$$(2.20)\qquad L^2 = \operatorname{clos}_{L^2}\left(\bigcup_{j\in\mathbf{Z}} V_j\right) = \operatorname{clos}_{L^2}\left(\bigcup_{j\in\mathbf{Z}} \widetilde{V}_j\right),$$

and that for each $j \in \mathbb{Z}$,

$$\begin{cases} V_{j+1} = V_j \dot{+} W_j, \\ \widetilde{V}_{j+1} = \widetilde{V}_j \dot{+} \widetilde{W}_j, \end{cases} \tag{2.21}$$

where $\dot{+}$ denotes direct-sum decomposition, and the duality condition is reflected by the orthogonality property

$$V_j \perp \widetilde{W}_j \quad \text{and} \quad \widetilde{V}_j \perp W_j, \qquad j \in \mathbb{Z}. \tag{2.22}$$

(See [1, Chap. 5] for more details.) As a consequence of (2.20) and (2.21), and the fact that

$$\bigcap_{j\in\mathbb{Z}} V_j = \bigcap_{j\in\mathbb{Z}} \widetilde{V}_j = \{0\},$$

we have

$$L^2 = \dot{\sum_{j\in\mathbb{Z}}} W_j = \dot{\sum_{j\in\mathbb{Z}}} \widetilde{W}_j. \tag{2.23}$$

Here and throughout, the "infinite direct-sum" $\dot{\sum}$ is defined, as usual, to be the L^2-closure of the truncated direct-sums:

$$\dot{\sum_{-m\le j\le n}}, \qquad m,\ n \in \mathbb{Z}_+.$$

More precisely, we have

$$\dot{\sum_{j\in\mathbb{Z}}} W_j = \operatorname{clos}_{L^2}\left(\bigcup_{m,n\in\mathbb{Z}_+} \dot{\sum_{-m\le j\le n}} W_j \right).$$

We will elaborate on the existence and uniqueness of the infinite direct-sum decompositions of functions $f \in L^2$ at the end of the next section. To further decompose the wavelet spaces W_j and $\widetilde{W}_j$, we consider the linear spaces

$$\begin{cases} U_n := \operatorname{clos}_{L^2}\langle \psi_n(\cdot - k)\colon\ k \in \mathbb{Z}\rangle, \\ \widetilde{U}_n := \operatorname{clos}_{L^2}\langle \widetilde{\psi}_n(\cdot - k)\colon\ k \in \mathbb{Z}\rangle, \end{cases} \tag{2.24}$$

and obtain the following result.

THEOREM 2. *For each $j = 0, 1, \ldots,$*

$$V_j = \dot{\sum_{0\le n<2^j}} U_n, \qquad W_j = \dot{\sum_{2^j\le n<2^{j+1}}} U_n, \tag{2.25}$$

$$\widetilde{V}_j = \dot{\sum_{0\le n<2^j}} \widetilde{U}_n, \qquad \widetilde{W}_j = \dot{\sum_{2^j\le n<2^{j+1}}} \widetilde{U}_n. \tag{2.26}$$

Consequently,

$$L^2 = U_0 \dot{+} \sum_{j\in\mathbb{Z}_+}^{\bullet} \sum_{2^j \le n < 2^{j+1}}^{\bullet} U_n = \widetilde{U}_0 \dot{+} \sum_{j\in\mathbb{Z}_+}^{\bullet} \sum_{2^j \le n < 2^{j+1}}^{\bullet} \widetilde{U}_n, \tag{2.27}$$

where, as in (2.23), *the infinite direct-sums are L^2-closures of the limits of the corresponding one-sided truncated direct-sums. Moreover,*

$$U_m \perp \widetilde{U}_n, \quad m \neq n, \quad m,n \in \mathbb{Z}_+, \tag{2.28}$$

and $\{\psi_m(\cdot - k)\colon\ k \in \mathbb{Z}\}$, $\{\widetilde{\psi}_n(\cdot - k)\colon\ k \in \mathbb{Z}\}$ are (biorthogonal) bases of U_m, $\widetilde{U}_n$, respectively, where $m,n \in \mathbb{Z}_+$.

It should be noted that the direct-sum decompositions in (2.27) cannot be written as $L^2 = \sum^{\bullet}_{n\in\mathbb{Z}_+} U_n$, in general, in the sense that the truncated projection operators may not converge strongly. The reason is that the families $\{\psi_m(\cdot - k)\colon\ k \in \mathbb{Z},\ m \in \mathbb{Z}_+\}$ and $\{\widetilde{\psi}_n(\cdot - k)\colon\ k \in \mathbb{Z},\ n \in \mathbb{Z}_+\}$ may not be Riesz bases. Nevertheless, the sequence of projection operators corresponding to truncation of the partial sum at $n = 2^j - 1$ converges strongly. This will be discussed at the end of next section. The biorthogonality between the wavelet $\psi = \psi_1$ and its dual $\widetilde{\psi} = \widetilde{\psi}_1$ as described by (2.16) can be generalized to wavelet packets as follows.

THEOREM 3. *Let $\ell \in \mathbb{Z}_+$ be arbitrarily chosen. Then both of the families*

$$\{\psi_{n;j,k}\colon\ j,k \in \mathbb{Z}, \quad 2^\ell \le n < 2^{\ell+1}\} \tag{2.29}$$

and

$$\{\widetilde{\psi}_{n;j,k}\colon\ j,k \in \mathbb{Z}, \quad 2^\ell \le n < 2^{\ell+1}\} \tag{2.30}$$

are bases of L^2, and they are biorthogonal in the sense that

$$\langle \psi_{n;j,k}, \widetilde{\psi}_{n';j',k'} \rangle = \delta_{n,n'}\delta_{j,j'}\delta_{k,k'} \tag{2.31}$$

for all $j,k,j',k',n,n' \in \mathbb{Z}$ with $2^\ell \le n,n' < 2^{\ell+1}$.

Of course, assertion (2.31) reduces to (2.16) when $\ell = 0$. In the next theorem, we will allow the (scaling) index j in (2.29) and (2.30) to depend on the index n, and obtain another pair of biorthogonal bases of L^2. For this purpose, we introduce the notation

$$\ell(n) := \lfloor \log_2 n \rfloor, \tag{2.32}$$

where $\lfloor x \rfloor$ denotes, as usual, the largest integer not exceeding x.

THEOREM 4. *Both of the families*

$$\{\psi_{0;0,k}, \psi_{n;\ell(n),k}, \psi_{n;\ell(n)+1,k}\colon\ k,n \in \mathbb{Z}, n \ge 1\} \tag{2.33}$$

and

$$\{\widetilde{\psi}_{0;0,k}, \widetilde{\psi}_{n;\ell(n),k}, \widetilde{\psi}_{n;\ell(n)+1,k}\colon\ k,n \in \mathbb{Z}, n \ge 1\} \tag{2.34}$$

are bases of L^2, and they are biorthogonal in the sense of (2.31).

There is, however, a common theme among the biorthogonal bases in Theorems 2–4, and a unified result can be stated as follows.

THEOREM 5. *Let $\mathcal{J}$ be a collection of ordered pairs (n, j), where $n \in \mathbb{Z}_+$, $j \in \mathbb{Z}$, such that the dyadic intervals*

$$I_{n,j} := [2^j n, 2^j(n+1)) \tag{2.35}$$

form a disjoint covering of the interval $(0, \infty)$, and that every bounded subinterval of $(0, \infty)$ is contained in the union of finitely many $I_{n,j}$. Then both of the families

$$\{\psi_{n;j,k}\colon\ (n,j) \in \mathcal{J}, \quad k \in \mathbb{Z}\} \tag{2.36}$$

and

$$\{\tilde{\psi}_{n;j,k}\colon\ (n,j) \in \mathcal{J}, \quad k \in \mathbb{Z}\} \tag{2.37}$$

are bases of L^2, and they are biorthogonal in the sense of (2.31) *for all (n, j), (n', j') in $\mathcal{J}$ and $k, k' \in \mathbb{Z}$.*

In the following, we will discuss the "stability" of the biorthogonal bases in (2.29) and (2.30). Since we already have the basis structure, it is sufficient to show that $\{\psi_{n;j,k}\}$ and $\{\tilde{\psi}_{n;j,k}\}$ in (2.29) and (2.30) are "dual frames," where duality is guaranteed by (2.31). Recall that a family $\{f_j\colon\ j \in J\}$ is said to constitute a frame of L^2 if there exist positive constants A and B such that

$$A\|f\|^2 \le \sum_{j\in J} |\langle f, f_j\rangle|^2 \le B\|f\|^2, \qquad f \in L^2 \tag{2.38}$$

(cf. [8], [7], and [1, Chap. 3]).

THEOREM 6. *Suppose that both*

$$\{\psi_{1;j,k}\colon\ j,k \in \mathbb{Z}\} \quad \textit{and} \quad \{\tilde{\psi}_{1;j,k}\colon\ j,k \in \mathbb{Z}\} \tag{2.39}$$

are frames of L^2. Then for any $\ell \in \mathbb{Z}_+$, both of the families in (2.29) *and* (2.30) *are also frames of L^2.*

In other words, if the families in (2.29) and (2.30) with $\ell = 0$ are frames of L^2, then they are frames of L^2 for any positive integer ℓ. However, the new frame bounds are usually exponential in ℓ as can be seen later from the proof of Theorem 6. Recall from Theorem 3 that each of the families (2.29) and (2.30) is "linearly independent" in the sense that no $\psi_{n';j',k'}$, $2^\ell \le n' < 2^{\ell+1}$ and $j', k' \in \mathbb{Z}$, lies in the L^2-closure of the (finite) linear span of

$$\psi_{n;j,k}, \qquad (n,j,k) \ne (n',j',k'),$$

where $2^\ell \le n < 2^{\ell+1}$ and $j, k \in \mathbb{Z}$. Hence, by a result on frames in [8] (see also [4]), it follows from Theorem 6 that both of the families in (1.5) and (1.6) (or (2.29) and (2.30)) are Riesz bases of L^2, provided, of course, that ψ is a wavelet with dual $\tilde{\psi}$.

To establish the results stated in this section, we need a sequence of lemmas that are of some independent interest.

3. Auxiliary results.

We first observe that the Laurent series P^λ and G^λ, $\lambda = 0, 1$, that satisfy (2.9) and (2.10) for some $R \in \mathcal{W}$ with $R(z) \ne 0$ on $|z| = 1$, also satisfy

$$\begin{aligned} &P^0(z)G^0(z) + P^1(z)G^1(z) = 1, \\ &P^0(-z)G^0(z) + P^1(-z)G^1(z) = 0, \qquad |z| = 1, \end{aligned} \tag{3.1}$$

and

$$P^\lambda(z)G^\mu(z)+P^\lambda(-z)G^\mu(-z)=\delta_{\lambda,\mu},\quad |z|=1,\quad \lambda,\mu=0,1. \tag{3.2}$$

We also remark that if P^λ, $G^\lambda \in \mathcal{W}$ satisfy (3.1) or (3.2), then there exists some $R\in\mathcal{W}$, with $R(z)\neq 0$ on $|z|=1$, such that

$$\begin{aligned}&P^0(z)G^0(z)+P^0(-z)G^0(-z)=1,\\ &P^1(z)=-zG^0(-z)R(z^2),\quad G^1(z)=\frac{-z^{-1}P^0(-z)}{R(z^2)},\quad |z|=1.\end{aligned} \tag{3.3}$$

That is, we have the following result (see [1, p. 148]).

LEMMA 1. *Let P^λ and G^λ, $\lambda=0,1$, be Laurent series in the class $\mathcal{W}$. Then the three statements* (3.1), (3.2), *and* (3.3) *are equivalent.*

Proof. That (3.3) implies (3.2) is trivial. On the other hand, to see that (3.2) implies (3.1), we will use the notation introduced in (2.11). It is clear that (3.2) is equivalent to the matrix identity

$$M^T(z)\widetilde{M}(z)=I,\qquad |z|=1, \tag{3.4}$$

where I denotes the identity matrix and A^T stands for the transpose of A. Hence, $M(z)$ is a nonsingular matrix for $|z|=1$ with inverse $\widetilde{M^T}(z)$, and we may also conclude that

$$M(z)\widetilde{M^T}(z)=I,\qquad |z|=1. \tag{3.5}$$

Multiplying out the matrices in (3.5), we see that two of the four identities constitute (3.1).

Finally, suppose that (3.1) holds. Replacing z by $-z$, we have

$$\begin{aligned}&P^0(z)G^0(-z)+P^1(z)G^1(-z)=0,\\ &P^0(-z)G^0(-z)+P^1(-z)G^1(-z)=1,\qquad |z|=1.\end{aligned} \tag{3.6}$$

Then (3.5) is a consequence of (3.1) and (3.6). In particular, the matrix $M(z)$ is nonsingular for $|z|=1$. Viewing $G^0(z)$ and $G^1(z)$ as unknowns in (3.1), we apply Cramer's rule to yield

$$\begin{aligned}G^0(z)&=\frac{P^1(-z)}{\Delta(z)};\\ G^1(z)&=-\frac{P^0(-z)}{\Delta(z)},\qquad |z|=1,\end{aligned} \tag{3.7}$$

where

$$\Delta(z):=\det M(z). \tag{3.8}$$

From the definition of $M(z)$ and $\Delta(z)$, it is clear that $\Delta(z)$ is an odd function in z; and hence, we may write

$$\Delta(z)=zR(z^2),\qquad |z|=1 \tag{3.9}$$

for some $R \in \mathcal{W}$. Since $M(z)$ is nonsingular on $|z| = 1$, we have $R(z) \neq 0$, $|z| = 1$. From (3.7) and (3.9) as well as the equivalence of (3.4) and (3.5), we establish (3.3). □

In what follows, we will always assume that P^0 and G^0 are dual symbols as in (2.9), that P^1 and G^1 are defined by (2.10), and that the series expressions (2.6) and (2.12) are used. With these (two-scale) coefficient sequences $\{p_n^\lambda\}$ and $\{\overline{g_{-n}^\lambda}\}$, $\lambda = 0, 1$, we introduce the linear operators $\mathcal{P}_\lambda$ and $\mathcal{G}_\lambda$, $\lambda = 0, 1$, on

$$\ell^2 := \left\{ \mathbf{v} = \{v_k\} \colon \sum_{k\in\mathbf{Z}} |v_k|^2 < \infty \right\}, \tag{3.10}$$

defined by

$$(\mathcal{P}_\lambda \mathbf{v})_\ell := \sum_{k\in\mathbf{Z}} p_{k-2\ell}^\lambda v_k, \quad \ell \in \mathbb{Z}, \quad \lambda = 0, 1, \tag{3.11}$$

$$(\mathcal{G}_\lambda \mathbf{v})_\ell := \sum_{k\in\mathbf{Z}} \overline{g_{-k+2\ell}^\lambda} v_k, \quad \ell \in \mathbb{Z}, \quad \lambda = 0, 1. \tag{3.12}$$

Then the adjoints $\mathcal{P}_\lambda^*$ and $\mathcal{G}_\lambda^*$ of $\mathcal{P}_\lambda$ and $\mathcal{G}_\lambda$, respectively, are given by

$$(\mathcal{P}_\lambda^* \mathbf{v})_\ell = \sum_{k\in\mathbf{Z}} \overline{p_{\ell-2k}^\lambda} v_k, \quad \ell \in \mathbb{Z}, \quad \lambda = 0, 1, \tag{3.13}$$

$$(\mathcal{G}_\lambda^* \mathbf{v})_\ell = \sum_{k\in\mathbf{Z}} g_{-\ell+2k}^\lambda v_k, \quad \ell \in \mathbb{Z}, \quad \lambda = 0, 1. \tag{3.14}$$

Indeed, by adopting the notation

$$\langle \mathbf{u}, \mathbf{v} \rangle_{\ell^2} = \sum_{k\in\mathbf{Z}} u_k \bar{v}_k, \tag{3.15}$$

where $\mathbf{u} = \{u_k\}$ and $\mathbf{v} = \{v_k\}$, for the inner product of the ℓ^2 space, we have

$$\begin{aligned} \langle \mathbf{u}, \mathcal{P}_\lambda \mathbf{v} \rangle &= \sum_{\ell\in\mathbf{Z}} u_\ell \overline{(\mathcal{P}_\lambda \mathbf{v})_\ell} \\ &= \sum_{k\in\mathbf{Z}} \left(\sum_{\ell\in\mathbf{Z}} \overline{p_{k-2\ell}^\lambda} u_\ell \right) \overline{v}_k = \langle \mathcal{P}_\lambda^* \mathbf{u}, \mathbf{v} \rangle, \end{aligned} \tag{3.16}$$

and similarly,

$$\langle \mathbf{u}, \mathcal{G}_\lambda \mathbf{v} \rangle = \langle \mathcal{G}_\lambda^* \mathbf{u}, \mathbf{v} \rangle. \tag{3.17}$$

We have the following result.

LEMMA 2. *Let $\mathcal{P}_\lambda$ and $\mathcal{G}_\lambda$ be as defined in* (3.11) *and* (3.12) *with adjoints $\mathcal{P}_\lambda^*$ and $\mathcal{G}_\lambda^*$, respectively. Then*

$$\mathcal{P}_\lambda \mathcal{G}_\mu^* = 2\delta_{\lambda,\mu} I, \qquad \lambda, \mu = 0, 1, \tag{3.18}$$

and

$$\mathcal{G}_0^* \mathcal{P}_0 + \mathcal{G}_1^* \mathcal{P}_1 = 2I, \tag{3.19}$$

where I is the identity operator on ℓ^2.

Remarks. (1) By taking the adjoints of both (3.18) and (3.19), we also have

$$\mathcal{G}_\mu \mathcal{P}_\lambda^* = 2\delta_{\lambda,\mu} I, \qquad \lambda, \mu = 0, 1, \tag{3.20}$$

and

$$\mathcal{P}_0^* \mathcal{G}_0 + \mathcal{P}_1^* \mathcal{G}_1 = 2I. \tag{3.21}$$

That is, the identities (3.18) and (3.19) are equivalent to (3.20) and (3.21), respectively.

(2) We can view $\mathcal{P}_\lambda$ and $\mathcal{G}_\lambda$, $\lambda = 0, 1$, as bi-infinite (also possibly finite) matrices, namely,

$$\mathcal{P}_\lambda = [p^\lambda_{k-2\ell}]_{\ell,k\in\mathbb{Z}}, \qquad \mathcal{G}_\lambda = [\overline{g^\lambda_{k-2\ell}}]_{\ell,k\in\mathbb{Z}}.$$

With $\mathcal{P}_\lambda^* := \overline{\mathcal{P}}_\lambda^T$ and $\mathcal{G}_\lambda^* := \overline{\mathcal{G}}_\lambda^T$ being the conjugate transposes of $\mathcal{P}_\lambda$ and $\mathcal{G}_\lambda$, respectively, and I being the identity matrix, then (3.18)–(3.21) can be viewed as matrix identities.

Proof. We will derive (3.18) and (3.19) via symbol calculus. For any sequence $\mathbf{u} = \{u_k\}_{k\in\mathbb{Z}} \in \ell^1$, set

$$\mathbf{u}(z) := \sum_{k\in\mathbb{Z}} u_k z^k.$$

According to (3.11) and (3.14), it is easy to verify that

$$(\mathcal{P}_\lambda \mathbf{v})(z^{-2}) = \sum_{\ell\in\mathbb{Z}} (\mathcal{P}_\lambda \mathbf{v})_\ell z^{-2\ell} = P^\lambda(z)\mathbf{v}(z^{-1}) + P^\lambda(-z)\mathbf{v}(-z^{-1})$$

and

$$(\mathcal{G}_\lambda^* \mathbf{v})(z^{-1}) = \sum_{\ell\in\mathbb{Z}} (\mathcal{G}_\lambda^* \mathbf{v})_\ell z^{-\ell} = 2G^\lambda(z)\mathbf{v}(z^{-2}).$$

Thus, we have, for any $\mathbf{u} \in \ell^1$ and $|z| = 1$,

$$\begin{aligned}\sum_{\ell\in\mathbb{Z}} (\mathcal{P}_\lambda \mathcal{G}_\mu^* \mathbf{u})_\ell z^{-2\ell} =& P^\lambda(z)(\mathcal{G}_\mu^* \mathbf{u})(z^{-1}) + P^\lambda(-z)(\mathcal{G}_\mu^* \mathbf{u})(-z^{-1}) \\ =& 2[P^\lambda(z)G^\mu(z) + P^\lambda(-z)G^\mu(-z)]\mathbf{u}(z^{-2}) = 2\delta_{\lambda,\mu}\mathbf{u}(z^{-2}),\end{aligned}$$

where the identity (3.2) has been used to arrive at the last equality. That is, we have $(\mathcal{P}_\lambda \mathcal{G}_\mu^* \mathbf{u})_k = 2\delta_{\lambda,\mu} u_k$ for all $k \in \mathbb{Z}$ and all $\mathbf{u} = \{u_k\}_{k\in\mathbb{Z}} \in \ell^1$. Hence, since ℓ^1 is dense in ℓ^2, we obtain (3.18).

On the other hand, we have, for any $\mathbf{v} \in \ell^1$,

$$\begin{aligned}&\sum_{k\in\mathbb{Z}} (\mathcal{G}_0^* \mathcal{P}_0 \mathbf{v} + \mathcal{G}_1^* \mathcal{P}_1 \mathbf{v})_k z^{-k} = (\mathcal{G}_0^* \mathcal{P}_0 \mathbf{v})(z^{-1}) + (\mathcal{G}_1^* \mathcal{P}_1 \mathbf{v})(z^{-1}) \\ &=2G^0(z)(\mathcal{P}_0 \mathbf{v})(z^{-2}) + 2G^1(z)(\mathcal{P}_1 \mathbf{v})(z^{-2}) \\ &=2G^0(z)[P^0(z)\mathbf{v}(z^{-1}) + P^0(-z)\mathbf{v}(-z^{-1})] + 2G^1(z)[P^1(z)\mathbf{v}(z^{-1}) + P^1(-z)\mathbf{v}(-z^{-1})] \\ &=2[P^0(z)G^0(z) + P^1(z)G^1(z)]\mathbf{v}(z^{-1}) + 2[P^0(-z)G^0(z) + P^1(-z)G^1(z)]\mathbf{v}(-z^{-1}) \\ &=2\mathbf{v}(z^{-1}),\end{aligned}$$

where the identity (3.1) has been used to arrive at the last equality. Thus,

$$(\mathcal{G}_0^* \mathcal{P}_0 \mathbf{v} + \mathcal{G}_1^* \mathcal{P}_1 \mathbf{v})_k = 2v_k \quad \text{for all} \quad k \in \mathbb{Z}.$$

Since this holds for all $\mathbf{v} \in \ell^1$, we obtain (3.19). □

As a consequence of Lemma 2, we see that

$$\left(\tfrac{1}{2}\mathcal{G}_\lambda^*\mathcal{P}_\lambda\right)\left(\tfrac{1}{2}\mathcal{G}_\lambda^*\mathcal{P}_\lambda\right) = \tfrac{1}{2}\mathcal{G}_\lambda^*\left(\tfrac{1}{2}\mathcal{P}_\lambda\mathcal{G}_\lambda^*\right)\mathcal{P}_\lambda = \tfrac{1}{2}\mathcal{G}_\lambda^*\mathcal{P}_\lambda,$$

and

$$\left(\tfrac{1}{2}\mathcal{G}_\lambda^*\mathcal{P}_\lambda\right)\left(\tfrac{1}{2}\mathcal{G}_\mu^*\mathcal{P}_\mu\right) = \tfrac{1}{2}\mathcal{G}_\lambda^*\left(\tfrac{1}{2}\mathcal{P}_\lambda\mathcal{G}_\mu^*\right)\mathcal{P}_\mu = 0, \qquad \lambda \neq \mu.$$

This shows that

(i) $\frac{1}{2}\mathcal{G}_\lambda^*\mathcal{P}_\lambda$, is a projection on ℓ^2, $\lambda = 0, 1$;

(ii) The ranges of $\frac{1}{2}\mathcal{P}_0^*\mathcal{G}_0$ and $\frac{1}{2}\mathcal{G}_1^*\mathcal{P}_1$ are orthogonal (since $\langle \mathcal{P}_0^*\mathcal{G}_0\mathbf{u}, \mathcal{G}_1^*\mathcal{P}_1\mathbf{v}\rangle_{\ell^2} = \langle \mathbf{u}, \mathcal{G}_0^*\mathcal{P}_0\mathcal{G}_1^*\mathcal{P}_1\mathbf{v}\rangle_{\ell^2} = 0$); while

(iii) The ranges of $\frac{1}{2}\mathcal{G}_0^*\mathcal{P}_0$ and $\frac{1}{2}\mathcal{G}_1^*\mathcal{P}_1$ form a direct-sum decomposition of ℓ^2.

We now return to our discussion of wavelet packets as defined in §2 (cf. (2.14)). From (2.14) and using the notation in (3.11), we have

$$\psi_{2n+\lambda}(x-\ell) = (\mathcal{P}_\lambda\{\psi_n(2x-\cdot)\})_\ell, \qquad \ell \in \mathbb{Z}, \quad \lambda = 0, 1. \tag{3.22}$$

Similarly, we also have, from (2.14) and (3.12),

$$\widetilde{\psi}_{2n+\lambda}(x-\ell) = (\mathcal{G}_\lambda\{\widetilde{\psi}_n(2x-\cdot)\})_\ell, \qquad \ell \in \mathbb{Z}, \quad \lambda = 0, 1. \tag{3.23}$$

As an application of (3.19) in Lemma 2, by putting (3.22) into (3.14), we obtain, for all $k \in \mathbb{Z}$,

$$\begin{aligned} &\psi_n(2x-k) \\ &\quad= \frac{1}{2}(\mathcal{G}_0^*(\mathcal{P}_0\{\psi_n(2x-\cdot)\}))_k + \frac{1}{2}(\mathcal{G}_1^*(\mathcal{P}_1\{\psi_n(2x-\cdot)\}))_k \\ &\quad= \frac{1}{2}(\mathcal{G}_0^*\{\psi_{2n}(x-\cdot)\})_k + \frac{1}{2}(\mathcal{G}_1^*\{\psi_{2n+1}(x-\cdot)\})_k \\ &\quad= \frac{1}{2}\sum_{\ell\in\mathbf{Z}} g_{2\ell-k}^0\psi_{2n}(x-\ell) + \frac{1}{2}\sum_{\ell\in\mathbf{Z}} g_{2\ell-k}^1\psi_{2n+1}(x-\ell). \end{aligned} \tag{3.24}$$

In the same manner, from (3.23), (3.21), and (3.13), we also have, for $k \in \mathbb{Z}$,

$$\begin{aligned} &\widetilde{\psi}_n(2x-k) \\ &\quad= \frac{1}{2}(\mathcal{P}_0^*(\mathcal{G}_0\{\widetilde{\psi}_n(2x-\cdot)\}))_k + \frac{1}{2}(\mathcal{P}_1^*(\mathcal{G}_1\{\widetilde{\psi}_n(2x-\cdot)\}))_k \\ &\quad= \frac{1}{2}(\mathcal{P}_0^*\{\widetilde{\psi}_{2n}(x-\cdot)\})_k + \frac{1}{2}(\mathcal{P}_1^*\{\widetilde{\psi}_{2n+1}(x-\cdot)\})_k \\ &\quad= \frac{1}{2}\sum_{\ell\in\mathbf{Z}} \overline{p_{k-2\ell}^0}\,\widetilde{\psi}_{2n}(x-\ell) + \frac{1}{2}\sum_{\ell\in\mathbf{Z}} \overline{p_{k-2\ell}^1}\,\widetilde{\psi}_{2n+1}(x-\ell). \end{aligned} \tag{3.25}$$

Observe that for $n = 0$, (3.24) and (3.25) give the so-called decomposition relations in wavelet analysis [1, Chap. 5]. In general, we call (3.24) and (3.25) "*decomposition formulas*" for the wavelet packets $\{\psi_n\}$ and $\{\widetilde{\psi}_n\}$, $n \in \mathbb{Z}_+$, respectively, and (3.19), (3.21) the "*operator forms*" of these decomposition formulas.

In the following, we give explicit expressions of the Fourier transforms of ψ_n and $\widetilde{\psi}_n$.

LEMMA 3. *Let $n \in \mathbb{Z}_+$ and consider its dyadic expansion*

$$n = \sum_{j=1}^{\infty} \varepsilon_j 2^{j-1}, \qquad \varepsilon_j \in \{0, 1\}. \tag{3.26}$$

Then

$$\widehat{\psi}_n(\omega) = \prod_{J=1}^{\infty} P^{\varepsilon_j}(e^{-i2^{-j}\omega}), \tag{3.27}$$

$$\widehat{\widetilde{\psi}}_n(\omega) = \prod_{j=1}^{\infty} \overline{G^{\varepsilon_j}(e^{-i2^{-j}\omega})}. \tag{3.28}$$

Remark. Since n is an integer, we note that all but finitely many ε_j in (3.26) are zeros.

Proof. We will prove (3.27) by induction. The proof of (3.28) is identical. From (2.4), noting that $\psi_0 = \phi$, we have (3.27) for $n = 0$. Suppose now that (3.27) is valid for all n, $0 \le n < 2^N$, where N is a nonnegative integer. Then for $2^N \le n < 2^{N+1}$ with the dyadic expansion (3.26), we have

$$\left\lfloor \frac{n}{2} \right\rfloor = \sum_{j=1}^{\infty} \varepsilon_{j+1} 2^{j-1} \le \frac{n}{2} < 2^N$$

and

$$n = 2\left\lfloor \frac{n}{2} \right\rfloor + \varepsilon_1.$$

Thus, from the Fourier transform formulation of (2.14), namely,

$$\widehat{\psi}_{2n+\lambda}(\omega) = P^{\lambda}(e^{-i\omega/2})\widehat{\psi}_n\left(\frac{\omega}{2}\right),$$

and applying the induction hypothesis, we obtain

$$\begin{aligned} \widehat{\psi}_n(\omega) &= P^{\varepsilon_1}(e^{-i\omega/2})\widehat{\psi}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2}\right) \\ &= P^{\varepsilon_1}(e^{-i\omega/2}) \prod_{j=1}^{\infty} P^{\varepsilon_{j+1}}(e^{-i2^{-j-1}\omega}) = \prod_{j=1}^{\infty} P^{\varepsilon_j}(e^{-i2^{-j}\omega}). \qquad \square \end{aligned}$$

We next discuss the duality properties between the wavelet packets $\{\psi_n\}_{n=1}^{\infty}$ and $\{\widetilde{\psi}_n\}_{n=1}^{\infty}$.

LEMMA 4. *For all $k, \ell \in \mathbb{Z}$, and $n \in \mathbb{Z}_+$,*

$$\langle \psi_n(\cdot - k), \widetilde{\psi}_n(\cdot - \ell) \rangle = \delta_{k,\ell}. \tag{3.29}$$

Proof. We will establish (3.29) by induction on n. The case $n = 0$ is our basic assumption (2.8) on the dual scaling functions $\psi_0 = \phi$ and $\widetilde{\psi}_0 = \widetilde{\phi}$. Suppose that (3.29) holds for $0 \le n < 2^N$, where N is a nonnegative integer. Then for $2^N \le n < 2^{N+1}$, since we can write $n = 2\lfloor \frac{n}{2} \rfloor + \lambda$ for some $\lambda \in \{0, 1\}$ according to the proof of Lemma 3, we have, from the Fourier transform formulations of both equations in (2.14),

$$\begin{aligned}
&\langle \psi_n(\cdot - k), \widetilde{\psi}_n(\cdot - \ell) \rangle \\
&= \frac{1}{2\pi} \int_{\mathbf{R}} \widehat{\psi}_n(\omega) \overline{\widehat{\widetilde{\psi}}_n(\omega)}\, e^{i(\ell - k)\omega}\, d\omega \\
&= \frac{1}{2\pi} \int_{\mathbf{R}} P^{\lambda}(e^{-i\omega/2}) G^{\lambda}(e^{-i\omega/2}) \widehat{\psi}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2}\right) \overline{\widehat{\widetilde{\psi}}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2}\right)}\, e^{i(\ell - k)\omega}\, d\omega \\
&= \frac{1}{2\pi} \int_0^{4\pi} e^{i(\ell - k)\omega} P^{\lambda}(e^{-i\omega/2}) G^{\lambda}(e^{-i\omega/2}) \sum_{j \in \mathbf{Z}} \widehat{\psi}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2} + 2\pi j\right) \overline{\widehat{\widetilde{\psi}}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2} + 2\pi j\right)}\, d\omega.
\end{aligned}$$

Since $\lfloor \frac{n}{2} \rfloor \le \frac{n}{2} < 2^N$, it follows from the induction hypothesis that $\langle \psi_{\lfloor \frac{n}{2} \rfloor}(\cdot - k), \widetilde{\psi}_{\lfloor \frac{n}{2} \rfloor}(\cdot - \ell) \rangle = \delta_{k,\ell}$ for all $k, \ell \in \mathbb{Z}$, and this is equivalent to

$$\sum_{j \in \mathbf{Z}} \widehat{\psi}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2} + 2\pi j\right) \overline{\widehat{\widetilde{\psi}}_{\lfloor \frac{n}{2} \rfloor}\left(\frac{\omega}{2} + 2\pi j\right)} = 1 \quad \text{a.e.,} \tag{3.30}$$

via the Poisson summation formula (see [1, pp. 45–46 and pp. 151–152]). Thus, we have, from (3.2) for $\mu = \lambda$ that

$$\begin{aligned}
&\langle \psi_n(\cdot - k), \widetilde{\psi}_n(\cdot - \ell) \rangle \\
&= \frac{1}{2\pi} \int_0^{4\pi} e^{i(\ell - k)\omega} P^{\lambda}(e^{-i\omega/2}) G^{\lambda}(e^{-i\omega/2})\, d\omega \\
&= \frac{1}{2\pi} \int_0^{2\pi} e^{i(\ell - k)\omega} [P^{\lambda}(e^{-i\omega/2}) G^{\lambda}(e^{-i\omega/2}) + P^{\lambda}(-e^{-i\omega/2}) G^{\lambda}(-e^{-i\omega/2})]\, d\omega \\
&= \frac{1}{2\pi} \int_0^{2\pi} e^{i(\ell - k)\omega}\, d\omega = \delta_{k,\ell}, \qquad k, \ell \in \mathbb{Z}.
\end{aligned}$$

This shows that (3.29) also holds for $2^N \le n < 2^{N+1}$. □

LEMMA 5. *For all* $k, \ell \in \mathbb{Z}$, $n \in \mathbb{Z}_+$, *and* $\lambda, \mu \in \{0, 1\}$, *with* $\lambda \ne \mu$,

$$\langle \psi_{2n+\lambda}(\cdot - k), \widetilde{\psi}_{2n+\mu}(\cdot - \ell) \rangle = 0. \tag{3.31}$$

Proof. By applying the Fourier transform formulations of (2.14) and the formulas (3.30) and (3.2), we have, as in the proof of Lemma 4, that

$$\begin{aligned}
&\langle \psi_{2n+\lambda}(\cdot - k), \widetilde{\psi}_{2n+\mu}(\cdot - \ell) \rangle \\
&= \frac{1}{2\pi} \int_{\mathbf{R}} \widehat{\psi}_{2n+\lambda}(\omega) \overline{\widehat{\widetilde{\psi}}_{2n+\mu}(\omega)}\, e^{i(\ell - k)\omega}\, d\omega \\
&= \frac{1}{2\pi} \int_{\mathbf{R}} P^{\lambda}(e^{-i\omega/2}) G^{\mu}(e^{-i\omega/2}) \widehat{\psi}_n\left(\frac{\omega}{2}\right) \overline{\widehat{\widetilde{\psi}}_n\left(\frac{\omega}{2}\right)} e^{i(\ell - k)\omega}\, d\omega \\
&= \frac{1}{2\pi} \int_0^{4\pi} e^{i(\ell - k)\omega} P^{\lambda}(e^{-i\omega/2}) G^{\mu}(e^{-i\omega/2}) \sum_{j \in \mathbf{Z}} \widehat{\psi}_n\left(\frac{\omega}{2} + 2\pi j\right) \overline{\widehat{\widetilde{\psi}}_n\left(\frac{\omega}{2} + 2\pi j\right)}\, d\omega \\
&= \frac{1}{2\pi} \int_0^{4\pi} e^{i(\ell - k)\omega} P^{\lambda}(e^{-i\omega/2}) G^{\mu}(e^{-i\omega/2})\, d\omega \\
&= \frac{1}{2\pi} \int_0^{2\pi} e^{i(\ell - k)\omega} [P^{\lambda}(e^{-i\omega/2}) G^{\mu}(e^{-i\omega/2}) + P^{\lambda}(-e^{i\omega/2}) G^{\mu}(-e^{-i\omega/2})]\, d\omega \\
&= \frac{1}{2\pi} \int_0^{2\pi} e^{i(\ell - k)\omega} \delta_{\lambda,\mu} d\omega = \delta_{\lambda,\mu} \delta_{k,\ell} = 0, \qquad \lambda \ne \mu.
\end{aligned}$$

This completes the proof of Lemma 5. □

Recall the spaces U_n of wavelet packets as defined in (2.24). Any f in U_n can be written as

$$f(x) = \sum_{k\in\mathbf{Z}} \bar{c}_k \psi_n(x-k) = \langle \{\psi_n(x-\cdot)\}, \mathbf{c}\rangle_{\ell^2}, \tag{3.32}$$

for some $\mathbf{c} = \{c_k\}_{k\in\mathbf{Z}} \in \ell^2$. From the decomposition formula (3.24), we have

$$\begin{aligned} f(2x) &= \langle \{\psi_n(2x-\cdot)\}, \mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2}\langle \mathcal{G}_0^*\{\psi_{2n}(x-\cdot)\}, \mathbf{c}\rangle_{\ell^2} + \frac{1}{2}\langle \mathcal{G}_1^*\{\psi_{2n+1}(x-\cdot)\}, \mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2}\langle \{\psi_{2n}(x-\cdot)\}, \mathcal{G}_0\mathbf{c}\rangle_{\ell^2} + \frac{1}{2}\langle \{\psi_{2n+1}(x-\cdot)\}, \mathcal{G}_1\mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2}\sum_{\ell\in\mathbf{Z}} \overline{(\mathcal{G}_0\mathbf{c})_\ell}\, \psi_{2n}(x-\ell) + \frac{1}{2}\sum_{\ell\in\mathbf{Z}} \overline{(\mathcal{G}_1\mathbf{c})_\ell}\, \psi_{2n+1}(x-\ell). \end{aligned} \tag{3.33}$$

By introducing the scaling operator

$$\delta f := f(2\cdot), \tag{3.34}$$

the formula in (3.33) implies that for $f \in U_n$, we have

$$\delta f = g + h, \tag{3.35}$$

where $g \in U_{2n}$, $h \in U_{2n+1}$. On the other hand, if $g = \sum_{\ell\in\mathbf{Z}} a_\ell \psi_{2n}(\cdot-\ell) \in U_{2n}$ and $h = \sum_{\ell\in\mathbf{Z}} b_\ell \psi_{2n+1}(\cdot-\ell) \in U_{2n+1}$ such that

$$g + h = 0, \tag{3.36}$$

then by Lemmas 4 and 5 we have

$$\begin{aligned} 0 &= \langle g+h, \tilde{\psi}_{2n}(\cdot-k)\rangle = a_k, \\ 0 &= \langle g+h, \tilde{\psi}_{2n+1}(\cdot-k)\rangle = b_k, \qquad k \in \mathbb{Z}. \end{aligned}$$

That is, we have $g = 0$ and $h = 0$. Noting from the definition in (2.14) that

$$U_{2n} \subseteq \delta U_n, \qquad U_{2n+1} \subseteq \delta U_n, \tag{3.37}$$

the above argument shows that

$$\delta U_n = U_{2n} \dot{+} U_{2n+1}, \qquad n \in \mathbb{Z}_+, \tag{3.38}$$

where "$\dot{+}$" indicates a "direct sum" of two linear spaces. Analogous results also hold for $\widetilde{U}_n$, namely,

$$\delta \widetilde{U}_n = \widetilde{U}_{2n} \dot{+} \widetilde{U}_{2n+1}, \qquad n \in \mathbb{Z}_+. \tag{3.39}$$

More generally, we have

$$\begin{aligned} \delta^\ell U_n &= U_{2^\ell n} \dot{+} U_{2^\ell n+1} \dot{+} \cdots \dot{+} U_{2^\ell n + 2^\ell - 1}, \\ \delta^\ell \widetilde{U}_n &= \widetilde{U}_{2^\ell n} \dot{+} \widetilde{U}_{2^\ell n+1} \dot{+} \cdots \dot{+} \widetilde{U}_{2^\ell n + 2^\ell - 1}, \end{aligned} \tag{3.40}$$

where $\ell, n \in \mathbb{Z}_+$, $\delta^0 := I$, and $\delta^\ell = \delta \cdot \delta^{\ell-1}$. Of course, the proof of (3.40) is simply repeated applications of (3.38) and (3.39). In addition, an equivalent statement of Lemma 5 is that

$$(3.41) \qquad U_{2n} \perp \tilde{U}_{2n+1} \quad \text{and} \quad U_{2n+1} \perp \tilde{U}_{2n}, \qquad n \in \mathbb{Z}_+.$$

We end this section by showing that the infinite direct-sums in (2.23) are indeed "direct-sum decompositions." More precisely, for any $f \in L^2$, we will show that there exist unique $g_j \in W_j$, $j \in \mathbb{Z}$, such that

$$(3.42) \qquad \lim_{m,n\to\infty} \left\| \sum_{j=-m}^{n} g_j - f \right\| = 0.$$

Consider the linear operators P_j and Δ_j, defined by

$$(3.43) \qquad P_j f := \sum_{k\in\mathbb{Z}} \langle f, \tilde{\phi}_{j,k} \rangle \phi_{j,k} \quad \text{and} \quad \Delta_j f := \sum_{k\in\mathbb{Z}} \langle f, \tilde{\psi}_{j,k} \rangle \psi_{j,k}.$$

It is clear that $P_{j+1} = P_j + \Delta_j$ for any $j \in \mathbb{Z}$, so that

$$(3.44) \qquad P_{n+1} = P_{-m} + \sum_{j=-m}^{n} \Delta_j, \qquad m,\ n \in \mathbb{Z}_+.$$

Let $f \in L^2$ and $\varepsilon > 0$ be arbitrarily given. Then by the definition of the MRA $\{V_j\}$, there exist some $J \in \mathbb{Z}_+$ and an $f_J \in V_J$ such that $\|f - f_J\| < \varepsilon$. Since $P_j(f_J) = f_J$ for all $j \geq J$, we have

$$\begin{aligned} \|P_j f - f\| &\leq \|P_j(f - f_J)\| + \|f_J - f\| \\ &\leq (\|P_j\| + 1)\varepsilon, \qquad j \geq J; \end{aligned}$$

and the uniform boundedness of $\|P_j\|$ (in fact, $\|P_j\| = \|P_0\|$ for all $j \in \mathbb{Z}$) now yields

$$(3.45) \qquad \lim_{j\to\infty} \|P_j f - f\| = 0.$$

Hence, it follows from (3.44), (3.45), and $\lim_{j\to-\infty} \|P_j f\| = 0$ (which is a consequence of $\cap V_j = \{0\}$), that

$$\left\| \sum_{j=-m}^{n} \Delta_j f - f \right\| \leq \|P_{n+1} f - f\| + \|P_{-m} f\| \to 0 \quad \text{as} \ m,\ n \to +\infty.$$

Since $\Delta_j f \in W_j$, we have established the existence of $g_j \in W_j$ in (3.42). To show the uniqueness of g_j, $j \in \mathbb{Z}$, we first observe from the duality property in (1.4) that

$$(3.46) \qquad \Delta_j \left(\sum_{\ell=-J}^{J} g_\ell \right) = \Delta_j g_j = g_j, \qquad |j| \leq J \in \mathbb{Z}_+.$$

Hence, for any fixed $j \in \mathbb{Z}$, we have, from (3.42) and (3.46),

$$0 = \lim_{J\to\infty} \left\| \Delta_j \left(\sum_{\ell=-J}^{J} g_\ell - f \right) \right\| = \|g_j - \Delta_j f\|.$$

That is, $g_j = \Delta_j f$. □

4. Proof of the main results. We are now ready to prove the theorems stated in §2.

Proof of Theorem 1. In view of Lemma 4, we only have to consider the case $m \neq n$. We first note that

$$U_n \subseteq \delta^t U_{\lfloor \frac{n}{2^t} \rfloor}, \qquad n, t \in \mathbb{Z}_+, \tag{4.1}$$

where as before, $\lfloor x \rfloor$ stands for the largest integer not exceeding x. Indeed, by observing that $n \in \left[2^t \lfloor \frac{n}{2^t} \rfloor, 2^t \left(\lfloor \frac{n}{2^t} \rfloor + 1\right)\right)$, it follows from (3.40) that

$$U_n \subseteq U_{2^t\lfloor\frac{n}{2^t}\rfloor} \dot{+} U_{2^t\lfloor\frac{n}{2^t}\rfloor+1} \dot{+} \cdots \dot{+} U_{2^t\lfloor\frac{n}{2^t}\rfloor+2^t-1} = \delta^t U_{\lfloor\frac{n}{2^t}\rfloor}.$$

Similarly, we also have

$$\widetilde{U}_n \subseteq \delta^t \widetilde{U}_{\lfloor \frac{n}{2^t} \rfloor}, \qquad n, t \in \mathbb{Z}_+. \tag{4.2}$$

Now, without loss of generality, let us assume that $m > n$ in (2.17). Using the dyadic expansions for both m and n, namely,

$$m = \sum_{j\in\mathbb{Z}_+} 2^j \varepsilon_j, \quad n = \sum_{j\in\mathbb{Z}_+} 2^j \varepsilon'_j, \quad \varepsilon_j, \varepsilon'_j \in \{0, 1\},$$

we can find some $t \in \mathbb{Z}_+$ such that $\varepsilon'_j = \varepsilon_j$ for all $j > t$, while $\varepsilon_t > \varepsilon'_t$; i.e., $\varepsilon_t = 1$, $\varepsilon'_t = 0$. Thus, by letting $n' := \sum_{j>t} 2^{j-t-1}\varepsilon_j$, we have $n' \in \mathbb{Z}_+$ and $\lfloor \frac{m}{2^t} \rfloor = 2n' + 1$, $\lfloor \frac{n}{2^t} \rfloor = 2n'$. Hence, it follows from (4.1) and (4.2) that $\psi_m(\cdot - k) \in U_m \subseteq \delta^t U_{2n'+1}$ and $\widetilde{\psi}_n(\cdot - \ell) \in \widetilde{U}_n \subseteq \delta^t \widetilde{U}_{2n'}$ for all $k, \ell \in \mathbb{Z}$, respectively. On the other hand, from (3.41), we have shown that $\delta^t U_{2n'+1} \perp \delta^t \widetilde{U}_{2n'}$ and therefore $\langle \psi_m(\cdot - k), \psi_n(\cdot - \ell)\rangle = 0$. This completes the proof of Theorem 1. □

Remark. In the above discussion, we have proved that for any integers $m > n \geq 0$, there exists a $t \in \mathbb{Z}_+$, such that $\lfloor \frac{m}{2^t} \rfloor - \lfloor \frac{n}{2^t} \rfloor = 1$, while $\lfloor \frac{m}{2^t} \rfloor$ is an odd integer and $\lfloor \frac{n}{2^t} \rfloor$ is an even integer.

Proof of Theorem 2. Noting that $\psi_0(\cdot - k) = \psi_{0;0,k}$ and $\psi_1(\cdot - k) = \psi_{1;0,k}$, in (2.18), (2.19), we see that $V_0 = U_0$, $W_0 = U_1$, $V_j = \delta^j V_0$ and $W_j = \delta^j W_0$. Thus, as an application of formula (3.40) for $\ell = j$ and $n = 0, 1$, we immediately obtain (2.25) for any $j \in \mathbb{Z}_+$. The proof of (2.26) is the same. Since each of $\{V_j\}$ and $\{\widetilde{V}_j\}$ forms a multiresolution analysis of L^2, it is clear that

$$L^2 = V_0 \dot{+} \overset{\bullet}{\sum_{j\in\mathbb{Z}_+}} W_j = \widetilde{V}_0 \dot{+} \overset{\bullet}{\sum_{j\in\mathbb{Z}_+}} \widetilde{W}_j.$$

Combining this fact with (2.25) and (2.26) gives (2.27). Finally, (2.28) is a consequence of Theorem 1. □

Proof of Theorem 3. By Theorems 1 and 2, we see that both of the families

$$\{\psi_n(\cdot - k)\colon\ k \in \mathbb{Z},\ 2^\ell \leq n < 2^{\ell+1}\} \quad \text{and} \quad \{\widetilde{\psi}_n(\cdot - k)\colon\ k \in \mathbb{Z},\ 2^\ell \leq n < 2^{\ell+1}\}$$

are bases of W_ℓ and $\widetilde{W}_\ell$, respectively, and are biorthogonal to each other. Thus, by observing the definitions (2.24) and (3.34), we see that

$$\{\psi_{n;j,k}\colon\ k \in \mathbb{Z},\ 2^\ell \leq n < 2^{\ell+1}\} \quad \text{and} \quad \{\widetilde{\psi}_{n;j',k}\colon\ k \in \mathbb{Z},\ 2^\ell \leq n < 2^{\ell+1}\}$$

are bases of $W_{\ell+j} = \delta^j W_\ell$ and $W_{\ell+j'} = \delta^{j'} W_\ell$, respectively. Since

$$L^2 = \dot{\sum_{j\in\mathbb{Z}}} W_{\ell+j} = \dot{\sum_{j'\in\mathbb{Z}}} \widetilde{W}_{\ell+j'},$$

both $\{\psi_{n;j,k}\colon\ j,k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\}$ and $\{\widetilde{\psi}_{n;j,k}\colon\ j,k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\}$ are bases of L^2. Moreover, from (2.21) and (2.22), we have

$$W_j \perp \widetilde{W}_{j'} \quad (\text{or } W_{\ell+j} \perp \widetilde{W}_{\ell+j'}), \quad j \ne j'; \quad j, j', \ell \in \mathbb{Z}. \tag{4.3}$$

Thus, (2.31) follows from (4.3) for $j \ne j'$. The assertion for $j' = j$ is a consequence of Theorem 1, namely,

$$\langle \psi_{n;j,k},\ \psi_{n';j,k'} \rangle = \langle \psi_n(\cdot - k),\ \psi_{n'}(\cdot - k') \rangle = \delta_{n,n'}\delta_{k,k'}.$$

This completes the proof of Theorem 3. □

Proof of Theorem 4. Fix any $\ell \in \mathbb{Z}_+$ and consider n with $2^\ell \le n < 2^{\ell+1}$. As seen in the proof of Theorem 3, $\{\psi_{n;\ell,k}\colon\ k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\}$ and $\{\psi_{n;\ell+1,k}\colon\ k \in \mathbb{Z},\ 2^\ell \le n < 2^{\ell+1}\}$ are bases of $W_{2\ell}$ and $W_{2\ell+1}$, respectively. Since

$$L^2 = V_0 \dotplus \dot{\sum_{\ell\in\mathbb{Z}_+}} W_\ell = U_0 \dotplus \dot{\sum_{\ell\in\mathbb{Z}_+}} W_{2\ell} + \sum_{\ell\in\mathbb{Z}_+} W_{2\ell+1},$$

it follows that the family of functions given in (2.33) is a basis of L^2. Similarly, the family given in (2.34) is also a basis of L^2. Hence, Theorem 4 follows by applying Theorems 1 and 2 as well as (4.3). □

Proof of Theorem 5. We first observe that (2.31) holds for all (n,j), $(n',j') \in \mathcal{J}$ and $k, k' \in \mathbb{Z}$. Indeed, as seen in the proof of Theorem 3, (2.31) holds for all $j' = j$, $n, n' \in \mathbb{Z}_+$ and $k, k' \in \mathbb{Z}$, no matter how $(n,j) \in \mathcal{J}$ or $(n',j') \in \mathcal{J}$ is chosen. Thus, it remains to show that if $j \ne j'$, $(n,j) \in \mathcal{J}$, $(n',j') \in \mathcal{J}$, and $k, k' \in \mathbb{Z}$, then

$$\langle \psi_{n;j,k}, \widetilde{\psi}_{n';j',k'} \rangle = 0. \tag{4.4}$$

Without loss of generality, we assume $j > j'$ and let $\ell := j - j'$, so that

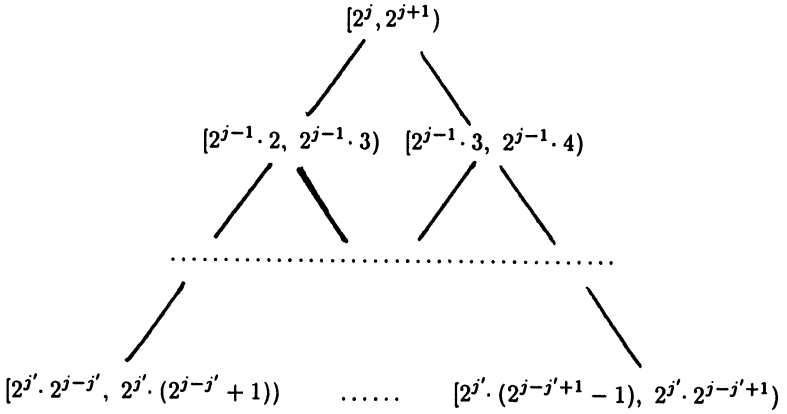
$$\langle \psi_{n;j,k}, \widetilde{\psi}_{n';j',k'} \rangle = \langle \psi_{n;\ell,k}, \widetilde{\psi}_{n';0,k'} \rangle. \tag{4.5}$$

Here, it is clear that

$$\begin{aligned} &\widetilde{\psi}_{n';0,k'} \in \widetilde{U}_{n'} \\ &\psi_{n;\ell,k} \in \delta^\ell U_n = U_{2^\ell n} \dotplus \cdots \dotplus U_{2^\ell n + 2^\ell - 1}. \end{aligned} \tag{4.6}$$

Since $\{I_{n,j} := [2^j n, 2^j(n+1))\colon\ (n,j) \in \mathcal{J}\}$ forms a disjoint covering of $(0,\infty)$, the family $\{2^{-j'} I_{n,j}\colon\ (n,j) \in \mathcal{J}\}$ is also a disjoint covering of $(0,\infty)$. Thus, since $j > j'$, it follows from $(n,j) \in \mathcal{J}$, $(n',j') \in \mathcal{J}$ and $(n,j) \ne (n',j')$ that $[n', n+1)$ and $[2^\ell n, 2^\ell(n+1))$ are disjoint; or equivalently, $n' \notin [2^\ell n, 2^\ell(n+1))$, where $\ell = j - j'$. By (2.28) and (3.40), we obtain

$$\widetilde{U}_{n'} \perp \dot{\sum_{2^\ell n \le j < 2^\ell(n+1)}} U_j = \delta^\ell U_n. \tag{4.7}$$



$[2^j, 2^{j+1})$
$[2^{j-1}\cdot 2,\ 2^{j-1}\cdot 3)$
$[2^{j-1}\cdot 3,\ 2^{j-1}\cdot 4)$
$[2^{j'}\cdot 2^{j-j'},\ 2^{j'}\cdot (2^{j-j'}+1))$
......
$[2^{j'}\cdot (2^{j-j'+1}-1),\ 2^{j'}\cdot 2^{j-j'+1})$

FIG. 1

Hence, (4.4) follows from (4.5), (4.6), and (4.7).

To complete the proof of Theorem 5, we have to show that $\{\psi_{n;j,k}\colon (n,j) \in \mathcal{J}, k \in \mathbb{Z}\}$ is complete in $L^2(\mathbb{R})$. Since the wavelet basis $\{\psi_{1;j,k}\colon j, k \in \mathbb{Z}\}$ is complete for $L^2(\mathbb{R})$, it is sufficient to demonstrate that each $\psi_{1;j,k}$ $(j, k \in \mathbb{Z})$ is in the L^2-closure of the linear span of $\{\psi_{n;s,t}\colon (n;s) \in \mathcal{J}, t \in \mathbb{Z}\}$. Given $j \in \mathbb{Z}$, then for any $j' \in \mathbb{Z}$, $j' \leq j$ we can decompose the interval $[2^j, 2^{j+1})$ as in the binary tree in Fig. 1.

Since $[2^j, 2^{j+1})$ is only covered by finitely many dyadic intervals $I_{n,s} = [2^s n, 2^s(n+1))$, $(n,s) \in \mathcal{J}$, we can find a sufficiently small $j' \in \mathbb{Z}$, with $j' \leq j$, such that $[2^j, 2^{j+1}) \subseteq \bigcup_{(n,s)\in\mathcal{J}_j} I_{n,s}$, where $(n,s) \in \mathcal{J}$, and $I_{n,s}$ appears in the above binary tree; and since it depends on j, we denote the set of these (n,s) by $\mathcal{J}_j$. Clearly $\mathcal{J}_j \subseteq \mathcal{J}$. For $k \in \mathbb{Z}$, we have $\psi_{1;j,k} \in \delta^j U_1 = \delta^{j'}(\delta^{j-j'} U_1)$. Thus, corresponding to each $(n,s) \in \mathcal{J}_j$, by using the formula (3.38) repeatedly, starting with $\delta^{j-j'} U_1 = \delta^{j-j'-1}(\delta U_1)$, we have

$$\psi_{1;j,k} \in \delta^{j'}(\delta^{j-j'} U_1) \subseteq \sum_{(n,s)\in\mathcal{J}_j}^{\bullet} \delta^s U_n.$$

This shows that $\psi_{1;j,k}$ is in the L^2-closure of the linear span of $\psi_{n;s,t}$ with $(n,s) \in \mathcal{J}_j \subset \mathcal{J}$ and $t \in \mathbb{Z}$; and consequently, $\{\psi_{n;j,k}\colon (n,j) \in \mathcal{J}, k \in \mathbb{Z}\}$ is complete in L^2. The same proof is valid for $\{\widetilde{\psi}_{n;j,k}\colon (n,j) \in \mathcal{J}, k \in \mathbb{Z}\}$. This completes the proof of Theorem 5. □

Remark. A formulation of Theorem 5 for the orthonormal setting (i.e., $\psi_n = \widetilde{\psi}_n$, $n \in \mathbb{Z}_+$) can be found in Coifman and Meyer [5].

Proof of Theorem 6. We first prove that, for each integer n satisfying $2^\ell \leq n < 2^{\ell+1}$, there exists some positive constant C_n, such that

$$\sum_{k\in\mathbb{Z}} |\langle f, \psi_{n;j,k}\rangle|^2 \leq C_n \sum_{k\in\mathbb{Z}} |\langle f, \psi_{1;j+\ell,k}\rangle|^2 \tag{4.8}$$

for all $j \in \mathbb{Z}$ and $f \in L^2(\mathbb{R})$. For this purpose, we will adopt the dyadic expansion for n, namely: $n = \sum_{t=1}^{\ell+1} \varepsilon_t 2^{t-1}$, where $\varepsilon_t \in \{0,1\}$ and $\varepsilon_{\ell+1} = 1$. By using the operator $\mathcal{P}_\lambda$ defined in (3.11), it follows from (3.22) that

$$\psi_{n;j,k} = 2^{-\frac{1}{2}}(\mathcal{P}_{\varepsilon_1}\{\psi_{\lfloor\frac{n}{2}\rfloor,j+1,\cdot}\})_k, \qquad k \in \mathbb{Z}, \tag{4.9}$$

or equivalently, in view of (3.11),

$$\psi_{n;j,k}(x) = 2^{-\frac{1}{2}} \sum_{m\in\mathbb{Z}} p^{\varepsilon_1}_{m-2k} \psi_{\lfloor \frac{n}{2} \rfloor; j+1,m}(x), \qquad j,k \in \mathbb{Z}. \tag{4.10}$$

Thus, we have, for any $f \in L^2$,

$$\begin{aligned} |\langle f, \psi_{n;j,k}\rangle| &\le 2^{-\frac{1}{2}} \sum_{m\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}|^{\frac{1}{2}} \cdot |p^{\varepsilon_1}_{m-2k}|^{\frac{1}{2}} \cdot |\langle f, \psi_{\lfloor \frac{n}{2} \rfloor; j+1,m}\rangle| \\ &\le 2^{-\frac{1}{2}} \left(\sum_{m\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}| \right)^{\frac{1}{2}} \left(\sum_{m\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}| \cdot |\langle f, \psi_{\lfloor \frac{n}{2} \rfloor; j+1,m}\rangle|^2 \right)^{\frac{1}{2}}. \end{aligned}$$

Moreover, by putting

$$D_\lambda := \max\left\{ \sum_{k\in\mathbb{Z}} |p^{\lambda}_{2k}|, \sum_{k\in\mathbb{Z}} |p^{\lambda}_{2k+1}| \right\}, \qquad \lambda \in \{0,1\}, \tag{4.11}$$

we have

$$\sum_{m\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}| = \sum_{m\in\mathbb{Z}} |p^{\varepsilon_1}_{m}| \le 2D_{\varepsilon_1},$$

and

$$\sum_{k\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}| = \begin{cases} \sum\limits_{k\in\mathbb{Z}} |p^{\varepsilon_1}_{2k}| & \text{for even } m, \\ \sum\limits_{k\in\mathbb{Z}} |p^{\varepsilon_1}_{2k+1}| & \text{for odd } m, \end{cases}$$

so that

$$\begin{aligned} \sum_{k\in\mathbb{Z}} |\langle f, \psi_{n;j,k}\rangle|^2 &\le D_{\varepsilon_1} \sum_{m\in\mathbb{Z}} \left(\sum_{k\in\mathbb{Z}} |p^{\varepsilon_1}_{m-2k}| \right) |\langle f, \psi_{\lfloor \frac{n}{2} \rfloor; j+1,m}\rangle|^2 \\ &\le D^2_{\varepsilon_1} \sum_{m\in\mathbb{Z}} |\langle f, \psi_{\lfloor \frac{n}{2} \rfloor; j+1,m}\rangle|^2. \end{aligned} \tag{4.12}$$

Now, since $\lfloor \frac{n}{2} \rfloor = \sum_{t=1}^{\ell} \varepsilon_{t+1} 2^{t-1}$, $\lfloor \frac{n}{2^2} \rfloor = \sum_{t=1}^{\ell-1} \varepsilon_{t+2} 2^{t-1}$, etc., repeated applications of the inequality (4.12) to $\psi_{\lfloor \frac{n}{2} \rfloor; j+1,k}$, $\psi_{\lfloor \frac{n}{2^2} \rfloor; j+2,k}, \dots, \psi_{1;j+\ell,k}$, yield

$$\sum_{k\in\mathbb{Z}} |\langle f, \psi_{n;j,k}\rangle|^2 \le (D_{\varepsilon_1} \cdots D_{\varepsilon_\ell})^2 \sum_{k\in\mathbb{Z}} |\langle f; \psi_{1;j+\ell,k}\rangle|^2. \tag{4.13}$$

Thus, (4.8) follows from (4.13) by setting

$$C_n := (D_{\varepsilon_1} D_{\varepsilon_2} \cdots D_{\varepsilon_\ell})^2. \tag{4.14}$$

Observe that C_n is a (finite) positive constant, since it follows from (4.11) and $\{p^{\lambda}_{k}\} \in \ell^1$ that D_λ is finite, $\lambda \in \{0,1\}$. In addition, by setting $D := \max\{D_0, D_1\}$, (4.14) implies that $C_n \le D^{2\ell}$. Thus, from (4.13), we have

$$\sum_{k\in\mathbb{Z}} \sum_{2^\ell \le n < 2^{\ell+1}} |\langle f, \psi_{n;j,k}\rangle|^2 \le 2^\ell D^{2\ell} \sum_{k\in\mathbb{Z}} |\langle f, \psi_{1;j+\ell,k}\rangle|^2. \tag{4.15}$$

If $\{\psi_{1;j,k}\colon\ j,k \in \mathbb{Z}\}$ constitutes a frame of L^2, then there exists a positive constant B, such that

$$\sum_{j,k\in\mathbf{Z}} |\langle f, \psi_{1;j,k}\rangle|^2 \le B\|f\|^2.$$

Thus, combining this inequality with (4.15) gives

$$\sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} |\langle f, \psi_{n;j,k}\rangle|^2 \le 2^\ell D^{2\ell} B\|f\|^2. \tag{4.16}$$

Similarly, by letting

$$\widetilde{D}_\lambda := \max\left\{\sum_{k\in\mathbf{Z}} |g^\lambda_{2k}|, \sum_{k\in\mathbf{Z}} |g^\lambda_{2k+1}|\right\}, \qquad \widetilde{D} := \max\{\widetilde{D}_0, \widetilde{D}_1\} \tag{4.17}$$

and assuming that $\{\widetilde{\psi}_{1;j,k}\colon\ j,k \in \mathbb{Z}\}$ is a frame of L^2, we have

$$\sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} |\langle f, \widetilde{\psi}_{n;j,k}\rangle|^2 \le 2^\ell \widetilde{D}^{2\ell} \widetilde{B}\|f\|^2, \qquad f \in L^2 \tag{4.18}$$

for some positive constant $\widetilde{B}$.

To complete the proof of Theorem 6, we still have to derive the lower estimates. Now, since $L^2 = \sum^{\bullet}_{j\in\mathbf{Z}} W_{j+\ell}$, we can write, for any $f \in L^2$,

$$f = \sum_{j\in\mathbf{Z}} g_{j+\ell}, \qquad g_{j+\ell} \in W_{j+\ell}, \quad j \in \mathbb{Z}. \tag{4.19}$$

Moreover, from Theorem 3 as well as its proof, we have

$$g_{j+\ell} = \sum_{k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} \langle g_{j+\ell}, \widetilde{\psi}_{n;j,k}\rangle \psi_{n;j,k} = \sum_{k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} \langle f, \widetilde{\psi}_{n;j,k}\rangle \psi_{n;j,k}, \tag{4.20}$$

where $\langle f, \widetilde{\psi}_{n;j,k}\rangle = \langle g_{j+\ell}, \widetilde{\psi}_{n;j,k}\rangle$ follows from (4.19) and the fact that $g_{j'+\ell} \in W_{j'+\ell} \perp \widetilde{W}_{j+\ell}$ and $\widetilde{\psi}_{n;j,k} \in \widetilde{W}_{j+\ell}$ for $j' \ne j$ (see (4.3)). Thus, from (4.19) and (4.20), it follows that

$$f = \sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} \langle f, \widetilde{\psi}_{n;j,k}\rangle \psi_{n;j,k}, \qquad f \in L^2. \tag{4.21}$$

By the same argument, we also have

$$f = \sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} \langle f, \psi_{n;j,k}\rangle \widetilde{\psi}_{n;j,k}, \qquad f \in L^2. \tag{4.22}$$

Hence, by (2.31), (4.21), and (4.22), we obtain, for any $f \in L^2$,

$$\begin{aligned} \|f\|^2 = \langle f, f\rangle &= \sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} \langle f, \psi_{n;j,k}\rangle \overline{\langle f, \widetilde{\psi}_{n;j,k}\rangle} \\ &\le \left(\sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} |\langle f, \psi_{n;j,k}\rangle|^2\right)^{\frac{1}{2}} \left(\sum_{j,k\in\mathbf{Z}}\ \sum_{2^\ell\le n<2^{\ell+1}} |\langle f, \widetilde{\psi}_{n;j,k}\rangle|^2\right)^{\frac{1}{2}}. \end{aligned} \tag{4.23}$$

On the other hand, from (4.16), (4.18), and (4.23), we conclude that

$$\sum_{j,k\in\mathbb{Z}} \sum_{2^\ell \le n < 2^{\ell+1}} |\langle f, \psi_{n;j,k}\rangle|^2 \ge 2^{-\ell}\widetilde{D}^{-2\ell}\widetilde{B}^{-1}\|f\|^2, \tag{4.24}$$

and

$$\sum_{j,k\in\mathbb{Z}} \sum_{2^\ell \le n < 2^{\ell+1}} |\langle f, \widetilde{\psi}_{n;j,k}\rangle|^2 \ge 2^{-\ell}D^{-2\ell}B^{-1}\|f\|^2. \tag{4.25}$$

A combination of the inequalities (4.16), (4.18), (4.24), and (4.25) completes the proof of Theorem 6. □

5. Algorithms for wavelets packets. In this section, we will give two change-of-bases algorithms using wavelet packets.

Given a function $f \in L^2$, we approximate f on the scale 2^{-N} by some

$$f_N(x) := \sum_{j\in\mathbb{Z}} \bar{c}_j \psi_0(2^N x - j) = \langle\{\psi_0(2^N x - \cdot)\}, \mathbf{c}\rangle_{\ell^2} \tag{5.1}$$

in V_N, where $\mathbf{c} = \{c_j\}_{j\in\mathbb{Z}} \in \ell^2$. Thus, from the formula

$$\psi_k(2x - j) = \tfrac{1}{2}(\mathcal{G}_0^*\{\psi_{2k}(x - \cdot)\})_j + \tfrac{1}{2}(\mathcal{G}_1^*\{\psi_{2k+1}(x - \cdot)\})_j \tag{5.2}$$

(see (3.24)), where $j \in \mathbb{Z}$ and $k \in \mathbb{Z}_+$, we obtain

$$\begin{aligned} f_N(x) &= \frac{1}{2}\langle \mathcal{G}_0^*\{\psi_0(2^{N-1}x - \cdot)\}, \mathbf{c}\rangle_{\ell^2} + \frac{1}{2}\langle \mathcal{G}_1^*\{\psi_1(2^{N-1}x - \cdot)\}, \mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2}\langle \{\psi_0(2^{N-1}x - \cdot)\}, \mathcal{G}_0\mathbf{c}\rangle_{\ell^2} + \frac{1}{2}\langle \{\psi_1(2^{N-1}x - \cdot)\}, \mathcal{G}_1\mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2^2}\langle \mathcal{G}_0^*\{\psi_0(2^{N-2}x - \cdot)\}, \mathcal{G}_0\mathbf{c}\rangle_{\ell^2} + \frac{1}{2^2}\langle \mathcal{G}_1^*\{\psi_1(2^{N-2}x - \cdot)\}, \mathcal{G}_0\mathbf{c}\rangle_{\ell^2} \\ &\quad + \frac{1}{2^2}\langle \mathcal{G}_0^*\{\psi_2(2^{N-2}x - \cdot)\}, \mathcal{G}_1\mathbf{c}\rangle_{\ell^2} + \frac{1}{2^2}\langle \mathcal{G}_1^*\{\psi_3(2^{N-2}x - \cdot)\}, \mathcal{G}_1\mathbf{c}\rangle_{\ell^2} \\ &= \frac{1}{2^2}\langle \{\psi_0(2^{N-2}x - \cdot)\}, \mathcal{G}_0^2\mathbf{c}\rangle_{\ell^2} + \frac{1}{2^2}\langle \{\psi_1(2^{N-2}x - \cdot)\}, \mathcal{G}_1\mathcal{G}_0\mathbf{c}\rangle_{\ell^2} \\ &\quad + \frac{1}{2^2}\langle \{\psi_2(2^{N-2}x - \cdot)\}, \mathcal{G}_0\mathcal{G}_1\mathbf{c}\rangle_{\ell^2} + \frac{1}{2^2}\langle \{\psi_3(2^{N-2}x - \cdot)\}, \mathcal{G}_1^2\mathbf{c}\rangle_{\ell^2} \\ &= \dots, \end{aligned} \tag{5.3}$$

where the operators $\mathcal{G}_0$ and $\mathcal{G}_1$ are defined in (3.12). Finally we have, for $\ell = 1, 2, \dots, M$,

$$f_N(x) = \frac{1}{2^\ell}\sum_{k=0}^{2^\ell - 1} \langle \{\psi_k(2^{N-\ell}x - \cdot)\}, \mathcal{G}_{k,\ell}\mathbf{c}\rangle_{\ell^2}, \tag{5.4}$$

where for $k = \sum_{j=1}^{\ell} \varepsilon_j 2^{j-1}$, $\varepsilon_j \in \{0, 1\}$,

$$\mathcal{G}_{k,\ell} := \mathcal{G}_{\varepsilon_1}\mathcal{G}_{\varepsilon_2}\cdots\mathcal{G}_{\varepsilon_\ell}. \tag{5.5}$$

That is, f_N has the unique decomposition

$$f_N = \sum_{k=0}^{2^\ell-1} g_{k,\ell} \in \delta^{N-\ell} \sum_{0\le k<2^\ell}^{\bullet} U_k = V_N, \tag{5.6}$$

where $g_{k,l} := \frac{1}{2^\ell}\langle\{\psi_k(2^{N-\ell}x-\cdot)\},\, \mathcal{G}_{k,\ell}\mathbf{c}\rangle_{\ell^2} \in \delta^{N-\ell}U_k$. This decomposition algorithm can be expressed recursively as follows:

$$\mathbf{c}^{k,\ell} = \tfrac{1}{2}\mathcal{G}_{\lambda_k}\mathbf{c}^{\lfloor k/2\rfloor,\ell-1}, \quad \ell = 1,\dots,M; \quad k = 0,\dots,2^\ell-1, \tag{5.7}$$

where $\mathbf{c}^{0,0} := \mathbf{c}$, $\lambda_k \in \{0,1\}$, satisfies $k = 2\lfloor\frac{k}{2}\rfloor + \lambda_k$; i.e., $\lambda_k = 0$ for even k, and $\lambda_k = 1$ for odd k. The procedure can be described by the binary tree as shown in Fig. 2. Here,

$$f_N(x) = \langle\{\psi_0(2^Nx-\cdot)\},\mathbf{c}\rangle_{\ell^2} = \sum_{k=0}^{2^\ell-1}\langle\{\psi_k(2^{N-\ell}x-\cdot)\},\mathbf{c}^{k,\ell}\rangle_{\ell^2}, \tag{5.8}$$

where $\ell = 1,2,\dots,M$.

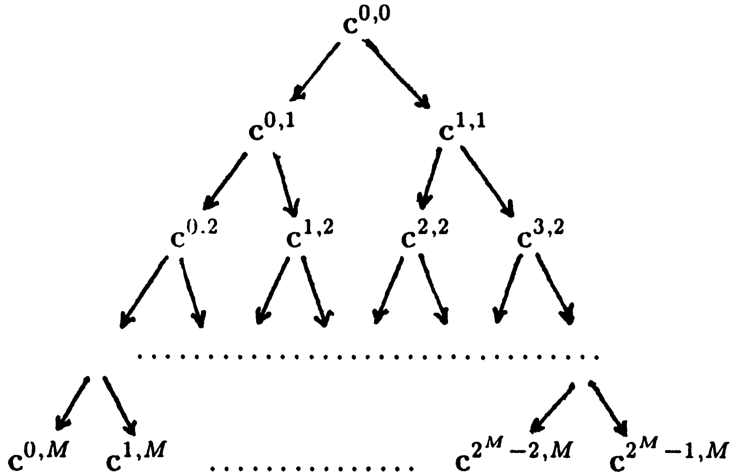


FIG. 2

On the other hand, for the reconstruction algorithm it follows from the representation (5.8) and the formula

$$\psi_k(x-j) = (\mathcal{P}_{\lambda_k}\{\psi_{\lfloor\frac{k}{2}\rfloor}(2x-\cdot)\})_j, \qquad j\in\mathbb{Z}, \tag{5.9}$$

where $\lambda_k\in\{0,1\}$ satisfies $k = 2\lfloor\frac{k}{2}\rfloor + \lambda_k$, that

$$\begin{aligned} f_N(x) &= \sum_{k=0}^{2^\ell-1}\langle\mathcal{P}_{\lambda_k}\{\psi_{\lfloor\frac{k}{2}\rfloor}(2^{N-\ell+1}x-\cdot)\},\mathbf{c}^{k,\ell}\rangle_{\ell^2} \\ &= \sum_{k=0}^{2^\ell-1}\langle\{\psi_{\lfloor\frac{k}{2}\rfloor}(2^{N-\ell+1}x-\cdot)\},\mathcal{P}^*_{\lambda_k}\mathbf{c}^{k,\ell}\rangle_{\ell^2} \\ &= \sum_{k=0}^{2^{\ell-1}-1}\langle\{\psi_k(2^{N-\ell+1}x-\cdot)\},\mathbf{c}^{k,\ell-1}\rangle_{\ell^2}, \end{aligned} \tag{5.10}$$

where

$$\mathbf{c}^{k,\ell-1} := \mathcal{P}_0^*\mathbf{c}^{2k,\ell} + \mathcal{P}_1^*\mathbf{c}^{2k+1,\ell}, \tag{5.11}$$

$\ell = M, M-1, \dots, 1$; $k = 0, 1, \dots, 2^{\ell-1}-1$, and the operators $\mathcal{P}_0^*$ and $\mathcal{P}_1^*$ are given in (3.13). Finally, for $\ell = 1$, we obtain

$$f_N(x) = \langle\{\psi_0(2^N x - \cdot)\}, \mathbf{c}^{0,0}\rangle_{\ell^2} = \langle\{\psi_0(2^N x - \cdot)\}, \mathbf{c}\rangle_{\ell^2}.$$

The procedure for the reconstruction algorithm can be described by the binary tree as shown in Fig. 3.

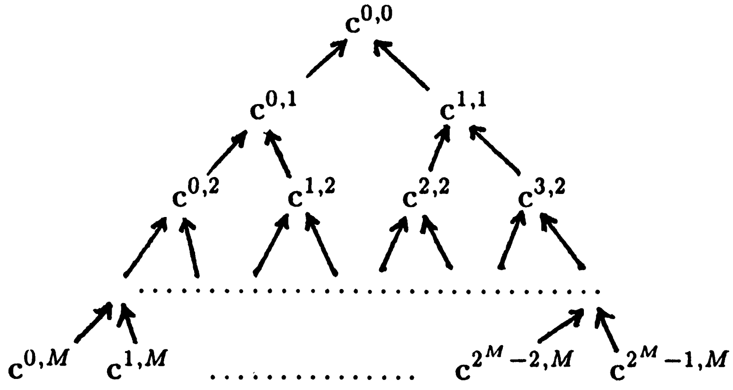

FIG. 3.

Both of the above decomposition and reconstruction algorithms are given relative to the wavelet packets $\{\psi_k\}$ and the decomposition

$$V_N = \delta^{N-\ell}\delta^{\ell}V_0 = \delta^{N-\ell}\overset{\bullet}{\sum_{0\le k<2^\ell}} U_k.$$

The computational complexity of these algorithms is $O(n\log n)$, where $n = 2^M$ is the number of operations for precomputing all the ψ_k, $k = 0, \dots, 2^M-1$. In the following we give another algorithms corresponding to Theorem 3.

Let $\ell \in \mathbb{Z}_+$ and $M \in \mathbb{Z}_+$ be fixed. As before, to a given $f \in L^2$, let f_N approximate f from V_N. Then since

$$V_N = W_{N-1}\dot{+}V_{N-1} = \cdots = W_{N-1}\dot{+}W_{N-2}\dot{+}\cdots\dot{+}W_{N-M}\dot{+}V_{N-M},$$

f_N has a unique decomposition

$$f_N = g_{N-1} + g_{N-2} + \cdots + g_{N-M} + f_{N-M}, \tag{5.12}$$

where $f_{N-M} \in V_{N-M}$ and $g_j \in W_j$, $j = N-M, \dots, N-1$. Write

$$f_j(x) = \sum_{k\in\mathbf{Z}} \overline{c_k^j}\psi_0(2^j x - k) = \langle\{\psi_0(2^j x - \cdot)\}, \mathbf{c}^j\rangle_{\ell^2},$$

and

$$g_j(x) = \sum_{k\in\mathbf{Z}} \overline{d_k^j}\psi_1(2^j x - k) = \langle\{\psi_1(2^j x - \cdot)\}, \mathbf{d}^j\rangle_{\ell^2},$$

where $\mathbf{c}^j = \{c_k^j\}_{k\in\mathbf{Z}} \in \ell^2$ and $\mathbf{d}^j = (d_k^j)_{k\in\mathbf{Z}} \in \ell^2$. From the decomposition formula (5.2), we have, for $k = 0$,

$$\begin{aligned} f_j(x) &= \left\langle \tfrac{1}{2}\mathcal{G}_0^*\{\psi_0(2^{j-1}x - \cdot)\}, \mathbf{c}^j \right\rangle_{\ell^2} + \left\langle \tfrac{1}{2}\mathcal{G}_1^*\{\psi_1(2^{j-1}x - \cdot)\}, \mathbf{c}^j \right\rangle_{\ell^2} \\ &= \left\langle \{\psi_0(2^{j-1}x - \cdot)\}, \tfrac{1}{2}\mathcal{G}_0\mathbf{c}^j \right\rangle_{\ell^2} + \left\langle \{\psi_1(2^{j-1}x - \cdot)\}, \tfrac{1}{2}\mathcal{G}_1\mathbf{c}^j \right\rangle_{\ell^2} \\ &= f_{j-1}(x) + g_{j-1}(x). \end{aligned} \tag{5.13}$$

Thus, it follows that

$$\mathbf{c}^{j-1} = \tfrac{1}{2}\mathcal{G}_0\mathbf{c}^j, \quad \mathbf{d}^{j-1} = \tfrac{1}{2}\mathcal{G}_1\mathbf{c}^j, \qquad j = N, N-1, \ldots, N-M+1. \tag{5.14}$$

This procedure is described by the graph in Fig. 4.

$$\begin{tikzcd} & \mathbf{d}^{N-1} & \mathbf{d}^{N-2} & & \mathbf{d}^{N-M} \\ \mathbf{c}^N \arrow[r] \arrow[ur] & \mathbf{c}^{N-1} \arrow[r] \arrow[ur] & \mathbf{c}^{N-2} \arrow[r] \arrow[ur] & \cdots \arrow[r] \arrow[ur] & \mathbf{c}^{N-M} \end{tikzcd}$$

FIG. 4

Moreover, since

$$g_j \in W_j = \delta^j W_1 = \delta^{j-\ell}\delta^\ell W_1 = \delta^{j-\ell} \dot{\sum_{2^\ell \le k < 2^{\ell+1}}} U_k,$$

then by applying the decomposition formula (5.2) again for $k = 1, 2, \ldots, 2^{\ell-1} - 1$, we have

$$\begin{aligned} g_j(x) &= \langle \{\psi_1(2^j - x\cdot)\}, \mathbf{d}^j \rangle_{\ell^2} \\ &= \frac{1}{2}\langle \mathcal{G}_0^*\{\psi_2(2^{j-1}x - \cdot)\}, \mathbf{d}^j \rangle_{\ell^2} + \frac{1}{2}\langle \mathcal{G}_1^*\{\psi_3(2^{j-1}x - \cdot)\}, \mathbf{d}^j \rangle_{\ell^2} \\ &= \frac{1}{2}\langle \{\psi_2(2^{j-1}x - \cdot)\}, \mathcal{G}_0\mathbf{d}^j \rangle_{\ell^2} + \frac{1}{2}\langle \{\psi_3(2^{j-1}x - \cdot)\}, \mathcal{G}_1\mathbf{d}^j \rangle_{\ell^2} \\ &= \cdots \\ &= \frac{1}{2^\ell} \sum_{k=2^\ell}^{2^{\ell+1}-1} \langle \{\psi_k(2^{j-\ell}x - \cdot)\}, \mathcal{G}_{k,\ell}\mathbf{d}^j \rangle_{\ell^2}, \end{aligned} \tag{5.15}$$

where the operator $\mathcal{G}_{k,\ell}$ is defined on ℓ^2 by (5.5). Writing

$$\mathbf{a}^{j,k,m} := \mathcal{G}_{k,m}\mathbf{d}^j, \qquad \mathbf{a}^{j,1,0} := \mathbf{d}^j, \tag{5.16}$$

we have, similar to (5.7), that

$$\mathbf{a}^{j,k,m} = \tfrac{1}{2}\mathcal{G}_{\lambda_k}\mathbf{a}^{j,\lfloor \frac{k}{2} \rfloor, m-1}, \tag{5.17}$$

where $m = 1, \ldots, \ell$, $k = 2^m, \ldots, 2^{m+1} - 1$, and $\lambda_k \in \{0, 1\}$, satisfying $k = 2\lfloor \frac{k}{2} \rfloor + \lambda_k$. Thus, we can finally conclude that

(5.18)

$$\begin{aligned} f_N(x) &= f_{N-M}(x) + \sum_{j=N-M}^{N-1} g_j(x) \\ &= \langle \{\psi_0(2^{N-M}x - \cdot)\}, \mathbf{c}^{N-M} \rangle_{\ell^2} + \sum_{j=N-M}^{N-1} \langle \{\psi_1(2^j x - \cdot)\}, \mathbf{d}^j \rangle_{\ell^2} \\ &= \langle \{\psi_0(2^{N-M}x - \cdot)\}, \mathbf{c}^{N-M} \rangle_{\ell^2} + \sum_{j=N-M}^{N-1} \sum_{2^\ell \le k < 2^{\ell+1}} \langle \{\psi_k(2^{j-\ell}x - \cdot)\}, \mathbf{a}^{j,k,\ell} \rangle_{\ell^2}, \end{aligned}$$

where $\mathbf{c}^{N-M}, \mathbf{d}^j$ and $\mathbf{a}^{j,k,\ell}$, $N-M \le j \le N-1$, $2^\ell \le k < 2^{\ell+1}$, are given by (5.14) and (5.17), respectively. This is the decomposition algorithm corresponding to Theorem 3.

On the other hand, if we start with

$$g_j(x) = \sum_{2^m \le k < 2^{m+1}} \langle \{\psi_k(2^{j-m}x - \cdot)\}, \mathbf{a}^{j,k,m} \rangle_{\ell^2}, \tag{5.19}$$

$m = \ell, \ell-1, \ldots, 1$, for some $\mathbf{a}^{j,k,m} \in \ell^2$; then by using (5.9) again, we obtain

$$\begin{aligned} g_j(x) &= \sum_{2^m \le k < 2^{m+1}} \langle \mathcal{P}_{\lambda_k}\{\psi_{\lfloor \frac{k}{2} \rfloor}(2^{j-m+1}x - \cdot)\}, \mathbf{a}^{j,k,m} \rangle_{\ell^2} \\ &= \sum_{2^m \le k < 2^{m+1}} \langle \{\psi_{\lfloor \frac{k}{2} \rfloor}(2^{j-m+1}x - \cdot)\}, \mathcal{P}^*_{\lambda_k}\mathbf{a}^{j,k,m} \rangle_{\ell^2} \\ &= \sum_{2^{m-1} \le k < 2^m} \langle \{\psi_k(2^{j-m+1}x - \cdot)\}, \mathbf{a}^{j,k,m-1} \rangle_{\ell^2}, \end{aligned}$$

where

$$\mathbf{a}^{j,k,m-1} := \mathcal{P}_0^*\mathbf{a}^{j,2k,m} + \mathcal{P}_1^*\mathbf{a}^{j,2k+1,m}, \tag{5.20}$$

$m = \ell, \ell-1, \ldots, 1$; $k = 2^{m-1}, \ldots, 2^m - 1$. Thus we obtain, for $N - M \le j \le N-1$,

$$g_j(x) = \langle \{\psi_1(2^j x - \cdot)\}, \mathbf{a}^{j,1,0} \rangle_{\ell^2} = \langle \{\psi_1(2^j x - \cdot)\}, \mathbf{d}^j \rangle_{\ell^2}. \tag{5.21}$$

With the above sequences $\mathbf{d}^j = \mathbf{a}^{j,1,0}$ and some $\mathbf{c}^{N-M} \in \ell^2$, where $f_{N-M}(x) = \langle \{\psi_0(2^{N-M}x - \cdot)\}, \mathbf{c}^{N-M} \rangle_{\ell^2}$, we can reconstruct $f_N(x) = \langle \{\psi_0(2^N x - \cdot)\}, \mathbf{c}^N \rangle_{\ell^2}$ by applying the formula

$$\mathbf{c}^j = \mathcal{P}_0^*\mathbf{c}^{j-1} + \mathcal{P}_1^*\mathbf{d}^{j-1}, \qquad j = N - M + 1, \ldots, N. \tag{5.22}$$

To see this, we simply observe that

$$\begin{aligned} \langle \{\psi_0(2^j x - \cdot)\}, \mathbf{c}^j \rangle_{\ell^2} &= f_j(x) = f_{j-1}(x) + g_{j-1}(x) \\ &= \langle \{\psi_0(2^{j-1}x - \cdot)\}, \mathbf{c}^{j-1} \rangle_{\ell^2} + \langle \{\psi_1(2^{j-1}x - \cdot)\}, \mathbf{d}^{j-1} \rangle_{\ell^2} \\ &= \langle \mathcal{P}_0\{\psi_0(2^j x - \cdot)\}, \mathbf{c}^{j-1} \rangle_{\ell^2} + \langle \mathcal{P}_1\{\psi_0(2^j x - \cdot)\}, \mathbf{d}^{j-1} \rangle_{\ell^2} \\ &= \langle \{\psi_0(2^j x - \cdot)\}, \mathcal{P}_0^*\mathbf{c}^{j-1} \rangle_{\ell^2} + \langle \{\psi_0(2^j x - \cdot)\}, \mathcal{P}_1^*\mathbf{d}^{j-1} \rangle_{\ell^2} \\ &= \langle \{\psi_0(2^j x - \cdot)\}, \mathcal{P}_0^*\mathbf{c}^{j-1} + \mathcal{P}_1^*\mathbf{d}^{j-1} \rangle_{\ell^2}. \end{aligned}$$

This procedure is described in Fig. 5.

$$\begin{tikzcd}
\mathbf{d}^{N-M} \arrow[dr] & \mathbf{d}^{N-M+1} \arrow[dr] & {} \arrow[dr] & \mathbf{d}^{N-1} \arrow[dr] & \\
\mathbf{c}^{N-M} \arrow[r] & \mathbf{c}^{N-M+1} \arrow[r] & \cdots \arrow[r] & \mathbf{c}^{N-1} \arrow[r] & \mathbf{c}^{N}
\end{tikzcd}$$

CONTINUOUS WAVELET DECOMPOSITIONS, MULTIRESOLUTION, AND CONTRAST ANALYSIS*

M. DUVAL-DESTIN†, M. A. MUSCHIETTI‡, AND B. TORRESANI§

Abstract. A continuous version of multiresolution analysis is described, starting from usual continuous wavelet decompositions. Scale discretization leads to decompositions into functions of arbitrary bandwidth, satisfying QMF-like conditions. Finally, a nonlinear multiresolution scheme is described, providing multiplicative reconstruction formulas.

Key words. wavelets, multiresolution analysis, contrast analysis

AMS subject classifications. 41A58, 42C15, 44A05, 44A35

Introduction. Wavelet analysis of a function $f \in L^2(I\!R)$ basically consists in the decomposition of f as a sum of wavelets $\psi_{(b,a)}(x) = \frac{1}{a}\,\psi\left(\frac{x-b}{a}\right)$, dilated and translated copies of the mother wavelet ψ, an integrable function with vanishing integral. The coefficients of the decomposition are nothing but the scalar products $\langle f, \psi_{(b,a)}\rangle$.

Continuous wavelet decompositions have been introduced (or reintroduced, since similar tools have been used by mathematicians for a long time to study certain classes of operators [Cal]) by Grossmann and Morlet [Gr-Mo], and many applications have been developed (see [Co-Gr-Tc] and the references therein), in particular in a signal analysis context [Gr-KM-Mo], [De]. The discretization of the continuous formulas was studied later [Da1], and handled by the introducion of the notion of frames of wavelets (see also [He-Wa]). Continuous wavelets and frames of wavelets were used later on for many problems of applied mathematics and physics, and in particular to model physiology of vision, following the program of Marr [Mar] (see also [Fr-Mo], [DD]). In particular, they allowed one of the authors to introduce the notion of scale-space contrast [DD], and to exhibit multiplicative reconstruction formulas from the contrast functions.

The discovery of orthonormal bases of wavelets by Stromberg [Str] and Meyer and his collaborators (see [Me] and the references therein) opened a new door in the understanding of the theory, making, in particular, the connection with subband coding, familiar to electrical engineers and image processors [Da2]. This, moreover, led to the construction of a large family (a library in the author's terminology) of orthonormal bases, called wavelet packets bases, providing adaptive decompositions of functions directly implementable in fast (pyramidal) algorithms [Co-M-Q-W]. A continuous analogue of wavelet packets was proposed in [To1], [To2], in which the pyramidal algorithmic structure is unfortunately lost. The key point of the construction of wavelet packets is that they allow us to control the relative bandwidth of the analyzing functions in the Fourier space (the so-called surtension factor), as a function of frequency.

We present here a general construction, allowing the construction of wavelet packets starting from the usual continuous wavelet analysis. By wavelet packets we mean families of functions generated from a single one by simple transformations and whose relative bandwidth is nonconstant (contrary to usual wavelets) and can be matched to a given analyzed function. Let us stress here that our construction is *not* a continuous version of that of [Co-M-Q-W], and is actually quite different. Starting from an admissible analyzing wavelet ψ, it is well known that one can associate with it a scaling function ϕ, and then mimic the multiresolution construction. This is briefly described in §1. In a similar way, the continuous decomposition over scales can be replaced by a discrete one, as shown in §2. The corresponding sequence of scale parameters can be chosen arbitrarily, and the functions appearing in the decomposition (the wavelet packets) must be matched to that sequence. As a particular case, a geometric sequence yields usual Littlewood–Paley decompositions. In §3 we continue developing the analogy between continuous wavelet analysis and multiresolution analysis. In particular, the scaling function can be expressed as a *continuous* infinite product of dilated copies of a low-pass filter, denoted by μ_0 (let us recall that a continuous product, or multiplicative integral $\prod_a^b (d\mu(x))\, f(x)$ is defined to equal $\exp[\int_a^b \ln f(x)\, d\mu(x)]$ whenever such an expression makes sense [Gui]). Then using the wavelet packets construction, a continuous finite product of such μ_0 filters yields new low-pass filters, denoted by m_0, which makes the connection with the quadrature mirror filters (QMFs) appearing in multiresolution analysis. Section 4 is devoted to the construction of contrast analysis. We define the infinitesimal contrast function $c_a(x)$ of $f(x)$ as (roughly speaking) the quotient of the details of $f(x)$ at scale a by the approximation of $f(x)$ at scale a. Then under some analyticity assumptions on $|\hat{\phi}|^2$, we show that such contrast functions provide a multiplicative decomposition of $f(x)$ over scales. Otherwise stated, $f(x)$ can be continuously factorized into exponentials of contrast functions. Such continuous product formulas can be discretized in the same way as in §3, yielding very simple factorization formulas, still interpretable in terms of the integrated contrast functions introduced in [DD]. This procedure is closely connected to models of human vision [DD], [Me-DD-Ge] in which the emphasis is put on multiresolution image processing and logarithmic light sensitivity.

1. Infinitesimal multiresolution analysis of $L^2(\mathbb{R})$.

1.1. Bilinear analysis. Let us start from standard notions of continuous wavelet analysis. (Throughout this paper, our conventions for Hermitian product and Fourier transform in $L^2(\mathbb{R})$ are the following ones: $\langle f, g\rangle = \int f(x)g(x)^*\, dx$, where the star denotes complex conjugation and $\hat{f}(\xi) = \langle f, \epsilon_\xi\rangle$, where $\epsilon_\xi(x) = \exp(i\xi x)$.) We will focus on the analysis of $L^2(\mathbb{R})$, and sometimes describe in a few words the corresponding results in the $H^2(\mathbb{R})$ context (we will denote here by $H^2(\mathbb{R}) = \{f \in L^2(\mathbb{R}), \hat{f}(\xi) = 0 \text{ for all } \xi \leq 0\}$ the complex Hardy space).

Generically, a *wavelet* (or mother wavelet) is a function $\psi \in L^1(\mathbb{R})$ such that the following admissibility condition holds:

$$c_\psi = \int_0^\infty \left|\hat{\psi}(u)\right|^2 \frac{du}{u} = \int_0^\infty \left|\hat{\psi}(-u)\right|^2 \frac{du}{u} = 1. \tag{1.1}$$

If $\hat{\psi}$ is differentiable, (1.1) basically means that $\hat{\psi}(0) = 0$, otherwise stated as

$$\int_{-\infty}^{\infty} \psi(x)\, dx = 0.$$

Such a mother wavelet provides the following analysis of $L^2(\mathbb{R})$: for any $(b,a) \in \mathbb{R} \times \mathbb{R}_+^*$, we introduce the wavelet

$$\psi_{(b,a)}(x) = \frac{1}{a}\,\psi\left(\frac{x-b}{a}\right), \tag{1.2}$$

and we have the following.

THEOREM 1. *Let ψ be a mother wavelet. Then any $f \in L^2(\mathbb{R})$ decomposes as follows*:

$$f = \int_{\mathbb{R}\times\mathbb{R}_+^*} \langle f, \psi_{(b,a)}\rangle\, \psi_{(b,a)}\, \frac{db\,da}{a} \tag{1.3}$$

strongly in $L^2(\mathbb{R})$.

Proof. The proof follows from standard arguments, and we sketch it for completeness. Let

$$T_f(b,a) = \langle f, \psi_{(b,a)}\rangle.$$

Then $T_f \in L^2(\mathbb{R}, db)$ by Young's convolution inequality. Define

$$d_a(x) = \int_{\mathbb{R}} T_f(b,a)\, \psi_{(b,a)}(x)\, db. \tag{1.4}$$

Again, Young's inequality ensures that $d_a \in L^2(\mathbb{R})$ for any $a \in \mathbb{R}_+^*$. Moreover, setting

$$s_\varepsilon^\rho(x) = \int_\varepsilon^\rho d_a(x)\, \frac{da}{a}\ , \tag{1.5}$$

we have that $s_\varepsilon^\rho \in L^2(\mathbb{R})$ and $|\hat{s_\varepsilon^\rho}(\xi)| < |\hat{f}(\xi)|$ almost everywhere, so that the Lebesgue dominated convergence theorem implies that

$$\lim_{\varepsilon\to 0,\rho\to\infty} ||f - s_\varepsilon^\rho||_2 = 0, \tag{1.6}$$

yielding the theorem.

Theorem 1 has been known for a long time by mathematicians as Calderón's identity [Cal], [Fr-Ja-We]. It was rediscovered more recently in a signal analysis context by Grossmann and Morlet [Gr-Mo], and interpreted as follows: $T_f \in L^2(\mathbb{R} \times \mathbb{R}_+^*)$ is called the wavelet transform of f with respect to the analyzing wavelet ψ. If ψ is sufficiently well localized in time and frequency (i.e., both ψ and $\hat{\psi}$ have sufficient decay at infinity), T_f gives information on the time-frequency localization of f. Conversely, (1.3) states that the wavelet transform is invertible on its range, allowing the reconstruction of the analyzed function from its wavelet transform.

If we restrict to the Hardy space $H^2(\mathbb{R})$, a weaker admissibility condition (concerning only the positive frequency part of ψ) is sufficient. Simply assuming that

$$c_\psi = \int_0^\infty \left|\hat{\psi}(u)\right|^2 \frac{du}{u} = 1,$$

Theorem 1 holds for any $f \in H^2(\mathbb{R})$.

We will need in the sequel a somewhat stronger assumption. We will call ψ an *infinitesimal wavelet* if ψ is a *real-valued* wavelet, belonging to the atomic Hardy space $H^1_a(I\!R)$. $H^1_a(I\!R)$ is the space of the functions of $L^1(I\!R)$ such that their Hilbert transform (we recall that the Hilbert transform $H.f$ of a function f can be defined in the Fourier space as $\widehat{H}.f(\xi) = -i\,\mathrm{sgn}(\xi)\hat{f}(\xi))$ is also in $L^1(I\!R)$ (see [Co-We] for a detailed account of the theory of real Hardy spaces).

Let then $\psi(x)$ be an infinitesimal wavelet, and let $q(x)$ be its autocorrelation function:

$$q(x) = \int_{-\infty}^{\infty} \psi(y)\psi(x+y)\, dy. \tag{1.7}$$

Clearly $q \in H^1_a(I\!R)$, and we easily check that

$$\int_0^{\infty} q(x)\, dx = \int_{-\infty}^{0} q(x)\, dx = 0. \tag{1.8}$$

Let

$$\begin{aligned} p(x) &= \frac{1}{x} \int_0^x q(y)\, dy, \qquad x > 0 \\ &= -\frac{1}{x} \int_x^0 q(y)\, dy, \qquad x < 0 \end{aligned} \tag{1.9}$$

denote the mean function of $q(x)$. We also have

$$\hat{p}(\xi) = \int_1^{\infty} |\hat{\psi}(t\xi)|^2 \frac{dt}{t}\ .$$

We will also denote $p_a(x) = \frac{1}{a} p\left(\frac{x}{a}\right)$.

LEMMA. $p \in L^1(I\!R)$.

Proof. Let q^+ (respectively, q^-) denote the restriction of q to the positive (respectively, negative) real axis. Since $q^+ \in H^1_a(I\!R)$, $q^+(x)$ admits an atomic decomposition with $(1,\infty)$-atoms,

$$q^+(x) = \sum_n \lambda_n^+ a_n^+(x), \tag{1.10}$$

where

$$\sum_n |\lambda_n^+| < \infty, \tag{1.11}$$

and the $(1,\infty)$-atoms $a_n^+(x)$ are compactly supported L^1-functions with support in an interval I_n^+, such that

$$\int a_n^+(x)\, dx = 0$$

and

$$||a_n^+||_\infty \leq \frac{1}{|I_n^+|}\ .$$

Moreover, such a decomposition is not unique, and (because of (1.8)) can be chosen in such a way that $I_n^+ \subset I\!R^+$. Indeed, if $q^+(x) = \sum_n \lambda_n^+ a_n^+(x)$ is an atomic decomposition of $q^+(x)$ with $(1,\infty)$-atoms $a_n^+(x)$, then it also admits an atomic decomposition $q^+(x) = \sum_n \lambda_n^+ b_n^+(x)$, where $b_n^+(x) = [a_n^+(x) + a_n^+(-x)]\chi^+(x)$ are also $(1,\infty)$-atoms, supported on the positive real axis (here $\chi^+(x)$ is the Heaviside step function). A similar property obviously holds for q^-. We then assume from now on that $\mathrm{Supp}(a_n^\pm) \subset I\!R^\pm$. Denote $p_n^+(x) = \frac{1}{x}\int_0^x a_n^+ \, dy(y)$ and $p_n^-(x) = -\frac{1}{x}\int_x^0 a_n^-(y)\, dy$. Then

$$\text{(1.12)} \qquad ||p||_1 \le \sum_n (|\lambda_n^+|\, ||p_n^+||_1 + |\lambda_n^-|\, ||p_n^-||_1),$$

so that $||p||_1 < \infty$ if the $||p_n^\pm||_1$ are uniformly bounded. Now consider for instance p_n^+, and let $I_n^+ = [a,b]$. Then,

$$\text{(1.13)} \qquad \begin{aligned} ||p_n||_1 &\le \frac{1}{b-a}\left[\int_a^{\frac{a+b}{2}} \frac{x-a}{x}\, dx + \int_{\frac{a+b}{2}}^b \frac{b-x}{x}\, dx\right] \\ &\le \frac{1}{b-a}\left[a \ln\frac{2a}{a+b} + b \ln\frac{2b}{a+b}\right], \end{aligned}$$

which yields the desired result. The lemma is then proved.

Then $0 \le \hat{p}(\xi) < \infty$. Let ϕ be such that

$$\text{(1.14)} \qquad \hat{p}(\xi) = \left|\hat{\phi}(\xi)\right|^2 = \int_{|\xi|}^\infty \left|\hat{\psi}(u\,\mathrm{sgn}(\xi))\right|^2 \frac{du}{u}.$$

In other words, $|\hat{\psi}(u\xi)|^2 = -u\,\partial_u|\hat{\phi}(u\xi)|^2$ for all $\xi \in I\!R$, and $\lim_{\xi\to\infty}|\hat{\phi}(\xi)|^2 = 0$. ϕ is called a *scaling function*, and we associate to it the corresponding

$$\text{(1.15)} \qquad \phi_{(b,a)}(x) = \frac{1}{a}\,\phi\left(\frac{x-b}{a}\right).$$

We will see in §3 that $\phi(x)$ satisfies some kind of scaling equation (see (3.7)), and that infinite product formulas for $\hat{\phi}(\xi)$ can be obtained (3.5). Clearly, (1.14) does not characterize ϕ; although it is in general unnecessary, one can always restrict to a real-valued $\hat{\phi}$. Notice that the squared modulus of the Fourier transform of the scaling function is by construction a decreasing (respectively, increasing) function for positive (respectively, negative) values of ξ.

To any $f \in L^2(I\!R)$ associate

$$\text{(1.16)} \qquad s_a(x) = \int_{I\!R} \langle f, \phi_{(b,a)}\rangle \phi_{(b,a)}(x)\, db,$$

that is,

$$s_a(x) = \int_a^\infty d_u(x)\,\frac{du}{u} = (f * p_a)(x).$$

Then $s_a \in L^2(I\!R)$, and we have the following decompositions, whose proofs are immediate from that of Theorem 1.

COROLLARY. *Let ψ be an infinitesimal wavelet, and ϕ an associated scaling function. Then any $f \in L^2(I\!R)$ can be expressed as*

$$\text{(1.17)} \qquad f = \lim_{a\to 0} s_a$$

$$= s_{a_0} + \int_0^{a_0} d_a \frac{da}{a} \tag{1.18}$$

strongly in $L^2(\mathbb{R})$.

The corollary also holds in the $H^2(\mathbb{R})$ context.

In terms of linear filtering, ϕ can be seen as a low-pass filter, and ψ as a band-pass filter. Indeed, it is usual to consider analyzing wavelets such that $\hat{\psi}(\xi)$ is well localized in the Fourier domain around some frequency ω_0. Then $\hat{\psi}(t\xi)$ is localized around $\xi \cong \omega_0/t$, and $\hat{p}(\xi)$ (and $\hat{\phi}(\xi)$), built by "gluing together the $|\hat{\psi}(t\xi)|^2, t \in [1, \infty[$" is centered on the zero frequency. Then s_a describes the low-frequency content of f up to the scale a (otherwise stated as the approximation at scale a), and d_a describes the content of f around the scale a (i.e., the details at scale a).

Denote now by Q_a and P_a the convolution operators, defined, respectively, by the multipliers $\hat{q}_a(\xi) = |\hat{\psi}(a\xi)|^2$ and $\hat{p}_a(\xi) = |\hat{\phi}(a\xi)|^2$:

$$\left[\widehat{Q_a f}\right](\xi) = \hat{q}_a(\xi)\hat{f}(\xi) = \hat{d}_a(\xi), \tag{1.19}$$

$$\left[\widehat{P_a f}\right](\xi) = \hat{p}_a(\xi)\hat{f}(\xi) = \hat{s}_a(\xi). \tag{1.20}$$

The previous corollary then yields an approximation of the identity by the operators Q_a and P_a. If we introduce the spaces

$$V_{(a)} = P_a.L^2(\mathbb{R}),$$

then it clearly follows from the monotonicity of $|\hat{\phi}|$ that for any $a < a'$, $V_{(a')} \subseteq V_{(a)}$. By analogy with the usual multiresolution analysis [Me], we call such a collection of spaces a continuous (or infinitesimal) multiresolution analysis. In particular, it must be remarked that $V_{(a)}$ increases to the whole $L^2(\mathbb{R})$ as $a \to 0$ and decreases to $\{0\}$ as $a \to \infty$. Notice that all the $V_{(a)}$ spaces are translation invariant; then they are not closed, except in the case where $|\hat{\phi}| = \chi_\Omega \rho$, where χ_Ω is the characteristic function of some measurable set Ω and ρ a bounded strictly positive function (see, e.g., [Ru]).

1.2. Linear analysis. It is well known that the reconstructing and the analyzing wavelets can be decoupled. Otherwise stated one can use different infinitesimal wavelets for the computation of the coefficients and for the synthesis of the analyzed function from the coefficients (see [Ho-Tc], [Ho] for beautiful applications of this property in different contexts). In such a case, the admissibility condition (1.1) has to be modified accordingly [Ho-Tc]. A particular example of such a decoupling, which has been known for a long time, consists in taking formally a Dirac distribution for the reconstructing wavelet. Assuming instead of (1.1) that

$$k_\psi = \int_0^\infty \hat{\psi}(u) \frac{du}{u} = \int_0^\infty \hat{\psi}(-u) \frac{du}{u} = 1, \tag{1.21}$$

we have the following decomposition of any $f \in L^2(\mathbb{R})$:

$$f(x) = \int_{\mathbb{R}_+^*} \langle f, \psi_{(x,a)} \rangle \frac{da}{a} \tag{1.22}$$

strongly in $L^2(\mathbb{R})$. This is the so-called Morlet reconstruction formula of f from its wavelet coefficients. Such a linear analysis (linear in the ψ function) generates a continuous multiresolution analysis as follows: introduce the *linear scaling function* $\varphi \in L^1(\mathbb{R})$, defined by

$$\hat{\varphi}(\xi) = \int_{|\xi|}^{\infty} \hat{\psi}(u\,\mathrm{sgn}(\xi))\,\frac{du}{u}. \tag{1.23}$$

φ is also such that $\hat{\psi}(u\xi) = -u\,\partial_u\hat{\varphi}(u\xi)$ for all $\xi \in \mathbb{R}$. Associate to φ the following functions:

$$\varphi_{(b,a)}(x) = \frac{1}{a}\,\varphi\left(\frac{x-b}{a}\right). \tag{1.24}$$

Finally, introduce

$$\delta_a(x) = T_f(x,a) = \langle f, \psi_{(x,a)}\rangle \tag{1.25}$$

and

$$\sigma_a(x) = \langle f, \varphi_{(x,a)}\rangle. \tag{1.26}$$

We then have the linear analogue of Theorem 1 and the corresponding corollary.

THEOREM 1′. *Let $\psi \in H^1_a(\mathbb{R})$ be a mother wavelet, such that* (1.21) *holds, and let φ be the associated linear scaling function. Then any $f \in L^2(\mathbb{R})$ can be decomposed as*

$$\begin{aligned} f &= \lim_{a\to 0} \sigma_a && (1.27)\\ &= \sigma_{a_0} + \int_0^{a_0} \delta_a\,\frac{da}{a}, \qquad a_0 \in \mathbb{R}^*_+ && (1.28)\\ &= \int_0^{\infty} \delta_a\,\frac{da}{a} && (1.29)\end{aligned}$$

strongly in $L^2(\mathbb{R})$.

1.3. Comments and examples. The bilinear analysis gives the convenient scheme for the construction of orthonormal bases of wavelets [Me], [Da2]. Moreover, it is better adapted for the characterization of functional spaces (see, e.g., [Fr-Ja-We], [Ho-Tc]). On the other hand, the linear analysis is very often used for signal analysis [Gr-KM-Mo], since it produces a simplified reconstruction formula, involving a one-dimensional integral.

There are many examples of admissible infinitesimal wavelets, some of which are described in [Gr-Mo] and [Gr-KM-Mo]. Actually, the simplest one arises quite naturally from infinitesimal multiresolution analysis. Indeed, let us take a Gaussian scaling function:

$$\phi(x) = \frac{1}{\sqrt{\pi}}\,e^{-x^2},$$

where the normalization constant is fixed so that (1.1) holds. Then in the bilinear analysis scheme, the infinitesimal wavelets can be deduced from (1.7), and we can choose

$$\psi(x) = \frac{2x}{\sqrt{\pi}}\,e^{-x^2},$$

i.e., a derivative of Gaussian. The case of linear analysis yields a more famous infinitesimal wavelet. Taking for φ a Gaussian function leads to the celebrated Laplacian of Gaussian, used for a long time in image analysis and processing, and vision (see, e.g., [DD], [Mar]):

$$\psi(x) = \frac{1}{\sqrt{\pi}} \, (1 - 2x^2) \, e^{-x^2}.$$

In the next section, we will see how such derivatives of Gaussians simply lead to differences of Gaussians, which are also used in image theory and vision.

2. Wavelet packets in $L^2(I\!R)$. An important problem is that of the discretization of the continuous formulas derived in §1. At least for numerical applications, we want to be able to get discrete approximations of the identity in $L^2(I\!R)$, and to control the discretization error. Such a problem was handled in [Dal], where the author developed the theory of frames of wavelets. In particular, focusing on the scale discretization problem: if $\Lambda = \{a_0\lambda_0^n, n \in Z\!\!Z\}$ denotes a geometric sequence in $I\!R$, for some positive λ_0, then $\sum_{\lambda\in\Lambda} Q_\lambda$ defines a linear operator, which is positive, bounded, and invertible with bounded inverse for a suitable choice of the λ_0 parameter and the infinitesimal wavelet ψ. Moreover, this operator can often be written as a small perturbation of the identity (up to some multiplicative constant), which permits us to consider the discretization as a good approximation of the continuous formula.

We are interested here in another way of discretizing the scales, such that the discretization errors are avoided. Such a procedure canonically produces new waveforms that we will call wavelet packets. Start from a strictly decreasing sequence of positive real numbers:

$$\cdots < a_{j+1} < a_j < a_{j-1} < \cdots$$

such that $\lim_{j\to-\infty} a_j = \infty$ and $\lim_{j\to+\infty} a_j = 0$.

Set

$$D_j(x) = \int_{a_{j+1}}^{a_j} d_a(x) \, \frac{da}{a} \, . \tag{2.1}$$

Then $D_j \in L^2(I\!R)$, and

$$\widehat{D_j}(\xi) = \hat{f}(\xi) \int_{a_{j+1}}^{a_j} \left|\hat{\psi}(a\xi)\right|^2 \frac{da}{a} \quad \text{almost everywhere.} \tag{2.2}$$

Introducing the function Ψ^j, such that

$$\left|\widehat{\Psi^j}(\xi)\right|^2 = \int_{a_{j+1}}^{a_j} \left|\hat{\psi}(a\xi)\right|^2 \frac{da}{a}, \tag{2.3}$$

we then have

$$\widehat{D_j}(\xi) = \hat{f}(\xi) \, \left|\widehat{\Psi^j}(\xi)\right|^2 . \tag{2.4}$$

We will refer to the Ψ^j functions as *wavelet packets*, since they are built up by gluing wavelets together (in the Fourier space, contrary to the case of those described in [Co-M-Q-W]). Such wavelet packets are also intuitively close to the atoms introduced in Littlewood–Paley theory (see, e.g., [Fr-Ja-We]), obtained via a segmentation of Calderón's formula (1.3) into integrals over dyadic cubes. In our case, the wavelet packets are obtained by a segmentation of (1.3) into integrals over strips in the time-scale plane. The result then is that the atoms are generated in a simple way. Notice that (2.3) does not completely define the wavelet packets. Once again, we can restrict to wavelet packets with positive-valued Fourier transform, but this is not necessary. By construction, the wavelet packets lead to a partition of unity in the Fourier space as follows:

$$\sum_{j=-\infty}^{+\infty} \left|\widehat{\Psi^j}(\xi)\right|^2 = \left|\widehat{\Phi^{j_0}}(\xi)\right|^2 + \sum_{j=j_0}^{\infty} \left|\widehat{\Psi^j}(\xi)\right|^2 = 1 \tag{2.5}$$

for all $\xi \in I\!R$, where we have set

$$\widehat{\Phi^j}(\xi) = \hat{\phi}(a_j\xi). \tag{2.6}$$

Defining the translates of the Φ^j and Ψ^j as $\Phi^j_b(x) = \Phi^j(x-b)$ and $\Psi^j_b(x) = \Psi^j(x-b)$, we then have the following.

THEOREM 2. *Let ψ be an infinitesimal wavelet, and let Ψ^j and Φ^j be associated wavelet packets and scaling functions as in* (2.3) *and* (2.6). *Then any $f \in L^2(I\!R)$ can be decomposed as*

$$f = \int_{I\!R} \langle f, \Phi^{j_0}_b\rangle\, \Phi^{j_0}_b\, db + \sum_{j=j_0}^{\infty} \int_{I\!R} \langle f, \Psi^j_b\rangle\, \Psi^j_b\, db \tag{2.7}$$

strongly in $L^2(I\!R)$.

Denote by $\mathbf{Q}_j$ the convolution operator, defined by the multiplier $|\widehat{\Psi^j}(\xi)|^2$, and set $\mathbf{P}_j = P_{a_j}$. Let V_j and W_j denote, respectively, the images of $L^2(I\!R)$ by $\mathbf{P}_j$ and $\mathbf{Q}_j$. This provides the following resolution of $L^2(I\!R)$:

$$\cdots \subset V_{j-1} \subset V_j \subset V_{j+1} \subset \cdots. \tag{2.8}$$

Again, it must be remarked that V_j increases to the whole $L^2(I\!R)$ as $j \to \infty$ and decreases to $\{0\}$ as $j \to -\infty$. Moreover, $V_j + W_j = V_{j+1}$, but in general $V_i \not\perp W_i$.

Remarks. The wavelet packets have vanishing integral by construction. Moreover, they can be seen as differences of two low-pass filters. Indeed, we have

$$\left|\widehat{\Psi^j}(\xi)\right|^2 = \left|\widehat{\Phi^{j+1}}(\xi)\right|^2 - \left|\widehat{\Phi^j}(\xi)\right|^2 \tag{2.9}$$

and the partial reconstructions

$$D^j(x) = \int_{I\!R} \langle f, \Psi^j_b\rangle\, \Psi^j_b(x)\, db \tag{2.10}$$

as differences of two smoothings of $f(x)$ at two consecutive scales:

$$D^j(x) = S^{j+1}(x) - S^j(x), \tag{2.11}$$

where

$$S^j(x) = \int_{I\!R} \langle f, \Phi^j_b\rangle\, \Phi^j_b(x)\, db. \tag{2.12}$$

Once more, we are close to the idea of the "difference of two smoothings" wavelet familiar in vision theory.

The same can be done in the linear analysis scheme. The wavelet packets are then defined as

$$\widehat{\Theta^j}(\xi) = \int_{a_{j+1}}^{a_j} \hat{\psi}(a\xi)\,\frac{da}{a} \tag{2.13}$$

and yield a partition of unity in the Fourier space:

$$\sum_{j=-\infty}^{+\infty} \widehat{\Theta^j}(\xi) = \hat{\varphi}(a_{j_0}\xi) + \sum_{j=j_0}^{\infty} \widehat{\Theta^j}(\xi) = 1. \tag{2.14}$$

The linear wavelet packets still appear as differences of smoothings at two consecutive scales, as

$$\widehat{\Theta^j}(\xi) = \hat{\varphi}(a_{j+1}\xi) - \hat{\varphi}(a_j\xi) \tag{2.15}$$

and every $f \in L^2(I\!R)$ decomposes as

$$f(x) = \sum_{j=-\infty}^{\infty} \langle f, \Theta^j_x \rangle, \tag{2.16}$$

where $\Theta^j_b(x) = \Theta^j(x-b)$.

The Gaussian example is once more very interesting, since it provides directly the DOGs, i.e., the differences of Gaussians at two different scales (see, e.g., [Mar]).

Consider the particular case where all the scale parameters a_j are generated from a unique one a_0 as a geometric sequence:

$$a_j = a_0\lambda^{-j}$$

for some positive real number $\lambda > 1$. Then the wavelet packets Ψ^j (and also the Θ^j) can be considered as wavelets in the usual sense, since they are generated from a unique function Ψ^0 (or Θ^0) by dilations by powers of λ. In particular, the bilinear analysis yields the usual Littlewood–Paley analysis (also called dyadic wavelet analysis in [Ma]).

Finally, let us stress that although we have chosen to use the term "Wavelet Packets," our construction is completely different than the wavelet packets construction proposed in [Co-M-Q-W]. Both constructions share the fact that the corresponding functions are of variable bandwidth, and that the bandwidth can be matched to a function to be analyzed.

3. Mirror filters and factorizable wavelet packets.

3.1. Mirror filters. The orthonormal bases of wavelet packets described, for example, in [Co-M-Q-W] are derived in a very simple algorithmic way from the so-called Quadrature Mirror Filters (QMFs), canonically associated with the multiresolution analysis. We will see in this section how infinitesimal multiresolution analysis can produce continuous versions of such filters, and how these infinitesimal filters can be put together to form QMFs for the wavelet packets. Let us start from the bilinear infinitesimal multiresolution analysis (the same arguments can be developed in the linear analysis scheme, too), with scaling function ϕ. If $|\hat{\phi}(a\xi)| \neq 0$, it follows from the monotonicity property of $|\hat{\phi}|$ that a determination of the complex logarithm $\ln\hat{\phi}(u\xi)$ can always be chosen for $0 \leq u \leq a$, so that the function

$$\nu_0(a\xi) = a\partial_a \ln\hat{\phi}(a\xi) \quad \forall a, \xi \quad \text{such that } \hat{\phi}(a\xi) \neq 0 \tag{3.1}$$

can be introduced. Then clearly

$$\ln\hat{\phi}(a\xi) = \int_0^a \nu_0(u\xi)\,\frac{du}{u} \tag{3.2}$$

and

$$\hat{\phi}(\xi) = \exp\left[\int_0^1 \nu_0(u\xi)\,\frac{du}{u}\right]. \tag{3.3}$$

Such a formula can be thought of as a continuous multiplicative formula, interpreting the exponential of the integral as a continuous product of exponentials. Indeed, setting

$$\mu_0(\xi) = e^{\nu_0(\xi)}, \tag{3.4}$$

we can write the Fourier transform of the scaling function as

$$\hat{\phi}(\xi) = \prod_{u=0}^{1}\left(\frac{du}{u}\right)\,\mu_0(u\xi), \tag{3.5}$$

the continuous product $\prod_{u=0}^{1}\left(\frac{du}{u}\right)$ with respect to the logarithmic measure $\frac{du}{u}$ being defined by the right-hand side of (3.3).

For ξ such that $\hat{\phi}(a\xi) \neq 0$, introduce now the functions $m_0^j(\xi)$, called the *integrated filters*:

$$m_0^j(\xi) = \prod_{u=a_{j+1}}^{a_j}\left(\frac{du}{u}\right)\,\mu_0(u\xi). \tag{3.6}$$

Such functions allow a discretization of the continuous product formula (3.5), and make the connection with the structure appearing in the usual multiresolution context. The Fourier transform of the scaling functions can be written as

$$\hat{\phi}(a_j\xi) = m_0^j(\xi)\hat{\phi}(a_{j+1}\xi). \tag{3.7}$$

Notice that this expression, together with the monotonicity of $|\hat{\phi}|$, can be used to define $m_0^j(\xi)$, according to

$$m_0^j(\xi) = \begin{cases} \frac{\hat{\phi}(a_j\xi)}{\hat{\phi}(a_{j+1}\xi)} \quad \forall\,\xi \quad \text{such that } \hat{\phi}(a_{j+1}\xi) \neq 0, \\ 0 \quad \forall\,\xi \quad \text{such that } \hat{\phi}(a_{j+1}\xi) = 0. \end{cases} \tag{3.8}$$

Introducing now the high-pass filter

$$m_1^j(\xi) = \begin{cases} \frac{\hat{\Psi}^j(\xi)}{\hat{\phi}(a_{j+1}\xi)} \quad \forall\,\xi \quad \text{such that } \hat{\phi}(a_{j+1}\xi) \neq 0, \\ 0 \quad \forall\,\xi \quad \text{such that } \hat{\phi}(a_{j+1}\xi) = 0, \end{cases} \tag{3.9}$$

an immediate consequence of (2.9) is that the filters m_0^j and m_1^j fulfill the quadrature mirror filter condition, that is,

$$\left|m_0^j(\xi)\right|^2 + \left|m_1^j(\xi)\right|^2 = 1 \ \ \forall j \in \mathbb{Z}, \ \ \forall \xi \in \mathbb{R} \ \ \text{such that } \hat{\phi}(a_{j+1}\xi) \neq 0. \tag{3.10}$$

3.2. Factorizable wavelet packets. We will call *factorizable wavelet packets* the wavelet packets generated by an infinitesimal wavelet ψ and a decreasing sequence $\{a_j\}$ of positive real numbers with the property that there exists a positive real $\lambda > 1$ such that for all $j \in \mathbb{Z}$,

$$a_{j+1} = \lambda^{-n(j)} a_j \tag{3.11}$$

for some $n(j) \in \mathbb{N}^*$. In other words, factorizable wavelet packets correspond to sequences of scale parameters that are subsequences of geometric sequences. Introduce then the filter m_0 such that

$$\hat{\phi}(\lambda\xi) = m_0(\xi)\hat{\phi}(\xi), \tag{3.12}$$

that is,

$$m_0(\xi) = \prod_{u=1}^{\lambda} \left(\frac{du}{u}\right) \ \mu_0(u\xi) = e^{\int_1^\lambda \nu_0(u\xi) \, \frac{du}{u}}. \tag{3.13}$$

In that case, all the integrated filters m_0^j factorize into products of dilated copies of m_0:

$$m_0^j(\xi) = \prod_{n=0}^{n(j)-1} m_0(\lambda^n a_j \xi). \tag{3.14}$$

This means that for numerical computations, the same filter can be used throughout the decomposition. It is then possible to build an algorithm for the computation of the wavelet packets coefficients with a pyramidal structure, as in the case of the QMF algorithm for the computation of the coefficients with respect to an orthonormal base of wavelets. Factorizable wavelet packets then seem more adapted for numerical implementation. This does not mean of course that nonfactorizable schemes are impossible to implement. There can be some specific problems (namely, in acoustics and voice analysis, or in vision) for which the optimal paving of the Fourier space is fixed by some phenomenological results, and do not a priori correspond to factorizable schemes. Nevertheless, depending on the required precision, it is likely that such pavings can be approached by pavings corresponding to factorizable schemes.

Remark. In the particular case where $n(j)$ is constant (and can be set to 1 without loss of generality), all the wavelet packets are obtained by dilations of a unique function Ψ, and all the integrated filters are dilated copies of m_0, too. The previous discussion then leads to a fast (i.e., $N \ln N$) algorithm, with pyramidal structure, to compute continuous wavelet decompositions. Such an algorithm is in the same spirit as the "Algorithme à Trous" discussed in [Ho-KM-T], since it is obtained by replacing the initial infinitesimal wavelet by another wavelet for which we can use QMFs. However, while the "Algorithme à Trous" is associated to an interpolation scheme, and then damages the localization of the wavelets in the Fourier space (see, e.g., [Du]), the one proposed here uses the function Ψ, which has essentially the same decay properties as ψ in the Fourier space. It then seems more adapted to signal analysis, at least for applications like those described in [Gr-KM-Mo]. Let us nevertheless stress that we have not proposed any discretization scheme for the (continuous) variations of the wavelet packets coefficient with respect to the translation parameter b. A brutal discretization of the translation parameter periodises the m_0 and then the m_1 filters, yielding a more usual QMF relation. However, the exact reconstruction property is then lost (notice that the errors can in general be controlled).

4. Factorization formulas and contrast analysis. We now describe a multiplicative way of reconstructing a function $f \in L^2(I\!R)$ from s_a and the contrast functions, which can be introduced as $c_a = \frac{d_a}{s_a}$. A precise meaning can be given to the multiplicative reconstruction formula, by making some analyticity assumptions on the scaling function ϕ, ensuring that the zeros of $s_a(x)$ are isolated (with respect to the dilation variable a, and for any $x \in I\!R$). We will discuss this analyticity property at the end of this section.

Let us first assume that s_a is a real analytic function of $a \in]0, \infty[$. Then, if $s_u(x)$ does not vanish for $u \in [a, A]$, we can write

$$s_a(x) = s_A(x)\; e^{-\int_a^A \partial_u \ln s_u(x)\, du}.$$

Now if $\partial_u s_u(x) = -d_u(x)/u$ (which is right under the assumptions made on the scaling function ϕ), we then have

$$s_a(x) = s_A(x)\; e^{\int_a^A \frac{d_u(x)}{s_u(x)} \frac{du}{u}}. \tag{4.1}$$

Let us now make sense of the integral when $s_u(x)$ vanishes in $[a, A]$. The goal is that (4.1) still holds in such a case. Let us assume that a_0 is the unique zero of $s_u(x)$ in the interval $[a, A]$, and set, for $\varepsilon > 0$,

$$\begin{aligned} s_a(x) &= \frac{s_a(x)}{s_{a_0-\varepsilon}(x)} \frac{s_{a_0-\varepsilon}(x)}{s_{a_0+\varepsilon}(x)} \frac{s_{a_0+\varepsilon}(x)}{s_A(x)} s_A(x) \\ &= s_A(x)\; \exp\left[\left(\int_a^{a_0-\varepsilon} \frac{du}{u} + \int_{a_0+\varepsilon}^A \frac{du}{u}\right) \frac{d_u(x)}{s_u(x)}\right] \frac{s_{a_0-\varepsilon}(x)}{s_{a_0+\varepsilon}(x)}. \end{aligned}$$

Taking the limit $\varepsilon \longrightarrow 0$, the analyticity of $s_u(x)$ implies the existence of $k \in I\!N$ and a function h such that $s_u(x) = (u - a_0)^k h(u, x)$, with $h(a_0, x) \neq 0$. Then

$$\lim_{\varepsilon \to 0} \frac{s_{a_0-\varepsilon}(x)}{s_{a_0+\varepsilon}(x)} = (-1)^k \quad \text{and} \quad \frac{d_u(x)}{s_u(x)} = \frac{k}{u - a_0} + g(u, x),$$

for some function g continuous at $u = a_0$, otherwise stated as

$$s_a(x) = s_A(x)\; \exp\left[\text{principal value} \int_a^A \frac{d_u(x)}{s_u(x)} \frac{du}{u} \;+\; k\pi i\right]. \tag{4.2}$$

Notice that such a specification of the integral coincides with the one obtained by redefining the (real) integration interval $a \leq u \leq A$ by the union of the two intervals $a \leq u \leq a_0 - \varepsilon$, $a_0 - \varepsilon \leq u \leq A$, and the half-circle of radius ε centered at a_0, and then taking the limit $\varepsilon \to 0$. Notice also that when $a_0 = a$ or $a_0 = A$, the integral diverges, which is compatible with (4.1).

Let us denote by Ξ the set of admissible infinitesimal wavelets such that in addition for any $f \in L^2(\mathbb{R})$, $s_a(x)$ is analytic with respect to a for any $x \in \mathbb{R}$. We can then introduce the *infinitesimal contrast function*

$$c_a(x) = -a\partial_a \ln s_a(x) \ \ \forall a, x \quad \text{such that } s_a(x) \neq 0 \tag{4.3}$$

$$= \frac{d_a(x)}{s_a(x)}, \tag{4.4}$$

that is, essentially the details of $f(x)$ at the scale a divided out by the approximation of $f(x)$ at the scale a (this explains the name of contrast function). Then we have shown the following.

THEOREM 3. *Let $\psi \in \Xi$ be an infinitesimal wavelet, and let $f \in L^2(\mathbb{R})$. Then, for any $a < A$, we have*

$$s_a(x) = s_A(x) \ \exp\left[\int_a^A c_u(x)\,\frac{du}{u}\right] \tag{4.5}$$

with the above specification of the integral.

Now (4.4) can also be written as a multiplicative integral, or continuous product as follows:

$$s_a(x) = s_A(x) \prod_{u=a}^{A} \left(\frac{du}{u}\right) e^{c_u(x)}, \tag{4.6}$$

the continuous product being defined by (2.5).

Remark. The factorization formula is independent of the determination of the complex logarithm between two singularities. It is then possible to specify a global determination of the logarithm for $a < u < A$, turning around the singularities.

Let us now come back to the question of the analyticity of $s_a(x)$. We have the following.

LEMMA. *If $|\hat{\phi}(\xi)|^2$ is infinitely differentiable, such that its derivatives satisfy the bound*

$$|\partial_\xi^k |\hat{\phi}(\xi)|^2| \ \leq \ K C^k k!\,(1+|\xi|)^{-1-k} \qquad \forall \xi \in \mathbb{R},\ k \in \mathbb{N} \tag{4.7}$$

for some constants $C, K > 0$, then for any $f \in L^2(\mathbb{R})$, $s_a(x)$ is an analytic function of $a \in \mathbb{R}_+^*$ for all $x \in \mathbb{R}$. Moreover, $\partial_a s_a(x) = -\frac{1}{a} d_a(x)$.

Remark. Actually, such assumptions imply the strong (i.e., in norm) analyticity of the map $a \to |\hat{\phi}(a\xi)|^2$ with values in $L^2(\mathbb{R})$.

Proof of the lemma. Set $h(\xi) = |\hat{\phi}(\xi)|^2$. Let us estimate the remainder of the Taylor series of $s_a(x)$ around $a = a_0$:

$$r_n = \frac{(a-a_0)^n}{n!}\ \partial_a \left[\int \hat{f}(\xi)\, h(a\xi)\xi^n d\xi\right]_{a=\tilde{a}_0} \tag{4.8}$$

for $\tilde{a}_0$ between a and a_0. By assumption, we can find some μ such that

$$\int \sup_{|a-\tilde{a}_0|<\mu} \left|\hat{f}(\xi)\,(\partial^n h)(a\xi)\xi^n\right| d\xi < \infty,$$

so that the integral and the derivative can be permuted. Then

$$|r_n| \leq |a-a_0|^n \; K C^n \int \left|\hat{f}(\xi)\right| \left(1+|\tilde{a}_0\xi|\right)^{-1-n} d\xi. \tag{4.9}$$

Then $\lim_{n\to\infty} \sup_{|a-\tilde{a}_0|<\epsilon} |r_n| = 0$ for $|a-a_0| < \epsilon$ and ϵ small enough, which proves the lemma.

It is worth noticing that contrast analysis becomes particularly simple in the case of the analysis of positive-valued functions, and positive-valued scaling functions (such as Gaussian functions for instance), as observed in [DD]. Indeed, in such cases one does not have to take care of the zeros of the s_a functions.

Let us finally briefly describe the discretization of the factorization formula, more precisely its relationship to the wavelet packets we described in §§2 and 3. Consider again the strictly decreasing sequence a_j of positive real numbers. Then for all integers $n > m$ the integral $\int_{a_m}^{a_n} c_u(x)\,\frac{du}{u}$ can be truncated into integrals over smaller intervals, and the factorization becomes

$$s_{a_n}(x) = s_{a_m}(x) \prod_{j=m}^{n-1} \exp\left[\int_{a_{j+1}}^{a_j} c_u(x)\,\frac{du}{u}\right],$$

which reduces to the trivial expression

$$s_{a_n}(x) = s_{a_m}(x) \prod_{j=m}^{n-1} \frac{s_{a_{j+1}}(x)}{s_{a_j}(x)}. \tag{4.10}$$

Such a simple factorization can still be expressed in terms of *integrated contrast coefficients*. Indeed, introducing a family of wavelet packets such that (2.3) holds, the associated integrated contrast coefficients can be defined as

$$C_j(x) = \frac{D_j(x)}{s_{a_j}(x)}, \tag{4.11}$$

so that the factorization formula reads

$$s_{a_n}(x) = s_{a_m}(x) \prod_{j=m}^{n-1} \left(1 + C_j(x)\right) . \tag{4.12}$$

The contrast coefficients form a sufficient information for the characterization of the analyzed function. The scheme defined by (4.8) can very easily be used for numerical computations [DD], [Me-DD-Ge].

Remark. Linear contrast analysis: Let us finally describe the linear analogue of the previous contrast analysis. Owing to Theorem 1′, we introduce the contrast function

$$\chi_a(x) = \frac{\delta_a(x)}{\sigma_a(x)}. \tag{4.13}$$

Then, assuming that $\hat{\varphi}$ is of class C^∞, such that in addition

$$\left|\partial_\xi^k |\hat{\varphi}(\xi)|\right| \leq K C^k k! (1+|\xi|)^{-1-k} \quad \forall \xi \in I\!R,\ k \in I\!N \tag{4.14}$$

for some positive constants C, K, we obtain the analyticity of $\sigma_a(x)$ and

$$\sigma_a(x) = \sigma_A(x) \prod_{u=a}^{A} \left(\frac{du}{u}\right) e^{\chi_u(x)}. \tag{4.15}$$

Such a continuous formula can also be discretized along the same lines as (4.6).

5. Conclusions. The continuous wavelet transform is naturally associated with an infinitesimal multiresolution scheme. The wavelet transform and the continuous set of approximations of the analyzed function are linked by some kind of scale derivative. This relationship is used to build a discrete set of wavelet packets by partial integration of the infinitesimal wavelet on scale intervals. Such wavelet packets allow exact reconstruction, though the scale axis has been discretized. If the sequence of scale parameters involved is factorizable as a subsequence of a geometric one, the scale discretization scheme can be combined with a pyramidal time discretization scheme. We then lose the exact reconstruction property (notice that the corresponding discretization errors can probably be controled through appropriate frame estimates). We have shown that this way of discretizing an infinitesimal multiresolution scheme on the scales uses the wavelet transform as a scale derivative. Moreover, it may be generalized to a logarithmic derivative. The resulting infinitesimal analysis is the "contrast function," and leads to a multiplicative reconstruction formula. Such a logarithmic way of performing multiscale analysis is, in particular, of great interest for the analysis of positive-valued signals, for which the troubles due to the zero-crossings are avoided. It may be extended directly to the two-dimensional case, and applied to image analysis. It then provides a rigorous framework to associate two basic properties of human vision: multiscale information processing and logarithmic light sensitivity [Me-DD-Ge]. The discrete reconstruction scheme, based on partial integrations of contrast functions, gives rise to formulas that are almost equivalent to "ratios of low pass filters" (ROLPs) decompositions that have already proved their efficiency in image processing [To-Ru-Va].

Acknowledgments. We are very indebted to Ph. Tchamitchian for many enlightening discussions, and particularly for showing us that $p \in L^1(I\!R)$. We thank D. J. Ripmeester for a careful reading of the manuscript. Thanks are also due to A. Grossmann and Y. Meyer. M. A. Muschietti is grateful to the Centre National de la Recherche Scientifique, the Universities of Aix-Marseille I and III, and the University of Nancy for kind invitations.

EXPONENTIALLY-IMPROVED ASYMPTOTIC SOLUTIONS OF ORDINARY DIFFERENTIAL EQUATIONS I: THE CONFLUENT HYPERGEOMETRIC FUNCTION*

F. W. J. OLVER†

Abstract. There has been renewed interest in both formal and rigorous theories of exponentially-small contributions to asymptotic expansions. In particular, a generalized asymptotic expansion was obtained for the confluent hypergeometric function $U(a, a-b+1, z)$ in which the parameters a and b are complex constants, and z is a large complex variable. This expansion is expressed in terms of generalized exponential integrals and has a larger region of validity and greater accuracy than conventional expansions of Poincaré type. The expansion was established by transformations and a re-expansion of an integral representation of $U(a, a-b+1, z)$. In this paper it is shown how the same result can be achieved by a direct differential-equation approach, thereby laying the foundation for a rigorous theory of generalized asymptotic solutions of linear differential equations.

Key words. factorial series, Gamma function, generalized asymptotic expansion, generalized exponential integral, incomplete Gamma function, superasymptotics

AMS subject classifications. primary 34E05; secondary 33C15

1. Introduction. The confluent hypergeometric function $U(a, a-b+1, z)$ has the well-known asymptotic expansion

$$U(a, a-b+1, z) \sim z^{-a} \sum_{s=0}^{\infty} (-)^s \frac{(a)_s (b)_s}{s!\, z^s}, \tag{1.1}$$

valid when the real or complex parameters a and b are fixed, and the argument $z \to \infty$ in the sector $|\mathrm{ph}\, z| \leqq \frac{3}{2}\pi - \delta$. Here $(a)_s$ and $(b)_s$ denote the ascending factorials $a(a+1)\cdots(a+s-1)$ and $b(b+1)\cdots(b+s-1)$, respectively, and δ is an arbitrary positive constant. If either a or b is a nonpositive integer, then the expansion (1.1) terminates and furnishes an exact representation of $U(a, a-b+1, z)$. In other cases, for given values of a, b, and z, $|z|$ being sufficiently large, the terms decrease numerically to a minimum; thereafter they increase unboundedly. The accuracy obtainable from (1.1) is limited, and greatest when the summation ceases close to the numerically smallest term. Approximately, this term is given by $s = \mathrm{int}\,[|z|]$, the integer part of $|z|$, or somewhat more exactly by $s = \mathrm{int}\,[|z| - \mathrm{Re}\, a - \mathrm{Re}\, b + 2]$.

In a recent paper [7] the author established the following result.

THEOREM 1.1. *Define $R_n(a, b, z)$ by*

$$U(a, a-b+1, z) = z^{-a} \sum_{s=0}^{n-1} (-)^s \frac{(a)_s (b)_s}{s!\, z^s} + R_n(a, b, z), \tag{1.2}$$

where

$$n = |z| - a - b + 1 + \alpha, \tag{1.3}$$

$|z|$ being large, a and b being fixed real or complex parameters, and $|\alpha|$ being bounded.

Then

$$R_n(a,b,z)=(-)^n 2\pi\frac{e^z z^{b-1}}{\Gamma(a)\Gamma(b)}\left\{\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\frac{F_{n+a+b-s-1}(z)}{z^s}\right.$$
$$\left.+(1-a)_m(1-b)_m R_{m,n}(a,b,z)\right\}, \tag{1.4}$$

where m is an arbitrary fixed nonnegative integer,

$$R_{m,n}(a,b,z)=O(e^{-z-|z|}z^{-m}),\qquad |\text{ph } z|\leqq\pi, \tag{1.5}$$

$$R_{m,n}(a,b,z)=O(z^{-m}),\qquad \pi\leqq|\text{ph } z|\leqq\tfrac{5}{2}\pi-\delta, \tag{1.6}$$

and δ denotes an arbitrary positive constant.

In this result F denotes the function defined by

$$F_p(z)=\frac{e^{-z}}{2\pi}\int_0^\infty\frac{e^{-zt}t^{p-1}}{1+t}\,dt, \tag{1.7}$$

when Re $p>0$ and $|\text{ph } z|<\frac{1}{2}\pi$, and by analytic continuation elsewhere.

It will be observed that Theorem 1.1 provides a re-expansion of the remainder term $R_n(a, b, z)$ when the original expansion (1.1) is truncated at or near its optimal stage; compare (1.3). In applications there are two advantages of the expansion given by (1.2) and (1.4), compared with (1.1). First, the total sector of validity $|\text{ph } z|\leqq\frac{5}{2}\pi-\delta$ is greater. Secondly, the attainable accuracy is considerably improved.

Another important feature of Theorem 1.1 is that it leads to a very clear understanding of the Stokes phenomenon: indeed, it was the insightful formal researches of Berry [1] on this aspect that motivated the research leading to Theorem 1.1. In brief, the explanation is that if n and $|z|$ are large, fixed, and approximately equal, then the functions $F_{n+a+b-s-1}(z)$ that appear in (1.4) change very rapidly, but *smoothly*, from being exponentially small to being almost constant as ph z passes continuously through either of the values $\pm\pi$.

The proof of Theorem 1.1 was based on an integral representation of the function $U(a, a-b+1, z)$. By suitable expansion of this representation, the remainder term $R_n(a, b, z)$ was expressed as a double integral, from which (1.4) was generated by appropriate transformations and re-expansion. Now the expansion (1.1) can also be obtained by direct application of the asymptotic theory of linear differential equations; see, for example, [5, Chap. 7, § 10]. Two questions naturally arise. Can the expansion (1.4) also be derived by a purely differential-equation approach? If so, can a more general theory be constructed, indeed, a theory that would be applicable in cases where no suitable integral representation of the wanted solution exists? Again, the formal researches of Berry [2] indicate that the answers to both questions are in the affirmative. The purpose of the present paper is to provide a rigorous proof of Theorem 1.1 based on differential-equation theory. The analysis we shall develop serves as a valuable preliminary to the more general case, treated in [10]. Other relevant references are [4] and [11].

In proving Theorem 1.1 we shall concentrate on the result (1.5) for the central sector $|\text{ph } z|\leqq\pi$. The result (1.6) in the abutting sectors $\pi\leqq|\text{ph } z|\leqq\frac{5}{2}\pi-\delta$ may then be derived by application of well-known connection formulae for $U(a, a-b+1, z)$; compare [7, § 5].

2. Properties of the function $F_p(z)$. We collect here results pertaining to the function $F_p(z)$ that will be needed in the present paper and its sequel [10]. In each result p and z may be real or complex.

In terms of the generalized exponential integral $E_p(z)$ and the incomplete Gamma function $\Gamma(1-p, z)$, $F_p(z)$ is given by

$$F_p(z)=\frac{\Gamma(p)}{2\pi}\frac{E_p(z)}{z^{p-1}}=\frac{\Gamma(p)}{2\pi}\Gamma(1-p,z). \tag{2.1}$$

From the definition (1.7) we easily derive the following identities:

$$F_{p+1}(z)+F_p(z)=\frac{\Gamma(p)}{2\pi}\frac{e^{-z}}{z^p}, \tag{2.2}$$

$$F_{p+2}(z)+F_{p+1}(z)=\frac{p}{z}\{F_{p+1}(z)+F_p(z)\}, \tag{2.3}$$

$$F_p'(z)=-F_{p+1}(z)-F_p(z), \qquad \frac{d}{dz}\{e^zF_p(z)\}=-e^zF_{p+1}(z). \tag{2.4}$$

By rotation of the integration path we derive the following continuation formula in which k denotes any integer:

$$F_p(ze^{2k\pi i})=ie^{-kp\pi i}\frac{\sin(kp\pi)}{\sin(p\pi)}+e^{-2kp\pi i}F_p(z), \qquad z\neq 0. \tag{2.5}$$

When $|z|$ is large and p is fixed, or bounded, we find by application of Watson's lemma [5, Chap. 4, § 3],

$$F_p(z)\sim\frac{e^{-z}}{2\pi}\sum_{s=0}^{\infty}(-)^s\frac{\Gamma(p+s)}{z^{p+s}}, \qquad |\text{ph } z|\leqq\tfrac{3}{2}\pi-\delta\,(<\tfrac{3}{2}\pi). \tag{2.6}$$

Next, when $|p|$ and $|z|$ are both large,

$$F_p(z)=\tfrac{1}{2}i\,e^{-p\pi i}[\text{erfc}\,\{c(\theta)\sqrt{\tfrac{1}{2}|z|}\}+e^{-|z|\{c(\theta)\}^2/2}O(z^{-1/2})], \tag{2.7}$$

the O-term being uniform with respect to $\theta\equiv\text{ph } z$ in the interval $[-\pi+\delta, 3\pi-\delta]$, and also uniform with respect to bounded values of $|p-|z||$. Here $c(\theta)$ is the continuous branch of the function

$$c(\theta)=\{2\,e^{i\theta}+2i(\theta-\pi)+2\}^{1/2} \tag{2.8}$$

that is asymptotic to $\pi-\theta$ as $\theta\to\pi$. The approximation (2.7) is derived in [6], and a graph of $c(\theta)$ is also included in this reference.[1] As a consequence of these results, the corresponding approximation for the sector $-3\pi+\delta\leq\text{ph } z\leqq\pi-\delta$, and the well-known asymptotic estimates

$$\text{erfc}\,(\zeta)=O(e^{-\zeta^2}\zeta^{-1}), \qquad \zeta\to\infty \text{ in } |\text{ph } \zeta|\leqq\tfrac{3}{4}\pi-\delta,$$
$$\text{erfc}\,(\zeta)=2+O(e^{-\zeta^2}\zeta^{-1}), \qquad \zeta\to\infty \text{ in } |\text{ph } (-\zeta)|\leqq\tfrac{3}{4}\pi-\delta,$$

we derive the following uniform estimates, again valid when $|z|$ is large and $|p-|z||$ is bounded:

$$F_p(z)=e^{-z-|z|}O(1), \qquad |\text{ph } z|\leqq\pi, \tag{2.9}$$

$$F_p(z)=e^{-z-|z|}O(z^{-1/2}), \qquad |\text{ph } z|\leqq\pi-\delta, \tag{2.10}$$

$$F_p(z)=\pm i\,e^{\mp p\pi i}+e^{-z-|z|}O(1), \qquad \pi\leqq\pm\text{ph } z\leqq 3\pi-\delta, \tag{2.11}$$

$$F_p(z)=\pm i\,e^{\mp p\pi i}+e^{-z-|z|}O(z^{-1/2}), \qquad \pi+\delta\leqq\pm\text{ph } z\leqq 3\pi-\delta. \tag{2.12}$$

In (2.11) either all upper signs are taken, or all lower signs; (2.12) is similar.

[1] The result (2.7) is contained in the proof of Theorem 1 of [6], rather than in the actual statement of this theorem.

3. Matching of the remainder term by a series of F-functions. The function $U(a, a-b+1, z)$ satisfies the equation

$$Lw=0, \tag{3.1}$$

in which L denotes the differential operator

$$\frac{d^2}{dz^2}+\left(\frac{a-b+1}{z}-1\right)\frac{d}{dz}-\frac{a}{z}.$$

If n is an arbitrary nonnegative integer and we apply the operator L to the nth partial sum of the series (1.1), then we find that

$$L\left\{z^{-a}\sum_{s=0}^{n-1}(-)^s\frac{(a)_s(b)_s}{s!\,z^s}\right\}=(-)^{n-1}\frac{A_n}{z^{n+a+1}}, \tag{3.2}$$

where

$$A_n=\frac{(a)_n(b)_n}{(n-1)!}=\frac{\Gamma(n+a)\Gamma(n+b)}{\Gamma(a)\Gamma(b)(n-1)!}. \tag{3.3}$$

Hence from (3.1) it follows that the remainder term in (1.2) satisfies

$$LR_n(a,b,z)=(-)^n\frac{A_n}{z^{n+a+1}}. \tag{3.4}$$

Our objective is to show that $R_n(a, b, z)$ can be expanded in the form (1.4) in which m is an arbitrary nonnegative integer, and the new remainder $R_{m,n}(a, b, z)$ is estimated by (1.5) and (1.6). We shall approach this problem by constructing a finite series of F-functions which, when operated upon by L, will match the right-hand side of (3.4) except for an asymptotically small term.

Consider first $L\{e^zF_p(z)/z^q\}$, where p and q are arbitrary constants. With the aid of (2.4) we find that

$$\frac{d}{dz}\left\{\frac{e^zF_p(z)}{z^q}\right\}=-\frac{e^zF_{p+1}(z)}{z^q}-q\frac{e^zF_p(z)}{z^{q+1}},$$

and hence

$$\frac{d^2}{dz^2}\left\{\frac{e^zF_p(z)}{z^q}\right\}=\frac{e^zF_{p+2}(z)}{z^q}+2q\frac{e^zF_{p+1}(z)}{z^{q+1}}+q(q+1)\frac{e^zF_p(z)}{z^{q+2}}.$$

As a consequence,

$$L\left\{\frac{e^zF_p(z)}{z^q}\right\}=\frac{e^zF_{p+2}(z)}{z^q}+(2q-a+b-1+z)\frac{e^zF_{p+1}(z)}{z^{q+1}}$$
$$+\{q(q-a+b)+(q-a)z\}\frac{e^zF_p(z)}{z^{q+2}}.$$

The term in $F_{p+2}(z)$ can be eliminated with the aid of (2.3); thus

$$L\left\{\frac{e^zF_p(z)}{z^q}\right\}=(p+2q-a+b-1)\frac{e^zF_{p+1}(z)}{z^{q+1}}+\{q(q-a+b)+(p+q-a)z\}\frac{e^zF_p(z)}{z^{q+2}}.$$

This equation may be rearranged in the form

$$L\left\{\frac{e^zF_p(z)}{z^q}\right\}=(p+q-a)\left\{\frac{e^zF_{p+1}(z)}{z^{q+1}}+\frac{e^zF_p(z)}{z^{q+1}}\right\}+(q+b-1)\frac{e^zF_{p+1}(z)}{z^{q+1}}$$
$$+q(q-a+b)\frac{e^zF_p(z)}{z^{q+2}}.$$

Then by use of (2.2) we arrive at

$$L\left\{\frac{e^zF_p(z)}{z^q}\right\}=\frac{p+q-a}{2\pi}\frac{\Gamma(p)}{z^{p+q+1}}+(q+b-1)\frac{e^zF_{p+1}(z)}{z^{q+1}}+q(q-a+b)\frac{e^zF_p(z)}{z^{q+2}}. \tag{3.5}$$

In order to make the asymptotic behaviour of the first term on the right-hand side of (3.5) match that of the right-hand side of (3.4), we must first arrange that the powers of z agree; thus

$$p+q=n+a. \tag{3.6}$$

From (3.3) and Stirling's formula, we derive

$$A_n\sim(\text{constant})\times e^{-n}n^{n+a+b-(1/2)},\qquad n\to\infty.$$

Also, with $q=n+a-p$,

$$(p+q-a)\Gamma(p)\sim(\text{constant})\times n\,e^{-p}p^{p-(1/2)},\qquad p\to\infty.$$

Evidently, apart from the constant factors, the asymptotic behaviour of these two expressions will be the same if we choose $p=n+a+b-1$ and, correspondingly, $q=1-b$. With these choices (3.5) becomes

$$L\left\{\frac{e^zF_{n+a+b-1}(z)}{z^{1-b}}\right\}=\frac{n}{2\pi}\frac{\Gamma(n+a+b-1)}{z^{n+a+1}}+(1-a)(1-b)\frac{e^zF_{n+a+b-1}(z)}{z^{3-b}}. \tag{3.7}$$

The second term on the right-hand side of the last equation is to be regarded as a residual, and to drive it into another residual, but with a higher power of z in the denominator, we consider (3.5) with q increased by unity, to $2-b$. At the same time, to preserve the asymptotic form of the other contribution, we decrease p by unity, to $n+a+b-2$; compare (3.6). Thus we have

$$L\left\{\frac{e^zF_{n+a+b-2}(z)}{z^{2-b}}\right\}=\frac{n}{2\pi}\frac{\Gamma(n+a+b-2)}{z^{n+a+1}}+\frac{e^zF_{n+a+b-1}(z)}{z^{3-b}}$$
$$+(2-a)(2-b)\frac{e^zF_{n+a+b-2}(z)}{z^{4-b}}.$$

Then by eliminating the final term from (3.7), we arrive at

$$\begin{aligned}&L\left\{\frac{e^zF_{n+a+b-1}(z)}{z^{1-b}}-(1-a)(1-b)\frac{e^zF_{n+a+b-2}(z)}{z^{2-b}}\right\}\\&=\frac{n}{2\pi z^{n+a+1}}\{\Gamma(n+a+b-1)-(1-a)(1-b)\Gamma(n+a+b-2)\}\\&\quad-(1-a)_2(1-b)_2\frac{e^zF_{n+a+b-2}(z)}{z^{4-b}}.\end{aligned} \tag{3.8}$$

The procedure may be repeated. The last term of the right member of (3.8) is now regarded as the residual, and we drive it into another residual with yet a higher power of z in the denominator by use of (3.5) with $p=n+a+b-3$ and $q=3-b$. Continuing in this manner we readily establish, by induction, the general result

$$\begin{aligned}&L\left\{\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\frac{e^zF_{n+a+b-s-1}(z)}{z^{s-b+1}}\right\}\\&=\frac{nB_{m,n}}{2\pi z^{n+a+1}}+(-)^{m-1}\frac{(1-a)_m(1-b)_m}{(m-1)!}\frac{e^zF_{n+a+b-m}(z)}{z^{m-b+2}},\end{aligned} \tag{3.9}$$

in which m is arbitrary, and

$$B_{m,n}=\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\Gamma(n+a+b-s-1). \tag{3.10}$$

On comparing (3.4) and (3.9) we perceive that the desired matching is representable in the form

$$L\left\{R_n(a,b,z)+(-)^{n-1}\frac{2\pi A_n}{nB_{m,n}}\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\frac{e^zF_{n+a+b-s-1}(z)}{z^{s-b+1}}\right\}$$
$$=(-)^{m+n}\frac{2\pi A_n}{nB_{m,n}}\frac{(1-a)_m(1-b)_m}{(m-1)!}\frac{e^zF_{n+a+b-m}(z)}{z^{m-b+2}}.$$

In § 4 we shall, in effect, invert the operator L in the last equation in order to estimate asymptotically the content of the braces in the left member. However, by comparison with the known result (1.4) we suspect that a simplifying approximation can be made for the ratio $A_n/(nB_{m,n})$. This is indeed the case, and the required result is as follows.

LEMMA 3.1. *Let a and b be fixed (or bounded) complex numbers and m be a fixed nonnegative integer. Then as $n\to\infty$*

$$\frac{\Gamma(n+a)\Gamma(n+b)}{\Gamma(n+1)}=\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\Gamma(n+a+b-s-1)$$
$$+(1-a)_m(1-b)_m\Gamma(n+a+b-m-1)O(1).$$

This result is proved in [12, Appendix]. See also [8], [9].

4. Estimation of $R_{m,n}(a, b, z)$. Throughout this section it will be understood that the parameters a and b are fixed (or bounded).

Let us return to (3.4) and (3.9). By combination, we obtain

$$LR_n(a,b,z)-L\left\{(-)^n\frac{2\pi}{\Gamma(a)\Gamma(b)}\sum_{s=0}^{m-1}(-)^s\frac{(1-a)_s(1-b)_s}{s!}\frac{e^zF_{n+a+b-s-1}(z)}{z^{s-b+1}}\right\}$$
$$=(-)^n\left\{A_n-\frac{n}{\Gamma(a)\Gamma(b)}B_{m,n}\right\}\frac{1}{z^{n+a+1}}$$
$$+(-)^{m+n}\frac{2\pi(1-a)_m(1-b)_m}{(m-1)!\,\Gamma(a)\Gamma(b)}\frac{e^zF_{n+a+b-m}(z)}{z^{m-b+2}}.$$

Hence, with $R_{m,n}(a, b, z)$ defined as in (1.4), we have

$$L\{e^zz^{b-1}R_{m,n}(a,b,z)\}=\frac{C_{m,n}}{z^{n+a+1}}+\frac{(-)^m}{(m-1)!}\frac{e^zF_{n+a+b-m}(z)}{z^{m-b+2}}, \tag{4.1}$$

where

$$C_{m,n}=\frac{\Gamma(a)\Gamma(b)}{2\pi(1-a)_m(1-b)_m}\left\{A_n-\frac{n}{\Gamma(a)\Gamma(b)}B_{m,n}\right\}. \tag{4.2}$$

And as a consequence of (3.3), (3.10), and Lemma 3.1 we note that as $n\to\infty$, with m fixed,

$$C_{m,n}=n\Gamma(n+a+b-m-1)O(1)=n^{n+a+b-m-(1/2)}e^{-n}O(1). \tag{4.3}$$

In order to invert the operator L in (4.1) we need two linearly independent solutions of the equation $Lw=0$. One of these has to be the solution that is recessive at infinity in the sector $|\text{ph}\, z|<\frac{1}{2}\pi$, that is, $U(a, a-b+1, z)$. As a second solution we select $V(a, a-b+1, z)$, the solution that is recessive at infinity in the sector $|\text{ph}\,(-z)|<\frac{1}{2}\pi$. For brevity, we shall denote these solutions by $U(z)$ and $V(z)$, respectively. Then their defining properties are expressed by

$$(4.4)\qquad U(z)=z^{-a}\{1+O(z^{-1})\},\qquad z\to\infty \text{ in } |\text{ph}\, z|\leqq\tfrac{3}{2}\pi-\delta;$$

$$(4.5)\qquad V(z)=e^{z}(-z)^{b-1}\{1+O(z^{-1})\},\qquad z\to\infty \text{ in } |\text{ph}\,(-z)|\leqq\tfrac{3}{2}\pi-\delta;$$

compare [5, Chap. 7, § 10.1].

Until the end of this section, we shall restrict $0\leqq\text{ph}\, z\leqq\pi$. The branch of z^{-a} in (4.4) is then the principal value, and the choice of branch of $(-z)^{b-1}$ in (4.5) is given by

$$(4.6)\qquad V(z)=e^{\pi i(1-b)}e^{z}z^{b-1}\{1+O(z^{-1})\},\qquad z\to\infty \text{ in } 0\leqq\text{ph}\, z\leqq\pi,$$

where z^{b-1} has its principal value. The Wronskian of the two solutions is

$$(4.7)\qquad \mathscr{W}\{U(z), V(z)\}=e^{\pi i(1-b)}e^{z}z^{b-a-1}.$$

By the method of variation of parameters, using (4.7), we find that one solution of (4.1) is given by

$$(4.8)\qquad R_{m,n}(a, b, z)=R^{(1)}_{m,n}(a, b, z)+R^{(2)}_{m,n}(a, b, z),$$

where

$$(4.9)\qquad e^{z}z^{b-1}R^{(1)}_{m,n}(a, b, z)=C_{m,n}\int_{z}^{\infty}\frac{K(z, t)}{t^{n+a+1}}\,dt,$$

$$(4.10)\qquad e^{z}z^{b-1}R^{(2)}_{m,n}(a, b, z)=\frac{(-)^{m}}{(m-1)!}\int_{z}^{\infty}\frac{K(z, t)}{t^{m-b+2}}\,e^{t}F_{n+a+b-m}(t)\,dt,$$

and

$$(4.11)\qquad K(z, t)=e^{\pi i(b-1)}\,e^{-t}t^{a-b+1}\{U(z)V(t)-V(z)U(t)\}.$$

From (2.6), (4.4), and (4.6) we may verify that as $z\to\infty$, the right members of (4.9) and (4.10) are $O(z^{-n-a})$ and $O(z^{-n-a-1})$, respectively. Hence with $R_{m,n}(a, b, z)$ defined by (4.8) it follows that $e^{z}z^{b-1}R_{m,n}(a, b, z)$ is $O(z^{-n-a})$. Again, with the aid also of (2.6) we see that the right-hand side of (1.4) becomes $O(z^{-n-a})$. This is precisely what is required by (1.2), and since there is only one solution of (3.4) that is $O(z^{-n-a})$ as $z\to\infty$, it follows that (4.8) *is* the correct choice of solution of (4.1) when $R_{m,n}(a, b, z)$ is defined by (1.2) and (1.4).

In order to estimate $R_{m,n}(a, b, z)$ from (4.8), (4.9), and (4.10), we need a uniform estimate of $K(z, t)$ when $|z|$ is large. This estimate will depend on the integration paths used in (4.9) and (4.10). We shall employ the same path for each integral, and our first restrictions are that $0\leqq\text{ph}\, t\leqq\pi$ and $|t|\geqq|z|$ everywhere on this path. Then from (4.4) and (4.6) we conclude that

$$(4.12)\qquad U(z)V(t)=z^{-a}\,e^{t}t^{b-1}O(1)$$

when $|z|$ is large in the sector $0\leqq\text{ph}\, z\leqq\pi$, uniformly for t on the path. As is customary in proofs of this nature, we now try to arrange that the same estimate applies to the other constituent $V(z)U(t)$ in the kernel $K(z, t)$. With this in view we prescribe the integration path in (4.9) and (4.10) to consist of: (i) a circular arc from $t=z$ to $t=|z|$, centered at the origin and described in the positive sense; (ii) the real axis from $t=|z|$

to $t=\infty$. This path is illustrated in Fig. 4.1. If z is real and positive, the circular arc is absent.

LEMMA 4.1. *Assume that*

$$|z| \geqq \tfrac{1}{2}\pi|a+b-1| \quad \textit{and} \quad 0 \leqq \operatorname{ph} z \leqq \pi.$$

Then on the integration path depicted in Fig. 4.1.

$$\left| e^{z-t}\left(\frac{z}{t}\right)^{a+b-1} \right| \leqq \exp\left\{ \frac{\pi^2 |\operatorname{Im}(a+b)|^2}{8|z|} \right\},$$

provided that $(z/t)^{a+b-1}$ *has its principal value.*

This result is proved in the Appendix. We note, in passing, that the bound is unity when $a+b$ is real, and is $1+O(z^{-1})$ in other circumstances.

Corresponding to (4.12), we have

$$V(z)U(t) = e^z z^{b-1} t^{-a} O(1),$$

and hence, by Lemma 4.1,

$$V(z)U(t) = z^{-a} e^t t^{b-1} O(1). \tag{4.13}$$

On substituting into (4.11) by means of (4.12) and (4.13) we obtain the desired estimate

$$K(z,t) = z^{-a} t^a O(1), \tag{4.14}$$

uniformly valid when t lies in the path depicted in Fig. 4.1 and $|z|$ is large.

Next, on substituting into (4.9) by means of (4.14), we obtain

$$e^z z^{b-1} R^{(1)}_{m,n}(a,b,z) = C_{m,n} z^{-a} O(1) \int_z^\infty \left| \frac{dt}{t^{n+1}} \right|.$$

On the chosen path

$$\int_z^\infty \left| \frac{dt}{t^{n+1}} \right| \leqq \frac{\pi}{|z|^n} + \frac{1}{n|z|^n}. \tag{4.15}$$

Hence we have

$$R^{(1)}_{m,n}(a,b,z) = C_{m,n} \frac{e^{-z}}{z^{n+a+b-1}} \left(\pi + \frac{1}{n} \right) O(1). \tag{4.16}$$

So far in the analysis we have not assumed any relationship between $|z|$ and n. It is at this stage that we introduce the condition (1.3) in which a, b, and α are bounded. Since $n \to \infty$ as $|z| \to \infty$, we may substitute for $C_{m,n}$ in (4.16) by means of (4.3). We obtain

$$R^{(1)}_{m,n}(a,b,z) = n^{n+a+b-m-(1/2)} e^{-n} \frac{e^{-z}}{z^{n+a+b-1}} O(1) = e^{-z-|z|} z^{-m+(1/2)} O(1). \tag{4.17}$$

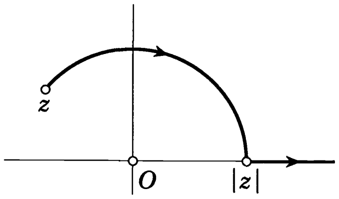

FIG. 4.1. *t-plane. Path for the integrals* (4.9) *and* (4.10). *Sector* $0 \leqq \operatorname{ph} z \leqq \pi$.

The corresponding estimation of $R^{(2)}_{m,n}(a, b, z)$ from (4.10) is more complicated. Consider first the circular arc from z to $|z|$. On this part of the path $|n+a+b-m-|t||$ is bounded; compare (1.3). Hence from (2.9) we obtain

$$F_{n+a+b-m}(t)=e^{-t-|t|}O(1).$$

Using this result and (4.14) we derive

$$\int_z^{|z|}\frac{K(z,t)}{t^{m-b+2}}e^tF_{n+a+b-m}(t)\,dt=z^{-a}O(1)\int_z^{|z|}\frac{e^{-|t|}|dt|}{|t^{m-a-b+2}|}=\frac{e^{-|z|}}{z^{m-b+1}}O(1). \tag{4.18}$$

Now consider the straight line segment from $|z|$ to ∞. On referring to (1.7) and (4.14) we perceive that

$$\begin{aligned}&\int_{|z|}^{\infty}\frac{K(z,t)}{t^{m-b+2}}e^tF_{n+a+b-m}(t)\,dt\\&\quad=O(z^{-a})\int_{|z|}^{\infty}\frac{dt}{t^{m-\operatorname{Re}a-\operatorname{Re}b+2}}\int_0^{\infty}\frac{e^{-t\tau}\tau^{n+\operatorname{Re}a+\operatorname{Re}b-m-1}}{1+\tau}\,d\tau.\end{aligned}$$

Provided that $m>\operatorname{Re}a+\operatorname{Re}b-1$, the integration order may be interchanged [3, Thm. 1]; thus

$$\begin{aligned}&\int_{|z|}^{\infty}\frac{K(z,t)}{t^{m-b+2}}e^tF_{n+a+b-m}(t)\,dt\\&\quad=O(z^{-a})\int_0^{\infty}\frac{\tau^{n+\operatorname{Re}a+\operatorname{Re}b-m-1}}{1+\tau}\,d\tau\int_{|z|}^{\infty}\frac{e^{-t\tau}}{t^{m-\operatorname{Re}a-\operatorname{Re}b+2}}\,dt.\end{aligned}$$

In terms of the incomplete Gamma function the inner integral on the right-hand side of the last equation is

$$\tau^{m-\operatorname{Re}a-\operatorname{Re}b+1}\Gamma(\operatorname{Re}a+\operatorname{Re}b-m-1,|z|\tau).$$

Since we are assuming that $m>\operatorname{Re}a+\operatorname{Re}b-1$, this quantity is bounded by

$$e^{-|z|\tau}|z|^{\operatorname{Re}a+\operatorname{Re}b-m-2}\tau^{-1};$$

compare [5, Chap. 3, eq. (1.05)]. Hence we see that

$$\begin{aligned}\int_{|z|}^{\infty}\frac{K(z,t)}{t^{m-b+2}}e^tF_{n+a+b-m}(t)\,dt&=\frac{O(1)}{z^{m-b+2}}\int_0^{\infty}\frac{e^{-|z|\tau}\tau^{n+\operatorname{Re}a+\operatorname{Re}b-m-2}}{1+\tau}\,d\tau\\&=e^{|z|}z^{b-m-2}F_{n+\operatorname{Re}a+\operatorname{Re}b-m-1}(|z|)O(1)=e^{-|z|}z^{b-m-2}O(1);\end{aligned} \tag{4.19}$$

compare (1.7) and (2.9).

We may now substitute into (4.10) by means of (4.18) and (4.19) to obtain

$$R^{(2)}_{m,n}(a,b,z)=e^{-z-|z|}z^{-m}O(1). \tag{4.20}$$

Then from (4.8), (4.17), and (4.20) we arrive at

$$R_{m,n}(a,b,z)=e^{-z-|z|}O(z^{-m+(1/2)}) \tag{4.21}$$

as $z\to\infty$ in the sector $0\leqq\operatorname{ph}z\leqq\pi$. A similar proof applies when $-\pi\leqq\operatorname{ph}z\leqq 0$.

To complete the proof of (1.5) we need to show that: (i) the order term in (4.21) can be strengthened to $O(z^{-m})$; (ii) the condition $m>\operatorname{Re}a+\operatorname{Re}b-1$ can be removed. Both steps are easily achieved simply by increasing m in (1.4) and using the estimate

$$F_{n+a+b-s-1}(z)=e^{-z-|z|}O(1)$$

as necessary for $s\leqq m-1$; compare, again, (2.9).

5. Conclusions. We have developed a new form of asymptotic analysis for the study of solutions of linear differential equations in order to establish an exponentially-improved asymptotic expansion of the confluent hypergeometric function $U(a, a-b+1, z)$ in the neighbourhood of the irregular singularity at $z=\infty$. This expansion was derived previously from an integral representation of $U(a, a-b+1, z)$. Our proof applies directly to the sector $|\text{ph } z| \leqq \pi$, which is the region of maximum exponential improvement. The corresponding results for the sectors $\pi \leqq |\text{ph } z| \leqq \frac{5}{2}\pi - \delta$ can be obtained by application of connection formulae.

The integral-representation approach also led to strict and realistic error bounds for the exponentially-improved asymptotic expansion of $U(a, a-b+1, z)$ in the sector $|\text{ph } z| \leqq \pi$. It may be feasible to obtain similar error bounds via our differential-equation approach, but this has not been explored in the present paper.

Appendix. Proof of Lemma 4.1. Write

$$\Phi(t) = \text{Re}\,\{t + (a+b-1)\ln t\},$$

where the logarithm assumes its principal value. Then on the path depicted in Fig. 4.1 we have

$$\left| e^{z-t}\left(\frac{z}{t}\right)^{a+b-1} \right| = e^{\Phi(z)-\Phi(t)}.$$

Let us consider the behaviour of $\Phi(t)$ at t passes along the contour $ABCD$ shown in Fig. A.1. Here ABC is the semicircle $t = \rho\, e^{i\chi}$, where $\rho = |z|$ and $\pi \geqq \chi \geqq 0$; CD is the segment of the real axis from $t=\rho$ to $t=\infty$. We shall also write

$$a+b-1 = \kappa_{\text{R}} + i\kappa_{\text{I}},$$

where κ_{R} and κ_{I} are real.

On CD we have

$$\Phi(t) = t + \kappa_{\text{R}} \ln t, \qquad \Phi'(t) = 1 + (\kappa_{\text{R}}/t).$$

Hence $\Phi(t)$ is nondecreasing, provided that $t \geqq -\kappa_{\text{R}}$ in the case $\kappa_{\text{R}} < 0$.

Now suppose that t lies on ABC and $\kappa_{\text{I}} \geqq 0$. Then

$$\Phi(t) = \rho\cos\chi + \kappa_{\text{R}}\ln\rho - \kappa_{\text{I}}\chi, \qquad \frac{d\Phi}{d\chi} = -\rho\sin\chi - \kappa_{\text{I}}.$$

Hence $\Phi(t)$ is nondecreasing.

Lastly, suppose that t lies on ABC and $\kappa_{\text{I}} = -\kappa'_{\text{I}}$, where $\kappa'_{\text{I}} > 0$. Then

$$\Phi(t) = \rho\cos\chi + \kappa_{\text{R}}\ln\rho + \kappa'_{\text{I}}\chi, \quad \frac{d\Phi}{d\chi} = -\rho\sin\chi + \kappa'_{\text{I}}, \quad \frac{d^2\Phi}{d\chi^2} = -\rho\cos\chi.$$

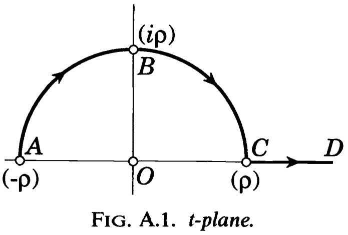

FIG. A.1. *t-plane.*

Suppose also that $\rho > \kappa_{\mathrm{I}}'$. Then $d\Phi/d\chi$ vanishes at $\chi = \chi_0$ and $\chi = \pi - \chi_0$, where $\chi_0 = \sin^{-1}(\kappa_{\mathrm{I}}'/\rho)$. The graph of $\Phi(t)$ plotted against χ is illustrated in Fig. A.2.

At C, $t = \rho$, $\chi = 0$, and $\Phi(t) = \Phi(\rho) = \rho + \kappa_{\mathrm{R}} \ln \rho$.

At $t = \rho\, e^{i\chi_0}$, $\Phi(t)$ is at a maximum, and we find that

$$\Phi(\rho\, e^{i\chi_0}) - \Phi(\rho) = \rho \cos \chi_0 - \rho + \kappa_{\mathrm{I}}'\chi_0 = h,$$

say. Similarly, at $t = \rho\, e^{i(\pi - \chi_0)}$, $\Phi(t)$ is at a minimum, and we find that

$$\Phi(\rho\, \mathrm{e}^{i\pi}) - \Phi(\rho\, e^{i(\pi-\chi_0)}) = h,$$

with the same h. Also, because $\chi_0 = \sin^{-1}(\kappa_{\mathrm{I}}'/\rho)$, we have

$$h = \rho(\cos \chi_0 - 1 + \chi_0 \sin \chi_0).$$

Since $0 \leqq \chi_0 \leqq \frac{1}{2}\pi$, we have by an elementary inequality $0 \leqq h \leqq \frac{1}{2}\rho\chi_0^2$, and hence by Jordan's inequality

$$0 \leqq h \leqq \tfrac{1}{2}\rho\left(\frac{\pi\kappa_{\mathrm{I}}'}{2\rho}\right)^2 = \frac{\pi^2\kappa_{\mathrm{I}}'^2}{8\rho}.$$

We require one further condition, given by $\rho \geqq \frac{1}{2}\pi\kappa_{\mathrm{I}}'$. The purpose of this condition is to ensure that $\Phi(\rho) \geqq \Phi(\rho\, e^{i\pi})$ and, in consequence, that the point C in Fig. A.2 does not lie below A.[2]

On combining the foregoing results we see that we can assert that if z and t are any two points on the path depicted in Fig. A.1, t being to the right of z, then in all cases

$$\Phi(z) - \Phi(t) \leqq h \leqq \frac{\pi^2\kappa_{\mathrm{I}}^2}{8\rho},$$

provided that $|z| \geqq -\kappa_{\mathrm{R}}$ when κ_{R} is negative, and $|z| \geqq -\frac{1}{2}\pi\kappa_{\mathrm{I}}$ when κ_{I} is negative. The last two conditions are certainly fulfilled when $|z| \geqq \frac{1}{2}\pi|\kappa_{\mathrm{R}} + i\kappa_{\mathrm{I}}| = \frac{1}{2}\pi|a + b - 1|$, and Lemma 4.1 follows.

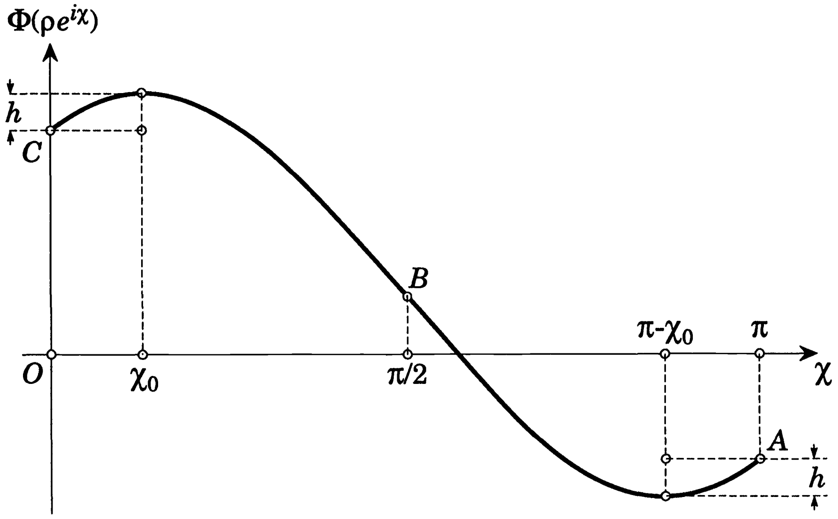

FIG. A.2. *Graph of $\Phi(\rho e^{i\chi})$ when κ_{I} is negative.*

[2] Actually, it would suffice for C to be no lower than the local minimum at $\chi = \pi - \chi_0$.

A GENERALIZATION OF LAGUERRE POLYNOMIALS*

R. KOEKOEK† AND H. G. MEIJER†

Abstract. The authors study orthogonal polynomials on $[0,+\infty)$ with respect to an inner product involving derivatives that cannot be derived from a weight function. These polynomials can be written as a ${}_3F_3$ hypergeometric series and they satisfy a second-order differential equation and a five term recurrence relation. At most one zero of each polynomial is located outside $(0,+\infty)$, the interior of the interval of orthogonality. As a special case Koornwinder's Laguerre polynomials $\{L_n^{\alpha,M}(x)\}_{n=0}^{+\infty}$ are included.

Key words. orthogonal polynomials, Laguerre polynomials, inner product

AMS subject classifications. 33A65, 33C45

1. Introduction. In [8] and [9] H. L. Krall introduced some generalizations of classical orthogonal polynomials which are orthogonal with respect to a weight function consisting of the classical weight function together with a delta function at the endpoint(s) of the interval of orthogonality. These polynomials were described in more detail by A. M. Krall in [7]. In [6] Koornwinder generalized this and computed the polynomials which are orthogonal on the interval $[-1,+1]$ with respect to a weight function of the form $(1-x)^\alpha(1+x)^\beta+M\cdot\delta(x+1)+N\cdot\delta(x-1)$. These polynomials are generalizations of the classical Jacobi polynomials. In [1] and [2] Bavinck and Meijer studied further generalizations of these polynomials in the ultraspherical case $(\alpha=\beta)$; they computed the polynomials $\{S_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$, which are orthogonal on the interval $[-1,+1]$ with respect to the inner product

$$\langle p,q\rangle=\frac{\Gamma(2\alpha+2)}{2^{2\alpha+1}\cdot\Gamma^2(\alpha+1)}\cdot\int_{-1}^{+1}(1-x^2)^\alpha\cdot p(x)q(x)\,dx+M\cdot[p(-1)q(-1)+p(1)q(1)]$$
$$+N\cdot[p'(-1)q'(-1)+p'(1)q'(1)].$$

As a limiting case Koornwinder found the polynomials $\{L_n^{\alpha,M}(x)\}_{n=0}^{+\infty}$, which are generalizations of the classical Laguerre polynomials $\{L_n^{(\alpha)}(x)\}_{n=0}^{+\infty}$ orthogonal on the interval $[0,+\infty)$ with respect to the weight function $(1/\Gamma(\alpha+1))\cdot x^\alpha e^{-x}+M\cdot\delta(x)$. These polynomials were described in detail in [4].

In the present paper we consider the polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$, which are orthogonal with respect to the inner product:

$$(1.1)\quad \langle p,q\rangle=\frac{1}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty}x^\alpha e^{-x}\cdot p(x)q(x)\,dx+M\cdot p(0)q(0)+N\cdot p'(0)q'(0),$$

where $\alpha>-1$, $M\geqq 0$, and $N\geqq 0$.

We will show that the polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ can be defined by

$$(1.2)\qquad L_n^{\alpha,M,N}(x)=A_0\cdot L_n^{(\alpha)}(x)+A_1\cdot\frac{d}{dx}L_n^{(\alpha)}(x)+A_2\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x),$$

where

$$(1.3)\begin{cases} A_0=1+M\cdot\binom{n+\alpha}{n-1}+\frac{n(\alpha+2)-(\alpha+1)}{(\alpha+1)(\alpha+3)}\cdot N\cdot\binom{n+\alpha}{n-2}+\frac{MN}{(\alpha+1)(\alpha+2)} \\ \qquad\cdot\binom{n+\alpha}{n-1}\binom{n+\alpha+1}{n-2}, \\ A_1=M\cdot\binom{n+\alpha}{n}+\frac{(n-1)}{(\alpha+1)}\cdot N\cdot\binom{n+\alpha}{n-1}+\frac{2MN}{(\alpha+1)^2}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-2}, \\ A_2=\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha}{n-1}+\frac{MN}{(\alpha+1)^2}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-1}. \end{cases}$$

For $N=0$ we have

$$L_n^{\alpha,M,0}(x)=L_n^{\alpha,M}(x)=\left[1+M\cdot\binom{n+\alpha}{n-1}\right]\cdot L_n^{(\alpha)}(x)+M\cdot\binom{n+\alpha}{n}\cdot\frac{d}{dx}L_n^{(\alpha)}(x),$$

Koornwinder's polynomials, and for $M=N=0$ we have

$$L_n^{\alpha,0,0}(x)=L_n^{(\alpha)}(x),$$

the classical Laguerre polynomials.

In [5] we studied further generalizations of these polynomials $\{L_n^{\alpha,M_0,M_1,\ldots,M_k}(x)\}_{n=0}^{+\infty}$, which are orthogonal on the interval $[0,+\infty)$ with respect to an inner product involving higher derivatives:

$$\langle p,q\rangle=\frac{1}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty}x^\alpha e^{-x}\cdot p(x)q(x)\,dx+\sum_{\nu=0}^{K}M_\nu\cdot p^{(\nu)}(0)q^{(\nu)}(0).$$

For $N>0$ the inner product (1.1) cannot be derived from a weight function, since $\langle 1,x^2\rangle\neq\langle x,x\rangle$. Many of the well-known properties of orthogonal polynomials can be proved by using the orthogonality with respect to a weight function (see [3] and [10]). So we may not expect these new polynomials to satisfy a three term recurrence relation and to have real simple zeros which lie in the interior of the interval of orthogonality.

In this paper we investigate some properties of the polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$. In this special case we have an explicit representation which allows us to find results concerning the zeros, for instance. For general results on the polynomials $\{L_n^{\alpha,M_0,M_1,\cdots,M_k}(x)\}_{n=0}^{+\infty}$, the reader is referred to [5].

2. The classical Laguerre polynomials. First we summarize the properties of the classical Laguerre polynomials $\{L_n^{(\alpha)}(x)\}_{n=0}^{+\infty}$ we will use. For details the reader is referred to [3] and [10].

Let $\alpha>-1$. The classical Laguerre polynomials $\{L_n^{(\alpha)}(x)\}_{n=0}^{+\infty}$ are orthogonal polynomials on the interval $[0,+\infty)$ with respect to the weight function $x^\alpha e^{-x}$ and with the normalization

$$(2.1)\qquad L_n^{(\alpha)}(0)=\binom{n+\alpha}{n}.$$

They can be defined by Rodrigues' formula

$$(2.2)\qquad L_n^{(\alpha)}(x)=\frac{1}{n!}\cdot x^{-\alpha}e^x\cdot\frac{d^n}{dx^n}[e^{-x}\cdot x^{n+\alpha}],\qquad n=0,1,2,3,\ldots.$$

The polynomials $\{L_n^{(\alpha)}(x)\}_{n=0}^{+\infty}$ satisfy the Laguerre differential equation

$$x \cdot \frac{d^2}{dx^2} L_n^{(\alpha)}(x) + (\alpha+1-x) \cdot \frac{d}{dx} L_n^{(\alpha)}(x) + n \cdot L_n^{(\alpha)}(x) = 0, \tag{2.3}$$

and a three term recurrence relation

$$\begin{gathered}(n+1) \cdot L_{n+1}^{(\alpha)}(x) + (x-2n-\alpha-1) \\ \cdot L_n^{(\alpha)}(x) + (n+\alpha) \cdot L_{n-1}^{(\alpha)}(x) = 0, \qquad n = 1, 2, 3, 4, \ldots, \\ L_0^{(\alpha)}(x) = 1 \quad \text{and} \quad L_1^{(\alpha)}(x) = \alpha + 1 - x.\end{gathered}$$

We have a simple differentiation formula:

$$\frac{d}{dx} L_n^{(\alpha)}(x) = -L_{n-1}^{(\alpha+1)}(x), \qquad n = 1, 2, 3, 4, \ldots \tag{2.4}$$

and a representation as a hypergeometric series

$$L_n^{(\alpha)}(x) = \binom{n+\alpha}{n} \cdot {}_1F_1(-n; \alpha+1; x), \qquad n = 0, 1, 2, 3, \ldots. \tag{2.5}$$

3. The orthogonality. In this section we prove the orthogonality of the polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ defined by (1.2) and (1.3) with respect to the inner product (1.1).

We will prove that $\langle p, L_n^{\alpha,M,N}\rangle = 0$ for every polynomial p with degree $[p] \leqq n-1$. First assume that the polynomial p can be written as $p(x) = x^2 \cdot q(x)$ for some polynomial q. Then we have degree $[q] \leqq n-3$ and $n \geqq 3$. In that case we find for $\langle p, L_n^{\alpha,M,N}\rangle$:

$$\begin{aligned}&\frac{1}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha+2} e^{-x} \cdot q(x) L_n^{\alpha,M,N}(x)\, dx \\ &= \frac{A_0}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha} e^{-x} \cdot x^2 q(x) L_n^{(\alpha)}(x)\, dx \\ &- \frac{A_1}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha+1} e^{-x} \cdot x q(x) L_{n-1}^{(\alpha+1)}(x)\, dx \\ &+ \frac{A_2}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha+2} e^{-x} \cdot q(x) L_{n-2}^{(\alpha+2)}(x)\, dx,\end{aligned}$$

which equals zero in view of the orthogonality property of the classical Laguerre polynomials.

Now we consider $p(x) = 1$ and $p(x) = x$. First let $p(x) = 1$; then we find for $\langle p, L_n^{\alpha,M,N}\rangle$:

$$\frac{1}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha} e^{-x} \cdot L_n^{\alpha,M,N}(x)\, dx + M \cdot L_n^{\alpha,M,N}(0)$$

$$\begin{aligned}&= \frac{A_0}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha} e^{-x} \cdot L_n^{(\alpha)}(x)\, dx - \frac{A_1}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha} e^{-x} \cdot L_{n-1}^{(\alpha+1)}(x)\, dx \\ &+ \frac{A_2}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^{\alpha} e^{-x} \cdot L_{n-2}^{(\alpha+2)}(x)\, dx \\ &+ M \cdot \left[\binom{n+\alpha}{n} \cdot A_0 - \binom{n+\alpha}{n-1} \cdot A_1 + \binom{n+\alpha}{n-2} \cdot A_2\right].\end{aligned} \tag{3.1}$$

And for $p(x)=x$ we obtain

$$\begin{aligned}
&\frac{1}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty} x^{\alpha+1}\,e^{-x}\cdot L_n^{\alpha,M,N}(x)\,dx+N\cdot\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}\\
&=\frac{A_0}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty} x^{\alpha+1}\,e^{-x}\cdot L_n^{(\alpha)}(x)\,dx\\
&-\frac{A_1}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty} x^{\alpha+1}\,e^{-x}\cdot L_{n-1}^{(\alpha+1)}(x)\,dx\\
&+\frac{A_2}{\Gamma(\alpha+1)}\cdot\int_0^{+\infty} x^{\alpha+1}\,e^{-x}\cdot L_{n-2}^{(\alpha+2)}(x)\,dx\\
&-N\cdot\left[\binom{n+\alpha}{n-1}\cdot A_0-\binom{n+\alpha}{n-2}\cdot A_1+\binom{n+\alpha}{n-3}\cdot A_2\right].
\end{aligned}\tag{3.2}$$

Using Rodrigues' formula (2.2) and integration by parts we find

$$\int_0^{+\infty} x^{\alpha+k}\,e^{-x}\cdot L_{n-i}^{(\alpha+i)}(x)\,dx=\binom{n-k-1}{n-i}\cdot\Gamma(\alpha+k+1)\tag{3.3}$$

where of course $\binom{p}{q}=0$ for $0\leqq p<q$.

Using this and (1.3) we find for (3.1) and (3.2) by straightforward calculations,

$$-A_1+(n-1)\cdot A_2+M\cdot\left[\binom{n+\alpha}{n}\cdot A_0-\binom{n+\alpha}{n-1}\cdot A_1+\binom{n+\alpha}{n-2}\cdot A_2\right]=0\tag{3.4}$$

and

$$(\alpha+1)\cdot A_2-N\cdot\left[\binom{n+\alpha}{n-1}\cdot A_0-\binom{n+\alpha}{n-2}\cdot A_1+\binom{n+\alpha}{n-3}\cdot A_2\right]=0.\tag{3.5}$$

This proves the orthogonality.

