^\varepsilon(t)-\Delta_2^\varepsilon(t))w(t)]+\delta^2 t\\&\to \delta^2 t \quad \text{as } \varepsilon\to 0.\end{aligned}$$

Namely,

$$E[\Delta(t)^2]=\delta^2 t.$$

Since $\tilde{y}(t)$ and $\tilde{X}(t)$ are continuous, $\Delta(t)$ is also continuous. Define $\tilde{w}(t)$ by

$$\tilde{w}(t)=\frac{1}{\delta}\Delta(t).$$

Then, according to the above argument, $\{\tilde{w}(t)\}$ is a continuous square integrable martingale with $E[\tilde{w}(t)]=0$ and $E[\tilde{w}(t)^2]=t$. Thus, $\tilde{w}(t)$ is a one-dimensional Brownian motion process. Hence the result of Step 2 is valid.

Therefore, in order to prove Step 2 we have only to show (5.5). Since $g(x)$ is differentiable, the mean value theorem yields

$$g(X+h)=g(X)+g'(\zeta)h, \qquad \zeta=X+\theta h, \quad 0<\theta<1.$$

Consider the expression (2.1)′, so that

$$x^\varepsilon(s)=X^\varepsilon(s)+h^\varepsilon(s) \quad \text{with } h^\varepsilon(s)=\left(\xi-\frac{\eta}{\kappa}\right)\exp\left[\frac{-\kappa s}{\varepsilon}\right].$$

Then

$$g(x^\varepsilon(s))=g(X^\varepsilon(s))+g'(\zeta^\varepsilon(s))h^\varepsilon(s),$$

where

$$\zeta^\varepsilon(s)=X^\varepsilon(s)+\theta^\varepsilon(s)h^\varepsilon(s), \qquad 0<\theta^\varepsilon(s)<1.$$

Observe that

$$\begin{aligned}g(x^\varepsilon(s))-g(\tilde{X}(s))&=[g(x^\varepsilon(s))-g(X^\varepsilon(s))]+[g(X^\varepsilon(s))-g(\tilde{X}(s))]\\&=g'(\zeta^\varepsilon(s))h^\varepsilon(s)+[g(X^\varepsilon(s))-g(\tilde{X}(s))],\end{aligned}$$

and so

$$(5.8)\quad |g(x^\varepsilon(s))-g(\tilde{X}(s))|^2\leqq 2[|g'(\zeta^\varepsilon(s))|^2|h^\varepsilon(s)|^2+|g(X^\varepsilon(s))-g(\tilde{X}(s))|^2].$$

Then we first evaluate the right-hand side of (5.8). By Assumption 2.1, since $|g'(\zeta)|\leqq c(1+|\zeta|^p)$ for all $\zeta\in R^1$, we see

$$|g'(\zeta^\varepsilon(s))||h^\varepsilon(s)|\leqq c[1+2^{p-1}(|X^\varepsilon(s)|^p+|h^\varepsilon(s)|^p)].$$

In the following we denote various positive constants independent of ε by the same symbol A. Notice the inequalities such that

$$|h^\varepsilon(s)|^2 \leqq A|\phi|^2 \exp\left[\frac{-2\kappa s}{\varepsilon}\right],$$

$$|h^\varepsilon(s)|^{2p} \leqq A|\phi|^{2p} \exp\left[\frac{-2\kappa p s}{\varepsilon}\right],$$

$$|g'(\zeta^\varepsilon(s))|^2|h^\varepsilon(s)|^2 \leqq A\left[|\phi|^2+|X^\varepsilon(s)|^{2p}|\phi|^2 + |\phi|^{2p+2}\exp\left[\frac{-2\kappa p s}{\varepsilon}\right]\right]\exp\left[\frac{-2\kappa s}{\varepsilon}\right].$$

Use the inequality such that $xy \leqq (x^2+y^2)/2$. Then

$$\begin{aligned}(5.9)\qquad &|g'(\zeta^\varepsilon(s))|^2|h^\varepsilon(s)|^2\\ &\leqq A\left[|\phi|^2+|X^\varepsilon(s)|^{4p}+|\phi|^4+|\phi|^{2p+2}\exp\left[\frac{-2\kappa p s}{\varepsilon}\right]\right]\\ &\times\exp\left[\frac{-2\kappa s}{\varepsilon}\right].\end{aligned}$$

By condition (iii) of Assumption 2.2, ϕ satisfies

$$|\phi|^2 \leqq lV(\phi), \qquad |\phi|^4 \leqq l^2V(\phi)^2,$$

$$\begin{aligned}|\phi|^{2p+2} = |\phi|^{2p}|\phi|^2 &\leqq \tfrac{1}{2}[|\phi|^{4p}+|\phi|^4]\\ &\leqq \tfrac{1}{2}[l^{2p}V(\phi)^{2p}+l^2V(\phi)^2].\end{aligned}$$

Recall Assumption 2.3: $E[V(\phi)^{mq}]<\infty$, $q=\max\{2p,2\}$, $m\geqq 2$. Then, since $2\leqq 2p\leqq q<mq$ for $m\geqq 2$, the Hölder inequality yields

$$E[V(\phi)^2] \leqq (E[V(\phi)^{2p}])^{1/p} \leqq (E[V(\phi)^{mq}])^{2/(mq)}<\infty,$$

and hence

$$E[|\phi|^2] \leqq (E[|\phi|^4])^{1/2} \leqq (E[|\phi|^{2p+2}])^{2/(p+1)}<\infty.$$

Further, the estimate (4.9) of Lemma 4.4 holds for $X^\varepsilon(s)$ with the following result:

$$E\left[\sup_{0\leqq s\leqq t}|X^\varepsilon(s)|^{4p}\right] \leqq 1+E\left[\sup_{0\leqq s\leqq t}|X^\varepsilon(s)|^{mq}\right]<\infty,$$

where $4p\leqq 2q\leqq mq$ for $m\geqq 2$. Therefore, taking expectation on (5.9) we have

$$(5.10)\qquad E[|g'(\zeta^\varepsilon(s))|^2|h^\varepsilon(s)|^2] \leqq A\exp\left[\frac{-2\kappa s}{\varepsilon}\right] \quad \text{for all } 0\leqq s\leqq t.$$

Next, set

$$\lambda^\varepsilon(t) = E\left[\int_0^t |g(X^\varepsilon(s))-g(\tilde{X}(s))|^2\,ds\right].$$

Notice that the estimates (4.9)′ and (4.9)″ of Lemma 4.4 hold for $g(X^\varepsilon(s))$ and $g(\tilde{X}(s))$. Then, since $g(X^\varepsilon(s)) \to g(\tilde{X}(s))$ with probability 1 as $\varepsilon \to 0$, by the dominated convergence theorem we get

$$\lambda^\varepsilon(t) \to 0 \quad \text{as } \varepsilon \to 0. \tag{5.11}$$

Accordingly, by (5.8), (5.10), and (5.11) we obtain

$$\begin{aligned} &E\left[\int_0^t |g(x^\varepsilon(s)) - g(\tilde{X}(s))|^2\, ds\right] \\ &\leqq 2\left[A\int_0^t \exp\left[\frac{-2\kappa s}{\varepsilon}\right] ds + \lambda^\varepsilon(t)\right] \\ &= 2\left[A\frac{\varepsilon}{2\kappa}\left(1 - \exp\left[\frac{-2\kappa t}{\varepsilon}\right]\right) + \lambda^\varepsilon(t)\right] \to 0 \quad \text{as } \varepsilon \to 0. \end{aligned}$$

Thus (5.5) holds. Hence the proof of Step 2 is complete.

Proof of Step 3. Obviously, the result of Step 3 follows from Steps 1 and 2.

Proof of Step 4. By virtue of Step 3, the limit process $\tilde{X}(t)$ has the same law with the solution $X(t)$ of SDE (2.2) with the initial state $X(0) = \eta/\kappa$. According to Lemma 5.1, the pathwise uniqueness holds for the solution of (2.2), which implies the law uniqueness. So the result of Step 4 holds. Moreover, by (4.3) of Lemma 4.2, $Y^\varepsilon(t)$ satisfies

$$E\left[\sup_{0 \leqq t \leqq T} |Y^\varepsilon(t)|^{2m}\right] \to 0 \quad \text{as } \varepsilon \to 0.$$

Steps 1–4 also imply the weak convergence of $y^\varepsilon(t)$ to $\kappa X(t)$ as $\varepsilon \to 0$. Hence the proof of Theorem 2.1 is complete.

Remark 5.1. In the proof of (5.5), a process $\theta^\varepsilon(t)$ arises from the mean value theorem. Let $\{\varepsilon_j\}_{j=1,2,\ldots}$ be a subsequence for which Remark 4.1 holds. For notational simplicity, and without loss of generality, we will usually *not* use the tilde notation, and simply assume that

$$X^{\varepsilon_j}(t) \to X(t) \text{ with probability 1 as } j \to \infty,$$

where $X(t)$ satisfies (2.2) and consider that $\{\varepsilon_j\} = \{\varepsilon\}$. Suppose that $g(x)$ is a twice continuously differentiable function satisfying

$$g''(x) \neq 0 \quad \text{for all } x \in R^1.$$

Then, for each $t \neq 0$,

$$\theta^\varepsilon(t) \to \tfrac{1}{2} \quad \text{on } \{\eta \neq \kappa\xi\} \quad \text{with probability 1} \quad \text{as } \varepsilon \to 0, \tag{5.12}$$

where $\phi = (\xi, \eta)$ is the initial vector given in (1.2).

We will show (5.12). In fact, by the theorem of Taylor, the following equations hold:

$$\begin{aligned} g(a+h) &= g(a) + hg'(a+\theta h) \\ &= g(a) + h\{g'(a) + \theta h g''(a + \theta_1\theta h)\} \\ &= g(a) + hg'(a) + \theta h^2 g''(a + \theta_1 \theta h), \end{aligned}$$

where $0 < \theta < 1$ and $0 < \theta_1 < 1$, and

$$g(a+h) = g(a) + hg'(a) + \tfrac{1}{2}h^2 g''(a + \theta_2 h),$$

where $0<\theta_2<1$. Thus

$$\theta h^2 g''(a+\theta_1\theta h)=\tfrac{1}{2}h^2 g''(a+\theta_2 h).$$

Consider that

$$a=X^\varepsilon(t),\qquad h=h^\varepsilon(t)=\left(\xi-\frac{\eta}{\kappa}\right)\exp\left[\frac{-\kappa t}{\varepsilon}\right],$$

$$\theta=\theta^\varepsilon(t)\quad\text{and}\quad\theta_i=\theta_i^\varepsilon(t),\quad\text{where } i=1,2.$$

Then, since $\exp[-\kappa t/\varepsilon]\neq 0$ for all $t\geqq 0$, we have

$$\theta^\varepsilon(t)\left(\xi-\frac{\eta}{\kappa}\right)^2 g''(X^\varepsilon(t)+\theta_1^\varepsilon(t)\theta^\varepsilon(t)h^\varepsilon(t))$$

$$=\frac{1}{2}\left(\xi-\frac{\eta}{\kappa}\right)^2 g''(X^\varepsilon(t)+\theta_2^\varepsilon(t)h^\varepsilon(t)),\quad\text{where } t\geqq 0.$$

Note that for each $t\geqq 0$,

$$X^\varepsilon(t)\to X(t)\quad\text{with probability 1}\quad\text{as } \varepsilon\to 0.$$

Observe that for each $t\neq 0$,

$$\exp\left[\frac{-\kappa t}{\varepsilon}\right]\to 0\quad\text{as } \varepsilon\to 0,$$

which implies that for each $t\neq 0$,

$$\theta_1^\varepsilon(t)\theta^\varepsilon(t)h^\varepsilon(t)\to 0\quad\text{and}\quad\theta_2^\varepsilon(t)h^\varepsilon(t)\to 0$$

with probability 1 as $\varepsilon\to 0$. Then, since $g''(x)$ is continuous in x, we see that for $t\neq 0$,

$$g''(X^\varepsilon(t)+\theta_1^\varepsilon(t)\theta^\varepsilon(t)h^\varepsilon(t))\to g''(X(t))\quad\text{with probability 1}\quad\text{as } \varepsilon\to 0$$

and

$$g''(X^\varepsilon(t)+\theta_2^\varepsilon(t)h^\varepsilon(t))\to g''(X(t))\quad\text{with probability 1}\quad\text{as } \varepsilon\to 0.$$

Therefore, for each $t\neq 0$,

$$\left(\lim_{\varepsilon\to 0}\theta^\varepsilon(t)\right)\left(\xi-\frac{\eta}{\kappa}\right)^2 g''(X(t))=\frac{1}{2}\left(\xi-\frac{\eta}{\kappa}\right)^2 g''(X(t))\quad\text{on } \{\eta\neq\kappa\xi\},$$

from which follows (5.12).

6. Appendix (a priori bounds of the solution of the Langevin equation). In order to prove the estimate (4.3)′ of Lemma 4.2 we shall need Lemma 6.1. Let us consider the solution $I(t)$ of the one-dimensional Langevin equation with a drift multiplied by $1/\varepsilon$:

$$dI(t)=-\frac{\kappa}{\varepsilon}I(t)\,dt+\delta\,dw(t)\quad\text{with } I(0)=0, \tag{6.1}$$

where κ and δ are positive constants, $0<\varepsilon\leqq 1$ is a small parameter, and $w(t)$ is the Brownian motion process.

LEMMA 6.1.

$$E[|I(t)-I(s)|^4]\leqq 15\delta^4(t-s)^2\quad\textit{for } 0\leqq s\leqq t\quad\textit{uniformly in } 0\leqq\varepsilon\leqq 1. \tag{6.2}$$

Definition 6.1. For $t \geqq 0$ and $a > 0$, define the function $\lambda(t; a)$ by

$$\lambda(t; a) = \left(\frac{1}{a}\right)(1 - \exp[-at]).$$

Here we will prove (6.2) by showing the following estimates:

$$E[|I(t)|^2] = \delta^2 \lambda\left(t; \frac{2\kappa}{\varepsilon}\right) \quad \text{for } t \geqq 0, \tag{6.3}$$

$$E[I(u)I(s)] = \frac{1}{2}\delta^2\left[\lambda\left(u+s; \frac{\kappa}{\varepsilon}\right) - \lambda\left(u-s; \frac{\kappa}{\varepsilon}\right)\right] \quad \text{for } u \geqq s, \tag{6.3$'$}$$

$$E[|I(t)|^4] = 6\delta^4\left(\frac{\varepsilon}{2\kappa}\right)\left[\lambda\left(t; \frac{2\kappa}{\varepsilon}\right) - \lambda\left(t; \frac{4\kappa}{\varepsilon}\right)\right] \quad \text{for } t \geqq 0, \tag{6.4}$$

$$E[|I(t)|^4] \leqq \frac{3}{2}\left(\frac{\delta^4}{\kappa^2}\right) \times \varepsilon^2 \quad \text{for } t \geqq 0, \tag{6.4$'$}$$

$$\begin{aligned} &E[|I(t) - I(s)|^2] \\ &\quad = \delta^2\left[\left(1 - \exp\left[\frac{-2\kappa s}{\varepsilon}\right]\right)\right. \\ &\qquad \times \left\{\lambda\left(t-s; \frac{2\kappa}{\varepsilon}\right) + \lambda\left(t-s; \frac{\kappa}{\varepsilon}\right) - 2\lambda\left(t-s; \frac{2\kappa}{\varepsilon}\right)\right\} + \left.\lambda\left(t-s; \frac{2\kappa}{\varepsilon}\right)\right] \\ &\qquad\qquad \text{for } 0 \leqq s \leqq t, \end{aligned} \tag{6.5}$$

$$E[|I(t) - I(s)|^2] \leqq 3\delta^2(t-s) \quad \text{for } 0 \leqq s \leqq t, \tag{6.5$'$}$$

$$E[(I(u) - I(s))^3 I(s)] = -A(u; s) \quad \text{for } u \geqq s \tag{6.6}$$

with a nonnegative and continuous function $A(u; s)$ of $u \geqq s$ satisfying

$$\begin{aligned} A(u; s) &\leqq \frac{3}{2}\delta^4\left[\left(\frac{\varepsilon}{\kappa}\right)\lambda\left(u-s; \frac{\kappa}{\varepsilon}\right)\right. \\ &\qquad + \left.\left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^2\left(\frac{\varepsilon}{\kappa}\right)\lambda\left(u-s; \frac{\kappa}{\varepsilon}\right)\right] \\ &\leqq 3\delta^4\left(\frac{\varepsilon}{\kappa}\right)(u-s) \quad \text{for } u \geqq s. \end{aligned} \tag{6.6$'$}$$

Step 1 (proof of (6.3) and (6.3)$'$). Since $I(u)$ has the form

$$I(u) = \exp\left[\frac{-\kappa u}{\varepsilon}\right]\int_0^u \exp\left[\frac{\kappa v}{\varepsilon}\right]\delta\, dw(v),$$

$$E[I(u)I(s)] = \delta^2\left(\frac{\varepsilon}{2\kappa}\right)\left[\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right] - \exp\left[\frac{-\kappa(u+s)}{\varepsilon}\right]\right] \quad \text{for } u \geqq s.$$

Namely, (6.3) and (6.3)$'$ hold.

Step 2 (proof of (6.4) and (6.4)'). The Ito formula applies to (6.1) with the following result:

$$|I(t)|^4 = -\frac{4\kappa}{\varepsilon}\int_0^t |I(u)|^4\,du + 6\delta^2\int_0^t |I(u)|^2\,du$$
$$+4\delta\int_0^t I(u)^3\,dw(u).$$

As is already shown by (4.6), since

$$E[|I(t)|^{2m}] < \infty \quad \text{for all } t \geqq 0 \quad \text{with } m \geqq 1,$$

we can take expectation on the both sides of the above equation and get

$$E[|I(t)|^4] = -\frac{4\kappa}{\varepsilon}\int_0^t E[|I(u)|^4]\,du + 6\delta^2\int_0^t E[|I(u)|^2]\,du.$$

For $t \geqq 0$, define the function $f_{2m}(t)$ by

$$f_{2m}(t) = E[|I(t)|^{2m}], \quad \text{where } m \geqq 1.$$

Then $f_4(t)$ satisfies the linear ordinary differential equation of first order:

$$\frac{d}{dt}f_4(t) = -\frac{4\kappa}{\varepsilon}f_4(t) + 6\delta^2 f_2(t), \qquad f_4(0) = 0,$$

where $f_2(t) = E[|I(t)|^2]$ is given by (6.3). Therefore,

$$f_4(t) = \exp\left[\frac{-4\kappa t}{\varepsilon}\right]\int_0^t \exp\left[\frac{4\kappa u}{\varepsilon}\right]6\delta^2 \times \delta^2\lambda\left(u; \frac{2\kappa}{\varepsilon}\right)du$$
$$= 6\delta^4\left(\frac{\varepsilon}{2\kappa}\right)\exp\left[\frac{-4\kappa t}{\varepsilon}\right]$$
$$\times\left[\frac{\varepsilon}{4\kappa}\left(\exp\left[\frac{4\kappa t}{\varepsilon}\right]-1\right) - \frac{\varepsilon}{2\kappa}\left(\exp\left[\frac{2\kappa t}{\varepsilon}\right]-1\right)\right],$$

which yields (6.4). The estimate (6.4)' follows from (6.4) and the inequality that if $0 < a < b$, then

$$0 \leqq \lambda(t; a) - \lambda(t; b) \leqq \frac{1}{a} \quad \text{for } t \geqq 0.$$

Step 3 (proof of (6.5) and (6.5)'). By the Ito formula applied to (6.1), we see that for $0 \leqq s \leqq t$,

$$|I(t) - I(s)|^2$$
$$= -\frac{2\kappa}{\varepsilon}\int_s^t (I(u) - I(s))I(u)\,du$$
$$+\int_s^t \delta^2\,du + 2\int_s^t (I(u) - I(s))\delta\,dw(u)$$
$$= -\frac{2\kappa}{\varepsilon}\int_s^t |I(u) - I(s)|^2\,du - \frac{2\kappa}{\varepsilon}\int_s^t (I(u) - I(s))I(s)\,du$$
$$+\int_s^t \delta^2\,du + 2\int_s^t (I(u) - I(s))\delta\,dw(u).$$

Take expectation on the above equation, which is possible by the estimate (4.6). For $t \geqq s$, define the function $f_{2m}(t;\, s)$ by

$$f_{2m}(t;\, s) = E[|I(t) - I(s)|^{2m}], \quad \text{where } m \geqq 1.$$

Then $f_2(t;\, s)$ satisfies

$$f_2(t;\, s) = -\frac{2\kappa}{\varepsilon}\int_s^t f_2(u;\, s)\, du - \frac{2\kappa}{\varepsilon}\int_s^t E[(I(u) - I(s))I(s)]\, du$$
$$+ \int_s^t \delta^2\, du \quad \text{for } t \geqq s.$$

It follows from (6.3) and (6.3)′ that for $s \leqq u \leqq t$,

$$E[(I(u) - I(s))I(s)] = E[I(u)I(s)] - E[|I(s)|^2]$$
$$= -\delta^2\left(\frac{\varepsilon}{2\kappa}\right) a(u;\, s),$$

where

$$a(u;\, s) = \left(1 - \exp\left[\frac{-\kappa(u - s)}{\varepsilon}\right]\right)\left(1 - \exp\left[\frac{-2\kappa s}{\varepsilon}\right]\right).$$

Namely, $f_2(t;\, s)$ satisfies the linear ordinary differential equation of first order:

$$\frac{d}{dt} f_2(t;\, s) = -\frac{2\kappa}{\varepsilon} f_2(t;\, s) + \delta^2(a(t;\, s) + 1) \quad \text{for } t \geqq s,$$
$$f_2(s;\, s) = 0.$$

The solution is computed as follows:

$$f_2(t;\, s)$$
$$= \exp\left[\frac{-2\kappa(t - s)}{\varepsilon}\right]\int_s^t \exp\left[\frac{2\kappa(u - s)}{\varepsilon}\right]\delta^2(a(u;\, s) + 1)\, du$$
$$= \delta^2 \exp\left[\frac{-2\kappa(t - s)}{\varepsilon}\right]$$
$$\cdot\left[\left(1 - \exp\left[\frac{-2\kappa s}{\varepsilon}\right]\right)\int_s^t \left(\exp\left[\frac{2\kappa(u - s)}{\varepsilon}\right] - \exp\left[\frac{\kappa(u - s)}{\varepsilon}\right]\right) du\right.$$
$$\left. + \int_s^t \exp\left[\frac{2\kappa(u - s)}{\varepsilon}\right] du\right]$$
$$= \delta^2\left[\left(1 - \exp\left[\frac{-2\kappa s}{\varepsilon}\right]\right)\right.$$
$$\cdot\left\{\frac{\varepsilon}{2\kappa}\left(1 - \exp\left[\frac{-2\kappa(t - s)}{\varepsilon}\right]\right)\right.$$
$$\left. - \frac{\varepsilon}{\kappa}\left(\exp\left[\frac{-\kappa(t - s)}{\varepsilon}\right] - \exp\left[\frac{-2\kappa(t - s)}{\varepsilon}\right]\right)\right\}$$
$$\left. + \frac{\varepsilon}{2\kappa}\left(1 - \exp\left[\frac{-2\kappa(t - s)}{\varepsilon}\right]\right)\right].$$

Rearrangement of this equation yields (6.5). Since $0 \leqq \lambda(u;\, a) \leqq u$ for all $u \geqq 0$ and $a > 0$, it follows from (6.5) that

$$f_2(t;\, s) \leqq \delta^2[\{(t-s)+(t-s)\}+(t-s)] \quad \text{for } t \geqq s,$$

which implies (6.5)$'$.

Step 4 (proof of (6.6) and (6.6)$'$). For $u \geqq s$, set

$$\tilde{I}(u;\, s) = I(u) - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right] I(s).$$

Then, for $u \geqq s$,

$$I(u) - I(s) = \tilde{I}(u;\, s) - \left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right) I(s)$$

and

$$\begin{aligned}(I(u)-I(s))^3 I(s) &= \tilde{I}(u;\, s)^3 I(s)\\ &\quad -3\left(1-\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)\tilde{I}(u;\, s)^2 I(s)^2\\ &\quad +3\left(1-\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^2 \tilde{I}(u;\, s) I(s)^3\\ &\quad -\left(1-\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^3 I(s)^4.\end{aligned}$$

Note that $\tilde{I}(u;\, s)$ and $I(s)$ are independent for $u > s$, since the Brownian motion $w(v)$ is a process with independent increments. So, if m and n are positive integers, then

$$E[\tilde{I}(u;\, s)^m I(s)^n] = E[\tilde{I}(u;\, s)^m] E[I(s)^n] \quad \text{for } u > s.$$

Moreover, for any $u \geq s$,

$$E[\tilde{I}(u;\, s)] = E[I(s)] = 0.$$

Therefore, for $u > s$,

$$\begin{aligned}&E[(I(u)-I(s))^3 I(s)]\\ (6.7)\qquad &\quad = -3\left(1-\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right) E[\tilde{I}(u;\, s)^2] E[|I(s)|^2]\\ &\qquad -\left(1-\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^3 E[|I(s)|^4].\end{aligned}$$

We note that (6.7) holds with $u = s$, since

$$E[(I(s)-I(s))^3 I(s)] = 0.$$

On the other hand, for $u \geqq s$,

$$\begin{aligned}E[\tilde{I}(u;\, s)^2] &= E\left[\left\{I(u) - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right] I(s)\right\}^2\right]\\ &= E[|I(u)|^2] - 2\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right] E[I(u) I(s)]\\ &\quad + \exp\left[\frac{-2\kappa(u-s)}{\varepsilon}\right] E[|I(s)|^2].\end{aligned}$$

For $u \geqq s$, define $\tilde{f}_2(u; s)$ and $f_I(u, s)$ by

$$\tilde{f}_2(u; s) = E[\tilde{I}(u; s)^2] \quad \text{and} \quad f_I(u, s) = E[I(u)I(s)].$$

Use the notation that $f_{2m}(u) = E[|I(u)|^{2m}]$ with $m \geqq 1$. Then, for $u \geqq s$

$$\tag{6.8} \begin{aligned} \tilde{f}_2(u; s) &= f_2(u) - 2\exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right] f_I(u, s) \\ &\quad + \exp\left[\frac{-2\kappa(u-s)}{\varepsilon}\right] f_2(s). \end{aligned}$$

For $u \geqq s$, set

$$\tag{6.9} \begin{aligned} A(u; s) &= 3\left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)\tilde{f}_2(u; s) f_2(s) \\ &\quad + \left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^3 f_4(s). \end{aligned}$$

Then, (6.7) can be written as

$$E[(I(u) - I(s))^3 I(s)] = -A(u; s) \quad \text{for } u \geqq s.$$

By the definition of $\tilde{f}_2(u; s)$ and $f_{2m}(s)$, where $m = 1$ and 2, $A(u; s)$ is a nonnegative and continuous function of $u \geqq s$, and hence (6.6) holds.

Next we must evaluate $A(u; s)$ for $u \geqq s$. Since the estimates (6.3) and (6.3)′ hold,

$$f_2(u) \leqq \delta^2\left(\frac{\varepsilon}{2\kappa}\right) \quad \text{for } u \geqq 0 \quad \text{and} \quad f_I(u, s) \geqq 0 \quad \text{for } u \geqq s.$$

Thus, it follows from (6.8) that for $u \geqq s$,

$$\begin{aligned} 0 \leqq \tilde{f}_2(u; s) &\leqq f_2(u) + \exp\left[\frac{-2\kappa(u-s)}{\varepsilon}\right] f_2(s) \\ &\leqq \delta^2\left(\frac{\varepsilon}{2\kappa}\right) + \exp\left[\frac{-2\kappa(u-s)}{\varepsilon}\right]\delta^2\left(\frac{\varepsilon}{2\kappa}\right) \\ &\leqq \delta^2\left(\frac{\varepsilon}{\kappa}\right). \end{aligned}$$

Combining this, (6.3), and (6.4)′ with (6.9) we see that for $u \geqq s$,

$$\begin{aligned} 0 \leqq A(u; s) &\leqq 3\left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)\delta^2\left(\frac{\varepsilon}{\kappa}\right) f_2(s) \\ &\quad + \left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^3 f_4(s) \\ &\leqq 3\left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)\delta^2\left(\frac{\varepsilon}{\kappa}\right) \times \delta^2\left(\frac{\varepsilon}{2\kappa}\right) \\ &\quad + \left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^3 \times \frac{3}{2}\frac{\delta^4}{\kappa^2} \times \varepsilon^2 \\ &= \frac{3}{2}\delta^4\left[\left(\frac{\varepsilon}{\kappa}\right)\lambda\left(u - s; \frac{\kappa}{\varepsilon}\right)\right. \\ &\quad \left. + \left(1 - \exp\left[\frac{-\kappa(u-s)}{\varepsilon}\right]\right)^2\left(\frac{\varepsilon}{\kappa}\right)\lambda\left(u - s; \frac{\kappa}{\varepsilon}\right)\right]. \end{aligned}$$

Namely, the first inequality of (6.6)′ holds. Note that

$$\lambda(v;\, a) \leqq v \quad \text{for } v \geqq 0 \quad \text{and} \quad a>0$$

and that

$$0 \leqq (1-\exp[-x])^2 \leqq 1-\exp[-x] < 1 \quad \text{for } x \geqq 0.$$

Then, by the first inequality of (6.6)′ we get

$$\begin{aligned} A(u;\, s) &\leqq \frac{3}{2}\delta^4\left[\left(\frac{\varepsilon}{\kappa}\right)(u-s)+\left(\frac{\varepsilon}{\kappa}\right)(u-s)\right] \\ &= 3\delta^4\left(\frac{\varepsilon}{\kappa}\right)(u-s) \quad \text{for all } u \geqq s, \end{aligned}$$

showing the second inequality of (6.6)′.

Proof of Lemma 6.1. The Ito formula applied to (6.1) yields that for $0 \leqq s \leqq t$,

$$\begin{aligned} &|I(t)-I(s)|^4 \\ &= -\frac{4\kappa}{\varepsilon}\int_s^t (I(u)-I(s))^3 I(u)\, du \\ &\quad +6\delta^2\int_s^t |I(u)-I(s)|^2\, du + 4\delta\int_s^t (I(u)-I(s))^3\, dw(u) \\ &= -\frac{4\kappa}{\varepsilon}\int_s^t |I(u)-I(s)|^4\, du - \frac{4\kappa}{\varepsilon}\int_s^t (I(u)-I(s))^3 I(s)\, du \\ &\quad +6\delta^2\int_s^t |I(u)-I(s)|^2\, du + 4\delta\int_s^t (I(u)-I(s))^3\, dw(u). \end{aligned}$$

Take expectation on the above equation, which is possible by the estimate (4.6). Use the function

$$f_{2m}(t;\, s) = E[|I(t)-I(s)|^{2m}] \quad \text{for } t \geqq s, \quad \text{where } m \geqq 1.$$

Then, for $u \geqq s$,

$$\begin{aligned} f_4(t;\, s) &= -\frac{4\kappa}{\varepsilon}\int_s^t f_4(u;\, s)\, du - \frac{4\kappa}{\varepsilon}\int_s^t E[(I(u)-I(s))^3 I(s)]\, du \\ &\quad +6\delta^2\int_s^t f_2(u;\, s)\, du. \end{aligned}$$

Namely, $f_4(t;\, s)$ satisfies the linear ordinary differential equation of first order:

$$\begin{aligned} \frac{d}{dt}f_4(t;\, s) &= -\frac{4\kappa}{\varepsilon}f_4(t;\, s) - \frac{4\kappa}{\varepsilon}E[(I(t)-I(s))^3 I(s)] \\ &\quad +6\delta^2 f_2(t;\, s) \quad \text{for } t \geqq s \end{aligned}$$

with the initial condition $f_4(s;\, s)=0$. The solution is given by

$$\begin{aligned} &f_4(t;\, s) \\ (6.10) \qquad &= \exp\left[\frac{-4\kappa(t-s)}{\varepsilon}\right] \\ &\quad \cdot \int_s^t \exp\left[\frac{4\kappa(u-s)}{\varepsilon}\right]\left\{-\frac{4\kappa}{\varepsilon}E[(I(u)-I(s))^3 I(s)] + 6\delta^2 f_2(u;\, s)\right\} du. \end{aligned}$$

Here (6.6) and (6.6)′ imply

$$-\frac{4\kappa}{\varepsilon}E[(I(u)-I(s))^3I(s)]=\frac{4\kappa}{\varepsilon}A(u;s)$$
$$\leqq 12\delta^4(u-s) \quad \text{for } u\geqq s.$$

On the other hand, (6.5)′ implies

$$6\delta^2 f_2(u;s)\leqq 18\delta^4(u-s) \quad \text{for } u\geqq s.$$

Combining these inequalities with (6.10), we obtain

$$f_4(t;s)\leqq \exp\left[\frac{-4\kappa(t-s)}{\varepsilon}\right]\int_s^t \exp\left[\frac{4\kappa(u-s)}{\varepsilon}\right](30\delta^4(u-s))\,du$$
$$\leqq 30\delta^4\int_s^t (u-s)\,du$$
$$=15\delta^4(t-s)^2 \quad \text{for } t\geqq s.$$

Hence the proof of Lemma 6.1 is complete.

Acknowledgments. The author is grateful to the referee for his valuable advice, and to Professor Z. Schuss for his encouraging criticism.

SOLVABILITY OF BOUNDARY VALUE PROBLEMS FOR SYSTEMS OF SINGULAR DIFFERENTIAL-ALGEBRAIC EQUATIONS*

ROSWITHA MÄRZ[†] AND EWA B. WEINMÜLLER[‡]

This paper is dedicated to Professor Hans J. Stetter on the occasion of his 60th birthday.

Abstract. This paper considers systems of linear singular differential-algebraic equations subject to two-point boundary conditions. Existence and uniqueness theory is given for the case when one can decouple the original problem in a boundary value problem for ODEs with a singularity of the first kind at the left endpoint of the interval, and a set of algebraic equations. This paper also studies the solvability of the system in its initial value version.

Key words. differential-algebraic equations, singular systems of ODEs, existence and uniqueness of bounded solutions, projection methods

1. Introduction. Implicit singular ordinary differential equations (ODEs) result often from modelling of phenomena in applied sciences and technics. Therefore, recently, their analytical properties essential for an efficient numerical treatment have been extensively studied. Typically, linear systems are of the form

$$\tilde{A}(t)x'(t) + \tilde{B}(t)x(t) = \tilde{f}(t), \qquad t \in (0,1], \tag{1.1}$$

where the coefficient matrix $\tilde{A}(t)$ is singular.

In numerous articles on analysis and numerical solution of linear and nonlinear differential-algebraic equations (DAEs) existence of sufficiently smooth solutions is assumed. Consequently, the Taylor series expansion of such a solution provides a tool in the study of the analytical features of the problem, and the properties of numerical methods applied for its approximate solution. We refer to [3] and [9] for more detailed information on this technique. Obviously, this approach justifies the question, under which circumstances can we guarantee the required smoothness of the solution $x(t)$ of (1.1). The answer in the case of constant coefficient matrices $\tilde{A}$ and $\tilde{B}$ is easy: smoothness of x depends merely on the smoothness of the right-hand side $\tilde{f}$. It is more complicated for the general problem (1.1); we have to consider additionally the smoothness of certain canonical subspaces; cf. [1] and [8]. One of the most important is the nullspace of $\tilde{A}(t)$. As defined in [1], we call the system of DAEs "normal" if rank of $\tilde{A}(t)$ is constant, and "singular" if it is not. Here, all phenomena known from classical theory of ODEs with singularities may occur.

The simplest class of normal DAEs are the so-called "transferable," or "index 1" systems; see [1] and [7]. Essentially, their solution $x(t)$ can be split into two parts, $x(t) = u(t) + v(t)$, such that $u(t)$ solves a set of classical ODEs, subject to boundary or initial conditions, and $v(t)$ satisfies a set of algebraic equations. Moreover, it can be shown that "index 1" problems are well posed and can be solved numerically in, more or less, a standard manner. Here, we study systems (1.1), where $\tilde{A}(t) \equiv tA(t)$,

$$tA(t)x'(t) + B(t)x(t) = \tilde{f}(t), \qquad t \in (0,1], \tag{1.2}$$

and the rank of $A(t)$ is constant as a function of t. This means that the system is transferable on $(0,1]$, and there is a rank change in matrix $\tilde{A}(t)$ for $t=0$. We show the solvability statements for initial and boundary value problems. It turns out that the eigenvalue stucture of the pair $\{A(0),\ B(0)\}$ already determines the first derivative of $x(t)$ and, in general, $x'(0)$ may become unbounded. This is a well-known fact in the theory of singular systems of ODEs; cf. [2], [5], and [6]. Thus a theory where the assumption of arbitrarily smooth solution remains unrelated to the rank of $\tilde{A}(t)$ seems questionable.

The following investigation of (1.2) may serve as basic knowledge in the further study of more involved singular DAEs, but it is also motivated by applications, where singular boundary value problems for systems of ODEs are augmented by sets of algebraic constraints. We derive the results combining techniques from the theory of transferable DAEs and the theory of singular boundary value problems. The crucial common element in both concepts is the use of projection matrices, which, appropriately chosen, guarantee certain commutativity properties, stated in Lemmas 2.2, 2.3, and 2.4. We can successfully link both techniques by partitioning the original boundary value problem for a system of DAEs into an equivalent system of singular boundary value problem of ODEs and a set of algebraic equations; see [4] and [7]. This equivalence is shown in Theorems 2.1 and 3.2. The paper is organized as follows: in §2, we study the constant coefficient case. We define the projection matrices, use them to construct a continuous solution $x \in C[0,1]$, and formulate conditions necessary for its uniqueness. In §3, we extend the existence and uniqueness results to the variable coefficient case. In particular, we heavily rely on the construction of the general solution presented in §2.

2. Constant coefficient case. We investigate the linear boundary value problem

$$tAx'(t)+Bx(t)=tf(t), \qquad 0<t\leq 1, \tag{2.1a}$$

$$B_0x(0)+B_1x(1)=\beta, \tag{2.1b}$$

where A, B are constant real $m\times m$ matrices, B_0, B_1 are constant real $k\times m$ matrices, such that $\operatorname{rank}[B_0B_1]=k, k\leq m$, and $f\in C[0,1]$ is a vector-valued function of dimension m. Here, we assume A to be singular, and denote by $Q\in \mathbb{R}^{m\times m}$ a projection matrix on the kernel of A, $\ker(A)=: N_0$. Finally, with $P:=I-Q$, we can reformulate (2.1a) and obtain

$$A(tPx(t))'+(B-A)x(t)=tf(t), \qquad 0<t\leq 1. \tag{2.2}$$

This suggests restricting the space of solutions x of (2.2) to

$$C^1_\pi := \{x\in C[0,1]:\ \pi x\in C^1[0,1],\ (\pi x)(t):=tPx(t),\ t\in[0,1]\}.$$

We note that $C^1_\pi \not\subseteq C^1[0,1]$, in general. Moreover, C^1_π does not depend on the special choice of Q, but it is entirely determined by $\ker(A)$. For the convenience of notation we use $C:=C[0,1]$, $C^1:=C^1[0,1]$, and $C^1_0:=C\cap C^1(0,1]$. Before discussing the system in its general form (2.1a), we consider an example in order to present the basic idea of the decoupling technique.

2.1. Case study. Given the problem

$$tAx'(t)+Bx(t)=tf(t), \qquad 0<t\leq 0, \tag{2.3}$$

where $m = 3$, $x = (x_1, x_2, x_3)^{\mathrm{T}}$ and

$$A = \operatorname{diag}(1,1,0), \quad B = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} \end{pmatrix}, \quad f = (f_1, f_2, f_3)^{\mathrm{T}}.$$

Since (2.3) does not include x_3', we attempt to decouple the system into two differential equations for $(x_1, x_2)^{\mathrm{T}}$ and one algebraic equation for x_3. Some elementary calculations yield,

$$t\begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2} \end{pmatrix}\begin{pmatrix} x_1'(t) \\ x_2'(t) \\ 0 \end{pmatrix} + \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{2} \end{pmatrix}\begin{pmatrix} 0 \\ 0 \\ x_3(t) \end{pmatrix}$$
$$+\begin{pmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & \frac{1}{2} & 0 \end{pmatrix}\begin{pmatrix} x_1(t) \\ x_2(t) \\ 0 \end{pmatrix} = t\begin{pmatrix} f_1(t) \\ f_2(t) \\ f_3(t) \end{pmatrix},$$

or equivalently, with $Q = \operatorname{diag}(0,0,1)$ and $P = \operatorname{diag}(1,1,0)$,

$$tGu'(t) + Gv(t) + BPu(t) = tf(t), \qquad 0 < t \leq 1, \tag{2.4}$$

where

$$x(t) \equiv Px(t) + Qx(t) =: u(t) + v(t), \qquad G = A + BQ.$$

Since G is regular, we multiply (2.4) by G^{-1} and have

$$tu'(t) + v(t) + \begin{pmatrix} 1 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} u(t) = t\begin{pmatrix} f_1(t) - 2f_3(t) \\ f_2(t) \\ 2f_3(t) \end{pmatrix},$$

which provides the desired decomposition,

$$\begin{pmatrix} x_1'(t) \\ x_2'(t) \end{pmatrix} = \frac{1}{t}\begin{pmatrix} -1 & 1 \\ -1 & 0 \end{pmatrix}\begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} + \begin{pmatrix} f_1(t) - 2f_2(t) \\ f_2(t) \end{pmatrix}, \quad 0 < t \leq 1, \tag{2.5a}$$

$$x_3(t) = -x_2(t) + 2tf_3(t). \tag{2.5b}$$

Clearly, the above separation method becomes impracticable if G is singular, so the crucial assumption for the investigation of the general case is the *regularity* of the matrix

$$G = A + BQ \equiv AP + BQ.$$

2.2. General case. We now execute the procedure presented in §2.1 to transform the general problem (2.1) and study its properties. We assume that the system (2.1a) is transferable for $t \in (0,1]$, or equivalently, $G = A + BQ$ is nonsingular; cf. [4]. It has been shown in [1, Thm. A.13] that two matrices A and B form a regular matrix pencil of index 1 if and only if A is singular, but G is not. Moreover, if G is nonsingular, then $Q_s := QG^{-1}B$ represents the projection onto N_0, along the subspace

$$S := \{z \in \mathbb{R}^m : Bz \in \operatorname{im}(A)\}.$$

We also denote $P_s := I - Q_s$.

THEOREM 2.1. *Let $x \in C^1_\pi$ satisfy the boundary value problem* (2.1). *Then the function pair $u := Px \in C^1_0$, $v := Qx \in C$ is a solution of the system*

$$tu'(t) + PG^{-1}Bu(t) = tPG^{-1}f(t), \qquad 0 < t \le 1, \tag{2.6a}$$

$$B_0P_su(0) + B_1P_su(1) = \beta - B_1QG^{-1}f(1), \tag{2.6b}$$

$$Qu(\delta) = 0, \tag{2.6c}$$

$$v(t) = -Q_su(t) + tQG^{-1}f(t), \qquad 0 < t \le 1, \tag{2.6d}$$

where $\delta \in (0, 1]$ is arbitrary but fixed. If $u \in C^1_0$, $v \in C$ solve the transformed system (2.6), *then $x := u + v \in C^1_\pi$ is a solution of the original problem* (2.1).

Proof. It is easy to see that $G^{-1}A = P$ and $G^{-1}BQ = Q$. Using these relations, we can reformulate (2.1a),

$$t(Px)'(t) + Qx(t) + G^{-1}BPx(t) = tG^{-1}f(t),$$

which implies

$$t(Px)'(t) + PG^{-1}BPx(t) = tPG^{-1}f(t), \tag{2.7a}$$

$$Qx(t) + Q_sPx(t) = tQG^{-1}f(t). \tag{2.7b}$$

Consequently, any solution $x \in C^1_\pi$ of (2.1a) solves (2.6a), (2.6d). Trivially, (2.1b) can be written as

$$B_0(u(0) + v(0)) + B_1(u(1) + v(1)) = \beta. \tag{2.8}$$

We evaluate (2.6d) at $t = 0$, and $t = 1$, substitute $v(0)$, $v(1)$ into (2.8), and obtain (2.6b),

$$B_0\underbrace{(I - Q_s)}_{P_s}u(0) + B_1\underbrace{(I - Q_s)}_{P_s}u(1) = \beta - B_0QG^{-1}f(1).$$

Finally, (2.6c) follows from $Q(Px(\delta)) = 0$, for any δ, and this concludes the proof of the first statement. Let us assume that $u \in C^1_0$, $v \in C$ solve the system (2.6). Then the multiplication of (2.6a) by Q and (2.6c) imply

$$t(Qu)'(t) = 0 \Rightarrow Qu(t) = \text{constant},$$

and since $Qu(\delta) = 0$, we have

$$Qu(t) = 0 \Rightarrow Pu(t) = u(t).$$

From the multiplication of (2.6d) by Q we conclude $v(t) = Qv(t)$. Consequently, $x := u + v \equiv Pu + Qv \in C^1_\pi$, and the result follows. □

According to Theorem 2.1, we can characterize solvability of (2.1) via discussion of (2.6a), (2.6b), and (2.6c). In the theory of singular boundary value problems, the conventional form of (2.6a) is

$$u'(t) = \frac{1}{t}Mu(t) + F(t), \qquad 0 < t \le 1, \tag{2.9}$$

where $M := -PG^{-1}B$ and $F(t) := PG^{-1}f(t)$. We use techniques developed in [2] to select a bounded solution $u \in C^1_0$ of (2.9).

Let us denote by $\Phi(t) \in C^1(0,1]$ the fundamental solution matrix of the homogeneous problem

$$\Phi'(t) = \frac{1}{t}M\Phi(t), \quad 0 < t \leq 1, \qquad \Phi(\delta) = I. \tag{2.10}$$

Then,

$$\Phi(t) = \exp\left(M \ln \frac{t}{\delta}\right) =: \left(\frac{t}{\delta}\right)^M,$$

and the general solution of (2.9) is

$$u(t) = \Phi(t)\left\{c + \int_\delta^t \Phi^{-1}(s)F(s)ds\right\}, \qquad 0 < t \leq 1. \tag{2.11}$$

It follows immediately that $u \in C[\delta, 1]$, but in general, $u \notin C[0,1]$.

LEMMA 2.2.

$$\Phi(t)P = P\Phi(t), \qquad \Phi(t)Q = Q\Phi(t) = Q \quad \forall t \in (0,1].$$

Proof.

$$MQ = \underbrace{-PG^{-1}B}_{M}Q = -P\underbrace{G^{-1}BQ}_{Q} = -PQ = 0 = Q(\underbrace{-PG^{-1}B}_{M}) = QM$$

$$\Rightarrow \Phi(t)Q = \left(I + \sum_{i=1}^{\infty}\frac{1}{i!}(tM)^i\right)Q = Q\Phi(t) = Q.$$

Moreover,

$$MP = M(P+Q) = M = -PG^{-1}B = -P^2G^{-1}B = PM \quad \Rightarrow \quad \Phi(t)P = P\Phi(t). \quad \square$$

Remark. $\Phi(t)P$ and $P\Phi(t)$ are identical solutions of (2.10), with $\Phi(\delta)P = P$. To show $Q\Phi(t) = Q$, we could also argue as follows:

$$(Q\Phi(t))' = Q\Phi'(t) = \frac{1}{t}QM\Phi(t) = -\frac{1}{t}QP\cdots \equiv 0 \Rightarrow Q\Phi(t) = \text{constant} = Q.$$

Using the commutativity rules given by Lemma 2.2, and $F(s) \equiv PF(s)$, $Q\Phi^{-1}(s)P \equiv 0$, we can rewrite (2.11), and obtain a new form for the general solution $u(t)$,

$$u(t) = Qc + \Phi(t)P\left\{c + \int_\delta^t \Phi^{-1}(s)F(s)ds\right\}, \qquad 0 < t \leq 1. \tag{2.12}$$

Obviously, condition (2.6c) holds if and only if

$$Qc = 0, \tag{2.13}$$

and any $u(t)$ given by (2.12) and satisfying (2.13) belongs to $\operatorname{im}(P)$.

So far, we have represented $\mathbb{R}^m$ as $\mathbb{R}^m = N_0 \oplus \operatorname{im}(P)$, with $N_0 \subseteq \ker(M)$. Now, we additionally decompose $\ker(M) := N_0 \oplus N_1$, in such a way that $N_1 \subseteq \operatorname{im}(P)$.

Moreover, we introduce the following notation:

X_0 is the invariant subspace of M, associated with eigenvalues $\lambda = 0$, in N_1;

X_- is the invariant subspace of M, associated with $\lambda = \sigma + i\eta \neq 0$ such that $\sigma \leq 0$;

X_+ is the invariant subspace of M, associated with $\lambda = \sigma + i\eta$, $\sigma > 0$.

Now, we immediately have

$$\mathbb{R}^m = N_0 \oplus X_0 \oplus X_- \oplus X_+, \qquad N_1 \subseteq X_0, \quad N_1 \subseteq \operatorname{im}(P). \tag{2.14}$$

LEMMA 2.3. *$X_0 \subseteq \operatorname{im}(P)$ can be chosen in such a way that $X_0 \oplus X_- \oplus X_+ = \operatorname{im}(P)$, holds.*

Proof. For a nontrivial eigenvalue $\lambda \neq 0$, we have

$$Mz_0 = \lambda z_0 \Longleftrightarrow PMz_0 = \lambda z_0 \Rightarrow Qz_0 = 0 \Longleftrightarrow Pz_0 = z_0.$$

Similarly, for any principal vector z_1, the defining equation $Mz_1 = \lambda z_1 + z_0$ implies $z_1 \in \operatorname{im}(P)$, and consequently, $X_- \oplus X_+ \subseteq \operatorname{im}(P)$. Let $\lambda = 0$ be an eigenvalue with the algebraic multiplicity $n_a = l+1$, and the geometric multiplicity $n_g = 1$. Then the set of generalized eigenvalues associated with λ solves

$$Mz_0 = 0, \quad Mz_1 = z_0, \ldots, \quad Mz_l = z_{l-1}, \quad z_0 \in N_1 \subseteq \operatorname{im}(P).$$

Since the general solution of $Mz_l = z_{l-1}$ is $z_l = \tilde{z}_l + \ker(M)$, where $M\tilde{z}_l = z_{l-1}$, z_l depends on $\dim(\ker(M))$ parameters. In general, $\dim(\ker(M)) \geq \dim(\ker(A)) = \operatorname{rank}(Q)$, and, therefore, the parameters can be fixed in such a way that $Qz_l = 0 \Leftrightarrow Pz_l = z_l$. For $k = l, l-1, \ldots, 2$,

$$Qz_{k-1} = QMz_k = 0 \Rightarrow z_{k-1} \in \operatorname{im}(P),$$

and the result follows. □

For the new decomposition of $\mathbb{R}^m$, given by (2.14), with $\operatorname{im}(P) = X_0 \oplus X_- \oplus X_+$, we need two additional projections $P_1, P_2 \in \mathbb{R}^{m\times m}$, such that

P_1 is a projection onto $X_0 \oplus X_-$, along the subspace $N_0 \oplus X_+$;

P_2 is a projection onto X_+, along the subspace $N_0 \oplus X_0 \oplus X_-$.

According to the construction,

$$P = P_1 + P_2, \qquad P_i = PP_i = P_iP, \quad i = 1, 2. \tag{2.15}$$

LEMMA 2.4.

$$\Phi(t)P_i = P_i\Phi(t), \qquad 0 < t \leq 1, \quad i = 1, 2.$$

Proof. Let $J = \operatorname{diag}(0, J_0, J_-, J_+)$ denote the Jordan canonical form of $M = EJE^{-1}$, where E is the matrix containing the generalized eigenvectors of M. Then we can write P as

$$E\begin{pmatrix} 0 & K_1 & K_2 & K_3 \\ 0 & I_0 & 0 & 0 \\ 0 & 0 & I_- & 0 \\ 0 & 0 & 0 & I_+ \end{pmatrix}E^{-1}.$$

From $MP = PM$, it follows immediately that $K_1J_0 = 0$, $K_2J_- = 0$,and $K_3J_+ = 0$ must hold and since J_-, J_+ are regular, $K_2 = K_3 = 0$. Consequently,

$$P_1 = E\begin{pmatrix} 0 & K_1 & 0 & 0 \\ 0 & I_0 & 0 & 0 \\ 0 & 0 & I_- & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}E^{-1}, \qquad P_2 = E\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & I_+ \end{pmatrix}E^{-1},$$

and $MP_i = P_iM$, $i = 1, 2$, which completes the proof. □

We now return to the formula (2.12), and use the projections P_1 and P_2 to derive the following, more precise representation for the general solution $u(t)$ of (2.9), subject to the initial condition (2.13),

$$\begin{aligned} u(t) &= \Phi(t)P_1c + \Phi(t)\int_\delta^0 P_1\Phi^{-1}(s)F(s)ds + \Phi(t)\int_0^t P_1\Phi^{-1}(s)F(s)ds \\ &\quad + \Phi(t)\left\{P_2c + \int_\delta^t P_2\Phi^{-1}(s)F(s)ds\right\}, \end{aligned}$$

which yields

$$\begin{aligned} u(t) &= \Phi(t)\left\{P_1c - \int_0^\delta P_1\Phi^{-1}(s)F(s)ds\right\} + t\int_0^1 P_1\Phi^{-1}(s)\Phi(1)F(st)ds \\ &\quad + \Phi(t)\left\{P_2c + \int_\delta^t P_2\Phi^{-1}(s)F(s)ds\right\}, \qquad 0 < t \leq 1. \end{aligned} \tag{2.16}$$

It is clear from the form of (2.16) that the behavior of $u(t)$, in particular for $t \to 0$, depends essentially on the structure of $\Phi(t)$. We first note that

$$\begin{aligned} \Phi(t)P_1 &= E \ \operatorname{diag}\left(0, \left(\frac{t}{\delta}\right)^{J_0}, \left(\frac{t}{\delta}\right)^{J_-}, 0\right) E^{-1}, \\ \Phi(t)P_2 &= E \ \operatorname{diag}\left(0, 0, 0, \left(\frac{t}{\delta}\right)^{J_+}\right) E^{-1}. \end{aligned}$$

For any Jordan box

$$L := \begin{pmatrix} \lambda & 1 & & & 0 \\ & \ddots & \ddots & & \\ & & \ddots & \ddots & \\ & & & \ddots & 1 \\ 0 & & & & \lambda \end{pmatrix}, \qquad L \in \mathbb{C}^{n\times n},$$

we deduct from the definition of $\Phi(t)$,

$$t^L = t^\lambda \begin{pmatrix} 1 & \ln t & \dots & \dots & \frac{(\ln t)^{n-1}}{(n-1)!} \\ & \ddots & \ddots & & \vdots \\ & & \ddots & \ddots & \vdots \\ & & & \ddots & \ln t \\ & & & & 1 \end{pmatrix}, \qquad t > 0,$$

and, consequently,

$$\lim_{t\to 0} \Phi(t)P_2 = 0,$$

$$\lim_{t\to 0} \Phi(t)\int_\delta^t P_2\Phi^{-1}(s)F(s)ds = 0.$$

Moreover, these parts of $\Phi(t)P_1$, contributed by the invariant subspaces associated with $\lambda = \sigma + i\eta \neq 0$, $\sigma \leq 0$, and by subspaces spanned by the principal vectors associated with $\lambda = 0$, have no limit, or become unbounded for $t \to 0$. Since the subspace spanned by the eigenvectors to $\lambda = 0$ provides bounded contribution in $\Phi(t)P_1$, we have to split X_0 again in order to separate the unbounded and bounded parts. Let $X_0 := N_1 \oplus H_1$, where H_1 is spanned by the principal vectors related to $\lambda = 0$. Then (2.14) becomes

$$\mathbb{R}^m = N_0 \oplus N_1 \oplus \underbrace{H_1 \oplus X_-}\oplus X_+. \tag{2.17}$$

We denote by R, the projection onto N_1, along $N_0 \oplus H_1 \oplus X_- \oplus X_+$, and by $H := P_1 - R$, the projection onto $H_1 \oplus X_-$, along $N_0 \oplus N_1 \oplus X_+$.

Then, $H = HP_1 = P_1H$, and

$$\Phi(t)R = R, \qquad 0 < t \leq 1.$$

We require,

$$Hc = \int_0^\delta H\Phi^{-1}(s)F(s)ds \Rightarrow Hu(0) = 0, \tag{2.18}$$

and obtain from (2.16),

$$\begin{aligned} u(t) &= Rc - \int_0^\delta R\Phi^{-1}(s)F(s)ds + t\int_0^1 P_1\Phi^{-1}(s)\Phi(1)F(st)ds \\ &+\Phi(t)\left\{P_2c + \int_\delta^t P_2\Phi^{-1}(s)F(s)ds\right\}, \qquad 0 < t \leq 1. \end{aligned} \tag{2.19}$$

This immediately implies

$$\lim_{t\to 0} u(t) = Rc - \int_0^\delta R\Phi^{-1}(s)F(s)ds, \tag{2.20}$$

and, therefore, (2.18) is necessary for $u \in C_0^1$. Finally, we consider the boundary conditions (2.6b) in order to determine the constants in P_2c and Rc. From the evaluation of (2.19) for $t = 0$ and $t = 1$, and substitution into (2.6b), we have

$$B_0P_sRc + B_1P_s(Rc + \Phi(1)P_2c) = \tilde{\beta}, \tag{2.21}$$

where

$$\begin{aligned} \tilde{\beta} := \beta - B_1QG^{-1}f(1) + B_0P_s\int_0^\delta R\Phi^{-1}(s)F(s)ds \\ - B_1P_s\left\{ - \int_0^\delta R\Phi^{-1}(s)F(s)ds + \int_0^1 P_1\Phi^{-1}(s)\Phi(1)F(s)ds \right. \\ \left. + \Phi(1)\int_\delta^1 P_2\Phi^{-1}(s)F(s)ds\right\}, \end{aligned}$$

and so, the boundary value problem (2.6) is uniquely solvable if the linear system (2.21) can be uniquely solved for the remaining free components of c. This is the case when for the coefficient matrix

$$T := B_0P_sR + B_1P_s\Phi(1)(R + P_2), \qquad T \in \mathbb{R}^{k\times m}, \tag{2.22}$$

the following conditions hold:

$$\operatorname{rank}(T) = k = \dim(N_1) + \dim(X_+), \tag{2.23}$$

$$\ker(T) = \ker(R + P_2) = N_0 \oplus H_1 \oplus X_-. \tag{2.24}$$

We summarize results from this section in the following theorem.

THEOREM 2.5. *The boundary value problem* (2.1) *has a unique solution* $x \in C^1_\pi$, *for arbitrary* $f \in C$, *and* $\beta \in \mathbb{R}^k$ *if and only if the coefficient matrix* T *given by* (2.22) *satisfies* (2.23) *and* (2.24).

COROLLARY 2.6. *The initial value problem* (2.1), $B_1 = 0$, *is uniquely solvable if and only if*

$$\Lambda := \{\lambda \in \mathbb{C}\backslash\{0\} : \det(\lambda A + B) = 0\} \subseteq \mathbb{C}_-, \tag{2.25}$$

and the following conditions hold for $T := B_0 P_s R$,

$$\begin{aligned}\operatorname{rank}(T) &= k = \dim(N_1),\\ \ker(T) &= \ker(R) = N_0 \oplus H_1 \oplus X_-.\end{aligned}$$

Proof. We first show that Λ and the set of nontrivial eigenvalues of M coincide. Let $\lambda \neq 0$ be an eigenvalue of M; then $z = Pz$ follows from $Mz = \lambda z$. Also,

$$\begin{aligned}
&-Mz + \lambda z = PG^{-1}BPz + \lambda Pz = 0\\
&\quad\Longleftrightarrow (I - Q)G^{-1}BPz + \lambda Pz = G^{-1}BPz - \underbrace{QG^{-1}B}_{Q_s} Pz + \lambda Pz = 0\\
&\quad\Longleftrightarrow BPz - GQ_sPz + \lambda\underbrace{(A + BQ)}_{G}Pz = BPz - GQ_sPz + \lambda APz = 0\\
&\quad\Longleftrightarrow \lambda APz + BPz - \underbrace{(A + BQ)}_{G}\underbrace{QG^{-1}B}_{Q_s} Pz = \lambda APz + BPz - BQ_sPz = 0\\
&\quad\Longleftrightarrow \lambda AP_sPz + B\underbrace{(I - Q_s)}_{P_s}Pz = (\lambda A + B)P_sz = 0.
\end{aligned}$$

Consequently, $\det(\lambda A + B) = 0$ and $\lambda \in \Lambda$.

Let us now assume $\lambda \in \Lambda$; then there exists a vector w such that

$$(\lambda A + B)w = 0, \qquad w \neq 0. \tag{2.26}$$

Multiplying (2.26) by PG^{-1}, we immediately obtain

$$\lambda P\underbrace{G^{-1}A}_{P}w + \underbrace{PG^{-1}B}_{-M=-MP}\, w = 0 \quad\Longleftrightarrow\quad (\lambda I - M)Pw = 0.$$

Moreover, multiplication of (2.26) by QG^{-1}, yields

$$\begin{aligned}
&\lambda Q\underbrace{G^{-1}A}_{P}w + \underbrace{QG^{-1}B}_{Q_s}(Qw + Pw) = 0\\
&\Longleftrightarrow Q\underbrace{G^{-1}BQ}_{I-P}w = -Q_sPw \quad\Longleftrightarrow\quad Qw = -Q_sPw.
\end{aligned}$$

This completes the proof, since $w \neq 0$ implies $Pw \neq 0$, and, therefore, $\det(\lambda I - M) = 0$ must hold. We conclude that Λ is the set of nontrivial eigenvalues of M, and it follows from $\Lambda \subseteq \mathbb{C}_-$ that X_+ is an empty set and $P_2 = 0$. □

Remarks.

1. If $X_0 \oplus X_+ = \emptyset$, then $\ker(M) = N_0$, and $\mathbb{R}^m = N_0 \oplus X_-$. In this case P_1 is a projection onto $X_- = \operatorname{im}(P), P = P_1 + P_2 = P_1 = R + H = H$. Also, $T = 0$, and the general solution (2.19) contains no free constants. It is $\lim_{t\to 0} u(t) = 0$, and $u \in C_0^1$, if it is subject to the homogeneous initial condition $u(0) = 0$. If the general solution given by (2.16) does not satisfy (2.18), then it becomes unbounded or has no limit as $t \to 0$.

2. If the smallest positive real part of the eigenvalues of M is sufficiently large, namely, $\sigma_{\min} > 1$, then $u \in C$ implies $u \in C^1$. This is also the case when, for the eigenvalue $\lambda \equiv \sigma = 1$, its algebraic and geometric multiplicities coincide. Additionally, if $QG^{-1}f \in C_0^1$, then the solution of the boundary value problem (2.1), $x \in C^1$. This follows immediately from (2.6d). We stress that $QG^{-1}f \in C_0^1$ is *necessary* for x to be in C^1.

3. For $\delta = 1$, $\Phi(1) = I$ (cf. (2.10)) and according to (2.19), the general continuous solution of (2.6a) and (2.6c) is

$$\begin{aligned} u(t) &= Rc - \int_0^1 R\Phi^{-1}(s)F(s)ds + t\int_0^1 P_1\Phi^{-1}(s)F(st)ds \\ &+\Phi(t)\left\{P_2c + \int_1^t P_2\Phi^{-1}(s)F(s)ds\right\}, \qquad 0 \le t \le 1. \end{aligned} \tag{2.27}$$

The linear system (2.21) can then be simplified to

$$B_0P_sRc + B_1P_s(Rc + P_2c) = \tilde{\beta}, \tag{2.28}$$

where

$$\begin{aligned} \tilde{\beta} := \beta - B_1QG^{-1}f(1) + B_0P_s\int_0^1 R\Phi^{-1}(s)F(s)ds \\ -B_1P_s\int_0^1 H\Phi^{-1}(s)F(s)ds. \end{aligned}$$

3. Variable coefficient case. Here, we discuss the linear system

$$tA(t)x'(t) + B(t)x(t) = tf(t), \qquad 0 < t \le 1, \tag{3.1a}$$

$$B_0x(0) + B_1x(1) = \beta, \tag{3.1b}$$

where A, B are real-valued continuous $m \times m$ matrices, $A(t) \neq 0$, and all other data is set as in (2.1). We assume that the kernel of A,

$$\ker(A(t)) =: N_0(t), \tag{3.2}$$

is nontrivial and smooth on $[0, 1]$, or equivalently, there exists a projection function $Q(t) \in \mathbb{R}^{m\times m}$, $Q \in C[0, 1]$, which maps $\mathbb{R}^m$ pointwise onto $N_0(t)$. We also define, $P(t) := I - Q(t)$. Moreover, let

$$G(t) := A(t) + B(t)Q(t) \tag{3.3}$$

be regular for all $t \in (0, 1]$. Under these assumptions, the differential-algebraic system (3.1a) is transferable on (0,1]. Recall that $G(t)$ is nonsingular if and only if the matrices $A(t)$, $B(t)$ form a regular matrix pencil of index 1. While the matrix pencil

$\{A(t),\ B(t)\}$ is regular with index 1 for $0 \le t \le 1$, the pencil $\{tA(t),\ B(t)\}$ is regular with index 1 for $0 < t \le 1$, and becomes singular at $t = 0$ when $B(0)$ is singular. The nullspace of $tA(t)$ is neither smooth nor of constant dimension, which changes in $t = 0$ from $m - \operatorname{rank}(A(t))$ to m.

Since,

$$A(t) \equiv A(t)P(t), \qquad tP(t)x'(t) = (tP(t)x(t))' - tP'(t)x(t) - P(t)x(t),$$

we rewrite (3.1a) and obtain

$$A(t)\{(tP(t)x(t))' - P(t)x(t)\} + (B(t) - tA(t)P'(t))x(t) = tf(t), \qquad 0 < t \le 0. \tag{3.4}$$

As previously, the solution space is

$$C^1_\pi := \{x \in C[0,1]:\ \pi x \in C^1[0,1],\ (\pi x)(t) := tP(t)x(t),\ t \in [0,1]\}.$$

As a first step in the investigation of (3.1) we derive the related, decoupled system analogous to (2.6). Again, $Q_s(t) := Q(t)G^{-1}(t)B(t)$, $P_s(t) := I - Q_s(t)$, where $Q_s(t)$ is the pointwise projection onto $N_0(t)$ along the subspace

$$S(t) := \{z \in \mathbb{R}^m:\ B(t)z \in \operatorname{im}(A(t))\}.$$

From the multiplication of (3.1a) by $P(t)G^{-1}(t)$ and $Q(t)G^{-1}(t)$, we have

$$\begin{aligned} &tP(t)\underbrace{G^{-1}(t)A(t)}_{P(t)}x'(t) + P(t)G^{-1}(t)B(t)x(t) = tP(t)G^{-1}(t)f(t),\\ &\iff t(P(t)x(t))' - tP'(t)x(t) + P(t)G^{-1}(t)B(t)x(t) = tP(t)G^{-1}(t)f(t),\\ &\quad 0 < t \le 1, \end{aligned} \tag{3.5}$$

and

$$\begin{aligned} &tQ(t)\underbrace{G^{-1}(t)A(t)}_{P(t)}x'(t) + Q(t)G^{-1}(t)B(t)x(t) = tQ(t)G^{-1}(t)f(t),\\ &\iff Q(t)G^{-1}(t)B(t)x(t) = tQ(t)G^{-1}(t)f(t), \qquad 0 < t \le 1. \end{aligned} \tag{3.6}$$

We introduce $u := Px$ and $v := Qx$, and reformulate (3.6):

$$\begin{aligned} &\underbrace{Q(t)G^{-1}(t)B(t)}_{Q_s}u(t) + Q(t)\underbrace{G^{-1}(t)B(t)Q(t)}_{I-P(t)}x(t) = tQ(t)G^{-1}(t)f(t)\\ &\Rightarrow v(t) = -Q_s(t)u(t) + tQ(t)G^{-1}(t)f(t), \qquad 0 < t \le 1. \end{aligned} \tag{3.7}$$

This implies

$$x(t) = u(t) + v(t) = P_s(t)u(t) + tQ(t)G^{-1}(t)f(t), \tag{3.8}$$

and the substitution of (3.8) into (3.5) yields

$$tu'(t) - M(t)u(t) = tF(t), \qquad 0 < t \le 1, \tag{3.9}$$

where

$$M(t) := -P(t)G^{-1}(t)B(t) + tP'(t)P_s(t),$$
$$F(t) := P(t)G^{-1}(t)f(t) + tP'(t)Q(t)G^{-1}(t)f(t).$$

Due to (3.8), the boundary conditions (3.1b) read

$$B_0P_s(0)u(0) + B_1P_s(1)u(1) = \beta - B_1Q(1)G^{-1}(1)f(1). \tag{3.10}$$

In order to be able to combine solutions $u(t)$, $v(t)$ of (3.9), and (3.7) to a solution $x(t)$ of (3.1a), it is necessary that $u(t) \in \mathrm{im}(P(t))$, $t \in (0,1]$.

LEMMA 3.1. *Let $u(t) \in C_0^1$ be a solution of* (3.9), *subject to*

$$Q(\delta)u(\delta) = 0, \qquad \delta \in (0,1]. \tag{3.11}$$

Then $Q(t)u(t) = 0$ for all $t \in (0,1]$.

Proof. $QF = 0$ follows from $QP'Q = -QPQ' = 0$. We multiply (3.9) by Q and conclude

$$tQ(t)u'(t) - tQ(t)P'(t)P_s(t)u(t) = 0,$$

and finally,

$$t\{Q(t)u'(t) + Q'(t)P(t)u(t)\} = 0,$$
$$t\{(Q(t)u(t))' - Q'(t)Q(t)u(t)\} = 0.$$

Consequently, for $U(t) := Q(t)u(t)$, $t > 0$, we obtain the following homogeneous initial value problem with trivial initial condition

$$U'(t) - Q'(t)U(t) = 0, \qquad 0 < t \le 1,$$
$$U(\delta) = 0,$$

which implies $U(t) \equiv Q(t)u(t) = 0, 0 < t \le 1$, and the result follows. Clearly, $u(t) \in \mathrm{im}(P(t))$, $0 < t \le 1$. □

Let us unite (3.7), (3.9), (3.10), and (3.11) to a system

$$tu'(t) - M(t)u(t) = tF(t), \qquad 0 < t \le 1, \tag{3.12a}$$
$$B_0P_s(0)u(0) + B_1P_s(1)u(1) = \beta - B_1Q(1)G^{-1}(1)f(1), \tag{3.12b}$$
$$Q(\delta)u(\delta) = 0, \qquad \delta \in (0,1], \tag{3.12c}$$
$$v(t) = -Q_s(t)u(t) + tQ(t)G^{-1}(t)f(t), \qquad 0 < t \le 1, \tag{3.12d}$$

and formulate the following assertion, in analogy to Theorem 2.1.

THEOREM 3.2. *Let $x \in C_\pi^1$ be a solution of* (3.1); *then the pair, $u := Px \in C_0^1$, $v := Qx \in C$ satisfies* (3.12). *For any $u \in C_0^1$ and $v \in C$, solving the system* (3.12), *we construct the solution of the boundary value problem* (3.1) *by $x := u + v \in C_\pi^1$.*

In order to find continuous solutions of (3.12), we first study the solution manifold of the singular system (3.12a),

$$u'(t) = \frac{1}{t}M(t)u(t) + F(t), \qquad 0 < t \le 1. \tag{3.13}$$

Let us assume that $M'(0)$ exists; then the matrix $M_1(t)$,

(3.14)
$$M_1(t) := \frac{1}{t}(M(t) - M(0)) = -\frac{1}{t}(P(t)G^{-1}(t)B(t) - P(0)G^{-1}(0)B(0)) + P'(t)P_s(t),$$

is continuous on $[0,1]$, and with

$$M(t) = M_0 + tM_1(t), \qquad M_0 := M(0),$$

we can reformulate (3.13) to

$$u'(t) = \frac{1}{t}M_0u(t) + F_1(t), \qquad 0 < t \leq 1, \tag{3.15}$$

where

$$F_1(t) := F(t) + M_1(t)u(t).$$

Since (3.15) is, formally, a system with constant coefficient matrix, its general solution is provided by (2.11). Let

$$\Phi_0(t) = \exp\left(M_0 \ln \frac{t}{\delta}\right) =: \left(\frac{t}{\delta}\right)^{M_0},$$

and $P_0 := P(0), Q_0 := Q(0) = I - P_0$; then Lemmas 2.2, 2.3, and 2.4 hold for Φ_0, P_0, Q_0, and the corresponding subspaces of M_0 and the general solution of (3.15) is

$$\begin{aligned} u(t) &= \Phi_0(t)\left\{c + \int_\delta^t \Phi_0^{-1}(s)F_1(s)ds\right\} \\ &= Q_0c + \Phi_0(t)P_0\left\{c + \int_\delta^t \Phi_0^{-1}(s)F_1(s)ds\right\} + Q_0\int_\delta^t F_1(s)ds. \end{aligned} \tag{3.16}$$

According to Lemma 3.1, it follows from $Q(\delta)u(\delta) = 0$ that $Q(t)u(t) = 0$ for all $t \in (0,1]$, which results in the following requirement on c

$$0 = Q(\delta)u(\delta) = Q(\delta)(Q_0c + P_0c) = Q(\delta)c.$$

Let us now associate with matrix M_0, projections P_1, P_2, R, H and the subspaces $N_0 := N(0)$, N_1, H_1, X_0, X_-, X_+, as defined in §2.2. Then the continuous solution $u \in C$ of (3.15) is

$$\begin{aligned} u(t) = {} & Q_0c + Q_0\int_\delta^t F_1(s)ds \\ & + Rc - \int_0^\delta R\Phi_0^{-1}(s)F_1(s)ds + t\int_0^1 P_1\Phi_0^{-1}(s)\Phi_0(1)F_1(st)ds \\ & + \Phi_0(t)\left\{P_2c + \int_\delta^t P_2\Phi_0^{-1}(s)F_1(s)ds\right\}, \qquad 0 < t \leq 1, \end{aligned} \tag{3.17}$$

where $P(\delta)c = c$, and, therefore,

$$\lim_{t\to 0} u(t) = Q_0P(\delta)c - Q_0\int_0^\delta F_1(s)ds + RP(\delta)c - \int_0^\delta R\Phi_0^{-1}(s)F(s)ds.$$

Moreover, the components $(Q_0 + R + P_2)P(\delta)c =: \gamma$ have to be chosen in a suitable way in order to satisfy boundary conditions (3.12b).

Since, $F_1(t)$ depends on $u(t)$, we interpret (3.17) as an operator equation, and use contraction techiques to show its solvability with respect to u. Therefore, let us discuss the integral operator $K : C[0,\delta] \to C[0,\delta]$,

$$\begin{aligned}(Ku)(t) :=& Q_0\gamma + Q_0 \int_\delta^t F_1(s)ds \\ &+R\gamma - \int_0^\delta R\Phi_0^{-1}(s)F_1(s)ds + t\int_0^1 P_1\Phi_0^{-1}(s)\Phi_0(1)F_1(st)ds \\ &+\Phi_0(t)\left\{P_2\gamma + \int_\delta^t P_2\Phi_0^{-1}(s)F_1(s)ds\right\}, \qquad 0 < t \le \delta,\end{aligned}$$

where $\gamma \in \mathbb{R}^m$ is a fixed vector. For u, $v \in C[0,\delta]$, we obtain

$$\begin{aligned}|(Ku)(t) - (Kv)(t)| \le& \left|\int_\delta^t Q_0M_1(s)(u(s)-v(s))ds\right| \\ &+\left|\int_0^\delta R\Phi_0^{-1}(s)M_1(s)(u(s)-v(s))ds\right| \\ &+\left|\int_0^1 tP_1\Phi_0^{-1}(s)\Phi_0(1)M_1(st)(u(st)-v(st))ds\right| \\ &+\left|\int_\delta^t \Phi_0(t)P_2\Phi_0^{-1}(s)M_1(s)(u(s)-v(s))ds\right|.\end{aligned} \tag{3.18}$$

We estimate (3.18) term by term; cf. [6]:

$$\begin{aligned}&\int_t^\delta |Q_0M_1(s)|ds \le \kappa_1\delta, \\ &\int_0^\delta |R\Phi_0^{-1}(s)M_1(s)|ds \le \kappa_2\delta, \\ t&\int_0^1 |P_1\Phi_0^{-1}(s)\Phi_0(1)M_1(st)|ds \le \kappa_3 t \le \kappa_3\delta, \\ &\int_t^\delta |\Phi_0(t)P_2\Phi_0^{-1}(s)M_1(s)|ds \le \kappa_4 \begin{cases} \delta\left(\dfrac{t}{\delta}\right)^{\sigma_{\min}}\left|\ln\dfrac{t}{\delta}\right|^n, & \sigma_{\min}\in(0,1), \\ t\left|\ln\frac{t}{\delta}\right|^{n+1}, & \sigma_{\min} = 1, \\ t\left|\ln\frac{t}{\delta}\right|^n, & \sigma_{\min} > 1, \end{cases} \\ &\le \kappa_4\delta,\end{aligned}$$

where $\sigma_{\min}$ is the smallest positive real part of the eigenvalues of M_0, and n is the dimension of the largest Jordan box associated with $\sigma_{\min}$. Consequently, it follows from (3.18), for sufficiently small $\delta > 0$, that

$$\|Ku - Kv\|_\infty \le \kappa\delta\,\|u - v\|_\infty < \|u - v\|_\infty$$

for any u, $v \in C[0,\delta]$, which means that K is contracting on $C[0,\delta]$ and has a unique fixed-point there. Equivalently, for any $\gamma = (Q_0 + R + P_2)P(\delta)c$, there exists a unique solution of (3.12a), $u(t) \in C[0,\delta]$, and this solution can be easily extended to $C[0,1]$.

We finally treat the question when u, given by (3.17), satisfies the boundary conditions (3.12b). The evaluation of (3.17) yields

$$\begin{aligned} u(0) &= (Q_0 + R)P(\delta)c \\ &\quad -Q_0 \int_0^\delta F_1(s)ds - \int_0^\delta R\Phi_0^{-1}(s)F(s)ds, \\ u(1) &= (Q_0 + R + \Phi_0(1)P_2)P(\delta)c \\ &\quad +Q_0 \int_\delta^1 F_1(s)ds - \int_0^\delta R\Phi_0^{-1}(s)F_1(s)ds \\ &\quad + \int_0^1 P_1\Phi_0^{-1}(s)\Phi_0(1)F_1(s)ds + \Phi_0(1)\int_\delta^1 P_2\Phi_0^{-1}(s)F_1(s)ds, \end{aligned}$$

and u is a unique solution of (3.12a), (3.12b), and (3.12c) if the linear system

$$Tc = \tilde{\beta}, \tag{3.19a}$$

$$T := \{B_0P_s(0)(Q_0 + R) + B_1P_s(1)(Q_0 + R + \Phi_0(1)P_2)\}P(\delta), \tag{3.19b}$$

$$\tilde{\beta} := \beta - B_1Q(1)G^{-1}(1)f(1) - B_0P_s(0)u_\beta(0) - B_1P_s(1)u_\beta(1), \tag{3.19c}$$

where

$$\begin{aligned} u_\beta(0) &:= -Q_0 \int_0^\delta F_1(s)ds - \int_0^\delta R\Phi_0^{-1}(s)F(s)ds, \\ u_\beta(1) &:= Q_0 \int_\delta^1 F_1(s)ds - \int_0^\delta R\Phi_0^{-1}(s)F_1(s)ds \\ &\quad + \int_0^1 P_1\Phi_0^{-1}(s)\Phi_0(1)F_1(s)ds + \Phi_0(1)\int_\delta^1 P_2\Phi_0^{-1}(s)F_1(s)ds, \end{aligned}$$

is uniquely solvable for the free components $(Q_0 + R)P(\delta)c$ and $P_2P(\delta)c$. Since

$$P_s(0)Q_0 = 0, \qquad \Phi_0(1)Q_0 = Q_0, \qquad \Phi_0(1)R = R,$$

we can rewrite (3.19b), and obtain

$$T = \{B_0P_s(0)R + B_1P_s(1)\Phi_0(1)(Q_0 + R + P_2)\}P(\delta). \tag{3.20}$$

We now recapitulate the results in the following theorem.

THEOREM 3.3. *Let $M(t)$ be differentiable at $t = 0$. Then the boundary value problem* (3.1) *has a unique solution $x \in C_\pi^1$, for any $f \in C$ and $\beta \in \mathbb{R}^k$, if and only if the matrix T, defined by* (3.19b), *satisfies the following conditions:*

$$\operatorname{rank}(T) = k = \dim(N_1) + \dim(X_+), \tag{3.21}$$

$$\ker(T) = \ker((Q_0 + R + P_2)P(\delta)). \tag{3.22}$$

Additionally, if the nullspace of $A(t)$ is constant, and we set $Q(t) \equiv Q_0$, then (3.20) *and* (3.22) *reduce to*

$$T = B_0P_s(0)R + B_1P_s(1)\Phi_0(1)(R + P_2)$$

and

$$\ker(T) = \ker(R + P_2) = N_0 \oplus H_1 \oplus X_-,$$

respectively.

COROLLARY 3.4. *Initial value problems are uniquely solvable if*

$$P_s(1)Q_0P(\delta) = 0, \qquad P_s(1)\Phi_0(1)P_2P(\delta) = 0.$$

This is the case when $P'(t) \equiv 0$ *and* $P_2 = 0$, *or equivalently, the matrix* $M(0) = -P(0)G^{-1}(0)B(0)$, *has no eigenvalues with positive real parts, and* $\det(\lambda A(0)+B(0)) = 0$ *and* $\lambda \neq 0$ *imply* $\mathrm{Re}(\lambda) < 0$.

Remarks.

1. If $A(t)$ and $B(t)$ are continuously differentiable at $t = 0$, so is $M(t)$.

2. Theorem 3.3 characterizes the existence of solutions $x \in C^1_\pi$. If $QG^{-1}f \in C^1_0$ and if all eigenvalues $\lambda = \sigma + i\eta$ with positive real parts, such that $\det(\lambda A(0)+B(0)) = 0$, satisfy the condition $\sigma > 1$, then $x \in C^1$.

UNIFORM HARMONIC APPROXIMATION ON COMPACT SETS IN $\mathbb{R}^k$, $k \geqq 3$*

VLADIMIR ANDRIEVSKII†

Abstract. Estimates of the best uniform approximation of a function f given on some compact set $K \subset \mathbb{R}^k$, $k \geqq 3$, by harmonic polynomials are obtained. The results connect approximation properties of the function f with its structural properties and the geometry of K. This corresponds to well-known results for analytic functions.

Key words. approximation, harmonic function

AMS(MOS) subject classifications. 31A25, 30C85

1. Introduction. Let K be a compact set of the k-dimensional Euclidean space $\mathbb{R}^k$, $k \geqq 3$ with a connected complement $D := \mathbb{R}^k \backslash K$.

Denote by Har (K) the class of all functions continuous on K and harmonic at its interior points, and let H_n, $n = 0, 1, \ldots$, be the class of all harmonic polynomials of degree at most n.

For a function f given on K and $n = 0, 1, \ldots$, we set

$$\|f\|_K := \sup \{|f(\mathbf{x})|, \mathbf{x} \in K\},$$

$$E_{n,\Delta}(f, K) := \inf \{\|f - h\|_K, h \in H_n\}.$$

The main purpose of this paper is to establish estimates for the quantity $E_{n,\Delta}(f, K)$ depending—like the known results for analytic functions (the reader can find the whole survey in [4] and [5])—on the smoothness properties of the function f and the geometric structure of the compact set K. Similar problems for the case $k = 3$ were investigated in [8] and [1].

2. Main definitions and results. In all that follows $c, c_1, c_2, \ldots$ denote constants depending maybe on K, k, or other quantities inessential for our investigations. The same symbols may be used for different constants in the statements of different results.

For $\mathbf{x} = (x_1, \ldots, x_k) \in \mathbb{R}^k$, $\mathbf{y} = (y_1, \ldots, y_k) \in \mathbb{R}^k$, and $\delta > 0$, we set, as usual,

$$|\mathbf{x} - \mathbf{y}|^2 := \sum_{j=1}^{k} (x_j - y_j)^2,$$

$$B(\mathbf{x}, \delta) := \{\mathbf{y}: |\mathbf{x} - \mathbf{y}| < \delta\}, \qquad B(\delta) := B(0, \delta),$$

$$S(\mathbf{x}, \delta) := \{\mathbf{y}: |\mathbf{x} - \mathbf{y}| = \delta\}, \quad S(\delta) := S(0, \delta), \quad S := S(1),$$

$$d(\mathbf{x}, K) := \inf \{|\mathbf{x} - \mathbf{y}|, \mathbf{y} \in K\}.$$

The domain D is called a John domain (see, for example, [6]) if each point $\mathbf{x} \in D$ can be joined to ∞ with a Jordan curve $\gamma = \gamma(\mathbf{x})$ satisfying the following property. If γ is defined by $\mathbf{y} = \mathbf{y}(s)$, $s \in [0, \infty]$, $\mathbf{y}(0) = \mathbf{x}$, $\mathbf{y}(\infty) = \infty$, where s is the arc length, then for every $s > 0$ we require

$$d(\mathbf{y}(s), K) \geqq cs, \qquad c = \text{const} \in (0, 1]. \tag{2.1}$$

Let $\omega(\delta)$, $\delta > 0$ be a positive nondecreasing function, such that

$$\omega(+0) = 0; \qquad \omega(2\delta) \leqq c\delta, \quad \delta > 0.$$

We denote by $C^{\omega}(E)$ the class of functions f given on $E \subset \mathbb{R}^k$ for which

$$|f(\mathbf{x}) - f(\mathbf{y}) \leqq c\omega(|\mathbf{x}-\mathbf{y}|), \qquad \mathbf{x}, \mathbf{y} \in \mathrm{E}.$$

THEOREM 1. *Let K be a compact set whose complement D is a John domain. Then for $f \in C^{\omega}(K) \cap \operatorname{Har}(K)$ the following estimate holds*:

$$E_{n,\Delta}(f, K) \leqq c_1\omega(n^{-c}), \qquad n = 1, 2, \ldots, \tag{2.2}$$

where the constants c, $c_1 > 0$ are independent of n.

The proof of Theorem 1 is based on the following fact that is analogous to the procedure of "removal of the poles" suggested in the case of approximation of analytic functions by Keldysh (see, for example, [7, pp. 21-27]).

LEMMA 1. *Let $K \subset B(R)$ for some $R > 0$, and let $D = \mathbb{R}^k \backslash K$ be a John domain. For any $\mathbf{y} \in D \cap B(3R)$ and sufficiently small $\varepsilon \geqq 0$, there exists a function $q_{\mathbf{y}}(\mathbf{x}) = q_{\mathbf{y}}(\mathbf{x}, \varepsilon)$ harmonic in $\overline{B(3R)}$ with the following properties*:

$$||\mathbf{x}-\mathbf{y}|^{-k+2} - q_{\mathbf{y}}(\mathbf{x})| \leqq \varepsilon, \qquad \mathbf{x} \in K; \tag{2.3}$$

$$\|q_{\mathbf{y}}\|_{\overline{B(3R)}} \leqq \exp\left\{c_1 d^{-c_2} \ln\left[\frac{c_3}{d\varepsilon}\right]\right\}, \tag{2.4}$$

where $d := d(\mathbf{y}, K)$.

Moreover, we shall show how Lemma 1 can be applied to the proof of the harmonic analogue of the well-known Bernstein-Walsh theorem; see also Theorem 3.1 in [2].

THEOREM 2. *Let K be an arbitrary compact set with a simply connected complement, and let the function f be harmonic in some neighbourhood of K. Then for some $q \in (0, 1)$, the estimate*

$$E_{n,\Delta}(f, K) \leqq cq^n, \qquad n = 0, 1, \ldots, \tag{2.5}$$

holds, where the constant c is independent of n.

3. Proof of Lemma 1. To begin, we recall some facts that will be needed below (see, for example, [3, pp. 206, 213]).

Let the function F be given and continuous on the sphere $S(\mathbf{y}, R), \mathbf{y} \in \mathbb{R}^k$, $R > 0$. By the Laplace formula, the solution of Dirichlet's problem

$$\Delta Q(\mathbf{x}) = 0, \qquad \mathbf{x} \in \mathbb{R}^k \backslash S(\mathbf{y}, R),$$

$$Q(\mathbf{x}) = F(\mathbf{x}), \qquad \mathbf{x} \in S(\mathbf{y}, R)$$

can be represented by the series

$$Q(\mathbf{x}) = \sum_{j=0}^{\infty} \left(\frac{|\mathbf{x}-\mathbf{y}|}{\mathrm{R}}\right)^j Y_j(F, \xi), \qquad \mathbf{x} \in B(\mathbf{y}, R); \tag{3.1}$$

$$Q(\mathbf{x}) = \sum_{j=0}^{\infty} \left(\frac{R}{|\mathbf{x}-\mathbf{y}|}\right)^{j+k-2} Y_j(F, \xi), \qquad \mathbf{x} \in \mathbb{R}^k \backslash \overline{B(\mathbf{y}, R)}, \tag{3.2}$$

where $\xi := (\mathbf{x}-\mathbf{y})/|\mathbf{x}-\mathbf{y}|$, $Y_j(F, \xi)$, $j = 0, 1, \ldots,$ are the surface harmonics satisfying

$$\| Y_j(F, \cdot)\|_S \leqq c_1(j+1)^{k-2}\|F\|_{S(\mathbf{y},R)}. \tag{3.3}$$

Now let $\mathbf{y}$ and ε be given. Let $\gamma \subset D$ be an arc from the definition of John domain, i.e., an arc with endpoints $\mathbf{y}$ and ∞ satisfying (2.1). Without loss of generality, we may assume that $\gamma \cap [\mathbb{R}^k \backslash B(R)]$ is a part of some ray from the origin.

In the following c will be the constant from (2.1).

Setting $s_1 := d/4$, $s_\nu := (1+c/4)s_{\nu-1}$, $\nu = 2, 3, \ldots$, we introduce the sequence of points

$$\mathbf{y}_0 := \mathbf{y}, \quad \mathbf{y}_\nu := \mathbf{y}(s_\nu), \quad \nu = 1, 2, \ldots .$$

Our next aim is to construct a sequence of harmonic functions $q_0, q_1, \ldots$ with some special properties.

To begin with, put $q_0(\mathbf{x}) = |\mathbf{x} - \mathbf{y}_0|^{-k+2}$. Assuming that the function q_ν is given, we describe the procedure of construction of the next function $q_{\nu+1}$, $\nu = 0, 1, \ldots$.

Since the function q_ν is harmonic in $\mathbb{R}^k \backslash \{\mathbf{y}_\nu\}$ by (3.2), we have for $\mathbf{x} \in \mathbb{R}^k \backslash B(\mathbf{y}_{\nu+1}, cs_{\nu+1}/2)$, $\xi = (\mathbf{x} - \mathbf{y}_{\nu+1})/|\mathbf{x} - \mathbf{y}_{\nu+1}| \in S$,

$$q_\nu(\mathbf{x}) = \sum_{j=0}^{\infty} \left(\frac{cs_{\nu+1}}{2|\mathbf{x} - \mathbf{y}_{\nu+1}|} \right)^{j+k-2} Y_j(q_\nu, \xi).$$

Put

$$q_{\nu+1}(\mathbf{x}) = \sum_{j=0}^{n_{\nu+1}} \left(\frac{cs_{\nu+1}}{2|\mathbf{x} - \mathbf{y}_{\nu+1}|} \right)^{j+k-2} Y_j(q_\nu, \xi),$$

where the large enough number $n_{\nu+1}$ will be chosen later.

Introducing the notation $N_0 := d^{-k+2}$,

$$N_\nu := \|q_\nu\|_{S(\mathbf{y}_{\nu+1}, cs_{\nu+1}/2)}, \qquad \nu = 1, 2, \ldots ,$$

we obtain

$$N_\nu \leqq c_1 \sum_{j=0}^{n_\nu} (j+1)^{k-2} 2^j N_{\nu-1} \leqq c_2 n_\nu^{k-1} 2^{n_\nu} N_{\nu-1} \leqq 3^{n_\nu} N_{\nu-1}.$$

Moreover,

$$\|q_0 - q_1\|_K \leqq c_1\, d^{-k+2} \sum_{j=n_1+1}^{\infty} j^{k-2} 2^{-j} \leqq c_2\, d^{-k+2} n_1^{k-2} 2^{-n_1}, \tag{3.4}$$

and for $\nu \geqq 1$,

$$\begin{aligned} \|q_\nu - q_{\nu+1}\|_K &\leqq c_1 N_\nu \sum_{j=n_{\nu+1}+1}^{\infty} j^{k-2} 2^{-j} \\ &\leqq c_2 n_{\nu+1}^{k-2} 2^{-n_{\nu+1}} N_\nu. \end{aligned} \tag{3.5}$$

We consider the case $n_{\nu+1} := tn_\nu$, $\nu = 1, 2, \ldots$, for some integer $t > 1$.

We claim that there exist a sufficiently large $n_1 = n_1(\varepsilon)$ and t such that

$$\|q_\nu - q_{\nu+1}\|_K \leqq \left(\frac{\varepsilon}{2} \right)^{\nu+1}, \qquad \nu = 0, 1, \ldots . \tag{3.6}$$

Indeed, according to (3.4), inequality (3.6) is valid for $\nu = 0$ if we set

$$n_1 = c_1 \ln \frac{c_2}{\varepsilon d}, \tag{3.7}$$

where c_1 and c_2 are sufficiently large.

Further, since for $t>2$,

$$N_\nu \leqq 3^{n_\nu} N_{\nu-1} \leqq \cdots \leqq 3^{n_\nu+n_{\nu-1}+\cdots+n_1} N_0 \leqq 3^{n_\nu(1+t^{-1}+\cdots)} N_0 \leqq 3^{2n_\nu} N_0, \tag{3.8}$$

we have, applying (3.5) and (3.8) for $\nu \geqq 1$ and fixed $t \geqq 6$,

$$\|q_\nu - q_{\nu+1}\|_K \leqq c_1 t^{k-2} n_\nu^{k-2} 2^{-tn_\nu} 3^{2n_\nu} N_0 \leqq c_2 2^{-n_\nu} N_0 \leqq c_3 d^{-k-2} 2^{-n_1 t^{\nu-1}} \leqq \left(\frac{\varepsilon}{2}\right)^{\nu+1},$$

if the constants c_1 and c_2 from the relation (3.7) are sufficiently large.

Since our curve γ satisfies condition (2.1) there exists an integer $m = c_1 \ln(c_2/d)$ such that $B(3R) \cap B(\mathbf{y}_{m+1}, cs_{m+1}/2) = \phi$.

We claim that the function $q_\mathbf{y}(\mathbf{x}) := q_m(\mathbf{x})$ satisfies the desired conditions (2.3) and (2.4).

In fact, for $\mathbf{x} \in K$ and $\varepsilon \leqq 1$,

$$\left||\mathbf{x}-\mathbf{y}|^{-k+2} - q_\mathbf{y}(\mathbf{x})\right| \leqq |q_0(\mathbf{x}) - q_1(\mathbf{x})| + \cdots + |q_{m-1}(\mathbf{x}) - q_m(\mathbf{x})| \leqq \frac{\varepsilon}{2} + \left(\frac{\varepsilon}{2}\right)^2 + \cdots \leqq \varepsilon.$$

Apart from this, according to (3.8),

$$\|q_\mathbf{y}\|_{\overline{\mathrm{B(3R)}}} \leqq \mathrm{N_m} \leqq 3^{2\mathrm{n_m}} \mathrm{N_0} \leqq \exp\{c_1 t^m n_1 - c_2 \ln d\} \leqq \exp\left\{c_3\, d^{-c_4} \ln \frac{c_5}{\varepsilon d}\right\}.$$

Lemma 1 is proved.

With reasoning completely similar to the construction and study of the properties of the function q_1, we can obtain the following result.

For $E \subset \mathbb{R}^k$ and $\delta > 0$ set

$$E_\delta := \{\mathbf{x}\colon d(\mathbf{x}, E) < \delta\}.$$

LEMMA 2. *Let $D = \mathbb{R}^k \backslash K$ be a John domain. For any point $\mathbf{y} \in K_{3\delta} \cap D_\delta$, $\delta > 0$, there exists a function $\psi_{\delta,\mathbf{y}}(\mathbf{x})$ harmonic in $K_{3\delta}$, satisfying*

$$\|\psi_{\delta,\mathbf{y}}\|_{K_{3\delta}} \leqq c_1 \delta^{-k+2},$$

$$\left||\mathbf{x}-\mathbf{y}|^{-k+2} - \psi_{\delta,\mathbf{y}}(\mathbf{x})\right| \leqq c_2 \delta^3 |\mathbf{x}-\mathbf{y}|^{-k-1}, \qquad \mathbf{x} \in \mathbb{R}^k \backslash B(\mathbf{y}, c_3\delta).$$

4. Two auxiliary operators. We shall need the following two standard operators (for details, see [9], [10]).

For given $f \in \mathrm{Har}\,(K)$, denote by $\tilde{f} := \mathscr{E}_K f$ a function, defined on $\mathbb{R}^k$ such that

$$\tilde{f}(\mathbf{x}) = f(\mathbf{x}), \qquad \mathbf{x} \in K,$$

$$\tilde{f}(\mathbf{x}) = 0, \qquad \mathbf{x} \in \mathbb{R}^k \backslash K_{c_1},$$

$$\|\tilde{f}\|_{\mathbb{R}^k} \leqq c_2 \|f\|_K,$$

and in addition if $f \in C^\omega(K)$, then $\tilde{f} \in C^\omega(\mathbb{R}^k)$.

Furthermore, for a continuous function g given on $\mathbb{R}^k$ and $\delta > 0$ set

$$g_\delta(\mathbf{x}) = (U_\delta g)(\mathbf{x}) := \int_{\mathbb{R}^k} g(\mathbf{x} + \delta \mathbf{y}) \Phi(\mathbf{y})\, d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^k,$$

where

$$\Phi(\mathbf{y}) := \begin{cases} c \exp\{|\mathbf{y}|^2/(|\mathbf{y}|^2-1)\}, & 0 \leqq |\mathbf{y}| < 1; \\ 0 & |\mathbf{y}| > 1, \end{cases}$$

and the constant c is chosen such that $\int_{\mathbb{R}^k} \Phi(\mathbf{y})\, d\mathbf{y} = 1$.

The function g_δ has partial derivatives of all orders in $\mathbb{R}^k$, and if $g \in C^\omega(\mathbb{R}^k)$, then

$$\|g_\delta - g\|_{\mathbb{R}^k} \leqq c_1 \omega(\delta);$$

$$\|\Delta g_\delta\|_{\mathbb{R}^k} \leqq c_2 \omega(\delta)\delta^{-2}.$$

In addition, if g is harmonic on $\overline{B(\mathbf{x}, \delta)}$, then

$$g_\delta(\mathbf{x}) = g(\mathbf{x}).$$

5. Proof of Theorem 1. Let f be a given function, and let $\delta = \delta(n)$ be a sufficiently small number, the value of which will be determined below. Consider the function $\varphi = \varphi_\delta := U_\delta \mathscr{E}_K f$. According to Green's formula it can be written in the form

$$\varphi(\mathbf{x}) = -\frac{1}{(k-2)\sigma} \int_{D_\delta} \frac{\Delta\varphi(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{k-2}}\, d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^k,$$

where $\sigma = 2\pi^{k/2}/(\Gamma(k/2))$ is the total area of the unit sphere S.

It is easy to see that the function

$$u(\mathbf{x}) = u_\delta(\mathbf{x}) := \frac{1}{(k-2)\sigma} \int_{D_\delta \cap K_{3\delta}} \Delta\varphi(\mathbf{y}) \psi_{\delta,\mathbf{y}}(\mathbf{x})\, d\mathbf{y}$$
$$- \frac{1}{(k-2)\sigma} \int_{D_\delta \setminus K_{3\delta}} \frac{\Delta\varphi(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{k-2}}\, d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^k,$$

where $\psi_{\delta,\mathbf{y}}(\mathbf{x})$ is a function from Lemma 2, satisfies the conditions

$$u \in \operatorname{Har}(\overline{K_{2\delta}}), \quad \|u\|_{\overline{K_{2\delta}}} \leqq c_1 \|f\|_K, \quad \|u - f\|_K \leqq c_2 \omega(\delta).$$

Consider now the next function $v := U_\delta \mathscr{E}_{\overline{K_{2\delta}}} u$. From the properties of the operators U_δ and $\mathscr{E}_K$ we conclude that

$$\begin{aligned} &\|v - f\|_K \leqq c_1 \omega(\delta); \\ &\|\Delta v\|_{\mathbb{R}^k} \leqq c_2 \|f\|_K \delta^{-2}; \\ &\Delta v(\mathbf{x}) = 0, \qquad \mathbf{x} \in K_\delta; \\ &v(\mathbf{x}) = 0, \qquad \mathbf{x} \in \mathbb{R}^k \setminus B(3R) \end{aligned} \tag{5.1}$$

for some $R > 0$ such that $K \subset B(R)$.

Applying Green's formula to the function v we obtain

$$v(\mathbf{x}) = \frac{1}{(k-2)\sigma} \int_{B(3R)\setminus K_\delta} \frac{\Delta v(\mathbf{y})}{|\mathbf{x}-\mathbf{y}|^{k-2}}\, d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^k.$$

Consider the function

$$q(\mathbf{x}) := \frac{1}{(k-2)\sigma} \int_{B(3R)\setminus K_\delta} \Delta v(\mathbf{y}) q_{\mathbf{y}} V(\mathbf{x})\, d\mathbf{y}, \qquad \mathbf{x} \in B(3R),$$

where $q_{\mathbf{y}}(\mathbf{x}) = q_{\mathbf{y}}(\mathbf{x}, \varepsilon)$, $\varepsilon = \delta^2\omega(\delta)$, is the function from Lemma 1. By virtue of Lemma 1, $q \in \operatorname{Har}(\overline{B(2R)})$ and

$$
\begin{aligned}
&\|v - q\|_K \leqq c_1\omega(\delta);\\
&\|q\|_{\overline{B(2R)}} \leqq c_2 \exp\{c_3\delta^{-c_4}\}.
\end{aligned}
\tag{5.2}
$$

By (3.1) and (3.3)

$$
q(\mathbf{x}) = \sum_{j=0}^{\infty} \left(\frac{|\mathbf{x}|}{2R}\right)^j Y_j(q, \xi); \quad \mathbf{x} \in B(2R), \quad \xi = \frac{\mathbf{x}}{|\mathbf{x}|};
$$

$$
\|Y_j(q, \cdot)\|_S \leqq c_5(j+1)^{k-2} \exp\{c_3\delta^{-c_4}\}.
$$

Considering the harmonic polynomial

$$
h_n(\mathbf{x}) := \sum_{j=0}^{n} \left(\frac{|\mathbf{x}|}{2R}\right)^j Y_j(q, \xi),
$$

we can estimate for $\mathbf{x} \in K$,

$$
|q(\mathbf{x}) - h_n(\mathbf{x})| \leqq c_6 \exp\{c_3\delta^{-c_4}\} \sum_{j=n+1}^{\infty} j2^{-j} \leqq c_7 \exp\{c_3\delta^{-c_4} - n \ln(\tfrac{3}{2})\}.
$$

Choosing $\delta := n^{-1/(2c_4)}$, we obtain by the inequalities (5.1) and (5.2) the desired estimate (2.2).

6. Proof of Theorem 2. The reasoning will be quite similar to that of Theorem 1. Without loss of generality, we may assume that $D = \mathbb{R}^k \backslash K$ is a John domain.

Fixing sufficiently small numbers $0 < d < \rho$ such that $f \in \operatorname{Har}(\overline{K_\rho})$, we consider the function $\varphi = \varphi_\delta := U_\delta \mathscr{E}_{\overline{K_\rho}} f$, where $0 < \delta < \rho - d$ will also be some fixed number.

By the properties of the operators U_δ and $\mathscr{E}_K$, we have

$$
\begin{aligned}
&\varphi(\mathbf{x}) = f(\mathbf{x}), \qquad \mathbf{x} \in \overline{K_d};\\
&\|\Delta\varphi\|_{\mathbb{R}^k} \leqq c_1;\\
&\varphi(\mathbf{x}) = 0, \qquad \mathbf{x} \in \mathbb{R}^k \backslash B(3R)
\end{aligned}
$$

for some R such that $K \subset B(R)$.

According to Green's formula we have

$$
\varphi(\mathbf{x}) = -\frac{1}{(k-2)\sigma} \int_{B(3R)\backslash K_d} \frac{\Delta\varphi(\mathbf{y})}{|\mathbf{x} - \mathbf{t}|^{k-2}}\, d\mathbf{y}, \qquad \mathbf{x} \in \mathbb{R}^k.
$$

Let n be large enough. Consider the function

$$
q(\mathbf{x}) := \frac{1}{(k-2)\sigma} \int_{B(3R)\backslash K_d} \Delta\varphi(\mathbf{y}) q_{\mathbf{y}}(\mathbf{x})\, d\mathbf{y}, \qquad \mathbf{x} \in \overline{B(3R)},
$$

where $q_{\mathbf{y}}(\mathbf{x}) = q_{\mathbf{y}}(\mathbf{x}, \varepsilon)$ is a function from Lemma 1, and $\varepsilon = \varepsilon(n)$ will be chosen below.

By the estimates (2.3) and (2.4) we obtain

$$
\begin{aligned}
&\|f - q\|_K \leqq c_1\varepsilon;\\
&\|q\|_{B(2R)} \leqq c_3\varepsilon^{-c}.
\end{aligned}
\tag{6.1}
$$

Since for $\mathbf{x} \in B(2R)$,

$$
q(\mathbf{x}) = \sum_{j=0}^{\infty} \left(\frac{|\mathbf{x}|}{2R}\right)^j Y_j(q, \xi), \qquad \xi = \frac{\mathbf{x}}{|\mathbf{x}|};
$$

$$
\|Y_j(q, \cdot)\|_S \leqq c_1(j+1)^{k-2}\varepsilon^{-c};
$$

we can obtain for the harmonic polynomial

$$h_n(\mathbf{x}) := \sum_{j=0}^{n} \left(\frac{|\mathbf{x}|}{2R}\right)^j Y_j(q, \xi),$$

the following estimate:

$$\|q - h_n\|_K \leqq c_1 \sum_{j=n+1}^{\infty} 2^{-j} j^{k-2} \varepsilon^{-c} \leqq c_2 2^{-n} n^{k-2} \varepsilon^{-c}. \tag{6.2}$$

It is easy to see that the desired estimate (2.5) follows from the inequalities (6.1) and (6.2) if $\varepsilon := q^n$, where $1 - q$ is positive and small enough.

Acknowledgment. This paper was completed while the author was visiting the Fachbereich Mathematik, Technische Universität Berlin, and the Mathematisches Institut, Justus-Liebig-Universität Giessen. The author wishes to thank the members of these universities for the pleasant mathematical atmosphere they offered him.

POSITIVE HERMITE INTERPOLATION BY QUADRATIC SPLINES*

AATOS LAHTINEN†

Abstract. Necessary and sufficient conditions are derived under which a quadratic spline preserves the positivity of a set of function values in the Hermite interpolation. As a corollary it is seen that positive interpolation is always possible over a set of nonnegative function values when a quadratic spline with suitable parameters is used.

Key words. quadratic spline, positive interpolation, parameters

AMS(MOS) subject classifications. 41A15, 41A29, 65D05, 65D07

1. Introduction. In the problem of positive interpolation a set of points where the measured or otherwise obtained ordinates are nonnegative is given, and the existence of a nonnegative interpolating function is considered. Such a function is needed in many practical situations, for instance in growth studies.

Spline functions offer good possibilities for the treatment of this problem. A simple linear spline as in [1] naturally gives a solution. However, it is usually desirable that the interpolating function has at least C^1-regularity. Under this condition the existence of positive interpolants has been studied for several types of splines (cf. [2], [4]–[6], [8], [9]). Especially [5] presents necessary and sufficient conditions under which the solution of the problem of positive interpolation is given by quadratic splines.

In some growth studies, the spline functions representing the boundary at different time levels must have a certain shape (cf. [3]). In these cases the derivatives at interpolating points also have to be taken into account. This leads to the problem of positive Hermite interpolation which is the subject of the present paper.

In §2 the problem is stated and a solution to the Hermite interpolation problem is given by using the quadratic splines of [7]. This solution has at most one additional breakpoint in each data interval. Section 3 considers positivity locally, that is, in a data interval. The situation is treated in terms of the endpoint derivatives m_i and m_{i+1} of the quadratic spline with a fixed additional breakpoint. Necessary and sufficient conditions to the local positivity are described as a region M_i in the $m_i m_{i+1}$-plane. The effect of the position of an additional breakpoint to the local positivity is considered in §4. Here the region M_i is taken as a function of the additional breakpoint. In §5 the main result, Theorem 1, gathers the local results together. Necessary and sufficient conditions are given for positive Hermite interpolation by quadratic splines in the whole interval. Finally, §6 establishes as a corollary that for nonnegative data a solution to the problem of positive interpolation by quadratic splines always exists.

2. The problem. We define at first the Hermite interpolation problem for quadratic splines as follows.

Let $[a, b]$ be an interval containing a mesh $(x_i)_1^n$ such that $a = x_1 < x_2 < \cdots < x_n = b$ and let $(y_i)_1^n$ and $(m_i)_1^n$ be real numbers. Find a quadratic spline s with the fewest number of breakpoints such that

$$s(x_i) = y_i, \qquad s'(x_i) = m_i, \quad i = 1, \ldots, n.$$

*Received by the editors June 10, 1991; accepted for publication (in revised form) May 5, 1992.

†Department of Mathematics, University of Helsinki, Hallituskatu 15, SF-00100 Helsinki, Finland.

Schumaker has in [7] given a solution to this problem. The construction is done separately to each subinterval $[x_i, x_{i+1}]$, $i = 1, \dots, n$.

If $m_i + m_{i+1} = 2\delta_i$, the solution s on $[x_i, x_{i+1}]$ is a parabola

$$s(x) = y_i + m_i(x - x_i) + \frac{m_{i+1} - m_i}{2\Delta x_i}(x - x_i)^2. \tag{2.1}$$

Here we have used the notation $\Delta x_i = x_{i+1} - x_i$, $\Delta y_i = y_{i+1} - y_i$, $\delta_i = \Delta y_i / \Delta x_i$.

If $m_i + m_{i+1} \neq 2\delta_i$, then s is on $[x_i, x_{i+1}]$ a quadratic spline with one breakpoint ξ_i, which can be freely chosen in the interval $]x_i, x_{i+1}[$.

$$s(x) = \begin{cases} y_i + m_i(x - x_i) + \frac{\mu_i - m_i}{2t_i \Delta x_i}(x - x_i)^2, & x_i \le x < \xi_i, \\ d_i + \mu_i(x - \xi_i) + \frac{m_{i+1} - \mu_i}{2(1 - t_i)\Delta x_i}(x - \xi_i)^2, & \xi_i \le x \le x_{i+1}, \end{cases} \tag{2.2}$$

where

$$t_i = \frac{\xi_i - x_i}{\Delta x_i}, \qquad \mu_i = 2\delta_i - t_i m_i - (1 - t_i) m_{i+1}, \tag{2.3}$$

$$d_i = (1 - t_i) y_i + t_i y_{i+1} + \tfrac{1}{2} t_i (1 - t_i) \Delta x_i (m_i - m_{i+1}). \tag{2.4}$$

Notice that $0 < t_i < 1, d_i = s(\xi_i)$ and $\mu_i = s'(\xi_i)$. The values d_i and μ_i are used in later considerations. They are a consequence of $s \in C^1[x_i, x_{i+1}]$ and of the interpolation conditions. For a fixed ξ_i, they are unique.

The quadratic spline s defined on an interval $[x_j, x_k] \subset [a, b]$ by (2.1) and (2.2) for $i = j, \dots, k - 1$ is called in the continuation *a solution of the Hermite interpolation problem*, or for short *a solution of the* HIP, on $[x_j, x_k]$ with data $(y_i)_j^k$ and $(m_i)_j^k$. This solution is characterized by having at most one breakpoint between interpolating points. The solution is, however, by no means unique because the additional breakpoints ξ_i remain as parameters expressed in terms of t_i.

Positive Hermite interpolation is a special case of Hermite interpolation. The formulation of this problem is as follows.

Let $[a, b]$ be an interval containing a mesh $(x_i)_1^n$ such that $a = x_1 < x_2 < \dots < x_n = b$, and let $(y_i)_1^n, y_i \ge 0, i = 1, \dots, n$ and $(m_i)_1^n$ be real numbers. Find a solution of the Hermite interpolation problem with data $(y_i)_1^n$ and $(m_i)_1^n$, which is nonnegative on $[a, b]$.

Our intention is to derive necessary and sufficient conditions for the existence of a positive Hermite interpolant and to examine the role of the breakpoints ξ_i in the process. As a corollary we will get results concerning positive interpolation.

Notice that the word "positive" is used as a synonym of nonnegative in this terminology.

3. Positivity on subintervals with fixed breakpoints. As a first step the positivity of the Hermite interpolation is considered on a subinterval $[x_i, x_{i+1}]$. Let there be given on $[x_i, x_{i+1}]$ values $y_i \ge 0, y_{i+1} \ge 0, m_i, m_{i+1}$ and a position $\xi_i \in]x_i, x_{i+1}[$ for an additional breakpoint if needed. The point ξ_i determines the value of parameter t_i via (2.3). Let then s be the solution of HIP on $[x_i, x_{i+1}]$ with this data so that the possible additional breakpoint is at ξ_i. The positivity of s is examined in different alternatives.

If $m_i + m_{i+1} = 2\delta_i$, the spline s is on $[x_i, x_{i+1}]$ a parabola defined in (2.1). Schmidt and Hess have shown in [5] that the positivity of such a spline s depends on the quantities

$$v_i = -\frac{2}{\Delta x_i}(y_i + \sqrt{y_i y_{i+1}}), \qquad i = 1, \ldots, n-1 \tag{3.1}$$

in the following way.

PROPOSITION 1. *If $m_i + m_{i+1} = 2\delta_i$, the solution s of the Hermite interpolation problem is positive on $[x_i, x_{i+1}]$ if and only if $m_i \geq v_i$.*

Thus we will concentrate for a while on the case where

$$(m_i, m_{i+1}) \notin L_i = \{(m_i, m_{i+1}) \mid m_i + m_{i+1} = 2\delta_i\}. \tag{3.2}$$

This means that the solution s of the HIP on $[x_i, x_{i+1}]$ is a quadratic spline with an additional breakpoint at a given point ξ_i as defined in (2.2).

A necessary condition for positivity is that

$$d_i = s(\xi_i) \geq 0. \tag{3.3}$$

This implies by (2.4) that positive Hermite interpolation with a fixed breakpoint is not possible for all data values. Therefore, we consider the relation of the derivative values m_i, m_{i+1} to other data values in a positive Hermite interpolant. In this setting there are given values $x_i, x_{i+1}, y_i, y_{i+1}, \xi_i$ and we will examine how these values determine a set M_i in the $m_i m_{i+1}$-plane so that every $(m_i, m_{i+1}) \in M_i$ gives a positive solution of HIP on $[x_i, x_{i+1}]$. The necessary condition for a pair (m_i, m_{i+1}) to produce a positive solution to the HIP is by (3.3),

$$(m_i, m_{i+1}) \in A_d = \{(m_i, m_{i+1}) \mid d_i \geq 0\}. \tag{3.4}$$

The positivity of s, a solution of the HIP with given data and the breakpoint at ξ_i is at first considered separately on the intervals $[x_i, \xi_i]$ and $[\xi_i, x_{i+1}]$, starting with the former. We have to treat several different cases. Notice that by the restriction (3.2) the points of the line L_i are excluded from these considerations.

Case 1. $(m_i, m_{i+1}) \in A_1 = \{(m_i, m_{i+1}) \in A_d \mid m_i = \mu_i\}$.

By (2.2) $s/[x_i, \xi_i]$ is of first degree and thus positive.

Case 2. $(m_i, m_{i+1}) \in A_2 = \{(m_i, m_{i+1}) \in A_d \mid m_i > \mu_i\}$.

When $m_i \neq \mu_i$, the restriction $s/[x_i, \xi_i]$ is a parabola given by (2.2). Its vertex is

$$(x^{(1)}, s(x^{(1)})) = \left(x_i - \frac{m_i}{\mu_i - m_i}\Delta x_i t_i,\ y_i - \frac{1}{2}\frac{m_i^2}{\mu_i - m_i}\Delta x_i t_i\right). \tag{3.5}$$

If $m_i > \mu_i$, then $s(x^{(1)}) \geq 0$ whence $s/[x_i, \xi_i] \geq 0$.

Case 3. $(m_i, m_{i+1}) \in A_3 = \{(m_i, m_{i+1}) \in A_d \mid m_i < \mu_i \ \wedge (m_i \geq 0 \vee \mu_i \leq 0)\}$.

In this case the vertex does not lie in the interval $]x_i, \xi_i[$. Therefore, $s/[x_i, \xi_i]$ is monotone and thus positive.

Case 4. $(m_i, m_{i+1}) \in A_d \setminus (A_1 \cup A_2 \cup A_3)$.

It is easy to see that $A_d \setminus (A_1 \cup A_2 \cup A_3) = \{(m_i, m_{i+1}) \in A_d \mid m_i < 0 \ \wedge \ \mu_i > 0\}$. This case is nonempty only when $y_i > 0$. In fact, if $y_i = 0$, then $s/[x_i, \xi_i]$ can be positive only if $m_i \geq 0$, which does not happen in Case 4.

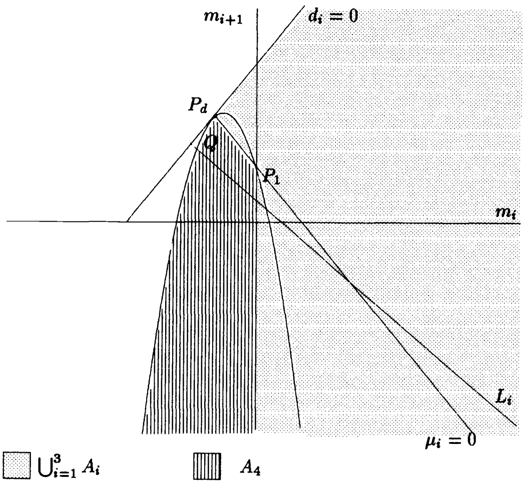

FIG. 1. *The sets* $\cup_{j=1}^3 A_j$ *and* A_4 *in a case where* $y_i y_{i+1} > 0$.

Now the minimum of the spline s is at the point $x^{(1)} \in \,]x_i, \xi_i[$. This means that $s/[x_i, \xi_i] \geq 0$ if and only if $s(x^{(1)}) \geq 0$. By (2.3) and (3.5) this condition is equivalent to

$$t_i \Delta x_i m_i^2 + 2y_i(1+t_i)m_i + 2y_i(1-t_i)m_{i+1} - 4y_i\delta_i \leq 0. \tag{3.6}$$

The closed region determined in the $m_i m_{i+1}$-plane by (3.6) is the inside of a parabola $m_{i+1} = p_i(m_i)$ opening downward. Here

$$p_i(m_i) = -\frac{t_i \Delta x_i}{2(1-t_i)y_i} m_i^2 - \frac{1+t_i}{1-t_i} m_i + \frac{2\delta_i}{1-t_i}. \tag{3.7}$$

The lines $d_i = 0$ and $m_i = \mu_i$ are both tangents to this parabola with points of tangency

$$P_d = (b_1, b_2) = \left(-\frac{2y_i}{t_i \Delta x_i}, \frac{2y_{i+1}}{(1-t_i)\Delta x_i}\right) \quad \text{and} \quad P_1 = \left(0, \frac{2\delta_i}{1-t_i}\right). \tag{3.8}$$

Furthermore, the parabola intersects the line $\mu_i = 0$ at the points P_d and P_1 and the line L_i at the points

$$Q = (v_i, w_i) \quad \text{and} \quad Q' = \left(-\frac{2}{\Delta x_i}(y_i - \sqrt{y_i y_{i+1}}), \frac{2}{\Delta x_i}(y_{i+1} - \sqrt{y_i y_{i+1}})\right), \tag{3.9}$$

where v_i is as (3.1) and

$$w_i = 2\delta_i - v_i = \frac{2}{\Delta x_i}(y_{i+1} + \sqrt{y_i y_{i+1}}). \tag{3.10}$$

Note that the points Q and Q' do not depend on t_i.

Thus $s/[x_i, \xi_i] \geq 0$ in Case 4 if and only if

$$(m_i, m_{i+1}) \in A_4 = \{(m_i, m_{i+1}) \in A_d \mid m_i < 0 \ \wedge \ \mu_i > 0 \ \wedge \ (3.6) \text{ is valid}\}. \tag{3.11}$$

If $y_i > 0$, the set A_4 is bounded by the parabola $m_{i+1} = p_i(m_i)$ up to the point P_d, by the line segment $P_d P_1$ and by the m_{i+1}-axis from the point P_1 downward (see Fig. 1). If $y_i = 0$, the set A_4 is empty.

The situation on the interval $[x_i, \xi_i]$ can be summed up as follows. If (3.2) is valid,

$$s/[x_i, \xi_i] \geq 0 \iff (m_i, m_{i+1}) \in \cup_{j=1}^{4} A_j \setminus L_i. \tag{3.12}$$

The part of the $m_i m_{i+1}$-plane that gives a positive solution to HIP on $[x_i, \xi_i]$ is the half plane $d_i \geq 0$ minus the line L_i and minus a wedge with its apex at P_d. The left side of the wedge is the line $d_i = 0$, and the right side a monotone part of the parabola $m_{i+1} = p_i(m_i)$ in case $y_i > 0$ (see Fig. 1). If $y_i = 0$, the right side of the wedge is the m_{i+1}-axis. The examination of the interval $[x_i, \xi_i]$ is now complete.

The situation on the interval $[\xi_i, x_{i+1}]$ can be treated quite in the same way as on $[x_i, \xi_i]$. Therefore, the discussion is shortened into two cases.

Case 5. $(m_i, m_{i+1}) \in A_5 = \{(m_i, m_{i+1}) \in A_d \mid m_{i+1} \leq 0 \ \vee \ \mu_i \geq 0\}$.

Analogously with Cases 1–3 it is seen that in Case 5 always $s/[\xi_i, x_{i+1}] \geq 0$.

Case 6. $(m_i, m_{i+1}) \in A_d \setminus A_5 = \{(m_i, m_{i+1}) \in A_d \mid m_{i+1} > 0 \ \wedge \ \mu_i < 0\}$.

This case is nonempty only when $y_{i+1} > 0$. In fact, if $y_{i+1} = 0$, then $s/[\xi_i, x_{i+1}]$ can be positive only if $m_{i+1} \leq 0$, which does not happen in Case 6.

In this case the minimum of the spline s is at a point $x^{(2)} \in]\xi_i, x_{i+1}[$. Thus $s/[\xi_i, x_{i+1}] \geq 0$ if and only if $s(x^{(2)}) \geq 0$. This is equivalent to

$$(1 - t_i)\Delta x_i m_{i+1}^2 - 2(2 - t_i)y_{i+1}m_{i+1} - 2t_i y_{i+1} m_i + 4y_{i+1}\delta_i \leq 0. \tag{3.13}$$

The closed region determined in the $m_i m_{i+1}$-plane by (3.13) is the inside of a parabola $m_i = q_i(m_{i+1})$ opening to the right. Here

$$q_i(m_{i+1}) = \frac{(1 - t_i)\Delta x_i}{2t_i y_{i+1}} m_{i+1}^2 - \frac{2 - t_i}{t_i} m_{i+1} + \frac{2\delta_i}{t_i}. \tag{3.14}$$

The lines $d_i = 0$ and $m_{i+1} = \mu_i$ are both tangents to this parabola with points of tangency P_d and, respectively,

$$P_2 = \left(\frac{2\delta_i}{t_i}, 0\right). \tag{3.15}$$

Furthermore, the parabola intersects the line $\mu_i = 0$ at the points P_d and P_2 and the line L_i at the same points Q and Q' as the parabola $m_{i+1} = p_i(m_i)$.

Thus $s/[\xi_i, x_{i+1}] \geq 0$ in Case 6 if and only if

$$(m_i, m_{i+1}) \in A_6 = \{(m_i, m_{i+1}) \in A_d \mid m_{i+1} > 0 \ \wedge \ \mu_i < 0 \ \wedge \ (3.13) \text{ is valid}\}. \tag{3.16}$$

If $y_{i+1} > 0$, the set A_6 is bounded by the parabola $m_i = q_i(m_{i+1})$ from the point P_d to the right, by the line segment $P_d P_2$ and by the m_i-axis from the point P_2 to the right. If $y_{i+1} = 0$, the set A_6 is empty.

The situation on the interval $[\xi_i, x_{i+1}]$ can be summed up as follows. If (3.2) is valid,

$$s/[\xi_i, x_{i+1}] \geq 0 \iff (m_i, m_{i+1}) \in \cup_{j=5}^{6} A_j \setminus L_i. \tag{3.17}$$

The part of the $m_i m_{i+1}$-plane that gives a positive solution to HIP on $[\xi_i, x_{i+1}]$ is the half plane $d_i \geq 0$ minus the line L_i and minus a wedge with its apex at P_d. The upper side of the wedge is the line $d_i = 0$ and the lower side a monotone part of the

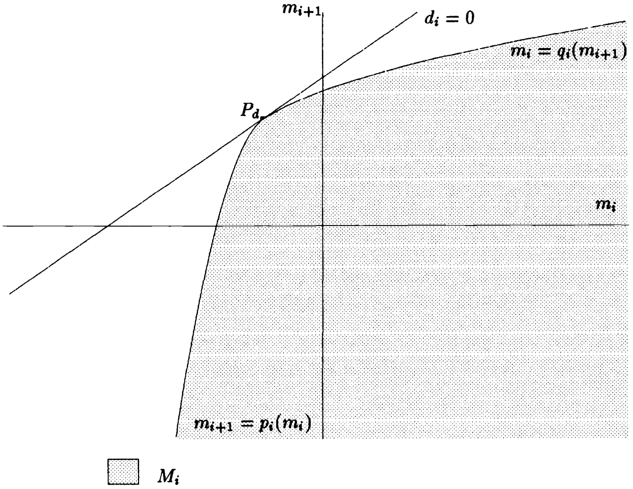

FIG. 2. *The set M_i in a case where $y_i y_{i+1} > 0$.*

parabola $m_i = q_i(m_{i+1})$ in case $y_{i+1} > 0$. If $y_{i+1} = 0$, the lower side of the wedge is the m_i-axis. The examination of the interval $[\xi_i, x_{i+1}]$ is complete.

The results of this paragraph can now be united. Denote

$$M_i = (\cup_{j=1}^{4} A_j) \cap (\cup_{j=5}^{6} A_j). \tag{3.18}$$

Note that the line L_i is no longer excluded.

PROPOSITION 2. *Let s be a solution of the Hermite interpolation problem on $[x_i, x_{i+1}]$ with data $y_i \geq 0, y_{i+1} \geq 0, m_i, m_{i+1}$, and let the possible additional breakpoint be at a point $\xi_i \in]x_i, x_{i+1}[$. Then $s \geq 0$ on $[x_i, x_{i+1}]$ if and only if*

$$(m_i, m_{i+1}) \in M_i.$$

Proof. If $(m_i, m_{i+1}) \notin L_i$, then the statement follows from (3.12), (3.17) and from the definition of M_i. If (m_i, m_{i+1}) lies in the line L_i, then by Proposition 1 $s \geq 0$ on $[x_i, x_{i+1}]$ if and only if $m_i \geq v_i$. On the other hand by the construction of M_i the set $\{(m_i, m_{i+1}) \in L_i \mid m_i \geq v_i\} \subset M_i$, the point $(v_i, 2\delta_i - v_i) = (v_i, w_i)$ being on the boundary of M_i. This proves the proposition. □

For later use we need a more detailed description of M_i (see Fig. 2). Firstly, suppose that $y_i y_{i+1} > 0$. Then we get from previous considerations that $(m_i, m_{i+1}) \in M_i$ if and only if

$$m_{i+1} \leq \begin{cases} p_i(m_i) & \text{if } m_i \leq b_1, \\ q_i^{-1}(m_i) & \text{if } m_i > b_1, \end{cases} \tag{3.19}$$

or equivalently

$$m_i \geq \begin{cases} p_i^{-1}(m_{i+1}) & \text{if } m_{i+1} \leq b_2, \\ q_i(m_{i+1}) & \text{if } m_{i+1} > b_2. \end{cases} \tag{3.20}$$

Here $(b_1, b_2) = P_d$ from (3.8), and p_i, q_i are determined by (3.7) and (3.14). Because p_i is monotone when $m_i \leq b_1$, it has an inverse function p_i^{-1} there. Similarly, q_i is monotone when $m_{i+1} \geq b_2$ and has an inverse function q_i^{-1}.

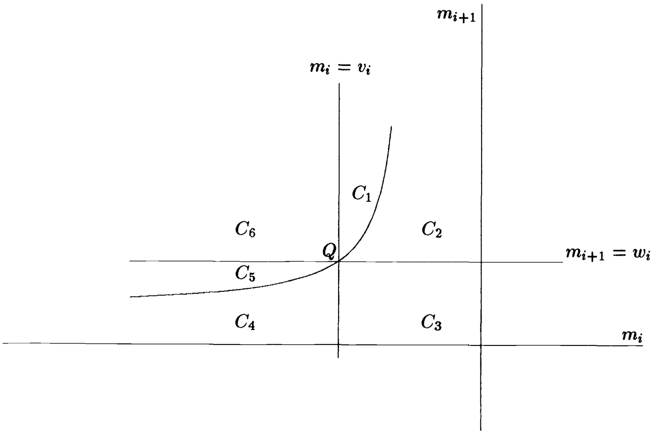

FIG. 3. *The partition of the $m_i m_{i+1}$-plane in the proof of Proposition* 3.

If $y_i = 0, y_{i+1} > 0$, then $(m_i, m_{i+1}) \in M_i$ if and only if (3.20) is valid with $p_i^{-1} = 0$. If $y_i > 0, y_{i+1} = 0$, then $(m_i, m_{i+1}) \in M_i$ if and only if (3.19) is valid with $q_i^{-1} = 0$. Finally, if $y_i = 0, y_{i+1} = 0$, then $(m_i, m_{i+1}) \in M_i$ if and only if

(3.21) $$m_i \geq 0 \ \wedge \ m_{i+1} \leq 0.$$

We notice that M_i is always closed, convex, and nonempty.

4. Positivity on subintervals. What we know up to now is exactly when the solution of the HIP is positive on $[x_i, x_{i+1}]$ if the place of the possible additional breakpoint ξ_i is fixed. In the problem of positive Hermite interpolation, however, the place of ξ_i is a free parameter. Therefore, we will next examine the dependence of the set $M_i = M_i(t_i)$ on the breakpoint ξ_i via t_i defined in (2.3).

PROPOSITION 3. *Let there be given on an interval $[x_i, x_{i+1}]$ data $y_i \geq 0, y_{i+1} \geq 0, m_i$ and m_{i+1}. There exists a positive solution of the Hermite interpolation problem on $[x_i, x_{i+1}]$ if and only if in the case where $y_i y_{i+1} > 0$,*

$$m_i > v_i \vee m_{i+1} < w_i \vee (m_i, m_{i+1}) = (v_i, w_i);$$

in the case where $y_i = 0, y_{i+1} > 0$,

$$m_i \geq 0;$$

in the case where $y_i > 0, y_{i+1} = 0$,

$$m_{i+1} \leq 0;$$

and in the case where $y_i = y_{i+1} = 0$,

$$m_i \geq 0 \ \wedge \ m_{i+1} \leq 0.$$

Proof. Firstly, suppose that $y_i y_{i+1} > 0$. We divide the $m_i m_{i+1}$-plane into four quadrants by the lines $m_i = v_i$ and $m_{i+1} = w_i$, which intersect at the point Q defined in (3.9). Furthermore, we divide the first and third quadrant by the branch of the hyperbola

(4.1) $$\Delta x_i m_i m_{i+1} - 2y_{i+1} m_i + 2y_i m_{i+1} = 0,$$

passing through the point Q. This branch is the track of the point P_d as a function of the parameter $t_i, 0 < t_i < 1$ (see Fig. 3).

We choose a point $P_o = (m_i^o, m_{i+1}^o)$ in each part of the $m_i m_{i+1}$-plane in a clockwise order and examine whether there exist values $t_i \in]0,1[$ so that $P_o \in M_i(t_i)$.

Case 1. $P_o \in C_1 = \{(m_i, m_{i+1}) \mid m_i > v_i \ \wedge \ m_{i+1} > (2y_{i+1}m_i)/(\Delta x_i m_i + 2y_i)\}$.

The boundary section $\partial M_i(t_i) \cap C_1$ is a monotone part of the parabola $m_{i+1} = p_i(m_i)$ (compare Figs. 1, 2, and 3). By (3.7) a point $P_o \in C_1$ belongs to $\partial M_i(t_i)$ if $t_i = t_i^{(1)}$, where

$$t_i^{(1)} = \frac{2y_i(2\delta_i - m_i^o - m_{i+1}^o)}{\Delta x_i m_i^{o^2} + 2y_i m_i^o - 2y_i m_{i+1}^o}, \tag{4.2}$$

supposing that $t_i^{(1)} \in]0,1[$. For the verification of this condition we first notice that on C_1 the numerator of $t_i^{(1)}$ is negative. For the denominator of $t_i^{(1)}$ we get a suitable upper bound,

$$\Delta x_i m_i^{o^2} + 2y_i m_i^o - 2y_i m_{i+1}^o < \Delta x_i v_i^2 + 2y_i v_i - 2y_i w_i = 0.$$

Thus $t_i^{(1)}$ is positive. Furthermore, it can be seen that on C_1,

$$\Delta x_i m_i^2 + 4y_i m_i - 4y_i \delta_i < \Delta x_i v_i^2 + 4y_i v_i - 4y_i \delta_i = 0,$$

and that the negativity of the left-hand side is equivalent to the inequality $t_i^{(1)} < 1$. It has been shown that $t_i^{(1)} \in]0,1[$.

The only boundary section of $M_i(t_i) \cap C_1$ that depends on t_i is the part of the parabola $m_{i+1} = p_i(m_i)$. From (3.7) we see that $p_i(m_i)$ is as a function of t_i monotonically increasing. This means that $t_i < u_i$ implies $M_i(t_i) \cap C_1 \subset M_i(u_i) \cap C_1$. So the point $P_o \in M_i(t_i) \cap C_1$ for every $t_i \in [t_i^{(1)}, 1[$. Thus a given point $P_o \in C_1$ lies in $M_i(t_i)$ if and only if the solution s of the HIP has an additional breakpoint ξ_i and

$$x_i + t_i^{(1)} \Delta x_i \le \xi_i < x_{i+1}. \tag{4.3}$$

Case 2. $P_o \in C_2 = \{(m_i, m_{i+1}) \mid m_{i+1} > w_i \ \wedge \ m_i \ge (2y_i m_{i+1})/(2y_{i+1} - \Delta x_i m_{i+1})\}$.

The boundary section $\partial M_i(t_i) \cap C_2$ is a monotone part of the parabola $m_i = q_i(m_{i+1})$ (compare Figs. 2 and 3). By (3.14) a point $P_o \in C_2$ belongs to $\partial M_i(t_i)$ if $t_i = t_i^{(2)}$, where

$$t_i^{(2)} = 1 + \frac{2y_{i+1}(2\delta_i - m_i^o - m_{i+1}^o)}{\Delta x_i m_{i+1}^{o^2} - 2y_{i+1} m_{i+1}^o + 2y_{i+1} m_i^o}. \tag{4.4}$$

As in Case 1 we see that $t_i^{(2)} \in]0,1[$. The only boundary section of $M_i(t_i) \cap C_2$ that depends on t_i is the part of the parabola $m_i = q_i(m_{i+1})$. As in Case 1 we see that $q_i(m_{i+1})$ is a monotone function of t_i, now decreasing. This means that $t_i < u_i$ implies $M_i(t_i) \cap C_2 \subset M_i(u_i) \cap C_2$. So the point $P_o \in M_i(t_i) \cap C_2$ for every $t_i \in [t_i^{(2)}, 1[$. Thus a given point $P_o \in C_2$ lies in $M_i(t_i)$ if and only if the solution s of the HIP has an additional breakpoint ξ_i and

$$x_i + t_i^{(2)} \Delta x_i \le \xi_i < x_{i+1}. \tag{4.5}$$

Case 3. $P_o \in C_3 = \{(m_i, m_{i+1}) \mid m_i \geq v_i \ \wedge \ m_{i+1} \leq w_i\}$.

The boundary $\partial M_i(t_i)$ is given by a strictly increasing concave function and the corner point of C_3, $Q = (v_i, w_i) \in \partial M_i(t_i)$ for every $t_i \in]0,1[$. This implies that $C_3 \subset M_i(t_i)$ for every $t_i \in]0,1[$. Thus a given point $P_o \in C_3$ lies in $M_i(t_i)$ for any additional breakpoint ξ_i,

$$x_i < \xi_i < x_{i+1}, \tag{4.6}$$

the solution s of the HIP has, and also if s has no additional breakpoint, i.e., if $m_i + m_{i+1} = 2\delta_i, m_i \geq v_i$.

Case 4. $P_o \in C_4 = \{(m_i, m_{i+1}) \mid m_i < v_i \ \wedge \ m_{i+1} \leq (2y_{i+1}m_i)/(\Delta x_i m_i + 2y_i)\}$.

As in Case 1 the boundary section $\partial M_i(t_i) \cap C_4$ is a monotone part of the parabola $m_{i+1} = p_i(m_i)$. Now $t_i > u_i$ implies $M_i(t_i) \cap C_4 \subset M_i(u_i) \cap C_4$. This means that the point $P_o \in M_i(t_i) \cap C_4$ for every $t_i \in]0, t_i^{(1)}]$. Thus a given point $P_o \in C_4$ lies in $M_i(t_i)$ if and only if the solution s of the HIP has an additional breakpoint ξ_i and

$$x_i < \xi_i \leq x_i + t_i^{(1)} \Delta x_i. \tag{4.7}$$

Case 5. $P_o \in C_5 = \{(m_i, m_{i+1}) \mid m_{i+1} < w_i \ \wedge \ m_i < (2y_i m_{i+1})/(2y_{i+1} - \Delta x_i m_{i+1})\}$.

As in Case 2 the boundary section $\partial M_i(t_i) \cap C_5$ is a monotone part of the parabola $m_i = q_i(m_{i+1})$. Now $t_i > u_i$ implies $M_i(t_i) \cap C_5 \subset M_i(u_i) \cap C_5$. This means that the point $P_o \in M_i(t_i) \cap C_5$ for every $t_i \in]0, t_i^{(2)}]$. Thus a given point $P_o \in C_5$ lies in $M_i(t_i)$ if and only if the solution s of the HIP has an additional breakpoint ξ_i and

$$x_i < \xi_i \leq x_i + t_i^{(2)} \Delta x_i. \tag{4.8}$$

Case 6. $P_o \in C_6 = \mathbf{R}^2 \setminus \cup_{j=1}^5 C_j$.

It is easy to see that in the case, where $y_i y_{i+1} > 0$,

$$C_6 = \{(m_i, m_{i+1}) \mid m_i \leq v_i \ \wedge \ m_{i+1} \geq w_i \ \wedge \ (m_i, m_{i+1}) \neq (v_i, w_i)\}.$$

By the arguments given in Case 3 it must be $M_i(t_i) \cap C_6 = \emptyset$ for every $t_i \in]0,1[$. Thus no $P_o \in C_6$ can give a positive Hermite interpolant.

The case $y_i y_{i+1} > 0$ is now completely examined. It has been shown that for any given data the solution of the HIP is positive in Cases 1, 2, 4, and 5 with a suitable choice of additional breakpoint and in Case 3 independent of the breakpoint. This proves the proposition in this case.

The treatment is valid with obvious modifications in cases where $y_i = 0$ or $y_{i+1} = 0$. The proposition is proved. □

From the proof we get also exact conditions for the choice of additional breakpoints. We state separately the case where the positivity is independent of the choice of breakpoint.

PROPOSITION 4. *Let there be given on an interval* $[x_i, x_{i+1}]$ *data* $y_i \geq 0, y_{i+1} \geq 0, m_i$ *and* m_{i+1}. *All solutions of the Hermite interpolation problem are positive on* $[x_i, x_{i+1}]$ *if and only if*

$$m_i \geq v_i \ \wedge \ m_{i+1} \leq w_i.$$

5. Positive Hermite interpolation. Now it can be stated when a quadratic spline defined by (2.1) and (2.2) will produce positive Hermite interpolation either independent of the choice of additional breakpoints or with a suitable choice of them.

THEOREM 1. *Let there be given on an interval $[a,b]$ a mesh $(x_i)_1^n$, $a = x_1 < x_2 < \cdots < x_n = b$ and real numbers $(y_i)_1^n, y_i \geq 0, i = 1, \ldots, n$ and $(m_i)_1^n$. There exists a quadratic spline as in (2.1) and (2.2) giving a positive solution of the Hermite interpolation problem on $[a,b]$ with this data if and only if at every point x_i, where $y_i = 0$,*

$$m_1 \geq 0 \; if \; i = 1, \quad m_i = 0 \; if \; i = 2, \ldots, n-1, \quad m_n \leq 0 \; if \; i = n,$$

and in every interval $[x_i, x_{i+1}]$, where $y_i y_{i+1} > 0$,

$$m_i > v_i \;\vee\; m_{i+1} < w_i \;\vee\; (m_i, m_{i+1}) = (v_i, w_i).$$

This result follows directly from Proposition 3. The conditions of Theorem 1 can also be verified by examining the validity of the following restrictions:

For $i = 1$ $\quad m_1 \geq 0$ $\quad$ if $y_1 = 0$;
For $i = 2, \ldots, n-1$ $\quad m_i = 0$ $\quad$ if $y_i = 0$ else
$m_i \leq w_{i-1}$ $\quad$ if $m_{i-1} = v_{i-1}$ else
$m_i < w_{i-1}$ $\quad$ if $m_{i-1} < v_{i-1}$;
For $i = n$ $\quad m_n \leq w_{n-1}$ $\quad$ if $m_{n-1} = v_{n-1} \;\vee\; y_n = 0$ else
$m_n < w_{n-1}$ $\quad$ if $m_{n-1} < v_{n-1}$.

Similarly we get the following result from Proposition 4.

THEOREM 2. *Let there be given on an interval $[a,b]$, a mesh $(x_i)_1^n$, $a = x_1 < x_2 < \cdots < x_n = b$, and real numbers $(y_i)_1^n, y_i \geq 0, i = 1, \ldots, n$ and $(m_i)_1^n$. Every quadratic spline as in (2.1) and (2.2), which is a solution of the Hermite interpolation problem with this data, is nonnegative on $[a,b]$ if and only if*

$$v_1 \leq m_1, \quad v_i \leq m_i \leq w_{i-1}, \quad i = 2, \ldots, n-1, \quad m_n \leq w_{n-1}.$$

In a situation where the conditions of Theorem 1 are valid but the conditions of Theorem 2 are not, some but not all additional breakpoints produce a positive Hermite interpolant. The proof of Proposition 3 gives necessary and sufficient conditions (formulas (4.2)–(4.8)) for the choice of the additional breakpoints.

The results imply that the problem of positive Hermite interpolation is not always solvable by using quadratic splines as in (2.1) and (2.2). In fact, if at an inner point x_i where $y_i = 0$ we have $m_i \neq 0$, then no Hermite interpolant of any kind can be positive in the neighbourhood of x_i.

On the other hand, by allowing in the quadratic spline more than one breakpoint between interpolating points we can in all other cases obtain a solution to the problem of positive Hermite interpolation. It is sufficient to consider the case where on an interval $[x_i, x_{i+1}]$ we have $y_i y_{i+1} > 0$, but the conditions of Theorem 1 are not fulfilled. In this situation we add a new interpolating point z_i to the interval $]x_i, x_{i+1}[$ and set both the function value and the derivative value to be zero at z_i. Now Theorem 1 shows that for this augmented data set we get a positive Hermite interpolant, which of course is also a solution to the original problem. This gives us the following modification of Theorem 1.

COROLLARY 1. *Let there be given on an interval $[a,b]$ a mesh $(x_i)_1^n$, $a = x_1 < x_2 < \cdots < x_n = b$ and real numbers $(y_i)_1^n, y_i \geq 0, i = 1, \ldots, n$ and $(m_i)_1^n$. There exists a nonnegative quadratic spline s on $[a,b]$ with $s(x_i) = y_i$ and $s'(x_i) = m_i$, $i = 1, \ldots, n$ if and only if at every point x_i where $y_i = 0$,*

$$m_1 \geq 0 \quad if\, i = 1; \quad m_i = 0 \quad if\, i = 2, \ldots, n-1; \quad m_n \leq 0 \quad if\, i = n.$$

6. Positive interpolation. Finally we would like to remark that because the set M_i is never empty, we can see from the theorems that the quadratic splines we use always give a solution to the problem of positive interpolation.

COROLLARY 2. *Let there be given on an interval* $[a,b]$ *a mesh* $(x_i)_1^n$, $a = x_1 < x_2 < \cdots < x_n = b$ *and real numbers* $(y_i)_1^n, y_i \geq 0, i = 1, \ldots, n$. *There exists a quadratic spline as in* (2.1) *and* (2.2) *that is a positive interpolant to this data.*

In fact, by choosing $m_i = 0, i = 1, \ldots, n$, for instance, we get for every set of additional breakpoints a positive Hermite interpolant, which is of course also a positive interpolant.

SUBDIVISION SCHEMES DETERMINED BY COEFFICIENTS OF A HURWITZ POLYNOMIAL*

I. YAD-SHALOM†

Abstract. The functional equation

$$E(t) = \sum_{i=0}^{k} a_i E(2t-i), \qquad \sum_{i=-\infty}^{\infty} E(t-i) = 1$$

is known to have a unique compactly supported continuous solution, given that $\{a_i\}_{i=0}^{k}$ is a positive sequence satisfying $\Sigma_i a_{2i} = \Sigma_i a_{2i-1} = 1$. This solution, $E(t)$, is also obtained by a subdivision algorithm. This paper discusses the particular case where $\Sigma_{i=0}^{k} a_i z^i$ is a Hurwitz polynomial, i.e., all zeros are in the left half plane.

The problem of Lagrange interpolation from the space $\{E(\cdot - i)\}$, $i \in Z$, was recently analyzed by Goodman and Micchelli [*SIAM J. Math. Anal.*, 23 (1992), pp. 766–784]. In particular, they showed that the problem is solvable under a condition similar to the B-spline case.

Here an alternative analysis is introduced, and results on the problem of Hermite interpolation are stated. The local linear independence of $\{E(\cdot - i)\}$, $i \in Z$, is discussed also for the case where $\Sigma_{i=0}^{k} a_i z^i$ is not a Hurwitz polynomial.

1. Introduction.

The functional equation

$$E(t) = \sum_{i=0}^{k} a_i E(2t-i)$$

has found important applications in the areas of computer aided geometric design and multiresolution analysis. The uniform normalized B-spline of order k (degree $k-1$) with integer knots $\{0, \ldots, k\}$ satisfies the equation above with the mask

$$a_i = 2^{-(k-1)} \binom{k}{i}, \qquad 0 \le i \le k\ .$$

Generally, solutions of such equations (if they exist) do not have an explicit form and they are approximated by subdivision schemes. These schemes originate in a well-known algorithm due to Lane and Riesenfeld. Subdivision schemes are useful for curve (surface) generation, and for a detailed discussion of this subject see, e.g., [DGL], [D], [MP], [CDM], and [DL].

Wavelets are deeply related to the equation above, and we refer the reader to [DAUB] for a discussion of orthonormal wavelets, and to [CW] and [M] for a discussion of prewavelets.

*Received by the editors July 29, 1991; accepted for publication (in revised form) May 1, 1992.

†Raymond and Beverly Sackler Faculty of Exact Sciences, School of Mathematical Sciences, Tel Aviv University, Ramat Aviv, Tel Aviv 69978, Israel.

Here we restrict ourselves to a certain class of equations (containing the B-spline equations), and we mainly analyze determinantal and sign properties of their compactly supported continuous solution. As we clarify now, some properties of the solution, $E(t)$, are particularly significant for the research areas mentioned above.

(i) [GM]. $\{E(t-i)\}_{i=-\infty}^{\infty}$ is a totally nonnegative sequence. Such a basis is particularly shape-preserving, and for a discussion of such representations we refer the reader to [G].

(ii) [GM]. $\{E(t-i)\}_{i=-\infty}^{\infty}$ is a locally linearly independent sequence in the sense of Definition 3.1. Such sequences are known to be L^2-stable, and this stability is important in multiresolution analysis.

Our motivation for this paper arises from an analysis done by [GM] and in the following we briefly survey their results.

The polynomial

$$A(z)=\sum_{i=0}^{k} a_i z^i, \qquad \{a_i\}_{i=0}^{k} \subset R \tag{1.1}$$

is termed a Hurwitz polynomial if all its zeros satisfy Re $z<0$ (see [GANT]). We will also call the associated sequence $\{a_i\}_{i=0}^{k}$, a Hurwitz sequence. In the particular case, where the zeros are real and negative, $\{a_i\}_{i=0}^{k}$ is termed a Polya frequency sequence.

Imposing the condition

$$A(1)=2, \qquad A(-1)=0, \tag{1.2}$$

we find that the Hurwitz sequence $\{a_i\}_{i=0}^{k}$ is positive ($a_i>0,\ 0\le i\le k$) and the functional equation

$$E(t)=\sum_{i=0}^{k} a_i E(2t-i)\ , \qquad \sum_{i=-\infty}^{\infty} E(t-i)=1 \tag{1.3}$$

has a unique continuous compactly supported solution (see also [MP], [CDM]). The function $E(t)$ is vanishing outside of $(0,k)$ and satisfies a variation diminishing property

$$S^-\left(\sum_{i=-\infty}^{\infty} \alpha_i E(t-i)\right) \le S^-\{\alpha_i\}, \qquad t\in(-\infty\ ,\ \infty), \quad \{\alpha_i\}_{i=\infty}^{\infty}\subset R, \tag{1.4}$$

where S^- counts strong sign changes of functions, sequences, respectively. Given a sequence $\{x_{\ell_\nu}\}_{\nu=0}^{r}$, $x_{\ell_\nu}<x_{\ell_{\nu+1}}$, where $\{\ell_\nu\}$ is a strictly increasing sequence of integers, the matrix

$$M\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r)\end{pmatrix}_{i,j} = E(x_{\ell_i}-\ell_j) \tag{1.5}$$

is totally nonnegative, i.e., all its minors are nonnegative. We denote the associated determinant by

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r)\end{pmatrix},$$

and, in particular,

$$(1.6)\qquad D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r) \end{pmatrix} \geq 0, \qquad x_{\ell_\nu} < x_{\ell_{\nu+1}}\,.$$

Moreover, (1.6) is positive if and only if

$$(1.7)\qquad x_{\ell_\nu} \in \operatorname{supp}(E(\cdot-\ell_\nu)) = (\ell_\nu\ ,\ \ell_\nu + k)$$

which is a well-known result for B-splines (see, e.g., [SCH]). Here and throughout this paper the support of a function is defined by $\operatorname{supp}(f) := \{x \mid f(x) \neq 0\}$.

The analysis in this paper is not based on [GM], and we believe that our proofs are simpler. First we establish in §3 the local linear independence of $\{E(\cdot - i)\}$, given that $\{a_i\}_{i=0}^k$ is a Hurwitz sequence. We also analyze the local linear independence where $\{a_i\}_{i=0}^k$ is a positive sequence and where $\{a_i\}_{i=0}^k$ is a mask of an interpolatory subdivision scheme. In §4 we introduce an alternative analysis for the problem of Lagrange interpolation, where $\{a_i\}_{i=0}^k$ is a Hurwitz sequence, and in §5 we discuss the Hermite interpolation problem.

Our proofs are mainly based on arguments of subdivision and arguments of Weak Tschebycheff (WT-) systems. A survey of WT-systems is found in [SCH] §2, and we completely follow the approach there. The results of subdivision theory are mainly taken from [D], which is a review paper summarizing known results (see also, e.g., [CDM], [DL], [DGL], [MP]). Other key results are Orlando's formula [GANT] and the total positivity of a Hurwitz matrix [KEMP], [AS], which are explained in §2.

We comment that subdivision schemes determined by a Hurwitz polynomial are a subclass of those that are analyzed in [Y]. The properties investigated there are Lipschitz continuity, variation diminishing properties, and bell-shaped refinable functions.

2. Subdivision preliminaries. In the following we clarify some well-known results related to subdivision schemes and functional equations. Unless otherwise stated, the results are taken from [D] (and the contributors are credited there).

A subdivision scheme is given by the formula

$$(2.1)\qquad f_i^{n+1} = \sum_{j=-\infty}^{\infty} a_{i-2j} f_j^n,$$

where $\{f_i^n\}_{i=-\infty}^{\infty} \subset R^d$ denotes the control points at level n, and $\{a_i\}_{i=0}^k$ ($a_0 \neq 0$, $a_k \neq 0$, $a_i = 0$ for $i < 0$, $i > k$) is the mask of the scheme.

Definition 2.1 (Convergence). Let (2.1) apply recursively to the initial data $\{f_i^0 = \delta_{i,0}\}_{i=-\infty}^{\infty} \subset R$. The scheme is said to converge if there exists a nontrivial continuous function $E(t)$ such that $|E(2^{-n}i) - f_i^n|$ tends to zero uniformly on i and on n.

The function $E(t)$ is supported on $(0, k)$ and is termed the refinable function of the scheme. The following fundamental theorem summarizes the relation between convergent schemes and functional equations.

Theorem 2.2. *Let $E(t)$ be the refinable function of a convergent scheme determined by $\{a_i\}_{i=0}^k$. Then $E(t)$ is the unique continuous, compactly supported solution to*

$$(2.2)\qquad E(t) = \sum_{i=0}^{k} a_i E(2t - i),$$

which satisfies also

$$\sum_{i=-\infty}^{\infty} E(t-i) = 1. \tag{2.3}$$

The sum rule

$$\sum_i a_{2i} = \sum_i a_{2i+1} = 1 \tag{2.4}$$

is a necessary condition for a convergent scheme, and it is equivalent to saying that the characteristic polynomial $A(z)$ given by

$$A(z) = \sum_{i=0}^{k} a_i z^i \tag{2.5}$$

satisfies

$$A(1) = 2, \qquad A(-1) = 0. \tag{2.6}$$

The following theorem is central for analyzing the smoothness of $E(t)$.

THEOREM 2.3. *Assume $k > 1$. Let $\{a_i^{(1)}\}_{i=0}^{k-1}$ be given by*

$$A^{(1)}(z) = 2(1+z)^{-1}A(z) = \sum_{i=0}^{k-1} a_i^{(1)} z^i \ . \tag{2.7}$$

If $\{a_i^{(1)}\}_{i=0}^{k-1}$ determines a convergent scheme, then $\{a_i\}_{i=0}^{k}$ also does. Moreover, let $E(t)$, $F(t)$ be the refinable functions associated with $\{a_i\}_{i=0}^{k}$, $\{a_i^{(1)}\}_{i=0}^{k-1}$; correspondingly then $E(t) \in C^1$ and

$$E'(t) = F(t) - F(t-1) \ . \tag{2.8}$$

The scheme determined by $\{a_i^{(1)}\}_{i=0}^{k-1}$ is termed the divided difference scheme. More generally, if $k > m$ and if $A(z)$ has an m-fold zero at $z = -1$, then the coefficients of $2^m \ (z+1)^{-m} \ A(z)$ determine the divided difference scheme of order m. It is also true that if the divided difference scheme of order m converges, then $E(t) \in C^m$. The mask of the divided difference scheme of order m, $\{a_i^{(m)}\}$ is given explicitly by

$$\sum_{i=0}^{k-m} a_i^{(m)} z^i = 2^m (z+1)^{-m} \left(\sum_{i=0}^{k} a_i z^i \right) . \tag{2.9}$$

Let the matrices A_0 and A_1 be defined by

$$\begin{aligned} (A_0)_{i,j} &= a_{i-2j+k-1}, \qquad 0 \le i,j \le k-1, \\ (A_1)_{i,j} &= a_{i-2j+k}, \qquad 0 \le i,j \le k-1, \end{aligned} \tag{2.10}$$

and let $\overline{f_i^n}$ denote the vector $(f_{i-(k-1)}^n, \dots, f_i^n)$. Then the following is true.

THEOREM 2.4.

(i) *The values at level* n, $\{f_i^n\}$, *satisfy*

$$\sum_i f_i^0 E(t-i) = \sum_i f_i^n E(2^n t - i), \tag{2.11}$$

and $\overline{f_j^n}$ *determines the behavior of* (2.11) *on* $[j2^{-n}, (j+1)2^{-n}]$.

(ii) *The transformation* (2.1) *is given also by* $\overline{f_{2i}^{n+1}} = A_0\overline{f_i^n}$, $\overline{f_{2i+1}^n} = A_1\overline{f_i^n}$. *Hence, for each* $i \in Z$ *there exist* $j \in Z$ *and a sequence* $\{i_\ell\}_{\ell=0}^n$ *such that*

$$\overline{f_i^n} = \prod_{\ell=1}^n A_{i_\ell}\overline{f_j^0}, \qquad i_\ell \in \{0,1\}. \tag{2.12}$$

(iii) [DGL]. A_0 *and* A_1 *have* $k-1$ *common eigenvalues counting multiplicities. The kth eigenvalue of* A_0 *is* a_0, *and the kth eigenvalue of* A_1 *is* a_k. (*Note that since* $a_0 \neq 0$, $a_k \neq 0$, *then it follows that* A_0, A_1 *are either both singular or both invertible.*)

(iv) *If the scheme converges, then for each* j *and for each sequence* $\{i_\ell\}_{\ell=1}^\infty$, *the product* (2.12) *tends to a multiple of the vector* $(1,\dots,1)$ *as* $n \to \infty$.

The singularity of the matrix A_0 is determined by the following result [GANT, p. 197].

THEOREM 2.5 (Orlando's formula). A_0 *is a singular matrix if and only if the polynomial* $A(z) = \sum_{i=0}^k a_i z^i$ *has a pair of opposite zeros* z *and* $-z$.

Positive schemes have the following property.

THEOREM 2.6. *Let* $\{a_i\}_{i=0}^k$, $k>1$, *be a positive mask satisfying* (2.4); *then*

(i) *The associated subdivision scheme converges*;

(ii) [MPIN]. *The refinable function* $E(t)$ *is positive on* $(0,k)$.

Now, we focus our attention on a Hurwitz sequence, $\{a_i\}_{i=0}^k$. The following theorem is a direct consequence of Theorems 2.3 and 2.6 (see also [GM], [Y]).

THEOREM 2.7. *Let* $\{a_i\}_{i=0}^k$ *be a Hurwitz sequence satisfying* (2.4), *and assume that* $A(z)$ *has an* m*-fold zero at* $z=-1$, $1 \le m < k$. *The scheme and its associated divided difference schemes up to order* $m-1$ *are convergent;* $\{a_i\}_{i=0}^k, \dots, \{a_i^{(m-1)}\}_{i=0}^{k-m+1}$ *are Hurwitz sequences.*

A key result here is that the bi-infinite matrix

$$A_{ij} = a_{i-2j} \tag{2.13}$$

is totally nonnegative if $\{a_i\}_{i=0}^k$ is a Hurwitz sequence (see [KEMP], [AS]).

Now applying (2.1) to the data at level n, $\{f_i^n\} \subset R$, it follows that

$$S^-\{f^{n+1}\} \subset S^-\{f^n\}, \tag{2.14}$$

and, consequently,

$$S^-\left\{\sum_i f_i^0 E(\cdot - i)\right\} \le S^-\{f_i^0\} \ . \tag{2.15}$$

This argument appears in [MP] for the particular case of a Polya frequency sequence (all roots of $\sum_{i=0}^k a_i z^i$ are real and negative).

3. Local linear independence. In the following let $\{a_i\}_{i=0}^k$ $(a_0 \neq 0\ ,\ a_k \neq 0)$ determine a convergent scheme, and let $E(t)$ be the associated refinable function that vanishes outside of the interval $(0,k)$. By Theorem 2.4 (iii) A_0 and A_1 are either both singular or both invertible.

DEFINITION 3.1. The functions $\{E(t-i)\}_{i=-\infty}^{\infty}$ are said to be locally linearly independent if $\{E(t-i)\}_{i=-(k-1)}^{0}$ are linearly independent on each subinterval of $[0,1]$.

LEMMA 3.2. *Assume that A_0 is invertible and the scheme converges*; *then the following statements are equivalent*:

(i) $\{E(t-i)\}_{i=-\infty}^{\infty}$ *are locally linearly independent*;

(ii) $\{E(t-i)\}_{i=-(k-1)}^{0}$ *are linearly independent on* [0,1].

Proof. We prove (ii) $\Rightarrow$ (i) (the converse is trivial). Assume in contradiction that $\sum_{i=-(k-1)}^{0} f_i^0 E(t-i) \not\equiv 0$ on [0,1], but there exist j and n such that

$$\sum_{i=-(k-1)}^{0} f_i^0 E(t-i) \equiv 0, \qquad t \in [\,j2^{-n},\ (j+1)2^{-n}\,].$$

By (2.11) it follows that

$$\sum_{i=j-(k-1)}^{j} f_i^n E(2^n t-i) \equiv 0, \qquad t \in [\,j2^{-n},\ (j+1)2^{-n}\,],$$

which implies that one of the following statements is true.

(a) $\{f_i^n\}_{i=j-(k-1)}^{j}$ is trivial.

(b) $\{E(2^n t-i)\}_{i=j-(k-1)}^{j}$ are linearly dependent on $[\,j2^{-n}, (j+1)2^{-n}\,]$.

Now, (b) is a contradiction to (ii) and (a), together with (2.12), is a contradiction to the nonsingularity of A_0 and A_1. □

THEOREM 3.3. *Let $\{a_i\}_{i=0}^k$ be a Hurwitz sequence satisfying* (2.4). *Then $\{E(t-i)\}$ are locally linearly independent.*

Proof. By Theorem 2.6 the scheme converges, and $\{E(t-i)\}_{i=-(k-1)}^{0}$ are positive functions on (0,1). Since all roots of $\sum_{i=0}^k a_i z^i$ are in the left half plane, then by Theorem 2.5 A_0 and A_1 are invertible. Thus, by Lemma 3.2 we discuss linear independence on $[0,1]$. Assume that $\sum_{i=-(k-1)}^{0} f_i^0 E(t-i) \equiv 0$ on $[0,1]$ and $\overline{f_0^0} = \{f_i^0\}_{i=-(k-1)}^{0}$ is nontrivial; then by the positivity of $\{E(t-i)\}$ it follows that $S^-(\overline{f_0^0}) > 0$. Also for each n and each $\{i_\ell\}_{\ell=0}^n$ we get by the nonsingularity of A_0, A_1 that $\prod_{\ell=1}^n A_{i_\ell}\overline{f_0^0}$ is nontrivial, and, consequently, $S^-(\prod_{\ell=1}^n A_{i_\ell}\overline{f_0^0}) > 0$. Thus, $S^-\{f_i^n\}$ tends to infinity, contradicting (2.14). □

The rest of this section is devoted to positive and interpolatory schemes, and we will not make use of these results in the following sections.

THEOREM 3.4. *Let $\{a_i\}_{i=0}^k$ be a positive mask satisfying* (2.4), *and let A_0 be invertible. Then the following statements are equivalent*:

(i) $\{E(t-i)\}$ *are locally linearly independent*;

(ii) *Each nontrivial common invariant subspace of A_0 and A_1 owns a nontrivial, nonnegative vector.*

(Note that at least one nontrivial common invariant subspace always exists, namely, $(1,1,\dots,1)$.)

Proof. As in the preceding proof the scheme converges, $\{E(t-i)\}_{i=-(k-1)}^{0}$ are positive on (0,1) and (i) is replaced by linear independence on $[0,1]$.

(ii) ⇒ (i) Let M be the space of all vectors $\overline{f_0^0}$ such that $\sum_i f_i^0 E(t-i) \equiv 0$ on $[0,1]$, and assume in contradiction that M is nontrivial. It is clear that M is a common invariant subspace of A_0, A_1, and by the positivity of $\{E(t-i)\}$ it follows that each nontrivial vector in M has at least one strong sign change, contradicting (ii).

(i) ⇒ (ii) Assume in contradiction that there exists a nontrivial common invariant subspace M such that each nontrivial vector in M has a strong sign change. Let $\overline{f_0^0} \in M$ be a nontrivial vector. Then all vectors of the form $\prod_{\ell=1}^{n} A_{i_\ell}\overline{f_0^0}$ are also in M, and also have a strong sign change. Since the scheme converges, $\lim_{\ell\to\infty}\prod_{\ell=1}^{\infty} A_{i_\ell}\overline{f_0^0}$ converges to a multiple of $(1,\ldots,1)$, which implies $\lim_{\ell\to\infty}\prod_{\ell=1}^{\infty} A_{i_\ell}\overline{f_0^0} = 0$, contradicting the linear independence. □

A scheme is said to be interpolatory if there exists $j \in Z$ such that $a_{2i+j} = \delta_{i,0}$. Obviously, $\{f_i^n\}$ is a subset of $\{f_i^{n+1}\}$, and if the scheme converges, then $E(i) = \delta_{i,j}$ for each $i \in Z$.

THEOREM 3.5. *Let $\{a_i\}_{i=0}^{k}$ determine a convergent interpolatory scheme, and assume that A_0 is invertible. Then $\{E(t-i)\}$ are locally linearly independent.*

Proof. Assume in contradiction that there exists a nontrivial $\{f_i^0\}_{i=-(k-1)}^{0}$ such that $\sum_{i=-(k-1)}^{0} f_i^0 E(t-i) \equiv 0$, on $[0,1]$. By the nonsingularity of A_0, A_1 it follows that for each n and each $\{i_\ell\}_{\ell=1}^{n}$, the vector $\overline{f_j^n} = \prod_{\ell=1}^{n} A_{i_\ell}\overline{f_0^0}$ is nontrivial. For a sufficiently large n there exists j such that the support of the functions $\{E(2^n t - i)\}_{i=j-(k-1)}^{j}$ is contained in $[0,1]$, and since the scheme is interpolatory, then $\{f_i^n\}_{i=j-(k-1)}^{j}$ are values of $\sum_{i=-(k-1)}^{0} f_i^0 E(t-i)$. Hence, there exists t such that $\sum_{i=-(k-1)}^{0} f_i^0 E(t-i) \neq 0$, and the contradiction is obtained. □

Remark 3.6. The four-point scheme (see, e.g., [D]) depends on a positive tension parameter w and is determined by

(3.1)
$$a_0 = -w, \quad a_1 = 0, \quad a_2 = \tfrac{1}{2} + w, \quad a_3 = 1, \quad a_4 = \tfrac{1}{2} + w, \quad a_5 = 0, \quad a_6 = -w.$$

The scheme is known to converge for $|w| < 0.5$. The polynomial $\sum_{i=0}^{k} a_i z^i$ has no pair of opposite zeros; thus, by Theorem 3.5 the $\{E(t-i)\}$ are locally linearly independent.

4. An alternative analysis of Lagrange interpolation.

Let $\{a_i\}_{i=0}^{k}$ be a Hurwitz sequence satisfying (2.4). Then $E(t)$ is continuous, and the following properties of $E(t)$ have already been discussed:

$$E(t) = 0, \qquad t \le 0\ , \quad t \ge k, \tag{4.1}$$

$$E(t) > 0, \qquad 0 < t < k, \tag{4.2}$$

$$S^-\left(\sum_i \alpha_i E(\cdot - i)\right) \le S^-\{\alpha_i\}, \tag{4.3}$$

$$\{E(\cdot - i)\},\ i \in Z \text{ are locally linearly independent.} \tag{4.4}$$

Only these properties of $E(t)$ play a role in this section.

In the following, let $\{\ell_\nu\}_{\nu=0}^{r}$ and $\{x_{\ell_\nu}\}_{\nu=0}^{r}$, $r \ge 0$, be strictly increasing sequences, and we define the set of points I by

$$I = \bigcup_{\nu=0}^{r} \text{supp}\,(E(.-\ell_\nu)) = \bigcup_{\nu=0}^{r} (\ell_\nu,\ \ell_\nu + k). \tag{4.5}$$

THEOREM 4.1.

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot - \ell_0) & \cdots & E(\cdot - \ell_r) \end{pmatrix} \geq 0 \quad \forall_\nu, \quad x_{\ell_\nu} < x_{\ell_{\nu+1}}. \tag{4.6}$$

Proof. We assume that $x_{\ell_\nu} \in I$ for all $_\nu$, since otherwise the determinant vanishes. For the particular sequence $x_{\ell_\nu} = \ell_\nu + \frac{1}{2}$ it is clear that the matrix (4.6) is lower triangular, and by (4.2) the diagonal is positive.

Now, we are under the following conditions:

(i) $\{E(t - \ell_\nu)\}_{\nu=0}^r$ is a sequence of continuous linearly independent functions on I;

(ii) There exists a sequence $\{x_{\ell_\nu}\}_{\nu=0}^r$ such that (4.6) is positive;

(iii) On I, $S^-(\sum_{\nu=0}^r \alpha_{\ell_\nu} E(\cdot - \ell_\nu)) \leq S^-\{\alpha_{\ell_\nu}\}_{\nu=0}^r$ for each sequence $\{\alpha_{\ell_\nu}\}_{\nu=0}^r$;

(i) and (iii), together with [SCH] Theorem 2.39, imply that either $\{E(\cdot - \ell_\nu)\}_{\nu=0}^r$ or $\{E(\cdot - \ell_0), \ldots, E(\cdot - \ell_{r-1}), -E(\cdot - \ell_r)\}$ is a WT-system on I. Hence, (4.6) is either nonnegative or nonpositive, and the proof is completed by (ii). □

THEOREM 4.2.

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot - \ell_0) & \cdots & E(\cdot - \ell_r) \end{pmatrix} > 0, \qquad x_{\ell_\nu} < x_{\ell_{\nu+1}} \tag{4.7}$$

if and only if

$$\forall \nu, \quad x_{\ell_\nu} \in \operatorname{supp}(E(\cdot - \ell_\nu)) = (\ell_\nu \ , \ \ell_\nu + k). \tag{4.8}$$

Proof. First, we prove that (4.7) ⇒ (4.8). Assume in contradiction that (4.8) is violated while (4.7) still holds. If the violation occurs at $\nu = r$, i.e., $x_{\ell_r} \notin \operatorname{supp}(E(\cdot - \ell_r))$, then either the last row of (4.7) or the last column of (4.7) vanish, contradicting the positivity of the determinant. Hence, the violation occurs at $\nu = q$, where $q < r$. By Theorem 4.1 it follows that (4.7) is a totally nonnegative matrix, and by [GANT, p. 100] we get

(4.9)

$$\begin{aligned} & D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot - \ell_0) & \cdots & E(\cdot - \ell_r) \end{pmatrix} \\ & \quad \leq D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_q} \\ E(\cdot - \ell_0) & \cdots & E(\cdot - \ell_q) \end{pmatrix} \cdot D\begin{pmatrix} x_{\ell_{q+1}} & \cdots & x_{\ell_r} \\ E(\cdot - x_{\ell_{q+1}}) & \cdots & E(\cdot - x_{\ell_r}) \end{pmatrix}. \end{aligned}$$

Now by a preceding argument we get

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_q} \\ E(\cdot - \ell_0) & \cdots & E(\cdot - \ell_q) \end{pmatrix} = 0, \tag{4.10}$$

and together with (4.9) it follows that (4.7) vanishes.

In the following we prove (4.8) ⇒ (4.7). The case $r = 0$ is obviously true, and we assume by induction that it is true for each sequence $\{x_{\ell_\nu}\}_{\nu=0}^j$, $j < r$. Assume in contradiction that (4.8) holds, and there exists $f(t)$ such that

$$f(t) = \sum_{\nu=0}^r \alpha_{\ell_\nu} E(t - \ell_\nu), \quad f(x_{\ell_\nu}) = 0 \quad \forall \nu, \quad \{\alpha_{\ell_\nu}\} \text{ nontrivial.} \tag{4.11}$$

First note that

$$\alpha_{\ell_\nu} \neq 0, \qquad 0 \leq \nu \leq r \tag{4.12}$$

since if $\alpha_{\ell_\nu} = 0$, then by deleting row ℓ_ν and column ℓ_ν the induction hypothesis is contradicted. In view of the local linear independence, $f(t)$ does not vanish on any subinterval contained in I.

Now we are under the following conditions:

(i) $\{E(t-\ell_\nu)\}_{\nu=0}^r$ is a WT-system of order $r+1$ on I;

(ii) $f(t)$ has $r+1$ zeros on I, namely, $\{x_{\ell_\nu}\}_{\nu=0}^r$;

(iii) The zeros of f are essential (since $E_{\ell_\nu}(x_{\ell_\nu}) \neq 0$; see [SCH, Def. 2.43]);

By [SCH, Thm. 2.45] it follows that $f(t)$ is vanishing on a subinterval of I, and the proof is complete. □

5. Hermite interpolation problem. In the following we assume that $\{a_i\}_{i=0}^k$ is a Hurwitz sequence satisfying (2.4), and that the characteristic polynomial $\sum_{i=0}^k a_i z^i$ has an $(m+1)$-fold zero at $z=-1$, $1 < m+1 < k$. By the results of §2 it follows that $E \in C^m$.

In general the Hermite interpolation problem of order m involves derivatives up to order m, and the interpolation points $\{x_{\ell_\nu}\}_{\nu=0}^r$ satisfy

$$x_{\ell_\nu} \le x_{\ell_{\nu+1}}, \qquad x_{\ell_\nu} < x_{\ell_{\nu+m+1}}, \tag{5.1}$$

where $\{\ell_\nu\}$ is a strictly increasing sequence of integers. The matrix we discuss is

$$M\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r)\end{pmatrix}_{i,j} = \frac{\partial}{\partial^{d_i}} E(x_{\ell_i}-\ell_j), \tag{5.2}$$

$$i,j = 0,\dots,r, \quad d_i = \max\{q : x_{\ell_i} = \cdots x_{\ell_{i-q}}\}.$$

In words, if $x_{\ell_\nu} = \cdots = x_{\ell_{\nu-q}} \neq x_{\ell_{\nu-q-1}}$, then the $\nu-q$ row contains the values of $\{E(x_{\ell_\nu}-\ell_\gamma)\}_{\gamma=0}^r$, the $\nu-q+1$ row contains the values of $\{E'(x_{\ell_\nu}-\ell_\gamma)\}_{\gamma=0}^r$, and the ν row contains the values of $\{E^{(q)}(x_{\ell_\nu}-\ell_\gamma)\}_{\gamma=0}^r$.

The following theorem is an immediate result of Theorem 4.1 and [SCH, Lemma 2.9].

THEOREM 5.1. *For each* $\{x_{\ell_\nu}\}_{\nu=0}^r$, $x_{\ell_\nu} \le x_{\ell_{\nu+1}}$, $x_{\ell_\nu} < x_{\ell_{\nu+m+1}}$, *we then have*

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r)\end{pmatrix} \ge 0. \tag{5.3}$$

The following theorem provides a necessary condition for nonsingularity of (5.3).

THEOREM 5.2. *For each* $\{x_{\ell_\nu}\}_{\nu=0}^r$, $x_{\ell_\nu} \le x_{\ell_{\nu+1}}$, $x_{\ell_\nu} < x_{\ell_{\nu+m+1}}$, *we then have*

$$D\begin{pmatrix} x_{\ell_0} & \cdots & x_{\ell_r} \\ E(\cdot-\ell_0) & \cdots & E(\cdot-\ell_r)\end{pmatrix} > 0 \tag{5.4}$$

only if

$$x_{\ell_\nu} \in \operatorname{supp}\,(E(\cdot-\ell_\nu)) \quad \forall\nu, \quad 0 \le \nu \le r. \tag{5.5}$$

Proof. Assume in contradiction that (5.5) is violated, i.e., there exists ν such that $x_{\ell_\nu} \notin \operatorname{supp}(E(\cdot-\ell_\nu))$. Substituting all the derivative values appearing in the matrix (5.4) by discrete divided differences according to the formula

$$\frac{\partial}{\partial^q} E(x_{\ell_i}-\ell_j) := q!\ [x_{\ell_i}, x_{\ell_i+h}, \dots, x_{\ell_i+qh}]E(\cdot-\ell_j), \tag{5.6}$$

the modified determinant is clearly zero for a sufficiently small h. Hence, (5.4) vanishes and the proof is completed. □

Now, we restrict ourselves to consecutive translates, and under this assumption Theorem 5.3 is a converse for Theorem 5.2. Originally, Theorem 5.3 was proved for the case $m = 1$, and its generalization to the current form is due to Mark Kon.

THEOREM 5.3. *Let* $\{x_\ell\}_{\ell=0}^r$ *satisfy*

$$x_\ell \le x_{\ell+1}, \quad x_\ell < x_{\ell+m+1}, \quad x_\ell \in \operatorname{supp}\,(E(\cdot - \ell)). \tag{5.7}$$

Then

$$D\begin{pmatrix} x_0 & \cdots & x_r \\ E(\cdot) & \cdots & E(\cdot - r) \end{pmatrix} > 0. \tag{5.8}$$

Proof. The case $r = 0$ is obvious, and we assume by induction that (5.7) $\Rightarrow$ (5.8) for each sequence $\{x_\ell\}_{\ell=0}^j$, $j < r$. Assume in contradiction that there exists $\{x_\ell\}_{\ell=0}^r$ satisfying (5.7), where (5.8) is vanishing. Hence, there exists $f(t)$ such that

$$f(t) = \sum_{\ell=0}^{r} \alpha_\ell E(t - \ell), \qquad \{\alpha_\ell\}_{\ell=0}^r \text{ nontrivial} \tag{5.9}$$

with

$$f(x_\ell) = 0 \quad \forall \ell, \quad 0 \le \ell \le r \tag{5.10}$$

and

$$\frac{\partial^j}{\partial t^j} f(x_\ell) = 0 \quad \text{if} \quad x_\ell = x_{\ell-j}, \quad 1 < j \le m\ . \tag{5.11}$$

First observe that $\alpha_0 \ne 0$, since otherwise

$$D\begin{pmatrix} x_1 & \cdots & x_r \\ E(\cdot - 1) & \cdots & E(\cdot - r) \end{pmatrix} = 0 \tag{5.12}$$

in both cases, $x_0 < x_1$ and $x_0 = x_1$, contradicting the induction hypothesis. By the same argument, $\alpha_r \ne 0$. Next observe that $f(t)$ does not vanish on any subinterval of

$$I = \bigcup_{\ell=0}^{r} \operatorname{supp}\,(E(\cdot - \ell)) = (0, r + k). \tag{5.13}$$

It is true since by the local linear independence and the previous observation it follows that if f vanishes on a subinterval, then there exists a trivial sequence $\{\alpha_\ell\}_{\ell=q}^{q+k-1}$ with $0 < q$, $q + k - 1 < r$. Since the support of E is of size k, then

$$D\begin{pmatrix} x_0 & \cdots & x_{q-1} \\ E(\cdot) & \cdots & E(\cdot - (q - 1)) \end{pmatrix} = 0, \tag{5.14}$$

contradicting the induction hypothesis.

Now, we count the zeros of f' on I. Let j be the number of points x_ℓ with $x_\ell \ne x_{\ell-1}$. Then f' has $r + 2$ zeros on I according to the following count:

(i) $r + 1 - j$ zeros follow from the multiplicities in $\{x_\ell\}_{\ell=0}^r$;

(ii) $j-1$ zeros follow from Rolle's theorem;

(iii) Two zeros near the boundaries of I follow also from Rolle's theorem since $f(0)=f(k+r)=0$.

By the results of §2 it is known that

$$E'(t)=F(t)-F(t-1), \tag{5.15}$$

where $F(t)$ is the refinable function of the divided difference scheme, which is also determined by a Hurwitz sequence, and $F(t)$ is supported on $(0,k-1)$. Hence $f'(t)$ is a function of the form

$$f'(t)=\sum_{\ell=0}^{r+1}\beta_\ell F(t-\ell), \tag{5.16}$$

and due to the above construction its zeros $\{y_i\}_{i=0}^{r+1}$ satisfy

$$0<y_0\le\cdots\le y_{r+1}<(r+1)+(k-1)\ , \qquad y_\ell<y_{\ell+m}. \tag{5.17}$$

The proof is complete by the following inductive argument on m. This theorem is true for $m=0$ (by the preceding section), and assume it is true for $0,\dots,m-1$. By Lemma 5.4 it follows that there exists some i such that $f'(t)$ vanishes on a subinterval containing y_i and y_{i+1}. Now, since one of the zeros (or both) is a zero of f, then f also vanishes on this subinterval, a contradiction. □

The following lemma is needed for the preceding proof.

LEMMA 5.4. *Assume that Theorem* 5.3 *holds for* $m=0,\dots,n$, *and let* $f(t)=\sum_{\ell=0}^{r}\alpha_\ell E(t-\ell)$, $1\le r$ *vanish at* $y_0,\dots,y_r$. *If*

$$0<y_0\le\cdots\le y_r<r+k, \qquad y_\ell<y_{\ell+n+1} \quad \forall\ell\ , \tag{5.18}$$

then there exists i *such that* f *vanishes on some interval containing* y_i,y_{i+1}.

Proof. By induction on r, the proof of the case $r=1$ is easy, and we assume the hypothesis is true for $1,\dots,r-1$.

First observe that there exists some q such that

$$y_q\notin(q,q+k)\ , \tag{5.19}$$

since otherwise $f\equiv0$, hence we assume $y_q\le q$. (The case $y_q\ge q+k$ is similar.) Define

$$g(t)=\sum_{\ell=0}^{q-1}\alpha_\ell E(t-\ell); \tag{5.20}$$

then $g=f$ on $(0,q]$. By induction hypothesis g vanishes on a subinterval of $(0,q]$ containing y_i,y_{i+1}, $i<q$, and the proof is completed. □

Acknowledgments. I would like to thank N. Dyn for useful discussions and the referees for their helpful comments. In particular, I would like to thank Mark Kon for the generalization of Theorem 5.3.

A CLASS OF BASES IN L^2 FOR THE SPARSE REPRESENTATION OF INTEGRAL OPERATORS*

BRADLEY K. ALPERT[†]

Abstract. A class of *multiwavelet* bases for L^2 is constructed with the property that a variety of integral operators is represented in these bases as sparse matrices, to high precision. In particular, an integral operator $\mathcal{K}$ whose kernel is smooth except along a finite number of singular bands has a sparse representation. In addition, the inverse operator $(I - \mathcal{K})^{-1}$ appearing in the solution of a second-kind integral equation involving $\mathcal{K}$ is often sparse in the new bases. The result is an order $O(n \log^2 n)$ algorithm for numerical solution of a large class of second-kind integral equations.

Key words. wavelets, integral equations, sparse matrices

AMS(MOS) subject classifications. 42C15, 45L10, 65R10, 65R20

Introduction. Families of functions $h_{a,b}$,

$$h_{a,b}(x) = |a|^{-1/2}\, h\left(\frac{x-b}{a}\right), \qquad a, b \in \mathbf{R}, \quad a \neq 0,$$

derived from a single function h by dilation and translation, which form a basis for $L^2(\mathbf{R})$, are known as *wavelets* (Grossman and Morlet [9]). In recent years, these families have received study by many authors, resulting in constructions with a variety of properties. Meyer [11] constructed orthonormal wavelets for which $h \in C^\infty(\mathbf{R})$. Daubechies [6] constructed compactly supported wavelets with $h \in C^k(\mathbf{R})$ for arbitrary k, and [6] gives an overview and synthesis of the field.

Beylkin, Coifman, and Rokhlin [4] develop the connection between wavelets and recent fast numerical algorithms devised by Rokhlin and other authors [3], [8], [14], [15]. These algorithms exploit analytical properties of specific linear operators to achieve, in each case, fast application of an operator to an arbitrary function. The operator and function are discretized to a matrix and vector; in the discrete representation a full $n \times n$-matrix is applied to a vector of length n in order $O(n)$ operations, as opposed to order $O(n^2)$ operations for naive matrix-vector multiplication. Each algorithm depends on "local smoothness" of the underlying operator. In particular, each algorithm may be viewed as the division of the operator matrix into order $O(n)$ square submatrices, each approximated by a matrix of low rank, followed by the fast application of the submatrices to the function vector.

In [4] it is observed that these numerical algorithms can be generalized by a technique in which the underlying operator is represented in a basis of wavelets. Discretization (i.e., truncation of the operator expansion) then results in an operator matrix that is approximated by a sparse matrix. The characteristics of the wavelets bases which lead to a sparse matrix representation are that

(1) The basis functions are orthogonal to low-order polynomials (have vanishing moments); and

Present address, National Institute of Standards and Technology, Boulder, Colorado 80303 (alpert@bldr.nist.gov).

(2) Most basis functions have small intervals of support.

An integral operator whose kernel is a smooth, nonoscillatory, function of its arguments over most of their range (and, therefore, can be approximated locally by low-order polynomials) will have negligible projection on most basis functions.

One difficulty of using wavelets bases for the representation of integral operators is that they do not form a basis for functions on a finite interval. Wavelet basis functions overlap in such a way that either the interval must be extended, a periodization must be performed, or the basis functions at the interval ends must be modified. In [4] the integrand is treated as periodic, with some loss of sparsity. In [13] Meyer showed how the basis functions overlapping the interval ends can be truncated and reorthogonalized to obtain a basis on the finite interval.

A second difficulty of using wavelets for the representation of integral operators is that projection onto the basis functions requires appropriate integration quadratures (as is true with other bases). The order of convergence of the quadratures determines the order of the numerical method as a whole. The difficulty is that quadratures must be employed for each element of the resulting matrix, leading to potentially high cost. On the other hand, use of the Nyström method, in which the interval is discretized into n points and the integral at each point is approximated by a quadrature, requires the application of quadratures only n times.

In this paper we construct a class of wavelet-like bases, which we call *multiwavelet* bases, which lead to the sparse representation of smooth integral operators on a finite interval. For each basis, the interval is recursively bisected; the basis functions on a given scale are supported on the dyadic subintervals of a particular size. Out of this class of bases, different bases differ in the number of basis functions supported on each subinterval, and this number corresponds to the order of convergence of expansions of C^∞ functions. The lack of overlap of the basis functions on a single scale eliminates the first difficulty (mentioned above) of using wavelets for the representation of integral operators. The second difficulty is eliminated by the construction of a discrete counterpart to the bases developed here. The latter construction is described in [2]. A principal advantage of the present construction is its simplicity.

In §1, we construct multiwavelet bases, and in §2 we prove that the representations in these bases of certain integral operators are sparse, to high precision. In §3 we give several numerical examples of the bases and the solution of second-kind integral equations and conclude with a discussion.

1. Multiwavelet bases.

1.1. The one-dimensional construction.

We construct a class of bases for $L^2(\mathbf{R})$ that can be readily revised to bases for $L^2[0,1]$. Each basis is comprised of dilates and translates of a finite set of functions $h_1, \dots, h_k$. In particular, these bases consist of orthonormal systems

$$(1) \qquad h^n_{j,m}(x) = 2^{m/2}\, h_j(2^m x - n), \qquad j = 1, \dots, k;\ m, n \in \mathbf{Z},$$

where the functions $h_1, \dots, h_k$ are piecewise polynomial, vanish outside the interval $[0,1]$, and are orthogonal to low-order polynomials (have vanishing moments),

$$(2) \qquad \int_0^1 h_j(x)\, x^i\, dx = 0, \qquad i = 0, 1, \dots, k-1.$$

We first restrict our attention to the finite interval $[0,1] \subset \mathbf{R}$, and we construct a basis for $L^2[0,1]$. We employ the multiresolution analysis framework developed by

Mallat [10] and Meyer [12], and discussed at length by Daubechies [6]. We suppose that k is a positive integer, and for $m = 0, 1, 2, \dots$ we define a space S^k_m of piecewise polynomial functions,

$$(3) \quad S^k_m = \{f : \begin{array}{l}\text{the restriction of } f \text{ to the interval } (2^{-m}n, 2^{-m}(n+1)) \text{ is}\\ \text{a polynomial of degree less than } k, \text{ for } n = 0, \dots, 2^m - 1,\\ \text{and } f \text{ vanishes elsewhere}\}.\end{array}$$

It is apparent that the space S^k_m has dimension $2^m k$ and

$$S^k_0 \subset S^k_1 \subset \cdots \subset S^k_m \subset \cdots.$$

For $m = 0, 1, 2, \dots$ we define the $2^m k$-dimensional space R^k_m to be the orthogonal complement of S^k_m in S^k_{m+1},

$$S^k_m \oplus R^k_m = S^k_{m+1}, \qquad R^k_m \perp S^k_m;$$

so we inductively obtain the decomposition

$$(4) \qquad S^k_m = S^k_0 \oplus R^k_0 \oplus R^k_1 \oplus \cdots \oplus R^k_{m-1}.$$

Suppose that functions $h_1, \dots, h_k : \mathbf{R} \to \mathbf{R}$ form an orthogonal basis for R^k_0. Since R^k_0 is orthogonal to S^k_0, the first k moments of $h_1, \dots, h_k$ vanish,

$$\int_0^1 h_j(x)\, x^i\, dx = 0, \qquad i = 0, 1, \dots, k-1.$$

The $2k$-dimensional space R^k_1 is spanned by the $2k$ orthogonal functions $h_1(2x), \dots, h_k(2x)$, $h_1(2x-1), \dots, h_k(2x-1)$, of which k are supported on the interval $[0, \frac{1}{2}]$ and k on $[\frac{1}{2}, 1]$. In general, the space R^k_m is spanned by $2^m k$ functions obtained from $h_1, \dots, h_k$ by translation and dilation. There is some freedom in choosing the functions $h_1, \dots, h_k$ within the constraint that they be orthogonal; by requiring normality and additional vanishing moments, we specify them uniquely, up to sign. The remainder of this subsection is devoted to the explicit construction of $h_1, \dots, h_k$; in the following sections we exploit only the property that $h_1, \dots, h_k$ form an orthonormal basis for R^k_0.

In preparation for the definition of $h_1, \dots, h_k$, we construct the k functions $f_1, \dots, f_k : \mathbf{R} \to \mathbf{R}$, supported on the interval $[-1, 1]$, with the following properties:

(1) The restriction of f_i to the interval $(0, 1)$ is a polynomial of degree $k - 1$;

(2) The function f_i is extended to the interval $(-1, 0)$ as an even or odd function according to the parity of $i + k - 1$;

(3) The functions $f_1, \dots, f_k$ satisfy the following orthogonality and normality conditions:

$$\int_{-1}^1 f_i(x)\, f_j(x)\, dx \equiv \langle f_i, f_j \rangle = \delta_{ij}, \qquad i, j = 1, \dots, k;$$

(4) The function f_j has vanishing moments,

$$\int_{-1}^1 f_j(x)\, x^i\, dx = 0, \qquad i = 0, 1, \dots, j + k - 2.$$

Properties 1 and 2 imply that there are k^2 polynomial coefficients that determine the functions $f_1, \ldots, f_k$, while properties 3 and 4 provide k^2 (nontrivial) constraints. It turns out that the equations uncouple to give k nonsingular linear systems that may be solved to obtain the coefficients, yielding the functions uniquely (up to sign). Rather than prove that these systems are nonsingular, however, we now determine $f_1, \ldots, f_k$ constructively.

We start with $2k$ functions that span the space of functions that are polynomials of degree less than k on the interval $(0,1)$ and on $(-1,0)$, then orthogonalize k of them, first to the functions $1, x, \ldots, x^{k-1}$, then to the functions $x^k, x^{k+1}, \ldots, x^{2k-1}$, and finally among themselves. We define $f_1^1, f_2^1, \ldots, f_k^1$ by the formula

$$f_j^1(x) = \begin{cases} x^{j-1}, & x \in (0,1), \\ -x^{j-1}, & x \in (-1,0), \\ 0, & \text{otherwise}, \end{cases}$$

and note that the $2k$ functions $1, x, \ldots, x^{k-1}, f_1^1, f_2^1, \ldots, f_k^1$ are linearly independent, hence span the space of functions that are polynomials of degree less than k on $(0,1)$ and on $(-1,0)$.

(1) By the Gram–Schmidt process we orthogonalize f_j^1 with respect to $1, x, \ldots, x^{k-1}$, to obtain f_j^2, for $j = 1, \ldots, k$. This orthogonality is preserved by the remaining orthogonalizations, which only produce linear combinations of the f_j^2.

(2) The next sequence of steps yields $k-1$ functions orthogonal to x^k, of which $k-2$ functions are orthogonal to x^{k+1}, and so forth, down to one function which is orthogonal to x^{2k-2}. First, if at least one of f_j^2 is not orthogonal to x^k, we reorder the functions so that it appears first, $\langle f_1^2, x^k \rangle \neq 0$. We then define $f_j^3 = f_j^2 - a_j \cdot f_0^2$ where a_j is chosen so $\langle f_j^3, x^k \rangle = 0$ for $j = 2, \ldots, k$, achieving the desired orthogonality to x^k. Similarly, we orthogonalize to $x^{k+1}, \ldots, x^{2k-2}$, each in turn, to obtain $f_1^2, f_2^3, f_3^4, \ldots, f_k^{k+1}$ such that $\langle f_j^{j+1}, x^i \rangle = 0$ for $i \leq j + k - 2$.

(3) Finally, we do Gram–Schmidt orthogonalization on $f_k^{k+1}, f_{k-1}^k, \ldots, f_1^2$, in that order, and normalize to obtain $f_k, f_{k-1}, \ldots, f_1$.

It is readily seen that the f_j satisfy properties (1)–(4) of the previous paragraph. Defining $h_1, \ldots, h_k : \mathbf{R} \to \mathbf{R}$ by the formula

$$h_i(x) = 2^{1/2} \, f_i(2x-1), \qquad i = 1, \ldots, k,$$

we obtain the equality

$$R_0^k = \text{linear span } \{h_i : \ i = 1, \ldots, k\},$$

and, more generally,

$$R_m^k = \text{linear span } \{h_{j,m}^n : \ h_{j,m}^n(x) = 2^{m/2} \, h_j(2^m x - n), \quad j = 1, \ldots, k; \ n = 0, \ldots, 2^m - 1\}. \tag{5}$$

We will show next that dilates and translates of the piecewise polynomial functions $h_1, \ldots, h_k$ form an orthonormal basis for $L^2(\mathbf{R})$. Furthermore, a subset of these dilates and translates, combined with a basis for S_0^k, forms a basis for $L^2[0,1]$.

1.2. Completeness of one-dimensional construction. We define the space S^k to be the union of the S_m^k, given by the formula

$$S^k = \bigcup_{m=0}^{\infty} S_m^k, \tag{6}$$

and observe that $\overline{S^k} = L^2[0,1]$. In particular, S^k contains the Haar basis for $L^2[0,1]$, consisting of functions piecewise constant on each of the subintervals $(2^{-m}n, 2^{-m}(n+1))$. Here the closure $\overline{S^k}$ is defined with respect to the L^2-norm,

$$\|f\| = \langle f, f\rangle^{1/2},$$

where the inner product $\langle f, g\rangle$ is defined by the formula

$$\langle f, g\rangle = \int_0^1 f(x)\, g(x)\, dx.$$

We let $\{u_1, \ldots, u_k\}$ denote an orthonormal basis for S_0^k; in view of (4), (5), and (6), the orthonormal system

$$\begin{aligned} B_k = {} & \{u_j : j = 1, \ldots, k\} \\ & \cup \{h_{j,m}^n : j = 1, \ldots, k;\ m = 0, 1, 2, \ldots;\ n = 0, \ldots, 2^m - 1\} \end{aligned}$$

spans $L^2[0,1]$; we refer to B_k as the *multiwavelet basis of order* k for $L^2[0,1]$.

Now we construct a basis for $L^2(\mathbf{R})$ by defining, for $m \in \mathbf{Z}$, the space $\tilde{S}_m^k$ by the formula

$$\begin{aligned} \tilde{S}_m^k = \{f : {} & \text{the restriction of } f \text{ to the interval } (2^{-m}n, 2^{-m}(n+1)) \text{ is} \\ & \text{a polynomial of degree less than } k, \text{ for } n \in \mathbf{Z}\} \end{aligned}$$

and observing that the space $\tilde{S}_{m+1}^k \backslash \tilde{S}_m^k$ is spanned by the orthonormal set

$$\{h_{j,m}^n :\ h_{j,m}^n(x) = 2^{m/2}\, h_j(2^m x - n),\ j = 1, \ldots, k;\ n \in \mathbf{Z}\}.$$

Thus $L^2(\mathbf{R})$, which is contained in $\overline{\bigcup_m \tilde{S}_m^k}$, has an orthonormal basis

$$\{h_{j,m}^n :\ j = 1, \ldots, k;\ m, n \in \mathbf{Z}\}.$$

1.3. Construction in multiple dimensions. The construction of bases for $L^2[0,1]$ and $L^2(\mathbf{R})$ can be extended to certain other function spaces, including $L^2[a,b]^d$ and $L^2(\mathbf{R}^d)$, for any positive integer d. We now outline this extension by giving the basis for $L^2[0,1]^2$, which is illustrative of the construction for any finite-dimensional space. We define the space $S_m^{k,2}$ by the formula

$$S_m^{k,2} = S_m^k \times S_m^k, \qquad m = 0, 1, 2, \ldots,$$

where S_m^k is defined by (3). We further define $R_m^{k,2}$ to be the orthogonal complement of $S_m^{k,2}$ in $S_{m+1}^{k,2}$,

$$S_m^{k,2} \oplus R_m^{k,2} = S_{m+1}^{k,2}, \qquad R_m^{k,2} \perp S_m^{k,2}.$$

Then $R_0^{k,2}$ is the space spanned by the orthonormal basis

$$\{u_i(x) h_j(y),\ h_i(x) u_j(y),\ h_i(x) h_j(y) :\ i, j = 1, \ldots, k\}.$$

Among these $3k^2$ basis elements each element $v(x,y)$ has no projection on low-order polynomials,

$$\int_0^1 \int_0^1 v(x,y)\, x^i\, y^j\, dx\, dy = 0, \qquad i, j = 0, 1, \ldots, k-1.$$

The space $R_m^{k,2}$ is spanned by dilations and translations of the $v(x,y)$ and the basis of $L^2[0,1]^2$ consists of these functions and the low-order polynomials $\{u_i(x) u_j(y) : i, j = 1, \ldots, k\}$.

1.4. Convergence of the multiwavelet bases. For a function $f \in L^2[0,1]$, a positive integer k, and $m = 0,1,2,\ldots$, we define the orthogonal projection $Q^k_m f$ of f onto S^k_m by the formula

$$(Q^k_m f)(x) = \sum_{j,n} \langle f, u^n_{j,m} \rangle \cdot u^n_{j,m}(x),$$

where $\{u^n_{j,m}\}$ is an orthonormal basis for S^k_m. The projections $Q^k_m f$ converge (in the mean) to f as $m \to \infty$. If the function f is several times differentiable, we can bound the error, as established by the following lemma.

LEMMA 1.1. *Suppose that the function $f : [0,1] \to \mathbf{R}$ is k times continuously differentiable, $f \in C^k[0,1]$. Then $Q^k_m f$ approximates f with mean error bounded as follows*:

$$\|Q^k_m f - f\| \le 2^{-mk} \frac{2}{4^k k!} \sup_{x\in[0,1]} |f^{(k)}(x)|. \tag{7}$$

Proof. We divide the interval $[0,1]$ into subintervals on which $Q^k_m f$ is a polynomial; the restriction of $Q^k_m f$ to one such subinterval $I_{m,n}$ is the polynomial of degree less than k that approximates f with minimum mean error. We then use the maximum error estimate for the polynomial which interpolates f at Chebyshev nodes of order k on $I_{m,n}$.

We define $I_{m,n} = [2^{-m}n, 2^{-m}(n+1)]$ for $n = 0,1,\ldots,2^m - 1$, and obtain

$$\begin{aligned}
\|Q^k_m f - f\|^2 &= \int_0^1 \left[(Q^k_m f)(x) - f(x)\right]^2 dx \\
&= \sum_n \int_{I_{m,n}} \left[(Q^k_m f)(x) - f(x)\right]^2 dx \\
&\le \sum_n \int_{I_{m,n}} \left[(C^k_{m,n} f)(x) - f(x)\right]^2 dx \\
&\le \sum_n \int_{I_{m,n}} \left(\frac{2^{1-mk}}{4^k k!} \sup_{x\in I_{m,n}} |f^{(k)}(x)|\right)^2 dx \\
&\le \left(\frac{2^{1-mk}}{4^k k!} \sup_{x\in[0,1]} |f^{(k)}(x)|\right)^2,
\end{aligned}$$

and by taking square roots we have bound (7). Here $C^k_{m,n} f$ denotes the polynomial of degree k, which agrees with f at the Chebyshev nodes of order k on $I_{m,n}$, and we have used the well-known maximum error bound for Chebyshev interpolation (see, e.g., [5]). □

The error of the approximation $Q^k_m f$ of f, therefore, decays like 2^{-mk}, and, since S^k_m has a basis of $2^m k$ elements, we have convergence of order k. For the generalization to d dimensions, a similar argument shows that the rate of convergence is of order k/d.

2. Sparse representation of integral operators. The matrix representations of integral operators in multiwavelet bases are sparse (to finite precision) for the same class of integral operators as is treated in [4], namely, all Calderon–Zygmund and pseudodifferential operators. In applications, an operator kernel commonly has the form

$$K(x,t) = f(x,t)\, s(|x-t|) + g(x,t), \tag{8}$$

where f and g are analytic functions of x, t and s is analytic except at the origin where it is singular. In the following development we initially restrict ourselves to a simple example of this latter class of kernels, with $K(x,t) = \log|x-t|$. Although this kernel is symmetric and convolutional, neither of these properties is related to the sparsity. Instead, a proof of sparsity (presented in Lemma 2.2 below) relies solely on derivative estimates provided by the Cauchy integral formula for intervals separated from the singularity. Later we treat the more general situation of (8) with $s(x) = \log(x)$.

We begin this section by introducing some notation for integral equations.

2.1. Second-kind integral equations. A linear Fredholm integral equation of the second kind is an expression of the form

$$f(x) - \int_a^b K(x,t)\, f(t)\, dt = g(x), \tag{9}$$

where we assume that the kernel K is in $L^2[a,b]^2$ and the unknown f and right-hand side g are in $L^2[a,b]$. For notational simplicity, we restrict our attention to the interval $[a,b] = [0,1]$. We use the symbol $\mathcal{K}$ to denote the integral operator of (9), given by the formula

$$(\mathcal{K}f)(x) = \int_0^1 K(x,t)\, f(t)\, dt$$

for all $f \in L^2[0,1]$ and $x \in [0,1]$. Suppose that $\{b_1, b_2, \ldots\}$ is an orthonormal basis for $L^2[0,1]$; the expansion of K in this basis is given by the formula

$$K(x,t) = \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} K_{ij}\, b_i(x)\, b_j(t), \tag{10}$$

where the coefficient K_{ij} is given by the expression

$$K_{ij} = \int_0^1 \int_0^1 K(x,t)\, b_i(x)\, b_j(t)\, dx\, dt, \qquad i,j = 1,2,\ldots. \tag{11}$$

Similarly, the functions f and g have expansions

$$f(x) = \sum_{i=1}^{\infty} f_i\, b_i(x), \qquad g(x) = \sum_{i=1}^{\infty} g_i\, b_i(x),$$

where the coefficients f_i and g_i are given by the formulae

$$f_i = \int_0^1 f(x)\, b_i(x)\, dx, \qquad g_i = \int_0^1 g(x)\, b_i(x)\, dx, \qquad i = 1,2,\ldots.$$

The integral equation (9) then corresponds to the infinite system of equations

$$f_i - \sum_{j=1}^{\infty} K_{ij}\, f_j = g_i, \qquad i = 1,2,\ldots.$$

The expansion for K may be truncated at a finite number of terms, yielding the integral operator R defined by the formula

$$(Rf)(x) = \int_0^1 \sum_{i=1}^n \sum_{j=1}^n (K_{ij}\, b_i(x)\, b_j(t))\, f(t)\, dt, \qquad f \in L^2[0,1], \quad x \in [0,1],$$

which approximates $\mathcal{K}$. Integral equation (9) is thereby approximated by the system

$$f_i - \sum_{j=1}^n K_{ij}\, f_j = g_i, \qquad i = 1, \dots, n, \tag{12}$$

which is a system of n equations in n unknowns. The system (12) may be solved numerically to yield an approximate solution to (9), given by the expression

$$f_R(x) = \sum_{i=1}^n f_i\, b_i(x).$$

How large is the error $e_R = f - f_R$ of the approximate solution? We follow the derivation by Delves and Mohamed in [7]. Defining g_R by the formula

$$g_R(x) = \sum_{i=1}^n g_i\, b_i(x),$$

we rewrite (9) and (12) in terms of operators $\mathcal{K}$ and R to obtain

$$(I - \mathcal{K})f = g,$$
$$(I - R)f_R = g_R.$$

Combining the latter equations yields

$$(I - \mathcal{K})e_R = (\mathcal{K} - R)f_R + (g - g_R).$$

Provided that $(I - \mathcal{K})^{-1}$ exists, we obtain the error bound

$$\|e_R\| \le \|(I - \mathcal{K})^{-1}\| \cdot \|(\mathcal{K} - R)f_R + (g - g_R)\|. \tag{13}$$

The error depends, therefore, on the conditioning of the original integral equation, as is apparent from the term $\|(I - \mathcal{K})^{-1}\|$, on the fidelity of the finite-dimensional operator R to the integral operator $\mathcal{K}$, and on the approximation of g_R to g.

2.2. Representation in multiwavelet bases. We consider integral operators $\mathcal{K}$ with kernels that are analytic, except at $x = t$, where they are singular. In particular, we analyze singularities of the form $\log|x - t|$. An operator with such a kernel K, expanded in one of the multiwavelet bases defined above, is represented as a sparse matrix. This sparseness is due to the smoothness of K on rectangles separated from the "diagonal."

DEFINITION 2.1. We say that a rectangular region oriented parallel to the coordinate axes x, t is *separated from the diagonal* if its distance in the horizontal or vertical direction from the line $x = t$ is at least the length of its longer side. In symbols, a region $[x, x+a] \times [t, t+b] \subset \mathbf{R}^2$ is separated from the diagonal if $a + \max\{a, b\} \le t - x$ or $b + \max\{a, b\} \le x - t$. This definition is illustrated in Fig. 1.

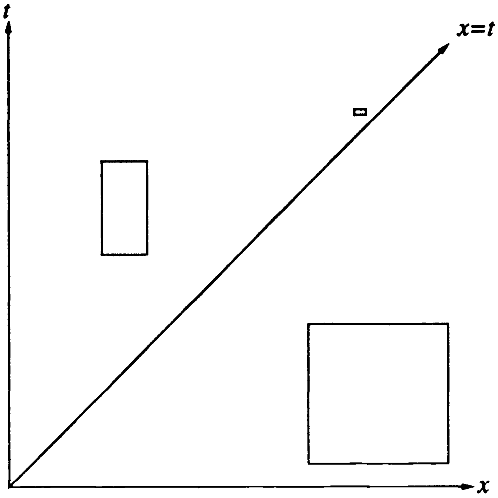

FIG. 1. *Rectangular regions (just) separated from the diagonal.*

Suppose that k is a positive integer and that $B_k = \{b_1, b_2, \ldots\}$ is the multiwavelet basis for $L^2[0,1]$ of order k, defined in §1. We let I_j denote the interval of support of b_j, and we assume that the sequence of basis functions $b_1, b_2, \ldots$ is ordered so that $I_1, I_2, \ldots$ have nonincreasing lengths. For large n, the matrix $\{K_{ij}\}_{i,j=1,\ldots,n}$ is sparse, to high precision, as is proved in the following propositions.

LEMMA 2.2. *Suppose that the function $K : [0,1] \times [0,1] \to \mathbf{R}$ is given by the formula $K(x,t) = \log|x-t|$. The expansion* (10) *of K in the multiwavelet basis B_k of order k has coefficients K_{ij} which satisfy the bound*

$$|K_{ij}| \le \frac{1}{8k \cdot 3^{k-1}} \tag{14}$$

whenever the rectangular region $I_i \times I_j$ is separated from the diagonal.

Proof. Suppose that the intervals I_i and I_j are given by the expressions $I_i = [x_0, x_0 + a]$ and $I_j = [t_0, t_0 + b]$; without loss of generality we assume (as one of two equivalent cases) that $b + \max\{a, b\} \le x_0 - t_0$. It is immediate from this inequality that

$$\left| \frac{x_0 + a/2 - x}{x_0 + a/2 - t} \right| \le \frac{1}{3} \tag{15}$$

for $(x,t) \in I_i \times I_j$.

We use the Taylor expansion for the natural logarithm about $c > 0$,

$$\log(c+y) = \log(c) + \left(\frac{y}{c}\right) - \frac{(y/c)^2}{2} + \frac{(y/c)^3}{3} - \frac{(y/c)^4}{4} + \cdots,$$

for $|y| < c$. We now let $c = x_0 + a/2 - t$ and $y = x - x_0 - a/2$ and for $(x,t) \in I_i \times I_j$ we obtain the formula

$$\log|x-t| = \log\left(x_0 + \left(\frac{a}{2}\right) - t\right) - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{x_0 + a/2 - x}{x_0 + a/2 - t}\right)^m. \tag{16}$$

We now apply (11), (16), (2), and (15), each in turn, to obtain

$$\begin{aligned}
|K_{ij}| &= \left| \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} K(x,t)\, b_i(x)\, b_j(t)\, dx\, dt \right| \\
&\le \int_{t_0}^{t_0+b} \left| \int_{x_0}^{x_0+a} \log|x-t|\, b_i(x)\, dx \right| |b_j(t)|\, dt \\
&= \int_{t_0}^{t_0+b} \left| \int_{x_0}^{x_0+a} \left[\log\left(x_0 + \frac{a}{2} - t\right) \right.\right. \\
&\qquad \left.\left. - \sum_{m=1}^{\infty} \frac{1}{m} \left(\frac{x_0 + a/2 - x}{x_0 + a/2 - t} \right)^m \right] b_i(x)\, dx \right| |b_j(t)|\, dt \\
&\le \int_{t_0}^{t_0+b} \left| \int_{x_0}^{x_0+a} \sum_{m=k}^{\infty} \frac{1}{m} \left(\frac{x_0 + a/2 - x}{x_0 + a/2 - t} \right)^m b_i(x)\, dx \right| |b_j(t)|\, dt \\
&\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} \frac{1}{k} \sum_{m=k}^{\infty} \left(\frac{1}{3} \right)^m |b_i(x)|\, dx\, |b_j(t)|\, dt \\
&\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} \frac{1}{2k \cdot 3^{k-1}} |b_i(x)|\, dx\, |b_j(t)|\, dt \\
&\le \frac{1}{2k \cdot 3^{k-1}} \int_{t_0}^{t_0+b} \sqrt{\left(\int_{x_0}^{x_0+a} {b_i}^2(x)\, dx \right) \left(\int_{x_0}^{x_0+a} 1\, dx \right)}\, |b_j(t)|\, dt \\
&\le \frac{\sqrt{ab}}{2k \cdot 3^{k-1}} \le \frac{1}{8k \cdot 3^{k-1}},
\end{aligned}$$

as was to be proved. □

We now consider a somewhat more general kernel.

LEMMA 2.3. *Suppose that the function $L : D \times D \to \mathbf{C}$ is given by the formula $L(z,w) = f(z,w) \log|z-w| + g(z,w)$, where D is the closed disk of radius $\frac{3}{2}$ centered at $z = \frac{1}{2}$ and f and g are analytic in a domain containing $D \times D \subset \mathbf{C}^2$. Suppose further that the function K is the restriction of L to $[0,1] \times [0,1]$. The expansion of K in the basis B_k has coefficients K_{ij} that satisfy the bound*

$$(17) \qquad |K_{ij}| \le \left(\frac{k}{8} + \frac{3}{16} \right) \frac{1}{3^{k-1}} \sup_{z,w \in \partial D} |f(z,w)| + \frac{2}{7 \cdot 8^k} \sup_{z,w \in \partial D} |g(z,w)|,$$

whenever the rectangular region $I_i \times I_j$ is separated from the diagonal.

Proof. We treat the parts of K separately by defining K' to be the restriction of $f(z,w) \log|z-w|$ to $[0,1] \times [0,1]$ and g' to be the restriction of g, so $K = K' + g'$.

We combine the method of proof used in Lemma 2.2 with the formula for the derivative of a product,

$$(18) \qquad \frac{\partial^m K'(x,t)}{\partial x^m} = \sum_{r=0}^{m} \binom{m}{r} \frac{\partial^r f(x,t)}{\partial x^r} \cdot \frac{\partial^{m-r} \log|x-t|}{\partial x^{m-r}}.$$

By the Cauchy integral formula we obtain

$$(19) \qquad \left| \frac{\partial^r f(x,t)}{\partial x^r} \right| \le r! \sup_{z,w \in \partial D} |f(z,w)|, \qquad \left| \frac{\partial^r g(x,t)}{\partial x^r} \right| \le r! \sup_{z,w \in \partial D} |g(z,w)|$$

for $(x,t) \in [0,1] \times [0,1]$. For the logarithm, differentiation yields the formula

$$\frac{\partial^{m-r} \log|x-t|}{\partial x^{m-r}} = \frac{(-1)^{m-r-1}(m-r-1)!}{(x-t)^{m-r}} \tag{20}$$

for $r < m$. Combining (18), (19), and (20), we obtain

$$\begin{aligned} \left|\frac{\partial^m K'(x,t)}{\partial x^m}\right| &\le \sum_{r=0}^{m} \binom{m}{r} \left|\frac{\partial^r f(x,t)}{\partial x^r}\right| \cdot \left|\frac{\partial^{m-r} \log|x-t|}{\partial x^{m-r}}\right| \\ &\le \sup_{z,w\in\partial D} |f(z,w)| \left(\sum_{r=0}^{m-1} \binom{m}{r} r! \frac{(m-r-1)!}{|x-t|^{m-r}} + m!\,|\log|x-t|| \right) \\ &\le S_f \cdot \left(m!\, \frac{2+\log m}{|x-t|^m} \right) \end{aligned} \tag{21}$$

for $|x-t| \le 1$ and $m \ge 1$, where $S_f = \sup_{z,w\in\partial D} |f(z,w)|$.

Suppose that the intervals I_i and I_j are given by the expressions $I_i = [x_0, x_0 + a]$ and $I_j = [t_0, t_0 + b]$; we assume without loss of generality that $b + \max\{a,b\} \le x_0 - t_0$. It follows directly from this inequality that

$$\left|\frac{x_0 + a/2 - x}{x_0 + a/2 - t}\right| \le \frac{1}{3} \tag{22}$$

for $(x,t) \in I_i \times I_j$. We now apply (11), (2), (21), and (22) to obtain

$$\begin{aligned} |K'_{ij}| &= \left| \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} K'(x,t)\, b_i(x)\, b_j(t)\, dx\, dt \right| \\ &\le \int_{t_0}^{t_0+b} \left| \int_{x_0}^{x_0+a} \sum_{m=0}^{\infty} \frac{(x_0 + a/2 - x)^m}{m!} \frac{\partial^m K'(x_0 + a/2, t)}{\partial x_0{}^m}\, b_i(x)\, dx \right| |b_j(t)|\, dt \\ &\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} \sum_{m=k}^{\infty} \left| \frac{x_0 + a/2 - x}{x_0 + a/2 - t} \right|^m S_f\, (2 + \log m)\, |b_i(x)|\, dx\, |b_j(t)|\, dt \\ &\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} S_f \sum_{m=k}^{\infty} \left(\frac{1}{3}\right)^m (m+1)\, |b_i(x)|\, dx\, |b_j(t)|\, dt \\ &\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} S_f \left(\frac{k}{2} + \frac{3}{4}\right) \frac{1}{3^{k-1}}\, |b_i(x)|\, dx\, |b_j(t)|\, dt \\ &\le S_f \left(\frac{k}{2} + \frac{3}{4}\right) \frac{1}{3^{k-1}} \int_{t_0}^{t_0+b} \sqrt{\left(\int_{x_0}^{x_0+a} b_i{}^2(x)\, dx \right) \left(\int_{x_0}^{x_0+a} 1\, dx \right)}\, |b_j(t)|\, dt \\ &\le S_f \left(\frac{k}{2} + \frac{3}{4}\right) \frac{\sqrt{ab}}{3^{k-1}} \\ &\le S_f \left(\frac{k}{8} + \frac{3}{16}\right) \frac{1}{3^{k-1}}. \end{aligned}$$

For the second term of $K_{ij} = K'_{ij} + g'_{ij}$ we obtain

$$\begin{aligned}
|g'_{ij}| &= \left| \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} g'(x,t)\, b_i(x)\, b_j(t)\, dx\, dt \right| \\
&\le \int_{t_0}^{t_0+b} \left| \int_{x_0}^{x_0+a} g'(x,t)\, b_i(x)\, dx \right| |b_j(t)|\, dt \\
&\le \int_{t_0}^{t_0+b} \int_{x_0}^{x_0+a} \sum_{m=k}^{\infty} \sup_{z,w\in\partial D} |g(z,w)|\, |x - x_0 - a/2|^m\, |b_i(x)|\, dx |b_j(t)|\, dt \\
&\le \int_{t_0}^{t_0+b} \sum_{m=k}^{\infty} \sup_{z,w\in\partial D} |g(z,w)|\, \frac{1}{8^m} \int_{x_0}^{x_0+a} |b_i(x)|\, dx |b_j(t)|\, dt \\
&\le \frac{\sqrt{ab}}{7\cdot 8^{k-1}} \sup_{z,w\in\partial D} |g(z,w)| \\
&\le \frac{2}{7\cdot 8^{k}} \sup_{z,w\in\partial D} |g(z,w)|.
\end{aligned}$$

Combining the estimates for K'_{ij} and g'_{ij} yields (17). □

The preceding lemma shows that for a smooth kernel K with logarithm singularity at $x = t$, the order k of the multiwavelet basis B_k in which K is expanded may be chosen large enough that the expansion coefficient K_{ij} is negligible, provided $I_i \times I_j$ is separated from the diagonal. As mentioned above, a similar statement can be proven for any kernel of the form $K(x,t) = f(x,t)\, s(|x-t|) + g(x,t)$, where f, g are entire analytic functions of two variables and s is an analytic function except at the origin (where it has a singularity), provided that s is integrable. More generally, any Calderon–Zygmund or pseudodifferential operator can be similarly expressed (see [4]).

The next lemma establishes the fact that, asymptotically, most regions $I_i \times I_j$ *are* separated from the diagonal.

LEMMA 2.4. *Suppose that* $I_1, \ldots, I_n$ *are the* (*nonincreasing*) *intervals of support of the first* n *functions of the basis* B_k. *Of the* n^2 *rectangular regions* $I_i \times I_j$, *we denote the number separated from the diagonal by* $S(n)$ *and the number "near" the diagonal by* $N(n) = n^2 - S(n)$. *Then* $N(n)$ *grows as* $O(n \log n)$; *in particular, for* $n = 2^l k$ *with* $l > 0$, *we have the formula*

$$N(n) = 6nlk - 15nk - 6lk^2 + 16k^2. \tag{23}$$

Proof. The restriction that $n = 2^l k$ ensures that the first n basis functions consist of those functions whose intervals of support have length at least 2^{1-l}. We define $S_1(p)$ to be the number of pairs (i,j) such that the rectangular region $I_i \times I_j$ is separated from the diagonal and $|I_i| = |I_j| = 2^{-p}$, and we observe that $S_1(p) = (2^p - 1)(2^p - 2)k^2$ for $p = 0, 1, 2, \ldots$. We further define $S_2(p,q)$ to be the number of pairs (i,j) such that $I_i \times I_j$ is separated from the diagonal and $|I_i| = 2^{-p}$, $|I_j| = 2^{-q}$, and we observe that $S_2(p,q) = S_1(\min\{p,q\})\, 2^{|p-q|}$ for $p, q = 0, 1, 2, \ldots$. Finally, we combine these formulae to obtain

$$
\begin{aligned}
S(n) &= \sum_{p=0}^{l-1} \left(S_1(p) + \sum_{q=p+1}^{l-1} (S_2(p,q) + S_2(q,p)) \right) \\
&= \sum_{p=0}^{l-1} S_1(p)\ (1 + 2(2^{l-p} - 2)) \\
&= \sum_{p=0}^{l-1} (2^p - 1)(2^p - 2)\, k^2\, (2^{l-p+1} - 3) \\
&= (4^l - 6 \cdot 2^l l + 15 \cdot 2^l + 6l - 16)\, k^2 \\
&= n^2 - 6nlk + 15nk + 6lk^2 - 16k^2,
\end{aligned}
$$

from which (23) follows directly. The assertion that the general growth of $N(n)$ is $O(n \log n)$ follows from (23) and the fact that N is a monotonic function of n. □

3. Numerical examples and discussion.

3.1. Basis functions. In this section we give numerical expressions for the multiwavelet functions $f_0, f_1, \ldots, f_{k-1}$ and show their graphs for several values of k. These functions were obtained using the procedure of §1, implemented in a simple Maple program (available from the author). Table 1 contains, for small k, the polynomials that represent the f_i on the interval $(0,1)$, together with the reflection formula to extend the functions to $(-1,1)$, which is their interval of support. Figure 2 shows the graphs of the functions for $k = 4$ and $k = 5$.

3.2. Integral operators and their inverses. We compute the expansion in multiwavelet bases of the integral operator $\mathcal{K}$ defined by the formula

$$(\mathcal{K}f)(x) = \int_0^1 \log|x - t|\, f(t)\, dt, \tag{24}$$

which yields the matrix

$$K^{(n)} = \{K_{ij}\}_{i,j=1,\ldots,n},$$

where

$$K_{ij} = \int_0^1 \int_0^1 K(x,t)\, b_i(x)\, b_j(t)\, dx\, dt$$

and $\{b_1, b_2, \ldots\}$ are a multiwavelet basis of $L^2[0,1]$. We approximate $K^{(n)}$ with a matrix $T^{(n)}$ whose elements are defined by the formula

$$T_{ij}^{(n)} = \begin{cases} K_{ij}, & \text{if } |K_{ij}| \geq \tau, \\ 0, & \text{otherwise,} \end{cases} \tag{25}$$

where the threshold τ is chosen so that a desired precision ϵ is maintained: $\|T^{(n)} - K^{(n)}\| \leq \epsilon \|K^{(n)}\|$. Here the norm $\|\cdot\|$ is the row-sum norm, $\|A\| = \max_i \sum_{j=1}^n |A_{ij}|$. The threshold τ is given by $\tau = \epsilon \|K^{(n)}\|/n$. This computation was performed for the multiwavelet basis of order $k = 4$, for various sizes n, as shown in Table 2.

An interesting property of many operators of second-kind integral equations is that their inverses, when they exist, are also sparse in multiwavelet coordinates (to

high precision). The operator $(I-K)^{-1}$ has the Neumann expansion $\sum_{i=0}^{\infty} K^i$, which converges if $\|K\| < 1$; thus $(I-K)^{-1}$ may be approximated to arbitrary precision by a polynomial in K. More generally (regardless of $\|K\|$), $(I-K)^{-1} = A\sum_{i=0}^{\infty}(I-(I-K)A)^i$, where $A = (I-K^H)/\|(I-K^H)(I-K)\|$. The Schulz method [16] (see also [2]), a classical iterative matrix inversion technique, can be used to compute the first 2^m terms of this expansion with m iterations. Analogous to Newton iteration, the mth Schulz iterate X_m to invert a matrix M is given by $X_m = 2X_{m-1} - X_{m-1}\,M\,X_{m-1}$, where $X_0 = M^H/\|M^H M\|$. The iterates satisfy the equation $I - X_m M = (I - X_{m-1}M)^2$, which assures their quadratic convergence to M^{-1}.

The terms K^i and $((I-K^H)(I-K))^i$, of which these expansions are composed, have representations in multiwavelets that are asymptotically sparse. Specifically, their $n \times n$-matrix representations, after thresholding, contain only order $O(n \log n)$ nonzero elements. This fact follows from arguments similar to those given in Lemmas 2.2 and 2.3. It is important to add, however, that the constants in these asymptotic estimates may not ensure useful sparsity for reasonable values of n.

For the operator $T^{(n)}$ defined above, the inverse $(I-T^{(n)})^{-1}$ is roughly as sparse as $I-T^{(n)}$. We have computed it by the Schulz method. Table 2 displays, for various precisions ϵ, the average number of elements per row in the matrices $I-T^{(n)}$ and $(I-T^{(n)})^{-1}$. Figure 3 displays the matrices for $n = 128$ and $\epsilon = 10^{-3}$.

3.3. Discussion. The results of the previous subsection demonstrate, for a particular integral operator, that the multiwavelet representations are sparse. The matrix has a peculiar structure in which the nonnegligible elements are contained in blocks lying along rays emanating from one corner of the matrix. Furthermore, the inverse

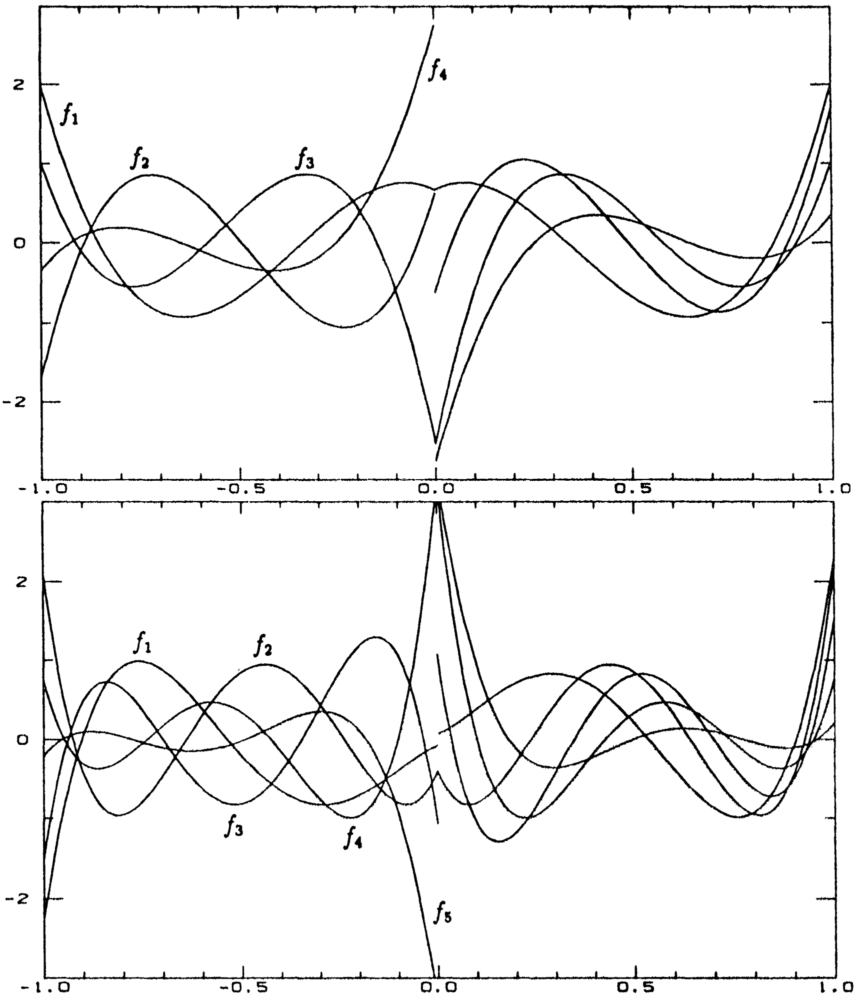

FIG. 2. *Functions $f_1, \ldots, f_k$ are graphed for $k = 4$ (top graph) and $k = 5$ (bottom). Each function (given in Table 1) is a polynomial on the interval $(0, 1)$, is an odd or even function on $(-1, 1)$, and is zero elsewhere.*

matrix shares that structure. This property is a general characteristic of integral operators with nonoscillatory kernels that possess diagonal singularities.