4. Some elementary properties. We start with the coefficients A_0, A_1, and A_2 defined by (1.3). It is not difficult to see that

$$A_0\geqq 1,\quad A_1\geqq 0,\quad\text{and}\quad A_2\geqq 0.$$

For the coefficient k_n of x^n in the polynomial $L_n^{\alpha,M,N}(x)$ we easily find, using (1.2),

$$k_n=\frac{(-1)^n}{n!}\cdot A_0.\tag{4.1}$$

And using (1.2), (2.4), (2.1), (3.4), and (1.3) we obtain

$$M\cdot L_n^{\alpha,M,N}(0)=A_1-(n-1)\cdot A_2=M\cdot\binom{n+\alpha}{n}\cdot\left[1-\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha+1}{n-2}\right].$$

Hence for $M>0$,

$$L_n^{\alpha,M,N}(0)=\binom{n+\alpha}{n}\cdot\left[1-\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha+1}{n-2}\right].\tag{4.2}$$

For $M=0$ we find the same formula by direct calculation.

Note that $L_n^{\alpha,M,N}(0)$ does not depend on M and that $L_n^{\alpha,M,N}(0)\leqq 0$ for $N>0$ and n large enough.

In the same way we obtain, using (1.2), (2.5), (2.1), (3.5), and (1.3),

$$-N\cdot\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}=(\alpha+1)\cdot A_2=N\cdot\binom{n+\alpha}{n-1}+\frac{MN}{(\alpha+1)}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-1}.$$

Hence for $N>0$,

$$\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}=-\binom{n+\alpha}{n-1}-\frac{M}{(\alpha+1)}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-1}. \tag{4.3}$$

For $N=0$ we find the same by direct calculation.

Note that

$$\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}$$

does not depend on N and that

$$\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}<0 \quad \text{for } n\geqq 1.$$

Finally, we take $n\geqq 2$. Then we have with (1.1), (1.2), (4.1), (2.4), (3.3), and the orthogonality property,

$$\lambda_n=\langle L_n^{\alpha,M,N}, L_n^{\alpha,M,N}\rangle=k_n\cdot\langle x^n, L_n^{\alpha,M,N}(x)\rangle=\binom{n+\alpha}{n}\cdot A_0\cdot[A_0+A_1+A_2]. \tag{4.4}$$

For $n=0$ and $n=1$ this formula remains valid.

5. Differential equation. In this section we will prove the following.

THEOREM. *The polynomials* $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ *satisfy a second-order differential equation of the form*

$$x\cdot p_2(x)\cdot\frac{d^2}{dx^2}L_n^{\alpha,M,N}(x)-p_1(x)\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x)+n\cdot p_0(x)\cdot L_n^{\alpha,M,N}(x)=0, \tag{5.1}$$

where $\{p_i(x)\}_{i=0}^{2}$ *are polynomials with*

$$\text{degree}\,[p_0]=\text{degree}\,[p_2]=2 \quad \textit{and} \quad \text{degree}\,[p_1]=3, \tag{5.2}$$

and all having the same leading coefficient which we take to be $(1/n)\cdot A_0\cdot(A_0+A_1+A_2)$.

Proof. We start with the differential equation (2.3) for the classical Laguerre polynomials:

$$x\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x)+(\alpha+1-x)\cdot\frac{d}{dx}L_n^{(\alpha)}(x)+n\cdot L_n^{(\alpha)}(x)=0. \tag{5.3}$$

Differentiation of (5.3) gives us

$$x\cdot\frac{d^3}{dx^3}L_n^{(\alpha)}(x)+(\alpha+2-x)\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x)+(n-1)\cdot\frac{d}{dx}L_n^{(\alpha)}(x)=0. \tag{5.4}$$

From the definition (1.2) we obtain, using (5.3),

$$L_n^{\alpha,M,N}(x)=q_0(x)\cdot\frac{d}{dx}L_n^{(\alpha)}(x)+q_1(x)\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x), \tag{5.5}$$

where

$$\begin{cases} q_0(x)=A_1-\dfrac{1}{n}\cdot A_0\cdot(\alpha+1-x), \\ q_1(x)=A_2-\dfrac{1}{n}\cdot A_0\cdot x. \end{cases} \tag{5.6}$$

Differentiation of (5.5) leads to

$$\begin{aligned} \frac{d}{dx}L_n^{\alpha,M,N}(x)&=q_0'(x)\cdot\frac{d}{dx}L_n^{(\alpha)}(x)+[q_0(x)+q_1'(x)]\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x) \\ &\quad+q_1(x)\cdot\frac{d^3}{dx^3}L_n^{(\alpha)}(x). \end{aligned} \tag{5.7}$$

Using (5.4) we find, from (5.7),

$$x\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x)=q_0^*(x)\cdot\frac{d}{dx}L_n^{(\alpha)}(x)+q_1^*(x)\cdot\frac{d^2}{dx^2}L_n^{(\alpha)}(x), \tag{5.8}$$

where

$$\begin{cases} q_0^*(x)=x\cdot q_0'(x)-(n-1)\cdot q_1(x), \\ q_1^*(x)=x\cdot[q_0(x)+q_1'(x)]-(\alpha+2-x)\cdot q_1(x). \end{cases} \tag{5.9}$$

Elimination of the second derivative of the classical Laguerre polynomial in (5.5) and (5.8) leads to

$$\begin{aligned} &[q_0(x)q_1^*(x)-q_0^*(x)q_1(x)]\cdot\frac{d}{dx}L_n^{(\alpha)}(x) \\ &=q_1^*(x)\cdot L_n^{\alpha,M,N}(x)-x\cdot q_1(x)\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x). \end{aligned} \tag{5.10}$$

We define

$$r(x)=q_0(x)q_1^*(x)-q_0^*(x)q_1(x). \tag{5.11}$$

It is easy to check that degree $[r]=2$. Hence $r\not\equiv 0$. So we have from (5.10) and (5.11),

$$\frac{d}{dx}L_n^{(\alpha)}(x)=\frac{q_1^*(x)}{r(x)}\cdot L_n^{\alpha,M,N}(x)-x\cdot\frac{q_1(x)}{r(x)}\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x). \tag{5.12}$$

Substituting (5.12) into (5.5) we obtain a second-order differential equation of the form

$$a_2(x)\cdot\frac{d^2}{dx^2}L_n^{\alpha,M,N}(x)+a_1(x)\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x)+a_0(x)\cdot L_n^{\alpha,M,N}(x)=0, \tag{5.13}$$

where

$$\begin{cases} a_2(x)=x\cdot\{q_1(x)\}^2\cdot r(x), \\ a_1(x)=-q_1(x)\cdot q_1^*(x)\cdot r(x)+x\cdot q_0(x)\cdot q_1(x)\cdot r(x)+\{q_1(x)\}^2\cdot r(x) \\ \qquad +x\cdot q_1(x)\cdot[q_1'(x)\cdot r(x)-q_1(x)\cdot r'(x)], \\ a_0(x)=-q_0(x)\cdot q_1^*(x)\cdot r(x)-q_1(x)\cdot\left[r(x)\cdot\dfrac{d}{dx}q_1^*(x)-q_1^*(x)\cdot r'(x)\right] \\ \qquad +\{r(x)\}^2. \end{cases} \tag{5.14}$$

From (5.11) it follows that

$$q_0(x)\cdot q_1^*(x)-r(x)=q_0^*(x)\cdot q_1(x). \tag{5.15}$$

Hence, the differential equation defined by (5.13) and (5.14) can be divided by $q_1(x)$, which gives us a differential equation of the form (5.13) with

$$\begin{cases} a_2(x)=x\cdot q_1(x)\cdot r(x), \\ a_1(x)=x\cdot q_0(x)\cdot r(x)-q_1^*(x)\cdot r(x)+q_1(x)\cdot r(x) \\ \qquad +x\cdot[q_1'(x)\cdot r(x)-q_1(x)\cdot r'(x)], \\ a_0(x)=q_1^*(x)\cdot r'(x)-r(x)\cdot \dfrac{d}{dx}q_1^*(x)-q_0^*(x)\cdot r(x). \end{cases} \tag{5.16}$$

Using (5.9) we obtain

$$a_1(x)=q_1(x)\cdot[(\alpha+3-x)\cdot r(x)-x\cdot r'(x)]. \tag{5.17}$$

And with (5.6), (5.9), (5.11), and (5.16) we find by straightforward calculations,

$$\begin{aligned} a_0(x)=q_1(x)\cdot\left[q_0^*(x)\cdot\left\{q_0^*(x)+\frac{d}{dx}q_1^*(x)\right\}-q_1^*(x)\cdot\frac{d}{dx}q_0^*(x)\right] \\ +q_1(x)\cdot q_1^*(x)\cdot[(n-1)\cdot\{q_0(x)+q_1'(x)\}-(\alpha+2-x)\cdot q_0'(x)]. \end{aligned}$$

Hence, the differential equation can be divided by $q_1(x)$ once more and we obtain a differential equation of the form (5.13) where

$$\begin{cases} a_2(x)=x\cdot r(x), \\ a_1(x)=(\alpha+3-x)\cdot r(x)-x\cdot r'(x), \\ a_0(x)=q_0^*(x)\cdot\left[q_0^*(x)+\dfrac{d}{dx}q_1^*(x)\right]-q_1^*(x)\cdot\dfrac{d}{dx}q_0^*(x) \\ \qquad +q_1^*(x)\cdot[(n-1)\cdot\{q_0(x)+q_1'(x)\}-(\alpha+2-x)\cdot q_0'(x)]. \end{cases}$$

This proves (5.1) with $p_2(x)=r(x)$, $p_1(x)=-a_1(x)$, and $n\cdot p_0(x)=a_0(x)$.

Now we can easily check that the leading coefficients of p_0, p_1, and p_2 all equal

$$\frac{1}{n}\cdot A_0\cdot(A_0+A_1+A_2).$$

6. Recurrence relation. All classical orthogonal polynomials orthogonal with respect to a weight function satisfy a three term recurrence relation. See, for instance, [3] and [10]. In this section we will prove the following.

THEOREM. *The polynomials* $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ *satisfy a five term recurrence relation of the form*

$$\begin{aligned} C_{n+2}^{(n)}\cdot L_{n+2}^{\alpha,M,N}(x)+C_{n+1}^{(n)}\cdot L_{n+1}^{\alpha,M,N}(x)+[C_n^{(n)}-x^2]\cdot L_n^{\alpha,M,N}(x) \\ +C_{n-1}^{(n)}\cdot L_{n-1}^{\alpha,M,N}(x)+C_{n-2}^{(n)}\cdot L_{n-2}^{\alpha,M,N}(x)=0. \end{aligned} \tag{6.1}$$

Proof. Since $x^2\cdot L_n^{\alpha,M,N}(x)$ is a polynomial of degree $n+2$ we may write

$$x^2\cdot L_n^{\alpha,M,N}(x)=\sum_{k=0}^{n+2}C_k^{(n)}\cdot L_k^{\alpha,M,N}(x). \tag{6.2}$$

Taking the inner product with $L_i^{\alpha,M,N}(x)$ on both sides of (6.2), we obtain

$$\langle L_i^{\alpha,M,N},L_i^{\alpha,M,N}\rangle\cdot C_i^{(n)}=\langle L_n^{\alpha,M,N}(x),x^2\cdot L_i^{\alpha,M,N}(x)\rangle, \tag{6.3}$$

which follows immediately from the definition of the inner product (1.1). Since $\langle p, L_n^{\alpha,M,N}\rangle = 0$ for every polynomial p with degree $[p] \leqq n-1$, we obtain

$$C_i^{(n)} = 0 \quad \text{for } i = 0, 1, 2, 3, \ldots, n-3. \tag{6.4}$$

This proves the theorem.

From (6.1) it easily follows that

$$C_{n+2}^{(n)} = \frac{k_n}{k_{n+2}} \neq 0, \tag{6.5}$$

where k_n denotes the coefficient of x^n in the polynomial $L_n^{\alpha,M,N}(x)$ given by (4.1). And for $C_{n-2}^{(n)}$ we obtain, from (6.3),

$$C_{n-2}^{(n)} = \frac{k_{n-2} \cdot \lambda_n}{k_n \cdot \lambda_{n-2}} \neq 0, \tag{6.6}$$

where λ_n is defined as in (4.4).

We remark that $C_{n+1}^{(n)}$, $C_n^{(n)}$, and $C_{n-1}^{(n)}$ can be computed by using (6.3), too. We omit the details because these coefficients are not essential here.

7. A Christoffel–Darboux type formula. The classical orthogonal polynomials satisfy the so-called Christoffel-Darboux formula, which gives some information about the zeros of the polynomials. See, for instance, [3] and [10]. In this section we derive an analogous formula for the new polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$.

From (6.1) we easily obtain

$$\begin{aligned} x^2 \cdot L_{n-i}^{\alpha,M,N}(x) &= C_{n-i+2}^{(n-i)} \cdot L_{n-i+2}^{\alpha,M,N}(x) + C_{n-i+1}^{(n-i)} \cdot L_{n-i+1}^{\alpha,M,N}(x) \\ &\quad + C_{n-i}^{(n-i)} \cdot L_{n-i}^{\alpha,M,N}(x) + C_{n-i-1}^{(n-i)} \cdot L_{n-i-1}^{\alpha,M,N}(x) + C_{n-i-2}^{(n-i)} \cdot L_{n-i-2}^{\alpha,M,N}(x) \end{aligned} \tag{7.1}$$

for $i = 0, 1, 2, 3, \ldots, n-2$.

Now it follows from (1.1) and (7.1) for $0 \leqq i-2 \leqq k \leqq i+2 \leqq n$ that

$$\frac{C_{n-k}^{(n-i)}}{\lambda_{n-i}} = \frac{C_{n-i}^{(n-k)}}{\lambda_{n-k}}. \tag{7.2}$$

From (6.1) and (7.2) we obtain

$$\begin{aligned} &(x^2 - y^2) \cdot \sum_{k=0}^{n} \frac{L_k^{\alpha,M,N}(x) L_k^{\alpha,M,N}(y)}{\lambda_k} \\ &= \frac{C_{n+2}^{(n)}}{\lambda_n} \cdot [L_{n+2}^{\alpha,M,N}(x) L_n^{\alpha,M,N}(y) - L_{n+2}^{\alpha,M,N}(y) L_n^{\alpha,M,N}(x)] \\ &\quad + \frac{C_{n+1}^{(n)}}{\lambda_n} \cdot [L_{n+1}^{\alpha,M,N}(x) L_n^{\alpha,M,N}(y) - L_{n+1}^{\alpha,M,N}(y) L_n^{\alpha,M,N}(x)] \\ &\quad + \frac{C_{n+1}^{(n-1)}}{\lambda_{n-1}} \cdot [L_{n+1}^{\alpha,M,N}(x) L_{n-1}^{\alpha,M,N}(y) - L_{n+1}^{\alpha,M,N}(y) L_{n-1}^{\alpha,M,N}(x)]. \end{aligned} \tag{7.3}$$

Note that we have, with (6.5),

$$C_{n+2}^{(n)} = \frac{k_n}{k_{n+2}} \quad \text{and} \quad C_{n+1}^{(n-1)} = \frac{k_{n-1}}{k_{n+1}}. \tag{7.4}$$

Formula (7.3) can be seen as a Christoffel-Darboux type formula for the polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$.

Dividing by x^2-y^2 and letting $y\to x$ we obtain the so-called "confluent form":

$$\begin{aligned}
&2x\cdot\sum_{k=0}^{n}\frac{\{L_k^{\alpha,M,N}(x)\}^2}{\lambda_k}\\
&=\frac{k_n}{\lambda_n\cdot k_{n+2}}\cdot\left[L_n^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_{n+2}^{\alpha,M,N}(x)-L_{n+2}^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x)\right]\\
(7.5)\qquad&+\frac{C_{n+1}^{(n)}}{\lambda_n}\cdot\left[L_n^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_{n+1}^{\alpha,M,N}(x)-L_{n+1}^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_n^{\alpha,M,N}(x)\right]\\
&+\frac{k_{n-1}}{\lambda_{n-1}\cdot k_{n+1}}\cdot\left[L_{n-1}^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_{n+1}^{\alpha,M,N}(x)-L_{n+1}^{\alpha,M,N}(x)\cdot\frac{d}{dx}L_{n-1}^{\alpha,M,N}(x)\right].
\end{aligned}$$

8. Representation as hypergeometric series. From the definition (1.2) and (2.5) we obtain

$$(8.1)\ L_n^{\alpha,M,N}(x)=\binom{n+\alpha}{n}\cdot\sum_{k=0}^{n}\left[\frac{(-n)_k}{(\alpha+1)_k}\cdot A_0+\frac{(-n)_{k+1}}{(\alpha+1)_{k+1}}\cdot A_1+\frac{(-n)_{k+2}}{(\alpha+1)_{k+2}}\cdot A_2\right]\cdot\frac{x^k}{k!}.$$

If we define

$$(8.2)\qquad L_n^{\alpha,M,N}(x)=\sum_{k=0}^{n}C_k\cdot\frac{x^k}{k!},$$

then it follows from (8.1) and (8.2) that

$$\begin{aligned}
&C_k=\binom{n+\alpha}{n}\cdot\frac{(-n)_k}{(\alpha+1)_{k+2}}\\
(8.3)\qquad&\quad\cdot[A_0\cdot(k+\alpha+1)(k+\alpha+2)+A_1\\
&\quad\cdot(k-n)(k+\alpha+2)+A_2\cdot(k-n)(k-n+1)]\\
&=\binom{n+\alpha}{n}\cdot[A_0+A_1+A_2]\cdot\frac{(-n)_k}{(\alpha+3)_k}\cdot\frac{(k+\beta_0)(k+\beta_1)}{(\alpha+1)_2},
\end{aligned}$$

where

$$(8.4)\quad\begin{cases}[A_0+A_1+A_2]\cdot(\beta_0+\beta_1)=(2\alpha+3)\cdot A_0+(\alpha+2-n)\cdot A_1-(2n-1)\cdot A_2,\\ [A_0+A_1+A_2]\cdot\beta_0\cdot\beta_1=(\alpha+1)(\alpha+2)\cdot A_0-n(\alpha+2)\cdot A_1+n(n-1)\cdot A_2.\end{cases}$$

Since

$$(8.5)\qquad (k+\beta_0)(k+\beta_1)=\beta_0\beta_1\cdot\frac{(\beta_0+1)_k\cdot(\beta_1+1)_k}{(\beta_0)_k\cdot(\beta_1)_k}$$

for $\beta_0\neq 0,-1,-2,-3,\ldots,$ and $\beta_1\neq 0,-1,-2,-3,\ldots,$ we obtain in that case, from (8.2), (8.3), and (8.5),

$$(8.6)\quad L_n^{\alpha,M,N}(x)=\frac{\beta_0\cdot\beta_1}{(\alpha+1)(\alpha+2)}\cdot[A_0+A_1+A_2]\cdot\binom{n+\alpha}{n}\cdot{}_3F_3\left(\begin{matrix}-n,\beta_0+1,\beta_1+1\\ \alpha+3,\beta_0,\beta_1\end{matrix}\middle|\,x\right).$$

With (4.2) we obtain

$$(8.7)[A_0+A_1+A_2]\cdot\frac{\beta_0\cdot\beta_1}{(\alpha+1)(\alpha+2)}=\binom{n+\alpha}{n}^{-1}\cdot L_n^{\alpha,M,N}(0)=1-\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha+1}{n-2}.$$

Hence

$$(8.8)\quad L_n^{\alpha,M,N}(x)=\left[1-\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha+1}{n-2}\right]\cdot\binom{n+\alpha}{n}\cdot{}_3F_3\left(\begin{matrix}-n,\beta_0+1,\beta_1+1\\ \alpha+3,\beta_0,\beta_1\end{matrix}\middle| x\right).$$

Now we examine β_0 and β_1 in somewhat greater detail. First we take $N>0$. The right-hand side of (8.7) is nonpositive for n large enough. So we have with (8.7) and the fact that $A_0+A_1+A_2>0$ for n sufficiently large (for instance),

$$(8.9)\qquad \beta_0\leqq 0 \quad\text{and}\quad \beta_1\geqq 0.$$

Furthermore, we have with (4.3), (8.2), and (8.3),

$$(8.10)\quad \binom{n+\alpha}{n}\cdot[A_0+A_1+A_2]\cdot\frac{(-n)(\beta_0+1)(\beta_1+1)}{(\alpha+1)(\alpha+2)(\alpha+3)}=C_1=\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\Bigg|_{x=0}<0$$

for $n\geqq 1$. Hence for $n\geqq 1$ we have

$$(8.11)\qquad (\beta_0+1)(\beta_1+1)>0.$$

From (8.9) and (8.10) it now follows that for n large enough,

$$(8.12)\qquad -1<\beta_0\leqq 0 \quad\text{and}\quad \beta_1\geqq 0.$$

Since

$$(8.13)\qquad \binom{n+\alpha}{n-i}\sim\frac{n^{\alpha+i}}{\Gamma(\alpha+i+1)}\quad\text{for } n\to+\infty,$$

we find, from (1.3) and (8.13) for $n\to+\infty$, that

$$(8.14)\quad \begin{cases} A_0\sim\dfrac{(\alpha+2)\cdot N}{(\alpha+1)(\alpha+3)}\cdot\dfrac{n^{\alpha+3}}{\Gamma(\alpha+3)} & \text{if } M=0,\\[2ex] A_0\sim\dfrac{M\cdot N}{(\alpha+1)(\alpha+2)}\cdot\dfrac{n^{2\alpha+4}}{\Gamma(\alpha+2)\Gamma(\alpha+4)} & \text{if } M>0,\end{cases}$$

$$(8.15)\quad \begin{cases} A_1\sim\dfrac{N}{(\alpha+1)}\cdot\dfrac{n^{\alpha+2}}{\Gamma(\alpha+2)} & \text{if } M=0,\\[2ex] A_1\sim\dfrac{2MN}{(\alpha+1)^2}\cdot\dfrac{n^{2\alpha+3}}{\Gamma(\alpha+1)\Gamma(\alpha+4)} & \text{if } M>0,\end{cases}$$

$$(8.16)\quad \begin{cases} A_2\sim\dfrac{N}{(\alpha+1)}\cdot\dfrac{n^{\alpha+1}}{\Gamma(\alpha+2)} & \text{if } M=0,\\[2ex] A_2\sim\dfrac{M\cdot N}{(\alpha+1)^2}\cdot\dfrac{n^{2\alpha+2}}{\Gamma(\alpha+1)\Gamma(\alpha+3)} & \text{if } M>0.\end{cases}$$

Hence for $n \to +\infty$ we have

$$(8.17)\quad \begin{cases} (2\alpha+3)\cdot A_0+(\alpha+2-n)\cdot A_1-(2n-1)\cdot A_2 \\ \quad \sim \dfrac{\alpha\cdot N}{(\alpha+1)(\alpha+3)}\cdot\dfrac{n^{\alpha+3}}{\Gamma(\alpha+2)} \qquad (M=0), \\ (2\alpha+3)\cdot A_0+(\alpha+2-n)\cdot A_1-(2n-1)\cdot A_2 \\ \quad \sim -\dfrac{M\cdot N}{(\alpha+1)^2(\alpha+2)}\cdot\dfrac{n^{2\alpha+4}}{\Gamma(\alpha+1)\Gamma(\alpha+4)} \qquad (M>0). \end{cases}$$

It follows from (8.4), (8.7), (8.14)-(8.17) for $n \to +\infty$, that

$$\begin{cases} \beta_0+\beta_1\sim\alpha & \text{if } M=0, \\ \beta_0+\beta_1\sim -1 & \text{if } M>0, \end{cases}$$

and

$$\begin{cases} \beta_0\cdot\beta_1\sim-(\alpha+1) & \text{if } M=0, \\ \beta_0\cdot\beta_1\sim-\dfrac{(\alpha+1)(\alpha+2)\Gamma(\alpha+3)}{M\cdot n^{\alpha+1}} & \text{if } M>0. \end{cases}$$

Hence for $M=0$ we have, for $n\to+\infty$,

$$\beta_0\to-1 \quad\text{and}\quad \beta_1\to\alpha+1$$

and for $M>0$ we have, for $n\to+\infty$,

$$\beta_0\to-1 \quad\text{and}\quad \beta_1\to 0.$$

In the case $N=0$ (Koornwinder's polynomials) we have

$$L_n^{\alpha,M}(x)=\binom{n+\alpha}{n}\cdot{}_2F_2\left(\begin{matrix}-n,\ \gamma+1\\ \alpha+2,\ \gamma\end{matrix}\,\middle|\, x\right),$$

where

$$\gamma=\frac{\alpha+1}{1+M\cdot\dbinom{n+\alpha+1}{n}}>0.$$

Note that for $n\to+\infty$,

$$\begin{cases} \gamma=\alpha+1 & \text{if } M=0, \\ \gamma\to 0 & \text{if } M>0. \end{cases}$$

9. The zeros. All orthogonal polynomials $\{P_n(x)\}_{n=0}^{+\infty}$ which are orthogonal with respect to a weight function have the nice property that the polynomial $P_n(x)$ has n real simple zeros, which are located in the interior of the interval of orthogonality.

Our polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ fail to have this property, but we will prove the following.

THEOREM. *The polynomial $L_n^{\alpha,M,N}(x)$ has n real simple zeros. At least $n-1$ of them lie in $(0, +\infty)$, the interior of the interval of orthogonality.*

In other words, at most one zero of $L_n^{\alpha,M,N}(x)$ lies in $(-\infty, 0]$.

Proof. Suppose that $x_1, x_2, \ldots, x_k$ are the zeros of $L_n^{\alpha,M,N}(x)$ which lie in $(0, +\infty)$ and have odd multiplicity. Define

$$p(x) = C \cdot (x-x_1)(x-x_2) \cdots (x-x_k), \qquad C \in \mathbb{R}$$

such that

$$p(x) \cdot L_n^{\alpha,M,N}(x) \geqq 0 \quad \forall x \geqq 0.$$

Define

$$h(x) = (x+d) \cdot p(x)$$

such that $h'(0) = 0$. This implies

$$d = -\frac{p(0)}{p'(0)} > 0,$$

since $p(0)$ and $p'(0)$ have opposite signs.

Hence

$$\langle h, L_n^{\alpha,M,N} \rangle = \frac{1}{\Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^\alpha e^{-x} \cdot h(x) L_n^{\alpha,M,N}(x)\, dx + M \cdot h(0) \cdot L_n^{\alpha,M,N}(0) > 0.$$

Hence degree $[h] \geqq n$, which implies $k \geqq n-1$. This proves the theorem.

Now we examine the nonpositive zero of $L_n^{\alpha,M,N}(x)$ in somewhat greater detail. In view of (4.1) we have $L_n^{\alpha,M,N}(x) > 0$ for $x < 0$ and $|x|$ large enough. This implies that the polynomial $L_n^{\alpha,M,N}(x)$ has a zero in $(-\infty, 0]$ if and only if $L_n^{\alpha,M,N}(0) \leqq 0$. From (4.2) it follows that $L_n^{\alpha,M,N}(0) \leqq 0$ if $N > 0$ and n is sufficiently large. Now we will prove the following.

THEOREM. *Let $N > 0$ and n be sufficiently large such that $L_n^{\alpha,M,N}(x)$ has a zero x_n in $(-\infty, 0]$. Then we have, for $M > 0$,*

$$-\frac{1}{2} \cdot \sqrt{\frac{N}{M}} \leqq x_n \leqq 0. \tag{9.1}$$

Furthermore, we have

$$x_n \to 0 \quad \textit{for } n \to +\infty. \tag{9.2}$$

Proof. Let $x_1, x_2, \ldots, x_{n-1}$ be the zeros of $L_n^{\alpha,M,N}(x)$ which lie in $(0, +\infty)$, and define

$$r(x) = (x-x_1)(x-x_2) \cdots (x-x_{n-1}).$$

Then we may write, in view of (4.1),

$$L_n^{\alpha,M,N}(x) = \frac{(-1)^n}{n!} \cdot A_0 \cdot r(x) \cdot (x-x_n),$$

where $x_n \leqq 0$. Since degree $[r] = n-1$ we have

$$\begin{aligned} 0 = \langle r, L_n^{\alpha,M,N} \rangle &= \frac{(-1)^n \cdot A_0}{n! \cdot \Gamma(\alpha+1)} \cdot \int_0^{+\infty} x^\alpha e^{-x} \cdot r^2(x) \cdot (x-x_n)\, dx \\ &\quad - \frac{(-1)^n}{n!} \cdot A_0 \cdot M \cdot r^2(0) \cdot x_n + \frac{(-1)^n}{n!} \cdot A_0 \cdot N \cdot r'(0) \\ &\quad \cdot [r(0) - x_n \cdot r'(0)]. \end{aligned} \tag{9.3}$$

Since the integral in (9.3) is nonnegative we must have

$$-M\cdot r^2(0)\cdot x_n+N\cdot r'(0)\cdot[r(0)-x_n\cdot r'(0)]\leqq 0.$$

Hence

$$[M\cdot r^2(0)+N\cdot\{r'(0)\}^2]\cdot x_n\geqq N\cdot r(0)\cdot r'(0)=-N\cdot|r(0)\cdot r'(0)|,$$

since $r(0)$ and $r'(0)$ have opposite signs. Now it follows that

$$2\sqrt{M\cdot N}\cdot|r(0)\cdot r'(0)|\cdot x_n\geqq[M\cdot r^2(0)+N\cdot\{r'(0)\}^2]\cdot x_n\geqq -N\cdot|r(0)\cdot r'(0)|.$$

Hence

$$2\sqrt{M\cdot N}\cdot x_n\geqq -N.$$

Now (9.1) follows for $M>0$.

If $x<0$ we may write

$$\begin{aligned}L_n^{\alpha,M,N}(x)&=L_n^{\alpha,M,N}(0)+x\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}\\&\quad+\frac{x^2}{2!}\cdot\left\{\frac{d^2}{dx^2}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}+\frac{x^3}{3!}\cdot\left\{\frac{d^3}{dx^3}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=\xi}\end{aligned}\tag{9.4}$$

for some ξ with $x<\xi<0$.

Since the zeros of $(d/dx)L_n^{\alpha,M,N}(x)$ all lie between two consecutive zeros of $L_n^{\alpha,M,N}(x)$ by Rolle's theorem and

$$\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}<0$$

we must have that all zeros of $(d/dx)L_n^{\alpha,M,N}(x)$ are positive. This means that $(d/dx)L_n^{\alpha,M,N}(x)$ is negative and increasing for $x<0$. In the same way we conclude that $(d^2/dx^2)L_n^{\alpha,M,N}(x)$ must be positive and decreasing for $x<0$. Hence

$$\left\{\frac{d^3}{dx^3}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=\xi}<0\quad\text{for }\xi<0.$$

Hence, with (9.4),

$$L_n^{\alpha,M,N}(x)>a\cdot x^2+b\cdot x+c\tag{9.5}$$

for $x<0$, where, with (4.2) and (4.3),

$$a=\frac{1}{2}\cdot\left\{\frac{d^2}{dx^2}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0},\tag{9.6}$$

$$b=\left\{\frac{d}{dx}L_n^{\alpha,M,N}(x)\right\}\bigg|_{x=0}=-\binom{n+\alpha}{n-1}-\frac{M}{(\alpha+1)}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-1}\tag{9.7}$$

and

$$c=L_n^{\alpha,M,N}(0)=\binom{n+\alpha}{n}\cdot\left[1-\frac{N}{(\alpha+1)}\cdot\binom{n+\alpha+1}{n-2}\right].\tag{9.8}$$

Using (1.2), (1.3), (2.1), and (2.4) we obtain

$$\begin{aligned}\left.\left\{\frac{d^2}{dx^2}L_n^{\alpha,M,N}(x)\right\}\right|_{x=0}&=\binom{n+\alpha}{n-2}+\frac{2M}{(\alpha+1)}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-2}\\&+\frac{n(\alpha+2)-\alpha}{(\alpha+1)(\alpha+2)(\alpha+4)}\cdot N\cdot\binom{n+\alpha}{n-1}\binom{n+\alpha+1}{n-2}\\&+\frac{2MN}{(\alpha+1)^2(\alpha+2)(\alpha+3)}\cdot\binom{n+\alpha}{n}\binom{n+\alpha+1}{n-1}\binom{n+\alpha+2}{n-2},\end{aligned}\tag{9.9}$$

which can be derived easier by using another representation given by (10.1) and (10.2). With (8.13) it follows from (9.6), (9.7), (9.8), and (9.9) that

$$\begin{cases}a\sim\text{const}\cdot n^{2\alpha+5} & \text{if } M=0,\\ a\sim\text{const}\cdot n^{3\alpha+6} & \text{if } M>0,\end{cases}\tag{9.10}$$

$$\begin{cases}b\sim-\text{const}\cdot n^{\alpha+1} & \text{if } M=0,\\ b\sim-\text{const}\cdot n^{2\alpha+2} & \text{if } M>0,\end{cases}\tag{9.11}$$

and

$$c\sim-\text{const}\cdot n^{2\alpha+3}\tag{9.12}$$

for $n\to+\infty$. The constants in (9.10), (9.11), and (9.12) are all positive. This implies for the sum of the roots of $a\cdot x^2+b\cdot x+c$ that

$$-\frac{b}{2a}\sim\text{const}\cdot n^{-\alpha-4}\to 0\quad\text{if } n\to+\infty,$$

and for the product of the roots,

$$\begin{cases}\dfrac{c}{a}\sim-\text{const}\cdot n^{-2}\to 0 & \text{if } n\to+\infty \text{ in the case } M=0,\\[2ex] \dfrac{c}{a}\sim-\text{const}\cdot n^{-\alpha-3}\to 0 & \text{if } n\to+\infty \text{ in the case } M>0.\end{cases}$$

In view of (9.5), the nonpositive zero x_n lies between the two roots of the "parabola" $a\cdot x^2+b\cdot x+c$. This proves (9.2).

10. Remark. The polynomials $\{L_n^{\alpha,M,N}(x)\}_{n=0}^{+\infty}$ can also be defined by

$$L_n^{\alpha,M,N}(x)=B_0\cdot L_n^{(\alpha)}(x)+B_1\cdot x\cdot L_{n-1}^{(\alpha+2)}(x)+B_2\cdot x^2\cdot L_{n-2}^{(\alpha+4)}(x),\tag{10.1}$$

where

$$\begin{cases}B_0=1-\dfrac{N}{(\alpha+1)}\cdot\dbinom{n+\alpha+1}{n-2},\\[2ex] B_1=-\dfrac{M}{(\alpha+1)}\cdot\dbinom{n+\alpha}{n}-\dfrac{(\alpha+2)\cdot N}{(\alpha+1)(\alpha+3)}\cdot\dbinom{n+\alpha}{n-2},\\[2ex] B_2=\dfrac{N}{(\alpha+1)(\alpha+2)(\alpha+3)}\cdot\dbinom{n+\alpha}{n-1}+\dfrac{M\cdot N}{(\alpha+1)^2(\alpha+2)(\alpha+3)}\\[2ex] \qquad\cdot\dbinom{n+\alpha}{n}\dbinom{n+\alpha+1}{n-1}.\end{cases}\tag{10.2}$$

This can be proved by using the formula

$$n \cdot L_n^{(\alpha)}(x) + (\alpha+1) \cdot \frac{d}{dx} L_n^{(\alpha)}(x) = -x \cdot L_{n-1}^{(\alpha+2)}(x),$$

which follows from the Laguerre differential equation and formula (5.1.13) in [8]. Note that we have

$$\binom{n+\alpha}{n} \cdot B_0 = L_n^{\alpha,M,N}(0),$$

where $B_0 \leqq 0$ if $N > 0$ and n is large enough,

$$A_2 = (\alpha+2)(\alpha+3) \cdot B_2,$$

and

$$B_1 \leqq 0 \quad \text{and} \quad B_2 \geqq 0.$$

Finally, for Koornwinder's polynomials $\{L_n^{\alpha,M}(x)\}_{n=0}^{+\infty}$ this representation yields

$$L_n^{\alpha,M,}(x) = L_n^{(\alpha)}(x) - \frac{M}{(\alpha+1)} \cdot \binom{n+\alpha}{n} \cdot x \cdot L_{n-1}^{(\alpha+2)}(x).$$

ON MULTIVARIATE ORTHOGONAL POLYNOMIALS*

YUAN XU†

Abstract. Orthogonal polynomials in several variables are studied. The results include a new formulation of the recurrence relation, characteri zation of orthogonality of polynomial sequences, an analogy of Christoffel–Darboux formula, and properties of reproducing kernel function.

Key words. multivariate orthogonal polynomials, three-term relation

AMS subject classifications. 42C05, 33C50

1. Introduction.

One of the most important characteristics of orthogonal polynomials in one variable is the three-term recurrence relation. Let $\{p_n(x)\}$ be a sequence of orthonormal polynomials, $p_n(x) = \gamma_n x^n + \cdots$. Then

$$xp_n(x) = a_n p_{n+1}(x) + b_n p_n(x) + c_n p_{n-1}(x), \tag{1.1}$$

where $p_{-1}(x) \equiv 0$, $a_n = \gamma_n/\gamma_{n+1}$ and $c_n = a_{n-1}$. One application of this relation leads to the Christoffel-Darboux formula

$$\sum_{k=0}^{n} p_k(x)p_k(y) = \frac{\gamma_n}{\gamma_{n+1}} \frac{p_{n+1}(x)p_n(y) - p_n(x)p_{n+1}(y)}{x-y}, \tag{1.2}$$

which plays a fundamental role in the study of orthogonal expansions, since

$$K_n(x,y) := \sum_{k=0}^{n} p_k(x)p_k(y) \tag{1.3}$$

represents the kernel of the partial sums of the orthogonal expansions.

The purpose of this paper is to study the corresponding formulas for multivariate orthogonal polynomials. There are only a few papers dealing with general theory of multivariate orthogonal polynomials (cf. [4], [8]–[11]). One of the difficulties lies in the following fact. For $n > 0$, let V_n be the set of polynomials of total degree n that are orthogonal to all polynomials of lower degree together with zero; then V_n is a vector space of dimension greater than one; there is no reason to assume that one basis for V_n is better than all others. There has been speculation that a general theory should be given for the class V_n rather than some basis of V_n (cf. [7], [11]). In this paper we shall try to follow this point of view.

In his important work [8]–[10], Kowalski introduced a matrix-vector notation to study the recurrence relation; he also characterized the orthogonality of a sequence of polynomials in several variables via recurrence relations. We shall state his main results in §2 after introducing the notation. In §3, we shall present another formulation of the recurrence relation; some important properties of the coefficient matrices will come out of the new formulation. These properties are then used to prove a simplified version of Kowalski's theorem. Moreover, an analogy of the Christoffel–Darboux

*Received by the editors February 14, 1991; accepted for publication August 31, 1992.

formula will be derived from the recurrence relation in §4; this analogy can be seen as given in terms of V_n rather than a particular basis of V_n. In §5, kernel function and some of its properties will be discussed. Finally, some examples will be given in §6. The work along this line will be continued in our future communications.

This work is inspired by a special recurrence relation for orthogonal polynomials in two variables that has been used to study minimal cubature formulas (cf. [2], [12]).

2. Preliminary. Let Π_n^d be the space of polynomials of total degree n in d variables, and let Π^d be the space of all polynomials in d variables. In all our notation, the superscript d will always associate with number of variables; we shall omit d from any notation after its initial definition, when it causes no confusion. A real valued linear functional $\mathcal{L}$ is said to be a quasi-inner product in Π^d if there exists a basis B of Π^d such that

$$\mathcal{L}(PQ)\begin{cases} =0 & \text{if } P\neq Q \\ \neq 0 & \text{if } P=Q \end{cases} \quad \forall\ P,Q\in B. \tag{2.1}$$

Examples include any linear functional expressible as an integral against a nonnegative weight function w, which induces the inner product $\langle\cdot,\cdot\rangle$,

$$\langle f,g\rangle=\mathcal{L}(fg)=\int_{\mathbb{R}^d} f(\mathbf{x})g(\mathbf{x})w(\mathbf{x})\,d\mathbf{x}. \tag{2.2}$$

For an inner product we take $\mathcal{L}(P^2)=1$ in (2.1).

Given a quasi-inner product $\mathcal{L}$ in Π^d, two polynomials P and Q are said to be orthogonal if $\mathcal{L}(PQ)=0$. For each $k\geq 0$, let $V_k^d\subset\Pi_k^d$ be the set of polynomials of total degree k that are orthogonal to all polynomials in Π_{k-1} together with zero. Then V_k^d is a vector space of dimension $r_k^d := \binom{k+d-1}{k}$. Clearly

$$\Pi_n=\bigoplus_{k=0}^{n} V_k \quad\text{and}\quad \Pi=\bigoplus_{k=0}^{\infty} V_k\ , \tag{2.3}$$

and V_k's are mutually orthogonal. We shall say that $\{V_k\}_{k=0}^{\infty}$ are orthogonal without refering to $\mathcal{L}$. A basis B of Π^d is called orthogonal if

$$B=\bigoplus_{k=0}^{\infty} B_k, \tag{2.4}$$

where B_k is a basis of V_k for each $k\geq 0$. If a basis of V_k is given by $B_k=\{P_1^k,P_2^k,\ldots,P_{r_k}^k\}$, we define vector

$$\mathbb{P}_k(\mathbf{x})=\left[P_1^k(\mathbf{x}),P_2^k(\mathbf{x}),\ldots,P_{r_k}^k(\mathbf{x})\right]^T. \tag{2.5}$$

Sometimes we shall say that $\mathbb{P}_k$ is a basis of V_k, and $\{\mathbb{P}_k\}_{k=0}^{\infty}$ is an orthogonal basis of Π^d. We shall also use the notation (2.5) for any polynomial sequence $\{P_j^k\}_{j=1}^{r_k}$, where the supscript k always means that p_j^k is of total degree k. For $\mathbf{x},\mathbf{y}\in\mathbb{R}^d$, we always write $\mathbf{x}=(x_1,x_2,\ldots,x_d)^T$, $\mathbf{y}=(y_1,y_2,\ldots,y_d)^T$.

We now state Kowalski's theorem. For $\mathbf{x}\in\mathbb{R}^d$, we define

$$\mathbf{x}\mathbb{P}_k(\mathbf{x})=\left[x_1\mathbb{P}_k^T|x_1\mathbb{P}_k^T|\cdots|x_d\mathbb{P}_k^T\right]^T.$$

Let $M_1, M_2, \ldots, M_d$ be any matrices with identical dimensions; we denote

$$bp\Big(\big[M_1|M_2|\cdots|M_d\big]\Big) = \big[M_1^T|M_2^T|\cdots|M_d^T\big]^T.$$

THEOREM K. *Let $B = \{P_i^k\}_{k=0}^{\infty}{}_{i=1}^{r_k}$ be an arbitrary sequence in Π^d. Then the following statements are equivalent:*

(1) *B is a basis of Π^d and there exists a linear functional $\mathcal{L}$ which defines a quasi-inner product in Π^d and satisfies*

$$\mathcal{L}(1) = 1, \quad \mathcal{L}(\mathbb{P}_k\mathbb{P}_\ell^T) = 0, \quad k \neq \ell.$$

(2) *For each $k \geq 0$, there exist (unique) matrices A_k, B_k, and C_k such that*

(a) $\operatorname{rank} A_k = r_{k+1}$;

(b) $\mathbf{x}\mathbb{P}_k = A_k\mathbb{P}_{k+1} + B_k\mathbb{P}_k + C_k\mathbb{P}_{k-1}$ $(C_0 = \mathbb{O}\ ,\ \mathbb{P}_{-1} = \mathbb{O})$;

and for an arbitrary sequence $D_0, D_1, \ldots,$ of matrices satisfying $D_kA_k = I$ (unit matrix) the recursion

(c) $I_0 = [1]$, $I_{k+1} = D_k bp(I_kC_{k+1}^T)$, $k = 0, 1, \ldots,$ *produces nonsingular symmetric matrices I_k.*

The notation $A : i \times j$ means that A is an $i \times j$ matrix. We note that the matrices in the recurrence relation (b) are of the dimensions $A_k : dr_k \times r_{k+1}$, $B_k : dr_k \times r_k$ and $C_k : dr_k \times r_{k+1}$.

3. Recurrence relation. For a matrix $P = (p_{ij})$ whose coefficients p_{ij} belong to Π^d, we denote by $\mathcal{L}(P)$ the matrix whose coefficients are numbers $\mathcal{L}(p_{ij})$. If $\{\mathbb{P}_k(\mathbf{x})\}_{k=0}^{\infty}$ is an orthogonal basis, we denote by H_k the matrix

$$H_k = \mathcal{L}(\mathbb{P}_k\mathbb{P}_k^T). \tag{3.1}$$

From the definition of the quasi-inner product, it follows that H_k is invertible. Indeed, the linear property of $\mathcal{L}$ and (2.1) imply that $\mathcal{L}(P^2) \neq 0$, $\forall\ P \neq 0$, $P \in \Pi^d$. Thus for any vector $\mathbf{c} \in \mathbb{R}^k$,

$$\mathbf{c}^T H_k \mathbf{c} = \mathcal{L}\big([\mathbf{c}^T\mathbb{P}_k]^2\big) \neq 0,$$

which implies that H_k is invertible.

THEOREM 1. *If $\{\mathbb{P}_k(\mathbf{x})\}_{k=0}^{\infty}$ is an orthogonal basis with respect to a quasi-inner product $\mathcal{L}$, $\mathbf{x} \in \mathbb{R}^d$, then for each $k \geq 0$, $1 \leq i \leq d$, there exist unique matrices $A_{k,i} : r_k \times r_{k+1}$, $B_{k,i} : r_k \times r_k$, $C_{k,i} : r_k \times r_{k-1}$ such that*

$$x_i\mathbb{P}_k = A_{k,i}\mathbb{P}_{k+1} + B_{k,i}\mathbb{P}_k + C_{k,i}\mathbb{P}_{k-1}, \qquad 1 \leq i \leq d\ ,\ k \geq 0, \tag{3.2}$$

where $\mathbb{P}_{-1} = 0$ and for all $1 \leq i \leq d$, $k \geq 0$,

$$A_{k,i}H_{k+1} = \mathcal{L}(x_i\mathbb{P}_k\mathbb{P}_{k+1}^T), \tag{3.3}$$

$$B_{k,i}H_k = \mathcal{L}(x_i\mathbb{P}_k\mathbb{P}_k^T), \tag{3.4}$$

$$A_{k,i}H_{k+1} = H_kC_{k+1,i}^T. \tag{3.5}$$

Furthermore, there exist matrices $D_{k,i} : r_{k+1} \times r_k$, $1 \leq i \leq d$, $E_k : r_{k+1} \times r_k$, and $F_k : r_{k+1} \times r_{k-1}$ such that

$$\mathbb{P}_{k+1} = \sum_{i=1}^{d} x_iD_{k,i}\mathbb{P}_k + E_k\mathbb{P}_k + F_k\mathbb{P}_{k-1}, \tag{3.6}$$

where

$$\sum_{i=1}^{d} D_{k,i}A_{k,i} = I, \tag{3.7}$$

$$\sum_{i=1}^{d} D_{k,i}B_{k,i} = -E_k, \qquad \sum_{i=1}^{d} D_{k,i}C_{k,i} = -F_k. \tag{3.8}$$

Proof. The existence of $A_{k,i}$, $B_{k,i}$, and $C_{k,i}$ follows easily from the orthogonality. Actually, (3.2) is just another formulation of Theorem K(b). Multiplying (3.2) by $\mathbb{P}_{k+1}^T$, $\mathbb{P}_k^T$, and $\mathbb{P}_{k-1}^T$ respectively and applying the quasi-inner product, we can easily check that (3.3), (3.4), and (3.5) hold. Equation (3.6) is a reformulation of the corresponding recursion formula of Kowalski [8, Thm. 2]. Substituting $x_i\mathbb{P}_k$ in (3.2) into (3.6), we get (3.7) and (3.8) from orthogonality. □

In the following, we denote by $A_k : dr_k \times r_{k+1}$ and $C_k : r_k \times dr_{k-1}$

$$A_k = \left[A_{k,1}^T | A_{k,2}^T | \cdots | A_{k,d}^T\right]^T \quad \text{and} \quad C_k = \left[C_{k,1} | C_{k,2} | \cdots | C_{k,d}\right]. \tag{3.9}$$

COROLLARY 1. *Let $A_{k,i}$, $C_{k,i}$, $1 \le i \le d$, $k \ge 0$, be as in Theorem 1. Then*

$$\operatorname{rank} A_k = r_{k+1}, \qquad \operatorname{rank} C_{k+1} = r_{k+1} \tag{3.10}$$

and

$$\operatorname{rank} A_{k,i} = \operatorname{rank} C_{k+1,i} = r_k\ , \qquad 1 \le i \le d. \tag{3.11}$$

Proof. Comparing (3.2) and Theorem K(b), we see that A_k in (3.9) is the same as A_k in Theorem K. Thus $\operatorname{rank} A_k = r_{k+1}$. From (3.5) we get that

$$A_k H_{k+1} = G_k C_{k+1}^T,$$

where $G_k : dr_k \times dr_k$ has H_k as diagonal blocks, $G_k = \operatorname{diag}(H_k, H_k, \ldots, H_k)$. Since H_k is invertible, we then have that G_k is invertible; thus

$$\operatorname{rank} C_{k+1} = \operatorname{rank} G_k C_{k+1}^T = \operatorname{rank} A_k H_{k+1} = \operatorname{rank} A_k,$$

which proves (3.10). We now prove (3.11). By (3.3) and (3.5), we only need to prove that $\mathcal{L}(x_i\mathbb{P}_k\mathbb{P}_{k+1}^T)$ has rank r_k. Suppose its rank is less than r_k. Then there exists a nonzero vector $\mathbf{c}_k$ such that

$$\mathbf{c}_k^T \mathcal{L}(x_i\mathbb{P}_k\mathbb{P}_{k+1}^T) = 0.$$

This means that $x_iQ \perp V_{k+1}$, where $Q = \mathbf{c}_k^T\mathbb{P}_k \in V_k$. However, $x_iQ \in \Pi_{k+1} = V_{k+1} \oplus \Pi_k$, thus $x_iQ \in \Pi_k$, which is a contradiction to $Q \in V_k$. □

We remark that the matrices $D_{k,i}$ in the recursion formula (3.6) are not unique when $d > 1$. A way of choosing $D_k = [D_{k,1}|D_{k,2}|\cdots|D_{k,d}]$ is given in [8]. It was also shown there that $\operatorname{rank} D_k = r_{k+1}$. However, it seems unlikely that anything can be said about the rank of $D_{k,i}$ (see Example 2 in §6). From (3.7) and the fact that $\operatorname{rank} A_k = r_k$, some $D_{k,i}$ may even be zero for d large. The recursion formula (3.6) may deserve further attention.

We note that the matrices $B_{k,i}H_k$ are symmetric by (3.4). This fact and the equation (3.5) that came out of the present form of the recurrence relation will enable us to derive an analogy of Christoffel–Darboux formula in §4. The importance of (3.10) can be seen in our next theorem, which simplifies Theorem K.

THEOREM 2. *Let* $B = \{P_j^k\}_{k=0}^{\infty}{}_{j=1}^{r_k}$, $P_1^0 \neq 0$, *be an arbitrary sequence in* Π^d. *Then the following statements are equivalent*:

(1) *There exists a linear function* $\mathcal{L}$ *which defines a quasi-inner product in* Π^d *and makes* $\{\mathbb{P}_k\}_{k=0}^{\infty}$ *an orthogonal basis in* Π^d;

(2) *For* $k \geq 0$, $1 \leq i \leq d$, *there exist matrices* $A_{k,i}$, $B_{k,i}$ *and* $C_{k,i}$ *such that*

(a) $\operatorname{rank} A_k = r_{k+1}$, $\operatorname{rank} C_{k+1} = r_{k+1}$;

(b) $x_i\mathbb{P}_k = A_{k,i}\mathbb{P}_{k+1} + B_{k,i}\mathbb{P}_k + C_{k,i}\mathbb{P}_{k-1}, \quad 1 \leq i \leq d.$

Proof. Clearly the fact that (1) implies (2) is contained in Theorem 1 and its corollary. To prove that (2) implies (1), we shall follow the outline of the proof in [10]. The linear functional

$$\mathcal{L}(1) = 1, \quad \mathcal{L}(\mathbb{P}_k) = 0, \quad k \geq 1$$

is well-defined on Π^d, since $\operatorname{rank} A_k = r_{k+1}$ implies that B is a basis of Π^d. We now use induction to prove that

$$\mathcal{L}(\mathbb{P}_i\mathbb{P}_j^T) = 0, \qquad i \neq j. \tag{3.12}$$

Let $k \geq 0$ be an integer. Assume that (3.12) holds for every i, j such that $0 \leq i \leq k$ and $j > i$. Note that $\operatorname{rank} A_k = r_{k+1}$ and (b) implies that there exist $D_{k,i}$ such that (3.6) holds. Therefore, for $\ell > k+1$,

$$\begin{aligned}\mathcal{L}(\mathbb{P}_{k+1}\mathbb{P}_\ell^T) =& \mathcal{L}\left(\sum_{i=1}^d x_i D_{k,i}\mathbb{P}_k\mathbb{P}_\ell^T\right)\\ =& \mathcal{L}\left(\sum_{i=1}^d D_{k,i}\mathbb{P}_k(A_{\ell,i}\mathbb{P}_{\ell+1} + B_{\ell,i}\mathbb{P}_\ell + C_{\ell,i}\mathbb{P}_{\ell-1})^T\right) = 0.\end{aligned}$$

The induction is complete. Next we prove that $H_k := \mathcal{L}(\mathbb{P}_k\mathbb{P}_{k+1}^T)$ is invertible. Clearly H_k is symmetric. From (b) and (3.12), we get that

$$A_{k,i}H_{k+1} = H_kC_{k+1,i}^T,$$

thus

$$A_kH_{k+1} = G_kC_{k+1}^T,$$

where $G_k = \operatorname{diag}(H_k, \ldots, H_k)$. Since $\mathcal{L}(1) = 1$, we see that $H_0 = \mathcal{L}(\mathbb{P}_0\mathbb{P}_0^T) = (P_1^0)^2$. Thus H_0 is invertible. Suppose H_k is invertible. Then G_k is invertible and by $\operatorname{rank} C_{k+1} = r_{k+1}$ we get

$$\operatorname{rank} A_kH_{k+1} = \operatorname{rank} G_kC_{k+1}^T = r_{k+1}.$$

However, $\operatorname{rank} A_k = r_{k+1}$ by (a) and $A_k : dr_k \times r_{k+1}$, $H_{k+1} : r_{k+1} \times r_{k+1}$; we then have (see [6, p. 66])

$$\begin{aligned}\operatorname{rank} H_{k+1} \geq \operatorname{rank}(A_kH_{k+1}^T) &\geq \operatorname{rank} A_k + \operatorname{rank} H_{k+1}^T - r_{k+1}\\ &= \operatorname{rank} H_{k+1}^T = \operatorname{rank} H_{k+1}.\end{aligned}$$

Therefore,

$$\operatorname{rank} H_{k+1} = \operatorname{rank} A_kH_{k+1}^T = r_{k+1},$$

which implies that H_{k+1} is invertible. By induction, we have then proved that H_k is invertible for each $k \geq 0$. Since H_k is symmetric and invertible there exist invertible matrices S_k and I_k such that $H_k = S_k I_k S_k^T$ and I_k is diagonal. For $\mathbb{Q}_k = S_k^{-1}\mathbb{P}_k$ we then have

$$\mathcal{L}(\mathbb{Q}_k\mathbb{Q}_k^T) = S_k^{-1}\mathcal{L}(\mathbb{P}_k\mathbb{P}_k^T)(S_k^{-1})^T = S_k^{-1}H_k(S_k^{-1})^T = I_k.$$

This proves that $\mathcal{L}$ defines a quasi-inner product in Π^d; $\mathcal{L}$ makes $\{\mathbb{P}_k\}_{k=0}^{\infty}$ an orthogonal basis by (3.12). The proof is completed. □

This theorem should be compared with that of Favard for polynomials in one variable (cf. [5, p.18–22]). We note that a comparison criterion of orthogonality for sequences of polynomials and an integral representation for a corresponding quasi-inner product are given in [9].

4. Christoffel–Darboux formula. The following theorem is a generalization of the well-known Christoffel–Darboux formula (1.3) (cf. [5, p.23]).

THEOREM 3. *Let* $\mathbf{x} \in \mathbb{R}^d$ *and* $\{\mathbb{P}_k(\mathbf{x})\}_{k=0}^{\infty}$ *satisfy*

$$(4.1) \qquad x_i\mathbb{P}_k = A_{k,i}\mathbb{P}_{k+1} + B_{k,i}\mathbb{P}_k + C_{k,i}\mathbb{P}_{k-1}, \qquad 1 \leq i \leq d,$$

where $\mathbb{P}_{-1} = 0$ *and*

$$(4.2) \qquad A_{k,i}H_{k+1} = H_kC_{k+1,i}^T, \qquad 1 \leq i \leq d,\ k \geq 0,$$

with H_k *being symmetric and invertible and* $B_{k,i}H_k$ *being symmetric. Then for any integer* $n \geq 0$, $\mathbf{x}, \mathbf{y} \in \mathbb{R}^d$,

$$(4.3) \sum_{k=0}^{n} \mathbb{P}_k^T(\mathbf{x})H_k^{-1}\mathbb{P}_k(\mathbf{y}) = \frac{\left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})\right]^T H_n^{-1}\mathbb{P}_n(\mathbf{y}) - \mathbb{P}_n^T(\mathbf{x})H_n^{-1}\left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{y})\right]}{x_i - y_i},$$

$$1 \leq i \leq d.$$

Proof. Let

$$\Sigma_k = \left[A_{k,i}\mathbb{P}_{k+1}(\mathbf{x})\right]^T H_k^{-1}\mathbb{P}_k(\mathbf{y}) - \mathbb{P}_k(\mathbf{x})^T H_k^{-1}\left[A_{k,i}\mathbb{P}_{k+1}(\mathbf{y})\right].$$

From the recurrence relation (4.1) we have

$$(4.4) \qquad \begin{aligned} \Sigma_k &= \left[x_i\mathbb{P}_k(\mathbf{x}) - B_{k,i}\mathbb{P}_k(\mathbf{x}) - C_{k,i}\mathbb{P}_k(\mathbf{x})\right]^T H_k^{-1}\mathbb{P}_k(\mathbf{y}) \\ &\quad - \mathbb{P}_k^T(\mathbf{x})H_k^{-1}\left[y_i\mathbb{P}_k(\mathbf{y}) - B_{k,i}\mathbb{P}_k(\mathbf{y}) - C_{k,i}\mathbb{P}_{k-1}(\mathbf{y})\right] \\ &= (x_i - y_i)\mathbb{P}_k^T(\mathbf{x})H_k^{-1}\mathbb{P}_k(\mathbf{y}) - \mathbb{P}_k^T(\mathbf{x})\left[B_{k,i}^T H_k^{-1} - H_k^{-1}B_{k,i}\right]\mathbb{P}_k(\mathbf{y}) \\ &\quad - \left[\mathbb{P}_{k-1}^T(\mathbf{x})C_{k,i}^T H_k^{-1}\mathbb{P}_k(\mathbf{y}) - \mathbb{P}_k^T(\mathbf{x})H_k^{-1}C_{k,i}\mathbb{P}_{k-1}(\mathbf{y})\right]. \end{aligned}$$

Since H_k and $B_{k,i}H_k$ are both symmetric, we have

$$B_{k,i}H_k = (B_{k,i}H_k)^T = H_kB_{k,i}^T,$$

which implies that

$$B_{k,i}^T H_k^{-1} = H_k^{-1}B_{k,i}.$$

Therefore, the second term in the right-hand side of (4.4) is zero. From (4.2) we have that

$$C_{k,i}^T H_k^{-1} = H_{k-1}^{-1}A_{k-1,i}.$$

Thus the third term in the right-hand side of (4.4) is

$$-\mathbb{P}_{k-1}^T(\mathbf{x})H_k^{-1}A_{k-1,i}\mathbb{P}_k(\mathbf{y}) + \mathbb{P}_k^T(\mathbf{x})A_{k-1,i}^T H_{k-1}^{-1}\mathbb{P}_{k-1}(\mathbf{y}) = \Sigma_{k-1}.$$

Therefore, (4.4) can be rewritten as

$$(x_i - y_i)\mathbb{P}_k^T(\mathbf{x})H_k^{-1}\mathbb{P}_k(\mathbf{y}) = \Sigma_k - \Sigma_{k-1}.$$

Summing this identity from zero to n and noticing that $\Sigma_{-1} = 0$, we obtain (4.3). □

COROLLARY. *Let $\{\mathbb{P}_k(\mathbf{x})\}_{k=0}^{\infty}$ be as in Theorem 1. Then*

(4.5)
$$\sum_{k=0}^{n}\mathbb{P}_k^T(\mathbf{x})H_k^{-1}\mathbb{P}_k(\mathbf{x}) = \mathbb{P}_n^T(\mathbf{x})H_n^{-1}\left[A_{n,i}\partial_i\mathbb{P}_{n+1}(\mathbf{x})\right] - \left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})\right]^T H_n^{-1}\partial_i\mathbb{P}_n(\mathbf{x}),$$

$$1 \le i \le d,$$

where $\partial_i = \partial/\partial x_i$ denotes the partial derivative with respect to x_i.

Proof. Since $\mathbb{P}_n(\mathbf{x})^T H_n^{-1}[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})]$ is a scalar function, it is equal to its own transpose. Thus,

$$\mathbb{P}_n(\mathbf{x})^T H_n^{-1}\left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})\right] = \left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})\right]^T H_n^{-1}\mathbb{P}_n(\mathbf{x}).$$

Therefore, the numerator of the right-hand side of (4.3) can be written as

$$\left[A_{n,i}\mathbb{P}_{n+1}(\mathbf{x})\right]^T H_n^{-1}\left[\mathbb{P}_n(\mathbf{y}) - \mathbb{P}_n(\mathbf{x})\right] - \mathbb{P}_n(\mathbf{x})^T H_n^{-1}A_{n,i}\left[\mathbb{P}_{n+1}(\mathbf{y}) - \mathbb{P}_{n+1}(\mathbf{x})\right].$$

Thus (4.5) follows from (4.3) by letting $y_i \to x_i$. □

In particular, if H_k is positive definite then the right-hand side of (4.5) is positive for all $\mathbf{x} \in \mathbb{R}^d$. The important examples include all orthogonal polynomials with respect to inner product (2.2). When $\{\mathbb{P}_k(\mathbf{x})\}_{k=0}^{\infty}$ in Theorem 3 is an orthogonal basis, $\mathbb{P}_k(\mathbf{x})$ is a basis for vector space V_k for each $k \ge 0$. However, (4.3) is actually independent of this particular basis of V_k. Let

$$K_n(\mathbf{x},\mathbf{y}) = \sum_{k=0}^{n-1}\mathbb{P}_k^T(\mathbf{x})H_k^{-1}\mathbb{P}_k(\mathbf{y}). \tag{4.6}$$

THEOREM 4. *Let V_k, $k \ge 0$, be defined via a quasi-inner product $\mathcal{L}$. Then $K_n(\cdot,\cdot)$ depends only on V_k rather than a particular basis of V_k.*

Proof. Let $\mathbb{P}_k$ be a basis of V_k. If $\mathbb{Q}_k$ is another basis, then there exists an invertible scalar matrix M_k such that

$$\mathbb{P}_k(\mathbf{x}) = M_k\mathbb{Q}_k(\mathbf{x}).$$

Let $H_k = H_k(\mathbb{P}) = \mathcal{L}(\mathbb{P}_k\mathbb{P}_k^T)$ and $H_k(\mathbb{Q}) = \mathcal{L}(\mathbb{Q}_k\mathbb{Q}_k^T)$. Then

$$H_k^{-1}(\mathbb{P}) = M_k^{-1}H_k^{-1}(\mathbb{Q})(M_k^T)^{-1}.$$

Therefore, we have

$$\mathbb{P}_k^T H_k^{-1}(\mathbb{P})\mathbb{P}_k = \mathbb{Q}_k^T H_k^{-1}(\mathbb{Q})\mathbb{Q}_k,$$

which proves the desired result. □

As a consequence of this theorem, the formula (4.3) can be seen as a natural extension of the Christoffel–Darboux formula of one variable, since the orthogonality is defined via V_k (cf. (2.4)). From this theorem, one can choose some convenient basis of V_k when dealing with $K_n(\cdot,\cdot)$. In particular, if an orthonormal basis of V_k is chosen, then there will be no inverse matrix operation in the formula, since H_k becomes an identity matrix. The choice of orthonormal basis is particularly preferable when we need to prove certain properties of $K_n(\cdot,\cdot)$, as we shall see in the next section.

We note that another expression of the Christoffel–Darboux formula is given in [4]. However, the formula is much more complicated; in particular, the numerator of the right-hand side in it has more terms than the left-hand side that is defined as (4.6).

5. Kernel function. For orthogonal polynomials in one variable, $K_n(\cdot,\cdot)$ is the reproducing kernel function; it has many important properties and applications. We now discuss some of its corresponding properties for multivariate orthogonal polynomials.

THEOREM 5. *Let $\mathcal{L}$ be an inner product in Π^d. Then*

(1) *$K_n(\cdot,\cdot)$ is the reproducing kernel, i.e., for all $P \in \Pi_{n-1}$,*

$$P(\mathbf{x}) = \mathcal{L}\big[K_n(\mathbf{x},\cdot)P(\cdot)\big]; \tag{5.1}$$

(2) *For an arbitrary point $\mathbf{t} \in \mathbb{R}^d$,*

$$K_n(\mathbf{t},\mathbf{t})^{-1} = \min \mathcal{L}[P^2], \tag{5.2}$$

where minimum is over all polynomials $P \in \Pi_{n-1}$ subject to the condition $P(\mathbf{t}) = 1$.

Proof. Since $\mathcal{L}$ is an inner product, by (2.1) there exists a basis $B = \{P_j^k\}_{k=0}^{\infty}{}_{j=0}^{r_k}$ of Π^d such that

$$\mathcal{L}(P_i^k P_j^\ell) = \delta_{ij}\delta_{k\ell}. \tag{5.3}$$

For any polynomial $P \in \Pi_{n-1}$, we have by orthogonality

$$P(\mathbf{x}) = \sum_{k=0}^{n-1} \mathbb{P}_k(\mathbf{x})^T \mathbf{a}_k(P), \quad \text{where } \mathbf{a}_k(P) = \mathcal{L}(P\mathbb{P}_k) \tag{5.4}$$

or

$$P(\mathbf{x}) = \sum_{k=0}^{n-1} \mathbb{P}_k(\mathbf{x})^T \mathcal{L}(P\mathbb{P}_k) = \mathcal{L}\big[K_n(\mathbf{x},\cdot)P(\cdot)\big],$$

which is (5.1). From (5.3) and (5.4), we also have

$$\mathcal{L}[P^2] = \sum_{k=0}^{n-1} \mathbf{a}_k(P)^T \mathbf{a}_k(P) = \sum_{k=0}^{n-1} \|\mathbf{a}_k(P)\|^2 ,$$

where $\|\cdot\|$ is the Euclidean norm, $\|\mathbf{a}\|^2 = \mathbf{a}^T\mathbf{a}$. If $P(\mathbf{t}) = 1$, we then have by Cauchy's inequality,

$$1 = P(\mathbf{t}) = \sum_{k=0}^{n-1} \mathbb{P}_k(\mathbf{t})^T \mathbf{a}_k(P) \le \sum_{k=0}^{n-1} \|\mathbf{a}_k(P)\| \, \|\mathbb{P}_k(\mathbf{t})\|$$

$$\le \sum_{k=0}^{n-1} \|\mathbf{a}_k(P)\|^2 \sum_{k=0}^{n-1} \|P_k(\mathbf{t})\|^2 = \mathcal{L}[P^2]K_n(\mathbf{t},\mathbf{t}),$$

where equality holds if and only if

$$\mathbf{a}_k(P) = KP_k(\mathbf{t}), \qquad K = [K_n(\mathbf{t},\mathbf{t})]^{-1}.$$

This proves (5.2), and the proof is completed. □

These two properties are completely analogous to the corresponding ones in one variable (cf. [5, p.38]); their proofs are similar as well. We enclosed the proof here to illustrate the importance of Theorem 4, which allows us to use orthonormal basis in the proof. We now briefly discuss the role of $K_n(\cdot,\cdot)$ as the kernel function of the orthogonal expansion. This part illustrates very well the point of view that we mentioned in the introduction (see also [11]). Most of the results in the following can be obtained from the standard theorems in inner product space.

Now let $\mathcal{L}$ be an inner product expressible in the form of (2.2), or more generally, we replace $w(\mathbf{x})\,d\mathbf{x}$ by some distribution $d\alpha$, $\int d\alpha > 0$. If $f \in L_{d\alpha}$, then by (2.3), the expansion

$$f \sim \sum_{k=0}^{\infty} U_k(f), \qquad U_k(f) = \operatorname{proj}_{V_k} f \tag{5.5}$$

can be formed (at least formally). Let $\mathbb{P}_k$ be a basis of V_k. Then $U_k(f)$ can be expressed by $\mathbb{P}_k$ as

$$U_k(f) = \mathbb{P}_k^T \mathbf{a}_k(f), \qquad \mathbf{a}_k(f) \in \mathbb{R}^{r_k}. \tag{5.6}$$

Therefore, we have

$$\int f\mathbb{P}_k\,d\alpha = \int U_k(f)\mathbb{P}_k\,d\alpha = \int \mathbb{P}_k\mathbb{P}_k^T\mathbf{a}_k(f) = H_k\mathbf{a}_k(f). \tag{5.7}$$

We shall call the expansion

$$f \sim \sum_{k=0}^{\infty} \mathbb{P}_k^T\mathbf{a}_k(f) = \sum_{k=0}^{\infty} \mathbb{P}_k^T H_k^{-1} \int f\mathbb{P}_k\,d\alpha \tag{5.8}$$

the Fourier orthogonal expansion of f. Let $S_nf = S_n(d\alpha, f)$ denote the nth partial sum of (5.8). Then we have from (4.6) that

$$S_nf(\mathbf{x}) = \int_{\mathbb{R}^d} K_n(\mathbf{x},\mathbf{y})f(\mathbf{y})\,d\alpha(\mathbf{y}).$$

Therefore, $K_n(\cdot,\cdot)$ is the kernel function of the partial sums. From Theorem 4, S_nf is defined in terms of V_k, $0 \le k \le n-1$, rather than some basis of V_k. The proof of the following theorem relies on this fact; otherwise, the proof is standard.

THEOREM 6. *Let $\mathcal{L}$ be an inner product associated with $d\alpha$ (or as in (2.2)), $f \in L^2_{d\alpha}$. Then among all polynomials P in Π_{n-1}, the integral*

$$\int |f(\mathbf{x}) - P(\mathbf{x})|^2\,d\alpha$$

becomes minimal if and only if $P = S_n(d\alpha, f)$.

Proof. Let $\mathbb{P}_k$ be an orthonormal basis of V_k. For any $P \in \Pi_{n-1}$ there exists $\mathbf{b}_k$ such that

$$P(\mathbf{x}) = \sum_{k=0}^{n-1} \mathbf{b}_k^T \mathbb{P}_k(\mathbf{x}).$$

Since $S_n f$ is defined in terms of V_k, we have

$$S_n f(\mathbf{x}) = \sum_{k=0}^{n-1} \mathbf{a}_k^T \mathbb{P}_k(\mathbf{x}), \qquad \text{where } \mathbf{a}_k = \int f \mathbb{P}_k \, d\alpha.$$

Then we follow the standard argument to get that

$$0 \le \int |f - P|^2 \, d\alpha = \int f^2 \, d\alpha - 2 \sum \mathbf{b}_k^T \int f \mathbb{P}_k \, d\alpha + \sum_k \sum_j \mathbf{b}_k^T \int \mathbb{P}_k \mathbb{P}_j^T \mathbf{b}_j$$

$$= \int f^2 \, d\alpha - 2 \sum_{k=0}^{n-1} \mathbf{b}_k^T \mathbf{a}_k + \sum_{k=0}^{n-1} \mathbf{b}_k^T \mathbf{b}_k$$

$$= \int f^2 \, d\alpha - \sum_{k=0}^{n-1} \mathbf{a}_k^T \mathbf{a}_k + \sum_{k=0}^{n-1} [\mathbf{a}_k^T \mathbf{a}_k + \mathbf{b}_k^T \mathbf{b}_k - 2\mathbf{b}_k^T \mathbf{a}_k] \; .$$

By Cauchy's inequality the third term in the right-hand side is nonnegative; and the integral is minimal if and only if $\mathbf{b}_k = \mathbf{a}_k$ or $P = S_n f$. □

The minimal itself leads to the Bessel's inequality, which, in terms of a basis $\mathbb{P}_k$ of V_k, is

$$\sum_{k=0}^{\infty} \mathbf{a}_k(f)^T H_k^{-1} \mathbf{a}_k(f) \le \int |f|^2 \, d\alpha,$$

where $\mathbf{a}_k(f)$ is given by (5.7). We note that $\mathbf{a}_k(f)^T H_k^{-1} \mathbf{a}_k(f)$ does not depend on a particular choice of the basis of V_k. When Π^d is dense in $L^2(d\alpha)$, the Parseval's identity that is (5.9) with equality holds and $S_n f$ converges to f in $L^2(d\alpha)$. For $d > 1$, the convergence behavior of $S_n f$ other than that of $L^2(d\alpha)$ has not been studied; one may start with the special bivariable orthogonal polynomials that have compact formulas such as those given in survey paper [7] by Koornwinder.

6. Examples. All examples in this section are given by polynomials in two variables which are orthogonal with respect to some weight functions w (see (2.2)). The first example deals with the simplest case that the orthogonal polynomials are the product of two univariant ones.

Example 1. Let $P_j^k(x_1, x_2) = p_{j-1}(x_1) q_{k-j+1}(x_2)$, $k \ge 0$, $1 \le j \le k+1$, where $p_j(x) = \gamma_j x^j + \cdots$ and $q_j(x) = \delta_j x^j + \cdots$ are the orthogonal polynomials on the symmetric intervals I_p and I_q with respect to even weight functions w_p and w_q, respectively. Then polynomials $\{P_j^k\}$ are orthogonal over the region $I_p \times I_q$ with respect to weight function $w_p(x_1) w_q(x_2)$. Examples of $\{p_j\}$ and $\{q_j\}$ include ultraspherical polynomials and Hermite polynomials. Let $\Gamma_{j+1} = \gamma_j / \gamma_{j+1}$, $\Delta_{j+1} = \delta_j / \delta_{j+1}$. We can easily verify that the recurrence relation (3.2) is

$$x_i \mathbb{P}_k = A_{k,i} \mathbb{P}_{k+1} + A_{k-1,i}^T \mathbb{P}_{k-1}, \qquad k \ge 0, \qquad i = 1, 2,$$

where

$$A_{k,1} = \big[\mathbb{O} \mid \operatorname{diag}(\Gamma_0, \Gamma_1, \dots, \Gamma_k)\big], \qquad A_{k,2} = \big[\operatorname{diag}(\Delta_k, \Delta_{k-1}, \dots, \Delta_0) \mid \mathbb{O}\big].$$

The recursion formula (3.6) now takes the form

$$\mathbb{P}_{k+1} = (x_1 D_{k,1} + x_2 D_{k,2})\mathbb{P}_k + F_k \mathbb{P}_{k-1},$$

where $D_{k,i}$, which are not unique, can be chosen as

$$D_{k,1} = \big[\mathbb{O} \mid \operatorname{diag}(\tfrac{1}{2}\Gamma_0^{-1}, \dots, \tfrac{1}{2}\Gamma_{k-1}^{-1}, \Gamma_k^{-1})\big]^T,$$
$$D_{k,2} = \big[\operatorname{diag}(\Delta_k^{-1}, \tfrac{1}{2}\Delta_{k-1}^{-1}, \dots, \tfrac{1}{2}\Delta_0^{-1}) \mid \mathbb{O}\big]^T,$$

and F_k are given by (3.8) with $C_{k,i} = A_{k-1,i}^T$.

As we pointed out before, the choice of orthonormal basis for V_k seems to be preferable in view of the Christoffel–Darboux formula. However, there are other bases that have been used in applications because of their other relatively simpler structures. An important example is the basis whose elements are monic polynomials (cf. [2], [11], [12]). Our next example illustrates this choice.

Example 2. Let $S = \{(x_1, x_2) \mid x_1 \geq 0, x_2 \geq 0, x_1 + x_2 \leq 1\}$. Let V_k be orthogonal with respect to the weight function $W_{\alpha,\beta,\gamma}$ that has support on S, $W_{\alpha,\beta,\gamma}(x_1, x_2) = x_1^\alpha x_2^\beta (1 - x_1 - x_2)^\gamma$, $(x_1, x_2) \in S$, $\alpha, \beta, \gamma > -1$.

One orthonormal basis of V_k is given by (cf. [7, p. 449])

$$P_j^k(x_1, x_2) = c_{jk}(1 - x_2)^j p_j^{(\beta,\gamma)}\left(\frac{x_1}{1 - x_2}\right) p_{k-j}^{(\alpha,\beta+\gamma+2j+1)}(x_2).$$

Here $p_j^{(a,b)}(x)$ is the classical Jacobi polynomial on $[0, 1]$ with respect to $w(x) = x^a(1-x)^b$, $c_{jk} \neq 0$ are the proper constants. It can be verified that the coefficient matrices in the recurrence relation (3.2) have the form

$$A_{k,1} = [T \mid \mathbf{a}], \qquad A_{k,2} = [D \mid \mathbb{O}],$$

where T is a tridiagonal matrix, D is a diagonal matrix, and $\mathbf{a} = (0, \dots, 0, a)^T$ for some $a \neq 0$.

Another basis that we consider is the monic one,

$$Q_{j+1}^k(x_1, x_2) = x_1^j x_2^{k-j} + q_j^k(x_1, x_2), \quad \text{where } q_j^k \in \Pi_{k-1},$$

$k \geq 0$, $0 \leq j \leq k$. These orthogonal polynomials are first considered in [1]; they have some very nice properties (see [1]–[3]). In [2], all coefficient matrices in the recurrence relation (3.2) have been given explicitly; the matrices $A_{k,i}$ are simply

$$A_{k,1} = (I_k \mid \mathbb{O}), \qquad A_{k,2} = (\mathbb{O} \mid I_k),$$

and $B_{k,i}$ are tridiagonal matrices, and $C_{k,i}$ are of the form $[T_k \mid \mathbf{a}]$, where T_k's are the tridiagonal matrices and $\mathbf{a} = (0, \dots, 0, a)^T$. We refer to [2] for the explicit formulas for $B_{k,i}$ and $C_{k,i}$. The matrices $D_{k,i}$ in (3.6) can be chosen to be very simple in many ways; however, there does not seem to be a choice that is better than all others. One possible choice is

$$D_{k,1} = (I_k \mid \mathbb{O})^T, \qquad D_{k,2} = (0 \mid \mathbf{e})^T,$$

where $\mathbf{e} = (0, \ldots, 0, 1)^T$. Since the monic orthogonal polynomials play a very important role in the study of the minimal cubature formulas (cf. [2], [12]), a more comprehensive study of them seems to be worthwhile.

Acknowledgment. I thank Professors H. Berens and H. Schmid for making me acquainted with their work and other assistance. I also thank Professor T. Koornwinder for bringing [10] to my attention.

ASKEY–WILSON POLYNOMIALS AS ZONAL SPHERICAL FUNCTIONS ON THE $SU(2)$ QUANTUM GROUP*

TOM H. KOORNWINDER[†]

Abstract. On the $SU(2)$ quantum group the notion of (zonal) spherical element is generalized by considering left and right invariance in the infinitesimal sense with respect to twisted primitive elements of the $sl(2)$ quantized universal enveloping algebra. The resulting spherical elements belonging to irreducible representations of quantum $SU(2)$ turn out to be expressible as a two-parameter family of Askey–Wilson polynomials. For a related basis change of the representation space a matrix of dual q-Krawtchouk polynomials is obtained. Big and little q-Jacobi polynomials are obtained as limits of Askey–Wilson polynomials.

Key words. quantum groups, $SU(2)$, spherical functions, infinitesimal invariance, Askey–Wilson polynomials, dual q-Krawtchouk polynomials, big q-Jacobi polynomials, little q-Jacobi polynomials

AMS subject classifications. 33D45, 33D80, 17B37

1. Introduction. One of the interesting aspects of the rapidly developing subject of quantum groups is that they seem to provide the natural setting for q-hypergeometric functions and orthogonal polynomials. For the relatively simple case of $SU_q(2)$ a first example of this phenomenon was given by Vaksman and Soĭbel'man [21] (see also Masuda et al. [14], [13] and the author [10]), where it was shown that the matrix elements of the irreducible representations of $SU_q(2)$ can be expressed in terms of little q-Jacobi polynomials. Next Noumi and Mimachi [16] showed that the "spherical harmonics" on quantum homogeneous spaces of $SU_q(2)$ can be expressed in terms of big q-Jacobi polynomials. As a following step, the author [11] gave an interpretation of a two-parameter family of Askey–Wilson polynomials (including continuous q-Legendre polynomials) as (zonal) spherical functions on $SU_q(2)$. Here the notion of spherical function was generalized in the sense that bi-invariance with respect to the quantum subgroup $U(1)$ was replaced by "infinitesimal" left and right invariance with respect to twisted primitive elements of the corresponding quantized universal enveloping algebra $\mathcal{U}_q(sl(2,\mathbb{C}))$. Since this paper [11] was meant as a survey paper, the full results were only announced there, while a proof was sketched for the most simple case (parameter values $\sigma = \tau = 0$) corresponding to the continuous q-Legendre polynomials. Nevertheless, the paper [11] has already had some follow-ups by (i) the work of Koelink [8] (appearing as a companion paper to the present paper), which culminates in a quantum group derivation of the continuous q-Legendre case of the Rahman–Verma addition formula [19] for continuous q-ultraspherical polynomials, and (ii) an announcement by Noumi and Mimachi [17], [15], where they extend the author's result to the expression of all corresponding matrix elements (not just the left and right infinitesimally invariant ones) as Askey–Wilson polynomials.

It is the purpose of the present paper to give full proofs of the results announced in [11]. The contents are as follows. In §2 we give the preliminaries about q-hypergeometric functions and orthogonal polynomials, mainly referring to Askey

*Received by the editors August 8, 1990; accepted for publication (in revised form) September 8, 1992. The research for this paper was done at CWI, Amsterdam.

[†] University of Amsterdam, Faculty of Mathematics and Computer Science, Plantage Muidergracht 24, 1018 TV Amsterdam, the Netherlands.

and Wilson [5] and Gasper and Rahman [7]. In §3 we give preliminaries on the quantum group $SL_q(2,\mathbb{C})$. Section 4 introduces the (σ,τ)-spherical elements on $SU_q(2)$ and derives an explicit Fourier series for such elements belonging to irreducible representations. An important tool here is the explicit matrix of dual q-Krawtchouk polynomials for the basis change from the standard basis to a basis of eigenfunctions for an (almost) twisted primitive element. This last result (already announced in [11]) is also crucial in Koelink [8].

In §5 we prove that the elementary (σ,τ)-spherical matrix elements, when expressed as polynomials, satisfy the same second-order q-difference equation as the Askey–Wilson polynomials. This is done by use of the Casimir operator on the quantum group. This way of proving that our polynomials are Askey–Wilson polynomials is different from the proof we had in mind when writing [11]. There we worked with the explicit Fourier series and the knowledge obtained from the quantum group theory that we were dealing with orthogonal polynomials. Then the result could be derived by deriving the three-term recurrence relation. Section 5 contains also the expression of the Haar functional as an Askey–Wilson integral, when applied to (σ,τ)-spherical elements. Finally, in §6 we examine the limit cases as σ or $\tau \to \infty$. For the Askey–Wilson polynomials this means a limit transition to big or little q-Jacobi polynomials.

Notation. $\mathbb{Z}_+$ denotes the set of nonnegative integers.

2. Preliminaries on q-hypergeometric orthogonal polynomials.

Let $0 < q < 1$. Define *q-shifted factorials*

$$(a;q)_n := \prod_{k=0}^{n-1}(1-aq^k),$$
$$(a;q)_\infty := \lim_{n\to\infty}(a;q)_n\,,$$
$$(a_1,\ldots,a_r;q)_n := \prod_{j=1}^{r}(a_j;q)_n\,,$$

and the *q-hypergeometric series*

$$(2.1)\qquad {}_{s+1}\phi_s\left[\begin{matrix}a_1,\ldots,a_{s+1}\\ b_1,\ldots,b_s\end{matrix};q,z\right] := \sum_{k=0}^{\infty}\frac{(a_1,\ldots,a_{s+1};q)_k\,z^k}{(b_1,\ldots,b_s;q)_k\,(q;q)_k}\,.$$

Usually in this paper we will have the case of a *terminating* series in (2.1), i.e., $a_1 = q^{-n}$ ($n \in \mathbb{Z}_+$), so the series terminates after the term with $k = n$. Then we require that $b_1,\ldots,b_s \notin \{1,q^{-1},\ldots,q^{-n+1}\}$. See Gasper and Rahman [7, Ch. 1] for standard facts about q-hypergeometric series.

Askey-Wilson polynomials are defined by

(2.2)
$$p_n(\cos\theta;a,b,c,d\mid q) := a^{-n}\,(ab,ac,ad;q)_n\;{}_4\phi_3\left[\begin{matrix}q^{-n},q^{n-1}abcd,ae^{i\theta},ae^{-i\theta}\\ ab,ac,ad\end{matrix};q,q\right].$$

See Askey and Wilson [5, (1.15)]. They are symmetric in a,b,c,d (cf. [5, p. 6]). Sometimes it will be useful to write the ${}_4\phi_3$ factor in (2.2) as

$$(2.3)\qquad r_n(\cos\theta;a,b,c,d\mid q) := {}_4\phi_3\left[\begin{matrix}q^{-n},q^{n-1}abcd,ae^{i\theta},ae^{-i\theta}\\ ab,ac,ad\end{matrix};q,q\right].$$

The orthogonality properties are stated in [5, Thms. 2.2, 2.5].

PROPOSITION 2.1. *Assume a,b,c,d are real, or if complex, appear in conjugate pairs, and that $|a|,|b|,|c|,|d| \le 1$, but the pairwise products of a,b,c,d have absolute value less than one, then*

$$\frac{1}{2\pi}\int_0^\pi p_n(\cos\theta)\,p_m(\cos\theta)\,w(\cos\theta)\,d\theta = \delta_{m,n}\,h_n\,,$$

where

$$p_n(\cos\theta) = p_n(\cos\theta; a,b,c,d \mid q),$$

$$w(\cos\theta) = \frac{(e^{2i\theta}, e^{-2i\theta}; q)_\infty}{(ae^{i\theta}, ae^{-i\theta}, be^{i\theta}, be^{-i\theta}, ce^{i\theta}, ce^{-i\theta}, de^{i\theta}, de^{-i\theta}; q)_\infty}\,,$$

$$\frac{h_n}{h_0} = \frac{(1-q^{n-1}abcd)\,(q,ab,ac,ad,bc,bd,cd;q)_n}{(1-q^{2n-1}abcd)\,(abcd;q)_n}\,, \tag{2.4}$$

$$h_0 = \frac{(abcd;q)_\infty}{(q,ab,ac,ad,bc,bd,cd;q)_\infty}\,. \tag{2.5}$$

PROPOSITION 2.2. *Assume a,b,c,d are real, or if complex, appear in conjugate pairs, and that the pairwise products of a,b,c,d are not ≥ 1, then*

$$\frac{1}{2\pi}\int_0^\pi p_n(\cos\theta)\,p_m(\cos\theta)\,w(\cos\theta)\,d\theta + \sum_k p_n(x_k)\,p_m(x_k)\,w_k = \delta_{m,n}\,h_n\,, \tag{2.6}$$

where $p_n(\cos\theta)$, $w(\cos\theta)$ and h_n are as in Proposition 2.1, while the x_k are the points $(eq^k + e^{-1}q^{-k})/2$ with e any of the parameters $a, b, c,$ or d whose absolute value is larger than one; the sum is over the $k \in \mathbb{Z}_+$ with $|eq^k| > 1$ and w_k is $w_k(a;b,c,d)$ as defined by [5, (2.10)] *when $x_k = (aq^k + a^{-1}q^{-k})/2$. (Be aware that $(1-aq^{2k})/(1-a)$ should be replaced by $(1-a^2q^{2k})/(1-a^2)$ in* [5, (2.10)].)

With notation as in Proposition 2.2 let $dm = dm_{a,b,c,d;q}$ be the normalized orthogonality measure for the Askey–Wilson polynomials. So, for any polynomial p,

$$\int_{-\infty}^{\infty} p(x)dm(x) = \frac{1}{h_0}\left\{\frac{1}{2\pi}\int_{-1}^{1} p(x)\,w(x)\,\frac{dx}{(1-x^2)^{\frac12}} + \sum_k p(x_k)\,w_k\right\}. \tag{2.7}$$

By [5, (5.7)–(5.9)] the Askey–Wilson polynomials, written as

$$R_n(e^{i\theta}) := {}_4\phi_3\left[\begin{matrix} q^{-n}, q^{n-1}abcd, ae^{i\theta}, ae^{-i\theta} \\ ab, ac, ad \end{matrix}; q, q\right],$$

are eigenfunctions of a second-order q-difference operator:

$$\begin{aligned} &A(-\theta)\,(R_n(q^{-1}e^{i\theta}) - R_n(e^{i\theta})) + A(\theta)(R_n(qe^{i\theta}) - R_n(e^{i\theta})) \\ &\quad = -(1-q^{-n})\,(1-q^{n-1}abcd)\,R_n(e^{i\theta}), \end{aligned} \tag{2.8}$$

where

$$A(\theta) := \frac{(1-ae^{i\theta})\,(1-be^{i\theta})\,(1-ce^{i\theta})\,(1-de^{i\theta})}{(1-e^{2i\theta})\,(1-qe^{2i\theta})}\,.$$

If $f(e^{i\theta})$ is a polynomial of degree $\le n$ in $\cos\theta$ and if (2.8) with R_n replaced by f is valid, then f will be a constant multiple of R_n.

We will need some special Askey–Wilson polynomials which happen to have simple explicit Fourier-cosine expansions: Chebyshev polynomials of the first kind

$$p_n(\cos\theta; 1, -1, q^{\frac{1}{2}}, -q^{\frac{1}{2}} \mid q) = (2 - \delta_{n,0})\,(q^n; q)_n \cos(n\theta) \tag{2.9}$$

(cf. [5, (4.25)]) and *continuous* q-Legendre polynomials

$$\begin{aligned} &p_n(\cos\theta; q^{\frac{1}{2}}, -q^{\frac{1}{2}}, q^{\frac{1}{2}}, -q^{\frac{1}{2}} \mid q) \\ &\quad = (-q;q)_n^2\,(q;q)_n \sum_{k=0}^{n} \frac{(q;q^2)_k\,(q;q^2)_{n-k}}{(q^2;q^2)_k\,(q^2;q^2)_{n-k}}\, e^{i(n-2k)\theta} \end{aligned}$$

(cf. [3, (3.1)] together with [5, (4.2), (4.20)]).

LEMMA 2.3. *The connection coefficients* $c_{k,n}$ *in*

$$p_n(x; q^{\frac{1}{2}}a, \beta, qa^2/\beta, q^{\frac{1}{2}}a \mid q) = \sum_{k=0}^{n} c_{k,n}\, p_k(x; a, -a, -q^{\frac{1}{2}}a, q^{\frac{1}{2}}a \mid q) \tag{2.10}$$

can be explicitly written as

$$\begin{aligned} c_{k,n} &= \frac{(qa^2, q; q)_n\,(q^{n+1}a^4; q)_k}{(qa^2, q, q^k a^4; q)_k\,(q;q)_{n-k}} \left(\frac{-q^{\frac{1}{2}}}{a^2\beta}\right)^{n-k} q^{(n-k)^2/2} \\ &\quad \times \left\{ {}_2\phi_1\left[\begin{matrix} q^{-n+k}, q^{-n}a^2 \\ q^{k+1}a^2 \end{matrix}; q, q^{n+\frac{1}{2}}a\beta\right]\right\}^2 . \end{aligned} \tag{2.11}$$

Proof. Askey and Wilson [5, (6.1), (6.2)] gave the connection coefficients between two families of Askey–Wilson polynomials with one common parameter. Their expression involved a terminating balanced ${}_5\phi_4$ of argument q. With our special choice of parameters in (2.10) this ${}_5\phi_4$ has the form occurring in the q-Clausen formula as given by formulas (2.16) (first identity) and (2.4) (with $\alpha = q^{-n}$) in Gasper and Rahman [6]. (Note that both the left- and right-hand side of this version of the q-Clausen formula are written differently from the usual formulation [6, (1.6)].) Substitution of this q-Clausen formula yields (2.11). □

Now substitute $a = 1$ in (2.10), (2.11) and apply (2.9). Then

$$p_n(\cos\theta; q^{\frac{1}{2}}, \beta, q/\beta, q^{\frac{1}{2}} \mid q) = \sum_{k=-n}^{n} c_{|k|,n}\,(q^{|k|}; q)_{|k|}\, e^{ik\theta},$$

with $c_{k,n}$ given by (2.11) for $a = 1$. When we switch to base q^2 and put $\beta = -q^{2\sigma+1}$ we obtain

$$p_n(\cos\theta; q, -q^{2\sigma+1}, -q^{-2\sigma+1}, q \mid q^2) = \sum_{k=-n}^{n} c_{|k|,n}\,(q^{2|k|}; q^2)_{|k|}\, e^{ik\theta} \tag{2.12}$$

with

$$\begin{aligned} (q^{2k}; q^2)_k\, c_{k,n} &= \frac{(q^2;q^2)_n^2\,(q^{2n+2};q^2)_k\, q^{(n-k)(n-k+2\sigma)}}{(q^2;q^2)_k^2\,(q^2;q^2)_{n-k}} \\ &\quad \times \left\{ {}_2\phi_1\left[\begin{matrix} q^{-2n+2k}, q^{-2n} \\ q^{2k+2} \end{matrix}; q^2, -q^{2n-2\sigma+2}\right]\right\}^2 . \end{aligned} \tag{2.13}$$

Finally, by Jackson's transformation formula [7, (III.7)], (2.13) can be rewritten as

$$\begin{aligned}(q^{2k};q^2)_k\, c_{k,n} =& \frac{(q^2;q^2)_{2n}^2\, q^{(n-k)(n-k+2\sigma)}}{(q^2;q^2)_n\,(q^2;q^2)_{n+k}\,(q^2;q^2)_{n-k}} \\ &\times \left\{ {}_3\phi_2\left[\begin{matrix} q^{-2n+2k}, q^{-2n}, -q^{-2n-2\sigma} \\ q^{-4n}, 0 \end{matrix}; q^2, q^2\right]\right\}^2 .\end{aligned} \tag{2.14}$$

Next we define *little q-Jacobi polynomials*

$$p_n(x;a,b;q) := {}_2\phi_1(q^{-n}, abq^{n+1}; aq; q, qx) \tag{2.15}$$

(cf. Andrews and Askey [1]) and *big q-Jacobi polynomials*

$$P_n^{(\alpha,\beta)}(x;c,d;q) = {}_3\phi_2\left[\begin{matrix} q^{-n}, q^{n+\alpha+\beta+1}, xq^{\alpha+1}/c \\ q^{\alpha+1}, -q^{\alpha+1}d/c \end{matrix}; q, q\right] \tag{2.16}$$

(cf. Andrews and Askey [2]). In this last reference some different normalization is suggested for the big q-Jacobi polynomials, but the authors are not very definite about it. Here we follow the normalization used by Noumi and Mimachi [16]. Little and big q-Jacobi polynomials are orthogonal with respect to discrete measures.

We define *dual q-Krawtchouk polynomials* by

$$R_n(q^{-x} - q^{x-N-c}; q^c, N \mid q) := {}_3\phi_2(q^{-n}, q^{-x}, -q^{x-N-c}; 0, q^{-N}; q, q). \tag{2.17}$$

These are special q-Racah polynomials and satisfy the orthogonality relations

$$\begin{aligned}&\frac{1}{(-q^c;q)_N}\sum_{x=0}^{N}(R_nR_m)(q^{-x} - q^{x-N-c}; q^c, N \mid q) \\ &\times \frac{(1+q^{2x-N-c})(-q^{-N-c}, q^{-N}; q)_x}{(1+q^{-N-c})(q, -q^{-c+1}; q)_x(-q^{x-2N-c})^x} = \delta_{nm}\,\frac{(q;q)_n}{(q^{-N};q)_n}\,(-q^{-N-c})^n,\end{aligned} \tag{2.18}$$

where $n, m = 0, \ldots, N$. See Askey and Wilson [4] and Stanton [20]. They satisfy (see [20]) the three-term recurrence relation

$$\begin{aligned} y\, R_n(y; q^c, N \mid q) =& (1 - q^{n-N})\, R_{n+1}(y; q^c, N \mid q) \\ &+ (q^{-N} - q^{-N-c})\, q^n\, R_n(y; q^c, N \mid q) \\ &- (1 - q^n)\, q^{-N-c}\, R_{n-1}(y; q^c, N \mid q). \end{aligned} \tag{2.19}$$

3. Preliminaries on the quantum $SL(2,\mathbb{C})$ group. The reader may use the author's survey [11] and the references given there for further reading in connection with this section. Fix $q \in (0,1)$. Let $\mathcal{A}_q$ be the complex associative algebra with unit 1, generators $\alpha, \beta, \gamma, \delta$, and relations

$$\begin{aligned} &\alpha\beta = q\beta\alpha, \quad \alpha\gamma = q\gamma\alpha, \quad \beta\delta = q\delta\beta, \quad \gamma\delta = q\delta\gamma, \quad \beta\gamma = \gamma\beta, \\ &\alpha\delta - q\beta\gamma = \delta\alpha - q^{-1}\beta\gamma = 1. \end{aligned} \tag{3.1}$$

It turns out that $\mathcal{A}_q$ becomes a Hopf algebra over $\mathbb{C}$ under the following actions of the comultiplication $\Delta\colon \mathcal{A}_q \to \mathcal{A}_q \otimes \mathcal{A}_q$, counit $\varepsilon\colon \mathcal{A}_q \to \mathbb{C}$ (unital multiplicative linear mappings), and antipode $S: \mathcal{A}_q \to \mathcal{A}_q$ (unital antimultiplicative linear mapping) on the generators

$$\Delta\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} = \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} \otimes \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix},$$
$$\varepsilon\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} = \begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \quad S\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} = \begin{pmatrix}\delta & -q^{-1}\beta\\ -q\gamma & \alpha\end{pmatrix},$$

where the formula for Δ has to be interpreted in the sense of matrix multiplication: $\Delta(\alpha) = \alpha \otimes \alpha + \beta \otimes \gamma$, etc.

A *Hopf $*$-algebra* is a Hopf algebra $\mathcal{A}$ over $\mathbb{C}$ with an involution $a \mapsto a^*$ such that $\mathcal{A}$ becomes a unital $*$-algebra and $\Delta: \mathcal{A} \to \mathcal{A} \otimes \mathcal{A}$ and $\varepsilon: \mathcal{A} \to \mathbb{C}$ are $*$-homomorphisms. Then it can be shown that S is invertible and that $S \circ * \circ S \circ * = \mathrm{id}$. We can make $\mathcal{A}_q$ into a Hopf $*$-algebra by taking for the involution the unital antimultiplicative antilinear mapping $a \mapsto a^*$ such that

$$\begin{pmatrix}\alpha^* & \beta^*\\ \gamma^* & \delta^*\end{pmatrix} = \begin{pmatrix}\delta & -q\gamma\\ -q^{-1}\beta & \alpha\end{pmatrix}.$$

Let $\mathcal{U}_q$ be the complex associative algebra with unit 1, generators A, B, C, D, and relations

$$AD = DA = 1, \quad AB = qBA, \quad AC = q^{-1}CA, \quad BC - CB = \frac{A^2 - D^2}{q - q^{-1}}. \tag{3.2}$$

We can make $\mathcal{U}_q$ into a Hopf $*$-algebra with comultiplication $\Delta: \mathcal{U}_q \to \mathcal{U}_q \otimes \mathcal{U}_q$, counit $\varepsilon: \mathcal{U}_q \to \mathbb{C}$, antipode $S: \mathcal{U}_q \to \mathcal{U}_q$, and involution $*: \mathcal{U}_q \to \mathcal{U}_q$ by requiring that

$$\begin{aligned}
&\Delta(A) = A \otimes A, \quad \Delta(D) = D \otimes D,\\
&\Delta(B) = A \otimes B + B \otimes D, \quad \Delta(C) = A \otimes C + C \otimes D,\\
&\varepsilon(A) = \varepsilon(D) = 1, \quad \varepsilon(B) = \varepsilon(C) = 0,\\
&S(A) = D, \quad S(D) = A, \quad S(B) = -q^{-1}B, \quad S(C) = -qC, && (3.3)\\
&\quad A^* = A, \quad D^* = D, \quad B^* = C, \quad C^* = B. && (3.4)
\end{aligned}$$

Two Hopf algebras $\mathcal{U}, \mathcal{A}$ are said to be *in duality* if there is a doubly nondegenerate bilinear form $(u, a) \mapsto \langle u, a\rangle: \mathcal{U} \times \mathcal{A} \to \mathbb{C}$ such that, for $u, v \in \mathcal{U}$, $a, b \in \mathcal{A}$,

$$\begin{aligned}
&\langle \Delta(u), a \otimes b\rangle = \langle u, ab\rangle, \quad \langle u \otimes v, \Delta(a)\rangle = \langle uv, a\rangle,\\
&\quad \langle 1_{\mathcal{U}}, a\rangle = \varepsilon_{\mathcal{A}}(a), \quad \langle u, 1_{\mathcal{A}}\rangle = \varepsilon_{\mathcal{U}}(u), \quad \langle S(u), a\rangle = \langle a, S(u)\rangle.
\end{aligned} \tag{3.5}$$

If $\mathcal{U}, \mathcal{A}$ are moreover Hopf $*$-algebras, then they are said to be *Hopf $*$-algebras in duality* if the above pairing satisfies in addition that

$$\langle u^*, a\rangle = \overline{\langle u, (S(a))^*\rangle}. \tag{3.6}$$

Instead of $\langle u, a\rangle$ we will also write $u(a)$ or $a(u)$.

It can be shown that $\mathcal{U}_q$ and $\mathcal{A}_q$ become Hopf $*$-algebras in duality with the following pairing between the generators:

$$\left\langle A, \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\right\rangle = \begin{pmatrix}q^{\frac{1}{2}} & 0\\ 0 & q^{-\frac{1}{2}}\end{pmatrix}, \quad \left\langle D, \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\right\rangle = \begin{pmatrix}q^{-\frac{1}{2}} & 0\\ 0 & q^{\frac{1}{2}}\end{pmatrix},$$
$$\left\langle B, \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\right\rangle = \begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix}, \quad \left\langle C, \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\right\rangle = \begin{pmatrix}0 & 0\\ 1 & 0\end{pmatrix}.$$

The pairing between products of generators then follows by the rules (3.5).

The element

$$\Omega := \frac{q^{-1}A^2 + qD^2 - 2}{(q^{-1} - q)^2} + BC = \Omega^* \tag{3.7}$$

is a *Casimir element* of $\mathcal{U}_q$: it commutes with any $X \in \mathcal{U}_q$.

In a Hopf algebra $\mathcal{U}$ an element u is called *group-like* if $\Delta(u) = u \otimes u$, *primitive* if $\Delta(u) = 1 \otimes u + u \otimes 1$, and *twisted primitive* (with respect to a group-like element g) if $\Delta(u) = g \otimes u + u \otimes S(g)$. In $\mathcal{U}_q$ the group-like elements are all elements A^n $(n \in \mathbb{Z})$ and (cf. Masuda et al. [12]).

LEMMA 3.1. *The twisted primitive elements with respect to A are the elements X in the linear span of $A - D$, B, and C. They satisfy*

$$\Delta(X) = A \otimes X + X \otimes D.$$

For $t \neq 1$ the twisted primitive elements with respect to A^t are the constant multiples of $A^t - A^{-t}$.

Let $\mathcal{U}$ and $\mathcal{A}$ be Hopf algebras in duality. For $u \in \mathcal{U}$ and $a \in \mathcal{A}$ define elements $u.a$ and $a.u$ of $\mathcal{A}$ by

$$u.a := (\mathrm{id} \otimes u)(\Delta(a)), \qquad a.u := (u \otimes \mathrm{id})(\Delta(a)). \tag{3.8}$$

Hence, if $v \in \mathcal{U}$,

$$(u.a)(v) = a(vu), \qquad (a.u)(v) = a(uv).$$

The operations defined in (3.8) are left, respectively, right algebra actions of $\mathcal{U}_q$ on $\mathcal{A}_q$:

$$(uv).a = u.(v.a), \quad a.(uv) = (a.u).v. \tag{3.9}$$

If $\Delta(u) = \sum_{(u)} u_{(1)} \otimes u_{(2)}$ $(u \in \mathcal{U})$ and $a, b \in \mathcal{A}$, then

$$u.(ab) = \sum_{(u)} (u_{(1)}.a)\,(u_{(2)}.b), \qquad (ab).u = \sum_{(u)} (a.u_{(1)})\,(b.u_{(2)}). \tag{3.10}$$

Furthermore, if $u \in \mathcal{U}$, $a \in \mathcal{A}$, then

$$(\mathrm{id} \otimes u.)(\Delta(a)) = \Delta(u.a); \tag{3.11}$$

and if, moreover, $v \in \mathcal{U}$, then

$$\langle v, u.a^* \rangle = \overline{\langle S(v)^*, S(u)^*.a \rangle}. \tag{3.12}$$

We call an element $a \in \mathcal{A}$ *left* (*right*) *invariant* with respect to an element $u \in \mathcal{U}$ if $u.a = \varepsilon(u)a$, respectively, $a.u = \varepsilon(u)a$. Note that the unit 1 of $\mathcal{A}$ is bi-invariant with respect to all $u \in \mathcal{U}$. If u is twisted primitive, then $\varepsilon(u) = 0$, and

$$\begin{aligned} u.a = 0 \quad &\text{and} \quad b.u = 0 \Longrightarrow u.(ab) = 0, \\ a.u = 0 \quad &\text{and} \quad b.u = 0 \Longrightarrow (ab).u = 0. \end{aligned}$$

LEMMA 3.2. *The left (or right) invariant elements of $\mathcal{A}$ with respect to some twisted primitive element of $\mathcal{U}$ form a unital subalgebra of $\mathcal{A}$. In particular, if $X \in \operatorname{Span}\{A-D, B, C\}$, then the set of all $a \in \mathcal{A}_q$ satisfying $X.a = 0$ (respectively $a.X = 0$) forms a unital subalgebra of $\mathcal{A}_q$.*

Let $\mathcal{U}$ and $\mathcal{A}$ be Hopf algebras in duality. A *matrix corepresentation* of $\mathcal{A}$ is a square matrix $t = (t_{i,j})$ of elements of $\mathcal{A}$ such that

$$\Delta(t_{i,j}) = \sum_k t_{i,k} \otimes t_{k,j}, \qquad \varepsilon(t_{i,j}) = \delta_{i,j}. \tag{3.13}$$

To a matrix corepresentation t of $\mathcal{A}$ corresponds a matrix representation of $\mathcal{U}$, also denoted by t and defined by

$$(t(u))_{i,j} := t_{i,j}(u) = \langle u, t_{i,j} \rangle, \qquad u \in \mathcal{U}.$$

The matrix entries of a corepresentation of $\mathcal{A}$ (elements of $\mathcal{A}$) are completely determined by the matrix entries of the corresponding representation of $\mathcal{U}$ (linear functionals on $\mathcal{U}$). A matrix corepresentation t of $\mathcal{A}$ is called *unitary* if $t^*_{i,j} = S(t_{j,i})$ and a representation t of $\mathcal{U}$ is called a *$*$-representation* if $t_{i,j}(u^*) = \overline{t_{j,i}(u)}$ $(u \in \mathcal{U})$. Note that a matrix corepresentation of $\mathcal{A}$ is unitary if and only if the corresponding matrix representation of $\mathcal{U}$ is a $*$-representation.

Up to equivalence, there is for each finite dimension precisely one irreducible matrix corepresentation of $\mathcal{A}_q$, which can be chosen to be unitary. The corresponding irreducible $*$-representation of $\mathcal{U}_q$ is realized as a representation $t^l = (t^l_{i,j})_{i,j=-l,-l+1,\ldots,l}$ $(l \in \frac{1}{2}\mathbb{Z}_+)$ on a $(2l+1)$-dimensional vector space with $\{e^l_n\}_{n=-l,-l+1,\ldots,l}$ as an orthonormal basis such that

$$\begin{aligned} &t^l(A)\, e^l_n = q^{-n}\, e^l_n, \qquad t^l(D)\, e^l_n = q^n\, e^l_n, \\ &t^l(B)\, e^l_n = \frac{(q^{-l+n-1} - q^{l-n+1})^{\frac{1}{2}}\, (q^{-l-n} - q^{l+n})^{\frac{1}{2}}}{q^{-1} - q}\, e^l_{n-1}, \\ &t^l(C)\, e^l_n = \frac{(q^{-l+n} - q^{l-n})^{\frac{1}{2}}\, (q^{-l-n-1} - q^{l+n+1})^{\frac{1}{2}}}{q^{-1} - q}\, e^l_{n+1}, \end{aligned} \tag{3.14}$$

with the convention that e^l_{-l-1} and e^l_{l+1} are zero. The $t^l_{i,j}$, being elements of $\mathcal{A}_q$, can be expressed in terms of the generators by expressions involving little q-Jacobi polynomials. The lowest dimensional cases are particularly simple:

$$t^0 = (t^0_{0,0}) = (1), \qquad t^{\frac{1}{2}} = \begin{pmatrix} t^{\frac{1}{2}}_{\frac{1}{2},\frac{1}{2}} & t^{\frac{1}{2}}_{\frac{1}{2},-\frac{1}{2}} \\ t^{\frac{1}{2}}_{-\frac{1}{2},\frac{1}{2}} & t^{\frac{1}{2}}_{-\frac{1}{2},-\frac{1}{2}} \end{pmatrix} = \begin{pmatrix} \delta & \gamma \\ \beta & \alpha \end{pmatrix},$$

(3.15)

$$t^1 = \begin{pmatrix} t^1_{1,1} & t^1_{1,0} & t^1_{1,-1} \\ t^1_{0,1} & t^1_{0,0} & t^1_{0,-1} \\ t^1_{-1,1} & t^1_{-1,0} & t^1_{-1,-1} \end{pmatrix} = \begin{pmatrix} \delta^2 & (1+q^2)^{\frac{1}{2}}\delta\gamma & \gamma^2 \\ (1+q^2)^{\frac{1}{2}}\delta\beta & 1 + (q+q^{-1})\beta\gamma & (1+q^2)^{\frac{1}{2}}\gamma\alpha \\ \beta^2 & (1+q^2)^{\frac{1}{2}}\beta\alpha & \alpha^2 \end{pmatrix}.$$

Define

$$\mathcal{A}^l_q := \operatorname{Span}\{t^l_{i,j} \mid i,j = -l, -l+1, \ldots, l\}. \tag{3.16}$$

PROPOSITION 3.3. *The $t^l_{i,j}$ $(i,j=-l,-l+1,\dots,l)$ form a basis of $\mathcal{A}^l_q$ and*

$$\mathcal{A}_q = \bigoplus\nolimits_{l\in\frac12\mathbb{Z}_+} \mathcal{A}^l_q\,. \tag{3.17}$$

Let $a := \sum_{i,j=-l}^{l} \gamma_{i,j}\, t^l_{i,j} \in \mathcal{A}^l_q$ $(\gamma_{i,j}\in\mathbb{C})$. Let $X\in\mathcal{U}_q$. It follows from (3.8) and (3.13) that

$$X.a = \sum\nolimits_{i,k} \left(\sum\nolimits_j t^l_{k,j}(X)\,\gamma_{i,j}\right) t^l_{i,k}, \tag{3.18}$$

$$a.X = \sum\nolimits_{k,j} \left(\sum\nolimits_i t^l_{i,k}(X)\,\gamma_{i,j}\right) t^l_{k,j}. \tag{3.19}$$

LEMMA 3.4. *With a and X as above we have the following:*

(i) $X.a = 0 \iff t^l(X)\left(\sum_{j=-l}^{l}\gamma_{ij}\, e^l_j\right) = 0$ *for all* i;

(ii) $a.X = 0 \iff t^l(X^*)\left(\sum_{i=-l}^{l}\overline{\gamma_{ij}}\, e^l_i\right) = 0$ *for all* j.

Proof. (i) By (3.18) and Proposition 3.3, $X.a=0 \iff \sum_j t^l_{k,j}(X)\,\gamma_{i,j} = 0$ for all $i,k \iff t^l(X)\left(\sum_{j=-l}^{l}\gamma_{ij}\,e^l_j\right)=0$ for all i.

(ii) By (3.19), $a.X = 0 \iff \sum_i t^l_{i,k}(X)\,\gamma_{i,j} = 0$ for all $k,j \iff \sum_i t^l_{k,i}(X^*)\,\overline{\gamma_{i,j}} = 0$ for all $k,j \iff t^l(X^*)\left(\sum_i \overline{\gamma_{i,j}}\, e^l_i\right) = 0$ for all j, where we used that t^l is a $*$-representation of $\mathcal{U}_q$. □

For the Casimir element Ω (cf. (3.7)) we compute from (3.14) that

$$t^l(\Omega) = \left(\frac{q^{-l-\frac12} - q^{l+\frac12}}{q^{-1}-q}\right)^2 \mathrm{id}\,.$$

Hence, by (3.18), (3.19),

$$\Omega.a = \left(\frac{q^{-l-\frac12} - q^{l+\frac12}}{q^{-1}-q}\right)^2 a = a.\Omega \quad \text{if } a\in\mathcal{A}^l_q\,. \tag{3.20}$$

The *tensor product* $t^l\otimes t^{l'}$ is defined as the matrix corepresentation of $\mathcal{A}_q$ with matrix entries

$$(t^l\otimes t^{l'})_{i,i';j,j'} := t^l_{i,j}\, t^{l'}_{i',j'} \qquad (i,j=-l,-l+1,\dots,l;\ i',j'=-l',-l'+1,\dots,l').$$

PROPOSITION 3.5. *$t^l\otimes t^{l'}$ is equivalent to the direct sum of the corepresentations t^k $(k=l+l',l+l'-1,\dots,|l-l'|)$.*

There is a unique linear functional $h\colon \mathcal{A}_q\to\mathbb{C}$, called the *Haar functional* on $\mathcal{A}_q$, with the properties

(i) $h(1)=1$;

(ii) $h(aa^*)\ge 0$ for all $a\in\mathcal{A}_q$;

(iii) $(h\otimes\mathrm{id})(\Delta(a)) = h(a)1 = (\mathrm{id}\otimes h)(\Delta(a))$.

Then $h(aa^*)>0$ if $a>0$. It can also be shown that

$$h((t^{l'}_{i',j'})^*\, t^l_{i,j}) = \delta_{l,l'}\,\delta_{i,i'}\,\delta_{j,j'}\, q^{2(l-i)}\,\frac{1-q^2}{1-q^{2(2l+1)}}\,. \tag{3.21}$$

For $\theta\in\mathbb{C}$ let $\pi^1_\theta\colon\mathcal{A}_q\to\mathbb{C}$ be the unital algebra homomorphism (one-dimensional representation of $\mathcal{A}_q$) defined by

$$\pi^1_\theta\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} := \begin{pmatrix} e^{i\theta} & 0\\ 0 & e^{-i\theta}\end{pmatrix}. \tag{3.22}$$

In particular, if $\theta \in \mathbb{R}$, π_θ^1 is a $*$-representation of $\mathcal{A}_q$. We have

$$\pi_\theta^1(t_{n,m}^l) = e^{-2in\theta}\,\delta_{n,m}. \tag{3.23}$$

4. (σ,τ)-spherical elements. Define, for $\sigma \in \mathbb{R}$,

$$X_\sigma := i\,q^{\frac12}\,B - i\,q^{-\frac12}\,C - \frac{q^{-\sigma}-q^{\sigma}}{q^{-1}-q}\,(A-D). \tag{4.1}$$

Then

$$X_\sigma^* = i\,q^{-\frac12}\,B - i\,q^{\frac12}\,C - \frac{q^{-\sigma}-q^{\sigma}}{q^{-1}-q}\,(A-D) = -S(X_\sigma) \tag{4.2}$$

by (3.3), (3.4), and X_σ is twisted primitive with respect to A (cf. Lemma 3.1):

$$\Delta(X_\sigma) = A\otimes X_\sigma + X_\sigma \otimes D.$$

Define also the twisted primitive element

$$X_\infty := D - A = \lim_{\sigma\to\infty}(q^{-1}-q)\,q^{\sigma}\,X_\sigma = \lim_{\sigma\to-\infty}(q-q^{-1})\,q^{-\sigma}\,X_\sigma.$$

Left or right invariance of an element of $\mathcal{A}_q$ with respect to X_∞ is the same as left or right invariance with respect to the diagonal quantum subgroup of $SL_q(2,\mathbb{C})$.

We will call an element $a \in \mathcal{A}_q$ *(σ,τ)-spherical* if a is left invariant with respect to X_σ and right invariant with respect to X_τ:

$$X_\sigma.a = 0 \quad\text{and}\quad a.X_\tau = 0.$$

The nonzero (σ,τ)-spherical elements in the subspaces $\mathcal{A}_q^l$ (defined by (3.16)) will be called *elementary (σ,τ)-spherical.* It follows from Lemma 3.2 that the (σ,τ)-spherical elements form a subalgebra with 1 of $\mathcal{A}_q$. Since the subspaces $\mathcal{A}_q^l$ are invariant under left and right action of $\mathcal{U}_q$ (cf. (3.18), (3.19)), it follows from the direct sum decomposition (3.17) that any (σ,τ)-spherical element in $\mathcal{A}_q$ will be a sum of elementary (σ,τ)-spherical elements.

From now on assume that σ and τ are finite. From (3.14) we obtain the following.

LEMMA 4.1. *Let $l \in \frac12\mathbb{Z}_+$, $a_{-l}, a_{-l+1}, \dots, a_l \in \mathbb{C}$. Let $v := \sum_{m=-l}^{l} a_m\, e_m^l$. Then*

$$t^l\left(iq^{\pm\frac12}B - iq^{\mp\frac12}C - \frac{q^{-\sigma}-q^{\sigma}}{q^{-1}-q}\,(A-D)\right)v = 0 \tag{4.3}$$

if and only if
(4.4)

$$i\,q^{\pm\frac12}\,(q^{-l+m}-q^{l-m})^{\frac12}\,(q^{-l-m-1}-q^{l+m+1})^{\frac12}\,a_{m+1} - i\,q^{\mp\frac12}\,(q^{-l+m-1}-q^{l-m+1})^{\frac12}$$
$$\times\,(q^{-l-m}-q^{l+m})^{\frac12}\,a_{m-1} - (q^{-\sigma}-q^{\sigma})\,(q^{-m}-q^{m})\,a_m = 0, \quad m = -l, -l+1, \dots, l,$$

with the convention that $a_{-l-1} = 0 = a_{l+1}$.

By Lemma 4.1 we easily find the general solution to (4.3) for low l: if $l = 0$, then $v = \text{const.}$; if $l = \frac12$, then $v = 0$; if $l = 1$, then

$$v = \text{const.}\left(-i\,q^{\mp\frac12}\,e_1^1 + \frac{q^{-\sigma}-q^{\sigma}}{(q^{-1}+q)^{\frac12}}\,e_0^1 - iq^{\pm\frac12}\,e_{-1}^1\right). \tag{4.5}$$

Also, if $\sigma = 0$, then the coefficient of a_m in (4.4) vanishes, so (4.4) becomes a two-term recurrence relation with solution $v = 0$ if $l \in \mathbb{Z}_+ + \frac{1}{2}$, and

$$v = \text{const.} \sum_{m=-l,-l+2,\ldots,l} q^{\mp\frac{1}{2}m} \left(\frac{(q^2;q^4)_{(l-m)/2}\,(q^2;q^4)_{(l+m)/2}}{(q^4;q^4)_{(l-m)/2}\,(q^4;q^4)_{(l+m)/2}} \right)^{\frac{1}{2}} e^l_m$$

if $l \in \mathbb{Z}_+$.

From Lemma 3.4 we derive the following.

LEMMA 4.2. *Let, for some $l \in \frac{1}{2}\mathbb{Z}_+$ and $\sigma, \tau \in \mathbb{R}$, $t^l(X_\sigma)$ and $t^l(X^*_\tau)$ have both one-dimensional zero-space spanned by $\sum_{m=-l}^{l} a_m e^l_m$ and $\sum_{m=-l}^{l} b_m e^l_m$, respectively. Then the (σ,τ)-spherical elements in $\mathcal{A}^l_q$ form a one-dimensional subspace spanned by*

$$\sum_{i,j=-l}^{l} \overline{b_i}\, a_j\, t^l_{i,j}\,. \tag{4.6}$$

In view of (3.15), (4.5), and (4.6), the (σ,τ)-spherical elements in $\mathcal{A}^1_q$ are just the constant multiples of

$$2\rho_{\sigma,\tau} + \frac{(q^{-\sigma} - q^{\sigma})(q^{-\tau} - q^{\tau})}{q^{-1} + q}\,, \tag{4.7}$$

where

$$\begin{aligned} \rho_{\sigma,\tau} :=& \tfrac{1}{2}\big(\alpha^2 + \delta^2 + q\gamma^2 + q^{-1}\beta^2 + i(q^{-\sigma} - q^{\sigma})(q\delta\gamma + \beta\alpha) \\ &- i(q^{-\tau} - q^{\tau})(\delta\beta + q\gamma\alpha) + (q^{-\sigma} - q^{\sigma})(q^{-\tau} - q^{\tau})\beta\gamma\big). \end{aligned} \tag{4.8}$$

Note that

$$\rho^*_{\sigma,\tau} = \rho_{\sigma,\tau}\,.$$

In order to compute the null space of $t^l(X_\sigma)$ in general, we consider the more general problem of finding the eigenvectors of $t^l(-DX_\sigma)$. Note that

$$(DX_\sigma)^* = DX_\sigma;$$

hence $t^l(-DX_\sigma)$ is selfadjoint. Clearly, $t^l(X_\sigma)$ and $t^l(-DX_\sigma)$ have the same zero space.

Let $\lambda \in \mathbb{R}$, $v = \sum_{m=-l}^{l} a_m\, e^l_m$. Then

$$t^l(-DX_\sigma)\, v = \lambda\, v$$

if and only if

(4.9)

$$\begin{aligned} -i\, q^{\frac{1}{2}}\, (q^{-l+m} - q^{l-m})^{\frac{1}{2}}\, (q^{-l-m-1} - q^{l+m+1})^{\frac{1}{2}}\, a_{m+1} + i\, q^{-\frac{1}{2}}\, (q^{-l+m-1} - q^{l-m+1})^{\frac{1}{2}} \\ \times (q^{-l-m} - q^{l+m})^{\frac{1}{2}}\, a_{m-1} + (q^{-\sigma} - q^{\sigma})\,(q^{-m} - q^{m})\, a_m = q^{-m}\, \lambda\, (q^{-1} - q)\, a_m \end{aligned}$$

for $m = -l, -l+1, \ldots, l$. Put

$$\begin{aligned} R_n &:= i^n\, q^{-\frac{1}{2}n(n-1)}\, q^{-n\sigma}\, (q^2;q^2)_n^{\frac{1}{2}}\, (q^{4l};q^{-2})_n^{-\frac{1}{2}}\, a_{-l+n}\,, \\ x &:= q^{-2l-\sigma}\, ((q^{-1} - q)\lambda + q^{\sigma} - q^{-\sigma}). \end{aligned}$$

Then (4.9) can be rewritten as

(4.10)
$$(1-q^{2n-4l})\,R_{n+1}-(1-q^{2n})\,q^{-4l-2\sigma}\,R_{n-1}+(q^{-4l}-q^{-4l-2\sigma})\,q^{2n}\,R_n=x\,R_n\,,\qquad n=0,1,\ldots,2l,$$

with the convention that $R_{-1}=0=R_{2l+1}$. We recognize (4.10) as the three-term recurrence relation (2.19) for the dual q-Krawtchouk polynomials (2.17). Thus the possible eigenvalues in (4.10) are

(4.11)
$$x_j:=q^{-2j-2l}-q^{2j-2l-2\sigma},\qquad j=-l,-l+1,\ldots,l,$$

and the corresponding eigenvectors, up to a constant factor, are given by

$$R_n=R_n(x_j;q^{2\sigma},2l\mid q^2).$$

When we translate this back to (4.9) we obtain the following.

THEOREM 4.3. *$t^l(-DX_\sigma)$ has simple spectrum consisting of eigenvalues*

$$\lambda_j:=\frac{-q^{2j-\sigma}+q^{\sigma-2j}-q^{\sigma}+q^{-\sigma}}{q^{-1}-q},\qquad j=-l,-l+1,\ldots,l,$$

with corresponding eigenvectors

$$\text{const.}\sum_{n=0}^{2l}i^{-n}\,q^{n\sigma}\,q^{n(n-1)/2}\,(q^2;q^2)_n^{-\frac12}\,(q^{4l};q^{-2})_n^{\frac12}\,R_n(x_j;q^{2\sigma},2l\mid q^2)\,e^l_{n-l}\,,$$

where x_j is given by (4.11).

Similarly, in order to compute the null space of $t^l(X_\sigma^*)$ in general, we consider the more general problem of finding the eigenvectors of $t^l(AX_\sigma^*)$. Note that

$$(AX_\sigma^*)^*=AX_\sigma^*;$$

so $t^l(AX_\sigma^*)$ is selfadjoint and has the same zero space as $t^l(X_\sigma^*)$. But also,

$$AX_\sigma^*=X_\sigma A=J(-X_\sigma^*D)=J(-DX_\sigma),$$

where $J:\mathcal{U}_q\to\mathcal{U}_q$ is the involutive algebra isomorphism generated by

$$J(A)=D,\quad J(D)=A,\quad J(B)=C,\quad J(C)=B$$

(well defined in view of (3.2)). Also observe from (3.14) that

$$t^l_{m,n}(J(X))=t^l_{-m,-n}(X),\qquad X\in\mathcal{U}_q.$$

LEMMA 4.4. *$\sum_{m=-l}^{l}a_m\,e^l_m$ is eigenvector of $t^l(-DX_\sigma)$ with eigenvalue λ if and only if $\sum_{m=-l}^{l}a_m\,e^l_{-m}$ is an eigenvector of $t^l(AX_\sigma^*)$ with eigenvalue λ.*

Since $X_\sigma^*D=DX_\sigma$, we see also that $t^l(X_\sigma)\,v=0$ if and only if $t^l(X_\sigma^*)\,(t^l(D)\,v)=0$. In combination with Lemma 4.4 this yields the following.

LEMMA 4.5. *Let $l \in \frac{1}{2}\mathbb{Z}_+$ and $c_{-l}, c_{-l+1}, \dots, c_l \in \mathbb{C}$. Then*

$$t^l(X_\sigma)\left(\sum_{m=-l}^{l} q^{-\frac{1}{2}m} c_m e_m^l\right) = 0 \Longleftrightarrow t^l(X_\sigma^*)\left(\sum_{m=-l}^{l} q^{\frac{1}{2}m} c_m e_m^l\right) = 0$$
$$\Longleftrightarrow t^l(X_\sigma)\left(\sum_{m=-l}^{l} q^{-\frac{1}{2}m} c_{-m} e_m^l\right) = 0.$$

So, by Theorem 4.3 and Lemma 4.2 we get the following.

LEMMA 4.6. *$t^l(X_\sigma)$ and $t^l(X_\sigma^*)$ have zero-dimensional null space if $l \in \mathbb{Z}_+ + \frac{1}{2}$ and one-dimensional null space spanned by*

$$\sum_{m=-l}^{l} q^{-\frac{1}{2}m}\, c_m^{l,\sigma}\, e_m^l, \quad \textit{respectively,} \quad \sum_{m=-l}^{l} q^{\frac{1}{2}m}\, c_m^{l,\sigma}\, e_m^l$$

if $l \in \mathbb{Z}_+$. Here

$$(4.12)\quad c_m^{l,\sigma} := \frac{i^m\, q^{-(l+\sigma)m}\, q^{m^2/2}}{(q^2;q^2)_{l+m}^{\frac{1}{2}}\,(q^2;q^2)_{l-m}^{\frac{1}{2}}}\; {}_3\phi_2\left[\begin{matrix} q^{-2l+2m}, q^{-2l}, -q^{-2l-2\sigma} \\ q^{-4l}, 0 \end{matrix}; q^2, q^2\right] = c_{-m}^{l,\sigma}.$$

Furthermore, the subspace of (σ,τ)-spherical elements in $\mathcal{A}_q^l$ is zero-dimensional if $l \in \mathbb{Z}_+ + \frac{1}{2}$ and one-dimensional if $l \in \mathbb{Z}_+$. For $l \in \mathbb{Z}_+$, the (σ,τ)-spherical elements are spanned by

$$(4.13)\qquad \sum_{n,m=-l}^{l} q^{(n-m)/2}\, c_m^{l,\sigma}\, \overline{c_n^{l,\tau}}\, t_{n,m}^l\,.$$

The symmetry $c_m^{l,\sigma} = c_{-m}^{l,\sigma}$ in (4.12) follows from Lemma 4.5, but this symmetry can also be shown for the ${}_3\phi_2$ in (4.12) by iteration of [7, (3.2.3)].

We already found that the (σ,τ)-spherical elements in $\mathcal{A}_q^1$ were spanned by the element given by (4.7). Since, by Proposition 3.5, the l-fold tensor product of the representation t^1 will be a direct sum of irreducible representations equivalent to t^k, $k = 0, 1, \dots, l$; the polynomials of degree $\le l$ in $\rho_{\sigma,\tau}$ will certainly be (σ,τ)-spherical elements contained in $\oplus_{k=0}^{l}\mathcal{A}_q^l$. On the other hand, the algebra homomorphism $\pi_{\theta/2}^1 \colon \mathcal{A}_q \to \mathbb{C}$ (cf. (3.22)) sends $(\rho_{\sigma,\tau})^k$ to $(\cos\theta)^k$, so the monomials $(\rho_{\sigma,\tau})^k$ will be linearly independent in $\mathcal{A}_q$. So the element given by (4.13) must be a polynomial of degree l in $\rho_{\sigma,\tau}$. Thus we can state the following.

PROPOSITION 4.7. *The algebra of (σ,τ)-spherical elements in $\mathcal{A}_q$ is generated by $\rho_{\sigma,\tau}$ (given by (4.8)) and is, as a linear space, the direct sum of the (σ,τ)-spherical elements in $\mathcal{A}_q^l$ $(l = 0, 1, 2, \dots)$, which are spanned by*

$$(4.14)\qquad \sum_{n,m=-l}^{l} q^{(n-m)/2}\, c_m^{l,\sigma}\, \overline{c_n^{l,\tau}}\, t_{n,m}^l = P_l^{\sigma,\tau}(\rho_{\sigma,\tau}),$$

where $P_l^{\sigma,\tau}$ is a certain polynomial of degree l.

Apply $\pi_{-\theta/2}^1$ to both sides of (4.14). Then, by (3.23),

$$(4.15)\qquad \sum_{n=-l}^{l} c_n^{l,\sigma}\, \overline{c_n^{l,\tau}}\, e^{in\theta} = P_l^{\sigma,\tau}(\cos\theta).$$

Remark 4.8. Consider (4.15) with $\sigma = \tau$, together with (4.12). Compare it with (2.12), together with (2.14). Then we obtain

$$P_l^{\sigma,\sigma} = \frac{|c_l^{l,\sigma}|^2}{(q^{2l+2};q^2)_l}\, p_l(\,.\,; -q^{2\sigma+1}, -q^{-2\sigma+1}, q, q \mid q^2), \tag{4.16}$$

where p_l is an Askey–Wilson polynomial (2.2).

LEMMA 4.9. *We have*

$$h\big(P_{l'}^{\sigma,\tau}(\rho)^*\, P_l^{\sigma,\tau}(\rho)\big) = \delta_{l,l'}\, \frac{(1-q^2)q^{2l}}{1-q^{2(2l+1)}}\, P_l^{\sigma,\sigma}(\tfrac{1}{2}(q+q^{-1}))\, P_l^{\tau,\tau}(\tfrac{1}{2}(q+q^{-1})). \tag{4.17}$$

Proof. Apply (3.21) and (4.14). The case $l \neq l'$ is clear. For $l = l'$ we have

$$\begin{aligned} h\big(P_l^{\sigma,\tau}(\rho)^*\, P_l^{\sigma,\tau}(\rho)\big) &= \sum_{n,m=-l}^{l} q^{n-m}\, c_n^{l,\tau}\, \overline{c_m^{l,\sigma}}\, \overline{c_n^{l,\tau}}\, c_m^{l,\sigma}\, q^{2(l-n)}\, \frac{1-q^2}{1-q^{2(2l+1)}} \\ &= \frac{(1-q^2)q^{2l}}{1-q^{2(2l+1)}} \left(\sum_{m=-l}^{l} q^{-m}\, |c_m^{l,\sigma}|^2\right) \left(\sum_{n=-l}^{l} q^{-n}\, |c_n^{l,\tau}|^2\right) \\ &= \frac{(1-q^2)q^{2l}}{1-q^{2(2l+1)}}\, P_l^{\sigma,\sigma}(\tfrac{1}{2}(q+q^{-1}))\, P_l^{\tau,\tau}(\tfrac{1}{2}(q+q^{-1})). \qquad \square \end{aligned}$$

5. The action of the Casimir operator. Let $\lambda \in \mathbb{Z}_+$, let Ω be the Casimir element given by (3.7), let $\rho_{\sigma,\tau}$ be given by (4.8) and $P_l^{\sigma,\tau}$ by (4.15). We have

$$\begin{aligned} \langle A^\lambda \Omega, P_l^{\sigma,\tau}(\rho_{\sigma,\tau})\rangle &= \langle A^\lambda, \Omega.P_l^{\sigma,\tau}(\rho_{\sigma,\tau})\rangle \\ &= \left(\frac{q^{-l-\frac{1}{2}} - q^{l+\frac{1}{2}}}{q^{-1}-q}\right)^2 \langle A^\lambda, P_l^{\sigma,\tau}(\rho_{\sigma,\tau})\rangle \\ &= \left(\frac{q^{-l-\frac{1}{2}} - q^{l+\frac{1}{2}}}{q^{-1}-q}\right)^2 P_l^{\sigma,\tau}(\tfrac{1}{2}(q^\lambda + q^{-\lambda})), \end{aligned} \tag{5.1}$$

where the second identity follows from (3.20). Let X_σ be given by (4.1).

LEMMA 5.1. *We have*

$$\begin{aligned} q(q^{-1}-q)^2 A^\lambda \Omega \;\in\; & f(q^\lambda)\,(A^{\lambda+2} - A^\lambda) + f(q^{-\lambda})\,(A^{\lambda-2} - A^\lambda) \\ & + (1-q)^2 A^\lambda + \mathcal{U}_q X_\sigma + X_\tau \mathcal{U}_q\,, \end{aligned} \tag{5.2}$$

where

$$f(q^\lambda) := \frac{(1+q^{\sigma+\tau+1+\lambda})\,(1+q^{-\sigma-\tau+1+\lambda})\,(1-q^{\sigma-\tau+1+\lambda})\,(1-q^{-\sigma+\tau+1+\lambda})}{(1-q^{2\lambda})\,(1-q^{2\lambda+2})}\,. \tag{5.3}$$

Proof. If $Y, Z \in \mathcal{U}_q$, then $Y \sim Z$ will mean that

$$Y \;\in\; Z + \mathcal{U}_q X_\sigma + X_\tau \mathcal{U}_q\,.$$

First observe that

$$A^\lambda BC = q^\lambda (B - q^{-1}C) A^\lambda C + q^\lambda C A^\lambda (q^{-1}C - B) + q^{2\lambda} A^\lambda CB.$$

Substitute

$$A^\lambda CB = A^\lambda BC - A^\lambda(A^2 - D^2)/(q - q^{-1})$$

and

$$q^{\frac{1}{2}}B - q^{-\frac{1}{2}}C = -i\big(X_\tau + (q^{-\tau} - q^\tau)(A - D)/(q^{-1} - q)\big) \tag{5.4}$$

and similarly for X_σ. Then

$$\begin{aligned} iq^{\frac{1}{2}}(1 - q^{2\lambda})(q^{-1} - q)\,A^\lambda BC \sim{}& \big(q^{-1}(q^{-\tau} - q^\tau) - q^\lambda(q^{-\sigma} - q^\sigma)\big)\,CA^{\lambda+1} \\ &- \big(q(q^{-\tau} - q^\tau) - q^\lambda(q^{-\sigma} - q^\sigma)\big)\,CA^{\lambda-1} + iq^{2\lambda+\frac{1}{2}}\,(A^{\lambda+2} - A^{\lambda-2}). \end{aligned} \tag{5.5}$$

Observe that

$$CA^\mu = (C - qB)A^\mu + q^{1-\mu}\,A^\mu(B - q^{-1}C) + q^{-2\mu}\,CA^\mu.$$

Substitute again (5.4) and its analogue for X_σ; we obtain

$$(q^{-2\mu} - 1)(q^{-1} - q)\,CA^\mu \sim i\big(q^{\frac{1}{2}-\mu}(q^{-\sigma} - q^\sigma) - q^{\frac{1}{2}}(q^{-\tau} - q^\tau)\big)\,(A^{\mu+1} - A^{\mu-1}).$$

Substitute this last equivalence in (5.5). We obtain

$$\begin{aligned} &(1 - q^{2\lambda})(q^{-1} - q)^2\,A^\lambda BC \sim (q^{-2\lambda-2} - 1)^{-1} \\ &\quad\times \big(q^{-1}(q^{-\tau} - q^\tau) - q^\lambda(q^{-\sigma} - q^\sigma)\big)\,\big(q^{-1-\lambda}(q^{-\sigma} - q^\sigma) - (q^{-\tau} - q^\tau)\big)\,(A^{\lambda+2} - A^\lambda) \\ &\quad\quad - (q^{-2\lambda+2} - 1)^{-1}\,\big(q(q^{-\tau} - q^\tau) - q^\lambda(q^{-\sigma} - q^\sigma)\big) \\ &\quad\cdot \big(q^{1-\lambda}(q^{-\sigma} - q^\sigma) - (q^{-\tau} - q^\tau)\big)(A^\lambda - A^{\lambda-2}) + q^{2\lambda}(q^{-1} - q)\,(A^{\lambda+2} - A^{\lambda-2}). \end{aligned}$$

Now add $(1 - q^{2\lambda})\,A^\lambda(q^{-1}A^2 + qD^2 - 2)$ to both sides and multiply both sides with $q(1 - q^{2\lambda})^{-1}$. Then the left-hand side becomes $q(q^{-1} - q)^2\,A^\lambda\Omega$ and the right-hand side can be rewritten as

$$f(q^\lambda)\,(A^{\lambda+2} - A^\lambda) + f(q^{-\lambda})\,(A^{\lambda-2} - A^\lambda) + (1 - q)^2\,A^\lambda$$

with f given by (5.3). □

Substitute (5.2) into the left-hand side of (5.1). With the notation

$$R_l(q^\lambda) := P_l^{\sigma,\tau}(\tfrac{1}{2}(q^\lambda + q^{-\lambda}))$$

we obtain

(5.6)

$$f(q^\lambda)\,(R_l(q^{\lambda+2}) - R_l(q^\lambda)) + f(q^{-\lambda})\,(R_l(q^{\lambda-2}) - R_l(q^\lambda)) = -(1 - q^{-2l})(1 - q^{2l+2})\,R_l(q^\lambda).$$

Since this is an identity of rational functions in q^λ which is valid for infinitely many values of q^λ, it will remain valid if q^λ is arbitrarily complex, in particular if q^λ is replaced by $e^{i\theta}$. Then we recognize (5.6) as the second-order q-difference equation for Askey–Wilson polynomials; cf. (2.8). Hence

$$R_l(e^{i\theta}) = \text{const.}\,p_l(\cos\theta; -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1} \mid q^2),$$

where p_l is an Askey–Wilson polynomial (2.2). We can compute the constant by comparing the coefficient of $e^{il\theta}$ at both sides (use (4.15)). The result generalizing (4.16) is the following.

THEOREM 5.2. *The polynomial $P_l^{\sigma,\tau}$ occurring in* (4.14) *and* (4.15) *equals*

$$P_l^{\sigma,\tau} = \frac{c_l^{l,\sigma}\,\overline{c_l^{l,\tau}}}{(q^{2l+2};q^2)_l}\, p_l(\,.\,; -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1} \mid q^2). \tag{5.7}$$

THEOREM 5.3. *Let $dm(x) = dm_{a,b,c,d;q}(x)$ be the normalized orthogonality measure for the Askey–Wilson polynomials $p_n(x;a,b,c,d \mid q)$ as in* (2.7). *Let p be any polynomial. Then*

$$h(p(\rho_{\sigma,\tau})) = \int p(x)\, dm_{a,b,c,d;q^2}(x), \tag{5.8}$$

where $a = -q^{\sigma+\tau+1}$, $b = -q^{-\sigma-\tau+1}$, $c = q^{\sigma-\tau+1}$, $d = q^{-\sigma+\tau+1}$.

Proof. By (4.17) (for $l' = 0$) and (5.7) the theorem is therefore valid for $p = P_l^{\sigma,\tau}$ ($l \in \mathbb{Z}_+$). □

In the proof of Theorem 5.3 we only used the case $l' = 0$ of (4.17). Substitution of (5.7) and (5.8) into (4.17) for general l, l' should yield the full orthogonality relations for the Askey–Wilson polynomials of these particular parameters. We can indeed check that this is true. For $l = l'$ the left-hand side of (4.17) becomes

$$\frac{|c_l^{l,\sigma}|^2\,|c_l^{l,\tau}|^2}{(q^{2l+2};q^2)_l^2} \int p_l(x;a,b,c,d;q^2)^2\, dm_{a,b,c,d;q^2}(x),$$

where a, b, c, d are as in Theorem 5.3, while the right-hand side becomes

$$\frac{|c_l^{l,\sigma}|^2\,|c_l^{l,\tau}|^2\,(q^2;q^2)_l^2}{(q^{2l+2};q^2)_l^2\, q^{4l}}\,(-q^{2\sigma+2}, -q^{-2\sigma+2}, -q^{2\tau+2}, -q^{-2\tau+2}; q^2)_l\,.$$

These two expressions are equal because of (2.4), (2.5), and (2.6).

Remark 5.4. It follows from (4.15), (4.12), and (5.7) that

$$\begin{aligned} &p_n(\cos\theta; -q^{(\sigma+\tau+1)/2}, -q^{(-\sigma-\tau+1)/2}, q^{(\sigma-\tau+1)/2}, q^{(-\sigma+\tau+1)/2} \mid q) \\ &\quad = \sum_{k=-n}^{n} \frac{(q^{n+1};q)_n\,(q;q)_{2n}}{(q;q)_{n+k}(q;q)_{n-k}}\, q^{(n-k)(n-k+\sigma+\tau)/2} \\ &\qquad \times {}_3\phi_2\left[\begin{matrix} q^{-n+k}, q^{-n}, -q^{-n-\sigma} \\ q^{-2n}, 0 \end{matrix}; q, q\right] {}_3\phi_2\left[\begin{matrix} q^{-n+k}, q^{-n}, -q^{-n-\tau} \\ q^{-2n}, 0 \end{matrix}; q, q\right] e^{ik\theta}. \end{aligned} \tag{5.9}$$

This formula, obtained from the quantum group interpretation, cannot be found in the literature in the case of general σ, τ. For $\sigma = \tau$ we already gave an analytic proof of (5.9) in (2.12), (2.14). In a forthcoming paper [9] we will give an analytic proof for (5.9) in general and even for an extension of it with one more parameter. There it will turn out that the addition formula for classical ultraspherical polynomials (for Legendre polynomials in the case of (5.9)) is a limit case of our result. So it may be considered as an alternative to the Rahman–Verma [19] addition formula. In fact its derivation will be similar as for the Rahman–Verma formula.

6. Little and big q-Jacobi polynomials as limit cases of Askey–Wilson polynomials. Propositions 6.1 and 6.3 in this section are limit results for special functions, motivated by quantum group theory, but independent of quantum groups in formulation and proof. Before the author's paper [11] these limits have not been mentioned in literature, although R. Askey told me that he had been aware of them already some years ago.

Let X_σ ($\sigma \in \mathbb{R}$) be given by (4.1). Let $\mathcal{B}_\sigma := \{a \in \mathcal{A}_q \mid X_\sigma.a = 0\}$. By Lemma 3.2, $\mathcal{B}_\sigma$ is a subalgebra of $\mathcal{A}_q$; and, by (3.12) and (4.2), $\mathcal{B}_\sigma$ is moreover a $*$-subalgebra. It follows from (3.11) that $\Delta(\mathcal{B}_\sigma) \subset \mathcal{A}_q \otimes \mathcal{B}_\sigma$. Thus the quantum group $SU_q(2)$ corresponding to the Hopf $*$-algebra $\mathcal{A}_q$ acts on the quantum space corresponding to the $*$-algebra $\mathcal{B}_\sigma$. Thus it is natural to conjecture that this quantum action of $SU_q(2)$ coincides with its action on some quantum sphere as considered by Podleś [18]. According to Noumi and Mimachi [17, §5] this is indeed the case and they have made a precise identification between the two models.

Here we will restrict ourselves to the question of finding the elementary (σ, ∞)-spherical elements in $\mathcal{A}_q$. These can also be characterized as the elements of $\mathcal{B}_\sigma$ belonging to irreducible subspaces (with respect to $SU_q(2)$) and being invariant with respect to the diagonal quantum subgroup of $SU_q(2)$. We will obtain these (σ, ∞)-spherical elements as limit cases for $\tau \to \infty$ of the corresponding (σ, τ)-spherical elements.

It follows from Proposition 4.7, Theorem 5.2, and (2.3) that the (σ, ∞)-spherical elements in $\mathcal{A}_q^l$ ($l = 0, 1, 2, \ldots$) are spanned by

$$\lim_{\tau \to \infty} r_l(\rho_{\sigma,\tau}; q^{\tau-\sigma+1}, q^{-\tau+\sigma+1}, -q^{-\tau-\sigma+1}, -q^{\tau+\sigma+1} \mid q^2), \tag{6.1}$$

provided this limit exists and is nonzero. The limit can be obtained from the following limit transition from general Askey–Wilson polynomials to general big q-Jacobi polynomials.

PROPOSITION 6.1. *Let Askey–Wilson polynomials and big q-Jacobi polynomials be denoted by* (2.3) *and* (2.16), *respectively. Then*

$$\begin{aligned}\lim_{a \to 0} r_n\Bigg(\frac{q^{\frac{1}{2}}x}{2a(cd)^{\frac{1}{2}}}; q^{\alpha+\frac{1}{2}}a(d/c)^{\frac{1}{2}}, q^{\frac{1}{2}}a^{-1}(c/d)^{\frac{1}{2}},\\ -q^{\frac{1}{2}}a^{-1}(d/c)^{\frac{1}{2}}, -q^{\beta+\frac{1}{2}}a(c/d)^{\frac{1}{2}} \mid q\Bigg) = P_n^{(\alpha,\beta)}(x; c, d; q).\end{aligned} \tag{6.2}$$

Proof. The left-hand side of (6.2) can be written as

$$\sum_{k=0}^{n} \frac{(q^{-n}, q^{n+\alpha+\beta+1}; q)_k\, q^k}{(q^{\alpha+1}, -q^{\alpha+1}d/c, -q^{\alpha+\beta+1}a^2, q; q)_k} \prod_{j=0}^{k-1}\left(1 - \frac{q^{\alpha+1}x}{c}\, q^j + \frac{q^{2\alpha+1}a^2d}{c}\, q^{2j}\right). \quad \square$$

From (6.1), (6.2), and (4.7) we now obtain the following.

THEOREM 6.2. *The (σ, ∞)-spherical elements in $\mathcal{A}_q^l$ ($l = 0, 1, 2, \ldots$) are spanned by*

$$P_l^{(0,0)}(q^{-1}(1 - q^{2\sigma})\beta\gamma - iq^{\sigma-1}(\delta\beta + q\gamma\alpha); q^{2\sigma}, 1; q^2),$$

where $P_l^{(0,0)}$ is a big q-Jacobi polynomial.

The above theorem corresponds nicely with the interpretation of big q-Jacobi polynomials on quantum spheres by Noumi and Mimachi [16].

We can also try to get the (∞, ∞)-spherical elements in $\mathcal{A}_q^l$ by the limit

$$\lim_{\tau \to \infty} r_l(\rho_{-\tau,\tau}; q^{2\tau+1}, q^{-2\tau+1}, -q, -q \mid q^2). \tag{6.3}$$

For this we need the following.

PROPOSITION 6.3. *Let Askey–Wilson polynomials and little q-Jacobi polynomials be denoted by* (2.3) *and* (2.15), *respectively. Then*

$$\lim_{a\to 0} r_n\left(\frac{q^{\frac{1}{2}}x}{2a^2}; q^{\alpha+\frac{1}{2}}a^2, q^{\frac{1}{2}}a^{-2}, -q^{\frac{1}{2}}, -q^{\beta+\frac{1}{2}} \mid q\right) = \frac{(q^{\beta+1};q)_n}{(q^{-n-\alpha};q)_n}\, p_n(x; q^\beta, q^\alpha; q). \tag{6.4}$$

Proof. Put $d := a^2$ in the proof of Proposition 6.1. Then we obtain for the limit in (6.4)

$${}_3\phi_2\left[\begin{matrix} q^{-n}, q^{n+\alpha+\beta+1}, q^{\alpha+1}x \\ q^{\alpha+1}, 0 \end{matrix}; q, q\right].$$

Now the proposition follows from [7, (III.7)] and (2.15). □

From (6.3), (6.4), and (4.7) we now obtain the following.

THEOREM 6.4. *The* (∞,∞)*-spherical elements in* $\mathcal{A}_q^l$ $(l = 0, 1, 2, \ldots)$ *are spanned by*

$$p_l(-q^{-1}\beta\gamma; 1, 1; q^2),$$

where p_l *is a little q-Jacobi polynomial.*

The (∞,∞)-spherical elements in $\mathcal{A}_q^l$ coincide with the bi-invariant elements in $\mathcal{A}_q^l$ with respect to the diagonal quantum subgroup of $SU_q(2)$. These last ones are well known; cf. for instance [10], where we find the same explicit expression as in Theorem 6.3.

Remark 6.5. Askey–Wilson polynomials, with q fixed but with dilation of the argument admitted, form a five-parameter family of orthogonal polynomials. When these parameters are chosen as the α, β, a, c, d in the left-hand side of (6.2) then, for each choice of α, β, we obtain a three-parameter family of orthogonal polynomials which contain on the one hand the continuous q-Jacobi polynomials in Rahman's notation $P_n^{(\alpha,\beta)}(x;q)$ (cf. [5, (4.17)]) and on the other hand big and little q-Jacobi polynomials as limit cases.

Remark 6.6. When we compare Proposition 6.1 with Proposition 2.2 we see that the orthogonal polynomials in x after the limit sign in the left-hand side of (6.2) will have continuous mass on the interval $[-2a(cd/q)^{\frac{1}{2}}, 2a(cd/q)^{\frac{1}{2}}]$ and discrete mass points on the two sets

$$\{cq^k + a^2dq^{-k-1} \mid k \in \mathbb{Z}_+,\ q^k > a(qc/d)^{-\frac{1}{2}}\}$$

and

$$\{-dq^k - a^2cq^{-k-1} \mid k \in \mathbb{Z}_+,\ q^k > a(qd/c)^{-\frac{1}{2}}\}.$$

Clearly, when $a \to 0$, the continuous mass interval shrinks to $\{0\}$, while the discrete mass points tend two the two infinite sets $\{cq^k \mid k \in \mathbb{Z}_+\}$ and $\{-dq^k \mid k \in \mathbb{Z}_+\}$, just the location for the mass points of the big q-Jacobi polynomials. A similar remark can be made about the limit transition in Proposition 6.3.

SOME INEQUALITIES FOR THE FIRST POSITIVE ZEROS OF BESSEL FUNCTIONS*

LEE LORCH†

Abstract. For the first positive zero $j = j_{\nu 1}$ of the Bessel function $J_\nu(x)$, it is shown for $-1 < \nu < \infty$, that (i) $j^2 - (\nu+1)(\nu+5)$ increases from zero to $+\infty$ so that $j^2 > (\nu+1)(\nu+5)$, and that

$$\text{(ii)}\qquad j^2 > \frac{24(\nu+1)^2}{1-2\nu+\sqrt{(2\nu+3)(2\nu+11)}} - 2(\nu^2-1).$$

These inequalities find use in the work of Ashbaugh and Benguria on bounding ratios of eigenvalues. In addition, some associated monotonicities and inequalities are established and some conjectures of Ismail and Muldoon on lower bounds for j are verified.

Key words. Bessel functions, zeros, inequalities, monotonicity

AMS subject classification. primary 33A40

1. Introduction and statement of principal results.

In the course of their work on bounding ratios of eigenvalues, including proofs of long-standing Payne–Pólya–Weinberger conjectures, Ashbaugh and Benguria [1], [2], [3], encountered the need for some inequalities for $j = j_{\nu 1}$, the first positive zero of the Bessel function $J_\nu(x)$.

They require the inequalities

$$(1)\qquad j^2 > (\nu+1)(\nu+5), \qquad -1 < \nu < \infty,$$

and

$$(2)\qquad j^2 > \frac{24(\nu+1)^2}{1-2\nu+\sqrt{(2\nu+3)(2\nu+11)}} - 2(\nu^2-1), \qquad -1 < \nu < \infty,$$

for the special values $\nu = \frac{1}{2}n - 1$, $n = 1, 2, \ldots$, where n is the dimension of the space in which the domains they study are embedded. To fill this need, proofs of (1) and (2) are among the results provided here.

A straightforward calculation shows that (2) provides a sharper (larger) lower bound for $j_{\nu 1}$ than does (1), i.e., that the right member of (1) is smaller than the right member of (2). Hence, it would suffice to prove only (2).

The inequality (2) can be rewritten readily as

$$1 + \frac{6(\nu+1)}{j^2 + 2(\nu^2-1)} < \frac{2\nu+5+\sqrt{(2\nu+3)(2\nu+11)}}{4(\nu+1)}, \qquad \nu > -1.$$

With $\nu = \frac{1}{2}n - 1$, this becomes

$$(2')\qquad 1 + \frac{6n}{2j^2 + n(n-4)} < \frac{n+3+\sqrt{(n+1)(n+9)}}{2n}, \qquad n > 0.$$

* Received by the editors March 24, 1992; accepted for publication (in revised form) August 17, 1992. The Natural Sciences and Engineering Research Council of Canada provided partial support for this work.

† Department of Mathematics, York University, North York, Ontario, Canada M3J 1P3.

In this form, the inequality establishes that Chiti's upper bound for $(j_{n/2}/j_{n/2-1})^2$ is more precise (i.e., smaller) than the upper bound for that ratio found by Brands and also jointly by Hile and Protter. This is discussed and references are provided in [2]. Here $j_\nu = j_{\nu 1}$.

However, a separate analysis of (1) will be included, inferring its validity from the more informative result that

$$f(\nu) = j^2 - (\nu+1)(\nu+5) \tag{3}$$

increases steadily from zero (since $f(-1^+) = 0$) to $+\infty$, $-1 < \nu < \infty$.

This monotonicity is obviously equivalent to the inequality

$$j\frac{dj}{d\nu} > \nu + 3, \qquad -1 < \nu < \infty, \tag{4}$$

which may have further interest because of its simplicity; it is in this formulation that the monotonicity of $f(\nu)$, and hence also the truth of the inequality (1), will be demonstrated.

The inequality (1) was formulated by Elbert [4], who proved it for $-1 < \nu < 0$, indicated a proof for $0 \le \nu < 1$, and conjectured its validity for $0 \le \nu < \infty$.

2. Collateral results. The proof of (4), beginning with inequalities found by Ismail and Muldoon [8], invites attention to various conjectures in [8]. These will be verified below (§6).

3. Proof of inequality (4). This proof involves a consideration of three subintervals (the first two overlap) of $-1 < \nu < \infty$:

$$\text{(A)} \quad -1 < \nu \le 1.4, \quad \text{(B)} \quad 0 \le \nu < 2, \quad \text{and} \quad \text{(C)} \quad 2 \le \nu < \infty.$$

In (A), inequalities due to Ismail and Muldoon [8] will yield the desired conclusion. In (B), the result follows from Elbert's concavity theorem $d^2j/d^2\nu < 0$, $\nu \ge 0$ [5] and the Elbert–Laforgia inequality $dj/d\nu > 1, \nu \ge 0$ [6]. In (C) the Elbert–Laforgia inequality will play the essential role.

Proof for (A). From [8, (6.2)], (4) will hold for $-1 < \nu \le 1.4$ if

$$2\left[1 + \frac{4(\nu+1)^2}{j^2}\right] \ge \nu + 3, \qquad -1 < \nu \le 1.4,$$

i.e., if $8(\nu+1) \ge j^2$, $-1 < \nu \le 1.4$.

This in turn will be the case, according to [8, (6.10)], if

$$8(\nu+1) \ge \frac{2(\nu+1)(\nu+5)(5\nu+11)}{7\nu+19}, \qquad -1 < \nu \le 1.4,$$

i.e., if $0 \ge 5\nu^2 + 8\nu - 21 = (\nu+3)(5\nu-7)$, which holds for this ν-interval.

Proof for (B). $0 \le \nu < 2$. Here, and below in the proof of (4′), we rely on Elbert's concavity theorem. Accordingly,

$$\left.\frac{dj}{d\nu}\right|_{\nu=\rho} > \left.\frac{dj}{d\nu}\right|_{\nu=\mu} > \frac{j_{\mu+h} - j_\mu}{h}, \quad \mu > \rho \ge 0, \quad h > 0. \tag{5}$$

Putting $\mu = 2$ and $h = \frac{1}{2}$, we have

$$\frac{dj}{d\nu} > 1.2556738, \qquad 0 \le \nu < 2,$$

so that

$$j\frac{dj}{d\nu}-\nu > 1.2556738j-\nu, \qquad 0 \le \nu < 2.$$

The right side is an increasing function of ν, since $dj/d\nu > 1$, $\nu \ge 0$. This lower bound exceeds 3 already when $\nu = 0$.

Proof for (C). Similarly, (4) holds if $j-\nu \ge 3$. This is the case for $\nu = 2$, since $j_{2,1} > 5$, and hence also for all $\nu > 2$, since $j_\nu - \nu$ is an increasing function in $0 \le \nu < \infty$.

This concludes the proof of (4), hence also of (1) and of the monotonicity of (3) for all $-1 < \nu < \infty$.

4. Remarks on the proof. (1) Martin Muldoon has pointed out in conversation that (1) by itself provides a lower bound smaller than that established in [8, (6.8)] for $-1 < \nu < 7$. If the proof of (1) were the only objective, Muldoon's observation would permit deleting the proofs of (A) and (B) above, retaining only the brief proof of case (C).

(2) Inequality (4), stated and proved for $j = j_{\nu 1}$, holds all the more for $j = j_{\nu k}$, $k = 2,3,\dots$, and, more generally, for $j = j_{\nu\kappa}$, $\kappa \ge 1$, defined in [6]. In particular, $j_{\nu\kappa} = j_{\nu k}$, $\kappa = k = 1,2,\dots$, and $j_{\nu\kappa} = y_{\nu k}$ when $\kappa = k-\frac{1}{2}$, $k = 1,2,3,\dots$, where $y_{\nu k}$ is the kth positive zero of $Y_\nu(x)$, the Bessel function of second kind. This extension follows from (4) on noting that, for fixed ν, (i) $j_{\nu\kappa}$ increases with κ (cf. [6]) and (ii) $dj_{\nu\kappa}/d\nu$ also increases with κ from the lemma in [11].

5. Proof of inequality (2). This will be proved in two overlapping installments: (A) $-1 < \nu \le 15$ and (B) $1.34 \le \nu < \infty$. The proof of (B), as noted below, will establish results (1′) and (3′), strengthening (1) and (3) in the interval $1.34 \le \nu < \infty$ and also (4′), which strengthens (4) in the interval $.05 < \nu < \infty$.

(A) For these ν, the already established Ismail–Muldoon lower bound [8, (6.9)] for j^2 exceeds the right member of (2), i.e., after dividing each by 2,

$$\begin{aligned}2^{2/3}[(\nu+2)(\nu+3)]^{1/3} &> \frac{12(\nu+1)}{1-2\nu+\sqrt{(2\nu+3)(2\nu+11)}}-\nu+1\\ &= \frac{3}{8}\sqrt{(2\nu+3)(2\nu+11)}-\frac{1}{4}\nu+\frac{5}{8}.\end{aligned}$$

This inequality holds for $-1 < \nu \le 15.28966\dots$.

To verify this, we multiply both sides of the inequality by 8 and then cube each side. This yields an equivalent inequality which, simplified, becomes

$$56\nu^3+740\nu^2+2098\nu+1927 > 9(2\nu+3)^{1/2}(2\nu+11)^{1/2}(4\nu^2+16\nu+31).$$

Squaring each side of this inequality, then collecting all terms and finally dividing by 256, leads to another inequality, again equivalent to (2), namely,

$$-8\nu^6+20\nu^5+1118\nu^4+5915\nu^3+13067\nu^2+12713\nu+4471 > 0,$$

which may be written as

$$(\nu+1)^2(-8\nu^4+36\nu^3+1054\nu^2+3771\nu+4471) > 0,$$

and, since $\nu > -1$, finally as

$$-8\nu^4+36\nu^3+1054\nu^2+3771\nu+4471 > 0.$$

This quartic has exactly one positive root, ν_0, which could be written in "exact form." Numerically, $\nu_0 = 15.28966\ldots$.

Thus, (2) has been proved for $-1 < \nu \leq \nu_0 = 15.28966\ldots$.

Remark. This shows that the Ismail–Muldoon lower bound in [8, (6.9)] for j^2 improves on the bound provided by (2) when $-1 < \nu < \nu_0$. The position is reversed for $\nu > \nu_0$, as is evident from the foregoing discussion.

(B) The proof of (2) for $\nu > \nu_0$ will in fact cover the larger interval $\nu \geq 1.34$, since doing so presents an opportunity to establish results yielding additional information. This will permit improving (1), (3), and (4) for appropriate infinite ν-intervals, although not for the entire interval $-1 < \nu < \infty$.

The inequality (2) can be rewritten in the form

$$(2'') \qquad \frac{j^2}{2(\nu+1)} > \frac{3}{8}\sqrt{(2\nu+3)(2\nu+11)} - \frac{1}{4}\nu + \frac{5}{8}.$$

Now, $(2\nu+3)(2\nu+11) < (2\nu+7)^2$ so that the right side of (2″) is less than $\frac{1}{2}(\nu + 13/2)$. Thus, (2″), and hence (2) would follow for those $\nu > -1$ for which

$$(1') \qquad j^2 > (\nu+1)\left(\nu + \frac{13}{2}\right),$$

an inequality stronger than (1) for those $\nu > -1$ for which it is valid.

Paralleling the discussion of (1), it will be shown that (1′) *holds for* $\nu \geq 1.34$ (and hence also (2) and (2″)). It is reversed for $\nu = 1.33$ [9, p. 195].

The inequality (1′) follows, since $f_1(1.34) > 0$ [9, p. 195], from the property that

$$(3') \qquad f_1(\nu) = j^2 - (\nu+1)\left(\nu + \frac{13}{2}\right)$$

is an increasing function of ν *for* $.05 \leq \nu < \infty$. However, $f_1(.04) > f_1(.05)$.

The monotonicity assertion concerning $f_1(\nu)$ is equivalent to the inequality

$$(4') \qquad j\frac{dj}{d\nu} - \nu > \frac{15}{4}, \qquad .05 \leq \nu < \infty,$$

an inequality which, by the way, reverses when $\nu = 0$.

The proof of (4′) is separated into four parts, the first of which alone suffices, together with (A), to complete the proof of (2) and (2″).

(i) $5 \leq \nu < \infty$. Since $dj/d\nu > 1$, $\nu \geq 0$, we have

$$j\frac{dj}{d\nu} - \nu > j - \nu,$$

an increasing function of $\nu \geq 0$. But $j - \nu > 15/4$ when $\nu = 5$, so that this part of the proof of (4′) is complete—and with it the proof of (2) and (2″) is also complete.

(ii) $3/2 \leq \nu < 5$. Putting $\mu = 5$ and $h = \frac{1}{2}$ in (5), we have

$$j\frac{dj}{d\nu} - \nu > 1.16865654j - \nu, \qquad 0 \leq \nu < 5,$$

an increasing function of ν. When $\nu = 3/2$, this lower bound exceeds 15/4, thus verifying (4′) also for $3/2 \leq \nu < 5$.

(iii) $.78 \leq \nu < 3/2$. Following the pattern of (ii),

$$\frac{dj}{d\nu} > \frac{j_{2,1} - j_{1.5,1}}{.5} > 1.28442564, \qquad \nu < \frac{3}{2},$$

and so

$$j\frac{dj}{d\nu} - \nu > 1.28442564j - \nu, \qquad \nu < \frac{3}{2},$$

an increasing function of ν which exceeds 15/4 [9, p. 195] when $\nu = .78$. This verifies (4′) also for $.78 \leq \nu < 3/2$.

(iv) $.05 \leq \nu < .78$. For this portion of the ν-interval, there is available a larger lower bound for $dj/d\nu$ than the one given by (5). From the mean-value theorem,

$$\frac{dj}{d\nu} = \left.\frac{dj}{d\nu}\right|_{\nu=0} + \nu\left.\frac{d^2j}{d\nu^2}\right|_{\nu=\mu}$$

for some $\mu, 0 < \mu < \nu$. Elbert and Laforgia [7] have shown that $d^3j/d\nu^3 > 0,\ \nu \geq 0$, so that $d^2j/d\nu^2$ is an increasing function of ν. Thus, we now have

$$\frac{dj}{d\nu} > \left.\frac{dj}{d\nu}\right|_{\nu=0} + \nu\left.\frac{d^2j}{d\nu^2}\right|_{\nu=0}, \qquad \nu > 0.$$

Using the numerical values [10, (1.1)] now yields the lower bound to be used here, i.e.,

$$\frac{dj}{d\nu} > 1.54288974 - .175493593\nu, \nu > 0. \tag{6}$$

The argument is now subdivided into several steps.

(a) $.34 \leq \nu < .78$. Here $dj/d\nu > 1.40600473$ so that

$$j\frac{dj}{d\nu} - \nu > 1.40600473j - \nu, \qquad 0 \leq \nu < .78,$$

an increasing function of ν which exceeds 15/4 already when $\nu = .34$ [9, p. 195].

(b) $.15 \leq \nu < .34$. Similarly, for this interval,

$$j\frac{dj}{d\nu} - \nu > 1.48322192j - \nu,$$

an increasing function of ν which exceeds 15/4 already when $\nu = .15$ [9, p. 195].

(c) The procedure is now clear. It can be applied successively to the intervals $.08 \leq \nu < .15, .06 \leq \nu < .08, .05 \leq \nu < .06$, using, as above, the values for $j_{\nu 1}$ recorded in [9, p. 195].

Remark. As noted in §1, (2) implies (1).

6. On some Ismail–Muldoon bounds. (1) Ismail and Muldoon observed numerically [8, p. 201] that their lower bound for $j_{\nu 1}^4$ in [8, (6.27)] is better (larger) than the lower bound given by [8, (6.24)], when $\nu > 0$.

Their implied conjecture thus suggests that the following inequality holds between these respective lower bounds for $j_{\nu 1}^4$:

$$\begin{aligned} &j_{01}^4 + \frac{56}{3}\nu^3 + 8(j_{01} + 4)\nu^2 + 8(j_{01}^2 + 10)\nu - 128 \ln\left(1 + \frac{\nu}{3}\right) \\ &\quad > j_{01}^4 + \frac{40}{3}\nu^3 + 8(j_{01} + 4)\nu^2 + 8(j_{01}^2 + 4)\nu, \qquad \nu > 0, \end{aligned}$$

i.e.,

$$3g(\nu) := \nu^3 + 9\nu - 24 \ln\left(1 + \frac{\nu}{3}\right) > 0, \qquad \nu > 0.$$

Now,

$$g'(\nu) = \frac{(\nu+3)(\nu^2+3) - 8}{\nu+3} > 0, \qquad \nu > -1,$$

while $g(0) = 0$, and so $g(\nu) > 0,\ \nu > 0$.

This verifies the Ismail–Muldoon conjecture and shows also that the bound in [8, (6.27)] becomes increasingly better than the one provided by [8, (6.24)], $0 < \nu < \infty$.

(2) Ismail and Muldoon observed numerically [8, p. 200] that the lower bound they provide in [8, (6.26)] is larger than the one they give in [8, (6.23)], thereby implying the conjecture that this ordering would hold for all $\nu > -1$. This is the case. These lower bounds for $j_{\nu 1}^4$ are, respectively,

$$\frac{96}{5}\left[1 + \nu\left\{1 + \frac{2}{3}(\nu+1)\right\}^{3/2}\right] + 16\nu^3 + 32\nu^2 + 80\nu + 64 - 128 \ln\left\{\frac{1}{2}(\nu+3)\right\}$$

and

$$\frac{96}{5}\nu\left[1 + \frac{2}{3}(\nu+1)\right]^{3/2} + \frac{96}{5} + \frac{32}{3}(\nu+1)^3.$$

Showing that the first of these exceeds the second for all $\nu > -1$ is equivalent to verifying that

$$F(\nu) := \nu^3 + 9\nu + 10 - 24 \ln\left\{\frac{1}{2}(\nu+3)\right\} > 0, \qquad \nu > -1.$$

Now, $F(-1) = 0$, while $F'(\nu) > 0,\ \nu > -1$, so that $F(\nu) > 0,\ \nu > -1$, thereby establishing the correctness of this conjecture.

(3) Another Ismail–Muldoon conjecture [8, line following (6.18), p. 198] (which they supported numerically) that can be confirmed readily is that Schafheitlin's upper bound for $j_{\nu 1}$, given by [8, (6.16)] is sharper (i.e., less) than the one provided by [8, (6.10)] for all $\nu > -1$. That is, for $\nu > -1$,

$$\frac{2(\nu+1)(\nu+5)}{1 + [1 - \frac{3}{4}(\nu+1)(\nu+5)/\{(\nu+2)(\nu+4)\}]^{1/2}} < \frac{2(\nu+1)(\nu+5)(5\nu+11)}{7\nu+19},$$

these being the respective upper bounds for $j_{\nu 1}^2$ recorded in [8, (6.16)] and [8, (6.10)].

By cross-multiplying and simplifying, this becomes

$$2(\nu+4) < (5\nu+11)\left[1 - \frac{3(\nu+1)(\nu+5)}{4(\nu+2)(\nu+4)}\right]^{1/2}.$$

Squaring both sides and simplifying leads to the equivalent (and obvious) inequality $9(\nu+1)^4 > 0, \nu > -1$.

(4) Another essentially correct Ismail–Muldoon conjecture [8, p. 198] states that Schafheitlin's upper bound for $j_{\nu 1}^2, A/(1+B)$, recorded in [8, (6.16)], is sharper (smaller) than the upper bound,

$$\frac{8(7\nu+19)(\nu+1)(\nu+2)(\nu+3)(\nu+6)}{42\nu^3 + 362\nu^2 + 1026\nu + 946}$$

provided by [8, (6.11)] when $\nu > -0.54$. Here

$$A = 2(\nu+1)(\nu+5),$$
$$B = [1 - \tfrac{3}{4}(\nu+1)(\nu+5)/\{(\nu+2)(\nu+4)\}]^{1/2}.$$

More precisely, it will be shown that there exists a unique $\rho = -0.534\ldots$ such that the difference of these bounds,

$$G(\nu) = \frac{A}{1+B} - \frac{8(7\nu+19)(\nu+1)(\nu+2)(\nu+3)(\nu+6)}{42\nu^3+362\nu^2+1026\nu+946}, \tag{7}$$

is negative for $\nu > \rho$. On the other hand, $G(\nu) > 0$ for $-1 < \nu < \rho$, so that [8, (6.11)] is better than [8, (6.16)] for $-1 < \nu < \rho$. When $\nu = \rho$, $G(\nu) = 0$.

Now,

$$\begin{aligned} G(\nu)H(\nu) &= (\nu+5)(21\nu^3+181\nu^2+513\nu+473) \\ &\quad - \left(2 + \sqrt{\frac{\nu^2+6\nu+17}{(\nu+2)(\nu+4)}}\right)(7\nu+19)(\nu+2)(\nu+3)(\nu+6), \end{aligned}$$

where

$$H(\nu) = \left(2 + \sqrt{\frac{\nu^2+6\nu+17}{(\nu+2)(\nu+4)}}\right)\frac{21\nu^3+181\nu^2+513\nu+473}{4(\nu+1)}.$$

Clearly, $H(\nu) > 0$, $-1 < \nu < \infty$, so that $G(\nu)$ and $G(\nu)H(\nu)$ have the same signs in $-1 < \nu < \infty$. Now,

$$\begin{aligned} (\nu+4)^{1/2}G(\nu)H(\nu) &= (\nu+4)^{1/2}(7\nu^4+94\nu^3+496\nu^2+1766\nu+996) \\ &\quad - (7\nu+19)(\nu+3)(\nu+6)(\nu+2)^{1/2}(\nu^2+6\nu+17)^{1/2} \\ &:= G_1(\nu) - G_2(\nu), \end{aligned}$$

whence $G(\nu)$ has the same signs in $-1 < \nu < \infty$ as does

$$G_1^2(\nu) - G_2^2(\nu) = -(\nu+1)^4(\nu+5)(28\nu^3+191\nu^2+371\nu+148). \tag{8}$$

Thus, the signs of $G(\nu)$ in $-1 < \nu < \infty$ are opposite (except when zero) to those of

$$\psi(\nu) = 28\nu^3+191\nu^2+371\nu+148. \tag{9}$$

Following the classical method of solving cubic equations, we put $\nu = x-(191/84)$ so that

$$\psi(\nu) = \frac{8}{84^3}q(x) = \frac{8}{84^3}[2073214x^3 - 4689594x - 2759281]. \tag{10}$$

The cubic $q(x)$ has precisely one real root ξ; this can be expressed in exact form, namely,

$$\begin{aligned} \xi = &\left\{\frac{2759281}{4146428} + \sqrt{\left(\frac{2759281}{4146428}\right)^2 - \left(\frac{781599}{1036607}\right)^3}\right\}^{1/3} \\ &+ \left\{\frac{2759281}{4146428} - \sqrt{\left(\frac{2759281}{4146428}\right)^2 - \left(\frac{781599}{1036607}\right)^3}\right\}^{1/3}. \end{aligned}$$

Thus, $\psi(\nu)$ has exactly one real root ρ, where

$$\rho = \xi - \frac{191}{84} = -0.534\ldots. \tag{11}$$

It is easy to see that $\psi(\nu) < 0$, and hence $G(\nu) > 0$, $-1 < \nu < \rho$, while $\psi(\nu) > 0$ so that $G(\nu) < 0$ for $\rho < \nu < \infty$ and $G(\rho) = 0$.

Remark. The inequalities (bounds) on $j_{\nu 1}$ and $jdj/d\nu$ borrowed from [8] to establish various inequalities above are not the sharpest provided in [8]. However, the sharper (and more complicated) bounds found in [8] do not appear to yield stronger inequalities of the type discussed herein.

7. Miscellaneous comments. Inequalities (1) and (4) are each "best possible" in a certain sense. Increasing the factor $\nu + 5$ by any fixed positive quantity reverses (1) in a neighbourhood of $\nu > -1$. This is the case as well if (1) is rewritten as $j^2 > \nu^2 + 6\nu + 5$. Increasing the lower bound by a positive constant would again reverse the inequality in a neighbourhood of $\nu = -1$. The same is true of (4) if the term $\nu + 3$ is increased by a fixed amount. For example, given $a > 0$,

$$j^2 < (\nu + 1)(\nu + 5 + a), \qquad -1 < \nu \leq a - 1 \tag{12}$$

and

$$j\frac{dj}{d\nu} < \nu + 3 + \frac{1}{2}a, \qquad -1 < \nu \leq -1 + \varepsilon. \tag{13}$$

Similarly, the monotonicity of (3) is "best possible" in that

$$f_a(\nu) := j^2 - (\nu + 1)(\nu + 5 + a), \qquad a > 0,$$

while ultimately increasing, decreases in $-1 < \nu \leq -1 + \varepsilon$.

To prove (12), we observe that, for $-1 < \nu \leq a - 1$,

$$(\nu + 1)(\nu + 5 + a) > 2(\nu + 1)(\nu + 3) > j^2.$$

The second inequality is a standard upper bound for j^2, recorded, e.g., in [8, (6.8)]. As to (13), it should be noted that $f_a(-1^+) = 0$ and that $f_a(\nu) < 0$, $-1 < \nu \leq a - 1$, from (12). This implies the comments about $f_a(\nu)$, and hence also (13), except for the ultimate increasing character of $f_a(\nu)$. This latter follows from the inequality $dj/d\nu > 1$ since $j - \nu$ increases and (as is clear from the well-known asymptotics of $j_{\nu 1}$ [9, p. 153, §5.3]) becomes infinite as $\nu \to \infty$ so that

$$j\frac{dj}{d\nu} > j > \nu + 3 + \frac{1}{2}a$$

for ν sufficiently large.

Also, for any $A > 0$, the inequality

$$j^2 > (\nu + 1)(\nu + A) \tag{14}$$

holds for all sufficiently large ν, depending on A, again as a consequence of the monotonicity of

$$j^2 - (\nu + 1)(\nu + A).$$

To establish this monotonicity, it suffices to note that

$$j\frac{dj}{d\nu} - \nu - \frac{1}{2}(A+1) > j - \nu - \frac{1}{2}(A+1)$$

becomes and remains positive since $j - \nu$ increases to $+\infty$ as $\nu \to \infty$.

Other inequalities discussed in previous sections are also "best possible" in the intervals in which they hold.

Another inequality might be useful for cases, such as those considered in [1], [2], [3], where $\nu \geq \frac{1}{2}$:

$$j^2 > (\nu+1)\left(\nu + \frac{2}{3}\pi^2 - \frac{1}{2}\right), \qquad \frac{1}{2} < \nu < \infty. \tag{15}$$

This becomes an equality when $\nu = \frac{1}{2}$.

The inequality is a consequence of the monotonicity of

$$\varphi(\nu) = j^2 - (\nu+1)\left(\nu + \frac{2}{3}\pi^2 - \frac{1}{2}\right), \qquad 0 \leq \nu < \infty,$$

since $\varphi(\frac{1}{2}) = 0$.

The proof that $\varphi(\nu)$ increases in $0 \leq \nu < \infty$ follows the same lines as for (4) and (4′). We have

$$\frac{1}{2}\varphi'(\nu) = j\frac{dj}{d\nu} - \nu - \frac{1}{3}\pi^2 - \frac{1}{4}.$$

(i) $4 \leq \nu < \infty$. Since $dj/d\nu > 1$, so that $\frac{1}{2}\varphi'(\nu) > j - \nu - \frac{1}{3}\pi^2 - \frac{1}{4}$, an increasing function of ν which is positive already when $\nu = 4$.

(ii) $1 \leq \nu < 4$. Here we use (5) with $\mu = 4, h = \frac{1}{2}$ so that $dj/d\nu > 1.18843804$. Thus,

$$\frac{1}{2}\varphi'(\nu) > 1.18843804j - \left(\frac{1}{3}\pi^2 + \frac{1}{4}\right), \qquad 1 \leq \nu < 4,$$

an increasing function of ν which is positive already when $\nu = 1$.

(iii) $0 \leq \nu < 1$. This remaining interval is subdivided into the subcases, $\frac{1}{2} \leq \nu < 1$, $\frac{1}{4} \leq \nu < \frac{1}{2}$, $0 \leq \nu < \frac{1}{4}$, which are treated successively in the same fashion as (ii).

Acknowledgment. Preprints of Ashbaugh and Benguria's work [1], [2], [3] were kindly shown to me by Martin Muldoon.

SPECTRA OF JACOBI MATRICES, DIFFERENTIAL EQUATIONS ON THE CIRCLE, AND THE $su(1,1)$ LIE ALGEBRA*

JULIAN EDWARD†

Abstract. A family of differential operators on the circle is shown to be isospectral to a certain family of bilaterally infinite Jacobi matrices. The spectral properties of the differential operators are then used to explain a previously noted isospectral deformation of the Jacobi matrices. Differential operators on the circle are used to provide realizations of principle and complementary series representations of $su(1,1)$.

Key words. Jacobi matrices, spectrum, differential equations, Lie algebra, $su(1,1)$

AMS subject classifications. 17B15, 39A70

1. Introduction. A bilaterally infinite Jacobi matrix is a symmetric tridiagonal matrix of the form

$$M = \begin{pmatrix} \ddots & \ddots & b_0 & & & 0 \\ & b_0 & a_0 & b_1 & & \\ & & b_1 & a_1 & b_2 & \\ & & & b_2 & a_2 & b_3 \\ 0 & & & \ddots & \ddots & \ddots \end{pmatrix}, \tag{1.1}$$

with $b_j > 0$ and $a_j \in \mathbb{R}$.

In cases where M, acting on $\ell^2(\mathbb{Z})$ (the set of square summable bilateral sequences), has discrete spectrum the eigenvalues have rarely been explicitly computed. One case where the eigenvalues have been computed explicitly is the case where M is connected with associated Meixner polynomials.

More explicitly, suppose

$$a_j = \delta j \quad \text{and} \quad b_j^2 = \alpha j^2 + \beta j + \gamma, \tag{1.2}$$

with $\alpha, \beta, \gamma, \delta \in \mathbb{R}$, and $\delta^2 > 4\alpha > 0$.

Then the spectrum of M was shown by Masson and Repka in [1] to be the following discrete set:

$$\lambda_j = j\sqrt{\delta^2 - 4\alpha} + \frac{1}{2}\left(1 + \frac{\beta}{\alpha}\right)(\sqrt{\delta^2 - 4\alpha} - \delta), \qquad j \in \mathbb{Z}. \tag{1.3}$$

To obtain this result, the authors above studied the properties of the left and right subdominant solutions to the second-order difference equation associated with M. Unfortunately, using these methods the authors were unable to explain the curious fact that the spectrum of M was independent of γ.

The main purpose of this note is to provide an alternative proof of (1.3) in a setting in which the independence of λ_j on γ is easily explained. It is also possible that the techniques used here could be useful in studying the spectra of other Jacobi matrices.

The key observation is the following. Let W be a closed curve, and let an arclength parametrization of W define a local coordinate x. Then the matrix M, acting on $\ell^2(\mathbb{Z})$, is isospectral to the following differential operator on W:

$$-\frac{i\partial}{\partial x}+q.$$

Here $q \in C^\infty(W)$, and the differential operator acts on the square integrable functions on W, $L^2(W)$. The observation is proven in §3.

The isospectral variation noted above will then be explained by the following.

LEMMA 1.1. *Suppose $\int q(x)dx = 0$. Then the spectrum of $-i\partial/\partial x + \gamma q(x)$ is independent of γ.*

This will be proven in §2. In §4, we use the connection between Jacobi matrices and differential operators on the unit circle, S^1, to obtain the principle and complementary series representations of the Lie algebra $su(1,1)$. The principle series representation is shown to be realized by a set of differential operators acting on $L^2(S^1)$. The complementary series representation is shown to be realized by a set of differential operators living on S^1 and acting on a Hilbert subspace of some Sobolev space over S^1.

The principle and complementary series representations of $su(1,1)$ arise in a number of differential equations [2]–[6], and the simplicity of the representations given here might make them a good approach to studying the properties of the differential equations.

2. The spectrum of a differential operator on S^1.

Let W be a closed curve in $\mathbb{R}^2$ of arclength L, and let an arclength parametrization of W provide a local coordinate x on W.

We define $L^2(W)$, the set of complex valued, square integrable functions on W, as

$$L^2(W) = \left\{ f \,\middle|\, \int_{x=0}^{L} |f(x)|^2 dx < \infty \right\}.$$

$L^2(W)$ is a Hilbert space equipped with inner product

$$\langle f, g\rangle = \frac{1}{L}\int_{x=0}^{L} f(x)\bar{g}(x)dx$$

and norm

$$\|f\|^2 = \frac{1}{L}\int_{x=0}^{L} |f(x)|^2 dx.$$

Let $C^\infty(W)$ be the set of infinitely differentiable functions on W.

Let $i = \sqrt{-1}$, and denote the differential operator $-i\partial/\partial x$ by D_x. Denote the spectrum of an operator A by $\sigma(A)$.

LEMMA 2.1. *Let $q \in C^\infty(W)$. Then*

$$\sigma(D_x + q) = \left\{ \frac{2\pi}{L}k + \frac{1}{L}\int_0^L q(x)\, dx;\ k \in \mathbb{Z} \right\}.$$

Proof. Suppose $(D_x+q)\phi = \lambda\phi$, $\phi \in L^2(W)$. Let $\phi(0) = C$. Then by uniqueness,

$$\phi(x_0) \;=\; C\,\exp\left(i\int_0^{x_0}(\lambda - q(x))dx\right).$$

Since $D_x + q - \lambda$ is an elliptic operator, it follows that $\phi \in C^\infty(W)$ [8]. In particular,

$$\phi(0) \;= \phi(L) \;=\; C\exp\left(i\int_0^{L}(\lambda - q(x))dx\right).$$

It follows that

$$\lambda \;=\; \frac{2\pi}{L}k + \frac{1}{L}\int_0^L q(x)dx \quad \text{with } k \in \mathbb{Z}.$$

Conversely, suppose $\lambda = 2\pi k/L + 1/L\int_0^L q(x)dx$. Let $\rho : \mathbb{R} \to W$ be an arclength preserving covering map. Define $\tilde{\phi} \in C^\infty(\mathbb{R})$ by

$$\tilde{\phi}(y_0) \;=\; \exp\left(i\int_0^{y_0}(\lambda - q\circ\rho(y))dy\right).$$

Then it is easy to verify that $\tilde{\phi}$ satisfies

$$\tilde{\phi}(y_0) = \tilde{\phi}(y_0 + L),$$
$$\left(-i\frac{\partial}{\partial y} + q\circ\rho\right)\tilde{\phi} = \lambda\tilde{\phi}.$$

It follows that there exists $\phi \in C^\infty(W)$, with $\phi\circ\rho = \tilde{\phi}$, such that

$$(D_x + q)\phi \;=\; \lambda\phi. \qquad \square$$

Note that Lemma 1 now follows.

Now let the usual arclength parametrization of S^1 provide the local coordinate θ.

THEOREM 1. *Let $A = (d + 2\sqrt{a}\cos\theta)D_\theta + 2e\sin\theta + 2e'\cos\theta$, with $d^2 > 4a$ and $e, e' \in \mathbb{R}$. Then $\sigma(A) = \{\sqrt{d^2 - 4a}\; k + e'(\sqrt{d^2-4a} - d)/\sqrt{a};\; k \in \mathbb{Z}\}$.*

Proof. Let $f : S^1 \to W$ be a diffeomorphism such that with respect to the coordinates θ and x on S^1 and W, respectively,

$$f'(\theta) \;=\; \frac{1}{d + 2\sqrt{a}\cos\theta}.$$

We use f to push A forward onto W. Let $u \in C^\infty(W)$. Then

$$\begin{aligned}((f_*A)u)(x) &= (A(u\circ f))(f^{-1}(x))\\ &= (D_x + q)u(x),\end{aligned}$$

where $q(f(x)) = 2e\sin\theta + 2e'\cos\theta$.

Since f_*A is isospectral to A, we can apply Lemma 2.

It follows from [7, eq. 3.645] that

$$\int_0^{2\pi}\frac{1}{d + 2\sqrt{a}\cos\theta}d\theta \;=\; \frac{2\pi}{\sqrt{d^2 - 4a}}. \tag{2.1}$$

Noting that $L = \int_0^{2\pi} f'(\theta)d\theta$, it follows from (2.1) that

$$\frac{1}{L}\int_0^L q(x)dx = \frac{1}{L}\int_0^{2\pi} \frac{(2e\sin\theta + 2e'\cos\theta)}{(d+2\sqrt{a}\cos\theta)d\theta}$$
$$= \left(\frac{e'}{\sqrt{a}}\right)(\sqrt{d^2-4a}-d). \qquad \square$$

The theorem now follows.

3. Differential operators on S^1 and Jacobi matrices. Let e_j be the column vector defined by

$$e_j = (\ldots,0,0,\underbrace{1}_{j},0,0,\ldots)^t.$$

The set of square summable bilateral sequences, denoted $\ell^2(\mathbb{Z})$, is given by

$$\left\{ u = \sum_{j=-\infty}^{\infty} u_j e_j \,\middle|\, u_j \in \mathbb{C}, \quad \sum_{j=-\infty}^{\infty} |u_j|^2 < \infty \right\}.$$

The inner product on $\ell^2(\mathbb{Z})$ of vectors $u = \sum_{j=-\infty}^{\infty} u_j e_j$ and $v = \sum_{j=-\infty}^{\infty} v_j e_j$ is given by

$$(u,v) = \sum_{j=-\infty}^{\infty} u_j \bar{v}_j.$$

PROPOSITION 1. *Let $M = (M_{m,n})$ be a bilaterally infinite Jacobi matrix acting on $\ell^2(\mathbb{Z})$ with $M_{n,n} = \delta n$, $M_{n,n-1} = M_{n-1,n} = \sqrt{\alpha n^2 + \beta n + \gamma}$, and $\delta^2 > 4\alpha > 0$. Then M has discrete spectrum.*

Proof. We prove this result by comparing M to a differential operator acting on $L^2(S^1)$. Let

$$B = (\delta + 2\sqrt{\alpha}\cos\theta)D_\theta + \sqrt{\alpha}e^{i\theta}.$$

Then B is a symmetric differential operator on $L^2(S^1)$, and, since $\delta + 2\sqrt{\alpha}\cos\theta > 0$, B is also elliptic. Denote its selfadjoint extension again by B. By the basic theory of pseudodifferential operators on compact manifolds, B has a discrete spectrum and $(B+i)^{-1}$ is a compact operator [8].