The kernel $K(x,t) = \log|x - t|$ of the previous subsection was chosen, however, because the projections K_{ij} could be computed analytically, thereby avoiding use of quadratures. The difficulty here with quadratures is that they would be required for each element K_{ij}, and would have to cope with the singularity of the logarithm. It was felt that the analytical computation would be more efficient. In fact, the analytical computation, which requires integrating monomials x^j $(0 \leq j < k)$ against the logarithm and combining the results with large coefficients, is a very poorly-conditioned procedure. The computations described above required quadruple-precision arithmetic to obtain single-precision accuracy for n as small as 64. This procedure is not recommended.

TABLE 2

The average number of elements per row of the matrices $S^{(n)} = I - T^{(n)}$ and $(S^{(n)})^{-1}$, where $T^{(n)}$ is defined in (25), is tabulated for various precisions ϵ and various sizes n. Here $k = 4$.

	$\epsilon = 10^{-2}$		$\epsilon = 10^{-3}$		$\epsilon = 10^{-4}$	
n	$S^{(n)}$	$(S^{(n)})^{-1}$	$S^{(n)}$	$(S^{(n)})^{-1}$	$S^{(n)}$	$(S^{(n)})^{-1}$
32	8.8	9.7	19.3	19.6	22.8	23.6
64	9.3	10.0	25.8	26.0	31.9	32.6
128	9.9	10.1	29.2	29.4	38.2	38.8
256	11.8	11.8	30.1	30.3	41.9	42.7

The fault lies, of course, not with the idea of projection to the multiwavelet basis, but with the method of projection. The integration should be performed numerically, with quadratures. As mentioned above, such a procedure would require use of quadratures for each matrix element K_{ij}, or potentially order $O(n \log n)$ times. A more efficient procedure is to use the Nyström method, in which only n quadrature applications are required. Numerical quadratures and a vector-space analogue of the multiwavelet bases are developed in [1], [2]; these tools enable efficient solution of second-kind integral equations using Nyström's method. We believe that the present paper, rather than directly providing numerical tools, offers a particularly simple framework in which to understand the ideas for sparse representation of integral operators.

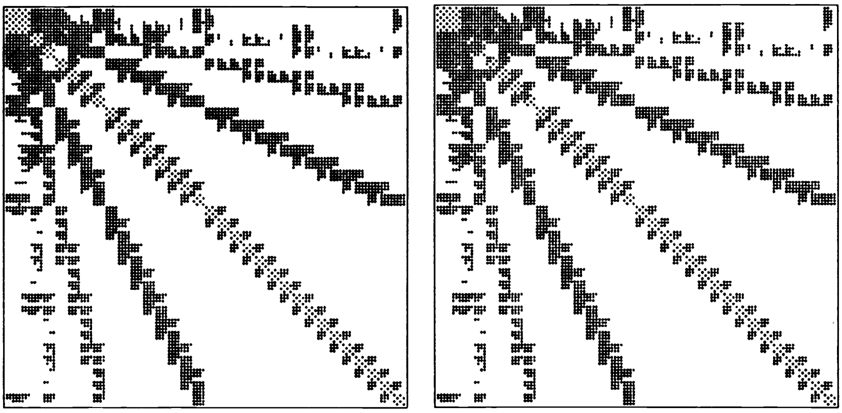

FIG. 3. *Matrices representing the operators $I - \mathcal{K}$ (left) and $(I - \mathcal{K})^{-1}$ (right), with $\mathcal{K}$ defined by (24), expanded in the multiwavelet basis of order $k = 4$, for $n = 128$. The dots represent elements above a threshold, which is determined so as to bound the relative truncation error at $\epsilon = 10^{-3}$.*

Acknowledgment. The bases constructed in this paper are the limiting case of the discrete construction in [2]; thanks to R. Coifman for prodding this author to consider the limit, which surprised us with its simplicity.

INEQUALITIES OF LITTLEWOOD–PALEY TYPE FOR FRAMES AND WAVELETS*

CHARLES K. CHUI[†] AND XIANLIANG SHI[†‡]

Abstract. Inequalities of Littlewood–Paley type for frames in both the wavelet and Weyl–Heisenberg settings, and those for any unconditional basis of the form $\psi_{j,k}(x) = 2^{\frac{j}{2}}\psi(2^j x - k)$, are established. In particular, if $\{\psi_{j,k}\}$ is a semi-orthogonal basis, then the Littlewood–Paley identity is obtained. A similar identity for the "biorthogonal wavelets" of Cohen, Daubechies, and Feauveau is also obtained.

Key words. Littlewood–Paley inequalities, frames, frame bounds, wavelets, biorthogonal wavelets

AMS(MOS) subject classifications. 41A17, 42C15

1. Introduction and results.

The objective of this paper is to establish certain inequalities and identities of Littlewood–Paley type and to discuss some of their important consequences. This section is devoted to introducing the necessary definitions and notation and to a discussion of the main results in this paper. For the sake of clarity, it will be divided into two subsections: with the first one on frames and the second one on wavelets.

1.1. Inequalities for frames.

The notion of frames was introduced by Duffin and Schaeffer [6] in their work on nonharmonic analysis. For the Hilbert space $L^2 := L^2(-\infty,\infty)$, a family of functions $\phi_k \in L^2$, $k \in \mathbb{Z}$, is said to be a frame of L^2 if there exist two positive constants, C_1 and C_2, with $0 < C_1 \le C_2 < \infty$, such that

$$C_1\|f\|^2 \le \sum_{k\in\mathbb{Z}} |\langle f, \phi_k\rangle|^2 \le C_2\|f\|^2 \tag{1.1}$$

for all $f \in L^2$. Here and throughout, $\|f\|$ denotes the L^2-norm of f. A frame $\{\phi_k\}$ is called a tight frame, if $C_1 = C_2$ (cf. [5], [6]). Note that even a tight frame with $C_1 = C_2 = 1$ is not necessarily a basis of L^2. For instance, if $\{\eta_k\}$, $k \in \mathbb{Z}$, is an orthonormal basis of L^2 and $\{\alpha_k\}$, $k \in \mathbb{Z}$, is any sequence of real numbers, then the family $\{\eta_k \cos\alpha_k, \eta_k \sin\alpha_k\}$, $k \in \mathbb{Z}$, which is certainly not a basis of L^2, is, however, a tight frame of L^2 with $C_1 = C_2 = 1$. Observe that $\{\alpha_k\}$ may be so chosen that every function in this nonbasis tight frame is nontrivial.

In this paper, we will only consider frames that are generated by a single function. Two types of such frames are of particular interest:

(i) *s.t. frames* (or frames generated by *scaling* and *translation* of a function $\psi \in L^2$) defined by:

$$(S_{j,k}\psi)(x) := a^{\frac{j}{2}}\psi(a^j x - kb), \qquad j,k \in \mathbb{Z}, \tag{1.2}$$

*Received by the editors May 28, 1991; accepted for publication (in revised form) April 21, 1992. This research was supported by National Science Foundation grants DMS-89-01345 and INT-87-12424.

where $a > 1$ and $b > 0$ are (fixed) constants, and

(ii) *w.h. frames* (or frames of Weyl–Heisenberg type, generated by a function $\phi \in L^2$) defined by

$$(H_{j,k}\phi)(x) := e^{ijpx}\phi(x - kq), \qquad j,k \in \mathbb{Z}, \tag{1.3}$$

where $p, q > 0$ and $pq \le 2\pi$.

1.1.1. s.t. frames. Let us first study s.t. frames. For any function $\psi \in L^2$, set

$$\psi_j(x) := a^j\overline{\psi(-a^jx)}, \qquad j \in \mathbb{Z}, \tag{1.4}$$

where again $a > 1$ is fixed. Then we have the so-called "semidiscrete integral wavelet transform":

$$(W_jf)(x) = (f * \psi_j)(x), \qquad j \in \mathbb{Z}, \quad f \in L^2, \tag{1.5}$$

where $*$ denotes the integral convolution on $(-\infty, \infty)$ (cf. [8], [9]). For this transform to have any practical value, it must be "stable"; and by this, we mean the existence of constants A and B, with $0 < A \le B < \infty$, such that

$$A\|f\|^2 \le \sum_{j\in\mathbb{Z}} \|W_jf\|^2 \le B\|f\|^2, \qquad f \in L^2. \tag{1.6}$$

On the other hand, in signal analysis, since ψ has the property of a bandpass filter, in order to be able to reconstruct the original signal from its wavelet transform (1.5), the function ψ must satisfy

$$A \le \sum_{j\in\mathbb{Z}} |\widehat{\psi}(a^j\omega)|^2 \le B \quad \text{a.e.}, \tag{1.7}$$

where $\widehat{\psi}$ is the Fourier transform of ψ, defined by

$$\widehat{\psi}(\omega) = \int_{-\infty}^{\infty} e^{-ix\omega}\psi(x)dx.$$

In fact, it is easy to see that (1.6) and (1.7) are equivalent, with the same constants A and B.

To generate an s.t. frame, we further discretize the transform W_jf in (1.5) by defining $S_{j,k}\psi$ as in (1.2), using another parameter $b > 0$. Then analogous to the stability condition (1.6) for semidiscrete integral wavelet transforms, we require

$$\psi_{j,k}(x) := (S_{j,k}\psi)(x) = a^{\frac{j}{2}}\psi(a^jx - kb) \tag{1.8}$$

to satisfy the frame condition:

$$A'\|f\|^2 \le \sum_{j,k\in\mathbb{Z}} |\langle f, \psi_{j,k}\rangle|^2 \le B'\|f\|^2, \qquad f \in L^2, \tag{1.9}$$

where $0 < A' \le B' < \infty$. Our result on s.t. frames is then an analogue of (1.7), as follows.

THEOREM 1. *Let $\{\psi_{j,k}\}$, as defined in* (1.8) *for some $a > 1$ and $b > 0$, be a frame of L^2 with frame bounds A' and B' as in* (1.9). *Then $\widehat{\psi}$ satisfies*

$$A' \leq \frac{1}{b}\sum_{j\in\mathbb{Z}}|\widehat{\psi}(a^j\omega)|^2 \leq B' \quad a.e., \tag{1.10}$$

for the same constants A' and B'.

From (1.10), we can easily derive other interesting inequalities. For instance, by integrating each term in

$$\frac{A'}{|\omega|} \leq \frac{1}{b}\sum_{j\in\mathbb{Z}}\frac{|\widehat{\psi}(a^j\omega)|^2}{|\omega|} \leq \frac{B'}{|\omega|}$$

over $1 \leq |\omega| \leq a$, we have

$$2A'\log a \leq \frac{1}{b}\sum_{j\in\mathbb{Z}}\int_{1\leq|\omega|\leq a}\frac{|\widehat{\psi}(a^j\omega)|^2}{|\omega|}d\omega \leq 2B'\log a,$$

which immediately yields

$$A' \leq \frac{1}{2b\log a}\int_{-\infty}^{\infty}\frac{|\widehat{\psi}(\omega)|^2}{|\omega|}d\omega \leq B'. \tag{1.11}$$

We remark that the so-called "compactibility condition" (1.11) for s.t. frames was also derived by Daubechies [5] by using techniques from trace-class operators. In addition, Daubechies [5] also observed that under the assumptions of Theorem 1, the quantity

$$\sum_{j\in\mathbb{Z}}|\widehat{\psi}(a^j\omega)|^2$$

is bounded from above and below by some positive constants. The contribution in Theorem 1 is that these constants are given by the frame bounds.

1.1.2. w.h. frames. For a function $\phi \in L^2$, consider the semidiscrete window Fourier transform (also known as short-time Fourier transform):

$$(F_jf)(x) = \int_{-\infty}^{\infty}e^{-ijpt}\overline{\phi(t-x)}f(t)dt, \qquad f \in L^2, \tag{1.12}$$

where $p > 0$ is a fixed constant. Then analogous to (1.6), the stability of the transform (1.12) is defined by the requirement:

$$C\|f\|^2 \leq \sum_{j\in\mathbb{Z}}\|F_jf\|^2 \leq D\|f\|^2, \qquad f \in L^2, \tag{1.13}$$

for some $0 < C \leq D < \infty$, independent of f. It is not difficult to see that (1.13) is equivalent to

$$C \leq \sum_{j\in\mathbb{Z}}|\hat{\phi}(\omega - jp)|^2 \leq D \quad \text{a.e.}, \tag{1.14}$$

for the same constants C and D. Further discretization of the transform $F_j f$ in (1.12) results in introducing

$$\phi^{j,k}(x) := (H_{j,k}\phi)(x) = e^{ijpx}\phi(x - kq), \tag{1.15}$$

as defined by (1.3), where $q > 0$ is the second discretization constant satisfying

$$0 < pq \leq 2\pi \tag{1.16}$$

(cf. [5] for the requirement of (1.16)). For $\{\phi^{j,k}\}$ to be a frame, we need constants $0 < C' \leq D' < \infty$, such that

$$C'\|f\|^2 \leq \sum_{j,k\in\mathbb{Z}} |\langle f, \phi^{j,k}\rangle|^2 \leq D'\|f\|^2, \qquad f \in L^2. \tag{1.17}$$

Our result on w.h. frames in this paper is the following inequalities, which are along the same line of (1.14).

THEOREM 2. *Let* $\{\phi^{j,k}\}$*, as defined in* (1.15) *for some* $p, q > 0$ *satisfying* (1.16)*, be a frame of* L^2 *with frame bounds* C' *and* D' *as in* (1.17)*. Then* ϕ *and* $\hat{\phi}$ *satisfy*

$$C' \leq \frac{1}{q}\sum_{j\in\mathbb{Z}} |\hat{\phi}(\omega - jp)|^2 \leq D', \quad \textit{and} \tag{1.18}$$

$$C' \leq \frac{2\pi}{p}\sum_{j\in\mathbb{Z}} |\phi(x - jq)|^2 \leq D' \quad \textit{a.e.}, \tag{1.19}$$

for the same constants C' *and* D'*.*

1.2. Results on wavelets. In the following, we will set $a = 2$ and $b = 1$ in the definition of $\psi_{j,k}$ in (1.8); that is, we will consider

$$\psi_{j,k}(x) = 2^{\frac{j}{2}}\psi(2^j x - k), \qquad j, k \in \mathbb{Z}. \tag{1.20}$$

Furthermore, we will also assume that $\{\psi_{j,k}\}$ in (1.20) is an unconditional basis of L^2 with constants $0 < K \leq L < \infty$, namely: it is complete and satisfies

$$K \sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2 \leq \left\| \sum_{j,k\in\mathbb{Z}} a_{j,k}\psi_{j,k} \right\|^2 \leq L \sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2 \tag{1.21}$$

for all $\{a_{j,k}\} \in \ell^2(\mathbb{Z}^2)$. However, this assumption does not guarantee that the dual basis $\{\psi^*_{j,k}\}$, relative to $\{\psi_{j,k}\}$, defined by

$$\psi^*_{j,k} \in L^2 \quad \text{and} \quad \langle \psi_{j,k}, \psi^*_{\ell,m}\rangle = \delta_{j,\ell}\delta_{k,m}, \tag{1.22}$$

is obtained by dyadic dilations and integral translations of a single function in the same manner as $\{\psi_{j,k}\}$ from ψ. We will give an elementary proof of this somewhat surprising result in §3. If it so happens that

$$\psi^*_{j,k} = \widetilde{\psi}_{j,k}, \qquad j, k \in \mathbb{Z}, \tag{1.23}$$

where

$$\widetilde{\psi}_{j,k}(x) := 2^{\frac{j}{2}}\widetilde{\psi}(2^j x - k) \tag{1.24}$$

for some $\widetilde{\psi} \in L^2$, then we will call $\widetilde{\psi}$ the "dual" of ψ. Since $\{\widetilde{\psi}_{j,k}\}$ is clearly an unconditional basis of L^2, it follows that ψ is the dual of $\widetilde{\psi}$, also. Observe that if ψ is an "orthonormal wavelet" in the sense that $\{\psi_{j,k}\}$ is an orthonormal basis of L^2, then ψ is self-dual with $\widetilde{\psi} = \psi$.

As a consequence of Theorem 1, we have the following inequalities of Littlewood–Paley type.

COROLLARY 3. *Let $\{\psi_{j,k}\}$, as defined in (1.20), be an unconditional basis of L^2, with bounds K and L as given in (1.21). Then the Fourier transform $\widehat{\psi}$ of ψ satisfies*

$$K \le \sum_{j\in\mathbb{Z}} |\widehat{\psi}(2^j\omega)|^2 \le L \quad a.e., \tag{1.25}$$

and consequently,

$$K \le \frac{1}{2\log 2}\int_{-\infty}^{\infty} \frac{|\widehat{\psi}(\omega)|^2}{|\omega|}d\omega \le L. \tag{1.26}$$

Furthermore, if ψ is a wavelet with dual $\widetilde{\psi}$ as defined in (1.22)–(1.24), then $\{\widetilde{\psi}_{j,k}\}$ is also an unconditional basis of L^2 with bounds L^{-1} and K^{-1}, and consequently,

$$L^{-1} \le \sum_{j\in\mathbb{Z}} |\widehat{\widetilde{\psi}}(2^j\omega)|^2 \le K^{-1} \quad a.e., \tag{1.27}$$

and

$$L^{-1} \le \frac{1}{2\log 2}\int_{-\infty}^{\infty} \frac{|\widehat{\widetilde{\psi}}(\omega)|^2}{|\omega|}d\omega \le K^{-1}. \tag{1.28}$$

There are two special cases that are of particular importance. We will discuss them separately.

1.2.1. Semi-orthogonal wavelets. Let $\{\psi_{j,k}\}$ be an unconditional basis of L^2 generated by some function ψ, as governed by (1.20) and (1.21). For each $j \in \mathbb{Z}$, set

$$W_j = \operatorname{clos}_{L^2} \operatorname{span}\{\psi_{j,k}\colon\ k \in \mathbb{Z}\}. \tag{1.29}$$

Then we say that ψ is a *"semi-orthogonal wavelet"* if

$$W_j \perp W_\ell, \qquad j,\ell \in \mathbb{Z}, \quad j \neq \ell. \tag{1.30}$$

The dual $\widetilde{\psi}$ of a semi-orthogonal wavelet ψ is easily obtained via the Fourier transform, namely

$$\widehat{\widetilde{\psi}}(\omega) = \frac{\widehat{\psi}(\omega)}{\Psi(\omega)}, \tag{1.31}$$

where

$$\Psi(\omega) := \sum_{j\in\mathbb{Z}} |\widehat{\psi}(\omega + 2\pi j)|^2. \tag{1.32}$$

By giving up the orthogonality of $\{\psi_{0,k}\colon\ k \in \mathbb{Z}\}$ it is possible to construct compactly supported ψ with certain desirable properties. For instance, the compactly supported spline-wavelets of Chui and Wang in [1] are symmetric for splines of even order and anti-symmetric for splines of order. In addition, explicit formulas of compactly supported semi-orthogonal spline wavelets and their duals were given in Chui and Wang [1], and a characterization of all the compactly supported ones in [2]. For this type of wavelets, we have the following result.

THEOREM 4. *Let ψ be a semi-orthogonal wavelet with dual $\tilde{\psi}$. Then*

$$\sum_{j\in\mathbb{Z}} \overline{\widehat{\psi}(2^j\omega)}\ \widehat{\tilde{\psi}}(2^j\omega) = 1 \quad a.e., \tag{1.33}$$

and consequently,

$$\int_{-\infty}^{\infty} \frac{\overline{\widehat{\psi}(\omega)}\ \widehat{\tilde{\psi}}(\omega)}{|\omega|} d\omega = 2\log 2. \tag{1.34}$$

In particular, if ψ is an orthonormal wavelet so that $\tilde{\psi} = \psi$, then its Fourier transform satisfies

$$\sum_{j\in\mathbb{Z}} |\widehat{\psi}(2^j\omega)|^2 = 1 \quad \text{a.e.}, \tag{1.35}$$

and

$$C_\psi := \int_{-\infty}^{\infty} \frac{|\widehat{\psi}(\omega)|^2}{|\omega|} d\omega = 2\log 2. \tag{1.36}$$

1.2.2. Nonorthogonal wavelets. Wavelets without any orthogonality structure have even more flexibility. For instance, examples of those ψ and their duals $\tilde{\psi}$ in $C^n(-\infty,\infty)$, where $n \in \mathbb{Z}_+$ is arbitrary, both with symmetry and compact support, have been constructed recently by Cohen, Daubechies, and Feauveau [4]. Following Cohen [3], we let $m_0(\omega)$ and $\tilde{m}_0(\omega)$ be two 2π-periodic Lip(α) continuous functions, $0 < \alpha < 1$, satisfying

$$\begin{gathered} \overline{m_0(\omega)}\tilde{m}_0(\omega) + \overline{m_0(\omega+\pi)}\tilde{m}_0(\omega+\pi) = 1; \\ m_0(0) = \tilde{m}_0(0) = 1; \qquad m_0(\pi) = \tilde{m}_0(\pi) = 1. \end{gathered} \tag{1.37}$$

Suppose that ϕ and $\tilde{\phi}$, defined by

$$\begin{aligned} \hat{\phi}(\omega) &= \prod_{j=1}^{\infty} m_0\left(\frac{\omega}{2^j}\right), \\ \hat{\tilde{\phi}}(\omega) &= \prod_{j=1}^{\infty} \tilde{m}_0\left(\frac{\omega}{2^j}\right), \end{aligned} \tag{1.38}$$

satisfy

$$|\phi(x)| + |\tilde{\phi}(x)| \le \frac{C}{1+|x|^{1+\varepsilon}}, \qquad x \in (-\infty,\infty),$$

for some $\varepsilon, C > 0$. Then ψ is a wavelet with dual $\widetilde{\psi}$, where

$$\begin{cases} \widehat{\psi}(\omega) = e^{-i\frac{\omega}{2}}\overline{\widetilde{m}_0\left(\frac{\omega}{2}+\pi\right)}\hat{\phi}\left(\frac{\omega}{2}\right), \\ \widehat{\widetilde{\psi}}(\omega) = e^{-i\frac{\omega}{2}}\overline{m_0\left(\frac{\omega}{2}+\pi\right)}\hat{\tilde{\phi}}\left(\frac{\omega}{2}\right), \end{cases} \tag{1.39}$$

in the sense that $\{\psi_{j,k}\}$ and $\{\widetilde{\psi}_{j,k}\}$, defined by (1.20) and (1.24), are both unconditional bases of L^2, such that

$$\langle \psi_{j,k}, \widetilde{\psi}_{\ell,m}\rangle = \delta_{j,\ell}\delta_{k,m},$$

(cf. Cohen [3]). Although this ψ is not semi-orthogonal, its Fourier transform still satisfies the same Littlewood–Paley identity, as follows.

THEOREM 5. *Let ψ be a wavelet with dual $\widetilde{\psi}$ as defined by* (1.37)–(1.39). *Then*

$$\sum_{j\in\mathbb{Z}} \overline{\widehat{\psi}(2^j\omega)}\;\widehat{\widetilde{\psi}}(2^j\omega) = 1, \qquad \omega \in \mathbf{R}, \tag{1.40}$$

and consequently,

$$\int_{-\infty}^{\infty} \frac{\overline{\widehat{\psi}(\omega)}\;\widehat{\widetilde{\psi}}(\omega)}{|\omega|} d\omega = 2\log 2. \tag{1.41}$$

Remark. For an orthonormal wavelet ψ, identity (1.35) is called the Littlewood–Paley identity. Hence, the results in (1.33) and (1.40) may be called Littlewood–Paley identities also. The significance of these identities is that when $\widetilde{\psi}$ is considered as a bandpass filter, so that $\{\widetilde{\psi}_{j,k}\}$ gives rise to a filter bank decomposition, the wavelet ψ can be used for perfect reconstruction. In other words, the pair $(\psi, \widetilde{\psi})$ constitutes an allpass filter as demonstrated by (1.33) and (1.40). We also remark that the value of C_ψ in (1.36) is needed in the reconstruction formula (from the integral wavelet transform) of Grossmann and Morlet.

2. Proofs.

In this section, we establish all the results stated in §1.

2.1. Proof of Theorem 1.

By (1.2), we have, for any $f \in L^2$,

$$\begin{aligned} \langle f, \psi_{j,k}\rangle &= a^{\frac{j}{2}} \int_{-\infty}^{\infty} f(x)\overline{\psi(a^j x - kb)}dx \\ &= \frac{1}{2\pi} a^{\frac{j}{2}} \int_{-\infty}^{\infty} \hat{f}(a^j\omega)\overline{\widehat{\psi}(\omega)}e^{ikb\omega}d\omega. \end{aligned}$$

Hence, by setting

$$T := \frac{2\pi}{b}, \tag{2.1}$$

we have

$$\begin{aligned}\sum_{j,k\in\mathbb{Z}}|\langle f,\psi_{j,k}\rangle|^2 &= \sum_{j\in\mathbb{Z}}\frac{a^j}{4\pi^2}\sum_{k\in\mathbb{Z}}\left|\int_{-\infty}^{\infty}\hat{f}(a^j\omega)\overline{\hat{\psi}(\omega)}e^{ikb\omega}d\omega\right|^2\\
&= \sum_{j\in\mathbb{Z}}\frac{a^jT^2}{4\pi^2}\sum_{k\in\mathbb{Z}}\left|\frac{1}{T}\int_0^T\left[\overline{\sum_{\ell\in\mathbb{Z}}\hat{f}(a^j(\omega+\ell T))\hat{\psi}(\omega+\ell T)}\right]e^{ik\frac{2\pi}{T}\omega}d\omega\right|^2 \qquad (2.2)\\
&= \sum_{j\in\mathbb{Z}}\frac{a^j}{2\pi b}\int_0^T\left|\sum_{\ell\in\mathbb{Z}}\hat{f}(a^j(\omega+\ell T))\overline{\hat{\psi}(\omega+\ell T)}\right|^2 d\omega.\end{aligned}$$

Therefore, it follows from (1.9) and (2.2) that

$$A'\|\hat{f}\|^2 \le \sum_{j\in\mathbb{Z}}\frac{a^j}{b}\int_0^T\left|\sum_{\ell\in\mathbb{Z}}\hat{f}(a^j(\omega+\ell T))\overline{\hat{\psi}(\omega+\ell T)}\right|^2 d\omega \le B'\|\hat{f}\|^2, \tag{2.3}$$

so that for any $M > 0$, $M \in Z$, and $\omega_0 \in (-\infty,\infty)$, we have

$$\sum_{j=-M}^{M}\frac{a^j}{b}\int_{a^{-j}\omega_0-\frac{T}{2}}^{a^{-j}\omega_0+\frac{T}{2}}\left|\sum_{\ell\in\mathbb{Z}}\hat{f}(a^j(\omega+\ell T))\overline{\hat{\psi}(\omega+\ell T)}\right|^2 d\omega \le B'\|\hat{f}\|^2.$$

Now, consider $\hat{f} = (1/\sqrt{2\varepsilon})\chi_{[\omega_0-\varepsilon,\omega_0+\varepsilon]}$, $\varepsilon > 0$. Then for sufficiently small ε, the above inequality becomes

$$\sum_{j=-M}^{M}\frac{a^j}{2\varepsilon b}\int_{a^{-j}(\omega_0-\varepsilon)}^{a^{-j}(\omega_0+\varepsilon)}|\hat{\psi}(\omega)|^2 d\omega \le B',$$

and thus, by taking $\varepsilon \to 0$ and $M \to \infty$ consecutively, we have

$$\frac{1}{b}\sum_{j\in\mathbb{Z}}|\hat{\psi}(a^j\omega)|^2 \le B' \quad \text{a.e.} \tag{2.4}$$

On the other hand, for any ω_0, $\eta > 0$, a positive integer M may be chosen so that

$$\int_{2a^M\omega_0(1+a)^{-1}}^{\infty}|\hat{\psi}(\omega)|^2 d\omega < \eta. \tag{2.5}$$

Also, for

$$0 < \varepsilon < \min\left\{\frac{a-1}{a+1}\omega_0, \frac{T}{2}\right\},$$

the function $\hat{f} = (1/\sqrt{2\varepsilon})\chi_{[\omega_0-\varepsilon,\omega_0+\varepsilon]}$ satisfies

$$\hat{f}(a^j(\omega+\ell T)) = 0$$

for all $\ell \in \mathbb{Z}$ with $|\ell| \geq (\varepsilon/a^j T)+1$ and all $\omega \in [a^{-j}\omega_0-(T/2), a^{-j}\omega_0+(T/2)]$. Hence, for this $\hat{f}$, we have

$$\begin{aligned}
&\sum_{j=-\infty}^{-M} \frac{a^j}{b} \int_{a^{-j}\omega_0-\frac{T}{2}}^{a^{-j}\omega_0+\frac{T}{2}} \left| \sum_{\ell\in\mathbb{Z}} \hat{f}(a^j(\omega+\ell T))\overline{\widehat{\psi}(\omega+\ell T)} \right|^2 d\omega \\
&\leq \sum_{j=-\infty}^{-M} \frac{a^j}{2\varepsilon b} \int_{a^{-j}\omega_0-\frac{T}{2}}^{a^{-j}\omega_0+\frac{T}{2}} \\
&\qquad \left[\sum_{\ell\in\mathbb{Z}} |\widehat{\psi}(\omega+\ell T)|^2 \chi_{[\omega_0-\varepsilon,\omega_0+\varepsilon]}(a^j(\omega+\ell T)) \right] \left(\frac{\varepsilon}{a^j T}+1 \right) d\omega \\
&\leq C \sum_{j=-\infty}^{-M} \int_{a^{-j}(\omega_0-\varepsilon)}^{a^{-j}(\omega_0+\varepsilon)} \left\{ |\widehat{\psi}(\omega)|^2 + \frac{a^j}{2\varepsilon}|\widehat{\psi}(\omega)|^2 \right\} d\omega.
\end{aligned} \tag{2.6}$$

Since $\varepsilon < (a-1/a+1)\omega_0$, the intervals

$$[a^{-j}(\omega_0-\varepsilon), a^{-j}(\omega_0+\varepsilon)], \qquad j \in \mathbb{Z},$$

are mutually disjoint; and hence, by (2.5), we have

$$\sum_{j=-\infty}^{-M} \int_{a^{-j}(\omega_0-\varepsilon)}^{a^{-j}(\omega_0+\varepsilon)} |\widehat{\psi}(\omega)|^2 d\omega \leq \int_{2a^M\omega_0(1+a)^{-1}}^{\infty} |\widehat{\psi}(\omega)|^2 d\omega < \eta,$$

so that it follows from (2.6) that

$$\begin{aligned}
&\sum_{j\in\mathbb{Z}} \frac{a^j}{b} \int_0^T \left| \sum_{\ell\in\mathbb{Z}} \hat{f}(a^j(\omega+\ell T))\overline{\widehat{\psi}(\omega+\ell T)} \right|^2 d\omega \\
&\leq \sum_{j=-M+1}^{\infty} \frac{a^j}{b} \int_0^T \left| \sum_{\ell\in\mathbb{Z}} \hat{f}(a^j(\omega+\ell T))\overline{\widehat{\psi}(\omega+\ell T)} \right|^2 d\omega \\
&\qquad + C\eta + \frac{C}{2\varepsilon} \int_{\omega_0-\varepsilon}^{\omega_0+\varepsilon} \sum_{j=-\infty}^{-M} |\widehat{\psi}(a^{-j}\omega)|^2 d\omega.
\end{aligned} \tag{2.7}$$

Therefore, by (2.3) and (2.7), we have

$$\begin{aligned}
I &:= \sum_{j=-M+1}^{\infty} \frac{a^j}{b} \int_0^T \left| \sum_{\ell\in\mathbb{Z}} \hat{f}(a^j(\omega+\ell T))\overline{\widehat{\psi}(\omega+\ell T)} \right|^2 d\omega \\
&\geq A' - C\eta - \frac{C}{2\varepsilon} \int_{\omega_0-\varepsilon}^{\omega_0+\varepsilon} \sum_{j=-\infty}^{-M} |\widehat{\psi}(a^{-j}\omega)|^2 d\omega.
\end{aligned} \tag{2.8}$$

On the other hand, for all sufficiently small $\varepsilon > 0$, it is clear that

$$\begin{aligned}
I &= \sum_{j=-M+1}^{\infty} \frac{a^j}{b} \int_{a^{-j}(\omega_0-\varepsilon)}^{a^{-j}(\omega_0+\varepsilon)} |\hat{f}(a^j\omega)\overline{\widehat{\psi}(\omega)}|^2 d\omega \\
&= \frac{1}{2b\varepsilon} \int_{\omega_0-\varepsilon}^{\omega_0+\varepsilon} \sum_{j=-M+1}^{\infty} |\widehat{\psi}(a^{-j}\omega)|^2 d\omega,
\end{aligned}$$

where $\hat{f} = (1/\sqrt{2\varepsilon})\chi_{[\omega_0-\varepsilon,\omega_0+\varepsilon]}$. Hence, in view of the boundedness property in (2.4), we may take $\varepsilon \to 0$ in (2.8) to arrive at

$$\sum_{j=-M+1}^{\infty} \frac{1}{b}|\hat{\psi}(a^{-j}\omega_0)|^2 \geq A' - C\eta - C\sum_{j=-\infty}^{-M} |\hat{\psi}(a^{-j}\omega_0)|^2 \tag{2.9}$$

for almost all $\omega_0 > 0$. Since $\eta > 0$ is arbitrary, (2.4) and (2.9) together yield

$$\frac{1}{b}\sum_{j\in\mathbb{Z}} |\hat{\psi}(a^{-j}\omega)|^2 \geq A' \tag{2.10}$$

for almost all $\omega > 0$. A similar argument holds for $\omega < 0$. Hence, by (2.4) and (2.10), we have completed the proof of Theorem 1.

2.2. Proof of Theorem 2. Instead of (2.1), we now consider $T = 2\pi/q$. Then it follows from (1.15) that, for any $f \in L^2$,

$$\begin{aligned}\sum_{j,k\in\mathbb{Z}} |\langle f, \phi^{j,k}\rangle|^2 &= \sum_{j,k\in\mathbb{Z}} \frac{1}{4\pi^2}\left|\int_{-\infty}^{\infty} e^{iq\omega(k-jp)}\overline{\hat{\phi}(\omega - jp)}\hat{f}(\omega)d\omega\right|^2 \\ &= \frac{T^2}{4\pi^2}\sum_{j,k\in\mathbb{Z}}\left|\frac{1}{T}\int_0^T \sum_{\ell\in\mathbb{Z}}\left\{\overline{\hat{\phi}(\omega+\ell T - jp)}\hat{f}(\omega+\ell T)\right\} e^{ik\frac{2\pi}{T}\omega}d\omega\right|^2 \\ &= \frac{T^2}{4\pi^2}\sum_{j\in\mathbb{Z}}\frac{1}{T}\int_0^T \left|\sum_{\ell\in\mathbb{Z}} \overline{\hat{\phi}(\omega+\ell T - jp)}\hat{f}(\omega+\ell T)\right|^2 d\omega.\end{aligned} \tag{2.11}$$

As in the proof of Theorem 1, we fix any ω_0 and $0 < \varepsilon < T/2$, and consider the function $\hat{f} = (1/\sqrt{2\varepsilon})\chi_{[\omega_0-\varepsilon,\omega_0+\varepsilon]}$. Then it follows from the frame bounds in (1.17) that (2.11) becomes

$$C' \leq \frac{1}{2\varepsilon}\int_{\omega_0-\varepsilon}^{\omega_0+\varepsilon} \sum_{j\in\mathbb{Z}} \frac{1}{q}|\hat{\phi}(\omega - jp)|^2 d\omega \leq D',$$

and this implies (1.18).

To derive (1.19), we set $T' = 2\pi/p$ and note that

$$\begin{aligned}\sum_{j,k\in\mathbb{Z}} |\langle f, \phi^{j,k}\rangle|^2 &= T'^2 \sum_{j,k\in\mathbb{Z}}\left|\frac{1}{T'}\int_0^{T'} \sum_{\ell\in\mathbb{Z}} \overline{f(x+\ell T')}\phi(x+\ell T' - kq)e^{ij\frac{2\pi}{T'}x}dx\right|^2 \\ &= T'^2\sum_{k\in\mathbb{Z}}\frac{1}{T'}\int_0^{T'}\left|\sum_{\ell\in\mathbb{Z}} \overline{f(x+\ell T)}\phi(x+\ell T - kq)\right|^2 dx.\end{aligned}$$

By the same proof as above, we also have (1.19). This completes the proof of the theorem.

2.3. Proof of Corollary 3. Let $\{\psi_{j,k}^*\}$ be the dual basis of L^2 relative to $\{\psi_{j,k}\}$. Then $\{\psi_{j,k}^*\}$ is also an unconditional basis of L^2, and it follows from (1.21) that

$$L^{-1}\sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2 \leq \left\|\sum_{j,k\in\mathbb{Z}} a_{j,k}\psi_{j,k}^*\right\|^2 \leq K^{-1}\sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2 \tag{2.12}$$

for all $\{a_{j,k}\} \in \ell^2(\mathbb{Z}^2)$. Now, for any $f \in L^2$, writing

$$f(x) = \sum_{j,k \in \mathbb{Z}} a_{j,k}\psi^*_{j,k}(x),$$

we have

$$a_{j,k} = \langle f, \psi_{j,k} \rangle,$$

so that (2.12) yields

$$L^{-1} \sum_{j,k \in \mathbb{Z}} |\langle f, \psi_{j,k} \rangle|^2 \le \|f\|^2 \le K^{-1} \sum_{j,k \in \mathbb{Z}} |\langle f, \psi_{j,k} \rangle|^2,$$

which is equivalent to

$$K\|f\|^2 \le \sum_{j,k \in \mathbb{Z}} |\langle f, \psi_{j,k} \rangle|^2 \le L\|f\|^2 \tag{2.13}$$

for all $f \in L^2$. Hence, (1.25) follows from Theorem 1 with $a = 2$ and $b = 1$. In addition, (1.26) follows from (1.11) for these specific values of a and b. Of course, (1.27) and (1.28) are now the analogous consequences of (2.12) with $\psi^*_{j,k}$ replaced by $\tilde{\psi}_{j,k}$, where $\tilde{\psi}$ is the dual of ψ.

2.4. Proof of Theorem 4. Before we go ahead to establish the theorem, let us first say something about the dual $\tilde{\psi}$ of ψ. In the first place, we note that $\{\psi_{0,k}\} = \{\psi(\cdot - k)\}$ is an unconditional basis of W_0, meaning, of course, that it is complete in W_0 and satisfies

$$K \sum_{k \in \mathbb{Z}} |b_k|^2 \le \left\| \sum_{k \in \mathbb{Z}} b_i \psi(\cdot - k) \right\|^2 \le L \sum_{k \in \mathbb{Z}} |b_k|^2 \tag{2.14}$$

for all $\{b_k\} \in \ell^2$, where $0 < K \le L < \infty$ are as in (1.21). Note that (2.14) is a consequence of (1.21) with the same bounds. It is well known (cf. [7]) that (2.14) is equivalent to

$$K \le \Psi(\omega) \le L \quad \text{a.e.} \tag{2.15}$$

for the same constants K and L, where $\Psi(\omega)$ was defined in (1.32). Hence, we have

$$\Psi(\omega) = \sum_{j \in \mathbb{Z}} c_j e^{-ij\omega}$$

for some $\{c_j\} \in \ell^2$, so that

$$\tilde{\psi}(x) = \sum_{j \in \mathbb{Z}} c_j \psi(x - j)$$

is in W_0. Secondly, from the definition of $\tilde{\psi}$ in (1.31), we see that

$$\sum_{k \in \mathbb{Z}} \hat{\tilde{\psi}}(\omega + 2\pi k)\overline{\hat{\psi}(\omega + 2\pi k)} = 1 \quad \text{a.e.}, \tag{2.16}$$

and by a standard argument, it can be shown that (2.16) is equivalent to

$$\langle \psi(\cdot - j), \tilde{\psi}(\cdot - k)\rangle = \delta_{j,k}, \qquad j,k \in \mathbb{Z}. \tag{2.17}$$

In the proof of Theorem 4, we orthonormalize $\{\psi_{j,k}\}$ as usual by defining a function η, with

$$\hat{\eta}(\omega) = \frac{\widehat{\psi}(\omega)}{\Psi(\omega)^{\frac{1}{2}}}. \tag{2.18}$$

In view of (2.15), we have $\eta \in W_0$, and

$$\eta_{j,k}(x) = 2^{\frac{j}{2}}\eta(2^j x - k), \qquad j,k \in \mathbb{Z},$$

constitute an orthonormal basis of L^2. Hence,

$$\sum_{j,k} |\langle f, \eta_{j,k}\rangle|^2 = \|f\|^2, \qquad f \in L^2,$$

and by Corollary 3 with $K = L = 1$, we have

$$\sum_{j\in\mathbb{Z}} |\hat{\eta}(2^j\omega)|^2 = 1 \quad \text{a.e.}, \tag{2.19}$$

so that (1.33) follows from (1.31), (1.32), (2.18), and (2.19). Furthermore, (1.34) is a consequence of (1.33) by following the same method of derivation of (1.11). This completes the proof of the theorem.

2.5. Proof of Theorem 5. By (1.39), we have

$$\overline{\widehat{\psi}(2\omega)}\ \widehat{\widetilde{\psi}}(2\omega) = \overline{m_0(\omega+\pi)}\widetilde{m}_0(\omega+\pi)\overline{\hat{\phi}(\omega)}\ \hat{\tilde{\phi}}(\omega),$$

and hence it follows from (1.37) and (1.38) that

$$\begin{aligned}\overline{\widehat{\psi}(2\omega)}\ \widehat{\widetilde{\psi}}(2\omega) &= (1 - \overline{m_0(\omega)}\widetilde{m}_0(\omega))\overline{\hat{\phi}(\omega)}\ \hat{\tilde{\phi}}(\omega) \\ &= \overline{\hat{\phi}(\omega)}\ \hat{\tilde{\phi}}(\omega) - \overline{\hat{\phi}(2\omega)}\ \hat{\tilde{\phi}}(2\omega).\end{aligned} \tag{2.20}$$

Under the assumption on the decay property of ϕ and $\tilde{\phi}$, we note that $\hat{\phi}$ and $\hat{\tilde{\phi}}$ are both continuous at zero and converge uniformly to zero as $|\omega| \to \infty$. Therefore, by telescoping, we have, from (2.20),

$$\sum_{j\in\mathbb{Z}} \overline{\widehat{\psi}(2^j\omega)}\ \widehat{\widetilde{\psi}}(2^j\omega) = \overline{\hat{\phi}(0)}\ \hat{\tilde{\phi}}(0) = 1$$

for all ω, where the assumption $m_0(0) = \widetilde{m}_0(0) = 1$ in (1.37) is used. This establishes (1.40). Since (1.41) follows from (1.40) as in the derivation of (1.11), we have completed the proof of the theorem.

3. Final remarks. In this paper we have established various inequalities and identities of Littlewood–Paley type, among which are those for the following three classes of functions:

(a) The collection $\mathcal{F}$ of all s.t. frames;

(b) The collection $\mathcal{R}$ of all ψ such that $\{\psi_{j,k}\}$, as defined in (1.20), is an unconditional basis of L^2;

(c) The subcollection $\mathcal{W}$ of functions in $\mathcal{R}$ that have duals as defined by (1.22)–(1.24).

It was shown in §2.3 that $\mathcal{R} \subset \mathcal{F}$, and, in fact, the bounds for the unconditional basis $\{\psi_{j,k}\}$ generated by any $\psi \in \mathcal{R}$ in (1.21) remain to be the frame bounds for the frame $\{\psi_{j,k}\}$. Hence, we have

$$\mathcal{W} \subset \mathcal{R} \subset \mathcal{F}. \tag{3.1}$$

Observe that even for any $\psi \in \mathcal{F}$, the result

$$\int_{-\infty}^{\infty} \frac{|\widehat{\psi}(\omega)|^2}{|\omega|} d\omega < \infty$$

from (1.11) already yields

$$\int_{-\infty}^{\infty} \psi(x)dx = \widehat{\psi}(0) = 0,$$

provided that $\widehat{\psi}$ is continuous at zero, which follows from a very weak growth condition of ψ, such as $\psi \in L^1(-\infty,\infty)$. Hence, it is already reasonable to call any $\psi \in \mathcal{F}$ a "wavelet." If, in addition, $\psi \in \mathcal{W}$ with dual $\widetilde{\psi}$, then by using the notion of "integral wavelet transform" as defined in (1.5), namely,

$$(W_j f)(x) = 2^j \int_{-\infty}^{\infty} f(y)\overline{\psi(2^j y - 2^j x)}dy,$$

the coefficients

$$a_{j,k} := 2^{\frac{-j}{2}}(W_j f)\left(\frac{k}{2^j}\right), \tag{3.2}$$

of the "wavelet series" expansion

$$f(x) = \sum_{j,k\in\mathbb{Z}} a_{j,k}\widetilde{\psi}_{j,k}(x) \tag{3.3}$$

of any $f \in L^2$, contain very important information of the "signal" f in time-frequency analysis.

Regarding (3.1), while it is obvious that $\mathcal{R}$ is a proper subset of $\mathcal{F}$, it is not immediately clear that $\mathcal{W}$ is properly contained in $\mathcal{R}$. In the following, we give a very simple proof of this fact.

Let $\psi \in L^2$ be such that $\{\psi_{j,k}\}$, as defined in (1.20), is any orthonormal basis of L^2, and consider the function

$$\eta(x) := \psi(x) - \bar{z}2^{\frac{1}{2}}\psi(2x),$$

where z is any complex parameter with $|z| < 1$. Then it is clear that $\eta \in \mathcal{R}$. In fact, we have

$$(1-|z|)^2 \sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2 \le \left\| \sum_{j,k\in\mathbb{Z}} a_{j,k}\eta_{j,k} \right\|^2 \le (1+|z|)^2 \sum_{j,k\in\mathbb{Z}} |a_{j,k}|^2$$

for any $\{a_{j,k}\} \in \ell^2(\mathbb{Z}^2)$. Let $\{\eta^*_{j,k}\}$ be the basis dual to $\{\eta_{j,k}\}$. Then it is easy to verify that

$$\text{(3.4)} \qquad \begin{aligned} \eta^*_{0,0}(x) &= \sum_{\ell=0}^{\infty} z^\ell \psi_{-\ell,0}(x), \\ \eta^*_{0,1}(x) &= \psi_{0,1}(x). \end{aligned}$$

Hence, for η to be in $\mathcal{W}$, the family $\{\eta^*_{j,k}\}$ must be given by

$$\eta^*_{j,k}(x) = 2^{\frac{j}{2}}\eta^*_{0,0}(2^jx-k),$$

and in particular,

$$\eta^*_{0,1}(x+1) = \eta^*_{0,0}(x),$$

so that (3.4) yields

$$\psi(x) = \eta^*_{0,1}(x+1) = \eta^*_{0,0}(x) = \psi(x) + \sum_{\ell=1}^{\infty} z^\ell \psi_{-\ell,0}(x),$$

or

$$\sum_{\ell=1}^{\infty} \psi_{-\ell,0}(x) z^\ell = 0.$$

This is not possible, unless $\psi_{-\ell,0}(x) = 0$ or $\psi(x) = 0$ for all x.

The consideration of $\eta^*_{0,0}$ in (3.4) was motivated by the fundamental work of Daubechies [5, p. 989], where a corresponding function $h^*_{0,0}$ was constructed by using the Meyer wavelet (cf. [10]). This function $h^*_{0,0}$ is not in $L^p(-\infty,\infty)$ for sufficiently small $p-1>0$ as shown by our derivation and (3.4) above. Note that this corrects a mistake in [5], where it was erroneously stated that $h^*_{0,0}$ was not in $L^p(-\infty,\infty)$ for large p. On the other hand, the fact that $\mathcal{W} \neq \mathcal{R}$ also follows from an earlier result of Tchamitchian [11], [12], as pointed out by Daubechies [5, p. 989] and Meyer [10, p. 127].

Acknowledgment. We are grateful to the referees for their valuable comments.

CONSERVATION LAWS WITH DISCONTINUOUS FLUX FUNCTIONS*

TORE GIMSE†

Abstract. The author studies the initial value problem for the scalar conservation law $u_t + f(u)_x = 0$ in one spatial dimension. The flow function may be discontinuous with a finite number of jump discontinuities. This paper proves existence of a weak solution, and the proof is constructive, suggesting a numerical method for the problem.

Key words. conservation laws, discontinuous flow, front tracking, porous media

AMS(MOS) subject classifications. 35L65, 35L67, 76T05

Introduction. In this paper we are interested in the Cauchy problem for the scalar conservation law

$$u_t + f(u)_x = 0, \tag{0.1}$$

that is, the initial value problem with $u(x, 0) = u_0(x)$ piecewise continuous of bounded variation, and so that $f_0(x) = f(u_0(x))$ has bounded variation.

The flux function f is supposed to be piecewise smooth with a finite number of jump discontinuities. For simplicity, we will consider flux functions with only one point of discontinuity, so that

$$\lim_{u \to \bar{u}^-} f(u) \neq \lim_{u \to \bar{u}^+} f(u),$$

$\bar{u}$ being the point of discontinuity. The extension to a finite number of discontinuities is outlined at the end of the paper.

This Cauchy problem may arise in several physical applications. For two phase flow in porous media we may have a discontinuous flux (flow) function if the flow properties change abruptly at some saturation. Such changes are obtained for the relative permeability at the irreducible saturation, both when measuring the relative permeability experimentally [11], [16], and when modeling flow properties on a network of pores [12]. This effect is due to discontinuous distribution of the low saturation, and is a jump from zero permeability value to a presumably small but positive value at this critical saturation. Simulations on discretized fracture apertures indicate possible major discontinuities for the nonwetting phase relative permeability, particularly for systems with small long-range correlation among apertures in the direction of the flow [19]. A discontinuity of the relative permeability yields a corresponding jump for the flow function. In standard texts of reservoir simulation and related topics, e.g., [4], relative permeability curves are assumed to be continuous, or approximated by continuous functions. This paper, however, suggests that also discontinuous functions, which in some cases may be more realistic, may be used with existence and stability results similar to those for the continuous problem.

It should be an object of further investigation if our results could be extended to be applicable also for hysteresis problems, that is, history dependent flow properties. Laboratory studies [6] indicate that we would expect to have an interval of saturations, say (u_1, u_2) where $f(u)$ is double valued, and the correct flow value is determined by

† Department of Mathematics, University of Oslo, N-0316, Oslo, Norway.

previous or neighboring saturation values. Marchesin et al. [17] have studied this problem, but their analysis is based on finite slopes of flow functions.

Another possible application is traffic flow analysis [15]. We propose the following model for two-lane unidirectional traffic on a freeway that involves a discontinuous flow function: Assume that all cars have the same length, and that the speed of cars in the left lane is constant, independent of the car density (at least at those values of interest here). In the right lane, a certain fraction of the cars drive with a low, fixed speed, but passing (by changing lanes only during passing, and with instantaneous acceleration) is possible. Thus, as long as the density in the left lane permits passing, that is, as long as there is space enough between the cars, the overall flow depends continuously upon the overall density. However, as the density reaches the value where the left lane density prohibits passing, the overall flow drops discontinuously to that of the two lanes considered separately. Although multilane traffic with passing has been studied previously (e.g., [18]), no model similar to the one proposed above is known by the author. The consequences of this model should be an object of future investigation.

In either application, the procedures of this paper are constructive, and suggest a numerical method. The major idea of our method is to approximate the flux function f with a piecewise linear function, and approximate the initial value function u_0 with a step function [3], [7], [9]. By this procedure the original Cauchy problem is approximated by Riemann problems, and the solution of these consists of shocks only. We call this method a front tracking method. Shocks of the solution are traced without numerical dispersion, whereas rarefaction waves are approximated by a sequence of small shocks. Such methods have been extensively developed by the Oslo group [1], [2], and have turned out to be computationally and mathematically successful.

The following definition simplifies the notation.

DEFINITION. Let u_- and u_+ denote the points $(\bar{u}, \lim_{u\to\bar{u}^-} f(u))$ and $(\bar{u}, \lim_{u\to\bar{u}^+} f(u))$, respectively. We write $u_- \prec u_+$ if $\lim_{u\to\bar{u}^-} f(u) < \lim_{u\to\bar{u}^+} f(u)$, and say that f is double valued at the jump discontinuity at $u = \bar{u}$.

Throughout this paper we will assume that $u_- \prec u_+$.The case $u_+ \prec u_-$ can be treated symmetrically. We will treat u_- and u_+ as being two different u values, and we will let $\bar{u}$ denote any of them.

The fact that f is discontinuous implies that the existence results of, e.g., Krushkov [13] and Kuznetsov [14] do not apply to this problem. A somewhat similar "discontinuous problem" is the problem with a flux function discontinuously varying with x. This latter problem is solved in [5] by combining a technique of Temple [20] with front tracking methods by Dafermos [3] and Holden, Holden and Høegh-Krohn [9]. In this paper we will build mainly on [9]. By using front tracking as our method of analysis, we can avoid estimates involving the boundedness of the derivative of f, and thereby we are able to prove existence of a solution of the Cauchy problem. Our work will be based on, extend, and partly parallel the previous works by Holden, Holden, and Høegh-Krohn [8], [9], where similar techniques are used to study the continuous case. As for their works, our method is based on the solution of Riemann problems for (0.1), which will be discussed in some detail.

1. The solution of the Riemann problem. In general, the Riemann problem of (0.1) is the initial value problem consisting of two constant states separated by a discontinuity,

$$u(x,0) = \begin{cases} u_l & \text{for } x < 0, \\ u_r & \text{for } x > 0. \end{cases} \tag{1.1}$$

The Riemann problem when neither of u_l, u_r equals $\bar{u}$ is easily solved by the well-known procedure of taking convex envelopes of f between u_l and u_r. Note that even though f is not continuous between u_l and u_r, the convex envelope of f with respect to the interval (u_l, u_r) is continuous and piecewise smooth. Thus, we obtain the familiar fan-like solution picture in the $x-t$ plane of waves propagating with finite speed. In general the waves are smooth (rarefaction waves) or shocks, the latter being discontinuities traveling with a certain shock speed. A shock wave with left and right states u_1 and u_2 will be denoted a u_1/u_2 shock. However, since we may have, for example, $u_l < \bar{u} < u_r$, then, if $\bar{u}$ is part of the solution, we should specify whether we have u_- or u_+.

Special care should be taken when either u_l or u_r equals $\bar{u}$. The following lemma is easily verified by examining convex envelopes.

LEMMA 1.1. *The Riemann problem with initial values $u_l = \bar{u}$ and $u_r \neq \bar{u}$ has a unique solution with waves of finite speed only.*

However, if $u_r = u_- < u_l$, or $u_r = u_+ > u_l$, we have to extend the concept of convex envelopes.

DEFINITION. The convex envelope of the function f with respect to the interval (u_l, u_+), where f is double valued at $u_- < u_+$, is defined by the convex envelope of f with respect to the interval (u_l, u_-) connected to the line from u_- to u_+.

The convex envelope defined above is a curve in the $u-f(u)$ space, which may have infinite slope with respect to u. Thus, a general Riemann problem (1.1) is solved by tracing the convex envelopes of f with respect to the interval (u_l, u_r), using the definition above if necessary. The solution generally consists of a fan of waves with finite speed, and possibly one shock u_-/u_+ or u_+/u_- with infinite speed. Note that the Riemann problem $u_l = u_-$, $u_r = u_+$ or vice versa, is solved by a single shock of infinite speed to the right in the $x-t$ plane. However, since the u value is constant across such a shock, we call it a zero shock. Thus, in the sense of u, a zero shock carries no information, but the flux value information is transported instantaneously.

See Fig. 1.1 for a simple example of a Riemann problem solution.

2. Shock interactions. After the Riemann problem solution is found, we want to study the interaction of several Riemann problems. We will be particularly interested in the case of a piecewise linear flux function f, which implies that the only waves present are shocks [3], [9]. We define a single collision to be a collision involving and creating waves of finite speed only. That is, two or more waves interact at some point (x, t), none of which has infinite speed, and the result contains no zero shock.

In the following, rightnext front (or Riemann problem) will mean the next front (Riemann problem) to the right of the present. Starting out with finitely many Riemann

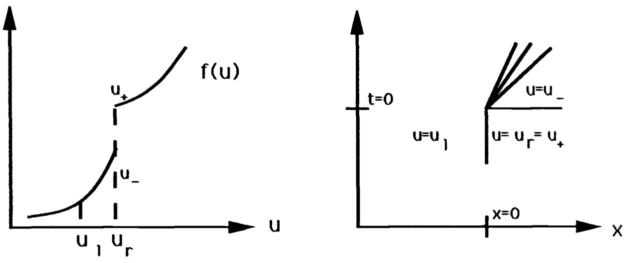

FIG. 1.1. *Discontinuous flux function and corresponding Riemann problem solution.*

problems as our initial data, we define the following algorithmic procedure for determining the solution $u(x, t)$:

(1) Solve the initial Riemann problems, starting from the left along the x axis. If a zero shock evolves, change the left state of the rightnext Riemann problem before solving that problem;

(2) After having finished at $t=0$, determine the first interaction to occur, say, at $t=\tau$. Denote the interacting constant states by $u_1, u_2, \dots, u_M$, $M>1$. Here u_1 is the leftmost state and u_M is the rightmost. The interaction is resolved by solving the Riemann problem with initial values $u_l=u_1$ and $u_r=u_M$. If a zero shock occurs, an interaction is created instantaneously at the rightnext front. If this happens, or if more interactions occur at the same time, treat them from the left, while changing the corresponding left value of the next front when zero shocks appear;

(3) When all interactions at τ are resolved, proceed to the next interaction at some greater time, etc.

As discussed above, a created zero shock, of course, will influence the rightnext front (or the rightnext interaction), but the following lemma assures limited distribution.

LEMMA 2.1. *A zero shock emerging from* (x, t) *interacts with the rightnext front instantaneously, but only with the rightnext.*

Proof. Assume that a u_-/u_+ shock is formed. The rightnext front is necessarily of the kind $u_+/\tilde{u}$ where $\tilde{u}\neq\bar{u}$, since if $\tilde{u}=u_+$ we had no front, and if $\tilde{u}=u_-$ the rightnext front was a zero shock as well, which is impossible since our resolution starts from the left. Thus, the rightnext front is turned into a Riemann problem with initial states u_- and $\tilde{u}$, which, by Lemma 1.1 is solved by shocks of finite speed only. A similar argument is valid if the zero shock is a u_+/u_- shock. □

If there is an interaction rightnext to the true collision, influence further to the right depends on the right state of that interaction.

Provided we have a finite number of interactions at time t, this completely resolves and continues the solution. It remains to be determined whether this procedure of resolution is well defined, that is, whether the solution is independent of the order in which simultaneous interactions are resolved. Firstly, by Lemmas 1.1 and 2.1, it is easily seen that the only cases that need to be checked are when more interactions occur with no fronts between them. The following lemma determines the resulting solution of a sequence of simultaneous interactions.

LEMMA 2.2. *For any finite sequence of simultaneous interactions creating zero shocks, the overall result is determined by the leftmost interaction.*

Proof. Let $I_1, I_2, \dots, I_N$ be the sequence of simultaneous interactions. Note that the left state of I_1 and the right state of I_N may be different from $\bar{u}$, but that the rest of the left and right states involved equal u_- and u_+ alternately. We will demonstrate that the order in which the interactions are treated does not affect the overall solution. Assume that the sequence of Is is already obtained, and that the next interaction to consider is I_1. Assume that the right state of I_1 is u_-. The case of $u_r=u_+$ is treated symmetrically. Thus, by the resolution of I_1, a u_+/u_- shock evolves, changing the left state of I_2 to u_+. However, by our assumption of the sequence, the right state of I_2 was u_+, so that the interaction I_2 is killed. The next interaction is not altered, and I_3 now is a new leftmost interaction in the remaining sequence. Thus, by continuing this argument, we see that the entire sequence is resolved by a u_+ state, which was determined by the u_+/u_- shock emerging from the leftmost interaction. □

Thus the resolution procedure defined by treating interactions with increasing x is well defined. We will define an event to be either a single collision or one or more simultaneous interactions, each creating zero shocks as described in Lemma 2.2. The latter will be denoted as a dual collision. See Fig. 2.1 for different kinds of events.

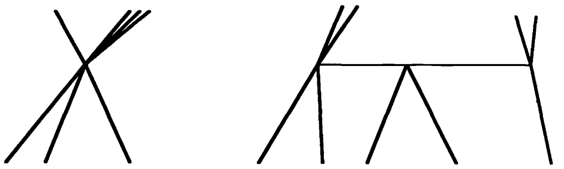

FIG. 2.1. *Single collision* (*left*) *and more interactions* (*right*).

Having determined the well-defined algorithm for treating Riemann problems locally, we are now able to examine the procedure of solving a finite number of initial Riemann problems globally as $t \to \infty$. The following theorem extends a result from [9].

THEOREM 2.3. *Given a piecewise linear flow function with one point of discontinuity, and an initial value function $u_0(x)$ consisting of finitely many constant states separated by discontinuities. Then, even for infinite time, only a finite number of events occur, and the overall solution $u(x, t)$ consists of a finite number of constant states, separated by shocks.*

Proof. Let N be the number of u values between which f is linear, plus the number of initial u values not in this set. Thus we may number the possible u values $w_1, w_2, \ldots, w_N$. Let $L(t)$ be the number of shock lines for $u(x, t)$, that is, the number of shock lines for a front w_i/w_j is $|i-j|$, and let $F(t)$ be the number of shocks in $u(x, t)$. Define the function $G(t) = NL(t) + F(t)$. Then $G(t)$ is obviously nonnegative. We will show that $G(t)$ is decreasing at each event, leaving us with a finite number of possible events only. First, if the event is a true collision, the theorem from [9] is valid. Examine, therefore, a dual collision. We will compare the dual collision with two collisions, connected by a zero shock of large but finite speed (see Fig. 2.2). Note that we may always find a speed S so that no other interaction takes place before the shock with speed S reaches the position of the right interaction. We name this the split case. Note that the result in the two cases are the same. Obviously, G_{before} and

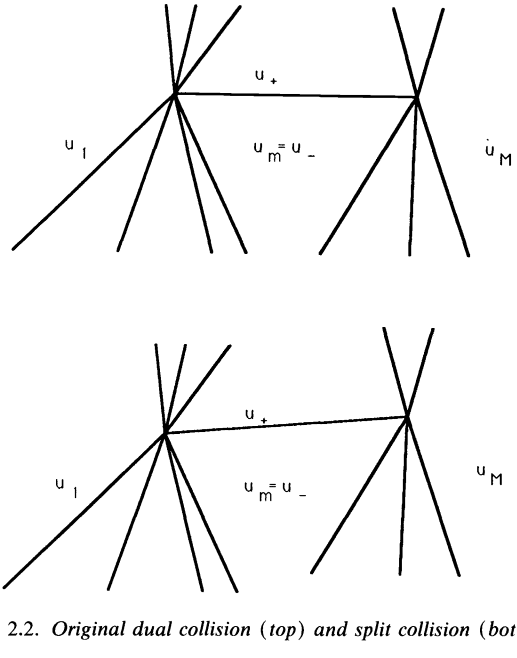

FIG. 2.2. *Original dual collision* (*top*) *and split collision* (*bottom*).

G_{after} is the same for the two cases, and since we know that G is decreasing for the split case [9], the same is valid for the dual collision. If more intermediate interactions were killed in between the left and right interaction, it is easily seen that G decreases even more. Thus, we have a finite number of interactions, which gives only a finite number of shocks, dividing the $x-t$ plane in a finite number of polygons where the solution u is constant. □

COROLLARY. *The total variation of the solution is nonincreasing.*

3. Stability. We now turn our interest to the stability of the solution, both with respect to $u_0(x)$ and the flux function $f(u)$. The following theorem ensures stability with respect to the initial data.

THEOREM 3.1. *If $u(x, t)$ and $v(x, t)$ solve* (0.1) *with initial value functions $u_0(x)$ and $v_0(x)$, respectively, u_0 and v_0 being step functions with finitely many values, and so that $u_0(x)=v_0(x)$ outside some finite interval $[-a, a]$, and f being piecewise linear with one point of discontinuity, then*

$$\int |u(x, t)-v(x, t)|\, dx \leqq \int |u_0(x)-v_0(x)|\, dx.$$

Proof. Assume that $u_0(x)$ and $v_0(x)$ are constant at the intervals $I_i=(a_i, a_{i+1})$, where $i=1,2,\ldots, M$, and $a_1=-\infty$, $a_{M+1}=\infty$. We want to construct a sequence $\{u_{0,n}\}_{n=1}^N$ so that $u_{0,1}=u_0$ and $u_{0,N}=v_0$. This construction is done by taking the intervals I_i one by one, and by moving the previous $u_{0,k}$ towards v_0 at $\frac{1}{3}$ of an interval every time. Thus, if $u_0=w_{s_i}$ and $v_0=w_{t_i}$ at interval I_i, then $N=\sum_{i=1}^M 3|s_i-t_i|$. Let $\{w_j\}$ be the set of initial and possible values for u. Note that $u_{0,i}$ differs from $u_{0,i+1}$ only at $\frac{1}{3}$ of some interval I_k, and that $|u_{0,i}-u_{0,i+1}|=|w_j-w_{j+1}|$ for some j at this interval. Furthermore, $|u_0(x)-v_0(x)|_{L_1}=\sum_{i=1}^{N-1}|u_{0,i}-u_{0,i+1}|_{L_1}$. Let $u_i(x, t)$ be the solution of (0.1) with initial value $u_{0,i}$. We then have

$$\begin{aligned}\int |u(x, t)-v(x, t)|\, dx &\leqq \int \sum_{i=1}^{N-1} |u_i-u_{i+1}|\, dx \\ &\leqq \int \sum_{i=1}^{N-1} |u_{0,i}-u_{0,i+1}|\, dx = \int |u_0(x)-v_0(x)|\, dx,\end{aligned}$$

the latter inequality by Lemma 3.2 below that is taken from [8]. □

LEMMA 3.2 (Holden, Holden, and Høegh-Krohn).

$$\int \sum_{i=1}^{N-1} |u_i-u_{i+1}|\, dx \leqq \int \sum_{i=1}^{N-1} |u_{0,i}-u_{0,i+1}|\, dx.$$

Proof. The proof [8] considers the time derivative of $\int |u_i-u_{i+1}|\, dx$ at the intervals from Theorem 3.1. To transfer the result from [8], we observe that this derivative is zero also if $u_i=u_-$ and $u_{i+1}=u_+$ or vice versa. □

Note that Theorem 3.1 implies stability also for higher-dimensional problems. This follows by the dimensional splitting analysis by Holden and Risebro [10].

Next we are interested in stability with respect to the flux function f. At this point we will assume that the discontinuity of f is fixed, and so are the two corresponding points u_- and u_+. With this assumption, we may state the theorem.

THEOREM 3.3. *Let f and g be piecewise linear functions with a coinciding point of discontinuity at $u=\bar{u}$, and let $v(x, t)$ and $u(x, t)$ be the corresponding solutions of $u_t+f(u)_x=0$ and $v_t+g(v)_x=0$ with the same initial value, a step function taking finitely* *many values*: $u_0(x)=v_0(x)$. *Then*

$$\frac{d}{dt}\int |u(x,t)-v(x,t)|\,dx \leqq TV_x(f(u_c(x,t))-g(v_c(x,t)))$$
$$\leqq TV_x(f(u_{0,c}(x,t))-g(v_{0,c}(x,t))),$$

where $u_c(x,t)$ *and the Total Variation* (TV_x) *are defined below.*

DEFINITION. Let u_i be the value of the step function $u(x,t)$ taken at the interval (a_i, a_{i+1}), $i=1,2,\dots,M$, for fixed t. Then $u_c(x,t)$ is defined by

$$u_c(x,t)=\begin{cases} u_i & \text{for } a_i \leqq x \leqq a_{i+1}-\varepsilon, \\ u_i+\dfrac{(x-a_{i+1}+\varepsilon)}{\varepsilon}(u_{i+1}-u_i) & \text{for } a_{i+1}-\varepsilon \leqq x \leqq a_{i+1}. \end{cases}$$

Here $\varepsilon=\frac{1}{3}\min_i\{a_{i+1}-a_i\}$.

Note that $u_c(x,t)$ is a piecewise linear, continuous function.

DEFINITION. $TV_x(f(u(x)))$ is defined by

$$TV_x(f(u(x)))=\sup\sum_{i=1}^{N}|f(u(x_{i+1}))-f(u(x_i))|,$$

where the supremum is taken over all finite partitions of $\{x_i\}$.

Note that u in the above definition should be continuous.

Proof of Theorem 3.3. The proof of Theorem 3.3 carries over literally from [8] by the following observation. Define the function $F(u)=f(u)-g(u)$, and note that since f and g are assumed to have identical discontinuities, F is continuous and piecewise linear. The analysis of [8] is based on estimates of $f-g$, and these estimates are still valid by the properties of F. □

We now have stability results for piecewise linear flux functions with piecewise constant initial data, and we will use this, together with knowledge of zero shocks, to conclude with existence and uniqueness results for problem (0.1).

4. Existence and uniqueness. We first restate the problem that will be our object of study for the rest of this paper. The equation is

$$u_t+f(u)_x=0, \tag{4.1}$$

with initial data $u(x,0)=u_0(x)$. The flux function f is measurable and continuous with bounded derivative, except at $u=\bar{u}$ as above. The initial value function $u_0(x)$ is measurable and of bounded variation, as is $f_0(x)=f(u_0(x))$. We assume there are values $u_s<\bar{u}<u_S$ and $x_s<x_S$, so that for $x\leqq x_s$, and $x\geqq x_S$, $u_0(x)$ is not in the interval (u_s, u_S). The latter restriction is put on $u_0(x)$ to avoid zero shocks traveling unlimited distances instantaneously. We have the following lemma to ensure this.

LEMMA 4.1. *There exist numbers s and S, $-\infty<s<S<\infty$, and so that for $x<x_s+st$ and $x>x_S+St$ we have either $u(x,t)<u_s$, or $u(x,t)>u_S$. In these areas the solution $u(x,t)$ is determined by the existence and uniqueness results in* [8].

Proof. Since $u_0(x)$ is of bounded variation, we may assume that x_S is so that either $u_0(x)<u_s$ or $u_0(x)>u_S$ for $x>x_S$, and similarly for $x<x_s$. The maximum speed of waves entering the region $x>x_S$ is then determined by the maximum slope of the function

$$f_S(u)=\begin{cases} f(u) & \text{for } u\leqq u_-, \\ f(u_-)+\dfrac{f(u_S)-f(u_-)}{u_S-u_-}(u-u_-) & \text{for } u_-\leqq u\leqq u_S, \\ f(u) & \text{for } u\geqq u_S. \end{cases}$$

By definition f_S has a finite maximum slope, S. Similarly we define f_s for waves entering the other region, $x < x_s$, and the lemma follows. □

Before proceeding we need the following lemma from [8].

LEMMA 4.2. *Assume that a measurable function f is approximated by a sequence of measurable, uniformly bounded functions $\{g_n\}$ satisfying*

$$|g_n(x) - f(x)| < \frac{1}{na_n} \quad \textit{for } x \in (a, b) - A_n,$$

where the Lebesgue measure of A_n, $m(A_n)$ satisfies $m(A_n) < 1/na_n$, $\{a_n\}$ being an increasing sequence of real numbers. Then for $m > n$, the sequence $\{g_n\}$ satisfies the following Cauchy criterion:

$$\int_a^b |g_n(x) - g_m(x)|\, dx \leqq \frac{2(b-a)}{na_n} + \frac{4M}{na_n},$$

where M is such that $|g_n(x)| < M$.

We are now in the position of constructing a sequence of solutions, which we will show converges to a solution of (4.1): For given k, we select k different u values, say $w_1, w_2, \ldots, w_k$, among which we should have the two entries for $\bar{u}$, u_-, and u_+. Then, for given f, we construct f_k by evaluating f at the chosen u values, making f_k piecewise linear between these values. Note that we by this construction keep the correct discontinuity. Finally we make a piecewise constant approximation of $u_0(x)$ from below, using only the k different u values at a finite number of sample points. We denote this approximation $u_{0,k}(x)$. Now, let $u_k(x, t)$ be the solution of the equation $u_t + f_k(u)_x = 0$ with initial data $u_{0,k}(x)$. This defines a sequence of solutions, and we have the following lemma.

LEMMA 4.3. *$\{u_i(x, t)\}$ is a Cauchy sequence in $L_{1,\mathrm{loc}}$.*

Proof. By the definitions made above, we apply Theorem 3.1,

$$\begin{aligned}&\int |u_i(x, t) - u_j(x, t)|\, dx \\ &\qquad \leqq \int |u_{0,i}(x) - u_{0,j}(x)|\, dx + tTV_x(f_i(u_{0,i,c}(x)) - f_j(u_{0,j,c}(x))).\end{aligned}$$

As for the corresponding result in [8] the right-hand terms vanish; the first by Lemma 4.2, and the second by the construction of f_i. Note that all f_i have the same discontinuity at $\bar{u}$, and are continuous elsewhere. Thus, the function F_{ij} defined by $F_{ij}(u) = f_i(u) - f_j(u)$ is continuous, which makes the second term vanish [8]. □

Since f is double valued at $u = \bar{u}$, we cannot conclude from Lemma 4.3 that the sequence of fluxes, $\{f_i(u_i)\}$ converges. However, by the knowledge of the Riemann problem solution we find the following lemma.

LEMMA 4.4. *If the original $u_0(x)$ is continuously increasing at x_0, where $u_0(x_0) = \bar{u}$, then for large i the approximated solution contains u_-, and vice versa.*

Proof. Since u_0 is continuously increasing, for i sufficiently large, the approximation $u_{0,i}$ is also increasing at x_0. Thus, the Riemann problem solution of convex envelopes invokes u_- but not u_+. □

LEMMA 4.5. *$\{f_i(u_i)\}$ is a Cauchy sequence in $L_{1,\mathrm{loc}}$.*

Proof. By Lemma 4.3 we know that $\{f_i(u_i)\}$ is Cauchy with respect to domains where $\{u_i\}$ is not converging to $\bar{u}$. Thus, it is sufficient to examine initial values close to $\bar{u}$. This is a study of cases, of which the continuously monotone cases are covered by Lemma 4.4. The remaining are true Riemann problems, of which we may have only finitely many (by the restrictions of u_0 and f_0), and by the Riemann problem solution algorithm, we have convergence also for these. □

We may now define the limiting functions of $\{u_i\}$ and $\{f_i(u_i)\}$ by defining the limit $u(x, t)$ to be the limit of $u_i(x, t)$ so that $f_i(u_i(x, t)) \to f(u(x, t))$. Note that this is a valid definition since by Lemma 4.3 we may define a family $\{\tilde{u}(x, t)\}$ so that for all $\tilde{u}$ in this family, $u_i \to \tilde{u}$ in $L_{1,\text{loc}}$. The $\tilde{u}$s differ only at sets of zero measure, or with respect to u_-/u_+. Thus, as f is single valued, $f_i(u_i) \to f(u)$ in $L_{1,\text{loc}}$, and the problem where f is double valued is resolved by Lemma 4.5, and thereby defining which $\bar{u}$ value to give the flux value $f(\bar{u})$.

THEOREM 4.6. *The limiting solution* $u(x, t)$ *defined above is a weak solution of* (4.1), *that is,*

$$\int_0^T \int (u(x, t)\phi_t(x, t) + f(u(x, t))\phi_x(x, t))\, dx\, dt + \int u_0(x)\phi(x, 0)\, dx = 0$$

for all $\phi \in C_0^1$.

Proof. Since every $u_i(x, t)$ is a weak solution of $u_t + f_i(u)_x = 0$, we have

$$\left| \int_0^T \int (u(x, t)\phi_t(x, t) + f(u(x, t))\phi_x(x, t))\, dx\, dt + \int u_0(x)\phi(x, 0)\, dx \right|$$

$$= \left| \int_0^T \int ([u(x, t) - u_i(x, t)]\phi_t(x, t) + [f(u(x, t)) - f_i(u_i(x, t))]\phi_x(x, t))\, dx\, dt \right.$$

$$\left. + \int (u_0(x) - u_{0,i}(x))\phi(x, 0)\, dx \right|$$

$$\leqq \int_0^T \int (|u(x, t) - u_i(x, t)|\,|\phi_t(x, t)|$$

$$+ |f(u(x, t)) - f_i(u_i(x, t))|\,|\phi_x(x, t)|)\, dx\, dt$$

$$+ \int |u_0(x) - u_{0,i}(x)|\,|\phi(x, 0)|\, dx.$$

Now let $K = \max\{|\phi|, |\phi_t|, |\phi_x|\}$, and investigate each term of the above expression:

$$\int_0^T \int |u(x, t) - u_i(x, t)|\,|\phi_t(x, t)|\, dx\, dt \leqq K \int_0^T \int |u(x, t) - u_i(x, t)|\, dx\, dt \to 0,$$

and

$$\int |u_0(x) - u_{0,i}(x)|\,|\phi(x, 0)|\, dx \leqq K \int |u_0(x) - u_{0,i}(x)|\, dx\, dt \to 0,$$

by the definition of $u(x, t)$ and $u_{0,i}(x)$. Finally, by Lemma 4.5 and the definition of $u(x, t)$,

$$\int_0^T \int |f(u(x, t)) - f_i(u_i(x, t))|\,|\phi_x(x, t)|\, dx\, dt$$

$$\leqq K \int_0^T \int |f(u(x, t)) - f_i(u_i(x, t))|\, dx\, dt \to 0. \qquad \square$$

Having proved existence of a weak solution, it remains to prove uniqueness of the solution. By uniqueness we mean that the constructive approach using front tracking gives a unique limit solution.

THEOREM 4.7. *The weak solution defined from Theorem* 4.6 *is the unique limit of the constructed sequence of piecewise constant solutions with respect to* $L_{1,\text{loc}}$.

Proof. Assume that both $v(x, t)$ and $u(x, t)$ are weak solutions of (4.1) constructed by the front tracking method. Then

$$\begin{aligned}\Delta &= \int |u(x, t) - v(x, t)|\, dx \\ &\leqq \int |u(x, t) - u_i(x, t)|\, dx + \int |u_i(x, t) - v(x, t)|\, dx \\ &\leqq \int |u(x, t) - u_i(x, t)|\, dx + \int |u_{0,i}(x) - u_0(x)|\, dx + t \sum_I TV_x(f_i(u_{0,i,c}) - f(u_0)),\end{aligned}$$

the latter by Theorem 3.3 and $v_0(x) = u_0(x)$. The sum runs over intervals I where u_0 is continuous. Thus, by the definitions of $u_{0,i}(x)$, $u_{0,i,c}(x)$, $u_i(x, t)$, $v(x, t)$, f_i, and f, Δ vanishes as $i \to \infty$. □

5. Finitely many discontinuities. The extension to a flow function with finitely many discontinuities where the one-sided limits exist is straightforward by the observation that the zero shocks that may occur at each Riemann problem solution are well defined. By well defined, we mean that given u_l and u_r we may have only one zero shock traveling to the left, and one traveling to the right. By symmetry arguments, the results of this paper are valid for zero shocks traveling in both positive and negative directions. Zero shocks colliding at a dual collision are identical, and, therefore, the algorithmic procedure for solving multiple Riemann problems is still valid when being careful about changing the correct left and right states at neighboring fronts and interactions.

ASYMPTOTIC BEHAVIOR OF ONE-STEP COMBUSTION MODELS WITH MULTIPLE REACTANTS ON BOUNDED DOMAINS*

JOEL D. AVRIN†

Abstract. The author considers reaction-diffusion systems on bounded domains modeling one-step reactions with Arrhenius kinetics in cases where the fuel consists of several species. The author assumes zero Neumann boundary conditions for the mass fractions and it is shown that one mass fraction decays to zero while, generally, residual amounts of the other species remain. These amounts are calculated explicitly from spatial averages of the initial conditions and it is shown that only if certain precise conditions are met will all mass fractions decay to zero. If additionally the temperature satisfies zero Neumann boundary conditions or fixed positive Dirichlet boundary conditions, then the temperature's asymptotic behavior is explicitly calculated as well.

Key words. reaction-diffusion equations, boundary conditions, spatial averages, steady-state convergence

AMS(MOS) subject classifications. 35B40, 35K57, 80A25

1. Introduction. We consider one-step reactions with multiple-species fuels that arise in combustion theory. An example of this type of reaction is (see, e.g., [6, p. 6])

$$2NO+Cl_2 \rightarrow 2NOCl. \tag{1.1}$$

The general one-step reaction involving the reactants and products $A_1, \dots, A_N$ can be written as

$$\sum_{i=1}^{N} \nu_i A_i \rightarrow \sum_{i=1}^{N} \mu_i A_i \tag{1.2}$$

where the stoichiometric coefficients ν_i and μ_i are positive integers; $\mu_i = 0$ (respectively, $\nu_i = 0$) for each A_i that is not a product (respectively, not a reactant) in (1.2). In (1.1), for example, if $A_1 = NO$, $A_2 = Cl_2$, and $A_3 = NOCl$, then $\nu_1 = \mu_3 = 2$, $\nu_2 = 1$, while $\nu_3 = \mu_1 = \mu_2 = 0$.

By relabeling, if necessary, we can assume that for some M with $1 < M < N$ $A_1, \dots, A_M$ are the reactants, i.e., $\nu_i \neq 0$, $i = 1, \dots, M$. Let $Y_i = Y_i(x, t)$, $i = 1, \dots, M$ denote the respective mass fractions of the A_i and let $T = T(x, t)$ denote the (dimensionless) temperature. Here $x \in \Omega$, a bounded domain with smooth boundary $\partial\Omega$, and $t \geqq 0$. For positive constants B and E let $f(T)$ denote the Arrhenius rate law $f(T) = B \exp(-E/T)$, and set

$$\omega = \left[\prod_{i=1}^{M} Y_i^{\nu_i}\right] f(T). \tag{1.3}$$

For $i = 1, \dots, M$ set $\alpha_i = m_i \nu_i$, where m_i is the molecular mass of the ith species, then the following system of reaction-diffusion equations models the reaction (1.2) within the framework of the isobaric approximation of slow combustion:

$$T_t = \Delta T + Q\omega, \tag{1.4a}$$

$$Y_{it} = d_i \Delta Y_i - \alpha_i \omega, \qquad i = 1, \dots, M. \tag{1.4b}$$

* Received by the editors April 1, 1992; accepted for publication (in revised form) August 5, 1992.

† Department of Mathematics, University of North Carolina at Charlotte, Charlotte, North Carolina 28223.

Here Q, $d_1, d_2, \ldots, d_M$ are positive constants, with Q denoting the heat release. By way of example, the reaction-diffusion equations for the reaction (1.1) are, with $\omega = Y_1^2 Y_2 f(T)$,

$$T_t = \Delta T + Q\omega, \tag{1.5a}$$

$$Y_{1t} = d_1 \Delta Y_1 - 2m_1\omega, \tag{1.5b}$$

$$Y_{2t} = d_2 \Delta Y_2 - m_2\omega. \tag{1.5c}$$

For further physical background on (1.3) and (1.4), see, e.g., [6], [27], or [13, pp. 57-59].

There is a wide body of literature associated with the simpler one-step reaction $A \rightarrow B$ and its associated set of reaction-diffusion equations. With $\Omega = \mathbb{R}$, the existence of traveling-wave solutions has been considered in [5], [14], [15], [23], [25], [26] and their stability vs. instability analyzed in [7], [21], [24]. The general Cauchy problem with $\Omega = \mathbb{R}$ has been considered in [1], [13], [19] and a similar model describing platelet aggregation has been studied in [17], [18]. The general Cauchy problem when Ω is a bounded domain has been studied, for example, in [2], [9], [10], [16], [20]; see also the references contained therein. Our purpose here will be to extend the qualitative theory developed in [2] to the system (1.4). Our basic tools will consist of standard comparison principles, a lemma appearing in a paper by Fitzgibbon and Martin [8, Lemma 2.5], and some integral estimates which we develop here that generalize some arguments used in [3].

We consider the following sets of boundary conditions on T and the Y_i, $i = 1, \ldots, M$: either

$$\frac{\partial T}{\partial \nu} = \frac{\partial Y_i}{\partial \nu} = 0 \quad \text{on } \partial\Omega, i = 1, \ldots, M, \tag{1.6}$$

where ν is the outward normal on Ω, or for a sufficiently smooth function g on $\partial\Omega$,

$$T = g \quad \text{on } \partial\Omega, \tag{1.7a}$$

$$\frac{\partial Y_i}{\partial \nu} = 0 \quad \text{on } \partial\Omega, i = 1, \ldots, M. \tag{1.7b}$$

Under these conditions it is possible to establish the following global existence and uniqueness result; the proof, by appealing to the techniques developed in [22, Chap. 14], is only a slight generalization of [2, Thm. 2.4] and can therefore be safely omitted.

THEOREM 1.1. *Let* $T_0 \equiv T(x, 0)$ *and* $Y_{i0} \equiv Y_i(x, 0)$, $i = 1, \ldots, M$, *be nonnegative and in* $C(\bar{\Omega})$ *and let w be the solution of the Dirichlet problem*

$$\Delta w = 0 \quad \text{in } \Omega, \tag{1.8a}$$

$$w = g \quad \text{on } \partial\Omega. \tag{1.8b}$$

For a given integer $k \geqq 2$ *choose g smooth enough so that* $w \in C^k(\bar{\Omega})$. *Then for either set of boundary conditions* (1.6) *or* (1.7) *there exist unique nonnegative global strong solutions* T *and* Y_i, $i = 1, \ldots, M$, *of* (1.4) *such that* $T, Y_i \in C^j((0, +\infty); C^k(\Omega)) \cap C([0, +\infty); C(\bar{\Omega}))$ *for each* $j \geqq 1$.

Before stating our main result we first note a fairly standard fact about the Laplace operator on Ω. Let $W_i(t) = \exp(d_i \Delta)$ where Δ is equipped with zero Neumann boundary conditions. Then for any $h \in C(\bar{\Omega})$ we have that

$$\lim_{t \to \infty} W_i(t)h = h_{AV} \tag{1.9}$$

uniformly in x, where

$$h_{AV}=\frac{1}{|\Omega|}\int_{\Omega} h(x)\,dx. \tag{1.10}$$

See, e.g., [2, Prop. 3.1] for a proof of this very intuitive result.

If we assume the conditions (1.6) and set $G(x,t)=T(x,t)+(Q/\alpha_1)Y_1(x,t)$, set $G_0=G(x,0)$ and let $(G_0)_{AV}$ equal the right-hand side of (1.10) with h replaced by G_0, then by taking appropriate linear combinations in (1.4), integrating over Ω, and dividing by $|\Omega|$ we obtain

$$\frac{1}{|\Omega|}\int_{\Omega} G(x,t)\,dx=(G_0)_{AV}. \tag{1.11}$$

Equation (1.11) will be useful to us in what follows; additionally, (1.11) serves as a basis for establishing uniform bounds on T. Bounds on all the Y_i follow immediately, since it is easy to see from the maximum principle that $\|Y_i(\cdot,t)\|_\infty \leqq \|Y_{i0}\|_\infty$, $i=1,\ldots,M$, for all $t\geqq 0$. That there exists a constant M_T such that $\|(T(\cdot,t)\|_\infty\leqq M_T$ for all $t\geqq 0$ follows from (1.11), using previous work by a number of authors on a particular class of reaction-diffusion systems of which (1.4) is a special case; see, e.g., [11] and the references contained therein. If conditions (1.7) are assumed, a bound on T can be obtained by modification of these arguments, but in fact boundedness of T in this case will follow independently from our convergence results below.

Let $(Y_{i0})_{AV}$ equal the right-hand side of (1.10) with h replaced by Y_{i0}, $i=1,\ldots,M$. By relabeling, if necessary, we can assume that $(1/\alpha_1)(Y_{10})_{AV}=\min_{1\leqq i\leqq M}\{(1/\alpha_i)(Y_{i0})_{AV}\}$. Set $(Z_{i0})_{AV}=(1/\alpha_i)(Y_{i0})_{AV}-(1/\alpha_1)(Y_{10})_{AV}$, $i=2,\ldots,M$, then each $(Z_{i0})_{AV}$ is nonnegative. With these preliminaries in mind we are ready to state our main result.

THEOREM 1.2. *Let T_0, Y_{i0}, $i=1,\ldots,M$, and $(Z_{i0})_{AV}$, $i=2,\ldots,M$, be as above and suppose without loss of generality that all of the $(Z_{i0})_{AV}$ are nonnegative. Suppose under either of the conditions* (1.6) *and* (1.7) *that T_0 is not identically zero and if conditions* (1.7) *are assumed suppose that $g(x)>0$ for all $x\in\partial\Omega$. Then $Y_1(x,t)$ converges uniformly in x to zero as $t\to\infty$, while*

$$\lim_{t\to\infty} Y_i(x,t)=\alpha_i(Z_{i0})_{AV},\qquad i=2,\ldots,M \tag{1.12}$$

uniformly in x. If conditions (1.6) *are assumed, $T(x,t)$ converges uniformly in x to $(G_0)_{AV}$ as $t\to\infty$, while if conditions* (1.7) *are assumed, $T(x,t)$ converges uniformly in x to w as $t\to\infty$, where w is as in* (1.8).

Remarks. (a) Note that Theorem 1.2 provides a complete description of the asymptotic behavior of the system (1.4), subject to the boundary conditions (1.6) or (1.7), whenever g is everywhere positive. The physical interpretation of (1.12) is that a residual amount of A_i always remains unless $(Z_{i0})_{AV}$ is identically zero, $i=2,\ldots,M$. There is certainly a precedent for the positivity assumption on g: see, e.g., [9], [20], and [10, §§ 5.1, 6.1, and 10.2] wherein the condition $g\equiv 1$ is assumed in a model of the one-species fuel case.

(b) The convergence of the Y_i to their respective steady-states is eventually exponential in t if and only if $\nu_1=1$. If $\nu_1>1$, the eventual convergence is no faster than a negative power of t, as we will see in the proof below.

The spatial averages of T and the Y_i for $t\geqq 0$ will also play a key role in the proof of Theorem 1.2. Following [8, § 2] we introduce the following notation for these quantities:

$$\bar{T}(t)=\frac{1}{|\Omega|}\int_\Omega T(x,t)\,dx, \tag{1.13a}$$

$$\bar{Y}_i(t)=\frac{1}{|\Omega|}\int_\Omega Y_i(x,t)\,dx, \qquad i=1,\dots,M. \tag{1.13b}$$

The following lemma follows from the proof of [8, Lemma 2.5] with only slight modifications made to the arguments so that they apply to (1.4) as well as the systems considered in [8].

LEMMA 1.1. *Let $\bar{T}$ and $\bar{Y}_i$, $i=1,\dots,M$, be as in* (1.13). *Then under the conditions of Theorem* 1.1 *we have that*

$$\lim_{t\to\infty}\|Y_i(\cdot,t)-\bar{Y}_i(t)\|_\infty=0, \qquad i=1,\dots,M \tag{1.14}$$

and if conditions (1.6) *are assumed we also have that*

$$\lim_{t\to\infty}\|T(\cdot,t)-\bar{T}(t)\|_\infty=0. \tag{1.15}$$

We will, for completeness, give a proof of Lemma 1.1 in § 3 below. The proof of Theorem 1.2 will appear in § 2. We close this section by demonstrating that under the conditions of Theorem 1.2 there exist constants $\alpha>0$ and $t_1>0$ such that $T(x,t)\geqq\alpha$ for all x in Ω and all $t\geqq t_1$.

PROPOSITION 1.2. *Under the conditions of Theorem* 1.1 *and the boundary conditions* (1.6) *there exists α and t_1 as noted above whenever T_0 is not identically zero.*

Proof. We have by Theorem 1.1 that $T(x,t)$ and $Y_i(x,t)$, $i\in\{1,2,3\}$, are nonnegative for all $t\geqq0$. Hence $\omega(x,s)$ is nonnegative for all $x\in\Omega$ and all $s\geqq0$ by (1.3). Let $W_0(t)=\exp(td_0\Delta)$ where Δ is equipped with zero Neumann boundary conditions, then T satisfies the integral equation

$$T(t)=W_0(t)T_0+Q\int_0^t W_0(t-s)\omega(s)\,ds, \tag{1.16}$$

where we have suppressed the dependence on x. Since $W_0(t)$ preserves nonnegativity, it follows from (1.16) (or the maximum principle) that $T(x,t)\geqq(W_0(t)T_0)(x)$ for all $t\geq0$. The result then follows from (1.9) with h replaced by T_0, since if T_0 is not identically zero then $(T_0)_{AV}$ is strictly positive; here we can have $\alpha=(T_0)_{AV}-\varepsilon$ for any ε with $0<\varepsilon\ll(T_0)_{AV}$.

PROPOSITION 1.3. *Under the conditions of Theorem* 1.1 *and the boundary conditions* (1.7) *there exist α and t_1 as noted above for any g with $g(x)>0$ for all $x\in\partial\Omega$.*

Proof. This result is almost identical to [2, Thm. 4.2]; we include a proof for completeness. Again we have that $\omega(x,s)$ is nonnegative for all $x\in\Omega$ and all $s\geqq0$. The integral equation for T is now (for w as in (1.8))

$$T(t)=W_0(t)(T_0-w)+w+Q\int_0^t W_0(t-s)\omega(s)\,ds, \tag{1.17}$$

where now Δ is equipped with zero Dirichlet boundary conditions. Again $W_0(t)$ is nonnegativity-preserving, thus

$$T(x,t)\geqq(W_0(t)(T_0-w))(x)+w(x) \tag{1.18}$$

for all $t\geqq0$. Since $\partial\Omega$ is compact there exists an $x_0\in\partial\Omega$ such that $g(x)\geqq g(x_0)>0$ for all $x\in\partial\Omega$. By the maximum principle $w(x)\geqq g(x_0)$ for all $x\in\Omega$. Meanwhile, if λ_1 is the first eigenvalue of $-\Delta$ then $\lambda_1 > 0$ and there exists a constant K_0 such that for all $h \in C(\bar{\Omega})$

$$\|W_0(t)h\|_\infty \leqq K_0 \|h\|_\infty e^{-\lambda_1 t} \tag{1.19}$$

for all $t \geqq 0$. The result now follows by substituting $T_0 - w$ for h in (1.19); here we can have $\alpha = g(x_0) - \varepsilon$ for any ε with $0 < \varepsilon \ll g(x_0)$.

2. Proof of Theorem 1.2. We first prove the theorem in the case that the $(Z_{i0})_{AV}$ are all positive. Setting $\bar{Z}_i \equiv (1/\alpha_i)\bar{Y}_i - (1/\alpha_1)\bar{Y}_1$ we have, by taking appropriate linear combinations of (1.4b) and integrating over Ω, that $\bar{Z}_i = (Z_{i0})_{AV}$, $i = 2, \ldots, M$, and hence that $\bar{Y}_i = \alpha_i (Z_{i0})_{AV} + (\alpha_i/\alpha_1)\bar{Y}_1$, $i = 2, \ldots, M$. By (1.14) we then have that

$$\lim_{t\to\infty} (Y_i(x, t) - (\alpha_i/\alpha_1)\bar{Y}_1(t)) = \alpha_i (Z_{i0})_{AV}, \qquad i = 2, \ldots, M. \tag{2.1}$$

Then by (2.1) and the nonnegativity of Y_1 we have that there exist constants $b_i > 0$ and $t_i > 0$, $i = 2, \ldots, M$, such that for all $x \in \Omega$ and all $t \geqq t_i$

$$Y_i(x, t) \geqq b_i; \tag{2.2}$$

in (2.2) we can take $b_i = \alpha_i (Z_{i0})_{AV} - \varepsilon$, $i = 2, \ldots, M$, for any ε with $0 < \varepsilon \ll \alpha_i (Z_{i0})_{AV}$. From Proposition 1.2 or 1.3 we have that there exist an $\alpha > 0$ and a $t_1 > 0$ such that

$$T(x, t) \geqq \alpha \tag{2.3}$$

for all $x \in \Omega$ and all $t \geqq t_1$. Set $t_0 = \max\{t_1, t_2, \ldots, t_M\}$; then from (2.2), (2.3), and the monotonicity if f we have that

$$-c\alpha_1 Y_1^{\nu_1}(x, t) \geqq -\alpha_1 \omega(x, t) \tag{2.4}$$

for all $x \in \Omega$ and all $t \geqq t_0$, where $c = b_2^{\nu_2} b_3^{\nu_3}, \ldots, b_M^{\nu_M} f(\alpha)$. Standard comparison principles (see, e.g., [22]) now assert that if $u = u(t)$ is a solution of the ODE initial-value problem

$$\dot{u} = -c\alpha_1 u^{\nu_1}, \tag{2.5a}$$

$$u(0) = \|Y_{10}\|_\infty, \tag{2.5b}$$

then for all $x \in \Omega$ and $t \geqq t_0$

$$0 \leqq Y_1(x, t) \leqq u(t - t_0). \tag{2.6}$$

But (2.5) can be easily solved by the method of separation: if $\nu_1 = 1$ then $u(t) = \|Y_{10}\|_\infty \exp(-c\alpha_1 t)$, while if $\nu_1 > 1$ then $u(t) = (at + b)^{-\gamma_1}$ where $\gamma_1 = 1/(\nu_1 - 1)$, $a = c\alpha_1/(\nu_1 - 1)$, and $b = \|Y_{10}\|_\infty^{1-\nu_1}$. In either case we have from (2.6) that $Y_1(x, t) \to 0$ uniformly in x as $t \to \infty$. Hence $\bar{Y}_1(t) \to 0$ by the bounded convergence theorem. The stated convergence of $Y_2, \ldots, Y_M$ now follows from (2.1). The stated convergence of $T(x, t)$ in the case that conditions (1.6) are assumed follows from (1.11), (1.15), and the convergence of Y_1 (and hence $\bar{Y}_1$) to zero.

We now focus on the case of boundary conditions as in (1.7) and let w be as in (1.8). By replacing T_0 and Y_{i0}, $i = 1, 2, 3$, by $T(x, t_0)$ and $Y_i(x, t_0)$, $i = 1, 2, 3$, if necessary, we can without loss of generality assume that (2.6) holds with $t_0 = 0$. Then, combining (2.6) with (1.19) we have for $K = \|Y_{20}\|_\infty^{\nu_2} \|Y_{30}\|_\infty^{\nu_M} \cdots \|Y_{M0}\|_\infty^{\nu_M} K_0 B$ that

$$\int_0^t W_0(t - s)\omega(s)\, ds \leqq K \int_0^t e^{-\lambda_1 (t-s)} [u(s)]^{\nu_1}\, ds, \tag{2.7}$$

where, on the left-hand side of (2.7), we suppress the x-dependence. In the case $\nu_1 = 1$ we then have, for $\lambda_2 = -c\alpha_1\nu_1$ and $K_1 = K\|Y_{10}\|_\infty$, that

$$\begin{aligned}\int_0^t W_0(t-s)\omega(s)\,ds &\leqq K_1\int_0^t e^{-\lambda_1(t-s)}\,e^{-\lambda_2 s}\,ds\\ &= K_1\,e^{-\lambda_1 t}\int_0^t e^{(\lambda_1-\lambda_2)s}\,ds \qquad (2.8)\\ &= \frac{K_1}{\lambda_1-\lambda_2}(e^{-\lambda_2 t}-e^{-\lambda_1 t}).\end{aligned}$$

We have dealt with the right-hand side of (2.8) in earlier works; see, e.g., [3], [4]. If $\nu_1 > 1$, let γ_1, a, and b be as above so that $u(t) = (at+b)^{-\gamma_1}$, then

$$(2.9)\qquad \int_0^t W_0(t-s)\omega(s)\,ds \leqq K\int_0^t e^{-\lambda_1(t-s)}(as+b)^{-\gamma_2}\,ds,$$

where $\gamma_2 = \gamma_1\nu_1 = \nu_1/(\nu_1-1)$; note that $b > 0$ so that the integral on the right-hand side of (2.9) is well defined.

Since $\gamma_2 > 1$, given $\varepsilon > 0$ we can select a constant $k > 0$ such that

$$(2.10)\qquad K\int_k^\infty (as+b)^{-\gamma_2}\,ds < \frac{\varepsilon}{2}.$$

Then, for this choice of k,

$$\begin{aligned}K\int_0^t e^{-\lambda_1(t-s)}(as+b)^{-\gamma_2}\,ds &\leqq Kb^{-\gamma_2}\,e^{-\lambda_1 t}\int_0^k e^{\lambda_1 s}\,ds+\frac{\varepsilon}{2} \qquad (2.11)\\ &= K_2\,e^{-\lambda_1 t}+\frac{\varepsilon}{2},\end{aligned}$$

where $K_2 = (1/\lambda_1)Kb^{-\gamma_2}(e^{\lambda_1 k}-1)$. We thus see by (2.11) that the right-hand side of (2.9) can be made as small as we wish by choosing t large enough. Hence from (2.8) and (2.9) we see that

$$(2.12)\qquad \lim_{t\to\infty}\int_0^t W_0(t-s)\omega(s)\,ds = 0$$

uniformly in x. The convergence of T to w now follows from (1.17), (2.12), and (1.19) with h replaced by $T_0 - w$.

We now consider the "critical" cases when some or all of the $(Z_{i0})_{AV}$ are zero. By relabeling, if necessary, we can assume that $(Z_{i0})_{AV} = 0$, $i = 2, \dots, M_0$, for some M_0 with $2 \leqq M_0 \leqq M$, and that $(Z_{i0})_{AV} > 0$, $i = M_0+1, \dots, M$. Then from the remarks preceding (2.1) we have that

$$(2.13)\qquad \bar{Y}_i(t) - \left(\frac{\alpha_i}{\alpha_1}\right)\bar{Y}_1(t) = 0, \qquad i = 2, \dots, M_0.$$

Combining (2.13) with (1.14), we obtain that

$$(2.14)\qquad \lim_{t\to\infty}\left\|Y_i(\cdot, t) - \left(\frac{\alpha_i}{\alpha_1}\right)Y_1(\cdot, t)\right\|_\infty = 0, \qquad i = 2, \dots, M_0.$$

Thus given $\varepsilon < 0$ there exists a constant $t_i > 0$ such that

$$(2.15)\qquad Y_i(x, t) \geqq \left(\frac{\alpha_i}{\alpha_1}\right)(Y_1(x, t) - \varepsilon), \qquad i = 2, \dots, M_0$$

for all $x \in \Omega$ and all $t \geqq t_i$. Meanwhile, as in the first part of the proof, we can find constants $b_i > 0$ and $t_i > 0$ such that (2.2) holds for all $x \in \Omega$ and $t \geqq t_i$, $i = M_0 + 1, \ldots, M$. Let t_1 and α also be as in the first part of the proof and set $t_0 = \max\{t_1, \ldots, t_M\}$, $d = \min\{\alpha_2/\alpha_1, \ldots, \alpha_{M_0}/\alpha_1\}$, $\nu_0 = \nu_2 + \cdots + \nu_{M_0}$, and $c = \alpha_1[\prod_{i=M_0+1}^{M} b^{\nu_i}]d^{\nu_0}f(\alpha)$. Then standard comparison principles now assert that if $u = u(t)$ solves the ODE initial-value problem

$$\dot{u} = -cu^{\nu_1}(u - \varepsilon)^{\nu_0} \tag{2.16a}$$

$$u(0) = \| Y_{10} \|_\infty, \tag{2.16b}$$

then for all $x \in \Omega$ and all $t \geqq t_0$

$$0 \leqq Y_1(x, t) \leqq u(t - t_0). \tag{2.17}$$

Setting $u_\varepsilon(t) = u(t) - \varepsilon$, we can rewrite (2.16a) as

$$\dot{u}_\varepsilon = -c(u_\varepsilon + \varepsilon)^{\nu_1}(u_\varepsilon)^{\nu_0}. \tag{2.18}$$

Then $u_\varepsilon(t) \leqq \bar{u}_\varepsilon(t)$ where $\bar{u}_\varepsilon$ solves the ODE initial-value problem

$$\dot{\bar{u}}_\varepsilon = -c(\bar{u}_\varepsilon)^{\nu} \tag{2.19a}$$

$$\bar{u}_\varepsilon(0) = \| Y_{10} \|_\infty - \varepsilon \tag{2.19b}$$

with $\nu = \nu_1 + \nu_0$. Since $\nu_i \geqq 1$, $i = 1, \ldots, M$, we have that $\nu > 1$; hence $\bar{u}_\varepsilon(t) = (at + b)^{-\gamma}$ where $\gamma = 1/(\nu - 1)$, $a = c/(\nu - 1)$, and $b = (\| Y_{10} \|_\infty - \varepsilon)^{1-\nu}$. Since $u(t) = u_\varepsilon(t) + \varepsilon \leqq \bar{u}_\varepsilon(t) + \varepsilon$, we have from (2.17) that for all $x \in \Omega$ and all $t \geqq t_0$

$$0 \leqq Y_1(x, t) \leqq (a(t - t_0) + b)^{-\gamma} + \varepsilon. \tag{2.20}$$

Since ε is arbitrary we conclude from (2.14) and (2.20) that $Y_i(x, t) \to 0$ uniformly, $i = 1, \ldots, M_0$, as $t \to \infty$.

The stated convergence of T in the case that conditions (1.6) are assumed now follows exactly as before from (1.11). In the case that conditions (1.7) are assumed, we need only slightly modify our arguments: (2.9) becomes

$$\begin{aligned} \int_0^t W_0(t - s)\omega(s)\,ds &\leqq K \int_0^t e^{-\lambda_1(t-s)}(as + b)^{-\gamma}\,ds + \varepsilon K \int_0^t e^{-\lambda_1(t-s)}\,ds \\ &\leqq K \int_0^t e^{-\lambda_1(t-s)}(as + b)^{-\gamma}\,ds + \varepsilon\left(\frac{1}{\lambda_1}\right)K. \end{aligned} \tag{2.21}$$

The integral on the right-hand side of (2.21) goes to zero exactly as before; combining this with the fact that ε is arbitrary we see that (2.12) again holds here. The convergence of T to w now follows as before, thus completing the proof of the theorem.

3. Proof of Lemma 1.1. We have seen in § 1 that T and the $Y_i(x, t)$ are uniformly bounded (specifically $\| Y_i(\cdot, t) \|_\infty \leqq \| Y_{i0} \|_\infty$, $i = 1, \ldots, M$, and $\| T(\cdot, t) \|_\infty \leqq M_T$ for all $t \geqq 0$). Hence by the Schauder estimates (see, e.g., [12]) there are uniform bounds for $|\nabla T|$ and $|\nabla Y_i|$ as well, $i = 1, \ldots, M$. Differentiating (1.4) through by ∇, and using these gradient estimates, the product and chain rules, and the smoothness of f, we then obtain uniform bounds for $|\partial/\partial t \nabla T|$ and $|\partial/\partial t \nabla Y_i|$, $i = 1, \ldots, M$. Let $Q_t = \Omega \times [0, t]$ for each $t > 0$. Integrating (1.4b) over Q_t we obtain

$$\| Y_1(\cdot, t) \|_1 + \alpha_1 \int_0^t \int_\Omega \omega(x, s)\,dx\,ds \leqq \| Y_{10} \|_1 \tag{3.1}$$

where $\|\cdot\|_p$ denotes the norm on $L^p(\Omega)$, $1 \leqq p < \infty$. Hence

$$\int_0^\infty \int_\Omega \omega(x, s)\, dx\, ds \leqq \left(\frac{1}{\alpha_1}\right) \| Y_{10} \|_1. \tag{3.2}$$

Multiplying (1.4b) by Y_i and integrating over Q_t we obtain

$$\int_0^t \int_\Omega |\nabla Y_i|^2\, dx\, ds \leqq \frac{1}{2} \| Y_{i0} \|_2^2, \qquad i = 1, \dots, M. \tag{3.3}$$

If conditions (1.6) are assumed, we multiply (1.4a) by T and integrate over Q_t to obtain

$$\frac{1}{2} \| T(\cdot, t) \|_2^2 + \int_0^t \int_\Omega |\nabla T|^2\, dx\, ds \leqq QM_T \int_0^t \int_\Omega \omega(x, s)\, dx\, ds + \frac{1}{2} \| T_0 \|_2^2. \tag{3.4}$$

From (3.3) and by combining (3.2) and (3.4) we thus see that

$$\int_0^\infty \int_\Omega |\nabla Y_i|^2\, dx\, ds < \infty, \qquad i = 1, \dots, M, \tag{3.5}$$

and if conditions (1.6) are assumed that

$$\int_0^\infty \int_\Omega |\nabla T|^2\, dx\, ds < \infty. \tag{3.6}$$

The uniform bounds on $|\partial/\partial t \nabla T|$ and $|\partial/\partial t \nabla Y_i|$, $i = 1, \dots, M$, Hölder's inequality, and (3.5), (3.6) then show that

$$\lim_{t\to\infty} \| |\nabla Y_i(\cdot, t)| \|_p = 0, \qquad i = 1, \dots, M \tag{3.7}$$

for all $p \geqq 1$ and, if conditions (1.6) are assumed, that

$$\lim_{t\to\infty} \| |\nabla T(\cdot, t)| \|_p = 0 \tag{3.8}$$

for all $p \geqq 1$.

If λ_i is the first positive eigenvalue of the operator $-d_i\Delta$ equipped with zero Neumann boundary conditions, then by eigenfunction expansion we see that

$$\lambda_i \| Y_i(\cdot, t) - \bar{Y}_i(t) \|_2 \leqq \| |\nabla Y_i(\cdot, t)| \|_2^2, \qquad i = 1, \dots, M \tag{3.9}$$

and hence

$$\lim_{t\to\infty} \| Y_i(\cdot, t) - \bar{Y}_i(t) \|_2 = 0, \qquad i = 1, \dots, M. \tag{3.10}$$

From (3.10), the uniform bounds on the Y_i, and Hölder's inequality, we then have that

$$\lim_{t\to\infty} \| Y_i(\cdot, t) - \bar{Y}_i(t) \|_p = 0, \qquad i = 1, \dots, M \tag{3.11}$$

for all $p \geqq 1$. Selecting $p > n$, we have from the standard Sobolev embedding theorems that there exists a constant $K = K(n, p, \Omega)$ such that

$$\| Y_i(\cdot, t) - \bar{Y}_i(t) \|_\infty \leqq K[\| Y_i(\cdot, t) - \bar{Y}_i(t) \|_p + \| |\nabla Y_i(\cdot, t)| \|_p], \qquad i = 1, \dots, M, \tag{3.12}$$

where we note that $\nabla \bar{Y}_i(t) = 0$. Thus (1.14) follows from (3.7), (3.11), and (3.12). Similarly, starting with (3.8), (1.15) follows if conditions (1.6) are assumed. This completes the proof of the lemma.

Remark. From (3.6) on, the arguments used here are virtually identical to those employed in the proof of [8, Lemma 2.5].

ON A DISSOLUTION-GROWTH PROBLEM WITH SURFACE TENSION IN THE NEIGHBORHOOD OF A STATIONARY SOLUTION*

F. ABERGEL[†], D. HILHORST[†], AND F. ISSARD-ROCH[†]

Abstract. The authors consider a one-phase Stefan problem with surface tension in dimension two and show a well-posedness result in the neighborhood of a stationary solution, in the case that the moving interface is parametrized in the form $y = f(x,t)$.

Key words. Stefan problem, surface tension, free boundary, nonlinear parabolic PDEs

AMS(MOS) subject classifications. 35K55, 35R35

1. Introduction.

Consider a system composed of a solid phase of a single compound and an incompressible liquid phase which is a dilute solution of that compound, and suppose that the evolution in time of the system is governed by two processes: a diffusion process in a diffusion layer in the fluid and a dissolution-growth process, located at the interface between solid and fluid.

The mathematical problem can be described by three basic equations

$$C_t = \Delta C \quad \text{in the diffusion layer,} \tag{1.1}$$

where $C = C(x,y,t)$ is the concentration in the liquid phase,

$$\frac{\partial C}{\partial n}|_{\Gamma(t)} = V_n, \tag{1.2}$$

where $\Gamma(t)$ denotes the interface between solid and fluid, n is the normal unit vector to the interface directed towards the fluid, and V_n is the normal velocity of $\Gamma(t)$,

$$V_n = -\alpha e^{\gamma K} + C|_{\Gamma(t)} \tag{1.3}$$

where α is a positive constant, the positive constant γ is proportional to the surface tension of the interface, and K is the curvature of the interface. Let us note that in view of (1.3), the boundary condition (1.2) can be rewritten as

$$\left(C - \frac{\partial C}{\partial n}\right)|_{\Gamma(t)} = \alpha e^{\gamma K}.$$

In this paper, we consider the case where the interface can be parametrized in the form $y = f(x,t)$ and denote by e the width of the diffusion layer. Then f and C

*Received by the editors August 13, 1991; accepted for publication (in revised form) July 9, 1992. Part of this project was finished while two of the authors (F.A. and D.H.) were visiting the Institute for Mathematics and Its Applications at the University of Minnesota.

[†]Laboratoire d' Analyse Numérique, Centre National de la Recherche Scientifique, et Université Paris Sud, 91405 Orsay Cédex, France.

satisfy the following (rescaled) problem:

$$P_0 \begin{cases} C_t = \Delta C \quad \text{in } Q_f := \{(x,y,t) \in \mathbb{R}^2 \times \mathbb{R}^+, f(x,t) < y < f(x,t)_+e\}, & \\ \left(C - \frac{\partial C}{\partial n}\right)(x, f(x,t), t) = \alpha e^{-\gamma(f_{xx}/(1+f_x^2)^{3/2})(x,t)}, & (x,t) \in \mathbb{R} \times \mathbb{R}^+, \\ \frac{\partial C}{\partial n}(x, f(x,t)+e, t) = 0, & (x,t) \in \mathbb{R} \times \mathbb{R}^+, \\ C(x+2L, y, t) = C(x,y,t), & (x,y,t) \in Q_f, \\ \frac{f_t}{(1+f_x^2)^{1/2}} = -\alpha e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} + C(x, f(x,t), t), & (x,t) \in \mathbb{R} \times \mathbb{R}^+, \\ f(x+2L, t) = f(x,t), & (x,t) \in \mathbb{R} \times \mathbb{R}^+, \\ f(x,0) = f_0(x), & x \in \mathbb{R}, \\ C(x,y,0) = C_0(x,y) \quad (x,y) \in \Sigma_f := \{(x,y) \in \mathbb{R}^2, f_0(x) < y < f_0(x)_+e\}, & \end{cases}$$

where f_0 and C_0 satisfy the hypothesis H_0:

$f_0 \in C_{\text{per}}^{3+\lambda}(\mathbb{R}), C_0 \in C_{\text{per}}^{2+\lambda}(\overline{\Sigma}_f)$ for some $\lambda \in (0,1)$, and C_0 satisfies the compatibility conditions

$$\frac{\partial C_0}{\partial n}(x, f_0(x)+e) = 0 \qquad x \in \mathbb{R},$$
$$\left(C_0 - \frac{\partial C_0}{\partial n}\right)(x, f_0(x)) = \alpha e^{-\gamma(f_0''/(1+f_0'^2)^{3/2})}(x) \qquad x \in \mathbb{R}.$$

(By the subscript per we denote functions periodic in the variable x with period $2L$.)

We remark that pairs of the form $(C, f) = (\alpha,$ constant $)$ are stationary solutions of problem P_0. The purpose of this paper is to prove the following existence and uniqueness result.

THEOREM 1.1. *There exists a positive constant $\rho_0 = \rho_0(T)$ such that if the initial data satisfies the condition*

$$\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|C_0 - \alpha\|_{\Sigma_f}^{(2+\lambda)} \leq \rho_0,$$

then P_0 has a unique solution (f, C) in $C_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\mathbb{R} \times [0,T]) \times C_{\text{per}}^{2+\lambda,1+\lambda/2}(\overline{Q_f^T})$, where $Q_f^T := \{(x,y,t) \in Q_f, t \in (0,T)\}$.

The paper is organized as follows. In §2, we present a physical derivation of the problem which is due to Cournil [5]. In §3, we transform problem P_0 into a problem on a fixed domain. In §4, we recall the definitions of the Hölder spaces that we use and prove some properties which are useful in the following sections. In §5, we consider a related linear problem and prove its well-posedness.

We prove Theorem 1.1 transposed to the coordinates of the fixed domain in §§6 and 7. An improved uniqueness result is given in §6. The existence proof is given in §7. It is done by means of a fixed point method: we iteratively solve the linear problem of §5, while considering as known the nonlinear terms. The idea is to show that the iterative map is a strict contraction from a ball of small enough radius $\rho > \rho_0$ into itself.

Let us remark that our proof would carry over to the case of a domain given by

$$\{(x,y,t) \in \mathbb{R}^2 \times \mathbb{R}^+, f(x,t) < y < A\}$$

with A a fixed constant. A suitable change of variables for transforming the problem to a fixed domain is then given by $\tilde{y} = (A-y)/(A-f(x,t))$, and the constants ρ_0

and ρ should be chosen small enough so that the interface does not hit the boundary $y = A$.

In a forthcoming paper we shall extend our method to the proof of local existence and uniqueness for arbitrary initial data. For the well-posedness of a very similar problem in the case of spherical symmetry we refer to [4], [7].

For local existence and uniqueness results for related problems we refer to a study of Duchon and Robert [6] of a quasistationary problem and to papers by X. Y. Chen [3] and Xinfu Chen [2] about a two phase problem.

2. The physical derivation. In heterogeneous media, a problem of interest is the creation or the consumption of one or more phases. These phenomena are accompanied by a change in the geometry of the reaction field and, in particular, by an evolution of interfaces. The interfaces are of essential importance: on the one hand, they determine the geometrical configuration of the system and on the other hand they intervene, by means of their curvature, in the equilibrium and stability conditions.

In this paper, we consider a system composed of a solid phase of a single compound and an incompressible liquid phase, which is a dilute solution of that compound. The evolution in time of this system induces mass transfer processes: a homogeneous one which consists of a diffusion process in a diffusion layer in the fluid and a heterogeneous one, namely, a dissolution-growth process, located at the interface between solid and liquid.

Let $y = f(x,t)$ be a parametrization of the interface, let e denote the width of the diffusion layer, and let $C(x,y,t)$ with $f(x,t) < y < f(x,t) + e$ denote the concentration in the liquid phase. The equations of the problem are deduced from the following physical laws.

(i) *Mass balance.* We shall assume that the fluid is essentially at rest, so that the convective velocity is negligible; let J denote the diffusion flux, which we suppose given by Fick's law:

$$J = -D \operatorname{grad} C, \tag{2.1}$$

where the diffusion coefficient D is a positive constant.

Upon writing the conservation of mass for an arbitrary subdomain ω consisting of the same particles for each time, we obtain

$$0 = \frac{d}{dt}\left(\int_{\omega_t} C dx\right) = \int_{\omega_t} C_t dx + \int_{\partial\omega_t^l} J.\vec{n} d\sigma + \int_{\partial\omega_t^s} (C - V^{-1})\vec{v}.\vec{n} d\sigma. \tag{2.2}$$

In (2.2) $\partial\omega_t^l$ (respectively, $\partial\omega_t^s$) is that part of $\partial\omega_t$ which makes contact with the liquid (respectively, solid) phase, V^{-1} is the concentration in the solid phase, and $\vec{v}$ is the velocity of the interface.

From (2.2) we easily obtain the governing equations

$$C_t = D\Delta C \tag{2.3}$$

in the fluid domain, and

$$D\frac{\partial C}{\partial n} = (V^{-1} - C)\vec{v}.\vec{n} \tag{2.4}$$

at the interface.

From now on, we shall assume that V^{-1} is much larger than C, and write (2.4) as

$$D\frac{\partial C}{\partial n} = V^{-1}\vec{v}.\vec{n}. \tag{2.5}$$

Upon using the fact that the interface is the graph of a function $f(x,t)$, we eventually write (2.5) under its final form

$$D\frac{\partial C}{\partial n} = V^{-1}\frac{ft}{\sqrt{1+f_x^2}}. \tag{2.6}$$

(ii) *Dissolution and growth of the solid.* We suppose that the kinetics of dissolution and growth follows Nernst's law, which derives, either from a rate determining diffusion in a layer of constant thickness, or from a rate determining first order interface reaction [8], namely,

$$J\cdot n|_{y=f(x,t)} = -h(C,R), \tag{2.7}$$

where R is the radius of curvature of the interface

$$R(x,t) = -\frac{(1+f_x^2)^{3/2}}{f_{xx}} \tag{2.8}$$

and the function h is given by

$$h(C,R) = K(C - s_0 e^{\gamma/R}), \tag{2.9}$$

where K is a kinetic constant, s_0 is the concentration at saturation of the solution, and γ is proportional to the surface tension of the interface.

Using (2.6)–(2.9), we deduce that

$$\frac{1}{V}f_t = (1+f_x^2)^{1/2}K(C(x,f(x,t),t) - s_0 e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}}), \tag{2.10}$$

whereas (2.1) and (2.7)–(2.9) imply the boundary condition

$$D\frac{\partial C}{\partial n} = K(C - s_0 e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}}) \tag{2.11}$$

on the interface $y = f(x,t)$, where n is the normal to the interface directed towards the fluid.

(iii) *Other boundary conditions.* We assume that C and f are periodic in the x-direction, namely,

$$\begin{cases} C(x+2L,y,t) = C(x,y,t) & \text{in } Q_f, \\ f(x+2L,t) = f(x,t) & \text{in } \mathbb{R}\times\mathbb{R}_+, \end{cases}$$

and that C satisfies the Neumann condition

$$\frac{\partial C}{\partial n}(x,f(x,t)+e,t) = 0, \qquad (x,t)\in\mathbb{R}\times\mathbb{R}^+. \tag{2.12}$$

Finally we set

$$\tilde{x} = \frac{Kx}{D}, \quad \tilde{y} = \frac{Ky}{D}, \quad \tilde{t} = \frac{K^2 t}{D}, \quad \tilde{C} = VC, \quad \tilde{\gamma} = \frac{K\gamma}{D},$$
$$\tilde{f} = \frac{Kf}{D}, \quad \alpha = Vs_0, \quad \tilde{L} = \frac{KL}{D}, \quad \tilde{e} = \frac{Ke}{D}$$

and omit the tilde. The equations (2.3), (2.11), (2.12), and (2.10) transform into

$$\begin{aligned}
&C_t = \Delta C \quad \text{in } Q_f := \{(x,y,t) \in \mathbb{R}^2 \times \mathbb{R}^+, f(x,t) < y < f(x,t) + e\},\\
&\left(C - \frac{\partial C}{\partial n}\right)(x, f(x,t), t) = \alpha e^{-\gamma(f_{xx}/(1+f_x^2)^{3/2})(x,t)}, \qquad (x,t) \in \mathbb{R} \times \mathbb{R}^+,\\
&\frac{\partial C}{\partial n}(x, f(x,t) + e, t) = 0, \qquad (x,t) \in \mathbb{R} \times \mathbb{R}^+,\\
&f_t = (1 + f_x^2)^{1/2}\left(-\alpha e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} + C(x, f(x,t), t)\right), \qquad (x,t) \in \mathbb{R} \times \mathbb{R}^+,
\end{aligned}$$

which, together with periodic boundary conditions and periodic initial conditions for C and f, yield Problem P_0.

3. Transformation of the problem to a problem on a fixed domain. Let us define new coordinates by

$$\hat{x} = x, \quad \hat{y} = y - f(x,t), \quad \hat{t} = t$$

and set

$$g(x,y,t) = C(x,y,t) - \alpha, \quad \hat{g}(\hat{x},\hat{y},\hat{t}) = g(x,y,t), \quad \hat{f}(\hat{x},\hat{t}) = f(x,t).$$

Some easy computations permit us to show that $\hat{g}$ and $\hat{f}$ satisfy

$$P\left\{\begin{array}{l}
\hat{g}_{\hat{t}} = \hat{g}_{\hat{x}\hat{x}} + \hat{g}_{\hat{y}\hat{y}} + \hat{f}_{\hat{x}}^2 \hat{g}_{\hat{y}\hat{y}} - (\hat{f}_{\hat{x}\hat{x}} - \hat{f}_{\hat{t}})\hat{g}_{\hat{y}} - 2\hat{f}_{\hat{x}}\hat{g}_{\hat{x}\hat{y}}\\
\qquad\qquad \text{in } Q_0 = \{(x,y,t) \in \mathbb{R}^2 \times \mathbb{R}^+, 0 < y < e\},\\
\hat{g}(\hat{x},0,\hat{t}) - (1 + \hat{f}_{\hat{x}}^2)^{1/2}\hat{g}_{\hat{y}}(\hat{x},0,\hat{t}) + \frac{\hat{f}_{\hat{x}}}{(1+\hat{f}_{\hat{x}}^2)^{1/2}}\hat{g}_{\hat{x}}(\hat{x},0,\hat{t})\\
\quad = \alpha(e^{-\gamma \hat{f}_{\hat{x}\hat{x}}/(1+\hat{f}_{\hat{x}}^2)^{3/2}} - 1) \quad (\hat{x},\hat{t}) \in \mathbb{R} \times \mathbb{R}^+\\
(1 + \hat{f}_{\hat{x}}^2)^{1/2}\hat{g}_{\hat{y}}(\hat{x},e,\hat{t}) - \frac{\hat{f}_x}{(1+\hat{f}_{\hat{x}}^2)^{1/2}}\hat{g}_{\hat{x}}(\hat{x},e,\hat{t}) = 0 \quad (\hat{x},\hat{t}) \in \mathbb{R} \times \mathbb{R}^+\\
\hat{g}(\hat{x} + 2L, \hat{y}, \hat{t}) = \hat{g}(\hat{x},\hat{y},\hat{t}) \quad \text{in } Q_0\\
\hat{g}(\hat{x},\hat{y},0) = \hat{g}_0(\hat{x},\hat{y}) \quad (\hat{x},\hat{y}) \in \mathbb{R} \times (0,e),\\
\text{where}\\
\hat{g}_0(\hat{x},\hat{y}) = C_0(x,y) - \alpha \quad (\text{with } \hat{y} = y - f_0(x)),\\
\text{and}\\
\hat{f}_{\hat{t}} = -(1 + \hat{f}_{\hat{x}}^2)^{1/2}(\alpha e^{-\gamma \hat{f}_{\hat{x}\hat{x}}/(1+\hat{f}_{\hat{x}}^2)^{3/2}} - \hat{g}(\hat{x},0,\hat{t}) - \alpha) \quad (\hat{x},\hat{t}) \in \mathbb{R} \times \mathbb{R}^+\\
\hat{f}(\hat{x} + 2L, \hat{t}) = \hat{f}(\hat{x},\hat{t}) \quad (\hat{x},\hat{t}) \in \mathbb{R} \times \mathbb{R}^+\\
\hat{f}(\hat{x},0) = \hat{f}_0(\hat{x}) \quad \hat{x} \in \mathbb{R},\\
\text{where}\\
\hat{f}_0(\hat{x}) = f_0(x).
\end{array}\right.$$

Remark 3.1. In what follows, it will be convenient to write

$$\begin{aligned}(1+f_x^2)^{1/2}&(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}}-1)\\&=-\gamma f_{xx}+(1+f_x^2)^{1/2}(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}}-1+\gamma f_{xx}/(1+f_x^2)^{1/2})\end{aligned}$$

and

$$(1+f_x^2)^{1/2}g(x,0,t)=g(x,0,t)-(1-(1+f_x^2)^{1/2})g(x,0,t);$$

this permits us to separate linear from nonlinear terms.

4. A few properties of Hölder spaces. In this paper we work with the Hölder spaces $C^{\ell,\ell/2}(\overline{\Omega}\times[0,T])$ as defined by Ladyženskaja, Solonnikov, and Ural'ceva [9]. We indicate below some notations and properties which will be useful in what follows.

Let $\Omega=\mathbb{R}\times\Omega'$, where Ω' is a smooth open set of $\mathbb{R}^{N-1}$ and $Q_T=\Omega\times(0,T)$. We define the space

$$C_{\text{per}}^{\ell,\ell/2}(\overline{Q}_T)=\Big\{f\in C^{\ell,\ell/2}(\overline{Q}_T),\\ f(x_1+2L,x',t)=f(x_1,x',t)\text{ for all }(x_1,x',t)\in\mathbb{R}\times\Omega'\times(0,T)\Big\}$$

of $2L$-periodic functions in the x_1-direction and define $C_{\text{per}}^{\ell}(\overline{\Omega})$ in a similar way.

In what follows we often use the notation

$$C^{m+\lambda,(m+\lambda)/2}(\overline{Q}_T);\quad\text{then } m=[\ell]\quad\text{and}\quad\lambda=\ell-[\ell].$$

Next we state some technical results which will be useful in the sequel.

LEMMA 4.1. (i) *Let $m\in\mathbb{N}$. There exists a constant $C>0$ which depends only on m such that*

$$\|fg\|_{Q_T}^{(m+\lambda)}\le C\|f\|_{Q_T}^{(m+\lambda)}\|g\|_{Q_T}^{(m+\lambda)}$$

for all $f,g\in C^{m+\lambda,(m+\lambda)/2}(\overline{Q}_T), 0<\lambda<1$.

(ii) *There exists a constant $C>0$ such that*

$$\left\|\frac{1}{f}\right\|_{Q_T}^{(1+\lambda)}\le C(\|f\|_{Q_T}^{(1+\lambda)})^2$$

for all $f\in C^{1+\lambda,(1+\lambda)/2}(\overline{Q}_T)$ such that $f\ge 1$.

(iii) *There exists a constant $C>0$ such that*

$$\|\varphi_o f\|_{Q_T}^{(1+\lambda)}\le C\|\varphi\|_{(-M,M)}^{(1+1)}\max\Big\{1,(\|f\|_{Q_T}^{(1+\lambda)})^2\Big\}$$

for all $f\in C^{1+\lambda,(1+\lambda)/2}(\overline{Q}_T)$ such that $-M\le f\le M$ and all $\varphi\in C^{1+1}([-M,M])$ (by which we mean the space of continuously differentiable functions with Lipschitz continuous derivatives).

Remark. We will use Lemma 4.1 (i) in cases where $g\in C^{m+\lambda,(m+\lambda)/2}(\overline{Q}_T)$ and $f\in C^{m+\lambda,(m+\lambda)/2}(\overline{\Sigma}_T)$ with $\Sigma_T=\mathbb{R}\times(0,T)$. Then we implicitly work with $\tilde{f}(x,y,t)=f(x,t)$ for all $(x,y,t)\in\overline{Q}_T$ so that $\tilde{f}\in C^{m+\lambda,(m+\lambda)/2}(\overline{Q}_T)$ and $\|\tilde{f}\|_{Q_T}^{(m+\lambda)}=\|f\|_{\Sigma_T}^{(m+\lambda)}$.

In what follows we will have to estimate terms of the form

$$E = \exp\left(-\gamma \frac{f_{xx}}{(1+f_x^2)^{3/2}}\right) - 1 + \frac{\gamma f_{xx}}{(1+f_x^2)^{1/2}}$$

as well as differences of such terms. To that purpose we set

$$\chi(s) = e^{\gamma s} - 1 - \gamma s.$$

Then

$$E = \chi\left(-\frac{f_{xx}}{(1+f_x^2)^{3/2}}\right) + \gamma f_{xx}\left(\frac{1}{(1+f_x^2)^{1/2}} - \frac{1}{(1+f_x^2)^{3/2}}\right). \tag{4.1}$$

Next we prove the following result.

Lemma 4.2. *There exists* $\delta_0 > 0$ *such that for all* $\delta \in (0, \delta_0)$ *and for all* $r \in C^{1+\lambda,(1+\lambda)/2}\,(\overline{\Sigma}_T)$ *satisfying* $\|r\|^{(1+\lambda)}_{\Sigma_T} \leq \delta$ *there holds*

$$\|\chi(r)\|^{(1+\lambda)}_{\Sigma_T} \leq \gamma^2 C(\|r\|^{(1+\lambda)}_{\Sigma_T})^2,$$

where C *is the constant introduced in Lemma* 4.1 (i).

Proof. We use the Taylor expansion

$$\chi(s) = \sum_{k=2}^{+\infty} \frac{\gamma^k s^k}{k!} = s^2 \sum_{k=0}^{\infty} \frac{\gamma^{k+2} s^k}{(k+2)!};$$

then we deduce from Lemma 4.1 (i) that, with C being the constant introduced there,

$$\begin{aligned}
\|\chi(r)\|^{(1+\lambda)}_{\Sigma_T} &\leq C\|r^2\|^{(1+\lambda)}_{\Sigma_T} \sum_{k=0}^{\infty} \frac{\gamma^{k+2}\|r^k\|^{(1+\lambda)}_{\Sigma_T}}{(k+2)!} \\
&\leq C^2(\|r\|^{(1+\lambda)}_{\Sigma_T})^2 \left\{ \sum_{k=0}^{\infty} \frac{\gamma^{k+2}}{(k+2)!} C^{k-1} (\|r\|^{1+\lambda}_{\Sigma_T})^k \right\} \\
&\leq \frac{1}{C\delta^2}(\|r\|^{(1+\lambda)}_{\Sigma_T})^2 \sum_{k=0}^{\infty} \frac{(\gamma C\delta)^{k+2}}{(k+2)!} \\
&\leq \frac{1}{C\delta^2}(e^{\gamma C\delta} - 1 - \gamma C\delta)(\|r\|^{(1+\lambda)}_{\Sigma_T})^2.
\end{aligned}$$

Lemma 4.3. *There exists* $\delta_0 > 0$ *such that for all* $\delta \in (0, \delta_0)$ *and for all* $r, r' \in C^{1+\lambda,(1+\lambda)/2}(\overline{\Sigma}_T)$ *satisfying* $\|r\|^{(1+\lambda)}_{\Sigma_T}, \|r'\|^{(1+\lambda)}_{\Sigma_T} \leq \delta$ *there exists* $K = K(\delta_0)$ *such that*

$$\|\chi(r) - \chi(r')\|^{(1+\lambda)}_{\Sigma_T} \leq K\|r - r'\|^{(1+\lambda)}_{\Sigma_T} \max\left(\|r\|^{(1+\lambda)}_{\Sigma_T}, \|r'\|^{(1+\lambda)}_{\Sigma_T}\right).$$

Proof. We have that

$$\begin{aligned}
\chi(s) - \chi(s') &= \sum_{k=2}^{\infty} \frac{\gamma^k}{k!}(s^k - s'^k) \\
&= (s - s') \sum_{k=2}^{\infty} \frac{\gamma^k}{k!} \sum_{p=0}^{k-1} s^p s'^{k-1-p},
\end{aligned}$$

which yields

$$\begin{aligned}\|\chi(r)-\chi(r')\|_{\Sigma_T}^{(1+\lambda)} &\le C\|r-r'\|_{\Sigma_T}^{(1+\lambda)}\sum_{k=2}^{\infty}\frac{\gamma^k}{k!}kC^{k-2}\delta^{k-1}\\ &\le \|r-r'\|_{\Sigma_T}^{(1+\lambda)}\sum_{j=1}^{\infty}\gamma\frac{\gamma^j C^j\delta^j}{j!}\\ &\le \gamma(e^{\gamma C\delta}-1)\|r-r'\|_{\Sigma_T}^{(1+\lambda)}\\ &\le \widetilde{K}\|r-r'\|_{\Sigma_T}^{(1+\lambda)}\max\left(\|r\|_{\Sigma_T}^{(1+\lambda)},\|r'\|_{\Sigma_T}^{(1+\lambda)}\right),\end{aligned}$$

where

$$\widetilde{K}=\gamma\frac{e^{\gamma C\delta}-1}{\delta}\le\gamma^2Ce^{\gamma C\delta_0}.$$

5. The linear problem. In this section we prove that there exists a unique solution of the following linear problem:

$$g_t-\Delta g=F_1 \quad \text{in } Q_T:=\{(x,y,t)\in\mathbb{R}\times(0,e)\times(0,T)\}, \tag{5.1}$$

$$(g-g_y)(x,0,t)+\alpha\gamma f_{xx}(x,t)=F_2(x,t),\ (x,t)\in\Sigma_T:=\mathbb{R}\times(0,T), \tag{5.2}$$

$$g_y(x,e,t)=F_3(x,t),\qquad (x,t)\in\Sigma_T, \tag{5.3}$$

$$g(x+2L,y,t)=g(x,y,t),\qquad (x,y,t)\in Q_T, \tag{5.4}$$

$$g(x,y,0)=g_0(x,y),\qquad (x,y)\in\mathbb{R}\times(0,e), \tag{5.5}$$

$$f_t-\alpha\gamma f_{xx}-g(x,0,t)=F_4(x,t)\quad \text{in } \Sigma_T, \tag{5.6}$$

$$f(x+2L,t)=f(x,t),\qquad (x,t)\in\Sigma_T, \tag{5.7}$$

$$f(x,0)=f_0(x),\qquad x\in\mathbb{R}, \tag{5.8}$$

where T is a fixed (arbitrary) positive number, $F_1\in C_{\text{per}}^{\lambda,\lambda/2}(\overline{Q}_T)$, $F_i\in C_{\text{per}}^{1+\lambda,(1+\lambda)/2}(\overline{\Sigma}_T)$, $i=2,\dots,4$, for some $\lambda\in(0,1)$, $f_0\in C_{\text{per}}^{3+\lambda}(\mathbb{R})$, $g_0\in C_{\text{per}}^{2+\lambda}(\mathbb{R}\times[0,e])$ and satisfies the compatibility conditions

$$\begin{aligned} g_{oy}(x,e) &=F_3(x,0), \qquad x\in\mathbb{R}\\ (g_0-g_{0y})(x,0)+\alpha\gamma f_0''(x) &=F_2(x,0), \qquad x\in\mathbb{R}.\end{aligned}$$

THEOREM 5.1. *Problem* (5.1)–(5.8) *has a unique solution*

$$(g,f)\in C_{\text{per}}^{2+\lambda,1+\lambda/2}(\overline{Q}_T)\times C_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T).$$

Furthermore, there exists a constant $C=C(T)$ *such that*

$$\begin{aligned}\|g\|_{Q_T}^{(2+\lambda)}+\|f\|_{\Sigma_T}^{(3+\lambda)} \le C\Big(&\|g_0\|_{\mathbb{R}\times(0,e)}^{(2+\lambda)}+\|f_0\|_{\mathbb{R}}^{(3+\lambda)}\\ &+\|F_1\|_{Q_T}^{(\lambda)}+\|F_2\|_{\Sigma_T}^{(1+\lambda)}+\|F_3\|_{\Sigma_T}^{(1+\lambda)}+\|F_4\|_{\Sigma_T}^{(1+\lambda)}\Big).\end{aligned}$$

Proof. We consider the mapping $\mathcal{L}:f\to\mathcal{L}(f)=h$ defined as follows. Given $f\in C_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ with $f(0)=f_0$ (where we use the notation $f(0)=f|_{t=0}$) we consider (5.1)–(5.5). By [9, Thm. 5.3 p. 320] this problem has a unique solution

$g \in C^{2+\lambda,1+\lambda/2}(\overline{Q}_T)$, and the uniqueness property together with the periodicity of the data implies that $g \in C^{2+\lambda,1+\lambda/2}_{\text{per}}(\overline{Q}_T)$. We then compute $h = \mathcal{L}f \in C^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T)$ as the unique solution of (5.6)–(5.8) [9, Thm. 5.1 p. 320]. The following results on continuous dependence then hold:

$$\|g\|^{(2+\lambda)}_{Q_T} \leq C_1 \Big(\|g_0\|^{(2+\lambda)}_{\mathbb{R}\times(0,e)} + \|F_1\|^{(\lambda)}_{Q_T} + \|F_2\|^{(1+\lambda)}_{\Sigma_T} + \|F_3\|^{(1+\lambda)}_{\Sigma_T} + \|f\|^{(3+\lambda)}_{\Sigma_T} \Big), \tag{5.9}$$

$$\|h\|^{(3+\lambda)}_{\Sigma_T} \leq C_2 \Big(\|f_0\|^{(3+\lambda)}_{\mathbb{R}} + \|F_4\|^{(1+\lambda)}_{\Sigma_T} + \|g\|^{(2+\lambda)}_{Q_T} \Big), \tag{5.10}$$

where C_1 and C_2 only depend on T, λ and on the parameters e, α, and γ.

Clearly if f is a fixed point of $\mathcal{L}$, i.e., if $\mathcal{L}(f) = f$ and if g is the solution of the problem (5.1)–(5.5), then (f, g) satisfies (5.1)–(5.8). Moreover, $\mathcal{L}$ is an affine mapping from the affine subspace $\{f \in C^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T), f(0) = f_0\}$ of $C^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T)$ into itself. The linear mapping $\mathcal{M}$ corresponding to $\mathcal{L}$, which is such that

$$\mathcal{L}(f) - \mathcal{L}(\bar{f}) = \mathcal{M}(f - \bar{f}), \tag{5.11}$$

is defined on

$$\overset{\circ}{C}{}^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T) := \{f \in C^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T), f(0) = 0\}$$

by

$$f \to \mathcal{M}(f) = k,$$

where k is the solution of

$$\begin{cases} k_t - \alpha\gamma k_{xx} = w(x,0,t) & \text{in } \Sigma_T, \\ k(x+2L,t) = k(x,t) & \text{in } \Sigma_T, \\ k(x,0) = 0 & x \in \mathbb{R}, \end{cases} \tag{5.12}$$

where w is the solution of

$$\begin{cases} w_t - \Delta w = 0 & \text{in } Q_T, \\ w - w_y = -\alpha\gamma f_{xx} & \text{on } \Sigma_T, \\ w_y(x,e,t) = 0, & (x,t) \in \Sigma_T, \\ w(x+2L,y,t) = w(x,y,t) & \text{in } Q_T, \\ w(x,y,0) = 0, & (x,y) \in \mathbb{R} \times (0,e). \end{cases} \tag{5.13}$$

In what follows we shall prove that $(Id - \mathcal{M})$ is a continuous invertible mapping from $\overset{\circ}{C}{}^{3+\lambda,(3+\lambda)/2}_{\text{per}}(\overline{\Sigma}_T)$ into itself; next we show that this property is equivalent to the existence of a unique fixed point of $\mathcal{L}$. Adding $f - \bar{f}$ to both sides of equality (5.11) yields

$$\mathcal{L}(f) - \mathcal{L}(\bar{f}) + f - \bar{f} - \mathcal{M}(f - \bar{f}) = f - \bar{f}$$

so that

$$(Id - \mathcal{M})(f - \bar{f}) = \mathcal{L}(\bar{f}) - \bar{f} - \mathcal{L}(f) + f.$$

Thus solving

$$\mathcal{L}(f) = f$$

is equivalent to solving

$$(Id - \mathcal{M})(f - \bar{f}) = \mathcal{L}(\bar{f}) - \bar{f},$$

which gives

$$f = \bar{f} + (Id - \mathcal{M})^{-1}(\mathcal{L}(\bar{f}) - \bar{f}). \tag{5.14}$$

In a first step we shall prove that $\mathcal{M}$ is a compact operator and in a second step that Ker $(Id - \mathcal{M}) = \{0\}$. It will then follow from the Fredholm alternative (see, for instance, Brezis [1, Thm. 6.1]) that the operator $(Id - \mathcal{M})$ is invertible.

(i) $\mathcal{M}$ is a compact operator from $\overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ into itself.

Let f be given in $\overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$; by [9] the solution w of (5.13) belongs to $\overset{\circ}{C}{}_{\text{per}}^{2+\lambda,(2+\lambda)/2}(\overline{Q}_T)$ so that also by [9] the solution k of (5.12) belongs to $\overset{\circ}{C}{}_{\text{per}}^{4+\lambda,2+\lambda/2}(\overline{\Sigma}_T)$. Thus $\mathcal{M}$ is a bounded operator from $\overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ into $\overset{\circ}{C}{}_{\text{per}}^{4+\lambda,2+\lambda/2}(\overline{\Sigma}_T)$. Using, furthermore, the compactness of the embedding from

$$\overset{\circ}{C}{}_{\text{per}}^{4+\lambda,2+\lambda/2}(\overline{\Sigma}_T) \quad \text{into } \overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$$

we conclude that $\mathcal{M}$ is a compact operator from $\overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ into itself.

(ii) Ker $(Id - \mathcal{M}) = \{0\}$.

Let $f \in \overset{\circ}{C}{}_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ be such that $(Id - \mathcal{M})f = 0$, i.e., $\mathcal{M}f = f$. Then if w is the unique solution of (5.13), f satisfies the system

$$\begin{cases} f_t - \alpha\gamma f_{xx} = w(x, 0, t) & \text{in } \Sigma_T, \\ f(x + 2L, t) = f(x, t) & \text{in } \Sigma_T, \\ f(x, 0) = 0, & x \in \mathbb{R}. \end{cases} \tag{5.15}$$

Next we multiply the differential equation in (5.15) first by f and then by $-\alpha\gamma f_{xx}$ and integrate by parts on $(-L, L)$. This gives

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{-L}^{L} f^2(x,t)dx + \alpha\gamma \int_{-L}^{L} f_x^2(x,t)dx \\ &= \int_{-L}^{L} w(x,0,t)f(x,t)dx \end{aligned} \tag{5.16}$$

and

$$\begin{aligned} &\frac{\alpha\gamma}{2}\frac{d}{dt}\int_{-L}^{L} f_x^2(x,t)dx + \alpha^2\gamma^2 \int_{-L}^{L} f_{xx}^2(x,t)dx \\ &= -\alpha\gamma \int_{-L}^{L} w(x,0,t)f_{xx}(x,t)dx. \end{aligned} \tag{5.17}$$

Now we multiply the differential equation in (5.13) by w and deduce from the boundary condition that w satisfies

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^e\int_{-L}^L w^2(x,y,t)\,dx\,dy+\int_0^e\int_{-L}^L(\operatorname{grad}w(x,y,t))^2dx\,dy\\ =\int_{-L}^L(w(x,0,t)+\alpha\gamma f_{xx}(x,t))w(x,0,t)dx.\end{aligned}\tag{5.18}$$

Using Young's inequality we deduce from (5.16) that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{-L}^L f^2(x,t)dx+\alpha\gamma\int_{-L}^L f_x^2(x,t)dx\\ \le\int_{-L}^L w^2(x,0,t)dx+\frac{1}{4}\int_{-L}^L f^2(x,t)dx.\end{aligned}\tag{5.19}$$

Adding (5.17), (5.18), and (5.19) yields

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{-L}^L f^2dx+\alpha\gamma\int_{-L}^L f_x^2dx+\frac{\alpha\gamma}{2}\frac{d}{dt}\int_{-L}^L f_x^2dx+\alpha^2\gamma^2\int_{-L}^L f_{xx}^2dx\\ +\frac{1}{2}\frac{d}{dt}\int_0^e\int_{-L}^L w^2dx\,dy+\int_0^e\int_{-L}^L(\operatorname{grad}w)^2dx\,dy\\ \le 2\int_{-L}^L w^2(x,0,t)dx+\frac{1}{4}\int_{-L}^L f^2dx.\end{aligned}\tag{5.20}$$

Finally we use the following result which we shall prove later.

LEMMA 5.2. *Let Ω be a bounded Lipschitzian domain in $\mathbb{R}^2$; for all $\varepsilon>0$ there exists a positive constant C_ε such that*

$$\int_{\partial\Omega}w^2(s)ds\le\varepsilon\iint_\Omega(\operatorname{grad}w)^2dx+C_\varepsilon\iint_\Omega w^2dx$$

for all $w\in H^1(\Omega)$.

We set $\varepsilon=\frac{1}{4}$ to deduce that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\left(\int_{-L}^L f^2dx+\alpha\gamma\int_{-L}^L f_x^2dx+\int_0^e\int_{-L}^L w^2dx\,dy\right)\\ \le\frac{1}{4}\int_{-L}^L f^2dx+2C_{1/4}\int_0^e\int_{-L}^L w^2dx\,dy.\end{aligned}\tag{5.21}$$

The inequality above is of the form $dY/dt \leq CY$, with

$$Y(t) = \frac{1}{2}\int_{-L}^{L} f^2 dx + \frac{\alpha\gamma}{2}\int_{-L}^{L} f_x^2 dx + \frac{1}{2}\int_{0}^{e}\int_{-L}^{L} w^2 dx\, dy,$$

and since $Y(0) = 0$ we conclude that $Y(t) = 0$ for all t. This implies that f and w are identically equal to zero and, therefore, that $Id - \mathcal{M}$ is an invertible mapping.

Finally the continuous dependence of the fixed point f of $\mathcal{L}$ on the data $F_i, i = 1, 2, 3, 4, f_0$, and g_0 can be seen as follows. Choose $\bar{f}(x,t) = f_0(x)$ in (5.14); then f is given by

$$f = f_0 + (Id - \mathcal{M})^{-1}(\mathcal{L}(f_0) - f_0), \tag{5.22}$$

and we deduce from (5.9), (5.10) that

$$\begin{aligned} \|\mathcal{L}(f_0)\|_{\Sigma_T}^{(3+\lambda)} \leq & C_3 \Big(\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|F_4\|_{\Sigma_T}^{(1+\lambda)} \\ & + \|g_0\|_{\mathbb{R}\times(0,e)}^{(2+\lambda)} + \|F_1\|_{Q_T}^{(\lambda)} + \|F_2\|_{\Sigma_T}^{(1+\lambda)} + \|F_3\|_{\Sigma_T}^{(1+\lambda)} \Big), \end{aligned} \tag{5.23}$$

where we have used the fact that $\|f_0\|_{\Sigma_T}^{(3+\lambda)} = \|f_0\|_{\mathbb{R}}^{(3+\lambda)}$. Therefore, since $(Id - \mathcal{M})^{-1}$ is a bounded operator, we have that

$$\|f\|_{\Sigma_T}^{(3+\lambda)} \leq C_4 \left(\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|\mathcal{L}(f_0)\|_{\Sigma_T}^{(3+\lambda)} \right). \tag{5.24}$$

The result of Theorem 5.1 then follows from (5.9), (5.23), and (5.24).

Proof of Lemma 5.2. We have that

$$\int_{\partial\Omega} w^2(s) ds = \|w\|_{H^0(\partial\Omega)}^2 \leq C\|w\|_{H^{1/2+\delta}(\Omega)}^2$$

for all $\delta > 0$. Next we use the following result given, for instance, by [10, p. 47]:

$$H^{1/2+\delta}(\Omega) = [H^1(\Omega), H^0(\Omega)]_{1/2-\delta}$$

so that

$$\|w\|_{H^{1/2+\delta}(\Omega)} \leq C(\delta)\|w\|_{H^1(\Omega)}^{1/2+\delta}\|w\|_{L^2(\Omega)}^{1/2-\delta}.$$

Choose for instance $\delta = \frac{1}{4}$. Then

$$\|w\|_{H^{3/4}(\Omega)} \leq C\|w\|_{H^1(\Omega)}^{3/4}\|w\|_{L^2(\Omega)}^{1/4},$$

that is,

$$\|w\|_{H^{3/4}(\Omega)}^2 \leq C(\|w\|_{H^1(\Omega)}^2)^{3/4}(\|w\|_{L^2(\Omega)}^2)^{1/4}.$$

Using the inequality

$$a^{3/4}b^{1/4} = (\varepsilon a)^{3/4}\left(\frac{b}{\varepsilon^3}\right)^{1/4} \leq \varepsilon a + \frac{b}{\varepsilon^3}$$

for all $a, b, \varepsilon > 0$, we deduce that

$$\|w\|_{H^{3/4}(\Omega)}^2 \leq C(\tilde{\varepsilon}\|w\|_{H^1(\Omega)}^2 + \|w\|_{L^2(\Omega)}^2/\tilde{\varepsilon}^3),$$

which implies the result of Lemma 5.2.

6. Uniqueness of the solution. We can prove a uniqueness result that holds in a larger class than that for which the existence result of §7 can be proven.

THEOREM 6.1. *There exists at most one solution (g, f) of Problem P such that $g \in L^\infty(0,T; W^{2,\infty}_{\text{per}}(\mathbb{R} \times (0,e)))$, $g_t \in L^\infty(Q_T)$ and $f \in L^\infty(0,T; W^{3,\infty}_{\text{per}}(\mathbb{R}))$, $f_t \in L^\infty(\Sigma_T)$.*

Proof. A detailed proof of this result would make the paper too bulky and we shall only sketch it briefly. The main idea is, similar to the linear problem, to obtain a differential inequality for the difference of two solutions. In fact, we can prove that the function

$$Y(t) = \int_0^e \int_{-L}^{L} (g_1 - g_2)^2 + \int_{-L}^{L} (f_1 - f_2)^2_x + \int_{-L}^{L} (f_1 - f_2)^2$$

satisfies an inequality of the form

$$\frac{dY}{dt} \leq MY \quad \text{with } Y(0) = 0,$$

where M can be chosen (using numerous integrations by parts and interpolation inequalities) so as to depend only on the bounds of g_1, g_2, f_1, f_2 in the spaces given in the statement of Theorem 6.1. This, of course, is enough to prove Theorem 6.1.

7. Existence. Upon omitting the tildas, we can rewrite the nonlinear problem P in the form

$$g_t - \Delta g = f_x^2 g_{yy} - 2f_x g_{xy} - f_{xx} g_y + f_t g_y \quad \text{in } Q_T, \tag{7.1}$$

$$\begin{aligned}(g - g_y)(x,0,t) + \alpha\gamma f_{xx}(x,t) &= \alpha(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} - 1 + \gamma f_{xx}) \\ &+ ((1+f_x^2)^{1/2} - 1)g_y(x,0,t) - \frac{f_x}{(1+f_x^2)^{1/2}} g_x(x,0,t), \quad (x,t) \in \Sigma_T,\end{aligned} \tag{7.2}$$

$$g_y(x,e,t) = (1 - (1+f_x^2)^{1/2}) g_y(x,e,t) + \frac{f_x}{(1+f_x^2)^{1/2}} g_x(x,e,t), \ (x,t) \in \Sigma_T, \tag{7.3}$$

$$g(x+2L,y,t) = g(x,y,t), \qquad (x,y,t) \in Q_T, \tag{7.4}$$

$$g(x,y,0) = g_0(x,y), \qquad (x,y) \in \mathbb{R} \times (0,e), \tag{7.5}$$

$$\begin{aligned}f_t - \alpha\gamma f_{xx} - g(x,0,t) &= -\alpha(1+f_x^2)^{1/2}\left(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} - 1 + \gamma\frac{f_{xx}}{(1+f_x^2)^{1/2}}\right) \\ &+ ((1+f_x^2)^{1/2} - 1)g(x,0,t) \quad \text{in } \Sigma_T,\end{aligned} \tag{7.6}$$

$$f(x+2L,t) = f(x,t), \qquad (x,t) \in \Sigma_T, \tag{7.7}$$

$$f(x,0) = f_0(x), \qquad x \in \mathbb{R}. \tag{7.8}$$

Remark that the left-hand sides of the equations in the linear problem (5.1)–(5.8) and in problem (7.1)–(7.8) coincide. Here again we suppose that

$$g_0 \in C^{2+\lambda}_{\text{per}}(\mathbb{R} \times [0, e]), f_0 \in C^{3+\lambda}_{\text{per}}(\mathbb{R})$$

and that g_0 satisfies compatibility conditions, namely, (7.2) and (7.3) in which f and g are replaced by f_0 and g_0.

Next we define

$$F_1(f,g) = f_x^2 g_{yy} - 2 f_x g_{xy} - f_{xx} g_y + f_t g_y, \tag{7.9}$$

$$\begin{aligned} F_2(f,g) =& \alpha(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} - 1 + \gamma f_{xx}), \\ &+ ((1+f_x^2)^{1/2} - 1) g_y(x,0,t) - \frac{f_x}{(1+f_x^2)^{1/2}} g_x(x,0,t), \end{aligned} \tag{7.10}$$

$$F_3(f,g) = (1 - (1+f_x^2)^{1/2}) g_y(x,e,t) + \frac{f_x}{(1+f_x^2)^{1/2}} g_x(x,e,t), \tag{7.11}$$

$$\begin{aligned} F_4(f,g) =& -\alpha(1+f_x^2)^{1/2}\left(e^{-\gamma f_{xx}/(1+f_x^2)^{3/2}} - 1 + \gamma \frac{f_{xx}}{(1+f_x^2)^{1/2}}\right) \\ &+ ((1+f_x^2)^{1/2} - 1) g(x,0,t), \end{aligned} \tag{7.12}$$

and prove the following preliminary lemma.

LEMMA 7.1. *Let $\delta_0 > 0$ be arbitrary.*

(i) *There exists a positive constant $K_1 = K_1(\delta_0)$ such that for each $\delta \in (0, \delta_0)$*

$$\|F_1(f,g)\|^{\lambda}_{Q_T} + \sum_{i=2}^{4} \|F_i(f,g)\|^{(1+\lambda)}_{\Sigma_T} \le K_1(\|f\|^{(3+\lambda)}_{\Sigma_T} + \|g\|^{(2+\lambda)}_{Q_T})^2$$

for all $f \in C^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ and $g \in C^{2+\lambda,1+\lambda/2}(\overline{Q}_T)$ satisfying $\|f\|^{(3+\lambda)}_{\Sigma_T} + \|g\|^{(2+\lambda)}_{Q_T} \le \delta$.

(ii) *There exists a constant $K_2 = K_2(\delta_0)$ such that for each $\delta \in (0, \delta_0)$ and for all $f, h \in C^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$, $g, k \in C^{2+\lambda,1+\lambda/2}(\overline{Q}_T)$ satisfying*

$$\max(\|f\|^{(3+\lambda)}_{\Sigma_T} + \|g\|^{(2+\lambda)}_{Q_T}, \|h\|^{(3+\lambda)}_{\Sigma_T} + \|k\|^{(2+\lambda)}_{Q_T}) \le \delta,$$

there holds

$$\begin{aligned} &\|F_1(f,g) - F_1(h,k)\|^{(\lambda)}_{Q_T} + \sum_{i=2}^{4} \|F_i(f,g) - F_i(h,k)\|^{(1+\lambda)}_{\Sigma_T} \\ &\le K_2 \delta \left(\|f - h\|^{(3+\lambda)}_{\Sigma_T} + \|g - k\|^{(2+\lambda)}_{Q_T}\right). \end{aligned}$$

Proof. (i) For F_i the property directly follows from Lemma 4.1 (i). Next we show the property for F_2. By Lemma 4.1 (i), (ii)

$$\left\| \frac{f_{xx}}{(1+f_x^2)^{j/2}} \right\|^{(1+\lambda)}_{\Sigma_T} \le C \|f_{xx}\|^{(1+\lambda)}_{\Sigma_T} \left(\|(1+f_x^2)^{j/2}\|^{1+\lambda}_{\Sigma_T}\right)^2 \quad \text{for } j = 1, 3.$$

Using also Lemma 4.1 (iii) we deduce that if $f \in C^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T)$ there exists a constant $K_1 = K_1(\delta_0)$ such that

$$\left\| \frac{f_{xx}}{(1+f_x^2)^{j/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \leq K_1 \|f\|_{\Sigma_T}^{(3+\lambda)} \quad \text{for } j = 1, 3.$$

Similarly we can check that there exists $K_2 = K_2(\delta_0)$ such that

$$\|(1+f_x^2)^{1/2} - 1\|_{\Sigma_T}^{(1+\lambda)} \leq K_2 \|f\|_{\Sigma_T}^{(3+\lambda)}$$

and $K_3 = K_3(\delta_0)$ such that

$$\left\| \frac{1}{(1+f_x^2)^{1/2}} - \frac{1}{(1+f_x^2)^{3/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \leq K_3 \left(\|f\|_{\Sigma_T}^{(3+\lambda)} \right)^2.$$

Thus using also (4.1) and Lemma 4.2 we deduce that

$$\begin{aligned} \|F_2(f,g)\|_{\Sigma_T}^{(1+\lambda)} &\leq K_4 \left\{ (\|f\|_{\Sigma_T}^{(3+\lambda)})^2 + \|f\|_{\Sigma_T}^{(3+\lambda)} \|g\|_{Q_T}^{(2+\lambda)} \right\} \\ &\leq K_5 \left(\|f\|_{\Sigma_T}^{(3+\lambda)} + \|g\|_{Q_T}^{(2+\lambda)} \right)^2, \end{aligned}$$

and that similar results hold for F_3 and F_4.

(ii) The property is obvious for F_1. For instance,

$$\begin{aligned} &\|f_x^2 g_{yy} - h_x^2 k_{yy}\|_{Q_T}^{(\lambda)} \\ &\quad \leq \|(f_x^2 - h_x^2) g_{yy}\|_{Q_T}^{(\lambda)} + \|h_x^2 (g_{yy} - k_{yy})\|_{Q_T}^{(\lambda)} \\ &\quad \leq C \left(\|g_{yy}\|_{Q_T}^{(\lambda)} \|f_x + h_x\|_{\Sigma_T}^{(\lambda)} \|f_x - h_x\|_{\Sigma_T}^{(\lambda)} + (\|h_x\|_{\Sigma_T}^{(\lambda)})^2 \|g_{yy} - k_{yy}\|_{Q_T}^{(\lambda)} \right) \\ &\quad \leq C\delta^2 \left(\|f - h\|_{\Sigma_T}^{(3+\lambda)} + \|g - k\|_{Q_T}^{(2+\lambda)} \right). \end{aligned}$$

As for F_2 we first consider the term

$$\begin{aligned} F &= \left\| \frac{f_x}{(1+f_x^2)^{1/2}} g_x(x,0,t) - \frac{h_x}{(1+h_x^2)^{1/2}} k_x(x,0,t) \right\|_{\Sigma_T}^{(1+\lambda)} \\ &\leq C \left\| \frac{f_x}{(1+f_x^2)^{1/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \|g_x(x,0,t) - k_x(x,0,t)\|_{\Sigma_T}^{(1+\lambda)} \\ &\quad + C \|k_x(x,0,t)\|_{\Sigma_T}^{(1+\lambda)} \left\| \frac{f_x}{(1+f_x^2)^{1/2}} - \frac{h_x}{(1+h_x^2)^{1/2}} \right\|_{\Sigma_T}^{(1+\lambda)}. \end{aligned}$$

Since

$$\frac{f_x}{(1+f_x^2)^{1/2}} - \frac{h_x}{(1+h_x^2)^{1/2}} = \left(\int_0^1 \frac{d\theta}{(1 + (\theta f_x + (1-\theta) h_x)^2)^{3/2}} \right) (f_x - h_x),$$

we deduce that

$$\begin{aligned}
&\left\| \frac{f_x}{(1+f_x^2)^{1/2}} - \frac{h_x}{(1+h_x^2)^{1/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \\
&\quad \le C_1 \left(\int_0^1 d\theta \|(1+(\theta f_x + (1-\theta)h_x)^2)^{3/2}\|_{\Sigma_T}^{(1+\lambda)} \right)^2 \|f_x - h_x\|_{\Sigma_T}^{(1+\lambda)} \\
&\quad \le C_2 \left(\|(1+f_x^2+h_x^2)^{3/2}\|_{\Sigma_T}^{(1+\lambda)} \right)^2 \|(f-h)_x\|_{\Sigma_T}^{(1+\lambda)} \\
&\quad \le C_3 \left(\|(1+f_x^2)^{3/2}\|_{\Sigma_T}^{(1+\lambda)} + \|(1+h_x^2)^{3/2}\|_{\Sigma_T}^{(1+\lambda)} \right)^2 \|(f-h)_x\|_{\Sigma_T}^{(1+\lambda)} \\
&\quad \le C \|(f-h)_x\|_{\Sigma_T}^{(1+\lambda)}
\end{aligned}$$

so that

$$\begin{aligned}
F &\le K \left(\|f_x\|_{\Sigma_T}^{(1+\lambda)} \|(g-k)_x(x,0,t)\|_{\Sigma_T}^{(1+\lambda)} \right. \\
&\qquad \left. + \|k_x(x,0,t)\|_{\Sigma_T}^{(1+\lambda)} \|(f-h)_x\|_{\Sigma_T}^{(1+\lambda)} \right) \\
&\le K\delta \left(\|f-h\|_{\Sigma_T}^{(3+\lambda)} + \|g-k\|_{Q_T}^{(2+\lambda)} \right).
\end{aligned}$$

The term $((1+f_x^2)^{1/2}-1)g_y(x,0,t) - ((1+h_x^2)^{1/2}-1)k_y(x,0,t)$ can be estimated in a similar way. Finally let us consider the term

$$E = \chi\left(\frac{-f_{xx}}{(1+f_x^2)^{3/2}} \right) + \frac{f_x^2 f_{xx}}{(1+f_x^2)^{3/2}}$$

in (4.1). Then we can estimate the difference

$$E_2 = \frac{f_x^2 f_{xx}}{(1+f_x^2)^{3/2}} - \frac{h_x^2 h_{xx}}{(1+h_x^2)^{3/2}}$$

as it has been done above with F. Finally we consider

$$E_1 = \chi\left(\frac{-f_{xx}}{(1+f_x^2)^{3/2}} \right) + \chi\left(\frac{h_{xx}}{(1+h_x^2)^{3/2}} \right).$$

We have that

$$\left\| \frac{f_{xx}}{(1+f_x^2)^{3/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \le C \|f_{xx}\|_{\Sigma_T}^{(1+\lambda)} \left(\|(1+f_x^2)^{3/2}\|_{\Sigma_T}^{(1+\lambda)} \right)^2 \le K\delta$$

so that by Lemma 4.3,

$$\begin{aligned}
E_1 &\le K'\delta \left\| \frac{f_{xx}}{(1+f_x^2)^{3/2}} - \frac{h_{xx}}{(1+h_x^2)^{3/2}} \right\|_{\Sigma_T}^{(1+\lambda)} \\
&\le K'\delta \|f-h\|_{\Sigma_T}^{(3+\lambda)}.
\end{aligned}$$

A similar proof can be given for F_3 and F_4.

Next we state the main result of this section.

THEOREM 7.2. *There exists a positive constant $\rho_0 = \rho_0(T)$ such that if the initial data satisfy the condition*

$$\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|g_0\|_{\mathbb{R}\times(0,e)}^{(2+\lambda)} \leq \rho_0, \tag{7.13}$$

then there exists a constant $\rho > \rho_0$ such that (7.1)–(7.8) *has a unique solution (f, g) in $C_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T) \times C_{\text{per}}^{2+\lambda,1+\lambda/2}(\overline{Q}_T)$ satisfying $\|f\|_{\Sigma_T}^{(3+\lambda)} + \|g\|_{Q_T}^{(2+\lambda)} \leq \rho$.*

Proof. We consider the mapping $\mathcal{T}$

$$(f, g) \to \mathcal{T}(f, g) = (f', g')$$

defined as follows: (f', g') is the solution of the linear problem (5.1)–(5.8) with initial conditions f_0 and g_0 and where the right-hand sides $F_i, i = 1, \ldots, 4$ are given by the formulas (7.9)–(7.12).

By Lemma 7.1 (i) and Theorem 5.1 the mapping $\mathcal{T}$ is well defined from the affine space

$$A = \left\{(f, g) \in C_{\text{per}}^{3+\lambda,(3+\lambda)/2}(\overline{\Sigma}_T) \times C_{\text{per}}^{2+\lambda,1+\lambda/2}(\overline{Q}_T), f(0) = f_0, g(0) = g_0\right\}$$

into itself. Next we define the norm $\|\cdot\|$ on A by

$$\|(f, g)\| = \|f\|_{\Sigma_T}^{(3+\lambda)} + \|g\|_{Q_T}^{(2+\lambda)}.$$

In what follows we prove that if the constant ρ_0 in (7.13) is small enough, then the mapping $\mathcal{T}$ has a unique fixed point in a certain ball. It follows from the study of the linear case (Theorem 5.1) that

$$\begin{aligned}\|\mathcal{T}(f, g)\| &= \|f'\|_{\Sigma_T}^{(3+\lambda)} + \|g'\|_{Q_T}^{(2+\lambda)} \\ &\leq \mathcal{C}\left(\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|g_0\|_{\mathbb{R}\times(0,e)}^{(2+\lambda)} + \|F_1\|_{Q_T}^{(\lambda)} + \sum_{i=2}^{4}\|F_i\|_{\Sigma_T}^{(1+\lambda)}\right),\end{aligned} \tag{7.14}$$

where $\mathcal{C}$ is a constant that depends on T. This implies that

$$\begin{aligned}\|\mathcal{T}(f, g) - \mathcal{T}(h, k)\| \leq \mathcal{C}\Bigg(&\|F_1(f, g) - F_1(h, k)\|_{Q_T}^{(\lambda)} \\ &+ \sum_{i=2}^{4}\|F_i(f, g) - F_i(h, k)\|_{\Sigma_T}^{(1+\lambda)}\Bigg).\end{aligned} \tag{7.15}$$

Also using Lemma 7.1 (ii), we deduce that if (f, g) and (h, k) satisfy

$$\|(f, g)\| \leq \delta, \|(h, k)\| \leq \delta,$$

then

$$\|\mathcal{T}(f, g) - \mathcal{T}(h, k)\| \leq \mathcal{C}K_2\delta\|(f - h, g - k)\|;$$

so that if

$$\delta < \frac{1}{\mathcal{C}K_2} \tag{7.16}$$

and if $\mathcal{B}(0,\delta)$ denotes the ball of center zero and radius δ, $\mathcal{T}$ is a strict contraction from the closed convex set $\mathcal{B}(0,\delta)\cap A$ into A.

Finally we deduce from (7.14) and from Lemma 7.1 (i) that if

$$\mathcal{C}\left(\|f_0\|_{\mathbb{R}}^{(3+\lambda)} + \|g_0\|_{\mathbb{R}\times(0,e)}^{(2+\lambda)} + K_1\left(\|f\|_{\Sigma_T}^{(3+\lambda)} + \|g\|_{Q_T}^{(2+\lambda)}\right)^2\right) \le \delta, \tag{7.17}$$

then $\mathcal{T}$ maps the set $\mathcal{B}(0,\delta)\cap A$ into itself. In turn, (7.17) is implied by the condition

$$\widetilde{\mathcal{C}}(\rho_0 + K_1\delta^2) \le \delta \tag{7.18}$$

with

$$\widetilde{\mathcal{C}} = \max(\mathcal{C}, 1).$$

Note that (7.18) implies that $\delta > \rho_0$ so that the set $\mathcal{B}(0,\delta)\cap A$ is nonempty. Choose, for example,

$$\delta = \frac{1}{2\widetilde{\mathcal{C}}K} \quad \text{and} \quad \rho_0 = \frac{1}{4\widetilde{\mathcal{C}}^2K}$$

with $K = \max(K_1, K_2)$. Then we can check that (7.16) and (7.18) are satisfied.

Acknowledgment. The authors are very indebted to M. Cournil, G. Santarini, and C. Bataillon for suggesting this problem, showing them the physical derivation, and for many fruitful discussions. D. Hilhorst wishes to thank Professor H. F. Weinberger for very inspiring comments.

GLOBAL BEHAVIOR OF POSITIVE SOLUTIONS TO NONLINEAR DIFFUSION PROBLEMS WITH NONLINEAR ABSORPTION THROUGH THE BOUNDARY*

NOEMÍ WOLANSKI†

Abstract. The author studies the global behavior of positive solutions to $u_t = \Delta\phi(u)$ in $B_R \times (0, T)$; $\partial\phi(u)/\partial\nu = f(u)$ on $S_R \times (0, T)$; and $u(x, 0) = u_0(x)$ in B_R. Here f and ϕ are increasing functions of u, positive for u positive which go to infinity as $u \to \infty$, and $0 < \phi'(u) < \infty$ in R. (ϕ may degenerate in either way at $u = 0$ if $u_0 \geqq \delta \geqq 0$.) It is proved that when $\phi'(u) \geqq C > 0$ in R there exists a unique global solution when f is sublinear and finite time blowup occurs when $\int^\infty (ds/f(s)) < \infty$. On the other hand, if one allows $\phi'(u)$ to go to zero as $u \to \infty$ finite time blowup may occur with f being sublinear. The author gives precise relations between ϕ and f that guarantee global existence or finite time blowup. Results are illustrated with a couple of examples.

1. Introduction.

In this paper we study the global behavior of positive solutions to a nonlinear diffusion problem with a nonlinear absorption-like boundary condition.

The problem we analyze is

$$
(1.1)\qquad
\begin{aligned}
&u_t = \Delta\phi(u) && \text{in } B_R \times (0, T),\\
&\frac{\partial\phi(u)}{\partial\nu} = f(u) && \text{on } S_R \times (0, T),\\
&u(x, 0) = u_0(x) && \text{in } B_R,
\end{aligned}
$$

where $B_R = \{|x| < R\}$; $S_R = \{|x| = R\}$ and u_0 is a smooth nonnegative function such that

$$
(1.2)\qquad \frac{\partial\phi(u_0)}{\partial\nu} = f(u_0) \quad \text{on } S_R.
$$

ϕ and f are increasing functions of u that are positive for u positive together with their derivatives, and which go to infinity as u goes to infinity.

The case $\phi(u) = u$ is well understood. In fact, classical results show that when $f(u)/u$ is bounded there is a global solution for any $u_0 \in L^\infty(B_R)$. On the other hand, we have proved in [LMW] that every solution blows up in finite time in L^∞-norm if $\int^\infty (ds/f(s)) < \infty$.

The general case is not well understood. For a proof of local existence and uniqueness of weak solutions when u_0 is allowed to vanish and $\phi'(0) = 0$, we refer to [A]. In fact, in this case we do not expect to have classical solutions since moving fronts could exist on which ∇u is discontinuous.

In this work we are interested in the local boundedness or finite time blowup of the solutions and not in their behavior near $u = 0$. This is the reason why we will assume throughout the paper that $0 < \phi'(u) < \infty$ in $\mathbf{R}$. (If this is not the case we will assume that $u \geqq \delta > 0$, which is guaranteed by u_0 being larger than δ and modifying ϕ on the interval $(-\delta/2, \delta/2)$ so as to have $0 < \phi' < \infty$ everywhere.) In this case the

compatibility condition (1.2) implies that any radial solution is a classical one if $f \in C^1(\mathbf{R})$ (see Proposition 2.1).

We find that the results valid in the case $\phi(u)=u$ continue to hold as long as $\phi'(u) \geqq C > 0$. Instead, when $\liminf_{(u\to\infty)} \phi'(u)=0$, blowup may occur with f being sublinear.

In fact, if ϕ is concave, $\liminf_{u\to\infty} f(u)\sqrt{\phi'(u)}/\phi(u) > 0$, and $\int^\infty (\sqrt{\phi'(s)}/f(s))\,ds < \infty$ every solution blows up in finite time. On the other hand, if $(f(u)\sqrt{\phi'(u)}/\phi(u))$ is bounded every solution exists globally.

We want to point out that as in [LMW] these results hold for every initial datum u_0 (not necessarily radial). Blowup results for some u_0 by concavity methods in the one-dimensional case can be found in [A].

Let us illustrate our results with some examples.

(a) Let $f(u)=u^q$, $\phi(u)=u^m$. There are two cases ($u_0 \geqq \delta > 0$).

(i) $m \geqq 1$.

If $q > 1$ every solution blows up in finite time.

If $q \leqq 1$ every solution exists globally.

(ii) $0 < m < 1$.

If $q > (m+1)/2$ every solution blows up in finite time.

If $q \leqq (m+1)/2$ every solution exists globally.

These results were first found in the one-dimensional case by Filo in [F]. Although the case $0 < m < 1$, $q=(m+1)/2$ was not covered by his proofs.

(b) Let $\phi(u)=\log(u+1)$.

If $f(u) \leqq C\sqrt{u+1}\log(u+1)$ every solution exists globally.

If $f(u) \geqq C\sqrt{u+1}(\log(u+1))^{1+\varepsilon}$ as $u\to\infty$ for some $\varepsilon>0$, every solution blows up in finite time.

Our results generalize [F] in two ways. First, we allow for general nonlinearities. Second, our domain is an N-dimensional ball (and even any simply connected two-dimensional smooth domain; see Remark 3.1).

In fact, some of the proofs in [F] require very special initial data, whose existence is proved only in the one-dimensional case with homogeneous ϕ and f.

For other papers dealing with the balance between reaction and diffusion or convection, or two reactions of opposite sign, we refer to [F], [ChLS], [LPSSt], [L], [LS], [LSm], [LMW2], and [ChFQ].

The rest of the paper is organized as follows. In § 2 we state and prove the global existence and in § 3 the finite time blowup results.

2. Global existence results. We state without proof the following result on local existence and continuation of classical solutions.

PROPOSITION 2.1. *Let $\phi \in C^{2+\alpha}$, $f \in C^1$ and $u_0 \in C^{2+\alpha}(\bar{B}_R)$, $u_0=u_0(r)$ satisfy the compatibility condition* (1.2). *If $\phi'(u)>0$ in $\mathbf{R}$ there exists $T>0$ and $u \in C^{2+\alpha,1+(\alpha/2)}(\bar{B}_R \times [0,T))$ solution of* (1.1). *If u cannot be continued as a classical solution beyond time T we have*

$$\limsup_{t\to T} |u(R,t)| = +\infty.$$

The proof is a trivial modification of the one in [LMW] for the heat equation. It is based on a fixed point argument in the space $C^{1+\alpha,(1+\alpha)/2}(\bar{B}_R \times [0,T])$ and the existence of classical solutions to the third boundary value problem in the linear case (see [LMW, Thm. 1.2, Cor. 1.2]).

For a proof of local existence, continuation, uniqueness, and comparison of weak solutions in the nonsymmetric case we refer to [A].

It is clear from the continuation results that in order to prove global existence it is enough to show that any local solution is a priori bounded on any finite time interval.

In order to state this result we need to consider two different situations, $\phi'(u) \geqq C > 0$ or $0 < \phi'(u) \leqq C$.

THEOREM 2.1. *Let Ω be a smooth domain. Let u be a weak solution of*

$$\begin{aligned} &u_t = \Delta\phi(u) && \text{in } \Omega \times (0, T), \\ &\frac{\partial\phi(u)}{\partial\nu} = f(u) && \text{on } \partial\Omega \times (0, T), \\ &u(x, 0) = u_0(x) && \text{in } \Omega. \end{aligned}$$

Let us assume that $\phi'(u) \geqq C > 0$ and $f(u)/(1+u) \leqq M < \infty$. There exists a constant L depending only on T and u_0 such that

$$u(x, t) \geqq L \quad \text{in } \Omega \times (0, T).$$

Proof. We follow here ideas in [LSU], [S], and [A]. Let $k > \|u_0\|_\infty$. Then,

$$(u-k)_t = \operatorname{div}\,(\phi'(u)\nabla(u-k)).$$

By taking $(u-k)^+ = \max\,(u-k, 0)$ as a test function, we obtain

$$\begin{aligned} \frac{1}{2}\int_\Omega ((u-k)^+)^2(x,t)\,dx &= \frac{1}{2}\int_\Omega ((u_0-k)^+)^2(x)\,dx \\ &\quad + \int_0^t \int_\Omega \operatorname{div}\,(\phi'(u)\nabla(u-k))(u-k)^+(x,s)\,dx\,ds \\ &= -\int_0^t \int_\Omega \phi'(u)|\nabla(u-k)^+|^2(x,s)\,dx\,ds \\ &\quad + \int_0^t \int_{\partial\Omega} f(u)(u-k)^+\,d\sigma\,ds \\ &\leqq -C\int_0^t \int_\Omega |\nabla(u-k)^+|^2\,dx\,ds + M\int_0^t \int_{\partial\Omega} u(u-k)^+\,d\sigma\,ds \\ &\quad + M\int_0^t \int_{\partial\Omega} (u-k)^+\,d\sigma\,ds. \end{aligned}$$

Thus, if $k \geqq 1$,

$$\begin{aligned} \frac{1}{2}\int_\Omega ((u-k)^+)^2(x,t)\,dx &+ C\int_0^t \int_\Omega |\nabla(u-k)^+|^2\,dx\,ds \\ &\leqq M\int_0^t \int_{\partial\Omega} ((u-k)^+)^2\,d\sigma\,ds + 2Mk\int_0^t \int_{\partial\Omega} (u-k)^+\,d\sigma\,ds. \end{aligned}$$

On the other hand, if $\mu(k) = \text{meas}\,\{(x,s) \in \Omega \times (0,T) \colon u(x,s) > k\}$,

$$\begin{aligned} \int_0^t \int_{\partial\Omega} (u-k)^+\,d\sigma\,ds &\leqq K\left\{\int_0^t \int_\Omega (u-k)^+\,dx\,ds + \int_0^t \int_\Omega |\nabla(u-k)^+|\,dx\,ds\right\} \\ &\leqq \frac{1}{2Mk}\int_0^t \int_\Omega ((u-k)^+)^2\,dx\,ds \\ &\quad + \frac{C}{2Mk}\int_0^t \int_\Omega |\nabla(u-k)^+|^2\,dx\,ds + \frac{M}{2}K^2(1+C^{-1})k\mu(k). \end{aligned}$$

Since

$$\int_{\partial\Omega}((u-k)^+)^2\,d\sigma \leqq K\left\{\int_\Omega ((u-k)^+)^2\,dx + \int_\Omega |\nabla((u-k)^+)^2|\,dx\right\}$$
$$= K\left\{\int_\Omega ((u-k)^+)^2\,dx + 2\int_\Omega (u-k)^+|\nabla(u-k)^+|\,dx\right\},$$

for any $\varepsilon > 0$,

$$\int_0^t\int_{\partial\Omega}((u-k)^+)^2\,d\sigma\,ds \leqq \varepsilon\int_0^t\int_\Omega |\nabla(u-k)^+|^2\,dx\,ds + C_\varepsilon\int_0^t\int_\Omega ((u-k)^+)^2\,dx\,ds.$$

So, we have

$$\frac{1}{2}\int_\Omega ((u-k)^+)^2(x,t)\,dx + \frac{C}{4}\int_0^t\int_\Omega |\nabla(u-k)^+|^2\,dx\,ds$$
$$\leqq K_1k^2\mu(k) + K_2\int_0^t\int_\Omega ((u-k)^+)^2\,dx\,ds.$$

Using Gronwall's inequality we see that the right-hand side is bounded for $t \leqq T$ by $K_3k^2\mu(k)$.

On the other hand, for any function $v(x, t)$,

$$\|v\|^2_{L^{2((N+2)/N)}(\Omega\times(0,t))} \leqq K_4\left\{\sup_{0\leqq s\leqq t}\|v(\cdot, s)\|^2_{L^2(\Omega)} + \|\nabla_v\|^2_{L^2(\Omega\times(0,t))}\right\};$$

thus,

$$\left(\int_0^T\int_\Omega ((u-k)^+)^{2((N+2)/2)}\,dx\,dt\right)^{N/(N+2)} \leqq K_5k^2\mu(k).$$

Let $h > k \geqq (\|u_0\|_{L^\infty} + 1)$. The latter inequality implies

$$(h-k)^2\mu(h)^{N/(N+2)} \leqq K_5k^2\mu(k), \tag{2.1}$$

and a simple modification of Stampacchia's argument ([KS], page 63), which is necessary due to the presence of k^2 on the right-hand side of (2.1), shows that there exists a constant $L > 0$ such that $\mu(L) = 0$.

In fact, let $k = \|u_0\|_{L^\infty} + 1$ in (2.1). Since for any k, $\mu(k) \leqq T \operatorname{meas}\Omega$ we have for $h > \|u_0\|_{L^\infty} + 1$,

$$\mu(h)^{N/(N+2)} \leqq \frac{K_5(\|u_0\|_{L^\infty}+1)^2 T \operatorname{meas}\Omega}{(h - \|u_0\|_{L^\infty} - 1)^2}.$$

Let $\beta = (N+2)/N$ and $\sigma = 2\beta/(\beta-1)$. From the inequality above we see that we can take $k_0 = k_0(T, N, \Omega, \|u_0\|_{L^\infty})$ large enough so as to have $k_0 > (1 + \|u_0\|_{L^\infty})$ and

$$\sqrt{K_5}\,2^{2+\sigma/2}\mu(k_0)^{(\beta-1)/2\beta} \leqq 1.$$

Set $d = K_5^\beta 2^{\beta(4+\sigma)}k_0^{2\beta}\mu(k_0)^{\beta-1}$ and $k_n = k_0 + d^{1/2\beta} - (d^{1/2\beta}/2^n)$. We claim that

$$\mu(k_n) \leqq \frac{\mu(k_0)}{2^{n\sigma}}. \tag{2.2}$$

In fact, for $h > k$,

$$\mu(h) \leqq \frac{K_5^\beta k^{2\beta}\mu(k)^\beta}{(h-k)^{2\beta}}.$$

Thus

$$\mu(k_{n+1}) \leqq \frac{K_5^\beta k_n^{2\beta} \mu(k_n)^\beta 2^{2\beta(n+1)}}{d}.$$

For $n=0$ this gives

$$\mu(k_1) \leqq \frac{K_5^\beta k_0^{2\beta} \mu(k_0)^{\beta-1} 2^{2\beta}}{K_5^\beta 2^{\beta(4+\sigma)} k_0^{2\beta} \mu(k_0)^{\beta-1}} \mu(k_0) = \frac{\mu(k_0)}{2^{\beta(2+\sigma)}} \leqq \frac{\mu(k_0)}{2^\sigma}.$$

Assuming that (2.2) is true,

$$\begin{aligned} \mu(k_{n+1}) &\leqq \frac{K_5^\beta k_n^{2\beta} 2^{2\beta(n+1)}}{d} \frac{\mu(k_0)^\beta}{2^{n\sigma\beta}} \\ &= \left(\frac{k_n}{k_0}\right)^{2\beta} 2^{2\beta(n+1)-\beta(4+\sigma)-n\sigma\beta} \mu(k_0) \\ &\leqq 2^{2n\beta-\beta\sigma-n\beta\sigma} \mu(k_0), \end{aligned}$$

since by construction $k_n/k_0 \leqq 2$. By the choice of σ,

$$2n\beta - \sigma\beta(n+1) \leqq -\sigma(n+1).$$

Taking limit as $(n \to \infty)$ in (2.2) we get

$$\mu(k_0 + d^{1/2\beta}) = 0.$$

This means that $u(x, t) \leqq k_0 + d^{1/2\beta} \leqq 2k_0$ in $\Omega \times (0, T)$.

Let us now analyze the case $0 < \phi'(u) \leqq C$ in $\mathbf{R}$.

THEOREM 2.2. *Let f and ϕ be strictly increasing smooth functions such that $0 < \phi'(u) \leqq C$. Assume ϕ concave or $f(u)/\phi(u)$ nondecreasing. Let $\sqrt{\phi'(u)}(f(u)/\phi(u)) \leqq M$ for $u \in \mathbf{R}$. For any positive classical solution of* (1.1) *there exists a constant L depending on u_0 and T such that*

$$u(x, t) \leqq L \quad \textit{in } B_R \times (0, T).$$

Proof. We prove it first for radially symmetric, radially increasing solutions such that $u_t \geqq 0$. The result follows by comparison with these solutions.

Assume first that $f(u)/\phi(u)$ is nondecreasing. Let $\beta(v) = \phi^{-1}(v)$ and $\theta = C^{-1}$, then $\beta'(v) \geqq \theta$ for $v \in \mathbf{R}$. v is a solution of

$$\text{(2.3)} \qquad \begin{cases} \beta(v)_t = \Delta v & \text{in } B_R \times (0, T) \\ v_r(R, t) = g(v(R, t)) & \text{on } (0, T), \\ v(x, 0) = v_0(x), \end{cases}$$

where $v_0 = \beta(u_0)$, $g(v) = f(\beta(v))$. From the hypothesis we have that

$$\text{(2.4)} \qquad \left(\frac{g(v)}{v}\right)^2 \leqq M\beta'(v).$$

Let

$$h(r, t) = 1 + \exp\left(-\frac{1}{TR} \int_0^t \int_0^r \int_0^s \frac{g(v(\eta, \tau))}{v(\eta, \tau)} d\eta \, ds \, d\tau\right);$$

then for $0 \leqq r \leqq R$, $0 < t \leqq T$,

$$\text{(2.5)} \qquad 2 \geqq h \geqq 1,$$

$$0 \geqq h_r \geqq -\frac{g(v(r,t))}{v(r,t)} h, \tag{2.6}$$

$$\frac{h_r^2}{h} \leqq \left(\frac{g(v(r,t))}{v(r,t)}\right)^2 h, \tag{2.7}$$

$$\Delta h \geqq -\frac{n}{R}\frac{g(v(r,t))}{v(r,t)} h, \tag{2.8}$$

$$h_t \leqq 0. \tag{2.9}$$

These inequalities are trivially verified by direct differentiation using the fact that $g(v(r,t))/v(r,t)$ is nondecreasing in r and t and the estimate

$$\frac{h_r}{r} \geqq -\frac{1}{R}\frac{g(v)}{v} h.$$

Let $V(r,t) = e^{-Kt}v(r,t)h(r,t)$. Then

$$\beta'(v)V_t - \Delta V + 2\frac{h_r}{h}V_r + \left\{\left(K - \frac{h_t}{h}\right)\beta'(v) + \frac{\Delta h}{h} - 2\frac{h_r^2}{h^2}\right\}V = 0 \quad \text{in } B_R \times (0,T),$$

$$V_r(R,t) - \left\{\frac{h_r}{h}(R,t) + \frac{g(v(R,t))}{v(R,t)}\right\}V(R,t) = 0, \qquad t > 0,$$

$$V(r,0) = v_0(r)h(r,0).$$

From (2.4) and the fact that $\beta'(v) \geqq \theta > 0$ we find that for another constant $\bar{M}$,

$$\frac{g(v)}{v} \leqq \bar{M}\beta'(v). \tag{2.10}$$

By (2.4)-(2.10) we see that there exists $K > 0$ such that

$$Kh(r,t)\beta'(v(r,t)) \geqq h_t\beta'(v) - \Delta h + 2\frac{h_r^2}{h}.$$

Also by (2.5),

$$\frac{h_r}{h}(R,t) + \frac{g(v(R,t))}{v(R,t)} \geqq 0.$$

By the maximum principle we see that

$$V(r,t) \leqq \|V_0\|_{L^\infty} \leqq 2\|v_0\|_{L^\infty}.$$

Thus,

$$v(r,t) \leqq 2\|v_0\|_{L^\infty} e^{Kt}.$$

Now, if $g(v)/v$ is not nondecreasing but β is convex, let $G(v)$ be defined by

$$\frac{G(v)}{v} = \max_{0 \leqq s \leqq v} \frac{g(s)}{s},$$

then

$$\left(\frac{G(v)}{v}\right)^2 \leqq M\beta'(v).$$

Let w be the solution of

$$\begin{aligned} &\beta(w)_t = \Delta w && \text{in } B_R \times (0, T), \\ &w_r(R, t) = G(w(R, t)), && t > 0, \\ &w(x, 0) = v_0(x) && \text{in } B_R. \end{aligned}$$

Then, since $G(v) \geqq g(v)$ in $\mathbf{R}$, $w \geqq v$ in $B_R \times (0, T)$. Thus v is bounded.

The general case with no further assumptions on u follows by comparison with the solution of (1.1) that starts with initial value $u_1(|x|)$ satisfying

$$\begin{gathered} u_1 \geqq \|u_0\|_{L^\infty}, \\ u_{1r} \geqq 0, \\ \Delta\phi(u_1) \geqq a > 0, \\ \phi(u_1)_r(R) = f(u_1(R)), \end{gathered}$$

in B_R. The solution that starts with initial value u_1 will have nonnegative time and radial derivative. We state this result as Lemma 2.1. In Lemma 2.2 we show that we can always find such a function.

LEMMA 2.1. *Let u_1 be a radially symmetric classical solution of* (1.1). *If $u_{1r}(x, 0) \geqq 0$ and $\Delta\phi(u_1)(x, 0) \geqq a > 0$, u_1 satisfies*

$$\left.\begin{aligned} u_{1r} \geqq 0 \\ u_{1t} \geqq 0 \end{aligned}\right. \quad \textit{in } B_R \times (0, T).$$

Proof. Let $0 < \tau < T$; then u_1, u_{1r} and u_{1t} are bounded in $B_R \times (0, \tau)$. Thus, there exist constants θ, $K > 0$ such that $\phi'(u_1)$, $|\phi''(u_1)| \leqq \theta$ in $B_R \times (0, \tau)$, and if $\beta = \phi^{-1}$, $v = \phi(u_1)$,

$$K \geqq -\frac{\beta''(v)}{\beta'(v)} v_t.$$

Letting $w = e^{-Kt} v_r(r, t)$ it is easy to see that w satisfies

$$\beta'(v) w_t - \Delta w = -\left[\frac{n-1}{r^2} + \beta''(v) v_t + K\beta'(v)\right] w,$$

so it is clear that w cannot attain a negative interior minimum. On the other hand, $w \geqq 0$ on $t = 0$ and $r = R$. Thus $w \geqq 0$ everywhere.

In order to prove that u_{1t} is nonnegative we need a different argument. In fact the $C^{2+\alpha, 1+(\alpha/2)}$ regularity of u_1 does not allow us to use flux boundary conditions for u_t. Following the approach in [LMW] we consider the functions $u_\varepsilon(x, t) = u_1(x, t + \varepsilon)$. Since $u_{1t}(x, 0) \geqq a > 0$ and u_{1t} is continuous there exists $\varepsilon_0 > 0$ such that $u_\varepsilon(x, 0) \geqq u_1(x, 0)$ in B_R for $0 < \varepsilon < \varepsilon_0$. It is easy to see that u_ε is a solution of (1.1). Also since u_1 is bounded in $B_R \times (0, \tau + \varepsilon_0)$ if $\tau + \varepsilon_0 < T$ we may assume that ϕ and ϕ' are bounded from above and below. Classical comparison principles then give us the inequality

$$u(x, t + \varepsilon) \geqq u(x, t)$$

in $B_R \times (0, \tau)$ for every $\varepsilon < \varepsilon_0$. This is $u_t \geqq 0$.

LEMMA 2.2. *Let γ, $L > 0$. There exist radially symmetric functions u_1, $u_2 \in C^{2+\alpha}(\bar{B}_R)$ such that $u_i \geqq 0$, $u_{ir} \geqq 0$, $\phi(u_i)_{rr} \geqq a$, $\phi(u_i)_r(R) = f(u_i(R))$, and $u_1 \geqq L$, $u_2 \leqq \gamma$ in B_R.*

Proof. Let $w_i \geqq 0$ smooth such that $w_i(0)=0$, $w_i'(r) \geqq a$, $w_i(R)=f(c_i)$, and

$$\int_0^R w_i(r)\, dr \leqq \tfrac{1}{2}\phi(c_i),$$

where

(i) c_1 is large enough as to have $\phi(c_1) \geqq 2\phi(L)$;

(ii) $c_2=\gamma$.

Then

$$u_i(x)=\phi^{-1}\left(\phi(c_i)-\int_{|x|}^R w_i(r)\, dr\right)$$

are the functions we are looking for.

3. Blowup results. In this section we prove the blowup results stated in § 1. As in the previous section we have to consider two different situations, depending on whether or not $\phi'(u) \geqq C > 0$.

THEOREM 3.1. *Let f and ϕ be strictly increasing smooth functions with $\int^\infty ds/f(s) < \infty$. Every positive solution of* (1.1) *blows up in L^∞-norm in finite time.*

Proof. The proof follows step by step that of Proposition 3.1 in [LMW], so we omit it here. The blowup result is proven first by very simple arguments for radially symmetric, radially increasing classical solutions and obtained afterwards for any positive solution by comparison by using Lemma 2.2 and the fact that any nonnegative solution is strictly positive in $\bar{B}_R$ for $t>0$.

A different argument has to be used to get a sharper blowup result when $\liminf_{u\to\infty} \phi'(u)=0$.

THEOREM 3.2. *Let f and ϕ be strictly increasing smooth functions such that ϕ is concave,* $\liminf_{u\to\infty} f(u)\sqrt{\phi'(u)}/\phi(u)>0$, *and* $\int^\infty (\sqrt{\phi'(s)}/f(s))\, ds < \infty$. *Every positive solution of* (1.1) *blows up in L^∞-norm in finite time.*

Proof. As in the proof of Theorem 3.1 we first consider radially symmetric, radially increasing classical solutions and get the general result by comparison with these solutions by using the construction in Lemma 2.2.

Let us first find some energy identities to be used in the proof. First multiply (1.1) by $\phi(u)_t$ and integrate to get

$$\int_0^t\int_{B_R} \phi'(u)u_t^2 = -\frac{1}{2}\int_0^t\int_{B_R} \frac{\partial}{\partial t}(|\nabla\phi(u)|^2)+\int_0^t\int_{S_R} \phi'(u)f(u)u_t\, d\sigma\, dt.$$

Let $\Phi(u)=\int_0^u \sqrt{\phi'(s)}\, ds$; $F(u)=\int_0^u \phi'(s)f(s)\, ds$. Then,

$$\int_0^t\int_{B_R} |\Phi(u)_t|^2+\frac{1}{2}\int_{B_R} |\nabla\phi(u)|^2=\frac{1}{2}\int_{B_R} |\nabla\phi(u_0)|^2+\int_{S_R} F(u)\, d\sigma-\int_{S_R} F(u_0)\, d\sigma. \tag{3.1}$$

Next multiply (1.1) by $\phi(u)$ and integrate to get

$$\int_0^t\int_{B_R} \phi(u)u_t=-\int_0^t\int_{B_R} |\nabla\phi(u)|^2+\int_0^t\int_{B_R} \phi(u)f(u)\, d\sigma\, dt.$$

Let $\Theta(u)=\int_0^u \phi(s)\, ds$. Then,

$$\int_{B_R} \Theta(u)(x,t)\, dx+\int_0^t\int_{B_R} |\nabla\phi(u)|^2=\int_{B_R} \Theta(u_0)\, dx+\int_0^t\int_{S_R} \phi(u)f(u)\, d\sigma\, dt. \tag{3.2}$$

Let us now compute

$$\begin{aligned}\Phi(u)_t\phi(u)_r &= \sqrt{\phi'(u)}u_t\phi(u)_r\\ &= \sqrt{\phi'(u)}\phi(u)_r\left(\phi(u)_{rr}+\frac{n-1}{r}\phi(u)_r\right)\\ &\geqq \sqrt{\phi'(u)}\phi(u)_r\phi(u)_{rr}\\ &= \frac{1}{2}\sqrt{\phi'(u)}\frac{\partial}{\partial r}|\phi(u)_r|^2.\end{aligned}$$

Thus

$$\int_{B_R}\Phi(u)_t\phi(u)_r \geqq -\frac{1}{4}\int_{B_R}\frac{\phi''(u)}{\sqrt{\phi'(u)}}u_r|\phi(u)_r|^2 + \frac{1}{2}R^{n-1}\omega_{n-1}\sqrt{\phi'(u(R,t))}(f(u(R,t)))^2.$$

Now, since $\phi''\leqq 0$ and $u_r\geqq 0$,

$$\int_{B_R}\Phi(u)_t\phi(u)_r \geqq \frac{1}{2}R^{n-1}\omega_{n-1}\sqrt{\phi'(u(R,t))}(f(u(R,t)))^2.$$

Applying Schwarz's inequality to the left-hand side and integrating in time we get

$$\int_0^t\sqrt{\phi'(u(R,s))}(f(u(R,s)))^2\,ds \leqq \varepsilon\int_0^t\int_{B_R}|\phi(u)_r|^2 + K\int_0^t\int_{B_R}|\Phi(u)_t|^2.$$

By (3.2) the right-hand side is bounded by

$$C_1 + K\int_0^t\int_{B_R}|\Phi(u)_t|^2 + \varepsilon\omega_{n-1}R^{n-1}\int_0^t\phi(u(R,s))f(u(R,s))\,ds,$$

where C_1 is a constant depending on u_0.

By hypothesis, $\phi(u)f(u)\leqq M + C\sqrt{\phi'(u)}(f(u))^2$; so we have

$$\int_0^t\sqrt{\phi'(u(R,s))}(f(u(R,s)))^2\,ds \leqq C_2 + \bar{K}\int_0^t\int_{B_R}|\Phi(u)_t|^2.$$

By (3.1) the right-hand side is bounded by

$$C_3 + KF(u(R,t)).$$

This is

$$\int_0^t\sqrt{\phi'(u(R,s))}(f(u(R,s)))^2\,ds \leqq C_3 + \hat{K}F(u(R,t)). \tag{3.3}$$

Let $G(u)=\sqrt{\phi'(u)}(f(u))^2$, $g(t)=\int_0^t G(u(R,s))\,ds$, and $H=G\circ F^{-1}$. By (3.3), since H is increasing,

$$g'(t) = G(u(R,t)) = H(F(u(R,t))) \geqq H\left(\frac{g(t)-C_3}{\hat{K}}\right). \tag{3.4}$$

Assume now that $\int^\infty(du/H(u))<\infty$. We deduce that g blows up in finite time. Therefore, u cannot exist globally. This implies that u must blow up in finite time.

The condition $\int^\infty(du/H(u))<\infty$ translates into $\int^\infty(\sqrt{\phi'(u)}/f(u))\,du<\infty$. Since this is our hypothesis the proof is finished.

REMARK 3.1. In the two-dimensional case our results extend to any simply connected smooth domain Ω. In fact, under a conformal mapping of Ω onto the disc B_1, a solution $v(y, t)$ of

$$\begin{aligned} &v_t = \Delta\phi(v) && \text{in } \Omega \times (0, T), \\ &\frac{\partial}{\partial \nu}\phi(v) = f(v) && \text{on } \partial\Omega \times (0, T), \\ &v(y, 0) = v_0(y) && \text{in } \Omega \end{aligned} \tag{3.5}$$

is transformed into a solution $u(x, t)$ of

$$\begin{aligned} &u_t = \alpha(x)\Delta\phi(u) && \text{in } B_1 \times (0, T), \\ &\alpha(x)\phi(u)_r = f(u) && \text{on } S_1 \times (0, T), \\ &u(x, 0) = u_0(x) && \text{in } B_1, \end{aligned} \tag{3.6}$$

where $0 < \alpha \leqq \alpha(x) \leqq \beta < \infty$ in $\bar{B}$. Since solutions of (3.6) can be compared to time increasing solutions of

$$\begin{aligned} &u_t = \alpha\Delta\phi(u) && \text{in } B_1 \times (0, T), \\ &\beta\phi(u)_r = f(u) && \text{on } S_1 \times (0, T), \\ &u(x, 0) = u_0(x) && \text{in } B_1, \end{aligned} \tag{3.7}$$

and all our results are valid for (3.7), we can extend our theorems to problem (3.5) for any smooth simply connected two-dimensional Ω (see [LMW] for the details).

BUCKLING EIGENVALUES FOR A CLAMPED PLATE EMBEDDED IN AN ELASTIC MEDIUM AND RELATED QUESTIONS*

BERNHARD KAWOHL†, HOWARD A. LEVINE‡, AND WALDEMAR VELTE§

Abstract. This paper considers the dependence of the sum of the first m eigenvalues of three classical problems from linear elasticity on a physical parameter in the equation. The paper also considers eigenvalues $\gamma_i(a)$ of a clamped plate under compression, depending on a lateral loading parameter a; $\Lambda_i(a)$, the Dirichlet eigenvalues of the elliptic system describing linear elasticity depending on a combination a of the Lamé constants, and eigenvalues $\Gamma_i(a)$ of a clamped vibrating plate under tension, depending on the ratio a of tension and flexural rigidity. In all three cases $a \in [0, \infty)$. The analysis of these eigenvalues and their dependence on a gives rise to some general considerations on singularly perturbed variational problems.

Key words. eigenvalue, asymptotic, parameter dependence, plate equation, elasticity, singular perturbation

AMS(MOS) subject classifications. 35J50, 35J55, 35P15, 49G05, 49G20

Introduction. Let, for $i = 1, 2, \ldots, \gamma_i$ be the eigenvalues of the equation for the clamped plate under compression, Γ_i be the eigenvalues for the equations of linear elasticity, and Λ_i be the eigenvalues for the equation for the vibrating clamped plate under tension. Briefly, our first result says that $\sum_{i=1}^{m} \gamma_i(a)$ and $\sum_{i=1}^{m} \Gamma_i(a)$ are strictly concave functions of a, while $\sum_{i=1}^{m} \Lambda_i(a)$ is concave. Moreover and in particular

$$\begin{aligned}
&\lim_{a\to\infty} \gamma_1(a) = +\infty \quad \text{and} \quad \lim_{a\to\infty} \frac{\gamma_1(a)}{\sqrt{a}} = 2,\\
&\lim_{a\to\infty} \Lambda_1(a) < \infty,\\
&\lim_{a\to\infty} \Gamma_1(a) = +\infty \quad \text{but} \quad \lim_{a\to\infty} \frac{\Gamma_1(a)}{a} = \lambda_1.
\end{aligned}$$

(Here λ_1 is the first Dirichlet eigenvalue for the Laplacian which is also known as the first eigenvalue for the fixed membrane.) The graphs of these functions are sketched in Figs. 1, 2, and 4 along with the previously known upper and lower bounds. The plan of the paper is as follows. In §1 we discuss $\gamma_i(a)$, $\Lambda_i(a)$ and $\Gamma_i(a)$. We use some ideas of [10], [11], [12] to obtain some of our results. In §§2 and 3 we consider generalizations, first to abstract linear problems and then to nonlinear problems. Throughout the paper $\{\lambda_i\}_{i\in N}$ denotes the ordered sequence of eigenvalues of the problem

$$\begin{aligned}
\Delta\psi + \lambda\psi &= 0 \quad \text{in } \Omega,\\
\psi &= 0 \quad \text{on } \partial\Omega,
\end{aligned}$$

while $\{\psi_j\}_{j\in N}$ denotes the corresponding sequence of orthonormal eigenfunctions.

1. The first eigenvalue of a clamped plate under compression. Let $\Omega \subset I\!R^N$ be a domain with smooth boundary and let $a \geq 0$ be a parameter. Consider the eigenvalue problem

$$\tag{1} \begin{aligned} \Delta\Delta u + au + \gamma(a)\Delta u &= 0 \quad \text{in } \Omega, \\ u = \frac{\partial u}{\partial n} &= 0 \quad \text{on } \partial\Omega, \end{aligned}$$

where $a > 0$ is given and represents the elasticity constant of a medium surrounding the plate. The function u stands for the transverse displacement [9] and $\gamma_1(a)$ is the minimal compression at which the plate exhibits buckling. Payne established the following inequality in [9]

$$\tag{2} \max\{\gamma_1(0),\ 2\sqrt{a}\} \leq \ \gamma_1(a) \ \leq \gamma_1(0) + \frac{a}{\lambda_1}.$$

(Indeed, he showed that (2) holds for each eigenvalue $\gamma_i(a)$ of (1).) Moreover, Levine and Protter derived the lower bound

$$\tag{3} \sum_{i=1}^{m} \gamma_i(a) \geq \frac{4\pi^2 N m^{(1+2/N)}}{(N+2)(\omega_N V)^{2/N}}$$

in [6]. Here ω_N denotes the surface area of the unit ball in $I\!R^N$ and V denotes the volume of Ω.

THEOREM 1. *The function* $F(a) = \sum_{i=1}^{m} \gamma_i(a)$ *is strictly concave and strictly increasing in* a *on* $[0, \infty)$.

For the proof we use the variational characterization of $F(a)$. It is well known that the Rayleigh quotient associated with (1) is given by

$$\tag{4} \mathcal{R}_a(v) = \frac{\int_\Omega (\Delta v)^2 dx + a \int_\Omega v^2 dx}{\int_\Omega |\nabla v|^2 dx},$$

where $v \in H_0^2(\Omega$. Let us first prove that $F(a)$ is concave by establishing that for any $a_0 \in [0, \infty)$ there exists $M \in I\!R$ such that

$$\tag{5} F(a) - F(a_0) \leq M(a - a_0) \quad \text{for any } a \in [0, \infty).$$

From the min–max characterization of eigenvalues (see [1, Vol. 1]) we know that

$$\tag{6} F(a) \leq \sum_{i=1}^{m} \mathcal{R}_a(v_i)$$

for every orthonormal system $\{v_1, \dots, v_m\}$ of admissible functions in $H_0^2(\Omega)$. Here $\{v_1, v_2, \dots, v_m\}$ are orthonormal with respect to $\int_\Omega \nabla v_i \nabla v_j \ dx$.

Let u_i^a denote the ith eigenfunction associated with (1), normalized to $||\nabla u_i^a||_{L^2(\Omega)} = 1$. Set $v_i = u_i^{a_0}$. Then (6) implies

$$F(a) - F(a_0) \leq (a - a_0) \sum_{i=1}^{m} \int_\Omega v_i^2 \ dx.$$

Therefore (5) holds with a positive M and $F(a)$ is strictly increasing and concave. To prove that $F(a)$ is strictly concave, suppose the contrary. Then there exists an interval $[b, c] \subset [0, \infty)$ such that

$$F(tb + (1-t)c) = tF(b) + (1-t)F(c)$$

holds for every $T \in [0, 1]$. In particular, setting $t = \frac{1}{2}$ and $a = (b+c)/2$

$$F(a) = \tfrac{1}{2}F(b) + \tfrac{1}{2}F(c). \tag{7}$$

We observe that

$$\gamma_i(b) = \mathcal{R}_b(u_i^b) \leq \mathcal{R}_b(u_i^a), \tag{8}$$

and that the same inequality holds with b replaced by c. Therefore we have from (7) and (8)

$$\begin{aligned} F(a) &\leq \frac{1}{2}\sum_{i=1}^{m} \mathcal{R}_b(u_i^a) + \frac{1}{2}\sum_{i=1}^{m} \mathcal{R}_c(u_i^a) \\ &= \sum_{i=1}^{m} \mathcal{R}_a(u_i^a) = F(a). \end{aligned}$$

But now equality must hold in (8) for every $i = 1, \ldots, m$. In particular $\gamma_1(b) = \mathcal{R}_b(u_1^a)$ and $\gamma_1(c) = \mathcal{R}_c(u_1^a)$; that is, $u = u_1^a$ is an eigenfunction corresponding to both $\gamma_1(b)$ and $\gamma_1(c)$. Subtraction of the corresponding differential equations (1) yields:

$$(\gamma_1(c) - \gamma_1(b))\Delta u + (c - b)u = 0. \tag{9}$$

If $\gamma_1(c) = \gamma_1(b)$ then (9) implies $c = b$ as desired. Otherwise u is an eigenfunction to the Laplace operator on Ω and satisfies both $u = 0$ and $\partial u/\partial n = 0$ on $\partial\Omega$, a contradiction to Hopf's second lemma. Therefore $c = b$ and this completes the proof of Theorem 1. □

Remark 1. In [10, p. 286ff] Polya and Schiffer proved concavity of sums of eigenvalues for some Neumann problems. Our result and proof are inspired by theirs. One might conjecture that each of the eigenvalues is concave in a separately. Numerical results in [5] indicate that in general this is not the case. Notice, however, that $\gamma_1(a)$ is strictly concave.

From now on we concentrate on the first eigenvalue $\gamma_1(a)$.

COROLLARY 2. *Inequalities* (2) *are strict for* $a > 0$.

Proof. By Theorem 1, equality cannot hold on the right-hand side of (2) for $a > 0$, nor on the left-hand side when $0 < a < \gamma_1^2(0)/4$. Moreover, we have after integration by parts in the denominator and by Schwarz's inequality

$$\begin{aligned} \gamma_1(a) = \mathcal{R}_a(u_1^a) &= \frac{\int_\Omega (\Delta u_1^a)^2 dx + a\int_\Omega (u_1^a)^2 dx}{\int_\Omega |\nabla u_1^a|^2 dx} \\ &\geq \left(\frac{\int_\Omega (\Delta u_1^a)^2 dx}{\int_\Omega (u_1^a)^2 dx}\right)^{1/2} + a\left(\frac{\int_\Omega (u_1^a)^2 dx}{\int_\Omega (\Delta u_1^a)^2 dx}\right)^{1/2} \geq 2\sqrt{a}. \end{aligned}$$

Thus $\gamma_1(a) = 2\sqrt{a}$ if and only if

$$\frac{\int_\Omega (\Delta u_1^a)^2 dx}{\int_\Omega (u_1^a)^2 dx} = a$$

and

$$\int_\Omega (\Delta u_1^a)^2 dx \cdot \int_\Omega (u_1^a)^2 dx = \left(\int_\Omega u_1^a \Delta u_1^a dx\right)^2,$$

and equality holds if and only if $\Delta u_1^a + \sqrt{a} u_1^a = 0$. But $u_1^a = 0 = \partial u_1^a/\partial n$ on $\partial\Omega$, so that $u_1^a = 0$. Thus, the strict inequalities

$$\max\{\gamma_1(0),\, 2\sqrt{a}\} < \gamma_1(a) < \gamma_1(0) + \frac{a}{\lambda_1} \tag{10}$$

hold. This completes the proof of Corollary 2. □

Of particular interest is the asymptotic behavior of the eigenvalue $\gamma_1(a)$ and the associated eigenfunction u_1^a as $a \to \infty$. We can give the following partial answer to this problem.

THEOREM 3. *Let u_1^a be a first eigenfunction, normalized so that $||\nabla u_1^a||_{L^2(\Omega)} = 1$, and $\gamma_1(a)$ the first eigenvalue of* (1). *Then $||u_1^a||_{L^2(\Omega)} \to 0$ and $\gamma_1(a)/\sqrt{a} \to 2$ as $a \to \infty$.*

The proof of Theorem 3 will proceed in several steps. The results of Theorems 1, 3, and inequality (2) are illustrated in Fig. 1.

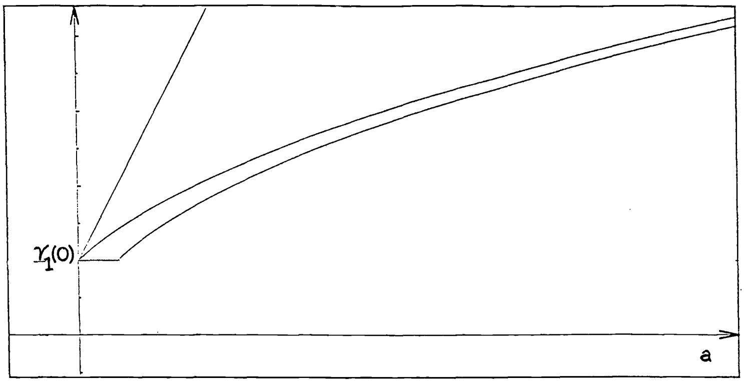

FIG. 1. $\gamma_1(a)$.

LEMMA 4. (a) *If Ω is starshaped with respect to zero, then $\gamma_1(a)/\sqrt{a}$ is decreasing, i.e.,*

$$\frac{\gamma_1(a)}{\sqrt{a}} > \frac{\gamma_1(b)}{\sqrt{b}} \quad \textit{for } 0 < a < b. \tag{11}$$

(b) *If Ω is a bounded domain, then there exists a constant $M \in (2, \infty)$ such that*

$$\frac{\gamma_1(a)}{\sqrt{a}} < M \quad \textit{as } a \to \infty. \tag{12}$$

It should be remarked that Rother [12] proved (12) under the assumptions of Lemma 4(a). To prove Lemma 4(a), recall that

$$\gamma_1(a) = \min_{u \in H_0^2(\Omega)} \mathcal{R}_a(u),$$

with $\mathcal{R}_a(u)$ defined by (4). Using the transformation

$$y_j = a^{1/4}x_j \quad \text{for } j = 1, \dots, N; \qquad v(y) = u(x(y)), \quad \frac{\partial u}{\partial x_j} = a^{1/4}\frac{\partial v}{\partial y_j},$$

the expression $\mathcal{R}_a(u)$ is converted into

$$\tilde{\mathcal{R}}_a(v) = \sqrt{a} \cdot \frac{\int_{\Omega_a}(\Delta v)^2 dx + \int_{\Omega_a} v^2 dx}{\int_{\Omega_a} |\nabla v|^2 dx},$$

where $\Omega_a = a^{1/4}\Omega$ is the image of Ω under the above transformation. Therefore $\gamma_1(a)/\sqrt{a}$ can be characterized through

$$\frac{\gamma_1(a)}{\sqrt{a}} = \min_{u \in H_0^2(\Omega_a)} \frac{\int_{\Omega_a}(\Delta v)^2 dx + \int_{\Omega_a} v^2 dx}{\int_{\Omega_a} |\nabla v|^2 dx}, \tag{13}$$

and (13) is equivalent to the original characterization of γ_1. At this point the starshapedness of Ω enters into the proof, because for starshaped domains we have

$$\Omega_a \subset \Omega_b \quad \text{for } 0 < a < b.$$

Since functions from $H_0^2(\Omega_a)$ can be continued by zero in $\overline{\Omega_b} \setminus \Omega_a$, property (11) follows from the well-known monotone dependence of eigenvalues on the domain Ω. This completes the proof of Lemma 4(a).

To prove Lemma 4(b) let B be a ball contained in Ω. Without loss of generality we may assume that Ω contains zero and that $a > 1$. Let $\tilde{u}_1^a$ be a first eigenfunction associated to the first eigenvalue $\tilde{\gamma}_1(a)$ on B. Then by the monotone dependence of γ_1 on Ω and by (11) we have

$$\frac{\gamma_1(a)}{\sqrt{a}} \leq \frac{\tilde{\gamma}_1(a)}{\sqrt{a}} \leq \tilde{\gamma}_1(1), \tag{14}$$

and this completes the proof of Lemma 4. □

Now we can prove the first statement of Theorem 3. Relation (14) implies

$$||u_1^a||^2_{L^2(\Omega)} \leq \frac{\tilde{\gamma}_1(1)}{\sqrt{a}}, \tag{15}$$

so that $u_1^a \to 0$ in $L^2(\Omega)$ of order $a^{-1/4}$. To complete the proof of Theorem 3 it suffices to combine (14) with the following result.

LEMMA 5. *If Ω is a ball or rectangular parallelepiped, then*

$$\lim_{a\to\infty} \frac{\gamma_1(a)}{\sqrt{a}} = 2. \tag{16}$$

To show (16), first in the one-dimensional case, we take $\{a_n\}_{n\in N} = \{\lambda_n\}_{n\in N} = \{n^2\pi^2\}_{n\in N}$ and $\overline{\Omega} = [0,1]$. With $\psi_n = c_n \sin(n\pi x)$, it is easy to see that there are constants $d_1, d_2 > 0$ such that for all n, with $\Omega_n = (0, 1/n) \cup (1 - 1/n, 1)$

$$\int_{\Omega_n} |\nabla\psi_n|^2 \, dx \leq \frac{d_1}{\lambda_n^{1/2}}$$

$$\int_{\Omega_n} |\psi_n|^2 \, dx \leq \frac{d_2}{\lambda_n^{3/2}},$$

where we normalize the ψ_n so that

$$\int_0^1 |\psi_n'|^2 \, dx = \lambda_n \int_0^1 \psi_n^2 \, dx = 1.$$

The eigenfunctions are uniformly oscillating on (0,1). The functions ψ_n are not admissible for the Rayleigh quotient (4), since they are not in $H_0^2(\Omega)$. In order to modify them near the boundary, we construct functions of the form $\phi_n = \psi_n \eta_\varepsilon$, where $\varepsilon = 1/n$ and η_ε is given by

$$\eta_\varepsilon(x) = \begin{cases} \phi_\varepsilon(x) & 0 \le x \le \frac{1}{n}, \\ 1 & \frac{1}{n} < x < 1 - \frac{1}{n}, \\ \phi_\varepsilon(1-x) & 1 - \frac{1}{n} \le x \le 1, \end{cases}$$

where, for $x \in (0, \varepsilon)$,

$$\phi_\varepsilon(x) = \frac{\int_0^x \, \mathrm{e}^{-\varepsilon^4/(y^2(\varepsilon^2 - y^2))} \, dy}{\int_0^\varepsilon \, \mathrm{e}^{-\varepsilon^4/(y^2(\varepsilon^2 - y^2))} \, dy}.$$

η_ε is of class C^2 in $(0,1)$, $\eta = \eta' = 0$ at $x = 0, 1$, and there are constants d_3, d_4, independent of ε such that $\max |\eta_\varepsilon'| \le d_3/\varepsilon$, $\max |\eta_\varepsilon''| \le d_4/\varepsilon^2$. Thus a tedious, but routine, calculation yields, using $\eta = \eta_{1/n}$ for notation,

$$\begin{aligned} \frac{\mathcal{R}_{\sqrt{\lambda_n}}(\psi_n \eta)}{\sqrt{\lambda_n}} &\le \frac{2 - \int_{\Omega_n} \, 2\psi_n \eta(\psi_n' \eta' + \psi_n \eta'') \, dx + \lambda_n^{-1} \int_{\Omega_n} \, (\psi_n \eta'' + \psi_n' \eta')^2 \, dx}{1 - \int_{\Omega_n} \, [(1 - \eta^2)(\psi_n')^2 + \psi_n^2 \eta \eta''] \, dx} \\ &\le \frac{2 + d_5 \lambda_n^{-1/2}}{1 - d_6 \lambda_n^{-1/2}} \end{aligned}$$

with constants d_5, d_6 independent of n. (Note that $\varepsilon = 1/n = \pi/\lambda_n^{1/2}$.) To verify (16) for arbitrary domains in higher dimensions, it is necessary to have good estimates for the local L^2 norms of the eigenfunction and its gradient near the boundary. For N-dimensional rectangles, however, the one-dimensional example is easily modified. If Ω is the unit ball in $\mathbb{R}^N$, then the radially symmetric eigenfunctions are given by

$$\psi_j(x) = c_j r^{-(N-2)/2} J_{(N-2)/2}(\sqrt{\lambda_j} r),$$

where J_ν is the usual Bessel function of order ν, the numbers $\lambda_j^{1/2}$ are the roots of J_ν in increasing order and the c_j's are normalizing constants chosen so that

$$\int_\Omega |\nabla \psi_j|^2 \, dx = \lambda_j \int_\Omega \psi_j^2 \, dx = 1,$$

or

$$\int_0^1 (\psi_j'(r))^2 r^{N-1} \, dr = \lambda_j \int_0^1 \psi_j^2(r) r^{N-1} \, dr = \omega_N^{-1}.$$

Precisely, we have

$$c_j^2 = \frac{2}{\lambda_j J_{(N-2)/2}^2(\sqrt{\lambda_j})},$$

with

$$\sqrt{\lambda_j} = (j + (N-3)/4)\pi + O\left(\frac{1}{j}\right)$$

and, for any index $\nu > -1$ as $r \to +\infty$ and some constant C_ν,

$$|J_\nu(r)| = C_\nu r^{-1/2}\left(1 + O\left(\frac{1}{r}\right)\right).$$

From these estimates we easily see that there are constants $d_1, d_2 > 0$ such that for all $j >> 1$,

$$\int_{1-1/\sqrt{\lambda_j}}^{1} \psi_j^2(r) r^{N-1}\, dr \le d_1 \lambda_j^{-3/2}$$

and

$$\int_{1-1/\sqrt{\lambda_j}}^{1} (\psi_j'(r))^2 r^{N-1}\, dr \le d_2 \lambda_j^{-1/2}.$$

Thus, if we take $\eta = \eta_\varepsilon(r)$ to be one on the ball of radius $1 - \varepsilon$, satisfy $0 < \eta < 1$ in the annular region $\{1 - \varepsilon < r < 1\}$ with $\eta(1) = \eta'(1) = 0$ and with $\varepsilon = \lambda_j^{-1/2}$, we see that with $\phi_j = \eta_\varepsilon \psi_j$, we again have

$$\frac{\mathcal{R}_{\sqrt{\lambda_j}}(\eta_\varepsilon \psi_j)}{\sqrt{\lambda_j}} \le \frac{2 + d_5 \lambda_j^{-1/2}}{1 - d_6 \lambda_j^{-1/2}}$$

for computable constants d_5, d_6. In fact we can choose η_ε so that for some d_3, d_4 the following estimates hold: $\max|\eta_\varepsilon'| \le d_3 \lambda_j^{-1/2}$ and $\max|\eta_\varepsilon''| \le d_4 \lambda_j^{-1}$. This together with (10) completes the proof of Lemma 5 and thus of Theorem 3. □

Remark 2. The limiting process in Theorem 3 can be recast as the singular perturbation problem of minimizing

$$I_\varepsilon(v) = \int_\Omega \varepsilon(\Delta v)^2 + v^2\, dx \quad \text{over} \quad \left\{ v \in H_0^2(\Omega) \mid \int_\Omega |\nabla v|^2 dx = 1 \right\}.$$

The formal limit problem for $\varepsilon = 0$ has no solution, but as the proof of Lemma 4 shows, for certain domains Ω there exists a minimizing sequence v_ε for I_0 such that $I_0(v_\varepsilon) \to 0$ as $\varepsilon \to 0$. Moreover, v_ε is highly oscillatory and the oscillations of v_ε are equidistributed. A similar qualitative behaviour has been observed by Müller in [8]. He minimized

$$\tilde{I}_\varepsilon(v) = \int_0^1 [\varepsilon(v_{xx})^2 + (v_x^2 - 1)^2 + v^2]\, dx \quad \text{over } H_0^2(0,1),$$

and showed that minimizers v_ε of $\tilde{I}_\varepsilon$ are rapidly and regularly oscillating and converge to zero in $L^2(\Omega)$. Moreover, the formal limit problem for $\varepsilon = 0$ has no solution, either. Theorem 3 shows that oscillatory behavior of this nature is not restricted to nonlinear problems, but can just as well occur for solutions of classical linear problems. In fact, physical intuition tells us that the buckled state of the plate should oscillate while its amplitude decreases as the ambient medium gets stiffer and stiffer.

Remark 3. *Linear elasticity system.* The above results were inspired by the paper [11] of W. Rother, who investigated the dependence of the first eigenvalue $\Lambda_1(a)$ of Lamé's operator on a parameter $a = (\lambda + \mu)/\mu$, where λ and μ are the Lamé constants. This eigenvalue can be characterized by

$$\Lambda_1(a) = \min\left\{ ||\nabla \underline{u}||^2 + a||\text{div}\ \underline{u}||^2 \mid \underline{u} \in [H_0^1(\Omega)]^N,\ ||\underline{u}||_{L^2(\Omega)^N} = 1 \right\}, \tag{17}$$

see, e.g., [2]. The associated system reads

$$\begin{aligned} \Delta \underline{u} + a \operatorname{grad} \operatorname{div} \underline{u} + \Lambda_1 \underline{u} &= 0 \quad \text{in } \Omega, \\ \underline{u} &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Problem (17) is related to the so-called fundamental Stokes' eigenvalue:

$$m_1 = \min \{ ||\nabla \underline{u}||^2 \mid \underline{u} \in [H_0^1(\Omega)]^N, \ \operatorname{div} \underline{u} = 0, \ ||\underline{u}||_{L^2(\Omega)^N} = 1 \}. \tag{18}$$

It was shown in [2] that m_1 is an upper bound for $\Lambda_1(a)$. In [11] Rother showed that $\Lambda_1(a)$ is increasing in a. Using the ideas above it can easily be shown that in fact $\sum_{i=1}^m \Lambda_i(a)$ is concave in a. The lower bound

$$\sum_{i=1}^{m} \Lambda_i(a) \geq \frac{3}{5} \left(\frac{2\pi^2}{V} \right)^{2/3} m^{5/3}$$

was derived in [6]. Under the technical assumption that $\partial\Omega \in C^{0,1}$, Rother showed that the upper bound m_1 is optimal in the sense that

$$\lim_{a \to \infty} \Lambda_1(a) = m_1. \tag{19}$$

In [4], it was shown that

$$\lambda_1 \leq \Lambda_1(a) \left(1 + \frac{a}{3}\right) \lambda_1.$$

See Fig. 2 for a graphical summary of the discussion of the results for $\Lambda_1(\cdot)$.

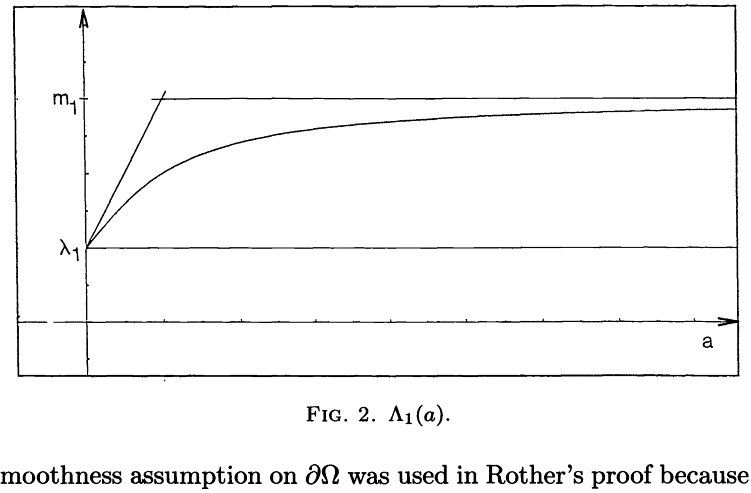

FIG. 2. $\Lambda_1(a)$.

The smoothness assumption on $\partial\Omega$ was used in Rother's proof because he decomposed the eigenfunctions orthogonally into divergence free and remaining components, and he then applied some results for the divergence operator. We can avoid these difficulties (and thus derive (19) without any regularity assumption on $\partial\Omega$) as follows: let $\underline{u}_n$ be a sequence of eigenvectors associated with the eigenvalue $\Lambda_1(n)$ and suppose that $n \to \infty$. Since $\Lambda_1(n) \leq m_1$ we know that $\underline{u}_n$ is uniformly bounded in $[H_0^1(\Omega)]^N$ and that div $\underline{u}_n \to 0$ as $n \to \infty$. Therefore, after possibly passing to a subsequence,

$\underline{u}_n$ has a weak limit $\underline{u}_\infty$ in $[H_0^1(\Omega)]^N$. Moreover, $\underline{u}_\infty$ has unit length in $L^2(\Omega)^N$. Since the map $v \mapsto \int_\Omega (\text{div } v)^2\, dx$ is convex and hence weakly lower semicontinuous in $[H_0^1(\Omega)]^N$, we conclude that $\text{div}\, \underline{u}_\infty = 0$. Finally it should be noted that u_n converges strongly in $[H_0^1(\Omega)]^N$ to u_∞, since $||u_n|| \to ||u_\infty||$ and u_n converges weakly. Therefore (19) must hold.

Remark 4. *Clamped plate under tension.* Instead of (1) consider the eigenvalue problem

$$\begin{aligned} \Delta\Delta u - a\Delta u - \Gamma u &= 0 \quad \text{in } \Omega, \\ u = \frac{\partial u}{\partial n} &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{20}$$

where $a = T/D$ is given. T describes tension and D the flexural rigidity of the plate. The eigenvalues Γ_i of (20) are characterized by means of the following Rayleigh quotient on $H_0^2(\Omega)$

$$\mathcal{R}_a(v) = \frac{\int_\Omega \{(\Delta v)^2 + a|\nabla v|^2\}\, dx}{\int_\Omega v^2\, dx}. \tag{21}$$

As in the proof of Theorem 1 it can be shown that $\sum_{i=1}^m \Gamma_i(a)$ is strictly concave and strictly increasing in a. The following estimates hold for $\Gamma_1(a)$:

$$\Gamma_1(0) + a\lambda_1 \le \Gamma_1(a) \le \Gamma_1(0) + a\sqrt{\Gamma_1(0)} \quad \text{for } a > 0; \tag{22}$$

see [9]. Here again λ_1 is the lowest eigenvalue of the corresponding fixed membrane problem and $\sqrt{\Gamma_1(0)}$ is the fundamental frequency of a clamped plate in the absence of tension. Notice that (22) is sharp for $a = 0$, and that (22) implies that the curve $(a, \Gamma_1(a))$ stays inside a certain cone. A consequence of our results is that the inequalities in (22) are necessarily strict, an assertion not claimed by Payne. The numerical results of [14] indicate that $\Gamma_1(a)$ is a concave function with an asymptote whose slope is not smaller than λ_1, see Figs. 3 and 4.

We claim that the eigenfunction u_a associated to $\Gamma_1(a)$ converges to ψ_1 and $\Gamma_1(a)$ converges to λ_1 as $a \to \infty$; see Fig. 4. Indeed, $\Gamma_i(a) \to \lambda_i$ for $i = 1, 2, \dots$, as $a \to \infty$. This is easy to see once we realize that letting $a \to \infty$ is equivalent to letting the flexural rigidity of the plate tend to zero. Thus, in the limit the plate should behave like a membrane. Setting $\varepsilon = 1/a$ we can rewrite the differential equation in (20) as

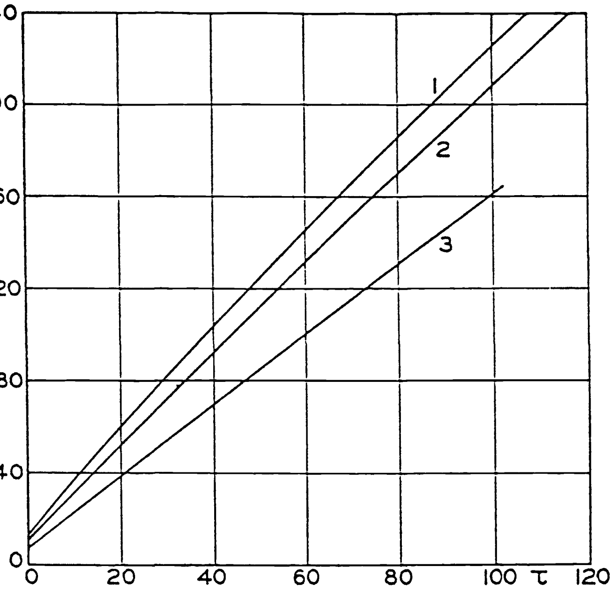
$$\varepsilon\Delta\Delta u - \Delta u - \lambda(\varepsilon)u = 0,$$

and view this differential equation as a singular perturbation of the membrane equation given at the end of the Introduction. In fact, asymptotic expansions for $\lambda_i(\varepsilon)$ and its corresponding eigenfunctions are well known and recorded, for instance, in [2, p. 392], [3], [15].

2. More general results, the linear case. The above result can be generalized in several ways: For example, let H be a Hilbert space and D_1, D_2 ($D_2 \subset D_1 \subset H$) be dense linear subspaces on which the nonnegative, selfadjoint operators E_1, E_2 are defined respectively. We shall assume that E_2 is strictly positive, i.e., $(x, E_2x) > 0$ unless $x = 0$. Let $(\cdot,\cdot)$ and $||\ \ ||$ denote the scalar product and corresponding norm on H. We let $\overline{D_i}$ be the completion of D_i in the norm $\{(x, E_ix) + ||x||^2\}^{\frac{1}{2}}$.

(A.1) For every $a \ge 0$ there exists $y_a \in \overline{D_2}$ such that

$$\begin{aligned} \Gamma(a) &= \inf\{(x, E_2x) + a(x, E_1x) \mid ||x|| = 1, x \in \overline{D_2}\ \} \\ &= (y_a, E_2y_a) + a(y_a, E_1y_a) =: J_a(y_a). \end{aligned}$$



Curve 1: Clamped Square Plate ($\pi/2 \geqq x, y \geqq -\pi/2$)
Curve 2: Clamped Circular Plate ($r = \sqrt{\pi}$)
Curve 3: Clamped Circular Plate ($r = 2$)

FIG. 3. *Numerical approximations of* $\Gamma_1(a)$, *copied from* [14] ($\tau = a$).

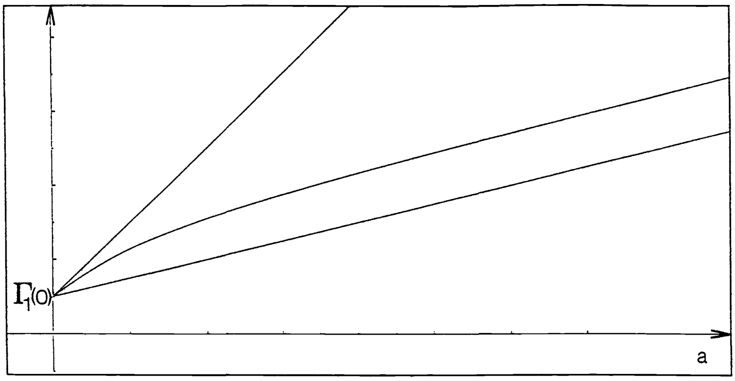


FIG. 4. $\Gamma_1(a)$.

THEOREM 6. *Suppose that* (A.1) *holds.*

(i) *If* $a < b$, *then*

$$(y_b, E_1 y_b) \leq \frac{\Gamma(b) - \Gamma(a)}{b - a} \leq (y_a, E_1 y_a), \tag{23}$$

and $\Gamma(a)$ *is a monotone nondecreasing function of* a.

(ii) $\Gamma(a)$ *is a concave function of* a.

(iii) $\Gamma(a)$ *is strictly increasing on an interval* $(\alpha, \beta) \subset (0, \infty)$ *if and only if* $(y_a, E_1 y_a) > 0$ *for all* $a \in (\alpha, \beta)$.

(iv) $\Gamma(a)$ *is strictly concave if* E_1 *and* E_2 *have no common eigenvector.*

COROLLARY 7. (i) $|\Gamma(b) - \Gamma(a)| \leq (y_0, E_1 y_0)\,|b - a|$. ($\Gamma(a)$ *is Lipschitz continuous.*)

(ii) $\tilde{F}(a) = (y_a, E_1 y_a)$ *is a nonincreasing function of* a.

(iii) $\Gamma(0) + a \lim_{b\to\infty}(y_b, E_1 y_b) \leq \Gamma(a) \leq \Gamma(0) + a(y_0, E_1 y_0)$.

The proof of Corollary 7 is immediate. Let us prove Theorem 6. Statement (i) is straightforward, since $\Gamma(b) = J_b(y_b) \leq J_b(y_a)$ and $\Gamma(a) = J_a(y_a) \leq J_a(y_b)$. To prove concavity, and thus statement (ii), we have $t\Gamma(a) = tJ_a(u_a) \leq tJ_a(y_t)$ and $(1-t)\Gamma(b) = (1-t)J_b(y_b) \leq (1-t)J_b(y_t)$ for any $t \in (0,1)$, where y_t is shorthand for $y_{ta+(1-t)b}$. Adding these inequalities, we have

$$t\Gamma(a) + (1-t)\Gamma(b) \leq \Gamma(ta + (1-t)b). \tag{24}$$

In order to prove (iii) we need only observe from (23) that $(y_a, E_1 y_a) > 0$ in (α, β) if and only if $\Gamma(a)$ is strictly increasing in (α, β). To prove (iv) notice that equality holds in (24) if and only if $\Gamma(b) = J_b(y_b) = J_b(y_t)$ and $J_a(y_t) = J_a(y_a) = \Gamma(a)$. The latter is equivalent to

$$E_2 y_t + bE_1 y_t - \Gamma(b) y_t = 0 \tag{25}$$

and

$$E_2 y_t + aE_1 y_t - \Gamma(a) y_t = 0.$$

Upon subtraction we see that

$$E_1 y_t = \frac{\Gamma(b) - \Gamma(a)}{b-a} y_t, \tag{26}$$

so that y_t is an eigenvector of the operator E_1. But now, using (25) or (26) it can be seen that y_t is an eigenvector of E_2, too. This proves Theorem 6. □

Remark 5. One particular consequence of (23) or Corollary 7(ii) is the following: If $(y_a, E_1 y_a) = 0$ for some $a > 0$, then $\Gamma(a)$ is constant on $[a, \infty)$ and $(y_b, E_1 y_b) = 0$ for $b \in [a, \infty)$.

In order to obtain information on the limit $a \to \infty$ we need more assumptions about the relationship between E_1 and E_2, e.g., the following assumption.

(A.2) There exists $\alpha \in (0,1]$ such that $(x, E_1 x) \leq (x, E_2 x)^\alpha$ for all $x \in \overline{D_2}$, $||x|| = 1$.

Then

$$(y_a, E_1 y_a) \leq (y_0, E_1 y_0) \leq (y_0, E_2 y_0)^\alpha = \Gamma(0)^\alpha. \tag{27}$$

For example, for the plate under tension, $E_2 u = \Delta\Delta u$, $E_1 u = \Delta u$ on $H_0^2(\Omega)$ and $H_0^1(\Omega)$ respectively, property (A.2) holds with $\alpha = \frac{1}{2}$. Or for the Lamé operator $E_2 = \Delta$ and $E_1 = \nabla(\text{div }) $ on $[H_0^1(\Omega)]^n$ property (A.2) holds with $\alpha = 1$. Also, by unique continuation the hypothesis of Theorem 6(iv) holds for this example.

$$\Gamma(a) \leq \inf\ \{(x, E_2 x) \mid ||x|| = 1,\ x \in \overline{D_2},\ (x, E_1 x) = 0\}. \tag{28}$$

One has to distinguish two cases: (1) The infimum in (28) is taken over an empty set. (2) The infimum in (28) is taken over a nonempty set.

In both cases the family $\{(y_a, E_1 y_a)\}_{\{a>0\}}$ is bounded in view of (27). In the second case, however $(x, E_1 x)^{1/2}$ is only a seminorm, since there are vectors for which $(x, E_1 x) = 0$ and consequently the kernel $\operatorname{Ker} E_1 = \{x \mid E_1 x = 0\}$ is not trivial. If the infimum in (28) is taken over an empty set, it is ∞ by convention and we assume the following.

(A.3.1) If $\operatorname{Ker} E_1 = \{0\}$, then $\overline{D_1} = \overline{D_2}$ and sequence which is bounded in $\overline{D_1}$ posesses a subsequence which converges strongly in H and weakly in $\overline{D_1}$. Equivalently, $\overline{D_1}$ is compactly embedded in H.

If the infimum is taken over a nonempty set, $\Gamma(a) \leq M < \infty$ for all a and some M. In that case we assume (A.3.2)

(A.3.2) If $\operatorname{Ker} E_1 \neq \{0\}$, then every sequence which is bounded in $\overline{D_2}$ possesses a subsequence which converges strongly in H and weakly in $\overline{D_1}$.

For reasons that will become obvious in the proof of Theorem 8(iii), we need an additional assumption, namely, (A.4).

(A.4) Let $\mathcal{E}_a = \{y_a \mid J_a(y_a) = \Gamma(a)\}$. For every $a \geq 0$ there exists $\tilde{y}_a \in \mathcal{E}_a$ such that

$$(\tilde{y}_a, E_1\tilde{y}_a) = \inf\{(y_a, E_1 y_a) \mid y_a \in \mathcal{E}_a\} =: F(a).$$

We can now establish an analogue to (19) or Remark 4.

THEOREM 8. *Suppose that* (A.1), (A.2), *and* (A.3) *hold. Then*

(i) $\lambda_1 = \lim_{a\to\infty} (y_a, E_1 y_a)$ *is the slope of the linear asymptote of* $\Gamma(a)$ *and* $\lambda_1 \leq (y_0, E_1 y_0) \leq \Gamma(0)^\alpha$.

(ii) *Moreover* λ_1 *is the smallest eigenvalue of* E_1 *and the family* $\{u_a\}$ *contains a sequence* $\{u_{a_n}\}$ *which converges strongly in* H *and weakly in* $\overline{D_1}$ *to an element of the first eigenspace of* E_1 *as* $a_n \to \infty$.

(iii) *Whenever* $\Gamma'(a)$ *exists and* (A.4) *holds, then* $\Gamma'(a) = \inf\{(y_a, E_1 y_a) \mid y_a \in \mathcal{E}_a\}$.

The proof of (i) follows from (27). To prove (ii) we notice that (i) and (A.3) imply the existence of a sequence y_{a_n} which converges weakly in $\overline{D_1}$ and strongly in H to a limit as $a_n \to \infty$ we distinguish the above two cases.

(1) If $\operatorname{Ker} E_1 = \{0\}$ the set $\{(y_a, E_1 y_a)\}$ is uniformly bounded and $\{y_a\}$ possesses a sequence which converges strongly in H and weakly in $\overline{D_i}$ to an element of $\overline{D_i}$.

(2) If $\operatorname{Ker} E_1 \neq \{0\}$ the set $\{(y_a, E_2 y_a)\}$ is uniformly bounded and $\{y_a\}$ possesses a sequence which converges strongly in H and weakly in $\overline{D_1}$ to an element of $\overline{D_1}$. Let us call the limit element y_∞. We have

$$\frac{(y_a, E_2\phi)}{a} + (y_a, E_1\phi) - \frac{\Gamma(a)}{a}(y_a, \phi) = 0$$

for every $\phi \in \overline{D_2}$, so that y_∞ is an eigenfunction for E_1:

$$(y_\infty, E_1\phi) - m(y_\infty, \phi) = 0$$

with $d = \lim_{a\to\infty} \Gamma(a)/a$. Notice that $||y_\infty|| = 1$ by assumption (A.3). By definition of λ_1, $d \geq \lambda_1$. It remains to show that $d = \lambda_1$, and we suppose in contrast that $d > \lambda_1$. Clearly E_1 has a smallest (nonnegative) eigenvalue $\mu_1 \leq \lambda_1$ and some associated eigenfunction $\psi_1 \in \overline{D_1}$. We claim $d = \lambda_1 = \mu_1$. Let $\varepsilon < d - \mu_1$. Since D_2 is dense in H and $D_2 \subset D_1 \subset H$, we can approximate $\psi_1 \in \overline{D_1}$ with a function $\phi_\varepsilon \in D_2$ such that $||\phi_\varepsilon|| = 1$ and $(\phi_\varepsilon, E_1\phi_\varepsilon) < \mu_1 + \varepsilon$. But this contradicts the choice of ε because

$$d \leq \lim_{a_n\to\infty} \frac{1}{a_n}(\phi_\varepsilon, E_2\phi_\varepsilon) + (\phi_\varepsilon, E_1\phi_\varepsilon) \leq \mu_1 + \varepsilon,$$

and thus concludes the proof of (ii). To prove (iii) we assume (A.4). Then for any decreasing sequence $a_n \to a$ there exists a number M such that $J_a(\tilde{y}_a) \leq J_{a_n}(\tilde{y}_{a_n}) \leq$

$J_{a_1}(\tilde{y}_{a_1}) \leq M$. Therefore $\{\tilde{y}_{a_n}\}$ has a subsequence, still denoted by $\{\tilde{y}_{a_n}\}$ with a limit $\tilde{y}_{a_\infty}$. We obtain

$$\Gamma(a) \leq J_a(\tilde{y}_{a_\infty}) \leq \liminf \Gamma(a_n) \leq \Gamma(a)$$

from the definition and the continuity properties of Γ. Therefore $y_{a_\infty} \in \mathcal{E}_a$. Furthermore, due to (27) and the monotonicity of F,

$$F(a) \leq (y_{a_\infty}, E_1 y_{a_\infty}) \leq \liminf(\tilde{y}_{a_n}, E_1\tilde{y}_{a_n}) = \liminf F(a_n) \leq F(a).$$

This proves that $F(a)$ equals the one-side derivative of Γ from the right. Since $\Gamma'(a)$ is assumed to exist, the proof of Theorem 8 is complete. □

3. More general results, the nonlinear case. For $i = 0, 1, 2$, let $J_i : X_i \to \mathbb{R}^+$ be a nonnegative weakly lower semicontinuous functional on a separable Banach space X_i.

THEOREM 9. *Suppose that $X_2 \subset X_1 \subset X_0$, and that there exists a unique minimizer u_0 in X_2 of $J_1(v)$ in $X_1 \cap \{v \mid J_0(v) = 1\}$. Let u_ε be a minimizer of $J_\varepsilon(v) := \varepsilon J_2(v) + J_1(v)$ on $X_2 \cap \{v \mid J_0(v) = 1\}$.*

(i) *Then $\Gamma(\varepsilon) = J_\varepsilon(u_\varepsilon)$ is monotone nondecreasing and concave in ε.*

(ii) *If X_1 is compactly embedded in X_0 and if J_1 is coercive, then u_ε converges to u_0 weakly in X_1 and strongly in X_0.*

(iii) *If X_2 is compactly embedded in X_1, then u_ε converges to u_0 weakly in X_2 and strongly in X_1 and X_0.*

The proof is straightforward if we use ideas from the proofs of Theorems 1 and 8. As an application for Theorem 9 consider the eigenvalue problem

$$\begin{aligned} \varepsilon\Delta\Delta u - \text{div}\,(|\nabla u|^{p-2}\nabla u) - \Gamma|u|^{p-2}u &= 0 \quad \text{in } \Omega \subset \mathbb{R}^n, \\ u = \frac{\partial u}{\partial n} &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{29}$$

for $1 < p < 2n/(n-p)$. Here $J_2(v) = ||\Delta v||^2_{L^2(\Omega)}$, $J_1(v) = ||\nabla v||^2_{L^p(\Omega)}$ and $J_0(v) = ||v||_{L^p(\Omega)}$, while $X_2 = H^2_0(\Omega)$, $X_1 = W^{1,p}_0(\Omega)$ and $X_0 = L^p(\Omega)$. Then, as $\varepsilon \to 0$, the solutions of (29) converge to the (unique) ground state of the formal limit problem,

$$\begin{aligned} \text{div}\,(|\nabla u|^{p-2}\nabla u) + \lambda|u|^{p-2}u &= 0 \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

For more details on this eigenvalue problem see, e.g., [7], [13].

Notes added in proof. Professor F. Goerisch has kindly informed us of [16], in which it is shown that the entire spectrum of the elasticity operator converges to the spectrum of the Stokes operator. Therefore Remark 3 of this paper extends to all eigenvalues.

In [17], the author re-establishes the results of [11] in three dimensions. The author's method of proof relies on the decomposition of the Lamé operator using quaternians and a generalized Cauchy–Riemann operator. His result thus appears to be restricted to three dimensions. However, no regularity of the boundary is required.

REGULARITY OF BOUNDARIES OF QUADRATURE DOMAINS IN TWO DIMENSIONS*

MAKOTO SAKAI†

Abstract. First, the author discusses regularity of the boundary of a bounded quadrature domain. It is shown that the boundary is very beautiful and it consists of regular, degenerate, double, and cusp points. Next the author discusses an unbounded quadrature domain and defines its global Schwarz function, showing that it is obtained as a translation of the inversion of a bounded quadrature domain if it is not dense in the whole plane. The author gives a complete description of unbounded quadrature domains of point differential functionals of finite order and determines all null quadrature domains in two dimensions.

Key words. quadrature domains, Schwarz functions, inversions

AMS(MOS) subject classifications. 30E20, 30E05, 30E99

In a previous paper [11], the author proved a regularity theorem on a boundary having a Schwarz function. Let Ω be an open subset of a disk $B_r(\zeta_0)$ with radius r and center ζ_0 such that the boundary $\partial\Omega$ of Ω contains the center ζ_0, and let $\Gamma = (\partial\Omega) \cap B_r(\zeta_0)$. We call a function S defined on $\Omega \cup \Gamma$ a Schwarz function of $\Omega \cup \Gamma$, more precisely, a Schwarz function of $\Omega \cup \Gamma$ at ζ_0 or in $B_r(\zeta_0)$, if

(i) S is holomorphic in Ω;

(ii) S is continuous on $\Omega \cup \Gamma$;

(iii) $S(\zeta) = \bar{\zeta}$ on Γ, where $\bar{\zeta}$ denotes the complex conjugate of ζ.

REGULARITY THEOREM [11]. *If there is a Schwarz function of* $\Omega \cup \Gamma$ *at* ζ_0, *then* ζ_0 *is* (1) *a regular,* (2) *degenerate,* (3) *double, or* (4) *cusp point of* Γ. *Namely, there is a small disk* $B = B_\delta(\zeta_0)$, *and one of the following must occur:*

(1) $\Omega \cap B$ *is simply connected and* $\Gamma \cap B$ *is a regular real analytic simple arc passing through* ζ_0.

(2) $\Gamma \cap B = \{\zeta_0\}$ *or* $\Gamma \cap B$ *is an infinite set accumulating at* ζ_0, *and is contained in a uniquely determined regular real analytic simple arc passing through* ζ_0. $\Gamma \cap B$ *is a proper subset of the arc or the whole arc.* $\Omega \cap B$ *is equal to* $B \setminus \Gamma$.

(3) $\Omega \cap B$ *consists of two simply connected components,* Ω_1 *and* Ω_2. $(\partial\Omega_1) \cap B$ *and* $(\partial\Omega_2) \cap B$ *are distinct regular real analytic simple arcs passing through* ζ_0. *They are tangent to each other at* ζ_0.

(4) $\Omega \cap B$ *is simply connected, and* $\Gamma \cap B$ *is a regular real analytic simple arc except for a cusp at* ζ_0. *The cusp is pointing into* $\Omega \cap B$. *It is a very special one. There is a holomorphic function* T *defined on a closed disk* $\overline{B_\varepsilon(0)}$ *such that*

(i) $T(0) = \zeta_0$, $T'(0) = 0$ *and* $T''(0) \neq 0$;

(ii) T *is univalent on the closure* $\bar{H}$ *of a half disk* $H = \{w \in B_\varepsilon(0); \operatorname{Im} w > 0\}$;

(iii) T *satisfies* $\Gamma \cap B \subset T((-\varepsilon, \varepsilon))$ *and* $T(\bar{H}) \subset \Omega \cup \Gamma$, *where* $(-\varepsilon, \varepsilon) = \{w; -\varepsilon < w = \operatorname{Re} w < \varepsilon\}$.

Conversely, if one of statements (1)-(4) holds, then $(\Omega \cap B_\rho(\zeta_0)) \cup (\Gamma \cap B_\rho(\zeta_0))$ has a Schwarz function for some $\rho > 0$.

In this paper, we apply the Regularity Theorem to quadrature domains and show regularity of boundaries of quadrature domains in two dimensions. Let μ be a complex measure on the complex plane $\mathbb{C}$. A nonempty open set Ω in $\mathbb{C}$ is called a quadrature

domain of μ if $|\mu|(\mathbb{C}\backslash\Omega)=0$ and if $\int|f|d|\mu|<+\infty$ and

$$\int f\,d\mu=\iint_{\Omega} f(z)\,dx\,dy \qquad (z=x+iy)$$

for every holomorphic and integrable function f in Ω.

Quadrature domains are closely related to domains that are solutions of an inverse problem in potential theory. The Newtonian potential of a measure μ is equal to that of the quadrature domain of μ in the exterior of the quadrature domain. Quadrature domains are also closely related to Hele-Shaw flows with a free boundary. We interpret a quadrature domain as a solution of a Hele-Shaw flow free boundary problem. On the other hand, we can express the solution of the Hele-Shaw flow free boundary problem as a quadrature domain of some measure. For these and further applications, we refer the reader to [9].

This paper consists of two parts. We devote the first part to the study of regularity of boundaries of bounded quadrature domains. In the second part we give a broad perspective of unbounded quadrature domains.

If a quadrature domain Ω of μ is bounded, then $1/(z-\zeta)$ is holomorphic and integrable on Ω for every fixed $\zeta\in\mathbb{C}\backslash\Omega$. Hence the Cauchy transform $\hat{\Omega}(\zeta)=\int_{\Omega}1/(z-\zeta)\,dx\,dy$ of Ω is equal to the Cauchy transform $\hat{\mu}(\zeta)=\int 1/(z-\zeta)\,d\mu(z)$ of μ on $\mathbb{C}\backslash\Omega$. Since $\hat{\Omega}(z)+\pi\bar{z}$ is holomorphic in Ω, we see that

$$S(z)=\frac{\hat{\Omega}(z)+\pi\bar{z}-\hat{\mu}(z)}{\pi}$$

is a Schwarz function of $(\Omega\cap B)\cup((\partial\Omega)\cap B)$ if B and the support of μ are disjoint, where $B=B_r(\zeta_0)$ and $\zeta_0\in\partial\Omega$. Applying our Regularity Theorem, we obtain a regularity theorem on boundaries of bounded quadrature domains. Let Ω be a bounded quadrature domain of μ such that the support of μ is contained in Ω. If we make a new domain $[\Omega]$ by adding all degenerate boundary points of Ω to Ω, then $[\Omega]$ is also a quadrature domain of μ, and the boundary of $[\Omega]$ consists of a finite number of real analytic closed curves having at most a finite number of double and cusp points in the sense of the Regularity Theorem.

In contrast with many known results on bounded quadrature domains, only a few results are known on unbounded quadrature domains. For example, let δ_0 be the Dirac measure at the origin. Then the bounded quadrature domain of δ_0 is the simplest quadrature domain. It is determined uniquely and is equal to a disk with center at the origin and radius $1/\sqrt{\pi}$. We know that there are many unbounded quadrature domains of δ_0, but we do not know all of them yet.

Here is a program proposed by Shapiro [12]. Let Ω be an unbounded quadrature domain of a complex measure with compact support. Let S be a Schwarz function defined on $\bar{\Omega}\backslash\overline{B_R}$ for some large disk $B_R=B_R(0)$. Namely, let S be a function such that (i) S is holomorphic in $\Omega\backslash\bar{B}_R$, (ii) S is continuous on $\bar{\Omega}\backslash\overline{B_R}$, (iii) $S(\zeta)=\bar{\zeta}$ on $(\partial\Omega)\backslash\overline{B_R}$, and (iv) $|S(z)|\leqq\alpha|z|$ on $\Omega\backslash\overline{B_R}$ for some constant $\alpha>0$. We can show the existence of the Schwarz function by using the generalized Cauchy transform. If

$$(*)\qquad S(z)\to\infty \quad \text{as } z\in\Omega\to\infty,$$

then $S_i(z)=1/S(1/z)$ is holomorphic in $\Omega'=\{1/z;\ z\in\Omega\}\cap B_r(0)$ for some r. By setting $S_i(0)=0$, we see that S_i is continuous on $\Omega'\cup\Gamma'$ and satisfies $S_i(\zeta)=\bar{\zeta}$ on Γ', where $\Gamma'=(\partial\Omega')\cap B_r(0)$. Thus S_i is a Schwarz function of $\Omega'\cup\Gamma'$ at 0. Shapiro [12] showed that if $\partial\Omega$ satisfies some regularity hypotheses, then $(*)$ is satisfied and the unbounded quadrature domain is obtained as an inversion of a bounded quadrature domain.

We shall show, by applying the Fuchs theorem, that (*) is actually satisfied if $\partial\Omega$ is unbounded. This will enable us to carry out the Shapiro program on unbounded quadrature domains. In particular, we obtain a complete description of unbounded quadrature domains of finite order.

During the first reading of this paper, one could omit § 2, except for the definition of the Schwarz function of an unbounded set and the statement of Corollary 2.6. Throughout the paper, $\bar{z}$ denotes the complex conjugate of z if z is a complex number. For a subset E of $\mathbb{C}$, $\bar{E}$ denotes the closure of E. We usually denote a boundary point by ζ instead of z.

I. Bounded quadrature domains.

1. Bounded quadrature domains of a complex measure, which contain the support of the measure. In the introduction we have already mentioned regularity of boundaries of bounded quadrature domains. We summarize it as the following proposition.

PROPOSITION 1.1. *Let Ω be a bounded quadrature domain of a complex measure μ, and let $\zeta_0 \in (\partial\Omega)\backslash\operatorname{supp}\mu$. Then there is a disk $B = B_\delta(\zeta_0)$, and one of statements (1)-(4) of the Regularity Theorem holds.*

COROLLARY 1.2. *Let Ω be a bounded quadrature domain of a complex measure μ. If $\zeta \in \partial\Omega$ is neither a regular, degenerate, double, nor a cusp point of $\partial\Omega$ in the sense of our Regularity Theorem, then $\zeta \in \operatorname{supp}\mu$, namely, $|\mu|(B_r(\zeta)) > 0$ for every $r > 0$.*

For example, let μ be a positive measure defined by $d\mu = 2(1-\sqrt{|x|})\,dx$ on $(-1, 1)$, and let $\Omega = \{z = x+iy;\ -1 < x < 1,\ x^2/2 - \frac{1}{2} < y < -x^2/2 + \frac{1}{2}\}$. Then Ω is the unique bounded quadrature domain of μ; see [9, Ex. 14.10, p. 123]. $(\partial\Omega)\backslash\{-1, 1\}$ consists of two real analytic simple arcs, but -1 and 1 are two points on $\partial\Omega$ that are neither a regular, degenerate, double, nor a cusp point. In this case, $\operatorname{supp}\mu = [-1, 1]$ and $\operatorname{supp}\mu$ contains -1 and 1, as asserted in Corollary 1.2.

Now we discuss a bounded quadrature domain Ω of a complex measure μ such that $\operatorname{supp}\mu$ is contained in Ω. To make things clear, we introduce a global Schwarz function of a bounded open set.

DEFINITION 1.3. Let Ω be a nonempty bounded open set in $\mathbb{C}$. A function S defined on $\bar{\Omega}\backslash K$ for some compact subset K of Ω is called a global Schwarz function of Ω, or a global Schwarz function of Ω holomorphic in $\Omega\backslash K$, if

(i) S is holomorphic in $\Omega\backslash K$;
(ii) S is continuous on $\bar{\Omega}\backslash K$;
(iii) $S(\zeta) = \bar{\zeta}$ on $\partial\Omega$.

The global Schwarz function of a bounded open set Ω holomorphic in $\Omega\backslash K$ is determined uniquely if $\Omega\backslash K$ is connected; see the note after Definition 3.1 in [11]. Next we prepare the following definition and proposition.

DEFINITION 1.4. Let Ω be an open proper subset of a disk $B_r(\zeta_0)$. Let g be a function continuous on $B_r(\zeta_0)\backslash\Omega$ and holomorphic in the interior of $B_r(\zeta_0)\backslash\Omega$. We say that g can be extended holomorphically from $B_r(\zeta_0)\backslash\Omega$ onto $B_r(\zeta_0)$ if there is a holomorphic function f in $B_r(\zeta_0)$ such that $f(z) = g(z)$ on $B_r(\zeta_0)\backslash\Omega$.

PROPOSITION 1.5. *Let Ω be an open subset of $B_r(\zeta_0)$ such that $\zeta_0 \in \partial\Omega$, and let $\Gamma = B_r(\zeta_0) \cap \partial\Omega$. Then $\Omega \cup \Gamma$ has the Schwarz function in $B_r(\zeta_0)$ if and only if $\hat{\Omega}$ can be extended holomorphically from $B_r(\zeta_0)\backslash\Omega$ onto $B_r(\zeta_0)$, where $\hat{\Omega}$ denotes the Cauchy transform $\hat{\Omega}(\zeta) = \int_\Omega 1/(z-\zeta)\,dx\,dy$ $(z = x+iy)$ of the characteristic function of Ω.*

Proof. We write B for $B_r(\zeta_0)$. Assume that $\Omega \cup \Gamma$ has the Schwarz function S in B, and let $\tilde{S}$ be the function defined by $\tilde{S}(z) = S(z)$ in Ω and $\tilde{S}(z) = \bar{z}$ on $B\backslash\Omega$. Set $f(z) = \hat{\Omega}(z) + \pi\bar{z} - \pi\tilde{S}(z)$. Then f is continuous in B and holomorphic in $B\backslash\Gamma = \Omega \cup (B\backslash(\Omega \cup \Gamma))$. Since Γ consists of real analytic arcs or is contained in the union of real analytic arcs by our Regularity Theorem, f is holomorphic in B and it is the holomorphic extension of $\hat{\Omega}$ from $B\backslash\Omega$ onto B.

Conversely, if a holomorphic function f in B satisfies $f(z)=\hat{\Omega}(z)$ on $B\backslash\Omega$, then $\hat{\Omega}(z)+\pi\bar{z}-f(z)$ is holomorphic in Ω and continuous on $\Omega\cup\Gamma$. Since $\Gamma\subset B\backslash\Omega$, $(\hat{\Omega}(z)+\pi\bar{z}-f(z))/\pi=\bar{z}$ on Γ. Hence $(\hat{\Omega}(z)+\pi\bar{z}-f(z))/\pi$ is the Schwarz function of $\Omega\cup\Gamma$ in B. □

Remark. From our Regularity Theorem we see that $\tilde{S}$ is Lipschitz continuous on $\overline{B_\delta(\zeta_0)}$ for every δ less than r; see [11, Corollary 5.5]. The proposition, together with the above fact, asserts that if $\hat{\Omega}$ can be extended holomorphically from $B_r(\zeta_0)\backslash\Omega$ onto $B_r(\zeta_0)$, then $\hat{\Omega}$ itself is Lipschitz continuous on $\overline{B_\delta(\zeta_0)}$ for every δ less than r.

We shall prove the following proposition.

Proposition 1.6. *Let Ω be a bounded quadrature domain of a complex measure μ such that* $\operatorname{supp}\mu$ *is contained in Ω. Then there is a global Schwarz function of Ω holomorphic in $\Omega\backslash\operatorname{supp}\mu$. Conversely, if there is a global Schwarz function of a nonempty bounded open set Ω holomorphic in $\Omega\backslash K$, then, for every neighborhood U of K with $\bar{U}\subset\Omega$, there is a complex measure μ such that* $\operatorname{supp}\mu$ *is contained in $\bar{U}$, and Ω is a quadrature domain of μ.*

Proof. If Ω is a bounded quadrature domain of μ such that $\operatorname{supp}\mu\subset\Omega$, then $(\hat{\Omega}(z)+\pi\bar{z}-\hat{\mu}(z))/\pi$ is a global Schwarz function of Ω holomorphic in $\Omega\backslash\operatorname{supp}\mu$. Conversely, if there is a global Schwarz function S of Ω holomorphic in $\Omega\backslash K$, then, from the proof of Proposition 1.5, we see that $f(z)=\hat{\Omega}(z)+\pi\bar{z}-\pi\tilde{S}(z)$, where $\tilde{S}(z)=S(z)$ in $\Omega\backslash K$ and $\tilde{S}(z)=\bar{z}$ on $\mathbb{C}\backslash\Omega$, is holomorphic in $\mathbb{C}\backslash K$. For a neighborhood U of K with $\bar{U}\subset\Omega$, take a modified function g of f such that g is of class C^1 in $\mathbb{C}$ and satisfies $g(z)=f(z)$ in $\mathbb{C}\backslash\bar{U}$. Set $\mu=-(1/\pi)(\partial g/\partial\bar{z})m$, where m denotes the two-dimensional Lebesgue measure. Then $\partial\hat{\mu}/\partial\bar{z}=\partial g/\partial\bar{z}$ in $\mathbb{C}$ and $\operatorname{supp}\mu$ is contained in $\bar{U}$. Hence $\hat{\mu}-g$ is holomorphic in $\mathbb{C}$ and tends to 0 as $z\to\infty$. Therefore, $\hat{\mu}=g$ in $\mathbb{C}$, and so

$$\hat{\mu}(z)=f(z)=\hat{\Omega}(z) \tag{1.1}$$

on $\mathbb{C}\backslash\Omega$. Since $\operatorname{supp}\mu\subset\bar{U}\subset\Omega$, $|\mu|(\mathbb{C}\backslash\Omega)=0$ and $\int|h|d|\mu|<+\infty$ for every holomorphic and integrable function h in Ω. Equation (1.1) implies that

$$\int\frac{1}{z-\zeta}\,d\mu(z)=\int_\Omega\frac{1}{z-\zeta}\,dm(z)$$

for every $\zeta\in\mathbb{C}\backslash\Omega$. Since every holomorphic and integrable function in Ω can be approximated in the mean by linear combinations of $1/(z-\zeta_j)$ with $\zeta_j\in\partial\Omega$; see Bers [2],

$$\int h\,d\mu=\int_\Omega h\,dm$$

holds for every holomorphic and integrable function h in Ω. Thus Ω is a quadrature domain of μ. □

Now we shall show regularity of the boundary of a bounded quadrature domain Ω of a complex measure μ such that $\operatorname{supp}\mu$ is contained in Ω.

Theorem 1.7. *Let Ω be a bounded quadrature domain of a complex measure μ such that* $\operatorname{supp}\mu\subset\Omega$. *Then*

(1) *Every boundary point of Ω is a regular, degenerate, double, or cusp point in the sense of the Regularity Theorem;*

(2) *Every nonisolated degenerate boundary point determines uniquely a regular real analytic simple arc, which tends to* $\operatorname{supp}\mu$ *and does not tend to the set of nondegenerate boundary points of Ω, or determines uniquely a regular real analytic simple closed curve,*

which does not meet supp μ *and the set of nondegenerate boundary points of* Ω. *The number of such arcs and closed curves is finite*;

(3) *There is at most a finite number of isolated degenerate boundary points that do not belong to the union of arcs and closed curves mentioned in* (2);

(4) *The union* $[\Omega]$ *of* Ω *and the set of degenerate boundary points is also a quadrature domain of* μ, *and* $\partial[\Omega]$ *consists of a finite number of real analytic closed curves having at most a finite number of double and cusp points.*

Proof. Let ζ_0 be a nonisolated degenerate boundary point of a bounded quadrature domain Ω. Then, by (2) of the Regularity Theorem, there is a regular real analytic simple arc J passing through ζ_0. Let $\zeta \in J$ and let Ψ be a holomorphic and univalent function defined in $B_\varepsilon(0)$ such that $J \subset \Psi((-\varepsilon, \varepsilon))$ and $\Psi(0) = \zeta$. Then $S_\Psi = \bar{\Psi} \circ \Psi^{-1}$, where $\bar{\Psi}(w) = \overline{\Psi(\bar{w})}$, is the Schwarz function of $(B_\delta(\zeta) \backslash J) \cup (J \cap B_\delta(\zeta))$ at ζ for some $\delta > 0$, and J can be extended onto $\Psi((-\varepsilon, \varepsilon))$.

We note that S_Ψ is equal to the global Schwarz function on Ω in a neighborhood of ζ. We extend J as much as possible. We denote it again by J. Then J has no endpoints in $\Omega \backslash \operatorname{supp} \mu$ by the above argument. J does not tend to the set of nondegenerate boundary points by the Regularity Theorem. Thus J is a regular real analytic simple arc that tends to supp μ or is a closed curve that does not meet supp μ.

Next assume that there is an infinite number of such arcs or closed curves J_j. On each J_j, we can find a nonisolated boundary points ζ_j. By choosing a subsequence if necessary, we may assume that ζ_j converges to a point $\zeta_0 \in \partial\Omega$ because $\partial\Omega$ is compact. By the Regularity Theorem, ζ_0 should be a nonisolated degenerate boundary point. Hence there exists j_0 such that $J_j = J_{j_0}$ for $j \geqq j_0$. This is a contradiction, and there is at most a finite number of such arcs and closed curves.

Finally assume that there is an infinite number of isolated degenerate boundary points ζ_j that do not belong to the union of such arcs and closed curves. Again we may assume that ζ_j converges to a boundary point ζ_0. By the Regularity Theorem, ζ_0 is a nonisolated degenerate boundary point and, for large j, ζ_j must be contained in the same arc or closed curve passing through ζ_0. This is again a contradiction. Hence the number of such ζ_j is finite. □

To show the converse of Theorem 1.7, we introduce and discuss the cluster set of a regular real analytic simple arc. Let J be a regular real analytic simple arc, namely, let ψ be a holomorphic and univalent function defined in a neighborhood of the open interval $(-1, 1)$, and let $J = \psi((-1, 1))$. We denote by C_J the union of $\cap \{\overline{\psi((-1, -1+\delta))};\ \delta > 0\}$ and $\cap \{\overline{\psi((1-\delta, 1))};\ \delta > 0\}$ and call it the cluster set of J. If J is a regular real analytic simple closed curve, then we interpret C_J as the empty set. It follows that $\bar{J} \backslash J \subset C_J \subset \bar{J}$.

Let J be a regular real analytic simple arc as in Theorem 1.7. Then, by our Regularity Theorem, we see that $J \cap C_J = \varnothing$. Namely, we obtain $C_J = \bar{J} \backslash J$. By the same reason, we see that if $J_1, \ldots, J_n$ are regular real analytic simple arcs or closed curves as in Theorem 1.7, then $J_j \cap \overline{J_k} = \varnothing$ for every distinct j and k.

THEOREM 1.8. *Let* $[\Omega]$ *be a bounded open set surrounded by a finite number of real analytic closed curves with at most a finite number of double and cusp points in the sense of our Regularity Theorem. Let* $J_1, \ldots, J_n$ *be regular real analytic simple arcs or closed curves such that* $\overline{J_j} \subset [\Omega]$ *and* $C_{J_j} = \overline{J_j} \backslash J_j$ *for every* j, *and* $J_j \cap \overline{J_k} = \varnothing$ *for every distinct* j *and* k. *Let* Ω *be an open subset of* $[\Omega]$ *such that* $[\Omega] \backslash \Omega$ *is a compact subset of* $\cup J_j$. *Then* Ω *is a quadrature domain of a complex measure* μ *such that* supp μ *is contained in* Ω.

Proof. At each boundary point ζ of Ω, by our Regularity Theorem, we can find a disk $B_\rho(\zeta)$ such that there is a Schwarz function of $(\Omega \cap B_\rho(\zeta)) \cup ((\partial\Omega) \cap B_\rho(\zeta))$ at

ζ. By continuing them, we obtain a global Schwarz function of Ω holomorphic in $\Omega\backslash K$, where K is a compact subset of Ω. Take a neighborhood U of K such that $\bar{U}\subset\Omega$. Then, by Proposition 1.6, Ω is a quadrature domain of a complex measure μ such that $\operatorname{supp}\mu\subset\bar{U}\subset\Omega$. □

Let Ω be a bounded quadrature domain of μ such that supp μ is contained in Ω, and let $[\Omega]$ be the union of Ω and the set of degenerate boundary points of Ω. Then every open set Ω' satisfying $\Omega\subset\Omega'\subset[\Omega]$ is a quadrature domain of μ. Hence Theorems 1.7 and 1.8 give a complete condition for a bounded open set Ω to be a quadrature domain of a complex measure μ such that supp μ is contained in Ω.

II. Unbounded quadrature domains.

2. A Schwarz function of an unbounded set. In this section, we shall discuss a Schwarz function S of an unbounded set in the complex plane $\mathbb{C}$ and show, in Corollary 2.6, that $1/S(1/z)$ is a Schwarz function at 0.

First we define a Schwarz function of an unbounded set. We denote by B_δ a disk with radius δ and center 0.

DEFINITION 2.1. Let Ω be an unbounded open subset of $\mathbb{C}\backslash\overline{B_\delta}$ such that $\Gamma=(\partial\Omega)\backslash\overline{B_\delta}$ is not empty. A function S defined on $\Omega\cup\Gamma$ is called a Schwarz function of $\Omega\cup\Gamma$, more precisely, a Schwarz function of $\Omega\cup\Gamma$ at ∞ or in $\mathbb{C}\backslash\overline{B_\delta}$ if

(i) S is holomorphic in Ω;

(ii) S is continuous on $\Omega\cup\Gamma$;

(iii) $S(\zeta)=\bar{\zeta}$ on Γ;

(iv) $|S(z)|\leqq\alpha|z|$ in $\Omega\backslash\overline{B_{\delta_0}}$ for some $\alpha>0$ and some $\delta_0>\delta$.

We note that condition (iv) is equivalent to the following if Γ is unbounded.

(iv′) $|S(z)|\leqq\alpha|z|^\beta$ in $\Omega\backslash\overline{B_{\delta_0}}$ for some constants α, $\beta>0$, and some $\delta_0>\delta$. Indeed, we apply the Fuchs theorem, Theorem 2.1′ in [11], to $S(z)/z$ and obtain $\lim_{z\in\Omega},\sup_{z\to\infty}|S(z)|/|z|\leqq 1$.

Next we note that the Schwarz function S is determined uniquely if Γ is an infinite set. If there is an accumulation point of Γ in $\mathbb{C}\backslash\overline{B_\delta}$, then the uniqueness follows immediately; see the note given after the definition of a Schwarz function for a bounded set, Definition 3.1, in [11]. In the case that there are no accumulation points of Γ in $\mathbb{C}\backslash\overline{B_\delta}$, we apply Corollary 2.6 below. Then $1/S(1/z)$ is a Schwarz function at 0, and so S is determined uniquely.

In the definition, we do not assume that $S(z)\to\infty$ as $z\in\Omega\to\infty$. But it is true if Γ is unbounded.

PROPOSITION 2.2. *Let S be the Schwarz function of $\Omega\cup\Gamma$ in $\mathbb{C}\backslash\overline{B_\delta}$. If Γ is unbounded, then*

$$|S(z)|>\frac{|z|}{5}\quad in\ \Omega\backslash\overline{B_R}$$

for a large disk B_R.

Remark. If Γ is bounded, then the conclusion of the lemma does not hold, in general. For example, $S(z)=1/z$ is the Schwarz function of $(\mathbb{C}\backslash\overline{B_1})\cup\partial B_1$ in $\mathbb{C}\backslash\overline{B_\delta}$ with $0<\delta<1$ and $\lim_{z\to\infty}S(z)=0$.

To prove Proposition 2.2, we introduce a function $F_c(z)=z(S(z)-cz)$ for a fixed complex number c with $|c|<1$. We set

$$m_c(r)=\inf\{|F_c(z)|;\ z\in\Omega\cap\partial B_r\}$$

for $r>\delta$.

LEMMA 2.3. *It follows that*

(1) *F_c is not constant in any connected component of $\Omega\backslash\overline{B_{\delta_1}}$ for some $\delta_1>\delta$;*

(2) *The integral $\int_{\Omega\cap\partial B_r} d\arg F_c$ is well defined and it is finite if $F_c(z)\neq 0$ on $\Omega\cap\partial B_r$.*

Proof. To prove (1), assume that F_c is identically equal to a constant k in a connected component D of Ω. Then $F_c(\zeta)=|\zeta|^2-c\zeta^2=|\zeta|^2(1-c\,e^{i2\theta})=k$ on $(\partial D)\backslash\overline{B_\delta}$, where $\zeta=|\zeta|\,e^{i\theta}$. Namely, $|\zeta|^2 w=k$, where $w=1-c\,e^{i2\theta}$. Since $(\partial D)\backslash\overline{B_\delta}$ is not empty and $w\neq 0$, $k\neq 0$. If $c\neq 0$, then the line $\{w;\ \arg w=\arg k\}$ and the circle $\{w;\ |w-1|=|c|\}$ crosses at most in two points. Hence $e^{2i\theta}$ has at most two solutions to the above equation, and so $\zeta=|\zeta|\,e^{i\theta}$ has at most four solutions. Thus $(\partial D)\backslash\overline{B_\delta}$ consists of at most four points and $D=\Omega$. This contradicts that Γ is unbounded. Hence $c=0$ and $|\zeta|^2=k$. This means that $k>0$ and $(\partial D)\backslash\overline{B_\delta}\subset\partial B_{\sqrt{k}}$. Since Γ is unbounded, $(\partial D)\backslash\overline{B_\delta}=\partial B_{\sqrt{k}}$ and D is an annulus surrounded by ∂B_δ and $\partial B_{\sqrt{k}}$. We note that such an annulus as well as k exists at most one. We obtain the required δ_1 by taking δ_1 so that $\delta_1\geqq\sqrt{k}$.

Next we prove (2). Since $F_c(z)\to F_c(\zeta)=|\zeta|^2(1-c\,e^{i2\theta})$ as $z\in\Omega\to\zeta=|\zeta|\,e^{i\theta}\in\partial\Omega$, $m_c(r)>0$ if $F_c(z)\neq 0$ on $\Omega\cap\partial B_r$. Let ds denote the line element of ∂B_r. Then

$$d\arg F_c=\frac{\partial\arg F_c}{\partial s}\,ds=\frac{\partial\log|F_c|}{\partial r}\,ds$$

along $\Omega\cap\partial B_r$ and

$$\left|\frac{\partial\log|F_c|}{\partial r}\right|\leqq|(\log F_c)'|=\frac{|F_c'|}{|F_c|}.$$

It follows that $F_c'(z)=(zS(z)-cz^2)'=zS'(z)+S(z)-2cz$. Corollary 5.4 in [11] asserts that $\lim_{z\in\Omega,z\to\zeta}S'(z)$ exists for every ζ on Γ and it is equal to $S'(\zeta)$ if ζ is an isolated point of Γ, and its modulus is equal to one if ζ is not an isolated point of Γ. Hence S' is bounded on $\Omega\cap\partial B_r$. Since $|F_c(z)|\geqq m_c(r)>0$, we see that $(\partial\log|F_c|)/(\partial r)$ is bounded on $\Omega\cap\partial B_r$. Thus the integral $\int_{\Omega\cap\partial B_r}|d\arg F_c|$ is finite. This proves (2). □

Let δ_0 be the number as in (iv) of Definition 2.1, and let δ_1 be the number as in (1) of Lemma 2.3. Take ρ so that $\rho>\max\{\delta_0,\delta_1\}$ and $F_0(z)=zS(z)\neq 0$ on $\Omega\cap\partial B_\rho$. We note that $m_0(\rho)>0$ and $\int_{\Omega\cap\partial B_\rho}d\arg F_0$ is finite. Take ε so that

$$0<\varepsilon<\tfrac{1}{5},\tag{2.1}$$

$$m=\inf\{m_c(\rho);\ |c|\leqq\varepsilon\}>0,\tag{2.2}$$

$$\iota=\sup\left\{\left|\int_{\Omega\cap\partial B_\rho}d\arg F_c\right|;\ |c|\leqq\varepsilon\right\}<+\infty.\tag{2.3}$$

We fix ρ and ε.

Now take λ so that $0<\lambda<\min\{m,\rho^2(1-3\varepsilon)\}$, take c so that $|c|\leqq\varepsilon$, and set

$$\Lambda_{\lambda,c}=\{z\in\Omega\backslash\overline{B_\rho};\ |F_c(z)|=\lambda\}.$$

Since $|F_c(z)|\geqq m>\lambda$ on $\Omega\cap\partial B_\rho$ by (2.2), $\Omega\cap\partial B_\rho\cap\overline{\Lambda_{\lambda,c}}=\varnothing$. Let

$$V=\cup\ \{B_{3\varepsilon t^2}(t^2);\ t\geqq\rho\},$$

take a neighborhood $U(\zeta)$ of $\zeta\in\Gamma\backslash B_\rho$ so that $U(\zeta)\subset B_{(1/3)|\zeta|}(\zeta)$ and $F_0(\Omega\cap U(\zeta))\subset B_{\varepsilon|\zeta|^2}(|\zeta|^2)$, and set

$$U=\cup\ \{U(\zeta);\ \zeta\in\Gamma\backslash B_\rho\}.$$

Since $|F_c(z)-F_0(z)|=|cz^2|\leqq\varepsilon(1+1/3)^2|\zeta|^2<2\varepsilon|\zeta|^2$ in $\Omega\cap U(\zeta)$, $F_c(\Omega\cap U)\subset V$.

Take $r>\rho$, and let $\{\Omega_n\}$ be a regular exhaustion of Ω such that there is at most one connected component of $\Omega_n\cap\partial B_\rho$ (respectively, $\Omega_n\cap\partial B_r$) on each connected component of $\Omega\cap\partial B_\rho$ (respectively, $\Omega\cap\partial B_r$). Take Ω_n so that $(\Omega\backslash\Omega_n)\cap(\overline{B_r}\backslash B_\rho)\subset U$. Since $F_c(\Omega\cap U)\subset V$ and $\operatorname{dist}(V,0)=\rho^2(1-3\varepsilon)>\lambda$, it follows that $(\Omega\backslash\Omega_n)\cap(\overline{B_r}\backslash B_\rho)\cap\overline{\Lambda_{\lambda,c}}=\varnothing$. Let

$$\Omega_{\lambda,c}(r,n)=\{z\in\Omega_n\cap(B_r\backslash\overline{B_\rho});\ |F_c(z)|>\lambda\}.$$

We may assume that $\partial\Omega_{\lambda,c}(r, n)$ consists of a finite number of piecewise real analytic simple closed curves. We note that the number of components of $\partial\Omega_{\lambda,c}(r, n)$, which are entirely contained in $\Lambda_{\lambda,c}$, does not depend on the choice of n if we take Ω_n so that $(\Omega\backslash\Omega_n)\cap(\overline{B_r}\backslash B_\rho)\subset U$. We denote it by $\nu_{\lambda,c}(r)$. Set

$$\Omega_{\lambda,c}=\{z\in\Omega\backslash\overline{B_\rho};\ |F_c(z)|>\lambda\}.$$

Lemma 2.4. *It follows that*

$$\nu_{\lambda,c}(r)\leqq\frac{1}{2\pi}\int_{\Omega_{\lambda,c}\cap\partial B_r} d\arg F_c+\gamma, \tag{2.4}$$

where $\gamma=(\iota+24\operatorname{Arcsin}\varepsilon)/(2\pi)$ *and* ι *is the number defined by* (2.3). *The number* γ *does not depend on the choice of* λ, c, *and* r.

Proof. We apply the argument principle to F_c in $\Omega_{\lambda,c}(r, n)$:

$$\int_{\partial\Omega_{\lambda,c}(r,n)} d\arg F_c=0.$$

It follows that $\int_J d\arg F_c\leqq 0$ for every arc J contained in $\Lambda_{\lambda,c}\cap\partial\Omega_{\lambda,c}(r, n)$. If a component J of $\partial\Omega_{\lambda,c}(r, n)$ is entirely contained in $\Lambda_{\lambda,c}$, then $\int_J d\arg F_c$ is equal to a positive integer multiple of -2π. Hence we obtain

$$\begin{aligned}0&=\int_{\partial\Omega_{\lambda,c}(r,n)} d\arg F_c\\ &\leqq -2\pi\nu_{\lambda,c}(r)-\int_{(\partial B_\rho)\cap\partial\Omega_{\lambda,c}(r,\,n)} d\arg F_c+\int_{(\partial B_r)\cap\partial\Omega_{\lambda,c}(r,n)} d\arg F_c\\ &\quad+\int_{(\partial\Omega_n)\cap\partial\Omega_{\lambda,c}(r,n)} d\arg \mathrm{F}_{\mathrm{c}}.\end{aligned} \tag{2.5}$$

Next we note that $F_c(\partial\Omega_n\cap(\overline{B_r}\backslash B_\rho))\subset V$. This implies that if J is a closed curve contained entirely in $(\partial\Omega_n)\cap\partial\Omega_{\lambda,c}(r, n)$, then $\int_J d\arg F_c=0$. For arcs in $(\partial\Omega_n)\cap\partial\Omega_{\lambda,c}(r, n)$, we may assume that all endpoints of arcs in $(\partial\Omega_n)\cap\partial\Omega_{\lambda,c}(r, n)$ are contained in $(\partial B_\rho)\cup(\partial B_r)$. We write ∂_n for the union of the arcs in $(\partial\Omega_n)\cap\partial\Omega_{\lambda,c}(r, n)$. We note that $|F_c(z)|>\lambda$ on $\Omega\cap\partial B_\rho$. Let $(\Omega\cap\partial B_\rho)_n$ (respectively, $(\Omega_{\lambda,c}\cap\partial B_r)_n$) be the union of connected components of $\Omega\cap\partial B_\rho$ (respectively, $\Omega_{\lambda,c}\cap\partial B_r$), which contains a connected component of $\Omega_n\cap\partial B_\rho$ (respectively, $(\partial\Omega_r)\cap\partial\Omega_{\lambda,c}(r, n)$), and set $\partial_n'=\partial_n+(\Omega\cap\partial B_\rho)_n-\Omega_n\cap\partial B_\rho-(\Omega_{\lambda,c}\cap\partial B_r)_n+(\partial B_r)\cap\partial\Omega_{\lambda,c}(r, n)$. Then, from (2.5), we obtain

$$2\pi\nu_{\lambda,c}(r)\leqq-\int_{(\Omega\cap\partial B_\rho)_n} d\arg F_c+\int_{(\Omega_{\lambda,c}\cap\partial B_r)_n} d\arg F_c+\int_{\partial_n'} d\arg F_c.$$

To estimate the integral on ∂_n', we consider three types of arcs contained in ∂_n: (1) an arc whose one endpoint is on ∂B_ρ and the other is on ∂B_r, (2) an arc whose two endpoints are on ∂B_ρ, and (3) an arc whose two endpoints are on ∂B_r. Let J be an arc of type (1), and let $\rho\, e^{i\varphi}$ and $r\, e^{i\psi}$ be the initial point and the terminal point of J, respectively. Then, by the assumption that there is at most one component of $\Omega_n\cap\partial B_\rho$ (respectively, $\Omega_n\cap\partial B_r$) on each connected component of $\Omega\cap\partial B_\rho$ (respectively, $\Omega\cap\partial B_r$), we can find uniquely determined circular arcs $K(\rho)\subset(\Omega\cap\partial B_\rho)_n$ and $K(r)\subset(\Omega_{\lambda,c}\cap\partial B_r)_n$ such that the initial points of $K(\rho)$ and $K(r)$ are on $\partial\Omega$ and the terminal points of $K(\rho)$ and $K(r)$ are equal to $\rho\, e^{i\varphi}$ and $r\, e^{i\psi}$, respectively. Namely, we can assign an arc $J'=K(\rho)+J-K(r)$ to J and regard it as an arc contained in ∂_n'. We apply the same argument to arcs of type (1) whose initial points are on ∂B_r, arcs of type (2) and arcs of type (3).

We shall estimate the integrals on arcs of type (1). Let $J_1, \ldots, J_{2l}$ be arcs of type (1), and let $\rho\, e^{i\varphi_j}$ and $r\, e^{i\psi_j}$ be endpoints of J_j, $j = 1, 2, \ldots, 2l$. We may assume that $0 \leqq \varphi_1 < \varphi_2 < \cdots < \varphi_{2l} < 2\pi$, $\psi_1 < \psi_2 < \cdots < \psi_{2l} < \psi_1 + 2\pi$, $\rho\, e^{i\varphi_j}$ is the initial point of J_j for odd j and $\rho\, e^{i\varphi_j}$ is the terminal point of J_j for even j. If $\rho\, e^{i\varphi_j}$ is the initial point of J_j, we can find $\varphi_j' < \varphi_j$ such that the circular arc $K_j(\rho)$ between $\rho\, e^{i\varphi_j'}$ and $\rho\, e^{i\varphi_j}$ are in $(\Omega \cap \partial B_\rho)_n$ and $\rho\, e^{i\varphi_j'} \in \partial\Omega$. We can also find $\psi_j' < \psi_j$ such that the circular arc $K_j(r)$ between $r\, e^{i\psi_j'}$ and $r\, e^{i\psi_j}$ are in $(\Omega_{\lambda,c} \cap \partial B_r)_n$ and $r\, e^{i\psi_j'} \in \partial\Omega$. Thus we assign an arc $J_j' = K_j(\rho) + J_j - K_j(r)$ to each J_j for odd j. Similarly, we assign an arc $J_j' = -K_j(r) + J_j + K_j(\rho)$ to each J_j for even j. We note that $F_c(J_j') \subset V$, $F_c(\rho\, e^{i\varphi'}) = \rho^2(1 - c\, e^{2i\varphi'})$ if $\rho\, e^{i\varphi'} \in \partial\Omega$ and $F_c(r\, e^{i\psi'}) = r^2(1 - c\, e^{2i\psi'})$ if $r\, e^{i\psi'} \in \partial\Omega$. We denote Arg w the principal value of arg w, namely, $-\pi < \operatorname{Arg} w \leqq \pi$. Then

$$\int_{J_j'} d \arg F_c = \operatorname{Arg}(1 - c\, e^{2i\psi_j'}) - \operatorname{Arg}(1 - c\, e^{2i\varphi_j'})$$

for odd j and

$$\int_{J_j'} d \arg F_c = \operatorname{Arg}(1 - c\, e^{2i\varphi_j'}) - \operatorname{Arg}(1 - c\, e^{2i\psi_j'})$$

for even j. Hence

$$\sum_{j=1}^{2l} \int_{J_j'} d \arg F_c = \sum_{j=1}^{l} \{\operatorname{Arg}(1 - c\, e^{2i\varphi_{2j}'}) - \operatorname{Arg}(1 - c\, e^{2i\varphi_{2j-1}'})\}$$
$$- \sum_{j=1}^{l} \{\operatorname{Arg}(1 - c\, e^{2i\psi_{2j}'}) - \operatorname{Arg}(1 - c\, e^{2i\psi_{2j-1}'})\}.$$

Since $\varphi_1' < \varphi_2' \leqq \cdots < \varphi_{2l}' \leqq \varphi_1' + 2\pi$ and $\psi_1' < \psi_2' \leqq \cdots < \psi_{2l}' \leqq \psi_1' + 2\pi$, the absolute value of each of the sums in the right-hand side is not greater than 4 Arcsin ε, and so

$$\sum_{j=1}^{2l} \int_{J_j'} d \arg F_c \leqq 8 \operatorname{Arcsin} \varepsilon.$$

Next we shall estimate the integrals on arcs of type (2). For the sake of simplicity, we consider arcs of type (2) contained in a simply connected open set D_1, which is surrounded by J_1, $L_1(r)$, J_2, and $-L_1(\rho)$, where J_1 and J_2 are arcs of type (1), $L_1(r)$ denotes the circular arc between $r\, e^{i\psi_1}$ and $r\, e^{i\psi_2}$, and $L_1(\rho)$ denotes the circular arc between $\rho\, e^{i\varphi_1}$ and $\rho\, e^{i\varphi_2}$.

The situation is complicated because $D_1 \cap \Omega_{\lambda,c}(r, n)$ may not be connected. Let D_1' be a connected component of $D_1 \cap \Omega_{\lambda,c}(r, n)$ such that $\partial D_1' \supset J_1$, and let $I_1, \ldots, I_k$ be arcs of type (2) contained in $\partial D_1'$. Let $\rho\, e^{i\theta_{2j}}$ and $\rho\, e^{i\theta_{2j-1}}$ be the initial point and the terminal point of I_j, $j = 1, \ldots, k$, respectively. We may assume that $\varphi_1 < \theta_1 < \theta_2 < \cdots < \theta_{2k} < \varphi_2$. By using an argument similar to the above, to each I_j, we assign an arc I_j' having endpoints $\rho\, e^{i\theta_{2j}'}$ and $\rho\, e^{i\theta_{2j-1}'}$. It follows that $\theta_1 < \theta_1' \leqq \theta_2' < \theta_2 < \cdots < \theta_{2k-1} < \theta_{2k-1}' \leqq \theta_{2k}' < \theta_{2k}$. Hence

$$\sum_{j=1}^{k} \int_{I_j'} d \arg F_c \leqq \sum_{j=1}^{k} \{\operatorname{Arg}(1 - c\, e^{2i\theta_{2j-1}'}) - \operatorname{Arg}(1 - c\, e^{2i\theta_{2j}'})\}. \tag{2.6}$$

Next we consider the case that there are arcs of type (2) contained in a simply connected open set D_2 surrounded by I_1 and the circular arc between $\rho\, e^{i\theta_1}$ and $\rho\, e^{i\theta_2}$. We take a connected component D_2' of $D_1 \backslash \overline{\Omega_{\lambda,c}(r, n)}$ such that $\partial D_2' \supset I_1$, and let $I_1^{(2)}, \ldots, I_{k(2)}^{(2)}$ be arcs of type (2) contained in $(\partial D_2') \backslash I_1$. As before, we can find arcs $I_j^{(2)'}$ and obtain an estimation similar to (2.6). We note here that the direction of $I_j^{(2)'}$

is opposite from that of I_1'. Thus if we add the integrals on all arcs I' assigned to I of type (2) contained in $\overline{D_2}$, then it is not greater than

$$\int_{\theta_1}^{\theta_2} |d \operatorname{Arg}(1-c\,e^{2i\theta})|.$$

Hence

$$\sum_{(2)} \int_{I_j'} d \arg F_c \leqq \int_{\theta=0}^{2\pi} |d \operatorname{Arg}(1-c\,e^{2i\theta})| = 8 \operatorname{Arcsin} \varepsilon,$$

where $\sum_{(2)}$ denotes the sum for arcs of type (2).

The same estimation holds for arcs of type (3), and we obtain

$$2\pi\nu_{\lambda,c}(r) \leqq -\int_{(\Omega\cap\partial B_\rho)_n} d \arg F_c + \int_{(\Omega_{\lambda,c}\cap\partial B_r)_n} d \arg F_c + 24 \operatorname{Arcsin} \varepsilon.$$

By letting $n\to\infty$, we obtain

$$2\pi\nu_{\lambda,c}(r) \leqq \int_{\Omega_{\lambda,c}\cap\partial B_r} d \arg F_c + 2\pi\gamma. \qquad \square$$

Now we apply the argument as in the proof of Theorem 1 in a paper of Fuchs [4] and prove the following.

LEMMA 2.5. *Inequality* (2.4) *implies that*

$$\nu_{\lambda,c}(r) \leqq \gamma + 2$$

for every $r \geqq \rho$.

Proof. Since $d \arg F_c = (\partial \log |F_c(r\,e^{i\theta})|)/(\partial r) r\,d\theta$ along $\Omega_{\lambda,c}\cap\partial B_r$, dividing by r and integrating the inequality at the end of the proof of Lemma 2.4 from ρ to R we get

$$(2.7) \qquad 2\pi \int_\rho^R \frac{\nu_{\lambda,c}(r)}{r}\,dr \leqq 2\pi\gamma \log(R/\rho) + \iint_{re^{i\theta}\in\Omega_{\lambda,c}(R)} \frac{\partial \log |F_c(r\,e^{i\theta})|}{\partial r}\,d\theta\,dr,$$

where $\Omega_{\lambda,c}(R) = \Omega_{\lambda,c} \cap B_R$. We have already seen that S' is bounded in $\Omega\cap(B_R\backslash\overline{B_\rho})$, and so we see that $(\partial \log |F_c|)/(\partial r)$ is bounded in $\Omega_{\lambda,c}(R)$. Hence we can reverse the order of integration with respect to θ and r. We fix θ and consider

$$\int_{re^{i\theta}\in\Omega_{\lambda,c}(R)} \frac{\partial \log |F_c(r\,e^{i\theta})|}{\partial r}\,dr.$$

The set $\Omega_{\lambda,c}(R)\cap\{z; \arg z=\theta\}$ consists of at most a countable number of open segments. The integral on each segment is equal to $\log|F_c(r_2\,e^{i\theta})| - \log|F_c(r_1\,e^{i\theta})|$, where $r_1\,e^{i\theta}$ and $r_2\,e^{i\theta}$ with $r_2 > r_1$ are the endpoints of the segment. The endpoints are contained in $\partial\Omega$, $\Lambda_{\lambda,c}$, or $(\partial B_\rho)\cup(\partial B_R)$.

First we consider the case that $\{z; \arg z=\theta\}$ does not meet $\Lambda_{\lambda,c}$. If the endpoint $r\,e^{i\theta}$ is contained in $\partial\Omega$, then $|F_c(r\,e^{i\theta})| = r^2|1-c\,e^{2i\theta}|$. Hence the integral is not greater than $\log|F_c(\mathrm{R}e^{i\theta})| - \log|F_c(\rho\,e^{i\theta})|$ if $\rho\,e^{i\theta}$ and $\mathrm{R}e^{i\theta}\in\overline{\Omega_{\lambda,c}(R)}$, $2\log R + \log|1-c\,e^{2i\theta}| - \log|F_c(\rho\,e^{i\theta})|$ if $\rho\,e^{i\theta}\in\overline{\Omega_{\lambda,c}(R)}$ and $\mathrm{R}e^{i\theta}\notin\overline{\Omega_{\lambda,c}(R)}$, $\log|F_c(\mathrm{R}e^{i\theta})| - 2\log\rho - \log|1-c\,e^{2i\theta}|$ if $\rho\,e^{i\theta}\notin\overline{\Omega_{\lambda,c}(R)}$ and $\mathrm{R}e^{i\theta}\in\overline{\Omega_{\lambda,c}(R)}$, and $2\log R - 2\log\rho$ if $\rho\,e^{i\theta}$ and $\mathrm{R}e^{i\theta}\notin\overline{\Omega_{\lambda,c}(R)}$. Since $|F_c(\rho\,e^{i\theta})|\geqq m$ by (2.2), the integral is bounded from above by $\log|F_c(\mathrm{R}e^{i\theta})| + \gamma_1$ or $2\log R + \gamma_1$, where γ_1 denotes a constant independent of the choice of λ, c, R, and θ.

Next we consider the case that $\{z; \arg z=\theta\}$ meets $\Lambda_{\lambda,c}$. Since $\Lambda_{\lambda,c}\cap B_R$ consists of a finite number of real analytic arcs and closed curves, $\{z; \arg z=\theta\}$ meets $\Lambda_{\lambda,c}$ finite times. If the endpoint $r\,e^{i\theta}$ is contained in $\Lambda_{\lambda,c}$, then $|F_c(r\,e^{i\theta})|=\lambda$. We note that $\Omega\cap\partial B_\rho\cap\overline{\Lambda_{\lambda,c}}=\varnothing$ and see that the integral is not greater than $\log|F_c(\mathrm{Re}^{i\theta})|+\gamma_1+\log^+\lambda\leqq\log|F_c(\mathrm{Re}^{i\theta})|+\gamma_1+\log^+ m$ or $2\log R+\gamma_1+\log^+ m$, where $\log^+\lambda=\max\{\log\lambda, 0\}$.

Since $|S(z)\gamma\leqq\alpha|z|$ in $\Omega\backslash\overline{B_{\delta_0}}$ for some α by (iv) of Definition 2.1, we obtain $|F_c(z)|=|z|\,|S(z)-cz|\leqq(\alpha+\varepsilon)|z|^2$ in $\Omega\backslash\overline{B_{\delta_0}}$. Setting $\gamma_2=\gamma_1+\log^+(\alpha+\varepsilon)+\log^+ m$, we obtain

$$\int_{re^{i\theta}\in\Omega_{\lambda,c}(R)}\frac{\partial\log|F_c(r\,e^{i\theta})|}{\partial r}\,dr\leqq 2\log R+\gamma_2.$$

By (2.7),

$$\int_\rho^R\frac{\nu_{\lambda,c}(r)}{r}\,dr\leqq(\gamma+2)\log R+\gamma_3,$$

where $\gamma_3=\gamma_2-\gamma\log\rho$.

Since $\nu_{\lambda,c}(r)$ is a nondecreasing function of r, this inequality is possible for large R only if $\nu_{\lambda,c}(r)\leqq\gamma+2$ for every $r\geqq\rho$. □

Thus we can find R such that all closed curves of $\Lambda_{\lambda,c}$ are contained in $\Omega\cap B_R$. In the above argument, $\gamma+2$ does not depend on the choice of λ and c, but R may depend on λ and c. The final step of our argument is to show that we can take R so that R is independent of the choice of λ and c.

Proof of Proposition 2.2. Set

$$\nu=\sup\{\nu_{\lambda,c}(r);\ r\geqq\rho,\ 0<\lambda<\min\{m,\rho^2(1-3\varepsilon)\},\ |c|\leqq\varepsilon\}$$

and take r_0, λ_0, and c_0 so that $\nu_{\lambda_0,c_0}(r_0)=\nu$. By using the same argument as in the proof of Lemma 3.3 in [11], for fixed r_0 and λ_0, we can find $\varepsilon_1>0$ such that $\nu_{\lambda_0,c}(r_0)=\nu$ for every c in $B_{\varepsilon_1}(c_0)\cap\overline{B_\varepsilon}$. Take $\varepsilon_2>0$ and c_1 so that $B_{\varepsilon_2}(c_1)\subset B_{\varepsilon_1}(c_0)\cap\overline{B_\varepsilon}$. By the definition of r_0, we see that $F_c(z)\neq 0$ in $\Omega\backslash\overline{B_{r_0}}$ for every c in $B_{\varepsilon_2}(c_1)$, namely, $S(z)\neq cz$ in $\Omega\backslash\overline{B_{r_0}}$ for every c in $B_{\varepsilon_2}(c_1)$. This implies that $|S(z)-c_1z|\geqq\varepsilon_2|z|$ in $\Omega\backslash\overline{B_{r_0}}$. We note that $\Gamma=(\partial\Omega)\backslash\overline{B_\delta}$ is unbounded, and we apply the Fuchs theorem, Theorem 2.1′ in [11], to $z/(S(z)-c_1z)$ in $\Omega\backslash\overline{B_{r_0}}$. We see that there exists $R>r_0$ such that $|z/(S(z)-c_1z)|\leqq 2/(1-\varepsilon)$ in $\Omega\backslash\overline{B_R}$. By (2.1), we obtain

$$|S(z)|>\frac{|z|}{5}\quad\text{in }\Omega\backslash\overline{B_R}.$$ □

COROLLARY 2.6. *Let S be the Schwarz function of $\Omega\cup\Gamma$ in $\mathbb{C}\backslash\overline{B_\delta}$. If Γ is unbounded, then*

$$S_i(z)=\begin{cases}\dfrac{1}{\overline{S(1/\bar z)}} & z\in(1/(\Omega\cup\Gamma))\cap B_r,\\ 0 & z=0,\end{cases}$$

is the Schwarz function of $((1/\Omega)\cap B_r)\cup(((1/\Gamma)\cap B_r)\cup\{0\})$ at 0 for some $r<1/\delta$, where $1/E$ for a set E denotes the inversion $\{1/z;\ z\in E\backslash\{0\}\}$ of E.

Proof. Take R as in Proposition 2.2. Then $|S(z)|>|z|/5$ in $\Omega\backslash\overline{B_R}$, and so $1/S(1/z)$ is holomorphic in $1/(\Omega\backslash\overline{B_R})$, is continuous on $1/((\Omega\cup\Gamma)\backslash\overline{B_R})$, and tends to 0 as $z\in 1/(\Omega\backslash\overline{B_R})\to 0$. On $1/\Gamma$, $1/S(1/\zeta)=1/(\overline{1/\zeta})=\bar\zeta$. Hence, S_i is the Schwarz function of $((1/\Omega)\cap B_r)\cup(((1/\Gamma)\cap B_r)\cup\{0\})$ at 0, where $r\leqq 1/R<1/\delta$. □

3. Regularity of boundaries of unbounded quadrature domains. In this section, we discuss regularity of boundaries of unbounded quadrature domains. First we shall define the generalized Cauchy transform of an unbounded open set. For two distinct and fixed points, ζ_1 and ζ_2 in $\mathbb{C}$, we define the generalized Cauchy kernel $K(z, \zeta; \zeta_1, \zeta_2)$ by

$$K(z,\zeta;\zeta_1,\zeta_2)=\frac{(\zeta-\zeta_1)(\zeta-\zeta_2)}{(z-\zeta)(z-\zeta_1)(z-\zeta_2)}$$
$$=\frac{1}{z-\zeta}+\frac{\zeta_2-\zeta}{\zeta_1-\zeta_2}\frac{1}{z-\zeta_1}+\frac{\zeta_1-\zeta}{\zeta_2-\zeta_1}\frac{1}{z-\zeta_2}$$

if $\zeta\in\mathbb{C}\backslash\{\zeta_1,\zeta_2\}$, and

$$K(z,\zeta;\zeta_1,\zeta_2)=0$$

if $\zeta=\zeta_1$ or ζ_2. We set

$$\hat{\mu}(\zeta;\zeta_1,\zeta_2)=\int K(z,\zeta;\zeta_1,\zeta_2)\,d\mu(z)$$

for a complex measure μ and call it the generalized Cauchy transform of μ. It is finite almost everywhere in $\mathbb{C}$ if

$$\iint_{\operatorname{supp}\mu\times\operatorname{supp}\mu}|K(z,\zeta;\zeta_1,\zeta_2)|d|\mu|(z)\,dm(\zeta)<+\infty,$$

where m denotes the two-dimensional Lebesgue measure, and it is holomorphic in the complement of supp μ because the total measure of a complex measure is finite. In contrast with the Cauchy transform, the generalized Cauchy transform can be also defined for a bounded measurable function in $\mathbb{C}$ that does not have compact support. For a bounded measurable function g in $\mathbb{C}$, we define the generalized Cauchy transform $\hat{\hat{g}}$ by

$$\hat{\hat{g}}(\zeta;\zeta_1,\zeta_2)=\int K(z,\zeta;\zeta_1,\zeta_2)g(z)\,dm(z).$$

We write $\hat{\hat{g}}(z)$ for $\hat{\hat{g}}(z;\zeta_1,\zeta_2)$. It is a continuous function in $\mathbb{C}$, vanishes at ζ_1 and ζ_2, and satisfies

$$\frac{\partial\hat{\hat{g}}}{\partial\bar{z}}=-\pi g$$

in the sense of distributions. Furthermore, it satisfies

$$|\hat{\hat{g}}(z)|\leqq\alpha|z|\log|z|$$

for large $|z|$, where α is a positive constant; see, e.g., Chapter IV of Kra [7]. We write $\hat{\hat{\Omega}}$ for $\hat{\hat{\chi}}_\Omega$, where Ω is an open set in $\mathbb{C}$, and χ_Ω denotes the characteristic function of Ω. It is continuous in $\mathbb{C}$ and holomorphic in $\mathbb{C}\backslash\bar{\Omega}$. The function $\hat{\hat{\Omega}}(z)+\pi\bar{z}$ is holomorphic in Ω.

Definition 3.1. Let Ω be an unbounded open proper subset of $\mathbb{C}\backslash\overline{B_\delta}$. Let g be a function continuous on $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$ and holomorphic in the interior of $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$. We say that g can be extended holomorphically from $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$ onto $\mathbb{C}\backslash\overline{B_\delta}$ with at most a simple pole at ∞ if there is a holomorphic function f in $\mathbb{C}\backslash\overline{B_\delta}$ such that

(i) $f(z)=g(z)$ on $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$;

(ii) $|f(z)|\leqq\alpha|z|$ in $\mathbb{C}\backslash\overline{B_{\delta_0}}$ for some $\alpha>0$ and some $\delta_0>\delta$.

Proposition 3.2. *Let Ω be an unbounded open subset of $\mathbb{C}\backslash\overline{B_\delta}$ such that $\Gamma = (\partial\Omega)\backslash\overline{B_\delta}$ is not empty. Then $\Omega\cup\Gamma$ has the Schwarz function at ∞ if and only if $\hat{\Omega}$ can be extended holomorphically from $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$ onto $\mathbb{C}\backslash\overline{B_\delta}$ with at most a simple pole at ∞.*

Proof. Let S be the Schwarz function of $\Omega\cup\Gamma$ at ∞, and let $\tilde{S}$ be the function defined by $\tilde{S}(z) = S(z)$ in Ω and $\tilde{S}(z) = \bar{z}$ on $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$. Set $f(z) = \hat{\Omega}(z) + \pi\bar{z} - \pi\tilde{S}(z)$. Then, by the same argument as in the proof of Proposition 1.3, we see that f is holomorphic in $\mathbb{C}\backslash\overline{B_\delta}$. By definition, $f = \hat{\Omega}$ on $(\mathbb{C}\backslash\overline{B_\delta})\backslash\Omega$. Since $|\hat{\Omega}(z)| \leqq \alpha_1|z|\log|z|$ and $|S(z)| \leqq \alpha_2|z|$ for large $|z|$ by (iv) of Definition 2.1, we see that $|f(z)| \leqq \alpha_3|z|\log|z|$ for large $|z|$, where α_1, α_2, and α_3 are positive constants. Hence f has at most a simple pole at ∞ and satisfies (ii) of Definition 3.1.

Conversely, if a holomorphic function f in $\mathbb{C}\backslash\overline{B_\delta}$ satisfies (i) for $g = \hat{\Omega}$ and (ii) of Definition 3.1, then $S(z) = (\hat{\Omega}(z) + \pi\bar{z} - f(z))/\pi$ is holomorphic in Ω, is continuous on $\Omega\cup\Gamma$, is equal to $\bar{z}$ on Γ, and satisfies

$$|S(z)| \leqq \frac{\alpha_1|z|\log|z| + (\pi+\alpha)|z|}{\pi} \leqq \alpha_2|z|\log|z|,$$

for large $|z|$, where α, α_1, and α_2 are positive constants. If Γ is bounded, then S has at most a simple pole at ∞. Hence $|S(z)| \leqq \alpha_3|z|$ for large $|z|$. If Γ is unbounded, then, by the note mentioned after Definition 2.1, we also obtain $|S(z)| \leqq \alpha_4|z|$ for large $|z|$. Here α_3 and α_4 are positive constants. Hence S is the Schwarz function of $\Omega\cup\Gamma$ at ∞. □

Holomorphic extensions of the Cauchy transforms of open sets are closely related to quadrature domains. We shall prove the following two lemmas.

Lemma 3.3. *Let Ω be a quadrature domain of a complex measure μ. Let $\zeta_0 \in (\partial\Omega)\backslash\operatorname{supp}\mu$, and let $B = B_r(\zeta_0)$ be a disk such that $B\cap\operatorname{supp}\mu = \varnothing$. Then $(\Omega\cap B)^\wedge$ can be extended holomorphically from $B\backslash\Omega$ onto B.*

Proof. We note that Ω may be unbounded. We may assume that $B\backslash\Omega$ contains more than two points. Take two distinct points, ζ_1 and ζ_2, on $B\backslash\Omega$, write $\hat{\mu}(\zeta)$ for $\hat{\mu}(\zeta; \zeta_1, \zeta_2)$, and write $\hat{E}$ for $\hat{\chi}_E$, where E denotes a Borel set in $\mathbb{C}$. Since the generalized Cauchy kernel $K(z, \zeta; \zeta_1, \zeta_2)$ given before Definition 3.1 is holomorphic and integrable on Ω for each fixed $\zeta \in \mathbb{C}\backslash\Omega$, we obtain $\hat{\mu}(\zeta) = \hat{\Omega}(\zeta)$ on $B\backslash\Omega$. Since $\hat{\Omega} = (\Omega\cap B)^\wedge + (\Omega\backslash B)^\wedge$,

$$(\Omega\cap B)^\wedge = \hat{\Omega} - (\Omega\backslash B)^\wedge = \hat{\mu} - (\Omega\backslash B)^\wedge$$

on $B\backslash\Omega$. By the assumption that $B\cap\operatorname{supp}\mu = \varnothing$, the right-hand side is holomorphic in B, and so $(\Omega\cap B)^\wedge$ can be extended holomorphically from $B\backslash\Omega$ onto B. We obtain the lemma because $(\Omega\cap B)^\wedge(\zeta) = (\Omega\cap B)^\wedge(\zeta) + a\zeta + b$, where $a = ((\Omega\cap B)^\wedge(\zeta_1) - (\Omega\cap B)^\wedge(\zeta_2))/(\zeta_2 - \zeta_1)$ and $b = (\zeta_1(\Omega\cap B)^\wedge(\zeta_2) - \zeta_2(\Omega\cap B)^\wedge(\zeta_1))/(\zeta_2 - \zeta_1)$ are constants. □

Lemma 3.4. *Let Ω be a quadrature domain of a complex measure μ with compact support. Let $B = B_R$ be a disk satisfying $\operatorname{supp}\mu \subset \bar{B}$, and assume that $(\mathbb{C}\backslash\bar{B})\backslash\Omega$ contains two distinct points, ζ_1 and ζ_2. Set $(\Omega\backslash\bar{B})^\wedge(\zeta) = (\Omega\backslash\bar{B})^\wedge(\zeta; \zeta_1, \zeta_2)$. Then $(\Omega\backslash\bar{B})^\wedge$ can be extended holomorphically from $(\mathbb{C}\backslash\bar{B})\backslash\Omega$ onto $\mathbb{C}\backslash\bar{B}$ with at most a simple pole at ∞.*

Proof. Since $K(z, \zeta; \zeta_1, \zeta_2)$ is holomorphic and integrable on Ω for every fixed ζ on $\mathbb{C}\backslash\Omega$, we obtain

$$(\Omega\backslash\bar{B})^\wedge(\zeta) = \hat{\mu}(\zeta; \zeta_1, \zeta_2) - (\Omega\cap\bar{B})^\wedge(\zeta; \zeta_1, \zeta_2)$$

on $(\mathbb{C}\backslash\bar{B})\backslash\Omega$. The right-hand side of the equality is a holomorphic function of ζ in

$\mathbb{C}\setminus\bar{B}$ because supp $\mu\subset\bar{B}$ and neither ζ_1 nor ζ_2 is contained in $\bar{B}$. Since $|K(z,\zeta;\zeta_1,\zeta_2)|\leqq\alpha|\zeta|$ for large $|\zeta|$ and for z on $\bar{B}$, we obtain $|\hat{\hat{\mu}}(\zeta;\zeta_1,\zeta_2)|\leqq\alpha_1|\zeta|$ and $|(\Omega\cap\bar{B})\hat{\ }(\zeta;\zeta_1,\zeta_2)|\leqq\alpha_2|\zeta|$ for large $|\zeta|$, where α, α_1, and α_2 are positive constants. Thus, by definition, $(\Omega\setminus\bar{B})\hat{\ }$ can be extended holomorphically from $(\mathbb{C}\setminus\bar{B})\setminus\Omega$ onto $\mathbb{C}\setminus\bar{B}$ with at most a simple pole at ∞. □

Now we apply Corollary 2.6 and show regularity of the boundary of an unbounded quadrature domain.

PROPOSITION 3.5. *Let Ω be an unbounded quadrature domain of a complex measure μ. Then, for every $\zeta\in(\partial\Omega)\setminus$*supp *$\mu$, there is a disk $B=B_\delta(\zeta)$ and one of the statements* (1)–(4) *of the Regularity Theorem holds. Furthermore, under the assumption that the support of μ is compact, we can find a disk $B=B_\delta$ such that one of the statements* (1)–(4) *of the Regularity Theorem holds, if we replace Ω and Γ by $(1/\Omega)\cap B_{1/\rho}$ and $((1/\Gamma)\cap B_{1/\rho})\cup\{0\}$, respectively, where ρ is chosen so that* supp $\mu\subset\overline{B_\rho}$.

Proof. The first assertion follows from Lemma 3.3, Proposition 1.5, and the Regularity Theorem. For the second assertion it is trivial if the boundary of Ω is bounded. If $\partial\Omega$ is unbounded, then, by Lemma 3.4 and Proposition 3.2, $(\Omega\setminus\overline{B_\rho})\cup(\Gamma\setminus\overline{B_\rho})$ has the Schwarz function S at ∞. By Corollary 2.6, $S_i(z)$ is the Schwarz function of $((1/\Omega)\cap B_{1/\rho})\cup(((1/\Gamma)\cap B_{1/\rho})\cup\{0\})$ at 0. The proposition follows from our Regularity Theorem. □

COROLLARY 3.6. *Let Ω be an unbounded quadrature domain of a complex measure with compact support. Then* (area $(\Omega\cap B_r))/(\pi r^2)$ *converges to $\frac{1}{2}$ or 1 as $r\to+\infty$.*

The corollary was conjectured by Shapiro [12] and proved under some regularity hypotheses on $\partial\Omega$. From the corollary, we can easily obtain the following result: If a quadrature domain Ω of a complex measure with compact support has infinite area, then $\int_{\Omega\setminus B_1}|z|^{-2}\,dm(z)=+\infty$; see in [9, Thm. 11.2].

Now we discuss an unbounded quadrature domain Ω of a complex measure μ with compact support such that $(\partial\Omega)\cap\operatorname{supp}\mu=\varnothing$; in other words, a quadrature domain Ω of μ such that supp μ is compact and contained in Ω. We introduce a global Schwarz function of an unbounded open set.

DEFINITION 3.7. Let Ω be an unbounded open set in $\mathbb{C}$. A function S defined on $\bar{\Omega}\setminus K$ for some compact subset K of Ω is called a global Schwarz function of Ω, or a global Schwarz function of Ω holomorphic in $\Omega\setminus K$, if it satisfies (i)–(iii) of Definition 1.3 and

(iv) $|S(z)|\leqq\alpha|z|$ in $\Omega\setminus B_R$ for some positive numbers α and R.

The global Schwarz function of Ω holomorphic in $\Omega\setminus K$ is determined uniquely, if $\Omega\setminus K$ is connected and if $\partial\Omega$ is an infinite set, see the note after Definition 3.1 in [11].

Next we shall prove an "unbounded" version of Proposition 1.6.

PROPOSITION 3.8. *Let Ω be an unbounded quadrature domain of a complex measure μ such that* supp μ *is compact and contained in Ω. Then there is a global Schwarz function of Ω holomorphic in $\Omega\setminus$*supp *μ. Conversely, if there is a global Schwarz function of an unbounded open set Ω holomorphic in $\Omega\setminus K$, then, for every relatively compact neighborhood U of K with $\bar{U}\subset\Omega$, there is a complex measure μ such that* supp μ *is contained in $\bar{U}$, and Ω is a quadrature domain of μ.*

Proof. If $\mathbb{C}\setminus\Omega$ consists of at most two points, then the family of holomorphic and integrable functions on Ω consists of just one function, the constant function with value zero. See [9, Lemma 11.3]. Hence Ω is a quadrature domain of any measure μ such that $|\mu|(\mathbb{C}\setminus\Omega)=0$. In this case, a global Schwarz function of Ω always exists and is not determined uniquely. For example, every rational function $r(z)$ having at most a simple pole at ∞ and satisfying $r(\zeta)=\bar{\zeta}$ on $\mathbb{C}\setminus\Omega$ is a global Schwarz function on Ω. Hence the proposition holds in this case.

Thus we may assume that $\mathbb{C}\backslash\Omega$ consists of more than two points. Take two distinct points ζ_1 and ζ_2 on $\mathbb{C}\backslash\Omega$, write $\hat{\hat{\mu}}(\zeta)$ for $\hat{\hat{\mu}}(\zeta;\zeta_1,\zeta_2)$ and write $\hat{\hat{E}}$ for $\hat{\hat{\chi}}_E$. If Ω is a quadrature domain of μ such that $\operatorname{supp}\mu$ is compact and contained in Ω, then, $S(z)=(\hat{\hat{\Omega}}(z)+\pi\bar{z}-\hat{\hat{\mu}}(z))/\pi$ satisfies (i)-(iii) of Definition 1.3 for $K=\operatorname{supp}\mu$. By the argument in the proof of Proposition 3.2, we see that S also satisfies (iv) of Definition 3.7, and so S is a global Schwarz function of Ω holomorphic in $\Omega\backslash\operatorname{supp}\mu$.

Conversely, assume that there exists a global Schwarz function S of Ω holomorphic in $\Omega\backslash K$. By Propositions 1.5 and 3.2, $f(z)=\hat{\hat{\Omega}}(z)+\pi\bar{z}-\pi\tilde{S}(z)$ is holomorphic in $\mathbb{C}\backslash K$, has at most a simple pole at ∞, and vanishes at ζ_1 and ζ_2, where $\tilde{S}$ denotes the function defined by $\tilde{S}(z)=S(z)$ in Ω and $\tilde{S}(z)=\bar{z}$ on $\mathbb{C}\backslash\Omega$. For a relatively compact neighborhood U of K with $\bar{U}\subset\Omega$, take a modified C^1-function g of f as in the proof of Proposition 1.6. Then we see that $\mu=-(1/\pi)(\partial g/\partial\bar{z})m$ satisfies $\partial\hat{\hat{\mu}}/\partial\bar{z}=\partial g/\partial\bar{z}$ in $\mathbb{C}$ and $\operatorname{supp}\mu\subset\bar{U}$. Since $\hat{\hat{\mu}}-g$ is a linear function in $\mathbb{C}$ and vanishes at ζ_1 and ζ_2, $\hat{\hat{\mu}}=g$ in $\mathbb{C}$. Hence $\hat{\hat{\mu}}(z)=f(z)=\hat{\hat{\Omega}}(z)$ on $\mathbb{C}\backslash\Omega$. We apply again the Bers approximation theorem replaced the Cauchy kernel $1/(z-\zeta)$ with the generalized Cauchy kernel $K(z,\zeta;\zeta_1,\zeta_2)$ and see that Ω is a quadrature domain of μ satisfying $\operatorname{supp}\mu\subset\bar{U}$. □

Now we shall show regularity of the boundary of an unbounded quadrature domain Ω of a complex measure μ such that $\operatorname{supp}\mu$ is compact and contained in Ω.

THEOREM 3.9. *Let Ω be an unbounded quadrature domain of a complex measure μ such that* $\operatorname{supp}\mu$ *is compact and contained in Ω. Then, by considering Ω and $[\Omega]$ in the topology of the Riemann sphere, we obtain the same consequence as in Theorem* 1.7. *Conversely, let $[\Omega]$ be an open subset of the Riemann sphere surrounded by a finite number of real analytic closed curves with at most a finite number of double and cusp points in the sense of the Regularity Theorem. Let $J_1,\dots,J_n$ be regular real analytic simple arcs or closed curves such that $\bar{J_j}\subset[\Omega]$ and $C_{J_j}=\bar{J_j}\backslash J_j$ for every j, and $J_j\cap\bar{J_k}=\varnothing$ for every distinct j and k. Let Ω be an open subset of $[\Omega]\cap\mathbb{C}$ such that $[\Omega]\backslash\Omega$ is a compact subset of $\bigcup J_j$ in the topology of the Riemann sphere. Then Ω is a quadrature domain of a complex measure μ such that* $\operatorname{supp}\mu$ *is compact in $\mathbb{C}$ and contained in Ω.*

Proof. By using the same argument as in the proof of Theorem 1.7, we obtain the first assertion of the theorem from Proposition 3.8. For the converse, we apply the same argument as in the proof of Theorem 1.8 and Proposition 3.8 if the point at infinity is not an isolated boundary point of Ω in the topology of the Riemann sphere. If ∞ is an isolated boundary point of Ω, then we take a function S so that S is holomorphic outside of a large disk and has at most a simple pole at ∞. At each finite boundary point of Ω, we take a Schwarz function as in the proof of Theorem 1.8. Then S becomes a global Schwarz function of Ω, and Ω is a quadrature domain of a complex measure μ such that $\operatorname{supp}\mu$ is compact and contained in Ω by Proposition 3.8. □

We shall finally prove the following.

THEOREM 3.10. *Let Ω be an unbounded quadrature domain of a complex measure μ such that* $\operatorname{supp}\mu$ *is compact and contained in Ω. Then*

(1) *$\bar{\Omega}=\mathbb{C}$ and all boundary points of Ω are degenerate in the sense of the Regularity Theorem*; *or*

(2) *Ω is a translation of the inversion of a bounded quadrature domain Ω_0 of some complex measure μ_0 such that* $\operatorname{supp}\mu_0\subset\Omega_0$. *Here the inversion of Ω_0 is the image of $\Omega_0\backslash\{0\}$ under a mapping $w\mapsto 1/w$.*

Proof. If $\bar{\Omega}=\mathbb{C}$, then, by Proposition 3.5, all boundary points of Ω are degenerate. Assume that $\mathbb{C}\backslash\bar{\Omega}\neq\varnothing$ and take a point ζ_0 in $\mathbb{C}\backslash\bar{\Omega}$. Set $w=T(z)=1/(z-\zeta_0)$, and let S be a global Schwarz function of Ω holomorphic in $\Omega\backslash K$ of which existence is guaranteed by Proposition 3.8.

If $\partial\Omega$ is unbounded, then, since S is continuous on $\partial\Omega$ and $S(z)\to\infty$ as $z\in\Omega\to\infty$ by Proposition 2.2, we can take K so that $S(z)\neq\overline{\zeta_0}$ in $\Omega\backslash K$. Set $S_T=\bar{T}\circ S\circ T^{-1}$, where $\bar{T}(z)=1/(z-\overline{\zeta_0})$. Then, S_T is a global Schwarz function of a bounded open set $\Omega_0=T(\Omega)$ holomorphic in $\Omega_0\backslash T(K)$. If $\partial\Omega$ is bounded, then we again take K so that $S(z)\neq\overline{\zeta_0}$ in $\Omega\backslash K$. $S_T=\bar{T}\circ S\circ T^{-1}$ is a global Schwarz function of a bounded open set $\Omega_0=T(\Omega)\cup\{0\}$ holomorphic in $\Omega_0\backslash T(K)\backslash\{0\}$.

By Proposition 1.6, we see that Ω_0 is a quadrature domain of some μ_0 such that supp $\mu_0\subset\Omega_0$. Ω is a translation of the inversion $1/(\Omega_0\backslash\{0\})$ of Ω_0 because $z=T^{-1}(w)=1/w+\zeta_0$. □

4. Quadrature domains of point differential functionals of finite order. In this section, we shall discuss "classical" quadrature domains, namely, quadrature domains of representing measures μ of point differential functionals

$$L(f)=\sum_{j=1}^{l}\sum_{k=1}^{n_j}a_{jk}f^{(k-1)}(z_j),$$

where z_j are distinct points and a_{jk} are constants independent of functions f. We assume that $a_{jn_j}\neq 0$ for every j and put $n=\sum_{j=1}^{l}n_j$. The natural number n is called the order of L.

Definition 4.1. Let Ω be an open set in $\mathbb{C}$. We call Ω a quadrature domain of L if

(i) $\{z_1,\ldots,z_l\}\subset\Omega$;

(ii) For every holomorphic and integrable function f in Ω,

$$L(f)=\int_\Omega f\,dm,$$

where m denotes the two-dimensional Lebesgue measure. We say that Ω is a quadrature domain of order n if Ω is a quadrature domain of some functional L of order n.

If Ω is a quadrature domain of L, then we can find a complex measure μ such that supp $\mu\subset\Omega$ and

$$L(f)=\int f\,d\mu$$

for every holomorphic function f in Ω. Hence Ω is a quadrature domain of the complex measure μ.

Definition 4.2. A nonempty open set Ω is called a null quadrature domain or a quadrature domain of order 0 if

$$\int_\Omega f\,dm=0$$

for every holomorphic and integrable function f in Ω.

Null quadrature domains are called quadrature domains of order 0 by Shapiro [12]; see Theorems 4.4 and 4.6 below. All null quadrature domains are unbounded. They are completely determined by the author [8]. We shall call Ω a quadrature domain of finite order if Ω is a quadrature domain of order n for a natural number n or a null quadrature domain. By Propositions 1.6 and 3.8 a quadrature domain Ω of finite order has a global Schwarz function of Ω. We note that it is determined uniquely if $\partial\Omega$ is an infinite set. The following lemma shows that the global Schwarz function of a quadrature domain of finite order can be extended meromorphically onto Ω. In what follows, we call the extended meromorphic function the global Schwarz function of Ω.

LEMMA 4.3. *A nonempty open set Ω in $\mathbb{C}$ is a quadrature domain of order n if and only if there is a global Schwarz function of Ω that can be extended meromorphically onto Ω and the extended meromorphic function has n poles in Ω.*

Proof. First we note that if $\mathbb{C}\backslash\Omega$ consists of at most two points, then the family of holomorphic and integrable functions in Ω consists of just one function, the constant function with value zero; see [9, Lemma 11.3]. Hence, in this case, Ω is a quadrature domain of any functional L if $\{z_1, \ldots, z_l\} \subset \Omega$. We can easily construct a meromorphic function S such that S has n poles in Ω, has at most a simple pole at ∞, and satisfies $S(\zeta) = \bar{\zeta}$ on $\partial\Omega$. For example, if $\mathbb{C}\backslash\Omega = \{\zeta_1, \zeta_2\}$ and if $n = 0$,

$$S(z) = \bar{\zeta}_1 \frac{z - \zeta_2}{\zeta_1 - \zeta_2} + \bar{\zeta}_2 \frac{z - \zeta_1}{\zeta_2 - \zeta_1}$$

is the required function.

Thus we may assume that $\mathbb{C}\backslash\Omega$ contains more than two points. Let ζ_1 and ζ_2 be two distinct points on $\mathbb{C}\backslash\Omega$. Let $\hat{L}(\zeta; \zeta_1, \zeta_2) = L(K(\cdot, \zeta; \zeta_1, \zeta_2))$, where K denotes the generalized Cauchy kernel. If Ω is a quadrature domain of order n, then by the proof of Proposition 3.8, we see that

$$S(z) = \frac{\hat{\Omega}(z; \zeta_1, \zeta_2) + \pi\bar{z} - \hat{L}(z; \zeta_1, \zeta_2)}{\pi}$$

is a global Schwartz function of Ω. The function $\hat{L}(z; \zeta_1, \zeta_2)$ is meromorphic in Ω and has poles in $\{z_1, \ldots, z_l\}$. At z_j it has a pole of order n_j. Hence S is meromorphic and has n poles in Ω.

Conversely, let S be a global Schwarz function of Ω. By the proof of Proposition 3.8, Ω is a quadrature domain of a complex measure μ such that supp μ is compact and contained in Ω, and S can be expressed as

$$S(z) = \frac{\hat{\Omega}(z; \zeta_1, \zeta_2) + \pi\bar{z} - \hat{\mu}(z; \zeta_1, \zeta_2)}{\pi}$$

in $\Omega\backslash\operatorname{supp}\mu$. If S can be extended meromorphically onto Ω and has n poles in Ω, then it is the same for $\hat{\mu}$. We denote the extension of $\hat{\mu}$ by M. It is a rational function that has n poles in Ω, has at most a simple pole at ∞, and vanishes at ζ_1 and ζ_2. Take a point differential functional L of order n so that $\hat{L}(\zeta, \zeta_1, \zeta_2) = (L(K(\cdot, \zeta; \zeta_1, \zeta_2))$ has the same poles as M has as a function of ζ. Then $\hat{L}(\zeta; \zeta_1, \zeta_2) - M(\zeta)$ is a linear function in $\mathbb{C}$ and vanishes at ζ_1 and ζ_2. Hence $\hat{L}(\zeta; \zeta_1, \zeta_2) = M(\zeta)$ in $\mathbb{C}$, and so

$$L(K(\cdot, \zeta; \zeta_1, \zeta_2)) = M(\zeta) = \hat{\mu}(\zeta; \zeta_1, \zeta_2) = \int K(z, \zeta; \zeta_1, \zeta_2)\, d\mu(z)$$

on $\mathbb{C}\backslash\Omega$. We apply again the Bers approximation theorem in [2] and see that μ is a representing measure of L. □

In contrast with a bounded quadrature domain Ω of an arbitrary complex measure μ satisfying supp $\mu \subset \Omega$, the boundary of a bounded quadrature domain of finite order has a special feature. Indeed, Aharonov and Shapiro proved in [1] that the boundary of a bounded connected quadrature domain of finite order is contained in the set of zeros of an irreducible polynomial of x and y. Gustafsson proved in [5] and [6] that the boundary consists of all zeros of the polynomial except for a finite set, namely, there are no nonisolated degenerate boundary points of a bounded quadrature domain of finite order. The core of the proof is to make use of the Schottky double of a regular domain.

There are satisfactory arguments on bounded quadrature domains of finite order. See the references cited above. Here we shall discuss unbounded quadrature domains of finite order.

First we shall discuss the case $\bar{\Omega}=\mathbb{C}$. Davis proved in his book [3] that if the global Schwarz function of a bounded quadrature domain is a rational function, then it is a linear fractional function. We make use of his idea and prove the following theorem.

THEOREM 4.4. *Let Ω be a quadrature domain of a functional L of order n such that $\bar{\Omega}=\mathbb{C}$ and $\mathbb{C}\backslash\Omega$ consists of more than $(n+1)^2$ points. Then the order is equal to* 0 *and*

(1) *$\mathbb{C}\backslash\Omega$ is contained in a line or the order is equal to* 1; *and*

(2) *$\mathbb{C}\backslash\Omega$ is contained in a circle.*

In the latter case, the functional L is of the form $L(f)=a_{11}f(z_1)$, where z_1 denotes the center of the circle, and a_{11} denotes a positive constant that is equal to the area of the inside of the circle.

In particular, if Ω is a quadrature domain of order n such that $\bar{\Omega}=\mathbb{C}$ and if Ω is neither an open set stated in (1) *nor one stated in* (2), *then $n\neq 0$ and $\mathbb{C}\backslash\Omega$ consists of at most $(n+1)^2$ points.*

Conversely, an open set Ω stated in (1) *is a quadrature domain of order* 0, *and an open set Ω stated in* (2) *is a quadrature domain of $L(f)=a_{11}f(z_1)$, where z_1 denotes the center of the circle and a_{11} denotes the area of the inside of the circle. If Ω is an open set such that $\mathbb{C}\backslash\Omega$ consists of $(n+2)$ points, $n\geqq 0$, then there is a functional L of order at most n such that Ω is a quadrature domain of L.*

Proof. Let Ω be a quadrature domain of a functional L of order n such that $\bar{\Omega}=\mathbb{C}$. By Lemma 4.3, a global Schwarz function S of Ω is meromorphic and has n poles in Ω. By (1) of Theorem 3.10 all boundary points of Ω are degenerate, and so S is holomorphic on $\mathbb{C}\backslash\Omega$. Hence S is a rational function having n poles in $\mathbb{C}$ and it has at most a simple pole at ∞. In other words, S is a rational function of order at most $n+1$ such that the denominator is a polynomial of degree n.

First we shall show that if $\mathbb{C}\backslash\Omega$ consists of more than $(n+1)^2$ points, then $n=0$ or 1 and S is a nonconstant linear fractional function such that $\bar{S}=S^{-1}$, where $\bar{S}(z)=\overline{S(\bar{z})}$. The function $\bar{S}$ is also a rational function of order at most $n+1$ such that the denominator is a polynomial of degree n. The composite $\bar{S}\circ S$ of S and $\bar{S}$ is a rational function of order at most $(n+1)^2$ such that the denominator is a polynomial of degree at most $(n+1)^2-1$, and so it has at most $(n+1)^2$ finite fixed points if it is not the identity. Since $(\bar{S}\circ S)(z)=\bar{S}(S(z))=\bar{S}(\bar{z})=\overline{S(z)}=z$ on $\partial\Omega$, $\bar{S}\circ S$ is the identity mapping of the Riemann sphere if $\mathbb{C}\backslash\Omega$ consists of more than $(n+1)^2$ points. Since $(S\circ\bar{S})(z)=z$ on $\{\bar{z};\, z\in\partial\Omega\}$, by the same reason, we see that $S\circ\bar{S}$ is also the identity mapping of the Riemann sphere. Hence S is a nonconstant linear fractional function such that $\bar{S}=S^{-1}$, and $n=0$ or 1.

Next we shall show that if Ω is a quadrature domain of order 0, then $\partial\Omega$ is contained in a line. The assumption $n=0$ implies that S has no poles in $\mathbb{C}$. Hence $S(z)=az+b$ for some constants $a\neq 0$ and b. Since $\bar{S}(z)=\bar{a}z+\bar{b}$ and $S^{-1}(z)=(1/a)z-b/a$, $\bar{a}=1/a$ and $\bar{b}=-b/a$. Hence $|a|=1$ and $b/\sqrt{-a}$ is real for a square root $\sqrt{-a}$ of $-a$. Set $w=\sqrt{-a}\,z$. Then $az+b=\bar{z}$ if and only if $2\operatorname{Re} w=w+\bar{w}=b/\sqrt{-a}$. Hence $\{z\in\mathbb{C};\, S(z)=az+b=\bar{z}\}$ is a line and $\partial\Omega$ is contained in the line.

Next we shall show that if Ω is a quadrature domain of a functional L of order 1, then $\partial\Omega$ is contained in a circle and L is the functional stated in (2). Since S is a linear fractional function having a pole in Ω, S can be expressed as $S(z)=(az+b)/(z+d)$, where a, b, and d are constants satisfying $ad-b\neq 0$. Since $\bar{S}(z)=(\bar{a}z+\bar{b})/(z+\bar{d})$ and $S^{-1}(z)=(-dz+b)/(z-a)$, we obtain $\bar{a}=-d$, $\bar{b}=b$, and $\bar{d}=-a$.

Set $w=z+d$. Then $(az+b)/(z+d)=\bar{z}$ if and only if $|w|^2=(z+d)(\bar{z}+\bar{d})=(z+d)(\bar{z}-a)=b-ad$. Hence $b-ad>0$, and $\partial\Omega$ is contained in a circle with center $-d$ and radius $\sqrt{b-ad}$. Since

$$S(z)=\frac{az+b}{z+d}=\frac{b-ad}{z+d}+a,$$

we see that

$$\hat{\hat{L}}(z;\zeta_1,\zeta_2)=\frac{-\pi(b-ad)}{z+d}+g(z)$$

in a neighborhood of $z=-d$, where g denotes a holomorphic function in the neighborhood. On the other hand, if $L(f)=a_{11}f(z_1)$, then, by the definition of the generalized Cauchy kernel $K(z,\zeta;\zeta_1,\zeta_2)$,

$$\hat{\hat{L}}(z;\zeta_1,\zeta_2)=\frac{-a_{11}}{z-z_1}+h(z),$$

where $h(z)$ is a linear function of z. Hence $a_{11}=\pi(b-ad)$ and $z_1=-d$, namely, a_{11} is the area of the inside of the circle and z_1 is the center of the circle.

Conversely, if $\mathbb{C}\backslash\Omega$ is contained in a line, then Ω is the union of two half planes and a subset of the line. It is easy to show that each half plane is a null quadrature domain; see the remark at the end of [8]. Hence Ω is a quadrature domain of order 0. If $\mathbb{C}\backslash\Omega$ is contained in a circle $\partial B_r(z_1)$, then Ω is a quadrature domain of $L(f)=\pi r^2 f(z_1)$ because $\mathbb{C}\backslash\overline{B_r(z_1)}$ is a null quadrature domain; see the same remark in [8], and $B_r(z_1)$ is a quadrature domain of $L(f)=\pi r^2 f(z_1)$.

The proof will be complete if we show that there is a functional L of order at most n and Ω is a quadrature domain of L if $\mathbb{C}\backslash\Omega$ consists of $(n+2)$ points. We may assume that $n\geqq 1$. The linear space of all holomorphic and integrable functions in Ω is of dimension n; see [9, Lemma 11.3]. Let $(f_1,\ldots,f_n)$ be a basis of the space, and let $W(f_1,\ldots,f_n)$ be the Wronskian of $(f_1,\ldots,f_n)$. Since $f_1,\ldots,f_n$ are linearly independent, we can choose a point z_1 in Ω so that $W(f_1,\ldots,f_n)(z_1)\neq 0$. Then a system of linear equations

$$\sum_{k=1}^{n} a_{1k}f_j^{(k-1)}(z_1)=\int_\Omega f_j\,dm, \qquad j=1,\ldots,n$$

has a unique solution $(a_{11},\ldots,a_{1n})$. Thus Ω is a quadrature domain of $L(f)=\sum_{k=1}^{n} a_{1k}f^{(k-1)}(z_1)$ of order at most n. □

Remark. In the proof of the proposition, we have chosen a point z_1 in Ω so that $W(f_1,\ldots,f_n)(z_1)\neq 0$. There is an infinite number of such points z_1. Hence there is an infinite number of functionals L such that Ω is a quadrature domain of L if one of $\int_\Omega f_j\,dm$ is not equal to zero. Thus, by deleting a point from Ω if necessary, we see that there are an infinite number of global Schwarz functions of Ω that are meromorphic in Ω if $\partial\Omega$ is a finite set. It is also not difficult to show that if $\mathbb{C}\backslash\Omega$ consists of $n+2$ points, then, for every given $z_1,\ldots,z_l$ in Ω and for every given $n_1,\ldots,n_l$ with $\sum n_j=n$, there exists only one global Schwarz function of Ω that has a pole at z_j of order at most n_j, $j=1,\ldots,l$ and is holomorphic in $\Omega\backslash\{z_1,\ldots,z_l\}$.

Next we give an example of quadrature domain Ω of order 1 such that $\bar{\Omega}=\mathbb{C}$, but $\mathbb{C}\backslash\Omega$ is not contained in a circle. By Theorem 4.4, $\mathbb{C}\backslash\Omega$ consists of four points.

Example. Let $f(z,\zeta)=K(z,\zeta;0,-1)$ be the generalized Cauchy kernel, namely,

$$f(z,\zeta)=\frac{1}{z-\zeta}-\frac{1+\zeta}{z}+\frac{\zeta}{z+1}=\frac{\zeta(\zeta+1)}{(z-\zeta)z(z+1)}. \tag{4.1}$$

First we calculate the integral of $f(z, \zeta)$ on $\mathbb{C}\backslash\{0, -1, \zeta\}$. Let $\partial B_r(c)$ be a circle passing through 0, -1, and ζ. Here we set $\zeta = \xi + i\eta$ and assume that $\eta \neq 0$. The integral is equal to the integral of $f(z, \zeta)$ on $B_r(c)$, and so it is equal to $\pi r^2 f(c, \zeta)$. Substituting c for z in (4.1), we obtain

$$f(c, \zeta) = \frac{\bar{c} - \bar{\zeta}}{|c-\zeta|^2} - \frac{(1+\zeta)\bar{c}}{|c|^2} + \frac{\zeta(\bar{c}+1)}{|c+1|^2}.$$

Since all denominators of fractions in the right-hand side are equal to r^2, we obtain

$$\int f(z, \zeta)\, dm = \pi r^2 f(c, \zeta) = \pi(\zeta - \bar{\zeta}) = 2\pi i \eta.$$

Now we shall take ζ so that $\Omega = \mathbb{C}\backslash\{0, -1, i, \zeta\}$ is the desired example. Let $g(z, \zeta) = f(z, \zeta)/f(z, i)$. If we can choose ζ so that $f(z_1, i) \neq 0$ and $g(z_1, \zeta) = \eta$ for some $z_1 \in \Omega$, then Ω is a quadrature domain of $L(f) = a_{11} f(z_1)$, where $a_{11} = 2\pi i/f(z_1, i)$. Indeed, $(f(z, i), f(z, \zeta))$ is a basis of the class of all holomorphic and integrable functions in Ω. By definition, $a_{11} f(z_1, i) = 2\pi i = \int f(z, i)\, dm$. On the other hand, $a_{11} f(z_1, \zeta) = 2\pi i f(z_1, \zeta)/f(z_1, i) = 2\pi i g(z_1, \zeta) = 2\pi i \eta = \int f(z, \zeta)\, dm$.

Finally we shall show that there is ζ such that $f(z_1, i) \neq 0$ and $g(z_1, \zeta) = \eta$ for some $z_1 \notin \{0, -1, i, \zeta\}$. By (4.1),

$$g(z, \zeta) = \frac{\zeta(\zeta+1)(z-i)}{i(i+1)(z-\zeta)}. \tag{4.2}$$

Hence g is a linear fractional function of z for fixed ζ and has a zero at i and a pole at ζ. Since $\lim_{z\to 0} g(z, \zeta) = (\zeta+1)/(i+1)$ and $\lim_{z\to -1} g(z, \zeta) = \zeta/i$, we can find $z_1 \notin \{0, -1, i, \zeta\}$ if $(\zeta+1)/(i+1) \neq \eta$ and $\zeta/i \neq \eta$. These are equivalent to $\eta \neq \xi + 1$ and $\xi \neq 0$, respectively. Namely, if ζ is not on the union of two lines $\{\eta = \zeta + 1\}$ and $\{\xi = 0\}$, then the unique solution z_1 to $g(z_1, \zeta) = \eta$ does not belong to $\{0, -1, i, \zeta\}$. From (4.2) we obtain

$$z_1 = \frac{\eta i(i+1)\zeta - i\zeta(\zeta+1)}{\eta i(i+1) - \zeta(\zeta+1)}.$$

If we take $\eta = 1$, then

$$z_1 = \frac{-\zeta}{i\zeta + (i-1)}.$$

Hence if we vary ζ on a line $\{\eta = 1\}$, then z_1 moves on a circle, and so $f(z_1, i) \neq 0$ for some $\zeta \neq i$.

For a bounded quadrature domain Ω of finite order, we have already mentioned that there are no nonisolated degenerate boundary points. As we have seen in Theorem 1.7, the union $[\Omega]$ of Ω and the set of isolated degenerate boundary points is also a quadrature domain of the same functional. Let S be the global Schwarz function of Ω, then it is also the global Schwarz function of $[\Omega]$, and it is a meromorphic function having n poles in Ω, where n denotes the order of the functional.

DEFINITION 4.5. Let Ω be a bounded quadrature domain of finite order. We call a point z in $[\Omega]$ a singular point of Ω if $S(z) = \bar{z}$. We call it a simple singular point if z is a simple $\bar{z}$-point of S, namely, if $S(z) = \bar{z}$ and $S'(z) \neq 0$. We call a point z in $[\Omega]$ a regular point of Ω if $S(z) \neq \bar{z}$.

Let Ω be a bounded quadrature domain of finite order. We note that singular points of Ω are isolated degenerate boundary points of Ω or are points in Ω. If ζ is a singular point in Ω, then $\Omega\backslash\{\zeta\}$ is also a quadrature domain of the functional. Hence there is at most a finite number of singular points of Ω. We note that every point in Ω is regular or singular and every boundary point of Ω is a regular, singular, double, or cusp point.

Let Ω be an arbitrary open set in $\mathbb{C}$. We say that Ω is the inversion of Ω_0 with respect to a point ω_0 if Ω is the image of $\Omega_0\backslash\{\omega_0\}$ under a mapping $w \mapsto 1/(w-\omega_0)$. The following proposition is essentially due to Shapiro.

THEOREM 4.6 [12, Thm. 3.3]. *Let Ω be an unbounded quadrature domain of order n such that $\bar{\Omega} \neq \mathbb{C}$. Then*

(1) *Ω is a translation of the inversion of a bounded quadrature domain Ω_0 of order $n+1$ with respect to a regular point or a regular boundary point of Ω_0;*
or

(2) *Ω is a translation of the inversion of a bounded quadrature domain Ω_0 of order $n+2$ with respect to a simple singular point of Ω_0, a double point, or a cusp point of $\partial\Omega_0$.*

Conversely, an open set Ω stated in (1) *or* (2) *is an unbounded quadrature domain of order n such that $\bar{\Omega} \neq \mathbb{C}$.*

Proof. Let ζ_0 be a point in $\mathbb{C}\backslash\bar{\Omega}$, and set $w = T(z) = 1/(z-\zeta_0)$. Then, by the proof of Theorem 3.10, Ω is a translation of the inversion of a bounded open set $\Omega_0 = T(\Omega)$ or $T(\Omega) \cup \{0\}$ with respect to the origin because $z = T^{-1}(w) = 1/w + \zeta_0$. $S_T = \bar{T} \circ S \circ T^{-1}$ is the global Schwarz function of Ω_0 and is meromorphic in Ω_0, where S denotes the global Schwarz function of Ω. Hence Ω_0 is a bounded quadrature domain of finite order. We add all isolated boundary points of Ω_0 to Ω_0 and make a quadrature domain $[\Omega_0]$.

To determine the order of $[\Omega_0]$, we note that $[\Omega_0]$ is of order m if and only if S_T has m poles in $[\Omega_0]$. We also note that S_T has m poles in $[\Omega_0]$ if and only if S has m $\overline{\zeta_0}$-points in $[\Omega] = T^{-1}([\Omega_0])$ because $\bar{T}(z) = 1/(z-\overline{\zeta_0})$. Here, if $0 \in [\Omega_0]$, then we consider $[\Omega]$ in the topology of the Riemann sphere and regard ∞ as a point in $[\Omega]$.

We shall apply the argument principle to $S(z)-\overline{\zeta_0}$ and count the number m of $\overline{\zeta_0}$-points of S in $[\Omega]$. First we consider the case that $\partial\Omega$ is bounded, namely, $[\Omega]$ is an open set containing ∞ in the Riemann sphere. Since $S(z)-\overline{\zeta_0} = \bar{z}-\overline{\zeta_0} \neq 0$ on $\partial[\Omega] \subset \partial\Omega$, the argument principle for domains in the Riemann sphere asserts that

$$m-n = \frac{1}{2\pi}\int_{\partial[\Omega]} d \arg\,(S(z)-\overline{\zeta_0})$$

if S is regular at ∞. Since $S(z)-\overline{\zeta_0} = \bar{z}-\overline{\zeta_0}$ on $\partial[\Omega]$ and ζ_0 belongs to the exterior of $[\Omega]$, we see that

$$\frac{1}{2\pi}\int_{\partial[\Omega]} d \arg\,(S(z)-\overline{\zeta_0}) = \frac{1}{2\pi}\int_{\partial[\Omega]} d \arg\,(\bar{z}-\overline{\zeta_0}) = 1.$$

Hence $m = n+1$. We note that S is regular at ∞ if and only if $S_T(0) \neq 0$. Thus the origin is a regular point of Ω_0. If S has a simple pole at ∞, then, by the argument principle, $m-(n+1) = 1$, and so $m = n+2$. In this case, $S_T(0) = 0$ and the origin is a simple singular point of Ω_0.

Next we consider the case that $\partial\Omega$ is unbounded, namely, 0 is a boundary point of $[\Omega_0]$. In this case, we note that $S(z) \to \infty$ as $z \to \infty$. For large R such that $S(z)-\overline{\zeta_0} \neq 0$ on $[\Omega]\backslash B_R$, we apply the argument principle to $S-\overline{\zeta_0}|[\Omega] \cap B_R$. Then

$$m-n = \frac{1}{2\pi}\int_{\partial([\Omega]\cap B_R)} d \arg\,(S(z)-\overline{\zeta_0}).$$

If 0 is a regular boundary point of $[\Omega_0]$, then, by the Regularity Theorem and Corollary 2.6,

$$\frac{1}{2\pi}\int_{[\Omega]\cap\partial B_R} d\arg\,(S(z)-\overline{\zeta_0}) \tag{4.3}$$

tends to $\frac{1}{2}$ as $R\to+\infty$. Since

$$\frac{1}{2\pi}\int_{\bar{B}_R\cap\partial[\Omega]} d\arg\,(S(z)-\overline{\zeta_o})=\frac{1}{2\pi}\int_{\bar{B}_R\cap\partial[\Omega]} d\arg\,(\bar{z}-\overline{\zeta_0}) \tag{4.4}$$

tends to $\frac{1}{2}$ as $R\to+\infty$, we obtain $m-n=1$. If 0 is a double or cusp point of $\partial[\Omega_0]$, then both (4.3) and (4.4) tend to 1 as $R\to+\infty$, and so $m-n=2$. Hence Ω_0 is of order $n+1$ if 0 is a regular boundary point of Ω_0 and is of order $n+2$ if 0 is a double or cusp point of $\partial\Omega_0$.

To show the converse, let Ω_0 be a bounded quadrature domain of order m, and let $\Omega=T^{-1}(\Omega_0\backslash\{\omega_0\})$, where $z=T^{-1}(w)=1/(w-\omega_0)+a$ denotes a translation of the inversion with respect to ω_0 and ω_0 is a fixed point on $\overline{\Omega_0}$ such that it is simple if it is a singular point. The global Schwarz function S_0 of Ω_0 has m poles and $S=\overline{T^{-1}}\circ S_0\circ T$ is the global Schwarz function of Ω because ω_0 is simple if it is a singular point of Ω. Hence Ω is a quadrature domain of finite order. Let n be the number of poles of S in Ω; here we consider Ω as a subset of $\mathbb{C}$. Then it is equal to the number of $\overline{\omega_0}$-points of S_0 in $[\Omega_0]\backslash\{\omega_0\}$.

If $\omega_0\in[\Omega_0]$ and if ∞ is a removable singularity of S, then $S_0(\omega_0)\neq\overline{\omega_0}$, and so

$$n-m=\frac{1}{2\pi}\int_{\partial[\Omega_0]} d\arg\,(S_0(w)-\overline{\omega_0})=\frac{1}{2\pi}\int_{\partial[\Omega_0]} d\arg\,(\bar{w}-\overline{\omega_0})=-1.$$

If $\omega_0\in[\Omega_0]$ and if ∞ is a simple pole of S, then ω_0 is a simple singular point, and so $(n+1)-m=-1$. If $\omega_0\in\partial[\Omega_0]$, for sufficiently small $\delta>0$, we obtain

$$\begin{aligned}n-m=&\frac{1}{2\pi}\int_{(\partial[\Omega_0])\backslash B_\delta(\omega_0)} d\arg\,(S_0(w)-\overline{\omega_0})\\&+\frac{1}{2\pi}\int_{-(\partial B_\delta(\omega_0))\cap[\Omega_0]} d\arg\,(S_0(w)-\overline{\omega_0}).\end{aligned}$$

The first term of the right-hand side of the equality is equal to

$$\frac{1}{2\pi}\int_{(\partial[\Omega_0])\backslash B_\delta(\omega_0)} d\arg\,(\bar{w}-\overline{\omega_0}).$$

Each term of the right-hand side of the equality tends to $-\frac{1}{2}$ as $\delta\to0$ if ω_0 is a regular point of $\partial[\Omega_0]$ and -1 if ω_0 is a double or cusp point of $\partial[\Omega_0]$. Hence $n-m=-1$ or -2. This completes the proof. □

COROLLARY 4.7. *Let Ω be a quadrature domain of finite order. If there is a nonisolated degenerate boundary point of Ω, then Ω is of order* 0 *and of type* (1) *of Theorem* 4.4 *or Ω is of order* 1 *and of type* (2) *of Theorem* 4.4.

COROLLARY 4.8. *Let Ω be a quadrature domain of finite order such that $\partial\Omega$ is neither a line nor a circle. Then each connected component of the exterior of Ω is not a quadrature domain of finite order.*

From the corollary, we see that the inside of an ellipse, which is not a circle, is not a quadrature domain of finite order because the outside of the ellipse is a quadrature domain of order 0; see § 5.

5. Null quadrature domains. By Theorems 4.4 and 4.6, we can construct all unbounded quadrature domains of order n, if we know all bounded quadrature domains of order $n+1$ and $n+2$. In [8], all quadrature domains of order 0 were determined. They are

(1) A domain whose boundary is a proper subset of a line in $\mathbb{C}$;
(2) A half plane;
(3) The exterior of a circle;
(4) The exterior of an ellipse;
(5) The exterior of a parabola;
(6) The complement of a closed parallel strip.

We shall here apply Theorems 4.4 and 4.6 for $n=0$ and construct all of them.

If $\bar{\Omega}=\mathbb{C}$, then by Theorem 4.4 Ω is a domain stated in (1) or in (6), where the closed parallel strip is a line. If $\bar{\Omega}\neq\mathbb{C}$, then by Theorem 4.6 Ω is a translation of the inversion of a bounded quadrature domain of order 1 or 2. A bounded quadrature domain of order 1 is a disk and all points and all boundary points of the disk are regular. The inversion of a disk with respect to a boundary point is a half plane and the inversion with respect to an interior point is the exterior of a circle. Hence they are domains stated (2) and (3), respectively.

For a bounded connected quadrature domain of order 2, it is known that $[\Omega]$ is simply connected; see Aharonov and Shapiro [1] and (2) of § 5 in [10]. By Corollary to Theorem 2.1 in Gustafsson [6], we see that $c+2d+e\leqq 1$, where c, d, and e denote the number of cusp, double, and singular points of Ω, respectively. Namely, there are no double points and there is at most one cusp or singular point in this case. It is also known that the domain is obtained as the image of the unit disk under a rational function R of order two, which is univalent in the unit disk; see Theorem 1 in Aharonov and Shapiro [1] and Chapter 14 of Davis [3].

If 0 is a singular point of the domain, then, as shown in [10, § 5, eqn. (2)], we may assume that the rational function R has the form $R(w)=w/(1+c_1w+c_2w^2)$, where $0<|c_2|<1$. It is also shown there that $S(z)=(1/\overline{c_2})z+O(z^2)$ in a neighborhood of 0, and so 0 is a simple singular point. Now the boundary of the inversion of the domain with respect to 0 is the image of $\{|w|=1\}$ under $w\mapsto(1+c_1w+c_2w^2)/w$. Since $1/w=\bar{w}$ on $\{|w|=1\}$, the boundary can be expressed as $\{\bar{w}+c_2w+c_1;\ |w|=1\}$. Since $0<|c_2|<1$, it is an ellipse and the inversion is a domain stated in (4).

If there is a cusp point on the boundary of a bounded connected quadrature domain of order two, we may assume that the domain is the image of the unit disk under $R(w)=w(1+w/(2+a))/(1-aw)$, where $|a|<1$, and $R(-1)=-1/(2+a)$ is the cusp; [10, § 5, eqn. (2)]. Hence the boundary of the inversion of the domain with respect to the cusp is the image of $\{|w|=1\}$ under

$$w\mapsto\frac{1}{R(w)-R(-1)}=\frac{(2+a)(1-aw)}{(1+w)^2}.$$

Since $1/w=\bar{w}$ on $\{|w|=1\}$, the right-hand side of the equality is equal to

$$\frac{(2+a)(\bar{w}-a)}{(1+w)(\bar{w}+1)}=\frac{(2+a)(\bar{w}-a)}{2(1+\operatorname{Re} w)}.$$

We set $(\bar{w}-a)/(1+\operatorname{Re} w)=x+iy$, $a=\alpha+i\beta$ and $w=u+iv$. Then $x=(u-\alpha)/(u+1)$ and $y=-(v+\beta)/(u+1)$. Hence we then have $u=-(x+\alpha)/(x-1)$ and $v=-(\beta x-(1+\alpha)y-\beta)/(x-1)$. Since $u^2+v^2=1$ on $\{|w|=1\}$, we obtain $(x+\alpha)^2+(\beta x-(1+\alpha)y-\beta)^2=(x-1)^2$ on $\{|w|=1\}$, namely, $(1+\alpha)(-2x+(1-\alpha))=(\beta x-(1+\alpha)y-\beta)^2$ on $\{|w|=1\}$. Since $|a|<1$, it follows that $1+\alpha\neq 0$. Hence the boundary of the inversion is a parabola. This is the case stated in (5).

Finally, we consider a bounded quadrature domain of order 2 that is not connected. Then each connected component is a bounded quadrature domain of order 1, and so it is a disk. If these two disks do not touch each other, then all boundary points are regular. Hence the only possibility is the case that these two disks touch each other at one point. Then the point is a double point and the inversion with respect to the point is the complement of a closed parallel strip with positive width stated as in (6).

MODIFIED FAR FIELD OPERATORS IN INVERSE SCATTERING THEORY*

DAVID COLTON†‡ AND PETER HÄHNER†§

Abstract. The dual space method for solving the inverse scattering problem reformulates the inverse problem as one in constrained optimization with weighted averages of the far field pattern u_∞ as data. Unfortunately there exists a discrete set of values of the wave number such that the infimum of the cost functional associated with the optimization scheme is not zero. In this paper, the authors show how this difficulty can be removed if instead of u_∞, $u_\infty - u_\infty^0$ is considered, where u_∞^0 is the far field pattern of a surface potential.

Key words. inverse scattering, acoustic waves, electromagnetic waves

AMS(MOS) subject classifications. 35J05, 35P25, 35R30

1. Introduction. In [5] and [6] Colton and Monk introduced a new method for solving the inverse scattering problem for time harmonic acoustic waves that has subsequently been referred to as the dual space method or the method of superposition of incident fields [3]. This method has been extended to the case of time harmonic electromagnetic waves by Blöhbaum [1] and Colton and Päivärinta [9]; see also [3]. The main advantage of the dual space method is that in the case of many incident waves the number of unknowns is significantly reduced by means of an averaging process. On the other hand, a disadvantage of the method is that it fails at a discrete set of values of the wave number corresponding to an interior eigenvalue for the obstacle problem or a transmission eigenvalue for the case of an inhomogeneous medium. In the case of an inhomogeneous medium, this disadvantage was overcome in [7] and [4] by replacing the far field pattern u_∞ by $u_\infty - u_\infty^0$, where u_∞^0 is the far field pattern corresponding to a ball with impedance boundary condition. A more flexible approach for the scalar case was given in [8] where u_∞ is again replaced by $u_\infty - u_\infty^0$, where now u_∞^0 is the far field pattern corresponding to an arbitrary modal expansion with an inequality constraint on the Fourier coefficients.

In this paper, we shall continue this study by examining the possibility of choosing u_∞^0 to be the far field pattern corresponding to a surface potential. It has not escaped our attention that in some ways the present approach resembles the modified integral equation method for the direct scattering problem that is usually associated with the names Brakhage, Leis, Panich, and Werner (cf. [2]). However, as pointed out in [8], the resemblance is somewhat superficial since the failure of the standard integral equation method for solving the direct scattering problem is due to the ansatz, whereas the failure of the dual space method at an eigenvalue is due to the fact that for such values of the wave number the set of far field patterns corresponding to arbitrary incident plane waves is not complete.

Before stating more precisely what will be done in this paper, we formulate the direct scattering problems under consideration. In the following, $D \subset \mathbb{R}^3$ is a bounded domain containing the origin with C^2 boundary ∂D such that $D_e := \mathbb{R}^3 \setminus \bar{D}$ is connected. We denote the unit exterior normal to ∂D (or to the boundary of any other domain)

by ν. The function n is a given positive function such that $m := 1 - n$ has compact support and $n \in C^{0,\alpha}(\mathbb{R}^3)$ in the scalar case and $n \in C^{1,\alpha}(\mathbb{R}^3)$ in the vector case, where $C^{0,\alpha}$ and $C^{1,\alpha}$ denote the usual Hölder spaces ($C_0^{0,\alpha}$ and $C_0^{1,\alpha}$ will denote Hölder spaces consisting of functions with compact support). The function n is called the refractive index of the inhomogeneous medium. The incident field in the scalar case is always $u^i(x, d) := \exp(i\kappa x \cdot d)$, $x \in \mathbb{R}^3$, where $\kappa > 0$ is the wave number and $d \in \Omega := \{x \in \mathbb{R}^3 : |x| = 1\}$. For the electromagnetic case the incident field is always given by

$$\begin{aligned} E^i(x, d, p) &:= \frac{i}{\kappa} \operatorname{curlcurl} \{p \exp(i\kappa x \cdot d)\}, \\ H^i(x, d, p) &:= \operatorname{curl} \{p \exp(i\kappa x \cdot d)\}, \qquad x \in \mathbb{R}^3, \end{aligned} \tag{1.1}$$

where $p \in \mathbb{R}^3$ is a constant vector denoting the polarization, E^i is the incident electric field, and H^i is the incident magnetic field. The corresponding scattered fields u^s and E^s, H^s are required to satisfy, respectively, the Sommerfeld radiation condition

$$\lim_{r \to \infty} r\left(\frac{\partial u^s}{\partial r} - i\kappa u^s\right) = 0$$

and the Silver–Müller radiation condition

$$\lim_{r \to \infty} (H^s \times x - rE^s) = 0$$

uniformly for all directions $\hat{x} := x/|x|$, where $r = |x|$. Finally, the total fields $u = u^i + u^s$ and $E = E^i + E^s$, $H = H^i + H^s$, are assumed to satisfy the regularity conditions $u \in C^2(D_e) \cap C(\bar{D}_e)$ and E, $H \in C^1(D_e) \cap C(\bar{D}_e)$ in the case of obstacle scattering and $u \in C^2(\mathbb{R}^3)$ and E, $H \in C^1(\mathbb{R}^3)$ in the case of scattering by an inhomogeneous medium.

We can now state the following direct scattering problems, each of which has a unique solution [3].

Direct acoustic obstacle problem. Find $u = u^i + u^s$ such that

$$\Delta u + \kappa^2 u = 0 \quad \text{in } D_e \tag{1.2}$$

and

$$u = 0 \quad \text{on } \partial D. \tag{1.3}$$

Direct acoustic inhomogeneous medium problem. Find $u = u^i + u^s$ such that

$$\Delta u + \kappa^2 n(x) u = 0 \quad \text{in } \mathbb{R}^3. \tag{1.4}$$

Direct electromagnetic obstacle problem. Find $E = E^i + E^s$ and $H = H^i + H^s$ such that

$$\operatorname{curl} E - i\kappa H = 0, \qquad \operatorname{curl} H + i\kappa E = 0 \quad \text{in } D_e \tag{1.5}$$

and

$$\nu \times E = 0 \quad \text{on } \partial D. \tag{1.6}$$

Direct electromagnetic inhomogeneous medium problem. Find $E = E^i + E^s$ and $H = H^i + H^s$ such that

$$\operatorname{curl} E - i\kappa H = 0, \qquad \operatorname{curl} h + i\kappa n(x) E = 0 \quad \text{in } \mathbb{R}^3. \tag{1.7}$$

Note that since n is assumed positive the inhomogeneous medium for acoustic waves is nonabsorbing and for electromagnetic waves is a dielectric.

Of primary concern in this paper is the inverse scattering problem corresponding to each of the above direct scattering problems. To formulate the inverse problems, we first note that for acoustic waves u^s has the asymptotic behavior

$$u^s(x, d) = \frac{\exp(i\kappa|x|)}{|x|} u_\infty(\hat{x}, d) + O\left(\frac{1}{|x|^2}\right)$$

as $|x| \to \infty$, where u_∞ is the *far field pattern* and for electromagnetic waves E^s has the asymptotic behavior

$$E^s(x, d, p) = \frac{\exp(i\kappa|x|)}{|x|} E_\infty(\hat{x}, d, p) + O\left(\frac{1}{|x|^2}\right)$$

as $|x| \to \infty$, where E_∞ is the *electric far field pattern.* For obstacle scattering, the inverse problem is to determine D from u_∞ or E_∞, and for scattering by an inhomogeneous medium the inverse problem is to determine n (or m) from u_∞ or E_∞. The dual space method reformulates each of these inverse problems as a problem of determining the minimum of a functional over a compact or weakly compact set. For our purposes, it is important to recall what form these functionals take.

Let $\tilde{u}$ be a given radiating solution of the Helmholtz equation (1.2) in $\mathbb{R}^3\backslash\{0\}$ with far field pattern $\tilde{u}_\infty$, and let $\tilde{E}$, $\tilde{H}$ be a given radiating solution of the Maxwell equations (1.5) in $\mathbb{R}^3\backslash\{0\}$ with electric far field pattern $\tilde{E}_\infty$. For $g \in L^2(\Omega)$, define the acoustic far field operator $\mathbf{F}_a$ by

$$(\mathbf{F}_a g)(\hat{x}) := \int_\Omega u_\infty(\hat{x}, d) g(d)\, ds(d), \qquad \hat{x} \in \Omega,$$

and the acoustic Herglotz wave function v by

$$v(x) := \int_\Omega \exp(i\kappa x \cdot d) g(d)\, ds(d), \qquad x \in \mathbb{R}^3.$$

For $g \in L^2(\Omega)$ a tangential vector field, define the electromagnetic far field operator $\mathbf{F}_e$ by

$$(\mathbf{F}_e g)(\hat{x}) := \int_\Omega E_\infty(\hat{x}, d, g(d))\, ds(d), \qquad \hat{x} \in \Omega,$$

and the electric Herglotz wave function E^i_g by

$$\begin{aligned} E^i_g(x) &:= \int_\Omega E^i(x, d, g(d))\, ds(d) \\ &= i\kappa \int_\Omega \exp(i\kappa x \cdot d) g(d)\, ds(d), \qquad x \in \mathbb{R}^3. \end{aligned}$$

Then the (unmodified) dual space method for solving the inverse scattering problem can be formulated as follows, where S is the set of C^2 surfaces that bound a domain D containing the origin such that D_e is connected and B is an open ball containing the support of $m := 1 - n$.

Inverse acoustic obstacle problem. Find $g \in L^2(\Omega)$ and $\Gamma \in S$ that minimize the functional

$$M_1(g, \Gamma) := \|\mathbf{F}_a g - \tilde{u}_\infty\|_{L^2(\Omega)} + \|\tilde{u} + v\|_{L^2(\Gamma)}.$$

Inverse acoustic inhomogeneous medium problem. Find $g \in L^2(\Omega)$, $m \in C_0^{0,\alpha}(B)$ and $w \in C^2(\bar{B})$ a solution of (1.4) in B that minimize the functional

$$M_2(g, w, m) := \|\mathbf{F}_a g - \tilde{u}_\infty\|_{L^2(\Omega)} + \|w - \tilde{u} - v\|_{L^2(\partial B)} + \left\| \frac{\partial}{\partial r}(w - \tilde{u} - v) \right\|_{L^2(\partial B)}.$$

Inverse electromagnetic obstacle problem. Find a tangential vector field $g \in L^2(\Omega)$ and $\Gamma \in S$ that minimize the functional

$$M_3(g, \Gamma) := \|\mathbf{F}_e g - \tilde{E}_\infty\|_{L^2(\Omega)} + \|\nu \times (\tilde{E} + E_g^i)\|_{L^2(\Gamma)}.$$

Inverse electromagnetic inhomogeneous medium problem. Find a tangential vector field $g \in L^2(\Omega)$, $m \in C_0^{1,\alpha}(B)$, and $(F, G) \in C^1(\bar{B})^2$ a solution of (1.7) in B that minimize the functional

$$M_4(g, F, G, m) := \|\mathbf{F}_e g - \tilde{E}_\infty\|_{L^2(\Omega)} + \|\hat{x} \times (F - \tilde{E} - E_g^i)\|_{L^2(\partial B)}$$
$$+ \|\hat{x} \times \operatorname{curl}(F - \tilde{E} - E_g^i)\|_{L^2(\partial B)}.$$

In the case of the acoustic inhomogeneous medium problem w and m are related by the Lippmann-Schwinger equation with incident field v and in the electromagnetic inhomogeneous medium problem F and m are related by the vector Lippmann-Schwinger equation (cf. [3]) with incident electric field E_g^i.

If κ is not an eigenvalue (as discussed in the opening paragraph), the infimum of each of these cost functionals is zero for exact far field data, and a solution of the inverse scattering problem is the limit of an appropriate minimizing sequence (cf. [3]). The same holds for the inhomogeneous medium problem for all $\kappa > 0$ in the case that n is not always real valued, i.e., $\operatorname{Im}(n(x)) \neq 0$ for some $x \in \mathbb{R}^3$ (cf. [11], whose methods also apply to the scalar case).

From the point of view of the numerical construction of solutions to the inverse scattering problem, it is highly desirable that for exact far field data the above cost functionals have an infimum equal to zero for all positive values of the wave number κ. Unfortunately, if κ is an eigenvalue this is not the case for each of the above cost functionals. This is due to the fact that for given far field patterns u_∞ and E_∞, there exist surfaces Γ and refractive indices n such that the integral operators $\mathbf{F}_a$ and $\mathbf{F}_e$ are not injective for a discrete set of κ values, and for such values of κ the functions $\tilde{u}_\infty$ and $\tilde{E}_\infty$ are in general not in the closure of the range of the operators $\mathbf{F}_a$ and $\mathbf{F}_e$, respectively (and hence the infimum of the cost functionals is not zero). The aim of this paper is to remedy this defect by replacing the kernel in the definition of $\mathbf{F}_a$ and $\mathbf{F}_e$ by $u_\infty - u_\infty^0$ and $E_\infty - E_\infty^0$, respectively, where u_∞^0 and E_∞^0 are the far field patterns of a surface potential. This change will of course necessitate changing the remaining terms in the cost functional in order to have the infimum be equal to zero.

To be more precise, consider the inverse acoustic obstacle problem, and let u^0 be the surface potential

$$u^0(x, d) := \frac{1}{4\pi} \int_{|y|=a} \varphi(y, d) \frac{\exp(i\kappa|x-y|)}{|x-y|} \, ds(y),$$

where a is such that if D is the unknown scattering obstacle, then it is known a priori that $\{x \in \mathbb{R}^3 : |x| \leqq a\} \subset D$. Then u^0 has the far field pattern

$$u_\infty^0(\hat{x}, d) := \frac{a^2}{4\pi} \int_\Omega \varphi(ay, d) \exp(-i\kappa a \hat{x} \cdot y) \, ds(y).$$

Now consider the operator $\mathbf{F}$ defined by

$$(1.8)\qquad \begin{aligned}(\mathbf{F}g)(\hat{x}) &:= \int_\Omega [u_\infty(\hat{x}, d) - u_\infty^0(\hat{x}, d)]g(d)\,ds(d)\\ &= \int_\Omega u_\infty(\hat{x}, d)g(d)\,ds(d) - a^2\int_\Omega (\mathbf{R}g)(d)\exp(-i\kappa a\hat{x}\cdot d)\,ds(d),\end{aligned}$$

where

$$(\mathbf{R}g)(y) := \frac{1}{4\pi}\int_\Omega \varphi(ay, d)g(d)\,ds(d), \qquad y \in \Omega.$$

Then by choosing a and φ appropriately or, more generally, choosing a and the operator $\mathbf{R}$ in (1.8) in an appropriate fashion, we will show that if in the definition of M_1 we replace the operator $\mathbf{F}_a$ by $\mathbf{F}$ and modify the second term, the resulting cost functional will have infimum equal to zero. More specifically, the integral equation $\mathbf{F}g = 0$ will have only the trivial solution $g = 0$, and $\tilde{u}_\infty$ will be in the closure of the range of $\mathbf{F}$. A similar analysis will also be done for the inverse acoustic inhomogeneous medium problem and the corresponding electromagnetic problems. These results remove the disadvantages of the dual space method referred to in the opening paragraph of this paper.

2. The inverse obstacle problem for acoustic waves. We denote by j_l the spherical Bessel function, by $h_l^{(1)}$, $h_l^{(2)}$ the spherical Hankel functions of the first and second kind of order l and by

$$\Phi(x, y) := \frac{1}{4\pi}\frac{\exp(i\kappa|x-y|)}{|x-y|}, \qquad x \neq y,$$

the fundamental solution to the Helmholtz equation. Let $a > 0$ be such that $\{x \in \mathbb{R}^3 \colon |x| \leqq a\} \subset D$ and $j_l(\kappa a) \neq 0$ for all $l \in \mathbb{N}_0$, i.e., $-\kappa^2$ is not an eigenvalue for the interior Dirichlet problem for the Laplace equation in $\{x \in \mathbb{R}^3 \colon |x| < a\}$. The condition that $\{x \in \mathbb{R}^3 \colon |x| \leqq a\} \subset D$ is only needed in the final step when we reformulate the inverse scattering problem as a constrained optimization problem. We denote by Y_l^k, $l = 0, 1, 2, \ldots, k = -l, \ldots, l$, an orthonormal basis of spherical harmonics on Ω. For $g \in L^2(\Omega)$,

$$g = \sum_{l=0}^{\infty}\sum_{k=-l}^{l} g_l^k Y_l^k,$$

we define

$$(2.1)\qquad \mathbf{R}g := \sum_{l=0}^{\infty}\sum_{k=-l}^{l} i^l g_l^k Y_l^k$$

and note that $\mathbf{R}\colon L^2(\Omega) \to L^2(\Omega)$ is a unitary operator.

We begin by defining the operator $\mathbf{F}$ for $g \in L^2(\Omega)$ by

$$(2.2)\qquad \begin{aligned}(\mathbf{F}g)(\hat{x}) := &\int_\Omega u_\infty(\hat{x}, d)g(d)\,ds(d)\\ &- a^2\int_\Omega (\mathbf{R}g)(d)\exp(-i\kappa a\hat{x}\cdot d)\,ds(d), \qquad \hat{x} \in \Omega.\end{aligned}$$

Our first aim is to prove the injectivity of the operator $\mathbf{F}$.

THEOREM 1. *Assume $\kappa > 0$. If $g \in L^2(\Omega)$ is a solution of* $\mathbf{F}g = 0$, *then* $g = 0$.

Proof. Let $g \in L^2(\Omega)$ be a solution of $\mathbf{F}g = 0$. We define

$$
\begin{aligned}
U^s(x) &:= \int_\Omega u^s(x, d) g(d)\, ds(d), \qquad x \in \bar{D}_e, \\
v(x) &:= \int_\Omega \exp(i\kappa x \cdot d) g(d)\, ds(d), \qquad x \in \mathbb{R}^3, \qquad (2.3)\\
u^0(x) &:= 4\pi \int_{|y|=a} \Phi(x, y)(\mathbf{R}g)\left(\frac{1}{a} y\right) ds(y), \qquad |x| > a.
\end{aligned}
$$

Then $U^s \in C^2(D_e) \cap C(\bar{D}_e)$ is a radiating solution of the Helmholtz equation in D_e, v is an entire solution to the Helmholtz equation, and $U^s(x) + v(x) = 0$ on ∂D. u^0 is also a radiating solution of the Helmholtz equation having the far field pattern

$$
\begin{aligned}
u^0_\infty(\hat{x}) &= a^2 \int_\Omega (\mathbf{R}g)(d) \exp(-i\kappa a \hat{x} \cdot d)\, ds(d) \\
&= \int_\Omega u_\infty(\hat{x}, d) g(d)\, ds(d) = U^s_\infty(\hat{x}), \qquad \hat{x} \in \Omega.
\end{aligned}
$$

Hence, if R is such that $\bar{D} \subset \{x \in \mathbb{R}^3 \colon |x| < R\}$ we have, by Rellich's lemma [2], [3], that $U^s(x) = u^0(x)$ for $|x| \geqq R$.

If $g \in L^2(\Omega)$ has the expansion

$$g = \sum_{l=0}^\infty \sum_{k=-l}^l g_l^k Y_l^k,$$

then

$$v(x) = 4\pi \sum_{l=0}^\infty \sum_{k=-l}^l g_l^k i^l j_l(\kappa|x|) Y_l^k(\hat{x}),$$

where the series converges uniformly with its derivatives on each compact set of $\mathbb{R}^3$ and

$$u^0(x) = 4\pi a^2 i\kappa \sum_{l=0}^\infty \sum_{k=-l}^l i^l g_l^k j_l(\kappa a) h_l^{(1)}(\kappa|x|) Y_l^k(\hat{x}),$$

where the series and its derivatives converge uniformly on each compact subset of $\{x \in \mathbb{R}^3 \colon |x| > a\}$. Using Green's theorem and $U^s + v = 0$ on ∂D we have

$$
\begin{aligned}
0 &= \int_{\partial D} \left[(U^s + v) \frac{\partial}{\partial \nu} \overline{(U^s + v)} - \overline{(U^s + v)} \frac{\partial}{\partial \nu} (U^s + v) \right] ds \\
&= \int_{|y|=R} \left[(u^0 + v) \frac{\partial}{\partial \nu} \overline{(u^0 + v)} - \overline{(u^0 + v)} \frac{\partial}{\partial \nu} (u^0 + v) \right] ds \\
&= \int_{|y|=R} \left(u^0 \frac{\partial}{\partial \nu} \overline{u^0} - \overline{u^0} \frac{\partial}{\partial \nu} u^0 \right) ds + 2i \operatorname{Im} \left\{ \int_{|y|=R} \left(u^0 \frac{\partial}{\partial \nu} \bar{v} - \bar{v} \frac{\partial}{\partial \nu} u^0 \right) ds \right\}.
\end{aligned}
$$

But

$$
\begin{aligned}
&\int_{|y|=R} \left(u^0 \frac{\partial}{\partial \nu} \overline{u^0} - \overline{u^0} \frac{\partial}{\partial \nu} u^0 \right) ds \\
&\quad = (4\pi a^2 \kappa)^2 \sum_{l=0}^\infty \sum_{k=-l}^l |g_l^k|^2 j_l(\kappa a)^2 (h_l^{(1)}(\kappa R) h_l^{(2)\prime}(\kappa R) - h_l^{(2)}(\kappa R) h_l^{(1)\prime}(\kappa R)) \kappa R^2 \\
&\quad = (4\pi a^2)^2 (-2i\kappa) \sum_{l=0}^\infty \sum_{k=-l}^l |g_l^k|^2 j_l(\kappa a)^2
\end{aligned}
$$

and

$$\int_{|y|=R}\left(u^0\frac{\partial}{\partial\nu}\bar{v}-\bar{v}\frac{\partial}{\partial\nu}u^0\right)ds$$

$$=(4\pi)^2a^2i\kappa\sum_{l=0}^{\infty}\sum_{k=-l}^{l}|g_l^k|^2j_l(\kappa a)(h_l^{(1)}(\kappa R)j_l'(\kappa R)-j_l(\kappa R)h_l^{(1)\prime}(\kappa R))\kappa R^2$$

$$=(4\pi)^2a^2\sum_{l=0}^{\infty}\sum_{k=-l}^{l}|g_l^k|^2j_l(\kappa a),$$

where we have used the Wronskian identities

$$W(h_l^{(1)},h_l^{(2)})(t)=h_l^{(1)}(t)h_l^{(2)\prime}(t)-h_l^{(2)}(t)h_l^{(1)\prime}(t)=\frac{-2i}{t^2},$$

$$W(h_l^{(1)},j_l)(t)=h_l^{(1)}(t)j_l'(t)-j_l(t)h_l^{(1)\prime}(t)=\frac{-i}{t^2}.$$

Hence we conclude that $g_l^k=0$ for all l, k, and thus $g=0$.

Remark 1. It is possible to get rid of the assumption $j_l(\kappa a)\neq 0$ for all $l\in\mathbb{N}_0$ by using

$$u^0(x)=4\pi\int_{|y|=a}\left\{\frac{\partial\Phi}{\partial\nu(y)}(x,y)-i\Phi(x,y)\right\}(\mathbf{R}g)\left(\frac{1}{a}y\right)ds(y),\qquad |x|>a,$$

and perturbing the kernel $u_\infty(\hat{x},d)$ by the corresponding far field pattern. In this case there are no longer any restrictions on a except that $a>0$ and $\{x\in\mathbb{R}^3\colon |x|\leqq a\}\subset D$.

Remark 2. In two dimensions with $d=(d_1,d_2)$ we have

$$g(d)=\sum_{l=-\infty}^{\infty}g_l(d_1+id_2)^l$$

and

$$(\mathbf{R}g)(d)=\sum_{l=-\infty}^{\infty}i^lg_l(d_1+id_2)^l=\sum_{l=-\infty}^{\infty}g_l(-d_2+id_1)^l.$$

Then

$$\int_\Omega\exp(-i\kappa a\hat{x}\cdot d)(\mathbf{R}g)(d)\,ds(d)=\int_\Omega\exp(i\kappa a\hat{x}\cdot d^*)g(d)\,ds(d),$$

where $d^*=(-d_2,d_1)$ has a simple geometrical interpretation.

The next lemma estimates the decay of the spherical Bessel function as $l\to\infty$.

LEMMA 1. For a fixed $t>0$ there exist positive constants $M>0$ and $C>0$ such that

$$j_l(t)\geqq C\frac{t^l}{1\cdot3\cdots(2l+1)}$$

for all $l\geqq M$.

Proof. Choose $M>t^2$. For $l\geqq M$ the sequence

$$a_p:=\left(\frac{t^2}{2}\right)^p\frac{1}{p!1\cdot3\cdots(2l+2p+1)},\qquad p\in\mathbb{N}_0,$$

is monotonically decreasing. Then we have for $l \geqq M$ that

$$j_l(t) = \sum_{p=0}^{\infty} \frac{(-1)^p t^{l+2p}}{2^p p! 1 \cdot 3 \cdots (2l+2p+1)}$$

$$\geqq \frac{t^l}{1 \cdot 3 \cdots (2l+1)} \left(1 - \frac{t^2}{2(2l+3)}\right) \geqq C \frac{t^l}{1 \cdot 3 \cdots (2l+1)}$$

for some constant $C > 0$.

The next theorem is a denseness theorem that is decisive in proving that the functional we shall replace M_1 with has infimum equal to zero for all $\kappa > 0$ (see the Introduction for the definition of M_1).

THEOREM 2. *Assume $\kappa > 0$. Then the linear space*

$$\operatorname{span}\{(j_l(\kappa|x|) + ia^2\kappa j_l(\kappa a) h_l^{(1)}(\kappa|x|))\, Y_l^k(\hat{x}) \colon l \in \mathbb{N}_0,\ k = -l, \ldots, l\}$$

is dense in $L^2(\partial D)$.

Proof. For $x, y \in \mathbb{R}^3$ we define χ by

$$\chi(x, y) = \frac{1}{a^2} \sum_{l=0}^{\infty} \sum_{k=-l}^{l} \frac{1}{j_l(\kappa a)} j_l(\kappa|x|) j_l(\kappa|y|)\, Y_l^k(\hat{x}) \overline{Y_l^k(\hat{y})}. \tag{2.4}$$

By Lemma 1 the series converges together with its derivatives uniformly on each compact subset of $\mathbb{R}^3 \times \mathbb{R}^3$. Assume $g \in L^2(\partial D)$ and

$$\int_{\partial D} \overline{g(x)}\, (j_l(\kappa|x|) + ia^2\kappa j_l(\kappa a) h_l^{(1)}(\kappa|x|))\, Y_l^k(\hat{x})\, ds(x) = 0$$

for all $l \in \mathbb{N}_0$, $k = -l, \ldots, l$. We must show $g = 0$. Define

$$u(x) := \int_{\partial D} \overline{g(y)} \{\Phi(x, y) + \chi(x, y)\}\, ds(y), \qquad x \in \mathbb{R}^3 \backslash \partial D.$$

Then $\Delta u + \kappa^2 u = 0$ in $\mathbb{R}^3 \backslash \partial D$ and if $r < a$ we have

$$\begin{aligned}
\int_{\Omega} u(r\hat{x})\, Y_l^k(\hat{x})\, ds(\hat{x}) &= \int_{\partial D} \overline{g(y)} \int_{\Omega} \{\Phi(r\hat{x}, y) + \chi(r\hat{x}, y)\} Y_l^k(\hat{x})\, ds(\hat{x})\, ds(y) \\
&= \int_{\partial D} \overline{g(y)} \Big\{ i\kappa h_l^{(1)}(\kappa|y|) j_l(\kappa r) \\
&\qquad + \frac{1}{a^2 j_l(\kappa a)} j_l(\kappa|y|) j_l(\kappa r) \Big\} Y_l^k(\hat{y})\, ds(y) \\
&= \frac{j_l(\kappa r)}{a^2 j_l(\kappa a)} \int_{\partial D} \overline{g(y)} \{j_l(\kappa|y|) + ia^2\kappa j_l(\kappa a) h_l^{(1)}(\kappa|y|)\} Y_l^k(\hat{y})\, ds(y) \\
&= 0
\end{aligned}$$

for all $l \in \mathbb{N}_0$, $k = -l, \ldots, l$. Hence $u = 0$ in a small ball with center at the origin and by unique continuation [2], [3], $u = 0$ in D.

For R such that $\bar{D} \subset \{x \in \mathbb{R}^3 \colon |x| < R\}$ we have $u(R\hat{x}) = u_1(R\hat{x}) + u_2(R\hat{x})$, where

$$\begin{aligned}
u_1(R\hat{x}) &:= \int_{\partial D} \Phi(R\hat{x}, y) \overline{g(y)}\, ds(y) \\
&= \sum_{l=0}^{\infty} \sum_{k=-l}^{l} \alpha_l^k h_l^{(1)}(\kappa R)\, Y_l^k(\hat{x})
\end{aligned}$$

and

$$u_2(R\hat{x}) := \int_{\partial D} \chi(R\hat{x}, y)\overline{g(y)}\,ds(y)$$

$$= \sum_{l=0}^{\infty} \sum_{k=-l}^{l} \frac{1}{a^2 i\kappa j_l(\kappa a)}\, \alpha_l^k j_l(\kappa R)\, Y_l^k(\hat{x})$$

with

$$\alpha_l^k = \int_{\partial D} i\kappa j_l(\kappa|y|)\overline{Y_l^k(\hat{y})g(y)}\,ds(y).$$

The series expansions for u_1 and u_2 converge uniformly together with their derivatives on $|x| = R$.

Using the fact that $u = 0$ in D and the continuity properties of single layer potentials with L^2 densities (see [12]) we conclude from Green's theorem that

$$0 = \int_{\partial D} \left\{ u \frac{\partial}{\partial \nu} \bar{u} - \bar{u} \frac{\partial}{\partial \nu} u \right\} ds$$

$$= \int_{|y|=R} \left\{ (u_1 + u_2) \frac{\partial}{\partial \nu} \overline{(u_1 + u_2)} - \overline{(u_1 + u_2)} \frac{\partial}{\partial \nu} (u_1 + u_2) \right\} ds$$

$$= \int_{|y|=R} \left\{ u_1 \frac{\partial}{\partial \nu} \overline{u_1} - \overline{u_1} \frac{\partial}{\partial \nu} u_1 \right\} ds + 2i \operatorname{Im} \left\{ \int_{|y|=R} \left\{ u_1 \frac{\partial}{\partial \nu} \overline{u_2} - \overline{u_2} \frac{\partial}{\partial \nu} u_1 \right\} ds \right\}.$$

But

$$\int_{|y|=R} \left\{ u_1 \frac{\partial}{\partial \nu} \overline{u_1} - \overline{u_1} \frac{\partial}{\partial \nu} u_1 \right\} ds$$

$$= \sum_{l=0}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2 \kappa R^2 (h_l^{(1)}(\kappa R) h_l^{(2)\prime}(\kappa R) - h_l^{(2)}(\kappa R) h_l^{(1)\prime}(\kappa R))$$

$$= \frac{-2i}{\kappa} \sum_{l=0}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2$$

and

$$\int_{|y|=R} \left\{ u_1 \frac{\partial}{\partial \nu} \overline{u_2} - \overline{u_2} \frac{\partial}{\partial \nu} u_1 \right\} ds$$

$$= -\frac{1}{a^2 i\kappa} \sum_{l=0}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2 \kappa R^2 \frac{1}{j_l(\kappa a)} (h_l^{(1)}(\kappa R) j_l'(\kappa R) - j_l(\kappa R) h_l^{(1)\prime}(\kappa R))$$

$$= \frac{1}{a^2 \kappa^2} \sum_{l=0}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2 \frac{1}{j_l(\kappa a)}.$$

Hence $\alpha_l^k = 0$ for all $l \in \mathbb{N}_0$, $k = -l, \ldots, l$, and thus $u = 0$ in D_e. We can now conclude from the jump relation for the normal derivative of the single layer potential that $g = 0$. The proof is finished.

If we now let $\tilde{u} \in C^2(\mathbb{R}^3 \setminus \{0\})$ be a radiating solution of the Helmholtz equation with the far field pattern $\tilde{u}_\infty$, we can choose for a given $\varepsilon > 0$ constants a_l^k, $l = 0, \dots, N$, $k = -l, \dots, l$ such that

$$\left\| \tilde{u} + 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l [j_l(\kappa|\cdot|) + ia^2\kappa j_l(\kappa a) h_l^{(1)}(\kappa|\cdot|)] Y_l^k \right\|_{L^2(\partial D)} \leqq \varepsilon.$$

Define

$$\begin{aligned} g_N &:= \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k Y_l^k, \\ v_N(x) &:= \int_\Omega \exp(i\kappa x \cdot d) g_N(d)\, ds(d) \\ &= 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l j_l(\kappa|x|) Y_l^k(\hat{x}), \qquad x \in \mathbb{R}^3, \\ U_N^s(x) &:= \int_\Omega u^s(x, d) g_N(d)\, ds(d), \qquad x \in \bar{D}_e, \end{aligned} \tag{2.5}$$

and

$$u_N^0(x) := i4\pi\kappa a^2 \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l j_l(\kappa a) h_l^{(1)}(\kappa|x|) Y_l^k(\hat{x}), \qquad |x| > 0.$$

Then using $U_N^s + v_N = 0$ on ∂D we have that

$$\|\tilde{u} - (U_N^s - u_N^0)\|_{L^2(\partial D)} \leqq \varepsilon,$$

and since

$$u_N^0(x) = 4\pi a^2 \int_\Omega \Phi(x, ad)(\mathbf{R} g_N)(d)\, ds(d), \qquad |x| > a,$$

we have

$$\sup_{\hat{x} \in \Omega} |\tilde{u}_\infty(\hat{x}) - (U_{N,\infty}^s(\hat{x}) - u_{N,\infty}^0(\hat{x}))| \leqq M\varepsilon$$

for some positive constant M, i.e.,

$$|(\mathbf{F} g_N)(\hat{x}) - \tilde{u}_\infty(\hat{x})| \leqq M\varepsilon$$

for all $\hat{x} \in \Omega$. Hence, if v and u^0 are defined by (2.3), u_∞ is the exact far field data, and S is the set of C^2 surfaces bounding a domain D containing the origin such that D_e is connected, the infimum of the functional

$$M_1(g, \Gamma) := \|\mathbf{F} g - \tilde{u}_\infty\|_{L^2(\Omega)} + \|\tilde{u} + v + u^0\|_{L^2(\Gamma)}$$

for $g \in L^2(\Omega)$, $\Gamma \in S$, is zero for all $\kappa > 0$, and the solution of the inverse scattering problem is the limit of an appropriate minimizing sequence. The aim of this section of our paper is now accomplished.

3. The inverse inhomogeneous medium problem for acoustic waves. We define the operator $\mathbf{F}$ as in (2.2), where $u_\infty(\hat{x}, d)$ is now to be understood as the far field pattern of the inhomogeneous medium problem corresponding to an incident plane wave propagating in direction d. In this section, $a > 0$ is only required to satisfy $j_l(\kappa a) \neq 0$ for all $l \in \mathbb{N}_0$. We again first prove that the operator $\mathbf{F}$ is injective.

THEOREM 3. *Assume $\kappa > 0$. If $g \in L^2(\Omega)$ is a solution of $\mathbf{F}g = 0$, then $g = 0$.*

Proof. The proof is almost identical to the proof of Theorem 1. The equality

$$0 = \int_{|y|=R} \left[(U^s + v) \frac{\partial}{\partial \nu} \overline{(U^s + v)} - \overline{(U^s + v)} \frac{\partial}{\partial \nu} (U^s + v) \right] ds$$

follows by Green's theorem and the fact that $w = (U^s + v)$ is a solution of $\Delta w + \kappa^2 n w = 0$ in $\mathbb{R}^3$, where n is real valued.

In the next theorem we assume that $\operatorname{supp}(1 - n) \subset B := \{x \in \mathbb{R}^3 \colon |x| < R\}$, where $R > a$, and define

$$X := \operatorname{span} \{(j_l(\kappa|x|) + ia^2 \kappa j_l(\kappa a) h_l^{(1)}(\kappa|x|)) Y_l^k(\hat{x}) \colon l \in \mathbb{N}_0, k = -l, \ldots, l\},$$

$$Y := \{w \in C^2(\bar{B}) \colon \Delta w + \kappa^2 n w = 0 \text{ in } B\},$$

$$W := \left\{ \left(h - w, \frac{\partial}{\partial r}(h - w) \right) \colon h \in X, w \in Y \right\} \subset L^2(\partial B) \times L^2(\partial B).$$

THEOREM 4. *Assume $\kappa > 0$. Then W is dense in $L^2(\partial B) \times L^2(\partial B)$.*

Proof. Suppose a, $b \in L^2(\partial B)$ satisfy

$$\int_{\partial B} \left[(h - w)\bar{a} + \frac{\partial}{\partial r}(h - w)\bar{b} \right] ds = 0 \tag{3.1}$$

for all $h \in X$, $w \in Y$. We must show $a = b = 0$. To this end, for χ given by (2.4) we define v by

$$v(x) := \int_{\partial B} \left[\overline{a(y)} \{\Phi(x, y) + \chi(x, y)\} + \overline{b(y)} \frac{\partial}{\partial |y|} \{\Phi(x, y) + \chi(x, y)\} \right] ds(y)$$

for $x \in \mathbb{R}^3 \setminus \partial B$. We compute, for $r < R$,

$$\begin{aligned} &\int_{\Omega} v(r\hat{x}) Y_l^k(\hat{x}) \, ds(\hat{x}) \\ &= \int_{\partial B} \overline{a(y)} \left\{ i\kappa j_l(\kappa r) h_l^{(1)}(\kappa|y|) + \frac{1}{a^2 j_l(\kappa a)} j_l(\kappa r) j_l(\kappa|y|) \right\} Y_l^k(\hat{y}) \, ds(y) \\ &+ \int_{\partial B} \overline{b(y)} \frac{\partial}{\partial |y|} \left\{ i\kappa j_l(\kappa r) h_l^{(1)}(\kappa|y|) + \frac{1}{a^2 j_l(\kappa a)} j_l(\kappa r) j_l(\kappa|y|) \right\} Y_l^k(\hat{y}) \, ds(y) = 0 \end{aligned}$$

for all $l \in \mathbb{N}_0$, $k = -l, \ldots, l$. Therefore, $v = 0$ in B, and we are able to conclude by the L^2 jump relations for surface potentials [12] that $v_+ := v|_{\mathbb{R}^3 \setminus \bar{B}}$ satisfies

$$v_+ = \bar{b} \quad \text{and} \quad \frac{\partial}{\partial r} v_+ = -\bar{a} \tag{3.2}$$

on ∂B. From (3.1) we now have that, for all $w \in Y$,

$$\int_{\partial B} \left(\frac{\partial v_+}{\partial r} w - v_+ \frac{\partial w}{\partial r} \right) ds = 0. \tag{3.3}$$

We want to show through a suitable choice of w that $v_+ = 0$. The theorem then follows by (3.2).

We define v^s and v^0 by

$$v^s(x) := \int_{\partial B} \left[\overline{a(y)} \Phi(x, y) + \overline{b(y)} \frac{\partial \Phi}{\partial |y|}(x, y) \right] ds(y), \qquad |x| > R,$$

$$v^0(x) := \int_{\partial B} \left[\overline{a(y)} \chi(x, y) + \overline{b(y)} \frac{\partial \chi}{\partial |y|}(x, y) \right] ds(y), \qquad x \in \mathbb{R}^3.$$

Then $v(x) = v^0(x) + v^s(x)$ for $|x| > R$, and

$$v^0(r\hat{x}) = 4\pi \sum_{l=0}^{\infty} \sum_{k=-l}^{l} i^l \alpha_l^k j_l(\kappa r) Y_l^k(\hat{x}), \qquad r \geqq 0,$$

$$v^s(r\hat{x}) = 4\pi \sum_{l=0}^{\infty} \sum_{k=-l}^{l} i^l \alpha_l^k (i\kappa a^2) j_l(\kappa a) h_l^{(1)}(\kappa r) Y_l^k(\hat{x}), \qquad r > R,$$

where

$$\alpha_l^k = \frac{(-i)^l}{4\pi a^2 j_l(\kappa a)} \int_{\partial B} [j_l(\kappa |y|) \overline{Y_l^k(\hat{y}) a(y)} + \kappa j_l'(\kappa |y|) \overline{Y_l^k(\hat{y}) b(y)}]\, ds(y),$$

$l \in \mathbb{N}_0$, $k = -l, \ldots, l$.

Since $\sum_{l=0}^{N} \sum_{k=-l}^{l} |\alpha_l^k|^2$ is possibly divergent for $N \to \infty$ we define

$$g_N := \sum_{l=0}^{N} \sum_{k=-l}^{l} \alpha_l^k Y_l^k$$

$$v_N^0(x) := \int_{\Omega} \exp(i\kappa x \cdot d) g_N(d)\, ds(d)$$

$$= 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} i^l \alpha_l^k j_l(\kappa |x|) Y_l^k(\hat{x})$$

and note that $v_N^0(x) \to v^0(x)$, $N \to \infty$, together with its derivatives uniformly on $\bar{B}$ since v^0 is an entire solution of the Helmholtz equation and v_N^0 are the partial Fourier sums of v^0. From the Lippmann-Schwinger equation (see [3, Chap. 8]) we see that the solutions U_N of the inhomogeneous medium problem corresponding to the incident wave v_N^0 converge together with their first and second derivatives uniformly on any bounded subset of $\mathbb{R}^3$ to the solution U corresponding to the incident wave v^0, $U_N \to U$, $N \to \infty$. Again, using the Lippmann-Schwinger equation, we can conclude that the scattered fields $U_N^s := U_N - v_N$ converge together with their derivatives to $U^s := U - v^0$ uniformly on $\mathbb{R}^3$, $U_N^s \to U^s$, $N \to \infty$.

We now want to show that $U^s(x) = v^s(x)$ for $|x| > R$. We know that

$$u_\infty(\hat{x}, d) = -\frac{\kappa^2}{4\pi} \int_B \exp(-i\kappa y \cdot \hat{x}) m(y) u(y, d)\, dy, \qquad \hat{x} \in \Omega, \tag{3.4}$$

and using (3.3) and Green's theorem we have that

$$\begin{aligned} &\int_{\partial B} \left[v^s(y) \frac{\partial}{\partial |y|} \exp(-i\kappa y \cdot \hat{x}) - \frac{\partial v^s}{\partial |y|}(y) \exp(-i\kappa y \cdot \hat{x}) \right] ds(y) \\ &= \int_{\partial B} \left[v^s(y) \frac{\partial}{\partial |y|} (\exp(-i\kappa y \cdot \hat{x}) + u^s(y, -\hat{x})) \right. \\ &\qquad \left. - \frac{\partial v^s}{\partial |y|}(y) (\exp(-i\kappa y \cdot \hat{x}) + u^s(y, -\hat{x})) \right] ds(y) \\ &= -\int_{\partial B} \left[v^0(y) \frac{\partial}{\partial |y|} u(y, -\hat{x}) - \frac{\partial v^0}{\partial |y|}(y) u(y, -\hat{x}) \right] ds(y) \\ &= -\kappa^2 \int_B m(y) v^0(y) u(y, -\hat{x})\, dy. \end{aligned} \tag{3.5}$$

From the reciprocity theorem [3, Thm. 8.8], (3.4), and (3.5) we now see that if U^s_∞ is the far field pattern of U^s, then

$$\begin{aligned}
U^s_\infty(\hat{x}) &= \lim_{N\to\infty} \int_\Omega g_N(d)u_\infty(\hat{x}, d)\, ds(d) \\
&= \lim_{N\to\infty} \int_\Omega g_N(d)u_\infty(-d, -\hat{x})\, ds(d) \\
&= -\frac{\kappa^2}{4\pi} \lim_{N\to\infty} \int_\Omega g_N(d) \int_B \exp(i\kappa d\cdot y)m(y)u(y, -\hat{x})\, dy\, ds(d) \\
&= -\frac{\kappa^2}{4\pi} \lim_{N\to\infty} \int_B v^0_N(y)m(y)u(y, -\hat{x})\, dy \\
&= -\frac{\kappa^2}{4\pi} \int_B v^0(y)m(y)u(y, -\hat{x})\, dy \\
&= \frac{1}{4\pi} \int_{\partial B} \left[v^s(y)\frac{\partial}{\partial |y|}\exp(-i\kappa y\cdot\hat{x}) - \frac{\partial v^s}{\partial |y|}(y)\exp(-i\kappa y\cdot \hat{x})\right] ds(y) \\
&= v^s_\infty(\hat{x}),
\end{aligned}$$

and hence by Rellich's lemma [2], [3], $U^s(x) = v^s(x)$ for $|x| > R$.

Finally, we compute for $R_1 > R$ that

$$\begin{aligned}
0 &= \int_{|y|=R_1} \left[(v^0+v^s)\frac{\partial}{\partial r}\overline{(v^0+v^s)} - \overline{(v^0+v^s)}\frac{\partial}{\partial r}(v^0+v^s)\right] ds \\
&= \int_{|y|=R_1} \left[v^s\frac{\partial}{\partial r}\overline{v^s} - \overline{v^s}\frac{\partial}{\partial r}v^s\right] ds + 2i \operatorname{Im}\left\{ \int_{|y|=R_1} \left[v^s\frac{\partial}{\partial r}\overline{v^0} - \overline{v^0}\frac{\partial}{\partial r}v^s\right] ds \right\} \\
&= (4\pi\kappa a^2)^2 \sum_{l=0}^{\infty}\sum_{k=-l}^{l} j_l(\kappa a)^2|\alpha_l^k|^2 W(h_l^{(1)}, h_l^{(2)})(\kappa R_1)\kappa R_1^2 \\
&= -2i\kappa(4\pi a^2)^2 \sum_{l=0}^{\infty}\sum_{k=-l}^{l} j_l(\kappa a)^2|\alpha_l^k|^2,
\end{aligned}$$

where W denotes the Wronskian, and hence $\alpha_l^k = 0$ for all $l \in \mathbb{N}_0$, $k = -l, \dots, l$. We can now conclude that $v_+ = 0$, and our proof is finished.

Now let $\tilde{u} \in C^2(\mathbb{R}^3\backslash\{0\})$ be a radiating solution of the Helmholtz equation with far field pattern $\tilde{u}_\infty$. If we set $m := 1 - n$ then, according to Theorem 4, for a given $\varepsilon > 0$ we can find the complex numbers a_l^k, $l = 0, \dots, N$, $k = -l, \dots, l$, and $w \in Y$ such that

$$\begin{aligned}
&\left\| w - \tilde{u} - 4\pi \sum_{l=0}^{N}\sum_{k=-l}^{l} a_l^k i^l [j_l(\kappa|\cdot|) + ia^2\kappa j_l(\kappa a)h_l^{(1)}(\kappa|\cdot|)]Y_l^k \right\|_{L^2(\partial B)} \\
&\quad + \left\| \frac{\partial}{\partial r}\left(w - \tilde{u} - 4\pi \sum_{l=0}^{N}\sum_{k=-l}^{l} a_l^k i^l [j_l(\kappa|\cdot|) + ia^2\kappa j_l(\kappa a)h_l^{(1)}(\kappa|\cdot|)]Y_l^k \right) \right\|_{L^2(\partial B)} \leqq \varepsilon.
\end{aligned} \tag{3.6}$$

We define

$$v^0(x) := \int_{\partial B} \left(\Phi(x, y) \frac{\partial w}{\partial |y|}(y) - \frac{\partial \Phi}{\partial |y|}(x, y) w(y) \right) ds(y), \qquad x \in B,$$

$$w^s(x) := -\int_B \Phi(x, y)(\Delta w(y) + \kappa^2 w(y))\, dy, \qquad x \in \mathbb{R}^3,$$

$$g_N := \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k Y_l^k,$$

$$v_N^0(x) := \int_\Omega \exp(i\kappa x \cdot d) g_N(d)\, ds(d)$$

$$= 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l j_l(\kappa |x|) Y_l^k(\hat{x}), \qquad x \in \mathbb{R}^3,$$

$$u_N^s(x) := \int_\Omega u^s(x, d) g_N(d)\, ds(d), \qquad x \in \mathbb{R}^3.$$

From Green's representation theorem we can conclude that $w = v^0 + w^s$. Again, applying Green's representation theorem to

$$w - \tilde{u} - 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l [j_l(\kappa |\cdot|) + ia^2 \kappa j_l(\kappa a) h_l^{(1)}(\kappa |\cdot|)] Y_l^k \tag{3.7}$$

in B and using (3.6), we have for $R_1 < R$ such that $\operatorname{supp}(m) \subset \{x \in \mathbb{R}^3 : |x| < R_1\}$ that

$$\sup_{|x| \leqq R_1} |v^0(x) - v_N^0(x)| \leqq C_1 \varepsilon,$$

and hence from the Lippmann-Schwinger equation

$$\sup_{x \in \mathbb{R}^3} |w^s(x) - u_N^s(x)| \leqq C_2 \varepsilon$$

for positive constants C_1, C_2. By applying Green's representation thereorem to the function (3.7) in $\mathbb{R}^3 \backslash \bar{B}$ and using the L^2 jump relations for surface potentials [12] we get

$$\left\| w^s - \tilde{u} - 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l ia^2 \kappa j_l(\kappa a) h_l^{(1)}(\kappa |\cdot|) Y_l^k \right\|_{L^2(\partial B)} \leqq C_3 \varepsilon$$

for a positive constant C_3. We can conclude that, for $R_2 > R$,

$$\sup_{|x| = R_2} \left| u_N^s(x) - \tilde{u}(x) - 4\pi \sum_{l=0}^{N} \sum_{k=-l}^{l} a_l^k i^l ia^2 \kappa j_l(\kappa a) h_l^{(1)}(\kappa |x|) Y_l^k(\hat{x}) \right| \leqq C_4 \varepsilon$$

for a positive constant C_4, and hence

$$\sup_{\hat{x} \in \Omega} \left| \int_\Omega u_\infty(\hat{x}, d) g_N(d)\, ds(d) - a^2 \int_\Omega \exp(-i\kappa a \hat{x} \cdot d)(\mathbf{R} g_N)(d)\, ds(d) - \tilde{u}_\infty(\hat{x}) \right| \leqq C_5 \varepsilon$$

for a positive constant C_5. Therefore, if v and u^0 are defined by (2.3) and u_∞ is the exact far field data, the infimum of the functional

$$M_2(g, w, m) := \|\mathbf{F} g - \tilde{u}_\infty\|_{L^2(\Omega)} + \|w - \tilde{u} - v - u^0\|_{L^2(\partial B)} + \left\| \frac{\partial}{\partial r}(w - \tilde{u} - v - u^0) \right\|_{L^2(\partial B)}$$

for $g \in L^2(\Omega)$, $m \in C_0^{0,\alpha}(B)$, $w \in Y$ is zero for all $\kappa > 0$, and the solution of the inverse scattering problem is the limit of an appropriate minimizing sequence. This completes the task of this section.

4. The inverse obstacle problem for electromagnetic waves. In this section we shall consider the inverse obstacle problem for electromagnetic waves in a manner analogous to that of § 2 for acoustic waves. We begin by defining some additional notation to that given in the Introduction. Let $a>0$ be such that $\{x\in\mathbb{R}^3\colon |x|\leqq a\}\subset D$, and

$$j_l(\kappa a)(j_l(\kappa a)+\kappa a j_l'(\kappa a))\neq 0$$

for all $l\in\mathbb{N}$, i.e., κ is not an eigenvalue for the interior Dirichlet problem for Maxwell's equations in $\{x\in\mathbb{R}^3\colon |x|<a\}$. We denote by Y_l^k, $l=0,1,2,\dots,k=-l,\dots,l$, an orthonormal basis of spherical harmonics on Ω and by

$$U_l^k(d):=\frac{1}{(l(l+1))^{1/2}}\operatorname{Grad} Y_l^k(d),\qquad V_l^k(d):=d\times U_l^k(d),\quad d\in\Omega,$$

$l\in\mathbb{N}$, $k=-l,\dots,l$, with Grad denoting the surface gradient, an orthonormal basis of $T^2(\Omega)$, the square integrable tangential fields on Ω (see [3]). For $g\in T^2(\Omega)$,

$$g=\sum_{l=1}^{\infty}\sum_{k=-l}^{l} a_l^k U_l^k+b_l^k V_l^k, \tag{4.1}$$

we define

$$\mathbf{R}g:=\sum_{l=1}^{\infty}\sum_{k=-l}^{l} i^l a_l^k V_l^k+ii^l b_l^k U_l^k$$

and note that $\mathbf{R}\colon T^2(\Omega)\to T^2(\Omega)$ is a unitary operator. Furthermore, we define

$$M_l^k(x):=\operatorname{curl}\{xj_l(\kappa|x|)Y_l^k(\hat{x})\},\qquad x\in\mathbb{R}^3,$$

and

$$N_l^k(x):=\operatorname{curl}\{xh_l^{(1)}(\kappa|x|)Y_l^k(\hat{x})\},\qquad x\in\mathbb{R}^3\backslash\{0\}.$$

We compute (use the asymptotic form of (6.71) and (6.26) in [3])

$$\int_\Omega \exp(i\kappa x\cdot d)U_l^k(d)\,ds(d)=\frac{4\pi i^l}{(l(l+1))^{1/2}i\kappa}\operatorname{curl} M_l^k(x)$$

and

$$\int_\Omega \exp(i\kappa x\cdot d)V_l^k(d)\,ds(d)=\frac{-4\pi i^l}{(l(l+1))^{1/2}}M_l^k(x),\qquad x\in\mathbb{R}^3,$$

and note the relations

$$\int_{|y|=R}\nu\times N_l^k\cdot\operatorname{curl}\overline{N_{\tilde{l}}^{\tilde{k}}}\,ds=l(l+1)R^2h_l^{(1)}(\kappa R)\frac{1}{R}(h_l^{(2)}(\kappa R)+\kappa Rh_l^{(2)\prime}(\kappa R))\delta_{l\tilde{l}}\delta_{k\tilde{k}},$$

$$\int_{|y|=R}\nu\times\operatorname{curl} N_l^k\cdot\operatorname{curlcurl}\overline{N_{\tilde{l}}^{\tilde{k}}}\,ds$$
$$=-\kappa^2R^2l(l+1)h_l^{(2)}(\kappa R)\frac{1}{R}(h_l^{(1)}(\kappa R)+\kappa Rh_l^{(1)\prime}(\kappa R))\delta_{l\tilde{l}}\delta_{k\tilde{k}},$$

$$\int_{|y|=R}\nu\times N_l^k\cdot\overline{N_{\tilde{l}}^{\tilde{k}}}\,ds=\int_{|y|=R}\nu\times\operatorname{curl} N_l^k\cdot\operatorname{curl}\overline{N_{\tilde{l}}^{\tilde{k}}}\,ds=0$$

for all l, $\tilde{l}\in\mathbb{N}$, $k=-l,\dots,l$, $\tilde{k}=-\tilde{l},\dots,\tilde{l}$. There are similar relations if N_l^k is replaced by M_l^k, in which case $h_l^{(1)}$ has to be replaced by j_l.

Analogous to the case of acoustic waves, we begin by defining the operator $\mathbf{F}$ for $g\in T^2(\Omega)$ by

$$\begin{aligned}(\mathbf{F}g)(\hat{x}):=&\int_\Omega E_\infty(\hat{x},d,g(d))\,ds(d)\\ &-\frac{i\kappa a^2}{4\pi}\hat{x}\times\int_\Omega(\mathbf{R}g)(d)\exp(-i\kappa a\hat{x}\cdot d)\,ds(d),\qquad \hat{x}\in\Omega,\end{aligned}\tag{4.2}$$

where $E_\infty(\hat{x}, d, p)$ is the electric far field pattern corresponding to the incident field (1.1) being scattered by the obstacle D.

We first show that the operator F is injective.

THEOREM 5. *Assume $\kappa > 0$. If $g \in T^2(\Omega)$ is a solution of* $\mathbf{F}g = 0$, *then* $g = 0$.

Proof. Let $g \in T^2(\Omega)$ be a solution of $\mathbf{F}g = 0$. We define

$$
\begin{aligned}
E^s_g(x) &:= \int_\Omega E^s(x, d, g(d))\, ds(d), \qquad x \in \bar{D}_e,\\
E^i_g(x) &:= \int_\Omega E^i(x, d, g(d))\, ds(d)\\
&= i\kappa \int_\Omega \exp(i\kappa x\cdot d) g(d)\, ds(d), \qquad x \in \mathbb{R}^3,\\
E^0_g(x) &:= a^2 \operatorname{curl} \int_\Omega \Phi(x, ad)(\mathbf{R}g)(d)\, ds(d), \qquad |x| > a.
\end{aligned}
\tag{4.3}
$$

Since $\mathbf{F}g = 0$ we have that $E^0_{g,\infty} = E_{g,\infty}$ and hence by Rellich's lemma [2], [3], $E^0_g(x) = E^s_g(x)$ for $|x| > R$, where R is such that $\bar{D} \subset \{x \in \mathbb{R}^3 \colon |x| < R\}$. Using Green's theorem we have

$$
\begin{aligned}
0 &= \int_{\partial D} [\nu \times (E^i_g + E^s_g)\cdot \operatorname{curl} \overline{(E^i_g + E^s_g)} - \nu \times \overline{(E^i_g + E^s_g)}\cdot \operatorname{curl}(E^i_g + E^s_g)]\, ds\\
&= \int_{|y|=R} [\nu \times (E^i_g + E^0_g)\cdot \operatorname{curl} \overline{(E^i_g + E^0_g)} - \nu \times \overline{(E^i_g + E^0_g)}\cdot \operatorname{curl}(E^i_g + E^0_g)]\, ds\\
&= \int_{|y|=R} [\nu \times E^0_g \cdot \operatorname{curl} \overline{E^0_g} - \nu \times \overline{E^0_g}\cdot \operatorname{curl} E^0_g]\, ds\\
&\quad + 2i \operatorname{Im}\left\{\int_{|y|=R} [\nu \times E^0_g \cdot \operatorname{curl} \overline{E^i_g} - \nu \times \overline{E^i_g}\cdot \operatorname{curl} E^0_g]\, ds\right\}.
\end{aligned}
\tag{4.4}
$$

We will now calculate the series expansions of E^0_g and E^s_g and put them into (4.4). Let g have the expansion (4.1). Then

$$
\begin{aligned}
E^i_g(x) &= i\kappa \sum_{l=1}^{\infty} \sum_{k=-l}^{l} a^k_l \int_\Omega \exp(i\kappa x\cdot d) U^k_l(d)\, ds(d) + b^k_l \int_\Omega \exp(i\kappa x\cdot d) V^k_l(d)\, ds(d)\\
&= 4\pi \sum_{l=1}^{\infty} \sum_{k=-l}^{l} i^l a^k_l \frac{1}{[l(l+1)]^{1/2}} \operatorname{curl} M^k_l(x)\\
&\quad - 4\pi i\kappa \sum_{l=1}^{\infty} \sum_{k=-l}^{l} i^l b^k_l \frac{1}{[l(l+1)]^{1/2}} M^k_l(x), \qquad x \in \mathbb{R}^3,
\end{aligned}
$$

$$
\begin{aligned}
E^0_g(x) &= a^2 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} \left\{ i^l a^k_l \operatorname{curl} \int_\Omega \Phi(x, ad) V^k_l(d)\, ds(d)\right.\\
&\qquad \left. + i^l b^k_l i \operatorname{curl} \int_\Omega \Phi(x, ad) U^k_l(d)\, ds(d)\right\}\\
&= a^2 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} i^l a^k_l \left(-i\kappa \frac{1}{[l(l+1)]^{1/2}}\right) j_l(\kappa a) \operatorname{curl} N^k_l(x)\\
&\quad + a^2 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} i^{(l+1)} b^k_l \left(i\kappa \frac{1}{[l(l+1)]^{1/2}}\right) \frac{1}{a} \{j_l(\kappa a) + \kappa a j_l'(\kappa a)\} N^k_l(x).
\end{aligned}
$$

Then we calculate for the first term in (4.4)

$$\int_{|y|=R} [\nu \times E_g^0 \cdot \operatorname{curl} \overline{E_g^0} - \nu \times \overline{E_g^0} \cdot \operatorname{curl} E_g^0]\, ds$$

$$= -2ia^4\kappa^3 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |a_l^k|^2 j_l(\kappa a)^2$$

$$-2ia^4\kappa \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |b_l^k|^2 \left[\frac{1}{a}(j_l(\kappa a) + \kappa a j_l'(\kappa a))\right]^2,$$

and for the second term in (4.4),

$$\int_{|y|=R} [\nu \times E_g^0 \cdot \operatorname{curl} \overline{E_g^i} - \nu \times \overline{E_g^i} \cdot \operatorname{curl} E_g^0]\, ds$$

$$= -4\pi\kappa^2 a^2 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |a_l^k|^2 j_l(\kappa a)$$

$$-4\pi a^2 \kappa \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |b_l^k|^2 \frac{1}{a}(j_l(\kappa a) + \kappa a j_l'(\kappa a)) \in \mathbb{R}.$$

Hence we conclude from (4.4) that $a_l^k = b_l^k = 0$ for all $l \in \mathbb{N}$, $k = -l, \dots, l$, i.e., $g = 0$. The theorem is now proved.

The next theorem is the analogous result to Theorem 2.

THEOREM 6. *Assume $\kappa > 0$. Then the linear space*

$$\operatorname{span}\{\nu \times (4\pi \operatorname{curl} M_l^k - ia^2\kappa j_l(\kappa a) \operatorname{curl} N_l^k),$$

$$\nu \times (4\pi M_l^k - ia\{j_l(\kappa a) + \kappa a j_l'(\kappa a)\} N_l^k),\, l \in \mathbb{N},\, k = -l, \dots, l\}$$

is dense in $T^2(\partial D)$.

Proof. We define for $x, y \in \mathbb{R}^3$ a matrix valued function $\chi(x, y)$ such that for $p \in \mathbb{C}^3$,

$$\chi(x, y)p = -4\pi\kappa \sum_{l=1}^{\infty} \frac{1}{l(l+1)} \frac{1}{a(j_l(\kappa a) + \kappa a j_l'(\kappa a))} \sum_{k=-l}^{l} M_l^k(y) \cdot p \operatorname{curl} \overline{M_l^k(x)}$$

(4.5)

$$-4\pi \sum_{l=1}^{\infty} \frac{1}{l(l+1)} \frac{1}{a^2 j_l(\kappa a)} \sum_{k=-l}^{l} \operatorname{curl} M_l^k(y) \cdot p \overline{M_l^k(x)}.$$

Similar arguments as in Theorem 2 show after some computation that the series converges uniformly along with its derivatives on compact subsets of $\mathbb{R}^3 \times \mathbb{R}^3$. Now let $g \in T^2(\partial D)$ be orthogonal to the linear space stated in the theorem. Define for $x \in \mathbb{R}^3 \backslash \partial D$,

$$E_g(x) := \operatorname{curl} \int_{\partial D} \Phi(x, y)\nu(y) \times \overline{g(y)}\, ds(y) + \int_{\partial D} \chi(x, y)(\nu(y) \times \overline{g(y)})\, ds(y).$$

For $r < a$ we have, using the vector addition theorem for the fundamental solution Φ [3, Thm. 6.27], that

$$\int_{\Omega} E_g(r\hat{x}) \cdot U_l^k(\hat{x})\, ds(\hat{x}) = \int_{\Omega} E_g(r\hat{x}) \cdot V_l^k(\hat{x})\, ds(\hat{x}) = 0$$

for all $l \in \mathbb{N}$, $k = -l, \dots, l$, and hence by unique continuation $E_g(x) = 0$ for $x \in D$. For R such that $\bar{D} \subset \{x \in \mathbb{R}^3 \colon |x| < R\}$ we again have from the vector addition theorem for

Φ that $E_g(R\hat{x}) = E_1(R\hat{x}) + E_2(R\hat{x})$ with

$$E_1(x) := \operatorname{curl} \int_{\partial D} \Phi(x, y)\nu(y) \times \overline{g(y)}\, ds(y)$$

$$= \sum_{l=1}^{\infty} \sum_{k=-l}^{l} \alpha_l^k N_l^k(x) + \beta_l^k \operatorname{curl} N_l^k(x),$$

$$E_2(x) := \int_{\partial D} \chi(x, y)(\nu(y) \times \overline{g(y)})\, ds(y)$$

$$= \sum_{l=1}^{\infty} \sum_{k=-l}^{l} -\frac{4\pi}{i\kappa a^2 j_l(\kappa a)} \alpha_l^k M_l^k(x) - \frac{4\pi\beta_l^k}{ia(j_l(\kappa a) + \kappa a j_l'(\kappa a))} \operatorname{curl} M_l^k(x),$$

where

$$\alpha_l^k = \frac{i\kappa}{l(l+1)} \int_{\partial D} (\nu(y) \times \overline{g(y)}) \cdot \operatorname{curl} \overline{M_l^k(y)}\, ds(y),$$

$$\beta_l^k = \frac{i\kappa}{l(l+1)} \int_{\partial D} (\nu(y) \times \overline{g(y)}) \cdot \overline{M_l^k(y)}\, ds(y).$$

By the continuity properties of vector potentials with L^2 densities (cf. [10], [11]) we have

$$0 = \int_{\partial D} \{\nu \times (E_1 + E_2) \cdot \operatorname{curl} \overline{(E_1 + E_2)} - \nu \times \overline{(E_1 + E_2)} \cdot \operatorname{curl} (E_1 + E_2)\}\, ds$$

$$= \int_{|y|=R} \{\nu \times E_1 \cdot \operatorname{curl} \overline{E_1} - \nu \times \overline{E_1} \cdot \operatorname{curl} E_1\}\, ds$$

$$+ 2i \operatorname{Im} \left\{ \int_{|y|=R} \{\nu \times E_1 \cdot \operatorname{curl} \overline{E_2} - \nu \times \overline{E_2} \cdot \operatorname{curl} E_1\}\, ds \right\}.$$

By using the series expansions for E_1 and E_2 we have

$$\int_{|y|=R} \{\nu \times E_1 \cdot \operatorname{curl} \overline{E_1} - \nu \times \overline{E_1} \cdot \operatorname{curl} E_1\}\, ds$$

$$= -\frac{2i}{\kappa} \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2 l(l+1) - 2i\kappa \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |\beta_l^k|^2 l(l+1)$$

and

$$\int_{|y|=R} \{\nu \times E_1 \cdot \operatorname{curl} \overline{E_2} - \nu \times \overline{E_2} \cdot \operatorname{curl} E_1\}\, ds$$

$$= -\sum_{l=1}^{\infty} \sum_{k=-l}^{l} |\alpha_l^k|^2 l(l+1) \frac{4\pi}{\kappa^2 a^2 j_l(\kappa a)}$$

$$- \sum_{l=1}^{\infty} \sum_{k=-l}^{l} |\beta_l^k|^2 l(l+1) \frac{4\pi\kappa}{a(j_l(\kappa a) + \kappa a j_l'(\kappa a))} \in \mathbb{R}.$$

Analogous to Theorem 2 we can now conclude that $E_g(x) = 0$ in D_e. We now have that $g = 0$ by the L^2 jump relations for vector potentials [10], [11], and the proof is finished.

Now let $\tilde{E}$, $\tilde{H}\in C^1(\mathbb{R}^3\backslash\{0\})$ be a radiating solution to Maxwell's equations with electric far field pattern $\tilde{E}_\infty$. For $\varepsilon>0$ we can choose constants a_l^k, $b_l^k\in\mathbb{C}$, $l=1,\dots,N$, $k=-l,\dots,l$ such that

$$\left\| \nu\times\left(\tilde{E}+\sum_{l=1}^{N}4\pi i^l\frac{1}{[l(l+1)]^{1/2}}\sum_{k=-l}^{l}a_l^k\left(\operatorname{curl} M_l^k-\frac{i\kappa a^2 j_l(\kappa a)}{4\pi}\operatorname{curl} N_l^k\right)\right.\right.$$
$$\left.\left.-\sum_{l=1}^{N}4\pi i^l\frac{i\kappa}{[l(l+1)]^{1/2}}\sum_{k=-l}^{l}b_l^k\left(M_l^k-\frac{ia(j_l(\kappa a)+\kappa a j_l'(\kappa a))}{4\pi}N_l^k\right)\right)\right\|_{L^2(\partial D)}\leqq\varepsilon.$$

Define

$$g_N:=\sum_{l=1}^{N}\sum_{k=-l}^{l}a_l^kU_l^k+b_l^kV_l^k,$$

$$(4.6)\qquad \begin{aligned} E^i_{g_N}(x)&:=i\kappa\int_\Omega \exp(i\kappa x\cdot d)g_N(d)\,ds(d)\\ &=\sum_{l=1}^{N}4\pi i^l\frac{1}{[l(l+1)]^{1/2}}\sum_{k=-l}^{l}a_l^k\operatorname{curl} M_l^k-i\kappa b_l^kM_l^k, \qquad x\in\mathbb{R}^3,\end{aligned}$$

$$E^s_{g_N}(x):=\int_\Omega E^s(x,d,g_N(d))\,ds(d), \qquad x\in\bar{D}_e,$$

and

$$E^0_{g_N}(x):=a^2\sum_{l=1}^{N}i^l\frac{1}{[l(l+1)]^{1/2}}$$
$$\cdot\sum_{k=-l}^{l}\left(-a_l^ki\kappa j_l(\kappa a)\operatorname{curl} N_l^k(x)-b_l^k\frac{\kappa}{a}(j_l(\kappa a)+\kappa a j_l'(\kappa a))N_l^k(x)\right), \qquad |x|>0.$$

Then, for $|x|>a$,

$$E^0_{g_N}(x)=a^2\operatorname{curl}\int_\Omega\Phi(x,ad)(\mathbf{R}g_N)(d)\,ds(d),$$

and hence

$$\|\nu\times(\tilde{E}-(E^s_{g_N}-E^0_{g_N}))\|_{L^2(\partial D)}\leqq\varepsilon$$

and

$$\sup_{\hat{x}\in\Omega}|(\mathbf{F}g_N)(\hat{x})-\tilde{E}_\infty(\hat{x})|\leqq C\varepsilon$$

for some positive constant C. We can now conclude that if E^i_g and E^0_g are defined by (4.3), E_∞ is the exact far field data and S is the set of C^2 surfaces bounding a domain D containing the origin such that D_e is connected, then the infimum of the functional

$$M_3(g,\Gamma):=\|\mathbf{F}g-\tilde{E}_\infty\|_{L^2(\Omega)}+\|\nu\times(\tilde{E}+E^i_g+E^0_g)\|_{L^2(\Gamma)}$$

for $g\in T^2(\Omega)$ and $\Gamma\in S$ is zero for all $\kappa>0$, and the solution of the inverse electromagnetic obstacle problem is the limit of an appropriate minimizing sequence.

5. The inverse inhomogeneous medium problem for electromagentic waves. In this section we assume that $n \in C^{1,\alpha}(\mathbb{R}^3)$ is a real valued function such that $n(x) \neq 0$ for all $x \in \mathbb{R}^3$ and $m := 1 - n$ has compact support. Again let $a > 0$ be such that $j_l(\kappa a)(j_l(\kappa a) + \kappa a j_l'(\kappa a)) \neq 0$ for all $l \in \mathbb{N}$. Let B, $\tilde{B}$, $\hat{B}$ be open balls with center at the origin such that

$$\operatorname{supp}(m) \subset \hat{B} \subset B \subset \tilde{B}$$

and $B := \{x \in \mathbb{R}^3 \colon |x| < R\}$, where $R > a$. We again define the operator $\mathbf{F}$ by (4.2), where $E_\infty(\hat{x}, p, d)$ is the electric far field pattern corresponding to the incident field (1.1) being scattered by the inhomogeneous medium. We first prove injectivity of the operator $\mathbf{F}$.

THEOREM 7. *Assume* $\kappa > 0$. *If* $g \in T^2(\Omega)$ *is a solution of* $\mathbf{F}g = 0$, *then* $g = 0$.

Proof. The proof is analogous to the proof of Theorem 5, where we use Gauss' theorem and (1.7) to arrive at

$$\int_{|y|=R} \{\nu \times (E_g^i + E_g^s) \cdot \operatorname{curl} \overline{(E_g^i + E_g^s)} - \nu \times \overline{(E_g^i + E_g^s)} \cdot \operatorname{curl}(E_g^i + E_g^s)\}\, ds = 0.$$

We will now prove the analogue of Theorem 4. We define

$$X := \operatorname{span}\{4\pi \operatorname{curl} M_l^k - ia^2\kappa j_l(\kappa a) \operatorname{curl} N_l^k,$$

$$4\pi M_l^k - ia\{j_l(\kappa a) + \kappa a j_l'(\kappa a)\} N_l^k,\ l \in \mathbb{N},\ k = -l, \dots, l\},$$

$$Y := \{(F, G) \in (C^1(\bar{B}))^2 \colon \operatorname{curl} F - i\kappa G = 0, \operatorname{curl} G + i\kappa n F = 0 \text{ in} B\},$$

and

$$W := \{(\nu \times (E - F), \nu \times \operatorname{curl}(E - F)) \colon E \in X, (F, G) \in Y\} \subset T^2(\partial B) \times T^2(\partial B).$$

THEOREM 8. *W is dense in* $T^2(\partial B) \times T^2(\partial B)$.

Proof. Suppose a, $b \in T^2(\partial B)$ satisfy

$$\int_{\partial B} \{\bar{a} \cdot [\nu \times (E - F)] + \bar{b} \cdot [\nu \times \operatorname{curl}(E - F)]\}\, ds = 0 \tag{5.1}$$

for all $E \in X$, $(F, G) \in Y$. We must show that $a = b = 0$. To this end, we define

$$U^s(x) := \operatorname{curl} \int_{\partial B} \nu(y) \times \bar{b}(y) \Phi(x, y)\, ds(y)$$

$$+ \frac{1}{\kappa^2} \operatorname{curlcurl} \int_{\partial B} \nu(y) \times \bar{a}(y) \Phi(x, y)\, ds(y), \qquad x \in \mathbb{R}^3 \backslash \partial B,$$

$$U^0(x) := \frac{1}{\kappa^2} \operatorname{curl} \int_{\partial B} \chi(x, y)(\nu(y) \times \bar{a}(y))\, ds(y)$$

$$+ \frac{1}{\kappa^2} \operatorname{curl} \int_{\partial B} \tilde{\chi}(x, y)(\nu(y) \times \bar{b}(y))\, ds(y),\ x \in \mathbb{R}^3,$$

and $U(x) := U^0(x) + U^s(x)$, $x \in \mathbb{R}^3 \backslash \partial B$, where χ is defined by (4.5) and $\tilde{\chi}(x, y) := \operatorname{curl}_y \chi(x, y)$ (the curl is applied to the row vectors of χ).

We compute for $r < R$ that

$$\int_\Omega U(r\hat{x}) \cdot U_l^k(\hat{x})\, ds(\hat{x}) = \int_\Omega U(r\hat{x}) \cdot V_l^k(\hat{x})\, ds(\hat{x}) = 0$$

for all $l \in \mathbb{N}$, $k = -l, \dots, l$, and hence $U = 0$ in B.

Defining $U_+ := U|_{\mathbb{R}^3\setminus\bar{B}}$ we have by the L^2 jump relations for vector potentials (see [10], [11]) that $\nu\times U_+ = \nu\times\bar{b}$ and $\nu\times\operatorname{curl} U_+ = \nu\times\bar{a}$ on ∂B in a L^2 sense. Setting $E=0$ in (5.1) and inserting these equalities into (5.1) now shows that

$$0=\int_{\partial B}\{\nu\times\operatorname{curl} U_+\cdot F+\nu\times U_+\cdot\operatorname{curl} F\}\,ds \tag{5.2}$$

for all $(F, G)\in Y$.

We now compute

$$\begin{aligned}U^0(x)&=4\pi\sum_{l=1}^{\infty}\sum_{k=-l}^{l} i^l\frac{1}{[l(l+1)]^{1/2}}\alpha_l^k\operatorname{curl} M_l^k(x)\\&\quad-4\pi\sum_{l=1}^{\infty}\sum_{k=-l}^{l} i\kappa i^l\frac{1}{[l(l+1)]^{1/2}}\beta_l^k M_l^k(x),\qquad x\in\mathbb{R}^3,\\U^s(x)&=-i\kappa a^2\sum_{l=1}^{\infty}\sum_{k=-l}^{l} i^l\frac{j_l(\kappa a)}{[l(l+1)]^{1/2}}\alpha_l^k\operatorname{curl} N_l^k(x)\\&\quad-\kappa a\sum_{l=1}^{\infty}\sum_{k=-l}^{l} i^l\frac{j_l(\kappa a)+\kappa a j_l'(\kappa a)}{[l(l+1)]^{1/2}}\beta_l^k N_l^k(x)\end{aligned}$$

for $|x|>R$, where

$$\begin{aligned}\alpha_l^k&=-\frac{(-i)^l}{[l(l+1)]^{1/2}a^2 j_l(\kappa a)}\left\{\frac{1}{\kappa^2}\int_{\partial B}\operatorname{curl}\overline{M_l^k(y)}\cdot(\nu(y)\times\overline{a(y)})\,ds(y)\right.\\&\qquad\left.+\int_{\partial B}\overline{M_l^k(y)}\cdot(\nu(y)\times\overline{b(y)})\,ds(y)\right\},\\\beta_l^k&=-\frac{(-i)^{(l+1)}}{[l(l+1)]^{1/2}a(j_l(\kappa a)+\kappa a j_l'(\kappa a))}\left\{\int_{\partial B}\overline{M_l^k(y)}\cdot(\nu(y)\times\overline{a(y)})\,ds(y)\right.\\&\qquad\left.+\int_{\partial B}\operatorname{curl}\overline{M_l^k(y)}\cdot(\nu(y)\times\overline{b(y)})\,ds(y)\right\}.\end{aligned}$$

If we now set

$$g_N:=\sum_{l=1}^{N}\sum_{k=-l}^{l}\alpha_l^k U_l^k+\beta_l^k V_l^k,$$

$$\begin{aligned}U_N^0(x)&:=\int_\Omega E^i(x,d,g_N(d))\,ds(d)\\&=i\kappa\int_\Omega \exp(i\kappa x\cdot d)g_N(d)\,ds(d),\qquad x\in\mathbb{R}^3,\end{aligned}\tag{5.3}$$

$$E_{g_N}^s(x)=\int_\Omega E^s(x,d,g_N(d))\,ds(d),\qquad x\in\mathbb{R}^3,$$

then from (4.6) U_N^0 converges uniformly together with its derivatives on compact subsets of $\mathbb{R}^3$ to U^0 as $N\to\infty$, and $E_{g_N}^s$ converges uniformly together with its derivatives on $\mathbb{R}^3$ to E_g^s as $N\to\infty$, where E_g^s denotes the scattered electric field corresponding to the incident field U^0.

We will now show that E_g^s and U^s coincide outside of a large sphere. We first note [3] that the vector Lippmann-Schwinger equation can be written as

$$E(x)=E^i(x)-\operatorname{curlcurl}\int_{\mathbb{R}^3}\Phi(x,y)m(y)E(y)\,dy,\qquad x\in\mathbb{R}^3\setminus\bar{B},$$

i.e.,

$$E^s(x) = -\text{curlcurl} \int_{\mathbb{R}^3} \Phi(x, y) m(y) E(y)\, dy, \qquad x \in \mathbb{R}^3 \backslash \bar{B},$$

is the scattered electric field corresponding to the incident field E^i. From this we deduce that for $\hat{x}$, $d \in \Omega$, $p \in \mathbb{R}^3$, the electric far field pattern E_∞ can be represented in terms of the total field E by

$$(5.4) \qquad E_\infty(\hat{x}, d, p) = -\frac{\kappa^2}{4\pi} \int_B \exp(-i\kappa \hat{x} \cdot y) m(y) (\hat{x} \times E(y, d, p)) \times \hat{x}\, dy.$$

Using the far field representation for the far field pattern U_∞ of U^s obtained from the representation theorem for U^s and (5.2), we compute, for arbitrary $p \in \mathbb{R}^3$, $\hat{x} \in \Omega$, that

$$\begin{aligned}
&p \cdot U_\infty(\hat{x}) \\
&= \frac{i\kappa}{4\pi} p \cdot \left\{ \hat{x} \times \int_{\partial B} \left(\nu(y) \times U^s(y) + \frac{1}{i\kappa} [\nu(y) \times \text{curl } U^s(y)] \times \hat{x} \right) \exp(-i\kappa \hat{x} \cdot y)\, ds(y) \right\} \\
&= \frac{1}{4\pi} \int_{\partial B} \Big(\nu(y) \times U^s(y) \cdot \text{curl}_y \{p \exp(-i\kappa \hat{x} \cdot y)\} \\
(5.5) \qquad &\qquad - \nu(y) \times \frac{i}{\kappa} \text{curl}_y\, \text{curl}_y \{p \exp(-i\kappa \hat{x} \cdot y)\} \cdot \frac{1}{i\kappa} \text{curl } U^s(y) \Big)\, ds(y) \\
&= \frac{1}{4\pi} \int_{\partial B} \left(\nu(y) \times U^s(y) \cdot H(y, -\hat{x}, p) - \nu(y) \times E(y, -\hat{x}; p) \cdot \frac{1}{i\kappa} \text{curl } U^s(y) \right) ds(y) \\
&= -\frac{1}{4\pi} \int_{\partial B} \left(\nu(y) \times U^0(y) \cdot H(y, -\hat{x}, p) - \nu(y) \times E(y, -\hat{x}, p) \cdot \frac{1}{i\kappa} \text{curl } U^0(y) \right) ds(y) \\
&= \frac{i\kappa}{4\pi} \int_B m(y) U^0(y) \cdot E(y, -\hat{x}, p)\, dy.
\end{aligned}$$

Hence, from (5.4) and (5.5) we arrive at

$$\begin{aligned}
p \cdot E_{g,\infty}(\hat{x}) &= \lim_{N \to \infty} p \cdot E_{g_N,\infty}(\hat{x}) \\
&= \lim_{N \to \infty} \int_\Omega p \cdot E_\infty(\hat{x}, d, g_N(d))\, ds(d) \\
&= \lim_{N \to \infty} \int_\Omega g_N(d) \cdot E_\infty(-d, -\hat{x}, p)\, ds(d) \\
&= \lim_{N \to \infty} \int_\Omega g_N(d) \\
&\qquad \cdot \int_B -\frac{\kappa^2}{4\pi} \exp(i\kappa d \cdot y) m(y) \{(d \times E(y, -\hat{x}, p)) \times d\}\, dy\, ds(d) \\
&= \lim_{N \to \infty} \int_B -\frac{\kappa^2}{4\pi} \frac{1}{i\kappa} \int_\Omega i\kappa g_N(d) \\
&\qquad \cdot \exp(i\kappa d \cdot y) m(y) \{(d \times E(y, -\hat{x}, p)) \times d\}\, ds(d)\, dy \\
&= \frac{i\kappa}{4\pi} \int_B m(y) E(y, -\hat{x}, p) \cdot U^0(y)\, dy \\
&= p \cdot U_\infty(\hat{x}),
\end{aligned}$$

i.e., $U_\infty(\hat{x}) = E_{g,\infty}(\hat{x})$ for all $\hat{x} \in \Omega$. We can now conclude by Rellich's lemma [2], [3], that $U^s(x) = E_g^s(x)$ for $|x|$ sufficiently large.

To complete the proof we will now show that $U = U^s + U^0$ vanishes identically, and hence by the L^2 jump relations for vector potentials $a = b = 0$. By Green's theorem we have for $R_1 > R$,

$$\begin{aligned} 0 &= \int_{|y|=R_1} \{\nu \times (U^0 + E_g^s) \cdot \operatorname{curl} \overline{(U^0 + E_g^s)} \\ &\qquad - \nu \times \overline{(U^0 + E_g^s)} \cdot \operatorname{curl} (U^0 + E_g^s)\}\, ds \\ &= \int_{|y|=R_1} \{\nu \times (U^0 + U^s) \cdot \operatorname{curl} \overline{(U^0 + U^s)} \\ &\qquad - \nu \times \overline{(U^0 + U^s)} \cdot \operatorname{curl} (U^0 + U^s)\}\, ds \\ &= \int_{|y|=R_1} \{\nu \times U^s \cdot \operatorname{curl} \overline{U^s} - \nu \times \overline{U^s} \cdot \operatorname{curl} U^s\}\, ds \\ &\quad + 2i \operatorname{Im}\left\{\int_{|y|=R_1} \{\nu \times U^s \cdot \operatorname{curl} \overline{U^0} - \nu \times \overline{U^0} \cdot \operatorname{curl} U^s\}\, ds\right\} \end{aligned} \tag{5.6}$$

and

$$\begin{aligned} &\int_{|y|=R_1} \{\nu \times U^s \cdot \operatorname{curl} \overline{U^s} - \nu \times \overline{U^s} \cdot \operatorname{curl} U^s\}\, ds \\ &\qquad = -2i\kappa^3 a^4 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} j_l(\kappa a)^2 |\alpha_l^k|^2 \\ &\qquad\quad - 2i\kappa a^2 \sum_{l=1}^{\infty} \sum_{k=-l}^{l} (j_l(\kappa a) + \kappa a j_l'(\kappa a))^2 |\beta_l^k|^2, \end{aligned} \tag{5.7}$$

$$\begin{aligned} &\int_{|y|=R_1} \{\nu \times U^s \cdot \operatorname{curl} \overline{U^0} - \nu \times \overline{U^0} \cdot \operatorname{curl} U^s\}\, ds \\ &\qquad = -\sum_{l=1}^{\infty} \sum_{k=-l}^{l} \kappa^2 a^2 j_l(\kappa a) 4\pi |\alpha_l^k|^2 \\ &\qquad\quad + \sum_{l=1}^{\infty} \sum_{k=-l}^{l} 4\pi\kappa a (j_l(\kappa a) + \kappa a j_l'(\kappa a)) |\beta_l^k|^2 \in \mathbb{R}. \end{aligned} \tag{5.8}$$

Inserting (5.7) and (5.8) into (5.6) we can now conclude that $\alpha_l^k = \beta_l^k = 0$ for all $l \in \mathbb{N}$, $k = -l, \ldots, l$, i.e., $U(x) = 0$ for $x \in \mathbb{R}^3 \backslash \bar{B}$, and hence $a = b = 0$ by the L^2 jump relations for vector potentials [10], [11]. This finishes the proof.

For $\tilde{E}, \tilde{H} \in C^1(\mathbb{R}^3 \backslash \{0\})$, a radiating solution to Maxwell's equations with electric far field pattern $\tilde{E}_\infty$, we now define the cost functional

$$\begin{aligned} M_4(g, F, G, m) := \|\mathrm{F}g - \tilde{E}_\infty\|_{L^2(\Omega)} + \|\hat{x} \times (F - \tilde{E} - E_g^i - E_g^0)\|_{L^2(\partial B)} \\ + \|\hat{x} \times \operatorname{curl} (F - \tilde{E} - E_g^i - E_g^0)\|_{L^2(\partial B)} \end{aligned}$$

for $m \in C_0^{1,\alpha}(\hat{B})$, $(F, G) \in Y$ and E_g^i, E_g^0 defined by (4.3). To prove that the infimum of the functional M_4 is zero for exact electric far field data E_∞ and all $\kappa > 0$ define

$m := 1-n$ and

$$g_N := \sum_{l=1}^{N} \sum_{k=-l}^{l} \alpha_l^k U_l^k + \beta_l^k V_l^k,$$

$$E_{g_N}^i(x) := i\kappa \int_\Omega \exp(i\kappa x\cdot d) g_N(d)\, ds(d), \qquad x \in \mathbb{R}^3,$$

$$E_{g_N}^s(x) := \int_\Omega E^s(x, d, g_N(d))\, ds(d), \qquad x \in \mathbb{R}^3,$$

$$U_N^s(x) := \sum_{l=1}^{N} \sum_{k=-l}^{l} \alpha_l^k i^l \frac{1}{[l(l+1)]^{1/2}} (-ia^2\kappa j_l(\kappa a)) \operatorname{curl} N_l^k(x)$$

$$+ \sum_{l=1}^{N} \sum_{k=-l}^{l} \beta_l^k i^l \frac{i\kappa}{[l(l+1)]^{1/2}} ia(j_l(\kappa a) + \kappa a j_l'(\kappa a)) N_l^k(x), \qquad x \in \mathbb{R}^3\backslash\{0\},$$

$$U_N^s(x) = a^2 \operatorname{curl} \int_\Omega (\mathbf{R}g_N)(d)\Phi(x, ad)\, ds(d), \qquad |x| > a.$$

Then, from (4.6) and Theorem 8, for a given $\varepsilon > 0$ we can find α_l^k, $\beta_l^k \in \mathbb{C}$, $l = 1, \dots, N$, $k = -l, \dots, l$, and $(F, G) \in Y$ such that

$$\|\hat{x} \times (F - \tilde{E} - E_{g_N}^i - U_N^s)\|_{L^2(\partial B)} + \|\hat{x} \times \operatorname{curl}(F - \tilde{E} - E_{g_N}^i - U_N^s)\|_{L^2(\partial B)} \leqq \varepsilon.$$

Defining

$$F^i(x) := -\operatorname{curl} \int_{\partial B} \nu(y) \times F(y)\Phi(x, y)\, ds(y) + \operatorname{grad} \int_{\partial B} \nu(y) \cdot F(y)\Phi(x, y)\, ds(y)$$

$$- \int_{\partial B} \nu(y) \times \operatorname{curl} F(y)\Phi(x, y)\, ds(y), \qquad x \in B,$$

$$F^s(x) := \operatorname{grad} \int_B \frac{1}{n} \operatorname{grad} n(y) F(y)\Phi(x, y)\, dy - \kappa^2 \int_B m(y)F(y)\Phi(x, y)\, dy, \qquad x \in \mathbb{R}^3,$$

we have from the Stratton-Chu formula [3, Thm. 6.1] that $F(x) = F^i(x) + F^s(x)$ in B. Since $\operatorname{div} F^i = 0$ in B $(F^i, (1/i\kappa) \operatorname{curl} F^i)$ is a solution to the Maxwell equations in B. On the other hand,

$$F^s(x) = -\operatorname{curlcurl} \int_B m(y)F(y)\Phi(x, y)\, dy, \qquad x \in \mathbb{R}^3\backslash\bar{B},$$

is the scattered part of the inhomogeneous medium problem solution corresponding to the incident field F^i. Using the representation theorems [2], [3], we now arrive at

$$\|F^i - E_{g_N}^i\|_{\infty,\tilde{B}} \leqq C_1\varepsilon, \tag{5.9}$$

$$\|\hat{x} \times (F^s - \tilde{E} - U_N^s)\|_{L^2(\partial\tilde{B})} \leqq C_2\varepsilon \tag{5.10}$$

for positive constants C_1, C_2. We, therefore, conclude from (5.9) and the vector Lippmann-Schwinger equation that

$$\|F^s - E_{g_N}^s\|_{\infty,\partial\tilde{B}} \leqq C_3\varepsilon, \tag{5.11}$$

and from (5.10) and (5.11),

$$\|E_{g_N,\infty} - \tilde{E}_\infty - U_{N,\infty}\|_{\infty,\Omega} \leqq C_4\varepsilon,$$

i.e.,

$$\|\mathbf{F}g_N - \tilde{E}_\infty\|_{\infty,\Omega} \leqq C_4\varepsilon$$

for positive constants C_3, C_4. It now follows that the infimum of M_4 is zero for all $\kappa > 0$, and the solution of the inverse electromagnetic inhomogeneous medium problem is the limit of an appropriate minimizing sequence.

DECOMPOSITION OF THE DISPLACEMENT VECTOR FIELD AND DECAY RATES IN LINEAR THERMOELASTICITY*

JAIME E. MUÑOZ RIVERA†

Abstract. The linear thermoelastic system is studied in the whole space $\mathbb{R}^n$, and it is proved that the displacement vector field can be decomposed into two parts, one that conserves its energy, and the other that decays uniformly to zero as time goes to infinity. The method used here is based on a new Lyapunov function.

Key words. linear thermoelasticity, energy decay rates

AMS(MOS) subject classifications. 35B40, 35M05

1. Introduction. In this work we will study the classical linear thermoelastic system for homogeneous isotropic materials. The system in question consists of n hyperbolic equations of motion coupled with the parabolic equation of energy. A first work about the asymptotic behavior of the solution of the thermoelastic system is given by Dafermos [3], who proved that they are asymptotically stable when time goes to infinity; in that work regularity and uniqueness results are also proved. Here we will study the decomposition of the displacement vector field and the asymptotic behaviour of the energy associated with each part of this decomposition. The question of partition of the energy was first investigated by Lax and Phillips [7] for a classical solution of the wave equation. There the authors established that the kinetic and the potential energies become asymptotically equal as time goes to infinity. Another work in this direction is that of Duffin [5], who proved that the equipartition is consummated in a finite time provided the initial data have compact support. Corresponding results for abstract hyperbolic equations have been obtained by Goldstein [6], Costa and Strauss [2], among others. It seems that a first work about the partition of the energy in the framework of isotropic linear thermoelasticity (system with dissipation) was given by Dassios and Grillakis [4]. There the authors studied how the energy associated with the longitudinal and thermal wave is divided into kinetic, strain, and thermal energy in the case $\Omega=\mathbb{R}^3$. They concluded that the rate of decay of the energy stored in the longitudinal and thermal wave is affected by the symmetric of the initial data, that is, if v_0, v_1, v_θ are the lowest nonvanishing moments of the initial displacement, initial velocity and initial temperature, respectively, then all of the three parts of the energy associated with the longitudinal and thermal wave decay to zero as $t\rightarrow+\infty$ at the rate $t^{-(m+3/2)}$, where $m=\min\{v_0+1, v_1, v_\theta\}$, and whenever the initial data have continuous fifth derivatives with compact support in $\mathbb{R}^3$, while the transverse wave conserves its energy.

For bounded anisotropic and inhomogeneous bodies Chirita [1] proved that the mean thermal energy tends to zero as time goes to infinity and that the asymptotic equipartition occurs between the Cesàro means of the kinetic and strain energies, which implies that the thermal effects do not influence explicitly the asymptotic equipartition of the mean kinetic and strain energies.

In special situations, that is, when the restoring force is proportional to the vector velocity of the displacement vector field, Pereira and Menzala [10] proved that in a

† National Laboratory for Scientific Computation (LNCC-CNPQ), Rua Lauro Muller 455, Botafogo, CEP. 22290, Rio de Janeiro, RJ, Brazil, and IMUFR, P.O. Box 68530, Rio de Janeiro, RJ, Brazil.

bounded, isotropic and inhomogeneous body the kinetic, strain, and thermal energy approach zero exponentially as $t \to +\infty$.