$L^2(S^1)$ is identified with $\ell^2(\mathbb{Z})$ by the unitary transformation $e^{ij\theta} \to e_j$. Via this identification, B induces the operator B' on $\ell^2(\mathbb{Z})$, and

$$(M-B')e_j = \left(\sqrt{\alpha(j+1)^2 + \beta(j+1) + \gamma} - \sqrt{\alpha}(j+1)\right)$$
$$\cdot e_{j+1} + \left(\sqrt{\alpha j^2 + \beta j + \gamma} - \sqrt{\alpha}j\right) e_{j-1}.$$

It follows that $M - B'$ is a bounded operator on $\ell^2(\mathbb{Z})$.

Since $(B'+i)^{-1}$ is a compact operator on $\ell^2(\mathbb{Z})$, it follows that $(M-B')(B'+i)^{-1}$ is also compact. Thus M differs from B' by a relatively compact perturbation, and it follows that M and B' have the same essential spectrum [9]. $\square$

Define a function on $\mathbb{Z}$ by

$$\pi_n = \begin{cases} \prod_{j=1}^{n}(\sqrt{a}j - e + e')/(\sqrt{a}(j-1) + e + e') & \text{if } n > 0, \\ 1 & \text{if } n = 0, \\ \prod_{j=1}^{-n}(-\sqrt{a}j + e + e')/(\sqrt{a}(1-j) - e + e') & \text{if } n < 0, \end{cases}$$

with $a, e, e' \in \mathbb{C}$.

LEMMA 3.1. *There exist constants $K_1, K_2 > 0$ such that*

$$K_1|n|^{(1-2e/\sqrt{a})3/4} \le |\pi_n| \le K_2|n|^{(1-2e/\sqrt{a})5/4} \quad \textit{if } n \neq 0.$$

Proof. Suppose that $n > 0$. Choose $j_0 \in \mathbb{N}$ such that for $j \ge j_0$, the following conditions are satisfied:

(i) $\sqrt{a}(j-1) + e + e' > 0$;

(ii) $|(\sqrt{a} - 2e)/(\sqrt{a}(j-1) + e + e')| < 1$;

(iii) $\frac{3}{4} < \sum_{\ell=0}^{\infty}(-1)^{\ell}/(\ell+1)((\sqrt{a} - 2e)/(\sqrt{a}(j-1) + e + e'))^{\ell} < \frac{5}{4}$.

Then, using the Taylor series of $\ln(1+x)$ for $|x| < 1$, we obtain

$$C_1 + \frac{3}{4}(\sqrt{a} - 2e)\sum_{j=j_0}^{n}\frac{1}{\sqrt{a}(j-1) + e + e'} \le \ln|\pi_n|$$

$$\le C_2 + \frac{5}{4}(\sqrt{a} - 2e)\sum_{j=j_0}^{n}\frac{1}{\sqrt{a}(j-1) + e + e'}$$

for some $C_1, C_2 > 0$. Hence

$$C_1' + \tfrac{3}{4}(1 - 2e/\sqrt{a})\ln n \le \ln|\pi_n| \le C_2' + \tfrac{5}{4}(1 - 2e/\sqrt{a})\ln n$$

for $C_1', C_2' > 0$.

Thus we obtain

$$e^{C_1'}n^{(1-2e/\sqrt{a})3/4} \le |\pi_n| \le e^{C_2'}n^{(1-2e/\sqrt{a})5/4}.$$

The proof for $n < 0$ is similar. □

We now prove (1.3).

THEOREM 2. *Let M satisfy the assumptions of Proposition* 1. *Then*

$$\sigma(M) = \left\{j\sqrt{\delta^2 - 4\alpha} + \frac{1}{2}\left(1 + \frac{\beta}{\alpha}\right)(\sqrt{\delta^2 - 4\alpha} - \delta);\ j \in \mathbb{Z}\right\}.$$

Proof. Consider the differential operator A on S^1 given by

$$A = (\delta + 2\sqrt{\alpha}\cos\theta)D_\theta + 2ei\sin\theta + 2e'\cos\theta,$$

with $e, e' \in \mathbb{C}$ chosen so that

$$2e'\sqrt{\alpha} - \alpha = \beta,$$
$$(e')^2 - e^2 + \sqrt{\alpha}e - \sqrt{\alpha}e' = \gamma. \quad □$$

We will show that A acting on $L^2(S^1)$ has the same spectrum as M acting on $\ell^2(\mathbb{Z})$. The theorem will then follow from Theorem 1. Note that by Theorem 1 and

Proposition 1 the operators A and M both have discrete spectrum; so it suffices to show that the eigenvalues coincide.

Under the identification $L^2(S^1) \sim \ell^2(\mathbb{Z}), A$ induces an operator A' on $\ell^2(\mathbb{Z})$ with

$$A'e_j = (\sqrt{\alpha}j + e + e')e_{j+1} + \delta j e_j + (\sqrt{\alpha}j - e + e')e_{j-1}.$$

Consider the operator $T : \ell^2(\mathbb{Z}) \to \ell^2(\mathbb{Z})$ given by $Te_j = 1/\sqrt{\pi_j}e_j$. Then

$$T^{-1}A'Te_j = \sqrt{\alpha(j+1)^2 + (2e'\sqrt{\alpha} - \alpha)(j+1) + (e')^2 - e^2 + \sqrt{\alpha}e - \sqrt{\alpha}e'}e_{j+1}$$
$$+\delta j e_j + \sqrt{\alpha j^2 + (2e'\sqrt{\alpha} - \alpha)j + (e')^2 - e^2 + \sqrt{\alpha}e - \sqrt{\alpha}e'}e_{j-1}.$$

Thus $M = T^{-1}A'T$. It remains to show that the eigenvalues of A and $T^{-1}A'T$ coincide.

Suppose $\lambda \in \sigma(A)$. Thus there exists $u(\theta) = \sum_{j=-\infty}^{\infty} u_j e^{ij\theta}$ such that

$$u \in L^2(S^1),$$
$$(A - \lambda)u = 0.$$

Since $A - \lambda$ is an elliptic differential operator, it follows that $u \in C^\infty(S^1)$. Hence

$$\lim_{|j|\to\infty} |u_j|\ |j|^p = 0 \quad \forall p \in \mathbb{N}. \tag{3.1}$$

Let $u' = \sum_{j=-\infty}^{\infty} u_j e_j$. It follows from Lemma 3 and (3.1) that

$$T^{-1}u' \in \ell^2(\mathbb{Z}).$$

Thus $T^{-1}u'$ is an eigenvector of $T^{-1}A'T$ with eigenvalue λ.

Conversely, suppose $\lambda \in \sigma(T^{-1}A'T)$. Thus there exists $u' = \sum u_j e_j$ satisfying $T^{-1}A'Tu' = \lambda u'$ with $u' \in \ell^2(\mathbb{Z})$. Consider the distribution on S^1 defined by

$$u(\theta) = \sum_{j=-\infty}^{\infty} \frac{u_j}{\sqrt{\pi_j}} e^{ij\theta}.$$

It is easily verified that $(A - \lambda)u = 0$ in the weak sense. Since $A - \lambda$ is elliptic, it follows that $(A - \lambda)u = 0$ in the strong sense and $u \in C^\infty(S^1)$. Thus $\lambda \in \sigma(A)$.

4. Representations of *su*(1,1). Consider the following differential operators on S^1:

$$T_1 = \cos\theta D_\theta + ae^{i\theta} + be^{-i\theta},$$
$$T_2 = \sin\theta D_\theta - aie^{i\theta} + bie^{-i\theta},$$
$$T_3 = D_\theta + a + b,$$

with $a, b \in \mathbb{C}$. The following is easily verified.

LEMMA 4.1. *$[T_1, T_2] = -iT_3$, $[T_2, T_3] = iT_1$, and $[T_3, T_1] = iT_2$.*

Thus for each $a, b \in \mathbb{C}$, the operators T_1, T_2, and T_3 form a representation on $su(1,1)$ on $C^\infty(S^1)$. We will show that for various values of a and b these operators are (up to conjugacy) the principle series and the complementary series.

Principle Series. Let $a = \frac{1}{2} - \sigma i$ and $b = \sigma i$, with $\sigma \in \mathbb{R}$, and consider T_1, T_2, T_3 acting on $L^2(S^1)$. As in the previous section, identify $L^2(S^1)$ with $\ell^2(\mathbb{Z})$ via the mapping $e^{ij\theta} \to e_j$, and let T_1', T_2' and T_3' be the transformed operators.

Thus

$$\begin{aligned}
T_1' ej &= (\tfrac{1}{2}j + \tfrac{1}{2} - \sigma i)e_{j+1} + (\tfrac{1}{2}j + \sigma i)e_{j-1},\\
T_2' ej &= -i(\tfrac{1}{2}j + \tfrac{1}{2} - \sigma i)e_{j+1} + i(\tfrac{1}{2}j + \sigma i)e_{j-1},\\
T_3' ej &= (j + \tfrac{1}{2})e_j.
\end{aligned}$$

Let π_n be the following complex valued function on $\mathbb{Z}$:

$$\pi_n = \begin{cases} \prod_{j=1}^{n} \left(\frac{j}{2} - \sigma i\right) \Big/ \left(\frac{j}{2} + \sigma i\right) & \text{if } n > 0,\\ 1 & \text{if } n = 0,\\ \prod_{j=1}^{-n} \left(\frac{1}{2} - \frac{j}{2} + \sigma i\right) \Big/ \left(\frac{1}{2} - \frac{j}{2} - \sigma i\right) & \text{if } n < 0. \end{cases}$$

Let $\mathcal{U} : \ell^2(\mathbb{Z}) \to \ell^2(\mathbb{Z})$ be the unitary transformation defined by $\mathcal{U}e_j = \sqrt{\pi_j}e_j$. Then it is easily verified that

$$\begin{aligned}
(\mathcal{U}T_1\mathcal{U}^{-1})e_j &= \sqrt{\tfrac{1}{4}(j+1)^2 + \sigma^2}\; e_{j+1} + \sqrt{\tfrac{1}{4}j^2 + \sigma^2}\; e_{j-1},\\
(\mathcal{U}T_2\mathcal{U}^{-1})e_j &= \tfrac{1}{i}\sqrt{\tfrac{1}{4}(j+1)^2 + \sigma^2}\; e_{j+1} - \tfrac{1}{i}\sqrt{\tfrac{1}{4}j^2 + \sigma^2}\; e_{j-1},\\
(\mathcal{U}T_3\mathcal{U}^{-1})e_j &= (j + \tfrac{1}{2})\; e_j.
\end{aligned}$$

This is precisely the action of the principal series representation.

Complementary series. Let $a = (t-s)/2$ and $b = (t+s)/2$, with $-1+|t| < s < -|t|$. Define a function π_n on $\mathbb{Z}$ by

$$\pi_n = \begin{cases} \prod_{j=1}^{n}(j+t+s)/(j-1+t-s) & \text{if } n > 0,\\ 1 & \text{if } n = 0,\\ \prod_{j=1}^{-n}(-j+t-s)/(1-j+t+s) & \text{if } n < 0. \end{cases}$$

By Lemma 3, either π_n or π_n^{-1} will be an unbounded function of n. Thus the technique used to obtain the principle series is not applicable in this case.

Instead, adapting the methods used in [10], we consider the weighted ℓ^2 space $\ell^2(\mathbb{Z}, \pi_j)$, with

$$\ell^2(\mathbb{Z}, \pi_j) = \left\{ \sum_{j=-\infty}^{\infty} u_j e_j \,\middle|\, u_j \in \mathbb{C} \quad \text{and} \quad \sum_{j=-\infty}^{\infty} |u_j|^2 \pi_j < \infty \right\}.$$

The inner product of $v = \sum_{j=-\infty}^{\infty} v_j e_j$ and $u = \sum_{j=-\infty}^{\infty} u_j e_j$ is given by $(u,v)_\pi = \sum_{j=-\infty}^{\infty} u_j \bar{v}_j \pi_j$.

Under the mapping $e_j \to e^{ij\theta}$, $\ell^2(\mathbb{Z}, \pi_j)$ is identified with some Hilbert space H, which, by Lemma 3, is the proper subspace of some Sobolev space.

Consider the operators T_1, T_2, and T_3 acting on H. These induce operators T_1', T_2', and T_3' acting on $\ell^2(\mathbb{Z}, \pi_j)$, given by

$$\begin{aligned}
T_1' e_j &= \left(\tfrac{1}{2}\right)(j + t - s)e_{j+1} + \left(\tfrac{1}{2}\right)(j + t + s)e_{j-1},\\
T_2' e_j &= \left(\tfrac{1}{2i}\right)(j + t - s)e_{j+1} - \left(\tfrac{1}{2i}\right)(j + t + s)e_{j-1},\\
T_3' e_j &= (j + t)e_j.
\end{aligned}$$

Let $\dot{e}_j = e_j/\sqrt{\pi_j}$. Then $\{\dot{e}_j | j \in \mathbb{Z}\}$ provides an orthonormal basis of $\ell^2(\mathbb{Z}, \pi_j)$. It is easily verified that

$$(4.1) \quad \begin{cases} (T_1'\dot{e}_{j+1}, \dot{e}_j)_\pi = (\dot{e}_{j+1}, T_1'\dot{e}_j)_\pi = \frac{1}{2}\sqrt{(j+t-s)(j+1+t+s)}, \\ (T_1'\dot{e}_{j+n}, \dot{e}_j)_\pi = 0 \quad \text{for } n \neq -1, 1. \end{cases}$$

Let $\mathcal{U} : \ell^2(\mathbb{Z}, \pi_n) \to \ell^2(\mathbb{Z})$ be the unitary transformation given by $\mathcal{U}\dot{e}_j = e_j$. Then it follows from (4.1) that

$$\mathcal{U}T_1'\mathcal{U}^{-1}e_j = \tfrac{1}{2}\sqrt{(j+t-s)(j+1+t+s)}e_{j+1} + \tfrac{1}{2}\sqrt{(j-1+t-s)(j+t+s)}e_{j-1}.$$

Similarly,

$$\mathcal{U}T_2'\mathcal{U}^{-1}e_j = \tfrac{1}{2i}\sqrt{(j+t-s)(j+1+t+s)}e_{j+1} - \tfrac{1}{2i}\sqrt{(j-1+t-s)(j+t+s)}e_{j-1},$$

and

$$\mathcal{U}T_3'\mathcal{U}^{-1}e_j = (j+t)e_j.$$

Thus the operators $\mathcal{U}T_1'\mathcal{U}^{-1}$, $\mathcal{U}T_2'\mathcal{U}^{-1}$, and $UT_3'\mathcal{U}^{-1}$ give the action of the complementary series representation of $su(1,1)$ on $\ell^2(\mathbb{Z})$.

CONVEXITY OF SOLUTIONS TO SOME ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS*

ANTONIO GRECO† AND GIOVANNI PORRU†

Abstract. This paper is concerned with positive solutions $u(x)$ to some special elliptic partial differential equations in a bounded convex domain $\Omega \subset R^N$. For a decreasing function $g(t)$ the transformation $v = g(u)$ is performed and, under appropriate restrictions on $g(t)$, it is proved that $v(x)$ is convex in Ω. Consequently, the level sets of $u(x)$ are convex.

Key words. elliptic equations, maximum principles, convexity

AMS subject classifications. 35B50, 35J99

1. Introduction.

In [1] Brascamp and Lieb show that the first (positive) eigenfunction of the Laplacian in a strictly convex domain $\Omega \subset R^N$ is log-concave. Their method makes use of the fact that the linear parabolic operator $\partial/\partial t - \Delta$, under homogeneous Dirichlet boundary conditions, preserves log-concavity of the initial data. Extending this method, Lions in [12] proves the log-concavity for the solution $u > 0$ of the problem

$$\Delta u = -h(u)u \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega,$$

where $h = h(t)$ is a positive real function satisfying

$$h'(t) \leq 0, \qquad h''(t)t + h'(t) \leq 0.$$

In [9], Korevaar gives a new proof of the above result by considering the concavity function

$$C(v; x, y) = v(z) - \frac{[v(x) + v(y)]}{2}, \qquad z = \frac{(x+y)}{2}, \tag{1.1}$$

where $x, y \in \Omega$. Of course, $v(x)$ is convex in Ω if and only if $C(v; x, y) \leq 0$ for all $(x, y) \in \Omega \times \Omega$. Consider the following elliptic equation:

$$a^{ij}(Dv)v_{ij} = b(x, v, Dv) \quad \text{in } \Omega, \tag{1.2}$$

where $v_i = \partial v/\partial x_i$, Dv is the gradient of v and the summation convention (here and in the sequel) over repeated indices is in effect. In [9] Korevaar shows that if $v(x)$ satisfies (1.2), where $b(x, v, p)$ is increasing with respect to v and jointly concave with respect to (x, v), then the concavity function (1.1) cannot attain any positive maximum in $\Omega \times \Omega$.

Extensions of Korevaar's method have been found independently by Caffarelli and Friedman [2], Caffarelli and Spruck [3], Kawohl [5], Kennington [6]. In [5] and [6] the maximum principle for the function (1.1) is proved under the conditions: $b \geq 0$, b strictly increasing with respect to v and $b(x, v, p)$ harmonic concave with respect to (x, v). (Note that if b is positive and concave then it is harmonic concave; the reverse

*Received by the editors January 17, 1992; accepted for publication (in revised form) October 19, 1992.

†Dipartimento di Matematica, Via Ospedale 72, 09124 Cagliari, Italy.

is not true in general.) The method of proof is by contradiction. By assuming that the function (1.1) has a positive maximum in $\Omega \times \Omega$ and by a suitable use of (1.2) it is possible to reach a contradiction.

In this paper we present an alternative proof of the last result by finding an elliptic (degenerate) inequality (in R^{2N}) satisfied by $C(v; x, y)$. Our proof does not require the assumption $b \geq 0$ and applies when $\partial b/\partial v \geq 0$. We also propose a new proof of a boundary point lemma.

Other techniques have been developed for studying convexity properties of solutions in [10] for ring domains and in [7] for parabolic equations.

2. A maximum principle. Let us state an unusual form of the classical maximum principle for elliptic degenerate inequalities.

LEMMA 2.1. *Let G be a domain in R^m and ϕ be a $C^2(G)$ solution of the differential inequality*

$$b^{hk}\phi_{hk} + b^h\phi_h \geq c\phi, \tag{2.1}$$

where $c \geq 0$ and the $m \times m$ matrix $[b^{hk}]$ is positive semidefinite in G. If for any compact set $K \subset G$ there exists a real number M and ν $(1 \leq \nu \leq m)$ indices $h_1, \dots, h_\nu$ such that it results (at each point in K) in

$$Mb^{h_i h_i} + b^{h_i} \geq 0, \qquad i = 1, \dots, \nu, \tag{2.2}$$

and

$$\sum_{i=1}^{\nu}\left(Mb^{h_i h_i} + b^{h_i}\right) > 0, \tag{2.3}$$

then ϕ cannot have any local positive maximum in G.

Proof. Suppose there are a point x_0 and a compact set K with $x_0 \in K \subset G$ so that $\Phi(x_0) > 0$ and $\Phi(x_0) > \Phi(x)$ for all $x \in \partial K$. We can choose $\varepsilon > 0$ small enough so that the function

$$\psi(x) = \phi(x) + \varepsilon\left(\exp(Mx^{h_1}) + \cdots + \exp(Mx^{h_\nu})\right)$$

has a local positive maximum value at some point $x_1 \in K$. At x_1 it must be

$$b^{hk}\psi_{hk} + b^h\psi_h \leq 0. \tag{2.4}$$

On the other hand, by using (2.1), (2.2), and (2.3) we find (at each point in K):

$$b^{hk}\psi_{hk} + b^h\psi_h \geq c\Phi + \varepsilon M \sum_{i=1}^{\nu}(Mb^{h_i h_i} + b^{h_i})\exp(Mx^{h_i}) > c\Phi.$$

The last inequality contradicts (2.4) at the point x_1. The lemma is proved. For $\nu = 1$ this lemma is proved in [4, pp. 31–32].

We also need the following result about matrices.

LEMMA 2.2. *Let $A = [a^{ij}]$ be a $N \times N$ positive semidefinite matrix. Then the $2N \times 2N$ new matrix*

$$B = \begin{pmatrix} \sigma^2 A & \sigma\tau A \\ \sigma\tau A & \tau^2 A \end{pmatrix}$$

is positive semidefinite for any pair of real numbers σ, τ.

Proof. If ξ is a vector in R^{2N}, let us denote by x the first N coordinates of ξ and by y the last N coordinates. We have $(B\xi, \xi) = (Az, z)$, where $z = \sigma x + \tau y$. The lemma follows.

DEFINITION 2.1. A function $f(x)$ is said to be harmonic concave in a convex domain $G \subset R^m$ if for any pair $x_1, x_2 \in G$ for which $f(x_1) + f(x_2) > 0$ it results

$$[f(x_1) + f(x_2)]f((x_1 + x_2)/2) \geq 2f(x_1)f(x_2).$$

Since no condition is imposed when $f(x_1) + f(x_2) \leq 0$ any nonpositive function is (according to our definition) harmonic concave. Of course, if a function is concave, then it is harmonic concave. It is easy to prove that if $f(x)$ is harmonic concave, then so is $f(x) + c$ for any negative constant c. (For a positive constant c the previous result is not true in general.) Definition 2.1 is natural for proving the following.

THEOREM 2.1. *Let Ω be a convex domain in R^N and let $v \in C^2(\Omega)$ be a solution of the strictly elliptic equation*

$$a^{ij}(Dv)v_{ij} = b(x, v, Dv), \tag{2.5}$$

where $a^{ij}(Dv)$ are smooth and $b(x, v, Dv)$ is smooth, nondecreasing with respect to v and harmonic concave with respect to (x, v). Then the concavity function defined in (1.1) *cannot have any local positive maximum in $\Omega \times \Omega$.*

Proof. We may suppose $a^{ij} = a^{ji}$. If v is a solution of (2.5) we set

$$\phi(x, y) = 2v(z) - v(x) - v(y), \tag{2.6}$$

where (here and in the sequel),

$$z = \frac{(x + y)}{2}.$$

Of course, we have $\phi(x, y) = 2C(v; x, y)$, with $C(v; x, y)$ introduced in (1.1). Let $(x, y) \in \Omega \times \Omega$ be a point at which

$$b(x, v(x), Dv(z)) + b(y, v(y), Dv(z)) > 0. \tag{2.7}$$

Since b is harmonic concave with respect to (x, v) we have

$$\begin{aligned} &[b(x, v(x), p) + b(y, v(y), p)]b\left(z, \frac{v(x) + v(y)}{2}, p\right) \\ &\qquad -2b(x, v(x), p)b(y, v(y), p) \geq 0 \end{aligned} \tag{2.8}$$

for all $p \in R^N$. At each point in $\Omega \times \Omega$ where (2.7) holds we define the second-order operator

$$\begin{aligned} L\phi \equiv &b^2(y, v(y), Dv(z))a^{ij}(Dv(z))\phi_{x_i x_j} \\ &+ 2b(y, v(y), Dv(z))b(x, v(x), Dv(z))a^{ij}(Dv(z))\phi_{x_i y_j} \\ &+ b^2(x, v(x), Dv(z))a^{ij}(Dv(z))\phi_{y_i y_j}. \end{aligned}$$

By Lemma 2.2, the operator L is elliptic (degenerate). By using (2.6) we find

$$\begin{aligned} L\phi = &b^2(y, v(y), Dv(z))[2^{-1}a^{ij}(Dv(z))v_{z_i z_j} - a^{ij}(Dv(z))v_{x_i x_j}] \\ &+ 2b(y, v(y), Dv(z))b(x, v(x), Dv(z))2^{-1}a^{ij}(Dv(z))v_{z_i z_j} \\ &+ b^2(x, v(x), Dv(z))[2^{-1}a^{ij}(Dv(z))v_{z_i z_j} - a^{ij}(Dv(z))v_{y_i y_j}]. \end{aligned}$$

Since

$$\phi_{x_s}(x,y) = v_{z_s}(z) - v_{x_s}(x), \qquad \phi_{y_s}(x,y) = v_{z_s}(z) - v_{y_s}(y),$$

we have

$$a^{ij}(Dv(z))v_{x_ix_j} = a^{ij}(Dv(x))v_{x_ix_j} + a^{ij}_{p_s} v_{x_ix_j}\phi_{x_s}.$$

Here and below we frequently apply the mean value theorem, so that in this instance $a^{ij}_{p_s}$ is evaluated at an intermediate point between $Dv(z)$ and $Dv(x)$. Similarly we find

$$a^{ij}(Dv(z))v_{y_iy_j} = a^{ij}(Dv(y))v_{y_iy_j} + a^{ij}_{p_s} v_{y_iy_j}\phi_{y_s}.$$

After use of these substitutions and of (2.5) at the points z, x, and y we find

$$\begin{aligned} L\phi{+}b^2&(y,v(y),Dv(z))a^{ij}_{p_s}v_{x_ix_j}\phi_{x_s} + b^2(x,v(x),Dv(z))a^{ij}_{p_s}v_{y_iy_j}\phi_{y_s} \\ &= 2^{-1}[b(y,v(y),Dv(z)) + b(x,v(x),Dv(z))]^2 b(z,v(z),Dv(z)) \\ &\quad - b^2(y,v(y),Dv(z))b(x,v(x),Dv(x)) - b^2(x,v(x),Dv(z))b(y,v(y),Dv(y)). \end{aligned}$$

We also have

$$\begin{aligned} b(z,v(z),Dv(z)) &= b\left(z, \frac{v(x)+v(y)}{2}, Dv(z)\right) + \frac{b_v\phi}{2}, \\ b(x,v(x),Dv(x)) &= b(x,v(x),Dv(z)) - b_{p_s}\phi_{x_s}, \\ b(y,v(y),Dv(y)) &= b(y,v(y),Dv(z)) - b_{p_s}\phi_{y_s}. \end{aligned}$$

Hence we find

$$\begin{aligned} L\phi{+}b^2&(y,v(y),Dv(z))Q^s\phi_{x_s} + b^2(x,v(x),Dv(z))P^s\phi_{y_s} \\ &= 4^{-1}[b(y,v(y),Dv(z)) + b(x,v(x),Dv(z))]^2 b_v\phi \\ &\quad + 2^{-1}\Bigg\{[b(x,v(x),p) + b(y,v(y),p)]^2 b\left(z, \frac{v(x)+v(y)}{2}, p\right) \\ &\qquad - 2[b(x,v(x),p) + b(y,v(y),p)]b(x,v(x),p)b(y,v(y),p)\Bigg\}, \end{aligned}$$

where $p = Dv(z)$ and

$$(2.9) \qquad Q^s = a^{ij}_{p_s}v_{x_ix_j} - b_{p_s}, \qquad P^s = a^{ij}_{p_s}v_{y_iy_j} - b_{p_s}.$$

Finally, by using hypothesis (2.8), we find

$$(2.10) \qquad L\phi + b^2(y,v(y),Dv(z))Q^s\phi_{x_s} + b^2(x,v(x),Dv(z))P^s\phi_{y_s} \geq c\phi,$$

where

$$c = 4^{-1}[b(y,v(y),Dv(z)) + b(x,v(x),Dv(z))]^2 b_v.$$

Since the entries in the first diagonal of the matrix relative to our operator L are

$$b^2(y,v(y),Dv(z))a^{ii}(Dv(z)) \quad \text{and} \quad b^2(x,v(x),Dv(z))a^{ii}(Dv(z)),$$

the assumptions of Lemma 2.1 are fulfilled. In fact, we may choose $m = 2N$, $h_1 = 1$, $h_2 = N+1$, and

$$M = 1 + \max\left[\sup\frac{|Q^1|}{a^{11}}, \sup\frac{|P^1|}{a^{11}}\right],$$

where the sup is taken over a compact set in $\Omega \times R^{N+1}$. Now we consider the points $(x, y) \in \Omega \times \Omega$ at which

$$b(x, v(x), Dv(z)) + b(y, v(y), Dv(z)) \leq 0. \tag{2.11}$$

At these points we define

$$L\phi \equiv a^{ij}(Dv(z))\phi_{x_i x_j} - 2a^{ij}(Dv(z))\phi_{x_i y_j} + a^{ij}(Dv(z))\phi_{y_i y_j}.$$

By Lemma 2.2, the operator L is elliptic (degenerate). By using (2.6) we find

$$\begin{aligned} L\phi =& 2^{-1}a^{ij}(Dv(z))v_{z_i z_j} - a^{ij}(Dv(z))v_{x_i x_j} \\ &- a^{ij}(Dv(z))v_{z_i z_j} + 2^{-1}a^{ij}(Dv(z))v_{z_i z_j} - a^{ij}(Dv(z))v_{y_i y_j}. \end{aligned}$$

By using the mean value theorem and equation (2.5) the last equality gives

$$\begin{aligned} L\phi &= - b(x, v(x), Dv(x)) - a^{ij}_{p_s} v_{x_i x_j} \phi_{x_s} - b(y, v(y), Dv(y)) - a^{ij}_{p_s} v_{y_i y_j} \phi_{y_s} \\ &= - b(x, v(x), Dv(z)) - Q^s \phi_{x_s} - b(y, v(y), Dv(z)) - P^s \phi_{y_s}, \end{aligned}$$

where Q^s and P^s are given by (2.9). The latter equation and assumption (2.11) imply

$$L\phi + Q^s \phi_{x_s} + P^s \phi_{y_s} \geq 0. \tag{2.12}$$

Hence the function $\phi(x, y)$ satisfies either (2.10) or (2.12) in $\Omega \times \Omega$. The theorem follows by Lemma 2.1.

Remark 2.1. Theorem 2.1 is proved (by using different methods) in [5] and in [6] in case of $b \geq 0$, $\partial b / \partial v > 0$, and in [9] in case b is concave.

3. Convexity results.

If $v(x)$ is not convex in Ω, then we have the following.

(i) $C(v; x, y)$ has a local positive maximum in $\Omega \times \Omega$; or

(ii) $C(v; x, y)$ becomes positive as (x, y) approaches $\partial(\Omega \times \Omega)$.

The (i) possibility has been discussed in Theorem 2.1. Now we examine the (ii) possibility.

LEMMA 3.1. *Let $\Omega \subset R^N$ be a bounded domain, strictly convex and with a smooth boundary $\partial\Omega$. Let $u \in C^1(\bar{\Omega})$, $u > 0$ in Ω, $u = 0$ on $\partial\Omega$ and $u_n < 0$ on $\partial\Omega$, where n is the exterior normal to $\partial\Omega$. Let $g : R^+ \longrightarrow R$ be a smooth function satisfying*

$$\lim_{u \to 0} g(u) = a \quad (\in R), \tag{3.1}$$

$$g'(u) < 0, \qquad \lim_{u \to 0} g'(u) = -\infty. \tag{3.2}$$

If $C(g(u); x, y)$ has not positive maxima in $\Omega \times \Omega$, then $C(g(u); x, y)$ cannot become positive as (x, y) approaches $\partial(\Omega \times \Omega)$.

Proof. We refer to [5, p. 115].

LEMMA 3.2. *Let $\Omega \subset R^N$ be a bounded domain, strictly convex and with a smooth boundary $\partial\Omega$. Let $u \in C^2(\bar{\Omega})$, $u > 0$ in Ω, $u = 0$ on $\partial\Omega$, and $u_n < 0$ on $\partial\Omega$, where n is the exterior normal to $\partial\Omega$. Let $g : R^+ \longrightarrow R$ be a smooth function satisfying*

$$\lim_{u \to 0} g(u) = +\infty, \tag{3.3}$$

$$g'(u) < 0, \qquad \lim_{u\to 0} g'(u) = -\infty, \tag{3.4}$$

$$g''(u) > 0, \qquad \lim_{u\to 0} g'(u)/g''(u) = 0. \tag{3.5}$$

Then $C(g(u); x, y)$ cannot become positive as (x, y) approaches $\partial(\Omega \times \Omega)$.

Proof. Otherwise there exist sequences $\{x_j\}$, $\{y_j\}$ in Ω with limits x_0, y_0 such that $(x_0, y_0) \in \partial(\Omega \times \Omega)$, and, for some positive ε,

$$C(g(u); x_j, y_j) \geq \varepsilon, \qquad j = 1, 2, \ldots. \tag{3.6}$$

By definition of C and (3.6) we have

$$g(u(z_j)) - 2^{-1}[g(u(x_j)) + g(u(y_j))] \geq \varepsilon, \qquad z_j = \frac{(x_j + y_j)}{2}. \tag{3.7}$$

If $x_0 \neq y_0$, then $(x_0 + y_0)/2 \in \Omega$. As j approaches infinity, $g(u(z_j))$ approaches $g(u((x_0 + y_0)/2))$ (a finite number), whereas x_j or y_j (or both) approaches $\partial\Omega$, where u vanishes. Hence, by using (3.3) we reach a contradiction. Suppose $x_0 = y_0$. Let us rewrite (3.7) as

$$[g(u(z_j)) - g(u(x_j))] + [g(u(z_j)) - g(u(y_j))] \geq 2\varepsilon.$$

By using the mean value theorem we find

$$g'(u(\xi_j))u_{\nu_j}(\xi_j)|x_j - y_j| - g'(u(\eta_j))u_{\nu_j}(\eta_j)|x_j - y_j| \geq 4\varepsilon,$$

where ξ_j lies between x_j and z_j, η_j lies between z_j and y_j, and ν_j is the unit vector $\nu_j = (y_j - x_j)/|y_j - x_j|$ (of course $x_j \neq y_j$ by (3.7)). By using once more the mean value theorem we obtain

$$-\Big(g''\big(u(\zeta_j)\big)u^2_{\nu_j}(\zeta_j) + g'\big(u(\zeta_j)\big)u_{\nu_j\nu_j}(\zeta_j)\Big)|x_j - y_j||\eta_j - \xi_j| \geq 4\varepsilon, \tag{3.8}$$

where ζ_j lies between ξ_j and η_j. Obviously ζ_j approaches x_0 as j approaches infinity. We may take subsequences $\{x_{j_k}\}$, $\{y_{j_k}\}$ so that the corresponding sequence of unit vectors $\{\nu_{j_k}\}$ converges to a unit vector ν. For short we suppose the original sequence to have this property. Let ν be tangential to $\partial\Omega$ at x_0. Since u vanishes and $u_n < 0$ on $\partial\Omega$ (by assumption), the Hessian matrix D^2u is strictly negative in all tangential directions. Consequently, since $g''(u) > 0$ and $g'(u) < 0$ as $j \longrightarrow \infty$ we get a contradiction in (3.8). Finally, let ν be nontangential. Then we have $u^2_\nu(x_0) > 0$. Assumptions (3.5) lead again to a contradiction (as $j \to \infty$) in (3.8). The lemma is proved.

Lemma 3.2 is stated in [5] without assumptions (3.5). The proof is similar to ours, but only the case $x_0 \neq y_0$ is taken into account. Lemma 3.1 and Lemma 3.2 are also proved in [9] by using assumptions (3.4), (3.5), and the additional restriction $\lim_{u\to 0} g(u)/g'(u) = 0$.

Acknowledgment. We are grateful to the referee for some suggestions that allowed us to improve our manuscript.

ONE-PHASE RIEMANN PROBLEM AND WAVE INTERACTIONS IN SYSTEMS OF CONSERVATION LAWS OF MIXED TYPE*

HAITAO FAN[†]

Abstract. The Riemann problem for any Riemann data lying outside of the elliptic region of a system of conservation laws of mixed type is established. The approach is a vanishing viscosity one. The solutions constructed are also admissible by the traveling wave criterion. The structure of the solutions is analyzed. Interactions among phase boundaries and shocks are studied.

Key words. conservation laws, phase transitions, traveling wave criterion, vanishing viscosity method, Riemann problem, shocks

AMS subject classifications. primary 35L65; secondary 35L67, 76L05

1. Introduction.

The field equations which express the principles of balance for one-dimensional continuous media are typically the nonlinear systems of conservation laws

$$U_t + F(U)_x = 0. \tag{1.1}$$

If the Jacobian matrix

$$\frac{\partial F}{\partial U} \tag{1.2}$$

has n distinct real eigenvalues, the system (1.1) is called strictly hyperbolic. If (1.2) has real eigenvalues and some of them are equal to each other at some point $U_0 \in \mathbb{R}^n$, the system (1.1) is said to be nonstrictly hyperbolic type and the point U_0 is called an umbilic point of (1.1). Real problems are often not strictly hyperbolic. For these kinds of systems, transitional shocks must be introduced into the system and the geometry of the state space is singular (cf. [11]–[15], [24], [25], [29]). Antman [1] discussed some interesting phenomena in the governing system of equations of a special class of motion, part of a very general family of nonlinear viscoelastic materials of hyperbolic-parabolic type.

Some models, for example, Stone's model (cf. [11]), the model for an elastic bar or van der Waals fluids undergoing phase transitions etc., have elliptic regions in which the eigenvalues of (1.2) are complex. The presence of elliptic regions adds more complexity to the systems, for instance, the local analysis may not apply in these kinds of systems and the problems must be considered in the large.

To study the mathematical phenomena involved in nonstrictly and hyperbolic-elliptic mixed type systems of conservation laws, we consider the p-system

$$u_t + p(w)_x = 0, \tag{1.3a}$$

$$w_t - u_x = 0, \qquad x \in \mathbb{R}, t > 0, \tag{1.3b}$$

[†] Center for Dynamical Systems and Nonlinear Studies, School of Mathematics, Georgia Institute of Technology, Atlanta, Georgia 30332.

which describes the one-dimensional longitudinal isothermal motion in elastic bars or fluids, where u is the velocity, w the specific volume, and p the pressure. For our purposes we set the function p to satisfy $p \in C^1(\mathbb{R})$ and

$$\begin{aligned} p'(w) &< 0 \quad \text{for } w \notin [\alpha, \beta], \\ p'(w) &> 0 \quad \text{for } w \in (\alpha, \beta) \end{aligned} \tag{1.3c}$$

so as to make the system (1.3a), (1.3b) a hyperbolic-elliptic mixed type system. We call the region $w < \alpha$ the α-phase region and $w > \beta$ the β-phase region. A shock with two ends in different phase regions is called a phase boundary. See Fig. 1.

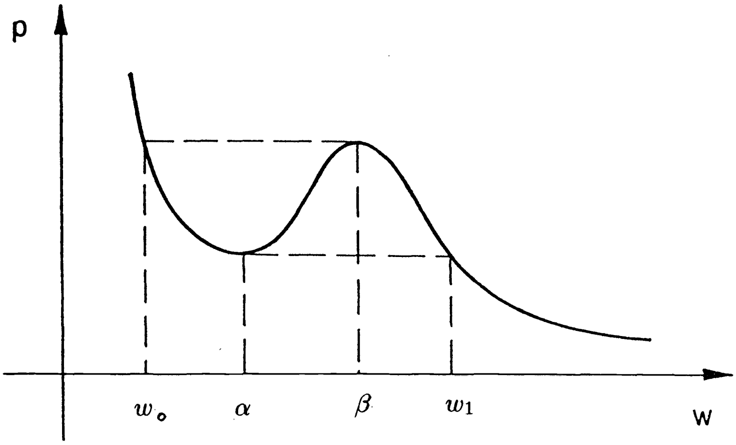

FIG. 1

In this paper, we establish the existence of the Riemann problem of (1.3) with arbitrary initial data

$$(u(x,0), w(x,0)) = \begin{cases} (u_-, w_-) & \text{for } x < 0, \\ (u_+, w_+) & \text{for } x > 0, \end{cases} \tag{1.4a}$$

$$w_\pm \notin (\alpha, \beta). \tag{1.4b}$$

We investigate the structure of the solutions we constructed. We also study the interactions among phase boundaries and "ordinary" shocks. We note that our technique can be generalized to the case where the system (1.1a), (1.1b) has finitely many elliptic regions as well as umbilic points.

Just as for hyperbolic systems of conservation laws, there is the issue of admissibility of solutions for the systems of hyperbolic-elliptic type like (1.3). Slemrod [24] proposed that an admissible solution of the Cauchy problem of (1.3) should be a $\epsilon \longrightarrow 0+$ limit of the solution (u_ϵ, w_ϵ) of the Cauchy problem

$$u_t + p(w)_x = \epsilon u_{xx} - \epsilon^2 A w_{xxx} - 2\epsilon^2 D w_x w_{xx}, \tag{1.5a}$$

$$w_t - u_x = 0, \tag{1.5b}$$

with the same initial value. We notice that Truskinovskii [30] independently proposed this criterion. A localized version of this criterion is the viscosity-capillarity traveling wave criterion, or the traveling wave criterion for short, which says that a shock of speed s connecting (u_1, w_1) and (u_2, w_2), satisfying Rankine–Hugoniot conditions, is admissible if (1.5) has a traveling wave solution of speed s connecting w_1 and w_2. When $A = \frac{1}{4}$ and $D = 0$, (1.5) reduces to the common form of viscosity

$$u_t + p(w)_x = \epsilon u_{xx}, \tag{1.6a}$$

$$w_t - u_x = \epsilon w_{xx}, \tag{1.6b}$$

with the same initial value. The corresponding traveling wave equation states that a shock solution to (1.3) is admissible if the problem

$$\frac{d^2\hat{w}}{d\zeta^2} = -2s\frac{d\hat{w}(\zeta)}{d\zeta} - s^2(\hat{w}(\zeta) - w_1) - (p(\hat{w}(\zeta)) - p(w_1)) \tag{1.7a}$$

$$\hat{w}(-\infty) = w_1, \quad \hat{w}(+\infty) = w_2, \quad \hat{w}'(\pm\infty) = 0 \tag{1.7b}$$

has a solution. Some works related to the traveling wave problem (1.7) can be found in [7], [8], [10], [13], [20]–[26], [30], [31] and references cited therein.

Our approach of establishing the existence of solutions of the Riemann problem (1.3) with the initial value (1.4) is to construct the solutions as a $\epsilon \to 0+$ limit of solutions of

$$u_t + p(w)_x = \epsilon t u_{xx}, \tag{1.8a}$$

$$w_t - u_x = \epsilon t w_{xx}, \qquad x \in \mathbb{R}, t > 0, \tag{1.8b}$$

and (1.4). We shall call solutions of (1.3), (1.4) constructed in this way the solutions satisfying similarity viscosity criterion. This approach was pursued by many authors [2]–[6], [8]–[10], [16], [27], [28], [32]. We can see that $(u(x/t), w(x/t))$ is a solution of (1.8) and (1.4) if and only if it is a solution of

$$\epsilon u'' = -\xi u' + p(w)', \tag{1.9a}$$

$$\epsilon w'' = -\xi w' - u', \tag{1.9b}$$

$$(u(-\infty), w(-\infty)) = (u_-, w_-), \qquad (u(+\infty), w(+\infty)) = (u_+, w_+), \tag{1.9c}$$

where $\xi = x/t$ and " $'$ " is $d/d\xi$.

For this case, where w_- and w_+ are separated by the interval (α, β), Slemrod [27] proved the existence of (1.9). Fan [6] showed that there is a sequence $\{\epsilon_n\}$, $\epsilon_n \to 0+$ as $n \to \infty$, such that $(u_{\epsilon_n}(\xi), w_{\epsilon_n}(\xi))$, provided by Slemrod in [27], converges to a weak solution of the Riemann problem (1.3) as $n \to \infty$. The condition needed in [6] is, besides (1.3c),

$$|p(w)| \to \infty \quad \text{as } |w| \to \infty. \tag{1.10}$$

The solution constructed in [27] and [6] is also admissible by the traveling wave criterion (1.7) (cf. [8]).

The existence of the Riemann problem (1.3) in the case $w_\pm < \alpha$, $u_- < u_+$ (or $w_\pm > \beta$, $u_- > u_+$) remains, in general, unproved. For convenience, we shall call the Riemann problems with initial data lying in the same phase region the one-phase Riemann problem. An understanding of the Riemann problem in this case is necessary for the study of the interactions between phase boundaries.

In this paper, we shall prove, as one of our results, the existence of the Riemann for any initial data outside of the elliptic region. We state this result more precisely in the following theorem.

THEOREM 1.1. *Suppose $|p(w)| \to \infty$ as $|w| \to \infty$. Then for any Riemann initial data lying outside of the elliptic region, there is a solution of the Riemann problem* (1.3), (1.4) *satisfying the similarity viscosity criterion and possessing at most two phase boundaries. Furthermore, this solution is also admissible according to the traveling wave criterion* (1.7). *As a consequence, solutions of* (1.3), (1.4), *which are admissible by the traveling wave criterion, always exist.*

After we establish the existence of the Riemann problem, we proceed to study the structure of these solutions. Then we apply our results to study the outcome of the interactions between phase boundaries and between a phase boundary and an "ordinary" shock.

This paper is divided into six sections. In §2 we utilize the Leray–Shauder type fixed point theory to prove that (1.9) has a solution if some a priori estimates are given. In §3 we prove the estimates needed in §2. We also prove that the total variations of the solutions, $(u_\epsilon(\xi), w_\epsilon(\xi))$, of (1.9) constructed in §2 are independent of $\epsilon > 0$. Then, by the well-known Helly theorem, we can extract a sequence $\{\epsilon_n\}$ such that $\epsilon_n \to 0+$ as $n \to \infty$ and $(u_{\epsilon_n}(\xi), w_{\epsilon_n}(\xi))$ converges almost everywhere to a weak solution of (1.3), and hence the first part of Theorem 1.1 is proved. We state these results more precisely in §4. In §5 we prove the second part of Theorem 1.1. We also study the structure of solutions of the Riemann problem. In §6 we continue to study the structure of the solutions under the assumption that $p(w)$ is convex for $w \leq \alpha$ and concave for $w \geq \beta$, which makes the description of the structure of the solutions easier. After collecting information about the structures of solutions, we investigate the interactions among phase boundaries and "ordinary" shocks.

2. Existence of the connecting orbit $(u_\epsilon(\xi), w_\epsilon(\xi))$. In this section, we shall prove that the boundary value problem (1.9) has a solution, provided some a priori estimates which we shall establish in the next section are given.

We consider, instead of (1.9), the following altered system:

$$\varepsilon u'' = -\xi u' + \mu p(w)', \tag{2.1a}$$

$$\varepsilon w'' = -\xi w' - \mu u', \tag{2.1b}$$

$$(u(\pm L),\ w(\pm L)) = (u_\pm,\ w_\pm), \tag{2.1c}$$

where $L > 1$, $0 \leq \mu \leq 1$.

First of all, we recall some preliminary results from [2] and [27]. The following lemma is from [2, Thm. 4.1] or [27, Lemma 2.1].

LEMMA 2.1. *Let $(u_\epsilon(\xi), w_\epsilon(\xi))$ be the solution of* (1.3). *Then one of the following holds on any subinterval (a, b) for which $p'(w_\epsilon(\xi)) < 0$:*

(1) *Both $u_\epsilon(\xi)$ and $w_\epsilon(\xi)$ are monotone on (a, b);*

(2) *One of the $u_\epsilon(\xi)$ and $w_\epsilon(\xi)$ is a strictly increasing (decreasing) function with no critical point on (a, b) while the other has at most one critical point that is necessarily a local maximum (minimum) point.*

Now, we rewrite Lemma 2.2 of [27], which describes the shape of a solution of (1.9) in the elliptic region $\{(u.w) \in \mathbb{R}^2 \ : \ w \in (\alpha, \beta)\}$.

LEMMA 2.2. *Let $(u(\xi), w(\xi))$ be a solution of* (2.1) *with $\mu > 0$. Then on any interval $(l_1, l_2) \subset (-L, L)$ for which $p'(w(\xi)) > 0$ the graph of $u(\xi)$ versus $w(\xi)$ is convex at points where $w'(\xi) > 0$ and concave at points where $w'(\xi) < 0$.*

By considering (2.1), the existence of the connecting orbit problem (1.9) can be proved, as shown in the following theorem.

THEOREM 2.3. *Suppose* $u_- < u_+$ *and* $w_\pm < \alpha$. *Then there is a solution of* (1.9) *satisfying*

$$(u(\xi_1), w(\xi_1)) \neq (u(\xi_2), w(\xi_2)) \quad \text{for any } \xi_1, \xi_2 \in (-\infty, +\infty), \xi_1 \neq \xi_2, \\ w(\xi_1) \geq \bar{w} := \min(w_-, w_+), \tag{2.2}$$

and that

(2.3) *there are at most two disjoint open intervals*(a, b) *such that*

$$w(\xi) \in (\bar{w}, \alpha) \quad \text{for } \xi \in (a, b), \quad \text{and} \tag{2.3a}$$

$$\text{either } w(a) = \bar{w}, \quad w(b) = \alpha \quad \text{or} \quad w(a) = \alpha, \quad w(b) = \bar{w}, \tag{2.3b}$$

provided that the possible solution of (2.1) *satisfying* (2.2) *and* (2.3) *is bounded in* $C^1([-L, +L])$,

$$\|(u, w)\|_{C^1([-L.L];\mathbb{R}^2)} < M,$$

for some $M > 0$ *independent of* $\mu \in [0, 1]$ *and* $L > 1$.

Proof. We rewrite (2.1) as

$$\varepsilon y''(\xi) = \mu f(y)' - \xi y'(\xi), \tag{2.4}$$

where

$$y(\xi) = \begin{pmatrix} u(\xi) \\ w(\xi) \end{pmatrix}, \qquad f(y(\xi)) = \begin{pmatrix} p(w) \\ -u(\xi) \end{pmatrix}.$$

A straightforward calculation shows

$$\begin{aligned} y(\xi) = & y(-L) + z(y) \int_{-L}^{\xi} \exp\left(\frac{-\zeta^2}{2\varepsilon}\right) d\tau + \frac{\mu}{\varepsilon} \int_{-L}^{\xi} f(y(\tau)) d\tau \\ & - \frac{\mu^2}{\varepsilon} \int_{-L}^{\xi} \int_{-L}^{\zeta} \tau f(y(\tau)) \exp\left(\frac{\tau^2 - \zeta^2}{2\varepsilon}\right) d\tau d\zeta, \end{aligned} \tag{2.5}$$

where

$$\begin{aligned} z(x) = & \frac{1}{\int_{-L}^{L} \exp(-\xi^2/2\varepsilon) d\xi} \left[y(+L) - y(-L) - \frac{\mu}{\varepsilon} \int_{-L}^{L} f(x(\tau)) d\tau \right. \\ & \left. + \frac{\mu}{\varepsilon^2} \int_{-L}^{L} \int_{-L}^{\zeta} \tau f(x(\tau)) \exp\left(\frac{\tau^2 - \zeta^2}{2\varepsilon}\right) d\tau d\zeta \right] \\ = & z_1(x) + \mu z_2(x). \end{aligned} \tag{2.6}$$

Choose $\eta \in (\bar{w}, \alpha)$. We are interested in those functions $(u(\xi), w(\xi)) \in C^1([-L, +L]; \mathbb{R}^2)$ satisfying

$$(u(\xi_1), w(\xi_1)) \neq (u(\xi_2), w(\xi_2)) \quad \text{for any } \xi_1, \xi_2 \in [-L, +L], \xi_1 \neq \xi_2, \\ \text{and } w(\xi_1) \geq \eta \tag{2.7}$$

and

$$\text{(2.8)}\qquad \begin{aligned}&\text{there are at most two disjoint open intervals } (a,b) \text{ such that}\\ &w(\xi)\in(\eta,\alpha)\quad\text{for } \xi\in(a,b),\quad\text{and}\\ &\text{either } w(a)=\eta,\quad w(b)=\alpha\quad\text{or}\quad w(a)=\alpha,\quad w(b)=\eta.\end{aligned}$$

Now, we consider the open subset in $C^1([-L,+L];\mathbb{R}^2)$:

$$\text{(2.9)}\qquad \begin{aligned}\Omega :=\bigl\{(u,w)\in C^1([-L,L];\mathbb{R}^2)\ :\ &\|(u,w)\|_{C^1([-L.L];\mathbb{R}^2)}<M+1,\\ &\text{and (2.7) and (2.8) are satisfied}\bigr\}.\end{aligned}$$

We define an integral operator

$$T:\overline{\Omega}\times[0,1]\to C^1([-L,L];\mathbb{R}^2)$$

by

$$\text{(2.10)}\qquad \begin{aligned}T(x,\mu)(\xi)=&y(-L)+z(x)\int_{-L}^{\xi}\exp\left(\frac{-\zeta^2}{2\varepsilon}\right)d\zeta+\frac{\mu}{\varepsilon}\int_{-L}^{\xi}f(x(\zeta))d\zeta\\ &-\frac{\mu}{\varepsilon^2}\int_{-L}^{\xi}\int_{-L}^{\zeta}\tau f(x(\tau))\exp\left(\frac{\tau^2-\zeta^2}{2\varepsilon}\right)d\tau d\zeta,\end{aligned}$$

where $z(x)$ is given by (2.8). It is clear that a fixed point of $T(x,\mu)$ is a solution of (2.1).

It is a matter of routine analysis to show that T maps $\overline{\Omega}\times[0,1]$ continuously into $C^1([-L,L];\mathbb{R}^2)$. Furthermore, we can verify, by taking $d/d\xi$ twice on (2.10), that

$$\varepsilon(T(x.\mu)(\xi))''=\mu f(x(\xi))'-\xi(T(x.\mu)(\xi))'.$$

This implies that T maps $\overline{\Omega}\times[0,1]$ into a bounded, with bound independent of μ, subset of $C^2([-L,L];\mathbb{R}^2)$. Thus T is a compact operator from $C^1([-L.L];\mathbb{R}^2)\times[0,1]$ into $C^1([-L,L];\mathbb{R}^2)$.

We recall the following fixed point theorem (see Mawhin [19, Thm. IV.1]).

PROPOSITION 2.4. *Let X be a real normed vector space and Ω a bounded open subset of X. Let $T:\overline{\Omega}\times[0,1]\to X$ be a compact operator. If*

(i) *$T(x,\mu)\neq x$ for $x\in\partial\Omega$, $\mu\in[0,1]$, and*

(ii) *the Leray-Shauder degree $D_I(T(x,0)-x,\Omega,)\neq 0$,*

then $T(x,1)=x$ has at least one solution in Ω.

To solve our problem, we take $X=C^1([-L,+L];\mathbb{R}^2)$. We can see that (ii) is satisfied. Indeed,

$$\text{(2.11)}\quad T(x,0)-x=\frac{y(L)-y(-L)}{\int_{-L}^{L}\exp(-\zeta^2/2\varepsilon)\,d\zeta}\int_{-L}^{\xi}\exp\left(-\frac{\zeta^2}{2\varepsilon}\right)d\zeta+y(-L)-x=:x_0-x,$$

where $x_0\in\Omega$, and hence the degree $D_I(T(x,0)-x,\Omega,)=1$.

Now, we preceed to verify (ii) of Proposition 2.4. We assume, for contradiction, that there is a fixed point of $T(x, \mu)$,

$$x = (u, w)(\xi) \in \partial\Omega. \tag{2.12}$$

Then one of the following cases must hold.

Case A. $\|(u(\xi), w(\xi))\|_{C^1([-L,L];\mathbb{R}^2)} = M + 1$.

This case is excluded by the inequality (2.4).

Case B. The condition (2.7) is violated.

In this case, there are $\xi_1, \xi_2 \in [-L, +L]$, $\xi_1 \neq \xi_2$, such that $(u(\xi_1), w(\xi_1)) = (u(\xi_2), w(\xi_2))$ and $w(\xi_1) \geq \eta$.

The curve $(u(\xi), w(\xi))$ in (u, w)-plane near $\xi = \xi_1$ and $\xi = \xi_2$ cannot go across each other[1], as shown in Fig. 2. Otherwise, the curve of $(u(\xi), w(\xi))$ plus a $C^1([-L, +L]; \mathbb{R}^2)$ perturbation still intersects itself and hence is not in Ω. Hence $x = (u(\xi), w(\xi))$ is not in $\partial\Omega$, which yields a contradiction.

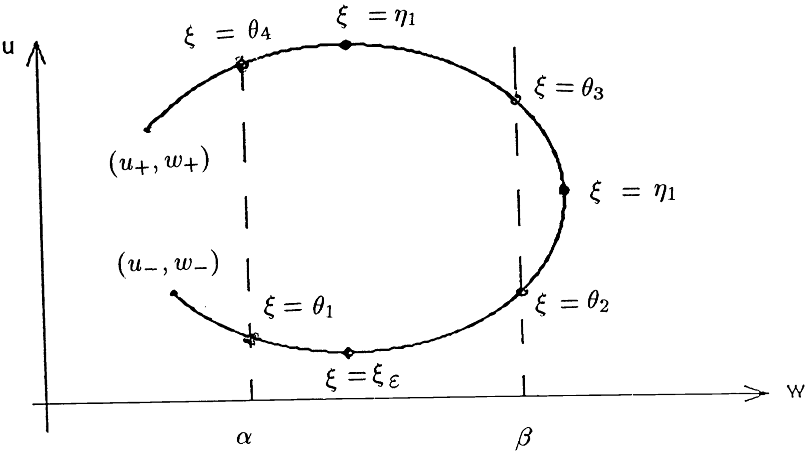

FIG. 2

From Lemma 2.1, we know that if $(u(\xi), w(\xi))$ stays inside the region $w \leq \alpha$, the curve $(u(\xi), w(\xi))$ cannot intersect itself. Thus, $w(\xi_3) > \alpha$ for some $\xi_3 \in [-L, +L]$.

We can further describe the curve $(u(\xi), w(\xi))$ in the (u, w)-plane as follows. There is an interval $[-L, \theta_1]$ such that $w(\xi) \leq \alpha$ and $w(\theta_1) = \alpha$, and by Lemma 2.1, $w'(\theta_1) > 0$. As ξ increases from θ_1, $(u(\xi), w(\xi))$ moves into the region $\alpha < w < \beta$. As long as $w'(\xi) > 0$ and $w(\xi) \in (\alpha, \beta)$, the curve $(u(\xi), w(\xi))$ in the (u, w)-plane

[1] We can make the above description rigorous by specifying a normal vector field $\mathbf{n}(\xi)$ along the curve $(u(\xi), w(\xi))$. Let y be the point $(u(\xi), w(\xi) + \mathbf{n}(\xi))$. Suppose the line connecting y and $(u(\xi), w(\xi))$, for ξ near ξ_1, intersects the portion of the curve $(u(\xi), w(\xi))$ in (u, w)-plane near $\xi = \xi_2$ at $(\bar{u}, \bar{w})$. Then we say the two portions of the curve $(u(\xi), w(\xi))$, near $\xi = \xi_1$ and ξ_2, respectively, do not go across each other if there is an interval $(\xi_1 - \theta_1, \xi_1 + \theta_2)$ such that

$$g(\xi) := ((\bar{u}, \bar{w}) - (u(\xi), w(\xi)))\mathbf{n}(\xi) \geq 0 \quad (\leq 0)$$

for $\xi \in (\xi_1 - \theta_1, \xi_1 + \theta_2)$ and

$$g(\xi_1 - \theta_1)g(\xi_1 + \theta_2) > 0.$$

The rest of the description of the curve can also be made rigorous in the same way.

is convex with respect to w. Let (θ_1, θ_2) be the largest interval such that $w'(\xi) > 0$ and $w(\xi) \in (\alpha, \beta)$. Then either $w(\theta_2) = \alpha$ or $w(\theta_2) \in (\alpha, \beta)$ and $w'(\theta_2) = 0$ hold. We assume, without loss of generality, that $w(\theta_2) = \beta$ and $w'(\theta_2) > 0$, since other cases are simpler. In view of Lemma 2.1, this interval is followed by another interval $[\theta_2, \theta_3]$ in which $w(\xi) \geq \beta$ and $u'(\xi) > 0$, while $w(\xi)$ has one and only one critical point which is a local maxima, and $w(\theta_3) = \beta$. Then there is the maximum interval $[\theta_3, \theta_4)$ in which $w(\xi) \in [\alpha, \beta]$, $w'(\xi) < 0$, and the curve $(u(\xi), w(\xi))$ in the (u, w)-plane is concave with respect to w. We see that at the right end of the interval, either $w(\theta_4) = \alpha$ or $w'(\theta_4) = 0$ must be true. Let us assume $w(\theta_4) = \alpha$ and $w'(\theta_4) < 0$, since the argument for this case covers the other cases and leads to the same conclusion. Thus, as ξ increases from θ_4, $(u(\xi), w(\xi))$ moves into the region $w < \alpha$.

From the shape of the curve $(u(\xi), w(\xi))$ in the (u, w)-plane for $\xi \in [-L, \theta_4]$, it is clear that

$$\xi_2 > \theta_4, \tag{2.13}$$

since otherwise, the curve will cross itself in the region $w \geq \alpha$.

Following $[\theta_3, \theta_4]$ is the interval (θ_4, θ_5) in which $w(\xi) < \alpha$. We, of course, pick the largest such interval, or more precisely,

$$\theta_5 := \sup\{\zeta \in [\theta_4, +L] \ : \ w(\xi) < \alpha \text{ for } \xi \in (\theta_4, \zeta)\}. \tag{2.14}$$

One of the following cases must occur.

Subcase B1. $\theta_5 = L$.

In this case, the derivative $w'(\xi) < 0$ if $w(\xi) \in [\alpha, \eta]$ for $\xi \in [\theta_4, \theta_5) = [\theta_4, +L)$ because if otherwise, $w(\xi)$ would have at least two extreme points in $(\theta_4, +L)$ which is impossible by Lemma 2.1. Furthermore, the point ξ_2 must satisfy $\xi_2 \in (\theta_4, L)$ and

$$w(\xi_2) \in (\alpha, \eta] \quad \text{and} \quad w'(\xi_2) < 0. \tag{2.15}$$

Hence $\xi_1 \in [-L, \theta_1)$ and

$$w'(\xi_1) > 0 \quad \text{and} \quad w(\xi) > w(\xi_1) = w(\xi_2) \quad \text{for } \xi \in (\xi_1, \xi_2). \tag{2.16}$$

Integrating (2.1b) over $[\xi_1, \xi_2]$ and using $(u(\xi_1), w(\xi_1)) = (u(\xi_2), w(\xi_2))$, (2.15), and (2.16), we obtain

$$0 < \int_{\xi_1}^{\xi_2} [w(\xi) - w(\xi_2)] d\xi = \varepsilon[w'(\xi_2) - w'(\xi_1)] < 0,$$

which is a contradiction. Thus, this case cannot happen.

Subcase B2. $\theta_5 < +L$.

For this case, $w(\theta_5) = \alpha$, and $w'(\theta_5) \geq 0$, $u(\xi)$ is decreasing over $[\theta_4 . \theta_5]$. $w(\xi)$ has one and only one critical point ζ_1 which is necessarily a local minima, and

$$u'(\xi) < 0 \quad \text{for } \xi \in (\theta_4, \theta_5). \tag{2.17a}$$

We claim that

$$w(\xi) > \alpha = w(\theta_5) \quad \text{for } \xi \in (\theta_5, \theta_5 + \delta) \tag{2.17b}$$

for some $\delta > 0$. Otherwise, α is a local maxima of $w(\xi)$, and hence

$$w'(\theta_5) = 0 \quad \text{and} \quad w''(\theta_5) \leq 0.$$

Thus, (2.1b) yields

$$\mu u'(\theta_5) = -\epsilon w''(\theta_5) \geq 0.$$

This inequality and (2.17a) imply that $u'(\theta_5) = 0$ and $w'(\theta_5) = 0$. Then, by the uniqueness of the initial value problem for (2.1), $(u(\xi), w(\xi)) \equiv (u(\theta_5), w(\theta_5))$, which violates the condition (2.1c). This contradiction proves (2.17b).

If

$$w(\zeta_1) < \eta, \tag{2.18}$$

then there are at least three disjoint subintervals (a_i, b_i), $i = 1, 2, 3$ lying in $[-L, \theta_1]$, $[\theta_4, \zeta_1]$ and $(\zeta_1, \theta_5]$, respectively, such that

$$\begin{aligned} &w(a_i) = \eta, \quad w(b_i) = \alpha, \quad i = 1, 3 \\ &w(a_2) = \alpha, \qquad w(b_2) = \eta \end{aligned} \tag{2.19}$$

It is clear that because of (2.18), $(u(\xi), w(\xi))$ plus some C^1 perturbations still have three disjoint subintervals (a_i, b_i), $i = 1, 2, 3$ satisfying (2.19). This simply says that $(u(\xi), w(\xi)) \notin \partial\Omega$, which contradicts (2.12), and hence

$$w(\zeta_1) \geq \eta.$$

By Lemmas 2.1 and 2.2, the portion of the curve $(u(\xi), w(\xi))$ for $\xi \in [\theta_5, +L]$ is confined in the domain $w \geq \eta$, and hence $w(+L) \neq w_+$, which is again a contradiction. Thus, Case B dose not occur.

Case C. The condition (2.3) fails to hold.

In fact, the arguments we used to handle the Subcase B2 can be applied to this case and yield a contradiction. This shows that Case C cannot happen either.

Summarizing our analysis for the above three cases, we find that if $(u(\xi), w(\xi)) \in \partial\Omega$, then $x = (u(\xi), w(\xi))$ cannot be a fixed point of $T(x, \mu)$ for $\mu \in [0, 1]$. Applying Proposition 2.4, we see that $T(x, 1)$ has a fixed point.

To prove the existence of solutions of (1.9), we need to pass to the limit $L \to \infty$. We follow Dafermos [2] and extend $(u(\xi), w(\xi))$ as follows:

$$(u(\xi; L), w(\xi; L)) = \begin{matrix} (u_+, w_+), & \xi > L, \\ (u_-, w_-), & \xi < -L. \end{matrix}$$

By the hypothesis (2.4), we see that $\{(u(\cdot; L), w(\cdot; L))\}$ is precompact in $C((-\infty, \infty); \mathbb{R}^2)$. So, there is a sequence $L_n \to \infty$ as $n \to \infty$ such that

$$(u(\xi; L_n), w(\rho; L_n)) \to (u(\xi, \infty), w(\xi, \infty))$$

uniformly as $n \to \infty$. By integrating (2.1a), (2.1b) with $\mu = 1$ twice from ξ_0, we can prove that the limit $(u(\xi, \infty),\ w(\xi, \infty))$ satisfies (1.9a), (1.9b). It remains to prove that $(u(\pm\infty, \infty),\ w(\pm\infty, \infty)) = (u_\pm,\ w_\pm)$. To this end, we manipulate (1.9a), (1.9b) to obtain

$$\frac{d}{d\xi}\left(\exp\left(\frac{\xi^2}{2\varepsilon}\right) y'(\xi)\right) = \frac{1}{\varepsilon}\left[f(y(\xi))' \exp\left(\frac{\xi^2}{2\varepsilon}\right)\right]$$

or

$$\exp\left(\frac{\xi^2}{2\varepsilon}\right) y'(\xi) = y'(0) + \frac{1}{\varepsilon}\int_0^\xi \nabla f(y) y'(\zeta) \exp\left(\frac{\zeta^2}{2\varepsilon}\right) d\zeta. \tag{2.20}$$

Applying (2.4) and Gronwell's inequality on (2.15), we obtain

$$\begin{aligned} |y'(\xi)| &\le |y'(0)| \exp\left(\frac{2R|\xi| - \xi^2}{2\varepsilon}\right) \\ &\le M \exp\left(\frac{2R|\xi| - \xi^2}{2\varepsilon}\right), \end{aligned} \tag{2.21}$$

where $R > 0$ depends at most on M, ν, and $\varepsilon > 0$. Inequality (2.21) holds for $y(\xi; L)$ also. Then

$$(u(\pm\infty, \infty), w(\pm\infty, \infty)) = (u_\pm, w_\pm)$$

follows from (2.21) easily. It remains to prove that the solution $(u(\xi, \infty), w(\xi, \infty))$ constructed above satisfies (2.2) and (2.3). Indeed, the same reasoning for Cases B and C implies that $(u(\xi, \infty), w(\xi, \infty))$ satisfies (2.8) and (2.9) also. Since $\eta \in (\bar{w}, \alpha)$ is chosen arbitrarily, (2.2) and (2.3) hold for $(u(\xi, \infty), w(\xi, \infty))$. □

COROLLARY 2.5. *Let* $(u(\xi), w(\xi))$ *be a solution of* (2.1) *or* (1.9) *satisfying* (2.2), (2.3).

(i) *The subset of* $[-L, +L]$

$$\{\ \xi \in [-L, +L] \ \ : \ \ w(\xi) \le \alpha\}$$

has at most two connected components. Furthermore, each component must have $-L$ *or* $+L$ *as one of its endpoints.*

(ii) *The set*

$$\{\ \xi \in [-L, +L] \ \ : \ \ w(\xi) \in (\alpha, \beta)\}$$

consists of at most two connected components.

(iii) *The set*

$$\{\ \xi \in [-L, +L] \ \ : \ \ w(\xi) \ge \beta\},$$

if nonempty, is an interval.

Proof. This is proved in our discussion in the proof of Theorem 2.3, Case B. □

The assumption (2.4) in above theorem can be replaced by a weaker one, as stated in the following theorem.

THEOREM 2.6. *The conclusion of Theorem* 2.3 *remains valid if* (2.4a) *is replaced by*

$$\sup_{-L \le \xi \le L} (|u(\xi)| + |w(\xi)|) \le M_1,$$

where M_1 *is independent of* $\mu \in [0, 1]$ *and* $L > 1$.

Proof. The proof is the same as that of Theorem 1.3 in [23]. □

Theorems 2.3 and 2.6 give the conditions under which (1.9) has a connecting orbit for $w_\pm < \alpha$ and $u_- < u_+$. Slemrod [27] proved the following theorem for the case $w_\pm < \alpha$ and $u_- < u_+$.

THEOREM 2.7. *Assume that $w_{\pm} < \alpha$ and $u_{-} < u_{+}$. Then, there is a solution of* (1.9) *satisfying*

$$w(\xi) \leq \alpha, \tag{2.22}$$

if every possible solution of (2.1) *satisfies*

$$||(u(\xi), w(\xi))||_{C([-L,+L];\mathbb{R}^2)} \leq C \tag{2.23}$$

for some constant C independent of $\mu \in [0,1]$ and $L > 1$.

3. A priori estimates. In this section, we shall prove the a priori estimates needed in Theorems 2.3 and 2.7 as well as some ϵ-independent estimates.

THEOREM 3.1. *Suppose $w_{\pm} < \alpha$ and $u_{-} < u_{+}$. Let $(u_\epsilon(\xi), w_\epsilon(\xi))$ be a solution of* (2.1) *with the properties* (2.2) *and* (2.3). *Then,*

$$||u_\epsilon(\xi)||_{C([-L,+L];\mathbb{R}^2)} \leq C, \tag{3.1}$$

where C is, throughout this section, a constant independent of $\epsilon > 0, \mu \in [0,1]$, and $1 < L \leq +\infty$.

Proof. When $\mu = 0$, our assertion can be easily verified. Thus, we assume $\mu > 0$ in the rest of the proof. We first prove $u_\epsilon(\xi) \geq C$. Let ξ_ϵ be a local minimum point of $u_\epsilon(\xi)$. Then either

$$w_\epsilon(\xi_\epsilon) \notin (\alpha, \beta), \qquad w'_\epsilon(\xi_\epsilon) < 0 \tag{3.2}$$

or

$$w_\epsilon(\xi_\epsilon) \in (\alpha, \beta), \qquad w'_\epsilon(\xi_\epsilon) > 0 \tag{3.3}$$

hold.

Case A. (3.2) holds.

In this case, by Lemma 2.1, $w(\xi_\epsilon) < \beta$. Otherwise, both $u_\epsilon(\xi)$ and $w_\epsilon(\xi)$ would have critical points in the set $\{\xi \in [-L,+L] : w_\epsilon(\xi) \geq \beta\}$, which is an interval by Corollary 2.5. Thus, $w(\xi_\epsilon) \leq \alpha$. Hence

$$\xi_\epsilon \in \{\xi \in [-L,+L] \ : \ w_\epsilon(\xi) \leq \alpha\} = [-L, \theta_1] \cup [\theta_4, +L], \tag{3.4}$$

where $\theta_1 \leq \theta_4$. If $\theta_1 < \theta_4$ and $\xi_\epsilon \in [-L, \theta_1]$, then $w'(\xi_\epsilon) < 0$ implies that $w_\epsilon(\xi)$ also has a critical point in $[-L, \theta_1]$, which is prohibited by Lemma 2.1. Thus, $\xi_\epsilon \in [\theta_4, L]$. Performing a calculation on (2.1), we obtain

$$\epsilon \frac{d}{d\xi}\left(\frac{du_\epsilon(\xi)}{dw_\epsilon(\xi)}\right) = \left(\frac{du_\epsilon(\xi)}{dw_\epsilon(\xi)} - \sqrt{-p'(w_\epsilon(\xi))}\right)\left(\frac{du_\epsilon(\xi)}{dw_\epsilon(\xi)} + \sqrt{-p'(w_\epsilon(\xi))}\right). \tag{3.5a}$$

This implies that, as ξ increases, $du_\epsilon(\xi)/dw_\epsilon(\xi)$ is decreasing if $|du_\epsilon(\xi)/dw_\epsilon(\xi)| \leq \sqrt{-p'(w_\epsilon(\xi))}$ and is increasing if $|du_\epsilon(\xi)/dw_\epsilon(\xi)| \geq \sqrt{-p'(w_\epsilon(\xi))}$. Thus the "initial" condition

$$\frac{du_\epsilon(\xi)}{dw_\epsilon(\xi)}\Big|_{\xi=\xi_\epsilon} = 0 \tag{3.5b}$$

leads to that for $\xi \in [\theta_4, +L]$,

$$\left|\frac{du_\epsilon(\xi)}{dw_\epsilon(\xi)}\right| \leq \max_{w_+ \geq w \geq \beta}\left(\sqrt{-p'(w)}\right), \tag{3.6}$$

and hence

$$u_\epsilon(\xi) \geq u_+ + (\alpha - w_-) \max_{w \in [w_+, \alpha]}\left(\sqrt{-p'(w)}\right). \tag{3.7}$$

Case B. (3.3) holds.

By Corollary 2.5, $[-L, L]$ can be divided as

$$[-L, L] = [-L, \theta_1] \cup (\theta_1, \theta_2) \cup [\theta_2, \theta_3] \cup (\theta_3, \theta_4) \cup [\theta_4, +L], \tag{3.8}$$

where, of course $\theta_1 \leq \theta_2 \leq \theta_3 \leq \theta_4$, and

$$\{\xi \in [-L, +L] \ : \ w_\epsilon(\xi) \leq \alpha\} = [-L, \theta_1] \cup [\theta_4, L], \tag{3.9a}$$

$$\{\xi \in [-L, +L] \ : \ w_\epsilon(\xi) \in (\alpha, \beta)\} = (\theta_1, \theta_2) \cup (\theta_3, \theta_4), \tag{3.9b}$$

$$\{\xi \in [-L, +L] \ : \ w_\epsilon(\xi) \geq \beta\} = [\theta_2, \theta_3]. \tag{3.9c}$$

It is clear that when (3.3) holds, $\xi_\epsilon \in (\theta_1, \theta_2) \neq \emptyset$ (cf. Fig. 2).

If $\xi_\epsilon \leq 0$, then the argument in the proof of Theorem 3.2 of [6] applies and yields $u_\epsilon(\xi) \geq C$. Thus, we assume

$$\xi_\epsilon > 0 \tag{3.10}$$

in the sequel of this proof.

Since ξ_ϵ is a local minimum point of $u(\xi)$, $u_\epsilon'(\xi) > 0$ for $\xi \in (\xi_\epsilon, \xi_\epsilon + \delta)$ for some $\delta > 0$. Then we can define

$$\eta_1 := \sup\{\zeta > \xi_\epsilon \ : \ u_\epsilon'(\xi) > 0 \text{ for } \xi \in (\xi_\epsilon, \zeta)\}. \tag{3.11}$$

Since $w_\epsilon(\xi_\epsilon) \leq \alpha$ and $w_\epsilon'(\xi_\epsilon) > 0$, there is a local maximum point η_2 of $w_\epsilon(\xi)$ with $\eta_2 > \xi_\epsilon$. We can further require that η_2 is the least of such points, i.e.,

$$\eta_2 := \sup\{\zeta > \xi_\epsilon \ : \ w_\epsilon'(\zeta) > 0\}. \tag{3.12}$$

Then, by Lemmas 2.1 and 2.2, $\eta_1 \notin (\xi_\epsilon, \eta_2)$, and hence (cf. Fig. 2)

$$\eta_1 > \eta_2 > \xi_\epsilon. \tag{3.13}$$

By integrating (2.1a) on (ξ_ϵ, ξ), where $\xi \in (\xi_\epsilon, \eta_2)$, we obtain

$$0 < \epsilon u_\epsilon'(\xi) = \int_{\xi_\epsilon}^{\xi} -\zeta u_\epsilon'(\zeta) d\zeta + \mu[\, p(w_\epsilon(\xi)) - p(w_\epsilon(\xi_\epsilon))\,].$$

It follows from (3.10) and (3.11) that $-\xi u'_{\epsilon_n}(\xi) < 0$ for $\xi \in (\xi_\epsilon, \eta_1)$. Thus, in view of (3.3), we have

$$\begin{aligned} 0 < \epsilon u'_\epsilon(\xi) &\leq \mu[p(w_\epsilon(\xi)) - p(w_\epsilon(\xi_\epsilon))] \\ &\leq \mu[p(w_\epsilon(\xi)) - p(\alpha)]. \end{aligned} \tag{3.14}$$

Therefore,

$$\alpha < w_\epsilon(\eta_2) \leq w_1. \tag{3.15}$$

Equation (3.13) also yields a useful inequality:

$$0 < \epsilon u'_\epsilon(\xi) \leq \mu(p(\beta) - p(\alpha)) \tag{3.16}$$

for $\xi \in [\xi_\epsilon, \eta_1]$.

Using (2.1), we can obtain

$$\frac{d^2 w_\epsilon}{du_\epsilon^2}(\xi) = \frac{-1}{\epsilon u'_\epsilon(\xi)}\left[1 + p'(w_\epsilon(\xi))\left(\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)}\right)^2\right]. \tag{3.17}$$

Hence, if

$$\left|\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)}\right| \leq \frac{1}{2\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})}$$

and $\xi \in [\xi_\epsilon, \eta_1]$, then

$$\frac{d^2 w_{\epsilon_n}}{du_{\epsilon_n}^2}(\xi) \leq \frac{-\mu}{2\epsilon u'_\epsilon(\xi)} \leq -\frac{1}{2(p(\beta) - p(\alpha))}. \tag{3.18}$$

Thus, as ξ decreases from η_2 to ξ_ϵ, $dw_\epsilon(\xi)/du_\epsilon(\xi)$ will increase from zero, and eventually

$$\left.\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)}\right|_{\xi=\eta_3} = \frac{1}{2\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})} \tag{3.19}$$

for some $\eta_3 \in (\eta_2, \xi_\epsilon)$ Let

$$\eta_4 := \sup\{\eta_3 \in (\xi_\epsilon, \eta_2) \ : \ \text{(3.19) is satisfied}\}. \tag{3.20}$$

Then,

$$\begin{aligned} \frac{1}{2\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})} &= \left.\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)}\right|_{\xi=\eta_4} - \left.\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)}\right|_{\xi=\eta_2} \\ &= \int_{u_\epsilon(\eta_2}^{ue(\eta_4)} \frac{d^2 w_{\epsilon_n}}{du_{\epsilon_n}^2}(\xi) d(u_\epsilon(\xi)) \geq \frac{u_\epsilon(\eta_2) - u_\epsilon(\eta_4)}{2(p(\beta) - p(\alpha))} \end{aligned}$$

or

$$0 \leq u_\epsilon(\eta_2) - u_\epsilon(\eta_4) \leq \frac{p(\beta) - p(\alpha)}{\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})}. \tag{3.21}$$

From (3.18), we also see that

$$\frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)} \geq \frac{1}{2\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})}$$

for $\xi \in (\xi_\epsilon, \eta_4)$. Thus,

$$\begin{aligned} 0 \leq & u_\epsilon(\eta_2) - u_\epsilon(\xi_\epsilon) = u_\epsilon(\eta_2) - u_\epsilon(\eta_4) + \int_{u_\epsilon(\xi_\epsilon)}^{u_\epsilon(\eta_4)} \frac{dw_\epsilon(\xi)}{du_\epsilon(\xi)} d(u_\epsilon) \\ \leq & \frac{p(\beta)-p(\alpha)}{\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})} + 2 \max_{w\in[w_0,w_1]} \left(\sqrt{|p'(w)|}\right)(w_1 - w_0). \end{aligned} \tag{3.22}$$

Similarly, we can prove that

$$\begin{aligned} 0 \leq & u_\epsilon(\eta_1) - u_\epsilon(\eta_2) \\ \leq & \frac{p(\beta)-p(\alpha)}{\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})} + 2 \max_{w\in[w_0,w_1]} \left(\sqrt{|p'(w)|}\right)(w_1 - w_0). \end{aligned} \tag{3.23}$$

Then we obtain

$$u_\epsilon(\xi_\epsilon) \geq u_\epsilon(\eta_1) - \frac{2(p(\beta)-p(\alpha))}{\max_{w\in[w_0,w_1]}(\sqrt{|p'(w)|})} - 4 \max_{w\in[w_0,w_1]} \left(\sqrt{|p'(w)|}\right)(w_1 - w_0). \tag{3.24}$$

If $u_\epsilon(\eta_1) \geq u_+$, then (3.24) shows that $u_\epsilon(\xi)$ is bounded from below uniformly in $\epsilon > 0$, $\mu \in [0,1]$, and $L > 1$. Now, we devote our attention to the case when

$$u_\epsilon(\eta_1) < u_+.$$

Then, $\eta_1 < L$ because $u_\epsilon(L) = u_+$. By the definition (3.11), of η_1, $u'_\epsilon(\eta_1) = 0$. Then, by Lemmas 2.1 and 2.2, η_1 has to be an extreme point for $u_\epsilon(\xi)$. Since $u'_\epsilon(\xi) > 0$ for $\xi \in (\xi_\epsilon, \eta_1)$, η_1 is a local maximum point. Lemmas 2.1 and 2.2 imply that either

$$w'_\epsilon(\eta_1) > 0 \quad \text{and} \quad w_\epsilon(\eta_1) \notin (\alpha, \beta) \tag{3.25}$$

or

$$w'_\epsilon(\eta_1) < 0 \quad \text{and} \quad w_\epsilon(\eta_1) \in (\alpha, \beta). \tag{3.26}$$

The case (3.25) cannot happen because it implies that $\eta_1 \in [-L, \theta_1]$, which violates the known fact that $\eta_1 > \xi_\epsilon \in [\theta_1, \theta_2)$. Then (3.26) and (3.25) imply that there is a local minimum point $\eta_5 > \eta_4$ of $u_\epsilon(\xi)$, which satisfies

$$u'_\epsilon(\eta_5) = 0 \quad \text{and} \quad w_\epsilon(\eta_5) \leq \alpha. \tag{3.27}$$

Then our argument for the Case A applies and gives us

$$|u_+ - u_\epsilon(\eta_5)| \leq (\alpha - w_+) \max_{w\in[w_+,\alpha]} \left(\sqrt{-p'(w)}\right). \tag{3.28}$$

Using (3.28) in (3.24), we obtain the desired result

(3.29)

$$\begin{aligned}u_\epsilon(\xi_\epsilon) \geq& u_\epsilon(\eta_1) - \frac{2(p(\beta)-p(\alpha))}{\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)} - 4\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)(w_1-w_0)\\ \geq& u_\epsilon(\eta_5) - \frac{2(p(\beta)-p(\alpha))}{\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)} - 4\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)(w_1-w_0)\\ \geq& u_+ - (\alpha - w_+)\max_{w\in[w_+,\alpha]}\left(\sqrt{-p'(w)}\right) - \frac{2(p(\beta)-p(\alpha))}{\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)}\\ &- 4\max_{w\in[w_0,w_1]}\left(\sqrt{|p'(w)|}\right)(w_1-w_0),\end{aligned}$$

which proves that $u_\epsilon(\xi)$ is bounded from below uniformly in $\epsilon > 0, \mu \in [0,1]$, and $L > 1$.

Similarly, we can also prove that $u_\epsilon(\xi)$ is bounded from above uniformly in $\epsilon > 0, \mu \in [0,1]$, and $L > 1$. □

In the remainder of this paper, we adopt the following notation:

(3.30a) $$u^* := \sup\{u_\epsilon(\xi) | \xi \in \mathbb{R}, \epsilon \in (0,1)\},$$

(3.30b) $$u_* := \inf\{u_\epsilon(\xi) | \xi \in \mathbb{R}, \epsilon \in (0,1)\}.$$

Once we established the a priori estimates for $u_\epsilon(\xi)$, we can proceed to prove the following results for $w_\epsilon(\xi)$ by using an argument similar to the one used in [2].

THEOREM 3.2. *Assume $w_\pm < \alpha$ and $u_- < u_+$. Let $(u_\varepsilon(\xi), w_\varepsilon(\xi))$ be a solution of* (2.1) *satisfying* (2.2) *and* (2.3). *Then*

(i) $||w_\varepsilon(\xi)||_{C([-l,+l];\mathbb{R}^2)} \leq C(\varepsilon)$ *where $C(\varepsilon)$ is independent of $\mu \in [0,1], L > 1$;*

(ii) *if $|p(w)| \to \infty$, as $|w| \to \infty$, and if $\mu = 1$, then $||w_\varepsilon(\xi)||_{C([-l,+l];\mathbb{R}^2)} \leq C$, where C is independent of $L > 1$ and $\varepsilon > 0$.*

Proof. We only prove that $w(\xi)$ is bounded from above uniformly. The other part of the proof is similar and is omitted.

(i) Without loss of generality, we assume $w_\varepsilon(\xi)$ has a local maximum point τ_ε. Without loss of generality, we further assume that

(3.31) $$\tau_\varepsilon \leq 0.$$

By Lemmas 2.1 and 2.2,

(3.32) $$u'_\epsilon(\tau_\varepsilon) > 0.$$

We define

(3.33) $$\eta := \inf\{\ \xi < \tau_\varepsilon\ :\ w'_\epsilon(\xi) > 0\}.$$

It is clear that $w'_\epsilon(\eta) \geq 0$. Integrating (2.1b), we obtain

(3.34) $$0 \geq -\epsilon w'_\epsilon(\eta) = -\int_\eta^{\tau_\epsilon} \xi w'_\epsilon(\xi)d\xi + \mu(u_\epsilon(\eta) - u_\epsilon(\tau_\varepsilon)).$$

By the definition (3.33), we see that $\xi w_\epsilon'(\xi) \leq 0$ on (η, τ_ε), and hence

$$0 \geq \int_\eta^{\tau_\varepsilon} \xi w_\epsilon'(\xi) d\xi \geq \mu(u_\epsilon(\eta) - u_\epsilon(\tau_\varepsilon)) \geq u_* - u^*. \tag{3.35}$$

If $\theta \leq \min(-1, \tau_n)$, then

$$\int_\eta^\theta \xi w_\epsilon'(\xi) d\xi \leq -\int_\eta^\theta w_\epsilon'(\xi) d\xi = w_\epsilon(\eta) - w_\epsilon(\theta).$$

From the definition (3.33), we know that either $\eta = -L$ or η is a local minimum point of $u_\epsilon(\xi)$. In view of Lemmas 2.1 and 2.2, $w_\epsilon(\eta) \in [\min(w_-, w_+), \beta]$. Then the above inequality yields

$$w_\epsilon(\theta) \leq -\int_\eta^\theta \xi w_\epsilon'(\xi) d\xi + w_\epsilon(\eta) \leq u^* - u_* + \beta. \tag{3.36}$$

In other words, $w_\epsilon(\xi)$ is bounded from above uniformly in $\epsilon > 0, \mu \in [0,1]$, and $L > 1$ if $\xi \leq \min(-1, \tau_\varepsilon)$. For $\xi \in (-1, \tau_\varepsilon]$, we have, from (2.1b), that

$$0 \leq -\epsilon w_\epsilon'(\xi) = \int_\xi^{\tau_\epsilon} -\zeta w_\epsilon'(\zeta) d\zeta + \mu(u_\epsilon(\xi) - u_\epsilon(\tau_\varepsilon)) \geq u_* - u^*.$$

This implies that

$$w_\epsilon(\tau_\varepsilon) \leq w_\epsilon(-1) + C_1(\epsilon) \leq u^* - u_* + \beta + C_1(\epsilon).$$

Thus, the statement (i) is proved.

(ii) It remains to consider the case when $\tau_\varepsilon \in (-1, 0]$ and $\mu = 1$. For each ϵ, we can choose $\zeta \in (-2, -1)$ such that $u_\epsilon(\zeta) \leq u^* - u_*$. By integrating (2.1a), with $\mu = 1$, on $[\theta, \tau_\varepsilon]$, we obtain

$$\begin{aligned} p(w_\epsilon(\tau_\varepsilon)) &= \epsilon u_\epsilon'(\tau_\varepsilon) - \epsilon u_\epsilon'(\theta) + p(w_\epsilon(\theta)) - \int_\theta^{\tau_\epsilon} \xi u_\epsilon'(\xi) d\xi \\ &\leq -\epsilon u_\epsilon'(\theta) + p(w_\epsilon(\theta)) - \int_\theta^{\tau_\epsilon} \xi u_\epsilon'(\xi) d\xi. \end{aligned} \tag{3.37}$$

Every term on the right-hand side of (3.33) is bounded uniformly in $\epsilon > 0$ and $L > 1$. Thus, by virtue of the assumption on p in the theorem, $w_\epsilon(\tau_\varepsilon)$ are bounded from below uniformly in $\epsilon > 0$ and $L > 1$. □

THEOREM 3.3. *Assume $w_\pm < \alpha$ and $u_- > u_+$. Let $(u_\varepsilon(\xi), w_\varepsilon(\xi))$ be a possible solution of* (2.1) *satisfying $w_\epsilon(\xi) \leq \alpha$. Then*

(i) $||u_\epsilon(\xi)||_{C([-L,+L];\mathbb{R}^2)} \leq C$, *where C is a constant independent of $L > 1$, $\mu \in [0,1]$ and $\varepsilon > 0$;*

(ii) $||w_\epsilon(\xi)||_{C([-L,+L];\mathbb{R}^2)} \leq C(\varepsilon)$, *where $C(\varepsilon)$ is independent of $\mu \in [0,1], L > 1$;*

(iii) *if $|p(w)| \to \infty$, as $|w| \to \infty$, and if $\mu = 1$, then $||w_\epsilon(\xi)||_{C([-L,+L];\mathbb{R}^2)} \leq C$, where C is independent of $L > 1$ and $\varepsilon > 0$.*

Proof. The proof is almost the same as that of Theorem 3.2. □

4. The existence of solutions of the one-phase Riemann problem. Combining Theorems 2.3, 2.4, 3.1, and 3.2, we obtain the following result.

THEOREM 4.1. (i) *Assume* $w_\pm < \alpha$ *and* $u_- < u_+$. *There is a solution* $(u_\epsilon(\xi), w_\epsilon(\xi))$ *of* (1.9) *satisfying*

$$(4.1)\quad \begin{aligned} &(u_\epsilon(\xi_1), w_\epsilon(\xi_1)) \neq (u_\epsilon(\xi_2), w_\epsilon(\xi_2)) \quad \textit{for any } \xi_1, \xi_2 \in (-\infty, +\infty), \xi_1 \neq \xi_2, \\ &\qquad w_\epsilon(\xi_1) \geq \bar{w} := +\min(w_-, w_+), \end{aligned}$$

and

(4.2) *there are at most two disjoint open intervals* (a, b) *such that*

$$(4.2a)\qquad w_\epsilon(\xi) \in (\bar{w}, \alpha),$$

and

$$(4.2b)\qquad \textit{either } w_\epsilon(a) = \bar{w}, \quad w_\epsilon(b) = \alpha \quad \textit{or} \quad w_\epsilon(a) = \alpha, \quad w_\epsilon(b) = \bar{w}.$$

(ii) *For the case* $w_\pm < \alpha$ *and* $u_- > u_+$, *there is a solution of* (1.9) *satisfying* $w_\epsilon(\xi) \leq \alpha$.

(iii) *There is a subsequence* $\{\varepsilon_n\}$, $\varepsilon_n \to 0+$ *as* $n \to \infty$, *such that* $(u_{\varepsilon_n}(\xi), w_{\varepsilon_n}(\xi))$ *given in* (i) *and* (ii) *converges almost everywhere to a weak solution* $(u(\xi), w(\xi))$ *of the Riemann problem* (1.3) *and* (1.4). *Furthermore, the solutions we constructed have at most two phase boundaries.*

Proof. Parts (i) and (ii) of Theorems 2.6, 3.1, 3.2, and 3.3 provide the a priori estimates needed by Theorem 2.3 and 2.7. Thus, parts (i) and (ii) are established.

(iii) From Corollary 2.5, we know that the solutions of (1.9) provided in (i), $u_\epsilon(\xi)$, and $w_\epsilon(\xi)$ are piecewise monotone. Thus, $(u_\varepsilon(\xi), w_\varepsilon(\xi))$ given in (i) has total variation bounded uniformly in $\varepsilon > 0$. Now the same arguments used in the proof of Theorem 3.2 of [1] or Theorem 4.1 of [27] prove the first part of our assertion. The second statement follows directly from (4.1) and (4.2). □

5. Structure of solutions of one-phase solutions. Before we proceed to study wave interactions in our system (1.3a), (1.3b), we have to have a clear picture of the structure of solutions of Riemann problems (1.3) we obtained in the last section.

DEFINITION 5.1. A solution of (1.3a), (1.3b) is said to be admissible according to viscosity-capillarity traveling wave criterion (or traveling wave criterion for short) if

(i) At each point ξ_0 of discontinuity of $(u(\xi), w(\xi))$, $(u(\xi_0-), w(\xi_0-))$ and $(u(\xi_0+), w(\xi_0+))$ exist, and

(ii) There are $v_k \in \mathbb{R}, k = 1, 2, \dots, n \in \mathbf{N}$, and $v_1 = w(\xi_0-), v_n = w(\xi_0+)$ such that the following boundary value problems have a solution:

$$(5.1a)\qquad \frac{d^2\hat{w}(\zeta)}{d\zeta^2} = -2\xi_0 \frac{d\hat{w}(\zeta)}{d\zeta} + p(\xi_0-) - p(\hat{w}(\zeta)) - \xi_0^2(\hat{w}(\zeta) - w(\xi_0-)),$$

$$(5.1b)\qquad \hat{w}(-\infty) = v_k, \quad \hat{w}(+\infty) = v_{k+1}, \quad \hat{w}'(\pm\infty) = 0.$$

THEOREM 5.1. *If $p(w)$ has the property that any straight line in (w,p)-plane intersects the graph of $p(w)$ at finite many points, then the solutions of* (1.3) *given by Theorem* 3.9, *which are admissible by the similarity viscosity criterion, are also admissible by the traveling wave criterion. Hence, solutions of* (1.3), *which are admissible by the traveling wave criterion, always exist.*

This theorem was first proved in [8] for the case where w_- and w_+ separated by the elliptic region (α,β). Although the above theorem is for any initial data with $w_\pm \notin (\alpha,\beta)$, the proof is basically the same as in [8]. Thus, we omit the proof.

Using the same technique developed in [3] and generalized in [6], we can prove the following theorem.

THEOREM 5.2. *Let $(u(\xi),w(\xi))$ be a solution of* (1.3). *Suppose ξ_0 is a point of discontinuity of $(u(\xi),w(\xi))$. Then one of the following holds*:

$$\lambda(w(\xi_0+)) \le \xi_0 \le \lambda(w(\xi_0+)), \tag{5.2a}$$

$$-\lambda(w(\xi_0+)) \le \xi_0 \le \lambda(w(\xi_0+)), \tag{5.2b}$$

$$-\lambda(w(\xi_0+)) \le \xi_0 \le -\lambda(w(\xi_0+)). \tag{5.2c}$$

THEOREM 5.3. *Let $(u(\xi),w(\xi))$ be a solution of* (1.3) *which satisfies the traveling wave criterion. Then $w(\xi)$ does not take value in (α,β), i.e., $w(\xi) \notin (\alpha,\beta)$ for almost all $\xi \in \mathbb{R}$.*

Proof. Assume, for contradiction, that $w(\xi_0-) \in (\alpha,\beta)$ for some $\xi_0 \in \mathbb{R}$. We claim that $w(\xi+) = w(\xi_0-)$ for $\xi \in (\xi_0-\delta,\xi_0)$ for some $\delta > 0$. Otherwise, one of the following two cases will occur.

Case (i). $w(\xi)$ is continuous on $(\xi_0-\delta,\xi_0)$ for some $\delta > 0$ and there is a sequence $\{\xi_n\} \subset (\xi_0-\delta,\xi_0)$ such that $\xi_n \to \xi_0-$ as $n \to \infty$ and $w(\xi_n+) \ne w(\xi_0-)$.

Case (ii). There is a sequence of points of discontinuity of $(u(\xi),w(\xi))$ such that $\xi_n \to \xi_0-$ as $n \to \infty$.

Case (ii) cannot occur because $w(\xi_n\pm) \in (\alpha,\beta)$ for large n and the Rankine–Hugoniot conditions at $\xi = \xi_n$ cannot hold.

We claim that Case (i) is also impossible. Indeed, we can integrate (1.9) over (ξ_n,ξ_0) to get

$$\xi_0 \frac{\Delta_n u}{\Delta_n w} = p'(\theta) - \frac{1}{\Delta_n w}\int_{\xi_n+}^{\xi_0-} (u(\zeta) - u(\xi_n+))d\zeta, \tag{5.3a}$$

$$\frac{\Delta_n u}{\Delta_n w} = -\xi_0 - \frac{1}{\Delta_n w}\int_{\xi_n+}^{\xi_0-} [w(\xi_n+) - w(\zeta)]d\zeta, \tag{5.3b}$$

where $\Delta_n w := w(\xi_0-) - w(\xi_n+) > 0$, $\Delta_n u := u(\xi_0-) - u(\xi_n+)$, and

$$\theta \in (w(\xi_n+), w(\xi_0-)).$$

It follows that

$$\xi_0 \lim_{n\to\infty} \frac{\Delta_n u}{\Delta_n w} = p'(w(\xi_0-)),$$
$$\lim_{n\to\infty} \frac{\Delta_n u}{\Delta_n w} = -\xi_0.$$

Then we arrive at the contradiction

$$\left(\lim_{n\to\infty}\frac{\Delta_n u}{\Delta_n w}\right)^2 = -p'(w(\xi_0-)) < 0.$$

It follows that there exist ξ_1 and ξ_2, which are points of discontinuity of $(u(\xi), w(\xi))$ such that $\xi_1 < \xi_0 < \xi_2$ and

$$w(\xi) = w(\xi_0-) \in (\alpha, \beta) \quad \text{for } \xi \in (\xi_1, \xi_2).$$

Therefore, according to the traveling wave criterion, both boundary value problems

$$\text{(5.4a)} \qquad \frac{d^2\hat{w}}{d\zeta^2} = -2\xi_1\frac{d\hat{w}(\zeta)}{d\zeta} - \xi_1^2(\hat{w}(\zeta) - w(\xi_1+)) - (p(\hat{w}(\zeta)) - p(w(\xi_1+))),$$

$$\text{(5.4b)} \qquad \hat{w}(-\infty) = w(\xi_1-), \quad \hat{w}(+\infty) = w(\xi_1+),$$

$$\text{(5.4c)} \qquad \hat{w}'(\pm\infty) = 0,$$

and

$$\text{(5.5a)} \qquad \frac{d^2\hat{w}}{d\zeta^2} = -2\xi_2\frac{d\hat{w}(\zeta)}{d\zeta} - \xi_2^2(\hat{w}(\zeta) - w(\xi_2-)) - (p(\hat{w}(\zeta)) - p(w(\xi_2-))),$$

$$\text{(5.5b)} \qquad \hat{w}(-\infty) = w(\xi_2-), \quad \hat{w}(+\infty) = w(\xi_2+),$$

$$\text{(5.5c)} \qquad \hat{w}'(\pm\infty) = 0$$

have solutions. A straightforward calculation shows that the eigenvalue for the linearized (near $\hat{w}(\zeta) = w(\xi_1+)$) problem of (5.4) is $\lambda = -\xi_1 \pm \sqrt{-p'(w(\xi_1+))}$. It is clear that $w(\xi_1+) = w(\xi_2-)$ is a node of (5.4). Thus, in order for (5.4) to have a solution, it is necessary that $\xi_1 \geq 0$. On the other hand, however, the same analysis shows that the solvability of (5.5) implies $0 \geq \xi_2 > \xi_1 \geq 0$. This contradiction proves our assertion.

6. Wave interactions in systems of mixed type. In this section, we study wave interactions involving phase boundaries. The study of interactions between waves, for instance phase boundaries and ordinary shocks, can be reduced to a study of, just as in the case of hyperbolic systems, Riemann problems (1.3). We shall provide a mechanism to quickly determine, at least qualitatively, the outcome of wave interactions in some situations.

For simplicity, we assume that

$$\text{(6.1)} \qquad p''(w)(w - \eta) < 0$$

for some $\eta \in (\alpha, \beta)$.

In the sequel, when we say solutions of (1.3), we mean weak solutions of (1.3) satisfying the traveling wave criterion, unless stated differently.

We first study the Riemann problem of (1.3) with initial value

$$(u(x,0),w(x,0)) = \begin{cases} (u_-,w_-) & \text{for } x<0, \\ (u_+,w_+) & \text{for } x>0\ , \end{cases} \tag{6.2}$$

where

$$w_- < \alpha < \beta < w_+. \tag{6.3}$$

We shall call the Riemann problem with (6.3) the two-phase Riemann problem.

For two-phase Riemann problem (1.3), (6.2), and (6.3), we know, from §2 of [7], that the unique centered solution $(u(\xi),w(\xi))$ of the Riemann (1.3), (6.2), and (6.3) consists of a shock $\xi = s_2$ such that $w_1 := w(s_2-) \le \alpha < \beta \le w(s_2+) =: w_2$, and two constant states (u_-,w_-) and (u_+,w_+). (u_-,w_-) are joined to $(u(s_2-),w(s_2-))$ by either a backward shock $\xi = s_1 < 0$ if $w(s_2-) < w_-$ or a backward rarefaction wave if $w(s_2-) > w_-$. (u_+,w_+) is connected to $(u(s_2+),w(s_2+))$ by either a forward shock $\xi = s_3 > 0$ if $w(s_2+) > w_+$ or a forward rarefaction wave if $w(s_2+) < w_+$. Thus, we can denote a solution of (1.3), for simplicity, by $\{w_1,w_2,s_2\}$. All the shocks mentioned in this paragraph, except possibly the phase boundaries, satisfy the Lax's shock admissibility criterion (cf. [17], [18]).

The following lemma is Lemma 4.1 from [7].

LEMMA 6.1. (1.3) *has a solution* $\{w_1,w_2,s_2\}$ *if and only if the following conditions hold:*

$$F(w_1,w_2,s_2) = u_+ - u_-, \tag{6.4}$$

where $w_1 \to w_2$ *is a connection with speed* s_2 *and* $w_1 \le \alpha < \beta \le w_2$*,*

$$\begin{aligned} F(w_1,w_2,s_2) :=& - s_1(w_1 - w_-)H(w_- - w_1) + H(w_1 - w_-+) \int_{w_-}^{w_1} \lambda(w)dw \\ & - s_2(w_2 - w_1) - H(w_2 - w_+)s_3(w_+ - w_2) \\ & + H(w_+ - w_2+) \int_{w_+}^{w_2} \lambda(w)dw, \end{aligned} \tag{6.5}$$

where $H(w)$ *is the heaviside function and*

$$s_k^2 := -\frac{p(w_k) - p(w_{k-1})}{w_k - w_{k-1}}, \quad k = 1,2,3, \quad w_0 := w_-, w_3 := w_+; \tag{6.6}$$

$$s_1 < 0, \quad s_3 > 0, \quad s_1 < s_2 < s_3, \tag{6.7a}$$

$$-\lambda(w_1) < s_1 < -\lambda(w_-), \quad \lambda(w_+) < s_3 < \lambda(w_2), \tag{6.7b}$$

$$-\lambda(w_2) < s_2 < \lambda(w_1), \tag{6.7c}$$

$$s_2 \le \lambda(w_2) \quad \textit{if } w_2 \ne w_+, \tag{6.7d}$$

$$s_2 \ge -\lambda(w_1) \quad \textit{if } w_1 \ne w_-. \tag{6.7e}$$

LEMMA 6.2 (see [22]). *For each w_1, there is at most one w_2 such that $w_1 \rightarrow w_2$ is a saddle-saddle connection of speed $s \geq 0$. As a consequence, the speed s is also unique.*

LEMMA 6.3 (see [7]). *Let $w_1 \rightarrow w_2$ be a saddle-saddle connection of speed $s \geq 0$ and $\bar{w}_1 \rightarrow \bar{w}_2$ a connection of speed $\bar{s} \geq 0$. If $\bar{w}_1 < w_1 < \alpha$ or $\bar{w}_1 > w_1 > \beta$, then $\bar{s} > s \geq 0$.*

LEMMA 6.4. *For each fixed $w_\pm$ with $w_- < \alpha < \beta < w_+$, we define*

(6.8)
$$A(w_-, w_+) := \{\{w_1, w_2, s_2\} \ : \ \{w_1, w_2, s_2\} \text{ is a solution to the Riemann problem of (1.3), (6.2), and (6.3) for some } u_\pm \in \mathbb{R}\}.$$

Then

(i) *$A(w_-, w_+)$ is a graph of a function $(w_1(s), w_2(s), s)$. Furthermore, $w_1(s)$ is a strictly decreasing function if $s \geq 0$ and $w_2(s)$ is a strictly decreasing function of s if $s \leq 0$;*

(ii) *$F(w_1, w_2, s_2)$ is a strictly decreasing function of s_2.*

Proof. (i) Since $\{w_1, w_2, s_2\}$ is a solution of the Riemann problem of (1.3), by the definition of the notation of $\{w_1, w_2, s_2\}$, $w_1 \rightarrow w_2$ must be a connection of speed s_2. We suppose $s_2 \geq 0$. If $w_1 \rightarrow w_2$ is a saddle-saddle connection, then, by Lemmas 6.2 and 6.3, w_1 is uniquely determined by s_2. If $w_1 \rightarrow w_2$ is not a saddle-saddle connection, then it has to be a saddle-node connection, since $s_2 \geq 0$. In view of (6.7d), $w_2 = w_+$ in this case, and hence w_1 is uniquely determined by

$$s_2^2 = -\frac{p(w_+) - p(w_1)}{w_+ - w_1}.$$

Thus, to prove that w_1 is a function of s_2, it suffices to prove that for each $s_2 \geq 0$, there cannot be two solutions $\{w_1, w_2, s_2\}$, $\{\bar{w}_1, \bar{w}_2, s_2\} \in A(w_-, w_+)$, where $w_1 \rightarrow w_2$ and $\bar{w}_1 \rightarrow \bar{w}_2$ are connections of the same speed s_2 and one of them is a saddle-saddle connection while the other is a saddle-node connection. To this end, we, without loss of generality, assume $\bar{w}_1 < w_1 < \alpha$. Then, by Lemma 6.3, $w_1 \rightarrow w_2$ must be a saddle-node connection, inferring $w_2 = w_+$, and $\bar{w}_1 \rightarrow \bar{w}_2$ is a saddle-saddle connection. Inspecting the graph of $p(w)$, noticing (6.1) and

$$\lambda(w_1) > s > \lambda(w_2), \qquad s < \lambda(\bar{w}_j), \quad j = 1, 2,$$

we can see that

$$\bar{s}_3 < \bar{s}_2 = s_2,$$

where $\bar{s}_3^2 = -(p(\bar{w}_2) - p(w))/(\bar{w}_2 - w_+)$, which cannot be true by (6.7a). This contradiction shows that if $s_2 \geq 0$, the w_1 in $\{w_1, w_2, s_2\} \in A(w_-, w_+)$ is a function of s_2 and hence so is the w_2. Similarly, we can prove that if $s_2 < 0$, the w_2 in $\{w_1, w_2, s_2\} \in A(w_-, w_+)$ is a function of s_2 and hence so is the w_1. Thus, the first statement of (i) is proved. The rest of the assertion (i) follows from Lemma 6.3.

(ii) The spirit of the proof for (ii) is similar to the proof of Lemma 4.4 of [7]. Thus we omit the proof. □

The above lemmas hold for the Riemann problems with

$$w_- < \alpha < \beta < w_+. \tag{6.9}$$

For the Riemann problems with

$$w_- > \beta > \alpha > w_+, \tag{6.10}$$

we can use the transformation $(u, w) \to (-u, -w)$ to convert the Riemann problem with (6.10) to that of (6.9). This is because $(u(x,t), w(x,t))$ is an admissible solution of

$$\begin{aligned} u_t + p(w)_x &= 0, \\ w_t - u_x &= 0, \qquad x \in \mathbb{R}, t > 0, \\ (u(x,0), w(x,0)) &= \begin{cases} (u_-, w_-) & \text{for } x < 0, \\ (u_+, w_+) & \text{for } x > 0, \end{cases} \end{aligned}$$

if and only if $(\bar{u}(x,t), \bar{w}(x,t)) = (-u(x,t), -w(x,t))$ is an admissible solution of

$$\begin{aligned} \bar{u}_t + (-p(-\bar{w}))_x &= 0, \\ \bar{w}_t - \bar{u}_x &= 0, \qquad x \in \mathbb{R}, t > 0, \\ (\bar{u}(x,0), \bar{w}(x,0)) &= \begin{cases} (-u_-, -w_-) & \text{for } x < 0, \\ (-u_+, -w_+) & \text{for } x > 0. \end{cases} \end{aligned}$$

Since $-p(-w)$ satisfies all the assumptions we need on $p(w)$, our results for the case $w_- < \alpha < \beta < w_+$ also hold for the admissible solutions of (6.10) with $w_- > \beta > \alpha > w_+$.

We state the results on the Riemann problem for the case $w_- > \beta > \alpha > w_+$ as follows. The unique centered solution $(u(\xi), w(\xi))$ of the Riemann (1.3), (6.2), and (6.9) has a shock $\xi = s_2$ such that $w_1 := w(s_2+) \leq \alpha < \beta \leq w(s_2-) =: w_2$ and two constant states, (u_-, w_-) and (u_+, w_+). (u_-, w_-) is joined to $(u(s_2-), w(s_2-))$ by either a backward shock $\xi = s_1 < 0$ if $w(s_2-) < w_-$ or a backward rarefaction wave if $w(s_2-) > w_-$. (u_+, w_+) is connected to $(u(s_2+), w(s_2+))$ by either a forward shock $\xi = s_3 > 0$ if $w(s_2+) > w_+$ or a forward rarefaction wave if $w(s_2+) < w_+$. Thus, we can denote a solution of (1.3), for simplicity, by $\{w_1, w_2, s_2\}$.

We can also define the function $F(w_1, w_2, s_2)$ as in Lemma 6.1 for the case $w_- > \beta > \alpha > w_+$. We shall, however, use $G(w_1, w_2, s_2)$ to denote it, i.e., $G(w_1, w_2, s_2) = F(w_1, w_2, s_2)$, to make this case distinct to readers' eyes. It is clear that (1.3), (6.2), and (6.9) have an admissible solution $\{w_1, w_2, s_2\}$ if and only if $G(w_1, w_2, s_2) = u_+ - u_-$.

LEMMA 6.5. *For each fixed $w_\pm$ with $w_+ < \alpha < \beta < w_-$, we define*

$$\begin{aligned} B(w_-, w_+) := \{\{w_1, w_2, s_2\} \ &: \ \{w_1, w_2, s_2\} \textit{ is a solution to the} \\ &\textit{Riemann problem of } (1.3),\ (6.2), \textit{ and } (6.9) \textit{ for some } u_\pm \in \mathbb{R}\}. \end{aligned} \tag{6.11}$$

Then

(i) *$B(w_-, w_+)$ is a graph of a function $(w_1(s), w_2(s), s)$. Furthermore, $w_1(s)$ is a strictly increasing function if $s \geq 0$, and $w_2(s)$ is a strictly increasing function of s if $s \leq 0$;*

(ii) *$G(w_1, w_2, s_2) = \bar{G}(s_2)$ is a strictly increasing function of s_2.*

The results in Lemmas 6.1–6.4 are for the case w_- and w_+ are separated by the spinodal region (α, β). Now, we concentrate on the case $w_\pm < \alpha$.

LEMMA 6.6. *Assume $w_\pm < \alpha$. Let $(u(\xi), w(\xi))$ be a centered solution of the Riemann problem satisfying the traveling wave criterion. If $w(\xi) \leq \alpha$, then each point of discontinuity of $(u(\xi), w(\xi))$ satisfies $\lambda(w(\xi_0-)) > \xi_0 > \lambda(w(\xi_0+))$ or $-\lambda(w(\xi_0-)) > \xi_0 > -\lambda(w(\xi_0+))$.*

Proof. This assertion follows directly from the assumption (6.1) and Lemma 2.2 of [7]. □

Remark. The above proposition generally does not hold without assumption (6.1).

As an application of the above analysis, we consider the wave interaction problem of (1.3) with the initial data

$$(u(x,0), w(x,0)) = \begin{cases} (u_-, w_-) & \text{for } x < -1, \\ (u_2, w_2) & \text{for } 1 > x > -1, \\ (u_+, w_+) & \text{for } x > 1. \end{cases} \tag{6.12}$$

The outcome of the interaction of the two shock waves $\{(u_-, w_-), (u_2, w_2)\}$ and $\{(u_2, w_2), (u_+, w_+)\}$ is the solution of the Riemann problem of (1.3) with initial value

$$(u(x,0), w(x,0)) = \begin{cases} (u_-, w_-) & \text{for } x < 0, \\ (u_+, w_+) & \text{for } x > 0\ . \end{cases} \tag{6.13}$$

We are interested in the interactions between ordinary shocks and phase boundaries and that between phase boundaries. To list all the possibilities of the interactions would be lengthy and perhaps unnecessary. Here, we only study two examples.

Example 1. Let $\{(u_-, w_-,), (u_2, w_2)\}$ be a phase boundary such that $w_- \longrightarrow w_2$ is a saddle-saddle connection with speed $s_2 \geq 0$, i.e., $0 \leq s_2 < \lambda(w_-), \lambda(w_2)$. Let $\{u_1, w_1), (u_+, w_+)\}$ be an ordinary admissible shock solution of (1.3) with speed $s_3 < 0$, i.e., $\lambda(w_2) > s_3 > \lambda(w_+)$. We further assume $w_+ > \beta$.

In this case, the two shocks must interact. A calculation shows that

$$u_- + F(w_-, w_2, s_2; w_-, w_+) = u_- + \bar{F}(s_2) < u_+; \tag{6.14}$$

see Fig. 3. We know from Lemma 6.1 that $\{\bar{w}_1, \bar{w}_2, \bar{s}_2\}$ is a solution of the Riemann problem (1.3) and (6.12) if and only if

$$u_- + \bar{F}(\bar{s}_2) = u_+,$$

which infers that

$$\bar{F}(s_2) < \bar{F}(\bar{s}_2).$$

By Lemma 6.4,

$$\bar{s}_2 < s_2,$$

and hence, by the same lemma,

$$\alpha > \bar{w}_1 > w_-.$$

We depict the result of the interaction $\{\bar{w}_1, \bar{w}_2, \bar{s}_2\}$, where $\bar{w}_1 < w_-$ and $\bar{s}_2 > s_2$ in Fig. 4.

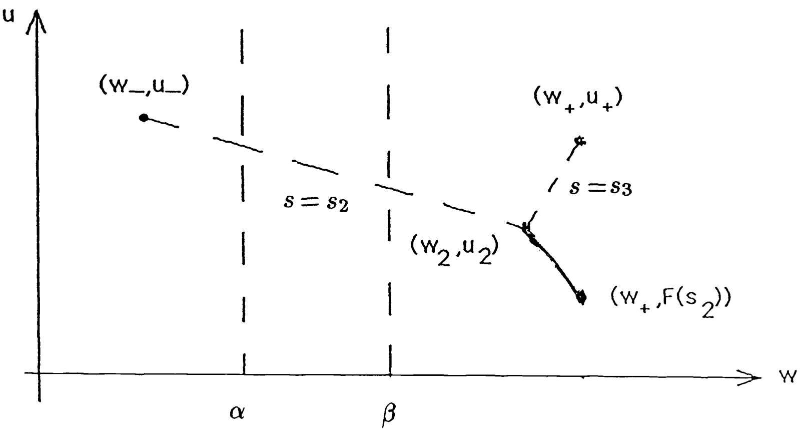

FIG. 3

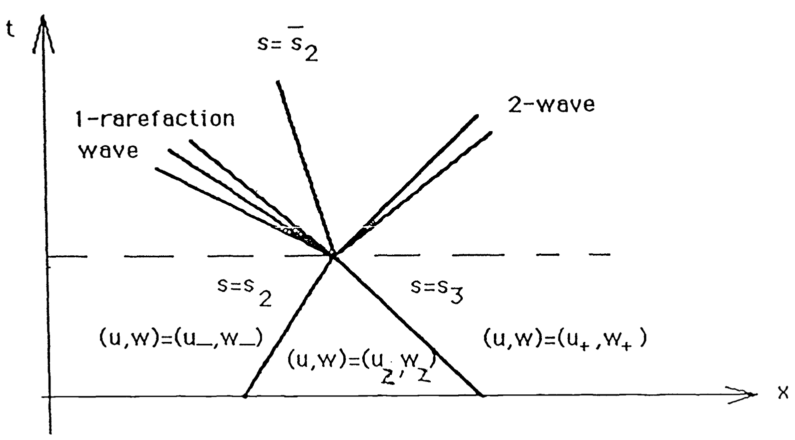

FIG. 4

Example 2. We consider the case when two phase boundaries interact. Let $\{(u_-, w_-,), (u_2, w_2)\}$ and $\{(u_2, w_2,), (u_+, w_+)\}$ be two phase boundaries with speed s_1 and s_2, respectively. We further assume that $w_\pm < \alpha$ and $w_2 > \beta$.

Above two phase boundaries interact if and only if $s_1 > s_2$. The outcome of the interaction is a solution of the Riemann problem (1.3), (6.11) with $w_\pm < \alpha$.

Case (i). $u_- \geq u_+$.

In this case, the solution of (1.3) and (6.11) satisfies $w(\xi) \leq \alpha$ and hence can be constructed easily by the classical method.

Case (ii). $u_- < u_+$.

Subcase (iia).

$$u_- < u_+ \leq u_- + \int_{w_-}^{\alpha} \sqrt{-p'(\eta)}d\eta + \int_{w_+}^{\alpha} \sqrt{-p'(\eta)}d\eta. \tag{6.15}$$

When (6.15) holds, there is no solution of (1.3), (6.13) satisfying $w(\xi) \leq \alpha$ and the Lax criterion (6.10). Then the solutions of (1.3), (6.11) must take values in the region $w > \beta$, i.e., $w(\xi) > \beta$ for some $\xi \in \mathbb{R}$.

Subcase (iib). $u_- < u_+$ but the second inequality of (6.15) is not satisfied.

In this case, the Riemann problem (1.3), (6.13) always has a solution which is confined in the region $w \leq \alpha$. Sometimes the Riemann problem also has another solution which satisfies $w(\xi) > \beta$ for some $\xi \in \mathbb{R}$ (cf. [22]). Although both of these solutions satisfy the traveling wave criterion, there is an example in [10] showing that, at least in that example, only the solution lying inside the region $w(\xi) \leq \alpha$ is admissible by the more "basic" vanishing viscosity criterion of the form

$$\begin{aligned} u_t + p(w)_x &= \epsilon u_{xx}, \\ w_t - u_x &= \epsilon w_{xx}, \end{aligned}$$

from which the traveling wave criterion is derived.

Acknowledgment. I would like to thank Professor M. Slemrod for his valuable suggestions and comments.

SOLITARY WAVES IN A TWO-LAYER FLUID WITH SURFACE TENSION*

S. M. SUN†‡ AND M. C. SHEN‡

Abstract. This paper deals with permanent gravity-capillary waves on the interface with surface tension in a two-layer, inviscid, and incompressible fluid between two horizontal, rigid boundaries. It is shown that, if the Bond number τ, a nondimensional surface tension coefficient, is greater than some critical value τ_0, and the Froude number F is less than, but near some critical value F_0, there exists a solitary wave solution which decays to zero at infinity. When τ is less than τ_0, solitary waves plus a small oscillation at infinity will appear, and the existence of such type of solutions will be investigated in a subsequent paper. Discussions about several critical cases, such as τ near τ_0 or a density ratio near some critical value, are also given.

Key words. solitary waves, two-layer fluids, surface tension

1. Introduction.

This paper concerns the existence of an interface solitary wave between two immiscible, inviscid, and incompressible fluids of different but constant densities in the presence of surface tension. The upper and lower boundaries are assumed to be horizontal and rigid. We choose a coordinate system moving with the wave at a constant speed C so that in reference to this system the fluid motion is steady. Let h^-, h^+ be the depths at infinity, and ρ^-, ρ^+ be the densities of the lower and upper layers, respectively, T be the constant surface tension coefficient, and g be the constant gravitational acceleration. Define $h = h^+/h^-$, $\rho = \rho^+/\rho^- < 1$, the Froude number $F = C^2/((1-\rho)gh)$, and the Bond number $\tau = T/(h^-C^2\rho^-)$. Let us briefly review the existent results for a solitary wave on a layer of fluid over a bottom in the presence of surface tension. This case corresponds to $\rho_+ = 0$. Apparently Korteweg and de Vries [1] first derived a model equation under long wave approximation when F is near 1. The equation is now called the K-dV equation, and for $\tau = 0$ possesses a progressive wave solution, the so-called solitary wave, which decays to zero at infinity for $F > 1$ but near 1. The existence of such a solution to the exact equations was proved by Friedrichs and Hyers [2] among others half a century later. However, if the surface tension is taken into account in the K-dV equation, there is another critical value $\tau_0 = \frac{1}{3}$ of the Bond number τ. When τ is near $\frac{1}{3}$, the K-dV equation is no longer valid and a fifth-order model equation was derived by Hunter and Vanden-Broeck [3]. For $\tau > \frac{1}{3}$, $F < 1$ but near 1, the K-dV equation has a solitary wave of depression. The existence of this type of solution to the exact equations was verified numerically in [3] and proved by Amick and Kirchgässner [4] and Sachs [5]. For $\tau > \frac{1}{3}$ but near $\frac{1}{3}$ and $F < 1$ but near 1, the existence of a new solitary wave of depression was proved by Sun and Shen [6]. For $0 < \tau < \frac{1}{3}$, $F > 1$ but near 1, the solitary wave solution of the K-dV equation represents a wave of elevation. The behavior of a solution to the exact equations for this case is quite different. Hunter and Vanden-Broeck [3] also computed the solution numerically and found that it consists of a solitary wave of elevation plus

small oscillations at infinity, which we will call a generalized solitary wave. Hunter and Scheurle [7] studied a generalized solitary wave solution of the fifth-order equation for $\tau < \frac{1}{3}$ but near $\frac{1}{3}$ and $F > 1$ but near 1. The existence of a generalized solitary wave solution to the exact equations for $0 < \tau < \frac{1}{3}$, $F > 1$ but near 1 has been given recently by Beale [8] and Sun [9] on the basis of different methods.

For the case of a two-layer fluid without surface tension, the first systematic study is due to Peters and Stoker [10]. Amick and Turner [11] have recently used the center manifold technique to study possible interface waves, and computational results have been given by Turner and Vanden-Broeck [12]. An existence proof of internal solitary waves has also been given by Bona and Sachs [13], which gives many interesting properties of these solitary wave solutions as well. For a two-layer fluid in the presence of surface tension, the critical values of F and τ are, respectively, found as $F_0 = (1+\rho/h)^{-1}$ and $\tau_0 = (1+\rho h)/3$. A K-dV equation can be derived for F near F_0 and possesses an approximate solitary wave solution if $\rho \neq h^2$ but not near h^2, and $\tau \neq \tau_0$ but not near τ_0. The main objectives of this paper are to prove that a solitary wave solution of the K-dV equation indeed is an approximate solution to the exact equations if $\tau > \tau_0$ but not near τ_0, $\rho \neq h^2$ but not near h^2, and $F < F_0$ but near F_0, and to consider the critical cases when τ is near τ_0 or ρ is near h^2.

The main result of this paper is the following existence result: If $\nu = F^{-1} = 1 + (\rho/h) + \lambda_1\epsilon, \lambda_1 > 0$ and $\tau > \tau_0$, then for small $\epsilon > 0$ there exists an internal solitary wave solution in the form

$$f^+(x,\psi) = \psi + \epsilon(\psi - h)S(x) + \epsilon((\psi - h)\omega(x) + \theta^+(x,\psi)) \quad \text{for } \ 0 < \psi < h\,,$$

$$f^-(x,\psi) = \psi - h\epsilon(\psi + 1)S(x) + \epsilon(-h(\psi + 1)\omega(x) + \theta^-(x,\psi)) \quad \text{for } \ -1 < \psi < 0,$$

where f^+, f^- are the streamline functions for the upper and lower layers, respectively; ψ is the stream function

$$S(x) = \frac{\lambda_1 h}{h^2 - \rho}\operatorname{sech}^2\frac{(\lambda_1/(\tau - \tau_0))^{1/2}\epsilon^{1/2}x}{2},$$

and $\omega, \theta^{\pm}$ are error terms with $\|\omega(x)\|_{X^s} \leq K\epsilon$ and $\|\theta(x,\psi)\|_{B^s} \leq K\epsilon$ for $s \geq 4$. Here K is a constant independent of ϵ and X^s, B^s are Banach spaces to be defined later. The interface is given by $\eta = f^+(x,0) = f^-(x,0) = \epsilon(-h)S(x) + O(\epsilon^2)$. The outline of our existence proof of the solitary wave solution is as follows: The fluid domain with an unknown interface is first transformed to a horizontal strip with a fixed interface and boundaries. Then the exact equations are linearized about a given constant state, and a solvability condition appears for the solution of the corresponding inhomogeneous equations. Since the eigenvalue problem for the linearized equations has no periodic eigenfunction, a Banach space of functions decaying to zero at infinity can be defined. We can obtain an integro-differential equation from the solvability condition and several a priori estimates for a solution in the Banach space. The partial differential equations are now studied on the basis of a Hilbert space with an inner product specially constructed for a two-layer problem in the presence of surface tension. A solution of these equations is then expressed in terms of eigenfunctions of an eigenvalue problem associated with the linearized equations and a priori estimates for this solution in the Banach space are obtained. By these estimates and contraction mapping theorem, the existence of a solitary wave decaying to zero at infinity is proved. Our approach is based upon several ideas due to Friedrichs and Hyers [2], Beale [8], and Ter-Krikorov [14]. For the case $\tau < \tau_0$, the eigenvalue problem for the linearized

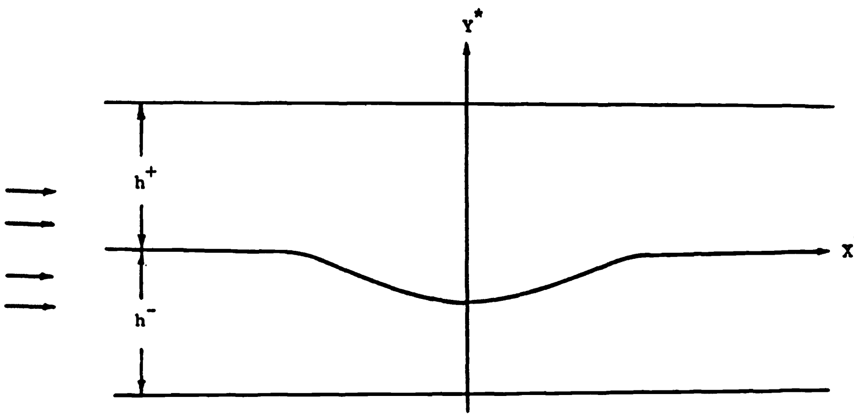

FIG. 1. *Configuration of a solitary wave.*

equations possesses a positive eigenvalue, and the corresponding eigenfunction is a periodic function. The main difficulty is to isolate the oscillatory part of a solution to the exact equations. We shall defer the existence proof of a solution for this case in a subsequent paper. Several critical cases also warrant consideration here. If τ is near τ_0 or ρ is near h^2, the present asymptotic theory is no longer valid and new asymptotic schemes have to be developed. We shall derive different approximate equations for the interface waves and obtain new solitary wave solutions to these equations. The justification of the formal derivation of a solitary wave solution for ρ near h^2 and $\tau > \tau_0$ but not near τ_0 is also presented. The justifications for the other cases will be deferred to subsequent investigation.

In §2, we formulate the problem in terms of nondimensional equations in a horizontal strip with a fixed interface. A formal derivation of the stationary K-dV equation and its solitary wave solution is presented in §3. An existence theorem of the approximate solitary wave solution to the exact equations is proved in §4. In §5, we discuss several critical cases for which the present asymptotic method fails, and we formally derive new model equations and their solitary wave solutions. In §6 we justify the formal method for ρ near h^2 and $\tau > \tau_0$ but not near τ_0. In the Appendix it is shown that there exists no positive eigenvalue of the linearized equations for $\tau > \tau_0$.

2. Formulation. We consider the irrotational flow of two immiscible, inviscid, and incompressible fluids of different but constant densities with surface tension at the interface and bounded by two horizontal rigid boundaries. In reference to the coordinate system moving at a speed C, the fluid flow becomes steady (Fig. 1), and the governing equations in terms of the stream function ψ^* are

$$\nabla^2\psi^{*-} = 0, \qquad -h^- < y^* < \eta^*(x^*), \tag{1}$$

$$\nabla^2\psi^{*+} = 0, \qquad \eta^*(x^*) < y^* < h^+, \tag{2}$$

where the velocity $\overline{v} = (u, v) = (\psi^*_{y^*}, -\psi^*_{x^*})$, and $y^* = \eta^*(x^*)$ is the interface. The boundary conditions are the following: At $y^* = \eta^*(x^*)$,

$$\eta^*_{x^*}\psi^{*\pm}_{y^*} + \psi^{*\pm}_{x^*} = 0, \tag{3}$$

$$\begin{aligned}(\rho^- - \rho^+)g\eta^* + \frac{\rho^-}{2}(\nabla\psi^{*-})^2 - \frac{\rho^+}{2}(\nabla\psi^{*+})^2 \\ - T\eta^*_{x^*x^*}(1 + (\eta^*_{x^*})^2)^{-3/2} = D;\end{aligned} \tag{4}$$

at $y^* = h^+$,

$$\psi^{*+}_{x^*} = 0; \tag{5}$$

at $y^* = -h^-$,

$$\psi^{*-}_{x^*} = 0. \tag{6}$$

Here D is the Bernoulli constant on the interface. Now we use x^*, ψ^* as independent variables and the so-called streamline function f^* as the dependent variable, where $\psi^*(x^*, f^*) =$ constant defines a streamline. It is obtained that

$$f^{*\pm}_{\psi^*} = \frac{1}{\psi^{*\pm}_{y^*}}, \qquad f^{*\pm}_{x^*} = -\frac{\psi^{*\pm}_{x^*}}{\psi^{*\pm}_{y^*}}.$$

By using the above relations, (1)–(6) become

$$(1 + (f^*_{x^*})^2) f^*_{\psi^*\psi^*} + (f^*_{\psi^*})^2 f^*_{x^*x^*} - 2 f^*_{\psi^*} f^*_{x^*} f^*_{x^*\psi^*} = 0 \tag{7}$$

for $0 < \psi^* < \psi_2$ and $-\psi_1 < \psi^* < 0$, where ψ_1 and ψ_2 are two constants and

$$f^* = \begin{cases} f^{*+}, & 0 < \psi^* < \psi_2, \\ f^{*-}, & -\psi_1 < \psi^* < 0. \end{cases}$$

If on $\psi^* = 0$, f^* goes to zero as $|x^*| \to \infty$, then $\psi_1 = Ch^-$ and $\psi_2 = Ch^+$. At $\psi^* = 0$,

$$f^{*+} = f^{*-}, \tag{8}$$

$$\begin{aligned} (\rho^- - \rho^+) g f^* - T f^*_{x^*x^*} (1 + (f^*_{x^*})^2)^{-3/2} + \frac{\rho^-}{2} \frac{1 + (f^{*-}_{x^*})^2}{(f^{*-}_{\psi^*})^2} \\ - \frac{\rho^+}{2} \frac{1 + (f^{*+}_{x^*})^2}{(f^{*+}_{\psi^*})^2} = D; \end{aligned} \tag{9}$$

at $\psi^* = -\psi_1$,

$$f^{*-} = -h^-; \tag{10}$$

at $\psi^* = \psi_2$,

$$f^{*+} = h^+. \tag{11}$$

To nondimensionalize (7)–(11), we measure ψ^* in units of ψ_1 so that $\psi = -1$ at bottom. Define

$$x = \frac{x^*}{h^-}, \quad \psi = \frac{\psi^*}{Ch^-}, \quad f = \frac{f^*}{h^-}, \quad b = \frac{D}{C^2 \rho^-},$$
$$\nu = F^{-1} = \frac{(1-\rho) g h^-}{C^2}.$$

Then we obtain from (7)–(11)

$$(1 + f_x^2) f_{\psi\psi} + f_\psi^2 f_{xx} - 2 f_\psi f_x f_{x\psi} = 0 \tag{12}$$

for $0 < \psi < h$ and $-1 < \psi < 0$ with f defined as f^+ and f^-, respectively, in these two regions. At $\psi = 0$,

$$f^+ = f^- , \tag{13}$$

$$\nu f - \tau f_{xx}(1 + f_x^2)^{-3/2} + \frac{1}{2}\frac{1 + (f_x^-)^2}{(f_\psi^-)^2} - \frac{\rho}{2}\frac{1 + (f_x^+)^2}{(f_\psi^+)^2} = b; \tag{14}$$

at $\psi = -1$,

$$f^- = -1; \tag{15}$$

at $\psi = h$,

$$f^+ = h. \tag{16}$$

Now let $f = \psi + w(x, \psi)$. The equations (12)–(16) become

$$\begin{aligned} w_{\psi\psi} + w_{xx} = & - 2 w_\psi w_{xx} + 2 w_x w_{x\psi} - w_x^2 w_{\psi\psi} + 2 w_x w_\psi w_{x\psi} \\ & - w_\psi^2 w_{xx} = F_1(w), \end{aligned} \tag{17}$$

in $-1 < \psi < 0$ and $0 < \psi < h$, and w^+, w^- are defined in the same way as f^+ and f^-. At $\psi = 0$,

$$w^+ = w^-, \tag{18}$$

$$w_\psi^- - \rho w_\psi^+ - \nu w + \tau w_{xx} = \frac{3}{2}(w_\psi^-)^2 - \frac{3\rho}{2}(w_\psi^+)^2 + F_1^*(w), \tag{19}$$

where $b = (1 - \rho)/2$ and

$$\begin{aligned} F_1^*(w) = & (1 + w_x^2)^{3/2} \left(\frac{w_x^2}{2(1 + w_\psi^-)^2} - \frac{\rho w_x^2}{2(1 + w_\psi^+)^2} \right) \\ & + \left(\frac{\nu w - (2 w_\psi^- + (w_\psi^-)^2)}{2(1 + w_\psi^-)^2} + \frac{\rho(2 w_\psi^+ + (w_\psi^+)^2)}{2(1 + w_\psi^+)^2} \right) \\ & \times ((1 + w_x^2)^{3/2} - 1) + \frac{1}{2}(1 + w_\psi^-)^{-2} - \frac{1 - 2 w_\psi^- + 3(w_\psi^-)^2}{2} \\ & - \rho/2(1 + w_\psi^+)^{-2} + \frac{\rho(1 - 2 w_\psi^+ + 3(w_\psi^+)^2)}{2}; \end{aligned}$$

at $\psi = -1$,

$$w^- = 0; \tag{20}$$

at $\psi = h$,

$$w^+ = 0. \tag{21}$$

3. Formal derivation. Assume that w and ν have asymptotic expansions of the following form:

$$w = \epsilon w_1 + \epsilon^2 w_2 + \cdots , \tag{22}$$

$$\nu = \lambda_0 + \epsilon \lambda_1 . \tag{23}$$

Substitution of (22) and (23) with x replaced by $\epsilon^{-1/2}x$ in (17) to (21) yields the equations for the first approximation

$$\begin{aligned} &w_{1\psi\psi} = 0 \quad \text{in } -1 < \psi < 0, \qquad 0 < \psi < h, \\ &w_1^+ = w_1^-, \qquad w_{1\psi}^- - \rho w_{1\psi}^+ - \lambda_0 w_1^- = 0 \quad \text{at } \psi = 0, \\ &w_1^- = 0 \quad \text{at } \psi = -1, \quad w_1^+ = 0 \quad \text{at } \psi = h. \end{aligned}$$

By using these equations it is easy to get

$$w_1^+ = \eta(x)(\psi - h), \qquad w_1^- = -h\eta(x)(\psi + 1), \quad \lambda_0 = 1 + \frac{\rho}{h}.$$

For the second approximation from the equations,

$$\begin{aligned} &w_{2\psi\psi} = - w_{1xx} \quad \text{in } -1 < \psi < 0, \quad 0 < \psi < h, \\ &w_2^+ = w_2^-, w_{2\psi}^- - \rho w_{2\psi}^+ - \lambda_0 w_2^- = \lambda_1 w_1^- - \tau w_{1xx}^- \\ &\qquad + \frac{3}{2}(w_{1\psi}^-)^2 - \frac{3\rho}{2}(w_{1\psi}^+)^2 \quad \text{at } \psi = 0, \\ &w_2^- = 0 \quad \text{at } \psi = -1; \qquad w_2^+ = 0 \quad \text{at } \psi = h. \end{aligned}$$

By using the solvability condition for w_2, we can have the following equation for $\eta(x)$:

$$\left(\tau - \frac{1 + \rho h}{3}\right) \eta_{xx} - \lambda_1 \eta + \frac{3}{2}\left(h - \frac{\rho}{h}\right) \eta^2 = 0. \tag{24}$$

The solution of (24), which decays at infinity, is

$$\eta(x) = \left(\frac{\lambda_1 h}{h^2 - \rho}\right) \operatorname{sech}^2 \left(\left(\frac{\lambda_1}{\tau - \tau_0}\right)^{1/2} \frac{x}{2}\right), \tag{25}$$

if $\rho \neq h^2$ but not near h^2 and $\tau \neq \tau_0 = (1 + \rho h)/3$ but not near τ_0. In the following we shall show that (25) indeed yields an asymptotic approximation to the solution of (17)–(21) when ν is sufficiently close to $1 + (\rho/h)$, $\rho \neq h^2$ but not near h^2, and $\tau > \tau_0$ but not near τ_0.

4. Existence theorem.

4.1. Preliminaries. In the following we always assume that $\rho \neq h^2$ but not near h^2, and $\tau > \tau_0$ but not near τ_0 unless specified otherwise. Let

$$\begin{aligned} &\nu = \lambda_0 + \lambda_1 \epsilon = \left(1 + \frac{\rho}{h}\right) + \lambda_1 \epsilon, \qquad \lambda_1 > 0, \\ &w^+(x, \psi) = \epsilon(\eta(x)(\psi - h) + \theta^+(x, \psi)) \quad \text{for } 0 < \psi < h, \\ &w^-(x, \psi) = \epsilon(\eta(x)(\psi + 1)(-h) + \theta^-(x, \psi)) \quad \text{for } -1 < \psi < 0. \end{aligned}$$

Substitute these expressions for w^+ and w^- in (17)–(21) and obtain

$$\theta^+_{\psi\psi} + \theta^+_{xx} = -\eta_{xx}(\psi - h) + \frac{1}{\epsilon}F_1(w^+) = F_2^+(x,\psi), \qquad 0 < \psi < h, \tag{26}$$

$$\theta^-_{\psi\psi} + \theta^-_{xx} = h\eta_{xx}(\psi + 1) + \frac{1}{\epsilon}F_1(w^-) = F_2^-(x,\psi), \qquad -1 < \psi < 0; \tag{27}$$

at $\psi = 0$,

$$\theta^+(x,0) = \theta^-(x,0), \tag{28}$$

$$\begin{aligned} \theta^-_\psi - \rho\theta^+_\psi - \lambda_0\theta^- + \tau\theta_{xx} &= \tau h\eta_{xx} + \lambda_1\epsilon(-h\eta + \theta^-) \\ &\quad + \frac{3}{2}\epsilon(-h\eta + \theta^-_\psi)^2 - \frac{3\rho}{2}\epsilon(\eta + \theta^+_\psi)^2 + F_1^*(w)\epsilon^{-1} \\ &= \tau h\eta_{xx} - \lambda_1 h\eta\epsilon + \frac{3}{2}\epsilon h^2\eta^2 - \frac{3\rho}{2}\epsilon\eta^2 + F_2^*(\eta,\theta) \\ &= G_1(x); \end{aligned} \tag{29}$$

at $\psi = -1$,

$$\theta^- = 0; \tag{30}$$

at $\psi = h$,

$$\theta^+ = 0\,. \tag{31}$$

Since

$$j(\psi) = \begin{cases} \psi - h, & 0 < \psi < h, \\ (\psi + 1)(-h), & -1 < \psi < 0, \end{cases}$$

is the nontrivial solution of the homogeneous equations (26)–(31); to solve θ from (26)–(31) we impose the following solvability condition:

$$\int_{-1}^{0} F_2^-(x,\psi)(-h)(\psi + 1)d\psi + \rho\int_0^h F_2^+(x,\psi)(\psi - h)d\psi + hG_1(x) = 0, \tag{32}$$

which was used in the formal derivation of (24). As we shall see later, this condition excludes the function $j(\psi)$ in the eigenfunction expansion of $\theta(x,\psi)$. From (17), (26), (27), (29), and (32), we obtain an equation for η,

$$\begin{aligned} &\left(\tau - \frac{1+\rho h}{3}\right)\eta_{xx} - \lambda_1\eta\epsilon + \frac{3h}{2}\epsilon\eta^2 - \frac{3\rho}{2h}\epsilon\eta^2 \\ &= \frac{1}{h^2}\left(-F_2^*(\eta,\theta) - \int_{-1}^{0}\frac{1}{\epsilon}F_1(w^-)(-h)(\psi + 1)d\psi - \rho\int_0^h \frac{1}{\epsilon}F_1(w^+)(\psi - h)d\psi\right) \\ &= \Psi^*(\eta,\theta). \end{aligned} \tag{33}$$

Since

$$S(x) = \left(\frac{\lambda_1 h}{h^2 - \rho}\right)\operatorname{sech}^2\left(\left(\frac{\lambda_1}{\tau - \tau_0}\right)^{1/2}\frac{\epsilon^{1/2}x}{2}\right) \tag{34}$$

is a solution of (33) with $\Psi^*(\eta,\theta)=0$, we write

$$\eta(x)=S(x)+\omega(x).$$

Then from (33), we have

$$\begin{aligned}(\tau-\tau_0)\omega_{xx}-\lambda_1\omega\epsilon+3\left(h-\frac{\rho}{h}\right)\epsilon S\omega \\ =-\frac{3}{2}\left(h-\frac{\rho}{h}\right)\epsilon\omega^2+\Psi^*(S+\omega,\theta) \\ =\Psi(\omega,\theta)(\tau-\tau_0).\end{aligned} \tag{35}$$

Also from (26), (27), and (29), we write

$$\begin{aligned}&F_2^+(x,\psi)=F^+(\omega,\theta),F_2^-(x,\psi)=F^-(\omega,\theta),\\ &G_1(x)=G(\omega,\theta).\end{aligned}$$

Our goal is to find a small solution of (26)–(31) and (35) when ϵ is small. Before we prove the existence theorem, let us define some Banach spaces to be used later.

We denote $H^s(\mathbf{R})$ as the usual Sobolev space on $\mathbf{R}$ with $s\geq 0$,

$$\begin{aligned}X^s=&\{f(x)\in L^2(\mathbf{R},\mathbf{R})\mid f(x)\cosh(\mu\epsilon^{1/2}x)\in H^s(\mathbf{R})\ \text{ with } f \text{ even and}\\ &\|f\|_{X^s}=\|f(x)\cosh(\mu\epsilon^{1/2}x)\|_{H^s(\mathbf{R})}\},\end{aligned}$$

where μ is a small constant to be determined later, and

$$\begin{aligned}Y^s=\Bigg\{&f(x,y)\in L^2(\mathbf{R}\times((-1,0)\cup(0,h)))\mid f(\cdot,y)\in X^s \text{ for almost all}\\ &y \text{ and } \|f\|_{Y^s}^2=\int_{-1}^{h}\|f\|_{X^s}^2dy<+\infty\Bigg\}.\end{aligned}$$

Define for $s\geq 2$,

$$\begin{aligned}B^s=\Bigg\{&f(x,y)\in L^2(\mathbf{R}\times((-1,0)\cup(0,h)))\ \Bigg|\ \frac{\partial^m f(x,y)}{\partial y^m}\in Y^{s-m},f^+(x,0)=f^-(x,0),\\ &\text{for } 0\leq m\leq 2,\left.\frac{\partial f^\pm(x,y)}{\partial y}\right|_{y=0}\in X^{s-2},\quad \text{with norm}\\ &\|f\|_{B^s}=\sum_{j=0}^{2}\{\|D^jf\|_{Y^{s-2}}+\|D_x^jf(\cdot,0)\|_{X^{s-2}}\}+\|f_y^\pm(\cdot,0)\|_{X^{s-2}}<+\infty\Bigg\},\end{aligned}$$

where $B^s\supset X^s$. Now we study (26)–(31) and (35) separately.

4.2. Auxiliary condition. First we take up (35). Let

$$\begin{aligned}\mathcal{L}(\omega)&=\omega_{xx}-\frac{\lambda_1}{\beta}\omega\epsilon+3\left(h-\frac{\rho}{h}\right)\epsilon\frac{S\omega}{\beta}\\ &=\Psi\quad \text{for } 0<x<+\infty,\end{aligned} \tag{36}$$

$$\omega_x = 0 \quad \text{at} \ x = 0, \quad \text{where } \beta = \tau - \tau_0.$$

The homogeneous equation $\mathcal{L}(\omega) = 0$ possesses two linearly independent solutions

$$\varphi(x) = -\left(\frac{\lambda_1^3}{\beta}\right)^{1/2} \operatorname{sech}^2 t \tanh t,$$

$$\psi(x) = -2\beta(\lambda_1^2 \epsilon^{1/2})^{-1}(\operatorname{sech}^2 t)(\tanh t)\left(5\left(\frac{3t}{8} + \frac{3}{8}(\sinh t)\cosh t + \frac{1}{4}(\sinh t)\cosh^3 t\right) - (\cosh^5 t)\sinh^{-1} t\right),$$

where $t = \frac{1}{2}(\lambda_1\epsilon/\beta)^{1/2}x$, $\varphi(x)$ and $\psi(x)$ are, respectively, odd and even functions. Assume $f(x)$ is bounded and even. Then

$$\begin{aligned} &\mathcal{L}(\omega) = f, \qquad 0 < x < +\infty, \\ &\omega_x = 0 \quad \text{at} \ x = 0, \end{aligned} \tag{37}$$

has the solution

$$\begin{aligned} \omega(x) &= \varphi(x)\int_0^x \psi(s)f(s)ds + \psi(x)\int_x^{+\infty} \varphi(s)f(s)ds \ \text{ for } x \geq 0 \\ &= \int_0^{+\infty} k^*(x,s)f(s)ds, \end{aligned} \tag{38}$$

and

$$\omega(x) = \int_0^{+\infty} k^*(-x,s)f(s)ds \quad \text{for } x < 0.$$

In the following we prove two lemmas for the estimates of $\omega(x)$.

LEMMA 1. *If $f(x) \in X^s$, $s \geq 0$ and μ is small, then*

$$\|\omega(x)\|_{X^{s+2}} \leq K\epsilon^{-1}\|f(x)\|_{X^s},$$

where K is independent of ϵ and $f(x)$.

Proof. Here we only prove the case $s = 0$. The proofs of other cases are the same. From (38) we know that if $f(x)$ is even; $\omega(x)$ is also even; therefore,

$$\begin{aligned} \|\omega(x)\cosh(\mu\epsilon^{1/2}x)\|^2_{L^2(\mathbf{R})} &\leq K\int_0^{+\infty} |\omega(x)\cosh(\mu\epsilon^{1/2}x)|^2 dx \\ &\leq K\int_0^{+\infty}\left(\int_0^{+\infty} |k^*(x,s)\cos(\mu\epsilon^{1/2}x)f(s)|ds\right)^2 dx \\ &= K\int_0^{+\infty}\left(\int_0^{+\infty} k'(x,s)g(s)ds\right)^2 dx = I, \end{aligned}$$

where

$$\begin{aligned} k'(x,s) &= |k^*(x,s)|\cosh(\mu\epsilon^{1/2}x)\cosh^{-1}(\mu\epsilon^{1/2}s), \\ g(s) &= f(s)\cosh(\mu\epsilon^{1/2}s), \end{aligned}$$

and

$$\begin{aligned} I &\le K\int_0^{+\infty}\int_0^{+\infty} k'(x,t)dt\int_0^{+\infty} k'(x,s)g^2(s)dsdx \\ &\le K\left(\max\left(\sup_s\int_0^{\infty} k'(x,s)dx, \sup_x\int_0^{+\infty} k'(x,s)ds\right)\right)^2 \|g(s)\|_{L^2}^2 . \end{aligned}$$

But

$$\begin{aligned} \int_0^{+\infty} k'(x,s)dx &\le K\Bigg(\int_0^{s} |\varphi(s)\psi(x)\mid \exp(\mu\epsilon^{1/2}(x-s))dx \\ &\qquad + \int_s^{+\infty} |\varphi(x)\psi(s)| \exp(\mu\epsilon^{1/2}(x-s))dx\Bigg) \\ &\le K\epsilon^{-1/2}\Bigg(\int_0^{s} \exp\left(\frac{\lambda_1\epsilon}{\beta}^{1/2}\frac{1}{2}(x-s) - \mu\epsilon^{1/2}(x-s)\right) dx \\ &\qquad + \int_s^{+\infty} \exp\left(\frac{\lambda_1\epsilon}{\beta}^{1/2}\frac{1}{2}(s-x) - \mu\epsilon^{1/2}(x-s)\right) dx\Bigg) \\ &\le K\epsilon^{-1} , \end{aligned}$$

if $0 < \mu < \frac{1}{2}(\lambda_1/\beta)^{1/2}$. The same is true for $\int_0^{+\infty} k'(x,s)ds$. Thus

$$\|\omega(x)\|_{X^0} \le K\epsilon^{-1}\|f(x)\|_{X^0} .$$

Also

$$\|\omega\|_{X^1}^2 \le K(\|\omega'(x)\cosh(\mu\epsilon^{1/2}x)\|_{L^2(\mathbf{R})}^2 + \|\omega\|_{X^0}^2) ,$$

and we only need to get the estimate for $\|\omega'(x)\cosh(\mu\epsilon^{1/2}x)\|_{L^2(\mathbf{R})}^2$. But from (38) we have

$$\begin{aligned} \omega'(x) &= \varphi'(x)\int_0^{x} \psi(s)f(s)ds + \psi'(x)\int_x^{+\infty} \varphi(s)f(s)ds \quad \text{for } x \ge 0 \\ &= \int_0^{+\infty} k_1^*(x,s)f(s)ds, \end{aligned}$$

where $\omega'(x)$ is odd and $k_1^*(x,s)$ has the same asymptotic behavior as $k^*(x,s)$, where x or s is large. Therefore, by the same argument, we have

$$\|\omega(x)\|_{X^1} \le K\epsilon^{-1}\|f\|_{X^0} .$$

However, $\omega(x)$ satisfies (37), and from (37) and the estimates of $\omega(x)$ in X^1, we have

$$\|\omega(x)\|_{X^2} \le K\epsilon^{-1}\|f\|_{X^0} ,$$

if $0 < \mu < (\lambda_1/4\beta)^{1/2}$. Also we have the following lemma, the proof of which is omitted.

LEMMA 2. *If* $u_1 \in H^s(\mathbf{R})$, $u_2 \in X^s$, $s \ge 1$, *then*

$$\|u_1u_2\|_{X^s} \le K\|u_1\|_{H^s}\|u_2\|_{X^s}.$$

Then by checking term by term in $\Psi(w,\theta)$ carefully and using Lemmas 1 and 2, we have the following.

THEOREM 1. *If $\omega, \theta \in B^s$ and $\|\omega\|_{B^s} = \|\omega\|_{X^s} \leq K\epsilon^{1/2}$, $\|\theta\|_{B^s} \leq K\epsilon$ (or $K\epsilon^{1/2}$) with $s \geq 3$, then $\Psi(\omega, \theta) \in X^{s-2}$,*

$$\|\Psi(\omega,\theta)\|_{X^{s-2}} \leq K\epsilon^2 \quad (or\ K\epsilon^{3/2}),$$

and

$$\|\mathcal{L}^{-1}\Psi(\omega,\theta)\|_{X^s} \leq K\epsilon \quad (or\ K\epsilon^{1/2}),$$

where

$$\mathcal{L}^{-1}\Psi(\omega,\theta) = \begin{cases} \displaystyle\int_0^{+\infty} k^*(x,s)\Psi(\omega,\theta)ds, & x \geq 0, \\ \displaystyle\int_0^{+\infty} k^*(-x,s)\Psi(\omega,\theta)ds, & x < 0. \end{cases}$$

4.3. Partial differential equations. Now we consider (26)–(31). First let us discuss the following equations:

(39) $$u^-_{xx} + u^-_{\psi\psi} = \varphi^-_1(x,\psi), \qquad -\infty < x < +\infty, \quad -1 < \psi < 0,$$

(40) $$u^+_{xx} + u^+_{\psi\psi} = \varphi^+_1(x,\psi), \qquad -\infty < x < +\infty, \quad 0 < \psi < h;$$

at $\psi = 0$,

(41) $$u^+(x,0) = u^-(x,0),$$

(42) $$\tau^{-1}(u^-_\psi - \rho u^+_\psi - \lambda_0 u^-) + u^-_{xx} = \varphi_2(x);$$

at $\psi = -1$,

(43) $$u^- = 0;$$

at $\psi = h$,

(44) $$u^+ = 0.$$

Here $\varphi_1(x,\psi) \in B^s$ and $\varphi_2(x) \in X^s$ for $s \geq 2$. Following Beale [8], we make use of the family of eigenfunctions of ψ satisfying

(45) $$v_{\psi\psi} - \sigma v = 0 \quad \text{in } -1 < \psi < 0 \quad \text{and} \quad 0 < \psi < h\,,$$

(46) $$v^+ = v^-, v^-_\psi - \rho v^+_\psi - \lambda_0 v^- - \tau\sigma v^- = 0 \quad \text{at } \psi = 0,$$

(47) $$v^- = 0 \quad \text{at } \psi = -1; \qquad v^+ = 0 \quad \text{at } \psi = h\,.$$

To discuss the completeness of the eigenfunctions of (45)–(47), first let us set up some Hilbert space. Let $(f(\psi), q) \in (L^2(-1,h)) \times \mathbf{R}$, where q is a constant and define

(48) $$\langle (f,q),(g,r)\rangle = \int_{-1}^0 f^-g^-d\psi + \rho\int_0^h f^+g^+d\psi - \tau qr,$$

(49) $$|(f,q)|^2 = \langle (f,q),(f,q)\rangle\,.$$

Then define

$$H = \left\{ (f,q) \in (L^2(-1,h)) \times \mathbf{R} \,\middle|\, \int_{-1}^{0} f^-(\psi)(-h)(\psi+1)d\psi \right.$$
$$+ \rho \int_0^h f^+(\psi)(\psi - h)d\psi + \tau h q = 0 \text{ and the norm is}$$
$$\left. \text{defined by (49)} \right\}.$$

We show that $\langle (f,q),(g,r)\rangle$ is an inner product. Since the proofs of other conditions are straightforward, the only thing that we need to prove is

$$\langle (f,q),(f,q)\rangle > 0,$$

if $0 \neq (f,q) \in H$. Let $u^* = -h(\psi+1)$ for $-1 < \psi < 0$, $u^* = \rho(\psi - h)$ for $0 < \psi < h$. Then if $(f,q) \in H$,

$$q = \frac{\int_{-1}^h f u^* d\psi}{-h\tau}.$$

So

$$q^2 \le (h\tau)^{-2} \left(\int_{-1}^0 (f^-)^2 d\psi + \int_0^h (\rho^{1/2} f^+)^2 d\psi \right)$$
$$\times \left(\int_{-1}^0 h^2(\psi+1)^2 + \rho \int_0^h (\psi - h)^2 d\psi \right)$$
$$= \tau^{-2}(1+\rho h) \frac{\int_{-1}^0 (f^-)^2 d\psi + \rho \int_0^h (f^+)^2 d\psi}{3}.$$

Therefore, by (48) and (49),

$$|(f,q)|^2 \ge (1 - (3\tau)^{-1}(1+\rho h)) \left(\int_{-1}^0 (f^-)^2 d\psi + \rho \int_0^h (f^+)^2 d\psi \right).$$

Thus if $\tau > \tau_0$, $|(f,q)| > 0$ unless $(f,q) = 0$. Hence H is a Hilbert space in reference to the inner product (48). Note that $|(f,q)|$ is equivalent to the norm $\|(f,q)\| = (\|f\|_{L^2}^2 + |q|^2)^{1/2}$ for $(f,q) \in H$.

LEMMA 3. *The space H is a Hilbert space.*

The condition imposed on any two functions in H is the orthogonal condition with the eigenfunction of (45)–(47) corresponding to $\sigma = 0$ under the inner product $\langle \cdot , \cdot \rangle$, and H is a closed subspace in $(L^2(-1,h) \times \mathbf{R})$. Hence H is a Hilbert space.

Next, we define an operator in H:

$$\mathcal{A}(u,q) = \left(u_{\psi\psi}, \tau^{-1}(u_\psi^- - \rho u_\psi^+ - \lambda_0 u^-)\Big|_{\psi=0} \right), \tag{50}$$

with

$$D(\mathcal{A}) = \{(u,q) \in H \mid u^- \in H^2(-1,0), u^+ \in H^2(0,h),$$
$$u^-(0) = u^+(0) = q, u^-(-1) = 0 = u^+(h)\}.$$

Obviously the solutions of (45)–(47) correspond to the eigenfunctions of $\mathcal{A}$ in H with eigenvalue σ and $\mathcal{A}$ closed and densely defined. The equality
(51)

$$\begin{aligned}\langle \mathcal{A}(u,q),(v,r)\rangle &= \int_{-1}^{0} u^{-}_{\psi\psi}v^{-}d\psi + \rho\int_{0}^{h} u^{+}_{\psi\psi}v^{+}d\psi - r(u^{-}_{\psi} - u^{+}_{\psi} - \lambda_0 u^{-})v^{+}\Big|_{\psi=0} \\ &= -\left(\int_{-1}^{0} u^{-}_{\psi}v^{-}_{\psi}d\psi + \rho\int_{0}^{h} u^{+}_{\psi}v^{+}_{\psi}d\psi\right) + \lambda_0 u^{-}(0)v^{-}(0),\end{aligned}$$

for $(u,q),(v,r) \in D(\mathcal{A})$, shows that $\mathcal{A}$ is symmetric with respect to $\langle\ \cdot\ ,\ \cdot\ \rangle$, and implies that all eigenvalues of $\mathcal{A}$, if they exist, must be real. By (51) and the Schwarz inequality,

$$\langle \mathcal{A}(u,q),(u,q)\rangle = -\left(\int_{-1}^{0}(u^{-}_{\psi})^2 d\psi + \rho\int_{0}^{h}(u^{+}_{\psi})^2 d\psi\right) + \lambda_0(u^{-}(0))^2 < 0,$$

if $(u,q) \in D(\mathcal{A})$ since

$$\begin{aligned}(u^{-}(0))^2 &= \left(\int_{-1}^{0} u^{-}_{\psi}d\psi\right)^2 \leq \int_{-1}^{0}(u^{-}_{\psi})^2 d\psi, \\ (u^{+}(0))^2 &= \left(\int_{0}^{h} u^{+}_{\psi}d\psi\right)^2 \leq h\int_{0}^{h}(u^{+}_{\psi})^2 d\psi,\end{aligned}$$

and $\lambda_0 = 1 + (\rho/h)$, where the equalities hold if and only if $u = j(\psi)$ defined in (32), which is not in H. This shows that all eigenvalues of $\mathcal{A}$ are nonpositive. From (51), H is invariant under $\mathcal{A}$. In order to show that the eigenfunctions of $\mathcal{A}$ is a basis of H, it suffices to show that $(\mathcal{A} - \sigma)^{-1}$ exists and is compact in H for some $\sigma > 0$. But $(\mathcal{A} - \sigma)(u, u(0)) = (f, q)$ is equivalent to solve

$$\begin{aligned}&u_{\psi\psi} - \sigma u = f \quad \text{in} \quad -1 < \psi < 0 \quad \text{and} \quad 0 < \psi < h, \\ &u^{+}(0) = u^{-}(0), u^{-}_{\psi} - \rho u^{+}_{\psi} - \lambda_0 u^{-} - \tau\sigma u^{-} = \tau q \quad \text{at} \ \psi = 0, \\ &u^{-} = 0 \quad \text{at} \ \psi = -1; \qquad u^{+} = 0 \quad \text{at} \ \psi = h.\end{aligned}$$

Then the solution of the above equations is easily obtained as follows:

$$\begin{aligned}u^{+} = -\frac{a(\psi - h)}{h} + \Bigg(&\sinh\sigma^{1/2}(\psi - h)\int_{0}^{\psi}\sinh\sigma^{1/2}\psi\left(f^{+} - \frac{a\sigma(\psi - h)}{h}\right)d\psi \\ &+ \sinh\sigma^{1/2}\psi\int_{\psi}^{h}\sinh\sigma^{1/2}(\psi - h)\left(f^{+} - \frac{a\sigma(\psi - h)}{h}\right)d\psi\Bigg) \\ &\Big/(\sigma^{1/2}\sinh\sigma^{1/2}h),\end{aligned}$$

$$\begin{aligned}u^{-} = a(\psi + 1) + \Bigg(&\sinh\sigma^{1/2}\psi\int_{-1}^{\psi}\sinh\sigma^{1/2}(\psi + 1)(f^{-} + a\sigma(\psi + 1))d\psi \\ &+ \sinh\sigma^{1/2}(\psi + 1)\int_{\psi}^{0}\sinh\sigma^{1/2}\psi(f^{-} + a\sigma(\psi + 1))d\psi\Bigg) \\ &\Big/(\sigma^{1/2}\sinh\sigma^{1/2}),\end{aligned}$$

where

$$a = \Gamma^{-1}(\sigma)\left(\tau q - (\sinh\sigma^{1/2})^{-1}\int_{-1}^{0}\sinh\sigma^{1/2}(\psi+1)f^{-}d\psi\right.$$
$$\left.+\rho(\sinh\sigma^{1/2}h)^{-1}\int_{0}^{h}\sinh\sigma^{1/2}(\psi-h)f^{+}d\psi\right),$$

and

$$\Gamma(\sigma) = \sigma^{1/2}(\mathrm{tanh}\sigma^{1/2})^{-1} + \rho\sigma^{1/2}(\mathrm{tanh}\sigma^{1/2}h)^{-1} - \lambda_0 - \tau\sigma \neq 0$$

for all $\sigma > 0$ as shown in the Appendix. Obviously $(u, u(0))$ constructed in this way is in H if $(f, q) \in H$. By standard arguments it is not difficult to show that $(\mathcal{A}-\sigma)^{-1}$ on H is compact. Furthermore, it follows that there are countably infinitely many eigenvalues, and the range of $(\mathcal{A}-\sigma)^{-1}$ is $D(\mathcal{A})$. Also in the Appendix the asymptotic behavior of these eigenvalues is given.

We summarize the results as follows.

LEMMA 4. *The system* (45)–(47) *has solutions* $v = v_n$, $\sigma = \sigma_n$, $n = 1, 2, \ldots$, *where* $(v_n(\psi), v_n(0)) \in H$, $\sigma_n < 0$. *The vectors* $(v_n(\psi), v_n(0))$, $n = 1, 2, \ldots$, *form a basis of* H *and are orthonormal with respect to the inner product* (50). *Here* $|\sigma_n| \cong K_1 n^2$ *for large* n *where* $K_1 \geq c > 0$ *with* c *fixed.*

Now we can deal with (39)–(44). Assume that $(\varphi_1(x,\psi), \varphi_2(x)) \in H$ for all $x \in \mathbf{R}$. By Lemma 4, we have

$$(\varphi_1(x,\psi), \varphi_2(x)) = \sum_{n=1}^{\infty} a_n(x)(v_n(\psi), v_n(0)),$$

where the convergence is under the norm (49) and

$$(52)\qquad a_n(x) = \int_{-1}^{0}\varphi_1^{-}(x,\psi)v_n^{-}(x)d\psi + \rho\int_{0}^{h}\varphi_1^{+}(x,\psi)v_n^{+}(x)d\psi - \tau\varphi_2(x)v_n(0).$$

Multiplying (39) and (40) on both sides by $v_n(\psi)$ and integrating by parts twice we have

$$(53)\qquad C_{nxx}(x) + \sigma_n C_n(x) = a_n(x),$$

where

$$C_n = \int_{-1}^{0}u^{-}(x,\psi)v_n^{-}(\psi)d\psi + \rho\int_{0}^{h}u^{+}(x,\psi)v_n^{+}(\psi)d\psi - \tau u^{-}(x,0)v_n^{-}(0).$$

If $a_n(x)$ and $C_n(x)$ are even, by finding the Green's function of (53) and following the same proof as in Lemma 1, we have the following.

LEMMA 5. *If* $a_n(x) \in X^s$ *and* $C_n(x)$ *satisfies* (53), *then* $C_n(x) \in X^{s+2}$,

$$\|C_n\|_{X^{s+i}} \leq K|\sigma_n|^{-(2-i)/2}\|a_n(x)\|_{X^s} \quad \textit{for } i = 0, 1, 2.$$

Therefore,

$$(54)\qquad (u(x,\psi), u(x,0)) = \sum_{n=1}^{\infty} C_n(x)(v_n(\psi), v_n(0))$$

is in the Hilbert space H, and

$$(55)\qquad \sum_{n=1}^{\infty} \|C_n(x)\|^2_{X^{s+i}} \le K \sum_{n=1}^{\infty} |\sigma_n|^{-(2-i)} \|a_n(x)\|^2_{X^s} \quad \text{for } i = 0, 1, 2.$$

If $(u(x,\psi), u(x,0))$ is defined by (54), by (55) we have

$$\sum_{i=0}^{2} (\|D^i_x u(x,\psi)\|_{Y^s} + \|D^j_x u(x,0)\|_{X^s}) \le K(\|\varphi_1(x,\psi)\|_{Y^s} + \|\varphi_2\|_{X^s}).$$

Since $(u(x,\psi), u(x,0))$ satisfies (39)–(44); so by (39) and (40)

$$\|u_{\psi\psi}\|_{Y^s} \le K(\|\varphi_1\|_{Y^s} + \|\varphi_2\|_{X^s}),$$

and by usual interpolation theorems, the same is true of u_ψ. Then by using $u = 0$ on $\psi = -1$ and h and $u(x,0) \in X^s$, we can easily show that

$$u_\psi(x,\psi)\Big|_{\psi=\psi_s} \in X_s$$

and

$$\|u_\psi(x,\psi_s)\|_{X^s} \le K(\|\varphi_1\|_{Y^s} + \|\varphi_2\|_{X^s}),$$

where ψ_s is fixed and when $\psi_s \to 0$, $u_\psi(x,\psi_s)$ in the limit corresponds to $u^+_\psi(x,0)$, and $u^-_\psi(x,0)$. So

$$\|u^\pm_\psi(x,0)\|_{X^s} \le K(\|\varphi_1\|_{Y^s} + \|\varphi_2\|_{X^s}).$$

If $\varphi_1(x,\psi)$ and $\varphi_2(x)$ have continuous derivatives at least up to $2s+2$ order with respect to x and ψ and $(\varphi_1, \varphi_2) \in H$, then we may multiply (39) and (40) by u_{xx} and integrate by parts several times to obtain

$$(56)\qquad \|u_{x\psi}\|_{Y^s} \le K(\|\varphi_1\|_{Y^s} + \|\varphi_2\|_{X^s}).$$

For the general $\varphi_1(x,\psi) \in Y^s$ and $\varphi_2 \in X^s$ with $(\varphi_1, \varphi_2) \in H$ we can construct a sequence of smooth functions in H approaching (φ_1, φ_2), and by usual techniques in elliptic operator theory we get the a priori estimate (56).

Now combining all estimates obtained we have

$$(57)\qquad \|u\|_{B^{s+2}} \le K(\|\varphi_1\|_{Y^s} + \|\varphi_2\|_{X^s}),$$

if $\varphi_1 \in Y^s$ and $\varphi_2 \in X^s$ with $(\varphi_1, \varphi_2) \in H$. Therefore we summarize the above results as follows.

THEOREM 2. *If $\varphi_1 \in Y^s$, $\varphi_2 \in X^s$ and $(\varphi_1, \varphi_2) \in H$, then the solution $u(x,\psi)$ of* (39)–(44) *exists in B^{s+2}, is unique in H, and satisfies* (57).

Now we use the following notation to express the solution of (39)–(44) in terms of $(\varphi_1(x,\psi), \varphi_2(x))$,

$$(58)\qquad u(x,\psi) = \mathcal{P}^{-1}(\varphi_1(x,\psi), \varphi_2(x)).$$

Let us go back to (26)–(31). Write

$$\begin{aligned} F_2(x,\psi) &= F^*(\omega,\theta) = M_1(\omega) + \tilde{F}_2(\omega,\theta), \\ G_1(x) &= G^*(\omega,\theta) = M_2(\omega) + \tilde{G}_1(\omega,\theta), \end{aligned}$$

where $M_1(\omega)$ and $M_2(\omega)$ contain only the terms with $\omega_{xx}, \epsilon\omega$, and $\epsilon S\omega$, which appear in F_2 and G_1, respectively, and $\tilde{F}_2$ and $\tilde{G}_1$ are the remainders. By the derivation of (35) from (32), we can see that the left-hand side of (35) denoted as $(\tau - \tau_0)\mathcal{L}(\omega)$ in (36) is from (M_1, M_2) only, and the right-hand side of (35) is from $(\tilde{F}_2, \tilde{G}_1)$ and the left-hand side of (32) is equal to $(\tau - \tau_0)(\mathcal{L}(\omega) - \Psi)$. Since $\mathcal{L}^{-1}$ exists, define

$$\begin{aligned} F(\omega,\theta) &= M_1(\mathcal{L}^{-1}(\Psi(\omega,\theta))) + \tilde{F}_2(\omega,\theta), \\ G(\omega,\theta) &= M_2(\mathcal{L}^{-1}(\Psi(\omega,\theta))) + \tilde{G}_1(\omega,\theta), \end{aligned}$$

which is equivalent to (F_2, G_1) for this problem. If we use this (F, G) in (32), then $(F(\omega,\theta), G(\omega,\theta)) \in H$ for all ω, and θ since by a similar derivation of (35) from (32) and noting that $\mathcal{L}^{-1}$ only appears in (M_1, M_2) we have

$$\begin{aligned} &\int_{-1}^{0} F^-(\omega,\theta)(-h)(\psi+1)d\psi + \rho\int_0^h F^+(\omega,\theta)(\psi - h)d\psi + \tau h G(\omega,\theta) \\ &\quad = (\tau - \tau_0)(\mathcal{L}(\mathcal{L}^{-1}(\Psi(\omega,\theta))) - \Psi(\omega,\theta)) = 0. \end{aligned}$$

If we assume that $\theta(x,\psi) \in B^{s+2}$ and $\omega \in X^{s+2}$, then by checking the terms in F^+, F^- and G very carefully and using Lemma 2 and Theorem 1, we have $F \in Y^s$, $G \in X^s$, and

$$\|F\|_{Y^s} \le K\epsilon(\|\theta\|_{B^{s+2}} + \|\omega\|_{X^{s+2}}), \tag{59}$$

$$\|G\|_{X^s} \le K\epsilon(\|\theta\|_{B^{s+2}} + \|\omega\|_{X^{s+2}}). \tag{60}$$

By Theorem 2, we obtain the following.

THEOREM 3. *If $\theta(x,\psi) \in B^{s+2}$ and $\omega(x) \in X^{s+2}$ are bounded with respect to their respective norms, then the solution of* (26)–(31) *with F_2 and G_1 replaced by F and G, respectively, exists and satisfies*

$$\|\mathcal{P}^{-1}(F,G)\|_{B^{s+2}} \le K\epsilon(\|\theta\|_{B^{s+2}} + \|\omega\|_{X^{s+2}}).$$

4.4. The existence proof. Now we need to solve (26)–(31) and (35), which is equivalent to (32). We know that

$$(F_2(x,\psi), G_1(x)) = (F^*(\omega,\theta), G^*(\omega,\theta)) \in H$$

since (32) implies that (F_2, G_1) satisfies the orthogonal condition defined for the space H. Convert (35) to

$$\omega = \mathcal{L}^{-1}(\Psi(\omega,\theta)), \tag{61}$$

and (26) to (31) to

$$\theta = \mathcal{P}^{-1}(F_2(\omega,\theta), G_1(\omega,\theta)). \tag{62}$$

Then instead of solving (61) and (62) together, we solve the following equivalent equations:

$$\theta = \mathcal{P}^{-1}(F(\omega,\theta), G(\omega,\theta)) = \mathcal{T}_1(\theta,\omega), \tag{63}$$

$$\omega = \mathcal{L}^{-1}(\Psi(\omega, \mathcal{P}^{-1}(F(\omega,\theta), G(\omega,\theta)))) = \mathcal{T}_2(\theta,\omega), \tag{64}$$

since we need to use this substitution once to meet the condition in Theorem 1 and $(F, G) \in H$ to satisfy the condition in Theorem 3. Now we need to prove that when ϵ is small, (63) and (64) possess a fixed point. First we define a closed convex set in the Banach space $B^{s+2} \times X^{s+2}$ for $s \geq 2$,

$$\mathcal{S}_b = \{Z = (\theta,\omega) \in B^{s+2} \times X^{s+2} \mid \quad |||Z||| = \|\theta\|_{B^{s+2}} + \|\omega\|_{X^{s+2}} \leq b\epsilon^{1/2}\}.$$

Let

$$\mathcal{T}(\theta,\omega) = (\mathcal{T}_1(\theta,\omega), \mathcal{T}_2(\theta,\omega)).$$

Then we try to find a fixed point of the operator $\mathcal{T}$ in $\mathcal{S}_b$. From Theorems 1 and 3 it follows that $\mathcal{T}$ maps $\mathcal{S}_b$ into itself if $K\epsilon^{1/2} < b$, which is always possible if ϵ is small. Also by using similar proofs as in Theorem 1 and 3 we have

THEOREM 4. *If* $Z^{(1)} = (\theta^{(1)}, \omega^{(1)})$ *and* $Z^{(2)} = (\theta^{(2)}, \omega^{(2)}) \in \mathcal{S}_b$, *then*

$$|||\mathcal{T}(Z^{(1)}) - \mathcal{T}(Z^{(2)})||| \leq K\epsilon^{1/2}|||Z^{(1)} - Z^{(2)}|||.$$

Now we may choose $K\epsilon^{1/2} \leq \frac{1}{2}$ in Theorem 4 for smaller ϵ so that $\mathcal{T}$ maps $\mathcal{S}_b$ into $\mathcal{S}_b$ and is a contraction in $\mathcal{S}_b$. By contraction mapping theorem, there exists a unique point (θ_0, ω_0) so that

$$\theta_0 = \mathcal{P}^{-1}(F(\omega_0,\theta_0), G(\omega_0,\theta_0)),$$
$$\omega_0 = \mathcal{L}^{-1}(\Psi(\omega_0,\theta_0)),$$

or equivalently,

$$\theta_0 = \mathcal{P}^{-1}(F^*(\omega_0,\theta_0), G^*(\omega_0,\theta_0)),$$
$$\omega_0 = \mathcal{L}^{-1}(\Psi(\omega_0,\theta_0)).$$

Finally we have the following theorem.

THEOREM 5. *If* $\nu = (1 + (\rho/h)) + \lambda_1\epsilon$, $\lambda_1 > 0$, *then for small* $\epsilon > 0$, *there exists a solution of* (12)–(16) *in the form*

$$f^+(x,\psi) = \psi + \epsilon(\psi - h)S(x) + \epsilon((\psi - h)\omega(x) + \theta^+(x,\psi)) \quad \text{for } 0 < \psi < h,$$
$$f^-(x,\psi) = \psi - h\epsilon(\psi + 1)S(x) + \epsilon(-h(\psi + 1)\omega(x) + \theta^-(x,\psi)) \quad \text{for } -1 < \psi < 0,$$

where

$$S(x) = \frac{\lambda_1 h}{h^2 - \rho}\operatorname{sech}^2\left(\left(\frac{\lambda_1}{\tau - \tau_0}\right)^{1/2} \epsilon^{1/2}\frac{x}{2}\right),$$

and $\omega(x) \in X^s$, $\theta \in B^s$ *with*

$$\|\omega(x)\|_{X^s} \leq K\epsilon \quad \text{and} \quad \|\theta(x,\psi)\|_{B^s} \leq K\epsilon$$

for $s \geq 4$, *where* K *is a constant independent of* ϵ. *The interface is given by*

$$\eta = \epsilon(-h)S(x) + O(\epsilon^2),$$

and $S(x)$ is indeed a first-order approximation to the exact solution.

5. Formal equations for the critical cases. In this section several critical cases are considered when the parameters in the problem are near some critical values so that (24) no longer holds. We shall only present the formal results here, and a rigorous justification of case 2 in the following will be given in §6. Cases 1 and 3 are similar to the results in [6], and their justifications will be deferred to subsequent investigation.

Case 1. τ is near $(1+\rho h)/3$ but h^2 is not near ρ. In (17)–(21), we let

$$\begin{aligned} &w = \epsilon^2 w_1 + \epsilon^3 w_2 + \epsilon^4 w_3 + \cdots, \\ &\nu = \lambda_0 + \epsilon^2 \lambda_1, \qquad \tau = \frac{1+\rho h}{3} + \epsilon \tau_1, \end{aligned}$$

and replace x with $\epsilon^{-1/2}x$. The equations for the first approximation are

$$\begin{aligned} &w_{1\psi\psi} = 0 \quad \text{in} \quad -1 < \psi < 0, \quad 0 < \psi < h, \\ &w_1^- = w_1^+, \qquad w_{1\psi}^- - \rho w_{1\psi}^+ - \lambda_0 w^- = 0 \quad \text{at } \psi = h, \\ &w = 0 \quad \text{at} \quad \psi = -1 \quad \text{and} \quad h. \end{aligned}$$

It is easily found that

$$\begin{aligned} &w_1^+ = \eta(x)(\psi - h), \qquad w_1^- = -h\eta(x)(\psi + 1), \\ &\lambda_0 = 1 + \frac{\rho}{h}, \end{aligned}$$

where $\eta(x)$ has to be determined.

The equations for the second-order approximation are

$$\begin{aligned} &w_{2\psi\psi} = -w_{1xx} \quad \text{in} \quad -1 < \psi < 0, \quad 0 < \psi < h, \\ &w_2^+ = w_2^-, w_{2\psi}^- - \rho w_{2\psi}^+ - \lambda_0 w_2^- = -\frac{(1+\rho h)w_{1xx}}{3} \quad \text{at } \psi = 0, \\ &w_2 = 0 \quad \text{at } \psi = -1 \quad \text{and} \quad h. \end{aligned}$$

Then

$$\begin{aligned} w_2^+ &= -\eta_{xx}\left(\frac{\psi^3}{6} - \frac{h\psi^2}{2} + \frac{h^2\psi}{3}\right) - a(x)\frac{\psi - h}{h}, \\ w_2^- &= h\eta_{xx}\left(\frac{\psi^3}{6} + \frac{\psi^2}{2} + \frac{\psi}{3}\right) + a(x)(\psi + 1), \end{aligned}$$

where $a(x)$ is an unknown function. Finally we proceed to the equations for the third approximation:

$$\begin{aligned} &w_{3\psi\psi} = -w_{2xx} \quad \text{in} \quad -1 < \psi < 0, \quad 0 < \psi < h, \\ &w_3^+ = w_3^-, w_{3\psi}^- - \rho w_{3\psi}^+ - \lambda_0 w_3^- = \lambda_1 w_1^- - \tau_1 w_{1xx} \\ &\qquad - \frac{(1+\rho h)w_{2xx}}{3} + \frac{3}{2}(h^2 - \rho)\eta^2 \quad \text{at } \psi = 0, \\ &w_3 = 0 \quad \text{at} \quad \psi = -1 \quad \text{and} \quad h. \end{aligned}$$

To solve these equations, the following solvability condition on $\eta(x)$ must hold

$$\lambda_1 \eta - \frac{3}{2}\left(h - \frac{\rho}{h}\right)\eta^2 - \tau_1 \eta_{xx} + \frac{(1+\rho h)\eta_{xxxx}}{45} = 0,$$

where $w_1^+ = \eta(x)(\psi - h)$, $w_1^- = -h\eta(x)(\psi + 1)$.

If $\lambda_1 > 0$, $\tau_1 > 0$, and

$$\lambda_1 = \frac{1620}{169}\left(\frac{\tau_1^2}{1+\rho h}\right),$$

This equation has a solution [6]

$$\eta(x) = 1225\tau_1^2\left(\left(h - \frac{\rho}{h}\right)169(1+\rho h)\right)^{-1}\operatorname{sech}^4(\alpha x),$$

$$\alpha = \frac{1}{2}\left(\frac{45\tau_1}{13(1+\rho h)}\right)^{1/2}.$$

Case 2. ρ is near h^2, but τ is not near $(1+\rho h)/3$. In this case we let

$$w = \epsilon w_1 + \epsilon^2 w_2 + \epsilon^3 w_3 + \epsilon^4 w_4 + \cdots,$$
$$\nu = \lambda_0 + \epsilon^2\lambda_1, \quad h^2 = \rho + \epsilon^2\sigma, \quad x \to \epsilon^{-1}x,$$

and substitute them for w, ν, and h^2 in (17)–(21). By the equations for the successive approximations we obtain

$$\left(\tau - \frac{1+h^3}{3}\right)\eta_{xx} - \left(\lambda + \frac{\sigma}{h}\right)\eta + 2h(1+h)\eta^3 = 0,$$

which also holds for $\sigma = 0$. A solitary wave solution of the above modified K-dV equation is given by

$$\eta(x) = \left(\frac{\lambda_1 + \sigma/h}{h(1+h)}\right)^{1/2}\operatorname{sech}\left(\left(\frac{\lambda_1+\sigma/h}{(\tau-(1+h^3))/3}\right)^{1/2}x\right),$$

where $\lambda_1 + (\sigma/h) > 0$ and $\tau > (1+h^3)/3$.

Case 3. τ is near $(1+\rho h)/3$ and h^2 is near ρ. Now we let

$$w = \epsilon^2 w_1 + \epsilon^3 w_2 + \epsilon^4 w_3 + \epsilon^5 w_4 + \cdots,$$
$$\rho = h^2 - \epsilon^4\sigma, \quad \nu = \lambda_0 + \epsilon^4\lambda_1, \quad \tau = \frac{1+h^3}{3} + \tau_1\epsilon^2,$$

in (17)–(21) and replace x by $\epsilon^{-1}x$. As before, from the equations for the successive approximations, we obtain

$$\frac{h}{45}(1+h^5)\eta_{xxxx} + \frac{h^2}{3}\eta\eta_{xx}(1-h^2) - \tau_1 h\eta_{xx} + \frac{2h^2}{3}(1-h^2)\eta_x^2$$
$$+ (\sigma + \lambda_1 h)\eta - 2h^2(1+h)\eta^3 = 0,$$

where $w_1^+ = \eta(x)(\psi - h)$, $w_1^- = -h\eta(x)(\psi + 1)$. Using the methods in [15], [16], we find that if $\tau_1 > 0$, $(\sigma + \lambda_1 h)(1+h^5) = 90(8-a)(10-a)^{-2}\tau_1^2$, then

$$\eta(x) = \frac{ab^2}{4}\operatorname{sech}^2\frac{abx}{2},$$

where

$$\begin{aligned} a &= \frac{-7 \pm (49 + 120t)^{1/2}}{t}, \\ t &= \frac{(2/5)(1+h)(1+h^5)}{h(1-h^2)^2}, \\ b &= \left(\frac{6\tau_1}{(1-h^2)h(10-a)} \right)^{1/2}, \\ \alpha^2 &= \frac{15(1-h^2)h}{1+h^5}. \end{aligned}$$

We note that here $8 - a > 0$ as can be easily shown, and $\tau_1 > 0$ and $\rho < 1$ implies $1 - h^2 > 0$ for sufficiently small ϵ.

6. Critical case for ρ near h^2. In this section, we shall justify the asymptotic method for the derivation of a solitary wave solution when ρ is near h^2 and $\tau > (1 + \rho h)/3$ but not near $(1 + \rho h)/3$. Since the existence proof is rather similar to the one presented in §3, many detailed derivations will be omitted.

First we rewrite (17) in the following form:

$$\begin{aligned} w_{\psi\psi} + w_{xx} &= (2w_x w_{\psi x} - w_x^2 w_{\psi\psi} + 2w_x w_\psi w_{x\psi})(1 + w_\psi)^{-2} \\ &\quad + w_{\psi\psi} w_\psi (2 + w_\psi)(1 + w_\psi)^{-2} = L_1(w), \end{aligned} \tag{65}$$

in $-1 < \psi < 0$ and $0 < \psi < h$. If we let

$$\begin{aligned} &\rho = h^2 - \sigma\epsilon^2, \quad \nu = \lambda_0 + \lambda_1\epsilon^2, \quad \tau > \frac{1 + h^3}{3}, \\ &\lambda_0 = 1 + h, \\ &w^+ = \epsilon(\eta(x)(\psi - h) + \theta^+(x, \psi)), \\ &w^- = \epsilon(\eta(x)(\psi + 1)(-h) + \theta^-(x, \psi)); \end{aligned}$$

in (65), (18)–(21), we obtain

$$\theta^+_{\psi\psi} + \theta^+_{xx} = -\eta_{xx}(\psi - h) + \frac{1}{\epsilon} L_1^+(w^+) = L_2^+(x, \psi), \qquad 0 < \psi < h, \tag{66}$$

$$\theta^-_{\psi\psi} + \theta^-_{xx} = h\eta_{xx}(\psi + 1) + \frac{1}{\epsilon} L_1^-(w^-) = L_2^-(x, \psi), \qquad -1 < \psi < 0, \tag{67}$$

at $\psi = 0$,

$$\theta^+(x, 0) = \theta^-(x, 0), \tag{68}$$

$$\begin{aligned} \theta^-_\psi - h^2\theta^+_\psi - \lambda_0\theta^- + \tau\theta_{xx} &= \tau h\eta_{xx} - (\lambda_1 h + \sigma)\eta\epsilon^2 + 2h^2(1 + h)\eta^3\epsilon^2 \\ &\quad + P_1^*(\eta, \theta) = G_2(x), \end{aligned} \tag{69}$$

where

$$\begin{aligned} P_1^*(\eta, \theta) = &-\sigma\epsilon^2\theta^+_\psi + \lambda_1\epsilon^2\theta^- - 2h^2(1 + h)\eta^3\epsilon^2 + \frac{3}{2}\epsilon(-h\eta + \theta^-_\psi)^2 \\ &- \frac{3}{2}(h^2 - \sigma\epsilon^2)\epsilon(\eta + \theta^+_\psi)^2 - 2\epsilon^2(-h\eta + \theta^-_\psi)^3 \\ &+ 2(h - \sigma\epsilon^2)\epsilon^2(\eta + \theta^+_\psi)^3 + (\epsilon^{-1}F_1^*(w) + 2\epsilon^2(-h\eta + \theta^-_\psi)^3 \\ &- 2(h^2 - \sigma\epsilon^2)\epsilon^2(\eta + \theta^+_\psi)^3). \end{aligned}$$

At $\psi = -1$ and $\psi = h_0$,

$$\theta = 0. \tag{70}$$

By the same reasoning as before, the solvability condition

$$\int_{-1}^{0} L_2^-(x,\psi)(-h)(\psi+1)d\psi + h^2 \int_0^h L_2^+(x,\psi)(\psi-h)d\psi + hG_2(x) = 0$$

implies

$$\begin{aligned}
&\left(\tau - \frac{1+h^3}{3}\right)\eta_{xx} - \left(\lambda_1 + \frac{\sigma}{h}\right)\epsilon^2\eta + 2h(1+h)\eta^3\epsilon^2 \\
&= \frac{1}{h^2}\left(-P_1^*(\eta,\theta) - \int_{-1}^{0} \frac{1}{\epsilon} L_1^-(w^-)(-h)(\psi+1)d\psi \right. \\
&\qquad \left. - h^2 \int_0^h \frac{1}{\epsilon} L_1^+(w^+)(\psi - h)d\psi \right) \\
&= \Psi_1^*(\eta,\theta).
\end{aligned} \tag{71}$$

If $\Psi_1^*(\eta,\theta) = 0$, then

$$T(\epsilon x) = \left(\frac{\lambda_1 + (\sigma/h)}{h(1+h)}\right)^{1/2} \operatorname{sech}\left(\frac{\lambda_1 + (\sigma/h)}{(\tau - (1+h^3)/3)^{1/2}}\epsilon x\right),$$

is a solution of (71), provided that $\lambda_1 + (\sigma/h) > 0$ and $\tau > (1+h^3)/3$ but not near $(1+h^3)/3$. Now let

$$\eta(x) = T(\epsilon x) + \omega(x).$$

Then by (71), we have

$$\begin{aligned}
&(\tau - \tau_0)\omega_{xx} - \left(\lambda_1 + \frac{\sigma}{h}\right)\epsilon^2\omega + 6h(1+h)\epsilon^2 T^2(\epsilon x)\omega(x) \\
&= -2h(1+h)\epsilon^2(3T(\epsilon x)\omega^2(x) + \omega^3(x)) + \Psi_1^*(T(\epsilon x) + \omega(x), \theta) \\
&= \Psi_1(\omega,\theta),
\end{aligned} \tag{72}$$

where $\tau_0 = (1+h^3)/3$. We need to prove that (66)–(70) and (72) possess a small solution (ω,θ).