In this work we will study the decomposition of the displacement vector field in $\mathbb{R}^n$ $(n>1)$ into two parts. One of them, the solenoidal part, that is, the nondissipative component that conserves its energy and the other, the dissipative component (irrotational) part for $n=3$), decays to zero when t approaches infinity. We will prove (§ 3) that both the displacement vector field in the dissipative direction and the deviation of the temperature decay as $t^{-n/2}$ when t tends to infinity. For $n=1$, the system is totally dissipative in the sense that the total energy decays to zero as $t \to 0$ as fast as $t^{-1/2}$. Moreover, we will find a parameter m for which the rate of decay increases with increasing values of m. More precisely we shall prove that the rate of decay of the energy increases as $t^{-(m+n/2)}$ if each component of the initial data is the m-derivative of a function that belongs to $L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n)$.

Through this result we improve the work of Dassios and Grillakis [4], which proved that such a decomposition exists for the displacement vector field in $\mathbb{R}^3$. The method we use here is different and simpler than that used in [4].

The outline of this paper is as follows: In § 2 we consider the Cauchy problem associated to the thermoelastic system. The existence of global solution under more general assumptions is shown in [3], but for the sake of completeness we briefly indicate the proof in the framework of semigroups of operators. In § 3 we study the asymptotic properties of the density function for the thermoelastic system with initial data in the dissipative direction by using a method based on the construction of a suitable Lyapunov's functional. Finally, in § 4 we study the decomposition of the displacement vector field when the initial data is taken in the domain of the operator associated with elliptic part of the thermoelastic system.

2. Existence, uniqueness, and regularity. In the absence of body forces and heat sources the linear thermoelastic system of a homogeneous and isotropic body occupies all space $\mathbb{R}^n$ is given by

$$\mathbf{u}_{tt} - (a^2 - b^2)\Delta \mathbf{u} - b^2 \nabla\{\operatorname{div} \mathbf{u}\} + \alpha \nabla \theta = 0 \quad \text{in } \mathbb{R}^n_x \times \mathbb{R}_t, \tag{2.1}$$

$$\theta_t - k\Delta\theta + \beta \operatorname{div} \mathbf{u}_t = 0 \quad \text{in } \mathbb{R}^n_x \times \mathbb{R}_t, \tag{2.2}$$

$$\mathbf{u}(x,0) = \mathbf{u}_0(x), \mathbf{u}_t(x,0) = \mathbf{u}_1(x), \theta(x,0) = \theta_0(x) \quad \text{in } \mathbb{R}^n_x, \tag{2.3}$$

where $a^2 = (\mu+\lambda)/\rho$, $b^2 = \lambda/\rho$, $\alpha = \gamma/\rho$, $\beta = \nu/k$. We are denoting by μ and λ the Lamé constants; by ρ the mass density, k is defined by $k = \lambda_0/c_\varepsilon$, where λ_0 is the thermal conductivity and c_ε is the specific heat. Finally ν is the thermal diffusivity.

Let's denote by $\mathbf{A}$ the operator on $[L^2(\mathbb{R}^n)]^n$ and by A the operator on $L^2(\mathbb{R}^n)$ with domain $D(\mathbf{A}) = [H^2(\mathbb{R}^n)]^n$, $D(A) = H^2(\mathbb{R}^n)$, respectively, such that

$$\mathbf{A}w = -(a^2 - b^2)\Delta w - b^2 \nabla \operatorname{div} \mathbf{w},$$

$$Aw = -k\Delta w,$$

where Δ, ∇, div stands for the Laplacian, the gradient and the divergence operator, $\mathbf{w}$ is a vector $\mathbf{w} = (w_1, \dots, w_n)$, and for $\Delta\mathbf{w}$ we are denoting $\Delta\mathbf{w} = (\Delta w_1, \dots, \Delta w_n)$.

It is well known that $\mathbf{A}$ and A are positive selfadjoint operators in the Hilbert space $[L^2(\mathbb{R}^n)]^n$ and $L^2(\mathbb{R}^n)$, respectively.

Let us define the space $\mathcal{H}$ as

$$\mathcal{H} = [H^1(\mathbb{R}^n)]^n \times [L^2(\mathbb{R}^n)]^n \times L^2(\mathbb{R}^n)$$

with norm given by

$$\|V\|_{\mathscr{H}}^2=\int_{\mathbb{R}^n}|\mathbf{u}|^2\,d\mathbf{x}+(a^2-b^2)\sum_{i=1}^{n}\int_{\mathbb{R}^n}|\nabla u_i|^2\,d\mathbf{x}+b^2\int_{\mathbb{R}^n}|\operatorname{div} u|^2\,d\mathbf{x}$$
$$+\int_{\mathbb{R}^n}|\mathbf{v}|^2\,d\mathbf{x}+\int_{\mathbb{R}^n}|\theta|^2\,d\mathbf{x}$$

for any $V=(\mathbf{u},\mathbf{v},\theta)^\tau$, where $\mathbf{u}=(u_1,\ldots,u_n)$ and $\mathbf{v}=(v_1,\ldots,v_n)$. We introduce the operator

$$\mathscr{A}\colon D(\mathscr{A})\subseteq\mathscr{H}\to\mathscr{H}$$
$$\mathscr{A}=-\begin{pmatrix}0 & -I & 0\\ \mathbf{A} & 0 & \alpha B\\ 0 & \beta B^* & A\end{pmatrix}$$

with domain

$$D(\mathscr{A})=[H^2(\mathbb{R}^n)]^n\times[H^1(\mathbb{R}^n)]^n\times H^2(\mathbb{R}^n),$$

where B is defined as $Bw=\nabla w$ with domain $D(B)=H^1(\mathbb{R}^n)$.

The existence result is stated in the following theorem.

THEOREM 2.1 (Existence and uniqueness). *Let* $(\mathbf{u}_0,\mathbf{u}_1,\theta_0)^\tau\in D(\mathscr{A})$ *and* $T>0$, *then for any* $\alpha,\beta\in\mathbb{R}$, $k>0$, *there exist only one strong solution of system* (2.1)-(2.3) *satisfying*

$$\mathbf{u}\in\mathbf{C}(0,T;[H^2(\mathbb{R}^n)]^n)\cap\mathbf{C}^1(0,T;[H^1(\mathbb{R}^n)]^n)\cap\mathbf{C}^2(0,T;[L^2(\mathbb{R}^n)]^n)$$
$$\theta\in\mathbf{C}(0,T;H^2(\mathbb{R}^n))\cap\mathbf{C}^1(0,T;L^2(\mathbb{R}^n)).$$

Proof. System (2.1)-(2.3) is equivalent to

$$\frac{d}{dt}U=\mathscr{A}U,\quad U(0)=U_0,\quad U\in D(\mathscr{A}),$$

where

$$U=\begin{pmatrix}\mathbf{u}\\ \mathbf{u}_t\\ \theta\end{pmatrix},\quad U_0=\begin{pmatrix}\mathbf{u}_0\\ \mathbf{u}_1\\ \theta_0\end{pmatrix}.$$

In order to establish the existence result it is sufficient to show that $\mathscr{A}$ is the infinitesimal generator of a strongly continuous semigroup. To prove this, let's define the operator $\mathscr{B}=-[1+(\alpha-\beta)^2]I+\mathscr{A}$, with $D(\mathscr{B})=D(\mathscr{A})$, where I denotes the identity operator in $\mathscr{H}$. First we prove that $\mathscr{B}$ is dissipative. Let us take $V=(\mathbf{u},v,\theta)^\tau$ in $D(\mathscr{A})$; then it follows that

$$(\mathscr{A}V,V)_{\mathscr{H}}=-\int_{\mathbb{R}^n}\mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}+(\alpha-\beta)\int_{\mathbb{R}^n}\mathbf{v}\cdot\nabla\theta\,d\mathbf{x}-k\int_{\mathbb{R}^n}|\nabla\theta|^2\,d\mathbf{x}$$
$$\leqq\frac{1}{2}[1+(\alpha-\beta)^2]\int_{\mathbb{R}^n}|\mathbf{v}|^2\,d\mathbf{x}+\frac{1}{2}\int_{\mathbb{R}^n}|\mathbf{u}|\,d\mathbf{x}-\frac{k}{2}\int_{\mathbb{R}^n}|\nabla\theta|^2\,d\mathbf{x}$$
$$\leqq\frac{1}{2}[1+(\alpha-\beta)^2]\|V\|_{\mathscr{H}}^2-\frac{k}{2}\int_{\mathbb{R}^n}|\nabla\theta|^2\,d\mathbf{x}.$$

Consequently, $\mathscr{B}$ satisfies

$$(\mathscr{B}V,V)_{\mathscr{H}}\leqq-\frac{1}{2}[1+(\alpha-\beta)^2]\|V\|_{\mathscr{H}}^2-\frac{k}{2}\int_{\mathbb{R}^n}|\nabla\theta|^2\,d\mathbf{x}.$$

Our next goal is to prove that $\operatorname{Im}[I-\mathscr{B}]=\mathscr{H}$, that is, for all $\mathbf{F}=(F_1, F_2, F_3)\in\mathscr{H}$ we can find $V=(u, v, \theta)\in D(\mathscr{A})=D(I-\mathscr{B})$ satisfying

$$\mu I+\mathscr{A}V=\mathbf{F};$$

here $\mu=2+(\alpha+\beta)^2$. In fact, by taking the Fourier transform to system and solving the result system we conclude that $\mathscr{B}$ is maximal monotone. Finally, since $D(\mathscr{B})$ is dense in $\mathscr{H}$, using Lummer-Phillips's theorem we conclude that $\mathscr{B}$ is the infinitesimal generator of a strongly continuous semigroup; so is $\mathscr{A}$. The required conclusion then follows. □

In order to obtain the decay of the energy associated to system (2.1)-(2.3), when the initial data is taken in $D(\mathscr{A})$, we will use the regularity result of system (2.1)-(2.3) and the density of $D(\mathscr{A}^3)$ in $D(\mathscr{A})$. The regularity and the density property are well known, but to assist the reader we briefly indicate the following remarks.

Remark 2.1. Let us define $D(\mathscr{A}^2)$ and $D(\mathscr{A}^3)$ as

$$D(\mathscr{A}^2)=\{V\in D(\mathscr{A});\ \mathscr{A}V\in D(\mathscr{A})\},$$

$$D(\mathscr{A}^3)=\{V\in D(\mathscr{A}^2);\ \mathscr{A}V\in D(\mathscr{A}^2)\}.$$

It is easy to see that whenever $U_0=(u_0, u_1, \theta_0)^\tau\in D(\mathscr{A}^3)$, we have

$$U=(u, u_t, \theta)^\tau\in\mathbf{C}^2(0, T; D(\mathscr{A}))$$

or, in particular,

$$u\in\mathbf{C}^3(0, T; H^2(\mathbb{R}^n)), \qquad \theta\in\mathbf{C}^2(0, T; H^2(\mathbb{R}^n)).$$

3. Asymptotic behaviour. The total energy in linear thermoelasticity for $\mathbb{R}^n$ in general does not decay to zero. In this section we will prove that the energy associated with the thermoelastic system decays to zero at the rate of $t^{-n/2}$ when time goes to infinity, provided the initial data is in the dissipative direction. Moreover, we will prove that the rate of decay increases if each component of the initial data is the m-derivative of a function that belongs to $L^2(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)$; when this is the case we will have that the total energy decays as $t^{-(m+n/2)}$ when $t\to+\infty$.

Let $\alpha=(\alpha_1,\dots,\alpha_n)\in\mathbb{N}^n$ and $x=(x_1,\dots,x_n)\in\mathbb{R}^n$; then we shall denote by $|\alpha|$, $\mathbf{x}^\alpha$, and ∂^α the following expressions:

$$|\alpha|=\sum_{i=1}^n\alpha_i,$$

$$\mathbf{x}^\alpha=x_1^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n},$$

$$\partial^\alpha=\left(\frac{\partial}{\partial x_1}\right)^{\alpha_1}\left(\frac{\partial}{\partial x_2}\right)^{\alpha_2}\cdots\left(\frac{\partial}{\partial x_n}\right)^{\alpha_n}.$$

Let us consider the following lemmas.

LEMMA 3.1. *Let v be a function in $L^2(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)$ for which there exist $f\in L^2(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)$ satisfying*

$$v=\partial^\alpha f, \quad \textit{where } |\alpha|=m.$$

Then we have

$$|\hat{v}(\xi)|\leqq[2\pi]^{-n/2}|\xi^\alpha|\int_{\mathbb{R}^n}|f(\mathbf{x})|\,d\mathbf{x}\quad\forall\xi\in\mathbb{R}^n, \tag{3.1}$$

where $\hat{v}$ denotes the usual Fourier transform of v.

Proof. Integration by parts of $\hat{v}$ implies that

$$\hat{v}(\xi)=[2\pi]^{-n/2}(-i)^{|\alpha|}|\xi^{\alpha}|\int_{\mathbb{R}^n} f(x)\, e^{ix\xi}\, dx, \tag{3.2}$$

where $i=\sqrt{-1}$. Since $f\in L^2(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)$, (3.2) yields (3.1). □

LEMMA 3.2. *If r is a positive real number, then we have*

$$\int_0^1 \eta^{2m}\, e^{-r\eta^2}\, d\eta \leqq (2m)!\sqrt{n/2}\,r^{-m-1/2}, \quad m=0,1,\dots. \tag{3.3}$$

Proof. Let us denote by I_m the integral in the left-hand side of (3.3). Straightforward calculations give the inequality

$$I_0=\int_0^1 e^{-r\eta^2}\, d\eta \leqq \sqrt{n/2}\,r^{-1/2}. \tag{3.4}$$

Integration by parts of I_m with $m>0$ implies

$$I_m \leqq (2r)^{-1}(2m-1)\int_0^1 \eta^{2m-2}\, e^{-r\eta^2}\, d\eta \leqq (2r)^{-1}(2m-1)I_{m-1}.$$

Consequently,

$$I_m \leqq r^{-m}(2m)!I_0.$$

Substitution of (3.4) into the last inequality gives (3.3). □

LEMMA 3.3. *If the initial data $\mathbf{u}_0$ and $\mathbf{u}_1$ are such that*

$$D_iu_o^j(\mathbf{x})=D_ju_o^i(\mathbf{x}), \qquad D_iu_1^j(\mathbf{x})=D_ju_1^i(\mathbf{x}) \quad \textit{for } i\neq j,$$

where $\mathbf{u}_0=(u_0^1,\dots,u_0^n)$, $\mathbf{u}_1=(u_1^1,\dots,u_1^n)$ then the solution $\mathbf{u}$ of system (2.1)-(2.3) also satisfies

$$D_iu^j(\mathbf{x},t)=D_ju^i(\mathbf{x},t), \qquad D_iu_t^j(\mathbf{x},t)=D_ju_t^i(\mathbf{x},t) \quad \textit{in } \mathbb{R}_x^n\times\mathbb{R}_t.$$

Proof. From system (2.1)-(2.3), it is easy to see that

$$C_{ij}\mathbf{u}=D_iu^j-D_ju^i$$

satisfies

$$\{C_{ij}\mathbf{u}\}_{tt}-\Delta\{C_{ij}\mathbf{u}\}=0,$$

$$C_{ij}\mathbf{u}(x,0)=0, \qquad C_{ij}\mathbf{u}_t(x,0)=0.$$

By the uniqueness of the solution the result follows. □

LEMMA 3.4. *Suppose that*

$$D_iF_j(\mathbf{x},t)=D_jF_i(\mathbf{x},t)$$

holds for all $i\neq j$. Then we have

$$\left|\sum_{i=1}^n \xi_i\hat{F}_i\right|^2=|\xi|^2|\hat{F}|^2,$$

where $\xi=(\xi_1,\dots,\xi_n)$.

Proof. Consider the Fourier transform of identity (i). Then we have

$$\xi_i\hat{F}_j=\xi_j\hat{F}_i \quad \text{for all } i\neq j.$$

Multiply the equality below by $\xi_j \bar{\hat{F}}_i$, and adding for $i \neq j$, we have

$$\sum_{\substack{i,j=1\\ i\neq j}}^{n} \operatorname{Re} \xi_i\xi_j \hat{F}_i \bar{\hat{F}}_j = \sum_{\substack{i,j=1\\ i\neq j}}^{n} \xi_j^2 |\hat{F}_i|^2.$$

Using this identity we conclude that

$$\left|\sum_{i=1}^{n} \xi_i \hat{F}_i\right|^2 = \sum_{i=1}^{n} \xi_i^2 |\hat{F}_i|^2 + \sum_{\substack{i,j=1\\ i\neq j}}^{n} \operatorname{Re} \xi_i\xi_j \hat{F}_i \bar{\hat{F}}_j$$

$$= \sum_{i=1}^{n} \xi_i^2 |\hat{F}_i|^2 + \sum_{\substack{i,j=1\\ i\neq j}}^{n} \xi_j^2 |\hat{F}_i|^2 = \left\{\sum_{i=1}^{n} \xi_i^2\right\}\left\{\sum_{i=1}^{n} |\hat{F}_i|^2\right\}$$

which proves Lemma 3.4. □

Let us define the energy associated to system (2.1)-(2.3) as

$$E_1(t) = \frac{1}{2}\int_{\mathbb{R}^n} \left[|\mathbf{u}_t|^2 + (a^2 - b^2)\sum_{i=1}^{n} |\nabla u_i|^2 + b^2 |\operatorname{div} \mathbf{u}|^2 + \frac{\alpha}{\beta}|\theta|^2\right] dx.$$

Applying Plancherel's identity to the energy function, we have

$$E_1(t) = \frac{1}{2}\int_{\mathbb{R}^n} \left[|\hat{\mathbf{u}}_t|^2 + (a^2 - b^2)\sum_{i=1}^{n} |\xi|^2 |\hat{u}_i|^2 + b^2 \left|\sum_{i=1}^{n} \xi_i \hat{u}_i\right|^2 + \frac{\alpha}{\beta}|\hat{\theta}|^2\right] d\xi,$$

where $\xi = (\xi_1, \ldots, \xi_n)$. Let us denote by $E(\xi, t)$ the energy density given by

$$E(\xi, t) = \frac{1}{2}|\hat{\mathbf{u}}_t|^2 + (a^2 - b^2)\sum_{i=1}^{n} |\xi|^2 |\hat{u}_i|^2 + b^2 \left|\sum_{i=1}^{n} \xi_i \hat{u}_i\right|^2 + \frac{\alpha}{\beta}|\hat{\theta}|^2.$$

Let us introduce the following functions:

$$E_2(t) = \frac{1}{2}\int_{\mathbb{R}^n} |\xi|^2 E(\xi, t)\, d\xi,$$

$$F(\xi, t) = \operatorname{sign}(\alpha) \operatorname{Re}\left\{i\theta(\xi, t)\sum_{i=1}^{n} \xi_i (\bar{\hat{u}}_i)_t\right\},$$

$$G(\xi, t) = \operatorname{sign}(\alpha) |\xi|^2 \operatorname{Re}\{\hat{\mathrm{u}}_t \cdot \bar{\hat{\mathbf{u}}}\}.$$

We will prove the asymptotic behaviour of the energy by studying the asymptotic properties of the total energy density $E(\xi, t)$. By taking the Fourier transform of the system (2.1)-(2.3), we have

$$\hat{\mathbf{u}}_{tt} + (a^2 - b^2)|\xi|^2 \hat{\mathbf{u}} + b^2\left(\sum_{i=1}^{n} \xi_i \hat{u}_i\right)\xi - \alpha i \xi \hat{\theta} = 0 \quad \text{in } \mathbb{R}^n_\xi \times \mathbb{R}_t, \tag{3.5}$$

$$\hat{\theta}_t + k|\xi|^2 \hat{\theta} - \beta i \sum_{i=1}^{n} \xi_i \{\hat{u}_i\}_t = 0 \quad \text{in } \mathbb{R}^n_\xi \times \mathbb{R}_t. \tag{3.6}$$

Under these conditions we have the following lemma.

LEMMA 3.5. *With the same hypotheses of Lemma* 3.3 *we have that the derivatives of the functions E, F, and G satisfy the following inequalities*:

$$\frac{d}{dt} E(\xi, t) = -k\frac{\alpha}{\beta}|\xi|^2 |\hat{\theta}|^2, \tag{3.7}$$

$$\begin{aligned}\frac{d}{dt}F(\xi, t) &\leqq -\beta|\xi|^2|\hat{\mathbf{u}}_t|^2 + k|\xi|^2|\hat{\theta}|\{|\xi|\,|\hat{\mathbf{u}}_t|\} \\ &\quad + (a^2-b^2)|\xi|\,|\hat{\theta}|\{|\xi|^2|\hat{\mathbf{u}}|\}\end{aligned} \tag{3.8}$$

$$\frac{d}{dt}G(\xi, t) \leqq |\xi|^2|\hat{\mathbf{u}}_t|^2 - a^2|\xi|^4|\hat{\mathbf{u}}|^2 + \alpha\{|\xi|\,|\hat{\theta}|\}\{|\xi|^2|\hat{\mathbf{u}}|\}. \tag{3.9}$$

Proof. Without loss of generality we can suppose that $\alpha > 0$. By Remark 2.1 the functions E, F, G are differentiable. Multiplying (3.5) and (3.6) by $\bar{\hat{\mathbf{u}}}_t$ and $(\alpha/\beta)\hat{\theta}$, respectively, and adding the real part of the product results we obtain (3.7). Let us find the derivative of the function F:

$$\frac{d}{dt}F(\xi, t) = \operatorname{Re}\left\{i\theta_t \sum_{i=1}^{n} \xi_i(\bar{\hat{u}}_i)_t\right\} + \operatorname{Re}\left\{i\theta \sum_{i=1}^{n} \xi_i(\bar{\hat{u}}_i)_{tt}\right\}.$$

From (3.5) and (3.6) it follows that

$$\begin{aligned}\frac{d}{dt}F(\xi, t) &= -\operatorname{Re}\left\{ik|\xi|^2\hat{\theta} \sum_{i=1}^{n} \xi_i(\bar{\hat{u}}_i)_t\right\} - \beta\left|\sum_{i=1}^{n} \xi_i\{\hat{u}_i\}_t\right|^2 \\ &\quad -\operatorname{Re}\left\{i|\xi|^2(a^2-b^2)\theta(\xi, t) \sum_{i=1}^{n} \xi_i(\bar{\hat{u}}_i)\right\} - \alpha|\xi|^2|\hat{\theta}|^2.\end{aligned}$$

From Lemma 3.4 we conclude that the above identity yields (3.8). Finally, let's calculate the derivative of the function G; then

$$\begin{aligned}\frac{d}{dt}G(\xi, t) &= |\xi|^2|\hat{\mathbf{u}}_t|^2 + |\xi|^2\hat{\mathbf{u}}_{tt}\cdot\bar{\hat{\mathbf{u}}} \\ &= |\xi|^2|\hat{\mathbf{u}}_t|^2 - |\xi|^4(a^2-b^2)|\hat{\mathbf{u}}|^2 - b^2|\xi|^2\left|\left(\sum_{i=1}^{n} \xi_i\hat{u}_i\right)\right|^2 \\ &\quad + \alpha i|\xi|^2 \sum_{i=1}^{n} \xi_i\bar{\hat{u}}_i\hat{\theta}.\end{aligned}$$

From Lemma 3.4 we conclude (3.9). The proof is now complete. □

Let us briefly mention a technical difficulty arising in the proof of the main result of this work. It is necessary to consider separately the asymptotic behaviour of the energy density in the ball $B(0,1) = \{\xi \in \mathbb{R}^n;\ |\xi| < 1\}$ and in its complementary set. We proceed first to estimate the decay of the energy density function in $\mathbb{R}^n \backslash B(0,1)$, and in this case we will prove that it approaches zero exponentially when $t \to \infty$. Then we prove that the density energy function decays algebraically in $B(0,1)$ when t approaches infinity.

THEOREM 3.1. *Let* $(\mathbf{u}_0, \mathbf{u}_1, \theta_0) \in D(\mathscr{A})$ *such that*

$$\mathbf{u}_0, \mathbf{u}_1 \in [L^1(\mathbb{R}^n)]^n, \qquad \theta_0 \in L^1(\mathbb{R}^n) \quad \textit{and}$$

$$D_i u_o^j(x) = D_j u_o^i(x), \qquad D_i u_1^j(x) = D_j u_1^i(x) \quad \textit{for all } i \neq j,$$

where $\mathbf{u}_0 = (u_0^1, \ldots, u_0^n)$, $\mathbf{u}_1 = (u_1^1, \ldots, u_1^n)$, *and* $\alpha\beta > 0$. *Then there exist a positive constant* C *such that the solution of system* (2.1)–(2.3) *satisfies*

$$E_1(t) + E_2(t) \leqq C\{E_1(0) + E_2(0)\}t^{-n/2} \quad \textit{when } t \to +\infty. \tag{i}$$

Moreover, if there exist functions $f_0^k, f_1^k, g_0 \in L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n)$ *such that*

$$\partial^{\alpha_k} f_0^k = u_0^k, \qquad \partial^{\beta_k} f_1^k = u_1^k \quad \textit{and} \quad \partial^{\alpha} g_0 = \theta_0 \qquad k = 1, \ldots, n. \tag{3.10}$$

Then we have

(ii) $$E_1(t)+E_2(t) \leqq C\{E_1(0)+E_2(O)\}t^{-m-n/2} \quad \textit{when } t \to +\infty,$$

where $m=\min\{|\alpha_k|+1, |\beta_k|, |\alpha|;\ k=1,\dots,n\}$.

Proof. Without loss of generality we can suppose that $\alpha, \beta>0$. Multiplying by $|\xi|^2$ relation (3.7) we obtain

$$\frac{d}{dt}|\xi|^2E(\xi,t)=-k\frac{\alpha}{\beta}|\xi|^4|\hat{\theta}|^2. \tag{3.11}$$

On the other hand from relation (3.8) it follows that

$$\begin{aligned}\frac{d}{dt}F(\xi,t) \leqq -\frac{1}{2}\beta|\xi|^2|\hat{\mathbf{u}}_t|^2+\frac{k^2}{2\beta}|\xi|^4|\hat{\theta}|^2+4\frac{a^2-b^2}{\beta a^2}|\xi|^2|\hat{\theta}|^2 \\ +\beta\frac{a^2}{16}|\xi|^4|\hat{\mathbf{u}}|^2,\end{aligned} \tag{3.12}$$

and from (3.9) we obtain

$$\frac{d}{dt}G(\xi,t) \leqq |\xi|^2|\hat{\mathbf{u}}_t|^2-\frac{1}{2}a^2|\xi|^4|\hat{\mathbf{u}}|^2+\frac{1}{2}\left(\frac{\alpha^2}{a^2}\right)|\xi|^2|\hat{\theta}|^2. \tag{3.13}$$

From (3.12) and (3.13) we conclude that

$$\begin{aligned}\frac{d}{dt}\left\{F(\xi,t)+\frac{\beta}{4}G(\xi,t)\right\} \leqq -\frac{\beta}{4}|\xi|^2|\hat{\mathbf{u}}_t|^2-\frac{\beta a^2}{16}|\xi|^4|\hat{\mathbf{u}}|^2 \\ +\frac{k^2}{2\beta}|\xi|^4|\hat{\theta}|^2+\left\{4\frac{a^2-b^2}{\beta a^2}+\frac{\beta\alpha^2}{8a^2}\right\}|\xi|^2|\hat{\theta}|^2.\end{aligned} \tag{3.14}$$

For convenience we introduce the function $H(\xi,t)$ defined as

$$H(\xi,t)=F(\xi,t)+\frac{\beta}{4}G(\xi,t)+N(1+|\xi|^2)E(\xi,t),$$

where N is a positive real number satisfying

$$N>\max\left\{\frac{k^2}{2\beta}; 4\frac{a^2-b^2}{\beta a^2}+\frac{\beta\alpha^2}{8a^2}\right\}+c_0,$$

where $c_0>0$ is chosen such that

$$H(\xi,t) \geqq (1+|\xi|^2)E(\xi,t). \tag{3.15}$$

From (3.7), (3.11), (3.14), and the definition of H and N we conclude that

$$\frac{d}{dt}H(\xi,t) \leqq -\frac{\beta}{4}|\xi|^2|\hat{\mathbf{u}}_t|^2-\frac{\beta a^2}{16}|\xi|^4-c_0(1+|\xi|^2)E(\xi,t).$$

From there it follows that there exists a positive constant c_1 satisfying

$$\frac{d}{dt}H(\xi,t) \leqq -c_1|\xi|^2E(\xi,t) \quad \forall \xi \in \mathbb{R}^n. \tag{3.16}$$

In order to prove part (i) we will consider two cases. First we will suppose that $|\xi| \geqq 1$. In this case the following inequalities are valid:

$$G(\xi, t) = \operatorname{Re}\{|\xi|^2 \hat{\mathbf{u}}_t \bar{\hat{\mathbf{u}}}\} \leqq \tfrac{1}{2}\{|\xi|^2|\hat{\mathbf{u}}_t|^2 + |\xi|^4|\hat{\mathbf{u}}|^2\} \quad \forall|\xi| \geqq 1,$$

$$F(\xi, t) = \operatorname{Re}\{i\xi\hat{\theta}\bar{\hat{\mathbf{u}}}_t\} \leqq \tfrac{1}{2}\{|\xi|^2|\hat{\mathbf{u}}_t|^2 + |\xi|^2|\hat{\theta}|^2\} \quad \forall|\xi| \geqq 1.$$

Thus, there exists a positive constant c_2 such that

$$H(\xi, t) \geqq c_2|\xi|^2 E(\xi, t), \tag{3.17}$$

which, together with (3.16), yields

$$\frac{d}{dt} H(\xi, t) + \gamma H(\xi, t) \leqq 0,$$

where $\gamma = c_1/c_2$. The last inequality, together with relation (3.15), implies that the energy density function satisfies

$$(1+|\xi|^2)E(\xi, t) \leqq H(\xi, t) \leqq H(\xi, 0)e^{-\gamma t} \quad |\xi| \geqq 1. \tag{3.18}$$

Integrating (3.18) in $\mathbb{R}^n \backslash B(0, 1)$ implies that

$$\int_{|\xi| \geqq 1} (1+|\xi|^2)E(\xi, t)\, d\xi \leqq c_3 E_2(0)e^{-\gamma t}. \tag{3.19}$$

Finally we will show that the asymptotic form of the density energy integral for the case $|\xi| \leqq 1$ decays algebraically, and the rate of decay increases with the increasing values of m defined in Theorem 3.1. First notice that the inequality

$$H(\xi, t) \leqq c_4 E(\xi, t) \quad \forall|\xi| \leqq 1 \tag{3.20}$$

holds. From (3.16) and (3.20) we obtain for $\gamma' = c_1/c_4$ that

$$\frac{d}{dt} H(\xi, t) + \gamma'|\xi|^2 H(\xi, t) \leqq 0,$$

which, together with (3.15), implies that

$$(1+|\xi|^2)E(\xi, t) \leqq H(\xi, t) \leqq H(\xi, 0)e^{-\gamma'|\xi|^2 t}. \tag{3.21}$$

Integrating over $B(0, 1)$ the last relation and applying Lemma 3.2, we conclude the validity of the inequality

$$\int_{|\xi| \leqq 1} (1+|\xi|^2)E(\xi, t)\, d\xi \leqq 2c_5 \int_{|\xi| \leqq 1} e^{-\gamma|\xi|^2 t}\, d\xi \leqq c_6 t^{-n/2} \tag{3.22}$$

because $H(\xi, 0)$ is bounded in $B(0, 1)$ since $\mathbf{u}_0, \mathbf{u}_1 \in [L^1(\mathbb{R}^n)]^n$, and $\theta_0 \in L^1(\mathbb{R}^n)$. From (3.19) and (3.22) part (i) follows. Finally in order to prove part (ii), let us suppose that there exist functions $f_0^k, f_1^k, g_0^k \in L^2(\mathbb{R}^n) \cap L^1(\mathbb{R}^n)$ satisfying (3.10). Then it follows that there exists a positive constant C satisfying

$$H(\xi, 0) \leqq C\{|\hat{\mathbf{u}}_1(\xi)|^2 + |\xi|^2|\hat{\mathbf{u}}_0(\xi)|^2 + |\hat{\theta}(\xi)|^2\}.$$

From 3.10 and Lemma 3.1 we have that

$$H(\xi, 0) \leqq C \sum_{k=1}^{n} |\xi^{\alpha_k}| \int_{\mathbb{R}^n} |f_0^k|\, d\xi + |\xi|^2 \sum_{k=1}^{n} |\xi^{\beta_k}| \int_{\mathbb{R}^n} |f_1^k|\, d\xi$$
$$+ \sum_{k=1}^{n} |\xi^{\alpha}| \int_{\mathbb{R}^n} |\mathscr{E}^k|\, d\xi,$$

from where it follows that there exists a positive constant C_2 such that

$$H(\xi,0)\leqq C_2\left[\sum_{k=1}^{n}|\xi^{\alpha_k}|+|\xi|^2\sum_{k=1}^{n}|\xi^{\beta_k}|+\sum_{k=1}^{n}|\xi^{\alpha}|\right],$$

where

$$C_2=\max\left\{\int_{\mathbb{R}^n}|f_0^k|\,d\xi,\int_{\mathbb{R}^n}|f_1^k|\,d\xi,\int_{\mathbb{R}^n}|g^k|\,d\xi;\,k=1,\dots,n\right\}.$$

Since

$$\begin{aligned}&\int_{|\xi\gamma\leqq 1}(1+|\xi|^2)E(\xi,t)\,d\xi\\&\leqq\int_{|\xi|\leqq 1}H(\xi,0)e^{-\gamma|\xi|^2t}\\&\leqq C_2\int_{|\xi|\leqq 1}\left[\sum_{k=1}^{n}|\xi^{\alpha_k}|+|\xi|^2\sum_{k=1}^{n}|\xi^{\beta_k}|+\sum_{k=1}^{n}|\xi^{\alpha}|\right]e^{-\gamma|\xi|^2t}\,d\xi\end{aligned}$$

by iterated integration and applying Lemma 3.2 we conclude that

$$\int_{|\xi|\leqq 1}(1+|\xi|^2)E(\xi,t)\,d\xi\leqq c_6t^{-m-n/2}\tag{3.23}$$

for some positive constant c_6. The conclusion of the theorem follows immediately from (3.19), (3.23). □

For the one-dimensional case there is no restriction on the initial data, that is, the system is totally dissipative in the sense that the total energy decays, as indicated in the following corollary.

COROLLARY 3.1. *Let* $(u_0,u_1,\theta_0)\in D(\mathscr{A})$ *such that* $u_0,u_1,\theta_0\in L^1(\mathbb{R}^1)$ *and* $\alpha\beta>0$. *Then there exist a positive constant C such that the solution of system* (1.1)-(1.3) *satisfies*

$$\text{(i)}\qquad E_1(t)+E_2(t)\leqq C\{E_1(0)+E_2(0)\}\frac{1}{\sqrt{t}}\quad\textit{when } t\to+\infty.$$

Moreover, if there exist functions $f_0,f_1,g_0\in L^2(\mathbb{R}^n)\cap L^1(\mathbb{R}^n)$ *such that*

$$\frac{d^r}{dx^r}f_0=u_0,\qquad\frac{d^s}{dx^s}f_1=u_1\quad\textit{and}\quad\frac{d^l}{dx^l}g_0=\theta_0,$$

then we have

$$\text{(ii)}\qquad E_1(t)+E_2(t)\leqq C\{E_1(0)+E_2(0)\}\left(\frac{1}{t}\right)^{m+1/2}\quad\textit{when } t\to+\infty,$$

where $m=\min\{r,s,l\}$.

Proof. For this case the energy of the system is given by

$$E_1(t)=\frac{1}{2}\int_{\mathbb{R}}|u_t(x,t)|^2+a^2|u_x(x,t)|^2+\frac{\alpha}{\beta}|\theta(x,t)|^2\,dx,$$

and the energy density is given by

$$E(\eta,t)=\frac{1}{2}\left\{|\hat{u}_t(\eta,t)|^2+a^2\eta^2|\hat{u}(\eta,t)|^2+\frac{\alpha}{\beta}|\hat{\theta}(\eta,t)|^2\right\}.$$

The auxiliary functions are

$$F(\eta, t) = \text{sign}\,(\alpha)\ \text{Re}\,\{i\eta\hat{\theta}(\eta, t)\bar{\hat{u}}_t(\eta, t)\},$$
$$G(\eta, t) = \text{sign}\,(\alpha)\ \text{Re}\,\{\eta^2\hat{u}_t(\eta, t)\bar{\hat{u}}(\eta, t)\}.$$

Finding the derivative of F and G gives

$$\frac{d}{dt}E(\eta, t) = -\frac{\alpha}{\beta}k^2\eta^2|\hat{\theta}|^2,$$

$$\frac{d}{dt}F(\eta, t) \leqq -\beta\eta^2|\hat{u}_t|^2 + k\eta^2|\hat{\theta}|\{\eta|\hat{u}_t|\} + a^2\eta|\hat{\theta}|\{\eta^2|\hat{u}|\},$$

$$\frac{d}{dt}G(\eta, t) \leqq |\hat{u}_t|^2 - a^2\eta^2|\hat{u}|^2 + \alpha\eta|\hat{\theta}|\,|\hat{u}|\}.$$

From here on we can repeat the proof as in Theorem 2.1. □

4. Decomposition of the displacement field. In this section we will study the decomposition of the displacement vector field in $\mathbb{R}^n$. We will prove that it can be decomposed into two parts, one of them the solenoidal part that conserves its energy and the other, a gradient (the irrotational part for $n = 3$) that decays as indicated in Theorem 3.1. In order to assist the reader we will show the conditions for which such decomposition holds for any vector field of $\mathbb{R}^n$.

Remark 4.1. Let us denote by $U(x)$ the function defined by

$$U(\mathbf{x}) = \frac{1}{2\pi}\ln|\mathbf{x}| \quad \text{if } n = 2,$$

$$U(\mathbf{x}) = -\frac{1}{(n-2)\sigma_n|\mathbf{x}|^{n-2}} \quad \text{if } n > 2,$$

where σ_n is the area of the unitary ball of $\mathbb{R}^n$. The solution of the problem

$$\Delta u = f \quad \text{in } \mathbb{R}^n \tag{4.1}$$

is given by

$$u(\mathbf{x}) = \int_{\mathbb{R}^n} U(\mathbf{x} - \xi)f(\xi)\,d\xi,$$

whenever f is a continuous function with compact support in $\mathbb{R}^n$. First note that for any v, and $\mathbf{C}^2$-function with compact support, the following identity is valid:

$$v(x) = \int_{\mathbb{R}^n} U(\mathbf{x} - \xi)\Delta v(\xi)\,d\xi \quad \text{in } \mathbb{R}^n.$$

Now we will prove that u satisfies (4.1). In fact, let ϕ be a $C^2(\mathbb{R}^n)$ function with compact support in $\mathbb{R}^n$. Then we have that

$$\begin{aligned}\int_{\mathbb{R}^n} \Delta u(\mathbf{x})\phi(\mathbf{x})\,d\mathbf{x} &= \int_{\mathbb{R}^n} \Delta\phi(\mathbf{x}) \int_{\mathbb{R}^n} U(\mathbf{x} - \xi)f(\xi)\,d\xi\,d\mathbf{x} \\ &\int_{\mathbb{R}^n} f(\xi) \int_{\mathbb{R}^n} U(\mathbf{x} - \xi)\Delta\phi(\mathbf{x})\,d\mathbf{x}\,d\xi \\ &= \int_{\mathbb{R}^n} f(\xi)\phi(\xi)\,d\xi \quad \forall\phi.\end{aligned}$$

By DuBois Raymond's lemma our assertion follows.

In the following lemma we will establish some regularity properties of the solution of (4.1).

LEMMA 4.1. *Let f be a function satisfying*

$$f \in C(\mathbb{R}^n)\ o(f) = o(|\mathbf{x}|^{-\theta}) \quad \text{when } |\mathbf{x}| \to +\infty;\ \theta > 2 \quad \text{for } n = 2.$$

Then there exists a continuous function u with $\partial^\alpha u \in H^1(\mathbb{R}^n)$ for $|\alpha| = 1$, satisfying (4.1). *Finally if*

$$f \in L^1(\mathbb{R}^n) \cap L^p(\mathbb{R}^n) \quad \text{for } n \geqq 3,$$

where $p \in \max\{q, q'\}$, $q > n/n-2$ and $(1/q)+(1/q') = 1$. Then there exists a solution u of (4.1) *satisfying $u \in L^q(\mathbb{R}^n)$; $\partial^\alpha u \in H^1(\mathbb{R}^n)|\alpha| = 1$.*

Proof. Let us denote by f_ν the regularization of f, that is, the convolution

$$f_\nu = \rho_\nu * f,$$

where ρ_ν is the mollifier, taken such that $\rho_\nu(-x) = \rho_\nu(x)$, $\int_{\mathbb{R}^n} \rho_\nu(\xi)\, d\xi = 1$, and $\rho_\nu(x) = 0$ if $|x| \leqq 1/\nu$. It is well known that f_ν converge to f in L^r for any $r \geqq 1$. Then the sequence $(u_\nu)_{\nu \in \mathbb{N}}$ given by

$$u_\nu(\mathbf{x}) = \int_{\mathbb{R}^n} U(\mathbf{x} - \xi) f_\nu(\xi)\, d\xi$$

satisfies the equation

$$\Delta u_\nu = f_\nu. \tag{4.2}$$

First we will consider the case $n = 2$. For this case the derivative of the function u_ν satisfies

$$\left|\frac{\partial}{\partial x_i} u_\nu(\mathbf{x})\right| \leqq \frac{1}{2\pi} \int_{\mathbb{R}^n} |\mathbf{x} - \xi|^{-1} |f_\nu(\xi)|\, d\xi.$$

If we denote by χ and χ_c the characteristic function on the open ball $B(0, 1)$ and its complementary, respectively, we have that

$$\int_{\mathbb{R}^n} |\mathbf{x} - \xi|^{-1} |f_\nu(\xi)|\, d\xi = [\chi|\xi|^{-1}] * |f_\nu| + [\chi_c|\xi|^{-1}] * |f_\nu|.$$

By the hypotheses on f we conclude that $f \in L^r(\mathbb{R}^n)$ for all $r \geqq 1$. From the fact that $\theta > 2$, there exist $p > 2$ such that $\theta - (1 - (2/p)) > 2$. Since $\chi|\xi|^{-1} \in L^1(\mathbb{R}^n)$ and $\chi_c|\xi|^{-1} \in L^p(\mathbb{R}^n)$, we have that

$$[\chi|\xi|^{-1}] * |f_\nu| \in L^p(\mathbb{R}^n) \quad \text{and} \quad [\chi_c|\xi|^{-1}] * |f_\nu| \in L^p(\mathbb{R}^n).$$

Therefore,

$$\frac{\partial}{\partial x_i} u_\nu(x) \in L^p(\mathbb{R}^n)$$

and

$$\int_{\mathbb{R}^n} \left|\frac{\partial}{\partial x_i} u_\nu(x)\right|^p d\mathbf{x} \leqq \frac{1}{2\pi} \int_{\mathbb{R}^n} \chi|\xi|^{-1}\, d\mathbf{x} \int_{\mathbb{R}^n} |f_\nu|^p\, d\mathbf{x} + \frac{1}{2\pi} \int_{\mathbb{R}^n} \chi_c|\xi|^p\, d\mathbf{x} \int_{\mathbb{R}^n} |f_\nu|\, d\mathbf{x}.$$

With the same reasoning we can conclude that

$$\int_{\mathbb{R}^n} \left|\frac{\partial}{\partial x_i} u_\nu(\mathbf{x}) - \frac{\partial}{\partial x_i} u_\mu(\mathbf{x})\right|^p d\mathbf{x}$$

$$\leqq \frac{1}{2\pi} \int_{\mathbb{R}^n} \chi|\xi|^{-1}\, d\mathbf{x} \int_{\mathbb{R}^n} |f_\nu - f_\mu|^p\, d\mathbf{x} + \frac{1}{2\pi} \int_{\mathbb{R}^n} \chi_c|\xi|^{-p}\, d\mathbf{x} \int_{\mathbb{R}^n} |f_\nu - f_\mu|\, d\mathbf{x},$$

hence $(\partial u_\nu/\partial x_i)_{\nu\in\mathbb{N}}$ is a Cauchy sequence $L^p(\mathbb{R}^n)$ then bounded. Since

$$u_\nu(\xi)-u_\nu(\mathbf{x})=\int_0^1\frac{d}{dt}u_\nu(t\xi-(1-t)\mathbf{x})\,dt$$

it follows that

$$u_\nu(\xi)-u_\nu(\mathbf{x})=\int_0^1\nabla u_\nu(t\xi+(1-t)\mathbf{x})\cdot[\xi-\mathbf{x}]\,dt.$$

Integrating over the ball B of center $\mathbf{x}$ and radius $\frac{1}{2}|\mathbf{x}-\mathbf{y}|$,

$$\begin{aligned}\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{x})\right| &\leqq\int_B\int_0^1|\nabla u_\nu(t\xi+(1-t)\mathbf{x})\cdot[\xi-\mathbf{x}]|\,dt\,d\xi\\ &\leqq|\mathbf{x}-\mathbf{y}|\int_B\int_0^1|\nabla u_\nu(t(\xi-\mathbf{x})+\mathbf{x})|\,dt\,d\xi.\end{aligned}$$

Making a change of variable we obtain that

$$\left|{}_B\, u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{x})\right|\leqq|\mathbf{x}-\mathbf{y}|\int_0^1t^{-2}\int_{tD}|\nabla u_\nu(\xi)|\,d\xi\,dt, \tag{4.3}$$

where D is disk of center at the origin of coordinates and radius equal to $t|\mathbf{x}-\mathbf{y}|$. Since $t\leqq 1$, we then have that the $tD\subseteq D$, from which it follows that

$$\int_{tD}|\nabla u_\nu(\xi)|\,d\xi\leqq\pi^{1/p'}|\mathbf{x}-\mathbf{y}|^{2/p'}t^{2/p'}\left(\int_D|\nabla u_\nu(\xi)|^p\,d\xi\right)^{1/p}.$$

The last inequality and (4.3) yield

$$\begin{aligned}&\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{x})\right|\\ &\quad\leqq\pi^{1/p'}|\mathbf{x}-\mathbf{y}|^{1+2/p'}\int_0^1t^{-2+2/p'}\left(\int_D|\nabla u_\nu(\xi)|^p\,d\xi\right)^{1/p}dt,\end{aligned}$$

from where it follows that

$$\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{x})\right|\leqq\pi^{1/p'}\frac{p}{p-2}|\mathbf{x}-\mathbf{y}|^{1+2/p'}\left(\int_D|\nabla u_\nu(\xi)|^p\,d\xi\right)^{1/p}.$$

In the same way we obtain

$$\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{y})\right|\leqq\pi^{1/p'}\frac{p}{p-2}|\mathbf{x}-\mathbf{y}|^{1+2/p'}\left(\int_D|\nabla u_\nu(\xi)|^p\,d\xi\right)^{1/p}.$$

By the triangle inequality we obtain

$$\begin{aligned}&\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2|u_\nu(\mathbf{x})-u_\nu(\mathbf{y})|\\ &\quad\leqq\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{x})\right|+\left|\int_B u_\nu(\xi)\,d\xi-\frac{\pi}{4}|\mathbf{x}-\mathbf{y}|^2u_\nu(\mathbf{y})\right|,\end{aligned}$$

from where it follows that

$$|u_\nu(\mathbf{x})-u_\nu(\mathbf{y})|\leqq 8\frac{p}{p-2}|\mathbf{x}-\mathbf{y}|^{1-2/p}\left(\int_D|\nabla u_\nu(\xi)|^p\,d\xi\right)^{1/p}. \tag{4.4}$$

With the same reasoning (for $\mathbf{y}=0$ and $u_\nu - u_\mu$ on the place of u_ν) we can prove that

$$|u_\nu(\mathbf{x}) - u_\mu(\mathbf{x})| \leqq |u_\nu(0) - u_\mu(0)| \\ + 8\frac{p}{p-2}|\mathbf{x}|^{1-2/p}\left(\int_D |\nabla u_\nu(\xi) - \nabla u_\mu(\xi)|^p \, d\xi\right)^{1/p}.$$

Then in order to prove that $(u_\nu)_{\nu\in\mathbb{N}}$ is a Cauchy sequence we only need to prove that the numerical sequence $(u_\nu(0))_{\nu\in\mathbb{N}}$ is convergent, but this follows immediately by the definition of u_ν and by the hypotheses on f. Then we conclude that there exists a continuous function u such that

$$u_\nu \to u \quad \text{uniformly on bounded sets of } \mathbb{R}^2,$$

$$\partial^\alpha u_\nu \to \partial^\alpha u \quad \text{strongly in } L^p(\mathbb{R}^2)\ p>2\ |\alpha|=1.$$

From (4.4) we also conclude that

$$|u(\mathbf{x})| \leqq |u(0)| + 8\frac{p}{p-2}|\mathbf{x}|^{1-2/p}\left(\int_D |\partial(\xi)|^p \, d\xi\right)^{1/p}.$$

Since $o(f) = o(|\mathbf{x}|^{-\theta})$, then $o(f_\nu) = o(|\mathbf{x}|^{-\theta})$ (consider the identity

$$f_\nu(\mathbf{x}) = \int_{|\xi|\leqq 1/\nu} \rho_\nu(\xi) f(\mathbf{x}-\xi)\, d\xi$$

and apply the hypotheses on f). We will prove that $\partial^\alpha u \in H^1(\mathbb{R}^n)$ for $|\alpha|=1$. In fact multiplying (4.2) by u_ν and integrating in $\mathbb{R}^n$ we have

$$\int_{\mathbb{R}^n} |\nabla u_\nu(\mathbf{x})|^2 \, d\mathbf{x} \leqq \int_{\mathbb{R}^n} |u_\nu|\,|f_\nu(\mathbf{x})| \, d\mathbf{x} \\ \leqq |u_\nu(0)| \int_{\mathbb{R}^n} |f_\nu(\mathbf{x})| \, d\mathbf{x} + C\int_{\mathbb{R}^n} |\mathbf{x}|^{1-2/p}|f_\nu(\mathbf{x})| \, d\mathbf{x}.$$

By the choice of p we have

$$\int_{\mathbb{R}^n} |\mathbf{x}|^{1-2/p}|f_\nu(\mathbf{x})| \, d\mathbf{x} \\ = \int_{|\mathbf{x}|\leqq N} |\mathbf{x}|^{1-2/p}|f_\nu(\mathbf{x})| \, d\mathbf{x} + \int_{|\mathbf{x}|\geqq N} |\mathbf{x}|^{1-2/p}|f_\nu(\mathbf{x})| \, d\mathbf{x} \\ \leqq C_1 + C_2 \int_{|\mathbf{x}|\geqq N} |\mathbf{x}|^{-\theta+1-2/p} \, d\mathbf{x} \leqq C_3.$$

It follows that there exists a constant C_4 such that

$$\int_{\mathbb{R}^n} |\nabla u_\nu(\mathbf{x})|^2 \, d\mathbf{x} \leqq C_4. \tag{4.5}$$

Moreover, since $f \in L^r(\mathbb{R}^n)$ for all $r \geqq 1$, we then have that

$$\int_{\mathbb{R}^n} |\Delta u_\nu(\mathbf{x})|^2 \, d\mathbf{x} \leqq \int_{\mathbb{R}^n} |f_\nu(\mathbf{x})|^2 \, d\mathbf{x},$$

from where it follows that Δu_ν is bounded. Then there exists a positive constant, say C_5, such that

$$\int_{\mathbb{R}^n} |\Delta u_\nu(\mathbf{x})|^2 \, d\mathbf{x} \leqq C_5. \tag{4.6}$$

From (4.5) and (4.6) the result follows for case $n=2$.

Let us consider the case $n>2$. We will prove that $(\partial^\alpha u_\nu)_{\nu\in\mathbb{N}}$ is bounded in $H^1(\mathbb{R}^n)$ for $|\alpha|=1$. In fact,

$$\begin{aligned} u_\nu(\mathbf{x}) &= \int_{\mathbb{R}^n} U(\xi) f_\nu(\mathbf{x}-\xi)\, d\xi \\ &= \int_{\mathbf{B}} U(\xi) f_\nu(\mathbf{x}-\xi)\, d\xi + \int_{\mathbf{B}^c} U(\xi) f_\nu(\mathbf{x}-\xi)\, d\xi, \end{aligned}$$

where by B and B^c we are denoting the unit ball with center at the origin and its complementary set, respectively. Let us denote by χ and χ_c the characteristic functions of B and B^c, respectively. Then we have

$$\begin{aligned} u_\nu(\mathbf{x}) &= \int_{\mathbb{R}^n} \chi(\xi) U(\xi) f_\nu(\mathbf{x}-\xi)\, d\xi + \int_{\mathbb{R}^n} \chi_c(\xi) U(\xi) f_\nu(\mathbf{x}-\xi)\, d\xi \\ &= [\chi U] * f_\nu + [\chi_c U] * f_\nu. \end{aligned}$$

It is easy to see that χU and $\chi_c U$ belong to $L^1(\mathbb{R}^n)$ and $L^q(\mathbb{R}^n)$ for $q>n/(n-2)$, respectively. Then by the hypotheses on f (case $n \geqq 3$) and Young's inequality we have

$$[\chi U] * f_\nu \in L^q(\mathbb{R}^n) \quad \text{and} \quad [\chi_c U] * f_\nu \in L^q(\mathbb{R}^n),$$

and

$$\begin{aligned} \left[\int_{\mathbb{R}^n} |u_\nu(\mathbf{x})|^q \, d\mathbf{x}\right]^{1/q} &\leqq C \int_{\mathbb{R}^n} |\chi_c U| \, d\mathbf{x} \left[\int_{\mathbb{R}^n} |f_\nu|^q \, d\mathbf{x}\right]^{1/q} \\ &\quad + C\left[\int_{\mathbb{R}^n} |\chi_c U|^q \, d\mathbf{x}\right]^{1/q} \int_{\mathbb{R}^n} |f_\nu| \, d\mathbf{x}. \end{aligned}$$

In the same way we have

$$\begin{aligned} &\left[\int_{\mathbb{R}^n} |u_\nu(\mathbf{x}) - u_\mu(\mathbf{x})|^q \, d\mathbf{x}\right]^{1/q} \\ &\quad \leqq C \int_{\mathbb{R}^n} |\chi_c U| \, d\mathbf{x} \left[\int_{\mathbb{R}^n} |f_\nu - f_\mu| \, d\mathbf{x}\right]^{1/q} \\ &\quad\quad + C\left[\int_{\mathbb{R}^n} |\chi_c U|^q \, d\mathbf{x}\right]^{1/q} \int_{\mathbb{R}^n} |f_\nu - f_\mu| \, d\mathbf{x}. \end{aligned}$$

Hence $(u_\nu)_{\nu\in\mathbb{N}}$ is a Cauchy sequence. Then it follows that there exists u in L^q such that

$$u_\nu \to u \quad \text{strong in } L^q(\mathbb{R}^n).$$

Since f_ν converges to f in $L^{q'}(\mathbb{R}^n)$ we conclude that the product $f_\nu u_\nu$ converges to fu in $L^1(\mathbb{R}^n)$. Then by multiplying (4.2) by u_ν and integrating in $\mathbb{R}^n$ we conclude that

$$\partial^\alpha u_\nu \to \partial^\alpha u \quad \text{strong in } L^2(\mathbb{R}^n) \qquad |\alpha|=1.$$

Finally by the hypotheses on f and (4.2) Δu_ν is bounded in $L^2(\mathbb{R}^n)$. Then the result follows.

LEMMA 4.2. *Let* $\mathbf{F}$ *be a vector field in* $[H^k(\mathbb{R}^n)]^n$ *such that the divergence of* $\mathbf{F}$ ($\operatorname{div}\mathbf{F} = g$) *satisfies conditions of Lemma* 4.1. *Then we can decompose* $\mathbf{F}$ *into two parts, both in* $[H^k(\mathbb{R}^n)]^n$, *one of them a gradient and the other as solenoidal function* (*that is, with null divergence*).

Proof. From Lemma 4.1 there exists a function p such that $\partial^\alpha p \in H^1(\mathbb{R}^n)$ for $|\alpha| = 1$, satisfying

$$\Delta p = \operatorname{div}\mathbf{F} \quad \text{in } \mathbb{R}^n.$$

Since $\Delta p = \operatorname{div}\mathbf{F} \in H^{k-1}(\mathbb{R}^n)$ we then have that $\partial^\alpha p \in H^k(\mathbb{R}^n)$ for all $|\alpha| = 1$; moreover, we have that

$$\mathbf{F} = \nabla p + (\mathbf{F} - \nabla p).$$

Then the result follows. □

As an application of Theorem 3.1 and Lemma 4.2 we conclude that the displacement field in thermoelasticity can be decomposed into two parts, one of them in the dissipative direction given by the gradient and the other, the solenoidal part that conserves its energy. We will express this result as the following theorem.

THEOREM 4.1. *Let* $\mathbf{u}_0$ *and* $\mathbf{u}_1$ *be vector fields in* $[H^2(\mathbb{R}^n)]^n$ *and* $[H^1(\mathbb{R}^n)]^n$, *respectively, such that* $\operatorname{div}\mathbf{u}_0$ *and* $\operatorname{div}\mathbf{u}_1$ *satisfy the hypotheses of Lemma* 4.2. *Then the displacement field in* $\mathbb{R}^n$, $n \geqq 2$, *can be decomposed into two parts, one of them solenoidal, which conserves its energy, and another totally dissipative, which decays as mentioned in Theorem* 3.1.

Proof. From Lemma 4.2 we can decompose the displacement field into two parts, say

$$\mathbf{u}_0 = \mathbf{u}_0^s + \mathbf{u}_0^i; \qquad \mathbf{u}_1 = \mathbf{u}_1^s + \mathbf{u}_1^i.$$

Where $\operatorname{div}(\mathbf{u}_0^s) = 0$, $\operatorname{div}(\mathbf{u}_1^s) = 0$, and $\mathbf{u}_c^i = \nabla p_0$, $\mathbf{u}_1^i = \nabla p_1$ for some functions p_0, p_1. Let us denote by $\mathbf{u}^s$ the solution of system

$$\begin{aligned} &\mathbf{u}^s_{tt} - (a^2 - b^2)\Delta\mathbf{u}^s = 0 \quad \text{in } \mathbb{R}^n_x \times \mathbb{R}_t, \\ &\mathbf{u}^s(0) = \mathbf{u}_0^s, \qquad \mathbf{u}^s_t(0) = \mathbf{u}_1^s \quad \text{in } \mathbb{R}^n{}_x. \end{aligned} \tag{4.7}$$

Taking the div operator on the above equation we conclude that

$$\operatorname{div}\mathbf{u}^s = \operatorname{div}\mathbf{u}^s_t = 0 \quad \text{in } \mathbb{R}^n_x.$$

From Theorem 2.1 there exists a solution $\mathbf{u}^i$ of system

$$\begin{aligned} \mathbf{u}^i_{tt} - (a^2 - b^2)\Delta\mathbf{u}^i - b^2\nabla(\operatorname{div}\mathbf{u}^i) + \alpha\nabla\theta = 0 \quad &\text{in } Q, \\ \theta_t - k\Delta\theta + \beta \operatorname{div}\mathbf{u}_t = 0 \quad &\text{in } Q, \\ \mathbf{u}^i(0) = \mathbf{u}^i_c, \quad \mathbf{u}^i_t(0) = \mathbf{u}^i_1, \quad \theta(0) = \theta_0 \quad &\text{in } Q. \end{aligned} \tag{4.8}$$

It is easy to see that $\mathbf{u} = \mathbf{u}^s + \mathbf{u}^i$ is the solution of system (2.1)-(2.3). By (4.7) we conclude that then solenoidal part conserves its energy, while the dissipative part, given by the solution of system 4.8, decays as indicated in Theorem 3.1; then the result follows. □

PERSISTENCE UNDER RELAXED POINT-DISSIPATIVITY (WITH APPLICATION TO AN ENDEMIC MODEL)*

HORST R. THIEME[†]

This paper is dedicated to Paul Waltman on the occasion of his 60th *birthday.*

Abstract. An approach to persistence theory is presented which focuses on the concept of *uniform weak persistence.* By using the most elementary dynamical systems concepts only, it can be shown that uniform weak persistence implies uniform strong persistence. This even holds under relaxed point dissipativity. Uniform weak persistence can be proved by the *method of fluctuation* or by analyzing the boundary flow for *acyclicity* with point dissipativity being only required in a neighborhood of the boundary. The approach is illustrated for a model describing the spread of a fatal infectious disease in a population that would grow exponentially without the disease. Sharp conditions are derived for both host and disease persistence and for host limitation by the disease.

Key words. persistence, permanence, dynamical systems, point dissipativity, compactness, acyclicity, epidemic (endemic) models, infectious diseases, endemicity, host limitation

AMS(MOS) subject classifications. 34C35, 92A15

Introduction. Persistence (or permanence) theory has developed into a mathematically fascinating area with important applications in mathematical ecology and epidemiology. It addresses the long-term survival of certain (if not all) components in ecological (or other) systems using and further developing the concepts and tools of dynamic systems theory. Fortunately enough, two papers by Hutson and Schmitt (preprint) and by Waltman (1991) will soon be available to give a survey of the theory as it stands now. See also Hofbauer and Sigmund (1988).

This paper addresses the following three points.

- Persistence theory in its present state is not only deep and powerful, but also conceptually difficult to grasp. Persistence is too relevant a topic to be left out from, let's say, an advanced course on mathematical modeling in ecology or epidemiology. In such a course we would expect that students are sufficiently familiar with differential equations, but are not necessarily experts in dynamical systems theory. So we present an approach which, at least for an important part, needs just the most elementary dynamical systems concepts.
- A standard assumption in today's persistence theory is point dissipativity, i.e., the existence of a bounded globally attracting set. This excludes the consideration of populations which, like the human, have grown and continue to grow without limits (at least in the time scale of interest). On the one hand, we try to establish persistence results for systems where some components are allowed to show unlimited growth. On the other hand, we suggest using persistence theory techniques to establish the boundedness of certain components of the system rather than assuming that all trajectories will be bounded.
- Persistence theory has so far focused rather on ecological than epidemiological models. In the epidemiology of infectious diseases persistence has two faces: persistence (or endemicity) of the disease and survival of the host population. We address both questions for host populations whose population size would increase in

*Received by the editors June 12, 1991; accepted for publication (in revised form) April 21, 1992.

[†]Department of Mathematics, Arizona State University, Tempe, Arizona 85287-1804.

absence of the disease. Further we derive conditions for the disease to limit the population growth.

Our approach is based on the concept of *uniform weak persistence*, which, to our knowledge, has been introduced by Freedman and Moson (1990) to supplement the concepts of *weak persistence*, *strong persistence*, and *uniform* (*strong*) *persistence* (with the last being close to *permanence*). We like to explain these concepts in terms of repelling sets.

We consider a metric space X with metric d. Let X be the union of two disjoint subsets X_1, X_2, and Φ a *continuous semiflow* on X_1, i.e., a continuous mapping $\Phi : [0,\infty) \times X_1 \to X_1$ with the following properties:

$$\Phi_t \circ \Phi_s = \Phi_{t+s}, \quad t, s \geq 0; \qquad \Phi_0(x) = x, \quad x \in X_1.$$

Here Φ_t denotes the mapping from X_1 to X_1 given by $\Phi_t(x) = \Phi(t,x)$. The *distance* $d(x,Y)$ of a point $x \in X$ from a subset Y of X is defined by

$$d(x,Y) = \inf_{y \in Y} d(x,y).$$

We use the same symbol d as for the metric because $d(x,y) = d(x,\{y\})$ for $x, y \in X$.

Let Y_2 be a subset of X_2.

Y_2 is called a *weak repeller* for X_1 if

$$\limsup_{t\to\infty} d(\Phi_t(x_1), Y_2) > 0 \quad \forall x_1 \in X_1.$$

Y_2 is called a *strong repeller* for X_1 if

$$\liminf_{t\to\infty} d(\Phi_t(x_1), Y_2) > 0 \quad \forall x_1 \in X_1.$$

Y_2 is called a *uniform weak repeller* for X_1 if there is some $\epsilon > 0$ such that

$$\limsup_{t\to\infty} d(\Phi_t(x_1), Y_2) > \epsilon \quad \forall x_1 \in X_1.$$

Y_2 is called a *uniform strong repeller* for X_1 if there is some $\epsilon > 0$ such that

$$\liminf_{t\to\infty} d(\Phi_t(x_1), Y_2) > \epsilon \quad \forall x_1 \in X_1.$$

Typically X_1 is open in X, and X_2 can be viewed as the "boundary" of X. The dynamical system Φ is called (*uniformly*) *weakly* or (*uniformly*) *strongly persistent* if X_2 is a (uniform) weak or (uniform) strong repeller for X_1.

Though weak persistence is of some interest also, uniform strong persistence is the desired property. Weak persistence does not exclude that certain components of the system get close to the boundary of extinction every now and then and are eventually wiped out by random effects. Most papers prove strong persistence first and show uniform strong persistence in a second step. Our strategy consists in proving uniform weak persistence rather than strong persistence as an intermediate result.

In our mathematical statements we speak about a certain set as a repeller for another set rather than say that the dynamical system is persistent. This gives us a greater terminological flexibility. For in endemic models, persistence of the host population and persistence (endemicity) of the disease are of separate interest and the study of each question requires us to choose the above sets X_1 and X_2 in a specific way. The repeller terminology has been used before, e.g., by Fonda (1988).

In §1 we give an elementary proof that uniform weak repellers are uniform strong repellers. This proof even works under relaxed point dissipativity. A similar result has been shown by Freedman and Moson (1990) under somewhat stronger assumptions. Point dissipativity can be removed completely at the cost of many technicalities: see §6.

In many epidemic models the *method of fluctuation* (see §2) presents an efficient and elementary way of proving uniform weak persistence. This method has been developed by Hirsch, Hanisch, and Gabriel (1985) to study global stability in certain monotone dynamical systems modeling the spread of parasitic diseases, but I feel that its main destination is persistence theory. The fluctuation method also has the advantage of providing some quantitative information.

In order to find sharp conditions for uniform weak persistence it may become necessary to study the "boundary flow" in the repeller-to-be, X_2 (§4). Then a deep plunge into dynamical systems theory becomes unavoidable, and we have to use an *acyclicity* consideration that is very similar to that needed for proving strong persistence (see Hutson and Schmitt and Waltman (1991) and the references therein, in particular Hale and Waltman (1989)). In proving uniform weak persistence, however, we are in the advantageous position that we can assume that the semiflow stays in a small neighborhood of the repeller-to-be, X_2. As already noticed by Freedman and Moson (1990), this means, e.g., that, if X_2 happens to be bounded, point dissipativity is for free even if X is unbounded. We have not explored whether there is a difference in proving uniform weak persistence as compared to strong persistence using *average Lyapunov functions* (Fonda (1988), Hofbauer and Sigmund (1988), Hutson and Schmitt).

We illustrate our approach by applying it to a model describing the spread of an infectious disease in a population that would grow without the disease. A special case of this model has been suggested by Anderson and May (1979) to study the question under which conditions infectious diseases can regulate population growth. With a different infection law, variants of this model have been studied by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990). We introduce a contact law that includes the ones used in the papers just mentioned. We establish conditions for the disease and/or the host population to persist, as well as for the disease to limit the growth of the population. In §3 we illustrate how far one can get in this discussion with combining the method of fluctuations and the elementary persistence theory in §1. In §5 we study a situation where one has to analyze the boundary flow. Section 7 discusses a case where one has to work with almost no point dissipativity at all. Other aspects of this model like the existence and stability of disease-free and endemic equilibrium states are discussed elsewhere (see Thieme).

Although all the examples presented here are finite-dimensional, we have stated and proved our theorems to apply in infinite dimensions as well. This requires some compactness assumptions that are automatically satisfied in finite dimensions, but adds little complication to the arguments. If point dissipativity is added, our assumptions are essentially the same as in Hale and Waltman (1989). Applicable hypotheses that guarantee these compactness assumptions without point dissipativity will be derived in a subsequent publication.

1. Uniform weak repellers are uniform strong repellers. In this section we prove a persistence result, which, in the language of differential equations, only uses that solutions are continuous in time and depend continuously on their initial data. For the formulation and proof of our result we use the dynamical systems framework, however, because this is the most efficient and beautiful way of doing it. But everything can easily be reformulated in terms of differential equations.

We consider a metric space X with metric d which is the disjoint union of an open subset X_1 and a closed subset X_2. The results of this section state that, under natural conditions, X_2 is a uniform strong repeller for X_1 whenever it is a uniform weak repeller (for definitions, see the Introduction). This has already been observed by Freedman and Moson (1990) in a slightly more restrictive setting than ours. Note that the semiflow does not need to be defined on the whole state space, but on X_1 only. This will allow us to use persistence theory methods to prove boundedness results by letting X_2 contain infinity in an appropriate way. Accordingly, our assumptions will only concern the behavior of the semiflow on X_1. If Φ is defined on the whole state space X, we require that X_1 rather than X_2 is forward invariant. It is sometimes easier, however, to check certain properties of the flow (like forward invariance) on X_2 rather than on X_1.

Remark 1.1. Let the semiflow Φ be defined and continuous on all of $[0,\infty) \times X$. Then the following hold:

(a) If X_2 is a weak repeller for X_1 and X_2 is forward invariant, then X_1 is forward invariant.

(b) If X_2 is forward invariant, but not closed (i.e., X_1 is not open), then X_2 is not a weak repeller for X_1.

Remark 1.1 implies that it is natural to assume that X_1 is forward invariant and open in X. As with all persistence results, this approach requires some compactness to be associated with the system; compare Freedman and Moson (1990). But compactness is only needed in a neighborhood of the repeller-to-be. First we use the following assumption, which may appear somewhat technical:

($\mathbf{C}_{1.1}$) There is some $\delta > 0$ with the following property: If $0 < \epsilon \leq \delta$ and $x_j \in X_1, t_j > 0$, are sequences such that $t_j \to \infty, j \to \infty$, and $\mathrm{d}(\Phi_{t_j}(x_j), X_2) = \epsilon$ for all j, then the sequence $\Phi_{t_j}(x_j)$ has a convergent subsequence.

PROPOSITION 1.2. *Let X be a metric space with metric d. Let X be the disjoint union of two sets X_1 and X_2, with X_1 open. Let Φ be a continuous semiflow on X_1 such that the compactness assumption* ($\mathbf{C}_{1.1}$) *is satisfied.*

Then X_2 is a uniform strong repeller for X_1 whenever it is a uniform weak repeller for X_1.

Proof. Assume that X_2 is a uniform weak repeller. Then there exists $\epsilon > 0$ such that

$$\limsup_{t \to \infty} d(\Phi_t(x), X_2) > \epsilon \quad \forall x \in X_1. \tag{1.1}$$

We can assume that $\epsilon < \delta$ in assumption ($\mathbf{C}_{1.1}$).

Now suppose that X_2 is not a uniform strong repeller for X_1. Then there exist sequences $x_j \in X_1$ and $0 < \epsilon_j \to 0$ such that

$$\liminf_{t \to \infty} d(\Phi_t(x_j), X_2) < \epsilon_j \quad \forall j. \tag{1.2}$$

We now find sequences $r_j < s_j < t_j$ with $r_j \to \infty, j \to \infty$ such that

$$d(\Phi_{s_j}(x_j), X_2) \to 0, \qquad j \to \infty, \tag{1.3}$$

$$d(\Phi_{r_j}(x_j), X_2) = \epsilon = d(\Phi_{t_j}(x_j), X_2), \tag{1.4}$$

$$d(\Phi_s(x_j), X_2) \leq \epsilon, \qquad r_j \leq s \leq t_j. \tag{1.5}$$

Moreover, we can choose any of the numbers $\tau_j \in \{r_j, s_j, t_j\}$ in the form $\tau_j = \rho_j + \sigma_j$ such that $\sigma_j \to \infty, j \to \infty$, and both

$$(1.6) \qquad d(x_j, X_2) \leq \epsilon, \qquad d(\Phi_{\tau_j}(x_j), X_2) \leq \epsilon$$

for all j. Hence, by our compactness condition, we can assume that, after taking a subsequence, the sequence $\Phi_{r_j}(x_j)$ converges.

Step 1. We claim that $t_j - r_j$ is unbounded.

We suppose that $t_j - r_j$ is bounded. Then $s_j - r_j \to s$ after choosing a subsequence. Let $\Phi_{r_j}(x_j) \to x$. As $d(x, X_2) = \epsilon$ by (1.4), we have $x \in X_1$. On the other hand, we have $\Phi_{s_j}(x_j) = \Phi_{s_j - r_j}(\Phi_{r_j}(x_j)) \to \Phi_s(x)$. As $x \in X_1$ and X_1 is forward invariant, $\Phi_s(x) \in X_1$. As $d(\Phi_s(x), X_2) = 0$ by (1.3) and as X_2 is closed, $\Phi_s(x) \in X_2$, a contradiction. This finishes Step 1.

Step 2. The contradiction.

Let x be the limit of $\Phi_{r_j}(x_j), j \to \infty$. As $d(x, X_2) = \epsilon$ by (1.4) and as $X = X_1 \cup X_2$, we have $x \in X_1$. By (1.5),

$$d(\Phi_r \circ \Phi_{r_j}(x_j), X_2) \leq \epsilon, \qquad 0 \leq r \leq t_j - r_j.$$

By Step 1, $t_j - r_j$ is unbounded. After passing to subsequences we can assume that $t_j - r_j$ is increasing and converges to infinity. Then

$$d(\Phi_r \circ \Phi_{r_k}(x_k), X_2) \leq \epsilon, \qquad 0 \leq r \leq t_j - r_j, \quad k \geq j.$$

By the continuity of Φ we can take the limit for $k \to \infty$:

$$d(\Phi_r(x), X_2) \leq \epsilon, \qquad 0 \leq r \leq t_j - r_j.$$

As $t_j - r_j \to \infty, j \to \infty$, this estimate holds for all $r \geq 0$, contradicting $x \in X_1$ and (1.1).

If X is a subset of $\mathbf{R}^n$ with the induced metric, or, more generally, a locally compact metric space, the somewhat technical condition $(\mathbf{C}_{1.1})$ can be replaced by requiring X_2 to be compact. This generalizes a result by Freedman and Moson (1990) who assume that the semiflow is defined on the whole state space and leaves X_2 forward invariant (see our Remark 1.1a). Our version allows to prove boundedness of trajectories by making X_2 contain infinity in an appropriate way; see §3.3 for an example.

THEOREM 1.3. *Let X be a locally compact metric space with metric d. Let X be the disjoint union of two sets X_1 and X_2 such that X_2 is compact. Let Φ be a continuous semiflow on X_1.*

Then X_2 is a uniform strong repeller for X_1, whenever it is a uniform weak repeller for X_1.

Proof. If X_2 is compact and X is locally compact, X_2 has a compact neighborhood. Hence $(\mathbf{C}_{1.1})$ is satisfied if δ is chosen sufficiently small.

If X is not locally compact, Proposition 1.2 can be improved by adapting the idea of a compact attracting set. As we do not make explicit use of this concept, we refer the reader to Hale and Waltman (1989), Hutson and Schmitt, and Waltman (1991). We assume that a neighborhood of X_2 is attracted to a certain set B. Point dissipativity would require that B is bounded. For our purposes it is sufficient that the intersection of B with some neighborhood of X_2 is bounded. Then we assume that the semiflow is compactifying on bounded sets.

($\mathbf{C}_{1.2}$) There are $\delta > 0$ and a subset B of X_1 with the following properties:

- If $x \in X_1$ and $d(x, X_2) < \delta$, then $\Phi_t(x) \in B$ for all sufficiently large t;
- If $0 < \epsilon < \delta$, the intersection of B with the ϵ-shell $\{x \in X; d(x, X_2) = \epsilon\}$ of X_2 is bounded.
- If $t_j \to \infty$ and x_j is a sequence in X_1 such that the sequence $\Phi_{t_j}(x_j)$ is bounded, then $\Phi_{t_j}(x_j)$ has a convergent subsequence in X.

Remark. The third condition in ($\mathbf{C}_{1.2}$) is satisfied if there exists some $t_0 > 0$ with the following two properties:

(i) Φ_{t_0} is compact, i.e., it maps bounded sets onto relatively compact sets;

(ii) For any bounded set B_1 there exists another bounded set B_2 such that $\Phi_{t_0}^{-1}(B_1) \subset B_2$.

THEOREM 1.4. *Let X be a metric space with metric d. Let X be the disjoint union of two sets X_1 and X_2, with X_1 open. Let Φ be a continuous semiflow on X_1 such that the compactness assumption* ($\mathbf{C}_{1.2}$) *is satisfied.*

Then X_2 is a uniform strong repeller for X_1, whenever it is a uniform weak repeller for X_1.

Proof. Let us revisit the proof of Proposition 1.2. Consider (1.1)–(1.6). As we can always replace x_j by $\Phi_{\tau_j}(x_j)$ with appropriate, arbitrarily large τ_j, the first assumption in ($\mathbf{C}_{1.2}$) allows us to assume that all x_j and their forward orbits are in the set B. By (1.4), we have that the sequence $\Phi_{r_j}(x_j)$ is contained in the intersection of B and the ϵ shell of X_2 that is bounded by the second assumption in ($\mathbf{C}_{1.2}$). The third assumption then implies that, after taking a subsequence, the sequence $\Phi_{r_j}(x_j)$ converges. Then we can proceed exactly as in the proof of Proposition 1.2.

Apparently there are two routes to uniform strong persistence. The first, traditional one, leads over proving strong persistence, the second, just established, uses uniform weak persistence as an intermediate result. As far as we understand the literature, there are basically two methods to establish strong persistence: using *average Lyapunov functions* (Fonda (1988), Hofbauer and Sigmund (1988), Hutson and Schmitt) or using an *acyclicity* condition for the flow on X_2 (Hale and Waltman (1989), Hutson and Schmitt, Waltman, (1991)). Everybody working with Lyapunov functions knows that they are a wonderful theoretical tool, but sometimes difficult to construct in practice. In surprisingly many cases it is possible to establish uniform weak persistence by ad hoc methods. If X is a subset of $\mathbf{R}^n$, it is often possible to use the *method of fluctuation* which yields additional interesting information (about ϵ in Definition 1.1a, e.g.). This method is explained in the next section and applied in §3, where its limitations are also discovered. Sometimes the fluctuation method can be extended to infinite dimensions. In Thieme and Castillo-Chavez, uniform strong persistence for an HIV/AIDS model (Theorem 4) was established using Theorem 4.2 in Hale and Waltman (1989). The conditions of Theorem 4.2 were checked by establishing uniform weak persistence (Theorem 3b in Thieme and Castillo-Chavez). So we could have concluded uniform strong persistence from our Theorem 1.4 as well.

The other method of showing strong persistence, acyclicity, works for establishing uniform weak persistence as well. It even does so under relaxed point dissipativity because, for checking uniform weak persistence rather than strong persistence, we can completely restrict the consideration to the semiflow in a neighborhood of the repeller-to-be. This will be elaborated in §4.

2. The method of fluctuation. The *method of fluctuation* has been developed and systematically used by Hirsch, Hanisch, and Gabriel (1985) for studying the spread of parasitic diseases. It is a very convenient method for analyzing the asymptotic behavior of solutions of finite-dimensional differential equations. Hirsch, Hanisch, and Gabriel mainly use it to establish the global stability of equilibria. If used for this purpose, the advantage of the method lies in the fact that, if it works at all, it works easily. The disadvantage consists in its restriction to differential equations, the vector fields of which have to satisfy stringent monotonicity requirements. It is a powerful tool, however, to show that certain sets are uniform weak repellers.

For a real-valued function f on $[t_0, \infty)$ we define

$$f_\infty = \liminf_{t \to \infty} f(t), \qquad f^\infty = \limsup_{t \to \infty} f(t).$$

The following lemma can be found in Hirsch, Hanisch, and Gabriel (1985).

LEMMA 2.1 (fluctuation lemma). *Let $f : [t_0, \infty) \to \mathbf{R}$ be a differentiable function that has no limit for $t \to \infty$. Then there are sequences $s_n, t_n \to \infty$ with the following properties:*

$$f(s_n) \to f_\infty, \qquad f'(s_n) = 0,$$
$$f(t_n) \to f^\infty, \qquad f'(t_n) = 0$$

for $n \to \infty$. If f is twice continuously differentiable, we have in addition that

$$f''(s_n) \geq 0, \quad f''(t_n) \leq 0, \quad n \in \mathbf{N}.$$

This statement is quite intuitive. If f has no limit for $t \to \infty$, it has to oscillate between f_∞ and f^∞. So we can choose appropriate sequences of local minima $f(s_n)$ and local maxima $f(t_n)$ that have the desired properties.

PROPOSITION 2.2. *Let $f : (t_0, \infty) \to \mathbf{R}$ be bounded and continuously differentiable. Then there are sequences $s_n, t_n \to \infty$ with the following properties:*

$$f(s_n) \to f_\infty, \qquad f'(s_n) \to 0,$$

$$f(t_n) \to f^\infty, \qquad f'(t_n) \to 0$$

for $n \to \infty$.

Proof. By Lemma 2.1 we can assume that $f(t)$ has a finite limit for $t \to \infty$. If the statement of this proposition does not hold, f' does not change sign for sufficiently large t and must be bounded away from zero. But this contradicts the convergence of $f(t)$ to a finite limit.

THEOREM 2.3. *Let D be a bounded interval in $\mathbf{R}$ and $g : (t_0, \infty) \times D \to \mathbf{R}$ be bounded and uniformly continuous. Further, let $x : (t_0, \infty) \to D$ be a solution of*

$$x' = g(t, x),$$

which is defined on the whole interval (t_0, ∞). Then there exist sequences $s_n, t_n \to \infty$ such that

$$\lim_{n \to \infty} g(s_n, x_\infty) = 0 = \lim_{n \to \infty} g(t_n, x^\infty).$$

Proof. As g is bounded, x' is bounded and so x is uniformly continuous on (t_0, ∞). As g is continuous, so is $x'(t)$ on (t_0, ∞). By Proposition 2.2, we find sequences $s_n, t_n \to \infty$ with the following properties:

$$x(s_n) \to x_\infty, \qquad x'(s_n) = g(s_n, x(s_n)) \to 0,$$

$$x(t_n) \to x^\infty, \qquad x'(t_n) = g(t_n, x(t_n)) \to 0,$$

for $n \to \infty$. As g is uniformly continuous, the assertion follows.

For establishing the uniform weak repeller relation we will mainly use the following version.

COROLLARY 2.4. *Let the assumptions of Theorem* 2.3 *be satisfied. Then*

$$\text{(a)} \qquad \liminf_{t\to\infty} g(t, x_\infty) \le 0 \le \limsup_{t\to\infty} g(t, x_\infty),$$

$$\text{(b)} \qquad \liminf_{t\to\infty} g(t, x^\infty) \le 0 \le \limsup_{t\to\infty} g(t, x^\infty).$$

3. Applications of the fluctuation method to an endemic model: persistence of host and disease. Host limitation. (Act I). We consider the spread of a potentially fatal infectious disease in a host population that would increase exponentially in the absence of the disease. The question of persistence can be posed in a twofold way: persistence of the host population, i.e., the disease does not extinguish the host; and persistence (or endemicity) of the disease, i.e., the disease does not go extinct itself. Moreover, we can ask whether the infectious disease limits the growth of the host population. In this section we use the method of fluctuation to show that an appropriate set is a uniformly weak repeller, and we use Theorem 1.3 to establish that it is a uniformly strong repeller. For host and disease persistence we could alternatively use the results in Freedman and Moson (1990) in order to get from uniform weak to uniform strong persistence; for host limitation the analogous step seems to require the more general Theorem 1.3.

Our model follows Anderson and May (1979), Busenberg and van den Driessche (1990), and Busenberg and Hadeler (1990). The host population is subdivided into susceptible, S, infective, I, and recovered, R, individuals (a latent period is ignored):

$$\begin{aligned} &N = S + I + R, \\ &\frac{d}{dt}S = \beta N - \mu S - C(N)S\frac{I}{N} + \rho R, \\ &\frac{d}{dt}I = C(N)S\frac{I}{N} - (\mu + \gamma + \alpha)I, \\ &\frac{d}{dt}R = \gamma I - (\mu + \rho)R. \end{aligned} \tag{3.1}$$

β, μ are the per capita birth and mortality (without the disease) rates. ρ is the rate at which immunity is lost. γ is the rate at which individuals recover from the disease, while α is the extra per capita mortality due to the disease. All these constants are assumed to be strictly positive with the possible exception of ρ, which may also be zero in case the disease infers permanent immunity. As we are interested in the case where the population size increases exponentially in absence of the disease, we assume

$$\beta > \mu.$$

Model (3.1) is more special than the models considered by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990) insofar as the disease only affects the mortality of infective individuals and not the mortality of recovered individuals and the fertility of infective and recovered individuals. Furthermore, vertical transmission is neglected. Diekmann and Kretzschmar (1991) combine reduced fertility of infectives with pair formation. This leads to a behavior of their model (bistability of solutions, global bifurcation of periodic solutions from a saddle connection) that is quite different from the one observed in the above-mentioned papers and also in this paper.

The key feature of this model that makes it different from the models considered by Anderson and May (1979) on one hand and Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990) on the other, is the way in which the rate $C(N)$ of effective contacts (i.e., contacts actually leading to an infection in case they occur between a susceptible and an infective individual) depends on the population size N. Anderson and May (1979) assume the classical mass action approach $C(N) = \text{const } N$, whereas Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990) assume $C(N) = \text{const}$. Anderson (1982) fits

$$C(N) = \text{const } N^{\delta}$$

to various communities and various childhood diseases and finds δ in the range between 0.03 and 0.07, i.e., the dependence of C on N is very weak for sufficiently large N. We must take into account, however, that these estimates are taken from different communities of constant size and do not necessarily reflect how the contact rate changes in a community of varying size. Using a handling time argument in modeling the contact rate for venereal diseases (in analogy to Holling's (1966, p. 11) derivation of a predator's functional response to the amount of prey) suggests the form chosen by Diekmann and Kretzschmar (1991) (see also Dietz (1982)),

$$C(N) = \frac{N}{\kappa_1 + \kappa_2 N}.$$

The handling time argument neglects, so to speak, competition in partner acquisition. Modeling the formation of short time social complexes, Heesterbeek and Metz derive an effective contact rate of the form

$$C(N) = \frac{\kappa_1 N}{1 + \kappa_2 N + \sqrt{1 + 2\kappa_2 N}}.$$

The two last forms of $C(N)$ approximate the form considered by Anderson and May (1979) at small population sizes and the form considered by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990) at large population sizes and interpolate in between.

The importance of the contact function C came particularly into focus by modeling the spread of HIV—see, e.g., Castillo-Chavez et al. (1989 a,b), Thieme and Castillo-Chavez—and is now taken into account also in other models (Brauer (1990), (1991), Pugliese (1990)).

The solutions of (3.1) have many interesting properties, which will be discussed in detail elsewhere (Thieme): Depending on the parameters, in particular on the values of C at zero and ∞, there may be a steady state in which the disease controls the population, or there may be exponential states in which both the sizes of the total population and the infective and removed parts increase exponentially. If $C(0) > 0$, there can even exist a state in which the population size decreases exponentially, i.e., the disease has converted the originally exponentially increasing population into an exponentially decreasing population. Here we concentrate on how the values of C at zero and ∞ affect the persistence of both host and disease and the limitation of the host population by the disease.

In view of the various forms of C discussed before, we make the following assumptions.

Assumptions 3.1. (a) $C(N)$ is a continuous function of $N \geq 0$ and continuously differentiable in $N > 0$.

(b) $C(N)$ is monotone nondecreasing in N.

(c) $C(N) > 0$ if $N > 0$.

Reformulation of the model. It is convenient to reformulate the model in terms of the fractions of the susceptible, infective, and recovered parts of the population:

$$x = \frac{S}{N}, \quad y = \frac{I}{N}, \quad z = \frac{R}{N}, \tag{3.2}$$

and express (3.1) in these terms:

$$\begin{aligned} \frac{d}{dt}N &= (\beta - \mu - \alpha y)N, \\ \frac{d}{dt}x &= \beta(1-x) - (C(N) - \alpha)xy + \rho z, \\ \frac{d}{dt}y &= C(N)xy - (\gamma + \alpha + \beta)y + \alpha y^2, \\ \frac{d}{dt}z &= \gamma y - (\beta + \rho)z + \alpha yz. \end{aligned} \tag{3.3}$$

Equations (3.2) suggest

$$x + y + z = 1, \tag{3.4}$$

which allows us to get rid of either x, y, or z, but it is convenient to have all equations available. Actually, it is easy to see that the manifold $x + y + z = 1$, $x, y, z \geq 0$, is forward invariant under the solution flow of (3.3), which implies that, for any initial data satisfying (3.4), the system (3.3) has a global (in forward direction) solution satisfying (3.4).

3.1. Persistence of the host population. As a first application of the persistence theory in §1 in combination with the fluctuation method, we show that the host population persists in the original Anderson and May (1979) model, or, more generally, if $C(0) = 0$.

THEOREM 3.2. *Let $C(0) = 0, N(0) > 0$. Then the population is uniformly persistent, i.e., $\liminf_{t\to\infty} N(t) \geq \epsilon$ with $\epsilon > 0$ not depending on the initial data.*

Proof. We have to show that the set $X_2 = \{N = 0, x \geq 0, y \geq 0, z \geq 0, x+y+z = 1\}$ is a uniform strong repeller for $X_1 = \{N > 0, x \geq 0, y \geq 0, z \geq 0, x + y + z = 1\}$. As the assumptions of Theorem 1.3 are obviously satisfied, it is enough to show that X_2 is a uniform weak repeller for X_1. We consider a trajectory for which $N^\infty < \infty$ and apply Corollary 2.4(b) to the y equation in (3.3):

$$0 \leq C(N^\infty) - (\gamma + \beta)y^\infty.$$

Here we have used that $x, y \leq 1$. We solve for y^∞,

$$y^\infty \leq \frac{C(N^\infty)}{\gamma + \beta}. \tag{3.5}$$

From the N equation in (3.3) we obtain

$$\liminf_{t\to\infty} \frac{\frac{d}{dt}N}{N} \geq \beta - \mu - \alpha y^{\infty}.$$

Hence N increases exponentially unless

$$y^{\infty} \geq \frac{\beta - \mu}{\alpha}. \tag{3.6}$$

Combining (3.5) and (3.6) we obtain

$$C(N^{\infty}) \geq \frac{(\beta - \mu)(\gamma + \beta)}{\alpha}. \tag{3.7}$$

As $C(0) = 0$ and C is continuous at 0, $N^{\infty} \geq \epsilon > 0$ with ϵ not depending on the initial data.

Actually we see from (3.7) that we can relax $C(0) = 0$ and require

$$C(0) < (\beta - \mu)\frac{\gamma + \beta}{\alpha}$$

instead. But for obtaining a sharp persistence result (for the survival of the population) the combination of the persistence Theorem 1.3 and the fluctuation method is not sufficient. In the next section we will develop a more sophisticated method to prove uniform weak persistence, which, following the lines of Hale and Waltman (1989), analyzes the semiflow on the repeller to-be, X_2. This method, which uses an acyclicity requirement, will be applied to our endemic model in §5.

3.2. Persistence of the disease. As another application of Theorem 1.3 and the method of fluctuation we look for conditions under which the disease is persistent. There are different ways in which disease persistence can be interpreted in our model. We have chosen to call the disease to be persistent or *endemic* in the population, if the fraction of infective individuals, y, is bounded away from zero. As we do not exclude that the population size increases or decreases, this is not equivalent to the number of infectives being bounded away from zero. If the population dies out and the fraction of infectives remains bounded away from zero, we would still say that the disease is persistent in the population. On the other hand, we would not call the disease persistent if both the population size and the number of infectives increase, let us say, exponentially with the exponential growth rate of the number of infectives being strictly less than the exponential growth rate of the total population.

We first derive a condition for the disease to be weakly uniformly persistent.

PROPOSITION 3.3. *Let $\alpha + \beta + \gamma < C(\infty)$. Then the disease is uniformly weakly persistent in so far as*

$$y^{\infty} = \limsup_{t\to\infty} y(t) \geq \epsilon$$

with $\epsilon > 0$ being independent of the initial data, provided that $y(0) > 0$.

Actually, the proof shows that

$$y^{\infty} \geq \min\left(\frac{\beta - \mu}{\alpha}, \frac{1}{1 + \frac{\gamma+\alpha}{\beta+\rho}}\left(1 - \frac{\gamma + \alpha + \beta}{C(\infty)}\right)\right).$$

Proof. We suppose that the disease is not uniformly weakly persistent and derive a contradiction. We can assume that

$$y^\infty < \frac{\beta - \mu}{\alpha}.$$

The N equation in (3.3) implies that

$$\liminf_{t\to\infty} \frac{\frac{d}{dt}N}{N} > 0,$$

i.e., $C(N(t)) \to C(\infty), t \to \infty$. We apply Corollary 2.4(b) to the z equation in (3.3):

$$0 \leq \gamma y^\infty - (\beta + \rho) z^\infty + \alpha y^\infty.$$

Here we have used that $y \leq 1$. Solving for z^∞ we obtain

$$z^\infty \leq \frac{\gamma + \alpha}{\beta + \rho} y^\infty.$$

We substitute (3.4) into the y equation in (3.3):

$$\frac{d}{dt} y = C(N)(1 - y - z)y - (\gamma + \alpha + \beta)y + \alpha y^2.$$

Hence

$$\liminf_{t\to\infty} \frac{\frac{d}{dt}y}{y} \geq C(\infty)\left(1 - y^\infty \left[1 + \frac{\gamma + \alpha}{\beta + \rho}\right]\right) - (\gamma + \alpha + \beta).$$

Hence, if in addition,

$$y^\infty < \frac{1}{1 + \frac{\gamma+\alpha}{\beta+\rho}} \left(1 - \frac{\gamma + \alpha + \beta}{C(\infty)}\right),$$

we have

$$\liminf_{t\to\infty} \frac{\frac{d}{dt}y}{y} > 0,$$

which implies that $y(t) \to \infty, t \to \infty$, in contradiction to the fact that y is bounded by one. This shows the estimate for y^∞ mentioned after the statement of this proposition.

As Theorem 1.3 requires compactness of the repeller to-be, we are forced to restrict our consideration to the case that $C(\infty) < \infty$. Without this restriction we cannot guarantee that $C(N)$ ends in a bounded set. In §7 we prove uniform strong persistence of the disease if $C(\infty) = \infty$. This requires a modification of the persistence results in §1, which unfortunately adds a lot of technicalities.

THEOREM 3.4. *Let $\alpha + \beta + \gamma < C(\infty) < \infty$. Then*

$$\liminf_{t\to\infty} y(t) \geq \epsilon > 0, \qquad \liminf_{t\to\infty} z(t) \geq \epsilon > 0$$

with $\epsilon > 0$ being independent of the initial data, provided that $y(0) > 0$.

Proof. As we cannot exclude that $N(t)$ is unbounded, we choose $X = \{(N, x, y, z);\ 0 \leq N \leq \infty, x, y, z \geq 0, x+y+z = 1\}$. In order to make X a metric space we introduce

$$\varphi(N) = \begin{cases} \frac{N}{(1+N)}, & 0 \leq N < \infty, \\ 1, & N = \infty, \end{cases}$$

and set

$$d\Big((N_1,x_1,y_1,z_2),(N_2,x_2,y_2,z_2)\Big)=|\varphi(N_1)-\varphi(N_2)|+|x_1-x_2|+|y_1-y_2|+|z_1-z_2|.$$

If $N_0<\infty$, the semiflow $\Phi_t(N_0,x_0,y_0,z_0)$ is defined to be the solution of (3.3) at time t, for initial data N_0,x_0,y_0,z_0. If $N_0=\infty$, then $\Phi_t(\infty,x_0,y_0,z_0)=(\infty,x(t),y(t),z(t))$ with x,y,z being the solutions of the x,y,z equations in (3.3), with $C(N)$ being replaced by $C(\infty)$. It is easy to see that Φ is a continuous semiflow. Our metric makes X a compact space. In a first step we show that y is bounded away from zero, or, even more, that $X_2=\{(N,x,0,z);0\leq N\leq\infty,x,z\geq 0,x+y+z=1\}$ is a uniform strong repeller for $X_1=\{(N,x,y,z);0\leq N\leq\infty,x,z\geq 0,y>0,x+y+z=1\}$. Notice that both X_1 and X_2 are forward invariant. By Proposition 3.3, X_2 is a uniform weak repeller for X_1 and hence a uniform strong repeller by Theorem 1.3. Notice that $d((N,x,y,z),X_2)=y$. Hence y is bounded away from zero, with the bound being independent of the initial data. In order to show that the same holds for z we apply Corollary 2.4(a) to the z equation:

$$0\geq\gamma y_\infty-(\beta+\rho)z_\infty.$$

We solve for z_∞:

$$z_\infty\geq\frac{\gamma}{\beta+\rho}y_\infty.$$

This finishes the proof.

3.3. Host limitation by the disease. We conclude this section by using persistence theory for finding a condition to guarantee that the disease limits the population growth. Here we restrict ourselves to the case that $C(\infty)=\infty$. The case $C(\infty)<\infty$ requires a more sophisticated acyclicity consideration and will be dealt with in §5.

We introduce the following expression:

$$\mathcal{P}_0=\frac{\beta-\mu}{\alpha}\left(1+\frac{\gamma}{\mu+\rho}\right). \tag{3.8}$$

PROPOSITION 3.5. *Let $C(\infty)=\infty,\mathcal{P}_0<1$, and $y(0)>0$. Then*

$$\liminf_{t\to\infty}N(t)\leq\hat{N}<\infty$$

with $\hat{N}$ not depending on the initial conditions.

The following result is in itself of interest.

LEMMA 3.6. (a) *There exists unique solutions $y^\diamond>0,z^\diamond>0$ of the equations*

$$\begin{aligned}1&=y^\diamond+z^\diamond,\\0&=\gamma y^\diamond-(\beta+\rho)z^\diamond+\alpha y^\diamond z^\diamond.\end{aligned}$$

(b) *Furthermore,*

$$y^\diamond>\frac{\beta-\mu}{\alpha}\iff\mathcal{P}_0<1.$$

(c) *Finally, $z^\infty\leq z^\diamond$ for any solution of* (3.3). *In particular,*

$$1-z^\infty\geq y^\diamond>0\quad\textit{and}\quad y_\infty\geq y^\diamond-x^\infty.$$

Proof. In order to show part (a) we substitute the first equation into the second:

$$0 = \gamma(1 - z^\diamond) - (\beta + \rho)z^\diamond + \alpha(1 - z^\diamond)z^\diamond =: \varphi(z^\diamond). \tag{3.9}$$

The function φ, defined in (3.9), is strictly concave, $\varphi(0) > 0, \varphi(1) < 0$. Hence, by the intermediate value theorem, there is a solution $z^\diamond \in (0, 1)$, which is unique.

In order to show part (c) we consider the z equation in (3.3) and the relation $1 = x + y + z$ with x, y, x being nonnegative, and obtain the differential inequality

$$\frac{d}{dt}z \leq \gamma(1 - z) - (\beta + \rho)z + \alpha(1 - z)z.$$

The fluctuation Lemma 2.1 provides a sequence $t_n \to \infty$, $n \to \infty$, such that $z'(t_n) \to 0$, $z(t_n) \to z^\infty$, $n \to \infty$. Hence

$$0 \leq \gamma(1 - z^\infty) - (\beta + \rho)z^\infty + \alpha(1 - z^\infty)z^\infty = \varphi(z^\infty).$$

As the function φ is strictly negative for arguments in $(z^\diamond, 1]$, we obtain $z^\infty \leq z^\diamond$. This implies $1 - z^\infty \geq 1 - z^\diamond = y^\diamond > 0$ and $y_\infty \geq 1 - z^\infty - x^\infty \geq y^\diamond - x^\infty$.

In order to show part (b) we solve the second equation in Lemma 3.6 for $z^\diamond$,

$$z^\diamond = \frac{\gamma y^\diamond}{\beta + \rho - \alpha y^\diamond},$$

and we substitute this expression into the first equation,

$$1 = y^\diamond\left(1 + \frac{\gamma}{\beta + \rho - \alpha y^\diamond}\right). \tag{3.10}$$

We also notice the constraint

$$y^\diamond < \frac{\beta + \rho}{\alpha}; \tag{3.11}$$

otherwise $z^\diamond$ would be undefined or strictly negative. The right-hand side of (3.10) is a strictly increasing function of $y^\diamond \geq 0$ under the constraint (3.11). We observe that

$$y^\natural = \frac{\beta - \mu}{\alpha}$$

also satisfies the constraint (3.11). Hence $y^\diamond > y^\natural$ if and only if

$$1 > y^\natural\left(1 + \frac{\gamma}{\beta + \rho - \alpha y^\natural}\right) = \mathcal{P}_0,$$

by the definition of $\mathcal{P}_0$ in (3.8). This concludes the proof of Lemma 3.6.

Proof of Proposition 3.5. Assume that $C(N_\infty) > c > C(0) \geq 0$. We will show that c cannot be chosen arbitrarily large without obtaining a contradiction. The choice of c will not depend on the initial data. Consider the y equation in (3.3). Recall (3.4), $x + y + z = 1$. By Lemma 3.6 (c) we have $1 - z^\infty > 0$, and we can assume

$$x(t) \geq \epsilon - y(t)$$

for large enough t, with $\epsilon > 0$ being independent of the initial data. Hence, for sufficiently large t,

$$\frac{d}{dt}y \geq \Big(C(N)(\epsilon - y) - (\gamma + \alpha + \beta)\Big)y.$$

Choose $c > 0$ such that

$$c\epsilon > \gamma + \alpha + \beta.$$

c can be chosen independently of the initial data. As $C(N(t)) \geq c$ for all large t, we have that $y(t) \geq \delta$ for all sufficiently large t, with some $\delta > 0$, which is independent of the initial data. Now consider the x equation in (3.3):

$$\frac{d}{dt}x \leq \beta + \rho - \delta(C(N) - \alpha)x$$

for sufficiently large t. Choose $c > \alpha$ and recall $C(N_\infty) > c$. Then

$$x^\infty \leq \frac{\beta + \rho}{\delta(c - \alpha)}.$$

Choosing c large enough, we can achieve that

$$x^\infty < \eta$$

for any given arbitrarily small $\eta > 0$. By Lemma 3.6(c) we have

$$y_\infty \geq y^\diamond - x^\infty > y^\diamond - \eta.$$

As $\mathcal{P}_0 < 1$, Lemma 3.6(b) implies that

$$y^\diamond > y^\sharp := \frac{\beta - \mu}{\alpha}.$$

By choosing $\eta > 0$ small enough, i.e., by choosing $c > 0$ large enough, we achieve that

$$y_\infty > y^\diamond - \eta > y^\sharp.$$

From the N equation in (3.3) we obtain that

$$\limsup_{t\to\infty} \frac{1}{N}\frac{d}{dt}N \leq \beta - \mu - \alpha y_\infty < \beta - \mu - \alpha y^\sharp = 0,$$

by the definition of $y^\sharp$. Hence N decreases with a strictly negative exponential rate, a contradiction to our assumption that $C(N_\infty) > c > C(0)$.

Once it is established that the population size cannot tend to infinity, its boundedness can be easily derived from Theorem 1.3.

THEOREM 3.7. *Let $C(\infty) = \infty$, $\mathcal{P}_0 < 1$, and $y(0) > 0$. Then*

$$\limsup_{t\to\infty} N(t) < c < \infty,$$

with c not depending on the initial data.

Proof. We choose X as in the proof of Theorem 3.4 with the same metric such that X becomes a compact space. Set

$$\begin{aligned} X_1 &= \{(N,x,y,z); 0 \leq N < \infty, x,y,z \geq 0, x+y+z=1\}, \\ X_2 &= \{(\infty,x,y,z); x,y,z \geq 0, x+y+z=1\}. \end{aligned}$$

By Proposition 3.5, X_2 is a weak uniform repeller for X_1. As X and X_2 are compact, we can apply Theorem 1.3, and X_2 is a uniform strong repeller for X_1. This implies the statement of the theorem.

We mention that the condition $\mathcal{P}_0 < 1$ is almost sharp. For, if $\mathcal{P}_0 > 1$, the existence of a solution to (3.3) can be shown with N being exponentially increasing and y being bounded away from zero.

4. Uniform persistence via acyclicity of the boundary flow. As we have noticed in the previous section we cannot always obtain sharp conditions for uniform weak persistence by the fluctuation method. So we adapt an approach suggested by Butler and Waltman (1986), Butler, Freedman, and Waltman (1986), and Hale and Waltman (1989) for showing (uniformly) strong persistence.

Again we consider a continuous semiflow Φ on a metric space X, with X being the disjoint union of sets two X_1, X_2, where X_1 is open.

Note that we do neither assume that X_2 is contained in the closure of X_1 nor that X_2 is forward invariant.

4.1. Uniform weak persistence. As uniform weak persistence may be of interest in itself and requires less stringent compactness properties than uniform strong persistence, we discuss it in a section of its own.

We assume the following weaker version of the compactness assumption in §1:

($\mathbf{C}_{4.1}$) There is some $\delta > 0$ with the following properties:

- If $x \in X$ such that $d(\Phi_t(x), X_2) < \delta$ for all $t \geq 0$, then the forward orbit of x has compact closure in X.
- If x_n is a sequence in X satisfying

$$\limsup_{t\to\infty} d(\Phi_t(x_n), X_2) \to 0, \qquad n \to \infty,$$

then $\bigcup_{n\in\mathbf{N}} \omega(x_n)$ has compact closure.

The ω*-limit set* of a point y is defined as usual:

$$\omega(y) = \bigcap_{t\geq 0} \overline{\Phi([t,\infty) \times \{y\})}.$$

We say that an element $y \in X$ has a full orbit, if there is a function $x(t)$, $-\infty < t < \infty$, such that $x(0) = y$ and $x(t+s) = \Phi_t(x(s))$ for all $t \geq 0, s \in \mathbf{R}$. The α*-limit set* of a full orbit $x(t)$ is defined by

$$\alpha(x) = \bigcap_{t\geq 0} \overline{x((-\infty,-t])}.$$

We recall that a subset M of X is called *forward invariant* if and only if $\Phi_t(M) \subset M, t > 0$, and *invariant* if and only if $\Phi_t(M) = M, t > 0$. A compact invariant subset M of $Y \subseteq X$ is called an *isolated compact invariant set in* Y if there is an open subset

U of X such that there is no invariant set $\tilde{M}$ with $M \subseteq \tilde{M} \subseteq U \cap Y$ except M. U is called an *isolating neighborhood* of M.

PROPOSITION 4.1. *Let M be a compact invariant subset of X_2 which is an isolated compact invariant set in X. Let (x_n) be a sequence of elements in X such that*

$$\limsup_{t\to\infty} d(\Phi_t(x_n), X_2) \to 0, \qquad n \to \infty,$$

and $\omega(x_n) \not\subseteq M$. Further assume that there is a sequence $(p_n), p_n \in \omega(x_n)$, with $d(p_n, M) \to 0$, $n \to \infty$. Then, after choosing a subsequence, the sets $\omega(x_n)$ converge (in the Hausdorff metric) to a subset ω of X_2 that is invariant, compact, and connected. Further, there exist an element $u \in \omega \setminus M$ with $\omega(u) \subseteq M$ and an element $w \in \omega \setminus M$ with a full orbit in $\omega \subseteq X_2$ whose α-limit set is contained in M. u can be chosen such that its forward orbit is arbitrarily close to M. w can be chosen such that its backwards orbit is arbitrarily close to M.

Remark. If all elements x_n are identical, it is sufficient to assume that M is an isolated compact invariant set in X_2. This way we obtain a version of the Butler and McGehee lemma (Waltman (1991)).

We mention that the ω and α-limit sets in Proposition 4.1 are nonempty and compact because of the compactness condition $(\mathbf{C}_{4.1})$.

Proposition 4.1 should be compared to the almost identical Lemma 4.3 in Hale and Waltman (1989). Notice that we can arrange $u, w \in \omega \subseteq X_2$. Our proof parallels the proof of Lemma 4.3 in Hale and Waltman (1989). We give an even more detailed proof here in order to convince the reader that our compactness assumptions $\big((\mathbf{C}_{4.1})$ rather than point-dissipativity and asymptotic smoothness$\big)$ are sufficient.

Proof. In view of our first assumptions in $(\mathbf{C}_{4.1})$, we can assume that $d(\Phi_t(x_n), X_2) < \delta$ for all $t \geq 0$. Otherwise we replace x_n by $\Phi_{\tau_n}(x_n)$ with suitably chosen τ_n. It follows from our compactness condition $(\mathbf{C}_{4.1})$ that the closure Ω of $\bigcup_{n=1}^{\infty} \omega(x_n)$ is compact. Hence, after choosing a subsequence, the sets $\omega(x_n)$ converge towards a set ω in the Hausdorff metric. ω inherits compactness, invariance, and connectedness from the sets $\omega(x_n)$. Our assumptions further imply $\omega \subseteq X_2$.

Let U, V be open sets in X such that $M \subset V \subset \bar{V} \subset U$, and U is an isolating neighborhood of M. We can choose U as small as needed and in particular as a subset of the δ neighborhood of X_2. As U is isolating, we have $\omega(x_n) \not\subseteq U$ because otherwise U would contain the compact invariant set $\omega(x_n) \cup M$, which is larger than the maximal (in U) compact invariant set M. As $\omega(x_n) \ni p_n \to M$ we find sequences $r_n < s_n < t_n$ with

$$\Phi_{r_n}(x_n) \in \partial V, \quad \Phi_{t_n}(x_n) \in \partial V, \quad \Phi_{s_n}(x_n) \to M, \tag{4.1}$$

$$\Phi_t(x_n) \in V, \qquad r_n < t < t_n. \tag{4.2}$$

For each n, r_n, s_n, t_n can be chosen arbitrarily large. In particular we can arrange that

$$d(\Phi_{r_n}(x_n), \omega(x_n)) \to 0, \quad d(\Phi_{t_n - j}(x_n), \omega(x_n)) \to 0, \quad j = 1, \cdots, n, \quad n \to \infty. \tag{4.3}$$

As $\bigcup_{n=1}^{\infty} \omega(x_n)$ has compact closure, we can choose subsequences such that

$$\Phi_{r_n}(x_n) \to u \in \partial V \cap \omega, \quad \Phi_{s_n}(x_n) \to v \in M, \quad \Phi_{t_n}(x_n) \to w \in \partial V \cap \omega. \tag{4.4}$$

We claim $\omega(u) \subset M$ and that w has a full orbit whose α-limit set is contained in M.

In order to show $\omega(u) \subset M$, we first assume that the sequence $s_n - r_n$ is bounded. After choosing subsequences we may assume that $s_n - r_n \to \sigma$, $n \to \infty$. As Φ is continuous, it follows from (4.4) that

$$v = \lim_{n\to\infty} \Phi_{s_n}(x_n) = \lim_{n\to\infty} \Phi_{s_n - r_n}(\Phi_{r_n}(x_n)) = \Phi_\sigma(u).$$

As $v \in M$ and M is invariant, we have $\omega(u) = \omega(v) \subset M$.

Hence we can assume that, after choosing subsequences, the sequence $s_n - r_n$ converges to ∞ for $n \to \infty$. This implies that u has a full forward orbit in $\bar{V} \cap \omega$. As ω is compact, the ω-limit set of u is nonempty, compact, and invariant. Hence $\omega(u) \subset M$.

To show that w has a full orbit with α-limit set in M we proceed similarly. First we assume that the sequence $t_n - s_n$ is bounded. After choosing subsequences we may assume that $t_n - s_n \to \tau, n \to \infty$. As Φ is continuous, we have from (4.4) that

$$w = \lim_{n\to\infty} \Phi_{t_n - s_n}(\Phi_{s_n}(x_n)) = \Phi_\tau(v).$$

As M is invariant and $v \in M$, we have $w \in M$, a contradiction, because $w \in \partial V$. So we can assume that the sequence $t_n - s_n$ converges to ∞ after choosing subsequences again. Let $j \in \mathbf{N}$. Then $\Phi_{t_n - j}(x_n) \in V$ for sufficiently large n. Now recall (4.3) and (4.4) and the compactness of the closure of $\bigcup_{n=1}^\infty \omega(x_n)$. Employing a diagonalization procedure we can assume that, after choosing a subsequence,

$$\Phi_{t_n - j}(x_n) \to w_j \in \bar{V} \cap \omega, \qquad n \to \infty.$$

As Φ is continuous, we have $\Phi_j(w_j) = w$, $\Phi_1(w_j) = w_{j-1}$. The definition

$$\Phi_{-j+s}(w) = \Phi_s(w_j), \qquad 0 \le s < 1,$$

provides a continuous backward orbit in ω starting from w. Further, by (4.2),

$$\Phi_{-j+s}(w) = \lim_{n\to\infty} \Phi_s(\Phi_{t_n - j}(x_n)) = \lim_{n\to\infty} \Phi_{t_n + s - j}(x_n) \in \bar{V}.$$

Hence we have a full continuous backward orbit in $\bar{V} \cap \omega$ starting at w. This backward orbit has compact closure because ω is compact. Thus the α-limit set of this orbit of w is a nonempty, compact, invariant subset of the isolating neighborhood U, and hence a subset of M.

LEMMA 4.2. *Let x_n be a sequence of elements in X satisfying*

$$\limsup_{t\to\infty} d(\Phi_t(x_n), X_2) \to 0, \qquad n \to \infty.$$

Then, after choosing a subsequence, $\omega(x_n) \to \omega, n \to \infty$, in the Hausdorff metric, with some compact, invariant, connected subset ω of X_2. Moreover, for every

$$z \in \Omega_\omega := \bigcup_{y \in \omega} \omega(y),$$

there exists a sequence $p_n \in \omega(x_n)$ such that $p_n \to z, n \to \infty$.

We remark that the ω-limit sets in Lemma 4.2 are nonempty, compact, and invariant by our compactness assumption $(\mathbf{C}_{4.1})$.

Proof. We can assume that all forward orbits of x_n lie in the δ neighborhood of X_2. The existence of ω now follows as in Proposition 4.1. Let $z \in \Omega_\omega$. Then $z \in \omega(y)$ for some $y \in \omega$. Let $\epsilon > 0$. Then there is some $t > 0$ such that $d(\Phi_t(y), z) < \epsilon$. As Φ is continuous, there is some neighborhood W of y such that $d(\Phi_t(w), z) < \epsilon$ for any $w \in W$. As $\omega(x_n) \to \omega$ in the Hausdorff metric, we have $\omega(x_n) \cap W \neq \emptyset$ for all sufficiently large n. So, for any large enough n, we find some $q \in \omega(x_n)$ such that $d(\Phi_t(q), z) < \epsilon$. As $\omega(x_n)$ is invariant, $p = \Phi_t(q) \in \omega(x_n), d(p, z) < \epsilon$.

We define

$$\Omega_2 = \bigcup_{y \in Y_2} \omega(y), \qquad Y_2 = \{x \in X_2; \Phi_t(x) \in X_2 \; \forall t > 0\}.$$

Our compactness assumption $(\mathbf{C}_{4.1})$ implies that Ω_2 has compact closure and is invariant. Following Hale and Waltman (1989), a finite covering $M = \bigcup_{k=1}^m M_k$ in X_2 is called *isolated* if the sets M_k are pairwise disjoint subsets of X_2, which are isolated compact invariant sets in X.

A set $M \subset X_2$ is said to be *chained* (in X_2) to another (not necessarily different) set $N \subset X_2$, symbolically $M \mapsto N$, if there is some $y \in X_2, y \notin M \cup N$, and a full orbit through y in X_2 whose α-limit set is contained in M and whose ω-limit set is contained in N.

A finite covering $M = \bigcup_{k=1}^m M_k$ is called *cyclic* if, after possible renumbering, $M_1 \mapsto M_1$ or $M_1 \mapsto M_2 \mapsto \cdots \mapsto M_k \mapsto M_1$ for some $k \in \{2, \ldots, m\}$. M is called an *acyclic covering* otherwise.

Notice that Y_2 and so Ω_2 may be empty, e.g., if all orbits starting in X_2 leave X_2 and never return. Then Ω_2 has an acyclic covering, namely, the empty set. In many applications, however, X_2 is forward invariant such that $Y_2 = X_2$.

PROPOSITION 4.3. *Let x_n be a sequence of elements in X_1 satisfying*

$$\limsup_{t \to \infty} d(\Phi_t(x_n), X_2) \to 0, \qquad n \to \infty.$$

Let $M = \bigcup_{k=1}^m M_k$ be an isolated covering of Ω_2 such that $\omega(x_n) \not\subseteq M_k$ for all n, k. Then M is cyclic.

Proof. As $\omega \subseteq Y_2$, we obtain that $\Omega_\omega \subseteq \Omega_2$. By Lemma 4.2 (after possible renumbering of the covering M) we have $\Omega_\omega \cap M_1 \neq \emptyset$, and there is a sequence $p_n \in \omega(x_n)$ such that $d(p_n, M_1) \to 0, n \to \infty$. As $\omega(x_n) \not\subseteq M_1$, Proposition 4.1 provides an element $u \in \omega \setminus M_1$ with a full orbit in X_2 whose α-limit set lies in M_1. As $\omega \subset Y_2$, $\omega(u) \subset M$. As $\omega(u)$ is connected and the M_k are pairwise disjoint and compact, $\omega(u) \subset M_k$ for some k. Either $k = 1$ and the proof is finished or, after possible renumbering, $\omega(u) \subset M_2$ and $M_1 \mapsto M_2$. As $u \in \omega, \omega(u) \subset M_2$, we have that $\Omega_\omega \cap M_2 \neq \emptyset$, and Lemma 4.2 provides a (possibly different) sequence $p_n \in \omega(x_n)$ with $d(p_n, M_2) \to 0, n \to \infty$. Repeating our argument, we find that M_2 is chained to some M_k. Continuing this way we finally obtain a cyclic chain because there are only finitely many M_k.

THEOREM 4.4. *Let X_1 be open and forward invariant under the continuous semiflow Φ on X. Let the compactness assumption $(\mathbf{C}_{4.1})$ hold. Assume that Ω_2 has an acyclic isolated covering $M = \bigcup_{k=1}^m M_k$ such that each part M_k of M is a weak repeller for X_1. Then X_2 is a uniform weak repeller for X_1.*

Proof. If X_2 is not a uniform weak repeller for X_1, then, by definition (see the Introduction), we find a sequence $x_n \in X_1$ satisfying

$$\limsup_{t\to\infty} d(\Phi_t(x_n), X_2) \to 0, \qquad n \to \infty.$$

As each part M_k of M is a weak repeller for X_1, we have $\omega(x_n) \not\subseteq M_k$. Hence the assumptions of Proposition 4.3 are satisfied and the covering M has to be cyclic, in contradiction to the assumptions of the theorem.

4.2. Uniform strong persistence. The next theorem is general enough to obtain all results for our endemic model that can possibly be obtained from an acyclicity consideration.

THEOREM 4.5. *Let X be locally compact, and let X_2 be compact in X and X_1 be forward invariant under the continuous semiflow Φ on X. Assume that Ω_2,*

$$\Omega_2 = \bigcup_{y\in Y_2} \omega(y), \qquad Y_2 = \{x \in X_2; \Phi_t(x) \in X_2\ \forall t > 0\},$$

has an acyclic isolated covering $M = \bigcup_{k=1}^m M_k$. If each part M_k of M is a weak repeller for X_1, then X_2 is a uniform strong repeller for X_1.

In case that Y_2 is empty, Ω_2 has an acyclic isolated covering, the empty set.

Theorem 4.5 has been stated in Freedman and Moson (1990) as a remark in the following form: If the assumptions of Theorem 4.5 are satisfied and X_2 is forward invariant and a weak repeller for X_1, then it is a uniform strong repeller for X_1.

Proof. As X_2 has a compact neighborhood in X, the compactness assumption $(\mathbf{C}_{4.1})$ is automatically satisfied. Hence, by Theorem 4.4, X_2 is a uniform weak repeller for X_1. Thus X_2 is a uniform strong repeller for X_1 by Theorem 1.3.

If we face infinite-dimensional dynamical systems, more complicated assumptions have to be made. We require the following compactness condition rather than point dissipativity and asymptotic smoothness (Hale and Waltman (1989)):

$(\mathbf{C}_{4.2})$ There exist $\delta > 0$ and a subset B of X with the following properties:

- If $x \in X$ and $d(x, X_2) < \delta$, then $d(\Phi_t(x), B) \to 0, t \to \infty$.
- The intersection $B \cap B_\delta(X_2)$ of B with the δ-neighborhood of X_2, $B_\delta(X_2) = \{x \in X; d(x, X_2) < \delta\}$ has compact closure.

THEOREM 4.6. *Let X_1 be open in X and forward invariant under Φ. Further, let the compactness assumption $(\mathbf{C}_{4.2})$ hold. Assume that Ω_2,*

$$\Omega_2 = \bigcup_{y\in Y_2} \omega(y), \qquad Y_2 = \{x \in X_2; \Phi_t(x) \in X_2\ \forall t > 0\},$$

has an acyclic isolated covering $M = \bigcup_{k=1}^m M_k$ such that each part M_k of M is a weak repeller for X_1. Then X_2 is a uniform strong repeller for X_1.

Proof. Apparently the assumptions of Theorem 4.4 are satisfied such that X_2 is a uniform weak repeller for X_1. This implies that X_1 is forward invariant under Φ. We now refine the arguments in Proposition 1.2. As X_2 is a uniform weak repeller for X_1, there exists some $\epsilon > 0$ such that

$$\limsup_{t\to\infty} d(\Phi_t(x), X_2) > \epsilon \quad \forall x \in X_1. \tag{4.5}$$

We can assume that $\epsilon < \delta$ in assumption $(\mathbf{C}_{4.2})$.

Now suppose that X_2 is not a uniform strong repeller for X_1. Then there exist sequences $x_j \in X_1$ and $0 < \epsilon_j \to 0$ such that

$$\liminf_{t\to\infty} d(\Phi_t(x_j), X_2) < \epsilon_j \quad \forall j. \tag{4.6}$$

For every j we can find sequences $r_{jn} < s_{jn} < t_{jn}$ with $r_{jn} \to \infty, n \to \infty$, such that

$$d(\Phi_{s_{jn}}(x_j), X_2) < \epsilon_j, \tag{4.7}$$

$$d(\Phi_{r_{jn}}(x_j), X_2) = \epsilon = d(\Phi_{t_{jn}}(x_j), X_2), \tag{4.8}$$

$$d(\Phi_t(x_j), X_2) < \epsilon, \qquad r_{jn} < t < t_{jn}. \tag{4.9}$$

By (4.8) and assumption $(\mathbf{C}_{4.2})$ we have that $d(\Phi_{r_{jn}}(x_j), B \cap B_\delta(X_2)) \to 0, n \to \infty$. We choose numbers n_j such that $d(\Phi_{r_{jn}}(x_j), B \cap B_\delta(X_2)) < 1/j$. As $B \cap B_\delta(X_2)$ has compact closure,we can assume that, after choosing a subsequence, $(\Phi_{r_{jn_j}}(x_j))$ converges for $j \to \infty$. We set $r_j = r_{jn_j}, s_j = s_{jn_j}, t_j = t_{jn_j}$. By (4.7)–(4.9), we have $r_j < s_j < t_j$ with $r_j \to \infty, j \to \infty$ such that

$$d(\Phi_{s_j}(x_j), X_2) \to 0, \qquad j \to \infty, \tag{4.10}$$

$$d(\Phi_{r_j}(x_j), X_2) = \epsilon = d(\Phi_{t_j}(x_j), X_2), \tag{4.11}$$

$$d(\Phi_s(x_j), X_2) < \epsilon, \qquad r_j < s < t_j, \tag{4.12}$$

with $\Phi_{r_j}(x_j)$ having a limit for $j \to \infty$. Then we conclude as in Proposition 1.2. First we show that $t_j - r_j \to \infty$. If not, the sequence $\Phi_{s_j}(x_j)$ also converges, and we can arrive at a contradiction in the same way as in Step 1 of Proposition 1.2. To perform Step 2 in Proposition 1.2 we only need the convergence of $\Phi_{r_j}(x_j)$, which we have. This finishes the proof.

5. Application of the acyclicity method to an endemic model: persistence and limitation of the host population. (Act II).

5.1. Host persistence. We intend to derive a sharp condition for persistence of the host population in model (3.1) under the assumption $C(0) > 0$. We have to show that the set $X_2 = \{N = 0, x \geq 0, y \geq 0, z \geq 0, x+y+z = 1\}$ is a uniform strong repeller for $X_1 = \{N > 0, x \geq 0, y \geq 0, z \geq 0, x+y+z = 1\}$. We want to apply Theorem 4.5. To this end we analyze the semiflow induced by (3.3) on the forward invariant set X_2, i.e., for $N \equiv 0$:

$$\begin{aligned} \frac{d}{dt}x &= \beta(1-x) - (C(0)-\alpha)xy + \rho z, \\ \frac{d}{dt}y &= C(0)xy - (\gamma+\alpha+\beta)y + \alpha y^2, \\ \frac{d}{dt}z &= \gamma y - (\beta+\rho)z + \alpha yz, \\ 1 &= x+y+z. \end{aligned} \tag{5.1}$$

This is a special case of the model studied by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990). They show the following.

PROPOSITION 5.1. (a) *Let* $C(0) \leq \beta+\alpha+\gamma$. *Then* $y(t), z(t) \to 0, x(t) \to 1$, $t \to \infty$.

(b) *Let* $C(0) > \beta+\alpha+\gamma$. *Then there exist unique equilibrium solutions to* (5.1) *such that* $x^\star, y^\star, z^\star > 0, x^\star+y^\star+z^\star = 1$. *Moreover,* $x(t), y(t)z(t) \to x^\star, y^\star, z^\star,$ $t \to \infty$, *for any solution x, y, z to* (5.1) *satisfying* $x(0) \geq 0, y(0) > 0, z(0) \geq 0, x(0) + y(0) + z(0) = 1$. *However, if x, y, z is a solution to* (5.1) *satisfying* $y(0) = 0,\ x(0) \geq 0, z(0) \geq 0,\ x(0) + z(0) = 1$, *then* $y \equiv 0$ *and* $x(t) \to 1, z(t) \to 0, t \to \infty$.

Hence $\Omega_2 = \bigcup_{\vec{y} \in X_2} \omega(\vec{y})$ consists of one or two elements, the disease-free equilibrium $N = 0, x = 1, y = 0 = z$, and the endemic equilibrium $N = 0, x = x^\star, y = y^\star, z = z^\star$. By Proposition 5.1 these equilibria cannot be chained to themselves. Furthermore, they cannot be chained to each other in a cyclic way. So they represent an acyclic covering for Ω_2. To show that this covering is isolated and a weak repeller for X_1, we analyze the behavior of

$$\frac{d}{dt}N = (\beta - \mu - \alpha y)N, \qquad N(0) > 0, \tag{5.2}$$

if y either stays close to zero or to $y^\star$ (in case that the latter exists). If y stays close to zero, N increases exponentially because we have assumed $\beta > \mu$. If we can show that N also increases exponentially if y stays close to $y^\star$, we are done: For every trajectory starting with $N(0) = 0$ converges to one of the two equilibria by Proposition 5.1, and no trajectory starting with $N(0) > 0$ can stay close to $N = 0, x = 1, y = z = 0$ or to $N = 0, x = x^\star, y = y^\star, z = z^\star$.

In our case it is actually possible to determine the equilibrium solutions in Proposition 5.1(b) explicitly. This seems no longer possible in the more complicated models by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990). Even in our special case the explicit solution of $y^\star$ is not very helpful in analyzing (5.2) if y stays close to $y^\star$. So we try to obtain information from the equilibrium equations. At this point it is not clear whether our procedure would also work for the above-mentioned more complicated models. We can restrict our consideration to the case that $C(0) > \beta + \alpha + \gamma$:

$$\begin{aligned} 0 &= C(0)(1 - y^\star - z^\star) - (\gamma + \alpha + \beta) + \alpha y^\star, \\ 0 &= \gamma y^\star - (\beta + \rho)z^\star + \alpha y^\star z^\star. \end{aligned}$$

We solve both equations for $z^\star$:

$$\begin{aligned} z^\star &= 1 - y^\star - \frac{\gamma + \alpha + \beta}{C(0)} + \frac{\alpha}{C(0)} y^\star, \\ z^\star &= \frac{\gamma y^\star}{\beta + \rho - \alpha y^\star}. \end{aligned} \tag{5.3}$$

From the second equation we learn the constraint

$$\alpha y^\star < \beta + \rho; \tag{5.4}$$

otherwise $z^\star$ is not positive. We equate the two equations in (5.3) and reorganize terms:

$$0 = 1 - y^\star - \frac{\gamma + \alpha + \beta}{C(0)} + \frac{\alpha}{C(0)} y^\star - \frac{\gamma y^\star}{\beta + \rho - \alpha y^\star}. \tag{5.5}$$

In the range (5.4), the right-hand side of (5.5) is a strictly decreasing function of $y^\star$ (recall $C(0) > \gamma + \alpha + \beta > \alpha$). Hence there is at most one solution to (5.3). If $y^\star$ approaches the minimum of 1 and $(\beta + \rho)/\alpha$, the right-hand side of (5.5) becomes negative. Hence, by the intermediate value theorem, we have a nontrivial solution if and only if the right-hand side of (5.5) is strictly positive for $y^\star = 0$, i.e., if

$$1 - \frac{\gamma + \alpha + \beta}{C(0)} > 0.$$

We are actually interested in the question whether

$$\beta - \mu - \alpha y^\star > 0, \quad \text{i.e., } y^\star < \frac{\beta - \mu}{\alpha}.$$

(Then we can conclude that N in (5.2) increases exponentially if y stays sufficiently close to $y^\star$.) Assuming $C(0) > \gamma + \alpha + \beta$, this is the case if and only if the right-hand side of (5.5) is strictly negative for $y^\star = (\beta - \mu)/\alpha$, i.e.,

$$1 - \frac{\beta - \mu}{\alpha} - \frac{\gamma + \alpha + \mu}{C(0)} - \frac{\gamma(\beta - \mu)}{\alpha(\mu + \rho)} < 0.$$

We reorganize this inequality:

$$\frac{1}{C(0)} > \mathcal{T}_0$$

with

$$\mathcal{T}_0 := = \frac{1 - \mathcal{P}_0}{\mu + \gamma + \alpha.}, \qquad \mathcal{P}_0 = \frac{\beta - \mu}{\alpha}\left(1 + \frac{\gamma}{\mu + \rho}\right). \tag{5.6}$$

We combine these considerations to the following statement.

THEOREM 5.2. *Let*

$$\frac{1}{C(0)} > \mathcal{T}_0,$$

with $\mathcal{T}_0$ *being defined in* (5.6) *Then the host population is strongly uniformly persistent, i.e.,*

$$\liminf_{t \to \infty} N(t) \geq \epsilon > 0,$$

with ϵ *not depending on the initial data unless* $N(0) = 0$.

The result in Theorem 5.2 is almost sharp because it can be shown that there is a solution to (3.3) with $N(t)$ exponentially decreasing if $1/C(0) < \mathcal{T}_0$ (see Thieme, Thm. 7.1).

5.2. Host limitation. In §3.3 we have shown that the disease keeps the host population bounded if $C(\infty) = \infty$ and $\mathcal{P}_0 < 1$. Now we will derive a sharp condition for the case that $C(\infty) < \infty$. To this end we want to study an appropriate boundary flow. As the boundary of interest contains $N = \infty$, we first have to extend the state space and the dynamical system. This is done in the same way as in Theorem 3.4, and X becomes a compact metric space. We will show that the set $X_2 = \{(N, x, y, z); N, x, y, z \geq 0, x + y + z = 1, N = \infty \text{ or } y = 0\}$ is a uniform strong repeller for the set $X_1 = \{(N, x, y, z); 0 \leq N < \infty, x, z \geq 0, y > 0, x + y + z = 1\}$. We want to apply Theorem 4.5. To this end we analyze the flow on the forward invariant set X_2, i.e., $N \equiv \infty$ and

$$(5.7)\qquad \begin{aligned} \frac{d}{dt}x &= \beta(1-x) - (C(\infty)-\alpha)xy + \rho z, \\ \frac{d}{dt}y &= C(\infty)xy - (\gamma+\alpha+\beta)y + \alpha y^2, \\ \frac{d}{dt}z &= \gamma y - (\beta+\rho)z + \alpha yz, \\ 1 &= x+y+z. \end{aligned}$$

Again this is a special case of the model studied by Busenberg and van den Driessche (1990) and Busenberg and Hadeler (1990).

PROPOSITION 5.3. (a) *Let* $C(\infty) \leq \beta+\alpha+\gamma$. *Then* $y(t), z(t) \to 0, x(t) \to 1,\ t \to \infty$. (b) *Let* $C(\infty) > \beta+\alpha+\gamma$. *Then there exist unique equilibrium solutions to* (5.7) *such that* $x^\star, y^\star, z^\star > 0, x^\star+y^\star+z^\star = 1$. *Moreover,* $x(t), y(t)z(t) \to x^\star, y^\star, z^\star,\ t \to \infty$, *for any solution* x, y, z *to* (5.7) *satisfying* $x(0) \geq 0, y(0) > 0, z(0) \geq 0, x(0)+y(0)+z(0) = 1$. *However, if* x, y, z *is a solution to* (5.7) *satisfying* $y(0) = 0,\ x(0) \geq 0, z(0) \geq 0,\ x(0)+z(0) = 1$, *then* $y \equiv 0$ *and* $x(t) \to 1, z(t) \to 0, N(t) \to \infty$ *for* $t \to \infty$.

Apparently the disease can only limit the host population if it becomes endemic, i.e., in the situation described in Proposition 5.3(b). Thus we assume $C(\infty) > \beta+\alpha+\gamma$. Then the set $\Omega_2 = \bigcup_{\vec{y}\in X_2}\omega(\vec{y})$ consists of two equilibria, the disease-free equilibrium $N = \infty, x = 1, y = 0, z = 0$, and the endemic equilibrium $N = \infty, x = x^\star, y = y^\star, z = z^\star$. Apparently the disease-free and the endemic equilibrium cannot be chained to themselves or (in a cyclic way) to each other in X_2. So we only need to show that each of these two equilibria are isolated for the semiflow on X and that the two equilibria do not attract orbits that start in X_1. For the disease-free equilibrium, this follows from Proposition 5.3 and from Theorem 3.4, which states that y remains bounded away from zero if $y(0) > 0$ with the bound being independent of $y(0)$. To prove the same for the endemic equilibrium, we analyze the behavior of

$$\frac{d}{dt}N = (\beta - \mu - \alpha y)N$$

and derive a condition that guarantees that N decreases exponentially if the solution stays close enough to the endemic equilibrium. This will imply that this equilibrium is the largest forward invariant set in a sufficiently small neighborhood and cannot attract orbits starting in X_1. The exponential decrease of N will follow if

$$\eta - \mu - \alpha y^\star < 0, \quad \text{i.e., } y^\star > \frac{\beta-\mu}{\alpha},$$

for $y^\star, z^\star > 0$ satisfying

$$\begin{aligned} 0 &= C(\infty)(1-y^\star-z^\star) - (\gamma+\alpha+\beta) + \alpha y^\star, \\ 0 &= \gamma y^\star - (\beta+\rho)z^\star + \alpha y^\star z^\star. \end{aligned}$$

A consideration analogous to the one leading to Theorem 5.2 shows that N exponentially decreases if y, z approach $y^\star, z^\star$, provided that $\mathcal{T}_0 > 1/C(\infty)$. We observe that $\mathcal{T}_0$ in (5.6) is a strictly increasing function of μ as long as $\mu \leq \beta$. Thus

$$(5.8)\qquad \mathcal{T}_0 < \frac{1}{\beta+\gamma+\alpha}$$

such that $\mathcal{T}_0 > 1/C(\infty)$ implies the assumption in Proposition 5.3(b), $C(\infty) > \beta + \gamma + \alpha$.

We combine these considerations into the following result.

THEOREM 5.4. *Let $N(0) > 0, y(0) > 0$ and*

$$\mathcal{T}_0 > \frac{1}{C(\infty)} > 0.$$

Then

$$\limsup_{t\to\infty} N(t) \leq c < \infty, \qquad \liminf_{t\to\infty} y(t) \geq \epsilon > 0$$

with c, ϵ being independent of the initial data.

Notice that $\mathcal{T}_0 > 1/C(\infty)$ includes $\mathcal{P}_0 < 1$. This condition is almost sharp because it can easily be seen that there is a solution with y being bounded away from zero and N exponentially increasing if $\mathcal{T}_0 < 1/C(\infty)$ and $C(\infty) > \beta + \alpha + \gamma$.

Combining Theorem 5.2 and 5.4 we see that the population size is bounded away from zero and infinity if

$$\frac{1}{C(0)} > \mathcal{T}_0 > \frac{1}{C(\infty)}, \tag{5.9}$$

i.e., the disease limits the population growth without eradicating the population. As we will see later (Theorem 7.1), the disease is endemic under this condition irrespective of whether $C(\infty) < \infty$ or $C(\infty) = \infty$. For the interested reader we mention that (3.3) has an equilibrium solution under (5.9). We will show elsewhere (Thieme, to appear) that the above-mentioned special (equilibrium or exponential) solutions, if they exist, are locally asymptotically stable in an appropriate sense.

6. "Weak" implies "strong" without point dissipativity. In this section we make an attempt to drop the point-dissipativity assumption more or less completely in order to find a sharp condition for endemicity of the disease without requiring that the population size be bounded or that $C(\infty) < \infty$.

Assumptions 6.1. Though we do not want to assume point dissipativity, we would like to take advantage of the possibility that some components of the dynamical system finally become bounded. Hence we assume the following:

(A) There is a subset Y_1 of X_1 such that, for all $x \in X_1$, there is some time $t(x) > 0$ with $\Phi_t(x) \in Y_1$ for all $t \geq t(x)$.

As we cannot require that semiorbits are bounded, we assume that they satisfy some kind of conditional compactness.

($\mathbf{C}_{6.1}$) For any bounded subset B of X_1 and any $y \in Y_1$, the orbit $\Phi([0,\infty) \times \{y\}) \cap B$ has compact closure.

This set may be empty. Then it will be relatively compact automatically. ω-limit sets are defined as usual:

$$\omega(y) = \bigcap_{t\geq 0} \overline{\Phi([t,\infty) \times \{y\})}.$$

Under our assumptions, $\omega(y)$ may be empty or unbounded. ($\mathbf{C}_{6.1}$) guarantees that the intersection of $\omega(y)$ with any bounded closed set is compact. Moreover, we require that

($\mathbf{C}_{6.2}$) $\bigcup_{y\in Y_1} \omega(y) \cap B$ has compact closure for any bounded subset B of Y_1.

Dropping point dissipativity requires certain orbits to be repelled in a fixed period of time.

(R) For any sufficiently small $\epsilon > 0$ there is a subset D of X_1 and some δ, $0 < \delta < \epsilon$, and a time $t > 0$ with the following properties:

(i) There is no element $x \in Y_1 \setminus D$ such that $d(x, X_2) = \epsilon$ and $d(\Phi_s(x), X_2) < \epsilon$ for all $0 < s \leq t$.

(ii) If $x \in Y_1 \setminus D$ is an element in Y_1 with semiorbit in Y_1 and $r \in (0, t]$ is such that $d(x, X_2) = \epsilon = d(\Phi_r(x), X_2)$ and $d(\Phi_s(x), X_2) < \epsilon$ for all $0 < s < r$, then $d(\Phi_s(x), X_2) \geq \delta$ for all $0 \leq s \leq r$.

(iii) $D \cap Y_1 \cap S_\epsilon(X_2)$ is bounded, where $S_\epsilon(X_2) = \{x \in X; d(x, X_2) = \epsilon\}$ is the ϵ shell of X_2 in X.

THEOREM 6.2. *Let X be a metric space with metric d. Let X be the disjoint union of two sets X_1 and X_2, with X_1 open in X. Let Φ be a continuous semiflow on X_1 such that Assumptions* 6.1 *are satisfied.*

Then X_2 is a uniform strong repeller for X_1, whenever it is a uniform weak repeller for X_1.

Proof. We follow the lines of the proof of Proposition 1.2. Assume that X_2 is a uniform weak repeller for X_1. Then there exists $\epsilon > 0$ such that

$$\limsup_{t\to\infty} d(\Phi_t(x), X_2) > \epsilon \quad \forall x \in X_1. \tag{6.1}$$

We can assume that ϵ is sufficiently small for Assumption 6.1 **(R)** to apply.

Now suppose that X_2 is not a uniform strong repeller for X_1. Then there exist sequences $x_j \in X_1$ and $0 < \epsilon_j \to 0$ such that

$$\liminf_{t\to\infty} d(\Phi_t(x_j), X_2) < \epsilon_j \quad \forall j. \tag{6.2}$$

For every j we can find sequences $r_{jn} < s_{jn} < t_{jn}$ with $r_{jn} \to \infty, n \to \infty$, such that

$$d(\Phi_{s_{jn}}(x_j), X_2) < \epsilon_j, \tag{6.3}$$

$$d(\Phi_{r_{jn}}(x_j), X_2) = \epsilon = d(\Phi_{t_{jn}}(x_j), X_2), \tag{6.4}$$

$$d(\Phi_s(x_j), X_2) < \epsilon, \quad r_{jn} < s < t_{jn}. \tag{6.5}$$

Replacing x_j by $\Phi_{\tau_j}(x_j)$ with a suitably chosen τ_j, we can assume that $d(x_j, X_2) \leq \epsilon$ and the semiorbits of all x_j lie in Y_1.

We choose B, D and t, δ according to Assumption 6.1 **(R)**.

Case 1. For infinitely many j there are infinitely many r_{jn} such that $\Phi_{r_{jn}}(x_j) \in D$.

After choosing subsequences we can assume that $\Phi_{r_{jn}}(x_j) \in D$ for all j, n. Let $B_\epsilon = D \cap Y_1 \cap S_\epsilon(X_2)$. By Assumption 6.1 **(R)** (iii), B_ϵ is bounded. Further, by (6.4), $\Phi_{r_{jn}}(x_j) \in B_\epsilon$ for all j, n. In particular, the sequence $\Phi_{r_{jn}}(x_j)$ is bounded. By the compactness assumption ($\mathbf{C}_{6.1}$), we have that $\omega(x_j) \cap B_\epsilon$ is nonempty and compact, and $\Phi_{r_{jn}}(x_j) \to \omega(x_j) \cap B_\epsilon, n \to \infty$. We now choose numbers n_j such that $d(\Phi_{r_{jn_j}}(x_j), \omega(x_j) \cap B_\epsilon) < 1/j$. By the compactness assumption ($\mathbf{C}_{6.2}$), we can assume that, after choosing subsequences, $\Phi_{r_{jn_j}}(x_j)$ converges. Setting $r_j = r_{jn_j}, s_j = s_{jn_j}, t_j = t_{jn_j}$, we now find sequences $r_j < s_j < t_j$ with $r_j \to \infty, j \to \infty$, such that

$$d(\Phi_{s_j}(x_j), X_2) \to 0, \qquad j \to \infty, \tag{6.6}$$

$$d(\Phi_{r_j}(x_j), X_2) = \epsilon = d(\Phi_{t_j}(x_j), X_2), \tag{6.7}$$

$$d(\Phi_s(x_j), X_2) < \epsilon, \qquad r_j < s < t_j, \tag{6.8}$$

with $\Phi_{r_j}(x_j)$ having a limit for $j \to \infty$. Then we conclude as in Proposition 1.2. First we show that $t_j - r_j \to \infty$. If not, the sequences $\Phi_{s_j}(x_j), \Phi_{t_j}(x_j)$ also converge, and we can conclude as in Step 1 of Proposition 1.2. To perform Step 2 in Proposition 1.2 we only need the convergence of $\Phi_{r_j}(x_j)$, which we have.

Case 2. If Case 1 does not hold, we can find numbers $r_j < s_j < t_j$ with $r_j \to \infty, j \to \infty$, such that (6.6)–(6.8) hold and $\Phi_{r_j}(x_j) \in Y_1 \setminus D$.

We claim that $t_j - r_j \leq t$. If not, (6.7) and (6.8) contradict Assumption 6.1 **(R)** (i).

As $t_j - r_j \leq t$ and $\Phi_{r_j}(x_j) \in Y_1 \setminus D$, we conclude from (6.7), (6.8), and Assumption 6.1 **(R)** (ii) that $d(\Phi_s(x_j), X_2) \geq \delta > 0$ for all $r_j \leq s \leq t_j$. Noticing that δ does not depend on j, we realize that this contradicts (6.6).

7. Disease persistence in an endemic model. (Act III). Theorem 6.2 allows us to prove uniform strong persistence of the disease for model (3.3) also if $C(\infty) = \infty$. In Theorem 3.4 we have dealt with the case $\alpha + \beta + \gamma < C(\infty) < \infty$.

We want to show that $X_2 = \{(N, x, 0, z); 0 \leq N < \infty, x, z \geq 0, x + z = 1\}$ is a uniform strong repeller for the forward invariant set $X_1 = \{(N, x, y, z); 0 \leq N < \infty, x, z \geq 0, y > 0, x + y + z = 1\}$, if $C(\infty) > \alpha + \beta + \gamma$. Proposition 3.3 guarantees that X_2 is a uniform weak repeller for X_1. We check Assumptions 6.1. Note that

$$d((N, x, y, z), X_2) = y.$$

As for **(A)** we simply choose $Y = X$. $(\mathbf{C}_{6.1})$ and $(\mathbf{C}_{6.2})$ are satisfied because our state space lies in $\mathbf{R}^4$.

In order to determine D, δ, t (in dependence of ϵ) we make the following consideration.

Assume that $y(0) = \epsilon$, $y(s) \leq \epsilon$, $0 \leq s \leq t$. Notice from the N equation in (3.3) that N is exponentially increasing on [0,t] if ϵ is chosen small enough. Now, from the z equation in (3.3),

$$\frac{d}{dt}z \leq \gamma\epsilon - (\beta + \rho)z + \alpha\epsilon, \qquad 0 \leq s \leq t.$$

Here we have used that $z \leq 1$. Using this fact again we find

$$z(s) \leq e^{-(\beta+\rho)s} + \epsilon\frac{\gamma + \alpha}{\beta + \rho}, \qquad 0 \leq s \leq t.$$

Hence there is a constant $c > 0$ and some $s_\epsilon > 0$ such that

$$z(s) \leq c\epsilon, \qquad s_\epsilon \leq s \leq t.$$

We substitute (3.4) into the y equation in (3.3):

$$\frac{d}{dt}y = C(N)(1 - y - z)y - (\gamma + \alpha + \beta)y + \alpha y^2.$$

We obtain

$$\frac{\frac{d}{dt}y}{y} \geq \begin{cases} -(\gamma + \alpha + \beta), & 0 \leq s \leq s_\epsilon, \\ C(N)(1 - \epsilon[1 + c]) - (\gamma + \alpha + \beta), & s_\epsilon < s < t. \end{cases}$$

Let $\eta = C(\infty) - (\gamma + \alpha + \beta) > 0$. Let $N_0 > 0$ be such that

$$C(N_0) - (\gamma + \alpha + \beta) > \frac{2\eta}{3}.$$

Choose ϵ so small that

$$C(N_0)(1 - \epsilon[1 + c]) - (\gamma + \alpha + \beta) > \frac{\eta}{3}.$$

As $N(s) \geq N_0$ for $0 \leq s \leq t$, we have

$$\begin{aligned} y(s) &\geq \epsilon e^{-(\gamma+\alpha+\beta)s}, \qquad 0 \leq s \leq s_\epsilon, \\ y(s) &\geq \epsilon e^{-(\gamma+\alpha+\beta)s_\epsilon} e^{\eta(s-s_\epsilon)/3}, \qquad s_\epsilon \leq s \leq t. \end{aligned}$$

Choose $t = t_\epsilon$ such that

$$e^{-(\gamma+\alpha+\beta)s_\epsilon} e^{\eta(t_\epsilon - s_\epsilon)/3} > 1,$$

and $D = \{(N, x, y, z) \in X; N \leq N_0\}$. Revising the above considerations, we realize that **(R)**(i) is satisfied. **(R)**(ii) readily follows from the y equation in (3.3),

$$\frac{\frac{d}{dt}y}{y} \geq -(\gamma + \alpha + \beta),$$

and we can choose $\delta = \epsilon e^{-(\gamma+\alpha+\beta)t}$. **(R)**(iii) is obviously satisfied because D is bounded.

We now conclude the following from Theorem 6.2.

THEOREM 7.1. *Let $\alpha + \beta + \gamma < C(\infty)$. Then*

$$\liminf_{t\to\infty} y(t) \geq \epsilon > 0, \qquad \liminf_{t\to\infty} z(t) \geq \epsilon > 0,$$

with ϵ being independent of the initial data provided that $y(0) > 0$.

Proof. If $C(\infty) < \infty$, the statement follows from Theorem 3.4. If $C(\infty) = \infty$, the first estimate follows from X_2 being a uniform strong repeller for X_1. See the considerations at the beginning of this section. The second estimate is established as in the proof of Theorem 3.4 via the fluctuation method.

We mention that the condition in Theorem 7.1 is sharp because it can be shown that $y(t), z(t) \to 0$, $t \to \infty$, if $\alpha + \beta + \gamma \geq C(\infty)$ (see Thieme, Thm. 3.1).

Acknowledgment. Sections 1, 2, and 3 essentially developed when I taught a course on mathematical models for the spread of infectious diseases at Arizona State University in the fall of 1990. I thank my students Feng Zhilan and Liu Zhongmin for their interest and patience and then chairman W. T. Trotter for letting the course run in spite of the low enrollment. I thank Hal L. Smith and Paul Waltman for their valuable suggestions and comments.

A GEOMETRIC PROOF OF THE KWONG–MCLEOD UNIQUENESS RESULT*

C. B. CLEMONS† AND C. K. R. T. JONES‡

Abstract. Kwong recently proved the uniqueness of positive radial solutions of a semilinear elliptic equation with a superlinear term of a specific form. This was then generalized by Kevin McLeod to include a wide class of nonlinear terms. This paper gives a geometric context to the proof of this result. While these previous proofs used comparison functions that work apparently on account of certain striking calculations, this proof shows that the argument is equivalent to controlling a certain unstable manifold in a transformed phase space.

Key words. uniqueness, semilinear elliptic equation, Emden–Fowler transformation, unstable manifold

1. Introduction. In this paper we provide a geometric proof for the uniqueness of positive radially symmetric solutions of

$$\Delta u + f(u) = 0 \tag{1.1}$$

with appropriate boundary conditions and under certain assumptions about the nonlinear term $f(u)$, which was formulated by McLeod [6]. From the work of Gidas, Ni, and Nirenberg [2], we know that positive solutions of (1.1) on a ball are necessarily radially symmetric. Thus our uniqueness result yields uniqueness of positive solutions for the full problem (1.1), with appropriate boundary conditions.

Radially symmetric solutions of (1.1) satisfy the equation

$$u_{rr} + \frac{n-1}{r}u_r + f(u) = 0, \tag{1.2}$$

together with the boundary condition

$$u_r(0) = 0. \tag{1.3}$$

On a ball, of radius R, we further impose the Dirichlet boundary condition

$$u(R) = 0. \tag{1.4}$$

The first uniqueness result for positive solutions was proved by Coffman [1], in the case $n = 3$ and $f(u) = u^3 - u$. McLeod and Serrin [7] then generalized Coffman's result to obtain uniqueness for $f(u) = u^p - u$ and $1 < p < n/(n-2)$, provided $n > 2$, with further restrictions on this range when $n > 4$. Recently, Kwong [4] proved uniqueness in the model case $f(u) = u^p - u$ over the full range $1 < p < (n+2)/(n-2)$, thus giving uniqueness whenever there is existence (an existence proof due to Strauss can be found in [8]).

Kwong introduced the use of Sturm oscillation and a continuation argument in the space dimension n. Recently, McLeod [6] greatly simplified Kwong's argument while generalizing the allowable $f(u)$ and avoiding the continuation argument. Simultaneous to McLeod's proof, Kwong and Zhang obtained another general result [5]. Our proof is motivated by that of McLeod.

Both Kwong and McLeod compared the roots of $\delta u = \delta u(r, \alpha)/\delta\alpha$ with the function $v := \lambda u + r\dot{u}$. The quantity δu satisfies the equation of variations for (1.2), and the determination of its zeros naturally leads to uniqueness results; however, the function v, which is used to control it, appears to work on account of certain striking calculations. These calculations lead to an equation for v which is a forced version of the equation of variations in which the forcing term depends only on u and λ. It turns out that the comparison function used by both Kwong and McLeod is related to the vector field of a transformed version of (1.2).

We shall cast (1.1) as a first-order system and study the resulting phase space from a geometric point of view. In order to make an autonomous system, we introduce r as a dependent variable and change the independent variable to t via $r = e^t$; thus (1.2) becomes the system

$$\begin{aligned} \dot{u} &= rv, \\ \dot{v} &= -(n-1)v - rf(u), \qquad \dot{x} = \frac{d}{dt} \\ \dot{r} &= r. \end{aligned} \tag{1.5}$$

Note that the singularity $r = 0$ has now been removed and replaced by an invariant plane! The set of solutions satisfying the boundary condition (1.3) form a manifold in the phase space of (1.5), namely, the unstable manifold of the line of critical points $\{v = r = 0\}$.

Uniqueness can also be approached through a study of the geometric contortions of this manifold. This in turn is studied using tangent vectors to the manifold that can be followed along trajectories as solutions of the equations of variation. The natural tangent vectors are the vector field itself and a vector tangent to the intersection of the manifold with a fixed r-plane. Indeed the approach described above for proving uniqueness amounts to a comparison between these two vectors. The comparison of these vectors is interpreted here as control over the tilting of this manifold. This control can also be achieved through determination of the normal to this unstable manifold, which is formed by taking the cross product of the vector field with this tangent vector. In fact, for uniqueness it turns out that we need to determine the sign of an appropriate component of this normal.

Unfortunately, this comparison (or equivalently control over the normal) does not work in (1.5) due to the changes of sign of both $f'(u)$ and the first component of the tangent vector; however, after a change of variables, this strategy can be rescued. The change of variables is known as the Emden–Fowler transformation; see [3], where $y = r^\lambda u$, whence (1.5) becomes

$$\begin{aligned} \dot{y} &= \nu, \\ \dot{\nu} &= -(-2\lambda + n - 2)\nu - \lambda(\lambda - n + 2)y - r^{\lambda+2} f(r^{-\lambda} y), \\ \dot{r} &= r. \end{aligned} \tag{1.6}$$

In these variables, the differential equation which the normal satisfies involves the same expression that appears as a forcing term in McLeod's approach. As mentioned above, a comparison between a tangent vector and a vector field is related to control over a normal. It is not evident in the Kwong–McLeod approach that the comparison is between a tangent vector and a vector field. However in Emden–Fowler variables the comparison between tangent vector and vector field is equivalent to the argument they use.

Our goal in this paper is then to give an alternative proof to McLeod's result, which is naturally motivated by the geometry and we believe explains the underlying mechanism for uniqueness.

The following assumptions will be imposed on the nonlinear term $f(u)$:

(1) $f(u)$ is in $C^1([0,\infty))$;

(2) $f(0) = 0$;

(3) There is a β so that $f(\beta) = 0$ and $f(u) < 0$ if $0 < u < \beta$.

These are standard conditions which say the zeros of $f(u)$ are like those of $u^p - u$. The most unusual condition assumed on $f(u)$ was formulated by McLeod and it is this condition that permits control over the forcing term mentioned above.

(4) Let $I(u,\lambda) = (\lambda + 2)f(u) - \lambda u(df/du)(u)$. Assume that for each $U > \beta$ there is a $\lambda = \lambda(U) > 0$ such that

$$I(u,\lambda) \leq 0 \quad \text{for } 0 \leq u < U, \quad \text{and}$$

$$I(u,\lambda) \geq 0 \quad \text{for } u > U.$$

THEOREM. *If $f(u)$ satisfies the above conditions, then* (1.2) *with boundary conditions* (1.3), (1.4) *have at most one positive solution.*

Remarks. (1) It is a pleasant exercise to check that $f(u) = u^P - u$ satisfies condition (5), and that as $\lambda \to 2/(p-1)$, $U \to \infty$.

(2) The assumption imposed by McLeod that λ depends continuously on U is not needed in our proof.

(3) The λ in (5) will be realized as the exponent in Emden–Fowler transformation.

2. Set-up and basic lemmas. Consider again (1.5). The $\{r = 0\}$-plane is invariant, and its flow is governed by

$$\begin{aligned} \dot{u} &= 0 \\ \dot{v} &= -(n-1)v \end{aligned} \qquad \cdot = \frac{d}{dt}. \tag{2.1}$$

Note that the u-axis is a line of stable points and that each vertical line is invariant. A natural phase space for problem (1.5) is $R^2 \times [0,\infty)$. The boundary conditions translate to looking for a trajectory $(u(t),\ v(t),\ r(t))$ that satisfies

$$\lim_{t\to-\infty}(u(t),\ v(t),\ r(t)) = (\alpha,0,0), \quad \text{and}$$

$$\lim_{t\to\tau}(u(t),\ v(t),\ r(t)) = (0,\beta,R), \quad \tau = \ell n R,$$

where $\beta < 0$ due to the flow and the following phase portrait development.

At a critical point in the $\{r = 0\}$ plane, the linearization is

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1-n & f(\alpha) \\ 0 & 0 & 1 \end{pmatrix}$$

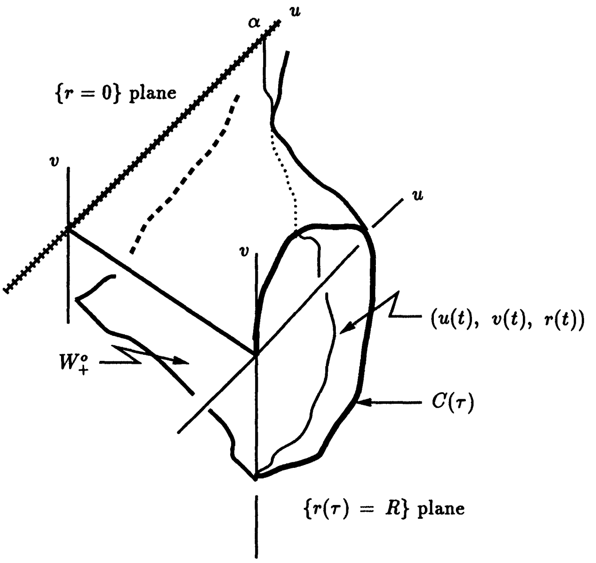

FIG. 1

with eigenvalues 0, $1 - n$, and 1. The stable eigenvector is (0,1,0). Eigenvectors associated with 0 and 1 are (1,0,0) and $(0,\ -f(\alpha)/n,\ 1)$, respectively. The unstable manifold points in the $r > 0$ direction. Near α, the local unstable manifolds foliate the center-unstable manifold of $(\alpha, 0, 0)$ W^{cu}_{loc}. Now set $W^o_{\text{loc}} : = \cup_{\alpha>0} W^u_{\text{loc}}(\alpha)$; then $W^o_+ : = \cup_{t>0}(W^o_{\text{loc}} \cdot t)$ is the surface containing all the solutions to problem (1.6).

The manifold W^o_+ is examined in more detail so as to isolate the properties associated with uniqueness. A solution $u(r)$ to problem (1.2) would satisfy $\dot{u}(0) = 0$, $u(R) = 0$, and in light of the last section, $u(0) = \alpha$ where α is a positive constant; henceforth, denote $u(r) : = u(r, \alpha)$. Similarly we denote a solution $(u(t),\ v(t),\ r(t))$ to problem (1.5) contained in W^o_+ by $u(t) := u(t, \alpha)$, $v(t) := v(t, \alpha)$, and $r(t)$, where α is given by $\lim_{t \to -\infty} u(t) = \alpha$.

The presence of more than one solution to problem (1.2)–(1.4) would say that there exists two trajectories, $(u(t, \alpha_1),\ v(t, \alpha_1),\ r(t))$ and $(u(t, \alpha_2), v(t, \alpha_2),\ r(t))$ of (1.5), contained in W^o_+ such that $(u(\tau, \alpha_1),\ v(\tau, \alpha_1),\ r(\tau)) = (0, \beta_1, R)$ and $(u(\tau, \alpha_2),$ $v(\tau, \alpha_2) r(\tau)) = (0, \beta_2, R)$.

Consider the intersection of W^o_+ with the $\{r(\tau) = R\}$-plane, $C(\tau) : = W^o_+ \bigcap \{\tau\}$; see Fig. 1. Nonuniqueness says that $C(\tau) \cap \{u = 0\}$ contains at least two elements. Center-unstable manifold theory gives that W^o_+ is sufficiently smooth so that the following may be defined. Let $T(t) = (\delta u(t, \alpha),\ \delta v(t, \alpha))$ be a tangent vector to $C(\tau)$ at the point $(u(t, \alpha),\ v(t, \alpha),\ r(t))$. When δr is set equal to zero, $(\delta u(t, \alpha), \delta v(t, \alpha))$ is a solution to the equation of variations associated with system (1.5),

$$\begin{aligned} \dot{\delta u} &= r \delta v, \\ \dot{\delta v} &= -(n-1)\delta v - r \frac{df(u)}{du} \delta u. \end{aligned} \tag{2.2}$$

Notice that $\lim_{t \to -\infty} \delta u(t, \alpha) = 1$, $\lim_{t \to -\infty} \delta v(t, \alpha) = 0$.

Two lemmas are used to prove uniqueness for $r(t) = R < \infty$. The first lemma sets up the necessary configuration of $C(t)$ in the case of nonuniqueness. This is related to a concept defined by Kwong as admissibility that is not strict. The second lemma argues that this configuration is not possible.

LEMMA 1. *Let τ be such that $r(\tau) = R$. Nonuniqueness to problem* (1.1)–(1.3) *implies that there exists a trajectory $(u(t,\hat{\alpha}),\ v(t,\hat{\alpha}),\ r(t))$ contained in W^o_+ with the following properties: there exist τ and $\hat{\alpha}$, where $-\infty < \tau_o < \hat{\tau} < \tau$, such that $u(\hat{\tau},\hat{\alpha}) = 0, \delta u(\tau_o,\hat{\alpha}) = 0$, and $\delta u(t,\hat{\alpha}) \neq 0$ for $t \in (-\infty,\tau_o) \cup (\tau_o,\hat{\tau})$. Moreover, $\delta u(\hat{\tau},\hat{\alpha}) = 0$, and $\delta v(\hat{\tau},\hat{\alpha}) < 0$.*

Proof of Lemma 1. Nonuniqueness at τ implies that there exist two trajectories, $(u(t,\alpha_1),\ v(t,\alpha_1),\ r(t))$ and $(u(t,\alpha_2),\ v(t,\alpha_2),\ r(t))$, contained in W^o_+ such that $u(\tau,\alpha_1) = u(\tau,\alpha_2) = 0$. Suppose $\alpha_1 < \alpha_2$ and, for no other trajectory in W^o_+ with $\alpha \in (0,\alpha_1) \cup (\alpha_1,\alpha_2)$, does $u(\tau,\alpha) = 0$; see Fig. 2.

Via continuity with respect to initial conditions and the intermediate value theorem, there exist $\hat{\alpha}$ and $\hat{\tau}$, where $\alpha_1 < \hat{\alpha} < \alpha_2$ and $\hat{\tau} < \tau$, such that $C(\hat{\tau})$ is tangent to the v-axis, and $u(\hat{\tau},\hat{\alpha}) = \delta u(\hat{\tau},\hat{\alpha}) = 0$.

Let $C(t,\alpha)$ be the portion of the curve $C(t)$ defined by $C(t,\alpha) = \{(u(t,\alpha), v(t,\alpha), r(t)) \in C(t) | a \in (0,\alpha]\}$. Also define the following curves in the tangent bundle to W^0_+ : $S_{C(\hat{\tau},\hat{\alpha})} = \{(\delta u(\hat{\tau},\alpha), \delta v(\tau,\hat{\alpha}),\ 0)$ for $(u(\hat{\tau},\alpha),\ v(\hat{\tau},\alpha),\ r(\tau)) \in C(\hat{\tau},\hat{\alpha})\}$ and $S_\gamma = \{(\delta u(t,\hat{\alpha}),\ \delta v(t,\hat{\alpha}))$ for $(u(t,\hat{\alpha}), v(t,\hat{\alpha}),\ r(t)) \in \gamma\}$, where γ is the curve $\gamma = \{(u(t,\hat{\alpha}),\ v(t,\hat{\alpha}),\ r(t)) | t \in (-\infty,\hat{\tau}]\}$. Observe that $C(\hat{\tau},\hat{\alpha})$ is homotopic to γ because they bound a portion of W^o_+ together with the u-axis and the r-axis. Also, $S_{C(\hat{\tau},\hat{\alpha})}$ is homotopic to S_γ.

Let I denote the winding number of a curve as in [3]. Since the winding number is homotopy invariant and $\delta\dot{u} = r\delta v$, we have $I(S_\gamma)=$ the number of zeros of $\delta u(t,\hat{\alpha})$ for $-\infty < t < \hat{\tau}$. Now, either $v(\tau,\alpha_1) > v(\tau,\alpha_2)$ or $v(\tau,\alpha_2) > v(\tau,\alpha_1)$. The first situation would imply that $I(S_\gamma) = I(C(\hat{\tau},\hat{\alpha})) = 1$. Because $(u(t),\ v(t)) = (\beta,0)$ is a solution of (4.5) and is contained in W^o_+, the first root of $\delta u(t,\hat{\alpha})$ must occur at some time before $u(t,\hat{\alpha}) = \beta$; see Fig. 2. If $v(\tau,\alpha_1) > v(\tau,\alpha_2)$, then $I(S_\gamma) = I(C(\hat{t},\hat{\alpha})) = 2$, and hence $\delta u(t,\hat{\alpha})$ has one root for $t \in (-\infty,\hat{\tau})$, thus proving the lemma.

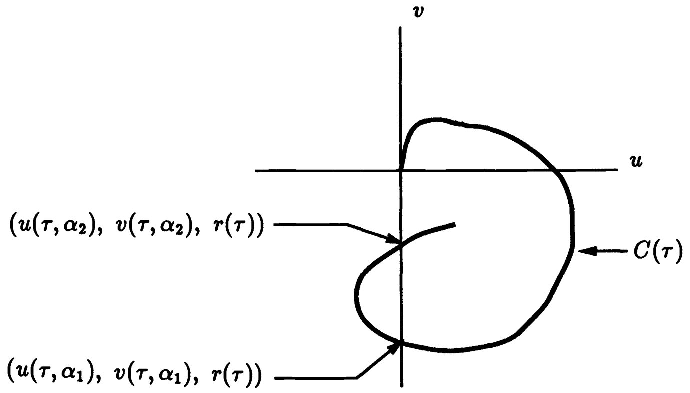
Now consider (1.6), which results from applying the Emden–Fowler transformation. The origin is a critical point. Linearizing about this point produces the matrix

$$\begin{pmatrix} 0 & 1 & 0 \\ -\lambda(\lambda+2-n) & -(n-2-\lambda) & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

The eigenvalues of the matrix are $\lambda, \lambda-n+2$, and 1. The associated eigenvectors are $(1,\lambda,0)$, $(1,\lambda-n+2,0)$, and $(0,0,1)$, respectively. If $\lambda < n-2$, a two-dimensional (or three-dimensional if $\lambda > n-2$) unstable manifold W^u_{loc} is associated with the origin. Set $W^u = \cap_{t>0} W^u_{\text{loc}} \cdot t$. The transformation from (u,v,r) to (y,ν,r), defined on $R^2 \times (0,\infty)$ by

$$T: \begin{cases} y = r^\lambda u, \\ \nu = r^{\lambda+1}v - \lambda r^\lambda u, \\ r = r, \end{cases} \tag{2.3}$$

carries W^u_{loc} to a submanifold of W^u, call is W^u_{pos}. Next consider the curve $C(\hat{\tau})$ defined in the proof of Lemma 1. Let $D(\hat{\tau}) = T(C(\hat{\tau}))$; then $D(\hat{\tau})$ is a curve in the $\{r = \hat{r}\}$ plane of the phase space associated with (1.7). Using the obvious definition



v
u
$(u(\tau,\alpha_2),\ v(\tau,\alpha_2),\ r(\tau))$
$C(\tau)$
$(u(\tau,\alpha_1),\ v(\tau,\alpha_1),\ r(\tau))$

FIG. 2

of the variables

$$\delta y(t,\alpha)=\left.\frac{\partial y(t,a)}{\partial \alpha}\right|_{a=\alpha},\qquad \delta v(t,\alpha)=\left.\frac{\partial v(t,a)}{\partial a}\right|_{a=\alpha},$$

we have the exact analogue of Lemma 1 in these variables; see Fig. 3.

LEMMA 2. *With the same hypothesis as Lemma* 1 *and $\tau = \ell nR$, there exists a trajectory $(u(t,\hat{\alpha}),\ v(t,\hat{\alpha}),\ r(t))$ contained in W^u_{pos} with the following properties: there exist τ_o and $\hat{\alpha}$, where $-\infty < \tau_o < \hat{\tau} < \tau$, such that $y(\hat{\tau},\hat{\alpha}) = 0$, $\delta y(\tau_o,\hat{\alpha}) = 0$, and $\delta y(t,\hat{\alpha}) \neq 0$ for $t \in (-\infty,\tau_o) \cup (\tau_o,\hat{\tau})$. Moreover, $\delta v(\hat{\tau},\hat{\alpha}) < 0$.*

Proof of Lemma 2. Lemma 2 follows easily from Lemma 1 because the zeros of $u(t,\hat{\alpha})$ and $y(t,\hat{\alpha})$ agree since $y = r^{\lambda}u$. Furthermore, $\delta y(t,\hat{\alpha}) = r^{\lambda}\delta u(t,\hat{\alpha})$, and so the zeros of δy and δu agree. The fact that $\delta v(\hat{\tau},\hat{\alpha}) < 0$ follows easily from the expression for δv obtained by differentiating (2.2).

3. Uniqueness proof. We shall interpret Lemma 2 in terms of the normal to the manifold W^u_{pos}. This is natural since Lemma 2 is a statement about a configuration of the unstable manifold that is forced by the assumption of nonuniqueness.

The vector field $(\dot{y},\dot{\nu},\dot{r})$ and the tangent vector $(\delta y,\delta\nu,0)$ are both tangent to W^u_{pos}. We denote $N(t,\alpha)$, the cross product of these two vectors, (in the order given) and use dual notation for its components.

$$N(t,\alpha)=(\delta y^*(t,\alpha),\ \delta\nu^*(t,\alpha),\ \delta r^*(t,\alpha)).$$

We then have the following.

LEMMA 3. *On the trajectory of Lemma* 2, *we have that the third component of the normal, $\delta r^*(\hat{\tau},\hat{\alpha}) > 0$.*

Proof.

$$\delta r^* = \begin{vmatrix} \dot{y} & \dot{\nu} \\ \delta y & \delta\nu \end{vmatrix} = \dot{y}\delta\nu - \dot{\nu}\delta y \quad \text{and} \quad t=\hat{\tau}, \alpha=\hat{\alpha}\delta y = 0, \delta\nu < 0 \quad \text{and} \quad \dot{y} < 0.$$

An equation for the components of the normal can be easily calculated. The

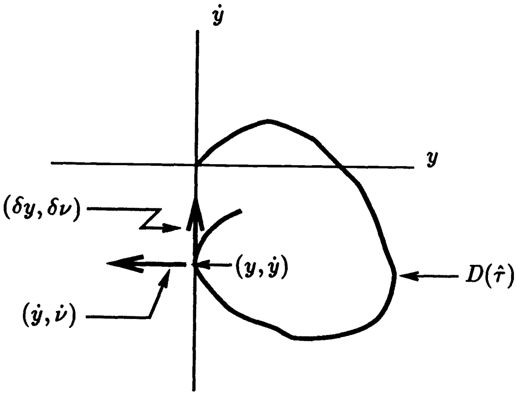


FIG. 3

equation of variations of (1.6) is

$$\delta\dot{y} = \delta\nu,$$

$$\delta\dot{\nu} = -(-2\lambda + n - 2)\delta\nu - \lambda(\lambda - n + 2)\delta y - r^2 \frac{df}{du}\delta y \tag{3.1}$$

$$- \frac{\partial}{\partial w}\left[r^{\lambda+2} f(r^{-\lambda} y)\right] \delta r,$$

$$\delta\dot{r} = \delta r.$$

If we abbreviate this as

$$\begin{pmatrix} \delta y \\ \delta\nu \\ \delta r \end{pmatrix}^{\cdot} = A \begin{pmatrix} \delta y \\ \delta\nu \\ \delta r \end{pmatrix}, \tag{3.2}$$

we can write the equation of the normal as

$$\begin{pmatrix} \delta y^* \\ \delta\nu^* \\ \delta r^* \end{pmatrix}^{\cdot} = (-A^* + (Tr\ A)I) \begin{pmatrix} \delta y^* \\ \delta\nu^* \\ \delta r^* \end{pmatrix}, \tag{3.3}$$

where A^* is the transpose of A. Using the identity

$$-A^*(\eta_1 \times \eta_2) = A\eta_1 \times \eta_2 + \eta_1 \times A\eta_2 - TrA(\eta_1 \times \eta_2),$$

from (3.3) we can calculate

$$(\delta r^*)^{\cdot} = +\frac{\partial}{\partial r}\left[r^{\lambda+2} f(r^{-\lambda} y)\right] \delta y^* - (-2\lambda + n - 2)\delta r^*. \tag{3.4}$$

Now

$$\frac{\partial}{\partial r}\left[r^{\lambda+2} f(r^{-\lambda} y)\right] = r^{\lambda+1}\left[(\lambda+2) f(u) - \lambda u \frac{df}{du}\right] = r^{\lambda+1} I(u, \lambda).$$

Moreover,

$$\delta y^* = -\begin{vmatrix} \dot{y} & \dot{r} \\ \delta y & 0 \end{vmatrix} = r\delta y,$$

so that (3.4) becomes

$$(\delta r^*)^{\cdot} = +r^{\lambda+2}I(u,\lambda)\delta y - (-2\lambda + n - 2)\delta r^*. \tag{3.5}$$

Using equation (3.5) and Lemma 3 we can complete the proof of the Theorem. The parameter λ is still free to be chosen. The quantity $\delta y(t, \hat{\alpha})$ changes sign at a certain value of $t = \tau_o$, and this is independent of λ. Let $U(\tau_o, \hat{\alpha}) = \hat{u}$. Then since u is monotone along the trajectory assumed by Lemma 2 we can force $I(u, \lambda)$ to change sign exactly once, at $\hat{u}$. We then see that $I(u, \lambda)\delta y$ has a fixed sign and it is easy to check that $I(u, \lambda)\delta y < 0$. We check that $e^{-2\lambda+(n-2)t}\delta r^* \to 0$ as $t \to -\infty$. But then $\delta r^*(\hat{\tau}, \hat{\alpha}) < 0$ from (3.5), which contradicts Lemma 3. It follows that the configuration described above is not possible, and hence uniqueness holds.

GEOMETRIC ANALYSIS OF A NONLINEAR BOUNDARY VALUE PROBLEM FROM PHYSICAL OCEANOGRAPHY*

STEVEN R. DUNBAR†

Abstract. A third-order nonlinear differential equation with two sets of boundary conditions is considered. These boundary value problems arise as boundary layer problems from a model of large scale ocean circulation. Using geometrical techniques from qualitative differential equations, such as Wazewski's theorem, invariant manifolds, and Lyapunov functions, the existence of solutions for each boundary value problem is given in a uniform way for all positive values of a parameter of the differential equation.

Key words. nonlinear boundary layer problem, Wazewski's theorem, Lyapunov function, La Salle invariance principle

AMS(MOS) subject classifications. 34B15, 34C30, 34C35, 86A05

1. Introduction.

This paper presents a geometric analysis of the equation

$$\phi''' + \lambda(\phi\phi'' - (\phi')^2) + 1 - \phi = 0 \tag{1}$$

with the "no-slip" boundary conditions

$$\begin{aligned} \phi(0) &= 0, \\ \phi'(0) &= 0, \\ \phi(\infty) &= 1 \end{aligned} \tag{2}$$

and also with the "stress-free" boundary conditions

$$\begin{aligned} \phi(0) &= 0, \\ \phi''(0) &= 0, \\ \phi(\infty) &= 1 \end{aligned} \tag{3}$$

for all positive values of the parameter λ. This equation and its boundary values arise from a similarity solution of the so-called barotropic quasi-geostrophic potential vorticity equation for one layer ocean circulation. A derivation of the equation and further references to the oceanography literature are in [11].

In [11] Ierley and Ruehr present extensive numerical calculations and matched asymptotic expansions for the solutions of (1)–(2) and (1)–(3) in several parameter cases. For (1)–(2) Ierley and Ruehr set $\phi''(0) = \beta$ and then numerically determined values β for each parameter value λ so that the boundary value problem has a solution. Thus $\beta(\lambda)$ uniquely identifies a solution to the boundary value problem through the initial conditions $\phi(0) = 0$, $\phi'(0) = 0$, $\phi''(0) = \beta$. In Fig. 1 of [11] there is a curve in the λ-β plane parametrically representing the solutions. For $\lambda \geq 0$ there is only a

†Department of Mathematics and Statistics, University of Nebraska-Lincoln, Lincoln, Nebraska, 68588.

single solution, corresponding to a value of $\beta \approx 1$. For λ in the range $\lambda_c \leq \lambda < 0$, where $\lambda_c \approx -0.79130$, there are two solutions which coincide at λ_c. Ierley and Ruehr also give asymptotic expansions for ϕ, which agree well with numerically computed solutions. The graphs of the expansion solutions are also in [11]. A subsequent paper by Troy [13] presents an analytic proof of the existence of at least one solution of the equations in the special case $\lambda > (27/4)^{1/3}$, for which the solutions must be asymptotically monotone.

The analysis in [11] for the boundary value problem (1)–(3) is analogous, using $\phi'(0) = \beta$. For $\lambda > 0$ there are two curves parametrically representing solutions; one with $\beta > 0$, the other with $\beta < 0$; see Fig. 4 in [11]. In [13], Troy proved analytically the existence of least one solution with $\beta = \phi'(0) > 0$ in the special case $\lambda > (27/4)^{1/3}$.

Section 2 of the present paper rigorously establishes the existence of a solution to (1)–(2) for *all* $\lambda > 0$ by a single geometric or dynamical systems method. Section 3 of the paper establishes the existence of at least one solution to (1)–(3) for all $\lambda > 0$. The proofs also give some bounds on the solutions as a secondary consequence of the geometric techniques.

The techniques of dynamical systems are useful for the analysis of nonlinear boundary value problems. A number of researchers have used these geometric techniques for a variety of nonlinear problems. For representative examples, see [3], [9], [10], [13], and [14]. Furthermore, the techniques employed here may give some insights into similar problems, e.g., the Falkner–Skann equation; see [8].

Dynamical systems methods translate differential equation problems into equivalent phase space problems in order to use the structure of the vector field, and the properties of solution curves. In particular, arguments in three-dimensional phase space are geometrically clear and easily motivated. Additional structure in the problem, such as invariant manifolds, is also revealed. The global structure of the invariant manifold can show where solutions to various boundary value problems occur. The variation of the manifold as problem parameters vary shows how solutions to boundary value problems can appear, disappear, coalesce, and vary with parameters. This is the approach adopted here. All arguments here could be expressed purely analytically, but they would lose motivation and geometric clarity. Moreover, no ingenious changes of independent or dependent variable need to be made in order to reveal aspects of the solution.

An overview of the paper will more fully describe the dynamical systems approach. The basic idea is related to the shooting method, or more formally to Wazewski's theorem. To make the paper self-contained, §2 contains a useful version of Wazewski's theorem. The third-order differential equation (1) is converted to a system of three first-order nonlinear equations by setting $u(s) = \phi(s)$, $v(s) = \phi'(s)$, $w(s) = \phi''(s)$, giving

$$\begin{aligned} u' &= v, \\ v' &= w, \\ w' &= \lambda v^2 - \lambda u w + u - 1. \end{aligned} \tag{4}$$

The system has only one equilibrium point $(1,0,0)$. The linearization of the system about this point always has one positive eigenvalue, and (4) has a corresponding one-dimensional unstable manifold. There are always two eigenvalues with negative real part, and so there is always a corresponding two-dimensional stable manifold. The two-dimensional stable manifold acts as a separatrix between the opposite branches of the unstable manifold. The unstable manifold as a set is attracting because it is transverse to the stable manifold at the equilibrium point. In this system, solutions along the unstable manifold are unbounded. Heuristically, any bounded solution of the equation, in particular a solution which satisfies the boundary condition $\phi(\infty) = 1$, cannot approach the unstable manifold except at the equilibrium point $(1, 0, 0)$. See Fig. 1.

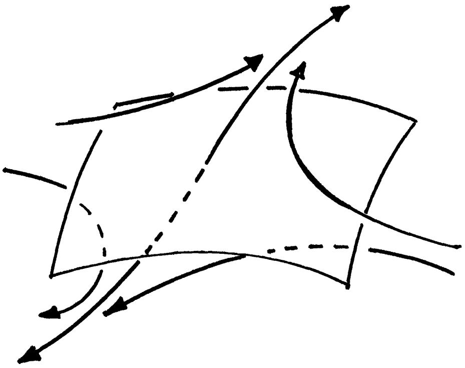

FIG. 1. *The orbits near the stable and unstable manifolds.*

An even simpler linear two-dimensional system analogous to (4) can convey the essential geometric elements of the argument. The analogous system is

$$\begin{aligned} u' &= 1 - u, \\ v' &= v, \end{aligned}$$

with boundary conditions $u(0) = 0$ and $u(\infty) = 1$. The equilibrium point is $(1, 0)$. The solutions of the system are $(1 + (u_0 - 1)e^{-t}, v_0 e^t)$. The unstable manifold is the line $u = 1$, and solutions starting at $(1, v_0)$ on this line will be unbounded. The stable manifold is the u-axis and all solutions starting at $(u_0, 0)$ will approach $(1, 0)$ as $t \to \infty$. Solutions starting at $(0, v_0)$ on the v-axis are $(1 - e^{-t}, v_0 e^t)$. All solutions (except when $v_0 = 0$) become unbounded as they approach the unstable manifold. The exception to becoming unbounded can be identified as the intersection of the stable manifold, along which solutions approach $(1, 0)$, with the initial condition set with coordinates $(0, v_0)$. See Fig. 2.

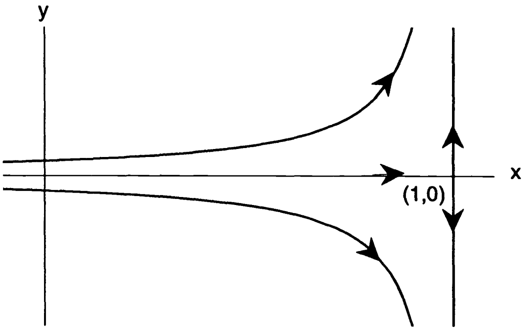

FIG. 2. *The simple two-dimensional analog system.*

This solution satisfies the boundary conditions and so is the solution we seek.

The situation for (4) is very similar but is complicated by the nonlinearity and the three-dimensional setting. The method is to use regions of space to capture the essence of the unboundedness along the unstable manifold. Removing a pair of regions in three-dimensional phase space suggested by the unboundedness of orbits approaching the unstable manifold defines a Wazewski set W which heuristically contains the bounded orbits. The immediate exit set of the Wazewski set W is disconnected. An interval Σ of initial values is defined. Orbits of the system starting at one end of the interval Σ will exit W into one of the removed regions, while orbits starting at the other end of Σ will exit W into the other region. By the connectedness of Σ, there must be an orbit starting on the interval that does not exit W. We show this orbit must remain bounded. Then, using the Lyapunov function

$$V_0(u,v,w) = \left(\frac{w^2}{2}\right) - \left(\frac{\lambda v^3}{3}\right) - (u-1)v,$$

with Lyapunov derivative

$$\dot{V}_0(u,v,w) = -\lambda u w^2 - v^2,$$

and the LaSalle Invariance Principle, this orbit must approach the equilibrium point $(1,0,0)$.

The LaSalle Invariance Principle weakens the requirements demanded of a Lyapunov function while still retaining a useful conclusion. This simplifies the task of finding a suitable Lyapunov function. The Lyapunov function $V_0(u,v,w)$ is not motivated by any energy function or physical reasoning. The Lyapunov function $V_0(u,v,w)$ and the related family of functions

$$V_\alpha(u,v,w) = \frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v + \alpha\left(vw + \frac{\lambda u v^2}{2} - \frac{(u-1)^2}{2}\right),$$

with Lyapunov derivative

$$\dot{V}_\alpha(u,v,w) = (\alpha - \lambda u)w^2 + \left(\frac{3\alpha\lambda v}{2} - 1\right)v^2,$$

play an important role in the paper. The family of Lyapunov functions V_α suggest yet another useful function

$$V_\infty(u,v,w) = vw + \frac{\lambda u v^2}{2} - \frac{(u-1)^2}{2},$$

with Lyapunov derivative

$$\dot{V}_\infty(u,v,w) = w^2 + \frac{3\lambda v^3}{2}.$$

It is worth describing how such a family of Lyapunov functions can be obtained. The equation system has simple polynomial terms so that "trial and error" arrangement and cancellation of the terms easily yields a Lyapunov derivative

$$\dot{V}_0(u,v,w) = -\lambda u w^2 - v^2,$$

which is negative definite for $u \geq 0$. Likewise, more "trial and error" arrangement of the derivative terms of the system leads to the Lyapunov derivative

$$\dot{V}_\alpha(u,v,w) = (\alpha - \lambda u)w^2 + \left(\frac{3\alpha\lambda v}{2} - 1\right)v^2,$$

which will be negative definite along bounded orbits with $u \geq 0$ for $\alpha < 0$ sufficiently small.

Alternatively, multiply (1) by ϕ'' and integrate from zero to s to obtain

$$\frac{(\phi''(s))^2}{2} - \frac{(\phi''(0))^2}{2} + \int_0^s \lambda\phi(z)(\phi''(z))^2\,dz - \frac{\lambda(\phi'(s))^3}{3} + \frac{\lambda(\phi'(0))^3}{3}$$
$$+\phi'(s) - \phi'(0) - \int_0^s \phi(z)\phi''(z)\,dz = 0.$$

Integrate the second integral by parts, rearrange, and use $\phi(0) = 0$, $\phi'(0) = 0$, $\phi''(0) = \beta$, to obtain

$$\frac{(\phi''(s))^2}{2} - \frac{\beta^2}{2} - \frac{\lambda(\phi'(s))^3}{3} + \phi'(s) - \phi(s)\phi'(s) = -\int_0^s \lambda\phi(z)(\phi''(z))^2\,dz - \int_0^s (\phi'(z))^2\,dz.$$

The right side of the equation is clearly decreasing on intervals where $\phi(s) > 0$. Converting the left side of the equation to u, v, w suggests the Lyapunov function V_0.

A third approach is to use the general procedure for constructing Lyapunov equations for third-order equations in [1]. For the general Lyapunov function given in [1] choosing $\alpha = 0$ and the weight function to be identically 1 yields the function V_0. Using the constant $\alpha \neq 0$ and the weight function to be identically 1 supplies V_α.

2. Existence of solutions to the no-slip problem. This section contains the proof of the following.

THEOREM 1. *For all $\lambda > 0$ there is at least one solution of the problem*

$$\phi''' + \lambda(\phi\phi'' - (\phi')^2) + 1 - \phi = 0, \tag{5}$$

with the "no-slip" boundary conditions

$$\begin{aligned} \phi(0) &= 0, \\ \phi'(0) &= 0, \\ \phi(\infty) &= 1. \end{aligned} \tag{6}$$

We begin the proof by converting (5) to a system of 3 first-order equations by setting $u = \phi$, $v = \phi'$, and $w = \phi''$. Here $' = d/ds$, so that s is the independent variable. Occasionally, in the spirit of dynamical systems theory, we will refer to the independent variable s as "time" even though the independent variable actually represents a spatial extent in the similarity solution. The equation (5) is equivalent to the system

$$\begin{aligned} u' &= v, \\ v' &= w, \\ w' &= \lambda v^2 - \lambda uw + u - 1. \end{aligned} \tag{7}$$

The following proposition is a variant of Wazewski's theorem, which is a formalization and extension of the "shooting method." This proposition recognizes that the flow defined by the solutions of a differential equation gives a topological mapping between regions of phase space. The statement is the same as in [4], where the proof is also given. Both the statement and the proof are variants of those given in [2]. The notation is the same as that in [2].

Consider the autonomous differential equation

$$\mathbf{y}' = \mathbf{f}(\mathbf{y}), \qquad \mathbf{y} \in \mathbf{R}^n, \quad ' = \frac{d}{ds}, \tag{8}$$

where $\mathbf{f} : \mathbf{R}^n \to \mathbf{R}^n$ is continuous and satisfies a Lipschitz condition. Let $\mathbf{y}(s; \mathbf{y}_0)$ be the unique solution of (8) satisfying $\mathbf{y}(0; \mathbf{y}_0) = \mathbf{y}_0$. For convenience set $\mathbf{y}(s; \mathbf{y}_0) = \mathbf{y}_0 \cdot s$. Let $U \cdot S$ be the set of points $\mathbf{y}_0 \cdot s$, where $\mathbf{y}_0 \in U$, $s \in S$.

In order to state the proposition some definitions are necessary. Given $W \subset \mathbf{R}^n$, set

$$W^- = \{\mathbf{y}_0 \in W : \text{any } s > 0, \quad \mathbf{y}_0 \cdot [0, s) \not\subset W\}.$$

W^- is called the *immediate exit set* of W. The continuity of $\mathbf{y}_0 \cdot s$ in s implies that interior points of W are not in the immediate exit set, or equivalently $W^- \subset (\partial W \cap W)$. Given $\Sigma \subset W$, let

$$\Sigma^0 = \{\mathbf{y}_0 \in \Sigma : \text{ there is an } s_0 \text{ such that } \mathbf{y}_0 \cdot s_0 \notin W\}.$$

For $\mathbf{y}_0 \in \Sigma^0$ define

$$T(\mathbf{y}_0) = \sup\{s : \mathbf{y}_0 \cdot [0, s] \subset W\}.$$

$T(\mathbf{y}_0)$ is called an *exit time*. Note that if $\mathbf{y}_0 \cdot T(\mathbf{y}_0) \in W$, then $\mathbf{y}_0 \cdot T(\mathbf{y}_0) \in W^-$. Note also that for $\mathbf{y}_0 \in W$, $T(\mathbf{y}_0) = 0$ if and only if $\mathbf{y}_0 \in W^-$. The notation $\mathrm{cl}(W)$ is used for the closure of W.

PROPOSITION 2. *Suppose*

(1) *If* $\mathbf{y}_0 \in \Sigma$ *and* $\mathbf{y}_0 \cdot [0, s_0] \subset \mathrm{cl}(W)$, *then* $\mathbf{y}_0 \cdot [0, s_0] \subset W$;

(2) *If* $\mathbf{y}_0 \in \Sigma$, $\mathbf{y}_0 \cdot [0, s_0] \subset W$, *and* $\mathbf{y}_0 \cdot s \notin W^-$ *for each* $s \in [0, s_0]$, *then there is an open set* V_s *about* $\mathbf{y}_0 \cdot s$ *disjoint from* W^-;

(3) $\Sigma = \Sigma^0$, Σ *is compact, and* Σ *intersects an orbit of* (8) *only once.*

Then the mapping $F(\mathbf{y}_0) = \mathbf{y}_0 \cdot T(\mathbf{y}_0)$ *is a homeomorphism from* Σ *to its image on* W^-.

The proof is in [4]. Notice that the first hypothesis is trivially satisfied if the set W is closed. The second hypothesis is satisfied if orbits from Σ have no tangencies to the boundary of W within W, i.e., no *internal tangencies.* The set Σ corresponds to an interval of initial conditions, and the third hypothesis is a technical hypothesis which will be satisfied in all reasonable cases.

The system (7) has just one equilibrium point, namely (1,0,0). It is easy to check that the Jacobian matrix of the linearization at (1,0,0) is

$$J(1,0,0) = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & -\lambda \end{pmatrix}.$$

The characteristic equation is

$$-r^3 - \lambda r^2 + 1 = 0.$$

Using the Routh–Hurwitz criterion (see [5]), it is easy to show that for all values of λ there is always one positive eigenvalue r_1 and two eigenvalues with negative real part. If $\lambda \geq (27/4)^{1/3}$, there are three real roots. If $\lambda < (27/4)^{1/3}$, there is a complex conjugate pair of eigenvalues with negative real part. Label the roots so that $r_1 > 0 > \mathrm{Re}(r_2) \geq \mathrm{Re}(r_3)$.

Consider the eigenvector $(1, r_1, r_1^2)^T$ (where T is used for the transpose) corresponding to the positive eigenvalue r_1. The unstable manifold of the equilibrium point $(1,0,0)$ is tangent to the eigenvector corresponding to the positive eigenvalue [7]. In fact, due to the special nature of the nonlinearity in (7), the solutions on the unstable manifold are precisely $(1,0,0)^T + C(1, r_1, r_1^2)^T e^{r_1 s}$, where C is an arbitrary nonzero constant; so the unstable manifold is the straight line through $(1,0,0)$ in the direction $(1, r_1, r_1^2)^T$. Therefore, the octant

$$\mathcal{O}_1 = \{(u,v,w) : u > 1, v > 0, w > 0\}$$

contains one branch of the unstable manifold. The other branch of the unstable manifold enters the region $\mathcal{O}_2 = \{(u,v,w) : u < 0\}$. The regions $\mathcal{O}_1$ and $\mathcal{O}_2$ surround most of the unstable manifold. Technical reasons related to the second hypothesis in Proposition 2 and the necessity to have the Lyapunov derivative of V_0 negative definite compel the choice $\mathcal{O}_2 = \{(u,v,w) : u < 0\}$ rather than the more obvious choice $\{(u,v,w) : u < 1, v < 0, w < 0\}$, which completely contains the branch of the unstable manifold in $\{u < 1\}$.

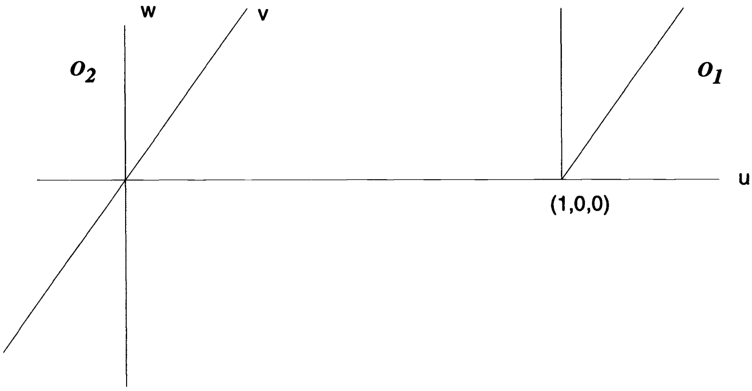

FIG. 3. *The regions $\mathcal{O}_1$ and $\mathcal{O}_2$.*

Define the Wazewski set $W = R^3 - (\mathcal{O}_1 \cup \mathcal{O}_2)$; see Fig. 3. The closed set W is the exterior of the disjoint regions and contains the local stable manifold of the point $(1,0,0)$. Since W is closed, hypothesis 1 of Proposition 2 is satisfied. Although the region W is the Wazewski set, it is more convenient and natural to work with the removed regions $\mathcal{O}_1$ and $\mathcal{O}_2$. Thus, much of the following will be done in terms of $\mathcal{O}_1$ and $\mathcal{O}_2$ and then referred back to the main object of interest, which is W.

In order to apply Proposition 2, we need to examine the immediate exit set W^-. This will show that the exit set is disconnected. First examine the vector field on the boundary of $\mathcal{O}_1$. This determines where an orbit that hits this portion of the boundary of W will go.

(1) Verification that the side, $v = 0$, is an exit set portion: On the plane quadrant $u > 1, v = 0, w > 0$, we have $v' = w > 0$ so that an orbit hitting this portion of the

boundary of W will immediately enter the octant $\mathcal{O}_1$. Therefore, the plane quadrant $\{u > 1, v = 0, w > 0\} \subset W^-$. We abbreviate this by saying the set is an exit set portion.

(2) Verification that the front, $u = 1$, is an exit set portion: On the plane quadrant $u = 1$, $v > 0$, $w > 0$, we have $u' = v > 0$.

(3) Verification that the bottom, $w = 0$, is an exit set portion: On the plane quadrant $u > 1$, $v > 0$, $w = 0$, we have $w' = \lambda v^2 - \lambda uw + u - 1 > 0$.

(4) Verification that the edge $u = 1$, $v = 0$, $w > 0$ is an exit set portion: On this edge, $u' = v = 0$, and $u'' = v' = w > 0$ so that an orbit touching this edge has a minimum in the u coordinate and has the v coordinate increasing. The orbit exits W into the octant $\mathcal{O}_1$.

(5) Verification that the edge $u > 1$, $v = 0$, $w = 0$ is an exit set portion: On this edge, $v' = w = 0$, $v'' = w' = \lambda v^2 - \lambda uw + u - 1 > 0$, so that v has a local minimum here, and $w' = u - 1 > 0$, and of course $u > 1$, so that an orbit touching this edge immediately enters the octant $\mathcal{O}_1$.

(6) Verification that the edge $w = 0$, $u = 1$, $v > 0$ is an exit set portion: On this edge, $w' = \lambda v^2 - \lambda uw + u - 1 > 0$ and $u' = v > 0$. Therefore any orbit touching this edge must enter the octant $\mathcal{O}_1$.

Next, examine the vector field on the boundary of $\mathcal{O}_2$.

(1) Verification that the face $u = 0$, $v < 0$ is an exit set portion: Here we have $u' = v < 0$ and so orbits touching this half of the face of $\mathcal{O}_2$ must immediately exit into $\mathcal{O}_2$.

(2) The face $u = 0$, $v > 0$ is *not* an exit set portion: Here we have $u' = v > 0$ and so orbits are actually entering the set W from $\mathcal{O}_2$.

(3) Verification that the negative w-axis, $u = 0$, $v = 0$, $w < 0$ is an immediate exit set portion: On this portion of the face of $\mathcal{O}_2$ an orbit has $u' = v = 0$, $u'' = v' = w < 0$ so that the u coordinate has a local maximum, and the orbit re-enters the region $\{u < 0\}$.

(4) The positive w-axis, $u = 0$, $v = 0$, $w > 0$ is *not* an immediate exit set portion: On this portion of the face of $\mathcal{O}_2$ an orbit has $u' = v = 0$, $u'' = v' = w > 0$ so that the u coordinate has a local minimum and the v-coordinate is increasing. Orbits passing through points on the positive w-axis remain in the Wazewski set W.

(5) The origin $(0, 0, 0)$ is part of the exit set since an orbit from this point has $u' = v = 0$, $u'' = v' = w = 0$, and $u''' = w' = -1$. Thus the orbit has a cubic singularity in u at the origin, and immediately enters $\mathcal{O}_2$.

Therefore, all of the boundary of the octant $\mathcal{O}_1$ except for the corner equilibrium point $(1, 0, 0)$ is in the exit set W^-. The portion of the exit set W^- on the boundary of $\mathcal{O}_2$ is an open half-plane $\{u = 0, v < 0\}$, together with the nonpositive w-axis. See Fig. 4. In fact, orbits in W may have internal tangencies to the boundary of W along the positive w-axis. Lemma 5 will show that orbits starting from the interval of initial conditions Σ cannot have these internal tangencies on the positive w-axis so hypothesis 2 of Proposition 2 will still be satisfied. Referring back to the Wazewski set W, the exit set W^- is obviously a disconnected set.

Next we define the set Σ needed by Proposition 2 to prove Theorem 1. The no-slip initial conditions set Σ will be a compact interval on the w-axis. Defining Σ requires some technical lemmas.

Lemma 3 shows solutions with $u(0) = 0$ and $v(0) = 0$ cannot grow unboundedly in the positive v or positive w directions without entering the octant $\mathcal{O}_1$.

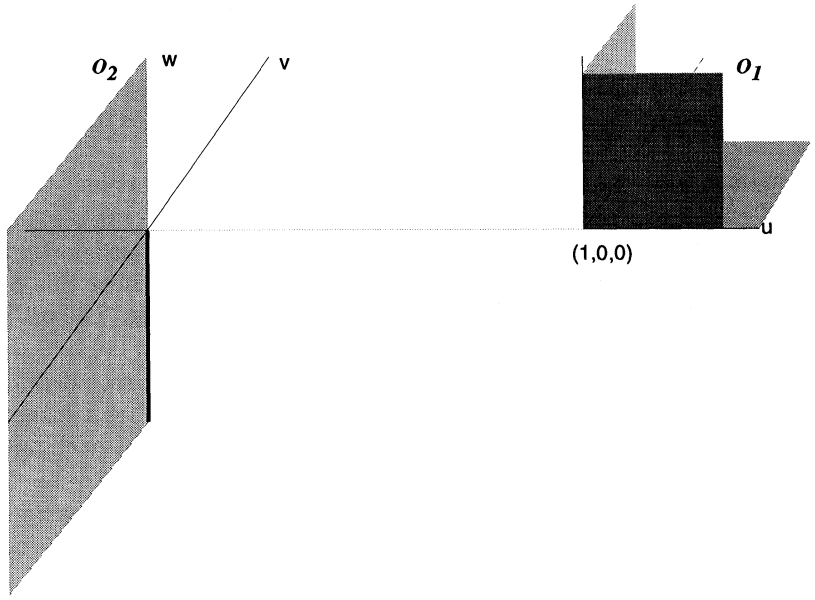

FIG. 4. *The exit set W^-.*

Some notation is necessary. Fix $w_0 > 0$, and let

$$u_0(v) = \int_0^v \frac{z}{\sqrt{2\lambda z^3/3 + w_0^2}}\, dz.$$

The integral clearly exists for all $v \geq 0$ and $u_0(v)$ is increasing. According to Gradshteyn and Ryzhik [6, §2.202, p. 71] it is not possible to express $u_0(v)$ in terms of the elementary functions. Let $v_0(u)$ be the inverse function. Additionally, let $\Lambda = \max(\lambda, 1/\sqrt{\lambda})$. Define the box-like region

$$R = \{(u, v, w) : 0 \leq u \leq 1, 0 \leq v \leq v_0(u) + \Lambda, 0 \leq w \leq (v_0(1) + \Lambda)v + w_0\};$$

see Fig. 5.

LEMMA 3. *An orbit of* (7) *starting from the point* $(0, 0, w(0))$ *with* $0 \leq w(0) \leq w_0$ *cannot leave the bounded region* R *except transversally through the floor* $0 \leq u \leq 1$, $0 \leq v \leq v_0(u) + \Lambda$, $w = 0$, *or transversally through the back wall* $u = 1$, $0 \leq v \leq v_0(1) + \Lambda$, $0 \leq w \leq (v_0(1) + \Lambda)v + w_0$ *into the octant* $\mathcal{O}_1$.

Proof. The proof proceeds by examining the vector field on the sides of the box-like region. The vector field points inward on some of these sides, so that an orbit cannot leave through these sides.

(Front Wall.) On the edge $u = 0$, $v = 0$, $0 < w \leq w_0$, orbits have $u' = 0$ but $u'' = v' > 0$. Therefore orbits starting on the edge actually enter R with a quadratic tangency. In the region R, the orbits have $u' = v > 0$; so the orbits cannot reverse direction and exit through the front wall $u = 0$, $0 \leq v \leq \Lambda$, $0 \leq w \leq (v_0(1) + \Lambda)v + w_0$.

(Side wall.) In the region R the orbits have $v' = w > 0$; so the orbits are increasing in v from zero and orbits cannot leave through the wall $0 \leq u \leq 1$, $v = 0$, and $0 \leq w \leq w_0$.

(Curved side wall.) The orbit has $w' = \lambda v^2 - \lambda uw + u - 1$, so that as long as the orbit is in the region where $0 \leq u < 1$, and $w > 0$, we know that $w' < \lambda v^2$. Now

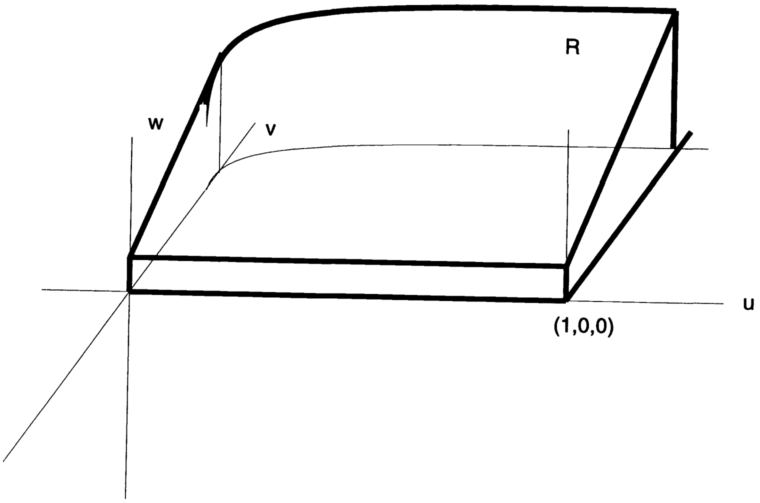

FIG. 5. *The bounded region R.*

$w' = v''$, so that this can be written as $v'' < \lambda v^2$. Multiply through by $v' = w > 0$ and integrate from zero to s to obtain

$$\frac{(v')^2}{2} - \frac{w(0)^2}{2} < \frac{\lambda v^3}{3}.$$

Rearrange and use $w(0) \leq w_0$ to get

$$v' < \sqrt{2\lambda v^3/3 + w_0^2}.$$

Therefore, orbits of the system (7) must have

$$u' = v,$$
$$v' < \sqrt{2\lambda v^3/3 + w_0^2}.$$

The outward normal (in the direction of increasing v) of the curved side wall $v = v_0(u) + \Lambda$, $0 \leq u < 1$, $0 < w \leq (v_0(1) + \Lambda)v + w_0$ is $(-\sqrt{2\lambda v^3/3 + w_0^2}/v, 1, 0)$. The dot product of the tangents to the orbits and the outward normal of the surface is therefore negative, and orbits cannot cross this side wall.

Because $\Lambda \geq 1/\sqrt{\lambda}$ and because $v_0(u)$ is increasing, the bottom edge of the curved side wall, $v = v_0(u) + \Lambda$, $0 < u \leq 1$, $w = 0$ lies in the region where $w' = \lambda v^2 - \lambda uw + u - 1 > 0$. Therefore, orbits from the initial condition set cannot leave the region R from the bottom edge of the curved side wall either.

(Ceiling.) For the orbits starting from $(0, 0, w(0))$ with $0 \leq w(0) \leq w_0$, we have $v'(0) = w(0) \geq 0$ and $w'(0) = -1 \leq 0$. Thus the orbit starts below the upward sloping open ceiling panel $w = (v_0(1) + \Lambda)v + w_0$, $0 < u < 1$, $0 \leq v \leq (v_0(1) + \Lambda)$. Suppose there is a first time s when the orbit hits the upward sloping ceiling panel:

$$w(s) = (v_0(1) + \Lambda)v(s) + w_0.$$

Then

$$w'(s) \geq (v_0(1) + \Lambda)v'(s),$$

or equivalently,

$$\lambda v^2 - \lambda uw + u - 1 \geq (v_0(1) + \Lambda)w.$$

Now substituting $w = (v_0(1) + \Lambda)v + w_0$ on the right:

$$\lambda v^2 - \lambda uw + u - 1 \geq (v_0(1) + \Lambda)^2 v + (v_0(1) + \Lambda)w_0. \tag{9}$$

But $\lambda v^2 \leq (v_0(1) + \Lambda)^2 v$ on the region $0 \leq v \leq v_0(1) + \Lambda$ and the remaining terms on the left-hand side of (9) are nonpositive and the remaining term on the right side of (9) is strictly positive which gives a contradiction. Alternatively, this argument says that the projection of the vector field on the normal vector of the ceiling plane is negative. That is, the vector field on the ceiling of the box points into the box and the orbit cannot leave the box through the ceiling. □

LEMMA 4. *Let*

$$A(\lambda) = \begin{cases} \sqrt{2}\lambda^{-1/4} & \text{for } 0 < \lambda < 2^{2/3}, \\ \sqrt{\lambda} & \text{for } 2^{2/3} \leq \lambda. \end{cases}$$

An orbit from $(0, 0, w(0))$ *with* $w(0) > A(\lambda)$ *cannot leave the bounded region* R *through the floor* $w = 0$. *Consequently, orbits from the* w*-axis with* $w(0) > A(\lambda)$ *can only leave* R *through the back wall* $u = 1$ *into the octant* $\mathcal{O}_1$.

Proof. Observe that $w' > 0$ when $u > 1 - \lambda v^2$ and $w = 0$. Thus, an orbit cannot leave the region R given in Lemma 3 through the floor outside the parabolic half-cylinder $u = 1 - \lambda v^2$ with $v \geq 0$.

Note that u and v are increasing for an orbit in R. Therefore, it remains to show that an orbit from $(0, 0, w(0))$ with $w(0) > A(\lambda)$ cannot go through the floor within the parabolic half-cylinder. In fact we will show that all the more so, the orbit cannot cross the downward sloping plane panel $w = A(\lambda) - \sqrt{\lambda}A(\lambda)v$ within the parabolic half-cylinder. See Fig. 6 for a diagram of the sloping floor panel.

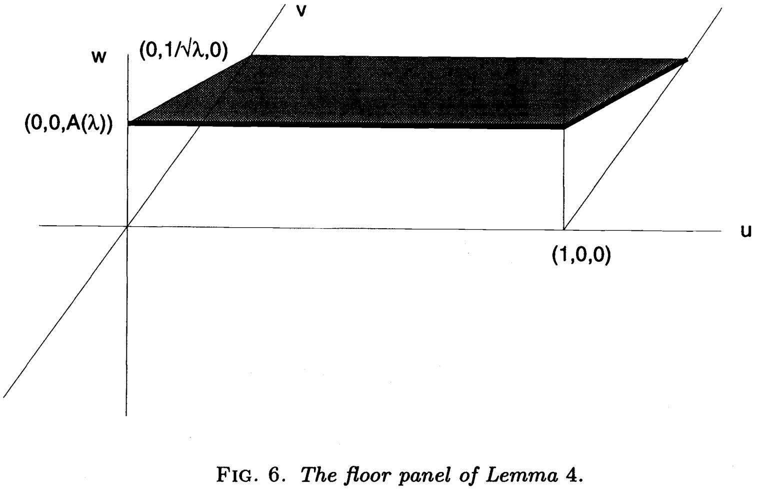

FIG. 6. *The floor panel of Lemma* 4.

At the initial time $s = 0$,

$$w(0) > A(\lambda) - \sqrt{\lambda}A(\lambda)v(0).$$

Suppose there is a first time s the orbit touches the downward sloping floor panel so that

$$w(s) = A(\lambda) - \sqrt{\lambda}A(\lambda)v(s).$$

Then $w'(s) + \sqrt{\lambda}A(\lambda)v'(s) \leq 0$. If this inequality is impossible within the parabolic half-cylinder, then the orbits cannot touch this plane panel.

Substitute the expressions from the differential equations and the equation of the plane into $w' + \sqrt{\lambda}A(\lambda)v'$ to obtain

$$-1 + \sqrt{\lambda}A^2 + (1 - \lambda A)u - \lambda A^2 v + (\lambda)^{3/2}Auv + \lambda v^2. \tag{10}$$

If the minimum value of (10) over the half parabola $0 \leq u \leq 1 - \lambda v^2$, $0 \leq v$ is positive, the proof is done. The expression (10) has only one critical point, which is easily seen to be a saddle point. Thus, if the values of (10) on the boundary of the half parabola over which the panel is defined are nonnegative, an orbit cannot cross the plane panel in the interior of the half parabola.

Consider first the case when $\lambda \geq 2^{2/3}$, so $A = \sqrt{\lambda}$. Over the edge $0 \leq u \leq 1$, $v = 0$ the value of (10) is

$$(\lambda^{3/2} - 1)(1 - u),$$

which is clearly nonnegative.

The value of (10) over the edge $u = 0$, $0 \leq v \leq 1/\sqrt{\lambda}$ is

$$-1 + \lambda v^2 - \lambda^2 v + \lambda^{3/2},$$

which is also nonnegative.

The value of (10) along the parabolic edge $u = 1 - \lambda v^2$, $0 \leq v \leq 1/\sqrt{\lambda}$ is

$$\lambda^{5/2}v^2(1 - \sqrt{\lambda}v),$$

also clearly nonnegative.

Now for the case $0 < \lambda < 2^{2/3}$, the expression for the projection is

$$1 + (1 - \sqrt{2}\lambda^{3/4})u - 2\sqrt{\lambda}v + \sqrt{2}\lambda^{5/4}uv + \lambda v^2. \tag{11}$$

Over the edge $0 \leq u \leq 1$, $v = 0$ the value of (11) is

$$1 + (1 - \sqrt{2}\lambda^{3/4})u,$$

which is clearly nonnegative. The value of (11) over the edge $u = 0$, $0 \leq v \leq 1/\sqrt{\lambda}$ is

$$(1 - \sqrt{\lambda}v)^2,$$

which is also nonnegative. Finally, the value of (11) along the parabolic edge $u = 1 - \lambda v^2$, $0 \leq v \leq 1/\sqrt{\lambda}$ is

$$(2 - \sqrt{2}\lambda^{3/4} + \sqrt{2}\lambda^{7/4}v^2)(1 - \sqrt{\lambda}v),$$

also clearly nonnegative. □

Remark. In Lemma 1 of [13], Troy obtained the uniform (in $\lambda > 0$) estimate that all orbits starting with $w(0) > 7/3$ enter $\mathcal{O}_1$. Lemma 4 provides an improvement on this estimate for the range $4(3/7)^4 < \lambda < (7/3)^2$. This range covers much of the interval for which the results are new.

LEMMA 5. *Define*

$$\Sigma = \{(0,0,\beta) : 0 \le \beta \le A(\lambda) + 1\},$$

where $A(\lambda)$ is the constant defined by Lemma 4. Then orbits starting from the initial condition set Σ cannot have internal tangencies in the Wazewski set W.

Proof. The proof will be accomplished by examining several cases. The case-by-case examination and variety of arguments among the cases seems to be required because the proof necessarily determines the long-time nonmonotone behavior of a family of solutions to a nonlinear initial value problem.

From the previous determination of the exit set W^-, the only possible place for an orbit to have an internal tangency in W is on the positive w-axis on the upper face of the region $\mathcal{O}_2$. Therefore, the proof will follow points from Σ forward in time and show that the orbits cannot touch the positive w-axis.

Some initial notation is necessary to establish the cases. Suppose, for a contradiction, that there is an orbit from Σ with an internal tangency. That is, suppose that there is an orbit from $(0, 0, w(0))$ that enters the region $u > 0$, crosses the u-w plane at $(u(T_2), 0, w(T_2))$ for some $T_2 > 0$ and then decreases to $(0, 0, w(T_7))$ for some $T_7 > T_2$, where $w(T_7) > 0$. In Fig. 7 is a diagram of the u-v projection of such a hypothesized orbit, together with the labeling of the important points. For the rest of the proof fix attention on this orbit. The cases will depend on the value of $u(T_2)$. (The notation for the times T_2, T_7 allows for additional intermediate times to be defined later.)

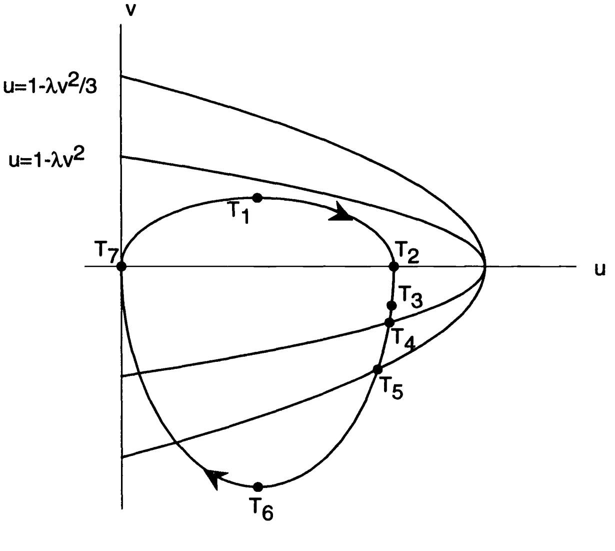

FIG. 7. *Diagram of the u-v projection of the orbit of the proof of Lemma 5.*

It will be convenient to use the abuse of notation $V_0(s) = V_0(u(s), v(s), w(s))$.

Case 1. $u(T_2) < 1$

Subcase (a). $\lambda \le (27/16)^{2/3} \approx 1.4174$.

The orbit from $(0, 0, w(0))$ enters the region $u > 0$ and crosses the floor $w = 0$ at T_1 in the region $0 < u < 1$, $u < 1 - \lambda v^2$. The orbit then decreases in v, until crossing the u-w plane with $u(T_2) < 1$ and $w(T_2) < 0$. The orbit continues decreasing in v until recrossing the u-v plane at $(u(T_6), v(T_6), 0)$ where $v(T_6) < 0$, and then the orbit approaches the point of internal tangency $(0, 0, w(T_7))$.

From the Lyapunov function $V_0(u, v, w) = w^2/2 - \lambda v^3/3 - (u-1)v$ we obtain that $V_0(s) > V_0(T_7) = (w(T_7))^2/2 > 0$ for $s < T_7$. In particular, $V_0(T_6) = -\lambda v(T_6)^3/3 - (u(T_6) - 1)v(T_6) > 0$ so that $u(T_6) > 1 - \lambda v(T_6)^2/3$. This means the orbit must cross the parabolic cylinder $u = 1 - \lambda v^2/3$ at some T_5. Therefore, at T_5, we have $u' + 2\lambda v v'/3 = v + 2\lambda v w/3 \geq 0$. So at T_5, $w \leq -3/(2\lambda)$. At T_5, $V_0(T_5) = w(T_5)^2/2 \geq 9/(8\lambda^2)$. Therefore, at T_2, $V_0(T_2) \geq w(T_2)^2/2 > 9/(8\lambda^2)$, and so we conclude that $w(T_2) < -3/(2\lambda)$.

Now at T_1 the orbit is in the region $w = 0$, $u > 0$, $v > 0$, and $u < 1 - \lambda v^2$. The maximum value of $V_0(u, v, w)$ on this region is $2/(3\sqrt{\lambda})$ occurring at $(1/\sqrt{\lambda}, 0, 0)$. Therefore $V_0(T_2) < V_0(T_1) \leq 2/(3\sqrt{\lambda})$. But for $\lambda \leq (27/16)^{2/3}$, $9/(8\lambda^2) \geq 2/(3\sqrt{\lambda})$; so we have a contradiction and no internal tangency is possible.

Subcase (b). $\lambda > (27/16)^{2/3}$.

For this case, we need some additional bounds on the orbit. These bounds will show that it is not possible for the orbit to loop around the "bubble" defined by $V_0(u, v, w) = 0$ in the region $v < 0$.

The previous argument shows that on the interval $0 < s < T_2$, where $v > 0$ an orbit with an internal tangency, must decrease in w to $w(T_2) < -3/(2\lambda)$. From the vector field this can only happen if the orbit passes through the half parabolic region $w = -3/(2\lambda)$, $v > 0$ and $0 < u < (2/5)(1 - \lambda v^2)$. By examining the vector field on the isocline surface $w' = \lambda v^2 - \lambda u w + u - 1 = 0$, we see that the orbit can pass from the region $w' < 0$ to $w' > 0$ in the half space $v > 0$ only where $w \geq -1/\lambda$. Therefore, at $s = T_2$ the orbit must still be in the region $w' < 0$ so $-\lambda u(T_2) w(T_2) + u(T_2) - 1 < 0$. Since $w(T_2) < -3/(2\lambda)$ we must have that $u(T_2) < 2/5$. Thereafter, in the region $v < 0$, certainly $u < 2/5$.

The previous subcase showed that $V_0(s) > 0$ for all $s \leq T_7$. Let T_4 be the time when the orbit crosses the parabolic cylinder $u = 1 - \lambda v^2$ with $v < 0$. Then $V_0(T_4) = w^2(T_4)/2 + 2\lambda v^3(T_4)/3 > 0$ or $w(T_4) < -\sqrt{4\lambda/3}(-v)^{3/2}$. In terms of u along $u = 1 - \lambda v^2$, we have $w < -\sqrt{4/3}(1-u)^{3/4}/\lambda^{1/4}$. The orbit has its minimum value of w at T_3 when the orbit crosses the $w' = 0$ isocline surface $\lambda v^2 - \lambda u w + u - 1 = 0$. At $s = T_3$ the u and w coordinates of the orbit satisfy $\lambda v^2 - \lambda u w + u - 1 = 0$, so $w > (1/\lambda)(1 - 1/u)$. For $s > T_3$ the w coordinate is increasing and the u coordinate is decreasing. In particular, $w(T_4) > (1/\lambda)(1 - 1/u(T_4))$ and we have all the more so that at T_4,

$$\frac{1}{\lambda}\left(1 - \frac{1}{u(T_4)}\right) < -\sqrt{\frac{4}{3}}\frac{(1 - u(T_4))^{3/4}}{\lambda^{1/4}}$$

Solving for u we obtain the estimate that $u(T_4) < (\sqrt{3}/2)\lambda^{-3/4}$.

Combining the arguments of the previous two paragraphs, we find that

$$u(T_4) < \min\left(\frac{2}{5}, \left(\frac{\sqrt{3}}{2}\right)\lambda^{-3/4}\right) \equiv u_4$$

and

$$\frac{1}{\lambda}\left(1 - \frac{1}{u_4}\right) < w(T_4) < -\sqrt{\frac{4}{3}}\frac{(1 - u_4)^{3/4}}{\lambda^{1/4}}. \tag{12}$$

Note that $u_4 = 2/5$ for $\lambda \leq (75/16)^{2/3} \approx 2.8009$.

Next we show that the orbit cannot cross the plane

$$w = -2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{1/4}}u + \sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{\lambda^{1/4}}. \tag{13}$$

The previous estimates (12) on the u and w coordinates show that the orbit is below this plane at $s = T_4$. If for some $s > T_4$ the orbit crosses the plane, then at that time we would have that

$$w' + 2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{1/4}}u' \geq 0$$

or

$$\lambda v^2 - \lambda uw + u - 1 + 2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{1/4}}v \geq 0.$$

By factoring and rearranging, this can be written as

$$\sqrt{\lambda}v\left(\sqrt{\lambda}v + 2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{3/4}}\right) - \lambda uw + u - 1 \geq 0.$$

At this time, we know that $\sqrt{\lambda}v < 0$ and $-\lambda uw + u - 1 < 0$. Thus, if we show that

$$\sqrt{\lambda}v + 2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{3/4}} \geq 0,$$

we will have reached the desired contradiction showing that the orbit cannot cross the plane.

To do this, we need a bound on the v coordinate. Now v has its minimum negative value at $s = T_6$ when $w = 0$. As shown above, $V_0(T_6) = -\lambda v(T_6)^3/3 - (u(T_6) - 1)v(T_6) < 2/(3\sqrt{\lambda})$. Since $0 \leq u(T_6) < 1$, it is easy to see that $v(T_6) > -2^{1/3}/\sqrt{\lambda}$. Therefore, we obtain the bound $v(s) > -2^{1/3}/\sqrt{\lambda}$. Then the desired contradiction can be obtained by showing that

$$-2^{1/3} + 2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{3/4}} \geq 0$$

for the values of $\lambda > (27/16)^{2/3}$ under consideration. For $(27/16)^{2/3} < \lambda \leq (75/16)^{2/3}$, $u_4 = 2/5$ and the calculation reduces to showing that

$$\lambda^{3/4} \leq \left(\frac{3}{5}\right)^{3/4}\frac{10}{2^{1/3}\cdot 3^{1/2}},$$

which is true for this range of λ.

For $\lambda > (75/16)^{2/3}$, $u_4 = \sqrt{3/4}\lambda^{-3/4}$ and the desired contradiction reduces to showing that

$$-2^{1/3} + \frac{8}{3}\left(1 - \sqrt{\frac{3}{4}}\lambda^{-3/4}\right)^{3/4} \geq 0.$$

or

$$\lambda^{-3/4} \leq \sqrt{\frac{4}{3}}\left(1 - \left(\frac{3\cdot 2^{1/3}}{8}\right)^{4/3}\right),$$

which is true for the range of λ under consideration. This shows the orbit cannot cross above the plane given by (13).

For $T_4 < s < T_7$, where $0 < u < u_4$ and the orbit cannot cross the plane

$$w = -2\sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{u_4\lambda^{1/4}}u + \sqrt{\frac{4}{3}}\frac{(1-u_4)^{3/4}}{\lambda^{1/4}},$$

then all the more so the orbit must satisfy

$$w < \sqrt{\frac{4}{3}}\frac{(1-u)^{3/4}}{\lambda^{1/4}}.$$

This means that over the curve $u = 1 - \lambda v^2$ the Lyapunov function must be negative. This is in contradiction to $V_0(T_7) > 0$. Therefore, no internal tangency is possible.

Case 2. $u(T_2) \geq 1$.

Consider the "Lyapunov" function

$$V_\infty(u, w, z) = vw + \frac{\lambda u v^2}{2} - \frac{(u-1)^2}{2}$$

with derivative along an orbit

$$\dot{V}_\infty = w^2 + \frac{3\lambda v^3}{2}.$$

Under the assumption that there is an orbit from $(0, 0, w(0))$ to $(0, 0, w(T_7))$ with an internal tangency, then along this orbit

$$0 = V_\infty(0, 0, w(T_7)) - V_\infty(0, 0, w(0)) = \int_0^{T_7}\left(w(z)^2 + \frac{3\lambda v(z)^3}{2}\right) dz.$$

If we show that $\int_0^{T_7}(w^2 + (3\lambda v^3/2))\,dz > 0$, then we will have a contradiction. Thus, V_∞ does not have a (positive) sign-definite Lyapunov derivative, but along hypothesized orbits with an internal tangency its value is increasing, leading to a contradiction. The proof is stated in terms of a single loop from the initial condition on the w-axis back to the hypothetical tangency on the w-axis. Nevertheless, if there is a multiple loop through the plane $v = 0$ before returning to the tangency on the w-axis, the proof is the same by setting T_0 to the last time the orbit passes through the plane $v = 0$ with $v' > 0$ before the tangency at T_7. If the orbit starts from the v-axis, the proof is again the same, a comment that is important for the next section on the stress-free boundary conditions.

We will show the integral is positive by breaking the interval of integration into portions from 0 to T_2, and from T_2 to T_7,

$$\int_0^{T_7} w^2\,dz + \frac{3\lambda}{2}\left(\int_0^{T_2} v^3\,dz + \int_{T_2}^{T_7} v^3\,dz\right).$$

For $0 < s < T_2$ we have $u'(s) = v > 0$, so that it is possible to solve for s in terms of u and express v as a function of u on the interval $0 < u < u(T_2) \equiv u_2$, say the result is $v_1(u)$. Likewise on the interval $T_2 < s < T_7$, $u'(s) = v < 0$ and so we can express v

as a function of u for $0 < u < u_2$, calling the result $v_2(u)$. The integrals can then be expressed as

$$\int_0^{T_7} w^2\,dz + \frac{3\lambda}{2}\left(\int_0^{u_2} v_1(u)^2\,du - \int_0^{u_2} v_2(u)^2\,du\right).$$

We will show that $v_1(u) > -v_2(u)$, and so the integral is positive.