We define X^s, Y^s, and B^s as before except that we need $f(x)\cosh(\mu\epsilon x) \in H^s(\mathbf{R})$ in the definition of X^s instead of $f(x)\cosh(\mu\epsilon^{1/2}x) \in H^s(\mathbf{R})$. Since $\varphi(x) = T(\epsilon x)$ is a solution of (72) with $\Psi_1(\omega,\theta) = 0$, it is not difficult to construct another linearly independent solution $\psi(x)$ with $\psi'(0) = 0$. Also we assume that Wronskian $(\varphi,\psi) = -1$. Therefore, if we let all functions be even in x, the even solution in x of (72) is

$$\begin{aligned}
\omega(x) &= \varphi(x)\int_0^x \psi(s)\Psi_1(\omega,\theta)ds + \psi(x)\int_x^{+\infty} \varphi(s)\Psi_1(\omega,\theta)ds \\
&= \int_0^{+\infty} k_1^*(x,s)\Psi_1(\omega,\theta)ds \quad \text{for } x \geq 0,
\end{aligned}$$

and

$$\omega(x) = \int_0^{+\infty} k_1^*(-x,s)\Psi_1(\omega,\theta)ds \quad \text{for } x < 0 .$$

We write $\omega(x) = \mathcal{L}^{-1}(\Psi_1(\omega,\theta))$. Similar to Lemmas 1 and 2, we have the following.

LEMMA 6. *If $f(x) \in X^s$, $s \geq 0$ and μ is small, then*

$$\|\mathcal{L}^{-1}(f(x))\|_{X^{s+2}} \leq K\epsilon^{-2}\|f(x)\|_{X^s}.$$

LEMMA 7. *If $u_1 \in H^s(\mathbf{R})$, $u_2 \in X^s$, $s \geq 1$, then*

$$\|u_1u_2\|_{X^s} \leq K\|u_1\|_{H^s}\|u_2\|_{X^s}.$$

The proofs are the same as before and omitted. Note that the functions in X^s and Y^s here have the different decay rate with the functions of these spaces in §4 when $x \to \infty$. By a refinement of the proof of Lemma 6, we have the following.

LEMMA 8. *If $f(x) \in X^s$, $s \geq 0$ and μ is small, then*

$$\left\|\frac{d}{dx}(\mathcal{L}^{-1}(f))\right\|_{X^s} \leq K\epsilon^{-1}\|f(x)\|_{X^s} .$$

The proof is omitted. Note that to prove Lemma 8, differentiating $\varphi(x)$ and $\psi(x)$ once will introduce an ϵ-factor.

Now we can write $\Psi_1(\omega,\theta)$ as follows:

$$\begin{aligned}\Psi_1(\omega,\theta) &= \frac{\epsilon}{6}h(1-h^2)(\omega+T(\epsilon x))_x^2 + \Psi_2(\omega,\theta)\\ &= I_1 + \Psi_2(\omega,\theta) .\end{aligned}$$

If $\omega,\theta \in B^s$ and $\|\omega\|_{X^s} \leq K\epsilon^{1/2}$, $\|\theta\|_{B^s} \leq K\epsilon^2$ with $s \geq 3$, then $\Psi_1(\omega,\theta) \in X^{s-2}$ and $\|\Psi_2(\omega,\theta)\|_{X^{s-2}} \leq K\epsilon^3$ by checking the terms in $\Psi_2(\omega,\theta)$ and $\Psi_1(\omega,\theta)$. Now if $\|\omega_x\|_{X^{s-2}} \leq K\epsilon^{3/2}$, then $\|I_1\|_{X^{s-2}} \leq K\epsilon^3$. Therefore, by Lemmas 6, 7, and 8, we have the following.

THEOREM 6. *If $\omega,\theta \in B^s$, $\|\omega\|_{X^s} \leq K\epsilon^{1/2}$, $\|\theta\|_{B^s} \leq K\epsilon^2$, and $\|\omega_x\|_{X^{s-2}} \leq K\epsilon^{3/2}$, then*

$$\|\mathcal{L}^{-1}\Psi_1(\omega,\theta)\|_{X^s} \leq K\epsilon$$

and

$$\left\|\frac{d}{dx}\mathcal{L}^{-1}\Psi_1(\omega,\theta)\right\|_{X^{s-2}} \leq K\epsilon^2.$$

For the partial differential equations (66)–(70), we have exactly the same theorems as Theorems 2 and 3. Let

$$\begin{aligned}L_2(x,\psi) = L^*(\omega,\theta) &= M_1(\omega) + \tilde{L}_2(\omega,\theta),\\ G_2(x) = G^*(\omega,\theta) &= M_2(\omega) + \tilde{G}_2(\omega,\theta),\end{aligned}$$

where $M_1(\omega)$ and $M_2(\omega)$ have the terms with $\omega_{xx}, \epsilon^2\omega$, and $\epsilon^2T\omega$ only in L_2 and G_2, respectively, and $\tilde{L}_2$ and $\tilde{G}_2$ are the remainders. Define

$$\begin{aligned}L(\omega,\theta) &= M_1(\mathcal{L}^{-1}(\Psi_1(\omega,\theta))) + \tilde{L}_2(\omega,\theta),\\ G(\omega,\theta) &= M_2(\mathcal{L}^{-1}(\Psi_1(\omega,\theta))) + \tilde{G}_2(\omega,\theta),\end{aligned}$$

where $\mathcal{L}(\omega) = \Psi_1(\omega, \theta)$ is the same as (72). Then $(L(\omega,\theta), G(\omega,\theta)) \in H$ for all ω and θ by a similar proof as this for F and G in §4.3. If we use the same notation $\mathcal{P}^{-1}$ as in (58), then we have the following theorem.

THEOREM 7. *If $\theta(x,\psi) \in B^{s+2}$, $\omega \in X^{s+2}$ with $\|\theta\|_{B^{s+2}} \leq K\epsilon$, $\|\omega\|_{X^{s+2}} \leq K\epsilon^{1/2}$, then the solution of* (66)–(70) *with* (L_2, G_2) *replaced by* (L, G) *exists and satisfies*

$$\|\mathcal{P}^{-1}(L,G)\|_{B^{s+2}} \leq K\epsilon^2(\|\theta\|_{B^{s+2}} + \|\omega\|_{X^{s+2}}).$$

Now we need to solve

$$\theta = \mathcal{P}^{-1}(L_2, G_2) = \mathcal{P}^{-1}(L,G) = \mathcal{T}_1(\theta,\omega) \tag{73}$$

and

$$\omega = \mathcal{L}^{-1}(\Psi_1(\omega,\theta)) = \mathcal{R}_1(\theta,\omega) \tag{74}$$

when ϵ is small. Then we substitute (73) in (74) once to obtain

$$\omega = \mathcal{R}_1(\mathcal{T}_1(\theta,\omega),\omega) = \mathcal{R}_2(\theta,\omega), \tag{75}$$

and another substitution yields

$$\omega = \mathcal{R}_2(\mathcal{T}_1(\theta,\omega),\omega) = \mathcal{T}_2(\theta,\omega). \tag{76}$$

Obviously (76) is equivalent to (74). Let us define a closed convex set in the Banach space $B^{s+2} \times X^{s+2}$ for $s \geq 2$,

$$\begin{aligned}\mathcal{S}_b = \big\{Z = (\theta,\omega) \in B^{s+2} \times X^{s+2} \mid |||Z||| &= \|\omega\|_{X^{s+2}} \\ + \|\theta\|_{X^{s+2}} < +\infty, \|\omega\|_{X^{s+2}} &+ \epsilon^{-1}\|\theta\|_{B^{s+2}} + \epsilon^{-1}\|\omega_x\|_{X^s} \leq b\epsilon^{1/2}\big\}.\end{aligned}$$

Let

$$\mathcal{T}(\theta,\omega) = (\mathcal{T}_1(\theta,\omega), \mathcal{T}_2(\theta,\omega)).$$

Then by Theorems 6 and 7, we have that $\mathcal{T}$ maps $\mathcal{S}_b$ into itself if ϵ is small. By checking L and G term by term and using the proof of Theorem 7, we have that if $Z^{(1)}$, $Z^{(2)} \in \mathcal{S}_b$,

$$\begin{aligned}&\|\mathcal{T}_1(\theta^{(1)},\omega^{(1)}) - \mathcal{T}_1(\theta^{(2)},\omega^{(2)})\|_{B^{s+2}} \\ &\qquad \leq K\epsilon(\|\theta^{(1)} - \theta^{(2)}\|_{B^{s+2}} + \epsilon^{1/2}\|\omega^{(1)} - \omega^{(2)}\|_{X^{s+2}}).\end{aligned} \tag{77}$$

Also by checking the terms in Ψ_1 and using Theorem 6, we have that if $Z^{(1)}$, $Z^{(2)} \in \mathcal{S}_b$, then

$$\|\mathcal{R}_2(\theta^{(1)},\omega^{(1)}) - \mathcal{R}_2(\theta^{(2)},\omega^{(2)})\|_{X^{s+2}} \leq K(\|\theta^{(1)} - \theta^{(2)}\|_{B^{s+2}} + \epsilon^{1/2}\|\omega^{(1)} - \omega^{(2)}\|_{X^{s+2}}).$$

By the definition of $\mathcal{T}_2$ and (77), we have

$$\|\mathcal{T}_2(\theta^{(1)},\omega^{(1)}) - \mathcal{T}_2(\theta^{(2)},\omega^{(2)})\|_{X^{s+2}} \leq K\epsilon^{1/2}(|||Z^{(1)} - Z^{(2)}|||).$$

Therefore if $K\epsilon^{1/2} \leq \frac{1}{2}$, then $\mathcal{T}$ is a contraction and possesses a fixed point in $\mathcal{S}_b$. So (73) and (74) have a solution in $\mathcal{S}_b$. Finally we summarize our results in the following.

THEOREM 8. *If* $\nu = (1+h)+\lambda_1\epsilon^2$, $\rho = h^2-\sigma\epsilon^2$, $\tau > (1+h^3)/3$ *with* $\lambda_1+\sigma/h > 0$, *then for small* $\epsilon > 0$, *there exists a solution of* (12)–(16) *in the form*

$$\begin{aligned}
f^+(x,\psi) &= \psi + \epsilon(\psi - h)T(\epsilon x) + \epsilon((\psi - h)\omega(x) + \theta^+(x,\psi)), \qquad 0 < \psi < h,\\
f^-(x,\psi) &= \psi - h(\psi + 1)T(\epsilon x)\epsilon + \epsilon(-h(\psi + 1)\omega(x) + \theta^-(x,\psi)), \qquad -1 < \psi < 0,
\end{aligned}$$

where

$$T(\epsilon x) = \left(\left(\frac{\lambda_1 + \sigma/h}{h(1+h)}\right)^{1/2} \operatorname{sech}\left(\frac{\lambda_1 + (\sigma/h)}{\tau - (1+h^3)/3}\right)^{1/2} \epsilon x\right),$$

and

$$\|\omega(x)\|_{X^s} \le K\epsilon, \qquad \|\theta(x,\psi)\|_{B^s} \le K\epsilon^2 \quad \text{and} \quad \|\omega_x\|_{X^{s-2}} \le K\epsilon^2,$$

for $s \ge 4$.

Appendix. Let

$$F(x) = -\Gamma(x) = \lambda_0 + \tau x - \sqrt{x}\left(\frac{\cosh\sqrt{x}}{\sinh\sqrt{x}} + \rho\frac{\cosh(\sqrt{x}h)}{\sinh(\sqrt{x}h)}\right). \tag{A.1}$$

Obviously as $x \to 0$, $F(x) \to 0$. We need to prove that $F(x) \ne 0$ for all x if $\tau > \tau_0 = (1+\rho h)/3$. We differentiate (A.1) to get

$$\begin{aligned}
F'(x) =& \tau - \frac{1}{4}\frac{\sinh(2x^{1/2}) - 2x^{1/2}}{x^{1/2}\sinh^2 x^{1/2}}\\
&- \frac{(\rho h/4)\sinh(2hx^{1/2}) - 2hx^{1/2}}{hx^{1/2}\sinh^2(hx^{1/2})},
\end{aligned}$$

and as $x \to 0$, $F'(x) \to \tau - (1+\rho h)/3 = \tau - \tau_0$. Now let $I(y) = (\sinh(2y) - 2y)/(y\sinh^2 y)$. Then

$$\begin{aligned}
F''(x) &= -\frac{1}{8}x^{1/2}I_y(x^{1/2}) - \frac{\rho}{8}x^{1/2}I_y(hx^{1/2}),\\
I_y(y) &= (2y\cosh(2y)\sinh^2 y - \sinh^2 y\sinh 2y - y\sinh^2 2y + 2y^2\sinh^2 y)\\
&\quad \times (y^2\sinh^4 y)^{-1} = \frac{I_1}{I_2}.
\end{aligned}$$

Now we show that for $y > 0$, $I_1 < 0$. By using some elementary identities, we have

$$\begin{aligned}
I_1(y) &= -2y\sinh^2 y - \sinh(2y)\sinh^2 y + 2y^2\sinh 2y\\
&= \sinh y\left(-2y\sinh y - \frac{1}{2}\cosh 3y + \frac{1}{2}\cosh y + 4y^2\cosh y\right)\\
&= \frac{1}{2}\sinh y(-4y\sinh y - \cosh 3y + \cosh y + 8y^2\cosh y)\\
&= \frac{1}{2}\sinh y\left(\sum_{n=0}^{\infty}(-4(2n+2) - 3^{2n+2}\right.\\
&\qquad \left. + 1 + 8(2n+2)(2n+1))y^{2n+2}/(2n+2)!\right).
\end{aligned}$$

It is easy to check that when $y \geq 3$,

$$3^y > y^2 + 3y + 1.$$

So $3^{2n} > (2n+2)(2n+1)$ for $n \geq 2$ and $3^{2n+2} > 8(2n+2)(2n+1)$. But for $n = 0$ and $n = 1$,

$$-4(2n+2) - 3^{2n+2} + 1 + 8(2n+2)(2n+1) = 0.$$

Therefore, $I_1(y) < 0$ for $y > 0$. So $F''(x) > 0$ for $x > 0$ and $F''(x) \to c_1 > 0$ as $x \to 0$ for some constant c_1. $F'(x)$ is monotonically increase for $x \geq 0$. If $\tau > \tau_0$, then $F'(x) > 0$, which means $F(x)$ is monotonically increase and so $F(x) > 0$ for all $x > 0$.

If $\sigma < 0$ by (45)–(47) σ should satisfy the equation

(A.2)

$$(\lambda_0 + \tau\sigma) \sin\sqrt{-\sigma}h \sin\sqrt{-\sigma} = \sqrt{-\sigma} \sin\sqrt{-\sigma}h \cos\sqrt{-\sigma} + \rho\sqrt{-\sigma} \sin\sqrt{-\sigma} \cos\sqrt{-\sigma}h.$$

If σ is large, then (A.2) becomes

$$\tau \sin(\sqrt{-\sigma}h) \sin\sqrt{-\sigma} = O\left(\frac{1}{(-\sigma)^{1/2}}\right).$$

Therefore, for larger σ, there is always a solution near each of the solutions of

$$\sin((-\sigma)^{1/2}h) \sin(-\sigma)^{1/2} = 0,$$

which means that the roots of (A.2) are infinite and σ_n has order of n^2 when n is large.

Remark. When $\tau < \tau_0$, we know that $F(x)$ in (A.1) is zero at $x = 0$, $F''(x) > 0$ for $x \geq 0$, $F'(0) = \tau - \tau_0 < 0$ and $F(x) \to +\infty$ as $x \to +\infty$. From these facts, it is easy to see that $F(x)$ has one and only one positive number $x_0 > 0$ so that $F(x_0) = 0$ and $F'(x_0) \neq 0$ since $F(x)$ is a strictly convex function for $x \geq 0$.

THE LINEAR SHALLOW WATER THEORY: A MATHEMATICAL JUSTIFICATION*

JAMES A. DONALDSON[†][‡] AND DANIEL A. WILLIAMS[†][§]

Abstract. The authors provide in the space of square integrable measurable functions a mathematical justification for the "shallow water" theory for time-dependent two-dimensional flows of an inviscid, irrotational, incompressible fluid moving under the influence of gravity. A by-product of this investigation is a new derivation of the "shallow water" equations.

Key words. shallow water equations, elliptic boundary-value problems, Cauchy problems, generalized transforms

AMS subject classifications. 35J25, 35L15, 35Q35, 76B15, 76D30

1. Introduction. We are concerned with a problem from the theory of water waves [15] which arises when one makes two basic assumptions: (i) the depth of the water is small (relative to some other quantity associated with the problem) and (ii) the amplitude of surface waves is small (relative to their wavelength). This leads to the following mathematical model, when we assume also that the fluid is incompressible, inviscid, and irrotational. Let the positive direction of the Y-axis be vertically upward; let the X-axis be at the mean height of the surface of the water at time $t = 0$; and let $B(X)$ be a function contained in $C^3(\mathbb{R})$. We are required to find a function $\Phi(X, Y, t)$ such that Φ satisfies the boundary-value problem

$$\Phi_{XX} + \Phi_{YY} = 0 \quad \text{in } \Omega_B \times \mathbb{R}^+; \tag{1.1}$$

$$\frac{\partial \Phi}{\partial n} = 0 \quad \text{on } \Gamma_B; \tag{1.2}$$

$$\Phi_Y = \eta_t, \qquad \Phi_t + \eta = 0 \quad \text{on } \Gamma \times \mathbb{R}^+; \tag{1.3a}$$

or equivalently,

$$\Phi_Y + \Phi_{tt} = 0 \quad \text{on } \Gamma \times \mathbb{R}^+; \tag{1.3b}$$

$$\Phi(X, 0, 0) = F_0(X) \quad \text{on } \Gamma; \tag{1.4a}$$

$$\Phi_t(X, 0, 0) = F_1(X) \quad \text{on } \Gamma, \tag{1.4b}$$

and where $Y = \eta(X, t)$ is the equation of the free surface,

$$\begin{aligned} &\Gamma = \{(X, 0) : X \in \mathbb{R}\}, \qquad \Gamma_B = \{(X, Y) : Y = -\epsilon B(X)\}, \\ &\Omega_B = \{(X, Y) : -\epsilon B(X) < Y < 0, X \in \mathbb{R}\}, \quad \text{and} \\ &\mathbb{R}^+ = \{r : r > 0\}. \end{aligned}$$

[§] This author's research was supported in part by Air Force Office of Scientific Research grant R1NM062.

The initial conditions (1.4a,b) result from specifying the initial surface elevation $\eta(X,0)$ and the initial velocity potential $\Phi(X,Y,0)$. We assume (i) there exist positive constants b_1, b_2, and b_3 such that $b_1 \leq B(X) \leq b_2$ and $B'(X) < b_3$, (ii) the parameter ϵ is a small positive number, and (iii) the density of the fluid and the acceleration due to gravity are constants which we equate to one. Furthermore, when we assume that B has bounded derivatives through order n in $\mathbb{R}$, B_n will denote $\sup_{x\in\mathbb{R}}\{\sum_{k=0}^{n} |B^{(k)}(x)|\}$.

For ϵ fixed (but not necessarily small) and F_0 and F_1 sufficiently smooth, Friedman and Shinbrot [4] and Garipov [6] have proved the existence of smooth solutions of (1.1)–(1.4) satisfying all conditions classically. Furthermore, they defined in $L^2(\Gamma)$ a self-adjoint (nonlocal) operator K with domain $H^1(\Gamma)$ related to (1.1)–(1.4) by the expression

$$\Phi_y(X,0,t) = K\Phi(X,0,t) = KW(X,t), \tag{1.5}$$

where $W(X,t)$ is the restriction to Γ of the unique solution $\Phi(X,Y,t)$ of (1.1)–(1.4) in $H^1(\Omega)$.

In the linear theory of "shallow water" (ϵ small), the hyperbolic initial-value problem

$$W^0_{tt} - \epsilon(BW^0_X)_X = 0, \quad W^0(X,0) = F_0(X), \quad W^0_t(X,0) = F_1(X) \tag{1.6}$$

plays an essential role. The partial differential equation in this problem is called the "shallow water" equation. Naturally, the replacement of the elliptic boundary value problem (1.1)–(1.4) by the hyperbolic initial-value problem in (1.6) in the "shallow water" theory requires justification.

Friedrichs [5] gave a derivation of the shallow water theory by a formal perturbation procedure in powers of a small parameter $\sigma = \kappa h$, where κ is the curvature of the surface at $t = 0$ and h is the depth of the water. Friedrichs' requirement that σ be small for the water to be considered "shallow" is equivalent to the small depth assumption made in (1.1)–(1.4a) since for this case σ is small whenever ϵ is. (Note: $0 < \kappa\epsilon b_1 \leq \sigma \leq \kappa\epsilon b_2$ and we assume the curvature is bounded.) Friedrichs stated that a rigorous mathematical justification of the "shallow water" theory requires a proof that the perturbation series is convergent, or asymptotically valid. For the case of simple harmonic motion of two-dimensional linear flows, this justification was provided by Shinbrot [13].

For the case of two-dimensional nonlinear flows many authors have contributed. In the space of analytic functions mathematical justifications for the theory have been given by Ovsjannikov [11] valid for periodic solutions, and by Kano and Nishida [8] valid for sufficiently small time t. In Sobolev space Nalimov [10] proved unique solvability when the region of the fluid has infinite depth, and gave a justification for the linear theory, Yosihara [16] proved unique solvability when the region of the fluid has finite depth and the bottom is almost horizontal, and Craig [1] proved unique solvability and provided mathematical justifications for the Boussinesq equations and the Korteweg–deVries equations when the region of the fluid has finite depth and the bottom is horizontal.

In a Sobolev space we provide a mathematical justification for the "shallow water" theory in the case of time-dependent two-dimensional linear flows where the region of the fluid has finite depth and the bottom is neither horizontal nor almost horizontal.

We recall from (1.3a) that

$$\eta(X,t) = -\Phi_t(X,0,t) = -W_t(X,t)$$

and define a function η^0 by

$$\eta^0(X,t) = -W_t^0(X,t),$$

where $W_t^0(X,t)$ is the solution of the initial-value problem in (1.6). A fundamental problem in the "shallow water" theory is to determine in terms of ϵ a bound for the error which results when η^0 is used to approximate η. (This, of course, would provide the mathematical justification.) It is the aim of this paper to obtain such a bound valid for all t in $[0, S]$, where S is an arbitrary fixed positive number. We prove the following.

THEOREM 1.1. *Let S be any positive number, and let $F_0 \in H^2(\Gamma)$ and $F_1 \in H^1(\Gamma)$. Then there exits a constant C, depending upon S, B_3, $\|F_0\|_{H^2(\Gamma)}$, and $\|F_1\|_{H^1(\Gamma)}$ such that*

$$\|\eta(X,t) - \eta^0(X,t)\|_{L^2(\Gamma)} \le C\epsilon^{1/2}$$

for $t \in [0, S]$.

A brief outline of the paper follows. In §2 we give definitions and notation, introduce a generalization of the Fourier transform and study some of its properties, and state an inequality arising from an abstract Cauchy problem.

In §3 the region Ω_B is mapped into a horizontal strip Ω. Under this mapping the Laplacian operator is sent into an elliptic operator L with variable coefficients, and the problem (1.1)–(1.4) is transformed into an initial-boundary value problem that is rewritten, after performing a separation of variables, as a well-posed time-independent elliptic boundary-value problem and an initial-value problem. Introduced then is a boundary-value problem involving an elliptic operator L_1 related to L. The boundary-value problems for L and L_1 play a fundamental role in defining on $L^2(\Gamma)$ two invertible, positive, self-adjoint operators T and T_1. The operator T is related to the previously mentioned operator K by $K = B(T^{-1} - \alpha I)$, and the operator T_1 has the virtue of having an explicit representation. The proof of a key inequality employed in the demonstration of Theorem 1.1 is given.

In §4 an apparently new derivation of the "shallow water" equations is given. This derivation depends heavily upon an explicit representation obtained for an operator K_1 defined by $K_1 = B(T_1^{-1} - \alpha I)$ and an implicit representation for the aforementioned operator K. Introduced also is another operator K_0, with domain $H^2(\Gamma)$, and an associated abstract Cauchy problem for which certain estimates for its solution and derivatives of its solutions are obtained.

In §5 the estimates obtained in §4 and the results of §3 are used to establish the estimate needed to provide a rigorous justification of the "shallow water" theory.

2. Preliminary results and definitions.

We define $H^s(\Gamma)$ to be the collection of tempered distributions u such that $(1 + |\lambda|^2)^{s/2}\hat{u}(\lambda)$ is in $L^2(\Gamma)$, normed by

$$\|u\|_{H^s(\Gamma)} = \left\{ \int_\Gamma (1 + |\lambda|^2)^s |\hat{u}(\lambda)|^2 d\lambda \right\}^{1/2},$$

where $\hat{u}$ is the Fourier transform of u. We denote by $H^s(\Omega)$ the collection of all functions which, together with their first s distributional derivatives, are in $L^2(\Omega)$.

This space is normed by

$$\|u\|_{H^s(\Omega)} = \left\{ \sum_{|\alpha|\le s} \int_\Omega |D^\alpha u|^2 dx dy \right\}^{1/2} .$$

For $f \in L^2(\mathbb{R})$ we define a transformation, a slight generalization of the Fourier transformation, by the formula

$$\tilde{f}(\lambda) = \mathcal{F}_B[f](\lambda) = \int_{\mathbb{R}} f(x) e^{i\lambda H(x)} dH,$$

where

$$H(x) = \int_0^x \frac{ds}{B(s)}.$$

We shall call $\tilde{f}$ the B-transform of f. One verifies easily the following properties of this transform.

LEMMA 2.1. *If $f \in C_0^\infty(\mathbb{R})$ and $B \in C^{m-1}(\mathbb{R})$, then*

$$\mathcal{F}_B\left[\left(B\frac{\partial}{\partial x}\right)^n f\right] = (-i\lambda)^n \mathcal{F}_B[f](\lambda), \qquad 0 \le n \le m.$$

LEMMA 2.2. *Let $f \in L^2(\mathbb{R})$. Then there exist constants C_1 and C_2 such that*

$$C_1\|f\|_{L^2(\mathbb{R})} \le \|\tilde{f}\|_{L^2(\mathbb{R})} \le C_2\|f\|_{L^2(\mathbb{R})}.$$

LEMMA 2.3. *Let B have bounded derivatives through order $n-1$. Then there exist constants M_1 and M_2 such that*

$$\|\lambda^n \tilde{f}(\lambda)\|_{L^2(\mathbb{R})} \le M_1 \sum_{1\le j\le n} \|\lambda^j \hat{f}(\lambda)\|_{L^2(\mathbb{R})},$$

and

$$\|\lambda^n \hat{f}(\lambda)\|_{L^2(\mathbb{R})} \le M_2 \sum_{1\le j\le n} \|\lambda^j \tilde{f}(\lambda)\|_{L^2(\mathbb{R})}.$$

LEMMA 2.4. *The norm $\| \ \|_{B^k}$, defined by*

$$\|f\|_{B^k}^2 = \int_{\mathbb{R}} (1+\lambda^2)^k |\tilde{f}(\lambda)|^2 d\lambda,$$

is equivalent to the norm $\|f\|_{H^k(\mathbb{R})}$.

LEMMA 2.5. *Let U satisfy the abstract Cauchy problem*

$$\begin{aligned} &U''(t) + LU(t) = G(t), \qquad t > 0, \\ &U(0) = U'(0) = 0, \end{aligned}$$

where L is a self-adjoint positive operator defined in a Hilbert space X, and $G(t)$ is an X-valued strongly continuous function of t, and let S be a fixed, but arbitrarily selected positive number. Then

$$\|U'(t)\|_X \le \int_0^S \|G(s)\|_X ds \quad \textit{for all } \ t \in [0, S].$$

3. Two associated elliptic boundary-value problems. We introduce new independent variables x and y and dependent variable ϕ, defined by

$$x = X, \qquad y = \frac{Y}{\epsilon B(X)} \quad \text{and} \quad \phi(x,y,t) = \Phi(X,Y,t).$$

Introduction of these variables transforms the domain Ω_B into a horizontal strip Ω, and sends (1.1)–(1.4) into the problem

$$L\phi = 0 \quad \text{in } \Omega \times \mathbb{R}^+, \tag{3.1}$$

$$M\phi = 0 \quad \text{on } \Gamma_b \times \mathbb{R}^+, \tag{3.2}$$

$$\phi_y + \epsilon B\phi_{tt} = 0 \quad \text{on } \Gamma \times \mathbb{R}^+, \tag{3.3}$$

$$\phi(x,0,0) = F_0(x), \qquad \phi_t(x,0,0) = F_1(x) \quad \text{on } \Gamma, \tag{3.4}$$

where

$$\begin{aligned} L\phi &= \phi_{yy} + \epsilon^2[B(B\phi_x)_x + B_x^2 y^2\phi_{yy} - 2BB_x y\phi_{xy} + (2B_x^2 - BB_{xx})y\phi_y], \\ M\phi &= \phi_y + \epsilon^2[B_x^2\phi_y + BB_x\phi_x], \\ \Omega &= \{(x,y) : -1 < y < 0, x \in \mathbb{R}\}, \qquad \Gamma_b = \{(x,-1) : x \in \mathbb{R}\}, \end{aligned}$$

and

$$\Gamma = \{(x,0) : x \in \mathbb{R}\}.$$

Let $\alpha > 0$, and let $f(x,t) \in C_0^\infty(\Gamma)$ for each fixed t. We rewrite the condition (3.3) in the form

$$\{\phi_y + (\alpha B\phi - Bf)\} + \{-(\alpha B\phi - Bf) + \epsilon B\phi_{tt}\} = 0$$

and note that this permits us to obtain the solution of (3.1)–(3.4) from a boundary-value problem and an initial-value problem. More specifically, we associate with (3.1)–(3.4) the boundary-value problem

$$L\psi = 0 \quad \text{in } \Omega, \tag{3.5}$$

$$M\psi = 0 \quad \text{on } \Gamma_b, \tag{3.6}$$

$$\psi_y + \alpha B\psi = Bf(x,t) \quad \text{on } \Gamma, \quad f \in C_0^\infty(\Gamma \times \{t\}), \tag{3.7}$$

$$\psi \in H^1(\Omega), \tag{3.8}$$

and observe that its solution ψ satisfies (3.1)–(3.4) if f is chosen so that the initial-value problem

$$-\epsilon\psi_{tt} + \alpha\psi = f(x,t) \quad \text{on } \Gamma \times \{0\} \times \mathbb{R}^+, \tag{3.9}$$

$$\psi(x,0,0) = F_0(x), \qquad \psi_t(x,0,0) = F_1(x) \quad \text{on } \Gamma, \tag{3.10}$$

is satisfied. Essentially what has happened here is a separation of variables.

THEOREM 3.1. *For each fixed $\epsilon > 0$ the boundary-value problem* (3.5)–(3.8) *has a unique solution.*

Proof. Rewriting (3.5)–(3.8) in the Ψ, X, Y variables and employing the invertible transformation

$$(x, y, \psi) \to (X, Y, \Psi),$$

defined by

$$X = x, \ Y = -\epsilon B(x) y, \qquad \Psi(X, Y) = \psi(x, y),$$

we obtain an elliptic boundary-value problem for which existence and uniqueness results have been given by Friedman and Shinbrot [3] and Garipov [6]. □

We consider also the related boundary-value problem

$$(3.11) \qquad L_1 \psi^1 = \psi^1_{yy} + \epsilon^2 B(B\psi^1_x)_x = 0 \quad \text{in } \Omega,$$

$$(3.12) \qquad M_1 \psi^1 = \psi^1_y = 0 \quad \text{on } \Gamma_b,$$

$$(3.13) \qquad \psi^1_y + \alpha B \psi^1 = B f_1(x, t) \quad \text{on } \Gamma, \qquad f_1 \in C_0^\infty(\Gamma),$$

$$(3.14) \qquad \psi^1 \in H^1(\Omega).$$

THEOREM 3.2. *There exists one and only one solution of* (3.11)–(3.14).

For $f \in C_0^\infty(\Gamma)$, let $\psi(x, y; f)$ and $\psi^1(x, y; f)$ be the unique solutions of (3.5)–(3.8) and (3.11)–(3.14) corresponding to boundary datum f prescribed in (3.7) and (3.13). We define operators $\bar{T}$ and $\bar{T}_1$ on $C_0^\infty(\Gamma)$ by the formulas

$$(3.15) \qquad \bar{T} f = \psi(x, 0; f)$$

and

$$(3.16) \qquad \bar{T}_1 f = \psi^1(x, 0; f).$$

THEOREM 3.3. *The operator $\bar{T}$ defined by* (3.15) *has an extension to a bounded linear operator T on $L^2(\Gamma)$. The operator T is positive, self-adjoint, and has no nontrivial null-space.*

THEOREM 3.4. *The same statement as Theorem* 3.3, *but with $\bar{T}_1$ and T_1 replacing $\bar{T}$ and T, respectively.*

The proofs of Theorems 3.3 and 3.4 are essentially the same, and outside of obvious modifications the arguments are the same as those appearing in the proof of Lemma 3.1 of [3]. For completeness we provide here a proof of Theorem 3.4.

Proof. Let $f \in C_0^\infty(\Gamma)$. Upon multiplying each side of equation (3.11) by ψ^1/B, integrating the resulting expression over Ω and then applying the divergence theorem, we obtain after using the boundary conditions (3.12)–(3.13),

$$(\text{I}) \qquad \int_\Omega \frac{1}{B}\{(\psi^1_y)^2 + \epsilon^2 B^2 (\psi^1_x)^2\}\, dx\, dy + \alpha \int_\Gamma (\psi^1)^2 dx = \int_\Gamma f \psi^1 dx.$$

Since the first term on the left side of (I) is clearly nonnegative, it follows that

$$\alpha \int_\Gamma (\psi^1)^2 dx \le \int_\Gamma f \psi^1 dx \le \|f\|_{L^2(\Gamma)} \cdot \|\psi^1\|_{L^2(\Gamma)}.$$

It follows that

$$\|\bar{T}_1 f\|_{L^2(\Gamma)} = \|\psi^1\|_{L^2(\Gamma)} \le \frac{1}{\alpha}\|f\|,$$

and we have that $\bar{T}_1$ is bounded. That $\bar{T}_1$ is a positive operator follows also from (I) since

$$\begin{aligned}\langle \bar{T}_1 f, f\rangle_{L^2(\Gamma)} &= \int_\Gamma (\bar{T}_1 f)\cdot f dx = \int_\Gamma \psi^1 f dx\\ &\ge \alpha \int_\Gamma (\psi^1)^2 dx \ge 0.\end{aligned}$$

To see that $\bar{T}_1$ is symmetric, let $\psi^2(x,y;g)$ be the solution of (3.11)–(3.14) satisfying the boundary condition (3.13) with g replacing f. We have

$$\begin{aligned}\langle \bar{T}_1 f, g\rangle_{L^2(\Gamma)} &= \int_\Gamma \psi^1 g dx\\ &= \alpha\int_\Gamma \psi^1\psi^2 dx + \int_\Omega \frac{1}{B}\{\psi^1_y\psi^2_y + \epsilon^2 B^2 \psi^1_x\psi^2_x\} dxdy\\ &= \int_\Gamma f\psi^2 dx = \langle f, \bar{T}_1 g\rangle_{L^2(\Gamma)}.\end{aligned}$$

Now since $\bar{T}_1$ is a bounded, positive, symmetric operator defined on a dense subset of $L^2(\Gamma)$, it has a self-adjoint extension T_1 to $L^2(\Gamma)$ with the same bound. Also, T_1 is a positive operator.

To show that T_1 has no nontrivial null-space, assume that $T_1 f = 0 = \psi^1(x,0;f)$ on Γ where we assume $f \in C_0^\infty(\Gamma)$. Then

$$\begin{aligned}0 &= \langle f, T_1 f\rangle_{L^2(\Gamma)} = \langle f, \psi^1\rangle_{L^2(\Gamma)}\\ &= \alpha\langle \psi^1, \psi^1\rangle_{L^2(\Gamma)} + \int_\Omega \frac{1}{B}\{(\psi^1_y)^2 + \epsilon^2 B^2 (\psi^1_x)^2\}\, dx\, dy\\ &\ge \frac{1}{b_2}\int_\Omega \left\{\frac{1}{2}[(\psi^1)^2 + (\psi^1_y)^2] + \epsilon^2 B^2(\psi^1_x)^2\right\} dx\, dy.\end{aligned}$$

Thus, $\psi^1 = \psi^1_x = \psi^1_y = 0$ almost everywhere in Ω. That $f = 0$ follows from the equality

$$\begin{aligned}0 &= \int_\Omega \frac{1}{B}\{\psi^1_y\phi_y + B^2\epsilon^2\psi^1_x\phi_x\}\, dx\, dy + \alpha\langle \psi^1, \phi\rangle_{L^2(\Gamma)}\\ &= \int_\Gamma f\phi dx \quad \text{for all } \phi \in H^1(\Omega). \qquad \square\end{aligned}$$

Consequences of the Theorems 3.3 and 3.4 are that T and T_1 have inverses T^{-1} and T_1^{-1}, respectively, and they are also positive self-adjoint operators. We observe also that conditions (3.8) and (3.14) guarantee that the restriction to the boundary Γ of the solutions of (3.4)–(3.8) and (3.11)–(3.14), respectively, are in $L^2(\Gamma)$.

We consider the inhomogeneous boundary value problem

$$Lu = G \quad \text{in } \Omega, \tag{3.17}$$

$$Mu = g \quad \text{on } \Gamma_b, \tag{3.18}$$

$$u = 0 \quad \text{on } \Gamma, \tag{3.19}$$

$$u \in H^2(\Omega), \tag{3.20}$$

and prove the following result.

THEOREM 3.5. *Let $G, G_x \in L^2(\Omega)$ and $g \in H^1(\Gamma_b)$, and let u satisfy* (3.17)–(3.20). *Then there exist positive numbers ϵ_0 and C such that*

$$\|u_y\|^2_{L^2(\Gamma)} \leq C\{\|G\|^2_{L^2(\Omega)} + \|G_x\|^2_{L^2(\Omega)} + \|g\|^2_{H^1(\Gamma_b)}\} \tag{3.21}$$

whenever $\epsilon < \epsilon_0$.

There are two cases: (i) B is a constant function, and (ii) B is a nonconstant function. The proof of (i) is straightforward and will be omitted. We give a proof of (ii) in a series of lemmas.

LEMMA 3.1. *Let $u \in H^2(\Omega)$. Then $u_y(x,0) \in L^2(\Gamma)$ and*

$$\|u_y\|^2_{L^2(\Gamma)} \leq 2(\|u_y\|^2_{L^2(\Omega)} + \|u_{yy}\|^2_{L^2(\Omega)}).$$

Proof.

$$u_y(x,0) = u_y(x,y) + \int_y^0 u_{yy}(x,y)dy$$

and

$$|u_y(x,0)| \leq |u_y(x,y)| + \int_y^0 |u_{yy}(x,y)|dy$$
$$\leq |u_y(x,y)| + \left\{\int_{-1}^0 dy\right\}^{1/2} \left\{\int_{-1}^0 |u_{yy}(x,y)|^2 dy]\right\}^{1/2}.$$

It follows that

$$|u_y(x,0)|^2 \leq 2\left(|u_y(x,y)|^2 + \int_{-1}^0 |u_{yy}(x,y)|^2 dy\right).$$

Upon integrating both sides of the last inequality over Γ and over $\{y : 0 \geq y \geq -1\}$ we obtain the inequality of Lemma 1. □

LEMMA 3.2. *Let $u(x,y)$ be the solution of* (3.17)–(3.20). *Then there exists a constant C such that*

$$\|u_y\|^2_{L^2(\Omega)} \leq C \cdot P,$$

where P is the expression in (3.21) *enclosed by braces.*

Proof. Let u satisfy (3.17)–(3.20), and let ρ and γ be, respectively, the largest and smallest of the three numbers b_1, b_2, and b_3. Now multiply each side of (3.17) by u, integrate the resulting expression over Ω, and apply the divergence theorem to obtain the inequality

$$\int_\Omega \{u_y^2 + \epsilon^2[(Bu_x - B_x y u_y)^2 - B_x^2 y u u_y + BB_x u u_x]\}dxdy$$
$$= \int_{\Gamma_b} ugdx - \int_\Omega uGdxdy.$$

Upon applying the elementary inequalities

$$\int_{\Gamma_b} u^2 dx \leq \int_\Omega u_y^2 dxdy, \qquad \int_\Omega u^2 dxdy \leq \int_\Omega u_y^2 dxdy, \tag{3.22}$$

simplifying, and then choosing ϵ appropriately, we obtain

$$\int_\Omega \{u_y^2 + \epsilon^2 u_x{}^2\}dxdy \leq D\left\{\int_\Omega |G|^2 dxdy + \int_{\Gamma_b} |g|^2 dx\right\} \tag{3.23}$$

from which follows the conclusion of the lemma immediately. □

LEMMA 3.3. *Let $u(x,y)$ be the solution of* (3.17)–(3.20). *Then there exist positive constants C_1 and δ such that for $\epsilon < \delta$ we have*

$$\|u_{yy}\|^2_{L^2(\Omega)} \leq C_1 \cdot P$$

where P is the expression enclosed by braces in (3.21).

Proof. Differentiate the equations in (3.17)–(3.20) with respect to x, and set $W = u_x$ to obtain the boundary-value problem

$$\begin{aligned} &LW + \epsilon^2[\rho_1 W_x + \rho_2 W_y + \rho_3 W] \\ &\qquad = G_x + \epsilon^2[\rho_4 u_y + \rho_5 u_{yy}] \quad \text{in } \Omega, \end{aligned} \tag{3.24}$$

$$MW = g_x + \epsilon^2[\rho_8 W + \rho_9 u_y] \quad \text{on } \Gamma_b, \tag{3.25}$$

$$W = 0 \quad \text{on } \Gamma, \tag{3.26}$$

$$W \in H^1(\Omega), \tag{3.27}$$

where the functions $\rho_1, \rho_2, \rho_3, \rho_4$, and ρ_5 are bounded on $\overline{\Omega}$, the closure of Ω, and ρ_8 and ρ_9 are bounded in $\mathbb{R}$. Furthermore, we define $\rho_6 = B_x^2 y$ and $\rho_7 = -BB_x$. (Here, we have assumed that B and its derivatives through the third order are bounded in $\mathbb{R}$.) The constant ρ, defined by

$$\rho = \max\left\{ \max_{1 \leq i \leq 7} \left[\sup_{(x,y)\in\overline{\Omega}} |\rho_i(x,y)| \right], \max_{i=8,9} \left[\sup_{(x,y)\in\Gamma_b} |\rho_i(x,y)| \right] \right\},$$

is positive since B is a nonconstant function by assumption. We proceed as in the proof of Lemma 3.2 to obtain

$$\begin{aligned} \int_\Omega &\{W_y^2 + \epsilon^2[B^2W_x^2 - 2BB_xyW_xW_y + B_x^2y^2W_y^2 \\ &\qquad - (\rho_1 + \rho_7)W_xW - (\rho_2 + \rho_6)W_yW - \rho_3W^2]\}dxdy \\ &= -\int_\Omega W\{G_x + \epsilon^2[\rho_4 u_y + \rho_5 u]\}dxdy \\ &\quad - \int_{\Gamma_b} W\{g_x + \epsilon^2[\rho_8 W + \rho_9 u_y]\}dx. \end{aligned}$$

Employing modifications of the inequalities in (3.22) and the inequality

$$\int_\Gamma u_y^2 dx \leq 2\int_\Omega (|u_y|^2 + |u_{yy}|^2)dxdy,$$

we can find ϵ_1 greater than zero and determine constants D, C_3, and λ so that

$$\begin{aligned} &\int_\Omega (W_y^2 + \epsilon^2 W_x^2 + W^2)dxdy \\ &\quad \leq D\left\{\int_\Omega |G_x|^2 dxdy + \int_{\Gamma_b} |g_x|^2 dx\right\} \\ &\qquad + D\int_\Omega \epsilon^2(2+\epsilon^2)[u_y^2 + u_{yy}^2]dxdy \\ &\quad \leq C_3 P + \lambda\epsilon^2 \int_\Omega u_{yy}^2 dxdy = P_1 \end{aligned}$$

whenever $\epsilon < \epsilon_1$. Thus for $\epsilon < \epsilon_1$ each of the quantities $\|u_x\|^2_{L^2(\Omega)}$, $\|u_{xy}\|^2_{L^2(\Omega)}$ and $\epsilon^2\|u_{xx}\|^2_{L^2(\Omega)}$ is equal to or less than P_1. From the differential equation (3.17) it is easily shown that there exists a constant γ such that

$$|u_{yy}|^2 \leq \gamma\epsilon^4\{|u_{xx}|^2 + |u_{xy}|^2 + |u_x|^2 + |u_y|^2\} + \gamma|G|^2.$$

Upon integrating the latter expression over Ω and employing the inequalities derived above, we obtain

$$\begin{aligned}\|u_{yy}\|^2_{L^2(\Omega)} &\leq \gamma\epsilon^2(1+3\epsilon^2)P_1 + \gamma\|G\|^2_{L^2(\Omega)}\\ &\leq \gamma\{1 + C_3\epsilon^2(1+3\epsilon^2)\}P + \gamma\lambda\epsilon^4(1+3\epsilon^2)\|u_{yy}\|^2_{L^2(\Omega)}\end{aligned}$$

or equivalently,

$$[1 - \gamma\lambda\epsilon^4(1+3\epsilon^2)]\|u_{yy}\|^2_{L^2(\Omega)} \leq \gamma\{1 + C_3\epsilon^2(1+3\epsilon^2)\}P.$$

For each fixed $\beta \in (0,1)$ there exists an $\epsilon_2 > 2$ such that

$$[1 - \gamma\lambda\epsilon^4(1+3\epsilon^2)] > \beta \quad \text{whenever } 0 < \epsilon < \epsilon_2.$$

Now set $\epsilon_0 = \min\{\epsilon_1, \epsilon_2\}$. For $0 < \epsilon < \epsilon_0$ it follows that

$$\|u_{yy}\|^2_{L^2(\Omega)} \leq C_2 \cdot P,$$

where $C_2 = (\gamma/\beta)[1 + 4C_3]$. This completes the proof of the lemma. □

The proof of the theorem is now immediate.

In a sequence of lemmas we collect certain properties of the solution of the boundary-value problem

$$L_1\varphi = \varphi_{yy} + \epsilon^2 B(B\varphi_x)_x = 0 \quad \text{in } \Omega, \tag{3.28}$$

$$\varphi_y = 0 \quad \text{on } \Gamma_b, \tag{3.29}$$

$$\varphi(x,0) = h(x) \quad \text{on } \Gamma, \tag{3.30}$$

$$\varphi(x,y) \in H^1(\Omega), \tag{3.31}$$

which will be of importance in the sequel.

LEMMA 3.4. *For $h \in L^2(\Gamma)$ the function $\tilde{\varphi}$, defined by*

$$\tilde{\varphi}(\lambda, y) = \frac{\cosh(\epsilon|\lambda|(y+1))}{\cosh(\epsilon|\lambda|)}\tilde{h}(\lambda), \tag{3.32}$$

is the $\mathcal{F}_B$ transform of the solution of (3.28)–(3.31).

Proof. Let $h \in C_0^\infty(\Gamma)$. Upon applying the B-transform to (3.28)–(3.30) we obtain a boundary-value problem for an ordinary differential equation in y for $\tilde{\varphi}(\lambda, y)$. Its solution is given by (3.32). It is clear that the one-parameter family of operators $\bar{S}(y)$, $-1 \leq y \leq 0$, defined by

$$\bar{S}(y)h(x) = \mathcal{F}_B^{-1}\left[\frac{\cosh(\epsilon|\lambda|(y+1))}{\cosh(\epsilon|\lambda|)}\tilde{h}(\lambda)\right] = \varphi(x,y),$$

is bounded on $C_0^\infty(\Gamma)$ with respect to the L^2 norm. Since $C_0^\infty(\Gamma)$ is dense in $L^2(\Gamma)$, $\bar{S}(y)$ can be extended by continuity to $S(y)$ on $L^2(\Gamma)$, where $S(y)$ has the same bound as $\bar{S}(y)$. □

LEMMA 3.5. *If $h \in H^k(\Gamma)$, then $\varphi_y(x,0) \in H^{k-1}(\Gamma)$.*

Proof. From (3.32) we obtain

$$\tilde{\varphi}_y(\lambda,0) = \epsilon|\lambda| \tanh(\epsilon|\lambda|)\tilde{h}(\lambda).$$

Thus we have

$$|\tilde{\varphi}_y(\lambda,0)|^2 \leq C_1\lambda^2|\tilde{h}(\lambda)|^2 \leq C_1(1+\lambda^2)|\tilde{h}(\lambda)|^2.$$

This inequality and the assumption that $h \in H^k(\Gamma)$, together with Lemma 2.4, guarantee that $\varphi_y(x,0) \in H^{k-1}(\Gamma)$. □

LEMMA 3.6. *If $h \in H^k(\Gamma)$, then $\varphi \in H^k(\Omega)$.*

Proof.

$$\begin{aligned}
\|\varphi\|^2_{H^k(\Omega)} &= \int_\Omega \sum_{|\alpha|\leq k} \left| \frac{\partial^{\alpha_1+\alpha_2}}{\partial x^{\alpha_1}\partial y^{\alpha_2}}\varphi\right|^2 dx\, dy \\
&= \int_{\mathbb{R}}\int_{-1}^{0} \sum_{|\alpha|\leq k} \left||\lambda|^{\alpha_1}\frac{\partial^{\alpha_2}}{\partial y^{\alpha_2}}\hat{\varphi}(\lambda,y)\right|^2 dy\, d\lambda \\
&\leq C_1 \int_{\mathbb{R}}\int_{-1}^{0} \sum_{|\alpha|\leq k}\sum_{j=1}^{\alpha_1} \left||\lambda|^{j}\frac{\partial^{\alpha_2}}{\partial y^{\alpha_2}}\tilde{\varphi}(\lambda,y)\right|^2 d\lambda\, dy \\
&\leq C_2 \int_{\mathbb{R}}\int_{-1}^{0} \sum_{|\alpha|\leq k}\sum_{j=0}^{k-\alpha_2} ||\lambda|^{\alpha_2+j}\epsilon^{\alpha_2}\Upsilon_{\alpha_2}(\lambda,y)\tilde{h}(\lambda)|^2 dy\, d\lambda \\
&\leq C_3 \int_{\mathbb{R}} \sum_{|\alpha|\leq k}\sum_{j=0}^{k}\binom{k}{j} ||\lambda|^{j}\tilde{h}(\lambda)|^2 d\lambda \\
&\leq C_4 \int_{\mathbb{R}} (1+|\lambda|^2)^k|\tilde{h}(\lambda)|^2 d\lambda \\
&\leq C_5\|h\|^2_{H^k(\Gamma)} < \infty,
\end{aligned}$$

and the conclusion is established. □

The function Υ_{α_2} is defined by

$$\Upsilon_{\alpha_2}(\lambda,y) = \begin{cases} \dfrac{\cosh(\epsilon|\lambda|(y+1))}{\cosh(\epsilon|\lambda|)} & \text{if } \alpha_2 \text{ is even,} \\ \dfrac{\sinh(\epsilon|\lambda|(y+1))}{\cosh(\epsilon|\lambda|)} & \text{if } \alpha_2 \text{ is odd.} \end{cases}$$

4. Derivation of the shallow water equations. In the last section it was shown that the inverse of T is a positive self-adjoint operator in $L^2(\Gamma)$. Since the restriction to Γ of the solution ψ of (3.5)–(3.8) is in the range of T, we may solve the equation

$$Tf(x,t) = \psi(x,0,t),$$

obtaining

$$f(x,t) = T^{-1}\psi(x,0,t).$$

Upon making this substitution for f the equations (3.9)–(3.10) become

$$\epsilon\psi_{tt}(x,0,t) + (T^{-1} - \alpha I)\psi(x,0,t) = 0, \qquad t > 0; \tag{4.1}$$

$$\psi(x,0,0) = F_0(x), \qquad \psi_t(x,0,0) = F_1(x), \tag{4.2}$$

a Cauchy problem for an abstract wave equation in $L^2(\Gamma)$. From (3.7) we obtain

$$\frac{1}{B}\psi_y(x,0,t) = (T^{-1} - \alpha I)\psi(x,0,t) \quad \text{on } \Gamma \times \mathbb{R}^+. \tag{4.3}$$

In an analogous way we show that

$$\frac{1}{B}\psi^1_y(x,0,t) = (T_1^{-1} - \alpha I)\psi^1(x,0,t) \quad \text{on } \Gamma \times \mathbb{R}^+. \tag{4.4}$$

Employing (3.32) and (4.4) we can give the following explicit representation for $(T_1^{-1} - \alpha I)\psi^1(x,0,t)$.

THEOREM 4.1. *Let $\psi^1(x,y,t;f)$ be the solution of* (3.11)–(3.14). *Then*

$$(T_1^{-1} - \alpha I)\psi^1(x,0,t) = \frac{1}{B}\mathcal{F}_B^{-1}\epsilon|\lambda|\tanh(\epsilon|\lambda|)\tilde{\psi}^1(\lambda,0,t). \tag{4.5}$$

This suggests that $T_1^{-1} - \alpha I$ is defined in $L^2(\Gamma)$ by the formula

$$(T_1^{-1} - \alpha I)h(x) = \frac{1}{B}\mathcal{F}_B^{-1}\{\epsilon|\lambda|\tanh(\epsilon|\lambda|)\tilde{h}(\lambda)\}$$

for all h such that the L^2-norm of the left side is bounded. It is readily seen that this is obtained when $h \in H^1(\Gamma)$.

Circumstances are not so convenient for

$$(T^{-1} - \alpha I)\psi(x,0,t);$$

we are able to provide an implicit representation only.

THEOREM 4.2. *Let $\psi(x,y,t;f)$ be the solution of* (3.5)–(3.8). *Then*

$$(T^{-1} - \alpha I)\psi(x,0,t) = \frac{1}{B}\mathcal{F}_B^{-1}\{\epsilon|\lambda|\tanh(\epsilon|\lambda|)\tilde{\psi}(\lambda,0,t)\} + G_1(x,t), \tag{4.6}$$

where

$$G_1(x,t) = T_1^{-1}(T_1 - T)f(x,t)$$

and $\mathcal{F}_B^{-1}$ is the inverse B*-transform.*

Proof. Let $f \in C_0^\infty(\Gamma)$. From $\psi_1(x,0,t) = \psi(x,0,t) + [\psi_1(x,0,t) - \psi(x,0,t)]$ and the definitions for T and T_1 we obtain

$$T_1 f(x,t) = Tf(x,t) + (T_1 - T)f(x,t).$$

It follows that

$$f(x,t) = T_1^{-1}(T_1 f(x,t)) = T_1^{-1}(Tf(x,t)) + T_1^{-1}(T_1 - T)f(x,t).$$

Thus

$$T^{-1}\psi(x,0,t) = T_1^{-1}\psi(x,0,t) + T_1^{-1}(T_1 - T)f(x,t)$$

or

$$(T^{-1} - \alpha I)\psi(x,0,t) = (T_1^{-1} - \alpha I)\psi(x,0,t) + T_1^{-1}(T_1 - T)f(x,t),$$

and the proof is complete. □

Friedman and Shinbrot [4] have shown that the domain of $(T^{-1} - \alpha I)$ is also $H^1(\Gamma)$. We now define two operators K and K_1 in $L^2(\Gamma)$ by the equations

$$\epsilon^2 Kh = (T^{-1} - \alpha I)h \quad \text{for } h \in H^1(\Gamma),$$
$$\epsilon^2 K_1 h = (T_1^{-1} - \alpha I)h \quad \text{for } h \in H^1(\Gamma),$$

respectively. Equations (4.1)–(4.2) then become

$$w_{tt}(x,t) + \epsilon K w(x,t) = 0, \qquad t > 0; \tag{4.7}$$
$$w(x,0) = F_0(x), \qquad w_t(x,0) = F_1(x), \tag{4.8}$$

where $w(x,t)$ is the restriction to Γ, $\psi(x,0,t)$, of the solution ψ of (3.5)–(3.8).

The solution of this initial-value problem is given explicitly by the formula

$$w(x,t) = \int_0^\infty \left\{ \cos(\sqrt{\epsilon\mu}t) dG_\mu F_0(x) + \frac{\sin(\sqrt{\epsilon\mu}t)}{\sqrt{\epsilon\mu}} dG_\mu F_1(x) \right\}, \tag{4.9}$$

where the family of projections G_μ, $-\infty < \mu < \infty$, is a resolution of the identity with respect to the operator K, and where F_0 and F_1 are in the domains of K and $K^{1/2}$, or equivalently in $H^1(\Gamma)$ and $H^{1/2}(\Gamma)$, respectively.

Now employ (4.7) and the representation given in Theorem 4.1 to get

$$\begin{aligned} w_{tt} &+ \frac{1}{\epsilon B}\mathcal{F}_B^{-1}[(\epsilon|\lambda|)^2 \tilde{w}(\lambda,t)] \\ &= \frac{1}{\epsilon B}\mathcal{F}_B^{-1}[\epsilon|\lambda|(\epsilon|\lambda| - \tanh(\epsilon|\lambda|))\tilde{w}(\lambda,t)] - G_1(x,t) \\ &= G_2(x,t,w), \end{aligned} \tag{4.10}$$

or equivalently,

$$w_{tt} - \epsilon(Bw_x)_x = G_2(x,t,w) \tag{4.11}$$

since the second term on the left side of (4.10) is $-\epsilon(Bw_x)_x$. If the right side of (4.11) is small, then solutions of (4.11) will be close to solutions of

$$w_{tt}^0 - \epsilon(Bw_x^0)_x = 0.$$

The latter equations are the usual equations of the linear "shallow water" theory for time-dependent, two-dimensional flows and are generally used in the applications rather than those in (1.1)–(1.4) or (4.7). In the next section it is shown that this derivation can be put on a rigorous basis.

We define an operator K_0 on $H^2(\Gamma)$ by

$$K_0 h(x) = \frac{1}{\epsilon^2 B}\mathcal{F}_B^{-1}[(\epsilon|\lambda|)^2 \tilde{h}(\lambda)] = -(Bh_x)_x, \tag{4.12}$$

and consider the abstract Cauchy problem in $L^2(\Gamma)$,

$$w_{tt}^0 + \epsilon K_0 w^0(x,t) = 0, \qquad t \in [0,S], \tag{4.13}$$

$$w^0(x,0) = F_0(x), \qquad w_t^0(x,0) = F_1(x), \tag{4.14}$$

where S is any positive number.

From the form of the solution of this problem, analogous to the formula in (4.9), we obtain the following estimates.

LEMMA 4.1. *Let $w^0(x,t)$ satisfy the initial value problem* (4.13) *and* (4.14). *Then*

$$\|D_t^k w^0(x,t)\|_{L^2(\Gamma)} = O(\epsilon^{(k/2)-(1/2)}), \qquad k = 0,1,2,\dots; \tag{4.15a}$$

$$\|(\epsilon K_0)^k w^0(x,t)\|_{L^2(\Gamma)} = O(\epsilon^{k-(1/2)}), \qquad k = 0,1,2,\dots. \tag{4.15b}$$

Here the constant in the "O" symbol depends upon S, $\|F_0\|_{H^2(\Gamma)}$ and $\|F_1\|_{H^2(\Gamma)}$ for $0 \le k \le 2$; and depends upon S, $\|F_0\|_{H^k(\Gamma)}$ and $\|F_1\|_{H^{k-1}(\Gamma)}$ for $k > 2$.

5. Establishment of error estimates. In this section we show that the derivation given above of the "shallow water" equations can be made rigorous by obtaining an estimate for the error

$$w_t(x,t) - w_t^0(x,t)$$

that results when (4.7)–(4.8) is replaced by the initial-value problem in (4.13)–(4.14). This satisfies Friedrichs' requirement, and therefore provides a mathematical justification for the "shallow water" theory.

THEOREM 5.1.

(i) *Let w and w^0 be solutions, respectively, of the initial-value problems* (4.7)–(4.8) *and* (4.13)–(4.14);

(ii) *Let F_0 be an element of $H^2(\Gamma)$; and*

(iii) *Let F_1 be an element of $H^1(\Gamma)$.*

Then for each $S > 0$ there exists a constant C (depending upon B_3, S, $\|F_0\|_{H^2(\Gamma)}$, and $\|F_1\|_{H^1(\Gamma)}$) such that

$$\|w_t(x,t) - w_t^0(x,t)\|_{L^2(\Gamma)} \le C\sqrt{\epsilon} \quad \textit{for } t \in [0,S]. \tag{5.1}$$

Remark. The estimate in the theorem is sharp as can be seen from a consideration of (1.1)–(1.4) for the special case when the bottom is horizontal ($B(x)$ a constant function). From its explicit solution one verifies directly that the estimate in (5.1) is satisfied.

Proof. The function

$$Z(x,t) = w(x,t) - w^0(x,t)$$

satisfies the initial-value problem

$$Z_{tt}(x,t) + \epsilon K Z(x,t) = -\epsilon(K - K_0)w^0(x,t), \tag{5.2}$$

$$Z(x,0) = Z_t(x,0) = 0. \tag{5.3}$$

An application of Lemma 2.5 to the initial-value problem (5.2) and (5.3) yields the inequality

$$\begin{aligned}\|Z_t(x,t)\|_{L^2(\Gamma)} &\le \int_0^S \{\|\epsilon(K-K_0)w^0(x,t)\|_{L^2(\Gamma)}\}dt \\ &\le \int_0^S \{\|\epsilon(K_1-K_0)w^0(x,t)\|_{L^2(\Gamma)} \\ &\qquad + \|\epsilon(K-K_1)w^0(x,t)\|_{L^2(\Gamma)}\}dt \\ &= I_1 + I_2.\end{aligned}$$

We first consider I_1. Employ Lemma 2.2 to obtain

$$\begin{array}{lrl}
\text{(i)} & b_1\|\epsilon(K_1 - K_0)w^0(x,t)\|_{L^2(\Gamma)} & \le \|\epsilon B(K_1 - K_0)w^0(x,t)\|_{L^2(\Gamma)} \\
\text{(ii)} & & = \|\mathcal{F}_B^{-1}[(|\lambda|\tanh(\epsilon|\lambda|) - |\epsilon|\lambda|^2)\widetilde{w^0}(\lambda,t)]\|_{L^2(\Gamma)} \\
\text{(iii)} & & \le C_1\||\lambda|(\tanh(\epsilon|\lambda|) - \epsilon|\lambda|)\widetilde{w^0}\|_{L^2(\Gamma)} \\
\text{(iv)} & & \le C_2\|\epsilon|\lambda|^2\widetilde{w^0}\|_{L^2(\Gamma)} \\
\text{(v)} & & = C_2\|\frac{1}{\epsilon}(\epsilon|\lambda|)^2\widetilde{w^0}\|_{L^2(\Gamma)} \\
\text{(vi)} & & \le C_3\left\|\frac{1}{\epsilon B}\mathcal{F}_B^{-1}[\epsilon^2|\lambda|^2\widetilde{w^0}]\right\|_{L^2(\Gamma)} \\
\text{(vii)} & & = C_3\left\|\frac{1}{\epsilon B}\mathcal{F}_B^{-1}[\widetilde{\epsilon B K_0 w^0}]\right\|_{L^2(\Gamma)} \\
\text{(viii)} & & \le C_4\|\epsilon K_0 w^0\|_{L^2(\Gamma)} \\
\text{(ix)} & & = O(\sqrt{\epsilon}).
\end{array}$$

From this last inequality follows the existence of C_5 such that $I_1 \le C_5\sqrt{\epsilon}$. In the above analysis (iv) is obtained from (iii) by employing the inequality $\tanh x \le x$, valid for $x \ge 0$; (vi) follows from (v) by applying Lemma 2.2; (vii) is obtained from (vi) by using the definition of K_0; and (ix) follows from (viii) by applying (4.15b). We turn now to I_2. From (4.3) and (4.4) we have

$$\epsilon(K - K_1)w^0(x,t) = \frac{1}{\epsilon B}[\psi_y(x,0,t) - \psi_y^1(x,0,t)],$$

where $\psi(x,y,t)$ and $\psi^1(x,y,t)$ are the solutions of (3.5)–(3.8) and (3.11)–(3.14), respectively, which assume the value $w^0(x,t)$ on Γ. The function u, defined by

$$u(x,y,t) = \psi(x,y,t) - \psi^1(x,y,t),$$

satisfies the boundary-value problem

$$\begin{array}{lc}
(5.4) & Lu = -(L - L_1)\psi^1 = -\epsilon^2 L_2\psi^1 \quad \text{in } \Omega, \\
(5.5) & Mu = -(M - M_1)\psi^1 = -\epsilon^2 M_2\psi^1 \quad \text{on } \Gamma_b, \\
(5.6) & u = 0 \quad \text{on } \Gamma.
\end{array}$$

Bounds for ψ^1 and its derivatives play a key role in establishing an estimate for $\|u_y\|_{L^2(\Gamma)}$ where u satisfies (5.4)–(5.6). Calculation of these bounds are facilitated by the explicit formula for ψ^1, namely,

$$\psi^1(x,y,t) = \mathcal{F}_B^{-1}\left\{\frac{\cosh(\epsilon|\lambda|(y+1))}{\cosh(\epsilon|\lambda|)}\widetilde{w^0}(\lambda,t)\right\}.$$

LEMMA 5.1. *The following estimates are valid for ψ^1 and its derivatives.*

$$\begin{array}{lc}
\text{(i)} & \|D^{\alpha_1+\alpha_2}\psi^1(x,y,t)\|_{L^2(\Omega)}^2 = O(\epsilon^{2\alpha_2-1}), \\
\text{(ii)} & \|D^{\alpha_1}\psi^1(x,-1,t)\|_{L^2(\Gamma_b)}^2 = O(\epsilon^{-1}).
\end{array}$$

Proof of (i). It is easily seen that

$$\begin{aligned} D^{\alpha_2}\psi^1(x,y,t) &= \epsilon^{\alpha_2}\psi_1^1(x,y,t), \quad \text{where} \\ \psi_1^1(x,y,t) &= F_B^{-1}[|\lambda|^{\alpha_2}\Upsilon_{\alpha_2}(\lambda,y,\epsilon)\widetilde{w^0}(\lambda,t)]. \end{aligned}$$

Thus

$$\begin{aligned}
&\int_\Omega |D^{\alpha_1+\alpha_2}\psi^1(x,y,t)|^2 dx\, dy \\
&= \epsilon^{2\alpha_2}\int_{-1}^{0}\left\{\int_\Gamma |D^{\alpha_1}\psi_1^1(x,y,t)|^2 dx\right\} dy \\
&= \epsilon^{2\alpha_2}\int_{-1}^{0}\left\{\int_\Gamma \left||\lambda|^{\alpha_1}\widehat{\psi_1^1}(\lambda,y,t)\right|^2 d\lambda\right\} dy \\
&\le M_1\epsilon^{2\alpha_2}\int_{-1}^{0}\left\{\sum_{k\le\alpha_1}\int_\Gamma \left||\lambda|^{k}\widetilde{\psi_1^1}\right|^2 d\lambda\right\} dy \\
&\qquad \text{(by Lemma 2.3)} \\
&\le M_1\epsilon^{2\alpha_2}\int_{-1}^{0}\left\{\sum_{k\le\alpha_1}\int_\Gamma \left||\lambda|^{k+\alpha_2}\Upsilon_{\alpha_2}(\lambda,y,\epsilon)\widetilde{w^0}(\lambda,t)\right|^2 d\lambda\right\} dy \\
&\qquad \text{(by definition of } \psi_1^1) \\
&\le M_2\epsilon^{2\alpha_2}\int_{-1}^{0}\left\{\sum_{k\le\alpha_1}\int_\Gamma \left||\lambda|^{k+\alpha_2}\widetilde{w^0}(\lambda,t)\right|^2 d\lambda\right\} dy \\
&\qquad \text{(since } |\Upsilon_{\alpha_2}|\le 1) \\
&\le M_3\epsilon^{2\alpha_2}\sum_{k\le\alpha_1}\int_\Gamma \left||\lambda|^{k+\alpha_2}\widetilde{w^0}(\lambda,t)\right|^2 d\lambda \\
&\le M_4\epsilon^{2\alpha_2}\sum_{k\le\alpha_1}\int_\Gamma \left\|\left[\left(B\frac{\partial}{\partial x}\right)^{k+\alpha_2} w^0(x,t)\right]\right\|^2 dx \\
&\qquad \text{(by Lemmas 2.1 and 2.2)} \\
&= M_4\epsilon^{2\alpha_2}\sum_{k\le\alpha_1}\int_\Gamma \left|[(BK_0)^{(k+\alpha_2)/2}w^0(x,t)]\right|^2 dx \\
&\qquad \text{(by definition of } K_0) \\
&\le M_5\epsilon^{2\alpha_2}\sum_{k\le\alpha_1}\sum_{j\le[(k+\alpha_2)/2]}\int_\Gamma |K_0^j w^0(x,t)|^2 dx \\
&\le M_6\epsilon^{2\alpha_2}\sum_{k\le\alpha_1}\sum_{j\le[(k+\alpha_2)/2]}\epsilon^{-2j}\epsilon^{2j-1} \\
&\qquad \text{(by 4.15b)} \\
&\le M_7\epsilon^{2\alpha_2-1},
\end{aligned}$$

where the M_i's are constants and $[(k+\alpha_2)/2]$ is the greatest integer in $(k+\alpha_2)/2$. More stringent conditions must be placed on F_0 and F_1 when $|\alpha| = \alpha_1+\alpha_2 \ge 2$.

$F_0 \in D(K_0^{|\alpha|/2})$ and $F_1 \in D(K_0^{(|\alpha|-1)/2})$ are sufficient. The second part of the lemma can be established by following a similar procedure. Now from Theorem 3.5 we obtain

$$\begin{aligned}\|u_y(x,0,t)\|^2_{L^2(\Gamma)} &\le \epsilon^4[\|L_2\psi^1\|^2_{L^2(\Omega)} + \|(L_2\psi^1)_x\|^2_{L^2(\Omega)} \\ &\qquad + \|M_2\psi^1\|^2_{L^2(\Gamma_b)} + \|(M_2\psi^1)_x\|^2_{L^2(\Gamma_b)}] \\ &\le A_1\epsilon^4\left\{\int_\Omega [|\psi^1_{xxy}|^2 + |\psi^1_{xyy}|^2 \right. \\ &\qquad + |\psi^1_{xx}|^2 + |\psi^1_y|^2 + |\psi^1_x|^2]dxdy \\ &\qquad \left. + \int_{\Gamma_b} [|\psi^1_{xx}|^2 + |\psi^1_x|^2]dx\right\} \\ &\le A_2\epsilon^3,\end{aligned}$$

and from (4.3) and (4.4),

$$\begin{aligned}|\epsilon(K-K_1)w^0(x,t)| &\le \frac{1}{\epsilon b_1}|\psi_y(x,0,t) - \psi^1_y(x,0,t)| \\ &\le \frac{1}{\epsilon b_1}|u_y(x,0,t)|.\end{aligned}$$

Thus,

$$\|\epsilon(K-K_1)w^0(x,t)\|_{L^2(\Gamma)} \le \frac{C}{\epsilon}\|u_y(x,0,t)\|_{L^2(\Gamma)} \le A_3\sqrt{\epsilon},$$

and there exists a constant C_2 such that $I_2 \le C_2\sqrt{\epsilon}$. This completes the proof of Theorem (5.1). □

The proof of Theorem (1.1) follows immediately since

$$\eta(X,t) - \eta^0(X,t) = W^0_t(X,t) - W_t(X,t) = w^0_t(x,t) - w_t(x,t) = -Z_t(x,t).$$

The L^2 estimate given for the error in approximating the surface wave $\eta(X,t)$ with $\eta^0(X,t)$ is generally not good enough in the theory of water waves. A pointwise estimate is needed. Such an estimate can be obtained if the initial functions $F_0(X)$ and $F_1(X)$ and the function $B(X)$ are sufficiently smooth. The following result provides such an estimate.

THEOREM 5.2. *Let S be any positive number, let $F_0 \in H^3(\Gamma)$ and $F_1 \in H^2(\Gamma)$, and let B have bounded derivatives through the fourth order. Then there exits a constant C, depending upon B_4, S, $\|F_0\|_{H^3(\Gamma)}$, and $\|F_1\|_{H^2(\Gamma)}$ such that*

$$|\eta(X,t) - \eta^0(X,t)| \le C\epsilon^{1/2} \tag{5.7}$$

for $t \in [0,S]$.

Proof (*sketch*). Under the conditions of the theorem we can establish the inequality

$$\|w_t(x,t) - w^0_t(x,t)\|_{H^1(\Gamma)} \le C\sqrt{\epsilon}. \tag{5.8}$$

Because of the inequality in Theorem 5.1 we note that to establish the inequality in (5.8) it is sufficient to show that

$$\|w_{xt}(x,t) - w^0_{xt}(x,t)\|_{L^2(\Gamma)} \le C\sqrt{\epsilon} \tag{5.9}$$

for $t \in [0, S]$, where C depends upon S, B_4, $\|F_0\|_{H^3(\Gamma)}$, and $\|F_1\|_{H^2(\Gamma)}$. The demonstration of the inequality in (5.9) follows that employed in the proof of Theorem 5.1 with modifications caused by the fact that the occurring initial-value problems are inhomogeneous. Now setting $E(x,t) = \eta^0(x,t) - \eta(x,t) = w_t(x,t) - w_t^0(x,t)$, we obtain

$$\begin{aligned}|E(x,t)| &\le \int_\Gamma |\hat{E}(\lambda,t)|d\lambda \\ &= \int_\Gamma (1+\lambda^2)^{-1/2}(1+\lambda^2)^{1/2}|\hat{E}(\lambda,t)|d\lambda \\ &\le \left(\int_\Gamma (1+\lambda^2)^{-1}d\lambda\right)^{1/2}\left(\int_\Gamma (1+\lambda^2)|\hat{E}(\lambda,t)|^2 d\lambda\right)^{1/2} \\ &\le C_1\|E\|_{H^1(\Gamma)} \le C\epsilon^{1/2}.\end{aligned}$$

6. Concluding remarks. We return again to the operator K in (1.5) and observe that this operator returns the normal derivative $\Phi_Y(X,0,t)$ on Γ of the harmonic function Φ when it operates on $\Phi(X,0,t)$, the boundary value of Φ on Γ. Therefore, K is a Dirichlet–Neumann operator. Yosihara [16] and Craig [1], [2], while investigating the nonlinear water wave problem, described Dirichlet–Neumann operators and established many of their properties. Although in their investigations the fluids had finite depth, the bottoms were horizontal or deviated only slightly from the horizontal. For the problem investigated here, for the case B a constant (the bottom is horizontal) we can give an explicit representation for K, namely,

$$Kh(x) = \mathcal{F}^{-1}(|\lambda|\tanh(\epsilon|\lambda|)\hat{h}(\lambda)) \tag{6.1}$$

for $h \in H^1(\Gamma)$. Here $\mathcal{F}^{-1}(f)$ denotes the inverse Fourier transformation of f. For this special case the representation in (6.1) agrees with the one given by Craig [2].

Largely due to the central role played by the generalized Fourier transform $\mathcal{F}_B$, and the requirement that the range of B be a finite closed interval contained in the positive y-axis in order to establish certain important estimates, the initial-boundary value problem (1.1)–(1.4) when the bottom Γ_B of the region Ω intersects its surface (the presence of beaches) does not lend itself to treatment using our approach. We believe, however, our approach can be modified and extended to treat time-dependent three-dimensional linear flows in regions without beaches.

Acknowledgments. We acknowledge here the contributions of Marvin Shinbrot, Late Professor of Mathematics at the University of Victoria, to the early stages of development of this work. It was he who pointed out that the existing justifications of the "shallow water" theory for time-dependent motion were deficient, and suggested that this theory be given a rigorous mathematical justification.

NONLINEAR STABILITY AND ASYMPTOTIC BEHAVIOR OF SHEARING MOTIONS OF A NON-NEWTONIAN FLUID*

JOHN A. NOHEL† AND ROBERT L. PEGO‡

Dedicated to James B. Serrin on the occasion of his 65th birthday.

Abstract. The goal is to establish the nonlinear stability of discontinuous steady states, and study the asymptotic behavior of solutions, for the initial-boundary value problem in one space dimension governing incompressible, isothermal shear flow of a non-Newtonian fluid driven by a constant pressure gradient. The fluid is assumed to be highly elastic and viscous; the non-Newtonian contribution to the shear stress satisfies a differential constitutive law characterized by a nonmonotone relation between the total *steady* shear stress and shear strain-rate that results in steady states having, in general, discontinuities in the strain rate. In a regime where Reynolds number is small compared to Deborah number, it is shown that every solution tends to a steady state as $t \to \infty$, and steady states that are nonlinearly stable, in a precise sense, are identified.

Key words. spurt, discontinuous steady states, delta-approximate solutions, gradient-like flow, Morse decomposition

1. Introduction.

In this paper we study issues of stability and asymptotic behavior for pressure-driven shear flows of an incompressible non-Newtonian fluid under isothermal conditions. We consider flow in the direction of the y-axis in the channel $-1 \le x \le 1$, and symmetric about the centerline $x = 0$; thus the flow variables are functions of x and time t. In dimensionless units, the dynamic equations governing the flow are

$$\text{(JSO)} \qquad \begin{aligned} \alpha v_t &= \left(\varepsilon v_x + \sigma + \bar{f}x\right)_x, \\ \sigma_t &= -\sigma + (Z+1)\,v_x, \\ Z_t &= -Z - \sigma v_x, \end{aligned}$$

for $-1 \le x \le 0$, $t > 0$, subject to the boundary conditions for $t > 0$:

$$\text{(BC)} \qquad v(-1,t) = 0, \qquad v_x(0,t) = 0, \qquad \sigma(0,t) = 0.$$

Here v represents fluid velocity, σ the polymer contribution to the shear stress, and Z is proportional to the first normal stress difference. The (constant) pressure gradient driving the flow is $\bar{f} > 0$, ε is the ratio of Newtonian viscosity to shear viscosity (scaled by relaxation time), and α is the ratio of Reynolds number to Deborah number. The second and third equations in (JSO) arise from the Johnson–Segalman–Oldroyd differential constitutive equations with a single relaxation time, that are assumed to

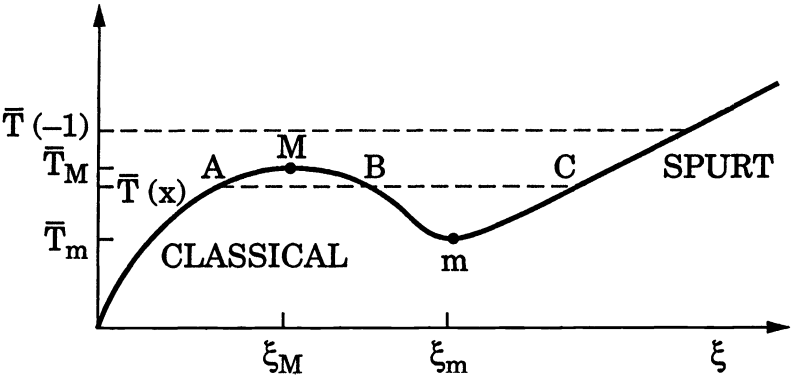

FIG. 1. ω *vs.* ξ.

govern the class of fluids under study. We refer to [8] for a derivation of the system (JSO) starting from balance laws and constitutive relations in three dimensions, and for references to relevant literature.

Throughout this paper, it is convenient to study the system (JSO) in the equivalent form:

$$\text{(JSO}_1\text{)}\qquad \begin{aligned} \alpha S_t &= \varepsilon S_{xx} + \alpha\sigma_t, \\ \sigma_t &= -\sigma + \frac{(Z+1)\left(S+\overline{T}-\sigma\right)}{\varepsilon}, \\ Z_t &= -Z - \frac{\sigma\left(S+\overline{T}-\sigma\right)}{\varepsilon}, \end{aligned}$$

where

$$\text{(1.1)}\qquad S := \varepsilon v_x + \sigma + \overline{f}\,x, \qquad \overline{T} := -\overline{f}\,x.$$

The boundary conditions become

$$\text{(BC}_1\text{)}\qquad S_x(-1,t) = 0, \qquad S(0,t) = 0, \qquad \sigma(0,t) = 0,$$

and the initial conditions are

$$\text{(IC}_1\text{)}\qquad S(x,0) = S_0(x), \qquad \sigma(x,0) = \sigma_0(x), \qquad Z(x,0) = Z_0(x).$$

The steady states $(\overline{S}(x), \overline{\sigma}(x), \overline{Z}(x))$ of (JSO$_1$) satisfy the following relations (see [8]):

$$\text{(1.2)}\qquad \overline{\sigma}(x) = \frac{\overline{v}_x}{1+\overline{v}_x^2}, \qquad \overline{Z}(x) + 1 = \frac{1}{1+\overline{v}_x^2},$$

$$\text{(1.3)}\qquad \overline{S}(x) = \varepsilon\overline{v}_x + \frac{\overline{v}_x}{1+\overline{v}_x^2} + \overline{f}\,x \equiv 0.$$

Thus the steady strain rate $\overline{v}_x(x)$ satisfies the equation $\omega(\overline{v}_x) = \overline{T} = -\overline{f}\,x$, where $\overline{T}$ is the total steady shear stress, and where

$$\text{(1.4)}\qquad \omega(\xi) = \frac{\xi}{1+\xi^2} + \varepsilon\xi, \qquad -\infty < \xi < \infty.$$

For $\varepsilon < \frac{1}{8}$, the function ω is not monotone (see Fig. 1). In this case, if $\overline{f}$ is sufficiently large, there are multiple steady states $\overline{v}_x(x)$ satisfying (1.3), which are discontinuous in x. The resulting steady velocity profiles $\overline{v}(x)$ have kinks at points where $\overline{v}_x$ is discontinuous. (For an example with one kink, see Fig. 2.)

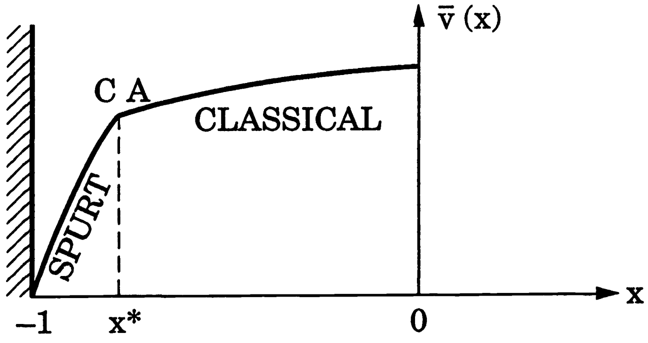

FIG. 2. *Velocity profile with a kink;* $\omega(\overline{v}_x(x)) = \overline{T}$.

Such steady states play a key role in one possible explanation of experimentally observed spurt and related phenomena that was proposed by Malkus, Nohel, and Plohr in [8]. The experiments involve highly elastic and viscous fluids, for which α and ε are both small, with $\varepsilon \sim 10^{-2}$ or 10^{-3}, and α is 7 to 10 orders of magnitude smaller than ε. The explanation in [8] is based on analytical results for the approximation of the governing system (JSO$_1$) when $\alpha = 0$; these results are summarized in Propositions 2.3 and 2.4 below. The results in [8] suggest that the spurt mechanism is a bulk material property of the viscoelastic fluid, rather than an an adhesive property as currently believed by many rheologists. As a consequence of the nonmonotone shear stress/strain-rate relation in Fig. 1, the polymeric fluid changes state in a thin layer near the boundary occuring whenever $\overline{T} > \overline{T}_M$, and giving the appearance of a "wall slip" layer; furthermore, this layer exhibits complicated dynamics.

The main focus of this paper is to show that in a regime where $\varepsilon < \frac{1}{8}$ is fixed and $\alpha > 0$ is sufficiently small, the dynamics of the full system (JSO$_1$) is similar to that generated by the approximate problem with $\alpha = 0$. We do so by studying the nonlinear stability of discontinuous steady states of (JSO$_1$) with respect to perturbations of initial data, and the large-time asymptotic behavior of solutions in general.

Precise statements of our main results appear in §3. But loosely speaking, we prove three results.

1. On any fixed interval $0 \le t \le T$ the solution (S, σ, Z) of (JSO$_1$) converges as $\alpha \to 0$ to the corresponding solution for $\alpha = 0$, for which $S = 0$ and the second and third equations of (JSO$_1$) reduce to a pair of quadratic, autonomous ordinary differential equations (ODEs) in which x enters only as a parameter through $\overline{T}$. (The case $\alpha = 0$ is thoroughly analyzed in [8]; a summary of those results will be given in §2.)

2. If α is small (in particular $\alpha\varepsilon^{-4}$ should be small), then any discontinuous steady state, for which $\omega(\overline{v}_x)$ takes values only on the strictly increasing portions of the graph of $\omega(\xi)$ (excluding a neighborhood of the max and min), is nonlinearly stable, in a sense made precise in §3. Stability holds when the perturbation from steady state in S is small in $H^1(-1,0)$ and the perturbations in σ, Z are small in $L^1(-1,0)$, and are bounded pointwise by some large constant. Hence, there are smooth initial data in the basin of Lyapunov stability of any such discontinuous steady state. Figure 3 illustrates the effect of such a perturbation on the strain rate $\overline{v}_x$ obtained from the kinked velocity profile in Fig. 2.

3. If α is sufficiently small, every solution of (JSO$_1$) converges as $t \to \infty$ to *some* steady state solution (possibly discontinuous, possibly unstable) with

$$S \to 0 \text{ in } H^1(-1,0), \qquad (\sigma(x,t), Z(x,t)) \to (\overline{\sigma}(x), \overline{Z}(x)) \tag{1.5}$$

for each x. We can guarantee that for some smooth solutions, the corresponding asymptotic state is discontinuous in x, and the convergence in (1.5) is not uniform; such solutions contain "transition layers." In general, we are unable to precisely identify the limiting steady solution for a given set of initial data.

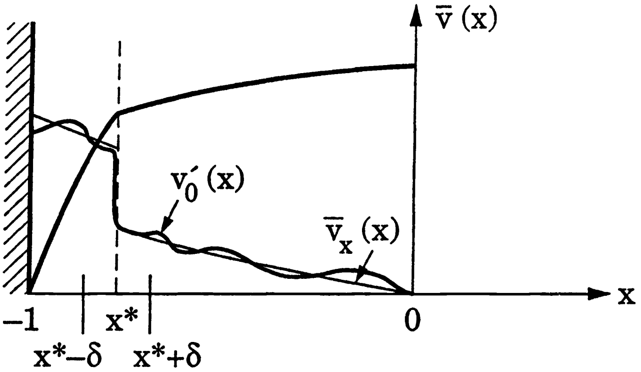

FIG. 3. *Smooth perturbation of velocity gradient.*

2. Summary of previous results.

Global existence of solutions to ($\mathrm{JSO_1}$) with the boundary conditions ($\mathrm{BC_1}$) and initial conditions ($\mathrm{IC_1}$) for arbitrary α and $\varepsilon > 0$ follows from a general result established in [9]. Somewhat different existence results have been obtained by Guillopé and Saut [4], [5]. We have the following.

THEOREM 2.1. (a) *Assume $S_0 \in H^s$, for some $s > \frac{3}{2}$, and σ_0, $Z_0 \in C^1$. Then there exists a unique* classical solution *of* ($\mathrm{JSO_1}$), ($\mathrm{BC_1}$), ($\mathrm{IC_1}$) *on* $[-1,0] \times [0,\infty)$ *having the regularity*

$$\begin{aligned} S &\in C([0,\infty), C^1) \cap C((0,\infty), H^2), \\ S_t &\in C((0,\infty), C^1), \\ \sigma,\ Z &\in C^1([0,\infty), C^1). \end{aligned}$$

(b) *Assume $S_0 \in H^1$, and σ_0, $Z_0 \in L^\infty$. Then there is a unique semiclassical solution on $[-1,0] \times [0,\infty)$ (possibly having discontinuities in the stress components) with*

$$\begin{aligned} S &\in C([0,\infty), H^1) \cap C((0,\infty), W^{2,\infty}), \\ S_t &\in C((0,\infty), H^s) \quad \textit{for all } s < 2, \\ \sigma,\ Z &\in C^1([0,\infty), L^\infty). \end{aligned}$$

Given any bounded measurable representatives σ_{0*}, Z_{0*} of the equivalence classes σ_0, $Z_0 \in L^\infty$, there exist unique bounded measurable functions $\sigma_*(x,t)$, $Z_*(x,t)$, representing $\sigma(\cdot,t)$, $Z(\cdot,t)$ for each $t > 0$, such that the map $t \mapsto \sigma_*(x,t)$, $Z_*(x,t)$ is C^1 for $t \geq 0$, and (S_*, σ_*, Z_*) satisfy the second and third equations of ($\mathrm{JSO_1}$) *for $t > 0$, where S_* is the unique continous representative of S.*

Throughout this paper, function spaces such as H^s, C^1, $W^{2,\infty}$, L^∞ refer to the interval $[-1,0]$. The class of solutions in Theorem 2.1(b) includes the discontinuous steady states mentioned in the introduction. In what follows, we will identify a solution (S,σ,Z) in case (b) with some representative (S_*,σ_*,Z_*) as described above; then the second and third equations in ($\mathrm{JSO_1}$) are satisfied pointwise for all $t > 0$. We remark that, as shown in [9], discontinuities in the stress components (σ, Z) for such solutions can neither be created nor destroyed in finite time. This is so because S is continuous, and solutions of the ODEs in (JSO$_1$) depend continuously on parameters both forward and backward in time.

Since (JSO$_1$) is endowed with the identity

$$\text{(L)} \qquad \frac{d}{dt}\left[\sigma^2 + (Z+1)^2\right] = -2\left[\sigma^2 + \left(Z + \frac{1}{2}\right)^2 - \frac{1}{4}\right],$$

it follows that σ and Z are globally bounded in (x,t), and these bounds are independent of α and ε. But although solutions of (JSO$_1$) exist globally, it has not been shown that S remains globally bounded in (x,t). Observe that identity (L) is independent of $\alpha, \varepsilon, \overline{T}$.

Nohel, Pego, and Tzavaras [9] studied the nonlinear stability of discontinuous steady states and asymptotic behavior as $t \to \infty$, for a model problem obtained from (JSO$_1$) by freezing Z at its steady state value $Z + 1 = 1/(1+v_x^2)$. The resulting model system has the form

$$\text{(M)} \qquad \begin{aligned} \alpha S_t &= \varepsilon S_{xx} + \alpha\sigma_t, \\ 0 &= \sigma_t + \sigma + g\left(\frac{(S + \overline{T} - \sigma)}{\varepsilon}\right), \end{aligned}$$

where $g(\xi) = \xi/(1+\xi^2)$. The steady states $(\overline{S}(x), \overline{\sigma}(x))$ of (M) satisfy $\overline{S}(x) = 0$, and, with $\overline{v}_x = (\overline{T} - \overline{\sigma})/\varepsilon$,

$$\varepsilon\overline{v}_x + g(\overline{v}_x) = \overline{T}.$$

System (M) admits energy estimates which imply that $S \in L^\infty([-1,0] \times [0,\infty))$ and $S(x,t) \to 0$ as $t \to \infty$, uniformly in x. The analysis of stability and asymptotic behavior reduces to studying invariant sets of the second equation in (M), a single ODE with x as parameter, forced by S with S small.

The results of [9] offered evidence that the discontinuous steady states of (JSO$_1$) are relevant to the study of the asymptotic behavior of smooth solutions. For system (M) with $\alpha = \varepsilon = 1$ (though this is not an essential assumption), it was shown that: (i) Every solution of (M) converges as $t \to \infty$ to some steady state. (ii) Discontinuous steady states satisfying $\varepsilon + g'(\overline{v}_x) \geq c_0 > 0$ for some c_0 are nonlinearly stable in the following sense: Restrict initial data (S_0, σ_0) such that the initial values are close to $(0, \overline{\sigma}(x))$ except on the union $\mathcal{U}$ of small subintervals centered around points $x_1, \ldots, x_n$ at which $\overline{v}_x$ is discontinuous. Then we have the following.

THEOREM 2.2. *Let $(0, \overline{\sigma}(x))$ be a steady state solution of* (M) *as described above, with a finite number of discontinuities, and satisfying*

$$\varepsilon + g'(\overline{v}_x(x)) \geq c_0 > 0 \quad \textit{for a.e. } x \in [-1,0]$$

for some positive constant c_0. If the measure of $\mathcal{U}$ is sufficiently small, there is a positive constant δ_0 depending on $\mathcal{U}$ such that, if $\delta < \delta_0$, then for any initial data $(S_0(x), \sigma_0(x))$ satisfying

$$\sup_{0 \leq x \leq 1} |S_0(x)| < \delta, \qquad \int_0^1 S_{0x}(x)^2\, dx < \frac{\delta^2}{2},$$

$$|\sigma_0(x) - \overline{\sigma}(x)| < \delta, \qquad x \in [0,1] \setminus \mathcal{U},$$

the corresponding solution $(S(x,t),\sigma(x,t))$ approaches the steady state $(0,\overline{\sigma}(x))$ as $t \to \infty$, in the sense that

$$S(x,t) \to 0 \quad \textit{uniformly},$$
$$\sigma(x,t) \to \overline{\sigma}(x) \quad \textit{for all } x \in [0,1] \setminus \mathcal{U}.$$

The main results of this paper, Theorems 3.4 and 3.5 below, are generalizations of Theorem 2.2 from the model problem (M) to the system (JSO$_1$).

The limiting case $\alpha = 0$ in (JSO$_1$) was studied by Malkus, Nohel, and Plohr in [8]. Their analysis of this case predicts spurt as well as latency, shape memory, and hysteresis under cyclic loading and unloading. Putting $\alpha = 0$ in (JSO$_1$), one has $S = 0$ and the second and third equations reduce to the system of quadratic ODEs parametrized by x:

$$\text{(Q)} \qquad \begin{aligned} \sigma_t &= -\sigma + \frac{(Z+1)\left(\overline{T}-\sigma\right)}{\varepsilon}, \\ Z_t &= -Z - \frac{\sigma\left(\overline{T}-\sigma\right)}{\varepsilon}. \end{aligned}$$

(Recall $\overline{T} = -\overline{f}x$.) The steady states of (Q) are identical with the steady states of (JSO$_1$) for $\alpha > 0$, but the dynamics of solutions of (Q) can be studied independently for each x in $[-1,0]$. Considering $\overline{T} = -\overline{f}x$ as a fixed parameter in (Q), we summarize the results of [8] as follows.

1. For each $\overline{T} \geq 0$, system (Q) has no periodic or homoclinic orbits, and every solution converges as $t \to \infty$ to some critical point.

2. The critical points of (Q) lie in the fourth quadrant of the (σ, Z)-phase plane, at the intersections of the circle

$$\Gamma := \left\{ (\sigma, Z) \mid \sigma^2 + \left(Z + \frac{1}{2}\right)^2 = \frac{1}{4} \right\}$$

and the parabola $Z = \sigma(\sigma - \overline{T})/\varepsilon$.

The character of the critical points is described as follows: In Fig. 1, denote the coordinates of the local maximum M and the local minimum m by $(\xi_M, \overline{T}_M)$ and $(\xi_m, \overline{T}_m)$, respectively; $\overline{T}_m$ and $\overline{T}_M$ are the critical values of the function $\omega(\xi)$, with $\overline{T}_m < \overline{T}_M$. There are three cases.

(i) If $0 < \overline{T} < \overline{T}_m$, there is a single critical point $A = (\sigma_A, Z_A)$ which is a globally attracting node.

(ii) If $\overline{T} > \overline{T}_M$, there is a single, globally attracting spiral point $C = (\sigma_C, Z_C)$.

(iii) If $\overline{T}_m < \overline{T} < \overline{T}_M$, there are three critical points A, B, C (see Fig. 4). A is an attracting node, B is a saddle point, and C is generally an attracting spiral point. (But for $\overline{T}$ close to $\overline{T}_m$, C is an attracting node.)

Two saddle-node bifurcations occur as $\overline{T}$ varies: As $\overline{T} \to \overline{T}_m$ from above, points B and C coalesce, and as $\overline{T} \to \overline{T}_M$ from below, points A and B coalesce. The set of critical points of (Q) in the full $(\sigma, Z, \overline{T})$ parameter space is a single smooth curve; this set is visualized in Fig. 5.

3. The asymptotic behavior of the solutions of (Q) is completely characterized as follows: For $\overline{T} < \overline{T}_m$ or $\overline{T} > \overline{T}_M$, every solution tends to the unique critical point, A or C, respectively. For $\overline{T}_m < \overline{T} < \overline{T}_M$, the behavior of solutions is described by Proposition 3.5 in [8], reproduced here as the following.

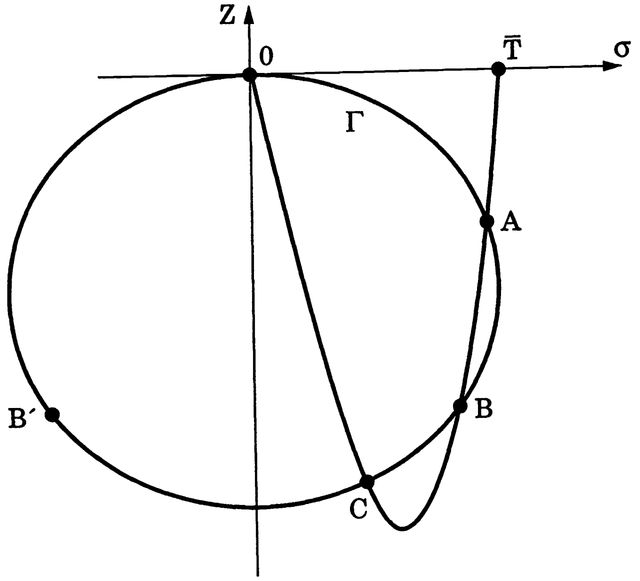

FIG. 4. *Critical points of* (Q) *in case* (iii).

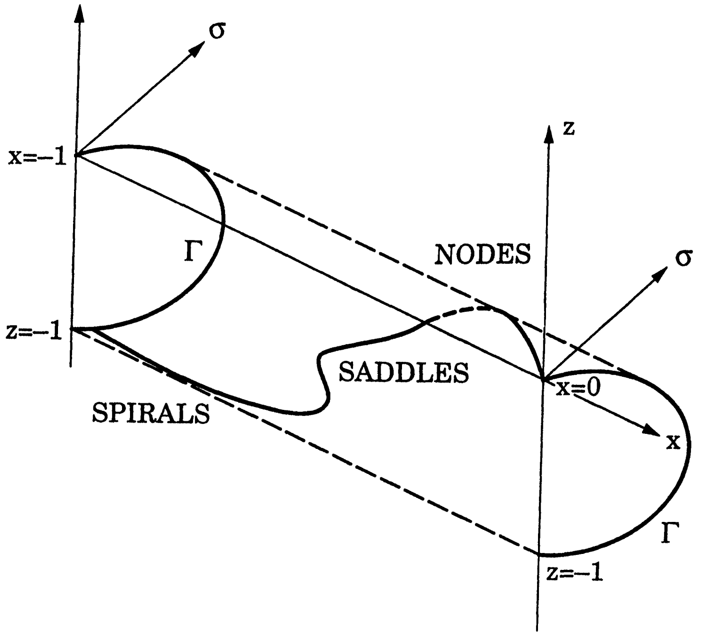

FIG. 5. *Manifold of equilibria of* (Q).

PROPOSITION 2.3. *The basin of attraction of A; i.e., the set of points that flow toward A as $t \to \infty$, comprises those points on the same side of the stable manifold of B as A; points on the other side are in the basin of attraction of C. Moreover, the arc of the circle Γ, through the origin, between $B = (\sigma_B, Z_B)$ and its reflection $B' = (-\sigma_B, Z_B)$, is contained in the basin of attraction of A.*

These results for (Q) have the following consequences for solutions $(0, \sigma, Z)$ of (JSO_1) with $\alpha = 0$, for $(x,t) \in [-1,0] \times [0,\infty)$.

PROPOSITION 2.4. *Consider* (JSO_1) *with* $\alpha = 0$.

(i) *The asymptotic behavior of any given solution may be completely characterized. For each x in $[-1,0]$, we have $(\sigma(x,t), Z(x,t)) \to A$, B or C as $t \to \infty$, according as to whether $(\sigma_0(x), Z_0(x))$ lies in the basin of attraction of A, on the stable manifold of B, or in the basin of attraction of C.*

(ii) *The stable steady states $(0, \overline{\sigma}, \overline{Z})$ of* (JSO$_1$) *with $\alpha = 0$ are those for which*

$$(\overline{\sigma}(x), \overline{Z}(x)) = A \quad \text{or} \quad C \quad \text{for a.e. } x \text{ in } [-1,0].$$

3. Statements of main results. Our main goal in this paper is to extend as far as possible the results of Proposition 2.4 for $\alpha = 0$ to the case when $\alpha > 0$ is small. Throughout this paper, ε is fixed, $0 < \varepsilon < \frac{1}{8}$. First, we study taking the limit $\alpha \to 0$ in a finite time interval $0 \le t \le T$. It will be convenient to write (JSO$_1$) in the more compact form

$$\begin{aligned} S_t &= \frac{\varepsilon}{\alpha} S_{xx} + a(x,u)S + b(x,u), \\ u_t &= G(x,u) + H(x,u)S, \end{aligned} \tag{3.1}$$

where $u = (\sigma, Z)$ and the components of $G = (G_1, G_2)$ and $H = (H_1, H_2)$ are

$$\begin{aligned} G_1(x,u) &= -\sigma + \frac{(Z+1)(\overline{T}-\sigma)}{\varepsilon}, & H_1(x,u) &= \frac{(Z+1)}{\varepsilon}, \\ G_2(x,u) &= -Z - \frac{\sigma(\overline{T}-\sigma)}{\varepsilon}, & H_2(x,u) &= -\frac{\sigma}{\varepsilon}, \end{aligned} \tag{3.2}$$

and

$$a(x,u) = H_1(x,u), \qquad b(x,u) = G_1(x,u). \tag{3.3}$$

In what follows, what is important about system (3.1) is that an a priori bound exists for $|u(x,t)|$ independent of S, namely, for some constant M_u independent of α (and ε), depending only on the initial data $u(x,0) = u_0(x)$,

$$\sup_{\substack{-1 \le x \le 0 \\ t \ge 0}} |u(x,t)| \le M_u. \tag{3.4}$$

Moreover, system (3.1) is linear in S, and the functions a, b, G, H and their Lipschitz constants with respect to u are bounded by some constant L/ε, where L is independent of α (and ε).

Our first result, proved in §4, bounds the H^1-norm of S globally in time for small α.

PROPOSITION 3.1. *Let (S,u) be a solution of (3.1) with the properties given by Theorem 2.1. Put $\lambda = \pi^2/4$ and let $\tilde{K}$ be the constant*

$$\tilde{K} = \int_0^{1/2\lambda} (2et)^{-1/2} e^{\lambda t/2}\, dt + \int_{1/2\lambda}^{\infty} \lambda^{1/2} e^{-\lambda t/2}\, dt.$$

If $\alpha \varepsilon^{-2} L \tilde{K} < \frac{1}{2}$, then

$$\|S(\cdot,t)\|_{H^1} \le 2\|S_0\|_{H^1} e^{-\varepsilon\lambda t/2\alpha} + \frac{4\alpha}{3\varepsilon} \sup_{0 \le \tau \le t} \|b(\cdot, u(\cdot,\tau))\|_{L^2}. \tag{3.5}$$

Immediate consequences of estimate (3.5) are the following.

COROLLARY 3.2. *Under the hypotheses above, there are constants* C_0, C_1, *depending only on initial data, such that*

$$\|S(\cdot,t)\|_{H^1} \le C_0 e^{-\varepsilon\lambda t/2\alpha} + C_1\alpha, \qquad t \ge 0, \tag{3.6}$$

$$\|S(\cdot,t)\|_{H^1} \le C_1\alpha, \qquad t \ge t_0(\alpha), \tag{3.7}$$

where

$$t_0(\alpha) = \frac{2\alpha\log\alpha^{-1}}{\varepsilon\lambda}, \quad C_1 = 2\|S_0\|_{H^1} + \frac{4}{3}M_u L\varepsilon^{-2}, \quad C_0 = 2\|S_0\|_{H^1}.$$

THEOREM 3.3. *Let* $(S,\sigma,Z)(x,t,\alpha)$ *denote the solution of* (JSO_1), *satisfying* (BC_1) *and* (IC_1). *Let* $(0,\overset{\circ}{\sigma}(x,t),\overset{\circ}{Z}(x,t))$ *be the solution of* (JSO_1) *with* $\alpha = 0$ *and initial data* $\overset{\circ}{\sigma}(x,0) = \sigma_0(x)$, $\overset{\circ}{Z}(x,0) = Z_0(x)$. *Fix* $T > 0$. *As* $\alpha \to 0$, *we have*

$$\begin{aligned} S(x,t,\alpha) &= 0 + O(\alpha), && t_0(\alpha) \le t \le T,\\ \sigma(x,t,\alpha) &= \overset{\circ}{\sigma}(x,t) + O(\alpha), && 0 \le t \le T,\\ Z(x,t,\alpha) &= \overset{\circ}{Z}(x,t) + O(\alpha), && 0 \le t \le T, \end{aligned} \tag{3.8}$$

uniformly with respect to x *on* $[-1,0]$.

The estimates for σ, Z are proved at the end of §4.

Our next result, proved in §5, concerns the stability of discontinuous steady states of (JSO_1) for small α. Recall that A, B, C are the critical points of (Q) in the (σ, Z)-phase plane, and depend on $\overline{T}$.

THEOREM 3.4. *Let* $h_0 > 0$. *Then there exist positive constants* α_0, δ_0, *and* K *so that the following holds for* $\alpha < \alpha_0$. *Let* $(0,\overline{u}(x))$ *be a steady state solution of* (3.1) *such that*

$$\overline{u}(x) = (\overline{\sigma}(x),\overline{Z}(x)) = \begin{cases} A & \textit{when } 0 \le \overline{T} \le \overline{T}_m + h_0,\\ A \text{ or } C & \textit{when } \overline{T}_m + h_0 \le \overline{T} \le \overline{T}_M - h_0,\\ C & \textit{when } \overline{T}_M - h_0 \le \overline{T} \end{cases}$$

for $-1 \le x \le 0$. *For* $0 < \delta < \delta_0$, *assume that*

$$\|S_0\|_{H^1} \le \delta \quad \textit{and} \quad |u_0(x) - \overline{u}(x)| \le \delta \quad \textit{for } x \in [-1,0]\setminus\mathcal{U},$$

where $\mathcal{U} \subset [-1,0]$ *is a set with* $\mathrm{meas}(\mathcal{U}) \le \delta^2$. *Then for all* $t > 0$, *the solution of* (3.1) *with these initial data satisfies*

$$\|S(\cdot,t)\|_{H^1} \le K\delta \quad \textit{and} \quad |u(x,t) - \overline{u}(x)| \le K\delta \quad \textit{for } x \in [-1,0]\setminus\mathcal{U}.$$

Remark 1. Theorem 3.4 permits the steady state stress components $\overline{u}(x)$ to exhibit an arbitrary pattern of discontinuities in the x-interval, where $\overline{u}(x) = A$ or C is possible.

Remark 2. Theorems 3.4 and 2.1 guarantee that such steady states $(0,\overline{u})$ are stable in the space $H^1 \times L^\infty$. But if $\|u_0 - \overline{u}\|_{L^\infty} < \delta$ is small, the set $\mathcal{U}$ will be empty, and u_0 will be discontinuous wherever $\overline{u}$ is. So the question arises: Can discontinuous steady states attract smooth, classical solutions?

Remark 3. The answer to this question is yes. Regardless of the pattern of discontinuities of $\overline{u}(x)$, clearly there are always smooth initial data (S_0, u_0) satisfying the hypotheses of Theorem 3.4 for arbitrary $\delta > 0$. It suffices that S_0 be small in H^1 and that $u_0 - \overline{u}$ be pointwise bounded, and small in L^1, since by Chebyshev's inequality,

$$\|u_0 - \overline{u}\|_{L^1} \leq \delta^3 \quad \text{implies meas}\{x : |u_0(x) - \overline{u}(x)| > \delta\} \leq \delta^2.$$

For u_0 smooth and $\overline{u}$ discontinuous, the "transition set" $\mathcal{U}$ will be nonempty; but the conclusion of Theorem 3.4 guarantees that $u(x,t) - \overline{u}(x)$ stays small for every fixed x for which it was small initially.

Remark 4. Using Theorem 3.5 below, it is possible to guarantee that for smooth initial data that satisfy the hypotheses of Theorem 3.4 with discontinuous $\overline{u}$, there is pointwise, nonuniform, convergence as $t \to \infty$ to an asymptotic state $(0, u_\infty(x))$ which is discontinuous, with $u_\infty(x) = \overline{u}(x)$ for $x \in [-1, 0] \setminus \mathcal{U}$.

Remark 5. When starting from rest with $(S_0, u_0) = (0, 0)$, and $\overline{f} > \overline{T}_M$, the solution of (JSO$_1$) with $\alpha = 0$ converges as $t \to \infty$ to the "top jumping" steady state $(0, \overline{u}(x))$ with

$$\overline{u}(x) = (\overline{\sigma}(x), \overline{Z}(x)) = \begin{cases} A & \text{for } x \text{ where } 0 \leq \overline{T} < \overline{T}_M, \\ C & \text{for } x \text{ where } \overline{T}_M < \overline{T} \end{cases}$$

(see [8]). Theorem 3.4 does not address the stability of this solution, nor that of corresponding "bottom jumping" solutions with $\overline{u}(x) = C$ when $\overline{T}$ is near $\overline{T}_m$; the crucial estimate (5.3) in §5 is not valid for such solutions.

Remark 6. It is seen in the proof that we require $K\alpha\varepsilon^{-4} < \frac{1}{2}$, where K is a fixed constant independent of α and ϵ.

The last issue we address for (JSO$_1$) is the asymptotic behavior of arbitrary solutions, when $\alpha > 0$ is small. Our ultimate goal is to prove the following.

THEOREM 3.5. *For any constant $M > 0$, there exists $\alpha_0 > 0$ such that if $0 < \alpha < \alpha_0$, then any solution (S, σ, Z) of* (JSO$_1$), (BC$_1$), (IC$_1$), *with initial values satisfying*

$$\|S_0\|_{H^1} + \|\sigma_0\|_{L^\infty} + \|Z_0\|_{L^\infty} \leq M,$$

converges as $t \to \infty$ to some steady state $(0, \overline{\sigma}(x), \overline{Z}(x))$, in the sense that as $t \to \infty$,

$$\begin{aligned} &\|S(\cdot, t)\|_{H^1} \to 0, \\ &\sigma(x,t) \to \overline{\sigma}(x) \quad \textit{for each } x \in [-1, 0], \\ &Z(x,t) \to \overline{Z}(x) \quad \textit{for each } x \in [-1, 0]. \end{aligned}$$

The proof of this theorem requires several steps, which we now outline. The main point of view underpinning the analysis is that for small α, the bound on S from Proposition 3.1 allows us to consider the evolution of $u = (\sigma, Z)$ as given *approximately* by the ODEs in (Q) for each $x \in [-1, 0]$ independently.

DEFINITION 3.6. For $\delta > 0$, a *δ-approximate solution* of the system (Q), written as

$$\dot{u} = G(x, u) \tag{3.9}$$

with x fixed, is a C^1-function $w : [0, \infty) \mapsto R^2$ such that

$$|\dot{w} - G(x, w)| \leq \delta, \qquad 0 \leq t < \infty,$$

where $|\cdot|$ denotes a vector norm in R^2.

Recall from §2 that in [8] it was shown that the system (Q) has no periodic of homoclinic orbits, and the critical points are always hyperbolic (except exactly when $\overline{T} = \overline{T}_m$ or $\overline{T}_M$, where the saddle-node bifurcations occur). We will see that for small δ, it follows that any δ-approximate solution of (3.9) must approximately stabilize as $t \to \infty$. One result we will use in this direction says that a δ-approximate solution w must enter a region where $|G(x,w)|$ is small, within a finite time T independent of x (although u may later leave this region).

PROPOSITION 3.7. *Let $\mathcal{E}$ denote the manifold of critical points of* (Q)*, given by*

$$\mathcal{E} = \{(x,u) \mid -1 \le x \le 0 \text{ and } G(x,u) = 0\}. \tag{3.10}$$

Let $\mathcal{N}$ be any neighborhood of $\mathcal{E}$ in $[-1,0] \times R^2$, and let $M_u > 0$. Then there exists $\delta_0 > 0$ and $T > 0$ such that if $0 \le \delta < \delta_0$, and if $u(x,t)$ satisfies (3.4) *and is such that $u(x,\cdot)$ is a δ-approximate solution of* (3.9) *for each x, then for each $x \in [-1,0]$ there exists $t < T$ with*

$$u(x,t) \in \mathcal{N}. \tag{3.11}$$

Since the proof is short and elementary, we give it here in order not to interrupt the development that follows.

Proof of Proposition 3.7. Choose $h > 0$ so that, defining

$$\mathcal{B}_h(\mathcal{E}) := \{(y,w) \in [-1,0] \times R^2 \mid \text{there exists } (x,u) \in \mathcal{E} \text{ with } |x-y| + |u-w| < h\},$$

we have $\mathcal{B}_{2h}(\mathcal{E}) \subset \mathcal{N}$. For any given $(x,u_0) \in [-1,0] \times R^2$, the (exact) solution $u(t)$ of (3.9) with $u(t_0) = u_0$ enters $\mathcal{B}_h(\mathcal{E})$ at some finite time t, by Proposition 2.4. Define the time of first entry by

$$T(x,u_0) = \inf_{t>0}\{t \mid u(t) \in \mathcal{B}_h(\mathcal{E})\}.$$

It is well known, and easy to prove, that $T(x,u_0)$ is an upper semicontinuous function of its arguments. Since an upper semicontinuous function defined on a compact set attains its maximum, then by confining attention to those solutions of (3.9) satisfying (3.4) we obtain that

$$T_0 := \sup\{T(x,u_0) \mid \ -1 \le x \le 0,\ |u_0| \le M_u \ < \infty\}.$$

Now, there exists $\delta_0 > 0$, independent of x, u_0, such that for $\delta < \delta_0$, any δ-approximate solution w to (3.9) with $w(0) = u_0$, $|u_0| < M_u$, satisfies $|w(t) - u(t)| < h$ for $0 \le t \le T_0$ (to prove this, use Gronwall's inequality). It follows that $w(t) \in \mathcal{B}_{2h}(\mathcal{E}) \subset \mathcal{N}$ for some $t < T_0$, and this completes the proof. □

Our strategy for proving $\|S\|_{H^1} \to 0$ as $t \to \infty$ involves a bootstrapping argument, based on an estimate which we will derive from Proposition 3.1, namely,

$$\limsup_{t\to\infty} \|S(\cdot,t)\|_{H^1} \le K\alpha \limsup_{t\to\infty} \|G(\cdot,u(\cdot,t))\|_{L^2}. \tag{3.12}$$

The idea is that if α is small, then the right side of (3.12) is small, so S is small and $u(x,\cdot)$ is a δ-approximate solution of (3.9) with δ small. This should lead to

$G(x,u(x,t))$ becoming small for large t, so that the right side of (3.12) is smaller, and S is smaller, etc.

The proof of Theorem 3.5 in §6 depends crucially on the following characterization of δ-approximate solutions to (3.9). We say a point $p \in R^2$ is a *recurrent point* of a δ-approximate solution $u(t)$ of (3.9) if there exists a sequence $\{t_n\}_{n=1}^{\infty}$ with $t_n \to \infty$ as $n \to \infty$, such that

$$u(t_n) \to p \quad \text{as } n \to \infty.$$

DEFINITION 3.8. For $x \in [-1,0]$ we define the set $R(x,\delta)$ of possible recurrent points of δ-approximate solutions of (3.9) by

$$R(x,\delta) = \{p \in R^2 \mid p \text{ is a recurrent point of some } \delta\text{-approximate solution of (3.9)}\}.$$

PROPOSITION 3.9. *There is a constant K independent of x, such that for $\delta > 0$ sufficiently small,*

$$\sup_{p\in R(x,\delta)} |G(x,p)| \leq K\delta \quad \textit{for all } x \in [-1,0]. \tag{3.13}$$

This result is a quantitative improvement (for a flow with a parameter x) of a remark of Conley [2, p. 17] asserting without proof that for a strongly gradient-like flow, if the (persistent) error made in following solutions is smaller than ε for time 1, then asymptotically the approximate solution will lie in any given neighborhood of the set of rest points, if ε is small enough. Also see Norton [10], who studies the general structure of flows with persistent errors.

The proof of Proposition 3.9 is the most technical part of this paper, and is given in §§7–10. It requires exploiting the gradient-like structure of the system (Q), and decomposing the phase space of (3.9) into a nested sequence of positively invariant sets, in such a way that Proposition 3.9 can be deduced. Recalling that Conley [2] defined a "Morse decomposition" of a flow to be a nested sequence of (positively *and* negatively) invariant sets, we call the (one-sided) decomposition that we require a "semi-Morse decomposition."

DEFINITION 3.10. A *semi-Morse decomposition* for the system (Q) is a finite nested sequence $\{M_j\}_{j=0}^{i}$ of subsets of the phase space $[-1,0] \times R^2$, with $M_0 \supset M_1 \supset \cdots \supset M_i$, such that each M_j is positively invariant for solutions of (Q).

In such a decomposition, if a solution $u(t)$ leaves one of the sets $M_j \setminus M_{j+1}$, it can do so only by entering M_{j+1}. We remark that this definition is related to the concept of an "index filtration" introduced by Franzosa [3] to study Morse decompositions via the Conley index.

The use we make of a semi-Morse decomposition in proving Proposition 3.9 is as a quantitative, rather than theoretical, tool (cf. [2], [3]). The result we seek to prove is the following.

PROPOSITION 3.11. *There exist positive constants δ_0 and K, such that for any $\delta < \delta_0$ and $x \in [-1,0]$, there exist nested sets*

$$M_0(x,\delta) \supset M_1(x,\delta) \supset \cdots \supset M_i(x,\delta),$$

which are positively invariant for δ-approximate solutions of (3.9) *and are such that*

(a) $|u| \leq M_u$ *implies* $u \in M_0(x,\delta)$;

(b) *For any given $j = 0,\ldots,i$, either every δ-approximate solution of* (3.9) *that lies in $M_j(x,\delta)$ must enter $M_{j+1}(x,\delta)$, or*

$$|G(x,u)| \leq K\delta \quad \textit{for all } u \in M_j(x,\delta) \setminus M_{j+1}(x,\delta). \tag{3.14}$$

Given this result, it is clear that for $\delta < \delta_0$ and any $x \in [-1,0]$, if $p \in R^2$ is a recurrent point for some δ-approximate solution of (3.9), then for some j, the point $p \in M_j(x,\delta) \setminus M_{j+1}(x,\delta)$, which must be a set where (3.14) holds. This will finish the proof of Proposition 3.9. We note that since the bounds available for δ do not depend on x, it will be necessary to study in particular detail the flow of (Q) for values of x near to where $\overline{T} = \overline{T}_m$ or $\overline{T}_M$ and saddle-node bifurcations occur.

4. Bounds for small α. In this section we prove Proposition 3.1 and the estimates for (σ, Z) in Theorem 3.3. Our method of obtaining estimates on S is to use the parabolic smoothing properties of the heat operator, and the variation of constants formula.

On the Hilbert space $X = L^2(-1,0)$, let Λ denote the operator with domain

$$D(\Lambda) = \{S \in H^2(-1,0) \mid S_x(-1) = 0 = S(0)\}$$

given by $\Lambda S = -S_{xx}$. The operator Λ is self-adjoint and positive, and $\lambda := \pi^2/4$ is its first eigenvalue. Parabolic smoothing estimates, for equations of the form $S_t + \Lambda S = f(t,S)$ are well discussed in Henry's book [6]; here we only need the following estimate, which has an elementary proof via eigenfunction expansions (see [6, p. 17]). Define

$$H_b^1 = \{v \in H^1(-1,0) \mid v(0) = 0\}$$

and recall the elementary estimates

$$\|v\|_{L^2} \le \|v\|_{L^\infty} \le \|v_x\|_{L^2} \quad \text{for } v \in H_b^1.$$

For $v \in H_b^1$, we define $\|v\|_{H^1} := \|v_x\|_{L^2}$.

LEMMA 4.1. *For $t > 0$ we have*

$$\text{(4.1)} \qquad \begin{aligned} \|e^{-\Lambda t}v\|_{H^1} &\le \|v\|_{H^1}e^{-\lambda t}, & v &\in H_b^1, \\ \|e^{-\Lambda t}v\|_{H^1} &\le \|v\|_{L^2}K(t), & v &\in L^2, \end{aligned}$$

where

$$\text{(4.2)} \qquad K(t) = \begin{cases} (2et)^{-1/2} & \text{for } t < \frac{1}{2}\lambda, \\ \lambda^{1/2}e^{-\lambda t} & \text{for } t > \frac{1}{2}\lambda. \end{cases}$$

For later reference, we remark that

$$\text{(4.3)} \qquad \int_0^\infty K(t)\,dt = \frac{3}{\pi\sqrt{e}} < \frac{2}{3}.$$

Now, apply the variation of constants formula to the first equation in (3.1). Suppressing the x-dependence, we obtain

$$\text{(4.4)} \qquad S(t) = e^{-\varepsilon\Lambda t/\alpha}S_0 + \int_0^t e^{-\varepsilon\Lambda(t-\tau)/\alpha}(aS+b)(\tau)\,d\tau.$$

Taking the norm and using the estimates of Lemma 4.1, we get

$$\text{(4.5)} \quad \|S(t)\|_{H^1} \le e^{-\varepsilon\lambda t/\alpha}\|S_0\|_{H^1} + \int_0^t K\left(\frac{\varepsilon(t-\tau)}{\alpha}\right)(L\varepsilon^{-1}\|S(\tau)\|_{L^2} + \|b(\tau)\|_{L^2})\,d\tau.$$

To prove Proposition 3.1, define

$$M_S(t) = \sup_{0\le\tau\le t} \|S(\tau)\|_{H^1}\, e^{\varepsilon\lambda\tau/2\alpha} e^{-\varepsilon\lambda t/2\alpha}, \qquad M_b(t) = \sup_{0\le\tau\le t} \|b(\tau)\|_{L^2}.$$

Let $T > 0$. From (4.5) we obtain, for $t \le T$,

$$e^{\varepsilon\lambda t/2\alpha}\|S(t)\|_{H^1} \le \|S_0\|_{H^1} + e^{\varepsilon\lambda t/2\alpha}\left[\varepsilon^{-1}LM_S(t)\int_0^t K\left(\frac{\varepsilon(t-\tau)}{\alpha}\right)e^{\varepsilon\lambda(t-\tau)/2\alpha}\,d\tau \right.$$
$$\left. + M_b(t)\int_0^t K\left(\frac{\varepsilon(t-\tau)}{\alpha}\right)d\tau\right].$$

Using (4.3), and since $\int_0^\infty K(t)e^{\lambda t/2}\,dt = \tilde{K}$, the right side is less than

$$\|S_0\|_{H^1} + e^{\varepsilon\lambda T/2\alpha}\left[\alpha\varepsilon^{-2}L\tilde{K}M_S(T) + \frac{2}{3}\alpha\varepsilon^{-1}M_b(T)\right].$$

Hence

$$(1-\alpha\varepsilon^{-2}L\tilde{K})M_S(T) \le \|S_0\|_{H^1}e^{-\varepsilon\lambda T/2\alpha} + \frac{2\alpha}{3\varepsilon}M_b(T),$$

and Proposition 3.1 follows.

To prove the estimates for (σ, Z) in Theorem 3.3, let $\mathring{u} = (\mathring{\sigma}, \mathring{Z})$, so that $(0, \mathring{u})$ is the solution of (JSO$_1$) with $\alpha = 0$ having initial data $(0, \sigma_0, Z_0)$. We have

$$u_t = G(x,u) + HS, \qquad \mathring{u}_t = G(x,\mathring{u}).$$

Then $(u-\mathring{u})_t = G(x,u) - G(x,\mathring{u}) + HS$. Using the fact that $u(x,0) = \mathring{u}(x,0)$, we obtain for $0 \le t \le T$,

$$|u(x,t) - \mathring{u}(x,t)| \le \varepsilon^{-1}L\int_0^t (|u(x,\tau)-\mathring{u}(x,\tau)| + |S(x,\tau)|)\,d\tau.$$

By the estimates in Corollary 3.2, for some constant K independent of α, depending on T,

$$\int_0^T |S(x,\tau)|\,d\tau \le K\alpha, \qquad -1 \le x \le 0.$$

Then as $\alpha \to 0$, Gronwall's inequality implies $u(x,t) - \mathring{u}(x,t) = O(\alpha)$ on $[0,T]$, uniformly with respect to x on [-1,0].

5. Stability of discontinuous steady states. In this section we prove Theorem 3.4. Our first step is to obtain another bound for S. Write the perturbation in u as $w(x,t) = u(x,t) - \overline{u}(x)$, and define

$$M_w(t) = \sup_{\substack{0\le\tau\le t\\ x\in[-1,0]\setminus\mathcal{U}}} |w(x,t)|, \qquad M_S(t) = \sup_{0\le\tau\le t} \|S(\cdot,t)\|_{H^1}.$$

Using (3.4) and the fact that $b(x,\overline{u}(x)) = 0$, we have, for $0 \le \tau \le t$,

$$\|b(\cdot,u(\cdot,\tau))\|_{L^2}^2 \le \varepsilon^{-2}L^2\|w(\cdot,\tau)\|_{L^2}^2 \le \varepsilon^{-2}L^2(M_w(t)^2 + \delta^2 M_{\bar{u}}^2).$$

Assuming $\alpha\varepsilon^{-2}L\tilde{K} < \frac{1}{2}$ we may invoke Proposition 3.1 to conclude that

$$M_S(t) \le 2\delta e^{-\varepsilon\lambda t/2\alpha} + \tfrac{4}{3}\alpha\varepsilon^{-2}L(M_w(t) + \delta M_u). \tag{5.1}$$

Next, since $G(x, \overline{u}(x)) = 0$ we may write

$$G(x, u) = 0 + J(x)w + E(x, w),$$

where the Jacobian matrix

$$J(x) = \frac{\partial G}{\partial u}(x, \overline{u}) = \begin{pmatrix} -\frac{1}{\varepsilon}(\overline{Z} + 1 + \varepsilon) & \frac{1}{\varepsilon}(\overline{T} - \overline{\sigma}) \\ -\frac{1}{\varepsilon}(\overline{T} - 2\overline{\sigma}) & -1 \end{pmatrix}, \tag{5.2}$$

and for some constant K, $|E(x, w)| \le \varepsilon^{-1}K|w|^2$ for $x \in [-1, 0]$, all w. Here and below (in this section), K denotes a generic constant independent of α and ε.

From the hypotheses of the theorem and the results of [8], it follows that the matrix norm $|J(x)| \le K/\varepsilon$ for all x and the eigenvalues of $J(x)$ have real parts bounded above by $-\gamma < 0$, where γ and K depend on h_0 but not on α or ε. Then (replacing K by a larger K if necessary) we have that for each $x \in [-1, 0]$,

$$|e^{tJ(x)}| \le \varepsilon^{-1}Ke^{-\gamma t}. \tag{5.3}$$

For each x, the perturbation w satisfies

$$w_t = J(x)w + E(x, w) + H(x, u)S.$$

Applying the variation of constants formula, we have

$$w(x, t) = e^{tJ}w_0 + \int_0^t e^{(t-\tau)J}(E + HS)(\tau)\, d\tau,$$

which we may bound as follows for $x \in [-1, 0] \setminus \mathcal{U}$:

$$|w(x, t)| \le \varepsilon^{-1}K\delta + \varepsilon^{-1}K\int_0^t e^{-\gamma(t-\tau)}(\varepsilon^{-1}K|w(x, \tau)|^2 + \varepsilon^{-1}L|S(x, \tau)|)\, d\tau.$$

Using estimate (5.1) and the fact that

$$\int_0^t e^{-\gamma(t-\tau)}|w(x, \tau)|^2\, d\tau \le \gamma^{-1}M_w(t)^2,$$

we find, taking the supremum over $x \in [-1, 0] \setminus \mathcal{U}$ (and taking K larger if necessary), that

$$M_w(t) \le K\delta(\varepsilon^{-1} + \alpha\varepsilon^{-4}) + K\alpha\varepsilon^{-4}M_w(t) + K\varepsilon^{-2}M_w(t)^2, \tag{5.4}$$

or

$$0 \le K_0\delta - K_1M_w(t) + K_2M_w(t)^2, \tag{5.5}$$

where

$$K_0 = K(\varepsilon^{-1} + \alpha\varepsilon^{-4}), \quad K_1 = 1 - K\alpha\varepsilon^{-4}, \quad K_2 = \varepsilon^{-2}K.$$

Suppose α is so small that $K\alpha\varepsilon^{-4} < \frac{1}{2}$, and δ is sufficiently small. Then, since $M_w(t)$ is continuous in t and $M_w(0) < \delta$, and since (5.5) is violated if $M_w(t) = 4K_0\delta/K_1$, we find

$$M_w(t) < 8K_0\delta \quad \text{for all } t > 0.$$

It then follows from (5.1) that for some K,

$$M_S(t) < K\delta \quad \text{for all } t > 0$$

as well. This finishes the proof of Theorem 3.4.

6. Convergence as $t \to \infty$. Here we prove Theorem 3.5, assuming the validity of Proposition 3.9, whose proof appears in §§7–10. In this section, K denotes a generic constant independent of α (but K may depend on ε and M).

Start with estimate (3.5) in Proposition 3.1, and translate from the interval $[0,t]$ to $[t_0, t_0+t]$ for $t_0 > 0$ to obtain for $t > 0$,

$$\|S(\cdot, t_0 + t)\|_{H^1} \le 2\|S(\cdot, t_0)\|_{H^1} e^{-\varepsilon\lambda t/2\alpha} + \frac{4\alpha}{3\varepsilon} \sup_{0\le\tau\le t} \|b(\cdot, u(\cdot, t_0+\tau))\|_{L^2}.$$

Letting $t \to \infty$, then $t_0 \to \infty$, we conclude that

$$S_\infty := \limsup_{t\to\infty} \|S(\cdot,t)\|_{H^1} \le \frac{4\alpha}{3\varepsilon} \limsup_{t\to\infty} \|b(\cdot, u(\cdot,t))\|_{L^2}. \tag{6.1}$$

Since $b = G_1$, this yields (3.12).

Our goal is to show that $S_\infty = 0$, then establish that $\lim_{t\to\infty} u(x,t)$ exists for each x by studying the ODE for u in (3.1). Recall that $b(x, u(x,t))$ is uniformly bounded independent of x, t, and α. Applying the Lebesgue dominated convergence theorem, we may easily infer that

$$\limsup_{t\to\infty} \|b(\cdot, u(\cdot,t))\|_{L^2} \le \| \limsup_{t\to\infty} | b(\cdot, u(\cdot,t))| \|_{L^2}. \tag{6.2}$$

We know that $|b(x,u)| \le |G(x,u)|$, so that b may be replaced by G on the right-hand side of (6.2). For large t we have the bound

$$|H(x, u(x,t))S(x,t)| \le K\|S(\cdot,t)\|_{H^1} \le 2KS_\infty.$$

Thus for x fixed and t large, we may consider $u(x,t)$ as a δ-approximate solution of (3.9) with

$$\delta = 2KS_\infty. \tag{6.3}$$

With $R(x,\delta)$ defined (see Definition 3.8) as the set of possible recurrent points of such δ-approximate solutions, it is clear that

$$\lim_{t\to\infty} \operatorname{dist}(u(x,t), R(x,\delta)) = 0, \tag{6.4}$$

and hence, for all $x \in [-1,0]$,

$$\limsup_{t\to\infty} |G(x,u(x,t))| \le \sup_{p\in R(x,\delta)} |G(x,p)|. \tag{6.5}$$

Invoking Proposition 3.9 and (6.1), (6.2), we obtain

$$S_\infty \le K\alpha\delta \le 2K^2\alpha S_\infty.$$

Hence if α is sufficiently small, so that $2K^2\alpha < 1$, it follows that $S_\infty = 0$.

To show that $\lim_{t\to\infty} u(x,t)$ exists, observe that since $S_\infty = 0$, any recurrent point of $u(x,\cdot)$ lies in $R(x,\delta)$ for all $\delta > 0$. By Proposition 3.9, such recurrent points must be critical points of (Q). Since critical points of (Q) are isolated and $u(x,t)$ is bounded, it follows that $u(x,t)$ must converge to some single critical point as $t \to \infty$. This finishes the proof of Theorem 3.5, assuming the validity of Proposition 3.9.

7. Local coordinates and estimates near the manifold of equilibria.

The next three sections are devoted to the proof of Proposition 3.11, from which Proposition 3.9 follows. The construction of the nested sets $M_j(x,\delta)$, which are positively invariant for δ-approximate solutions of (3.9) with x fixed, must be done differently in three cases. For some small $h_0 > 0$, which will be fixed later, the cases correspond to:

(i) $\overline{T} \le \overline{T}_m - h_0$ or $\overline{T} \ge \overline{T}_M + h_0$. In this case system (Q) has a single uniformly attracting critical point, A or C;

(ii) $\overline{T}_m + h_0 \le \overline{T} \le \overline{T}_M - h_0$. System (Q) has three uniformly hyperbolic critical points, a saddle B, and two attracting points A and C;

(iii) $|\overline{T} - \overline{T}_m| < h_0$ or $|\overline{T} - \overline{T}_M| < h_0$. System (Q) undergoes a saddle-node bifurcation.

To define the sets $M_j(x,\delta)$, we need to construct local coordinate systems near the manifold $\mathcal{E}$ of critical points defined in (3.10), using linear approximation of (Q) and the unstable and center manifold theorems. The number h_0 above, for example, is determined by applying the center manifold theorem in a neighborhood of the saddle-node bifurcation points.

In the rest of this section, we study the manifold of critical points $\mathcal{E}$ and describe local coordinate systems for (x,u) near the manifold $\mathcal{E}$ in three regimes:

(a) near the curves of stable critical points $(x,A(x))$ and $(x,C(x))$;

(b) near the curve of saddle points $(x,B(x))$;

(c) near the saddle-node bifurcation points.

In each coordinate system, we derive the basic estimates for δ-approximate solutions of (3.9) that will be used to construct the semi-Morse decomposition. Some of the sets $M_j(x,\delta)$ will not depend on δ; in such cases, the second argument may be omitted.

7.1. Critical points of (3.9).

Without loss of generality, we may assume that $\overline{f} > \overline{T}_M$, so that as x ranges from zero to -1, $\overline{T} = -\overline{f}x$ ranges from zero to $\overline{f} > \overline{T}_M$. Then we may define $x_M < x_m$ in [-1,0] so that

$$-\overline{f}x_M = \overline{T}_M, \qquad -\overline{f}x_m = \overline{T}_m. \tag{7.1}$$

From (1.2)–(1.4), we have that the manifold of critical points $\mathcal{E}$ is the union of three curves:

$$\begin{aligned}\mathcal{E} = \{(x,A(x)) \mid x_M \le x \le 0\} \;&\cup\; \{(x,B(x)) \mid x_M \le x \le x_m\} \\ &\cup\; \{(x,C(x)) \mid -1 \le x \le x_m\}.\end{aligned}$$

For $P = A$, B, or C, the critical point $P(x)$ has the form

$$P(x) = (\sigma_P(x), Z_P(x)) = \left(\frac{\xi}{1+\xi^2}, \frac{-\xi^2}{1+\xi^2}\right), \tag{7.2}$$

where $\xi = \xi_P(x)$ is a root of $\omega(\xi) = \overline{T}$. Here

$\xi_A(x)$ is the smallest root, defined for $x_M \le x \le 0$;
$\xi_B(x)$ is the middle root, defined for $x_M \le x \le x_m$;
$\xi_C(x)$ is the largest root, defined for $-1 \le x \le x_m$.

Let us recall now from [8] some properties of the linearization of (3.9) at the critical points $(x, P(x))$. For $P = A$, B, or C define

$$J_P(x) = \frac{\partial G}{\partial u}(x, P(x)) = \begin{pmatrix} -\frac{1}{\varepsilon}\left(\varepsilon + \frac{1}{1+\xi^2}\right) & \xi \\ -\frac{1}{\varepsilon}\left(\varepsilon\xi - \frac{\xi}{1+\xi^2}\right) & -1 \end{pmatrix}. \tag{7.3}$$

We have $\varepsilon \operatorname{tr} J_P(x) = -2\varepsilon - 1/(1+\xi_P^2) < 0$ always. Also, $\varepsilon \det J_P(x) = (1+\xi_P^2)\omega'(\xi_P)$, which is positive for $P = A$, $x_M < x \le 0$, and for $P = C$, $-1 \le x < x_m$, and is negative for $P = B$, $x_M < x < x_m$. Correspondingly, we have the following (see [8]).

LEMMA 7.1.

(1) *For $x_M < x \le 0$, $J_A(x)$ has two negative eigenvalues.*
(2) *For $-1 \le x < x_m$, $J_C(x)$ has two eigenvalues with negative real part.*
(3) *For $x_M < x < x_m$, $J_B(x)$ has one negative and one positive eigenvalue.*
(4) *For $x = x_M$, $J_A(x) = J_B(x)$ has one zero and one negative eigenvalue.*
(5) *For $x = x_m$, $J_C(x) = J_B(x)$ has one zero and one negative eigenvalue.*

Note also since $\varepsilon\xi \le \omega(\xi) = \overline{T}$, we have $\varepsilon|J_P(x)| \le K$ independent of x, P, and ε, where $|\cdot|$ is the matrix norm. For ε fixed, $|J_P(x)| \le K_0$ independent of x and P.

7.2. Local coordinates. For later reference, we note that if $(x, P(x))$ is a critical point of (3.9), then since $G(x, P(x)) = 0$ and G is quadratic, we may write

$$G(x,u) = J_P(x)(u - P(x)) + E(x, u - P(x)), \quad \text{where } |E(x,w)| \le K_1|w|^2 \tag{7.4}$$

for all $w \in R^2$, and some constant K_1 independent of x.

Case (a). We study uniformly stable branches of the manifold of critical points. For $h > 0$ given, put

$$\mathcal{E}_a(h) = \{(x, A(x)) \mid x_M + h \le x \le 0\} \cup \{(x, C(x)) \mid -1 \le x \le x_m - h\}. \tag{7.5}$$

LEMMA 7.2. *Let $h > 0$. Then there exist positive constants $K_2 > 0$ and $\gamma > 0$ such that whenever $(x, P(x)) \in \mathcal{E}_a(h)$, then with $J = J_P(x)$ we have*

$$|\exp(Jt)| \le K_2 e^{-\gamma t}, \qquad t \ge 0, \tag{7.6}$$

and, with $D = D_P(x)$ defined by

$$D = \int_0^\infty \exp(Jt)^T \exp(Jt)\, dt, \tag{7.7}$$

we have $D^T = D$, $J^T D + DJ^T = -I$, *where* I *is the* 2×2 *identity matrix, and for all* $w \in R^2$,

$$w^T DJw = -\frac{1}{2}|w|^2, \qquad \frac{1}{2|J|}|w|^2 \le w^T Dw \le \frac{K_2^2}{2\gamma}|w|^2. \tag{7.8}$$

For the proof, see [1, Appendix 4].

Now suppose that $u = u(x,t)$ is a δ-approximate solution of (3.9), with x fixed so that $(x, P(x)) \in \mathcal{E}_a(h)$ as above. That is,

$$u_t = G(x,u) + f(t), \quad \text{where } |f(t)| \le \delta, \tag{7.9}$$

and f is continuous. Define $w(t) = u(x,t) - P(x)$. Using (7.4) we have, with $J = J_P(x)$,

$$w_t = Jw + E(x,w) + f(t), \qquad |f(t)| \le \delta.$$

From this we derive, using the inequalities (7.8),

$$\frac{d}{dt} w^T Dw = 2w^T D(Jw + E + f) \le -|w|^2 + \frac{K_2^2}{\gamma}|w|(K_1|w|^2 + \delta).$$

Thus we obtain

$$\frac{d}{dt} w^T Dw \le -\frac{1}{2}|w|^2 < 0, \tag{7.10}$$

provided

$$|w|\frac{K_1 K_2^2}{\gamma} \le \frac{1}{4} \quad \text{and} \quad \frac{|w|}{4} > \left(\frac{K_2^2}{\gamma}\right)\delta.$$

Using (7.8), we conclude that (7.10) also follows if

$$K_a \delta \le (w^T Dw)^{1/2} \le \frac{1}{K_a}, \tag{7.11}$$

where K_a is a suitable constant (depending on h but not on x).

Case (b). We consider a uniformly hyperbolic branch of saddle points in the manifold of critical points. For $h > 0$ given, put

$$\mathcal{E}_b(h) = \{(x, B(x)) \mid x_M + h \le x \le x_m - h\}. \tag{7.12}$$

Denote the eigenvalues of $J_B(x)$ by $\lambda_1(x)$, $\lambda_2(x)$, with $\lambda_1(x) < 0 < \lambda_2(x)$ for $x_M < x < x_m$. Let $R(x)$ be a smooth matrix defined for $x \in (x_M, x_m)$ whose columns $r_1(x)$, $r_2(x)$ are eigenvectors of $J_B(x)$ corresponding, respectively, to $\lambda_1(x)$ and $\lambda_2(x)$. For $(x,u) \in (x_M, x_m) \times R^2$, change variables to $(x, \tilde{w})$ by requiring

$$u - B(x) = R(x)\tilde{w} = r_1(x)\tilde{w}_1 + r_2(x)\tilde{w}_2. \tag{7.13}$$

Invoking the unstable manifold theorem, see [7], we have the following.

LEMMA 7.3. *Let* $h > 0$. *Then there exists* $\eta_0 > 0$ *such that, for* $x_M + h \le x \le x_m - h$, *the unstable manifold of* $B(x)$ *in* (3.9) *is parametrized locally by*

$$\tilde{w}_1 = \phi(x, \tilde{w}_2) \quad \textit{for } |\tilde{w}_2| \le \eta_0, \tag{7.14}$$

where $\phi(x,y)$ is smooth, with $\phi(x,0) = 0 = \partial\phi/\partial y(x,0)$ for all x.

We make a further change of variables to (x,w), putting

$$w_1 = \tilde{w}_1 - \phi(x,\tilde{w}_2), \qquad w_2 = \tilde{w}_2. \tag{7.15}$$

Then, given $h > 0$, there exists $\eta_1 > 0$ such that the change of variables from (x,u) to (x,w) is smooth and defined for

$$x_M + h \le x \le x_m - h, \qquad |w|_\infty = \max(|w_1|,|w_2|) \le \eta_1. \tag{7.16}$$

In terms of the variables (x,w), the system (3.9) may be written in the form

$$\begin{aligned} w_{1t} &= \lambda_1(x)w_1 + F_1(x,w_1,w_2), \\ w_{2t} &= \lambda_2(x)w_2 + F_2(x,w_1,w_2), \end{aligned} \tag{7.17}$$

where, with $F(x,w) = (F_1,F_2)$, F is smooth, with $F(x,0) = 0 = \partial F/\partial w(x,0)$, and moreover, since $w_1 = 0$ is an invariant manifold of (7.17), $F_1(x,0,w_2) = 0$ for $|w_2| \le \eta_1$. Hence for some constant K_0, we have the estimates

$$|F_1(x,w)| \le K_0|w_1||w|_\infty, \qquad |F_2(x,w)| \le K_0|w|_\infty^2 \quad \text{for } |w|_\infty \le \eta_1. \tag{7.18}$$

Suppose now $u = u(x,t)$ is a δ-approximate solution of (3.9), where $(x,B(x)) \in \mathcal{E}_b(h)$ as above. For some $\eta > 0$ (depending on h but not on x), if $|u(x,t) - B(x)| < \eta$, we may change variables from (x,u) to (x,w) as above, obtaining

$$\begin{aligned} w_{1t} &= \lambda_1(x)w_1 + F_1(x,w_1,w_2) + f_1(t), \\ w_{2t} &= \lambda_2(x)w_2 + F_2(x,w_1,w_2) + f_2(t), \end{aligned} \tag{7.19}$$

where for some $K > 0$ (depending on h but not on x), $|f(t)|_\infty \le K\delta$. Then so long as $|w|_\infty \le \eta_1$, we have

$$\begin{aligned} \frac{d}{dt}w_1^2 = 2w_1(\lambda_1 w_1 + F_1 + f_1) &\le 2\lambda_1 w_1^2 + 2|w_1|(K_0|w_1||w|_\infty + K\delta) \\ &\le \lambda_1 w_1^2 < 0, \end{aligned} \tag{7.20}$$

provided that

$$2K_0|w|_\infty < \tfrac{1}{2}|\lambda_1| \quad \text{and} \quad 4K\delta < |\lambda_1||w_1|. \tag{7.21}$$

Similarly,

$$\begin{aligned} \frac{d}{dt}w_2^2 = 2w_2(\lambda_2 w_2 + F_2 + f_2) &\ge 2\lambda_2 w_2^2 - 2|w_2|(K_0|w|_\infty^2 + K\delta) \\ &\ge \lambda_2 w_2^2 > 0, \end{aligned} \tag{7.22}$$

provided that

$$2K_0|w_2| < \tfrac{1}{2}|\lambda_2| \quad \text{and} \quad 2K_0|w_1|^2 < \tfrac{1}{2}\lambda_2|w_2| \quad \text{and} \quad 2K\delta < \tfrac{1}{2}|\lambda_2||w_2|. \tag{7.23}$$

Case (c). We study the branches of critical points close to the bifurcation points $(x_M, A(x_M))$ and $(x_m, C(x_m))$. For $h > 0$, define

$$\begin{aligned} \mathcal{E}_c(h) =& \{(x,P(x)) \mid P = A \text{ or } B \text{ and } x_M \le x \le x_M + h\} \\ &\cup \ \{(x,P(x)) \mid P = C \text{ or } B \text{ and } x_m - h \le x \le x_m\}. \end{aligned} \tag{7.24}$$

Note that $\mathcal{E} = \mathcal{E}_a(h) \cup \mathcal{E}_b(h) \cup \mathcal{E}_c(h)$ for any $h > 0$.

We study a neighborhood of the point (x_0, P_0), which denotes either saddle-node bifurcation point $(x_M, A(x_M))$ or $(x_m, C(x_m))$. From Lemma 7.1, The Jacobian matrix $J_0 = \partial G/\partial u(x_0, P_0)$ at this point has eigenvalues $\lambda_1 < 0$, $\lambda_2 = 0$. We let r_1, r_2 denote corresponding right eigenvectors of J_0, and let R be the matrix with columns r_1, r_2.

Now, we wish to augment system (3.9) by regarding x as an unknown satisfying the equation $\dot{x} = 0$. Define

$$U = \begin{pmatrix} u \\ x \end{pmatrix}, \qquad \tilde{G}(U) = \begin{pmatrix} G(x,u) \\ 0 \end{pmatrix}, \qquad \tilde{J} = \frac{\partial \tilde{G}}{\partial U}(U_0) = \begin{pmatrix} J_0 & G_x \\ 0 & 0 \end{pmatrix},$$

where $U_0 = (P_0, x_0)$ and $G_x = \partial G/\partial x(x_0, P_0)$. System (3.9) becomes the augmented system $U_t = \tilde{G}(U)$. The Jacobian matrix of this system at U_0 is $\tilde{J}$, which has (generalized) eigenvectors of the form

$$\tilde{r}_1 = \begin{pmatrix} r_1 \\ 0 \end{pmatrix}, \qquad \tilde{r}_2 = \begin{pmatrix} r_2 \\ 0 \end{pmatrix}, \qquad \tilde{r}_3 = \begin{pmatrix} a_1 r_1 \\ 1 \end{pmatrix},$$

satisfying $\tilde{J}\tilde{r}_1 = \lambda_1 \tilde{r}_1$, $\tilde{J}\tilde{r}_2 = 0$, $\tilde{J}\tilde{r}_3 = a_2 \tilde{r}_2$, where a_1, a_2 are determined by requiring

$$G_x = -\lambda_1 a_1 r_1 + a_2 r_2. \tag{7.25}$$

Thus, if $\tilde{R}$ is the matrix with columns $\tilde{r}_1$, $\tilde{r}_2$, $\tilde{r}_3$, we have

$$\tilde{J}\tilde{R} = \tilde{R}\Lambda, \qquad \Lambda = \begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & 0 & a_2 \\ 0 & 0 & 0 \end{pmatrix}.$$

Next, make a change of variables from $U = (u, x)$ to $\tilde{W} = (\tilde{w}, y)$, where

$$U - U_0 = \tilde{R}\tilde{W}, \quad \text{i.e.,} \quad u - P_0 = r_1\tilde{w}_1 + r_2\tilde{w}_2 + a_1 r_1 y, \quad x - x_0 = y.$$

In these variables, the system becomes

$$\tilde{W}_t = \Lambda\tilde{W} + \tilde{F}(\tilde{W}), \tag{7.26}$$

where $\tilde{F}(0) = 0$ and $\partial\tilde{F}/\partial\tilde{W}(0) = 0$, and in fact, $\tilde{F}_3 = 0$.

We may now apply the center manifold theorem to system (7.26); see [7]. The result is the following.

LEMMA 7.4. *There exists $h_1 > 0$, and a neighborhood $\mathcal{N}_h$ of $\tilde{W} = 0$, such that* (7.26) *has a locally invariant manifold in $\mathcal{N}_h$ of the form*

$$\tilde{w}_1 = \phi(\tilde{w}_2, y), \quad \textit{with } \phi(0,0) = 0, \quad \partial\phi(0,0) = 0,$$

where $\partial\phi$ is the gradient of ϕ. Here ϕ is defined for $\max(|\tilde{w}_2|, |y|) < h_1$ *and ϕ is C^k (k is arbitrary, but $\mathcal{N}_h$ depends on k).*

The center manifold need not be unique, but since $\lambda_1 < 0$, the center manifold is a center-unstable manifold, so any solution $\tilde{W}(t)$ that lies in $\mathcal{N}_h$ for all $t < 0$ must lie in each such center-unstable manifold [7]. In particular, equilibria in $\mathcal{N}_h$ and their local unstable manifolds lie in the center manifold above.

We make a further change of variables, defining

$$w_1 = \tilde{w}_1 - \phi(\tilde{w}_2, y), \qquad w_2 = \tilde{w}_2. \tag{7.27}$$

For some $h_2 > 0$, the change of variables from $U = (u, x)$ to $W = (w, y)$ is C^k (for any fixed k) and is defined for $|W|_\infty = \max(|w_1|, |w_2|, |y|) \leq h_2$. In these variables, the system becomes

$$\begin{aligned} w_{1t} &= \lambda_1 w_1 + F_1(w_1, w_2, y), \\ w_{2t} &= a_2 y + F_2(w_1, w_2, y), \\ y_t &= 0, \end{aligned} \tag{7.28}$$

or $W_t = \Lambda W + F(W)$, where

$$F(0) = 0, \qquad \frac{\partial F}{\partial W}(0) = 0, \quad \text{and} \quad F_1(0, w_2, y) = 0; \tag{7.29}$$

the center manifold $w_1 = 0$ is locally invariant. For some $K_0 > 0$ we have the estimates

$$|F_1(w)| \leq K_0 |w_1| |W|_\infty, \qquad |F_2(W)| \leq K_0 |W|_\infty^2 \quad \text{for } |W|_\infty \leq h_2. \tag{7.30}$$

In what follows, we need to study a bit more closely the equation on the center manifold. From the results so far, there exists a C^k function $a(w_2, y)$ such that on the center manifold $w_1 = 0$ we have

$$w_{2t} = a(w_2, y)y + bw_2^2 = a_2 y + F_2(0, w_2, y), \tag{7.31}$$

where $a(0,0) = a_2$ and $b = \frac{1}{2}\partial^2 F_2/\partial w_2^2(0)$.

LEMMA 7.5. *With an appropriate choice of the null eigenvector r_2, we have that $b = 1$. Moreover, we have*

$$a_2 < 0 \quad at\ (x_M, A(x_M)), \qquad a_2 > 0 \quad at\ (x_m, C(x_m)).$$

Proof. Provided we show $b \neq 0$, we can arrange $b = 1$ by replacing r_2 by r_2/b. (The corresponding value of a_2 is replaced by ba_2.) To compute b and a_2, let ℓ be a left null eigenvector of J_0, satisfying $\ell J_0 = 0$. Then a_2 is determined by $a_2 = \ell G_x / \ell r_2$. From (7.3) we see that we may take, with $\xi = \xi_P(x_0)$,

$$r_2 = \begin{pmatrix} \varepsilon\xi \\ \varepsilon + \frac{1}{1+\xi^2} \end{pmatrix}, \qquad \ell = (1, \xi). \tag{7.32}$$

Then from (3.2) we compute

$$G_x = -\frac{\overline{f}}{\varepsilon}\begin{pmatrix} Z_P + 1 \\ -\sigma_P \end{pmatrix} = -\frac{\overline{f}}{\varepsilon}\begin{pmatrix} \frac{1}{1+\xi^2} \\ -\frac{\xi}{1+\xi^2} \end{pmatrix}.$$

Hence $\ell r_2 = \varepsilon\xi + \omega(\xi) > 0$, and $\ell G_x = (-\overline{f}/\varepsilon)(1-\xi^2)/(1+\xi^2) = \overline{f}(1+\xi^2) > 0$, which follows from $0 = \omega'(\xi) = \varepsilon + (1-\xi^2)/(1+\xi^2)^2$ at $\xi = \xi_P(x_0)$. So, with the choice of r_2 in (7.32), we have $a_2 > 0$ at both saddle-node bifurcation points.

To compute b, we use (7.29) and the fact that $\partial\phi(0,0)=0$ from Lemma 7.4. We have

$$2b = \frac{\partial^2 F_2}{\partial w_2^2}(0) = \frac{\partial^2 \tilde{F}_2}{\partial \tilde{w}_2^2}(0) = \ell\, \partial^2 G(r_2, r_2),$$

where $\partial^2 G$ is the Hessian of G. From (3.2) and (7.32) we compute $b = \frac{1}{2}\ell\, \partial^2 G(r_2,r_2) = \xi(\varepsilon(\xi^2-1) - 1/(1+\xi^2))$. Since $\omega'(\xi)=0$ we have $\varepsilon = (\xi^2-1)/(1+\xi^2)^2$, so we find $b = \xi^3(\xi^2-3)/(1+\xi^2)^2$. Now $\omega'(\sqrt{3}) = \varepsilon - \frac{1}{8} < 0$, so $\xi_A(x_M)^2 < 3 < \xi_C(x_m)^2$. Thus we find that $b<0$ at $(x_M, A(x_M))$, and $b>0$ at $(x_m, C(x_m))$. Replacing r_2 by r_2/b as discussed previously, the Lemma follows. □

Now suppose that $u = u(x,t)$ is a δ-approximate solution of (3.9), lying in a neighborhood of one of the saddle-node bifurcation points, where the change of variables from (u,x) to (w,y) is defined. In the (w,y) variables, we have

$$\begin{aligned} w_{1t} &= \lambda_1 w_1 + F_1(w_1,w_2,y) + f_1(t), \\ w_{2t} &= w_2^2 + a(w_2,y)y + g_2(w_1,w_2,y) + f_2(t), \\ y_t &= 0, \end{aligned} \tag{7.33}$$

where for some constant $K>0$, $|f(t)|_\infty \le K\delta$, and $|g_2(w_1,w_2,y)| \le K|w_1||W|_\infty$. Then, so long as $|W|_\infty \le h_2$, we have the following estimates:

$$|w_1|_t = (\operatorname{sgn} w_1)(\lambda_1 w_1 + F_1 + f_1) \le \lambda_1|w_1| + K_0|w_1||W|_\infty + K\delta \le \tfrac{1}{2}\lambda_1|w_1| < 0, \tag{7.34}$$

provided that

$$K_0|W|_\infty \le \tfrac{1}{4}|\lambda_1| \quad \text{and} \quad 4K\delta \le |\lambda_1||w_1|. \tag{7.35}$$

Also, we have

$$\operatorname{sgn}(w_{2t}) = \operatorname{sgn}(w_2^2 + ay), \tag{7.36}$$

provided

$$2K\max(\delta, h_2|w_1|) \le |w_2^2 + ay|. \tag{7.37}$$

8. A semi-Morse decomposition: case (i).

In this section we construct nested, positively invariant sets

$$M_0(x) \supset M_1(x) \supset M_2(x,\delta) \tag{8.1}$$

in the case (i) mentioned at the start of §7, namely, the case when the system (3.9) has a single uniformly attracting critical point. This is the simplest case.

We first mention that in all the cases (i), (ii), and (iii), the first positively invariant set $M_0(x)$ will be chosen, independently of both x and δ, in the form

$$M_0(x) = \{u = (\sigma, Z) \mid \sigma^2 + (Z+1)^2 \le K\} \tag{8.2}$$

for $K>1$ sufficiently large, so that $|u| \le M_u$ implies $u \in M_0(x)$. For a δ-approximate solution of (3.9), we may obtain

$$\frac{d}{dt}(\sigma^2 + (Z+1)^2) \le -2(\sigma^2 + (Z+1)Z) + (\sigma^2 + (Z+1)^2)^{1/2}\delta.$$

It follows that the set in (8.2) is positively invariant for δ-approximate solutions , if δ is sufficiently small, independent of x.

Now let $h > 0$. (This number will be fixed in §10.) We employ the variables introduced in §7, Case (a). For $(x, P(x)) \in \mathcal{E}_a(h)$, $P = A$ or C, we select $D = D_P(x)$ and put

$$N_P(x,\delta) = \{u = P(x) + w \mid (w^T D w)^{1/2} \leq K_a \delta\}, \tag{8.3}$$

where K_a is the constant in (7.11). According to (7.10) we have the following.

LEMMA 8.1. *The sets $N_P(x,\tilde{\delta})$ are positively invariant for δ-approximate solutions of* (3.9) *provided $\delta \leq \tilde{\delta} \leq 1/K_a^2$.*

Case (i) corresponds, by definition, to the cases

$$x_m + h \leq x \leq 0 \quad \text{and} \quad -1 \leq x \leq x_M - h. \tag{8.4}$$

Corresponding to these two subcases, the unique critical point of (3.9) is $P = A$ or C, respectively. For x satisfying (8.4), we put

$$M_1(x) = N_P\left(x, \frac{1}{K_a^2}\right), \qquad M_2(x,\delta) = N_P(x,\delta), \tag{8.5}$$

assuming $\delta \leq 1/K_a^2$. With these definitions, the sets in (8.1) now satisfy the following.

PROPOSITION 8.2. *Let $h > 0$. Then there exist constants $\delta_0 > 0$, $K > 0$ such that, if $\delta \leq \delta_0$ and x satisfies* (8.4), *then every δ-approximate solution of* (3.9) *that lies in $M_j(x,\delta)$ must enter $M_{j+1}(x,\delta)$, for $j = 0$ and 1. Hence, every recurrent point of such a δ-approximate solution must lie in $M_2(x,\delta)$. Moreover, we have*

$$\sup_{u \in M_2(x,\delta)} |G(x,u)| \leq K\delta. \tag{8.6}$$

Proof. If $u \in M_2(x,\delta)$, then by using Lemma 7.2 we have $|u - P(x)|^2 \leq 2K_0 K_a^2 \delta^2$, so (8.6) follows. From (7.10), (7.11) it is clear that any δ-approximate solution lying in $M_1(x)$ must enter $M_2(x,\delta)$. To prove the analogous assertion for $M_0(x)$, we apply Proposition 3.7. Let

$$\mathcal{N} = \{(x,u) \in [-1,0] \times R^2 \mid u \in M_1(x) \text{ if } x \text{ satisfies (8.4)}\}.$$

Now $\mathcal{N}$ is a neighborhood of $\mathcal{E}$, the manifold of critical points; so by Proposition 3.7, there exists $\delta_0 > 0$ such that, if $\delta < \delta_0$ and x satisfies (8.4), then any δ-approximate solution of (3.9) lying in $M_0(x)$ will enter $M_1(x)$. This finishes the proof of Proposition 8.2. □

9. A semi-Morse decomposition: case (ii). Case (ii) corresponds to

$$x_M + h \leq x \leq x_m - h. \tag{9.1}$$

Here h will be fixed in §10, as we have mentioned earlier. Because of the presence of the saddle B in this case, the semi-Morse decomposition we require has more sets than in the last section, seven in all: $M_0(x,\delta), \ldots, M_6(x,\delta)$. A sketch of the decomposition is given in Fig. 6; a detail of the neighborhood of the saddle B appears in Fig. 7. In

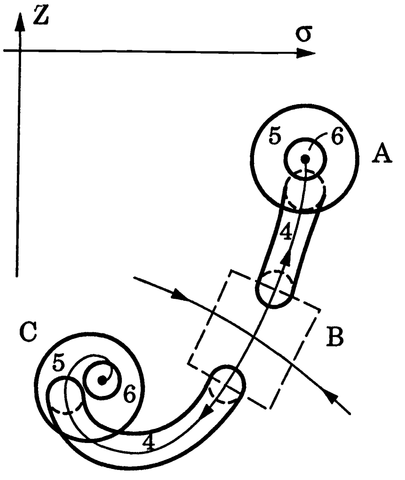

FIG. 6. *Semi-Morse decomposition, case* (ii).

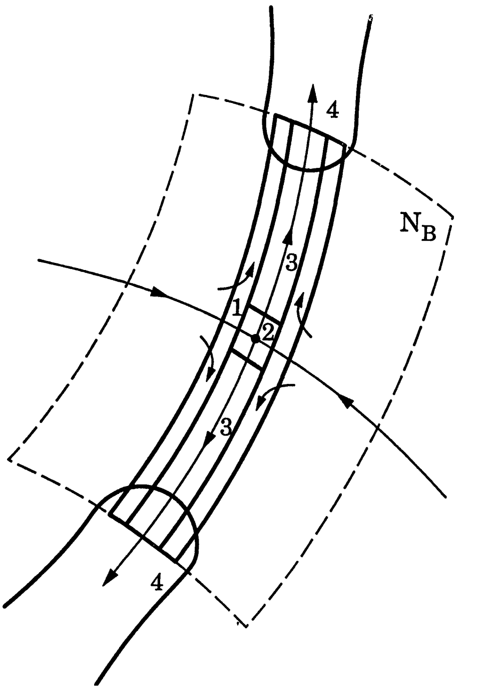

FIG. 7. *Detail near the saddle.*

these figures, the numbers $j = 0, \ldots, 6$ indicate the location of the region $M_j \setminus M_{j+1}$; the flow proceeds in increasing numerical order.

The smallest sets in the semi-Morse decomposition will be neighborhoods of the stable critical points A and C. Using Lemma 8.1 and the definition in (8.3), we will put

$$\begin{aligned} M_6(x,\delta) &= N_A(x,\delta) \cup N_C(x,\delta), \\ M_5(x) &= N_A\left(x, \frac{1}{K_a^2}\right) \cup N_C\left(x, \frac{1}{K_a^2}\right). \end{aligned} \tag{9.2}$$

We note that from (7.10), (7.11) it is clear that for $\delta < 1/K_a^2$, any δ-approximate solution of (3.9) lying in $M_5(x)$ must enter $M_6(x,\delta)$.

Now, to study the flow near the saddle point B, recall the results of §7, case (b). In the notation of that section, for x satisfying (9.1), and $\eta \le \eta_1$ (η_1 is given in (7.16)), we may define a neighborhood of $B(x)$ by

$$N_B(x,\eta) = \{u = B(x) + R(x)(w_1 + \phi(x,w_2), w_2)^T \mid |w|_\infty \le \eta\}. \tag{9.3}$$

From the estimates (7.20)–(7.23) we may infer the following.

LEMMA 9.1. *There exist constants $\eta_2, K_b > 0$ (depending on h but not on x) such that if $K_b\delta \le \eta_2$ and $u = u(x,t)$ is a δ-approximate solution lying in $N_B(x,\eta_2)$, then*

$$\begin{array}{ll} |w_1| \ge K_b\delta & \textit{implies } |w_1| \textit{ is strictly decreasing;} \\ |w_2| \ge K_b \max(\delta, w_1^2) & \textit{implies } |w_2| \textit{ is strictly increasing.} \end{array}$$

To define the next set $M_4(x,\delta)$ of the decomposition, we construct sets $F_A(x)$, $F_C(x)$ that serve as "funnels" to connect the neighborhood $N_B(x,\eta_2)$ to $M_5(x)$. In $N_B(x,\eta_2)$, the points corresponding to $(w_1,w_2) = (0,\eta_2)$ and $(0,-\eta_2)$ lie on the unstable manifold of the saddle $B(x)$, and the corresponding (exact) forward trajectories of (3.9) from these points approach the stable critical points $A(x)$ and $C(x)$ as $t \to \infty$, respectively (upon a suitable choice of the orientation of the eigenvector r_2 in §7).

To construct $F_A(x)$, let $z(x,t)$ denote the exact solution of $z_t = G(x,z)$, so that $z(x,0)$ corresponds to $(w_1,w_2) = (0,\eta_2)$. Because solutions of (3.9) depend continuously on x and initial data, and the fact that $N_A(x,1/K_a^2)$ is positively invariant, there exist constants $\eta > 0$, $T > 0$ (depending on h but not on x) such that

$$\{u \in R^2 \mid |u - z(x,T)| \le \eta\} \subset N_A\left(x, \frac{1}{K_a^2}\right)$$

for x satisfying (9.1).

Let L be an upper bound for the Lipschitz constant of G in M_0, and let $\kappa > 2L$. Suppose $u = u(x,t)$ is a δ-approximate solution of (3.9), and so satisfies (7.9). Then

$$\begin{aligned} \frac{d}{dt}|u-z|^2 e^{-2\kappa t} &= 2e^{-2\kappa t}(u-z)^T(-\kappa(u-z) + G(x,u) - G(x,z) + f) \\ &\le 2e^{-2\kappa t}((-\kappa + L)|u-z|^2 + |u-z|\delta) < 0, \end{aligned} \tag{9.4}$$

provided $2\delta < \kappa|u-z|$. From this we deduce the following.

LEMMA 9.2. *For x satisfying (9.1), define*

$$F_A(x) = \{u \in R^2 \mid |u - z(x,t)| \le \eta e^{\kappa(t-T)} \textit{ for some } t \in [0,T]\}.$$

Then, if $\delta < \kappa\eta e^{-\kappa T}/2$ and $\delta < 1/K_a^2$, the set $F_A(x) \cup N_A(x,1/K_a^2)$ is positively invariant for δ-approximate solutions of (3.9). Moreover, any δ- approximate solution lying in $F_A(x)$ must enter $N_A(x,1/K_a^2)$.

In a similar manner, we construct the set $F_C(x)$, and we may say that for δ satisfying the conditions of Lemma 9.2, the set

$$M_4(x) = F_A(x) \cup F_C(x) \cup M_5(x)$$

is positively invariant for δ-approximate solutions, and any δ-approximate solution lying in $M_4(x)$ must enter $M_5(x)$.

The remaining sets $M_1(x,\delta)$ through $M_3(x,\delta)$ will be defined by using the coordinates (w_1,w_2) in the neighborhood of the saddle point B. Let $K>0$ be a uniform bound for the Lipschitz constant of the change of variables from (w_1,w_2) to u in $N_B(x,\eta_2)$. Define

$$N_1(x)=\left\{u\in N_B(x,\eta_2)\mid |w_1|\le\frac{\eta e^{-\kappa T}}{K}\right\}.$$

By Lemma 9.1, if $\delta<\eta e^{-\kappa T}/KK_b$, then any δ-approximate solution of (3.9) which leaves $N_1(x)$ must do so at a point where $w_2=\eta_2$ or $-\eta_2$ and $|w_1|<\eta e^{-\kappa T}/K$. Thus this solution must enter one of the funnels in $M_4(x)$. We define

$$M_1(x)=N_1(x)\cup M_4(x).$$

Next, with reference to Lemma 9.1 we define

$$N_2(x,\delta)=\{u\in N_1(x)\mid |w_1|\le K_b\delta\},$$
$$N_3(x,\delta)=\{u\in N_1(x)\mid |w|_\infty\le K_b\delta\},$$

and put

$$M_2(x,\delta)=M_4(x)\cup N_2(x,\delta),\qquad M_3(x,\delta)=M_2(x,\delta)\setminus N_3(x,\delta).$$

For δ sufficiently small (independent of x), the sets $M_1(x)$, $M_2(x,\delta)$, and $M_3(x,\delta)$ are positively invariant for δ-approximate solutions. Note that we have

$$\begin{aligned}M_1(x)\setminus M_2(x,\delta)&\subset\{u\in N_1(x)\mid |w_1|\ge K_b\delta\},\\ M_2(x,\delta)\setminus M_3(x,\delta)&\subset\{u\in N_1(x)\mid |w|_\infty\le K_b\delta\}=N_3(x,\delta),\\ M_3(x,\delta)\setminus M_4(x)&\subset\{u\in N_1(x)\mid |w_1|\le K_b\delta\ \text{ and }\ |w_2|\ge K_b\delta\}.\end{aligned}$$

By Lemma 9.1, for δ sufficiently small, if $u(x,t)$ is any δ-approximate solution lying in $M_1(x)\setminus M_2(x,\delta)$, then $|w_1|$ is strictly decreasing, so u must enter $M_2(x,\delta)$. If u lies in $M_3(x,\delta)\setminus M_4(x)$, then $|w_2|$ is strictly increasing, so u must enter $M_4(x)$.

PROPOSITION 9.3. *Let $h>0$. Then there exist constants $\delta_0>0$, $K>0$ such that, if $\delta\le\delta_0$ and x satisfies* (9.1), *then:*

- *The sets $M_j(x,\delta)$ are positively invariant for δ-approximate solutions of* (3.9) *for $j=0,\dots,6$.*
- *For $j=0,1,3,4,$ and 5, every δ-approximate solution that lies in $M_j(x,\delta)$ must enter $M_{j+1}(x,\delta)$.*

Hence every recurrent point of a δ-approximate solution must lie either in $N_3(x,\delta)\supset M_2(x,\delta)\setminus M_3(x,\delta)$ or in $M_6(x,\delta)$, and there we have

$$\sup_{u\in N_3(x,\delta)}|G(x,u)|\le K\delta,\qquad \sup_{u\in M_6(x,\delta)}|G(x,u)|\le K\delta. \tag{9.5}$$

Proof. The inequality (9.5) follows easily from the definitions of $N_3(x,\delta)$ and $M_6(x,\delta)$ and Lemma 7.2. The only assertion remaining to be proved is, that for δ sufficiently small (depending on h but not on x), if $u(x,t)$ is a δ-approximate solution lying in $M_0(x)$, then u enters $M_1(x)$. But this is proved exactly the same as in the proof of Proposition 8.2, by using Proposition 3.7, this time taking

$$\mathcal{N}=\{(x,u)\in[-1,0]\times R^2\mid u\in M_1(x)\text{ if }x\text{ satisfies (9.1)}\}.$$

10. A semi-Morse decomposition: case (iii). In this section we study the behavior of δ-approximate solutions of (3.9) for x near x_m and x_M, the points at which saddle-node bifurcations occur in (3.9). In fact, it suffices to consider x near x_m (where the critical points B and C coalesce); the situation for x near x_M (where A and B coalesce) is entirely analogous. The constructions in this section are similar to those in §9. The semi-Morse decomposition can consist of as many as nine sets, $M_0(x,\delta), \ldots, M_8(x,\delta)$. A sketch appears in Fig. 8, with details of the neighborhood of the saddle-node pair in Figs. 9 and 10, corresponding to a fixed δ, for two different values of x near x_m with $x < x_m$. (Two other possibilities occur with $x > x_m$, when the critical points B and C do not exist.) As before, the numeral $j = 0, \ldots, 8$ in the figures indicate the region $M_j \setminus M_{j+1}$.

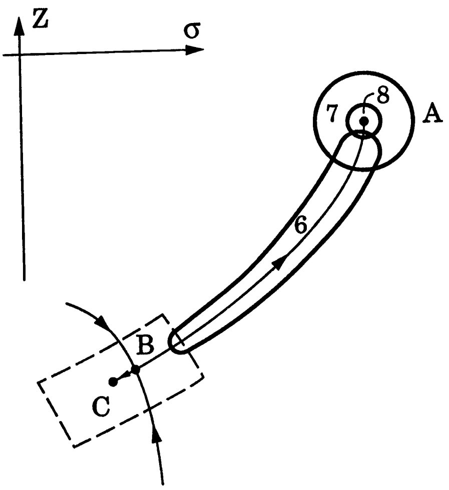

FIG. 8. *Semi-Morse decomposition, case* (iii).

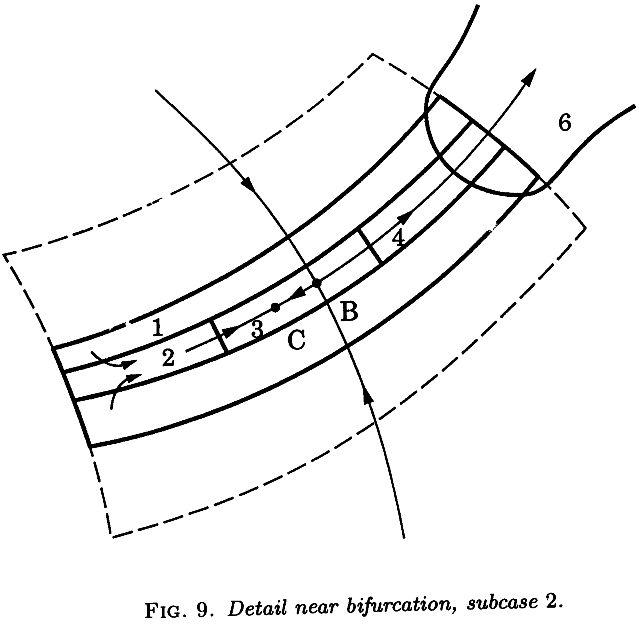

FIG. 9. *Detail near bifurcation, subcase* 2.

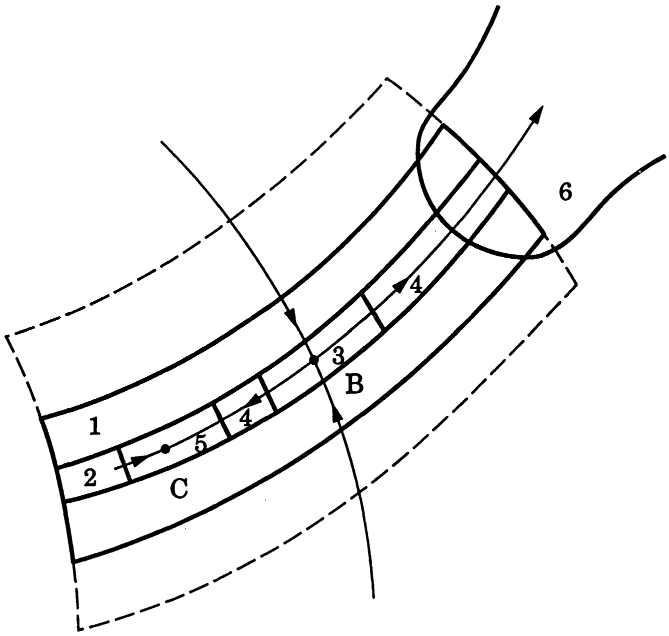

FIG. 10. *Detail near bifurcation, subcase* 3.

To begin, we invoke all the analysis of §7, case (c). In terms of the variables $W = (w_1, w_2, y)$ (recall $y = x - x_m$), the results in (7.33)–(7.37) have been obtained. We may summarize these as follows.

LEMMA 10.1. *There exist positive constants h_2, K_c, and h such that for $K_c\delta < h_2$ and $|x - x_m| < h$, if $u = u(x,t)$ is a δ-approximate solution of* (3.9) *satisfying $|w|_\infty = \max(|w_1|, |w_2|) \le h_2$, then*

$$\begin{array}{ll} |w_1| \ge K_c\delta & \textit{implies } |w_1| \textit{ is strictly decreasing;} \\ |w_2^2 + ay| \ge \max(K_c\delta, |w_1|) & \textit{implies } \operatorname{sgn}(w_{2\,t}) = \operatorname{sgn}(w_2^2 + ay). \end{array}$$

Moreover, if h is sufficiently small (*independent of x*) *we have*

$$\begin{aligned} &\frac{\partial}{\partial y}(w_2^2 + ay) \ge \frac{1}{2}a_2 > 0, \qquad \frac{\partial^2}{\partial w_2^2}(w_2^2 + ay) \ge 1 \quad \textit{for } |y| < h, \ |w_2| \le h_2, \\ &h_2^2 + a(h_2, y)y > 0 \quad \textit{for } |y| < h. \end{aligned} \tag{10.1}$$

The result of this lemma fixes the value of h to be used below and in previous sections. Now, for $|x - x_m| < h$, the smallest sets in the semi-Morse decomposition will be neighborhoods of the stable critical point $A(x)$. Using Lemma 8.1 we put

$$M_8(x,\delta) = N_A(x,\delta), \qquad M_7(x) = N_A\left(x, \frac{1}{K_a^2}\right).$$

From (7.10), (7.11), for $\delta < 1/K_a^2$, any δ-approximate solution lying in $M_7(x)$ must enter $M_8(x,\delta)$.

For the next step, we introduce a funnel $F_A(x)$, constructed in a manner entirely analogous to that in section 9, having the form in Lemma 9.2, where now $z(x,0)$ corresponds to the point $(w_1, w_2) = (0, h_2)$, whose (exact) forward trajectory under (3.9) approaches $A(x)$ as $t \to \infty$. We define

$$M_6(x) = F_A(x) \cup M_7(x).$$

Provided $\delta < \min(\kappa\eta e^{-\kappa T}/2, 1/K_a^2)$, the set $M_6(x)$ is positively invariant for δ-approximate solutions, and any such solution lying in $M_6(x)$ must enter $M_7(x)$.

The remaining constructions are carried out in the local coordinates (w_1, w_2, y) defined near the bifurcation point. Let $K > 0$ be a uniform bound for the Lipschitz constant of the change of variables from (u, x) to (w, y), and define, for $|x - x_m| < h$,

$$N_1(x) = \left\{ u \mid |w|_\infty \leq h_2 \text{ and } |w_1| \leq \frac{\eta e^{-\kappa T}}{K} \right\}.$$

By Lemma 10.1, if $K_c\delta < \eta e^{-\kappa T}/K$, then any δ-approximate solution which leaves $N_1(x)$ must do so at a point where $w_2 = h_2$; thus this solution enters $M_6(x)$. We define

$$M_1(x) = N_1(x) \cup M_6(x).$$

Then $M_1(x)$ is positively invariant for δ-approximate solutions, if δ is sufficiently small (independent of x). Moreover, by using Proposition 3.7 exactly as in the proof of Propositions 8.2 and 9.3, it is clear that for δ sufficiently small and $|x - x_m| < h$, any δ-approximate solution in $M_0(x)$ must enter $M_1(x)$.

Next, we define, for $|x - x_m| < h$,

$$N_2(x, \delta) = \{u \in N_1(x) \mid |w_1| \leq K_c\delta\},$$
$$M_2(x, \delta) = N_2(x, \delta) \cup M_6(x).$$

By Lemma 10.1, it is clear that $M_2(x, \delta)$ is positively invariant for δ-approximate solutions, and any such solution lying in $M_1(x)$ must enter $M_2(x, \delta)$, since $|w_1|$ is strictly decreasing in $M_1(x) \setminus M_2(x, \delta)$.

Now, for a δ-approximate solution lying in $N_2(x, \delta)$, Lemma 10.1 implies

$$\operatorname{sgn}(w_{2t}) = \operatorname{sgn}(w_2^2 + ay) \quad \text{provided } |w_2^2 + ay| \geq K_c\delta. \tag{10.2}$$

The remaining constructions subdivide into three cases (illustrated in Fig. 11).

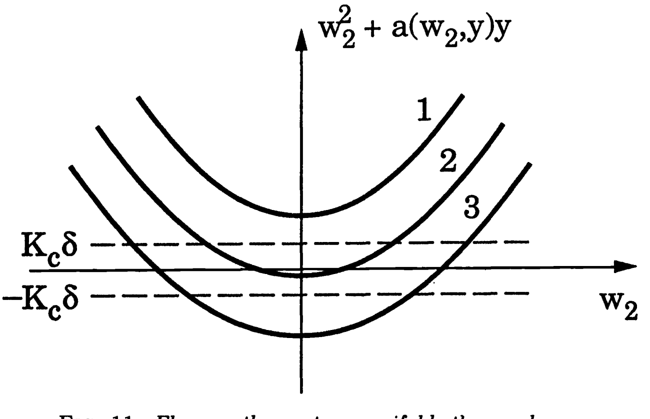

FIG. 11. *Flow on the center manifold: three subcases.*

(1) In the simplest case, $x = x_m + y$ is such that

$$w_2^2 + ay > K_c\delta \quad \text{for all } |w_2| \leq h_2.$$

In this case, the critical points B and C are absent, and w_2 is strictly increasing in $N_2(x,\delta)$. Thus every δ-approximate solution lying in $M_2(x,\delta)$ must enter $M_6(x)$. We define

$$M_j(x,\delta) = M_6(x) \quad \text{for } j = 3,\ 4, \text{ and } 5.$$

(2) In the next case (which includes $x = x_m$) we have

$$\{w_2 \mid |w_2^2 + ay| \leq K_c\delta\} = [\gamma_1, \gamma_2]$$

for some interval $[\gamma_1, \gamma_2]$ depending on x and δ. In this case, the critical points may or may not be absent. We define

$$\begin{aligned} M_3(x,\delta) &= M_6(x) \cup \{u \in N_2(x,\delta) \mid w_2 \geq \gamma_1\}, \\ M_4(x,\delta) &= M_6(x) \cup \{u \in N_2(x,\delta) \mid w_2 \geq \gamma_2\}, \\ M_5(x,\delta) &= M_6(x). \end{aligned}$$

It is clear that for δ sufficiently small, each $M_j(x,\delta)$ is positively invariant for δ-approximate solutions and every δ-approximate solution lying in $M_j(x,\delta)$ must enter $M_{j+1}(x,\delta)$, for $j = 2$, 4, and 5. Moreover, for $u \in M_3(x,\delta) \setminus M_4(x,\delta)$ we have $\gamma_1 \leq w_2 \leq \gamma_2$, so for some constant K we have

$$|G(x,u)| \leq K\delta \quad \text{for } u \in M_3(x,\delta) \setminus M_4(x,\delta).$$

(3) In the last case, we have

$$\{w_2 \mid |w_2^2 + ay| \leq K_c\delta\} = [\gamma_1, \gamma_2] \cup [\gamma_3, \gamma_4]$$

for some $\gamma_1 \leq \gamma_2 \leq \gamma_3 \leq \gamma_4$ depending on x and δ. For a δ-approximate solution lying in $N_2(x,\delta)$, w_2 is strictly increasing if $w_2 \leq \gamma_1$ or $w_2 \geq \gamma_4$, and w_2 is strictly decreasing if $\gamma_2 \leq w_2 \leq \gamma_3$. We put

$$\begin{aligned} M_3(x,\delta) &= M_6(x) \cup \{u \in N_2(x,\delta) \mid \gamma_1 \leq w_2\}, \\ M_4(x,\delta) &= M_6(x) \cup \{u \in N_2(x,\delta) \mid \gamma_1 \leq w_2 \leq \gamma_3 \text{ or } \gamma_4 \leq w_2\}, \\ M_5(x,\delta) &= M_6(x) \cup \{u \in N_2(x,\delta) \mid \gamma_1 \leq w_2 \leq \gamma_2\}. \end{aligned}$$

It is clear that for δ sufficiently small, each $M_j(x,\delta)$ is positively invariant for δ-approximate solutions, and every δ-approximate solution lying in $M_j(x,\delta)$ must enter $M_{j+1}(x,\delta)$ for $j = 2$ and 4. Moreover, for some constant K we clearly have

$$|G(x,u)| \leq K\delta \quad \text{for } u \in M_j(x,\delta) \setminus M_{j+1}(x,\delta) \quad \text{for } j = 3 \quad \text{and} \quad 5.$$

This finishes our analysis of case (iii), and concludes the proof of Proposition 3.11.

ANTIPLANE SHEARING MOTIONS OF A VISCO-PLASTIC SOLID*

J. M. GREENBERG[†] AND ANNE NOURI[‡]

Abstract. The authors consider antiplane shearing motions of an incompressible isotropic visco-plastic solid. The flow rule employed is a properly invariant generalization of Coulomb sliding friction and assumes a constant yield stress or threshold above which plastic flow occurs. In this model stresses above yield are possible; but when this condition obtains, the plastic flow rule forces the plastic strain to change so as to lower the stress levels in the material and dissipate energy. On the yield surface, the flow rule looks like the classical one for a rate independent elastic-perfectly plastic material when the velocity gradients are small enough but differs from the classical model for large gradients.

Key words. plastic waves, visco-plasticity, time-dependent problems

1. Introduction.

In this note we consider antiplane shearing motions of an incompressible isotropic visco-plastic solid. This work generalizes and compliments earlier work of Greenberg [1], [2], where he considered simple shearing flows for such materials. The flow rule we employ is a properly invariant generalization of Coulomb sliding friction and assumes a constant yield stress or threshold above which plastic flow occurs. As with most such theories, we assume a multiplicative decomposition of the deformation gradient into an elastic and plastic part, and we assume further that the deviatoric part of the Cauchy Stress tensor depends only on the elastic portion of the deformation gradient. For antiplane shearing motions this decomposition presents no precedence problems; i.e., does the elastic deformation precede the plastic or vice versa? One key feature of this model is that stresses above yield are possible. When this condition obtains, the plastic flow rule forces the plastic strain to change so as to lower the stress levels in the material and dissipate energy. The principal difficulty in formulating this model occurs when the stress is at yield. Motivated by results of Seidman [3], Utkin [4], and Filippov [5] on sliding modes induced by discontinuous vector fields, we are led to the flow rule advanced in (2.38). On the yield surface, this flow rule looks like the classical one for a rate independent elastic-perfectly plastic material when the velocity gradients are small enough but differs from the classical model for large gradients. This rule differentiates between loading and unloading and generates an energy identity which guarantees that uniqueness obtains for initial and initial-boundary value problems.

The organization of this paper is as follows. In §2 we develop the appropriate equations describing antiplane shearing flows in visco-plastic solids. Section 3 focuses on the uniqueness issue. Our basic estimate is that the energy associated with the difference between two solutions generated by the same data is nonincreasing. This estimate relies in an essential way on the definition of the plastic flow rule. In §4 we examine a one-dimensional signalling problem and discuss (1) the structure of this

solution, and (2) a procedure to analytically obtain an approximate solution. We also compare this solution with what obtains for the more studied model of a rate independent elastic-perfectly plastic material where uniqueness fails. Section 5 deals with a numerical experiment for a two-dimensional signalling problem in the corner domain $r > 0$ and $\pi/2 < \theta < 2\pi$. Here the stresses are singular as one approaches the corner and care must be taken in the implementation of the boundary conditions.

We note that in the last several years there have been a number of other efforts aimed at capturing the essence of plastic flows. Antman and Szymczak [6], [7] have advanced a finite deformation theory of such materials which is similar in spirit to ours but differs in a number of essential ways. Their model is formally rate independent where ours is not but their model also requires a history dependent strain hardening mechanism. The predictions of the two theories are often qualitatively different; these differences arise since in their model the imposition of large loads tends to elevate the yield stress and create a temporally constant permanent plastic deformation, whereas in our model such loading would generate a constant plastic deformation rate and thus a plastic deformation which varies linearly in time. This may be seen by examining the solution constructed in §4. Other efforts on elasto-plastic modelling may be found in Coleman and Owen [8], Buhite and Owen [9], Coleman and Hodgdon [10], and Owen [11].

2. Model development.

We say that a body is undergoing antiplane shear if material points $\xi = \xi_1\mathbf{e}_1 + \xi_2\mathbf{e}_2 + \xi_3\mathbf{e}_3$ move to $\mathbf{x} = x_1\mathbf{e}_1 + x_2\mathbf{e}_2 + x_3\mathbf{e}_3$ with

$$x_1 = \xi_1, \quad x_2 = \xi_2, \quad \text{and } x_3 = \xi_3 + \phi(\xi_1, \xi_2, t) \tag{2.1}$$

under the action of a Cauchy stress tensor of the form

$$\begin{aligned} T = &-\pi(\mathbf{e}_1 \otimes \mathbf{e}_1 + \mathbf{e}_2 \otimes \mathbf{e}_2 + \mathbf{e}_3 \otimes \mathbf{e}_3) \\ &+(S_{11}\mathbf{e}_1 \otimes \mathbf{e}_1 + S_{22}\mathbf{e}_2 \otimes \mathbf{e}_2 + S_{33}\mathbf{e}_3 \otimes \mathbf{e}_3) \\ &+S_{31}(\mathbf{e}_1 \otimes \mathbf{e}_3 + \mathbf{e}_3 \otimes \mathbf{e}_1) + S_{32}(\mathbf{e}_2 \otimes \mathbf{e}_3 + \mathbf{e}_3 \otimes \mathbf{e}_2). \end{aligned} \tag{2.2)^1 $(}$$

Here, π is the hydrostatic pressure and S is the deviatoric stress tensor and satisfies

$$\text{trace}(S) = S_{11} + S_{22} + S_{33} = 0. \tag{2.3}$$

Relative to the above basis, the matrix representation of the Cauchy stress is given by

$$\mathcal{J} = -\pi \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + \begin{pmatrix} S_{11} & 0 & S_{31} \\ 0 & S_{22} & S_{32} \\ S_{31} & S_{32} & S_{33} \end{pmatrix}, \tag{2.4}$$

and relative to the same basis the deformation gradient is given by

$$\mathcal{F} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ F_{31} & F_{32} & 1 \end{pmatrix}, \tag{2.5}$$

[1] $\mathbf{e}_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$, $\mathbf{e}_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$, and $\mathbf{e}_3 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ are the standard basis elements for R^3 and $\mathbf{e}_i \otimes \mathbf{e}_j = \mathbf{e}_i\mathbf{e}_j{}^{\top}$ are the standard basis elements for linear operators from R^3 to R^3.

where

$$F_{31} = \frac{\partial \phi}{\partial x_1} \quad \text{and} \quad F_{32} = \frac{\partial \phi}{\partial x_2}. \tag{2.6}$$

Noting that matrices

$$\mathcal{F}_{(a,b)} \overset{\text{def}}{:=} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ a & b & 1 \end{pmatrix}$$

satisfy the commutation relation

$$\mathcal{F}_{(a_1,b_1)}\mathcal{F}_{(a_2,b_2)} = \mathcal{F}_{(a_2,b_2)}\mathcal{F}_{(a_1,b_1)} = \mathcal{F}_{(a_1+a_2,b_1+b_2)}, \tag{2.7}$$

we feel justified in decomposing the deformation gradient $\mathcal{F}$ into its elastic and plastic parts $\mathcal{E}$ and $\mathcal{P}$ by

$$\mathcal{E} \overset{\text{def}}{:=} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ e_{31} & e_{32} & 1 \end{pmatrix} \quad \text{and} \quad \mathcal{P} \overset{\text{def}}{:=} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ p_{31} & p_{32} & 1 \end{pmatrix}, \tag{2.8}$$

where

$$\mathcal{F} = \mathcal{E}\mathcal{P} = \mathcal{P}\mathcal{E} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ e_{31}+p_{31} & e_{32}+p_{32} & 1 \end{pmatrix}. \tag{2.9}$$

For such antiplane shear flows one need not make any assumption about the precedence of the elastic and plastic parts of the flow.