At $s = T_2$, $u(T_2) \geq 1$, $v(T_2) = 0$, and $w(T_2) < 0$ so that $v' = w < 0$. Thus it is possible to express s in terms of v and so to express u as a function of v in a neighborhood of $v = 0$ and $u = u_2$. In fact, $du/dv = v/w = 0$ at $s = T_2$ and

$$\left.\frac{d^2u}{dv^2}\right|_{T_2} = \frac{1}{w(T_2)} - \frac{v(T_2)w'(T_2)}{w(T_2)^3} = \frac{1}{w(T_2)}.$$

Note that $w'(T_2) = \lambda v^2(T_2) - \lambda u(T_2)w(T_2) + u(T_2) - 1 > 0$. For $T_2 - \epsilon < s < T_2$, $v > 0$ and $w < w(T_2) < 0$, Thus for $v > 0$, $d^2u/dv^2 = 1/w - vw'/w^3 > 1/w(T_2)$. Likewise for $v < 0$, $d^2u/dv^2 = 1/w - vw'/w^3 < 1/w(T_2)$. Then for $v > 0$, $u(v) > u_2 + (1/w(T_2))v^2 > u(-v)$. See Fig. 8. In terms of the functions $v_1(u)$ and $v_2(u)$, we have that $v_1(u) > -v_2(u)$ for $u - \delta < u < u_2$, for some small δ. We want to show that this inequality can be continued to the entire interval $0 < u < u_2$.

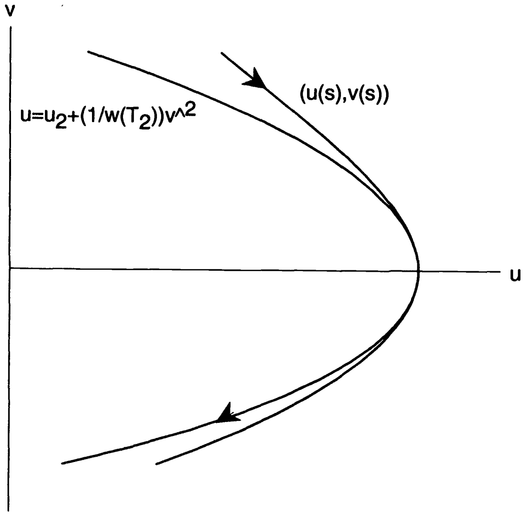

FIG. 8. *u as a function of v in a neighborhood of $v = 0$ and $u = u_2$.*

Consider $u^* = \max\{0 < u < u_2 : v_1(u) = -v_2(u)\}$. Let $v^* = v_1(u^*) = -v_2(u^*)$. There are two times $0 < s_1 < T_2 < s_2 < T_7$ such that $u(s_1) = u^* = u(s_2)$. Then at the point u^*,

$$\frac{w(s_2)}{v^*} = -\frac{w(s_2)}{v(s_2)} = -\left.\frac{dv_2}{du}\right|_{u^*} < \left.\frac{dv_1}{du}\right|_{u^*} = \frac{w(s_1)}{v(s_1)} = \frac{w(s_1)}{v^*}.$$

Therefore, $w(s_2) < w(s_1)$.

However, by the choice of $u^* = u(s_1) = u(s_2)$,

$$\begin{aligned}
&V_\infty(u(s_2), v(s_2), w(s_2)) - V_\infty(u(s_1), v(s_1), w(s_1))\\
&= \int_{s_1}^{s_2} w^2(z) + \frac{3\lambda v^3(z)}{2}\, dz\\
&= \int_{s_1}^{s_2} w^2(z)\, dz + \frac{3\lambda}{2}\left(\int_{u^*}^{u_2} v_1^2(u)\, du - \int_{u^*}^{u_2} v_2^2(u)\, du\right)\\
&= \int_{s_1}^{s_2} w^2(z)\, dz + \frac{3\lambda}{2}\left(\int_{u^*}^{u_2} (v_1^2(u) - v_2^2(u))\, du\right)\\
&> 0,
\end{aligned}$$

so that

$$v(s_1)w(s_1) + \frac{\lambda u(s_1)v^2(s_1)}{2} - \frac{(u(s_1)-1)^2}{2} < v(s_2)w(s_2) + \frac{\lambda u(s_2)v^2(s_2)}{2} - \frac{(u(s_2)-1)^2}{2}.$$

Because $u(s_1) = u(s_2)$ and $v(s_1) = -v(s_2)$, this reduces to $v(s_1)w(s_1) < v(s_2)w(s_2)$ or $w(s_1) < -w(s_2)$.

From the Lyapunov function V_0 we know that

$$\frac{w(s_2)^2}{2} - \frac{\lambda v(s_2)^3}{3} - (u(s_2)-1)v(s_2) < \frac{w(s_1)^2}{2} - \frac{\lambda v(s_1)^3}{3} - (u(s_1)-1)v(s_1)$$

or

$$w(s_2)^2 - w(s_1)^2 < -\frac{2\lambda v(s_1)^3}{3} - 2(u(s_1)-1)v(s_1).$$

From the previous paragraphs $w(s_2)^2 > w(s_1)^2$, and so the u^* and v^* cannot occur in the region $u \geq 1 - \lambda v^2/3$. Because $w(s_2) < w(s_1) < -w(s_2)$, we cannot have $w(s_2) > 0$.

Similar to what was shown in shown in Case 1, subcase (a), crossing the parabolic cylinder $u = 1 - \lambda v^2/3$ from $u > 1 - \lambda v^2/3$ to $u < 1 - \lambda v^2/3$ must take place with $-3\lambda/2 < w$. The value of V_0 at the crossing would then satisfy $V_0 < 9\lambda^2/8$. But the orbit cannot later recross the parabolic cylinder from inside to outside again, because as in Case 1, subcase (a), that would require $V_0 > 9\lambda^2/8$ in contradiction to the fact that V_0 is decreasing. Finally ihe orbit cannot cross the plane $w = 0$ with $u < 1-\lambda v^2/3$ because then $V_0 < 0$, in contradiction to the fact that $V_0 > 0$ on $0 < s < T_7$.

Finally then, the conclusion is established by ruling out all possibilities for the orbit to return to the positive w-axis. □

LEMMA 6. *Define* $\Sigma = \{(0,0,\beta) : 0 \leq \beta \leq A(\lambda) + 1\}$ *where A is the constant defined by Lemma* 4. *Then there is* β_0, $0 \leq \beta_0 \leq A(\lambda) + 1$ *such that the the orbit starting from* $(0,0,\beta_0)$ *remains in* W *for all* s; *that is,* $\Sigma \neq \Sigma^0$.

Proof. Consider an orbit starting from $(0, 0, A(\lambda) + 1)$. The orbit immediately enters the interior of the bounded region R, where $u' = v > 0$, and so u is increasing. The orbit must stay above the floor panel given in Lemma 4. In particular, the orbit cannot approach the equilibrium point $(1, 0, 0)$. The orbit also cannot exit through $w = 0$ because $w' > 0$ for $v > 1/\sqrt{\lambda}$ and $w = 0$. In summary, the conclusion of the technical Lemmas 3 and 4 is that the orbit must exit R through the back wall $u = 1$ into the octant $\mathcal{O}_1$. Lemma 1 of [13] reaches essentially the same conclusion, by analytic rather than geometric techniques. However, that lemma does not simultaneously establish the boundedness of the orbits.

It is easy to see by the vector field examination done previously on the boundaries of W that the orbit which begins at the origin $(0,0,0)$ of the phase space immediately enters the octant $\mathcal{O}_2$.

Now define the initial set Σ to be the connected interval on the w-axis from $(0,0,0)$ to $(0,0,w_0)$, where $w_0 = A(\lambda) + 1$ as mentioned previously. If all orbits starting on Σ leave the Wazewski set W then by Proposition 2, the exit time mapping from the segment Σ to the boundary of W is a homeomorphism. Yet Lemmas 3 and 4 show that one orbit exits W through one component of the exit set and goes into $\mathcal{O}_1$. Another orbit leaves W through the other component of the exit set into $\mathcal{O}_2$. This is a contradiction, so there is at least one orbit starting on Σ which does not leave the Wazewski set W. □

Finally, the orbit starting from $(0,0,\beta_0)$ identified in the previous Lemma must be the solution of (1) with the no-slip boundary conditions (2) . This follows from the next two lemmas.

LEMMA 7. *An orbit not entering $\mathcal{O}_1$ or $\mathcal{O}_2$ must remain bounded with $u > 0$.*

Proof. From its initial point $(0,0,\beta_0) \in \Sigma$ the orbit enters the region R given in Lemma 3. There is an upper bound on v for orbits in R, namely $v_0(1) + \Lambda$. The orbit cannot enter $\mathcal{O}_1$ and so must have $v' = w < 0$ if $u > 1$ and $v > 0$. Thus, the orbit has $v_0(1) + \Lambda$ as an upper bound for v.

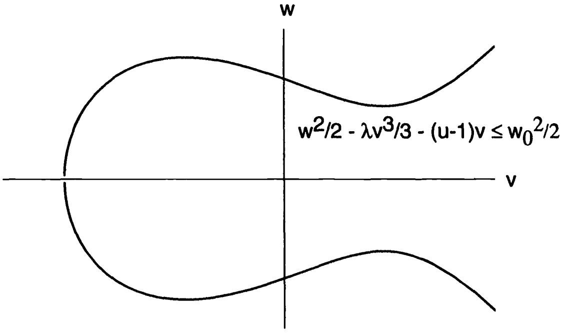

FIG. 9. *A cross section for $u \geq 0$ of the region containing the special orbit.*

Since the orbit does not enter $\mathcal{O}_2$, the Lyapunov function $V_0(u,v,w)$ is always decreasing. Therefore,

$$\frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v \leq \frac{w_0^2}{2},$$

where $w_0 = A(\lambda) + 1$ is the maximum w coordinate of the initial condition set Σ. Then for $u \geq 0$, $v \leq 0$ the orbits must lie in the region

$$-\sqrt{w_0^2 + 2(u-1)v + \frac{2\lambda v^3}{3}} \leq w \leq \sqrt{w_0^2 + 2(u-1)v + \frac{2\lambda v^3}{3}}.$$

See Fig. 9 for a sketch of the region. For each $u \geq 0$ the maximum extent in $v < 0$ occurs when

$$w_0^2 + 2(u-1)v + \frac{2\lambda v^3}{3} = 0.$$

A graph of u versus v for this relation shows that there is a minimum value of $v < 0$ satisfying this relationship; see Fig. 10. Combining this result with the bound for

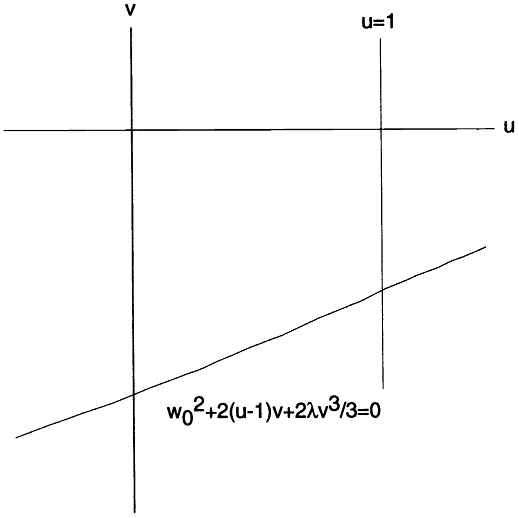

FIG. 10. *The graph of u versus v for* $w_0^2 + 2(u-1)v + 2\lambda v^3/3 = 0$.

$v > 0$ gives a global bound on the v coordinate of the special orbit. This argument is essentially the same as one already used in Lemma 5.

Since

$$\frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v \leq \frac{w_0^2}{2}$$

and v is bounded, if u is also bounded above, then w must be bounded.

Now for the Lyapunov function $V_\alpha(u,v,w) = w^2/2 - \lambda v^3/3 - (u-1)v + \alpha[vw + \lambda uv^2 - (u-1)^2/2]$ choose $\alpha < 0$ so small that $3\alpha\lambda v/2 - 1 < 0$ for all s. Then $\dot{V}_\alpha < 0$ and $V_\alpha(u,v,w)$ is decreasing along the special orbit. That is,

$$\frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v + \alpha\left[vw + \lambda uv^2 - \frac{(u-1)^2}{2}\right] \leq \frac{w_0^2}{2} - \frac{\alpha}{2}$$

for all s. We see that if w is bounded, then u must also be bounded.

Consequently, if the special orbit is unbounded, then u and w must be unbounded together. Since the orbit must always satisfy

$$\frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v \leq \frac{w_0^2}{2},$$

it is not possible for u and w to be simultaneously unbounded in $v < 0$. If u and w are unbounded together in the region $v > 0$ then ultimately $u > 1$ and $w < 0$ since the orbit cannot enter $\mathcal{O}_1$. But then $w' = \lambda v^2 - \lambda uw + (u-1) > 0$ and so w cannot decrease unboundedly.

This argument shows that the u and w coordinates must be bounded and so the special orbit is bounded. □

LEMMA 8. *The orbit starting from the initial point* $(0, 0, \beta_0)$ *must satisfy the boundary condition* $u(\infty) = 1$.

Proof. Since this special orbit must remain bounded with $u > 0$, consider the Lyapunov function

$$V_0(u,v,w) = \frac{w^2}{2} - \frac{\lambda v^3}{3} - (u-1)v.$$

It has already been noted that the derivative along an orbit $\dot{V}_0 = -\lambda uw^2 - v^2$ is negative so long as $u > 0$. By the LaSalle Invariance Principle, the ω-limit set is contained in the set where $\dot{V}_0 = 0$. Thus the ω-limit set of the orbit is an invariant set contained in the line $u > 0$, $w = 0$, $v = 0$ and so can only be the equilibrium point $(1, 0, 0)$. That is, the special orbit must satisfy the boundary condition $u(\infty) = 1$. □

This completes the proof of Theorem 1.

3. Existence of solutions to the stress-free problem. This section contains the proof of the following.

THEOREM 9. *For all $\lambda > 0$ there is at least one solution to the equation*

$$\phi''' + \lambda(\phi\phi'' - (\phi')^2) + 1 - \phi = 0,$$

satisfying the "stress-free" boundary conditions

$$\begin{aligned} \phi(0) &= 0, \\ \phi''(0) &= 0, \\ \phi(\infty) &= 1. \end{aligned}$$

The proof of this theorem is substantially the same as the proof of Theorem 1. The Wazewski set W is still appropriate and many of the same lemmas still apply. The main task is to identify the initial value set Σ and to establish that there are no internal tangencies.

LEMMA 10. *The orbit of the system* (7) *starting from the point* $(0, 1/\sqrt{\lambda}, 0)$ *on the positive v-axis leaves the set W and enters the octant $\mathcal{O}_1$.*

Proof. The initial tangent vector has $u'(0) = 1/\sqrt{\lambda}$, and $w'(0) = \lambda v^2 - \lambda uw + u - 1 = 0$ but with $w''(0) = 2\lambda vw - \lambda vw - \lambda uw' + v = 1/\sqrt{\lambda} > 0$ so that the orbit immediately enters the region R described in Lemma 3. Then the orbit has $w > 0$ and so v is increasing. This means in turn that the orbit stays in the region $v > 1/\sqrt{\lambda}$. Therefore, the orbit cannot exit the region R through the floor $w = 0$ since $w' > 0$ for $v > 1/\sqrt{\lambda}$. Furthermore, just as in Lemma 3, the orbit is bounded above in the v and the w coordinates. The u coordinate is increasing since $v > 0$. Thus the orbit must continue to increase until it exits the set W through the back wall $u = 1$ into the octant $\mathcal{O}_1$. □

LEMMA 11. *Define*

$$\Sigma = \left\{ (0, \beta, 0) : 0 \leq \beta \leq \frac{1}{\sqrt{\lambda}} \right\}.$$

Then orbits starting from the initial condition set Σ cannot have internal tangencies in the Wazewski set W.

Proof. The proof is the same as that of Lemma 5 since that proof does not depend on the initial conditions. □

The last argument to be filled in is the following.

LEMMA 12. *There is β_0, $0 \leq \beta_0 \leq 1/\sqrt{\lambda}$ such that the orbit starting from $(0, \beta_0, 0)$ remains in W for all s; that is, $\Sigma \neq \Sigma^0$.*

Proof. Consider the orbit starting from $(0, 1/\sqrt{\lambda}, 0)$. By the conclusion of technical Lemma 10 the orbit must exit R through the back wall $u = 1$ into the octant

$\mathcal{O}_1$. As noted before, the orbit from the origin $(0,0,0)$ of the phase space immediately enters the region $\mathcal{O}_2$.

Suppose all orbits starting on the connected interval Σ defined in Lemma 11 leave the Wazewski set W. Then by Proposition 2, the exit time mapping from Σ to the boundary of W is a homeomorphism. Yet one orbit exits W through one component of the exit set and enters $\mathcal{O}_1$. Another orbit leaves W through the other component of the exit set into $\mathcal{O}_2$. This is a contradiction, so there is at least one orbit starting on Σ which does not leave the Wazewski set W. □

The orbit starting from $(0,\beta_0,0)$ identified in the previous Lemma 12 must be bounded with $u > 0$ as shown by the proof of Lemma 7. The orbit starting from the initial point $(0,\beta_0,0)$ satisfies the boundary condition $u(\infty) = 1$ by the same argument as in Lemma 8. This finishes the proof of Theorem 9.

Acknowledgment. I would like to thank Professor Lloyd Jackson for helpful conversations during the course of this work.

BOUNDARY AND INTERIOR SPIKE LAYER FORMATION FOR AN ELLIPTIC EQUATION WITH SYMMETRY*

ARNALDO S. DO NASCIMENTO†

Abstract. Consider the problem $\nabla[k(\|x\|)\nabla U_\lambda]+\lambda f(U_\lambda)=0$, $x\in B$: unit ball in R^n, $\nabla U_\lambda\cdot\hat{n}/_{\partial B}=0$. Conditions are given on k and f that guarantee the formation of boundary layer and also of a spike layer around the origin as $\lambda\to\infty$ for some particular radially symmetric solutions to the above problem. In the first case, the nodal curve of the solution approaches ∂B as $\lambda\to\infty$, while in the second one it shrinks toward the origin as $\lambda\to\infty$. Range location for the value of the solution on ∂B, in the first case, and at the origin in the second one, is given for λ sufficiently large. Only radially symmetric solutions are considered since they are the only ones that can be stable equilibria of the corresponding parabolic equation.

Key words. convergence in measure, nodal curves, maximum principle, radially symmetric solution

AMS(MOS) subject classifications. 35B25, 35B40, 34E15

1. Introduction. Consider the following nonlinear eigenvalue problem:

$$\begin{aligned}&\nabla[k(\|x\|)\nabla U_\lambda]+\lambda f(U_\lambda)=0, \qquad x\in B,\\ &\nabla U_\lambda\cdot\hat{n}/_{\partial B}=0,\end{aligned}\tag{1.1}$$

where B is the unit ball in R^n, $\hat{n}$ the unit vector orthogonal to ∂B, $\|\cdot\|$ the Euclidian norm, $\lambda\in(0,\infty)$, $k(\|x\|)$ a positive function in $C^2(\bar{B},R)$, and $f\in C^2(R,R)$ satisfies

$$\exists a, b\in R, b<0<a: f(b)=f(0)=f(a)=0, \qquad f'(0)>0, \tag{h$_1$}$$

$$\operatorname{sgn} f''(U)=-\operatorname{sgn} U \quad \forall U\in R,\ U\neq 0. \tag{h$_2$}$$

To simplify notation we shall drop the subscript λ in the notation of the solution U_λ and consider $n=2$.

We restrict our study to the radially symmetric solutions to (1.1) due to the fact that if the corresponding parabolic problem is considered, that is,

$$\begin{aligned}&\frac{\partial U}{\partial t}=\nabla[k(\|x\|)\nabla U]+\lambda f(U), \quad (t,x)\in(0,\infty)\times B,\\ &\nabla U\cdot\hat{n}/_{\partial B}=0,\end{aligned}\tag{1.2}$$

then any stable equilibrium solution to (1.2) in $W^{1,2}(B)$ must exhibit such symmetry. Conversely, if $W_r^{1,2}(B)$ stands for the space of radially symmetric functions of $W^{1,2}(B)$, then any radially symmetric equilibrium of (1.2), which is stable in $W_r^{1,2}(B)$, turns out to be stable in the larger space $W^{1,2}(B)$, too. Also it is well known that if $k(\|x\|)=$ constant, then any stable equilibrium solution of (1.2) must be a constant function. This is no longer the case if $k(\|x\|)$ is allowed to vary in a suitable manner. These results will appear in a forthcoming paper.

Roughly speaking, by boundary layer formation we mean that a radial solution $U(x,\lambda)$ to (1.1) exhibits the following geometrical feature: for any R, $0<R<1$, $r=\|x\|$, $U(r,\lambda)$ converges uniformly to a constant solution on $[0,R]$, as $\lambda\to\infty$ and $U(r,\lambda)$ varies abruptly in $[R,1]$ so that $|U_r(r,\lambda)|$ assumes arbitrarily large values in $[R,1]$ as $\lambda\to\infty$.

† Universidade Federal de São Carlos-DM, 13560—São Carlos, SP, Brasil.

The very same interpretation can be given for interior spike layer formation by replacing the above interval by $[0, R]$.

Borrowing the terminology used in the literature for reaction-diffusion equations, we herein refer to k as the diffusion function and to f as the reaction term.

The following result has been proved in [1]. Let $\tilde{\lambda}_n$, $n \geqq 0$, be the nth eigenvalue of the linearized problem ($\tilde{\lambda}_0 = 0$):

$$(1.3)\qquad \begin{aligned} &(k(r)U_r)_r + k(r)\frac{U_r}{r} + \lambda f'(0)U = 0, \qquad r \in (0, 1), \\ &\qquad\qquad\qquad U_r(0) = 0, \qquad U_r(1) = 0. \end{aligned}$$

Suppose that f satisfies (h_1) and (h_2) and the diffusion function k satisfies

$$(1.4)\qquad r^2(k^{1/2})_{rr} + r(k^{1/2})_r \leqq k^{1/2}, \qquad 0 < r < 1.$$

Note that $k \equiv$ const. satisfies the inequality.

If $\lambda \in (\tilde{\lambda}_n, \tilde{\lambda}_{n+1})$, $n \geqq 1$, then there are exactly $(2n+3)$ radially symmetric solutions of (1.1), three of them being the constant solutions 0, a, and b. For $\lambda \in (0, \tilde{\lambda}_1)$, the only solutions are the constant ones: 0, a, and b.

If C_k, $k \geqq 1$, denotes the branch of radially symmetric solutions of (1.1) bifurcating from the zero solution at $\lambda = \tilde{\lambda}_k$, then C_k is defined for all $\lambda \geqq \tilde{\lambda}_k$, and the solutions in it, denoted by $\phi_k(r, \lambda)$, $0 \leqq r \leqq 1$, are characterized by having exactly k simple zeros in $(0, 1)$ and satisfy $b < \phi_k(r, \lambda) < a$, $r \in [0, 1]$.

Moreover, $C_k = C_k^+ \cup C_k^-$, where $\phi_k \in C_k^+$ if $\phi_k(0, \lambda) > 0$, $\phi_k \in C_k^-$ if $\phi_k(0, \lambda) < 0$.

Throughout this paper by $\phi_n^+(r, \lambda)[\phi_n^-(r, \lambda)]$, $n \geqq 1$, we mean a solution to (1.1) in $C_n^+[C_n^-]$, $\lambda > \tilde{\lambda}_n$, and $r_1(\lambda), \dots, r_n(\lambda)$, where $0 < r_1(\lambda) < \cdots < r_n(\lambda) < 1$ stand for the zeros of $\phi_n^+(r, \lambda)[\phi_n^-(r, \lambda)]$ in $(0, 1)$. They are simple zeros and, in particular, $(d/dr)\,\phi_1^+(r, \lambda) < 0$ $[(d/dr)\phi_1^-(r, \lambda) > 0]$ in $(0, 1)$.

In other words, the above results yield the global bifurcation diagram for the radially symmetric solutions to (1.1). We are concerned here with the asymptotic behavior of the solution $\phi_1^+(., \lambda)[\phi_1^-(., \lambda)]$ as we follow the bifurcation branch $C_1^+[C_1^-]$.

We prove that if, besides the assumptions (h_1) and (h_2), f and k are related to each other according to

$$(h_3)\qquad k_m \int_0^b f > k_M \int_0^a f,$$

where $k_m = \min_{0 \leqq r \leqq 1} k(r)$ and $k_M = \max_{0 \leqq r \leqq 1} k(r)$, then $r_1(\lambda) \to 1$ as $\lambda \to \infty$. Also $\phi_1^+(r, \lambda)$ converges uniformly as $\lambda \to \infty$ to the constant solution $U(r) = a$ in $[0, \bar{r}]$ for any $\bar{r}$ such that $0 < \bar{r} < 1$.

It follows from (h_3) that there are number α and β, $b < \beta \leqq \alpha < 0$ satisfying

$$\frac{k_M}{k_m}\int_0^a f = \int_0^\beta f \quad \text{and} \quad \frac{k_m}{k_M}\int_0^a f = \int_0^\alpha f.$$

Then we also prove that $\beta \leqq \lim_{n\to\infty} \inf \phi_n^+(1, \lambda_n) \leqq \lim_{n\to\infty} \sup \phi_n^+(1, \lambda) \leqq \alpha < 0$ for any sequence $\{\lambda_n\}_{n \in N}$ such that $\lambda_n \to \infty$ as $n \to \infty$. Note that the closer k_m is taken to k_M, the nearer α is to β. See Fig. 1 below. In particular, for the case of constant diffusion, that is, $k(r) \equiv$ const., then $\lim_{\lambda\to\infty} \phi_1^+(1, \lambda) = c$ where c is the unique negative number, $b < c < 0$ so that

$$\int_0^a f = \int_0^c f, \quad \text{where } b < c < 0 < a.$$

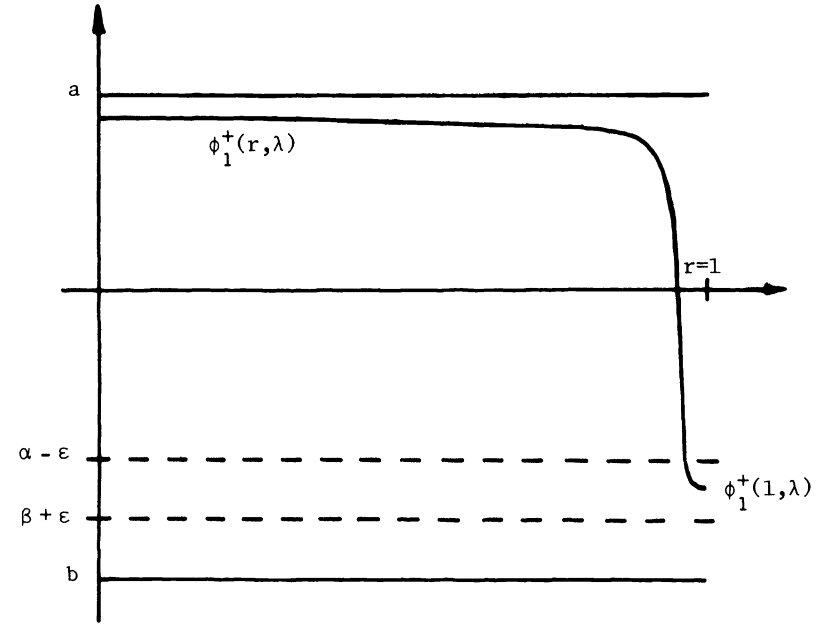

FIG. 1

Condition (h_3) means that the area of the negative bump of f, namely, $\int_0^b f$, is bigger than the area of the positive bump of f, namely, $\int_0^a f$, multiplied by (k_M/k_m). In particular, altogether it implies that

$$\int_0^b f > \left(\frac{k_M}{k_m}\right)\int_0^a f = \int_0^\beta f = \left(\frac{k_M}{k_m}\right)\int_0^\alpha f.$$

Using hypotheses (h_1), (h_2), and (h_3), similar results hold for solutions $\phi_1^-(r,\lambda)$, as we follow the bifurcation half branch C_1^-, except that now $r_1(\lambda)\to 0$ as $\lambda\to\infty$. Also it follows that for any $\varepsilon>0$, ε: small, there is $\Lambda=\Lambda(\varepsilon)$ such that $b<\beta+\varepsilon<\phi_1^+(1,\lambda)<\alpha+\varepsilon<0$ for $\lambda\geqq\Lambda$.

Note that by setting $\lambda=1/\varepsilon$, then as $\lambda\to\infty$, (1.1) can be viewed as the following singularly perturbed semilinear elliptic problem:

$$\varepsilon\nabla[k(\|x\|)\nabla U_\varepsilon]+f(U_\varepsilon)=0,$$
$$U_\varepsilon.\hat{n}/_{\partial B}=0.$$

There is a vast literature in singularly perturbed problems, and among others the reader is referred to [2], [3], [4], [5], [8], [10], and [11].

In this paper the following should be seen as the major contributions: the emphasis on the relationship between the diffusion function k and the reaction term f in determining the asymptotic behavior of the nodal curves of $\phi_1^+(.,\lambda)$ and $\phi_1^-(.,\lambda)$, the formation of layer along with its location, and finally the asymptotic behavior of the solutions on the layer's locus.

Herein, once a solution $\phi_n^+(.,\lambda)\in C_n^+$ is taken, we follow the bifurcation branch, and the results are accomplished by using comparison techniques based on maximum principles, convergence in measure to the equilibrium solutions and equalities that relate the areas of the negative and positive bumps of f, up to the end points of the first half loops of the solution $\phi_1^+(r,\lambda)$ in the phase plane and the maximum and minimum attained by $k(r)$, $r\in[0,1]$.

Condition (1.4) above was assumed in [1] to guarantee that each C_n^+, C_n^-, $n \geqq 1$, was monotone in λ and did not present secondary bifurcation. However, for the purpose of this work (1.4) need not be assumed. Indeed, all we need here is to have each C_n^+, C_n^-, $n \geqq 1$ defined for all λ, $\lambda > \tilde{\lambda}$, and the nodal properties which follow from the work of Rabinowitz [6] and from the Sturm-Liouville theory, respectively.

2. The case $\phi_1^+(.,\lambda) \in C_1^+$: boundary layer. In this section we only deal with the solution $\phi_1^+(.,\lambda)$, and, therefore, for simplicity in notation we drop the superscript +, thus just writing $\phi_1(.,\lambda)$.

In view of the previous considerations, instead of problem (1.1), it suffices to consider

$$\begin{gathered}(k(r)U_r)_r + k(r)\frac{U_r}{r} + \lambda f(U) = 0, \qquad 0 < r < 1,\\ U_r(0) = U_r(1) = 0.\end{gathered} \tag{2.1}$$

LEMMA 2.1. *Let* $k_m = \min_{0 \leqq r \leqq 1} k(r)$, $k_M = \max_{0 \leqq r \leqq 1} k(r)$ *and suppose that* f *satisfies* (h_1), (h_2), *and* (h_3). *Then it holds that*

$$k_m \int_0^{\phi_1(1,\lambda)} f < k_M \int_0^{\phi_1(0,\lambda)} f$$

for any $\lambda > \tilde{\lambda}_1$, *where* $\tilde{\lambda}_1$ *is the first positive eigenvalue of problem* (1.2).

Proof. The solution $\phi_1(r,\lambda)$ satisfies

$$\frac{d}{dr}\left[\frac{(k\phi_{1,r})^2}{2} + \int_0^r \frac{(k\phi_{1,r})^2}{s}\,ds + \lambda \int_0^r k(s)\frac{d}{ds}F(\phi_1(s,\lambda))\,ds\right] = 0$$

for $r \in (0,1)$, where $F(\phi) = \int_0^\phi f$.

Therefore, the expression between brackets is constant in [0, 1], and taking $r = 0$, we conclude that this constant is zero. Since $\phi_{1,r}(1,\lambda) = 0$, we obtain

$$\int_0^1 \frac{(k(s)\phi_{1,s})^2}{s}\,ds + \lambda \int_0^1 k(s)\frac{d}{ds}F(\phi_1(s,\lambda))\,ds = 0,$$

which, by its turn, implies that

$$\left(\int_0^{r_1(\lambda)} kf(\phi_1)\phi_{1,s}\,ds + \int_{r_1(\lambda)}^1 kf(\phi_1)\phi_{1,s}\,ds\right) < 0,$$

for all $\lambda > \tilde{\lambda}_1$.

On $[0, r_1(\lambda)]$ it holds that $f(\phi_1(r,\lambda)) \geqq 0$, $\phi_{1,r} \leqq 0$ and on $[r_1(\lambda), 1]$, $f(\phi_1(r,\lambda)) \leqq 0$, and $\phi_{1,r} \leqq 0$.

Hence

$$0 < \int_{r_1(\lambda)}^1 kf(\phi_1)\phi_{1,s}\,ds < -\int_0^{r_1(\lambda)} kf(\phi_1)\phi_{1,s}\,ds,$$

and with k_m and k_M as defined above:

$$0 < k_m \int_{r_1(\lambda)}^1 \frac{d}{ds}F(\phi_1(s,\lambda))\,ds < -k_M \int_0^{r_1(\lambda)} \frac{d}{ds}F(\phi_1(s,\lambda))\,ds.$$

But $F(\phi_1(r_1,\lambda)) = 0$, and then $k_m F(\phi_1(1,\lambda)) < k_M F(\phi_1(0,\lambda))$, that is,

$$k_m \int_0^{\phi_1(1,\lambda)} f < k_M \int_0^{\phi_1(0,\lambda)} f,$$

and the lemma is proved.

In what follows, Lemma 2.1 will be useful in the sense that if $\{\lambda_n\}_{n\in N}$, $\lambda_n\to\infty$ as $n\to\infty$ is such that $\phi_1(1,\lambda_n)$ converges as $n\to\infty$, then we easily conclude that $b<\lim_{n\to\infty}\phi(1,\lambda_n)\leqq 0$. This yields information about the asymptotic behavior of $r_1(\lambda_n)$ for if $r_1(\lambda_n)\not\to 1$, as $n\to\infty$, by constructing a supersolution in a convenient interval we are able to prove that $\lim_{n\to\infty}\phi(1,\lambda_n)=b$.

We will work now toward proving that $r_1(\lambda)\to 1$, as $\lambda\to\infty$ and to this end let us consider the following linear eigenvalue problem:

$$(2.2)\qquad \begin{aligned}&(k\psi_r)_r+k\frac{\psi_r}{r}+\mu f'(0)\psi=0, \qquad R<r<1,\\ &\psi(R)=\psi(1)=0,\end{aligned}$$

where $0<R<1$. It is well known that the eigenfunction $J(r)$ corresponding to the first eigenvalue μ_0 of (2.2) is of one sign in $(R,1)$. By multiplying by a constant, if necessary, we can suppose $b<J(r)<0$ in $(R,1)$.

LEMMA 2.2. *Suppose that there is R, $0<R<1$ and a sequence $\{\lambda_n\}_{n\in N}$, $\lambda_n>\tilde\lambda_1$, $\lambda_n\to\infty$ as $n\to\infty$ such that $r_1(\lambda_n)$; the unique zero of $\phi_1(r,\lambda_n)$ in $(0,1)$ satisfies $0<r_1(\lambda_n)\leqq R$ for any n. Let μ_0 and $J(r)$ be the principal eigenvalue and eigenfunction of* (2.2), *as above. Then $J(r)\geqq\phi_1(r,\lambda_n)$ in $[R,1]$ for n sufficiently large.*

Proof. On $[R,1]$ we have $\phi_1(r,\lambda_n)\leqq 0$ and $\phi_{1,r}(1,\lambda_n)=0$. Moreover, J can be taken as negative in $(R,1)$.

Let us suppose by contradiction that for any Λ, there is n such that $\lambda_n\geqq\Lambda$ and $\tilde r\in[R,1]$ such that $0>\phi_1(\tilde r,\lambda_n)>J(\tilde r)$. By continuity there are numbers $\tilde r_1(\lambda_n)$ and $\tilde r_2(\lambda_n)$, $\tilde r_1(\lambda_n)\leqq\tilde r(\lambda_n)<\tilde r_2(\lambda_n)<1$ such that $J(\tilde r_1)=\phi_1(\tilde r_1,\lambda_n)$, $J(\tilde r_2)=\phi_1(\tilde r_2,\lambda_n)$, and $\phi_1(r,\lambda_n)>J(r)$ in $(\tilde r_1,\tilde r_2)$.

There are two cases to consider.

Case 1. $r_1(\lambda_n)<R$ for infinitely many n.

In this case, as a consequence, $R<\tilde r_1(\lambda_n)<\tilde r_2(\lambda_n)<1$. In order to resort to a comparison technique, we set

$$\xi(r)=\frac{J(r)}{\phi_1(r,\lambda_n)},$$

which satisfies

$$\xi_{rr}+\left[\frac{k_r}{k}+\frac{1}{r}+\frac{2\phi_{1,r}}{\phi_1}\right]\xi_r+\frac{1}{k}\left[\mu_0 f'(0)-\lambda_n\frac{f(\phi_1(r,\lambda_n))}{\phi_1(r,\lambda_n)}\right]\xi=0$$

for $\tilde r_1(\lambda_n)<r<\tilde r_2(\lambda_n)$ and $\xi(\tilde r_1)=\xi(\tilde r_2)=1$.

Note that by virtue of hypotheses (h_1) and (h_2) in $(\tilde r_1,\tilde r_2)$ it holds that

$$f'(0)\geqq\frac{f(\phi_1(r,\lambda_n))}{\phi_1(r,\lambda_n)}\geqq\frac{f(J(r))}{J(r)}\geqq\frac{f(J_m)}{J_m}>0,$$

where $J_m=\min\{J(r),\ \tilde r_1(\lambda)\leqq r\leqq\tilde r_2(\lambda)\}$.

The assumption that for any Λ there is $\lambda_n\geqq\Lambda$ and $\tilde r$, $R<\tilde r<1$, such that $\phi_1(\tilde r,\lambda_n)>J(\tilde r)$ prevents $\phi_1(r,\lambda_n)$ from approaching the equilibrium solution $b\equiv$ const. for λ_n: large, and this by its turn yields a lower bound for $[f(\phi_1(r,\lambda_n))/\phi_1(r,\lambda_n)]$. Therefore, by taking Λ large enough it is possible to make the coefficient of ξ in equation above negative in $(\tilde r_1,\tilde r_2)$.

Summing up we have $\xi(\tilde r_1)=\xi(\tilde r_2)=1$ and $\xi(r)>0$ in $(\tilde r_1,\tilde r_2)$. In particular, ξ assumes its maximum in $(\tilde r_1,\tilde r_2)$ since $\xi(\tilde r)>1$. But this is impossible according to the remarks above and a well-known maximum principle. See [9].

Case 2. $r_1(\lambda_n) = R$ for infinitely many n.

In this case we have $R = \tilde{r}_1(\lambda_n) < \tilde{r}_2(\lambda_n) < 1$ and ξ would still satisfy (2.3) with different boundary conditions, namely, $\xi(R) > 0$, $\xi(1) = 0$, $\xi_r(R) = 0$, and $\xi > 0$ in $(R, 1)$.

The computation $\xi_r(R) = 0$ can be accomplished by applying l'Hôpital's rule twice and using (2.2) and (2.1).

Now an application of the maximum principle referred to above yields a contradiction, and the lemma is proved.

LEMMA 2.3. *Under the hypotheses and notation of Lemma* 2.2 *it holds that*

$$\lim_{n\to\infty} \int_R^1 J(r) f(\phi_1(r, \lambda)) r\, dr = 0.$$

Proof. Since $\phi_1(r, \lambda_n)$ is an equilibrium solution of (2.1), with the notation set forth there, but by dropping the index n for simplicity we have

$$J(r)(rk(r)\phi_{1,r})_r = -\lambda r f(\phi_1(r, \lambda))J(r), \qquad R \leqq r \leqq 1.$$

But $(rk\phi_{1,r}J)_r = J(rk\phi_{1,r})_r + rJ_r\phi_{1,r}k(r)$, and, therefore, $-\lambda r f(\phi_1)J(r) = (rk\phi_{1,r}J)_r - rJ_r\phi_{1,r}k$. Again $(rk\phi_1 J_r)_r = r\phi_{1,r}kJ_r + \phi_1(rkJ_r)_r = r\phi_{1,r}J_r k - f'(0)\mu_0 r\phi_1 J$, since J satisfies problem (2.2).

Henceforth by combining the last two equalities, $(rJk\phi_{1,r})_r - (rk\phi_1 J_r)_r - f'(0)\mu_0 r\phi_1 J = -\lambda rJ f(\phi_1)$.

Integrating the above equality from R to 1 and bearing in mind that $J(R) = 0$, $\phi_{1,r}(1, \lambda) = 0$ we obtain

$$[-rk(r)\phi_1(r, \lambda)J_r(r)]/{}_R^1 - f'(0)\mu_0 \int_R^1 J(r)\phi_1(r, \lambda) r\, dr = -\lambda \int_R^1 J(r) f[\phi_1(r, \lambda)] r\, dr.$$

In $[R, 1]$, $b < \phi_1(r, \lambda) < 0$, for any $\lambda \geqq \tilde{\lambda}_1$ and since J does not depend on λ we conclude that

$$\lim_{\lambda\to\infty} \int_R^1 J(r) f(\phi_1(r, \lambda)) r\, dr = 0.$$

LEMMA 2.4. *Under the hypotheses of Lemma* 2.2 *and with notation set forth there it holds that* $\phi_1(r, \lambda_n) \to b$ *in* $[R, 1]$, *in measure as* $n \to \infty$. *In particular,* $\phi_1(1, \lambda_n) \to b$ *as* $n \to \infty$.

Proof. Again for simplicity we just write λ for λ_n.

Roughly speaking, the idea of the proof consists of first concluding that $\phi_1(., \lambda)$ approaches in measure a zero of f, which can be seen from the previous lemma and second by using Lemma 2.2, which yields a super solution to the equilibria of problem (2.1) in $[R, 1]$ and, consequently, prevents $\phi_1(., \lambda)$ from approaching the zero solution in $[R, 1]$.

There remains only the constant solution b for $\phi_1(., \lambda)$ to converge to, as $\lambda \to \infty$. A similar idea has previously been used by de Figueiredo in [7].

To this end let us take $\varepsilon > 0$ arbitrarily small and set $I_\varepsilon = \{r \in [R, 1]: R + \varepsilon \leqq r \leqq 1 - \varepsilon\}$. Recall that by Lemma 2.2 $0 \geqq J(r) \geqq \phi_1(r, \lambda) > b$, in I_ε for λ sufficiently large.

Therefore, there is $m(\varepsilon) < 0$, $m(\varepsilon) = \sup\{J(r), r \in I_\varepsilon\}$ so that

$$\int_{I_\varepsilon} J(r) f(\phi_1(r, \lambda)) r\, dr \geqq m(\varepsilon) \int_{I_\varepsilon} f(\phi_1(r, \lambda)) r\, dr > 0$$

for any λ sufficiently large.

Suppose now that there is a $\delta > 0$ and a subsequence $\{\lambda_n\}$, $\lambda_n \to \infty$ as $n \to \infty$, such that the Lebesgue measure m^* of the sets $I_{\varepsilon,n} = \{r \in I_\varepsilon m(\varepsilon) \geqq \phi_1(r, \lambda_n) \geqq b + \varepsilon\}$ satisfies $m^*(I_{\varepsilon,n}) \geqq \delta$ for any n.

It follows from the hypotheses on f, namely, (f_1) and (f_2) that there is negative constant f_m so that $f(\phi_1(r, \lambda_n)) \leqq f_m$ in $I_{\varepsilon,n}$.

Therefore,

$$m(\varepsilon) \int_{I_\varepsilon} f(\phi_1(r, \lambda_n)) r\, dr \geqq m(\varepsilon) \int_{I_{\varepsilon,n}} f(\phi_1(r, \lambda_n)) r\, dr$$

$$\geqq m(\varepsilon) f_m m^*(I_{\varepsilon,n}) \geqq m(\varepsilon) f_m \delta > 0 \quad \text{for any } n.$$

But this is a contradiction since from the first chain of inequalities in this proof and Lemma 2.2 it follows that

$$\lim_{n\to\infty} \int_{I_\varepsilon} f(\phi_1(r, \lambda_n)) r\, dr = 0.$$

Therefore, for any $\varepsilon > 0$, $\lim_{n\to\infty} m^*(I_{\varepsilon,n}) = 0$, and our claim follows. Also $\phi_1(1, \lambda) \to b$, as $\lambda \to \infty$, since $\phi_{1,r} < 0$ on $[R, 1)$.

The sequence of previous results culminate with the following theorem.

THEOREM 2.5. *If* $k_m \int_0^b f > k_M \int_0^a f$ *holds, with* k_m *and* K_M *as before, then* $r_1(\lambda)$, *the unique zero of the solution* $\phi_1(r, \lambda)$ *in* $[0, 1]$, *satisfies* $\lim_{\lambda\to\infty} r_1(\lambda) = 1$.

Proof. Suppose by contradiction that there is a subsequence $\{\lambda_n\}$ and R, $0 < R < 1$ such that $0 < r_1(\lambda_n) \leqq R$.

The same notation of Lemma 2.2 is being used for simplicity, and hopefully this will not cause any confusion.

By Lemma 2.1,

$$k_m \int_0^{\phi_1(1,\lambda_n)} f < k_M \int_0^{\phi_1(0,\lambda_n)} f, \qquad \lambda > \tilde{\lambda}_1,$$

and $\lim_{n\to\infty} \phi_1(1, \lambda_n) = b$ by Lemma 5.4. Therefore, taking the limit, as $n \to \infty$, we obtain

$$k_m \int_0^b f \leqq \lim_{n\to\infty} k_M \int_0^{\phi_1(0,\lambda_n)} f \leqq k_M \int_0^a f,$$

which is against our assumption.

LEMMA 2.6. *Under the hypotheses* (h_1), (h_2), *and* (h_3) *it holds that* $\phi_1(r, \lambda) \to a$, *in measure, for* $0 \leqq r \leqq 1$, *as* $\lambda \to \infty$. *In particular,* $\phi_1(r, \lambda) \to a$, *uniformly, in* $[0, \bar{r}]$, *as* $\lambda \to \infty$ *for any* $\bar{r}$ *such that* $0 < \bar{r} < 1$.

Proof. Let us take $\varepsilon > 0$. Consider $r_\varepsilon = 1 - (\varepsilon/2)$ and the following eigenvalue problem:

$$(k\psi_r)_r + k\frac{\psi_r}{r} + \mu f'(0)\psi = 0, \qquad 0 < r < r_\varepsilon,$$

$$\psi_r(0) = \psi(r_\varepsilon) = 0.$$

Let μ_0 be the first positive eigenvalue of the above problem and J its corresponding eigenfunction. We can take $J(r) > 0$ in $[0, r_\varepsilon)$.

Hereafter the proof parallels the proofs of the foregoing lemmas, and, therefore, we go rather fast, omitting some details.

Note that since $r_1(\lambda)$, the unique zero of $\phi_1(r, \lambda)$ in $(0, 1)$ satisfies $r_1(\lambda) \to 1$, as $\lambda \to \infty$, we can suppose that for λ: large enough, $r_\varepsilon < r_1(\lambda) < 1$.

Proceeding as in the proof of Lemma 2.2 it can be proved that for λ sufficiently large, $J(r) \leqq \phi_1(r, \lambda)$ in $[0, r_\varepsilon]$.

The very same computations done in the proof of Lemma 2.3 yield

$$\lim_{\lambda\to\infty}\int_0^{r_\varepsilon} J(r)f(\phi_1(r,\lambda))r\,dr=0. \tag{2.3}$$

We now use an argument similar to that used in the proof of Lemma 2.4 to conclude, in view of the above equality that $\phi_1(r,\lambda)\to a$, in $[0,r_\varepsilon]$, as $\lambda\to\infty$, in measure. Since $\phi_1(r,\lambda)$ is a decreasing function in $[0,r_\varepsilon]$, the Lebesgue measure m^* of the set $J_\varepsilon(\lambda)=\{r\in[0,r_\varepsilon]\colon 0\leqq\phi_1(r,\lambda)<a-\varepsilon\}$ satisfies $\lim_{\lambda\to\infty} m^*J_\varepsilon(\lambda)=0$, and so for λ: large enough we have $J_\varepsilon(\lambda)\subset[1-\varepsilon,r_\varepsilon]$. Hence for λ: large enough $m^*\{r\in[0,1]\colon b<\phi_1(r,\lambda)<a-\varepsilon\}<\varepsilon$. As for the uniform convergence of $\phi_1(r,\lambda)$ to a, in $[0,\bar r]$, as $\lambda\to\infty$, for any $\bar r\in(0,1)$ it can be proved by contradiction once we realize that $\phi_1(r,\lambda)$ is a decreasing function in $[0,1]$ and use (2.3) above along with Theorem 2.5.

The claim follows.

LEMMA 2.7. *Assuming the existence of* $\phi_{1,\infty}(1)=\lim_{n\to\infty}\phi_1(1,\lambda_n)$, *it holds that* $b<\phi_{1,\infty}(1)\leqq 0$, *where* $\lambda_n\to\infty$ *as* $n\to\infty$.

Proof. Taking the limit as $n\to\infty$ in the inequality derived in Lemma 2.1 and using hypothesis (h_3) we obtain

$$k_m\int_0^{\phi_{1,\infty}(1)} f\leqq k_M\int_0^a f<k_m\int_0^b f,$$

which means that $b<\phi_{1,\infty}\leqq 0$. The lemma is proved.

As said before, it follows from (h_3) that there are unique numbers α and β, $b<\beta<\alpha<0$, satisfying

$$\frac{k_M}{k_m}\int_0^a f=\int_0^\beta f \quad\text{and}\quad \frac{k_m}{k_M}\int_0^a f=\int_0^\alpha f.$$

Next we prove that $b<\beta\leqq\phi_{1,\infty}(1)\leqq\alpha<0$. To this end we need some additional lemmas.

LEMMA 2.8. *With notation set forth above and under hypotheses* (h_1), (h_2), *and* (h_3) *it holds that*

$$\lim_{\lambda\to\infty}\frac{1}{\lambda}\int_0^1 rk(r)\phi_{1,r}^2(r,\lambda)\,dr=0.$$

Proof. Since $\phi_1(r,\lambda)$ is an equilibrium solution to (2.1) it satisfies

$$\frac{1}{\lambda}\int_0^1 rk(r)\phi_{1,r}^2(r,\lambda)\,dr=\int_0^1 r\phi_1(r,\lambda)f[\phi_1(r,\lambda)]\,dr.$$

The second integral in the above inequality has a uniformly bounded integrand in $[0,1]$, and Lemma 2.6 assures us that $\phi_1(r,\lambda)\to a$ in measure, as $\lambda\to\infty$, for $0\leqq r\leqq 1$. Then an application of the Lebesgue Convergence Theorem yields the desired result.

LEMMA 2.9. *Under hypotheses* (h_1), (h_2), *and* (h_3) *it holds that any sequence* $\{\lambda_n\}_{n\in N}$, $\lambda_n\to\infty$ *as* $n\to\infty$, *has a subsequence* $\{\lambda_{n_k}\}_{k\in N}$ *such that*

$$\lim_{k\to\infty}\frac{1}{\lambda_{n_k}}\int_0^1\frac{[k(r)\phi_{1,r}(r,\lambda_{n_k})]^2}{r}\,dr=0.$$

Proof. To simplify notation we set

$$g_n(r)=\frac{rk(r)\phi_{1,r}^2(r,\lambda_n)}{\lambda_n}$$

for $0 \leqq r \leqq 1$. Then Lemma 2.8 says that

$$\lim_{n\to\infty} \int_0^1 g_n(r)\,dr = 0.$$

Therefore, all we have to prove is that

$$\lim_{n\to\infty} \int_0^1 g_n(r) \frac{k(r)}{r^2}\,dr = 0.$$

If we call

$$h_m(r) = \frac{k(r)}{r^2} \chi_{[1/m,1]}(r),$$

for $0 \leqq r \leqq 1$, $m \in N$, $m \geqq 1$, where $\chi_{[1/m,1]}$ stands for the characteristic function of $[1/m, 1]$, then $h_m(r) \to h(r)$, pointwise in $[0, 1]$, as $m \to \infty$, where $h(r) = k(r)/r^2$ for $r \in (0, 1]$ and $h(0) = 0$.

Let us call $\delta_{nm} = \int_0^1 h_m(r) g_n(r)\,dr$. Then

$$\begin{aligned} 0 < \delta_{nm} &= \int_0^1 g_n(r) \frac{k(r)}{r^2} \chi_{[1/m,1]}(r)\,dr \\ &\leqq \int_0^1 \frac{k^2(r)\phi_{1,r}^2(r, \lambda_n)}{\lambda_n r}\,dr = -\int_0^1 k(r) \frac{d}{dr} F[\phi_1(r, \lambda_n)]\,dr \\ &\leqq k_M \int_0^1 \left| \frac{d}{dr} F[\phi_1(r, \lambda_n)] \right| dr = k_M V_{F[\phi_1]}[0, 1] \\ &= k_M V_F[\phi_1(1, \lambda_n), \phi_1(0, \lambda_n)] \leqq k_M V_F[a, b] < \infty. \end{aligned}$$

In the first equality above we used an equality derived in the proof of Lemma 2.1. Also $V_f[a, b]$ stands for the total variation of f over $[a, b]$, and $V_F[a, b] < \infty$ follows from the fact that $f \in C^2(R, R)$.

So the double real sequence satisfies $0 < \delta_{nm} < V_f[a, b] < \infty$, and hence it has a subsequence (labelled again δ_{nm}) that converges.

Moreover, for a fixed m_0, we have

$$\lim_{n\to\infty} \delta_{nm} = \lim_{n\to\infty} \int_0^1 h_{m_0}(r) g_n(r) \leqq k_M m_0^2 \lim_{n\to\infty} \int_0^1 g_n(r)\,dr = 0.$$

As a consequence the two limits can be interchanged, yielding $\lim_{n\to\infty} \lim_{m\to\infty} \delta_{nm} = \lim_{m\to\infty} \lim_{n\to\infty} \delta_{nm} = 0$. Next, using the monotone convergence theorem, we obtain

$$\begin{aligned} \lim_{n\to\infty} \int_0^1 h(r) g_n(r)\,dr &= \lim_{n\to\infty} \lim_{m\to\infty} \int_0^1 g_n(r) h_m(r)\,dr \\ &= \lim_{m\to\infty} \lim_{n\to\infty} \delta_{nm} = 0 \quad \text{by the above calculation.} \end{aligned}$$

The lemma is proved.

LEMMA 2.10. *Let $\{\lambda_n\}_{n \in N}$ be such that $\lambda_n \to \infty$ as $n \to \infty$ and $\phi_1(1, \lambda_n)$ converges. Then*

$$k_m \lim_{n\to\infty} \int_0^{\phi_1(0,\lambda_n)} f \leqq k_M \lim_{n\to\infty} \int_0^{\phi_1(1,\lambda_n)} f.$$

Proof. Since $0 < \phi_1(1, \lambda) < b$ for any $\lambda \geqq \bar{\lambda}_1$, a sequence as above always exists.

It follows from the equality (derived in the proof of Lemma 2.1) that

$$\int_0^1 \frac{[k(r)\phi_{1,r}(r\lambda_n)]^2}{r}\,dr + \int_0^1 k(r)\frac{d}{dr}F[\phi_1(r,\lambda_n)]\,dr = 0.$$

This, along with Lemma 2.9, implies that

$$\lim_{k\to\infty}\int_0^1 k(r)\frac{d}{dr}F[\phi_1(r,\lambda_{n_k})]\,dr = 0$$

for any subsequence $\{\lambda_{n_k}\}_{k\in N}$ of the above sequence. For simplicity, we drop the subscript k in the notation of the subsequence.

With the notation set forth before we have

$$\begin{aligned}0 &\leqq \lim_{n\to\infty}\int_{r_1(\lambda_n)}^1 k(r)f[\phi_1(r,\lambda_n)]\phi_{1,r}(r,\lambda_n)\,dr\\ &= -\lim_{n\to\infty}\int_0^{r_1(\lambda_n)} k(r)f[\phi_1(r,\lambda_n)]\phi_{1,r}(r,\lambda_n)\,dr.\end{aligned}$$

A careful examination of the signs of the above integrands over the respective intervals of integration yields

$$\begin{aligned}0 &\leqq \lim_{n\to\infty}\left\{-k_m\int_0^{r_1(\lambda_n)}\frac{d}{dr}F[\phi_1(r,\lambda_n)]\,dr\right\}\\ &\leqq \lim_{n\to\infty}\left\{k_M\int_{r(\lambda_n)}^1 \frac{d}{dr}F[\phi_1(r,\lambda_n)]\,dr\right\},\end{aligned}$$

that is, $\lim_{n\to\infty} k_m \int_0^{\phi_1(0,\lambda_n)} f \leqq \lim_{n\to\infty} k_M \int_0^{\phi_1(1,\lambda_n)} f$. While comparing this to Lemma 2.1, note that the roles of $\phi_1(0,\lambda_n)$ and $\phi_1(1,\lambda_n)$ have been inverted here.

LEMMA 2.11. *Under the hypotheses of Lemma* 2.9, *and with α and β as before, and assuming the existence of*

$$\phi_{1,\infty}(1) = \lim_{n\to\infty}\phi_1(1,\lambda_n), \quad \textit{then } b < \beta \leqq \phi_{1,\infty}(1) \leqq \alpha < 0.$$

Proof. From Lemma 2.9 and previous results we obtain

$$k_m\int_0^a f \leqq k_M\int_0^{\phi_{1,\infty}(1)}.$$

But $\int_0^\alpha f = (k_m/k_M)\int_0^a f$ and, therefore, $\int_0^\alpha f \leqq \int_0^{\phi_{1,\infty}(1)} f$, that is, $b < \phi_{1,\infty}(1) \leqq \alpha < 0$.

On the other hand, Lemma 2.1 and the assumption that

$$\frac{k_M}{k_m}\int_0^a f = \int_0^\beta f,$$

where $b < \beta < 0 < a$, yield

$$\int_0^{\phi_{1,\infty}(1)} f \leqq \frac{k_M}{k_m}\int_0^a f = \int_0^\beta f < \int_0^b f.$$

Therefore, $\phi_{1,\infty}(1) \geqq \beta$, and, summing up, we have $b < \beta \leqq \phi_{1,\infty}(1) \leqq \alpha < 0$.

Note that if we knew that $\lim_{\lambda\to\infty}\phi(1,\lambda)$ existed, then there would be no need to resort to subsequences in the proof of Lemma 2.9.

COROLLARY 2.12. *With the above notation we have* $b < \beta \leqq \lim_{n\to\infty} \inf \phi_1(1, \lambda_n) \leqq \lim_{n\to\infty} \sup \phi_1(1, \lambda_n) \leqq \alpha < 0$ *for any sequence* $\{\lambda_n\}_{n\in N}$ *such that* $\lambda_n \to \infty$ *as* $n \to \infty$.

It follows by noting that $\lim_{n\to\infty} \inf \phi_1(1, \lambda_n)$ *and* $\lim_{n\to\infty} \sup \phi_1(1, \lambda_n)$ *are, respectively, the smallest and largest cluster points of the sequence* $\phi_1(1, \lambda_n)$.

COROLLARY 2.13. *If the diffusion function is constant, that is,* $k(r) = \text{const.}$, *then* $\lim_{\lambda\to\infty} \phi(1, \lambda) = c$, *where c is the unique negative number so that* $\int_0^a f = \int_0^c f$ *and* $b < c < 0 < a$.

Proof. It follows once we note that in this case $\int_0^a f = \int_0^\alpha f = \int_0^\beta f$ with $b < \alpha < 0$ and $b < \beta < 0$, and, therefore, $\alpha = \beta$ in view of hypothesis (h_2).

3. The case $\phi_1^-(., \lambda) \in C_1^-$: interior spike. This case can be handled in essentially the same way we handled the previous one, except for the order in which some lemmas are applied. Also, as a consequence of the fact that now $r_1(\lambda)$, the unique zero of $\phi_1(r, \lambda)$ in $(0, 1)$ satisfies $r_1(\lambda) \to 0$ as $\lambda \to \infty$; modifications must be introduced in some lemmas. We just indicate these modifications and how the proofs can be accomplished based on the foregoing results.

To start with we remark that in this case Lemma 2.1 provides insufficient information about the behavior of $r_1(\lambda)$ as $\lambda \to \infty$, since it does not contradict hypothesis (h_3). However, that can be overcome by adapting Lemma 2.9 to suit this case. Recall that $(d/dr)\phi_1^-(r, \lambda) > 0$ in $(0, 1)$.

LEMMA 3.1. *Suppose that* $\{\lambda_n\}_{n\in N}$ *is such that* $r_1(\lambda_n) \to \bar{r}$, *as* $n \to \infty$, *where* $0 \leqq \bar{r} \leqq 1$ *and* $\lim_{n\to\infty} \phi_1^-(0, \lambda_n)$ *and* $\lim_{n\to\infty} \phi_1^-(1, \lambda_n)$ *exist.*

Then under hypotheses (h_1), (h_2), *and* (h_3),

$$k_m \cdot \lim_{n\to\infty} \int_0^{\phi_1^-(0,\lambda_n)} f \leqq k_M \cdot \lim_{n\to\infty} \int_0^{\phi_1^-(1,\lambda_n)} f.$$

Proof. First, consider $0 < \bar{r} < 1$. Also take $\varepsilon > 0$, ε: small and set $r_\varepsilon^- = \bar{r} - (\varepsilon/2)$, $r_\varepsilon^+ = \bar{r} + (\varepsilon/2)$.

Then by constructing a supersolution to problem (2.1) in $[0, r_\varepsilon^-]$ and a subsolution to the same problem in $[r_\varepsilon^+, 1]$ we can follow mutatis mutandis the proof of Lemma 2.6 to conclude that $\phi_1^-(r, \lambda_n) \to b$ in measure, as $n \to \infty$, in $[0, \bar{r}]$ and $\phi_1^-(r, \lambda_n) \to a$, in measure, as $n \to \infty$, in $[\bar{r}, 1]$. In particular, for any $\varepsilon > 0$, $\phi_1^-(r, \lambda_n) \to b$, uniformly, as $n \to \infty$, in $[0, r_\varepsilon^-]$.

Also, since $\phi_1^-(r, \lambda_n)$ satisfies

$$\frac{1}{\lambda_n} \int_0^1 k(r)[\phi_{1,r}^-(r, \lambda_n)]^2 r \, dr = \int_0^1 \phi_1^-(r, \lambda_n) f[\phi_1^-(r, \lambda_n)] r \, dr,$$

we can use the Lebesgue Convergence Theorem to conclude that the limit as $n \to \infty$ of the left-hand side of the above equality is zero.

The same argument used in the proof of Lemma 2.9 yields

$$\lim_{n\to\infty} \frac{1}{\lambda_n} \int_0^1 \frac{[k(r)\phi_{1,r}^-(r, \lambda_n)]^2}{r} \, dr = 0 \quad \text{and, therefore,}$$

$$\lim_{n\to\infty} \left[\int_0^{r_1(\lambda_n)} k(r) \frac{d}{dr} F(\phi_1^-(r, \lambda_n)) \, dr + \int_{r_1(\lambda_n)}^1 k(r) \frac{d}{dr} F(\phi_1^-(r, \lambda_n)) \, dr \right] = 0.$$

Following the proof of Lemma 2.9, with natural adaptations, the desired result is obtained. The case $\bar{r} = 0$ as well as $\bar{r} = 1$ can be proved in a similar way.

Toward proving that $r_1(\lambda) \to 0$, as $\lambda \to \infty$, we suppose by contradiction that there is a sequence $\{\lambda_n\}_{n\in N}$ so that $r_1(\lambda_n) \to \bar{r}$, as $n \to \infty$, with $0 < \bar{r} \leqq 1$. Hence Lemma 3.1

can be evoked to conclude that $\lim_{n\to\infty} \phi_1^-(0, \lambda_n) = b$ and, therefore,

$$k_m \lim_{n\to\infty} \int_0^{\phi_1^-(0,\lambda_n)} f = k_m \int_0^b f \leqq k_M \lim_{n\to\infty} \int_0^{\phi_1^-(1,\lambda_n)} f \leqq k_M \int_0^a f,$$

which contradicts hypothesis (h_3).

Hence $r_1(\lambda) \to 0$ as $\lambda \to \infty$.

Also, following the proof of Lemma 2.6 we can show that $\phi_1^-(r, \lambda) \to a$, in measure, for $0 \leqq r \leqq 1$, as $\lambda \to \infty$. In particular $\phi_1^-(r, \lambda) \to a$, uniformly in $[\bar{r}, 1]$, as $\lambda \to \infty$ for any $\bar{r}$ such that $0 < \bar{r} < 1$.

Now Lemma 2.1, which also holds in this case, and our hypotheses assure us that if $\lim_{n\to\infty} \phi_1^-(0, \lambda_n) = \phi_{1,\infty}^-(0)$, then

$$\int_0^\alpha f = \frac{k_m}{k_M} \int_0^a f \leqq \int_0^{\phi_{1,\infty}^-(0)} f,$$

that is, $b < \phi_{1,\infty}^-(0) \leqq \alpha < 0$.

On the other hand, Lemma 3.1 yields

$$\int_0^{\phi_{1,\infty}(0)} f \leqq \frac{k_M}{k_m} \int_0^a f = \int_0^\beta f \quad \text{and so } b < \beta \leqq \phi_{1,\infty}^- \leqq \alpha < 0.$$

Likewise $b < \beta \leqq \lim_{n\to\infty} \inf \phi_1^-(0, \lambda_n) \leqq \lim_{n\to\infty} \sup \phi_1^-(0, \lambda_n) \leqq \alpha < 0$.

Note that since by the maximum principle $b < \phi_1^-(., \lambda) < a$ in $[0, 1]$, for any $\lambda > \tilde{\lambda}_1$, it follows that for any p, $1 \leqq p \leqq \infty$, $\lim_{\lambda\to\infty} \|\phi_1^-(., \lambda) - a\|_p = 0$, where as usual $\|.\|_p$ denotes the norm of the space $L^p[0, 1]$.

In view of the above conclusions it is easy to see that given any $\varepsilon > 0$, ε: small there is $\Lambda = \Lambda(\varepsilon)$ such that $b < \beta - \varepsilon < \phi_1^-(0, \lambda) < \alpha + \varepsilon < 0$ for $\lambda \geqq \Lambda$. See Fig. 2.

Remark 3.1. As for the general case $\phi_n^+(., \lambda) \in C_n^+[\phi_n^-(., \lambda) \in C_n^-]$, it still should hold, under hypotheses (h_1), (h_2), and (h_3), that the area determined by the negative

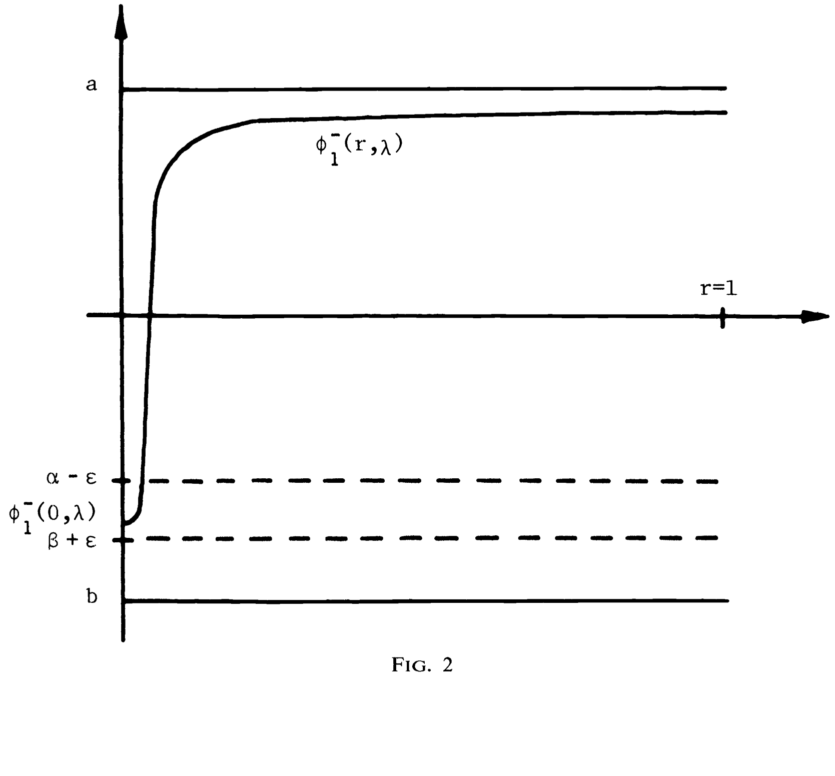

FIG. 2

bumps of $\phi_n^+(.,\lambda)[\phi_n^-(.,\lambda)]$ approaches zero as $\lambda\to\infty$. Let us point out that if $r_i(\lambda)$, $i=1,\dots,n$ stand for the zeros of $\phi_n^+(r,\lambda)$ $[\phi_n^-(r,\lambda)]$, $0<r<1$, where $0<r_1(\lambda)<\cdots< r_n(\lambda)<1$ and $\lambda>\tilde{\lambda}_n$, then there are unique $s_i(\lambda)$, $1\leqq i\leqq n-1$ such that $0<r_1(\lambda)< s_1(\lambda)<\cdots<r_{n-1}<s_{n-1}(\lambda)<r(\lambda)<1$, and

$$\frac{d}{dr}\phi_n^+(s_i)=0 \qquad \left[\frac{d}{dr}\phi_n^-(s_i)=0\right], \qquad 1\leqq i\leqq n-1.$$

Now it seems that the asymptotic behavior of $r_i(\lambda)$, $i=1,\dots,n$, for $n\geqq 2$ bears no resemblance to the case $n=1$. Actually the fact that the unique zero of $\phi_1^+(r,\lambda)$ $[\phi_1^-(r,\lambda)]$ in $(0,1)$ satisfies $r_1(\lambda)\to 1$ $[r_1(\lambda)\to 0]$ as $\lambda\to\infty$ might be a mere consequence of (h_3) forcing the area determined by negative part of $\phi_1^+(r,\lambda)$ $[\phi_1^-(r,\lambda)]$ in its graph shrink to zero as $\lambda\to\infty$ and should not be taken as a clue for determining the asymptotic behavior of $r_i(\lambda)$, $i=1,\dots,n$ for $n\geqq 2$. Instead, it seems that in the general case the focus should be shifted to the asymptotic behavior of $s_i(\lambda)$, $i=1,\dots,n-1$.

Remark 3.2. By reversing the inequality in hypothesis (h_3) it is possible to obtain the very same results of §§ 2 and 3 with the roles of the equilibria a and b switched.

Remark 3.3. Let us consider, instead of (1.1), the more general equation

$$\begin{gathered}\nabla\cdot[k(r)\nabla U(x)]+\lambda s(r)f(U(x))=0, \qquad x\in B,\\ \nabla U\cdot \hat{n}/_{\partial B}=0,\end{gathered} \tag{3.1}$$

where $r=\|x\|$ and $s(r)$ is a positive function in $C^2([0,1],R)$. The existence of two solutions, $U_1^+(r,\lambda)$ and $U_1^-(r,\lambda)$, of (3.1) having the same properties of the solutions $\phi_1^+(r,\lambda)$ and $\phi_1^-(r,\lambda)$ considered in this paper can be deduced from [1].

Set $s_m=\min_{0\leqq r\leqq 1} s(r)$, $s_M=\max_{0\leqq r\leqq 1} s(r)$, and let

$$s_m k_m\int_0^b f> s_M k_M\int_0^a f. \tag{h_3'}$$

Then under hypotheses (h_1), (h_2), and (h_3'), the techniques used in §§ 2 and 3 can be easily adapted to suit the above equation. Hence the same conclusions concerning the formation of boundary and interior spike formation can be drawn for the solutions $U_1^+(r,\lambda)$ and $U_1^-(r,\lambda)$, respectively.

SPECTRAL AND NONLINEAR EFFECTS IN CERTAIN ELLIPTIC SYSTEMS OF THREE VARIABLES*

LIGE LI† AND YAPING LIU†

Abstract. In this paper, the authors use the method of decomposing operator to prove the existence of positive solutions to certain elliptic biological interacting systems of three species in all possible patterns of interactions in terms of the combinations of competition, symbiosis, and predation under the homogeneous Robin–Dirichlet boundary conditions. The existence of positive solutions on large domains and the asymptotic stability of positive steady states for some cases are also proved. The main idea is that the existence of positive solutions and their properties can be characterized by the spectral properties of certain operators of Schrödinger type and by the equilibria of the system.

Key words. positive solutions, reaction-diffusion equations, steady states, principal eigenvalues of linear operators, equilibrium, spectral radius, bifurcation, stability

1. Introduction.

In this paper we are concerned with the problem of positive solutions to nonlinear elliptic systems with three unknown functions. To better demonstrate the methods and the underlying ideas, we shall first investigate the following system:

$$(1)\qquad \begin{aligned} -\Delta u &= uf(u,v,w), \\ -\Delta v &= vg(u,v) && \text{in } \Omega, \\ -\Delta w &= wh(u,w), \\ B_1u = B_2v &= B_3w = 0 && \text{on } \partial\Omega, \end{aligned}$$

where Ω is a bounded domain in $\mathbf{R}^n$ with smooth boundary $\partial\Omega$ and $B_iu = a_i(x)u + b_i(x)\partial u/\partial\mathbf{n}$ are the Robin–Dirichlet boundary conditions with $a_i, b_i \in C(\mathbf{R}^n)$, $0 \not\equiv a_i(x) \geq 0, b_i(x) \geq 0$, and $a_i(x) + b_i(x) > 0$ on $\partial\Omega$ for $i = 1, 2, 3$. Moreover, f, g, h are C^1 monotone functions. This is the steady state of the reaction-diffusion system with initial data $\tilde{u}$, $\tilde{v}$, $\tilde{w}$:

$$(2)\qquad \begin{aligned} u_t - \Delta u &= uf(u,v,w), \\ v_t - \Delta v &= vg(u,v) && \text{in } (0,T)\times\Omega, \\ w_t - \Delta w &= wh(u,w), \\ B_1u = B_2v &= B_3w = 0 && \text{on } [0,T)\times\partial\Omega, \\ u(0,x) &= \tilde{u}(x), \\ v(0,x) &= \tilde{v}(x) && \text{in } \Omega, \\ w(0,x) &= \tilde{w}(x). \end{aligned}$$

Here u, v, w may represent the densities of interacting populations in problems arising from ecology, microbiology, immunology, etc. The functions f, g, h serve as the relative growth rates of these populations. We say that two species are in cooperation if each of their relative growth functions is increasing in the other; and that they are in competition if these functions are decreasing in the other opposer. In case of predation, one of the functions involved will be increasing in the prey while the other decreasing in the predator. For example, if w is a predator with u as its prey, then $f_w < 0$ and $h_u > 0$. See [40, Chap. 14] for details.

† Department of Mathematics, Kansas State University, Manhattan, Kansas 66506.

In §4, we shall extend the results on system (1) to the following more general elliptic system:

$$\begin{aligned} -\Delta u &= uf(u,v,w), \\ -\Delta v &= vg(u,v,w) &&\text{in } \Omega, \\ -\Delta w &= wh(u,w), \\ B_1 u = B_2 v &= B_3 w = 0 &&\text{on } \partial\Omega. \end{aligned} \tag{3}$$

The problem of positive solutions for single and two interacting species with diffusion can be traced back to the late 70s and early 80s. The pioneering investigations along this avenue include [2], [5], [9], [10], [11], [15], [16], [23], [24], [34], [36], [38], [39], [40], and many others. Since then a considerable amount of interest and intensive studies have been devoted to the systems of two interacting species, which may be termed as 2 × 2 systems in short. See [3], [4], [6], [7], [12], [14], [20], [21], [26], [29], [30], [35], [41], etc. In [16], [26], [37], [42] a good account of biological background was provided.

An important early discovery on the problem of positive coexistence of 2 × 2 systems is the following: the instability of the marginal densities, i.e., the individual species with the other species absent, implies the positive coexistence of both species provided that the interacting species are a priori bounded. See, for example, [2], [4], [9], [34], [37] for various predation and competition models. Later it was found that the stable marginal densities can also yield positive coexistence in competing interactions. See, for instance, [14], [30]. These two facts together tell us that it is the signs of the principal eigenvalues of the linearization of the PDE system at the related marginal densities that determine the positive coexistence when considering predation and competition. This includes the above instability principle. In case of symbiosis, the positive equilibria play an essential role. More specifically, for a system of two cooperative species, if the positive marginal densities exist and the system has a positive equilibrium, then it has a positive solution [21], [29]. We thus conclude that the positive coexistence for a 2 × 2 interacting system is determined by the spectral properties and the distribution of the equilibria of this system.

The problems arising from experimental and natural sciences, engineering, and technology often involve more than two components and challenge us to deal with 3 × 3 interacting systems. Recent research in neurobiochemistry has shown that the mechanism of the process of pain inducing and suppressing of human beings is closely related to the interactions between certain biochemical substances distributing along the neuropath nets. For example, it is known that two neurotransmitters, acetylcholine and triethylcholine, compete for chemical receptors. The first one can induce the pain while the second one serves as a suppressor. These two are both predated through deprivation of receptors by a third neuropeptide of a choline with a double group of

$$N^+\!\begin{matrix} /CH_3 \\ \backslash CH_3 \end{matrix}$$

in its structural formula (see [43]). The positive coexistence of such three species will affect the physiological feeling in an individual in response to a pain stimulation in terms of sensitivity and of tolerance. This problem can be modeled by system (1) or (3) with a suitable choice of the terms f, g, h.

As we have pointed out, the problem of the existence of positive solutions to 2 × 2 reaction-diffusion systems has been well investigated. However, the problem of three variables is far from being solved. To our knowledge, only some particular cases have been studied. A two predator, one prey model in a particular form of system (1) was considered in [42]. In [45], a special case of system (3) in a predator-prey-mutualist model was discussed. In [25] certain properties of positive solutions for a model of three species prey-predator system were investigated using the monotone scheme of upper-lower solutions. A general formulation of the mathematical problem of reaction-diffusion systems can be found in [16], [40]. In [31] the following system was studied:

$$\begin{aligned}\frac{\partial u_1}{\partial t} &= d_1\Delta u_1 + \alpha_1 u_1\left(1-\frac{u_1}{K_1}\right) - \frac{\alpha_1 u_1 u_2}{1+\beta u_3},\\ \frac{\partial u_2}{\partial t} &= d_2\Delta u_2 + \alpha_2 u_2\left(1-\frac{u_2}{K_2}\right) - \gamma u_1 u_2,\\ \frac{\partial u_3}{\partial t} &= d_3\Delta u_3 + \alpha_3 u_3\left(1-\frac{u_3}{1+u_1}\right).\end{aligned} \tag{4}$$

Here $d_i, \alpha_i, K_i, \beta, \gamma$ are positive constants. This is a model of two competitors with one cooperator. In [31] the authors applied the technique of upper-lower solutions to give certain conditions for the existence of positive solutions to system (4) and to its steady state under the homogeneous Dirichlet and Neumann boundary condition. In [22] the following system (one predator u, two preys v, w) was investigated:

$$\begin{aligned}-\Delta u &= u(a-u-cv-dw),\\ -\Delta v &= v(e+fu-v+gw) \qquad \text{in } \Omega,\\ -\Delta w &= w(\alpha-\beta u-\gamma v-w),\\ u &= v = w = 0 \qquad \text{on } \partial\Omega.\end{aligned} \tag{5}$$

Taking a or e as a bifurcation parameter, the author applied the fixed point index theory on positive cones to give a set of conditions under which the system (5) has positive solutions. In [17] the theory of fixed point index was also applied to a 3×3 predator-prey chain model.

The goal of this paper is to investigate the existence of positive solutions to 3×3 elliptic systems. As we mentioned in the foregoing paragraph about the 2×2 systems, the spectral properties of the linearization at marginal densities determine the positive coexistence in case of predations and competitions while it is dominated by the equilibria of the system in symbiotic interactions. We shall prove in this paper that the above principle for 2×2 systems carries over to 3×3 systems. More precisely, it may be formulated as follows. If the system is purely of symbiosis, then we have the positive coexistence provided that the system has a positive equilibrium (C_1, C_2, C_3), i.e., $f(C_1, C_2, C_3) = g(C_1, C_2) = h(C_1, C_3) = 0$ in the case of system (1) and $f(C_1, C_2, C_3) = g(C_1, C_2, C_3) = h(C_1, C_3) = 0$ in system (3). If the system involves only predation or competition or both, then the positive coexistence is characterized by the signs of the principal eigenvalues of certain differential operators that are determined by the marginal densities. That is, the spectral property of the system plays the primary role. If the system involves symbiosis together with predation and (or) competition, then the conditions for positive coexistence of three species will be a cocktail of the property of the equilibria and the spectral property of the system in question.

The results we are going to present in the following cover all possible interactions involving three species defined by the system (1) and (3), which include some of the earlier results as special cases. Moreover, the functions f, g, h are not specifically given and could be nonlinear. In this sense this paper gives a somewhat more general and systematic treatment of the problem on positive coexistence to certain general 3×3 elliptic systems. The methods employed in this paper are different from those used in the above mentioned papers. Our major approach is based on the method of decomposing operator, which is motivated by the idea used in [3]. In §2 we first improve this method by showing that the decomposing operators are C^1 mappings and their derivatives are either positive or negative operators. Then we combine this with the fixed point theory in order intervals due to [1] and with the bifurcation analysis to develop the techniques for the proofs.

Part of the results in §3 under the special case of Dirichlet boundary condition were presented in the AMC(1990) meeting and its proceeding.

2. Preliminaries. In this section we give several lemmas that are important in the sequel. In what follows, $\lambda_1(L)$ will denote the first eigenvalue of a suitable linear operator L and $r(L)$ the spectral radius of L. First we define the class $\mathcal{F} \subset C(\overline{\Omega} \times \mathbf{R})$ by the following.

DEFINITION 1. $p \in \mathcal{F}$ if and only if $p \in C(\overline{\Omega} \times \mathbf{R})$, p is C^1 in second component, $-L < p_u(x,u) < 0$ in $\Omega \times \mathbf{R}$ for some $L > 0$, and

$$\overline{\lim_{u \to +\infty}} p(x,u) < \lambda_1 \text{ uniformly for } x \in \Omega. \tag{6}$$

Here $\lambda_1 = \lambda_1(-\Delta)$ is the first eigenvalue of the equation

$$\begin{aligned} -\Delta u &= \lambda u \quad \text{in } \Omega, \\ Bu &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{7}$$

where $Bu = a(x)u + b(x)\partial u/\partial \mathbf{n}$ is the Robin boundary operator with $a, b \in C(\mathbf{R}^n), 0 \not\equiv a(x) \geq 0, b(x) \geq 0$, and $a(x) + b(x) > 0$ on $\partial\Omega$. The above inequality (6) will be satisfied if $p(x,C) < \lambda_1$ in Ω for some constant $C > 0$.

LEMMA 1. *Let $c(x) \in L^\infty(\Omega)$ and P be a positive constant such that $P + c(x) > 0$ for almost every $x \in \Omega$. Then*

(1) $\lambda_1(\Delta + c) > 0 \Leftrightarrow r[(-\Delta + P)^{-1}(P + c)] > 1$;
(2) $\lambda_1(\Delta + c) < 0 \Leftrightarrow r[(-\Delta + P)^{-1}(P + c)] < 1$;
(3) $\lambda_1(\Delta + c) = 0 \Leftrightarrow r[(-\Delta + P)^{-1}(P + c)] = 1$.

Proof. See Lemma 2 [29]. □

Let $\boldsymbol{K} = C(\overline{\Omega})^+$ be the positive cone of the ordered Banach space $C(\overline{\Omega})$. For $u_1, u_2 \in C(\overline{\Omega})$, define the order interval $[[u_1, u_2]] := \{u \in C(\overline{\Omega}) : u_1 \leq u \leq u_2 \text{ in } \Omega\}$. Let e be the unique solution of

$$\begin{aligned} -\Delta e &= 1 \quad \text{in } \Omega, \\ Be &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{8}$$

Then define the ordered Banach space $C_e(\overline{\Omega})$ by $C_e(\overline{\Omega}) = \bigcup_{\lambda \in \mathbf{R}^+} \lambda[[-e, e]] = \bigcup_{\lambda \in \mathbf{R}^+} [[-\lambda e, \lambda e]]$ with norm $\|u\|_e = \inf\{\lambda > 0 : -\lambda e \leq u \leq \lambda e\}$, the Minkowski functional. Let $\boldsymbol{K}_e := C_e(\overline{\Omega})^+$. (See [1] for details.)

LEMMA 2. *Let $p \in \mathcal{F}$. Consider*

$$\begin{aligned} -\Delta u &= up(x,u) \quad \textit{in } \Omega, \\ Bu &= 0 \quad \textit{on } \partial\Omega. \end{aligned} \tag{9}$$

(i) *If $\lambda_1(\Delta + p(x,0)) > 0$, then* (9) *has a unique positive solution.*

(ii) *If $\lambda_1(\Delta + p(x,0)) \le 0$, then $u \equiv 0$ is the only nonnegative solution of* (9).

Proof. (i) Let $\lambda_1(\Delta + p(x,0)) > 0$. Define operator $A : C(\overline{\Omega}) \to C(\overline{\Omega})$ by $Au = (-\Delta+P)^{-1}(up(x,u)+Pu)$, where $(-\Delta+P)^{-1}$ is under the boundary condition $Bu = 0$. $P > 0$ is to be chosen. Since $A'(0) = (-\Delta + P)^{-1}[p(x,0) + P]$ and $\lambda_1(\Delta+p(x,0)) > 0$, we have $r(A'(0)) > 1$ by Lemma 1. $A'(0)$ is strongly positive from $C(\overline{\Omega})$ to $C_e(\overline{\Omega})$ for $P > \max_{x\in\overline{\Omega}}\{-p(x,0)\}$. (See Theorem 4.2 in [1].) By Theorem 4.3 and Lemma 7.5 of [1], there exist $\epsilon \in (0,1]$ and $\underline{u} > 0$ such that $A(\tau\underline{u}) > \tau\underline{u}$ for all $\tau \in (0,\epsilon)$.

Let $\tilde{b}(x) = b(x)+\delta$ with $\delta > 0$, and let $\tilde{\lambda}_1 = \tilde{\lambda}_1(-\Delta)$ be the first eigenvalue under the boundary condition $\tilde{B}u = 0$, where $\tilde{B}u = au+\tilde{b}\partial u/\partial\mathbf{n}$. By the continuous dependence of eigenvalues on the boundary conditions (see, [13, Chap. 6] or use directly the variational formula for the principal eigenvalue), we chose δ small enough such that

$$\overline{\lim_{u\to+\infty}} p(x,u) < \tilde{\lambda}_1 \text{ uniformly for } x \in \Omega.$$

Let u be a positive eigenfunction corresponding to $\tilde{\lambda}_1$. Claim: $u > 0$ on $\overline{\Omega}$. $u > 0$ in Ω by the maximum principle. If $x_0 \in \partial\Omega$ is such that $u(x_0) = 0$, then u attains its nonpositive minimum at x_0. By the Hopf lemma (see [40, Chap. 8]), $\partial u/\partial\mathbf{n} < 0$ at x_0. On the other hand, $\partial u/\partial\mathbf{n} = -(a/\tilde{b})u = 0$ at x_0, a contradiction. Thus the claim is true and we can choose $\tilde{u} = uK$ with K large enough such that $\tilde{u} > \underline{u}$ and $p(x,\tilde{u}) < \tilde{\lambda}_1$ for all $x \in \Omega$. Therefore, $-\Delta\tilde{u} = \tilde{\lambda}_1\tilde{u} > \tilde{u}p(x,\tilde{u})$. Then $(-\Delta + P)\tilde{u} > \tilde{u}p(x,\tilde{u}) + P\tilde{u}$. We also have $B\tilde{u} \ge \tilde{B}\tilde{u} = 0$ on $\partial\Omega$ since $\tilde{b} > b \ge 0$ and $\partial\tilde{u}/\partial\mathbf{n} = -(a/\tilde{b})\tilde{u} \le 0$. Thus $\tilde{u} > (-\Delta + P)^{-1}[\tilde{u}p(x,\tilde{u}) + P\tilde{u}] = A\tilde{u}$ by the maximum principle. Let $C_0 = \max_{x\in\overline{\Omega}}\tilde{u}(x)$ and $P > 2\max\{\sup_{(x,u)\in\overline{\Omega}\times[0,C_0]}|p(x,u)|, C_0L\}$. Then A is an increasing, compact operator on the order interval $[[\tau\underline{u},\tilde{u}]]$ for a fixed $\tau \in (0,\epsilon)$. By Corollary 6.2 in [1] , A has a maximum fixed point $\overline{u} \in [[\tau\underline{u},\tilde{u}]]$. $\overline{u}$ is thus a strictly positive solution.

For the proof of the uniqueness see, for example, [17], [25].

(ii) Suppose u is a positive solution of (9). Then $(\Delta + p(x,u))u = 0$, and hence $\lambda_1(\Delta + p(x,u)) = 0$. Since $p(x,0) > p(x,u)$ in Ω, we have $\lambda_1(\Delta + p(x,0)) > \lambda_1(\Delta + p(x,u)) = 0$, a contradiction. □

Note 1. The above lemma generalizes Lemma 3 in [29] and the related result in [26] since we do not assume here the existence of a constant $C_0 > 0$ such that $p(x,C_0) \le 0$, for all $x \in \Omega$, and the boundary condition is also more general. When the applications to biology and chemical reaction are concerned, the assumption that $p(x,C_0) \le 0$ for some $C_0 > 0$ rules out many particularly important and useful models with mild change rates in the growth functions. $p(x,u) = cg(x)/(1+g(x)u)$ with $c > 0$ and $g(x) > 0$ is such an example.

In view of Lemma 2, for all $p \in \mathcal{F}$, let u_p be the unique positive solution of (9) if $\lambda_1(\Delta + p(x,0)) > 0$ and $u_p \equiv 0$ otherwise. The following result is motivated by the method in [3] §3 for a 2 × 2 predator-prey model.

LEMMA 3. *If the constant L in the definition of the class $\mathcal{F}$ is independent of functions p, then*

(i) *The mapping $p \mapsto u_p$ is continuous in sense of $\mathcal{F} \to C^{1,\alpha}(\Omega \times \mathbf{R})$ where $\alpha \in (0,1)$;*

(ii) *If $p_1 \ge p_2 \not\equiv p_1$, then either $u_{p_1} > u_{p_2}$ or $u_{p_1} \equiv u_{p_2} \equiv 0$.*

Proof. See Lemma 4 in [29] where it was proved for the Dirichlet boundary condition. But the arguments work also for the Robin boundary condition. See also [17]. □

LEMMA 4. *Let $c \in L^\infty(\Omega)$. If $\lambda_1(\Delta + c(x)) < 0$, where Δ is taken under the boundary condition $Bu = 0$ on $\partial\Omega$, then $(\Delta + c(x))^{-1}$ is a negative operator on $C(\overline{\Omega})$, i.e., it maps the positive cone $\boldsymbol{K}$ into $-\boldsymbol{K}$. More precisely, if $0 \not\equiv (\Delta + c(x))\phi \geq 0$, then $\phi < 0$.*

Proof. See Lemma 2.2 in [30], where it was proved for the Dirichlet boundary condition. But the method applys also to the Robin boundary condition as well because the maximum principle still applies. □

The following is a well-known result on a general version of the Hopf lemma.

LEMMA 5. *Assume $c(x) \in L^\infty(\Omega)$. Let $0 \not\equiv u \geq 0$ and $\Delta u + c(x)u \leq 0$ in Ω. If $u(x_0) = 0$ for a point $x_0 \in \partial\Omega$, then $\partial u(x_0)/\partial\mathbf{n} < 0$.*

Note 2. In this lemma no restriction on the sign of the function $c(x)$ is imposed due to the assumption $u \geq 0$. For a proof see [18, §1].

We impose the following hypotheses on the functions f, g, h:

(H1) $f \in C^1(\mathbf{R} \times \mathbf{R} \times \mathbf{R})$, $g, h \in C^1(\mathbf{R} \times \mathbf{R})$. $f(\cdot, v, w), g(u, \cdot), h(u, \cdot) \in \mathcal{F}$ for any fixed $u, v, w \in C(\overline{\Omega})^+$. $f_v, f_w, g_u, h_u \neq 0$ and all partial derivatives are uniformly bounded on $\mathbf{R} \times \mathbf{R} \times \mathbf{R}$ and on $\mathbf{R} \times \mathbf{R}$, respectively.

(H2) $\min\{f(0,0,0), g(0,0), h(0,0)\} > \lambda_1(-\Delta)$.

The hypothesis (**H1**) implies that the species u, v, w can survive by themselves in the absence of the other species, i.e., the equations

$$-\Delta u = uf(u,0,0) \quad \text{in } \Omega, B_1 u = 0 \quad \text{on } \partial\Omega,$$

$$-\Delta v = vg(0,v) \quad \text{in } \Omega, B_2 v = 0 \quad \text{on } \partial\Omega,$$

$$-\Delta w = wh(0,w) \quad \text{in } \Omega, B_3 w = 0 \quad \text{on } \partial\Omega,$$

have positive solutions u_0, v_0, w_0, respectively. This follows immediately from Lemma 2 since $\lambda_1(\Delta + f(0,0,0)) > 0$, $\lambda_1(\Delta + g(0,0)) > 0$, $\lambda_1(\Delta + h(0,0)) > 0$.

The functions u_0, v_0, w_0 will always denote the unique positive solutions of the above equations, respectively, in the sequel.

By hypothesis (**H1**), f_v, f_w, g_u, h_u do not change signs. So the pattern of interaction between each pair of two species is either predation, or symbiosis, or competition. We will use the following notation:

$$u \longrightarrow v \quad \text{if } u \text{ preys on } v,$$

$$u -\!\!\circ\!\!- v \quad \text{if } u, v \text{ cooperate},$$

$$u \longleftrightarrow v \quad \text{if } u, v \text{ compete}.$$

For example, $v \longleftarrow u \longrightarrow w$ represents a one predator(u) two prey(v, w) model, whereas $v -\!\!\circ\!\!- u \longleftrightarrow w$ means that u, v cooperate and u, w compete.

According to Lemma 2 we define the operators $S, T : C(\overline{\Omega}) \to C(\overline{\Omega})$ as follows. For $u \in C(\overline{\Omega})$, Su is the unique positive solution of the equation

$$\begin{aligned} -\Delta v &= vg(u,v) && \text{in } \Omega, \\ B_2 v &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{10}$$

if $\lambda_1(\Delta + g(u,0)) > 0$ and $Su \equiv 0$ otherwise. Tu is determined similarly from the equation

$$
\begin{aligned}
-\Delta w &= wh(u,w) && \text{in } \Omega,\\
B_3 w &= 0 && \text{on } \partial\Omega.
\end{aligned}
\tag{11}
$$

Let $U_1 = \{u \in C(\overline{\Omega}) : Su > 0\}$, $U_2 = \{u \in C(\overline{\Omega}) : Tu > 0\}$. By Lemma 3, it is easy to see that the operators S and T are continuous operators and that if u, v cooperate or u is a prey of v, then S is a strictly increasing operator in the sense that $u_1 \not\equiv u_2 \geq u_1$ and $u_2 \in U_1$ implies $Su_2 > Su_1$, and that if u, v compete or u preys on v, then S is a strictly decreasing operator in the sense that $u_1 \not\equiv u_2 \geq u_1$ and $u_1 \in U_1$ implies $Su_2 < Su_1$. A similar conclusion is true for T with respect to U_2. Moreover, we have the following.

LEMMA 6. *The operators S, T defined above are C^1 mappings on U_1 and U_2, respectively. Moreover, the Fréchet derivative S' (or T') is either a positive operator or a negative operator.*

Proof. Define $F : C(\overline{\Omega}) \oplus C(\overline{\Omega}) \to C(\overline{\Omega})$ by $F(u,v) := -v + (-\Delta)^{-1}[vg(u,v)]$, where $(-\Delta)^{-1}$ is taken under the boundary condition $B_2 v = 0$. Let D_2 represent the derivative with respect to the second component. Then it can be verified that $D_2 F(u,v) = -I + (-\Delta)^{-1}[vg(u,v)]_v = -I + (-\Delta)^{-1}[g(u,v) + vg_v(u,v)]$, i.e., $D_2F(u,v)\phi = -\phi + (-\Delta)^{-1}[g(u,v)\phi + vg_v(u,v)\phi]$ for $\phi \in C(\overline{\Omega})$. Let $u^0 \in U_1$. We claim that $(D_2F)^{-1}$ exists and is bounded at (u^0, Su^0). It is equivalent to showing that 1 is not an eigenvalue of the operator $(-\Delta)^{-1}[vg(u^0,v)]_v$ at $v^0 = Su^0$. Suppose that there exists a $\phi \in C(\overline{\Omega})$, $\phi \neq 0$ such that $(-\Delta)^{-1}[v^0 g(u^0,v^0)]_v \phi = \phi$. Then $(\Delta + [v^0 g(u^0,v^0)]_v)\phi = 0 = 0 \cdot \phi$. This implies $0 \in \sigma(\Delta + [v^0 g(u^0,v^0)]_v)$. On the other hand, $-\Delta v^0 = v^0 g(u^0,v^0)$ implies $\lambda_1(\Delta + g(u^0,v^0)) = 0$. Since $g_v < 0$, it follows that $\lambda_1(\Delta + [v^0 g(u^0,v^0)]_v) < \lambda_1(\Delta + g(u^0,v^0)) = 0$. Thus $0 \notin \sigma(\Delta + [v^0 g(u^0,v^0)]_v)$. This contradiction shows that $D_2 F$ is nonsingular at (u^0, Su^0). Applying the implicit function theorem in Banach spaces (see Chapter 8 in [33]) to $F(u,v) = 0$, we see that there is a unique C^1 curve $v = \eta(u)$ in a neighborhood V of u^0 with $\eta(u^0) = Su^0$ and $F(u, \eta(u)) \equiv 0$. Note that $F(u,v) = 0$ if and only if v is a solution of the equation

$$
\begin{aligned}
-\Delta v &= vg(u,v) && \text{in } \Omega,\\
B_2 v &= 0 && \text{on } \partial\Omega.
\end{aligned}
\tag{12}
$$

Therefore, $Su = \eta(u)$ and S is a C^1 mapping from U_1 to $\boldsymbol{K}$. We, therefore, denote by $S'(u)$ the Fréchet derivative of S at u. Since $F(u,v) = -v + (-\Delta)^{-1}[vg(u,v)]$, we have $F_v = -I + (-\Delta)^{-1}(vg)_v$, $F_u = (-\Delta)^{-1} vg_u$. From $F(u, Su) = 0$ we conclude that $F_u + F_v S'(u) = 0$ by the chain rule. (See Chapter 6 in [33].) Therefore, $S'(u) = -F_v^{-1} F_u = -[-I + (-\Delta)^{-1}(vg)_v]^{-1}(-\Delta)^{-1} vg_u = -(\Delta + g + vg_v)^{-1} vg_u$, i.e., $S'(u) = -(\Delta + g + vg_v)^{-1}(vg_u)I$. Notice that $\lambda_1(\Delta + g) = 0$ because $(\Delta + g(u,v))v = 0$ for $v = Su > 0$. Therefore, $\lambda_1(\Delta + g + vg_v) < 0$ due to $g_v < 0$, and consequently $(\Delta + g + vg_v)^{-1}$ is a negative operator by Lemma 4. Since $v > 0$ and g_u has a definite sign, we conclude that $S'(u)$ is either a positive or a negative operator. The same conclusion can be drawn from the operator T. □

Note 3. If the functions g and h are C^2 functions, then the operators S and T are C^2 mappings [33].

With the operators S and T discussed above, we define and denote the operator $A : C(\overline{\Omega}) \to C(\overline{\Omega})$ by $Au = (-\Delta + P)^{-1}[uf(u, Su, Tu) + Pu]$, where $P > 0$ is a constant. Let $A_\theta = \theta A$ for $0 < \theta \leq 1$. Clearly, $\overline{u}$ is a fixed point of A in $\boldsymbol{K}$ if and only

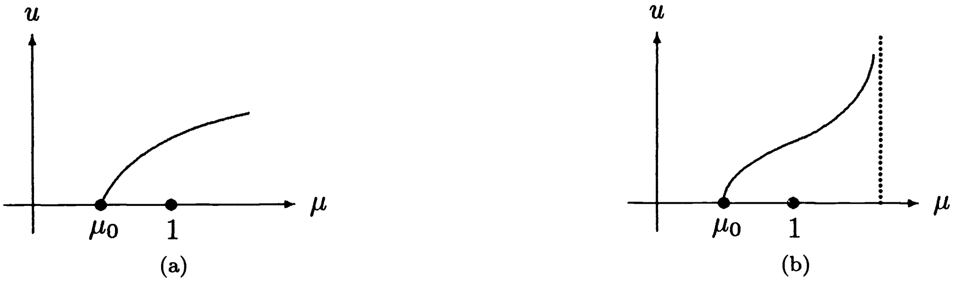

FIG. 1.

if $(\overline{u}, S\overline{u}, T\overline{u})$ is a nonnegative solution of (1). We are looking for the positive fixed point $\overline{u}$ of A with $S\overline{u} > 0$, $T\overline{u} > 0$.

LEMMA 7. *For a given $C > 0$, the operator A defined above is a positive, compact operator on $[[0, C]]$ for large P. If no predation is involved in system* (1), *then A is also increasing on $[[0, C]]$ for large P.*

Proof. Since $Au = (-\Delta + P)^{-1}[uf(u, Su, Tu) + Pu]$ and S, T are continuous, we see that A is compact. If $P > \sup_{u \in [[0,C]]} |f(u, Su, Tu)|$, then A is positive on $[[0, C]]$. Finally, if no predation is involved in system (1), then by Lemma 3 $f(u, Su, Tu)$ is increasing in u in the second and third components. Choose $P > \max_{u \in [[0,C]]} |D_1 f(u, Su, Tu)|$, where D_1 denotes the derivative with respect to the first component. Then A is an increasing operator on $[[0, C]]$. □

Let $\boldsymbol{X}$ be a Banach space, K be a compact linear strongly positive operator on $\boldsymbol{X}$ and F be a strictly positive continuous nonlinear operator on $\boldsymbol{X}$ with $F(0) = 0$. Consider the eigenvalue problem $u = \mu H u$ with $H = KF$, $(\mu, u) \in \mathbf{R} \times \boldsymbol{X}$. We have the following.

LEMMA 8. *Assume $H'(0)$ exists with $r(H'(0)) > 1$. If there exists no $\mu \in (0, 1]$ such that in its neighborhood the equation $u = \mu H u$ has solution u with $\|u\| \to \infty$, then H has a positive fixed point in $\boldsymbol{K}$.*

Proof. This is a simple consequence of the so-called nonlinear Krein–Rutman theorem (see, for example, Theorem 7.H in [44]), which says that for a strongly positive compact operator H, the $1/r(H'(0))$ is the only bifurcation point of μ for positive solutions $(\mu, u) > (0, 0)$, and that the bifurcation branch is unbounded. Note that for $\mu \leq 0$, the equation $u = \mu H u$ has no positive solution and the possibility of a bifurcation from ∞ in $(0, 1]$ is ruled out by our assumption. Therefore, the bifurcation diagram must be one of the cases in Fig. 1(a) and 1(b). Note that $\mu_0 = r(H'(0))^{-1} < 1$. The equation $u = \mu H u$ thus has a positive solution for each $\mu \in (\mu_0, 1]$. Let $\mu = 1$ to conclude the lemma. □

LEMMA 9. *The positive fixed points of A_θ have an a priori bound for $\theta \in (0, 1]$ if no symbiosis relation is involved in system* (1).

Proof. Let $A_\theta(u_\theta) = u_\theta$, $\theta \in (0, 1]$, $u_\theta \in \boldsymbol{K}$. Then

$$-\Delta u_\theta = \theta u_\theta f(u_\theta, Su_\theta, Tu_\theta) + P(\theta - 1) u_\theta. \tag{13}$$

Consider the following cases.

(1) Both v and w are predated by u. Then $f(u, Su, Tu) \leq f(u, C_2, C_3)$, where $C_2 = \max_{x \in \overline{\Omega}} v_0(x)$, $C_3 = \max_{x \in \overline{\Omega}} w_0(x)$. Also $f(0, C_2, C_3) \geq f(0, 0, 0) > \lambda_1(-\Delta)$.

(2) v is a prey for u while w is not. Then $f(u, Su, Tu) \leq f(u, C_2, 0)$ and $f(0, C_2, 0) \geq f(0, 0, 0) > \lambda_1(-\Delta)$.

(3) w is a prey for u while v is not. Then $f(u,Su,Tu) \le f(u,0,C_3)$ and $f(0,0,C_3) \ge f(0,0,0) > \lambda_1(-\Delta)$.

(4) Neither v nor w is a prey of u. Then $f(u,Su,Tu) \le f(u,0,0)$.

In any case, there exist $\overline{C}_2, \overline{C}_3 \ge 0$, independent of θ such that $f(u,Su,Tu) \le f(u,\overline{C}_2,\overline{C}_3)$ for any $u \in \boldsymbol{K}$ and $f(0,\overline{C}_2,\overline{C}_3) > \lambda_1(-\Delta)$. It thus follows from (13) that $-\Delta u_\theta \le \theta u_\theta f(u_\theta,\overline{C}_2,\overline{C}_3)$.

In case that $f(u,\overline{C}_2,\overline{C}_3) < 0$ as $u \ge C$ for some constant $C > 0$, the general maximum principle implies immediately that $u_\theta \le C$.

In case that $f(u,\overline{C}_2,\overline{C}_3) \ge 0$ for all $u \ge 0$, we find that u_θ is a lower solution of

$$(14)\qquad \begin{aligned} -\Delta u &= uf(u,\overline{C}_2,\overline{C}_3) && \text{in } \Omega,\\ B_1 u &= 0 && \text{on } \partial\Omega, \end{aligned}$$

because $0 < \theta \le 1$, $f \ge 0$, $u_\theta > 0$. Since we have already shown $f(0,\overline{C}_2,\overline{C}_3) > \lambda_1(-\Delta)$ and $\overline{\lim}_{u\to+\infty} f(u,\overline{C}_2,\overline{C}_3) < \lambda_1(-\Delta)$ by hypothesis (**H1**), as in the proof of Lemma 2, (14) has a unique positive solution $\overline{u}$, which is larger than or equal to any lower solution to (14). Thus $\overline{u} \ge u_\theta$. Note that $\overline{u}$ does not depend on θ. Therefore, $K = \max_{x\in\Omega} \overline{u}(x)$ is the a priori bound we need. □

PROPOSITION 1. *Assume that no symbiotic interaction is involved in system* (1). *Then A has a positive fixed point if $\lambda_1(\Delta + f(0,v_0,w_0)) > 0$.*

Proof. A is strongly positive from $C(\overline{\Omega})$ to $C_e(\overline{\Omega})$. (See Theorem 4.2 in [1] or Proposition 7.51 in [44]). $A'(0) = (-\Delta + P)^{-1}[f(0,v_0,w_0) + P]$ and $\lambda_1(\Delta + f(0,v_0,w_0)) > 0$ imply $r(A'(0)) > 1$. We apply Lemmas 9 and 8 to conclude this proposition. □

3. Results.

3.1. The existence theorem. In this section we give the conditions for the existence of positive solutions to the system (1) in all possible ten cases of interactions in three species in terms of the combinations of competition, symbiosis, and predation.

For $u_i, v_i, w_i \in C(\overline{\Omega})$ or $= +\infty, i = 1,2$, let $\ll (u_1,v_1,w_1),(u_2,v_2,w_2) \gg := \{(u,v,w) \in C(\overline{\Omega}) \oplus C(\overline{\Omega}) \oplus C(\overline{\Omega}) : (u_1,v_1,w_1) < (u,v,w) < (u_2,v_2,w_2) \text{ in } \Omega\}$.

Let u_0, v_0, w_0 denote, respectively, the unique positive density of species u, v, w while the other two species are absent. (See the paragraph following the statement of hypotheses (**H1**), (**H2**) in §2.)

THEOREM 1. *Let f,g,h satisfy* (**H1**) *and* (**H2**). *Then the following are true.*

Case 1. $v \longrightarrow u \longleftarrow w$. *System* (1) *has a positive solution if and only if* $\lambda_1(\Delta + f(0,v_0,w_0)) > 0$.

Case 2. $v -\!\!\circ\!\!- u -\!\!\circ\!\!- w$. *If system* (1) *has a positive equilibrium* (C_1,C_2,C_3), *then it has a positive solution in* $\ll (u_0,v_0,w_0),(C_1,C_2,C_3) \gg$.

Case 3. $v \longleftrightarrow u \longleftrightarrow w$. *Assume* $\lambda_1(\Delta + f(0,v_0,w_0)) > 0$, $\lambda_1(\Delta + g(u_0,0)) > 0$, $\lambda_1(\Delta + h(u_0,0)) > 0$; *then system* (1) *has a positive solution in*$\ll (0,0,0),(u_0,v_0,w_0) \gg$.

Note 4. *If one of* $\lambda_1(\Delta + g(u_0,0))$ *and* $\lambda_1(\Delta + h(u_0,0))$ *is* 0, *the conclusion is still true.*

Case 4. $v -\!\!\circ\!\!- u \longleftarrow w$. *Assume that* $\lambda_1(\Delta + f(0,v_0,w_0)) > 0$ *and the subsystem*

$$(15)\qquad \begin{aligned} -\Delta u &= uf(u,v,0),\\ -\Delta v &= vg(u,v), \end{aligned}$$

has a positive equilibrium (C_1,C_2), *i.e.*, $f(C_1,C_2,0) = 0, g(C_1,C_2) = 0$. *Then system* (1) *has a positive solution in* $\ll (0,v_0,w_0),(C_1,C_2,+\infty) \gg$.

Case 5. $v \longleftrightarrow u \longleftarrow w$. *Assume* $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$, $\lambda_1(\Delta + g(u_0, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (0, 0, w_0), (u_0, v_0, +\infty) \gg$.

Case 6. $v \mathrel{-\!\!\circ\!\!-} u \longleftrightarrow w$. *Assume that the subsystem*

$$\begin{aligned} -\Delta u &= uf(u, v, 0) \\ -\Delta v &= vg(u, v) \end{aligned} \tag{16}$$

has a positive equilibrium (C_1, C_2) *and that* $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$, $\lambda_1(\Delta + h(C_1, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (0, v_0, 0), (C_1, C_2, w_0) \gg$.

Note 5. *The above conclusion generalizes the existence result of Theorem* 2.7 *in* [31, §2], *where the condition* $\alpha_1(1 - K_2) > \lambda_0 d_1$ *implies* $\lambda_1(\Delta + f(0, 0, w_0)) > 0$ *in our term and* $\alpha_2 - \gamma K_1 > \lambda_0 d_2$ *implies* $\lambda_1(\Delta + h(C_1, 0)) > 0$.

Case 7. $v \longleftarrow u \longrightarrow w$. *Let* u_1 *be the unique positive solution of*

$$\begin{aligned} -\Delta u &= uf(u, v_0, w_0) && \text{in } \Omega, \\ B_1 u &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{17}$$

(*Existence is guaranteed by Lemma* 2 *since* $\lambda_1(\Delta + f(0, v_0, w_0)) \geq \lambda_1(\Delta + f(0, 0, 0)) > 0$). *Assume that* $\lambda_1(\Delta + g(u_1, 0)) \geq 0$ *and* $\lambda_1(\Delta + h(u_1, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (u_0, 0, 0), (u_1, v_0, w_0) \gg$.

Case 8. $v \mathrel{-\!\!\circ\!\!-} u \longrightarrow w$. *Let* $C = \max_{x \in \overline{\Omega}} w_0(x)$. *Assume*

$$\begin{aligned} -\Delta u &= uf(u, v, C), \\ -\Delta v &= vg(u, v) \end{aligned} \tag{18}$$

has a positive equilibrium (C_1, C_2) *and* $\lambda_1(\Delta + h(C_1, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (u_0, v_0, 0), (C_1, C_2, w_0) \gg$.

Case 9. $v \longleftarrow u \longleftrightarrow w$. *Assume* $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$ *and* $\lambda_1(\Delta + g(u_0, 0)) \geq 0$. *Let* u_1 *be the unique positive solution of*

$$\begin{aligned} -\Delta u &= uf(u, v_0, 0) && \text{in } \Omega, \\ B_1 u &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{19}$$

(*Existence is guaranteed by Lemma* 2 *since* $\lambda_1(\Delta + f(0, v_0, 0)) \geq \lambda_1(\Delta + f(0, 0, 0)) > 0$.) *Suppose* $\lambda_1(\Delta + h(u_1, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (0, 0, 0), (u_1, v_0, w_0) \gg$.

Case 10. $v \longleftarrow u \longleftarrow w$. *Assume* $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$ *and* $\lambda_1(\Delta + g(u_0, 0)) \geq 0$. *Then system* (1) *has a positive solution in* $\ll (0, 0, w_0), (+\infty, v_0, +\infty) \gg$.

Note 6. *The condition* $\lambda_1(\Delta + g(u_0, 0)) \geq 0$ *can be weakened to* $\lambda_1(\Delta + g(u_1, 0)) \geq 0$, *where* u_1 *is the unique positive solution of*

$$\begin{aligned} -\Delta u &= uf(u, 0, w_0) && \text{in } \Omega, \\ B_1 u &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{20}$$

if $\lambda_1(\Delta + f(0, 0, w_0)) > 0$ *and* $u_1 \equiv 0$ *otherwise. Thus, for example, if* $\lambda_1(\Delta + f(0, 0, w_0)) \leq 0$, *then* $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$ *would imply the existence of a positive solution to system* (1).

Proof.

Case 1. In this case $f_v, f_w < 0$, $g_u, h_u > 0$. Let $Au := (-\Delta + P)^{-1} u[f(u, Su, Tu) + P]$. Assume $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$. By Proposition 1, A has a fixed point $\overline{u} > 0$. $S\overline{u} > S0 = v_0 > 0$, $T\overline{u} > T0 = w_0 > 0$. $(\overline{u}, S\overline{u}, T\overline{u})$ is thus a positive solution of system (1).

Conversely, let $(\overline{u}, \overline{v}, \overline{w})$ be a positive solution. Then $\overline{v} = S\overline{u} > S0 = v_0$, $\overline{w} = T\overline{u} > T0 = w_0$, and thus $f(0, v_0, w_0) > f(0, \overline{v}, \overline{w})$. Therefore, $\lambda_1(\Delta + f(0, v_0, w_0)) > \lambda_1(\Delta + f(0, \overline{v}, \overline{w})) > 0$ since the equation

$$(21) \qquad \begin{array}{ll} -\Delta u = uf(u, \overline{v}, \overline{w}) & \text{in } \Omega, \\ B_1 u = 0 & \text{on } \partial\Omega \end{array}$$

has positive solution $\overline{u}$.

Case 2. In this case $f_v, f_w, g_u, h_u > 0$. $-\Delta u_0 = u_0 f(u_0, 0, 0) < u_0 f(u_0, Su_0, Tu_0)$ implies $u_0 < Au_0$. Equation

$$(22) \qquad \begin{array}{ll} -\Delta v = vg(C_1, v) & \text{in } \Omega, \\ B_2 v = 0 & \text{on } \partial\Omega \end{array}$$

has a unique positive solution $v_1 = SC_1$. The constant C_2 is an upper solution of (22), and the function ϵv_1 is a lower solution to (22) for $\epsilon \in (0, 1]$. When ϵ is small, we have $\epsilon v_1 < C_2$. There thus exists a positive solution $\tilde{v}$ of (22) in $[[\epsilon v_1, C_2]]$. By the uniqueness, $\tilde{v} = v_1$. This shows that $SC_1 \leq C_2$. Similarly, $TC_1 \leq C_3$. So $-\Delta C_1 = 0 = C_1 f(C_1, C_2, C_3) \geq C_1 f(C_1, SC_1, TC_1)$. Thus $C_1 \geq AC_1$. By a similar argument, we see that $u_0 \leq C_1$. By Corollary 6.2 in [1] and Lemma 7, A has a positive fixed point $\overline{u} \in [[u_0, C_1]]$. Therefore, $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of (1). Also, $C_1 \not\equiv \overline{u} \leq C_1$ implies $v_0 = S0 < S\overline{u} < SC_1 \leq C_2$ and $w_0 = T0 < T\overline{u} < TC_1 \leq C_3$ by the strict monotonicity of the operators S and T. Since $-\Delta u_0 = u_0 f(u_0, 0, 0)$, $-\Delta\overline{u} = \overline{u} f(\overline{u}, S\overline{u}, T\overline{u})$, $-\Delta C_1 = 0 = C_1 f(C_1, C_2, C_3)$, and $f(u, 0, 0) < f(u, S\overline{u}, T\overline{u}) < f(u, C_2, C_3)$, we conclude that $u_0 < \overline{u} < C_1$ according to Lemma 3.

Case 3. In this case $f_v, f_w, g_u, h_u < 0$. By Proposition 1, A has a positive fixed point $\overline{u}$. By Lemma 3, $\overline{u} \leq u_0$. Thus $v_0 = S0 > S\overline{u} \geq Su_0 > 0$ and $w_0 = T0 > T\overline{u} \geq Tu_0 > 0$. Then $\overline{u} < u_0$. Therefore, $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution.

Case 4. In this case $f_v, g_u, h_u > 0$, $f_w < 0$. Since $A'(0) = (-\Delta + P)^{-1}[f(0, v_0, w_0) + P]$ and $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$, we have $r(A'(0)) > 1$. It is easy to check that the restriction of A on $C_e(\overline{\Omega})$ is strongly positive. By the Krein–Rutman theorem, $r(A'(0))$ is an eigenvalue of $A'(0)$ with a positive eigenvector and $A'(0)$ has no other eigenvalues with positive eigenvectors. Let $A_\theta = \theta A$ and $R = C_1$. Suppose $A_\theta u = u$ with $u \in \partial B_R(0) \cap \boldsymbol{K}$ for some $\theta \in (0, 1]$. Then $-\Delta u = \theta uf(u, Su, Tu) + P(\theta - 1)u$. Since u, Su, and Tu are in $W^{2,p}(\Omega)$ for any $p > 0$ and f is C^1, we see from the above equality that $u \in W^{3,p}(\Omega)$ for any $p > 0$. By the Sobolev imbedding theorem, $u \in C^2(\overline{\Omega})$. Now $u \leq C_1$ implies $Su \leq C_2$. If u attains its maximum at $x_0 \in \Omega$, let $u(x_0) = \max_{x \in \overline{\Omega}} u(x) = C_1 > 0$. Since $Tu > T0 = w_0 > 0$, we have $0 \leq -\Delta u(x_0) \leq \theta u(x_0) f(u(x_0), Su(x_0), Tu(x_0)) < \theta u(x_0) f(u(x_0), C_2, w_0(x_0)) \leq \theta C_1 f(C_1, C_2, 0) = 0$, a contradiction. If u attains its maximum only on the boundary of Ω, let $u(x_0) = \max_{x \in \overline{\Omega}} u(x) = C_1 > 0$ for some $x_0 \in \partial\Omega$. Because $\partial\Omega$ is smooth, we can choose a ball $B \subset \Omega$ such that $\overline{B} \cap \partial\Omega = \{x_0\}$. Since $f(u(x_0), Su(x_0), Tu(x_0)) < f(C_1, C_2, 0) = 0$, B can be chosen so small such that $f(u(x), Su(x), Tu(x)) < 0$ on $\overline{B}$. We have $-\Delta u(x) \leq \theta u(x) f(u(x), Su(x), Tu(x)) < 0$ on $\overline{B}$. Applying the Hopf lemma (Lemma 5) to u in the domain B, we conclude that $\partial u(x_0)/\partial \mathbf{m} > 0$ for any outward pointing direction $\mathbf{m}$ with respect to ∂B. Therefore, $\partial u(x_0)/\partial \mathbf{n} > 0$ with respect to $\partial\Omega$. Then $B_1 u(x_0) = a_1(x_0) u(x_0) + b_1(x_0) \partial u(x_0)/\partial \mathbf{n} > 0$, contradicting the boundary condition $B_1 u = 0$. In any case it shows that A_θ has no fixed point on $\partial B_R(0) \cap \boldsymbol{K}$ for $0 < \theta \leq 1$. Therefore, $Au \neq \lambda u$ for all $\lambda \in [1, \infty)$ and for all $u \in \partial B_R(0) \cap \boldsymbol{K}$. By Theorem 13.2 in [1], The operator A has a positive fixed point $\overline{u} \in [[0, C_1]]$. Now $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of (1). $T\overline{u} > T0 = w_0$. $C_1 \not\equiv \overline{u} \leq C_1$ implies

$v_0 = S0 < S\overline{u} < SC_1 \leq C_2$. Thus it follows from Lemma 3 that $\overline{u} < C_1$, using a similar argument to the proof of Case 2.

Case 5. In this case $f_v, f_w, g_u < 0$, $h_u > 0$. By Proposition 1, the operator A has a positive fixed point $\overline{u}$. Since $T\overline{u} > T0 = w_0 > 0$, we have by Lemma 3, $\overline{u} < u_0$. Thus $v_0 = S0 > S\overline{u} > Su_0 \geq 0$. Therefore, $(\overline{u}, S\overline{u}, T\overline{u})$ is in $\ll (0,0,w_0), (u_0, v_0, +\infty) \gg$.

Case 6. In this case $f_v, g_u > 0$, $f_w, h_u < 0$. That $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$ implies $r(A'(0)) > 1$. Similarly as in the proof of Lemma 2, we can show that there exists $\underline{u} > 0$ with $\underline{u} < C_1$ and $A\underline{u} > \underline{u}$. Since $SC_1 \leq C_2$ and $TC_1 \geq 0$, we have $-\Delta C_1 = 0 = f(C_1, C_2, 0) \geq f(C_1, SC_1, TC_1)$. This shows $C_1 \geq AC_1$. By Lemma 7 and Corollary 6.2 in [1], A has a positive fixed point $\overline{u} \in [[\underline{u}, C_1]]$. $\overline{u} \neq C_1$ implies $0 \leq TC_1 < T\overline{u} < T0 = w_0$ and $0 < v_0 = S0 < S\overline{u} < SC_1 \leq C_2$. It follows that $\overline{u} < C_1$ by the argument used in the proof of Case 2. Therefore, $(\overline{u}, S\overline{u}, T\overline{u}) \in \ll (0, v_0, 0), (C_1, C_2, w_0) \gg$.

Case 7. In this case, $f_v, f_w > 0$, $g_u, h_u < 0$. By Proposition 1, the operator A has a positive fixed point $\overline{u}$. Since in this case $S\overline{u} < S0 = v_0$, $T\overline{u} < T0 = w_0$, we have $f(0, S\overline{u}, T\overline{u}) < f(0, v_0, w_0)$. Lemma 3 implies $\overline{u} < u_1$. Thus $S\overline{u} > Su_1 \geq 0, T\overline{u} > Tu_1 \geq 0$. Hence $u_0 < \overline{u}$ and $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution to system (1).

Case 8. In this case $f_v, f_w, g_u > 0$, $h_u < 0$. Similarly, as in Case 4, the operator A has a positive fixed point $\overline{u} \in [[0, C_1]]$ and $\overline{u} \neq C_1$. Therefore, $v_0 = S0 < S\overline{u} < SC_1 \leq C_2$ and $w_0 = T0 > T\overline{u} > TC_1 \geq 0$. Thus $u_0 < \overline{u} < C_1$. $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of system (1).

Case 9. In this case $f_v > 0$, $f_w, g_u, h_u < 0$. By Proposition 1, A has a positive fixed point $\overline{u}$. $S\overline{u} < S0 = v_0$ and $T\overline{u} \geq 0$ imply $f(0, S\overline{u}, T\overline{u}) < f(0, v_0, 0)$. Lemma 2 then asserts that $\overline{u} < u_1$. Then $0 \leq Tu_1 < T\overline{u} < T0 = w_0$. By Lemma 2, either $S\overline{u} > 0$ or $S\overline{u} \equiv 0$. Suppose $S\overline{u} \equiv 0$, then $\overline{u}$ is the positive solution of

$$(23) \qquad \begin{aligned} -\Delta u &= uf(u, 0, T\overline{u}) && \text{in } \Omega, \\ B_1 u &= 0 && \text{on } \partial\Omega. \end{aligned}$$

The inequality $f(0, 0, T\overline{u}) < f(0, 0, 0)$ implies $\overline{u} < u_0$ by Lemma 3. Hence $S\overline{u} > Su_0 \geq 0$, a contradiction. Therefore, $S\overline{u} > 0$. $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution to system (1).

Case 10. In this case $f_v, h_u > 0$, $f_w, g_u < 0$. By Proposition 1, the operator A has a positive fixed point $\overline{u}$. $S\overline{u} < S0 = v_0$, $T\overline{u} > T0 = w_0 > 0$. Similarly, as in Case 9, we can show that $S\overline{u} > 0$. Consequently, $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of system (1) in $\ll (0, 0, w_0), (+\infty, v_0, +\infty) \gg$. □

What follows is a result on the existence of positive solutions over large domains. In addition to the hypothesis **(H1)**, we assume that there are constants $\overline{C}_i > 0$, $i = 2, 3$ such that $g(0, \overline{C}_2) = 0$, $h(0, \overline{C}_3) = 0$. The hypothesis **(H2)** will be replaced by the following weakened one.

(H2′) $f(0,0,0) > 0$, $g(0,0) > 0$, and $h(0,0) > 0$.

We say that a domain Ω is large if Ω contains a ball $B_R(0)$ with large radius R. Then we have the following.

PROPOSITION 2. *Under the above assumptions on f, g, h, system* (1) *in the case of* $(v \longrightarrow u \longleftarrow w)$ *has a positive solution on large domains if it has a positive equilibrium* (C_1, C_2, C_3).

Proof. We first have $C_2 > \overline{C}_2$ because $g(C_1, C_2) = g(0, \overline{C}_2) = 0$ and $g_u > 0$, $g_v < 0$. Similarly, $C_3 > \overline{C}_3$. So $f(0, \overline{C}_2, \overline{C}_3) > f(C_1, C_2, C_3) = 0$. We claim that when Ω is large, there exist unique positive solutions $v_0 > 0, w_0 > 0$, respectively, to the equations

$$\begin{aligned} &-\Delta v = vg(0,v) \quad \text{in } \Omega, B_2 v = 0 \quad \text{on } \partial\Omega, \\ &-\Delta w = wh(0,w) \quad \text{in } \Omega, B_3 w = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Because $\lambda(-\Delta) \sim 1/(d(\Omega))^n$, where $d(\Omega)$ is the diameter and n the dimension of the domain Ω, the $d(\Omega)$ can be chosen so large that $\min\{\lambda_1(\Delta+g(0,0)), \lambda_1(\Delta+h(0,0))\} > 0$. Lemma 2 then asserts the existence of v_0, w_0. We have $v_0 < \overline{C}_2$, $w_0 < \overline{C}_3$ since $\overline{C}_2, \overline{C}_3$ are the a priori bounds for v_0, w_0, respectively, on every domain by the general maximum principle. Thus $f(0, v_0(x), w_0(x)) > f(0, \overline{C}_2, \overline{C}_3) > 0$ for all x. Therefore, $\lambda_1(\Delta + f(0, v_0, w_0)) > 0$ on large domains. Then apply Case 1 of Theorem 1 to complete the proof. □

Note 7. An interesting remark can be drawn by comparing this proposition with Case 1 in Theorem 1. That is, on an ordinary domain the spectral property of a two predator-one prey system determines the existence of positive solutions, while the equilibrium of the system dominates on a large domain. The solutions to an elliptic system over a large domain can be related to a singular perturbation problem, that is, a problem with a small diffusion rate. Under certain conditions the equilibrium might have a significant effect on the solutions. This idea had been adopted explicitly or implicitly by various authors. See, for example, [5], [8], [19], [28].

3.2. Bifurcations. Consider the following system

$$\begin{aligned} &-d\Delta u = uf(u,v,w), \\ &-\Delta v = vg(u,v) \qquad \text{in } \Omega, \\ &-\Delta w = wh(u,w), \\ &B_1 u = B_2 v = B_3 w = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{24}$$

where $d > 0$ is a constant and the boundary operators $B_i u = a_i(x)u + b_i(x)\partial u/\partial \mathbf{n}$ are defined as in §1. We assume that f, g, h are C^2 functions, that (**H1**) is satisfied, and that $g(0,0), h(0,0) > \lambda_1(-\Delta)$. Let $C_{B_i}(\overline{\Omega})$ be the subspace of $C(\overline{\Omega})$, subject to the boundary condition $B_i u = 0$. Motivated by the method of [9] in two species of predator-prey relationship over an interval in $\mathbf{R}^1$, we give the uniqueness and stability of the positive solutions of (24) on various patterns of interactions.

THEOREM 2. *Under the above assumptions, if in* (24), $\lambda_1(d\Delta + f(0, v_0, w_0)) > 0$ *for some* $d > 0$, *then there is a neighborhood* $\mathcal{N}$ *of* $(0, v_0, w_0)$ *in* $C_{B_1}(\overline{\Omega}) \oplus C_{B_2}(\overline{\Omega}) \oplus C_{B_3}(\overline{\Omega})$ *such that there exists a unique positive solution* (u,v,w) *of system* (24) *in* $\mathcal{N}$ *for some range of d. This is true for all ten cases, and these solutions are stable in cases* 1, 7, 10 *in Theorem* 1.

Proof. Define $F(d,u) := d\Delta u + uf(u, Su, Tu)$, where the operators S and T are those defined in the paragraph right before Lemma 6 and $d > 0$ is the diffusion rate. It is easy to identify the linearization operator $F_u(d,0) = d\Delta + f(0, v_0, w_0)I$. The first eigenvalue of $F_u(d,0)$ depends smoothly on d for $d > 0$. Note that the spectral $\sigma(F_u(d,0))$ in $C_{B_1}(\overline{\Omega})$ coincides with that in $L^2(\overline{\Omega})$. Using the variational estimate of the selfadjoint operator $F_u(d,0)$ (under the boundary condition $B_1 u = 0$), we derive that $\lambda_1(F_u(d,0)) < 0$ for d large enough. Therefore, by the assumption of this theorem, there exists a $\overline{d} > 0$ for which $\lambda_1(F_u(\overline{d},0)) = 0$. Note that $F(d,0) \equiv 0$ for any given d. It is easy to see that $\overline{d}$ is a bifurcation point of d for the equation $F(d,u) = 0$. Indeed, let $\phi > 0$ be the corresponding eigenfunction of $F_u(\overline{d},0)\phi = 0$. Then an elementary calculation shows that $\operatorname{Ker}(F_u(\overline{d},0)) = \langle \phi \rangle$, the linear space generated by ϕ, and a function $\xi \in \operatorname{Range}(F_u(\overline{d},0))$ if and only if $\langle \phi, \xi \rangle = 0$, where

$\langle \cdot, \cdot \rangle$ denotes the inner product in $L^2(\Omega)$. Therefore, Codim(Range($F_u(\bar{d},0)$)) $= 1$. Finally, $F_{ud}(\bar{d},0) = \Delta$ and $F_{ud}\phi \notin$ Range($F_u(\bar{d},0)$) because $\langle \phi, \Delta\phi \rangle = -\int_\Omega |\nabla\phi|^2 dx + \int_{\partial\Omega} \phi\partial\phi/\partial\mathbf{n}ds < 0$ (otherwise $\phi \equiv 0$, which is contrary to $\phi > 0$). Thus the Crandall–Rabinowitz bifurcation theorem (see Theorem 13.5 in [40]) asserts the claim about $\bar{d}$. Therefore, we have a $\delta > 0$ and a C^1 bifurcating pair $d = d(s)$, $u = u(s) = s(\phi + \psi(s))$ with $d(0) = \bar{d}$, $\psi(0) = 0$, and $F(d(s), u(s)) = 0$ for $|s| < \delta$. We claim that $(u(s), Su(s), Tu(s))$ is a positive solution of system (24) for small $s > 0$. To this end we note first that $B_1\phi = a_1(x)\phi + b_1(x)\partial\phi/\partial\mathbf{n} = 0$ on $\partial\Omega$. For $x \in \partial\Omega$, if $b_1(x) = 0$, then $\phi(x) = 0$, and consequently $\partial\phi(x)/\partial\mathbf{n} < 0$ by Lemma 5. If $b_1(x) > 0$, then $\phi(x) > 0$. Otherwise $\phi(x) = 0$ implies $\partial\phi(x)/\partial\mathbf{n} = (a_1(x)/b_1(x))\phi(x) = 0$, which is contrary to Lemma 5. Let $F_1 = \{x \in \partial\Omega : b_1(x) = 0\}$. Then $\partial\phi(x)/\partial\mathbf{n} < 0$ on F_1. The continuity of b_1 implies that F_1 is compact. Thus there exists an open neighborhood U of F_1 and a positive number ϵ_1 such that $|\partial\phi(x)/\partial\mathbf{n}| > \epsilon_1$ on U. Let $F_2 = \partial\Omega \setminus U$. Then F_2 is compact and $\phi(x) > 0$ on F_2. Thus there exists an $\epsilon_2 > 0$ such that $\phi(x) > \epsilon_2$ on F_2. The a priori boundedness of the solution u implies that $u \in C^m(\bar{\Omega})$ for some $m > 1$ by the Sobolev imbedding theorem. Since $u(s) = s(\phi + \psi(s))$ and $\phi \in C^\infty$, it follows that $\psi(s) \in C^m(\bar{\Omega})$. Combining the fact that ψ is a C^1 mapping of s, we conclude that $\partial\psi(s)/\partial\mathbf{n}|_{\partial\Omega}$ is uniformly bounded for $|s| \leq \delta$. Putting all the above facts together with $\psi(s) = o(s)$, we can see that $u(s) = s(\phi + \psi(s)) > 0$ for small $s > 0$. Since $S0 = v_0 > 0$, $T0 = w_0 > 0$, and $u(s) \to 0$ as $s \to 0$, similar arguments can show that $Su(s) > 0$, $Tu(s) > 0$ for small $s > 0$.

The local uniqueness follows from that of the bifurcation solution.

In order to investigate the stability of the bifurcating solution, we first notice that the eigenfunction $\phi \notin$ Range($F_u(\bar{d},0)$) $= \{\xi : \langle \xi, \phi \rangle = 0\}$, and thus can apply the Rabinowitz theorem on the stability of bifurcating solutions (see, for example, Theorem 13.8 in [40]). In our case it claims that

$$\lim_{s\to 0} \frac{sd'(s)\lambda_1'(\bar{d})}{\eta(s)} = -1, \tag{25}$$

where the function $\lambda_1(d) = \lambda_1(F_u(d,0))$ is the principal eigenvalue of the operator $F_u(d,0)$, while $\eta(s)$ is the principal eigenvalue corresponding to the linearization of the bifurcating solution $u(s)$. By the variational estimate of the principal eigenvalue, it is clear that $\lambda_1'(d) < 0$. Let us estimate $d'(s)$. We have $-d(s)\Delta u(s) = u(s)f(u(s), Su(s), Tu(s))$. Namely, $-d(s)\Delta(s(\phi + \psi(s))) = s(\phi + \psi(s))f(s(\phi + \psi(s)), S(s(\phi+\psi(s))), T(s(\phi+\psi(s))))$. Dividing s on both sides and then taking the derivative with respect to s and evaluating at $s = 0$, it gives

$$\begin{aligned} &-d'(0)\Delta\phi - \bar{d}[\Delta\psi'(0)] \\ &= \psi'(0)f(0, v_0, w_0) + \phi[f_u(0, v_0, w_0)\phi + f_v(0, v_0, w_0)S'(0)\phi + f_w(0, v_0, w_0)T'(0)\phi]. \end{aligned}$$

The existence of the Fréchet derivative of the left-hand side is due to that of the right-hand side. Multiplying ϕ on both sides and then taking integral by part, we come up with the following equation:

$$-d'(0)\int_\Omega (\Delta\phi)\phi dx = \int_\Omega \phi^2[f_u\phi + f_vS'(0)\phi + f_wT'(0)\phi]dx. \tag{26}$$

Here we have used the cancellation

$$\langle \bar{d}\Delta\psi'(0) + \psi'(0)f(0, v_0, w_0), \phi \rangle = \langle \psi'(0), \bar{d}\Delta\phi + f(0, v_0, w_0)\phi \rangle = \langle \psi'(0), 0 \rangle = 0.$$

Note that by the proof of Lemma 6, $S'(u) = -(\Delta + g + vg_v)^{-1}(vg_u)I$, and $T'(u) = -(\Delta + h + wh_w)^{-1}(wh_u)I$, where $g = g(u(s), v(s))$, $h = h(u(s), w(s))$, $v(s) = Su(s)$, $w(s) = Tu(s)$. Notice also that $\lambda_1(\Delta + g) = \lambda_1(\Delta + h) = 0$. Therefore, $\lambda_1(\Delta + g + vg_v) < 0$ and $\lambda_1(\Delta + h + wh_w) < 0$ since $g_v < 0$, $h_w < 0$. First of all we consider the case of $v \longleftarrow u \longrightarrow w$ (Case 7 in Theorem 1). With the fact that $g_u < 0$ and $h_u < 0$ in mind, Lemma 4 then concludes that $S'(u)$ and $T'(u)$ are negative operators. Hence the right-hand side of (26) is negative because $f_u\phi < 0$, $f_v > 0$, $f_w > 0$, and $\phi > 0$. We then obtain immediately that $d'(0) < 0$. Therefore, $d'(s) < 0$ for small s. As a consequence, the function $\eta(s)$ in (25) must be negative for small positive s, and, therefore, the bifurcating solutions are stable. In case of $v \longrightarrow u \longleftarrow w$, $f_v < 0$, $f_w < 0$, $S'(u)$ and $T'(u)$ are positive operators; in case of $v \longleftarrow u \longleftarrow w$, $f_v > 0$, $f_w < 0$, $S'(u)$ is a negative operator while $T'(u)$ is a positive operator. Thus in each of these cases, the right-hand side of (26) is negative; therefore, $d'(s) < 0$ and the same conclusion follows. □

Note 8. To see that the above analysis on the equation $d\Delta u + uf(u, Su, Tu) = 0$ actually gives the bifurcation for system (24) at the point $(\bar{d}, (0, v_0, w_0))$, let us compute the spectrum of the linearization $\mathcal{L}$ of system (24) at $(0, v_0, w_0)$. It is easy to see that

(27)
$$\mathcal{L} = \begin{bmatrix} d\Delta + f(0, v_0, w_0) & 0 & 0 \\ v_0 g_u(0, v_0) & \Delta + g(0, v_0) + v_0 g_v(0, v_0) & 0 \\ w_0 h_u(0, w_0) & 0 & \Delta + h(0, w_0) + w_0 h_w(0, w_0) \end{bmatrix}.$$

Now $\mathcal{L} = \mathcal{L}_1 + B$, where $\mathcal{L}_1 = (d\Delta, \Delta, \Delta)^T$ and B is a bounded linear operator on $C_{B_1}(\bar{\Omega}) \oplus C_{B_2}(\bar{\Omega}) \oplus C_{B_3}(\bar{\Omega})$ given by (27) with the differential operators $d\Delta$, Δ, Δ being deleted. Because $\mathcal{L}$ has compact resolvent, the spectrum of $\mathcal{L}$ consists of only eigenvalues. Let $\mathcal{L}(\xi_1, \xi_2, \xi_3)^T = \lambda(\xi_1, \xi_2, \xi_3)^T$, where λ and $(\xi_1, \xi_2, \xi_3)^T$ is an eigenpair of the operator $\mathcal{L}$. It is easy to check that if $\xi_1 \neq 0$, then $\lambda \in \sigma(d\Delta + f(0, v_0, w_0))$. In case that $\xi_1 = 0$, letting $\xi_2 = 0$ or $\xi_3 = 0$ alternatively, we arrive at the relation $\sigma(\mathcal{L}) = \sigma(d\Delta + f(0, v_0, w_0)) \bigcup \sigma(\Delta + g(0, v_0) + v_0 g_v(0, v_0)) \bigcup \sigma(\Delta + h(0, w_0) + w_0 h_w(0, w_0))$. Note that the spectrums of the last two terms are in the subset $\{z : \text{Re}(z) \leq c < 0\}$ for some constant c. In order to have a bifurcation of system (24) we need the principal eigenvalue of $\mathcal{L}$ across zero. This can take place only for that of the operator $d\Delta + f(0, v_0, w_0)$, where d serves as a bifurcation parameter. This is equivalent to letting $\lambda_1(\bar{d}\Delta + f(0, v_0, w_0)) = 0$ as we did in the proof of Theorem 2.

Note 9. Theorem 2 gives the local results on the existence of positive solutions in terms of certain small range of the diffusion rate d, while Theorem 1 yields the global results, which are not subject to the diffusion rate.

4. Extensions. The methods developed in the previous sections apply also to system (3). The hypotheses **(H1)** and **(H2)** can be modified in the obvious way to accommodate the functions f, g, and h for this system. It is routine to verify that system (3) has a grand total of thirty-two possible nonequivalent types in combinations of the interactions between u, v, and w in terms of predation, competition and symbiosis. Of them eight are predations. First we need the following notation.

Let the functions u_0, v_0, and w_0 be as before. In view of the Lemma 2, let v^0 be the unique positive solution of the following equation

(28)
$$\begin{aligned} -\Delta v &= vg(0, v, w_0) && \text{in } \Omega, \\ B_2 v &= 0 && \text{on } \partial\Omega, \end{aligned}$$

if $\lambda_1(\Delta+g(0,0,w_0)) > 0$ and $v^0 \equiv 0$ otherwise. The functions $u_0 > 0$, $v_0 > 0$, $w_0 > 0$, and $v^0 \geq 0$, are totally determined by the shape of the domain Ω and the functions f, g, h in the system.

Notice that in system (3) the density v is determined by both u and w through the equation $-\Delta v = vg(u,v,w)$ and that v has no direct effect on the density w since $h_v \equiv 0$. By $w \longrightarrow v$ and $w \longleftarrow v$ we mean that $g_w < 0$ and $g_w > 0$, respectively.

From the last equation in system (3), we write $w = Tu$ as before, where $Tu > 0$ or $Tu \equiv 0$ depends on $\lambda_1(\Delta+h(u,0)) > 0$ or ≤ 0. Put $w = Tu$ in the second equation of (3); we can define the solution $v = Su$, where $Su > 0$ or $Su \equiv 0$ depends on whether $\lambda_1(\Delta + g(u,0,Tu)) > 0$ or ≤ 0. Plainly, $v^0 = S0$. Again, T is a strictly increasing or decreasing operator on the subset $U_2 = \{u \in C(\overline{\Omega}) : Tu > 0\}$, but the same conclusion may not be true for S in some cases. More precisely, S is strictly increasing on $U_1 = \{u \in C(\overline{\Omega}) : Su > 0\}$ if $g_u > 0$ and $g_w \cdot h_u > 0$, while S is strictly decreasing on U_1 if $g_u < 0$ and $g_w \cdot h_u < 0$. With the operators S and T in hand, we can define the operator A in the same way as before, $Au = (-\Delta + P)^{-1}[uf(u,Su,Tu) + Pu]$. The property of A depends on the particular pattern in system (3).

Lemma 9 is still true except for the case $v \longleftarrow u \longleftarrow w \longleftarrow v$. For this exceptional case we can impose certain mild conditions on the nonlinearities f, g, or h to keep Lemma 9 valid. For example, we assume that there exists a $C_0 > 0$ such that $h(u, C_0) \leq 0$ for any $u \geq 0$. Then for any positive solution w of

$$\begin{aligned} -\Delta w &= wh(u,w) && \text{in } \Omega, \\ B_3 w &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{29}$$

$w \leq C_0$. We have the following.

LEMMA 9′. *The positive fixed points of A_θ have an a priori bound for $\theta \in (0,1]$ if no symbiosis relation is involved in system* (3).

PROPOSITION 1′. *Assume that no symbiotic interaction is involved in system* (3). *Then A has a positive fixed point if $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$.* □

The proofs of Lemma 9′ and Proposition 1′ follow the same arguments as in that of Lemma 9 and Proposition 1, respectively.

The existence result is the following.

THEOREM 1′. *Let f, g, h satisfy the corresponding* (**H1**) *and* (**H2**). *Then the following are true.*

Case 1. $v \longrightarrow u \longleftarrow w \longleftarrow v$. *System* (3) *has a positive solution if and only if* $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$.

Case 2. $v \multimap u \multimap w \longleftarrow v$. *If system* (3) *has a positive equilibrium* (C_1,C_2,C_3), *then it has a positive solution in* $\ll (u_0,v^0,w_0),(C_1,C_2,C_3) \gg$.

Case 3. $v \longleftrightarrow u \longleftrightarrow w \longrightarrow v$. *Assume* $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$, $\lambda_1(\Delta + g(u_0,0,w_0)) \geq 0$ *and* $\lambda_1(\Delta + h(u_0,0)) \geq 0$. *Then system* (3) *has a positive solution in* $\ll (0,0,0),(u_0,v_0,w_0) \gg$.

Case 4. $v \multimap u \longleftarrow w \longleftarrow v$. *Assume that* $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$ *and that the system*

$$\begin{aligned} -\Delta u &= uf(u,v,c), \\ -\Delta v &= vg(u,v,w), \\ -\Delta w &= wh(u,w) \end{aligned} \tag{30}$$

has a positive equilibrium (C_1,C_2,C_3), *i.e.,* $f(C_1,C_2,c) = g(C_1,C_2,C_3) = h(C_1,C_3) = 0$, *where* $c = \min_{x\in\overline{\Omega}} w_0(x)$. (*Note that if* $b_3(x) > 0$ *for all* $x \in \partial\Omega$ *in the boundary condition, then* $c > 0$.) *Then* (3) *has a positive solution in* $\ll (0,v^0,w_0),(C_1,C_2,C_3) \gg$.

Case 5. $v \,{-\!\!\circ\!\!-}\, u \longleftrightarrow w \longrightarrow v$. *Assume*

$$\begin{aligned} -\Delta u &= uf(u,v,0), \\ -\Delta v &= vg(u,v,0) \end{aligned} \tag{31}$$

has positive equilibrium (C_1, C_2) *and* $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$, $\lambda_1(\Delta + g(0,0,w_0)) \geq 0$, $\lambda_1(\Delta + h(C_1,0)) \geq 0$. *Then* (3) *has a positive solution in* $\ll (0,v^0,0),(C_1,C_2,w_0) \gg$.

Proof.

Case 1. In this case $f_v, f_w < 0$, $g_u, g_w, h_u > 0$, and S is an increasing operator. Let $Au := (-\Delta + P)^{-1}u[f(u,Su,Tu) + P]$. Assume $\lambda_1(\Delta + f(0,v^0,w_0)) > 0$. By Proposition 1′, A has a fixed point $\overline{u} > 0$. $T\overline{u} > T0 = w_0 > 0$, $S\overline{u} > S0 = v^0 > v_0 > 0$. $(\overline{u}, S\overline{u}, T\overline{u})$ is thus a positive solution to system (3).

Conversely, let $(\overline{u},\overline{v},\overline{w})$ be a positive solution. Then $\overline{w} = T\overline{u} > T0 = w_0$, $\overline{v} = S\overline{u} > S0 = v^0$, $f(0,v^0,w_0) > f(0,\overline{v},\overline{w})$. Therefore, $\lambda_1(\Delta + f(0,v^0,w_0)) > \lambda_1(\Delta + f(0,\overline{v},\overline{w})) > 0$ since the equation

$$\begin{aligned} -\Delta u &= uf(u,\overline{v},\overline{w}) && \text{in } \Omega, \\ B_1 u &= 0 && \text{on } \partial\Omega \end{aligned} \tag{32}$$

has positive solution $\overline{u}$.

Case 2. In this case $f_v, f_w, g_u, g_w, h_u > 0$ and S is an increasing operator. It is similar to Case 2 of Theorem 1, showing that A has a positive fixed point $\overline{u} \in [[u_0, C_1]]$. Therefore, $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of (3). Also, $C_1 \not\equiv \overline{u} \leq C_1$ implies $w_0 = T0 < T\overline{u} < TC_1 \leq C_3$ and $v_0 < v^0 = S0 < S\overline{u} < SC_1 \leq C_2$. It then follows from Lemma 3 that $u_0 < \overline{u} < C_1$.

Case 3. In this case $f_v, f_w, g_u, g_w, h_u < 0$. The operator A has a positive fixed point $\overline{u}$ by Proposition 1′. $\overline{u} \leq u_0$ by Lemma 3. Therefore, $T\overline{u} < T0 = w_0$ and $S\overline{u} < v_0$. $\lambda_1(\Delta + g(\overline{u},0,T\overline{u})) > \lambda_1(\Delta + g(u_0,0,w_0)) \geq 0$. Thus $S\overline{u} > 0$. Then $\overline{u} < u_0$ and $T\overline{u} > Tu_0 \geq 0$. $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution.

Case 4. In this case $f_v, g_u, g_w, h_u > 0$, $f_w < 0$, and the operators S and T are increasing. We argue similarly as in Case 4 of Theorem 1 that the operator A has a positive fixed point $\overline{u} \in [[0, C_1]]$. Now $(\overline{u}, S\overline{u}, T\overline{u})$ is a positive solution of (3). $T\overline{u} > T0 = w_0$. That $C_1 \not\equiv \overline{u} \leq C_1$ implies $T\overline{u} < TC_1 \leq C_3$. Thus $v_0 < v^0 = S0 < S\overline{u} < SC_1 \leq C_2$, and consequently we can show that $\overline{u} < C_1$ as we did in the proof of Case 4 in Theorem 1.

Case 5. In this case $f_v, g_u > 0$, $f_w, g_w, h_u < 0$ and S is an increasing operator. Similarly as in Case 6 of Theorem 1, we can show that A has a positive fixed point $\overline{u} \leq C_1$. $\overline{u} \not\equiv C_1$ implies $0 \leq TC_1 < T\overline{u} < T0 = w_0$ and $0 \leq v^0 = S0 < S\overline{u} < SC_1 \leq C_2$. Hence $\overline{u} < C_1$. Therefore $(\overline{u}, S\overline{u}, T\overline{u}) \in \ll (0,v^0,0),(C_1,C_2,w_0) \gg$. □

For the details on the statements and proofs of the other twenty-seven cases of system (3), and for Case $h = h(u,v,w)$ in the system (3), see [32].

The analogue of Theorem 2 is the following.

THEOREM 2′. *Consider the following system:*

$$\begin{aligned} -d\Delta u &= uf(u,v,w), \\ -\Delta v &= vg(u,v,w) && \text{in } \Omega, \\ -\Delta w &= wh(u,w), \\ B_1 u = B_2 v &= B_3 w = 0 && \text{on } \partial\Omega, \end{aligned} \tag{33}$$

where we impose similar assumptions as in Theorem 2. *If* $\lambda_1(d\Delta + f(0,v^0,w_0)) > 0$ *for some* $d > 0$ *in system* (33), *then there is a neighborhood* $\mathcal{N}$ *of* $(0,v^0,w_0)$ *in*

$C_{B_1}(\overline{\Omega}) \oplus C_{B_2}(\overline{\Omega}) \oplus C_{B_3}(\overline{\Omega})$ *such that there exists a unique positive solution* (u, v, w) *of system* (33) *in* $\mathcal{N}$ *for some range of* d. *This is true for all thirty-two patterns. These solutions are stable in the following four cases of predations:* $v \longrightarrow u \longleftarrow w \longleftarrow v$, $v \longleftarrow u \longrightarrow w \longleftarrow v$, $v \longrightarrow u \longrightarrow w \longrightarrow v$, *and* $v \longleftarrow u \longleftarrow w \longrightarrow v$.

The proof of this theorem is just a step-by-step imitation of that used for Theorem 2. □

Note 10. The four cases of predation stated in the last assertion of the above theorem are among the eight possible patterns of predation in system (33). In the other four cases the local bifurcating positive solutions are, in general, not stable.

Acknowledgment. The authors thank the referees for their very helpful commentary. They suggested the title for this paper and pointed out [34], [37], and many other references to us. The expository review in §1 is greatly under their influence.

ORTHONORMAL BASES OF COMPACTLY SUPPORTED WAVELETS II. VARIATIONS ON A THEME*

INGRID DAUBECHIES†

Abstract. Several variations are given on the construction of orthonormal bases of wavelets with compact support. They have, respectively, more symmetry, more regularity, or more vanishing moments for the scaling function than the examples constructed in Daubechies [*Comm. Pure Appl. Math.*, 41 (1988), pp. 909-996].

Key words. wavelets, orthonormal bases, regularity, symmetry

AMS(MOS) subject classifications. 26A16, 26A18, 26A27, 39B12

1. Introduction. This paper concerns the construction of orthonormal bases of wavelets, i.e., orthonormal bases $\{\psi_{jk};\, j, k \in \mathbb{Z}\}$ for $L^2(\mathbb{R})$, where

$$\psi_{jk}(x) = 2^{-j/2}\psi(2^{-j}x - k) \tag{1.1}$$

for some (very particular!) $\psi \in L^2(\mathbb{R})$. The functions (1.1) are *wavelets* because they are all generated from one single function by dilations and translations. Note that wavelets need not be orthogonal or even linearly independent. In fact, the "first" wavelets were neither [1], [2]. See [3], [4] for discussions of wavelet expansions using nonindependent wavelets, with continuous [3] or discrete [4] dilation and translation labels. Even the special case of orthonormal wavelets need not always be of the form (1.1). Basic dilation factors different from 2 are possible: there exist orthonormal bases in which this factor is any rational $p/q > 1$ [5]; in more than one dimension we may even choose a dilation *matrix* instead of an isotropic dilation factor. In these more general cases, it may be necessary to introduce more than one ψ (but always a finite number). We shall restrict ourselves to one dimension here, and to the dilation factor 2, as in (1.1). Bases with factor 2 are by far the easiest to implement for numerical computations.

All interesting examples of orthonormal wavelet bases can be constructed via *multiresolution analysis.* This is a framework developed by Mallat [6] and Meyer [7], in which the wavelet coefficients $\langle f, \psi_{jk}\rangle$ for fixed j describe the difference between two approximations of f, one with resolution 2^{j-1}, and one with the coarser resolution 2^j. The following succinct review of multiresolution analysis suffices for the understanding of this paper; for more details, examples, and proofs we refer the reader to [6] and [7].

The successive approximation spaces V_j in a multiresolution analysis can be characterized by means of a *scaling function* ϕ. More precisely, we assume that the integer translates of ϕ are an orthonormal basis for the space V_0, which we define to be the approximation space with resolution 1. The approximation spaces V_j with resolution 2^j are then defined as the closed linear spans of the ϕ_{jk} $(k \in \mathbb{Z})$, where

$$\phi_{jk} = 2^{-j/2}\phi(2^{-j}x - k). \tag{1.2}$$

To ensure that projections on the V_j describe successive approximations, we require $V_0 \subset V_{-1}$, which implies

$$\cdots V_2 \subset V_1 \subset V_0 \subset V_{-1} \subset V_{-2} \subset \cdots. \tag{1.3}$$

* Received by the editors May 29, 1990; accepted for publication (in revised form) May 23, 1992.

† Mathematics Department, Rutgers University, New Brunswick, New Jersey 08903 and AT&T Bell Laboratories, 600 Mountain Avenue, Murray Hill, New Jersey 07974.

This imposes a restriction on ϕ: since $\phi \in V_0 \subset V_{-1} = \overline{\operatorname{Span}\{\phi_{-1k};\, k \in \mathbb{Z}\}}$, there must exist c_n such that

$$\phi(x) = \sum_n c_n \phi(2x - n). \tag{1.4}$$

In order to have a complete description of $L^2(\mathbb{R})$, we also impose

$$\bigcap_{j \in \mathbb{Z}} V_j = \{0\}, \qquad \overline{\bigcup_{j \in \mathbb{Z}} V_j} = L^2(\mathbb{R}). \tag{1.5}$$

For every multiresolution analysis as described above, there exists a corresponding orthonormal basis of wavelets defined by

$$\psi(x) = \sum_{n \in \mathbb{Z}} (-1)^n c_{-n+1} \phi(2x - n), \tag{1.6}$$

where c_n are the coefficients in (1.4). We can prove [6], [7] (see also below) that the ψ_{0n} are then an orthonormal basis for the orthogonal complement W_0 of V_0 in V_{-1}. This phenomenon repeats itself at every resolution level j. It follows that, for every j, the $\langle f, \psi_{jk} \rangle$ determine the difference in information between the approximations $P_j f$, $P_{j-1} f$ at resolutions 2^j, 2^{j-1}, respectively:

$$P_{j-1} f = P_j f + \sum_k \langle f, \psi_{jk} \rangle \psi_{jk}.$$

Consequently, by (1.3) and (1.5), the $(\psi_{jk};\, j, k \in \mathbb{Z})$ constitute an orthonormal basis for $L^2(\mathbb{R})$.

One advantage of the "nested" structure of a multiresolution analysis is that it leads to an efficient tree-structured algorithm for the decomposition and reconstruction of functions (given either in continuous or sampled form). Instead of computing all the inner products $\langle f, \psi_{jk} \rangle$ directly, we proceed in a hierarchic way:

—compute $\langle f, \phi_{jk} \rangle$ for the finest resolution level j wanted (if the data are given in a discrete fashion, then these discrete data can just be taken to be $\langle f, \phi_{jk} \rangle$);

—then compute $\langle f, \psi_{j-1k} \rangle$ *and* $\langle f, \phi_{j-1k} \rangle$ at the next finest resolution level by applying (1.4) and (1.7),

$$\langle f, \psi_{j-1k} \rangle = \frac{1}{\sqrt{2}} \sum_n (-1)^n c_{-n+2k+1} \langle f, \phi_{jn} \rangle,$$

$$\langle f, \phi_{j-1k} \rangle = \frac{1}{\sqrt{2}} \sum_n c_{n-2k} \langle f, \phi_{jn} \rangle;$$

—iterate until the coarsest desired resolution level is attained.

The total complexity of this calculation is lower, despite the computation of the seemingly unnecessary $\langle f, \phi_{jk} \rangle$, than if the $\langle f, \psi_{jk} \rangle$ were computed directly.

This brief review shows how to construct an orthonormal basis of wavelets from any "decent" function ϕ satisfying an equation of type (1.4). An example of such a construction is given by the Battle–Lemarié wavelets, consisting of spline functions [8], [9], [10]. In general, constructions starting from a choice of ϕ lead to ϕ, ψ, which are not compactly supported (see, e.g., [15], [25] for a more detailed discussion). The construction can, however, also be viewed differently. The Fourier transform of (1.4) is

$$\hat{\phi}(\xi) = \left[\frac{1}{2} \sum_n c_n e^{in\xi/2}\right] \hat{\phi}\left(\frac{\xi}{2}\right),$$

which implies

$$\hat{\phi}(\xi) = \left[\prod_{j=1}^{\infty} m_0(2^{-j}\xi)\right] \hat{\phi}(0), \tag{1.7}$$

with $m_0(\xi)=\frac{1}{2}\sum_n c_n e^{in\xi}$, so that, up to normalization, ϕ is completely determined by the c_n. Fixing the c_n, therefore, also defines a multiresolution analysis. The c_n have to satisfy certain conditions. Combining $\langle\phi_{0k},\phi_{0l}\rangle=\delta_{kl}$ with (1.4) immediately leads to

$$(1.8)\qquad \sum_n c_n c_{n-2k}=2\delta_{k0},$$

where we have assumed, as we shall do in the sequel, that the c_n are real. In terms of $m_0(\xi)$, (1.8) can be rewritten as

$$(1.9)\qquad |m_0(\xi)|^2+|m_0(\xi+\pi)|^2=1.$$

To ensure that ϕ is well defined, the infinite product in (1.7) must converge, which implies $m_0(0)=1$ or

$$(1.10)\qquad \sum_n c_n=2.$$

It follows that ϕ is uniquely determined by (1.4), up to normalization, which we fix by requiring $\int dx\,\phi(x)=1$. One can show (see, e.g., [12]) that (1.9) implies that ϕ is in $L^2(\mathbb{R})$, but unfortunately (1.8) is not sufficient to guarantee orthonormality of the ϕ_{0n}. A counterexample is $c_0=c_3=1$, all other $c_n=0$, which leads to $\phi(x)=\frac{1}{3}$ for $0\leqq x<3$, $\phi(x)=0$ otherwise. Such counterexamples are rare, however. If $N_2-N_1=3$, then the example above, $c_0=c_3=1$, is the only one. For a detailed discussion, see [12], [13], [22].

If we exclude these thin sets of "bad" choices for the c_n (which can be done by various means [6], [7], [12], [13], [15]), then we can build orthonormal bases of wavelets starting from the c_n. Once orthonormality of the ϕ_{0k} is established, all the rest follows easily. Formula (1.6) for ψ leads immediately to orthogonality of the ψ_{0l} and ϕ_{0k},

$$\begin{aligned}\langle\psi_{0l},\phi_{0k}\rangle&=\frac{1}{2}\sum_{n,m}(-1)^n c_{-n+2l+1}c_{m-2k}\langle\phi_{-1n},\phi_{-1m}\rangle\\&=\frac{1}{2}\sum_n(-1)^n c_{-n+2l+1}c_{n-2k}=0.\end{aligned}$$

The last equality follows from the substitution $n=-m+2(k+l)+1$ for the summation index n. Similar manipulations prove

$$\langle\psi_{0l},\psi_{0k}\rangle=\delta_{kl}$$

and

$$(1.11)\qquad \sum_k[\langle f,\phi_{0k}\rangle\phi_{0k}+\langle f,\psi_{0k}\rangle\psi_{0k}]=\sum_n\langle f,\phi_{-1n}\rangle\phi_{-1n}.$$

It follows that both $\{\phi_{-1n};\,n\in\mathbb{Z}\}$ and $\{\phi_{0k},\psi_{0k};\,k\in\mathbb{Z}\}$ are orthonormal bases for V_{-1}. (In other words, (1.8) ensures that (1.4) and (1.6) describe an orthonormal basis transformation.) It follows that $W_0=\overline{\text{Span}\,(\psi_{0k})}$ is the orthogonal complement of V_0 in V_{-1}, and hence that the $\{\psi_{jk};\,j,k\in\mathbb{Z}\}$ constitute an orthonormal basis for $L^2(\mathbb{R})$.

Constructing ψ from the c_n rather than from ϕ has the advantage of allowing better control over the supports of ϕ and ψ. If $c_n=0$ for $n<N_1$, $n>N_2$, then support $(\phi)\subset[N_1,N_2]$ (see [11a], [14]). In [15] this method was used to construct orthonormal bases of wavelets with compact support, and arbitrarily high preassigned regularity (the size of the support increases linearly with the number of continuous derivatives). These orthonormal basis functions and the associated multiresolution analysis have been tried out for several applications, ranging from image processing to numerical analysis [16]. For some of these applications, variations on the scheme of [15] were requested, emphasizing other properties. The goal of this and the next paper is to present a number of these variations.

The construction in [15] relied on the identity

$$\sum_{j=0}^{N-1}\binom{N-1+j}{j}[(\cos\alpha)^{2N}(\sin\alpha)^{2j}+(\sin\alpha)^{2N}(\cos\alpha)^{2j}]=1. \tag{1.12}$$

Since

$$\left|\frac{1+e^{i\xi}}{2}\right|^2=\left(\cos\frac{\xi}{2}\right)^2,$$

(1.12) suggests the choice

$$m_0(\xi)=\left(\frac{1+e^{i\xi}}{2}\right)^N Q(e^{i\xi}), \tag{1.13}$$

where Q is a trigonometric polynomial with real coefficients such that

$$|Q(e^{i\xi})|^2=\sum_{j=0}^{N-1}\binom{N-1+j}{j}\left(\frac{1-\cos\xi}{2}\right)^j. \tag{1.14}$$

By (1.12), any such m_0 will satisfy (1.9). To determine Q, we have to extract the "square root" of the right-hand side of (1.5). This can be done by using a lemma of Riesz [17]. Denote the right-hand side of (1.14) by $P_N(e^{i\xi})$, and extend P_N to all of $\mathbb{C}$. We have $\overline{P_N(z)}=P_N(\bar{z})$ and $P_N(z^{-1})=P_N(z)$. Consequently, the zeros of P_N come either in real duplets, r_k and r_k^{-1}, or in complex quadruplets, z_l, $\bar{z}_l$, z_l^{-1}, and $\bar{z}_l^{-1}$,

$$\begin{aligned}P_N(z)&=4^{-N+1}\binom{2N-2}{N-1}z^{-N+1}\prod_k(z-r_k)(z-r_k^{-1})\\&\quad\cdot\prod_l(z-z_l)(z-\bar{z}_l)(z-z_l^{-1})(z-\bar{z}_l^{-1})\\&=4^{-N+1}\binom{2N-2}{N-1}\prod_k\frac{(z-r_k)(r_k-z^{-1})}{r_k^2}\\&\quad\cdot\prod_l\frac{(z-z_l)(z-\bar{z}_l)(z_l-z^{-1})(\bar{z}_l-z^{-1})}{|z_l|^2z^2}.\end{aligned}$$

It follows that $P_N(e^{i\xi})=|Q_N(e^{i\xi})|^2$, with

$$Q_N(z)=2^{-N+1}\binom{2N-2}{N-1}^{1/2}\prod_k\frac{(z-r_k)}{\sqrt{|r_k|}}\prod_l\frac{(z^2+|z_l|^2-2z\operatorname{Re}z_l)}{|z_l|}. \tag{1.15}$$

This gives a recipe for the construction of m_0:

(1) For given N, determine the zeros of P_N;

(2) Choose one zero out of every pair of real zeros r_l, r_l^{-1} of P_N, and one conjugated pair out of every quadruplet z_k, z_k^{-1}, $\bar{z}_k$, $\bar{z}_k^{-1}$.

(3) Compute the product Q_N, and substitute into (1.12).

The result is a polynomial in $e^{i\xi}$ of degree $2N-1$, corresponding to an orthonormal basis of wavelets in which the basic wavelet ψ_N has support width $2N-1$. Since (1.6) can be rewritten as

$$\hat{\psi}(\xi)=e^{i((\xi/2)+\pi)}\overline{m_0\left(\frac{\xi}{2}+\pi\right)}\hat{\phi}\left(\frac{\xi}{2}\right),$$

and since (1.13) has a zero of order N at π, it follows that ψ_N has N vanishing moments,

$$\int dx\, x^l \psi_N(x) = 0, \qquad l = 0, 1, \ldots, N-1,$$

which is useful for quantum field theory [18] and numerical analysis applications [19]. The regularity of the ψ_N constructed in [15] increases linearly with their support width, $\psi_N \in C^{\alpha(N)}$, with $\lim_{N\to\infty} N^{-1}\alpha(N) = .2075$ [23], [24], [25]. Plots of ϕ and ψ for various values of N can be found in [15], [25].

Depending on the application they had in mind, several scientists (mathematicians or engineers) have requested possible variations on the construction in [15]. The following are the most recurrent wish items.

(1) More symmetry: the functions ϕ, ψ in [15] are very asymmetric. Complete symmetry is incompatible with the orthonormal basis condition (see [15, p. 971], or § 2 below), but is less asymmetry possible?

(2) Better frequency resolution: orthonormal bases with basic multiplication factor 2 correspond to frequency intervals of 1 octave. Is better possible (e.g., $\frac{1}{2}$ octave), without giving up compact support?

(3) More regularity: is better regularity than in [15] achievable for the same support width?

(4) More vanishing moments: for a fixed support width $2N-1$, the ψ_N of [15] have the maximum number of vanishing moments. The functions ϕ_N do not satisfy any moment condition, except $\int dx\, \phi_N(x) = 1$. For numerical analysis applications, it may be useful to give up some zero moments of ψ in order to obtain zero moments for ϕ, i.e., to have

$$\begin{aligned} &\int dx\, \phi(x) = 1, \\ (1.16) \qquad &\int dx\, x^l \phi(x) = 0, \qquad l = 1, \ldots, L, \\ &\int dx\, x^l \psi(x) = 0, \qquad l = 0, \ldots, L. \end{aligned}$$

How can such ϕ, ψ be constructed? They would have the advantage that inner products with smooth functions are particularly appealing:

$$\begin{aligned} \int dx\, \phi_{-jk}(x) f(x) &= 2^{j/2} \int dx\, \phi(2^j(x - 2^{-j}k)) f(x) \\ &= 2^{-j/2} f(2^{-j}k) + \text{correction terms in } f^{(L+1)} \end{aligned}$$

(use the Taylor expansion of f around $2^{-j}k$; the second through $(L+1)$th terms vanish because of (1.16)). Moreover, if the $(L+1)$th derivative of f is uniformly bounded, then the correction terms in this formula are of order $2^{-(L+1/2)j}$.

The purpose of this and the next paper is to show how such variations can be constructed. In § 2 we handle symmetry, in § 3 regularity, and in § 4 vanishing moments for ϕ. The next paper shows how to obtain better frequency localization.

2. More symmetry. If we restrict our attention to orthonormal bases of *compactly supported wavelets only*, then it is impossible to obtain ψ which is either symmetric or antisymmetric, except for the trivial Haar case ($c_0 = 1$, $c_1 = -1$, all other $c_n = 0$). This is the content of the following theorem.

THEOREM 2.1. *Let ψ, ϕ be defined as in* § 1, *from a finite set of coefficients* c_n *satisfying* (1.9) *and* (1.11), *with orthonormal* ϕ_{0n}. *If* ψ *is either symmetric or antisymmetric around some axis, then* ψ *is the Haar function.*

A proof can be found in [25, Chap. 8].

It is thus a fact of life that symmetric or antisymmetric ψ, however desirable they might be in applications, are just not possible within a framework of orthonormal bases of continuous, compactly supported wavelets. On the other hand, ϕ and ψ do not really need to be quite as asymmetric as in [15], where the extreme asymmetry of ψ, ϕ proceeds from choices made in their construction. In practice, the $2(N-1)$ zeros of P_N consist of one real pair r, r^{-1} and n_0^{-1} quadruplets of complex zeros z_l, $\bar{z}_l$, z_l^{-1}, $\bar{z}_l^{-1}$ if $N=2n_0$ is even, and of n_0 quadruplets if $N=2n_0+1$ is odd. To construct Q_N, we need to select one of the two real zeros, and one pair z_l, $\bar{z}_l$ out of every quadruplet. The choice made in [15] is the so-called *extremal phase* choice: we chose systematically all zeros with modulus smaller than one. Other choices may lead to less asymmetric ϕ. The following argument shows why.

A sequence of real numbers $(\alpha_n)_{n\in\mathbb{Z}}$ is said to define a *linear phase filter* if the phase of the function $\alpha(\xi)=\sum_n \alpha_n e^{in\xi}$ is a linear function of ξ, i.e., if, for some $l\in\mathbb{Z}/2$,

$$\alpha(\xi)=e^{il\xi}|\alpha(\xi)|.$$

This means that the α_n are symmetric around l, $\alpha_n=\alpha_{2l-n}$. If the sequence does not define a linear phase filter, then the deviation from linearity of the phase of $\alpha(\xi)$ reflects the asymmetry of the α_n. The Fourier transform of ϕ is given by the infinite product (1.7). If c_n were symmetric around l, then we would have $m_0(\xi)=e^{il\xi}|m_0(\xi)|$, hence

$$\hat{\phi}(\xi)=\exp\left[il\sum_{j=1}^{\infty}2^{-j}\xi\right]\prod_{j=1}^{\infty}|m_0(2^{-j}\xi)||\hat{\phi}(0)|=e^{il\xi}|\hat{\phi}(\xi)|,$$

so that ϕ would be symmetric around l as well. As explained above, this is impossible for c_n satisfying (1.8). The closer the phase of m_0 is to linear phase, the closer the phase of $\hat{\phi}$ will be to linear phase, and the less asymmetric ϕ will be. In our case, m_0 is a product of factors of type

$$(2.1)\qquad \begin{aligned}(z-z_l)(z-\bar{z}_l)&=e^{i\xi}(e^{i\xi}-R_l\,e^{i\alpha_l})(1-e^{-i\xi}R_l\,e^{-i\alpha_l})\\ &=e^{i\xi}[e^{i\xi}-2R_l\cos\alpha_l+R_l^2\,e^{-i\xi}],\end{aligned}$$

with possibly an extra factor

$$(2.2)\qquad (z-r)=e^{i\xi/2}[e^{i\xi/2}-r\,e^{i\xi/2}].$$

The total phase of m_0 is a sum of the phase contributions of each factor. Apart from linear phase terms, the phase contributions of (2.1) and (2.2) are, respectively,

$$(2.3)\qquad \Phi_l(\xi)=\text{arctg}\left(\frac{(1-R_l^2)\sin\xi}{(1+R_l^2)\cos\xi-2R_l\cos\alpha_l}\right),$$

$$(2.4)\qquad =\text{arctg}\left(\frac{1+r}{1-r}\,tg\frac{\xi}{2}\right).$$

The valuation of arctg should be chosen so that Φ_l is continuous in $[0,2\pi]$, and $\Phi_l(0)=0$. Since the denominator in (2.3) has two zeros, namely,

$$\xi=\xi_l=\text{Arc}\cos\left(\frac{2R_l}{1+R_l^2}\cos\alpha_l\right)$$

and $\xi = 2\pi - \xi_l$, $\Phi_l(2\pi) = \Phi_l(0) + \varepsilon_l 2\pi$, with $\varepsilon_l = \pm 1$. Something similar happens in the $(z-r)$ case. In order to extract only the nonlinear part of Φ_l, we define, therefore,

$$\Psi_l(\xi) = \operatorname{arctg}\left(\frac{(1-R_l^2)\sin\xi}{(1+R_l^2)\cos\xi - 2R_l\cos\alpha_l}\right) - \frac{\xi}{2\pi}\Phi_l(2\pi)$$

or

$$= \operatorname{arctg}\left(\frac{1+r}{1-r}\, tg\frac{\xi}{2}\right) - \frac{\xi}{2\pi}\Phi_l(2\pi).$$

In order to obtain m_0 as close to linear phase as possible, we have to choose the zeros to retain from every quadruplet or duplet in such a way that $\Psi_{tot}(\xi) = \sum_l \Psi_l(\xi)$ is as close to zero as possible. In practice, we have $2^{\lfloor N/2 \rfloor}$ choices (and not 2^{N-1}, as was mistakenly stated in [15]). This number can be reduced by another factor of 2: for every choice, the complementary choice (choosing all the other zeros) leads to the complex conjugate m_0 (up to a phase shift), and, therefore, to the mirror image of ϕ. For $N = 2$ or 3, there is, therefore, effectively only one pair ϕ_N, ψ_N. For $N \geqq 4$, we can compare the $2^{\lfloor N/2 \rfloor - 1}$ different choices for Ψ_{tot} in order to find the closest to linear phase. It turns our that the net effect of a change of choice from z_l, $\bar{z}_l$ to z_l^{-1}, $\bar{z}_l^{-1}$ is most significant if R_l is close to 1, and if α_l is close to either zero or π. In Fig. 1 we show the graphs for $\Psi_{tot}(\xi)$ for $N = 4$ and 10, both for the original construction in [15] and for the case with flattest Ψ_{tot}. The "least asymmetric" ϕ and ψ, associated with the flattest possible Ψ_{tot}, are plotted in Fig. 2 for $N = 4$ and 10. A table for the corresponding c_n can be found in [25, p. 198], as well as figures for $N = 6, 8$.

Remarks.

(1) In this discussion we have restricted ourselves to the case where m_0 and $|Q|^2$ are given by (1.13) and (1.14), respectively. This means that the ϕ in Fig. 2 are the least asymmetric possible, given that N moments of ψ are zero, and that ϕ has support width $2N-1$. (This is the minimum width for N vanishing moments.) If ϕ may have larger support width, then it can be made even more symmetric. These wider solutions correspond to a variation on (1.14), i.e., to

$$|Q(e^{i\xi})|^2 = \sum_{j=0}^{N-1} \binom{N-1+j}{j} \left(\frac{1-\cos\xi}{2}\right)^j + \left(\frac{1-\cos\xi}{2}\right)^N R(\cos\xi), \tag{2.5}$$

where R is any odd polynomial such that the right-hand side of (2.5) is positive for

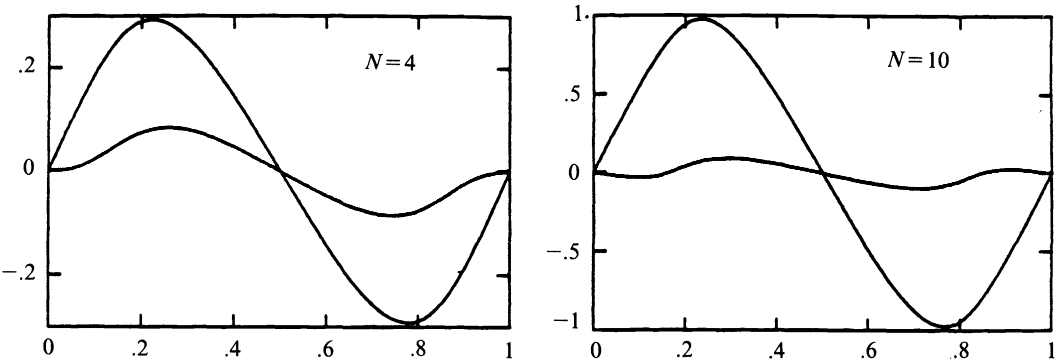

FIG. 1. *Plots of $\Psi_{tot}(\xi)$ for the cases $N = 4$ and 10. In both cases we plot Ψ_{tot} for the construction in [15], and the much flatter Ψ_{tot} corresponding to the closest to linear phase choice. The horizontal axis gives $\xi/2\pi$, the vertical axis Ψ_{tot}/π.*

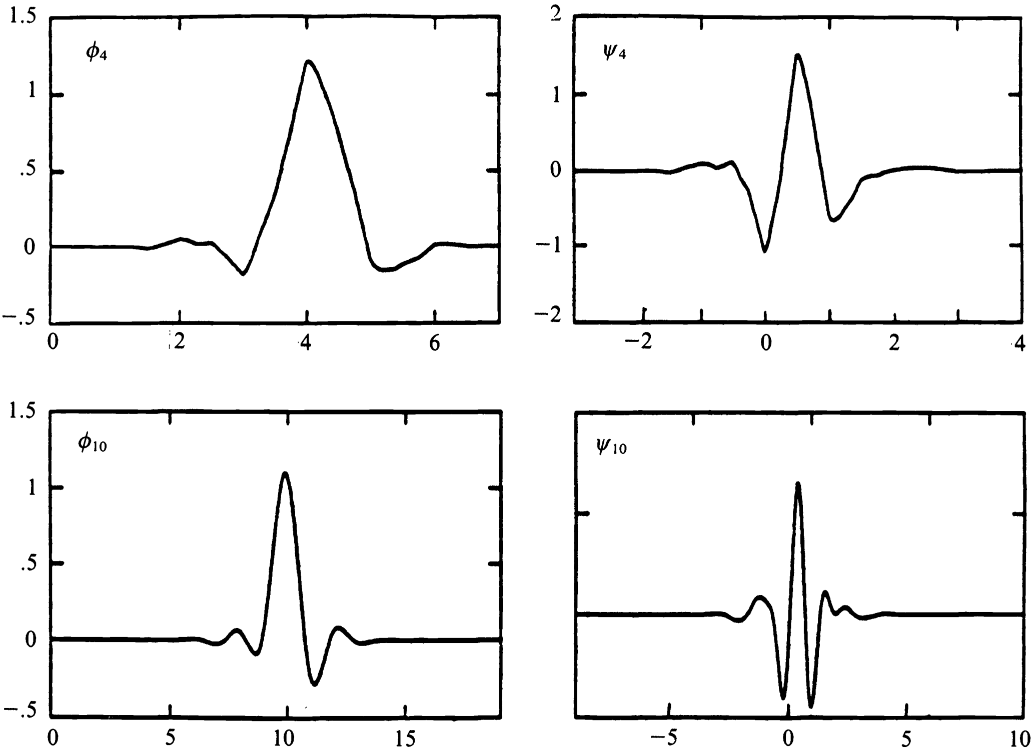

FIG. 2. *Plots of* ϕ_N, ψ_N *closest to linear phase, for the cases* $N=4$ *and* 10. *In every case, support* $(\phi_N)=[0, 2N-1]$, *support* $(\psi_N)=[-N+1, N]$.

all ξ. The functions ϕ constructed in § 4, for instance, are more symmetric than those in Fig. 2, but they have large support width.

(2) We can achieve even more symmetry by going a little beyond the multiresolution scheme explained in § 1, and by "mirroring" the filters at every odd step. For more details, see [25, p. 256].

(3) In [21] the construction of orthonormal bases of wavelets is generalized to "biorthogonal bases," i.e., to two dual unconditional bases $\{\psi_{jk};\ j, k\in\mathbb{Z}\}$ and $\{\tilde{\psi}_{jk};\ j, k\in\mathbb{Z}\}$. The construction in [21] corresponds to a decomposition+reconstruction scheme in which the reconstruction filters differ from the decomposition filters. In this more general framework, complete symmetry *can* be achieved. Orthonormality is then lost, however, which is less desirable for some applications.

3. More regularity. The regularity of the wavelets ψ_n constructed in [15] increases linearly with their support width, $\psi_N\in C^{\alpha(N)}$, $\lim N^{-1}\alpha(N)=.2075$. The technique used in [15] to control the regularity of ϕ_N, ψ_N involved constructing $m_0(\xi)$ so that it contained the factor $\frac{1}{2}(1+e^{i\xi})$ with as high multiplicity as possible,

$$m_0(\xi)=\left(\frac{1+e^{i\xi}}{2}\right)^N Q_N(\xi), \tag{3.1}$$

where Q_N is a polynomial in $e^{i\xi}$ of order $N-1$ (see § 1). Since $\prod_{j=0}^{\infty}(1+\exp(i2^{-j}\xi))/2=e^{i\xi}(\sin\xi/\xi)$, we find (use (1.7))

$$\hat{\phi}_N(\xi)=e^{iN\xi/2}\left[\frac{\sin\xi/2}{\xi/2}\right]^N\prod_{j=1}^{\infty}Q_N(2^{-j}\xi).$$

Together with control on the infinite product of Q_N (see [15]), this leads to decay for $\hat{\phi}_N$ as $|\xi|\to\infty$, hence to regularity for ϕ_N, ψ_N.

In this argument, imposing high order divisibility of m_0 by $\frac{1}{2}(1+e^{i\xi})$ is used as a technical tool to obtain regularity. On the other hand, regularity for ϕ *implies* that m_0 is of type (3.1). More precisely, if ϕ is compactly supported and $\phi\in C^L$, then m_0 must be divisible by $[\frac{1}{2}(1+e^{i\xi})]^L$; see [22], [21]. Since $\phi_N\in C^{\mu N}$ for large N, with $\mu\simeq .2$, this means that at least $\frac{1}{5}$ of the factors $(1+e^{i\xi})$ in $m_{0,N}$ are necessary. Can the others be dispensed with, allowing even shorter support for the same regularity, or higher regularity for the same support width? The answer is yes.

In [11b], an alternative way was used to determine the regularity of functions ϕ satisfying an equation of type (1.4). Unlike the methods in [15], the method of [11b] does not use the Fourier transform. Instead, two N-dimensional matrices T_0, T_1 are defined, $(T_0)_{i,j}=c_{2i-j-1}$, $(T_1)_{i,j}=c_{2i-j}$, $1\leqq i, j\leqq N$, where we assume $c_n=0$ for $n<0$ or $n>N$. Divisibility of m_0 by $(1+e^{i\xi})$ with multiplicity L is equivalent to

$$\sum_{n=0}^{N} c_n(-1)^n n^l=0, \qquad l=0,\ldots,L-1. \tag{3.2}$$

In terms of the matrices T_0, T_1, this implies that there exists a flag of subspaces $U_1\subset\cdots\subset U_L$ of $\mathbb{R}^N$, with $\dim U_j=j$, such that

- U_j is left-invariant under both T_0, T_1.
- The left restrictions of T_0, T_1 to U_j have the j eigenvalues $1,\frac{1}{2},\ldots,2^{-j+1}$.

Let V_L be the subspace for $\mathbb{R}^N$ orthogonal to U_L; V_L is right invariant for T_0, T_1. If, for some $\lambda<1$, $C>0$, and for all $m\in\mathbb{N}$,

$$\|T_{d_1}\cdots T_{d_m}|_{V_L}\|\leqq C\lambda^m 2^{-m(L-1)} \qquad (d_j=1 \text{ or } 0), \tag{3.3}$$

then (3.2) implies that $\phi\in C^L$, and that its Lth derivative $\phi^{(L)}$ is Hölder continuous with exponent $|\log_2\lambda|$; if λ is best possible in (3.3), then $|\log_2\lambda|$ is the best possible Hölder exponent for $\phi^{(L)}$. In principle (3.3) involves infinitely many inequalities; in practice we substitute finitely many conditions sufficient to ensure that (3.3) holds for all m [11b, Prop. 3.11]. The value of ϕ and its derivatives at any point x in support (ϕ) is governed by the behavior of the infinite product $T_{d_1(x)}T_{d_2(x)}\cdots T_{d_m(x)}\cdots$, where $d_j(x)$ are the digits in the binary expansion of x, $x=\lfloor x\rfloor+\sum_{j=1}^{\infty} d_j(x)2^{-j}$. Special, "local" inequalities of type (3.3), valid only for certain sequences $(d_n)_{n\in\mathbb{N}}$, can, therefore, be translated into local regularity estimates, leading, in many examples, to a hierarchy of fractal sets corresponding to different local Hölder exponents. For more details, see [11b].

This approach can be used to study the regularity of compactly supported basis wavelets, which all correspond to an equation of type (1.4) with finitely many coefficients. For the examples of [15], this analysis was carried out in [11b] for $N=2,3,4$ (for higher N, checking (3.3) becomes very complicated). In these three cases, the best possible Hölder exponent for the highest order well-defined derivative of ϕ_N was determined; these results were significantly better than what had been obtained in [15] via Fourier analysis. Table 1 compares the regularity results of [15] and [11b].

The optimal estimates obtained in [11] illustrate again that some of the factors $(1+e^{i\xi})$ of m_0, or, equivalently, some of the sum rules (3.2), which we impose in order to obtain regularity, are "wasted" in the final construction. N sum rules can deliver up to $N-1$ continuous derivatives if everything else cooperates; because of the other constraints on the c_n (i.e., (1.8)), wavelets do not achieve this optimal number. We can, therefore, drop some of the sum rules, and use the additional degrees of freedom

TABLE 1
The regularity of the wavelets of [15], *as obtained via Fourier methods (middle column) or via the matrix method of* [11b] *(right column). to obtain better λ in (3.3), i.e., better regularity than in Table 1. We present here the cases of wavelets with support width 3 and 5.

For $|\text{support } \phi|=3$, there is a one-parameter family of choices c_n satisfying (1.8) and (1.10) (see [15, p. 946]), namely,

$$c_0=\frac{\nu(\nu-1)}{(\nu^2+1)},\quad c_1=\frac{(1-\nu)}{(\nu^2+1)},\quad c_2=\frac{(\nu+1)}{(\nu^2+1)},\quad c_3=\frac{\nu(\nu+1)}{(\nu^2+1)}.$$

These c_n satisfy $\sum c_n(-1)^n=0$; imposing a second sum rule leads to $\nu=\pm 3^{-1/2}$, which corresponds to the "standard" case $N=2$. The matrices T_0 and T_1 are 3×3-matrices; since we have one sum rule, we can restrict our attention to the reduced matrices $T_0|_{V_1}$, $T_1|_{V_1}$,

$$T_0|_{V_1}=\frac{1}{\nu^2+1}\begin{pmatrix}\nu(\nu-1) & 0\\ 1-\nu^2 & \nu(\nu+1)\end{pmatrix},\qquad T_1|_{V_1}=\frac{1}{\nu^2+1}\begin{pmatrix}\nu(\nu+1) & \nu(\nu-1)\\ 0 & 1-\nu^2\end{pmatrix}.$$

We restrict our attention to $\nu\geqq 0$. (A change of sign $\nu\to-\nu$ corresponds to $c_n\to c_{3-n}$, i.e., to mirroring ϕ with respect to $\frac{3}{2}$.) Since (3.3) has to hold, in particular when all the d_j are identical, $d_j\equiv 0$ or $d_j\equiv 1$, the constant λ is bounded below by the spectral radii $\rho(T_j|_{V_1})$ of $T_j|_{V_1}$, $j=0$ or 1. It follows that (3.3) can only be satisfied if $\nu<1$. For $\nu\geqq 1/\sqrt{3}$, we can find M so that both $MT_j|_{V_1}M^{-1}$, $j=0,1$, are symmetric; consequently,

$$\begin{aligned}\lambda &\leqq \max(\|MT_j|_{V_1}M^{-1}\|;\ j=0,1)=\max(\rho(MT_j|_{V_1}M^{-1});\ j=0,1)\\ &=\max(\rho(T_j|_{V_1});\ j=0,1)=\frac{\nu(\nu+1)}{1+\nu^2}.\end{aligned}$$

This is, moreover, the best possible λ. If $\nu<1/\sqrt{3}$, then $T_0|_{V_1}$ and $T_1|_{V_1}$ are not simultaneously "symmetrizable," and we have to do some more work. In every case

$$\lambda\geqq\max\left(\frac{\nu(\nu+1)}{1+\nu^2},\ \frac{1-\nu^2}{1+\nu^2}\right). \tag{3.4}$$

For $\nu=.25$, e.g., the tricks of Proposition 3.11 in [11b] suffice to show that equality holds in (3.4), and

$$\lambda=\frac{1-1/16}{1+1/16}=.88235\ldots.$$

The lowest value for the right-hand side of (3.4), and, therefore, the best candidate for the "most regular possible" ϕ, occurs for $\nu=.5$. In this case, $T_1|_{V_1}$ has only one (degenerate) eigenvalue, .6, and the matrix is not diagonalizable. Since (3.3) has to hold for $d_j\equiv 1$, it follows that we can at best hope to establish $\lambda=.6(1+\varepsilon)$.

In fact, we cannot achieve even this much. It turns out that $[\rho(T_0, T^{12})]^{1/13} \simeq .659676 \cdots > .6$, meaning that we can certainly not hope for a smaller λ than $.659 \cdots$. Using all the tricks in Proposition 3.11 in [11b], and checking a collection of building blocks with up to 17 factors, we find $\lambda \leqq .666$. More work leads to smaller upper bounds for λ; presumably the best value is the .659 obtained above.

Figure 3 shows the function ϕ for a few choices of ν ($\nu = .75$, .5 and .25). In each case ϕ is continuous, and we can compute its Hölder exponent from our estimate for λ. Even with our less than optimal estimate $\lambda \leqq .666$, the case $\nu = .5$ leads to a better Hölder exponent than the "standard" example $\nu = 1/\sqrt{3}$. This might be surprising: the graph of ϕ for $\nu = .5$ seems more jagged than for $\nu = 1/\sqrt{3}$. However, the peaks in the $\nu = .5$ example are "less sharp": the steepest slope of the peak around $x = 1$, e.g., is

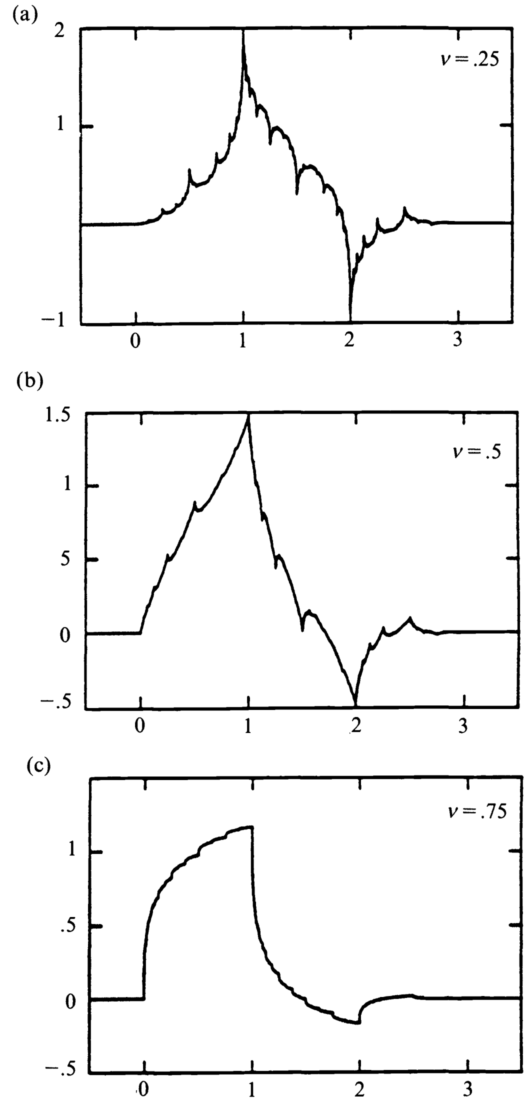

FIG. 3. *The functions ϕ defined by $c_0 = \nu(\nu+1)/(1+\nu^2)$, $c_1 = (\nu+1)/(\nu^2+1)$, $c_2 = (1-\nu)/(\nu^2+1)$, $c_3 = \nu(\nu-1)/(\nu^2+1)$, for different values of ν. As outlined in the text we can prove that the Hölder exponents of these functions are at least* (a) .180572, (b) .5864, (c) .251539. *For* a, c *these numbers are sharp: for* b *the true Hölder exponent is conjectured to be* .60017.

less steep than its counterpart for $\nu = 1/\sqrt{3}$, and this steepness is what is really expressed by a low Hölder exponent.

For |support ϕ| $= 5$ we have no analytical expression for all the possible choices of the c_n. Since the "standard" example, with its 3 sum rules, achieves C^1-regularity (see Table 1), for which at least 2 sum rules are necessary, we can drop at most one sum rule. We explore what this extra degree of freedom can give us by perturbing around the standard example. More precisely, we have

$$m_0(\xi) = \left(\frac{1+e^{i\xi}}{2}\right)^2 Q(\xi), \tag{3.5}$$

with

$$|Q(\xi)|^2 = P(\cos\xi), \tag{3.6}$$

$$P(x) = 2 - x + \frac{a}{4}(1-x)^2, \tag{3.7}$$

where a can be chosen freely, subject to the constraint that the right-hand side of (3.6) is nonnegative for all ξ. The example of [15] with support width 5 corresponds to m_0 with a zero of order 3 at $\xi = \pi$, hence to P with a zero at $x = -1$, which gives $a = 3$. If we impose that P has a zero close to $x = -1$, e.g., at $x = -1 - \delta$ (where $\delta \geqq 0$, since otherwise the positivity constraint would be violated), then $a = 4(\delta+3)/(\delta+1)(\delta+2)^2$, and $P(x) = (x+1+\delta)/(\delta+1)(\delta+2)^2[x^2(\delta+3) - x(\delta+3)^2 + 2(\delta+2)^2]$. The other two roots of P are, therefore, given by $x_\pm = \frac{1}{2}(\delta+3) \pm \frac{1}{2}[(\delta+3)^2 - 8(\delta+2)^2/(\delta+3)]^{1/2}$. Each of the three roots of $P(x)$, namely, $x_0 = -1-\delta$, and $x_\pm$, corresponds to two roots in $z = e^{i\xi}$ of $P(\cos\xi)$ (use $\frac{1}{2}(z+z^{-1}) = x \Rightarrow z = x \pm \sqrt{x^2-1}$). This leads to the candidates $Q_\varepsilon(\xi) = N(e^{i\xi} + \delta + 1 + \varepsilon\sqrt{\delta(\delta+2)})\ (e^{i\xi} - z_+(\delta))\ (e^{i\xi} - z_-(\delta))$, where $z_\pm(\delta) = x_\pm(\delta) - \sqrt{x_\pm(\delta)^2 - 1}$ and $\varepsilon = \pm 1$. The choice $\varepsilon = +1$ corresponds to choosing all the zeros of Q inside the unit circle; the choice $\varepsilon = -1$ gives one (real) zero outside, and two complex conjugate zeros inside the unit circle. For $\varepsilon = +1$, the choice $\delta = 0$ (i.e., the example of [15]) minimizes max $(\rho(T_0|_{V_2}), \rho(T_1|_{V_2}))$ (where ρ denotes the spectral radius), so that $\delta = 0$ leads to the most regular ϕ. For $\varepsilon = -1$, the situation is different. We find a minimum for max $(\rho(T_0|_{V_2}), (\rho(T_1|_{V_2}))$ at $\delta = .07645485\ldots$ (value determined numerically). As in the case where |support ϕ| $= 2$, this minimum for the spectral

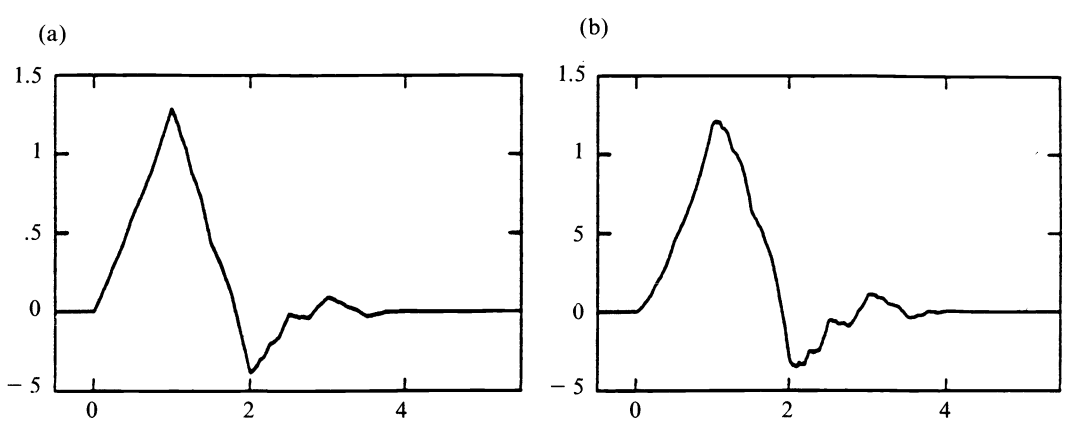

FIG. 4. *Two examples of* ϕ *with* |*support* ϕ| $= 5$. (a) *Corresponds to the construction in* [15], (b) *is the "most regular"* ϕ *constructed here. In both cases* $\phi \in C^1$; *the Hölder exponent of* ϕ' *is* .0878 *for* (a), *and at least* .40198 *for* (b) (*it is conjectured to be* .41762 *for* (b)).

radii $\rho(T_j|_{V_2})$ corresponds to a degenerate largest eigenvalue of $T_1|_{V_2}$, and we find again that $T_1|_{V_2}$ is not diagonalizable. Consequently, we can only hope to establish

$$\lambda \leqq 2(1+\varepsilon)\max\left(\rho(T_0|_{V_2}), \rho(T_1|_{V_2})\right) = (1+\varepsilon).74865\cdots.$$

In order to obtain $\varepsilon < .01$, we already have to consider a large number of building blocks $T_{d_1}\cdots T_{d_m}$, the longest of which has $d_j = 1$ for $j = 1, \ldots, m$, and $m \geqq 700$! It seems likely that arbitrarily small ε can be attained by more work. Figure 4 shows both the standard example of [15] and the most regular ϕ obtained here for $|\text{support } \phi| = 5$. It is apparent that the present example is much more regular; both functions are C^1 (even though the function of [15] seems to have peaks, these peaks are not really sharp—see [11b]), but the Hölder exponent of ϕ' is significantly better in the example constructed here.

4. Vanishing moments for ϕ. In this subsection we want to construct ϕ, ψ with compact support,

$$|\text{supp } \phi| = |\text{supp } \psi| = 2M - 1$$

and such that

$$\int dx\, \phi(x) = 1,$$

$$\int dx\, x^l \phi(x) = 0 \quad \text{for } l = 1, \ldots, L-1, \tag{4.1}$$

$$\int dx\, x^l \psi(x) = 0 \quad \text{for } l = 0, \ldots, L-1.$$

The need for orthonormal bases with this property first came up in the application of wavelet bases to numerical analysis in the work of Beylkin, Coifman, and Rokhlin [19]. The desirability of vanishing moments for ϕ is explained in the introduction: if (4.1) is satisfied, then the inner product of ϕ_{jk} with a smooth function f only depends on $f(2^j k)$ and derivatives of f of order $\geqq L$. (In a later version of their work, Beylkin, Coifman, and Rokhlin did not require (4.1), however.) Imposing such vanishing moments on ϕ also increases its symmetry. Because these orthonormal wavelet bases with vanishing moments for both ϕ and ψ were requested by Coifman, I have named these wavelets *coiflets*. Condition (4.1) corresponds to a *coiflet of order L*.

The Fourier transforms of ϕ, ψ are given by $\hat{\phi}(\xi) = \prod_{j=1}^{\infty} m_0(2^{-j}\xi)$ $\hat{\psi}(\xi) = m_1(\xi/2)\hat{\phi}(\xi/2)$, with

$$m_0(\xi) = \sum_{n=N_1}^{N_2} c_n e^{in\xi}, \qquad m_1(\xi) = \sum_n (-1)^n c_{-n+1} e^{in\xi} = -e^{i\xi}\overline{m_0(\xi+\pi)}.$$

Note that the lower limit N_1 in the sum over n will in general not be zero in this subsection: we have lost our freedom to translate by integers because (4.1) is not invariant under such translations (the conditions on ψ are translation-invariant, but the conditions on ϕ are not). The conditions (4.1) are equivalent to

$$\hat{\phi}(0) = 1, \quad \left(\frac{d^l}{d\xi^l}\hat{\phi}\right)(0) = 0 \quad \text{for } l = 1, \ldots, L-1,$$

$$\left(\frac{d^l}{d\xi^l}\hat{\psi}\right)(0) = 0 \quad \text{for } l = 0, \ldots, L-1.$$

In terms of m_0, these become

$$m_0^{(l)}(\xi+\pi)=0 \quad \text{for } l=0,\dots,L-1, \tag{4.2}$$

$$m_0(0)=1, \quad m_0^{(l)}(0)=0 \quad \text{for } l=1,\dots,L-1. \tag{4.3}$$

By (4.2), m_0 has a zero of order L in $\xi=\pi$. Consequently, m_0 has to be of the form

$$m_0(\xi)=\left(\frac{1+e^{i\xi}}{2}\right)^L Q(e^{i\xi}), \tag{4.4}$$

where

$$|Q(e^{i\xi})|^2=\sum_{j=0}^{L-1}\binom{L-1+j}{j}\left(\frac{1-\cos\xi}{2}\right)^j+\left(\frac{1-\cos\xi}{2}\right)^L R(\cos\xi), \tag{4.5}$$

and R is an odd polynomial [15]. On the other hand (4.3) implies

$$m_0(\xi)=1+(1-e^{i\xi})^L S(e^{i\xi}). \tag{4.6}$$

Together, (4.4) and (4.6) lead to L independent linear constraints on the coefficients of S. Imposing that Q be of the form (4.5), with R an odd polynomial, leads to further quadratic constraints. For small values of L, the whole collection of constraint equations can be solved more or less by hand; for values of L larger than 6, the situation becomes untractable. We propose, therefore, an approach which from the start satisfies (4.2) and (4.3) (the linear constraints on S are built in), and we tackle (4.5) afterwards.

For the sake of convenience, we restrict ourselves to L even, $L=2K$. A similar analysis can be carried out for L odd. We impose that m_0 be of the form

$$m_0(\xi)=\left(\cos^2\frac{\xi}{2}\right)^K\left[\sum_{k=0}^{K-1}\binom{K-1+k}{k}\left(\sin^2\frac{\xi}{2}\right)^k+\left(\sin^2\frac{\xi}{2}\right)^K f(\xi)\right]. \tag{4.7}$$

Since $\cos^2\xi/2=\frac{1}{4}e^{-i\xi}(1+e^{i\xi})^2$, this clearly has a zero of order $2K$ at $\xi=\pi$. On the other hand, (4.7) can be rewritten as (use (1.13))

$$m_0(\xi)=1+\left(\sin^2\frac{\xi}{2}\right)^K\left[-\sum_{k=0}^{K-1}\binom{K-1+k}{k}\left(\cos^2\frac{\xi}{2}\right)^k+\left(\cos^2\frac{\xi}{2}\right)^K f(\xi)\right].$$

This clearly satisfies (4.3). It remains, therefore, to tailor f so that m_0 satisfies (1.10).

For the sake of convenience we shall use f such that

$$f(\xi)=\sum_{n=0}^{K'} f_n e^{in\xi}, \tag{4.8}$$

i.e., $f_n=0$ for all $n<0$. This is by no means the only choice possible; we could also decide to distribute the f_n as symmetrically around zero as possible, so that the support of ϕ would be more symmetrical around $x=0$. It turns out, however, that this symmetrical choice can lead to larger support widths for ϕ than (4.8) (this happens, e.g., for $K=3$). From (4.5) we obtain

$$\begin{aligned}&\left|\sum_{k=1}^{K-1}\binom{K-1+k}{k}\left(\sin^2\frac{\xi}{2}\right)^k+\left(\sin^2\frac{\xi}{2}\right)^K f(\xi)\right|^2\\ &\quad=\sum_{j=0}^{2K-1}\binom{2K-1+j}{j}\left(\sin^2\frac{\xi}{2}\right)^j+\left(\sin^2\frac{\xi}{2}\right)^{2K} R(\cos\xi),\end{aligned} \tag{4.9}$$

where R is an odd polynomial. Rewriting (4.9) leads to

$$\begin{aligned}\left[\sum_{k=0}^{K-1}\binom{K-1+k}{k}s_2^k\right]^2+\sum_{k=0}^{K-1}\binom{K-1+k}{k}s_2^{k+K}[f(\xi)+\overline{f(\xi)}]\\ +s_2^{2K}|f(\xi)|^2=\sum_{j=0}^{2K-1}\binom{2K-1+j}{j}s_2^j+s_2^{2K}R(\cos\xi),\end{aligned}\tag{4.10}$$

where s_2 denotes $\sin^2(\xi/2)$. We shall determine the f_n by identifying coefficients of s_2^j.

Both $f(\xi)+\overline{f(\xi)}$ and $|f(\xi)|^2$ can be written as polynomials in $\cos\xi$, hence in s_2. It follows that only the first term in the left-hand side of (4.10), which is independent of f, contains terms in s_2^j with $j\leqq K-1$. Fortunately, these terms cancel the corresponding terms in s_2^j in the right-hand side of (4.10) because of the identity

$$\sum_{k=0}^{K}\binom{N_1-1+k}{k}\binom{N_2-1+K-k}{K-k}=\binom{N_1+N_2-1+K}{K}.\tag{4.11}$$

(See [26, (5.27)].)

We next concern ourselves with the terms in s_2^j, $j=K,\dots,2K-1$. Only the first two terms in the left-hand side of (4.10) contribute, leading to linear constraints in the f_n. Define g_n by

$$f(\xi)+\overline{f(\xi)}=\sum_{n=0}^{K'}g_ns_2^n.\tag{4.12}$$

Using $s_2=-\frac{1}{4}e^{-i\xi}(1-e^{i\xi})^2$, we find that the f_n and g_n are related through

$$\begin{aligned}f_0&=\frac{1}{2}\sum_{n=0}^{K'}\binom{2n}{n}4^{-n}g_n,\\ f_k&=(-1)^k\sum_{n=k}^{K'}\binom{2n}{n-k}4^{-n}g_n\quad\text{for } k\neq 0.\end{aligned}\tag{4.13}$$

In practice we will determine the g_n and then calculate the f_n and f via (4.13).

Identification of the terms in s_2^j, $j=K,\dots,2K-1$ on both sides of (4.10) gives

$$\begin{aligned}&\sum_{k=j-K+1}^{K-1}\binom{K-1+k}{k}\binom{K-1+j-k}{j-k}\\ &\qquad+\sum_{k=0}^{\min(K',j-K)}\binom{j-1-k}{j-K-k}g_k=\binom{2K-1+j}{j}.\end{aligned}$$

Using (4.11) again, and substituting $j=K+l$, $l=0,\dots,K-1$, we can reduce this to

$$\sum_{m=\max(0,l-K')}^{l}\binom{K-1+m}{m}g_{l-m}=2\sum_{k=0}^{l}\binom{K-1+k}{k}\binom{2K-1+l-k}{K+l-k}.\tag{4.14}$$

This is a system of K linear equations in $\min(K,K'+1)$ unknowns. It has no solutions if $K'+1<K$. If $K'\geqq K-1$, then the invertibility of the triangular matrix

$$M_{ij}=\binom{K-1+i-j}{i-j},\qquad K-1\geqq i\geqq j\geqq 0$$

immediately leads to

$$g_k=2\binom{2K-1+k}{K+k},\qquad k=0,\dots,K-1.$$

It remains to determine the $g_K, \dots, g_{K'}$. They are given by the constraint that

$$\sum_{k=0}^{K-1} \sum_{l=0}^{K'-K} \binom{K-1+k}{k} g_{K+l} s_2^{k+l} + |f(\xi)|^2 \tag{4.15}$$

should be an odd polynomial in $\cos \xi$. Since (4.15) can be rewritten as a polynomial of degree K' in $\cos \xi$, this results in $\lfloor (K'+1)/2 \rfloor$ equations for $K'-K+1$ unknowns. It follows that $K' \geqq 2K-1$ (no miraculous cancellations occur). In the examples worked out here, $K' = 2K-1$. In these examples a solution has to be found for a system of K quadratic equations in K unknowns; every such solution corresponds to a coiflet of order $2K$, with support width $3K-1$.

The system of K equations to be solved can be written out a little more explicitly. Writing x_m, $m = 0, \dots, K-1$ for the K unknown g_{K+m}, we have

$$|f(\xi)|^2 = \sum_{l=-(2K-1)}^{2K-1} e^{il\xi} \sum_{k=\max(0,-l)}^{\min(2K-1, 2K-1-l)} f_k \overline{f_{l+k}}$$

with

$$\begin{aligned} f_k = (1-\tfrac{1}{2}\delta_{k0})(-1)^k \Bigg[2 \sum_{n=k}^{K-1} \binom{2n}{n-k} 4^{-n} \binom{2K-1+n}{K+n} \\ + \sum_{m=0}^{K-1} \binom{2m+2K}{m+K-k} 4^{-m-K} x_m \Bigg], \qquad 0 \leqq k \leqq K-1 \end{aligned} \tag{4.16}$$

$$f_k = (-1)^k \sum_{m=k-K}^{K-1} \binom{2m+2K}{m+K-k} 4^{-m-K} x_m, \qquad K \leqq k \leqq 2K-1. \tag{4.17}$$

On the other hand, the first term in (4.15) can be rewritten as

$$\begin{aligned} &\sum_{j=0}^{2K-2} s_2^j \sum_{m=\max(0,j-K+1)}^{\min(j,K-1)} \binom{K-1+j-m}{j-m} x_m \\ &= \sum_{l=-(2K-2)}^{2K-2} e^{il\xi} (-1)^l \sum_{j=|l|}^{2K-2} 4^{-j} \binom{2j}{j+l} \sum_{m=\max(0,j-K+1)}^{\min(j,K-1)} \binom{K-1+j-m}{j-m} x_m. \end{aligned}$$

The K equations in the unknowns $x_0, \dots, x_{K-1}$ are, therefore,

$$\sum_{k=0}^{2(K-r)-1} f_k \overline{f_{2r+k}} + \sum_{j=2r}^{2K-2} 4^{-j} \binom{2j}{j+2r} \sum_{m=\max(0,j-K+1)}^{\min(j,K-1)} \binom{K-1+j-m}{j-m} x_m = 0, \tag{4.18}$$

where $r = 0, \dots, K-1$, and where (4.16), (4.17) have to be substituted for the f_k.

As a quadratic system (4.18) can have many solutions or no solutions at all. The following heuristic argument suggests that (4.18) will have solutions for sufficiently large K. We can rewrite (4.7) as

$$\begin{aligned} m_0(\xi) = \frac{1}{2} + 2^{-4K+1} K \binom{2K}{K} \sum_{k=0}^{K-1} \frac{(-1)^k}{2k+1} \binom{2K-1}{K+k} (e^{i(2k+1)\xi} + e^{-i(2k+1)\xi}) \\ + \left(\cos^2 \frac{\xi}{2}\right)^K \left(\sin^2 \frac{\xi}{2}\right)^K f(\xi). \end{aligned} \tag{4.19}$$

Let us concentrate on the first two terms in (4.19). For large K, the coefficient of $e^{i(2k+1)\xi}$ tends to

$$2^{-4K+1} K \binom{2K}{K} \frac{(-1)^k}{2k+1} \binom{2K-1}{K+k} \underset{K\to\infty}{\sim} \frac{(-1)^k}{\pi(2k+1)},$$

which is exactly the Fourier coefficient of the characteristic function $\chi(\xi)=1$ for $|\xi|\leqq\pi/2$, 0 for $|\xi|\geqq\pi/2$,

$$\chi(\xi)=\frac{1}{2}+\sum_{k=0}^{\infty}(-1)^k\frac{1}{\pi(2k+1)}(e^{i(2k+1)\xi}+e^{-i(2k+1)\xi}).$$

This is, in fact, a perfectly legitimate choice for m_0: $m_0=\chi$ leads to $\hat{\phi}(\xi)=1$ for $|\xi|\leqq\pi, 0$ otherwise, or $\phi(x)=\sin\pi x/\pi x$. The corresponding wavelet basis is C^∞, satisfies (4.1) for arbitrarily large L, but has rather slow decay at ∞. Our ansatz (4.7) or (4.19) for m_0 can, therefore, be viewed as a truncation to finite length of χ, consistent with the restrictions (4.2), (4.3), and where an additional f has to be introduced to fit (1.9). Since for $K\to\infty$, χ itself already satisfies all the conditions (1.9), (4.2), (4.3), it seems reasonable to hope that for large K, a slight perturbation of χ might satisfy (1.9), (4.2), (4.3).

Based on this perturbation argument, we can look for a solution to (4.18) "close to" $x_m\equiv 0$. For $K=1,2,3,4$, and 5 we have (1°) determined the system (4.18) with the symbolic manipulation package MACSYMA, (2°) found a solution by Newton's method, starting from the initial point $x_m\equiv 0$, $m=0,\dots,K-1$. The resulting m_0 are tabulated in Table 2. For $K=5$ the coefficients are given with less precision than for $K\leqq 4$ because the roundoff error, even with double precision, was sufficient to perturb decimals beyond the 10th decimal. Note that Table 2 corrects a mistake in the first entry in the corresponding Table 8.1 in [25]. Graphs for the corresponding ϕ, ψ can be found in [25, Fig. 8.3].

Remarks.

(1) The functions ϕ and ψ corresponding to Table 2 are almost symmetric. For some of these examples, there exists a pair of biorthogonal bases very close to the orthonormal basis (their graphs are almost indistinguishable), which have, moreover, the advantage of corresponding to rational c_n (see [21]).

(2) The approach given above has the merit of giving a method for the construction of coiflets of any order L (modulo the solution of a system of $L/2$ quadratic equations in $L/2$ variables). It does not necessarily give the smoothest coiflet of order L, however! For small L, everything can be worked out more or less by hand, and we find some solutions different from the coiflets given above.

For $L=2$, the smoothest coiflet is found by substituting

$$f(\xi)=a\,e^{i\xi}+b\,e^{2i\xi},$$

rather than (4.8) into (4.7), leading to a less symmetric coiflet with support width 5; in this case support $\phi=[-1,4]$. The system of quadratic equations reduces to a single equation, so that everything can be solved explicitly. We find

$$a=(s-1)/2,\quad b=(-s+3)/2,\quad \text{with } s=\pm\sqrt{15}.$$

The choice $s=-\sqrt{15}$ gives the most regular coiflet of order 2. The corresponding ϕ is plotted in Fig. 5. This ϕ is continuously differentiable; using the methods of [11] we find that its derivative has Hölder exponent .191814... .

For $L=4$, we find, unlike the $L=2$ case, that the best regularity for ϕ is achieved by distributing its support as symmetrically as possible. This corresponds to choosing

$$f(\xi)=a\,e^{-i\xi}+b+c\,e^{i\xi}+d\,e^{2i\xi}.$$

The resulting set of equations reduces to two linear and two quadratic equations. All this can be reduced to one equation for a of degree 4, which has 2 real and 2 complex solutions. One of the real roots leads to a twice continuously differentiable ϕ,

c_0= & .168333606358, & c_6= & .026019488227.
\end{array}$$

As in Table 2, these c_n are normalized so that their sum equals 1. We have plotted the corresponding ϕ in Fig. 6.

For $L=6$ explicit computation of all the solutions is more complicated, but still feasible. There exists no solution so that support $(\phi)=[-8,9]$. For the ansatz

$$f(\xi)=a\,e^{-i\xi}+b+c\,e^{i\xi}+d\,e^{2i\xi}+e\,e^{3i\xi}+f\,e^{4i\xi},$$

corresponding to support $(\phi)=[-7,10]$, there are two solutions. The most regular of these solutions is twice differentiable; it is given by

$$\begin{array}{rlrl}
c_{-7}= & -.000152916987, & c_2= & .269094527854,\\
c_{-6}= & .000315249697, & c_3= & .558133106629,\\

ORTHONORMAL BASES OF COMPACTLY SUPPORTED WAVELETS III. BETTER FREQUENCY RESOLUTION*

A. COHEN† AND INGRID DAUBECHIES‡

Abstract. Standard orthonormal bases of wavelets with dilation factor 2 use wavelets with one octave bandwidth. Orthonormal bases with $\frac{1}{2}$ octave or even smaller bandwidth wavelets are constructed. These wavelets are special cases of the "wavelet packet" construction by R. Coifman and Y. Meyer [Yale University, preprint, 1990].

Key words. wavelets, orthonormal bases, frequency resolution

AMS(MOS) subject classifications. 26A16, 26A18, 26A27, 39B12

1. Introduction. In the preceding paper [1] one of us showed how to construct variations to [2] in order to obtain orthonormal bases of compactly supported wavelets with various desirable properties. In this paper we show how to construct orthonormal bases with better frequency localization.

We shall continue to use here the notation and terminology given in [1, § 1]. When we need equation $(1.n)$ in [1], we shall refer to it as [1, $(1.n)$].

2. Statement of the problem. The Fourier transform $\hat{\psi}$ and ψ for an orthonormal wavelet basis of type [1, (1.1)] is, in most cases of practical interest, concentrated around a frequency band $a \leqq |\omega| \leqq 2a$. This "concentration" should be understood more or less loosely, depending on the example. For the Meyer basis [3], where $\hat{\psi}$ has compact support, we find support $(\hat{\psi}) \subset \{\omega;\ \pi - \varepsilon \leqq |\omega| \leqq 2\pi + 2\varepsilon\}$ for some $\varepsilon \in]0, \pi/3]$ (the "standard" choice is $\varepsilon = \pi/3$). For the functions constructed in [2], support$(\hat{\psi}) = \mathbb{R}$ (since support(ψ) is compact), but graphs of $\hat{\psi}$ show a reasonably good concentration around $\pi \leqq |\omega| \leqq 2\pi$ (see Fig. 7 in [2]).

It is the use of the dilation factor 2 in the definition [1, (1.1)] of the orthonormal basis that forces ψ to have a bandwidth of at least one octave. In many applications, especially those where a stationary high frequency component can be present (texture in images, music in acoustical signal analysis), it is desirable to have better frequency localization [4]. We present several approaches to the construction of such bases.

3. Noninteger dilation factors. Since the one-octave bandwidth is forced by the use of powers of 2, a natural way to obtain smaller bandwidth is to use a smaller dilation factor, e.g., $\frac{3}{2}$. There do indeed exist orthonormal wavelet bases for noninteger rational dilation factors α (for $\alpha = (k+1)/k$, $k \in \mathbb{N}$ this is an extension of Meyer's construction proposed by David [3]; for $\alpha = p/q$, a construction method is given in Auscher's Ph.D. thesis [5]). Unfortunately, these cannot correspond to a multiresolution analysis with compactly supported ϕ and ψ. For $\alpha = \frac{3}{2}$, e.g., $V_0 \subset V_{-1}$ implies the

‡ Mathematics Department, Rutgers University, New Brunswick, New Jersey 08903, and AT&T Bell Laboratories, 600 Mountain Avenue, Murray Hill, New Jersey 07974. Part of this author's work was done while visiting the University of Paris IX, Paris-Dauphine.

existence of two sequences, $(c_{1,n})_{n\in\mathbb{Z}}$ and $(c_{2,n})_{n\in\mathbb{Z}}$, such that

$$\phi(x)=\sum_n c_{1,n}\phi\left(\frac{3}{2}x-n\right),$$
(1)
$$\phi(x-1)=\sum_n c_{2,n}\phi\left(\frac{3}{2}x-n\right).$$

If ϕ were compactly supported, then both sequences would be finite. But (1) can be rewritten as

$$\frac{3}{2}\hat{\phi}\left(\frac{3}{2}\xi\right)=\left(\sum_n c_{1,n}\,e^{in\xi}\right)\hat{\phi}(\xi),$$

$$\frac{3}{2}e^{i3\xi/2}\hat{\phi}\left(\frac{3}{2}\xi\right)=\left(\sum_n c_{2,n}\,e^{in\xi}\right)\hat{\phi}(\xi),$$

implying

$$\sum_n c_{1,n}\,e^{in\xi}=e^{i3\xi/2}\sum_n c_{2,n}\,e^{in\xi},$$

which is impossible for finite sequences. The same phenomenon occurs for any noninteger α.

In practical applications, it is desirable to have finite sequences c_n for the hierarchic decomposition + reconstruction scheme sketched in [1, § 1]. We can, of course, always use truncated versions of infinite sequences, but untruncated finite sequences are preferable. Therefore, noninteger α does not seem to be a good solution. (Note, however, that Kovačević and Vetterli [10] have constructed subband filtering schemes with FIR filters and rational noninteger dilation factors; these do not correspond to a multiresolution analysis with a single ϕ.)

4. Integer dilation factors larger than 2. Another candidate for wavelet bases with better frequency localization is given by constructions with a dilation factor *larger* than 2. In general, a multiresolution scheme with dilation factor N uses one scaling function ϕ, and $N-1$ different wavelets ψ^l, $l=1,\dots,N-1$ [5]. The function ϕ satisfies an equation of type [1, eqn. (1.4)], $\phi(x)=\sum_n c_n\phi(Nx-n)$, or $\hat{\phi}(\xi)=m_0(\xi/N)\hat{\phi}(\xi/N)$, with $m_0(\xi)=N^{-1}\sum_n c_n\,e^{in\xi}$. The different ψ^l can all be written as linear combinations of the $\phi(Nx-n)$. There exist, therefore, trigonometric polynomials m_l so that $\hat{\psi}^l(\xi)=m_l(\xi/N)\hat{\phi}(\xi/N)$ (we assume compact support for ϕ and the ψ^l, so that m_0 and the m_l are indeed polynomials and not infinite series). Orthonormality of the different subspaces in the multiresolution analysis then implies that the $N\times N$ matrix $\mathbb{M}(\xi)$ with entries

$$\mathbb{M}_{lk}(\xi)=m_{l-1}\left(\xi+\frac{2\pi}{N}(k-1)\right)$$

is unitary for all ξ [5]. For $N=2$, this reduces to the standard requirements $m_1(\xi)=e^{i\xi}\overline{m_0(\xi+\pi)}\lambda(\xi)$, with $|\lambda(\xi)|=1$, and $\lambda(\xi+\pi)=\lambda(\xi)$, and $|m_0(\xi)|^2+|m_0(\xi+\pi)|^2=1$. The second condition is [1, eqn. (1.9)] again. If both m_0 and m_1 are trigonometric polynomials, then the only possible choices for $\lambda(\xi)$ are $\lambda(\xi)=\lambda\,e^{ik\xi}$, with $\lambda\in\mathbb{C}$, $|\lambda|=1$ and $k\in\mathbb{Z}$. The simplest choice $\lambda(\xi)\equiv 1$ corresponds to [1, eqn. (1.6)].

For general N, the step of one resolution space V_j to the coarser space V_{j+1} corresponds to a jump of $\log_2 N$ octaves in frequency, since there is a dilation factor N between the two resolutions, and every factor 2 corresponds to one octave. Each of the $N-1$ wavelets ψ^l corresponds therefore to, on average, a bandwidth of

$(N-1)^{-1}\log_2 N$. For $N=4$, for instance, we would have 3 wavelets for 2 octaves, corresponding to an average $\frac{2}{3}$-octave per wavelet, which is better than the 1-octave bandwidth attained by bases with $N=2$.

This naive computation of the average bandwidth of the ψ^l is deceptive, however, as illustrated by the following example. Given an orthonormal wavelet basis with dilation factor 2, the following easy trick generates an orthonormal wavelet basis with dilation factor 4. Let us, for this paragraph only, use a tilde to distinguish the wavelets, spaces in the multiresolution analysis, etc.... for the $N=4$ construction from their counterparts in the $N=2$ case. Define

$$\tilde{m}_0(\xi)=m_0(\xi)m_0(2\xi),$$
$$\tilde{m}_1(\xi)=m_0(\xi)m_1(2\xi),$$
$$\tilde{m}_2(\xi)=m_1(\xi)m_1(2\xi),$$
$$\tilde{m}_3(\xi)=m_1(\xi)m_0(2\xi),$$

where $m_1(\xi)=e^{i\xi}\overline{m_0(\xi+\pi)}$, and $m_0(\xi)$ is the trigonometric polynomial associated with the given orthonormal wavelet basis with $N=2$. Because m_0 satisfies [1, eqn. (1.9)], we easily check that the 4×4 matrix $\tilde{\mathbb{M}}(\xi)$ is indeed unitary for all ξ. The corresponding function $\tilde{\phi}$ is given by

$$\hat{\tilde{\phi}}(\xi)=\prod_{j=1}^{\infty}\tilde{m}_0(4^{-j}\xi)=\prod_{j=1}^{\infty}[m_0(2^{-2j}\xi)m_0(2^{-2j+1}\xi)]=\prod_{j=1}^{\infty}m_0(2^{-j}\xi)=\hat{\phi}(\xi),$$

so that $\tilde{\phi}\equiv\phi$. The scaling spaces $\tilde{V}_j$, spanned by the $\tilde{\phi}(4^{-j}x-k)$, are, therefore, the subsequence of scaling spaces V_m with even index, $\tilde{V}_j=V_{2j}$. The wavelets $\tilde{\psi}^l$, $l=1,2,3$ are given by

$$\hat{\tilde{\psi}}^l(\xi)=\hat{\tilde{m}}_l\left(\frac{\xi}{4}\right)\hat{\phi}\left(\frac{\xi}{4}\right).$$

In particular,

$$\hat{\tilde{\psi}}^1(\xi)=m_1\left(\frac{\xi}{2}\right)m_0\left(\frac{\xi}{4}\right)\hat{\phi}\left(\frac{\xi}{4}\right)=m_1\left(\frac{\xi}{2}\right)\hat{\phi}\left(\frac{\xi}{2}\right)=\hat{\psi}(\xi),$$

or $\tilde{\psi}^1\equiv\psi$. Since the function ψ is essentially a 1-octave bandwidth function, this shows that the computation above of the average bandwidth of $\frac{2}{3}$-octave for the $\tilde{\psi}^l$ was indeed naive and misleading. The other two wavelets, $\tilde{\psi}^2$, $\tilde{\psi}^3$, are functions not existing in the $N=2$ case, which have in fact better frequency localization. They generate spaces $\tilde{W}_j^2$, $\tilde{W}_j^3$, which together with $\tilde{W}_j^1=W_{2j}$ complement $\tilde{V}_j=V_{2j}$ to constitute $\tilde{V}_{j-1}=V_{2j-2}$,

$$V_{2j-2}=V_{2j}\oplus W_{2j}\oplus\tilde{W}_j^2\oplus\tilde{W}_j^3.$$

Since $V_{2j}\oplus W_{2j}=V_{2j-1}$, it follows that $\tilde{W}_j^2\oplus\tilde{W}_j^3=W_{2j-1}$. This construction of an $N=4$ multiresolution analysis from an $N=2$ case corresponds therefore to a splitting of all the odd-indexed W_{2j-1} into two spaces, each of approximately $\frac{1}{2}$-octave bandwidth functions, while the even-index W_{2j} remain untouched, and are still generated by 1-octave bandwidth functions.