Our basic constitutive assumption is that under a change of reference frame E transforms in the same way as F and that the deviatoric stress S is an isotropic, frame indifferent, trace free function of the elastic deformation gradient E.[2] The constraint that S is an isotropic, frame indifferent function of E implies that $\mathcal{S}$ must have the functional form

$$\mathcal{S} = \alpha I + \beta \mathcal{E}\mathcal{E}^{\top} + \gamma \mathcal{E}^{-\top}\mathcal{E}^{-1} \tag{2.10}$$

or

(2.11)[3]

$$\mathcal{S} = \alpha \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + \beta \begin{pmatrix} 1 & 0 & e_{31} \\ 0 & 1 & e_{32} \\ e_{31} & e_{32} & 1+e_{31}^2+e_{32}^2 \end{pmatrix} + \gamma \begin{pmatrix} 1+e_{31}^2 & e_{31}e_{32} & -e_{31} \\ e_{31}e_{32} & 1+e_{32}^2 & -e_{32} \\ -e_{31} & -e_{32} & 1 \end{pmatrix},$$

where α, β, and γ are functions of the invariants of $\mathcal{E}\mathcal{E}^{\top}$, in this case the scalar $e_{31}^2 + e_{32}^2$. Equation (2.4) implies that $\mathcal{S}_{21} = \mathcal{S}_{12} = 0$ and this, in turn, implies that $\gamma \equiv 0$ while the condition that trace$\mathcal{S} = 0$ implies that $\alpha = -\beta(1 + ((e_{31}^2 + e_{32}^2)/3))$. Combining these identities with (2.11) yields

$$\mathcal{S} = \beta \begin{pmatrix} -\frac{1}{3}(e_{31}^2 + e_{32}^2) & 0 & e_{31} \\ 0 & -\frac{1}{3}(e_{31}^2 + e_{32}^2) & e_{32} \\ e_{31} & e_{32} & \frac{2}{3}(e_{31}^2 + e_{32}^2) \end{pmatrix}. \tag{2.12}$$

[2] E is the tensor whose matrix representation relative to the basis elements $\mathbf{e_i} \otimes \mathbf{e_j}$ is given by $(2.8)_1$.

[3] For details see Gurtin [12].

In the sequel we shall assume that β is a positive constant. Equation (2.12) implies that we may regard the elements S_{31} and S_{32} as basic descriptors of our system. In terms of these $\mathcal{S}$ and $\mathcal{E}$ take the form

$$\mathcal{S} = \begin{pmatrix} -\frac{1}{3\beta}(S_{31}^2 + S_{32}^2) & 0 & S_{31} \\ 0 & -\frac{1}{3\beta}(S_{31}^2 + S_{32}^2) & S_{32} \\ S_{31} & S_{32} & \frac{2}{3\beta}(S_{31}^2 + S_{32}^2) \end{pmatrix} \tag{2.13}$$

and

$$\mathcal{E} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ \frac{S_{31}}{\beta} & \frac{S_{32}}{\beta} & 1 \end{pmatrix}. \tag{2.14}$$

We now turn to the equations of motion. Equation (2.1) implies that the Eulerian velocity field $\mathbf{u}$ is of the form

$$\mathbf{u} = u(x_1, x_2, t_1)\mathbf{e_3}, \tag{2.15}$$

where

$$u(x_1, x_2, t_1) = \frac{\partial \phi}{\partial t_1}(x_1, x_2, t_1); \tag{2.16}$$

and (2.16), when combined with (2.6), implies that

$$\frac{\partial F_{31}}{\partial t_1} - \frac{\partial u}{\partial x_1} = 0 \tag{2.17}$$

and

$$\frac{\partial F_{32}}{\partial t_1} - \frac{\partial u}{\partial x_2} = 0. \tag{2.18}$$

Additionally, (2.9) and (2.14) imply that

$$F_{31} = \frac{S_{31}}{\beta} + p_{31} \tag{2.19}$$

and

$$F_{32} = \frac{S_{32}}{\beta} + p_{32}. \tag{2.20}$$

Balance of momentum in the $\mathbf{e_1}$ and $\mathbf{e_2}$ directions implies that

$$\frac{\partial}{\partial x_1}\left(\pi + \frac{(S_{31}^2 + S_{32}^2)}{3\beta}\right) = \frac{\partial}{\partial x_2}\left(\pi + \frac{(S_{31}^2 + S_{32}^2)}{3\beta}\right) = 0 \tag{2.21}$$

or equivalently that

$$\pi = \pi_0(x_3, t) - \frac{(S_{31}^2 + S_{32}^2)}{3\beta}(x_1, x_2, t), \tag{2.22}$$

whereas balance of momentum in the $\mathbf{e}_3$ direction yields

$$\rho_0 \frac{\partial u}{\partial t_1} - \frac{\partial S_{31}}{\partial x_1} - \frac{\partial S_{32}}{\partial x_2} = -\frac{\partial \pi_0}{\partial x_3}. \tag{2.23}$$

Here, ρ_0 is the constant mass density of the material. Since $\partial\pi_0/\partial x_3$ depends on x_3 and t_1, whereas all quantities on the left-hand side of (2.23) depend only on x_1, x_2, and t_1, we conclude that for antiplane shearing flows $\partial\pi_0/\partial x_3$ is independent of x_3. In what follows we shall assume this quantity is zero.

We now turn our attention to "yield condition" and the flow rule for the plastic strain tensor $\mathcal{P}$ of $(2.8)_2$. We assume that yield is determined by whether the scalar $S_{31}^2 + S_{32}^2$ exceeds a threshold S_y^2 or not. This assumption relies on the special form of $\mathcal{S}$ (see (2.13)) and is equivalent to a yield criteria determined by the norm of $\mathcal{S}$, where

$$\|\mathcal{S}\|^2 \overset{\text{def}}{:=} \mathcal{S}_{ij}\mathcal{S}_{ij} = 2(S_{31}^2 + S_{32}^2) + \frac{2}{3\beta^2}(S_{31}^2 + S_{32}^2)^2 \tag{2.24}$$

or one based on the maximum shear stress

$$S_*^2 \overset{\text{def}}{:=} \max_{\{\mathbf{e}|\mathbf{e}\cdot\mathbf{e}=1\}} \|\mathcal{S}\mathbf{e} - (\mathcal{S}\mathbf{e}\cdot\mathbf{e})\mathbf{e}\|^2. \tag{2.25}$$

In the sequel we let H denote the Heaviside function

$$H(x) \overset{\text{def}}{:=} \begin{cases} 0, & x < 0 \\ 1, & x > 0 \end{cases} \tag{2.26}$$

and define ψ_1 and ψ_2 by

$$\psi_1 = \frac{1}{2}\int_{-\infty}^{(S_{31}^2+S_{32}^2)} H(x - S_y^2)\, dx \tag{2.27}$$

and

$$\psi_2 = \int_{-\infty}^{\sqrt{S_{31}^2+S_{32}^2}} H(x - S_y)\, dx, \tag{2.28}$$

where $S_y > 0$ is the "yield stress."

We shall confine our attention to the Coulomb type sliding law

$$\frac{\partial p_{31}}{\partial t_1} = \frac{1}{\beta T_0}\frac{\partial \psi_1}{\partial S_{31}} = \frac{S_{31}}{\beta T_0} H(S_{31}^2 + S_{32}^2 - S_y^2) \tag{2.29}$$

and

$$\frac{\partial p_{32}}{\partial t_1} = \frac{1}{\beta T_0}\frac{\partial \psi_1}{\partial S_{32}} = \frac{S_{32}}{\beta T_0} H(S_{31}^2 + S_{32}^2 - S_y^2), \tag{2.30}$$

though much of what we say applies equally well to the flow rule

$$\frac{\partial p_{31}}{\partial t_1} = \frac{S_y}{\beta T_0}\frac{\partial \psi_2}{\partial S_{31}} = \frac{S_y S_{31}}{\beta T_0\sqrt{S_{31}^2 + S_{32}^2}} H\left(\sqrt{S_{31}^2 + S_{32}^2} - S_y\right) \tag{2.31}$$

and

$$\frac{\partial p_{32}}{\partial t_1} = \frac{S_y}{\beta T_0}\frac{\partial \psi_2}{\partial S_{32}} = \frac{S_y S_{32}}{\beta T_0\sqrt{S_{31}^2 + S_{32}^2}} H\left(\sqrt{S_{31}^2 + S_{32}^2} - S_y\right). \tag{2.32}$$

The constant β is the shear modulus in (2.12), S_y is the yield stress, and $T_0 > 0$ is a fixed relaxation time. The flow rule is defined for $S_{31}^2 + S_{32}^2 \neq S_y^2$ and the problem remains to define it on the yield surface.

We first note that if $S_{31}^2 + S_{32}^2 \neq S_y^2$, we can combine (2.17)–(2.20) and (2.29) and (2.30) to obtain the following system for S_{31}, S_{32}, and u:

$$\frac{1}{\beta}\frac{\partial S_{31}}{\partial t_1} - \frac{\partial u}{\partial x_1} = \frac{-S_{31}H(S_{31}^2 + S_{32}^2 - S_y^2)}{\beta T_0}, \tag{2.33}$$

$$\frac{1}{\beta}\frac{\partial S_{32}}{\partial t_1} - \frac{\partial u}{\partial x_2} = \frac{-S_{32}H(S_{31}^2 + S_{32}^2 - S_y^2)}{\beta T_0}, \tag{2.34}$$

and

$$\rho_0\frac{\partial u}{\partial t_1} - \frac{\partial S_{31}}{\partial x_1} - \frac{\partial S_{32}}{\partial x_2} = 0. \tag{2.35}$$

Equations (2.33) and (2.34) imply that for $S_{31}^2 + S_{32}^2 \neq S_y^2$,

$$\begin{aligned}\frac{\partial}{\partial t_1}(S_{31}^2 + S_{32}^2) &= 2\beta\left(S_{31}\frac{\partial u}{\partial x_1} + S_{32}\frac{\partial u}{\partial x_2}\right)\\ &\quad -\frac{2}{T_0}(S_{31}^2 + S_{32}^2)H(S_{31}^2 + S_{32}^2 - S_y^2),\end{aligned} \tag{2.36}$$

and (2.36), together with the results of [3], [4], [5], motivates our extension of the flow rule on the yield surface $S_{31}^2 + S_{32}^2 = S_y^2$. We extend (2.29) and (2.30) to the yield surface $S_{31}^2 + S_{32}^2 = S_y^2$ by

$$\frac{\partial p_{31}}{\partial t_1} = \frac{\alpha S_{31}}{\beta T_0} \quad\text{and}\quad \frac{\partial p_{32}}{\partial t_1} = \frac{\alpha S_{32}}{\beta T_0}, \tag{2.37}$$

where

$$\alpha = \begin{cases} 1 \ \text{ if } S_{31}^2 + S_{32}^2 = S_y^2 \ \text{ and } \ S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2} > \dfrac{S_y^2}{\beta T_0},^{4} \\ \beta T_0\left(S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2}\right)\Big/ S_y^2 \ \text{ if } S_{31}^2 + S_{32}^2 = S_y^2 \ \text{ and} \\ 0 \le S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2} \le \dfrac{S_y^2}{\beta T_0}, \\ 0 \ \text{ if } S_{31}^2 + S_{32}^2 = S_y^2 \ \text{ and } \ S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2} < 0. \end{cases} \tag{2.38}$$

[4] The relations (2.37) and (2.38) transform in a frame indifferent fashion.

In the sequel we shall confine our attention to the extended flow rule (2.29), (2.30), (2.37) and (2.38). The relevant equations are

$$\frac{1}{\beta}\frac{\partial S_{31}}{\partial t_1} - \frac{\partial u}{\partial x_1} = -\frac{\alpha S_{31}}{\beta T_0}, \tag{2.39}$$

$$\frac{1}{\beta}\frac{\partial S_{32}}{\partial t_1} - \frac{\partial u}{\partial x_2} = -\frac{\alpha S_{32}}{\beta T_0}, \tag{2.40}$$

$$\rho_0\frac{\partial u}{\partial t_1} - \frac{\partial S_{31}}{\partial x_1} - \frac{\partial S_{32}}{\partial x_2} = 0, \tag{2.41}$$

where now

$$\alpha = \begin{cases} 1 \quad \text{if } S_{31}^2 + S_{32}^2 > S_y^2, \\ 1 \quad \text{if } S_{31}^2 + S_{32}^2 = S_y^2 \quad \text{and} \quad \dfrac{\beta T_0}{S_y^2}\left(S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2}\right) > 1, \\ \dfrac{\beta T_0}{S_y^2}\left(S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2}\right) \quad \text{if } S_{31}^2 + S_{32}^2 = S_y^2 \quad \text{and} \\ 0 \le \dfrac{\beta T_0}{S_y^2}\left(S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2}\right) \le 1, \\ 0 \quad \text{if } S_{31}^2 + S_{32}^2 = S_y^2 \quad \text{and} \quad \dfrac{\beta T_0}{S_y^2}\left(S_{31}\dfrac{\partial u}{\partial x_1} + S_{32}\dfrac{\partial u}{\partial x_2}\right) < 0, \\ 0 \quad \text{if } S_{31}^2 + S_{32}^2 < S_y^2, \end{cases} \tag{2.42}$$

and these are solved together with appropriate initial and boundary conditions. Having solved the above system for S_{31}, S_{32}, and u we recover the deformation gradients F_{31} and F_{32} by solving

$$\frac{\partial F_{31}}{\partial t_1} - \frac{\partial u}{\partial x_1} = 0 \quad \text{and} \quad \frac{\partial F_{32}}{\partial t_1} - \frac{\partial u}{\partial x_2} = 0 \tag{2.43}$$

together with appropriate initial conditions. The plastic strains p_{31} and p_{32} are then given by

$$p_{31} = F_{31} - \frac{S_{31}}{\beta} \quad \text{and} \quad p_{31} = F_{32} - \frac{S_{32}}{\beta}. \tag{2.44}$$

These equations should be contrasted with what obtains in the more commonly studied theory of rate independent elastic-perfectly plastic materials. In that theory (2.37), (2.39)–(2.41), (2.43) and (2.44) still hold but α is given by

(2.45)

$$\alpha = \begin{cases} \frac{\beta T_0}{S_y^2}\left(S_{31}\frac{\partial u}{\partial x_1} + S_{32}\frac{\partial u}{\partial x_2}\right) & \text{if } S_{31}^2 + S_{32}^2 = S_y^2 \quad \text{and} \\ 0 \leq \frac{\beta T_0}{S_y^2}\left(S_{31}\frac{\partial u}{\partial x_1} + S_{32}\frac{\partial u}{\partial x_2}\right), & \\ 0 \quad \text{if } S_{31}^2 + S_{32}^2 = S_y^2 \quad \text{and} \quad \frac{\beta T_0}{S_y^2}\left(S_{31}\frac{\partial u}{\partial x_1} + S_{32}\frac{\partial u}{\partial x_2}\right) < 0, & \\ 0 \quad \text{if } S_{31}^2 + S_{32}^2 < S_y^2. & \end{cases}$$

The unboundedness of α on the yield surface $S_{31}^2 + S_{32}^2 = S_y^2$ presents difficulties not encountered in our model. In particular, across nonstationary shocks where F_{31}, F_{32}, u, S_{31}, and S_{32} experience jump discontinuities, we must admit jumps in the plastic strains p_{31} and p_{32}. The reason for this is that in the classical rate independent theory—α as in (2.45)—we must allow "dirac" type singularities in the terms $\alpha S_{31}/\beta T_0$ and $\alpha S_{32}/\beta T_0$ and therefore, we cannot conclude that

$$cn_1[p_{31}] = cn_2[p_{32}] = 0. \tag{2.46}$$

Here, c is the normal velocity of the shock wave and $\mathbf{n}=(n_1, n_2)$ is the unit normal to the shock. In our model α is bounded, no "dirac" type singularities arise in the terms $\alpha S_{31}/\beta T_0$ and $\alpha S_{32}/\beta T_0$, and thus (2.46) holds. This implies that with our model all nonstationary shocks satisfy $c^2 = 1$; that is, they propagate with the speed of elastic signals. With our model, the only surfaces across which the plastic strains can jump are stationary, i.e., $c = 0$. Such jumps are also allowed in the classical theory.

We conclude this section by writing down a dimensionless version (2.39)–(2.44). We let

(2.47)

$$x = \sqrt{\frac{\rho_0}{\beta}}\frac{x_1}{T_0}, \quad y = \sqrt{\frac{\rho_0}{\beta}}\frac{x_2}{T_0}, \quad t = \frac{t_1}{T_0}$$

$$v = \sqrt{\frac{\rho_0}{\beta}}u, \quad \tau_{31} = \frac{S_{31}}{\beta}, \quad \tau_{32} = \frac{S_{32}}{\beta}, \quad \text{and } \tau_y = \frac{S_y}{\beta}$$

and observe that (2.39)–(2.42) transform to

$$\frac{\partial \tau_{31}}{\partial t} - \frac{\partial v}{\partial x} = -\hat{\alpha}\tau_{31}, \tag{2.48}$$

$$\frac{\partial \tau_{32}}{\partial t} - \frac{\partial v}{\partial y} = -\hat{\alpha}\tau_{32}, \tag{2.49}$$

$$\frac{\partial v}{\partial t} - \frac{\partial \tau_{31}}{\partial x} - \frac{\partial \tau_{32}}{\partial y} = 0, \tag{2.50}$$

where

(2.51)
$$\hat{\alpha} = \begin{cases} 1 \quad \text{if } \tau_{31}^2 + \tau_{32}^2 > \tau_y^2, \\ 1 \quad \text{if } \tau_{31}^2 + \tau_{32}^2 = \tau_y^2 \quad \text{and} \quad \dfrac{1}{\tau_y^2}\left(\tau_{31}\dfrac{\partial v}{\partial x_1} + \tau_{32}\dfrac{\partial v}{\partial x_2}\right) > 1, \\ \dfrac{1}{\tau_y^2}\left(\tau_{31}\dfrac{\partial v}{\partial x_1} + \tau_{32}\dfrac{\partial v}{\partial x_2}\right) \quad \text{if } \tau_{31}^2 + \tau_{32}^2 = \tau_y^2 \text{ and} \\ 0 \leq \dfrac{1}{\tau_y^2}\left(\tau_{31}\dfrac{\partial v}{\partial x_1} + \tau_{32}\dfrac{\partial v}{\partial x_2}\right) \leq 1, \\ 0 \quad \text{if } \tau_{31}^2 + \tau_{32}^2 = \tau_y^2 \quad \text{and} \quad \dfrac{1}{\tau_y^2}\left(\tau_{31}\dfrac{\partial v}{\partial x_1} + \tau_{32}\dfrac{\partial v}{\partial x_2}\right) < 0, \\ 0 \quad \text{if } \tau_{31}^2 + \tau_{32}^2 < \tau_y^2. \end{cases}$$

The transformed versions of (2.43) and (2.44) are

(2.52)
$$\frac{\partial F_{31}}{\partial t} - \frac{\partial v}{\partial x} = 0 \quad \text{and} \quad \frac{\partial F_{32}}{\partial t} - \frac{\partial v}{\partial y} = 0$$

and

(2.53)
$$p_{31} = F_{31} - \tau_{31} \quad \text{and} \quad p_{32} = F_{32} - \tau_{32}.$$

3. Uniqueness results.

Our task in this section is to establish the following

THEOREM 3.1. *Let Ω be an open domain in R^2 with smooth boundary $\partial\Omega$. Then, there is at most one piecewise smooth,*[5] *$L^2_{\text{loc}}(\Omega)$ solution $(\tau_{31}, \tau_{32}, v)$ to* (2.48)–(2.51) *satisfying*

(3.1)
$$\lim_{t\to 0^+} (\tau_{31}, \tau_{32}, v)(x,y,t) = (\tau_{31}^0, \tau_{32}^0, v^0)(x,y),$$

(3.2)
$$\lim_{(x,y)\in\Omega;(x,y)\to\partial\Omega_1} (n_1\tau_{31} + n_2\tau_{32})(x,y,t) = f_1(x,y,t),$$

(3.3)
$$\lim_{(x,y)\in\Omega;(x,y)\to\partial\Omega_2} v(x,y,t) = f_2(x,y,t).$$

Here $\partial\Omega = \partial\Omega_1 \cup \partial\Omega_2$, $\partial\Omega_1 \cap \partial\Omega_2$ is at worst a finite collection of points, $\mathbf{n}=(n_1,n_2)$ is the unit exterior normal to $\partial\Omega_1$, and the f_i's are smooth functions in $L^2_{\text{loc}}(\partial\Omega_i \times [0,\infty))$.

Proof. We first note that if $(\tau_{31}^b, \tau_{32}^b, v^b)$ and $(\tau_{31}^a, \tau_{32}^a, v^a)$ are two solutions to (2.48)–(2.51), then their differences satisfy

(3.4)
$$\frac{\partial}{\partial t}(\tau_{31}^b - \tau_{31}^a) - \frac{\partial}{\partial x}(v^b - v^a) = -(\hat{\alpha}^b\tau_{31}^b - \hat{\alpha}^a\tau_{31}^a),$$

(3.5)
$$\frac{\partial}{\partial t}(\tau_{32}^b - \tau_{32}^a) - \frac{\partial}{\partial y}(v^b - v^a) = -(\hat{\alpha}^b\tau_{32}^b - \hat{\alpha}^a\tau_{32}^a),$$

and

(3.6)
$$\frac{\partial}{\partial t}(v^b - v^a) - \frac{\partial}{\partial x}(\tau_{31}^b - \tau_{31}^a) - \frac{\partial}{\partial y}(\tau_{32}^b - \tau_{32}^a) = 0.$$

[5] This formulation admits shocks which propagate with normal velocity c satisfying $c^2 = 1$.

Here, $\hat{\alpha}^b$ and $\hat{\alpha}^a$ represent the bounded function $\hat{\alpha}$ defined in (2.51) evaluated at $(\tau^b_{31}, \tau^b_{32}, v^b)$ and $(\tau^a_{31}, \tau^a_{32}, v^a)$, respectively. The last three identities imply that

$$\begin{aligned}
&\frac{1}{2}\frac{\partial}{\partial t}\left[(\tau^b_{31}-\tau^a_{31})^2+(\tau^b_{32}-\tau^a_{32})^2+(v^b-v^a)^2\right]\\
&\quad-\frac{\partial}{\partial x}\left[(\tau^b_{31}-\tau^a_{31})(v^b-v^a)\right]-\frac{\partial}{\partial y}\left[(\tau^b_{32}-\tau^a_{32})(v^b-v^a)\right]\\
&\quad=-\left[(\tau^b_{31}-\tau^a_{31})(\hat{\alpha}^b\tau^b_{31}-\hat{\alpha}^a\tau^a_{31})+(\tau^b_{32}-\tau^a_{32})(\hat{\alpha}^b\tau^b_{32}-\hat{\alpha}^a\tau^a_{32})\right].
\end{aligned}\tag{3.7}$$

We now claim that

$$p \overset{\text{def}}{:=} (\tau^b_{31}-\tau^a_{31})(\hat{\alpha}^b\tau^b_{31}-\hat{\alpha}^a\tau^a_{31})+(\tau^b_{32}-\tau^a_{32})(\hat{\alpha}^b\tau^b_{32}-\hat{\alpha}^a\tau^a_{32})\tag{3.8}$$

is nonnegative. In verifying this assertion there is no loss in generality in assuming that

$$0 \le \hat{\alpha}^a \le \hat{\alpha}^b \le 1.\tag{3.9}$$

We first note that p may be rewritten as

$$\begin{aligned}
p = {}&\hat{\alpha}^a\left[(\tau^b_{31}-\tau^a_{31})^2+(\tau^b_{32}-\tau^a_{32})^2\right]\\
&+(\hat{\alpha}^b-\hat{\alpha}^a)\left[(\tau^b_{31})^2-\tau^a_{31}\tau^b_{31}+(\tau^b_{32})^2-\tau^a_{32}\tau^b_{32}\right].
\end{aligned}\tag{3.10}$$

If $\hat{\alpha}^a = 0$, then $(\tau^a_{31})^2+(\tau^a_{32})^2 \le \tau_y^2$ and $\tau^a_{31}\tau^b_{31}+\tau^a_{32}\tau^b_{32} \le \tau_y\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}$ and, therefore, (3.10) implies that

$$p \ge \hat{\alpha}^b\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}\left(\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}-\tau_y\right).\tag{3.11}$$

If $\hat{\alpha}^b = 0$, then (3.10) implies that $p = 0$, whereas if $0 < \hat{\alpha}^b \le 1$, (2.51) implies that $\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2} \ge \tau_y$, and (3.11) then yields $p \ge 0$. We now turn to the case where $0 < \hat{\alpha}^a \le \hat{\alpha}^b \le 1$. If $\hat{\alpha}^b = \hat{\alpha}^a$, the nonnegativity of p follows from (3.10), and thus to complete the verification that $p \ge 0$ it suffices to consider the case where $0 < \hat{\alpha}^a < \hat{\alpha}^b \le 1$. Here we know that $(\tau^a_{31})^2+(\tau^a_{32})^2 = \tau_y^2$ and $(\tau^b_{31})^2+(\tau^b_{32})^2 \ge \tau_y^2$. The former identity, along with (3.10) and $\tau^a_{31}\tau^b_{31}+\tau^a_{32}\tau^b_{32} \le \tau_y\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}$, implies that

$$\begin{aligned}
p \ge {}&\hat{\alpha}^a\left[(\tau^b_{31}-\tau^a_{31})^2+(\tau^b_{32}-\tau^a_{32})^2\right]\\
&+(\hat{\alpha}^b-\hat{\alpha}^a)\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}\left(\sqrt{(\tau^b_{31})^2+(\tau^b_{32})^2}-\tau_y\right),
\end{aligned}\tag{3.12}$$

and (3.12), $0 < \hat{\alpha}^a < \hat{\alpha}^b \le 1$, and $(\tau^b_{31})^2+(\tau^b_{32})^2 \ge \tau_y^2$ complete the proof of the assertion that p is nonnegative.

For any $(x_0, y_0) \in I\!R^2$, $r_0 > 0$, $T > 0$, and $0 \le t \le T$ we let

$$C(x_0, y_0, r_0, t) \overset{\text{def}}{:=} \{(x,y) | (x-x_0)^2+(y-y_0)^2 < (r_0+T-t)^2\}.\tag{3.13}$$

The identity (3.7) implies that if $(\tau^b_{31}, \tau^b_{32}, v^b)$ and $(\tau^a_{31}, \tau^a_{32}, v^a)$ are two solutions of (2.48)-(2.51) taking on the same data (3.1)–(3.3), then

$$\frac{1}{2}\int_{C(x_0,y_0,r_0,t)\cap\Omega}((\tau^b_{31}-\tau^a_{31})^2+(\tau^b_{32}-\tau^a_{32})^2+(v^b-v^a)^2)\,dx\,dy\tag{3.14}$$

$$
\begin{aligned}
&+\int_0^T \left(\int_{C(x_0,y_0,r_0,t)\cap\Omega} p(x,y,t)\,dx\,dy\right) dt\\
&+\int_0^T \left(\int_{\partial C(x_0,y_0,r_0,T)\cap\Omega} \left(\frac{1}{2}((\tau_{31}^b-\tau_{31}^a)^2+(\tau_{32}^b-\tau_{32}^a)^2+(v^b-v^a)^2)\right.\right.\\
&\left.\left.-(v^b-v^a)\left(\frac{(x-x_0)(\tau_{31}^b-\tau_{31}^a)}{(r_0+T-t)}+\frac{(y-y_0)(\tau_{32}^b-\tau_{32}^a)}{(r_0+T-t)}\right)\right)ds\right)dt\\
&=0.
\end{aligned}
$$

Here,

$$\partial C(x_0,y_0,r_0,t)=\{(x,y)|(x-x_0)^2+(y-y_0)^2=(r_0+T-t)^2\}. \tag{3.15}$$

The vector $((x-x_0)/(r_0+T-t),(y-y_0)/(r_0+T-t))$ is the unit exterior normal to $\partial C(x_0,y_0,r_0,t)$, and ds is arc length along $\partial C(x_0,y_0,r_0,t)$. Since

$$
\begin{aligned}
&-(v^b-v^a)\left(\frac{(x-x_0)(\tau_{31}^b-\tau_{31}^a)}{(r_0+T-t)}+\frac{(y-y_0)(\tau_{32}^b-\tau_{32}^a)}{(r_0+T-t)}\right)\\
&\geq -|v^b-v^a|\sqrt{(\tau_{31}^b-\tau_{31}^a)^2+(\tau_{32}^b-\tau_{32}^a)^2}\\
&\geq -\frac{1}{2}((\tau_{31}^b-\tau_{31}^a)^2+(\tau_{32}^b-\tau_{32}^a)^2+(v^b-v^a)^2)
\end{aligned}
\tag{3.16}
$$

and since $p\geq 0$, we see that all three integrals in (3.15) are nonnegative and their sum is zero. From this we obtain

$$\int_{C(x_0,y_0,r_0,T)\cap\Omega}((\tau_{31}^b-\tau_{31}^a)^2+(\tau_{32}^b-\tau_{32}^a)^2+(v^b-v^a)^2)dxdy=0, \tag{3.17}$$

which is the desired uniqueness result.

4. A signalling problem.

In this section we consider an elementary one-dimensional signalling problem for the normalized system (2.48)–(2.53). The solution is of the form

$$(\tau_{31},\tau_{32},v)=(\tau(x,t),0,v(x,t)),\qquad 0<x<\infty, \tag{4.1}$$

where τ and v satisfy

$$\frac{\partial\tau}{\partial t}-\frac{\partial v}{\partial x}=-\hat{\alpha}\tau,\qquad 0<x<\infty, \tag{4.2}$$

$$\frac{\partial v}{\partial t}-\frac{\partial\tau}{\partial x}=0,\qquad 0<x<\infty, \tag{4.3}$$

and

$$\hat{\alpha}=\begin{cases}1 & \text{if } \tau^2>\tau_y^2,\\ 1 & \text{if } \tau^2=\tau_y^2 \text{ and } \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x}>1,\\ \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x}, & \text{if } \tau^2=\tau_y^2 \text{ and } 0\leq\frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x}\leq 1,\\ 0 & \text{if } \tau^2=\tau_y^2 \text{ and } \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x}<0,\\ 0 & \text{if } \tau^2<\tau_y^2,\end{cases} \tag{4.4}$$

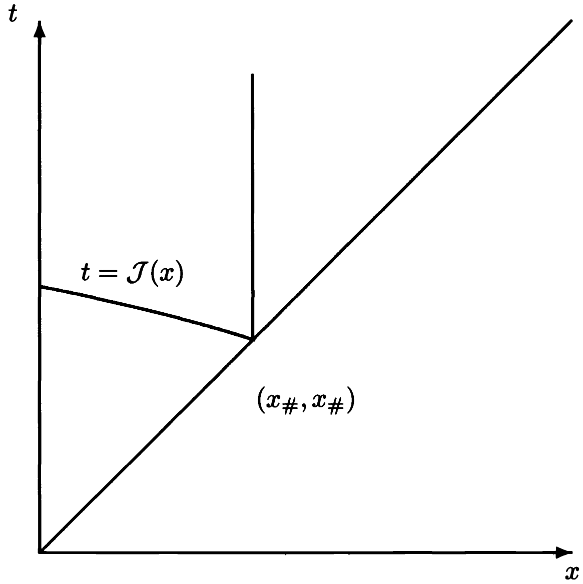

FIG. 1

and the initial and boundary conditions

$$(\tau, v)(x,0) = (0,0), \qquad 0 < x < \infty \tag{4.5}$$

and

$$v(0,t) = -\tau_0, \quad \text{where } \tau_0 > \tau_y. \tag{4.6}$$

We note that the results of the previous section guarantee there is at most one solution to the above problem.

In the region $0 \le t < x$, we have $(\tau, v) \equiv (0,0)$. Moreover, $\tau + v$ is continuous across the curve $t = x$ and thus satisfies $\tau_-(t,t) + v_-(t,t) \equiv 0$. The difficult part of the problem is to show there is a curve $t = \mathcal{J}(x)$, $0 < x < x_{\#}$, with $-1 < d\mathcal{J}/dx \le 0$, such that in the region $x < t < \mathcal{J}(x)$ with $0 < x < x_{\#}$, τ and v satisfy

$$\tau > \tau_y, \tag{4.7}$$

$$\frac{\partial \tau}{\partial t} - \frac{\partial v}{\partial x} = -\tau \quad \text{and} \quad \frac{\partial v}{\partial t} - \frac{\partial \tau}{\partial x} = 0, \tag{4.8}$$

the boundary condition (4.6) and $\tau_-(t,t) + v_-(t,t) = 0$. On the curve $t = \mathcal{J}(x)$ we have $\lim_{\epsilon \to 0^+} \tau(x, \mathcal{J}(x) - \epsilon) = \tau_y$ and $\hat{v}(x) \overset{\text{def}}{:=} \lim_{\epsilon \to 0^+} v(x, \mathcal{J}(x) - \epsilon)$ satisfies $0 \le d\hat{v}/dx \le \tau_y$. In the region $\mathcal{J}(x) < t$ and $0 < x < x_{\#}$ we have $\tau(x,t) = \tau_y$ and $v(x,t) = \hat{v}(x)$, whereas in $x_{\#} \le x < t$, $\tau \equiv \tau_y$ and $v(x,t) = \hat{v}(x_{\#}) = -\tau_y$ (see Fig. 1).

The existence of a curve $t = \mathcal{J}(x)$ with the desired properties may be established by converting the system (4.6), (4.8), and $\tau_-(t,t) + v_-(t,t) = 0$ to integral equations for τ and v in $x < t$, verifying that for $0 < t - x \ll 1$ the stress satisfies $\tau > \tau_y$, and finally by obtaining qualitative information on the level line $t = \mathcal{J}(x)$ defined by $\lim_{\epsilon \to 0^+} \tau(x, \mathcal{J}(x) - \epsilon) = \tau_y$.

Rather than perusing that approach we shall show how to obtain simple approximate solutions satisfying (4.6)–(4.8) and $\tau_-(t,t) + v_-(t,t) = 0$ as well as approximations to the level line $t = \mathcal{J}(x)$.

We note that for each integer $N \geq 1$ the system (4.8) has solutions

(4.9)
$$v_N = -\tau_0 + \sum_{k=1}^{N} \lambda_{(k)}(t) x^{2k-1}$$

and

(4.10)[6]
$$\tau_N = \lambda_0(t) + \sum_{k=1}^{N} \dot{\lambda}_{(k)} x^{2k}/2k$$

where the coefficients satisfy

(4.11)
$$\dot{\lambda}_0 + \lambda_0 = \lambda_1,$$

(4.12)
$$\ddot{\lambda}_k + \dot{\lambda}_k = 2k(2k+1)\lambda_{k+1}, \qquad 1 \leq k \leq N-1,$$

and

(4.13)
$$\ddot{\lambda}_N + \dot{\lambda}_N = 0.$$

These solutions satisfy the boundary condition $v_N(0^+, t) = -\tau_0$ and have $2N+1$ free parameters which are determined by insisting that the equation

(4.14)
$$\tau_N(t,t) + v_N(t,t) = 0$$

is satisfied to $O(t^{2N})$ as $t \to 0^+$. The approximate curve $t = \mathcal{J}_N(x)$ is subsequently determined by solving $\tau_N(x, \mathcal{J}_N(x)) = \tau_y$. An easy calculation shows that $\mathcal{J}_N(x) = O((\tau_0 - \tau_y)/\tau_0)$ and $d\mathcal{J}_N/dx < 0$ which guarantees that the number $x^N_{\#}$ defined by $\mathcal{J}_N(x^N_{\#}) = x^N_{\#}$ is $O((\tau_0 - \tau_y)/\tau_0)$, and thus on the boundary $x = t$, $\tau_N(t,t) + v_N(t,t)$ is at worst $O((\tau_0 - \tau_y)/\tau_0)^{2N+1}$ for $0 \leq t \leq x^N_{\#}$. We continue the approximate solutions to the rest of the region described by Fig. 1 via the extensions procedure used for the exact solution; that is, for $0 < t < x$,

(4.15)
$$(\tau_N, v_N) \equiv (0, 0),$$

for $\mathcal{J}_N(x) < t$ and $0 < x < x^N_{\#}$

(4.16)
$$v_N(x,t) = v_N(x, \mathcal{J}_N(x)) \quad \text{and} \quad \tau_N(x,t) = \tau_y,$$

and for $x_{\#} \leq x < t$,

(4.17)
$$v_N(x,t) = v_N(x_{\#}, \mathcal{J}_N(x_{\#})) \quad \text{and} \quad \tau_N(x,t) = \tau_y.$$

We are then guaranteed that the error made in failing to meet the boundary condition $\tau_N(t,t) + v_N(t,t) = 0$ is at worst $O((\tau_0 - \tau_y)/\tau_0)^{2N+1}$ for all $t > 0$. We shall present the details of this procedure for the case $N = 1$.

In this case,

(4.18)
$$v_1 = -\tau_0 + (\lambda_{1,0} + \lambda_{1,1} e^{-t}) x$$

[6] Here · denotes differentiation with respect to t.

and

$$\tau_1 = (\lambda_{1,0} + \lambda_{1,1} t e^{-t} + \lambda_{0,1} e^{-t}) - \frac{\lambda_{1,1} e^{-t} x^2}{2}, \tag{4.19}$$

and the insistence that $\tau_1(t,t) + v_1(t,t) = O(t^3)$ as $t \to 0^+$ implies that

$$\begin{aligned} \lambda_{1,0} + \lambda_{0,1} &= \tau_0 \\ \lambda_{1,0} - \lambda_{0,1} + 2\lambda_{1,1} &= 0 \\ \lambda_{0,1} - 5\lambda_{1,1} &= 0 \end{aligned} \tag{4.20}$$

and hence that

$$v_1 = \tau_0 \left(-1 + \frac{(3 + 5e^{-t})x}{8} \right) \tag{4.21}$$

and

$$\tau_1 = \frac{\tau_0}{8} \left(3 + t e^{-t} + 5e^{-t} - \frac{e^{-t} x^2}{2} \right). \tag{4.22}$$

The approximate curve $t = \mathcal{J}_1(x)$ is obtained by solving $\tau_1(x, \mathcal{J}_1(x)) = \tau_y$ or equivalently the equation

$$\left(3 + \mathcal{J}_1 e^{-\mathcal{J}_1} + 5e^{-\mathcal{J}_1} - \frac{x^2 e^{-\mathcal{J}_1}}{2} \right) = \frac{8\tau_y}{\tau_0}. \tag{4.23}$$

The fact that $0 < \tau_y/\tau_0 < 1$ guarantees the unique solvability of this equation for $0 \leq x \ll 1$ and that $\mathcal{J}_1(0) = O(2((\tau_0 - \tau_y)/\tau_0))$. A quick calculation also shows that

$$\frac{d\mathcal{J}_1}{dx} = \frac{-2x}{(8 + 2\mathcal{J}_1 - x^2)} < 0. \tag{4.24}$$

The number $x^1_{\#}$, where $\mathcal{J}_1(x^1_{\#}) = x^1_{\#}$ satisfies

$$\left(3 + x^1_{\#} e^{-x^1_{\#}} + 5e^{-x^1_{\#}} - \frac{(x^1_{\#})^2 e^{-x^1_{\#}}}{2} \right) = \frac{8\tau_y}{\tau_0}, \tag{4.25}$$

and for $0 < \tau_0 - \tau_y$ small enough we are guaranteed that $x^1_{\#} = O((\tau_0 - \tau_y)/\tau_0)$. This estimate, when combined with (4.24), implies that $-1 < d\mathcal{J}_1/dx$ for $0 \leq x \leq x^1_{\#}$.

Our final task is to show that the function

$$\hat{v}_1(x) \overset{\text{def}}{:=} \tau_0 \left(-1 + \frac{(3 + 5e^{-\mathcal{J}_1(x)})x}{8} \right) \tag{4.26}$$

satisfies

$$0 \leq \frac{d\hat{v}_1}{dx}(x) \leq \tau_y, \qquad 0 \leq x \leq x^1_{\#}. \tag{4.27}$$

The defining relation (4.26) implies that

$$\frac{d\hat{v}_1}{dx}(x) = \tau_0 \left(\frac{3 + 5e^{-\mathcal{J}_1(x)}}{8} \right) - \frac{5\tau_0 e^{-\mathcal{J}_1(x)}}{8} x \mathcal{J}_1'(x), \tag{4.28}$$

and this relationship, when combined with (4.23) and (4.24), implies that

$$(4.29)\qquad \frac{d\hat{v}_1}{dx}(x) = \tau_y + \frac{\tau_0 e^{-\mathcal{J}_1}((x^2-2\mathcal{J}_1)(8+2\mathcal{J}_1-x^2)+20x^2)}{16(8+2\mathcal{J}_1-x^2)}.$$

The fact that $\mathcal{J}_1(x) \geq x^1_{\#}$ for $0 \leq x \leq x^1_{\#} = O((\tau_0-\tau_y)/\tau_0)$ implies that the second term in (4.29) is negative and this provides the desired upper bound for $d\hat{v}_1/dx$. The desired lower bound is an immediate consequence of (4.28) and the bounds for $d\mathcal{J}_1/dx$.

We conclude this section by contrasting the above solution with what obtains if we replace our flow rule—α given by (4.4)—with the one generated by (2.31) and (2.32) and also by the flow rule associated with a rate independent elastic-perfectly plastic material. In the former case, (4.2) is replaced by

$$(4.30)\qquad \frac{\partial \tau}{\partial t} - \frac{\partial v}{\partial x} = -\alpha\tau_y,$$

and (4.4) is unchanged.

In the region $0 \leq t < x$ we have $(\tau, v) \equiv (0,0)$, and $\tau + v$ is continuous across $x = t$. For $0 \leq x \leq t \leq 2(\tau_0-\tau_y)/\tau_y$ we have

$$(4.31)\qquad v = -\tau_0 + \frac{\tau_y x}{2} \quad\text{and}\quad \tau = \tau_0 - \frac{\tau_y t}{2};$$

for $0 \leq x \leq 2(\tau_0-\tau_y)/\tau_y$ and $t \geq 2(\tau_0-\tau_y)/\tau_y$ we have

$$(4.32)\qquad v = -\tau_0 + \frac{\tau_y x}{2} \quad\text{and}\quad \tau = \tau_y,$$

and finally for $2(\tau_0-\tau_y)/\tau_y \leq x < t$ we have

$$(4.33)\qquad v = -\tau_y \quad\text{and}\quad \tau = \tau_y.$$

With this flow rule the curve $t = \mathcal{J}(\cdot)$ is the constant function $\mathcal{J}(x) = 2(\tau_0 - \tau_y)/\tau_y$, $0 \leq x \leq 2(\tau_0-\tau_y)/\tau_y$. Equations (2.52) and (2.53), the initial conditions $(F_{31}, p_{31})(x,0) = (0,0)$ for $x > 0$, and (4.31)–(4.33) allow us to determine (F_{31}, p_{31}). The result is

$$(4.34)\quad (F_{31}, p_{31}) = \begin{cases} (0,0), \qquad 0 \leq t < x, \\ (\tau_0 + \tau_y(\frac{t}{2} - x), \tau_y(t-x)), \qquad 0 \leq x < t < \frac{2(\tau_0-\tau_y)}{\tau_y}, \\ (\tau_0 + \tau_y(\frac{t}{2} - x), \tau_{01} - \tau_y + \tau_y(\frac{t}{2} - x)), \frac{2(\tau_0-\tau_y)}{\tau_y} \leq t \quad\text{and} \\ 0 \leq x < \frac{2(\tau_0-\tau_y)}{\tau_y}, \\ (\tau_y, 0), \frac{2(\tau_0-\tau_y)}{\tau_y} < x < t. \end{cases}$$

It is worth noting that the above solution is unique. This can be established using the arguments of §3 directly on the system (4.30) and (4.3)–(4.6).

We now examine the signaling problem for a rate independent elastic-perfectly plastic material. Equations (4.1)–(4.3) and (4.5) and (4.6) still hold, except now $\hat{\alpha}$ is given by

$$(4.35)\qquad \hat{\alpha} = \begin{cases} 0 & \text{if } \tau^2 < \tau_y^2 \\ 0 & \text{if } \tau^2 = \tau_y^2 \quad\text{and}\quad \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x} < 0, \\ \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x} & \text{if } \tau^2 = \tau_y^2 \quad\text{and}\quad 0 \leq \frac{\tau}{\tau_y^2}\frac{\partial v}{\partial x}. \end{cases}$$

We also have

$$\frac{\partial F_{31}}{\partial t} - \frac{\partial v}{\partial x} = 0, \quad \frac{\partial p_{31}}{\partial t} = \hat{\alpha}\tau, \quad \text{and} \quad F_{31} = \tau + p_{31}, \tag{4.36}$$

and these satisfy the initial conditions

$$(F_{31}, p_{31})(x, 0) = (0, 0), x > 0. \tag{4.37}$$

We seek solutions with structure similar to that obtained for the previous two models. Specifically, a shock curve $t = \hat{t}(x)$ such that in the region $0 < t < \hat{t}(x)$,

$$(F_{31}, p_{31}, \tau, v) = (0, 0, 0, 0), \tag{4.38}$$

and in the region $t > \hat{t}(x)$ the shear stress τ is at yield, i.e.,

$$\tau(x, t) = \tau_y, \qquad \hat{t}(x) < t. \tag{4.39}$$

We interpret (4.3) and $(4.36)_1$ as conservation laws, and this, together with (4.38) and (4.39), implies that on $t = \hat{t}(x)$,

$$v^-(x, \hat{t}(x)) + \tau_y \frac{d\hat{t}}{dx} = 0 \tag{4.40}$$

and

$$F_{31}^-(x, \hat{t}(x)) + v^-(x, \hat{t}(x)) \frac{d\hat{t}}{dx} = 0. \tag{4.41}$$

Here, $(v^-, F_{31}^-)(x, \hat{t}(x)) = \lim_{\epsilon \to 0^+}(v, F_{31})(x - \epsilon, \hat{t}(x))$. The identity (4.39) also implies that in $t > \hat{t}(x)$ the velocity v is a function of x only. Near $x = 0$ we choose

$$v(x, t) = -\tau_0 + \lambda x, \lambda > 0. \tag{4.42}$$

With this choice we obtain

$$p_{31} = \lambda(t - \hat{t}(x)) + p_-(x) \tag{4.43}$$

and

$$F_{31} = \tau_y + \lambda(t - \hat{t}(x)) + p_-(x). \tag{4.44}$$

Equation (4.40), together with $\hat{t}(0) = 0$, then yields

$$\hat{t}(x) = \frac{\tau_0^2 - (\tau_0 - \lambda x)^2}{2\lambda\tau_y}, \tag{4.45}$$

and (4.41), (4.44), and (4.45) imply that

$$p_-(x) = \frac{(\tau_0 - \lambda x)^2 - \tau_y^2}{\tau_y}. \tag{4.46}$$

We now let

$$x_\# = \frac{\tau_0 - \tau_y}{\lambda} \tag{4.47}$$

and note that

$$p_-(x) > 0, \qquad 0 \le x < x_\#, \tag{4.48}$$

$$p_-(x_\#) = 0, \tag{4.49}$$

and

$$\frac{d\hat{t}}{dx}(x_\#) = 1. \tag{4.50}$$

In the region $(\tau_0^2 - (\tau_0 - \lambda x)^2)/2\lambda\tau_y < t$ and $0 \le x < x_\# = (\tau_0 - \tau_y)/\lambda$ our solution is given by

$$F_{31} = \tau_y + \lambda\left(t + \frac{\tau_0^2 - (\tau_0 - \lambda x)^2}{2\lambda\tau_y}\right), \tag{4.51}$$

$$p_{31} = \lambda\left(t + \frac{\tau_0^2 - (\tau_0 - \lambda x)^2}{2\lambda\tau_y}\right), \tag{4.52}$$

$$v = -\tau_0 + \lambda x, \tag{4.53}$$

$$\tau = \tau_y. \tag{4.54}$$

The shock curve is continued to $x > x_\#$ by

$$\hat{t}(x) = \frac{\tau_0^2 - \tau_y^2}{2\lambda\tau_y} + \left(x - \frac{\tau_0 - \tau_y}{\lambda}\right) \tag{4.55}$$

and in the region $((\tau_0^2 - \tau_y^2)/2\lambda\tau_y) + (x - ((\tau_0 - \tau_y)/\lambda)) < t$ and $(\tau_0 - \tau_y)/\lambda = x_\# < x$,

$$F_{31} = \tau_y, \quad p_{31} = 0, \quad v = -\tau_y, \quad \text{and } \tau = \tau_y. \tag{4.56}$$

The line $x = x_\# = (\tau_0 - \tau_y)/\lambda$ is a stationary contact discontinuity and across it p_{31} jumps while the other fields are continuous. The interesting fact about the signaling problem for this model is the lack of uniqueness of solutions; we have a compatible solution for every $\lambda > 0$. This observation points out one of the weaknesses of the classical model.

5. Computational experiments. In this section we present the results of a computational experiment performed on the normalized system (2.48)–(2.52) when the pressure gradient is zero. The results reported deal with a two-dimensional generalization of the signalling problem of the previous section.

The experiment deals with the system (2.48)–(2.51) solved in the region $r > 0$ and $\pi/2 < \theta < 2\pi$, where $r = \sqrt{x^2 + y^2}$. At time $t = 0$ we assume that

$$(\tau_{31}, \tau_{32}, v) = (0, 0, 0) \tag{5.1}$$

for $r > 0$ and $\pi/2 < \theta < 2\pi$, and for $t > 0$ we assume that

$$v\left(r, \frac{\pi}{2}^+\right) = v(r, 2\pi^-) = \tau_0, \qquad r > 0, \tag{5.2}$$

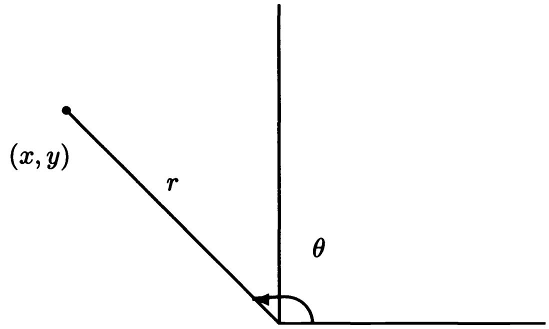

FIG. 2

where $\tau_0 > \tau_y$, and again $\tau_y > 0$ is the yield stress.

The elastic version of this problem, namely, the system

$$\frac{\partial \tau_{31}}{\partial t} - \frac{\partial v}{\partial x} = 0, \tag{5.3}$$

$$\frac{\partial \tau_{32}}{\partial t} - \frac{\partial v}{\partial y} = 0, \tag{5.4}$$

$$\frac{\partial v}{\partial t} - \frac{\partial \tau_{31}}{\partial x} - \frac{\partial \tau_{32}}{\partial y} = 0, \tag{5.5}$$

together with (5.1) and (5.2), was considered by Keller and Blank [13]. They obtained exact solutions to this and a number of other problems with self similar structure. Relevant to us here is the singular nature of $\tau_{31}^2 + \tau_{32}^2$ as $r \to 0^+$. Their results demonstrate that

$$\tau_{31}^2 + \tau_{32}^2 = O\left(\frac{t}{r}\right)^{2/3}, \qquad r \to 0^+. \tag{5.6}$$

This singular behavior also obtains for the plastic flow problem and forces us to treat the boundary conditions in our numerical simulation carefully. Our integration scheme for (2.48)–(2.51) is based on a symmetrized operator splitting algorithm for the governing differential equations. At time $t = nh$, $n = 0, 1, 2, \ldots$, our approximate solution consists of lattice data

$$(\tau_{31}, \tau_{32}, v)^n_{(k,m)} = (\tau_{31}, \tau_{32}, v)\left(\frac{(2k-1)}{2}h, \frac{(2m-1)}{2}h, nh\right). \tag{5.7}$$

For the problem under consideration the boundaries are not part of the computational lattice but are offset from it by a distance of $h/2$. The computational lattice is

$$\mathcal{S} = \{(k,m) \mid k \leq 0 \text{ and } m = 0, \pm 1, \pm 2, \ldots\} \cup \{(k,m) \mid k \geq 1 \text{ and } m \leq 0\}. \tag{5.8}$$

To update the data (5.7) we successively solve

$$\frac{\partial \tau_{31}}{\partial t} - \frac{\partial v}{\partial x} = 0, \quad \frac{\partial \tau_{32}}{\partial t} = 0, \quad \text{and} \quad \frac{\partial v}{\partial t} - \frac{\partial \tau_{31}}{\partial x} = 0, \quad 0 \leq t \leq h, \tag{5.9}$$

$$\frac{\partial\tau_{31}}{\partial t}=0,\quad \frac{\partial\tau_{32}}{\partial t}-\frac{\partial v}{\partial y}=0,\quad\text{and}\quad \frac{\partial v}{\partial t}-\frac{\partial\tau_{32}}{\partial y}=0,\quad 0\le t\le h, \tag{5.10}$$

and

$$\frac{\partial\tau_{31}}{\partial t}=-\hat\alpha\tau_{31},\quad \frac{\partial\tau_{32}}{\partial t}=-\hat\alpha\tau_{32},\quad\text{and}\quad \frac{\partial v}{\partial t}=0,\quad 0\le t\le h, \tag{5.11}$$

where of course $\hat\alpha$ is defined in (2.51). For (5.9) we use the approximate solution defined by (5.7) as initial data and let $(\tau_{31}^1,\tau_{32}^1,v^1)_{(k,m)}$ denote the value of this solution at $t=h$ on the lattice $\mathcal{S}$. We then solve (5.10) using the $(\tau_{31}^1,\tau_{32}^1,v^1)_{(k,m)}$ as initial data and let $(\tau_{31}^2,\tau_{32}^2,v^2)_{(k,m)}$ denote value of the solution at $t=h$ on $\mathcal{S}$. Finally, we solve (5.11) with $(\tau_{31}^2,\tau_{32}^2,v^2)_{(k,m)}$ as initial data and let $(\tau_{31}^3,\tau_{32}^3,v^3)_{(k,m)}$ denote the value of this solution at $t=h$ on $\mathcal{S}$.

We then repeat the process solving (5.10) first with the data (5.7), and, we let $(\tau_{31}^4,\tau_{32}^4,v^4)_{(k,m)}$ denote the lattice update at $t=h$. We then solve (5.9) using $(\tau_{31}^4,\tau_{32}^4,v^4)_{(k,m)}$ as initial data and let $(\tau_{31}^5,\tau_{32}^5,v^5)_{(k,m)}$ denote the lattice update. Finally we solve (5.11) with data $(\tau_{31}^5,\tau_{32}^5,v^5)_{(k,m)}$ and let $(\tau_{31}^6,\tau_{32}^6,v^6)_{(k,m)}$ denote the lattice update at $t=h$. The desired approximate solution $(\tau_{31},\tau_{32},v)_{(k,m)}^{(n+1)}$ is then obtained by averaging $(\tau_{31}^3,\tau_{32}^3,v^3)_{(k,m)}$ and $(\tau_{31}^6,\tau_{32}^6,v^6)_{(k,m)}$; that is,

$$(\tau_{31},\tau_{32},v)_{(k,m)}^{(n+1)}=\tfrac{1}{2}(\tau_{31}^3+\tau_{31}^6,\tau_{32}^3+\tau_{32}^6,v^3+v^6)_{(k,m)}. \tag{5.12}$$

Of course, all of the intermediate updates are solved subject to the boundary conditions of the original problem. Here these boundary conditions manifest themselves as reflection conditions at those lattice points that are a distance $h/2$ away form the actual boundary. Formal accuracy could be maintained if we used either $(\tau_{31}^3,\tau_{32}^3,v^3)_{(k,m)}$ or $(\tau_{31}^6,\tau_{32}^6,v^6)_{(k,m)}$ for the updated approximate solution but either of these updates alone would, over time, tend to introduce asymmetries into the approximates not present in the actual solution. These asymmetries are removed with the algorithm employed.

The results of our experiment are shown in Figs. 3–7. Each snapshot shows two different representations of the velocity field and the total shear stress, namely the quantity $\sqrt{\tau_{31}^2+\tau_{32}^2}$. This simulation was run with $h=1/50$, $\tau_y=1$, and $\tau_0=1.3$. The contours on the velocity plots are spaced 0.1 apart and run from $v=0$ to $v=1.3$. The stress contours run from 1 to 3.2 in increments of 0.2. In these snapshots one sees not only the plane wave solutions of the previous section but also the effect of the corner singularity which are confined to the region $0\le r\le t$ and $\pi/2<\theta<2\pi$.

For comparison we have run the elastic version of this problem with the same boundary conditions and same values of h, τ_y, and τ_0. These results are shown in Figs. 8–12.

It should be noted that for both problems the velocity fields satisfy the additional condition

$$\lim_{r\to t^+} v(r,\theta,t)=0,\qquad \frac{\pi}{2}<\theta<2\pi \tag{5.13}$$

and that our numerical solutions meet this consistency condition automatically.

A GEOMETRIC SINGULAR PERTURBATION ANALYSIS OF DETONATION AND DEFLAGRATION WAVES*

I. GASSER† AND P. SZMOLYAN†

Abstract. The existence of steady plane wave solutions of the Navier–Stokes equations for a reacting gas is analyzed. Under the assumption of an ignition temperature the existence of detonation and deflagration waves close to the corresponding waves of the ZND-model is proved in the limit of small viscosity, heat conductivity, and diffusion. The method is constructive, since the classical solutions of the ZND-model serve as singular solutions in the context of geometric singular perturbation theory. The singular solutions consist of orbits on which the dynamics are slow-driven by chemical reaction and of orbits on which the dynamics are fast-driven by gasdynamic shocks. The approach is geometric and leads to a clear, complete picture of the existence, structure, and asymptotic behavior of detonation and deflagration waves.

Key words. detonations, deflagrations, shock waves, traveling waves, singular perturbations

1. Introduction.

We study plane wave solutions of the Navier–Stokes equations for a reacting gas in one space dimension. We consider the simplest possible chemical reaction of one reactant that is converted to the product by a one-step exothermic reaction. The equations governing the reacting flow are given by

$$\begin{aligned}(\rho)_t + (\rho u)_x &= 0,\\ (\rho u)_t + (\rho u^2 + p)_x &= (\mu u_x)_x,\\ \left[\rho\left(\frac{u^2}{2}+e\right)\right]_t + \left[\rho u\left(\frac{u^2}{2}+e\right)+pu\right]_x &= (\lambda T_x)_x + (q\rho D Y_x)_x + (\mu u u_x)_x,\\ (\rho Y)_t + (\rho u Y)_x &= (\rho D Y_x)_x - k\rho Y\phi(T).\end{aligned} \tag{1.1}$$

In these equations the variables ρ, u, p, e, T, and Y are the density, velocity, pressure, specific energy, temperature, and reactant mass fraction of the gas. The unburned gas corresponds to $Y = 1$; a totally burned gas corresponds to $Y = 0$. All variables will be made dimensionless later on. The constants μ, λ, and D are, respectively, viscosity, heat conductivity, and diffusion coefficients. We assume an ideal gas, i.e., the pressure is given by $p = R\rho T$, where R is the gas constant. The specific energy is given by $e = c_v T + qY$, where c_v is the specific heat at constant volume and q is the heat release parameter. The assumption of an exothermic reaction implies that q is positive. For the usual Arrhenius kinetics $\phi(T) = e^{-E/RT}$ holds, where E is an activation energy. We will have to modify this later because of the cold boundary difficulty. The above equations are standard; see, e.g., Fickett and Davis [3] or Williams [16].

Detonation and deflagration waves are traveling wave solutions, i.e., solutions depending only on $\xi = x - ct$, of (1.1) connecting an unburned state at $\xi = -\infty$ to a burned state at $\xi = \infty$. Due to Galilei invariance it suffices to consider the case $c = 0$, that is, the stationary problem corresponding to (1.1).

$$
\begin{aligned}
(\rho u)_x &= 0, \\
(\rho u^2 + p)_x &= (\mu u_x)_x, \\
\left[\rho u\left(\frac{u^2}{2} + e\right) + pu\right]_x &= (\lambda T_x)_x + (q\rho D Y_x)_x + (\mu u u_x)_x, \\
(\rho u Y)_x - (\rho D Y_x)_x &= -k\rho Y\phi(T).
\end{aligned}
\tag{1.2}
$$

Throughout this paper we denote by f_-, respectively, f_+, the value of any function f at $x = -\infty$, respectively, $x = \infty$. Neglecting all dissipative effects, i.e., setting $\lambda = \mu = D = 0$, in (1.2) gives the ZND-model (named after Zeldovich, Neumann, and Döring):

$$
\begin{aligned}
(\rho u)_x &= 0, \\
(\rho u^2 + p)_x &= 0, \\
\left[\rho u\left(\frac{u^2}{2} + e\right) + pu\right]_x &= 0, \\
(\rho u Y)_x &= -k\rho Y\phi(T).
\end{aligned}
\tag{1.3}
$$

We briefly review the classical analysis of detonation and deflagration waves for the ZND-model; see, e.g., Courant and Friedrichs [1] and Williams [16], since it will be basic in our analysis of the corresponding waves of (1.2). The first equation in (1.3) implies that the mass flux ρu has a constant value denoted by $m = \rho_- u_-$. The fluxes of momentum and energy are also constant; this gives the Rankine–Hugoniot conditions for a shock wave, which describe possible burned states ρ and p for given ρ_-, p_-, and Y_-. By integrating the second and the third equation in (1.3) we obtain the equation of the Raleigh line

$$
p - p_- = -m^2\left(\frac{1}{\rho} - \frac{1}{\rho_-}\right)
\tag{1.4}
$$

and the equation of the Hugoniot curves

$$
e_- - e = \frac{1}{2}(p + p_-)\left(\frac{1}{\rho} - \frac{1}{\rho_-}\right).
\tag{1.5}
$$

Due to the dependence of the internal energy on the mass fraction Y of the reactant, the usual Hugoniot curve of gasdynamics is shifted for $Y \neq Y_-$. For a given state on the left there exist—depending on the value of m—two, one, or no completely burned right state. The burned state for the critical value of m, for which there exists just one burned state, is the Chapman–Jouget point. There are two fundamentally different processes possible; those that are compressive are called detonations, the ones that are expansive are called deflagrations. The burned state on the detonation branch closer to the unburned state is called weak detonation point; the corresponding process is called a weak detonation. The burned state on the detonation branch farther away from the unburned state is called strong detonation point; the corresponding process is called a strong detonation. A similar classification holds for deflagrations; see Fig. 1. In a weak deflagration wave the variable Y is determined by a scalar differential equation; the gasdynamic variables are in equilibrium following a curve parametrized by Y. Strong deflagrations are ruled out because of entropy considerations. On the other hand, the ZND-structure for a strong detonation is that of an inert gasdynamic

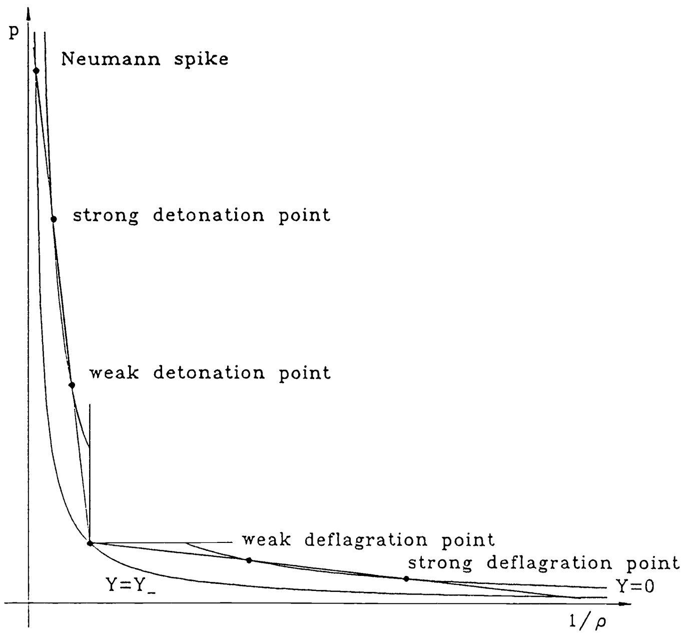

FIG. 1. *Chapman–Jouget diagram.*

shock wave that compresses and heats the gas, followed by a weak deflagration in which the reaction takes place. In Fig. 1 the ZND-structure of a strong detonation corresponds to an instantaneous jump from the unburned state to the intersection of the Raleigh line and the Hugoniot curve of the unburned state, followed by a deflagration along the Raleigh line to the burned state.

Clearly, there is some arbitrariness in this construction and questions of uniqueness arise; e.g., another possible structure of a strong detonation, starting at the unburned state as a gasdynamic shock followed by a deflagration to an intermediate partially burned state followed by another shock and another deflagration wave to the burned state, cannot be ruled out by considering (1.3) alone.

A standard criterion to distinguish unphysical solutions of hyperbolic conservation laws—obtained by neglecting all dissipative effects—from physical solutions is to accept only those solutions which are limits of solutions of the dissipative equations as the dissipation coefficients go to zero. For initial value problems corresponding to hyperbolic conservation laws this is one of the main open problems of the subject. On the level of shock waves, however, the existence of viscous profiles, which converge to the shock wave as the dissipation coefficients go to zero, is a well-established admissibility criterion (see, e.g., Smoller [12]).

Thus, the question of admissibility of ZND-waves leads to the question of the existence of solutions of (1.2) connecting an unburned state to a burned state. Additionally, the convergence of solutions of (1.2) to solutions of (1.3) for $(\lambda, \mu, D) \to 0$ has to be analysed. The first difficulty encountered is the well-known cold boundary difficulty, i.e., the unburned state is no stationary point of (1.2) for the usual Arrhenius kinetics $\phi(T) = \exp(-E/RT)$, unless $T_- = 0$, holds. The usual remedy is to modify the function $\phi(T)$, such that $\phi(T)$ vanishes identically for T below a certain ignition temperature T_i. More precise assumptions will be made later. Under this assumption detonation and deflagration waves are heteroclinic orbits connecting fixed points of (1.2).

The existence of detonation and deflagration waves of system (1.1) has been analysed by many authors, usually under the simplifying assumptions: Prandtl number $Pr = \frac{3}{4}$ and (or) Lewis number $Le = 1$. We refer to Hirschfelder and Curtiss [9] and Wood [17]. The activation energy E is typically very large, thus another frequently used approach is to consider (1.2) in the limit $E \to \infty$; see Lu and Ludford [11] and Holmes and Stewart [10]. Gardner [4] used the Conley index to prove the existence of detonation waves for the reactive Navier–Stokes equations in Lagrangian coordinates. He made no assumptions on Lewis and Prandtl numbers, but omitted the species diffusion term from the energy balance equation. The convergence of these solutions of (1.2) to solutions of the ZND-model is not discussed by these authors. Recently, Wagner [14], [15] obtained results on the ZND-limit for detonation and deflagration waves. Under the assumption of Prandtl number $\frac{3}{4}$ he proves existence of viscous profiles by topological arguments. A priori estimates and a compactness argument allow him to conclude that ZND-waves are (almost everywhere) limits of (certain subsequences of) solutions of (1.2) for $\lambda \to 0$ and constant ratios μ/λ and D/λ.

In our approach we only assume the existence of an ignition temperature and that the values of μ, λ, and D in a scaled version of (1.2) are small. No assumptions on the Lewis number and the Prandtl number are made. We consider system (1.2) as a singularly perturbed system of ordinary differential equations, which can be written in the form

$$\begin{aligned}
\mu u_x &= m(u-u_\pm) + mR\left(\frac{T}{u} - \frac{T_\pm}{u_\pm}\right),\\
\lambda T_x &= mc_p(T-T_\pm) - mRu\left(\frac{T}{u} - \frac{T_\pm}{u_\pm}\right) + mq(Z-Z_\pm) - \frac{m}{2}(u-u_\pm)^2,\\
DY_x &= u(Y-Z),\\
Z_x &= -k\frac{Y}{u}\phi(T),
\end{aligned} \tag{1.6}$$

where the variable Z is defined by the third equation (see §2). We prove the existence of detonation and deflagration waves close to the corresponding waves of the ZND-model. Our method is constructive since the classical solutions of the ZND-model serve as singular solutions in the context of geometric singular perturbation theory. The singular solutions consist of orbits on which the dynamics are slow-driven by the chemical reaction and of orbits on which the dynamics are fast-driven by gasdynamic shocks. Methods from dynamical systems theory allow us to conclude the existence of solutions of system (1.6) close to these singular solutions. Our approach is geometric and leads to a clear, complete picture of the existence, structure, and asymptotic behavior of detonation and deflagration waves. We obtain a complete characterization of the global flow in a two-dimensional invariant manifold, which contains all fixed points and all heteroclinic orbits of (1.6); from this point of view, the situation becomes particularly transparent. In the usual situation, that for a given unburned state (ρ_-, u_-, T_-, Y_-) the temperature at the two corresponding burned states is above ignition, our results can be summarized in the following theorem.

MAIN THEOREM. *Assume that the function* $\phi(T)$ *is smooth, with ignition temperature* T_i. *For* $\mu = \varepsilon\hat{\mu}$, $\lambda = \varepsilon\hat{\lambda}$, $D = \varepsilon\hat{D}$ *with* $\hat{\mu}, \hat{\lambda}, \hat{D} > 0$ *there exists* $\varepsilon_0 = \varepsilon_0(\hat{\mu}, \hat{\lambda}, \hat{D}) > 0$ *such that the following assertions hold for* $0 < \varepsilon < \varepsilon_0$.

(i) *Let* (ρ_-, u_-, T_-, Y_-), *with* $T_- < T_i$, *be an unburned state corresponding to a detonation. Then there exists a unique strong detonation wave solution of* (1.2).

(ii) *Let* (ρ_-, u_-, T_-, Y_-), *with* $T_- = T_i$, *be an unburned state corresponding to a detonation. Then there exists a two-dimensional manifold (with boundary) formed by all strong detonation wave solution of* (1.2). *The boundary of the manifold of strong detonation waves is formed by a strong detonation wave that has the appearance of a gasdynamic shock followed by a weak deflagration and by a unique weak detonation wave followed by a gasdynamic shock.*

(iii) *Let* (ρ_-, u_-, T_-, Y_-) *be an unburned state corresponding to a deflagration. Then there exists a unique weak deflagration wave solution of* (1.2) *if and only if* $T_- = T_i$ *holds. Strong deflagration wave solutions do not exist.*

(iv) *In suitable parametrizations all the detonation and deflagration waves converge to the corresponding waves of the* ZND*-model, uniformly in* C^1*-norm away from the location of gasdynamic shocks as* $\varepsilon \to 0$.

We remark that our method is not directly applicable in the case of Chapman–Jouget processes because the Chapman–Jouget point is a nonhyperbolic fixed point of (1.6) corresponding to a turning point in the context of singular perturbation theory.

We briefly outline the organization of the paper. In §2 we derive (1.6) and perform the scaling to obtain the final form of the governing equations. The necessary results from geometric singular perturbation theory are briefly explained in §3. In §4 we apply our method to the simpler problem of viscous profiles for gasdynamic shocks. This problem has been solved by Gilbarg [7]; however, we have included this example to illustrate the method and because we need the results on the structure of gasdynamic shocks in our analysis of detonation waves. The main result is proved in §5. Technical difficulties due to the ignition temperature assumption require a slight extension of the methods of §3. In §6 we discuss qualitative properties of detonation and deflagration waves, and prove the existence of incompletely burned detonation and deflagration waves.

2. Singularly perturbed scaled equations. By using $\rho u = m$ and integrating the second and third equation in (1.2) we obtain

$$\mu u_x = m(u - u_\pm) + mR\left(\frac{T}{u} - \frac{T_\pm}{u_\pm}\right), \tag{2.1}$$

$$\lambda T_x + \mu u u_x + q\rho D Y_x = m[c_v(T - T_\pm) + q(Y - Y_\pm) + (u^2 - u_\pm^2)/2 + R(T - T_\pm)]. \tag{2.2}$$

We define a new variable

$$Z = Y - \rho D\frac{Y_x}{m} = Y - D\frac{Y_x}{u} \tag{2.3}$$

to obtain a first-order system. Since Y_x must vanish at $x = \pm\infty$,

$$Z_- = Y_-, \qquad Z_+ = Y_+ \tag{2.4}$$

must hold. In the new variable the equation for Y in (1.2) has the form

$$Z_x = -k\frac{Y}{u}\phi(T). \tag{2.5}$$

By substituting for $\mu u u_x$ and $q\rho D Y_x$ from (2.1) and (2.3), and by using the relation

$$c_p = c_v + R \tag{2.6}$$

for the specific heat at constant pressure c_p and the specific heat at constant volume c_v, we obtain the final form of (2.2):

$$\text{(2.7)}\quad \lambda T_x = mc_p(T - T_\pm) - mRu\left(\frac{T}{u} - \frac{T_\pm}{u_\pm}\right) + mq(Y - Y_\pm) - \frac{m}{2}(u - u_\pm)^2.$$

Equations (2.1), (2.7), (2.3), and (2.5) are system (1.6). We denote by $M^2 = u^2/\gamma RT$ the square of the Mach number, where $\gamma = c_p/c_v$ is the ratio of the specific heats. For given $P_- = (u_-, T_-, Y_-, Z_-)$ we are interested in completely burned fixed points of (1.6). A straightforward calculation yields the following lemma.

LEMMA 2.1. *For a given unburned state P_-, there exist fixed points corresponding to completely burned states if and only if*

$$\text{(2.8)}\qquad \frac{(M_-^2 - 1)^2}{2(\gamma + 1)M_-^2} \geq qY_-$$

holds; $M_-^2 > 1$ corresponds to a detonation, and $M_-^2 < 1$ corresponds to a deflagration. Strict inequality in (2.8) *implies the existence of a completely burned state $P^\star = (u^\star, T^\star, 0, 0)$, with $M^{\star 2} < 1$, corresponding to a strong detonation or a weak deflagration, and of a state $P_\star = (u_\star, T_\star, 0, 0)$, with $M_\star^2 > 1$, corresponding to a weak detonation or a strong deflagration. Equality in* (2.8) *implies the existence of a unique completely burned state—with Mach number one—corresponding to the Chapman–Jouget detonation or deflagration point.*

In the following we set $(u_+, T_+, Y_+, Z_+) = (u^\star, T^\star, 0, 0)$ in (1.6) and use the scaling in Table 1 to make the equations dimensionless.

TABLE 1
Scaling.

Quantity	Unit	Scaling factor
x	m	$u^\star/k$
u	m s^{-1}	$u^\star$
T	K	$T^\star$
Z	1	
Y	1	
μ	kg m s^{-1}	$mu^\star/k$
λ	kg m^3 s^{-3} K^{-1}	$c_p mu^\star/k$
D	m^2 s^{-1}	$u^{\star 2}/k$
m	kg s^{-1}	
R, c_v, c_p	m^2 s^{-2} K^{-1}	
q	m^2 s^{-2}	$c_pT^\star$
k	s^{-1}	

The scaled quantity is obtained by dividing the unscaled quantity by its reference value, and is denoted by superscript $\sim$. If we define $\tilde\phi(\tilde T) = \phi(\tilde T T^\star)$, we obtain the scaled equations

$$\text{(2.9)}\qquad \tilde\mu \tilde u_{\tilde x} = \tilde u - 1 + \frac{1}{\gamma M^{\star 2}}\left(\frac{\tilde T}{\tilde u} - 1\right),$$

$$\text{(2.10)}\qquad \tilde\lambda \tilde T_{\tilde x} = \tilde T - 1 - \frac{\gamma - 1}{\gamma}(\tilde T - \tilde u) + \tilde q Z - \frac{(\gamma - 1)M^{\star 2}}{2}(\tilde u - 1)^2,$$

$$\text{(2.11)}\qquad \tilde D Y_{\tilde x} = \tilde u(Y - Z),$$

$$\text{(2.12)}\qquad Z_{\tilde x} = -\frac{Y}{\tilde u}\tilde\phi(\tilde T).$$

System (2.9)–(2.12) is singularly perturbed, because the parameters $\tilde{\mu}$, $\tilde{\lambda}$, and $\tilde{D}$ are typically very small. The actual size of these parameters in a given problem is given by the scaling in Table 1. In this paper we consider the ZND-limit, i.e., the limit of vanishing dissipation (see §1). In the limit process $(\tilde{\mu}, \tilde{\lambda}, \tilde{D}) \rightarrow 0$ various singular limits are possible depending on the ratios of the parameters. Typically, the Lewis number $Le \sim \tilde{\lambda}/\tilde{D}$ and the Prandtl number $Pr = \tilde{\mu}/\tilde{\lambda}$ satisfy $Le \sim 1$ and $Pr \sim \frac{3}{4}$ (see [16]). Therefore, it is reasonable to consider the limit $(\tilde{\mu}, \tilde{\lambda}, \tilde{D}) \rightarrow 0$ with fixed ratios Pr and Le. However, we do not make the common simplifying assumptions $Le = 1$ and $Pr = \frac{3}{4}$. The analysis of the ZND-limit for the case of constant ratios Pr and Le is carried out in §5, certain extensions to nonconstant ratios and other singular limits are briefly discussed in §6.

From here on we use the scaled quantities, therefore, we drop the superscript $\tilde{}$. The scaled fixed points are still denoted by $P^\star$, $P_\star$, and P_-; obviously, $P^\star = (1, 1, 0, 0)$ holds.

3. Geometric singular perturbation theory. The dynamical systems approach to singular perturbation problems origins—in its modern form—in the work of Fenichel [2], but has only recently become more popular. In Szmolyan [13] a method—based on this invariant manifold approach—is developed to prove the existence of transversal heteroclinic orbits of singularly perturbed differential equations. In this section we briefly summarize the necessary results from [2], [13] to provide the framework for our analysis of (2.9)–(2.12) in §§4 and 5. We consider singularly perturbed systems of differential equations in the standard form

$$\begin{aligned} \dot{x} &= f(x, y), \\ \varepsilon \dot{y} &= g(x, y), \end{aligned} \tag{3.1}$$

with $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$, $\varepsilon_0 > 0$ small, and $(x, y) \in \mathbf{R}^{m+k}$. We assume that $f \in \mathbf{R}^m$ and $g \in \mathbf{R}^k$ are C^r functions of (x, y), with $r \geq 2$. The independent variable is t. We call (3.1) the slow problem. By transforming to the variable $\tau = t/\varepsilon$ we obtain the equivalent fast problem

$$\begin{aligned} x' &= \varepsilon f(x, y), \\ y' &= g(x, y). \end{aligned} \tag{3.2}$$

By setting $\varepsilon = 0$ in (3.1) and (3.2) we obtain the reduced problem

$$\begin{aligned} \dot{x} &= f(x, y), \\ 0 &= g(x, y), \end{aligned} \tag{3.3}$$

and the layer problem

$$\begin{aligned} x' &= 0, \\ y' &= g(x, y). \end{aligned} \tag{3.4}$$

The basic idea is to obtain solutions of (3.1) as smooth perturbations of composite orbits of the decoupled limiting equations (3.3) and (3.4). We make the following assumptions.

(i) The equation $g(x, y) = 0$ has a smooth manifold of solutions. Let $\mathcal{C}$ be a compact submanifold of this manifold which is given as a graph of a C^r function $h : U \subset \mathbf{R}^m \rightarrow \mathbf{R}^k$.

(ii) There exist integers k_s and k_u, with $k = k_s + k_u$, such that the matrix $\partial g(x, h(x))/\partial y$ has k_s eigenvalues with negative real part uniformly bounded away from zero, and k_u eigenvalues with positive real part uniformly bounded away from zero for all $x \in U$.

Interpret the following assertions in an appropriate neighbourhood V of $\mathcal{C}$. Under the above assumptions the reduced problem (3.3) defines a flow on $\mathcal{C}$. Additionally, $\mathcal{C}$ is an invariant manifold of fixed points for the flow defined by (3.4). We denote the k_s-dimensional local stable manifold of $q \in \mathcal{C}$ by $\mathcal{F}^s(q)$ and, similarly, the k_u-dimensional local unstable manifold by $\mathcal{F}^u(q)$. It is shown in [2, Thm. 9.1] that for sufficiently small ε the manifold $\mathcal{C}$ perturbs to a locally invariant center-like manifold $\mathcal{C}_\varepsilon$ with a $m+k_s$-dimensional center-stable manifold $\mathcal{C}^s_\varepsilon$ and a $m+k_u$-dimensional center-unstable manifold $\mathcal{C}^u_\varepsilon$. The flow on $\mathcal{C}_\varepsilon$ is a regular perturbation of the reduced problem on $\mathcal{C}$. Furthermore, there exist invariant foliations of $\mathcal{C}^s_\varepsilon$ and $\mathcal{C}^u_\varepsilon$ by k_s-dimensional manifolds $\mathcal{F}^s_\varepsilon(q)$ and k_u-dimensional manifolds $\mathcal{F}^u_\varepsilon(q)$, $q \in \mathcal{C}_\varepsilon$, respectively. The dependence of these manifolds on ε is C^{r-1}, even at $\varepsilon = 0$. For details we refer to Fenichel [2]. Background material can be found in Guckenheimer and Holmes [6] and Hirsch, Pugh, and Shub [8].

In our analysis we encounter for a given flow compact invariant manifolds $\mathcal{M}$ with boundary $\partial\mathcal{M}$. In order to apply results from invariant manifold theory $\mathcal{M}$ has to be overflowing (inflowing) invariant. In the following we do not mention this condition explicitly each time, but always assume that it has been achieved by a standard local modification of the flow near $\partial\mathcal{M}$.

Let $p \in \mathcal{C}$ be a hyperbolic fixed point of (3.3). Let $\Gamma^s(p)$ and $\Gamma^u(p)$ denote the local stable and unstable manifold of p for the reduced problem. We define the singular stable and unstable manifold, respectively, by

$$W^s(p) = \bigcup_{q \in \Gamma^s(p)} \mathcal{F}^s(q), \qquad W^u(p) = \bigcup_{q \in \Gamma^u(p)} \mathcal{F}^u(q). \tag{3.5}$$

It follows from [2, Thm. 12.2] that $W^s(p)$ perturbs smoothly to the stable manifold $W^s_\varepsilon(p)$ of the hyperbolic fixed point p of (3.1) for small ε. Similarly, $W^u(p)$ perturbs smoothly to the unstable manifold $W^u_\varepsilon(p)$.

Usually, the manifold of solutions of $g(x, y) = 0$ has several branches. Let $\mathcal{C}_1$ and $\mathcal{C}_2$ be two manifolds, which satisfy conditions (i) and (ii). Let $p_1 \in \mathcal{C}_1$ be a hyperbolic fixed point of (3.3) with unstable manifold Γ^u_1, and $p_2 \in \mathcal{C}_2$ be a hyperbolic fixed point of (3.3) with stable manifold Γ^s_2. Assume that $q_1 \in \Gamma^u_1$ and $q_2 \in \Gamma^s_2$ are connected by a heteroclinic orbit η of (3.4). Let $\gamma_1 \subset \Gamma^u_1$ be the solution segment of (3.3) connecting p_1 and q_1, similarly, $\gamma_2 \subset \Gamma^s_2$ connects q_2 and p_2. Then, we call $\omega = \gamma_1 \cup \eta \cup \gamma_2$ the singular orbit connecting p_1 and p_2. Note, that we allow $p_1 = q_1$ or $p_2 = q_2$. Clearly, $\eta \subset W^u(p_1) \cap W^s(p_2)$ holds.

THEOREM 3.1. *Under the assumptions made in this section, assume that the singular unstable manifold $W^u(p_1)$ and the singular stable manifold $W^s(p_2)$ intersect transversally and locally unique along the orbit ω. Then there exists a locally unique transversal heteroclinic orbit ω_ε of* (3.1) *for small ε. The orbit ω_ε has a transition layer and is uniformly close to ω.*

The theorem follows from the smooth dependence of the involved manifolds on ε, and from the stability of transversal intersection under small perturbations. If the singular stable and unstable manifolds intersect transversally in an s-dimensional manifold $\mathcal{D}$ of singular heteroclinic orbits, we obtain the existence of a locally unique s-dimensional manifold $\mathcal{D}_\varepsilon$ of heteroclinic orbits of (3.1) for small ε. Details and examples are given in Szmolyan [13]. For suitable parametrizations ω_ε converges uniformly to ω in C^1-norm, away from the location of the transition layer.

LEMMA 3.2. *Under the above assumptions we parametrize γ_1 and γ_2 by $t \in \mathbf{R}_0^-$ and $t \in \mathbf{R}_0^+$, respectively, such that $\gamma_1(0) = q_1$ and $\gamma_2(0) = q_2$ hold. Let $\mathcal{V}$ be a manifold which intersects η transversally. We parametrize ω_ε such that $\omega_\varepsilon = \omega_\varepsilon(t)$, $t \in \mathbf{R}$, $\omega_\varepsilon(0) = \omega_\varepsilon \cap \mathcal{V}$ holds. Then*

$$\lim_{\varepsilon \to 0} \omega_\varepsilon(t) = \begin{cases} \gamma_1(t), & t < 0, \\ \gamma_2(t), & t > 0, \end{cases}$$

holds. The convergence is uniform in $C^1((-\infty, -\delta])$ and $C^1([\delta, \infty))$ for $\delta > 0$.

The proof of this intuitive result, based on the estimates in Theorem 9.1, (iii), [2], is straightforward and is omitted. We will also encounter the following simpler situation, which is contained in Theorem 3.1, if $\mathcal{C}_1 = \mathcal{C}_2$ holds.

COROLLARY 3.3. *Assume that there exist two hyperbolic fixed points p_1 and p_2 in a manifold $\mathcal{C}$, which satisfies conditions* (i), (ii). *Suppose that p_1 and p_2 are connected by a transversal heteroclinic orbit ω of* (3.3). *Then there exists a transversal heteroclinic orbit $\omega_\varepsilon \subset \mathcal{C}_\varepsilon$ of* (3.1) *for small ε. The orbit ω_ε has no transition layer and is uniformly close to ω in $C^1(\mathbf{R})$-norm.*

In higher dimensions it is usually difficult to prove transversality of the intersection of the singular stable and unstable manifolds. An analytic method to prove transversality based on an application of the Melnikov integral is given in [13]. However, we shall see that for detonation and deflagration waves the transversality condition is trivially satisfied. In §5 we shall need some extensions of the above results because (1.6) has a one-dimensional manifold of nonhyperbolic, fixed points due to the ignition temperature assumption.

4. Structure of gasdynamic shocks.

The Rankine–Hugoniot conditions for gasdynamic shocks for an ideal gas are derived from the three conservation laws in (1.3). Viscous profiles for a gasdynamic shock are heteroclinic orbits of the first two equations in (1.6). In our scaling the equations are

$$\begin{aligned} \mu u_x &= u - 1 + \frac{1}{\gamma M^{\star 2}} \left(\frac{T}{u} - 1 \right), \\ \lambda T_x &= T - 1 - \frac{\gamma - 1}{\gamma}(T - u) + qZ - \frac{(\gamma - 1)M^{\star 2}}{2}(u - 1)^2. \end{aligned} \tag{4.1}$$

Note, that the constant qZ vanishes in a nonreactive gas; however, we include this term for later convenience. For $Z = 0$, (4.1) are the equations for a viscous profile connecting the states corresponding to the unscaled states $(u_\star, T_\star)$ and $(u^\star, T^\star)$. We write (4.1) as

$$\begin{aligned} \mu \dot{u} &= f(u, T), \\ \lambda \dot{T} &= g(u, T), \end{aligned} \tag{4.2}$$

where the superscript "$\cdot$" denotes differentiation with respect to x. The equations $f(u, T) = 0$ and $g(u, T) = 0$ describe two parabolas in the u, T-plane, which we denote by F and G, respectively. The strict inequality (2.8) implies that the two parabolas intersect as shown in Fig. 2 for $Z \geq 0$. For increasing values of Z, the minimum of the parabola G decreases. More specifically, the following properties are easily verified for $u > 0$ and $T > 0$:

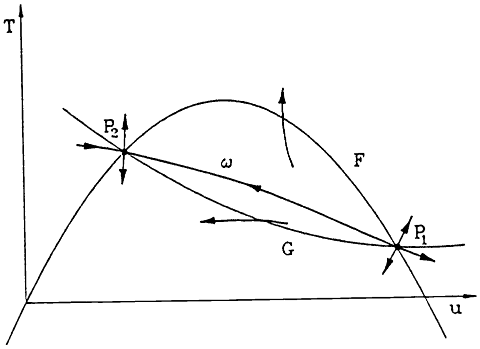

FIG. 2. *Shock structure.*

(a) $f_T > 0$, $g_T > 0$;

(b) there exist exactly two fixed points $P_1 = (u_1, T_1)$ and $P_2 = (u_2, T_2)$ with $u_1 > u_2$;

(c) $g_u > 0$ on G for $u_2 \leq u \leq u_1$;

(d) $g_u/g_T < f_u/f_T$ at P_1, and $g_u/g_T > f_u/f_T$ at P_2;

(e) there exists $u_2 < u_0 < u_1$, such that $f_u < 0$ for $u < u_0$, $f_u > 0$ for $u > u_0$ hold on F.

For sufficiently large Z, the values of T_1 become negative, which makes the problem physically meaningless. Properties (a)–(d) imply that P_1 is an unstable node and that P_2 is a saddle. Furthermore, all orbits cross the boundary of the region between F and G in the outward direction. Since the stable manifold of P_2 points into this region, we obtain the following lemma.

LEMMA 4.1. *In the above situation, there exists a transversal heteroclinic orbit ω connecting P_1 and P_2 for all values of μ and λ. The variables T and u are monotone along ω.*

This result is proved in Gilbarg [7] for general thermodynamics. If $\lambda, \mu \to 0$ simultaneously, the viscous profile converges to the shock wave. Gilbarg also analysed the limiting behavior of these viscous profiles as the ratios $\lambda/\mu \to 0$ and $\mu/\lambda \to 0$, respectively. We show how these limits fit into the framework developed in §3. In the first case we rewrite (4.2) as

$$\begin{aligned} \dot{u} &= f(u,T), \\ \varepsilon\dot{T} &= g(u,T), \end{aligned} \tag{4.3}$$

where $\varepsilon = \lambda/\mu$ is small. Thus, (4.3) is of the form (3.1); property (a) implies that conditions (i) and (ii) from §3 are satisfied on compact segments $\mathcal{C} \subset G$. The corresponding reduced problem is one-dimensional and has a (singular) heteroclinic orbit ω connecting P_1 and P_2 as shown in Fig. 3. In our graphics orbits of the reduced problem are indicated by single arrrows, orbits of the layer problem are indicated by double arrows. The transversality condition of Corollary 3.3 is trivially satisfied, and we conclude the existence of a transversal heteroclinic orbit ω_ε of (4.3) uniformly close to ω for small ε. This proves uniform convergence of the orbits given by Lemma 4.1 to ω as the ratio $\lambda/\mu \to 0$.

In the second case we rewrite (4.2) as

$$\varepsilon\dot{u} = f(u,T), \qquad \dot{T} = g(u,T), \tag{4.4}$$

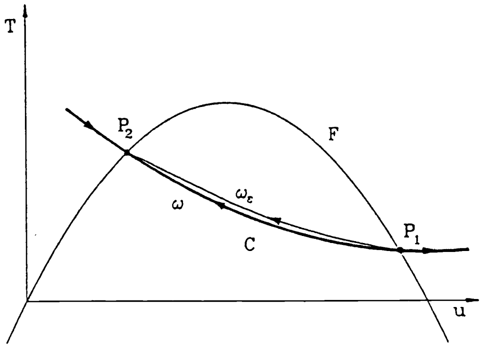

FIG. 3. $\lambda/\mu \to 0$.

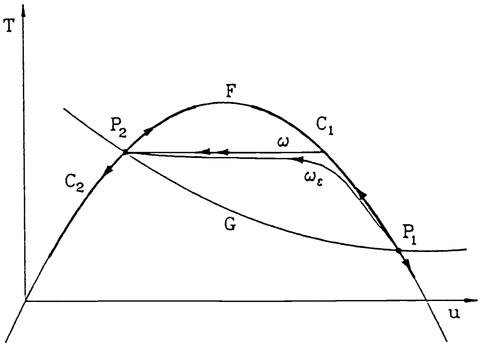

FIG. 4. $\mu/\lambda \to 0$.

where $\varepsilon = \mu/\lambda$ is small. In this case the manifold of the reduced problem is the parabola F, however, conditions (i), (ii) from §3 are only satisfied for u bounded away from u_0 due to property (e). Thus, the reduced problem is defined on compact segments $\mathcal{C}_1$ and $\mathcal{C}_2$ of the right and left branch of F (compare Fig. 4); P_1 and P_2 are both unstable fixed points of the one-dimensional reduced problem on $\mathcal{C}_1$ and $\mathcal{C}_2$, respectively. It is easy to see, that there exists a singular heteroclinic orbit ω, because each point in $\mathcal{C}_1$ is connected to a point $\mathcal{C}_2$ by a (horizontal) heteroclinic orbit of the corresponding layer problem (3.4). The transversality condition of Theorem 3.1 is trivially satisfied, and we conclude the existence of a transversal heteroclinic orbit ω_ε of (4.4) uniformly close to ω for small ε. This proves uniform convergence of the orbits given by Lemma 4.1 to ω as the ratio $\mu/\lambda \to 0$.

5. Detonation and deflagration waves. In this section we consider (2.9)–(2.12) for small μ, λ and D with fixed ratios Pr and Le, i.e., we set $\mu = \varepsilon\hat{\mu}$, $\lambda = \varepsilon\hat{\lambda}$ and $D = \varepsilon\hat{D}$, where ε is small; $\hat{\mu}$, $\hat{\lambda}$, and $\hat{D}$ are positive constants. We assume that $\phi(T)$ is smooth, with ignition temperature T_i, i.e., $\phi(T) = 0$ for $T \leq T_i$. Thus, we obtain

$$\varepsilon\hat{\mu}u_x = u - 1 + \frac{1}{\gamma M^{\star 2}}\left(\frac{T}{u} - 1\right), \tag{5.1}$$

$$\varepsilon\hat{\lambda}T_x = T - 1 - \frac{\gamma - 1}{\gamma}(T - u) + qZ - \frac{(\gamma - 1)M^{\star 2}}{2}(u - 1)^2, \tag{5.2}$$

$$\varepsilon \hat{D} Y_x = u(Y - Z), \tag{5.3}$$

$$Z_x = -\frac{Y}{u}\phi(T). \tag{5.4}$$

Obviously, (5.1)–(5.4) is of the form (3.1), with the slow variable Z, and the fast variables u, T, and Y. Therefore, the methods from §3 are applicable. Mathematically, the equations define a smooth dynamical system on the phase space $\mathbf{R}^+ \times \mathbf{R} \times \mathbf{R} \times \mathbf{R}$, where we keep in mind that only $T > 0$ and $Y \in [0,1]$ have physical meaning. By setting $\varepsilon = 0$, we obtain the reduced problem

$$0 = u - 1 + \frac{1}{\gamma M^{\star 2}}\left(\frac{T}{u} - 1\right), \tag{5.5}$$

$$0 = T - 1 - \frac{\gamma - 1}{\gamma}(T - u) + qZ - \frac{(\gamma - 1)M^{\star 2}}{2}(u - 1)^2, \tag{5.6}$$

$$0 = u(Y - Z), \tag{5.7}$$

$$Z_x = -\frac{Y}{u}\phi(T). \tag{5.8}$$

Equations (5.5)–(5.7) define the one-dimensional manifold $\mathcal{C}$, on which (5.8) defines a flow. Note that (5.5) does not depend on Y, Z, and (5.6) does not depend on Y. For $u > 0$, (5.7) implies $Y = Z$. Thus, we can visualize $\mathcal{C}$ in three-dimensional u, T, Z-space. In the u, T-plane (5.5) describes the parabola F from §4, in u, T, Z-space (5.5) is a cylinder $\mathcal{P}$ with crossection F for each $Z \in \mathbf{R}$. Note that the parabola F, and hence $\mathcal{P}$, correspond to the Raleigh line in Fig. 1. By using (5.5) to eliminate u^2 in (5.6) we obtain

$$0 = T\frac{\gamma + 1}{2\gamma} + qZ + u\frac{\gamma - 1}{2\gamma}(1 + \gamma M^{\star 2}\ ) - 1 - \frac{(\gamma - 1)M^{\star 2}}{2}. \tag{5.9}$$

This equation describes a plane $\mathcal{K}$, on which the values of T decrease for increasing u and Z. Thus, $\mathcal{P}$ and $\mathcal{K}$ intersect in the parabola $\mathcal{C}$ as shown in Fig. 5. Clearly, all fixed points of (5.1)–(5.4) must lie on $\mathcal{C}$. Due to (2.8) the Z coordinate of the vertex of $\mathcal{C}$ lies at $Z = Z_0 < 0$; for a Chapman–Jouget process $Z_0 = 0$ holds. We choose compact segments $\mathcal{C}_1$ and $\mathcal{C}_2$ on each branch of the smooth one-dimensional manifold $\mathcal{C}$, which can be parametrized by Z away from the vertex, i.e.,

$$\mathcal{C}_k = \{(u_k(Z), T_k(Z), Z, Z)\ :\ Z \in I\}, \qquad k = 1, 2.$$

The closed interval I has to be chosen, such that $u_2(Z)$ is bounded away from zero. The layer equations with the fast independent variable $\xi = x/\varepsilon$ are

$$\hat{\mu} u_\xi = u - 1 + \frac{1}{\gamma M^{\star 2}}\left(\frac{T}{u} - 1\right), \tag{5.10}$$

$$\hat{\lambda} T_\xi = T - 1 - \frac{\gamma - 1}{\gamma}(T - u) + qZ - \frac{(\gamma - 1)M^{\star 2}}{2}(u - 1)^2, \tag{5.11}$$

$$\hat{D} Y_\xi = u(Y - Z), \tag{5.12}$$

$$Z_\xi = 0. \tag{5.13}$$

The layer problem is the gasdynamic shock problem (4.1) coupled to the trivial equation (5.12), which adds one unstable dimension for $u > 0$. The discussion in §4 implies

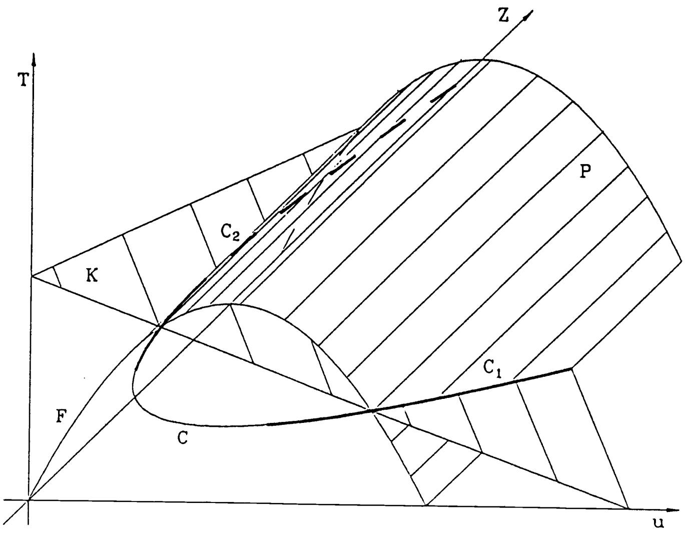

FIG. 5. *Phase space.*

that all points $P_1 \in \mathcal{C}_1$ are unstable nodes of (5.10)–(5.12) with three-dimensional unstable manifolds $\mathcal{F}^u(P_1)$. All points $P_2 \in \mathcal{C}_2$ are saddle points of (5.10)–(5.12) with one-dimensional stable manifolds $\mathcal{F}^s(P_2)$ and two-dimensional unstable manifolds $\mathcal{F}^u(P_2)$. For $Z \in I$ the real parts of the corresponding eigenvalues of the linearization are uniformly bounded away from zero. Thus, conditions (i) and (ii) from §3 are satisfied on $\mathcal{C}_1$ and $\mathcal{C}_2$, and the invariant manifold theory from §3 is applicable.

Lemma 3.2 implies that for $Z \in I$ each point $P_1(Z) \in \mathcal{C}_1$ is connected to the point $P_2(Z) \in \mathcal{C}_2$ by a heteroclinic orbit $\omega(Z)$ of (5.10)–(5.13). The u, T-component of the orbit $\omega(Z)$ is the viscous profile for the gasdynamic shock connecting $(u_1(Z), T_1(Z))$ and $(u_2(Z), T_2(Z))$, the coordinate $Y = Z$ is constant. Thus, there exists a smooth, two-dimensional manifold $\mathcal{S}$ of orbits connecting $\mathcal{C}_1$ and $\mathcal{C}_2$ (see Fig. 6).

The next step in our construction of singular detonation and deflagration waves is the analysis of the reduced problem (5.5)–(5.8), which is governed by the one-dimensional equation

$$(5.14) \qquad Z_x = -\frac{Z}{u_k(Z)}\,\phi(T_k(Z)), \qquad k = 1, 2.$$

Fixed points of (5.14) have to satisfy $Z = 0$ or $\phi(T_k(Z)) = 0$, $k = 1, 2$. Clearly, $Z = 0$ gives the fixed points $P_\star \in \mathcal{C}_1$ and $P^\star \in \mathcal{C}_2$. The reaction rate $\phi(T_k(Z)) = 0$, whenever $T_k(Z) \leq T_i$, $k = 1, 2$, holds.

On $\mathcal{C}_1$ the temperature is a strictly decreasing function of Z; therefore, there exists at most one solution Z_1 of the equation $T_1(Z) = T_i$, and $\phi(T_1(Z)) = 0$ for $Z \geq Z_1$. In this section we assume the existence of such $Z_1 > 0$. The case that $\mathcal{C}_1$ consists entirely of fixed points of (5.14) is less interesting and can be analysed similarly. On $\mathcal{C}_2$ the temperature is a strictly decreasing function of Z if and only if the point $P^\star$ lies on the left side of the vertex of the parabola F in the u, T-plane; this holds for $\gamma M^{\star 2} < 1$. In the case $\gamma M^{\star 2} > 1$ the temperature on $\mathcal{C}_2$ increases to the maximum value $(1 + \gamma M^{\star 2})^2/(4\gamma M^{\star 2})$ at the top of $\mathcal{P}$ and decreases for larger values of Z. Therefore, the equation $T_2(Z) = T_i$ has either one or two solutions. In this section we discuss the case of a unique solution $Z_2 > 0$, the other case of

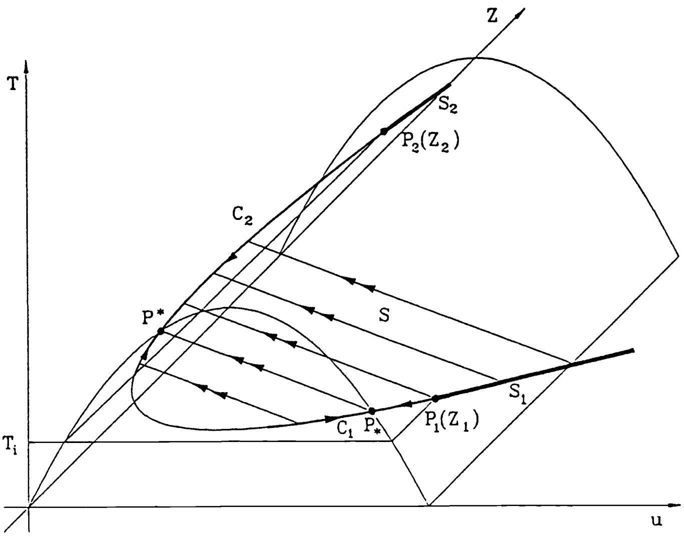

FIG. 6. *Singular invariant manifolds.*

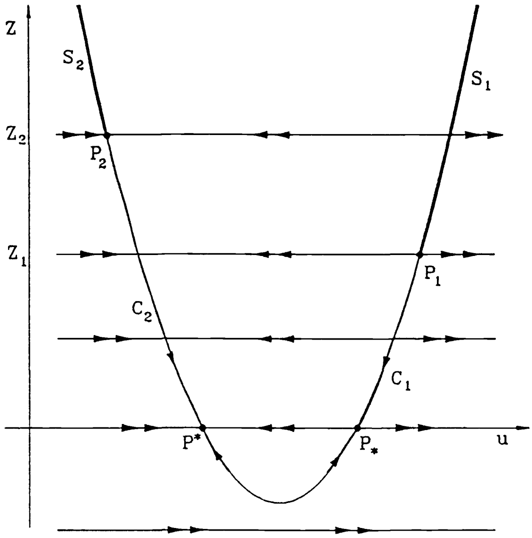

FIG. 7. *Singular orbits.*

incompletely burned states is discussed in §6. Since $T_2(Z) > T_1(Z)$ holds, we conclude $Z_2 > Z_1$. In this discussion we have implicitly assumed that the interval I has been choosen large enough such that the interval $[0, Z_2]$ is contained in the interior of I. Thus, we have the situation shown in Fig. 7. On C_1 (5.14) has the hyperbolic attracting fixed point $P_\star$ and a continuum of (necessarily nonhyperbolic) fixed points $S_1 = \{P_1(Z) : Z \in I, Z \geq Z_1\}$. Since there are no other fixed points on C_1, the point $P_1(Z_1)$ is connected to $P_\star$ by a heteroclinic orbit of (5.5)–(5.8). The situation on C_2 is similar. There exists a continuum of fixed points $S_2 = \{P_2(Z) : Z \in I, Z \geq Z_2\}$, and the point $P_2(Z_2)$ is connected to the attracting hyperbolic fixed point $P^\star$ by a heteroclinic orbit of (5.5)–(5.8).

The given unburned state P_- lies in S_1 for $M_-^2 > 1$, and in S_2 for $M_-^2 < 1$. However, it is clear that P_- is not a particularly distinguished fixed point of (5.1)–(5.4). Thus, we prefer to think of $P^\star$ as a given subsonic burned state, which determines $P_\star$, S_1, and S_2. Then, all points in S_1 are possible left states for detonation waves with burned states $P_\star$ or $P^\star$; all points in S_2 are possible left states for deflagration waves with burned states $P_\star$ or $P^\star$. We summarize our discussion in the following theorem.

THEOREM 5.1. *Under the assumptions made in this section, the following singular heteroclinic orbits connecting fixed points of* (5.1)–(5.4) *exist.*

(i) *The point $P_\star$ is connected to $P^\star$ by the heteroclinic orbit of* (5.10)–(5.13).

(ii) *The point $P_1(Z_1)$ is connected to $P_\star$ by the heteroclinic orbit of* (5.5)–(5.8).

(iii) *There exists a two-dimensional manifold $\mathcal{D}$ (with boundary) of singular orbits from $P_1(Z_1)$ to $P^\star$. These orbits consist of the solution segment of* (5.5)–(5.8) *from $P_1(Z_1)$ to $P_1(Z)$, the heteroclinic orbit of* (5.10)–(5.13) *from $P_1(Z)$ to $P_2(Z)$, and the solution segment of* (5.5)–(5.8) *from $P_2(Z)$ to $P^\star$ for $Z \in (0, Z_1]$. The boundary of $\mathcal{D}$ is formed by the singular orbit corresponding to $Z = Z_1$ and by the singular orbits from* (i) *and* (ii).

(iv) *For $Z_1 < Z < Z_2$ the point $P_1(Z)$ is connected to $P^\star$ by a heteroclinic orbit of* (5.10)–(5.13) *from $P_1(Z)$ to $P_2(Z)$ followed by the solution segment of* (5.5)–(5.8) *from $P_2(Z)$ to $P^\star$.*

(v) *For $Z \geq Z_2$ the point $P_1(Z)$ is connected to $P_2(Z)$ by the heteroclinic orbit of* (5.10)–(5.13).

(vi) *The point $P_2(Z_2)$ is connected to $P^\star$ by the heteroclinic orbit of* (5.5)–(5.8). *All these singular orbits lie in the manifold $\mathcal{S}$. There are no other singular heteroclinic orbits.*

The situation is shown in Fig. 7. In cases (iv) and (v) it is possible, that $T_1(Z)$ is negative; then the singular orbit is physically meaningless and only included for mathematical completeness. If we replace the heteroclinic orbits of the layer problem (5.10)–(5.13) in Theorem 5.1 by jump discontinuities in the fast gasdynamic variables u and T, then the theorem describes all solutions of the ZND-model (1.3) with right states $P^\star$ and $P_\star$. However, Fig. 7 reveals more details than the classical Chapman–Jouget diagram in Fig. 1. Furthermore, as should be obvious by now, Theorem 5.1 is the basis for the proof of the main theorem from §1, which follows, if we prove that the singular heteroclinic orbits perturb to heteroclinic orbits of (5.1)–(5.4) for small ε. Theorem 3.1 does not apply directly because all fixed points of (5.5)–(5.8) in S_1 and S_2 are nonhyperbolic. Clearly, this nongeneric situation, that could be destroyed by small perturbations, is caused by the ignition temperature assumption.

THEOREM 5.2. *Under the assumptions made in this section, there exists $\varepsilon_0 = \varepsilon_0(\hat{\mu}, \hat{\lambda}, \hat{D}) > 0$, such that the following assertions hold for* (5.1)–(5.4) *for $0 < \varepsilon < \varepsilon_0$.*

(i) *$P^\star$ and $P_\star$ are hyperbolic fixed points, with two-dimensional and one-dimensional stable manifolds, respectively. S_1 and S_2 are one-dimensional manifolds of fixed points.*

(ii) *The singular heteroclinic orbits from Theorem* 5.1, (i)–(vi) *perturb smoothly to heteroclinic orbits of* (5.1)–(5.4) *connecting the corresponding fixed points.*

(iii) *All connecting orbits lie in a smooth, two-dimensional, invariant manifold $\mathcal{S}_\varepsilon$, which is a graph over the u, Z-plane. The flow in $\mathcal{S}_\varepsilon$ is as shown in Fig.* 8.

Proof. The manifolds $\mathcal{C}_1$ and $\mathcal{C}_2$ satisfy conditions (i) and (ii) from §3, and we conclude the existence of the center-like manifolds $\mathcal{C}_{i,\varepsilon}$, their stable and unstable manifolds $\mathcal{C}^s_{i,\varepsilon}$ and $\mathcal{C}^u_{i,\varepsilon}$, and their invariant foliations $\mathcal{F}^s_{i,\varepsilon}$ and $\mathcal{F}^u_{i,\varepsilon}$, respectively, for

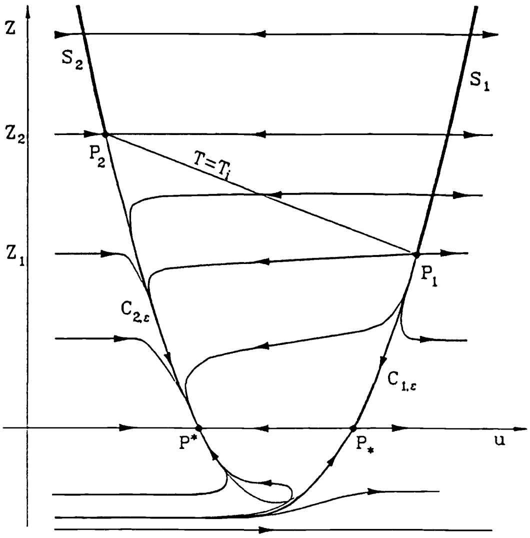

FIG. 8. *Flow in* $\mathcal{S}_\varepsilon$.

$i = 1, 2$, and ε sufficiently small. $\mathcal{C}^u_{1,\varepsilon}$ and $\mathcal{C}^s_{2,\varepsilon}$ are smooth perturbations of

$$\mathcal{C}^u_1 = \bigcup_{P_1 \in \mathcal{C}_1} \mathcal{F}^u(P_1), \qquad \mathcal{C}^s_2 = \bigcup_{P_2 \in \mathcal{C}_2} \mathcal{F}^s(P_2).$$

We conclude from Theorem 5.1 that the four-dimensional manifold $\mathcal{C}^u_1$ and the two-dimensional manifold $\mathcal{C}^s_2$ intersect transversally in the two-dimensional manifold $\mathcal{S}$ (see Fig. 6). The stability of transversal intersection proves the existence a smooth, invariant manifold

$$\mathcal{S}_\varepsilon = \mathcal{C}^u_{1,\varepsilon} \cap \mathcal{C}^s_{2,\varepsilon},$$

C^1-close to $\mathcal{S}$ for small ε. The manifold $\mathcal{S}$ is a graph, i.e., $T = T(u, Z)$ and $Y = Z$ on $\mathcal{S}$; thus, $\mathcal{S}_\varepsilon$ is a graph over the u, Z-plane.

Next, we discuss the existence of heteroclinic orbits in $\mathcal{S}_\varepsilon$. Since $P_\star$ and $P^\star$ are stable hyperbolic fixed points of (5.5)–(5.8), they must lie in $\mathcal{C}_{1,\varepsilon}$ and $\mathcal{C}_{2,\varepsilon}$, respectively, and satisfy assertion (i), which can be also verified by direct computation for arbitrary ε. The existence of a (purely gasdynamic) heteroclinic orbit connecting $P_\star$ and $P^\star$ follows either from Theorem 3.1 or from Lemma 4.1 by restricting the flow to the invariant subspace $Y = Z = 0$. The last argument implies also the existence of (purely gasdynamic) heteroclinic orbits connecting $P_1(Z)$ and $P_2(Z)$ for $Z \geq Z_2$.

Since S_1 and S_2 are sets of fixed points for (5.1)–(5.4), they are invariant. Thus, Theorem 9.1 in [2] implies $S_1 \subset \mathcal{C}_{1,\varepsilon}$ and $S_2 \subset \mathcal{C}_{2,\varepsilon}$. Since there are no other fixed points, the one-dimensional flow on $\mathcal{C}_{1,\varepsilon}$ must connect $P_1(Z_1)$ and $P_\star$. Similarly, there exists an orbit from $P_2(Z_2)$ to $P^\star$ in $\mathcal{C}_{2,\varepsilon}$. This proves the persistence of the orbits given by (ii) and (vi) in Theorem 5.1. Thus, the region on $\mathcal{S}_\varepsilon$ bounded by the orbits from $P_\star$ to $P^\star$, from $P_1(Z_1)$ to $P_\star$, from $P_2(Z_2)$ to $P^\star$, from $P_1(Z_2)$ to $P_2(Z_2)$, and by the curve of fixed points $\{P_1(Z) : Z_1 \leq Z \leq Z_2\}$ is invariant (see Fig. 8). Since there are no other fixed points, all points in this region belong to the stable manifold of $P^\star$ and assertion (ii) follows. This proves that the flow is as shown in Fig. 8, which shows the flow in the union of $\mathcal{C}^s_{2,\varepsilon}$ and the smooth extension of $\mathcal{S}_\varepsilon$ in $\mathcal{C}^u_{1,\varepsilon}$; $\mathcal{S}_\varepsilon$ is the region between $\mathcal{C}_{1,\varepsilon}$ and $\mathcal{C}_{2,\varepsilon}$. □

For a given unburned state P_- the main result in §1 follows from Lemma 2.1, Theorem 5.2, and Lemma 3.2. Weak detonation waves and weak deflagration waves are heteroclinic orbits of the type described in Corollary 3.3; they have no internal layers. Strong detonation waves are orbits of the type described in Theorem 3.1; the gasdynamic shock corresponds to an internal layer.

6. Discussion and extensions. Our analysis proves the existence of weak detonation waves and weak deflagration waves for unburned temperatures exactly at ignition. The process is driven by the chemical reaction; the gasdynamic variables are close to equilibrium. Strong detonation waves with unburned temperature below ignition are unique; the temperature is raised above ignition by the gasdynamic shock. Then the reaction proceeds like a weak deflagration. There is a one-parameter family of strong detonation waves with unburned temperature exactly at ignition. In one of the two extreme cases the detonation wave has the usual structure of a gasdynamic shock followed by a weak deflagration. The other limiting case is a weak detonation followed by a nonreactive gasdynamic shock. In the intermediate cases the process starts like a weak detonation; then the temperature is raised by a gasdynamic shock, and the process is completed like a weak deflagration.

In the following we discuss the monotonicity properties of temperature and pressure. The discussion is based on the fact that strict monotonicity of a variable along a singular orbit is preserved for small ε. For $\gamma M^{\star 2} < 1$, temperature is strictly increasing along all singular orbits. Thus, temperature is strictly increasing along all detonation and deflagration waves for $\gamma M^{\star 2} < 1$ and small ε. For $\gamma M^{\star 2} > 1$, temperature is strictly increasing along weak detonations. However, on the deflagration branch temperature is increasing for temperatures close to ignition but decreasing near $P^\star$. Therefore, the temperature has a maximum in the interior of weak deflagration and strong detonation waves for $\gamma M^{\star 2} > 1$ and small ε. Pressure is strictly increasing along weak detonation waves and strictly decreasing along weak deflagration waves for small ε. Hence, for a strong detonation wave the pressure attains its maximum after the gasdynamic shock; this peak in pressure corresponds to the familiar Neumann spike [16].

In §5 we mentioned the possibility of incompletely burned states. For $\gamma M^{\star 2} > 1$ it is possible that the equation $T_2(Z) = T_i$ has two solutions $0 < Z_2' < Z_2$. In this case $T^\star < T_i$ holds, and, clearly, the temperature on $\mathcal{C}_1$ is below ignition. Thus, complete combustion is impossible. However, in this case a weak deflagration and strong detonations with a partial burned state exist for small ε. More precisely, there exists a weak deflagration wave with unburned state $P_2(Z_2)$ and burned state $P_2(Z_2')$. There exists a family of strong detonation waves with unburned state $P_1(Z)$ and burned state $P_2(Z_2')$ for $Z_2' < Z < Z_2$. The existence of these waves follows from the existence of the corresponding singular heteroclinic orbits similar to the proof of Theorems 5.2. The existence of weak deflagration waves with an incomplete burned state is discussed in Wagner [15]; the existence of strong detonation waves with a partial burned state seems to be new.

In our analysis we have assumed that $\hat{\mu}$, $\hat{\lambda}$, and $\hat{D}$ in (5.1)–(5.4) are arbitrary constants. Since the values of these parameters have no impact on the analysis of §5, our results are uniformly valid as long as $\hat{\mu}$, $\hat{\lambda}$, and $\hat{D}$ are bounded from below and from above by some positive constants. More precisely, for fixed values $0 < \alpha < \beta < \infty$ a constant $\varepsilon_0(\alpha, \beta) > 0$ exists, such that the assertions of Theorem 5.2 hold for

$0 < \varepsilon < \varepsilon_0$ for all $\alpha < \hat{\mu} < \beta$, $\alpha < \hat{\lambda} < \beta$, and $\alpha < \hat{D} < \beta$.

The case that $(\mu, \lambda, D) \to 0$ along a smooth curve in parameterspace with asymptotically bounded ratios can be treated in the following way. We set

$$\mu = \varepsilon\hat{\mu}(\varepsilon), \quad \lambda = \varepsilon\hat{\lambda}(\varepsilon), \quad D = \varepsilon\hat{D}(\varepsilon)$$

in (2.9)–(2.12), where $\hat{\mu}$, $\hat{\lambda}$, $\hat{D}$ are smooth, positive functions on an interval $[0, \varepsilon_1]$ with $\varepsilon_1 > 0$. This gives a system of the form (3.1), where the function g depends smoothly on ε. The theory outlined in §3 applies also to the case that the right-hand side in (3.1) depends smoothly on ε (see [2], [13]). The corresponding reduced problem is just (5.5)–(5.8), and the layer problem is (5.10)–(5.13) with $\hat{\mu} = \hat{\mu}(0)$, $\hat{\lambda} = \hat{\lambda}(0)$, and $\hat{D} = \hat{D}(0)$, i.e., we have exactly the situation analysed in §5. The particular simple dependence of the right-hand side g on ε, and the results in [13] imply that there exists $\varepsilon_0 > 0$, such that the assertions of the Main Theorem in §1 hold in this situation as well for all ε, $0 < \varepsilon < \varepsilon_0$.

The methods used in this paper can be applied to various other possible (less physical) singular limits, i.e., to cases where μ, λ, and D are of different orders of magnitude. In Gasser [5] a similar analysis in the case $\mu = \varepsilon\hat{\mu}$, $\lambda = \varepsilon\hat{\lambda}$, and $D = \hat{D}$ with positive constants $\hat{\mu}$, $\hat{\lambda}$, $\hat{D}$, and ε small is given. For $\varepsilon = 0$ this problem decouples into a two-dimensional reduced problem describing chemistry and diffusion, and a two-dimensional layer problem describing pure gasdynamics. By applying the methods of §3 we obtain essentially the same results on the existence of detonation and deflagration waves.

For strong shocks $\hat{\mu}$ and $\hat{\lambda}$ may depend on the gasdynamic variables. If we consider $\hat{\mu} = \hat{\mu}(u, T, Y)$, $\hat{\lambda} = \hat{\lambda}(u, T, Y)$, and $\hat{D} = \hat{D}(u, T, Y)$ to be smooth functions, which are bounded from below and from above by some positive constants, all our results remain valid, since these positive factors in (5.1)–(5.4) do not change the geometry and the analysis of the problem.

TRAVELLING WAVES FOR MUTUALIST SPECIES*

KONSTANTIN MISCHAIKOW† AND VIVIAN HUTSON‡

Abstract. A reaction-diffusion model for n mutalistic species is considered. The existence of a travelling wave analogous to a bistable wave for a single species is proved. Stability and uniqueness of the wave is considered, and the question of the "dominance" of the equilibria is discussed.

Key words. travelling waves, mutualism, symbiosis, reaction-diffusion, Conley index, connected simple systems

AMS subject classifications. 35K57, 92D25

1. Introduction.

Travelling wave problems for two interacting species whose dynamics are governed by a pair of reaction-diffusion equations have been much studied recently. To quote two examples only, Dunbar [5] has considered this problem for a predator-prey model, and Gardner [11] for a pair of competing species. It appears that a third class of model, that of mutualistic (sometimes called symbiotic) interactions, has not been considered from this point of view. However, it has been argued (see Hutson [13] and Hutson, Law, and Lewis [14]) that perhaps somewhat in contrast with the situation for the above types of interaction it is particularly important in this case to include diffusion to avoid the somewhat paradoxical conclusions predicted by ordinary differential equation models of mutualism when the mutualism is obligate (that is neither species can exist on its own). Our first objective then is to show that travelling waves exist for obligate mutualists, indeed even for a system of n obligate mutualists, and to discuss some of the properties of these waves.

We consider a system of reaction-diffusion equations

$$\frac{\partial u_i}{\partial t} = \mu_i \frac{\partial^2 u_i}{\partial x^2} + h_i(u) \qquad (i = 1, \dots, n), \tag{1.1}$$

where $u = (u_1, \dots, u_n)$, with spatial domain $\mathbf{R}$, the μ_i (assumed > 0) being diffusion coefficients. The phase plane (when $n = 2$) for the reaction system is described in Fig. 1, the detailed assumptions concerning the h_i being given in assumption (H1)–(H5) in §2. The reaction phase plane suggests that there is a broad analogy with the one species bistable case treated, for example, in Fife [6, pp. 106–109], based on the equation

$$\frac{\partial u}{\partial t} = \mu \frac{\partial^2 u}{\partial x^2} + m(u),$$

where m has the zeros $0, u^*, 1$ with $0 < u^* < 1$, $m(u) < 0$ for $0 < u < u^*$, and $m(u) > 0$ for $u^* < u < 1$. We shall show that this is indeed the case, proving in §4 that for some velocity c and arbitrary n, there is a monotone travelling wave (which we call a bistable wave) from a stable critical point A to another stable critical point

B. In §5 we demonstrate that for c large enough there is a travelling wave from A to C, and that a monotone such wave exists in the case $n = 2$.

A variety of techniques have been used to prove the existence of travelling waves, ranging from topological methods (Conley and Gardner [4], Gardner [10], [11]) to shooting methods based on Wazewski's principle (Dunbar [5]). Our second objective is to further develop the first class of methods, with the aim of treating a considerably wider class of systems, while at the same time reducing the technicalities to a minimum. The approach here may be compared with the use of classical degree theory, where the technicalities on which the theory rests do not appear in the results (such as the Leray–Schauder fixed point theorem). The abstract results presented in the Appendix are based on a development of the Conley index theory, Conley's connection matrix, and transition matrices. We then deduce in §3 two abstract continuation theorems which allow us to prove our existence results by carrying out a homotopy of the system to a simpler one. It is necessary here to construct "isolating neighborhoods" in phase space (analogous to open sets in degree theory) and to show that no bounded solution of interest can be internally tangent to the boundary of the neighborhood; this is done in §4.

The techniques presented in this paper are not new in the sense that Conley promoted the use of his index in proving existence of connecting orbits in the early 1970s and numerous people have since successfully used his ideas. Within the context of the types of travelling wave problems discussed here the most notable applications can be found in the works of Conley [2], Conley and Gardner [4], and Gardner [11]. For the single species problem one can find our approach sketched out in [2] (in particular, see the example IV.2.6). That these ideas could be applied to two-species problems was first demonstrated in [4] (competing species) and [11] (predator-prey). What we claim to show in this paper is, that in fact, this is a very general technique and can be straightforwardly applied to problems involving n-species. It is our contention that this approach can also be applied to higher-dimensional problems of mixed type, i.e., systems involving mutualist, competitive, and predator-prey species simultaneously (see [19] and [20]). It should also be remarked that whereas [4] and [11] apply a connection index to find connecting orbits, we use the connected simple system associated with the Conley index to obtain existence.[1] Results of [17] seem to imply that these two approaches are theoretically equivalent. Nevertheless, it is the authors' opinion that the connected simple system is the more basic concept, and thus, more natural to work with it. Furthermore, the global bifurcation results of [17] are obtained in the context of connected simple systems, and hence, they can be applied directly to the results obtained by our approach. (For examples of how these theorems can be applied to find nonmonotone bistable waves, the reader is referred to [20]).

2. Preliminaries. Consider the system of equations (1.1) and let $h_i(u) = u_i f_i(u)$. Take R to be the open rectangle in $\mathbf{R}^n_+$ with opposite vertices $A = (0, \ldots, 0)$ and $B = (1, \ldots, 1)$. We make the following hypothesis concerning the reaction system:

$$u_i' = h_i(u) = u_i f_i(u), \qquad (i = 1, \ldots, n) \tag{2.1}$$

corresponding to (1.1). It is assumed that the following assumptions hold in a neighborhood of $\bar{R}$ where all indices run over $1, \ldots, n$.

[1] Gardner has informed us that Conley originally considered using connected simple systems in their work, but then later formulated the connection index approach which first appeared in their joint paper.

(H1) $f_i \in C^2(\bar{R}, \mathbf{R})$.

(H2) $\partial f_i/\partial u_j > 0\,(i \neq j)$, that is, the interactions are mutualistic, and $\partial f_i/\partial u_i < 0$, that is, intraspecific competition holds.

(H3) A is a global attractor for the flow in any "face" $u_i = 0$, that is, the mutualism is obligate.

(H4) There are exactly three equilibria $A = (0,\dots,0)$, $B = (1,\dots,1)$ and $C = (c_1,\dots,c_n)$ with $0 < c_i < 1$ for all i. All three critical points are hyperbolic; A and B are stable and C has a one-dimensional unstable manifold.

(H5) The region $R_1 = \{u : f_i(u) > 0 \text{ for all } i = 1,\dots,n\}$ is connected and $B, C \in \bar{R}_1$. Also $R_2 = \{u : f_i(u) < 0 \text{ for all } i = 1,\dots,n\}$ is connected and $A, C \in \bar{R}_2$. Finally, $R_3 = \{u | u_i > 1, f_i(u) < 0 \text{ for all } i = 1,\dots,n\}$ is connected and $B \in \bar{R}_3$.

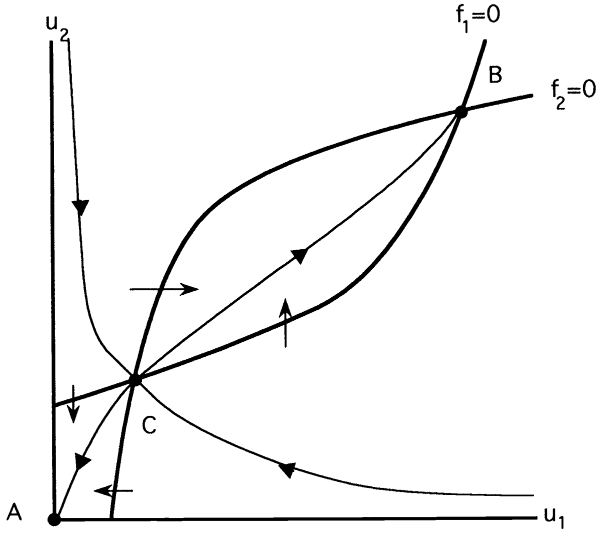

FIG. 1. *The phase plane for the reaction system when $n = 2$. The arrows give the vector field. The stable and unstable manifolds of C are shown with lighter lines.*

These assumptions yield simply the n-dimensional equivalent of the two-species mutualist system with phase plane as in Fig. 1. The following explicit example may help in visualising the type of model considered. For simplicity it is a three species case with some symmetry, but there is no essential difficulty in giving a similar n-species version or relaxing the symmetry. For any $\beta \in (\frac{1}{2}, 4)$ take

$$f_i(u) = -1 - u_i + (1 + 2\beta)\frac{\sum(i)}{1 + \beta\sum(i)},$$

where

$$\sum(i) = \sum_{j \neq i, j=1}^{3} u_j.$$

It is straightforward to show that there are exactly three equilibria A, C, B in $\mathbf{R}^3_+$ with coordinates $(0,0,0)$, $1/(2\beta)(1,1,1)$, and $(1,1,1)$, respectively. It is clear that on the diagonal $u_1 = u_2 = u_3$, starting from the origin, the sign of each f_i is negative, then changes to positive at C and then changes again to negative at B. On the other hand, consider the two-dimensional subsystem in a "face" $u_3 = 0$, for example. Then one can check easily that for β in the range prescribed above, the only equilibrium is the origin A, and drawing the null isoclines one can readily convince oneself that A is a global attractor. It follows rather easily that (H1)–(H5) hold.

There are several observations worth making at this point, the relevance of which will appear later in the proofs.

Remark 2.1. If $u \in B_\epsilon(B)$ such that $f_i(u) > 0$ for all $i = 1, \dots, n$, then $u_i < 1$. This follows from (H2) which determines the direction of ∇f_i and then (H5) which implies that $u_i < 1$ rather than $u_i > 1$.

Remark 2.2. Since the reaction system is a cooperative system it is a monotone system, and hence, using [12] by (H5) if u lies in the stable manifold of C, then it is impossible for $u_i - c_i > 0$ for all $i = 1, \dots, n$.

Remark 2.3. There exist connecting orbits from C to A and C to B which lie in the regions R_1 and R_2. To see why this is so, notice that a branch of the local unstable manifold of C lies in R_2. Assume for the moment that R_2 is positively invariant under the reaction flow. Since $u \in R_2$ implies $f_i(u) < 0$ for all $i = 1, \dots, n$, $u_i(t)$ is decreasing. However, the faces defined by $u_i = 0$ are invariant, hence $u_i(t) > 0$ for all $t > 0$. Since A is the only other critical point in $\bar{R}_2$, any point on this branch of the local unstable manifold of C limits to A. Thus, it only needs to be shown that $\bar{R}_2$ is positively invariant. Let $u \in \partial \bar{R}_2 \backslash \{C\}$. If $u_i = 0$ for some i then $\lim_{t \to \infty} u(t) = A$ by (H3). So assume $u_i > 0$ for all i, in which case $u \in \partial \bar{R}_2 \backslash \{C\}$ implies that there exists $j \in \{1, \dots, n\}$ such that $f_j(u) = 0$. On the other hand, since $u \neq C$, there exists f_i such that $f_i(u) \neq 0$. Of course, in this case $f_i(u) < 0$. Thus the tangent vector to the flow at u is given by $u_i' \leq 0$ and $u_j' = 0$. Note now that $u' \cdot \nabla f_j(u) < 0$, i.e., $f_j(u(\epsilon)) < 0$ for $0 < \epsilon \ll 1$, and hence the point u is entering the region R_2. A similar argument holds for the existence of a C to B orbit.

We seek travelling wave solutions of (1.1), that is solutions of the form $(u_1(x - ct), \dots, u_n(x - ct))$ where $c \in \mathbf{R}$ is the wave speed. Substitution into (1.1) yields the system of equations

$$\mu_i u_i'' + c u_i' + h_i(u) = 0 \qquad (i = 1, \dots, n), \tag{2.2}$$

where $u = (u_1, \dots, u_n)$, and "dash" denotes differentiation with respect to the argument $x - ct$ which, in an abuse of notation, we continue to refer to as t to fit the standard dynamical systems terminology. The corresponding first-order system is

$$u_i' = p_i \qquad (i = 1, \dots, n), \tag{2.3a}$$

$$\mu_i p_i' = -c p_i - h_i \qquad (i = 1, \dots, n). \tag{2.3b}$$

Notice that if $A = (a_1, \dots, a_n)$ is a critical point of the reaction system, then $A_0 = (A, 0) = (a_1, \dots, a_n, 0, \dots, 0)$ is a critical point of (2.3).

Following the discussion in the introduction, we consider in particular two types of travelling waves, which we describe as a Fisher wave and a bistable wave to emphasize the relation to the classical one-species types of wave; see [1] for basic facts concerning these waves, including existence proofs. A "connection" of two equilibria of the system (2.3) is a heteroclinic orbit from one critical point to the other. It is said to be monotone (here taken arbitrarily to be increasing always) if each $u_i(\cdot)$ is increasing. A Fisher wave is a monotone connection of A_0 to C_0, and a bistable wave is a connection of A_0 to B_0, where A and B are stable critical points for the reaction system.

Finally, it is convenient to note the following formulae derived from (2.3):

$$\mu_i \frac{dp_i}{du_i} = -c - p_i^{-1} h_i(u), \tag{2.4}$$

$$\frac{1}{2}\mu_i[p_i^2(u_{i1}) - p_i^2(u_{i0})] = -c\int_{u_{i0}}^{u_{i1}} p_i(s)ds - \int_{u_{i0}}^{u_{i1}} H_i(s)ds, \tag{2.5}$$

which hold along a monotone section of an orbit which is parameterized by u_i, where H_i denotes h_i in an obvious sense.

3. Two abstract continuation theorems. In this section we present a pair of abstract theorems upon which the existence results for the bistable and Fisher waves are based. The basic idea for the first theorem is quite simple:

1. Construct a homotopy of the $2n$-dimensional system to a system with an invariant two-dimensional subsystem on which the dynamics are those of the standard one species bistable problem.
2. Prove the existence of a wave speed for which the heteroclinic orbit occurs in the two-dimensional subsystem.
3. Construct a homotopy back to the original problem and conclude that for some wave speed the heteroclinic orbit, and hence the travelling wave exists for the original problem.

Theorems in this spirit are quite well known and are the basis for most applications of degree theory. In this latter setting a typical theorem goes as follows. Given a parameterized family of functions $f^\sigma : U \to \mathbf{R}$ such that the zeros of the functions do not lie on the boundary of U, then the degree of the function at one parameter value is the same as the degree at any other parameter value. Furthermore, if the degree is nonzero then for any σ there exists $x^\sigma \in U$ such that $f^\sigma(x^\sigma) = 0$. There are two key ingredients to this theorem:

(i) The zeros do not occur on the boundary, and

(ii) At some parameter value one can compute the degree.

Though, as was indicated in the introduction, our approach is based on the Conley index rather than degree theory, the spirit of the two methods have much in common.

Before stating the theorems let us establish some notation. Let $\phi : \mathbf{R} \times X \to X$ be a flow on a locally compact space. Given a compact set N, let

$$N^T = \{x \in N | \phi([-T,T],x) \subset N\}.$$

N is called an *isolating neighborhood* if there exists $T > 0$ such that $N^T \subset \text{int}(N)$. Let $N^\infty = \bigcap_{T>0} N^T$. It is easy to check that N^∞ is an invariant set, i.e., $\phi(\mathbf{R}, N^\infty) = N^\infty$. Clearly, N is an isolating neighborhood if and only if $x \in N^\infty$ implies $x \notin \partial N$. Notice that the role played by isolating neighborhoods in Conley index theory is equivalent to that played by the above mentioned set U in degree theory. An invariant set S is called *isolated* if there exists an isolating neighborhood N of S such that $S = N^\infty$.

A simple, but as we shall see, useful decomposition of an invariant set S is that of an *attractor-repeller* (A-R) pair. Let $\omega(U)$ and $\omega^*(U)$ denote the omega and alpha limit sets of U, respectively. $A \subset S$ is called an *attractor* in S if there exists a neighborhood U of A such that $\omega(U \cap S) = A$. The *dual repeller* of A, denoted by A^* is defined by $A^* = \{x \in S|\omega(x) \cap A = \emptyset\}$. The pair (A, A^*) make up an A-R pair. Notice that given an A-R pair decomposition of S, if $x \in S$, then $x \in A \cup A^*$ or $\omega(x) \subset A$ and $\omega^*(x) \subset A^*$, i.e., S is made up of the attractor A, its dual repeller A^*, and connecting orbits from A^* to A. Thus, if one lets $C(A^*, A)$ denote the set of connecting orbits from A^* to A, then $S = A \cup A^* \cup C(A^*, A)$.

Since the complicated $2n$-dimensional problem will be mapped by a homotopy to a simple two-dimensional problem we need to discuss what is meant by continuing isolating neighborhoods and isolated invariant sets. Consider a parameterized family of flows $\phi(t,x,\sigma) = \phi^\sigma(t,x)$, where $\sigma \in [0,1]$ is the parameter value. Define the parameter flow to be $\Phi : \mathbf{R} \times X \times [0,1] \to X \times [0,1]$ by

$$\Phi(t,x,\sigma) = (\phi^\sigma(t,x),\sigma).$$

Let N^σ denote an isolating neighborhood for the flow ϕ^σ. One says that the isolating neighborhood N^1 continues to N^0 if there exists N an isolating neighborhood of Φ, the parameter flow, such that $N|_{X\times\{0\}} = N^0$ and $N|_{X\times\{1\}} = N^1$. Similarly, if S^σ denotes an isolated invariant set under ϕ^σ, then S^0 continues to S^1 if there exist corresponding isolating neighborhoods that continue.

We are now ready to present the hypotheses for the abstract theorem, and start with the homotopy discussed in the previous paragraph. With this in mind we write down the following two parameter set of equations:

$$(\mathrm{TW}^{c,\sigma}) \qquad \begin{aligned} u' &= p, \\ M(\sigma)p' &= -cp - H(u,\sigma), \end{aligned}$$

where $u,p \in \mathbf{R}^n$, $M(\sigma)$ is a diagonal matrix with positive entries μ_i^σ, $c \in \mathbf{R}$ is the wave speed, $\sigma \in [0,1]$ is the homotopy parameter, and $H : \mathbf{R}^n \times [0,1] \to \mathbf{R}^n$. The corresponding family of reaction systems is given by

$$(\mathrm{R}^\sigma) \qquad u' = H(u,\sigma).$$

We shall adopt the convention that at $\sigma = 0$ we are at the original system we wish to study, i.e., $H(u,0) = h(u)$ and $\mu_i^0 = \mu_i$, and at $\sigma = 1$ we have the simple two-dimensional invariant subsystem for which we can prove the existence of a travelling wave solution. We formalize this via the following assumption.

Assumption I. For the reaction system (R^1) there exists a one-dimensional attracting invariant subspace $L \subset \mathbf{R}^n$. Furthermore, the dynamics on L are as in Fig. 2, i.e., the set of bounded solutions consist of the hyperbolic critical points $\{A,B,C\}$ and the heteroclinic connections $C \to A$ and $C \to B$.

FIG. 2. *The dynamics on L.*

We now state the assumption concerning the homotopy from $\sigma = 1$ to $\sigma = 0$. Let $A_0^1 = (A^1,0), B_0^1 = (B^1,0)$, and $C_0^1 = (C^1,0)$.

Assumption II. A^σ and B^σ continue as critical points for (R^σ) and N^σ continue as isolating neighborhoods for $(\mathrm{TW}^{c,\sigma})$ such that (B_0^σ, A_0^σ) is an attractor-repeller pair for $(N^{c,\sigma})^\infty$, the invariant set isolated by N^σ under the flow generated by $(\mathrm{TW}^{c,\sigma})$. Furthermore, for $\sigma = 1$, if there exists an $A_0^1 \to B_0^1$ solution to $(\mathrm{TW}^{c,1})$ for some value of c, then the connecting orbit belongs to $(N^{c,1})^\infty$.

THEOREM 3.1. *Given Assumptions* I *and* II, *there exists a bistable travelling wave from* A_0 *to* B_0 *for some wave speed* $\bar{c}$.

The reader is referred to the appendix for the technical aspects of the proof of this theorem. The general idea, however, is quite simple. Assumption I is used to guarantee that the Conley index (as a connected simple system) differs for $c \approx +\infty$ and $c \approx -\infty$. Now Assumption II, along with an a priori bound guarantees that the index remains the same throughout the homotopy for $|c|$ sufficiently large. Of course this implies that the index at $c^0 \approx +\infty$ and $c^0 \approx -\infty$ differ, and hence there exists an A_0^0 to B_0^0 connection for some intermediate wave speed $\bar{c} = \bar{c}^0$.

With regard to the existence of a Fisher wave we have the following result.

THEOREM 3.2. *Let A and C be hyperbolic critical points for the reaction system* (2.2)*, where A is stable and C has a one-dimensional unstable manifold. If there exists a $C \rightarrow A$ heteroclinic orbit, a solution to* (2.2)*, then there exists a $\hat{c}$ such that for all $c \in (\hat{c}, \infty)$ there is an $A_0 \to C_0$ connecting orbit for the travelling wave system* (2.3).

Again the proof of this theorem appears in the appendix; however, we remark at this point that it follows directly from results of Conley and Fife [3] and McCord [16].

4. Existence of a bistable wave. We shall show that a straightforward application of the abstract Theorem 3.1 yields the existence of a monotone A_0 to B_0 connection for the system (2.3), and so, a bistable travelling wave for the reaction-diffusion system (1.1). In particular, we shall prove the following theorem.

THEOREM 4.1. *Under hypotheses* (H1)–(H5)*, there exists a wave speed $\bar{c}$ for which there is a monotone $A_0 \to B_0$ connection for* (2.3).

Of course, to apply Theorem 3.1, one needs to demonstrate that Assumptions I and II are satisfied. This shall be done in several steps beginning with the construction of the homotopy F. Let

$$\phi_i = \{u | f_i(u) = 0\},$$

so that ϕ_i represents the zero surface of f_i. By the assumption (H4)

$$\bigcap_{i=1}^{n} \phi_i = \{B, C\}.$$

Let L denote the diagonal of $\mathbf{R}^n$. Since $B \in L$, there exists an index j such that ϕ^j intersects L transversally and such that this intersection contains at least two points. By a reordering of the indices, we arrange that $j = 1$, and from (H4) we may assume without loss of generality that this intersection has exactly two points. For, if there are more points in the intersection, then we may homotope ϕ^1 to eliminate the extra points of intersection; in view of (H4) this can be done without changing the number of critical points. Let $\rho = f^1$, and define

$$\begin{aligned} F_i(u, \sigma) &= (1-\sigma) f_i + \sigma \rho(u_i, u_2, \ldots, u_{i-1}, u_1, u_{i+1}, \ldots, u_n), \\ \mu_i^\sigma &= \mu_i(1-\sigma) + \sigma\,. \end{aligned}$$

For $\sigma \in [0, 1]$ consider the system

$$\text{(TW}(c,\sigma)) \qquad \begin{aligned} &(4.1\text{a}) & u_i' &= p_i, \\ &(4.1\text{b}) & \mu_i^\sigma p_i' &= -cp_i - u_i F_i(u, \sigma). \end{aligned}$$

Obviously, this is a particular choice for the general system ($\text{TW}^{c,\sigma}$). As σ varies, the position of the intermediate critical point varies; let this be denoted by C^σ for the reaction system and C_0^σ for the travelling wave system.

The second step in applying Theorem 3.1 is to construct an isolating neighborhood. The fact that we are looking for monotone $A \rightarrow B$ connecting orbits strongly suggests how the isolating neighborhood should be chosen. In particular, monotonicity implies two things; $0 \le u_i(t) \le 1$, and $0 \le p_i(t)$ for $t \in \mathbf{R}$. This suggests choosing a rectangular box, $\mathcal{R} = \mathcal{R}_u \times \mathcal{R}_p$, where $\mathcal{R}_u = [0,1]^n = \bar{R}$ and $\mathcal{R}_p = [0,K]^n$ for some sufficiently large K. Clearly, if $A \to B$ is monotone then $A_0 \to B_0 \subset \mathcal{R}$. On the other hand, it is equally obvious that $\mathcal{R}$ is not an isolating neighborhood since the critical points are elements of $\partial\mathcal{R}$. This suggests defining

$$N^\sigma = \mathcal{R} \cup \bar{B}_\epsilon(A_0) \cup \bar{B}_\epsilon(B_0) \backslash B_\epsilon(C_0^\sigma),$$

where $B_\epsilon(P)$ and $\bar{B}_\epsilon(P)$ denote the open and closed balls, respectively, with center P and radius ϵ. With this choice of N^σ we can now verify that Assumption I is satisfied.

LEMMA 4.2. *Assumption* I *is satisfied by the equations* (4.1).

Proof. It is clear from the symmetry in the construction of $F(\cdot, 1)$ that L is an invariant subspace of $\mathbf{R}^n$ under the reaction system R^1, and that the zero sets of $F_i(\cdot, 1)$ intersect L transversally at exactly two points, B and C^σ. It thus follows from (H4) and (H5) that Assumption I holds. □

The main burden of the proof is to show that Assumption II is satisfied, and while not overwhelmingly difficult, does involve several rather technical steps. Recall from the discussion at the beginning of §3, that N being an isolating neighborhood is equivalent to showing that $N^\infty \cap \partial N = \emptyset$. In Lemma 4.3 we will show that (B_0, A_0) form an attractor-repeller pair for $(N^{c,\sigma})^\infty$, the invariant set in N^σ under the flow induced by $(\mathrm{TW}^{c,\sigma})$. Thus, $(N^{c,\sigma})^\infty = A_0 \cup B_0 \cup C(A_0, B_0)$. Since $A_0 \cup B_0 \subset \mathrm{int}(N^\sigma)$, we only need to demonstrate that $(A_0 \to B_0) \cap \partial N^\sigma = \emptyset$. This will be done via a series of propositions and lemmas. To see what is involved notice that ∂N^σ is a subset of the points in

$$(\partial\mathcal{R}_u \times \mathcal{R}_p) \cup (\mathcal{R}_u \times \partial\mathcal{R}_p),$$
$$\partial(B_\epsilon(A_0) \cup B_\epsilon(B_0)) \backslash \mathcal{R},$$

and

$$\partial(B_\epsilon(C_0^\sigma)) \cap \mathcal{R}.$$

Thinking of N^σ as a "box" and of the p_i's as defining "vertical directions," we refer to $\partial\mathcal{R}_u \times \mathcal{R}_p$ as the sides of N^σ, elements of $\mathcal{R}$ where $p_i = 0$ for some i as lying on the bottom of N^σ, and elements of $\mathcal{R}$ where $p_i = K$ for some i as lying on the top of N^σ. Lemmas 4.4 and 4.5 assert that an $A_0 \to B_0$ orbit cannot touch the top and bottom of the box respectively. Next we prove Proposition 4.6 which guarantees that there is no tangency to the small ball around the critical point C_0. Finally, Proposition 4.7 implies that if $u \in A_0 \to B_0$, then $u \in \mathcal{R}_u$, i.e., $A_0 \to B_0$ does not intersect the sides of $\mathcal{R}$ nor $\partial(B_\epsilon(C_0^\sigma)) \cap \mathcal{R}$.

LEMMA 4.3. (B_0, A_0) *forms an attractor repeller pair for* $(N^{c,\sigma})^\infty$ *under the flow generated by* $(\mathrm{TW}^{c,\sigma})$.

Proof. Since $p_1 \geq 0$ for all $(u,p) \in N^\sigma \backslash (B_\epsilon(A_0) \cup B_\epsilon(B_0))$, $-u_1$ acts as a Lyapunov function for the flow on this subset of N^σ. On the other hand, if ϵ is sufficiently small, then the fact that A_0 and B_0 are hyperbolic critical points insures, via the Hartman–Grobman theorem, that the only bounded orbits in $B_\epsilon(A_0) \cup B_\epsilon(B_0)$ are the critical points themselves. □

LEMMA 4.4. *There exists* K *such that on any orbit in* $(N^{c,\sigma})^\infty$, $p_i < K/2$ *for* $(\sigma, c) \in [0,1] \times \mathbf{R}$ *and all* i.

Proof. Since any such orbit has $p_i = 0$ at its endpoints, at a maximum of p_i, $dp_i/du_i = 0$. Therefore, from (4.1b), $p_i = -c^{-1}u_i F_i(u, \sigma)$. This provides a bound on p_i for $|c| \geq 1$.

Consider next $|c| < 1$, and with $H_i(u, \sigma) = u_i F_i(u, \sigma)$, set

$$m = \max_i \max_{\bar{R}} |H_i(u, \sigma)|.$$

Suppose that $p_i \geq 0$ for $u_i \in [u_{i0}, u_{i1}]$ and that it vanishes at these points. We claim that

$$p_i < 2\mu_i^{-1}[|c| + (c^2 + 2\mu_i m)^{1/2}] = p_{M_i}$$

say. For, if this is false for some i and u_i, then $p_i(u_i) = p_{M_i}$. Then from (2.5) and the mean value theorem for integrals, since $p_i(u_{i0}) = 0$,

$$\tfrac{1}{2}\mu_i p_{M_i}^2 \leq |c| p_{M_i} + m.$$

Hence

$$p_{M_i} < \mu_i^{-1}[|c| + (c^2 + 2\mu_i m)^{1/2}],$$

a contradiction. It is thus clear that a choice of K with the stated properties is possible.

LEMMA 4.5. *Suppose $(u,p) \notin \bar{B}_\epsilon(A_0) \cup \bar{B}_\epsilon(B_0)$. If $p_i = 0$ for some i, then $(u,p) \notin (N^{c,\sigma})^\infty$.*

Proof. Under the stated conditions, if $(u,p) \in (N^{c,\sigma})^\infty$ then $p_i = p_i' = 0$ and $p_i'' \geq 0$. Differentiating (4.1b) we obtain

$$\mu_i^\sigma p_i'' = -\sum_{j \neq i} \frac{\partial F_i}{\partial u_j} u_j' < 0,$$

unless $p_j = u_j' = 0$ for all $j = 1, \ldots, n$. In this case $p_j = p_j' = 0$ for all $j = 1, \ldots, n$, so from (4.1b) the point is a critical point. □

PROPOSITION 4.6. *Orbits in $(N^{c,\sigma})^\infty$ are not tangent to $\bar{B}_\epsilon(C_0) \cap \partial N^\sigma$ for small enough ϵ.*

Proof. The proof follows from examining the linearized operations about the critical point C_0^σ. What needs to be shown is that a monotone orbit from A_0 to B_0 cannot be tangent to a small enough ball centered at C_0^σ. Observe that if all the eigenvalues are complex then the solutions near C_0^σ will oscillate, and hence, exit N^σ. Thus, if there is a tangency, both of the following must hold: there must be a real nonnegative eigenvalue, and a real nonpositive eigenvalue with corresponding eigenvectors, respectively, each of the form (u,p) with $u_i > 0$ for all $i = 1, \ldots, n$ (if not, then the eigenvector points out of N^σ). We shall rule out these possibilities by a contradiction argument. So suppose there exist $c \geq 0$ and an eigenvalue $\lambda \geq 0$ with associated eigenvector having $u_i > 0$ for all i. Linearization leads to the system

$$-\lambda u_i + p_i = 0, \tag{4.2}$$

$$-\Sigma a_{i_k} u_k - (c + \lambda\mu_i)p_i = 0. \tag{4.3}$$

Substitution of the first equation in the second yields the relation

$$T_i u_i + \sum_{k \neq i} a_{ik} u_k = 0, \tag{4.4}$$

where $T_i = (c + \lambda\mu_i)\lambda + a_{ii}$. Of course from (H2), $a_{ii} < 0$, $a_{ij} > 0\,(i \neq j)$ for any i. It follows that $T_i < 0$ for each i, as the summation term in (4.4) is strictly positive. Thus $a_{ii} \leq T_i < 0$. Note finally that for some i, $\Sigma a_{i_k} u_k > 0$, as otherwise (H5) is contradicted, the matrix $[a_{ij}]$ being nonsingular by (H4). Hence

$$-a_{ii}u_i < \sum_{k \neq i} a_{i_k} u_k = -T_i u_i\,.$$

This contradicts the above inequality, and shows that if $c \geq 0$, an eigenvector with $u_i > 0$ (for all i) cannot be associated with a nonnegative eigenvalue. When $c \leq 0$, an analogous argument holds for a nonpositive eigenvalue. □

PROPOSITION 4.7. *Let $(u,p) \in (N^{c,\sigma})^\infty \backslash (A_0 \cup B_0)$, then $u_i \in (0,1)$.*

The proof of this proposition entails checking the travelling wave near the critical points A_0 and B_0 and along the sides of R. The following lemma will prove useful.

LEMMA 4.8. *Let (u,p) be a solution to $(\mathrm{TW}^{c,\sigma})$ and assume that $u_i(t_0)$ is a local maximum (minimum) of $u_i(t)$, then $f_i(u,\sigma) > 0$ (< 0).*

Proof. If $u_i(t_0)$ is a local maximum (minimum) of $u_i(t)$, then $u_i' = p_i = 0$. Now consider the second derivative

$$\begin{aligned} p_i' &= \mu_i^{-1}(-cp_i - u_i f_i(u,\sigma)) \\ &= \mu_i^{-1}(-u_i f_i(u,\sigma)) \end{aligned}$$

Thus $u_i'' < 0$ if and only if $f_i(u,\sigma) > 0$. □

We shall now show that away from the critical points $A_0 \rightarrow B_0$ does not intersect the sides of R.

LEMMA 4.9. *If $(u,p) \in (N^{c,\sigma})^\infty \backslash (B_\epsilon(A_0) \cup B_\epsilon(B_0))$, then $u_i \in (0,1)$.*

Proof. There are two cases to consider; $u_j = 0$ and $u_j = 1$ for some $j = 1, \ldots, n$. So assume that $u_j = 0$, then $(u,p) \in \partial N^\sigma \backslash (B_\epsilon(A_0) \cup B_\epsilon(B_0))$. $(u,p) \in (N^{c,\sigma})^\infty$ implies that $p_j = 0$ (otherwise (u,p) leaves N^σ in forward or backward time). But, as is easy to check, $\{(u,p) | u_j = p_j = 0\}$ is an invariant subspace. Thus (u,p) must lie on a bounded orbit on this hyperplane contradicting the fact that $(u,p) \in A_0 \rightarrow B_0$.

Thus, we can assume that $u_j = 1$ and $p_j = 0$. Note that $F_j(u,\sigma) < 0$, if $u \in \mathcal{R} \backslash B_0$ and $u_j = 1$. By Lemma 4.8, this implies that u_j attains a local minimum at this point, contradicting the monotonicity assumption. □

Notice that we have reduced the problem to studying the trajectory $A_0 \rightarrow B_0$ in the regions $B_\epsilon(A_0)$ and $B_\epsilon(B_0)$. The following lemma shows that as $t \rightarrow -\infty$, $u_i(t)$ remains positive for $i = 1, \ldots, n$.

LEMMA 4.10. *If $(u,p) \in (N^{c,\sigma})^\infty \cap B_\epsilon(A_0)$, then $u_i, p_i > 0$, for $i =, \ldots, n$.*

Proof. We first show that $p_i > 0$ for each $i = 1, \ldots, n$. Note first that from the proof of Lemma 4.5 there cannot be a point on the orbit where $p_i = p_i' = 0$. From (H1)–(H5) there is a choice of $\epsilon > 0$ such that the p_i equation may be written in the form

$$\mu_i p_i' = -cp_i + k_i u_i[1 + \delta(u)], \tag{4.5}$$

with $k_i > 0$ and $|\delta(u)| < \frac{1}{2}$ for $|u| \leq \epsilon$. Assume that an orbit in $(N^{c,\sigma})^\infty$ cuts the boundary of $B_\epsilon(A_0) \cap \mathbf{R}_+^n$ at $t = 0$. From the definition, it must necessarily converge to A_0 as $t \rightarrow -\infty$. Now suppose that as t decreases from zero on this orbit $p_i = 0$ first at u_i. Then it follows from (4.5) that if $u_i > 0$ ($u_i < 0$, respectively), u_i has a strict minimum (respectively, a strict maximum). In the first case, the orbit clearly cannot approach A_0 without another turning point. But such a turning point can only be a minimum. So this possibility is ruled out. In the second case, a similar argument shows that in fact, the orbit cannot cut the boundary of $B_\epsilon(A_0) \cap \partial\mathbf{R}_+^n$. Hence, p_i cannot vanish. Obviously, then $u_i > 0$ also, for otherwise it must have a minimum at which $p_i = 0$, which was ruled out above. □

The proof of Proposition 4.7 will be complete once we show the following.

LEMMA 4.11. *If $(u,p) \in (N^{c,\sigma})^\infty \cap B_\epsilon(B_0)$, then $u_i < 1$, for $i, \ldots, n$.*

The proof of Lemma 4.10 was made easy by the fact that the hyperplanes $u_i = 0$ define invariant subspaces for the travelling wave system. Of course, near the critical point B_0 we do not have such nice control on the invariant subspaces, thus the proof of Lemma 4.11 is more complicated. The assumption (H4) is important at this point. Since B_0 is a hyperbolic fixed point Hartman–Grobmann implies that we can reduce the problem to a careful study of the flow of the linearized system about B_0. To keep the notation to a minimum we first translate the origin to $(1,\dots,1)$. With this in mind we make the following definitions. For fixed σ let $H : \mathbf{R}^n \to \mathbf{R}^n$ be defined by $H(u) = (u_1F^1(u,\sigma),\dots,u_nF^n(u,\sigma))$. The linearized version of $(\mathrm{TW}^{c,\sigma})$ at the point B_0 is given by

$$\begin{aligned} u' &= p, \\ Mp' &= -cp - DH(B_0)u. \end{aligned} \tag{4.6}$$

To further simplify the notation we shall write this system as

$$\begin{aligned} u_i' &= p_i, \\ \mu_i^\sigma p_i' &= -cp_i - g_i(u), \end{aligned} \tag{4.7}$$

where $g_i(u) = \nabla F_i(B,\sigma)\cdot u$. Define $\mathbf{e}^i \in \mathbf{R}^n$ by

$$\mathbf{e}^i \cdot \nabla F_j(B,\sigma) = \delta^i_j.$$

Define $\rho = (\rho_1,\dots,\rho_n)$, where $\rho_i \in \{0,\pm 1\}$. Now define the closed cones

$$\begin{aligned} K(\rho) &= cl\left\{u = \sum \alpha_i e^i | \alpha_i = \rho_i = 0 \text{ or } \alpha_i\rho_i > 0\right\}, \\ Q(\rho) &= cl\{u|u_i = \rho_i = 0 \,\text{or}\, u_i\rho_i > 0\}. \end{aligned}$$

By Remark 2.1, $K(-1,-1,\dots,-1) \subset Q(1,1,\dots,1)$. Consider Fig. 3 which describes the zero sets for g_i and the cones $K(\rho)$ and $Q(\rho)$ for $n = 2$. Using it and the linearized system we shall now give a simple proof of Lemma 4.11 for the special case $n = 2$.

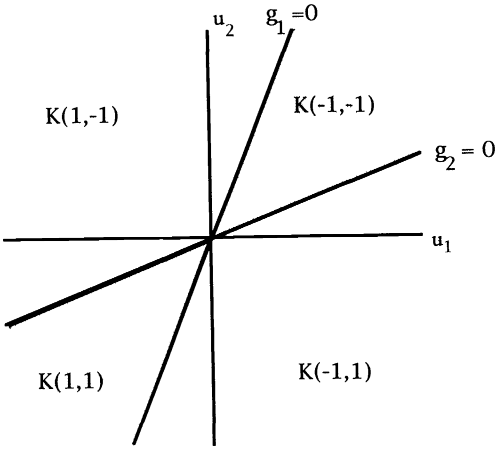

FIG. 3

LEMMA 4.12. *Let $n = 2$, and let $(u(t),p(t))$ be a solution to (4.7) such that $u(0) \in Q(-1,-1)$, $p(0) \in Q(1,1)$, and $\lim_{t\to\infty}(u(t),p(t)) = (0,0)$. Then $u([0,\infty)) \subset Q(-1,-1)$.*

Proof. Assume not, then there exists a first time t_0 such that $u(t_0) \in \partial Q(-1,\ldots,-1)$ and $p(t_0) \in Q(1,\ldots,1)$. Without loss of generality we can, therefore, assume that $u_1(t_0) = 0$ and $p_1(t_0) > 0$. Since $\lim_{t\to\infty} u_1(t) = 0$, there exists $t_1 > t_0$ such that $u_1(t_1)$ is a local max of u_1. Now by Lemma 4.8 and the fact that $u_1(t_1) > 0$ we have that

$$u(t_1) \in K(1,*) \cap Q(1,*),$$

where $*$ should be replaced by either $+1$ or -1. From Fig. 3, it is clear that this implies that

$$u(t_1) \in K(1,-1) \cap Q(1,1).$$

In turn this implies that there exists $t_2 > t_0$ such that $u_2(t_2)$ is a local maximum of u_2. Since $K(1,1) \subset Q(-1,-1)$, it is clear that $t_1 \neq t_2$. So assume that $t_2 > t_1$. Then $u(t_2) \in K(-1,1)$ and for all $t > t_2$, $u(t) \in K(-1,1)$. This contradicts the existence of t_1. Assuming that $t_1 > t_2$ leads to a similar contradiction. □

Notice that in the proof of Lemma 4.12 it was essential that $K(-1,-1) \subset Q(1,1)$, and thus, separated the cones $K(1,-1)$ and $K(-1,1)$ in $Q(1,1)$. The proof of Lemma 4.11 will now follow by induction on n the number of species. But first we prove a simple lemma.

LEMMA 4.13. *Let $\hat{u}_n > 0$ and define $\hat{u} = (\hat{u}_1,\ldots,\hat{u}_n)$ by $g_i(\hat{u}) = 0$ for $i = 1,\ldots,n-1$. Then $\hat{u}_i > 0$ for all i.*

Proof. Notice that $\hat{u} = \theta \mathbf{e}^n$, for some $\theta \in \mathbf{R}$. By Remark 2.1, $e_i^n < 0$ for $i = 1,\ldots,n$. Now $\hat{u}_n > 0$ implies $\theta < 0$, and hence, $\hat{u}_i > 0$ for $i = 1,\ldots,n$. □

Proof of Lemma 4.11. The proof is by induction on n the dimension of the reaction system. Lemma 4.12 guarantees that the result is true for $n = 2$. So assume that the result is true for $n \leq \bar{n}$. We need to show that it holds for $n = \bar{n} + 1$.

Let $\gamma = \cup_{t\geq 0} u(t)$. There are two cases to consider. First, there exists i, such that $\gamma \subset \cup_{\rho_i=-1} Q(\rho)$, and second, such an i does not exist. If we are in the first case, then without loss of generality we can assume that $i = n$. Now define $\bar{\gamma} = \cup_{t\geq 0}(u_1(t),\ldots,u_{n-1}(t),0)$, i.e., the projection of γ onto the subspace $\mathbf{R}^{n-1} \times \{0\}$. By the induction hypothesis $\bar{\gamma} \subset Q(-1,\ldots,-1) \subset \mathbf{R}^{n-1}$ and the lemma holds.

Now consider the second possibility. The argument which follows is probably clearer if one keeps Fig. 4 in mind (this is the figure corresponding to $n = 3$). In this case there exists t_1 such that $u_n(t_1) > 0$, and hence there exists

$$\hat{u}_n = \max_{t>0} u_n(t) > 0.$$

Let us choose t_1 such that $u_n(t_1) = \hat{u}_n$. Now define $\hat{\gamma}$ to be the projection of γ onto the space $\mathbf{R}^{n-1} \times \{\hat{u}_n\}$. For $i = 1,\ldots,n-1$, define $\hat{u}_i$ by $g_i(\hat{u}_i) = 0$ and let $\hat{u} = (\hat{u}_1,\ldots,\hat{u}_n)$. Since we want to work on the subspace $\mathbf{R}^{n-1} \times \{\hat{u}_n\}$ define $\hat{\mathbf{e}}^i = (e_1^i,\ldots,e_{n-1}^i,0)$. Similarly, define $\hat{K}(\rho)$ as before but in terms of the $\hat{\mathbf{e}}^i$'s and $\hat{Q}(\rho)$ as the orthants in $\mathbf{R}^{n-1}\times\{\hat{u}_n\}$ based at the point $\hat{u}$. By the induction hypothesis, it is clear that $\hat{\gamma} \subset \hat{Q}(-1,\ldots,-1)$. Of course, this does not yet prove the lemma, since by Lemma 4.13 $\hat{u}_i > 0$, and thus, $\hat{Q}(-1,\ldots,-1) \not\subset Q(-1,\ldots,-1)$. However, $u(t_1) = \hat{u}+w$ where $w_i \leq 0$ for $i = 1,\ldots,n-1$, and w_n=0. Now, $\hat{u} = \theta\mathbf{e}^n$ where $\theta < 0$; hence $g_n(\hat{u}) < 0$. Furthermore, $w \cdot \mathbf{e}^n < 0$, thus $g_n(u(t_1)) = g_n(\hat{u} + w) < g_n(\hat{u}) < 0$. Therefore, $u(t_1) \notin K(*,\ldots,*,1)$. Of course, this contradicts the assumption that at t_1, u_n has a local maximum. □

5. Existence of a Fisher wave. As an application of Theorem 3.2, we show that for large c there is an $A_0 \to C_0$ connection. Unfortunately, the argument does not

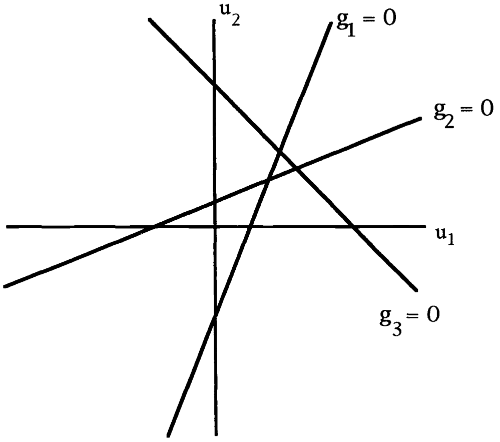

FIG. 4. *Zero sets for g_i on the plane $\mathbf{R}^2 \times \{\hat{u}_n\}$ where $\hat{u}_n > 0$.*

show that this is a monotone connection. However, for two species we can establish the occurence of a monotone $A_0 \to C_0$ connection, i.e., a Fisher wave. The difficulty in extending this result to n species is that we are not able to deal with the local analysis near C_0 to show that there is no oscillation in $B_\epsilon(C_0)$.

THEOREM 5.1. *For large enough c, there exists an $A_0 \to C_0$ connection, and if $n = 2$, there exists a monotone $A_0 \to C_0$ connection (that is, there is a Fisher wave).*

Proof. The first part of this theorem follows directly from (H4), Remark 2.3, and the application of Theorem 3.2.

The stronger result for the case $n = 2$ can be obtained as follows. In close analogy with the proof of Theorem 4.1, define

$$N = \{(u,p) \mid 0 \le u_i \le c_i; 0 \le p_i \le K\} \cup \bar{B}_\epsilon(A) \cup \bar{B}_\epsilon(C).$$

With the exception of the dynamics in $B_\epsilon(C_0)$, the relevant lemmas and propositions of the previous section are still applicable. Thus, to show that N is an isolating neighborhood with attractor-repeller pair (C_0, A_0), it is clearly enough to rule out tangencies to $B_\epsilon(C_0)$. Furthermore, by Lemma 4.10 we have monotonicity in $B_\epsilon(A_0)$, and hence, showing monotonicity in $B_\epsilon(C_0)$ will establish the result. As C_0 is hyperbolic, the flow in $B_\epsilon(C_0)$ may be approximated by the flow generated by the linearization. We shall show that all the associated eigenvalues are real, and that the eigenvector corresponding to the negative eigenvalue of smallest magnitude is of the form $(u_1, u_2, p_1, p_2) = (+, +, -, -)$. This is enough to prove the result.

With $A_{ij} = c_i \partial f_i / \partial u_j$, from assumption (H2) (see also Fig. 1), $a_{ii} < 0, a_{ij} > 0$ for $(i \ne j)$, and $\Delta = a_{11}a_{22} - a_{12}a_{21} < 0$. Linearization leads to the matrix

$$\begin{vmatrix} -\lambda & 0 & 1 & 0 \\ 0 & -\lambda & 0 & 1 \\ -\frac{a_{11}}{\mu_1} & -\frac{a_{12}}{\mu_1} & -\frac{c+\lambda\mu_1}{\mu_1} & 0 \\ -\frac{a_{21}}{\mu_2} & -\frac{a_{22}}{\mu_2} & 0 & -\frac{c+\lambda\mu_2}{\mu_2} \end{vmatrix},$$

and the eigenvalues λ are the solutions of

$$F(\lambda) \overset{\text{def}}{=} [\lambda(\lambda\mu_1 + c) + a_{11}]\,[\lambda(\lambda\mu_2 + c) + a_{22}] - a_{12}a_{21} = 0.$$

We claim that for c large enough positive, there are three negative real roots $\lambda_1, \lambda_2, \lambda_3$ with $\lambda_3 \leq \lambda_2 < \lambda_1$, and one positive root. Also, $-c/2\mu < \lambda_1 < 0$ where $\mu = \max(\mu_1, \mu_2)$. In the following we assume without loss of generality that $\mu_1 > \mu_2$.

The existence of one positive root is obvious, for $F(0) = \Delta < 0$. We have

$$F(-c/\mu_2) = \Delta - c^2 a_{22}(\mu_2 - \mu_1)/\mu_2^2 < 0.$$

Also,

$$16\mu_1^3 F\left(-\frac{c}{2\mu_1}\right) = [c^2 - 4\mu_1 a_{11}]\,[c^2(2\mu_1 - \mu_2) - 4\mu_1^2 a_{22}] - 16\mu_1^3 a_{12}a_{21} > 0$$

for large enough c. These inequalities establish the claim.

Finally, to find the direction of the eigenvector ϕ associated with λ_1, we note that from the matrix it is of the form $\phi = (u_1, u_2, \lambda_1 u_1, \lambda_1 u_2)$. Substitution in the third equation then yields

$$u_1\left[-\frac{c^2}{2\mu_1} + a_{11}\right] + a_{12}u_2 = 0,$$

and taking c large, we obtain the result. □

6. Travelling waves of invasion and dominance. From the point of view of applications it is important to discover whether a bistable wave with negative speed can exist; such a wave may be described as a "wave of invasion" since the species migrate into a spatial region where their initial density is low. Since the mutualism is obligate, so that all species must be present for survival, it is not immediately clear whether such a wave can exist. From another point of view, this question can be phrased in terms of the relative dominance of the equilibria A and B; see [6] for a discussion in the one species case, and [4]. It is natural to define B as dominant (over A) if a monotone increasing travelling wave has negative wave speed, for then the solution u of the reaction-diffusion system (1.1) will approach B on compact sets. The following result gives a condition for dominance of B and also says something about the basin of attraction; a complementary result for the dominance of A may be obtained in a very similar manner. The result is weaker than the necessary and sufficient condition that may be obtained for the one species case, but it seems likely that such a condition may be very hard to find in the present case.

We start by defining a function ϕ which is used to construct a subsolution. Let $M \in C([0,1], \mathbf{R})$ with $M(0) = 0$, and consider the equation

$$\phi'' + M(\phi) = 0 \tag{6.1}$$

with $\phi'(0) = 0$. Put $V(u) = \int_0^u M(s)ds$, and assume that $V(1) > 0$. A simple energy argument shows that for some $b \in [0,1]$, the solution of (6.1) with $\phi(0) = b$ reaches zero (obviously symmetrically) at some time t_0. Define $\phi(t) = 0$ for $|t| > t_0$.

LEMMA 6.1. *Define*

$$M(u) = \min_{1 \leq i \leq n} \mu_i^{-1} h_i(u_1, \dots, u_n),$$

and suppose that $V(1) > 0$. Then $\underline{\phi} = (\phi, \dots, \phi)$ is a subsolution for the reaction-diffusion system (1.1), and a solution $u(x,t)$ with $u(x,0) \geq \underline{\phi}(x)$ tends to B uniformly on compact sets. Furthermore, a bistable wave exists, and its speed $c < 0$.

Proof. The assertions concerning the subsolution follow directly from [13]. From Theorem 4.1 a bistable wave exists. Necessarily, its speed c is less than zero, for otherwise a contradiction would be obtained by translating the travelling wave so that at $t = 0$ it is above the subsolution. □

The speed of travelling waves is also of practical importance. For two species, if $\mu_1 \ll \mu_2$, there are formal arguments which suggest that invading waves are "slow" in the sense that $|c|$ is proportional to $\mu_1^{1/2}$, whereas "dying out" waves are fast with c proportional to $\mu_2^{1/2}$. However, the following result is the only rigorous result known to us.

LEMMA 6.2. *Let ρ_1 be positive with*

$$\rho_1^2 = 4 \min_{1\le i\le n} \max_{u\in \bar{R}} h_i(u). \tag{6.2}$$

For a bistable wave with $c < 0$, we have $|c| \le \rho_1$.

Proof. For convenience put $\rho = -c$. We shall show that if $\rho > \rho_1$, for a monotone orbit in $\bar{R}$, $p_i > 0$. Assume contrary to the assertion that p_i is the first of the p's to vanish and p_i has its first zero at $u_i = \alpha \in [0, b_i]$. On $u_i \in [0, \alpha]$ we may parameterize the orbit with u_i, and write $H(u_i) = h_i(u)$. Let L be the line $p_i = \rho u_i/2\mu_i$ in the $u_i - p_i$ plane. Near $u = 0$, $H(u) < 0$, so from (2.3), $\mu_i(dp_i/du_i) > \rho$, and $p_i > \rho u_i/\mu_i$. Thus the orbit lies initially above L. Furthermore, since $p_i(\alpha) = 0$, the orbit must cut L, first, say, at $(\beta, \rho\beta/2\mu_1)$. So from (2.3) again,

$$\begin{aligned}\mu_i \frac{dp_i}{du_i} &= p - \frac{2\mu_i H(\beta)}{\rho\beta}\\ &\ge \rho - \frac{2\mu_i}{\rho} \max\left[\frac{H(\beta)}{\beta}\right]\\ &> \frac{\rho}{2}\end{aligned}$$

from (6.2). However, as the orbit cuts L at β, $dp_i/du_i < \rho/2\mu_i$ there. This is a contradiction. □

7. Stability and uniqueness[2]**.** We consider here the stability of a bistable wave. Partial results on uniqueness are also obtained. The main tool in the investigation is a comparison principle for pseudomonotone systems analogous to that commonly used for a scalar diffusion equation; its validity here rests on the mutualistic assumption (H2).

Let U be an open neighborhood of $\bar{R}$. A smooth function $\underline{u} : \mathbf{R} \times [0, \infty) \to U$ is said to be a *subsolution* of (1.1) if

$$\frac{\partial \underline{u}_i}{\partial t} \le \mu_i \frac{\partial^2 \underline{u}_i}{\partial x^2} + h_i(\underline{u}).$$

A *supersolution* $\bar{u}$ is defined by reversing the inequality.

THEOREM 7.1 [24, §32]. *Let $\underline{u}$ and $\bar{u}$ be a subsolution and a supersolution, respectively, of* (1.1) *with $\underline{u}(x, 0) \le \bar{u}(x, 0)$. Then $\underline{u}(x, t) \le \bar{u}(x, t)$ for $x, t \in \mathbf{R} \times (0, \infty)$.*

Note that it is a consequence of our assumptions (H1), (H2), (H4), and (H5) that there is an $\eta \in \mathbf{R}^n$ with strictly positive components, such that the derivative in

[2] This type of result; generalizing the single species result in [7], seems first to have been considered in [15] and [10]. The version here is essentially due to Paul Fife.

the direction η of each f_i at B is negative. This will be used in the discussion of a subsolution which follows.

Let $u^*(x-ct)$ be a bistable travelling wave, and in (1.1) change to the travelling wave coordinate $z = x - ct$ obtaining the system

$$\frac{\partial u_i}{\partial t} = \mu_i \frac{\partial^2 u_i}{\partial z^2} + c\frac{\partial u_i}{\partial z} + h(u) \tag{7.1}$$

for which $u = u^*(z)$ is a stationary solution. Clearly Theorem 7.1 remains valid with an obvious redefinition of sub- and supersolutions. We shall use comparison functions of the form

$$\underline{u}_i(z,t) = u_i^*(z - z_0 + \alpha\epsilon\eta_i e^{-\sigma t}) - \epsilon\eta_i e^{-\sigma t},$$
$$\bar{u}_i(z,t) = u_i^*(z + z_1 - \alpha\epsilon\eta_i e^{-\sigma t}) + \epsilon\eta_i e^{-\sigma t},$$

with ϵ chosen so small that $\underline{u}$, $\bar{u} \in U$.

THEOREM 7.2. *For sufficiently small ϵ and σ, sufficiently large α,and any z_0, z_1, the functions $\underline{u}$, $\bar{u}$ are a sub- and supersolution, respectively, of* (7.1).

Proof. This is a generalization of [7, Lem. 4.1]. Let

$$N_i(u_i) = -\frac{\partial u_i}{\partial t} + \mu_i\frac{\partial^2 u_i}{\partial z^2} + c\frac{\partial u_i}{\partial t} + h_i(u).$$

With $q = \eta e^{-\sigma t}$, the argument of the u_i being $z - z_0 + \alpha\epsilon\eta_i e^{-\sigma t}$,

$$\begin{aligned} N_i(\underline{u}_i) &= \mu_i\frac{d^2u_i^*}{dz^2} + c\frac{du_i^*}{dz} + h_i(u^* - \epsilon q) - \sigma\epsilon q_i + \alpha\sigma\epsilon q_i\frac{du_i^*}{dz} \\ &= -h_i(u^*) + h_i(u^* - \epsilon q) - \sigma\epsilon q_i + \alpha\sigma\epsilon q_i\frac{du_i^*}{dz}. \end{aligned} \tag{7.2}$$

The above remark concerning the derivative in the direction η together with C^1 continuity shows that for small enough ϵ_0 and δ there is a constant k such that

$$h(u^* - \epsilon q) - h(u^*) \geq k\epsilon q, \qquad (0 \leq \epsilon \leq \epsilon_0,\ |B - u^*| < \delta). \tag{7.3}$$

However, $du^*/dz > 0$ as the wave is monotone, so when (7.3) holds,

$$N_i(u_i) > (k - \sigma)q_i > 0, \qquad (\sigma < k).$$

A similar argument is clearly valid for $|u^* - A| < \delta$ by choosing δ and ϵ_0 smaller if necessary.

The result will follow if we can show that a similar result holds also for u^* in neither of the above neighborhoods. Since the orbit is strictly monotone, there is a number δ' depending only on δ such that in this region $|u_i^*| > \delta'$ and $|u_i^* - 1| > \delta'$ for each i. Then, du_i^*/dz is positive and bounded away from zero. Thus from (7.2) for α large enough, $N_i(\underline{u}_i) > 0$. This proves that under the stated assumptions, $\underline{u}$ is a subsolution, and a similar proof shows that $\bar{u}$ is a supersolution. □

THEOREM 7.3. *All bistable waves have the same wave speed.*

Proof. In addition to the travelling wave u^* with speed c considered above, suppose there is a second travelling wave u^{**} with speed c_1. It is clearly possible to choose z_0 and z_1 such that

$$\underline{u}(z,0) \leq u^{**}(z,0) \leq \bar{u}(z,0).$$

Thus by Theorem 7.1, for all $t \geq 0$,

$$\underline{u}(z,t) \leq u^{**}(z,t) \leq \bar{u}(z,t).$$

However, the left and right sides approach $u^*(z - z_0)$ and $u^*(z + z_1)$, respectively, as $t \to \infty$. If now $c_1 \neq c$, then u^{**} could not be contained in this way between two translates of the stationary solution u^*. This contradiction therefore establishes the theorem. □

This result leaves open the question of whether there can be two distinct travelling waves for given wave speed. We are not able to resolve this in general, although the result can be shown to hold for two species (that is $n = 2$), by using an argument based on a comparison of the projection of the orbits on $\mathbf{R}^2$. The argument does not appear to generalize to more than two species.

THEOREM 7.4. *Every monotone bistable travelling wave is L_∞ stable.*

Proof. Let $\delta > 0$ and let $u(x,t)$ be an exact solution of (6.1) such that $|u(z,0) - u^*(z)| < \delta$ for all z. By the construction of the sub- and supersolutions, it is clear that there are numbers K and K' independent of δ such that $\epsilon < K\delta$ and

$$\underline{u}(z,0) < u(z,0) < \bar{u}(z,0),$$

$$|\underline{u}(z,t) - u^*(z)| + |\bar{u}(z,t) - u^*(z)| < K'\delta, \qquad ((z,t) \in \mathbf{R} \times \mathbf{R}_+).$$

By Theorem 7.1, $\underline{u}(z,t) \leq u(z,t) \leq \bar{u}(z,t)$, and combining these inequalities we obtain the relation

$$|u(z,t) - u^*(z)| < L'\delta, \qquad (t \geq 0).$$

This completes the proof of stability. □

Appendix. The proofs of Theorems 3.1 and 3.2 are presented here. It is assumed that the reader is familiar with the Conley index theory (see [2], [22], [23]), Conley's connection matrix (see [8]) and transition matrices (see [9], [17], [18], [21]), however, we begin by establishing some notation.

In what follows S always denotes an isolated invariant set and N an isolating neighborhood. Let (N,L) be an index pair for S, then the homotopy type of the pointed space $(N/L,[L])$ is usually referred to as the Conley index. There exists, however, a finer version of the index which will be used in the proof. First a definition. A *connected simple system* consists of a collection I_o of pointed spaces along with a collection I_m of homotopy classes of maps between these such that:

1. $\hom(X,X') = \{[f] \in [X,X'] | [f] \in I_m\}$ is nonempty and consists of a single element for each ordered pair X, X' of spaces in I_o;
2. if $X, X', X'' \in I_o$, $[f] \in \hom(X,X')$, and $[f'] \in \hom(X',X'')$, then $[f' \circ f] \in \hom(X,X'')$;
3. $\hom(X,X) = \{[1_X]\}$ for all $X \in I_m$.

Recall ([2], [20]) that the Conley index of S forms a connected simple system where $I_o = \{(N/L,[L]) | (N,L)$ is an index pair for $S\}$ and I_m consists of the flow defined maps between the elements of I_o. The connected simple system of the Conley index of S is denoted by $I(S)$. The following result [2], [22] is crucial to our analysis.

FACT. *If (A^c, A^{c*}) is an attractor repeller pair for S^c which continues for $c \in \mathbf{R}$ and $S^{c_i} = A^{c_i} \cup A^{c_i *}$ when $i = 0,1$, but $I(S^{c_0}) \not\sim I(S^{c_1})$, then for some $c \in (c_0, c_1)$ there exists a connecting orbit from A^{c*} to A^c.*

The $\mathbf{Z}_2$ homology Conley index of S is denoted and defined by

$$CH_*(S) := H_*(N/L,[L];\mathbf{Z}_2).$$

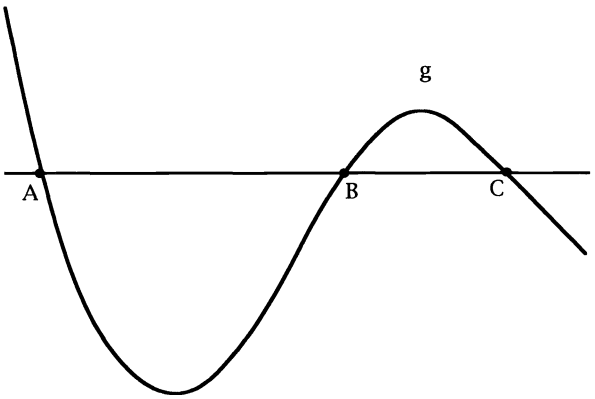

FIG. A.1

Given a Morse decomposition of S, $\mathbf{M}(S) = \{M(i) | i \in (P, >)\}$, where P is the indexing set for the Morse sets $M(i)$ and $>$ is a strict partial order on P, recall that the connection matrix

$$\Delta : \bigoplus_{i \in P} CH_*(M(i)) \longrightarrow \bigoplus_{i \in P} CH_*(M(i)).$$

We shall always take the direct sum according to a nonincreasing order in P. This has the effect of making Δ into a strictly upper triangular matrix.

The proof of Theorem 3.1 breaks down into three steps. The first is to study the dynamics of the two-dimensional system defined over L. The second is to relate these results with the the full travelling wave system ($\mathrm{TW}^{c,1}$), and the final step is to homotope these results back to the complicated system ($\mathrm{TW}^{c,0}$). As will become obvious, this theorem is a triviality since most of the difficulties have been assumed away.

Since L is an invariant line under the reaction system (R^1) we can think of the dynamics on L as being given by a scalar differential equation

$$\xi' = g(\xi), \tag{A.1}$$

where $\xi \in \mathbf{R}$ and $g : \mathbf{R} \to \mathbf{R}$. Assumption I implies that $g(\xi)$ has exactly 3 zeros, $\{a, b, c\}$, and must have the form given in Fig. A.1. Now define $G : \mathbf{R} \to \mathbf{R}$ by $G'(\xi) = g(\xi)$. Obviously $G(a) > G(c)$ and $G(b) > G(c)$. Without loss of generality assume that $G(a) > G(b)$. The corresponding travelling wave system can then be written as

$$\begin{aligned} \xi' &= \eta, \\ \eta' &= -c\eta - G'(\xi), \end{aligned} \tag{A.2c}$$

where $c \in \mathbf{R}$ is the wave speed and $\eta \in \mathbf{R}$. Clearly the fixed points of (A.2c) are $\{\alpha = (a, 0), \beta = (b, 0), \gamma = (c, 0)\}$. Now define

$$V(\xi, \eta) := \frac{\eta^2}{2} + G(\xi),$$

then $dV/dt = -c\eta^2$, i.e., for $c > 0$, V is a Lyapunov function for (A.2). Let $s(c)$ denote the set of bounded solutions to (A.2c), then by Assumption I, $s(c)$ is an isolated invariant set.

LEMMA A.1. *Let $c > 0$, then:*

(i) $\mathbf{M}(s(c)) = \{\alpha, \beta, \gamma | \alpha > \beta > \gamma\}$ *is a Morse decomposition of* $s(c)$.

(ii) $CH_k(s(c)) \approx CH_k(\alpha) \approx CH_k(\beta) \approx \begin{cases} \mathbf{Z}_2, & \text{if } k = 1; \\ 0, & \text{otherwise.} \end{cases}$

(iii) $CH_k(\gamma) \approx \begin{cases} \mathbf{Z}_2, & \text{if } k = 0; \\ 0, & \text{otherwise.} \end{cases}$

(iv) *There exists* c_l *such that for all* $c \in (0, c_l)$ *the connection matrix takes the form*

$$\Delta_l = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

(v) *There exists* c_r *such that for all* $c \in (0, c_r)$ *the connection matrix takes the form*

$$\Delta_r = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Proof. (i) follows from $dV/dt = -c\eta^2$ and the assumption that $G(\alpha) > G(\beta) > G(\gamma)$. (ii) and (iii) follow from the fact that the unstable manifolds of α and β are one-dimensional, while γ is an attracting critical point. (iv) and (v) follow from a simple phase portrait analysis. □

Since L is an attracting invariant line under (R^1) one immediately obtains similar results for S^c, the set of bounded solutions for $(\mathrm{TW}^{c,1})$, in a neighborhood of $s(c)$ as a subset of $\mathbf{R}^{2n}$.

LEMMA A.2. *Let $c > 0$, then:*

(i) $\mathbf{M}(S^c) = \{A_0^1, B_0^1, C_0^1 | A_0^1 > B_0^1 > C_0^1\}$ *is a Morse decomposition of* S^c.

(ii) $CH_k(S^c) \approx CH_k(A_0^1) \approx CH_k(B_0^1) \approx \begin{cases} \mathbf{Z}_2, & \text{if } k = 1; \\ 0, & \text{otherwise.} \end{cases}$

(iii) $CH_k(C_0^1) \approx \begin{cases} \mathbf{Z}_2, & \text{if } k = 0; \\ 0, & \text{otherwise.} \end{cases}$

(iv) *There exists* c_l *such that for all* $c \in (0, c_l]$ *the connection matrix takes the form defined above.*

(v) *There exists* c_r *such that for all* $c \in [c_r, \infty)$ *the connection matrix takes the form defined above.*

LEMMA A.3. *The transition matrix between* Δ_l *and* Δ_r *is*

$$T = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

Proof. Since $A_0^1 > B_0^1 > C_0^1$ is an admissible ordering which continues over the parameter range $c \in (0, \infty)$, T must be an upper triangular matrix with respect to this ordering. Furthermore, T is a degree 0 map of the form $I + N$ where I is the identity and N is strictly upper triangular [18]. Finally, T satisfies $T\Delta_l = \Delta_r T$. The only matrix which meets all these conditions is the desired matrix. □

COROLLARY A.4. *There exists* $c \in [c_l, c_r]$ *for which an* $A^1 \to B^1$ *travelling wave occurs.*

Let $I((N^{c,1})^\infty)$ denote the connected simple system of the Conley index for $(N^{c,1})^\infty$ under the flow induced by $(\mathrm{TW}^{c,1})$.

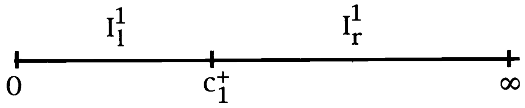

FIG. A.2

COROLLARY A.5 [16, §6]. *For $c \in (0, c_l]$, $I((N^{c,1})^\infty) = I_l^1$ and for $c \in [c_r, \infty)$, $I((N^{c,1})^\infty) = I_r^1$. Furthermore, $I_r^1 \not\succ I_l^1$.*

It might be helpful to visualize the content of this last corollary. Let $c_1^+ := \inf\{c_r\}$, and $c_1^- := \sup\{c_l\}$. Of course $c_1^- \leq c_1^+$. To simplify the picture assume that $c_1^- = c_1^+$. Then Corollary 5 is summarized in Fig. A.2.

Recall that $dV/dt = -c\eta^2$ and that $G(a) > G(b)$. Thus it is impossible for an $A_0^1 \to B_0^1$ to exist if $c \leq 0$. Therefore, for the isolated invariant set N_1, the connected simple system I_l^1 continues over $c \leq 0$, i.e., Fig. A.2 extends to Fig. A.3.

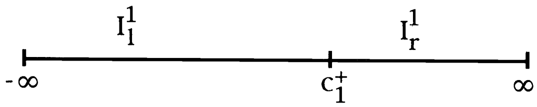

FIG. A.3

Now consider the homotopy from $\sigma = 1$ back to the original system at $\sigma = 0$. First, by [3] there exists an a priori bound Γ such that $|c| > \Gamma$ implies that there does not exist an $A_0^\sigma \to B_0^\sigma$ solution to $(\mathrm{TW}^{c,\sigma})$ for all $\sigma \in [0,1]$. Therefore, $I_l^\sigma \not\succ I_r^\sigma$ where the connected simple systems are computed for $-c < -\Gamma$ and $c > \Gamma$, respectively. In particular, $I_l^0 \not\succ I_r^0$ and therefore an $A_0 \to B_0$ solution exists. This completes the proof of Theorem 3.1. For a pictorial description of this argument see Fig. A.4.

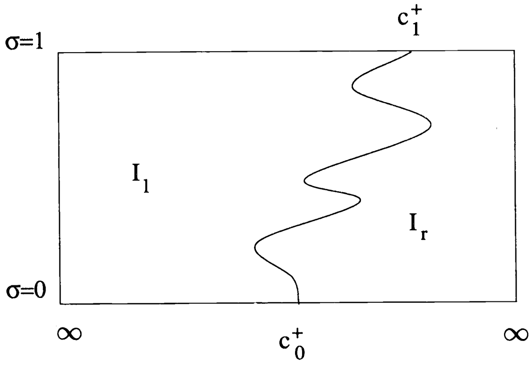

FIG. A.4

Proof of Theorem 3.2. Let $S = A \cup C \cup C(C, A)$ which is obviously an isolated invariant set. Let N be an isolating neighborhood of S under the reaction flow. Since A is an attractor, the stable manifold of A intersects transversely with the unstable manifold of C. By a result of [16], this implies that $CH_k(S) \approx 0$ for all $k = 0, 1, \ldots$. Now by [3], there exists $\hat{c} > 0$ such that given $c < -\hat{c} \ll -1$, there exists an isolating neighborhood $\bar{N}$ in the travelling wave system such that $(A_0 \cup C_0) \subset \bar{N}$ and $CH_{k+n}(\bar{N}^\infty) \approx CH_k(S) \approx 0$ for all $k = 0, 1, \ldots$. Of course the indices of A_0 and C_0 are not trivial, and hence there exists a connecting orbit from C_0 to A_0. Now, by a symmetry argument, one has that for $c > \hat{c}$, there exists an A_0 to C_0 connecting orbit. □

A final remark is necessary. The introduction of connection matrices and transition matrices in the proof of Theorem 3.1 is not really necessary. Since (A.2c) is two-dimensional, a phase portrait analysis is sufficient to convince oneself that the connected simple systems are different at high and at low wave speeds. On the other hand, it is clear that for some problems Assumption I is too restrictive (see [19]). A weaker assumption would be the following:

Assumption I*. For the reaction system (R_1) there exists a k-dimensional attracting invariant subspace $L \subset \mathbf{R}^n$. Furthermore, the dynamics on L under (R_1) can be described by a gradient flow, i.e.,

$$\xi' = \nabla G(\xi).$$

In this case, under this assumption if one could determine the connection matrices for $c \approx \infty$ and for $c \approx 0$ and they were related by an appropriate transition matrix, then the proof, and hence the result of Theorem 3.1 is still valid.

Acknowledgments. Apart from the acknowledgment already made to Paul Fife in §7, V. Hutson wishes particularly to thank him for sharing his exceptional insights on travelling wave problems. V. Hutson wishes also to acknowledge generous support from the Leverhulme Trust, which made possible a visit to the Georgia Institute of Technology in 1989, and also support from Sheffield University and Georgia Tech for a short visit in 1990.

STABILITY OF EQUILIBRIA FOR A CLASS OF TIME-REVERSIBLE, $D_n \times O(2)$-SYMMETRIC HOMOGENEOUS VECTOR FIELDS*

I-HENG McCOMB†‡ AND CHJAN C. LIM†§

Abstract. First-order, time-reversible n-body problems in three-space whose velocity fields consist of sums of identical two-body interactions are studied under a set of natural symmetry assumptions. Up to linearization about maximally symmetric equilibria, the entire class is shown to be represented by a two-parameter normal form. The symmetries of the class are used to find formulas for the eigenvalues of the linearized problems. The class of problems is divided into two families, one in which vector field components in the spatial directions act in concert, and one in which they act in opposition. When the components act in concert, the equilibria are (i) unstable when interaction strength grows with distance, (ii) stable when interaction strength decays and $n = 3, 4$, and (iii) stable or unstable when interaction strength decays and $n > 4$, depending as the singularity of the vector field varies across a critical value. When components act in opposition, stability and instability are interchanged. A nonlinear application of this analysis is the establishment of symmetric near-equilibrium periodic solutions.

Key words. time reversibility, symmetry, normal modes, stability

AMS subject classifications. 34, 70K15

Introduction. We consider the first-order three-dimensional motion of n bodies under a time-reversible vector field given by the sum of identical two-body interactions, where the time reversal reverses one spatial direction while fixing the other two. We impose a set of natural symmetry assumptions, and ask what can be said about the linearizations of these vector fields about maximally symmetric equilibria *entirely on the basis of the symmetries.*

First-order n-body problems have $3n$-dimensional phase space (whereas second-order problems such as Newtonian mechanical n-body problems have $6n$-dimensional phase space). In the notation we will use we have vector fields

$$\frac{dr}{dt} = f(r), \tag{0.1}$$

where $r = (r_1, \ldots, r_n)$ with $r_j = (x_j, y_j, z_j) \in \mathbf{R}^3$ and $f = (f_1, \ldots, f_n)$ with $f_j = (f_j^x, f_j^y, f_j^z)$. Since the vector field consists of the sum of identical two-body interactions (and under translational symmetry, of course), $f(r)$ is of the form

$$f_j(r) = \sum_{k \neq j} \frac{F(r_j - r_k)}{|r_j - r_k|^\alpha} + \text{const}, \tag{0.2}$$

where $F = (F^x, F^y, F^z)$ and the constant is independent of j.

Time reversibility is a symmetry. A vector field problem is said to be time-reversible when there exists a phase space reflection R which anticommutes with the vector field. For a time-reversible vector field, whenever $r(t)$ is a solution, so is $Rr(-t)$. A time-symmetric solution is one for which $r(t)=Rr(-t)$, or equivalently, any solution which passes through the time-symmetry plane Fix R. More general reversible systems are discussed in detail in Sevryuk [S]. Here we assume that $f(r)$ is time-reversible with respect to reflection across the (x, y)-plane, i.e.,

$$\text{(H1)} \qquad Rf(r)=-f(Rr),$$

where

$$(0.3) \qquad Rr=(\bar{r}_1, \ldots, \bar{r}_n), \qquad \bar{r}_j=(x_j, y_j, -z_j).$$

It is natural to assume that the time-reversal direction (here the z-direction) is the only distinguished direction. Hence we assume $f(r)$ is $O(2)$-symmetric with respect to the z-axis. Letting R_θ denote rotation by θ about the origin applied to each of the n pairs (x_j, y_j), and K_θ denote reflection in the (x, y)-plane across the line obtained when the x-axis is rotated by θ about the origin, we have

$$\text{(H2)} \qquad R_\theta f(r)=f(R_\theta r), \quad K_\theta f(r)=f(K_\theta r) \quad \forall \theta.$$

Finally, we assume that $f(r)$ is homogeneous. To cast this assumption as a symmetry of the problem, we write: there exists β such that

$$\text{(H3)} \qquad f(\delta r)=\delta^{-\beta} f(r)$$

for all positive real δ (where equality holds up to a constant corresponding to pure translation). We will refer to β as the "singularity" of the vector field. Homogeneity is a natural assumption if we consider the approximation of a problem by its leading term.

We show that vector field problems of the form (0.1), (0.2) are D_n-symmetric. Under D_n symmetry and time reversibility (H1), regular horizontal n-gons are the only maximally symmetric equilibria. In particular, we consider the equilibria given by r^0, where

$$(0.4) \qquad r_j^0=\left(\cos\frac{2\pi j}{n}, \sin\frac{2\pi j}{n}, 0\right).$$

Note that these equilibria are actually relative equilibria in the sense that

$$(0.5) \qquad f_j(r^0)=\text{const} \quad (\text{independent of } j) \quad \forall j.$$

Any translation, rotation, or scaling of these equilibria are, of course, also equilibria (corresponding to translational, $O(2)$, and homogeneity symmetries of the problem).

When vertical and horizontal components of the vector field act in concert, we obtain the following stability results:

(i) When interaction strength grows over distance, regular horizontal n-gons are unstable;

(iia) For $n=3, 4$, when interaction strength decays over distance, regular horizontal n-gons are stable;

(iib) For $n>4$, when interaction strength decays over distance, regular horizontal n-gons are stable or unstable, depending as the singularity β passes through a "stability threshold" $\beta^*(n)<\infty$, where stability refers to ellipticity. (Hyperbolic stability is disallowed by time reversibility, so ellipticity is the strongest stability obtainable by linear analysis.) Numerical studies indicate that for problems of type (iib), $\beta^*(n)$

decreases with increasing n, i.e., that less singular cases are more stable for decaying interaction. When the components of the vector field act in opposition, stability and instability are of course interchanged.

To obtain these results, we use the symmetry properties of the class of problems to exhibit a normal form for linear analysis of the entire class. We show that up to linearization about regular horizontal n-gons, our class of vector field problems reduces to two 2-parameter families, parametrized by the relative magnitudes of the vertical and horizontal components, and by the singularity strength β. One physical example which may be treated under this setting is the sedimentation under gravity of n small clustered spheres in a highly viscous fluid, studied experimentally by [JMS], and analytically under the Stokeslet model (infinite viscosity and point particle approximation) in [H], [CLLS], [GKL], and [TK]. The Stokeslet interaction is given by

$$F(x, y, z)=\left(\frac{xz}{(x^2+y^2+z^2)^{3/2}}, \frac{yz}{(x^2+y^2+z^2)^{3/2}}, \frac{x^2+y^2+2z^2}{(x^2+y^2+z^2)^{3/2}}\right).$$

We obtain formulas for the eigenvalues, essentially as in [H], but for the whole class, and in terms of the assumed symmetries. The (spectral) stability of the equilibria is studied analytically and numerically. The Stokeslet problem falls under case (ii) above, with $\beta=1$. We have $\beta^*(7)<1<\beta^*(6)$ so that regular horizontal n-gons are stable for $n=3, 4, 5, 6$ and unstable for $n \geqq 7$, in agreement with [JMS] and [H]. Another example is the dipole-type interaction given by

$$F(x, y, z)=\left(\frac{3xz}{(x^2+y^2+z^2)^{5/2}}, \frac{3yz}{(x^2+y^2+z^2)^{5/2}}, \frac{-(x^2+y^2)+2z^2}{(x^2+y^2+z^2)^{5/2}}\right).$$

Here vertical and horizontal components act in opposition and $\beta=3$.

The linear analysis of this class of problems, besides providing stability information, serves as a basis for nonlinear results and investigations. For example, for $0<\beta<\beta^*(n)$, a time-reversible Lyapunov center type theorem for spatially symmetric systems [GKL] applies, and we are able to establish the existence of families of symmetric, near-equilibrium periodic solutions when a nonresonance condition holds.

1. D_n symmetry. We have stated as assumptions the time reversibility and $O(2)$ symmetry of our class. We now show that D_n symmetry is a consequence of the identical two-body interaction form of $f(r)$ given by (0.2). Let

$$\begin{aligned}\mathscr{C}(r_1, r_2, \ldots, r_n)&=(r_2, \ldots, r_n, r_1),\\ \mathscr{T}(r_1, r_2, \ldots, r_n)&=(r_n, \ldots, r_2, r_1),\end{aligned} \tag{1.1}$$

and

$$\hat{\mathscr{C}}=R_{-2\pi/n}\mathscr{C}, \tag{1.2a}$$

$$\hat{\mathscr{T}}=K_{\pi/n}\mathscr{T}, \tag{1.2b}$$

with R_θ and K_θ as defined in (H2). From the form of $f(r)$ given by (0.2), we see that

$$\mathscr{C}f(r)=f(\mathscr{C}r) \quad \text{and} \quad \mathscr{T}f(r)=f(\mathscr{T}r). \tag{1.3}$$

By $O(2)$ symmetry (H2), we have

$$\hat{\mathscr{C}}f(r)=f(\hat{\mathscr{C}}r) \quad \text{and} \quad \hat{\mathscr{T}}f(r)=f(\hat{\mathscr{T}}r). \tag{1.4}$$

Moreover,

$$\hat{\mathscr{C}}r^0=\hat{\mathscr{T}}r^0=r^0. \tag{1.5}$$

Hence we find

$$\gamma f(r) = f(\gamma r) \quad \gamma r^0 = \cdot\cdot^0 \quad \forall \gamma \in \Gamma = (\hat{\mathscr{C}}, \hat{\mathscr{T}}) \cong D_n. \tag{1.6}$$

2. Isotypic decomposition. In the eigenvalue analysis to follow, we will require the Γ-isotypic decomposition for our space $\mathbf{R}^{3n}$ (cf. [GSS]). Recall that each Γ-isotypic component of a space is the direct sum of all Γ-isomorphic copies occurring in a decomposition of the space into Γ-irreducible subspaces (i.e., into Γ-invariant subspaces with no proper, nontrivial Γ-invariant subspaces). Every space has a unique Γ-isotypic decomposition. We begin by listing the one- and two-dimensional irreducible representations of D_n (up to isomorphism). When n is odd, the one-dimensional irreducible representations are

$$W_{++}, \quad \hat{\mathscr{C}} = 1, \quad \hat{\mathscr{T}} = 1, \tag{2.1a}$$

$$W_{+-}, \quad \hat{\mathscr{C}} = 1, \quad \hat{\mathscr{T}} = -1. \tag{2.1b}$$

When n is even, there are in addition

$$W_{-+}, \quad \hat{\mathscr{C}} = -1, \quad \hat{\mathscr{T}} = 1, \tag{2.1c}$$

$$W_{--}, \quad \hat{\mathscr{C}} = -1, \quad \hat{\mathscr{T}} = -1. \tag{2.1d}$$

There are int $((n-1)/2)$ distinct two-dimensional irreducible representations:

$$W_k \cong \mathbf{C}, \qquad \hat{\mathscr{C}}_z = e^{i2\pi k/n} z, \quad \hat{\mathscr{T}} z = \bar{z}, \tag{2.2}$$

where $z \in \mathbf{C}$ and $(\bar{\ })$ denotes complex conjugation.

We proceed with the isotypic decomposition of $\mathbf{R}^{3n}$. We write

$$\mathbf{R}^{3n} = H \oplus V, \tag{2.3}$$

where

$$H = \{ r \in \mathbf{R}^{3n} \mid z_j = 0 \quad \forall j \} \tag{2.4a}$$

and

$$V = \{ r \in \mathbf{R}^{3n} \mid x_j = y_j = 0 \quad \forall j \}. \tag{2.4b}$$

We note that H and V are Γ-invariant, i.e., $\Gamma H \subseteq H$ and $\Gamma V \subseteq V$. We decompose H as

$$H = H_0 \oplus H_1 \oplus \cdots \oplus H_{n-1}, \tag{2.5}$$

where

$$H_l = \{ r \in H \mid r_{j+1} = R_{2\pi l/n} r_j \}. \tag{2.6}$$

Identifying $r \in H_l$ such that $r_1 = \rho$ with $\rho = (\xi, \eta, 0) \in \mathbf{R}^3$, we have

$$\hat{\mathscr{C}}_\rho = R_{2\pi(l-1)/n} \rho, \qquad \hat{\mathscr{T}} \rho = K_{\pi/n} R_{-2\pi l/n} \rho. \tag{2.7}$$

We see that

$$\begin{aligned}
&H_0 \cong_\Gamma W_1, \\
&H_1 \cong_\Gamma W_{++} \oplus W_{+-}, \\
&H_l \cong_\Gamma W_{l-1} \quad \text{for } l = 2, \ldots, \text{int}\left(\frac{n-1}{2}\right) + 1, \\
&H_l \cong_\Gamma W_{n-(l-1)} \quad \text{for } l = \text{int}\left(\frac{n+2}{2}\right) + 1, \ldots, n-1, \\
&H_{(n/2)+1} \cong_\Gamma W_{-+} \oplus W_{--} \quad \text{when } n \text{ even},
\end{aligned} \tag{2.8}$$

where $\cong_\Gamma$ denotes Γ-isomorphism. Next we decompose V as

$$V = V_0 \oplus V_1 \oplus \cdots \oplus V_{\mathrm{int}\,(n/2)}, \tag{2.9}$$

where V_k is the real space

$$V_k = \mathbf{R}(v_k^r, v_k^i) \tag{2.10a}$$

with

$$\begin{aligned} v_k^r &= \left(1, \cos\frac{2\pi k}{n}, \ldots, \cos\frac{2\pi k(n-1)}{n}\right), \\ v_k^i &= \left(0, \sin\frac{2\pi k}{n}, \ldots, \sin\frac{2\pi k(n-1)}{n}\right). \end{aligned} \tag{2.10b}$$

In the basis $\{v_k^r, v_k^i\}$ for V_k, we have for any $v_k \in V_k$,

$$\begin{aligned} \hat{\mathscr{C}} v_k &= \begin{pmatrix} \cos\frac{2\pi k}{n} & \sin\frac{2\pi k}{n} \\ -\sin\frac{2\pi k}{n} & \cos\frac{2\pi k}{n} \end{pmatrix} v_k, \\ \hat{\mathscr{T}} v_k &= \begin{pmatrix} \cos\frac{2\pi k}{n} & -\sin\frac{2\pi k}{n} \\ -\sin\frac{2\pi k}{n} & -\cos\frac{2\pi k}{n} \end{pmatrix} v_k. \end{aligned} \tag{2.11}$$

We see that

$$\begin{aligned} &V_0 \cong_\Gamma W_{++}, \\ &V_k \cong_\Gamma W_k \quad \text{for } k = 1, \ldots, \mathrm{int}\left(\frac{n-1}{2}\right), \\ &V_{n/2} \cong_\Gamma W_{--} \quad \text{when } n \text{ even}. \end{aligned} \tag{2.12}$$

We arrive at the isotypic decomposition of $\mathbf{R}^{3n}$ that we want:

$$\begin{aligned} &\mathbf{R}^{3n} \cong_\Gamma W_{++}^2 \oplus W_{+-} \oplus W_1^3 \oplus \cdots \oplus W_{(n-1)/2}^3 \quad (n \text{ odd}), \\ &\mathbf{R}^{3n} \cong_\Gamma W_{++}^2 \oplus W_{+-} \oplus W_{-+} \oplus W_{--}^2 \oplus W_1^3 \oplus \cdots \oplus W_{(n-2)/2}^3 \quad (n \text{ even}). \end{aligned} \tag{2.13}$$

3. Eigenvalue structure. On the basis of the isotypic decomposition (2.13) and time reversibility (H1), we can make qualitative statements about the eigenvalues of the linearization L of f at r^0. We have

$$L \equiv df|_{r^0} = \begin{pmatrix} \partial_{r_1} f_1|_{r^0} & \partial_{r_2} f_1|_{r^0} & \cdots & \partial_{r_n} f_1|_{r^0} \\ \partial_{r_1} f_2|_{r^0} & \partial_{r_2} f_2|_{r^0} & \cdots & \partial_{r_n} f_2|_{r^0} \\ \vdots & \vdots & \ddots & \vdots \\ \partial_{r_1} f_n|_{r^0} & \partial_{r_2} f_n|_{r^0} & \cdots & \partial_{r_n} f_n|_{r^0} \end{pmatrix} = (\partial_{r_j} f_i|_{r^0}), \tag{3.1}$$

where the notation on the right means that the (i, j)th 3×3 block of L is given by

$$\partial_{r_j} f_i|_{r^0} = \begin{pmatrix} \partial f_i^x/\partial x_j|_{r^0} & \partial f_i^x/\partial y_j|_{r^0} & \partial f_i^x/\partial z_j|_{r^0} \\ \partial f_i^y/\partial x_j|_{r^0} & \partial f_i^y/\partial y_j|_{r^0} & \partial f_i^y/\partial z_j|_{r^0} \\ \partial f_i^z/\partial x_j|_{r^0} & \partial f_i^z/\partial y_j|_{r^0} & \partial f_i^z/\partial z_j|_{r^0} \end{pmatrix}. \tag{3.2}$$

Consider W any L-invariant subspace of $\mathbf{R}^{3n}$. On W, we have $LR = -RL$ by time reversibility (H1) so when $Lu = \lambda u$,

$$L(Ru) = -R(Lu) = -\lambda(Ru), \tag{3.3}$$

i.e., λ is an eigenvalue of $L|_W$ if and only if $-\lambda$ is. Now since f depends only on the relative positions $r_j - r_k$ $(j \neq k)$, H_0 and V_0 are clear!y L-invariant, and moreover, $L|_{H_0} = 0$ and $L|_{V_0} = 0$ (corresponding, respectively, to horizontal and vertical translational motion). Next, we observe that isotypic components are L-invariant. To see this, let W^s be any isotypic component. Ker L is Γ-invariant since if $u \in \operatorname{Ker} L$, we have $L(\gamma u) = \gamma(Lu) = 0$. Then $W \cap \operatorname{Ker} L$ is a Γ-invariant subspace of W and since W is irreducible, either $W \cap \operatorname{Ker} L = W$ or $W \cap \operatorname{Ker} L = 0$. We see that either $LW = 0$ or LW is isomorphic to W. Hence $LW^s \subseteq W^s$. Using the isotypic decomposition (2.13), we are now in a position to perform our eigenvalue structure analysis.

We see immediately that $L = 0$ when restricted to W^2_{++} ($L = 0$ when restricted to $V_0 \cong_\Gamma W_{++}$), W_{+-}, and W_{-+} (n even) since λ, an eigenvalue of any L-invariant subspace, implies that $-\lambda$ is also an eigenvalue. Together with the two zero eigenvalues corresponding to horizontal translation, we have so far counted five zero eigenvalues when n is odd, and an additional zero eigenvalue when n is even.

Next we consider the components W^2_{--} and W^3_k. W_{--} is one-dimensional so it is trivially absolutely irreducible. The action of Γ on $W_k \cong \mathbf{C}$ (given by (2.2)) is also absolutely irreducible (in the sense that when W_k is viewed as a real space, the only linear maps that commute with Γ are multiples of the identity). Hence in an appropriate basis,

$$L|_{W^s} = \begin{pmatrix} a_{11}I & \cdots & a_{1s}I \\ \vdots & \ddots & \vdots \\ a_{s1}I & \cdots & a_{ss}I \end{pmatrix}, \tag{3.4}$$

where $I = 1, s = 2$ for $W^s = W^2_{--}$ and $I = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, $s = 3$ for $W^s = W^3_k$. We see that the eigenvalues of $L|_{W^s}$ are exactly the eigenvalues of

$$A = \begin{pmatrix} a_{11} & \cdots & a_{1s} \\ \vdots & \ddots & \vdots \\ a_{s1} & \cdots & a_{ss} \end{pmatrix}, \tag{3.5}$$

each with multiplicity dim W. Since λ is an eigenvalue of A if and only if $-\lambda$ is, we see that W^2_{--} has eigenvalues $\pm\lambda$, while W^3_k has eigenvalues $0, \pm\lambda$ each of multiplicity two. Since there are int $((n-1)/2)$ components W^3_k, we have counted $2 \cdot$ int $((n-1)/2)$ zero eigenvalues and int $((n-1)/2)$ pairs $\pm\lambda$ of multiplicity two. When n is even, W^2_{--} contributes an additional pair $\pm\lambda$. However, the two zero eigenvalues from W^3_1 correspond to H_0 so they have already been counted. We actually have $2 \cdot$ int $((n-3)/2)$ additional zero eigenvalues.

In fact, we can say more. Noting that W^2_{--} arises (in the n even case) from $V_{n/2}$ and part of $H_{n/2+1}$, we see that in some basis, $R|_{W^2_{--}} = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$. Then if in this basis $A = (a_{ij})$, time reversibility (H1) implies

$$\begin{pmatrix} a_{11} & a_{12} \\ -a_{21} & -a_{22} \end{pmatrix} = \begin{pmatrix} -a_{11} & a_{12} \\ -a_{21} & a_{22} \end{pmatrix}, \tag{3.6}$$

i.e., $a_{11} = a_{22} = 0$. We see that the eigenvalues of A are real or pure imaginary. In the case of W^3_k, we have (in some basis)

$$R|_{W^s_k} = \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & -I \end{pmatrix}, \tag{3.7}$$

where $I = \binom{1\ 0}{0\ 1}$. If in this basis, $A = (a_{ij})$, $RL = -LR$ (H1) implies

$$(3.8) \qquad \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ -a_{31} & -a_{32} & -a_{33} \end{pmatrix} = \begin{pmatrix} -a_{11} & -a_{12} & a_{13} \\ -a_{21} & -a_{22} & a_{23} \\ -a_{31} & -a_{32} & a_{33} \end{pmatrix},$$

i.e., $a_{11} = a_{12} = a_{21} = a_{22} = a_{33} = 0$. Hence the eigenvalues of A satisfy $\lambda(\lambda^2 - a_{31}a_{13} - a_{32}a_{23}) = 0$. Again, all eigenvalues are real or pure imaginary.

In summary, we have the following.

THEOREM I (eigenvalue structure). *Consider $dr/dt = f(r)$, where $f(r)$ has the form* (0.2) *and satisfies the symmetry relations* (H1)-(H3). *Then the linearization of f at maximally symmetric equilibria has the following*:

(i) 5 *zero eigenvalues corresponding to three dimensions of translational motion, one dimension of scale contraction or expansion, and one dimension of rotation about center (average position)*;

(ii) 1 *additional zero eigenvalue when n is even, corresponding to a type of horizontal displacement which produces vertical translation only—the relevant subspace is that spanned by $r \in H_{n/2+1}$, where $r_1 = (-\sin(2\pi/n), \cos(2\pi/n), 0)$*;

(iii) int $((n-1)/2)$ *pairs of real or pure imaginary eigenvalues $\pm\lambda$, each of multiplicity two*;

(iv) $2 \cdot \operatorname{int}((n-3)/2)$ *more zero eigenvalues (forced by time reversibility)*;

(v) 1 *additional pair of real or pure imaginary eigenvalues $\pm\lambda$ when n is even.*

4. Relation between eigenvalues of L and L^2. It turns out that it is convenient to obtain the eigenvalues of L from the eigenvalues of $L^2|_V$, so we exhibit the relation between the two sets of eigenvalues. By time reversibility (H1) we have $fR = -Rf$ so that $L^2R = RL^2$. We see that $L^2H \subseteq H$ and $L^2V \subseteq V$.

Consider (λ, u) an eigenvalue/vector pair for L. From (3.3), $Lu = \lambda u$ and $L(Ru) = -\lambda(Ru)$, so for $\lambda \neq 0$, u must have nonzero vertical part. Writing $u = h + v$ where $h \in H$, $v \in V$, we have $L^2h + L^2v = \lambda^2h + \lambda^2v$. Since H and V are L^2-invariant, we have in particular,

$$(4.1) \qquad L^2v = \lambda^2v.$$

Hence every nonzero eigenvalue of L is the square root of an eigenvalue of $L^2|_V$.

Conversely, let (μ, v) be an eigenvalue/vector pair for $L^2|_V$. Since $LW^s \subseteq W^s$ for any isotypic component W^s, each W^s is also L^2-invariant. For some W^s, there exists $u \in W^s$ such that $L^2u = \mu u$. For $L|_{W^s} \neq 0$, we know $L|_{W^s}$ has exactly one pair of eigenvalues $\pm\lambda$ (of some multiplicity but semisimple) and the rest zero. Letting $E_\pm$ denote the eigenspaces corresponding to $\pm\lambda$, we can write $u = u_+ + u_- + n$ such that $u_+ \in E_+$, $u_- \in E_-$, and $n \in \operatorname{Ker} L$. Then

$$(4.2) \quad L^2u = L^2(u_+ + u_- + n) = L(\lambda u_+ - \lambda u_-) = \lambda^2(u_+ + u_-) = \mu u = \mu(u_+ + u_- + n).$$

From (4.2), we have

$$(4.3) \qquad (\lambda^2 - \mu)(u_+ + u_-) = \mu n;$$

so when $\mu \neq 0$, we have $n = 0$ and $\mu = \lambda^2$. We see that every nonzero eigenvalue of $L^2|_V$ is the square of an eigenvalue of L. (In fact, the same would be true even in the nonsemisimple case.)

Thus we can find the (nonzero) eigenvalues of L by finding the (nonzero) eigenvalues of $L^2|_V$ and taking their square roots. We define

$$(4.4) \qquad \mathcal{L} \equiv L^2|_V$$

and note that the eigenvalues of $\mathscr{L}$ must be real (since the eigenvalues of L are real or pure imaginary).

5. Eigenvalues of $\mathscr{L}$. Since $\gamma L^2 = L\gamma L = L^2\gamma$ for all $\gamma \in \Gamma$, we have

$$\hat{\mathscr{C}}\mathscr{L} = \mathscr{L}\hat{\mathscr{C}} \quad \text{and} \quad \hat{\mathscr{T}}\mathscr{L} = \mathscr{L}\hat{\mathscr{T}}. \tag{5.1}$$

This means that (in the basis $(z_1, z_2, \dots, z_n)$) advancing the rows of $\mathscr{L}$ by 1 is equivalent to advancing the columns by -1, and that exchanging the jth and $(n-j)$th rows of $\mathscr{L}$ for all j is equivalent to exchanging the jth and $(n-j)$th columns for all j. Hence

$$\mathscr{L} = \begin{pmatrix} L_n & L_1 & L_2 & \cdots & L_{n-1} \\ L_{n-1} & L_n & L_1 & \cdots & L_{n-2} \\ L_{n-2} & L_{n-1} & L_n & \cdots & L_{n-3} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ L_1 & L_2 & L_3 & \cdots & L_n \end{pmatrix} \quad \text{with } L_j = L_{n-j}. \tag{5.2}$$

Direct calculation in this basis gives

$$L_j = \sum_{k=1}^{n} \left[\frac{\partial f_n^z}{\partial x_k}\bigg|_{r^0} \cdot \frac{\partial f_k^x}{\partial z_j}\bigg|_{r^0} + \frac{\partial f_n^z}{\partial y_k}\bigg|_{r^0} \cdot \frac{\partial f_k^y}{\partial z_j}\bigg|_{r^0} \right]. \tag{5.3}$$

We see by (5.2) that $\mathscr{L}$ is circulant. Hence $\mathscr{L}$ can be diagonalized by

$$U = \frac{1}{\sqrt{n}} \begin{pmatrix} 1 & 1 & 1 & \cdots & 1 \\ 1 & \omega & \omega^2 & \cdots & \omega^{n-1} \\ 1 & \omega^2 & \omega^4 & \cdots & \omega^{2(n-1)} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & \omega^{n-1} & \omega^{2(n-1)} & \cdots & \omega^{(n-1)^2} \end{pmatrix}, \qquad \omega = e^{i2\pi/n} \tag{5.4}$$

as

$$U^*\mathscr{L}U = \operatorname{diag}(p(1), p(\omega), \dots, p(\omega^{n-1})), \tag{5.5a}$$

where

$$p(\mu) = L_n + L_1\mu + \cdots + L_{n-1}\mu^{n-1} \tag{5.5b}$$

and U^* is the conjugate transpose of U (and equal to U^{-1}). (For diagonalization of circulant matrices, cf. [O].) Hence the eigenvalues of $\mathscr{L}$ are

$$p(1), p(\omega), \dots, p(\omega^{n-1}) \tag{5.6}$$

with p given by (5.5b).

6. Normal form for $F = (F^x, F^y, F^z)$. The calculations so far have depended only on the time reversibility and $D_n \times O(2)$ symmetry of the vector field $f(r)$ and thus apply to general problems with those symmetries. (We may replace the two-body interaction form (0.2) for f with the assumption that f commutes with an action of D_n fixing some horizontal equilibrium and then calculate eigenvalues exactly as described.) Here we obtain the general form of vector fields in our class up to linearization about r^0 using the full information we have on $f(r)$. We show that the entire class of problems may be divided into two families, parametrized by the degree of singularity β associated with the homogeneity of $f(r)$ and by the relative magnitudes of the vertical versus horizontal components of the vector field.

First, f is time-reversible (H1) if and only if

$$\begin{aligned} F^x(x, y, -z) &= -F^x(x, y, z), \\ F^y(x, y, -z) &= -F^y(x, y, z), \\ F^z(x, y, -z) &= F^z(x, y, z). \end{aligned} \tag{6.1}$$

Since we are concerned with the linearization of f about r^0, we may take as representative,

$$\begin{aligned} F^x(x, y, z) &= a(x, y)z, \\ F^y(x, y, z) &= b(x, y)z, \\ F^z(x, y, z) &= c(x, y). \end{aligned} \tag{6.2}$$

We must also incorporate the implications of $O(2)$ symmetry (H2) (cf. [GSS]). $SO(2)$ symmetry (commutation with rotations) implies (F^x, F^y) has length dependent oniy on z and $|(x, y)| = \sqrt{x^2+y^2}$, and direction given by a rotation ϕ of $\arg((x, y))$, where ϕ depends only on z. Moreover, F^z must depend only on z and $|(x, y)|$. Hence we have representative forms

$$\begin{aligned} a(x, y) &= g(x^2+y^2)(x \cos \phi - y \sin \phi), \\ b(x, y) &= g(x^2+y^2)(x \sin \phi + y \cos \phi), \\ c(x, y) &= c(x^2+y^2), \end{aligned} \tag{6.3}$$

where ϕ is a constant. In addition, we require flip symmetry in the (x, y)-plane. We should, therefore, take $\sin \phi = 0$. Finally, homogeneity (H3) forces the functions g and c to take particular monomial (possibly fractional powered) forms depending on β.

We have

$$f_j(r) = \sum_{k \neq j} \frac{F(r_j - r_k)}{|r_j - r_k|^\alpha} \tag{0.2}$$

with $F = (F^x, F^y, F^z)$ given by

$$\begin{aligned} F^x(x, y, z) &= g \cdot (x^2+y^2)^{\alpha/2-\beta/2-1} \cdot xz, \\ F^y(x, y, z) &= g \cdot (x^2+y^2)^{\alpha/2-\beta/2-1} \cdot yz, \\ F^z(x, y, z) &= c \cdot (x^2+y^2)^{\alpha/2-\beta/2}, \end{aligned} \tag{6.4}$$

where g and c are now constants. Although α appears in this form for $f(r)$, it is not a parameter since in linearization about r^0 the effects of α factor out of the numerator and denominator. Thus we arrive at our normal form for f:

$$f_j(r) = \sum_{k \neq j} \frac{F(r_j - r_k)}{|r_j - r_k|^{\beta+2}} \tag{0.2'}$$

with $F = (F^x, F^y, F^z)$ given by

$$\begin{aligned} F^x(x, y, z) &= g \cdot xz, \\ F^y(x, y, z) &= g \cdot yz, \\ F^z(x, y, z) &= c \cdot (x^2+y^2). \end{aligned} \tag{6.5}$$

We see that up to linearization, our class of vector field problems is parametrized by g/c and β. The class may be divided into two families according to the sign of g/c.

When $g/c > 0$, we say that the vertical and horizontal components of the vector field act "in concert"; when $g/c < 0$, we say they act "in opposition." The Stokeslet problem corresponds to $g/c = \beta = 1$, and the dipole example to $g/c = -3$, $\beta = 3$.

7. Eigenvalue calculation. We are now in a position to obtain formulas for the nonzero eigenvalues of the linearization of $f(r)$ at r^0 as functions of the singularity β and the constants g and c. Combining (5.3), (5.5b), and (6.5), and after much manipulation (see Appendix), we arrive at

$$\begin{aligned}\lambda_l^2 = -gc\beta \sum_{j\neq n}\sum_{k\neq n} &\left[\left(1+\cos\frac{2\pi kl}{n}\right)\left(1-\cos\frac{2\pi k}{n}\right)\left(1-\cos\frac{2\pi jl}{n}\right)\right.\\ &\left.\cdot\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1} \qquad (7.1)\\ &\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}\end{aligned}$$

or

$$\begin{aligned}\lambda_l^2 = -\frac{gc\beta}{4} \sum_{j\neq n}\sum_{k\neq n} &\left[\left(1+\cos\frac{2\pi kl}{n}\right)\left(1-\cos\frac{2\pi jl}{n}\right)-\left(1+\cos\frac{2\pi k}{n}\right)\right.\\ &\left.\cdot\, p_l\left(\cos\frac{2\pi k}{n}\right)\left(1+\cos\frac{2\pi j}{n}\right)p_l\left(\cos\frac{2\pi j}{n}\right)\right] \qquad (7.1')\\ &\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2}\right]^{-1},\end{aligned}$$

where p_l is a notational device referring to the polynomial given by

$$\sin(lt) = \sin t \cdot p_l(\cos t). \qquad (7.2)$$

(It can be shown easily by induction on l that $\sin(lt)$ always has the form (7.2).) Hence up to sign and the scaling factor $|gc|$, the linearizations about r^0 in our class depend only on β. Throughout the rest of our discussion, we will take $gc = 1$. The implications for other values of gc are obvious.

Noting that $\lambda_l^2 = \lambda_{n-l}^2$ and $\lambda_0^2 = 0$, we see that it is enough to compute λ_l^2 for $l = 1, \ldots, \operatorname{int}(n/2)$. The double nature of these eigenvalues is as expected from our eigenvalue structure analysis. Figure 1 shows the dependence of λ_l^2 on β for a typical n.

8. Stability thresholds. Recall that by stability of a case in our vector field class we mean that the linearization of $f(r)$ at r^0 has only zero and pure imaginary eigenvalues, i.e., that λ_l^2 is nonpositive for all l. When λ_l^2 is positive for some l, then r^0 is clearly unstable under $f(r)$. We investigate the cases $\beta < 0$ and $\beta > 0$ separately.

We begin with the case $\beta < 0$. From (7.1') we have for $l = 1$ (with $gc = 1$),

$$\begin{aligned}\lambda_1^2 &= -\frac{\beta}{4}\sum_{j\neq n}\sum_{k\neq n}\left[\left(1+\cos\frac{2\pi k}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right)-\left(1+\cos\frac{2\pi k}{n}\right)\left(1+\cos\frac{2\pi j}{n}\right)\right]\\ &\qquad\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2}\right]^{-1} \qquad (8.1)\\ &= \frac{\beta}{2}\sum_{k\neq n}\left(1+\cos\frac{2\pi k}{n}\right)\Big/\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2}\sum_{j\neq n}\cos\frac{2\pi j}{n}\Big/\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2}.\end{aligned}$$

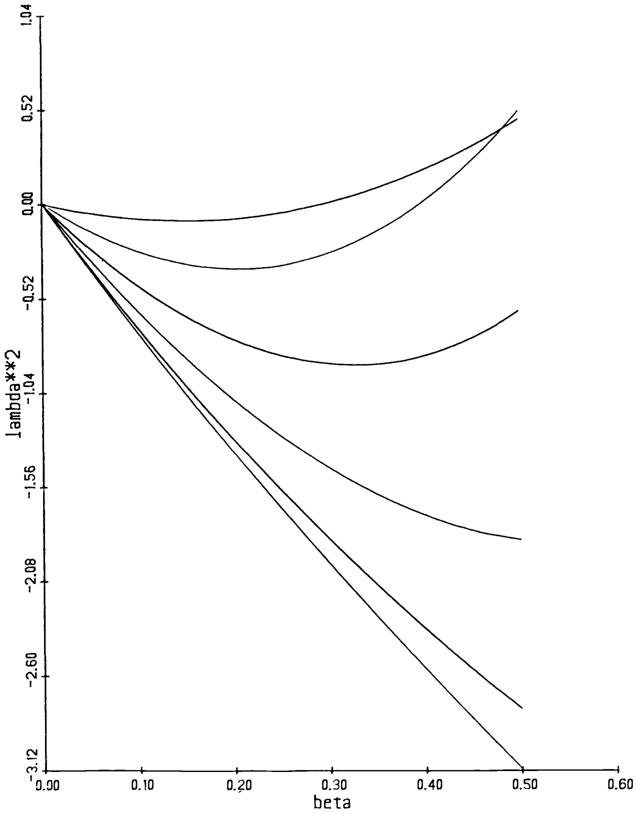

FIG. 1. λ_l^2 *as* β *varies. The case* $n=12$ *is shown, with curves for* $l=1,\ldots,6$ *appearing from top to bottom* $(g=c=1)$.

Since the sum over k in (8.1) is always positive and β is negative, the sign of λ_1^2 depends only on the sign of the sum over j in (8.1):

$$s(\beta, n)=\sum_{j\neq n}\frac{\cos(2\pi j/n)}{(2(1-\cos(2\pi j/n)))^{\beta/2}}. \tag{8.2}$$

Keeping n fixed, we first observe that as $\beta\to 0^-$, $s(\beta, n)\to -1$. Next, we note that all terms of $s(\beta, n)$ are nondecreasing functions of β except when j is such that $\pi/3<2\pi j/n<\pi/2$ or $2\pi-\pi/2<2\pi j/n<2\pi-\pi/3$. On the other hand, when $2\pi j/n$ falls in one of these regions, we can consider the sum of the jth and $2j$th (modulo n) terms. If we define

$$s_j(\beta, n)\equiv\frac{\cos(2\pi j/n)}{(2(1-\cos(2\pi j/n)))^{\beta/2}}+\frac{\cos(2\pi 2j/n)}{(2(1-\cos(2\pi 2j/n)))^{\beta/2}}, \tag{8.3}$$

then differentiating with respect to β and rearranging, we obtain

$$s_j'(\beta, n)>0 \tag{8.4}$$

if and only if

$$\beta<2\cdot\frac{\ln\left(\dfrac{\cos(4\pi j/n)\ln(2(1-\cos(4\pi j/n)))}{-\cos(2\pi j/n)\ln(2(1-\cos(2\pi j/n)))}\right)}{\ln(2(1+\cos(2\pi j/n)))}. \tag{8.5}$$

But the right-hand side of (8.5) is always positive so when $\beta<0$, (8.5) and hence (8.4) holds. We see that $s(\beta,n)$ is nondecreasing and approaches -1 as $\beta\to0^-$, so $s(\beta,n)$ is negative. Then we have $\lambda_1^2>0$ for all $\beta<0$ (any n) so that the $\beta<0$ case is always unstable. (Note that by "any n" we mean $n\geqq3$ since the cases $n=1,2$ are static in relative coordinates.)

Next we consider the $\beta>0$ case. We will require the identities

$$\begin{gathered}\sum_{k\neq n}1=n-1,\\ \sum_{k\neq n}\cos\frac{2\pi k}{n}=-1,\\ \sum_{k\neq n}\left(1+\cos\frac{2\pi k}{n}\right)p_l\left(\cos\frac{2\pi k}{n}\right)=n-2l.\end{gathered} \tag{8.6}$$

The first is obvious, the second is clear when we consider that $\cos(2\pi k/n)=\operatorname{Re}(\exp i(2\pi k/n))$, and the third is easily proved by induction on n. From the formulas for λ_l^2 (7.1′) and the identities (8.6), we have as $\beta\to0^+$,

$$\lambda_l^2\to-\frac{\beta}{4}[(n-1-1)(n-1+1)-(n-2l)^2]=\beta\left[n\left(\frac{1}{2}-l\right)+l^2\right], \tag{8.7}$$

so that $\lambda_l^2\to0^-$ as $\beta\to0^+$. On the other hand, as $\beta\to+\infty$, the dominant terms in the sum for λ_l^2 are those corresponding to $j,k=1,n-1$ so that

$$\lambda_l^2\to4\beta\frac{(1-\cos^2(2\pi l/n))\cos(2\pi/n)}{(2(1-\cos(2\pi/n)))^{\beta+1}} \tag{8.8}$$

as long as the right-hand side of (8.8) is nonzero (otherwise the next term must be examined). We see that as $\beta\to+\infty$, λ_l^2 is positive as long as $n>4$ (and $l\neq n/2$ for n even). Hence it is clear that for $n>4$, the stability threshold $\beta^*(n)$ exists. Studying the λ_l^2 numerically for $n\leqq20$, the first eigenvalue squared in each case to become positive as β increases is λ_1^2. It can be shown that λ_1^2 is zero for exactly one value of positive β by studying the behavior of $s(\beta,n)$ defined in (8.2). Table 1 shows approximate values of $\beta^*(n)$ for $4<n\leqq20$. For $n=5$, we have, in fact, $\beta^*(5)=2$ exactly:

TABLE 1
Stability thresholds.

n	$\beta^*(n)$	n	$\beta^*(n)$
5	2.000	13	0.258
6	1.121	14	0.232
7	0.772	15	0.210
8	0.585	16	0.192
9	0.470	17	0.176
10	0.391	18	0.163
11	0.334	19	0.152
12	0.292	20	0.142

writing $s(2,5)$ in terms of the golden number $\tau = 2\cos(\pi/5) = (1+\sqrt{5})/2$ (cf. [C]), it is easily seen that $s(2,5)=0$.

The case for $n \leqq 4$ is somewhat different. The property which distinguishes the cases $n \leqq 4$ from the cases $n > 4$ is that in the former, none of the $2\pi k/n$ have positive cosine while all in the latter have at least $\cos(2\pi/n) > 0$. In fact, the cases $n \leqq 4$ are stable for all $\beta > 0$. To see this, we simply calculate the eigenvalues explicitly for $n = 3, 4$ (the cases $n = 1, 2$ are static in relative coordinates). For $n = 3$, $\lambda_1^2 = -\beta/(2 \cdot 3^\beta)$ and for $n = 4$, $\lambda_1^2 = -\beta/2^{3\beta/2}$, $\lambda_2^2 = -2\beta/2^{3\beta/2}$. Hence we have stability for all $\beta > 0$.

In summary, we have the following.

THEOREM II (stability threshold). *Consider $dr/dt = f(r)$, where $f(r)$ has the form* (0.2) *and satisfies the symmetry relations* (H1)-(H3). *Then for $gc > 0$ (with g and c as appearing in* (6.5)):

(i) *For all $n \geqq 3$, r^0 is unstable when $\beta < 0$;*

(iia) *For $n = 3, 4$, r^0 is stable when $\beta > 0$;*

(iib) *For $n > 4$, there exists $\beta^*(n) < \infty$ such that r^0 is stable for all $0 < \beta < \beta^*(n)$ (take $\beta^*(n)$ to be the largest such β for which this is true).*

9. Nonresonant periodic solutions. We begin by stating the time-reversible, spatially symmetric version of the nonresonant Lyapunov center theorem essentially as it appears in [GKL]. Consider a system of ODEs

$$\frac{dx}{dt} = f(x), \qquad x \in \mathbf{R}^n \tag{9.1}$$

with an equilibrium at x_0. Assume there exists $R : \mathbf{R}^n \to \mathbf{R}^n$ such that

$$f(Rx) = -Rf(x), \qquad Rx_0 = x_0 \quad \text{(time reversibility);}$$

and a compact Lie group Γ which acts on $\mathbf{R}^n$ and such that

$$f(\gamma x) = \gamma f(x), \quad \gamma x_0 = x_0 \quad \forall \gamma \in \Gamma \quad \text{(spatial symmetry).}$$

Next, consider Σ a subgroup of $\Gamma \times S^1$, where $\Gamma \times S^1$ acts on the Banach space of 2π-periodic mappings $\mathbf{R} \to \mathbf{R}^n$ as

$$(\gamma, \theta) \cdot x(t) = \gamma x(t+\theta) \quad \forall (\gamma, \theta) \in \Gamma \times S^1.$$

A periodic solution $x(t)$ of (9.1) is said to have symmetry Σ when $(\gamma, \theta) \cdot x(t) = x(t)$ for all $(\gamma, \theta) \in \Sigma$. From [GKL] we have the following.

THEOREM. *Assume that the Γ-equivariant system* (9.1) *has a Γ-invariant equilibrium x_0. Assume*

$$\pm\omega_0 i \quad \textit{are nonzero eigenvalues of } (df)_{x_0}, \quad \textit{and}$$

$$k\omega_0 i \quad \textit{is not an eigenvalue of } (df)_{x_0} \quad \textit{for } k = 2, 3, \ldots.$$

Assume that the generalized eigenspace V_i corresponding to the eigenvalues $\pm\omega_0 i$ has the form

$$V_i = W \oplus W,$$

where Γ acts absolutely irreducibly on W. Assume finally that (9.1) *has time-reversal symmetry R fixing x_0 and that the subgroup $\Sigma \subseteq \Gamma \times S^1$ satisfies*

$$\dim \operatorname{Fix}(\Sigma) \cap V_i = 2,$$

$$R(\operatorname{Fix}(\Sigma) \cap V_i) = \operatorname{Fix}(\Sigma) \cap V_i,$$

$$R|\operatorname{Fix}(\Sigma) \cap \operatorname{Ker}(df)_{x_0} = I.$$

Then there exists an $m+1$-parameter family of periodic solutions to (9.1), *with period near $2\pi/\omega_0$ and symmetry Σ, where*

$$m=\dim \operatorname{Fix}(\Sigma)\cap \operatorname{Ker}(df)_{x_0}.$$

To apply this theorem to our class of problems, we need to check several conditions. First, for $0<\beta<\beta^*(n)$, we know all eigenvalues are pure imaginary, so we may take $\omega_0=|i\lambda_l|$, with any l from $1,\dots,\operatorname{int}(n/2)$. The nonresonance condition ($k\omega_0 i$ not an eigenvalue for $k=2,3,\dots$) must be checked but seems to hold generically in this class. That $V_i=W\oplus W$ holds can be seen by taking the isotypic decomposition (2.13) and arguing (by uniqueness of isotypic decompositions) that since the null part of any component W_k^3 is Γ-isomorphic to W_k, V_i must be of the required form. (For $l=n/2$, the relevant component is W_{--}^2, which is also of the required form.) We note finally that, apart from the null direction corresponding to vertical translation which may clearly be ignored, all zero eigenvalues of $(df)_{r^0}$ correspond to *horizontal* null directions so that $R|\operatorname{Fix}(\Sigma)\cap\operatorname{Ker}(df)_{r^0}=I$ holds for any Σ we choose. Hence to apply the theorem, it is sufficient to check nonresonance and to look for two-dimensional fixed point subspaces which are R-invariant. We obtain the following.

THEOREM III (nonresonant periodic solutions). *Consider $dr/dt=f(r)$, where $f(r)$ has the form* (0.2) *and satisfies the symmetry relations* (H1)-(H3). *Let $gc>0$ (with g and c as appearing in* (6.5)) *and let $0<\beta<\beta^*(n)$. Let λ be any nonzero eigenvalue of $(df)_{r^0}$ and $E_{\pm\lambda}$ the eigenspace corresponding to $\pm\lambda$. Assume the following nonresonance condition holds*:

$$k\lambda \quad \textit{is not an eigenvalue of } (df)_{r^0} \quad \textit{for } k=2,3,\dots.$$

Let Σ be any subgroup of $\Gamma\times S^1\cong D_n\times S^1$ such that

(i) $\dim\operatorname{Fix}(\Sigma)\cap E_{\pm\lambda}=2$;

(ii) $\operatorname{Fix}(\Sigma)\cap E_{\pm\lambda}$ *is left invariant by R*;

(iii) $\dim\operatorname{Fix}(\Sigma)\cap\operatorname{Ker}(df)_{r^0}=m.$

Then there exists an $m+1$-parameter family of periodic solutions to $dr/dt=f(r)$ with period near $2\pi/|i\lambda|$ and symmetry Σ.

The resulting symmetric families of periodic solutions are listed and described in [GKL] for $3\leqq n\leqq 6$ (there for the Stokeslet problem, but the results apply equally here). The relevant subgroups of $D_n\times S^1$ are listed in full in [GSS]. Independent calculations for the period of small orbits in the Stokeslet problem when $n=4$ for synchronous rhombi (corresponding here to the eigenvalues $\pm\lambda_2$) are performed in [TK].

10. Remarks. The focus here has been on exploiting symmetry properties to extract information about our class of problems. Several related vector field classes (e.g., inhomogeneous problems satisfying the other symmetry relations of our class, or $Z_n\times SO(2)$ rather than $D_n\times O(2)$) can be studied in essentially the same way. The information obtained here about the linearized problem provides the basis for nonlinear investigations such as the determination of families of near-equilibrium periodic solutions performed above.

Since physical problems tend to have integer values of the singularity strength β, and since $\beta^*(n)<1$ for $n>6$, we do not expect to find clusters of more than 6 bodies persisting in nature for problems of the type considered when vertical and horizontal components act in concert (e.g., in the sedimentation problem). In fact, when $\beta\neq 1$, under decay-type interaction, we expect only to find clusters of 3, 4, or 5 bodies. When the components act in opposition (as in the dipole example), we do not expect to find clusters of 3 or 4 bodies under decay-type interaction.

The parameter β may also be viewed as a bifurcation parameter for the family of decay-type problems in the class considered above. It can be shown that the family undergoes a time-reversible, equivariant pitchfork bifurcation as β passes through the critical value $\beta^*(n)$ (McComb, [M]).

Appendix: derivation of eigenvalue formulas. (Note: indices should be taken modulo n where appropriate.) The nonzero eigenvalues of the linearization of $f(r)$ at r^0 are given by (5.6):

$$\lambda_l^2 = p(\omega^l), \tag{A.0}$$

where $\omega = \exp i2\pi/n$ and

$$p(\mu) = L_n + L_1\mu + \cdots + L_{n-1}\mu^{n-1} \tag{5.5b}$$

with

$$L_j = \sum_{k=1}^{n} \left[\frac{\partial f_n^z}{\partial x_k}\bigg|_{r^0} \cdot \frac{\partial f_k^x}{\partial z_j}\bigg|_{r^0} + \frac{\partial f_n^z}{\partial y_k}\bigg|_{r^0} \cdot \frac{\partial f_k^y}{\partial z_j}\bigg|_{r^0} \right]. \tag{5.3}$$

If we define

$$A_{13}(i,j) = \frac{\partial f_i^x}{\partial z_j}\bigg|_{r^0}, \quad A_{23}(i,j) = \frac{\partial f_i^y}{\partial z_j}\bigg|_{r^0}, \quad A_{31}(i,j) = \frac{\partial f_i^z}{\partial x_j}\bigg|_{r^0}, \quad A_{32}(i,j) = \frac{\partial f_i^z}{\partial y_j}\bigg|_{r^0}, \tag{A.1}$$

we have

$$L_j = \sum_{k=1}^{n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)]. \tag{5.3'}$$

Taking the appropriate derivatives and substituting in r^0, we have, for $k \neq n$,

$$\begin{aligned} A_{31}(n,k) &= \frac{\beta c(1-\cos(2\pi k/n))}{(2(1-\cos(2\pi k/n)))^{\beta/2+1}}, \\ A_{31}(n,n) &= -\sum_{k\neq n} A_{31}(n,k), \\ A_{32}(n,k) &= \frac{\beta c(-\sin(2\pi k/n))}{(2(1-\cos(2\pi k/n)))^{\beta/2+1}}, \\ A_{32}(n,n) &= -\sum_{k\neq n} A_{32}(n,k), \end{aligned} \tag{A.2}$$

and for $k \neq j$,

$$\begin{aligned} A_{13}(k,j) &= \frac{g(\cos(2\pi j/n) - \cos(2\pi k/n))}{(2(1-\cos(2\pi(j-k)/n)))^{\beta/2+1}}, \\ A_{13}(j,j) &= -\sum_{k\neq j} A_{13}(j,k) = \sum_{k\neq j} A_{13}(k,j), \\ A_{23}(k,j) &= \frac{g(\sin(2\pi j/n) - \sin(2\pi k/n))}{(2(1-\cos(2\pi(j-k)/n)))^{\beta/2+1}}, \\ A_{23}(j,j) &= -\sum_{k\neq j} A_{23}(j,k) = \sum_{k\neq j} A_{23}(k,j). \end{aligned} \tag{A.3}$$

We see that for $j \neq n$, we have

$$
\begin{aligned}
L_j &= \sum_{k=1}^{n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&= \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&\quad + \sum_{k \neq j} [A_{31}(n,j)A_{13}(k,j) + A_{32}(n,j)A_{23}(k,j)] \\
&\quad - \sum_{k \neq n} [A_{31}(n,k)A_{13}(n,j) + A_{32}(n,k)A_{23}(n,j)] \\
&= \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&\quad + \sum_{k \neq j,n} [A_{31}(n,j)A_{13}(k,j) + A_{32}(n,j)A_{23}(k,j)] \\
&\quad + [A_{31}(n,j)A_{13}(n,j) + A_{32}(n,j)A_{23}(n,j)] \\
&\quad - \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(n,j) + A_{32}(n,k)A_{23}(n,j)] \\
&\quad - [A_{31}(n,j)A_{13}(n,j) + A_{32}(n,j)A_{23}(n,j)] \\
&= \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&\quad + \sum_{k \neq j,n} [A_{31}(n,j)A_{13}(k,j) + A_{32}(n,j)A_{23}(k,j)] \\
&\quad - \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(n,j) + A_{32}(n,k)A_{23}(n,j)].
\end{aligned}
\tag{A.4}
$$

We also have

$$
\begin{aligned}
L_n &= \sum_{k=1}^{n} [A_{31}(n,k)A_{13}(k,n) + A_{32}(n,k)A_{23}(k,n)] \\
&= \sum_{k \neq n} [A_{31}(n,k)A_{13}(k,n) + A_{32}(n,k)A_{23}(k,n)] \\
&\quad + \sum_{k \neq n} A_{31}(n,k) \sum_{j \neq n} A_{13}(n,j) + \sum_{k \neq n} A_{32}(n,k) \sum_{j \neq n} A_{23}(n,j) \\
&= \sum_{k \neq n} \Bigg[A_{31}(n,k)\Big(A_{13}(k,n) + \sum_{j \neq n} A_{13}(n,j) \Big) \\
&\qquad + A_{32}(n,k)\Big(A_{23}(k,n) + \sum_{j \neq n} A_{23}(n,j) \Big) \Bigg] \\
&= \sum_{k \neq n} \sum_{j \neq k,n} [A_{31}(n,k)A_{13}(n,j) + A_{32}(n,k)A_{23}(n,j)] \\
&= \sum_{j \neq n} \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(n,j) + A_{32}(n,k)A_{23}(n,j)].
\end{aligned}
\tag{A.5}
$$

Noting that

$$
\begin{aligned}
\sum_{j \neq n} L_j &= \sum_{j \neq n} \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&\quad + \sum_{j \neq n} \sum_{k \neq j,n} [A_{31}(n,j)A_{13}(k,j) + A_{32}(n,j)A_{23}(k,j)] - L_n \\
&= \sum_{j \neq n} \sum_{k \neq j,n} [A_{31}(n,k)A_{13}(k,j) + A_{32}(n,k)A_{23}(k,j)] \\
&\quad - \sum_{k \neq n} \sum_{j \neq k,n} [A_{31}(n,j)A_{13}(j,k) + A_{32}(n,j)A_{23}(j,k)] - L_n \\
&= -L_n,
\end{aligned}
\tag{A.6}
$$

we see that the eigenvalues we seek are

$$\lambda_l^2 \equiv p(\omega^l) = -\sum_{j=1}^{n} L_j\left(1-\cos\frac{2\pi jl}{n}\right) + i\sum_{j=1}^{n} L_j\left(\sin\frac{2\pi jl}{n}\right). \tag{A.7}$$

But $L_j = L_{n-j}$ so $\operatorname{Im}(\lambda_l^2) = 0$ (as expected). Hence we have

$$\lambda_l^2 = -\sum_{j=1}^{n} L_j\left(1-\cos\frac{2\pi jl}{n}\right), \tag{A.8}$$

where L_j is given by (A.4). Note that $\lambda_l^2 = \lambda_{n-l}^2$ and $\lambda_0^2 = 0$.

Substituting (A.4) into (A.8) we obtain

$$\begin{aligned}
\lambda_l^2 &= -\sum_{j\neq n} L_j\left(1-\cos\frac{2\pi jl}{n}\right)\\
&= -\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(k,j)+A_{32}(n,k)A_{23}(k,j)]\left(1-\cos\frac{2\pi jl}{n}\right)\\
&\quad -\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,j)A_{13}(k,j)+A_{32}(n,j)A_{23}(k,j)]\left(1-\cos\frac{2\pi jl}{n}\right)\\
&\quad +\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(n,j)+A_{32}(n,k)A_{23}(n,j)]\left(1-\cos\frac{2\pi jl}{n}\right)
\end{aligned}$$

$$\begin{aligned}
&= -\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(k,j)+A_{32}(n,k)A_{23}(k,j)]\left(1-\cos\frac{2\pi jl}{n}\right)\\
&\quad +\sum_{k\neq n}\sum_{j\neq k,n}[A_{31}(n,k)A_{13}(k,j)+A_{32}(n,k)A_{23}(k,j)]\left(1-\cos\frac{2\pi kl}{n}\right)\\
&\quad +\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(n,j)+A_{32}(n,k)A_{23}(n,j)]\left(1-\cos\frac{2\pi jl}{n}\right)\\
&= \sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(k,j)+A_{32}(n,k)A_{23}(k,j)]\left(\cos\frac{2\pi jl}{n}-\cos\frac{2\pi kl}{n}\right)\\
&\quad +\sum_{j\neq n}\sum_{k\neq j,n}[A_{31}(n,k)A_{13}(n,j)+A_{32}(n,k)A_{23}(n,j)]\left(1-\cos\frac{2\pi jl}{n}\right).
\end{aligned} \tag{A.9}$$

Now substituting according to (A.2)-(A.3),

$$\begin{aligned}
\lambda_l^2 = gc\beta\sum_{j\neq n}\sum_{k\neq j,n}&\Bigg\{\left[\left(1-\cos\frac{2\pi k}{n}\right)\left(\cos\frac{2\pi j}{n}-\cos\frac{2\pi k}{n}\right)-\sin\frac{2\pi k}{n}\left(\sin\frac{2\pi j}{n}-\sin\frac{2\pi k}{n}\right)\right]\\
&\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi(j-k)}{n}\right)\right)^{\beta/2+1}\right]^{-1}\Bigg\}\\
&\cdot\left(\cos\frac{2\pi jl}{n}-\cos\frac{2\pi kl}{n}\right)\\
-gc\beta\sum_{j\neq n}\sum_{k\neq j,n}&\Bigg\{\left[\left(1-\cos\frac{2\pi k}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right)+\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\right]\\
&\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi(j-k)}{n}\right)\right)^{\beta/2+1}\right]^{-1}\Bigg\}\\
&\cdot\left(1-\cos\frac{2\pi jl}{n}\right).
\end{aligned} \tag{A.10}$$

Simplifying (A.10),

(A.11)

$$
\begin{aligned}
\lambda_l^2 = gc\beta \sum_{j\neq n}\ \sum_{k\neq j,n} & \left[\left(\cos\frac{2\pi j}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi(j-k)}{n}\right)\right]\left(\cos\frac{2\pi jl}{n}-\cos\frac{2\pi kl}{n}\right)\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi(j-k)}{n}\right)\right)^{\beta/2+1}\right]^{-1}\\
-gc\beta \sum_{j\neq n}\ \sum_{k\neq j,n} & \left[\left(\cos\frac{2\pi(j-k)}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi j}{n}\right)\right]\left(1-\cos\frac{2\pi jl}{n}\right)\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}\\
= gc\beta \sum_{k\neq n}\ \sum_{\substack{k-j\\ \neq k,n}} & \left[\left(\cos\frac{2\pi[k-(k-j)]}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi(k-j)}{n}\right)\right]\\
& \cdot\left(\cos\frac{2\pi[k-(k-j)]l}{n}-\cos\frac{2\pi kl}{n}\right)\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi(k-j)}{n}\right)\right)^{\beta/2+1}\right]^{-1}\\
-gc\beta \sum_{k\neq n}\ \sum_{j\neq k,n} & \left[\left(\cos\frac{2\pi(k-j)}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi j}{n}\right)\right]\left(1-\cos\frac{2\pi jl}{n}\right)\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}\\
= gc\beta \sum_{k\neq n}\ \sum_{j\neq k,n} & \left[\left(\cos\frac{2\pi(j-k)}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi j}{n}\right)\right]\\
& \cdot\left[\left(\cos\frac{2\pi(j-k)l}{n}-\cos\frac{2\pi kl}{n}\right)-\left(1-\cos\frac{2\pi jl}{n}\right)\right]\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}\\
= gc\beta \sum_{k\neq n}\ \sum_{j\neq n} & \left[\left(\cos\frac{2\pi(j-k)}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi j}{n}\right)\right]\\
& \cdot\left[\left(\cos\frac{2\pi(j-k)l}{n}-\cos\frac{2\pi kl}{n}\right)-\left(1-\cos\frac{2\pi jl}{n}\right)\right]\\
& \cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}.
\end{aligned}
$$

Defining

$$\begin{aligned} C(k)&=\frac{\beta c}{(2(1-\cos(2\pi k/n)))^{\beta/2+1}},\\ G(j)&=\frac{g}{(2(1-\cos(2\pi j/n)))^{\beta/2+1}}, \end{aligned}\tag{A.12}$$

we have

$$\begin{aligned} \lambda_l^2&=\sum_{j\neq n}\sum_{k\neq n}C(k)G(j)\left[\left(\cos\frac{2\pi(j-k)l}{n}-\cos\frac{2\pi kl}{n}\right)-\left(1-\cos\frac{2\pi jl}{n}\right)\right]\\ &\quad\cdot\left[\left(\cos\frac{2\pi(j-k)}{n}-\cos\frac{2\pi k}{n}\right)+\left(1-\cos\frac{2\pi j}{n}\right)\right]\\ &=\sum_{j\neq n}\sum_{k\neq n}C(k)G(j)\\ &\quad\cdot\left[\cos\frac{2\pi kl}{n}\cos\frac{2\pi jl}{n}+\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}-\cos\frac{2\pi kl}{n}-\left(1-\cos\frac{2\pi jl}{n}\right)\right]\\ &\quad\cdot\left[\cos\frac{2\pi k}{n}\cos\frac{2\pi j}{n}+\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}-\cos\frac{2\pi k}{n}+\left(1-\cos\frac{2\pi j}{n}\right)\right]\\ &=\sum_{j\neq n}\sum_{k\neq n}C(k)G(j)\\ &\quad\cdot\left\{\cos\frac{2\pi kl}{n}\cos\frac{2\pi jl}{n}\cos\frac{2\pi k}{n}\cos\frac{2\pi j}{n}+\cos\frac{2\pi kl}{n}\cos\frac{2\pi jl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\right.\\ &\qquad-\cos\frac{2\pi kl}{n}\cos\frac{2\pi jl}{n}\cos\frac{2\pi k}{n}+\cos\frac{2\pi kl}{n}\cos\frac{2\pi jl}{n}\left(1-\cos\frac{2\pi j}{n}\right)\\ &\qquad+\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\cos\frac{2\pi k}{n}\cos\frac{2\pi j}{n}+\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\\ &\qquad-\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\cos\frac{2\pi k}{n}+\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\left(1-\cos\frac{2\pi j}{n}\right)\\ &\qquad-\cos\frac{2\pi kl}{n}\cos\frac{2\pi k}{n}\cos\frac{2\pi j}{n}-\cos\frac{2\pi kl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\\ &\qquad+\cos\frac{2\pi kl}{n}\cos\frac{2\pi k}{n}-\cos\frac{2\pi kl}{n}\left(1-\cos\frac{2\pi j}{n}\right)\\ &\qquad-\left(1-\cos\frac{2\pi jl}{n}\right)\cos\frac{2\pi k}{n}\cos\frac{2\pi j}{n}-\left(1-\cos\frac{2\pi jl}{n}\right)\sin\frac{2\pi j}{n}\sin\frac{2\pi k}{n}\\ &\qquad\left.+\left(1-\cos\frac{2\pi jl}{n}\right)\cos\frac{2\pi k}{n}-\left(1-\cos\frac{2\pi jl}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right)\right\}. \end{aligned}\tag{A.13}$$

By eliminating terms which are odd in k (since they sum to zero over $k \neq n$) and rearranging,

(A.14)

$$\begin{aligned}\lambda_l^2 = \sum_{j\neq n}\sum_{k\neq n} C(k)G(j)\Bigg\{ &\cos\frac{2\pi kl}{n}\cos\frac{2\pi k}{n}\left(\cos\frac{2\pi jl}{n}\cos\frac{2\pi j}{n} - \cos\frac{2\pi jl}{n} - \cos\frac{2\pi j}{n} + 1\right) \\ &+ \cos\frac{2\pi kl}{n}\left(\cos\frac{2\pi jl}{n}\left(1-\cos\frac{2\pi j}{n}\right) - \left(1-\cos\frac{2\pi j}{n}\right)\right) \\ &+ \cos\frac{2\pi k}{n}\left(-\left(1-\cos\frac{2\pi jl}{n}\right)\cos\frac{2\pi j}{n} + \left(1-\cos\frac{2\pi jl}{n}\right)\right) \\ &-\left(1-\cos\frac{2\pi jl}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right) \\ &+\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\Bigg\}, \\ = -\sum_{j\neq n}\sum_{k\neq n} C(k)G(j)\Bigg\{ &\left(1+\cos\frac{2\pi kl}{n} - \cos\frac{2\pi k}{n} - \cos\frac{2\pi kl}{n}\cos\frac{2\pi k}{n}\right) \\ &\cdot\left(1-\cos\frac{2\pi jl}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right) \\ &-\sin\frac{2\pi kl}{n}\sin\frac{2\pi jl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi j}{n}\Bigg\}, \\ = -\sum_{j\neq n}\sum_{k\neq n} C(k)G(j)\Bigg\{ &\left(1+\cos\frac{2\pi kl}{n}\right)\left(1-\cos\frac{2\pi k}{n}\right)\left(1-\cos\frac{2\pi jl}{n}\right)\left(1-\cos\frac{2\pi j}{n}\right) \\ &-\sin\frac{2\pi kl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi jl}{n}\sin\frac{2\pi j}{n}\Bigg\}.\end{aligned}$$

Hence the nonzero eigenvalues of the linearization of f at r^0 are λ_l such that

(7.1)

$$\begin{aligned}\overset{2}{\lambda_l} = -gc\beta &\sum_{j\neq n}\sum_{k\neq n} \\ &\cdot\left[\left(1+\cos\left(\frac{2\pi kl}{n}\right)\right)\left(1-\cos\frac{2\pi k}{n}\right)\left(1-\cos\frac{2\pi jl}{n}\right)\right. \\ &\left.\cdot\left(1-\cos\frac{2\pi j}{n}\right) - \sin\frac{2\pi kl}{n}\sin\frac{2\pi k}{n}\sin\frac{2\pi jl}{n}\sin\frac{2\pi j}{n}\right] \\ &\cdot\left[\left(2\left(1-\cos\frac{2\pi k}{n}\right)\right)^{\beta/2+1}\left(2\left(1-\cos\frac{2\pi j}{n}\right)\right)^{\beta/2+1}\right]^{-1}\end{aligned}$$

UNCONDITIONAL BASES OF WAVELETS FOR SOBOLEV SPACES*

GUSTAF GRIPENBERG[†]

Abstract. It is shown that an orthonormal wavelet basis for $L^2(\mathbb{R})$ associated with a multiresolution is an unconditional basis for the Sobolev space $\mathcal{H}^t(\mathbb{R})$, $t \in [-s, s]$, provided the father wavelet belongs to $\mathcal{H}^s(\mathbb{R})$ and the square of its absolute value has finite moments. A criterion for when the wavelet belongs to $\mathcal{H}^s(\mathbb{R})$ is given.

Key words. basis, unconditional, Sobolev space, wavelet, multiresolution

AMS subject classifications. primary 42C15; secondary 46B15, 46E35, 39B99

1. Introduction.

The purpose of this paper is to extend some of the results in [13] on unconditional bases for the Sobolev space $\mathcal{H}^s(\mathbb{R}; \mathbb{C})$, which are of the form $\{\psi(2^m \bullet -k)\}_{m,k\in\mathbb{Z}}$ where ψ is a mother wavelet, that is, $\{2^{m/2}\psi(2^m \bullet -k)\}_{m,k\in\mathbb{Z}}$ is an orthonormal basis for $L^2(\mathbb{R}; \mathbb{C})$. (Here $\bullet$ denotes a generic argument.) The analysis in this paper is restricted to the one-dimensional case, where there is also a father wavelet φ such that $V_{m+1} = V_m \oplus W_m$, where V_m is the space spanned by $\{\varphi(2^m \bullet -k)\}_{k\in\mathbb{Z}}$ and W_m is the space spanned by $\{\psi(2^m \bullet -k)\}_{k\in\mathbb{Z}}$. In other words, the wavelets are obtained from a multiresolution.

It is proved below that if ψ and φ belong to $\mathcal{H}^s(\mathbb{R}; \mathbb{C})$, where $s \geq 0$ and both functions decay sufficiently rapidly (e.g., all moments of the square of the absolute value are finite), then we get an unconditional basis for $\mathcal{H}^t(\mathbb{R}; \mathbb{C})$ for all $t \in [-s, s]$. In order to obtain this result one has to extend a known criterion (see [6], [15]) for when φ, $\psi \in \mathcal{H}^s(\mathbb{R}; \mathbb{C})$, to the case where the functions are not necessarily compactly supported. This criterion involves the spectral radius of an operator, and in the case of compactly supported wavelets the problem is reduced to calculating the spectral radius of a matrix. This means, for example, that one knows exactly for which positive values of s the wavelets constructed in [3] give rise to unconditional bases in $\mathcal{H}^s(\mathbb{R}; \mathbb{C})$.

The main point of this paper is not that it is possible to construct an unconditional wavelet basis, because this is well known and holds true, as can be seen from [13], for a large number of other types of functional spaces too, but to find out exactly what assumptions are needed on the wavelets. It turns out that the hypotheses one has to use are quite natural, and this constitutes additional evidence for the claim that wavelets are an extremely useful tool.

2. Statement of results.

First we have to define what we mean by a multiresolution or a multiresolution analysis as it is often called. We say that $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ is a multiresolution of $L^2(\mathbb{R}; \mathbb{C})$ provided that the following four conditions hold.

$$\varphi \in L^2(\mathbb{R}; \mathbb{C}) \text{ and } V_m \text{ is, for each } m \in \mathbb{Z}, \text{ the closed subspace of } L^2(\mathbb{R}; \mathbb{C}) \text{ spanned by } \{\varphi(2^m \bullet -k)\}_{k\in\mathbb{Z}}, \tag{1}$$

$$V_m \subset V_{m+1}, \qquad m \in \mathbb{Z}, \tag{2}$$

(3) $\lim_{m\to\infty} P_m f = f$ for every $f \in L^2(\mathbb{R};\mathbb{C})$, where P_m is the orthogonal projection of $L^2(\mathbb{R};\mathbb{C})$ onto V_m,

(4) $\{\varphi(\bullet - k)\}_{k\in\mathbb{Z}}$ is an orthonormal set in $L^2(\mathbb{R};\mathbb{C})$.

The function φ is then said to be the father wavelet or scaling function.

The definition of a multiresolution is often given in a slightly different form (but with exactly the same content); see, e.g., [1], [4], and [11]–[13], so that the fact that $\{\varphi(2^m \bullet -k)\}_{k\in\mathbb{Z}}$ spans V_m is a consequence of the other assumptions. Condition (3) is often formulated as the requirement that $\bigcup_{m=-\infty}^{\infty} V_m$ is dense in $L^2(\mathbb{R};\mathbb{C})$ and it is combined with the assumption that $\bigcap_{m=-\infty}^{\infty} V_m = \{0\}$, which follows from the other conditions; see [1, p. 443] and note that the moment conditions assumed there are not used in the proof of this statement. It is not really essential that $\{\varphi(\bullet - k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis; it would suffice (as is often done) to require that it is an unconditional basis in which case it is a Riesz basis (see [8, Thm. 2.2.2]), but from such a basis one easily constructs an orthonormal one.

Since $\varphi \in V_0 \subset V_1$ it follows that φ can be expressed in terms of the functions $\{\varphi(2\bullet -k)\}_{k\in\mathbb{Z}}$ which span V_1, that is,

$$\varphi = 2\sum_{k\in\mathbb{Z}} \alpha(k)\varphi(2\bullet -k), \tag{5}$$

where

$$\alpha(k) = \int_{\mathbb{R}} \varphi(x)\overline{\varphi(2x-k)}\,\mathrm{d}x, \qquad k \in \mathbb{Z}.$$

We call this sequence α the filter associated with the multiresolution and it turns out to be crucial for the analysis and in particular for computations involving the wavelets, cf. [14].

If we take Fourier transforms of both sides of (5), then we get

$$\hat{\varphi}(2\bullet) = \hat{\alpha}(\bullet)\hat{\varphi}(\bullet). \tag{6}$$

From this equation one sees the advantages of having the normalizing factor 2 in (5). Here we have defined the Fourier transform of φ to be $\hat{\varphi} = \int_{\mathbb{R}} \mathrm{e}^{-2\pi\mathrm{i}\bullet x}\varphi(x)\,dx$ and the Fourier transform of α to be $\hat{\alpha} = \sum_{k\in\mathbb{Z}} \mathrm{e}^{-2\pi\mathrm{i}\bullet k}\alpha(k)$. Thus $\hat{\alpha}$ is periodic with period 1. It is possible to prove (see, e.g., [11, p. 31]) that

$$|\hat{\alpha}(\bullet)|^2 + \left|\hat{\alpha}\left(\bullet + \tfrac{1}{2}\right)\right|^2 = 1 \quad \text{a.e. on } \mathbb{R}. \tag{7}$$

Sequences α that satisfy (7) are called conjugate quadrature filters.

Having found the filter α we can define the mother wavelet ψ as follows:

$$\psi = 2\sum_{k\in\mathbb{Z}} (-1)^k \overline{\alpha(1-k)}\varphi(2\bullet -k).$$

For the Fourier transforms this implies that

$$\hat{\psi}(2\bullet) = -\mathrm{e}^{-2\pi\mathrm{i}\bullet}\overline{\hat{\alpha}\left(\bullet + \tfrac{1}{2}\right)}\hat{\varphi}(\bullet). \tag{8}$$

It follows from these definitions that the sets

$$\{2^{m/2}\psi(2^m \bullet -k)\}_{m,k\in\mathbb{Z}},$$

and

$$\{2^{m_0/2}\varphi(2^{m_0} \bullet -k), 2^{m/2}\psi(2^m \bullet -k)\}_{m\geq m_0,k\in\mathbb{Z}},$$

where $m_0 \in \mathbb{Z}$ is arbitrary, are orthonormal bases for $L^2(\mathbb{R};\mathbb{C})$; see, e.g., [4] or [13].

The Sobolev space $\mathcal{H}^s(\mathbb{R};\mathbb{C})$ consists of all functions f (or tempered distributions in the case where $s < 0$) such that

$$\|f\|^2_{\mathcal{H}^s(\mathbb{R})} = \int_{\mathbb{R}} (1+|\omega|^2)^s |\hat{f}(\omega)|^2 \,\mathrm{d}\omega < \infty.$$

If s is a nonnegative integer N, then $\mathcal{H}^N(\mathbb{R};\mathbb{C})$ consists of all square integrable functions f that are $N-1$ times continuously differentiable such that $f^{(N-1)}$ is locally absolutely continuous with a square integrable derivative. As an equivalent norm we can then take

$$\sqrt{\sum_{j=0}^{N} \int_{\mathbb{R}} |f^{(j)}(x)|^2 \, dx}.$$

It follows from the definition of the mother wavelet that $\left|\hat{\varphi}(\bullet)\right|^2 = \sum_{p\geq 1}\left|\hat{\psi}(2^p\bullet)\right|^2$ almost everywhere on $\mathbb{R}$ (see [11, p. 31]), and it is then quite easy to see that if $s \geq 0$, then $\varphi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$ if and only if $\psi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$; cf. [15, Prop. 10.2].

In the case where the wavelets φ and ψ, and then also the filter α, have compact support, the following theorem can essentially be found in [6] and [15]. The proof given below is a modification of that in [15]. For related results, see also [2], [5], and [9].

THEOREM 1. *Let $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ be a multiresolution of $L^2(\mathbb{R};\mathbb{C})$ with filter α and mother wavelet ψ. Let $M \geq 1$ be an integer and assume that $|\bullet|^{M+1}\varphi \in L^2(\mathbb{R};\mathbb{C})$ and that*

$$\int_{\mathbb{R}} x^j \psi(x)\,\mathrm{d}x = 0, \qquad j = 0,1,2,\dots, M-1. \tag{9}$$

Let a be the function

$$a = \frac{\hat{\alpha}(\bullet)}{\left(\cos(\pi\bullet)\right)^M}.$$

Then a is continuous and periodic and the operator A: $C([0,1];\mathbb{C}) \to C([0,1];\mathbb{C})$, defined by

$$Af = \left|a\left(\frac{\bullet}{2}\right)\right|^2 f\left(\frac{\bullet}{2}\right) + \left|a\left(\frac{\bullet+1}{2}\right)\right|^2 f\left(\frac{\bullet+1}{2}\right),$$

has spectral radius $\rho \geq 1$. In particular, $\rho > 1$ if $\int_{\mathbb{R}} x^M\psi(x)\,\mathrm{d}x \neq 0$.

If $s < M - \log_4(\rho)$, then $\varphi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$ and if $\rho > 1$ and $\varphi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$, then $s < M - \log_4(\rho)$.

It is proved below that it follows from the assumption $|\bullet|^{M+1}\varphi \in L^2(\mathbb{R};\mathbb{C})$ that $|\bullet|^{M+1}\psi \in L^2(\mathbb{R};\mathbb{C})$ too, and therefore the integrals in (9) are well defined. If there is some closed subspace of $C([0,1];\mathbb{C})$ invariant under A that contains all the constants, then one sees from the fact that A is a positive operator that the spectral radius of A restricted to this subspace is ρ as well. This observation is important in the case where the parent wavelets have compact support because one can then find an invariant subspace of trigonometric polynomials and ρ is the spectral radius of a matrix.

Concerning bases, we have the following result.

THEOREM 2. *Let $s \geq 0$ and assume that $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ is a multiresolution of $L^2(\mathbb{R};\mathbb{C})$ with mother wavelet ψ such that $\varphi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$, and $|\bullet|^N\varphi \in L^2(\mathbb{R};\mathbb{C})$ for all $N \geq 0$. Then the sets*

$$\{\psi(2^m \bullet -k)\}_{m,k\in\mathbb{Z}},$$

and

$$\{\varphi(2^{m_0} \bullet -k), \psi(2^m \bullet -k)\}_{m\geq m_0,k\in\mathbb{Z}},$$

where $m_0 \in \mathbb{Z}$ is arbitrary, are unconditional bases for $\mathcal{H}^t(\mathbb{R};\mathbb{C})$, $t \in [-s,s]$.

In [13] the corresponding assumptions are that s is an integer and that for all $j \geq 0$ one has $\sup_{x\in\mathbb{R}}(1+|x|)^j|\varphi^{(s)}(x)| < \infty$. In the case of wavelets with compact support, one can calculate exactly for which values of s we have $\varphi \in \mathcal{H}^s(\mathbb{R};\mathbb{C})$; see [6], and for these spaces we immediately get an unconditional basis as well.

As one sees from the proof, one could use a number of slightly different sets of assumptions. The ones used here are not necessarily the weakest possible, but they are reasonable and simple.

3. Proof of Theorem 1. First we give some auxiliary results. By $\mathbb{T}$ we denote $\mathbb{R}/\mathbb{Z}$, i.e., functions defined on $\mathbb{T}$ are periodic functions on $\mathbb{R}$ with period 1.

LEMMA 3. *Let $N \geq 1$ and let $(\{V_m\}_{m\in\mathbb{Z}}, \varphi)$ be a multiresolution of $L^2(\mathbb{R};\mathbb{C})$ with filter α and mother wavelet ψ such that $|\bullet|^N\varphi \in L^2(\mathbb{R};\mathbb{C})$. Then $\hat{\varphi}$, $\hat{\psi} \in \mathcal{H}^N(\mathbb{R};\mathbb{C})$ and $\hat{\alpha} \in \mathcal{H}^N(\mathbb{T};\mathbb{C})$. Moreover,*

$$\sum_{k\in\mathbb{Z}}|\hat{\varphi}(\omega+k)|^2 = \sum_{k\in\mathbb{Z}}|\hat{\psi}(\omega+k)|^2 = 1, \qquad \omega \in [0,1], \tag{10}$$

where the series converge uniformly.

Note that $\hat{\alpha} \in \mathcal{H}^N(\mathbb{T};\mathbb{C})$ means that $\hat{\alpha}$ is an $N-1$ times continuously differentiable periodic function and $\hat{\alpha}^{(N-1)}$ is absolutely continuous with a locally square integrable derivative.

Proof of Lemma 3. The fact that $\varphi \in \mathcal{H}^N(\mathbb{R};\mathbb{C})$ is a direct consequence of the moment condition and the definition of $\mathcal{H}^N(\mathbb{R};\mathbb{C})$. But from now on we use the equivalent characterization of $\mathcal{H}^N(\mathbb{R};\mathbb{C})$ in terms of square integrable derivatives.

It follows from the fact that $\{\varphi(\bullet-k)\}_{k\in\mathbb{Z}}$ and $\{\psi(\bullet-k)\}_{k\in\mathbb{Z}}$ are orthonormal sets that (10) holds for almost every $\omega \in [0,1]$; see [11, p. 31]. Because

$$\hat{\varphi}(\omega) = \hat{\varphi}(\eta) + \int_\omega^\eta \hat{\varphi}'(\xi)\,\mathrm{d}\xi, \qquad \omega,\eta \in [0,1],$$

we have

$$|\hat{\varphi}(\omega+k)|^2 \leq 2\int_0^1 |\hat{\varphi}(\eta+k)|^2\,\mathrm{d}\eta + 2\int_0^1 |\hat{\varphi}'(\xi+k)|^2\,\mathrm{d}\xi, \quad \omega \in [0,1], \quad k \in \mathbb{Z}.$$

Since $\hat{\varphi}$ and $\hat{\varphi}' \in L^2(\mathbb{R};\mathbb{C})$ we get the result that the first series in (10) converges uniformly.

It follows that for each $\omega \in [0,1]$ there exist numbers $k_\omega \in \mathbb{Z}$ and $\epsilon_\omega > 0$ such that $|\hat{\varphi}(\xi+k_\omega)| > 0$ when $|\xi-\omega| < 2\epsilon_\omega$. Since $[0,1]$ is compact we can choose finitely many of these points ω_j, $j = 1,2,\dots,n$ such that $[0,1] \subset \bigcup_{j=1}^n(\omega_j-\epsilon_{\omega_j}, \omega_j+\epsilon_{\omega_j})$. Therefore $|\hat{\varphi}(\xi+k_{\omega_j})| \geq C$ for some constant $C > 0$ when $|\xi-\omega_j| < \epsilon_{\omega_j}$ and $j = 1,\dots,n$. But $\hat{\alpha}(\xi) = \hat{\varphi}(2(\xi+k_{\omega_j}))/\hat{\varphi}(\xi+k_{\omega_j})$ by (6) and by the periodicity of $\hat{\alpha}$, and therefore we deduce that $\hat{\alpha}$ is $N-1$ times continuously differentiable, and $\hat{\alpha}^{(N-1)}$ is absolutely continuous with a square integrable derivative on the interval $(\omega_j - \epsilon_{\omega_j}, \omega_j + \epsilon_{\omega_j})$. Since $[0,1] \subset \bigcup_{j=1}^{n}(\omega_j - \epsilon_{\omega_j}, \omega_j + \epsilon_{\omega_j})$ we conclude that $\hat{\alpha} \in \mathcal{H}^N(\mathbb{T};\mathbb{C})$.

From (8) we get

$$2^N \hat{\psi}^{(N)}(2\bullet) = \sum_{j=0}^{N} \binom{N}{j} \hat{\beta}^{(j)}(\bullet)\hat{\varphi}^{(N-j)}(\bullet),$$

where $\hat{\beta}(\bullet) = -\mathrm{e}^{-2\pi \mathrm{i}\bullet}\overline{\hat{\alpha}\left(\bullet + \frac{1}{2}\right)}$. Because $\sup_{\omega\in\mathbb{R}}|\hat{\alpha}^{(j)}(\omega)| < \infty$ for $j = 0, 1, \dots, N-1$, $\int_0^1 |\hat{\alpha}^{(N)}(\omega)|^2 \, \mathrm{d}\omega < \infty$, and $\hat{\alpha}^{(N)}$ is periodic, these conclusions hold for $\hat{\beta}$ as well. Since, moreover, (10) holds and $\hat{\varphi} \in H^N(\mathbb{R};\mathbb{C})$ we see that $\int_{\mathbb{R}} |\hat{\psi}^{(N)}(\omega)|^2 \, d\omega < \infty$, and hence $\hat{\psi} \in \mathcal{H}^N(\mathbb{R};\mathbb{C})$.

Repeating the argument used above we now see that the second series in (10) converges uniformly too. □

We replace the function a defined above by $\hat{\alpha}(\bullet)(\mathrm{e}^{\pi\mathrm{i}\bullet}\cos(\pi\bullet))^{-M}$. This change will not affect the operator A, but a will now be periodic with period 1, and this is in some parts of the argument desirable (although not very essential).

We apply Lemma 3 with $N = M + 1$, and then we note that assumption (9) implies that $\hat{\psi}^{(j)}(0) = 0$ for $j = 0, 1, \dots, M-1$. By (8) and the fact that $|\hat{\varphi}(0)| = 1$ (see [11, p. 31]) it follows that we also have $\hat{\alpha}^{(j)}(\frac{1}{2}) = 0$ for $j = 0, 1, \dots, M-1$. Thus we get by Taylor's formula that

$$\hat{\alpha} = \frac{\hat{\alpha}^{(M)}(1/2)}{M!}\left(\bullet - \frac{1}{2}\right)^M + \frac{1}{M!}\int_{1/2}^{\bullet} \hat{\alpha}^{(M+1)}(\xi)(\bullet - \xi)^M \, \mathrm{d}\xi.$$

From this formula we can deduce with the aid of Hölder's inequality that a is absolutely continuous and $a' \in L^p(\mathbb{T};\mathbb{C})$, $1 \le p < 2$. Thus we can conclude that a is in fact Hölder continuous, for example, with exponent $\frac{1}{4}$, i.e.,

$$\sup_{\omega,\eta\in[0,1]} \frac{|a(\omega) - a(\eta)|}{|\omega - \eta|^{1/4}} < \infty.$$

Next we study the operator A. By changing variables and using the periodicity of $|a|$ we easily see that for all f, $g \in C(\mathbb{T};\mathbb{C})$ we have

$$\int_0^1 (Af)(\omega)g(\omega)\, \mathrm{d}\omega = \int_0^1 f(\omega)2|a(\omega)|^2 g(2\omega)\, \mathrm{d}\omega. \tag{11}$$

In particular, this implies that if we define numbers σ_m by

$$\sigma_m = 2^m \int_0^1 |\sin(\pi 2^m \omega)|^{2M} \prod_{k=0}^{m-1} |a(2^k\omega)|^2 \, \mathrm{d}\omega, \qquad m \ge 1, \tag{12}$$

then it follows from m applications of (11) that

$$\sigma_m = \int_0^1 (A^m 1)(\omega)|\sin(\pi\omega)|^{2M} \, \mathrm{d}\omega, \qquad m \ge 1. \tag{13}$$

Thus we have

$$\sigma_m \leq \|A^m\|, \qquad m \geq 1, \tag{14}$$

where $\|\bullet\|$ denotes the operator norm.

Let

$$\mu \overset{\text{def}}{=} \inf_{\omega\in\mathbb{R}} \left(|a(\omega)|^2 + \left|a\left(\omega+\tfrac{1}{2}\right)\right|^2 \right).$$

It is clear that $(A^m 1)(\omega) \geq \mu^m$, $\omega \in [0,1]$, hence $\|A^m\| \geq \mu^m$, and it follows that the spectral radius of A is at least μ. Since $|\cos(\pi\omega)| \leq 1$ for all ω we conclude from (7) and the definition of a that $\mu \geq 1$.

If $\int_{\mathbb{R}} x^M \psi(x)\,dx \neq 0$, then $\hat{\psi}^{(M)}(0) \neq 0$, and it follows that $\hat{\alpha}^{(M)}(\frac{1}{2}) \neq 0$ and therefore $a(\frac{1}{2}) \neq 0$. But $a(0) = 1$ because $\hat{\alpha}(0) = \lim_{\omega\to 0} \hat{\varphi}(2\omega)/\hat{\varphi}(\omega) = 1$ by (6), and $|\cos(\pi\omega)| < 1$ when $\omega \notin \mathbb{Z}$. Therefore it follows from (7) and the definition of a that $\mu > 1$. Thus we have established the claims about the spectral radius.

If we replace a by the standard approximation

$$a_n = \frac{1}{n+1} \int_0^1 \left(\frac{\sin((n+1)\pi t)}{\sin(\pi t)} \right)^2 a(\bullet - t)\,dt,$$

then we see that the functions a_n are uniformly Hölder continuous and bounded, and $a_n \to a$ uniformly as $n \to \infty$. We define the operator $A_n : C([0,1];\mathbb{C}) \to C([0,1];\mathbb{C})$ by

$$A_n f = \left| a_n\left(\frac{\bullet}{2}\right) \right|^2 f\left(\frac{\bullet}{2}\right) + \left| a_n\left(\frac{\bullet+1}{2}\right) \right|^2 f\left(\frac{\bullet+1}{2}\right).$$

Because $\widehat{a_n}(k) = \max\{0, 1 - (|k|/n+1)\}\hat{a}(k)$ it follows that a_n is a trigonometric polynomial. (We have defined the Fourier transform of the periodic function a to be $\hat{a} = \int_0^1 e^{-2\pi i \bullet \omega} a(\omega)\,d\omega$.) But then $|a_n|^2$ is a trigonometric polynomial as well, and the support of the Fourier transform of $|a_n|^2$ is contained in $[-2n, 2n]$. If now $f \in C([0,1];\mathbb{C})$ is a trigonometric polynomial, then

$$|a_n(\bullet)|^2 f(\bullet) = \sum_{k\in\mathbb{Z}} e^{2\pi i k \bullet} \sum_{j=-2n}^{2n} \widehat{|a_n|^2}(j) \hat{f}(k-j),$$

where the sum is actually a finite one. Then

$$A_n f = 2 \sum_{k\in\mathbb{Z}} e^{2\pi i k \bullet} \sum_{j=-2n}^{2n} \widehat{|a_n|^2}(j) \hat{f}(2k-j),$$

because the odd terms cancel. Thus we see that if the support of the Fourier transform of f is contained in $[-2n+1, 2n-1]$, then the same holds true for the support of the Fourier transform of $A_n f$. Thus A_n maps a finite-dimensional space of trigonometric polynomials into itself, and therefore there is an eigenvalue λ_n of A_n such that $|\lambda_n| = \rho_n$, where ρ_n is the spectral radius of A_n restricted to this space. We denote the corresponding eigenfunction by v_n and we normalize it so that $\|v_n\|_{C([0,1])} = 1$. We note that ρ_n is also equal to the spectral radius of A_n in the space $C([0,1];\mathbb{C})$, because $\|A_n^m\| = \|A_n^m 1\|_{C([0,1])}$, where $\|\bullet\|$ is the operator norm in any one of these spaces.

Define a new operator $B_n : C([0,1] \times [0,1]; \mathbb{C}) \to C([0,1] \times [0,1]; \mathbb{C})$ by

$$(B_n h)(\omega, \eta) = \left| a_n\left(\frac{\omega}{2}\right)\right|^2 h\left(\frac{\omega}{2}, \frac{\eta}{2}\right) + \left| a_n\left(\frac{\omega+1}{2}\right)\right|^2 h\left(\frac{\omega+1}{2}, \frac{\eta+1}{2}\right), \qquad \omega, \eta \in [0,1].$$

We can also define B in a similar way with a_n replaced by a. We note that B_n applied to a function that does not depend on its second argument gives the same result (as a function of its first argument) as A_n applied to the same function (with only one argument). Since $\|B_n^m\| = \|B_n^m 1\|_{C([0,1]^2)}$ and $\|A_n^m\| = \|A_n^m 1\|_{C([0,1])}$ we therefore conclude that $\|B_n^m\| = \|A_n^m\|$ and these operators have the same spectral radius. Moreover, $B_n \to B$ as $n \to \infty$. Define the function $g_n \in C([0,1] \times [0,1]; \mathbb{C})$ by

$$g_n(\omega, \eta) = \frac{v_n(\omega) - v_n(\eta)}{|\omega - \eta|^{1/4}}, \qquad \omega, \eta \in [0,1].$$

Then we get

$$2^{-1/4} B_n g_n - \rho_n g_n = b_n,$$

where

$$b_n(\omega, \eta) = \frac{\left(\left|a_n\left(\frac{\eta}{2}\right)\right|^2 - \left|a_n\left(\frac{\omega}{2}\right)\right|^2\right) v_n\left(\frac{\eta}{2}\right) + \left(\left|a_n\left(\frac{\eta+1}{2}\right)\right|^2 - \left|a_n\left(\frac{\omega+1}{2}\right)\right|^2\right) v_n\left(\frac{\eta+1}{2}\right)}{|\omega - \eta|^{1/4}}$$

for all ω, $\eta \in [0,1]$. Since a_n is uniformly Hölder continuous with exponent $\frac{1}{4}$, $\sup_{\eta \in [0,1]} |v_n(\eta)| = 1$, $\rho_n \to \rho$, and $B_n \to B$ as $n \to \infty$, we conclude that

$$\sup_{n \geq 1} \sup_{\omega, \eta \in [0,1]} |g_n(\omega, \eta)| < \infty.$$

But this means that the functions v_n are uniformly Hölder continuous, in particular, equicontinuous, and we may pass to the limit and get a nontrivial function $v \in C([0,1]; \mathbb{C})$ such that $Av = \lambda v$, where $|\lambda| = \rho$. But then we have by (13), because $\sup_{\omega \in [0,1]} |v(\omega)| = 1$,

$$\begin{aligned} \rho^m \int_0^1 |v(\omega)|^2 |\sin(\pi\omega)|^{2M} \, d\omega &= \left| \int_0^1 (A^m v)(\omega) \overline{v(\omega)} |\sin(\pi\omega)|^{2M} \, d\omega \right| \\ &\leq \int_0^1 (A^m 1)(\omega) |\sin(\pi\omega)|^{2M} \, d\omega = \sigma_m. \end{aligned}$$

Combining this result with (14) and the fact that $\lim_{m \to \infty} \|A^m\|^{1/m} = \rho$, we conclude that

$$\sum_{m=1}^{\infty} 4^{-pm} \sigma_m < \infty \quad \text{if and only if } p > \log_4(\rho). \tag{15}$$

Let us define the function q by

$$q = \frac{(\pi \bullet)^M \hat{\varphi}(\bullet)}{\left(e^{\pi i \bullet} \sin(\pi \bullet)\right)^M \hat{\varphi}(0)}.$$

Using the same kind of argument that was used when proving that a was continuous, we can prove that q is continuous as well. The important point, however, is that since $\prod_{k=1}^{\infty}\cos(\pi 2^{-k}\bullet) = \sin(\pi\bullet)/(\pi\bullet)$ and $\hat{\varphi} = \hat{\varphi}(0)\prod_{k=1}^{\infty}\hat{\alpha}(2^{-k}\bullet)$ (see [11, p. 34]), it follows that

$$q = \prod_{k=1}^{\infty} a(2^{-k}\bullet). \tag{16}$$

(Recall that we introduced a factor $e^{\pi i \bullet}$ in the definition of a for technical reasons.)

By Lemma 3 there exists an integer J such that $\sum_{j=-J}^{J-1}|\hat{\varphi}(\omega+j)|^2 \geq \frac{1}{2}$ for all $\omega \in [0,1]$. Since $|q(\omega)| \geq |\hat{\varphi}(\omega)|$, $\omega \in \mathbb{R}$, we have for some constant C,

$$\frac{1}{2} \leq \sum_{j=-J}^{J-1} |q(\omega+j)|^2 \leq C, \qquad \omega \in [0,1]. \tag{17}$$

Let $p > 0$. It follows from the definition of q that

$$\varphi \in \mathcal{H}^{M-p}(\mathbb{R};\mathbb{C}) \quad \text{if and only if} \quad \int_{\mathbb{R}} (1+\omega^2)^{-p}|q(\omega)|^2\big|\sin(\pi\omega)\big|^{2M}\,d\omega < \infty.$$

Because $p > 0$ we get after integrating by parts that

$$\begin{aligned}&\int_{\mathbb{R}} (1+\omega^2)^{-p}|q(\omega)|^2\big|\sin(\pi\omega)\big|^{2M}\,d\omega \\ &\quad = \int_0^{\infty} 2p\omega(1+\omega^2)^{-p-1}\int_{-\omega}^{\omega} |q(\eta)|^2\big|\sin(\pi\eta)\big|^{2M}\,d\eta\,d\omega,\end{aligned}$$

where equality holds in the case where one of the integrals diverges too. There are positive constants C_1 and C_2 such that $C_1 \leq 4^{pm}\int_{2^{m-1}J}^{2^m J} 2p\omega(1+\omega^2)^{-p-1}\,d\omega \leq C_2$, and hence we see that

$$\varphi \in \mathcal{H}^{M-p}(\mathbb{R};\mathbb{C}) \quad \text{if and only if} \quad \sum_{m=1}^{\infty} 4^{-pm}\int_{-2^m J}^{2^m J} |\sin(\pi\omega)|^{2M}|q(\omega)|^2\,d\omega < \infty. \tag{18}$$

Using (16), changing variables, and invoking the periodicity of $|a|$ we get

$$\begin{aligned}&\int_{-2^m J}^{2^m J} |\sin(\pi\omega)|^{2M}|q(\omega)|^2\,d\omega \\ &\quad = \int_{-2^m J}^{2^m J} |\sin(\pi\omega)|^{2M}\prod_{k=1}^{m}|a(2^{-k}\omega)|^2|q(2^{-m}\omega)|^2\,d\omega \\ &\quad = 2^m\int_{-J}^{J} |\sin(\pi 2^m\omega)|^{2M}\prod_{k=0}^{m-1}|a(2^k\omega)|^2|q(\omega)|^2\,d\omega \\ &\quad = 2^m\int_0^1 |\sin(\pi 2^m\omega)|^{2M}\prod_{k=0}^{m-1}|a(2^k\omega)|^2\sum_{j=-J}^{J-1}|q(\omega+j)|^2\,d\omega.\end{aligned}$$

If we combine this result with (12), (15), (17), and (18), then we see that when $p > 0$ we have $\varphi \in \mathcal{H}^{M-p}(\mathbb{R};\mathbb{C})$ if and only if $p > \log_4(\rho)$. But this is exactly the claim of the theorem, and the proof is completed. □

4. Proof of Theorem 2. We use the following result on projections onto spaces spanned by translations of one function.

LEMMA 4. *Let $\phi \in L^2(\mathbb{R};\mathbb{C})$ be such that $\{\phi(\bullet - k)\}_{k\in\mathbb{Z}}$ is an orthonormal set in $L^2(\mathbb{R};\mathbb{C})$. Let $m \in \mathbb{Z}$ and denote by P_m the orthogonal projection onto the closed subspace of $L^2(\mathbb{R};\mathbb{C})$ spanned by $\{\phi(2^m \bullet -k)\}_{k\in\mathbb{Z}}$. Then, for every $f \in L^2(\mathbb{R};\mathbb{C})$,*

$$\widehat{P_m f} = \hat{\phi}(2^{-m}\bullet)g_m(\bullet), \tag{19}$$

where

$$g_m = \sum_{j\in\mathbb{Z}} \hat{f}(\bullet + 2^m j)\overline{\hat{\phi}(2^{-m}\bullet + j)}. \tag{20}$$

Moreover,

$$\|P_m f\|^2_{L^2(\mathbb{R})} = \int_{-2^{m-1}}^{2^{m-1}} |g_m(\omega)|^2\,\mathrm{d}\omega,$$

and for every $t \in \mathbb{R}$,

$$\|P_m f\|^2_{\mathcal{H}^t(\mathbb{R})} = \int_{-2^{m-1}}^{2^{m-1}} \sum_{k\in\mathbb{Z}} (1 + |\omega + 2^m k|^2)^t \left|\hat{\phi}(2^{-m}\omega + k)\right|^2 |g_m(\omega)|^2\,\mathrm{d}\omega.$$

Proof of Lemma 4. First we derive a formula for $\widehat{P_m f}$. We have

$$P_m f = \sum_{k\in\mathbb{Z}} 2^m \langle f, \phi(2^m \bullet -k)\rangle \phi(2^m \bullet -k),$$

where the series converges in $L^2(\mathbb{R};\mathbb{C})$ and $\langle \bullet, \bullet\rangle$ denotes the inner product in $L^2(\mathbb{R};\mathbb{C})$. Now the Fourier transform of $\phi(2^m \bullet -k)$ is $2^{-m}\mathrm{e}^{-2\pi \mathrm{i} 2^{-m}k\bullet}\hat{\phi}(2^{-m}\bullet)$, and therefore we have

$$\widehat{P_m f} = \hat{\phi}(2^{-m}\bullet)\sum_{k\in\mathbb{Z}} \mathrm{e}^{-2\pi\mathrm{i}2^{-m}k\bullet}\langle f, \phi(2^m \bullet -k)\rangle.$$

Using Plancherel's theorem we get

$$\begin{aligned}\langle f, \phi(2^m \bullet -k)\rangle &= \int_{\mathbb{R}} \hat{f}(\omega)2^{-m}\mathrm{e}^{2\pi\mathrm{i}2^{-m}k\omega}\overline{\hat{\phi}(2^{-m}\omega)}\,\mathrm{d}\omega \\ &= \int_0^1 \mathrm{e}^{2\pi\mathrm{i}k\omega}\sum_{j\in\mathbb{Z}} \hat{f}(2^m(\omega + j))\overline{\hat{\phi}(\omega + j)}\,\mathrm{d}\omega,\end{aligned}$$

and we see that if we define the function g_m by (20), then

$$\langle f, \phi(2^m \bullet -k)\rangle = \widehat{g_m(2^m\bullet)}(-k). \tag{21}$$

Now we combine this result with the Fourier inversion theorem for square integrable periodic functions and conclude that (19) holds.

We have $\|P_m f\|^2_{L^2(\mathbb{R})} = 2^m \sum_{k\in\mathbb{Z}} |\langle f, \phi(2^m \bullet -k)\rangle|^2$ because $\{2^{m/2}\phi(2^m \bullet -k)\}_{k\in\mathbb{Z}}$ is an orthonormal set, and therefore it follows from (21) and Plancherel's theorem that

$$\begin{aligned}\|P_m f\|^2_{L^2(\mathbb{R})} &= 2^m \sum_{k\in\mathbb{Z}} |\widehat{g_m(2^m\bullet)}(-k)|^2 \\ &= 2^m \int_{-1/2}^{1/2} |g_m(2^m\omega)|^2\,\mathrm{d}\omega = \int_{-2^{m-1}}^{2^{m-1}} |g_m(\omega)|^2\,\mathrm{d}\omega.\end{aligned}$$

The last claim is an immediate consequence of the fact that g_m is periodic with period 2^m. This completes the proof. □

It follows from the assumptions and Lemma 3 that $\hat{\varphi}$, $\hat{\psi} \in C^\infty(\mathbb{R};\mathbb{C})$ and that $\hat{\alpha} \in C^\infty(\mathbb{T};\mathbb{C})$. If there is an integer $M \geq 1$ such that (9) holds but $\int_{\mathbb{R}} x^M \psi(x)\,\mathrm{d}x \neq 0$, then it follows from Theorem 1 that $s < M - \log_4(\rho)$. If no such integer M exists, then (9) holds for every $M \geq 1$ and we can fix $M > s$ to be an arbitrary integer. But then we have again $s < M - \log_4(\rho)$ either because $\rho > 1$, and we can apply Theorem 1, or because $\rho = 1$ and $s < M = M - \log_4(\rho)$. Thus we see that there exists a number $\delta > 0$ such that $s + 2\delta < M - \log_4(\rho)$, that is, $\varphi \in \mathcal{H}^{s+2\delta}(\mathbb{R};\mathbb{C})$ by Theorem 1. Moreover, we get that

$$\hat{\psi}^{(j)}(0) = 0, \qquad j = 0, 1, \dots, \lfloor s+\delta \rfloor. \tag{22}$$

Next we show that

$$\begin{aligned} &\sup_{\omega\in\mathbb{R}} \sum_{k\in\mathbb{Z}} \left(1 + |\omega + k|^2\right)^{s+\delta} |\hat{\varphi}(\omega + k)|^2 < \infty, \\ &\sup_{\omega\in\mathbb{R}} \sum_{k\in\mathbb{Z}} \left(1 + |\omega + k|^2\right)^{s+\delta} |\hat{\psi}(\omega + k)|^2 < \infty. \end{aligned} \tag{23}$$

Since $\sup_{\omega\in\mathbb{R}} |\hat{\alpha}(\omega)| \leq 1$ by (7) and therefore $|\hat{\psi}(2\omega)| \leq |\hat{\varphi}(\omega)|$, $\omega \in \mathbb{R}$, by (6), we see that the second claim is a consequence of the first; so we will only prove that one.

Choose an integer m so large that $m \geq 1 + s/(2\delta)$. It follows from one of the basic Sobolev inequalities (see, e.g., [7, p. 27]) that there is a constant C_1 such that for all $\epsilon \in (0,1)$ and all $k \in \mathbb{Z}$,

$$\sup_{\omega\in[0,1]} |\hat{\varphi}(\omega + k)|^2 \leq C_1\epsilon \int_0^1 |\hat{\varphi}^{(m)}(\xi + k)|^2\,\mathrm{d}\xi + C_1\epsilon^{-1/(2m-1)} \int_0^1 |\hat{\varphi}(\xi + k)|^2\,\mathrm{d}\xi.$$

Choose $\epsilon = (1 + k^2)^{-(s+\delta)}$ and note that $\epsilon^{-1/(2m-1)}(1 + k^2)^{s+\delta} \leq (1 + k^2)^{s+2\delta}$. We conclude that

$$\begin{aligned} &\sup_{\omega\in[0,1]} (1 + k^2)^{s+\delta} |\hat{\varphi}(\omega + k)|^2 \\ &\qquad \leq C_1 \int_0^1 |\hat{\varphi}^{(m)}(\xi + k)|^2\,\mathrm{d}\xi + C_1 \int_0^1 (1 + k^2)^{s+2\delta} |\hat{\varphi}(\xi + k)|^2\,\mathrm{d}\xi. \end{aligned}$$

Now we have $\sum_{k\in\mathbb{Z}} \int_0^1 |\hat{\varphi}^{(m)}(\xi + k)|^2\,\mathrm{d}\xi < \infty$ because $|\bullet|^m \varphi(\bullet) \in L^2(\mathbb{R};\mathbb{C})$ and $\sum_{k\in\mathbb{Z}} \int_0^1 (1 + |\xi + k|^2)^{s+2\delta} |\hat{\varphi}(\xi + k)|^2\,\mathrm{d}\xi < \infty$ because $\varphi \in \mathcal{H}^{s+2\delta}(\mathbb{R};\mathbb{C})$, and therefore we get the desired conclusion.

Denote the orthogonal projection onto the space spanned by $\{\varphi(2^m \bullet - k)\}_{k\in\mathbb{Z}}$ by P_m and the one onto the space spanned by $\{\psi(2^m \bullet - k)\}_{k\in\mathbb{Z}}$ by Q_m. We claim that there exists a constant C_2 such that for every $m \geq 0$, $f \in L^2(\mathbb{R};\mathbb{C})$, and every t with $|t| \leq s + \delta$, we have

$$\begin{aligned} \|P_0 f\|_{\mathcal{H}^t(\mathbb{R})} &\leq C_2 \|P_0 f\|_{L^2(\mathbb{R})}, \\ \|Q_m f\|_{\mathcal{H}^t(\mathbb{R})} &\leq C_2 2^{mt} \|Q_m f\|_{L^2(\mathbb{R})}. \end{aligned} \tag{24}$$

If $t \geq 0$ these inequalities follow immediately from Lemma 4 and (23). If $t < 0$ the first inequality is trivially true, and in order to get the second one we note that by

(22) there exists a constant C_3 such that $|\hat{\psi}(\eta)| \leq C_3|\eta|^{s+\delta}$ when $|\eta| \leq 1$. Thus we see from some easy estimates and (10) that

$$\begin{aligned}
&\sup_{|\omega|\leq 2^{m-1}} \sum_{k\in\mathbf{Z}} \left(1+|\omega+k2^m|^2\right)^t \left|\hat{\psi}(2^{-m}\omega+k)\right|^2 \\
&\leq \sup_{|\omega|\leq 2^{m-1}} (1+|\omega|^2)^t |\hat{\psi}(2^{-m}\omega)|^2 \\
&\quad + \sup_{|\omega|\leq 2^{m-1}} \sum_{k\in\mathbf{Z}\setminus\{0\}} \left(1+|\omega+k2^m|^2\right)^t \left|\hat{\psi}(2^{-m}\omega+k)\right|^2 \\
&\leq C_3 2^{2mt}|\omega|^{-2t}(1+|\omega|^2)^t + 2^{2mt-2t}\sum_{k\in\mathbf{Z}}\left|\hat{\psi}(2^{-m}\omega+k)\right|^2 \\
&\leq 2^{2mt}(C_3+4^{-t}),
\end{aligned}$$

and the last claim follows from Lemma 4 as well.

The rest of the proof now follows that in [13]. Let $f \in L^2(\mathbb{R};\mathbb{C})$ and $t \in [-s,s]$ be arbitrary. Since $f = P_0 f + \sum_{m=0}^{\infty} Q_m f$ and $|\langle g,h\rangle_{\mathcal{H}^t(\mathbb{R})}| \leq \|g\|_{\mathcal{H}^{t-\delta}(\mathbb{R})}\|h\|_{\mathcal{H}^{t+\delta}(\mathbb{R})}$ by Hölder's inequality, we get from (24) that

$$\begin{aligned}
\|f\|^2_{\mathcal{H}^t(\mathbb{R})} &\leq 2\|P_0 f\|^2_{\mathcal{H}^t(\mathbb{R})} + 2\sum_{m=0}^{\infty}\|Q_m f\|^2_{\mathcal{H}^t(\mathbb{R})} + 4\sum_{m=1}^{\infty}\sum_{k=0}^{m-1}\left|\langle Q_m f, Q_k f\rangle_{\mathcal{H}^t(\mathbb{R})}\right| \\
&\leq 2C_2^2\left(\|P_0 f\|^2_{L^2(\mathbb{R})} + \sum_{m=0}^{\infty} 4^{mt}\|Q_m f\|^2_{L^2(\mathbb{R})}\right) \\
&\quad + 4\sum_{m=1}^{\infty}\sum_{k=0}^{m-1}\|Q_m f\|_{\mathcal{H}^{t-\delta}(\mathbb{R})}\|Q_k f\|_{\mathcal{H}^{t+\delta}(\mathbb{R})} \\
&\leq 4C_2^2\Bigg(\|P_0 f\|^2_{L^2(\mathbb{R})} + \sum_{m=0}^{\infty} 4^{mt}\|Q_m f\|^2_{L^2(\mathbb{R})} \\
&\qquad + \sum_{m=1}^{\infty} 2^{mt}\|Q_m f\|_{L^2(\mathbb{R})} \sum_{k=0}^{m-1} 2^{-\delta(m-k)}2^{kt}\|Q_k f\|_{L^2(\mathbb{R})}\Bigg).
\end{aligned}$$

Next we observe that $\sum_{k=1}^{\infty} 2^{-\delta k} < \infty$ is an upper bound for the the norm of the mapping $\eta \in \ell^2(\mathbb{N};\mathbb{R}) \to \sum_{k=0}^{\bullet-1} 2^{-\delta(\bullet-k)}\eta(k) \in \ell^2(\mathbb{N};\mathbb{R})$, and hence there exists a constant C such that

$$\|f\|^2_{\mathcal{H}^t(\mathbb{R})} \leq C\left(\|P_0 f\|^2_{L^2(\mathbb{R})} + \sum_{m=0}^{\infty} 4^{mt}\|Q_m f\|^2_{L^2(\mathbb{R})}\right), \qquad t \in [-s,s]. \tag{25}$$

In order to get a lower bound for $\|f\|^2_{\mathcal{H}^t(\mathbb{R})}$ we choose an arbitrary integer $M > 0$ and take

$$g = P_0 f + \sum_{m=0}^{M} 4^{mt} Q_m f.$$

Then

$$|\langle f,g\rangle_{L^2(\mathbb{R})}| = \|P_0 f\|^2_{L^2(\mathbb{R})} + \sum_{m=0}^{M} 4^{mt}\|Q_m f\|^2_{L^2(\mathbb{R})}. \tag{26}$$

But on the other hand we have by Hölder's inequality and (25) that

$$\begin{aligned}|\langle f,g\rangle_{L^2(\mathbb{R})}| &\le \|f\|_{\mathcal{H}^t(\mathbb{R})}\|g\|_{\mathcal{H}^{-t}(\mathbb{R})}\\ &\le \|f\|_{\mathcal{H}^t(\mathbb{R})}\sqrt{C}\sqrt{\|P_0f\|^2_{L^2(\mathbb{R})}+\sum_{m=0}^{M}4^{-mt}4^{2mt}\|Q_mf\|^2_{L^2(\mathbb{R})}}.\end{aligned}$$

If we combine this result with (26) and let $M\to\infty$, then we get

$$\text{(27)}\qquad \frac{1}{C}\left(\|P_0f\|^2_{L^2(\mathbb{R})}+\sum_{m=0}^{\infty}4^{mt}\|Q_mf\|^2_{L^2(\mathbb{R})}\right)\le\|f\|^2_{\mathcal{H}^t(\mathbb{R})},\qquad t\in[-s,s].$$

To complete the proof, let $P_{0,k}$ and $Q_{m,k}$ be the orthogonal (in $L^2(\mathbb{R};\mathbb{C})$) projections onto the spaces spanned by $\varphi(\bullet-k)$ and $\psi(2^m\bullet-k)$, respectively. By the orthogonality of the projections and the fact that $P_{m+1}=P_m+Q_m$ (see [11, p. 31]) we have

$$\text{(28)}\qquad \begin{aligned}\|P_0f\|^2_{L^2(\mathbb{R})}&=\sum_{k\in\mathbb{Z}}\|P_{0,k}f\|^2_{L^2(\mathbb{R})}=\sum_{m=-\infty}^{-1}\sum_{k\in\mathbb{Z}}\|Q_{m,k}f\|^2_{L^2(\mathbb{R})},\\ \|Q_mf\|^2_{L^2(\mathbb{R})}&=\sum_{k\in\mathbb{Z}}\|Q_{m,k}f\|^2_{L^2(\mathbb{R})}.\end{aligned}$$

Since $P_{0,k}f=\langle f,\varphi(\bullet-k)\rangle\varphi(\bullet-k)$ and $Q_{m,k}f=2^m\langle f,\psi(2^m\bullet-k)\rangle\psi(2^m\bullet-k)$, we get the desired conclusion in the case $m_0=0$ from (25), (27), (28), and [10, Thm. 7.1].

If $m_0\neq 0$, we can use essentially the same argument as in the case where $m_0=0$. This completes the proof. □

LEAST SQUARES APPROXIMATION BY RADIAL FUNCTIONS*

E. QUAK[†], N. SIVAKUMAR[†], AND J. D. WARD[†][‡]

This paper is dedicated to the memory of Professor Lothar Collatz.

Abstract. This paper is concerned with the study of continuous least squares approximation on a bounded domain in $\mathbb{R}^s$ by certain classes of radial functions. The approximating subspace is spanned by translates $F(\cdot - x_j)$ of a given radial function F, where the (distinct) "centers" $\{x_j\}_{j=1}^N$ are allowed to be scattered. The main result gives quantitative estimates for the Euclidean norms of the inverses of these least squares matrices. In general, the estimates involve the dimension of the ambient space, the minimal separation distance between the centers, the number of centers, and of course the function itself. However, if F is the scaled Gaussian, it is possible to dispense with the dependence on the number of centers. Also established along the way are results involving radial interpolation matrices where the interpolation points are small perturbations of the centers. These results are perhaps of independent interest as previous interpolation results had been obtained only for interpolation at the centers.

Key words. conditionally negative definite, completely monotone, interpolation, least squares, radial

1. Introduction.

The purpose of this paper is to investigate the problem of continuous least squares approximation by translates of radial functions from certain classes. Let F denote a radial function on $\mathbb{R}^s$ and $X := \{x_i\}_{i=1}^N$ a set of distinct points (called centers) in a bounded, closed domain $\Omega \subset \mathbb{R}^s$. Define $h_i(x) := F(x - x_i)$ and $S_X :=$ span$\{h_i\colon 1 \le i \le N\}$. In recent years, considerable attention has been paid to the problem of interpolation from the space S_X, i.e., finding suitable classes of radial functions F, so that for given data $d_1, \ldots, d_N \in \mathbb{R}$, there exists a unique function $h \in S_X$ satisfying the interpolation conditions $h(x_i) = d_i$, $i = 1, \ldots, N$; or, equivalently, the interpolation matrix $(h_i(x_j))_{i,j=1}^N$ is nonsingular. If F is a conditionally positive definite radial function of order zero or a conditionally negative radial function of order one (see §2 for the appropriate definitions), then it is known that the associated interpolation matrix is invertible [M], [MN], [S1]. Quantitative estimates for the Euclidean norms of the inverses of these matrices have been derived in [B], [NW1], [NW2], [Su2], [Ba].

One consequence of the invertibility of the aforementioned interpolation matrix is the linear independence of the functions h_i, i.e., the space S_X is N-dimensional. Our aim in this paper is to study certain aspects of the problem of continuous least squares approximation from the space S_X, where the underlying radial function F belongs to either of the two classes mentioned above.

More precisely, we are interested in the following issue: let $X = \{x_1, \ldots, x_N\}$ be a set of centers such that the minimal separation distance $2q := \min_{j \ne \ell} \|x_j - x_\ell\| > 0$. We call a closed and bounded domain $\Omega \subset \mathbb{R}^s$ *admissible with respect to X*, if for

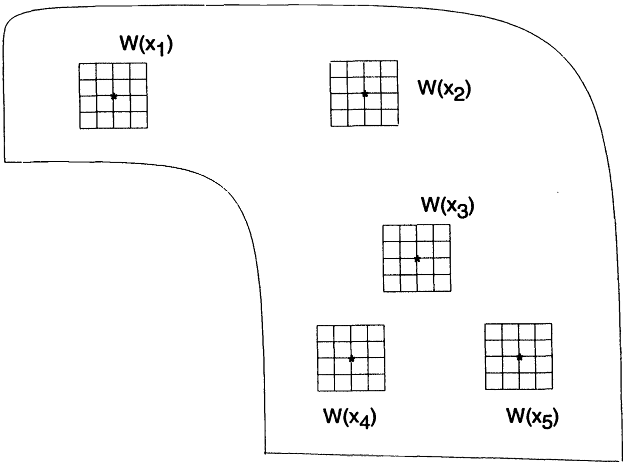

FIG. 1

each x_i, the s-dimensional cube $W(x_i)$ centered at x_i, and with side length $2qs^{-1/2}$, is contained in Ω (see Fig. 1).

Suppose that $f \in C(\Omega)$. The coefficients (with respect to the basis $\{h_i\}$) of the best least squares approximant to f from S_X are the components of the solution vector α to the matrix equation $A_X\alpha = z$, where A_X is the $N \times N$ matrix whose (i,j)th entry is $\langle h_i, h_j\rangle$, with $\langle\ ,\ \rangle$ being the standard inner product on $L^2(\Omega)$. The components of the N-vector z are $\langle h_i, f\rangle$, $i = 1,\dots,N$ (see, for instance, [de B], [C]). The primary intent of this paper (Theorem 4.6, Corollary 4.7, Propositions 4.8, and 4.10) is to give quantitative estimates for $\|A_X^{-1}\|_2$, i.e., the Euclidean norm of the inverse of the matrix A_X for continuous least squares approximation over admissible domains and associated with conditionally positive definite radial functions of order zero and conditionally negative definite radial functions of order one.

The present paper is restricted to the continuous least squares problem because its theoretical aspects are more tractable than those of its discrete counterpart. Yet, it is our belief that the basic principles of our arguments (notably the approach outlined in the following paragraph) carry over to the case of discrete least squares approximation. Thus, our paper could serve as a preliminary step towards the eventual treatment of the discrete problem.

Our approach here is to relate the problem of continuous least squares approximation from S_X to that of interpolation from S_X. However, this interpolation problem is not the standard one mentioned earlier (i.e., where the centers and the interpolation points coincide), but rather one where the interpolation points are small perturbations of the centers. Our results pertaining to this latter interpolation problem (e.g., Theorem 3.2, Theorem 3.6, and Proposition 3.11), though auxiliary for our purposes here, are, in fact, new and may also be of some independent interest.

In general, the estimates we obtain for $\|A_X^{-1}\|_2$ depend on the dimension s of the underlying space, the minimal separation distance $2q$ between the centers, the number of centers N, and of course the function F itself. The only restriction placed on Ω is that it be admissible with respect to the given set X of centers. As is to be expected, specific information regarding the roles of q and N can only be ascertained by a case by case analysis of the various radial functions of interest. However, our methods are sufficiently general in scope to allow readers to carry out such a careful analysis for functions of their choice. For our part, we have chosen four functions for purposes of illustration: the "absolute value" function, the Hardy multiquadric, the inverse multiquadric and the scaled Gaussian. It is shown (Proposition 4.8) that for the first three functions, the influence of N on the estimates for $\|A_X^{-1}\|_2$ is of at most polynomial growth, whereas the influence of the minimal separation distance essentially stems from the role of q in the interpolation problem described in the previous paragraph. On the other hand, the Gaussian differs from the other three functions in that it is possible to bound the corresponding $\|A_X^{-1}\|_2$ by a quantity independent of N (Proposition 4.10).

With regard to the conditioning of the least squares matrices considered in this paper, the crucial parameters that govern our estimates are the number of centers N and the separation parameter q. Usually, in many applications of least squares approximation, the number N is kept relatively small. Therefore, the negative impact of N, if any, on the conditioning should not be too severe (in the case of the scaled Gaussian, the number N plays no role at all). As we reduce questions concerning least squares to those involving interpolation, it stands to reason that our estimates for least squares reflect the good (or bad) behaviour of the corresponding interpolation matrices. It turns out that these matrices are very sensitive to the separation parameter q. However, the least squares problem allows us the freedom of choosing the centers in an appropriate fashion; e.g., in certain instances, it may be possible to keep the minimal separation distance quite large (especially when N is reasonably small). Furthermore, there are also other ways of improving the conditioning of the least squares problem. Often, the radial functions in question offer additional parameters (whose influence can be clearly quantified) that can be used to counter the effects of small separation distances, e.g., the constant c in the Hardy multiquadric or the scaling parameter in the Gaussian. A judicious choice of these parameters effectively leads to a new basis which, while being significantly better conditioned than the old one, can still be analyzed along the same lines as the original basis itself (Remarks 4.9(ii) and 4.11).

Certain important aspects of least squares approximation are not addressed in this paper. In particular, we do not discuss the rate of approximation as the dimension N of the approximating subspace S_X increases. Results of this nature have been obtained recently in [BDR].

We close this section with an outline of the paper: in §2, we discuss necessary preliminaries concerning conditionally negative (positive) definite radial functions. The third section, which is rather technical in nature, deals with the issue of obtaining estimates for certain interpolation matrices where the interpolation points and centers do not coincide. The main results are presented in §4. The paper concludes with §5 where sharper results are obtained in some specific instances. The optimality of one such estimate is also demonstrated therein.

2. Background and preliminaries.

We begin with a discussion of a class of functions which is well known for its multivariate interpolation properties [D], [GV], [P].

DEFINITION 2.1. A continuous function F: $\mathbb{R}^s \to \mathbb{C}$ is said to be conditionally negative (positive) definite of order m if for every finite set $\{x_j\}_{j=1}^N$ of distinct points in $\mathbb{R}^s$, and for every set of complex numbers $\{c_j\}_{j=1}^N$ satisfying

$$\sum_{j=1}^{N} c_j q(x_j) = 0$$

for every $q \in \Pi_{m-1}$ (the space of s-variate polynomials of total degree at most $m-1$), we have

$$\sum_{j,k=1}^{N} \bar{c}_j c_k F(x_j - x_k) \le 0 \qquad (\ge 0).$$

This class of conditionally negative (positive) definite functions of order m (on $\mathbb{R}^s$) will be denoted by $N_m^s(P_m^s)$.

DEFINITION 2.2. A continuous function g: $\mathbb{R}^+ \to \mathbb{R}$ is said to be a conditionally negative (positive) definite *radial* function of order m if $g \circ (\|\cdot\|)$ is in $N_m^s(P_m^s)$. (Henceforth, $\|\cdot\|$ will denote the standard Euclidean (ℓ_2) norm in $\mathbb{R}^s$.) We denote the set of all such functions by $RN_m^s(RP_m^s)$. The class RN_m^s includes those functions g which are continuous on $[0,\infty)$ and for which $(-1)^{m+1}d^m/d\sigma^m g(\sqrt{\sigma})$ is completely monotonic on $(0,\infty)$; i.e.,

$$(-1)^{m+1}\frac{d^m}{d\sigma^m} g(\sqrt{\sigma}) = \int_0^\infty e^{-\sigma t} d\mu(t),$$

where $d\mu(t)$ is some nonnegative measure on $[0,\infty)$. This latter class of functions is denoted by RN_m^∞. We also define the class RP_m^∞ by requiring that f belong to RP_m^∞ precisely when $-f$ belongs to RN_m^∞. Now suppose that F: $\mathbb{R}^s \to \mathbb{R}$ is continuous and that it is *radially symmetric*, i.e., $F(x) = F(y)$ if $\|x\| = \|y\|$, x, $y \in \mathbb{R}^s$. It is clear that F may be identified with the following function g_F: $\mathbb{R}^+ \to \mathbb{R}$, given by

$$g_F(r) = F(x), \quad \text{where } \|x\| = r.$$

Consequently, we will indulge in a slight abuse of notation and say that a function F: $\mathbb{R}^s \to \mathbb{R}$ belongs to $RN_m^\infty(RP_m^\infty)$ if F is continuous, radially symmetric, and its associated function g_F (as defined above) is in $RN_m^\infty(RP_m^\infty)$. Our emphasis in this paper will be on functions F: $\mathbb{R}^s \to \mathbb{R}$ that belong to RP_0^∞ or RN_1^∞. Although this may seem quite specialized, these two cases indeed cover many of the radial functions of interest [P]. Functions in RP_0^∞ and RN_1^∞ possess useful representations which we intend to exploit. Indeed, if $F \in RP_0^\infty$, then [S2]

$$F(x) = \int_0^\infty e^{-\|x\|^2 t} d\mu(t), \qquad x \in \mathbb{R}^s, \tag{2.1}$$

where $d\mu(t)$ is a positive measure satisfying the conditions

$$\int_0^1 d\mu(t) < \infty; \qquad \int_1^\infty e^{-t} d\mu(t) < \infty.$$

On the other hand, if $F \in RN_1^\infty$, then F may be realized as [M], [NW2], [S2], [Sul]

$$F(x) = F(0) + \int_0^\infty \frac{1 - e^{-\|x\|^2 t}}{t} d\mu(t), \qquad x \in \mathbb{R}^s, \tag{2.2}$$

where $d\mu(t)$ is a positive measure such that

$$\int_0^1 d\mu(t) < \infty; \qquad \int_1^\infty \frac{d\mu(t)}{t} < \infty.$$

While the results obtained in this paper are quite general, we wish to intersperse them with certain specific illustrations. For such purposes, we shall use the following four functions: $F_1(x) := \|x\|$, $F_2(x) := (1+\|x\|^2)^{1/2}$, $F_3(x) := (1+\|x\|^2)^{-1/2}$, and $F_4(x) := e^{-\rho\|x\|^2}$ $(\rho > 0)$. It is known that $F_1 \in RN_1^\infty$, and is represented by the measure $d\mu_1(t) := \frac{1}{2}(\pi t)^{-1/2}dt$. The Hardy multiquadric F_2 belongs to RN_1^∞ and has the representing measure $d\mu_2(t) := \frac{1}{2}e^{-t}(\pi t)^{-1/2}dt$. Both the inverse multiquadric F_3 and the scaled Gaussian F_4 belong to RP_0^∞; while F_3 is represented by the measure $2d\mu_2(t)$, the measure $d\mu_4(t) := \delta(t-\rho)dt$ (i.e., point evaluation at ρ) represents F_4. The reader, if pressed to do so, will no doubt be able to carry out similar analyses for other radial functions as well.

3. Concerning some quadratic forms. In the following, we assume that we are given two sequences, $\{x_j\}_{j=1}^N$, $\{y_j\}_{j=1}^N$, of points in $\mathbb{R}^s$ such that

$$(3.1)\qquad \begin{array}{ll} \text{(i)} & x_j \neq x_\ell, y_j \neq y_\ell \quad \text{for } j \neq \ell,\ 1 \le j,\ \ell \le N, \\ \text{(ii)} & x_j - y_j = d \in \mathbb{R}^s\backslash\{0\} \quad \text{for } 1 \le j \le N. \end{array}$$

Definition 3.1. Let F: $\mathbb{R}^s \to \mathbb{R}$, $F \in RP_0^\infty$ or RN_1^∞, and set $A(F)$ to be the $N \times N$ matrix given by

$$(3.2)\qquad A(F) := \{F(y_j - x_\ell)\}_{j,\ell=1}^N.$$

Furthermore, let

$$(3.3)\qquad \begin{aligned} A_1(F) &:= \frac{A(F)+A(F)^T}{2}, \\ A_2(F) &:= \frac{A(F)-A(F)^T}{2}, \end{aligned}$$

and

$$U_N := \left\{ \alpha = (\alpha_1, \alpha_2, \dots, \alpha_N) \in \mathbb{R}^N : \quad \sum_{j=1}^N \alpha_j = 0 \right\}.$$

The primary focus of interest in this section is the quadratic form $\langle A_1(F)\alpha, \alpha\rangle$, $\alpha \in \mathbb{R}^N$, associated with F in RP_0^∞ and RN_1^∞. (Throughout this paper, our matrices will act on real vectors only.) We denote this quadratic form by $Q_0(F)$ if $F \in RP_0^\infty$, and by $Q_1(F)$ if $F \in RN_1^\infty$. The analysis of $Q_0(F)$ and $Q_1(F)$—which will supply us with a useful tool—begins with the following.

Theorem 3.2. *Let $F \in RP_0^\infty$ or RN_1^∞, and let $d\mu$ be its representing measure. Suppose that $\alpha = (\alpha_1, \dots, \alpha_N) \in \mathbb{R}^N$ and that $Q_0(F)$ and $Q_1(F)$ are defined as above. Then for $m = 0, 1$, the following holds:*

$$\begin{aligned} Q_m(F) &= \sum_{j,\ell=1}^N \alpha_j\alpha_\ell F(x_j - x_\ell) \\ &- \frac{2(-1)^m}{(2\pi)^s}\int_0^\infty \frac{1}{t^{s/2+m}}\int_{\mathbb{R}^s} e^{-\|u\|^2/4t}\sin^2\left(\frac{u\cdot d}{2}\right)\left|\sum_{j=1}^N \alpha_j e^{ix_j\cdot u}\right|^2 du\,d\mu(t) \\ &=: I(\mu) - (-1)^m J(\mu, d). \end{aligned}$$

Proof. Let $m = 0$ or 1. From Definition 3.1,

$$
\begin{aligned}
Q_m(F) &= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \left[\frac{F(y_j - x_\ell) + F(y_\ell - x_j)}{2} \right] \\
&= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell F(x_j - x_\ell) - \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \\
&\quad \times \left[\frac{F(x_j - x_\ell) - F(y_j - x_\ell) + F(x_\ell - x_j) - F(y_\ell - x_j)}{2} \right] \\
&= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell F(x_j - x_\ell) - (-1)^m \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \int_0^\infty \frac{1}{t^m} \\
&\quad \times \left[\frac{e^{-\|x_j - x_\ell\|^2 t} - e^{-\|y_j - x_\ell\|^2 t} + e^{-\|x_\ell - x_j\|^2 t} - e^{-\|y_\ell - x_j\|^2 t}}{2} \right] d\mu(t),
\end{aligned}
\tag{3.4}
$$

where the last step follows from (2.1) and (2.2). Using now the fact that

$$
e^{-\|\xi\|^2 t} = \frac{1}{(2\pi)^s t^{s/2}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4t} e^{-i\xi\cdot u} du, \qquad t > 0, \quad \xi \in \mathbb{R}^s,
$$

(3.1) and (3.4), we see that

$$
\begin{aligned}
Q_m(F) &= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell F(x_j - x_\ell) - \frac{(-1)^m}{(2\pi)^s} \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \int_0^\infty \frac{1}{t^{s/2+m}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4t} \\
&\quad \times \left[\frac{e^{-i(x_j - x_\ell)\cdot u} - e^{-i(x_j - x_\ell - d)\cdot u} + e^{-i(x_\ell - x_j)\cdot u} - e^{-i(x_\ell - x_j - d)\cdot u}}{2} \right] du d\mu(t) \\
&= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell F(x_j - x_\ell) - \frac{(-1)^m}{(2\pi)^s} \int_0^\infty \frac{1}{t^{s/2+m}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4t} \\
&\quad \times \left[\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \left[\frac{e^{-i(x_j - x_\ell)\cdot u}\{1 - e^{id\cdot u}\} + e^{-i(x_\ell - x_j)\cdot u}\{1 - e^{id\cdot u}\}}{2} \right] \right] du d\mu(t) \\
&= \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell F(x_j - x_\ell) \\
&\quad - \frac{(-1)^m}{(2\pi)^s} \int_0^\infty \frac{1}{t^{s/2+m}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4t} \\
&\quad \times \left[\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell e^{-i(x_j - x_\ell)\cdot u} \{1 - e^{id\cdot u}\} \right] du d\mu(t).
\end{aligned}
\tag{3.5}
$$

Since the numbers $Q_m(F)$ and

$$
\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell e^{-i(x_j - x_\ell)\cdot u} = \left| \sum_{j=1}^{N} \alpha_j e^{i x_j \cdot u} \right|^2 = \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \cos[u \cdot (x_j - x_\ell)]
$$

are real, it follows that

$$\begin{aligned} Re &\left[\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell e^{-i(x_j-x_\ell)\cdot u}\{1 - e^{idu}\}\right] \\ &= [1-\cos(d\cdot u)]\left[\sum_{j,\ell=1}^{N} \alpha_j\alpha_\ell e^{-i(x_j-x_\ell)\cdot u}\right] \\ &= 2\sin^2\left(\frac{u\cdot d}{2}\right)\left|\sum_{j=1}^{N}\alpha_j e^{ix_j\cdot u}\right|^2 . \end{aligned}$$

Consequently, we conclude from (3.5) that

$$\begin{aligned} Q_m(F) &= \sum_{j,\ell=1}^{N} \alpha_j\alpha_\ell F(x_j - x_\ell) \\ &- \frac{2(-1)^m}{(2\pi)^s}\int_0^\infty \frac{1}{t^{s/2+m}}\int_{\mathbb{R}^s} e^{-\|u\|^2/4t}\sin^2\left(\frac{u\cdot d}{2}\right)\left|\sum_{j=1}^{N}\alpha_j e^{ix_j\cdot u}\right|^2 du d\mu(t), \end{aligned}$$

as claimed. □

Remark 3.3. The expression $I(\mu)$ given in Theorem 3.2 has been studied in detail in [NW2]. In particular, the following theorem was established there.

THEOREM 3.4. *Let $F \in RP_0^\infty$ or RN_1^∞, and let $d\mu$ be its representing measure. Let $\Gamma(z)$ denote the standard gamma function, $2q = \min_{j\neq\ell}\|x_j - x_\ell\|$,*

$$\delta := 12\left[\frac{\pi\Gamma^2\left(\frac{s+2}{2}\right)}{9}\right]^{1/(s+1)} \quad \text{and} \quad C_s := \frac{\delta^s}{2^{s+1}\Gamma((s+2)/2)}.$$

Then

$$\frac{(-1)^m I(\mu)}{\|\alpha\|^2} \geq \frac{C_s}{q^s}\int_0^\infty \frac{e^{-\delta^2/q^2 t}}{t^{s/2+m}} d\mu(t) =: I'(\mu),$$

where $\alpha = (\alpha_1, \ldots, \alpha_N) \in \mathbb{R}^N\backslash\{0\}$ is arbitrary if $F \in RP_0^\infty (m = 0)$ and belongs to U_N if $F \in RN_1^\infty (m = 1)$.

Remark 3.5. (i) Suppose that $J(\mu, d)$ is given by Theorem 3.2. Since

$$\left|\sum_{j=1}^{N}\alpha_j e^{iu\cdot x_j}\right|^2 = \sum_{j,\ell=1}^{N}\alpha_j\alpha_\ell\cos[u\cdot(x_j - x_\ell)] \leq N\|\alpha\|^2, \qquad \alpha \in \mathbb{R}^N,$$

we see that

$$\begin{aligned} 0 \leq J(\mu, d) &\leq N\|\alpha\|^2\left[\frac{2}{(2\pi)^s}\int_{\mathbb{R}^s}\sin^2\left(\frac{u\cdot d}{2}\right)\left[\int_0^\infty \frac{e^{-\|u\|^2/4t}}{t^{s/2+m}} d\mu(t)\right] du\right] \\ &=: N\|\alpha\|^2\tilde{J}(\mu, d). \end{aligned}$$

(ii) In certain specific cases, it is possible to estimate $J(\mu, d)/\|\alpha\|^2$ from above by a quantity independent of N (see Proposition 3.11 and also §5).

THEOREM 3.6. *Let $F \in RP_0^\infty$ or RN_1^∞, and let $d\mu$ be its representing measure. Suppose that $F(0) \geq 0$ if $F \in RN_1^\infty$ and that $I'(\mu) > N\widetilde{J}(\mu, d)$. Then*

$$\|A_1(F)\alpha\| \geq [I'(\mu) - N\widetilde{J}(\mu, d)]\|\alpha\|, \qquad \alpha \in \mathbb{R}^N.$$

Proof. If $F \in RP_0^\infty$, then on the one hand, Theorems 3.2 and 3.4 and Remark 3.5 show that

$$\langle A_1(F)\alpha, \alpha\rangle \geq [I'(\mu) - N\widetilde{J}(\mu, d)]\|\alpha\|^2, \qquad \alpha \in \mathbb{R}^N.$$

On the other hand, $\langle A_1(F)\alpha, \alpha\rangle \leq \|A_1(F)\alpha\|\|\alpha\|$ by the Cauchy–Schwarz inequality. The desired result is now immediate.

Suppose now that $F \in RN_1^\infty$ and $\alpha \in U_N$. Using Theorems 3.2 and 3.4 and Remark 3.5 once again, we deduce that

$$\begin{aligned} -\langle A_1(F)\alpha, \alpha\rangle &= -I(\mu) - J(\mu, d) \\ &\geq [I'(\mu) - N\widetilde{J}(\mu, d)]\|\alpha\|^2, \qquad \alpha \in U_N. \end{aligned}$$

This guarantees that $A_1(F)$ has $N-1$ negative eigenvalues while the condition $F(0) \geq 0$ and (2.2) ensure that the trace of $A_1(F)$ is nonnegative. Thus $A_1(F)$ is conditionally negative definite and the required result now follows from [B]. □

We now turn to some specific illustrations involving the functions F_i, $1 \leq i \leq 4$.

PROPOSITION 3.7. *Let F be one of the functions F_i, $i = 1, 2, 3, 4$, and denote the corresponding expressions $I(\mu)$ by I_i, $1 \leq i \leq 4$, respectively. Suppose that $\alpha = (\alpha_1, \ldots, \alpha_N) \in R^N\backslash\{0\}$ is subject to the restriction that $\alpha \in U_N$ if $i = 1, 2$, but is arbitrary if $i = 3, 4$. Then the following estimates hold:*

(i) $-I_1/\|\alpha\|^2 \geq (C_s\Gamma((s+1)/2)/2\delta^{s+1}\sqrt{\pi})q =: I_1'$;

(ii) $-I_2/\|\alpha\|^2 \geq (C_s/2\delta^{(s+3)/2})(e^{-2\delta/q}/q^{(s-3)/2}\sqrt{\pi}) =: I_2'$;

(iii) *If* $q < 1$, *then* $I_3/\|\alpha\|^2 \geq (C_s/\delta^{(s+1)/2}\sqrt{\pi})a^{(s-3)/2}[1-e^{-a\delta}]\, e^{-\frac{\delta}{q}(1/a+a)}/q^{(s-1)/2}$ $=: I_3'$, *where a is an absolute constant for which $\delta > 2a$;*

(iv) $I_4/\|\alpha\|^2 \geq C_s e^{-\delta^2/(q^2\rho)}/q^s\rho^{s/2} =: I_4'$.

Proof. (i) Recall that $d\mu_1(t) = \frac{1}{2}(\pi t)^{-1/2}dt$. Using this in Theorem 3.4, we obtain

$$\begin{aligned} \frac{-I_1}{\|\alpha\|^2} &\geq \frac{C_s}{2q^s\sqrt{\pi}} \int_0^\infty \frac{e^{-\delta^2/q^2t}}{t^{(s+3)/2}}dt \\ &= C_s\frac{q}{2\sqrt{\pi}} \int_0^\infty e^{-\delta^2 u}u^{(s-1)/2}du \quad \left(\text{where } u = \frac{1}{q^2t}\right) \\ &= \frac{C_s\Gamma((s+1)/2)\,q}{2\delta^{s+1}\sqrt{\pi}}. \end{aligned}$$

(ii) By Theorem 3.4, and the fact that $d\mu_2(t) = \frac{1}{2}(\pi t)^{-1/2}e^{-t}dt$,

$$\frac{-I_2}{\|\alpha\|^2} \geq \frac{C_s}{2q^s\sqrt{\pi}} \int_0^\infty \frac{e^{-\delta^2/q^2t}e^{-t}}{t^{(s+3)/2}}dt$$

$$= \frac{C_s q}{2\sqrt{\pi}} \int\limits_0^\infty e^{-\delta^2 u} e^{-1/q^2 u} u^{(s-1)/2} du \qquad \left(\text{by setting } u = \frac{1}{q^2 t}\right)$$

$$\geq \frac{C_s q}{2\sqrt{\pi}} \int\limits_{1/\delta q}^\infty e^{-\delta^2 u} e^{-1/q^2 u} u^{(s-1)/2} du$$

$$\geq \frac{C_s q e^{-\delta/q}}{2(\delta q)^{(s-1)/2}\sqrt{\pi}} \int\limits_{1/\delta q}^\infty e^{-\delta^2 u} du$$

(as $u \mapsto u^{(s-1)/2}$ and $u \mapsto e^{-1/q^2 u}$ are increasing functions)

$$= \frac{C_s}{2\delta^{(s+3)/2}\sqrt{\pi}} \frac{e^{-2\delta/q}}{q^{(s-3)/2}}.$$

(iii) By Stirling's formula, $\lim_{s\to\infty} \delta/(s+2) = 6/e$, so there exists a positive absolute constant a such that $\delta > 2a$. Now, since $d\mu_3(t) = (\pi t)^{-1/2} e^{-t} dt$ and $m = 0$, we get

$$\frac{I_3}{\|\alpha\|^2} \geq \frac{C_s}{\sqrt{\pi} q^s} \int\limits_0^\infty e^{-\delta^2/q^2 t} \frac{e^{-t}}{t^{(s+1)/2}} dt$$

$$= \frac{C_s}{\sqrt{\pi} q} \int\limits_0^\infty e^{-\delta^2 u} \frac{e^{-1/q^2 u}}{u} u^{(s-1)/2} du \qquad \left(u = \frac{1}{q^2 t}\right).$$

As the function $u \mapsto (e^{-1/q^2 u})/u$ increases on $[0, 1/q^2]$, and $q < 1$, we see that

$$\frac{I_3}{\|\alpha\|^2} \geq \frac{C_s}{q\sqrt{\pi}} \int\limits_{a/\delta q}^{2a/\delta q} e^{-\delta^2 u} \frac{e^{-1/q^2 u}}{u} u^{(s-1)/2} du$$

$$\geq \frac{C_s}{q\sqrt{\pi}} \frac{\delta q}{a} e^{-\delta/(aq)} \left(\frac{a}{\delta q}\right)^{(s-1)/2} \int\limits_{a/\delta q}^{2a/\delta q} e^{-\delta^2 u} du$$

$$\geq \frac{C_s}{\delta^{(s+1)/2}} \frac{a^{(s-3)/2}}{\sqrt{\pi}} (1 - e^{-\frac{a\delta}{q}}) \frac{e^{-\delta/q((1/a)+a)}}{q^{(s-1)/2}}$$

$$\geq \frac{C_s}{\delta^{(s+1)/2}} \frac{a^{(s-3)/2}}{\sqrt{\pi}} (1 - e^{-a\delta}) \frac{e^{-\delta/q((1/a)+a)}}{q^{(s-1)/2}}.$$

(iv) Recall that $m = 0$ and $d\mu_4(t) = \delta(t - \rho)dt$. So

$$\frac{C_s}{q^s} \int_0^\infty \frac{e^{-\delta^2/q^2 t}}{t^{s/2+m}} d\mu_4(t) = \frac{C_s e^{-\delta^2/(q^2 \rho)}}{q^s \rho^{s/2}}. \qquad \square$$

PROPOSITION 3.8. *Let $\widetilde{F}$ be one of the functions F_i, $1 \leq i \leq 3$, and let the corresponding expressions $\widetilde{J}(\mu, d)$ be denoted by $\widetilde{J}_i$, $1 \leq i \leq 3$. Then the following hold:*

(i) $\widetilde{J}_2, \widetilde{J}_3 \leq \widetilde{J}_1$;

(ii) $\widetilde{J}_1 \leq (2\Gamma((s+1)/2)\,\omega_{s-1}/\pi^{s+1/2})\|d\| =: J'\|d\|$,

where ω_{s-1} denotes the $s-1$-dimensional volume of the unit sphere in $\mathbb{R}^s$.

Proof. (i) $\widetilde{J}_2 \le \widetilde{J}_1$ because $d\mu_2(t) \le d\mu_1(t)$.

Next, observe that

$$\begin{aligned}\widetilde{J}_3 &= \frac{2}{(2\pi)^s}\int_{\mathbb{R}^s} \sin^2\left(\frac{u\cdot d}{2}\right)\left[\frac{1}{\sqrt{\pi}}\int_0^\infty e^{-\|u\|^2/4t}\frac{e^{-t}}{t^{(s+1)/2}}dt\right] du\\ &= \frac{2}{(2\pi)^s}\int_{\mathbb{R}^s} \sin^2\left(\frac{u\cdot d}{2}\right)\left[\frac{1}{\sqrt{\pi}}\int_0^\infty (te^{-t})\frac{e^{-\|u\|^2/4t}}{t^{(s+3)/2}}dt\right] du\\ &\le 2e^{-1}\frac{2}{(2\pi)^s}\int_{\mathbb{R}^s} \sin^2\left(\frac{u\cdot d}{2}\right)\left[\frac{1}{2\sqrt{\pi}}\int_0^\infty \frac{e^{-\|u\|^2/4t}}{t^{(s+3)/2}}dt\right] du\\ &= 2e^{-1}\widetilde{J}_1 < \widetilde{J}_1.\end{aligned}$$

(ii) Employing the substitution $w = 1/4t$ in the expression for $\widetilde{J}_1$ above leads to

$$\begin{aligned}\widetilde{J}_1 &= \frac{2^{s+1}}{(2\pi)^s\sqrt{\pi}}\int_{\mathbb{R}^s} \sin^2\left(\frac{u\cdot d}{2}\right)\left(\int_0^\infty e^{-\|u\|^2 w}w^{(s-1)/2}dw\right) du\\ &= \frac{2}{\pi^{s+1/2}}\Gamma\left(\frac{s+1}{2}\right)\int_{\mathbb{R}^s} \sin^2\left(\frac{u\cdot d}{2}\right)\frac{du}{\|u\|^{s+1}}\\ &\le \frac{2\Gamma\left((s+1)/2\right)}{\pi^{s+1/2}}\left[\frac{1}{4}\int_{\|u\|\le\frac{2}{\|d\|}}\frac{|u\cdot d|^2}{\|u\|^{s+1}}du + \int_{\|u\|>\frac{2}{\|d\|}}\frac{du}{\|u\|^{s+1}}\right]\\ &\le \frac{2\Gamma\left((s+1)/2\right)}{\pi^{s+1/2}}\left[\frac{1}{4}\|d\|^2\int_{\|u\|\le\frac{2}{\|d\|}}\frac{du}{\|u\|^{s-1}} + \int_{\|u\|>\frac{2}{\|d\|}}\frac{du}{\|u\|^{s+1}}\right],\end{aligned}$$

by the Cauchy–Schwarz inequality. Computing each of the two integrals above using polar coordinates, we see that

$$\begin{aligned}\widetilde{J}_1 &\le \frac{2\Gamma\left((s+1)/2\right)}{\pi^{s+1/2}}\left[\frac{1}{4}\|d\|^2\omega_{s-1}\int_0^{2/\|d\|}dr + \omega_{s-1}\int_{2/\|d\|}^\infty\frac{dr}{r^2}\right]\\ &= \frac{2\Gamma\left((s+1)/2\right)}{\pi^{s+1/2}}\omega_{s-1}\left[\frac{\|d\|}{2}+\frac{\|d\|}{2}\right] = \frac{2\Gamma\left((s+1)/2\right)\omega_{s-1}}{\pi^{s+1/2}}\|d\|. \qquad \square\end{aligned}$$

Theorem 3.6, taken in conjunction with Propositions 3.7 and 3.8, yields the following.

COROLLARY 3.9. *Suppose that I_i', $1 \le i \le 3$, and J' are given by Propositions* 3.7 *and* 3.8, *respectively. If $NJ'\|d\| < I_i'$, $1 \le i \le 3$, then*

$$\|A_1(F_i)\alpha\| \ge [I_i' - NJ'\|d\|]\|\alpha\|, \qquad 1 \le i \le 3, \quad \alpha \in \mathbb{R}^N.$$

Remark 3.10. (i) The function $F(x) := \|x\|^{2\beta}$, $x \in \mathbb{R}^s$, $0 < \beta < 1$, belongs to RN_1^∞ and is represented by the measure $d\mu(t) = \beta[\Gamma(1-\beta)]^{-1}t^{-\beta}\,dt$. We can show that the corresponding expressions $\widetilde{I}(\mu)$ and $\widetilde{J}(\mu, d)$ satisfy the following estimates:

$$\widetilde{I}(\mu) \ge \frac{C_s\beta\Gamma\left(\beta+(s/2)\right)}{[\Gamma(1-\beta)]\delta^{2\beta+s}}q^{2\beta} \quad \text{and} \quad \widetilde{J}(\mu,d) \le \frac{\Gamma\left((s+2\beta)/2\right)\omega_{s-1}\|d\|^{2\beta}}{\pi(1-\beta)\Gamma(1-\beta)}.$$

It is evident that the special case $\beta = \frac{1}{2}$ corresponds exactly to the function F_1.

(ii) Let $\widetilde{J}_2$ be given by Proposition 3.8. With a little more effort, we can show that

$$\widetilde{J}_2 \le \begin{cases} \dfrac{\omega_{s-1}}{\pi^s}\left[4\Gamma\left(\dfrac{s+1}{2}\right) + \displaystyle\sum_{j=0}^{p} \frac{p!}{j!}\Gamma(j+1)\right] \|d\|^2 & \text{if } s = 2p+1; \\ \dfrac{\omega_{s-1}}{\pi^s}\left[4\Gamma\left(\dfrac{s+1}{2}\right) + \displaystyle\sum_{j=0}^{p} \frac{p!}{j!}\Gamma\left(j+\frac{1}{2}\right)\right] \|d\|^2 & \text{if } s = 2p. \end{cases}$$

For future reference, we abbreviate this estimate by $\widetilde{J}_2 \le J''\|d\|^2$.

The next result deals with the Gaussian F_4; it pursues a somewhat different tack leading to a lower estimate for $\|A_1(F_4)\alpha\|$ that does not involve N.

PROPOSITION 3.11. *Suppose that I_4' is given by Proposition* 3.7 *and that $\alpha \in \mathbb{R}^N$. If $\|d\| \le q$, then*

$$\|A_1(F_4)\alpha\| \ge [I_4' - D_s(\rho, q)\|d\|]\, \|\alpha\|,$$

where

$$D_s(\rho, q) := \pi^{-s}\rho q \left[1 + 6s \sum_{n=0}^{\infty} (n+3)^s e^{-\rho n^2 q^2}\right].$$

Proof. As before, in view of the Cauchy–Schwarz inequality, it suffices to prove that

$$\langle A_1(F_4)\alpha, \alpha\rangle \ge [I_4' - D_s(\rho, q)\|d\|]\, \|\alpha\|^2.$$

Since $m = 0$ and $d\mu_4(t) = \delta(t-\rho)dt$, Theorem 3.2 implies

$$\begin{aligned} \langle A_1(F_4)\alpha, \alpha\rangle &= I_4 - \frac{2}{(2\pi)^s \rho^{s/2}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4\rho} \sin^2\left(\frac{u\cdot d}{2}\right) \left|\sum_{j=1}^{N} \alpha_j e^{ix_j\cdot u}\right|^2 du \\ &=: I_4 - J_4. \end{aligned} \tag{3.6}$$

By Proposition 3.7 (iv),

$$I_4 \ge I_4'\|\alpha\|^2. \tag{3.7}$$

So it remains to show that

$$|J_4| \le D_s(\rho, q)\|d\|\, \|\alpha\|^2. \tag{3.8}$$

To this end, we write

$$\begin{aligned} J_4 &= \frac{2}{(2\pi)^s \rho^{s/2}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4\rho} \sin^2\left(\frac{u\cdot d}{2}\right) \left[\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell e^{-i(x_j - x_\ell)\cdot u}\right] du \\ &= 2\sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \frac{1}{(2\pi)^s \rho^{s/2}} \int_{\mathbb{R}^s} e^{-\|u\|^2/4\rho} \sin^2\left(\frac{u\cdot d}{2}\right) e^{-i(x_j - x_\ell)\cdot u} du \qquad (3.9) \\ &= \frac{2}{\pi^s} \sum_{j,\ell=1}^{N} \alpha_j \alpha_\ell \frac{1}{(2\pi)^s} \int_{\mathbb{R}^s} \widehat{F_4}(u) \sin^2\left(\frac{u\cdot d}{2}\right) e^{i(x_\ell - x_j)\cdot u} du. \end{aligned}$$

Let

$$\Delta_d F_4(x) := F_4(x+d) - 2F_4(x) + F_4(x-d).$$

It is quite straightforward to verify that

$$(\widehat{\Delta_d F_4})(u) = -4\widehat{F_4}(u)\sin^2\left(\frac{u\cdot d}{2}\right);$$

so from (3.9),

$$\begin{aligned} J_4 &= -\frac{1}{2\pi^s}\sum_{j,\ell=1}^{N}\alpha_j\alpha_\ell\frac{1}{(2\pi)^s}\int_{\mathbb{R}^s}(\widehat{\Delta_d F_4})(u)e^{i(x_\ell-x_j)\cdot u}du \\ &= -\frac{1}{2\pi^s}\sum_{j,\ell=1}^{N}\alpha_j\alpha_\ell(\Delta_d F_4)(x_\ell-x_j), \\ &= -\frac{1}{2\pi^s}\left[\sum_{j=1}^{N}|\alpha_j|^2(\Delta_d F_4)(0) + \sum_{\substack{j,\ell=1\\ j\neq\ell}}^{N}\alpha_j\alpha_\ell(\Delta_d F_4)(x_\ell-x_j)\right], \end{aligned}$$

whence

$$\begin{aligned} |J_4| &\le \frac{1}{2\pi^s}\left[\sum_{j=1}^{N}|\alpha_j|^2|(\Delta_d F_4)(0)| + \sum_{j,\ell=1}^{N}{}'|\alpha_j\alpha_\ell||(\Delta_d F_4)(x_\ell-x_j)|\right] \\ &=: \frac{1}{2\pi^s}[S_1+S_2], \end{aligned} \tag{3.10}$$

where $\sum'$ in the penultimate line indicates that $j\neq\ell$ in that sum. In order to estimate S_1, note that

$$|(\Delta_d F_4)(0)| = 2|1-e^{-\rho\|d\|^2}| \le 2\rho\|d\|^2,$$

so

$$S_1 \le 2\rho\|d\|^2\|\alpha\|^2. \tag{3.11}$$

We now take up S_2: observe that

$$\begin{aligned} S_2 &\le \sum_{j,\ell=1}^{N}{}'\frac{|\alpha_j|^2+|\alpha_\ell|^2}{2}|\Delta_d F_4(x_\ell-x_j)| \\ &\le \max\{\gamma_N,\tilde{\gamma}_N\}\|\alpha\|^2, \end{aligned} \tag{3.12}$$

where

$$\gamma_N := \max_j\sum_{\ell=1}^{N}{}'|(\Delta_d F_4)(x_\ell-x_j)| \quad\text{and}\quad \tilde{\gamma}_N := \max_\ell\sum_{j=1}^{N}{}'|(\Delta_d F_4)(x_\ell-x_j)|.$$

Let j_0 and ℓ_0 be the indices where the maximum values of γ_N and $\tilde{\gamma}_N$ are attained, respectively, and suppose that $y\in\mathbb{R}^s$ with $\|y\|>\|d\|$. Plainly,

$$\begin{aligned}|(\Delta_d F_4)(y)| &= \left|e^{-\rho\|y\|^2} - e^{-\rho\|y-d\|^2} + e^{-\rho\|y\|^2} - e^{-\rho\|y+d\|^2}\right| \\ &\le \left|e^{-\rho\|y\|^2} - e^{-\rho\|y-d\|^2}\right| + \left|e^{-\rho\|y\|^2} - e^{-\rho\|y+d\|^2}\right|.\end{aligned}$$

By the Mean Value Theorem,

$$\begin{aligned}\left|e^{-\rho\|y\|^2} - e^{-\rho\|y-d\|^2}\right| &\le \big|\,\|y\| - \|y-d\|\,\big|\,2\rho\max\{\|y\|, \|y-d\|\}e^{-\rho[\min\{\|y\|,\|y-d\|\}]^2} \\ &\le \|d\|2\rho[\|y\| + \|d\|]e^{-\rho[\|y\|-\|d\|]^2}\end{aligned}$$

and

$$\left|e^{-\rho\|y\|^2} - e^{-\rho\|y+d\|^2}\right| \le \|d\|2\rho[\|y\| + \|d\|]e^{-\rho[\|y\|-\|d\|]^2}.$$

Therefore,

$$\gamma_N = \sum_{\substack{\ell=1\\ \ell\neq j_0}}^{N} |(\Delta_d F_4)(x_\ell - x_{j_0})| \le 4\rho\|d\| \sum_{\substack{\ell=1\\ \ell\neq j_0}}^{N} [\|x_\ell - x_{j_0}\| + \|d\|]e^{-\rho[\|x_\ell - x_{j_0}\|-\|d\|]^2}.$$

Adapting at this stage an argument from [NW1, pp. 79–80] and noting that $\|x_\ell - x_{j_0}\| \ge 2q > \|d\|$, we conclude from the above that

$$\gamma_N \le 12s\rho\|d\| \sum_{n=1}^{\infty}(n+2)^{s-1}\kappa_n,$$

where

$$\begin{aligned}\kappa_n &:= \sup\{[\|y\| + \|d\|]e^{-\rho[\|y\|-\|d\|]^2}; nq \le \|y\| \le (n+1)q\} \\ &\le [(n+1)q + \|d\|]e^{-\rho[nq-\|d\|]^2} \le (n+2)qe^{-\rho(n-1)^2q^2}.\end{aligned}$$

Consequently,

$$\begin{aligned}\gamma_N &\le 12s\rho\|d\|q\sum_{n=1}^{\infty}(n+2)^s e^{-\rho(n-1)^2q^2} \\ &= 12s\rho\|d\|q\sum_{n=0}^{\infty}(n+3)^s e^{-\rho n^2q^2}.\end{aligned} \tag{3.13}$$

The same argument also shows

$$\tilde{\gamma}_N \le 12s\rho\|d\|q\sum_{n=0}^{\infty}(n+3)^s e^{-\rho n^2q^2}. \tag{3.14}$$

Thus, from (3.12), (3.13), and (3.14), it follows that

$$S_2 \le 12s\rho q\|d\|\ \|\alpha\|^2\sum_{n=0}^{\infty}(n+3)^s e^{-\rho n^2q^2}. \tag{3.15}$$

Finally, from (3.10), (3.11), and (3.15), we may conclude that

$$\begin{aligned}|J_4| &\leq \frac{1}{2\pi^s}\left[2\rho q\|d\| + 12s\rho q\|d\|\sum_{n=0}^{\infty}(n+3)^s e^{-\rho n^2 q^2}\right]\|\alpha\|^2\\ &\leq D_s(\rho, q)\|d\|\ \|\alpha\|^2,\end{aligned}$$

thereby completing the proof. □

It is natural to ask whether the procedure adopted in the preceding proposition can be adapted to other comparable situations. It turns out that while the method itself can be extended to certain other situations, it may not always yield better results. To convey a general idea of the matter, let us suppose that $\alpha \in U_N$, $F \in RN_1^\infty$, and that its representing measure is $d\mu$. Then, under fairly mild conditions on F—conditions that do not preclude any of the commonly used functions—it is shown in [Ba] that the generalized Fourier transform $\widehat{F}$ of F is given by

$$\widehat{F}(u) = -K_s\int_0^\infty e^{-\|u\|^2/4t}\frac{d\mu(t)}{t^{s/2+1}}, \qquad u \in \mathbb{R}^s\backslash\{0\}.$$

(Hereafter, K_s will denote a generic constant that depends on s but whose actual numerical value is likely to change from one appearance to another.) Consequently,

$$\begin{aligned}J(\mu, d) &= -K_s\int_{\mathbb{R}^s}\sin^2\left(\frac{u\cdot d}{2}\right)\left|\sum_{j=1}^{N}\alpha_j e^{iu\cdot x_j}\right|^2\widehat{F}(u)du\\ &= K_s\int_{\mathbb{R}^s}(\Delta_d(F(\cdot)))^\wedge(u)\left|\sum_{j=1}^{N}\alpha_j e^{iu\cdot x_j}\right|^2 du,\end{aligned}$$

where, as before, $\Delta_d F(x) = F(x+d) + F(x-d) - 2F(x)$. Again, from [Ba] (noting that if F satisfies the mild conditions mentioned above, then so does $\Delta_d F$), we see that

$$\begin{aligned}J(\mu, d) &= K_s\sum_{j,\ell=1}^{N}\alpha_j\alpha_\ell\Delta_d F(x_j - x_\ell)\\ &= K_s\|\alpha\|^2[F(d) - F(0)] + K_s\sum_{j\neq\ell}\alpha_j\alpha_\ell\Delta_d F(x_j - x_\ell).\end{aligned}$$

The packing argument from [NW1, p. 79] (as employed in Proposition 3.11) once again leads to

$$|J(\mu, d)| \leq K_s\|\alpha\|^2\left[|F(d) - F(0)| + \sum_{n=1}^{\infty}n^{s-1}\kappa_n(d)\right],$$

where $\kappa_n(d) := \sup\{|\Delta_d F(x)|\colon nq \leq \|x\| < (n+1)q\}$. Now, the point is that if we expect to get a good estimate for $J(\mu, d)$ in terms of a quantity that is independent of N and which approaches zero along with $\|d\|$, then $\kappa_n(d)$ should be very well behaved. Indeed, this does happen for the Gaussian and possibly other functions which decay sufficiently rapidly at infinity. However, $\kappa_n(d)$ may not always exhibit such desirable behaviour; in fact, even for $s = 2$ and $F = F_1$, the rate of decay of $\kappa_n(d)$ is not rapid enough to suit our purposes.

4. Main results. Let $X = \{x_1, \ldots, x_N\}$ be a set of distinct centers and $2q = \min_{j \neq \ell} \|x_j - x_\ell\|$. For each center x_i, recall that $W(x_i)$ is the s-dimensional cube centered at x_i and with side length $2qs^{-1/2}$, i.e.,

$$W(x_i) := \{x \in \mathbb{R}^s : \ \|x - x_i\|_\infty \leq qs^{-1/2}\},$$

where $\| \ \|_\infty$ denotes the supremum norm in $\mathbb{R}^s$. Note that $\|x - x_i\| \leq q$ for all $x \in W(x_i)$ and, therefore, the cubes $W(x_i)$ are essentially disjoint. Recall also that for the given set X of centers, a closed and bounded domain $\Omega \subset \mathbb{R}^s$ is called admissible with respect to X, if $W(x_i) \subset \Omega$ for all $i = 1, \ldots, N$.

We are interested in the problem of finding the best L^2 approximation to a given $f \in C(\Omega)$, from a linear subspace of functions in $C(\Omega)$. The latter space will be the span of the functions $F(\cdot - x_i)$, where F is an appropriate radial function.

DEFINITION 4.1. Let $F \in RP_0^\infty$ or RN_1^∞, and suppose that Ω is an admissible domain with respect to the set $X = \{x_1, \ldots, x_N\}$ of distinct centers. The N-dimensional linear space $S_X \subset C(\Omega)$ is defined as

$$S_X := \ \text{span}\{F(x - x_i) : 1 \leq i \leq N\}. \tag{4.1}$$

DEFINITION 4.2. For a given function $f \in C(\Omega)$ and the space S_X as in Definition 4.1, the continuous least squares approximation problem is to find the best L_2 approximant to f from S_X, i.e., to find a function $s^* \in S_X$ such that

$$\|f - s^*\| = \inf_{s \in S_X} \|f - s\|.$$

Here $\|f\| = \langle f, f\rangle^{\frac{1}{2}} = \left(\int_\Omega f(x)^2 dx\right)^{\frac{1}{2}}$ is the usual L_2 norm and $\langle f, g\rangle$ is the corresponding inner product $\int_\Omega f(x)g(x)dx$.

As is well known, the best L_2 approximant to $f \in C(\Omega)$ can be found by solving the linear system of the so-called *normal equations*:

$$A_X \alpha = z, \tag{4.2}$$

where $\alpha = (\alpha_i)_{1 \leq i \leq N} \in \mathbb{R}^N$, and A_X is an $N \times N$ matrix with

$$A_X = \left(\langle F(\cdot - x_i), F(\cdot - x_j)\rangle\right)_{1 \leq i,j \leq N} \quad \text{and} \quad z = \left(\langle F(\cdot - x_i), f\rangle\right)_{1 \leq i \leq N}.$$

Our aim is to estimate $\langle A_X \alpha, \alpha\rangle$ from below. We begin with the following.

LEMMA 4.3.

$$\langle A_X \alpha, \alpha\rangle = \left\| \sum_{j=1}^N \alpha_j F(\cdot - x_j) \right\|^2 \geq \sum_{k=1}^N \int_{W(x_k)} \left| \sum_{j=1}^N \alpha_j F(x - x_j) \right|^2 dx.$$

Proof. From the definition of A_X, we obtain

$$\begin{aligned} \langle A_X \alpha, \alpha\rangle &= \sum_{i,j=1}^N \alpha_i \alpha_j \int_\Omega F(x - x_i) F(x - x_j)\, dx \\ &= \int_\Omega \left(\sum_{i=1}^N \alpha_i F(x - x_i)\right) \left(\sum_{j=1}^N \alpha_j F(x - x_j)\right) dx \end{aligned} \tag{4.3}$$

$$
\begin{aligned}
&= \int_\Omega \left| \sum_{j=1}^N \alpha_j F(x - x_j) \right|^2 dx \\
&\geq \int_{\bigcup_{k=1}^N W(x_k)} \left| \sum_{j=1}^N \alpha_j F(x - x_j) \right|^2 dx \\
&= \sum_{k=1}^N \int_{W(x_k)} \left| \sum_{j=1}^N \alpha_j F(x - x_j) \right|^2 dx. \qquad \square
\end{aligned}
$$

We want to express the integral over each cube $W(x_k)$ as the limit of certain Riemann sums whose point evaluations are taken over an equally spaced grid of points in $W(x_k)$. In view of Lemma 4.3, this will ultimately allow us to relate lower bounds on the quadratic form of the least squares matrix to those of certain interpolation matrices.

In what follows, let $\mathbf{i} = (i_1, \dots, i_s) \in \mathbb{Z}_+^s$ be an index vector, and define $\mathbf{e} = (1, 1, \dots, 1)$. By $\mathbf{i} \leq \mathbf{j}$, we mean $i_\ell \leq j_\ell$ for $\ell = 1, \dots, s$.

LEMMA 4.4. *Let X and Ω be as before. If $\alpha \in \mathbb{R}^N$, then*

$$
\langle A_X \alpha, \alpha \rangle \geq \underline{\lim}_{r \to \infty} \frac{2q^s s^{-s/2}}{r^s} \sum_{\substack{-r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e} \\ 0 \leq i_1 \leq r-1}} \|A_1^{(\mathbf{i})}(F)\alpha\|^2,
$$

where

$$
\begin{aligned}
A_1^{(\mathbf{i})}(F) &:= \frac{1}{2}(A^{(\mathbf{i})}(F) + A^{(\mathbf{i})}(F)^T), \\
A^{(\mathbf{i})}(F) &:= (F(y_k^{(\mathbf{i})} - x_j))_{1 \leq k,j \leq N}, \\
y_k^{(\mathbf{i})} &:= x_k + \frac{qs^{-1/2}}{r}\left(\mathbf{i} + \frac{1}{2}\mathbf{e}\right), \qquad -r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e}.
\end{aligned}
$$

Proof. Consider the following equally spaced grid of points:

$$
x_k + \frac{qs^{-1/2}}{r}\mathbf{i} \in W(x_k), \qquad -r\mathbf{e} \leq \mathbf{i} \leq r\mathbf{e},
$$

where $1 \leq k \leq N$ and $r \in \mathbb{N}_+^s$.

As the function F is continuous, the integral (4.3) can be recovered as the limit of Riemann sums. We choose as points of evaluation, the centers of the refined cubes in $W(x_k)$, namely,

$$
y_k^{(\mathbf{i})} := x_k + \frac{qs^{-1/2}}{r}\left(\mathbf{i} + \frac{1}{2}\mathbf{e}\right), \qquad -r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e}.
$$

As the side length of the refined cubes is $qs^{-1/2}r^{-1}$, we obtain

$$
\begin{aligned}
\langle A_X \alpha, \alpha \rangle &\geq \sum_{k=1}^N \underline{\lim}_{r \to \infty} \frac{q^s s^{-s/2}}{r^s} \sum_{-r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e}} \left| \sum_{j=1}^N \alpha_j F(y_k^{(\mathbf{i})} - x_j) \right|^2 \\
&= \underline{\lim}_{r \to \infty} \frac{q^s s^{-s/2}}{r^s} \sum_{-r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e}} \sum_{k=1}^N \left| \sum_{j=1}^N \alpha_j F(y_k^{(\mathbf{i})} - x_j) \right|^2 .
\end{aligned}
$$

A closer inspection of this representation reveals that it involves the matrices

$$A^{(\mathbf{i})}(F) = (F(y_k^{(\mathbf{i})} - x_j))_{1\le k,j\le N},$$

which are $N \times N$ *interpolation* matrices for radial interpolation at the points $y_k^{(\mathbf{i})}$. More precisely,

$$\begin{aligned}\langle A_X\alpha,\alpha\rangle &\ge \underline{\lim}_{r\to\infty}\frac{q^s s^{-s/2}}{r^s}\sum_{-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}}\sum_{k=1}^{N}\left|\sum_{j=1}^{N}\alpha_j F(y_k^{(\mathbf{i})}-x_j)\right|^2\\ &= \underline{\lim}_{r\to\infty}\frac{q^s s^{-s/2}}{r^s}\sum_{-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}}\|A^{(\mathbf{i})}(F)\alpha\|^2.\end{aligned}$$

The interpolation matrices which are (in general) not symmetric can be split up into a symmetric and a skew symmetric part, i.e.,

$$\begin{aligned}A^{(\mathbf{i})}(F) &= A_1^{(\mathbf{i})}(F) + A_2^{(\mathbf{i})}(F), \quad \text{where}\\ A_1^{(\mathbf{i})}(F) &= \frac{(A^{(\mathbf{i})}(F) + A^{(\mathbf{i})}(F)^T)}{2}, \quad \text{and}\\ A_2^{(\mathbf{i})}(F) &= \frac{(A^{(\mathbf{i})}(F) - A^{(\mathbf{i})}(F)^T)}{2}.\end{aligned}$$

Now the matrices $A_1^{(\mathbf{i})}(F)$ and $A_2^{(\mathbf{i})}(F)$ warrant further scrutiny. For any $\mathbf{i}$ with $-r\,\mathbf{e} \le \mathbf{i} \le (r-1)\,\mathbf{e}$, we have from the radiality of F,

$$\begin{aligned}&A_1^{(\mathbf{i})}(F)\\ &= \left(\frac{1}{2}\left(F(y_k^{(\mathbf{i})} - x_j) + F(y_j^{(\mathbf{i})} - x_k)\right)\right)_{1\le j,k\le N}\\ &= \left(\frac{1}{2}\left(F\left(x_k + \frac{qs^{-1/2}}{r}\left(\mathbf{i}+\frac{1}{2}\mathbf{e}\right) - x_j\right)\right.\right.\\ &\qquad\left.\left.+\ F\left(x_j + \frac{qs^{-1/2}}{r}\left(\mathbf{i}+\frac{1}{2}\mathbf{e}\right) - x_k\right)\right)\right)_{1\le j,k\le N}\\ &= \left(\frac{1}{2}\left(F\left(x_j + \frac{qs^{-1/2}}{r}\left(-\mathbf{i}-\frac{1}{2}\mathbf{e}\right) - x_k\right)\right.\right.\\ &\qquad\left.\left.+\ F\left(x_k + \frac{qs^{-1/2}}{r}\left(-\mathbf{i}-\frac{1}{2}\mathbf{e}\right) - x_j\right)\right)\right)_{1\le j,k\le N}\\ &= \left(\frac{1}{2}\left(F\left(x_k + \frac{qs^{-1/2}}{r}\left(-(\mathbf{i}+\mathbf{e})+\frac{1}{2}\mathbf{e}\right) - x_j\right)\right.\right.\\ &\qquad\left.\left.+\ F\left(x_j + \frac{qs^{-1/2}}{r}\left(-(\mathbf{i}+\mathbf{e})+\frac{1}{2}\mathbf{e}\right) - x_k\right)\right)\right)_{1\le j,k\le N}\\ &= \left(\frac{1}{2}\left(F(y_k^{(-\mathbf{i}-\mathbf{e})} - x_j) + F(y_j^{(-\mathbf{i}-\mathbf{e})} - x_k)\right)\right)_{1\le j,k\le N} = A_1^{(-\mathbf{i}-\mathbf{e})}(F).\end{aligned}$$

In a similar manner, it can be shown that

$$A_2^{(\mathbf{i})}(F) = -A_2^{(-\mathbf{i}-\mathbf{e})}(F).$$

Consequently,

$$\begin{aligned}\|A^{(\mathbf{i})}(F)\alpha\|^2+\|A^{(-\mathbf{i}-\mathbf{e})}(F)\alpha\|^2&=\|A_1^{(\mathbf{i})}(F)\alpha+A_2^{(\mathbf{i})}(F)\alpha\|^2+\|A_1^{(\mathbf{i})}(F)\alpha-A_2^{(\mathbf{i})}(F)\alpha\|^2\\&=2\|A_1^{(\mathbf{i})}(F)\alpha\|^2+2\|A_2^{(\mathbf{i})}(F)\alpha\|^2,\end{aligned}$$

where the last equality follows from the parallelogram identity.

Therefore, if Σ^* denotes the sum over the set of multi-indices $-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}$, $0\le i_1\le r-1$, and Σ^{**} denotes the sum taken over the set $-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}$, $-r\le i_1\le -1$, then

$$\begin{aligned}\sum_{-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}}\|A^{(\mathbf{i})}(F)\alpha\|^2&=\sum{}^{*}\|A^{(\mathbf{i})}(F)\alpha\|^2+\sum{}^{**}\|A^{(\mathbf{i})}(F)\alpha\|^2\\&=\sum{}^{*}\|A^{(\mathbf{i})}(F)\alpha\|^2+\sum{}^{*}\|A^{(-\mathbf{i}-\mathbf{e})}(F)\alpha\|^2\\&=\sum{}^{*}\left(\|A^{(\mathbf{i})}(F)\alpha\|^2+\|A^{(-\mathbf{i}-\mathbf{e})}(F)\alpha\|^2\right)\\&=\sum{}^{*}2\left(\|A_1^{(\mathbf{i})}(F)\alpha\|^2+\|A_2^{(\mathbf{i})}(F)\alpha\|^2\right)\\&\ge 2\sum{}^{*}\|A_1^{(\mathbf{i})}(F)\alpha\|^2,\end{aligned}$$

and finally,

$$\langle A_X\alpha,\alpha\rangle\ge\underline{\lim}_{r\to\infty}\frac{2q^s s^{-s/2}}{r^s}\sum_{\substack{-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}\\0\le i_1\le r-1}}\|A_1^{(\mathbf{i})}(F)\alpha\|^2.\qquad\square$$

We shall now investigate a subset of the grid points $y_k^{(\mathbf{i})}$ which are close to the points x_j. As a consequence, we shall obtain lower bounds on the quadratic form of the least squares matrix in terms of lower bounds on the quadratic form of certain interpolation matrices.

LEMMA 4.5. *Suppose* $0<\varepsilon\le 1$ *is fixed. Let*

$$P_\varepsilon(r):=\{\mathbf{i}:\|\mathbf{i}\|_\infty\le\varepsilon r-\tfrac12\text{ and }i_1\ge 0\}\quad\text{for }r\in\mathbb{N}.$$

Then the following statements hold:

(i) *There is an index* $r_0(\varepsilon)\in\mathbb{N}$ *such that* $P_\varepsilon(r)\neq\emptyset$ *for all* $r\ge r_0(\varepsilon)$;

(ii) $P_\varepsilon(r)\subset\{\mathbf{i}:-r\mathbf{e}\le\mathbf{i}\le(r-1)\mathbf{e}\text{ and }0\le i_1\le r-1\}$;

(iii) *The cardinality of* $P_\varepsilon(r)$ *is* $(2\lfloor\varepsilon r-\frac12\rfloor+1)^{s-1}(\lfloor\varepsilon r-\frac12\rfloor+1)$ *for* $r\ge r_0(\varepsilon)$, *where* $\lfloor a\rfloor$ *denotes the integer part of* a;

(iv) $d^{(\mathbf{i})}:=y_j^{(\mathbf{i})}-x_j$, $1\le j\le N$, *is independent of* j *and*

$$\|d^{(\mathbf{i})}\|\le q\varepsilon,\quad\mathbf{i}\in P_\varepsilon(r),\quad r\ge r_0(\varepsilon).$$

Proof. Assertions (i)–(iii) are straightforward to verify. To prove (iv), note that from Lemma 4.4,

$$d^{(\mathbf{i})}=x_j+\frac{qs^{-1/2}}{r}\left(\mathbf{i}+\frac12\mathbf{e}\right)-x_j=\frac{qs^{-1/2}}{r}\left(\mathbf{i}+\frac12\mathbf{e}\right),$$

which is clearly independent of j. Moreover, as $\mathbf{i}\in P_\varepsilon(r)$, this also implies that

$$\|d^{(\mathbf{i})}\|=\frac{qs^{-1/2}}{r}\|\mathbf{i}+\frac12\mathbf{e}\|\le\frac{qs^{-1/2}}{r}\left(\|\mathbf{i}\|_\infty+\frac12\|\mathbf{e}\|_\infty\right)s^{1/2}\le q\varepsilon.\qquad\square$$

Our primary result can now be stated.

THEOREM 4.6. *Let F belong to RP_0^∞ or RN_1^∞ and let $d\mu$ be its representing measure. Assume that Ω is an admissible domain with respect to a set $X = \{x_1, \dots, x_N\}$ of centers, and that $2q = \min_{j \neq \ell} \|x_j - x_\ell\| > 0$. Suppose that $I'(\mu)$ and $\tilde{J}(\mu, d)$ are given by Theorem* 3.4 *and Remark* 3.5(i), *respectively. If $P_\varepsilon(r)$ and $d^{(\mathbf{i})}$ are as in Lemma* 4.5, *then the following hold:*

(i) *There exists $0 < \varepsilon \le 1$, $\varepsilon = \varepsilon(s, q, \mu, N)$, and $r_0(\varepsilon) \in \mathbb{N}$ such that $P_\varepsilon(r) \neq \emptyset$ for all $r \ge r_0(\varepsilon)$ and*

$$N\tilde{J}(\mu, d^{(\mathbf{i})}) < \tfrac{1}{2} I'(\mu)$$

for $\mathbf{i} \in P_\varepsilon(r)$.

(ii) *With ε as in* (i) *and $\alpha \in \mathbb{R}^N$, $\|\alpha\| = 1$, we have*

$$\langle A_X \alpha, \alpha \rangle \ge 2^{s-2} s^{-s/2} q^s I'(\mu)^2 \varepsilon^s.$$

Proof. (i) It is clear from its definition that $\tilde{J}(\mu, d) \to 0$ with d. So there exists a $\delta = \delta(s, q, \mu, N)$ such that

$$N\tilde{J}(\mu, d) < \tfrac{1}{2} I'(\mu) \quad \text{for } \|d\| \le \delta. \tag{4.4}$$

Choose $\varepsilon = \min(\delta/q, 1)$ and $r_0(\varepsilon)$ as in Lemma 4.5 (i). By assertion (iv) of the same lemma,

$$\|d^{(\mathbf{i})}\| \le q\varepsilon \le \delta, \quad \mathbf{i} \in P_\varepsilon(r), \quad r \ge r_0(\varepsilon).$$

So by (4.4),

$$N\tilde{J}(\mu, d^{(\mathbf{i})}) < \tfrac{1}{2} I'(\mu) \quad \text{for } \mathbf{i} \in P_\varepsilon(r).$$

(ii) By Lemma 4.4,

$$\langle A_X \alpha, \alpha \rangle \ge \underline{\lim}_{r \to \infty} \frac{2q^s s^{-s/2}}{r^s} \sum_{\substack{-r\mathbf{e} \le \mathbf{i} \le (r-1)\mathbf{e} \\ 0 \le i_1 \le r-1}} \|A_1^{(\mathbf{i})}(F)\alpha\|^2.$$

Let ε be chosen as in part (i) and $r \ge r_0(\varepsilon)$. Using the results of part (i) of the present theorem, along with Theorem 3.6 and Lemma 4.5 (ii) and (iii), we obtain

$$\begin{aligned}
\langle A_X \alpha, \alpha \rangle &\ge \underline{\lim}_{r \to \infty} \frac{2q^s s^{-s/2}}{r^s} \sum_{\mathbf{i} \in P_\varepsilon(r)} \|A_1^{(\mathbf{i})}(F)\alpha\|^2 \\
&\ge \underline{\lim}_{r \to \infty} \frac{2q^s s^{-s/2}}{r^s} \left(2 \left\lfloor \varepsilon r - \frac{1}{2} \right\rfloor + 1 \right)^{s-1} \left(\left\lfloor \varepsilon r - \frac{1}{2} \right\rfloor + 1 \right) \frac{I'(\mu)^2}{4} \\
&\ge \underline{\lim}_{r \to \infty} 2^{s-2} s^{-s/2} q^s I'(\mu)^2 \frac{(\lfloor \varepsilon r - \frac{1}{2} \rfloor)^s}{r^s} \\
&= 2^{s-2} s^{-s/2} q^s I'(\mu)^2 \varepsilon^s. \qquad \square
\end{aligned}$$

COROLLARY 4.7. *Suppose that the assumptions of Theorem* 4.6 *hold, and let ε be given by part* (i) *of that theorem. Then the least squares matrix A_X is invertible and*

$$\|A_X^{-1}\| \le 2^{-s+2} s^{s/2} q^{-s} I'(\mu)^{-2} \varepsilon^{-s}.$$

Proof. If $\alpha \in \mathbb{R}^N$ with $\|\alpha\| = 1$, then the Cauchy–Schwarz inequality and Theorem 4.6 imply that $\|A_X\alpha\| \geq 2^{s-2}s^{-s/2}q^s I'(\mu)^2\varepsilon^s$. The required result follows from this because

$$\|A_X^{-1}\| = \left\{\frac{1}{\inf \|A_X\alpha\|} \colon \alpha \in \mathbb{R}^N, \|\alpha\| = 1\right\}. \qquad \square$$

Patently, the quantity ε, in terms of which the estimates in Theorem 4.6 and Corollary 4.7 are given, is of little practical use if it cannot be quantified. Now it is clear from the proof of Theorem 4.6 that the task of quantifying ε is indeed that of describing precisely the relationship between $\tilde{J}(\mu, d)$ and $\|d\|$. The next result serves as an illustration in this regard. Even though it is confined to the three functions F_i, $1 \leq i \leq 3$, the principle of the argument may be extended readily to other functions of one's choosing.