In the next section we show how to do better than this construction by splitting *every* W_j (as opposed to only the odd-indexed ones) into two parts.

5. Wavelet bases with $\frac{1}{2}$-octave bandwidth wavelets. At the end of the previous section, we had split W_1 into two $\frac{1}{2}$-octave spaces, $\tilde{W}_1^2\oplus\tilde{W}_1^3$. Dyadic dilations of these spaces are then $\frac{1}{2}$-octave components for any W_m, and these spaces can be used to decompose all of $L^2(\mathbb{R})$. This decomposition can also be derived directly. The key idea is to start from a conventional multiresolution analysis with dilation factor 2, and to split every space W_j into two $\frac{1}{2}$-octave bandwith subspaces. They key to this splitting is [1, eqn. (1.8)] and the computation leading to [1, eqn. (1.11)]. As shown in [1, § 1], condition [1, (1.8)] ensures that [1, (1.4)] and [1, (1.6)] define an orthonormal basis transform in V_{-1}, from $\{\sqrt{2}\phi(2x-n);\ n\in\mathbb{Z}\}$ to $\{\phi(x-n), \psi(x-n);\ n\in\mathbb{Z}\}$. For the argument to work, it is not essential that the functions appearing in the two sides of [1, (1.4)] are dilated versions of each other. The same argument would work just as well for *any* function f such that the $f(x-k)$ constitute an orthonormal set; with the definitions

$$g_1(x)=2^{-1/2}\sum_n c_n f(x-n),$$

$$g_2(x)=2^{-1/2}\sum_n (-1)^n c_{-n+1} f(x-n),$$

the functions $(g_1(x-2n), g_2(x-2m))_{n,m\in\mathbb{Z}}$ are another orthonormal basis for $\overline{\text{Span}\,(f(x-k))}$.

Given α_n satisfying [1, (1.8)], i.e., $\sum_n \alpha_n\alpha_{n+2k}=2\delta_{k0}$, we can therefore define, for any basic wavelet ψ, the functions $\tilde{\psi}_1$, $\tilde{\psi}_2$ by

$$\tilde{\psi}_1(x)=2^{-1/2}\sum_n \alpha_n\psi(x-n)$$

$$\tilde{\psi}_2(x)=2^{-1/2}\sum_n (-1)^n\alpha_{-n+1}\psi(x-n); \tag{2}$$

the functions $\tilde{\psi}_1(x-2n)$, $\tilde{\psi}_2(x-2n)$ then constitute an orthogonal basis for W_0; consequently $(2^{-j/2}\tilde{\psi}_1(2^{-j}x-2n), 2^{-j/2}\tilde{\psi}_2(2^{-j}x-2n);\ j, n\in\mathbb{Z})$ is an orthonormal basis for $L^2(\mathbb{R})$. The Fourier transforms of $\tilde{\psi}_1$, $\tilde{\psi}_2$ will be concentrated on respectively the higher and lower half of the bandwidth of ψ. The bandwidth of $\tilde{\psi}_1$ is, therefore, approximately $\log_2\frac{4}{3}=2-\log_2 3$ octaves, that of $\tilde{\psi}_2$ approximately $\log_2\frac{3}{2}=\log_2 3-1$ octaves. The supportwidth of $\tilde{\psi}_1$, $\tilde{\psi}_2$ will of course be larger than that of ψ.

In Fig. 1 we show two different constructions of $\tilde{\psi}_1$, $\tilde{\psi}_2$, built from two different functions ψ. In each case we have chosen for α_n the same coefficients c_n as used for the definition of ψ (via [1, (1.4)], [1, (1.6)]). We may, of course, also choose different α_n. The support width of $\tilde{\psi}_1$, $\tilde{\psi}_2$ is twice as large as that of ψ. In general, we have

$$|\text{support}(\tilde{\psi}_1)|=|\text{support}\,(\tilde{\psi}_2)|=(\#\text{ of nonzero }\alpha_n)-1$$
$$+(\#\text{ of nonzero }c_n)-1.$$

For the choice $\alpha_n=c_n$ made in Fig. 1, we have, therefore,

$$|\text{support}\,(\tilde{\psi}_1)|=|\text{support}\,(\tilde{\psi}_2)|=2|\text{support}\,(\psi)|.$$

Note that with the choice $\alpha_n=c_n$ the two wavelets constructed here are (up to dilation) exactly the two "new" wavelets constructed in the previous section.

The plots of $|\hat{\tilde{\psi}}_1|$, $|\hat{\tilde{\psi}}_2|$ in Fig. 1 have "side-lobes" that make the splitting less than perfect. Such side-lobes are unavoidable. We have

$$\hat{\tilde{\psi}}_1(\xi)=a(\xi)\hat{\psi}(\xi), \qquad \hat{\tilde{\psi}}_2(\xi)=e^{i\xi}\overline{a(\xi+\pi)}\hat{\psi}(\xi),$$

with $a(\xi)=2^{-1/2}\sum_n \alpha_n e^{in\xi}$. Condition [1, (1.8)] implies $|a(\xi)|^2+|a(\xi+\pi)|^2=2$. For small $|\xi|\leqq\xi_0$ we have $|\hat{\tilde{\psi}}_1|\simeq\sqrt{2}|\hat{\psi}|$, or $|a(\xi)|\simeq\sqrt{2}$. Consequently, $|a(\xi+\pi)|\simeq 0$ for $|\xi|\leqq\xi_0$. Since a is periodic, this implies $|a(\xi+\pi)|\simeq 0$ for $|\xi-2\pi|\leqq\xi_0$, or $|a(\xi)|\simeq\sqrt{2}$, hence $|\hat{\tilde{\psi}}_1|\simeq\sqrt{2}|\hat{\psi}|$ in this region also. This causes the "side-lobes" on the figure. The only way to reduce them is to start from ψ with very concentrated Fourier transform

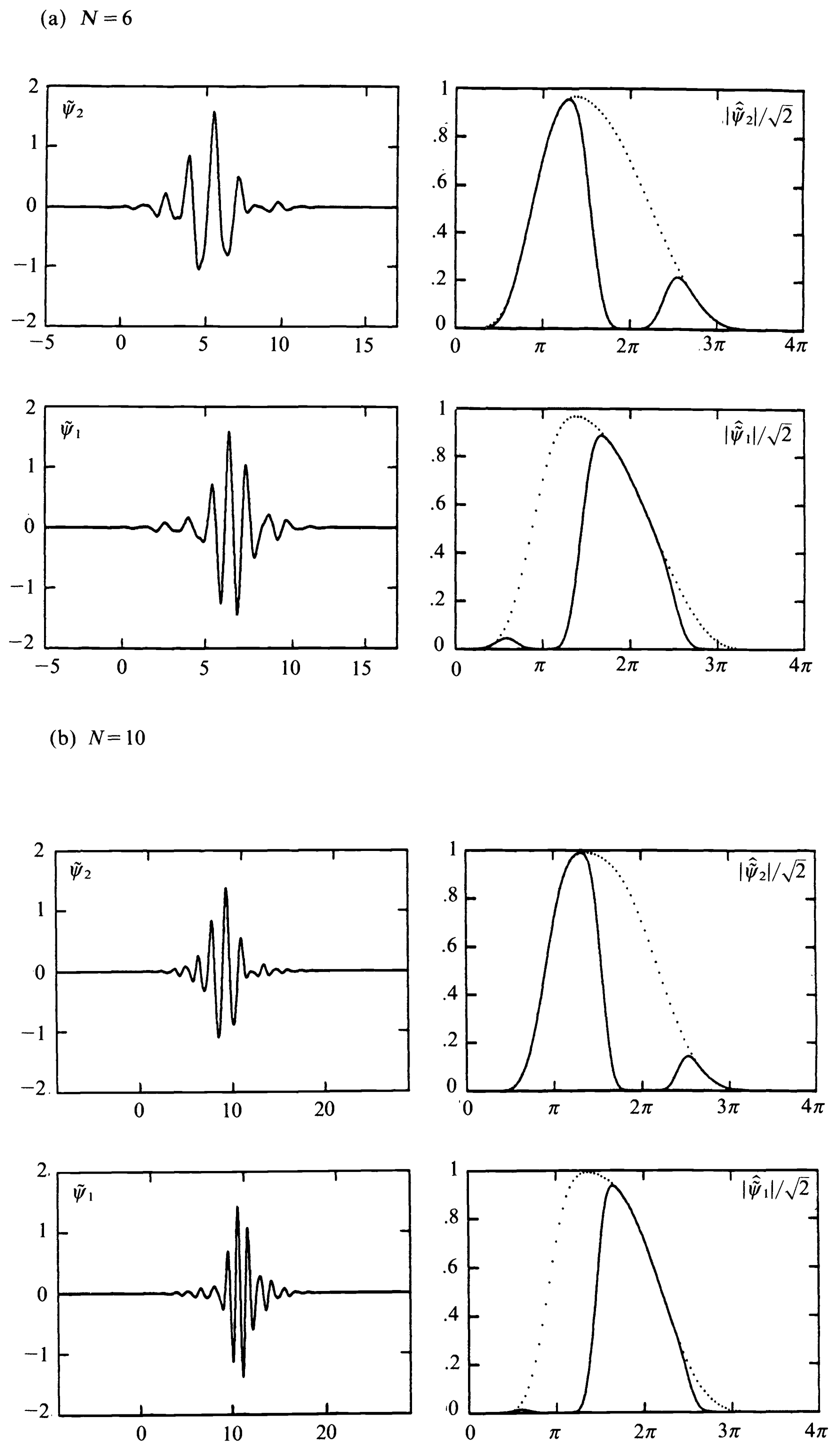

FIG. 1. *Graphs of the "$\frac{1}{2}$-octave bandwidth" functions* $\tilde\psi_1$, $\tilde\psi_2$ *and the absolute values of their Fourier transforms* $|\hat{\tilde\psi}_1|$, $|\hat{\tilde\psi}_2|$. *The dotted line in each case is the graph of* $|\hat\psi|$. *We have* $2|\hat\psi|^2 = |\hat{\tilde\psi}_1|^2 + |\hat{\tilde\psi}_2|^2$. (*This is clearly illustrated by the graphs. Note that we have plotted* $|\hat{\tilde\psi}_1|/\sqrt{2}$ *and* $|\hat{\tilde\psi}_2|/\sqrt{2}$ *in order to make the comparison with* $|\hat\psi|$.) *In both cases the* α_n (*see* (2)) *are the same as the coefficients* c_n *from which* ψ *is defined*; *the function* ψ *in these two examples corresponds to* (a) *the case* $N=6$ *in* [1, § 2] *and* (b) *the case* $N=10$ *in* [1, § 2].

$|\hat{\psi}|$. This is why the effect becomes less pronounced as N increases. (The Fourier transform $|\hat{\psi}|$ becomes more concentrated as N increases; see Fig. 7 in [2].)

Remarks.

(1) In case even better frequency localization is desired, this splitting trick can be repeated: we can replace ψ by $2j$ functions, each corresponding to a 2^{-j}-octave bandwidth, and which have to be translated by integer multiples of 2^j,

$$\overline{\text{Span}\,\{\psi(x-n)\}}=\overline{\text{Span}\,\{\tilde{\psi}_l(x-2^jm);\ l=1,\dots,2^j,\ m\in\mathbb{Z}\}}.$$

At every splitting, the "side-lobe effect" takes its toll, however, marring the frequency localization; see [8].

(2) The functions $\tilde{\psi}_1$, $\tilde{\psi}_2$ constructed are special cases of the "wavelet packets" discovered by Coifman and Meyer [6], which in one framework encompass many different choices of orthonormal bases, of which the wavelet is one extreme example. Another extreme within the same framework is a basis closer in spirit to the windowed Fourier transform; infinitely many intermediate choices are possible; see [9] for applications.

6. Multidimensional "splitting." The "splitting trick" also allows selective splitting in higher-dimensional multiresolution analysis. For the sake of simplicity we restrict ourselves to two dimensions. A standard way of generating a two-dimensional wavelet basis from a one-dimensional multiresolution analysis is to define [7]

$$\begin{aligned}\Phi(x,y)&=\phi(x)\phi(y),\\ \Psi^1(x,y)&=\psi(x)\phi(y),\\ \Psi^2(x,y)&=\phi(x)\psi(y),\\ \Psi^3(x,y)&=\psi(x)\psi(y).\end{aligned}\tag{3}$$

The orthonormal basis of wavelets is then given by the $\Psi^l_{j,k}$, with $l=1,2,3$, $j\in\mathbb{Z}$ and $k=(k_1,k_2)\in\mathbb{Z}^2$ defined by

$$\Psi^l_{j,k}(x,y)=2^{-j}\Psi^l(2^{-j}x-k_1,2^{-j}y-k_2).$$

A good way to visualize what this construction means is to look at it in the Fourier plane for the special choice $\hat{\phi}(\xi)=(2\pi)^{-1/2}$ if $|\xi|\leqq\pi$, 0 otherwise, and the corresponding $\hat{\psi}(\xi)=(2\pi)^{-1/2}$ if $\pi<|\xi|\leqq 2\pi$, 0 otherwise. We easily check that for this choice the space V_j is exactly $L^2([-2^{-j}\pi,2^{-j}\pi])$, and $W_j=L^2([-2^{-j+1}\pi,-2^{-j}\pi]\cup[2^{-j}\pi,2^{-j+1}\pi])$, so that the whole ladder of one-dimensional multiresolution spaces can be simply represented by the supports of the corresponding functions. Of course, these particular ϕ and ψ decay too slowly to be useful in practice, but the visualization they lead to in Fourier space is still "morally true" for other, more useful choices, even though the splitting is not as clean cut. The two-dimensional multiresolution spaces $\mathbf{V}_j$, and their complement spaces $\mathbf{W}^l_j$, generated by (3) can also be written

$$\begin{aligned}\mathbf{V}_j&=V_j\otimes V_j,\\ \mathbf{W}^1_j&=W_j\otimes V_j,\\ \mathbf{W}^2_j&=V_j\otimes W_j,\\ \mathbf{W}^3_j&=W_j\otimes W_j.\end{aligned}$$

For the special choices of ϕ, ψ described above, these two-dimensional spaces are again L^2-spaces of particular domains carved out in the Fourier plane. For instance, $\mathbf{V}_j = L^2([-2^{-j}\pi, 2^{-j}\pi]) \otimes L^2([-2^{-j}\pi, 2^{-j}\pi]) = L^2([-2^{-j}\pi, 2^{-j}\pi] \times [-2^{-j}\pi, 2^{-j}\pi])$; in particular, $\mathbf{V}_0 = L^2([-\pi, \pi]^2)$. For every j, the sum $\mathbf{W}_j^1 \oplus \mathbf{W}_j^2 \oplus \mathbf{W}_j^3$ is the orthogonal complement in $\mathbf{V}_{j-1}$ of $\mathbf{V}_j$, which corresponds to the annulus $[-2^{-j+1}\pi, 2^{-j+1}\pi]^2 \backslash [-2^{-j}\pi, 2^{-j}\pi]^2$. All this is visualized in Fig. 2(a): the small central square corresponds to (say) $\mathbf{V}_0$; adding to it the two vertical rectangles corresponding to $\mathbf{W}_0^1$, the two horizontal rectangles for $\mathbf{W}_0^2$, and the four corner squares for $\mathbf{W}_0^3$ lead to the bigger square representing $\mathbf{V}_{-1}$. The structure then repeats in the next annulus, to constitute $\mathbf{V}_{-2}$. The angular resolution in the Fourier plane of this scheme is not very good, as shown by the figure. Figure 2(b) shows what the same two-dimensional construction looks like when we start from a one-dimensional multiresolution analysis with dilation factor 4, as given in § 4. In this case the one-dimensional scheme has already three wavelets,

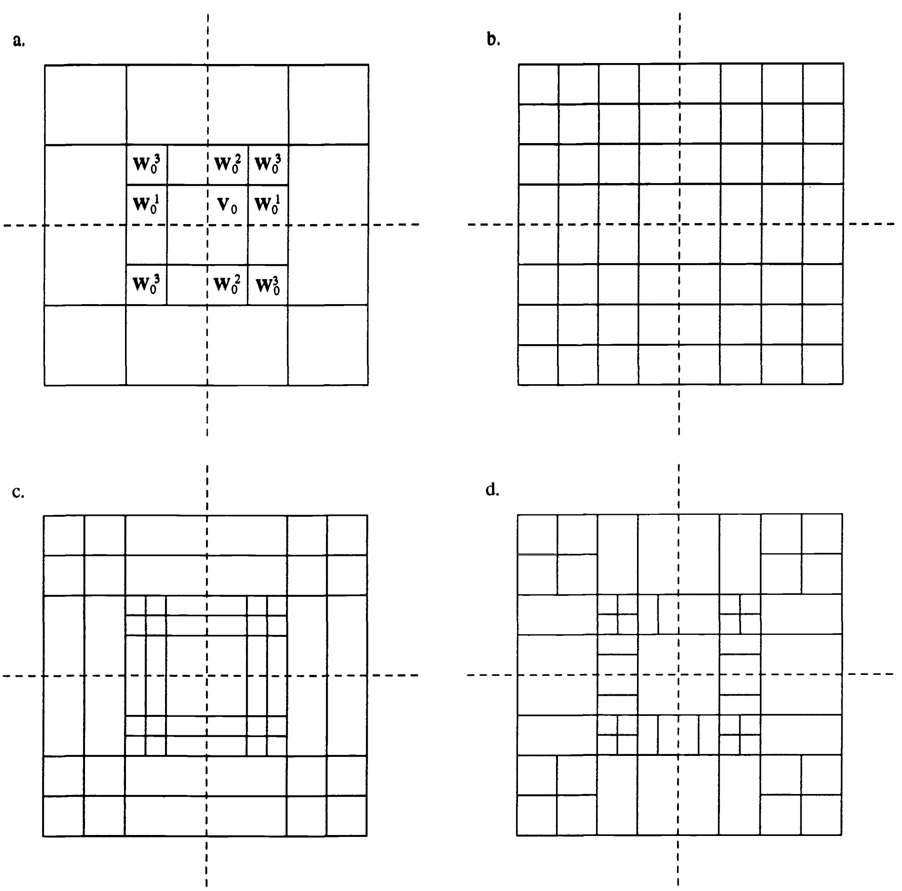

FIG. 2. *Visualization of the localization in the Fourier plane achieved by various two-dimensional multiresolution schemes*:

(a) *the standard product scheme starting from a one-dimensional analysis with dilation factor* 2,

(b) *product scheme from a one-dimensional analysis with dilation factor* 4, *derived from a multiresolution analysis with factor* 2 *as in* § 4,

(c) *product scheme from a one-dimensional analysis with two* $\frac{1}{2}$*-octave bandwidth wavelets rather than one* 1*-octave bandwidth wavelet*,

(d) *a nonproduct scheme obtained by the "splitting trick."*

so that the two-dimensional product scheme ends up with $2\times 3+3^2=15$ wavelets. Figure 2(b) represents one step (with dilation 4) in the multiresolution scale, as compared to two steps (with dilation factor 2), i.e., two successive annuli in Fig. 2(a). The central part of the two pictures is identical; the only difference between the two pictures is that the outer annulus of Fig. 2(a) is split into many pieces to give Fig. 2(b), while the inner annulus is untouched. This corresponds to the "splitting of one level out of two" shown at the end of § 4. The result is good angular resolution for some wavelets (corresponding to the outer layer in Fig. 2(b)), bad for others (corresponding to the most central rectangles in Fig. 2(b)).

Figure 2(c) shows the same picture again, with two steps in a multiresolution analysis with dilation factor 2, but for a product structure of type (3) starting from the two $\frac{1}{2}$-octave bandwidth wavelets constructed in § 5, rather than the 1-octave bandwidth wavelet ψ. The scaling function Φ is the same, but there are now $2\times 2+2^2=8$ wavelets (as opposed to 3 for Fig. 2(a), and 15 for Fig. 2(b)). Figure 2(c) can be obtained from Fig. 2(a) by splitting every annulus (inner as well as outer) into halves by cuts in both horizontal and vertical directions. This improves the angular resolution on the squares in the corners (corresponding to the $\mathbf{W}_j^3$ of Fig. 2(a), but does nothing for the angular resolution of the rectangles (corresponding to $\mathbf{W}_j^2$ or $\mathbf{W}_j^1$ in Fig. 2(a)), which were split better in the outer annulus of Fig. 2(b). The best angular resolution can be obtained by giving up a product structure analogous to (3) and just carving up every one of the $\mathbf{W}_j^l$ spaces of Fig. 2(a) vertically and/or horizontally, by applying the "splitting trick" in x and/or y, until the desired resolution is achieved. An example is given in Fig. 2(d). This still corresponds to an orthonormal basis, and to a fast algorithm for decomposing and reconstructing functions, as described in [1, § 1], although the organization is somewhat more complex. If even better angular resolution is required, then we can repeat the splitting trick as many times as necessary.

Acknowledgment. I. Daubechies would like to thank Professor Y. Meyer and the University of Paris IX for inviting her and for their hospitality.

MARKOV–BERNSTEIN AND NIKOLSKII INEQUALITIES, AND CHRISTOFFEL FUNCTIONS FOR EXPONENTIAL WEIGHTS ON (–1,1)*

D. S. LUBINSKY[†] AND E. B. SAFF[‡]

Abstract. Exponential weights $w := e^{-Q}$ are considered, where $Q : (-1,1) \to \mathbf{R}$ is even, convex, and sufficiently smooth. For example, the results may be applied to

$$w(x) := (1-x^2)^{\alpha}, \qquad \alpha > 0,$$
$$w(x) := \exp(-(1-x^2)^{-\alpha}), \qquad \alpha > 0, \quad \text{or}$$
$$w(x) := \exp(-\exp_k(1-x^2)^{-\alpha}), \quad \alpha > 0, \quad k \geq 1,$$

where $\exp_k = \exp(\exp(\cdots))$ denotes the kth iterated exponential.

Weighted Markov and Bernstein inequalities such as

$$\|P'w\|_{L_\infty[-1,1]} \leq CQ'(a_{2n})\|Pw\|_{L_\infty[-1,1]},$$

and

$$|P'w|(x) \leq \frac{Cn}{\sqrt{1-|x|/a_n}}\|Pw\|_{L_\infty[-1,1]}, \qquad |x| < a_n,$$

are established for polynomials P of degree at most n. Here a_n is the nth Mhaskar–Rahmanov–Saff number for Q. For the special weights listed above, a more explicit form is given to $Q'(a_{2n})$. Estimates are deduced for Christoffel functions such as

$$\sup_{x\in[-1,1]} \lambda_n^{-1}(w^2,x)w(x) \leq CQ'(a_{2n}),$$

and also Nikolskii inequalities.

Key words. Markov–Bernstein inequalities, Nikolskii inequalities, non-Szegő weights, Christoffel functions, orthogonal polynomials

AMS(MOS) subject classifications. primary 41A17, 42C05; secondary 41A10

1. Introduction and statement of results. Throughout, $\mathcal{P}_n$ denotes the class of real polynomials of degree at most n, and $\|\cdot\|_{L_p(\mathcal{S})}$ denotes the L_p norm over any measurable $\mathcal{S} \subset \mathbf{R}$ $(0 < p \leq \infty)$. Furthermore, C, C_1, $C_2, \ldots,$ denote positive constants independent of n, $P \in \mathcal{P}_n$, and $x \in \mathbf{R}$, which are not necessarily the same in different occurrences.

The classical inequalities of Markov and Bernstein are, respectively,

$$\|P'\|_{L_\infty[-1,1]} \leq n^2\|P\|_{L_\infty[-1,1]} \tag{1.1}$$

and

$$|P'(x)| \leq n(1-x^2)^{-1/2}\|P\|_{L_\infty[-1,1]} \tag{1.2}$$

for $P \in \mathcal{P}_n$ and $|x| < 1$. The interest in these inequalities lies in their application to rates of approximation by polynomials, to discretisation procedures, to approximation processes, and so on.

Naturally, such important inequalities have been generalized to treat a host of situations, such as in L_p spaces, and with weights inserted. We cannot hope here to review the history and the contributions of the many authors. A fairly typical example of those in the literature is [1, Thm. 8.4.7, p. 107]:

$$\|P'(x)\sqrt{1-x^2}w(x)\|_{L_p[-1,1]} \leq Cn\|Pw\|_{L_p[-1,1]}, \tag{1.3}$$

$P \in \mathcal{P}_n$, $n \geq 1$. Here $0 < p \leq \infty$, and $w(x)$ is either a Jacobi weight $(1-x)^\alpha(1+x)^\beta$, where α, $\beta > -1$, or something similar. See [15, Thm. 19, p. 164], [1], [2], [3] for further discussion and references.

The aim of this paper is to treat weights $w(x)$ that may decay more rapidly at ± 1 than Jacobi weights; for example,

$$w(x) := W_{0,\alpha}(x) := \exp(-(1-x^2)^{-\alpha}), \qquad \alpha > 0, \tag{1.4}$$

or

$$w(x) := W_{k,\alpha}(x) := \exp(-\exp_k[(1-x^2)^{-\alpha}]), \quad \alpha > 0, \quad k \geq 1, \tag{1.5}$$

where

$$\exp_k := \exp(\exp(\exp\cdots)) \quad (k \text{ times})$$

denotes the kth iterated exponential. However, our results apply equally well to the classical ultraspherical weight

$$w(x) := (1-x^2)^\alpha, \qquad \alpha > 0.$$

For $\alpha = \frac{1}{2}$, the weight $W_{0,\alpha}$ of (1.4) is similar to a Pollaczek weight, and its orthogonal polynomials were considered in [15, pp. 82–83]. Asymptotics, and spacing of zeros of the orthogonal polynomials for $W_{k,\alpha}$, have been considered in [2], [12].

To the best of our knowledge, the Markov–Bernstein inequalities in this paper are new for the weights $W_{k,\alpha}$ for all the range of parameters. To those with an interest in orthogonal polynomials, it is noteworthy that Szegő's condition

$$\int_{-1}^{1} \frac{\log w(x)}{\sqrt{1-x^2}}dx > -\infty \tag{1.6}$$

is violated by $W_{0,\alpha}$ of (1.4) if $\alpha \geq \frac{1}{2}$ and by all the weights $W_{k,\alpha}$ of (1.5). Since the Markov–Bernstein inequalities have various applications to orthogonal polynomials associated with non-Szegő weights, such as estimates for Christoffel functions, they are of particular interest.

In fact, the results of this paper bear a close resemblance to results for exponential weights on the real line [4], [5], [6], [9], [10], [17], and more specifically to Erdös weights $W^2 = e^{-2Q}$ on $\mathbf{R}$: These have the property that Q grows faster than any polynomial at infinity.

In the analysis of those weights, and the ones treated in this paper, the Mhaskar–Rahmanov–Saff number plays an important role. Let us suppose that $w = e^{-Q}$, where $Q : (-1,1) \to \mathbf{R}$ is even, and differentiable in (0,1). Suppose, furthermore, that $tQ'(t)$ is positive and increasing in (0,1) with limits zero and infinity at zero and 1, respectively, and

$$\int_0^1 \frac{tQ'(t)}{\sqrt{1-t^2}}dt = \infty. \tag{1.7}$$

Then the uth Mhaskar–Rahmanov–Saff number, $a_u = a_u(Q)$, is defined to be the root of

$$(1.8) \qquad u = \frac{2}{\pi}\int_0^1 \frac{a_u t Q'(a_u t)}{\sqrt{1-t^2}}dt, \qquad u > 0.$$

The importance of a_u lies in the identity (cf. [13], [14])

$$(1.9) \qquad \|Pw\|_{L_\infty[-1,1]} = \|Pw\|_{L_\infty[-a_n,a_n]}, \quad P \in \mathcal{P}_n, \quad n \geq 1,$$

which we refer to as the *Mhaskar–Saff identity.* Of course $a_n \to 1$ as $n \to \infty$. As an illustration of its rate of approach, we note that for $w = W_{0,\alpha}$,

$$(1.10) \qquad 1 - a_n \sim n^{-1/(\alpha+1/2)}, \qquad n \to \infty,$$

and for $w = W_{k,\alpha}$,

$$(1.11) \qquad 1 - a_n \sim (\log_k n)^{-1/\alpha}, \qquad n \to \infty,$$

where $\log_k = \log(\log(\log\cdots))$ (k times) denotes the kth iterated logarithm. Furthermore, we are using $\sim$ in the sense of [15]: if $\{c_n\}_{n=1}^\infty$ and $\{d_n\}_{n=1}^\infty$ are real positive sequences, then

$$c_n \sim d_n, \qquad n \to \infty,$$

means that for n large enough,

$$C_1 \leq \frac{c_n}{d_n} \leq C_2.$$

We are now ready to define our class of weights.

DEFINITION 1.1. Let $w := e^{-Q}$, where

(i) Q is even and continuously differentiable in (-1,1), while Q'' is continuous in (0,1);

(ii) $Q' \geq 0$ and $Q'' \geq 0$ in (0,1);

(iii) $\int_0^1 (tQ'(t))/(\sqrt{1-t^2})dt = \infty$;

(iv) Let

$$(1.12) \qquad T(x) := 1 + \frac{xQ''(x)}{Q'(x)}, \qquad x \in (0,1).$$

We assume that

$$(1.13) \qquad \begin{array}{ll} \text{(a)} & T \text{ is increasing in } (0,1); \\ \text{(b)} & T(0+) > 1; \\ \text{(c)} & T(x) = O(Q'(x)),\ x \to 1^-. \end{array}$$

Under the above conditions, we write $w \in \mathcal{W}$.

We remark that (1.13) is a rather weak regularity condition, while (iii) is required for the existence of a_n. Further, we note that most of our results really only require the above hypotheses to be satisfied for x near 1. However, for simplicity, we shall not pursue this point. In any event, $W_{k,\alpha} \in \mathcal{W}$, $k \geq 0$, $\alpha > 0$.

Following are our Markov–Bernstein inequalities for $P'w$.

THEOREM 1.2. *Let $w \in \mathcal{W}$.*

(i) *For $n \geq 1$ and $P \in \mathcal{P}_n$,*

$$\|P'w\|_{L_\infty[-1,1]} \leq CnT(a_{2n})^{1/2}\|Pw\|_{L_\infty[-1,1]}. \tag{1.14}$$

(ii) *For $n \geq 1$, $P \in \mathcal{P}_n$, and $|x| < a_n$,*

$$|P'w|(x) \leq \frac{Cn}{\sqrt{1-|x|/a_n}}\|Pw\|_{L_\infty[-1,1]}. \tag{1.15}$$

We remark that under mild additional conditions, which are satisfied for $W_{k,\alpha}$ for all $k \geq 0$, $\alpha > 0$,

$$nT(a_{2n})^{1/2} \sim Q'(a_{2n}), \qquad n \to \infty, \tag{1.16}$$

(see Lemma 3.2(ii) below), so one may reformulate (1.14) as

$$\|P'w\|_{L_\infty[-1,1]} \leq CQ'(a_{2n})\|Pw\|_{L_\infty[-1,1]}. \tag{1.17}$$

One may combine (1.14) and (1.15) as follows:

COROLLARY 1.3. *Let $w \in \mathcal{W}$. For $n \geq 1$, $P \in \mathcal{P}_n$, and $x \in [-1,1]$,*

$$|P'w|(x) \leq \frac{Cn}{|1-|x|/a_n|^{1/2} + T(a_{2n})^{-1/2}}\|Pw\|_{L_\infty[-1,1]}. \tag{1.18}$$

The above is the analogue of the classical consequence of (1.1) and (1.2):

$$|P'(x)| \leq \frac{Cn}{|1-|x||^{1/2}+n^{-1}}\|P\|_{L_\infty[-1,1]}, \quad P \in \mathcal{P}_n, \quad x \in (-1,1).$$

As examples of Theorem 1.2, we present the following.

COROLLARY 1.4. (i) *Let $\alpha > 0$ and $W_{0,\alpha}$ be given by (1.4). Then for $n \geq 1$ and $P \in \mathcal{P}_n$,*

$$\|P'W_{0,\alpha}\|_{L_\infty[-1,1]} \leq Cn^{(2\alpha+2)/(2\alpha+1)}\|PW_{0,\alpha}\|_{L_\infty[-1,1]}. \tag{1.19}$$

(ii) *Let $k \geq 1$, $\alpha > 0$, and $W_{k,\alpha}$ be given by (1.5). Then for $n \geq 1$ and $P \in \mathcal{P}_n$,*

$$\|P'W_{k,\alpha}\|_{L_\infty[-1,1]} \leq Cn\left[\prod_{j=1}^{k}\log_j n\right]^{1/2}(\log_k n)^{(\alpha+1)/2\alpha}\|PW_{k,\alpha}\|_{L_\infty[-1,1]}. \tag{1.20}$$

(iii) *Let $\alpha > 0$ and $w(x) := (1-x^2)^\alpha$. Then for $n \geq 1$ and $P \in \mathcal{P}_n$,*

$$\|P'w\|_{L_\infty[-1,1]} \leq Cn^2\|Pw\|_{L_\infty[-1,1]}. \tag{1.21}$$

We remark that under mild additional conditions involving Q''', which hold for $W_{k,\alpha}$, $k \geq 0$, $\alpha > 0$, we can show that (1.14) is sharp with respect to the dependence on n. The proof is lengthy, and involves analysis of L_∞ extremal polynomials for w. For the proof in a closely related situation, we refer the reader to [7, pp. 71–78]. Note that (1.21) is a classical inequality for ultraspherical weights [1].

Next, we turn to inequalities for $(Pw)'$. These are different from those for $P'w$, since for x close to a_n, $|(Pw)'|(x)$ admits a far better estimate than $|P'w|(x)$. A similar situation occurs for Erdös weights on $\mathbf{R}$ (cf. [6]).

THEOREM 1.5. *Let $w \in \mathcal{W}$. Then*
(a) *For $n \geq 1$, $P \in \mathcal{P}_n$ and $|x| < a_n$,*

$$(1.22) \qquad |(Pw)'(x)| \leq \frac{Cn}{(1-|x|/a_n)^{1/2} + T(a_{2n})^{-1/2}} \|Pw\|_{L_\infty[-1,1]};$$

(b) *For $n \geq 1$, $P \in \mathcal{P}_n$ and $|x| \leq a_n$,*

$$(1.23) \qquad |(Pw)'(x)| \leq CnT(a_{2n}) \left\{ \left(1 - \frac{|x|}{a_n}\right)^{1/2} + (nT(a_{2n}))^{-1/3} \right\} \|Pw\|_{L_\infty[-1,1]}.$$

In particular,

$$(1.24) \qquad |(Pw)'(a_n)| \leq C(nT(a_{2n}))^{2/3} \|Pw\|_{L_\infty[-1,1]}.$$

Note that for suitable A, and $|x|/a_n \geq 1 - AT(a_{2n})^{-1}$, (1.23) provides a better estimate than (1.22), while for $|x|/a_n < 1 - AT(a_{2n})^{-1}$, (1.22) provides a better estimate.

Next, we turn to estimates of *Christoffel functions.* Recall that the nth Christoffel function for w^2 is

$$(1.25) \qquad \lambda_n(w^2, x) := \inf_{P \in \mathcal{P}_{n-1}} \frac{1}{P^2(x)} \int_{-1}^{1} (Pw)^2(t)\,dt, \qquad x \in (-1,1).$$

It turns out that a particularly simple way to find upper bounds for λ_n^{-1} involves the Markov–Bernstein inequality for w. This idea has been used elsewhere [7].

THEOREM 1.6. *Let $w \in \mathcal{W}$. Then for $n \geq 1$,*

$$(1.26) \qquad \sup_{x \in [-1,1]} \lambda_n^{-1}(w^2, x) w^2(x) \leq CnT(a_{2n})^{1/2}.$$

We note that this result is sharp under mild additional conditions on Q; see [9] for the proof in a similar situation. As a corollary of the above estimate, we obtain Nikolskii inequalities.

COROLLARY 1.7. *Let $w \in \mathcal{W}$ and $0 < p < q \leq \infty$. Then for $n \geq 1$ and $P \in \mathcal{P}_n$,*

$$(1.27) \qquad \|Pw\|_{L_q[-1,1]} \leq C(nT(a_{2n})^{1/2})^{1/p - 1/q} \|Pw\|_{L_p[-1,1]}.$$

This paper is organized as follows. In §2, we present the basic ingredients of the proof—contour integral estimates, and integral equations with logarithmic kernel. In §3, we prove some technical lemmas. In §4, we present estimates for the measure $\mu_n(x)$, and in §5, we estimate the majorisation function $U_n(x+iy)$. In §6, we prove the Markov–Bernstein inequalities, and in §7, we prove Theorems 1.6 and Corollary 1.7.

2. The two basic ingredients. The first ingredient is potential theory and an integral equation used in majorisation of weighted polynomials.

LEMMA 2.1. *Let $w := e^{-Q} \in \mathcal{W}$. For $n \geq 1$, let $a_n = a_n(Q)$ be the root of* (1.8). *For $x \in (-1,1) \backslash \{0\}$, let*

$$(2.1) \qquad \mu_n(x) := \frac{2}{\pi^2} \int_0^1 \frac{\sqrt{1-x^2}}{\sqrt{1-s^2}} \frac{a_n s Q'(a_n s) - a_n x Q'(a_n x)}{n(s^2 - x^2)} ds.$$

Furthermore, let

$$\chi_n := \frac{2}{\pi}\int_0^1 \frac{Q(a_n t)}{\sqrt{1-t^2}}\,dt + n\log 2, \tag{2.2}$$

and for $z \in \mathbf{C}$ such that $|z| < 1/a_n$, let

$$U_n(z) := \int_{-1}^1 (\log|z-t|)\mu_n(t)\,dt - \frac{Q(a_n|z|)}{n} + \frac{\chi_n}{n}. \tag{2.3}$$

(a) *Then for almost every $x \in (-1,1)$,*

$$0 < \mu_n(x) < \infty, \tag{2.4}$$

$$\int_{-1}^1 \mu_n(x)dx = 1, \tag{2.5}$$

and

$$\int_{-1}^1 \frac{\mu_n(x)}{1-x}dx = \frac{Q'(a_n)}{n}. \tag{2.6}$$

(b) *Furthermore,*

$$U_n(x) = 0, \qquad x \in [-1,1], \tag{2.7}$$

and

$$(xU_n'(x))' < 0, \quad U_n(x) < 0, \quad U_n'(x) < 0, \quad x \in \left(1, \frac{1}{a_n}\right). \tag{2.8}$$

(c) *For $n \geq 1$, $P \in \mathcal{P}_n$ and $z \in \mathbf{C}$ such that $|z| < 1$,*

$$|P(z)w(|z|)| \leq \|Pw\|_{L_\infty[-a_n,a_n]} \exp\left(nU_n\left(\frac{z}{a_n}\right)\right). \tag{2.9}$$

Furthermore,

$$\|Pw\|_{L_\infty[-1,1]} = \|Pw\|_{L_\infty[-a_n,a_n]}, \tag{2.10}$$

and if P is not identically zero,

$$|Pw|(x) < \|Pw\|_{L_\infty[-a_n,a_n]}, \qquad |x| > a_n. \tag{2.11}$$

Proof. See [11, Lemmas 5.1, 5.2, pp. 28–34]. One sets $f(x) := Q(a_n x)$, $x \in [-1/a_n, 1/a_n]$ in [11].

(a) The constant B in [11, eqn. (5.4), p. 28] is zero in view of (1.8), and the function μ_n above is the function $g(f;t)$ or $L[f'](t)$ of [11]. Then (2.5) and (2.6) are, respectively, (5.6) and (5.23) in [11].

(b) The identity (2.7) follows from [11, eqn. (5.1), p. 28]. Furthermore, (5.25) and (5.26) in [11, p. 23] ensure that $U_n'(a_n) = U_n(a_n) = 0$ and the first relation in (2.8), which is (5.27) in [11, p. 32], then implies the other two.

(c) See [13, pp. 74–75], or see [11, p. 51]. □

Next, we turn to estimates for derivatives of weighted polynomials, derived via Cauchy's integral formula. This method has been used elsewhere [4], [6].

LEMMA 2.2. *Let $w \in \mathcal{W}$. Let $x \in (-1,1)$, $\epsilon \in (0, 1-|x|)$, and $P \in \mathcal{P}_n$ for some $n \geq 1$. Then*

$$(2.12) \qquad |(Pw)'(x)| \leq \epsilon^{-1} e^{\tau} \|Pw\|_{L_\infty[-1,1]} \max_{|t-x|=\epsilon} \exp\left(nU_n\left(\frac{t}{a_n}\right)\right),$$

where

$$(2.13) \qquad \tau := \begin{cases} Q'(3\epsilon)2\epsilon, & \text{if } |x| \leq 2\epsilon, \\ \left[\frac{Q'(|x|+\epsilon)}{|x|} + Q''(|x|+\epsilon)\right]2\epsilon^2 & \text{if } |x| > 2\epsilon. \end{cases}$$

Proof. Fix $x \in (-1,1)$ and define the entire function

$$\hat{w}(t) := \exp(-Q(x) - Q'(x)(t-x)), \qquad t \in \mathbf{C},$$

so that $\hat{w}^{(j)}(x) = w^{(j)}(x)$, $j = 0, 1$. Then

$$(2.14) \qquad \begin{aligned} |(Pw)'(x)| = |(P\hat{w})'(x)| &= \left|\frac{1}{2\pi i}\int_{|t-x|=\epsilon} \frac{(P\hat{w})(t)}{(t-x)^2}dt\right| \\ &\leq \frac{1}{\epsilon}\max_{|t-x|=\epsilon} |P\hat{w}|(t) \\ &\leq \frac{1}{\epsilon}\max_{|t-x|=\epsilon} |\hat{w}(t)/w(|t|)| \cdot \max_{|t-x|=\epsilon} |P(t)w(|t|)| \\ &\leq \frac{1}{\epsilon}\max_{|t-x|=\epsilon} |\hat{w}(t)/w(|t|)| \cdot \|Pw\|_{L_\infty[-1,1]} \cdot \max_{|t-x|=\epsilon} \exp(nU_n(t/a_n)), \end{aligned}$$

by (2.9). It remains to estimate $|\hat{w}(t)/w(|t|)|$. Suppose first that $|x| \leq 2\epsilon$. Then for $|t-x| = \epsilon$,

$$(2.15) \qquad \begin{aligned} |\hat{w}(t)/w(|t|)| &= \exp(-Q(x) - Q'(x)(\operatorname{Re} t - x) + Q(|t|)) \\ &\leq \exp(-Q(|x|) + Q'(2\epsilon)\epsilon + Q(|x|+\epsilon)), \end{aligned}$$

where we have used the monotonicity of Q and Q'. Finally,

$$Q(|x|+\epsilon) - Q(|x|) \leq Q'(|x|+\epsilon)\epsilon \leq Q'(3\epsilon)\epsilon,$$

and (2.13) follows for $|x| \leq 2\epsilon$.

Next, suppose $x > 2\epsilon$. Then

$$(2.16) \qquad \begin{aligned} -Q(x) - Q'(x)(\operatorname{Re} t - x) + Q(|t|) &= Q(|t|) - Q(\operatorname{Re} t) \\ &\quad + Q(\operatorname{Re} t) - Q(x) - Q'(x)(\operatorname{Re} t - x) \\ &= Q'(\xi)(|t| - \operatorname{Re} t) + \tfrac{1}{2}Q''(\eta)(\operatorname{Re} t - x)^2, \end{aligned}$$

where ξ lies between $\operatorname{Re} t$ and $|t|$, and η lies between $\operatorname{Re} t$ and x. Here $\xi, \eta \in [x-\epsilon, x+\epsilon]$. Furthermore, by the elementary inequality $(a^2+b^2)^{1/2} \leq a + b^2/a$, for $a, b > 0$,

$$|t| - \operatorname{Re} t \leq \frac{(\operatorname{Im} t)^2}{\operatorname{Re} t} \leq \frac{\epsilon^2}{x-\epsilon} \leq \frac{2\epsilon^2}{x},$$

so

$$Q'(\xi)(|t| - \operatorname{Re} t) \le \frac{2Q'(x+\epsilon)\epsilon^2}{x}. \tag{2.17}$$

Furthermore, $uQ''(u) = Q'(u)(T(u) - 1)$ is increasing in (0,1), so

$$\eta Q''(\eta) \le (x+\epsilon)Q''(x+\epsilon),$$

and hence

$$Q''(\eta) \le \frac{x+\epsilon}{x-\epsilon}Q''(x+\epsilon) \le 3Q''(x+\epsilon).$$

Then

$$\tfrac{1}{2}Q''(\eta)(\operatorname{Re} t - x)^2 \le \tfrac{3}{2}\epsilon^2 Q''(x+\epsilon). \tag{2.18}$$

Combining (2.14) to (2.18) yields (2.13) for $x \ge 2\epsilon$, and the case $x \le -2\epsilon$ is similar. □

3. Technical lemmas. In this section, we present some elementary consequences of the hypothesis $w \in \mathcal{W}$.

LEMMA 3.1. *Let* $w = e^{-Q} \in \mathcal{W}$.

(i) *We have for* $0 < x \le Lx < 1$,

$$L^{T(x)} \le \frac{LxQ'(Lx)}{xQ'(x)} \le L^{T(Lx)}. \tag{3.1}$$

(ii) $Q'(x)$ *and* $xQ''(x)$ *are increasing in* $(0,1)$.

(iii)

$$\frac{xQ''(x)}{Q'(x)} \sim T(x) \quad \textit{in } (0,1]. \tag{3.2}$$

(iv)

$$\frac{Q'(x)}{x} \le (T(0+) - 1)^{-1}Q''(x) \quad \textit{in } (0,1], \tag{3.3}$$

and

$$Q'(0) = 0. \tag{3.4}$$

(v)

$$\int_0^{1/2} \frac{Q'(x)}{x}dx < \infty. \tag{3.5}$$

Proof. (i) Now

$$\frac{LxQ'(Lx)}{xQ'(x)} = \exp\left(\int_x^{Lx} \frac{d}{dt}\log[tQ'(t)]dt\right) = \exp\left(\int_x^{Lx} \frac{T(t)}{t}dt\right).$$

Here the monotonicity of T ensures that

$$T(x)\log L \le \int_x^{Lx} \frac{T(t)}{t}dt \le T(Lx)\log L.$$

Then (3.1) follows.

(ii) Since

$$xQ''(x) = (T(x) - 1)Q'(x), \tag{3.6}$$

the monotonicity of T and Q' yields the monotonicity of $xQ''(x)$.

(iii) By (3.6), for $x \in (0,1)$,

$$xQ''(x) = T(x)Q'(x)\left(1 - \frac{1}{T(x)}\right)\begin{cases} \le T(x)Q'(x) \\ \ge T(x)Q'(x)\left(1 - \frac{1}{T(0+)}\right). \end{cases}$$

(iv) Firstly, (3.6), the monotonicity of T and the fact that $T(0+) > 1$ yield (3.3). Next, the evenness of Q and continuity of Q' force (3.4).

(v) If $0 < \delta < \frac{1}{2}$, inequality (3.3) yields

$$\int_\delta^{1/2} \frac{Q'(s)}{s} ds \le (T(0+) - 1)^{-1}\left[Q'(1/2) - Q'(\delta)\right].$$

Now let $\delta \to 0+$. □

LEMMA 3.2. *Let $w = e^{-Q} \in \mathcal{W}$ and $a_n = a_n(Q)$, $n \ge 1$.*

(i) *For $j = 1, 2$ and n large enough,*

$$Q^{(j)}(a_n) = O(nT(a_n)^{j-1/2}). \tag{3.7}$$

(ii) *If also*

$$\frac{Q'(x)}{Q(x)} \sim T(x), \qquad x \text{ near } 1, \tag{3.8}$$

then for $j = 0, 1, 2$, and n large enough,

$$Q^{(j)}(a_n) \sim nT(a_n)^{j-1/2}. \tag{3.9}$$

(iii) *We have*

$$Q'(a_n) = O(n^2); \tag{3.10}$$

$$T(a_n) = O(n^2). \tag{3.11}$$

(iv) *For $t \in (0, \infty)$,*

$$\frac{1}{tT(0+)} \ge \frac{a_t'}{a_t} \ge \frac{1}{tT(a_t)}. \tag{3.12}$$

(v) *For $u \in (0, \infty)$ and $r \ge 1$,*

$$\frac{a_{ru}}{a_u} \ge 1 + \frac{\log r}{T(a_{ru})}. \tag{3.13}$$

Proof.

$$\text{(i)} \qquad \frac{n}{a_nQ'(a_n)} = \frac{2}{\pi}\int_0^1 \frac{a_ntQ'(a_nt)}{a_nQ'(a_n)}\frac{1}{\sqrt{1-t^2}}dt$$

$$\begin{aligned}&\geq \frac{2}{\pi}\int_0^1 t^{T(a_n)}\frac{1}{\sqrt{1-t^2}}dt \quad \text{(by (3.1))}\\ (3.14)\qquad &\geq \frac{2}{\pi}\left(1-\frac{1}{T(a_n)}\right)^{T(a_n)}\int_{1-1/T(a_n)}^1 \frac{1}{\sqrt{1-t^2}}dt\\ &\geq C\left(1-\frac{1}{T(0+)}\right)^{T(0+)} T(a_n)^{-1/2}.\end{aligned}$$

Then (3.7) follows for $j=1$, and (3.2) implies it for $j=2$.

(ii) From (3.14),

$$\begin{aligned}\frac{n}{a_nQ'(a_n)} &\leq \frac{2}{\pi}\int_0^{1-1/T(a_n)}\frac{Q'(a_nt)}{Q'(a_n)}\frac{1}{\sqrt{1-t^2}}dt+\frac{2}{\pi}\int_{1-1/T(a_n)}^1\frac{1}{\sqrt{1-t^2}}dt\\ &\leq C_1T(a_n)^{1/2}\int_0^1\frac{Q'(a_nt)}{Q'(a_n)}dt+C_1T(a_n)^{-1/2}\\ &= C_1T(a_n)^{1/2}\frac{Q(a_n)-Q(0)}{a_nQ'(a_n)}+C_1T(a_n)^{-1/2}\\ &\leq C_2T(a_n)^{1/2}\frac{Q(a_n)}{a_nQ'(a_n)}+C_1T(a_n)^{-1/2}\leq C_3T(a_n)^{-1/2},\end{aligned}$$

n large enough, by (3.8) and monotonicity of Q. Hence

$$a_nQ'(a_n)\sim nT(a_n)^{1/2}.$$

Then (3.2) yields (3.9) for $j=2$, and (3.8) yields it for $j=0$.

(iii) From (3.7) and (1.13),

$$Q'(a_n)=O(nT(a_n)^{1/2})=O(nQ'(a_n)^{1/2}),$$

whence (3.10) follows. Then (1.13) yields (3.11).

(iv) Differentiating (1.8) with respect to u yields

$$\begin{aligned}1&=\frac{2}{\pi}\int_0^1\frac{d}{du}(a_utQ'(a_ut))\frac{dt}{\sqrt{1-t^2}}\\ &=\frac{2}{\pi}\int_0^1 T(a_ut)Q'(a_ut)a_u't\frac{dt}{\sqrt{1-t^2}}\\ &=\frac{a_u'}{a_u}\frac{2}{\pi}\int_0^1 T(a_ut)a_utQ'(a_ut)\frac{dt}{\sqrt{1-t^2}}.\end{aligned}$$

Since

$$T(0+)\leq T(a_ut)\leq T(a_u),\qquad t\in(0,1],$$

we obtain (3.12) from (1.8).

(v)

$$\frac{a_{ru}}{a_u} = \exp\left(\int_u^{ru} \frac{a_t'}{a_t} dt\right) \;\geq\; \exp\left(\int_u^{ru} \frac{dt}{tT(a_t)}\right)$$

$$\geq \exp\left(\frac{\log r}{T(a_{ru})}\right) \;\geq\; 1 + \frac{\log r}{T(a_{ru})}. \qquad \square$$

LEMMA 3.3. *Let $w \in \mathcal{W}$.*

(i) *For $0 < \alpha < \Delta$, we have*

$$\frac{a_{\Delta n} Q'(a_{\Delta n})}{a_{\alpha n} Q'(a_{\alpha n})} \geq \frac{\Delta}{\alpha} > 1, \qquad n \geq 1. \tag{3.15}$$

(ii) *For $n \geq 1$ and $x \in [-1, 1]$,*

$$a_n x Q'(a_n x)(1 - |x|)^{1/2} \leq Cn. \tag{3.16}$$

Furthermore, for $n \geq 1$ and $s \in [-a_n, a_n]$,

$$sQ'(s)\left(1 - \frac{|s|}{a_n}\right)^{1/2} \leq Cn. \tag{3.17}$$

Proof.

(i)

$$\frac{a_{\Delta n} Q'(a_{\Delta n})}{a_{\alpha n} Q'(a_{\alpha n})} = \exp\left(\int_{\alpha n}^{\Delta n} \frac{d}{dt}[\log(a_t Q'(a_t))] dt\right)$$

$$= \exp\left(\int_{\alpha n}^{\Delta n} T(a_t)\frac{a_t'}{a_t} dt\right) \geq \exp\left(\int_{\alpha n}^{\Delta n} \frac{dt}{t}\right) = \frac{\Delta}{\alpha},$$

by (3.12).

(ii) Now uniformly for $|x| \in [0, 1)$,

$$\int_{|x|}^1 \frac{ds}{\sqrt{1 - s^2}} \sim (1 - |x|)^{1/2}. \tag{3.18}$$

Hence for $|x| \in [0, 1)$,

$$a_n x Q'(a_n x)(1 - |x|)^{1/2} = a_n |x| Q'(a_n |x|)(1 - |x|)^{1/2}$$

$$\leq C a_n |x| Q'(a_n |x|) \frac{2}{\pi} \int_{|x|}^1 \frac{ds}{\sqrt{1 - s^2}}$$

$$\leq C \frac{2}{\pi} \int_{|x|}^1 a_n s Q'(a_n s) \frac{ds}{\sqrt{1 - s^2}} \leq Cn.$$

For $|x| = 1$, (3.16) is trivial. Setting $x = s/a_n$ yields (3.17). $\square$

4. Estimates for the measure μ_n. In this section, we present some estimates for the measure $\mu_n(x)$ that are of independent interest. The methods we use are similar to those in [4], [6], [9].

THEOREM 4.1. *Let $w \in \mathcal{W}$. Then for $n \geq 1$,*

$$\text{(a)} \quad \max_{x\in[-1,1]} \mu_n(x)\sqrt{1-x^2} \leq C; \tag{4.1}$$

$$\text{(b)} \quad \max_{x\in[-1,1]} \mu_n(x)/\sqrt{1-x^2} \leq CT(a_n). \tag{4.2}$$

As a corollary, we shall deduce the following.

COROLLARY 4.2. *For $n \geq 1$,*

$$\max_{x\in[-1,1]} \mu_n(x) \leq CT(a_n)^{1/2}. \tag{4.3}$$

Under mild additional conditions, we can show the following.

THEOREM 4.3. *In addition to $w \in \mathcal{W}$, let us assume* (3.8). *Fix $\beta \in (0,1)$. Then we have*

$$\sqrt{1-x^2}\mu_n(x) \geq C, \quad |x| \leq \frac{a_{\beta n}}{a_n}, \quad n \geq 1. \tag{4.4}$$

We note that under mild additional conditions, we can show that (4.2) and (4.3) are sharp. See, respectively, [5] and [8] for the sharpness of (4.2) and (4.3) in the related situation of Erdös weights. We turn now to the proofs of the above results.

Proof of Theorem 4.1(a). Since μ_n is even, we may consider $x \in (0,1)$. For $n \geq 1$, and s, $x \in (0,1)$, set

$$\Delta_n(s,x) := \frac{a_n sQ'(a_n s) - a_n xQ'(a_n x)}{a_n s - a_n x}. \tag{4.5}$$

Then

$$\sqrt{1-x^2}\mu_n(x) = \frac{2a_n}{n\pi^2}(1-x^2)\int_0^1 \frac{\Delta_n(s,x)}{s+x}\frac{ds}{\sqrt{1-s^2}}. \tag{4.6}$$

Note that since $(uQ'(u))' = Q'(u)T(u)$ is increasing in (0,1), $uQ'(u)$ is convex in (0,1). Hence for each fixed x, $\Delta_n(s,x)$ is an increasing function of $s \in (0,1)$.

Case I. $x \in [0, \frac{1}{4}]$. Now suppose that $x \in [0, \frac{1}{4}]$. Then $s \in (2x, 1]$ implies

$$\Delta_n(s,x) \leq \frac{a_n sQ'(a_n s)}{a_n s - a_n s/2} = 2Q'(a_n s).$$

Furthermore, $s \in (0, 2x]$ implies

$$\Delta_n(s,x) \leq \Delta_n(2x,x) \leq \frac{a_n 2xQ'(a_n 2x)}{a_n 2x - a_n x} = 2Q'(a_n 2x).$$

Hence for $0 \leq x \leq \frac{1}{4}$,

$$\begin{aligned}\sqrt{1-x^2}\mu_n(x) &\leq \frac{C_1}{n}(1-|x|)\left[\int_0^{2x}\frac{Q'(a_n 2x)}{s+x}ds + \int_{2x}^1 \frac{2Q'(a_n s)}{s}\frac{ds}{\sqrt{1-s^2}}\right] \\ &\leq \frac{C_2}{n}(1-|x|)\left[2Q'(1/2) + \int_{2x}^{1/2}\frac{Q'(a_n s)}{s}ds + \int_{1/2}^1 \frac{a_n sQ'(a_n s)}{\sqrt{1-s^2}}ds\right] \\ &\leq C,\end{aligned}$$

by Lemma 3.1(v) and the definition of a_n.

Case II. $x \in [\frac{1}{4}, 1)$. Next, suppose $\frac{1}{4} \leq x < 1$. Let

$$\delta(x) := \frac{1-x}{4}.$$

From (4.6) and as $x + 4\delta(x) = 1$, we have

$$\begin{aligned}\sqrt{1-x^2}\mu_n(x) &\leq \frac{C}{n}(1-x)\int_0^1 \frac{\Delta_n(s,x)}{\sqrt{1-s^2}}ds \\ &= \frac{C}{n}4\delta(x)\left[\int_0^{x-\delta(x)} + \int_{x-\delta(x)}^{x+\delta(x)} + \int_{x+\delta(x)}^1\right]\frac{\Delta_n(s,x)}{\sqrt{1-s^2}}ds \qquad (4.7) \\ &=: \frac{4C}{n}(I_1 + I_2 + I_3).\end{aligned}$$

Firstly,

$$\begin{aligned}I_1 &\leq \delta(x)\int_0^{x-\delta(x)} \frac{a_n x Q'(a_n x)}{a_n x - a_n s}\frac{ds}{\sqrt{1-s^2}} \\ &\leq C_1\delta(x)xQ'(a_n x)\int_0^{x-\delta(x)}\frac{ds}{(x-s)^{3/2}} \quad (\text{as } 1-s \geq x-s > 0) \qquad (4.8) \\ &\leq C_2 Q'(a_n x)\delta(x)^{1/2} \leq C_3 n,\end{aligned}$$

by (3.16). Next, if $s \in [x-\delta(x), x+\delta(x)]$, there exists ξ between s and x such that

$$\begin{aligned}\Delta_n(s,x) &= \frac{d}{du}(uQ'(u))\Big|_{u=a_n\xi} = T(a_n\xi)Q'(a_n\xi) \\ &\leq T(a_n[x+\delta(x)])Q'(a_n[x+\delta(x)]) \\ &\leq \delta(x)^{-1}\int_{x+\delta(x)}^{x+2\delta(x)} T(a_n s)Q'(a_n s)ds \\ &= (a_n\delta(x))^{-1}\int_{x+\delta(x)}^{x+2\delta(x)} \frac{d}{ds}(a_n sQ'(a_n s))ds \\ &\leq (a_n\delta(x))^{-1}a_n[x+2\delta(x)]Q'(a_n[x+2\delta(x)]) \\ &\leq C_4\delta(x)^{-3/2}a_n[x+2\delta(x)]Q'(a_n[x+2\delta(x)])\int_{x+2\delta(x)}^1\frac{ds}{\sqrt{1-s^2}} \\ &\qquad (\text{observe } 1-[x+2\delta(x)] = 2\delta(x)) \\ &\leq C_4\delta(x)^{-3/2}\int_{x+2\delta(x)}^1 \frac{a_n sQ'(a_n s)}{\sqrt{1-s^2}}ds \\ &\leq C_5\delta(x)^{-3/2}n.\end{aligned}$$

Then

$$\begin{aligned} I_2 &\leq \delta(x)\int_{x-\delta(x)}^{x+\delta(x)} C_5\delta(x)^{-3/2}n\frac{ds}{\sqrt{1-s^2}} \\ &\leq C_5\delta(x)^{-1/2}n\int_{x-\delta(x)}^{1}\frac{ds}{\sqrt{1-s^2}} \leq C_6 n, \end{aligned} \tag{4.9}$$

as $1-(x-\delta(x)) = 5\delta(x)$. Finally,

$$I_3 \leq \delta(x)\int_{x+\delta(x)}^{1}\frac{a_n sQ'(a_n s)}{a_n\delta(x)}\frac{ds}{\sqrt{1-s^2}} \leq Cn, \tag{4.10}$$

by the definition of a_n. Combining (4.7) to (4.10) yields

$$\sqrt{1-x^2}\mu_n(x) \leq C, \qquad x \in [\tfrac{1}{4}, 1). \qquad \square$$

Proof of Theorem 4.1(b). With the notation (4.5), and by (4.6), we have for $1 > |x| \geq \frac{1}{2}$,

$$\begin{aligned} \mu_n(x)/\sqrt{1-x^2} &\leq \frac{C}{n}\int_0^1 \frac{\Delta_n(s,x)}{\sqrt{1-s^2}}ds \\ &\leq \frac{C}{n}\int_0^1 \frac{\Delta_n(s,1)}{\sqrt{1-s^2}}ds, \end{aligned} \tag{4.11}$$

since $\Delta_n(s,x)$ is increasing in x for fixed s (as in the proof of Theorem 4.1(a)). Now let

$$\begin{aligned} A_n := a_n\int_0^1\frac{\Delta_n(s,1)}{\sqrt{1-s^2}}ds &= \int_0^1 \frac{a_nQ'(a_n)-a_nsQ'(a_ns)}{(1-s)^{3/2}(1+s)^{1/2}}ds \\ &\leq \int_0^1 \frac{a_nQ'(a_n)-a_nsQ'(a_ns)}{(1-s)^{3/2}}ds. \end{aligned}$$

Integrating by parts, we have

$$\begin{aligned} A_n &\leq \frac{2}{(1-s)^{1/2}}(a_nQ'(a_n)-a_nsQ'(a_ns))\Bigg|_{s=0}^{s=1} \\ &\quad -\int_0^1\frac{2}{(1-s)^{1/2}}\frac{d}{ds}(a_nQ'(a_n)-a_nsQ'(a_ns))ds \\ &= -2a_nQ'(a_n)+2a_n\int_0^1\frac{T(a_ns)Q'(a_ns)}{(1-s)^{1/2}}ds \\ &\leq 4T(a_n)\int_{1/2}^1\frac{Q'(a_ns)}{\sqrt{1-s}}ds \quad \text{(by the monotonicity of } Q' \text{ and } (1-s)^{-1/2}\text{)} \\ &\leq CT(a_n)a_n^{-1}\int_{1/2}^1\frac{a_nsQ'(a_ns)}{\sqrt{1-s^2}}ds \leq C_1T(a_n)n. \end{aligned}$$

Then from (4.11), we obtain for $\frac{1}{2} \leq |x| \leq 1$,

$$\mu_n(x)/\sqrt{1-x^2} \leq C_2 \frac{a_n}{n} A_n \leq C_3 T(a_n).$$

Since (4.1) implies that for $|x| \leq \frac{1}{2}$,

$$\mu_n(x) \leq C_4 \leq C_5 T(a_n),$$

we have our result. □

Proof of Corollary 4.2. For $x^2 \leq 1 - 1/T(a_n)$, (4.1) implies

$$\mu_n(x) \leq \frac{C}{\sqrt{1-x^2}} \leq C_1 T(a_n)^{1/2}.$$

For $1 \geq x^2 \geq 1 - 1/T(a_n)$, inequality (4.2) implies

$$\mu_n(x) \leq CT(a_n)\sqrt{1-x^2} \leq CT(a_n)^{1/2}. \quad \square$$

Finally, we turn to the following.

Proof of Theorem 4.3. Let $0 < \beta < \Delta < 1$. Now from (2.1), and the positivity of

$$\frac{a_n s Q'(a_n s) - a_n x Q'(a_n x)}{a_n s - a_n x},$$

we see that for $|x| \leq a_{\beta n}/a_n$,

$$\sqrt{1-x^2}\mu_n(x) \geq \frac{2}{n\pi^2} \int_{a_{\Delta n}/a_n}^{1} \frac{1-x^2}{s^2-x^2} \frac{a_n s Q'(a_n s) - a_n x Q'(a_n x)}{\sqrt{1-s^2}} ds.$$

Now for $s \in [a_{\Delta n}/a_n, 1]$, and $|x| \leq a_{\beta n}/a_n$,

$$\begin{aligned}\frac{a_n s Q'(a_n s) - a_n x Q'(a_n x)}{a_n Q'(a_n)} &= \frac{a_n s Q'(a_n s)}{a_n Q'(a_n)} \left[1 - \frac{a_n x Q'(a_n x)}{a_n s Q'(a_n s)}\right] \\ &\geq s^{T(a_n)} \left[1 - \frac{a_{\beta n} Q'(a_{\beta n})}{a_{\Delta n} Q'(a_{\Delta n})}\right] \quad \text{(by (3.1))} \\ &\geq s^{T(a_n)} \left[1 - \frac{\beta}{\Delta}\right],\end{aligned}$$

by (3.15). Furthermore, as $s^2 > x^2$ for $s \in [a_{\Delta n}/a_n, 1]$,

$$1 - x^2 \geq s^2 - x^2 > 0.$$

Hence

$$\sqrt{1-x^2}\mu_n(x) \geq \frac{2}{n\pi^2} \left[1 - \frac{\beta}{\Delta}\right] a_n Q'(a_n) \int_{a_{\Delta n}/a_n}^{1} s^{T(a_n)} \frac{ds}{\sqrt{1-s^2}}.$$

Now by (3.13), for $n \geq 1$,

$$\frac{a_{\Delta n}}{a_n} \leq 1 - \frac{C}{T(a_n)}.$$

Hence if δ is small enough,

$$\sqrt{1-x^2}\mu_n(x) \geq \frac{2}{n\pi^2}\left[1-\frac{\beta}{\Delta}\right] a_n Q'(a_n) \int_{1-\delta/T(a_n)}^{1} s^{T(a_n)} \frac{ds}{\sqrt{1-s^2}}$$
$$\geq CT(a_n)^{1/2}\left(1-\frac{\delta}{T(a_n)}\right)^{T(a_n)} \int_{1-\delta/T(a_n)}^{1} \frac{ds}{\sqrt{1-s^2}}$$
$$\geq C_1,$$

by (3.9). □

We remark that we used (3.8) only in the last two lines of the above proof, in estimating $a_nQ'(a_n)$ from below.

5. Estimates for the majorisation function U_n. In this section, we estimate the quantity

$$\max_{|t-x|=\epsilon} \exp\left(nU_n\left(\frac{t}{a_n}\right)\right),$$

which appears in Lemma 2.2. Recall that the majorisation function is defined by (2.3).

THEOREM 5.1. *Let $w := e^{-Q} \in \mathcal{W}$. Let $0 < \beta < 1$, and for a fixed $\eta > 0$, let*

$$\epsilon_n := \eta(nT(a_n)^{1/2})^{-1}, \qquad n \geq 1. \tag{5.1}$$

Then

$$\max_{|t-x|\leq\epsilon_n} \exp\left(nU_n\left(\frac{t}{a_n}\right)\right) \leq C, \tag{5.2}$$

uniformly for $n \geq 1$ and for real x satisfying

$$|x| \leq a_{\beta n}. \tag{5.3}$$

Proof. Let $|t-x| \leq \epsilon_n$. Then we can write $t/a_n = a+ib$, where

$$|a| \leq \frac{|x|+\epsilon_n}{a_n} \leq \frac{a_{\beta n} + \eta/[nT(a_n)^{1/2}]}{a_n}$$
$$\leq \frac{a_{\beta n}(1+C\eta/T(a_n))}{a_n},$$

where in the last inequality we used the fact that $n^{-1} \leq C_1T(a_n)^{-1/2}$, which follows from (3.11). Now, if η is small enough, we get from (3.13) that $a_{\beta n}(1+C\eta/T(a_n))/a_n < 1$, and so

$$|x| + \epsilon_n < a_n. \tag{5.4}$$

Also,

$$|b| \leq \frac{\epsilon_n}{a_n} \leq \frac{\epsilon_n}{a_1}. \tag{5.5}$$

Then since $|a| < 1$, $U_n(a) = 0$ (see (2.7)); so we have from (2.3),

$$\begin{aligned}
U_n(t/a_n) &= U_n(a+ib) - U_n(a) \\
&= \int_{-1}^{1} \log\left|\frac{a+ib-t}{a-t}\right| \mu_n(t)dt - \frac{Q(a_n[a^2+b^2]^{1/2})}{n} + \frac{Q(a_n|a|)}{n} \\
&\leq \frac{1}{2}\int_{-1}^{1} \log\left[1+\left(\frac{b}{a-t}\right)^2\right] \mu_n(t)dt \\
&= \frac{1}{2}\int_{-1}^{1} \log\left[1+\left(\frac{|b|}{|a|-t}\right)^2\right] \mu_n(t)dt \quad \text{(as } \mu_n \text{ is even)} \\
&\leq \int_{0}^{1} \log\left[1+\left(\frac{|b|}{|a|-t}\right)^2\right] \mu_n(t)dt \qquad (5.6) \\
&\leq C_1 T(a_n)^{1/2} \int_{0}^{1} \log\left[1+\left(\frac{|b|}{|a|-t}\right)^2\right] dt \quad \text{(by Corollary 4.2)} \\
&= C_1 T(a_n)^{1/2}|b| \int_{(|a|-1)/|b|}^{|a|/|b|} \log\left[1+\frac{1}{s^2}\right] ds \quad \text{(substituting } |a|-t = s|b|) \\
&\leq C_1 T(a_n)^{1/2}\left(\frac{\epsilon_n}{a_1}\right) \int_{-\infty}^{\infty} \log\left[1+\frac{1}{s^2}\right] ds \quad \text{(by (5.5))} \\
&\leq \frac{C_2}{n},
\end{aligned}$$

by the choice (5.1) of ϵ_n. Hence $\exp(nU_n(t/a_n)) \leq \exp(C_2)$. □

Note that in the above result, we used the bound in Corollary 4.2 for μ_n. Next, we use the bound of Theorem 4.1(a).

THEOREM 5.2. *Let $w \in \mathcal{W}$. Let $n \geq 1$, and for real x satisfying*

$$|x| \leq a_n\left(1 - \frac{4}{n^2 a_1^2}\right), \tag{5.7}$$

let

$$\epsilon_n(x) := \frac{1}{n}\left(1 - \frac{|x|}{a_n}\right)^{1/2}. \tag{5.8}$$

Then

$$\max_{|t-x|\leq\epsilon_n(x)} \exp\left(nU_n\left(\frac{t}{a_n}\right)\right) \leq C. \tag{5.9}$$

Proof. Let x satisfy (5.7), and for $|t-x| \leq \epsilon_n(x)$, write $t/a_n = a + ib$. Then

$$\begin{aligned}|a| &\le \frac{|x|+\epsilon_n(x)}{a_n}\\ &= 1-\frac{1-|x|}{a_n}+\frac{\epsilon_n(x)}{a_n}\\ &\le 1+\epsilon_n(x)\left[-n^2\epsilon_n(x)+\frac{1}{a_1}\right] \quad \text{(by (5.8))}\\ &\le 1-\frac{n^2\epsilon_n^2(x)}{2},\end{aligned} \tag{5.10}$$

since (5.7) and (5.8) ensure that $\epsilon_n(x) \ge 2/(n^2 a_1)$. Furthermore,

$$|b| \le \frac{\epsilon_n(x)}{a_1}. \tag{5.11}$$

Since (2.7) shows that $U_n(a) = 0$, we obtain from (5.6),

$$\begin{aligned}U_n\left(\frac{t}{a_n}\right) &= U_n(a+ib)-U_n(a)\\ &\le \int_0^1 \log\left[1+\left(\frac{|b|}{|a|-t}\right)^2\right]\mu_n(t)dt\\ &\le C\int_0^1 \log\left[1+\left(\frac{|b|}{|a|-t}\right)^2\right]\frac{dt}{\sqrt{1-t}} \quad \text{(by Theorem 4.1(a))}\\ &= C|b|\int_{(|a|-1)/|b|}^{|a|/|b|}\log\left[1+\frac{1}{s^2}\right]\frac{ds}{\sqrt{1-|a|+s|b|}},\end{aligned}$$

by the substitution $|a|-t = s|b|$. Now let

$$\delta := \delta(a) := \frac{1-|a|}{2}. \tag{5.12}$$

We write

$$U_n\left(\frac{t}{a_n}\right) \le C|b|\left(\int_{-2\delta/|b|}^{-\delta/|b|}+\int_{-\delta/|b|}^{|a|/|b|}\right)\log\left[1+\frac{1}{s^2}\right]\frac{ds}{\sqrt{2\delta+s|b|}} =: I_1+I_2. \tag{5.13}$$

Then

$$\begin{aligned}I_1 &= C|b|^{1/2}\int_{-2\delta/|b|}^{-\delta/|b|}\log\left[1+\frac{1}{s^2}\right]\frac{ds}{\sqrt{2\delta/|b|+s}}\\ &\le C|b|^{1/2}\log\left[1+\left(\frac{|b|}{\delta}\right)^2\right]\int_0^{\delta/|b|}u^{-1/2}du\end{aligned} \tag{5.14}$$

$$= C|b|^{1/2}\log\left[1+\left(\frac{|b|}{\delta}\right)^2\right]2\left(\frac{\delta}{|b|}\right)^{1/2}$$
$$\leq 4C|b|\delta^{-1/2},$$

where we have used the inequality $\log[1+u^2] \leq 2u$, $u \in [0,\infty)$.

Next,

$$I_2 = C|b|\int_{-\delta/|b|}^{|a|/|b|}\log\left[1+\frac{1}{s^2}\right]\frac{ds}{\sqrt{2\delta+s|b|}}$$
$$\leq C|b|\delta^{-1/2}\int_{-\delta/|b|}^{|a|/|b|}\log\left[1+\frac{1}{s^2}\right]ds \tag{5.15}$$
$$\leq C|b|\delta^{-1/2}\int_{-\infty}^{\infty}\log\left[1+\frac{1}{s^2}\right]ds.$$

So from (5.13) to (5.15) and (5.11),

$$nU_n\left(\frac{t}{a_n}\right) \leq nC_1|b|\delta^{-1/2} \leq nC_1\epsilon_n(x)\delta^{-1/2} \leq C_2,$$

since (5.12) and (5.10) show that

$$\delta = \frac{1-|a|}{2} \geq \frac{n^2\epsilon_n^2(x)}{4}. \qquad \square$$

Finally, we use the bound of Theorem 4.1(b).

THEOREM 5.3. *Let $w \in \mathcal{W}$ and let $\eta > 0$ be fixed. For $n \geq 1$, and $|x| \leq a_n$, let*

$$\epsilon_n(x) := \eta\min\left\{(nT(a_n))^{-2/3}, \left(nT(a_n)\sqrt{1-|x|/a_n}\right)^{-1}\right\}. \tag{5.16}$$

Then if η is small enough (independently of x),

$$\max_{|t-x|\leq\epsilon_n(x)}\exp\left(nU_n\left(\frac{t}{a_n}\right)\right) \leq C. \tag{5.17}$$

Proof. Let $|x| \leq a_n$ and for $|t-x| \leq \epsilon_n(x)$, write $t/a_n = a+ib$. Here,

$$|b| \leq \frac{\epsilon_n(x)}{a_n} \leq \frac{\epsilon_n(x)}{a_1}. \tag{5.18}$$

Furthermore, by (3.11),

$$nT(a_n) \geq C_1T(a_n)^{3/2},$$

so

$$\epsilon_n(x) \leq \eta(nT(a_n))^{-2/3} \leq \eta C_2T(a_n)^{-1},$$

and hence

$$|x|+\epsilon_n(x) \leq a_n\left(1+\frac{C_3\eta}{T(a_n)}\right) \leq a_{2n}, \tag{5.19}$$

if η is small enough. In particular, then

$$\frac{|t|}{a_n} \le \frac{|x| + \epsilon_n(x)}{a_n} \le \frac{a_{2n}}{a_n} < 1. \tag{5.20}$$

Thus $U_n(t/a_n)$ is well defined for $|t - x| \le \epsilon_n(x)$. We now consider the cases $|a| \le 1$ and $|a| > 1$ separately.

Case I. $|a| \le 1$. Then $U_n(a) = 0$, and by (5.6),

$$\begin{aligned}
U_n\left(\frac{t}{a_n}\right) &= U_n(a+ib) - U_n(a)\\
&\le \int_0^1 \log\left[1 + \left(\frac{|b|}{|a|-t}\right)^2\right] \mu_n(t)\,dt\\
&\le CT(a_n)\int_0^1 \log\left[1 + \left(\frac{|b|}{|a|-t}\right)^2\right] \sqrt{1-t}\,dt \quad \text{(by Theorem 4.1(b))}\\
&= CT(a_n)|b| \int_{(|a|-1)/|b|}^{|a|/|b|} \log\left[1+\frac{1}{s^2}\right](1-|a|+s|b|)^{1/2}ds\\
&\qquad \text{(substituting } |a| - t = s|b|)\\
&\le CT(a_n)|b| \int_{-\infty}^{\infty} \log\left[1+\frac{1}{s^2}\right]\{(1-|a|)^{1/2} + |sb|^{1/2}\}\,ds\\
&\qquad \text{(by the inequality } (u+v)^{1/2} \le |u|^{1/2} + |v|^{1/2},\ u+v\ge 0)\\
&= CT(a_n)|b|(1-|a|)^{1/2}\int_{-\infty}^{\infty} \log\left[1+\frac{1}{s^2}\right] ds\\
&\qquad +CT(a_n)|b|^{3/2}\int_{-\infty}^{\infty} \log\left[1+\frac{1}{s^2}\right]|s|^{1/2}ds \qquad (5.21)\\
&\le C_1\left\{T(a_n)\epsilon_n(x)\left(1-\frac{|x|}{a_n}+\frac{\epsilon_n(x)}{a_n}\right)^{1/2} + T(a_n)\epsilon_n(x)^{3/2}\right\}\\
&\qquad \left(\text{by choice, } |a| \ge \tfrac{|x|}{a_n} - \tfrac{\epsilon_n(x)}{a_n}\right)\\
&\le C_1\left\{T(a_n)\epsilon_n(x)\left(1-\frac{|x|}{a_n}\right)^{1/2} + \frac{T(a_n)\epsilon_n(x)^{3/2}}{a_n^{1/2}} + T(a_n)\epsilon_n(x)^{3/2}\right\}\\
&\le C_2\left\{T(a_n)\epsilon_n(x)\left(1-\frac{|x|}{a_n}\right)^{1/2} + T(a_n)\epsilon_n(x)^{3/2}\right\}.
\end{aligned}$$

Then

$$nU_n\left(\frac{t}{a_n}\right) \le C_2\left\{nT(a_n)\epsilon_n(x)\left(1-\frac{|x|}{a_n}\right)^{1/2} + nT(a_n)\epsilon_n(x)^{3/2}\right\} \le C_3,$$

by the choice (5.16) of $\epsilon_n(x)$.

Case II. $|a| > 1$. Since $U_n(a) < 0$ (see (2.8)), we have

$$\begin{aligned} U_n\left(\frac{t}{a_n}\right) &= U_n(a+ib) - U_n(a) + U_n(a) \\ &\leq \int_0^1 \log\left[1 + \left(\frac{|b|}{|a|-t}\right)^2\right] \mu_n(t)dt \quad \text{(by (5.6))} \\ &\leq \int_0^1 \log\left[1 + \left(\frac{|b|}{1-t}\right)^2\right] \mu_n(t)dt, \end{aligned}$$

as $|a| - t > 1 - t$, $t \in [0,1]$. The argument of Case I with $a = 1$ then shows that the above integral is bounded above by the right-hand side of (5.21) (with 1 substituted for a there). Thus,

$$\begin{aligned} nU_n\left(\frac{t}{a_n}\right) &\leq nCT(a_n)|b|^{3/2} \int_{-\infty}^{\infty} \log\left[1 + \frac{1}{s^2}\right] |s|^{1/2} ds \\ &\leq C_1 nT(a_n)\epsilon_n(x)^{3/2} \leq C_2. \quad \square \end{aligned}$$

6. Proofs of Theorems 1.2–1.5.

Proof of Theorem 1.2(i). First, let $0 < \beta < 1$, and let, as in (5.1),

$$\epsilon_n := \eta(nT(a_n)^{1/2})^{-1}, \qquad n \geq 1.$$

Then Lemma 2.2 and (5.2) ensure that for $P \in \mathcal{P}_n$, and $|x| \leq a_{\beta n}$,

$$|(Pw)'(x)| \leq \epsilon_n^{-1} e^{\tau_n(x)} \|Pw\|_{L_\infty[-1,1]} C,$$

where, as in (2.13),

$$\tau_n(x) := \begin{cases} Q'(3\epsilon_n)2\epsilon_n, & \text{if } |x| \leq 2\epsilon_n, \\ \left[\frac{Q'(|x|+\epsilon_n)}{|x|} + Q''(|x|+\epsilon_n)\right]2\epsilon_n^2, & \text{if } |x| > 2\epsilon_n. \end{cases}$$

Since $\epsilon_n \to 0$ as $n \to \infty$,

$$Q'(3\epsilon_n)2\epsilon_n \leq C_1, \qquad n \geq 1.$$

Next, from (5.4), $|x| + \epsilon_n < a_n$, if η is small enough. So for $|x| \geq 2\epsilon_n$,

$$Q'(|x| + \epsilon_n)|x|^{-1}\epsilon_n^2 \leq \tfrac{1}{2}Q'(a_n)\epsilon_n \leq CnT(a_n)^{1/2}\epsilon_n \leq C_3,$$

by (3.7) and the choice of ϵ_n. Furthermore, by Lemma 3.1(ii), if $|x| \geq \frac{1}{4}$,

$$Q''(|x| + \epsilon_n)\epsilon_n^2 \leq \frac{a_n}{|x| + \epsilon_n} Q''(a_n)\epsilon_n^2 \leq C_4 T(a_n)^{1/2} n^{-1} \leq C_5,$$

by (3.7), (3.11) and the choice of ϵ_n. If $|x| \leq \frac{1}{4}$,

$$Q''(|x| + \epsilon_n)\epsilon_n^2 \leq (|x| + \epsilon_n)Q''(|x| + \epsilon_n)\epsilon_n \leq \tfrac{1}{2}Q''(1/2)\epsilon_n \leq C_6,$$

by Lemma 3.1(ii). Thus we have shown that

$$\tau_n(x) \le C_7, \qquad |x| \le a_{\beta n}.$$

So for $P \in \mathcal{P}_n$, $n \ge 1$,

$$\|(Pw)'\|_{L_\infty[-a_{\beta n},a_{\beta n}]} \le C_8 n T(a_n)^{1/2} \|Pw\|_{L_\infty[-1,1]}. \tag{6.1}$$

Choosing $\beta = \frac{1}{2}$, and replacing n by $2n$, yields for $P \in \mathcal{P}_n \subset \mathcal{P}_{2n}$,

$$\|(Pw)'\|_{L_\infty[-a_n,a_n]} \le C_8 2n T(a_{2n})^{1/2} \|Pw\|_{L_\infty[-1,1]}. \tag{6.2}$$

Then, as

$$Q'(a_{2n}) = \mathrm{O}(nT(a_{2n})^{1/2}),$$

we obtain

$$\|P'w\|_{L_\infty[-a_n,a_n]} \le C_8 2n T(a_{2n})^{1/2} \|Pw\|_{L_\infty[-1,1]}.$$

The Mhaskar–Saff identity (1.9) then yields Theorem 1.2(i). □

Proof of Theorem 1.2(ii). Suppose that $n \ge 1$, and

$$|x| \le a_n \left(1 - \frac{A}{T(a_{2n})}\right), \tag{6.3}$$

where A is some fixed but large enough positive number. Note that then, by (3.11),

$$|x| \le a_n(1 - 4n^{-2}a_1^{-2}), \tag{6.4}$$

if only A is large enough. Thus (5.7) is satisfied. Let

$$\hat{\epsilon}_n(x) := \eta n^{-1} \left(1 - \frac{|x|}{a_n}\right)^{1/2},$$

where $\eta \in (0,1)$ is fixed and independent of n and x, but small enough. Note then that $\hat{\epsilon}_n(x) \le \epsilon_n(x)$, where $\epsilon_n(x)$ is defined by (5.8). Then Lemma 2.2 and (5.9) ensure that for $P \in \mathcal{P}_n$,

$$|(Pw)'(x)| \le \hat{\epsilon}_n(x)^{-1} e^{\tau_n(x)} \|Pw\|_{L_\infty[-1,1]} C,$$

where

$$\tau_n(x) := \begin{cases} Q'(3\hat{\epsilon}_n(x))2\hat{\epsilon}_n(x), & \text{if } |x| \le 2\hat{\epsilon}_n(x), \\ \left[\frac{Q'(|x|+\hat{\epsilon}_n(x))}{|x|} + Q''(|x| + \hat{\epsilon}_n(x))\right] 2\hat{\epsilon}_n(x)^2, & \text{if } |x| > 2\hat{\epsilon}_n(x). \end{cases}$$

Since $\hat{\epsilon}_n(x) \to 0$ as $n \to \infty$, uniformly for the above range of x, we have

$$\tau_n(x) \le C, \quad \text{if} \quad |x| \le 2\hat{\epsilon}_n(x).$$

Next, if $2\hat{\epsilon}_n(x) \le |x| \le \frac{1}{4}$, then for n large enough,

$$\begin{aligned} \tau_n(x) &= \left[\frac{Q'(|x| + \hat{\epsilon}_n(x))}{|x|} + Q''(|x| + \hat{\epsilon}_n(x))\right] 2\hat{\epsilon}_n(x)^2 \\ &\le 2Q'(|x| + \hat{\epsilon}_n(x))\hat{\epsilon}_n(x) + 2(|x| + \hat{\epsilon}_n(x))Q''(|x| + \hat{\epsilon}_n(x))\hat{\epsilon}_n(x) \\ &\le \frac{2Q'(1/2)\eta}{n} + \frac{2(1/2)Q''(1/2)\eta}{n} \to 0, \end{aligned}$$

as $n \to \infty$, by Lemma 3.1(ii). If $|x| \geq \frac{1}{4}$, then we estimate $\tau_n(x)$ as follows: First note that by (6.4),

$$\frac{\hat{\epsilon}_n(x)}{(1-|x|/a_n)} = \eta n^{-1}\left(1-\frac{|x|}{a_n}\right)^{-1/2} \leq C_1\eta.$$

Hence,

$$\begin{aligned} 1-\frac{|x|+2\hat{\epsilon}_n(x)}{a_n} &= 1-\frac{|x|}{a_n}-\frac{2\hat{\epsilon}_n(x)}{a_n} \\ &\geq \left(1-\frac{|x|}{a_n}\right)\left(1-\frac{2C_1\eta}{a_1}\right) \\ &\geq \frac{1}{2}\left(1-\frac{|x|}{a_n}\right) \geq \frac{\eta}{2}\hat{\epsilon}_n(x), \end{aligned} \tag{6.5}$$

if η is small enough. Then as $|x| \geq \frac{1}{4}$, Lemma 3.1(ii) shows that

$$\begin{aligned} Q''(|x|+\hat{\epsilon}_n(x))\hat{\epsilon}_n(x)^2 &\leq \left(\int_{|x|+\hat{\epsilon}_n(x)}^{|x|+2\hat{\epsilon}_n(x)} Q''(t)dt\right)\frac{|x|+2\hat{\epsilon}_n(x)}{|x|+\hat{\epsilon}_n(x)}\hat{\epsilon}_n(x) \\ &\leq 2\hat{\epsilon}_n(x)Q'(|x|+2\hat{\epsilon}_n(x)) \\ &\leq C_2 n^{-1}\left\{1-\frac{|x|+2\hat{\epsilon}_n(x)}{a_n}\right\}^{1/2} Q'(|x|+2\hat{\epsilon}_n(x)) \\ &\qquad \text{(by (6.5) and the choice of } \hat{\epsilon}_n(x)) \\ &\leq C, \end{aligned}$$

by (3.17) of Lemma 3.3. Also then,

$$Q'(|x|+\hat{\epsilon}_n(x))|x|^{-1}\hat{\epsilon}_n(x)^2 \leq 4Q'(|x|+2\hat{\epsilon}_n(x))\hat{\epsilon}_n(x) \leq C,$$

as above. So

$$\tau_n(x) \leq C,$$

uniformly for $|x| \leq a_n(1-A/T(a_{2n}))$, and we have

$$|(Pw)'(x)| \leq \hat{\epsilon}_n(x)^{-1}C_1\|Pw\|_{L_\infty[-1,1]} \leq \frac{C_2 n}{\sqrt{1-|x|/a_n}}\|Pw\|_{L_\infty[-1,1]}, \tag{6.6}$$

$P \in \mathcal{P}_n$, uniformly for $|x| \leq a_n(1-1/T(a_{2n}))$. On the other hand, if

$$a_n > |x| \geq a_n\left(1-\frac{A}{T(a_{2n})}\right),$$

then (6.2) shows that

$$|(Pw)'(x)| \leq C_3 nT(a_{2n})^{1/2}\|Pw\|_{L_\infty[-1,1]} \leq \frac{C_3 n}{\sqrt{1-|x|/a_n}}\|Pw\|_{L_\infty[-1,1]}.$$

Summarizing, we have shown that

$$\max_{x\in[-a_n,a_n]}\left|(Pw)'(x)\sqrt{1-|x|/a_n}\right| \le C_4 n\|Pw\|_{L_\infty[-1,1]}, \tag{6.7}$$

$P \in \mathcal{P}_n$, $n \ge 1$. Since (3.17) implies that

$$Q'(x)\sqrt{1-|x|/a_n} \le Cn,$$

for $\frac{1}{4} \le |x| \le 1$, and this inequality is trivial for $|x| \le \frac{1}{2}$, we have shown that

$$\max_{x\in[-a_n,a_n]}|P'w|(x)\sqrt{1-|x|/a_n} \le C_4 n\|Pw\|_{L_\infty[-1,1]}, \tag{6.8}$$

$P \in \mathcal{P}_n$, $n \ge 1$, which completes the proof of the theorem. □

Proof of Corollary 1.3. It follows directly from Theorem 1.2(i), (ii), that (1.18) holds for $|x| < a_n$, since

$$\left[\left(1-\frac{|x|}{a_n}\right)^{1/2}+T(a_{2n})^{-1/2}\right]^{-1} \sim \min\left\{\left|1-\frac{|x|}{a_n}\right|^{-1/2}, T(a_{2n})^{1/2}\right\}.$$

We can then reformulate (1.18) for $|x| < a_n$ as

$$\left\{\left(1-\left(\frac{x}{a_n}\right)^2\right)^2+T(a_{2n})^{-2}\right\}[(P'w)(x)]^4 \le Cn^2\|Pw\|^4_{L_\infty[-1,1]}, \tag{6.9}$$

$|x| \le a_n$, $P \in \mathcal{P}_n$. Now $\psi(x) := \{(1-(x/a_n)^2)^2+T(a_{2n})^{-2}\}P'(x)^4 \in \mathcal{P}_{4n}$, and by the Mhaskar–Saff identity applied to $w^4 = e^{-4Q}$, (for which $a_{4n}(4Q) = a_n(Q)$), we have

$$\|\psi w^4\|_{L_\infty[-1,1]} = \|\psi w^4\|_{L_\infty[-a_n,a_n]}.$$

Hence (6.9) holds for $x \in [-1,1]$, and so does (1.18). □

Proof of Corollary 1.4(i). It obviously suffices to estimate $T(a_n)$ for $W_{0,\alpha} = e^{-Q}$ given by (1.4). A straightforward calculation shows that

$$T(x) = \frac{2(1+\alpha x^2)}{1-x^2} \sim (1-|x|)^{-1}, \qquad x \in (-1,1).$$

Furthermore,

$$Q'(x) \sim x(1-|x|)^{-\alpha-1}, \qquad x \in (-1,1),$$

and

$$T(x) \sim \frac{Q'(x)}{Q(x)}, \qquad x \text{ near } 1,$$

so by (3.9), for large enough n, $Q'(a_n) \sim nT(a_n)^{1/2}$, which implies

$$(1-a_n)^{-\alpha-1} \sim n(1-a_n)^{-1/2},$$

and hence

$$1-a_n \sim n^{-1/(\alpha+1/2)}.$$

Then $T(a_n) \sim n^{1/(\alpha+1/2)}$, and Theorem 1.2(i) yields Corollary 1.4(i). □

Proof of Corollary 1.4(ii). Let

$$\exp_0(x) := x, \quad \exp_\ell(x) := \exp(\exp_{\ell-1}(x)), \quad \ell \geq 1,$$

and

$$F_0(x) := 1, \quad F_\ell(x) := \prod_{j=1}^{\ell} \exp_j(x), \quad \ell \geq 1,$$

and

$$Q(x) := \exp_k((1-x^2)^{-\alpha}).$$

Note that

$$\frac{d}{dx}\exp_\ell(x) = F_\ell(x), \qquad \ell \geq 0,$$

and

$$\frac{d}{dx}F_\ell(x) = F_\ell(x)\sum_{j=0}^{\ell-1} F_j(x).$$

A straightforward calculation shows that

$$Q'(x) = F_k((1-x^2)^{-\alpha})2\alpha x(1-x^2)^{-\alpha-1},$$

and

$$T(x) = \frac{2}{1-x^2}\left\{\sum_{\ell=0}^{k-1} F_\ell((1-x^2)^{-\alpha})\alpha x^2(1-x^2)^{-\alpha} + 1 + \alpha x^2\right\}.$$

Hence for x close to 1,

$$Q'(x) \sim F_k((1-x^2)^{-\alpha})(1-x^2)^{-\alpha-1},$$
$$T(x) \sim F_{k-1}((1-x^2)^{-\alpha})(1-x^2)^{-\alpha-1},$$

and

$$T(x) \sim \frac{Q'(x)}{Q(x)}.$$

Then by (3.9), $Q'(a_n) \sim nT(a_n)^{1/2}$ implies

$$F_k((1-a_n^2)^{-\alpha})(1-a_n^2)^{-\alpha-1} \sim n\left[F_{k-1}((1-a_n^2)^{-\alpha})\right]^{1/2}(1-a_n^2)^{-(\alpha+1)/2}.$$

Taking logarithms shows that for n large enough,

$$\exp_{k-1}((1-a_n^2)^{-\alpha}) = \log n - \frac{1}{2}\sum_{j=0}^{k-2}\exp_j((1-a_n^2)^{-\alpha}) - \frac{\alpha+1}{2}\log(1-a_n^2) + \mathrm{O}(1),$$

which implies that as $n \to \infty$,

$$\exp_{k-1}((1-a_n^2)^{-\alpha}) = \log n + O\left(\frac{\log\log n}{\log n}\right).$$

From this it readily follows that for $0 \le j \le k-1$, and n large enough,

$$\exp_j((1-a_n^2)^{-\alpha}) = \log_{k-j} n + o(1).$$

Then for n large enough,

$$\begin{aligned} T(a_n) \sim F_{k-1}((1-a_n^2)^{-\alpha})(1-a_n^2)^{-\alpha-1} &\sim \left(\prod_{j=1}^{k-1} \log_{k-j} n\right) (\log_k n)^{(\alpha+1)/\alpha} \\ &= \left(\prod_{j=1}^{k-1} \log_j n\right) (\log_k n)^{(\alpha+1)/\alpha}. \end{aligned}$$

Now Theorem 1.2(i) yields the result. □

Proof of Corollary 1.4(iii). Here $w = e^{-Q}$, where $Q(x) = -\alpha \log(1-x^2)$. Then

$$Q'(x) = \frac{2\alpha x}{1-x^2},$$

and a simple calculation shows that

$$T(x) = \frac{2}{1-x^2}.$$

Then (1.8) yields

$$\begin{aligned} n &\sim \int_{1/2}^1 \frac{Q'(a_n t)}{\sqrt{1-t^2}} dt \sim \int_{1/2}^1 \frac{1}{\sqrt{1-t}(1-a_n t)} dt \\ &= \int_0^{1/2} \frac{ds}{\sqrt{s}(1-a_n+a_n s)} \sim \int_0^{1-a_n} \frac{ds}{\sqrt{s}(1-a_n)} + \int_{1-a_n}^{1/2} \frac{ds}{s} \\ &\sim (1-a_n)^{-1/2} + \log\left[\frac{1}{2(1-a_n)}\right]. \end{aligned}$$

Then we deduce that

$$1 - a_n \sim n^{-2},$$

and hence

$$T(a_n) \sim n^2.$$

Again, Theorem 1.2(i) yields the result. □

Proof of Theorem 1.5(a). From (6.2) and (6.7),

$$|(Pw)'(x)| \le C_5 n \min\{T(a_{2n})^{1/2}, (1-|x|/a_n)^{-1/2}\} \|Pw\|_{L_\infty[-1,1]}$$

for $|x| < a_n$ and $P \in \mathcal{P}_n$. This immediately yields (1.22). □

Proof of Theorem 1.5(b). We remark that (1.23) is implied by (1.22), in a somewhat stronger form, if $|x| \le \frac{1}{2}$. So we may assume that $|x| \ge \frac{1}{2}$. Let

$$\epsilon_n(x) := \eta \min\left\{(nT(a_{2n}))^{-2/3}, \left(nT(a_{2n})\sqrt{1-|x|/a_n}\right)^{-1}\right\}.$$

Then by Lemma 2.2 and Theorem 5.3,

$$|(Pw)'(x)| \le \epsilon_n(x)^{-1} e^{\tau_n(x)} \|Pw\|_{L_\infty[-1,1]} C,$$

$P \in \mathcal{P}_n$, $\frac{1}{2} \le |x| \le a_n$, where

$$\begin{aligned}\tau_n(x) &= \left[\frac{Q'(|x|+\epsilon_n(x))}{|x|} + Q''(|x|+\epsilon_n(x))\right] 2\epsilon_n(x)^2 \\ &\le 4[Q'(|x|+\epsilon_n(x)) + Q''(|x|+\epsilon_n(x))]\epsilon_n(x)^2.\end{aligned}$$

Now, by (3.11),

$$\epsilon_n(x) \le \eta(nT(a_{2n}))^{-2/3} \le \frac{C\eta}{T(a_{2n})}.$$

Then by (3.13),

$$|x| + \epsilon_n(x) \le a_n\left(1 + \frac{C_1\eta}{T(a_{2n})}\right) \le a_{2n},$$

if only η is small enough. Hence the monotonicity of $Q'(u)$ and $uQ''(u)$ yield

$$\begin{aligned}\tau_n(x) &\le C[Q'(a_{2n}) + Q''(a_{2n})]\epsilon_n^2(x) \\ &\le C_1 nT(a_{2n})^{3/2}(nT(a_{2n}))^{-4/3} \quad \text{(by (3.7) and the choice of } \epsilon_n(x)) \\ &= C_1 n^{-1/3} T(a_{2n})^{1/6} \le C_2,\end{aligned}$$

by (3.11). Hence for $|x| < a_n$ and $P \in \mathcal{P}_n$,

$$\begin{aligned}|(Pw)'(x)| &\le \epsilon_n(x)^{-1} C_3 \|Pw\|_{L_\infty[-1,1]} \\ &\le C_4 \max\left\{(nT(a_{2n}))^{2/3}, nT(a_{2n})\left(1-\frac{|x|}{a_n}\right)^{1/2}\right\} \|Pw\|_{L_\infty[-1,1]}.\end{aligned}$$

Then (1.23) follows for $|x| < a_n$ and (1.24) follows by continuity. □

7. Proof of Theorem 1.6 and Corollary 1.7.

Proof of Theorem 1.6. Let $P \in \mathcal{P}_{n-1}$ and choose $\xi \in [-a_n, a_n]$ such that

$$|Pw|(\xi) = \|Pw\|_{L_\infty[-1,1]}.$$

Let

$$\delta := \tfrac{1}{2}(CnT(a_{2n-2})^{1/2})^{-1}, \tag{7.1}$$

where C is as in (1.22). Then for $t \in (\xi - \delta, \xi + \delta) \cap (-1,1)$, there is a $\zeta \in (\xi - \delta, \xi + \delta) \cap (-1,1)$ such that

$$\begin{aligned}|Pw|(t) &= |(Pw)(\xi) + (Pw)'(\zeta)(t-\xi)| \\ &\geq |Pw|(\xi) - \|(Pw)'\|_{L_\infty[-a_n,a_n]}\delta \\ &\geq \|Pw\|_{L_\infty[-1,1]} - \left(\frac{\delta^{-1}}{2}\right)\|Pw\|_{L_\infty[-1,1]}\delta = \frac{1}{2}\|Pw\|_{L_\infty[-1,1]},\end{aligned}$$

by (1.22). So if $x \in (-1,1)$,

$$\int_{-1}^{1} \frac{(Pw)^2(t)dt}{(Pw)^2(x)} \geq \int_{(\xi-\delta,\xi+\delta)\cap(-1,1)} \frac{1}{4}\|Pw\|^2_{L_\infty[-1,1]}dt/(Pw)^2(x) \geq \frac{\delta}{4}.$$

Thus

$$\lambda_n(w^2,x)w^{-2}(x) = \inf_{P\in\mathcal{P}_{n-1}} \int_{-1}^{1}(Pw)^2(t)dt/(Pw)^2(x) \geq \frac{\delta}{4}.$$

Taking account of the definition (7.1) of δ, we obtain (1.25). □

Proof of Corollary 1.7. We use a very standard argument (see, for example, [17]) but provide the details for the reader's convenience.

Step 1. Let

$$\rho_n := nT(a_{2n-2})^{1/2}, \qquad n \geq 1.$$

By Theorem 1.6, in the form proved above,

$$(Pw)^2(x) \leq C\rho_n \int_{-1}^{1}(Pw)^2(t)dt \quad \forall x \in [-1,1], \quad P \in \mathcal{P}_{n-1}.$$

Hence

$$\|Pw\|_{L_\infty[-1,1]} \leq C\rho_n^{1/2}\|Pw\|_{L_2[-1,1]}.$$

Applying this to $w^k = e^{-kQ}$, and noting that $a_{2kn}(kQ) = a_{2n}(Q)$ yields for $P \in \mathcal{P}_{n-1}$,

$$\|P^k w^k\|_{L_\infty[-1,1]} \leq C_1\rho_n^{1/2}\|P^k w^k\|_{L_2[-1,1]}, \tag{7.2}$$

and hence

$$\|Pw\|_{L_\infty[-1,1]} \leq C\rho_n^{1/(2k)}\|Pw\|_{L_{2k}[-1,1]}.$$

So we have (1.27) for $q = \infty$ and $p = 2k$.

Step 2. Let $p > 0$, and choose an integer k such that $2k > p$. Then by (7.2),

$$\begin{aligned}\|Pw\|^{2k}_{L_\infty[-1,1]} &\leq C\rho_n \int_{-1}^{1}(Pw)^{2k}(t)dt \\ &\leq C\rho_n\|Pw\|^{2k-p}_{L_\infty[-1,1]}\int_{-1}^{1}|Pw|^p(t)dt;\end{aligned}$$

so if P is not identically zero,

$$\|Pw\|^p_{L_\infty[-1,1]} \le C\rho_n \int_{-1}^1 |Pw|^p(t)dt.$$

This is still trivially true if P is identically zero. Then (1.27) follows for $q = \infty$ and any $p > 0$.

Step 3. We let $p > 0$, and may assume $q < \infty$. Then

$$\begin{aligned}\|Pw\|^q_{L_q[-1,1]} &= \int_{-1}^1 |Pw|^{q-p}(t)|Pw|^p(t)dt \\ &\le \|Pw\|^{q-p}_{L_\infty[-1,1]}\|Pw\|^p_{L_p[-1,1]} \\ &\le (C\rho_n)^{(q-p)/q}\|Pw\|^{q-p}_{L_q[-1,1]}\|Pw\|^p_{L_p[-1,1]},\end{aligned}$$

by (1.27) for the case already proven; so if P is not identically zero,

$$\|Pw\|^p_{L_q[-1,1]} \le (C\rho_n)^{(q-p)/q}\|Pw\|^p_{L_p[-1,1]}. \qquad \square$$

UNIVERSAL BOUNDS FOR THE LOW EIGENVALUES OF NEUMANN LAPLACIANS IN N DIMENSIONS*

MARK S. ASHBAUGH† AND RAFAEL D. BENGURIA‡

Abstract. The authors consider bounds on the Neumann eigenvalues of the Laplacian on domains in $\mathbb{R}^n$ in the light of their recent results on Dirichlet eigenvalues, in particular, their proof of the Payne–Pólya–Weinberger conjecture via spherical rearrangement. They prove the bound $1/\mu_1 + 1/\mu_2 \geq A/2\pi$ for the first two nonzero Neumann eigenvalues for an arbitrary bounded domain Ω in two dimensions and also the stronger (and optimal) bound $\mu_2 \leq \pi(j'_{1,1})^2/A$ for domains having a 4-fold rotational symmetry. (Here $j'_{1,1} \approx 1.84118$ denotes the first positive zero of the derivative of the Bessel function $J_1(x)$ and A is the area of the domain Ω.) The authors also obtain analogues of these results for domains in $\mathbb{R}^n$. Previous results in this vein are due to Szegö, who proved $\mu_1 \leq \pi(j'_{1,1})^2/A$ and $1/\mu_1 + 1/\mu_2 \geq 2A/\pi(j'_{1,1})^2$ for simply connected domains in $\mathbb{R}^2$, and to Weinberger, who proved the general result $\mu_1 \leq (C_n/|\Omega|)^{2/n} p^2_{n/2,1}$ for arbitrary domains in $\mathbb{R}^n$ (here $C_n = \pi^{n/2}/\Gamma(n/2+1) =$ volume of the unit ball in $\mathbb{R}^n$, and $p_{\nu,k}$ denotes the kth positive zero of the derivative of $x^{1-\nu}J_\nu(x)$, where $J_\nu(x)$ represents the standard Bessel function of the first kind of order ν).

Key words. eigenvalues of Neumann Laplacians, universal eigenvalue inequalities, zeros of Bessel functions

AMS subject classifications. 35P15, 49Gxx, 35J05, 33A40

1. Introduction.

In this paper we consider bounds on combinations of the low eigenvalues of the Neumann problem

$$-\Delta u = \mu u \quad \text{on } \Omega, \tag{1.1a}$$

$$\frac{\partial u}{\partial n} = 0 \quad \text{on } \partial\Omega \tag{1.1b}$$

for Ω a bounded domain in $\mathbb{R}^n$ having a smooth boundary. It is well known that this problem has spectrum $\{\mu_i\}_{i=0}^{\infty}$ diverging to infinity and satisfying

$$0 = \mu_0 < \mu_1 \leq \mu_2 \leq \cdots . \tag{1.2}$$

For the closely related Dirichlet problem, with eigenvalues

$$0 < \lambda_1 < \lambda_2 \leq \lambda_3 \leq \cdots \longrightarrow \infty, \tag{1.3}$$

we now have a variety of universal bounds on eigenvalues, such as

$$\lambda_{m+1} - \lambda_m \leq \frac{4}{mn}(\lambda_1 + \cdots + \lambda_m), \tag{1.4}$$

where n = spatial dimension (i.e., for $\Omega \subset I\!\!R^n$) due to Payne, Pólya, and Weinberger [34], [35] (and to Thompson [43] for the relatively straightforward extension from 2 to n dimensions),

$$\lambda_3 \leq 5\lambda_1 + \frac{\lambda_1^2}{\lambda_2} - \lambda_2 \tag{1.5}$$

for $n = 2$ due to Brands [11],

$$\frac{\lambda_3}{\lambda_1} \leq \frac{7(15+\sqrt{345})}{60} \approx 3.9170 \tag{1.6}$$

and

$$\frac{\lambda_2 + \lambda_3}{\lambda_1} \leq \frac{15+\sqrt{345}}{6} \approx 5.5957 \tag{1.7}$$

for $n = 2$ due to Marcellini [28], and

$$\frac{\lambda_2}{\lambda_1} \leq \frac{j_{n/2,1}^2}{j_{n/2-1,1}^2} = \left.\frac{\lambda_2}{\lambda_1}\right|_{n\text{-dimensional ball}}, \tag{1.8}$$

$$\frac{\lambda_4}{\lambda_2} < \frac{j_{n/2,1}^2}{j_{n/2-1,1}^2}, \tag{1.9}$$

and

$$\sum_{k=1}^{n} \frac{1}{\lambda_{k+1} - \lambda_1} \geq \frac{2j_{n/2-1,1}^2 + n(n-4)}{6\lambda_1} \tag{1.10}$$

due to us [3]–[7]. (Here and throughout the paper $j_{\nu,k}$ denotes the kth positive zero of the Bessel function $J_\nu(x)$.) Other contributors to these developments include Hile and Protter [20] and Chiti [14], [15]; indeed, (1.10) was developed directly from results of Chiti in [14] and [15] while (1.8) and (1.9) were developed using ideas introduced by Chiti in [15].

For a given dimension all the inequalities given above exhibit a universal bound on combinations of eigenvalues in the sense that the bound holds without regard to the particular size or shape of the domain.

In his surveys of this subject (which also discuss similar results for certain operators involving powers of the Laplacian and in particular the biharmonic operator), Protter remarked that no bound for the Neumann eigenvalues similar to (1.4) had yet been found [39, pp. 192–193] and [40, p. 119]. Indeed, almost simultaneously it was shown that no such bound for Neumann eigenvalues could possibly hold. In [16] (see also Shubin's comments in [2]) Colin de Verdière showed that given any nondecreasing sequence of positive numbers of length ℓ there exists a domain Ω having these values as $\mu_1, \mu_2, \ldots, \mu_\ell$. Thus $\mu_1, \ldots, \mu_\ell$ are completely unconstrained, aside from the obvious $0 < \mu_1 \leq \mu_2 \leq \cdots \leq \mu_\ell$ for any finite ℓ. While this result might suggest that it is pointless to pursue universal eigenvalue inequalities for the Neumann problem, this is really only partly true. For example, if in two dimensions one adds the area A (volume

$|\Omega|$ in dimension n) to the list of objects between which one seeks constraints then some interesting inequalities may be obtained. Returning to the Dirichlet problem for a moment, there is the celebrated Faber–Krahn inequality [17], [23], [24],

$$\lambda_1 \geq \frac{\pi j_{0,1}^2}{A}, \tag{1.11}$$

which says that $\lambda_1 A$ takes its minimum when Ω is a disk and, similarly, in n dimensions we have

$$\lambda_1 \geq \left(\frac{C_n}{|\Omega|}\right)^{2/n} j_{n/2-1,1}^2, \tag{1.12}$$

where C_n = volume of the unit ball in $I\!R^n$ and again $j_{\nu,k}$ denotes the kth positive zero of the Bessel function $J_\nu(x)$. We also have

$$\lambda_2 > \frac{2\pi j_{0,1}^2}{A} \tag{1.13}$$

in $I\!R^2$ and an analogous result in $I\!R^n$ (due to Peter Szego; see [38, p. 336]).

There are similar results for the Neumann problem. In two dimensions we have the result

$$\mu_1 \leq \frac{\pi p_{1,1}^2}{A} \tag{1.14}$$

of Szegö [42], which he proved for simply connected domains via conformal mapping techniques ("the method of conformal transplantation"; see Bandle [10], for example). Later, Weinberger [44], using more general methods, showed that (1.14) and its n-dimensional analogue,

$$\mu_1 \leq \left(\frac{C_n}{|\Omega|}\right)^{2/n} p_{n/2,1}^2, \tag{1.15}$$

hold for arbitrary domains in $I\!R^2$ and $I\!R^n$, respectively. Here $p_{\nu,k}$ denotes the kth positive zero of the derivative of $x^{1-\nu}J_\nu(x)$. Also Szegö and Weinberger noticed that Szegö's proof of (1.14) for simply connected domains in $I\!R^2$ extends to prove the bound

$$\frac{1}{\mu_1} + \frac{1}{\mu_2} \geq \frac{2A}{\pi p_{1,1}^2} \tag{1.16}$$

for such domains. The bounds of Szegö and Weinberger are optimal (isoperimetric) with equality if and only if Ω is a disk (n-dimensional ball in the case of Weinberger's result (1.15)). It might also be mentioned that Szegö's work on the maximum of $A\mu_1$ was motivated by an earlier conjecture and partial proof of the result (1.14) by Kornhauser and Stakgold [22], who were interested in proving that $\mu_1 < \lambda_1$ in two dimensions and who proposed the route $\mu_1(\Omega) \leq \mu_1(D) < \lambda_1(D) \leq \lambda_1(\Omega)$, where D denotes the disk of the same area as Ω. Pólya [37] then proved $\mu_1 < \lambda_1$ by other means, which actually showed that $\mu_1 \leq 4\pi/A$ and hence that $\mu_1/\lambda_1 \leq 4/j_{0,1}^2 \approx .6917$. With Szegö's proof of (1.14) the constant here is reduced to its optimum value, i.e., $\mu_1/\lambda_1 \leq p_{1,1}^2/j_{0,1}^2 \approx .5862$ with equality if and only if Ω is a disk, at least for the case of simply connected domains (in $\mathbb{R}^2$). Weinberger's subsequent generalization (1.15) then widened the class of domains to which this optimal inequality applies as well as making possible the extension to n dimensions, $\mu_1/\lambda_1 \leq p_{n/2,1}^2/j_{n/2-1,1}^2$. Of course, all of these results make use of the Faber–Krahn inequality, (1.11) or (1.12). Further results along the lines of the inequality $\mu_1 < \lambda_1$ suggested by Kornhauser and Stakgold are due to Payne [32], who proved $\mu_{k+1} < \lambda_k$ $(k = 1, 2, \dots)$ for a convex domain in $\mathbb{R}^2$ with a C^2 boundary, and to Levine and Weinberger [26] (see also [25]), who proved various elegant generalizations of this result to $\mathbb{R}^n$, including the result $\mu_{k+n-1} < \lambda_k$ $(k = 1, 2, \dots)$ for a bounded convex domain in $\mathbb{R}^n$ $(n \geq 2)$ with a sufficiently smooth boundary. At about the same time Aviles [9] showed that $\mu_k < \lambda_k$ $(k = 1, 2, \dots)$ for a bounded domain in $\mathbb{R}^n$ $(n \geq 2)$ with smooth boundary if the mean curvature of the boundary is nonnegative at each of its points. Aviles' result also follows from the general approach of Levine and Weinberger. Of course, the result of Aviles only becomes of interest when $n \geq 3$ since in two dimensions nonnegative mean curvature of the boundary at each point is equivalent to convexity of the domain, and Payne's result $\mu_{k+1} < \lambda_k$ (the $n = 2$ case of the Levine–Weinberger result stated above) is always as strong or stronger than Aviles' $\mu_k < \lambda_k$. Payne has suggested that perhaps $\mu_k \leq \lambda_k$ $(k = 1, 2, \dots)$ holds for any bounded domain in $\mathbb{R}^n$ $(n \geq 2)$ [25] (the $n = 1$ case of this holds as an equality). This conjecture of Payne was recently proved by Friedlander [18] under the hypothesis of a C^1 boundary (see also the related paper of Mazzeo [30]). It might also be noted that such a result cannot hold in general for bounded domains on manifolds; see [12, p. 83] or [13, p. 44, Thm. 3]. Other interesting inequalities between Dirichlet and Neumann eigenvalues have been obtained by Hersch and others; see Hersch's comments on Pólya's paper [37] which appear on pp. 509–510 of [19] for references to these.

In this paper we attempt to go beyond (1.16) in various ways.

Our results are more modest than (1.16) in that they are not optimal but on the other hand they generalize to any dimension n and they are not restricted to simply connected domains. What we prove is that

$$(1.17) \qquad \frac{1}{\mu_1} + \frac{1}{\mu_2} \geq \frac{A}{2\pi}$$

(observe that $p_{1,1} = j_{1,1}' \approx 1.84118 < 2$) for arbitrary domains in two dimensions (this inequality is a special case of a result of Bandle [10, p. 127] which applies to membranes of variable density, but her method of proof, which is based on Szegö's, requires that Ω be simply connected and does not generalize to the n-dimensional case) and its generalization to n dimensions,

$$(1.18) \qquad \frac{1}{\mu_1} + \frac{1}{\mu_2} + \cdots + \frac{1}{\mu_n} \geq \frac{n}{n+2}\left(\frac{|\Omega|}{C_n}\right)^{2/n}.$$

We also prove the optimal bound

$$(1.19) \qquad \mu_2 \leq \frac{\pi p_{1,1}^2}{A}$$

for domains in $\mathbb{R}^2$ with 4-fold rotational symmetry (with equality if and only if the domain is a disk) and a generalization of this to n dimensions. Finally, we investigate the tightness of the bound (1.18) asymptotically as n goes to infinity. We show that

(1.18) is relatively tight in the sense that the first term of the asymptotic expansion of the right-hand side agrees with that of the quantity $1/\mu_1 + 1/\mu_2 + \cdots + 1/\mu_n$ when Ω is a ball (this value is $(n/p_{n/2,1}^2)\left(|\Omega|/C_n\right)^{2/n}$). Similarly, the bound

$$\mu_1 \le (n+2)\left(\frac{C_n}{|\Omega|}\right)^{2/n}, \tag{1.20}$$

which follows from (1.18), is seen to be a relatively tight approximation to the optimal bound (1.15) of Weinberger. These asymptotic results follow from inequalities for the zeros $p_{\nu,1}$ which were recently derived by Lorch and Szego [27]. While it seems likely that these zeros might have been investigated previously, we were unable to find any such information in the literature (see related comments below concerning the Neumann eigenvalues of the unit ball in n dimensions).

Since our results are not optimal (aside from (1.19) and its n-dimensional generalizations) the possibility is left open that the bound

$$\frac{1}{\mu_1} + \frac{1}{\mu_2} + \cdots + \frac{1}{\mu_n} \ge \frac{n(|\Omega|/C_n)^{2/n}}{p_{n/2,1}^2} \tag{1.21}$$

might hold. This bound would be isoperimetric with equality if and only if Ω were an n-dimensional ball (presumably) and would imply Weinberger's bound (1.15).

There is a loose analogy between the ratio results for Dirichlet eigenvalues with which we started our discussion and the results for Neumann eigenvalues discussed above. In particular, if we identify μ_k with $\lambda_{k+1} - \lambda_1$ for $k = 1, 2, 3, \ldots$ and then identify $|\Omega|^{-2/n}$ with λ_1 (or vice versa), then our bound (1.8) for λ_2/λ_1 is identified with Weinberger's bound (1.15) for $|\Omega|^{2/n}\mu_1$ in the sense that these upper bounds are in each case optimal with the maximum being taken on if and only if Ω is an n-dimensional ball. The methods of proof are even almost identical, the main difference being that since in the Neumann case $\mu_0 = 0$ and the corresponding eigenfunction is constant, Weinberger's proof is somewhat simpler (in particular, he is not faced with proving properties of ratios of Bessel functions). Similarly, the bounds (1.17) and (1.18) that we establish in this paper can be viewed as the Neumann analogues of our extension (1.10) of certain inequalities of Chiti. Finally, we mention the further conjecture (for $\Omega \subset \mathbb{R}^2$)

$$\frac{\lambda_2 + \lambda_3}{\lambda_1} \le \frac{2j_{1,1}^2}{j_{0,1}^2} \approx 5.077 \tag{1.22}$$

of Payne, Pólya, and Weinberger [35] for the Dirichlet problem and its connection to Szegö's bound (1.16) and its possible generalization (1.21). The n-dimensional generalization of the conjecture (1.22) would seem to be

$$\frac{\lambda_2 + \cdots + \lambda_{n+1}}{\lambda_1} \le \frac{nj_{n/2,1}^2}{j_{n/2-1,1}^2} \tag{1.23}$$

(also only a conjecture). However, at this point the analogy appears to break down. The Neumann analogue of (1.22)

$$A(\mu_1 + \mu_2) \le 2\pi p_{1,1}^2 \tag{1.24}$$

is definitely *not* true. It does not even hold for all rectangles, whereas (1.22) does. This explains why we look at the quantity $(1/\mu_1 + \cdots + 1/\mu_n)|\Omega|^{-2/n}$ and not at $|\Omega|^{2/n}(\mu_1 + \cdots + \mu_n)$ in this paper. Going the other way, the Dirichlet analogue of the conjecture (1.21) is

$$\sum_{k=1}^{n} \frac{1}{\lambda_{k+1} - \lambda_1} \geq \frac{n}{\left[j_{n/2,1}^2 / j_{n/2-1,1}^2 - 1\right] \lambda_1}, \tag{1.25}$$

which would follow from the conjecture (1.23). While we do not prove (1.21) here, the bounds (1.17) and (1.18) that we do establish are weaker versions of it in the same way that the bound (1.10) is a slightly weaker inequality than the conjectured bound (1.25) above. In both cases the closeness of the approximation for large n is borne out by the asymptotics as n goes to infinity.

One last remark seems in order before we close our introduction. This concerns the Neumann eigenvalues of the unit ball in n dimensions ($n \geq 2$). Somewhat surprisingly, these eigenvalues seem never to have been studied systematically. Since these eigenvalues are determined by the zeros $\tilde{p}_{\nu+1,k}^{(\ell)}$ of the functions $[x^{-\nu} J_{\nu+\ell}(x)]'$ for $\nu = n/2 - 1$ and $\ell = 0, 1, 2, \ldots$ some of them are readily found using known results. In particular, those for the two-dimensional case, for which $\nu = 0$, are all to be found from the roots $j'_{\ell,k}$ of the functions $J'_\ell(x)$ for $\ell = 0, 1, 2, \ldots$. Similarly, for the three-dimensional case the eigenvalues may be found in terms of the roots $a'_{\ell,k}$ of the derivatives of the spherical Bessel functions $j_\ell(x)$ for $\ell = 0, 1, 2, \ldots$. (We follow Abramowitz and Stegun [1] for all our notation concerning Bessel, and related functions; in particular, spherical Bessel functions are defined in eqn. 101.1 on p. 437.) Beyond these cases, only that of spherically symmetric eigenfunctions and their associated eigenvalues can be treated in terms of tabulated results. Since in that case $\ell = 0$ and since $x^\nu \left[x^{-\nu} J_\nu(x)\right]' = -J_{\nu+1}(x)$ the radial eigenvalues are easily found from the zeros $j_{n/2,k}$ of $J_{n/2}(x)$. However, in no other cases beyond $n = 3$ do the Neumann eigenvalues of the n-dimensional ball seem to be readily computable in terms of tabulated quantities. The functions $r^{-\nu} J_{\nu+\ell}(r)$, where $\nu = n/2 - 1$ and $\ell = 0, 1, 2, \ldots$ (and perhaps including an additional constant factor) might well be called "ultraspherical Bessel functions" (as in ultraspherical polynomials) in analogy with the three-dimensional case, since they arise naturally when solving the Helmholtz equation by separation of variables on a ball in $I\!R^n$. The parameter ℓ indexes the eigenvalues of the angular part of the Laplacian in spherical coordinates (these eigenvalues are given by $\ell(\ell + n - 2)$ in dimension n). In particular, for the n-dimensional unit ball $\mu_1 = \mu_2 = \cdots = \mu_n$ occur as $\ell = 1$ eigenvalues and would be denoted $(\tilde{p}_{n/2,1}^{(1)})^2$ in the notation above. However, since only the $\ell = 1$ case ever occurs in this paper, and since the Bessel function then occurring in $[x^{-\nu} J_{\nu+\ell}(x)]'$ has order $\nu + 1 = n/2$, it is convenient for us to use the notation $p_{n/2,1}$, rather than $\tilde{p}_{n/2,1}^{(1)}$, to denote the relevant zeros.

2. Universal bounds for sums of reciprocals of Neumann eigenvalues.

In this section we prove the inequalities (1.17) and (1.18). Specifically, we prove the following.

THEOREM 2.1. *Consider the Neumann problem* (1.1) *for a bounded domain* $\Omega \subset I\!R^n$ ($n \geq 2$) *having smooth boundary. Then the first n nonzero eigenvalues satisfy*

$$\frac{1}{\mu_1} + \frac{1}{\mu_2} + \cdots + \frac{1}{\mu_n} \geq \frac{n}{n+2} \left(\frac{|\Omega|}{C_n} \right)^{2/n}, \tag{2.1}$$

where $|\Omega|$ = *Lebesgue measure of* Ω *and* $C_n = \pi^{n/2}/\Gamma(n/2+1)$ = *the volume of the unit ball in* $I\!R^n$.

Proof. The proof is a relatively easy application of the variational characterization of the eigenvalues μ_i. To be specific, we note that if we let $\{u_i\}_{i=0}^{\infty}$ be an orthonormal set of eigenfunctions for (1.1) in correspondence with the μ_i (so that $-\Delta u_i = \mu_i u_i$ for $i = 0, 1, 2, \ldots$) and we let $\mathcal{H}$ denote the Sobolev space $H^1(\Omega)$, then the eigenvalues μ_i can be characterized by

$$\mu_i = \min_{\substack{u \in \mathcal{H}\setminus\{0\} \\ u \perp \text{ span } (u_0, u_1, \ldots, u_{i-1})}} \frac{\int_\Omega |\nabla u|^2 dx}{\int_\Omega u^2 dx}. \tag{2.2}$$

(Here dx denotes standard Lebesgue measure in $I\!R^n$.) The key to the proof is to choose trial functions φ_i for each of the eigenfunctions u_i and insure that these are orthogonal to the preceding eigenfunctions $u_0, u_1, \ldots, u_{i-1}$. For the n trial functions $\varphi_1, \ldots, \varphi_n$ we simply choose

$$\varphi_j = x_j \quad \text{for } j = 1, \ldots, n, \tag{2.3}$$

but before we can use these we must make certain adjustments requiring two topological arguments. The first is to insure orthogonality of each of the φ_j's ($j = 1, \ldots, n$) to the eigenfunction u_0 (which is actually just the constant function $1/\sqrt{|\Omega|}$). This is done by using the Brouwer fixed point theorem precisely as done by Weinberger [44] (or see [10] or our papers [3], [4]). Simply by translating the origin appropriately we can guarantee $\varphi_j \perp u_0$ for $j = 1, \ldots, n$ (for the special case of $\varphi_j = x_j$ considered here this can be viewed simply as choosing to put the origin at the center of mass of Ω considered as a uniform mass distribution in $I\!R^n$). Next we argue, via the Borsuk–Ulam theorem (see [41, p. 266], [29, p. 170], or [31, p. 361]), that a suitable rotation of axes can be made so as to insure that

$$\int_\Omega \varphi_j u_i dx = \int_\Omega x_j u_i dx = 0 \tag{2.4}$$

for $j = 2, 3, \ldots, n$ and $i = 1, \ldots, j-1$. To see this, recall that the Borsuk–Ulam theorem says that a continuous mapping f from S^{n-1} (the unit sphere in $I\!R^n$) to $I\!R^{n-1}$, which is antipode preserving, i.e., $f(-\sigma) = -f(\sigma)$ for all $\sigma \in S^{n-1}$ must vanish somewhere (for $n \geq 2$). We apply this theorem first to the mapping $f_n : S^{n-1} \longrightarrow I\!R^{n-1}$ defined componentwise by

$$f_{n,k} : \sigma \longrightarrow \int_\Omega x_n u_k dx \quad \text{for } k = 1, \ldots, n-1, \tag{2.5}$$

where σ denotes the direction of the x_n axis (which we regard as free to vary over S^{n-1} by rotation; note that we leave the directions of the other axes ambiguous but that this has no effect on the values of the integrals in (2.5)). Since f_n is antipode preserving the Borsuk–Ulam theorem now tells us that there is a direction $\sigma_n \in S^{n-1}$ for which $f_n(\sigma_n) = 0$. We take this direction (its negative $-\sigma_n$ would serve equally well) as the direction of our x_n axis. This process is then repeated with functions $f_{n-1}, f_{n-2}, \ldots, f_2$ in sequence where the function $f_\ell : S^{\ell-1} \longrightarrow I\!R^{\ell-1}$ (for $\ell = 2, 3, \ldots,$ or $n-1$) is defined componentwise by

$$f_{\ell,k} : \sigma \longrightarrow \int_\Omega x_\ell u_k dx \quad \text{for } k = 1, 2, \ldots, \ell-1, \tag{2.6}$$

and σ is to be regarded as a variable for the direction of the x_ℓ axis and is free to range over all unit vectors perpendicular to the ones already fixed. That is, when considering f_ℓ we should consider its argument σ to vary over the sphere $S^{\ell-1}$ of values perpendicular to the directions $\sigma_{\ell+1}, \dots, \sigma_n$ of the axes $x_{\ell+1}, \dots, x_n$ which have been previously fixed in this inductive process. Once we choose σ_2, the direction of the x_2 axis, σ_1 is effectively fixed, and finally, we have reached the choice of axes that yields the orthogonality conditions (2.4). Note that the rotations we performed to get (2.4) cannot disrupt the orthogonality of each of the trial functions φ_j to the eigenfunction u_0 and thus, by (2.2), we arrive at

$$\mu_i \leq \frac{\int_\Omega |\nabla \varphi_i|^2 dx}{\int_\Omega \varphi_i^2 dx} = \frac{\int_\Omega dx}{\int_\Omega x_i^2 dx} = \frac{|\Omega|}{\int_\Omega x_i^2 dx} \tag{2.7}$$

for $i = 1, 2, \dots, n$. By inverting and summing on i we obtain

$$\sum_{i=1}^n \frac{1}{\mu_i} \geq \frac{\int_\Omega r^2 dx}{|\Omega|}, \tag{2.8}$$

where $r = |x|$ is the usual radial variable in spherical coordinates. Finally, it is easy to see by a simple rearrangement argument (see [37] or [44] for similar arguments) that

$$\int_\Omega r^2 dx \geq \int_{\Omega^*} r^2 dx, \tag{2.9}$$

where Ω^* denotes the n-dimensional ball of volume $|\Omega|$ having its center at the origin (Ω^* is called the spherical rearrangement of Ω). Since Ω^* has radius r_* where $|\Omega| = C_n r_*^n$ it is now easily computed that

$$\int_{\Omega^*} r^2 dx = nC_n \int_0^{r_*} r^{n+2-1} dr = \frac{n}{n+2} |\Omega| \left(\frac{|\Omega|}{C_n} \right)^{2/n}, \tag{2.10}$$

and putting this together with (2.8) and (2.9) immediately yields (2.1). □

Remark. Our application of the Borsuk–Ulam theorem above also occurred in our proof of (1.10) (see [5]) and in an argument in [6]. Both of these results concerned Dirichlet eigenvalues. Also, rearrangement arguments paralleling those given above occur in [37], [44] as already mentioned and also in work of Chiti [14], [15] and ourselves [3], [4], [6], where these references are roughly listed in order of complication (the first two deal with Neumann eigenvalues while the last five deal with Dirichlet eigenvalues; [44] and [3], [4], [6] give optimal bounds and hence involve Bessel functions as trial functions while the others use simpler trial functions). It might also be noted that in the two-dimensional case an argument leading to (2.4) could be made directly, without recourse to the Borsuk–Ulam theorem.

3. Asymptotics for large dimension.

In this section we present the following theorem, which shows that for a ball in n dimensions the ratio of the two sides of (2.1) approaches 1 as $n \to \infty$. More precisely, we have the following.

THEOREM 3.1. *For an n-dimensional ball,*

$$\frac{\left(\frac{1}{\mu_1} + \cdots + \frac{1}{\mu_n} \right)}{\left[n \left(|\Omega| / C_n \right)^{2/n} / (n+2) \right]} = 1 + O\left(\frac{1}{n} \right). \tag{3.1}$$

This theorem is a direct consequence of bounds for the zeros $p_{\nu,1}$ of $[x^{1-\nu}J_\nu(x)]'$ proved recently by Lorch and Szego [27]. The left-hand side of (3.1) reduces simply to

$$\frac{n+2}{p^2_{n/2,1}} \tag{3.2}$$

and (3.1) now follows immediately from the inequalities

$$2\nu + \frac{4}{\nu+3} < p^2_{\nu,1} < 2\nu + 2 \quad \text{for } \nu > -1 \tag{3.3}$$

of Lorch and Szego. We note that the upper bound in (3.3) for $\nu = n/2$ and $n = 1, 2, 3, \ldots$ is already a consequence of our inequality (2.1).

4. Bounds for domains with rotational symmetry. We begin by considering simply connected domains in two dimensions since slightly more detailed results can be obtained for them. We then turn back to general domains in n dimensions and obtain results for $\mu_1 + \cdots + \mu_n$ that are analagous to those we found earlier for $(\lambda_2 + \cdots + \lambda_{n+1})/\lambda_1$ (see §3 of [5]), where the λ_i's here represent the Dirichlet eigenvalues of $-\Delta$ on Ω. In addition, in two dimensions we shall obtain the bound $A\mu_2 \leq \pi(j'_{1,1})^2$ for any domain $\Omega \subset I\!R^2$ with 4-fold rotational symmetry and smooth boundary.

If a simply connected domain in two dimensions has a k-fold rotational symmetry about a point (which we take as our origin) with $k \geq 3$, then it follows relatively easily that $\mu_2 = \mu_1$ so that Weinberger's bound may be applied to produce various strengthenings of the previous results in this paper.

LEMMA 4.1. *If $\Omega \subset I\!R^2$ is a simply connected domain with k-fold symmetry where $k \geq 3$, then $\mu_2 = \mu_1$.*

Proof. Assume that Ω has k-fold rotational symmetry where $k \geq 3$, and let R_k denote the operation of rotating by $2\pi/k$ radians in the counterclockwise sense. Let u_1 be a real eigenfunction for μ_1. Then $u_1(R_kx)$ is also an eigenfunction for μ_1 and one of two conditions must hold: either (1) $u_1(R_kx)$ is a constant multiple of $u_1(x)$ or (2) $u_1(R_kx)$ and $u_1(x)$ are linearly independent eigenfunctions for μ_1. We now show that case (1) cannot occur, and hence that μ_1 is an eigenvalue of multiplicity at least two. Since Ω is simply connected, a well-known observation of Pleijel [36] (or see, for example, [10, p. 128], [19, p. 510], [21, p. 46], [33, p. 466]) shows that u_1 must have a crossing nodal line that is non–self-intersecting and meets the boundary $\partial\Omega$ at exactly two points, x_1 and x_2. This follows simply from the fact that if u_1 had a closed nodal line (the only other possibility), then we would have a domain Ω' (the nodal domain inside the closed nodal line) strictly smaller than Ω but with a smaller first Dirichlet eigenvalue (recall Pólya's result $\mu_1 < \lambda_1$), in contradiction to the well-known monotonicity of eigenvalues property (see [10], for example). In case (1) it is clear that the k points $R^i_kx_1$, for $i = 0, 1, \ldots, k-1$, must all be points where the nodal line of u_1 meets $\partial\Omega$ (as must the points $R^i_kx_2$ for $i = 0, 1, \ldots, k-1$). But this is impossible since the points $R^i_kx_1$ for $i = 0, 1, \ldots, k-1$ are all distinct and there are k of them with $k \geq 3$, in contradiction to the fact that the nodal line meets the boundary only at the two points x_1 and x_2. □

With Lemma 4.1 in hand the following inequalities are immediate (for a simply connected domain with k-fold rotational symmetry where $k \geq 3$ and with a smooth boundary):

$$\mu_2 \leq \frac{\pi(j'_{1,1})^2}{A}, \tag{4.1}$$

$$A(\mu_1 + \mu_2) \le 2\pi(j'_{1,1})^2, \tag{4.2}$$

and

$$\frac{1}{\mu_1} + \frac{1}{\mu_2} \ge \frac{2A}{\pi(j'_{1,1})^2}. \tag{4.3}$$

These are, of course, optimal results but (4.1) and (4.2), at least, could not be expected to continue to apply in the absence of k-fold symmetry (see §5). Also, (4.3) is just a special case of Szegö's result (1.16).

Under the assumption that Ω is 4-fold rotationally symmetric, but without assuming that Ω is simply connected or using facts about nodal lines, we can still prove (4.1), (4.2), and (4.3) in two dimensions. The only result above that cannot be proved in this context is the equality $\mu_2 = \mu_1$ of Lemma 4.1. We can also prove analogues of (4.2) and (4.3) in n dimensions. We begin with these since this is the most general part of the argument.

In n dimensions we consider domains Ω situated with respect to Cartesian coordinate axes such that with respect to rotation in each coordinate plane (i.e., $\binom{n}{2}$ planes) Ω has rotational symmetry of order 4. We shall follow closely Weinberger's proof while incorporating our 4-fold symmetry hypotheses.

THEOREM 4.2. *Let Ω be a bounded domain in $I\!R^n$ with smooth boundary and suppose that Ω is invariant with respect to* 90° *rotations in the coordinate planes spanned by each pair of* (*Cartesian*) *coordinate axes. Then*

$$\sum_{i=1}^{n} \mu_i \le n\left(\frac{C_n}{|\Omega|}\right)^{2/n} p^2_{n/2,1} \tag{4.4}$$

and

$$\sum_{i=1}^{n} \frac{1}{\mu_i} \ge \frac{n\left(|\Omega|/C_n\right)^{2/n}}{p^2_{n/2,1}}. \tag{4.5}$$

Proof. One works with trial functions $\varphi_j = g(r)x_j/r$ for $j = 1, \dots, n$ as introduced by Weinberger [44]. By the symmetry of Ω, orthogonality to u_0 is assured. But now one would like to use the extended Rayleigh–Ritz inequality which, in the special case in which we need it, asserts that

$$\sum_{j=1}^{n} \mu_j \le \sum_{j=1}^{n} \frac{\int_\Omega |\nabla \varphi_j|^2 dx}{\int_\Omega \varphi_j^2 dx} \tag{4.6}$$

if the φ_j's are pairwise orthogonal (and each is orthogonal to u_0). To see that these orthogonality conditions hold, the integrals $\int_\Omega \varphi_i\varphi_j dx = \int_\Omega [g(r)^2/r^2] x_i x_j dx$ for $i \ne j$ are investigated. Under a change of variables by a 90° rotation in the x_ix_j-coordinate plane this integral is seen to change to its negative and hence it must vanish. Thus

$$\int_\Omega \varphi_i\varphi_j dx = 0 \quad \text{for } i \ne j, \quad 1 \le i, \quad j \le n, \tag{4.7}$$

and use of (4.6) is justified. Before we can proceed, though, we also need to show that the integrals $\int_\Omega \varphi_j^2 dx$ are the same for all $j = 1, 2, \dots, n$. This again follows easily by a 90° rotational change of variables applied to the integral $\int_\Omega [\varphi_i^2 - \varphi_j^2]dx$. Thus the denominators in the right-hand side of (4.6) are all equal (as are the numerators by a similar argument). Hence we can sum to arrive at

$$\sum_{j=1}^{n} \mu_j \leq \frac{\sum_{j=1}^{n} \int_\Omega |\nabla \varphi_j|^2 dx}{(1/n) \sum_{j=1}^{n} \int_\Omega \varphi_j^2 dx} = \frac{n \int_\Omega [g'(r)^2 + (n-1)g(r)^2/r^2]\, dx}{\int_\Omega g(r)^2 dx}. \tag{4.8}$$

If we now make Weinberger's choice of function $g(r)$ (this would be $G(r)$ in his notation) we obtain (4.4), as desired. Inequality (4.5) follows from the Cauchy–Schwarz inequality applied as follows:

$$n^2 = \left(\sum_{j=1}^{n} \frac{1}{\sqrt{\mu_j}} \sqrt{\mu_j} \right)^2 \leq \left(\sum_{j=1}^{n} \frac{1}{\mu_j} \right) \left(\sum_{j=1}^{n} \mu_j \right). \quad \square$$

In two dimensions we can go beyond Theorem 4.2 to the following.

THEOREM 4.3. *Let $\Omega \subset I\!R^2$ be a bounded domain having 4-fold rotational symmetry. Then*

$$\mu_j \leq \frac{\pi \left(j'_{1,1}\right)^2}{A} \quad \textit{for } j = 1, 2, \tag{4.9}$$

and hence also $A(\mu_1 + \mu_2) \leq 2\pi \left(j'_{1,1}\right)^2$.

Proof. We develop separate inequalities for μ_1 and μ_2. To do this we use the variational characterizations of μ_1 and μ_2. By the 4-fold symmetry of Ω we can insist that u_1 be either even or odd under rotation by 180°. We use this together with rotational freedom to argue that we can make a choice of axes so that $\int_\Omega \varphi_2 u_1 \, dx = 0$. If u_1 were even, then by employing a 180°-rotational change of variables in the integral $\int_\Omega \varphi_2 u_1 \, dx$ we find that it equals its own negative and is hence zero. If u_1 were odd, then a 180° rotation of the coordinate system reverses the sign of $\int_\Omega \varphi_2 u_1 \, dx$, implying that for some choice of rotated coordinates $\int_\Omega \varphi_2 u_1 \, dx$ vanishes. We then obtain

$$\mu_j \leq \frac{\int_\Omega |\nabla \varphi_j|^2 \, dx}{\int_\Omega \varphi_j^2 \, dx} \quad \text{for } j = 1, 2, \tag{4.10}$$

which in turn yields

$$\mu_j \leq \frac{\int_\Omega [g'(r)^2 + (n-1)g(r)^2/r^2] \, dx}{\int_\Omega g(r)^2 \, dx}, \tag{4.11}$$

since as before neither $\int_\Omega \varphi_j^2 \, dx$ nor $\int_\Omega |\nabla \varphi_j|^2 \, dx$ varies with j. Weinberger's choice of function $g(r)$ then yields the inequalities (4.9) of the theorem. □

If u_1 happens to be even, then our proof above actually yields more.

THEOREM 4.4. *With hypotheses as in Theorem 4.3 suppose, in addition, that u_1 is even, i.e., that $u_1(-x) = u_1(x)$ for all $x \in \Omega$. Then*

$$\mu_j \leq \frac{\pi (j'_{1,1})^2}{A} \quad \textit{for } j = 2, 3, \tag{4.12}$$

and hence also $A(\mu_2+\mu_3) \le 2\pi(j_{1,1}')^2$.

For the proof we simply use the argument above which led to (4.9) but noting that $\int_\Omega \varphi_i u_1\,dx = 0$ for $i = 1,2$ is automatic (since u_1 is even) so that we can, by making a suitable rotation, view φ_1 and φ_2 as trial functions for u_2 and u_3, respectively.

Theorem 4.4 has potential relevance for nonsimply connected domains. One can imagine a domain in the shape of a gasket having 4 holes and which is 4-fold rotationally invariant. If the holes are elongated and come close to disconnecting the domain into a disk and an annulus (of appropriate radii), then it seems reasonable to expect that u_1 will be 4-fold rotationally invariant with its nodal set consisting of 4 short curves connecting the holes.

5. Examples in two dimensions. For rectangles (always assuming an $a \times b$ rectangle with $a \ge b > 0$) we obtain

$$\mu_1 = \frac{\pi^2}{a^2}, \tag{5.1}$$

$$\mu_2 = \begin{cases} \dfrac{\pi^2}{b^2} & \text{if } \dfrac{1}{2} \le \dfrac{b}{a} \le 1, \\ \dfrac{4\pi^2}{a^2} & \text{if } 0 < \dfrac{b}{a} \le \dfrac{1}{2}. \end{cases} \tag{5.2}$$

Thus

$$A\mu_1 = \frac{\pi^2 b}{a}, \tag{5.3}$$

$$A\mu_2 = \begin{cases} \dfrac{\pi^2 a}{b} & \text{if } \dfrac{1}{2} \le \dfrac{b}{a} \le 1, \\ \dfrac{4\pi^2 b}{a} & \text{if } 0 < \dfrac{b}{a} \le \dfrac{1}{2}, \end{cases} \tag{5.4}$$

$$A(\mu_1+\mu_2) = \begin{cases} \pi^2\left(\dfrac{b}{a}+\dfrac{a}{b}\right) & \text{if } \dfrac{1}{2} \le \dfrac{b}{a} \le 1, \\ 5\pi^2 b/a & \text{if } 0 < \dfrac{b}{a} \le \dfrac{1}{2}, \end{cases} \tag{5.5}$$

$$\frac{1}{A}\left(\frac{1}{\mu_1}+\frac{1}{\mu_2}\right) = \begin{cases} \dfrac{\left(\dfrac{b}{a}+\dfrac{a}{b}\right)}{\pi^2} & \text{if } \dfrac{1}{2} \le \dfrac{b}{a} \le 1, \\ \dfrac{5a}{4\pi^2 b} & \text{if } 0 < \dfrac{b}{a} \le \dfrac{1}{2}, \end{cases} \tag{5.6}$$

and

$$\frac{\mu_2}{\mu_1} = \begin{cases} \dfrac{a^2}{b^2} & \text{if } \dfrac{1}{2} \le \dfrac{b}{a} \le 1, \\ 4 & \text{if } 0 < \dfrac{b}{a} \le \dfrac{1}{2}. \end{cases} \tag{5.7}$$

From these it follows that among rectangles $A\mu_2$ and $A(\mu_1+\mu_2)$ take their maxima for the 2:1 rectangle. Also $(1/\mu_1 + 1/\mu_2)/A$ takes its minimum among rectangles at the square.

Note that the 2:1 rectangle shows that the disk does not maximize $A(\mu_1+\mu_2)$ (for the disk $A(\mu_1+\mu_2) \approx 21.2996$). Of course, Weinberger's result guarantees that $A\mu_1$ is maximized at the disk. It seems likely, too, that the disk minimizes $(1/\mu_1 + 1/\mu_2)/A$. We also hazard the guess that $\mu_2/\mu_1 \leq 4$ for all *convex* domains. Finally, we note that our inequality (1.17) provides the lower bound $1/2\pi \approx .15915$ to $(1/\mu_1 + 1/\mu_2)/A$, which would be only about 15 percent low if the optimal bound were its value at the disk($\approx .18780$).

Acknowledgment. We would like to thank Hans Weinberger for several useful comments and, in particular, for a more general formulation of Lemma 4.1. We are also grateful to Lee Lorch and Peter Szego for sharing the results in [27] with us prior to publication.

AN EXISTENCE THEOREM FOR A FREE BOUNDARY PROBLEM OF HYPERSONIC FLOW THEORY*

VINCENT GIOVANGIGLI†

Abstract. The author considers a free boundary problem arising in hypersonic flow theory. The model describes an axisymmetric thin viscous shock layer in the vicinity of the stagnation point of a blunt body. The governing equations on the symmetry line reduce to a two-point boundary value problem with four unknowns and a free boundary. The free boundary problem is reduced to a nonlinear eigenvalue problem through a change of variable. Existence of a solution is achieved by deriving a priori estimates and by using the Leray–Schauder topological degree theory.

Key words. free boundary, viscous shock layer, existence

AMS subject classifications. 65L10, 76N99

1. Introduction.

An interesting free boundary problem arising in hypersonic flow theory is that of thin viscous shock layers. In these models, the governing equations are of compressible boundary layer type with a normal pressure gradient and are solved between the body surface and the shock. Usual boundary conditions are imposed at the body wall, whereas the Rankine–Hugoniot relations are written at the shock which is the free boundary. These models have been found successful is predicting hypersonic flows past blunt bodies; for more details we refer to Blottner [2], Bush [3], Davis [5], Ho and Probstein [7], Laboudigue, Giovangigli, and Candel [8], and to the references therein.

In this paper, we investigate an axisymmetric thin viscous shock layer for a perfect gas in the vicinity of the stagnation point of a blunt body. Only the governing equations on the symmetry line are considered. The corresponding solutions provide the initial conditions for a finite difference method proceeding in the downstream direction [2], [5], [8] as it has been shown rigorously by Oleinik [10] in the incompressible flat boundary layer case. Another point of view is that these solutions are similar approximated solutions that are valid in the neighborhood of the stagnation streamline as are the solutions of the Falkner–Skan equations for incompressible boundary layers.

The thin viscous shock layer governing equations along the symmetry line reduce to a two-point boundary value problem with four unknowns and with a free boundary. The four reduced solution components are the normal and tangential velocities, the pressure, and the temperature. The tangential velocity and the temperature are governed by second-order equations and are specified at the boundaries. On the other hand, the normal velocity and the pressure are governed by first-order equations, but there are two boundary conditions for the normal velocity and one for the pressure. The extra boundary condition for the normal velocity is thus used to determine the free boundary. By introducing a reduced normal coordinate, the free boundary problem is first transformed into a nonlinear eigenvalue problem. Existence of a solution is then achieved by deriving a priori estimates and by using the Leray–Schauder topological degree theory. The main difficulty consists in deriving a priori estimates of the solution components. In particular, obtaining strictly positive upper and lower bounds for

*Received by the editors November 13, 1991; accepted for publication (in revised form) August 13, 1992.

†Centre de Mathématiques Appliquées and Centre National de la Recherche Scientifique, Ecole Polytechnique 91128 Palaiseau cedex, France.

the free boundary is essential and rely on the presence of a negative pressure gradient term in the tangential momentum equation. The method of proof is similar to the one used by Berestycki, Nicolaenko, and Scheurer for flame problems [1], [6]. This proof differs from those of Weyl [11] and McLeod and Serrin [9] in the case of similar flat boundary layers which were based on shooting techniques. It is not known whether such a solution is unique as in the compressible boundary layer case [9] at variance with the incompressible boundary layer case [4]. Finally, to the author's knowledge, the results that are presented in this paper are new.

The thin viscous shock layer equations are presented in §2 for self-completeness. A priori estimates and existence of a solution are obtained in §3.

2. Setting of the problem. In this section, for self-completeness, we derive the first-order axisymmetric thin viscous shock layer equations on the symmetry line. For more details on the derivation of the model, we refer to Blottner [2], Bush [3], Davis [5], Ho and Probstein [7], Laboudigue, Giovangigli, and Candel [8], and to the references therein.

2.1. Viscous shock layers. The axisymmetric viscous shock layer equations can be derived by writing the Navier–Stokes equations in a local coordinate system (s,n), where s is measured along the body surface and n normal to the body surface. The shock Reynolds number Re_σ is assumed to be large $Re_\sigma = \rho_\infty V_\infty d/\mu_\sigma \gg 1$, where ρ_∞ denotes the density in front of the shock, V_∞ the uniform velocity in front of the shock, d the radius of curvature at the nose of the blunt body, and μ_σ the viscosity behind the shock, and the order of magnitude of the terms in the equations is determined with respect to the inverse square root of Re_σ. Only first-order terms are kept from both a viscous and an inviscid view point, so that the governing equations are uniformly valid between the shock and the body surface. The total mass conservation equation then takes the form

$$\frac{\partial}{\partial s}(\mathcal{R}\rho U) + \frac{\partial}{\partial n}(\mathcal{H}\mathcal{R}\rho V) = 0, \tag{2.1}$$

where ρ is the density, $\mathcal{H} = 1 + \kappa n$ a curvature term, κ the positive curvature of the body surface, $\mathcal{R}$ the radius from the axis of symmetry, (U,V) the mass averaged flow velocity components in the local coordinate system, and the tangential momentum conservation equation is

$$\frac{\rho U}{\mathcal{H}}\frac{\partial U}{\partial s} + \rho V\frac{\partial U}{\partial n} + \frac{\rho\kappa UV}{\mathcal{H}} + \frac{1}{\mathcal{H}}\frac{\partial P}{\partial s} - \frac{1}{\mathcal{H}\mathcal{R}}\frac{\partial}{\partial n}\Big(\mathcal{H}\mathcal{R}\mu\frac{\partial U}{\partial n}\Big) = 0, \tag{2.2}$$

where P is the pressure and μ the viscosity. The normal momentum conservation can also be written

$$\frac{\rho U}{\mathcal{H}}\frac{\partial V}{\partial s} + \rho V\frac{\partial V}{\partial n} - \frac{\rho\kappa U^2}{\mathcal{H}} + \frac{\partial P}{\partial n} = 0, \tag{2.3}$$

and the energy conservation equation is

$$\rho c_p\frac{U}{\mathcal{H}}\frac{\partial T}{\partial s} + \rho c_p V\frac{\partial T}{\partial n} - \frac{U}{\mathcal{H}}\frac{\partial P}{\partial s} - V\frac{\partial P}{\partial n} - \mu\Big(\frac{\partial U}{\partial n}\Big)^2 - \frac{1}{\mathcal{H}\mathcal{R}}\frac{\partial}{\partial n}\Big(\mathcal{H}\mathcal{R}k\frac{\partial T}{\partial n}\Big) = 0, \tag{2.4}$$

where T is the temperature, c_p the constant pressure specific heat—assumed to be a constant—and k the thermal conductivity. Furthermore, the state law reads

$$\rho = \frac{\gamma}{\gamma - 1}\frac{P}{c_p T}, \tag{2.5}$$

where γ denotes the ratio of specific heats $\gamma = c_p/c_v$.

The boundary conditions at the shock are provided by the Rankine–Hugoniot relations in the high Mach number limit $M_\infty = V_\infty^2/(\gamma P_\infty) \gg 1$, where P_∞ denotes the uniform pressure in front of the shock. Denoting by $n = \sigma(s)$ the shock location, we have

$$V\big(s,\sigma(s)\big) = V_\infty \cos(\phi+\theta)\sin\theta - \epsilon V_\infty \sin(\phi+\theta)\cos\theta, \tag{2.6}$$

$$U\big(s,\sigma(s)\big) = V_\infty \cos(\phi+\theta)\cos\theta + \epsilon V_\infty \sin(\phi+\theta)\sin\theta, \tag{2.7}$$

$$P\big(s,\sigma(s)\big) = \frac{2\rho_\infty V_\infty^2}{\gamma+1}\sin^2(\phi+\theta), \qquad T\big(s,\sigma(s)\big) = \frac{2\gamma V_\infty^2}{(\gamma+1)^2 c_p}\sin^2(\phi+\theta), \tag{2.8}$$

where $\epsilon = (\gamma-1)/(\gamma+1)$ and where ρ_∞ denotes the density of air in front of the shock. Remark also that from (2.5) and (2.8) we have $\rho\big(s,\sigma(s)\big) = \rho_\infty/\epsilon$. In these relations ϕ denotes the angle between the axis of symmetry and the tangent to the body surface and θ the angle between the tangent to the body surface and the tangent to the shock, i.e., $\tan\theta = (d\sigma/ds)/(1+\kappa\sigma)$. The radius $\mathcal{R}$ is also given by $\mathcal{R} = r + n\cos\phi$, where r denotes the distance from the axis of symmetry to the body surface and the positive curvature κ, the radius r and the angle ϕ are given function of s such that $-\kappa = d\phi/ds$ and $\sin\phi = dr/ds$. Futhermore, with $s = 0$ corresponding to the symmetry axis, i.e., the stagnation streamline, we have $\kappa(s) = 1/d + O(s^2)$, $\phi(s) = \pi/2 - s/d + O(s^3)$, and $r(s) = s + O(s^3)$, where $d = 1/\kappa(0)$ is the radius of curvature at the nose of the blunt body. On the other hand, at the body surface, we have

$$V(s,0) = 0, \qquad U(s,0) = 0, \qquad T(s,0) = T_w, \tag{2.9}$$

where T_w denotes the body wall temperature.

2.2. Thin viscous shock layers. The thin shock layer approximation is now used in order to simplify the system (2.1)–(2.9). In the thin layer limit, we have $\epsilon = (\gamma-1)/(\gamma+1) \ll 1$, which yields the following orders of magnitude $s/d = O(1)$, $n/d = O(\epsilon)$, $\rho/\rho_\infty = O(1/\epsilon)$, $U/V_\infty = O(1)$, $V/V_\infty = O(\epsilon)$, $P/(\rho_\infty V_\infty^2) = O(1)$, and $c_p T/V_\infty^2 = O(1)$. Note that in the thin layer approximation we still have $\epsilon Re_\sigma \gg 1$ and $\epsilon M_\infty^2 \gg 1$, although $\epsilon \ll 1$ [3], [7]. Under the thin layer approximation, we thus have $\mathcal{H}(s,n) = 1 + \kappa(s)n = 1 + O(\epsilon)$ and $\mathcal{R}(s,n) = r(s) + n\cos\phi(s) = r(s)\big(1 + O(\epsilon)\big)$ so that up to first-order we may replace $\mathcal{H}$ by 1 and $\mathcal{R}$ by r in (2.1)–(2.9). An examination of the normal momentum equation also indicates that the terms $\rho U(\partial V/\partial s)$ and $\rho V(\partial V/\partial n)$ are of lower order and can thus be neglected. Similarly, the terms $U(\partial P/\partial s)$ and $V(\partial P/\partial n)$ can be eliminated from the energy conservation equation. The first-order axisymmetric thin viscous shock layer equations are thus found to be

$$\frac{1}{r}\frac{\partial(r\rho U)}{\partial s} + \frac{\partial(\rho V)}{\partial n} = 0, \tag{2.10}$$

$$\rho U\frac{\partial U}{\partial s} + \rho V\frac{\partial U}{\partial n} + \kappa\rho UV + \frac{\partial P}{\partial s} - \frac{\partial}{\partial n}\Big(\mu\frac{\partial U}{\partial n}\Big) = 0, \tag{2.11}$$

$$-\kappa\rho U^2+\frac{\partial P}{\partial n}=0, \tag{2.12}$$

$$\rho c_p U\frac{\partial T}{\partial s}+\rho c_p V\frac{\partial T}{\partial n}-\mu\left(\frac{\partial U}{\partial n}\right)^2-\frac{\partial}{\partial n}\left(k\frac{\partial T}{\partial n}\right)=0. \tag{2.13}$$

Note that the curvature term $\kappa\rho UV$ is usually neglected in the tangential momentum equation, but is kept here for consistency with the curvature term $\kappa\rho U^2$ in the normal momentum equation. The boundary conditions (2.6)–(2.8) can also be simplified since we now have $\sigma/d=O(\epsilon)$ so that $\cos\theta=1+O(\epsilon^2)$ and $\sin\theta=d\sigma/ds+O(\epsilon^2)=O(\epsilon)$, which yields

$$V\big(s,\sigma(s)\big)-U\big(s,\sigma(s)\big)\frac{d\sigma}{ds}(s)=-\epsilon V_\infty\sin\phi(s),\qquad U\big(s,\sigma(s)\big)=V_\infty\cos\phi(s), \tag{2.14}$$

$$P\big(s,\sigma(s)\big)=\frac{2\rho_\infty V_\infty^2}{(\gamma+1)}\sin^2\phi(s),\qquad T\big(s,\sigma(s)\big)=\frac{2\gamma V_\infty^2}{(\gamma+1)^2c_p}\sin^2\phi(s), \tag{2.15}$$

and the values of ρ, V, U, P, T at the shock will be denoted by ρ_σ, V_σ, U_σ, P_σ, and T_σ, respectively, in the following. On the other hand, the boundary conditions (2.9) at the body surface are unchanged. Finally note that $V_\sigma-U_\sigma(d\sigma/ds)$, T_σ, P_σ, and T_w are even functions of s as are expected to be V, T, P, and σ, whereas U_σ, r, and $\pi/2-\phi$ are odd functions of s as is expected to be U.

2.3. Transformed equations. We now recast the governing equations into a simpler form, and we simultaneously transform the free boundary problem into a nonlinear eigenvalue problem. Assuming a positive shock location σ, we may introduce the new independent variables (ξ,ζ)—similar to the Howarth–Dorodnitsyn variables [2]—defined by

$$\xi=\frac{S(s)}{|S(s)|}|S(s)|^{1/4},\qquad \zeta=\frac{1}{l}\frac{U_\sigma(s)r(s)}{\sqrt{2S(s)}}\int_0^n\rho(s,\nu)\,d\nu, \tag{2.16}$$

where S and l are given by

$$S=\int_0^s\rho_\sigma(t)\mu_\sigma(t)U_\sigma(t)r^2(t)dt,\qquad l=\frac{U_\sigma(s)r(s)}{\sqrt{2S(s)}}\int_0^{\sigma(s)}\rho(s,\nu)\,d\nu, \tag{2.17}$$

so that l is the new unknown associated with the shock location σ. We also introduce the new dependent variables

$$v=\frac{\xi l}{2U_\sigma}\frac{\partial s}{\partial\xi}\left(U\frac{\partial\zeta}{\partial s}+V\frac{\partial\zeta}{\partial n}\right),\qquad u=\frac{1}{U_\sigma}\frac{\partial s}{\partial\xi}\left(U\frac{\partial\xi}{\partial s}+V\frac{\partial\xi}{\partial n}\right)=\frac{U}{U_\sigma}, \tag{2.18}$$

$$p=\frac{P-P(0,\sigma(0))}{\rho_\sigma U_\sigma^2},\qquad \theta=\frac{T}{T_\sigma}, \tag{2.19}$$

and after lengthy calculations, the transformed governing equations are shown to be

$$\frac{\xi}{2}\frac{\partial u}{\partial\xi}+u\left(1+\frac{\xi}{2l}\frac{\partial l}{\partial\xi}\right)+\frac{1}{l}\frac{\partial v}{\partial\zeta}=0, \tag{2.20}$$

$$\frac{\xi u}{2}\frac{\partial u}{\partial \xi}+\alpha u^2+\frac{\mathcal{K}uv}{\rho}+\frac{v}{l}\frac{\partial u}{\partial \zeta}+\frac{2\alpha p\rho_\sigma}{\rho}+\frac{\xi\rho_\sigma}{2\rho}\frac{\partial p}{\partial \xi}-\frac{1}{l^2}\frac{\partial}{\partial \zeta}\left(\eta\frac{\partial u}{\partial \zeta}\right)=0, \tag{2.21}$$

$$-\frac{\mathcal{K}u^2}{\rho_\sigma}+\frac{1}{l}\frac{\partial p}{\partial \zeta}=0, \tag{2.22}$$

$$\frac{\xi u}{2}\frac{\partial \theta}{\partial \xi}+\beta u\theta+\frac{v}{l}\frac{\partial \theta}{\partial \zeta}-e\eta\left(\frac{\partial u}{\partial \zeta}\right)^2-\frac{1}{l^2}\frac{\partial}{\partial \zeta}\left(\lambda\frac{\partial \theta}{\partial \zeta}\right)=0, \tag{2.23}$$

where α, β, e, and $\mathcal{K}$ are functions of ξ coefficients given by

$$\alpha=\frac{\xi}{2U_\sigma}\frac{\partial U_\sigma}{\partial \xi},\qquad \beta=\frac{\xi}{2T_\sigma}\frac{\partial T_\sigma}{\partial \xi},\qquad e=\frac{U_\sigma^2}{c_pT_\sigma},\qquad \mathcal{K}=\frac{\kappa\sqrt{2S}}{U_\sigma r},$$

and where the reduced transport coefficients η and λ are given by

$$\mu=\frac{\rho\mu}{\rho_\sigma\mu_\sigma},\qquad \lambda=\frac{\rho k}{\rho_\sigma\mu_\sigma c_p}.$$

In particular, keeping in mind that $\xi=\delta s+O(s^3)$ with $\delta>0$, in the neighborhood of $\xi=0$, we have $\alpha=\alpha(0)+O(\xi^2)$, $\beta=O(\xi^2)$, $e=O(\xi^2)$, and $\mathcal{K}=\mathcal{K}(0)+O(\xi^2)$, with $\alpha(0)>0$ and $\mathcal{K}(0)>0$. The corresponding boundary conditions for $\zeta=1$ are now

$$v(\xi,1)=v_\sigma(\xi),\qquad u(\xi,1)=u_\sigma(\xi),\qquad p(\xi,1)=p_\sigma(\xi),\qquad \theta(\xi,1)=\theta_\sigma(\xi), \tag{2.24}$$

where $v_\sigma=\big(V_\sigma-U_\sigma(d\sigma/ds)\big)\sqrt{2S}/(U_\sigma\mu_\sigma r)$, $u_\sigma=1$, $p_\sigma=-2(\gamma-1)/(\gamma+1)^2$, and $\theta_\sigma=1$ are known functions of ξ, and at the body surface $\zeta=0$ we have

$$v(\xi,0)=0,\qquad u(\xi,0)=0,\qquad \theta(\xi,0)=\theta_w(\xi), \tag{2.25}$$

where $\theta_w=T_w/T_\sigma$ denotes the reduced body wall temperature. Remark that the coefficients α, β, e, $\mathcal{K}$, v_σ, u_σ, p_σ, θ_σ, and θ_w are now even functions of ξ as are expected to be the new unknowns v, u, p, θ, and l.

2.4. Equations along the symmetry axis and locally similar solutions. In this paper, we only investigate the solutions along the symmetry line $\xi=0$. These solutions provide the initial conditions for a finite difference method proceeding in the downstream direction [2], [5], [8] as it has been shown rigorously by Oleinik in the incompressible flat boundary layer case [10]. These solutions on the stagnation streamline $\xi=0$ are also locally similar approximated solutions that are valid in the neighborhood of the symmetry line as are the solutions of the Falkner–Skan equations for incompressible boundary layers. More specifically, replacing all the coefficients by their constant quadratic approximations in (2.20)–(2.25) yields that $\beta=0$ and $e=0$ and that α, $\mathcal{K}$, v_σ, u_σ, p_σ, θ_σ, and θ_w are constants. But then the resulting system of partial differential equations posseses similar solutions functions of ζ alone, i.e., such that $\partial/\partial\xi=0$, and these similar solutions are governed by the same equations as the one that are strictly valid along the stagnation streamline $\xi=0$ since only the grouping $\xi(\partial/\partial\xi)$ appears in the governing equations (2.20)–(2.25).

Since now we only consider the solutions along the stagnation streamline $\xi=0$, we formally drop the ξ dependence in order to avoid notational complexity. Therefore,

v, u, p, θ, and l now stand, respectively, for $v(0,\cdot)$, $u(0,\cdot)$, $p(0,\cdot)$, $\theta(0,\cdot)$, and $l(0)$ and α, v_σ, u_σ, p_σ, θ_σ, and θ_w stand, respectively, for $\alpha(0)$, $v_\sigma(0)$, $u_\sigma(0)$, $p_\sigma(0)$, $\theta_\sigma(0)$, and $\theta_w(0)$. Denoting by $'$ the derivation with respect to ζ, the equations on the symmetry line $\xi = 0$ are then

$$u + \frac{v'}{l} = 0, \tag{2.26}$$

$$\alpha u^2 + cuv\theta + \frac{vu'}{l} + 2\alpha p\theta - \frac{\big(\eta(\theta)u'\big)'}{l^2} = 0, \tag{2.27}$$

$$-cu^2 + \frac{p'}{l} = 0, \tag{2.28}$$

$$\frac{v\theta'}{l} - \frac{\big(\lambda(\theta)\theta'\big)'}{l^2} = 0, \tag{2.29}$$

where we have introduced the notation $c = \mathcal{K}(0)/\rho_\sigma$ and we have $c > 0$ and $\alpha > 0$. Note that we have used the relation $\rho_\sigma/\rho = \theta$, which is valid for $\xi = 0$, since $U = 0$ on the symmetry line implies that $P = P_\sigma$ from (2.12) and (2.15). The boundary conditions are also given by (2.24) and (2.25) specialized to $\xi = 0$,

$$v(1) = v_\sigma, \qquad u(1) = u_\sigma, \qquad p(1) = p_\sigma, \qquad \theta(1) = \theta_\sigma, \tag{2.30}$$

$$v(0) = 0, \qquad u(0) = 0, \qquad \theta(0) = \theta_w, \tag{2.31}$$

where $v_\sigma < 0$, $u_\sigma = 1$, $p_\sigma < 0$, $\theta_\sigma = 1$, and $\theta_w > 0$. An explicit calculation also yields that $v_\sigma = -(\epsilon Re_\sigma/2)^{1/2}$, $p_\sigma = -2\epsilon/(\gamma+1)$ and $\theta_w = T_w/T_\sigma$ so that we may assume for convenience that $v_\sigma < -1$, $-1 < p_\sigma$ and $\theta_w < 1$, since in the thin layer approximation we have $\epsilon Re_\sigma \gg 1$ and $\epsilon \ll 1$ and since the body wall temperature is always lower than the shock temperature. Still note that these later assumptions are not strictly needed in the proof but simplify the analytic expression of various lower and upper bound introduced in the proof. The reduced transport coefficients η and λ are also functions of the reduced temperature θ only since $\rho_\sigma/\rho = \theta$, and we assume that these functions $\theta \to \eta(\theta)$ and $\theta \to \lambda(\theta)$ are smooth and such that $0 < \inf_{\mathbb{R}} \eta$, $\|\eta\|_{C^2(\mathbb{R})} < +\infty$, $0 < \inf_{\mathbb{R}} \lambda$, and $\|\lambda\|_{C^2(\mathbb{R})} < +\infty$.

Finally, we remark now that there are two boundary conditions for the reduced tangential velocity u and the reduced temperature θ which are governed by second-order equations, but that there are two boundary conditions for the reduced normal velocity v and one boundary condition for the reduced pressure p which are governed by first-order equations. The extra boundary condition for the reduced normal velocity v will thus be used to determine the eigenvalue l associated with the free boundary σ.

3. Existence of a solution. In this section, we prove the existence of a solution for the two point boundary value problem (2.26)–(2.31). The fundamental unknowns are v, u, p, θ, which are defined on $[0,1]$, and l. The method of proof is based on a priori estimates and on the Leray–Schauder topological degree theory. This method of proof is similar to the one used in [1] and [6] and differs from the one used by Weyl

[11] and McLeod and Serrin [9] for flat boundary layers which were based on shooting techniques.

3.1. A fixed point formulation. We introduce the Banach space $X = C^1[0,1] \times C^2[0,1] \times C^1[0,1] \times C^2[0,1] \times \mathbb{R}$ equipped with the norm

$$\|(v,u,p,\theta,l)\| = \max\left(\|v\|_{C^1[0,1]}, \|u\|_{C^2[0,1]}, \|p\|_{C^1[0,1]}, \|\theta\|_{C^2[0,1]}, |l|\right),$$

and the open set $\mathcal{O} = \{\, x = (v,u,p,\theta,l) \in X;\ l > 0 \,\}$, and we consider, for $\tau \in [0,1]$, the mapping K_τ from $\mathcal{O}$ to X defined by

$$K_\tau(v,u,p,\theta,l) = \Big(\mathcal{V},\mathcal{U},\mathcal{P},\mathcal{T}, l - \mathcal{V}(1) + v_\tau\Big), \tag{3.1}$$

where $\mathcal{V}$, $\mathcal{U}$, $\mathcal{P}$, and $\mathcal{T}$ are solutions of

$$(1-\tau)u + \tau\mathcal{U} + \frac{\mathcal{V}'}{l} = 0, \tag{3.2}$$

$$(1-\tau)\Big(\alpha(u^+)^2 + cu^+v\theta + \frac{vu'}{l} + 2\alpha p\theta\Big) + \tau\Big(\mathcal{U} - \frac{1}{2}\Big) - \frac{1}{l^2}\big(\eta_\tau(\theta)\mathcal{U}'\big)' = 0, \tag{3.3}$$

$$-(1-\tau)cu^2 + \frac{\mathcal{P}'}{l} = 0, \tag{3.4}$$

$$(1-\tau)\frac{v\theta'}{l} - \frac{1}{l^2}\big(\lambda_\tau(\theta)\mathcal{T}'\big)' = 0, \tag{3.5}$$

with the boundary conditions

$$\text{(a)}\ \mathcal{V}(0) = 0, \qquad \text{(b)}\ \mathcal{U}(0) = 0, \qquad \text{(c)}\ \mathcal{U}(1) = 1, \tag{3.6}$$

$$\text{(a)}\ \mathcal{P}(1) = p_\tau, \qquad \text{(b)}\ \mathcal{T}(0) = \theta_\tau, \qquad \text{(c)}\ \mathcal{T}(1) = 1, \tag{3.7}$$

where $u^+ = \max(0,u)$ and where

$$v_\tau = (1-\tau)v_\sigma - \tau, \qquad p_\tau = (1-\tau)p_\sigma - \tau, \qquad \theta_\tau = (1-\tau)\theta_w + \tau,$$

$$\eta_\tau = (1-\tau)\eta + \tau, \qquad \lambda_\tau = (1-\tau)\lambda + \tau.$$

Note that solutions of (2.26)–(2.31) such that $u \geq 0$ are fixed points of K_0, and the converse will be shown to be true in the following.

PROPOSITION 3.1. *The operator K_τ is well defined from $\mathcal{O}$ to X and for any closed bounded set $B \subset \mathcal{O}$, the mapping $(\tau,v,u,p,\theta,l) \to K_\tau(v,u,p,\theta,l)$ from $[0,1]\times B$ to X is compact.*

The proof of Proposition 3.1 relies of the following lemma.

LEMMA 3.2. *Let $\chi \in C^1[0,1]$ and $q \in C^0[0,1]$ be such that $\chi > 0$ and $q \geq 0$. Then for any $a, b \in \mathbb{R}$ and any $h \in C^0[0,1]$, the boundary value problem*

$$-(\chi\phi')' + q\phi = h, \qquad \phi(0) = a, \qquad \phi(1) = b,$$

has a unique solution $\phi \in C^2[0,1]$ *and* $\|\phi\|_{C^2[0,1]} \leq C\big(\|h\|_{C^0[0,1]} + |a| + |b|\big)$ *where the constant* C *only depends on* $\|\chi\|_{C^1[0,1]}$, $1/\inf_{[0,1]}\chi$ *and* $\|q\|_{C^0[0,1]}$. *Moreover, if* $\chi \in C^2[0,1]$, $q \in C^1[0,1]$, *and if* h *satisties a Lipschitz condition, i.e.,* $h \in \mathrm{Lip}[0,1]$, *then* $\phi'' \in \mathrm{Lip}[0,1]$ *and* $\|\phi''\|_{\mathrm{Lip}[0,1]} \leq \Gamma\big(\|h\|_{\mathrm{Lip}[0,1]} + |a| + |b|\big)$ *where the constant* Γ *only depends on* $\|\chi\|_{C^2[0,1]}$, $1/\inf_{[0,1]}\chi$ *and* $\|q\|_{C^1[0,1]}$ *and where we have defined* $\|h\|_{\mathrm{Lip}[0,1]} = \|h\|_{C^0[0,1]} + \sup\{\ |(h(x) - h(y)|/|x-y|,\ x,y \in [0,1],\ x \neq y\ \}$.

Sketch of the proof. Replacing ϕ and h by $\phi - \phi_0$ and $h + (\chi\phi_0')' - q\phi_0$, where $\phi_0(\zeta) = a + (b-a)\zeta$, it is easy to check that only the case $a = b = 0$ needs to be considered. In this situation, the weak formulation

$$\forall\psi \in H_0^1(0,1), \qquad \int_0^1 \chi(t)\phi'(t)\psi'(t)dt + \int_0^1 q(t)\phi(t)\psi(t)dt = \int_0^1 h(t)\psi(t)dt,$$

has a unique solution $\phi \in H_0^1$ from Poincaré's inequality and the Lax–Milgram Theorem. Using Poincaré's inequality $2\int_0^1 \phi^2(t)dt \leq \int_0^1 \phi'^2(t)dt$ also yields the estimate $(\inf_{[0,1]}\chi/2)\|\phi\|_{H_0^1(0,1)} \leq \|h\|_{L^2[0,1]}$. Moreover, we have $(\chi\phi')' = q\phi - h$ in the distribution sense so that $\chi\phi' \in H^1(0,1)$ and thus $\phi' \in H^1(0,1)$. This implies now that $\chi\phi'' = -\chi'\phi' + q\phi - h$ and, therefore, that $\|\phi\|_{H_0^2(0,1)} \leq C\|h\|_{L^2[0,1]}$. The two norm inequalities of the lemma are then easily obtained from these estimates and the relation $\chi\phi'' = -\chi'\phi' + q\phi - h$, making use of the inequalities $\|\psi\|_{C^0(0,1)} \leq C\|\psi\|_{H^1[0,1]}$ and $\|\psi\|_{L^2(0,1)} \leq C\|\psi\|_{C^0[0,1]}$.

Proof of Proposition 3.1. For a given $(v,u,p,\theta,l) \in \mathcal{O}$, we deduce from Lemma 3.2 that there exists a unique $\mathcal{U} \in C^2[0,1]$ such that (3.3), (3.6(b)), and (3.6(c)) hold and a unique $\mathcal{T} \in C^2[0,1]$ such that (3.5), (3.7(b)), and (3.7(c)) hold. The functions $\mathcal{V}$ and $\mathcal{P}$ can then be obtained by a simple integration and trivially $\big(\mathcal{V},\mathcal{U},\mathcal{P},\mathcal{T},l-\mathcal{V}(1)+v_T\big) \in X$. Moreover, for any closed bounded set $B \subset \mathcal{O}$, it is easy to check by using Lemma 3.2 and (3.2)–(3.7) that $\mathcal{V}'$, $\mathcal{U}''$, $\mathcal{P}'$, and $\mathcal{T}''$ are equi-Lipschitzian so that compactness is straightforward by using Ascoli's theorem.

Now we introduce the open bounded set Ω of X defined by

$$\begin{aligned}\Omega = \Big\{(v,u,p,\theta,l) \in X\ ;\ &\|v\|_{C^1[0,1]} < R,\ \|u\|_{C^2[0,1]} < R,\ \|p\|_{C^1[0,1]} < R,\\ &\|\theta\|_{C^2[0,1]} < R,\ 0 < A < l < B\Big\},\end{aligned} \tag{3.8}$$

where R, A, and B are positive constants, and the following proposition shows that the degree $d(I - K_\tau, \Omega, 0)$ can be defined for suitable R, A, and B.

PROPOSITION 3.3. *There exist constants* R, A, *and* B *such that*

$$\forall\tau \in [0,1] \quad (I - K_\tau)(\partial\Omega) \not\ni 0. \tag{3.9}$$

Proposition 3.3 relies on Lemmas 3.4 and 3.5 in which we derive strong estimates for fixed points of K_τ.

3.2. A priori estimates.

LEMMA 3.4. *There exist positive constants* m, A, *and* B *such that for any* $\tau \in [0,1]$ *and any fixed point* $(v,u,p,\theta,l) \in \mathcal{O}$ *of* K_τ *we have*

$$-m \leq v \leq 0, \qquad 0 \leq u \leq m, \qquad -m \leq p \leq 0, \tag{3.10}$$

$$0 \leq \theta \leq m, \qquad A < l < B. \tag{3.11}$$

Proof. Let $(v,u,p,\theta,l) \in \mathcal{O}$ be a fixed point of K_τ for some $\tau \in [0,1]$, i.e., be such that $v = \mathcal{V}$, $u = \mathcal{U}$, $p = \mathcal{P}$, $\theta = \mathcal{T}$, and $\mathcal{V}(1) = v_\tau$. By applying the maximum principle to the energy equations (3.5), we first deduce that $\theta_w \leq \theta_\tau \leq \theta \leq 1$. Hence θ is uniformly bounded by positive constants. From the normal momentum equation (3.4) we also deduce that p is nondecreasing so that $p(\zeta) \leq p_\tau \leq p_\sigma < 0$, and thus p is negative on $[0,1]$.

Assume now that the minimum of u over $[0,1]$ is negative. Then there exists a point $\zeta_0 \in (0,1)$ such that $u(\zeta_0) < 0$, $u'(\zeta_0) = 0$ and $u''(\zeta_0) \geq 0$ since $u(0) = 0$ and $u(1) = 1$. Then using the tangential momentum conservation equation (3.3) we obtain that

$$\eta_\tau\big(\theta(\zeta_0)\big)u''(\zeta_0) = (1-\tau)2\alpha p(\zeta_0)\theta(\zeta_0) + \tau u(\zeta_0) - \frac{\tau}{2},$$

which implies that $u''(\zeta_0) < 0$, a contradiction. Therefore, $u \geq 0$ over $[0,1]$ and u^+ can be replaced by u in (3.3). From (3.2) we now deduce that v is nonincreasing on $[0,1]$, and thus that $v_\sigma \leq v_\tau \leq v \leq 0$. We now want to estimate the maximum of u over $[0,1]$. Let us denote M as this maximum and assume that $M > 1$ since otherwise $u \leq M = 1$. Then there exists $\zeta_1 \in (0,1)$ such that $u(\zeta_1) = M$, $u'(\zeta_1) = 0$ and $u''(\zeta_1) \leq 0$. Using the tangential momentum conservation equation (3.3) we obtain that

$$(1-\tau)\alpha M^2 + \tau M \leq (1-\tau)\Big(-cMv(\zeta_1)\theta(\zeta_1) - 2\alpha p(\zeta_1)\theta(\zeta_1)\Big) + \frac{\tau}{2},$$

and since $M \geq 1$, $\theta_w \leq \theta \leq 1$ and $0 \leq -v \leq -v_\sigma$ we deduce that

$$M^2 \leq \left(\frac{c}{\alpha}\right)(-v_\sigma)M - 2p(\zeta_1).$$

However, by integrating the normal momentum equations (3.4), we obtain that

$$-p(\zeta_1) = -p_\tau + (1-\tau)cl\int_{\zeta_1}^1 u^2(t)dt \leq 1 + Mcl\int_0^1 u(t)dt,$$

since $-1 \leq p_\tau < 0$ and $0 \leq u \leq M$, and this implies that

$$-p(\zeta_1) \leq 1 + Mc(-v_\sigma), \tag{3.12}$$

since by integrating the mass conservation equation (3.2) and by using $v(0) = 0$ and $v(1) = v_\tau$ we obtain that

$$l\int_0^1 u(t)dt = -v_\tau \leq -v_\sigma. \tag{3.13}$$

Therefore, $M^2 \leq (2 + 1/\alpha)c(-v_\sigma)M + 2$ and thus $M^2 \leq (2+1/\alpha)(1+c)(-v_\sigma)M$ since $M \geq 1$ and $-v_\sigma \geq 1$ so that $M \leq (2+1/\alpha)(1+c)(-v_\sigma)$. We then deduce that p is bounded from (3.12), and letting $m > (2+1/\alpha)(1+c)^2(-v_\sigma)^2$ yields that $-m \leq v \leq 0$, $0 \leq u \leq m$, $-m \leq p \leq 0$, and $0 \leq \theta \leq m$.

We now estimate the eigenvalue l. From the relation (3.13) and since $u \leq m$ we first deduce that $1 \leq -v_\tau \leq lm$ so that $l \geq 1/m$, and we may choose $A < 1/m$. In order to obtain an upper bound for l, we then start with the tangential momentum equation (3.3) that we multiply by l^2 and that we write in the form

$$l^2\Big(-(1-\tau)2\alpha p\theta + \frac{\tau}{2}\Big) = (1-\tau)\Big((1+\alpha)l^2u^2 + cl^2uv\theta + l(vu)'\Big) + \tau l^2 u - \big(\eta_\tau(\theta)u'\big)' = 0,$$

making use of (3.2). Noting that the left-hand side coefficient $-(1-\tau)2\alpha p\theta + \tau/2$ is always larger than the positive constant $\delta = \min(-2\alpha\theta_w p_\sigma, \frac{1}{2})$ and that $cl^2uv\theta$ is nonpositive, we get that

$$l^2\delta \le (1-\tau)\Big((1+\alpha)l^2u^2 + l(vu)'\Big) + \tau l^2 u - \big(\eta_\tau(\theta)u'\big)'.$$

Integrating this inequality between r and s, where $0 \le r \le s \le 1$, and using the preceding a priori estimates then yields

$$l^2\delta(s-r) \le (1-\tau)\big((1+\alpha)l^2m\int_r^s u(t)\,dt - lv(r)u(r)\big) + \tau l^2\int_r^s u(t)\,dt - \int_r^s \big(\eta_\tau(\theta)u'\big)'(t)\,dt,$$

so that by using (3.13) we obtain

$$l^2\delta(s-r) \le lm(3+\alpha)(-v_\sigma) + \eta_\tau\big(\theta(r)\big)u'(r) - \eta_\tau\big(\theta(s)\big)u'(s).$$

Dividing this inequality by $\eta_\tau\big(\theta(r)\big)\eta_\tau\big(\theta(s)\big)$ we deduce that

$$\frac{l^2\delta(s-r)}{\overline{\eta}^2} \le \frac{lm(3+\alpha)(-v_\sigma)}{\underline{\eta}^2} + \frac{u'(r)}{\eta_\tau\big(\theta(s)\big)} - \frac{u'(s)}{\eta_\tau\big(\theta(r)\big)},$$

where $\underline{\eta} = \min(1, \inf_{\mathbb{R}}\eta)$, and $\overline{\eta} = \max(1, \sup_{\mathbb{R}}\eta)$, and integrating this inequality successively over $[0,s]$, with respect to r, and over $[0,1]$, with respect to s, and noting that

$$\int_0^1 \left(\int_0^s \left(\frac{u'(r)}{\eta_\tau\big(\theta(s)\big)} - \frac{u'(s)}{\eta_\tau\big(\theta(r)\big)}\right) dr\right) ds = \int_0^1 \frac{2u(s)-1}{\eta_\tau\big(\theta(s)\big)}\,ds \le \frac{2m}{\underline{\eta}},$$

we obtain that $l^2\delta \le l3m(3+\alpha)(-v_\sigma)\omega^2 + 12m\omega^2$, where $\omega = \overline{\eta}/\underline{\eta}$ and thus that $l \le 5m(3+\alpha)(-v_\sigma)\omega^2/\delta$. We may, therefore, choose $B > 5m(3+\alpha)(-v_\sigma)\omega^2/\delta$, and the proof is now complete. Note that the upper bound for the eigenvalue has been obtained because of the negative pressure term $2\alpha p\theta$ in the tangential momentum conservation equation. Remark also that the bounds A and B are such that $A < 2 < B$, which will be needed in the following.

From Lemma 3.4 and the relations (3.2)–(3.7) we now deduce the following result.

LEMMA 3.5. *There exist positive constants R, A, and B such that for any $\tau \in [0,1]$ and any fixed point $(v,u,p,\theta,l) \in \mathcal{O}$ of K_τ we have*

$$\|v\|_{C^1[0,1]} < R, \qquad \|u\|_{C^2[0,1]} < R, \qquad \|p\|_{C^1[0,1]} < R,$$

$$\|\theta\|_{C^2[0,1]} < R, \qquad A < l < B.$$

Proof. Keeping the notation of Lemma 3.4 we deduce from the relations (3.2) and (3.4) that $|v'| \le Bm$ and $|p'| \le Bcm^2$. From (3.3) and (3.2) we can also write that

$$\big(\eta_\tau(\theta)u'\big)' = l(1-\tau)(uv)' + \chi, \tag{3.14}$$

where $\chi = l^2(1-\tau)\big((1+\alpha)u^2 + cuv\theta + 2\alpha p\theta\big) + l^2\tau(u - \frac{1}{2})$. From Lemma 3.4 we know that χ is bounded independently of $(\tau, v, u, p, \theta, l)$, say $|\chi| \le K$. Integrating (3.14) between r and s, where $0 \leq r \leq s \leq 1$, and using the inequalities $|\chi| \leq K$ and (3.10), (3.11), we then obtain that

$$-(K + Bm^2) \leq \eta_\tau(\theta(s))u'(s) - \eta_\tau(\theta(r))u'(r) \leq K + Bm^2,$$

which is, therefore, valid for any $r, s \in [0,1]$. Dividing this inequality by $\eta_\tau(\theta(r))$, integrating with respect to r, between zero and 1, and dividing by $\int_0^1 (1/\eta_\tau(\theta))(r)\,dr$, we obtain that

$$-(K + Bm^2) \leq \eta_\tau(\theta(s))u'(s) \leq K + Bm^2 + \overline{\eta},$$

where $\overline{\eta} = \max(1, \sup_{\mathbf{R}} \eta)$, and dividing by $\eta_\tau(\theta(s))$ we get that $|u'| \leq (K+Bm^2+1)\omega$, where $\omega = \overline{\eta}/\underline{\eta}$ and $\underline{\eta} = \min(1, \inf_{\mathbf{R}} \eta)$. The same argument can now be applied to $|\theta'|$, and, therefore, $|u''|$ and $|\theta''|$ are also bounded independently of $(\tau, v, u, p, \theta, l)$ from (3.3) and (3.5) and the proof is complete.

3.3. Calculation of $d(I - K_\tau, \Omega, 0)$.

PROPOSITION 3.6. *Under the same hypotheses as Proposition* 3.3 *we have*

$$\forall \tau \in [0,1] \quad d(I - K_\tau, \Omega, 0) = -1.$$

Proof. From the homotopy invariance of the degree we know that $d(I-K_\tau, \Omega, 0) = d(I - K_1, \Omega, 0)$. But K_1 is a mapping depending only on l which reads

$$K_1(v, u, p, \theta, l) = (\mathcal{V}_1, \mathcal{U}_1, \mathcal{P}_1, \mathcal{T}_1, l - \mathcal{V}_1(1) - 1).$$

Introducing now the homotopy

$$H_\tau(v, u, p, \theta, l) = (\tau\mathcal{V}_1, \tau\mathcal{U}_1, \tau\mathcal{P}_1, \tau\mathcal{T}_1, l - \mathcal{V}_1(1) - 1),$$

we may easily check that the map $(\tau, v, u, p, \theta, l) \to H_\tau(v, u, p, \theta, l)$ from $[0,1] \times \overline{\Omega}$ to X is compact. Moreover, if (v, u, p, θ, l) is a fixed point of H_τ, then we have $v = \tau\mathcal{V}_1$, $u = \tau\mathcal{U}_1$, $p = \tau\mathcal{P}_1$, $\theta = \tau\mathcal{T}_1$ and $\mathcal{V}_1(1) = -1$. Thus $(\mathcal{V}_1, \mathcal{U}_1, \mathcal{P}_1, \mathcal{T}_1, l)$ is a fixed point of K_1, and we deduce from Proposition 3.3 that $\|\mathcal{V}_1\|_{C^1[0,1]} < R$, $\|\mathcal{U}_1\|_{C^2[0,1]} < R$, $\|\mathcal{P}_1\|_{C^1[0,1]} < R$, $\|\mathcal{T}_1\|_{C^2[0,1]} < R$, and $0 < A < l < B$. Hence $\|v\|_{C^1[0,1]} = \tau\|\mathcal{V}_1\|_{C^1[0,1]} < R$, $\|u\|_{C^2[0,1]} = \tau\|\mathcal{U}_1\|_{C^2[0,1]} < R$, $\|p\|_{C^1[0,1]} = \tau\|\mathcal{P}_1\|_{C^1[0,1]} < R$ and $\|\theta\|_{C^2[0,1]} = \tau\|\mathcal{T}_1\|_{C^2[0,1]} < R$. We have thus shown that

$$\forall \tau \in [0,1] \quad (I - H_\tau)(\partial\Omega) \not\ni 0,$$

so that $d(I - H_\tau, \Omega, 0)$ is well defined and $d(I - H_1, \Omega, 0) = d(I - H_0, \Omega, 0)$. Now since $H_1 = K_1$ we deduce that $d(I - K_0, \Omega, 0) = d(I - H_0, \Omega, 0)$, and since H_0 is a mapping which reads

$$H_0(v, u, p, \theta, l) = (0, 0, 0, 0, l - \mathcal{V}_1(1) - 1),$$

we deduce from the multiplicative property of the degree that

$$d(I - K_1, \Omega, 0) = d(\chi(l) + 1, (A, B), 0),$$

where we have defined $\chi(l) = \mathcal{V}_1(1)$. However, a straightforward calculation leads to

$$\mathcal{U}_1(\zeta) = \frac{1}{2}(1 - \mathrm{ch}(l\zeta)) + \frac{1 + \mathrm{ch}(l)}{2\mathrm{sh}(l)}(\mathrm{sh}(l\zeta)),$$

which implies by integration that

$$\mathcal{V}_1(\zeta) = -\frac{l\zeta}{2} + \frac{\mathrm{sh}(l\zeta)}{2} - \frac{1+\mathrm{ch}(l)}{2\mathrm{sh}(l)}(\mathrm{ch}(l\zeta) - 1),$$

and that $\mathcal{V}_1(1) = -l/2$ so that finally

$$\chi(l) = -\frac{l}{2}$$

(this simple result is the origin for choosing the constant $\frac{1}{2}$ as the limit of $-2\alpha p\theta$ in the homotopy path (3.3)) so that $d(I - K_1, \Omega, 0) = -1$ since we have seen in the proof of Lemma 3.4 that $A < 2 < B$.

We can now state the main result of this section.

THEOREM 3.7. *There exists a solution* $(v, u, p, \theta, l) \in \mathcal{O}$ *of the thin viscous shock layer problem* (2.26)–(2.31).

Remark. Due to the lack of knowledge on the linearized system deduced from (2.26)–(2.31), it is not known if such a solution is unique. A similar problem also arises for extending Oleinik's method of proof [10] to the system (2.20)–(2.25). More specifically, wellposedness and a priori estimates for linearized systems deduced from (2.20)–(2.25), with $\xi(\partial/\partial\xi)$ replaced by finite differences, would be needed in order to estimate the ξ derivatives of the solution components.

ON SOLUTIONS TO THE LINEAR BOLTZMANN EQUATION WITH EXTERNAL ELECTROMAGNETIC FORCE*

FRANTIŠEK CHVÁLA†, TOMMY GUSTAFSSON‡, AND ROLF PETTERSSON‡

Abstract. The authors consider the linear space-inhomogeneous Boltzmann equation in the full space $\mathbb{R}^3$ with external electromagnetic force. First, existence and uniqueness results about mild L^1-solutions are presented for soft and hard interactions, together with global boundedness in time for higher moments in the hard interaction case. Then, in the case of spatially homogeneous forces, mild $L^{1;q} \cap L^{p;q}$-solutions, $1 \leq p, q \leq \infty$, are constructed by an iteration procedure using an a priori estimate given by the corresponding homogeneous solution. Furthermore, some results about L^p-solutions are presented for space-inhomogeneous forces.

Key words. linear Boltzmann equation, external forces, electromagnetic force, mild solution, L^p-solution, $L^{1;q} \cap L^{p;q}$-solutions, higher moments, collision operator estimates

AMS subject classification. primary 76P05

Introduction. Consider a gas mixture consisting of two components, one formed by charged, the other by neutral, particles. Suppose that external electric and magnetic fields are imposed upon the mixture. We shall be concerned with the evolution of the distribution function $f(\mathbf{v}, \mathbf{x}, t)$ for the charged particles ($\mathbf{v} \in \mathbb{R}^3$, $\mathbf{x} \in \mathbb{R}^3$, and $t \in \mathbb{R}_+$ denoting the velocity, space, and time variables, respectively), in case the initial distribution $\varphi(\mathbf{v}, \mathbf{x})$ of the charged particles is given and the distribution function $F(\mathbf{v}, \mathbf{x}, t)$ for the neutral particles is known. Let each of the charged particles have mass m and charge q, and let the ratio of the mass of a charged particle to the mass of a neutral particle be κ. Denote by $\mathbf{\Gamma}(\mathbf{x}, t)$ and $\mathbf{\Omega}(\mathbf{x}, t)$ the (q/m)-multiples of the external electric and magnetic fields, respectively. Under some physically motivated hypotheses (cf. [Ce]) f is a solution of the following Cauchy problem for the linear Boltzmann kinetic equation:

$$\text{(0.1a)} \qquad \frac{\partial f}{\partial t} + \mathbf{v} \cdot \frac{\partial f}{\partial \mathbf{x}} + (\mathbf{\Gamma} + \mathbf{v} \times \mathbf{\Omega}) \cdot \frac{\partial f}{\partial \mathbf{v}} = Q[f, F] \quad \text{on } \mathbb{R}^3 \times \mathbb{R}^3 \times \mathbb{R}_+,$$

$$\text{(0.1b)} \qquad f(\cdot, \cdot, 0) = \varphi \quad \text{on } \mathbb{R}^3 \times \mathbb{R}^3.$$

The differential operator on the left-hand side of (0.1a) is the streaming operator, and $Q[f, F]$ is the Bolztmann collision term. Recall that

$$Q[f, F](\mathbf{v}, \mathbf{x}, t) = \int (f'F'_* - fF_*) B(\theta, w) \, d\mathbf{v}_* \, d\theta \, d\varepsilon, \qquad \mathbf{v}, \mathbf{x} \in \mathbb{R}^3, \quad t \in \mathbb{R}_+,$$

where

$$f' = f(\mathbf{v}', \mathbf{x}, t), \quad F'_* = F(\mathbf{v}'_*, \mathbf{x}, t), \quad f = f(\mathbf{v}, \mathbf{x}, t), \quad F_* = F(\mathbf{v}_*, \mathbf{x}, t),$$
$$\mathbf{w} = \mathbf{v} - \mathbf{v}_*,$$
$$\mathbf{v}' = \mathbf{v} - \frac{2}{1+\kappa} (\mathbf{w} \cdot \mathbf{e}) \mathbf{e},$$
$$\mathbf{v}'_* = \mathbf{v}_* + \frac{2\kappa}{1+\kappa} (\mathbf{w} \cdot \mathbf{e}) \mathbf{e},$$
$$\mathbf{e} = (\sin\theta \cos\varepsilon, \sin\theta \sin\varepsilon, \cos\theta);$$

$B:[0, \pi/2)\times(0,\infty)\to\mathbb{R}_+$ is closely related to the differential cross section; the range of integration is $\mathbb{R}^3\times[0,\pi/2)\times[0,2\pi)$. In accordance with the physical meaning F is measurable and nonnegative on $\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+$.

Throughout this paper we use the convention $v=|\mathbf{v}|$, etc.

Supposing the collisions are governed by an inverse power-law interaction potential $U(\rho)=\text{const}\cdot\rho^{-(k-1)}(k>2)$ depending on the distance ρ of two colliding particles, the function B factorizes as follows [Ce]:

$$B(\theta, w)=w^{\gamma}\cdot b(\theta), \qquad 0\leqq\theta<\frac{\pi}{2}, \qquad w>0, \tag{0.2}$$

where $\gamma=(k-5)/(k-1)$ and b is a specified continuous nonnegative function on $[0,\pi/2)$ satisfying $b(\theta)=\mathcal{O}(\theta)$ when $\theta\to 0_+$, and $b(\theta)=\mathcal{O}((\pi/2-\theta)^{-(k+1)/(k-1)})$ when $\theta\to\pi/2_-$. Following [Gr], the interaction potential is called soft or hard acccordingly as $2<k\leqq 5$ or $k>5$, respectively. In the hard-sphere model of interaction the function B satisfies (0.2) with $\gamma=1$ and $b(\theta)=\sin\theta\cos\theta$. In the following we speak of soft or hard interactions for $-3<\gamma\leqq 0$ or $0\leqq\gamma\leqq 1$, respectively.

From the mathematical point of view it is considerably more convenient to redefine the function b in a left neighbourhood of $\pi/2$, so that for some $\alpha>-1$

$$b(\theta)=\mathcal{O}\left(\left(\frac{\pi}{2}-\theta\right)^{\alpha}\right), \quad \text{when } \theta\to\frac{\pi}{2}-,$$

a so-called angular cut-off. Physically it means ignoring part of the grazing collisions. For a detailed discussion of the cut-off technique, the reader is referred to [Ce], [TM], or [Ar].

Throughout this paper we consider B of the form (0.2), where $-3<\gamma\leqq 1$ and b is any nonnegative measurable function on $(0,\pi/2)$ satisfying

$$0<\int_0^{\pi/2} b(\theta)\,d\theta<\infty. \tag{0.3}$$

Particularly, (0.3) holds if b satisfies

$$0\leqq b(\theta)\leqq b_0\sin\theta(\cos\theta)^{\alpha}, \qquad 0\leqq\theta<\frac{\pi}{2}, b_0=\text{const}>0, \quad \alpha>-1. \tag{0.4}$$

As a consequence of (0.3) the collision term Q can be split as follows:

$$Q[f,F]=Kf-\nu\cdot f,$$

where K is the gain collision operator, defined by

$$Kf(\mathbf{v},\mathbf{x},t)=\int f'F'_*B(\theta,w)\,d\mathbf{v}_*\,d\theta\,d\varepsilon, \qquad \mathbf{v},\mathbf{x}\in\mathbb{R}^3, \quad t\in\mathbb{R}_+,$$

and ν is the collision frequency,

$$\nu(\mathbf{v},\mathbf{x},t)=2\pi\int F_*B(\theta,w)\,d\mathbf{v}_*\,d\theta, \qquad \mathbf{v},\mathbf{x}\in\mathbb{R}^3, \quad t\in\mathbb{R}_+ \tag{0.5}$$

(the ranges of integration for the former and the latter integrals are $\mathbb{R}^3\times[0,\pi/2)\times[0,2\pi)$ and $\mathbb{R}^3\times[0,\pi/2)$, respectively).

This leads to an alternative form of problem (0.1):

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\frac{\partial f}{\partial \mathbf{x}}+(\mathbf{\Gamma}+\mathbf{v}\times\mathbf{\Omega})\cdot\frac{\partial f}{\partial \mathbf{v}}+\nu\cdot f=Kf \quad \text{on } \mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+, \tag{0.6a}$$

$$f(\cdot,\cdot,0)=\varphi \quad \text{on } \mathbb{R}^3\times\mathbb{R}^3. \tag{0.6b}$$

The aim of this paper is to present criteria for existence and uniqueness of a solution f of the problem (0.6), and to study boundedness of its moments, i.e., functions (of the time variable) $\|f_\sigma(\cdot,\cdot,t)\|$, where $f_\sigma(\mathbf{v},\mathbf{x},t)=(1+v^2)^{\sigma/2}f(\mathbf{v},\mathbf{x},t)$, $\sigma\geqq 0$ the norm $\|\cdot\|$ being taken in a convenient Lebesgue space.

The present paper, which is a shorter version of a preprint, below called [CGP], is based on earlier results by three authors [Ch], [Gu1], [P1], [P2]. The paper [Ch] studies properties of some operators related to the Boltzmann collision term. In [Gu1] L^p-estimates are given for solutions to the nonlinear, space-homogeneous Boltzmann equation. The papers [P1] and [P2] study solutions to the linear space-inhomogeneous Boltzmann equation in the periodic boundary case without external forces.

Section 1 of this paper presents the ordinary differential equations related to the external electromagnetic field. It also considers solutions to the linear Boltzmann equation in mild form in the case of external forces. In § 2 mild L^1-solutions are constructed by an iteration procedure both for hard and soft interactions. The main results in this section concern existence, uniqueness, and global boundedness in time for higher moments in the hard interaction case. Section 3 deals with mild $L^{1;q}\cap L^{p;q}$-solutions, $1\leqq p, q\leqq\infty$, constructed by an iteration procedure similar to that of § 2, when the external forces and the neutral particle distribution are spatially homogeneous. A necessary a priori estimate is obtained by introducing a new device, a spatially homogeneous solution, which is an upper bound for the L^q-norm with respect to the space variable of the solution from § 2. Section 4 gives some results on existence and uniqueness of L^p-solutions in the soft interaction case with spatially inhomogeneous external forces using boundedness of the gain term in the collision operator.

Remark 1. In the case of stationary external forces the results in §§ 2–4 concerning moments $\|(1+v^2)^{\sigma/2}f(\mathbf{v},\mathbf{x},t)\|$ can be generalized to moments corresponding to total energies, $\|(\phi(\mathbf{x})+v^2)^{\sigma/2}f(\mathbf{v},\mathbf{x},t)\|$. Here $\phi=\phi(\mathbf{x})$ is a potential for $\mathbf{\Gamma}$, $\mathbf{\Gamma}=-\frac{1}{2}\operatorname{grad}\phi$ with $\inf_{\mathbf{x}\in\mathbb{R}^3}\phi(\mathbf{x})=1$. For details on such results and their proofs, see § 5 in [CGP].

Remark 2. Notice that the linear Boltzmann equation, studied in this paper, is different from the linearized one, which is derived from the nonlinear equation. One essential difference with respect to methods is that the monotonicity property (e.g., $f_{n+1}\geqq f_n$), central to our approach, does not hold for the linearized equation.

1. Preliminaries. In connection with transforming problem (0.6) into a purely integral form, we shall be concerned with solution $\mathbf{v}=\mathbf{v}(t)=\mathbf{v}(\mathbf{u},\mathbf{y},t)$, $\mathbf{x}=\mathbf{x}(t)=\mathbf{x}(\mathbf{u},\mathbf{y},t)$ to the characteristic problem of the streaming operator:

$$\frac{d\mathbf{v}}{dt}=\mathbf{\Gamma}(\mathbf{x},t)+\mathbf{v}\times\mathbf{\Omega}(\mathbf{x},\mathrm{t}), \qquad \mathbf{v}(0)=\mathbf{u}, \tag{1.1a}$$

$$\frac{d\mathbf{x}}{dt}=\mathbf{v}, \qquad \mathbf{x}(0)=\mathbf{y}. \tag{1.1b}$$

In the rest of this paper we assume the following hypothesis.

Hypothesis 1.1.

(i) There exists a unique, locally absolutely continuous function on $\mathbb{R}_+$, satisfying (1.1) for almost every $t\in\mathbb{R}_+$.

(ii) The Jacobian of the transformation

$$(\mathbf{u},\mathbf{y})\mapsto(\mathbf{v}(\mathbf{u},\mathbf{y},t),\mathbf{x}(\mathbf{u},\mathbf{y},t)),\qquad \mathbf{u},\mathbf{y}\in\mathbb{R}^3,$$

is equal to 1 for every $t\in\mathbb{R}_+$.

PROPOSITION 1.2. *Hypothesis* 1.1 *is satisfied, if* $\mathbf{\Gamma}$ *and* $\mathbf{\Omega}$ *satisfy the following conditions of Carathéodory type*:

(i) *For every* $\mathbf{x}\in\mathbb{R}^3$ *the functions* $\mathbf{\Gamma}(\mathbf{x},\cdot)$, $\mathbf{\Omega}(\mathbf{x},\cdot)$ *are measurable on* $\mathbb{R}_+$;

(ii) *For every* $t\in\mathbb{R}_+$ *the functions* $\mathbf{\Gamma}(\cdot,t)$, $\mathbf{\Omega}(\cdot,t)$ *and all their first-order derivatives are continuous on* $\mathbb{R}^3$;

(iii) *There exists a function* $\rho_0\in L^1_{\mathrm{loc}}(\mathbb{R}_+)$ *such that*

$$|\mathbf{\Gamma}(\mathbf{x},t)|\leqq\rho_0(t),\qquad \mathbf{x}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,$$

$$|\mathbf{\Omega}(\mathbf{x},t)|\leqq\rho_0(t),\qquad \mathbf{x}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,$$

$$|\mathbf{\Gamma}(\mathbf{x}_1,t)-\mathbf{\Gamma}(\mathbf{x}_2,t)|\leqq\rho_0(t)\cdot|\mathbf{x}_1-\mathbf{x}_2|,\qquad \mathbf{x}_1,\mathbf{x}_2\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,$$

$$|\mathbf{\Omega}(\mathbf{x}_1,t)-\mathbf{\Omega}(\mathbf{x}_2,t)|\leqq\rho_0(t)\cdot|x_1-x_2|,\qquad \mathbf{x}_1,\mathbf{x}_2\in\mathbb{R}^3,\quad t\in\mathbb{R}_+.$$

Proof. For an extensive discussion, see [CGP]; cf. also [Ku]. □

Remark. Cf. also Chapter XI, § 2, [GMP] about assumptions on the exterior Lorentz force $\mathbf{a}=\mathbf{\Gamma}(\mathbf{x},t)+\mathbf{v}\times\mathbf{\Omega}(\mathbf{x},t)$ to guarantee unique solvability of problem (1.1).

Notation. We employ a convention introduced in [KS]. For a function h defined on $\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+$, the symbol $h^{\#}$ denotes the function specified on the same domain by

$$h^{\#}(\mathbf{u},\mathbf{y},t)=h(\mathbf{v}(t),\mathbf{x}(t),t)\qquad \mathbf{u},\mathbf{y}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,$$

where $\mathbf{v}(t),\mathbf{x}(t)$ is the solution to (1.1).

In connection with the problem (0.6) we shall also consider the following related problem:

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\frac{\partial f}{\partial\mathbf{x}}+(\mathbf{\Gamma}+\mathbf{v}\times\mathbf{\Omega})\cdot\frac{\partial f}{\partial\mathbf{v}}+\nu\cdot f=g,\tag{1.2a}$$

$$f(\cdot,\cdot,0)=\varphi,\tag{1.2b}$$

where g is a given function defined on $\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+$.

Notation. The Lebesgue measure in $\mathbb{R}^n$ is denoted by mes.

DEFINITION. Let Hypothesis 1.1 be satisfied, and let

$$\nu^{\#}(\mathbf{u},\mathbf{y},\cdot)\in L^1_{\mathrm{loc}}(\mathbb{R}_+),\ g^{\#}(\mathbf{u},\mathbf{y},\cdot)\in L^1_{\mathrm{loc}}(\mathbb{R}_+),\qquad \mathbf{u},\mathbf{y}\in\mathbb{R}^3.\tag{1.3}$$

A real-valued function f is called a *mild solution* of the problem (1.2) if there exists $M\subset\mathbb{R}^3\times\mathbb{R}^3$, mes $M=0$, such that $f^{\#}$ is defined on $(\mathbb{R}^3\times\mathbb{R}^3\backslash M)\times\mathbb{R}_+$ and satisfies the relation

$$\begin{gathered}f^{\#}(\mathbf{u},\mathbf{y},t)=\varphi(\mathbf{u},\mathbf{y})+\int_0^t g^{\#}(\mathbf{u},\mathbf{y},s)\,ds-\int_0^t\nu^{\#}(\mathbf{u},\mathbf{y},s)f^{\#}(\mathbf{u},\mathbf{y},s)\,ds,\\ (\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3\backslash M,\qquad t\in\mathbb{R}_+.\end{gathered}\tag{1.4}$$

Another formulation of (1.2) is the *exponential form*

$$\begin{gathered}f^{\#}(\mathbf{u},\mathbf{y},t)=\varphi(\mathbf{u},\mathbf{y})\exp\left(-\int_0^t\nu^{\#}(\mathbf{u},\mathbf{y},s)\,ds\right)\\ +\int_0^t g^{\#}(\mathbf{u},\mathbf{y},r)\exp\left(-\int_r^t\nu^{\#}(\mathbf{u},\mathbf{y},s)\,ds\right)dr,\\ (\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3\backslash M,\quad t\in\mathbb{R}_+.\end{gathered}\tag{1.5}$$

By straightforward calculations we obtain the following lemma on the connection between (1.4) and (1.5).

LEMMA 1.3. *Let* (1.3) *be satisfied. Then f is a mild solution of problem* (1.2) *if and only if the exponential form* (1.5) *holds.*

Remark. For an extensive discussion see [PL] (cf. also [P1]).

DEFINITION. The notion of a mild solution of the problem (0.6) is defined in a similar manner, viz. as a function f such that $(Kf)^{\#}(\mathbf{u},\mathbf{y},\cdot)\in L^1_{\mathrm{loc}}(\mathbb{R}_+)$, $(\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3\backslash M$, and satisfying (1.4) with g replaced by Kf.

Remark. In our paper mild solutions play a central role. They are mathematically easy to use, and also physically natural. (For instance the iterate f_{n+1}, constructed for generating a solution, represents the distribution of particles undergone at most n collisions.) In dealing with the (different) nonlinear and linearized Boltzmann equations, other solution concepts are often used, e.g., the renormalized solutions; cf. [PL]. In the present situation, however, such devices seem to introduce unnecessarily technical complications without adding new insights.

2. L^1-solutions. In this section a mild L^1-solution of the problem (0.6) is constructed as a limit of a monotone sequence of suitably defined iterates. The construction was used in [P1], [P2] to treat a (periodic) boundary value problem for the linear Boltzmann equation without external forces; now it is applied to the Cauchy problem for the full linear Boltzmann equation. Under general conditions we prove existence of a solution together with mass conservation, and uniqueness. We also prove that higher moments of the solution exist (if they do so initially) for both soft and hard interactions, and that they are globally bounded in the hard interaction case.

Notation. Let $1\leqq p\leqq\infty$. The positive cone of the space L^p is denoted by L^p_+. The weighted L^p-space with the weight function $(1+v^2)^{\sigma/2}$, $\sigma\geqq 0$ is denoted by L^p_σ and the corresponding norm by $\|\cdot\|_{p,\sigma}$. Set $\|\cdot\|_{1\cap p}=\|\cdot\|_1+\|\cdot\|_p$ and $\|\cdot\|_{1\cap p,\sigma}=\|\cdot\|_{1,\sigma}+\|\cdot\|_{p,\sigma}$.

Note that the collision frequency is well defined; cf. (0.2), (0.3), and (0.5), whenever

$$\text{(2.1a)}\qquad F(\cdot,\mathbf{x},t)\in L^1_\gamma(\mathbb{R}^3),\quad \mathbf{x}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+\quad \text{if } 0\leqq\gamma\leqq 1,$$

$$\text{(2.1b)}\qquad F(\cdot,\mathbf{x},t)\in L^1(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3),\quad \mathbf{x}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+\quad \text{if } -3<\gamma<0;$$

indeed, in the latter case there holds for every $\mathbf{v},\mathbf{x}\in\mathbb{R}^3$, $t\in\mathbb{R}_+$:

$$\int_{\mathbb{R}^3} w^\gamma F(\mathbf{v}_*,\mathbf{x},t)\,d\mathbf{v}_*\leqq \operatorname*{ess\text{-}sup}_{v_*\in\mathbb{R}^3} F(\mathbf{v}_*,\mathbf{x},t)\cdot\int_{|\mathbf{v}_*-\mathbf{v}|<1} w^\gamma\,d\mathbf{v}_*+\int_{\mathbb{R}^3} F(\mathbf{v}_*,\mathbf{x},t)\,d\mathbf{v}_*.$$

The following relation is valid whenever one of the integrals exists [Ce]:

$$\text{(2.2)}\qquad \int_{\mathbb{R}^3}(Kf)(\mathbf{v},\mathbf{x},t)\,d\mathbf{v}=\int_{\mathbb{R}^3}\nu(\mathbf{v},\mathbf{x},t)f(\mathbf{v},\mathbf{x},t)\,d\mathbf{v},\qquad \mathbf{x}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+.$$

LEMMA 2.1. *Let F satisfy* (2.1), *and let $\{f_n\}_{n=0}^\infty$ be a sequence of functions defined on $\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+$ recursively by*

$$f_0^{\#}(\mathbf{u},\mathbf{y},t)=0,\quad \mathbf{u},\mathbf{y}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,$$

$$\text{(2.3)}\qquad \begin{aligned} f_{n+1}^{\#}(\mathbf{u},\mathbf{y},t)&=\varphi(\mathbf{u},\mathbf{y})\exp\left(-\int_0^t \nu^{\#}(\mathbf{u},\mathbf{y},s)\,ds\right)+\int_0^t (Kf_n)^{\#}(\mathbf{u},\mathbf{y},r)\\ &\quad\cdot\exp\left(-\int_r^t \nu^{\#}(\mathbf{u},\mathbf{y},s)\,ds\right)dr,\quad \mathbf{u},\mathbf{y}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,\quad n=0,1,\ldots.\end{aligned}$$

Then $\{f_n\}_{n=0}^\infty$ is a nondecreasing sequence if φ is a nonnegative measurable function on $\mathbb{R}^3\times\mathbb{R}^3$.

Proof. By induction, cf. [P1]. □

LEMMA 2.2. *If the hypothesis of Lemma* 2.1 *is satisfied and* $\varphi\in L^1_+(\mathbb{R}^3\times\mathbb{R}^3)$, *then for every* $n=0,1,\dots,$

$$\|f_n(\cdot,\cdot,t)\|_1\leqq\|\varphi\|_1,\qquad t\in\mathbb{R}_+.$$

Proof. By (2.3) and Lemma 1.3 the following mild form holds:

$$(2.4)\quad f_n^{\#}(\cdot,\cdot t)+\int_0^t\nu^{\#}(\cdot,\cdot,s)f_n^{\#}(\cdot,\cdot s)\,ds=\varphi+\int_0^t(Kf_{n-1})^{\#}(\cdot,\cdot,s)\,ds,\qquad t\in\mathbb{R}_+,$$

where (by induction) all terms belong to $L^1_+(\mathbb{R}^3\times\mathbb{R}^3)$, $t\in\mathbb{R}_+$.

By integrating (2.4) we get, in view of relation (2.2), Hypothesis 1.1(ii), and Lemma 2.1,

$$\|f_n(\cdot,\cdot t)\|_1-\|\varphi\|_1=\int_0^t\int_{\mathbb{R}^3}\int_{\mathbb{R}^3}[K(f_{n-1}-f_n)](\mathbf{v},\mathbf{x},s)\,d\mathbf{v}\,d\mathbf{x}\,ds\leqq 0,\qquad t\in\mathbb{R}_+.\quad\square$$

THEOREM 2.3. *Let* (2.1) *hold and* $\varphi\in L^1_+(\mathbb{R}^3\times\mathbb{R}^3)$; *then there exists a mild solution* f *of the problem* (0.6) *such that* $f(\cdot,\cdot,t)\in L^1_+(\mathbb{R}^3\times\mathbb{R}^3), t\in\mathbb{R}_+$, *and*

$$(2.5)\qquad \|f(\cdot,\cdot,t)\|_1\leqq\|\varphi\|_1,\qquad t\in\mathbb{R}_+.$$

Proof. Set $f(\mathbf{v},\mathbf{x},t)=\lim_{n\to\infty}f_n(\mathbf{v},\mathbf{x},t)$, $(\mathbf{v},\mathbf{x})\in\mathbb{R}^3\times\mathbb{R}^3$, $t\in\mathbb{R}_+$, where $\{f_n\}_0^\infty$ is the nondecreasing sequence defined in Lemma 2.1. Then by Levi's monotone convergence theorem f is measurable, and, using also Lemma 2.2, we have

$$\|f(\cdot,\cdot,t)\|_1=\lim_{n\to\infty}\|f_n(\cdot,\cdot,t)\|_1\leqq\|\varphi\|_1,\qquad t\in\mathbb{R}_+.$$

Moreover, letting $n\to\infty$ in (2.4), we see that there exists $M\subset\mathbb{R}^3\times\mathbb{R}^3$ such that mes $M=0$, and

$$f^{\#}(\mathbf{u},\mathbf{y},t)=\varphi(\mathbf{u},\mathbf{y})+\int_0^t(Kf)^{\#}(\mathbf{u},\mathbf{y},s)\,ds-\int_0^t\nu^{\#}(\mathbf{u},\mathbf{y},s)f^{\#}(\mathbf{u},\mathbf{y},s)\,ds,$$

$$(\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3\backslash M,\qquad t\in\mathbb{R}_+.\quad\square$$

Remark. For $-3<\gamma\leqq0$ it follows by (2.1), (2.2), and the proof of Theorem 2.3 that equality holds in relation (2.5). For $0<\gamma<1$, see Theorem 2.5 below.

Notation. Given $\sigma\geqq0$, $R>1$, we define a function $h_{\sigma,R}:\mathbb{R}_+\to\mathbb{R}_+$ as follows:

$$(2.6)\qquad \begin{aligned} h_{\sigma,R}(u)&=(1+u^2)^{\sigma/2}\quad\text{for } 0\leqq u\leqq R-1,\\ h_{\sigma,R}(u)&=\text{constant}\quad\text{for } R\leqq u<\infty,\end{aligned}$$

and $dh_{\sigma,R}/du$ is continuous on $\mathbb{R}_+$ and decreasing on $(R-1,R)$. Denote for measurable functions $g:\mathbb{R}^3\to\mathbb{R}$,

$$\|g\|_{1,\sigma,R}=\|h_{\sigma,R}g\|_1.$$

Notation.

$$\tilde{\Gamma}(t)=\operatorname*{ess-sup}_{\mathbf{x}\in\mathbb{R}^3}|\mathbf{\Gamma}(\mathbf{x},t)|,\qquad t\in\mathbb{R}_+,\quad\text{and}$$

$$\tilde{\Gamma}_0=\operatorname*{ess-sup}_{\mathbf{x}\in\mathbb{R}^3,t\in\mathbb{R}_+}|\mathbf{\Gamma}(\mathbf{x},t)|.$$

If $\mathbf{v}(t),\mathbf{x}(t)$ is the solution of (1.1), then there holds

$$(2.7)\qquad \begin{aligned} &\frac{d}{dt}(1+v^2(t))^{\sigma/2}=\sigma(1+v^2(t))^{\sigma/2-1}\mathbf{v}(t)\cdot\mathbf{\Gamma}(\mathbf{x}(t),t),\qquad t\in\mathbb{R}_+,\\ &\left|\frac{d}{dt}h_{\sigma,R}(v(t))\right|\leqq\sigma\tilde{\Gamma}(t)(1+v^2(t))^{\sigma/2-1}v(t),\qquad t\in\mathbb{R}_+.\end{aligned}$$

These elementary relations are derived noticing that $d\mathbf{v}(t)/dt = \mathbf{\Gamma}(\mathbf{x}(t), t) + \mathbf{v}(t) \times \mathbf{\Omega}(\mathbf{x}(t), t)$ and $\mathbf{v} \cdot (\mathbf{v} \times \mathbf{\Omega}) = 0$.

The following proposition gives local boundedness in time for moments of our mild solution.

THEOREM 2.4. *Let* $\tilde{\Gamma} \in L^1_{\mathrm{loc}}(\mathbb{R}_+)$, $-3 < \gamma < 1$, $\sigma_0 \geqq 2$. *When* $-1 \leqq \gamma$, *let* (2.1) *hold together with* $\text{ess-sup}_{\mathbf{x}\in\mathbb{R}^3, t\in\mathbb{R}_+} \|F(\cdot, \mathbf{x}, t)\|_{1,\sigma_0+\gamma} < \infty$; *otherwise, let* $\text{ess-sup}_{\mathbf{x}\in\mathbb{R}^3, t\in\mathbb{R}_+} \|F(\cdot, \mathbf{x}, t)\|_{1\cap\infty,\sigma_0-1} < \infty$. *If* $\varphi \in L^1_{\sigma,+}(\mathbb{R}^3 \times \mathbb{R}^3)$ *for some* σ *such that* $0 < \sigma \leqq \sigma_0$, *then the mild solution* f (*given in Theorem* 2.3) *satisfies*

$$\|f(\cdot, \cdot, t)\|_{1,\sigma} \leqq \|\varphi\|_{1,\sigma} \exp(\psi(t)), \qquad t \in \mathbb{R}_+,$$

where $\psi(t) = \sigma(\int_0^t \tilde{\Gamma}(s)\, ds + ct)$ *and* c *is a positive constant.*

Proof. Let $\{f_n\}_{n=0}^{\infty}$ be the sequence of iterates (defined in Lemma 2.1) with limit f. Using (2.4) we have, for $t \in \mathbb{R}_+$,

$$\frac{\partial}{\partial t}(f_n^{\#}) = (Kf_{n-1})^{\#} - (\nu f_n)^{\#} \leqq (Kf_n)^{\#} - (\nu f_n)^{\#} = Q[f_n, F]^{\#}.$$

By multiplying with $h^{\#}_{\sigma,R}$ and integrating we get

$$h^{\#}_{\sigma,R} f_n^{\#} \leqq h_{\sigma,R}\varphi + \int_0^t \frac{\partial h^{\#}_{\sigma,R}}{\partial s} \cdot f_n^{\#}\, ds + \int_0^t h^{\#}_{\sigma,R} Q^{\#}[f_n, F]\, ds.$$

Further integration gives (after a change of variables)

$$\iint h_{\sigma,R} f_n\, d\mathbf{x}\, d\mathbf{v} \leqq \|\varphi\|_{1,\sigma} + \sigma \int_0^t \tilde{\Gamma}(s) \|f_n(\cdot, \cdot, s)\|_{1,\max(0,\sigma-1)}\, \mathrm{ds}$$

$$+ \int_0^t \iiiint\!\!\int [h_{\sigma,R}(v') - h_{\sigma,R}(v)]$$

$$\cdot f_n F_* B\, d\theta\, d\varepsilon\, d\mathbf{v}_*\, d\mathbf{x}\, d\mathbf{v}\, ds.$$

Here

$$h_{\sigma,R}(v') - h_{\sigma,R}(v) \leqq \sigma C_1 \cos\theta w (1 + v^2)^{(\sigma-2)/2} (1 + v_*)^{\max(1,\sigma-1)}$$

for some positive constant C_1 (see [P2] if $v' > v$). Thus (with a constant C_2)

$$\iint h_{\sigma,R} f_n\, d\mathbf{x}\, d\mathbf{v} \leqq \|\varphi\|_{1,\sigma} + \sigma \int_0^t \tilde{\Gamma}(s) \|f_n(\cdot, \cdot. s)\|_{1,\max(0,\sigma-1)}\, ds$$

$$+ \sigma C_2 \int_0^t \|f_n(\cdot, \cdot s)\|_{1,\max(0,\tilde{\sigma})}\, ds$$

$$\leqq \|\varphi\|_{1,\sigma} + \sigma \int_0^t (\tilde{\Gamma}(s) + C_2) \|f_n(\cdot, \cdot, s)\|_{1,\sigma-\delta}\, ds,$$

where $\tilde{\sigma} = \sigma + \gamma - 1$ if $\gamma \geqq -1$, $\tilde{\sigma} = \sigma - 2$ if $-3 < \gamma < -1$, and the last member of these inequalities is independent of R and valid for some $\delta > 0$.

To obtain the first inequality in the case $-3 < \gamma < -1$ we split the integral with respect to $\mathbf{v}_*$ into two parts, one corresponding to $|\mathbf{v} - \mathbf{v}_*| \leqq 1$ and the other to $|\mathbf{v} - \mathbf{v}_*| \geqq 1$, and thus

$$\int_{\mathbb{R}^3} (1 + v_*^2)^{(\sigma-1)/2} F(\mathbf{v}_*, \mathbf{x}, s) w^{1+\gamma}\, d\mathbf{v}_* \leqq C \cdot \underset{\mathbf{x}\in\mathbb{R}^3, t\in\mathbb{R}_+}{\text{ess-sup}} \|F(\cdot, \mathbf{x}, t)\|_{1\cap\infty,\sigma_0-1}.$$

Next let $R \to \infty$. Then $h_{\sigma,R}(v) \nearrow (1+v^2)^{\sigma/2}$, and

$$\|f_n(\cdot,\cdot,t)\|_{1,\sigma} \leqq \|\varphi\|_{1,\sigma} + \sigma \int_0^t (\tilde{\Gamma}(s)+C_2)\|f_n(\cdot,\cdot,s)\|_{1,\sigma-\delta}\,ds.$$

Using Gronwall's lemma, we obtain

$$\|f_n(\cdot,\cdot,t)\|_{1,\sigma} \leqq \|\varphi\|_{1,\sigma} \exp(\psi(t)),$$

where $\psi(t) = \sigma(\int_0^t \tilde{\Gamma}(s)\,ds + C_2 t)$, $t \in \mathbb{R}_+$. Letting $n \to \infty$, and noticing $f_n \nearrow f$, the theorem follows. □

Now, employing Theorem 2.4 we find the following theorem about mass conservation and uniqueness for the mild solution from Theorem 2.3.