PROPOSITION 4.8. *Suppose that F is one of the three functions F_i, $1 \leq i \leq 3$. Let I_i', $1 \leq i \leq 3$, and J' be given by Propositions* 3.7 *and* 3.8, *respectively. Then the corresponding least squares matrix satisfies the following estimate*:

$$\|A_X^{-1}\| \leq \begin{cases} \dfrac{4s^{s/2}(J')^s N^s}{(I_i')^{s+2}} & \text{if } \dfrac{I_i'}{2J'Nq} < 1; \\[2ex] \dfrac{2^{2-s}s^{s/2}}{q^s(I_i')^2} & \text{if } \dfrac{I_i'}{2J'Nq} \geq 1. \end{cases}$$

Proof. Note that for $F = F_i$, $1 \leq i \leq 3$, we have from Proposition 3.8, $\tilde{J}(\mu, d) \leq J'\|d\|$ (recall here that J' depends only on s). Now let $\delta = I_i'/(2J'N)$ in (4.4), so that ε in Part (i) of Theorem 4.6 may be chosen to be $\min\{I_i'/(2J'Nq), 1\}$. The stated result now follows from Corollary 4.7. $\square$

Remark 4.9. (i) It is important to note that in each of the three estimates (corresponding to F_i, $1 \leq i \leq 3$) given above, the influence of the number of centers N, if present, manifests itself only by way of the factor N^s. However, the influence of the minimal separation distance of the centers varies with the function (as with interpolation). For instance, in the case of F_1, this is reflected in terms of the factor q^{-s-2}, whereas for F_2, the corresponding term is $q^{(3s-s^2)/2}e^{+\text{const}/q}$.

(ii) It is clear from (i) that a small separation parameter q can wreak havoc on the estimates involving the multiquadric. To counter this effect, it is recommended that one use the function $F_2^c(x) := \sqrt{c^2 + \|x\|^2} = c\sqrt{1 + \|x/c\|^2}$, $0 < c < 1$. Note that under this change of scale, the set of centers X with minimal separation distance $2q$ is transformed to a new set Y of centers with minimal separation $2q/c$. Our analysis can now be carried out with respect to the set Y; of course, the new separation parameter is $q' := q/c > q$. In other words, given a set of centers $\{x_i\}$ with (perhaps damagingly) small separation distance, we forgo the basis $F_2(\cdot - x_i)$ in favour of the better conditioned basis $F_2^c(\cdot - x_i)$ for an appropriate choice of c. Clearly, our methods of analysis of F_2^c do not differ significantly from those of F_2 (the transition essentially involves a mere change in scale). Yet, this choice of a new basis will improve considerably the overall stability of the least squares process.

To explain further this improvement in stability, let us draw attention to the fact that the two limiting cases of F_2^c, viz., $c = 0$ and $c = 1$, correspond to the functions F_1 and F_2, respectively. Recalling the roles of the separation parameter q in the estimates involving these limiting cases, we see that the exponential influence of q, felt in the case of $c = 1$, gets mitigated for smaller values of c as the respective bounds gradually begin to mirror the estimate corresponding to $c = 0$.

(iii) It is possible to obtain an estimate for the least squares matrix associated with the function $F(x) = \|x\|^{2\beta}$, $x \in \mathbb{R}^s$, $0 < \beta < 1$, using Remark 3.10 (i) and Corollary 4.7.

(iv) The estimate for F_2 derived in Proposition 4.8 can be improved using Remark 3.10 (ii); this is because $\tilde{J}(\mu, d)$ can actually be estimated in terms of $\|d\|^2$. Precisely, the following upper bound may be obtained:

$$\|A_X^{-1}\| \leq \begin{cases} \dfrac{2^{-s/2+2}s^{s/2}(J'')^{s/2}N^{s/2}}{(I_2')^{s/2+2}} & \text{if } \left(\dfrac{I_2'}{2J''Nq^2}\right)^{1/2} < 1; \\ \dfrac{2^{2-s}s^{s/2}}{q^s(I_2')^2} & \text{if } \left(\dfrac{I_2'}{2J''Nq^2}\right)^{1/2} \geq 1. \end{cases}$$

It is evident that the estimates in Theorem 4.6 (and hence those of Corollary 4.7 and Proposition 4.8) all involve the number of centers N. It is no less evident that the entry of this factor was occasioned solely by the restriction $N\tilde{J}(\mu, d^{(\mathbf{i})}) < I'(\mu)/2$ - an unavoidable consequence of the interpolation estimates of Theorem 3.6. However, as the interpolation estimate for the Gaussian given in Proposition 3.11 avoids the quantity N, it is not surprising that the following least squares estimate for F_4 also shares the same desirable feature.

PROPOSITION 4.10. *Let I_4' and $D_s(\rho, q)$ be as in Propositions 3.7 and 3.11, respectively. Suppose that A_X is the least squares matrix associated with F_4. Then*

$$\|A_X^{-1}\| \leq \begin{cases} \dfrac{4s^{s/2}[D_s(\rho,q)]^s}{(I_4')^{s+2}} & \textit{if } \dfrac{I_4'}{2D_s(\rho,q)q} < 1; \\ \dfrac{2^{2-s}s^{s/2}}{q^s(I_4')^2} & \textit{if } \dfrac{I_4'}{2D_s(\rho,q)q} \geq 1. \end{cases}$$

Proof. We proceed as in Theorem 4.6, also adhering to the notation therein. Let $\alpha \in \mathbb{R}^N$, $\|\alpha\| = 1$. As before, we have

$$\langle A_X\alpha, \alpha\rangle \geq \underline{\lim}_{r\to\infty} \frac{2q^s s^{-s/2}}{r^s} \sum_{\substack{-r\mathbf{e} \leq \mathbf{i} \leq (r-1)\mathbf{e} \\ 0 \leq i_1 \leq r-1}} \|A_1^{(\mathbf{i})}(F_4)\alpha\|^2.$$

We wish to bound $\|A_1^{(\mathbf{i})}(F_4)\alpha\|^2$ from below without involving N. To this end, we invoke Proposition 3.11: If $\varepsilon = \min\{I_4'/(2D_s(\rho,q)q), 1\}$ and $\mathbf{i} \in P_\varepsilon(r)$, then $\|d^{(\mathbf{i})}\| \leq q\varepsilon \leq q$ and $D_s(\rho,q)\|d^{(\mathbf{i})}\| < I_4'/2$. Therefore, as in the proof of part (ii) of Theorem 4.6, we have

$$\langle A_X\alpha, \alpha\rangle \geq 2^{s-2}s^{-s/2}q^s(I_4')^2\varepsilon^s.$$

This implies

$$\langle A_X\alpha, \alpha\rangle \geq \begin{cases} \dfrac{(I_4')^{s+2}}{4s^{s/2}[D_s(\rho,q)]^s} & \text{if } \dfrac{I_4'}{2D_s(\rho,q)q} < 1; \\ \dfrac{2^{s-2}(I_4')^2q^s}{s^{s/2}} & \text{if } \dfrac{I_4'}{2D_s(\rho,q)q} \geq 1, \end{cases}$$

whence the required result follows as in Corollary 4.7. □

Remark 4.11. Recall that $D_s(\rho,q) = \pi^{-s}\rho q\left[1 + 6s\sum_{n=0}^{\infty}(n+3)^s e^{-\rho n^2 q^2}\right]$ and $I_4' = C_s e^{-\delta^2/(q^2\rho)}/(q^s\rho^{s/2})$. So it is obvious from the preceding proposition that the number N plays no role whatsoever in determining the stability of A_X^{-1}. On the other hand, as in the case of the multiquadric, a small separation parameter q can have a severe impact on the estimate. The scaling parameter ρ can now be chosen judiciously to alleviate this negative effect. For instance, if ρ is chosen to be of the order q^{-2}, then both I_4' and the term $e^{-\rho n^2 q^2}$ are rendered independent of q, and $D_s(\rho, q)$ is of the order q^{-1}. Thus, the impact (on the least squares estimate) of the exponential term involving q can be lessened significantly to that of q^{-s}.

5. Some sharper estimates. If $s = 1$, $F = F_1$, and the centers are equally spaced (i.e., $q = \text{const}/N$) in some admissible domain, then Proposition 4.8 and Remark 4.9 (i) indicate that the norm of the inverse of the associated least squares matrix is $O(N^4)$. We shall demonstrate that it is actually $O(N^3)$. To this end, a careful scrutiny of the arguments leading up to Theorem 4.6, and consequently Proposition 4.8, reveals that the quantity N^3 in the estimate for $\langle A_X\alpha, \alpha\rangle$—and hence for $\|A_X^{-1}\|$—comes from $(I_1')^{s+2}$, whereas the extra factor N is a result of the restriction $N\tilde{J}_1 < I_1'/2$ in Theorem 4.6. If, however, we can somehow bypass $\tilde{J}_1$, and, as with the Gaussian, estimate $J_1/\|\alpha\|^2$ (where $J_1 := J(\mu_1, d)$) directly by a quantity that is independent of N (but approaching zero with d, of course), then the desired sharper estimate will obtain. So let us consider the expression J_1 for $s = 1$. Recalling that $F_1 \in RN_1^\infty$, we find from Theorem 3.2 that for $s = 1$,

$$J_1 = \frac{1}{\pi}\int_0^\infty \frac{1}{t^{3/2}}\int_{\mathbb{R}} e^{-u^2/4t}\sin^2\left(\frac{ud}{2}\right)\left|\sum_{j=1}^N \alpha_j e^{i\cdot ux_j}\right|^2 du\,d\mu_1(t)$$
$$= \frac{1}{2\pi^{3/2}}\int_{\mathbb{R}} \sin^2\left(\frac{ud}{2}\right)\left|\sum_{j=1}^N \alpha_j e^{iux_j}\right|^2\left[\int_0^\infty e^{-u^2/4t}\frac{dt}{t^2}\right]du,$$

by the definition of $d\mu_1(t)$ and Fubini's theorem. Evaluating the inner integral using the substitution $w = 1/4t$, we see that

$$J_1 = \frac{2}{\pi^{3/2}}\int_{\mathbb{R}} \frac{\sin^2(ud/2)}{u^2}\left|\sum_{j=1}^N \alpha_j e^{iux_j}\right|^2 du$$
$$= \frac{d^2}{2\pi^{3/2}}\int_{\mathbb{R}} \left(\frac{\sin(ud/2)}{ud/2}\right)^2\left|\sum_{j=1}^N \alpha_j e^{iux_j}\right|^2 du$$
$$= \frac{d^2}{2\pi^{3/2}}\sum_{j,\ell=1}^N \alpha_j\alpha_\ell\int_{\mathbb{R}} \left(\frac{\sin(ud/2)}{ud/2}\right)^2 e^{iu(x_j - x_\ell)}du.$$

Let $M(x) := (1-|x|)\chi_{[-1,1]}(x)$ denote the centered second-order cardinal B-spline. Recall that $\widehat{M}(\xi) = (\sin(\xi/2)/(\xi/2))^2, \xi \in \mathbb{R}$, so

$$J_1 = \frac{d^2}{2\pi^{3/2}}\sum_{j,\ell=1}^N \alpha_j\alpha_\ell\int_{\mathbb{R}} \widehat{M}(ud)e^{iu(x_j - x_\ell)}du$$
$$= \frac{d}{2\pi^{3/2}}\sum_{j,\ell=1}^N \alpha_j\alpha_\ell\int_{\mathbb{R}} [M(\cdot/d)]^\wedge(u)e^{iu(x_j - x_\ell)}du$$
$$= \frac{d}{\sqrt{\pi}}\sum_{j,\ell=1}^N \alpha_j\alpha_\ell M\left(\frac{x_j - x_\ell}{d}\right).$$

Now, if $d < 2q$ (remember that we are interested only in small d), then $|x_j - x_\ell| > d$ for $j \neq \ell$, so $M\left(x_j - x_\ell/d\right) = 0$, $j \neq \ell$. Consequently,

$$J_1 = \frac{d}{\sqrt{\pi}}\|\alpha\|^2, \qquad d < 2q,$$

which is an expression clearly free of N. (We also note in passing that since $d\mu_2(t) \leq d\mu_1(t)$,

$$J_2 := J(\mu_2, d) \leq J_1 = \frac{d}{\sqrt{\pi}}\|\alpha\|^2 \text{ provided } s = 1 \quad \text{and} \quad d < 2q.$$

A similar statement also holds for $J(\mu_3, d)$. Consequently, the estimate for $\|A_X^{-1}\|$, corresponding to $F = F_2$ and F_3 for equally spaced centers, can be strengthened in the univariate case.)

Having derived the estimate $\|A_X^{-1}\| = O(N^3)$ for $F = F_1$, $s = 1$, and equally spaced centers, we now wish to point out that it is optimal at least when the number of centers is odd. Let the centers x_i be given by $x_i := i/(k+1) \in \Omega = [0,1]$, $i = 1, \ldots, k = 2m+1$. We shall show that there exists a constant D such that $\|A_X^{-1}\| \geq Dk^3$ for large k.

Firstly, a direct computation yields an exact expression for the entries of A_X:

$$\begin{aligned} A_X(i,j) = \langle |\cdot - x_i|, |\cdot - x_j|\rangle &= \frac{1}{3} - \frac{(i+j)}{2(2m+2)} + \frac{ij}{(2m+2)^2} + \frac{|i-j|^3}{3(2m+2)^3} \\ &=: P_{ij} - \frac{1}{3(2m+2)^3} G(|i-j|), \end{aligned}$$

where $G(x) = -|x|^3$. Now we select suitable vectors λ which "annihilate" linear polynomials, and use them to estimate $\|A_X\lambda\|/\|\lambda\|$ from above. Indeed, let $\lambda \in \mathbb{R}^{2m+1}$ be given by

$$\lambda_j := (-1)^j \binom{2m}{j}, \qquad 0 \leq j \leq 2m.$$

If P denotes the matrix whose entries are P_{ij} (as defined above), then $P\lambda = 0$. Thus,

$$A_X\lambda = \frac{-1}{3(2m+2)^3} B\lambda, \quad \text{where } B_{ij} = G(|i-j|).$$

Clearly, B corresponds to the radial interpolation matrix associated with G. An appeal to Theorems 3.4 and 4.1 of [BSW] (taking q there to be 1) reveals that

$$\frac{\|B\lambda\|^2}{\|\lambda\|^2} = O(1), \qquad m \to \infty.$$

Thus,

$$\|A_X^{-1}\| \geq D(2m+2)^3 \text{ for large } m,$$

and the proof is complete.

(We do note that in [BSW], the aforesaid assertion was actually proved for the function $x \mapsto |x|^{2\beta}$, $0 < \beta < 1$, which belongs to RN_1^∞. The function $G(x) = -|x|^3$, however, belongs to RN_2^∞, but the proof in [BSW] does extend to the case $\beta = \frac{3}{2}$ and $m = 2$. The representing measure for G is given by $\left(\frac{3}{4}\right)(\pi t)^{-1/2}\,dt$.)

Acknowledgment. We thank Phil Smith for a stimulating conversation concerning least squares approximation.

ESTIMATES FOR LARGE DEVIATIONS IN RANDOM TRIGONOMETRIC POLYNOMIALS*

GEORGE BENKE[†] [‡] AND W. J. HENDRICKS[†]

Abstract. Let $F(t) = \sum_{n=1}^{N} a_n \exp(iX_n t)$, where $X_1, X_2, \ldots, X_N$ are independent random variables and the coefficients a_n are real or complex constants. Probabilistic estimates of the form

$$P\left[\sup_{t\in K} |F(t) - E[F(t)]| \geq C\sqrt{N\log N}\right] \leq \epsilon$$

are obtained where K is an interval on the real line, C may be chosen more or less arbitrarily, and ϵ is an explicit function of C, K, N, and the random variables. This method includes trigonmetric interpolation and straightforward probabilistic techniques to obtain explicit numerical bounds that are applicable in a variety of engineering applications, particularly in the study of maximal sidelobe level for random arrays. Specific numerical examples are computed, and references to both the engineering and mathematical literature are provided.

1. Introduction.

In this paper we obtain probabilistic bounds for large deviations for a particular class of random trigonometric polynomials and show that these estimates are associated in a natural way with what is known in the engineering literature as the maximal sidelobe level problem for random phased arrays. These arrays have been studied extensively in the engineering community through simulations and various approximations, but a mathematically rigorous presentation of their probabilistic properties has not been given in either the mathematical or the engineering literature. Since the problem embraces both the engineering and mathematical disciplines, the subsequent paragraphs of this introductory section provide an explanation of the relevant terminology and of the mathematical and physical setting for the problem. In §2 we develop the means for deriving the probabilistic estimates through a sequence of lemmas, after which we are able to state our main theorem and ensuing corollaries. Section 3 gives specific examples of these results.

A phased array consists of a finite collection of transmitting or receiving elements distributed in space. These elements transmit or receive energy from some field such as an acoustic, electromagnetic, or seismic field. By adjusting the phases of the signals at the individual sensing elements of the array the contribution from each element can be added coherently with those of the other array elements, resulting in a more sensitive array response to an incoming signal. The array elements, along with the inter-element connections required to coherently add the elemental responses, constitute a phased array antenna. Antennas of this type have been used for many years in areas such as radar, sonar, seismology, and radio astronomy. The books by Steinberg [15] and Haykin [5] give a more detailed overview of these application areas. One advantage of

phased array antennas derives from the fact that array elements can be located over a large region in space. This gives the antenna a large effective aperture, and therefore the ability to form very narrowly focused beams. By adjusting the phases of the signals at the individual elements, the beam of the antenna can be steered quickly in different directions without the motion of any physical components. Another advantage results from the fact that the signals from each sensor are accessible, thereby allowing for sophisticated processing algorithms that can mitigate the effects of correlated noise, multipath, and other undesirable phenomena.

In order to describe more fully the notion of a phased array, consider an array of omnidirectional receiving elements located at positions $\mathbf{x}_1, \dots, \mathbf{x}_N$ in Euclidean space $\mathbf{R}^3$, and let S be a propagating scalar plane wave with waveform s. That is, let s be a complex-valued function defined on the real line $\mathbf{R}$ and define S at position $\mathbf{x} \in \mathbf{R}^3$ and time $\tau \in \mathbf{R}$ by

$$S(\mathbf{x}, \tau) = s\left(\tau - \frac{\mathbf{n} \cdot \mathbf{x}}{c}\right),$$

where $\mathbf{n}$ is a unit vector indicating the direction of propagation and c is the propagation velocity of the wave. The element at position $\mathbf{x}_n$ receives the signal

$$g_n(\tau) \equiv S(\mathbf{x}_n, \tau) + \eta_n(\tau),$$

where η_n is a sample function of a stochastic process that models the noise at time τ and position $\mathbf{x}_n$. Since the array elements are located at different positions, radiation from a given direction will typically arrive at different sensors at different times. As a result, a delay must be applied at each sensor if the elemental signal responses are to add coherently. In "delay and sum" processing, the functions g_n are combined in this way by forming

$$D(\tau) \equiv \sum_{n=1}^{N} g_n(\tau - \tau_n) = \sum_{n=1}^{N} s\left(\tau - \tau_n - \frac{\mathbf{n} \cdot \mathbf{x}_n}{c}\right) + \sum_{n=1}^{N} \eta_n(\tau - \tau_n),$$

where $\tau_1, \dots, \tau_N$ represent a set of delays. If we choose $\tau_n = -(\mathbf{n} \cdot \mathbf{x}_n)/c$, then

$$D(\tau) = Ns(\tau) + H(\tau),$$

where H gives the combined noise output of the array, and we say that we have steered the beam of the array in the direction $\mathbf{n}$. Note that this choice of the τ_n gives an array signal response of N times that of each of the elemental signal responses. By adjusting the delays we thus observe that the maximal array response can be made to point in any prescribed direction—hence the notion of steering the beam.

Without being overly concerned about the existence of limits, let us define

$$\langle g, h \rangle = \lim_{T \to \infty} \frac{1}{2T} \int_{-T}^{T} g(t)\overline{h(t)}dt \quad \text{and} \quad \|h\| = \langle h, h \rangle^{1/2}.$$

Assume that the noise components and signal are uncorrelated, that is, assume that

$$\langle \eta_k, \eta_j \rangle = 0 \quad \text{for } k \neq j \quad \text{and} \quad \langle \eta_n, s \rangle = 0 \quad \text{for } n = 1, \dots, N.$$

Assume also that $\|\eta_n\|$ is the same for all n, and, therefore, denote $\|\eta_n\|$ by $\|\eta\|$. Then:

$$\left(\frac{\|D\|}{\|H\|}\right)^2 = N\left(\frac{\|s\|}{\|\eta\|}\right)^2 + 1;$$

therefore, the (power) signal to noise ratio for the array is approximately N times the signal to noise ratio at each receiving element. Thus, arrays with arbitrarily high sensitivity can be created by using sufficiently many sensors.

In order to examine the directional sensitivity of an array it is convenient to consider a monochromatic signal of (radian) frequency ω:

$$s(\tau) = \exp(i\,\omega\,\tau),$$

and to neglect noise. Thus if $\mathbf{n}$ gives the direction of a propagating plane wave

$$S(\mathbf{x},\tau) = \exp\left(i\omega\left(\tau - \frac{\mathbf{n}\cdot\mathbf{x}}{c}\right)\right)$$

and delays τ_n are chosen to maximize sensitivity in a direction $\mathbf{n}_0$, the delay and sum array output is

$$\begin{aligned} D(\tau) &= \sum_{n=1}^{N} \exp\left(i\omega\left(\tau + \frac{\mathbf{n}_0\cdot\mathbf{x}_n}{c} - \frac{\mathbf{n}\cdot\mathbf{x}_n}{c}\right)\right) \\ &= e^{i\omega\tau}\sum_{n=1}^{N}\exp\left(i\frac{\omega}{c}(\mathbf{n}_0 - \mathbf{n})\cdot\mathbf{x}_n\right) \\ &= s(\tau)F\left(\frac{\omega}{c}(\mathbf{n}_0 - \mathbf{n})\right), \end{aligned}$$

where F is the trigonometric polynomial on $\mathbf{R}^3$ given by

$$F(\boldsymbol{\gamma}) = \sum_{n=1}^{N}\exp\left(i\boldsymbol{\gamma}\cdot\mathbf{x}_n\right).$$

Note that the array output D can be expressed as the product of a time factor s (the signal) and a space factor F, and that $F(0) = N$. Infinite spatial resolution would be obtained if $F(\boldsymbol{\gamma}) = 0$ for all $\boldsymbol{\gamma} \neq 0$—i.e., if F were a delta function. The directional characteristics of the array are, therefore, embodied in the trigonometric polynomial F. The question then becomes "How closely does F resemble a delta function?" Being a trigonometric polynomial, F is almost periodic, so that, strictly speaking, F is globally never very close to a delta function. However, since $|\mathbf{n} - \mathbf{n}_0| \leq 2$, the array directivity is determined for all directions by $F(\boldsymbol{\gamma})$ for $|\boldsymbol{\gamma}| \leq 2\omega/c$. This ball is called the visible region. Recall that the Fourier transform of the delta function is a constant and the trigonometric polynomial F is (up to normalization) the inverse Fourier transform of the discrete measure μ with unit masses at $\mathbf{x}_1, \ldots, \mathbf{x}_N$. The problem of approximating the delta function by F is, therefore, equivalent to approximating (in some sense) Lebesgue measure by the discrete measure μ. It seems reasonable, therefore, to space the $\mathbf{x}_n$ evenly over some region of space (the aperture). However, with uniform spacing of array elements F becomes periodic with a period that varies linearly with N/L, where L is the size of the aperture. Hence, if N is fixed, for sufficiently large apertures there will exist $\boldsymbol{\gamma}_0 \neq 0$ in the visible region for which $F(\boldsymbol{\gamma}_0) = N$, and the graph of $|F|$ will have a large peak at $\boldsymbol{\gamma}_0$. Such peaks are called grating lobes. These are undesirable since they give the antenna a multiple beam characteristic. On the other hand, large apertures cause $|F(\boldsymbol{\gamma})|$ to fall rapidly from peaks where $F(\boldsymbol{\gamma}) = N$. This is a desirable feature, since it gives the antenna array a narrow main beam, thereby providing good spatial resolution. It is also desirable to keep N, the number of array sensors, small relative to the aperture size L since the cost of an array is largely determined by the number of sensor elements.

In the 1960s Lo, in a series of papers [11]–[13], introduced an approach for overcoming the grating lobe problem while keeping the element density N/L small. Lo's method was to space the array elements randomly, thereby destroying the periodicities that occur when array elements are spaced uniformly. The array is then characterized by the random trigonometric polynomial

$$F(\boldsymbol{\gamma}) = \sum_{n=1}^{N} \exp\left(i\boldsymbol{\gamma}\cdot\mathbf{X}_n\right),$$

where $\mathbf{X}_1, \ldots, \mathbf{X}_N$ are independent random variables. The maximal sidelobe level problem in random array theory is to determine the distribution of the random variable

$$\sup_{\boldsymbol{\gamma}\in K} |F(\boldsymbol{\gamma})|$$

for a given compact set K. This is an extremely difficult problem. However, for most practical scenarios the probability density functions of the $\mathbf{X}_n$ are such that the expectation $E[F(\boldsymbol{\gamma})]$ can be explicity computed for each $\boldsymbol{\gamma}$. It is, therefore, of interest to estimate probabilities of the following type:

$$P\left[\sup_{\boldsymbol{\gamma}\in K} |\, F(\boldsymbol{\gamma}) - E[F(\boldsymbol{\gamma})]\,| > \lambda\right]$$

for various (nonnegative) values of λ.

The particular problem considered in this paper is the one-dimensional problem of estimating the supremum of the modulus of expressions of the form

$$G(t) = \sum_{n=1}^{N} a_n \left(e^{iX_n t} - E\left[e^{iX_n t}\right]\right), \tag{1.1}$$

where $X_1, X_2, \ldots, X_N$ are independent real-valued random variables that assume values in the interval $[-L, L]$, $a_1, a_2, \ldots, a_N$ are real or complex constants, and t is a real number. In the context of one-dimensional line arrays, the variable t corresponds to the direction variable $(\omega/c)\cos\theta$ (not time), where θ is the angle between the propagation direction and the line containing the array elements. Consequently, the set K can be regarded as representing an interval of arrival angles, and the problem being considered is that of estimating the peak response to signals emanating from this set of arrival angles. The engineering literature (e.g., Donvito and Kassam [3], Lo [11]–[13], Steinberg [15], [16]) contains several interesting studies of this problem, along with accompanying computer simulations of random sums of the form (1.1). Frequently there are simplifying assumptions such as process stationarity or an omission of a rigorous analysis of the effects of Central Limit Theorem approximations. Such simplifications are understandable, due to the difficulty of obtaining precise probabilistic estimates for these sums.

A different type of random trigonometric polynomial has been the object of mathematical investigation by Kahane [8], who considers the supremum problem for series of the form

$$F(t) = \sum_{n=1}^{N} X_n f_n(t), \tag{1.2}$$

where the f_n are complex trigonometric polynomials and the X_n are various types of random variables. In engineering terminology, Kahane considers signals having random amplitudes and deterministic frequencies, while we consider signals having deterministic amplitudes and random frequencies. Kahane (Chapter 6) traces the study of random trigonometric polynomials of the form (1.2) back to Zygmund [18], who considers convergence properties of such series ($N = \infty$), and to Salem and Zygmund [14]. Observe that in the work of Kahane and his predecessors the frequencies in the trigonometric polynomials are integral, resulting in periodic functions. By contrast, the frequencies X_n that we consider are nonintegral, so that our random functions are not periodic. This creates a significant problem in the subsequent analysis.

For $G(t)$ given by (1.1), we will obtain estimates of the form

$$P\left[\sup_{t\in K} |G(t)| \geq C\sqrt{N\log N}\right] \leq \epsilon,$$

where K is some interval on the real line. The constant C may be chosen more or less arbitrarily, and the ϵ depends on the values of C, K, N, and the properties of the random variables that specify the frequencies. In Kahane's analysis of the bounds for the distribution of the supremum over the set K, any dependency upon the measure of the set K is absorbed in unspecified constants occurring in his estimates. Our formulation, which is oriented toward explicit estimates that might occur in an application, exhibits the specific role that the measure of K and the other parameters play in the estimates.

In the analysis of the probability of large deviations of $|G(t)|$ it is tempting to use Central Limit Theorem approximations because the resulting quantities lend themselves to relatively straightforward analysis. It should be observed, however, that unless there is a careful error analysis when Central Limit Theorem approximations are invoked there may be probabilistic terms on the order of $1/\sqrt{N}$ that must be included in whatever estimates are proposed. For example, see the discussion on the Berry-Esseen error estimate that is presented in detail in Chung [2, §7.1], Breiman [1, p. 184], or Feller [4, p. 515]. In particular, it should be noted that Chung [2, exercise 3, p. 231] gives an example of a $1/\sqrt{N}$ *lower* bound for the Central Limit Theorem error approximation. As a consequence, when the probabilities we seek to estimate are less than $1/\sqrt{N}$, a more sensitive analysis is required.

It should be emphasized at the outset that we are especially interested in obtaining probabilistic estimates for large deviations of $|G(t)|$ when N, the number of summands, is large, perhaps on the order of 10,000. Hence, the probabilities being estimated are quite small. We make no assumptions about stationarity of the process $G(t)$, and do not use any Central Limit Theorem approximations to estimate the probabilities of interest. Any approximations made during the course of our analysis are incorporated explicitly in the estimates that we provide. Despite the mathematical rigors that this approach imposes, we are able to provide reasonable bounds that are useful in applications when the number of summands is large, along with the assurance that there are no terms unaccounted for that might dominate the probabilities being estimated.

2. Main results. In this section we present our main theorem and several simple corollaries. While the theorem is fairly general in its statement, the corollaries are sufficiently specific to lead directly to applications. We illustrate the use of these corollaries and the main theorem in the following section. The proof of the main theorem is broken down into a sequence of lemmas, the first of which is of some interest in its own right. It is a Shannon–Whittaker type of sampling theorem where the interpolation formula involves an absolutely convergent series whose convergence rate is governed by a parameter R. This same parameter also governs the degree of oversampling required as compared to the usual Nyquist rate.

We begin with some notation and definitions (see [9]). Let K denote the function

$$K(t) = \frac{1}{2\pi}\left(\frac{\sin t/2}{t/2}\right)^2 .$$

Then the Fourier transform $\widehat{K}$ is given by

$$\widehat{K}(\gamma) = \int_{-\infty}^{\infty} K(t)\, e^{-i\gamma t}\, dt = \max\{1 - |\gamma|, 0\}.$$

The Fourier inversion theorem also applies, giving

$$K(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} \widehat{K}(\gamma)\, e^{i\gamma t}\, d\gamma.$$

For $R > 1$ denote by V_R the function

$$V_R(t) = \frac{1}{R-1}\left(R^2K(Rt) - K(t)\right).$$

Then

$$\widehat{V}_R(\gamma) = \frac{R}{R-1}\widehat{K}\left(\frac{\gamma}{R}\right) - \frac{1}{R-1}\widehat{K}(\gamma).$$

Thus, $\widehat{V}_R$ is real valued and has a graph that is a trapezoid extending from $-R$ to R with a flat section of height 1 extending from -1 to $+1$.

LEMMA 1. *Let ν be a bounded measure supported in the interval $[-L, L]$, and let*

$$f(t) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{it\gamma}\, d\nu(\gamma)$$

denote the inverse Fourier transform of ν. Then for any $R > 1$ and all real t

$$f(t) = \frac{\pi}{R}\sum_{n=-\infty}^{\infty} V_R\left(Lt - \frac{n\pi}{R}\right) f\left(\frac{n\pi}{RL}\right),$$

where the series converges absolutely for all t and

$$V_R(t) = \frac{1}{2\pi(R-1)}\left(R^2\left(\frac{\sin Rt/2}{Rt/2}\right)^2 - \left(\frac{\sin t/2}{t/2}\right)^2\right).$$

Proof. Let $V_{R,L}(t) = L\,V_R(Lt)$; then

$$\widehat{V}_{R,L}(\gamma) = \begin{cases} 1 & \text{for } |\gamma| \le L, \\ 0 & \text{for } |\gamma| \ge RL, \end{cases}$$

and is continuous and piecewise linear. For fixed $t \in \mathbf{R}$, let $\phi_t(\gamma) = \widehat{V}_{R,L}(\gamma)\,e^{i\gamma t}$. Expressing ϕ_t in a Fourier series relative to the interval $[-RL, RL]$ gives

$$\phi_t(\gamma) = \sum_{n=-\infty}^{\infty} c_n(t)\exp\left(i\frac{\pi n\gamma}{RL}\right), \quad \text{where} \tag{2.1}$$

$$\begin{aligned} c_n(t) &= \frac{1}{2RL}\int_{-RL}^{RL}\phi_t(\xi)\exp\left(-\frac{i\pi n\xi}{RL}\right)d\xi \\ &= \frac{\pi}{RL}\frac{1}{2\pi}\int_{-\infty}^{\infty}\widehat{V}_{R,L}(\xi)\exp\left(i\left(t-\frac{n\pi}{RL}\right)\xi\right)d\xi \\ &= \frac{\pi}{RL}V_{R,L}\left(t-\frac{n\pi}{RL}\right) \\ &= \frac{\pi}{R}V_R\left(Lt-\frac{n\pi}{R}\right). \end{aligned}$$

When this expression is substituted into (2.1) we obtain

$$\phi_t(\gamma) = \frac{\pi}{R}\sum_{n=-\infty}^{\infty} V_R\left(Lt-\frac{n\pi}{R}\right)\exp\left(i\frac{\pi n\gamma}{RL}\right), \tag{2.2}$$

where the series converges absolutely.

Now consider $f(t) = (1/2\pi)\int_{-L}^{L} e^{i\gamma t}\,d\nu(\gamma)$. Since ν is supported in $[-L, L]$, we may write

$$f(t) = \frac{1}{2\pi}\int_{-RL}^{RL}\widehat{V}_{R,L}(\gamma)\,e^{i\gamma t}\,d\nu(\gamma) = \frac{1}{2\pi}\int_{-RL}^{RL}\phi_t(\gamma)\,d\nu(\gamma).$$

Using the absolute convergence of the series (2.1) gives

$$\begin{aligned} f(t) &= \frac{1}{2\pi}\int_{-RL}^{RL}\left(\frac{\pi}{R}\sum_{n=-\infty}^{\infty}V_R\left(Lt-\frac{n\pi}{R}\right)\exp\left(i\frac{\pi n\gamma}{RL}\right)\right)d\nu(\gamma) \\ &= \frac{\pi}{R}\sum_{n=-\infty}^{\infty}V_R\left(Lt-\frac{n\pi}{R}\right)\frac{1}{2\pi}\int_{-\infty}^{\infty}\exp\left(i\frac{\pi n\gamma}{RL}\right)d\nu(\gamma) \\ &= \frac{\pi}{R}\sum_{n=-\infty}^{\infty}V_R\left(Lt-\frac{n\pi}{R}\right)f\left(\frac{n\pi}{RL}\right). \qquad \square \end{aligned}$$

LEMMA 2. *For all $y \in \mathbf{R}$,*

$$\frac{\pi}{R}\sum_{n=-\infty}^{\infty}\left|V_R\left(y-\frac{n\pi}{R}\right)\right| \le \frac{R+1}{R-1}, \quad \textit{where}$$

$$V_R(t)=\frac{1}{2\pi(R-1)}\left(R^2\left(\frac{\sin Rt/2}{Rt/2}\right)^2-\left(\frac{\sin t/2}{t/2}\right)^2\right).$$

Proof. We use the Poisson summation formula, which is

$$2\pi\lambda\sum_{n=-\infty}^{\infty} f(2\pi\lambda n)=\sum_{n=-\infty}^{\infty}\widehat{f}\left(\frac{n}{\lambda}\right), \quad \text{where}$$

$\widehat{f}(\gamma)=\int_{-\infty}^{\infty} f(t)\,e^{-i\gamma t}\,dt$ and λ is any positive constant. This formula is valid for $f\in L^1(\mathbf{R})$, if f is also of bounded variation (Zygmund [18, p. 68]).

Let $f(x)=K(x-y)$, so that $\widehat{f}(\gamma)=e^{-i\gamma y}\,\widehat{K}(\gamma)$. Since K is in $L^1(\mathbf{R})$ and is also of bounded variation, so is f. Using the Poisson summation formula with $\lambda=\frac{1}{2}R$ gives

$$\begin{aligned}\frac{\pi}{R}\sum_{n=-\infty}^{\infty}K\left(y-\frac{n\pi}{R}\right)&=2\pi\lambda\sum_{n=-\infty}^{\infty}f(2\pi\lambda n)\\&=\sum_{n=-\infty}^{\infty}\widehat{f}(2Rn)=\sum_{n=-\infty}^{\infty}e^{-i2Rny}\,\widehat{K}(2Rn).\end{aligned}$$

Since $\widehat{K}(\gamma)=0$ for $|\gamma|\ge 1$, the right-hand sum has only one nonzero term, corresponding to $n=0$. Inasmuch as $\widehat{K}(0)=1$, this term evaluates to 1. The same argument applied to $R\,K\,(Rx)$ instead of $K(x)$ gives

$$\frac{\pi}{R}\sum_{n=-\infty}^{\infty}RK\left(R\left(y-\frac{n\pi}{R}\right)\right)=1 \quad \text{for all } y,$$

whence

$$\begin{aligned}&\frac{\pi}{R}\sum_{n=-\infty}^{\infty}\left|V_R\left(y-\frac{n\pi}{R}\right)\right|\\&\le\frac{\pi}{R}\sum_{n=-\infty}^{\infty}\frac{1}{R-1}\left(R^2K\left(R\left(y-\frac{n\pi}{R}\right)\right)+K\left(y-\frac{n\pi}{R}\right)\right)\\&=\frac{1}{R-1}\left(\frac{R\pi}{R}\sum_{n=-\infty}^{\infty}RK\left(R\left(y-\frac{n\pi}{R}\right)\right)+\frac{\pi}{R}\sum_{n=-\infty}^{+\infty}K\left(y-\frac{n\pi}{R}\right)\right)\\&=\frac{R+1}{R-1}. \qquad \square\end{aligned}$$

LEMMA 3. *Let $f(t) = (1/2\pi)\int_{-L}^{L} e^{i\gamma t} d\nu(\gamma)$, where ν is a bounded measure supported on $[-L, L]$. Suppose that K is an interval on the real line of the form $K = [n_1\pi/RL, n_2\pi/RL]$, where $R > 1$ and n_1 and n_2 are integers. Let M be a positive integer. Then*

$$\sup_{t\in K}|f(t)| \leq \left(\frac{R+1}{R-1}\right)\left[\max_{n_1-M\leq n\leq n_2+M}\left|f\left(\frac{n\pi}{RL}\right)\right| + \frac{8\|f\|_\infty}{\pi^2 M}\right].$$

Proof. For $t \in K$, use the interpolation result of Lemma 1 to write

$$\begin{aligned} f(t) &= \frac{\pi}{R}\sum_{n=-\infty}^{\infty} f\left(\frac{n\pi}{RL}\right) V_R\left(Lt - \frac{n\pi}{R}\right) \\ &= \frac{\pi}{R}\left(\sum_{n=-\infty}^{n_1-M-1} + \sum_{n=n_1-M}^{n_2+M} + \sum_{n=n_2+M+1}^{\infty}\right) f\left(\frac{n\pi}{RL}\right) V_R\left(Lt - \frac{n\pi}{R}\right) \\ &= S_1 + S_2 + S_3. \end{aligned}$$

Now let $\mathcal{A}$ be the set of integers n such that $n_1 - M \leq n \leq n_2 + M$, and by Lemma 2,

$$|S_2| \leq \max_{n\in\mathcal{A}}\left|f\left(\frac{n\pi}{RL}\right)\right| \frac{\pi}{R}\sum_{n=-\infty}^{\infty}\left|V_R\left(Lt - \frac{n\pi}{R}\right)\right| \leq \frac{R+1}{R-1}\max_{n\in\mathcal{A}}\left|f\left(\frac{n\pi}{RL}\right)\right|.$$

Next, consider S_3.

$$\begin{aligned} |S_3| &\leq \|f\|_\infty \frac{\pi}{R}\sum_{n=n_2+M+1}^{\infty}\left|V_R\left(Lt - \frac{n\pi}{R}\right)\right| \\ &\leq \|f\|_\infty \frac{\pi}{R}\sum_{n=n_2+M+1}^{\infty}\frac{4}{\pi(R-1)\left(Lt - n\pi/R\right)^2} \\ &\leq \|f\|_\infty \frac{\pi}{R}\sum_{n=n_2+M+1}^{\infty}\frac{4R^2}{\pi(R-1)\pi^2(n_2-n)^2} \\ &= \|f\|_\infty \frac{4R}{\pi^2(R-1)}\sum_{n=M+1}^{\infty}\frac{1}{n^2} \\ &\leq \|f\|_\infty \frac{4}{\pi^2}\left(\frac{R}{R-1}\right)\frac{1}{M}. \end{aligned}$$

We have the same estimate for $|S_1|$, so that for $t \in K$,

$$|f(t)| \leq \frac{R+1}{R-1}\max_{n\in\mathcal{A}}\left|f\left(\frac{n\pi}{RL}\right)\right| + \frac{8}{\pi^2}\left(\frac{R}{R-1}\right)\frac{\|f\|_\infty}{M}. \qquad \square$$

Remark. In the proof of the main theorem, we will apply this lemma to functions that are linear combinations of functions of the form

$$f_\omega(t) = e^{iXt} - E[e^{iXt}]$$

for random variables X taking values $X(\omega)$ in the interval $[-L, L]$. Since

$$E[e^{iXt}] = \int_{-L}^{L} e^{i\gamma t}\, dF_X(\gamma),$$

where F_X is the cumulative distribution function of X, it is clear that for each ω in the probability space $f_\omega(t)$ is the inverse Fourier transform of a measure supported on $[-L, L]$.

LEMMA 4. *Let (Ω, P) be a probability space, and suppose Z_n for $n = 1, 2, \dots, N$ are real-valued measurable functions defined on $\Omega \times \mathbf{R}$. Suppose further that for all real t,*

(1) $E[Z_n(\cdot, t)] = 0$ *for* $n = 1, 2, \dots, N$;

(2) $Z_1(\cdot, t), \dots, Z_N(\cdot, t)$ *are independent random variables*;

(3) *There exist functions $\beta_1, \dots, \beta_N$ such that for $n = 1, \dots, N$ and all real γ:*

$$E\left[e^{\gamma Z_n(\cdot,t)}\right] \le e^{\gamma^2 \beta_n(t)}.$$

Let $F(\cdot, t) = \sum_{n=1}^{N} Z_n(\cdot, t)$. Then if $\lambda > 0$ and $a > 0$, and $t_1, \dots, t_q$ are real numbers,

$$P\left[|F(\cdot, t_k)| \ge \frac{a}{\lambda} \text{ for some } k = 1, \dots, q\right] \le 2\sum_{k=1}^{q} \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right).$$

Proof. Let $a > 0$ and $\lambda > 0$ be given. To simplify notation we will write $F(t)$ for $F(\cdot, t)$ and $Z(t)$ for $Z(\cdot, t)$. Then for each fixed real number t_k,

$$\begin{aligned} E[e^{\lambda F(t_k)}] &= E\left[\prod_{n=1}^{N} \exp(\lambda Z_n(t_k))\right] \\ &= \prod_{n=1}^{N} E[\exp(\lambda Z_n(t_k))] \le \prod_{n=1}^{N} \exp(\lambda^2 \beta_n(t_k)) \\ &= \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k)\right). \end{aligned}$$

For any nonnegative random variable X and any real number y, $y\,P[X \ge y] \le E[X]$. (This is one form of Markov's inequality.) Consequently,

$$P\left[e^{\lambda F(t_k)} \ge e^a\right] \le e^{-a} E\left[e^{\lambda F(t_k)}\right] \le \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right),$$

or

$$P[F(t_k) \ge a/\lambda] \le \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right).$$

To estimate $P[F(t_k) \le -a/\lambda]$, apply the same argument to the random variable $-F(t_k)$, giving

$$\begin{aligned} P[|F(t_k)| \ge a/\lambda] &= P[F(t_k) \ge a/\lambda] + P[F(t_k) \le -a/\lambda] \\ &\le 2\exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right). \end{aligned}$$

Hence

$$P[\,|F(t_k)| \ge a/\lambda \text{ for some } k \in \{1, \dots, q\}\,] \le 2\sum_{k=1}^{q} \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right). \qquad \square$$

THEOREM. *Let $X_1, \dots, X_N$ be independent random variables taking values in the interval $[-L, L]$. For real $a_1, \dots, a_N$ and $\phi_1, \dots, \phi_N$ consider the function $F(t)$ defined by*

$$F(t) = \sum_{n=1}^{N} a_n \sin(X_n t + \phi_n),$$

and let $\mu_n(t) = E[\sin(X_n t + \phi_n)]$. Define $G(t)$ by $G(t) = F(t) - E[F(t)]$. Suppose that there exist functions $\beta_1, \dots, \beta_N$ such that for each integer $n = 1, \dots, N$ and for all real numbers γ and real values of t,

$$E[\exp(\gamma a_n(\sin(X_n t + \phi_n) - \mu_n(t)))] \le \exp(\gamma^2 \beta_n(t)).$$

Then for $a > 0, \lambda > 0, R > 1$, integer $M > 1$ and an interval $K = [n_1\pi/RL, n_2\pi/RL]$, where n_1 and n_2 are integers, we have

$$(2.3)\quad P\left[\sup_{t\in K} |G(t)| \ge \left(\frac{R+1}{R-1}\right)\left(\frac{a}{\lambda} + \frac{8\|G\|_\infty}{\pi^2 M}\right)\right] \le 2\sum_{k=1}^{q} \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right),$$

where $t_1, \dots, t_q$ is the set of points of the form $\pi k/RL$ for $k = n_1 - M, \dots, n_2 + M$ and $q = |n_2 - n_1| + 2M + 1$.

Remark. Note that by taking $\phi_n = 0$ for each n gives $F(t)$ as the sum of $\sin X_n t$ terms, and $\phi_n = \pi/2$ for all n gives $F(t)$ as a sum of $\cos X_n t$ terms, while other values of ϕ_n give $F(t)$ as a sum of a mixture of sine and cosine terms. This observation will be used without further comment.

Proof. By definition,

$$G(t) = F(t) - E[F(t)] = \sum_{n=1}^{N} a_n(\sin(X_n t + \phi_n) - \mu_n(t)),$$

where $\mu_n(t) = E[\sin(X_n t + \phi_n)]$. Let

$$Z_n(t) = a_n(\sin(X_n t + \phi_n) - \mu_n(t)).$$

Let $a > 0, \lambda > 0, M > 1$ and an interval $K = [n_1\pi/RL, n_2\pi/RL]$ be given. Then by hypothesis, Lemma 4 applies, giving

$$(2.4)\quad P[|G(t_k)| \ge a/\lambda \text{ for some } k = 1, \dots, q] \le 2\sum_{k=1}^{q} \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right),$$

where $t_1, \dots, t_q$ is the set of points of the form $k\pi/RL$ for $k = n_1 - M, \dots, n_2 + M$.

By Lemma 3 we have the following inclusion of events:

$$\left[\sup_{t\in K} |G(t)| < \left(\frac{R+1}{R-1}\right)\left(\frac{a}{\lambda} + \frac{8\|G\|_\infty}{\pi^2 M}\right)\right] \supset \left[|G(t_k)| < \frac{a}{\lambda} \text{ for all } k = 1, \dots, q\right].$$

Therefore, by (2.4),

$$\begin{aligned} P\left[\sup_{t\in K} |G(t)| < \left(\frac{R+1}{R-1}\right)\left(\frac{a}{\lambda} + \frac{8\|G\|_\infty}{\pi^2 M}\right)\right] &\ge P\left[|G(t_k)| < \frac{a}{\lambda} \text{ for all } k = 1, \dots, q\right] \\ &= 1 - P\left[|G(t_k)| \ge \frac{a}{\lambda} \text{ for some } k = 1, \dots, q\right] \\ &\ge 1 - 2\sum_{k=1}^{q} \exp\left(\lambda^2 \sum_{n=1}^{N} \beta_n(t_k) - a\right). \qquad \square \end{aligned}$$

We now present two useful corollaries of the main theorem. In the next section we will give some specific examples that apply these corollaries.

COROLLARY 1. *Suppose that in the main theorem* $|a_n| \leq 1$ *for* $n = 1, \ldots, N$ *and* $|\beta_n(t)| \leq B$ *for* $n = 1, \ldots, N$ *and all* t. *Then for any* $\xi_1 > 0$ *and* $\xi_2 \in (0,\ 1.6R]$,

$$P\left[\sup_{t\in K}|G(t)| \geq (\xi_1+\xi_2)\sqrt{N\log N}\right] \leq 2\left[\left(|K|L+\frac{32\rho}{\pi\xi_2}\right)\frac{R}{\pi}+3\right]N^{-(1/4B)(\xi_1/\rho)^2},$$

where $R = \sqrt{N/\log N}$ *and* $\rho = (R+1)/(R-1)$.

Proof. Let ξ_1, ξ_2, and N be given, and assume that for $n = 1, 2, \ldots, N$, $|\beta_n(t)| \leq B$ for all t. Under these hypotheses, (2.3) becomes

$$P\left[\sup_{t\in K}|G(t)| \geq \left(\frac{R+1}{R-1}\right)\left(\frac{a}{\lambda}+\frac{8\|G\|_\infty}{\pi^2 M}\right)\right] \leq 2q\exp\left(\lambda^2 NB - a\right). \tag{2.5}$$

In order to rewrite the event given in the left side of (2.5), select a and λ so that

$$\rho\frac{a}{\lambda} = \xi_1\sqrt{N\log N}. \tag{2.6}$$

Next, let $R = \sqrt{N/\log N}$, $\rho = (R+1)/(R-1)$ and $M = [16\rho R/(\pi^2\xi_2)] + 1$. The use of the greatest integer function in the definition of M and the condition that $\xi_2 \in (0,\ 1.6R]$ ensure that M is an integer larger than 1, as required in the hypotheses of the theorem. Upon substitution and using the fact that $|a_n| \leq 1$ implies that $\|G\|_\infty \leq 2N$, we have

$$\rho\frac{a}{\lambda}+\rho\frac{8\|G\|_\infty}{\pi^2 M} \leq \rho\frac{a}{\lambda}+\frac{\rho 16N\xi_2}{16\rho R} = (\xi_1+\xi_2)\sqrt{N\log N}.$$

We have, therefore, the following event inclusion:

$$\left[\sup_{t\in K}|G(t)| \geq (\xi_1+\xi_2)\sqrt{N\log N}\right] \subset \left[\sup_{t\in K}|G(t)| \geq \rho\left(\frac{a}{\lambda}+\frac{8\|G\|_\infty}{\pi^2 M}\right)\right].$$

It follows from (2.5) that

$$P\left[\sup_{t\in K}|G(t)| \geq (\xi_1+\xi_2)\sqrt{N\log N}\right] \leq 2q\exp\left(\lambda^2 NB - a\right). \tag{2.7}$$

This bound holds for all positive values of a and λ, so we will minimize it, subject to the constraint given by (2.6) that $a/\lambda = \xi_1\sqrt{N\log N}/\rho$. If we substitute in for a in (2.7) and simply consider the exponent, we must select λ to minimize the function $f(\lambda)$ given by

$$f(\lambda) = \lambda^2 NB - \lambda\frac{\xi_1}{\rho}\sqrt{N\log N}.$$

The minimum occurs at the following values for λ and a:

$$\lambda = \frac{\xi_1}{2B\rho}\sqrt{\frac{\log N}{N}} \quad\text{and}\quad a = \frac{1}{2B}\left(\frac{\xi_1}{\rho}\right)^2\log N.$$

When these values are substituted in (2.7) the resulting bound is

$$2q\exp\left(\frac{1}{4B}\left(\frac{\xi_1}{\rho}\right)^2\log N - \frac{1}{2B}\left(\frac{\xi_1}{\rho}\right)^2\log N\right) = 2qN^{-(1/4B)(\xi_1/\rho)^2}. \tag{2.8}$$

Finally, observe that $q = |n_2 - n_1| + 2M + 1$ and $|K| = |n_2 - n_1|\pi/RL$, and use the bound from (2.8) along with this value of q in (2.7) to obtain the result. □

Remark. In Examples (a)–(b) of the next section Corollary 1 is used, with a typical value of B being 0.5. In Example (c), where Corollary 2 is used, we will use a fairly modest restriction on $|K|$ to give small enough values of B to significantly improve the resulting estimates.

COROLLARY 2. *Suppose that in the main theorem we have* $|a_n| \le 1$, $|X_n| \le L$, $n_1 = 0$, *and that for some* $\theta > 0$,

$$|\beta_n(t)| \le \theta\, t^2 \quad \textit{for all } n = 1, 2, \dots, N \quad \textit{and all real } t.$$

Assume that the set $K = [0, n_2\pi/RL]$ *is selected so that* $t_q \equiv (n_2 + M)\pi/RL$ *satisfies the inequality* $\theta\, t_q^2 \le B$. *Then, with* ξ_1, ξ_2, R, ρ, *and*M *defined in the same manner as in Corollary* 1,

$$P\left[\sup_{t\in K} |G(t)| \ge (\xi_1 + \xi_2)\sqrt{N \log N}\right] \le 2\left[\left(|K|L + \frac{32\rho}{\pi\xi_2}\right)\frac{R}{\pi} + 3\right] N^{-(1/4B)(\xi_1/\rho)^2}.$$

Proof. Let ξ_1, ξ_2, and N be given, and assume that for some $\theta > 0$, $|\beta_n(t)| \le \theta t^2$ for each t, for $n = 1, \dots, N$. Then, under the remaining hypotheses of the Corollary, for each t_k of the form $k\pi/RL, k = -M, \dots, n_2 + M$, and for each $n = 1, \dots, N$ we have

$$|\beta_n(t_k)| \le \theta\, t_k^2 \le \theta\, t_q^2 \le B. \tag{2.9}$$

The inequalities given by (2.9) allow us to use (2.3) to derive the bound corresponding to (2.5) in the proof of Corollary 1. Now follow the same proof as in the rest of Corollary 1, using the same definitions of R, ρ, M, a, and λ. □

3. Examples. In this section we give several examples that apply the two corollaries of the preceding section. The main task in applying our results is to obtain good estimates for the functions $\beta_n(t)$. We provide two examples to illustrate Corollary 1, in which $\beta_n(t) \le \frac{1}{2}$ for $n = 1, 2, \dots, N$ for each t. Our third example, illustrating Corollary 2, leads to the estimate $\beta_n(t) \le \theta t^2$ for some positive θ and shows that the bound for the probability being estimated can be lowered significantly, depending upon how the set K and the random variables X_n are chosen.

In each of the examples to follow we define $Z_n(t)$ by

$$Z_n(t) = a_n(\sin(X_n t + \phi_n) - \mu_n(t)),$$

where $\mu_n(t) = E[\sin(X_n t + \phi_n)]$, and a_n is real. In any application of our results there are a number of tradeoffs possible between the various parameters involved. Specifically, these parameters are N, the number of array elements; $(\xi_1 + \xi_2)\sqrt{N \text{log} N}$, the desired level for the supremum; $|K|$, the Lebesgue measure of the set K; the location of the set K; the aperture width $2L$; the manner in which the X_n are distributed in $[-L, L]$; and the desired upper bound on the probability being estimated. We do not explore all the possibilities, but will illustrate the effects of some of the parameters. In particular, we will see the dramatic effect that changes in the desired supremum level have upon the resulting probabilities.

Before proceeding to the details of the examples to illustrate Corollary 1, we prove a proposition that has independent interest and application beyond the present setting and which leads to a value of $B = \frac{1}{2}$ in Corollary 1. Letac [10] and Vogt [17], working independently of each other, both suggested proofs for this interesting result. The proof given herein contains elements from each of these proofs. In addition, a proof can be found in Hoeffding [7].

PROPOSITION 1. *Let Y be a random variable taking values in the interval* $[-1, 1]$ *and for which* $E[Y] = \mu$. *Then*

$$E[e^{\gamma(Y-\mu)}] \leq e^{\gamma^2/2} \quad \textit{for all real values of } \gamma.$$

Proof. It suffices to prove the result for $\gamma > 0$, since the proposition is trivially true for $\gamma = 0$, and for $\gamma < 0$ the following proof can be applied to the random variable $Z = -Y$. Hence, for $\gamma > 0$ define the function $k(\gamma)$ by

$$k(\gamma) = \log(E[e^{\gamma Y}]).$$

Next, calculate $k'(\gamma)$ and $k''(\gamma)$:

$$\begin{aligned} k'(\gamma) &= \frac{E\left[Ye^{\gamma Y}\right]}{E\left[e^{\gamma Y}\right]} \qquad \text{and} \\ k''(\gamma) &= \frac{E\left[e^{\gamma Y}\right]E\left[Y^2e^{\gamma Y}\right] - \left(E\left[Ye^{\gamma Y}\right]\right)^2}{\left(E\left[e^{\gamma Y}\right]\right)^2} \\ &= \frac{E\left[Y^2e^{\gamma Y}\right]}{E\left[e^{\gamma Y}\right]} - (k'(\gamma))^2 \\ &\leq 1 - (k'(\gamma))^2 \quad (\text{since } |Y| \leq 1) \\ &\leq 1. \end{aligned}$$

Observe that the definition of k gives $k(0) = 0$ and $k'(0) = \mu$.

Now we apply the fundamental theorem of calculus to both k and k'. Since $\gamma > 0$ and $k''(t) \leq 1$ for $t > 0$ we can write

$$\begin{aligned} k'(\gamma) &= k'(0) + \int_0^\gamma k''(t)dt \leq \mu + \gamma \quad \text{and} \\ k(\gamma) &= k(0) + \int_0^\gamma k'(t)dt \leq \int_0^\gamma (\mu + t)dt = \mu\gamma + \frac{\gamma^2}{2}. \end{aligned}$$

Therefore, for $0 < \gamma < \infty$ we have, from the definition of $k(\gamma)$,

$$\begin{aligned} \log\left(E\left[e^{\gamma Y}\right]\right) &\leq \mu\gamma + \frac{\gamma^2}{2}, \quad \text{or} \\ E\left[e^{\gamma Y}\right] &\leq e^{\mu\gamma + \gamma^2/2} \\ E\left[e^{\gamma(Y-\mu)}\right] &\leq e^{\gamma^2/2}. \qquad \square \end{aligned}$$

Kahane [8, p. 67] defines a random variable X to be a subnormal variable if

$$E[e^{\gamma X}] \leq e^{\gamma^2/2} \quad \text{for all real } \gamma.$$

Hence, Propositon 1 asserts that if Y is any random variable assuming values only in the interval $[-1, 1]$, then $Y - E[Y]$ is a subnormal variable. In particular, the random variables

$$Z_n(t) = a_n(\sin(X_nt + \phi_n) - \mu_n(t))$$

are subnormal whenever $|a_n| \leq 1$.

Example. (a) Consider

$$G(t) = \sum_{n=1}^{N} a_n \left(\sin(X_n t + \phi_n) - \mu_n(t)\right) = \sum_{n=1}^{N} Z_n(t)$$

with only the assumptions that the X_n are independent, $|X_n| \leq L$, $|a_n| \leq 1$, and ϕ_n arbitrary. According to Proposition 1,

$$E[e^{\gamma Z_n(t)}] \leq e^{\gamma^2/2} \quad \text{for all } n, \gamma, \text{and } t,$$

so that for such functions $G(t)$ we can apply Corollary 1 with $B = \frac{1}{2}$.

Before proceeding to calculation of the bounds for the probabilities in Example (a), we simplify our notation and calculations. In Corollary 1 the supremum level is being compared to the quantity $(\xi_1 + \xi_2)\sqrt{N\log N}$, with the bound for the probability being a function of ξ_1 and ξ_2. Let $l = \xi_1 + \xi_2$. With l held constant and ξ_1 varying in the interval $(0, l)$, there can be significant changes in the bound, depending upon how ξ_1 and ξ_2 are chosen. This can be seen simply by noting that ξ_1, as part of the exponent in the bound, has a more profound effect than does ξ_2. In fact, a straightforward but somewhat tedious analysis of the bound for the probability in Corollary 1 shows that ξ_2 should be chosen as a small positive number, and ξ_1 chosen very close to its upper limit of l. We do not seek the value of ξ_2 that minimizes the bound, since the calculations are cumbersome. However, for our examples, which are taken for $N = 10,000$, a convenient and good choice is to select ξ_2 so that

$$\frac{32\rho}{\pi\xi_2} = 100\sqrt{\log N}, \quad \text{whereby}$$
$$\frac{\xi_2}{\rho} = \frac{0.102}{\sqrt{\log N}} \quad \text{and} \quad \frac{\xi_1}{\rho} = \frac{l}{\rho} - \frac{0.102}{\sqrt{\log N}}.$$

If $N = 10,000$, then $R = \sqrt{N/\log N} = 32.95$, $\rho = (R+1)/(R-1) = 1.063$, and $\xi_1/\rho = l/\rho - 0.0336$. With K, L, l, and the X_n still unspecified, Corollary 1 can thus be formulated as

$$P\left[\sup_{t\in K} |G(t)| \geq l\sqrt{N\log N}\right]$$
$$\leq \frac{2\left(|K|L + 100\sqrt{\log N} + 0.288\right)}{\pi\sqrt{\log N}} \times N^{1/2-(1/4B)(0.941\,l-0.0336)^2}.$$

In the example being considered we can take $B = \frac{1}{2}$ and $\sqrt{N\log N} = 303.5$. Choosing ξ_1 and ξ_2 as indicated above and a "time-bandwidth" product of $|K|L = 1000$ yields

(3.1)
$$P\left[\sup_{t\in K}\left|\sum_{n=1}^{10,000} Z_n(t)\right| \geq 303.5\,l\right] \leq \frac{2(1,000 + 303.5 + 0.288)}{3.035\,\pi} \times 10^{2-2(0.941\,l-0.0336)^2}$$

for all collections of N phase angles ϕ_n and coefficients a_n, $|a_n| \leq 1$, and N independent random variables X_n assuming values in $[-L, L]$. In particular, if each $a_n = 1$

and $\phi_n = 0$ we have a sum of $N \sin(X_n t) - \mu_n(t)$ terms, and if each $\phi_n = \pi/2$ we have a sum of $N \cos(X_n t) - \mu_n(t)$ terms. The bound is given below for $l = 1.75$, 2, and 3. As can be seen from Table 1, the probability bounds are extremely sensitive to changes in l.

TABLE 1

l	Upper bound
1.75	1.71×10^{-1}
2	4.02×10^{-3}
3	7.51×10^{-12}

Example. (b) For t real consider the complex-valued function $G(t)$ defined by

$$G(t) = \sum_{n=1}^{N} a_n \left(e^{iX_n t} - E[e^{iX_n t}]\right),$$

where for each $n, |a_n| \leq 1$ and the X_n are independent random variables for which $|X_n| \leq L$. Then, for any nonnegative number a and for each fixed $t \in K$ we have the following set inclusion in the probability space Ω:

$$\left[\omega : |G(\omega, t)| \geq a\sqrt{2}\right] \subset \left[\omega : |\Re G(\omega, t)| \geq a\right] \cup \left[\omega : |\Im G(\omega, t)| \geq a\right].$$

Consequently, we can apply the result of Example (a) to both the real and imaginary parts of $G(t)$ to bound the right-hand side of:

$$P\left[\sup_{t \in K} |G(t)| \geq a\sqrt{2}\right] \leq P\left[\sup_{t \in K} |\Re G(t)| \geq a\right] + P\left[\sup_{t \in K} |\Im G(t)| \geq a\right].$$

Before proceeding to our third example, we state and prove two propositions that are used to specify the functions $\beta_n(t)$ that are needed in order to use Corollary 2.

PROPOSITION 2. *If* $\alpha \geq 0.5575$, *then*

$$e^x - x \leq e^{\alpha x^2} \quad \textit{for all real numbers } x. \tag{3.2}$$

Proof. For real x and y let

$$z(x, y) = e^{yx^2} - e^x + x.$$

Note that for a fixed x, $z(x, y)$ is an increasing function of y. Hence $z(x, y)$ is positive for all points above the curve $z(x, y) = 0$. That is,

$$\{(x, y) \,|\, z(x, y) \geq 0\} = \{(x, \xi) \,|\, \xi \geq y, \text{ where } z(x, y) = 0\}.$$

Therefore, the inequality (3.2) is valid if and only if the horizontal line $y = \alpha$ lies above the curve $z(x, y) = 0$. Thus, the best lower bound for α is y_0, where (x_0, y_0) is a global maximum for the curve $z(x, y) = 0$, which can be written as

$$y = \frac{1}{x^2} \log(e^x - x).$$

An analysis of this curve shows it to have only one critical point, which occurs at the maximum. Using Newton's method to solve $y' = 0$ gives the maximum at $x_0 = 0.6400\ldots$ and $y_0 = 0.5574\ldots$. □

PROPOSITION 3. *Let X be a random variable assuming values only in the interval $[-L, L]$, and suppose that for each real t the random variable $Z(t) = \sin(Xt) - E[\sin(Xt)]$. Suppose that for some constant $w > 0$ (independent of t and j) the following condition holds for every real t:*

$$|E[Z^j(t)]| \leq |wt|^j \quad \textit{for } j = 1, 2, 3, \ldots .$$

Then for each real t we have the following bound:

$$E\left[e^{\gamma Z(t)}\right] \leq e^{\gamma^2 \alpha (wt)^2} \quad \textit{for all real } \gamma,$$

where α is given by Proposition 2.

Proof. The conditions on Z and its moments allow us to write

$$\begin{aligned} E\left[e^{\gamma Z(t)}\right] &= E\left[1 + \gamma Z(t) + \sum_{j=2}^{\infty} \frac{(\gamma Z(t))^j}{j!}\right] \\ &\leq 1 + \sum_{j=2}^{\infty} \frac{|\gamma|^j \, |E[Z^j(t)]\,|}{j!} \\ &\leq 1 + \sum_{j=2}^{\infty} \frac{|\gamma|^j \, |wt|^j}{j!} = e^{|\gamma w t|} - |\gamma w t|. \end{aligned}$$

By Proposition 2, the last expression is bounded above by $\exp\left(\alpha \gamma^2 (wt)^2\right)$. □

Remark. In Proposition 3 we always have $E\left[e^{\gamma Z(t)}\right] \leq e^{\gamma^2/2}$, by Proposition 1. By suitably restricting the set K from which the t values are chosen so that, for some B, $\alpha(wt)^2 \leq B < \frac{1}{2}$ it is possible to improve upon the estimates given by Corollary 1. In this way we exploit the bounds given by Corollary 2 in our concluding example.

Example. (c) Our final example illustrates an application of Corollary 2. For even, positive integers N define N random variables X_n by

$$X_n = Y_n + nw \text{ for integers } n = \frac{-N}{2}, \ldots, \frac{N}{2} - 1,$$

where the Y_n are uniformly distributed on the interval $(0, w)$. Now let $w = 2L/N$, so that the interval $[-L, L]$ is divided into N bins of width w with X_n uniformly distributed on the nth bin. Let

$$Z_n(t) = \sin X_n t - \mu_n(t).$$

By the integral mean value theorem, for each real t and each integer n, we have

$$\mu_n(t) = \frac{1}{w} \int_0^w \sin(nw + y)t \, dy = \sin \xi$$

for some $\xi \in (\, nwt, (n+1)wt\,)$. Hence

$$E[Z_n^j(t)] = \frac{1}{w} \int_0^w (\sin(nw + y)t - \sin \xi)^j \, dy.$$

By the derivative mean value theorem

$$|\sin(nw+y)t-\sin\xi| \leq |wt|, \quad \text{so that}$$

$$\left|E[Z_n^j(t)]\right| \leq |wt|^j.$$

According to Proposition 3 we have

$$E\left[e^{\gamma Z_n(t)}\right] \leq \exp\left(\alpha\gamma^2|wt|^2\right),$$

which gives $\beta_n(t) = \alpha w^2t^2$. Thus in Corollary 2, $\theta = \alpha w^2 = \alpha(2L/N)^2$ for this example. We are interested in sets K of the form $K = [0, n_2\pi/RL]$, where the integer n_2, which essentially determines the extent of the set K, is selected so that $t_q = (n_2+M)\pi/RL$. The restriction in Corollary 2 that $\theta t_q^2 \leq B$ becomes

$$\alpha(2L/N)^2\, t_q^2 \leq B, \quad \text{or} \quad t_q \leq \frac{N\sqrt{B}}{2L\sqrt{\alpha}}.$$

In terms of n_2, with $R = \sqrt{N/\log N}$, this gives

$$n_2+M \leq \frac{N\sqrt{B}}{2L\sqrt{\alpha}} \cdot \frac{L\sqrt{N}}{\pi\sqrt{\log N}} \leq \frac{0.214\sqrt{B}\,N^{3/2}}{\sqrt{\log N}}.$$

To compare Examples (a) and (c) we use the same substitutions for N, M, ξ_1, and ξ_2 as in Example (a) and Corollary 1. Therefore,

$$N = 10,000, \quad \frac{\rho}{\xi_2} = \frac{\sqrt{\log N}}{0.102}, \quad R = 32.95, \quad \text{and} \quad M = \left[\frac{16\,R\rho}{\pi^2\xi_2}\right]+1 = 1592,$$

giving

$$n_2 \leq 0.0706\sqrt{B}\,10^6 - M \leq 7.06\sqrt{B}\,10^4 - 1,592.$$

To illustrate, let $B = \frac{1}{4}$. Then any $n_2 \leq 33,708$ gives a set K satisfying the hypotheses of Corollary 2. In Example (c), let $n_2 = 32,000$, so that $K = [0, 3.2\times 10^4\,\frac{\pi}{RL}]$. Thus, $|K|L = 32,000\frac{\pi}{R} = 3051$, and the estimate in Corollary 2 corresponding to (3.1) is

$$P\left[\sup_{t\in K}\left|\sum_n \sin(X_nt)-\mu_n(t)\right| \geq 303.5\,l\right] \leq \frac{2(3051+303.5+0.288)}{3.035\pi} \times 10^{2-4(0.941l-0.0336)^2}.$$

We now tabulate the bounds for the two Corollaries using the above set K, but different $B's$. (See Table 2.) The estimate for Corollary 1 uses $B = \frac{1}{2}$ and $|K|L = 3051$ to obtain the analogue of (3.1). The estimate for Corollary 2 uses $B = \frac{1}{4}$. The Corollary 1 estimate applies to any collection of X_n distributed independently on $[-L, L]$, while the Corollary 2 estimate is valid for X_n distributed according to the bin approach as described in Example (c).

TABLE 2

l	Cor. 1 Upper bound	Cor. 2 Upper bound
1.50	1.13×10^{-0}	1.80×10^{-3}
1.75	4.39×10^{-1}	2.75×10^{-6}
2.00	1.03×10^{-2}	1.52×10^{-9}

In the case of the Corollary 1 upper bound, the value of $l = 1.5$ gives a bound larger than 1, so a larger value of l needs to be chosen. A comparison of the bounds derived from the two Corollaries shows that in the bin example for t near zero, the bounds for the probabilities of deviation from the mean are lowered significantly. An explanation for this lies in the fact that the bin approach provides more control in the manner in which the X_n are distributed, resulting in less chance of a large deviation when t is small. Plots of the variance of $G(t)$, as a function of t, also show that when t is near zero the variance under the bin approach is considerably smaller than, for example, when the X_n are distributed independently and uniformly across the entire aperture $[-L, L]$, though for larger t the two variances approach the same limiting value of $N/2$ as t increases. Further details and plots of these phenomena can be found in Hendricks [6].

SELBERG INTEGRALS AND HYPERGEOMETRIC FUNCTIONS ASSOCIATED WITH JACK POLYNOMIALS*

JYOICHI KANEKO†

Abstract. A new class of hypergeometric functions of several variables is introduced by using Jack polynomials and a multivariate generalization of Aomoto's result iş given [*SIAM J. Math. Anal.*, 18 (1987), pp. 545-549].

Key words. Selberg integrals, Jack polynomials, hypergeometric functions

AMS subject classifications. 33A15, 33A35, 33A65

1. Introduction. Let $D_{\lambda_1,\lambda_2,\lambda}(x_1,\ldots,x_n)$ be the Selberg density:

$$\prod_{i=1}^{n} x_i^{\lambda_1}(1-x_i)^{\lambda_2} \prod_{1\le i<j\le n} |x_i-x_j|^{\lambda}, \quad \lambda_1,\lambda_2>-1, \quad \lambda>0,$$

and put

$$S_{n,m}(\lambda_1,\lambda_2,\lambda,\mu\colon t_1,\ldots,t_m) \quad (S_{n,m}(t) \text{ for short})$$
$$=\int_{[0,1]^n} \prod_{\substack{1\le i\le n\\1\le k\le m}} (x_i-t_k)^{\mu} D_{\lambda_1,\lambda_2,\lambda}(x_1,\ldots,x_n)\,dx_1\cdots dx_n.$$

We assume for simplicity that t_i, $1\le i\le m$, lies in $\mathbb{C}-[0,1]$ if μ is not a nonnegative integer.

The celebrated formula of Selberg [Se] is

$$(1)\quad S_{n,0}(\lambda_1,\lambda_2,\lambda)=\prod_{i=1}^{n}\frac{\Gamma(i(\lambda/2)+1)\Gamma(\lambda_1+1+(i-1)(\lambda/2))\Gamma(\lambda_2+1+(i-1)(\lambda/2))}{\Gamma((\lambda/2+1)\Gamma(\lambda_1+\lambda_2+2+(n+i-2)(\lambda/2))}.$$

Selberg's evaluation had come to light around 1980 from a dormancy of nearly forty years. Since then this type of integral with Selberg density and its generalizations have been studied intensively by many authors, e.g., [Ao1], [Ao2], [Ao3], [As], [Kad], and [Ma2]. Among them we must mention a result of Aomoto [Ao1]:

$$S_{n,1}(\lambda_1,\lambda_2,\lambda,1;t)=S_{n,0}(\lambda_1,\lambda_2,\lambda)\frac{n!}{\prod_{i=1}^{n}(\alpha+\beta+n+i)}P_n^{(\alpha,\beta)}(1-2t),$$

where $P_n^{(\alpha,\beta)}(x)$ denotes the Jacobi polynomial of degree n and $\alpha=-1+2(\lambda_1+1)/\lambda$, $\beta=-1+2(\lambda_2+1)/\lambda$. The purpose of the present paper is to give a multivariate generalization of this result. Namely, we show that $S_{n,m}(t)$ with $\mu=1$ or $\mu=-\lambda/2$ can be expressed by the hypergeometric function constructed from Jack polynomials which will be defined in § 3.2. (For the precise form of the expression see Theorem 5 in § 6.1.) The rough idea of proof is as follows. First we calculate a holonomic system for $S_{n,m}(t)$ (Theorem 1). Also, it can be verified that the hypergeometric function ${}_2F_1^{(\alpha)}(a,b;c;t_1,\ldots,t_m)$ referred to above satisfies a holonomic system of the same form (Theorem 4 in § 4.3). Then we can adjust the parameters α, a, b, c to make these two systems identical. Therefore, the desired expression follows from the uniqueness property of the solution (Theorem 2 in § 4.1). As a by-product we give a new proof of the integration formula of Jack polynomials conjectured by Macdonald [Ma3] and

* Received by the editors March 13, 1991; accepted for publication (in revised form) October 19, 1992.

† Department of Mathematics, College of General Education, Kyushu University, Fukuoka 810, Japan.

proved by Kadell [Kad]. In § 7 we show that $S_{n.m}(t)$ with $\mu=1$ is a special case of generalized Jacobi polynomials defined and studied by Koornwinder [Ko], Vretare [V], and Debiard [D].

While preparing this paper, the author was notified by A. Korányi that he had introduced the same hypergeometric functions ${}_2F_1^{(\alpha)}(a, b; c; t_1, \dots, t_m)$ in [Kor] and that his student Z. Yan also had proved our Theorem 4 by a similar method in his thesis (see [Y]).

2. Holonomic system for $S_{n,m}(t)$.

2.1. Holonomic system. We denote by Φ the function $D_{\lambda_1,\lambda_2,\lambda}(x)\prod_{1\le i\le n, 1\le k\le m}(x_i-t_k)^{\mu}$, and by ω the logarithmic 1-form $d\log\Phi$. Let ∇_ω be the covariant differentiation defined by $\nabla_\omega\varphi = d\varphi+\omega\wedge\varphi$ for an $(n-1)$-form φ. Since $d(\Phi\varphi)=\Phi\nabla_\omega\varphi$, the Stokes formula gives

$$\int_{[0,1]^n}\Phi\nabla_\omega\varphi=0 \tag{2}$$

as long as the left-hand side exists. Let us denote by $^*dx_i$ the $(n-1)$-form $(-1)^{i-1}dx_1\wedge\cdots\wedge dx_{i-1}\wedge dx_{i+1}\wedge\cdots\wedge dx_n$, and put

$$\varphi_0=\sum_{i=1}^n {}^*dx_i,$$

$$\varphi_1=\sum_{i=1}^n x_i\,{}^*dx_i,$$

$$\psi_k=\sum_{i=1}^n (x_i-t_k)^{-1}\,{}^*dx_i,\qquad 1\le k\le m.$$

The covariant differentiation of these forms are

$$\nabla_\omega\varphi_0=\left[\lambda_1\sum_{i=1}^n x_1^{-1}-\lambda_2\sum_{i=1}^n(1-x_i)^{-1}+\mu\sum_{\substack{1\le i\le n\\1\le k\le m}}(x_i-t_k)^{-1}\right]\theta, \tag{3}$$

$$\nabla_\omega\varphi_1=\left[n\left(1+\lambda_1+\lambda_2+m\mu+\frac{n-1}{2}\lambda\right)-\lambda_2\sum_{i=1}^n(1-x_i)^{-1}+\mu\sum_{\substack{1\le i\le n\\1\le k\le m}}\frac{t_k}{x_i-t_j}\right]\theta, \tag{4}$$

$$\begin{aligned}\nabla_\omega\psi_k=\Bigg[&(\mu-1)\sum_{i=1}^n(x_i-t_k)^{-2}-\lambda\sum_{1\le i<j\le n}((x_i-t_k)(x_j-t_k))^{-1}+\lambda_1 t_k^{-1}\\ &\cdot\left(\sum_{i=1}^n(x_i-t_k)^{-1}-\sum_{i=1}^n x_i^{-1}\right)-\lambda_2(1-t_k)^{-1}\left(\sum_{i=1}^n(1-x_i)^{-1}+\sum_{i=1}^n(x_i-t_k)^{-1}\right)\\ &+\mu\sum_{\substack{l=1\\l\ne k}}^m(t_k-t_l)^{-1}\left(\sum_{i=1}^n(x_i-t_k)^{-1}-\sum_{i=1}^n(x_i-t_l)^{-1}\right)\Bigg]\theta,\end{aligned} \tag{5}$$

where θ denotes the volume n-form: $\theta=dx_1\wedge\cdots\wedge dx_n$. For n-forms ξ, η, we write $\xi\sim\eta$ if $\xi-\eta=\nabla_\omega\varphi$ for some $(n-1)$-form φ. It follows from (3) and (4) that

$$\left[\lambda_1\sum_{i=1}^n x_i^{-1}\right]\theta\sim\left[n\left(1+\lambda_1+\lambda_2+m\mu+\frac{n-1}{2}\lambda\right)-\mu\sum_{\substack{1\le i\le n\\1\le k\le m}}\frac{1-t_k}{x_i-t_k}\right]\theta,$$

$$\left[\lambda_2\sum_{i=1}^n(1-x_i)^{-1}\right]\theta\sim\left[n\left(1+\lambda_1+\lambda_2+m\mu+\frac{n-1}{2}\lambda\right)+\mu\sum_{\substack{1\le i\le n\\1\le k\le m}}\frac{t_k}{x_i-t_k}\right]\theta.$$

Substituting these into (5), we obtain

$$
\begin{aligned}
\nabla_\omega \psi_k \sim \Bigg[& (\mu-1)\sum_{i=1}^{n}(x_i-t_k)^{-2}-\lambda\sum_{1\le i<j\le n}((x_i-t_k)(x_j-t_k))^{-1} \\
& +(\lambda_1 t_k^{-1}-\lambda_2(1-t_k)^{-1})\left(\sum_{i=1}^{n}(x_i-t_k)^{-1}\right) \\
& -t_k^{-1}\left(n\left(1+\lambda_1+\lambda_2+m\mu+\frac{n-1}{2}\lambda\right)-\mu\sum_{\substack{1\le i\le n\\ 1\le l\le m}}\frac{1-t_l}{x_i-t_l}\right) \\
& -(1-t_k)^{-1}\left(n\left(1+\lambda_1+\lambda_2+m\mu+\frac{n-1}{2}\lambda\right)+\mu\sum_{\substack{1\le i\le n\\ 1\le l\le m}}\frac{t_l}{x_i-t_l}\right) \\
& +\mu\sum_{\substack{l=1\\ l\ne k}}^{m}(t_k-t_l)^{-1}\left(\sum_{i=1}^{n}(x_i-t_k)^{-1}-\sum_{i=1}^{n}(x_i-t_l)^{-1}\right)\Bigg]\theta.
\end{aligned} \tag{6}
$$

On the other hand, one can easily show that

$$
\frac{\partial S_{n,m}(t)}{\partial t_k}=-\mu\int_{[0,1]^n}\Phi\left[\sum_{i=1}^{n}(x_i-t_k)^{-1}\right]\theta, \tag{7}
$$

$$
\begin{aligned}
\frac{\partial^2 S_{n,m}(t)}{\partial t_k^2}=\int_{[01]^n}\Phi\Bigg[& (\mu^2-\mu)\sum_{i=1}^{n}(x_i-t_k)^{-2} \\
& +2\mu^2\sum_{1\le i<j\le n}((x_i-t_k)(x_j-t_k))^{-1}\Bigg]\theta.
\end{aligned} \tag{8}
$$

Suppose now that the ratio $(\mu^2-\mu)/2\mu^2$ equals $(\mu-1)/(-\lambda)$, i.e., $\mu=1$ or $\mu=-\lambda/2$. Then by (8) the first two sums of the right-hand side of (6) add up to a constant multiple of $\partial^2 S_{n,m}(t)/\partial t_k^2$. Hence, by virtue of (7) and (8), taking ψ_k for φ of (2) yields a partial differential equation of $S_{n,m}(t)$ for each k. Moreover, its principal part contains only $\partial^2 S_{n,m}(t)/\partial t_k^2$. Thus we have proved the following.

THEOREM 1. *Assume* $\mu=1$ *or* $\mu=-\lambda/2$. *Then* $S_{n,m}(\lambda_1,\lambda_2,\lambda,\mu;\, t)$ *satisfies the following holonomic system*:

$$
\begin{aligned}
& t_i(1-t_i)\frac{\partial^2 F}{\partial t_i^2}+\left\{c-\frac{1}{\alpha}(m-1)-\left(a+b+1-\frac{1}{\alpha}(m-1)\right)t_i\right\}\frac{\partial F}{\partial t_i}-abF \\
& +\frac{1}{\alpha}\left\{\sum_{\substack{j=1\\ j\ne i}}^{m}\frac{t_i(1-t_i)}{t_i-t_j}\frac{\partial F}{\partial t_i}-\sum_{\substack{j=1\\ j\ne i}}^{m}\frac{t_j(1-t_j)}{t_i-t_j}\frac{\partial F}{\partial t_j}\right\}=0, \qquad i=1,\dots,m,
\end{aligned} \tag{9}
$$

where $\alpha=\lambda/2$, $a=-n$, $b=(2/\lambda)(\lambda_1+\lambda_2+m+1)+n+1$, $c=(2/\lambda)(\lambda_1+m)$ *if* $\mu=1$, *and* $\alpha=2/\lambda$, $a=(\lambda/2)n$, $b=-(\lambda_1+\lambda_2+1)+\lambda/2(m-n+1)$, $c=-\lambda_1+(\lambda/2)m$ *if* $\mu=-\lambda/2$.

Remark. The rank of the holonomic system (9) is 2^m. This and related matters will be treated in a forthcoming paper.

2.2. Cases of $m=1,2$. In case $m=1$, (9) is nothing but the Gauss hypergeometric equation. Hence if $\mu=1$ the result of Aomoto [Ao1] mentioned above follows at once from (9). In case $m=2$, (9) is related with the holonomic system (F_4) of Appell's hypergeometric function F_4 [A-K] in the following way. The system (F_4) is

$$x(1-x)\frac{\partial^2 F}{\partial x^2}-y^2\frac{\partial^2 F}{\partial y^2}-2xy\frac{\partial^2 F}{\partial x\,\partial y}+(c_1-(a+b+1)x)\frac{\partial F}{\partial x}$$

$$-(a+b+1)y\frac{\partial F}{\partial y}-abF=0,$$

$$y(1-y)\frac{\partial^2 F}{\partial y^2}-x^2\frac{\partial^2 F}{\partial x^2}-2xy\frac{\partial^2 F}{\partial x\,\partial y}+(c_2-(a+b+1)y)\frac{\partial F}{\partial y}$$

$$-(a+b+1)x\frac{\partial F}{\partial x}-abF=0.$$

Let $\phi:\mathbb{C}^2\to\mathbb{C}^2$ be defined by $\phi(t_1,t_2)=(t_1t_2,(1-t_1)(1-t_2))=(x,y)$. Then $\phi^*(F_4)$, the pull back of the system (F_4) by ϕ, is [Kat]

$$(t_1-t_2)\left\{t_1(1-t_1)\frac{\partial^2 F}{\partial t_1^2}+(c_1-(a+b+1)t_1)\frac{\partial F}{\partial t_1}-abF\right\}+\varepsilon(t_2-1)\left(t_1\frac{\partial F}{\partial t_1}-t_2\frac{\partial F}{\partial t_2}\right)=0,$$

$$(t_2-t_1)\left\{t_2(1-t_2)\frac{\partial^2 F}{\partial t_2^2}+(c_1-(a+b+1)t_2)\frac{\partial F}{\partial t_2}-abF\right\}+\varepsilon(t_1-1)\left(t_2\frac{\partial F}{\partial t_2}-t_1\frac{\partial F}{\partial t_1}\right)=0,$$

where $\varepsilon=c_1+c_2-a-b-1$. Putting $c_1=c-(1/\alpha)$ and $c_2=a+b-c+1$ we see that $\phi^*(F_4)$ reduces to the system (9). It is known that if c_1 and c_2 are not integers, then (F_4) has the following four linearly independent solutions near the origin [A-K, p. 52]:

$$F_4(a,b,c_1,c_2;x,y)=\sum_{m,n=0}^{\infty}\frac{(a)_{m+n}(b)_{m+n}}{(c_1)_m(c_2)_n}\frac{x^my^n}{m!\,n!},$$

$$\begin{aligned}&x^{1-c_1}F_4(a-c_1+1,b-c_1+1,2-c_1,c_2;x,y),\\ (10)\qquad &y^{1-c_2}F_4(a-c_2+1,b-c_2+1,c_1,2-c_2;x,y),\\ &x^{1-c_1}y^{1-c_2}F_4(a-c_1-c_2+2,b-c_1-c_2+2,2-c_1,2-c_2;x,y),\end{aligned}$$

where $(a)_n=\Gamma(a+n)/\Gamma(a)$. Hence when $\mu=1$ we get

$$S_{n,2}(\lambda_1,\lambda_2,\lambda,1;t_1,t_2)=(-1)^n\cdot S_{n,0}(\lambda_1+1,\lambda_2+1,\lambda)$$

$$\cdot F_4(a,b,c_1,c_2;t_1t_2,(1-t_1)(1-t_2)),$$

where $a=-n$, $b=(2/\lambda)(\lambda_1+\lambda_2+3)+n-1$, $c_1=(2/\lambda)(\lambda_1+1)$, $c_2=(2/\lambda)(\lambda_2+1)$.

The case of $\mu=-\lambda/2$ will be treated in § 6.2.

3. Hypergeometric function.

3.1. Jack symmetric functions. We recall here the basic properties of Jack symmetric functions. Our reference is the fundamental [St].

Let $\kappa=(\kappa_1,\kappa_2,\ldots)$ be a partition and $\kappa'=(\kappa_1',\kappa_2',\ldots)$ be the conjugate partition. The number κ_1' of parts of κ is denoted by $l(\kappa)$ and called the length of κ. We write $|\kappa|=d$ if $\kappa_1+\kappa_2+\cdots=d$. If ν is another partition, then write $\nu\leq\kappa$ if $|\nu|=|\kappa|$ and $\nu_1+\nu_2+\cdots+\nu_i\leq\kappa_1+\kappa_2+\cdots+\kappa_i$ for all i. If κ has $m_i=m_i(\kappa)$ parts equal to i, then write

$$z_\kappa=(1^{m_1}2^{m_2}\cdots)m_1!\,m_2!\cdots.$$

Let $t=(t_1, t_2, \ldots)$ be an infinite set of indeterminates. We define the *minomial symmetric function* $m_\kappa = m_\kappa(t)$ indexed by partition $\kappa = (\kappa_1, \kappa_2, \ldots)$ by

$$m_\kappa = \sum t_1^{\kappa_1} t_2^{\kappa_2} \ldots,$$

where the summation sign indicates that we are to form all distinct monomials in t_i with exponent $\kappa_1, \kappa_2, \ldots$. The *power sum symmetric function* p_κ is defined by

$$p_\kappa = p_{\kappa_1} p_{\kappa_2}, \ldots, \qquad p_d = \sum t_i^d = m_{(d)},$$

where (d) denotes the partition $(d, 0, 0, \ldots)$.

Let α be a parameter, and let $\mathbb{Q}(\alpha)$ denote the field of all rational functions of α with rational coefficients. We define a scalar product $\langle\,,\rangle$ on the vector space of all symmetric functions of t of bounded degree over the field $\mathbb{Q}(\alpha)$ by the condition

$$\langle p_\kappa, p_\nu \rangle = \delta_{\kappa\nu} z_\kappa \alpha^{l(\kappa)},$$

where $\delta_{\kappa\nu} = 0$ if $\kappa \neq \nu$ and $\delta_{\kappa\kappa} = 1$. The *Jack symmetric function* $J_\kappa = J_\kappa^{(\alpha)}(t)$ are defined to be the unique symmetric function satisfying the following three conditions.

(P1) (orthogonality). $\langle J_\kappa, J_\nu \rangle = 0$ if $\kappa \neq \nu$.

(P2) (triangularity). If we write J_κ in terms of the monomial symmetric functions $J_\kappa = \sum_\nu v_{\kappa\nu}(\alpha) m_\nu$, then $v_{\kappa\nu}(\alpha) = 0$ unless $\nu \leq \kappa$.

(P3) (normalization). If $|\kappa| = d$, then the coefficient $v_{\kappa,1}d$ of $t_1 t_2 \cdots t_d$ in J_κ is equal to $d!$.

Setting all but finitely many variables equal to 0 (say $t_{m+1} = t_{m+2} = \cdots = 0$) in J_κ, we obtain a polynomial $J_\kappa^{(\alpha)}(t_1, \ldots, t_m)$ which we call the *Jack polynomial.* Note that the Jack polynomials $J_\kappa(t_1, \ldots, t_r)$ vanish for $r < l(\kappa)$ and are linearly independent otherwise [St, Prop. 2.5]. We will write J_n for $J_{(n)}$. Clearly we have $J_1 = t_1 + t_2 + \cdots$. Define the differential operator $D(\alpha)$ by

$$D(\alpha) = \frac{\alpha}{2} \sum_{i=1}^{m} t_i^2 \frac{\partial^2}{\partial t_i^2} + \sum_{\substack{1 \leq i,j \leq m \\ i \neq j}} \frac{t_i^2}{t_i - t_j} \frac{\partial}{\partial t_i}. \tag{11}$$

Then the Jack polynomials $J_\kappa^{(\alpha)}(t_1, \ldots, t_m)$ with $l(\kappa) \leq m$ are eigenfunctions of $D(\alpha)$ [St, Thm. 3.1]:

$$D(\alpha) J_\kappa^{(\alpha)}(t_1, \ldots, t_m) = e_\kappa(\alpha) J_\kappa^{(\alpha)}(t_1, \ldots, t_m), \tag{12}$$

where the eigenvalue $e_\kappa(\alpha)$ is given by

$$e_\kappa(\alpha) = \alpha \sum_{i=1}^{m} \kappa_i \frac{(\kappa_i - 1)}{2} - \sum_{i=1}^{m} (i-1)\kappa_i + (m-1)|\kappa|. \tag{13}$$

By [St, Prop. 2.3] we have

$$(t_1 + \cdots + t_m)^d = \alpha^d d! \sum_{|\kappa| = d} J_\kappa j_\kappa^{-1}, \tag{14}$$

where $j_\kappa = \langle J_\kappa, J_\kappa \rangle$. The value of j_κ is given by [St, Thm. 5.8]

$$\begin{aligned} j_\kappa &= \prod_{s \in \kappa} h_*^\kappa(s) h_\kappa^*(s), \\ h_\kappa^*(s) &= \kappa_j' - i + \alpha(\kappa_i - j + 1), \\ h_*^\kappa(s) &= \kappa_j' - i + 1 + \alpha(\kappa_i - j), \end{aligned} \tag{15}$$

where a partition κ is identified with its diagram: $\kappa = \{s=(i,j)\colon 1\le i\le l(\kappa), 1\le j\le \kappa_i\}$. We change the normalization by defining

$$C_\kappa^{(\alpha)}(t_1,\ldots,t_m)=\alpha^{|\kappa|}|\kappa|!J_\kappa^{(\alpha)}j_\kappa^{-1} \tag{16}$$

to get

$$(t_1+\cdots+t_m)^d=\sum_{|\kappa|=d}C_\kappa^{(\alpha)}(t). \tag{17}$$

We will also need the explicit formula of $C_\kappa^{(\alpha)}(t)$ evaluated at $t_1=t_2=\cdots=t_r=1$, $t_{r+1}=t_{r+2}=\cdots=t_m=0$, which we denote by $C_\kappa^{(\alpha)}(1^r)$ [St, Thm. 5.4]:

$$C_\kappa^{(\alpha)}(1^r)=\alpha^{|\kappa|}|\kappa|!j_\kappa^{-1}\prod_{(i,j)\in\kappa}(r-(i-1)+\alpha(j-1)). \tag{18}$$

3.2. Hypergeometric function. We assume from now on that $\alpha>0$. We define a generalized factorial function $[a]_\kappa^{(\alpha)}$ by

$$[a]_\kappa^{(\alpha)}=\prod_{i=1}^{l(\kappa)}\left(a-\frac{1}{\alpha}(i-1)\right)_{\kappa_i}. \tag{19}$$

Definition. Let $a_1,\ldots,a_p,b_1,\ldots,b_q$ be complex numbers such that $b_j-(1/\alpha)\times(i-1)$, $1\le j\le q$, $1\le i\le m$, are neither negative integers nor zero. The *hypergeometric function* ${}_pF_q^{(\alpha)}(a_1,\ldots,a_p;\,b_1,\ldots,b_q;\,t_1,\ldots,t_m)$ is defined by the series

$$\begin{aligned}&{}_pF_q^{(\alpha)}(a_1,\ldots,a_p;\,b_1,\ldots,b_q;\,t)\\&=\sum_{d=0}^{\infty}\sum_{|\kappa|=d}\frac{[a_1]_\kappa^{(\alpha)}\cdots[a_p]_\kappa^{(\alpha)}}{[b_1]_\kappa^{(\alpha)}\cdots[b_q]_\kappa^{(\alpha)}}\frac{C_\kappa^{(\alpha)}(t)}{d!}.\end{aligned} \tag{20}$$

Remark. The hypergeometric function ${}_pF_q^{(\alpha)}$ for $\alpha=2$ was first introduced by Herz [H] by means of Laplace transforms. The zonal polynomial expansion as in (20) was found by Constantine [C].

Next we consider the convergence of the series (20). It is necessary to estimate $C_\kappa^{(\alpha)}(t)$. For this we content ourselves with the following lemma.

Lemma 1. *Let* $\|t\|=\max\{|t_1|,\ldots,|t_m|\}$ *and* $\beta=\max\{1,1/\alpha\}$. *Then*

$$|C_\kappa^{(\alpha)}(t)|\le C\cdot\alpha^d\cdot(\beta m)^{(3/2)d}\cdot d^{m/2}\|t\|^d,\qquad d=|\kappa|, \tag{21}$$

where C denotes a constant depending only on m.

Proof. Write

$$J_\kappa^{(\alpha)}(t)=\sum_{|\nu|=d}a_\nu p_\nu,\qquad d=|\kappa|,$$

so that

$$j_\kappa=\sum_{|\nu|=d}a_\nu^2 z_\nu\alpha^{l(\nu)}.$$

By Cauchy's inequality we have

$$|J_\kappa^{(\alpha)}(t)|\le j_\kappa^{1/2}\left\{\sum_{|\nu|=d}\frac{p_\nu^2}{z_\nu\alpha^{l(\nu)}}\right\}^{1/2}. \tag{22}$$

It follows from (15) that

$$j_\kappa\ge\beta^{-2d}\prod_{(i,j)\in\kappa}h_{ij}^2,$$

where h_{ij} is the hook-length of κ at (i,j):

$$h_{ij}=\kappa_i+\kappa_j'-i-j+1.$$

Let f_κ denote the number of standard tableau of shape κ [Ma1, p. 5]. The hook formula gives

$$f_\kappa = \frac{d!}{\prod_{(i,j)\in\kappa} h_{ij}}.$$

The asymptotic behavior of f_κ has been determined by Regev [R], which implies

$$f_\kappa \le C_1 m^d,$$

where C_1 is a constant depending only on m. Hence

$$C_1^{-1} m^{-d} d! \le \prod_{(i,j)\in\kappa} h_{ij},$$

so that we have

$$j_\kappa \ge C_1^{-2}(\beta m)^{-2d}(d!)^2. \tag{23}$$

Let h_d denote the dth *complete symmetric function*: $h_d = \sum_{|\nu|=d} m_\nu$. Then we have $h_d = \sum_{|\nu|=d} z_\nu^{-1} p_\nu$ (see [Ma1, p. 171]). Hence

$$\left|\sum_{|\nu|=d} \frac{p_\nu^2}{z_\nu \alpha^{l(\nu)}}\right| \le \|t\|^{2d}\binom{m+d-1}{d}(\beta m)^d. \tag{24}$$

Stirling's formula gives $\binom{m+d-1}{d} \le C_2 \cdot d^m$, C_2 a constant depending only on m. Therefore, (21) is a consequence of (22), (23), and (24).

Proposition 1. (1) *If $p \le q$, then the series* (20) *converges absolutely for all $t \in \mathbb{C}^m$.*

(2) *If $p = q+1$, then* (20) *converges absolutely for $\|t\| < \rho$ for some positive constant ρ.*

(3) *If $p > q+1$, then* (20) *diverges unless it terminates.*

Proof. We compare the series (20) with the generalized hypergeometric series

$${}_pF_q(a_1, \ldots, a_p;\, b_1, \ldots, b_q;\, z) = \sum_{d=0}^{\infty} \frac{(a_1)_d \cdots (a_p)_d}{(b_1)_d \cdots (b_q)_d} \frac{z^d}{d!}, \tag{25}$$

which is known to have radius of convergence $\rho = \infty$ if $p \le q$, $\rho = 1$ if $p = q+1$, $\rho = 0$ if $p > q+1$ unless it terminates. Put

$$a_{ji} = a_j - \frac{1}{\alpha}(i-1), \qquad b_{ki} = b_k - \frac{1}{\alpha}(i-1), \quad 1 \le j \le p, \quad 1 \le k \le q, \quad 1 \le i \le m.$$

It follows from Lemma 1 that

$$|C_\kappa^{(\alpha)}(t)| \le C \cdot R^d \|t\|^d$$

for some R. Note also that

$$\kappa_1!\kappa_2! \cdots \kappa_m! \le d!, \qquad d = |\kappa|.$$

These inequalities imply

$$\begin{aligned}
&\sum_{d=0}^{\infty} \sum_{|\kappa|=d} \left| \frac{[a_1]_\kappa^{(\alpha)} \cdots [a_p]_\kappa^{(\alpha)}}{[b_1]_\kappa^{(\alpha)} \cdots [b_q]_\kappa^{(\alpha)}} \frac{C_\kappa^{(\alpha)}(t)}{d!} \right| \\
&\le C \cdot \sum_{d=0}^{\infty} \sum_{|\kappa|=d} \left| \frac{[a_1]_\kappa^{(\alpha)} \cdots [a_p]_\kappa^{(\alpha)}}{[b_1]_\kappa^{(\alpha)} \cdots [b_q]_\kappa^{(\alpha)}} \right| \frac{(R\|t\|)^d}{\kappa_1! \cdots \kappa_m!} \\
&\le C \cdot \prod_{i=1}^{m} \left\{ \sum_{\kappa_i=0}^{\infty} \left| \frac{(a_{1i})_{\kappa_i} \cdots (a_{pi})_{\kappa_i}}{(b_{1i})_{\kappa_i} \cdots (b_{qi})_{\kappa_i}} \right| \frac{(R\|t\|)^{\kappa_i}}{\kappa_i!} \right\}.
\end{aligned}$$

Thus parts (1) and (2) of the theorem are clear (put $\rho = R^{-1}$ in Case (2)).

For the proof of divergence in the case of (3), note first that if $\kappa=(d)=(d,0,\dots,0)$ and $t=1^r$, then (15) and (18) give

$$C_d^{(\alpha)}(1^r)=\left\{\prod_{i=1}^{d}(1+\alpha(i-1))\right\}^{-1}\left\{\prod_{i=1}^{d}(r+\alpha(i-1))\right\},$$

where $C_d^{(\alpha)}(t)$ is short for $C_{(d)}^{(\alpha)}(t)$. Suppose $t\neq(0,\dots,0)$ and put $\tau=\min_{1\leq i\leq m,t_i\neq 0}\{|t_i|\}$, $r=$ the number of nonzero t_i. Then we have

$$\begin{aligned}\sum_{d=0}^{\infty}\sum_{|\kappa|=d}&\left|\frac{[a_1]_\kappa^{(\alpha)}\cdots[a_p]_\kappa^{(\alpha)}}{[b_1]_\kappa^{(\alpha)}\cdots[b_q]_\kappa^{(\alpha)}}\frac{C_\kappa^{(\alpha)}(t)}{d!}\right|\\ &\geq\sum_{d=0}^{\infty}\left|\frac{(a_1)_d\cdots(a_p)_d}{(b_1)_d\cdots(b_q)_d}\right|\frac{\tau^d}{d!}\cdot C_d^{(\alpha)}(1^r).\end{aligned}$$

Since $C_d^{(\alpha)}(1^r)\geq 1$, we get the divergence.

4. Holonomic system for the hypergeometric function.

4.1. Uniqueness theorem. The following uniqueness property was first proved in the case $\alpha=2$ by Muirhead [Mu]. His proof can be easily generalized for general α.

THEOREM 2. *Assume that $c-(1/\alpha)(i-1)$ is not a negative integer or zero for $1\leq i\leq m$. Then each of the m differential equations in the system* (9) *has the same unique formal power series solution $F(t)$ subject to the following conditions*:

(a) *$F(t)$ is a symmetric function of $t_1,\dots,t_m$; and*

(b) *$F(t)$ has a formal power series expansion at $(0,\dots,0)$ with $F(0)=1$.*

Proof. Since we assume that $F(t)$ is symmetric, it is sufficient to consider the first differential equation of (9) $(i=1)$

$$\begin{aligned}&t_1(1-t_1)\frac{\partial^2F}{\partial t_1^2}+\left\{c-\frac{1}{\alpha}(m-1)-\left(a+b+1-\frac{1}{\alpha}(m-1)\right)t_1\right\}\frac{\partial F}{\partial t_1}-abF\\ &\quad+\frac{1}{\alpha}\left\{\sum_{j=2}^{m}\frac{t_1(1-t_1)}{t_1-t_j}\frac{\partial F}{\partial t_1}-\sum_{j=2}^{m}\frac{t_j(1-t_j)}{t_1-t_j}\frac{\partial F}{\partial t_j}\right\}=0.\end{aligned}\tag{26}$$

As in James [J] we transform (26) to a partial differential equation in terms of the elementary symmetric function $r_1,\dots,r_m$ of $t_1,\dots,t_m$. Let $r_j^{(i)}$ for $j=1,\dots,m-1$ denote the jth elementary symmetric function formed from the variables $t_1,\dots,t_m$ omitting t_i. Then clearly

$$r_j=t_ir_{j-1}^{(i)}+r_j^{(i)},\qquad j=2,\dots,m-1.\tag{27}$$

Introducing dummy variables

$$\begin{aligned}r_0&=r_0^{(i)}=0,\\ r_j&=0\qquad(j=-1,-2,\dots\text{ and }m+1,m+2,\dots),\\ r_j^{(i)}&=0\qquad(j=-1,-2,\dots\text{ and }m,m+1,\dots),\end{aligned}$$

we may extend the relations (27) to hold for $-\infty<j<\infty$. As

$$\frac{\partial}{\partial t_i}=\sum_{\nu=1}^{m}r_{\nu-1}^{(i)}\frac{\partial}{\partial r_\nu},$$

$$\frac{\partial^2}{\partial t_1^2}=\sum_{\mu,\nu=1}^{m}r_{\mu-1}^{(1)}r_{\nu-1}^{(1)}\frac{\partial^2}{\partial r_\mu\,\partial r_\nu},$$

the differential equation (26) becomes

$$\begin{aligned}&\sum_{\mu,\nu=1}^{m} t_1(1-t_1)r_{\mu-1}^{(1)}r_{\nu-1}^{(1)}\frac{\partial^2 F}{\partial r_\mu\,\partial r_\nu}\\ &\quad+\sum_{j=1}^{m}\left\{(c-(a+b+1)t_1)r_{j-1}^{(1)}+\frac{1}{\alpha}\left(\sum_{i=2}^{m}\frac{t_i(1-t_1)}{t_1-t_i}\,r_{j-1}^{(1)}-\sum_{i=2}^{m}\frac{t_i(1-t_i)}{t_1-t_i}\,r_{j-1}^{(i)}\right)\right\}\\ &\qquad\cdot\frac{\partial F}{\partial r_j}-abF=0.\end{aligned}\tag{28}$$

It follows from (27) that

$$\sum_{i=2}^{m}\left(\frac{t_i(1-t_1)}{t_1-t_i}\,r_{j-1}^{(1)}-\frac{t_i(1-t_i)}{t_1-t_i}\,r_{j=1}^{(i)}\right)=\sum_{i=2}^{m}\frac{t_i}{t_1-t_i}(r_{j-1}^{(1)}-r_{j-1}^{(i)}+r_j^{(1)}-r_j^{(i)})$$

and that

$$\sum_{i=2}^{m}(r_{j-1}^{(1)}-r_{j-1}^{(i)}+r_j^{(1)}-r_j^{(i)})=m(r_{j-1}^{(1)}+r_j^{(1)})-(m-j+1)r_{j-1}-(m-j)r_j.$$

Denoting by $r_j^{(1,\,i)}$ the jth elementary symmetric function in the variables $t_2,\dots,t_m$ omitting t_i $(i\neq 1)$, we have

$$\begin{aligned}&\sum_{i=2}^{m}\frac{t_1}{t_1-t_i}(r_{j-1}^{(1)}-r_{j-1}^{(i)}+r_j^{(1)}-r_j^{(i)})\\ &\quad=\sum_{i=2}^{m}t_1(r_{j-2}^{(1,i)}+r_{j-1}^{(1,i)})\qquad (r_{-1}^{(1,i)}=0)\\ &\quad=-((m-j+1)(r_{j-1}-r_{j-1}^{(1)})+(m-j)(r_j-r_j^{(1)})).\end{aligned}$$

Hence

$$\begin{aligned}&(c-(a+b+1)t_1)r_{j-1}^{(1)}+\frac{1}{\alpha}\sum_{i=2}^{m}\left(\frac{t_i(1-t_1)}{t_1-t_i}\,r_{j-1}^{(1)}-\frac{t_i(1-t_i)}{t_1-t_i}\,r_{j-1}^{(i)}\right)\\ &\quad=c-\frac{1}{\alpha}(j-1)r_{j-1}^{(1)}+\left(a+b+1-\frac{1}{\alpha}j\right)r_j^{(1)}-(a+b+1)r_j.\end{aligned}$$

On the other hand, we see that

$$\begin{aligned}t_1r_{\mu-1}^{(1)}r_{\nu-1}^{(1)}&=r_\mu r_{\nu-1}^{(1)}-r_\mu^{(1)}r_{\nu-1}^{(1)}\\ &=r_\mu r_{\nu-1}^{(1)}-r_\mu^{(1)}(r_{\nu-1}-t_1r_{\nu-2}^{(1)})\\ &=r_\mu r_{\nu-1}^{(1)}-r_\mu^{(1)}r_{\nu-1}+t_1r_\mu^{(1)}r_{\nu-2}^{(1)}.\end{aligned}$$

Iterating this relation we have

$$\begin{aligned}t_1r_{\mu-1}^{(1)}r_{\nu-1}^{(1)}=r_\mu r_{\nu-1}^{(1)}-r_{\nu-1}r_\mu^{(1)}+r_{\mu+1}r_{\nu-2}^{(1)}-r_{\nu-2}r_{\mu+1}^{(1)}+\cdots\\ +r_{\mu+\nu-1}r_0^{(1)}-r_0r_{\mu+\nu-1}^{(1)}+t_1r_{\mu+\nu-1}^{(1)}r_{-1}^{(1)}\end{aligned}$$

and $r_{-1}^{(1)}=0$. Therefore the differential equation (28) becomes

$$\begin{aligned}&\sum_{\mu,\nu=1}^{m}\left\{\sum_{j=1}^{m}a_{\mu\nu}^{(j)}(r_{j-1}^{(1)}-r_j+r_j^{(1)})\right\}\frac{\partial^2 F}{\partial r_\mu\,\partial r_\nu}\\ &\quad+\sum_{j=1}^{m}\left\{\left(c-\frac{1}{\alpha}(j-1)\right)r_{j-1}^{(1)}+\left(a+b+1-\frac{1}{\alpha}j\right)r_j^{(1)}-(a+b+1)r_j\right\}\\ &\qquad\cdot\frac{\partial F}{\partial r_j}-abF=0,\end{aligned}\tag{29}$$

where $a_{\mu\nu}^{(j)} = a_{\nu\mu}^{(j)}$ and for $\mu \le \nu$,

$$a_{\mu\nu}^{(j)} = \begin{array}{ll} r_{\mu+\nu-j} & \text{for } 1 \le j \le \mu \\ 0 & \text{for } \mu < j \le \nu \\ -r_{\mu+\nu-j} & \text{for } \nu < j \le \mu+\nu \\ 0 & \text{for } \mu+\nu < j \qquad j = 1, \dots, m. \end{array}$$

In (29) we can equate coefficients of $r_{j-1}^{(1)}$ to zero for $j = 1, \dots, m$ according to [J, Lemma, p. 371] to obtain the system of partial differential equations $(a_{\mu\nu}^{(0)} = 0)$:

$$\begin{aligned} &\sum_{\mu,\nu=1}^{m} (a_{\mu\nu}^{(j-1)} + a_{\mu\nu}^{(j)}) \frac{\partial^2 F}{\partial r_\mu \, \partial r_\nu} + \left(c - \frac{1}{\alpha}(j-1)\right) \frac{\partial F}{\partial r_j} + \left(a+b+1-\frac{1}{\alpha}(j-1)\right) \frac{\partial F}{\partial r_{j-1}} \\ &- \delta_{1j} \left\{ \sum_{\mu,\nu=1}^{m} \left(\sum_{i=1}^{m} a_{\mu\nu}^{(i)} r_i \right) \frac{\partial^2 F}{\partial r_\mu \, \partial r_\nu} + (a+b+1) \sum_{i=1}^{m} r_i \frac{\partial F}{\partial r_i} + abF \right\} = 0, \qquad j = 1, \dots, m. \end{aligned} \tag{30}$$

Now we put

$$F(r_1, \dots, r_m) = \sum_{j_1, \dots, j_m = 0}^{\infty} c(j_1, \dots, j_m) r_1^{j_1} \cdots r_m^{j_m} \tag{31}$$

with $c(0, \dots, 0) = 1$. Order the coefficients $c(j_1, \dots, j_m)$ in lexicographic ordering, counting j_m as the first letter and j_1 as the last. Substituting (31) in the differential equation (30) with $j = k$ and putting $r_{k+1} = \cdots = r_m = 0$, we obtain a recurrence relation which expresses $j_k(j_k - 1 + c - (1/\alpha)(k-1))c(j_1, \dots, j_k, 0, \dots, 0)$ in terms of coefficients of lower order. Since $j_k - 1 + c - (1/\alpha)(k-1)$ is not zero by assumption, one can iterate this reduction until one reaches $c(0, \dots, 0)$ which we put equal to one. Hence all the coefficients $c(j_1, \dots, j_m)$ of (31) are uniquely determined by the recurrence relations. This completes the proof of Theorem 2.

Remark. As a matter of fact the series (31) is absolutely convergent in a neighborhood of the origin. We will show that the series (31) is nothing but the hypergeometric series ${}_2F_1^{(\alpha)}(a, b; c; t)$ (Theorem 4 in § 4.3).

As was noted by Muirhead [Mu, p. 995], the coefficients $c(j_1, \dots, j_m)$ are functions of a, b, c, α, and j_i and are independent of the dimension m in the sense that $c(j_1, \dots, j_k, 0, \dots, 0) = c(j_1, \dots, j_k)$. In fact the coefficients in the system (30) do not involve m explicitly, so that the recurrence relations determining $c(j_1, \dots, j_k, 0, \dots, 0)$ and those of $c(j_1, \dots, j_k)$ are the same. We rearrange the series (31) as a series of Jack polynomials:

$$F(t) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} a_\kappa C_\kappa^{(\alpha)}(t). \tag{32}$$

The expressions of power products of the elementary symmetric functions by monomial symmetric functions m_κ and those of m_κ by the Jack polynomials do not explicitly depend on m by virtue of [Mal, (2.3), p. 13] and the definition of Jack symmetric functions. Hence a_κ are independent of m, i.e., $a_{(\kappa_1, \dots, \kappa_h, 0, \dots, 0)} = a_{(\kappa_1, \dots, \kappa_h)}$.

COROLLARY 1. *The solution $F(t)$ in Theorem 2 can be obtained as a series of Jack polynomials $F(t) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} a_\kappa C_\kappa^{(\alpha)}(t)$ with coefficients a_κ independent of m.*

4.2. Properties of Jack polynomials. For later use, we prepare some properties of Jack polynomials following [Mu] closely in the case $\alpha = 2$.

The *generalized binomial coefficient* $\binom{\kappa}{\sigma}$ is defined as the coefficient of $C_\sigma^{(\alpha)}(t)/C_\sigma^{(\alpha)}(1^m)$ in the binomial expansion

$$\frac{C_\kappa^{(\alpha)}(1+t_1,\dots,1+t_m)}{C_\kappa^{(\alpha)}(1^m)}=\sum_{s=0}^{|\kappa|}\sum_{|\sigma|=s}\binom{\kappa}{\sigma}\frac{C_\sigma^{(\alpha)}(t)}{C_\sigma^{(\alpha)}(1^m)}. \tag{33}$$

Denote $\sigma\subseteq\kappa$ if $\sigma_i\le\kappa_i$ for any i. We first state crucial properties of generalized binomial coefficients whose proofs were not given in [Mu].

THEOREM 3. (a) $\binom{\kappa}{\sigma}=0$ *unless* $\sigma\subseteq\kappa$.

(b) *The generalized binomial coefficients* $\binom{\kappa}{\sigma}$ *are independent of the dimension* m.

We leave the proof to § 5. As in [Mu] we introduce the following differential operators:

$$E=\sum_{i=1}^m t_i\frac{\partial}{\partial t_i},\qquad \varepsilon=\sum_{i=1}^m\frac{\partial}{\partial t_i},$$

$$\delta(\alpha)=\frac{\alpha}{2}\sum_{i=1}^m t_i\frac{\partial^2}{\partial t_i^2}+\sum_{\substack{1\le i,j\le m\\ i\ne j}}\left[\frac{t_i}{t_i-t_j}\right]\frac{\partial}{\partial t_i}.$$

First, by Euler's identity,

$$EC_\kappa^{(\alpha)}(t)=|\kappa|C_\kappa^{(\alpha)}(t). \tag{34}$$

For the partition κ, we put $\kappa_{(i)}=(\kappa_1,\kappa_2,\dots,\kappa_i+1,\dots,\kappa_m)$ and $\kappa^{(i)}=(\kappa_1,\kappa_2,\dots,\kappa_i-1,\dots,\kappa_m)$ and call them admissible if the parts are in nonincreasing order. Observe that if $|\kappa|=|\sigma|+1$, then $\binom{\kappa}{\sigma}=0$ unless $\sigma=\kappa^{(i)}$ for some i. We have

$$\frac{\varepsilon C_\kappa^{(\alpha)}(t)}{C_\kappa^{(\alpha)}(1^m)}=\sum_{i=1}^m\binom{\kappa}{\kappa^{(i)}}\frac{C_{\kappa^{(i)}}^{(\alpha)}(t)}{C_{\kappa^{(i)}}^{(\alpha)}(1^m)}, \tag{35}$$

$$\frac{\delta(\alpha)C_\kappa^{(\alpha)}(t)}{C_\kappa^{(\alpha)}(1^m)}=\sum_{i=1}^m\binom{\kappa}{\kappa^{(i)}}\left(\frac{\alpha}{2}(\kappa_i-1)+\frac{1}{2}(m-i)\right)\frac{C_{\kappa^{(i)}}^{(\alpha)}(t)}{C_{\kappa^{(i)}}^{(\alpha)}(1^m)}. \tag{36}$$

The summations in (35) and (36) are over all i such that $\kappa^{(i)}$ is admissible. This convention will be used in all future summations involving $\kappa_{(i)}$ and $\kappa^{(i)}$. Equation (35) can be proved in the following way:

$$\begin{aligned}\frac{\varepsilon C_\kappa^{(\alpha)}(t)}{C_\kappa^{(\alpha)}(1^m)}&=\sum_{i=1}^m\frac{\partial C_\kappa^{(\alpha)}(t)}{\partial t_i}C_\kappa^{(\alpha)}(1^m)\\ &=\lim_{\lambda\to0}\frac{C_\kappa^{(\alpha)}(t_1+\lambda,\dots,t_m+\lambda)-C_\kappa^{(\alpha)}(t)}{\lambda C_\kappa^{(\alpha)}(1^m)}\\ &=\lim_{\lambda\to0}\sum_{i=1}^m\binom{\kappa}{\kappa^{(i)}}\frac{C_{\kappa^{(i)}}^{(\alpha)}(t)}{C_{\kappa^{(i)}}^{(\alpha)}(1^m)}+\text{terms of higher degree in }\lambda\\ &=\sum_{i=1}^m\binom{\kappa}{\kappa^{(i)}}\frac{C_{\kappa^{(i)}}^{(\alpha)}(t)}{C_{\kappa^{(i)}}^{(\alpha)}(1^m)}.\end{aligned}$$

Equation (36) follows by noting that $\delta(\alpha)=\frac{1}{2}(\varepsilon D(\alpha)-D(\alpha)\varepsilon)$ and by applying the operators ε and $D(\alpha)$ to $C_\kappa^{(\alpha)}(t)/C_\kappa^{(\alpha)}(1^m)$.

Next we show that

$$p_1\exp(t_1+\cdots+t_m)=\frac{\sum_{d=0}^\infty\sum_{|\kappa|=d}dC_\kappa^{(\alpha)}}{d!}, \tag{37}$$

$$\text{(38)} \qquad \frac{\alpha}{2} p_2 \exp(t_1+\cdots+t_m) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} \left(\rho_\kappa(\alpha)+\left(1-\frac{\alpha}{2}\right)d\right) \frac{C_\kappa^{(\alpha)}(t)}{d!},$$

$$\text{(39)} \qquad \frac{\alpha}{2} p_1 p_2 \exp(t_1+\cdots+t_m) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} (d-2)\left(\rho_\kappa(\alpha)+\left(1-\frac{\alpha}{2}\right)d\right) \frac{C_\kappa^{(\alpha)}(t)}{d!},$$

where $p_i = t_1^i+\cdots+t_m^i$ and $\rho_\kappa(\alpha)=\sum_{i=1}^m [\kappa_i((\alpha/2)\kappa_i - i)]$. Note that $e_\kappa(\alpha)=\rho_\kappa(\alpha)+(m-(\alpha/2))|\kappa|$. Equation (37) follows from (17) since

$$\begin{aligned} p_1 \exp(t_1+\cdots+t_m) &= \sum_{d=0}^{\infty} \frac{p_1^{d+1}}{d!} = \sum_{d=0}^{\infty} \frac{dp_1^d}{d!} \\ &= \sum_{d=0}^{\infty} \sum_{|\kappa|=d} \frac{dC_\kappa^{(\alpha)}(t)}{d!}. \end{aligned}$$

Applying $D(\alpha)$ to both sides of

$$\text{(40)} \qquad \exp(t_1+\cdots+t_m) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} \frac{C_\kappa^{(\alpha)}(t)}{d!}$$

and equating coefficients of $C_\kappa^{(\alpha)}(t)$ using (12) and (13) gives (38). Applying E to both sides of (38) and equating coefficients of $C_\kappa^{(\alpha)}$ using (38) gives (39). Using these formulas we obtain

$$\text{(41)} \qquad \sum_{i=1}^{m} \binom{\kappa_{(i)}}{\kappa} C_{\kappa_{(i)}}^{(\alpha)}(1^m) = m(|\kappa|+1)C_\kappa^{(\alpha)}(1^m),$$

$$\text{(42)} \qquad \sum_{i=1}^{m} \binom{\kappa_{(i)}}{\kappa}\left(\kappa_i - \frac{1}{\alpha}(i-1)\right) C_{\kappa_{(i)}}^{(\alpha)}(1^m) = |\kappa|(|\kappa|+1)C_\kappa^{(\alpha)}(1^m),$$

$$\text{(43)} \qquad \begin{aligned} &\sum_{i=1}^{m} \binom{\kappa_{(i)}}{\kappa}\left(\kappa_i - \frac{1}{\alpha}(i-1)\right)^2 C_{\kappa_{(i)}}^{(\alpha)}(1^m) \\ &\quad = \frac{2}{\alpha}(|\kappa|+1)\left(\rho_\kappa(\alpha)+\frac{1}{2}(m+1)|\kappa|\right)C_\kappa^{(\alpha)}(1^m). \end{aligned}$$

Applying ε to both sides of (40) and equating coefficients of $C_\kappa^{(\alpha)}(t)$ gives (41). Applying $\delta(\alpha)$ to both sides of (37) and collecting coefficients of $C_\kappa^{(\alpha)}(t)$ using (37) gives (42). Applying $\delta(\alpha)$ to both sides of (38) and collecting coefficients of $C_\kappa^{(\alpha)}(t)$ using (37), (38), (39), (41), and (42) gives (43).

4.3. Holonomic system. We want to show that the hypergeometric function ${}_2F_1^{(\alpha)}(a, b; c; t)$ satisfies the holonomic system (9). For this, as in [Mu], we will deal with the differential equation formed by summing the differential equations in the system (9):

$$\text{(44)} \qquad \begin{aligned} &\sum_{i=1}^{m} t_i(1-t_i)\frac{\partial^2 F}{\partial t_i^2} + \sum_{i=1}^{m}\left\{c - \frac{1}{\alpha}(m-1) - \left(a+b+1-\frac{1}{\alpha}(m-1)\right)t_i\right\} \\ &\quad \cdot \frac{\partial F}{\partial t_i} - mabF + \frac{2}{\alpha}\sum_{\substack{1\le i,j\le m \\ i\ne j}} \frac{t_i(1-t_i)}{t_i - t_j}\frac{\partial F}{\partial t_i} = 0. \end{aligned}$$

LEMMA 2. *Assume that $c-(1/\alpha)(i-1)$ is not a negative integer or zero for $1 \le i \le m$. Then the solution $F(t)$ of (44) of the form*

$$\text{(45)} \qquad F(t) = \sum_{d=0}^{\infty} \sum_{|\kappa|=d} \gamma_\kappa C_\kappa^{(\alpha)}(t), \qquad \gamma_{(0)} = 1$$

is unique if the coefficients γ_κ are independent of m.

Proof. Substituting (45) in (44) and using (12), (34), (35), and (36), we obtain the following recurrence relations for γ_κ:

$$\begin{aligned}(46)\qquad &\sum_{i=1}^{m}\binom{\kappa_{(i)}}{\kappa}\left\{\frac{\alpha}{2}(c+\kappa_i)-\frac{1}{2}(i-1)\right\}C^{(\alpha)}_{\kappa_{(i)}}(1^m)\gamma_{\kappa_{(i)}}\\ &=\left\{\frac{\alpha}{2}mab+\rho_\kappa(\alpha)+\frac{\alpha}{2}(a+b)|\kappa|+\frac{1}{2}(m+1)|\kappa|\right\}C^{(\alpha)}_{\kappa}(1^m)\gamma_\kappa.\end{aligned}$$

Put $\beta_\kappa=\alpha^{|\kappa|}|\kappa|!\,j_\kappa^{-1}[c]^{(\alpha)}_\kappa\gamma_\kappa$. Then, in virtue of (18), (46) becomes

$$\begin{aligned}(47)\qquad &\sum_{i=1}^{m}\binom{\kappa_{(i)}}{\kappa}(m+\alpha\kappa_i-i+1)\beta_{\kappa_{(i)}}\\ &=\left\{\frac{\alpha}{2}mab+\rho_\kappa(\alpha)+\frac{\alpha}{2}(a+b)|\kappa|+\frac{1}{2}(m+1)|\kappa|\right\}\beta_\kappa.\end{aligned}$$

Now assume that γ_κ and hence β_κ are independent of m. For an arbitrary partition κ we take $m>l(\kappa)$ so that $\kappa_{(m+1)}$ is not admissible. Then, on replacing m in (47) with $m+1$, we have

$$\begin{aligned}(48)\qquad &\sum_{i=1}^{m}\binom{\kappa_{(i)}}{\kappa}(m+\alpha\kappa_i-i+2)\beta_{\kappa_{(i)}}\\ &=\left\{\frac{\alpha}{2}(m+1)ab+\rho_\kappa(\alpha)+\frac{\alpha}{2}(a+b)|\kappa|+\frac{1}{2}(m+2)|\kappa|\right\}\beta_\kappa.\end{aligned}$$

Subtracting each side of (46) from that of (48) yields

$$(49)\qquad \sum_{i}\binom{\kappa_{(i)}}{\kappa}\beta_{\kappa_{(i)}}=\left(\frac{\alpha}{2}ab+\frac{|\kappa|}{2}\right)\beta_\kappa,$$

and equating constant terms of (47) gives

$$(50)\qquad \sum_{i}\binom{\kappa_{(i)}}{\kappa}(\alpha\kappa_i-i+1)\beta_{\kappa_{(i)}}=\left\{\rho_\kappa(\alpha)+\frac{\alpha}{2}|\kappa|(a+b)+\frac{|\kappa|}{2}\right\}\beta_\kappa.$$

As κ runs over all partitions of d, (49) and (50) give equations in all the unknown β corresponding to partitions of $d+1$, since any partition of $d+1$ can be expressed as $\kappa_{(i)}$ for some i and some partition κ of d. For partitions κ and ν with $|\nu|=|\kappa|$, write $\nu\leq^R\kappa$ (reverse lexicographic order) if $\nu=\kappa$ or the first nonvanishing difference $\kappa_i-\nu_i$ is positive. We prove that (49) and (50) determine β_κ uniquely ($\beta_{(0)}=1$) by induction on $\leq^R$ of indices κ. Suppose that the β_ν with $|\nu|<|\kappa|$ or $\nu\nleq^R\kappa$ have been determined and that $\kappa_1=\cdots=\kappa_r>\kappa_{r+1}$. Put $\sigma=\kappa^{(r)}$ and replace κ in (49) and (50) by σ. Then, as

$$\binom{\sigma_{(r)}}{\sigma}=\binom{\kappa}{\sigma}\neq 0,$$

it is readily verified that (49) and (50) afford an explicit formula of β_κ in terms of lower-order ones ((49) alone will do in case $r=1$). Thus β_κ are uniquely determined.

LEMMA 3. *${}_2F_1^{(\alpha)}(a,b;c;t)$ is a solution of the differential equation* (44).

Proof. It suffices to show that

$$(51)\qquad \gamma_\kappa=\frac{[a]^{(\alpha)}_\kappa[b]^{(\alpha)}_\kappa}{[c]^{(\alpha)}_\kappa|\kappa|!}$$

satisfies the recurrence relations (46). Substituting (51) into (46), the problem reduces to showing that

$$\sum_{i=1}^{m}\binom{\kappa_{(i)}}{\kappa}\left(a+\kappa_i-\frac{1}{\alpha}(i-1)\right)\left(b+\kappa_i-\frac{1}{\alpha}(i-1)\right)C^{(\alpha)}_{\kappa_{(i)}}(1^m)$$
$$=\frac{2}{\alpha}(|\kappa|+1)\left(\frac{\alpha}{2}mab+\rho_\kappa(\alpha)+\frac{\alpha}{2}(a+b)|\kappa|+\frac{1}{2}(m+1)|\kappa|\right)C^{(\alpha)}_{\kappa}(1^m).$$

But this follows at once from (41), (42), and (43).

As the coefficients γ_κ given by (51) are clearly independent of m, it follows from Lemmas 2 and 3 that the hypergeometric function ${}_2F_1^{(\alpha)}(a, b; c; t)$ is the unique solution of (44) among the formal series of form (45) with γ_κ being independent of m. On the other hand, the unique formal series solution $F(t)$ of (9) given by Theorem 2 also satisfies (44) and is of the form (45) with γ_κ being independent of m. Therefore, we get the desired equality $F(t)={}_2F_1^{(\alpha)}(a, b; c; t)$.

We summarize our results in the following theorem.

THEOREM 4. *${}_2F_1^{(\alpha)}(a, b; c; t_1, \ldots, t_m)$ is the unique solution of each of the m differential equations in the system* (9) *subject to the following conditions*:

(a) *$F(t)$ is a symmetric function of $t_1, \ldots, t_m$*; and

(b) *$F(t)$ is analytic at the origin with $F(0)=1$.*

5. Proof of Theorem 3.

5.1. Preliminaries. Define rational functions $g^\lambda_{\mu\nu}=g^\lambda_{\mu\nu}(\alpha)$ by

$$J_\mu(t)J_\nu(t)=\sum_\lambda j_\lambda^{-1}g^\lambda_{\mu\nu}(\alpha)J_\lambda(t).$$

Note that $g^\lambda_{\mu\nu}=0$ unless $|\lambda|=|\mu|+|\nu|$, $\mu\subseteq\lambda$ and $\nu\subseteq\lambda$ [St, Corollary 6.4]. If $\mu\subseteq\lambda$ then the skew shape λ/μ (regarded as a difference $\lambda-\mu$ of diagrams) is called a *horizontal strip* if no two different points of λ/μ lie in the same column. Call a horizontal strip λ/μ an *n-strip* if $|\lambda/\mu|=n$. Then $g^\lambda_{\mu n}=g^\lambda_{\mu(n)}\neq 0$ if and only if $\mu\subseteq\lambda$ and λ/μ is a horizontal n-strip [St, Prop. 5.3]. Moreover, $g^\lambda_{\mu n}$ has the explicit evaluation [St, Thm. 6.1]:

$$g^\lambda_{\mu n}=n!\,\alpha^n\left(\prod_{s\in\mu}A_{\lambda\mu}(s)\right)\left(\prod_{s\in\lambda}B_{\lambda\mu}(s)\right), \tag{52}$$

where

$$A_{\lambda\mu}(s)=\begin{cases}h^\mu_*(s), & \text{if } \lambda/\mu \text{ does not contain a square in the same column as } s,\\ h^*_\mu(s), & \text{otherwise,}\end{cases}$$

$$B_{\lambda\mu}(s)=\begin{cases}h^*_\lambda(s), & \text{if } \lambda/\mu \text{ does not contain a square in the same column as } s,\\ h^\lambda_*(s), & \text{otherwise.}\end{cases}$$

We will use only the case $n=1$ of this formula.

Let $x=(x_1, x_2, \ldots)$ be other variables. Then we have [St, Prop. 4.2]:

$$J_\lambda(t, x)=\sum_{\mu,\nu}g^\lambda_{\mu\nu}(\alpha)J_\mu(t)j_\mu^{-1}J_\nu(x)j_\nu^{-1}. \tag{53}$$

We will also need some explicit formulas. Let $l(\lambda)=m$ and write $\lambda-I=\lambda-I_m=(\lambda_1-1, \lambda_2-1, \ldots, \lambda_m-1)$. Then there holds [St, Props. 5.1 and 5.5]

$$J_\lambda(t_1, \ldots, t_m)=\prod_{i=1}^{m}h^\lambda_*(i, 1)t_1\cdots t_mJ_{\lambda-I}(t_1, \ldots, t_m). \tag{54}$$

Consequently, $v_{\lambda\lambda}(\alpha)$ is given by [St, Thm. 5.6]:

$$v_{\lambda\lambda}(\alpha)=\prod_{s\in\lambda} h_*^\lambda(s). \tag{55}$$

In this section we will denote the generalized binomial coefficient by $\binom{\kappa}{\sigma}_m$ to express its apparent dimensional dependence in the definition (33).

We proceed via a sequence of lemmas.

Lemma 4. *For fixed d with $|\sigma|\le d\le|\kappa|$, we have*

$$\binom{|\kappa|-|\sigma|}{d-|\sigma|}\binom{\kappa}{\sigma}_m=\sum_{|\tau|=d}\binom{\kappa}{\tau}_m\binom{\tau}{\sigma}_m .$$

Proof. Let s be an indeterminate. By definition of $\binom{\kappa}{\sigma}_m$ we have

$$\begin{aligned}\frac{J_\kappa(1+s+t_1,\dots,1+s+t_m)}{J_\kappa(1^m)}&=\sum_\tau\binom{\kappa}{\tau}_m\frac{J_\tau(s+t_1,\dots,s+t_m)}{J_\tau(1^m)}\\&=\sum_\tau\binom{\kappa}{\tau}_m\left\{\sum_\sigma s^{|\lambda|-|\sigma|}\binom{\tau}{\sigma}_m\frac{J_\sigma(t)}{J_\sigma(1^m)}\right\},\end{aligned}$$

while we see that

$$\frac{J_\kappa(1+s+t_1,\dots,1+s+t_m)}{J_\kappa(1^m)}=\frac{\sum_\sigma(1+s)^{|\kappa|-|\sigma|}\binom{\kappa}{\sigma}_m J_\sigma(t)}{J_\sigma(1^m)}.$$

Hence equating the coefficients of $s^{d-|\sigma|}J_\sigma(t)$ of each of the right sides of these equalities gives the desired result.

Lemma 5. *Let μ and ν be partitions with $|\mu|=|\nu|$ and of lengths $\le m$. Then*

$$\begin{aligned}\sum_\tau J_\tau(1^m)^{-1}g_{\tau 1}^{\nu}\binom{\mu}{\tau}_m&=J_\mu(1^m)^{-1}J_\nu(1^m)^{-1}j_\nu\\&\quad\cdot\sum_\rho J_\rho(1^m)j_\rho^{-1}g_{\mu 1}^{\rho}\binom{\rho}{\nu}_m-mJ_\nu(1^m)^{-1}\binom{\mu}{\nu}_m .\end{aligned}\tag{56}$$

Proof. Multiplying both sides of (33) (in which we replace κ and λ with μ and ν, respectively) by p_1 yields

$$\frac{p_1J_\mu(1+t_1,\dots,1+t_m)}{J_\mu(1^m)}=\sum_\tau\binom{\mu}{\tau}_m J_\tau(1^m)^{-1}\left\{\sum_\nu j_\nu^{-1}g_{\tau 1}^{\nu}J_\nu(t)\right\}.\tag{57}$$

As $p_1=1+t_1+\cdots+1+t_m-m$ we see that

$$\begin{aligned}&\frac{p_1J_\mu(1+t_1,\dots,1+t_m)}{J_\mu(1^m)}\\&=J_\mu(1^m)^{-1}\left\{\sum_\rho j_\rho^{-1}g_{\mu 1}^{\rho}J_\rho(1+t_1,\dots,1+t_m)-mJ_\mu(1+t_1,\dots,1+t_m)\right\}\\&=J_\mu(1^m)^{-1}\sum_\rho j_\rho^{-1}g_{\mu 1}^{\rho}J_\rho(1^m)\left\{\sum_\nu\binom{\rho}{\nu}_m\frac{J_\nu(t)}{J_\nu(1^m)}\right\}-m\sum_\tau\binom{\mu}{\sigma}_m\frac{J_\tau(t)}{J_\tau(1^m)}.\end{aligned}\tag{58}$$

Then equating the coefficients of $J_\nu(t)$ in (57) and (58) gives (56).

Note that if $|\mu|=|\nu|$ and $\mu\ne\nu$, then $\binom{\mu}{\nu}_m=0$ and that $\binom{\mu}{\mu}_m=1$.

By Lemma 4, for the proof of Theorem 3, it will suffice to prove the case $|\kappa|=|\sigma|+1$ of the theorem, which we assume henceforth. For a partition $\sigma=(\sigma_1,\sigma_2,\dots)$, write $\sigma_-=(\sigma_1,\sigma_2,\dots,\sigma_{m-1})$.

LEMMA 6. *Suppose that* (a) *holds in the dimensions* $\leq m-1$ *and that* $\sigma_- \not\subseteq \kappa$. *Then* $\binom{\kappa}{\sigma}_m = 0$.

Proof. Since $j_d^{-1}J_d(t_m) = (\alpha^d d!)^{-1}t_m^d$ by (15) and (18), (53) implies that

$$\begin{aligned} J_\kappa(1+t_1, \ldots, 1+t_m) &= \sum_{\mu,d} (\alpha^d d!)^{-1} g_{\mu d}^\kappa j_\mu^{-1} J_\mu(1+t_1, \ldots, 1+t_{m-1})(1+t_m)^d \\ &= \sum_{\substack{\mu,\lambda,d \\ \lambda\subseteq\mu}} (\alpha^d d!)^{-1} j_\mu^{-1} J_\mu(1^{m-1}) J_\lambda(1^{m-1})^{-1} \\ &\quad \cdot g_{\mu d}^\kappa \binom{\mu}{\lambda}_{m-1} J_\lambda(t_1, \ldots, t_{m-1})(1+t_m)^d, \\ J_\sigma(t_1, \ldots, t_m) &= \sum_{\nu,d} (\alpha^d d!)^{-1} g_{\nu d}^\sigma j_\nu^{-1} J_\nu(t_1, \ldots, t_{m-1}) t_m^d. \end{aligned}$$

Substituting these into (33), we get

$$\begin{aligned} &\sum_{\substack{\mu,\lambda,d \\ \lambda\subseteq\mu}} (\alpha^d d!)^{-1} j_\mu^{-1} J_\mu(1^{m-1}) J_\lambda(1^{m-1})^{-1} g_{\mu d}^\kappa \binom{\mu}{\lambda}_{m-1} J_\lambda(t_1, \ldots, t_{m-1})(1+t_m)^d \\ &= \sum_{\substack{\sigma,\nu,d \\ \nu\subseteq\sigma}} (\alpha^d d!)^{-1} j_\nu^{-1} J_\kappa(1^m) J_\sigma(1^m)^{-1} g_{\nu d}^\sigma \binom{\kappa}{\sigma}_m J_\nu(t_1, \ldots, t_{m-1}) t_m^d. \end{aligned} \tag{59}$$

Put $\nu = \sigma_-$ and $t_m = 1$ in (59). Then comparing the coefficients of $J_{\sigma_-}(t_1, \ldots, t_{m-1})$ to both sides gives

$$\sum_\tau J_\tau(1^m)^{-1} g_{\sigma_-\sigma_m}^\tau \binom{\kappa}{\tau}_m = 0.$$

Suppose first that $\sigma_m = 0$. Then τ must be identical with σ, so that $\binom{\kappa}{\sigma}_m = 0$. The general case follows using induction on σ_m.

LEMMA 7. *For a partition* $\lambda = l^p$, $p \leq m$, *we have*

$$\binom{\lambda}{\lambda^{(p)}}_m = pl.$$

Proof. As the proof of the case $p = m$ is clear, we assume $p < m$. By putting $t_{p+1} = \cdots = t_m = 0$ in (33) and using (53), we have

$$\sum_{\mu,\nu} g_{\mu\nu}^\lambda J_\mu(1+t_1, \ldots, 1+t_p) j_\mu^{-1} J_\nu(1^{m-p}) j_\nu^{-1} = J_\lambda(1^m) \sum_\sigma \binom{\lambda}{\sigma}_m \frac{J_\sigma(t_1, \ldots, t_p)}{J_\sigma(1^m)}.$$

Equating the coefficients of $m_{\lambda^{(p)}}(t_1, \ldots, t_p)$ of both sides yields

$$l g_{\lambda 0}^\lambda j_\lambda^{-1} v_{\lambda\lambda} + g_{\lambda^{(p)}1}^\lambda j_{\lambda^{(p)}}^{-1} v_{\lambda^{(p)},\lambda^{(p)}} J_1(1^{m-p}) j_1^{-1} = J_\lambda(1^m) J_{\lambda^{(p)}}^{-1}(1^m) v_{\lambda^{(p)},\lambda^{(p)}} \binom{\lambda}{\lambda^{(p)}}_m.$$

Thus the desired result follows at once if we substitute the explicit formulas of $g_{\nu n}^\lambda$, j_λ, $J_\lambda(1^r)$, and $v_{\lambda\lambda}$.

LEMMA 8. *We have*

$$\begin{aligned} v_{(r^p,1^s),(r^{p-1},r-1,1^{s+1})} &= p(r-1) \sum_{i=0}^s \left\{ \prod_{j=0}^{i-1} \frac{p+s-j+\alpha(r-1)}{s-j+\alpha(r-1)} (s-j) \right\} \frac{s-i+\alpha r}{s-i+\alpha(r-1)} \\ &\quad \cdot v_{(r^{p-1},r-1,1^{s-i}),(r^{p-1},r-1,1^{s-i})}. \end{aligned}$$

Proof. Equation (53) implies that

$$J_{(r^p,1^s)}(t_1, \ldots, t_{p+s+1}) = \sum_\lambda (\alpha^d d!)^{-1} g_{\lambda d}^{(r^p,1^s)} j_\lambda^{-1} J_\lambda(t_1, \ldots, t_{p+s}) t_{p+s+1}^d.$$

From this one can easily deduce that

$$\begin{aligned} v_{(r^p,1^s),(r^{p-1},r-1,1^{s+1})} = {} & \alpha^{-1} g^{(r^p,1^s)}_{(r^{p-1},r-1,1^s),1} \dot{j}^{-1}_{(r^{p-1},r-1,1^s)} v_{(r^{p-1},r-1,1^s),(r^{p-1},r-1,1^s)} \\ & + \alpha^{-1} g^{(r^p,1^s)}_{(r^p,1^{s-1}),1} \dot{j}^{-1}_{(r^p,1^{s-1})} v_{(r^p,1^{s-1}),(r^{p-1},r-1,1^s)}, \end{aligned}$$

where we see by (15) and (52) that

$$g^{(r^p,1^s)}_{(r^{p-1},r-1,1^s),1} \dot{j}^{-1}_{(r^{p-1},r-1,1^s)} = \alpha p(r-1) \frac{s+\alpha r}{s+\alpha(r-1)},$$

$$g^{(r^p,1^s)}_{(r^p,1^{s-1}),1} \dot{j}^{-1}_{(r^p,1^{s-1})} = \alpha s \frac{p+s+\alpha(r-1)}{s+\alpha(r-1)}.$$

Using this formula recursively, we arrive at the desired formula.

Proof of Theorem 3(a). We shall prove (a) of Theorem 3 by induction on the dimension m, the proof being clear for the case $m=1$. We assume that $l(\kappa)=m$. By Lemma 6 we may also assume $\sigma_- \subseteq \kappa$ and $\sigma \not\subseteq \kappa$. We proceed by induction on $d = \kappa_{m-1} - \kappa_m$, $d \geq 0$: Suppose that (a) holds in the cases $\kappa_{m-1} - \kappa_m \leq d-1$. The proof of the case $\kappa_{m-1} = \kappa_m$ is clear because $\sigma \not\subseteq \kappa$ implies $\sigma_- \not\subseteq \kappa$. Suppose $\sigma_m - \kappa_m \geq 2$ and put $\mu = \kappa^{(m-1)}$ and $\nu = \sigma$ in (56). Then one can easily verify by induction on d that all the terms of both sides of (56) except the one with $\binom{\kappa}{\sigma}_m$ vanish, so that $\binom{\kappa}{\sigma}_m = 0$. Hence it suffices to consider the case $\sigma_m = \kappa_m + 1$. Since $|\kappa| = |\sigma| + 1$, it follows that $\kappa_{m-1} - \sigma_{m-1} \leq 2$.

Case $\kappa_{m-1} = \sigma_{m-1}$. Put $\mu = \kappa^{(m-1)}$ and $\nu = \sigma$ in (56). Then by using Lemma 6 one can easily show that $\binom{\kappa}{\sigma}_m = 0$ if $d=1$. Similarly if $d \geq 2$, one can deduce that $\binom{\kappa}{\sigma}_m$ is proportional to

$$\binom{\kappa^{(m-1)}}{\sigma^{(m-1)}},$$

so that $\binom{\kappa}{\sigma}_m = 0$ by induction on d.

Case $\kappa_{m-1} = \sigma_{m-1} + 1$. It necessarily follows that $m \geq 3$ and $d \geq 2$. Note that $\kappa^{(m-1)}_{(m)} = \sigma_{(p)}$ for some $p \leq m-2$. Putting $\mu = \kappa^{(m-1)}$ and $\nu = \sigma$ in (56), we have

$$\begin{aligned} & J_{\sigma^{(m)}}(1^m)^{-1} g^{\sigma}_{\sigma^{(m)}1} \binom{\kappa^{(m-1)}}{\sigma^{(m)}}_m \\ & = \{J_{\kappa^{(m-1)}}(1^m) J_\sigma(1^m)\}^{-1} \dot{j}_\sigma \\ & \quad \cdot \left\{ J_{\kappa^{(m-1)}_{(m)}}(1^m) \dot{j}^{-1}_{\kappa^{(m-1)}_{(m)}} g^{\kappa^{(m-1)}_{(m)}}_{\kappa^{(m-1)}1} \binom{\kappa^{(m-1)}}{\sigma}_m + J_\kappa(1^m) \dot{j}_\kappa^{-1} g^{\kappa}_{\kappa^{(m-1)}1} \binom{\kappa}{\sigma}_m \right\}. \end{aligned}$$

Observe that (18) implies

$$J_\kappa(1^m) J_{\kappa^{(j)}}(1^m)^{-1} J_{\kappa^{(j)}_{(i)}}(1^m) J_{\kappa_{(i)}}(1^m)^{-1} = 1. \tag{60}$$

Hence the proof of $\binom{\kappa}{\sigma}_m = 0$ is equivalent to show that

$$\binom{\sigma_{(p)}}{\sigma}_m = \left(\dot{j}^{-1}_{\sigma_{(p)}} g^{\sigma_{(p)}}_{\sigma^{(m)}_{(p)}1} \right)^{-1} \dot{j}_\sigma^{-1} g^{\sigma}_{\sigma^{(m)}1} \binom{\sigma^{(m)}_{(p)}}{\sigma^{(m)}}_m. \tag{61}$$

Note first that by (15) and (52) we have

$$\begin{aligned} \dot{j}_\lambda^{-1} g^{\lambda}_{\lambda^{(p)}1} & = \prod_{j=1}^{\lambda_p - 1} h_*^{\lambda^{(p)}}(p,j) h_*^{\lambda}(p,j)^{-1} \cdot \prod_{i=1}^{p-1} h^*_{\lambda^{(p)}}(i, \lambda_p) h^*_\lambda(i, \lambda_p)^{-1} \\ & = \prod_{j=1}^{\lambda_p - 1} \frac{(\lambda'_j - p + 1 + \alpha(\lambda_p - j - 1))}{(\lambda'_j - p + 1 + \alpha(\lambda_p - j))} \cdot \prod_{i=1}^{p-1} \frac{(p - i - 1 + \alpha(\lambda_i - \lambda_p + 1))}{(p - i + \alpha(\lambda_i - \lambda_p + 1))}. \end{aligned} \tag{62}$$

Suppose $d\geq 3$, so that $\sigma_{m-1}>\sigma_m$. Then by induction on d we see that

$$\binom{\sigma_{(p)}^{(m-1)}}{\sigma^{(m-1)}}_m=\left(j^{-1}_{\sigma_{(p)}^{(m-1)}}g^{\sigma_{(p)}^{(m-1)}}_{\sigma_{(p)}^{(m-1,m)}1}\right)^{-1}j^{-1}_{\sigma^{(m-1)}}g^{\sigma^{(m-1)}}_{\sigma^{(m-1,m)}1}\binom{\sigma_{(p)}^{(m-1,m)}}{\sigma^{(m-1,m)}}_m, \tag{63}$$

where $\sigma^{(m-1,m)}=(\sigma_1,\sigma_2,\dots,\sigma_{m-1}-1,\sigma_m-1)$. Observe that the coefficients of

$$\binom{\sigma_{(p)}^{(m)}}{\sigma^{(m)}}_m \quad\text{and}\quad \binom{\sigma_{(p)}^{(m-1,m)}}{\sigma^{(m-1,m)}}_m$$

are the same in view of (62). Put $\mu=\sigma_{(p)}^{(m-1)}$ and $\nu=\sigma$ (respectively, $\mu=\sigma_{(p)}^{(m-1,m)}$, $\nu=\sigma^{(m)}$) in (56). Then by (60) we have

$$\binom{\sigma_{(p)}^{(m-1)}}{\sigma^{(m-1)}}_m=j_\sigma\left(g^{\sigma}_{\sigma^{(m-1)}1}\right)^{-1}j^{-1}_{\sigma_{(p)}}g^{\sigma_{(p)}}_{\sigma_{(p)}^{(m-1)}1}\binom{\sigma_{(p)}}{\sigma}_m,$$

$$\binom{\sigma_{(p)}^{(m-1,m)}}{\sigma^{(m-1,m)}}_m=j_{\sigma^{(m)}}\left(g^{\sigma^{(m)}}_{\sigma^{(m-1,m)}1}\right)^{-1}j^{-1}_{\sigma_{(p)}^{(m)}}g^{\sigma_{(p)}^{(m)}}_{\sigma_{(p)}^{(m-1,m)}1}\binom{\sigma_{(p)}^{(m)}}{\sigma^{(m)}}_m.$$

Again by (62) the coefficients of

$$\binom{\sigma_{(p)}}{\sigma}_m \quad\text{and}\quad \binom{\sigma_{(p)}^{(m)}}{\sigma^{(m)}}_m$$

are the same. Hence substituting these into (63) yields (61).

The case $d=2$ must be treated separately. Note that $\sigma_{m-1}=\sigma_m$. Using (56), one can easily show that $\binom{\kappa}{\sigma}_m$ is proportional to $\binom{\kappa^{(i)}}{\sigma^{(i)}}_m$ for $i\neq p$, $m-1$, m. Iterating this, for the proof of (61), we may assume that $\sigma_{m-1}=\sigma_{m-2}=\cdots=\sigma_{p+1}$, $\sigma_p+1=\sigma_{p+1}=\cdots=\sigma_1$. Suppose $p\leq m-3$. Then (61) is a consequence of (56) with $\mu=\sigma_{(p)}^{(m)}$ and $\nu=\sigma$. Hence assume $p=m-2$. We shall calculate $\binom{\sigma_{(p)}}{\sigma}_m$ explicitly. It follows from (54) that

$$\begin{aligned}&J_{\sigma_{(p)}}(1+t_1,\dots,1+t_m)\\ &\quad=\prod_{\substack{1\leq i\leq m\\ 1\leq j\leq\sigma_m}}h_*^{\sigma_{(p)}}(i,j)\{(1+t_1)\cdots(1+t_m)\}^{\sigma_m}J_{\sigma_{(p)}-\sigma_m I}(1+t_1,\dots,1+t_m)\\ &\quad=J_{\sigma_{(p)}}(1^m)\prod_{\substack{1\leq i\leq m\\ 1\leq j\leq\sigma_m}}h_*^{\sigma_{(p)}}(i,j)\{(1+t_1)\cdots(1+t_m)\}^{\sigma_m}\sum_\tau\binom{\sigma_{(p)}-\sigma_m I}{\tau}_m\frac{J_\tau(t)}{J_\tau(1^m)},\end{aligned}\tag{64}$$

where $\sigma_{(p)}-\sigma_m I=(\sigma_1-\sigma_m,\dots,\sigma_{m-1}-\sigma_m,0)$. We compute the coefficient of J_σ in the right-hand side of (64). For this it suffices to consider only the terms of $\tau=\sigma-\sigma_m I$ or $\sigma_{(p)}-\sigma_m I$. Since $g^{\lambda}_{\sigma_{(p)}-\sigma_m I,1}m-1\neq 0$ only if $\sigma_{(p)}-\sigma_m I\subseteq\lambda$ and $1^{m-1}\subseteq\lambda$, we see that

$$m_{1^{m-1}}(t)J_{\sigma_{(p)}-\sigma_m I}(t)=c_1t_1\cdots t_mJ_{\sigma-\sigma_m I}(t)+c_2J_{\sigma_{(p)}^{(m)}-(\sigma_m-1)I}(t),$$

which implies that

$$\begin{aligned}\binom{\sigma_{(p)}}{\sigma}_m&=J_\sigma(1^m)J_{\sigma_{(p)}}(1^m)^{-1}\prod_{\substack{1\leq i\leq m\\ 1\leq j\leq\sigma_m}}h_*^{\sigma_{(p)}}(i,j)h_*^{\sigma}(i,j)^{-1}\\ &\quad\cdot\left\{J_{\sigma_{(p)}-\sigma_m I}(1^m)J_{\sigma-\sigma_m I}(1^m)^{-1}\binom{\sigma_{(p)}-\sigma_m I}{\sigma-\sigma_m I}_m+\sigma_m c_1\right\}.\end{aligned}\tag{65}$$

Write $[m_\lambda(t)]f(t)$ as the coefficient of m_λ when the symmetric function $f(t)$ is expanded in terms of the monomial symmetric functions. Put

$$d_1=[t_1\cdots t_m m_{\sigma-\sigma_m I}(t)]m_{1^{m-1}}(t)m_{\sigma_{(p)}-\sigma_m I}(t)$$

$$d_2=[t_1\cdots t_m m_{\sigma-\sigma_m I}(t)]m_{1^{m-1}}(t)m_{\sigma_{(p+1)}-\sigma_m I}(t).$$

Observe that $d_1=1$, $d_2=m-p=2$ (respectively, $d_1=m-p+1=3$, $d_2=0$) when $\sigma_{(p+1)}=\sigma_{(m-1)}$ is admissible, i.e., $\sigma_{m-1}<\sigma_{m-2}$ (respectively, $\sigma_{m-1}=\sigma_{m-2}$). Thus we get

$$\begin{aligned}c_1=v^{-1}_{\sigma-\sigma I_m,\sigma-\sigma_m I}\{d_1 v_{\sigma_{(p)}-\sigma_m I,\sigma_{(p)}-\sigma_m I}+d_2 v_{\sigma_{(p)}-\sigma_m I,\sigma_{(m-1)}-\sigma_m I}\\ -c_2 v_{\sigma^{(m)}_{(p)}-(\sigma_m-1)I,\sigma-(\sigma_m-1)I}\},\end{aligned}\tag{66}$$

in which (55) implies that

$$\begin{aligned}c_2&=v_{\sigma_{(p)}-\sigma_m I,\sigma_{(p)}-\sigma_m I}\cdot v^{-1}_{\sigma^{(m)}_{(p)}-\sigma_m I,\sigma^{(m)}_{(p)}-\sigma_m I}\\ &=\prod_{i=2}^{m-1}(i+\alpha(\sigma_p+1-\sigma_m))^{-1}.\end{aligned}$$

By using (55) and Lemma 8 we have

$$v^{-1}_{\sigma-\sigma_m I,\sigma-\sigma_m I}\cdot v_{\sigma_{(p)}-\sigma_m I,\sigma_{(p)}-\sigma_m I}=p(1+\alpha(\sigma_p-\sigma_m)),$$

$$v^{-1}_{\sigma-\sigma_m I,\sigma-\sigma_m I}\cdot v_{\sigma_{(p)}-\sigma_m I,\sigma_{(m-1)}-\sigma_m I}=p(\sigma_p+1-\sigma_m),$$

$$\begin{aligned}&v^{-1}_{\sigma-\sigma_m I,\sigma-\sigma_m I}\cdot v_{\sigma^{(m)}_{(p)}-(\sigma_m-1)I,\sigma-(\sigma_m-1)I}\\ &=p(\sigma_p+1-\sigma_m)\frac{1+\alpha(\sigma_p+2-\sigma_m)}{1+\alpha(\sigma_p+1-\sigma_m)}(2+\alpha(\sigma_p-\sigma_m))\prod_{i=3}^{m-1}(i+\alpha(\sigma_p+1-\sigma_m))\\ &\quad+p(\sigma_p+2-\sigma_m)\frac{m-1+\alpha(\sigma_p+1-\sigma_m)}{1+\alpha(\sigma_p+1-\sigma_m)}(1+\alpha(\sigma_p-\sigma_m))\prod_{i=2}^{m-2}(i+\alpha(\sigma_p+1-\sigma_m)).\end{aligned}$$

Substituting these to (66) yields (whether $\sigma_{(m-1)}$ is admissible or not)

$$c_1=\alpha p(\sigma_p+1-\sigma_m)(3+\alpha(\sigma_p-\sigma_m))(2+\alpha(\sigma_p+1-\sigma_m))^{-1}.$$

Hence substituting this into (65) and using (15) and Lemma 7, we finally obtain

$$\binom{\sigma_{(p)}}{\sigma}_m=p(\sigma_p+1-\sigma_m)(2+\alpha(\sigma_p+1))(2+\alpha(\sigma_p+1-\sigma_m))^{-1}.$$

This also gives

$$\binom{\sigma^{(m-1,m)}_{(p)}}{\sigma^{(m-1,m)}}_m=p(\sigma_p+2-\sigma_m)(2+\alpha(\sigma_p+1))(2+\alpha(\sigma_p+2-\sigma_m))^{-1}.$$

On the other hand, by virtue of (56), we have

$$\binom{\sigma^{(m)}_{(p)}}{\sigma^{(m)}}_m=j^{-1}_{\sigma^{(m)}}g^{\sigma^{(m)}}_{\sigma^{(m-1,m)}1}j_{\sigma^{(m)}_{(p)}}(g^{\sigma^{(m)}_{(p)}}_{\sigma^{(m-1,m)}_{(p)}1})^{-1}\binom{\sigma^{(m-1,m)}_{(p)}}{\sigma^{(m-1,m)}}_m.$$

Hence it remains only to prove

$$j_{\sigma}^{-1} g^{\sigma}_{\sigma^{(m)}1}\left(j^{-1}_{\sigma_{(p)}} g^{\sigma_{(p)}}_{\sigma^{(m)}_{(p)}1}\right)^{-1} j^{-1}_{\sigma^{(m)}} g^{\sigma^{(m)}}_{\sigma^{(m-1,m)}1}\left(j^{-1}_{\sigma^{(m)}_{(p)}} g^{\sigma^{(m)}_{(p)}}_{\sigma^{(m-1,m)}_{(p)}1}\right)^{-1}$$
$$=(\sigma_p+1-\sigma_m)(2+\alpha(\sigma_p+2-\sigma_m))$$
$$\cdot\{(\sigma_p+2-\sigma_m)(2+\alpha(\sigma_p+1-\sigma_m)\}^{-1},$$

provided $p=m-2$. But this follows at once from (62).

Case $\kappa_{m-1}=\sigma_{m-1}+2$. In this case we see $\kappa_1=\sigma_1,\dots,\kappa_{m-2}=\sigma_{m-2}$. Putting $\mu=\kappa^{(m-1)}$ and $\nu=\sigma$ in (56), one can easily show that $\binom{\kappa}{\sigma}_m=0$ when $\sigma\not\subseteq\kappa$ is equivalent to (61) with $p=m-1$. But the latter can be proved in the same way as in the case of $\kappa_{m-1}=\sigma_{m-1}+1$ using (56). So we omit the details of the proof.

Proof of (b). Induction on $|\kappa|$, the case $|\kappa|=1$ being clear. Suppose $\kappa=\sigma_{(p)}$ and that $\sigma_{(r)}$ are admissible for some $r\neq p$. Put $\mu=\kappa$ and $\nu=\sigma_{(r)}$ in (56). Then by (a) we have

$$\binom{\kappa_{(r)}}{\sigma_{(r)}}_m=\left(j^{-1}_{\kappa_{(r)}}g^{\kappa_{(r)}}_{\kappa 1}\right)^{-1}j^{-1}_{\sigma_{(r)}}g^{\sigma_{(r)}}_{\sigma 1}\binom{\kappa}{\sigma}_m .$$

The coefficient of $\binom{\kappa}{\sigma}_m$ is independent of the dimension m by definition, and the proof follows by induction.

5.3. Expression of $\binom{\kappa}{\sigma}$ by $g^{\lambda}_{\mu\nu}$.

PROPOSITION 2. *We have*

$$\binom{\kappa}{\sigma}=\sum_{\mu}(j_\sigma j_\mu)^{-1}g^{\kappa}_{\sigma\mu}.$$

Proof. Suppose first that $|\kappa|=|\sigma|+1$. Since $\binom{\kappa}{\sigma}$'s are independent of the dimension, we see

$$\begin{aligned}\frac{J_\kappa(1,t_1,\dots,t_m)}{J_\kappa(1^{m+1})}&=\sum_{\lambda\subseteq\kappa}\binom{\kappa}{\lambda}\frac{J_\lambda(t_1-1,\dots,t_m-1)}{J_\lambda(1^{m+1})}\\ &=\sum_{\lambda\subseteq\kappa}\binom{\kappa}{\lambda}J_\lambda(1^{m+1})^{-1}J_\lambda(1^m)\sum_{\sigma\subseteq\lambda}(-1)^{|\lambda|+|\sigma|}\binom{\lambda}{\sigma}\frac{J_\sigma(t)}{J_\sigma(1^m)}.\end{aligned}\tag{67}$$

On the other hand it follows from (53) that

$$J_\kappa(1,t)=\sum_{\substack{\sigma\subseteq\kappa\\ \nu\subseteq\kappa}}g^{\kappa}_{\sigma\nu}J_\nu(1)j_\nu^{-1}J_\sigma(t)j_\sigma^{-1}.\tag{68}$$

As $\binom{\sigma}{\sigma}=1$, equating the coefficients of $J_\sigma(t)$ with $|\sigma|=|\kappa|-1$ in (67) and (68) gives

$$\{J_\kappa(1^{m+1})J_\sigma(1^{m+1})^{-1}-J_\kappa(1^m)J_\sigma(1^m)^{-1}\}\binom{\kappa}{\sigma}=J_1(1)j_1^{-1}j_\sigma^{-1}g^{\kappa}_{\sigma 1}.$$

Clearly $J_1(1)=1$ and (60) imply that the coefficient of $\binom{\kappa}{\sigma}$ is 1, which completes the proof in the case $|\kappa|=|\sigma|+1$.

Suppose now that $|\kappa|-|\sigma|=r$ $(r\geq 2)$ and that the proposition holds in the cases $|\kappa|-|\sigma|<r$. It follows from Lemma 4 (with $d=|\sigma|+1$) that

$$\begin{aligned}r\binom{\kappa}{\sigma}&=\sum_{|\tau|=|\sigma|+1}\binom{\kappa}{\tau}\binom{\tau}{\sigma}\\ &=\sum_{|\tau|=|\sigma|+1}\left(\sum_{|\nu|=r-1}(j_\tau j_\nu)^{-1}g^{\kappa}_{\tau\nu}\right)(j_\sigma j_1)^{-1}g^{\tau}_{\sigma 1}.\end{aligned}$$

Since $j_1=\alpha$, it remains only to prove that

$$\sum_{\tau,\nu}(j_\tau j_\nu)^{-1}g^\kappa_{\tau\nu}g^\tau_{\sigma 1}=\alpha r\sum_\mu j_\mu^{-1}g^\kappa_{\mu\sigma}.$$

Let $m\geq l(\kappa)$. Since $J_1(t)=J_1(t_1,\dots,t_m)=t_1+\cdots+t_m$, it follows from (14) that

$$\begin{aligned}J_\sigma(t)(t_1+\cdots+t_m)^r&=J_\sigma(t)J_1(t)(t_1+\cdots+t_m)^{r-1}\\&=\sum_\tau j_\tau^{-1}g^\tau_{\sigma 1}J_\tau(t)\left(\sum_\nu \alpha^{r-1}(r-1)!\,j_\nu^{-1}J_\nu(t)\right)\\&=\alpha^{r-1}(r-1)!\sum_{\lambda,\nu,\tau}(j_\lambda j_\nu j_\tau)^{-1}g^\tau_{\sigma 1}g^\lambda_{\tau\nu}J_\lambda(t).\end{aligned}\tag{69}$$

On the other hand, we see that

$$\begin{aligned}J_\sigma(t)(t_1+\cdots+t_m)^r&=J_\sigma(t)\left(\sum_\mu \alpha^r r!\,j_\mu^{-1}J_\mu(t)\right)\\&=\alpha^r r!\sum_{\lambda,\mu}(j_\lambda j_\mu)^{-1}g^\lambda_{\mu\sigma}J_\lambda(t).\end{aligned}\tag{70}$$

Comparing the coefficients of $J_\kappa(t)$ in (69) and (70) completes the proof.

Remark. Theorem 3 and Proposition 2 have been announced also by Lassalle [L]. The full proofs have not yet appeared as of July 1992. Our proof of Theorem 3 is a rather messy case-by-case check. It would be interesting to find an intrinsic proof. (Of course, it will be better to give a direct proof of Proposition 2.)

6. Consequences.

6.1. Main result. The following transformation formula of solutions of the system (9) can be proved in the exact same way as in the case of the Gaussian hypergeometric equation and we omit the proof.

PROPOSITION 3. *If $F(t_1,\dots,t_m)$ is a solution of the system* (9), *then $(t_1\cdots t_m)^{-a}F(1/t_1,\dots,1/t_m)$ is also a solution of the system obtained from* (9) *by replacing b by $a-c+1+(1/\alpha)(m-1)$ and c by $a-b+1+(1/\alpha)(m-1)$.*

Note that the integral

$$\begin{aligned}&(-1)^{\lambda mn/2}(t_1\cdots t_m)^{-\lambda n/2}S_{n,m}\left(\lambda_1,\lambda_2,\lambda,\frac{-\lambda}{2};\frac{1}{t_1},\dots,\frac{1}{t_m}\right)\\&\quad=\int_{[0,1]^n}\prod_{i=1}^n x_i^{\lambda_1}(1-x_i)^{\lambda_2}\prod_{1\leq i<j\leq n}|x_i-x_j|^\lambda\prod_{\substack{1\leq i\leq n\\1\leq k\leq m}}(1-x_it_k)^{-\lambda/2}\,dx_1\cdots dx_n\end{aligned}\tag{71}$$

is analytic at the origin. Combining Theorems 1, 4, and Proposition 3 gives our main result in the following.

THEOREM 5. *We have*

$$\begin{aligned}&\int_{[0,1]^n}\prod_{\substack{1\leq i\leq n\\1\leq k\leq m}}(x_i-t_k)D_{\lambda_1,\lambda_2,\lambda}(x_1,\dots,x_n)\,dx_1\cdots dx_n\\&\quad=C_1\cdot{}_2F_1^{\lambda/2}\left(-n,\frac{2}{\lambda}(\lambda_1+\lambda_2+m+1)+n-1;\frac{2}{\lambda}(\lambda_1+m);t_1,\dots,t_m\right),\end{aligned}\tag{72}$$

$$\begin{aligned}&\int_{[0,1]^n} \prod_{\substack{1\le i\le n\\ 1\le k\le m}} (1-x_it_k)^{-\lambda/2} D_{\lambda_1,\lambda_2,\lambda}(x_1,\dots,x_n)\,dx_1\cdots dx_n\\ &\quad= C_2\cdot {}_2F_1^{2/\lambda}\left(\frac{\lambda}{2}n, \frac{\lambda}{2}(n-1)+\lambda_1+1; \lambda(n-1)+\lambda_1+\lambda_2+2; t_1,\dots,t_m\right),\end{aligned}\tag{73}$$

where $C_1=S_{n,0}(\lambda_1+m, \lambda_2, \lambda)$ *and* $C_2=S_{n,0}(\lambda_1, \lambda_2, \lambda)$.

This theorem gives a rather short proof of Macdonald's conjecture (C5) [Ma3, p. 197]. Namely, the following.

COROLLARY 2. *Let* $\kappa=(\kappa_1, \kappa_2, \dots)$ *be a partition of length* $\le n$. *Then*

$$\begin{aligned}&\int_{[0,1]^n} J_\kappa^{2/\lambda}(x_1,\dots,x_n)D_{\lambda_1,\lambda_2,\lambda}(x_1,\dots,x_n)\,dx_1\cdots dx_n\\ &\quad=J_\kappa^{2/\lambda}(1,\dots,1)\\ &\qquad\cdot\prod_{i=1}^{n}\frac{\Gamma(i(\lambda/2)+1)\Gamma(\kappa_i+\lambda_1+(\lambda/2)(n-i)+1)\Gamma(\lambda_2+(\lambda/2)(n-i)+1)}{\Gamma((\lambda/2)+1)\Gamma(\kappa_i+\lambda_1+\lambda_2+(\lambda/2)(2n-i-1)+2)}.\end{aligned}\tag{74}$$

Proof. Let $m\ge n$. We notice the Cauchy identity [St, Prop. 2.1, p. 79]:

$$\sum_\nu J_\nu^{(\alpha)}(x_1,\dots,x_n)J_\nu^{(\alpha)}(t_1,\dots,t_m)j_\nu^{-1}=\prod_{\substack{1\le i\le n\\ 1\le k\le m}}(1-x_it_k)^{-1/\alpha},\tag{75}$$

where the summation is over all partitions ν. Put $\alpha=2/\lambda$ and substitute the left-hand side of (75) into that of (73). Equating the coefficients of $J_\kappa^{(2/\lambda)}(t_1,\dots,t_m)$ of both sides gives

$$\begin{aligned}&\int_{[0,1]^n} J_\kappa^{2/\lambda}(x_1,\dots,x_n)D_{\lambda_1,\lambda_2,\lambda}(x_1,\dots,x_n)\,dx_1\cdots dx_n\\ &\quad=C_2\cdot\frac{[(\lambda/2)n]_\kappa^{(\alpha)}[(\lambda/2)(n-1)+\lambda_1+1]_\kappa^{(\alpha)}}{[\lambda(n-1)+\lambda_1+\lambda_2+2]_\kappa^{(\alpha)}}\left(\frac{2}{\lambda}\right)^{|\kappa|}.\end{aligned}$$

Now the desired equality (75) follows at once from (1), (15), (18), and (19).

5.2. Case of $m=1,2$. In case $m=1$, putting $a=(\lambda/2)n$, $b=(\lambda/2)(n-1)+\lambda_1+1$, $c=\lambda(n-1)+\lambda_1+\lambda_2+2$ in (73) yields the following integral representation of the Gauss hypergeometric function:

$$\begin{aligned}{}_2F_1(a, b; c; t)=C_3\cdot&\int_{[0,1]^n}\prod_{i=1}^{n}x_i^{b-a+(a/n)-1}(1-x_i)^{c-a-b+(a/n)-1}\prod_{1\le i<j\le n}|x_i-x_j|^{2a/n}\\ &\cdot\prod_{i=1}^{n}(1-x_it)^{-a/n}\,dx_1\cdots dx_n\\ C_3=S_{n,0}&\left(b-a+\frac{a}{n}-1, c-a-b+\frac{a}{n}-1, \frac{2a}{n}\right)^{-1}.\end{aligned}$$

In case $m=2$, one can easily deduce from (10) that

$$\begin{aligned}{}_2F_1^{(\alpha)}(a, b; c; t_1, t_2)=C_4\cdot F_4&\left(a, b, c-\frac{1}{\alpha}, a+b-c+1, t_1t_2, (1-t_1)(1-t_2)\right)\\ &+C_5\cdot((1-t_1)(1-t_2))^{c-a-b}\\ &\cdot F_4\left(c-b, c-a, c-\frac{1}{\alpha}, c-a-b+1, t_1t_2, (1-t_1)(1-t_2)\right).\end{aligned}\tag{76}$$

Putting $t_2=0$ in (76) yields

$$\begin{aligned}{}_2F_1(a,b;c;t_1)&=C_4\cdot{}_2F_1(a,b;a+b-c+1;1-t_1)\\&\quad+C_5(1-t_1)^{c-a-b}\,{}_2F_1(c-b,c-a;c-a-b+1;1-t_1).\end{aligned}$$

The connection formula of solutions of the Gauss hypergeometric equation [W-W, p. 291] then gives the values of C_4 and C_5:

$$C_4=\frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)},\qquad C_5=\frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)}.$$

Combining (73) and (76), we get

$$\begin{aligned}&\int_{[0,1]^n}\prod_{\substack{1\le i\le n\\k=1,2}}(1-x_it_k)^{-\lambda/2}D_{\lambda_1,\lambda_2,\lambda}(x_1,\dots,x_n)\,dx_1\cdots dx_n\\&=C_2C_4\cdot F_4\Big(\frac{\lambda}{2}n,\frac{\lambda}{2}(n-1)+\lambda_1+1,\frac{\lambda}{2}(2n-3)+\lambda_1+\lambda_2+2,\frac{\lambda}{2}-\lambda_2;t_1t_2,(1-t_1)(1-t_2)\Big)\\&\quad+C_2C_5((1-t_1)(1-t_2))^{\lambda_2-(\lambda/2)+1}F_4\Big(\frac{\lambda}{2}(n-1)+\lambda_2+1,\frac{\lambda}{2}(n-2)+\lambda_1+\lambda_2+2,\\&\qquad\qquad\frac{\lambda}{2}(2n-3)+\lambda_1+\lambda_2+2,\\&\qquad\qquad\lambda_2-\frac{\lambda}{2}+2;t_1t_2,(1-t_1)(1-t_2)\Big).\end{aligned}$$

7. Relation with generalized Jacobi polynomials.

For $\alpha>-1$, $\beta>-1$, and $\gamma\ge-\frac{1}{2}$ put

$$w(x)=w^{\alpha,\beta,\gamma}(x)=\prod_{i=1}^m(1-x_i)^\alpha(1+x_i)^\beta\prod_{1\le i<j\le m}(x_i-x_j)^{2\gamma+1},\qquad x\in\Omega$$

where Ω is the region

$$\Omega=\{x\in\mathbb{R}^m\,|\,-1\le x_m\le x_{m-1}\le\cdots\le x_1\le 1\}.$$

As a total ordering of partitions we still use the reverse lexicographic order $\le^R$: For partitions κ and ν, denote $\nu\le^R\kappa$ if $\nu=\kappa$ or the first nonvanishing difference $\kappa_i-\nu_i$ is positive (we do not assume $|\kappa|=|\nu|$). Hereafter we will restrict partitions to have length $\le m$. A symmetric polynomial $p(x)$ is said to have degree κ with leading term $c_\kappa m_\kappa$ if

$$p(x)=\sum_{\nu\le^R\kappa}c_\nu m_\nu,\qquad c_\kappa\ne 0.$$

Definition [Ko], [V], [D]. The *generalized Jacobi polynomials* $p_\kappa^{\alpha,\beta,\gamma}(x)$ are defined by

(1) $p_{(0)}=1$;

(2) $p_\kappa^{\alpha,\beta,\gamma}(x)$ is a symmetric polynomial with leading term m_κ;

(3) $\int_\Omega p_\kappa^{\alpha,\beta,\gamma}(x)q(x)w^{\alpha,\beta,\gamma}(x)\,dx=0$ if $q(x)$ is a symmetric polynomial and degree $q\le^R\kappa$.

THEOREM 6. *We have*

$$S_{n,m}(\lambda_1,\lambda_2,\lambda,1;t_1,\dots,t_m)=2^{-n}\cdot S_{n,0}(\lambda_1,\lambda_2,\lambda)p^{\alpha,\beta;\gamma}_{(n^m)}(1-2t_1,\dots,1-2t_m),$$

where $\alpha=(2/\lambda)(\lambda_1+1)-1$, $\beta=(2/\lambda)(\lambda_2+1)-1$, $\gamma=(\lambda/2)-(1/2)$, *and* (n^m) *is the partition* $(n,\dots,n)$.

Proof. Note first that the leading term of

$$S_{n,m}(\lambda_1,\lambda_2,\lambda,1;(1-t_1)/2,\dots,(1-t_m)/2) \text{ is } 2^{-n}S_{n,0}(\lambda_1,\lambda_2,\lambda)(t_1\cdots t_m)^n.$$

Hence it remains to prove

$$\int_{[0,1]^m} S_{n,m}(\lambda_1,\lambda_2,\lambda;t)q(t)D_{\alpha,\beta,2\gamma+1}(t)\,dt=0, \tag{77}$$

where $q(t)$ is a symmetric polynomial with degree $<^R(n^m)$. Clearly it will be sufficient to consider the case $q(t)=J^{(\lambda/2)}_\kappa(t)$ with $\kappa<^R(n^m)$. Put

$$\Delta^{(\alpha,\beta,\gamma)}=\sum_{i=1}^m\left\{t_i(1-t_i)\frac{\partial^2}{\partial t_i^2}+\left[\alpha+1-(\alpha+\beta+2)t_i+(2\gamma+1)\sum_{\substack{j=1\\ j\neq i}}^m\frac{t_i(1-t_i)}{t_i-t_j}\right]\frac{\partial}{\partial t_i}\right\}.$$

Then for polynomials f and g we have [V, Thm. 4.3]

$$\int_{[0,1]^m}(\Delta^{(\alpha,\beta,\gamma)}f)gD_{\alpha,\beta,2\gamma+1}(t)\,dt=\int_{[0,1]^n}f(\Delta^{(\alpha,\beta,\gamma)}g)D_{\alpha,\beta,2\gamma+1}(t)\,dt. \tag{78}$$

One can easily deduce from (44) that

$$\Delta^{(\alpha,\beta,\gamma)}S_{n,m}(\lambda_1,\lambda_2,\lambda,1;t)=-\frac{2mn}{\lambda}\left(\lambda_1+\lambda_2+m+1+\frac{\lambda}{2}(n-1)\right)S_{n,m}(\lambda_1,\lambda_2,\lambda,1;t).$$

Now suppose that (77) holds for any symmetric polynomial with degree $<^R\kappa$ and that $\kappa<^R(n^m)$. We prove

$$\int_{[0,1]^n}S_{n,m}(\lambda_1,\lambda_2,\lambda,1;t)J^{\lambda/2}_\kappa(t)D_{\alpha,\beta,2\gamma+1}(t)\,dt=0. \tag{79}$$

It is readily verified by using (11), (12), and (37) that

$$\Delta^{(\alpha,\beta,\gamma)}J^{\lambda/2}_\kappa(t)=-\frac{2}{\lambda}\left(2e_\kappa\left(\frac{\lambda}{2}\right)+(\lambda_1+\lambda_2+2)|\kappa|\right)J^{\lambda/2}_\kappa(t)+q(t),$$

where $q(t)$ is a symmetric polynomial with degree $<^R\kappa$. On using (13), we observe that

$$\frac{2mn}{\lambda}\left(\lambda_1+\lambda_2+m+1+\frac{\lambda}{2}(n-1)\right)\neq\frac{2}{\lambda}\left(2e_\kappa\left(\frac{\lambda}{2}\right)+(\lambda_1+\lambda_2+2)|\kappa|\right)$$

provided $\lambda>0$ and $\lambda_1+\lambda_2>0$. Hence (79) follows from (78) for such λ, λ_1, and λ_2. For other values of λ_1 and λ_2, (79) holds by analytic continuation. This completes the proof of the theorem.

THE INITIAL VALUE PROBLEM FOR A SYSTEM MODELLING UNIDIRECTIONAL LONGITUDINAL ELASTIC-PLASTIC WAVES*

MICHAEL SHEARER† AND DAVID G. SCHAEFFER‡

Abstract. The authors analyze initial value problems for a hyperbolic system of equations that is a simplification of models of dynamic longitudinal elastoplastic deformations in a rod with hardening. The simplified system has a positive characteristic speed associated with stress waves, and a zero speed associated with the time independence of hardening during elastic deformation. The equations are piecewise linear in stress derivatives, and thus fully nonlinear. The main result is that for bounded uniformly continuous initial data, the Cauchy problem has a unique continuous solution that can be approximated by piecewise linear solutions of the equations.

Key words. elastoplasticity, hyperbolic equations, fully nonlinear partial differential equations, initial value problem, weak solutions

1. Introduction. In this paper we analyze initial value problems for a hyperbolic system of equations that is a simplification of models of longitudinal elastoplastic deformations in a rod. In longitudinal deformation there is only one nontrivial component of stress, which we label σ, and one component of velocity, w. We consider models with hardening, in which the yield stress (the threshold beyond which the material deforms plastically) depends on the stress history. This dependence is incorporated into the hardening variable γ, which is the maximum previous stress at a material point. The longitudinal elastoplasticity models, studied by many authors [1], [4], [6], [7], are given in [5] in the form

$$(1.1)\qquad \begin{array}{ll} \text{(a)} & \partial_t w = \partial_x \sigma, \\ \text{(b)} & \partial_t \sigma + K\partial_t \gamma = \partial_x w, \\ \text{(c)} & \partial_t \gamma = \begin{cases} 0 & \text{if} \quad \sigma < \gamma \quad \text{(elastic)}, \\ (\partial_t \sigma)_+ & \text{if} \quad \sigma = \gamma \quad (\text{plastic if } \partial_t \sigma \geq 0). \end{cases} \end{array}$$

Here, $K = K(\gamma) > -1$ is a given nonzero function, ∂_t, ∂_x are contractions of $\partial/\partial t, \partial/\partial x$, and

$$(1.2)\qquad (\partial_t \sigma)_+ = \begin{cases} \partial_t \sigma & \text{if } \partial_t \sigma \geq 0, \\ 0 & \text{if } \partial_t \sigma \leq 0. \end{cases}$$

System (1.1) has elastic wave speeds ±1 and 0, and plastic wave speeds $\pm(1+K)^{-1/2}$.

In [5], we simplified the model by taking $K(\gamma)$ constant. Here, we not only take K to be constant, but we also reduce the dimension of the system, eliminating one characteristic variable, corresponding to waves with negative speed. Specifically, we

write a system of two equations relating stress and hardening, dropping the velocity:

$$\text{(1.3)}\qquad \begin{aligned} &\text{(a)}\quad \partial_t u + k\partial_t v + \partial_x u = 0,\\ &\text{(b)}\quad \partial_t v = \begin{cases} 0 & \text{if } \ u < v \quad \text{(elastic)},\\ (\partial_t u)_+ & \text{if } \ u = v \quad \text{(plastic if } \partial_t u \geq 0\text{)}. \end{cases} \end{aligned}$$

For simplicity, we have relabelled the stress as u, and the hardening as v. The parameter $k > -1$ is related to K by $k = (1+K)^{1/2} - 1$. We call system (1.3) the *unidirectional model.*

The material deforms *elastically* when $u < v$ or $u = v$ and $\partial_t u \leq 0$. Then (1.3) reduces to the system

$$\text{(1.4)}\qquad \begin{aligned} \partial_t u + \partial_x u &= 0,\\ \partial_t v &= 0, \end{aligned}$$

which has wave speeds $c_o = 0$ and $c_E = 1$. We have normalized the elastic wave speed c_E to be one. Note that the variable v is constant in time in elastic deformation.

When $u = v$ and $\partial_t u \geq 0$, the material deforms *plastically*, and (1.3) reduces to a scalar equation:

$$\text{(1.5)}\qquad \partial_t u + \frac{1}{1+k}\partial_x u = 0,$$

with (plastic) wave speed $c_P = (1+k)^{-1}$. By imposing the additional restriction $k > -1$, we ensure that both elastic and plastic waves have positive wave speed. Note that for $-1 < k < 0$, the plastic wave speed is greater than the elastic wave speed, whereas for $k > 0$, the elastic wave speed is larger. For longitudinal motion, the range $-1 < k < 0$ is, therefore, unphysical. However, in reducing the equations for multidimensional deformation with a nonassociative flow rule to a one-dimensional model, the entire range $k > -1$ assumes physical significance. This point is discussed further in [5].

Since solutions of elastoplasticity problems appear to have no spontaneous tendency to form shocks in finite time, we shall be concerned only with continuous solutions in this paper. In particular, for system (1.3) with k constant, the equations are piecewise linear, so that the only shocks expected in solutions of initial boundary value problems are those propagating from initial or boundary conditions. The restriction to continuous solutions also helps to justify the simplification of taking k to be constant. The objective in studying the simplified system is to understand the behavior of solutions locally in space and time, so that the solution is close to a constant, making k close to constant. The principal nonlinearity involved is, therefore, the switch between (1.4) and (1.5). Dropping the quasilinear dependence of the equations through the function k enables us to focus on the nonlinearity due to the switch.

To see how solutions of (1.1) are related to those of (1.3), consider a solution of (1.1) which is unidirectional in the sense that w, σ in each elastic or plastic region are functions of $x - ct$, with $c = 1$ (for elastic deformation), or $c = (1+K)^{-1/2}$ (for plastic deformation). Correspondingly, $\partial_t \gamma = 0$, or $\gamma = \sigma$ (respectively). Then in particular, we have the equation

$$c^{-1}\partial_t \sigma + \partial_x \sigma = 0.$$

This equation may be written in the form (1.3), setting $u = \sigma, v = \gamma, k = (1+K)^{1/2} - 1$. Conversely, if (σ, γ) is a piecewise smooth solution of (1.3), then σ is a function of $x - ct$

in each elastic or plastic region. If w is defined in an elastic or plastic region up to a constant by (1.1a,b), then the triple (w, σ, γ) satisfies (1.1) in that region. However, solutions of (1.1) typically are not unidirectional, and therefore do not satisfy (1.3). Moreover, it is generally not possible to construct the additional variable w in (1.1) so that a solution of (1.3) corresponds to a unidirectional solution of (1.1).

The purpose of the simplified model is to isolate the role of fully nonlinear wave interactions in the global behavior of solutions, while retaining sufficient structure in the equations to preserve the main phenomena. This paper may be viewed as a step toward proving existence results for initial boundary value problems for the full equations (1.1). We show some of the analytical difficulties inherent in dynamic elastoplasticity models, and demonstrate how they are resolved for the simplified system. The additional complication of having waves propagating in both directions (left and right) is an obstacle to extending the results of this paper to the larger system (1.1), because of the possibility of sustained wave interactions through repeated reflections.

The main result is that for bounded uniformly continuous initial data, the Cauchy problem for system (1.3) has a unique solution within a suitable class of bounded continuous functions. The proof of this result is based in part upon ideas related to those of Glimm in his treatment of the Cauchy problem for systems of hyperbolic conservation laws [2]. In particular, we approximate the solution by continuous piecewise linear solutions. Discontinuities in the first derivatives of the approximate solutions are treated as waves that propagate and interact. We use a functional of the piecewise linear approximate solutions that bounds the total spatial variation, is decreasing in time, and estimates the number of discontinuities. To show that this functional is decreasing, we rely heavily on the unidirectional property of the simplified system (1.3).

It is instructive to consider the evolution of initial data shown in Fig. 1.1(a). Initially, $u < v$ everywhere, so that according to (1.4), the graph of v remains fixed while the graph of u moves to the right with speed $c_E = 1$. At some time $t = t_1$, the graph of u first touches the graph of v. At this moment plastic deformation begins and the graph of v is pushed up where it is in contact with the graph of u (i.e., the maximum stress $v(x,t)$ increases). The subsequent motion is shown as a succession of pictures in Fig. 1.1. (The times t_i shown in Fig. 1.1 are defined in Fig. 1.2.) Figure 1.2 shows the (x,t)-plane for this solution, in which a region of plastic deformation (where (1.5) is satisfied) is surrounded by a region of elastic deformation (where (1.4) is satisfied). The solution shown in Fig. 1.1 may be obtained using the method of characteristics, but it is not clear how to use the method of characteristics to prove a general existence result for the Cauchy problem because the boundary between regions of elastic and plastic deformation must be found as part of the solution.