THEOREM 2.5. *Let* $\tilde{\Gamma} \in L^1_{\text{loc}}(\mathbb{R}_+)$, $-3<\gamma<1$, *and let* (2.1) *hold together with* $\text{ess-sup}_{\mathbf{x}\in\mathbb{R}^3, t\in\mathbb{R}_+} \|F(\cdot,\mathbf{x},t)\|_{1,2+\max(-1,\gamma)} < \infty$. *If* $\varphi \in L^1_+(\mathbb{R}^3\times\mathbb{R}^3)$, *then there exists a nonnegative mild solution f to the problem* (0.6), *such that*

$$\|f(\cdot,\cdot,t)\|_1 = \|\varphi\|_1, \qquad t\in\mathbb{R}_+. \tag{2.8}$$

Moreover, the solution f is unique in the following sense: if $\tilde{f} = \tilde{f}(\cdot,\cdot,t) \in L^1_+(\mathbb{R}^3\times\mathbb{R}^3)$, $t\in\mathbb{R}_+$, *is a mild solution of* (0.6) *such that* $\|\tilde{f}(\cdot,\cdot,t)\|_1 \leqq \|\varphi\|_1$, $t\in\mathbb{R}_+$, *then* $\tilde{f}(\cdot,\cdot,t) = f(\cdot,\cdot,t)$ *almost everywhere in* $\mathbb{R}^3\times\mathbb{R}^3$, $t\in\mathbb{R}_+$.

Proof. Consider the case $0 \leqq \gamma < 1$. Let $\varphi_R = \varphi\cdot\chi_R$, where $\chi_R(\mathbf{v},\mathbf{x}) = 1$ if $|\mathbf{v}| \leqq R$ and zero otherwise. Let f and f_R be the solutions obtained in Theorem 2.3 with initial data φ and φ_R, respectively. Since $\varphi_R \in L^1_{\sigma,+}(\mathbb{R}^3\times\mathbb{R}^3)$, $t\in\mathbb{R}_+$, for all $\sigma \geqq 0$, it follows by Theorem 2.4 that $f_R(\cdot,\cdot,t) \in L^1_{\sigma,+}(\mathbb{R}^3\times\mathbb{R}^3)$, $t\in\mathbb{R}_+$, for $0\leqq\sigma\leqq 2$. Choose especially $\sigma=\gamma$. Thus both the right-hand side and the left-hand side of (2.2) with f replaced by f_R exist and are equal. Now integrate the appropriate modification of (2.4), and let $n\to\infty$. We conclude that

$$\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} f_R(\mathbf{v},\mathbf{x},t)\,d\mathbf{v}\,d\mathbf{x} = \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \varphi_R(\mathbf{v},\mathbf{x})\,d\mathbf{v}\,d\mathbf{x}, \qquad t\in\mathbb{R}_+. \tag{2.9}$$

Next, let $\{f_n\}$ and $\{f_{nR}\}$ be the sequences from Theorem 2.3 with limits f and f_R, respectively. Then, by induction, $f_{nR} \leqq f_n$, and hence $f_R \leqq f$. So by Theorem 2.3 and (2.9) we have

$$\begin{aligned}\|f(\cdot,\cdot,t)-f_R(\cdot,\cdot,t)\|_1 &= \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} f(\mathbf{v},\mathbf{x},t)\,d\mathbf{v}\,d\mathbf{x} - \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} f_R(\mathbf{v},\mathbf{x},t)\,d\mathbf{v}\,d\mathbf{x}\\ &\leqq \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \varphi(\mathbf{v},\mathbf{x})\,d\mathbf{v}\;d\mathbf{x} - \int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \varphi_R(\mathbf{v},\mathbf{x})\,d\mathbf{v}\,d\mathbf{x}\\ &= \|\varphi(\cdot,\cdot)-\varphi_R(\cdot,\cdot)\|_1, \quad t\in\mathbb{R}_+.\end{aligned}$$

Now let $R\to\infty$. We conclude that $f_R(\cdot,\cdot,t)\to f(\cdot,\cdot,t)$ in $L^1(\mathbb{R}^3\times\mathbb{R}^3)$ when $R\to\infty$, $t\in\mathbb{R}_+$. Hence (2.8) follows.

For the case $-3<\gamma<0$, see the remark after Theorem 2.3.

It remains to prove uniqueness. Let $\tilde{f}$ be any mild nonnegative solution of (0.6). Then by Lemma 1.3 $\tilde{f}$ satisfies also the exponential form (1.5) with $g = K\tilde{f}$. Hence

$$\tilde{f}^*(\cdot,\cdot,t) - f^*_{n+1}(\cdot,\cdot,t) = \int_0^t K(\tilde{f}-f_n)^*(\cdot,\cdot,r)\cdot\exp\left(-\int_r^t \nu^*(\cdot,\cdot,s)\,ds\right)dr,$$

and, by induction we find that $f_n \leqq \tilde{f}$, $n = 0, 1, \dots$. So $f(\cdot, \cdot, t) - \tilde{f}(\cdot, \cdot, t) \leqq 0$, $t \in \mathbb{R}_+$. But by (2.8),

$$\|f(\cdot, \cdot, t)\|_1 = \|\varphi\|_1 \geqq \|\tilde{f}(\cdot, \cdot, t)\|_1, \qquad t \in \mathbb{R}_+.$$

Thus, $f(\cdot, \cdot, t) = \tilde{f}(\cdot, \cdot, t)$ almost everywhere in $\mathbb{R}^3 \times \mathbb{R}^3$, $t \in \mathbb{R}_+$. □

We have arrived at the main result of this section, global boundedness in time for moments of the mild solution in the hard interaction case.

THEOREM 2.6. *Let* $\tilde{\Gamma}_0 < \infty$, $0 \leqq \gamma < 1$, *and let* ess-sup$_{\mathbf{x} \in \mathbb{R}^3, t \in \mathbb{R}_+}$ $\|F(\cdot, \mathbf{x}, t)\|_{1, \sigma_0 + \gamma} < \infty$ *for some* $\sigma_0 \geqq 2$, *and* ess-inf$_{\mathbf{x} \in \mathbb{R}^3, t \in \mathbb{R}_+}$ $\|F(\cdot, \mathbf{x}, t)\|_1 > 0$. *If* $\varphi \in L^1_{\sigma,+}(\mathbb{R}^3 \times \mathbb{R}^3)$ *for some* σ *such that* $0 \leqq \sigma \leqq \sigma_0$, *then there exists a unique nonnegative mild solution f of the problem* (0.6) *such that*

$$\|f(\cdot, \cdot, t)\|_1 = \|\varphi\|_1, \qquad t \in \mathbb{R}_+,$$

$$\|f(\cdot, \cdot, t)\|_{1,\sigma} \leqq C \|\varphi\|_{1,\sigma}, \qquad t \in \mathbb{R}_+,$$

where C is a constant not depending on φ.

Proof. Let φ_R and f_R be as in the proof of Theorem 2.5. Then the solution f_R satisfies

$$\frac{\partial f_R^\#(\mathbf{u}, \mathbf{y}, t)}{\partial t} = Q[f_R, F]^\#(\mathbf{u}, \mathbf{y}, t), (\mathbf{u}, \mathbf{y}) \in \mathbb{R}^3 \times \mathbb{R}^3 \backslash M, \qquad t \in \mathbb{R}_+ \backslash M_{\mathbf{u},\mathbf{y}},$$

with mes $M =$ mes $M_{\mathbf{u},\mathbf{y}} = 0$. By multiplying by $(1 + v(t)^2)^{\sigma/2}$ and integrating, we get (after some changes of variables)

$$\begin{aligned} &\int_{\mathbb{R}^3} \int_{\mathbb{R}^3} (1 + v^2)^{\sigma/2} f_R(\mathbf{v}, \mathbf{x}, t) \, d\mathbf{v} \, d\mathbf{x} \\ &= \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} (1 + v^2)^{\sigma/2} \varphi(\mathbf{v}, \mathbf{x}) \, d\mathbf{v} \, d\mathbf{x} \\ &\quad + \sigma \int_0^t \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} (1 + v^2)^{(\sigma-2)/2} (\mathbf{v} \cdot \mathbf{\Gamma}(\mathbf{x}, s)) f_R(\mathbf{v}, \mathbf{x}, s) \, d\mathbf{v} \, d\mathbf{x} \, ds + I(t), \qquad t \in \mathbb{R}_+. \end{aligned} \tag{2.10}$$

Using $f_R \in L^1_{\sigma_0 + \gamma}$ (cf. Theorem 2.4),

$$\begin{aligned} I(t) = \int_0^t \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \int_0^{2\pi} \int_0^{\pi/2} &[(1 + (v')^2)^{\sigma/2} - (1 + v^2)^{\sigma/2}] \\ &\cdot f_R(\mathbf{v}, \mathbf{x}, s) F(\mathbf{v}_*, \mathbf{x}, s) B(\theta, w) \, d\theta \, d\varepsilon \, d\mathbf{v}_* \, d\mathbf{v} \, d\mathbf{x} \, ds. \end{aligned}$$

Differentiating (2.10) with respect to t we obtain

$$\begin{aligned} &\frac{d}{dt} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} (1 + v^2)^{\sigma/2} f_R(\mathbf{v}, \mathbf{x}, t) \, d\mathbf{v} \, d\mathbf{x} \\ &= \sigma \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} (1 + v^2)^{\sigma/2 - 1} (\mathbf{v} \cdot \mathbf{\Gamma}(\mathbf{x}, t)) f_R(\mathbf{v}, \mathbf{x}, t) \, d\mathbf{v} \, d\mathbf{x} + \frac{d}{dt} I(t). \end{aligned} \tag{2.11}$$

To estimate the last term $dI(t)/dt$, use the following fundamental inequality (Proposition 2.1 in [P2]):

$$\begin{aligned} &(1 + (v')^2)^{\sigma/2} - (1 + v^2)^{\sigma/2} \\ &\leqq K_1 \cdot w \cos \theta (1 + v_*)^{\max(1, \sigma - 1)} (1 + v^2)^{(\sigma-2)/2} - K_2 \cdot w \cos^2 \theta (1 + v^2)^{(\sigma-1)/2}, \end{aligned} \tag{2.12}$$

with positive constants K_1 and K_2 (depending only on σ and κ). Then, as derived in the proof to Theorem 3.1 in [P2], there exist constants $c_0, c_1, c_2 > 0$ such that

$$\text{(2.13)}\quad \frac{d}{dt} I(t) \leqq c_1 \|f_R(\cdot, \cdot, t)\|_{1,\sigma+\gamma-1} + c_2 \|f_R(\cdot, \cdot, t)\|_{1,\sigma-1} - c_0 \|f_R(\cdot, \cdot, t)\|_{1,\sigma+\gamma}.$$

As a consequence of (2.11) and (2.13) we obtain

$$\frac{d}{dt} \|f_R(\cdot, \cdot, t)\|_{1,\sigma} \leqq \sigma_0 \tilde{\Gamma}_0 \|f_R(\cdot, \cdot, t)\|_{1,\sigma-1} + c_1 \|f_R(\cdot, \cdot, t)\|_{1,\sigma+\gamma-1}$$
$$+ c_2 \|f_R(\cdot, \cdot, t)\|_{1,\sigma-1} - c_0 \|f_R(\cdot, \cdot, t)\|_{1,\sigma+\gamma}.$$

Hence,

$$\text{(2.14)}\qquad \frac{d}{dt} \|f_R(\cdot, \cdot, t)\|_{1,\sigma} \leqq c \|f_R(\cdot, \cdot t)\|_{1,\sigma-\delta} - c_0 \|f_R(, \cdot, t)\|_{1,\sigma},$$

where $c > 0$ is a constant and δ satisfies $0 < \delta < \min(\sigma, 1-\gamma)$ and $k\delta = \sigma$ for some nonnegative integer k. It follows from (2.14) that

$$\|f_R(\cdot, \cdot, t)\|_{1,\sigma} \leqq \|\varphi\|_{1,\sigma} + c \int_0^t \exp[-c_0(t-s)] \cdot \|f_R(\cdot, \cdot, s)\|_{1,\sigma-d}\, ds \leqq \text{const} \cdot \|\varphi\|_{1,\sigma},$$

if $\|f_R(\cdot, \cdot, t)\|_{1,\sigma-\delta}$ is globally bounded.

By proceeding step by step, starting with the value $\|f_R(\cdot, \cdot, s)\|_{1,0}$, we obtain consecutively that $\|f_R(\cdot, \cdot, t)\|_{1,n\delta}$, $n = 0, 1, \ldots, k$, are globally bounded on $\mathbb{R}_+$, and that $\|f_R(\cdot, \cdot t)\|_{1,n\delta} \leqq \text{const} \cdot \|\varphi\|_{1,n\delta}$. Finally, let f be the unique mild solution, with initial data φ, of Theorem 2.5. Then by the proof of Theorem 2.5, $f_R(\cdot, \cdot, t) \to f(\cdot, \cdot, t)$ in $L^1_{n\delta}(\mathbb{R}^3 \times \mathbb{R}^3)$ as $R \nearrow \infty$, $t \in \mathbb{R}_+$. This completes the proof. □

3. $L^{1;q} \cap L^{p;q}$-solutions. This section treats existence and global boundedness of solutions to the problem (0.6) in the Banach spaces $L^{1;q}_\sigma(\mathbb{R}^3 \times \mathbb{R}^3) \cap L^{p;q}_\sigma(\mathbb{R}^3 \times \mathbb{R}^3)$, $1 \leqq p, q \leqq \infty$, $\sigma \geqq 0$, where

$$L^{p;q}_\sigma(\mathbb{R}^3 \times \mathbb{R}^3) = \{f : f \text{ measurable on } \mathbb{R}^3 \times \mathbb{R}^3,\ \|f\|_{p,\sigma;q} < \infty\},$$

and

$$\|f(\cdot, \cdot)\|_{p,\sigma;q} = \left(\int_{\mathbb{R}^3} \left(\int_{\mathbb{R}^3} |f(\mathbf{v}, \mathbf{x})(1+v^2)^{\sigma/2}|^q\, d\mathbf{x} \right)^{p/q} d\mathbf{v} \right)^{1/p}.$$

The corresponding positive cones are $L^{p;q}_{\sigma,+} = \{f \in L^{p;q}_\sigma : f \geqq 0 \text{ almost everywhere}\}$. For $\sigma = 0$ we shorten the notation, $L^{p;q} = L^{p;q}_0$ with $\|\cdot\|_{p;q} = \|\cdot\|_{p,0;q}$. We will assume that the distribution function F of the neutral particles, the electric field $\mathbf{\Gamma}$, and the magnetic field $\mathbf{\Omega}$ are spatially homogeneous.

The first part of the section considers (0.6) in $L^{1;q}(\mathbb{R}^3 \times \mathbb{R}^3)$, with $1 \leqq q \leqq \infty$, for a function $B(\theta, w)$ given by (0.2) and (0.3). We prove that a unique solution exists and that its $L^{1;q}$-norm is nonincreasing with respect to time; see Theorems 3.1 and 3.4. Moreover, for higher velocity moments global estimates are obtained for hard interactions; see Theorem 3.3.

The second part gives an L^∞-estimate of the gain operator K, when the function $B(\theta, w)$ satisfies (0.2) and (0.4) (with $\alpha = \gamma$). Together with the results of the first part, this implies global estimates of the solution to (0.6) in $L^{1;q}_+(\mathbb{R}^3 \times \mathbb{R}^3) \cap L^{p;q}(\mathbb{R}^3 \times \mathbb{R}^3)$, where $1 \leqq p, q \leqq \infty$; see Theorems 3.8 and 3.10.

Since $\mathbf{\Gamma} = \mathbf{\Gamma}(t)$, $\mathbf{\Omega} = \mathbf{\Omega}(t)$, the solution of (1.1) is given by

$$\text{(3.1)}\qquad \mathbf{v}(t) = \mathbf{v}(\mathbf{u}, t),\ \mathbf{x}(t) = \mathbf{y} + \int_0^t \mathbf{v}(s)\, ds, \qquad t \in \mathbb{R}_+.$$

For fixed $\mathbf{u}\in\mathbb{R}^3$, it follows by (3.1) that the Jacobian of the transformation $\mathbf{y}\mapsto\mathbf{x}(t)$ equals one for every $t\in\mathbb{R}_+$. Furthermore, by Hypothesis 1.1, the Jacobian of the transformation $\mathbf{u}\mapsto\mathbf{v}(t)$ is also equal to one for every $t\in\mathbb{R}_+$. In the proofs below those transformations will be used without comments.

With F spatially homogeneous, condition (2.1) corresponds to F being measurable on $\mathbb{R}^3\times\mathbb{R}_+$, and

$$(3.2\text{a})\qquad F(\cdot,t)\in L^1_\gamma(\mathbb{R}^3),\quad t\in\mathbb{R}_+\quad \text{if } 0\leqq\gamma\leqq 1,$$

$$(3.2\text{b})\qquad F(\cdot,t)\in L^1(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3),\quad t\in\mathbb{R}_+\quad \text{if } -3<\gamma<0.$$

Notation. For measurable functions $g:\mathbb{R}^3\times\mathbb{R}^3\to\mathbb{R}$ such that $g(\mathbf{u},\cdot)\in L^q(\mathbb{R}^3)$, almost every $\mathbf{u}\in\mathbb{R}^3$, set

$$g_q(\mathbf{u})=\|g(\mathbf{u},\cdot)\|_q.$$

For measurable functions $g:\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+\to\mathbb{R}$ such that $g(\mathbf{u},\cdot,t)\in L^q(\mathbb{R}^3)$, almost every $\mathbf{u}\in\mathbb{R}^3$, $t\in\mathbb{R}_+$, set

$$g_q(\mathbf{u},t)=\|g(\mathbf{u},\cdot,t)\|_q,$$

and

$$g_q^{\#}(\mathbf{u},t)=g_q(\mathbf{v}(\mathbf{u},t),t).$$

Consider the L^q-norm, with respect to $\mathbf{y}$, of the gain term $(Kg)^{\#}$. By the Minkowski inequality,

$$\begin{aligned}\|(Kg)^{\#}(\mathbf{u},\cdot,t)\|_q&=\left\|\int_{\mathbb{R}^3}\int_0^{2\pi}\int_0^{\pi/2} g(\mathbf{v}(t)',\mathbf{x}(t),t)F(\mathbf{v}'_*,t)b(\theta)|\mathbf{v}(t)-\mathbf{v}_*|^\gamma\,d\theta\,d\varepsilon\,d\mathbf{v}_*\right\|_q\\&\leqq\int_{\mathbb{R}^3}\int_0^{2\pi}\int_0^{\pi/2}\|g(\mathbf{v}(t)',\mathbf{x}(t),t)\|_q F(\mathbf{v}'_*,t)b(\theta)|\mathbf{v}(t)-\mathbf{v}_*|^\gamma\,d\theta\,d\varepsilon\,d\mathbf{v}_*.\end{aligned}$$

After the transformation $\mathbf{x}(t)\mapsto\mathbf{y}$ we find that $\|g(\mathbf{v}(t)',\mathbf{x}(t),t)\|_q=g_q(\mathbf{v}(t)',t)$. Hence the right-hand side of the inequality above equals $(Kg_q)(\mathbf{v}(t),t)=(Kg_q)^{\#}(\mathbf{u},t)$. We conclude that

$$(3.3)\qquad \|(Kg)^{\#}(\mathbf{u},\cdot,t)\|_q\leqq(Kg_q)^{\#}(\mathbf{u},t)\quad \text{a.e. } \mathbf{u}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+.$$

In the proofs to follow, (3.3) is essential.

In Theorem 3.1 below we prove that the $L^{1;q}$-norm of the mild solution f of problem (0.6) is nonincreasing with time. The main idea of the proof is to take the L^q-norm with respect to $\mathbf{y}$ of the mild equation in the exponential form (1.5). By use of (3.3) it follows that the right-hand side of (1.5) is bounded by the corresponding spatially homogeneous version of (1.5). We then prove that there is a unique spatially homogeneous solution, which is an upper bound for $f_q(\mathbf{u},t)=\|f(\mathbf{u},\cdot t)\|_q$.

THEOREM 3.1. *Let* $-3<\gamma\leqq 1$, $1\leqq q\leqq\infty$, *and suppose* (3.2) *holds. If* $\varphi\in L_+^{1;q}$, *then there exists a mild solution f of problem* (0.6), *with initial data* φ, *such that* $f(\cdot,\cdot,t)\in L_+^{1;q}$, $t\in\mathbb{R}_+$. *Moreover,*

$$\|f(\cdot,\cdot,t)\|_{1;q}\leqq\|\varphi\|_{1;q},\qquad t\in\mathbb{R}_+.$$

Proof. Consider the sequence of iterates given by (2.3). If, in the initial function, φ is replaced by φ_n, where $\varphi_n(\mathbf{u},\mathbf{y})=\varphi(\mathbf{u},\mathbf{y})$ if $|\mathbf{u}|\leqq n$, and $\varphi_n(\mathbf{u},\mathbf{y})=0$ otherwise, we still obtain a nonnegative and nondecreasing sequence $\{f_n\}_0^\infty$. By (3.3) and the Minkowski inequality it follows that the sequence satisfies the inequality

$$\begin{aligned}(3.4)\quad f^{\#}_{n+1,q}(\mathbf{u},t)&\leqq \varphi_{n,q}(\mathbf{u})\exp\left(-\int_0^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)\\ &\quad+\int_0^t (Kf_{n,q})^{\#}(\mathbf{u},s)\exp\left(-\int_s^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)ds,\quad \mathbf{u}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+;\end{aligned}$$

here and below $\varphi_{n,q}=(\varphi_n)_q$, and $f_{n,q}=(f_n)_q$. Now, since $\nu\geqq 0$, we obtain by induction that

$$(3.5)\qquad f^{\#}_{n,q}(\cdot,t)\in L^1_\sigma(\mathbb{R}^3)\quad\text{for all } \sigma\geqq 0,\quad t\in\mathbb{R}_+.$$

Next, consider the spatially homogeneous sequence $\{g_{n,m}\}_{m=0}^\infty$ (depending on q) defined by

$$\begin{aligned}g^{\#}_{n,0}(\mathbf{u},t)&=f^{\#}_{n,q}(\mathbf{u},t),\\ (3.6)\quad g^{\#}_{n,m+1}(\mathbf{u},t)&=\varphi_{n,q}(\mathbf{u})\exp\left(-\int_0^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)\\ &\quad+\int_0^t (Kg_{n,m})^{\#}(\mathbf{u},s)\exp\left(-\int_s^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)ds,\quad \mathbf{u}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+.\end{aligned}$$

Notice that (3.4) implies that $\{g_{n,m}\}$ is nondecreasing, and (3.5) implies that $g_{n,m}(\cdot,t)\in L^1_\sigma(\mathbb{R}^3)$, $\sigma\geqq 0$, $t\in\mathbb{R}_+$. We now conclude by the proof of Theorem 2.3 that $g_{n,m}$ converges when $m\to\infty$ to a nonnegative mild solution g_n of the spatially homogeneous version of (0.6) with initial data $\varphi_{n,q}$; moreover, $g_n(\cdot,t)\in L^1_+(\mathbb{R}^3)$, $t\in\mathbb{R}_+$, and

$$(3.7)\qquad \|g_n(\cdot,t)\|_1\leqq\|\varphi_{n,q}\|_1\leqq\|\varphi_q\|_1,\qquad t\in\mathbb{R}_+.$$

By the construction of g_n we have $f_{n,q}=g_{n,0}\leqq g_n$. Hence

$$\|f_n(\cdot,\cdot,t)\|_{1;q}=\|f_{n,q}(\cdot,t)\|_1\leqq\|g_n(\cdot,t)\|_1\leqq\varphi_q\|_1=\|\varphi\|_{1;q},\qquad t\in\mathbb{R}_+.$$

Finally, set $f(\mathbf{v},\mathbf{x},t)=\lim_{n\to\infty}f_n(\mathbf{v},\mathbf{x},t)$, $(\mathbf{v},\mathbf{x})\in\mathbb{R}^3\times\mathbb{R}^3$, $t\in\mathbb{R}_+$. Then f is measurable and by monotone convergence

$$\|f(\cdot,\cdot,t)\|_{1;q}=\lim_{n\to\infty}\|f_n(\cdot,\cdot,t)\|_{1;q}\leqq\|\varphi\|_{1;q},\qquad t\in\mathbb{R}_+.$$

Moreover, letting $n\to\infty$ in (2.4), we establish that f is a mild solution of problem (0.6). □

Remark. (i) For later reference let $g(\mathbf{v},t)=\lim_{n\to\infty}g_n(\mathbf{v},t)$, $\mathbf{v}\in\mathbb{R}^3$, $t\in\mathbb{R}_+$. Then g is a mild solution to (0.6) with initial data φ_q, and if $\text{ess-sup}_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_{1,2+\max(-1,\gamma)}<\infty$, $-3<\gamma<1$, then by Theorem 2.5 $\|g(\cdot,t)\|_1=\|\varphi_q\|_1$, $t\in\mathbb{R}_+$. Moreover, by the uniqueness part of Theorem 2.5, it follows that, with $g_0=0$ instead of $g_{n,0}=f_{n,q}$ and φ_q instead of $\varphi_{n,q}$ in (3.6), we obtain a sequence $\{g_m\}$ which converges to the same solution g.

(ii) In the theorems that follow the mild solution of (0.6) is the (solution that here was constructed as the) pointwise limit of the iterate functions $\{f_n\}$ defined by (2.3) (with φ replaced by φ_n).

Next, the solution of Theorem 3.1 is studied for higher velocity moments. Local boundedness in the case $-3<\gamma<1$ and global boundedness in the case $0\leqq\gamma\leqq 1$ follow immediately from Theorems 2.4 and 2.6, respectively.

THEOREM 3.2. *Let* $-3<\gamma<1$, $\sigma_0\geqq 2$. *When* $-1\leqq\gamma$, *let* (3.2) *hold together with* $\text{ess-sup}_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_{1,\sigma_0+\gamma}<\infty$; *otherwise, let* $\text{ess-sup}_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_{1\cap\infty,\sigma_0-1}<\infty$. *Let* $\varphi\in L^{1;q}_{\sigma,+}$ *with* $1\leqq q\leqq\infty$, *and* $0\leqq\sigma\leqq\sigma_0$. *Then the mild solution f given in Theorem* 3.1 *satisfies* $f(\cdot,\cdot,t)\in L^{1;q}_{\sigma}$, $t\in\mathbb{R}_+$, *and*

$$\|f(\cdot,\cdot,t)\|_{1,\sigma;q}\leqq\|\varphi\|_{1,\sigma;q}\cdot\exp(\psi(t)),\qquad t\in\mathbb{R}_+,$$

where $\psi(t)=\sigma_0(\int_0^t\tilde{\Gamma}(s)\,ds+ct)$ *and c is a positive constant.*

THEOREM 3.3. *In addition to the assumptions of Theorem* 3.2 *suppose that* $0\leqq\gamma<1$, $\tilde{\Gamma}_0<\infty$, *and that* $\text{ess-inf}_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_1>0$. *Then the mild solution f satisfies*

$$\|f(\cdot,\cdot,t)\|_{1,\sigma;q}\leqq c\cdot\|\varphi\|_{1,\sigma;q},\quad t\in\mathbb{R}_+,$$

where c is a positive constant independent of φ.

Proofs of Theorems 3.2 *and* 3.3. Let f be the mild solution given in Theorem 3.1. Let g be the space homogeneous mild solution with initial data φ_q. Then by the proof of Theorem 3.1,

$$\|f(\mathbf{v},\cdot,t)\|_q=f_q(\mathbf{v},t)\leqq g(\mathbf{v},t)\quad\text{a.e. }\mathbf{v}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+. \tag{3.8}$$

Finally, (3.8), together with Theorems 2.4 and 2.6, implies Theorems 3.2 and 3.3, respectively. □

The solution f in Theorems 3.1–3.3 is unique in the following sense.

THEOREM 3.4. *Suppose that* $-3<\gamma<1$, (3.2) *holds*, $\text{ess-sup}_{t\in\mathbb{R}+}\|F(\cdot,t)\|_{1,2+\gamma}<\infty$ *when* $0<\gamma<1$, *and that* $\varphi\in L^{1;q}_{\max(0,\gamma),+}$. *If f is the mild solution of* (0.6) *obtained in Theorem* 3.1 *and if* $\tilde{f}$ *is any mild solution to* (0.6) *such that* $\tilde{f}(\cdot,\cdot,t)\in L^{1;q}_{+}$ *and* $\nu(\cdot,t)\tilde{f}_q(\cdot,t)\in L^1$, *then*

$$\tilde{f}(\mathbf{u},\mathbf{y},t)=f(\mathbf{u},\mathbf{y},t)\quad\textit{for a.e. }(\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3,\qquad t\in\mathbb{R}_+.$$

Proof. By differentiating the $L^{1;q}$-norm (with respect to time) of the difference between f and $\tilde{f}$ we obtain (cf. [Gu2, Lemma 1.4])

$$\begin{aligned}\frac{d}{dt}\|f^*(t)-\tilde{f}^*(t)\|_{1;q}=&\int_{\mathbb{R}^3}(((f-\tilde{f})^*)_q(\mathbf{u},t))^{1-q}\\&\cdot\int_{\mathbb{R}^3}\operatorname{sgn}(f-\tilde{f})^*(\mathbf{u},\mathbf{y},t)\\&\cdot(|f-\tilde{f}|^*(\mathbf{u},\mathbf{y},t))^{q-1}\frac{d}{dt}(f-\tilde{f})^*(\mathbf{u},\mathbf{y},t)\,d\mathbf{y}\,d\mathbf{u}.\end{aligned}$$

We have

$$\frac{d}{dt}(f-\tilde{f})^*(\mathbf{u},\mathbf{y},t)=(K(f-\tilde{f}))^*(\mathbf{u},\mathbf{y},t)-\nu^*(\mathbf{u},t)(f-\tilde{f})^*(\mathbf{u},\mathbf{y},t),$$

$$\text{for a.e. }(\mathbf{u},\mathbf{y})\in\mathbb{R}^3\times\mathbb{R}^3,\qquad t\in\mathbb{R}_+.$$

Hence

$$\begin{aligned}&\frac{d}{dt}\|f^*(t)-\tilde{f}^*(t)\|_{1;q}\\&\leqq\int_{\mathbb{R}^3}((f-\tilde{f})^*_q(\mathbf{u},t))^{1-q}\int_{\mathbb{R}^3}(|f-\tilde{f}|^*(\mathbf{u},\mathbf{y},t))^{q-1}(K|f-\tilde{f}|)^*(\mathbf{u},\mathbf{y},t)\,d\mathbf{y}\,d\mathbf{u}\\&\quad-\int_{\mathbb{R}^3}\nu^*(\mathbf{u},t)((f-\tilde{f})^*_q(\mathbf{u},t))^{1-q}\int_{\mathbb{R}^3}(|f-\tilde{f}|^*(\mathbf{u},\mathbf{y},t))^q\,d\mathbf{y}\,d\mathbf{u}.\end{aligned}$$

(Observe here and also below that by the transformation $\mathbf{y}\to\mathbf{x}(t)$ we get $((f-\tilde{f})^{\#})_q(\mathbf{u}, t)=(f-\tilde{f})^{\#}_q(\mathbf{u}, t)$.)

Now, using Hölder's inequality on the first term on the right-hand side and observing that the second term equals $\int_{\mathbb{R}^3} \nu^{\#}(\mathbf{u}, t)(f-\tilde{f})^{\#}_q(\mathbf{u}, t)\, d\mathbf{u}$ it follows that

$$\frac{d}{dt}\|f^{\#}(t)-\tilde{f}^{\#}(t)\|_{1;q} \leqq \int_{\mathbb{R}^3} \|(K(f-\tilde{f}))^{\#}\|_q(\mathbf{u}, t)\, d\mathbf{u} - \int_{\mathbb{R}^3} \nu^{\#}(\mathbf{u}, t)(f-\tilde{f})^{\#}_q(\mathbf{u}, t)\, d\mathbf{u}.$$

Finally, by (3) the first term on the right is less than or equal to $\int_{\mathbb{R}^3} (K(f-\tilde{f})_q)^{\#}(\mathbf{u}, t)$; so after the transformation $\mathbf{u}\to\mathbf{v}(t)$ it follows by (2.2) that the right-hand side is not greater than zero. Thus the theorem is proved. Note also that by Theorem 3.2 all integrals involved exist. □

For the next part we need some *L^∞-properties* of the gain operator K. Here the dependence on $\mathbf{x}$ and t plays no role and will, therefore, be left out.

The following transformation of Kg is used. Let $E_{\mathbf{v},\bar{\mathbf{v}}}$ denote the plane in $\mathbb{R}^3$ through $\tilde{\mathbf{v}}=((1+\kappa)/2)\mathbf{v}+((1-\kappa)/2)\bar{\mathbf{v}}$ and orthogonal to $\mathbf{v}-\bar{\mathbf{v}}$;

$$E_{\mathbf{v},\bar{\mathbf{v}}}=\{\mathbf{u}\in\mathbb{R}^3;\ (\mathbf{u}-\tilde{\mathbf{v}})\cdot(\mathbf{v}-\bar{\mathbf{v}})=0\}.$$

The corresponding Lebesgue measure is $\int dE$.

LEMMA 3.5. *The gain term can be represented as follows*:

$$Kg(\mathbf{v})=\left(\frac{1+\kappa}{2}\right)^{1+\gamma}\int_{\mathbb{R}^3} g(\mathbf{v}')|\mathbf{v}-\mathbf{v}'|^{\gamma-2}\int_{E_{\mathbf{v},\mathbf{v}'}} F(\mathbf{v}'_*)b(\theta)(\sin\theta)^{-1}(\cos\theta)^{-\gamma}\, dE'_*\, d\mathbf{v}'.$$

Proof. The proof is a straightforward generalization of the proof in [Ca]. □

Below we consider $B(\theta, w)$ satisfying (0.2) and (0.4) (with $\alpha=\gamma$). Let $h_{\sigma,R}$ be as in (2.6), and denote $\|g\|_{\infty,\sigma,R}=\|h_{\sigma,R}g\|_\infty$ for measurable functions $g:\mathbb{R}^3\to\mathbb{R}$.

LEMMA 3.6. *Suppose* $-1<\gamma\leqq 1$, $F\in L^\infty_{2+\sigma_1}(\mathbb{R}^3)$, *where* $\sigma_1>0$, $g\in L^1_{\sigma,+}(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3)$, *where* $0\leqq\sigma\leqq\sigma_1$. *Then, for every* $\varepsilon>0$ *there is a constant* c_ε *such that for* $1<R<\infty$,

$$Kg(\mathbf{v})h_{\sigma,R}(v)\leqq c_\varepsilon\|g\|_{1,\sigma}+\varepsilon\|g\|_{\infty,\sigma,R},\qquad \mathbf{v}\in\mathbb{R}^3. \tag{3.9}$$

In particular, if $g\in L^1_+(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3)$, *then it holds that*

$$Kg(\mathbf{v})\leqq c_\varepsilon\|g\|_1+\varepsilon\|g\|_\infty,\qquad \mathbf{v}\in\mathbb{R}^3. \tag{3.10}$$

The constant c_ε *may be chosen such that it depends only on* ε, R, σ, σ_1, *and the* $L^\infty_{\sigma_1}$*-norm of* F.

Proof. Cf. [Gu1], or see [CGP]. □

In the next lemma we present (in the hard interaction case) a lower bound of the collision frequency

$$\nu(\mathbf{v}, t)=2\pi\int_0^{\pi/2} b(\theta)\, d\theta\int_{\mathbb{R}^3} F(\mathbf{v}_*, t)|\mathbf{v}-\mathbf{v}_*|^\gamma\, d\mathbf{v}_*.$$

LEMMA 3.7. *Suppose* $\gamma\geqq 0$, *and that* (3.2) *holds*, ess-sup$_{t\in\mathbb{R}_+}$ $\|F(\cdot, t)\|_\infty<\infty$, *and* $\inf_{t\in\mathbb{R}_+}\|F(\cdot, t)\|_1>0$. *Then*

$$\nu(\mathbf{v}, t)\geqq c_1,\quad \mathbf{v}\in\mathbb{R}^3,\quad t\in\mathbb{R}_+,\quad \textit{for some positive constant } c_1. \tag{3.11}$$

Proof. Cf. [Gu1, Lemma 3.1]. □

Our next theorem concerns existence and global estimates of a solution to (0.6) in the Banach spaces $L^{1;q}_+\cap L^{p;q}$, $1\leqq p\leqq\infty$. The $L^{1;q}\cap L^{\infty;q}$ case is obtained by exploiting the L^∞-estimate of the gain operator K given in Lemma 3.6. Combining this with the known $L^{1;q}$ case in Theorem 3.1, the final result follows by linear interpolation.

THEOREM 3.8. *Let* $0\leqq\gamma\leqq 1$, $1\leqq p, q\leqq\infty$. *Suppose* (3.2) *holds together with* ess-sup$_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_{\infty,\sigma}<\infty$ *for some* $\sigma>2$, *and* ess-inf$_{t\in\mathbb{R}_+}\|F(\cdot,t)\|_1>0$. *If* $\varphi\in L_+^{1;q}\cap L^{p;q}$, *then there exists a mild solution f of the problem* (0.6) *with initial data* φ, *such that* $f(\cdot,\cdot,t)\in L_+^{1;q}\cap L^{p;q}$, $t\in\mathbb{R}_+$,

$$\|f(\cdot,\cdot,t)\|_{1;q}\leqq|\varphi\|_{1;q},\qquad t\in\mathbb{R}_+,$$

and

$$\|f(\cdot,\cdot,t)\|_{p;q}\leqq C(\|\varphi\|_{1;q}+\|\varphi\|_{p;q}),\qquad t\in\mathbb{R}_+.$$

Here C is a constant not depending on φ.

Proof. We first prove the theorem in the case $p=\infty$. By Theorem 3.1 there exists a mild solution $f(\cdot,\cdot,t)\in L_+^{1;q}$, $t\in\mathbb{R}_+$, to (0.6a) with initial data φ. Let g be the spatially homogeneous mild solution to (0.6a) with initial data φ_q. Then by construction of f and g (cf. the remark after Theorem 3.1)

$$f_q(\mathbf{v},t)\leqq g(\mathbf{v},t)\quad \text{a.e. } \mathbf{v}\in\mathbb{R}^3,\qquad t\in\mathbb{R}_+. \tag{3.12}$$

Consider the sequence $\{g_m\}_{m=0}^{\infty}$ defined by

$$\begin{aligned} &g_0^{\#}(\mathbf{u},t)=0,\\ &g_{m+1}^{\#}(\mathbf{u},t)=\varphi_q(\mathbf{u})\exp\left(-\int_0^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)\\ &\qquad+\int_0^t (Kg_m)^{\#}(\mathbf{u},s)\exp\left(-\int_s^t \nu^{\#}(\mathbf{u},\tau)\,d\tau\right)ds,\\ &\qquad(\mathbf{u},t)\in\mathbb{R}^3\times\mathbb{R}_+. \end{aligned}$$

Applying the upper bound (3.10) on Kg_m and the lower bound (3.11) of ν, we get

$$g_{m+1}^{\#}(\mathbf{u},t)\leqq\varphi_q(\mathbf{u})+\frac{1}{c_1}\left(c_\varepsilon\|\varphi_q\|_1+\varepsilon\ \underset{t\in\mathbb{R}_+}{\text{ess-sup}}\ \|g_m(\cdot,t)\|_\infty\right). \tag{3.13}$$

Since $g_0=0$, it follows by induction that ess-sup$_{t\in\mathbb{R}_+}\|g_m(\cdot,t)\|_\infty<\infty$ for $m=0,1,2,\dots$. Now with $\varepsilon=c_1/2$, after a rearrangement of (3.13), using $g_m\leqq g_{m+1}$,

$$\|g_m(\cdot,t)\|_\infty\leqq 2\|\varphi_q\|_\infty+\left(\frac{2c_\varepsilon}{c_1}\right)\|\varphi_q\|_1,\qquad m=0,1,2,\dots,\quad t\in\mathbb{R}_+.$$

The right-hand side is independent of m and g_m increases pointwise towards g (with the exception of a null set) when $m\to\infty$. Hence

$$\|g(\cdot,t)\|_\infty\leqq 2\|\varphi_q\|_\infty+\left(\frac{2c_\varepsilon}{c_1}\right)\|\varphi_q\|_1,\qquad t\in\mathbb{R}_+. \tag{3.14}$$

Moreover, by Theorem 2.5,

$$\|g(\cdot,t)\|_1=\|\varphi_q\|_1,\qquad t\in\mathbb{R}_+. \tag{3.15}$$

Next, for any fixed $t\in\mathbb{R}_+$, let T_t be the linear operator such that, given $\varphi\in L_+^1(\mathbb{R}^3)$, $T_t\varphi$ is the spatially homogeneous mild solution at time t of (0.6a) with initial data φ. Then, by (3.14) and (3.15) T_t is a bounded linear operator on $L_+^1(\mathbb{R}^3)$ and on $L_+^1(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3)$. Using the extended interpolation theorem of Riesz-Thorin (cf. [BL, Thm. 3.1.2]), the observation that the K-functional (cf. [BL]) is not altered when considering only nonnegative functions, and that the interpolation space $(L^1(\mathbb{R}^3), L^1(\mathbb{R}^3)\cap L^\infty(\mathbb{R}^3))_{1/p',p}=L^1(\mathbb{R}^3)\cap L^p(\mathbb{R}^3)$, where $1/p+1/p'=1$ (cf. [Gul]), we obtain that T_t is bounded on $L^1_+(\mathbb{R}^3) \cap L^p(\mathbb{R}^3)$ for any p with $1 \leqq p \leqq \infty$. Furthermore, for some constant C,

$$\|T_t\varphi\|_p \leqq C(\|\varphi\|_1 + \|\varphi\|_p), \qquad t \in \mathbb{R}_+. \tag{3.16}$$

From here the theorem follows by (3.12), (3.15), and (3.16) with $\varphi = \varphi_q$. □

The last theorem of this section examines higher moments of the solution of Theorem 3.8. In the proof we employ the following elementary inequality of Gronwall type; cf. [Gu1].

LEMMA 3.9. *Let h_1, h_2, and g be nonnegative and continuous functions on $\mathbb{R}_+$. If h_1 is positive, g is locally absolutely continuous on $\mathbb{R}_+$, and*

$$\frac{dg}{dt} + h_1 g \leqq h_2 \quad \textit{for a.e. } t \in \mathbb{R}_+,$$

then

$$\sup_{t\in\mathbb{R}_+} g(t) \leqq g(0) + \sup_{t\in\mathbb{R}_+}\left(\frac{h_2(t)}{h_1(t)}\right).$$

THEOREM 3.10. *Let $0 \leqq \gamma < 1$, $0 \leqq \bar\sigma \leqq \sigma$, $1 \leqq p, q \leqq \infty$. Suppose* (3.2) *holds together with* $\text{ess-sup}_{t\in\mathbb{R}_+} \|F(\cdot, t)\|_{\infty, 2+\max(\sigma,\gamma)} < \infty$, *and* $\text{ess-inf}_{t\in\mathbb{R}_+} \|F(\cdot, t)\|_1 > 0$. *If $\varphi \in L^{1,q}_{\sigma,+} \cap L^{p;q}_{\bar\sigma}$, then there exists a mild solution f of the problem* (0.6) *such that $f(\cdot, \cdot, t) \in L^{1;q}_{\sigma,+} \cap L^{p;q}_{\bar\sigma}$, $t \in \mathbb{R}_+$,*

$$\|f(\cdot,\cdot,t)\|_{1,\bar\sigma;q} \leqq C_0\|\varphi\|_{1,\bar\sigma;q}, \qquad t \in \mathbb{R}_+,$$

$$\|f(\cdot,\cdot,t)\|_{p,\bar\sigma,q} \leqq C_1(\|\varphi\|_{1,\bar\sigma;q} + \|\varphi\|_{p,\bar\sigma;q}), \qquad t \in \mathbb{R}_+.$$

Here C_0 and C_1 are constants not depending on φ.

Proof. As in the proof of Theorem 3.8 we first prove the theorem in the case $p = \infty$. Let f and g be as in the proof of Theorem 3.8. Then (cf. Theorem 3.3) there holds

$$\|f(\cdot,\cdot,t)\|_{1,\sigma;q} \leqq \|g_i(\cdot,t)\|_{1,\sigma} \leqq C \cdot \|\varphi\|_{1,\sigma;q}, \qquad t \in \mathbb{R}_+ \tag{3.17}$$

for some constant C not dependent on φ. Moreover, since g is a spatially homogeneous mild solution of (0.6a) with initial data φ_q, it follows that for almost every $\mathbf{u} \in \mathbb{R}^3$, $g^\#(\mathbf{u}, \cdot)$ is locally absolutely continuous on $\mathbb{R}_+$. Hence, for any σ: $0 \leqq \sigma \leqq \bar\sigma$,

$$\begin{aligned}\frac{\partial}{\partial t}[g^\#(\mathbf{u},t)h^\#_{\sigma,R}(\mathbf{u},t)] + \nu^\#(\mathbf{u},t)g^\#(\mathbf{u},t)h^\#_{\sigma,R}(\mathbf{u},t)\\ = (Kg)^\#(\mathbf{u},t)h^\#_{\sigma,R}(\mathbf{u},t) + g^\#(\mathbf{u},t)\frac{\partial}{\partial t}h^\#_{\sigma,R}(\mathbf{u},t)\end{aligned} \tag{3.18}$$

for $\mathbf{u} \in \mathbb{R}^3 \backslash M$, $t \in \mathbb{R}_+ \backslash M_{\mathbf{u}}$, with $\operatorname{mes} M = \operatorname{mes} M_{\mathbf{u}} = 0$. Next by (2.7), (3.9), (3.11), (3.17), and (3.18) we obtain

$$\begin{aligned}\frac{\partial}{\partial t}[g^\#(\mathbf{u},t)h^\#_{\sigma,R}(\mathbf{u},t)] + c_1 g^\#(\mathbf{u},t)h^\#_{\sigma,R}(\mathbf{u},t)\\ \leqq c_\varepsilon\|\tilde\varphi_q\|_{1,\tilde\varphi} + \varepsilon\|g(\cdot,t)\|_{\infty,\sigma,R} + \sigma\tilde\Gamma_0\|g(\cdot,t)\|_{\infty,\max(\sigma-1,0)}.\end{aligned} \tag{3.19}$$

Thus, by Theorem 3.8, the right-hand side of (3.19) with $0 \leqq \sigma \leqq \min(1, \bar\sigma)$ is finite. Applying Lemma 3.9 we find after a rearrangement with $\varepsilon = c_1/2$ and in the limit $R \to \infty$,

$$\sup_{t\in\mathbb{R}_+}\|g(\cdot,t)\|_{\infty,\sigma} \leqq 2\|\varphi_q\|_{\infty,\bar\sigma} + \frac{2}{c_1}\left(c_\varepsilon\|\varphi_q\|_{1,\bar\sigma} + \bar\sigma\tilde\Gamma_0\sup_{t\in\mathbb{R}_+}\|g(\cdot,t)\|_{\infty,\max(\sigma-1,0)}\right). \tag{3.20}$$

Now, (3.20) shows that the right-hand side of (3.19) is finite for $0 \leqq \sigma \leqq \min(2, \bar\sigma)$. Hence, repeating the above it follows, by induction, that (3.20) is valid for $0 \leqq \sigma \leqq \bar\sigma$.

Thus, using Theorem 3.8 and (3.17), there is a constant $\tilde{C}$ not dependent on φ such that

$$\|g(\cdot,t)\|_{\infty,\tilde\sigma} \leqq \tilde{C}(\|\varphi_q\|_{1,\tilde\sigma}+\|\varphi_q\|_{\infty,\tilde\sigma}), \qquad t\in\mathbb{R}_+. \tag{3.21}$$

Finally, by (3.17) and (3.21), the linear operator T_t defined at the end of the proof of Theorem 3.8 is bounded on $L^1_{\tilde\sigma,+}(\mathbb{R}^3)$ and on $L^\infty_{\tilde\sigma,+}(\mathbb{R}^3)$. Thus $g(\cdot,t)\in L^1_{\tilde\sigma,+}(\mathbb{R}^3)\cap L^p_{\tilde\sigma}(\mathbb{R}^3)$, $t\in\mathbb{R}_+$, and there is a constant C not dependent on φ such that

$$\|g(\cdot,t)\|_{p,\tilde\sigma} \leqq C(\|\varphi_q\|_{1,\tilde\sigma}+\|\varphi_q\|_{p,\tilde\sigma}), \qquad t\in\mathbb{R}_+. \tag{3.22}$$

By (3.12) and (3.22) the theorem is proved. □

4. L^p-solutions in the soft interaction case. The main result of this section is Theorem 4.6, concerning existence and uniqueness of solutions in $L^p(\mathbb{R}^3\times\mathbb{R}^3)$, $1\leqq p\leqq\infty$. Here Lemma 4.3 plays an important role implying that the collision operator is bounded on L^p if the ratio of masses (κ) does not equal one (see Proposition 4.4). A similar approach was used in [Mo] to treat L^1 and L^∞ cases under some hypotheses more restrictive than ours.

LEMMA 4.1. *Let h be a measurable function on $\mathbb{R}^N\times\mathbb{R}^N$ and H the linear integral operator with the kernel h (i.e., $(Hg)(\mathbf{v})=\int_{\mathbb{R}^N}h(\mathbf{v},\mathbf{u})g(\mathbf{u})\,d\mathbf{u}$). If* ess-sup$_{\mathbf{u}\in\mathbb{R}^N}\int_{\mathbb{R}^N}|h(\mathbf{v},\mathbf{u})|\,d\mathbf{v}<\infty$, *then H is a bounded mapping from $L^1(\mathbb{R}^N)$ into itself. If in addition* ess-sup$_{\mathbf{v}\in\mathbb{R}^N}\int_{\mathbb{R}^N}|h(\mathbf{v},\mathbf{u})|\,d\mathbf{v}<\infty$, *then for every $1\leqq p\leqq\infty$, H is a bounded mapping from $L^p(\mathbb{R}^N)$ into itself.*

Proof. See, e.g., [Ed]. □

It is well known that the gain collision operator K has the following form (cf. [Ce]),

$$(Kg)(\mathbf{v},\mathbf{x},t)=\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')g(\mathbf{v}',\mathbf{x},t)\,d\mathbf{v}'.$$

If the distribution function for the neutral particles F depends also on $\mathbf{x}$ and/or t, so does the kernel k; since F is nonnegative, the same holds for k. Recall that (cf. [Ce])

$$\int_{\mathbb{R}^3}k(\mathbf{v}',\mathbf{v})\,d\mathbf{v}'=\nu(\mathbf{v}), \qquad \mathbf{v}\in\mathbb{R}^3. \tag{4.1}$$

Throughout this section it is tacitly assumed that B satisfies (0.2) and (0.4) (with $\alpha=\gamma$).

LEMMA 4.2. *Suppose that $-1<\gamma\leqq 1$ and (2.1) holds. If also $\kappa\neq 1$, then*

$$\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')\,d\mathbf{v}'\leqq b_0\left|\frac{1+\kappa}{1-\kappa}\right|^{1+\gamma}\int_{\mathbb{R}^3}\bar{k}(\mathbf{v}',\mathbf{v})\,d\mathbf{v}'.$$

Here $\bar{k}$ is the kernel of the gain collision operator with $b(\theta)=\sin\theta(\cos\theta)^\gamma$.

Proof. According to (0.4) and Lemma 3.5

$$\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')\,d\mathbf{v}'\leqq b_0\left(\frac{1+\kappa}{2}\right)^{1+\gamma}\int_{\mathbb{R}^3}|\mathbf{v}-\mathbf{v}'|^{\gamma-2}\int_{\mathbf{u}\cdot(\mathbf{v}-\mathbf{v}')=0}F(\tilde{\mathbf{v}}+\mathbf{u})\,dE_{\mathbf{u}}\,d\mathbf{v}',$$

where $\tilde{\mathbf{v}}=((1+\kappa)/2)\mathbf{v}+((1-\kappa)/2)\mathbf{v}'$. Set $\mathbf{r}=\mathbf{v}'-\mathbf{v}$, and use $\mathbf{r}$ as the variable integration instead of $\mathbf{v}'$. Introduce spherical coordinates $(r,\boldsymbol{\alpha})$ for $\mathbf{r}$. Then, by Fubini's theorem,

$$\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')\,d\mathbf{v}'\leqq b_0\left(\frac{1+\kappa}{2}\right)^{1+\gamma}\int_S\int_{\mathbf{u}\cdot\boldsymbol{\alpha}=0}\int_0^\infty r^\gamma\cdot F\left(\mathbf{v}+\frac{1-\kappa}{2}r\boldsymbol{\alpha}+\mathbf{u}\right)dr\,dE_{\mathbf{u}}\,d\boldsymbol{\alpha},$$

where S denotes the unit sphere in $\mathbb{R}^3$.

Substituting $|(1-\kappa)/(1+\kappa)|r\mapsto r$, the right-hand side equals

$$b_0\left(\frac{1+\kappa}{2}\right)^{1+\gamma}\left|\frac{1+\kappa}{1-\kappa}\right|^{1+\gamma}\int_S\int_{\mathbf{u}\cdot\boldsymbol{\alpha}=0}\int_0^\infty r^\gamma F\left(\mathbf{v}+\frac{1+\kappa}{2}r\boldsymbol{\alpha}+\mathbf{u}\right)dr\,dE_{\mathbf{u}}\,d\boldsymbol{\alpha}.$$

Finally, noticing that $\mathbf{v}+((1+\kappa)/2)\mathbf{r}=((1+\kappa)/2)\mathbf{v}'+((1-\kappa)/2)\mathbf{v}$, the proof is completed. □

LEMMA 4.3. *Suppose that* $-1<\gamma\leqq 1$. *If* $F\in L^{\infty}_{\sigma_0}(\mathbb{R}^3)$ *for some* $\sigma_0>2$, *then*

$$\mathbf{k}(\mathbf{v},\mathbf{v}')\leqq b_0\|F\|_{\infty,\sigma_0}\left(\frac{1+\kappa}{2}\right)^{1+\gamma}\frac{2\pi}{\sigma_0-2}|\mathbf{v}-\mathbf{v}'|^{\gamma-2}\left(1+\frac{1}{4}\left(\kappa|\mathbf{v}-\mathbf{v}'|+\frac{v^2-v'^2}{|\mathbf{v}-\mathbf{v}'|}\right)^2\right)^{-(\sigma_0-2)/2},$$

$\mathbf{v},\mathbf{v}'\in\mathbb{R}^3$, $\mathbf{v}\neq\mathbf{v}'$.

Proof. Cf. [Ch, Lemma 4.4]. □

PROPOSITION 4.4. *Suppose that* $-1<\gamma\leqq 0$, $F\in L^{\infty}_{\sigma_0}$ *with* $\sigma_0>3$, *and* $0\leqq\sigma<\sigma_0-3-\gamma$. *Then K is a bounded mapping from* $L^1_{\sigma}(\mathbb{R}^3)$ *into itself. If moreover* $\kappa\neq 1$, *then K is a bounded mapping from* $L^p_{\sigma}(\mathbb{R}^3)$ *into itself for every p*: $1\leqq p\leqq\infty$.

Proof. To prove the latter assertion of the proposition, it is sufficient to show that the linear integral operator $\tilde{K}$ with the kernel

$$\tilde{k}(\mathbf{v},\mathbf{v}')=\left(\frac{1+v^2}{1+v'^2}\right)^{\sigma/2}k(\mathbf{v},\mathbf{v}'),\qquad \mathbf{v},\mathbf{v}'\in\mathbb{R}^3,\quad \mathbf{v}\neq\mathbf{v}'$$

represents a bounded mapping from $L^p(\mathbb{R}^3)$ into itself for every $1\leqq p\leqq\infty$. Denoting $\mathbf{r}=\mathbf{v}'-\mathbf{v}$ again in view of

$$\frac{1+v^2}{1+v'^2}\leqq\frac{2+(v'+r)^2}{1+v'^2}\leqq 2\frac{1+v'^2+r^2}{1+v'^2}\leqq 2(1+r^2),\qquad \mathbf{v},\mathbf{v}'\in\mathbb{R}^3,$$

we find, using Lemma 4.3, that

$$\tilde{k}(\mathbf{v},\mathbf{v}')\leqq\frac{c}{r^{2-\gamma}}(1+r^2)^{1-\sigma_0/2+\sigma/2},\qquad \mathbf{v},\mathbf{v}'\in\mathbb{R}^3,\quad v\geqq v'. \tag{4.2}$$

On the other hand,

$$\tilde{k}(\mathbf{v},\mathbf{v}')\leqq k(\mathbf{v},\mathbf{v}'),\quad \mathbf{v},\mathbf{v}'\in\mathbb{R}^3,\quad \mathbf{v}\neq\mathbf{v}',\quad v\leqq v'. \tag{4.3}$$

Thus, the relations (4.2) and (4.3) give

$$\tilde{k}(\mathbf{v},\mathbf{v}')\leqq k(\mathbf{v},\mathbf{v}')+\frac{c}{r^{2-\gamma}}(1+r^2)^{1-\sigma_0/2+\sigma/2},\qquad \mathbf{v},\mathbf{v}'\in\mathbb{R}^3,\quad \mathbf{v}\neq\mathbf{v}'. \tag{4.4}$$

Due to (4.1), (2.1), and Lemma 4.2 there holds

$$\sup_{\mathbf{v}'\in\mathbb{R}^3}\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')\,d\mathbf{v}<\infty,\ \sup_{\mathbf{v}\in\mathbb{R}^3}\int_{\mathbb{R}^3}k(\mathbf{v},\mathbf{v}')\,d\mathbf{v}'<\infty. \tag{4.5}$$

Finally (4.4), and (4.5) together with Lemma 4.1 show that the integral operator $\tilde{K}$ with kernel $\tilde{k}$ is bounded on $L^p(\mathbb{R}^3)$ for $1\leqq p\leqq\infty$, which was to be proved.

The first assertion of the proposition is proved in the same way. The only difference is the following. Since the case $\kappa=1$ is not excluded, Lemma 4.2 is not applicable; hence the second relation in (4.5) cannot be referred to. As a consequence, using Lemma 4.1 we obtain just boundedness of $\tilde{K}$ as a mapping from $L^1(\mathbb{R}^3)$ into itself. □

LEMMA 4.5. *Let* $\mathbf{\Gamma}$ *be bounded on* $\mathbb{R}^3\times[0,T]$, *where* $T>0$. *Then there exists a constant* $c>1$ (*depending on T*) *such that the following assertion holds*: *For every* $t\in[0,T]$ *and every* $\mathbf{u},\mathbf{y}\in\mathbb{R}^3$,

$$\frac{1}{c}(1+u^2)\leqq 1+|\mathbf{v}(\mathbf{u},\mathbf{y},t)|^2\leqq c(1+u^2).$$

Proof. Differentiate v^2 along the characteristics and use Gronwall's lemma. □

Notation. Let $L^p_{\sigma}(\mathbb{R}^3\times\mathbb{R}^3)=L^{p;p}_{\sigma}(\mathbb{R}^3\times\mathbb{R}^3)$ with norms $\|g(\cdot,\cdot)\|_{p,\sigma}=\|g(\cdot,\cdot)\|_{p,\sigma;p}$ (cf. § 3).

THEOREM 4.6. *Suppose that* $\tilde{\Gamma}_0<\infty$, $-1<\gamma\leqq 0$, $1\leqq p\leqq\infty$ *if* $\kappa\neq 1$, $p=1$ *if* $\kappa=1$. *Furthermore, let* $\operatorname{ess-sup}_{\mathbf{x}\in\mathbb{R}^3,t\in[0,T]}\|F(\cdot,\mathbf{x},t)\|_{L^{\infty}_{\sigma_0}(\mathbb{R}^3)}<\infty$ *for some* $\sigma_0>3$, $T>0$, *and let*

$\varphi \in L^p_{\sigma,+}(\mathbb{R}^3\times\mathbb{R}^3)$ *with* $0\leqq\sigma<\sigma_0-3-\gamma$. *Then there exists a unique positive mild solution* f *of the problem* (0.6) *such that*

$$\|f(\cdot,\cdot,t)\|_{p,\sigma}\leqq C_T\|\varphi\|_{p,\sigma},\qquad t\in[0,T],$$

C_T *being a constant* (*depending on* T).

Proof. Existence. Consider the sequence $\{f_n\}_{n=0}^{\infty}$ of functions defined on $\mathbb{R}^3\times\mathbb{R}^3\times\mathbb{R}_+$ recursively by (2.3). Clearly, by a Minkowsky inequality,

$$\begin{aligned}\|f^{\#}_{n+1}(\cdot,\cdot,t)\|_{p,\sigma}&\leqq\|\varphi\|_{p,\sigma}\\ &+\int_0^t\|(Kf_n)^{\#}(\cdot,\cdot,s)\|_{p,\sigma}\,ds,\qquad t\in[0,T],\quad n=0,1,\ldots.\end{aligned}\tag{4.6}$$

In view of Lemma 4.5 it is easy to verify that for every function g defined on $\mathbb{R}^3\times\mathbb{R}^3\times[0,T]$ such that $g(\cdot,\cdot,s)\in L^p_\sigma(\mathbb{R}^3\times\mathbb{R}^3)$, $s\in[0,T]$, there holds

$$c^{-\sigma/2}\|g(\cdot,\cdot,s)\|_{p,\sigma}\leqq\|g^{\#}(\cdot,\cdot,s)\|_{p,\sigma}\leqq c^{\sigma/2}\|g(\cdot,\cdot,s)\|_{p,\sigma},\qquad s\in[0,T],$$

where $c>1$ is the constant figuring in Lemma 4.5. Using this fact, the relation (4.6) implies

$$\begin{aligned}\|f_{n+1}(\cdot,\cdot,t)\|_{p,\sigma}&\leqq c^{\sigma/2}\|\varphi\|_{p,\sigma}\\ &+c^{\sigma}\int_0^t\|(Kf_n)(\cdot,\cdot,s)\|_{p,\sigma}\,ds,\qquad t\in[0,T],\quad n=0,1,\ldots.\end{aligned}$$

By Proposition 4.4 the operator $K: L^p_\sigma\to L^p_\sigma$ is bounded so that

$$\begin{aligned}\|f_{n+1}(\cdot,\cdot,t)\|_{p,\sigma}&\leqq c^{\sigma/2}\|\varphi\|_{p,\sigma}\\ &+c^{\sigma}k_{p,\sigma}\int_0^t\|f_n(\cdot,\cdot,s)\|_{p,\sigma}\,ds,\qquad t\in[0,T],\quad n=0,1,\ldots,\end{aligned}$$

where $k_{p,\sigma}$ denotes the norm of K. Using a lemma of Gronwall type, we find that

$$\|f_n(\cdot,\cdot,t)\|_{p,\sigma}\leqq C_T\|\varphi\|_{p,\sigma},\qquad t\in[0,T],\quad n=0,1,\ldots.\tag{4.7}$$

Now set $f(\mathbf{v},\mathbf{x},t)=\lim_{n\to\infty}f_n(\mathbf{v},\mathbf{x},t)$, $(\mathbf{v},\mathbf{x})\in\mathbb{R}^3\times\mathbb{R}^3$, $t\in[0,T]$. Then f is nonnegative (since all the iterates f_n are nonnegative), and by Levi's monotone convergence theorem f is measurable and, also using (4.7), we have

$$\begin{aligned}\int_{\mathbb{R}^3\times\mathbb{R}^3}(f(\mathbf{v},\mathbf{x},t)(1+v^2)^{\sigma/2})^p\,d\mathbf{v}\,d\mathbf{x}&=\lim_{n\to\infty}\int_{\mathbb{R}^3\times\mathbb{R}^3}(f_n(\mathbf{v},\mathbf{x},t)(1+v^2)^{\sigma/2})^p\,d\mathbf{v}\,d\mathbf{x}\\ &\leqq(C_T\|\varphi\|_{p,\sigma})^p,\qquad t\in[0,T].\end{aligned}$$

Moreover, letting $n\to\infty$ in (2.4) we obtain a mild solution of the problem (0.6).

Uniqueness. Now suppose that there are two mild solutions g and h. Then the difference $g-h$ is a mild solution of the problem (0.6) with $\varphi\equiv0$. Hence,

$$\|(g-h)(\cdot,\cdot,t)\|_{p,\sigma}\leqq k_{p,\sigma}\int_0^t\|(g-h)(\cdot,\cdot,s)\|_{p,\sigma}\,ds,\qquad t\in[0,T]$$

and an application of Gronwall's lemma gives $g(\cdot,\cdot,t)=h(\cdot,\cdot,t)$ in $L^p_\sigma(\mathbb{R}^3\times\mathbb{R}^3)$ for every $t\in[0,T]$. □

Next, we show that the gain collision operator K is bounded on $L^1_\sigma\cap L^p_\sigma$, including the case $\kappa=1$. This leads to the existence of solutions to (0.6) in $L^1_\sigma\cap L^p_\sigma$, see Theorem 4.9.

DEFINITION. The norm on $L^1_\sigma\cap L^p_\sigma$ is $\|\cdot\|_{1\cap p,\sigma}$.

PROPOSITION 4.7. *Let* $-1<\gamma\leqq0$, *and let* $F\in L^1_{\sigma,+}(\mathbb{R}^3)\cap L^\infty_\sigma(\mathbb{R}^3)$ *for some* $\sigma\geqq0$. *Then K is a bounded linear operator from* $L^1_\sigma(\mathbb{R}^3)$ *into itself. The norm of K is majorized by a multiple of* $\|F\|_{1\cap\infty,\sigma}$.

Proof. Using the kinetic energy conservation law and splitting the domain of integration we find after some calculations that

$$\int_{\mathbb{R}^3} |Kf(\mathbf{v})(1+v^2)^{\sigma/2}|\, d\mathbf{v} \leqq \text{const.}\left(\frac{4\pi}{3+\gamma}\|F\|_{\infty,\sigma}\|f\|_{1,\sigma} + \|F\|_{1,\sigma}\|f\|_{1,\sigma}\right). \qquad \square$$

PROPOSITION 4.8. *Suppose that* $-1<\gamma\leqq 0$, $F\in L^1_{\sigma_0,+}(\mathbb{R}^3)\cap L^\infty_{2+\sigma_0}(\mathbb{R}^3)$ *for some* $\sigma_0>0$, $0\leqq\sigma\leqq\sigma_0$, *and that* $1\leqq p\leqq\infty$. *Then K is a bounded operator from* $L^1_\sigma(\mathbb{R}^3)\cap L^p_\sigma(\mathbb{R}^3)$ *into itself. The norm of K is majorized by a multiple of* $\|F\|_{1\cap\infty,2+\sigma_0}$.

Proof. By Lemma 3.6, and Proposition 4.7, using linear interpolation (cf. the proof of Theorem 3.8) we obtain the asserted result. $\square$

The following theorem can now be proved in the same manner as Theorem 4.6.

THEOREM 4.9. *Suppose that* $-1<\gamma\leqq 0$, $\tilde{\Gamma}_0<\infty$, $1\leqq p\leqq\infty$, *and that* ess-$\sup_{\mathbf{x}\in\mathbb{R}^3, t\in[0,T]}\|F(\cdot,\mathbf{x},t)\|_{1\cap\infty,2+\sigma_0}<\infty$ *for some* $\sigma_0>0$, $T>0$. *If* $\varphi\in L^1_{\sigma,+}(\mathbb{R}^3\times\mathbb{R}^3)\cap L^p_\sigma(\mathbb{R}^3\times\mathbb{R}^3)$, *where* $0\leqq\sigma\leqq\sigma_0$, *then there exists a unique nonnegative mild solution f of the problem* (0.6) *such that*

$$\|f(\cdot,\cdot,t)\|_{1\cap p,\sigma}\leqq C_T\|\varphi\|_{1\cap p,\sigma}, \qquad t\in[0,T].$$

Here C_T *is a constant* (*depending on* T).

Remark. A similar result can also be obtained by combining the results of Theorem 2.4 and Theorem 4.6.

ON THE AMPLITUDE EQUATIONS ARISING AT THE ONSET OF THE OSCILLATORY INSTABILITY IN PATTERN FORMATION*

JOSÉ M. VEGA†

Abstract. A well-known system of two amplitude equations is considered that describes the weakly nonlinear evolution of many nonequilibrium systems at the onset of the so-called oscillatory instability. Those equations depend on a small parameter, ε, that is a ratio between two distinguished spatial scales. In the limit $\varepsilon \to 0$, a simpler asymptotic model is obtained that consists of two complex cubic Ginzburg–Landau equations, coupled only by spatially averaged terms.

Key words. pattern formation, oscillatory instability, amplitude equations, Ginzburg–Landau equations

AMS subject classifications. 35K55, 35B25, 35B32, 35B35

1. Introduction and formulation. This paper deals with the following parabolic problem:

$$A_t = (1+i\alpha)A_{xx} - \varepsilon-1A_x + \mu A - (1+i\beta)A|A|^2 + (\gamma+i\delta)A|B|^2, \tag{1.1}$$

$$B_t = (1+i\alpha)B_{xx} + \varepsilon-1B_x + \mu B - (1+i\beta)B|B|^2 + (\gamma+i\delta)B|A|^2, \tag{1.2}$$

$$A(x+1,t) = A(x,t)\exp(-ia), \quad B(x+1,t) = B(x,t)\exp(ia) \text{ if } x \in \mathbb{R},\ t > 0, \tag{1.3}$$

$$A(x,0) = A_0(x), \quad B(x,0) = B_0(x) \quad \text{if } x \in \mathbb{R}. \tag{1.4}$$

Here A and B are appropriately smooth complex-valued functions of the spatial variable x and the time t; i is the imaginary unit; the real parameters α, β, γ, δ, μ, and a are such that

$$\mu > 0, \quad \gamma < 1, \quad \text{and} \quad 0 \le a < 2\pi, \tag{1.5}$$

and the real parameter $\varepsilon > 0$ is assumed to be small. The functions A_0 and B_0 appearing in the initial conditions (1.4) are appropriately smooth. Then, as we shall see in §3, the problem (1.1)–(1.4) is well posed and its solution is defined in $0 < t < \infty$. In addition, we shall consider the problem (1.1)–(1.4) under one of the following additional conditions:

$$A(x,t) = -B(-x,t) \quad \text{if } x \in \mathbb{R},\ t \ge 0, \tag{1.6}$$

$$A(x,t) = B(-x,t) \quad \text{if } x \in \mathbb{R},\ t \ge 0. \tag{1.7}$$

*Received by the editors March 4, 1991; accepted for publication (in revised form) September 2, 1992. This research was partially supported by Dirección General de Investigación Científica y Técnica grant PB-90-0271.

†Escuela Técnica Superior de Ingenieros Aeronáuticos, Universidad Politécnica de Madrid, 28040 Madrid, Spain.

As we shall see in §3 each of these conditions is compatible with (1.1)–(1.4) in the following sense: if a solution of (1.1)–(1.4) satisfies that condition for $t = 0$, then the condition holds for all $t > 0$.

Equations (1.1), (1.2) appear as a normal form in a weakly nonlinear analysis of nonequilibrium systems at the onset of the so-called *oscillatory instability*; see [1]–[4]. In particular, they have been used in the analysis of wave dynamics in doubly diffusive and binary fluid convection (see [1], [5], [6]), and some of their solutions have been seen to describe qualitatively the results of some experiments (see [7]–[11]).

Let us now explain briefly how these equations are obtained and where conditions (1.3), (1.6), and (1.7) come from. We consider a system of PDEs of the form

$$\frac{\partial u}{\partial T} = G\left(\frac{\partial^2}{\partial X^2}, u; R\right) \quad \text{in } -\infty < X < \infty,\ T > 0, \tag{1.8}$$

where $u = (u_1, \ldots, u_N)$ is a function of the space variable X, and the time variable T, R is a control parameter, and G is a nonlinear differential operator (invariant under space translations, $X \to X + c$, and reflection, $X \to -X$) such that $G(\partial^2/\partial X^2, 0; R) \equiv 0$ (the uniform state $u \equiv 0$ is a stationary solution of (1.8) for all R).

Let $\varphi(\omega, k^2, R) = 0$ (ω = growth rate, k = wave number) be the complex dispersion relation of the linearized problem about $u = 0$. We assume that the growth rate of the most unstable modes are of the form

$$\omega = \pm i\Omega + c_{1\pm}R \mp c_2 k_0(k - k_0) - c_{3\pm}(k - k_0)^2 + o(|R|) + o(|k - k_0|^2),$$

$$\omega = \pm i\Omega + c_{1\pm}R \pm c_2 k_0(k + k_0) - c_{3\pm}(k + k_0)^2 + o(|R|) + o(|k + k_0|^2),$$

as $R \to 0$ and $k \to \pm k_0$, while $\operatorname{Re}\omega < 0$ otherwise. Here the coefficients Ω and k_0 are real, while $c_{1\pm}$, c_2 and $c_{3\pm}$ are complex, and such that $c_{1-} = \bar{c}_{1+}$, $c_{3-} = \bar{c}_{3+}$ (overbars stand for the complex conjugate) and

$$\Omega > 0, \quad k_0 > 0, \quad \operatorname{Re} c_{1+} > 0, \quad \operatorname{Re} c_2 = 0, \quad \operatorname{Re} c_{3+} > 0. \tag{1.9}$$

Notice that the corresponding neutrally stable modes at $R = 0$ are of the form

$$u = U_0[A\exp(i\Omega T + ik_0 X) + B\exp(i\Omega T - ik_0 X)] + \text{c.c.}$$

for a certain eigenvector $U_0 \in \mathbb{C}^N$, where the complex amplitudes A and B are arbitrary and c.c. stands for the complex conjugate. That mode is the superposition of two wavetrains that are travelling in opposite directions. The weakly nonlinear stability of those pairs of waves, as $R \to 0$, is analyzed by appropriately scaling the complex amplitudes and allowing them to depend on the slow time and space variables $t = \varepsilon^2 T$ and $x = \varepsilon X$, where the small parameter $\varepsilon > 0$ is defined by $\varepsilon^2 = R$. If the ansatz

$$u = \varepsilon U_0[A(x,t)\exp(i\Omega T + ik_0 X) + B(x,t)\exp(i\Omega T - ik_0 X)] + \text{c.c.} + O(\varepsilon^2) \tag{1.10}$$

is inserted into (1.8) and the appropriate solvability conditions are applied at the orders $O(\varepsilon^2)$ and $O(\varepsilon^3)$, then the following evolution equations are obtained (at the order $O(\varepsilon^3)$):

$$A_t = c_{3+}A_{xx} - \left(\frac{c_2 k_0}{i\varepsilon}\right)A_x + c_{1+}A + c_4 A|A|^2 + c_5 A|B|^2, \tag{1.11}$$

$$B_t = c_{3+}B_{xx} + \left(\frac{c_2k_0}{i\varepsilon}\right)B_x + c_{1+}B + c_4B|B|^2 + c_5B|A|^2, \tag{1.12}$$

where the coefficients c_{1+}, c_2, and c_{3+} are as defined above, and c_4 and c_5 depend on the leading nonlinear terms of (1.8). Equations (1.11), (1.12) may be obtained quite directly by symmetry considerations (see [1]), but the actual values of the coefficients c_4 and c_5 must be obtained by the process described above (which usually leads to quite tedious calculations, even with the help of symbolic algebra). Notice that the coefficient $(c_2k_0/i\varepsilon)$ is real and large as $\varepsilon \to 0$ if $c_2 \neq 0$ as we are assuming (the assumption $c_2 = 0$ would restrict the analysis to a codimension-two point of the parameter space of (1.8)). In addition to (1.9), the following supercriticality assumption will be made:

$$\operatorname{Re} c_4 < 0, \qquad \operatorname{Re}(c_4 + c_5) < 0. \tag{1.13}$$

In fact, if (1.13) does not hold, then (1.11), (1.12) possess solutions that either are unbounded as $t \to \infty$ or blow up in a finite time, as is readily seen by considering spatially uniform solutions.

Now, let us impose the following spatial periodicity condition on the solutions of (1.8):

$$u(X + L, T) \equiv u(X, T), \tag{1.14}$$

where the period L depends on ε in such a way that $\varepsilon L \to l > 0$ and $2\pi\,\mathrm{fract}\,(k_0L/2\pi) \to d$ as $\varepsilon \to 0$ (fract(z) stands for the fractionary part of the real z). Then if condition (1.14) is imposed on (1.10), the following conditions are obtained (to the leading order):

$$A(x + l, t) \equiv A(x, t)\exp(-id), \quad B(x + l, t) \equiv B(x, t)\exp(id). \tag{1.15}$$

Observe that the conditions (1.14) are appropriate to analyze the problem (1.8) in a finite interval, $0 < X < L/2$, if the boundary conditions at $X = 0$ and $L/2$ are either of the Dirichlet ($u = 0$) or Neumann ($u_X = 0$) type. This is readily seen when u is extended to $-\infty < X < \infty$ by means of the appropriate reflexion principle:

$$u(X + mL/2, T) \equiv -u(-X + mL/2, T) \quad \text{(Dirichlet), or} \tag{1.16}$$

$$u(X + mL/2, T) \equiv u(-X + mL/2, T) \quad \text{(Neumann)} \tag{1.17}$$

for each integer m. When (1.16) or (1.17) are imposed on (1.10), then (to leading order) we obtain (1.15) and

$$A(x, t) \equiv -B(-x, t) \text{ (Dirichlet), or} \tag{1.18}$$

$$A(x, t) \equiv B(-x, t) \text{ (Neumann).} \tag{1.19}$$

Now, by applying in (1.11), (1.12), (1.15) an appropriate transformation of the type $A(x, t) \to A(x, t)\exp(iet)$, $B(x, t) \to B(x, t)\exp(iet)$ (to make real the coefficients of A and B in (1.11) and (1.12), respectively), and rescaling the variables A, B, x, and t, and the small parameter ε, we obtain (1.1)–(1.3); conditions (1.5) readily follow from

(1.13). By the same process, the additional condition (1.18) (respectively, (1.19)) leads to (1.6) (respectively, (1.7)).

Therefore, the problem (1.1)–(1.4) seems to be appropriate to analyze spatially periodic patterns of (1.8) near the instability limit. Pattern formation in finite intervals, under homogeneous Dirichlet or Neumann boundary conditions, is analyzed by imposing (1.6) or (1.7).

The main object of this paper is to obtain rigorously the following approximate model (of (1.1)–(1.4)) in the limit $\varepsilon \to 0$: $A(x,t) \simeq V(x - t/\varepsilon, t)$, $B(x,t) \simeq W(x + t/\varepsilon, t)$, where the functions $(y,t) \to V(y,t)$ and $(z,t) \to W(z,t)$ satisfy, in first approximation,

$$V_t = (1 + i\alpha)V_{yy} + \mu V - (1 + i\beta)V|V|^2 + (\gamma + i\delta)V\langle|W|^2\rangle, \tag{1.20}$$

$$W_t = (1 + i\alpha)W_{zz} + \mu W - (1 + i\beta)W|W|^2 + (\gamma + i\delta)W\langle|V|^2\rangle, \tag{1.21}$$

$$V(y + 1, t) = V(y,t)\exp(-ia), \quad W(z + 1, t) = W(z,t)\exp(ia), \tag{1.22}$$

$$V(y,0) = A_0(y), \quad W(z,0) = B_0(z), \tag{1.23}$$

if $y, z \in \mathbb{R}$, $t > 0$. Here, the spatial average $\langle\cdot\rangle$ is defined by

$$\langle f\rangle = \int_0^1 f(\xi,t)d\xi \tag{1.24}$$

for each function $f \in C(\mathbb{R} \times [0,\infty[)$ that is periodic, of period 1, in its first argument (as $|V|^2$ and $|W|^2$ are; see (1.22)). In addition, we shall see that if A and B satisfy one of the additional conditions, (1.6) or (1.7), then $\langle|W|^2\rangle = \langle|V|^2\rangle$ for all $t \geq 0$, and the model (1.20)–(1.23) may be further simplified to

$$V_t = (1 + i\alpha)V_{yy} + \mu V - (1 + i\beta)V|V|^2 + (\gamma + i\delta)V\langle|V|^2\rangle, \tag{1.25}$$

$$V(y + 1, t) = V(y,t)\exp(-ia), \ V(y,0) = A_0(y) \quad \text{if } y \in \mathbb{R}, \ t > 0. \tag{1.26}$$

These two models were first obtained, independently, by Knobloch and De Luca [12] and by Alvarez-Pereira and Vega [13]. In both cases a formal derivation was made, by means of perturbation techniques. In fact, in [13] the problem under consideration was not of the type (1.8), but (1.20)–(1.23) and (1.25)–(1.26) appeared in a weakly nonlinear stability analysis, in two space dimensions, of travelling plane wave-fronts in a reaction-diffusion system arising in combustion theory; that problem is essentially more involved than (1.8), and the models (1.20)–(1.23) and (1.25)–(1.26) were obtained in a particular limit.

The paper is organized as follows. For convenience, a formal derivation (by means of a two-time scales method) of (1.20)–(1.23) is given in §2. Section 3 includes some preliminaries concerning the model (1.1)–(1.4), a rigorous derivation of the approximate models and some basic properties of these models. Finally, in §4 we describe further properties of the approximate models, and make some conjectures.

2. A formal derivation of the model (1.20)–(1.23). Here we give a formal derivation of model (1.20)–(1.23) by means of perturbation techniques (the second asymptotic model is easily obtained from the first one, as it will be seen in §3). That derivation will give the key idea for the rigorous analysis of next section. In addition, it will provide some insight into the nature of the limit $\varepsilon \to 0$, by explaining why it is natural to expect the appearance of the spatial averaged terms in the approximate models.

As $\varepsilon \to 0$, there are two obvious time scales in (1.1), (1.2):

$$t \sim 1 \quad \text{and} \quad \tau \equiv t/\varepsilon \sim 1. \tag{2.1}$$

The latter comes when balancing A_t with $-\varepsilon^{-1}A_x$ in (1.1) (or B_t with $\varepsilon^{-1}B_x$ in (1.2)). Then we shall seek the expansions

$$A(x,t) = \tilde{A}_0(x,\tau,t) + \varepsilon\tilde{A}_1(x,\tau,t) + \cdots, \quad B(x,t) = \tilde{B}_0(x,\tau,t) + \varepsilon\tilde{B}_1(x,\tau,t) + \cdots.$$

When these expansions are inserted into (1.1)–(1.3), and the coefficients of ε^0 and ε^1 are set to zero, the following problems are obtained:

$$\tilde{A}_{0\tau} + \tilde{A}_{0x} = 0, \quad \tilde{B}_{0\tau} - \tilde{B}_{0x} = 0, \tag{2.2}$$

$$\tilde{A}_{1\tau} + \tilde{A}_{1x} = -\tilde{A}_{0t} + (1+i\alpha)\tilde{A}_{0xx} + \tilde{A}_0\left[\mu - (1+i\beta)|\tilde{A}_0|^2 + (\gamma+i\delta)|\tilde{B}_0|^2\right], \tag{2.3}$$

$$\tilde{B}_{1\tau} - \tilde{B}_{1x} = -\tilde{B}_{0t} + (1+i\alpha)\tilde{B}_{0xx} + \tilde{B}_0\left[\mu - (1+i\beta)|\tilde{B}_0|^2 + (\gamma+i\delta)|\tilde{A}_0|^2\right], \tag{2.4}$$

$$\tilde{A}_j(x+1,\tau,t) \equiv \tilde{A}_j(x,\tau,t)\exp(-ia), \quad \tilde{B}_j(x+1,\tau,t) \equiv B_j(x,\tau,t)\exp(ia), \tag{2.5}$$

$$\tilde{A}_0(x,0,0) \equiv A_0(x), \quad \tilde{B}_0(x,0,0) \equiv B_0(x), \quad \tilde{A}_1(x,0,0) \equiv \tilde{B}_1(x) \equiv 0 \tag{2.6}$$

for $j = 0$ and 1. The wave equations (2.2) readily yield $\tilde{A}_0(x,\tau,t) \equiv V_0(x-\tau,t)$, $\tilde{B}_0(x,\tau,t) \equiv W_0(x+\tau,t)$, for some functions $(y,t) \to V_0(y,t)$ and $(z,t) \to W_0(z,t)$ that satisfy (1.22), (1.23) (see (2.5), (2.6)) and are otherwise arbitrary (at the moment). Then the solution of (2.3), (2.4) may be found in close-form

$$\begin{aligned}\tilde{A}_1(x,\tau,t) = V_1(x-\tau,t) &+ \tau\left[-V_{0t} + (1+i\alpha)V_{0yy} + V_0\left(\mu - (1+i\beta)|V_0|^2\right)\right]\\ &+ \left(\frac{\gamma+i\delta}{2}\right)V_0\int_0^{\tau+x}|W_0(z,t)|^2dz,\end{aligned} \tag{2.7}$$

$$\begin{aligned}\tilde{B}_1(x,\tau,t) = W_1(x+\tau,t) &+ \tau\left[-W_{0t} + (1+i\alpha)W_{0zz} + W_0\left(\mu - (1+i\beta)|W_0|^2\right)\right]\\ &+ \left(\frac{\gamma+i\delta}{2}\right)W_0\int_0^{\tau-x}|V_0(y,t)|^2dy\end{aligned} \tag{2.8}$$

for some functions V_1 and W_1 (to be determined at later stages).

Now, by eliminating secular terms in the fast time scale, i.e., by requiring the right-hand side of (2.7) to be bounded as $\tau \to \infty$ ($t =$ constant in this time scale) we readily obtain

$$-V_{0t} + (1+i\alpha)V_{0yy} + V_0\left[\mu - (1+i\beta)|V_0|^2\right] \\ + (\gamma + i\delta)V_0 \lim_{\tau\to\infty}(2\tau)^{-1}\int_0^{\tau+x} |W_0(z,t)|^2 dz = 0.$$

Notice that for each fixed value of $y = x - \tau$, the first three terms in the left-hand side of this equation are constant (recall that $t =$ constant at this time stage), while the last one is of the form $(\gamma + i\delta)V_0 \lim_{\tau\to\infty}(2\tau)^{-1}\int_0^{2\tau+y} |W_0(z,t)|^2 dz$, and since $|W_0(z+1,t)|^2 \equiv |W_0(z,t)|^2$ (see (1.22)), we have $(2\tau)^{-1}\int_0^{2\tau+y} |W_0(z,t)|^2 dz = \langle |W_0|^2\rangle + O(\tau^{-1})$ as $\tau \to \infty$, where the spatial average $\langle\cdot\rangle$ was defined in (1.24). Then V_0 and W_0 satisfy (1.20). Equation (1.21) is obtained in a completely similar way, by eliminating secular terms in (2.8), and the derivation of (1.20)–(1.23) is complete.

Observe that, to the leading order, in the fast time scale ($\tau \sim 1$), the amplitudes A and B satisfy the wave equations (2.2), whose solution represents two waves that are travelling in opposite directions. If one moves in a reference frame attached to the wave associated with A (i.e., if $x - \tau =$ constant), then the wave associated with B is seen to travel at a speed 2 in the fast time scale, or at a speed $2/\varepsilon$ ($\to \infty$ as $\varepsilon \to 0$) in the slow time scale. Therefore, if $t \sim 1$, then the spatial structure of B is not appreciated from the reference frame moving with A; only the spatial mean value of $|B|^2$ over a period is seen. This explains the appearance of the spatial averages in the asymptotic equations, and suggests the main argument in the proof of Theorem 3.4 below.

3. Main results concerning the models (1.1)–(1.4), (1.20)–(1.23), and (1.25)–(1.26).

Here we first consider some preliminary properties of the model (1.1)–(1.4). Then, the approximate models (1.20)–(1.23) and (1.25)–(1.27) are rigorously derived. Finally, some basic properties of the approximate models are given.

3.1. The model (1.1)–(1.4).

In order to prove that the model (1.1)–(1.4) is well posed we could modify appropriately an abstract result by Ghidaglia [14] that was used be Temam [15] to prove the well-posedness of the standard complex cubic Ginzburg–Landau equation in finite domains with standard boundary conditions. Nevertheless, for the sake of brevity, we shall follow a more direct approach, based on a classical result by Henry [16].

THEOREM 3.1. *If $\gamma < 1$ and if the functions A_0 and B_0 belong to* (*the complexified space of*) $C^{2+\alpha}([0,1])$, *for some* $\alpha \in]0,1[$, *and satisfy* (1.3), *then* (1.1)–(1.4) *possess a unique classical solution,* $(x,t) \to (A(x,t), B(x,t))$, *such that* $A, B \in C^{2+\alpha,1+\alpha/2}([0,1] \times [0,T])$ *for all* $T > 0$. *In addition,* $A, B \in C^{2k,k}([0,1]\times[T_1,T_2])$ *whenever* $0 < T_1 < T_2$ *and* $k \geq 0$.

Proof. We first state (1.1)–(1.4) in an appropriate abstract setting (after decomplexification and restriction to the bounded interval $0 \leq x \leq 1$, with the appropriate boundary conditions at $x = 0, 1$, obtained from (1.3)) as

$$\frac{du}{dt} + Lu = f(u) \quad \text{if } t > 0, \qquad u(0) = u_0 \in D(L), \tag{3.1}$$

where the linear operator $L : D(L) \to X \equiv L_2(]0,1[)^4$ is defined in such a way that $f : X \to X$ is a substitution perator, and

$$D(L) = \{u \in H_2(]0,1[)^4 : u \text{ satisfies the boundary conditions at } x = 0,1\}.$$

Then the operator L is sectorial in X, and f is locally Lipschitzian and maps bounded sets into bounded sets. Then, by applying [17, p. 55, Thm. 3.3.4], it follows that (3.1) possesses a unique mild solution, $u \in C([0,T[, X)$, in a maximal interval of existence, $0 \le t < T$, and one of the following alternatives holds: either (i) $T = \infty$, or (ii) $T < \infty$ and there is a sequence, $\{t_m\} \subset \mathbb{R}$, such that $t_m \to T^-$ and $\|u(t_m)\|_X \to \infty$. But since $\gamma < 1$, according to the result in Lemma 3.3 below (that may be seen as an a priori estimate on (3.1)) the alternative (ii) cannot hold. Then $T = \infty$, and we obtain global existence and uniqueness of mild solutions. Further regularity of u is obtained as usual, by means of parabolic estimates [17, VII-10] (those estimates are readily extended to apply for boundary conditions such as (1.3)) and imbedding theorems [17, II-3]. □

Now we prove that the additional conditions (1.6) and (1.7) are compatible with the model (1.1)–(1.4).

LEMMA 3.2. *If a classical solution of* (1.1)–(1.4) *satisfies* (1.6) (*respectively,* (1.7)) *at* $t = 0$, *then* (1.6) (*respectively,* (1.7)) *holds for all* $t > 0$.

Proof. Let (A, B) be a classical solution of (1.1)–(1.4) satisfying (1.6) (if it satisfies (1.7) the argument is similar) at $t = 0$, and let the pair of functions A_1 and B_1 be defined by $A_1(x,t) \equiv -B(-x,t)$ and $B_1(x,t) \equiv -A(-x,t)$. The pair (A_1, B_1) satisfies (1.1)–(1.3), and since (1.6) holds at $t = 0$, $A_1(x,0) = A(x,0)$ and $B_1(x,0) = B(x,0)$ for all $x \in \mathbb{R}$. Then, by uniqueness of (1.1)–(1.4), $A_1(x,t) = A(x,t)$ and $B_1(x,t) = B(x,t)$ for all $x \in \mathbb{R}$ and all $t > 0$, i.e., condition (1.6) holds for all $t > 0$, as stated. □

3.2. A rigorous derivation of the approximate models. As suggested by the formal derivation in §2, the approximate models will be obtained, in Theorem 3.4, by means of an averaging method. To apply that method we need some estimates on (1.1)–(1.4) that hold uniformly as $\varepsilon \to 0$ (see Lemma 3.5 below). Two basic inequalities that will be used systematically in the proof of Lemma 3.3 are first given.

If $u \in C^1([0,1] \times \mathbb{R})$ *is such that* $\int_0^1 u(x)dx = 0$, *then*

$$\|u\|_{L_q(]0,1[)} \le k_{qr}\|u_x\|^{\alpha}_{L_r(]0,1[)} \cdot \|u\|^{1-\alpha}_{L_r(]0,1[)}, \tag{3.2}$$

whenever $q > r \ge 1$, *where* $\alpha = 1/r - 1/q$, *and the constant* k_{qr} *depends only on* q *and* r (*it is independent of* u). *If* $v \in C^1([0,1], \mathbb{C})$ *and* $q > 1$, *then*

$$\|v\|^2_{L_{2q}(]0,1[)} \le \|v\|^2_{L_2(]0,1[)} + 2k_{q1}\|v\|^{1+1/q}_{L_2(]0,1[)} \cdot \|v_x\|^{1-1/q}_{L_2(]0,1[)}, \tag{3.3}$$

where the constant k_{q1} *is defined as in* (3.2).

The inequality (3.2) is given in, e.g., [17, pp. 62–63], while (3.3) is obtained by applying (3.2) (and Hölder's inequality) to the function $x \to u(x) \equiv |v(x)|^2 - \|v\|^2_{L_2(]0,1[)}$.

We now give some uniform estimates on the solutions of (1.1)–(1.4). For the sake of brevity, we shall not try to obtain the best possible values of the bounding constants K_0, T, and C_0. Notice that these constants are independent of ε, that C_0 is also independent of the particular solution of (1.1)–(1.4), and that K_0 and T depend on it only through $\phi_j(0)$.

LEMMA 3.3. *If* $\gamma < 1$, *for each classical solution of* (1.1)–(1.4) *and for* $j = 0, 1,$ *and* 2, *let the functions* $t \to \phi_j(t)$ *be defined by*

$$\phi_j(t) \equiv \int_0^1 \left[\left| \frac{\partial^j A}{\partial x^j} \right|^2 + \left| \frac{\partial^j B}{\partial x^j} \right|^2 \right] dx. \tag{3.4}$$

Then, for $j = 0, 1,$ and 2, ϕ_j satisfies

$$\phi_j(t) \leq K_0 \quad \text{for all } t \geq 0, \quad \text{and } \phi_j(t) \leq C_0 \quad \text{for all } t \geq T, \tag{3.5}$$

where the constants K_0 and T (respectively, C_0) depend only on β, γ, δ, μ, $\phi_1(0)$, $\phi_2(0)$, and $\phi_3(0)$ (respectively, on β, γ, δ, and μ).

Proof. The estimates (3.5) will be obtained successively for ϕ_0, ϕ_1, and ϕ_2. For the sake of clarity we shall simplify the notation as follows. Every constant appearing below that depends only on β, γ, δ, μ, $\phi_1(0)$, $\phi_2(0)$, and $\phi_3(0)$ (respectively, on β, γ, δ, and μ) will be denoted always as K (respectively, as C).

Step 1. *The estimates* (3.5) *for* ϕ_0. Let us multiply (1.1) by $\bar{A}$, (1.2) by $\bar{B}$, add the resulting equations, take the real part, integrate on $0 < x < 1$, integrate by parts, use (1.3), and apply Hölder's inequality twice to obtain

$$\begin{aligned} \frac{d\phi_0}{dt} &= -2\phi_1 + 2\mu\phi_0 - 2\int_0^1 [|A|^4 + |B|^4 - 2\gamma|A|^2|B|^2]\,dx \\ &\leq -2\phi_1 + 2\mu\phi_0 - 2C\int_0^1 [|A|^4 + |B|^4]\,dx \leq -2\phi_1 + 2\mu\phi_0 - C\phi_0^2 \quad \text{if } t > 0, \end{aligned} \tag{3.6}$$

where $C = \min\{1, 1-\gamma\} > 0$. Since $\phi_1(t) \geq 0$ for all $t > 0$, the estimates (3.5) readily follow (with, e.g., $K_0 = \max\{\phi_0(0), 2\mu/C\}$, $C_0 = 4\mu/C$ and $T = (2\mu)^{-1}\log[\max\{1, 2 - 4\mu/C\phi_0(0)\}]$ if $\mu > 0$, while $K_0 = \phi_0(0)$, $C_0 = 1$, and $T = \max\{0, (\phi_0(0) - 1)/C\phi_0(0)\}$ if $\mu \leq 0$).

Step 2. *The estimates* (3.5) *for* ϕ_1. Now, we multiply (1.1) by $-\bar{A}_{xx}$, (1.2) by $-\bar{B}_{xx}$, add the resulting equations, take the real part, integrate on $0 < x < 1$, integrate by parts and use (1.3). Then, the following equation follows:

$$\begin{aligned} \frac{d\phi_1}{dt} &= -\,2\phi_2 + 2\mu\phi_1 \\ &\quad - \int_0^1 \left\{2|A|^2|A_x|^2 + 2|B|^2|B_x|^2 + [(|A|^2)_x]^2 + [(|B|^2)_x]^2\right\} dx + F_1 + F_2 \end{aligned} \tag{3.7}$$

for all $t > 0$, where

$$\begin{aligned} F_1 &= -\gamma\int_0^1 \left[(A\bar{A}_{xx} + \bar{A}A_{xx})|B|^2 + (B\bar{B}_{xx} + \bar{B}B_{xx})|A|^2\right] dx \\ &\leq 4|\gamma|\left[\int_0^1 (|A|^6 + |B|^6)\,dx \int_0^1 (|A_{xx}|^2 + |B_{xx}|^2)\,dx\right]^{1/2}, \\ F_2 &= i\int_0^1 \left[(A\bar{A}_{xx} - \bar{A}A_{xx})(\beta|A|^2 - \delta|B|^2) + (B\bar{B}_{xx} - \bar{B}B_{xx})(\beta|B|^2 - \delta|A|^2\right] dx \\ &\leq 4(|\beta| + |\delta|)\left[\int_0^1 (|A|^6 + |B|^6)\,dx \int_0^1 (|A_{xx}|^2 + |B_{xx}|^2)\,dx\right]^{1/2}, \end{aligned}$$

or, by using (3.3) (with $q = 3$), $F_1 + F_2 \leq C\phi_0(t)[\phi_0(t) + \phi_1(t)]^{1/2}\phi_2(t)^{1/2}$ if $t > 0$, where the constant C is as defined above (in fact, C depends only on β, γ, and δ). Then, (3.7) yields $d\phi_1/dt \leq -2\phi_2 + 2\mu\phi_1 + C\phi_0(\phi_0 + \phi_1)^{1/2}\phi_2^{1/2}$ if $t > 0$, and since the function $z \to f(z) \equiv -z + cz^{1/2}$ ($c \geq 0$ being a constant) satisfies $f(z) \leq c^2/4$ for all $z \geq 0$, we have

$$\frac{d\phi_1}{dt} \leq -\phi_2 + 2\mu\phi_1 + \frac{C^2\phi_0^2(\phi_0 + \phi_1)}{4} \quad \text{if } t > 0. \tag{3.8}$$

Then, if the constant $K > 0$ is such that $2\mu + C^2\phi_0(t)^2/4 \leq K$ for all $t > 0$, we multiply (3.6) by K and add the resulting equation to (3.8) to obtain $d(\phi_1 + K\phi_0)/dt \leq -K(\phi_1 + K\phi_0) + K(K + 2\mu)\phi_0 + C\phi_0^3/4$ if $t > 0$, and the first estimate (3.5) readily follows for ϕ_1. The second estimate (3.5) is obtained in a similar way, when taking into account that it holds for ϕ_0, and using an appropriate linear combination of the inequalities (3.6) and (3.8).

Step 3. *The estimates* (3.5) *for* ϕ_2. Again, we shall use the following equation, which is obtained by differentiating (1.1) and (1.2) with respect to x, multiplying the resulting equations by $-\bar{A}_{xxx}$ and $-\bar{B}_{xxx}$, respectively, adding, taking the real part, integrating on $0 < x < 1$, integrating by parts, and using (1.3):

$$\frac{d\phi_2}{dt} = -2\phi_3 + 2\mu\phi_2 + F_3 + F_4 \quad \text{if } t > 0, \tag{3.9}$$

where ϕ_3 is defined as in (3.4) and (recall that c.c. stands for the complex conjugate)

$$\begin{aligned} F_3 &= (1 + i\beta) \int_0^1 \left[\bar{A}_{xxx}\left(A|A|^2\right)_x + \bar{B}_{xxx}\left(B|B|^2\right)_x\right] dx + \text{c.c.} \\ &\leq 6|1 + \beta| \int_0^1 \left[|A|^2|A_x||A_{xxx}| + |B|^2|B_x||B_{xxx}|\right] dx, \end{aligned}$$

$$\begin{aligned} F_4 &= -(\gamma + i\delta) \int_0^1 \left[\bar{A}_{xxx}\left(A|B|^2\right)_x + \bar{B}_{xxx}\left(B|A|^2\right)_x\right] dx + \text{c.c.} \\ &\leq 2|\gamma + i\delta| \int_0^1 [(2|A||B_x| + |B||A_x|)|B||A_{xxx}| \\ &\qquad + (2|B||A_x| + |A||B_x|)|A||B_{xxx}|]\, dx. \end{aligned}$$

But, according to the mean value theorem, if $t > 0$, then $|A(x,t)|^2 \leq 2\phi_0(t) + \phi_1(t)$, and $|B(x,t)|^2 \leq 2\phi_0(t) + \phi_1(t)$. Then, by applying Hölder's inequality we readily obtain $F_3 + F_4 \leq C[\phi_0(t) + \phi_1(t)]\phi_1(t)^{1/2}\phi_3(t)^{1/2}$ for all $t > 0$, where the constant C is as defined at the beginning of the proof (in fact, it depends only on β, γ, and δ). Then, (3.9) yields $d\phi_2/dt = -2\phi_3 + 2\mu\phi_2 + C(\phi_0 + \phi_1)\phi_1^{1/2}\phi_3^{1/2}$ if $t > 0$, and by the argument leading to (3.8) above,

$$\frac{d\phi_2}{dt} \leq 2\mu\phi_2 + \frac{C^2(\phi_0 + \phi_1)^2\phi_1}{4} \quad \text{if } t > 0. \tag{3.10}$$

Now, if (3.8) is multiplied by $\lambda = 1 + 2|\mu| > 0$, the resulting equation is added to (3.10) and the first estimate (3.5) for ϕ_0 and ϕ_1 is used, then the following inequality is obtained: $d(\phi_2 + \lambda\phi_1)/dt \leq -(\phi_2 + \lambda\phi_1) + K$ if $t > 0$, where the constant K is as defined at the beginning of the proof. By using this inequality, the first estimate (3.5) readily follows for ϕ_2. Again, the second estimate (3.5) is obtained similarly, when taking into account that it holds for ϕ_0 and ϕ_1, and using the appropriate linear combination of (3.8) and (3.10). Thus, the proof is complete. □

Now, we show that if ε is sufficiently small, then the solutions of (1.1)–(1.4) satisfy approximately (1.20)–(1.23), in an appropriate uniform sense.

THEOREM 3.4. *If $\gamma < 1$ and $0 < \varepsilon < 1$, let (A, B) be a classical solution of* (1.1)–(1.3) *in $-\infty < x < \infty$, $t \geq 0$, and let the functions V and W be defined by*

$$V(y,t) \equiv \varepsilon^{-4/5} \int_t^{t+\varepsilon^{4/5}} A(y+\tau/\varepsilon, \tau)\, d\tau, \quad W(z,t) \equiv \varepsilon^{-4/5} \int_t^{t+\varepsilon^{4/5}} B(z-\tau/\varepsilon, \tau)\, d\tau.$$

Then, for all $y, z \in \mathbb{R}$, and $t \geq 0$, V and W satisfy

$$V_t = (1+i\alpha)V_{yy} + \mu V - (1+i\beta)V|V|^2 + (\gamma + i\delta)V\langle|W|^2\rangle + \varphi_1(y,t), \tag{3.11}$$

$$W_t = (1+i\alpha)W_{zz} + \mu W - (1+i\beta)W|W|^2 + (\gamma + i\delta)W\langle|V|^2\rangle + \varphi_2(z,t), \tag{3.12}$$

$$V(y+1,t) = V(y,t)\exp(-ia), \quad W(z+1,t) = W(z,t)\exp(ia), \tag{3.13}$$

$$V(y,t) = A(y+t/\varepsilon, t) + \psi_1(y,t), \quad W(z,t) = B(z-t/\varepsilon, t) + \psi_2(z,t), \tag{3.14}$$

where the spatial average $\langle\cdot\rangle$ is defined by (1.24) *and the functions φ_j and ψ_j satisfy, for $j = 1$ and 2,*

$$\|\varphi_j(\cdot,t)\|_\infty, \quad \|\psi_j(\cdot,t)\|_\infty \leq K_0\varepsilon^{1/5} \quad \textit{if } t \geq 0, \tag{3.15}$$

$$\|\varphi_j(\cdot,t)\|_\infty, \quad \|\psi_j(\cdot,t)\|_\infty \leq C_0\varepsilon^{1/5} \quad \textit{if } t \geq T \tag{3.16}$$

for some constants K_0, T, and C_0 such that K_0 and T (respectively, C_0) depend only on $\|A(\cdot,0)\|_{H^2(]0,1[)}$, $\|B(\cdot,0)\|_{H^2(]0,1[)}$, β, γ, δ, and μ (respectively, on β, γ, δ, and μ). Here $H^2(]0,1[)$ is the usual (complexified) Sobolev space and $\|\cdot\|_\infty$ is the sup *norm (if $g \in C^2(\mathbb{R})$, then $\|f\|_{H^2(]0,1[)} = [\int_0^1 (|f(\xi)|^2 + |f'(\xi)|^2 + |f''(\xi)|^2)\, d\xi]^{1/2}$ and $\|g\|_\infty = \sup\{|g(\xi)| : \xi \in \mathbb{R}\}$).*

Proof. We shall only obtain the estimate (3.15) (the proof below extends straightforwardly to obtain (3.16), when using the second estimate (3.5) of Lemma 3.3). As in the proof of Lemma 3.3, every constant depending only on $\|A(\cdot,0)\|_{H^2(]0,1[)}$, $\|B(\cdot,0)\|_{H^2(]0,1[)}$, β, γ, δ, and μ will be denoted always as K.

Let the functions v and w be defined by

$$v(y,t) \equiv A(y+t/\varepsilon, t), \quad w(z,t) \equiv B(z-t/\varepsilon, t), \tag{3.17}$$

which are readily seen to satisfy, for all $y, z \in \mathbb{R}$ and all $t \geq 0$,

$$v_t = (1+i\alpha)v_{yy} + \mu v - (1+i\beta)v|v|^2 + (\gamma+i\delta)v|w(y-2t/\varepsilon, t)|^2, \tag{3.18}$$

$$w_t = (1+i\alpha)w_{zz} + \mu w - (1+i\beta)w|w|^2 + (\gamma+i\delta)w|v(z+2t/\varepsilon, t)|^2, \tag{3.19}$$

$$v(y+1,t) = v(y,t)\exp(-ia), \quad w(z+1,t) = w(z,t)\exp(ia). \tag{3.20}$$

Also, according to Lemma 3.5 (see also (3.17) and (3.20)),

$$\int_0^1 (|v|^2 + |v_y|^2 + |v_{yy}|^2)\, dy + \int_0^1 (|w|^2 + |w_z|^2 + |w_{zz}|^2)\, dz \leq K \quad \text{if } t \geq 0,$$

$$\|v(\cdot,t)\|_\infty + \|w(\cdot,t)\|_\infty \le K \quad \text{if } t > 0 \tag{3.21}$$

for some constant K, where the second inequality follows the first one. Then (3.18), (3.19) implies that $\int_0^1 |v_t|^2 dy + \int_0^1 |w_t|^2 dz \le K$ for all $t > 0$, for some constant K, and (see also (3.20)) for all $y_0, z_0 \in \mathbb{R}$, and all $t_0 \ge 0$,

$$\int_{t_0}^{t_0+1} \left[\int_{y_0}^{y_0+1} (|v|^2 + |v_y|^2 + |v_{yy}|^2 + |v_t|^2)\, dy \right] dt \le K,$$
$$\int_{t_0}^{t_0+1} \left[\int_{z_0}^{z_0+1} (|w|^2 + |w_z|^2 + |w_{zz}|^2 + |w_t|^2)\, dz \right] dt \le K$$

for some constant K. Finally, by imbedding theorems (the Sobolev space $H^{2,1}$ ($]a,b[\times]t_0, t_0+1[$) is continuously imbedded into the Hölder space $C^{1/2,1/4}$ ($[a,b] \times [t_0, t_0+1]$); see, e.g., [11, II-3]) we have

$$|v(y,t_2) - v(y,t_1)| + |w(z,t_2) - w(z,t_1)| \le K(t_2 - t_1)^{1/4} \tag{3.22}$$

if $y, z \in \mathbb{R}$, $0 \le t_1 \le t_2 \le t_1 + 1$, and this estimate and (3.21) are sufficient to obtain the required result.

To see that, first notice that since

$$V(y,t) = \varepsilon^{-4/5} \int_t^{t+\varepsilon^{4/5}} v(y,\tau) d\tau, \qquad W(z,t) = \varepsilon^{-4/5} \int_t^{t+\varepsilon^{4/5}} w(z,\tau) d\tau, \tag{3.23}$$

(3.20) readily implies that (3.13) holds. Also, if $0 < \varepsilon < 1$, then by using (3.22) we obtain, for all $y \in \mathbb{R}$ and all $t \ge 0$,

$$\begin{aligned} |\psi_1(y,t)| &= \varepsilon^{-4/5} \left| \int_t^{t+\varepsilon^{4/5}} (v(y,\tau) - v(y,t)) dt \right| \\ &\le K\varepsilon^{-4/5} \int_t^{t+\varepsilon^{4/5}} (t-\tau)^{1/4} = (4K/3)\varepsilon^{1/5}, \end{aligned} \tag{3.24}$$

and the estimate (3.15) holds for ψ_1 (similarly it is seen that this estimate holds for ψ_2). Finally, to obtain the estimate (3.15) for φ_1 (it is obtained for φ_2 a similar way) observe that φ_1 is given by

$$\varphi_1(y,t) = (1+i\beta)\varepsilon^{-4/5} F_1 + (\gamma + i\delta)\varepsilon^{-4/5}(F_2 + F_3 + F_4), \tag{3.25}$$

as obtained when (3.18) is integrated in $]t, t+\varepsilon^{4/5}[$, and the resulting equation is multiplied by $\varepsilon^{-4/5}$, where

$$F_1 \equiv \int_t^{t+\varepsilon^{4/5}} v(y,\tau)|v(y,\tau)|^2 d\tau - \varepsilon^{4/5} V(y,t)|V(y,t)|^2,$$

$$F_2 \equiv \int_t^{t+\varepsilon^{4/5}} [V(y,t) - v(y,\tau)]\, |w(y - 2\tau/\varepsilon, \tau)|^2 d\tau,$$

$$F_3 \equiv V(y,t) \int_t^{t+\varepsilon^{4/5}} \left[|w(y-2\tau/\varepsilon,\tau)|^2 - |w(y-2\tau/\varepsilon,t)|^2 \right] d\tau,$$

$$F_4 \equiv V(y,t) \left[\varepsilon^{4/5} \langle |W(\cdot,t)|^2 \rangle - \int_t^{t+\varepsilon^{4/5}} |w(y-2\tau/\varepsilon,t)|^2 d\tau \right].$$

Then, to end up the proof, we only need to show that

$$|F_j| \leq K\varepsilon \quad \text{if} \quad t \geq 0 \quad \text{for } j = 1, \dots, 4. \tag{3.26}$$

But the first three estimates (3.26) are readily obtained, by the argument leading to (3.24), when using (3.21) and (3.22), while the fourth one comes from the following expression, which is obtained by means of (3.20):

$$\begin{aligned}
&\int_t^{t+\varepsilon^{4/5}} |w(y - 2\tau/\varepsilon, t)|^2 d\tau \\
&\quad = (\varepsilon/2) \int_{y-2t/\varepsilon}^{y-2t/\varepsilon - 2\varepsilon^{-1/5}} |w(\xi, y)|^2 d\xi \\
&\quad = (\varepsilon/2) \mathrm{Int}(2\varepsilon^{-1/5}) \langle |W(\cdot, t)|^2 \rangle - (\varepsilon/2) \int_0^{\mathrm{Fract}(2\varepsilon^{-1/5})} |w(\xi, t)|^2 d\xi,
\end{aligned}$$

where Int and Fract stand for the integral and fractionary parts, respectively. When (3.26) is substituted into (3.25), the estimate (3.15) is obained for φ_1. Thus, the proof is complete. □

Finally, if ε is sufficiently small, then the solutions of (1.1)–(1.4) that satisfy one of the additional conditions, (1.6) or (1.7), are approximate solutions of (1.25)–(1.27), in an appropriate uniform sense.

THEOREM 3.5. *Under the assumptions of Theorem* 3.4, *let us assume that* (A, B) *satisfy one of the additional assumptions,* (1.6) *or* (1.7). *Then the function* V *is such that, for all* $y \in \mathbb{R}$ *and all* $t \geq 0$,

$$V_t = (1 + i\alpha)V_{yy} + \mu V - (1 + i\beta)V|V|^2 + (\gamma + i\delta)V\langle |V|^2 \rangle + \varphi(y, t), \tag{3.27}$$

$$V(y + 1, t) = V(y, t) \exp(-ia), \tag{3.28}$$

$$V(y, t) = A(y + t/\varepsilon, t) + \psi(y, t), \tag{3.29}$$

where the functions φ *and* ψ *satisfy*

$$\|\varphi(\cdot, t)\|_\infty, \quad \|\psi(\cdot, t)\|_\infty \leq K_0 \varepsilon^{1/5} \quad \text{if } t \geq 0, \tag{3.30}$$

$$\|\varphi(\cdot, t)\|_\infty, \quad \|\psi(\cdot, t)\|_\infty \leq C_0 \varepsilon^{1/5} \quad \text{if } t \geq T \tag{3.31}$$

for some constants K_0, T, *and* C_0 *such that* K_0 *and* T (*respectively,* C_0) *depend only on* $\|A(\cdot, 0)\|_{H^2(]0,1[)}$, β, γ, δ, *and* μ (*respectively, on* β, γ, δ, *and* μ). *Here the average* $\langle \cdot \rangle$, *the norm* $\| \cdot \|_\infty$ *and the space* $H^2(]0, 1[)$ *are as defined in Theorem* 3.4.

Proof. The result is obtained from that in Theorem 3.4 when taking into account that if (A, B) satisfy one of the additional assumptions, (1.6) or (1.7), then $\langle |V|^2 \rangle = \langle |W|^2 \rangle$ for all $t \geq 0$. □

Remark 3.6. According to Theorem 3.4 (respectively, Theorem 3.5), each solution of (1.1)–(1.3) (respectively, of (1.1)–(1.3), (1.6) or (1.1)–(1.3), (1.7)) satisfies approximately, in the uniform sense of the estimates (3.15) (respectively, (3.30)), the model (1.20)–(1.23) (respectively, (1.25)–(1.26)). The estimates (3.16) (respectively, (3.31)) are independent of the particular solution of (1.1)–(1.3) (respectively, of (1.1)–(1.3), (1.6) or (1.1)–(1.3), (1.7)) that is considered, but they apply only for sufficiently large time.

3.3. Some basic properties of the approximate models. Here we give two basic properties of the approximate models, namely, that they are well posed and possess a globally attracting set.

THEOREM 3.7. *If* $\gamma < 1$ *and the functions* A_0 *and* B_0 (*respectively,* A_0) *belong to the complexified space of* $C^{2+\alpha}([0,1])$, *for some* $\alpha \in]0,1[$, *and satisfy* (1.22) (*respectively,* (1.26)), *then the problem* (1.20)–(1.23) (*respectively,* (1.25)–(1.26)) *possesses a unique solution,* $A, B \in$ (*respectively,* $A \in$)$C^{2+\alpha,1+\alpha/2}([0,1] \times [0,T])$ *for all* $T > 0$. *In addition there is a constant* C, *depending only on* α, β, γ, δ, *and* μ, *such that, for each solution of* (1.20)–(1.23) (*respectively,* (1.25)–(1.26)) *there is a constant* T *that satisfies, for* $k = 0$ *and* 1,

$$\|A(\cdot,t)_{C^k([0,1])} + \|B(\cdot,t)\|_{C^k([0,1])} \leq C \quad \left(\textit{respectively, } \|A\|_{C^k([0,1])} \leq C\right)$$

for all $t \geq T$.

Proof. The proof of the first statement is completely similar to that of Theorem 3.1, and the second statement is proven by the ideas in the proof of Lemma 3.3. □

Remark 3.8. If, in addition to the assumptions in Theorem 3.7, $\mu \leq 0$, then the constant C may be taken arbitrarily small; this means that the trivial solutions of (1.20)–(1.23) and (1.25)–(1.26), $A \equiv B \equiv 0$ and $A \equiv 0$, are globally, asymptotically stable in this case. Therefore, if $\mu \leq 0$, then the dynamics of the approximate models are trivial. If $\gamma = 1$ (respectively, $\gamma < 1$), then both approximate models possess solutions that are unbounded as $t \to \infty$ (respectively, that blow up in a finite time), as is seen by considering spatially uniform solutions of both models.

4. Concluding remarks. We have considered the models (1.1)–(1.3), (1.1)–(1.3), (1.6), and (1.1)–(1.3), (1.7) that, as it was explained in §1, are normal forms that apply at the onset of the so-called oscillatory instability in a large variety of physical problems. In the limit $\varepsilon \to 0$, we obtained (formally in §2, and rigorously in §3) two simpler approximate models, (1.20)–(1.23) and (1.25)–(1.26). In addition, we have seen that both models are well posed, and possess a globally attracting set. Some remarks concerning these models are in order.

(A) Both aproximate models possess an inertial manifold of finite dimension. This result may be seemingly proved by extending the analysis in [18], on the standard cubic complex Ginzburg–Landau equation.

(B) The approximate model (1.20)–(1.23) possesses a two-parameter family of travelling waves of the form $V = R\exp(i\omega t + iky + id)$, $W = 0$, or $V = 0$, $W = R\exp(i\omega t + iky + id)$ for appropriate values of the real constants R, ω, k, and d, and a four-parameter family of quasi-periodic waves of the form $V = R_1 \exp(i\omega_1 t + ik_1 y + id_1)$, $W = R_2 \exp(i\omega_2 t + ik_2 y + id_2)$, for appropriate values of the real constants R_1, R_2, ω_1, ω_2, k_1, k_2, d_1, and d_2 (see [19]). These wave-like solutions may lose their stability either under uniform or under nonuniform perturbations; in the second case, the solutions are said to be modulationally unstable. At the onset of the modulational instability, the model (1.20)–(1.23) may be reduced to the Kuramoto–Sivashinsky equation (see [19]) that, as is well known, exhibits chaotic behavior. Therefore, we may expect chaotic solutions of (1.20)–(1.23) for appropriate values of the parameters. The same conjecture can be made in connection with the approximate model (1.25), (1.26).

(C) The particular wave-like solutions of (1.20)–(1.23) and (1.25), (1.26) mentioned in (B) are such that the moduli of V and W are spatially uniform. More general solutions, with spatially nonuniform modulus, are of great physical interest;

in particular, they provide a description of the so-called *blinking states* of the original model (1.8), which have been detected in experiments (see [10], [11]). Both models are expected to possess such solutions. In particular, if $\alpha = \beta = \delta = 0$, then it may be seen that every stationary solution of (1.25), (1.26) is such that either (i) θ =constant or (ii) $R \neq 0$ for all $y \in [0,1]$, where R and θ are the modulus and the argument of V. The stationary solutions of type (i) may be obviously obtained in closed form, in terms of elliptic functions. The solutions of type (ii) are readily seen to be such that $d\theta/dx = c/R^2$ for some constant $c \neq 0$; then R satisfies $R'' + \mu R - R^3 - c^2/R^3 + \gamma R \int_0^1 R^2 dy = 0$, and this equation is again solved in terms of elliptic functions. In addition, the evolution problem (1.25), (1.26) is gradient-like (admits the Lyapunov function $\varphi : H^2(]0,1[) \to \mathbb{R}$ defined by $\varphi(V) \equiv \int_0^1 (|V'(y)|^2 - \mu|V(y)|^2) + \int_0^1 (|V(y)|^4/2)\, dy - \gamma[\int_0^1 |V(y)|^2 dy]^2)$, and the stability of these solutions is readily analyzed. We do not include a complete study of these solutions and of their stability because it has been announced in [12]. Sufficient conditions for the existence of stable solutions of (1.25), (1.26) in the general (nonreal coefficients) case would be of great interest.

SOME EXISTENCE THEOREMS FOR AN N-DIMENSIONAL PARABOLIC EQUATION WITH A DISCONTINUOUS SOURCE TERM*

ROBERTO GIANNI† AND PAOLA MANNUCCI†

Abstract. The authors consider an n-dimensional semilinear equation of parabolic type with a discontinuous source term arising from combustion theory. The authors prove a local existence for a classical solution having a "regular" free boundary. In this regard, the free boundary is a surface through which the discontinuous source term exhibits a switch-like behaviour. The authors specify conditions under which this solution and its free boundary are global in time. The authors also prove uniqueness and continuous dependence theorems.

Key words. combustion, semilinear parabolic equation, regularity of the solution and of the free boundary, discontinuous source term, uniqueness, continuous dependence

AMS subject classifications. 35K57, 35R35, 80A25

Introduction. In this paper we will study a free boundary problem arising from combustion theory. The equation ruling this phenomenon is parabolic with a discontinuous source term:

$$u_t - \Delta u = \mathbb{H}(u-1) \quad \text{in } Q \times [0, T], \tag{0.1}$$

where $\mathbb{H}$ is the Heaviside function and Q is an open subdomain of $\mathbb{R}^N$.

These kinds of problems were investigated by Norbury and Stuart in [1], where the equation was derived from a combustion problem in a porous medium. In further papers Norbury and Stuart have studied some mathematical aspects of such problems but only for the one-dimensional case. (See [2], [3], [4].)

In this problem the free boundary is the level set $\{u=1\}$ that divides Q into two subdomains Q_1 and Q_2 in which $u>1$ and $u<1$, respectively. We will investigate the regularity of the free boundary, its global in time existence, and the possibility of describing it as a surface of the form $x_i = f(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_N, t)$.

In [5] the authors prove analogous results in the one-dimensional case.

For the sake of simplicity, in this paper we will work in two dimensions with $Q = \{(x, y)/0<x<1; 0<y<1\}$, but the techniques we use can be applied to a general domain in $\mathbb{R}^N$ which we can assume to have its boundary S in the class O^2 in the sense specified in p. 9 of [6].

Moreover, we will consider the simple equation (0.1), while in [5] a quite general quasilinear equation was considered. These assumptions are made only to make the proofs simpler and are not going to restrict in any way the validity of the theorems. For example, instead of (0.1) we can consider the equation

$$u_t - \nabla \cdot (K(u)\nabla u) = f(u)\mathbb{H}(u-1),$$

where, as far as the global results are concerned, $K(u)$ is a constant and $f(u)$ is assumed to be a positive nondecreasing function belonging to $C^1(\mathbb{R})$.

More precisely in this paper we will prove a local in time existence theorem for a solution of (0.1) having a "regular" free boundary, then we will find particular boundary conditions and initial data which assure "global" existence of such a solution.

Moreover, we will investigate uniqueness and continuous dependence results for problem (0.1).

In the following we will denote with α, $\alpha \in (0, 1)$, any suitable Hölder exponent not specified further.

Where not differently specified, we will use the notation of [6].

1. Local existence. Let us now consider the following two-dimensional parabolic problem:

$$u_t = \Delta u + \mathbb{H}(u-1), \tag{1.1}$$

$$u(x, y, 0) = h(x, y), \tag{1.2}$$

$$u(0, y, t) = K_1(y, t), \tag{1.3a}$$

$$u(1, y, t) = K_2(y, t), \tag{1.3b}$$

$$u(x, 0, t) = K_3(x, t), \tag{1.3c}$$

$$u(x, 1, t) = K_4(x, t), \tag{1.3d}$$

where $(x, y) \in Q = (0, 1) \times (0, 1)$, $t \in (0, T)$. Let $Q_T = Q \times (0, T)$, $\partial_p Q_T$ the parabolic boundary of Q_T, and S_T the lateral boundary of Q_T.

In (1.1), $\mathbb{H}(\eta)$ is the Heaviside function so defined: $\mathbb{H}(\eta) = 1$ if $\eta > 0$ and $\mathbb{H}(\eta) = 0$ if $\eta \leqq 0$. Let us list the assumptions we will use

$$\begin{cases} K_i \in H^{\beta,\beta/2}([0, 1] \times [0, T]), & i = 1, \dots, 4, \\ K_{iy}(y, t) \in H^{\beta,\beta/2}([0, 1] \times [0, T]), & i = 1, 2, \\ K_{ix}(x, t) \in H^{\beta,\beta/2}([0, 1] \times [0, T]), & i = 3, 4, \quad \beta > \frac{3}{4}, \\ K_{it}(x; y, t) \in L_\infty([0, 1] \times [0, T]), & i = 1, \dots, 4, \end{cases} \tag{1.4}$$

$$h(x, y) \in H^{1+\beta}(\bar{Q}), \beta > \tfrac{3}{4}, \tag{1.5}$$

$$|\Delta h| \leqq M, \tag{1.6}$$

$$\begin{cases} A_0 = \{(x, y) \colon h(x, y) = 1\} \text{ admits the representation } y = f_0(x), \quad 0 \leqq x \leqq 1, \\ f_0(x) \in H^{1+\beta}([0, 1]), \\ h > 1 \quad \text{in } \{(x, y) \in \bar{Q} \colon y > f_0(x)\}, \\ h < 1 \quad \text{in } \{(x, y) \in \bar{Q} \colon y < f_0(x)\}, \end{cases} \tag{1.7}$$

(1.8) $h_y(x, y) \geqq \gamma > 0$ in a neighbourhood relative to $\bar{Q}$ of the curve $y = f_0(x)$,

$$\begin{cases} \text{zero order compatibility conditions are satisfied on } \partial_p Q_T, \\ \text{this means that the boundary and initial data} \\ \text{are a continuous function on } \partial_p Q_T. \end{cases} \tag{1.9}$$

Remark 1.1. As far as we are only concerned with a local existence theorem, we can relax the assumptions (1.4)–(1.6). In fact, we can just assume that $K_3(x, t)$, $K_4(x, t)$ are Hölder continuous with exponent $\alpha \in (0, 1)$ and $K_1(y, t)$, $K_2(y, t)$ satisfy (1.4) only in a neighbourhood of $(0, f_0(0), 0)$ and $(1, f_0(1), 0)$ in the plane $\{x = 0\}$ and $\{x = 1\}$, respectively, while $h(x, y)$ satisfies (1.5), (1.6) only in a neighbourhood of the curve $y = f_0(x)$ which is still assumed to belong to $H^{1+\beta}([0, 1])$. This means that the assumptions on the regularity of the boundary and initial data are made only "near" the curve $y = f_0(x)$ while the regularity required for the boundary conditions away from this curve will be the weakest needed to have the existence of a weak solution of the problem, for example, in $W_2^{1,0}(Q_T) \cap C^0(\bar{Q}_T)$.

THEOREM 1.1. *Under the assumptions* (1.4)-(1.9), *a function* $u(x, y, t)$ *exists such that*

$$u\in H^{\alpha,\alpha/2}(\overline{Q_T}),\quad \nabla u\in H^{\alpha,\alpha/2}(\bar{Q}'_T)\quad \forall\varepsilon'>0, \tag{1.10}$$

with $Q'=(0,1)\times(\varepsilon', 1-\varepsilon')$,

$$u_{xx}, u_{yy}, u_{xy}, u_t\in L_2(Q'_T)\quad \forall\varepsilon'>0 \tag{1.11}$$

satisfying (1.2)-(1.3d) *and* (1.1) *almost everywhere. Moreover, for a sufficiently small* T_1 *we have*

$$|u_t|\leqq M\quad \textit{in } Q_{T_1}, \tag{1.12}$$

and denoting with A_{T_1} *the level set*

$$A_{T_1}=\{(x, y, t)\,|\,(x, y)\in\bar{Q}, t\in(0, T_1), u(x, y, t)=1\},$$

we have that A_{T_1} *is the graph of a function of the form* $y=f(x, t)$ *with* $f_x(x, t)\in H^{\alpha,\alpha/2}([0,1]\times[0,T_1])$, $|f_t(x,t)|\leqq M$ *in* $[0,1]\times[0,T_1]$.

The proof of Theorem 1.1 will follow as a consequence of Propositions 1.1, 1.2, and 1.3 below. Let us consider a sequence of approximating problems:

$$u_{nt}=\Delta u_n+\mathbb{H}_n(u_n-1), \tag{1.13}$$

$$u_n(x, y, 0)=h_n(x, y), \tag{1.14}$$

$$u_n(0, y, t)=K_{1n}(0, y, t), \tag{1.15a}$$

$$u_n(1, y, t)=K_{2n}(1, y, t), \tag{1.15b}$$

$$u_n(x, 0, t)=K_{3n}(x, 0, t), \tag{1.15c}$$

$$u_n(x, 1, t)=K_{4n}(x, 1, t), \tag{1.15d}$$

where:

$$\left\{\begin{array}{l} h_n\in C^\infty(\bar{Q}),\ K_{in}\in C^\infty([0,1]\times[0,T]) \\ \text{and they converge, respectively, to } h \text{ and } K_i \\ \text{in the } C^1\text{-norm}, \\ i=1,\dots,4, \end{array}\right. \tag{1.16}$$

$$\left\{\begin{array}{l} \nabla h_n \text{ has norm in } H^\beta(\bar{Q}) \text{ bounded independently of } n \\ \text{and } \Delta h_n \text{ is bounded independently} \\ \text{of } n \text{ in } Q, \end{array}\right. \tag{1.17a}$$

$$\left\{\begin{array}{l} K_{iny}(y,t),\ i=1,2 \text{ and } K_{inx}(x,t),\ i=3,4 \text{ have the norms in } H^{\beta,\beta/2} \text{ bounded} \\ \text{independently of } n \text{ with } \beta \text{ as in (1.4)-(1.7)}, \\ K_{int}(x,t),\ i=1,\dots,4, \text{ have their norm in } L_\infty \text{ bounded independently of } n, \end{array}\right. \tag{1.17b}$$

$$\left\{\begin{array}{l} \mathbb{H}_n \text{ are monotonically increasing functions of their argument}, \\ \mathbb{H}_n\in C^\infty(\mathbb{R}), \\ \lim_n \|\mathbb{H}_n-\mathbb{H}\|_{C^2}=0 \text{ in } \mathbb{R}\backslash(-\varepsilon,\varepsilon)\quad \forall\varepsilon>0, \\ \lim_n \|\mathbb{H}_n-\mathbb{H}\|_{2,\mathbb{R}}=0. \end{array}\right. \tag{1.18}$$

$$\left\{\begin{array}{l} \text{Moreover, we can assume that the boundary data (1.14)-(1.15d)} \\ \text{satisfy the zero-order compatibility conditions.} \end{array}\right. \tag{1.19}$$

From (1.16), (1.17a), it follows that, for sufficiently large n, the level set $A_{0n} = \{(x, y): h_n(x, y) = 1\}$ can be described as the graph of a function of the form $y = f_{0n}(x)$, $0 \leqq x \leqq 1$, and $f_{0n}(x) \in H^{1+\beta}([0, 1])$, f_{0n} bounded independently of n in $H^{1+\beta}$. Here and in the following M will denote any constant independent of n. Let $Q' = (0, 1) \times (\varepsilon', 1 - \varepsilon')$, for all $\varepsilon' > 0$.

PROPOSITION 1.1. *Under the assumptions* (1.16)-(1.19), *problem* (1.13)-(1.15d) *admits a unique classical solution* $u_n(x, y, t)$ *such that*

$$u_n(x, y, t) \in H^{2+\alpha, 1+\alpha/2}(Q_T), \tag{1.20}$$

and the following estimates hold:

$$\max_{Q_T} |u_n| \leqq M, \tag{1.21}$$

$$|u_n|_{Q_T}^{(\alpha)} \leqq M, \tag{1.22}$$

$$|u_n|_{Q'_T}^{(1+\alpha)} \leqq M(\varepsilon') \quad \forall \varepsilon' > 0, \tag{1.23}$$

$$\|u_{nxx}, u_{nyy}, u_{nxy}, u_{nt}\|_{2, Q'_T} \leqq M(\varepsilon') \quad \forall \varepsilon' > 0 \tag{1.24}$$

with M *and* $M(\varepsilon')$ *independent of* n.

Proof. By means of Theorem 6.4, p. 460 and Theorem 12.1, p. 223 of [6] we obtain (1.20). The estimate (1.21) follows from Theorem 2.1 of [6, p. 425].

Theorem 1.1 of [6, p. 419] gives the uniform Hölder continuity with exponent α of the function $u_n(x, y, t)$ and hence estimate (1.22). Estimates (1.23) and (1.24) follow from inequality (10.12) p. 355 and the corollary at the end of Theorem 9.1, p. 341 of [6].

Remark 1.2. Because of the uniform Hölder continuity of $\{u_{ny}\}$ it is obvious that, in the (x, y)-plane, a neighbourhood Q_1 of the curve $y = f_0(x)$ can be chosen such that, in $Q_{1T_0} = Q_1 \times (0, T_0)$ (with T_0 sufficiently small); we have

$$u_{ny}(x, y, t) \geqq \gamma > 0 \quad \forall n > N, \quad \text{with } N \text{ sufficiently large}, \tag{1.25}$$

with γ, Q_1, T_0 independent of n.

PROPOSITION 1.2. *Under the assumptions* (1.16)-(1.19), *we have*

$$|u_{nt}| \leqq M \quad \forall n, \tag{1.26}$$

in Q_{T_1} *with* T_1 *suitably small*; *here* M *does not depend on* n.

Proof. Let us define $\hat{Q}_1 = \{(x, y)/x \in (0, 1); f_0(x) - \varepsilon < y < f_0(x) + \varepsilon\}$ and $\hat{Q}_{1T_1} = \hat{Q}_1 \times (0, T_1)$, with T_1 so small that $u_n < 1 - \varepsilon^*$ on $\{(x, y, t)/x \in (0, 1);\ y = f_0(x) - \varepsilon;\ 0 < t < T_1\}$ and $u_n > 1 + \varepsilon^*$ on $\{(x, y, t)/x \in (0, 1); y = f_0(x) + \varepsilon; 0 < t < T_1\}$ for all n sufficiently large and a suitable ε^*. (This is possible because of (1.22).) Moreover, we can assume $\hat{Q}_{1T_1} \subset Q_{1T_0}$ (see Remark 1.2).

In $\hat{Q}_{1T_1}$, $v_n(x, y, t) = u_{nt}(x, y, t)$ satisfies the following system of equations:

$$\begin{aligned} &v_{nt} - \Delta v_n = \mathbb{H}'_n(u_n - 1) v_n \quad \text{in } \hat{Q}_{1T_1}, \\ &v_n(x, y, t) = D_n(x, y) \quad \text{on } \partial_p \hat{Q}_{1T_1}, \end{aligned} \tag{1.27}$$

D_n is a function bounded independently of n; this result can be obtained using assumptions (1.16), (1.17a), (1.17b) and applying Theorem 10.1 of [6, p. 204] to the problem satisfied by $v_n = u_{nt}$.

This implies that, regarding $\mathbb{H}'_n(u_n - 1) v_n$ as a known source term, we can represent the solution v_n of (1.27) as the sum of two functions v_{1n} and v_{2n}, where v_{1n} is the solution of the homogeneous heat equation with the same initial and boundary data of problem (1.27) and v_{2n} is the solution of equation (1.27) in $\hat{Q}_{1T_1}$ with zero Dirichlet boundary data.

It is quite simple to prove that $|v_{1n}| \leqq M$ in $\hat{Q}_{1T_1}$.

Using the Green function G, we can express v_{2n} in the following form:

$$v_{2n} = \int_0^t \int_{\hat{Q}_1} G(x, y, \xi_1, \xi_2, t, \tau)\mathbb{H}'_n(u_n - 1)v_n \, d\xi_1 \, d\xi_2 \, d\tau. \tag{1.28}$$

Hence we have

$$v_n = v_{1n} + \int_0^t \int_{\hat{Q}_1} G(x, y, \xi_1, \xi_2, t, \tau)\mathbb{H}'_n(u_n - 1)v_n \, d\xi_1 \, d\xi_2 \, d\tau, \tag{1.29}$$

where v_{1n} is regarded as a bounded known term.

Let us define

$$\Omega(t) = \max_{\hat{Q}_1 \times (0,t)} |v_n(x, y, t)|, \qquad N(t) = \max_{\hat{Q}_1 \times [0,t]} |v_{1n}(x, y, t)|.$$

Then we have

$$\Omega(t) \leqq N(t) + \left| \int_0^t \Omega(\tau) \int_{\hat{Q}_1} C(t-\tau)^{-1} \exp\left(\frac{-C(|x-\xi_1|^2 + |y-\xi_2|^2)}{t-\tau} \right) \cdot \mathbb{H}'_n(u_n - 1) \, d\xi_1 \, d\xi_2 \, d\tau \right|.$$

Now, using (1.25), we can multiply and divide $\mathbb{H}'_n(u_n - 1)$ by u_{ny}, thus obtaining

$$\Omega(t) \leqq N(t) + C\left| \int_0^t \Omega(\tau) \int_{\hat{Q}_1} (t-\tau)^{-1} \exp\left(\frac{-C(|x-\xi_1|^2 + |y-\xi_2|^2)}{t-\tau} \right) \cdot \frac{d}{dy}(\mathbb{H}_n(u_n - 1)) \frac{1}{u_{ny}} \, d\xi_1 \, d\xi_2 \, d\tau \right|.$$

Integrating in ξ_2, we get

$$\Omega(t) \leqq N(t) + \frac{C}{\gamma} \left| \int_0^t \Omega(\tau) \int_0^1 (t-\tau)^{-1} \exp\left(\frac{-C|x-\xi_1|^2}{t-\tau} \right) d\xi_1 \, d\tau \right|.$$

Now we multiply and divide the argument of the above integral by $|x-\xi_1|^{1/2}/(t-\tau)^{1/4}$, and, keeping in mind that the quantity

$$\exp\left(\frac{-C|x-\xi_1|^2}{t-\tau} \right) \frac{|x-\xi_1|^{1/2}}{(t-\tau)^{1/4}}$$

is bounded, we obtain (choosing if necessary a new constant C)

$$\Omega(t) \leqq N(t) + \frac{C}{\gamma} \int_0^t \Omega(\tau) \int_0^1 \frac{(t-\tau)^{-3/4}}{|x-\xi_1|^{1/2}} \, d\xi_1 \, d\tau.$$

Now if we set

$$C_0 = \max_{x \in (0,1)} \int_0^1 |x-\xi_1|^{-1/2} \, d\xi_1,$$

we have

$$\Omega(t) \leqq N(t) + \frac{CC_0}{\gamma} \int_0^t \Omega(\tau)(t-\tau)^{-3/4} \, d\tau.$$

Then, multiplying by $CC_0/(t-\tau)^{3/4}\gamma$ both sides of the inequality and integrating in t, we get

$$\begin{aligned}\Omega(t)-N(t)&\leqq\frac{CC_0}{\gamma}\int_0^t N(\tau)(t-\tau)^{-3/4}\,d\tau\\&\quad+\frac{C^2C_0^2}{\gamma^2}\int_0^t(t-\tau)^{-3/4}\int_0^\tau\Omega(\theta)(\tau-\theta)^{-3/4}\,d\theta\,d\tau\\&=\frac{CC_0}{\gamma}\int_0^t N(\tau)(t-\tau)^{-3/4}\,d\tau\\&\quad+\frac{C^2C_0^2}{\gamma^2}\int_0^t\Omega(\theta)\int_\theta^t(t-\tau)^{-3/4}(\tau-\theta)^{-3/4}\,d\tau\,d\theta.\end{aligned}$$

Integrating this last term by means of the substitution $\tau=\theta+(t-\theta)z$, we obtain

$$\Omega(t)-N(t)\leqq\frac{CC_0}{\gamma}\int_0^t N(\tau)(t-\tau)^{-3/4}\,d\tau+\frac{C^2C_0^2}{\gamma^2}\int_0^t M(t-\theta)^{-1/2}\Omega(\theta)\,d\theta,$$

where $M=\int_0^1 z^{-3/4}(1-z)^{-3/4}\,dz$.

Iterating this procedure as in [7, Chap. 3, § 15], we finally obtain for $\Omega(t)$ an integral inequality of the following kind:

$$\Omega(t)\leqq F(t)+\int_0^t K(t-\tau)\Omega(\tau)\,d\tau,$$

with $K(t-\tau)$ bounded independently of n and $F(t)$ depending on $N(t)$ but not on n.

Applying Gronwall's lemma, we get $\Omega(t)\leqq M$ in $(0,T_1)$ with M independent of n.

Since u_{nt} is bounded uniformly on n in $\hat{Q}_{1T_1}$, is straightforward to prove, by means of standard theorems (see [6, Thm. 5.1, p. 444]), that the same result holds true in Q_{T_1}.

PROPOSITION 1.3. *Under the assumptions* (1.16)-(1.19), *in* $Q_{T_1}=Q\times(0,T_1)$, *with* T_1 *suitable small, the level set* $A^n_{T_1}=\{(x,y,t)/(x,y)\in Q;\ t\in(0,T_1)/u_n(x,y,t)=1\}$ *is represented by a regular surface* $y=f_n(x,t)$ *with*

(1.30) $$|f_{nx}|^{(\alpha)}\leqq M\quad in\ [0,1]\times[0,T_1],$$

(1.31) $$|f_{nt}|\leqq M\quad in\ (0,1)\times(0,T_1).$$

Proof. Clearly we have that $A^n_0=\{(x,y)\in Q/h_n(x,y)=1\}$ is a "regular" curve on the plane $t=0$, and if we choose n sufficiently large this set has a distance greater than $\varepsilon/2$ from the curves $y=f_0(x)-\varepsilon$, $y=f_0(x)+\varepsilon$; then for a sufficiently large n and small T_1, $A^n_{T_1}$ lies in $\hat{Q}_{1T_1}$. (Remember in this regard that u_n are uniformly Hölder continuous.) Then, using (1.25), Propositions 1.1 and 1.2, we can apply the inverse function theorem to the function u_n to get that $A^n_{T_1}$ is representable in the form $y=f_n(x,t)$ and estimates (1.30), (1.31) hold.

Let us now turn to the proof of Theorem 1.1.

Proof of Theorem 1.1. We now consider the sequences $\{u_n\}$, $\{f_n\}$ of solutions of the approximating problems (1.13)-(1.15d). Using (1.21)-(1.24), (1.26), (1.30)-(1.31), we see that it is possible to extract from $\{u_n\}$ and from $\{f_n\}$ two subsequences u_{nk} and

f_{nk} that converge, respectively, to the functions u and f, in the following sense:

$$\begin{cases} u_{nk} \xrightarrow{C^0} u \in H^{\alpha,\alpha/2}(\bar{Q}_T) \quad \forall T, \\ \nabla u_{nk} \xrightarrow{C^0} \nabla u \in H^{\alpha,\alpha/2}(\bar{Q}'_T) \quad \forall T, \quad \forall \varepsilon' > 0, \text{ with} \\ Q'_T = (0,1)\times(\varepsilon', 1-\varepsilon')\times(0,T), \\ u_{nkxx};\ u_{nkyy};\ u_{nkxy},\ u_{nkt} \xrightarrow{w-L_2} u_{xx},\ u_{yy},\ u_{xy},\ u_t \in L_2(Q'_T) \quad \forall \varepsilon' > 0, \\ (\text{“}w-L_2\text{” weak convergence in } L_2), \\ |u_t| \leqq M \quad \text{in } Q_{T_1}, \\ f_{nk}(x,t) \xrightarrow{C^0} f(x,t) \text{ with } f(x,t) \text{ Lipschitz continuous in } x \text{ and } t \text{ in} \\ \quad \cdot [0,1]\times[0,T_1], \\ f_{nkx}(x,t) \xrightarrow{C^0} f_x(x,t) \in H^{\alpha,\alpha/2}([0,1]\times[0,T_1]). \end{cases} \tag{1.32}$$

Here T_1 is the constant determined in Propositions 1.2 and 1.3.

To prove that $u(x,y,t)$ is a solution of problem (1.1)-(1.3d) we have to show that

$$\mathbb{H}_n(u_n - 1) \xrightarrow{w-L_2} \mathbb{H}(u-1).$$

We can easily obtain that $\mathbb{H}_n(u_n-1) \xrightarrow{w-L_2} \phi(x,y,t)$, and then

$$u_t - \Delta u = \phi(x,y,t) \quad \text{in } Q_T, \tag{1.33}$$

with $\phi(x,y,t) \in L_\infty(Q_T)$, $\phi(x,y,t) = 0$ if $u(x,y,t) < 1$; $\phi(x,y,t) = 1$ if $u(x,y,t) > 1$; $0 \leqq \phi(x,y,t) \leqq 1$ in $\mathbb{A} = \{(x,y,t) \in Q_T\colon u(x,y,t) = 1\}$.

However, it can be proved that either meas $\mathbb{A} = 0$ or $\phi(x,y,t) = 0$ almost everywhere in $\mathbb{A}$.

In fact, using Lemma A.4 of [8, p. 53], since $\nabla u(x,y,t)$ and $u_t(x,y,t)$ are in L_2, we get $u_t \equiv u_x \equiv u_y \equiv 0$ almost everywhere in $\mathbb{A}$. Still applying Lemma A.4 of [8, p. 53] to the functions $u_x(x,y,\bar{t})$ and $u_y(x,y,\bar{t})$ (remember that because of Fubini's lemma, $u_{xx}(x,y,\bar{t})$ and $u_{yy}(x,y,\bar{t})$ are in $L_2((0,1)\times(0,1))$, for almost all $\bar{t}$), we get $u_{xx}(x,y,\bar{t}) \equiv u_{yy}(x,y,\bar{t}) \equiv 0$ almost everywhere in $\mathbb{A} \cap \{t = \bar{t}\}$, for almost all $\bar{t}$. Hence $u_{xx}(x,y,t) \equiv u_{yy}(x,y,t) \equiv 0$ almost everywhere in $\mathbb{A}$.

Hence, because of (1.33), we have that $\phi(x,y,t) = 0$ almost everywhere in $\mathbb{A}$, then $\phi(x,y,t) \equiv \mathbb{H}(u-1)$ almost everywhere, that is, $u(x,y,t)$ is a solution of (1.1)-(1.3d). To be sure that $y = f(x,t)$ is the representation of the level set $\{u = 1\}$ it only remains to prove the inequalities $u > 1$ in $Q^1_{T_1} = \{(x,y,t) \in Q_{T_1};\ y > f(x,t)\}$, and $u < 1$ in $Q^2_{T_1} = \{Q \backslash \bar{Q}^1_{T_2}\}$. They can be easily obtained by means of the strong maximum principle, so we will not go into the details of the proof.

Proposition 1.4a. *Let $u(x,y,t)$ be the solution of* (1.1)-(1.3d). *Under assumptions* (1.4)-(1.9) *and the assumption $K_{1t} \in H^{\alpha,\alpha/2}([0,1]\times[0,T])$, $i = 1,\dots,4$, then $u_t \in H^{\gamma,\gamma/2}(\mathscr{Q}\times[\tau,T_1])$, $\gamma \in (0,\alpha]$, for all $\tau \in (0,T_1)$, with T_1 suitably small, where $\mathscr{Q}$ is any closed domain contained in $\bar{Q}$ and not containing the corners of the square.*

Proof. Clearly it suffices to work in $\hat{Q}_{1T_1}$ instead of Q_T because in $Q_T \backslash \hat{Q}_{1T_1}$ the result follows from standard theorems on heat equation. Let us consider the solution u_n of the approximating problem (1.13)-(1.15d) under assumptions (1.16)-(1.18) and

$K_{\text{int}} \in H^{\alpha,\alpha/2}$, $|K_{\text{int}}|^{(\alpha)} \leqq M$, for all n. It is important to notice that, using inequality (10.12), p. 155, and the corollary of [6, p. 342], it is easy to prove:

$$|u_{nxx}, u_{nyy}, u_{nxy}, u_{nt}|_q \leqq M, \qquad q = 1/(1-\beta); \tag{A.1}$$

$$|\nabla u_n(x, y, t)|^{(1-4(1-\beta))} \leqq M \tag{A.2}$$

(here β is the same of assumptions (1.4)-(1.9), (1.16)-(1.18)) in $\mathcal{Q} \times [0, T]$. At this point setting $v_n = u_{nt}$, we have that (1.27) can be written in the alternative form:

$$v_{nt} - \Delta v_n + \frac{\mathbb{H}_n(u_n-1)}{u_{ny}} v_{ny} - \frac{\mathbb{H}_n(u_n-1)u_{nyy}}{(u_{ny})^2} v_n = \frac{\partial}{\partial y}\left(\frac{\mathbb{H}_n(u_n-1)v_n}{u_{ny}}\right),$$

where $[\mathbb{H}_n(u_n-1)]/u_{ny}$, $[\mathbb{H}_n(u_n-1)u_{nyy}]/(u_{ny})^2$, $[\mathbb{H}_n(u_n-1)v_n]/u_{ny}$, are regarded as known coefficients belonging respectively to L_∞, L_q, L_∞ (remember for this purpose that from Proposition 1.3, v_n is uniformly bounded in Q_{T_1}). At this point, using Theorem 10.1 of [6, p. 204] we get that

$$|v_n|^{(7)} \leqq M(\tau, \mathcal{Q}) \quad \forall n \text{ on } \mathcal{Q} \times [\tau, T_1] \quad \forall \tau \in (0, T_1), \quad \gamma \in (0, \alpha]. \tag{A.3}$$

Finally, using a diagonal technique, we get Proposition 1.4a.

Remark 1.4b. It is easy to observe that γ and $M(\tau, \mathcal{Q})$ in (A.3) depend on τ, $\mathcal{Q}$ and on the boundary data. This implies that if we consider boundary data whose norms are bounded in their respective spaces by a certain fixed constant $K > 0$, then u_{nt}, u_t are uniformly Hölder continuous with the same Hölder exponent γ. This will turn out to be very useful in the continuous dependence theorem.

In the following theorem we want to prove an important generalization of Theorem 1.1. Namely, we will relax the assumptions (1.5) and (1.6), which guarantee the boundedness of u_t up to the boundary.

THEOREM 1.2. *Under the assumptions* (1.4), (1.7)-(1.9), *if we substitute* (1.5) *with*

$$h(x, y) \in H^{1+\gamma}(\bar{Q}), \qquad \gamma \in (0, 1) \tag{1.5bis}$$

and if we drop (1.6), *we can prove that a function $u(x, y, t)$ exists, such that $u \in H^{\alpha,\alpha/2}(\overline{Q_T})$. For a suitable $\alpha \in (0, 1)$, u_t, u_{xx}, u_{yy}, $u_{xy} \in L_2(Q' \times [\tau, T])$, $\nabla u \in H^{\gamma'}(\bar{Q}'_T)$, $\gamma' \in (0, \gamma]$, for all $\tau > 0$, for all $\varepsilon' > 0$, where $Q' = (0, 1) \times (\varepsilon', 1-\varepsilon')$, $|u_t| \leqq M(\tau)$ in $Q \times [\tau, T_1]$ for all $\tau > 0$ and T_1 suitably small, u satisfies* (1.2)-(1.3d) *and* (1.1) *almost everywhere, and has a level set $\{u = 1\}$ which is representable by a function $y = f(x, t)$ which is Lipschitz continuous with respect to x and t in any subdomain of the form $[0, 1] \times [\tau, T_1]$ and continuous in $[0, 1] \times [0, T_1]$.* (*Equation* (1.5bis) *is different from* (1.5), *where β had to be greater than $\frac{3}{4}$.*)

Proof. Proceeding as we did in Theorem 1.1 we can show that a solution $u(x, y, t)$ of problem (1.1)-(1.3d) exists, having $u \in H^{\alpha,\alpha/2}(\bar{Q}_T)$. As far as the Hölder continuity of ∇u is concerned, it can be easily obtained representing u_n (u_n is, as usual, the solution of a suitable approximating problem) as the sum of two functions u_{1n}, u_{2n}; the first solves the homogeneous heat equation with the boundary data of u_n and the second solves the heat equation with $\mathbb{H}_n(u_n-1)$ as a source term and zero boundary data. At this point the uniform Hölder continuity of ∇u_n in $\bar{Q}'_T$ is obtained in the following way: we split u_{1n} in two functions $\bar{u}_{1n}$ and $\hat{u}_{1n}$. The first one satisfies the heat equation with the same lateral boundary conditions of u_{1n} and "regular" initial data and the second one satisfies the heat equation with zero lateral boundary conditions and suitable initial data. At this point the desired result follows by applying inequality (10.12) of [6, p. 355] and the corollary at the end of Theorem 9.1 of [6, p. 341] to the boundary value problems satisfied by u_{2n}, $\bar{u}_{1n}$; moreover, since $\hat{u}_{1n}$ can be seen as the restriction to the domain $\bar{Q}_T$ of a function $z(x, y, t)$ solving a Cauchy problem for the heat equation in the half plane $\{t \geqq 0\}$ (z_n is obtained from $\hat{u}_{1n}$ by reflection), the estimates on $\nabla \hat{u}_{1n}$ follow from Theorem 11.1 of [6, p. 211]. As far as the L_2-estimates of u_t, u_{xx}, u_{yy}, u_{xy} are concerned, they can be easily obtained by applying inequality (10.12) of [6, p. 355] to the problem solved by u_n. The estimate of Theorem 1.2 on the Lipschitz continuity of $f(x, t)$ follows from an estimate on u_t analogous to (1.26); this can be obtained as done in Proposition 1.2. In fact, in $\hat{Q}_{1T_1}$ we have that u_n can be written as the sum of two functions u_{1n} and u_{2n}, solutions of the following systems of equations:

$$u_{1nt} - \Delta u_{1n} = 0, \tag{1.34}$$

$$u_{1n} = u_n \quad \text{on } \partial_p \hat{Q}_{1T_1}, \tag{1.35}$$

$$u_{2nt} - \Delta u_{2n} = H_n(u_n - 1), \tag{1.36}$$

$$u_{2n} = 0 \quad \text{on } \partial_p \hat{Q}_{1T_1}. \tag{1.37}$$

Splitting u_{1n} in two functions, $\bar{u}_{1n}$ and $\hat{u}_{1n}$, as done before and using the Green's function to represent $\hat{u}_{1n}$, the first estimate of Theorem 16.3 of [6, p. 413] together with assumptions (1.17b) and (1.5bis) yields the following inequality:

$$|u_{1nt}| \leqq M_1(\varepsilon) + \frac{M_2(\varepsilon)}{t^{(1/2)+\varepsilon}} \quad \forall \varepsilon \in (0, \tfrac{1}{2}),$$

with $M_1(\varepsilon)$ and $M_2(\varepsilon)$ independent of n (again we use the fact that $\hat{u}_{1n}$ can be seen as the restriction to the domain $\overline{Q_T}$ of a function $z_n(x, y, t)$ solving a Cauchy problem for the heat equation in the half plane $\{t \geqq 0\}$).

With regard to u_{2n}, differentiating (1.36) with respect to t, we obtain for $u_{2nt} = v_{2n}$,

$$v_{2nt} - \Delta v_{2n} = H_n'(u_n - 1) v_n,$$

$$v_{2n} = 0 \quad \text{on } \partial \hat{Q}_1 \times [0, T_1],$$

$$v_{2n}(x, y, 0) = H_n(h_n - 1),$$

where $v_n = u_{nt}$.

Let $v_{1n} = u_{1nt}$. Then we have

$$\begin{aligned} v_n = v_{1n} + v_{2n} = v_{1n} &+ \int_0^t \int_{\hat{Q}_1} G(x, y, t, \xi_1, \xi_2, \tau) H_n'(u_n - 1) v_n \, d\xi_1 \, d\xi_2 \, d\tau \\ &+ \int_{\hat{Q}_1} G(x, y, t, \xi_1, \xi_2, 0) H_n(h_n - 1) \, d\xi_1 \, d\xi_2. \end{aligned} \tag{1.38}$$

Using again estimates of Theorem 16.3 of [6], we easily get that

$$\left| \int_{\hat{Q}_1} G(x, y, t, \xi_1, \xi_2, 0) H_n(h_n - 1) \, d\xi_1 \, d\xi_2 \right| \leqq \frac{C(\varepsilon)}{t^{(1/2)+\varepsilon}}, \quad \text{with } \varepsilon \in (0, \tfrac{1}{2}).$$

Hence we have

$$|v_n| \leqq M_3(\varepsilon) + \frac{M_4(\varepsilon)}{t^{(1/2)+\varepsilon}} + \int_0^t \int_{\hat{Q}_1} G(x, y, t, \xi_1, \xi_2, \tau) H_n'(u_n - 1) |v_n| \, d\xi_1 \, d\xi_2 \, d\tau,$$

with $M_3(\varepsilon)$ and $M_4(\varepsilon)$ independent of n.

Let $\hat{v}_n(x, y, t)$ be the solution of the following integral equation:

$$\hat{v}_n = M_3(\varepsilon) + \frac{M_4(\varepsilon)}{t^{(1/2)+\varepsilon}} + \int_0^t \int_{\hat{Q}_1} G(x, y, t, \xi_1, \xi_2, \tau) H_n'(u_n - 1) \hat{v}_n \, d\xi_1 \, d\xi_2 \, d\tau.$$

We have that

$$|v_n| \leqq \hat{v}_n.$$

Moreover, following the procedure of [7, Chap. 3, § 15], we obtain

$$|v_n| \leqq \hat{v}_n \leqq C_1(\varepsilon) + \frac{C_2(\varepsilon)}{t^{(1/2)+\varepsilon}}.$$

Now it is straightforward to prove, by means of standard results on parabolic equations, that the same estimate holds in the whole of the domain Q_{T_1}.

The last inequality allows us to get an analogous estimate for f_{nt} and hence for f_t.

The continuity of the function $f(x, t)$ up to $\{t = 0\}$ is an easy consequence of the assumptions and the Hölder continuity of $u(x, y, t)$. This concludes the proof.

In general it seems possible to extend the proof when $\nabla h \in C^0(\bar{Q})$.

Remark 1.3. It is important to stress that assumptions (1.7) can be relaxed. In fact, we can only require that $A_0 = \{(x, y) \in Q / h(x, y) = 1\}$ is represented by a regular parametric curve

$$\text{(1.7bis)} \qquad \begin{cases} x = x(s), \\ y = y(s), \quad 0 \leqq s \leqq 1, \end{cases}$$

with $x(s), y(s) \in H^{1+\beta}([0, 1])$, $x'^2(s) + y'^2(s) \neq 0$ for all $s \in [0, 1]$ and such that ∇h does not vanish at any point of the curve. As a result, in this case we will get that the interface can be represented by a Lipschitz continuous parametric regular surface of the form

$$x = f(r, t), \quad y = g(r, t) \quad (t \text{ as usual represents the time variable})$$

so that a solution of problem (1.1)-(1.3d) will be now represented by the triplet of functions (u, f, g).

The proof is similar to the one above, except Proposition 1.2. In fact, in this case, we have to divide the domain $\hat{Q}_{1T_1}$, in a finite number of subdomains $(\hat{Q}_{1T_1})_i$, $i = 1, \ldots, N$, such that in each $(\hat{Q}_{1T_1})_i$, at least one between u_x and u_y is always different from zero. This is always possible because of the assumptions and of the Hölder continuity of ∇u. At this point an estimate of the integral (1.29) can be done as in Proposition 1.2.

Remark 1.4. It is important to stress that, as far as we are concerned, with a local existence theorem, the domain Q can be chosen with a different shape as long as it is sufficiently smooth; for example, with its boundary in C^2. In fact, proceeding as we did in Proposition 1.1, we can still prove that ∇u_n is uniformly continuous; then if $\nabla h_n \neq 0$ on A_0 for all $n > N$, it remains different from zero in $U \times [0, \hat{T}]$ with U a suitable neighbourhood of A_0 and $\hat{T}$ sufficiently small. At this point the proof goes on as before.

With regard to the global existence theorems which we will prove in the following section, it is easy to realize that the domain Q, which will be chosen to be a square, can be generalized, and we can consider a more general domain of the form $Q = \{(x, y): 0 < x < 1;\ F_1(x) < y < F_2(x)$, with $F_1(x) < F_2(x)\}$. Global existence of the interface will be proved until it touches one between the surfaces $y = F_i(x)$, $i = 1, 2$.

2. Some cases of global existence. From the previous section we see that, for proving the existence of a "regular" free boundary in Q_T, under the assumptions of Theorem 1.1, the crucial point is to find an estimate which bounds away from zero, uniformly in n, $u_{ny}(x, y, t)$ in Q_T (u_n is, as usual, the solution of the approximating problem (1.13)-(1.15d)). (In general, as we have seen in Remark 1.3, it is sufficient to have one between u_{nx} or u_{ny} bounded away from zero in Q_T.) Following the sketch of the proof of Theorem 1.1 it is easy to prove that, if we have an estimate of the type $u_{ny} > 0$ on the parabolic boundary $\partial_p Q_T$, a "regular" free boundary exists in all Q_T. In fact, if we write down an approximating problem as in Theorem 1.1 and we set $u_{ny} = v_n$, we have that v_n solves the parabolic equation

$$v_{nt} - \Delta v_n = \mathbb{H}'_n(u_n - 1)v_n,$$

and $v_n > 0$ on $\partial_p Q_T$. This implies that $v_n \geqq 0$ in $\overline{Q_T}$. Regarding $\mathbb{H}'_n(u_n - 1)v_n$ as a positive source term and applying the maximum principle, we get $v_n = u_{ny} \geqq \delta > 0$ in $\bar{Q}_T$, with δ independent of n. At this point the global existence theorem we are looking for can be proved by means of the same techniques of Theorem 1.1.

We give below some simple examples. More general results can be proved essentially in the same way. Naturally, it is possible that, in this regard, stronger assumptions on the boundary data have to be done.

(a) Dirichlet Problem.

$$u_t = \Delta u + \mathbb{H}(u-1), \tag{2.1}$$

$$u(x, y, 0) = h(x, y), \tag{2.2}$$

$$u(0, y, t) = K_1(y, t), \tag{2.3a}$$

$$u(1, y, t) = K_2(y, t), \tag{2.3b}$$

$$u(x, 0, t) = K_3(x, t), \tag{2.4a}$$

$$u(x, 1, t) = K_4(x, t), \tag{2.4b}$$

with

$$\begin{cases} h_y(x, y) \geqq \gamma > 0 \quad \text{in } Q \\ K_3(x, t) < 1, \quad K_4(x, t) > 1, \quad K_{1y}(y, t) \geqq \gamma > 0, \\ K_{2y}(y, t) \geqq \gamma > 0 \quad \text{in } (0, 1) \times (0, T). \end{cases} \tag{2.5}$$

If (2.5) and all the assumptions of Theorem 1.1 are satisfied, and if K_3 and K_4 satisfy the following conditions

$$K_{3t} - K_{3xx} \leqq 0, \qquad K_{4t} - K_{4xx} \geqq 1, \tag{2.6}$$

since the approximating boundary data can be chosen such that they still satisfy (2.5), (2.6), an estimate on the sign of u_{ny} on the boundary follows immediately from the maximum principle and Hopf's theorem, and hence a global result can be proved as in the previous section.

Remark 2.1. Let us observe that the first assumption of (2.5) can be relaxed, requiring h_y to be nonnegative in Q and strictly positive on the curve $y = f_0(x)$.

(b) Mixed Problem. A special problem with mixed boundary conditions can be studied in a simple way. In fact, if we consider

$$u_t = \Delta u + \mathbb{H}(u-1), \tag{2.1}$$

$$u(x, y, 0) = h(x, y), \tag{2.2}$$

$$u(0, y, t) = K_1(y, t), \tag{2.3a}$$

$$u(1, y, t) = K_2(y, t), \tag{2.3b}$$

$$u_y(x, 0, t) = K_3(x, t), \tag{2.7a}$$

$$u_y(x, 1, t) = K_4(x, t), \tag{2.7b}$$

under the assumptions (2.5) for $h(x, y)$, $K_1(y, t)$, $K_2(y, t)$, $K_3(x, t) \geqq 0$, and $K_4(x, t) \geqq 0$, the proof follows analogously to the one sketched in the previous case (a).

(c) Neumann Problem.

$$u_t = \Delta u + \mathbb{H}(u-1), \tag{2.1}$$

$$u(x, y, 0) = h(x, y), \tag{2.2}$$

$$u_x(0, y, t) = K_1(y, t), \tag{2.8a}$$

$$u_x(1, y, t) = K_2(y, t), \tag{2.8b}$$

$$u_y(x, 0, t) = K_3(x, t), \tag{2.9a}$$

$$u_y(x, 1, t) = K_4(x, t), \tag{2.9b}$$

with

$$\begin{cases} h_y(x, y) \geqq \gamma > 0, \\ K_{1y}(y, t) < 0, \\ K_{2y}(y, t) > 0, \\ K_3(x, t) \geqq 0, \\ K_4(x, t) \geqq 0. \end{cases} \tag{2.10}$$

Even in this case the regularity follows directly from an estimate on the sign of u_{ny}. Again, this estimate is an immediate consequence of the maximum principle.

3. Uniqueness. In this section we prove an uniqueness result. Let us remark that the right-hand side of (0.1), $\mathbb{H}(*)$ is not Lipschitz continuous and moreover it has the "wrong" sign. Thus the usual techniques cannot be applied (see [9]) and uniqueness turns out not to be a trivial problem.

To make the calculations simpler and to give a more geometrical idea of the techniques applied we will prove uniqueness in a one-dimensional case. (Regularity of the free boundary for the one-dimensional problem follows from [5].)

We assign Dirichlet conditions on the lateral boundary. We stress the fact that this assumption is not essential for our approach.

For the sake of simplicity we introduce the new unknown $u-1$, that we call u again. Let us consider:

$$u_t - u_{xx} = \mathbb{H}(u) \quad \text{in } Q_T = (0, 1) \times (0, T), \tag{3.1}$$

$$u(x, 0) = h(x) \quad \text{in } [0, 1], \tag{3.2}$$

$$u(0, t) = \phi(t) \quad \text{in } [0, T], \tag{3.3}$$

$$u(1, t) = \psi(t) \quad \text{in } [0, T]. \tag{3.4}$$

$$\begin{cases} h(x), \phi(t), \psi(t), \text{ are continuous and } h(x) > 0 \text{ if } x > b, \; h(x) < 0 \\ \text{if } x < b, \; \psi(t) > 0, \; \phi(t) < 0. \text{ Let } u_1(x, t) \text{ and } u_2(x, t) \text{ be} \\ \text{two continuous "weak" solutions in } Q_T \text{ of system (3.1)-(3.4),} \\ \text{(that is, } u_i \in C^0(\bar{Q}_T), \; u_{ixx}, u_{it} \in L_2(Q'_T), \; Q' \subset [0, 1], \; u_{ix} \in C^0(Q_T), \\ i = 1, 2, \text{ and satisfying in a classical sense (3.2)-(3.4) and (3.1) almost} \\ \hfill \text{everywhere).} \\ \text{Let } s_1(t) \text{ and } s_2(t) \text{ represent their level sets } \{u_1 = 0\}, \{u_2 = 0\}, \text{ respectively.} \\ \text{Moreover, let } s_1(t) \text{ and } s_2(t) \text{ be continuous on } [0, T]. \end{cases} \tag{3.5}$$

THEOREM 3.1. *Let (u_1, s_1) and (u_2, s_2) be two solutions of system (3.1)-(3.4) in Q_T, satisfying the assumptions (3.5), and such that either $|u_{1x}| \geqq \gamma > 0$ in a neighbourhood U of s_1 or $|u_{2x}| \geqq \gamma > 0$ in a neighbourhood U of s_2. Then $u_1 \equiv u_2$ and $s_1 \equiv s_2$ in Q_T.*

Proof. Let us put $v := u_2 - u_1$. The function v solves the following problem:

$$\begin{aligned} &v_t - v_{xx} = \mathbb{H}(u_2) - \mathbb{H}(u_1) \quad \text{in } Q_T, \\ &v(x, 0) = v(0, t) = v(1, t) = 0. \end{aligned} \tag{3.6}$$

If $(u_1, s_1) \neq (u_2, s_2)$, we can assume, without loss of generality, that a bifurcation between the two curves $x = s_1(t)$, $x = s_2(t)$ occurs at $t = 0$.

Now $v(x, t)$ can be expressed by means of the Green function $G(x; t; \xi, \tau)$, and we have

$$v(x, t) = \int_0^t d\tau \int_0^1 G(x; t; \xi; \tau) f(\xi, \tau)\, d\xi, \tag{3.7}$$

where $f(x, t) = \mathbb{H}(u_2) - \mathbb{H}(u_1)$, and then $|f(x, t)| = \chi_{Q_{1,2}}$ ($\chi_{Q_{1,2}}$ is the characteristic function of $Q_{1,2} = \{(x, t) \in Q_T\colon s_i(t) \leqq x \leqq s_j(t);\ i, j = 1, 2;\ s_j(t) > s_i(t);\ 0 \leqq t \leqq T\}$). Because of the assumptions we have made, we can also assume that $|u_{1x}| \geqq \gamma > 0$ in $Q_{1,2}$.

Then we have

$$\begin{aligned} |u_1(s_2(t), t) - u_2(s_2(t), t)| &= |u_1(s_2(t), t)| = |u_1(s_2(t), t) - u_1(s_1(t), t)| \\ &\geqq \gamma |s_2(t) - s_1(t)|. \end{aligned}$$

This last inequality is a consequence of the Lagrange mean value theorem and of the assumptions we have made. Hence

$$\begin{aligned} |v(x, t)| &\leqq C \left| \int_0^t \int_0^1 (t-\tau)^{-1/2} \exp\left(\frac{-C(|x-\xi|^2)}{(t-\tau)} \right) \chi_{Q_{1,2}}\, d\xi\, d\tau \right| \\ &\leqq C_1 \int_0^t \frac{|s_1(\tau) - s_2(\tau)|}{\sqrt{t-\tau}}\, d\tau \\ &\leqq C_1 \int_0^t \frac{|u_1(s_2(\tau), \tau) - u_2(s_2(\tau), \tau)|}{\gamma} \frac{1}{\sqrt{t-\tau}}\, d\tau \\ &= C_1 \int_0^t \frac{\|u_1 - u_2\|_{C^0(Q_T)}}{\gamma \sqrt{t-\tau}}\, d\tau. \end{aligned}$$

Then

$$\|u_1 - u_2\|_{C^0(Q_T)} \leqq C_1 \frac{2\sqrt{T}}{\gamma} \|u_1 - u_2\|_{C^0(Q_T)},$$

which for a sufficiently small T gives an absurdum, implying $(u_1, s_1) \equiv (u_2, s_2)$.

Using the same techniques, an equivalent uniqueness theorem can be obtained in the multidimensional case. Let u_1 and u_2 be two "weak" solutions of (1.1)-(1.3d), continuous on $\bar{Q}_T$ and such that their level sets $\{u_1 = 1\}$ and $\{u_2 = 1\}$ have a parametric representation (according to Remark 1.3) $x = f_i(r, t)$, $y = g_i(r, t)$, $i = 1, 2$.

(Let $\hat{S}$ be one between the graphs represented by the parametric surfaces ($x = f_i$; $y = g_i$, $i = 1, 2$), for example, $x = f_1$, $y = g_1$.)

For such solutions the following theorem holds.

THEOREM 3.2. *Let* (u_1, f_1, g_1) *and* (u_2, f_2, g_2) *be two solutions of system* (1.1)-(1.3d) *in* Q_T, *with* u_1 *and* u_2 *continuous on* $\overline{Q_T}$, ∇u_1, $\nabla u_2 \in C^0(\bar{Q}'_T)$, (*with* Q' *as in Theorem* 1.1), f_i *and* g_i *Lipschitz continuous for* $i = 1, 2$; *let, moreover,* $\hat{S}$ *satisfy this condition*: *for all* $P \in \hat{S}$ *at least one of the two assertions holds*:

(a) *There exists an open set* V *such that* $P \in V$; $|u_{1x}| \geqq \gamma > 0$ *in* V *and* $\hat{S}$ *is represented in* V *by a function of the form* $x = F_1(y, t)$;

(b) *There exists an open set* V *such that* $P \in V$; $|u_{1y}| \geqq \gamma > 0$ *in* V *and* $\hat{S}$ *is represented in* V *by a function of the form* $y = G_1(x, t)$; *then* $u_1 \equiv u_2$ *in* Q_T.

(An analogous statement holds if we assume $\hat{S}$ to be the graph represented by $x = f_2$, $y = g_2$.)

We want to stress that this uniqueness theorem implies that the whole sequence of approximating solutions (u_n, f_n) found in § 1 converges, so that the technique displayed in Theorem 1.1 is constructive.

4. Continuous dependence on the data. To fix the basic ideas of the proof, we prove a local continuous dependence theorem for a Dirichlet problem. This means that any solution $u(x, y, t)$, as in Theorem 1.1, depends continuously from the initial and boundary data in a domain Q_{T_1} with T_1 suitably small (naturally T_1 is independent of the particular solution $u(x, y, t)$ chosen). Moreover, we can observe that, in general, if the boundary data satisfy conditions which guarantee the existence of solutions of problem (1.1)-(1.3d) having Lipschitz continuous interfaces in Q_T, represented as functions of the (x, t) variables and such that in their neighbourhood $u_y \geqq \delta > 0$, then our local existence theorem become global (that is, it holds in all Q_T). Other initial boundary value problems can be treated similarly.

THEOREM 4.1. *Let* ${}_1u$ *and* ${}_2u$ *be two functions satisfying* (1.1)-(1.3d) *in the sense specified in Theorem* 1.1, *in* Q_{T_1}, *for a suitable* $T_1 > 0$, *with the same regularity as in Theorem* 1.1. *Let* $y = {}_1f(x, t)$ *and* $y = {}_2f(x, t)$ *be the functions that represent the level sets* $\{{}_1u = 1\}$ *and* $\{{}_2u = 1\}$, *respectively. We assume that* (1.4)-(1.9) *hold and that* ${}_1f$, ${}_2f$ *have the same regularity as in Theorem* 1.1.

Then for each $\hat{\varepsilon} > 0$, $\varepsilon' > 0$ *a* $\delta > 0$ *exists such that if*

(4.1) $$|{}_1h - {}_2h|_{Q}^{(1+\beta)} \leqq \delta,$$

(4.2) $$|{}_1K_i - {}_2K_i|^{(\beta)}_{([0,1]\times[0,T_1])} \leqq \delta, \qquad i = 1, \dots, 4,$$

(4.3) $$|{}_1K_{iy} - {}_2K_{iy}|^{(\beta)}_{([0,1]\times[0,T_1])} \leqq \delta, \qquad i = 1, 2, \beta > \tfrac{3}{4},$$

(4.4) $$\|{}_1K_{it} - {}_2K_{it}\|_{q,((0,1)\times(0,T_1))} \leqq \delta, \qquad i = 1, \dots, 4, \quad q > 4,$$

then

(4.5) $$\|{}_1u - {}_2u\|_{C^0(\bar{Q}_{T_1})} \leqq \hat{\varepsilon},$$

(4.6) $|{}_1u - {}_2u|^{(1+\gamma)}_{(\bar{Q}'_{T_1})} \leqq \hat{\varepsilon}$, *with* $Q' = (0, 1) \times (\varepsilon', 1 - \varepsilon')$ *and* $\gamma = \min(\beta, 1 - 4/q)$,

(4.6bis) $$\|{}_1u - {}_2u\|^{(2)}_{3,Q'_T} \leqq \hat{\varepsilon},$$

(4.7) $\|{}_1u - {}_2u\|^{(2)}_{q,D} \leqq \hat{\varepsilon}$, *where* D *is a domain strictly contained in* Q_T $\forall q > 2$,

(4.7bis) $$\|{}_1u_t - {}_2u_t\|_{C^0(Q'\times[\tau,T_1])} \leqq \hat{\varepsilon},$$

(4.8) $$\|{}_1f - {}_2f\|_{C^0([0,1]\times[0,T_1])} \leqq \hat{\varepsilon},$$

(4.9) $$|{}_1f_x - {}_2f_x|^{(\gamma)}_{([0,1]\times[0,T_1])} \leqq \hat{\varepsilon}.$$

Proof. Let us consider the system of equations satisfied by $w = {}_1u - {}_2u$. We have that $w(x, y, t)$ can be expressed as the sum of two functions w_1, w_2 such that w_1 satisfies the homogeneous heat equation with the same boundary and initial data of w and w_2 satisfies the equation

$$w_{2t} - \Delta w_2 = \mathbb{H}({}_1u - 1) - \mathbb{H}({}_2u - 1) \tag{4.10}$$

with zero boundary and initial data.

As far as w_1 is concerned, we can easily get (by means of a standard maximum principle) that

$$\|w_1\|_{C^0(Q_{T_1})} \leqq \delta. \tag{4.11}$$

We now find an estimate for w_2, solution of (4.10). Using the Green function we get that

$$|w_2(x, y, t)| \leqq \int_0^t d\tau \int_Q |G(x, y, t, \xi_1, \xi_2, \tau)| \chi_{Q_{1,2}} \, d\xi_1 \, d\xi_2, \tag{4.12}$$

where $\chi_{Q_{1,2}}$ is the characteristic function of $Q_{1,2} = \{(x, y, t) \in Q_T\colon {}_if(x, t) \leqq y \leqq {}_jf(x, t)$; $i, j = 1, 2$; ${}_jf(x, t) > {}_if(x, t)$; $0 \leqq x \leqq 1$; $0 \leqq t \leqq T_1\}$. Since we are proving a local continuous dependence, there is no loss of generality in assuming that for a suitable T_1 and sufficiently small γ, both the graphs of ${}_1f(x, t)$ and ${}_2f(x, t)$ lie in a region where ${}_1u_y$, ${}_2u_y \geqq \gamma > 0$.

We have

$$\begin{aligned} |{}_1u(x, {}_2f(x, t), t) - {}_2u(x, {}_2f(x, t), t)| &= |u_1(x, {}_2f(x, t), t) - 1| \\ &= |u_1(x, {}_2f(x, t), t) - u_1(x, {}_1f(x, t), t)| \\ &\geqq \gamma |{}_1f(x, t) - {}_2f(x, t)|. \end{aligned}$$

This last inequality is a consequence of the Lagrange mean value theorem.

Hence we get

$$\|u_1 - u_2\|_{C^0(Q_{T_1})} \geqq \gamma |{}_1f(x, t) - {}_2f(x, t)|. \tag{4.13}$$

This implies that, using (4.12),

$$\|w_2\|_{C^0(Q_t)} \leqq \frac{C}{\gamma} \int_0^t \int_0^1 (t-\tau)^{-1} \exp\left(\frac{-C(|x-\xi_1|^2)}{(t-\tau)}\right) \|{}_1u - {}_2u\|_{C^0(Q_\tau)} \, d\xi_1 \, d\tau.$$

Hence

$$\|w\|_{C^0(Q_t)} \leqq \|w_1\|_{C^0(Q_{T_1})} + C_1 \int_0^1 (t-\tau)^{-3/4} \|w\|_{C^0(Q_T)} \, d\tau.$$

Now, using (4.11), we easily get (4.5), and then, because of (4.13), we also get (4.8).

At this point it is easy to realize that (4.6) holds true, in fact from (4.8) we get that w satisfies a parabolic equation whose source term is bounded and different from zero only between ${}_1f$ and ${}_2f$, that is, in a region whose measure can be made as small as we want choosing a sufficiently small δ. At this point, using inequality (10.12) p. 355 of [6], and the corollary at the end of Theorem 9.1, p. 341 of [6], (4.6) and (4.7) follow immediately, and hence (4.9).

As far as (4.7bis) is concerned, it can be easily obtained using (4.6bis), Proposition 1.4a and Remark 1.4b, since it is simple to prove that two functions which are uniformly Hölder continuous and are "near" in the L_2-norm are also "near" in the C^0-norm.

Using (4.7bis) and (4.8) and setting $W \equiv {}_1u(x, y, \bar{t}) - {}_2u(x, y, \bar{t})$, we have that $W(x, y)$ satisfies an elliptic equation of the kind $\Delta W = \hat{F}_{\bar{t}}$ in Q, where $\|\hat{F}\|_{q,Q''}$, $q \geqq 2$, can be made as small as we want for all $\bar{t} > 0$ and $Q'' \subset \subset Q$ taking δ sufficiently small.

Then, using inequality (10.11) of Theorem 10.1 of [11, p. 173], we have that for all $\bar{t} \in (0, T_1] \| W \|^{(2)}_{2,Q''} \leqq \varepsilon$.

Naturally in this regard δ will depend on $\bar{t}$ and on $d \equiv \text{dist}(Q'', \partial Q)$.

We have proved a local continuous dependence theorem under the assumptions of Theorem 1.1. Actually, following step by step the sketch of the proof, we get continuous dependence theorems in the other cases we have treated in this paper, and in particular we have a global continuous dependence theorem in all the cases in which we have proved a global existence theorem (at least until one of the interfaces of the two solutions touches one of the boundary planes $\{y=0\}$; $\{y=1\}$).

In particular, using the same techniques, we get a local continuous dependence theorem in the case of Remark 1.3.

We want to stress again that the local existence theorem as well as the uniqueness and continuous dependence theorems that we have proved for the two-dimensional case can be obtained in the same way in the general N-dimensional case. Naturally, additional technical complications and some extra assumptions are required to prove global existence theorems in the N-dimensional case.

THIN PLATES AND COMPRESSIVE MEMBRANE SOLUTIONS II: A NONEXISTENCE RESULT*

M. E. BREWSTER†

Abstract. It is proved that there is no sequence of solutions of the radially-symmetric von Kármán thin plate equations with non–self-equilibrating pressure load and clamped boundary conditions that has compressive Föppl membrane asymptotics.

Key words. thin plates, compressive membranes, singular perturbations, nonexistence

AMS subject classifications. 34E20, 73K10

1. Introduction.

The deflection of a thin plate can be described by a singular perturbation problem that reduces to the membrane problem for infinitesimal thickness. In [2] formal asymptotic expansions of the plate deflection based on compressive membrane solutions were derived when the edge of the plate is elastically supported against rotation. Also, it was observed that asymptotics based on compressive Föppl membrane theory failed for the clamped plate. In this paper, we present a rigorous proof to support the conjecture that clamped plate solutions do not have compressive Föppl membrane asymptotics.

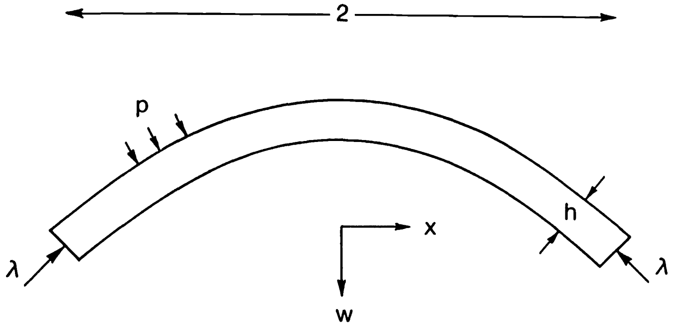

FIG. 1

We consider a thin circular plate subject to a vertical deflection $w(x)$ for $x \in [0, 1]$, where x is radial position (see Fig. 1). The constant h is proportional to the thickness-to-radius ratio. A transverse pressure load $p(x)$ and a radial compressive stress λ at the edge ($x = 1$) are imposed. We consider radially-symmetric solutions where the radial stress $v(x)$ is compressive (positive).

The equations of the von Kármán theory (cf. [10]), a nonlinear model that neglects shear stress, are

$$h^2\left(\frac{d^2u}{dx^2}+\frac{3}{x}\frac{du}{dx}\right)+uv=g(x), \tag{1a}$$

$$\frac{d^2v}{dx^2}+\frac{3}{x}\frac{dv}{dx}=u^2, \tag{1b}$$

where

$$u=\frac{1}{x}\frac{dw}{dx}, \qquad g(x)=\frac{1}{hx^2}\int_0^x sp(s)ds.$$

We assume that the pressure load is non–self-equilibrating; that is, $g(1)\neq 0$. The variables may be rescaled according to the magnitude of g; thus, without loss of generality, we assume

$$g(1)=1. \tag{2}$$

The boundary conditions at $x=0$ ensure smoothness at the origin:

$$\frac{dv}{dx}(0)=0, \qquad \frac{du}{dx}(0)=0. \tag{3}$$

At the edge of the plate, we specify the radial stress and also impose the clamped-edge condition:

$$v(1)=\lambda, \tag{4a}$$

$$u(1)=0. \tag{4b}$$

The Föppl membrane equations are obtained by setting $h=0$ in (1a), (1b). From (1a) we get

$$u_0v_0=g(x), \tag{5a}$$

and by eliminating u between (5a) and (1b),

$$\frac{d^2v_0}{dx^2}+\frac{3}{x}\frac{dv_0}{dx}=\frac{g^2(x)}{v_0^2}, \tag{5b}$$

where the zero subscript denotes a membrane solution. We cannot satisfy all of the boundary conditions of the plate problem—we choose

$$\frac{dv_0}{dx}(0)=0, \qquad v_0(1)=\lambda_0. \tag{6}$$

Some background on these problems is given in [1]. The result we will make use of is the existence of compressive ($\lambda>0$) membrane solutions (see [3]).

2. Review of attempts at formal asymptotics. We briefly recall from [2] the attempts to derive formal asymptotic expansions for the clamped plate with compressive radial stress. Let (u_0, v_0) be a compressive solution of the Föppl membrane equations (5). We consider an expansion based on (u_0, v_0):

$$u(x;h) = u_0(x) + x^{-3/2}w(x;h), \tag{7}$$

$$v(x;h) = v_0(x) + v_1(x;h), \tag{8}$$

where we assume $w \ll u_0$, $v_1 \ll v_0$, and $v_0 > 0$. (The w in (7) should not be confused with the vertical deflection.) Then the plate equations (1a), (1b) become

$$h^2\frac{d^2w}{dx^2} + v_0w = -(w + x^{3/2}u_0)v_1 + h^2\left(\frac{3}{4x^2}w - x^{-3/2}\frac{d}{dx}\left(x^3\frac{du_0}{dx}\right)\right), \tag{9}$$

$$\frac{d^2v_1}{dx^2} + \frac{3}{x}\frac{dv_1}{dx} = 2x^{-3/2}wu_0 + x^{-3}w^2. \tag{10}$$

Assuming the right-hand side of (9) is negligible, then the WKBJ approximation is

$$w \sim \frac{c}{v_0^{1/4}}\cos(\tilde{x} + \phi), \qquad c \ll 1, \tag{11}$$

where

$$\tilde{x} = \frac{1}{h}\int^x v_0^{1/2}(s)ds. \tag{12}$$

But the assumption that $c \ll 1$ implies the clamped boundary condition (4b) cannot be satisfied, since

$$u_0(1) = \frac{g(1)}{v_0(1)} = \frac{1}{\lambda_0} \neq 0. \tag{13}$$

We may attempt a WKBJ-like construction for the clamped plate if we drop the assumption that the leading-order term is the Föppl membrane solution. We suppose

$$v(x) \sim v_0(x) + O(h^2)$$

with $v_0 > 0$ and $v_0 = O(1)$ as $h \to 0$, $x > 0$. Then

$$u(x) \sim \frac{g}{v_0} + \frac{\kappa}{x^{3/2}v_0^{1/4}}\cos(\tilde{x} + \phi), \tag{14}$$

where $\tilde{x}$ is defined in (12).

To satisfy the clamped boundary condition (4b), we must have

$$\frac{g(1)}{\lambda} + \frac{\kappa}{\lambda^{1/4}}\cos\theta = 0,$$

where $\theta = \tilde{x} + \phi$ evaluated at $x = 1$. Thus,

$$\kappa = -\frac{g(1)}{\lambda^{3/4}\cos\theta}.$$

Assuming $g(1) \neq 0$, then $\kappa \neq 0$. Observe that the oscillatory term in (14) is $O(1)$.

Upon substitution of (14), (1b) becomes

$$\frac{d^2v}{dx^2} + \frac{3}{x}\frac{dv}{dx} \sim \frac{g^2}{v_0^2} + \frac{\kappa^2}{2x^3 v_0^{1/2}}(\cos(2\tilde{x} + 2\phi) + 1) - \frac{2g\kappa}{x^{3/2}v_0^{5/4}}\cos(\tilde{x} + \phi). \tag{15}$$

The expansion

$$v(x) \sim v_0(x) - h^2 \frac{\kappa^2}{8x^3 v_0^{5/2}} \cos(2\tilde{x} + 2\phi) - h^2 \frac{2g\kappa}{x^{3/2} v_0^{9/4}} \cos(\tilde{x} + \phi)$$

satisfies (15) to leading order provided

$$\frac{d^2v_0}{dx^2} + \frac{3}{x}\frac{dv_0}{dx} = \frac{g^2}{v_0^2} + \frac{\kappa^2}{2x^3 v_0^{1/2}}. \tag{16}$$

It is shown in [2] that (16) has no solutions that are bounded at the origin, and, furthermore, solutions of (16) satisfy

$$v_0'(x) \to -\infty \quad \text{as } x \to 0.$$

Such a function cannot provide a valid asymptotic expansion for solutions of (1), (3), as the formula

$$x^3 v'(x) = \int_0^x s^3 u^2(s) ds$$

demonstrates that $v'(x) > 0$ for all $x > 0$.

3. Statement of nonexistence result. Standard usage of the term "asymptotic" is well understood and precise when used in a positive sense; an asymptotic formula is stated, which may be verified according to, for example, the definition of [4]. Our result, however, is a negative result and it is not so clear what is meant by the nonexistence of an asymptotic expansion based on a given family of outer (membrane) solutions. It is not possible to list or construct all candidates for an expansion; in addition to the classical boundary layer [6], there exist the possibilities of internal layers [8], global breakdown [2], combinations of the above, or perhaps something entirely new. Because of these difficulties, we formulate a definition of "compressive membrane asymptotics" based on the principles of membrane theory.

The stresses employed in membrane theory—the radial stress, v, and the hoopstress $(xv)'$—will be assumed to be bounded (as $h \to 0$). In von Kármán plate theory, the bending stress, $h(u' + (1+\nu)u)$ is included. For membrane theory, the thickness h is zero; thus, the bending stress must be negligible as $h \to 0$. The balance of forces to produce equilibrium, given in the membrane theory by (5a), will be assumed to hold to leading order. To ensure that we are considering compressive membrane states, the radial stress v is assumed positive and bounded away from zero. These conditions are assumed to hold in the least restrictive sense possible—at a point. For purposes of simplifying the proof we will assume that, while the point at which these hypotheses hold is not necessarily fixed, the set of such points must be bounded away from the center of the plate ($x = 0$). At the end of this section, we discuss the relaxation of the last hypothesis.

The conditions described above are incorporated in the following.

DEFINITION. We say that a sequence $\{u_n, v_n, h_n\}$ of solutions of the plate equations (1a), (1b) has compressive membrane asymptotics if

(i) As $n \to \infty$,

$$h_n \to 0; \tag{17}$$

(ii) For some m, $C > 0$, x_0 and points $\{x_n\}$,

$$0 < x_0 < x_n \leq 1, \tag{18a}$$

$$v_n(x_n) \geq m > 0, \tag{18b}$$

$$|v_n(x_n)| + |v_n'(x_n)| \leq C \quad \text{for } n = 1, 2, \dots, \tag{18c}$$

$$|u_n(x_n)v_n(x_n) - g(x_n)| + |h_n u_n'(x_n)| \to 0 \quad \text{as } n \to \infty. \tag{18d}$$

Here is the nonexistence theorem, to be proved in the following sections.

THEOREM 1. *Let $g(x)$ be twice continuously differentiable on $[0,1]$ and $g(1)$ be nonzero. Then there does not exist a sequence of solutions of the clamped plate problem $(1), (3), (4)$ that has compressive membrane asymptotics.*

For technical reasons, the case $x_n \to 0$ was excluded in (18a). We consider here a formal argument to support the conjecture that Theorem 1 would still hold if (18a) were relaxed. The asymptotic formula for solutions of (1a), (1b) derived in [2] is

$$u(x;h) \sim u_0(x) + \frac{c}{x^{3/2} v_0^{1/4}(x)} \sqrt{\frac{\pi}{2}}\, \tilde{x}^{1/2} J_1(\tilde{x}), \tag{19}$$

$$v(x,h) \sim v_0(x), \tag{20}$$

where $\tilde{x}$ is defined in (12). This formula is valid for all $x \in [0,1]$, provided $c \ll h^{1/2}$. Then for $\tilde{x} = O(1)$,

$$|uv - g| + |hu'| \sim O\left(\frac{c}{h^{3/2}}\right)\left(\frac{1}{\tilde{x}} J_1(\tilde{x})\right)' + O\left(\frac{c}{h^{1/2}}\right)\frac{1}{\tilde{x}} J_1(\tilde{x}). \tag{21}$$

Supposing (18d) to hold with $(h_n)^{-1}x_n = O(1)$, then we must have $c \ll h^{1/2}$, at most. Thus (19) gives

$$u(x) - u_0(x) \ll h^{1/2} \quad \text{for } x = O(1), \quad x > 0, \tag{22}$$

which is a *stronger* result than we get in the proof of Theorem 1 as stated. In particular, if $u_0(1) \neq 0$, then the clamped edge condition cannot be satisfied.

In the following two sections, we develop some transformations and lemmas that are needed in the proof of Theorem 1, which is carried out in §6. In §4, we transform the von Kármán plate equations (1a), (1b) into a first-order "fast-slow" system. That is, the variables depending essentially on the "slow" scale (x) are separated from the variables depending on the "fast" scale (x/h). These transformations are motivated by the formal asymptotic expansion for the case of elastically-supported boundary conditions presented in [2]. Lemmas 1 and 2, which are stated and proved in §5, provide a justification of the formal asymptotics (11) when the hypotheses (17), (18) are satisfied. When the clamped edge boundary condition is also assumed to hold, as in Theorem 1, then (13) provides a contradiction.

4. Transformations. We consider the deviation of the plate solutions from a given compressive membrane solution (u_0, v_0) satisfying the Föppl membrane equations (5) on $(\xi_0, 1]$ with $\xi_0 \geq 0$ and v_0 positive on $(\xi_0, 1]$. Following the formal asymptotics above, and motivated by transformations in [7], we define

$$u_1(t) = v_0^{1/4} x^{3/2}(u - u_0), \qquad v_1(t) = v_0^{1/4} x^{3/2}(v - v_0), \tag{23}$$

where

$$t = \int_{\xi_1}^{x} v_0^{1/2}(s)ds \tag{24}$$

with $\xi_0 < \xi_1 \leq 1$. The interval $(\xi_0, 1]$ maps onto $(T_0, T_1]$ under the change of variables (24), where $T_0 \geq -\infty$ and $0 \leq T_1 < +\infty$. Upon substitution into (1a), (1b), we have

$$h^2 \frac{d^2 u_1}{dt^2} + u_1 + \beta v_1 = -\gamma u_1 v_1 + h^2 q - h^2 \alpha u_1, \tag{25a}$$

$$\frac{d^2 v_1}{dt^2} - 2\beta u_1 + \alpha v_1 = \gamma u_1^2, \tag{25b}$$

for $t \in (T_0, T_1]$, where $\alpha(t), q(t)$, and $\gamma(t) \in C(T_0, T_1]$, and

$$\beta(t) = \frac{g(x)}{v_0^2(x)} \in C^1(T_0, T_1]. \tag{26}$$

Formulas for α, q, and γ are given in Appendix A.

We now convert these two second-order equations into a first-order "fast-slow" system by the substitution of

$$\mathbf{z}_I = \begin{pmatrix} u_1 + \beta v_1 \\ h\frac{d}{dt}u_1 \end{pmatrix}, \qquad \mathbf{z}_{II} = \begin{pmatrix} v_1 \\ \frac{d}{dt}v_1 + 2h^2\beta\frac{d}{dt}u_1 \end{pmatrix} \tag{27}$$

into (26a), (26b) to give

$$h\frac{d}{dt}\mathbf{z}_I = B\left(\mathbf{z}_I + Q(t, \mathbf{z}_I, \mathbf{z}_{II})\right) + hF_I(t, \mathbf{z}_I, \mathbf{z}_{II}; h), \tag{28a}$$

$$\frac{d}{dt}\mathbf{z}_{II} = A\mathbf{z}_{II} + F_{II}(t, \mathbf{z}_I, \mathbf{z}_{II}; h), \tag{28b}$$

where $A(t)$ is continuous on $(T_0, T_1]$,

$$B = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \quad \text{and} \quad Q(t, \mathbf{x}, \mathbf{y}) = \begin{pmatrix} \gamma(x_1 - \beta y_1)y_1 \\ h\left(\frac{d\beta}{dt}y_1 + \beta y_2\right) \end{pmatrix}. \tag{29}$$

The $O(h^0)$ linear terms in (28a), (28b) are $B\mathbf{z}_I$ and $A\mathbf{z}_{II}$, respectively; thus the "fast" system (28a) and the "slow" system (28b) decouple at this level. Quadratic terms are contained in Q and F_{II}. Also, terms that are $o(h^0)$ appear in F_I, F_{II}, and Q. The formulas for these terms are given in Appendix A.

5. Properties of the fast-slow system. In this section, we derive some results concerning the asymptotic behavior of solutions of a class of fast-slow systems that contains (28) as a special case. Consider the system

$$h\frac{d}{dt}\mathbf{z}_I = B\left(\mathbf{z}_I + \nabla_I\phi(t,\mathbf{z}_I,\mathbf{z}_{II};h)\right) + hF_I(t,\mathbf{z}_I,\mathbf{z}_{II};h), \tag{30a}$$

$$\frac{d}{dt}\mathbf{z}_{II} = A(t)\mathbf{z}_{II} + F_{II}(t,\mathbf{z}_I,\mathbf{z}_{II};h), \tag{30b}$$

where ∇_I represents the gradient with respect to the "fast" components, $\mathbf{z}_I$. The vectors $\mathbf{z}_I, \mathbf{z}_{II}$ are of arbitrary finite dimension, and the matrix B is assumed to be antisymmetric, which implies the eigenvalues are pure imaginary. To ensure the existence of solutions of (30), the right-hand side of (30) is assumed to depend continuously on $t \in [\tau_0, T_1]$ and $\mathbf{z}_I, \mathbf{z}_{II}$ whenever $|\mathbf{z}_I| + |\mathbf{z}_{II}| < C_0$ for some $C_0 > 0$. The notation $|\cdot|$ represents the Euclidean vector norm. Further, suppose that for $J = I, II$,

$$F_J(t,\mathbf{z}_I,\mathbf{z}_{II},h) = O\left((|\mathbf{z}_I| + |\mathbf{z}_{II}|)^2\right) + o(h^0) \quad \text{as } h, |\mathbf{z}_I|, |\mathbf{z}_{II}| \to 0; \tag{31}$$

that is, there exist positive constants C_1, C_2 such that

$$|F_J(t,\mathbf{z}_I,\mathbf{z}_{II},h)| \le C_1\left((|\mathbf{z}_I| + |\mathbf{z}_{II}|)^2\right) + \psi(h)$$

whenever $t \in [\tau_0, T_1]$ and $h + |\mathbf{z}_I| + |\mathbf{z}_{II}| < C_2$, where

$$\psi(h) \downarrow 0 \quad \text{as } h \to 0.$$

Also, suppose that

$$\begin{gathered} \phi = O\left((|\mathbf{z}_I| + |\mathbf{z}_{II}|)^3\right) + o(h^0), \\ \frac{\partial\phi}{\partial t} = O\left((|\mathbf{z}_I| + |\mathbf{z}_{II}|)^3\right) + o(h^0), \\ \nabla_J\phi = O\left((|\mathbf{z}_I| + |\mathbf{z}_{II}|)^2\right) + o(h^0) \end{gathered} \tag{32}$$

as $h, |\mathbf{z}_I|, |\mathbf{z}_{II}| \to 0, \quad J = I, II$.

We begin with a formal asymptotic study of (30) assuming $h \to 0$ and that the solution is also small. Thus we neglect nonlinear terms and terms that are $o(h^0)$ to obtain

$$h\frac{d}{dt}\mathbf{z}_I = B\mathbf{z}_I, \tag{33a}$$

$$\frac{d}{dt}\mathbf{z}_{II} = A(t)\mathbf{z}_{II}. \tag{33b}$$

Given functions $\mathbf{z}_I, \mathbf{z}_{II}$ on $[\tau_0, T_1]$, we define a scalar function

$$\mathcal{A}(t) = \left(|\mathbf{z}_I(t)|^2 + |X^{-1}(t)\mathbf{z}_{II}(t)|^2\right)^{1/2}, \tag{34}$$

where X is a fundamental matrix solution of (33b) with $X(T_1) = I$. Because A is continuous on $[\tau_0, T_1]$, then X is invertible on this interval and $\mathcal{A}$ is well defined. If $(\mathbf{z}_I, \mathbf{z}_{II})$ is a solution of (30), then

$$\frac{1}{2}\frac{d}{dt}\mathcal{A}^2 = \frac{1}{h}\mathbf{z}_I^T B\mathbf{z}_I + \mathbf{z}_{II}^T X^{-1T}\left((X^{-1})'\mathbf{z}_{II} + X^{-1}A\mathbf{z}_{II}\right). \tag{35}$$

Because B is antisymmetric, $\mathbf{z}_I^T B \mathbf{z}_I = 0$. Also, from

$$X' = AX,$$

we obtain

$$(X^{-1})' = -X^{-1}A.$$

Hence,

$$\frac{d}{dt}\mathcal{A}^2 = 0;$$

that is, $\mathcal{A}$ is a constant.

Next, we consider the full system (30). Let $(\mathbf{z}_I, \mathbf{z}_{II})$ be a solution of (30) and define $\mathcal{A}$ by (34) as before. Then

$$\frac{1}{2}\frac{d}{dt}\mathcal{A}^2 = \mathbf{z}_I^T \frac{d}{dt}\mathbf{z}_{II} + (X^{-1}\mathbf{z}_{II})^T X^{-1} F_{II}. \tag{36}$$

Now

$$\mathbf{z}_I^T \frac{d}{dt}\mathbf{z}_I = (\mathbf{z}_I + \nabla_I \phi)^T \frac{d}{dt}\mathbf{z}_I - \nabla_I \phi^T \frac{d}{dt}\mathbf{z}_I,$$

and substitution from (30a) gives

$$\begin{aligned}\mathbf{z}_I^T \frac{d}{dt}\mathbf{z}_I &= (\mathbf{z}_I + \nabla_I \phi)^T \left(\frac{1}{h}\, B(\mathbf{z}_I + \nabla_I \phi) + F_I\right) - \nabla_I \phi^T \frac{d}{dt}\mathbf{z}_I,\\ &= F_I^T(\mathbf{z}_I + \nabla_I \phi) - \nabla_I \phi^T \frac{d}{dt}\mathbf{z}_I,\end{aligned}$$

where we have used the assumption that B is antisymmetric to eliminate the $O(h^{-1})$ term. Thus,

$$\frac{1}{2}\frac{d}{dt}\mathcal{A}^2 = F_I^T(\mathbf{z}_I + \nabla_I \phi) - \nabla_I \phi^T \frac{d}{dt}\mathbf{z}_I + (X^{-1}\mathbf{z}_{II})^T X^{-1} F_{II}. \tag{37}$$

Integrating from τ to t gives

$$\mathcal{A}^2(t) - \mathcal{A}^2(\tau) = -2(\phi(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h) - \phi(\tau, \mathbf{z}_I(\tau), \mathbf{z}_{II}(\tau); h)) + 2\int_\tau^t f(s)ds, \tag{38}$$

where

$$\begin{aligned} f(t) =& F_I^T\,(t, \mathbf{z}_I(t), \mathbf{z}_I(t); h)\,(\mathbf{z}_I(t) + \nabla_I \phi(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h))\\ &+ \frac{\partial \phi}{\partial t}(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h)\\ &+ \nabla_{II}\phi(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h)\,(A(t)\mathbf{z}_{II}(t) + F_{II}(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h))\\ &+ (X^{-1}(t)\mathbf{z}_{II}(t))^T\, X^{-1}(t) F_{II}(t, \mathbf{z}_I(t), \mathbf{z}_{II}(t); h).\end{aligned} \tag{39}$$

We now derive from the integral equation (38) an integral inequality for $\mathcal{A}(t)$. First, note that since $X^{-1}(t)$ is bounded on $[\tau_0, T_1]$, then the definition of $\mathcal{A}$, (34), implies

$$\mathbf{z}_I(t) = O(\mathcal{A}(t)) \quad \text{and} \quad \mathbf{z}_{II}(t) = O(\mathcal{A}(t)) \tag{40}$$

for $t \in [\tau_0, T_1]$. From (40), hypotheses (31), (32) and the integral equation (38), there exist positive constants C_1, C_2, independent of h, such that

$$\mathcal{A}^2(t) - \mathcal{A}^2(\tau) \leq C_1 \left(\mathcal{A}^3(t) + \mathcal{A}^3(\tau)\right) + C_1 \int_\tau^t \mathcal{A}^3(s)ds + \psi(h) \tag{41}$$

whenever

$$h + \mathcal{A}(s) \leq C_2 \tag{42}$$

for all $s \in [\tau, t]$ with $\tau_0 \leq \tau \leq t \leq T_1$, where

$$\psi(h) \downarrow 0 \quad \text{as } h \to 0.$$

We now present Lemma 1, which will be used in the proof of our second lemma on the validity of the formal asymptotic expansion (7), (8). The proof of Lemma 1 is given in Appendix B.

LEMMA 1. *Let $z(s) \geq 0$ be a continuous function defined on $s \in [0, 1]$, satisfying*

$$z^2(s) - z^2(0) \leq z^3(s) + z^3(0) + \int_0^s z^3(r)dr + \epsilon, \tag{43}$$

where $\epsilon \geq 0$. Then there exist $\delta_0 > 0$ and $k_0 > 0$ such that $z(s) \leq 4\delta$ for $s \in [0, 1]$ whenever $0 \leq z(0) \leq \delta \leq \delta_0$ and $\epsilon \leq k_0\delta^2$.

We will now apply Lemma 1 to obtain estimates for $\mathcal{A}$. Consider $h \in (0, C_2/2)$ and suppose $\mathcal{A}(\tau) \leq C_2/8$ for some $\tau \in [\tau_0, T_1]$. Because $\mathcal{A}$ is continuous, there is a largest value T_2 in $(\tau, T_1]$ such that (42) is satisfied on $[\tau, T_2]$. Thus, (41) holds on $[\tau, T_2]$. Let

$$\begin{aligned} m &= \max\{1, T_1 - \tau_0\}, & s &= \frac{t - \tau}{T_2 - \tau} \\ z(s) &= mC_1\mathcal{A}(t), & \epsilon &= m^2C_1^2\psi(h). \end{aligned} \tag{44}$$

Then, from (41),

$$\begin{aligned} z^2(s) - z^2(0) &= m^2C_1^2(\mathcal{A}^2(t) - \mathcal{A}^2(\tau)) \\ &\leq m^2C_1^3(\mathcal{A}^3(t) + \mathcal{A}^3(\tau)) + m^2C_1^3 \int_\tau^t \mathcal{A}^3(p)dp + m^2C_1^2\psi(h) \\ &\leq \frac{1}{m}(z^3(s) + z^3(0)) + \frac{T_2 - \tau}{m} \int_0^s z^3(r)dr + \epsilon \\ &\leq z^3(s) + z^3(0) + \int_0^s z^3(r)dr + \epsilon \end{aligned}$$

for $s \in [0, 1]$. From Lemma 1, if for some $\delta > 0$, we have

$$z(0) = mC_1\mathcal{A}(\tau) \leq \delta \leq \delta_0, \tag{45}$$

$$\epsilon = m^2C_1^2\psi(h) \leq k_0\delta^2, \tag{46}$$

then

$$z(s) = mC_1\mathcal{A}(t) \leq 4\delta \quad \text{for } t \in [\tau, T_2]. \tag{47}$$

If $\mathcal{A}(\tau) \leq \delta_0/mC_1$, then we may choose δ such that (45) is satisfied and

$$\delta \leq \frac{C_2}{8}mC_1.$$

Thus, (47) implies $\mathcal{A}(T_2) \leq C_2/2$. If $T_2 < T_1$, then there exists $T_2^* > T_2$ such that (42) holds on $[\tau, T_2^*]$, contradicting the assumption that T_2 is the largest such value. Hence $T_2 = T_1$, and (47) holds for $t \in [\tau, T_1]$. We now have the following.

LEMMA 2. *Suppose that* (31), (32) *are satisfied by the fast-slow system* (30) *defined on* $[\tau_0, T_1]$. *There exist a constant* $\delta_1 > 0$ *and a positive function* $h_1(\delta)$ *such that if*

$$0 \le \delta \le \delta_1 \quad \textit{and} \quad 0 < h < h_1(\delta), \tag{48}$$

$(\mathbf{z}_I, \mathbf{z}_{II})$ *is a solution, in a neighborhood of* $\tau \in [\tau_0, T_1]$, *of* (30) *for this value of* h, $\mathcal{A}(t)$ *is defined as in* (34) *and*

$$\mathcal{A}(\tau) \le \delta, \tag{49}$$

then $(\mathbf{z}_I, \mathbf{z}_{II})$ *can be extended to the interval* $[\tau, T_1]$, *and on this interval*

$$\mathcal{A}(t) \le 4\delta. \tag{50}$$

Proof. Let

$$0 < \delta_1 < \min\left(\frac{C_2}{8}, \frac{\delta_0}{mc_1}\right) \quad \text{and} \quad 0 < h_1(\delta) < \min\left(\frac{C_2}{2}, \tilde{h}\right), \tag{51}$$

where $\psi(\tilde{h}) \le k_0\delta^2$, $\tilde{h} > 0$. Such an $\tilde{h}$ exists, since $\psi(h) \to 0$ as $h \to 0$. Then, as in the discussion above, (48), (49) imply that (50) holds on the interval of existence (to the right) of the solution. Therefore, the solution values are finite at the right-hand endpoint of the interval of existence, which must be the entire interval $[\tau, T_1]$ (cf. [4], p. 15). □

The proof of this result was motivated to some extent by [9]. There are some important differences in the result of [9] and our Lemma 2. We do not require the initial condition $\mathcal{A}(\tau)$ to be $O(h)$, and the bounds given in Lemma 2 apply only for $O(1)$ intervals. The form of the system (30), particularly with respect to nonlinear terms, is more restrictive than the systems considered in [9].

6. Proof of Theorem 1.

We now present the proof of the nonexistence result (Theorem 1), which was stated in §2. The proof is by contradiction; thus, suppose there exists a sequence $\{u_n, v_n, h_n\}$, $n = 1, 2, \ldots$ satisfying the clamped plate problem (1), (3), (4) for some sequence of edge loads, $\{\lambda_n = v_n(1)\}$, and further suppose that this sequence has compressive membrane asymptotics; that is, (17), (18) are satisfied. We may extract a subsequence such that for some constants v_∞, v'_∞ and for some $\xi_1 \in [x_0, 1]$,

$$x_{n_k} \to \xi_1, \quad v_{n_k}(x_{n_k}) \to v_\infty \quad \text{and} \quad v'_{n_k}(x_{n_k}) \to v'_\infty \tag{52}$$

as $k \to \infty$. To simplify notation, we drop the repeated subscript. Hypothesis (18) implies $v_\infty \ge m > 0$. Also, one integration of (1b) gives

$$\frac{dv}{dx}(x) = x^{-3} \int_0^x s^3 u^2(s)\,ds \ge 0;$$

hence $v'_\infty \ge 0$.

Let (u_0, v_0) be the solution of the Föppl membrane equations (5a), (5b) satisfying

$$v_0(\xi_1) = v_\infty, \qquad v'_0(\xi_1) = v'_\infty. \tag{53}$$

It is shown in Appendix C that v_0 exists and is positive on an interval $(\xi_0, 1]$ with

$$x_0 \leq \xi_0 < \xi_1.$$

There exists an integer $N \geq 1$ such that

$$\xi_0 < x_n \quad \text{for } n \geq N.$$

Because $v_0 \in C^1(\xi_0, 1]$ and from (52), we have

$$\text{(54a)} \qquad v_n(x_n) - v_0(x_n) \to 0, \quad v_n'(x_n) - v_0'(x_n) \to 0 \quad \text{as } n \to \infty.$$

Further, $u_0 \in C^1(\xi_0, 1]$ from the assumption that g is continuously differentiable. Thus, $\{u_0'(x_n)\}$ is a bounded sequence, and hypotheses (17), (18b), (18d) imply

$$\text{(54b)} \qquad u_n(x_n) - u_0(x_n) \to 0 \quad \text{and} \quad h_n(u_n'(x_n) - u_0'(x_n)) \to 0 \quad \text{as } n \to \infty.$$

We now apply the transformations (23)–(27) to each solution $(u_n(x), v_n(x))$ with corresponding thickness h_n to obtain a sequence $\mathbf{z}_{In}(t)$, $\mathbf{z}_{IIn}(t)$ of solutions of the fast-slow system (28). According to the definition (24) of t, $x = \xi_0$, ξ_1 and 1 correspond to $t = T_0$, 0, and T_1, respectively. Let the sequence $\{t_n\} \in (T_0, T_1], n \geq N$ correspond to $\{x_n\}$ as in definition (24). Then by (52), $t_n \to 0$ as $n \to \infty$. From (23), (27), (54), we have

$$\mathbf{z}_{In}(t_n), \mathbf{z}_{IIn}(t_n) \to 0 \quad \text{as } n \to \infty.$$

Let $\tau_0 = \inf_{n \geq N} t_n$. The fundamental matrix solution $X(t)$ of (33b) is independent of n and its inverse is bounded uniformly for $t \in [\tau_0, T_1]$. Hence, from (34),

$$\text{(55)} \qquad \mathcal{A}_n(t_n) \to 0 \quad \text{as } n \to \infty.$$

We now apply Lemma 2. It is easy to show that the hypotheses (31), (32) are satisfied on $[\tau_0, T_1]$ for the system (28), where the elements of (28) are defined in Appendix A. By (17), (55), and Lemma 2,

$$\text{(56)} \qquad \mathcal{A}_n(T_1) \to 0 \quad \text{as } n \to \infty.$$

We defined $X(T_1)$ as the identity matrix, so from (35) and (56) we have

$$|\mathbf{z}_{In}(T_1)|^2 + |\mathbf{z}_{IIn}(T_1)|^2 \to 0 \quad \text{as } n \to \infty.$$

From (27), we have

$$|u_{1n}(T_1) + \beta(T_1)(\lambda_n - \lambda_0)| + |\lambda_n - \lambda_0| \to 0 \quad \text{as } n \to \infty.$$

Hence, $\lambda_n \to \lambda_0$ and $u_{1n}(1) \to 0$ as $n \to \infty$. But, by (23),

$$u_{1n}(T_1) = \lambda_0^{1/4}(u_n(1) - u_0(1)).$$

The clamped edge assumption gives $u_n(1) = 0$, so

$$u_{1n}(T_1) = -\frac{g(1)}{\lambda_0^{3/4}} \neq 0$$

by the assumption of non–self-equilibrating load, i.e., $g(1) \neq 0$. We have arrived at a contradiction, and thus the assumption that a sequence of clamped plate solutions exist that asymptotically approach the family of compressive membrane solutions must be false. □

7. Conclusion. The definition of compressive membrane asymptotics appears to be rather weak, but, as shown in Lemma 2, guarantees strong (uniform) convergence of a subsequence to some membrane solution. This convergence provides a contradiction to the clamped boundary condition, which is not satisfied by the membrane solution.

Referring to our earlier discussion of the formal asymptotics in §2, one could conjecture that clamped plate solutions also do not converge *weakly* to compressive membrane solutions. This conjecture has not been addressed in Theorem 1, as the definition of asymptotic approach is too restrictive to allow weak convergence. The extension of the proof of Theorem 1 to the case of weak convergence is under investigation.

The clamped circular plate problem provides a striking example of a singular perturbation problem where some solutions of the "outer" problem have no counterpart in the original problem. We have presented here a rigorous justification of an aspect of this phenomenon.

Appendix A. Some formulas from the transformations discussed in §3 are given below. Let

$$\mathcal{L} = \frac{d^2}{dx^2} + \frac{3}{x}\frac{d}{dx}.$$

Then

$$\begin{aligned}
\alpha(t) &= \frac{x^{3/2}}{v_0^{3/4}(x)}\,\mathcal{L}\left(x^{-3/2}\,v_0^{-1/4}(x)\right), \qquad q(t) = -\frac{x^{3/2}}{v_0^{3/4}(x)}\,\mathcal{L}\,u_0(x),\\
\beta(t) &= \frac{g(x)}{v_0^2(x)}, \qquad \gamma(t) = x^{-3/2}v_0^{-5/4}(x),\\
A(t) &= \begin{pmatrix} 0 & 1\\ -\alpha - 2\beta^2 & 0\end{pmatrix},\\
F_I(t,\mathbf{x},\mathbf{y};h)_1 &= -2h\beta^2 x_2,\\
F_I(t,\mathbf{x},\mathbf{y};h)_2 &= -h\alpha x_1 + h\alpha\beta y_1 + hq,\\
F_{II}(t,\mathbf{x},\mathbf{y};h)_1 &= -2h\beta x_2,\\
F_{II}(t,\mathbf{x},\mathbf{y};h)_2 &= -2h^2\alpha\beta x_1 + 2h\,\frac{d\beta}{dt}x_2 + 2h^2\beta q\\
&\quad + \gamma(x_1 - 3\beta y_1)(x_1 - \beta y_1) + 2h^2\alpha\beta^2 y_1.
\end{aligned}$$

For the system in form (31), we have

$$\phi(t,\mathbf{x},\mathbf{y}) = \frac{\gamma}{2}(x_1 - 2\beta y_1)x_1 y_1 + h\frac{d\beta}{dt}x_2 y_1 + h\beta x_2 y_2.$$

This gives

$$\nabla_I \phi = Q.$$

Appendix B.

Proof of Lemma 1. Suppose

$$0 < \delta \le \delta_0 \quad \text{and} \quad 0 \le \epsilon \le k_0\delta^2,$$

where $\delta_0 = 1/14$ and $k_0 = 37/14$. We first show that there exists a continuous function $\bar{z}(s)$ that satisfies the integral equation

$$\bar{z}^2(s) - \delta^2 = \bar{z}^3(s) + \delta^3 + \int_0^s \bar{z}^3(r)dr + \epsilon, \tag{57}$$

for $s \in [0,1]$, $\bar{z} \in [\delta, 4\delta]$. At $s = 0$, (57) becomes

$$\bar{z}^3(0) - \bar{z}^2(0) + \delta^2 + \delta^3 + \epsilon = 0. \tag{58}$$

Let $P(\zeta) = \zeta^3 - \zeta^2 + \delta^2 + \delta^3 + \epsilon$. Clearly, $P(\delta) > 0$. Also,

$$P(2\delta) = 5\delta^3 - 3\delta^2 + \epsilon \le \delta^2(5\delta_0 - 3 + k_0) = 0. \tag{59}$$

Thus, P has a zero in $(\delta, 2\delta]$, say $\bar{z}_0$. Let $\bar{z}(s)$ be the solution of the initial-value problem

$$(2\bar{z} - 3\bar{z}^2)\bar{z}' = \bar{z}^3, \qquad \bar{z}(0) = \bar{z}_0. \tag{60}$$

Then $\bar{z}$ is also a solution of (57). Solving (60) gives $\bar{z}$ implicitly as

$$s = \frac{2(\bar{z}(s) - \bar{z}_0)}{\bar{z}_0 \bar{z}(s)} - 3 \log \frac{\bar{z}(s)}{\bar{z}_0}. \tag{61}$$

For $\bar{z} \in [\delta, 4\delta]$ we have

$$\frac{ds}{d\bar{z}} = \frac{2 - 3\bar{z}}{\bar{z}^2} > 0. \tag{62}$$

Hence, the inverse function theorem guarantees the existence of $\bar{z}(s)$ on some interval $[0, s(4\delta)]$. To estimate the size of this interval, (61) gives

$$s(4\delta) \ge \frac{1}{2\delta_0} - 3\log 4 \ge 1. \tag{63}$$

Thus (61) can be inverted to give a single-valued function $\bar{z}(s)$ for $s \in [0,1]$, $\bar{z} \in [\delta, 4\delta]$ satisfying (57).

We now show that $\bar{z}(s)$ is an upper bound for any positive, continuous solution of

$$z^2(s) - z^2(0) \le z^3(s) + z^3(0) + \int_0^s z^3(r)dr + \epsilon \tag{64}$$

for $s \in [0,1]$ with $z(0) \le \delta < \bar{z}(0)$. Suppose this is not true. Then by continuity of z and $\bar{z}$, there is a smallest value, $s^* > 0$, such that $z(s^*) = \bar{z}(s^*)$. Thus,

$$\bar{z}(s) > z(s) > 0 \quad \text{for } 0 \le s < s^*. \tag{65}$$

The integral (in)equalities (57), (64) give

$$\begin{aligned}\bar{z}^2(s^*) &= \bar{z}^3(s^*) + \delta^2 + \delta^3 + \int_0^{s^*} \bar{z}^3(r)dr + \epsilon \\ &> z^3(s^*) + z(0)^2 + z(0)^3 + \int_0^{s^*} z^3(r)dr \ge z^2(s^*),\end{aligned}$$

contradicting that $\bar{z}(s^*) = z(s^*)$. Hence,

$$z(s) < \bar{z}(s) \le 4\delta \quad \text{for } 0 \le s \le 1,$$

as required for the proof of Lemma 1. □

Appendix C. The following existence-uniqueness result is required for the proof of Theorem 1.

LEMMA 3. *Let g be continuous on* $[0,1]$. *Then the solution of the Föppl membrane equation*

$$v'' + \frac{3}{x}v' = \frac{g^2}{v^2}, \qquad x \in [0,1] \tag{66}$$

with initial conditions

$$v(\xi_1) = v_\infty > 0, \qquad v'(\xi_1) = v'_\infty \geq 0 \tag{67}$$

has a unique solution that exists for $x \in (\xi_0, 1]$, *where* $\xi_0 < \xi_1 < 1$.

Proof. By the standard results [4], there exists a unique solution of (66), (67) on an interval $J = (\xi_0, \xi_2)$, with $\xi_1 \in J$. Integrating (66) once gives

$$x^3 v'(x) = \xi_1^3 v'(\xi_1) + \int_{\xi_1}^{x} s^3 \frac{g^2(s)}{v(s)} ds.$$

Thus $v'(x) \geq 0$ for $x \in J$. Further,

$$v(x) \geq v_\infty > 0 \quad \text{for } x \geq \xi_1.$$

The right-hand side of (66) is bounded and satisfies a Lipschitz condition with respect to v for $v \geq v_\infty$. Thus by the Picard–Lindelöf theorem [5], the solution exists and is unique on $(\xi_0, 1]$. □

Acknowledgment. The author wishes to thank H. B. Keller for suggesting this problem.

SOME GENERAL EXISTENCE PRINCIPLES AND RESULTS FOR $(\phi(y'))=qf(t,y,y'), 0<t<1$*

DONAL O'REGAN†

Abstract. Existence principles and results are reported for the second-order differential equation $(\phi(y'))'=qf(t,y,y')$, $0<t<1$ with y satisfying Dirichlet or mixed boundary data. In particular the case $\phi(v)=|v|^{n-2}v$, $n>1$ is included.

Key words. p-Laplacian, boundary value problems, existence principles

AMS subject classification. 34B15

1. Introduction. In this article existence results are presented for the second-order differential equation

$$(1.1) \qquad (|u'|^{n-2}u')'=q(t)f(t,u,u'), \quad 0<t<1 \quad \text{and} \quad n\in\mathbf{R}, \quad n>1$$

with u satisfying either the Dirichlet boundary condition

(i) $u(0)=a, u(1)=b$

or the mixed boundary condition

(ii) $u'(0)=a, u(1)=b.$

Equations of the above form occur in the study of the n-Laplace equation [9], non-Newtonian fluid theory [8], and the turbulent flow of a gas in a porous medium [1], [6]. The existence results obtained in this paper will improve, extend, and compliment the existing theory found in [1], [4], [9]. In fact even new results are obtained for the case $n=2$.

We summarize briefly known results for the Dirichlet boundary value problem when $n=2$. In [5], [7] it was shown that if f satisfies the monotonicity condition

$$uf(t,u,0)>0 \quad \text{for } |u|>M \quad \text{and} \quad t\in[0,1],$$

together with the growth condition (Bernstein-Nagumo)

$$|f(t,u,p)|\leqq \psi(|p|) \text{ for } (t,u)\in[0,1]\times[-M,M],$$

where $\psi\colon[0,\infty)\to(0,\infty)$ is a continuous function and

$$2M<\int_0^\infty \frac{x\,dx}{\psi(x)},$$

then

$$(*) \qquad \begin{aligned} &y''=f(t,y,y'), \quad 0<t<1, \\ &y(0)=y(1)=0 \end{aligned}$$

has a $C^2[0,1]$ solution. The technique (which uses arguments based on the supremum norm) is referred to as the Bernstein-Nagumo theory in the literature.

On the other hand, suppose $f(t,u,p)=f_1(t,u,p)+f_2(t,u,p)$ and the monotonicity condition above is replaced by

$$uf_1(t,u,p)\geqq a|u|^2 \quad \text{for } (t,u,p)\in[0,1]\times\mathbf{R}^2,$$

* Received by the editors November 20, 1991; accepted for publication (in revised form) August 31, 1992.

together with

$$|f_2(t, u, p)| \leqq K\{|u|^\alpha + |p|^\beta + 1\} \quad \text{for } 0 \leqq \alpha, \beta < 1.$$

The results in [12], [13] imply that if f_1 satisfies a growth condition of the form

$$|f_1(t, u, p)| \leqq Ap^2 + B \quad \text{with } A, B \text{ constants},$$

then $(*)$ has a solution provided $a > -\pi^2$. The technique uses arguments based on the L^2 norm.

The paper will be divided into three main parts. General existence principles will be obtained in § 2. These will reduce our analysis to obtaining a priori bounds for a certain class of problems. In § 3 the L^2 theory will be extended to discuss the general boundary value problem (1.1). We use the L^n norm to obtain a priori bounds as described in § 2. In § 4 the Bernstein-Nagumo theory will be extended for problems of the above form.

To conclude this introduction we will use the following two theorems, which appear in the literature. Our first is a fixed point result, called the nonlinear alternative of Leray-Schauder [5], [7], [11]. By a map being *compact* we mean it is continuous with relatively compact range. A map is *completely continuous* if it is continuous and the image of every bounded set in the domain is contained in a compact subset of the range.

THEOREM 1.1. *Assume U is a relatively open subset of a convex set K in a Banach space E. Let $G: \bar{U} \to K$ be a compact map, $p \in U$, and $N_\lambda(u) = N(u, \lambda)$: $\bar{U} \times [0, 1] \to K$ a family of compact maps (i.e., $N(\bar{U} \times [0, 1])$ is contained in a compact subset of K and N: $\bar{U} \times [0, 1] \to K$ is continuous) with $N_1 = G$ and $N_0 = p$, the constant map to p. Then either*

(i) *G has a fixed point in $\bar{U}$; or*

(ii) *There is a point $u \in \partial U$ and $\lambda \in (0, 1)$ such that $u = N_\lambda u$.*

The next theorem involves results in integral inequalities [2], [3].

THEOREM 1.2. (a) *Suppose $y \in C^1[0, 1]$ with $y(0) = 0$. Then for any $p > 1$,*

$$\int_0^1 |y|^p \, dx \leqq \frac{1}{\mu_p} \int_0^1 |y'|^p \, dx,$$

where

$$\mu_p = \left(\frac{1}{p}(p-1)^{1/p} B\left(\frac{1}{p}, \frac{p-1}{p}\right)\right)^p = (p-1)\left(\int_0^1 \frac{ds}{(1-s^p)^{1/p}}\right)^p.$$

(b) *Suppose $y \in C^1[0, 1]$ with $y(0) = 0$. Then for any $p > 0$,*

$$\int_0^1 |y| \, |y'|^p \, dx \leqq \frac{1}{\eta_p} \int_0^1 |y'|^{p+1} \, dx,$$

where

$$\eta_p = 1 + \frac{2p \ln(p)}{p^2 - 1} \quad \textit{if } p \neq 1, \quad \textit{whereas } \eta_1 = 2.$$

(c) *Suppose $y \in C^1[0, 1]$ with $y(0) = y(1) = 0$. Then for any $p > 1$,*

$$\int_0^1 |y|^p \, dx \leqq \frac{1}{\sigma_p} \int_0^1 |y'|^p \, dx,$$

where

$$\sigma_p = 2^p(p-1)\left(\int_0^1 \frac{ds}{(1-s^p)^{1/p}}\right)^p.$$

(d) *Suppose* $y \in C^1[0,1]$ *with* $y(0)=y(1)=0$. *Then for any* $p>0$,

$$\int_0^1 |y||y'|^p\,dx \leqq \frac{1}{\omega_p}\int_0^1 |y'|^{p+1}\,dx,$$

where

$$\omega_p = 2\left[1+\frac{2p\ln(p)}{p^2-1}\right] \quad \textit{if } p\neq 1, \quad \textit{whereas } \eta_1 = 4.$$

Remarks. (i) When $p=2$, $\sigma_2=\pi^2$ and we have Wirtinger's inequality.

(ii) Note σ_p is the first eigenvalue [4] of

$$(\phi_p(y'))' + \lambda\phi_p(y) = 0, \quad 0<t<1, \quad \phi_p(u) = |u|^{p-2}u,$$
$$y(0)=y(1)=0.$$

(iii) When $p=1$, $\eta_1 = 2$ and we have Opial's inequality.

Proof. (a) and (b). These follow from [2, pp. 376-377].

(c) and (d). Since $y(0)=0$, a slight modification of the arguments in [2, pp. 376–379] yields for $p>0$, $q\geqq 0$ constants,

$$\int_0^{1/2} |y|^p|y'|^q\,dx \leqq K(p,q,p+q)\int_0^{1/2} |y'|^{p+q}\,dx, \tag{1.2}$$

where

$$K(p,q,p+q) = \frac{p(p/2)^p}{(p+q-1)(p+q)}(I(p,q,p+q))^{-p}$$

and

$$I(p,q,p+q) = \int_0^1 \left(1+\frac{(p+q)(q-1)t}{p}\right)^{(-1-p)/p}[1+(q-1)t]t^{(1/p)-1}\,dt.$$

In addition, since $y(1)=0$, a quick calculation yields

$$\int_{1/2}^1 |y|^p|y'|^q\,dx \leqq K(p,q,p+q)\int_{1/2}^1 |y'|^{p+q}\,dx. \tag{1.3}$$

Now (1.2) and (1.3) yield

$$\int_0^1 |y|^p|y'|^q\,dx \leqq K(p,q,p+q)\int_0^1 |y'|^{p+q}\,dx.$$

Notice that

$$K(p,0,p) = \frac{(p/2)^p}{(p-1)}\left(B\left(\frac{1}{p},\frac{p-1}{p}\right)\right)^{-p} = \frac{1}{2^p(p-1)}\left(\int_0^1 \frac{ds}{(1-s^p)^{1/p}}\right)^{-p},$$

which yields (c). Also notice that

$$K(1,q,q+1) = \frac{1}{2}\left(1+\frac{2q\ln(q)}{q^2-1}\right)^{-1} \quad \text{if } q\neq 1,$$

whereas $K(1,1,2)=\frac{1}{4}$, which yields (d). □

2. Existence principles. This section establishes existence principles for the general boundary value problem

$$(2.1)\qquad \begin{gathered}(\phi(y'))' = q(t)f(t, y, y'), \qquad 0<t<1,\\ y(0)=a, \qquad y(1)=b \;\text{ or }\; y'(0)=a, \qquad y(1)=b,\end{gathered}$$

where $q \in C(0, 1)$, f: $[0, 1]\times\mathbf{R}^2\to\mathbf{R}$ and $\phi:\mathbf{R}\to\mathbf{R}$ are continuous. The conditions on ϕ will be motivated by the physically reasonable situation [1],

$$\phi_n(u)=|u|^{n-2}u, \qquad 1<n\leqq 2.$$

We begin by obtaining an existence principle for the problem

$$(2.2)\qquad \begin{gathered}(\phi(y'))' = q(t)f(t, y, y'), \qquad 0<t<1,\\ y'(0)=a, \qquad y(1)=b.\end{gathered}$$

THEOREM 2.1. *Let $f:[0, 1]\times\mathbf{R}^2\to\mathbf{R}$ be continuous, and suppose*

$$(2.3)\qquad q\in C(0,1) \quad \textit{with } q>0 \quad \textit{on } (0,1)$$

$$(2.4)\qquad \begin{cases}\phi \textit{ is a continuous and strictly increasing map from}\\ (-\infty,\infty) \textit{ onto } (-\infty,\infty),\end{cases}$$

$$(2.5)\qquad \int_0^1 q(s)\,ds<\infty,$$

and

$$(2.6)\qquad \phi^{-1} \quad \textit{is continuously differentiable on } (-\infty,\infty)$$

are satisfied. In addition, assume there is a constant K^*, independent of λ, such that

$$|y|_1=\max\left\{\sup_{[0,1]}|y(t)|, \sup_{[0,1]}|y'(t)|\right\}\equiv\max\{|y|_0, |y'|_0\}\leqq K^*$$

for any solution y to

$$(2.7)_\lambda\qquad \begin{gathered}(\phi(y'))' = \lambda q(t)f(t, y, y'), \qquad 0<t<1,\\ y'(0)=a, \qquad y(1)=b\end{gathered}$$

for each $\lambda\in(0, 1)$. Then (2.2) *has at least one solution $y\in C^1[0, 1]$ with $(\phi(y'))'\in C(0, 1)$.*

Remark. When $\phi(u)=\phi_n(u)=|u|^{n-2}u$, then assumption (2.6) will be true if $1<n\leqq 2$.

Proof. Solving $(2.7)_\lambda$ is equivalent to finding a $y\in C^1[0, 1]$ that satisfies

$$(2.8)\qquad y(t)=b-\int_t^1\phi^{-1}\left(\phi(a)+\lambda\int_0^s q(u)f(u, y(u), y'(u))\,du\right)ds.$$

Define the operator $N_\lambda: C_B^1[0, 1]\to C_B^1[0, 1]$ by

$$(N_\lambda y)(t)=b-\int_t^1\phi^{-1}\left(\phi(a)+\lambda\int_0^s q(u)f(u, y(u), y'(u))\,du\right)ds.$$

Here $C_B^1[0, 1]=\{u\in C^1[0, 1]$: $u'(0)=a$, $u(1)=b\}$. Of course $(2.7)_\lambda$ is equivalent to the fixed point problem $y=N_\lambda y$. Certainly N_λ is continuous since ϕ^{-1} is and completely continuous by the Arzela-Ascoli theorem. To see this let $\Omega\subseteq C_B^1[0, 1]$ be bounded, i.e., $|u|_1 \leqq M$ for all $u \in \Omega$; here $M > 0$ is a constant. Firstly $N_\lambda \Omega$ is bounded. This follows from the inequalities

$$N_\lambda u(t)| \leqq |b| + \int_0^1 G(s)\, ds \quad \text{and} \quad |(N_\lambda u)'(t)| \leqq G(1),$$

where

$$G(s) = \max\left\{\left|\phi^{-1}\left(-|\phi(a)| - M_1 \int_0^s q(u)\, du\right)\right|, \left|\phi^{-1}\left(|\phi(a)| + M_1 \int_0^s q(u)\, du\right)\right|\right\} \tag{2.9}$$

and $M_1 = \sup |f(t, w_1, w_2)|$, where the supremum is computed over $[0, 1] \times [-M, M] \times [-M, M]$. We next show the equicontinuity of $N_\lambda \Omega$ on $[0, 1]$. For $u \in \Omega$ and $t, s \in [0, 1]$ we have

$$\begin{aligned} |N_\lambda u(t) - N_\lambda u(s)| &= \left|\int_s^t \phi^{-1}\left(\phi(a) + \lambda \int_0^v q(z) f(z, u(z), u'(z))\, dz\right) dv\right| \\ &\leqq \left|\int_s^t G(v)\, dv\right|, \end{aligned} \tag{2.10}$$

where G is described in (2.9). In addition, the Mean Value theorem yields

$$\begin{aligned} &|(N_\lambda u)'(t) - (N_\lambda u)'(s)| \\ &= \left|\phi^{-1}\left(\phi(a) + \lambda \int_0^t q(z) f(z, u(z), u'(z))\, dz\right)\right. \\ &\qquad \left. - \phi^{-1}\left(\phi(a) + \lambda \int_0^s q(z) f(z, u(z), u'(z))\, dz\right)\right| \\ &\leqq \sup |(\phi^{-1})'(x)| \left|\int_s^t q(z) f(z, u(z), u'(z))\, dz\right| \\ &\leqq M_1 \sup |(\phi^{-1})'(x)| \left|\int_s^t q(z)\, dz\right|, \end{aligned} \tag{2.11}$$

where the supremum is computed over $[-|\phi(a)| - M_1 \int_0^1 q(z)\, dz,\ |\phi(a)| + M_1 \int_0^1 q(z)\, dz]$, and $M_1 = \sup f(t, w_1, w_2)|$ with the supremum computed over $[0, 1] \times [-M, M] \times [-M, M]$. The equicontinuity of $N_\lambda \Omega$ on $[0, 1]$ now follows from (2.10), (2.11), and assumptions (2.5) and (2.6). Thus the Arzela-Ascoli theorem implies that N_λ is completely continuous. Set

$$U = \{u \in C_B^1[0, 1] : |u|_1 < K^* + 1\}, \qquad K = C_B^1[0, 1],$$
$$E = C^1[0, 1], \qquad N_0 y(t) = at + (b - a).$$

Remark. Note that $N(\bar{U} \times [0, 1])$ is contained in a compact subset of K. To see this let $N(u_n, \lambda_n)$ be any sequence in $N(\bar{U} \times [0, 1])$. Then as above $N(u_n, \lambda_n)$ is uniformly bounded (since G is (2.9) does not depend on the λ chosen) and equicontinuous on $[0, 1]$; so the Azela-Ascoli theorem again yields the result.

Apply Theorem 1.1 to deduce that N_1 has a fixed point, i.e., (2.2) has a solution $y \in C^1[0, 1]$. The fact that $(\phi(y'))' \in C(0, 1)$ follows from (2.8) with $\lambda = 1$. □

It is possible to improve the results of Theorem 2.1 if f is independent of its third variable, i,e., consider the boundary value problem

$$(2.12)\qquad \begin{gathered}(\phi(y'))'=q(t)f(t,y),\qquad 0<t<1,\\ y'(0)=a,\qquad y(1)=b.\end{gathered}$$

THEOREM 2.2. *Suppose* $f\colon[0,1]\times\mathbf{R}\to\mathbf{R}$ *is continuous and* (2.3), (2.4), *and* (2.5) *are satisfied. In addition, assume there is a constant* K^*, *independent of* λ, *such that* $|y|_0\leqq K^*$ *for any solution* y *to*

$$(2.13)_\lambda\qquad \begin{gathered}(\phi(y'))'=\lambda q(t)f(t,y),\quad 0<t<1,\\ y'(0)=a,\qquad y(1)=b\end{gathered}$$

for each $\lambda\in(0,1)$. *Then* (2.12) *has at least one solution* $y\in C^1[0,1]$ *with* $(\phi(y'))'\in C(0,1)$.

Remark. When $\phi(u)=\phi_n(u)=|u|^{n-2}u$, then since assumption (2.6) need *not* be satisfied in this situation, it is sufficient that $n>1$.

Proof. Solving $(2.13)_\lambda$ is equivalent to finding a $y\in C[0,1]$ that satisfies

$$(2.14)\qquad y(t)=b-\int_t^1\phi^{-1}\left(\phi(a)+\lambda\int_0^s q(u)f(u,y(u))\,du\right)ds.$$

Define the operator $N_\lambda\colon C_B[0,1]\to C_B[0,1]$. Here $C_B[0,1]=\{u\in C[0,1]\colon u(1)=b\}$, by

$$(N_\lambda y)(t)=b-\int_t^1\phi^{-1}\left(\phi(a)+\lambda\int_0^s q(u)f(u,y(u))\,du\right)ds.$$

Note N_λ is continuous and completely continuous (see (2.10)). Set

$$U=\{u\in C_B[0,1]\colon|u|_0<K^*+1\},\quad K=C_B[0,1],\quad E=C[0,1],$$
$$N_0y(t)=at+(b-a).$$

Now $N(\bar{U}\times[0,1])$ is contained in a compact subset of K; so apply Theorem 1.1 to deduce that N_1 has a fixed point y. The fact that $y\in C^1[0,1]$ with $y'(0)=a$ and $(\phi(y'))'\in C(0,1)$ follows from (2.14) with $\lambda=1$. □

We next obtain an existence principle for the problem

$$(2.15)\qquad \begin{gathered}(\phi(y'))'=q(t)f(t,y,y'),\quad 0<t<1,\\ y(0)=a,\qquad y(1)=b.\end{gathered}$$

THEOREM 2.3. *Suppose* $f\colon[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous and* (2.3), (2.4), (2.5), *and* (2.6) *are satisfied. In addition, assume there is a constant* K^*, *independent of* λ, *such that* $|y|_1\leqq K^*$ *for any solution* y *to*

$$(2.16)_\lambda\qquad \begin{gathered}(\phi(y'))'=\lambda q(t)f(t,y,y'),\quad 0<t<1,\\ y(0)=a,\qquad y(1)=b\end{gathered}$$

for each $\lambda\in(0,1)$. *Then* (2.15) *has at least one solution* $y\in C^1[0,1]$ *with* $(\phi(y'))'\in C(0,1)$.

Proof. Solving $(2.16)_\lambda$ is equivalent to finding a $y\in C^1[0,1]$ which satisfies

$$(2.17)\qquad y(t)=a+\int_0^t\phi^{-1}\left(A-\lambda\int_s^1 q(z)f(z,y(z),y'(z))\,dz\right)ds,$$

where A satisfies

$$(2.18)\qquad b-a=\int_0^1\phi^{-1}\left(A-\lambda\int_s^1 q(z)f(z,y(z),y'(z))\,dz\right)ds.$$

We first show that A exists and is unique. Let $y \in C^1[0,1]$ be fixed with

$$H(x)=\int_0^1 \phi^{-1}(x-\lambda I(s))\,ds, \quad \text{where } I(s)=\int_s^1 q(z)f(z,y(z),y'(z))\,dz.$$

Certainly H is continuous since ϕ^{-1} is continuous (in particular, ϕ^{-1} is uniformly continuous on compact sets). Also there exists x_0, $x_1 \in [0,1]$ with $I(x_0) \leqq I(s) \leqq I(x_1)$ for all $s \in [0,1]$. Consequently, we have

$$\phi^{-1}(x-\lambda I(x_1)) \leqq H(x) \leqq \phi^{-1}(x-\lambda I(x_0)).$$

From this inequality it follows that H is a continuous function from $(-\infty,\infty)$ onto $(-\infty,\infty)$. Thus the Intermediate Value theorem implies there exists $A \in (-\infty,\infty)$ with $H(A)=b-a$. In addition, if $A_1 < A_2$, then since ϕ^{-1} is strictly increasing we have $H(A_1) < H(A_2)$. Thus A is unique.

Define the operator N_λ: $C_B^1[0,1] \to C_B^1[0,1]$. Here $C_B^1[0,1] = \{u \in C^1[0,1] : u(0)=a, u(1)=b\}$, by

$$(N_\lambda y)(t)=a+\int_0^t \phi^{-1}\left(A-\lambda\int_s^1 q(z)f(z,y(z),y'(z))\,dz\right)ds,$$

where A satisfies (2.18). We claim that $N_\lambda : C_B^1[0,1] \to C_B^1[0,1]$ is continuous. Let $u_n \to u$, $u_n' \to u'$ uniformly on $[0,1]$. We need to show that $N_\lambda u_n \to N_\lambda u$, $(N_\lambda u_n)' \to (N_\lambda u)'$ uniformly on $[0,1]$. Associate A_n with u_n and A with u in (2.18). Then

$$\begin{aligned} N_\lambda u_n(t)-N_\lambda u(t) = \int_0^t \Bigg(&\phi^{-1}\left(A_n-\lambda\int_s^1 q(z)f(z,u_n(z),u_n'(z))\,dz\right) \\ &-\phi^{-1}\left(A-\lambda\int_s^1 q(z)f(z,u(z),u'(z))\,dz\right)\Bigg)ds \end{aligned} \tag{2.19}$$

and

$$\begin{aligned} (N_\lambda u_n)'(t)-(N_\lambda u)'(t) = &\phi^{-1}\left(A_n-\lambda\int_t^1 q(z)f(z,u_n(z),u_n'(z))\,dz\right) \\ &-\phi^{-1}\left(A-\lambda\int_t^1 q(z)f(z,u(z),u'(z))\,dz\right), \end{aligned} \tag{2.20}$$

where

$$\begin{aligned} 0 = \int_0^1 \Bigg(&\phi^{-1}\left(A_n-\lambda\int_s^1 q(z)f(z,u_n(z),u_n'(z))\,dz\right) \\ &-\phi^{-1}\left(A-\lambda\int_s^1 q(z)f(z,u(z),u'(z))\,dz\right)\Bigg)ds. \end{aligned} \tag{2.21}$$

If we show $\lim_{n\to\infty} A_n = A$, then (2.19), (2.20), together with the fact that ϕ^{-1} is continuous, implies $N_\lambda : C_B^1[0,1] \to C_B^1[0,1]$ is continuous.

To see that $\lim_{n\to\infty} A_n = A$, notice that (2.21), together with the Mean Value theorem for integrals, implies that there exists $\eta_n \in [0,1]$ with

$$\begin{aligned} 0 = &\phi^{-1}\left(A_n-\lambda\int_{\eta_n}^1 q(z)f(z,u_n(z),u_n'(z))\,dz\right) \\ &-\phi^{-1}\left(A-\lambda\int_{\eta_n}^1 q(z)f(z,u(z),u'(z))\,dz\right). \end{aligned}$$

Thus

$$A_n - \lambda \int_{\eta_n}^{1} q(z)f(z, u_n(z), u_n'(z))\,dz = A - \lambda \int_{\eta_n}^{1} q(z)f(z, u(z), u'(z))\,dz,$$

and since $u_n \to u$, $u_n' \to u'$ uniformly on $[0, 1]$ we have $\lim_{n\to\infty} A_n = A$.

We next claim that N_λ is completely continuous. To see this let $\Omega \subseteq C_B^1[0, 1]$ be bounded, i.e., $|u|_1 \leqq M$, for all $u \in \Omega$. Here $M > 0$ is a constant. We first show that there exists a constant N^* with

$$|A_u| \leqq N^* \quad \text{for all } u \in \Omega.$$

Remark. Here A_u is given in (2.18), i.e., $A = A_u$ and $y = u$.

Since

$$b - a = \int_0^1 \phi^{-1}\left(A_u - \lambda \int_s^1 q(z)f(z, u(z), u'(z))\,dz\right) ds,$$

then the Mean Value theorem for integrals implies that there exists $\xi \in [0, 1]$ with

$$\phi^{-1}\left(A_u - \lambda \int_\xi^1 q(z)f(z, u(z), u'(z))\,dz\right) = b - a.$$

Consequently,

$$A_u = \lambda \int_\xi^1 q(z)f(z, u(z), u'(z))\,dz + \phi(b - a),$$

which implies

$$|A_u| \leqq M_1 \int_0^1 q(z) + \phi(b - a) \equiv N^*,$$

where $M_1 = \sup |f(t, w_1, w_2)|$ and the supremum is computed over $[0, 1] \times [-M, M] \times [-M, M]$.

Next we show that $N_\lambda\Omega$ is bounded. This follows from the following inequalities:

$$|N_\lambda u(t)| \leqq |a| + \int_0^1 J(s)\,ds \quad \text{and} \quad |(N_\lambda u)'(t)| \leqq J(0),$$

where

$$J(s) = \max\left\{\left|\phi^{-1}\left(-N^* - M_1 \int_s^1 q(u)\,du\right)\right|, \left|\phi^{-1}\left(N^* + M_1 \int_s^1 q(u)\,du\right)\right|\right\}.$$

We next show the equicontinuity of $N_\lambda\Omega$ on $[0, 1]$. For $u \in \Omega$ and $t, s \in [0, 1]$ we have (following the ideas of Theorem 2.1)

$$|N_\lambda u(t) - N_\lambda u(s)| \leqq \left|\int_s^t J(v)\,dv\right|$$

and

$$|(N_\lambda u)'(t) - (N_\lambda u)'(s)| \leqq M_1 \sup |(\phi^{-1})'(x)| \left|\int_s^t q(z)\,dz\right|,$$

where the supremum is computed over $[-N^*-M_1\int_0^1 q(z)\,dz, N^*+M_1\int_0^1 q(z)\,dz]$. Thus the Arzela-Ascoli theorem implies that N_λ is completely continuous. Set

$$U=\{u\in C_B^1[0,1]:|u|_1<K^*+1\},\ K=C_B^1[0,1],\ E=C^1[0,1],\ N_0y(t)=a+(b-a)t$$

and apply Theorem 1.1 to deduce the result. □

Again the result of Theorem 2.3 can be improved if we are interested in solutions to

$$(2.22)\qquad \begin{aligned}&(\phi(y'))'=q(t)f(t,y),\quad 0<t<1,\\ &y(0)=a,\qquad y(1)=b.\end{aligned}$$

THEOREM 2.4. *Suppose $f:[0,1]\times\mathbf{R}\to\mathbf{R}$ is continuous and* (2.3), (2.4), *and* (2.5) *are satisfied. In addition, assume there is a constant K^*, independent of λ, such that $|y|_0\leqq K^*$ for any solution y to*

$$(2.23)_\lambda\qquad \begin{aligned}&(\phi(y'))'=\lambda q(t)f(t,y),\quad 0<t<1,\\ &y(0)=a,\qquad y(1)=b\end{aligned}$$

for each $\lambda\in(0,1)$. Then (2.22) *has at least one solution $y\in C^1[0,1]$ with $(\phi(y'))'\in C(0,1)$.*

Proof. In this case the operator $N_\lambda: C_B[0,1]\to C_B[0,1]$, here $C_B[0,1]=\{u\in C[0,1]: u(0)=a,\ u(1)=b\}$, is defined by

$$(N_\lambda y)(t)=a+\int_0^t \phi^{-1}\left(A-\lambda\int_s^1 q(u)f(u,y(u))\,du\right)ds,$$

where

$$b-a=\int_0^1\phi^{-1}\left(A-\lambda\int_s^1 q(u)f(u,y(u))\,du\right)ds. \qquad □$$

3. A priori bounds using the $\mathbf{L}^n$-norm. The existence principles of the previous section are now used to examine (1.1) with Dirichlet or mixed boundary data. The cases where q is nonsingular or singular are discussed separately. We remark here that the results for the case $n=2$ extend and complement those in [12], [13]. The results reported in this section are for homogeneous boundary data; however, the nonhomogeneous case could be considered by a change of variables [13].

3.1. Mixed boundary data. In this subsection we discuss the boundary value problems

$$(3.1)\qquad \begin{aligned}&(\phi_n(y'))'=q(t)f(t,y,y'),\quad 0<t<1,\quad 1<n\leqq 2,\\ &y'(0)=y(1)=0,\end{aligned}$$

and

$$(3.2)\qquad \begin{aligned}&(\phi_n(y'))'=q(t)f(t,y),\quad 0<t<1,\quad n>1,\\ &y'(0)=y(1)=0,\end{aligned}$$

where $\phi_n(u)=|u|^{n-2}u$.

THEOREM 3.1 (nonsingular case). *Suppose $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ is continuous and $q\in C[0,1]$ satisfies $q>0$ on $(0,1)$. In addition, assume f has the decomposition $f(t,u,v)=g(t,u,v)+h(t,u,v)$ with $g,h:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ continuous. Now suppose*

$$(3.3)\quad |h(t,u,v)|\leqq K\{|u|^\alpha+|v|^\beta+1\}\ \textit{for constants } K,\alpha,\beta\ \textit{ with } 0\leqq\alpha,\beta<n-1,$$

for $a, b \in \mathbf{R}$, $ug(t, u, v) \geqq a|u|^n + b|u||v|^{n-1}$ for $(t, u, v) \in [0, 1] \times \mathbf{R}^2$ and

(3.4) $|g(t, u, v)| \leqq A(t, u)|v|^n + B(t, u)$, *where $A(t, u)$ and $B(t, u)$ are bounded on bounded sets.*

Then (3.1) *has a solution $y \in C^1[0, 1]$ with $(\phi_n(y'))' \in C[0, 1]$ in each of the following cases:*

(i) $a \geqq 0, b \geqq 0$;
(ii) $a < 0$, $b \geqq 0$ *and* $|a|N_0 < \mu_n$, *where* $N_0 = \sup_{[0,1]} q(t)$;
(iii) $a \geqq 0$, $b < 0$ *and* $|b|N_0 < \eta_{n-1}$;
(iv) $a < 0$, $b < 0$ *and* $|a|N_0\eta_{n-1} + |b|N_0\mu_n < \mu_n\eta_{n-1}$,

where η_{n-1} and μ_n are as described in Theorem 1.2.

Proof. To prove existence of a solution we apply Theorem 2.1. Let y be a solution to

$$(3.5)_\lambda \qquad \begin{aligned}&(\phi_n(y'))' = \lambda q(t)f(t, y, y'), \quad 0 < t < 1, \quad 1 < n \leqq 2, \quad 0 < \lambda < 1,\\ &y'(0) = y(1) = 0.\end{aligned}$$

Now $(\phi_n(y'))' = \lambda qg(t, y, y') + \lambda qh(t, y, y')$, together with $\int_0^1 (\phi_n(y'))' y\, dx = -\int_0^1 |y'|^n dx$, implies

$$(3.6) \qquad \int_0^1 |y'|^n dt \leqq -\lambda \int_0^1 qyg(t, y, y')\, dt + \int_0^1 q|y||h(t, y, y')|\, dt.$$

For notational purposes let

$$\|y_n\|_n = \left\{\int_0^1 |y|^n dt\right\}^{1/n}.$$

In addition, (3.3) yields

$$(3.7) \quad \int_0^1 q|y||h(t, y, y')|\, dt \leqq K \int_0^1 q|y|^{\alpha+1} dt + K \int_0^1 q|y||y'|^\beta dt + K \int_0^1 q|y|\, dt.$$

Now Hölder's inequality yields

$$(3.8) \qquad \sup_{[0,1]} |y(t)| = \sup_{[0,1]} \left|\int_0^t y'(s)\, ds\right| \leqq \|y'\|_n,$$

and so

$$(3.9) \qquad \int_0^1 q|y|^{\alpha+1} dt \leqq K_1\|y'\|_n^{\alpha+1} \quad \text{and} \quad \int_0^1 q|y|\, dt \leqq K_1\|y'\|_n,$$

where $K_1 = \int_0^1 q(s)\, ds$. Also Hölder's inequality implies

$$(3.10) \qquad \begin{aligned}\int_0^1 q|y||y'|^\beta dt &\leqq \|y'\|_n \int_0^1 q|y'|^\beta dt\\ &\leqq \|y'\|_n\left\{\int_0^1 [q(t)]^{n/(n-\beta)} dt\right\}^{(n-\beta)/n} \|y'\|_n^\beta = K_2\|y'\|_n^{\beta+1},\end{aligned}$$

where$K_2 = \{\int_0^1 [q(t)]^{n/(n-\beta)} dt\}^{(n-\beta)/n}$. Putting (3.9) and (3.10) into (3.7) and then (3.6) yields

$$(3.11) \quad \|y'\|_n^n \leqq -\lambda \int_0^1 qyg(t, y, y')\, dt + KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n.$$

Case (i). $a \geqq 0$, $b \geqq 0$.

Then $yg(t, y, y') \geqq 0$, and so (3.11) implies

$$\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n.$$

Thus there exists a constant M_0 independent of λ with

$$\|y'\|_n \leqq M_0 \tag{3.12}$$

for each solution y to $(3.5)_\lambda$.

Case (ii). $a<0$, $b \geqq 0$.

Then with $N_0 = \sup_{[0,1]} q(t)$,

$$-\lambda \int_0^1 qyg(t, y, y')\,dt \leqq (-a)\int_0^1 q|y|^n\,dt \leqq \frac{(-a)N_0}{\mu_n}\|y'\|_n^n \tag{3.13}$$

by Theorem 1.2. Putting (3.13) into (3.11) yields

$$\left(1+\frac{aN_0}{\mu_n}\right)\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n,$$

and we again have (3.12) since $|a|N_0 < \mu_n$.

Case (iii). $a \geqq 0$, $b<0$.

Then

$$-\lambda \int_0^1 qyg(t, y, y')\,dt \leqq (-b)N_0\int_0^1 |y|\,|y'|^{n-1}\,dt \leqq \frac{(-b)N_0}{\eta_{n-1}}\|y'\|_n^n \tag{3.14}$$

by Theorem 1.2. Putting (3.14) into (3.11) yields

$$\left(1+\frac{bN_0}{\eta_{n-1}}\right)\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n,$$

and we again have (3.12).

Case (iv). $a<0$, $b<0$.

Combining Cases (ii) and (iii) will again yield (3.12) in this case.

Now (3.8) and (3.12) yield

$$\sup_{[0,1]} |y(t)| \leqq \|y'\|_n \leqq M_0 \tag{3.15}$$

for any solution y to $(3.5)_\lambda$. This bound, together with (3.3) and (3.4), implies that there exist constants A and B independent of λ with

$$|(\phi_n(y'))'| \leqq Aq|y'|^n + Bq.$$

Consequently,

$$\int_0^1 |(\phi_n(y'))'|\,dt \leqq AN_0\|y'\|_n^n + BK_1 \leqq AN_0M_0^n + BK_1 \equiv M_2, \tag{3.16}$$

where $N_0 = \sup_{[0,1]} q(t)$ and $K_1 = \int_0^1 q(s)\,ds$.

In addition, since

$$|y'(t)|^{n-2}y'(t) = \int_0^t (|y'(s)|^{n-2}y'(s))'\,ds = \int_0^t |(\phi_n(y'(s)))'|\,ds,$$

we have for $t\in[0,1]$,

$$\||y'(t)|^{n-2}y'(t)|\leqq\int_0^1|(\phi_n(y'(s)))'|\,ds\leqq M_2$$

by (3.16). Consequently, $|y'(t)|\leqq M^{1/(n-1)}\equiv M_1$, and so

$$\sup_{[0,1]}|y'(t)|\leqq M_1 \tag{3.17}$$

for each solution y to $(3.5)_\lambda$.

Thus (3.15), (3.17), together with Theorem 2.1, yield the result. □

We also immediately have the following.

THEOREM 3.2. *Suppose* $f:[0,1]\times\mathbf{R}\to\mathbf{R}$ *is continuous and* $q\in C[0,1]$ *satisfies* $q>0$ *on* $(0,1)$. *In addition, assume* f *has the decomposition* $f(t,u)=g(t,u)+h(t,u)$ *with* $g,h:[0,1]\times\mathbf{R}\to\mathbf{R}$ *continuous. Now suppose*

$$|h(t,u)|\leqq K\{|u|^\alpha+1\}\quad \textit{for constants } K,\alpha\quad \textit{with } 0\leqq\alpha<n-1, \tag{3.18}$$

$$\textit{for } a\in\mathbf{R},\quad ug(t,u)\geqq a|u|^n\quad \textit{for } (t,u)\in[0,1]\times\mathbf{R}. \tag{3.19}$$

Then (3.2) *has a solution* $y\in C^1[0,1]$ *with* $(\phi_n(y'))'\in C(0,1)$ *in each of the following cases*:

(i) $a\geqq0$;

(ii) $a<0$ *and* $|a|N_0<\mu_n$, *where* $N_0=\sup_{[0,1]}q(t)$ *and* μ_n *is as described in Theorem* 1.2.

Proof. This follows from the ideas of Theorem 3.1 except we now use Theorem 2.2. □

THEOREM 3.3 (singular case). *Suppose* $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous with assumptions* (2.3) *and* (2.5) *being satisfied. In addition assume* f *has the decomposition* $f(t,u,v)=g(t,u,v)+h(t,u,v)$ *with* $g,h:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *continuous. Now suppose* (3.3) *holds and*

$$\begin{gathered}\textit{for } a,b\in\mathbf{R},\ ug(t,u,v)\geqq a|u|^n+b|u|\,|v|^{n-1}\ \textit{for } (t,u,v)\in[0,1]\times\mathbf{R}^2\ \textit{and}\\ \textit{there exists } \gamma,\ 0\leqq\gamma<n\ \textit{with } |g(t,u,v)|\leqq A(t,u)|v|^\gamma+B(t,u),\\ \textit{where } A(t,u)\ \textit{and } B(t,u)\ \textit{are bounded on bounded sets}\end{gathered} \tag{3.20}$$

$$\int_0^1 q^\theta(s)\,ds<\infty,\quad \textit{where } \theta=\max\left\{\frac{n}{n-\gamma},\frac{n}{n-\beta}\right\}. \tag{3.21}$$

Then (3.1) *has a solution* $y\in C^1[0,1]$ *with* $(\phi_n(y'))'\in C(0,1)$ *in each of the following cases*:

(i) $a\geqq0$, $b\geqq0$;

(ii) $a<0$, $b\geqq0$ *and* $|a|Q_0<1$, *where* $Q_0=\int_0^1 q(t)\,dt$;

(iii) $a\geqq0$, $b<0$, $Q_1<\infty$ *and* $|b|Q_1<1$, *where* $Q_1=(\int_0^1 q^n(s)\,ds)^{1/n}$;

(iv) $a<0$, $b<0$, $Q_1<\infty$ *and* $|a|Q_0+|b|Q_1<1$.

Proof. Exactly the same reasoning as in Theorem 3.1 yields

$$\|y'\|_n^n\leqq-\lambda\int_0^1 qyg(t,y,y')\,dt+KK_1\|y'\|_n^{\alpha+1}+KK_2\|y'\|_n^{\beta+1}+KK_1\|y'\|_n \tag{3.22}$$

for any solution y to $(3.5)_\lambda$.

Case (i). $a \geqq 0$, $b \geqq 0$.
Then

$$\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n.$$

So there exists a constant M_0 independent of λ with

$$\|y'\|_n \leqq M_0. \tag{3.23}$$

Case (ii). $a<0$, $b \geqq 0$.
Then

$$-\lambda \int_0^1 qyg(t, y, y')\,dt \leqq (-a)\|y'\|_n^n \int_0^1 q(t)\,dt = (-a)Q_0\|y'\|_n^n \tag{3.24}$$

using (3.8). Putting (3.24) into (3.22) yields

$$(1+aQ_0)\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n;$$

so again (3.23) is satisfied.

Case (iii). $a \geqq 0$, $b<0$.
Then Hölder's inequality yields

$$-\lambda \int_0^1 qyg(t, y, y')\,dt \leqq (-b)\|y'\|_n \int_0^1 q|y'|^{n-1}\,dt \leqq (-b)\|y'\|_n^n \left(\int_0^1 q^n(s)\,ds\right)^{1/n}. \tag{3.25}$$

Putting (3.25) into (3.22) yields

$$(1+bQ_1)\|y'\|_n^n \leqq KK_1\|y'\|_n^{\alpha+1} + KK_2\|y'\|_n^{\beta+1} + KK_1\|y'\|_n;$$

so again (3.23) is satisfied.

Case (iv). $a<0$, $b<0$. Combining Cases (ii) and (iii) will again yield (3.23) in this case.

Thus

$$\sup_{[0,1]} |y(t)| \leqq \|y'\|_n \leqq M_0 \tag{3.26}$$

for any solution y to $(3.5)_\lambda$. In addition, there exist constants A and B independent of λ with

$$|(\phi_n(y'))'| \leqq Aq|y'|^\tau + Bq,$$

where $\tau = \max\{\beta, \gamma\}$. Now Hölder's inequality yields

$$\begin{aligned}\int_0^1 |(\phi_n(y'))'|\,dt &\leqq A\|y'\|_n^\tau \left(\int_0^1 [q(t)]^{n/(n-\tau)}\,dt\right)^{(n-\tau)/n} + B\int_0^1 q(t)\,dt \\ &\leqq AM_0^\tau \left(\int_0^1 [q(t)]^{n/(n-\tau)}\,dt\right)^{(n-\tau)/n} + B\int_0^1 q(t)\,dt \equiv M_2\end{aligned}$$

and the result now follows as in Theorem 3.1. □

THEOREM 3.4. *Suppose* $f:[0,1]\times\mathbf{R}\to\mathbf{R}$ *is continuous with assumptions* (2.3) *and* (2.5) *being satisfied. In addition, assume* f *has the decomposition* $f(t,u)=g(t,u)+h(t,u)$ *with* $g, h:[0,1]\times\mathbf{R}\to\mathbf{R}$ *continuous. Now assume* (3.18) *and* (3.19) *are satisfied. Then* (3.2) *has a solution* $y\in C^1[0,1]$ *with* $(\phi_n(y'))'\in C(0,1)$ *in each of the following cases*:

(i) $a\geqq 0$;

(ii) $a<0$ *and* $|a|Q_0<1$, *where* $Q_0=\int_0^1 q(t)\,dt$.

3.2. Dirichlet boundary data. In this subsection we discuss the boundary value problems

$$(3.27)\qquad \begin{aligned}&(\phi_n(y'))' = q(t)f(t, y, y'), \quad 0<t<1, \quad 1<n\leqq 2,\\ &y(0)=y(1)=0,\end{aligned}$$

and

$$(3.28)\qquad \begin{aligned}&(\phi_n(y'))' = q(t)f(t, y), \quad 0<t<1, \quad n>1,\\ &y(0)=y(1)=0.\end{aligned}$$

Essentially the same reasoning as in § 3.1 immediately yields the following.

THEOREM 3.5. *Suppose* $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous and* $q\in C[0,1]$ *satisfies* $q>0$ *on* $(0,1)$. *In addition, assume* f *has the decomposition* $f(t,u,v)=g(t,u,v)+h(t,u,v)$ *with* $g, h:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *continuous. Now suppose* (3.3) *and* (3.4) *hold. Then* (3.27) *has a solution* $y\in C^1[0,1]$ *with* $(\phi_n(y'))'\in C[0,1]$ *in each of the following cases*:

(i) $a\geqq 0$, $b\geqq 0$;

(ii) $a<0$, $b\geqq 0$ *and* $|a|N_0<\sigma_n$, *where* $N_0=\sup_{[0,1]} q(t)$;

(iii) $a\geqq 0$, $b<0$ *and* $|b|N_0<\omega_{n-1}$;

(iv) $a<0$, $b<0$ *and* $|a|N_0\omega_{n-1}+|b|N_0\sigma_n<\sigma_n\omega_{n-1}$, *where* ω_{n-1} *and* σ_n *are as described in Theorem* 1.2.

THEOREM 3.6. *Suppose* $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous with assumptions* (2.3) *and* (2.5) *being satisfied. In addition assume* f *has the decomposition* $f(t,u,v)=g(t,u,v)+h(t,u,v)$ *with* $g, h:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *continuous. Now suppose* (3.3), (3.20), *and* (3.21) *are satisfied. Then* (3.27) *has a solution* $y\in C^1[0,1]$ *with* $(\phi_n(y'))'\in C(0,1)$ *in each of the following cases*:

(i) $a\geqq 0$, $b\geqq 0$;

(ii) $a<0$, $b\geqq 0$, *and* $|a|Q_0<1$, *where* $Q_0=\int_0^1 q(t)\,dt$;

(iii) $a\geqq 0$, $b<0$, $Q_1<\infty$, *and* $|b|Q_1<1$, *where* $Q_1=(\int_0^1 q^n(s)\,ds)^{1/n}$;

(iv) $a<0, b<0, Q_1<\infty$, *and* $|a|Q_0+|b|Q_1<1$.

Remark. We also have obvious analogues of Theorems 3.2 and 3.4 for the Dirichlet boundary value problem (3.28).

Remark. If $n=2$ we can replace $ug(t,u,v)\geqq a|u|^2+b|u||v|$ in assumption (3.4) and (3.20) by $ug(t,u,v)\geqq a|u|^2+b|u||v|+cuv$, and the results of Theorems 3.5 and 3.6 are again true.

It is possible to improve the results of this section if Theorem 1.2 is replaced by inequalities of the form

$$\int_0^1 |y|^p q(x)\,dx\leqq C_{1,p}\int_0^1 |y'|^p\,dx \quad\text{and}\quad \int_0^1 |y||y'|^{p-1}q(x)\,dx\leqq C_{2,p}\int_0^1 |y'|^p\,dx,$$

where $C_{1,p}$ and $C_{2,p}$ are the best possible constants (see Theorem 3.8). Here $q\in C^1(0,1)$ is measurable and positive almost everywhere on [0, 1]. For completeness we state the extensions for the mixed boundary data. It should, however, be remarked that $C_{1,p}$ and $C_{2,p}$ are extremely difficult to compute exactly in many situations; so the following results are more theoretical than practical.

THEOREM 3.7. *Suppose* $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous and* f *has the decomposition* $f(t,u,v)=g(t,u,v)+h(t,u,v)$ *with* $g, h:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *continuous. Also suppose one of the following holds*:

(a) $q\in C[0,1]\cap C^1(0,1)$ *with* $q>0$ *on* $(0,1)$ *and assumptions* (3.3) *and* (3.4) *are satisfied*;

(b) $q\in C^1(0,1)$ *with assumptions* (2.3), (2.5), (3.3), (3.20), *and* (3.21) *are satisfied.*

Then (3.1) *has a solution in each of the following cases*:

(i) $a \geqq 0$, $b \geqq 0$;

(ii) $a < 0$, $b \geqq 0$ *and* $|a| C_{1,n} < 1$;

(iii) $a \geqq 0$, $b < 0$, $\int_0^1 q^n(s)\, ds < \infty$ *and* $|b| C_{2,n} < 1$;

(iv) $a < 0$, $b < 0$, $\int_0^1 q^n(s)\, ds < \infty$ *and* $|a| C_{1,n} + |b| C_{2,n} < 1$.

Proof. The only changes are that (3.10), (3.24), and (3.25) become

$$\int_0^1 |y|\,|y'|^\beta q(x)\, dx \leqq C_{2,\beta+1} \int_0^1 |y'|^{\beta+1}\, dx \leqq C_{2,\beta+1} \|y'\|_n^{\beta+1}, \tag{3.10)*}$$

$$(-a) \int_0^1 q(x)|y|^n\, dx \leqq (-a) C_{1,n} \|y'\|_n^n, \qquad a < 0, \tag{3.24)*}$$

and

$$(-b) \int_0^1 |y|\,|y'|^{n-1} q(x)\, dx \leqq (-b) C_{2,n} \|y'\|_n^n, \qquad b < 0. \qquad \square \tag{3.25)*}$$

Remark. There is an obvious result also for the boundary value problem (3.2).

The following theorem guarantees the existence of $C_{1,n}$ and $C_{2,n}$.

THEOREM 3.8. *Suppose* $q \in C^1(0, 1)$ *with assumptions* (2.3) *and* (2.5) *holding.*

(a) *Then for* $p > 1$,

$$\begin{aligned} &\lambda((u')^{p-1})' + q(x) u^{p-1} = 0, \\ &\lim_{x\to 0} u(x) = 0, \lim_{x\to 1} [u'(x)]^{p-1} = 0, \\ &\|u'\|_p = 1 \end{aligned} \tag{3.29}$$

has solutions (u, λ) *with* $u \in C^2(0, 1)$ *and* $u(x) > 0$, $u'(x) > 0$ *on* $(0, 1)$. *In addition, there is a largest value of* λ *such that* (3.29) *has a solution, and if* $C_{1,p}$ *denotes this value, then for any* $y \in C^1[0, 1]$,

$$\int_0^1 |y|^p q(x)\, dx \leqq C_{1,p} \int_0^1 |y'|^p\, dx.$$

(b) *Assume* $\int_0^1 q^p(x)\, dx < \infty$. *Then for* $p > 1$,

$$\begin{aligned} &(\lambda p(u')^{p-1} - (p-1) u (u')^{p-2} q(x))' + q(x)(u')^{p-1} = 0, \\ &\lim_{x\to 0} u(x) = 0, \lim_{x\to 1} (\lambda p(u')^{p-1} - (p-1) u (u')^{p-2} q(x)) = 0, \\ &\|u'\|_{p-1} = 1 \end{aligned} \tag{3.30}$$

has solutions (u, λ) *with* $u \in C^2(0, 1)$ *and* $u(x) > 0$, $u'(x) > 0$ *on* $(0, 1)$. *In addition, there is a largest value of* λ *such that* (3.30) *has a solution, and if* $C_{2,p}$ *denotes this value then for any* $y \in C^1[0, 1]$,

$$\int_0^1 |y|\,|y'|^{p-1} q(x)\, dx \leqq C_{2,p} \int_0^1 |y'|^p\, dx.$$

Proof. (a) This follows from [2, Thm. 1] once we show that $T: L^p \to L^p$ defined by

$$Tu(x) = [q(x)]^{1/p} \int_0^x u(t)\, dt$$

is compact.

(b) This follows from [2, Thm. 1] once we show that $G: L^p \to L^p$ defined by

$$Gu(x) = q(x) \int_0^x u(t)\, dt$$

is compact.

We will show that T is compact. A similar argument works for G. Recall [10] that if (T_n) is a sequence of compact linear operators from a normed space X into a Banach space Y and if $\|T_n - T\| \to 0$ as $n \to \infty$, then the limit operator T is compact.

Let T_n be defined by

$$T_n u(x) = [w_n(x)]^{1/p} \int_0^x u(t)\, dt,$$

where

$$w_n(x) = \begin{cases} q(x) & \text{if } q(x) \leqq n, \\ n & \text{if } q(x) > n. \end{cases}$$

We first show that $T_n: L^p \to C[0,1] \subseteq L^p$ is compact. To do this we apply the Arzela-Ascoli theorem. Fix $n \in \{1, 2, \dots\}$. Let $\Omega \subseteq L^p$ be bounded, i.e., there exist $M > 0$ with $\|u\|_p \leqq M$ for all $u \in \Omega$. Certainly $T_n\Omega$ is bounded and the equicontinuity on $[0,1]$ follows since for $t, s \in [0,1]$ and $u \in \Omega$, we have

$$\begin{aligned}|(T_n u)(t) - (T_n u)(s)| &= \left| [w_n(t)]^{1/p} \int_0^t u(z)\, dz - [w_n(s)]^{1/p} \int_0^s u(z)\, dz \right| \\ &\leqq [w_n(t)]^{1/p} \left| \int_s^t u(z)\, dz \right| + \left| \int_0^s u(z)\, dz \right| \left| [w_n(t)]^{1/p} - [w_n(s)]^{1/p} \right| \\ &\leqq [w_n(t)]^{1/p} M |t-s|^{(p-1)/p} + M \left| [w_n(t)]^{1/p} - [w_n(s)]^{1/p} \right|\end{aligned}$$

by Hölder's inequality. The equicontinuity of $T_n\Omega$ now follows from the continuity of w_n. Consequently, T_n is compact.

Remark. If q is continuous on $[0,1]$, then $T: L^p \to L^p$ is compact by the above argument with q replacing w_n.

We now show that $\|T_n - T\|_p \to 0$ as $n \to \infty$. Notice that

$$\begin{aligned}\|T_n(u) - T(u)\|_p &= \left(\int_0^1 |([w_n(x)]^{1/p} - [q(x)]^{1/p}) \int_0^x u(s)\, ds|^p\, dx \right)^{1/p} \\ &\leqq \|u\|_p \left(\int_0^1 |[w_n(x)]^{1/p} - [q(x)]^{1/p}|^p\, dx \right)^{1/p},\end{aligned}$$

and so by taking the supremum over all u of norm 1 yields

$$\|T_n - T\|_p \leqq \left(\int_0^1 |[w_n(x)]^{1/p} - [q(x)]^{1/p}|^p\, dx \right)^{1/p} \equiv c_n.$$

It remains to show $c_n \to 0$ as $n \to \infty$. If this is so, then T is compact. We first show that $\lim_{n\to\infty} \int_0^1 |w_n(x) - q(x)|\, dx = 0$. To do this notice that w_n is continuous on $[0,1]$ for each n and $\lim_{n\to\infty} w_n(x) = q(x)$ almost everywhere on $[0,1]$. Now since $w_n(x) \leqq q(x)$ almost everywhere on $[0,1]$, we may apply the Lebesgue dominated convergence theorem to deduce

$$\lim_{n\to\infty} \int_0^1 |w_n(x) - q(x)|\, dx = 0.$$

Finally, to show $\lim_{n\to\infty} c_n = \lim_{n\to\infty} \|w_n^{1/p} - q^{1/p}\|_p = 0$ we use the following result [14, p. 76]: *suppose* $f \in L^p$, $f_n \in L^p$ *with* $f_n \to f$ *almost everywhere on* $[0, 1]$ *and* $\lim_{n\to\infty} \|f_n\|_p = \|f\|_p$. *Then* $\lim_{n\to\infty} \|f_n - f\|_p = 0$.

With $f_n = w_n^{1/p}$, $f = q^{1/p}$ we see that

$$\lim_{n\to\infty} \|w_n^{1/p}\|_p = \lim_{n\to\infty} \left(\int_0^1 w_n(x)\,dx\right)^{1/p} = \left(\int_0^1 q(x)\,dx\right)^{1/p} = \|q^{1/p}\|_p,$$

and so the result follows. Consequently, $T: L^p \to L^p$ is compact. A similar argument shows that G is compact. □

4. Bernstein–Nagumo theory. This section extends the Bernstein-Nagumo theory [7] to boundary value problems of the form (1.1) with Dirichlet or mixed boundary data. We begin by examining

$$(4.1) \qquad \begin{aligned} &(\phi(y'))' = q(t)f(t, y), \quad 0 < t < 1, \\ &y(0) = a, \quad y(1) = b, \end{aligned}$$

and

$$(4.2) \qquad \begin{aligned} &(\phi(y'))' = q(t)f(t, y), \quad 0 < t < 1, \\ &y'(0) = a, \quad y(1) = b. \end{aligned}$$

THEOREM 4.1. (a) *Suppose* $f: [0, 1] \times \mathbf{R} \to \mathbf{R}$ *and suppose* (2.3), (2.4), *and* (2.5) *are satisfied. In addition, assume*

(4.3) *there is a constant* $M > 0$ *such that* $yf(t, y) > 0$ *for* $|y| > M$ *and for all* $t \in [0, 1]$.

Then (4.1) *has at least one solution* $y \in C^1[0, 1]$ *with* $(\phi(y'))' \in C(0, 1)$.

(b) *Suppose* $f: [0, 1] \times \mathbf{R} \to \mathbf{R}$, *and suppose* (2.3), (2.4), (2.5), *and* (4.3) *are satisfied. In addition, assume* $\phi(a) = 0$. *Then* (4.2) *has at least one soultion* $y \in C^1[0, 1]$ *with* $(\phi(y'))' \in C(0, 1)$.

Proof. (a) Suppose y is any solution to

$$(4.4)_\lambda \qquad \begin{aligned} &(\phi(y'))' = \lambda q(t)f(t, y), \quad 0 < t < 1, \quad 0 < \lambda < 1, \\ &y(0) = a, \quad y(1) = b. \end{aligned}$$

We claim $\sup_{[0,1]} |y(t)| \leqq \max\{M, |a|, |b|\} \equiv M_1$. Once this is shown the result follows from Theorem 2.4. If $|y|$ achieves its maximum at zero or 1, then, trivially $\sup_{[0,1]} |y(t)| \leqq M_1$. Suppose now that $|y|$ achieves a positive maximum at $t_0 \in (0, 1)$ with $|y(t_0)| > M$. Then $y'(t_0) = 0$. Now the differential equation yields

$$y(t_0)(\phi(y'))'(t_0) = \lambda q(t_0) y(t_0) f(t_0, y(t_0)) > 0.$$

Without loss of generality assume $y(t_0) > 0$. Then there exists a $\delta > 0$ with

$$(\phi(y'))'(t) > 0 \quad \text{for } t \in (t_0 - \delta, t_0 + \delta) \subseteq (0, 1).$$

Consequently,

$$(4.5) \qquad \phi(y'(t)) < \phi(0) \quad \text{for } t \in (t_0 - \delta, t_0),$$

whereas

$$(4.6) \qquad \phi(y'(t)) > \phi(0) \quad \text{for } t \in (t_0, t_0 + \delta).$$

Now if $\phi(0) \geqq 0$, then (4.6) implies $\phi(y'(t)) > 0$ for $t \in (t_0, t_0 + \delta)$, and since ϕ^{-1} is increasing we have $y'(t) > 0$ for $t \in (t_0, t_0 + \delta)$. This contradicts the maximality of $|y(t_0)| = y(t_0)$. On the other hand, if $\phi(0) < 0$, then (4.5) implies $\phi(y'(t)) < 0$ for $t \in (t_0 - \delta, t_0)$, and so $y'(t) < 0$ for $t \in (t_0 - \delta, t_0)$, a contradiction.

A similar contradiction is established if $y(t_0)<0$. Thus $|y(t_0)|\leqq M$, and our claim is established.

(b) Suppose y is any solution to

$$(4.7)_\lambda \qquad \begin{aligned} &(\phi(y'))' = \lambda q(t)f(t,y), \quad 0<t<1, \quad 0<\lambda<1, \\ &y'(0)=a, \quad y(1)=b. \end{aligned}$$

We claim $\sup_{[0,1]}|y(t)|\leqq \max\{M,|b|\}\equiv M_2$. If $|y|$ achieves its maximum at 1, then trivially $\sup_{[0,1]}|y(t)|\leqq M_2$. On the other hand, if $|y|$ achieves a nonzero maximum at $t_0\in(0,1)$, then as in part (a), we have $|y(t_0)|\leqq M$. Finally, suppose $|y|$ achieves a nonzero maximum at zero with $|y(0)|>M$. Then $y(0)f(0,y(0))>0$, and so this together with the differential equations yields

$$y(t)(\phi(y'))'(t)>0$$

for $t>0$ and close to zero. Assume without loss of generality that $y(0)>0$. Then there exists an interval $(0,\delta)$ with $(\phi(y'))'>0$ for $t\in(0,\delta)$. Integration from zero to $t(t<\delta)$ with the fact that $\phi(a)=0$ yields $\phi(y'(t))>0$ for $t\in(0,\delta)$. Thus $y'(t)>0$ for $t\in(0,\delta)$, which contradicts the maximality of $|y(0)|=y(0)$. A similar contradiction is established if $y(0)<0$. Thus $|y(0)|\leqq M$, and our claim is established. The result now follows from Theorem 2.2. □

Finally, in this paper we consider the more general problems

$$(4.8) \qquad \begin{aligned} &(\phi(y'))' = q(t)f(t,y,y'), \quad 0<t<1, \\ &y(0)=a, \quad y(1)=b, \end{aligned}$$

and

$$(4.9) \qquad \begin{aligned} &(\phi(y'))' = q(t)f(t,y,y'), \quad 0<t<1, \\ &y'(0)=0, \quad y(1)=b. \end{aligned}$$

THEOREM 4.2. *Suppose* $f:[0,1]\times\mathbf{R}^2\to\mathbf{R}$ *is continuous and* (2.3), (2.4), (2.5), *and* (2.6) *are satisfied. In addition, suppose*

(4.10) *there is a constant* $M\geqq 0$ *such that* $yf(t,y,0)>0$ *for* $|y|>M$ *and for all* $t\in[0,1]$,

(4.11) $\phi(-u)=-\phi(u)$ *for* $u\neq 0$,

and

(4.12) *there is a continuous function* $\psi:[0,\infty)\to(0,\infty)$ *such that* $|f(t,u,v)|\leqq\psi(|v|)$ *for* $(t,u)\in[0,1]\times[-M_3,M_3]$. *Here* $M_3=\max\{M,|a|,|b|\}$ *if we are examining* (4.8), *whereas* $M_3=\max\{M,|b|\}$ *if we are interested in* (4.9).

Also assume **one** *of the following holds*:

(4.13) q *is continuous on* $[0,1]$ *and*

$$2M_3\sup_{[0,1]}q(t)<\int_{\phi(c)}^{\infty}\frac{\phi^{-1}(u)}{\psi(\phi^{-1}(u))}\,du$$

or

$$(4.14) \qquad \int_0^1 q(t)\,dt<\int_{\phi(c)}^{\infty}\frac{du}{\psi(\phi^{-1}(u))}$$

or

$$\text{there exists } p>1 \text{ with } \int_0^1 [q(t)]^{p/(p-1)}\,dt<\infty \text{ and} \tag{4.15}$$
$$(2M_3)^{1/p}\left(\int_0^1 [q(t)]^{p/(p-1)}\,dt\right)^{(p-1)/p} < \int_{\phi(c)}^{\infty} \frac{(\phi^{-1}(u))^{1/p}}{\psi(\phi^{-1}(u))}\,du.$$

Here $c=|b-a|$ *if we are examining* (4.8), *whereas* $c=0$ *if we are interested in* (4.9). *Then* (4.8) *and* (4.9) *have at least one solution* $y\in C^1[0,1]$ *with* $(\phi(y'))'\in C(0,1)$.

Proof. Essentially the same reasoning as in Theorem 4.1 yields

$$\sup_{[0,1]}|y(t)|\leqq M_3 \tag{4.16}$$

for any solution y to

$$(\phi(y'))'=\lambda q(t)f(t,y,y'),\quad 0<t<1,\quad 0<\lambda<1, \qquad y(0)=a,\quad y(1)=b, \tag{4.17$_\lambda$}$$

or

$$(\phi(y'))'=\lambda q(t)f(t,y,y'),\quad 0<t<1,\quad 0<\lambda<1, \qquad y'(0)=0,\quad y(1)=b. \tag{4.18$_\lambda$}$$

Now each point $t\in[0,1]$ for which $|y'(t)|>c$ belongs to an interval $[\mu,\nu]$ such that y' maintains a fixed sign on $[\mu,\nu]$ and $|y'(\mu)|$ and/or $|y'(\nu)|$ is c.

Case (i). Suppose (4.13) holds.

To be definite assume $y'>0$ on (μ,ν) and $y'(\mu)=c$. Then $(\phi(y'))'\leqq q(t)\psi(y')$ for $t\in(\mu,\nu)$. Multiply by y' and integrate from μ to t to obtain

$$\int_\mu^t \frac{\phi^{-1}(\phi(y'))(\phi(y'))'}{\psi(\phi^{-1}(\phi(y')))}\,ds=\int_\mu^t \frac{y'(\phi(y'))'}{\psi(y')}\,ds\leqq \sup_{[0,1]} q(t)\int_0^t y'\,ds.$$

Thus

$$H(\phi(y'(t)))=\int_{\phi(c)}^{\phi(y'(t))}\frac{\phi^{-1}(u)}{\psi(\phi^{-1}(u))}\,du\leqq 2M_3\sup_{[0,1]} q(t),$$

and so since $H:[0,\infty)\to[0,\infty)$ is increasing we have

$$|y'(t)|=y'(t)\leqq \phi^{-1}\left(H^{-1}\left(2M_3\sup_{[0,1]} q(t)\right)\right)\equiv M_4.$$

The other possibilities are treated similarly, and the same bound on $|y'(t)|$ is obtained. Thus

$$\sup_{[0,1]}|y'(t)|\leqq \max\{M_4,|c|\}. \tag{4.19}$$

Now (4.16), (4.19), together with Theorems 2.1 or 2.3, yield the result.

Case (ii). Suppose (4.14) holds.

To be definite assume $y'<0$ on (μ,ν) and $y'(\mu)=-c$. Then $-(\phi(y'))'\leqq q(t)\psi(-y')$ for $t\in(\mu,\nu)$, and integrate from μ to t to obtain

$$\int_\mu^t \frac{-(\phi(y'))'}{\psi(\phi^{-1}(\phi(-y')))}\,ds\leqq\int_\mu^t q(s)\,ds.$$

Now using (4.11) we obtain

$$J(\phi(-y'(t)))=\int_{\phi(c)}^{\phi(-y'(t))}\frac{du}{\psi(\phi^{-1}(u))}\leqq\int_0^1 q(s)\,ds,$$

and so

$$|y'(t)|=-y'(t)\leqq\phi^{-1}\left(J^{-1}\left(\int_0^1 q(s)\,ds\right)\right)\equiv M_5.$$

The other possibilities are treated similarly, and the same bound on $|y'(t)|$ is obtained. Thus

$$\sup_{[0,1]}|y'(t)|\leqq\max\{M_5,|c|\}. \tag{4.20}$$

Now (4.16) and (4.20) yield the result.

Case (iii). Suppose (4.15) holds.

To be definite assume $y'>0$ on (μ,ν) and $y'(\mu)=c$. Then $(\phi(y'))'\leqq q(t)\psi(y')$ for $t\in(\mu,\nu)$. Multiply by $(y')^{1/p}$, and integrate from μ to t to obtain

$$\int_\mu^t\frac{[\phi^{-1}(\phi(y'))]^{1/p}(\phi(y'))'}{\psi(\phi^{-1}(\phi(y')))}\,ds\leqq\int_\mu^t q(s)(y'(s))^{1/p}\,ds.$$

Thus Hölder's inequality yields

$$G(\phi(y'(t)))=\int_{\phi(c)}^{\phi(y'(t))}\frac{[\phi^{-1}(u)]^{1/p}}{\psi(\phi^{-1}(u))}\,du\leqq(2M_3)^{1/p}\left(\int_0^1[q(t)]^{p/(p-1)}\,dt\right)^{(p-1)/p}.$$

Consequently,

$$|y'(t)|=y'(t)\leqq\phi^{-1}\left(G^{-1}\left((2M_3)^{1/p}\left(\int_0^1[q(t)]^{p/(p-1)}\,dt\right)^{(p-1)/p}\right)\right)\equiv M_6.$$

The other possibilities are treated similarly, and the same bound on $|y'(t)|$ is obtained. Thus

$$\sup_{[0,1]}|y'(t)|\leqq\max\{M_6,|c|\}. \qquad \square$$

NEGATIVE EIGENVALUES FOR A NONLINEAR DIFFERENTIAL EQUATION ON ℝ*

W. ROTHER†

Abstract. This paper considers a nonlinear eigenvalue problem involving a second-order ordinary differential equation on ℝ with variable coefficients. One of the coefficients may be negative on some subsets of ℝ and both may be unbounded. In case that the coefficients are positive constants this problem has been studied by H. Berestycki and P.-L. Lions [*Arch. Rational Mech. Anal.*, 82 (1983), pp. 313-345]. The paper shows that the problem has a negative eigenvalue and a positive classical solution decaying exponentially at infinity. Moreover, in some special cases the existence of bifurcation is proved. The main tools are direct methods from the calculus of variations, some comparison techniques, and Lebesgue's theorem on monotone functions.

Key words. nonlinear ordinary differential equation, negative eigenvalue, variational methods, bifurcation

AMS subject classification. 34B15

1. Introduction. In the present paper we study the nonlinear Dirichlet problem

$$(1.1)\qquad \begin{gathered} -u''-q(t)|u|^{\sigma_1}u+r(t)|u|^{\sigma_2}u=\lambda u \quad \text{for } t\in\mathbb{R}, \\ \lim_{t\to-\infty} u(t)=\lim_{t\to\infty} u(t)=0, \end{gathered}$$

where σ_1 and σ_2 are positive constants, λ is negative, and $q(\cdot)$ and $r(\cdot)$ are real-valued functions.

In case that $r\equiv 0$ and $N\geqq 2$ (replace u'' by Δu), this problem has been considered by many authors. See, for instance, [4], [5], [7]-[10], [13], [16]-[18], [20]-[23] and the literature quoted therein. In case $N=1$ and $r\equiv 0$, existence of nontrivial solutions and bifurcation in $L^p(\mathbb{R})$ has been proved in [19] and [20]. In [20] (respectively, [19]), the author assumes that the function q satisfies

$$0<A\leqq q(t)(1+|t|)^a\leqq B<\infty$$

for some constant $a\in[0,2)$ (respectively, $a=0$).

Moreover, Zhu and Zhou [23] proved that bifurcation occurs in $H^1(\mathbb{R})$ if $r\equiv 0$, $\sigma_1<4$, and q is a continuous function on $\mathbb{R}$ satisfying $q(t)\to q_\infty>0$ as $|t|\to\infty$ and $q(t)\geqq q_\infty$ for $t\in\mathbb{R}$.

Similar results for the Dirichlet problem on $(0,\infty)$ were obtained in [11], [15], and [17, Thm. 7.4].

In all cases quoted above the only bifurcation point is $\lambda=0$, i.e., the infimum of the essential spectrum of the linearization $-u''$ (respectively, $-\Delta u$).

In case q and r are positive constants and $N=1$ or $N\geqq 3$, existence results for (1.1) have been proved in [3] (see also [14, Thm. 2; Remark p. 160-161]).

Suppose, for instance, that $\sigma_1<\sigma_2$. Then, Berestycki and Lions (see [3, Ex. 2, Thms. 1 and 5]) have shown that (1.1) has a positive classical solution, decaying

* Received by the editors February 3, 1992; accepted for publication (in revised form) September 3, 1992.

† Department of Mathematics, University of Bayreuth, P.O.B. 101251, W-8580 Bayreuth, Germany.

exponentially at infinity if and only if $q > q^*$, where

$$q^* = \left(\frac{|\lambda|}{2}\right)^{(\sigma_2-\sigma_1)/\sigma_2} r^{\sigma_1/\sigma_2}\sigma_2(2+\sigma_1)(\sigma_2-\sigma_1)^{(\sigma_1-\sigma_2)/\sigma_2}\sigma_1^{-\sigma_1/\sigma_2}(2+\sigma_2)^{-\sigma_1/\sigma_2}.$$

Hence it seems to be an interesting question if (1.1) possesses a positive classical solution when the function q is negative on some subsets of $\mathbb{R}^N$ and $r(\cdot)$ is unbounded.

In [12] we presented some existence results for this problem when $N \geqq 3$, $0 < \sigma_1 < 4/(N-2)$, and $\sigma_2 \geqq 4/(N-2)$. We supposed that q and r satisfy some growth conditions on a certain subset $\mathscr{B}$ of $\mathbb{R}^N$, and outside of $\mathscr{B}$ we required the functions r and $q_- = \min(q, 0)$ to be locally integrable. To prove that the solutions decay exponentially at infinity we had to assume that the corresponding eigenvalues λ are negative (see Corollaries 1.1 and 1.2 in [12]), and had to show that some λ are negative. We had to impose rather restrictive conditions on the functions q and r (see [12, Thms. 1.3-1.5]). By the way, in case $r \equiv 0$, the eigenvalues are always negative, and the proof of this fact is evident (see, for instance, [7, p. 571] and Lemma 3.11).

In the following, we present some results for the case $N = 1$. It turns out that we need no additional assumptions in this case to show that $\lambda < 0$ holds for some eigenvalues λ (see Lemmas 3.12 and 4.3). Moreover, if $\sigma_1 < 2(2-a)$ (the constant a may be chosen as in condition (i.c)) we can show that there exists a sequence of solution pairs (u_n, λ_n), with $\lambda_n < 0$, bifurcating from $\lambda = 0$ (see Thm. 1.2). Using some standard techniques (see Lemma 3.10) and assuming that q is bounded above near infinity, we prove that the corresponding solutions u (respectively, u_n) decay exponentially at infinity. The main tool in the proof of Theorem 1.2 is Lebesgue's theorem on monotone functions. We use this theorem to show that the monotone decreasing energy $I(\cdot)$ is almost everywhere differentiable. Even in the case where $r \equiv 0$ the results of Theorems 1.1 and 1.2 seem to be new since q may change sign and may be unbounded below.

To present our results, we start with the formulation of some conditions for σ_1, σ_2, and the functions q and r. For the constants σ_1 and σ_2, we consider the cases

(i) $0 < \sigma_1 < 4$ and $0 < \sigma_2$; and

(ii) $4 \leqq \sigma_1$ and $\sigma_1 < \sigma_2$.

In case (i), we assume

(i.a) That the functions $q, r: \mathbb{R} \to \mathbb{R}$ are measurable, that r is nonnegative and that r and $q_- = \min(q, 0)$ are locally integrable;

(i.b) That the function $q_+ = \max(q, 0)$ can be written as $q_+ = q_1 + q_2$, where q_1 satisfies $0 \leqq q_1 \in L^\infty$ so that $q_1(t) \to 0$ as $|t| \to \infty$, and the function q_2 satisfies $0 \leqq q_2 \in L^{p_1}$ for some constant $p_1 \in [1, \infty) \cap (2/(4-\sigma_1), \infty)$;

(i.c) That there exist constants $t_0 \geqq 1$, $a > 0$, and $\mathscr{K} > 0$, and a measurable function $f: [t_0, \infty) \to [0, \infty)$, satisfying $f(t) \to \infty$ as $t \to \infty$, such that

(1) $q(t) \geqq f(t)t^{-a}$ and $r(t) \leqq \mathscr{K}t^b$ hold for all $t \geqq t_0$ or

(2) $q(t) \geqq f(-t)(-t)^{-a}$ and $r(t) \leqq \mathscr{K}(-t)^b$ hold for all $t \leqq -t_0$.

Here, the constant b is defined by $b = (2-a)(\sigma_2/\sigma_1) - 2$.

If (ii) is satisfied, we assume

(ii.a) That condition (i.a) holds true and that there exists a positive constant r_0 so that $r(t) \geqq r_0$ holds almost everywhere in $\mathbb{R}$;

(ii.b) that condition (i.b) is satisfied with the exception that the function q_2 satisfies $0 \leqq q_2 \in L^{p_2}$ for some $p_2 \in ((2+\sigma_2)/(\sigma_2-\sigma_1), \infty)$;

(ii.c) and that condition (i.c) holds true.

Remark 1.1. (a) The only assumption which the functions q_- and r have to fulfill on $(-\infty, t_0)$ (respectively, $(-t_0, \infty)$) is to be locally integrable. So q_- and r may have singularities on $(-\infty, t_0)$ (respectively, $(-t_0, \infty)$), q_- may decrease very fast to $-\infty$ as $t \to -\infty$ (respectively, $t \to \infty$) and r may increase very fast to $+\infty$ as $t \to -\infty$ (respectively, $t \to \infty$).

(b) In case (ii) it is assumed that $r(t) \geqq r_0 > 0$ holds for almost all $t \in \mathbb{R}$. Hence condition (ii.c) only can be fulfilled if $b \geqq 0$, i.e., if $a \leqq 2(1-(\sigma_1/\sigma_2))$.

(c) If v is a solution of the equation

$$-v'' - q(-t)|v|^{\sigma_1} v + r(-t)|v|^{\sigma_2} v = \lambda v \quad \text{in } \mathbb{R},$$

then $u(t) = v(-t)$ is a solution of (1.1). Hence, we may assume without restriction that part (1) of condition (i.c), respectively (ii.c), is satisfied.

Then we will prove the following results.

THEOREM 1.1. (a) *Suppose that* (i) *or* (ii) *holds true and that* $\sigma_1 \geqq 2(2-\mathrm{a})$. *Then, there exists a positive function* $u \in C^1 \cap H^1$ *and a negative constant* λ *such that* (1.1) *holds in the sense of distributions. In case* $\sigma_1 = 2(2-\mathrm{a})$, *we have* $\|u\|_2 = 1$.

(b) *If q and r are continuous, then u is twice continuously differentiable and* (1.1) *holds in the classical sense. Moreover, in case there exist positive constants* t_1 *and C such that*

$$q(t) \leqq C \quad \textit{holds for almost all } |t| \geqq t_1,$$

the function u decays exponentially as $|t| \to \infty$.

THEOREM 1.2. (a) *Suppose that* (i) *and* (ii) *hold true and that* $\sigma_1 < 2(2-\mathrm{a})$. *Then, there exist a sequence* (u_n) *of pairwise distinct functions* $u_n \in C^1 \cap H^1$ *and a sequence of negative constants* (λ_n) *such that* u_n *is positive and* (u_n, λ_n) *solves* (1.1) *in the sense of distributions. Letting* $n \to \infty$, *it follows that*

$$\|u_n\|_{H^1}^2 + \int |q||u_n|^{2+\sigma_1}\, dt + \int r|u_n|^{2+\sigma_2}\, dt \to 0$$

and $\lambda_n \to 0$. *In particular, we see that* $\lambda = 0$ *is a bifurcation point for* (1.1) *in* H^1 *and in* $L^2 \cup L^\infty$.

(b) *The assertions of Theorem* 1.1(b) *hold true if we replace u by* u_n.

2. Some preliminaries. By $L^p = L^p(\mathbb{R})$ and $L^p_{\text{loc}} = L^p_{\text{loc}}(\mathbb{R})$ $(1 \leqq p \leqq \infty)$, we denote the usual Lebesgue spaces, and $\|\cdot\|_p$ is the norm on L^p. If $1 < p < \infty$, the dual index p' is defined by $p' = p/(p-1)$. Moreover, H^1 denotes the Sobolev space $H^1(\mathbb{R}) = W^{1,2}(\mathbb{R})$, and the norm $\|\cdot\|_{H^1}$ is defined by $\|u\|_{H^1} = (\|u'\|_2^2 + \|u\|_2^2)^{1/2}$. Finally, $C^1 = C^1(\mathbb{R})$ is the space of the continuously differentiable functions, and $C_0^\infty = C_0^\infty(\mathbb{R})$ denotes the set of all functions that have compact support and derivatives of any order.

LEMMA 2.1. *Each function* $u \in H^1$ *can be identified with a Hölder continuous function on* $\mathbb{R}$, *still denoted by u, such that* $\lim_{|t| \to \infty} u(t) = 0$,

$$|u(t_1) - u(t_2)| \leqq \|u'\|_2 |t_1 - t_2|^{1/2} \quad \textit{holds for all } t_1, t_2 \in \mathbb{R},$$

and $\|u\|_\infty \leqq \sqrt{2}\, \|u'\|_2^{1/2} \|u\|_2^{1/2}$.

Proof. For $\varphi \in C_0^\infty$ we have

$$|\varphi(t_1) - \varphi(t_2)| = \left| \int_{t_2}^{t_1} \varphi'(s)\, ds \right| \leqq \|\varphi'\|_2 |t_1 - t_2|^{1/2}$$

and $\varphi^2(t) = 2\int_{-\infty}^t \varphi'(s)\varphi(s)\, ds$. Since C_0^∞ is dense in H^1, we obtain the assertion. □

3. Proof of Theorem 1.1. We start with the following lemma.

LEMMA 3.1. *Suppose that* (i) *and* (i.a)–(i.c) *hold true. Then there exist positive constants* α_1 *and* β_1, *and for each* $\varepsilon > 0$ *a constant* $C_{1,\varepsilon} \geqq 0$, *such that*

$$(2+\sigma_1)^{-1} \int q_+ |u|^{2+\sigma_1}\, dt \leqq \varepsilon \|u'\|_2^2 + C_{1,\varepsilon}(\|u\|_2^{2+\alpha_1} + \|u\|_2^{2+\beta_1})$$

holds for all $u \in H^1$.

Proof. From Lemma 2.1 and Hölder's inequality we conclude that

$$\int q_1 |u|^{2+\sigma_1}\, dt \leqq 2^{\sigma_1/2} \|q_1\|_\infty \|u'\|_2^{\sigma_1/2} \|u\|_2^{2+(\sigma_1/2)}.$$

The constant p_1 may be chosen as in condition (i.b). Then, in case $p_1 = 1$ we see that

$$\int q_2 |u|^{2+\sigma_1}\, dt \leqq 2^{1+(\sigma_1/2)} \|q_2\|_1 \|u'\|_2^{1+(\sigma_1/2)} \|u\|_2^{1+(\sigma_1/2)}.$$

Further, if $p_1 > 1$, we obtain

$$\begin{aligned}\int q_2 |u|^{2+\sigma_1}\, dt &\leqq \|q_2\|_{p_1} \|u\|_\infty^{2+\sigma_1-(2/p_1')} \|u\|_2^{2/p_1'} \\ &\leqq 2^{(1/p_1)+(\sigma_1/2)} \|q_2\|_{p_1} \|u'\|_2^{(1/p_1)+(\sigma_1/2)} \|u\|_2^{1+(1/p_1')+(\sigma_1/2)}.\end{aligned}$$

Since $\sigma_1 < 4$, $p_1 > 2/(4-\sigma_1)$, and $\sigma_1 < 2$ if $p_1 = 1$, the assertion follows from Young's inequality. □

LEMMA 3.2. *Suppose that* (ii) *and* (ii.a)–(ii.c) *hold true. Then there exist positive constants* α_2 *and* β_2, *and for each* $\varepsilon > 0$ *a constant* $C_{2,\varepsilon} \geqq 0$, *such that*

$$(2+\sigma_1)^{-1} \int q_+ |u|^{2+\sigma_1}\, dt \leqq \varepsilon \|u\|_{2+\sigma_2}^{2+\sigma_2} + C_{2,\varepsilon}(\|u\|_2^{\alpha_2} + \|u\|_2^{\beta_2})$$

holds for all $u \in H^1$.

Proof. For $\gamma_1 = \sigma_1/\sigma_2$, we see that $2+\sigma_1 = \gamma_1(2+\sigma_2) + (1-\gamma_1)2$. Hence, by Hölder's inequality, it follows that

$$\int q_1 |u|^{2+\sigma_1}\, dt \leqq \|q_1\|_\infty \left(\int |u|^{2+\sigma_2}\, dt \right)^{\gamma_1} \left(\int |u|^2\, dt \right)^{1-\gamma_1}.$$

The constant p_2 may be chosen as in condition (ii.b). Then it follows that $(2+\sigma_1)p_2' < 2+\sigma_2$. Thus, there exists a constant $\gamma_2 \in (0,1)$ such that $(2+\sigma_1)p_2' = \gamma_2(2+\sigma_2) + (1-\gamma_2)2$. Now, Hölder's inequality implies

$$\int q_2 |u|^{2+\sigma_1}\, dt \leqq \|q_2\|_{p_2} \left(\int |u|^{2+\sigma_2}\, dt \right)^{\gamma_2/p_2'} \left(\int |u|^2\, dt \right)^{(1-\gamma_2)/p_2'}.$$

Since $\gamma_1, \gamma_2/p_2' \in (0,1)$, the assertion follows by Young's inequality. □

In the following, we always assume that either (i) and (i.a)–(i.c) (part (1)) or (ii) and (ii.a)–(ii.c) (part (1)) are fulfilled. The functional ξ may be defined by

$$\xi(u) = \frac{1}{2} \int |u'|^2\, dt - (2+\sigma_1)^{-1} \int q(t)|u|^{2+\sigma_1}\, dt + (2+\sigma_2)^{-1} \int r(t)|u|^{2+\sigma_2}\, dt.$$

Moreover, for $\mu \geqq 0$, we define the set S_μ by

$$S_\mu = \left\{ u \in H^1;\ \int |q_-||u|^{2+\sigma_1}\, dt < \infty,\ \int r(t)|u|^{2+\sigma_2}\, dt < \infty \text{ and } \|u\|_2 \leqq \mu \right\}.$$

Since $r(t) \geqq r_0 > 0$ holds in case (ii), we conclude from Lemmas 3.1 and 3.2 that $\xi(\cdot)$ is bounded below on S_μ. Hence

$$I(\mu) = \inf_{u \in S_\mu} \xi(u)$$

is a well-defined real number.

LEMMA 3.3. *Let $k = (a-2)/\sigma_1$. Then there exists a function $h:[1,\infty) \to \mathbb{R}$ such that $h(s) \to -\infty$ as $s \to \infty$, and*

$$I(s^{k+(1/2)}) \leqq s^{2k-1} h(s) \quad \textit{holds for all } s \in [1,\infty).$$

Proof. The function $\varphi \in C_0^\infty$ may be chosen such that supp $\varphi \subset (t_0, \infty)$ and $\|\varphi\|_2 = 1$. Moreover, for $s \geqq 1$ we define the function φ_s by $\varphi_s(t) = s^k \varphi(s^{-1}t)$. Since $\|\varphi_s\|_2 = s^{k+(1/2)}$, we see that

$$\begin{aligned} I(s^{k+(1/2)}) \leqq \xi(\varphi_s) = s^{2k-1}\Big(\frac{1}{2}\int |\varphi'|^2\,dt - s^{2+\sigma_1 k}(2+\sigma_1)^{-1}\int_{t_0}^{\infty} q(st)|\varphi(t)|^{2+\sigma_1}\,dt \\ + s^{2+\sigma_2 k}(2+\sigma_2)^{-1}\int_{t_0}^{\infty} r(st)|\varphi(t)|^{2+\sigma_2}\,dt\Big). \end{aligned} \tag{3.1}$$

Now, from (i.c), respectively, (ii.c), we conclude that the right-hand side of (3.1) is less than or equal to $s^{2k-1}h(s)$, where

$$\begin{aligned} h(s) = \frac{1}{2}\int |\varphi'|^2\,dt - \inf_{x \geqq st_0} f(x)(2+\sigma_1)^{-1}\int_{t_0}^{\infty} t^{-a}|\varphi(t)|^{2+\sigma_1}\,dt \\ + \mathcal{K}(2+\sigma_2)^{-1}\int_{t_0}^{\infty} t^{b}|\varphi(t)|^{2+\sigma_2}\,dt. \end{aligned}$$

Since $\inf_{x \geqq st_0} f(x) \to \infty$ as $s \to \infty$, we obtain the assertion. □

LEMMA 3.4. *In case*

(i) $\sigma_1 > 2(2-a)$, *there exists a constant* $\mu > 0$ *such that* $I(\mu) < 0$;

(ii) $\sigma_1 = 2(2-a)$, *it follows that* $I(1) < 0$;

(iii) $\sigma_1 < 2(2-a)$, *there exists a constant* $\mu_0 > 0$ *such that* $I(\mu) < 0$ *holds for all* $\mu \in (0, \mu_0]$.

Proof. The constant k may be chosen as in Lemma 3.3. Then, in case (i) we have that $k+\frac{1}{2} > 0$, in case (ii) $k + \frac{1}{2} = 0$, and in case (iii) $k + \frac{1}{2} < 0$. Hence, the assertions follow from Lemma 3.3. □

LEMMA 3.5. *Suppose that there exists a $\mu > 0$ such that $I(\mu) < 0$. Moreover, the constants α_i and β_i $(i = 1, 2)$ may be chosen as in Lemma* 3.1, *respectively, Lemma* 3.2. *Then, there exists a nonnegative function $u \in S_\mu$ such that $\|u\|_2 > 0$ and $\xi(u) = I(\mu)$. Furthermore, there exists a constant C, independent of μ, so that*

$$\|u'\|_2^2 + \int |q_-||u|^{2+\sigma_1}\,dt + \int r|u|^{2+\sigma_2}\,dt \leqq C(\mu^{2+\alpha_1} + \mu^{2+\beta_1})$$

holds in case (i) *and*

$$\|u'\|_2^2 + \int |q_-||u|^{2+\sigma_1}\,dt + \int r|u|^{2+\sigma_2}\,dt \leqq C(\mu^{\alpha_2} + \mu^{\beta_2})$$

holds in case (ii).

Proof. We start with case (i). Let $(u_n) \subset S_\mu$ be a sequence such that $\xi(u_n) \to I(\mu)$. Then, we may assume without restriction that $\xi(u_n) \leqq 0$ and $u_n \geqq 0$. Hence, we obtain from Lemma 3.1 that

$$\begin{aligned}\frac{1}{4}\|u_n'\|_2^2 + (2+\sigma_1)^{-1}\int |q_-||u_n|^{2+\sigma_1}\,dt + (2+\sigma_2)^{-1}\int r|u_n|^{2+\sigma_2}\,dt \\ \leqq C_{1,1/4}(\mu^{2+\alpha_1} + \mu^{2+\beta_1})\end{aligned} \tag{3.2}$$

holds for all n.

In particular, we see that (u_n) is bounded in H^1. Then, using Lemma 2.1, the reflexivity of H^1, the Arzela-Ascoli theorem, and a standard diagonal process, it follows that there exists a subsequence of (u_n), still denoted by (u_n), and a $u \in H^1$ such that $u_n \to_w u$ in H^1 and $\sup_{|t| \leqq d} |u(t) - u_n(t)| \to_{n\to\infty} 0$ holds for all $d \geqq 0$. Moreover, by (3.2), Fatou's lemma and the uniform boundedness principle it follows that $u \in S_\mu$. Using the fact that $q_1 \in L^\infty$ and that $q_1(t) \to 0$ as $|t| \to \infty$, we verify that

$$\int q_1|u_n|^{2+\sigma_1}\,dt \to \int q_1|u|^{2+\sigma_1}\,dt.$$

Since $\|u|^{2+\sigma_1} - |u_n|^{2+\sigma_1}| \leqq c|u-u_n|(|u|^{1+\sigma_1} + |u_n|^{1+\sigma_1})$ holds for all n and a constant c, we obtain by Hölder's inequality and Lemma 3.1:

$$\begin{aligned}&\int q_2\|u|^{2+\sigma_1} - |u_n|^{2+\sigma_1}|\,dt \\ &\leqq c\left(\int q_2|u-u_n|^{2+\sigma_1}\,dt\right)^{1/(2+\sigma_1)} \\ &\quad\cdot\left(\int q_2(|u|^{1+\sigma_1} + |u_n|^{1+\sigma_1})^{(2+\sigma_1)/(1+\sigma_1)}\,dt\right)^{(1+\sigma_1)/(2+\sigma_1)} \\ &\leqq c'\left(\int q_2|u-u_n|^{2+\sigma_1}\,dt\right)^{1/(2+\sigma_1)}.\end{aligned}$$

The constant p_1 may be chosen as in condition (i.b).

If $p_1 = 1$, we define $p_1' = (2+\sigma_1)p_1' = \infty$, then we obtain for each constant $R > 0$:

$$\begin{aligned}&\int q_2|u-u_n|^{2+\sigma_1}\,dt \\ &\leqq \|q_2\|_{p_1}\|u-u_n\|^{2+\sigma_1}_{L^{(2+\sigma_1)p_1'}(\{t;|t|<R\})} + \|q_2\|_{L^{p_1}(\{t;|t|\geqq R\})}\|u-u_n\|^{2+\sigma_1}_{(2+\sigma_1)p_1'}.\end{aligned}$$

Since $\|q_2\|_{L^{p_1}(\{t;|t|\geqq R\})} \to 0$ as $R \to \infty$, we see that

$$\int q_2|u-u_n|^{2+\sigma_1}\,dt \to 0 \quad (n \to \infty)$$

and

$$\int q_2|u_n|^{2+\sigma_1}\,dt \to \int q_2|u|^{2+\sigma_1}\,dt.$$

The above results show that

$$I(\mu) \leqq \xi(u) \leqq \liminf \xi(u_n) = I(\mu) < 0.$$

Moreover, (3.2) holds true if we replace u_n by u.

Since $\xi(u) < 0$, it follows that $\|u\|_2 > 0$. Finally, the fact that u_n converges pointwise to u shows that u is nonnegative.

Now, we assume that (ii) and (ii.a)-(ii.c) are fulfilled. The sequence $(u_n) \subset S_\mu$ may be chosen as above. Then, according to Lemma 3.2, we obtain

$$\frac{1}{2}\|u_n'\|_2^2+(2+\sigma_1)^{-1}\int |q_-||u_n|^{2+\sigma_1}\,dt+(2(2+\sigma_2))^{-1}\int r|u_n|^{2+\sigma_2}\,dt \leqq C_{2,\varepsilon}(\mu^{\alpha_2}+\mu^{\beta_2})$$

for $\varepsilon = r_0/(2(2+\sigma_2))$ and all n. Here, the constant $r_0 > 0$ is chosen as in (ii.a). Then, proceeding as above, we obtain the assertion. □

LEMMA 3.6. *Suppose that there exists a constant $\mu > 0$ such that $I(\mu) < 0$. Further, we assume that the function u is chosen according to Lemma* 3.5. *Then* (1.1) *holds in the sense of distributions if*

$$\lambda = \|u\|_2^{-2}\left(\|u'\|_2^2 - \int q|u|^{2+\sigma_1}\,dt + \int r|u|^{2+\sigma_2}\,dt\right).$$

Proof. Since $u \in L^\infty$, we see that $q|u|^{\sigma_1}u$ and $r|u|^{\sigma_2}u$ are locally integrable. Using this fact, it is not difficult to show that for each $\varphi \in C_0^\infty$ the function

$$\varepsilon \to \Phi(\varepsilon) = \xi(\|u\|_2\|u+\varepsilon\varphi\|_2^{-1}(u+\varepsilon\varphi))$$

is differentiable at $\varepsilon = 0$. But $d\Phi(\varepsilon)/d\varepsilon\,|_{\varepsilon=0} = 0$ then implies the assertion. □

LEMMA 3.7. *The constants μ and λ and the function u may be chosen as in Lemma* 3.6. *Then u is positive and continuously differentiable. Moreover, if q and r are continuous, then u is twice continuously differentiable and* (1.1) *holds in the classical sense.*

Proof. The function F may be defined by

$$F(t) = -q(t)u^{1+\sigma_1}(t) + r(t)u^{1+\sigma_2}(t) - \lambda u(t).$$

Since u is bounded, we see that F is locally integrable. Then, for a fixed x, we define

$$U(t) = \int_x^t \int_x^s F(y)\,dy\,ds.$$

Hence, U is continuously differentiable.

For $\varepsilon > 0$, we define $F_\varepsilon = F^*\rho_\varepsilon$, where ρ_ε is a mollifier (cf. [1, p. 29]), and

$$U^\varepsilon(t) = \int_x^t \int_x^s F_\varepsilon(y)\,dy\,ds.$$

Then, it is not difficult to verify that

$$(3.3) \qquad F_\varepsilon \to F \quad \text{and} \quad U^\varepsilon \to U \quad \text{in} \quad L^1_{\text{loc}} \quad \text{as } \varepsilon \to 0.$$

Since $(U^\varepsilon)'' = F_\varepsilon$, we conclude from (3.3) that $U'' = F$ holds in the sense of distributions. Thus, we see that

$$(3.4) \qquad u(t) = U(t) + c_1 t + c_2$$

holds for all t and some constants c_1 and c_2 (cf. [1, Cor. 3.27]). But (3.4) shows that u is continuously differentiable.

Now, suppose that $u(x) = 0$ holds for some x. Since $u \geqq 0$, it follows that $u'(x) = 0$. The function U may be defined as above. Then, we also have $U(x) = 0$ and $U'(x) = 0$. Thus, the constants c_1 and c_2 in (3.4) are zero, and $u(t) = U(t)$ holds for all t.

The function F can be written as $F = Gu$, where G again is locally integrable. Then, for $R > 0$ and all $t \in I_R(x) := (x-R, x+R)$, we obtain

$$u(t) \leqq \int_x^t \int_x^s |G(y)|u(y)\,dy\,ds \leqq R\|G\|_{L^1(I_R(x))} \cdot \sup_{y \in I_R(x)} u(y).$$

Hence, we see that

$$\sup_{y\in I_R(x)} u(y) \leqq R\|G\|_{L^1(I_R(x))} \cdot \sup_{y\in I_R(x)} u(y). \tag{3.5}$$

But (3.5) shows that there is an $R>0$ such that $\sup_{y\in I_R(x)} u(y)=0$. Since u is continuous, the above argument shows that if $u(x)=0$ holds for some x, then $u(x)=0$ holds for all x. However, $u\equiv 0$ contradicts $\|u\|_2>0$.

Finally, we assume that the functions q and r are continuous. Then, we conclude from Lemma 2.1 that F also is continuous and that U is twice continuously differentiable. Thus, (3.4) shows that u is twice continuously differentiable. □

LEMMA 3.8. *The constant λ in Lemma 3.6 always satisfies $\lambda\leqq 0$.*

Proof. For all $t\in(0,1]$ we have $\xi(u)\leqq\xi(tu)$. Hence

$$\lambda=\|u\|_2^{-2}\, d\xi\frac{(tu)}{dt}\bigg|_{t=1}\leqq 0. \qquad □$$

LEMMA 3.9. *Suppose that the constant λ in Lemma 3.6 is negative. Then we have $\|u\|_2=\mu$.*

Proof. If $\|u\|_2<\mu$, then it follows that

$$\lambda=\|u\|_2^{-2}\, d\xi\frac{(tu)}{dt}\bigg|_{t=1}=0. \qquad □$$

LEMMA 3.10. *Suppose that λ is negative and that there exist positive constants t_1 and C such that*

$$q(t)\leqq C \quad \textit{holds for almost all } |t|\geqq t_1.$$

Then, for each $\alpha\in(0,|\lambda|^{1/2})$, there exists a constant C_α such that

$$u(t)\leqq C_\alpha \exp(-\alpha|t|) \textit{ holds for all } t.$$

Proof. From Lemma 3.6 we conclude that

$$\int u'\varphi'\,dt\leqq -|\lambda|\int u\varphi\,dt + C\int u^{1+\sigma_1}\varphi\,dt$$

holds for all nonnegative functions $\varphi\in C_0^\infty(\{t;|t|\geqq t_1\})$.

Now let $\varepsilon\in(0,|\lambda|-\alpha^2)$. Then, since u vanishes at infinity, there exists a $t_2>t_1$ such that $u^{\sigma_1}(t)\leqq\varepsilon/C$ holds for all $|t|\geqq t_2$. Hence, we obtain

$$\int u'v'\,dt\leqq -|\lambda|\int uv\,dt+\varepsilon\int uv\,dt \tag{3.6}$$

for all nonnegative functions $v\in H_0^1(\{t;|t|\geqq t_2\})$.

Since u is bounded, we can find a constant $C_\alpha>0$ such that

$$u(t)\leqq C_\alpha\exp(-\alpha|t|)=:\psi_\alpha(t) \quad \text{holds for all } |t|\leqq t_2+1. \tag{3.7}$$

Because $\psi_\alpha''(t)=\alpha^2\psi_\alpha(t)(t\neq 0)$, it follows from (3.6) that

$$\int (u'-\psi_\alpha')v'\,dt\leqq -\alpha^2\int (u-\psi_\alpha)v\,dt. \tag{3.8}$$

From (3.7), we conclude that $(u-\psi_\alpha)_+\in H_0^1(\{t;|t|\geqq t_2\})$. Inserting $v=(u-\psi_\alpha)_+$ in (3.8) finishes the proof. □

Lemmas 3.9 and 3.10 motivate the question if the constant λ is negative. The first result in this direction is the following.

LEMMA 3.11. *The constants μ and λ and the function u may be chosen as in Lemma 3.6. Moreover, we assume that $\sigma_2 \leqq \sigma_1$ or $r\equiv 0$. Then it follows that $\lambda<0$.*

Proof. Suppose that $\sigma_2\leqq\sigma_1$. Then $\xi(u)<0$ implies that

$$(2+\sigma_1)^{-1}\lambda<\|u\|_2^{-2}\xi(u)<0.$$

In case that $r\equiv 0$, we may assume without restriction that $\sigma_2\leqq\sigma_1$. □

LEMMA 3.12. *If $\sigma_1\geqq 2(2-a)$, then λ is negative.*

Proof. In the following, we take up an idea that we found in [2] (see Lemma 13). Assume that $\lambda\geqq 0$. Then, we obtain

$$\int u'\varphi'\,dt+\mathcal{K}\int t^b u^{1+\sigma_2}\varphi\,dt\geqq 0 \tag{3.9}$$

for all nonnegative functions $\varphi\in C_0^\infty((t_0,\infty))$, where t_0 is defined as in condition (i.c), respectively, (ii.c).

Moreover, via regularization it follows that (3.9) holds for all nonnegative functions $\varphi\in H_0^1((t_0,\infty))$ with compact support.

For $t\geqq t_0$, we define $\psi(t)=Ct^{-1/2}$, where the constant $C\in(0,(3/4\mathcal{K})^{1/\sigma_2}]$ is chosen such that

$$\psi(t)\leqq u(t)\quad\text{holds on } [t_0,t_0+1]. \tag{3.10}$$

Then, it follows that

$$-\psi''(t)+\mathcal{K}t^b\psi^{1+\sigma_2}(t)=C\{\mathcal{K}C^{\sigma_2}t^{b-1/2-\sigma_2/2}-\tfrac{3}{4}t^{-5/2}\}.$$

From the definition of the constant b and the fact that $\sigma_1\geqq 2(2-a)$ we obtain that $b-\frac12-\sigma_2/2\leqq-\frac52$. Hence,

$$-\psi''(t)+\mathcal{K}t^b\psi^{1+\sigma_2}(t)\leqq 0\quad\text{holds for all } t\geqq t_0. \tag{3.11}$$

Since $\psi',\psi^{1+\sigma_2}\in L^2((t_0,\infty))$, we conclude from (3.11) that

$$\int \psi'\varphi'\,dt+\mathcal{K}\int t^b\psi^{1+\sigma_2}\varphi\,dt\leqq 0 \tag{3.12}$$

holds for all nonnegative functions $\varphi\in H_0^1((t_0,\infty))$ with compact support. The function $\zeta\in C_0^\infty$ may be chosen such that $0\leqq\zeta\leqq 1$, $\zeta\equiv 1$ on the unit ball and $\zeta(t)=0$ holds for $|t|\geqq 2$. Moreover, for $n\in\mathbb{N}$, we define $\zeta_n(t)=\zeta(n^{-1}t)$. Then, according to (3.10), we see that the support of the function $(\psi-u)_+\zeta_n$ is a compact subset of (t_0,∞) and that $(\psi-u)_+\zeta_n\in H_0^1((t_0,\infty))$. Moreover, since

$$\int_{t_0}^\infty((\psi-u)_+')^2\zeta_n\,dt=\int_{t_0}^\infty(\psi-u)'(((\psi-u)_+\zeta_n)'-(\psi-u)_+\zeta_n')\,dx,$$

we obtain from (3.9) and (3.12) that

$$\begin{aligned}&\int_{t_0}^\infty((\psi-u)_+')^2\zeta_n\,dt+\mathcal{K}\int_{t_0}^\infty t^b(\psi^{1+\sigma_2}-u^{1+\sigma_2})(\psi-u)_+\zeta_n\,dt\\ &\leqq-\int_{t_0}^\infty(\psi-u)'(\psi-u)_+\zeta_n'\,dt\\ &\leqq\frac1n\|\zeta'\|_\infty\|(\psi-u)'\|_{L^2((t_0,\infty))}\left(\int_{t_0}^{2n}\psi^2(t)\,dt\right)^{1/2}.\end{aligned}\tag{3.13}$$

Since $\int_{t_0}^{2n} \psi^2(t)\,dt = C^2(\log 2n - \log t_0)$, it follows that the right-hand side of (3.13) converges to zero as $n \to \infty$. Hence, we see that

$$\psi(t) \leqq u(t) \quad \text{holds for all } t \geqq t_0. \tag{3.14}$$

But (3.14) contradicts $u \in L^2$. □

Proof of Theorem 1.1. The assertions of Theorem 1.1 now follow from Lemmas 3.4–3.7, 3.9, 3.10, and 3.12. □

4. The case where $\sigma_1 < 2(2-a)$. From Lemma 3.4 it follows that there is a $\mu_0 > 0$ such that $I(\mu) < 0$ holds for all $\mu \in (0, \mu_0]$. Thus, Lemmas 3.5–3.7 show that for each $\mu \in (0, \mu_0]$ there exist a positive function $u_\mu \in S_\mu$ and a constant λ_μ such that $\xi(u_\mu) = I(\mu)$ and (u_μ, λ_μ) solves (1.1).

Since $I(\cdot)$ is a monotone decreasing function on $[0, \mu_0]$, we can find a measurable subset $\mathcal{M}$ of $(0, \mu_0)$ such that $(0, \mu_0) \backslash \mathcal{M}$ has measure zero and $I(\cdot)$ is differentiable on $\mathcal{M}$ (see [6, Thm. 17.12]).

LEMMA 4.1. *For each $\mu \in \mathcal{M}$ we have $I'(\mu) = \mu^{-1}\|u_\mu\|_2^2\lambda_\mu$.*

Proof. Let $\mu \in \mathcal{M}$ and $\varphi(t) = \xi(tu_\mu)$. Then φ is a continuously differentiable function on $(0, \infty)$ satisfying $\varphi(1) = I(\mu)$ and $\varphi'(1) = \lambda_\mu\|u_\mu\|_2^2$. For $\varepsilon > 0$ we can find a $\delta > 0$ such that

$$|\varphi'(t) - \varphi'(1)| \leqq \varepsilon\|u_\mu\|_2^2 \quad \text{holds for } t \in [1-\delta, 1+\delta]. \tag{4.1}$$

From (4.1), we conclude that

$$\varphi'(t) \leqq \varphi'(1) + \varepsilon\|u_\mu\|_2^2 \quad \text{holds for all } t \in (1, 1+\delta]. \tag{4.2}$$

Hence

$$\varphi(t) = \varphi(1) + \int_1^t \varphi'(s)\,ds \leqq I(\mu) + (t-1)(\lambda_\mu + \varepsilon)\|u_\mu\|_2^2.$$

Since $I(t\mu) \leqq \varphi(t)$, we see that

$$\frac{I(t\mu) - I(\mu)}{(t\mu - \mu)} \leqq \mu^{-1}(\lambda_\mu + \varepsilon)\|u_\mu\|_2^2. \tag{4.3}$$

But (4.3) implies $I'(\mu) \leqq \mu^{-1}\|u_\mu\|_2^2\lambda_\mu$.

Next, we conclude from (4.1) that

$$\varphi'(t) \geqq \varphi'(1) - \varepsilon\|u_\mu\|_2^2 \quad \text{holds for all } t \in [1-\delta, 1). \tag{4.4}$$

Hence, we obtain

$$I(t\mu) \leqq \varphi(t) = \varphi(1) - \int_t^1 \varphi'(s)\,ds \leqq I(\mu) + (t-1)(\lambda_\mu - \varepsilon)\|u_\mu\|_2^2$$

and

$$(I(t\mu) - I(\mu))/(t\mu - \mu) \geqq \mu^{-1}(\lambda_\mu - \varepsilon)\|u_\mu\|_2^2 \quad \text{for } t \in [1-\delta, 1). \tag{4.5}$$

Now, (4.5) implies $I'(\mu) \geqq \mu^{-1}\|u_\mu\|_2^2\lambda_\mu$. □

LEMMA 4.2. *There exists a constant C such that*

$$|I(\mu_1) - I(\mu_2)| \leqq C|\mu_1 - \mu_2| \quad \textit{holds for all } \mu_1, \mu_2 \in [0, \mu_0].$$

Proof. Without restriction we may assume that $\mu_1 < \mu_2$. Then, since $I(\mu_2) \leqq I(\mu_1)$

and $I(\mu_1) \leqq \xi((\mu_1/\mu_2)u_{\mu_2})$, it follows that

$$\begin{aligned}|I(\mu_1)-I(\mu_2)| = I(\mu_1)-I(\mu_2) &\leqq \xi\left(\left(\frac{\mu_1}{\mu_2}\right)u_{\mu_2}\right)-\xi(u_{\mu_2})\\ &= \left(\left(\frac{\mu_1}{\mu_2}\right)^2-1\right)\frac{1}{2}\int |u'_{\mu_2}|^2\,dt\\ &\quad+\left(1-\left(\frac{\mu_1}{\mu_2}\right)^{2+\sigma_1}\right)(2+\sigma_1)^{-1}\int q|u_{\mu_2}|^{2+\sigma_1}\,dt\\ &\quad+\left(\left(\frac{\mu_1}{\mu_2}\right)^{2+\sigma_2}-1\right)(2+\sigma_2)^{-1}\int r|u_{\mu_2}|^{2+\sigma_2}\,dt\\ &\leqq \left(1-\left(\frac{\mu_1}{\mu_2}\right)^{2+\alpha_1}\right)(2+\sigma_1)^{-1}\int q_+|u_{\mu_2}|^{2+\sigma_1}\,dt.\end{aligned}$$

Moreover,

$$1-\left(\frac{\mu_1}{\mu_2}\right)^{2+\sigma_1}=(2+\sigma_1)\int_{\mu_1/\mu_2}^{1} t^{1+\sigma_1}\,dt \leqq (2+\sigma_1)\left(1-\left(\frac{\mu_1}{\mu_2}\right)\right)$$

implies that

$$|I(\mu_1)-I(\mu_2)| \leqq \left(1-\left(\frac{\mu_1}{\mu_2}\right)\right)\int q_+|u_{\mu_2}|^{2+\sigma_1}\,dt.$$

Since $\sigma_1<4$, we conclude from Lemmas 3.1 and 3.5 that

$$\int q_+|u_{\mu_2}|^{2+\sigma_1}\,dx \leqq c(\mu_2^{2+\alpha_1}+\mu_2^{2+\beta_1})$$

holds for some constant c, and consequently that

$$|I(\mu_1)-I(\mu_2)| \leqq c|\mu_1-\mu_2|(\mu_0^{1+\alpha_1}+\mu_0^{1+\beta_1}). \qquad \square$$

LEMMA 4.3. *There exists a sequence* (μ_n) *of pairwise distinct constants* $\mu_n \in (0, \mu_0)$ *such that* $\lim_{n\to\infty}\mu_n=0$ *and* $\lambda_{\mu_n}<0$ *holds for all n.*

Proof. Suppose that $\lambda_\mu \geqq 0$ holds for all $\mu \in (0,\mu_0)$. Then, according to Lemma 3.8, $\lambda_\mu=0$ holds for all $\mu\in(0,\mu_0)$.

Now, Lemma 4.1 implies $I'(\mu)=0$ for all $\mu \in \mathcal{M}$. Moreover, Lemma 4.2 shows that $I(\cdot)$ is absolutely continuous on $[0,\mu_0]$.

Hence, from Theorem 18.15 in [6], we conclude that $I(\cdot)$ is constant. But $I(\mu)=I(\mu_0)<0$ for all $\mu\in[0,\mu_0]$ contradicts $I(0)=0$. Thus, there exists a constant $\mu_1\in(0,\mu_0)$ such that $\lambda_{\mu_1}<0$. Next, repeating this procedure, we can find a $\mu_2\in(0,\min(\mu_1,\frac{1}{2}))$ so that $\lambda_{\mu_2}<0$. Moreover, by induction we can show that for each n there is a constant $\mu_n\in(0,\min(\mu_{n-1},1/n))$ so that $\lambda_{\mu_n}<0$. $\square$

LEMMA 4.4. *The sequence* (μ_n) *may be chosen as in Lemma* 4.3. *Then, we have* $\lim_{n\to\infty}\lambda_{\mu_n}=0$.

Proof. Since $\lambda_{\mu_n}<0$, it follows that $\|u_{\mu_n}\|_2=\mu_n$ (see Lemma 3.9) and that $|\lambda_{\mu_n}|\leqq \mu_n^{-2}\int q_+|u_{\mu_n}|^{2+\sigma_1}\,dt$ (see Lemma 3.6). Now, the assertion follows from Lemmas 3.1 and 3.5 and the fact that $\mu_n\to 0$ as $n\to\infty$. $\square$

Proof of Theorem 1.2. Let $u_n=u_{\mu_n}$ and $\lambda_n=\lambda_{\mu_n}$. Then, from Lemmas 3.1 and 3.5, we obtain that

$$\|u_n\|_{H^1}^2+\int |q||u_n|^{2+\sigma_1}\,dt+\int r|u_n|^{2+\sigma_2}\,dt\to 0 \tag{4.6}$$

as $n \to \infty$. Moreover, Lemma 2.1 and (4.6) imply that $\|u_n\|_p \to 0$ if $p \in [2, \infty]$. The remaining assertions follow from the above results. □

SOME ERGODIC THEOREMS FOR SOLUTIONS OF HOMOGENEOUS DIFFERENTIAL EQUATIONS*

KRZYSZTOF WYSOCKI†

Abstract. Consider $x'=f(x)$, where f is defined on a cone K with nonempty interior in a Banach space X. This paper studies the conditions on f that ensure that the directions of the solutions, $x(t)/\|x(t)\|$, converge to the same point $u \in K$ no matter what initial conditions are. Problems of this type often arise in some models from population biology. The results are obtained for maps that are homogeneous of degree 1. In the proofs Hilbert's projective metric is used.

Key words. cones, eigenvectors, Hilbert's projective metric, irreducible operators, order-preserving flows, homogeneous differential equations

AMS subject classifications. 34E, 34H, 47B, 47H

Introduction. In this paper we investigate the asymptotic behavior of directions of solutions of homogeneous differential equations.

More precisely, if K is a cone with nonempty interior in a Banach space X, $f: K \to X$ is positively homogeneous of degree 1 and $x(t, \xi)$ denotes a solution of $x'=f(x)$, $x(0)=\xi$, we ask when

$$\frac{x(t, \xi)}{\|x(t, \xi)\|} \to u \in K$$

for all ξ in the interior of K.

This question arises in many places. It appears in some problems in mathematical economics and in some models from population biology; see [9], [14]. In the population biology literature results concerning this type of the behavior of the solutions are called "ergodic theorems." Here the term "ergodic" refers to the behavior of solutions which is independent of the initial conditions.

We will study this question under an additional assumption that the flow generated by $x'=f(x)$ is order-preserving. In recent years several authors have analyzed convergence of bounded trajectories of certain types of differential equations by exploiting order-preserving properties of their flows; see, e.g., Hirsch [4]. In this article we use a simple fact that order-preserving flows which are also homogeneous of degree 1 are nonexpansive with respect to so-called Hilbert's projective metric d.

Our problem is also related to the question about eigenvectors of cone maps which are homogeneous of degree 1. If $f: K \to X$ is homogeneous of degree 1 and $x(t, \xi)/\|x(t, \xi)\| \to u$ for all $\xi \in \operatorname{int} K$, then u is necessarily an eigenvector of f, and if $u \in \operatorname{int} K$, then f has a unique eigenvector u of norm 1 in int K. Observe that if X is finite-dimensional and f is homogeneous of degree 1 with $f(K) \subseteq K$, then an application of Brouwer's fixed point theorem implies that f has a normalized eigenvector in K. We will consider two possibilities: convergence of directions to an eigenvector in int K and to an eigenvector in ∂K.

In § 1 we recall a few facts about cones and linear cone maps. In particular, we define Hilbert's projective metric d and list some of their properties.

The fact that d is a metric on $S_0=\{x \in \operatorname{int} K, \|x\|=1\}$ and that topologies of S_0 induced by d and $\|\cdot\|$ are identical makes Hilbert's projective metric a useful tool in our considerations.

† School of Mathematics, Georgia Institute of Technology, Atlanta, Georgia 30332.

In § 2 we give proofs of main results. Convergence of directions to an eigenvector in int K is considered in Theorem 2.1. The following is a special case of this theorem: Suppose that $f: K \to \mathbf{R}^n$ is homogeneous of degree 1 and the flow of $x' = f(x)$ is order-preserving. Assume that f has an eigenvector u of norm 1 in int K and that $f'(u)$ exists, and $f'(u) + \alpha I$ is a nonnegative irreducible matrix for some $\alpha > 0$. Then for any $x \in \operatorname{int} K$, $x(t, x_0)$ is defined in int K for all $t \geqq 0$ and $x(t, x_0)/\|x(t, x_0)\| \to u$.

The second possibility, convergence to an eigenvector in ∂K, is considered in Theorem 2.1. This case presents some difficulties. A complication here is that f is defined only on K and may not have a Fréchet derivative at any point of ∂K. Fréchet differentiability of f at an eigenvector u is replaced by the existence of a Gateaux derivative at u. In fact, many maps of interest have a Gateaux derivative at points of ∂K.

In § 3 we illustrate an application of these results to particular classes of maps which were introduced and analyzed by Nussbaum in [7] and [8]. Finally, let us mention some related problems which are not considered here. We can consider the time-dependent differential equation $x' = f(t, x)$, where $f: \mathbf{R}_+ \times K \to X$. In this situation there are no obvious candidates for asymptotic behavior of solutions, but we can ask for a condition on f which guarantees that any two solutions behave in a similar way. For instance, when

$$\left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - \frac{x(t, x_1)}{\|x(t, x_1)\|} \right\| \to 0 \quad \text{for all } x_0, x_1 \in \operatorname{int} K$$

or when any two solutions are asymptotically proportional, i.e.,

$$\frac{x_i(t, x_0)}{x_i(t, x_1)} \to c_i,$$

where c_i is a constant independent of initial condition and $x_i(t, \cdot)$ is the ith component of $x(t, \cdot)$ if $X = \mathbf{R}^n$? These questions were studied by Birkhoff and Kotlin in [1] for systems of linear differential equations and asymptotic proportionality by Thieme in [13] for sublinear difference and differential equations.

In [11], Schanbacher obtained results about behavior

$$\frac{T(t)f}{\|T(t)f\|} \quad \text{as } t \to \infty,$$

where $\{T(t)\}$ is a strongly continuous semigroup of positive linear operators on a Banach lattice E and f an element of a positive cone in E.

1. Preliminaries. In this section we state some results on cones in Banach spaces and so-called Hilbert projective metric.

Let X be a real Banach space. A subset K of X is a cone if K is a closed, convex set such that $\lambda K \subseteq K$, for all $\lambda \geqq 0$, and $K \cap (-K) = \{0\}$. A cone K induces a partial ordering on X by $x \leqq y$ if and only if $y - x \in K$. We shall write $x < y$ if $x \leqq y$ but $x \neq y$, while $x \ll y$ indicates that $y - x \in \operatorname{int} K$. Two elements $x, y \in K$ are comparable if there exist positive numbers α, β such that

$$\alpha x \leqq y \leqq \beta x.$$

A cone $K \subseteq X$ is called normal if there is a constant $M > 0$ such that for any $x, y \in K$ if $x \leqq y$ then $\|x\| \leqq M\|y\|$.

By K^* we will denote dual cone, i.e.,

$$K^* = \{\psi \in X^*;\ \psi(x) \geqq 0 \text{ for all } x \in K\}.$$

It is easy to see that if $x \in \operatorname{int} K$, then $\psi(x) > 0$ for all $\psi \in K^*$ and that $x \in \partial K$ if and only if $\psi(x) = 0$ for some $\psi \in K^*$.

Throughout this paper we will always assume that the interior of K, $\operatorname{int} K$, is nonempty and that K is normal.

If x and y are comparable, following notation in [2], we define numbers $m(y/x)$ and $M(y/x)$ by

$$m\left(\frac{y}{x}\right) = \sup\{\alpha > 0;\ \alpha x \leqq y\},$$

$$M\left(\frac{y}{x}\right) = \inf\{\beta > 0;\ y \leqq \beta x\}.$$

Definition 1.1. If x and y are comparable elements of K and $\alpha = m(y/x)$ and $\beta = M(y/x)$, the Hilbert projective metric $d(x, y)$ is defined by

$$d(x, y) := \log \frac{\beta}{\alpha}.$$

If x and y are nonzero elements of K which are noncomparable, we set $d(x, y) = \infty$.

It is not difficult to show, see, e.g., [2], that for all x, y, z in $K \backslash \{0\}$ we have that

$$\begin{aligned} &d(x, z) \leqq d(x, y) + d(y, z),\\ &d(x, y) = d(y, x),\\ &d(x, y) = 0 \Leftrightarrow y = \alpha x \quad \text{for some } \alpha > 0, \quad \text{and}\\ &d(\alpha x, \beta y) = d(x, y) \quad \text{for all } \alpha, \beta > 0. \end{aligned}$$

It follows that d is a pseudometric on $\operatorname{int} K$ and a metric when restricted to $S_0 := \{v \in \operatorname{int} K;\ \|v\| = 1\}$. Moreover, there is a constant $M > 0$ such that

$$\|x - y\| \leqq M[\exp d(x, y) - 1]$$

for all $x, y \in S_0$, and if $u \in \operatorname{int} K$ and $B_r(u) \in \operatorname{int} K$, then

$$d(x, u) \leqq \log\left(\frac{r + \|x - u\|}{r - \|x - u\|}\right) \quad \text{for all } x \in B_r(u).$$

The above inequalities imply that $\|\cdot\|$ and d induce the same topology on S_0. In [14], Thompson has introduced an interesting variant of Hilbert's projective metric. If $x, y \in K \backslash \{0\}$ are comparable, Thomson defines $\bar{d}(x, y)$ by

$$\bar{d}(x, y) = \max\left\{\log M\left(\frac{y}{x}\right), \log M\left(\frac{x}{y}\right)\right\},$$

and if $x, y \in K \backslash 0$ are not comparable, $\bar{d}(x, y) = \infty$.

The restriction of $\bar{d}$ to $\operatorname{int} K$ is a metric and $\|\cdot\|$ and $\bar{d}$ give the same topology on $\operatorname{int} K$. For more information about Hilbert's projective metric and its applications we send the interested reader to Bushell [2], [3] and Nussbaum [7], [8].

We will also need few results concerning linear cone maps.

If $L: X \to X$ is a bounded linear map, L has a natural extension $\tilde{L}$ to the complexification $\tilde{X}$ of X, i.e.,

$$\begin{aligned} &\tilde{X} = \{x + iy;\ x, y \in X\},\\ &\|x + iy\| := \sup_{\theta \in [0, 2\pi]} \|x \cos \theta + y \sin \theta\|, \quad \text{and}\\ &\tilde{L}(x + iy) = Lx + iLy. \end{aligned}$$

We will assume that whenever statements about spectra of L are made they refer to $\tilde{L}$ defined on $\tilde{X}$.

By $r(L)$ we will denote the spectral radius of L and by $r_e(L)$ the essential spectral radius of L. The essential spectral radius of L, $r_e(L)$, can be defined (see [6]) by

$$r_e(L)=\lim_{n\to\infty}(q(L^n))^{1/n},$$

where

$$q(L)=\inf\{\|L+K\|;\ K \text{ is a compact linear map}\}.$$

It is proved in [6] that if $L\in L(X)$ and $L(K)\subseteq K$, and $r_e(L)<r(L)$, then L has an eigenvector $u\in K$ with an eigenvalue $r=r(L)$ and L^* has an eigenvector $u^*\in K^*$ with the same eigenvalue $r=r(L)$.

If L is compact this result is the Krein-Rutman theorem.

Moreover, if $\lambda\in\sigma(L)$ and $|\lambda|>r_e(L)$, then λ is an eigenvalue of finite algebraic multiplicity and λ is an isolated point of $\sigma(L)$.

DEFINITION 1.2. Let $L\in L(X)$ be such that $L(K)\subseteq K$. The map L is called irreducible if $(\lambda I-L)^{-1}(x)\in \operatorname{int} K$ for any $x\in K\backslash\{0\}$ and any $\lambda>r(L)$.

Remark 1.1. One can define an irreducible map even if int K is empty (see [10]). The definition in [10] agrees with the one above when int K is nonempty.

If K is the standard cone in $\mathbf{R}^n$, i.e., $K=\{x;\ x_i\geqq 0 \text{ for } 1\leqq i\leqq n\}$ and L is a nonnegative matrix the above definition is equivalent to the following one: L is irreducible if for each pair (i,j) with $1\leqq i,j\leqq n$ there is an integer p such that the entry in row i and column j of L^p is positive.

The next result provides information about uniqueness of positive eigenvectors of L and L^*. In the special case, $X=R^n$, it is a classical result of Perron and Frobenius.

THEOREM 1.1 [10]. *Let $L\in L(X)$ be irreducible, and $r=r(L)>0$ is a pole of $(zI-L)^{-1}$.*

Then we have

(1) *r is a pole of order* 1; *and*

(2) *L and L^* have eigenvectors $u\in \operatorname{int} K$ and $u^*\in \operatorname{int} K^*$, respectively, with eigenvalue r;*

(3) $\dim\ker(rI-L)=1$.

2. Some ergodic theorems. Let us consider the differential equation

$$\begin{aligned} x'(t)&=f(x),\\ x(0)&=x_0\in \operatorname{int} K. \end{aligned} \tag{1}$$

We are interested in the conditions on f which will guarantee that $x(t,x_0)/\|x(t,x_0)\|$ converges to the same point of int K, no matter what x_0 is. We start by proving a simple lemma which provides the candidate for a limit of $x(t,x_0)/\|x(t,x_0)\|$.

LEMMA 2.1. *Assume that $f\colon \operatorname{int} K\to X$ is a locally Lipschitz map which can be continuously extended to K. Assume that f is positively homogeneous of degree* 1, *i.e., $f(tx)=tf(x)$ for all $t>0$ and $x\in K$, and that any solution of* (1) *is defined for all $t\geqq 0$ and stays in* int K. *If*

$$\frac{x(t,x_0)}{\|x(t,x_0)\|}\to u,\quad t\to\infty\quad \textit{for all } x_0\in \operatorname{int} K,$$

then u is an eigenvector of f.

Proof. Observe that by homogeneity of f and uniqueness of solutions, we have

$$x(t,\lambda x_0)=\lambda x(t,x_0) \tag{2}$$

for any $x_0 \in \operatorname{int} K$ and $\lambda > 0$. Take $\psi \in K^*\backslash\{0\}$ so that $\psi(u) = 1$. Then it follows that

$$\frac{x(t, x_0)}{\psi(x(t, x_0))} \to u. \tag{3}$$

From continuous dependence of solutions on initial conditions and (2) and (3) we get

$$\frac{x(t, u)}{\psi(x(t, u))} = \lim_{s\to\infty} \frac{\left[x\left(t, \dfrac{x(s, x_0)}{\psi(x(s, x_0))}\right)\right]}{\left[\psi\left(x\left(t, \dfrac{x(s, x_0)}{\psi(x(s, x_0))}\right)\right)\right]}$$

$$= \lim_{s\to\infty} \frac{x(t+s, x_0)}{\psi(x(t+s, x_0))} = u \quad \text{for any } t \geqq 0.$$

Hence $x(t, u) = \psi(x(t, u))u$ for any $t \geqq 0$.

After differentiating the above equality we obtain

$$f(x(t, u)) = x'(t, u) = \psi(x'(t, u))u$$
$$= \psi(f(x(t, u)))u.$$

Now our claim follows by taking the limit as $t \to 0^+$. □

The following definition will be useful in our considerations.

Definition 2.1. Let X be a Banach space with ordering induced by a cone K and $f: K \to X$ be locally Lipschitz. We say that the flow generated by (1) is order-preserving if $x(t, x_0) \leqq x(t, x_1)$ for all $t \geqq 0$, whenever $x_0 \leqq x_1$.

Remark 2.1. In practice it can be difficult to check that the flow is order-preserving. When $f: K \to X$ satisfy: whenever $x \leqq y$ with $y - x \in \partial K$ there is $\psi \in K^*\backslash\{0\}$ for which $\psi(y-x) = 0$ and $\psi(f(x)) \leqq \psi(f(y))$ then, as it is shown in [5], the flow of (1) is order-preserving.

If K is the standard cone in $\mathbf{R}^n$ and $f: K \to \mathbf{R}^n$, then the above condition implies that the flow of (1) preserves ordering if whenever x, y are in K with $x_j \leqq y_j$ for all $1 \leqq j \leqq n$ and $x_i = y_i$ for some $1 \leqq i \leqq n$, then $f_i(x) \leqq f_i(y)$, where f_i denotes the ith component of f.

Our interest of order-preserving flows stems from the following simple lemma.

Lemma 2.2. *Suppose that $f: \operatorname{int} K \to X$ is locally Lipschitz and positively homogeneous of degree* 1. *If the flow generated by* (1) *is order-preserving, then*

$$d(x(t, x_0), x(t, x_1)) \leqq d(x_0, x_1) \quad \text{and} \quad \bar{d}(x(t, x_0), x(t, x_1)) \leqq \bar{d}(x_0, x_1)$$

for all $x_0, x_1 \in \operatorname{int} K$ and $t \geqq 0$.

Proof. Let $x_0, x_1 \in \operatorname{int} K$ and $\alpha = m(x_1/x_0)$ and $\beta = M(x_1/x_0)$. Then, by definition of Hilbert's projective metric, we have that

$$\alpha x_0 \leqq x_1 \leqq \beta x_0 \quad \text{and} \quad d(x_0, x_1) = \log\frac{\beta}{\alpha}.$$

Since the flow is order-preserving and f is homogeneous of degree 1,

$$\alpha x(t, x_0) \leqq x(t, x_1) \leqq \beta x(t, x_0).$$

This implies that

$$\alpha \leqq m\left(\frac{x(t, x_1)}{x(t, x_0)}\right) \leqq M\left(\frac{x(t, x_1)}{x(t, x_0)}\right) \leqq \beta,$$

and so

$$d(x(t, x_0), x(t, x_1)) \leqq d(x_0, x_1).$$

The proof for $\bar{d}$ is similar. □

Using this lemma we prove the following.

LEMMA 2.3. *Let $f\colon K \to X$ be continuous and $f_{|\text{int } K}$ locally Lipschitz. Assume that f is positively homogeneous of degree 1 and that the flow of (1) is order-preserving. Define $S = \{v \in K;\ \|v\| = 1\}$ and $S_0 = \{v \in \text{int } K;\ \|v\| = 1\}$. Suppose that there is $u \in S$ and $\delta > 0$ such that*

$$\lim_{t\to\infty} \left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - u \right\| = 0$$

for all $x_0 \in W = \{v \in S_0;\ \|v - u\| < \delta\}$.

Then it follows that

$$\lim_{t\to\infty} \left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - u \right\| = 0$$

for all $x_0 \in S_0$.

Proof. Let

$$U = \left\{ x_0 \in S_0;\ \lim_{t\to\infty} \left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - u \right\| = 0 \right\}.$$

Because $U \neq \emptyset$ and S_0 is connected it suffices to show that U is open and closed in the norm topology of S_0. To see that U is open we take $y \in U$ and $t_0 > 0$ such that $x(t_0, y)/\|x(t_0, y)\| \in W$. Let $\varepsilon > 0$ be such that $\{z \in S_0;\ d(x(t_0, y), z) < \varepsilon\} \subset W$. Define $V = \{z \in S_0;\ d(y, z) < \varepsilon\}$. Since the topologies induced by $\|\cdot\|$ and d on S_0 are identical, V is an open neighborhood of y in S_0. It suffices to show that $V \subseteq U$. Take $y_1 \in V$. Then $d(x(t, y), x(t, y_1)) \leqq d(y, y_1) < \varepsilon$ and, by definition of $\varepsilon > 0$, it follows that $a = x(t_0, y_1)/\|x(t_0, y_1)\| \in W$. Hence

$$\lim_{s\to\infty} \left\| \frac{x(s, a)}{\|x(s, a)\|} - u \right\| = 0$$

and, since

$$\frac{x(s, a)}{\|x(s, a)\|} = \frac{x(s + t_0, y_1)}{\|x(s + t_0, y_1)\|}$$

we get that

$$\lim_{t\to\infty} \left\| \frac{x(t, y_1)}{\|x(t, y_1)\|} - u \right\| = 0.$$

This proves $V \subseteq U$.

To see that U is closed, let $\{x_n\} \subseteq U$ be such that $\lim_{n\to\infty} \|x_n - x_0\| = 0$ for some $x_0 \in S_0$. Then $\lim_{n\to\infty} d(x_n, x_0) = 0$. We know that there is a constant $M > 0$ such that

$$\|x - y\| \leqq M[e^{d(x, y)} - 1] \quad \text{for all } x, y \in S_0.$$

Take $\varepsilon > 0$ and $n_0 \in N$ so that

$$e^{d(x_0, x_{n_0})} - 1 \leqq \frac{\varepsilon}{2M}.$$

Since $x_{n_0} \in U$, there is $t_0 > 0$ so that

$$\left\| \frac{x(t, x_{n_0})}{\|x(t, x_{n_0})\|} - u \right\| < \frac{\varepsilon}{2} \quad \text{for all } t \geqq t_0.$$

Then

$$\left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - u \right\| \leqq \left\| \frac{x(t, x_0)}{\|x(t, x_0)\|} - \frac{x(t, x_{n_0})}{\|x(t, x_{n_0})\|} \right\| + \frac{\varepsilon}{2}$$

$$\leqq M[e^{d(x(t,x_0),x(t,x_{n_0}))} - 1] + \frac{\varepsilon}{2}$$

$$\leqq M[e^{d(x_0,x_{n_0})} - 1] + \frac{\varepsilon}{2} \leqq \varepsilon.$$

Hence $x_0 \in U$ and U is closed. □

Note that if $\Sigma_0 = \{v \in \operatorname{int} K;\ \psi(v) = 1\}$ and $S_0 = \{v \in \operatorname{int} K;\ \|v\| = 1\}$, then the map $S_0 \ni v \to t_v v \in \Sigma_0$, where t_v is a unique $t > 0$ so that $t_v v \in \Sigma_0$, defines an isometry between (Σ_0, d) and (S_0, d). This implies that topologies induced by $\|\cdot\|$ and d on Σ_0 are the same.

Now, if $\Sigma = \{v \in K;\ \psi(v) = 1\}$ and if $u \in \Sigma$ and $\delta > 0$ are such that

$$\lim_{t\to\infty} \left\| \frac{x(t, x_0)}{\psi(x(t, x_0))} - u \right\| = 0 \quad \text{for all } x_0 \in W = \{v \in \Sigma_0;\ \|v - u\| < \delta\},$$

then a minor modification of the proof of Lemma 2.3 shows that

$$\lim_{t\to\infty} \left\| \frac{x(t, x_0)}{\psi(x(t, x_0))} - u \right\| = 0 \quad \text{for all } x_0 \in \Sigma_0.$$

Now we state our result.

THEOREM 2.1. *Let $f: \operatorname{int} K \to X$ be continuous and $f_{|\operatorname{int} K}$ locally Lipschitz and positively homogeneous of degree* 1. *Assume that the flow of* (1) *is order-preserving and that $f(u) = \lambda u$ for some $u \in \operatorname{int} K$ with $\|u\| = 1$ and $\lambda \in \mathbf{R}$. Assume that f is differentiable at u and that there is a constant α such that $A = (\alpha I + f'(u))$ sends K into itself, $r_e(A) < r(A)$, and A is irreducible. Finally, suppose that* $\sup_{v \in S_0} \|f(v)\| < \infty$.

Then for any $x_0 \in \operatorname{int} K$, $x(t, x_0)$ is defined for all $t \geqq 0$ and $x(t, x_0) \in \operatorname{int} K$, and

$$\frac{x(t, x_0)}{\|x(t, x_0)\|} \to u \quad \textit{as } t \to \infty.$$

In the proof of this theorem it will be more convenient to use $x(t, x_0)/\psi(x(t, x_0))$, where $\psi \in K^* \backslash \{0\}$ is such that $\psi(u) = 1$. Observe that, by remarks following the proof of Lemma 2.3, in order to prove Theorem 2.1 it suffices to find $\delta > 0$ such that $x(t, x_0)/\psi(x(t, x_0)) \to u$ for all $x_0 \in \Sigma_0$ with $\|x_0 - u\| < \delta$.

For the proof we shall need a few more lemmas.

LEMMA 2.4. *Let $L \in L(X)$ be such that $L(K) \subseteq K$ and $Lu \leqq ru$ for some $u \in \operatorname{int} K$ and $r > 0$. Then the spectral radius of L, $r(L)$, is less than or equal to r.*

Proof. Define $X_u = \{x \in X;\ -\alpha u \leqq x \leqq \alpha u$ for some $\alpha\}$ and $\|x\|_u = \inf\{\alpha \geqq 0;\ -\alpha u \leqq x \leqq \alpha u\}$. Then X_u is a normed space with the norm $\|\cdot\|_u$, and since K is normal and $u \in \operatorname{int} K$, we have that $X_u = X$ and the norms $\|\cdot\|$, $\|\cdot\|_u$ are equivalent. It follows that

$$r(L) = \lim_{n\to\infty} \|L^n\|_u^{1/n}.$$

By definition of $\|\cdot\|_u$, we have

$$-\|x\|_u u \leqq x \leqq \|x\|_u u \quad \text{for all } x \in X.$$

Since $L(K) \subseteq K$ and $Lu \leqq ru$, iteration of the above inequalities gives

$$-\|x\|_u r^n u \leqq L^n x \leqq \|x\|_u r^n u \quad \text{for all } n \in N.$$

Hence $\|L^n\|_u \leqq r^n$ and the assertion follows. □

For the proof of the next lemma see [7].

LEMMA 2.5. *Let $L \in L(X)$ be a bounded linear operator such that $L(K) \subseteq K$ and $r(L) \leqq r$. Assume that $Lu \leqq ru$ for some $u \in K\{0\}$. Let $\psi \in K^*$ be so that $\psi(u) = 1$ and $\Lambda x = Lx - \psi(Lx)u$. Then $r(\Lambda) \leqq r$.*

Recall that if $L \in L(X)$, then the modulus of stability of L is defined by

$$s(L) = \sup\{\operatorname{Re}\lambda;\ \lambda \in \sigma(L)\}.$$

LEMMA 2.6. *Let $L \in L(X)$ be such that $L(K) \subseteq K$ and $Lu \leqq ru$ with $u \in \operatorname{int} K$ and $r > 0$. Assume that $r_e(L) < r(L)$ and that L is irreducible. If $\Lambda x = Lx - \psi(Lx)u$, $x \in X$, where $\psi \in K^*$ is such that $\psi(u) = 1$, then*

$$s(\Lambda) < r.$$

Proof. Lemmas 2.4 and 2.5 show that $r(\Lambda) \leqq r$. Hence it suffices to show that $r(\Lambda) < r$. The proof proceeds by contradiction, so we assume that $r(\Lambda) = r$.

Since $x \mapsto \psi(Lx)u$ is a compact linear map, it follows that $r_e(\Lambda) = r_e(L)$ and

$$r_e(\Lambda) < r(\Lambda) = r.$$

Thus r is an eigenvalue of Λ. Denote by v a corresponding eigenvector. There are two cases to consider, namely:

(1) $Lu \leqq ru$ but $Lu \neq ru$; and

(2) $Lu = ru$.

Case (1). We will show that if $Lu \leqq ru$ but $Lu \neq ru$, then $r(L) < r$. It is not difficult to see that if $Lw = \mu w$ for some $w \in K\backslash\{0\}$ and $\mu > 0$, and $Lu \leqq ru$, then $\mu \leqq r$. Now, take $\lambda > r(L)$ and define $x = ru - Lu \in K\backslash\{0\}$ and $y = (\lambda I - L)^{-1}u$.

Because L is irreducible, $y \in \operatorname{int} K$ and

$$(\lambda I - L)^{-1}x = r(\lambda I - L)^{-1}u - L(\lambda I - L)^{-1}u = ry - Ly \in \operatorname{int} K.$$

Hence there is $\varepsilon > 0$ such that

$$Ly \leqq (r - \varepsilon)y.$$

Because $r_e(L) < r(L)$, L has an eigenvector in K with an eigenvalue $r(L)$, which, in view of the remark above, satisfies $r(L) \leqq r - \varepsilon$.

On the other hand,

$$Lv - \psi(Lv)u = rv,$$

and, since $r(L) < r$, we have $v = -\psi(Lv)(rI - L)^{-1}(u)$.

Let $z = (rI - L)^{-1}u$. Then $\psi(z) > 0$ and $0 = \psi(v) = -\psi(Lv)\psi(z)$. This implies that $Lv = rv$ and $r(L) = r$, a contradiction.

Case (2). We know that L^* has an eigenvector w^* corresponding to r and $w^*(u)=1$.

Let

$$Y:=\{x\in X;\ \psi(x)=0\}\quad\text{and}$$
$$Y_1:=\{x\in X;\ w^*(x)=0\}.$$

Define $\Lambda_1: X\to X$ by

$$\Lambda_1:=Lx-w^*(Lx)u.$$

Since X is a direct sum of $\{tu;\ t\in\mathbf{R}\}$ and of Y and both of these subspaces are invariant under Λ, we have that

$$\sigma(\Lambda)=\sigma(\Lambda\,|\,Y)\cup\{0\}.$$

Let $B: Y\to Y_1$ and $C: Y_1\to Y$ be given by

$$B(y)=y-w^*(y)u\quad\text{and}$$
$$C(z)=z\psi(z)u.$$

Then $CB=I_{|Y}$, $BC=I_{|Y_1}$ and $CLB=\Lambda$. It follows that

$$\sigma(\Lambda\,|\,Y)=\sigma(L\,|\,Y_1). \tag{4}$$

As the algebraic multiplicity of r is equal to 1 and $u\notin Y_1$, we find by (4) that

$$\sigma(\Lambda\,|\,Y)=\{\lambda;\ \lambda\in\sigma(L),\ \lambda\neq r\}.$$

Hence $r\notin\sigma(\Lambda)$ and again we have a contradiction. □

After these preliminary lemmas we are ready to prove Theorem 2.1.

Proof of Theorem 2.1. Observe that without loss of generality we can assume that $f(u)=0$, i.e., $\lambda=0$. In fact, if $g(x)=-\lambda x+f(x)$ and $y(t,x_0)=e^{-\lambda t}x(t,x_0)$, then $g(u)=0$, g has the same properties as f and $y'(t,x_0)=g(y(t,x_0))$.

Homogeneity of f implies that

$$x(t,\alpha x_0)=\alpha x(t,x_0)\quad\text{for any }\alpha>0\quad\text{and}\quad x_0\in\operatorname{int}K. \tag{5}$$

Take $x_0\in\operatorname{int}K$ and let $\beta>0$ be such that $u\leqq\beta x_0$. Because the flow of (1) is order-preserving and f has linear growth, we have that

$$u\leqq\beta x(t,x_0)\quad\text{for } t\geqq 0$$

and so $x(t,x_0)\in\operatorname{int}K$ for $t\geqq 0$.

Let $\psi\in K^*\backslash\{0\}$ be so that $\psi(u)=1$ and $\Sigma_0=\{v\in\operatorname{int}K;\ \psi(v)=1\}$. It is more convenient to work with

$$y(t,x_0)=\frac{x(t,x_0)}{\psi(x(t,x_0))}\quad\text{than}\ \frac{x(t,x_0)}{\|x(t,x_0)\|}.$$

Then $y(t,x_0)$ satisfies

$$\begin{aligned}&y'(t,x_0)=f(y(t,x_0))\psi(f(y(t,x_0)))y(t,x_0)\\&y(0,x_0)=\frac{x_0}{\psi(x_0)}.\end{aligned}\tag{6}$$

Moreover, $y(t,x_0)\in\operatorname{int}K$ for all $t\geqq 0$.

We claim that $y(t,x_0)\to u$ as $t\to\infty$ for all $x_0\in\operatorname{int}K$.

Let $Y=\{z\in X;\ \psi(z)=0\}$. Note that if $x\in X$, then it can be written as

$$x=x-\psi(x)u+\psi(x)u,$$

where $x-\psi(x)u\in Y$. Hence $X=X_0\oplus Y$, where $X_0=\text{span}\,(u)$. Write $y(t,x_0)=z(t)+\alpha(t)u$, with $z(t)\in Y$ and $\alpha(t)\in\mathbf{R}$.

Since $\psi(y(t,x_0))=1$, we see that $\alpha(t)=1$, and so

$$y(t,x_0)=z(t)+u, \qquad t\geqq 0.$$

Of course, $z(t)$ satisfies

$$\tag{7} \begin{aligned} z'(t)&=h(z(t)),\\ z(0)&=\frac{x_0}{\psi(x_0)}-u, \end{aligned}$$

where $h(z)=f(u+z)-(u+z)\psi(f(u+z))$. Thus it is enough to show that $z(t)\to 0$, $t\to\infty$. The equation (7) can be written as

$$\tag{8} \begin{aligned} z'(t)&=Bz(t)+g(z(t)),\\ z(0)&=z_0=\frac{x_0}{\psi(x_0)}-u, \end{aligned}$$

with $g: Y\to Y$ satisfying

$$\frac{\|g(z)\|}{\|z\|}\to 0 \quad \text{as } \|z\|\to 0$$

and

$$Bz=h'(0)=f'(u)z-\psi(f'(u)z):=Lz-\psi(Lz)u.$$

By the variation of constants formula solutions of (8) take the form

$$\tag{9} z(t)=e^{Bt}z_0+\int_0^t e^{B(t-s)}g(z(s))\,ds.$$

Let $\Lambda x=Ax\psi(Ax)u$ with $A=\alpha I+L$. Note that, since $f(u)=0$ and f is homogeneous of degree 1, we have that

$$Lu=f(u)=0.$$

Since $Au=\alpha u$, $u\in\text{int}\,K$, Lemma 2.2 implies that $r(A)\leqq\alpha$ and since $r_e(A)<r(A)$, Lemma 2.4 shows that $s(\Lambda)<\alpha$. Because $\Lambda z=(\alpha I+B)z$ for any $z\in Y$ we see that $\sigma(\Lambda\,|\,Y)=\sigma(B)+\alpha$. This shows that $s(B)=\mu<0$. Hence $\|e^{Bt}\|\leqq Me^{\mu_0 t}$ for some M and $\mu<\mu_0<0$.

From this, by Gronwall's inequality applied to (9), we obtain

$$\|z(t,z_0)\|\leqq M_1\,e^{\mu_1 t},$$

where $M_1>0$ and $\mu_1<0$ for z_0 close to zero.

Hence $z(t,z_0)\to 0$ for $\|z_0\|<\delta_0$, where δ_0 is small. This implies that

$$\frac{x(t,x_0)}{\psi(x(t,x_0))}\to u \quad \text{for any } x_0\in\{v\in\Sigma_0;\ \|v-u\|<\delta\}$$

with δ small. Application of Lemma 2.3 finishes the proof. □

In $\mathbf{R}^n$, Theorem 2.1 takes the following simple form.

COROLLARY 2.1. *Let K be the standard cone in $\mathbf{R}^n$ and f: int $K\to\mathbf{R}^n$ be a locally Lipschitz map. Assume that the flow generated by f is order-preserving, that f is positively* *homogeneous of degree* 1 *and* $f(u)=\lambda u$ *for some* $u\in\operatorname{int}K$ *with* $\|u\|=1$ *and* $\lambda\in\mathbf{R}$. *Finally, assume that f is differentiable at u and if*

$$L:=f'(u)=\left[\frac{\partial f_i}{\partial x_j}(u)\right],$$

then $A:=\alpha I+L$ *is an irreducible matrix for some* $\alpha>0$. *Then*

$$\lim_{t\to\infty}\frac{x(t,x_0)}{\|x(t,x_0)\|}=u$$

for all $x_0\in\operatorname{int}K$.

Proof. Compactness and the Perron-Frobenius theorem imply that $r_e(A)=0$ and $r(A)>0$. The other assumptions of Theorem 2.1 are trivially satisfied. □

Remark 2.2. Observe that Theorem 2.1 and Corollary 2.1, and Lemma 2.3 remain true if we replace the assumption that the flow of (1) is order-preserving by a weaker, namely that the flow is nonexpansive with respect to Hilbert's projective metric d.

If in Theorem 2.1, $f(u)=0$, i.e., $\lambda=0$, then any point of $\{\alpha u;\ \alpha\geqq 0\}$ is equilibrium and we can ask about convergence of $x(t,x_0)$ for any $x_0\in\operatorname{int}K$.

PROPOSITION 2.1. *Assume that f satisfies all assumptions of Theorem* 2.1. *and that* $\lambda=0$.

Then there is a continuous function $\gamma:\operatorname{int}K\to\mathbf{R}_+$ *such that for any* $x_0\in\operatorname{int}K$

$$\|x(t,x_0)-\gamma(x_0)u\|\to 0\quad \textit{as } t\to\infty.$$

Moreover, γ *is order-preserving and homogeneous of degree* 1.

Proof. Recall that the topologies induced by $\|\cdot\|$ and Thompson's metric $\bar d$ on $\operatorname{int}K$ are identical. Therefore, it suffices to prove the result for the metric $\bar d$. Let $\{t_n\}$ be any increasing sequence converging to infinity.

It follows from Theorem 2.1 that

$$\lim_{n\to\infty}\frac{x(t_n,x_0)}{\psi(x(t_n,x_0))}=u \tag{10}$$

for any $x_0\in K$, where $\psi\in K^*\backslash\{0\}$ is such that $\psi(u)=1$.

Since $x(t,u)=u$ and $x(t,\cdot)$ is order-preserving and homogeneous of degree 1, a sequence $\{\bar d(x(t_n,x_0),u)\}$ must be decreasing.

Let $\lim_{n\to\infty}\bar d(x(t_n,x_0),u)=\alpha$. If $\alpha=0$, then $x(t,x_0)\to\gamma(x_0)u$ with $\gamma(x_0)=1$. Hence we can assume that $\alpha>0$.

Then

$$\bar d\left(x(t_n,x_0),\frac{x(t_n,x_0)}{\psi(x(t_n,x_0))}\right)\to\alpha. \tag{11}$$

Since $\bar d(y,\alpha y)=|\log\alpha|$, the above implies that

$$\psi(x(t_n,x_0))\to\{e^{-\alpha},e^{\alpha}\}\quad\text{as } n\to\infty.$$

Without loss of generality we may assume that $\psi(x(t_{n_k},x_0))\to e^{\alpha}$ for some subsequence $\{t_{n_k}\}$. As $x(t,e^{\alpha}u)=e^{\alpha}u$ and the flow is order-preserving, Lemma 2.2 implies

$$\bar d(x(t,x_0),e^{\alpha}u)\leqq\bar d(x(t_{n_k},x_0),e^{\alpha}u)\quad\text{for } t\geqq t_{n_k}.$$

This implies that

$$x(t,x_0)\to e^{\alpha}u\quad\text{as } t\to\infty,$$

and that $\gamma(x_0)=e^{\alpha}$.

If $x_0, y_0 \in \operatorname{int} K$ are such that $x_0 \leqq y_0$, then

$$\gamma(x_0)u = \lim_{t\to\infty} x(t, x_0) \leqq \lim_{t\to\infty} x(t, y_0) = \gamma(y_0)u,$$

which proves that γ is order-preserving. Homogeneity of γ follows from the homogeneity of $x(t, \cdot)$.

To verify that $\gamma : \operatorname{int} K \to \mathbf{R}_+$ is a continuous function, take $x_0 \in \operatorname{int} K$ and $\varepsilon > 0$. Let $\rho > 0$ be such that $\rho|\gamma(x_0)| < \varepsilon$. Define $B = \{x \in \operatorname{int} K;\ -\rho x_0 < x - x_0 < \rho x_0\}$. Then B is open in int K and, since γ is order-preserving and homogeneous of degree 1,

$$(1-\rho)\gamma(x_0) \leqq \gamma(x) \leqq (1+\rho)\gamma(x_0)$$

for all $x \in B$.

Then we have

$$|\gamma(x) - \gamma(x_0)| \leqq \rho|\gamma(x_0)| < \varepsilon$$

for all $x \in B$, which shows that γ is continuous. □

Until now we have assumed that f has an eigenvector in the interior of K. But there are examples of maps which have eigenvectors in ∂K and not in int K. One of the difficulties in this case is that as f is only defined on K it may no longer be Fréchet differentiable at any point of the boundary of K. The Fréchet differentiability of f at u will be replaced by the existence of a Gâteaux derivative at u. In fact, many maps of interest possess Gâteaux derivative at points of ∂K. We restrict our attention to the case: $X = \mathbf{R}^n$ and K the standard cone in $\mathbf{R}^n$.

It will be convenient to introduce some notation.

If $x \in (x_1, \dots, x_n) \in \mathbf{R}^n$, then we define the support of x by

$$\operatorname{supp}(x) = \{i \in \{1, \dots, n\};\ x_i \neq 0\} \subseteq \{1, \dots, n\}.$$

If J is a subset of $\{1, \dots, n\}$ let

$$\mathbf{R}^n_J = \{x \in \mathbf{R}^n;\ \operatorname{supp}(x) \subseteq J\},$$

$$K_J = \{x \in K;\ \operatorname{supp}(x) \subseteq J\},$$

$$C_J = \{x \in \mathbf{R}^n;\ x_i \geqq 0 \text{ for all } i \notin J\},$$

$$P_J = \text{orthogonal projection onto } \mathbf{R}^n_J,$$

$$Q_J = I - P_J.$$

Let $f : K \to \mathbf{R}^n$ be a continuous map, $u \in \partial K$ and $J = \operatorname{supp}(u)$. We say that $\phi : C_J \to \mathbf{R}^n$ is a Gâteaux derivative of f at u if

$$\lim_{t\to 0^+} \frac{f(u+tx) - f(u)}{t} = \phi(x) \quad \text{for all } x \in C_J. \tag{12}$$

Note that in general ϕ is not linear.

The following properties of ϕ can be deduced from properties of f.

Lemma 2.7 [8]. *Let $f : K \to \mathbf{R}^n$ be a continuous map and $u \in \partial K$ with $J = \operatorname{supp}(u)$. Let $\phi : C_J \to \mathbf{R}^n$ be a Gâteaux derivative of f at u. If f is Lipschitz on $B_r(u) \cap K$ with a constant k, then ϕ is Lipschitz with the same constant k and the limit in* (12) *is uniform in $x \in C_J$ such that $\|x\| \leqq 1$.*

If g is a positively homogeneous map of degree 1 such that $g(K) \subseteq K$, define

$$r_K(g) = \sup\{\lambda \geqq 0;\ g(v) = \lambda v \quad \text{for some } v \in K \backslash \{0\}\},$$

and $r_K(g) = 0$ if g has no eigenvector in K.

Now we can state the next theorem.

THEOREM 2.2. *Assume that* $f: K \to \mathbf{R}^n$ *is continuous and* $f_{|\mathrm{int}\, K}$ *is locally Lipschitz. Assume that* f *generates order-preserving flow,* f *is homogeneous of degree* 1 *and that*

$$f(u) = \lambda u \quad \textit{for some } u \in \partial K \backslash \{0\} \quad \textit{with } \|u\| = 1 \quad \textit{and} \quad \lambda \in \mathbf{R}$$

and f *has no eigenvectors in* int K.

Let $J = \operatorname{supp}(u)$. *Suppose that there is an open neighborhood* U *of* u *such that* $f_{|U \cap K}$ *is Lipschitz.*

Let $h = \alpha I + f$, *for some* $\alpha \geqq 0$, *be such that* $h(K) \subseteq K$ *and that the Gâteaux derivative* ϕ *of* h *at* u *satisfies*

$$\phi(x) = \phi(P_J x) + \phi(Q_J x)$$

for any $x \in C_J$. *Finally, assume that* $A := \phi_{|\mathbf{R}^n_J}$ *is linear and irreducible and that* $r_K(Q_J \phi Q_J) < \lambda$. *Then for any* $x_0 \in \mathrm{int}\, K$, $x(t, x_0) \in \mathrm{int}\, K$ *for all* $t \geqq 0$ *and*

$$\lim_{t \to \infty} \frac{x(t, x_0)}{\|x(t, x_0)\|} = u.$$

Proof. As in the proof of Theorem 2.1, we may assume that $\alpha = 0$ and $h = f$. Because $f(0) = 0$ and $f(K) \subseteq K$, it follows that $x_i'(t, x_0) \geqq 0$. Hence $x(t, x_0) \geqq x_0 \in \mathrm{int}\, K$, and since f has a linear growth, $x(t, x_0) \in \mathrm{int}\, K$ for all $t \geqq 0$ and $x_0 \in \mathrm{int}\, K$.

Let $\psi \in K^* \backslash \{0\}$ be such that $\psi(u) = 1$. Clearly, it is enough to show that

$$\lim_{t \to \infty} \frac{x(t, x_0)}{\psi(x(t, x_0))} = u.$$

Furthermore, application of Lemma 2.3 shows that it suffices to prove the result for $x_0 \in \Sigma_0 = \{v \in \mathrm{int}\, K;\ \psi(v) = 1\}$ such that $\|x_0 - u\|$ is sufficiently small. If we write

$$y(t) = \frac{x(t, x_0)}{\psi(x(t, x_0))} = z(t) + u,$$

then the problem reduces to showing that $z(t) \to 0$ for $x_0 \in \Sigma_0$ so that $\|x_0 - u\|$ is small. A simple calculation shows that $z(t)$ satisfies

$$\begin{aligned} &z'(t) = f(z(t) + u)\psi(f(z(t) + u))(z(t) + u) := h(z(t)), \\ (13) \qquad &z(0) = x_0 - u, x_0 \in \Sigma. \end{aligned}$$

We have that

$$\lim_{s \to 0} \frac{1}{s}[h(sz) - h(0)] = \phi(z)\psi(\phi(z))u\lambda u$$

for any $z \in C_J$, and the above limit is uniform in $z \in C_J$, $\|z\| \leqq 1$.

Hence

$$h(z) = \phi(z) - \psi(\phi(z))u - \lambda z + R(z),$$

where

$$\frac{\|R(z)\|}{\|z\|} \to 0 \quad \text{as } \|z\| \to 0, z \in C_J.$$

To simplify the notation we write $P = P_J$, $Q = Q_J$, $z_1 = P_z$, and $z_2 = Qz$.

Using the assumptions about ϕ we get that

$$
\begin{aligned}
h(z) &= Az_1 + Q\phi(z_2) + P\phi(z_2) - \psi(Az_1 + \phi(z_2))u - \lambda z - R(z) \\
&= [(A-\lambda)z_1 - \psi((A-\lambda)z_1)u] + [P\phi(z_2) - \psi(\phi(z_2) - \lambda z_2)u] \\
&\quad + [Q\phi(z_2) - \lambda z_2] + R(z) \\
&= Lz_1 + g(z_2) + [Q\phi(z_2) - \lambda z_2] + R(z),
\end{aligned}
\tag{14}
$$

where $L:\mathbf{R}^n_J \to \mathbf{R}^n_J$ and $g: K_{J'} \to \mathbf{R}^n$, $(J' = \{1, \dots, n\}\backslash J)$ are defined by

$$Lz_1 = [(A-\lambda)z_1 - \psi((A-\lambda)z_1)u],$$

$$g(z_2) = [P\phi(z_2) - \psi(\phi(z_2) - \lambda z_2)u].$$

Because f is Lipschitz map, g is also Lipschitz and there is a constant $M_1 > 0$ such that

$$\|g(z_2)\| \leqq M_1\|z_2\| \quad \text{for any } z_2 \in K_{J'}.$$

The map L has only eigenvalues with real part less than zero, and so there are constants $M_2 > 0$ and $\mu > 0$ such that

$$\|e^{Lt}\| \leqq M_2\, e^{-\mu t} \quad \text{for any } t \geqq 0.$$

Consider $Q\phi$ restricted to $K_{J'}$.

Since $Q\phi(K_{J'}) \subseteq K_{J'}$ and $r_K(Q\phi Q) < \lambda$, we see that $Q\phi_{K_{J'}}$ does not have eigenvectors in $K_{J'}$ with eigenvalues $\geqq \lambda$.

Let $\eta > 0$ and $B: \mathbf{R}^n_{J'} \to \mathbf{R}^n_{J'}$ be a positive linear map. Let $T_\eta := Q\phi_{K_{J'}} + \eta B$. Then $T_\eta(K_{J'}) \subseteq \operatorname{int} K_{J'}$; applying Brouwer's fixed point theorem, we find $w_\eta \in K_{J'}$ with $\|w_\eta\| = 1$ and $\lambda_\eta > 0$ such that

$$T_\eta w_\eta = \lambda_\eta w_\eta.$$

A standard compactness argument shows that for a sufficiently small η we have that $\lambda_\eta < \lambda$.

Fix η so that $\lambda_\eta < \lambda$ and let $w := w_\eta$, $\lambda_1 := \lambda_\eta$. Define

$$(\mathbf{R}^n_{J'})_w = \{x \in \mathbf{R}^n_{J'};\ -\alpha w \leqq x \leqq \alpha w \text{ for some } \alpha > 0\},$$

and $\|x\|_w = \inf\{\alpha > 0;\ -\alpha w \leqq x \leqq \alpha w\}$. Obviously, $\mathbf{R}^n_{J'} = (\mathbf{R}^n_{J'})_w$ and the norms $\|\cdot\|$ and $\|\cdot\|_w$ are equivalent on $\mathbf{R}^n_{J'}$.

Let $x \in K_{J'}$ and $\beta > \|x\|_w$. Then $x \leqq \beta w$ and

$$
\begin{aligned}
0 \leqq Q\phi(x) \leqq \beta Q\phi(w) &= \beta Q\phi(w) + \beta\eta Bw - \beta\eta Bw \\
&= \beta T_\eta w - \beta\eta Bw = \beta\lambda_1 w - \beta\eta Bw \leqq \beta\lambda_1 w.
\end{aligned}
$$

From this we deduce that

$$\|Q\phi(x)\|_w \leqq \lambda_1\|x\|_w \quad \text{for any } x \in K_{J'}.$$

Since $y(t) = z(t) + u \geqq 0$ and $\operatorname{supp}(u) = J$, we see that $z(t) \in C_J$ for $t \geqq 0$. Now, we can write (13) as a system of two equations

$$z_1'(t) = Lz_1(t) + g(z_2(t)) + R_1(z(t)), \tag{15}$$

$$z_2'(t) = Q\phi(z_2(t)) - \lambda z_2(t) + R_2(z(t)), \tag{16}$$

where $z(t)=z_1(t)+z_2(t)=Pz(t)+Qz(t)$ and $R_1(z)=PR(z)$, $R_2(z)=QR(z)$. Observe that

$$\frac{\|R_i(z)\|}{\|z\|}\to 0 \quad \text{as } \|z\|\to 0,\ i=1,2.$$

The variation of constants formula applied to solutions of (15) and (16) gives

$$z_1(t)=e^{Lt}z_1(0)+\int_0^t e^{L(t-s)}g(z_2(s))\,ds+\int_0^t e^{L(t-s)}R_1(z(s))\,ds \tag{17}$$

and

$$z_2(t)=e^{\lambda t}z_2(0)+\int_0^t e^{\lambda(t-s)}Q\phi(z_2(s))\,ds+\int_0^t e^{\lambda(t-s)}R_2(z(s))\,ds. \tag{18}$$

These formulas together with $\|g(z_2)\leqq M_1\|z_2\|$ and $\|e^{Lt}\|\leqq M_2e^{-\mu t}$ give

$$\begin{aligned}\|z_1(t)\|\leqq M_2e^{\mu t}\|z_1(0)\|+M_1M_2\int_0^t e^{\mu(t-s)}\|z_2(s)\|\,ds\\ +M_2\int_0^t e^{\mu(t-s)}\|R_1(z(s))\|\,ds\end{aligned} \tag{19}$$

and

$$\begin{aligned}\|z_2(t)\|_w&\leqq e^{\lambda t}|z_2(0)|+\lambda_1\int_0^t e^{-\lambda(t-s)}\|z_2(s)\|_w\,ds+\int_0^t e^{\lambda(t-s)}\|R_2(z(s))\|_w\\ &\leqq e^{\lambda t}|z_2(0)|+\lambda_1\int_0^t e^{\lambda(t-s)}\|z_2(s)\|_w\,ds+\frac{1}{m_0}\int_0^t e^{\lambda(t-s)}\|R_2(z(s))\|\,ds,\end{aligned} \tag{20}$$

where m_0 is a constant so that

$$m_0\|x\|_w\leqq\|x\|<m_1\|x\|_w.$$

Let $\mu_1=\lambda-\lambda_1$, $\mu_2=\min\{\mu_1,\mu\}$, $a=m_1/m_0$ and $M_3=\max\{M_1M_2a,\ a+M_2\}$. Take $\varepsilon>0$ so that $\varepsilon<\min\{\mu/9M_3,\ 1/M_3\}$. Then there is $\delta>0$ such that

$$\|R_i(z)\|\leqq\varepsilon\|z\| \quad \text{if } \|z\|\leqq\delta,\quad i=1,2.$$

Put

$$\delta_1:=\frac{1}{M_3}\frac{\sqrt{M_3\varepsilon}}{\sqrt{M_3\varepsilon}+1}\delta.$$

We claim that if $\|z(0)\|=\|x_0-u\|\leqq\delta_1$, then $\|z(t)\|\leqq\delta$ for $t\geqq 0$. Define $t_0:=\inf\{t\geqq 0;\ \|z(t)\|=\delta\}>0$ and assume that $t_0<\infty$.

For any $t\in[0,t_0]$, we have

$$\begin{aligned}\|z_1(t)\|\leqq M_2e^{\mu_2 t}\|z_1(0)\|+M_1M_2\int_0^t e^{\mu_2(t-s)}\|z_2(s)\|\,ds\\ +\varepsilon M_2\int_0^t e^{\mu_2(t-s)}\|z(s)\|ds\end{aligned} \tag{21}$$

and

$$\begin{aligned}\|z_2(t)\|_w\leqq e^{\lambda t}|z_2(0)|+\lambda_1\int_0^t e^{-\lambda(t-s)}\|z_2(s)\|_w\,ds\\ +\frac{\varepsilon}{m_0}\int_0^t e^{\lambda(t-s)}\|z(s)\|\,ds.\end{aligned} \tag{22}$$

Taking $u(t) := e^{\lambda t}\|z_2(t)\|_w$, the second inequality is equivalent to

$$u(t) \leqq u(0) + \lambda_1 \int_0^t u(s)\, ds + \frac{\varepsilon}{m_0}\int_0^t e^{\lambda s}\|z(s)\|\, ds. \tag{23}$$

If $w(t) = \int_0^t u(s)\, ds$, the above inequality implies

$$\frac{d}{ds}(e^{\lambda_1 s}w(s)) \leqq e^{\lambda_1 s}u(0) + \frac{\varepsilon}{m_0} e^{\lambda_1 s}\int_0^s e^{\lambda \tau}\|z(\tau)\|\, d\tau,$$

which after integration on $[0, t]$ gives

$$e^{\lambda_1 t}w(t) \leqq \frac{u(0)}{\lambda_1}(1 - e^{\lambda_1 t})\frac{\varepsilon e^{\lambda_1 t}}{m_0\lambda_1}\int_0^t e^{\lambda s}\|z(s)\|\, ds + \frac{\varepsilon}{m_0\lambda_1}\int_0^t e^{(\lambda-\lambda_1)s}\|z(s)\| ds.$$

Multiplying the last inequality by $\lambda_1 e^{\lambda_1 t}$ and substituting in (22) we obtain

$$\|z_2(t)\|_w \leqq e^{\mu_2 t}|z_2(0)| + \frac{\varepsilon}{m_0}\int_0^t e^{\mu_2(t-s)}\|z(s)\|\, ds. \tag{24}$$

Since $m_0|z_2| \leqq \|z_2\| \leqq m_1|z_2|$, we get

$$\|z_2(t)\| \leqq a e^{\mu_2 t}\|z_2(0)\| + b\int_0^t e^{\mu_2(t-s)}\|z(s)\|\, ds, \tag{25}$$

where $a = m_1/m_0$ and $b = \varepsilon a$.

Now, using (25) we can estimate the second term in (21):

$$\begin{aligned}\int_0^t e^{\mu_2(t-s)}\|z_2(s)\|\, ds &\leqq a\|z_2(0)\|\int_0^t e^{\mu_2(t-s)}e^{\mu_2 s}\, ds\\ &\quad + b\int_0^t e^{\mu_2(t-s)}\left[\int_0^s e^{\mu_2(s\tau)}\|z(\tau)\|\, d\tau\right] ds\\ &= a\|z_2(0)\|e^{\mu_2 t}t + b\int_0^t (t-s)e^{-\mu_2(t-s)}\|z(s)\|\, ds.\end{aligned}$$

Thus

$$\begin{aligned}\|z_1(t)\| &\leqq (M_2 + M_1M_2at)e^{\mu_2 t}\|z_1(0)\|\\ &\quad + M_1M_2b\int_0^t e^{\mu_2(t-s)}(t-s)\|z(s)\|\, ds + \varepsilon M_2\int_0^t e^{\mu_2(t-s)}\|z(s)\|\, ds.\end{aligned} \tag{26}$$

Adding (25) and (26) we get that

$$\begin{aligned}\|z(t)\| &\leqq M_3\|z(0)\|e^{\mu_2 t}(1+t) + M_3\varepsilon\int_0^t e^{\mu_2(t-s)}\|z(s)\|\, ds\\ &\quad + M_3\varepsilon\int_0^t e^{\mu_2(t-s)}(t-s)\|z(s)\|\, ds.\end{aligned} \tag{27}$$

Let $\alpha(t) := M_3\|z(0)\|(1+t)$, $\beta(t) := e^{\mu_2 t}\|z(t)\|$ and $c := M_3\varepsilon$.

Define $N: C[0, t_0] \to C[0, t_0]$ by

$$(Nv)(t) = \int_0^t (t-s)v(s)\, ds.$$

Because $(Nv)(t) \geqq 0$ if $v(t) \geqq 0$, repeated application of N to both sides of (27) gives

$$\beta(t) \leqq \sum_{k=0}^{n} c^k(N^k\alpha)(t) + \sum_{k=0}^{n} c^{k+1}(N^k w)(t) + c^{n+1}(N^{n+1}\beta)(t) \tag{28}$$

for any $n \in N$ and $w(t) = \int_0^t \beta(s)\, ds$.

It is easy to see that

$$(N^k\alpha)(t)=\frac{1}{(2k-1)!}\int_0^t (t-s)^{2k-1}\alpha(s)\,ds$$

and

$$(N^k w)(t)=\frac{1}{(2k)!}\int_0^t (t-s)^{2k}\beta(s)\,ds.$$

As $c^{n+1}(N^{n+1}\beta)(t)\to 0$ uniformly on $[0, t_0]$, by taking a limit in (28), we deduce that

$$\begin{aligned}\beta(t)&\leqq \alpha(t)+\int_0^t \sum_{k=1}^{\infty}\frac{c^k(t-s)^{2k-1}}{(2k-1)!}\alpha(s)\,ds\\ &\quad +c\int_0^t \beta(s)\,ds+\int_0^t \sum_{k=1}^{\infty}\frac{c^{k+1}(t-s)^{2k}}{(2k)!}\beta(s)\,ds\\ &\leqq \alpha(t)+\sqrt{c}\int_0^t e^{\sqrt{c}(t-s)}\alpha(s)\,ds+c\int_0^t \beta(s)\,ds\\ &\quad +\sqrt{c}\int_0^t e^{\sqrt{c}(t-s)}\beta(s)\,ds\\ &\leqq \alpha(t)+\sqrt{c}\int_0^t e^{\sqrt{c}(t-s)}\alpha(s)\,ds+2\sqrt{c}\int_0^t e^{\sqrt{c}(t-s)}\beta(s)\,ds.\end{aligned}\tag{29}$$

If $\alpha_1(t)=e^{\sqrt{c}t}\alpha(t)+\sqrt{c}\int_0^t e^{\sqrt{c}s}\alpha(s)\,ds$, then integration by parts implies

$$\begin{aligned}\alpha_1(t)&=e^{\sqrt{c}t}\alpha(t)\int_0^t e^{-\sqrt{c}s}\alpha(s)\,ds\\ &=\alpha(0)+\int_0^t e^{\sqrt{c}s}\alpha'(s)\\ &=\alpha(0)\left(1+\frac{1}{\sqrt{c}}\right).\end{aligned}\tag{30}$$

It follows from (29) and (30) that

$$e^{\sqrt{c}t}\beta(t)\leqq \alpha(0)\left(1+\frac{1}{\sqrt{c}}\right)+2\sqrt{c}\int_0^t e^{\sqrt{c}s}\beta(s)\,ds,$$

and by Gronwall's inequality,

$$e^{\sqrt{c}t}\beta(t)\leqq \alpha(0)\left(1+\frac{1}{\sqrt{c}}\right)e^{2\sqrt{c}t}.$$

Hence

$$\beta(t)\leqq \alpha(0)\left(1+\frac{1}{\sqrt{c}}\right)e^{3\sqrt{c}t}$$

and

$$\|z(t)\|\leqq M_3\|z(0)\|\left(1+\frac{1}{\sqrt{c}}\right)e^{\mu_3 t},\tag{31}$$

where $\mu_3=3\sqrt{c}\,\mu_2<0$.

Because

$$\|z(0)\|\leqq \frac{1}{M_3}\frac{\sqrt{c}}{\sqrt{c}+1}\,\delta:=\delta_1,$$

the above inequality implies

$$\|z(t)\| \leqq \delta e^{\mu_3 t} \quad \text{for any } 0 \leqq t \leqq t_0,$$

which contradicts the definition of t_0. Hence $\|z(t)\| \leqq \delta$ for all $t \geqq 0$. Now, the same arguments show that $\|z(t)\| \leqq \delta e^{\mu_3 t}$ for all $t \geqq 0$ and this completes the proof. □

3. Applications. In this section we will illustrate applications of the results of § 2.

One of the problems in applying these results is an a priori existence of an eigenvector u of f satisfying $u \in \operatorname{int} K$ or $u \in \partial K$ and $r_K(Q\phi Q) < \lambda$. Even for a simple-looking map these questions can be difficult. We will define classes of maps $\mathcal{M}$, $\mathcal{M}_-$, $\mathcal{M}_+$ which were rigorously analyzed by Nussbaum in [7] and [8]. To keep this section self-contained we will quote some of his results.

Suppose that K is the standard cone in $\mathbf{R}^n$. If $r \in \mathbf{R}$, and $\sigma = (\sigma_1, \ldots, \sigma_n)$ is a probability vector, i.e., $\sigma_i \geqq 0$, $i = 1, \ldots, n$ and $\sum_{i=1}^n \sigma_i = 1$, define for $x \in \operatorname{int} K$

$$M_{r\sigma}(x) = \left[\sum_{i=1}^n \sigma_i x_i^r \right]^{1/r} \quad \text{if } r \neq 0$$

and

$$M_{0\sigma}(x) = \prod_{j=1}^n x_j^{\sigma} = \lim_{r \to 0} M_{r\sigma}(x) \quad \text{for } x \in \operatorname{int} K.$$

Each of the maps $M_{r\sigma}$ is obviously C^∞ on $\operatorname{int} K$ and extends continuously to K. For each i, let Γ_i be a finite collection of ordered pairs (r, σ), $r \in \mathbf{R}$ and σ a probability vector.

For each pair $(r, \sigma) \in \Gamma_i$ assume that $c_{ir\sigma}$ is a positive number. Let

$$f_i(x) = \sum_{(r,\sigma) \in \Gamma_i} c_{ir\sigma} M_{r\sigma}(x) \tag{32}$$

and $f(x) = (f_1(x), \ldots, f_n(x))$. Of course, $f: \operatorname{int} K \to \operatorname{int} K$ and f can be continuously extended to K.

If $f: \operatorname{int} K \to \operatorname{int} K$ is a map such that each of its components can be written as in (32), we say that $f \in M$.

If $f \in M$ and each of the components f_i has the form (32) with $r \geqq 0$ for all $(r, \sigma) \in \Gamma_i$ we write $f \in M_+$ and if each component f_i can be written as in (32) with $r < 0$ for all $(r, \sigma) \in \Gamma_i$, then $f \in M_-$.

Note that the sets Γ_i are not uniquely determined by f_i, for example $(x^r)^{1/r} = x$. By $\mathcal{M}(\mathcal{M}_+, \mathcal{M}_-)$ we denote the smallest sets of maps $f: \operatorname{int} K \to \operatorname{int} K$ such that $M \subseteq \mathcal{M}(M_+ \subseteq \mathcal{M}_+, M_- \subseteq \mathcal{M}_-)$ and $\mathcal{M}(\mathcal{M}_+, \mathcal{M}_-)$ is closed under addition of functions, composition of functions and multiplication by positive numbers. It is known (see [8]) that if $f \in \mathcal{M}(\mathcal{M}_+, \mathcal{M}_-)$, then $f_{|\operatorname{int} K}$ is C^∞ and extends continuously to K and is order-preserving. Hence, by Remark 2.1, the flow of (1) with f in one of these classes is automatically order-preserving.

Definition 3.1. If $g: \operatorname{int} K \to K$ is continuous, order-preserving and homogeneous of degree 1 map, then the nonnegative $n \times n$ matrix $A = (a_{ij})$ is called an "incidence matrix for g" if whenever $a_{ij} > 0$, there is a positive c and a probability vector σ such that the jth component of σ, σ_j, is positive and

$$g_i(x) \geqq cx^{\sigma} \quad \text{for all } x \in \operatorname{int} K.$$

For maps with incidence matrices Nussbaum proves the following.

Theorem 3.1. *Assume that $g: \operatorname{int} K \to \operatorname{int} K$ is C^1, g extends continuously to K, g is positively homogeneous of degree 1 and order-preserving. If g has an incidence matrix A which is irreducible, then g has an eigenvector $u \in \operatorname{int} K$ with $\|u\| = 1$.*

Many maps in $\mathcal{M}_+$ have irreducible incidence matrices. If $g \in \mathcal{M}_+$, then $D_x g(x) = A$ is an incidence matrix for g and $D_x g(x)$, $D_x g(y)$ satisfy

$$\alpha D_x g(x) \leqq D_x g(y) \leqq \beta D_x g(x) \tag{33}$$

for some $\alpha, \beta > 0$, depending on $x, y \in \operatorname{int} K$.

Having this the following corollary is an immediate consequence of Theorem 2.1.

COROLLARY 3.1. *Let $f: K \to \mathbf{R}^n$ be such that for some $\alpha \geqq 0$ the map $g: K \to K$ defined by $g(x) = \alpha x + f(x)$ is in the class $\mathcal{M}_+$. Assume that there is $x \in \operatorname{int} K$ such that $D_x g(x)$ is irreducible.*

Then g has an eigenvector $u \in \operatorname{int} K$ such that $\|u\| = 1$, and for any $x_0 \in \operatorname{int} K$ we have that

$$\frac{x(t, x_0)}{\|x(t, x_0)\|} \to u, \qquad t \to \infty.$$

Proof. That g has an eigenvector $u \in \operatorname{int} K$ follows from Theorem 3.1. Then, since $D_x g(x)$ is irreducible and (33) holds, it follows that $D_x g(u)$ is also irreducible. By Theorem 2.1, if $y(t)$ is a solution of $y'(t) = g(y(t))$, we have

$$\frac{y(t, x_0)}{\|y(t, x_0)\|} \to u \quad \text{for any } x_0 \in \operatorname{int} K.$$

But $y(t, x_0) = e^{\alpha t} x(t, x_0)$, $x'(t) = f(x(t))$ and the conclusion follows. □

The existence of eigenvectors in $\operatorname{int} K$ for maps in the class $\mathcal{M}_-$ is more subtle.

Let A be a subset of M_- such that if $g \in A$, then for any two elements (r, σ) and (r', σ') of Γ_i, $1 \leqq i \leqq n$, we have that σ and σ' are comparable.

We denote by $\mathcal{A}$ the smallest set of functions $g: \operatorname{int} K \to \operatorname{int} K$ which is closed under composition and contains A. It is known that if $g \in \mathcal{A}$, then $g: \operatorname{int} K \to \operatorname{int} K$, g is C^1, order-preserving, and homogeneous of degree 1. Moreover, if $D_x g(x)$ is irreducible for some $x \in \operatorname{int} K$, then g has an eigenvector u in $\operatorname{int} K$.

COROLLARY 3.2. *Let $f: \operatorname{int} K \to \mathbf{R}^n$ be such that $g = \alpha I + f$ belongs to $\mathcal{A}$. If for some $x \in \operatorname{int} K$, $D_x g(x)$ is irreducible, then*

$$\lim_{t \to \infty} \frac{x(t, x_0)}{\|x(t, x_0)\|} = u \qquad \text{for each } x_0 \in \operatorname{int} K,$$

where u is an eigenvector of g in int K.

Proof. By the previous remarks the proof is similar to the proof of Corollary 3.1. □

Now we will give a result concerning convergence to a boundary point of ∂K for maps in $\mathcal{M}_-$. We have the following.

PROPOSITION 3.1. *Let $g \in \mathcal{M}_-$. Then g is Lipschitz on K. If $u \in \partial K - \{0\}$, then for all $x \in C_J$,*

$$\lim_{t \to t^+} t^{-1}[g(u + tx) - g(u)] \equiv \phi(x)$$

exists and $\phi \in \mathcal{M}_-$.

Moreover, the above limit is uniform for $u \in C_J$ such that $\|u\| \leqq 1$. For all $u \in C_J$

$$\phi(u) = \phi(P_J u) + \phi(Q_J u)$$

and $\phi_{|\mathbf{R}^n_J}$ is linear. If $D_x g(x)$ is irreducible at $x \in$ int K and $g(u) = \lambda u$ for some $u \in \partial K \backslash \{0\}$ with supp $(u) = J$ *and*

$$r_K(Q_J \phi Q_J) \leqq \lambda,$$

then g has no eigenvector in int K.

Using the above proposition and Theorem 2.2 we obtain the following.

COROLLARY 3.3. *Assume that* $f\colon K\to \mathbf{R}$ *and* g *is defined by* $g(x)=\alpha x+f(x)$, $\alpha \geqq 0$. *Assume that* $D_xg(x)$ *is irreducible for some* $x\in \operatorname{int} K$ *and that* $g(u)=\lambda u$ *for some* $u\in \partial K\backslash\{0\}$ *with* $\operatorname{supp}(u)=J$ *and* $\|u\|=1$. *Moreover, assume that*

$$r_K(Q_J\phi Q_J)<\lambda.$$

Then for any $\xi_0\in \operatorname{int} K$,

$$\lim_{t\to\infty}\frac{x(t,\xi_0)}{\|x(t,\xi_0)\|}=u.$$

Proof. The proof follows from Theorem 2.2 and the previous proposition. □

We will close this section by considering a very special example. Let $f\colon K\to \mathbf{R}^4$ by

$$\begin{aligned}
f_1(x)&=\alpha_1x_1+\beta_1\theta(x_1,x_2)+\gamma_1\theta(x_1,x_4)+\delta_1\theta(x_2,x_3),\\
f_2(x)&=\alpha_2x_2+\beta_2\theta(x_1,x_2)+\gamma_2\theta(x_1,x_4)+\delta_2\theta(x_2,x_3),\\
f_3(x)&=\alpha_3x_3+\beta_3\theta(x_3,x_4)+\gamma_3\theta(x_1,x_4)+\delta_3\theta(x_2,x_3),\\
f_4(x)&=\alpha_4x_4+\beta_4\theta(x_3,x_4)+\gamma_4\theta(x_1,x_4)+\delta_4\theta(x_2,x_3).
\end{aligned}\tag{34}$$

Here θ stands for the harmonic mean:

$$\theta(s,t)=\frac{st}{s+t}=\frac{1}{2}\left[\frac{1}{2}s^{-1}+\frac{1}{2}t^{-1}\right]^{-1}.$$

The coefficients β_i, γ_i, δ_i satisfy

(H.1) β_i, γ_i, δ_i are nonnegative for $1\leqq i\leqq 4$;

(H.2) δ_1, γ_2, γ_3, δ_4 are strictly greater than zero;

(H.3) $\alpha_1<\alpha_2+\beta_2$, $\alpha_2<\alpha_1+\beta_1$, $\alpha_3<\alpha_4+\beta_4$, $\alpha_4<\alpha_3+\beta_3$.

It is easy to see that if $\alpha>|\alpha_i|$ for $1\leqq i\leqq 4$, then $g=\alpha I+f$ is in the class $\mathcal{M}_-$.

This four-dimensional map has been introduced by Schoen in his studies of a model from the population biology.

The following is known about f; for the proof see [8].

Let $a_1, a_2\in \mathbf{R}$, and $b_i, c_i\geqq 0$ for $i=1,2$, and assume that at least one of b_1, c_1, b_2, or c_2 is positive. Consider the equation

$$a_1+b_1t(1+t)^{-1}c_1t=a_2+b_2(1+t)^{-1}+c_2t^{-1}.$$

If this equation has a positive solution, then it is unique, say τ. Define

$$\sigma(a_1,b_1,c_1,a_2,b_2,c_2)=a_1+b_1\tau(1+\tau)^{-1}+c_1\tau.$$

If $c_1=0$ and $c_2>0$ and $a_2\geqq a_1+b_1$, let

$$\sigma(a_1,b_1,c_1,a_2,b_2,c_2)=a_2.$$

If $c_1>0$ and $c_2=0$ and $a_1\geqq a_2+b_2$, let

$$\sigma(a_1,b_1,c_1,a_2,b_2,c_2)=a_1.$$

If $c_1=c_2=0$ and $a_1\geqq a_2+b_2$ or $a_2\geqq a_1+b_1$, define

$$\sigma(a_1,b_1,c_1,a_2,b_2,c_2)=\max(a_1,a_2).$$

If

$$\sigma(\alpha_1+\gamma_1,\beta_1,\delta_1,\alpha_2+\delta_2,\beta_2,\gamma_2)\leqq\sigma(\alpha_3,\beta_3,0,\alpha_4,\beta_4,0)\tag{35}$$

or

$$(36) \qquad \sigma(\alpha_3+\delta_3, \beta_3, \gamma_3, \alpha_4+\gamma_4, \beta_4, \delta_4) \leqq \sigma(\alpha_1, \beta_1, 0, \alpha_2, \beta_2, 0),$$

then f has no eigenvector in int K.

If neither inequality is satisfied, then f has a unique eigenvector in int K. Having this we can state the following.

COROLLARY 3.4. *Let f be defined by* (34) *and let f satisfy* (H.1), (H.2), *and* (H.3). *If none of the inequalities* (35) *and* (36) *are satisfied, then*

$$\frac{x(t, x_0)}{\|x(t, x_0)\|} \to u \quad \textit{for all } x_0 \in \text{int } K,$$

where u is the unique normalized eigenvector of f in int K.

Proof. It is easy to see that if $\alpha > \sum_{i=1}^4 |\alpha_i|$ and $g = \alpha I + f$ is in $\mathcal{M}_-$, then $D_x g(x)$ is irreducible at each $x \in \text{int } K$. Thus g has a unique eigenvector u in int K, and the result follows from Corollary 3.2. □

If β_1 and β_2 are positive and (36) is satisfied with strict inequality, then f has a unique normalized eigenvector $u = (u_1, u_2, 0, 0)$, $u_i > 0$.

If β_3 and β_4 are positive and (35) is satisfied with strict inequality, then f has a unique normalized eigenvector $v = (0, 0, v_3, v_4)$, $v_i > 0$. Hence we can state the following.

COROLLARY 3.5. *If f is as in* (34) *and either* (35) *or* (36) *is satisfied with strict inequality, then we have*

$$\lim_{t\to\infty} \frac{x(t, \xi_0)}{\|x(t, \xi_0)\|} = w \quad \textit{for any } \xi_0 \in \text{int } K,$$

where $w = (w_1, w_2, 0, 0)$ if $\beta_1, \beta_2 > 0$ and (36) *holds with strict inequality, or $w = (0, 0, w_3, w_4)$ if $\beta_3, \beta_4 > 0$ and* (35) *holds with strict inequality.*

Proof. The proof follows from Corollary 3.3. □

Acknowledgment. I would like to thank Professor Roger Nussbaum for suggesting this problem and for helpful discussions.

EXPLICIT FORMULA FOR THE BEST LINEAR PREDICTOR OF PERIODICALLY CORRELATED SEQUENCES*

A. G. MIAMEE†

Abstract. Explicit formulas expressing the best linear predictor and prediction error of a periodically correlated sequence in terms of a related multivariate stationary sequence are obtained. Algorithms for determining this best linear predictor and this predictor error are also outlined.

Key words. periodically correlated sequences, best linear predictor, prediction error, multivariate stationary sequences

AMS subject classifications. 60G10, 60G25

1. Introduction. A sequence X_n, $n \in Z$ of elements of a Hilbert space H is called a *periodically correlated sequence* (PCS) if there exists an integer $T > 0$ such that for any τ, $n \in Z$,

$$(X_{n+\tau}, X_n) = (X_{n+T+\tau}, X_{n+T}).$$

The *smallest* such T is called its period. (If $T = 1$ the sequence is called *stationary.*) For a PCS X_n, its *correlation function*

$$R(n, \tau) = (X_{n+\tau}, X_n)$$

is periodic in n with period T and, therefore, has the representation [1]

$$R(n, \tau) = \sum_{k=0}^{T-1} R_k(\tau) \exp(2\pi ikn/T). \tag{1}$$

For convenience we complete the definition of the functions $R_k(\tau)$, $k = 0, \dots, T-1$ to all integers using $R_k(\tau) = R_{k+T}(\tau)$.

There is a very close tie between the class of PCS's and that of multivariate stationary sequences (SS). For example it is well known and easy to check that: *A sequence X_n is periodically correlated if and only if the T-variate sequence $\underline{Y}_n = (X_{nT}, X_{nT+1}, \dots, X_{nT+T-1})^T$ constructed from consecutive blocks of length T from the process X_n is stationary.* Another such close tie is the subject of the following result proved in [1].

THEOREM 1.1 (Gladyshev). *Function* (1) *is the correlation function of some* PCS *if and only if the matrix-valued function*

$$\underline{R}(\tau) = (R_{kk'}(\tau))_{k,k'=0}^{T-1}$$

with

$$R_{kk'}(\tau) = R_{k'-k}(\tau) \exp(2\pi ik\tau/T), \tag{2}$$

is the matrical correlation function of some T-variate SS $\underline{Z}_n$.

Using this theorem and the well-known spectral representation of multivariate SS's we can show [9], [10]

$$R_k(\tau) = \int_0^{2\pi} \exp(-i\tau\lambda)\, dF_k(\lambda), \tag{3}$$

where dF_k's are complex-valued measures defined on $[0, 2\pi)$. Identifying $[0, 2\pi)$ with the unit circle in the standard way we can extend the definition of the measures dF_k beyond the interval $[0, 2\pi)$.

We note from formulas (1) and (2) that the periodically correlated sequence X_n must be harmonizable, i.e.,

$$X_n = \int_0^{2\pi} e^{in\lambda}\, dZ(\lambda),$$

where $dZ(\lambda)$ is an H-valued measure satisfying

$$(Z(\Lambda'), Z(\Lambda))_H = \sum_{k=-T+1}^{T-1} F_k(\Lambda' \cap (\Lambda - 2\pi k/T)),$$

($\Lambda - a$ stands for the set of all points $\lambda - a$, with $\lambda \in \Lambda$). In other words the spectrum of the PCS X_n is concentrated on $2T-1$ straight line segments $\lambda - \mu = 2\pi k/T$, $k = -T+1, \dots, T-1$ contained in the square $[0, 2\pi) \times [0, 2\pi)$. For more information on PCS's, see [1], [3], [4], [7].

It turns out that this second associated multivariate SS $\underline{Z}_n$ is more useful for prediction purposes than the first one. This is because of the fact that it captures more prediction properties of the original PCS X_n (see next section). However, so far no explicit representation of this $\underline{Z}_n$ process in terms of the original PCS X_n (in time domain) is available in the literature, and this is needed for our prediction purposes here. In § 3 we will obtain explicit expressions of the original PCS X_n and its associated multivariate SS $\underline{Z}_n$ (of Theorem 1.1) in terms of each other. These explicit expressions play an important role in finding our formulas for the best linear predictor and prediction error in § 4. These expressions seem to be equally important in studying other prediction problems concerning the PCS's.

2. Preliminaries. Let H be a Hilbert Space whose inner product is denoted by $(,)$, and let T be a positive integer. The direct sum $H \oplus, \dots, \oplus H$ of T copies of H is defined to be the Cartesian product of T copies of H. However, the elements of $H \oplus, \dots, \oplus \mathrm{H}$ are denoted by $X_0 \oplus, \dots, \oplus X_{T-1}$ rather than by $(X_0, X_1, \dots, X_{T-1})$, which is saved for the space H^T to be defined shortly. It is well known that $H \oplus, \dots, \oplus H$ with the usual addition and scalar multiplication becomes a Hilbert space when equipped with the *Euclidean inner product*

$$\langle X, Y \rangle = \sum_{j=0}^{T-1} (X_j, Y_j)$$

of $X = X_0 \oplus, \dots, \oplus X_{T-1}$ and $Y = Y_0 \oplus, \dots, \oplus Y_{T-1}$. Throughout this paper the direct sum $H \oplus, \dots, \oplus H$ will be denoted by K.

Following [6], H^T denotes the *Cartesian product* of H with itself T times, i.e., the set of all column vectors $\underline{X} = (X^0, \dots, X^{T-1})^T$ with $X^i \in H$ for all $i = 0, \dots, T-1$. We endow the space H^T with a Gramian structure: For $\underline{X}$ and $\underline{Y}$ in H^T their *Gramian* denoted by $((\underline{X}, \underline{Y}))$ is given by

$$((\underline{X}, \underline{Y})) = [(X^i, Y^j)]_{i,j=0}^{T-1}.$$

We can easily verify that

$$((\underline{X}, \underline{X})) \geqq \underline{0}; \qquad (\underline{X}, \underline{X}) = \underline{0} \Leftrightarrow \underline{X} = \underline{0};$$

$$\left(\left(\sum_{k=1}^{m} \underline{A}_k \underline{X}_k, \sum_{l=1}^{n} \underline{B}_l \underline{Y}_l\right)\right) = \sum_{k=1}^{m} \sum_{l=1}^{n} \underline{A}_k ((\underline{X}_k, \underline{Y}_l)) \underline{B}_l^*$$

for any $\underline{X}, \underline{X}_k, \underline{Y}_l \in H^T$ and any $T \times T$ matrices, $\underline{A}_k, \underline{B}_l$. We say that $\underline{X}$ is *orthogonal* to $\underline{Y}$ in H^T if $((\underline{X}, \underline{Y})) = \underline{0}$. A *closed subset* $\underline{M}$ of H^T is called a *subspace* if $\underline{A}\underline{X} + \underline{B}\underline{Y} \in \underline{M}$ whenever $\underline{X}, \underline{Y} \in \underline{M}$ and $\underline{A}, \underline{B}$ are $T \times T$ matrices. It is interesting and easy to see that $\underline{M}$ is a subspace of H^T if there exists a subspace M of H such that $\underline{M} = M^T$ [9], [10]. Let's denote the *orthogonal projection* of $X \in H$ on a subspace M of H by $(X \mid M)$. Given a vector $\underline{X} = (X^0, \ldots, X^{T-1}) \in H^T$, its projection on a subspace $\underline{M} = M^T$, denoted by $(\underline{X} \mid \underline{M})$, is the vector whose ith component is $(X^i \mid M)$ for each $i = 0, \ldots, T-1$. It is easy to see that $(\underline{X} \mid \underline{M})$ is the unique vector in $\underline{M}$ such that $\underline{X} - (\underline{X} \mid \underline{M}) \perp \underline{Y}$ for all $\underline{Y} \in \underline{M}$. For any set of vectors $\{\underline{X}_j : j \in J\}$ in H^T, the span closure $\overline{\text{sp}}\,\{\underline{X}_j : j \in J\}$ is the smallest closed subspace of H^T containing all the linear combinations of $\underline{X}_j$'s formed with *$T \times T$ matrices* as coefficients.

A sequence $\underline{X}_n$ in H^T is called a *stationary sequence* if the Gramian $((\underline{X}_m, \underline{X}_n))$ depends *only* on $m - n$.

For a sequence X_n in H, we define its *past-present subspace* at time n by

$$H(X; n) = \overline{\text{sp}}\,\{X_k : k \leqq n\}$$

and its *remote past subspace* by

$$H(X; -\infty) = \bigcap_n H(X; n).$$

The past-present subspace $\underline{H}(\underline{X}; n)$ and the remote past $\underline{H}(\underline{X}, -\infty)$ of a sequence $\underline{X}_n$ in H^T are similarly defined to be the subspaces

$$\underline{H}(\underline{X}; n) = \overline{\text{sp}}\,\{\underline{X}_k : k \leqq n\},$$
$$\underline{H}(\underline{X}; -\infty) = \bigcap_n \underline{H}(\underline{X}; n)$$

of H^T.

For a sequence $\underline{X}_n$ in H^T we can also define the subspace $H(\underline{X}; n)$ of H by

$$H(\underline{X}; n) = \overline{\text{sp}}\,\{X_k^j : k \leqq n, 0 \leqq j \leqq T-1\}.$$

A sequence $X_n(\underline{X}_n)$ in $H(H^T)$ is called *nondeterministic* if $X_n(\underline{X}_n)$ does not belong to $H(\underline{X}; n-1)(\underline{H}(\underline{X}; n-1))$ for every n, and it is called *purely nondeterminstic* if $H(X; -\infty) = 0$ $(\underline{H}(\underline{X}; -\infty) = \underline{0})$.

For a nondeterministic sequence $X_n(\underline{X}_n)$ in $H(H^T)$ the *best linear predictor* $X_{n,\nu}(\underline{X}_{n,\nu})$ of a future value $X_{n+\nu}(\underline{X}_{n+\nu})$, given its past-present $H(X; n)(\underline{H}(\underline{X}; n))$ is its projection

$$X_{n,\nu} = (X_{n+\nu} \mid H(X; n))(\underline{X}_{n,\nu} = (\underline{X}_{n+\nu} \mid \underline{H}(\underline{X}; n)))$$

on $H(X; n)(\underline{H}(\underline{X}; n))$.

3. Explicit expression of PCS X_n and its associate multivariate SS $\underline{Z}_n$ in terms of each other. In this section we will give some explicit expressions between a PCS X_n in H and its associated SS $\underline{Z}_n$ (mentioned in § 1) in K^T. Note that Gladyshev's Theorem 1.1 gives *only* the relation between the *correlation functions* of X_n and $\underline{Z}_n$. However, in order for us to use this theorem for the prediction of a PCS, we should know the relation between these processes *themselves.*

We start with the following theorem.

THEOREM 3.1. *A sequence X_n in H is periodically correlated with period T if and only if the sequence $\underline{Z}_n = [Z_n^k]_{k=0}^{T-1}$ in K^T with*

$$Z_n^k = \bigoplus_{j=0}^{T-1} X_{n+j} \exp\left(2\pi i k(n+j)/T\right)$$

is stationary.

Proof. If part. Assuming $\underline{Z}_n$ is a SS in K^T then its 0th component Z_n^0 is a stationary sequence in K. So, for each $m, n \in Z$ we have

$$\langle Z_m^0, Z_n^0 \rangle = \langle Z_{m+1}^0, Z_{n+1}^0 \rangle.$$

Expanding each side and multiplying through by T we get

$$\sum_{j=0}^{T-1} (X_{m+j}, X_{n+j}) = \sum_{j=0}^{T-1} (X_{m+1+j}, X_{n+1+j}) \quad \text{for all } m, n \in Z.$$

Eliminating like terms from both sides of this equality, we get

$$(X_m, X_n) = (X_{m+T}, X_{n+T}) \quad \text{for all } m, n \in Z.$$

This shows that X_n is a PCS with Period T.

Only if part. For any $m, n \in Z$ and any $0 \leqq k, k' \leqq T-1$ we can write

$$\begin{aligned} T\langle Z_m^k, Z_n^{k'} \rangle &= \sum_{j=0}^{T-1} (X_{m+j}, X_{n+j} \exp(2\pi i(km + kj - k'n - k'j)/T) \\ &= (X_m, X_n) \exp(2\pi i(km - k'n)/T) \\ &\quad + \sum_{j=1}^{T-1} (X_{m+j}, X_{n+j}) \exp(2\pi i(km + kj - k'n - k'j)/T) \\ &= \sum_{j=1}^{T-1} (X_{m+j}, X_{n+j}) \exp(2\pi i(km + kj - k'n - k'j)/T) \\ &\quad + (X_{m+T}, X_{n+T}) \exp(2\pi i(km + kT - k'n - k'T)/T) \\ &= \sum_{j=1}^{T} (X_{m+j}, X_{n+j}) \exp(2\pi i(km + kj - k'n - k'j)/T). \end{aligned}$$

The third equality follows from the periodicity assumption on X_n. Letting $J = j-1$, we get

$$\begin{aligned} T\langle Z_m^k, Z_n^{k'} \rangle &= \sum_{J=0}^{T-1} (X_{m+J+1}, X_{n+J+1}) \exp(2\pi i(km + k(J+1) - k'n - k'(J+1))/T) \\ &= \sum_{J=0}^{T-1} (X_{(m+1)+J}, X_{(n+1)+J}) \exp(2\pi i[k(m+1) + kJ - k'(n+1) - k'J]/T) \\ &= T\langle Z_{m+1}^k, Z_{n+1}^{k'} \rangle, \end{aligned}$$

which shows that $\underline{X}_n$ is stationary and completes the proof. □

Now, assuming that X_n is a PCS with correlation function (1) we want to find the matricial correlation function of its associated SS $\underline{Z}_n$ introduced in the last theorem.

For any $\tau \in Z$ and $0 \leqq k, k' \leqq T-1$ the matricial correlation function of $\underline{Z}_n$ is given by

$$\begin{aligned} R_{kk'}(\tau) = \langle Z_\tau^k, Z_0^{k'} \rangle &= \frac{1}{T} \sum_{j=0}^{T-1} (X_{\tau+j}, X_j) \exp(2\pi i(k\tau + kj - k'j)/T) \\ &= \frac{1}{T} \sum_{j=0}^{T-1} R(j, \tau) \exp(2\pi i(kj + k\tau - k'j)/T) \\ &= \frac{1}{T} \exp(2\pi i k\tau/T) \sum_{j=0}^{T-1} R(j, \tau) \exp(2\pi i(k-k')j/T). \end{aligned}$$

By inverting the Fourier sum (1) we get

$$R_k(\tau)=\frac{1}{T}\sum_{n=0}^{T-1} R(n,\tau)\exp(-2\pi ikn/T).$$

Using this we can continue to write

$$R_{kk'}(\tau)=\exp(2\pi ik\tau/T)R_{k'-k}(\tau).$$

This shows that the process $\underline{Z}_n$ introduced in Theorem 3.1 has actually the same matricial correlation suggested in Gladyshev's Theorem 1.1. So, we have obtained an explicit expression for the SS $\underline{Z}_n$ in terms of the original PCS X_n.

The following proposition helps us to express the PCS X_n in terms of its associated SS $\underline{Z}_n$. In order to do that, however, we must identify H with the subspace $H\oplus 0\oplus\cdots\oplus 0$ of K.

PROPOSITION 3.2. *If the matricial correlation function* $(R_{kk'}(\tau))_{k,k'=0}^{T-1}$ *of a* SS $\underline{Z}_n=[Z_n^k]_{k=0}^{T-1}$ *in* K^T *and the correlation function* $R(n,\tau)$ *are related as in the Theorem* 1.1, *then the sequence*

$$X_n=\sum_{k=0}^{T-1}\frac{1}{\sqrt{T}}Z_n^k\exp(-2\pi ikn/T)$$

is a PCS *in* K *with correlation function* $R(n,\tau)$.

Proof. We can write

$$\begin{aligned}(X_{n+\tau},X_n)&=\left(\frac{1}{\sqrt{T}}\sum_{k=0}^{T-1}Z_{n+\tau}^k\exp\left(-2\pi i((n+\tau)k/T),\frac{1}{\sqrt{T}}\sum_{k'=0}^{T-1}Z_n^{k'}\exp(-2\pi ink'/T)\right)\right)\\&=\frac{1}{T}\sum_{k=0}^{T-1}\sum_{k'=0}^{T-1}(Z_{n+\tau}^k,Z_n^{k'})\exp(-2\pi ik\tau/T)\exp(2\pi in(k'-k)/T)\\&=\frac{1}{T}\sum_{k=0}^{T-1}\sum_{k'=0}^{T-1}R_{kk'}(\tau)\exp(-2\pi ik\tau/T)\exp(2\pi in(k'-k)/T)\\&=\frac{1}{T}\sum_{k=0}^{T-1}\sum_{k'=0}^{T-1}R_{k'-k}(\tau)\exp(2\pi in(k'-k)/T)\\&=\frac{1}{T}\sum_{j=0}^{T-1}TR_j(\tau)\exp(2\pi inj/T)=R(n,\tau).\end{aligned}$$

The fourth equality follows from (2) and the last one from (1). □

We close this section with the following Lemma.

LEMMA 3.3. *Let* X_n *be a* PCS *whose correlation function* $R(n,\tau)$ *and spectral measures* $dF_k(\lambda)$ *satisfy* (1) *and* (3), *respectively. Then, the matricial spectral measure* $d\underline{F}_x=(dF_{kk'})_{k,k'=0}^{T-1}$ *defined by*

(4) $$F_{kk'}(\Lambda)=F_{k'-k}(\Lambda+2\pi k/T)\quad \textit{for each Borel subset } \Lambda \textit{ of } [0,2\pi),$$

is the spectral measure of its associated SS $\underline{Z}_n$.

Proof. From (2) and (3) we can write

$$\begin{aligned}(Z_\tau^k,Z_0^{k'})&=\exp(2\pi ik\tau/T)\int_0^{2\pi}\exp(-i\lambda\tau)\,dF_{k'-k}(\lambda)\\&=\int_0^{2\pi}\exp(-i\tau(\lambda-2\pi ik/T)\,dF_{k'-k}(\lambda)).\end{aligned}$$

The proof is now immediate. □

4. Explicit formulas for the predictor and predictor error of a PCS. The problem of finding an algorithm for determining the best linear predictor is important in applications of stochastic processes. In this section we will give formulas expressing the best linear predictor and prediction error of PCS X_n in terms of the predictor and prediction error matrix of its associated multivariate SS $\underline{Z}_n$ given in the last sections. Using this, along with the available algorithms for determining the predictor of multivariate SS's, we then will outline algorithms for finding the predictor and prediction error of X_n.

The following theorem gives formulas for expressing the ν-step predictor $X_{n,\nu}$ of a PCS X_n in terms of the predictor of its associated SS $\underline{Z}_n$ given in Theorems 1.1 and 3.1. We would like to point out, however, that our SS $\underline{Z}_n$ here is quite different from the SS Z_n used in [7]. In fact, Z_n is just the 0th component Z_n^0 of the SS $\underline{Z}_n$. This new SS $\underline{Z}_n$ captures more properties of X_n, and hence seems to be more useful for prediction purposes.

THEOREM 4.1. *If the ν-step predictor of the associated* SS $\underline{Z}_n$ *of a* PCS X_n *has an autoregressive representation*

$$\underline{Z}_{n,\nu} = \sum_{k=0}^{\infty} \underline{A}_k^{\nu} \underline{Z}_{n-k}, \tag{5}$$

then the best linear predictor $X_{n,\nu}$ of $X_{n+\nu}$ based on its past-present at n can be expressed as

$$X_{n,\nu} = \frac{1}{\sqrt{T}} \sum_{k=0}^{\infty} \left(\sum_{j=0}^{T-1} a_{k0j}^{\nu} \exp\left(2\pi ij(n-k)/T\right) \right) X_{n-k}, \tag{6}$$

where

$$\underline{A}_k^{\nu} = (a_{klj}^{\nu})_{l,j=0}^{T-1}.$$

It is interesting to note that the coefficients a_{k0j}^{ν} in (6) are exactly those in the Fourier decomposition of the coefficients in the periodically varying autoregressive prediction formula for the PCS X_n.

Before proving Theorem 4.1 we need to prove two more lemmas.

LEMMA 4.2. *For each n, the subspace $H(\underline{Z}; n)$ of $K = H \oplus \cdots \oplus H$ is of the form*

$$H(\underline{Z}; n) = H(X; n) \oplus H(X; n-1) \oplus \cdots \oplus H(X; n-T+1).$$

Proof. Take any $0 \leqq k \leqq T-1$ and $m \leqq n$ and consider the linear combination

$$\sum_{j=0}^{T-1} \sqrt{T}\, Z_m^j \exp\left(-2\pi ij(m+k)/T\right)$$

in $H(\underline{Z}; n)$. We can write it as

$$\begin{aligned}
&\sum_{j=0}^{T-1} \sqrt{T}\, Z_m^j \exp\left(-2\pi ij(m+k)/T\right) \\
&\quad = \sum_{j=0}^{T-1} \left(\bigoplus_{l=0}^{T-1} X_{m+l} \exp\left(2\pi ij(m+l)/T\right) \exp\left(-2\pi ij(m+k)/T\right) \right) \\
&\quad = \bigoplus_{l=0}^{T-1} X_{m+l} \left(\sum_{j=0}^{T-1} \exp\left(2\pi ij(l-k)\right) \right) \\
&\quad = \bigoplus_{l=0}^{T-1} T X_{m+l} \delta_{lk}.
\end{aligned}$$

This proves that

$$0\oplus\cdots\oplus\underset{\substack{\uparrow\\ j\text{th term}}}{H(X;\,n+j)}\oplus 0\cdots\oplus 0\subseteq H(\underline{Z};\,n)\quad\text{for each } 0\leqq j\leqq T-1.$$

This in turn shows that

$$H(X;\,n)\oplus H(X;\,n-1)\oplus\cdots\oplus H(X;\,n+T-1)\subseteq H(\underline{Z};\,n)\quad\text{for each } n.$$

The other inclusion is an immediate consequence of the fact that for each $0\leqq j\leqq T-1$ and each $m\leqq n$,

$$\sqrt{T}\,Z_m^j=\bigoplus_{k=0}^{T-1}X_{m+k}\exp\left(2\pi ij(m+k)/T\right)$$

belongs to $H(X;\,n)\oplus H(X;\,n+1)\oplus\cdots\oplus H(X;\,n+T-1)$. □

LEMMA 4.3. *For each n, the subspace $\underline{H}(\underline{Z};\,n)$ of K^T can be expressed as $\underline{H}(\underline{Z};\,n)=(H(\underline{Z};\,n))^T$.*

Proof. Take any finite linear combination

$$\underline{Z}=\sum_{k\leqq n}\underline{A}_k\underline{Z}_k$$

in $\underline{H}(\underline{Z};\,n)$, and consider its ith component Z^i, $0\leqq i\leqq T-1$. We have

$$Z^i=\sum_{k\leqq n}\sum_{j=0}^{T-1}(A_k)_{i,j}Z_k^j.$$

Clearly $Z^i\in H(\underline{Z};\,n)$, which implies $\underline{Z}\in(H(\underline{Z};\,n))^T$. Thus

$$sp\{\underline{Z}_k:\,k\leqq n\}\subseteq(H(\underline{Z};\,n))^T.$$

Taking closure on the left-hand side we get $\underline{H}(\underline{Z};\,n)\subseteq(H(\underline{Z};\,n))^T$. The other inclusion follows from a similar argument.

Proof of the Theorem 4.1. Considering the 0th component $Z_{n,\nu}^0$ of the predictor $\underline{Z}_{n,\nu}$, we can write

$$\begin{aligned}Z_{n,\nu}^0&=(\underline{Z}_{n+\nu}\,|\,\underline{H}(\underline{Z};\,n))^0\\&=(Z_{n,\nu}^0\,|\,H(\underline{Z};\,n))\\&=\left(\bigoplus_{s=0}^{T-1}X_{n+\nu+s}\,\middle|\,\bigoplus_{s=0}^{T-1}H(X;\,n+s)\right)\\&=\bigoplus_{s=0}^{T-1}(X_{n+\nu+s}\,|\,H(X;\,n+s)).\end{aligned}$$

(The second equality follows from Lemma 4.3 and our earlier comment on the relation between projection in K^T and the projection in K. The third equality follows from Lemma 4.2.)

On the other hand we can write

$$\begin{aligned}Z_{n,\nu}^0&=\left(\sum_{k=0}^{\infty}\underline{A}_K^\nu\underline{Z}_{n-k}\right)^0=\sum_{k=0}^{\infty}\left(\sum_{j=0}^{T-1}a_{k0j}^\nu Z_{n-k}^j\right)\\&=\frac{1}{\sqrt{T}}\sum_{k=0}^{\infty}\sum_{j=0}^{T-1}a_{k0j}^\nu\left(\bigoplus_{s=0}^{T-1}X_{n-k+s}\exp\left(2\pi ij(n-k)/T\right)\right)\\&=\bigoplus_{s=0}^{T-1}\frac{1}{\sqrt{T}}\left[\sum_{k=0}^{\infty}\left(\sum_{j=0}^{T-1}a_{k0j}^\nu\exp\left(2\pi ij(n-k)/T\right)\right)X_{n-k+s}\right].\end{aligned}$$

Hence by comparison we get

$$(X_{n+\nu}|H(X;n))=\sum_{k=0}^{\infty}\sum_{j=0}^{T-1}\frac{1}{\sqrt{T}}a_{k0j}^{\nu}\exp(2\pi ij(n-k)/T)X_{n-k},$$

which completes the proof. □

Now we will find a formula for the prediction error $g^{\nu}(n)=\|X_{n+\nu}-X_{n,\nu}\|$ of a PCS X_n. In contrast to the stationary case where the prediction error is independent of time n, here the prediction error $g^{\nu}(n)$ does vary with time. However, it varies in a periodic way. So, $g^{\nu}(n)$ can be written as

$$g^{\nu}(n)=\sum_{k=0}^{T-1}g_k^{\nu}\exp(2\pi ikn/T).$$

By inverting this we get

$$g_k^{\nu}=\frac{1}{T}\sum_{n=0}^{T-1}g^{\nu}(n)\exp(-2\pi ink/T).$$

Using this we can write

$$\begin{aligned}
Tg_k^{\nu}&=\sum_{n=0}^{T-1}(X_{n+\nu}-X_{n,\nu},X_{n+\nu}-X_{n,\nu})\exp(-2\pi ink/T)\\
&=\sum_{n=0}^{T-1}(X_{n+\nu}-X_{n,\nu},(X_{n+\nu}-X_{n,\nu})\exp(2\pi ink/T))\\
&=\sum_{n=0}^{T-1}(X_{n+\nu}-X_{n,\nu},(X_{n+\nu}-X_{n,\nu})\exp(2\pi ik(n+\nu)/T))\exp(2\pi ik\nu/T)\\
&=T\exp(2\pi ik\nu/T)\langle Z_{\nu}^{0}-Z_{0,\nu}^{0},Z_{\nu}^{k}-Z_{0,\nu}^{k}\rangle.
\end{aligned}$$

Dividing through by T we get

$$g_k^{\nu}=\exp(2\pi ik\nu/T)G_{0k}^{\nu}.$$

We have thus proven the following theorem, which provides a formula for the prediction error of our PSC X_n.

THEOREM 4.4. *With the notation of Theorem* 4.1 *the prediction error* $g^{\nu}(n)$ *of a* PCS X_n *can be written as*

$$g^{\nu}(n)=\sum_{k=0}^{T-1}G_{0k}^{\nu}\exp(2\pi ik(n+\nu)/T), \tag{7}$$

where

$$\underline{G}^{\nu}=(G_{kk'}^{\nu})_{k,k'=0}^{T-1}$$

is the ν*-step prediction error matrix of predicting its associate* SS $\underline{Z}_n$ *in* K^T.

In the rest of this section we present an algorithm for determining the best linear predictor and the prediction error of a PCS X_n under the following assumption.

Assumption 4.5. Suppose X_n is a PCS whose corresponding spectral measure $d\underline{F}_X$ given by (4) is absolutely continuous with respect to the Lebesgue measure and

(i) Its derivative $\underline{F}'_X(\lambda)$ is almost everywhere invertible;

(ii) All entries of $\underline{F}'_X(\lambda)$ belong to L^{∞};

(iii) All entries of $\underline{F}'_X(\lambda)^{-1}$ belong to L_1.

PROPOSITION 4.6. *If the* PCS X_n *satisfies the requirement of Assumption* 4.5, *then its associate* SS $\underline{Z}_n$ *in* K^T *given in Theorems* 1.1 *and* 3.1, *considered as a multivariate process with components in the Hilbert space K, satisfies Masani's conditions in* § 5 *of* [5].

Proof. By Lemma 3.3 the matricial spectral measure $\underline{F}_z$ of $\underline{Z}_n$ is exactly the same as the spectral measure $\underline{F}_X$. On the other hand, Masani's conditions in § 5 of [5] are exactly those given in Assumption 4.5. This completes the proof. □

Thus under Assumption 4.5 the matricial density function $\underline{F}'_X$ admits a factorization of the form

$$\underline{F}'_X(\lambda) = \underline{\Phi}(\lambda)\underline{\Phi}^*(\lambda),$$

where the optimal factor $\underline{\Phi}$ and its inverse $\underline{\Phi}^{-1}$ have square integrable entries whose negative Fourier coefficients are zero, i.e.,

$$\underline{\Phi}(\lambda) = \sum_{k=0}^{\infty} \underline{C}_k \exp(ik\theta), \qquad \underline{\Phi}^{-1}(\theta) = \sum_{k=0}^{\infty} \underline{D}_k \exp(ik\theta).$$

(For this and other important results about prediction of multivariate SS's see [5], [6].) It is also well known (cf. [5], [6]) that the corresponding T-variate SS $\underline{Z}_n$ has an autoregressive representation of the form (5) with $\underline{A}_k^\nu$ given by

$$\underline{A}_k^\nu = \sum_{n=0}^{k} \underline{C}_{\nu+n}\underline{D}_{k-n}. \tag{8}$$

Under these conditions there is actually an algorithm developed in [6] which allows us to find the matrix coefficients $\underline{C}_k$'s and $\underline{D}_k$'s from the Fourier coefficients of the matricial function $\underline{M}(\lambda) = \underline{F}'_X(\lambda) - \underline{I}$. Hence, we can first find $\underline{C}_k$'s and $\underline{D}_k$'s and put them in (8) to find the autoregressive coefficients $\underline{A}_k^\nu$. Then we can use relation (5) to find the best linear predictor $X_{n,\nu}$ of the given PCS X_n. In a similar fashion we can use the results of [6] to find the prediction error matrix $\underline{G}^\nu$ of the ν-step prediction of the multivariate SS $\underline{Z}_n$ (which is given in terms of $\underline{C}_k$'s and $\underline{D}_k$'s) and use those in conjunction with (7) to find the prediction errors of the original PCS X_n.

Acknowledgment. The author is glad to acknowledge the referees' comments which improved the original version of this paper.

NONORTHOGONAL WAVELET PACKETS*

CHARLES K. CHUI† AND CHUN LI‡

Abstract. The notion of orthonormal wavelet packets introduced by Coifman and Meyer is generalized to the nonorthogonal setting in order to include compactly supported and symmetric basis functions. In particular, dual (or biorthogonal) wavelet packets are investigated and a stability result is established. Algorithms for implementations are also developed.

Key words. multiresolution analysis, scaling functions, wavelets, dual wavelets, wavelet packets, frames, tree algorithms, decomposition and reconstruction algorithms

AMS subject classifications. primary 41A58; secondary 42C30

1. Introduction.

Orthogonal wavelet packets (also called wave packets) introduced by Coifman and Meyer [5] (see also [6], [11]) are used to further decompose wavelet components. Based on Daubechies' compactly supported orthogonal wavelets [7], procedures for both computations and implementation can be made very efficient. However, the intrinsic property of lack of symmetry persists. This causes phase distortion in applications that require lossy data compression and decompression. More recently, compactly supported symmetric wavelets are available by sacrificing orthogonality partially [2] or totally [4]. A unified treatment of such wavelets is given in [1, Thm. 5.19]. Thus, it is natural to extend the study of orthonormal wavelet packets to the nonorthogonal setting. This extension is valuable because linear-phase filters (resulting from symmetric wavelets) cannot be constructed by using compactly supported orthogonal wavelets, but can be constructed by using semi-orthogonal or biorthogonal ones. In addition, wavelet packets provide better frequency localization than wavelets while time-domain localization is not lost [6], [11]. This capability enhances the application of wavelet decomposition in processing signals with high-frequency components. Of course when nonorthogonal wavelets are being considered, two very fundamental problems must be considered, namely, the existence of duals and the stability requirement. The difficulty of these problems propagates when the notion of orthogonal wavelet packets is generalized to the nonorthogonal setting. The objective of this paper is to give a careful treatment of this generalization, with special emphasis on the consideration of dual wavelet packets, stability, and development of algorithms. We emphasize that our starting point is based on the work of Coifman and Meyer [5].

Throughout this paper, the space of all square-integrable functions on the real line will be denoted, as usual, by $L^2 := L^2(\mathbb{R})$, and the notation for inner product and Fourier transform of functions in L^2 is given by

$$\langle f, g\rangle = \int_{-\infty}^{\infty} f(x)\overline{g(x)}\,dx \tag{1.1}$$

and

$$\hat{f}(\omega) = \int_{-\infty}^{\infty} e^{-i\omega x} f(x)\, dx, \tag{1.2}$$

respectively. Also the norm of any f in L^2 will be denoted by $\|f\| = \langle f, f\rangle^{1/2}$; and for any function f, we will always use the notation

$$f_{j,k}(x) := 2^{j/2} f(2^j x - k). \tag{1.3}$$

A function $\psi \in L^2$ will be called a "wavelet" if there exists another function $\widetilde{\psi} \in L^2$, called the "dual wavelet" of ψ, such that the family

$$\{\psi_{j,k}\colon\ j,k \in \mathbb{Z}\}$$

is a Riesz (or unconditional) basis of L^2, and the collection

$$\{\widetilde{\psi}_{j,k}\colon\ j,k \in \mathbb{Z}\}$$

is the corresponding dual (or biorthogonal) basis in the sense that

$$\langle \psi_{j,k}, \widetilde{\psi}_{j',k'}\rangle = \delta_{j,j'}\delta_{k,k'} \tag{1.4}$$

for all $j, k, j', k' \in \mathbb{Z}$. In this paper, when we call a family a "basis" of any subspace of L^2, we always mean that it is a Schauder basis of this subspace. Unless we specify explicitly, these Schauder bases need not be Riesz bases. Recall that a Riesz basis is a Schauder basis satisfying the additional condition that the L^2-norm of any series representation and the ℓ^2-norm of its coefficient sequence are equivalent. We shall call this extra requirement the "stability" condition. A very powerful tool for constructing wavelets is the consideration of multiresolution analyses (MRA) of L^2, introduced by Meyer [10] and Mallat [9]. A function that "generates" any MRA of L^2 is called a "scaling function."

In the study of scaling functions and wavelets, the symbol of a sequence is often used. For convenience, we will usually consider symbols

$$A(z) = \sum_{n \in \mathbf{Z}} a_n z^n$$

of sequences $\{a_n\}$ in ℓ^1, namely, $\Sigma |a_n| < \infty$. The collection of such Laurent series is called the Wiener class, which will be denoted by $\mathcal{W}$.

The outline of this paper is as follows. In §2, we will introduce the necessary notations and definitions and state the main results of this paper. Of particular importance is that if $\psi_1 := \psi$ is a wavelet with dual $\widetilde{\psi}_1 := \widetilde{\psi}$, so that both $\{\psi_{j,k}\}$ and $\{\widetilde{\psi}_{j,k}\}$ are Riesz bases of L^2, then for each nonnegative integer ℓ, both

$$\{\psi_{n;j,k}\colon\ j,k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\} \tag{1.5}$$

and its dual family

$$\{\widetilde{\psi}_{n;j,k}\colon\ j,k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\} \tag{1.6}$$

are also Reisz bases of L^2. Here, $\{\psi_n\}$ is the sequence of "wavelet packets" induced by the wavelet ψ and its corresponding scaling function $\psi_0 := \phi$, and $\{\tilde{\psi}_n\}$ denotes the corresponding sequence of dual wavelet packets. This is a consequence of Theorems 3 and 6. It is interesting to point out that only finitely many ψ_n's are used in the family (1.5), and that when infinitely many ψ_n's are considered, then stability (or unconditionality) may be lost in general. This negative result is due to Cohen and Daubechies [3] and was brought to our attention by Albert Cohen. Preliminary results in this paper, which are perhaps of some independent interest, are derived in §3, and proofs of the main results are given in §4 . In §5, two algorithms for implementation will be developed.

2. Main results. If P^0 and G^0 are Laurent series in the Wiener class $\mathcal{W}$ satisfying

$$\begin{aligned} P^0(z) &= \left(\frac{1+z}{2}\right)^N S(z), \\ G^0(z) &= \left(\frac{1+z}{2}\right)^{\tilde{N}} \tilde{S}(z), \end{aligned} \tag{2.1}$$

$$S(1) = \tilde{S}(1) = 1, \tag{2.2}$$

and

$$\begin{aligned} &\inf_{j>0} \max_{\omega} \prod_{k=1}^{j} |S(e^{i2^{-k}\omega})|^{\frac{1}{j}} < 2^{N-\frac{1}{2}}, \\ &\inf_{j>0} \max_{\omega} \prod_{k=1}^{j} |\tilde{S}(e^{i2^{-k}\omega})|^{\frac{1}{j}} < 2^{\tilde{N}-\frac{1}{2}}, \end{aligned} \tag{2.3}$$

where N and $\tilde{N}$ are positive integers, then the infinite products

$$\begin{aligned} \hat{\phi}(\omega) &:= \prod_{k=1}^{\infty} P^0(e^{-i\omega/2^k}); \\ \hat{\tilde{\phi}}(\omega) &:= \prod_{k=1}^{\infty} \overline{G^0(e^{-i\omega/2^k})} \end{aligned} \tag{2.4}$$

converge in L^2, and the limit functions are Fourier transforms of some functions ϕ, $\tilde{\phi} \in L^2$, that generate two (possibly different) multiresolution analyses (MRA) $\{V_n\}$ and $\{\tilde{V}_n\}$, respectively, of L^2 (see [4] and [1, Thm. 5.22]). In addition, from (2.4), it follows that $\hat{\phi}$ and $\hat{\tilde{\phi}}$ satisfy

$$\begin{aligned} \hat{\phi}(\omega) &= P^0(z)\hat{\phi}\left(\frac{\omega}{2}\right), \\ \hat{\tilde{\phi}}(\omega) &= \overline{G^0(z)}\,\hat{\tilde{\phi}}\left(\frac{\omega}{2}\right), \end{aligned} \tag{2.5}$$

where $z = e^{-i\omega/2}$; and writing

$$\begin{aligned} P^0(z) &= \frac{1}{2}\sum_{n\in\mathbf{Z}} p_n^0 z^n, \\ G^0(z) &= \frac{1}{2}\sum_{n\in\mathbf{Z}} g_n^0 z^n, \end{aligned} \tag{2.6}$$

we see that (2.5) is equivalent to the "two-scale relations"

$$\begin{aligned}\phi(x) &= \sum_{k\in\mathbf{Z}} p_k^0 \phi(2x-k),\\ \tilde{\phi}(x) &= \sum_{k\in\mathbf{Z}} \overline{g_{-k}^0}\tilde{\phi}(2x-k),\end{aligned} \tag{2.7}$$

of the "scaling functions" ϕ and $\tilde{\phi}$. Hence, the sequences $\{p_k^0\}$ and $\{\overline{g_{-k}^0}\}$ are the corresponding "two-scale sequences," and $P^0(z)$ and $\overline{G^0(z)}$ the corresponding "two-scale symbols," of the scaling functions ϕ and $\tilde{\phi}$, respectively.

We will say that ϕ and $\tilde{\phi}$ are dual to each other if they satisfy

$$\langle \phi(\cdot - j), \tilde{\phi}(\cdot - k)\rangle = \delta_{j,k}, \qquad j,k \in \mathbb{Z}. \tag{2.8}$$

Under the assumptions (2.1)–(2.3), a necessary and sufficient condition for the duality relationship (2.8) is that P^0 and G^0 are "dual two-scale symbols," in the sense that

$$P^0(z)G^0(z) + P^0(-z)G^0(-z) = 1, \qquad |z| = 1. \tag{2.9}$$

A proof of this statement is given in [1, Thm. 5.22] (see also [4] for the case of polynomial symbols). It should be noted that the assumptions in (2.1)–(2.3) for P^0 and G^0 can be somewhat weakened. Hence, for more generality, we will drop this requirement, but simply assume that $\hat{\phi}$ and $\hat{\tilde{\phi}}$ defined in (2.4) are in L^2, $\{V_n\}$ and $\{\tilde{V}_n\}$ are MRA of L^2, and that (2.8) and (2.9) are satisfied.

Next, let us consider an arbitrary Laurent series $R(z)$ of class $\mathcal{W}$, which never vanishes on the unit circle $|z| = 1$. By Wiener's lemma, we also have $1/R(z) \in \mathcal{W}$, and this yields two other Laurent series in $\mathcal{W}$, namely,

$$\begin{aligned}P^1(z) &:= -zG^0(-z)R(z^2),\\ G^1(z) &:= -z^{-1}P^0(-z)/R(z^2).\end{aligned} \tag{2.10}$$

The reason for introducing P^1 and G^1 is that the two matrices

$$\begin{aligned}M(z) &:= \begin{bmatrix} P^0(z) & P^1(z)\\ P^0(-z) & P^1(-z)\end{bmatrix},\\ \widetilde{M}(z) &:= \begin{bmatrix} G^0(z) & G^1(z)\\ G^0(-z) & G^1(-z)\end{bmatrix}\end{aligned} \tag{2.11}$$

are nonsingular for $|z| = 1$, independent of the choice of R, and that $M^T(z)$ and $\widetilde{M}(z)$ are inverses of each other. A discussion of this result will be given in the next section. Now, we write

$$\begin{aligned}P^1(z) &= \frac{1}{2}\sum_{n\in\mathbf{Z}} p_n^1 z^n,\\ G^1(z) &= \frac{1}{2}\sum_{n\in\mathbf{Z}} g_n^1 z^n,\end{aligned} \tag{2.12}$$

and set

$$\psi_0 := \phi \quad \text{and} \quad \tilde{\psi}_0 := \tilde{\phi}. \tag{2.13}$$

Then, in view of (2.7), following Coifman and Meyer [5] we may introduce two sequences of L^2-functions, $\{\psi_n\}$ and $\{\widetilde{\psi}_n\}$, defined by

$$(2.14)\qquad \begin{aligned} \psi_{2n+\lambda}(x) &:= \sum_{k\in\mathbf{Z}} p_k^\lambda \psi_n(2x-k), \quad \lambda = 0,1, \\ \widetilde{\psi}_{2n+\lambda}(x) &:= \sum_{k\in\mathbf{Z}} \overline{g_{-k}^\lambda}\, \widetilde{\psi}_n(2x-k), \quad \lambda = 0,1, \end{aligned}$$

where $n = 0, 1, \dots$.

Of course, (2.14) reduces to (2.7) when $\lambda = 0$ and $n = 0$. The functions

$$(2.15)\qquad \psi := \psi_1 \quad \text{and} \quad \widetilde{\psi} := \widetilde{\psi}_1,$$

obtained by setting $\lambda = 1$ and $n = 0$ in (2.14), are dual wavelets in the sense of (1.4); that is,

$$(2.16)\qquad \langle \psi_{j,k}, \widetilde{\psi}_{\ell,m}\rangle = \langle \psi_{1;j,k}, \widetilde{\psi}_{1;\ell,m}\rangle = \delta_{j,\ell}\delta_{k,m}, \quad j,k,\ell,m \in \mathbb{Z}.$$

We will document this statement in a moment. In general, we call $\{\psi_n\}$ and $\{\widetilde{\psi}_n\}$ sequences of *wavelet packets*, and $\{\widetilde{\psi}_n\}$ the dual of $\{\psi_n\}$. In the orthonormal setting, where $\widetilde{\psi}_n = \psi_n$, $n = 0, 1, \dots$ (obtained by considering $\overline{G^\lambda(z)} = P^\lambda(z)$ and $|R(z)| = 1$ for $|z| = 1$ and $\lambda = 0, 1$, in (2.10)), the functions ψ_n become the orthonormal wavelet packets introduced by Coifman and Meyer [5]. (See also [6], [11], and [1, Chap. 7].) The duality of the scaling functions in (2.8) and that of the wavelets ψ and $\widetilde{\psi}$ (as defined by (2.15)), for $j = \ell = 0$ in (2.16), are generalized to wavelet packets in this paper as follows.

THEOREM 1. *Assume that $\hat{\phi}$ and $\hat{\tilde{\phi}}$ defined in* (2.4) *are in L^2 and generate two* MRA *of L^2, and that* (2.8) *and* (2.9) *are satisfied. Then, for all $m, n = 0, 1, \dots,$ and $k, \ell \in \mathbb{Z}$,*

$$(2.17)\qquad \langle \psi_m(\cdot - k), \widetilde{\psi}_n(\cdot - \ell)\rangle = \delta_{m,n}\delta_{k,\ell}.$$

Let us turn to a discussion of the MRA generated by the scaling functions $\psi_0 = \phi$ and $\widetilde{\psi}_0 = \widetilde{\phi}$, namely,

$$(2.18)\qquad \begin{cases} V_j := \operatorname{clos}_{L^2}\langle \psi_{0;j,k}\colon\ k \in \mathbb{Z}\rangle, \\ \widetilde{V}_j := \operatorname{clos}_{L^2}\langle \widetilde{\psi}_{0;j,k}\colon\ k \in \mathbb{Z}\rangle, \end{cases}$$

and the (complementary) wavelet spaces

$$(2.19)\qquad \begin{cases} W_j := \operatorname{clos}_{L^2}\langle \psi_{1;j,k}\colon\ k \in \mathbb{Z}\rangle, \\ \widetilde{W}_j := \operatorname{clos}_{L^2}\langle \widetilde{\psi}_{1;j,k}\colon\ k \in \mathbb{Z}\rangle, \end{cases}$$

generated by the wavelets $\psi = \psi_1$ and $\widetilde{\psi} = \widetilde{\psi}_1$. Recall that