Our analysis of continuous solutions is based upon a detailed treatment of the *scale invariant initial value problem* (SI problem for short), which is the initial value problem for (1.3) with piecewise linear initial conditions:

$$(1.6)\qquad \begin{aligned} &\text{(a)} \qquad u(x,0) = \begin{cases} a_L x & \text{if} \quad x < 0, \\ a_R x & \text{if} \quad x > 0. \end{cases} \\ &\text{(b)} \qquad v(x,0) = \begin{cases} b_L x & \text{if} \quad x < 0, \\ b_R x & \text{if} \quad x > 0. \end{cases} \end{aligned}$$

To ensure that $u \leq v$ everywhere, we require that

$$(1.7)\qquad a_L \geq b_L, \qquad a_R \leq b_R.$$

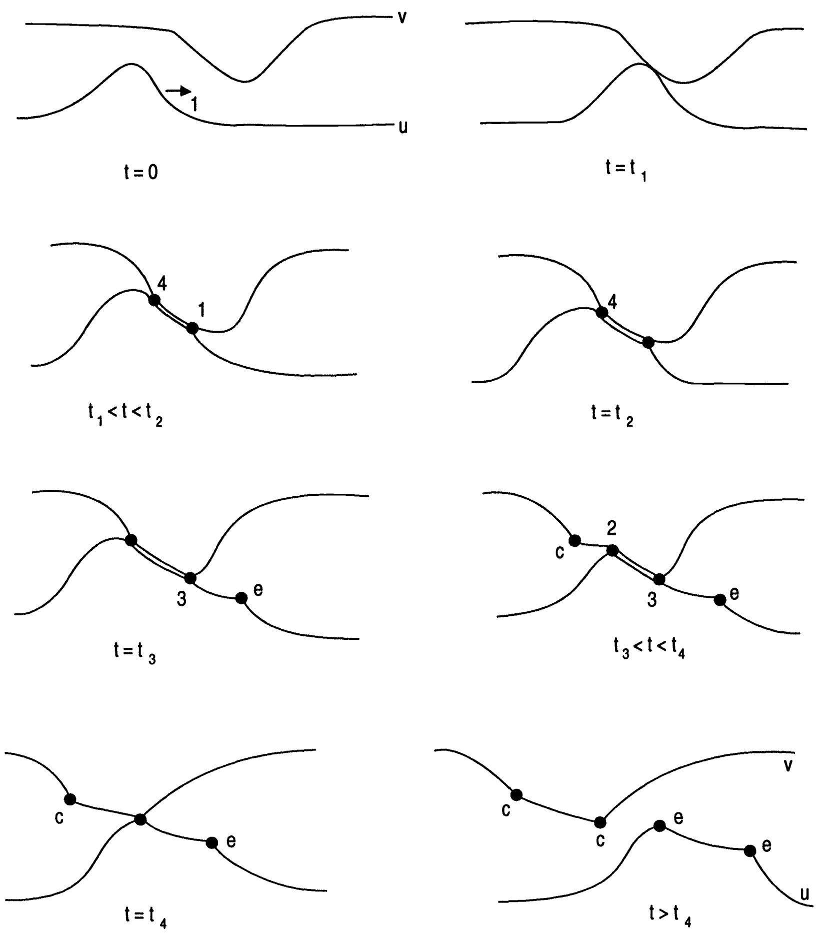

FIG. 1.1. *Labels refer to the classification of waves in* §2.

The initial value problem (1.3), (1.6) is called scale invariant because (1.3) and the initial conditions (1.6) are unchanged by the scaling

$$\begin{aligned} x &\longmapsto \alpha x, & t &\longmapsto \alpha t, \\ u &\longmapsto \alpha^{-1} u, & v &\longmapsto \alpha^{-1} v \end{aligned} \tag{1.8}$$

for any $\alpha > 0$.

In a companion paper [5], we solve the corresponding SI problem for the larger system (1.1). In this paper, we prove the existence of a solution of the Cauchy problem, with general initial data, but only for the simpler system of (1.3). In the proof, we use detailed information about solutions of SI problems for (1.3). We treat the SI problem for (1.3) in §2 for $k > 0$. The solution is continuous and piecewise linear. Jumps in derivatives of the solution propagate along characteristics, or along boundaries between regions of elastic and plastic deformation, which we call fronts or elastic-plastic boundaries. In §2, we classify the fronts into four types. An interesting point here is that one of the types of front has negative speed, even though all characteristic speeds are nonnegative.

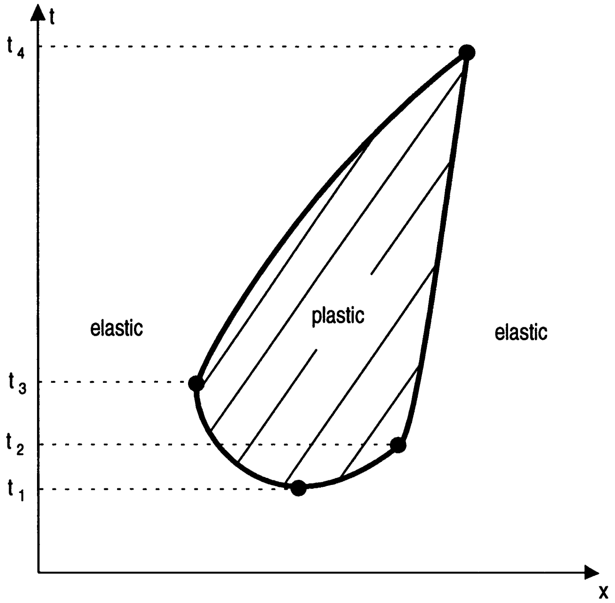

FIG. 1.2. *Elastic and plastic regions.*

In §3, we solve the Cauchy problem for bounded continuous initial data. The solution is continuous globally in time, and it is unique within the class of solutions we seek, namely those that can be approximated by continuous piecewise linear solutions of initial value problems having piecewise linear initial conditions.

In Appendix A, we consider the SI problem when $k < 0$ in (1.3). We demonstrate nonuniqueness of solutions of the SI problem for certain initial data, and nonexistence of continuous solutions for other initial data. Nonuniqueness can be resolved by imposing an entropy condition analogous to the Lax entropy condition for shock waves. We conjecture that nonexistence may be overcome by introducing a class of discontinuous solutions.

2. Solution of the scale invariant problem for $k > 0$.

For a given solution of (1.3), the (x, t)-plane is divided into regions in which either (1.4) is satisfied or (1.5) is satisfied. We refer to these regions as *elastic* regions or *plastic* regions, respectively. Within an elastic region there are characteristics with speed $c_E = 1$, which we call *elastic* characteristics, and characteristics with speed $c_o = 0$, which we call *contact* characteristics. Within a plastic region, there is just one family of characteristics, the *plastic* characteristics, which have speed $c_P = (1 + k)^{-1}$.

We seek a continuous piecewise differentiable solution of the SI problem (1.3), (1.6) when $k > 0$. If the solution is unique, then it must be invariant under the scaling (1.8). Therefore, we suppose that

$$(u,v)(x,t) = t\left(f\left(\frac{x}{t}\right), g\left(\frac{x}{t}\right)\right) \tag{2.1}$$

for some functions f and g. For such a solution, the conditions for plastic or elastic deformation are invariant under the scalings $x \to \alpha x, t \to \alpha t$ for any $\alpha > 0$. Therefore the elastic and plastic regions for a solution of the SI problem form wedges in the (x, t)−plane with vertices at the origin. The following lemma establishes the property that solutions of the SI problem are piecewise linear.

LEMMA 2.1. *Within a plastic region not containing the plastic characteristic $x = c_P t$, or within an elastic region not containing the elastic characteristic $x = c_E t$ or the contact characteristic $x = 0$, a solution of* (1.3) *of the form* (2.1) *is linear.*

Proof. In a plastic region, $u = v$, so that $f = g$ in (2.1). Substituting into (1.5) we obtain

$$f - \xi f' + (1+k)^{-1} f' = 0, \tag{2.2}$$

where $\xi = x/t$. By hypothesis, $\xi \neq c_P = (1+k)^{-1}$. Therefore, (2.2) has the general solution $f(\xi) = a(\xi - (1+k)^{-1})$, where a is an arbitrary constant. In this case,

$$u(x,t) = v(x,t) = ax - a(1+k)^{-1} t. \tag{2.3}$$

In an elastic region, substituting (2.1) into (1.4) gives the pair of equations

$$\begin{aligned} f - \xi f' + f' &= 0, \\ g - \xi g' &= 0. \end{aligned} \tag{2.4}$$

Since $\xi \neq 1$ and $\xi \neq 0$ by hypothesis, we obtain

$$f(\xi) = a(\xi - 1), \qquad g(\xi) = b\xi,$$

for which

$$u(x,t) = a(x-t), \qquad v(x,t) = bx. \tag{2.5}$$

This completes the proof. □

Note that solution (2.3) in a plastic region has one free parameter a, whereas solution (2.5) in an elastic region has two free parameters, a and b. The structure of solutions of the SI problem is a fan of adjacent wedges in the (x,t)-plane. In each wedge the solution is linear and specified by a point (a,b) in the plane, with $a = b$ if the wedge lies in a plastic region. The boundaries $x/t =$ constant between adjacent wedges are rays across which the solution is continuous but its derivative has a jump corresponding to a jump in the pair (a,b). We call such a ray a *single wave*. Therefore, we may represent the solution of the SI problem as a sequence of points in the (a,b) plane. To start with, we classify all the different types of single waves.

2.1. Single waves. Consider a single wave $x/t = s$ with speed s across which (u,v) is continuous but the first derivative of (u,v) may jump. We use the notation (u_E, v_E) for (u,v) if the material is deforming elastically, and the notation (u_P, v_P) at points of plastic deformation. For a function $w(x,t)$, the notation $[w]$ means the jump in w across the wave:

$$[w] = w(st+, t) - w(st-, t).$$

From Lemma 2.1, we know that within an elastic region or a plastic region, the only possible single waves are characteristics. We classify these in the usual way for hyperbolic equations, giving the corresponding changes across the waves in the parameters a and b, which are the spatial derivatives of the variables u, v. The time derivatives are determined from the differential equations by the spatial derivatives.

Elastic waves. Elastic on both sides.

$$[a] \neq 0, \quad [b] = 0, \quad s = 1.$$

Contact waves. Elastic on both sides.

$$[a] = 0, \quad [b] \neq 0, \quad s = 0.$$

Plastic waves. Plastic on both sides.

$$[a] = [b] \neq 0, \qquad s = (1+k)^{-1}.$$

Elastic-plastic boundaries. These are single waves $x = st$. On one side the material deforms elastically, and on the other side the material deforms plastically. Compatibility conditions for these waves are derived [4] using continuity of the functions u, v across the wave, and the appropriate differential equation from (1.3) on each side of the boundary.

Continuity at $x = st$ yields the conditions

$$\begin{aligned} u_E(st,t) &= u_P(st,t), \\ v_E(st,t) &= v_P(st,t) = u_P(st,t). \end{aligned}$$

We use one equation to discard v_P as an unknown, and differentiate the remaining equations, recalling $\partial_t v_E = 0$, to obtain

$$\begin{aligned} (\partial_t + s\partial_x)u_E &= (\partial_t + s\partial_x)u_P, \\ s\partial_x v_E &= (\partial_t + s\partial_x)u_P, \end{aligned} \tag{2.6}$$

From (1.3),

$$\begin{aligned} \partial_t u_E &= -\partial_x u_E, \\ \partial_t u_P &= -(1+k)^{-1}\partial_x u_P. \end{aligned} \tag{2.7}$$

Eliminating $\partial_x u_P$ and $\partial_x u_E$ from (2.6), (2.7), we get

$$\frac{\partial_t u_E}{\partial_t u_P} = \frac{1 - s(1+k)}{1-s}. \tag{2.8}$$

For future use, we record the result of solving (2.6), (2.7) for s and for $a_P = \partial_x u_P$ in terms of $a = \partial_x u_E$ and $b = \partial_x v_E$:

$$s = \frac{a}{a-b}, \tag{2.9}$$

$$0 > \partial_x u_P = a_P = \frac{ab(1+k)}{b+ka}. \tag{2.10}$$

From (2.10) we see that the elastic state (a,b) lies on a hyperbola determined by a_P:

$$(a - c_1)(b - c_2) = c_3, \tag{2.11}$$

where

$$c_1 = \frac{a_P}{1+k}, \quad c_2 = \frac{a_P k}{1+k} = kc_1, \quad c_3 = \frac{a_P^2 k}{(1+k)^2} = c_1 c_2.$$

To classify and understand the elastic-plastic boundaries, we use the following observations repeatedly, relying on (2.7) to express time derivatives in terms of spatial derivatives.

(i) For plastic deformations, $\partial_t u_P > 0$, which implies

$$a_P < 0, \tag{2.12}$$

as in (2.10).

(ii) In an *elastic-to-plastic boundary* $x = st$, the deformation is elastic before the boundary has passed (i.e., for smaller t), and plastic after the boundary has passed (i.e., for larger t). Consequently, in order that the material achieve plastic yield $u = v$ at the boundary, it must be loading elastically: $\partial_t u_E > 0$, which implies $a < 0$.

(iii) In a *plastic-to-elastic boundary* $x = st$, the deformation is plastic before the boundary has passed (i.e., for smaller t), and elastic after the boundary has passed (i.e., for larger t). Consequently, the material must be unloading elastically: $\partial_t u_E < 0$, which implies $a > 0$.

There are significant differences in the description of elastic-plastic boundaries, and in the solution of the SI problem, between the cases $k > 0$ and $k < 0$. *For the remainder of this section, we restrict our attention to the case* $k > 0$. In Appendix A, we return to the case $k < 0$.

From (2.8), (2.12) we draw the following conclusions:

1. $\partial_t u_E = a > 0$ implies $s < (1+k)^{-1}$ or $s > 1$;
2. $\partial_t u_E = a < 0$ implies $(1+k)^{-1} < s < 1$.

We use Fig. 2.1 to distinguish four types of elastic-plastic boundaries, shown in Fig. 2.2. Figure 2.1 shows the (a, b) plane when $k > 0$, with the shaded areas corresponding to constraints on elastic states in each type of elastic-plastic boundary, as explained below. The hyperbola of (2.11) for a fixed value of a_P intersects each of the four shaded regions of Fig. 2.1, as shown.

Type 1. $s > 1$. Fast elastic-to-plastic boundary. The speed and the plastic state are determined by the elastic state (a, b) through relations (2.9), (2.10). From (i), (ii), and $s > 1$ we deduce that $a < b < 0$, shown as region 1 in Fig. 2.2. There is exactly one hyperbola (2.11) through (a, b), and the plastic state $(a_P, a_P), a_P < 0$ is determined by the intersection of the hyperbola with the line $a = b, a < 0$.

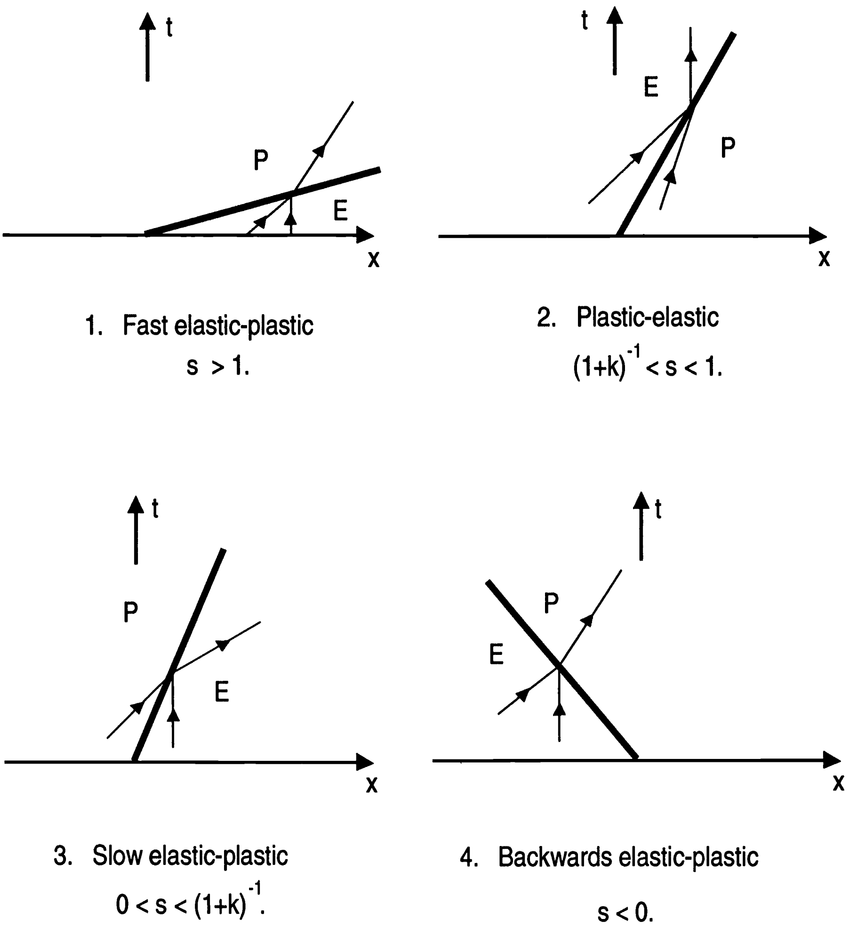
Type 2. $(1+k)^{-1} < s < 1$. Plastic-to-elastic boundary. Here, the plastic state determines a curve of elastic states (a, b). But now the material unloads elastically, so $a > 0$, from (iii) above. The inequalities on s and a_P further imply that $-ka < b < 0$. The corresponding region is labelled 2 in Fig. 2.2. Note that the possible elastic states (a, b) and the corresponding plastic state lie on different arms of the same hyperbola (2.11).

Type 3. $0 < s < (1+k)^{-1}$. Slow elastic-to-plastic boundary. Elastic loading and inequalities on s lead to $0 < -ka < b$ and $a < 0$, shown as region 3 in Fig. 2.2.

Type 4. $s < 0$. Backwards elastic-to-plastic boundary. Elastic loading and inequalities on s lead to $b < a < 0$, shown as region 4 in Fig. 2.2.

In each of the pictures of Fig. 2.1 we have shown the characteristics when $k > 0$. Note that for each boundary exactly two characteristics enter the boundary and one characteristic leaves the boundary. In Fig. 2.3, we show graphs of u, v adjacent to an elastic-plastic boundaries of each of the four types. Note that elastic-plastic boundaries of types 2 and 3 carry a maximum of u and a minimum of v, respectively, whereas u and v are monotonically decreasing across elastic-plastic boundaries of types 1 and 4.

2.2. Solution of the SI problem for $k > 0$. The solution of the SI problem is represented in three ways in Figs. 2.5–2.8.



1. Fast elastic-plastic $s > 1$.

2. Plastic-elastic $(1+k)^{-1} < s < 1$.

3. Slow elastic-plastic $0 < s < (1+k)^{-1}$.

4. Backwards elastic-plastic $s < 0$.

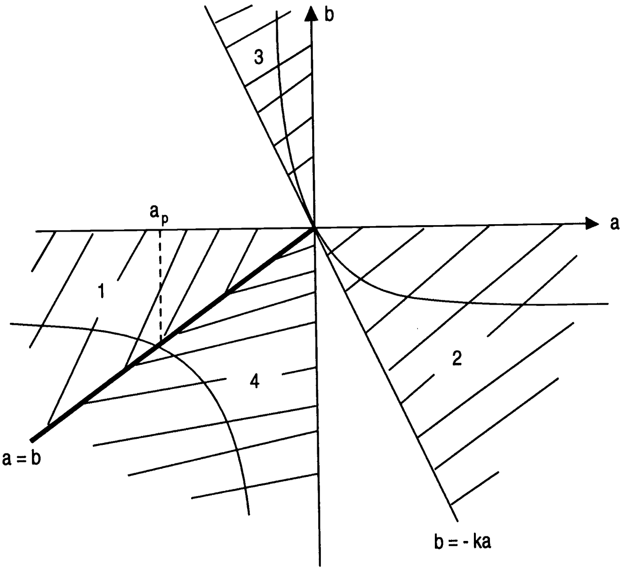

FIG. 2.2. *Location of elastic state (a, b) in elastic-plastic boundaries.*

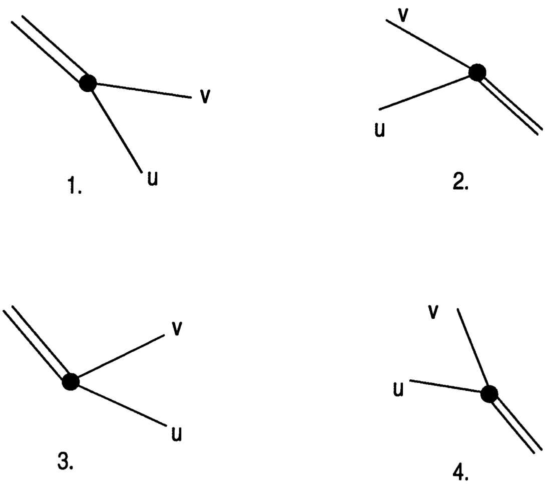

FIG. 2.3. *Graphs of u, v across elastic-plastic boundaries.*

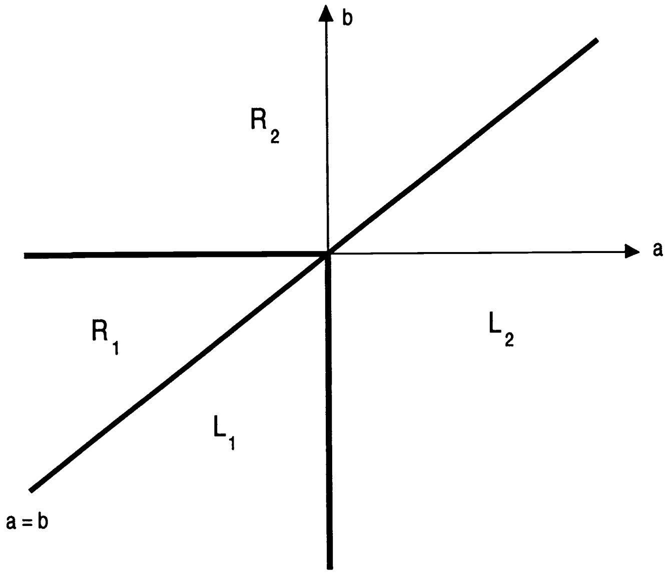

FIG. 2.4. *Location of left and right states.*

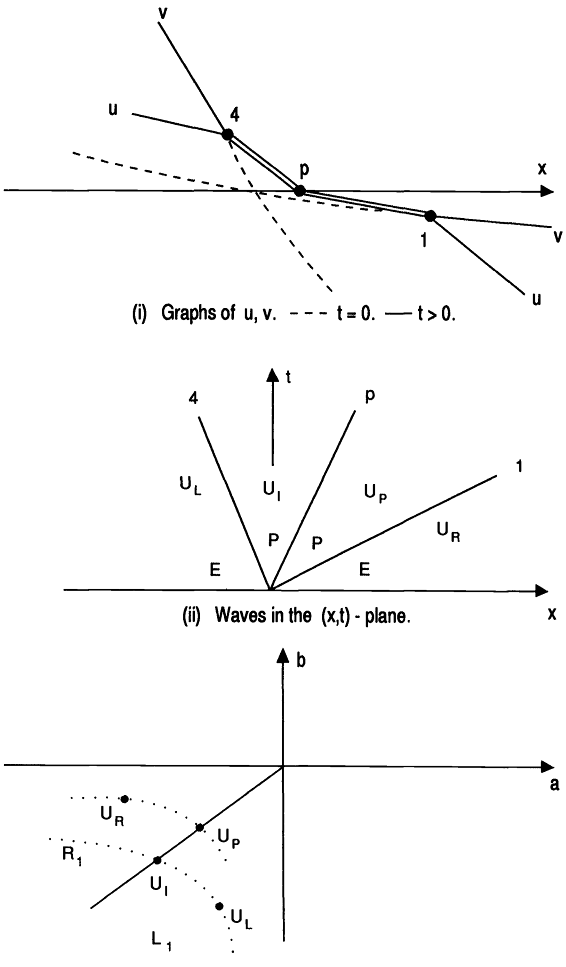
(i) Graphs of u and v as functions of x for fixed $t > 0$. Corners in these graphs represent single waves, labelled according to the conventions established above, namely, e for elastic waves, p for plastic waves, and c for contact waves, and a number 1 to 4 to label the type of elastic-plastic boundaries.

(ii) A picture of the (x, t)-plane to show the location of waves and plastic and elastic regions.

(iii) A picture of the (a, b)-plane representing the sequence of values of $\partial_x u$ and $\partial_x v$ between waves. This picture is augmented in the discussion below by formulae for the sequence of points (a, b) between waves.

Since the solution of the SI problem is piecewise linear and scale invariant, it consists of a sequence of single waves joining wedges $\{(x, t) : \alpha < x/t < \beta, t > 0\}$ in



(i) Graphs of u, v. - - - t = 0. —— t > 0.

(ii) Waves in the (x,t) - plane.

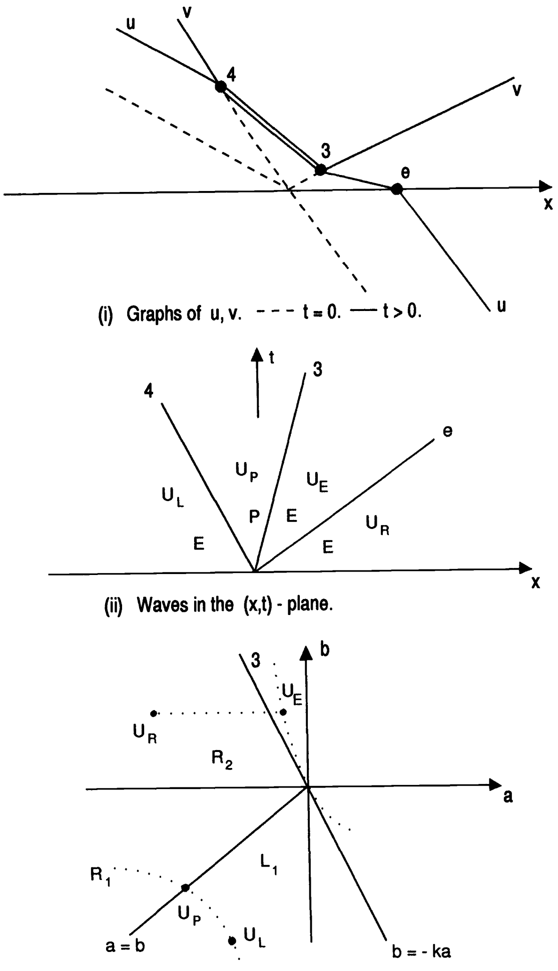
(iii) States in the (a,b) - plane.

FIG. 2.5. *Solution of the* SI *problem. Case* $L_1 R_1$.

the (x,t)-plane. In each wedge the derivatives $\partial_x u, \partial_x v, \partial_t u, \partial_t v$ are all constant. In each wedge we can use the differential equation (1.3) to find the time derivatives in terms of the spatial derivatives, and across each wave, jumps in the time derivatives are determined by jumps in the spatial derivatives, as we have seen. Therefore, the solution may be expressed as a sequence of points in the (a,b)-plane (representing spatial derivatives $(\partial_x u, \partial_x v)$), together with an explanation of the type of single wave separating adjacent wedges in the (x,t)-plane. We refer to each point (a,b) in the sequence as a *state*, since it corresponds to a uniform state (2.3) or (2.5), and we use the notation $U = (a,b)$.

The initial data (1.6) correspond to two points (a_L, b_L), (a_R, b_R) that are the first and last points in the sequence. The types of waves in the sequence vary with the initial data. Because of the restrictions (1.7) on the initial data, $U_L = (a_L, b_L), U_R = (a_R, b_R)$ lie in nonoverlapping regions in the (a,b)-plane, specifically,

$$
\begin{aligned}
a \geq b \quad & \text{for left states} \quad U_L = (a_L, b_L), \\
a \leq b \quad & \text{for right states} \quad U_R = (a_R, b_R).
\end{aligned}
$$



(i) Graphs of u, v. - - - t = 0. —— t > 0.

(ii) Waves in the (x,t) - plane.

(iii) States in the (a,b) - plane.

FIG. 2.6. *Solution of the* SI *problem. Case* L_1R_2.

Each of these regions is further divided into two sectors (see Fig. 2.4).

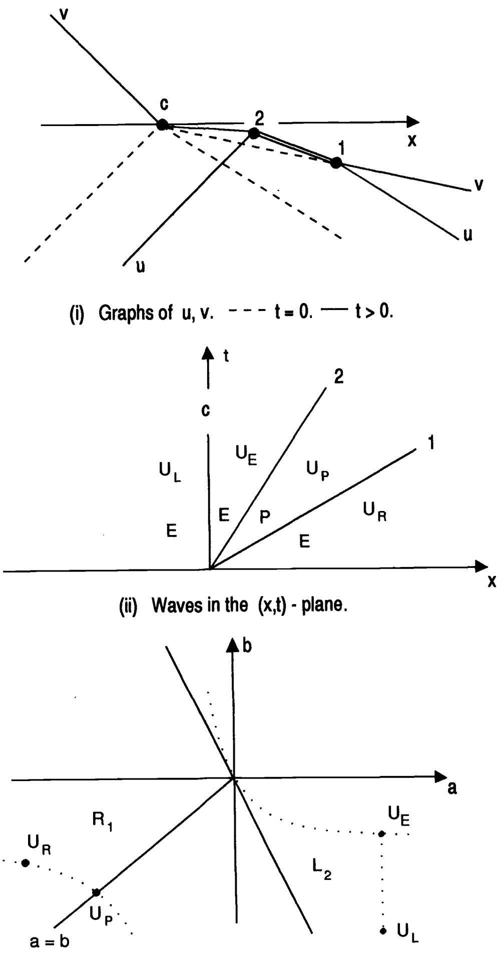
L_1	$b \leq a \leq 0$,
L_2	$b \leq a$ and $a \geq 0$,
R_1	$a \leq b \leq 0$,
R_2	$a \leq b$ and $a \leq 0$.

Given the partition of left and right regions into two sectors, there are four possible combinations of left and right states in different sectors. For each $i = 1$ or $2, j = 1$ or 2, the solution of the SI problem involves the same sequence of single waves for every $U_L \in L_i, U_R \in R_j$.

Case L_1R_1: $U_L = (a_L, b_L) \in L_1$, $U_R = (a_R, b_R) \in R_1$.

Since $(a_R, b_R) \in R_1$, the right state is loading elastically, and reaches plastic yield $u = v$ at a type 1 elastic-plastic boundary

$$x = s_1 t, \qquad s_1 = \frac{a_R}{a_R - b_R} > 1. \tag{2.13}$$



(i) Graphs of u, v. - - - t = 0. —— t > 0.

(ii) Waves in the (x,t) - plane.

(iii) States in the (a,b) - plane.

FIG. 2.7. *Solution of the* SI *problem. Case* L_2R_1.

The plastic state $U_P = (a_P, b_P)$ to the left of this boundary in the (x,t)-plane is also determined by the right state, through (2.10):

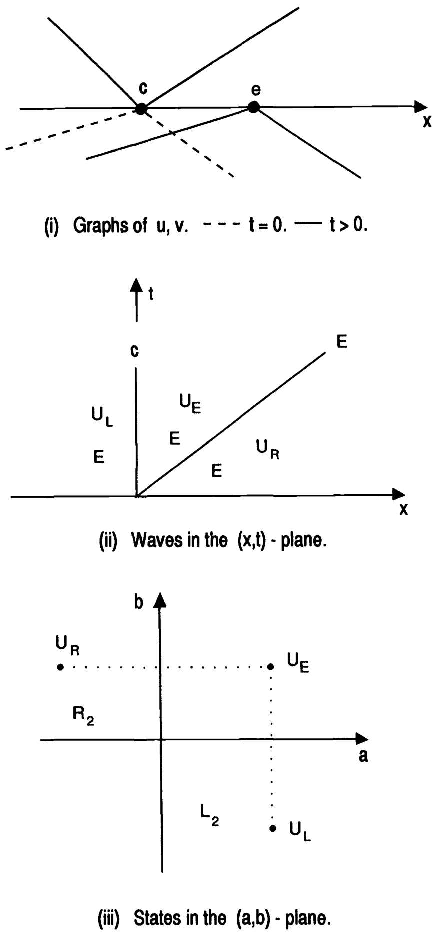
$$a_P = b_P = \frac{a_R b_R (1+k)}{b_R + k a_R}. \tag{2.14}$$

Similarly, since $(a_L, b_L) \in L_1$, the left state loads elastically until it reaches plastic yield at a type 4 elastic-plastic boundary

$$x = s_4 t, \qquad s_4 = \frac{a_L}{a_L - b_L} < 0. \tag{2.15}$$

The plastic state $U_I = (a_I, b_I)$ to the right of this boundary in the (x,t)-plane is also determined by the left state, through (2.10):

$$a_I = b_I = \frac{a_L b_L (1+k)}{b_L + k a_L}. \tag{2.16}$$



(i) Graphs of u, v. - - - t = 0. —— t > 0.

(ii) Waves in the (x,t) - plane.

(iii) States in the (a,b) - plane.

FIG. 2.8. *Solution of the* SI *problem. Case* L_2R_2.

Finally, there is a plastic wave $x = (1+k)^{-1}t$ across which $a = b$ jumps from a_I to a_P.

The solution for $t > 0$ and the corresponding pictures of the (x,t)-plane and (a,b)-plane are shown in Fig. 2.5 for representative choices of $U_L = (a_L, b_L) \in L_1$, $U_R = (a_R, b_R) \in R_1$. In Fig. 2.5(i) we show the solution itself with corners (i.e., waves) marked by dots, labelled according to the classification of single waves. The material is deforming plastically where the two graphs coincide, indicated by double lines. Note that the slopes of the different line segments, while all negative, need not be in the relations suggested by the figure. For example, the slope at P may jump down or up, depending on the location of U_L and U_R. This is most easily seen in Fig. 2.5(iii): clearly in this figure, U_L and U_R may be chosen in L_1 and R_1, respectively, so that U_I lies closer to the origin than U_P, in which case the slope at P would jump down. Letting $\xi = x/t \to c_P = (1+k)^{-1}$ in (2.2), we see that the plastic corner labelled p necessarily lies on the x axis.

Case L_1R_2: $U_L = (a_L, b_L) \in L_1$, $U_R = (a_R, b_R) \in R_2$.

Since $(a_L, b_L) \in L_1$, the left state loads elastically until it reaches plastic yield at a type 4 elastic-plastic boundary given by (2.15), with the plastic state $U_I = (a_I, b_I)$ on the right given by (2.16).

The right state $U_R = (a_R, b_R)$ may or may not be loading elastically (depending on the sign of a_R), but in any case, it remains elastic and uniform up until $x = t$, i.e., in the wedge $0 < t \leq x$. The ray $x = t$ is then an elastic wave, and U_R can jump to a new state $U_E = (a_E, b_R)$. (Recall that b does not change across an elastic wave.)

We now have to reconcile a determined plastic state U_P to the left in the (x,t)-plane of an elastic state U_E depending on a free parameter a_E. The only available wave is a plastic-to-elastic boundary of type 2. Indeed, U_E must lie in the region labelled 3 in Fig. 2.4, and be such that U_E lies on the hyperbola of (2.11), with $a_P = a_I$:

$$\frac{ab(1+k)}{b+ka} = a_I. \tag{2.17}$$

Setting $b = b_R$, and solving (2.17) for $a = a_E$, with a_I given by (2.16), we get

$$a_E = \left(k\left(\frac{1}{b_L} - \frac{1}{b_R}\right) + \frac{1}{a_L}\right)^{-1}. \tag{2.18}$$

Case L_2R_1: $U_L = (a_L, b_L) \in L_2$, $U_R = (a_R, b_R) \in R_1$.

As in case L_1R_1, the right state is loading elastically, and reaches plastic yield $u = v$ at a type 1 elastic-plastic boundary given by (2.13), with the corresponding plastic state $U_P = (a_P, a_P)$ given by (2.14).

The left state has $a_L > 0$. Therefore, the left state is unloading elastically and remains uniform for all $t > 0$. The line $t = 0$ is a contact wave across which $b = \partial_x v$ jumps. The elastic state immediately to the right of this wave in the (x,t)-plane is $U_E = (a_L, b_E)$. The parameter b_E is determined by compatibility with the plastic state U_P. The only available elastic-plastic boundary is of type 2. From equation (2.10), with $(a,b) = U_E = (a_L, b_E)$, and equation (2.14), we obtain

$$b_E = k\left(\frac{k}{b_R} + \frac{1}{a_R} - \frac{1}{a_L}\right)^{-1}. \tag{2.19}$$

Case L_2R_2: $U_L = (a_L, b_L) \in L_2$, $U_R = (a_R, b_R) \in R_2$.

Here, the solution is purely elastic. There is a contact wave on the t-axis and an elastic wave $x = t$. The intermediate elastic state is $U_E = (a_L, b_R)$.

Finally, it is easy to check that the solution is continuous with respect to the data. In particular, if U_L or U_R lies on the boundary of one of the regions, then the solution can be obtained as a limit of solutions with initial data from any of the adjacent regions.

3. Solution of the Cauchy problem.

In this section we prove existence and uniqueness results for the pure initial value problem (Cauchy problem):

$$\begin{gathered} \partial_t u + k\partial_t v + \partial_x u = 0, \quad -\infty < x < \infty, \quad t > 0, \\ \partial_t v = \begin{cases} \partial_t u & \text{if} \quad u = v \quad \text{and} \quad \partial_t u \geq 0, \\ 0 & \text{otherwise,} \end{cases} \end{gathered} \tag{3.1}$$

with continuous initial data (u_o, v_o):

$$(u,v)(x,0) = (u_o, v_o)(x), \qquad -\infty < x < \infty. \tag{3.2}$$

A continuous function $(u,v)(x,t)$ is a *solution* (more precisely, a *weak solution*) of the Cauchy problem (3.1), (3.2) if

$$\iint_{\mathbb{R}^2} \{(u(x,t)+kv(x,t))\phi_t(x,t)+u(x,t)\phi_x\}\,dx\,dt=0 \tag{3.3}$$

for each C^1 function $\phi(x,t)$ with compact support in the upper half plane $t>0$, if

$$v(x,t)=\max\left\{v_o(x),\ \max_{0\le s\le t} u(x,s)\right\},\quad -\infty<x<\infty,\quad t>0, \tag{3.4}$$

and if

$$(u,v)(x,0)=(u_o,v_o)(x),\qquad -\infty<x<\infty. \tag{3.5}$$

We remark that if a piecewise C^1 continuous function (u,v) satisfies (3.1) almost everywhere, and satisfies (3.2), then it is a solution.

The proofs of existence and uniqueness depend upon a careful analysis of solutions of initial value problems in which the initial data are piecewise linear and continuous. In particular, we study the propagation and interaction of discontinuities in the derivatives $\partial_x u, \partial_x v$ of the solution. Much of this section is devoted to studying piecewise linear continuous solutions of (3.1).

3.1. Piecewise linear solutions. For our purposes a function $f:\mathbb{R}^{>}\to\mathbb{R}^{K}$ will be called *piecewise linear* on a subset Ω of $\mathbb{R}^{>}$ if it is continuous on Ω, and there are a finite number of disjoint open sets $\Omega_j\subset\Omega, j=1,\dots,k$, with $\Omega=\overline{\cup_{j=1}^k\Omega_j}$ such that f is affine on each Ω_j. (Note that each Ω_j has polygonal boundary.) Our main goal in this subsection (§3.1) is to prove the following existence result for piecewise linear initial data. This is the main step in proving the general existence theorem for general continuous bounded initial data (see Theorem 3.11).

THEOREM 3.1. *If* $u_o(x)\le v_o(x)$ *are piecewise linear and continuous, and are constant outside a bounded interval, then there is a global solution of the initial value problem* (3.1), (3.2) *that is piecewise linear and continuous in the upper half plane.*

The proof of this result depends on an analysis of functionals that describe the propagation of discontinuities in derivatives of the solution. We begin by introducing some terminology in §3.1.1. In §3.1.2, we define and analyze the functionals, in a process we call *corner counting.* In §3.1.3, we describe the detailed structure of piecewise linear solutions of system (3.1), and in §3.1.4, we complete the proof of Theorem 3.1. Section 3.1.5 is concerned with properties of the solution operator, which takes given piecewise linear initial data to the solution given in Theorem 3.1. These properties are used in §3.2, in which it is shown that the piecewise linear solutions converge to a continuous solution of (3.1), (3.2).

3.1.1. Terminology. Let $U=(u(x,t),v(x,t))$ be a solution of (3.1) for $(x,t)\in\mathbb{R}\times[0,T_o]$ for some $T_o>0$. Assume that U is piecewise linear and continuous on $\mathbb{R}\times[0,T_o]$. Consider a fixed value t_o of t in $[0,T_o]$. An open interval $J=(x_1,x_2)$ (which may be unbounded) is called an *elastic interval* if $(u,v)(x,t_o)$ represents an elastic deformation for all $x\in J$. That is, J is an elastic interval if $u(x,t_o)<v(x,t_o)$ or $\partial_t u(x,t_o)<0$ for all x in J. Similarly, $J=(x_1,x_2)$ is called a *plastic interval* if $(u,v)(x,t_o)$ represents a plastic deformation for all $x\in J$: i.e., $u(x,t_o)=v(x,t_o)$ and $\partial_t u(x,t_o)\ge 0$ for all x in J. (Equality is allowed in the latter inequality to include the degenerate case of neutral loading, in which u and v are equal to the same constant

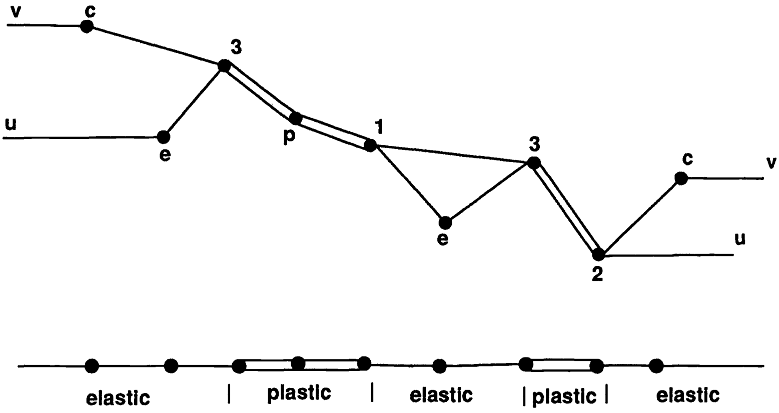


FIG. 3.1(a). *Graphs of piecewise linear u, v illustrating regular points, elastic intervals and plastic intervals.* $F(t) = 9$.

in the interval J.) We shall always assume that elastic intervals and plastic intervals are *maximal* in the sense that they are not contained in larger intervals of the same type.

The solution (u, v) has a *corner* at $x = x_o$ (we also say x_o is a corner) if either $\partial_x u(x, t_o)$ or $\partial_x v(x, t_o)$ is discontinuous at $x = x_o$. A corner x_o is called an *elastic-plastic boundary* if x_o is an endpoint of an elastic interval. As in §2, we shall often refer to a curve in the (x, t)-plane as an elastic-plastic boundary if it is the union of points (x_o, t_o), where x_o is an elastic-plastic boundary at time t_o. A characteristic curve $x = \gamma(t)$ is called a *corner characteristic* if there is a corner at $x = \gamma(t)$ for each t. We shall often speak of corner characteristics at a fixed time, meaning the corner at that time, which lies on a corner characteristic. A corner characteristic is called *monotone* if both $u(x, t)$ and $v(x, t)$ are monotone in x across the corner for each t. If the corner is a local extremum for u or v, then the corner characteristic is called *nonmonotone*.

In Fig. 3.1(a), we show examples of graphs of $u(x, t_o), v(x, t_o)$ at fixed t_o, with regular corners of various types defined in §2. We also show the elastic intervals and plastic intervals. The only nonmonotone corner characteristics in these examples involve a minimum of u at one of the corner characteristics labelled e.

Since $(u(x, t), v(x, t))$ is assumed to be piecewise linear, there are a finite number of corners at each time $t \in [0, T_o]$, and each corner lies on a corner characteristic, or is an elastic-plastic boundary, or is the origin of a local SI problem. (Here we use the term *local* to indicate that the solution is scale invariant only locally in space and time.) A point (x_o, t_o), with $t_o < T_o$, is called a *regular corner point* if there is exactly one corner characteristic or elastic-plastic boundary containing (x_o, t_o). If there is a corner at $x = x_o, t = t_o$ that is not a regular corner point, then it is the origin of a nontrivial local SI problem; such a point will be called an *intersection point.* We shall occasionally refer to intersection points as *collision points* (because they involve the collision of two or more corners or of the graph of u with the graph of v) or as *interaction points* (because, thinking of corners as acceleration waves, intersection points give rise to wave interactions).

3.1.2. Corner counting. We proceed to construct a global solution of the initial value problem for piecewise linear continuous and bounded initial data $(u_o(x), v_o(x))$

satisfying $u_o(x) \leq v_o(x)$ for all x.

Initially, there may be some finite number of SI problems to solve. Then over some time interval, there are no interactions. That is, the solution has corner characteristics and elastic-plastic boundaries, but these curves do not intersect, and moreover, $u < v$ in each elastic interval. Let $T > 0$ be the maximum time for which there are no interactions for $0 < t < T$.

At time T, there are interactions, which form centers for SI problems. The solution proceeds by solving these SI problems.

The proof of Theorem 3.1 depends upon an analysis of functionals that at each time measure the number of corners, corner characteristics, and extrema in the solution. We define these functionals as follows. Our definitions are guided by the functionals used by Glimm in the context of the Cauchy problem for hyperbolic systems of conservation laws [2].

Let $n(t)$ be the number of corners at time t, and let $L(t)$ denote the number of corner characteristics. If both $\partial_x u$ and $\partial_x v$ jump at a corner characteristic in an elastic interval, then count each separately (i.e., such a corner characteristic contributes 2 to $L(t)$).

Finally, we count the number of *approaching pairs.* First define an *approaching pair* at time t to be a pair of corners x_o, x_1 such that $x_o < x_1$ and u have a local maximum at x_o while v has a local minimum at x_1. Let $Q(t)$ be the number of approaching pairs at time t. Define

$$F(t) = L(t) + 2Q(t). \tag{3.6}$$

We illustrate these quantities and their relationship to each other and the structure of solutions by appealing to Fig. 3.1. In Fig. 3.1(a), we have $n(t) = 9, L(t) = 5, Q(t) = 2, F(t) = 9$. (The points labelled c, e, p each contribute 1 to $L(t)$; each point labelled 3 contributes 1 to $Q(t)$; each of the nine corners contributes 1 to $n(t)$.) In Fig. 3.1(b), we have taken the same sequence of elastic and plastic intervals, but have perturbed the graphs of u and v to show a solution with fewer corners. Specifically, in Fig. 3.1(a), one of the corners in the left-hand semi-infinite elastic interval labelled c or e may be removed (in Fig. 3.1(b), we retained only e), and the plastic corner p may be removed. Then $n(t) = 7, L(t) = 3, Q(t) = 2, F(t) = 7$. In an extreme case, we could have neutral loading (i.e., $u = v$) in both semi-infinite elastic intervals. This would reduce the number of corner characteristics by two, giving $n(t) = 5, L(t) = 1, Q(t) = 2, F(t) = 5$. We illustrate the extreme case in Fig. 3.1(c).

This discussion suggests that we can estimate the number of corners $n(t)$ in the solution by $3L(t) + 2$, which involves only the number of corner characteristics. But this latter number generally increases with time. However, we may obtain a nonincreasing upper bound for this estimate by including the term $Q(t)$ that counts the number of approaching pairs. This term is analogous to the term measuring *the potential for future interaction* in Glimm's analysis of conservation laws [2]. In fact, we show in Theorem 3.2 that $n(t)$ is bounded by $3F(t) + 2$, and then go on to show in Lemma 3.5 that $F(t)$ is nonincreasing in time t. We then have a global upper bound ((3.8) below) for the number of corners in the solution. This is a major step in showing that the solution may be continued, and remains piecewise linear, for all time.

The estimate $3L(t) + 2$ for $n(t)$ is justified loosely as follows. As suggested by our discussion of Fig. 3.1, each elastic interval contains a corner characteristic, providing we adopt the convention that neutral loading is plastic. (This result is proved

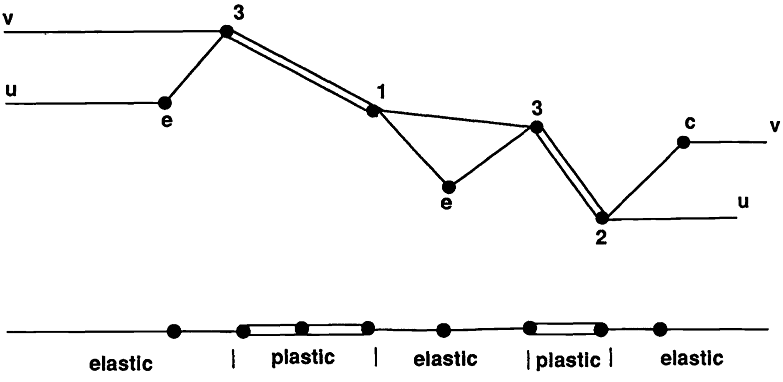

FIG. 3.1(b). *Graphs of piecewise linear u, v illustrating regular points, elastic intervals and plastic intervals.* $F(t) = 7$.

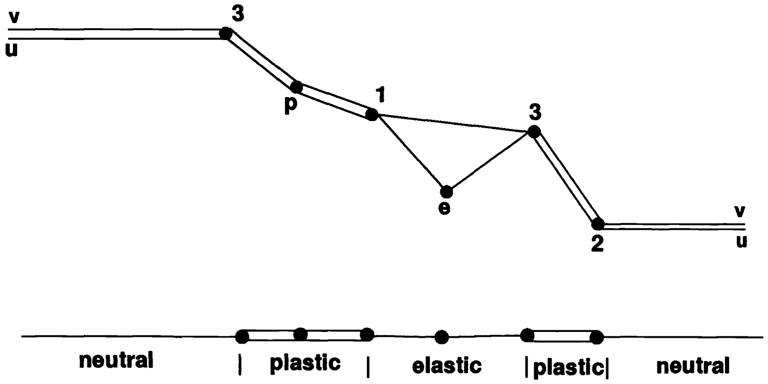

FIG. 3.1(c). *Graphs of piecewise linear u, v illustrating regular points, elastic intervals and plastic intervals.* $F(t) = 5$.

as Lemma 3.3 below.) Moreover, any corner that is not a corner characteristic is an elastic-plastic boundary. Therefore, we get an upper bound for the number of corners, in terms of the number of corner characteristics, by assuming that all corner characteristics (whether elastic or plastic or contact) are embedded in a bounded elastic interval containing no other corner characteristics. The endpoints of this interval, which are elastic-plastic boundaries, contribute another two corners. In this way, each corner characteristic counts as three in our estimate of the number of corners in the solution. Now, if there are corner characteristics in the semi-infinite intervals (as in Fig. 3.1(b)), then we overestimate the number of elastic-plastic boundaries in this counting, and hence $n(t) < 3L(t)$, but if both semi-infinite intervals have neutral loading, i.e., with no corners, and are adjacent to plastic intervals, then we have missed two elastic-plastic boundaries. Therefore, we must add two to our estimate of the number of corners in the solution. In particular, the configuration in Fig. 3.1(c) is minimal in the sense that this estimate is achieved: $n(t) = 3L(t) + 2$. We formalize the estimate in Theorem 3.2 below.

THEOREM 3.2. *Let $(u(x,t), v(x,t))$ be a piecewise linear continuous solution of* (1.3) *for $-\infty < x < \infty$, t in an open interval I. Then*

$$\begin{aligned} n(t) &\le 3L(t) + 2 \\ &\le 3F(t) + 2. \end{aligned} \tag{3.7}$$

The proof depends upon the following observation, which we state as a lemma.

LEMMA 3.3. *Let $(u(x,t), v(x,t))$ be a piecewise linear continuous solution of* (1.3) *for $-\infty < x < \infty$, t in an open interval I. At a fixed $t \in I$, every bounded elastic interval contains a corner characteristic. Moreover, if $\partial_x u$ and $\partial_x v$ have bounded support, then any semi-infinite elastic interval also contains a corner characteristic.*

Proof. We argue by contradiction. Let $J = (x_1, x_2)$ be a bounded elastic interval at time t_o that does not contain a corner characteristic. Then $u(x,t_o)$ and $v(x,t_o)$ are affine for $x \in J$. But the endpoints of J are elastic-plastic boundaries, so that $u(x_1,t) = v(x_1,t)$ and $u(x_2,t) = v(x_2,t)$. Consequently, $u(x,t) = v(x,t)$ for all $x \in J$. Since J is an elastic interval, we have $\partial_x u = -\partial_t u > 0$, and $\partial_x u$ is constant. Moreover, $\partial_t v = 0$ in J. It follows that there is a subinterval K of J, and $\tau < t$ in I such that

$$u(x,\tau) > u(x,t) = v(x,t) = v(x,\tau) \quad \text{for all } x \in K.$$

But this is impossible, since $u(x,t) \leq v(x,t)$ for all (x,t).

A similar argument applies to semi-infinite elastic intervals when $\partial_x u$ and $\partial_x v$ have bounded support. Specifically, if J is such an interval, then the finite endpoint is an elastic-plastic boundary, so $u = v$ there. Since u and v cannot be equal and constant throughout an elastic interval, and they have to be constant outside some finite interval, there must be a corner characteristic somewhere in J. □

Proof of Theorem 3.2. The number of corners in the closure of a bounded elastic interval is less than or equal to the number of corner characteristics, plus two, as discussed above with reference to Fig. 3.1. It then follows from Lemma 3.3 that this number is less than or equal to three times the number of corner characteristics. The only corners in a plastic interval are the corner characteristics, so that the number of corners in each such interval is also less than or equal to three times the number of corner characteristics. Finally, we add 2 to this formula to admit the possibility that two unbounded elastic intervals have elastic-plastic boundary points that have not yet been counted as corners. This proves the first inequality in (3.6). The second inequality is trivial, since $Q(t) \geq 0$. □

The proof of Theorem 3.1 depends upon using solutions of SI problems to analyze the behavior of the functionals $L(t), Q(t), F(t)$.

LEMMA 3.4. *$Q(t)$ is a nonincreasing function of time.*

Proof. As a first step in the proof, we note that no critical points in $u(x,t)$ or $v(x,t)$ (as functions of x for fixed t) are created through collisions. This is because each intersection point (x_o,t_o) is the center of a local SI problem, for which the solution for $t > t_o$ (given in §3) has at most one critical point in u and v. Therefore, the solution for $t < t_o$ near (x_o,t_o) has at least the same number of critical points in the same variables. (For example, if $u(.,t)$ has a maximum for $t > t_o$, then $\partial_x u > 0$ for x to the left of the maximum, and $\partial_x u < 0$ for x to the right of the maximum for $t > t_o$. But then $\partial_x u > 0$ for small x, and $\partial_x u < 0$ for large x for $t < t_o$, so that $u(.,t)$ also has at least one maximum for $t < t_o$.)

Now maxima of u are carried by elastic corner characteristics or type 2 elastic-plastic boundaries; therefore, maxima of u travel with speed *at least* $(1+k)^{-1}$, the plastic wave speed. On the other hand, minima of v are carried by contact corner characteristics or type 3 elastic-plastic boundaries; therefore, minima of v travel with speed *at most* $(1+k)^{-1}$. Consequently, once a maximum of u is to the right of a minimum of v, it remains so for all future time. Since no critical points are created, $Q(t)$ cannot increase. □

The functionals $L(t), Q(t), F(t)$ change only due to intersections. Therefore, we can understand the global behavior of $F(t)$ by analyzing how $L(t), Q(t)$ change locally near an intersection point. We shall speak of changes of the functionals *across* an intersection point (x_o, t_o), meaning the effect of that intersection point on changes in the functionals as t crosses t_o.

More precisely, this local analysis can be performed by assuming that the only corners in the solution are carried by curves entering or emanating from the intersection point. That is, when discussing an intersection point in isolation, we shall consider $L(t), Q(t)$ to be defined by considering the solution only in a small neighborhood of that point, i.e., $L(t)$ is the number of corner characteristics in the neighborhood at time t, and $Q(t)$ is the number of approaching pairs in the neighborhood at time t. The neighborhood of an intersection point (x_o, t_o) can clearly be defined so that $L(t)$ and $Q(t)$ are constant for $t < t_o$, and for $t > t_o$.

LEMMA 3.5. *$F(t)$ is nonincreasing.*

Proof. We need only show that $F(t)$ is nonincreasing across intersection points. Let (x_o, t_o) be an intersection point. Then it is the center of an SI problem. Therefore, the data and solution fall into one of the four cases $L_iR_j, \quad i, j = 1, 2$ of §2. In all cases we have $Q(t) = 0$ after the intersection. Except for the case L_2R_2, we have $L(t) \leq 1$, and hence $F(t) \leq 1$, after the intersection. Apart from this case, we have $L(t) \geq 1$ before intersection, since if $L(t) = 0$, then either there is no intersection, or two elastic-plastic boundaries pinch off a plastic region, which is necessarily case L_2R_2. (Specifically, an elastic-plastic boundary of type 2, carrying a maximum of u converges from the left on an elastic-plastic boundary of type 3, carrying a minimum of v. All other intersections of elastic-plastic boundaries pinch off elastic intervals, which necessarily contain a corner characteristic.) Since $Q(t) \geq 0$, we see that $F(t) \geq 1$ before intersection and since $F(t) \leq 1$ after the intersection, we have completed the proof except in the case L_2R_2.

In case L_2R_2, we have $L(t) \leq 2, Q(t) = 0$ after the intersection, so that $F(t) \leq 2$. Therefore, if $Q(t) \geq 1$ before the intersection, we have $F \geq 2$ before the intersection and the proof is complete. Therefore, suppose $Q(t) = 0$ before the intersection. But in case L_2R_2 we have $\partial_x u_L > 0$ and $\partial_x v_R > 0$. Thus, before the intersection, either u has a maximum and v has a minimum, or at least one of u and v is monotonic increasing. In the former case, since $Q(t) = 0$, the maximum of u must be to the right of the minimum of v. But then it stays on the right, and there can be no intersection of these corners. For the other possibility, namely, one of $u(x,t), v(x,t)$ being monotonic increasing in x, this means that the deformation is elastic. If $\partial_x u > 0$, then from (1.3), $\partial_t u < 0$, so $u(x,t)$ is decreasing in time, and the deformation remains elastic, with no intersection. If $\partial_x v > 0$, then since the graph of $u(x,t)$ is to the right of the graph of $v(x,t)$, it remains to the right, the deformation remains elastic, and again there is no intersection. We have shown that $Q(t) \geq 1$ in Case L_2R_2 before the intersection point. This completes the proof. □

The consequence of Theorem 3.2 and Lemma 3.5 is that the number of corners $n(t)$ is bounded as long as the solution can be constructed by solving SI problems and using propagation along characteristics:

$$n(t) \leq 3F(t) + 2 \leq 3F(0) + 2. \tag{3.8}$$

Another immediate consequence of Lemma 3.5 is the following property.

LEMMA 3.6. *If $L(t)$ increases across an intersection point, then $2Q(t)$ decreases across that intersection point by at least the same amount.*

Proof. The proof of Lemma 3.5 demonstrated that $F(t)$ decreases across intersection points. The result now follows immediately from the definition of $F(t)$. □

The solution of the initial value problem with piecewise linear continuous initial data continues by solving SI problems at intersection points. This process can continue as long as there are a finite number of intersection points. Let T^* be the maximal time with the property that the solution is defined, and has a finite number of intersection points for $-\infty < x < \infty, 0 \leq t \leq T$, for each $T, 0 < T < T^*$. We now consider the solution defined on the region $-\infty < x < \infty, 0 \leq t < T^*$. Within this region, intersection points are still isolated in space-time, but of course they may in principle accumulate at some point on the boundary, with $t = T^*$. (Because u and v are constant outside an interval, the intersection points cannot approach $x = \pm\infty$ in finite time.)

LEMMA 3.7. *There are a finite number of intersection points across which L changes. If L and Q are constant across an intersection point, then $L(t) = 1$ and $Q(t) = 0$ across the intersection point.*

Proof. Lemma 3.4 implies that there are a finite number of intersection points at which Q decreases, since $Q(t)$ is a nonincreasing nonnegative integer valued function. Therefore, by Lemma 3.6, there are a finite number of points at which $L(t)$ increases. Since $L(t)$ is a nonnegative integer valued function, there can only be a finite number of intersection points across which $L(t)$ can decrease. Therefore, there are a finite number of intersection points across which L changes.

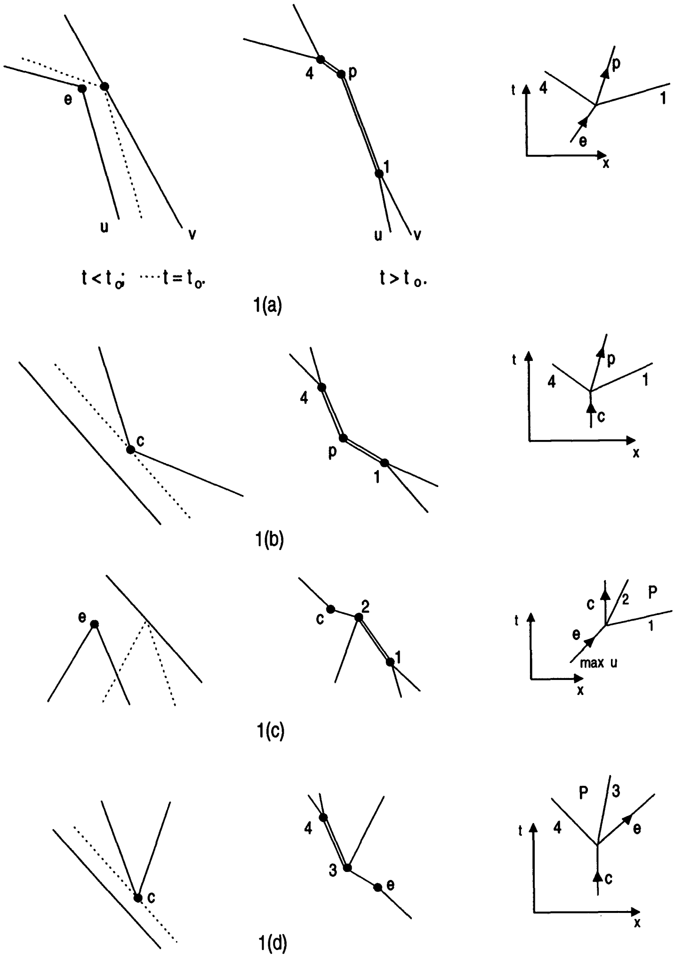
To show the second statement of the lemma, we argue as in the proof of Lemma 3.5. Considering intersection points as centers of SI problems, note that case L_2R_2 is ruled out because $Q(t)$ necessarily decreases across the intersection point in that case. Therefore, we have $L(t) \leq 1$ and $Q(t) = 0$ after the intersection. Lemma 3.4 then implies $Q(t) = 0$ across the intersection point. If $L(t) = 0$ is constant across the intersection point, then either there is no intersection or we are again in case L_2R_2. Therefore, $L(t) = 1$ across the intersection point. □

We have shown that after a certain time $T < T^*$, every intersection point has $L(t) = 1$ and $Q(t) = 0$ across the intersection point. We refer to such intersection points as *generic*. There is a finite list of possible generic intersection points for $T < t < T^*$, as we now discuss.

3.1.3. Generic collisions.

Consider intersection points having the property that $L(t) = 1, Q(t) = 0$ are constant across the intersection point. Because $L(t) = 1$, there is exactly one corner characteristic entering the intersection point, and exactly one corner characteristic leaving the intersection point.

Suppose the entering corner characteristic is plastic. Then at each time it lies in a plastic interval. If this plastic interval is bounded, then the endpoints both approach the intersection point, and form elastic-plastic boundaries that pinch off the plastic region containing the corner characteristic. But the only pair of approaching elastic-plastic boundaries pinching off a plastic region involves a type 2 front to the left of a type 3 front. In this case, we have seen that $Q(t) = 1$ and is, therefore, ruled out by the requirement $Q(t) = 0$. On the other hand, if there were any bounded elastic intervals, whose endpoints approach the intersection point, then by Theorem 3.2 there would be additional elastic corner characteristics, giving $L(t) \geq 2$. We conclude that if a plastic corner characteristic enters the intersection point, then there is at most one elastic-plastic boundary entering the intersection point. Since the plastic corner characteristic and the elastic-plastic boundary approach, we must have a type 2 front to the left of the corner characteristic, or a type 3 front to the right of the corner



1(a)

1(b)

1(c)

1(d)

FIG. 3.2 (1). *First touch.*

characteristic. These are the only possible intersections involving a plastic corner characteristic for which $L(t) = 1$ and $Q(t) = 0$.

If the entering corner characteristic is elastic or a contact, then a similar argument leads to the conclusion that there can be at most two elastic-plastic boundaries entering the intersection point. For otherwise, a pair of fronts would pinch off a plastic region, which was just ruled out because this implies $Q(t) \geq 1$.

Using these observations, we compile an exhaustive list of intersection points having the property that $L(t) = 1$ and $Q(t) = 0$ across the intersection point. This list is represented in Fig. 3.2. In this figure, we also include the additional case in which $Q(t)$ decreases and $L(t)$ increases keeping $F(t)$ constant.

Remarks. We conjecture that Fig. 3.2 includes all the possible collisions of corners in piecewise linear continuous solutions that cannot be altered qualitatively by small perturbations of the solution, that is, that generic intersection points are generic in the usual sense. We also conjecture that Fig. 3.2 includes all the possible intersection points in piecewise linear continuous solutions across which $F(t)$ is constant.

We divide the collisions into four categories as follows.

1. First touch. An elastic corner characteristic reaches a point of plastic yield ($u =$

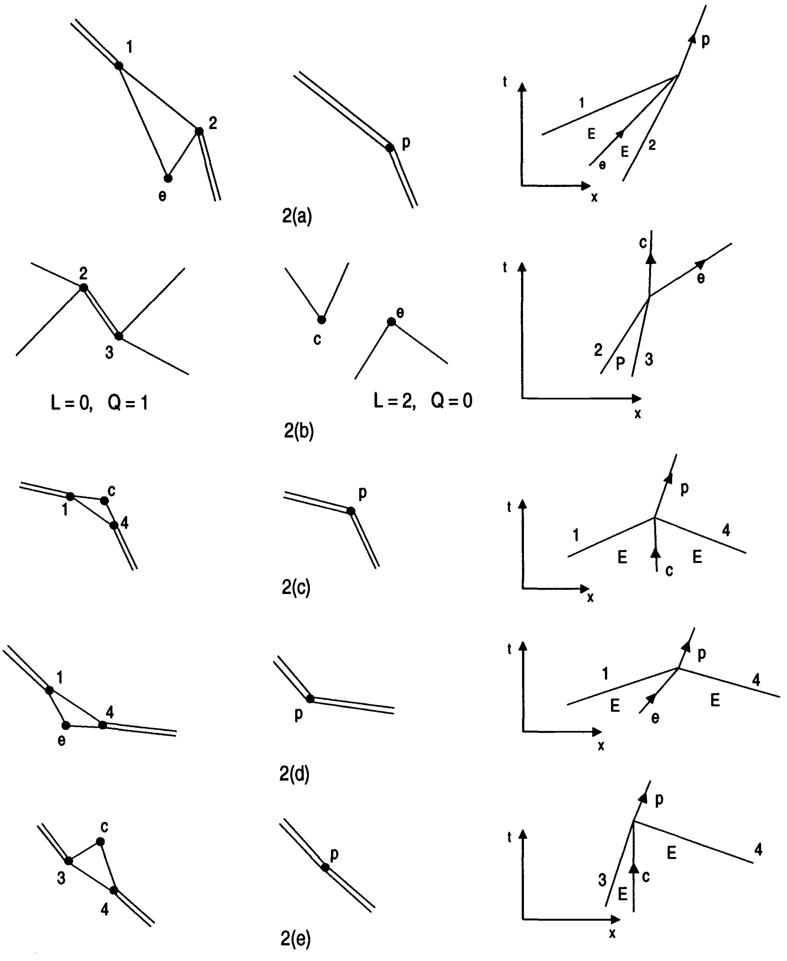


FIG. 3.2 (2). *Collisions of elastic-plastic boundaries.*

v) at the corner, and one of the variables is smooth (i.e., linear) at the intersection.

2. Collision of two elastic-plastic boundaries. Some such collisions involve corner characteristics.

3. Collision of an elastic-plastic boundary and a monotone corner characteristic.

4. Collision of an elastic-plastic boundary and a nonmonotone corner characteristic.

In Fig. 3.2 we show graphs of u, v before, at, and after collision, and the lines in the (x, t)-plane representing elastic-plastic boundaries and corner characteristics. This list of "generic" collisions is the basis for much of the analysis of this section, so we spend some time interpreting the information of Fig. 3.2.

Here are some properties that we read from Fig. 3.2, referring only to the intersection points shown there.

1. $L(t)$ and $Q(t)$ are unchanged across every collision except one (Fig. 3.2.2b), in which $L(t)$ increases by 2 while $Q(t)$ decreases by 1. $F(t)$ is unchanged in each case.

2. In case 2, the collision of elastic-plastic boundaries, an elastic region is pinched off except in case 2(b), where a plastic region is pinched off.

3. In case 3, in which an elastic-plastic boundary collides with a monotone corner

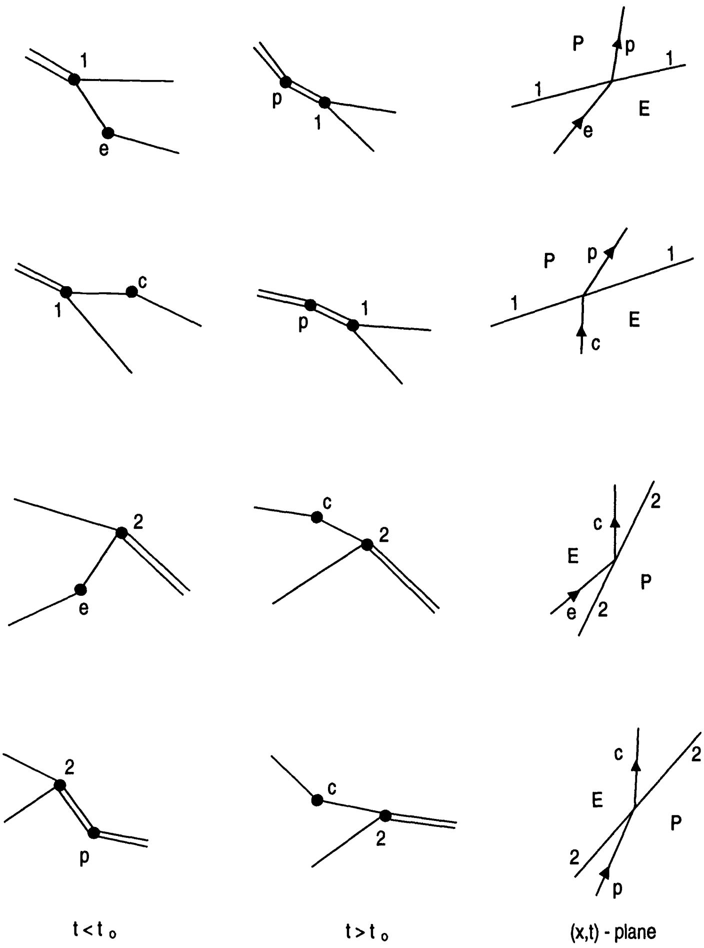

FIG. 3.2 (3). (*Types* 1, 2.) *Elastic-plastic boundary, monotone corner characteristic.*

characteristic, the type of the boundary is unchanged, and the corner characteristic remains monotone.

4. In case 4, in which an elastic-plastic boundary collides with a nonmonotone corner characteristic, the type of the boundary is changed, and the corner characteristic becomes monotone.

5. Only monotonic corner characteristics leave intersection points. In particular, if a nonmonotone corner characteristic enters an intersection point, then a monotone corner characteristic leaves.

6. All intersection points involving monotone corner characteristics and monotone elastic-plastic boundaries (of type 1 or 4) have $\partial_x u < 0$ and $\partial_x v < 0$ in a neighborhood of the intersection point.

3.1.4. Proof of Theorem 3.1. Consider the structure of a solution that is piecewise linear up to some maximal time T^*. By (3.8), the number of corners, and hence the number of corner characteristics, is bounded above at each time t in the interval $[0, T^*)$. Since T^* is maximal, there must be an infinite number of intersection points in $(-\infty, \infty) \times [0, T^*)$; for otherwise the solution could be continued, and remain piecewise linear, past T^*. But Lemma 3.7 states that after a finite number

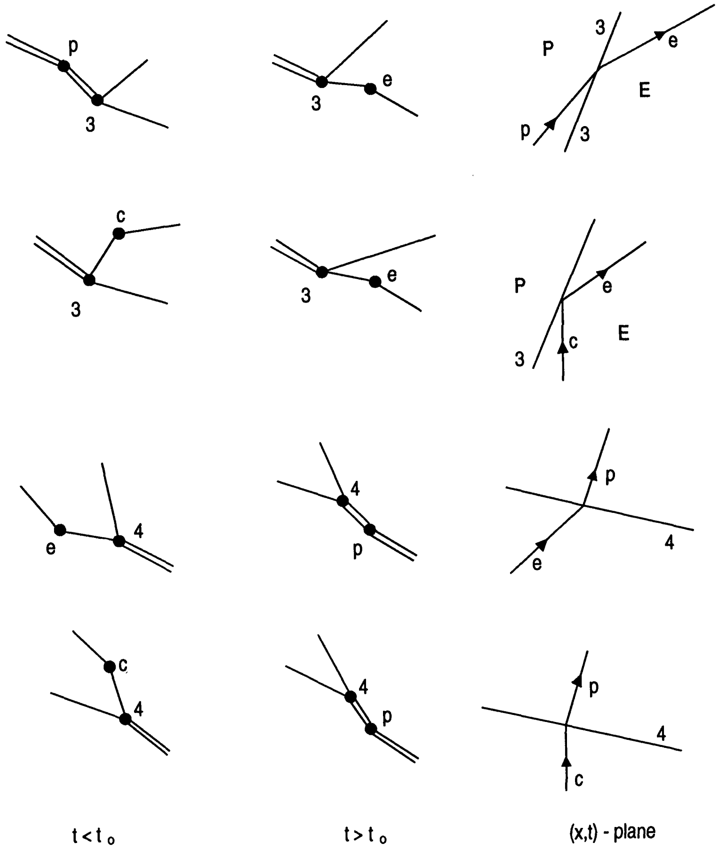

FIG. 3.2 (3). (*cont.*).(*Types* 3, 4.) *Elastic-plastic boundary, monotone corner characteristic.*

of intersections, i.e., after some time $T < T^*$, all intersection points have $L(t) = 1, Q(t) = 0$. Thereafter, corner characteristics are neither created nor destroyed, and their interactions occur only according to the list in Fig. 3.2.

Let us trace a single corner characteristic C as it propagates forward in time $t > T$ through intersection points listed in Fig. 3.2. By property 5, if C is nonmonotonic, either there are no intersection points on C, or it becomes monotonic after the first intersection point. In discussing further intersection points on C, we are, therefore, restricted to those in Fig. 3.2 involving only monotone corner characteristics. Regarding these, there are only two cases in which a plastic corner characteristic enters an intersection point.

(a) An elastic-plastic boundary of type 2 also enters the intersection point, in which case the corner characteristic emerges as a contact corner characteristic with

$$\partial_x u > 0 \quad \text{and} \quad \partial_x v < 0.$$

(b) An elastic-plastic boundary of type 3 also enters the intersection point, in which case the corner characteristic emerges as an elastic corner characteristic with

$$\partial_x u < 0 \quad \text{and} \quad \partial_x v > 0.$$

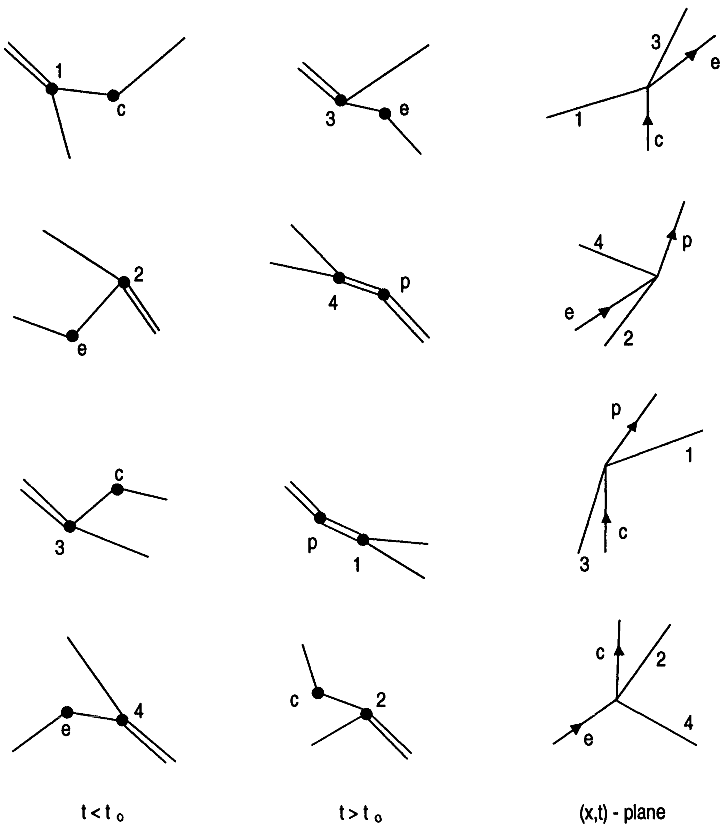

FIG. 3.2 (4). *Elastic-plastic boundary, nonmonotone corner characteristic.*

Moreover, the remaining intersections involving type 2 or type 3 elastic-plastic boundaries may be summarized as follows.

(c) An elastic corner characteristic enters a type 2 elastic-plastic boundary from the left, and emerges as a contact corner characteristic, also on the left. In the elastic region, in particular along the corner characteristics, we have

$$\partial_x u > 0 \quad \text{and} \quad \partial_x v < 0.$$

(d) A contact corner characteristic enters a type 3 elastic-plastic boundary from the right, and emerges as an elastic corner characteristic, also on the right. In the elastic region, in particular along the corner characteristics, we have

$$\partial_x u < 0 \quad \text{and} \quad \partial_x v > 0.$$

Suppose a portion of C is a plastic corner characteristic. Then the next intersection point on C must be one of (a) or (b); therefore, C becomes either a contact corner characteristic with $\partial_x u > 0$ and $\partial_x v < 0$, or an elastic corner characteristic with $\partial_x u < 0$ and $\partial_x v > 0$. In either case, there can be no further intersections along C, because neither of (c) or (d) is consistent with these possibilities, and intersection with a monotone elastic-plastic boundary of type 1 or 4 is ruled out by property 6 above.

Suppose on the other hand that C never becomes a plastic corner characteristic. The only intersections in which neither the incoming nor the outgoing monotone corner characteristics are plastic are given by (c) and (d). But then the outgoing characteristics are inconsistent with the possibility of further intersection points.

We conclude that there are at most two intersection points on C for $t > T$. Therefore, there are at most a finite number of intersection points in the solution for $t < T^*$, so they cannot accumulate. We have shown that $T^* = \infty$, and the solution remains piecewise linear in (x, t) for all time. This concludes the proof of Theorem 3.1. □

3.1.5. Properties of the solution operator. We first show that piecewise linear continuous solutions of the Cauchy problem with piecewise linear continuous initial data depend monotonically on the initial data in the following sense. We put the obvious partial order on pairs of functions: $U_o(x) = (u_o(x), v_o(x)) \leq U_1(x) = (u_1(x), v_1(x))$ if $u_o(x) \leq u_1(x)$ and $v_o(x) \leq v_1(x)$ for all x. Let $S(t)$ denote the solution operator:

$$S(t)U_o(x) = (u(x,t), v(x,t)).$$

We say that $S(t)$ is *monotonically increasing* if $U_o \leq U_1$ implies $S(t)U_o \leq S(t)U_1$.

THEOREM 3.8. *$S(t)$ is monotonically increasing on piecewise linear continuous functions.*

Proof. We begin by showing that solutions of the scale invariant problem depend monotonically on the initial data. For the SI problem, note that increasing $(u_o(x), v_o(x))$ is the same as decreasing a_L and b_L, and/or increasing a_R and b_R.

Case L_2R_2 is trivial. In the other cases, we note that corner characteristics are pinned on the x-axis at the appropriate value of x determined by the characteristic speed. For a plastic corner characteristic, both u and v are zero at this point, while for an elastic (respectively, contact) corner characteristic, only u (respectively, v) is zero at this point. This property follows by letting $\xi = x/t$ approach the characteristic speed in (2.3) or (2.5).

The strategy of the proof is to first increase a_R, b_R, and show that the solution functions u, v both increase, and then to decrease a_L, b_L, showing again that the solution functions u, v both increase.

In case L_1R_1 (see Fig. 2.5), the elastic-plastic boundary of type 1 is independent of the elastic-plastic boundary of type 4, because the plastic corner characteristic in the solution is fixed. Increasing a_R, b_R clearly increases a_P, while decreasing a_L, b_L clearly decreases a_I. Both of these correspond to an increase in u, v.

Consider cases L_1R_2 (see Fig. 2.6) and L_2R_1 (see Fig. 2.7). First note that a_E is decreased in case L_1R_2, and b_E is increased in case L_2R_1 by increasing a_R, b_R, or decreasing a_L, b_L. But a_P is decreased in case L_1R_2, and increased in case L_2R_1. These observations lead to the conclusion that u and v increase in both cases when the initial data are increased.

By continuity, the same conclusion holds when the data are degenerate, corresponding to the boundary between two of the L_iR_j cases. Now consider the action of $S(t)$ on general piecewise linear continuous functions. Any points of intersection of graphs of u or of v for different data may be treated as SI problems, for which we have established monotonicity. It now follows that $S(t)$ is monotonically increasing on piecewise linear continuous functions. We omit the details of the argument. □

Next we show that $S(t)$ is a contraction with respect to the sup norm on piecewise linear continuous functions. We define the supremum norm (or L_∞ norm) on piecewise linear continuous functions $U(x) = (u,v)(x)$ as follows:

$$||U|| = \sup_x \max\{u(x), v(x)\}.$$

THEOREM 3.9. *$S(t)$ is an L_∞ contraction on piecewise linear continuous functions.*

Proof. The proof relies on the following lemma, reflecting an obvious property of solutions.

LEMMA 3.10. *Let $(u_1, v_1), (u_2, v_2)$ be two piecewise linear continuous solutions of the Cauchy problem. If the solutions differ by a constant α at time $t = 0$,*

$$u_1(x,0) - u_2(x,0) = \alpha, \qquad v_1(x,0) - v_2(x,0) = \alpha,$$

then they differ by the same constant for all $t \geq 0$:

$$u_1(x,t) - u_2(x,t) = \alpha, \qquad v_1(x,t) - v_2(x,t) = \alpha.$$

Proof of Theorem 3.9. Consider two sets of initial data $U_o^i(x)$, $i = 1, 2$, and let $U^i(x,t) = S(t)U_o^i(x)$ be the corresponding solutions of the Cauchy problem.

Let $\alpha = ||U_o^2 - U_o^1||$. Then by monotonicity we have the following inequalities for $t > 0$, since they are true for $t = 0$.

$$\begin{aligned} u_1 - \alpha \leq u_2 \leq u_1 + \alpha, \\ v_1 - \alpha \leq v_2 \leq v_1 + \alpha, \end{aligned}$$

i.e., $||U^1(.,t) - U^2(.,t)|| = ||S(t)U_o^1 - S(t)U_o^2| \leq ||U_o^2 - U_o^1||$, as required. □

3.2. Convergence to a continuous solution. We can now prove the following existence result.

THEOREM 3.11. *Let the initial data $(u_o(x), v_o(x))$ be bounded and continuous, and satisfy $u_o(x) \leq v_o(x)$ for each x. Then there is a solution $(u,v)(x,t)$ of the Cauchy problem* (1.3) *that is bounded and continuous.*

Proof. Let (u_o^n, v_o^n) denote the continuous approximation of the initial data (u_o, v_o), defined as follows:

$$(u_o^n, v_o^n)\left(\frac{j}{n}\right) = (u_o, v_o)\left(\frac{j}{n}\right), \qquad -n^2 \leq j \leq n^2.$$

(u_o^n, v_o^n) is linear on each subinterval $j/n \leq x \leq (j+1)/n$, and constant outside the interval $(-n^2, n^2)$. Then

$$\begin{aligned} & u_o^n(x) \leq v_o^n(x), \qquad -\infty < x < \infty \\ & \sup_x |u_o^n(x)| \leq \sup_x |u_o(x)|, \\ & \sup_x |v_o^n(x)| \leq \sup_x |v_o(x)|. \end{aligned} \tag{3.9}$$

Moreover, it is easy to see that $\{(u_o^n, v_o^n)\}$ converges uniformly to (u_o, v_o) on every interval $[-N, N]$.

Let $(u^n, v^n)(x,t) = S(t)(u_o^n, v_o^n)(x)$ denote the solution of the Cauchy problem with initial data $(u_o^n, v_o^n)(x)$. Since $S(t)$ is a contraction, we have

$$||S(t)(u_o^n, v_o^n) - S(t)(u_o^m, v_o^m)|| \leq ||(u_o^n, v_o^n) - (u_o^m, v_o^m)||.$$

But $\{(u^n_o, v^n_o)\}$ is uniformly convergent, so $(u^n, v^n)(x,t)$ satisfies the uniform Cauchy criterion as a function of both x and t, and hence converges uniformly in t as well as in x to a uniformly continuous function $(u,v)(x,t)$.

To see that (u,v) is a solution of the Cauchy problem, we simply take limits in the weak formulation. That is, each member of the sequence satisfies (3.2)–(3.4), and by uniform convergence, we can take the appropriate limits, and conclude that (u,v) satisfies equations (3.2)–(3.4) also. □

3.3. Uniqueness of entropy solutions. Let $X = BUC(\mathbb{R})$ be the space of bounded uniformly continuous functions with norm $||f||_X = \sup_x |f(x)|$, and let $Y = X \times X$ with norm $||(u,v)|| = ||u||_X + ||v||_X$. Define $Z = BUC([0,\infty), Y)$, with norm $||U||_Z = \sup_0 ||U(t)||_Y$. An *entropy solution* of the Cauchy problem (3.1) is a solution that can be approximated in Z by piecewise linear continuous solutions over finite time intervals. Let $S(t)$ denote the unique continuous extension of $S(t)$ to the closed subset $\{(u,v) \in Y : u(x) \le v(x), -\infty < x < \infty\}$ of Y.

THEOREM 3.12. *Let the initial data $(u_o(x), v_o(x))$ be in the space Y, and satisfy $u_o(x) \le v_o(x)$ for each x. Then there is exactly one entropy solution $(u,v)(x,t)$ of the Cauchy problem* (1.3).

Proof. Let U, V be two entropy solutions with the same initial data U_o, and let U^n, V^n be the corresponding piecewise linear approximations of U, V, respectively. Then $U^n_o(x) = U^n(x,0), V^n_o(x) = V^n(x,0)$ both converge uniformly to $U_o(x)$ and $U^n(x,t) = S(t)U^n_o(x)$, $V^n(x,t) = S(t)V^n_o(x)$. Therefore,

$$U(.,t) = \lim_{n\to\infty} S(t)U^n_o = S(t)U_o = \lim_{n\to\infty} S(t)V^n_o = V(.,t).$$

This completes the proof. □

A. Appendix. Negative *k*.

In our treatment [5] of the SI problem for the piecewise linear longitudinal model ((1.1), with k constant), we investigated the implications of negative k in some detail. For the unidirectional model of this paper, we discuss two of the mathematical issues raised in [5]. Specifically, we demonstrate nonexistence and nonuniqueness of solutions of the SI problem (1.3)–(1.6) if $-1 < k < 0$. (Recall that $k > -1$ ensures that plastic and elastic waves propagate with positive speed. For the longitudinal model (1.1), $k > -1$ ensures hyperbolicity.)

A.1. Nonuniqueness for $k < 0$. First note that $-1 < k < 0$ implies that $c_E = 1 < c_P = (1+k)^{-1}$. That is, elastic characteristics are slower than plastic characteristics. This has little effect on elastic-plastic boundaries of types 1,3,4 but has a profound effect on those of type 2. For elastic-plastic boundaries of types 1,3,4, the u-characteristics (composed of elastic and plastic characteristics, see §3.1.3) pass through the front, while the contact characteristics enter. This is true for all $k > -1$. For elastic-plastic boundaries of type 2, however, the contact characteristics leave the front, and the u-characteristics enter from both sides if $k > 0$, but *leave* the front from both sides if $-1 < k < 0$. Thus, for $-1 < k < 0$, elastic-plastic boundaries of type 2 are unstable in the sense of Lax [3]. We call these *entropy-violating fronts.* A consequence of allowing entropy-violating fronts is that there are multiple solutions of some SI problems. In fact we shall construct two-parameter families of solutions of SI problems with the same initial data.

First we show how the construction of elastic-plastic boundaries in §2 must be modified when $-1 < k < 0$. The hyperbola of (2.11) still describes possible elastic states adjacent to an elastic-plastic boundary for a given plastic state. The hyperbola

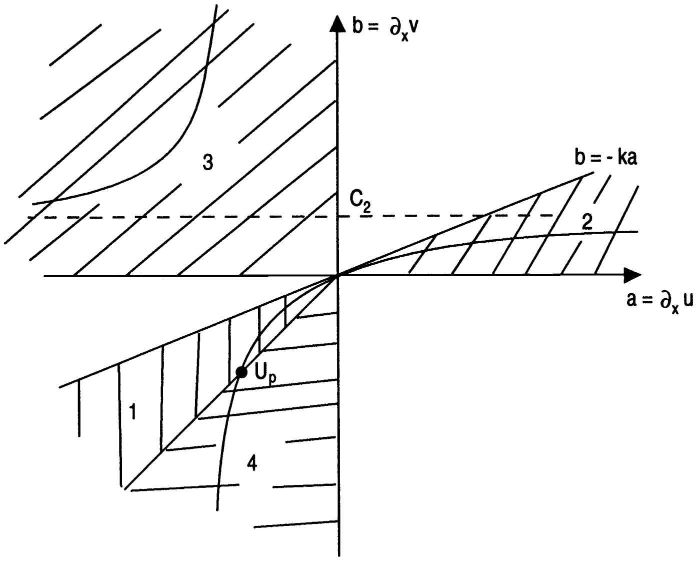

FIG. A.1. $k < 0$.

is redrawn in Fig. A.1 for $-1 < k < 0$, together with the various regions corresponding to elastic-plastic boundaries of types 1–4. (This figure is the analogue of Fig. 2.2, in which $k > 0$.)

Consider a plastic right state $U_R = U_P$, and let U_L lie on the portion of the hyperbola in region 2, as shown in Fig. A.1. Then one solution of the SI problem is an elastic-plastic boundary of type 2, shown in Fig. A.2. Since plastic characteristics move faster than the front, while elastic and contact characteristics move more slowly, it is not surprising that we can insert additional waves ahead of and behind the front, and adjust the speed of the front, without changing the initial data. These solutions are shown in Fig. A.3(a), with the corresponding construction shown in Fig. A.3(b). Here, U_R is joined to an arbitrary plastic state U_I. Then U_I is joined to an arbitrary point U_E in Region 2 on the hyperbola through U_I. The point U_E now determines the elastic and contact characteristic fronts. U_E is joined to the point U_C shown in the figure by an elastic wave, and U_C is joined to U_L by a contact corner characteristic. Each of these solutions involves an entropy-violating front, unless U_I and U_E are at the origin. In that case, the construction and solution are shown in Fig. A.4. Here, there is a neutrally loaded region, in which $\partial_x u = \partial_x v = 0$, and the material is in both the elastic and the plastic state. This is the preferred solution of the SI problem, since it does not contain an entropy-violating front.

A.2. Nonexistence for $k < 0$. Now we turn to the issue of nonexistence of solutions of SI problems for some choices of initial conditions. In Fig. A.5, we have divided the (a, b)-plane into regions, somewhat as we did in Fig. 2.4 for $k > 0$.

We proceed by varying U_R. If U_R is in Region R_1, then there is an elastic-plastic boundary of type 1, like there is for $k > 0$. However, as U_R approaches the ray labelled OA, the speed of this front approaches $c_P = (1 + k)^{-1}$, and U_P goes to infinity. Since the solution (u, v) remains bounded near the front, this suggests that the solution is tending towards a jump discontinuity.

For U_R in Region R_2, there can be no continuous solution of the SI problem. The

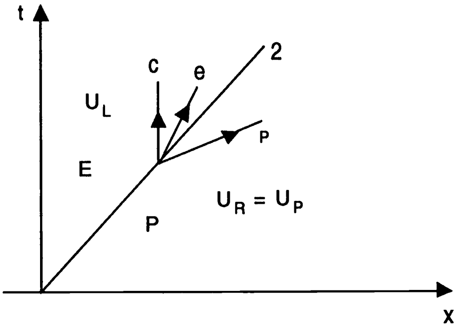

FIG. A.2. *Entropy-violating front.*

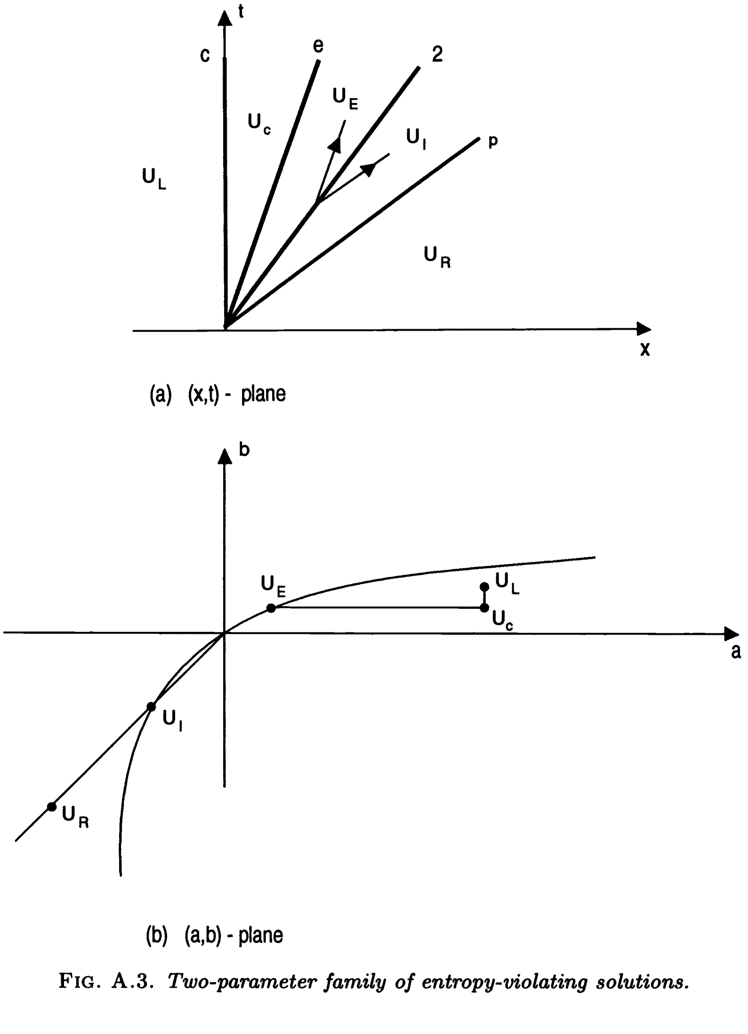

FIG. A.3. *Two-parameter family of entropy-violating solutions.*

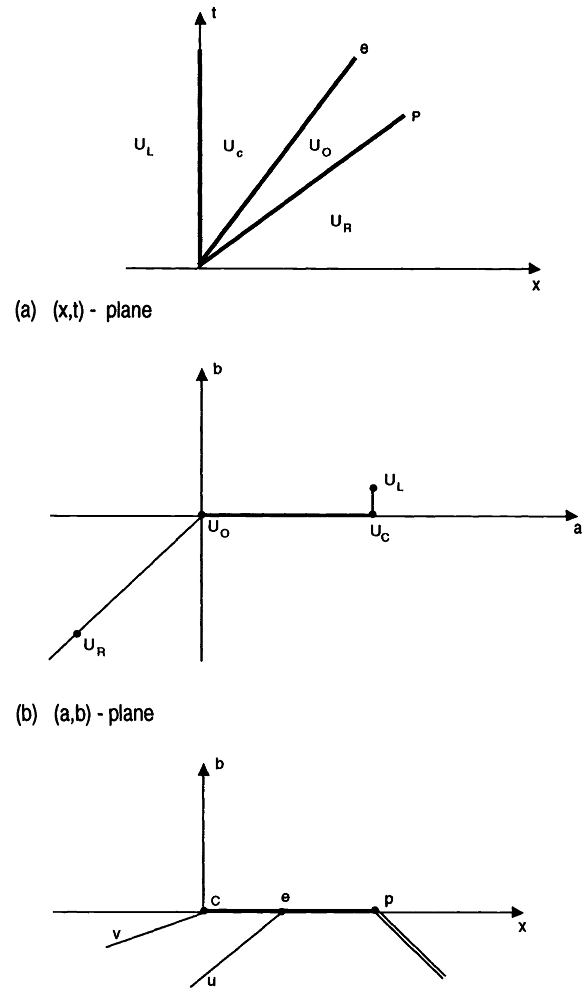
elastic state reaches yield along a curve $x = st$, where s is given by (2.9), and satisfies

$$c_E = 1 < s < (1+k)^{-1} = c_P$$

in the wedge R_2:

$$-ka_R < b_R < 0.$$



(a) (x,t) - plane

(b) (a,b) - plane

(c) Solution graphs for t > 0.

FIG. A.4. *Entropy solution.*

However, the plastic state $U_P = (a_P, a_P)$ to which U_R would be connected is given by (2.14):

$$a_P = b_P = \frac{a_R b_R(1+k)}{b_R + ka_R} > 0, \tag{A.1}$$

which violates the condition (2.12) for plastic deformation; therefore, there can be no solution if U_R is in region R_2. However, the behavior of the continuous solution as U_R approaches region R_2 from within region R_1 suggests that there may be discontinuous solutions of the SI problem when U_R is in region R_2. We plan to investigate discontinuous solutions in a future paper.

If U_R is in Region R_3, then there can be a type 3 elastic-plastic boundary, like there is for $k > 0$. However, for U_L in Region L_1, the plastic state U_P is determined; therefore, the hyperbola in the construction of the type 3 elastic-plastic boundary is

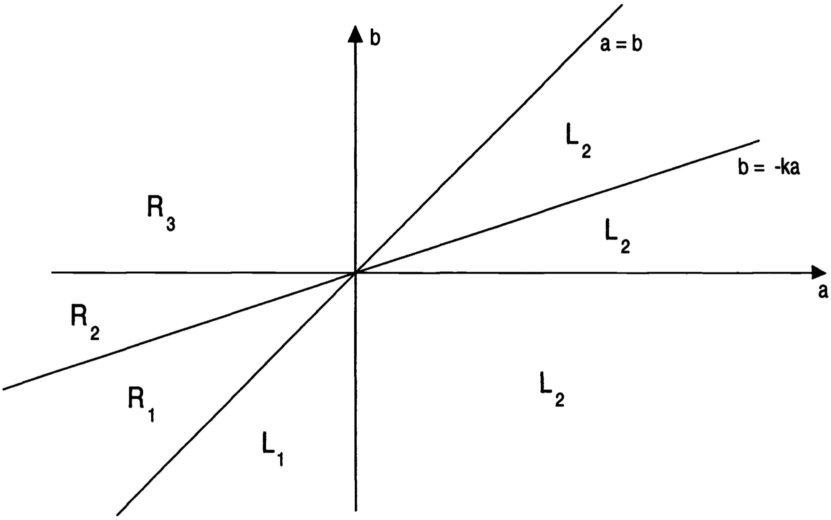


FIG. A.5. *The (a, b)-plane for $k < 0$.*

fixed by U_L. For U_R above the horizontal asymptote of this hyperbola,

$$a_R > c_1 = \frac{a_P k}{a_P + b_P},$$

there is no problem, since a faster elastic characteristic can be used to move $\partial_x U$ onto the hyperbola. But for $a_R < c_1$, there can be no global solution because no matter which elastic front is used, the elastic state does not lie on a portion of the hyperbola defined by U_L corresponding to elastic-to-plastic fronts.

Finally, for U_L in Region L_2, we saw in §A.1 that an apparent problem with nonuniqueness of solutions is resolved by imposing the entropy condition. But there is also an unresolved problem with existence similar to the situation for U_L in Region L_1.

A LEVEL SET FORMULATION FOR THE SOLUTION OF THE DIRICHLET PROBLEM FOR HAMILTON–JACOBI EQUATIONS*

STANLEY OSHER†

Abstract. A level set formulation for the solution of the Hamilton–Jacobi equation $F(x, y, u, u_x, u_y) = 0$ is presented, where u is prescribed on a set of closed bounded noncharacteristic curves. A time dependent Hamilton–Jacobi equation is derived such that the zero level set at various time t of this solution is precisely the set of points (x, y) for which $u(x, y) = t$. This gives a fast and simple numerical method for generating the viscosity solution to $F = 0$. The level set capturing idea was first introduced by Osher and Sethian [*J. Comput. Phys.*, 79 (1988), pp. 12–49], and the observation that this is useful for an important computer vision problem of this type was then made by Kimmel and Bruckstein in [*Technion* (*Israel*) *Computer Science Report*, CIS #9209, 1992] following Bruckstein [*Comput. Vision Graphics Image Process*, 44 (1988), pp. 139–154]. Finally, it is noted that an extension to many space dimensions is immediate.

Key words. Hamilton–Jacobi equation, viscosity solution, level set, numerical method

AMS subject classifications. 35L99, 65M05

Introduction. We are interested in solving a general first-order partial differential equation for a function $z = u(x, y)$ of the type

$$F(x, y, z, p, q) = 0, \tag{0.1}$$

where $p = u_x$, $q = u_y$.

This is a classical problem in partial differential equations (P.D.E.). In fact, the method of characteristics was invented to solve it. Typically we are given Cauchy data on a curve Γ, i.e., for

$$x = x_0(s), \qquad y = y_0(s); \tag{0.2a}$$

then

$$z = z_0(s). \tag{0.2b}$$

The data is assumed to be noncharacteristic, i.e., by the chain rule we have

$$\dot{z}_0(s) = p_0(s)\dot{x}_0(s) + q_0(s)\dot{y}_0(s), \tag{0.3}$$

while

$$F(x_0(s), y_0(s), z_0(s), p_0(s), q_0(s)) = 0. \tag{0.4}$$

In order to solve (0.3) and (0.4) locally for smooth $p_0(s)$, $q_0(s)$, the implicit function theorem requires

$$\dot{y}_0 F_p(x_0, y_0, z_0, p_0, q_0) \neq \dot{x}_0 F_q(x_0, y_0, z_0, p_0, q_0). \tag{0.5}$$

This is the noncharacteristic criterion.

* Received by the editors October 1, 1992; accepted for publication (in revised form) December 16, 1992.

† Department of Mathematics, University of California, Los Angeles, California 90024. This research was supported by Army Research Office grant DAAL03-91-G0162 and National Science Foundation grant DMS 91-03104.

Given (0.5), one then generates characteristic curves via

$$\begin{aligned}\frac{dx}{dt} &= F_p,\\ \frac{dy}{dt} &= F_q,\\ \frac{dz}{dt} &= pF_p + qF_q,\\ \frac{dp}{dt} &= -F_x - pF_z,\\ \frac{dq}{dt} &= -F_y - qF_z.\end{aligned} \tag{0.6}$$

The initial data "propagates" along these curves and criterion (0.5) guarantees that we generate a smooth solution locally in time. However, in finite time characteristic curves generally intersect (caustics develop). Fourier Integral Operators (FIO) were developed in the sixties and seventies (see, e.g., [8]) to take care of the resulting multivaluedness (and to do a lot more, of course).

A classical example is the eiconal equation from geometrical optics:

$$p^2 + q^2 = 1. \tag{0.7}$$

If Γ is convex, the solution rapidly develops a caustic. Rather than continuing it as a multivalued solution à la FIO, we may use the recently developed notion of viscosity solutions [3], [4], [5] for Hamilton–Jacobi equations to continue the solution uniquely as a single-valued uniformly continuous function having "kinks"—i.e., jumps in the first derivative. For most real-world problems this is the appropriate class.

We shall propose an analytic and numerical method for solving (0.1), (0.2) when Γ is a compact set of closed curves dividing R^2 up into Ω and its complement Ω^c, neither of which needs to be compact. We call Ω the "interior" and Ω^c the "exterior."

This method generalizes easily to compact hypersurfaces dividing up R^n into an interior and exterior. In this paper we shall stick to R^2 for simplicity of exposition only.

The present work has three main antecedents. In [12] Osher and Sethian introduced the concept of a level set formulation to propagate curves and surfaces. The problem analyzed there was as follows. We wish to move a closed curve Γ normal to itself with normal velocity u_n. This velocity might be geometrically based; e.g., it might be a function of the curvature of Γ. The level set formulation easily treats self-intersections, topological changes, kinks, and higher space dimensions. Theoretical justification for this method (along with a great deal of other very important theory) came later in [2], [6], [7].

Briefly, one finds a function $\psi(x, y, t)$ so that at $t = 0$ we have

$$\psi(x,y,0) = 0 \Leftrightarrow (x,y) \in \Gamma, \tag{0.8a}$$

$$\psi(x,y,0) > 0 \quad \text{in } \Omega, \tag{0.8b}$$

$$\psi(x,y,0) < 0 \quad \text{in } \Omega^c, \tag{0.8c}$$

and $\psi(x, y, 0)$ is a uniformly continuous and monotonic strictly decreasing function of distance to Γ near Γ, which we call $\Gamma(0)$.

We require that $\Gamma(t)$ evolves so that

$$\psi(x,y,t) = 0 \Leftrightarrow (x,y) \in \Gamma(t). \tag{0.9a}$$

This means that for $(x(t), y(t)) \in \Gamma(t)$,

$$\frac{d}{dt}\psi(x(t), y(t), t) = 0, \tag{0.9b}$$

$$\psi_x x_t + \psi_y y_t + \psi_t = 0. \tag{0.9c}$$

Rearranging terms, we arrive at

$$\psi_t = -u_n\sqrt{\psi_x^2 + \psi_y^2}. \tag{0.9d}$$

At this point we imagine that u_n is defined throughout R^n, not just on $\Gamma(t)$, and that this is done in a natural way. Thus all level sets of ψ move according to this law.

If u_n is a given function of (x, y), then this is a Hamilton–Jacobi equation and we seek the viscosity solution [4], [5]. This has an interesting physical interpretation for flames. Sethian's entropy condition [15] follows for the viscosity solution (see [12] for the proof).

If u_n is the curvature of the level set, the equation becomes

$$\psi_t = \frac{\psi_{xx}\psi_y^2 - 2\psi_{xy}\psi_x\psi_y + \psi_{yy}\psi_x^2}{\psi_x^2 + \psi_y^2}. \tag{0.10}$$

Thus, we can define the motion of a square via its mean curvature using (0.10) and following the level set. Again, this was rigorously justified in [2], [7] for general curves modulo some unusual exceptions.

As a numerical device this approach has many advantages over tracking. We simply set up a fixed, Eulerian grid, solve (0.9) numerically, and let the plotter find the front. Self-intersections, kinks, topological changes, and multispace dimensions are treated routinely. Of course, we have to construct stable, accurate, and efficient methods for (0.9). See [12], [13] for a description of such methods.

The second antecedent is [10]. There the authors wished to solve a problem in computer vision. We are given $z(x, y)$, describing the surface of an object that is illuminated by an overhead light source at infinity. In the simplest model the intensity of light $I(x, y)$ is given by

$$I(x,y) - \frac{1}{\sqrt{1+p^2+q^2}} = 0 = F(x,y,z,p,q). \tag{0.11}$$

The shape-from-shading problem is: given $0 < I(x, y) \leqq 1$, find $u(x, y)$. This is a very well studied problem, but only recently in [11], [14] was the correct theory of viscosity solutions brought to consideration. In [10], the authors assumed that they were given a level surface of u, i.e., (0.2) for $z_0 \equiv 0$. What they proposed was to use the methods of [12] to propagate the level surface to generate the solution of (0.11). We now recognize this as a general method for solving (0.1) for Dirichlet data. We shall describe and justify it in the next section.

Finally, the third crucial antecedent came in Bruckstein [1]. There the author transformed the shape-from-shading problem into a level set propagation P.D.E. and realized the advantages of this formulation. The link with the propagation methods of [12] and the viscosity solution concept came later in [10] for this important problem.

1. Description and justification of the method. Let Γ be a compact set of disjoint closed curves in R^2, dividing R^2 up into an interior Ω and an exterior Ω^c. We wish to solve for $z = u(x,y)$,

$$F(x,y,z,p,q) = 0, \tag{1.1a}$$

with Dirichlet data on Γ written locally as

$$x = x_0(s), \tag{1.1b}$$

$$y = y_0(s), \tag{1.1c}$$

$$z = z_0(s), \tag{1.1d}$$

which is noncharacteristic for (1.1a).

We next assume that $z_0(s)$ can be continued into a set containing Γ as a function $w(x,y)$ so that the function $n(x,y)$ defined by

$$z(x,y) = w(x,y) + n(x,y) \tag{1.2}$$

is the unknown. This has the effect of changing F and setting $z_0 \equiv 0$ in (1.1d). Thus we have the zero level set of the solution to a simple related P.D.E. as boundary data. This new P.D.E. continues to be called F and the new unknown function is z.

The noncharacteristic criterion then becomes

$$p_0 F_p + q_0 F_q \neq 0 \tag{1.3}$$

on Γ.

Now we wish to construct a function of three variables $v(x,y,t)$, $t \geqq 0$ such that if

$$v(x,y,t) = 0, \quad \text{then} \tag{1.4a}$$

$$z = u(x,y) = t. \tag{1.4b}$$

Of course any such function will not be unique. However, all of them will satisfy on the level set (1.4):

$$\frac{\partial}{\partial x} v(x,y,u(x,y)) = 0 = v_x + v_t u_x, \tag{1.5a}$$

$$\frac{\partial}{\partial y} v(x,y,u(x,y)) = 0 = v_y + v_t u_y. \tag{1.5b}$$

Thus, at least formally on this level set,

$$F\left(x,y,t,\frac{-v_x}{v_t},\frac{-v_y}{v_t}\right) = 0 \quad \text{on } \{v = 0\}. \tag{1.6}$$

We shall choose $v(x,y,0)$ to be a uniformly continuous function vanishing only for (x,y) on Γ, $v > 0$ in Ω, $v < 0$ in Ω^c, and v is a strictly monotone function of distance to Γ near Γ.

The noncharacteristic criterion of (0.3) guarantees that we may invert (1.6) locally for v_t near Γ. To devise a numerical algorithm based on time evolution we need the following assumption.

Assumption 1. An explicit inversion formula exists for (1.6) near Γ so that the formula

$$v_t + H(x, y, t, v_x, v_y) = 0 \tag{1.7}$$

with $H > 0$ near Γ implies (1.6) near $(x, y) \in \Gamma$, $t = 0$.

We note that H must be homogeneous of degree one in v_x, v_y.

Some geometric analysis of Assumption 1 is in order. We wish to solve (1.6) for v_t. By the implicit function theorem this is valid if (1.3) is valid near Γ, i.e.,

$$pF_p + qF_q \neq 0.$$

As pointed out by Evans, this says that the zero level set (in (p, q) space) of F is star shaped.

Another interesting observation of Evans concerns the link with steady multidimensional conservation laws. Equation (1.7) is an ordinary Hamilton–Jacobi equation, while (1.1) might be a conservation law admitting shock solutions. This may provide a connection between conservation laws and Hamilton–Jacobi equations in multidimensions.

We now have our analytical method for solving (1.1), kinks and all. (Numerical methods may be easily constructed using the results of [12], [13].)

We solve (1.7) on all of R^n (we really only need to do this near $\Gamma(t)$) with uniformly continuous initial data.

$$v(x, y, 0) = v_0(x, y), \tag{1.8a}$$

with

$$v_0(x, y) = 0 \quad \text{if and only if } (x, y) \in \Gamma, \tag{1.8b}$$

$$v_0(x, y) > 0 \quad \text{if and only if } (x, y) \in \Omega, \tag{1.8c}$$

$$v_0(x, y) < 0 \quad \text{if and only if } (x, y) \in \Omega^c. \tag{1.8d}$$

Then, to compute $u(x, y)$ for $(x, y) \in \Omega$ we calculate the level sets via the relation

$$v(x, y, t) = 0 \Leftrightarrow t = u(x, y). \tag{1.9}$$

This allows us to generate $u(x, y)$ by building it up through this level set formulation.

It is clear from the classical method of characteristics (see, e.g., [9]) that if Γ is a smooth curve and F and H are smooth functions near Γ, then the solution to (1.1) is locally (near Γ) the same as (1.9) for $t > 0$ and small. We now claim that the level set generated function (1.9) is a viscosity solution to

$$-1 + H(x, y, u, u_x, u_y) = 0 \tag{1.10}$$

if v is the viscosity solution to (1.7), (1.8).

We now recall the definition of viscosity solution; see, e.g., [3].

DEFINITION 1.1. Let $\psi \in C^2$ near $(\bar{x}, \bar{y}, \bar{t})$. Suppose $v - \psi$ has a local minimum (maximum) at $(\bar{x}, \bar{y}, \bar{t})$. Then v is a viscosity supersolution (subsolution) of (1.7) at this point if

$$\psi_t + H(x, y, v, \psi_x, \psi_y) \geqq 0 (\leqq 0) \text{at } (\bar{x}, \bar{y}, \bar{t}) \tag{1.11}$$

for all such ψ.

DEFINITION 1.2. v is a viscosity solution at this point if it is both a viscosity sub and supersolution.

The fact that $H > 0$ indicates that v is strictly decreasing in t near this point. In fact, if $v - \psi$ has a local maximum there, then

$$\psi_t < -H,$$

which means that ψ is strictly decreasing there.

We take ψ so that

$$v(x, y, t) \leqq \psi(x, y, t) \quad \text{near } (\bar{x}, \bar{y}, \bar{t}) \tag{1.12a}$$

and

$$v(\bar{x}, \bar{y}, \bar{t}) = \psi(\bar{x}, \bar{y}, \bar{t}). \tag{1.12b}$$

Then, for t satisfying $\bar{t} < t < \bar{t} + \varepsilon$ for $\varepsilon > 0$ small,

$$\begin{aligned} v(\bar{x}, \bar{y}, t) \; - \; & v(\bar{x}, \bar{y}, \bar{t}) \leqq \psi(\bar{x}, \bar{y}, t) - \psi(\bar{x}, \bar{y}, \bar{t}) \\ & = \psi_t(\bar{x}, \bar{y}, \bar{t})(t - \bar{t}) \quad (\text{where } \bar{t} < \bar{t} < t) \\ & < -\bar{H}(t - \bar{t}). \end{aligned} \tag{1.13}$$

Thus v is uniformly strictly decreasing for $t > \bar{t}$. This is true for all such $\bar{t}$ and t in any neighborhood in which $v(x, y, t)$ is a viscosity solution. Thus there exists an increasing uniformly continuous inverse function h such that

$$h(v(x, y, t)) = u(x, y) - t. \tag{1.14}$$

What remains to be shown is that u is a viscosity solution to

$$-1 + H(x, y, u, u_x, u_y) = 0. \tag{1.15}$$

This follows directly from [2, Thm. 5.2] under the hypothesis that H is independent of u. Thus we make that assumption for theoretical purposes only and conclude. (This key theorem of [2] was motivated by problems involving motion of level sets such as those described in [12].)

2. Examples. Given the shape-from-shading problem described above, with a remote generally nonoverhead light source whose direction cosines are $(\alpha, \beta, -\gamma)$ for $\gamma > 0$, with respect to the normal to the surface $z = u(x, y)$, we wish to solve

$$I(x, y)\sqrt{1 + u_x^2 + u_y^2} - \alpha u_x - \beta u_y - \gamma = 0 \tag{2.1a}$$

with

$$u = 0 \quad \text{on } \Gamma = \partial\Omega. \tag{2.1b}$$

The noncharacteristic criterion is satisfied if $\gamma\sqrt{1+p^2+q^2} \neq I$. Equation (1.6) becomes in this case

$$I(x,y)\sqrt{1+\frac{v_x^2}{v_t^2}+\frac{v_y^2}{v_t^2}}+\frac{\alpha v_x}{v_t}+\frac{\beta v_y}{v_t}-\gamma=0. \tag{2.2}$$

This can be inverted to obtain our version of (1.7):

$$v_t+\frac{(\mathrm{sign}(I^2-\gamma^2))\gamma(\alpha v_x+\beta v_y)+I\sqrt{v_x^2(-\beta^2+1-I^2)+v_y^2(-\alpha^2+1-I^2)+2\alpha\beta v_x v_y}}{|\gamma^2-I^2|}=0. \tag{2.3}$$

Note that if, for example, $\gamma = 1 \Leftrightarrow \alpha = \beta = 0$, the resulting overhead formula

$$v_t+\frac{I}{\sqrt{1-I^2}}\sqrt{v_x^2+v_y^2}=0 \tag{2.4}$$

gives difficulties near $I = 1$. This is inherent in the problem [11], [14]. In the general case the method has problems because of a possibly negative quantity under the square root sign, unless $I \leqq \gamma$. If this inequality fails we must require that the gradients satisfy

$$v_x^2(1-I^2-\beta^2)+v_y^2(1-I^2-\alpha^2)+2\alpha\beta v_x v_y \geqq 0 \tag{2.5a}$$

if

$$I>\gamma. \tag{2.5b}$$

This is, of course, required at the zero level set of $v(x,y,t)$ from (2.1a) using (2.3) and the related (1.5a, b), but it does present some numerical difficulties.

Example 2. Control-optimal cost determination:

$$-(\sin y)u_x+(\sin x)u_y+|u_y|-\tfrac{1}{2}\sin^2 y-(1-\cos x)=0, \tag{2.6a}$$

$$u=0 \quad \text{on } \Gamma, \text{ which is noncharacteristic, which means} \tag{2.6b}$$

$$\tfrac{1}{2}\sin^2 y+(1-\cos x)\neq 0 \quad \text{on } \Gamma. \tag{2.6c}$$

We are led to

$$v_t+\frac{|v_y|+(\sin x)v_y-(\sin y)v_x}{1/2\sin^2 y+(1-\cos x)}=0, \tag{2.7}$$

and the quantity $H(x,y,u_x,u_y)$ defined above is assumed to be strictly positive near Γ. (Of course, if it is strictly negative, everything works with a different initialization, merely reversing the inequalities in (1.8c, d).)

Acknowledgments. We would like to thank Professor A. M. Bruckstein for making us aware of his work in this area and Professor L. C. Evans for informing us of the existence of Theorem 5.2 in [2] and for some very constructive comments on a first draft of the paper.

THREE-DIMENSIONAL STEADY WATER WAVES GENERATED BY PARTIALLY LOCALIZED PRESSURE DISTURBANCES*

TIEN-YU SUN†

Abstract. The author constructs a class of three-dimensional exact steady water waves resulting from a partially localized pressure disturbance on the free surface. The term *partially localized* means that the pressure disturbances are periodic in the direction of the flow and are decaying rapidly in the transverse direction. The resulting exact steady flows exhibit symmetric doubly periodic wave patterns at infinity on either side of the pressure disturbance. The surface tension effect is taken into account, and this enables the author to use the Implicit Function Theorem in his construction.

Key words. water waves, free boundary problem, inviscid incompressible flows

AMS subject classifications. 35R35, 76B15

1. Introduction. We are concerned with steady wave motions of an infinite ocean of water, bounded above by a free surface and below by a flat bottom. The problem is to determine the velocity field and the free surface as an exact steady solution of the equations of water waves; see (2.1)–(2.5). Earlier work on exact steady water waves used complex formulation of the problem, and hence the results were limited to two-dimensional flows. See Wehausen and Laitone [7] for a detailed reference. Methods applicable to three-dimensional flows were considered by Beale [1] and Hewgill, Reeder, and Shinbrot [2]. In [5], with no pressure disturbance on the free surface, Reeder and Shinbrot proved the existence of symmetric doubly periodic solutions of (2.1)–(2.5), treating them as nonlinear interactions of two periodic plane waves. The surface tension effect is crucial in their construction. In contrast to the two-dimensional periodic waves, the existence of three-dimensional symmetric doubly periodic solutions becomes a small divisor problem when the surface tension effect is omitted. See Plotnikov [4].

In this paper, the method developed by Beale in the two-dimensional setting is applied to the three-dimensional problem. By applying a specific class of pressure disturbances on the free surface, we show that a class of three-dimensional exact steady solutions can be constructed as in [1]. It is well known that steady flows of water resulting from pressure disturbances on the free surface may have various wave patterns at infinity. For two-dimensional flows, it has been shown that the steady wave generated by a localized pressure disturbance has periodic wave patterns at infinity. When the surface tension effect is included, capillary waves appear upstream and gravity waves appear downstream. See Lighthill [3] and Whitham [8] for the linear theory and Beale [1] for the nonlinear result. The wave patterns at infinity remain a major concern in constructing three-dimensional steady water waves. Further complication arises from the fact that a three-dimensional linear steady wave may exhibit a complicated wave pattern like the wake after a ship. Again see Lighthill [3] and Whitham [8] for the linear theory of ship waves.

The main result of this paper can be stated as follows. We assume that the pressure disturbances applied on the free surface are partially localized and are small in amplitude. By partially localized, we mean the pressure disturbances are periodic

in the direction of the flow and are decaying rapidly in the transverse direction. We seek exact solutions which are small perturbations of the uniform horizontal flow with constant flow speed U_0 and constant depth h. When the flow speed U_0 and the period of the pressure disturbance are within a certain range, we show that there exists a two-parameter family of three-dimensional exact steady waves which exhibit symmetric doubly periodic wave patterns at infinity on either side of the pressure disturbance. The symmetric doubly periodic waves appearing are those constructed by Reeder and Shinbrot in [5]. The two parameters involved are a phase shift at infinity on each side of the partially localized pressure disturbance. If the pressure disturbance is even in the transverse direction, the resulting solutions can be regarded as steady waves traveling along a vertical wall. As in [5], the surface tension effect is important in our construction.

In §2, the problem is formulated in detail. In the problem, we assume that a partially localized pressure disturbance with wave number k_1 in the direction of flow is applied on the free surface. In §3, symmetric doubly periodic waves with flow speed U_0 and wave number k_1 in the direction of the flow are constructed. In comparison to [5], §3 provides an alternative construction of the symmetric doubly periodic waves which uses a different set of relevant parameters. In §4, exact steady flows resulting from a partially localized pressure disturbances on the free surface are constructed.

2. Preliminaries. We begin by describing the three-dimensional equations of water waves, with the surface tension effect taken into account on the free surface. Suppose a coordinate system (X, Y, Z) is chosen so that the X, Y directions are horizontal and the Z direction points upward. Let (U, V, W) and $Z = S(X, Y)$ be the unknown velocity field and free surface, respectively. Assuming the ocean has a flat bottom, the fluid occupies the domain $\{(X, Y, Z) : 0 < Z < S(X, Y)\}$. Now the equations of water waves can be stated as follows:

$$U_X + V_Y + W_Z = 0, \tag{2.1}$$

$$\begin{aligned} W_Y - V_Z &= 0, \\ U_Z - W_X &= 0, \\ V_X - U_Y &= 0, \end{aligned} \tag{2.2}$$

$$W = 0 \text{ on } Z = 0, \tag{2.3}$$

$$W - US_X - VS_Y = 0 \text{ on } Z = S(X, Y), \tag{2.4}$$

$$gS - \beta_0 D \cdot \frac{DS}{\sqrt{1 + |DS|^2}} + \frac{1}{2}(U^2 + V^2 + W^2) + \rho_0{}^{-1}(P - P_0) = C \quad \text{on } Z = S(X, Y), \tag{2.5}$$

where $D = (\partial_X, \partial_Y)$. Here P is the pressure on the free surface, P_0 is the atmospheric pressure, and ρ_0 is the constant density of the fluid. The parameters g and β_0 are the gravitational acceleration and the surface tension coefficient, respectively. Equations (2.1) and (2.2) are due to the incompressibility and irrotationality of the fluid; (2.3) and (2.4) are the streamline conditions on the bottom and top surfaces; (2.5) is Bernoulli's equation.

When $P = P_0$, the uniform horizontal flow with $S(X,Y) = h > 0$, $U = U_0$ and $V = W = 0$ is a trivial solution of the above boundary value problem. Hence, when $P - P_0$ is small, we seek exact solutions of (2.1) – (2.5) which are small perturbations of the uniform horizontal flow. On the free surface, we suppose $P - P_0 = \epsilon\, \rho_0\, ghp(X,Y)$, where

(2.6) p is periodic in X and is decaying rapidly in the Y direction.

The factor $\rho_0 gh$ is inserted for convenience. We can assume that the velocity (U, V, W) and the free surface S have the form

$$\begin{aligned} U &= U_0\,(1 + \epsilon\, u), \\ V &= \epsilon\, U_0\, v, \quad W = \epsilon\, U_0\, w, \\ S &= h\,(1 + \epsilon\, \eta). \end{aligned} \tag{2.7}$$

By stretching the vertical coordinate, we can transform the fluid domain to a fixed horizontal slab. We set

$$\begin{aligned} x &= X/h, \qquad y = Y/h, \\ z &= Z/h(1 + \epsilon\, \eta). \end{aligned}$$

Now the new fluid domain is $\{(x, y, z) : 0 < z < 1\}$; and (2.1)–(2.5) are transformed to

$$\{\,(1 + \epsilon\,\eta)\,u_x - \epsilon\, z\, \eta_x\, u_z\,\} + \{\,(1 + \epsilon\,\eta)\,v_y - \epsilon\, z\, \eta_y\, v_z\,\} + w_z = 0, \tag{2.8}$$

$$\begin{aligned} w_y - \sigma\, v_z - \epsilon\, z\, \sigma\, \eta_y\, w_z &= 0, \\ \sigma\, u_z - w_x + \epsilon\, z\, \sigma\, \eta_x\, w_z &= 0, \\ v_x - u_y - \epsilon\, z\, \sigma\, \eta_x\, v_z + \epsilon\, z\, \sigma\, \eta_y\, u_z &= 0, \end{aligned} \tag{2.9}$$

$$w = 0 \quad \text{on } z = 0, \tag{2.10}$$

$$w - \epsilon\, u\, \eta_x - \epsilon\, v\, \eta_y = \eta_x \quad \text{on } z = 1, \tag{2.11}$$

$$\eta - \beta \nabla \cdot \frac{\nabla \eta}{\sqrt{1 + \epsilon^2\, |\, \nabla \eta\, |^2}} + \gamma\, u + \frac{\epsilon}{2}\, \gamma\, (\, u^2 + v^2 + w^2\,) + p = 0 \quad \text{on } z = 1, \tag{2.12}$$

where $\nabla = (\,\partial_x,\, \partial_y\,)$ and $\sigma = (1 + \epsilon\, \eta)^{-1}$. The parameters

$$\beta = \beta_0\, /\, gh^2, \qquad \gamma = {U_0}^2\, /\, gh$$

are the dimensionless coefficient of surface tension and the Froude number, respectively.

The free surface is now removed at the price of introducing nonlinear terms into the interior equations. For ϵ sufficiently small, we can treat η as already known and solve (2.8)–(2.11) for (u, v, w). This enables us to regard (u, v, w) as a function of η, and we are led to solve (2.12) as a functional equation of η. Linear approximations can be found by solving (2.8)–(2.12) with $\epsilon = 0$. Based on the solvability of the linear problem, exact solutions are constructed using the implicit function theorem.

Now we introduce the function spaces that are used in the subsequent sections. Let $\ell_1 = \pi/k_1$ and

$$\begin{aligned}\Omega &= \{(x,y,z) : -\ell_1 < x < \ell_1,\, 0 < z < 1\},\\ \Gamma &= \{(x,y) : -\ell_1 < x < \ell_1\}.\end{aligned}$$

For a nonnegative integer s, let $H^s(\Omega)$ and $H^s(\Gamma)$ be the Sobolev spaces of functions that are periodic in x with period $2\ell_1$, with derivatives up to order s in L^2. A subscript e or o is used to indicate the subspaces of functions that are even or odd in x. In particular, for $v \in H^s_e(\Gamma)$, v can be written as

$$v = \sum_{m=0}^{+\infty} v_m(y) \cos mk_1x,$$

and its H^s norm is given by

$$|\, v\,|_s = \left\{ \sum_{m=0}^{+\infty} \int_{-\infty}^{+\infty} (1 + m^2{k_1}^2 + \xi^2)^s \,|\, \widehat{v_m}(\xi)\,|^2 \, d\xi \right\}^{1/2}.$$

Here $\widehat{\ }$ is the Fourier transform in y with ξ as the dual variable. When $s > 0$ is nonintegral, these spaces are defined according to the usual generalization. Given $\rho > 0$, ${}_\rho H^s(\Omega)$ and ${}_\rho H^s(\Gamma)$ represent subspaces of $H^s(\Omega)$ and $H^s(\Gamma)$ consisting of functions v which decay rapidly in the y direction such that $(\cosh \rho y) v \in H^s$, with norms $|\, v\,|_{s,\rho} = |\, (\cosh \rho y)\, v\,|_s$. Again, a subscript e or o is used to indicate subspaces of ${}_\rho H^s$ consisting of functions which are even or odd in x.

As for functions which are doubly periodic in x and y with periods $2\ell_1 = 2\pi/k_1$ and $2\ell_2 = 2\pi/k_2$, let

$$\begin{aligned}\widetilde{\Omega} &= \{(x,y,z) : -\ell_1 < x < \ell_1,\, -\ell_2 < y < \ell_2,\, 0 < z < 1\},\\ \widetilde{\Gamma} &= \{(x,y) : -\ell_1 < x < \ell_1,\, -\ell_2 < y < \ell_2\}.\end{aligned}$$

$H^s(\widetilde{\Omega})$ and $H^s(\widetilde{\Gamma})$ represent Sobolev spaces of functions doubly periodic in x and y, whose derivatives up to order s are in L^2, provided $s \geq 0$ is an integer, or the usual generalization when s is nonintegral but > 0. A subscript (e,e), (e,o), (o,e), or (o,o) is used to indicate subspaces with specific symmetries in x and y. For example, $H^s_{e,o}(\widetilde{\Omega})$ are the subspaces of $H^s(\widetilde{\Omega})$ consisting of functions that are even in x and odd in y.

3. Symmetric doubly periodic waves. The problem in the next section is to construct exact steady waves traveling with flow speed U_0 in the x direction, generated by a partially localized pressure disturbance with wave number k_1 in the same direction. In this section, we construct a family of exact doubly periodic solutions of (2.8)–(2.12) with $p = 0$. As we will see, these exact solutions are the symmetric doubly periodic waves that the solutions of our problem tend to as $y \to \pm\infty$. In [5], Reeder and Shinbrot proved the existence of symmetric doubly periodic water waves by regarding them as nonlinear interactions of incoming periodic plane waves with their reflections off a vertical wall. Incident wavelengths and incident angles within a specific set were used as the parameters of the problem. In this regard, the present section provides an alternative construction which uses a different set of relevant parameters.

In what follows, we will assume that the symmetric doubly periodic waves considered have flow speed U_0 and wave number k_1 in the x direction. We first consider (2.8)–(2.12) with $\epsilon = 0$ and assume the linear approximation considered has η given by

$$\eta(x,y) = \cos k_1 x \, \cos k_2 y. \tag{3.1}$$

Here the wave number k_2 is yet to be determined. With η given by (3.1), it is easy to solve (2.8)–(2.11) and obtain

$$\begin{aligned} u &= \frac{-k_1{}^2}{\mid k \mid} \frac{\cosh \mid k \mid z}{\sinh \mid k \mid} \cos k_1 x \, \cos k_2 y, \\ v &= \frac{k_1 k_2}{\mid k \mid} \frac{\cosh \mid k \mid z}{\sinh \mid k \mid} \sin k_1 x \, \sin k_2 y, \\ w &= -k_1 \frac{\sinh \mid k \mid z}{\sinh \mid k \mid} \sin k_1 x \, \cos k_2 y, \end{aligned} \tag{3.2}$$

where $k = (k_1, k_2)$ and $\mid k \mid = (k_1{}^2 + k_2{}^2)^{1/2}$. Consequently,

$$\eta - \beta \nabla^2 \eta + \gamma u = b(k_1, k_2) \cos k_1 x \, \cos k_2 y.$$

Here the function $b(\cdot,\cdot)$ is given by

$$b(\tau_1, \tau_2) = 1 + \beta \mid \tau \mid^2 - \gamma \frac{\tau_1{}^2}{\mid \tau \mid} \coth \mid \tau \mid, \tag{3.3}$$

where $\tau = (\tau_1, \tau_2)$ and $\mid \tau \mid = (\tau_1{}^2 + \tau_2{}^2)^{1/2}$. Hence, in order for η and (u, v, w) given by (3.1) and (3.2) to satisfy (2.12), we need wave number k_2 to satisfy $b(k_1, k_2) = 0$.

Now, for each fixed parameter $\beta > 0$, define

$$\gamma_0(\beta) = \min_{\xi \in \mathbf{R}} \frac{1 + \beta \xi^2}{\xi \coth \xi}.$$

It was pointed out in Lemma 2 in [1] that $\gamma_0(\beta) < 1$, provided $\beta < \frac{1}{3}$. Moreover, when $\beta < 0.02$ and the flow speed U_0 is within a range so that the Froude number γ satisfies $\gamma_0(\beta) < \gamma < 1$, the equation

$$1 + \beta \xi^2 - \gamma \xi \coth \xi = 0$$

has two simple positive roots, k_G, k_T, where $0 < k_G < k_T$. Note that, from (3.3), we have $b(k_G, 0) = b(k_T, 0) = 0$. The following lemma is used to determine the wave number k_2 in the transverse direction.

LEMMA 3.1. *Suppose β and γ are fixed parameters with $0 < \beta < 0.02$ and $\gamma_0(\beta) < \gamma < 1$. Let $b(\cdot,\cdot)$ be the function defined in (3.3). For $\tau_1 > 0$ so that $k_G < \tau_1 < k_T$, the equation $b(\tau_1, \xi) = 0$ has a unique positive root $\xi = k_2$ which is simple. When $0 < \tau_1 < k_G$ or $k_T < \tau_1$, the equation $b(\tau_1, \xi) = 0$ has no real roots.*

Proof. See Appendix. □

In this paper, we will always assume that the water is deep enough such that $\beta < 0.02$. When $\gamma_0(\beta) < \gamma < 1$ and $k_G < k_1 < k_T$, with wave number k_2 determined by solving $b(k_1,\xi) = 0$, η and (u,v,w) given by (3.1) and (3.2) provide us a linear approximation of symmetric doubly periodic waves.

The wave number k_2 determined by the flow speed U_0 and wave number k_1 provide us a first approximation of the wave number in the transverse direction. For fixed U_0 and k_1, an exact solution of (2.8)–(2.12) based on linear approximation (3.1), (3.2) should have wave number in the y direction fairly close to k_2 when ϵ is sufficiently small. We can assume that the exact wave number in the y direction is $\theta(\epsilon)k_2$. Here we suppose $\theta = \theta(\epsilon)$ is close to 1 for ϵ sufficiently small. Now we stretch the y coordinate axis by setting $\tilde{y} = \theta y$ and replace the (x, y, z) coordinate system by $(x, \tilde{y}, z)$ instead. As a result, (2.8)–(2.12) are transformed to

$$\{(1+\epsilon\eta)\,u_x - \epsilon\, z\,\eta_x\, u_z\} + \theta\,\{(1+\epsilon\eta)\,v_{\tilde{y}} - \epsilon\, z\,\eta_{\tilde{y}}\, v_z\} + w_z = 0, \tag{3.4}$$

$$\begin{aligned} \theta\, w_{\tilde{y}} - \sigma\, v_z - \epsilon\,\theta\, z\,\sigma\,\eta_{\tilde{y}}\, w_z &= 0,\\ \sigma\, u_z - w_z + \epsilon\, z\,\sigma\,\eta_x\, w_z &= 0,\\ v_x - \theta\, u_{\tilde{y}} - \epsilon\, z\,\sigma\,\eta_x\, v_z + \epsilon\,\theta\, z\,\sigma\eta_{\tilde{y}}\, u_z &= 0, \end{aligned} \tag{3.5}$$

$$w = 0 \quad \text{on } z = 0, \tag{3.6}$$

$$w - \epsilon\, u\,\eta_x - \epsilon\,\theta\, v\,\eta_{\tilde{y}} = \eta_x \quad \text{on } z = 1, \tag{3.7}$$

$$\eta - \beta\tilde{\nabla}\cdot\frac{\tilde{\nabla}\eta}{[1+\epsilon^2\,|\,\tilde{\nabla}\eta\,|^2]^{1/2}} + \gamma\, u + \frac{\epsilon}{2}\,(u^2+v^2+w^2) = 0 \quad \text{on } z = 1. \tag{3.8}$$

Here $\tilde{\nabla} = (\,\partial_x,\ \theta\,\partial_{\tilde{y}}\,)$ and $\sigma = (1+\epsilon\eta)^{-1}$. Thus, by introducing the stretching factor θ as an unknown, the doubly periodic waves sought now have a fixed period $2\ell_2 = 2\pi/k_2$ in the $\tilde{y}$ direction. In comparison to the construction in [5], the symmetric doubly periodic waves considered there have both of the periods determined by the incident wavelength and the incident angle. Hence no stretching of the coordinate axis was needed to determine the domain occupied by the symmetric doubly periodic waves. However, the Froude number had to be determined as part of the solution.

A careful examination of (3.4)–(3.8) suggests that we can assume the exact solution has the same symmetries in x and $\tilde{y}$ as in (3.1) and (3.2). In particular, we seek η and (u,v,w) so that η, u are even in x and v, w are odd in x. An immediate consequence is that $V = \epsilon\, U_0\, v$ is identically zero along $x = 0$. Generally speaking, we cannot expect (2.1)–(2.5) to have a unique exact doubly periodic solution unless some kind of normalization is imposed. For this reason, we suppose

$$\int_0^{S(0,Y)} U(0,Y,Z)\,dZ = U_0\, h. \tag{3.9}$$

In terms of the new coordinates, (3.9) can be written as

$$(1+\epsilon\eta)\int_0^1 u\,dz + \eta = 0 \quad \text{on } x = 0. \tag{3.10}$$

Integrating (3.10) with respect to $\tilde{y}$, we obtain

$$\int_{-\ell_2}^{\ell_2}\int_0^1 (1+\epsilon\eta)\,u\,dz d\tilde{y} = -\int_{-\ell_2}^{\ell_2} \eta\, d\tilde{y} \quad \text{on } x = 0. \tag{3.11}$$

In what follows, we will solve (3.4)–(3.8) with (3.11) as the normalization. When $\epsilon = 0$, this modified system has $\theta = 1$, and η, (u, v, w) given by (3.1) and (3.2) as solution.

We start the construction by finding (u, v, w) that satisfies (3.4)–(3.7) and (3.11) for prescribed η, θ, and ϵ. We suppose that $\eta \in H^{s+3/2}_{e,e}(\tilde{\Gamma})$, where s is an integer $> \frac{3}{2}$. Let

$$Y = \{\, (u, v, w) \in H^{s+1}_{e,e}(\tilde{\Omega}) \times H^{s+1}_{o,o}(\tilde{\Omega}) \times H^{s+1}_{o,e}(\tilde{\Omega}) : w(x, \tilde{y}, 0) = 0 \,\}$$

and

$$Z = H^{s}_{o,e}(\tilde{\Omega}) \times H^{s}_{o,o}(\tilde{\Omega}) \times H^{s}_{e,e}(\tilde{\Omega}) \times H^{s}_{e,o}(\tilde{\Omega}) \times H^{s+1/2}_{o,e}(\tilde{\Gamma}) \times \mathbf{R}.$$

We can rewrite (3.4), (3.5), (3.7), and (3.11) as

$$L(\epsilon\,\eta, \theta)(u, v, w) = \left(0, \vec{0}, \eta_x, -\int_{-\ell_2}^{\ell_2} \eta(0, \tilde{y})\, d\tilde{y} \right), \tag{3.12}$$

where $L(\epsilon\,\eta, \theta)$ is a bounded linear operator from Y to Z, depending smoothly on η, θ, and ϵ. To examine the range of $L(\epsilon\,\eta, \theta)$, suppose $\vec{g} = (g_1, g_2, g_3)$ and $(f, \vec{g}, q, c) \in Z$ such that

$$L(\epsilon\,\eta, \theta)(u, v, w) = (f, \vec{g}, q, c) \tag{3.13}$$

for some (u, v, w) in Y. Note that, from (3.13), we see that $\vec{g}$ is a curl in the (X, Y, Z) coordinates and thus its divergence with respect to (X, Y, Z) has to be zero. In terms of the new coordinates, $\vec{g}$ satisfies

$$\{\, (1 + \epsilon\,\eta)\, g_{1,x} - \epsilon\, z\, \eta_x\, g_{1,z} \,\} + \theta \{\, (1 + \epsilon\,\eta)\, g_{2,\tilde{y}} - \epsilon\, z\, \eta_{\tilde{y}}\, g_{2,z} \,\} + g_{3,z} = 0. \tag{3.14}$$

This indicates that the range of $L(\epsilon\,\eta, \theta)$ is a subspace of Z which varies with η, θ, and ϵ. For each $\vec{g}$, define $\vec{\tilde{g}} = (\tilde{g}_1, \tilde{g}_2, \tilde{g}_3)$ by

$$\begin{gathered} \tilde{g}_1 = (1 + \epsilon\,\eta)\, g_1, \qquad \tilde{g}_2 = \theta\, (1 + \epsilon\,\eta)\, g_2, \\ \tilde{g}_3 = g_3 - \epsilon\, z\, \eta_x\, g_1 - \epsilon\, \theta\, z\, \eta_{\tilde{y}}\, g_2, \end{gathered} \tag{3.15}$$

and let $J(\epsilon\,\eta, \theta) : Z \to Z$ be the linear operator which maps $(f, \vec{g}, q, c)$ to $(f, \vec{\tilde{g}}, q, c)$. Let Z_0 be the subspace of Z consisting of $(f, \vec{g}, q, c)$ such that

$$g_{1,x} + g_{2,\tilde{y}} + g_{3,z} = 0. \tag{3.16}$$

Now if $(f, \vec{g}, q, c) \in Z$ is in the range of $L(\epsilon\,\eta, \theta)$, then (3.14) implies that $\vec{\tilde{g}}$ defined by (3.15) satisfies

$$\tilde{g}_{1,x} + \tilde{g}_{2,\tilde{y}} + \tilde{g}_{3,z} = 0.$$

That is to say, $J(\epsilon\,\eta, \theta)$ maps the range of $L(\epsilon\,\eta, \theta)$ into Z_0, which is independent of η, θ, and ϵ. It is clear that operator J is bounded and is depending smoothly on η, θ, and ϵ. Moreover, $J(0, 1)$ is the identity operator. Hence, for η in a bounded set in $H^{s+3/2}_{e,e}(\tilde{\Gamma})$ and θ close to 1, $J(\epsilon\,\eta, \theta)$ is invertible when ϵ is sufficiently small. For this reason, since

$$J(\epsilon\,\eta, \theta) \left(0,\, \vec{0},\, \eta_x,\, -\int_{-\ell_2}^{\ell_2} \eta(0, \tilde{y})\, d\tilde{y} \right) = \left(0,\, \vec{0},\, \eta_x,\, -\int_{-\ell_2}^{\ell_2} \eta(0, \tilde{y})\, d\tilde{y} \right),$$

(3.12) and

$$(JL)(\epsilon\eta,\theta)(u,v,w) = \left(0,\ \vec{0},\ \eta_x,\ -\int_{-\ell_2}^{\ell_2} \eta(0,\tilde{y})\,d\tilde{y}\right)$$

share the same solution. In the following lemma, we show that $JL(0,1) = L(0,1)$, as an operator from Y to Z_0, is invertible.

LEMMA 3.2. *Given $(f,\vec{g},q,c) \in Z_0$, there is a unique solution in Y of the problem*

$$u_x + v_{\tilde{y}} + w_z = f, \tag{3.17}$$

$$w_{\tilde{y}} - v_z = g_1, \tag{3.18}$$

$$u_z - w_x = g_2, \tag{3.19}$$

$$v_x - u_{\tilde{y}} = g_3, \tag{3.20}$$

$$w = q \quad on\ z = 1, \tag{3.21}$$

$$w = 0 \quad on\ z = 0, \tag{3.22}$$

$$\int_{-\ell_2}^{\ell_2}\int_0^1 u(0,\tilde{y},z)\,dz d\tilde{y} = c. \tag{3.23}$$

The solution (u,v,w) satisfies

$$|\,u\,|_{s+1} + |\,v\,|_{s+1} + |\,w\,|_{s+1} \le C\left(|\,f\,|_s + \sum_{i=1}^{3} |\,g_i\,|_s + |\,q\,|_{s+1/2} + |\,c\,|\right). \tag{3.24}$$

Since the proof is similar to that of Lemma 5 in [1], we will summarize it as follows. First, we consider the case with $q = 0$. Assume that the solution (u,v,w) is known for the time being. Let

$$l_n(z) = \sqrt{2}\cos n\pi z, \qquad m_n(z) = \sqrt{2}\sin n\pi z$$

for $n \ge 1$, and let $l_0(z) = 1$. To expand u, v, and w in eigenfunctions in z, we define

$$w_n(x,\tilde{y}) = \int_0^1 w(x,\tilde{y},z)\,m_n(z)\,dz,$$
$$g_{in}(x,\tilde{y}) = \int_0^1 g_i(x,\tilde{y},z)\,m_n(z)\,dz \quad \text{for } i = 1,2,$$

and define u_n, v_n, f_n, and g_{3n} as similar products with l_n. Multiply (3.17) and (3.20) by $l_n(z)$, (3.18) and (3.19) by $m_n(z)$, and integrate with respect to z. We obtain

$$u_{n,x} + v_{n,\tilde{y}} + n\pi\, w_n = f_n, \qquad n \ge 0, \tag{3.25}$$

$$w_{n,\tilde{y}} + n\pi\, v_n = g_{1n}, \qquad n \geq 1, \tag{3.26}$$

$$-\, n\pi\, u_n - w_{n,x} = g_{2n}, \qquad n \geq 1, \tag{3.27}$$

$$v_{n,x} - u_{n,\tilde{y}} = g_{3n}, \qquad n \geq 0. \tag{3.28}$$

Since $(f, \vec{g}, q, c)$ is in Z_0, $\vec{g}$ satisfies (3.16). Multiplying (3.16) by m_n and integrating with respect to z, we have

$$g_{1n,x} + g_{2n,\tilde{y}} - n\pi\, g_{3n} = 0 \quad \text{for } n \geq 1.$$

This implies, for $n \geq 1$, that (3.28) is automatically satisfied when (3.26) and (3.27) hold. Hence, for $n \geq 1$, u_n, v_n, and w_n can be determined by solving (3.25)–(3.27) by expanding in Fourier series in x and $\tilde{y}$. Similarly, we can determine u_0 and v_0 by solving (3.25), (3.28) with normalization (3.23). Now define

$$u(x, \tilde{y}, z) = \sum_{n=0}^{+\infty} u_n(x, \tilde{y})\, l_n(z),$$

$$v(x, \tilde{y}, z) = \sum_{n=0}^{+\infty} v_n(x, \tilde{y})\, l_n(z),$$

$$w(x, \tilde{y}, z) = \sum_{n=1}^{+\infty} w_n(x, \tilde{y})\, m_n(z).$$

It can be shown as in Lemma 5 in [1] that (u, v, w) thus defined solves (3.17)–(3.23) and satisfies estimate (3.24) with $q = 0$. Finally, it remains to remove the assumption $q = 0$. Given $(f, \vec{g}, q, c) \in Z_0$, we can find $\tilde{q} \in H^{s+1}_{o,e}(\tilde{\Omega})$ so that $\tilde{q} = q$ on $z = 1$, $\tilde{q} = 0$ on $z = 0$, and

$$|\, \tilde{q}\, |_{s+1} \leq C\, |\, q\, |_{s+1/2}.$$

Now if we set $w = \tilde{w} + \tilde{q}$, then the problem of solving for $(u, v, \tilde{w})$ brings us back to the previous case and we are done.

Since both J and L depend smoothly on η, θ, and ϵ, it follows from Lemma 3.2 that for η in a bounded set in $H^{s+1/2}_{e,e}(\tilde{\Gamma})$ and θ close to 1, $JL(\epsilon\eta, \theta)$ as an operator from Y to Z_0 is invertible for ϵ sufficiently small. Consequently, the solution of (3.12) is given by

$$(u, v, w) = (\, JL(\epsilon\,\eta, \theta)\,)^{-1} \left(0, \vec{0},\, \eta_x,\, -\int_{-\ell_2}^{\ell_2} \eta(0, \tilde{y})\, d\tilde{y}\right) \tag{3.29}$$

and is depending smoothly on η, θ, and ϵ.

Now because of (3.29), we are led to solve (3.8) as a nonlinear equation for η and θ. For ϵ close to zero, we seek η of the form

$$\eta = \cos k_1 x\, \cos k_2 \tilde{y} + \tilde{\eta} \tag{3.30}$$

in which $\tilde{\eta}$ is even in x and $\tilde{y}$, such that

$$\iint_{\widetilde{\Gamma}} \tilde{\eta}(x,\tilde{y}) \cos k_1 x \cos k_2 \tilde{y}\, dx d\tilde{y} = 0. \tag{3.31}$$

Let $X^{s+3/2}(\widetilde{\Gamma})$ be the subspace of $H^{s+3/2}_{e,e}(\widetilde{\Gamma})$ consistingof $\tilde{\eta}$ that satisfies (3.31). We can write Bernoulli's equation (3.8) as

$$B(\tilde{\eta}, \theta, \epsilon) = 0, \tag{3.32}$$

where B is a smooth function from an open subset of $X^{s+3/2}(\widetilde{\Gamma}) \times \mathbf{R}^2$ to $H^{s-1/2}_{e,e}(\widetilde{\Gamma})$. When $\epsilon = 0$, (3.32) has a trivial solution $\tilde{\eta} = 0$, $\theta = 1$. In what follows, we will assume that the wave numbers k_1 and k_2 satisfy the condition

$$b(mk_1, nk_2) \neq 0 \quad \text{for all } (m,n) \quad \text{except for } (m,n) = (1,1). \tag{3.33}$$

Here $b(\cdot,\cdot)$ is the function defined in (3.3). Based on (3.33), we will show that the Fréchet derivative

$$B_{(\tilde{\eta},\theta)}(0,1,0) : X^{s+3/2}(\widetilde{\Gamma}) \times \mathbf{R} \longrightarrow H^{s-1/2}_{e,e}(\widetilde{\Gamma})$$

has a bounded inverse.

In §4, we will limit the range of wave number k_1 to

$$\max\left(k_G, \frac{k_T}{2}\right) < k_1 < k_T.$$

When $\beta < 0.02$ and the Froude number is within the range $\gamma_0(\beta) < \gamma < 1$, Lemma 3.1 implies that equation $b(k_1, \xi) = 0$ has a unique positive root $\xi = k_2$ which is simple. For $m \neq 1$, mk_1 lies outside the range $[k_G, k_T]$ and so equation $b(mk_1, \xi) = 0$ has no real roots. As a result, condition (3.33) is met. For a detailed discussion of the set of excluded parameters, see §7 in [5].

When $\epsilon = 0$,

$$B(\tilde{\eta}, \theta, 0) = \eta - \beta \widetilde{\nabla}^2 \eta + \gamma u, \tag{3.34}$$

where $\widetilde{\nabla} = (\partial_x, \theta\, \partial_{\tilde{y}})$ and η is given by (3.30). (u,v,w) is a function of $\tilde{\eta}$ and θ, determined by

$$u_x + \theta\, v_{\tilde{y}} + w_z = 0, \tag{3.35}$$

$$\begin{aligned} \theta\, w_{\tilde{y}} - v_z &= 0, \\ u_z - w_x &= 0, \\ v_x - \theta\, u_{\tilde{y}} &= 0, \end{aligned} \tag{3.36}$$

$$w = 0 \quad \text{on } z = 0, \tag{3.37}$$

$$w = \eta_x \quad \text{on } z = 1, \tag{3.38}$$

$$\int_{-\ell_2}^{\ell_2} \int_0^1 u\, dz d\tilde{y} = -\int_{-\ell_2}^{\ell_2} \eta\, d\tilde{y} \quad \text{on } x = 0. \tag{3.39}$$

Given any $\tilde{\eta} \in X^{s+3/2}(\tilde{\Gamma})$, because of (3.31), we can express $\tilde{\eta}$ as

$$\tilde{\eta} = \sum_{(m,n)\neq(1,1)} a_{mn} \cos mk_1 x \cos nk_2 \tilde{y}.$$

As a result, η given by (3.30) has Fourier expansion

$$\eta = \sum_{m,n=0}^{+\infty} a_{mn} \cos mk_1 x \cos nk_2 \tilde{y},$$

where $a_{11} = 1$. By solving (3.35)–(3.39), we obtain

$$(3.40) \qquad u = -a_{00} - \sum_{(m,n)\neq(0,0)} a_{mn} \frac{m^2 {k_1}^2}{\psi_{mn}} \frac{\cosh \psi_{mn} z}{\sinh \psi_{mn}} \cos mk_1 x \cos nk_2 \tilde{y},$$

where $\psi_{mn} = (m^2 {k_1}^2 + \theta^2 n^2 {k_2}^2)^{1/2}$. It follows that

$$(3.41) \quad B(\tilde{\eta}, \theta, 0) = (1-\gamma)\, a_{00} - \sum_{(m,n)\neq(0,0)} b(mk_1, \theta nk_2)\, a_{mn} \cos mk_1 x \cos nk_2 \tilde{y}.$$

Note that the derivative $B_{(\tilde{\eta},\theta)}(0,1,0)$ is given by

$$(\tilde{\eta}, \tilde{\theta}) \longmapsto B(\tilde{\eta}, 1, 0) + \tilde{\theta}\, B_\theta(0,1,0).$$

When $\theta = 1$, the coefficient $b(k_1, k_2)$ in (3.41) is equal to zero. This implies that $B(\cdot, 1, 0)$ is a linear operator from $X^{s+3/2}(\tilde{\Gamma})$ to $X^{s-1/2}(\tilde{\Gamma})$. From (3.3), it is easy to see that, when $\mid \tau \mid$ is sufficiently large, coth $\mid \tau \mid$ is close to 1 and the term $\beta \mid \tau \mid^2$ becomes dominant in $b(\tau_1, \tau_2)$. Thus, for m and n sufficiently large, we have

$$\mid b(mk_1, nk_2) \mid \geq C\, (m^2 {k_1}^2 + n^2 {k_2}^2).$$

As a result, $B(\cdot, 1, 0)$ has a bounded inverse from $X^{s-1/2}(\tilde{\Gamma})$ to $X^{s+3/2}(\tilde{\Gamma})$.

Next we compute the derivative $B_\theta(0,1,0)$. When $\tilde{\eta} = 0$, (3.40) gives

$$u = -\frac{{k_1}^2}{\psi_{11}} \coth \psi_{11} \cos k_1 x \cos k_2 \tilde{y} \quad \text{on } z = 1,$$

where $\psi_{11} = ({k_1}^2 + \theta^2 {k_2}^2)^{1/2}$. Note that, given a smooth function f, we have

$$\{ \partial_\theta f(\theta k_2) \}_{\theta=1} = \{ \xi \partial_\xi f(\xi) \}_{\xi=k_2}.$$

This simple fact leads to

$$u_\theta = \left\{ \xi \partial_\xi \left(\frac{-{k_1}^2 \coth \sqrt{{k_1}^2 + \xi^2}}{\sqrt{{k_1}^2 + \xi^2}} \right) \right\}_{\xi = k_2} \cos k_1 x \cos k_2 \tilde{y}.$$

Hence, from (3.34), we obtain

$$\begin{aligned} B_\theta(0,1,0) &= 2\beta {k_2}^2 \cos k_1 x \cos k_2 \tilde{y} + \gamma u_\theta \\ &= k_2 \{ \partial_\xi b(k_1, \xi) \}_{\xi = k_2} \cos k_1 x \cos k_2 \tilde{y}. \end{aligned}$$

From Lemma 3.1, since k_2 is a simple root of $b(k_1, \xi) = 0$, $\{\partial_\xi\, b(k_1, \xi)\}_{\xi=k_2} \neq 0$. Thus the derivative $B_\theta(0, 1, 0)$ is nonzero.

Now let $f \in H^{s-1/2}_{e,e}(\widetilde{\Gamma})$ be arbitrary and consider the equation

$$B(\tilde{\eta}, 1, 0) + \tilde{\theta}\, B_\theta(0, 1, 0) = f.$$

Since the operator $B(\cdot, 1, 0)$ ranges in $X^{s-1/2}(\widetilde{\Gamma})$ and $B_\theta(0, 1, 0)$ is orthogonal to $X^{s-1/2}(\widetilde{\Gamma})$ in the L^2 sense, $\tilde{\theta}$ should be chosen so that

$$f - \tilde{\theta}\, B_\theta(0, 1, 0) \in X^{s-1/2}(\widetilde{\Gamma}).$$

Then

$$B(\tilde{\eta}, 1, 0) = f - \tilde{\theta}\, B_\theta(0, 1, 0)$$

has a unique solution $\tilde{\eta}$ in $X^{s+3/2}(\widetilde{\Gamma})$. It is easy to see that the Fréchet derivative $B_{(\tilde{\eta},\theta)}(0, 1, 0)$ is bijective. Thus, by the open mapping theorem, $B_{(\tilde{\eta},\theta)}(0, 1, 0)$ has a bounded inverse.

Now by the implicit function theorem, for each ϵ sufficiently close to zero, (3.32) has a solution $(\tilde{\eta}(\epsilon), \theta(\epsilon))$ near $(0, 1)$ in $X^{s+3/2}(\widetilde{\Gamma}) \times \mathbf{R}$, depending smoothly on ϵ. By (3.29) and (3.30), $(\tilde{\eta}(\epsilon), \theta(\epsilon))$ thus obtained provides us with an exact doubly periodic solution of (3.4)–(3.8) and (3.11).

Finally, we point out that given any constant a in a bounded set, if η, θ, and (u, v, w) satisfy (3.4)–(3.8) with ϵ replaced by $a\epsilon$, then $a\eta(a\epsilon)$, $\theta(a\epsilon)$, and $au(a\epsilon)$, $av(a\epsilon)$, $aw(a\epsilon)$ also satisfy the same problem. Moreover, if we translate the $(x, \tilde{y})$ coordinates by $(0, \delta)$, then

$$\begin{aligned} &a\eta(x, \tilde{y} - \delta; a\epsilon), \quad \theta(a\epsilon), \quad au(x, \tilde{y} - \delta, z; a\epsilon), \\ &av(x, \tilde{y} - \delta, z; a\epsilon), \qquad aw(x, \tilde{y} - \delta, z; a\epsilon) \end{aligned} \tag{3.42}$$

still satisfy (3.4)–(3.8) with ϵ replaced by $a\epsilon$. By construction, when $\epsilon = 0$, we have

$$a\eta(x, \tilde{y} - \delta; 0) = a \cos k_1 x \cos k_2(\tilde{y} - \delta). \tag{3.43}$$

Thus, by treating the constants a and δ as two free parameters, we obtain a two-parameter family of doubly periodic solutions. The constants a and δ can be interpreted as amplitude and phase shift, respectively.

4. Flows due to a partially localized pressure disturbance.

We now turn to the main issue of this paper. Suppose that, in (2.12), we are given a pressure disturbance p which is periodic in x with period $2\ell_1 = 2\pi / k_1$ and is in ${}_\rho H^{s-1/2}_e(\Gamma)$ for some integer $s > \frac{3}{2}$. The problem is to solve (2.8)–(2.12) for η and (u, v, w), provided ϵ is sufficiently small. Note that, by definition of the ${}_\rho H^s$ spaces, the pressure disturbance p is partially localized in the sense that p and its derivatives are decaying rapidly as $y \longrightarrow \pm\infty$. In the following discussion, we will assume that the wave number k_1 is in the range

$$\max\left(k_G, \frac{k_T}{2}\right) < k_1 < k_T. \tag{4.1}$$

Under this circumstance, when the surface tension effect is small and the flow speed U_0 is within a certain range, we are able to use the symmetric doubly periodic waves discussed in §3 to construct solutions of (2.8)–(2.12).

4.1. A linearized problem. We first construct linear approximations by solving (2.8)–(2.12) with $\epsilon = 0$. Consider

$$u_x + v_y + w_z = 0, \tag{4.2}$$

$$\begin{aligned} w_y - v_z &= 0, \\ u_z - w_x &= 0, \\ v_x - u_y &= 0, \end{aligned} \tag{4.3}$$

$$w = 0 \quad \text{on } z = 0, \tag{4.4}$$

$$w = \eta_x \quad \text{on } z = 1, \tag{4.5}$$

$$\eta - \beta \nabla^2 \eta + \gamma u + p = 0 \quad \text{on } z = 1, \tag{4.6}$$

where $\nabla = (\partial_x, \partial_y)$. Assume that, in (4.6), the given pressure disturbance p has the form

$$p = \sum_{m=0}^{+\infty} p_m(y) \cos mk_1 x.$$

We seek a solution of (4.2)–(4.6) which has η even in x. Let

$$\eta = \sum_{m=0}^{+\infty} \eta_m(y) \cos mk_1 x.$$

By applying Fourier series in the x direction and Fourier transform in the y direction, we can solve (4.2)–(4.5) and regard (u, v, w) as a function of η. We obtain

$$\widehat{u}(x, \xi, z) = \sum_{m=1}^{+\infty} -\frac{m^2 {k_1}^2}{\psi_m(\xi)} \widehat{\eta_m}(\xi) \frac{\cosh \psi_m(\xi) z}{\sinh \psi_m(\xi)} \cos mk_1 x,$$

where $\psi_m(\xi) = (m^2 {k_1}^2 + \xi^2)^{1/2}$, $\widehat{}$ is the Fourier transform in y with dual variable ξ. It remains to solve (4.6) as a linear equation for η. From (4.6), by taking Fourier transform with respect to y, we see that η solves (4.6) if

$$\sum_{m=0}^{+\infty} \{b(mk_1, \xi)\, \widehat{\eta_m}(\xi) + \widehat{p_m}(\xi)\} \cos mk_1 x = 0.$$

Here $b(\cdot, \cdot)$ is the function given in (3.3). Hence we are led to solve

$$b(mk_1, \xi)\, \widehat{\eta_m}(\xi) + \widehat{p_m}(\xi) = 0 \tag{4.7}$$

for each integer $m \geq 0$.

We now discuss properties of the function $b(\cdot, \cdot)$ in more detail.

LEMMA 4.1. *Let ρ be any positive constant $< k_1$. For each integer $m \geq 0$, the function*

$$b(mk_1, z) = 1 + \beta\, (m^2 {k_1}^2 + z^2) - \gamma \frac{m^2 {k_1}^2}{\sqrt{m^2 {k_1}^2 + z^2}} \coth \sqrt{m^2 {k_1}^2 + z^2}$$

is an analytic function in z over the strip $\{z : |\operatorname{Im} z| \leq \rho\}$. Furthermore,

$$|b(mk_1, z)| \geq c\,(m^2{k_1}^2 + |\operatorname{Re} z|^2)$$

when m or $\operatorname{Re} z$ is sufficiently large. Here c is a positive constant independent of m.

Note that, for any complex number ω,

$$|\coth \omega|^2 = \frac{\sinh^2 \operatorname{Re}\omega + \cos^2 \operatorname{Im}\omega}{\sinh^2 \operatorname{Re}\omega + \sin^2 \operatorname{Im}\omega}.$$

It is clear that $|\coth\sqrt{m^2{k_1}^2 + z^2}|$ is close to 1 provided m or $\operatorname{Re} z$ is sufficiently large. Based on this observation, the proof of Lemma 4.1 is straightforward and is thus omitted. The following corollary concerns roots of analytic functions $b(mk_1, z)$.

COROLLARY 4.2. *Suppose parameters β and γ are the same as in Lemma 3.1. Given $k_1 > 0$ such that*

$$\max\left(k_G, \frac{k_T}{2}\right) < k_1 < k_T,$$

there exists a positive number $\rho_* < k_1$ such that

(i) *for each nonnegative integer $m \neq 1$, $b(mk_1, z)$ is nonzero for all z in the strip $|\operatorname{Im} z| \leq \rho_*$;*

(ii) *$b(k_1, z)$ has two roots in the strip $|\operatorname{Im} z| \leq \rho_*$, all real and simple.*

Proof. See Appendix. □

The following lemma is used to solve (4.7).

LEMMA 4.3. *Suppose b is an analytic function from a strip $\{\xi + i\phi : |\phi| \leq \rho\}$ to $\mathbf{C}$ satisfying $|b(\xi + i\phi)| \geq c_0 |\xi|^m$ for ξ sufficiently large, where $m \geq 0$, $\rho > 0$. Suppose that b has only a finite number of roots, all real and simple. Given $f \in {}_\rho H^s(\mathbf{R})$, $s \geq 0$ with the property that $\hat{f}(\xi) = 0$ at each ξ for which $b(\xi) = 0$, we define η as the inverse transform of $\hat{f}(\xi)/b(\xi)$. Then η is the unique function in $L^1(\mathbf{R})$ satisfying $b\hat{\eta} = \hat{f}$; $\eta \in {}_\rho H^{s+m}(\mathbf{R})$ and*

$$|\eta|_{s+m,\rho} \leq C|f|_{s,\rho}.$$

Here the constant C depends on b but not on f.

Proof. See Lemma 3 in [1]. □

In what follows, beside (4.1), we will also assume that $p \in {}_\rho H_e^{s-1/2}(\Gamma)$ where $\rho < \rho_*$. Here ρ_* is the constant that appears in Corollary 4.2. Under these assumptions, with $0 < \beta < 0.02$ and $\gamma_0(\beta) < \gamma < 1$, we are able to show that (4.2)–(4.6) have a two-parameter family of solutions which exhibit doubly periodic wave patterns at infinity. See (4.17), (4.18) below.

Since $p \in {}_\rho H_e^{s-1/2}(\Gamma)$, in (4.7), $p_m(y)$ is in ${}_\rho H^{s-1/2}(\mathbf{R})$ for each $m \geq 0$. Now, for each nonnegative integer $m \neq 1$, Corollary 4.2 implies that $b(mk_1, z) \neq 0$ for all z in the strip $|\operatorname{Im} z| \leq \rho$. Thus, by Lemmas 4.1 and 4.3, there exists a $\eta_m(y)$ in ${}_\rho H^{s+3/2}(\mathbf{R})$ that satisfies (4.7). As for $m = 1$, Corollary 4.2 shows that $b(k_1, z) = 0$ has only two roots $\xi = \pm k_2$, all real and simple. We will show that, when $m = 1$, (4.7) has a solution η_1 of the form

$$\eta_1 = \eta_1^+ + \eta_1^0 + \eta_1^- \tag{4.8}$$

in which $\eta_1^\pm(y) = a^\pm \zeta^\pm(y) \cos k_2(y - \delta^\pm)$ and $\eta_1^0 \in {}_\rho H^{s+3/2}(\mathbf{R})$. Here $\zeta^\pm(y)$ are two C^∞ cut-off functions such that $0 \leq \zeta^+ \leq 1$, $\zeta^+(y) = 1$ for $y \geq 1$, $\zeta^+(y) = 0$ for $y \leq -1$, and $\zeta^-(y) = 1 - \zeta^+(y)$.

From distribution theory, we know that the Fourier transforms of $\zeta^{\pm}$ are

$$\widehat{\zeta^{\pm}}(\xi) = \sqrt{\frac{\pi}{2}}\,\delta(\xi) \pm \frac{\widehat{\chi}(\xi)}{i\,\xi}, \tag{4.9}$$

in which $\delta(\xi)$ is the delta function and $\chi = \partial_y\,\zeta^+$. It is immediate from (4.9) that the transforms of $\eta_1^{\pm}$ are

$$\begin{aligned} \widehat{\eta_1^{\pm}}(\xi) = {} & \pm \frac{a^{\pm}\, e^{i\,k_2\,\delta^{\pm}}}{2i\,(\xi + k_2)}\,\widehat{\chi}(\xi + k_2) \pm \frac{a^{\pm}\, e^{-i\,k_2\,\delta^{\pm}}}{2i\,(\xi - k_2)}\,\widehat{\chi}(\xi - k_2) \\ & + \sqrt{\frac{\pi}{8}}\left[e^{i\,k_2\,\delta^{\pm}}\,\delta(\xi + k_2) + e^{-i\,k_2\,\delta^{\pm}}\,\delta(\xi - k_2)\right]. \end{aligned} \tag{4.10}$$

From (4.10), since $\pm k_2$ are simple roots of $b(k_1, \xi) = 0$, we have

$$\begin{aligned} \left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{\pm}\right)}\right](k_2) &= \pm a^{\pm}\, e^{-i\,k_2\,\delta^{\pm}}\; c, \\ \left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{\pm}\right)}\right](-k_2) &= \mp a^{\pm}\, e^{i\,k_2\,\delta^{\pm}}\; c, \end{aligned} \tag{4.11}$$

where c is a nonzero, pure imaginary, complex number.

Now if a solution of the form (4.8) does exist, then we have

$$b(k_1,\cdot)\,\widehat{\left(\eta_1^{0}\right)} = -\widehat{p_1} - b(k_1,\cdot)\,\widehat{\left(\eta_1^{+}\right)} - b(k_1,\cdot)\,\widehat{\left(\eta_1^{-}\right)}. \tag{4.12}$$

Since η_1^0 decays rapidly as $y \longrightarrow \pm\infty$, its transform $\widehat{\eta_1^0}$ is a smooth function of ξ and so

$$\left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{0}\right)}\right](\pm\,k_2) = 0.$$

Hence we are led to choose the amplitudes $a^{\pm}$ such that

$$\left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{+}\right)}\right](k_2) + \left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{-}\right)}\right](k_2) = -\widehat{p_1}(k_2),$$

that is to say,

$$a^{+}\, e^{-i\,k_2\,\delta^{+}} - a^{-}\, e^{-i\,k_2\,\delta^{-}} = -\frac{\widehat{p_1}(k_2)}{c} \tag{4.13}$$

according to (4.11). Here c is a nonzero, pure imaginary, complex number. The real and imaginary parts of the complex numbers in (4.13) form a linear system of two equations in $a^{\pm}$, whose determinant is $-\sin k_2(\delta^+ - \delta^-)$. Given phase shifts $\delta^{\pm}$ so that $\sin k_2(\delta^+ - \delta^-) \neq 0$, we can uniquely determine the solution $a_0^{\pm}$ of (4.13). Clearly, the amplitudes $a_0^{\pm}$ satisfy

$$\mid a_0^{\pm} \mid \leq C \mid \widehat{p_1}(k_2) \mid \tag{4.14}$$

for some constant C. Note that, since $p_1(y)$ is real-valued, $\widehat{p_1}(-k_2)$ is equal to the complex conjugate of $\widehat{p_1}(k_2)$. From (4.11), it is easy to see that the amplitudes $a_0^{\pm}$ determined above also satisfy

$$\left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{+}\right)}\right](-k_2) + \left[b(k_1,\cdot)\,\widehat{\left(\eta_1^{-}\right)}\right](-k_2) = -\widehat{p_1}(-k_2).$$

Consequently, the right-hand side of (4.12) vanishes at $\xi = \pm k_2$.

Now (4.12) can be rewritten as

$$b(k_1,\cdot)\,\widehat{(\eta_1^0)} = \widehat{f}, \tag{4.15}$$

where

$$f = -p_1 - \left[b(k_1,\cdot)\,(\eta_1^+)^\wedge\right]^\vee - \left[b(k_1,\cdot)\,(\eta_1^-)^\wedge\right]^\vee.$$

Note that, by construction, $\widehat{f}(\pm k_2) = 0$. Moreover $b(k_1,\xi)\,(\eta_1^\pm)^\wedge(\xi)\cos k_1x$ are the transforms of the left-hand side of (4.6) with $p = 0$ and η replaced by $\eta_1^\pm(y)\cos k_1x$. From §3, we know that $a_0^\pm \cos k_1x \cos k_2(y - \delta^\pm)$ are the surface elevations of two linear symmetric doubly periodic waves. Consequently, $\eta_1^\pm(y)\cos k_1x$ satisfies (4.6) with $p = 0$ for $|y| \geq 1$, and we can regard $[b(k_1,\cdot)\,(\eta_1^\pm)^\wedge]^\vee$ as two smooth functions of y with compact support in $|\,y\,| \leq 1$. Thus the function f defined above is in ${}_\rho H^{s-1/2}(\mathbf{R})$ with

$$|\,f\,|_{s-1/2,\rho} \leq C(\,|\,p_1\,|_{s-1/2,\rho} + |\,\widehat{p_1}(k_2)\,|\,).$$

By Lemma 4.3, (4.15) has a solution η_1^0 in${}_\rho H^{s+3/2}(\mathbf{R})$ and

$$|\,\eta_1^0\,|_{s+3/2,\rho} \leq C(\,|\,p_1\,|_{s-1/2,\rho} + |\,\widehat{p_1}(k_2)\,|\,). \tag{4.16}$$

With all the η_m determined, for each pair of phase shifts $\delta^\pm$ such that

$$\sin k_2(\delta^+ - \delta^-) \neq 0,$$

we obtain a solution η of the form (4.6) of the form

$$\begin{aligned}\eta = {} & a_0^+\,\zeta^+(y)\cos k_1x\,\cos k_2(y - \delta^+) + \eta^* \\ & + a_0^-\,\zeta^-(y)\cos k_1x\,\cos k_2(y - \delta^-),\end{aligned} \tag{4.17}$$

where

$$\eta^* = \eta_1^0(y)\cos k_1x + \sum_{m\neq 1} \eta_m(y)\cos mk_1x. \tag{4.18}$$

To complete our discussion of the linearized problem, we will show that η^* is in ${}_\rho H_e^{s+3/2}(\Gamma)$.

To estimate $|\,\eta^*\,|_{s+3/2,\rho}$, it suffices to consider $|e^{\pm\rho y}\eta^*|_{s+3/2}$. Note that

(4.19)

$$\begin{aligned}|\,e^{\pm\rho y}\eta^*\,|_{s+3/2} = {} & \int_{-\infty}^{+\infty} (1 + k_1{}^2 + \xi^2)^{s+3/2}|(e^{\pm\rho y}\eta_1^0)^\wedge(\xi)|^2\,d\xi \\ & + \sum_{m\neq 1}\int_{-\infty}^{+\infty} (1 + m^2k_1{}^2 + \xi^2)^{s+3/2}\,|\,(e^{\pm\rho y}\eta_m)^\wedge(\xi)\,|^2\,d\xi.\end{aligned}$$

Here the first term in (4.19) is finite because of (4.16). As in the proof of the Paley–Wiener theorem, given a function $f \in {}_\rho H^s(\mathbf{R})$, its Fourier transform $\widehat{f}$ can be extended to an analytic function over the strip $\{\xi + i\phi : |\,\phi\,| < \rho\}$ by defining

$$\widehat{f}(\xi + i\phi) = \widehat{(e^{\phi x} f)}(\xi).$$

Moreover, $\widehat{f}$ has boundary values in the sense $\widehat{f}(\cdot + i\phi) \to \widehat{f}(\cdot \pm i\rho)$ in $L^2(\mathbf{R})$ as $\phi \to \pm\rho$. See [6]. For each nonnegative integer $m \neq 1$, we can extend $\eta_m(y)$ and $p_m(y)$ into analytic functions over the strip $|\operatorname{Im} z| \leq \rho$, where $\rho < \rho_*$. By Corollary 4.2, for each such m, $b(mk_1, z) \neq 0$ for any z in $|\operatorname{Im} z| \leq \rho$. Now (4.7) implies that $\widehat{p_m}(z) / b(mk_1, z)$ is an analytic function over the strip and is equal to the $\widehat{\eta_m}(z)$ along the real line. Thus, for each nonnegative integer $m \neq 1$, we have

$$\widehat{\eta_m}(z) = \widehat{p_m}(z) / b(mk_1, z)$$

for all z in the strip $|\operatorname{Im} z| \leq \rho$. Now, by Lemma 4.1, the second term in (4.19) can be estimated as follows:

$$\begin{aligned}
&\sum_{m\neq 1} \int_{-\infty}^{+\infty} (1 + m^2k_1{}^2 + \xi^2)^{s+3/2} \,|\, (e^{\pm \rho y}\eta_m)\widehat{\ }(\xi) \,|^2 \, d\xi \\
&= \sum_{m\neq 1} \int_{-\infty}^{+\infty} (1 + m^2k_1{}^2 + \xi^2)^{s+3/2} \,|\, \widehat{\eta_m}(\xi \pm i\rho) \,|^2 \, d\xi \\
&= \sum_{m\neq 1} \int_{-\infty}^{+\infty} (1 + m^2k_1{}^2 + \xi^2)^{s+3/2} \frac{|\, \widehat{p_m}(\xi \pm i\rho) \,|^2}{|\, b(mk_1, \, \xi \pm i\rho) \,|^2} \, d\xi \\
&\leq C \sum_{m\neq 1} \int_{-\infty}^{+\infty} (1 + m^2k_1{}^2 + \xi^2)^{s-1/2} \,|\, \widehat{p_m}(\xi \pm i\rho) \,|^2 \, d\xi \\
&\leq C \,|\, p \,|_{s-1/2,\rho}^2.
\end{aligned}$$

The above estimate and (4.16) show that η^* is in ${}_\rho H_e^{s+3/2}(\Gamma)$, where

$$|\, \eta^* \,|_{s+3/2,\rho} \leq C(\,|\, p \,|_{s-1/2,\rho} + |\, \widehat{p_1}(k_2) \,|\,). \tag{4.20}$$

Since $p_1(y)$ is in ${}_\rho H^{s-1/2}(\mathbf{R})$, where $s > \frac{3}{2}$, $|\, \widehat{p_1}(k_2) \,|$ is then bounded above by $|p_1|_{s-1/2,\rho}$. Thus, from (4.14) and (4.20), we obtain

$$|\, \eta^* \,|_{s+3/2,\rho} + |\, a_0^+ \,| + |\, a_0^- \,| \leq C \,|\, p \,|_{s-1/2,\rho} \tag{4.21}$$

for some constant C.

4.2. The nonlinear problem. We now show that we can use the exact symmetric doubly periodic waves of §3 to construct exact solutions of (2.8)–(2.12), which exhibit doubly periodic wave patterns as $y \to \pm\infty$. Note that the symmetric doubly periodic waves considered have wave number $\theta(\epsilon)\, k_2$ in the y direction. For the same reason as in §3, we stretch the y coordinate by setting $\tilde{y} = \theta(\epsilon)\, y$. Here $\theta(\epsilon)$ is the stretching factor determined in §3. After the stretching, we are led to consider

$$\{(1 + \epsilon\eta)\, u_x - \epsilon\, z\, \eta_x\, u_z\} + \theta\, \{(1 + \epsilon\eta)\, v_{\tilde{y}} - \epsilon\, z\, \eta_{\tilde{y}}\, v_z\} + w_z = 0, \tag{4.22}$$

$$\begin{aligned}
\theta\, w_{\tilde{y}} - \sigma\, v_z - \epsilon\, \theta\, z\, \sigma\, \eta_{\tilde{y}}\, w_z &= 0, \\
\sigma\, u_z - w_x + \epsilon\, z\, \sigma\, \eta_x\, w_z &= 0, \\
v_x - \theta\, u_{\tilde{y}} - \epsilon\, z\, \sigma\, \eta_x\, v_z + \epsilon\, \theta\, z\, \sigma\, \eta_{\tilde{y}}\, u_z &= 0,
\end{aligned} \tag{4.23}$$

$$w - \epsilon\, u\, \eta_x - \epsilon\, \theta\, v\, \eta_{\tilde{y}} = \eta_x \quad \text{on } z = 1, \tag{4.24}$$

(4.25)
$$w = 0 \quad \text{on } z = 0,$$

(4.26)
$$\eta - \beta \widetilde{\nabla} \cdot \frac{\widetilde{\nabla} \eta}{[1 + \epsilon^2 \mid \widetilde{\nabla} \eta \mid^2]^{1/2}} + \gamma u + \frac{\epsilon}{2} \gamma (u^2 + v^2 + w^2) + p = 0 \quad \text{on } z = 1.$$

Here $\sigma = (1 + \epsilon \eta)^{-1}$ and $\widetilde{\nabla} = (\partial_x, \theta \partial_{\tilde{y}})$.

We seek a surface elevation η of the form

(4.27)
$$\eta = \eta^+ + \eta^0 + \eta^-$$

in which $\eta^0 \in {}_\rho H_e^{s+3/2}(\Gamma)$ and

$$\eta^\pm = \zeta^\pm(\tilde{y})\, \eta_*^\pm(x, \tilde{y}, a^\pm, \delta^\pm, \epsilon).$$

Here $\eta_*^\pm$ are the doubly periodic surface elevations in (3.42). $\zeta^\pm(\tilde{y})$ are C^∞ cut-off functions so that $0 \leq \zeta^+ \leq 1$, $\zeta^+(\tilde{y}) = 1$ for $\tilde{y} > 1$, $\zeta^+(\tilde{y}) = 0$ for $\tilde{y} < -1$, and $\zeta^-(\tilde{y}) = 1 - \zeta^+(\tilde{y})$. Similarly, we seek (u, v, w) of the form

(4.28)
$$\begin{aligned} u &= u^+ + u^0 + u^-, \\ v &= v^+ + v^0 + v^-, \\ w &= w^+ + w^0 + w^-, \end{aligned}$$

in which

$$(u_0, v_0, w_0) \in {}_\rho H_e^{s+1}(\Omega) \times [{}_\rho H_o^{s+1}(\Omega)]^2$$

and

$$(u^\pm, v^\pm, w^\pm) = (\zeta^\pm u_*^\pm, \zeta^\pm v_*^\pm, \zeta^\pm w_*^\pm).$$

Here $(u_*^\pm, v_*^\pm, w_*^\pm)$ are the correction terms of the doubly periodic velocities in (3.42), corresponding to $\eta_*^\pm$.

We now summarize the main result of this paper. Suppose that $0 < \beta < 0.02$. In case of air-water interface at 20°C, with standard value for g, this corresponds to $h >$ 10cm. Furthermore, assume that the Froude number γ is within the range $\gamma_0(\beta) < \gamma < 1$ and a pressure disturbance $p \in {}_\rho H_e^{s-1/2}(\Gamma)$ with $s > \frac{3}{2}$ is given. Let

$$p(x, \tilde{y}) = \sum_{m=0}^{+\infty} p_m(\tilde{y}) \cos m k_1 x.$$

We consider the case in which p's wave number k_1 in the x direction satisfies

$$\max(k_G, k_T/2) < k_1 < k_T$$

and $0 < \rho < \rho_*$. The constant ρ_* is described in Corollary 4.2. We have the following.

THEOREM 4.4. *With the assumptions above, let k_2 be the positive root of equation $b(k_1, \xi) = 0$. When the Fourier transform $\widehat{p_1}$is nonzero at k_2, for each pair of phase shifts $\delta^\pm$ such that* $\sin k_2(\delta^+ - \delta^-) \neq 0$, (4.22)–(4.26) *has a solution $\eta(\epsilon)$,* $(u(\epsilon), v(\epsilon), w(\epsilon))$ *of the form* (4.27) *and* (4.28) *for each ϵ sufficiently small.*

From each solution of (4.22)–(4.26), we can define (U, V, W) and S according to (2.7). After returning to the original (X, Y, Z) coordinates, we obtain a two-parameter family of exact solutions of (2.1)–(2.5) which exhibit doubly periodic wave patterns as $Y \to \pm\infty$.

By multiplying all three equations in (4.23) by $(1 + \epsilon\,\eta)$, we can rewrite (4.22)–(4.24) as

$$\{L_0 + \epsilon\, L_1(\eta)\}(u, v, w) = (0, \vec{0}, \eta_x), \tag{4.29}$$

in which L_0 and $L_1(\eta)$ are linear operators, with $L_1(\eta)$ depending linearly on η. Suppose that (4.22)–(4.24) do have a solution η and (u, v, w) of the form (4.27) and (4.28). Note that we can rearrange (4.29) as

$$\begin{aligned}\{\, L_0 + \epsilon\, L_1(\eta)\,\}(u^0, v^0, w^0) &= (0, \vec{0}, \eta_x) - \{L_0 + \epsilon\, L_1(\eta)\}(u^\pm, v^\pm, w^\pm)\\ &= \Big[(0, \vec{0}, {\eta^\pm}_x) - \{L_0 + \epsilon\, L_1(\eta^\pm)\}(u^\pm, v^\pm, w^\pm)\Big]\\ &\quad - \epsilon\, L_1(\eta^\pm)(u^\mp, v^\mp, w^\mp) - \epsilon\, L_1(\eta^0)(u^\pm, v^\pm, w^\pm)\\ &\quad + (0, \vec{0}, {\eta^0}_x).\end{aligned} \tag{4.30}$$

Here each term with ± represents a sum of two terms. In (4.30), the first two terms on the right vanish for $|\ \tilde{y}\ | \geq 1$ since $\eta_*^\pm$ and $(u_*^\pm, v_*^\pm, w_*^\pm)$ satisfy (3.4), (3.5), and (3.7). The third and fourth terms decay rapidly as $\tilde{y} \to \pm\infty$ since $\eta^0 \in {}_\rho H_e^{s+3/2}(\Omega)$. Therefore, if we can invert $L_0{+}\epsilon\, L_1(\eta)$ over an appropriate space of functions which decay rapidly as $\tilde{y} \to \pm\infty$, then we can regard (u^0, v^0, w^0) as a function of η^0, $a^\pm$, $\delta^\pm$, and ϵ.

Let

$$\begin{aligned} Y &= \{(u, v, w) \in {}_\rho H_e^{s+1}(\Omega) \times [\,{}_\rho H_o^{s+1}(\Omega)\,]^2 \,:\, w(x, \tilde{y}, 0) = 0\},\\ Z &= [\,{}_\rho H_o^s(\Omega)\,]^2 \times [\,{}_\rho H_e^s(\Omega)\,]^2 \times {}_\rho H_o^{s+1/2}(\Gamma)\end{aligned}$$

and, for each η of the form (4.27), regard $L_0 + \epsilon\, L_1(\eta)$ as a linear operator from Y to Z. To take a closer look at the range of $L_0 + \epsilon\, L_1(\eta)$, suppose we have

$$\{\, L_0 + \epsilon\, L_1(\eta)\,\}(u, v, w) = (f, \vec{g}, q) \tag{4.31}$$

for some $(u, v, w) \in Y$. Here $(f, \vec{g}, q)$ is in Z with $\vec{g} = (g_1, g_2, g_3)$. As in (3.13), (4.31) implies that $\vec{g}$ is a curl in the original (X, Y, Z) coordinates. Therefore, (3.14) still holds for $\vec{g}$. Now if we define $\widetilde{g} = (\tilde{g}_1, \tilde{g}_2, \tilde{g}_3)$ as we did in (3.15), then $\widetilde{g}$ satisfies

$$\tilde{g}_{1,x} + \tilde{g}_{2,\tilde{y}} + \tilde{g}_{3,z} = 0. \tag{4.32}$$

Furthermore, by(3.15) and (4.31),

$$\begin{aligned}\tilde{g}_3 &= v_x - \theta\, u_{\tilde{y}} + \epsilon\,\theta\, z\,(\eta_{\tilde{y}}\, w_x - \eta_x\, w_{\tilde{y}}),\\ &= v_x - \theta\, u_{\tilde{y}} + \epsilon\,\theta\, z\,\{(\eta_{\tilde{y}}\, w)_x - (\eta_x\, w)_{\tilde{y}}\},\end{aligned} \tag{4.33}$$

which shows that $\tilde{g}_3$ is a divergence with respect to x, $\tilde{y}$. Motivated by (4.32) and (4.33), we define a subspace Z_0 of Z as follows. Let φ be a C^∞ function of compact support on $\mathbf{R}$ with $\varphi(0) = 1$. Let Z_0 be the subspace of Z consisting of $(f, \vec{g}, q)$ in which $\vec{g} = (g_1, g_2, g_3)$ satisfies

$$g_{1,x} + g_{2,\tilde{y}} + g_{3,z} = 0, \tag{4.34}$$

$$\int_{-\ell_1}^{+\ell_1} \widehat{g_3}(x,0,z)\,dx = 0, \tag{4.35}$$

$$\int_{-\infty}^{+\infty}\int_0^1 \frac{\varphi^2(\xi)}{\xi^2}\left\{\int_{-\ell_1}^{+\ell_1} \widehat{g_3}(x,\xi,z)\,dx\right\}^2 dzd\xi < +\infty. \tag{4.36}$$

Here $\widehat{\ }$ is the Fourier transform with respect to $\tilde{y}$ with dual variable ξ, and $\ell_1 = \pi/k_1$. Condition (4.36) states that the quantity in the brackets is zero at $\xi = 0$ in a generalized sense. The square of the norm in Z_0 is a set equal to the square of the norm in Z plus the term in (4.36).

As in §3, let $J(\epsilon\eta) : Z \to Z$ be the linear operator in (3.15) that maps $(f,\vec{g},q)$ to $(f,\widetilde{g},q)$. Now we can treat $J(\epsilon\eta)\,\{L_0 + \epsilon\, L_1(\eta)\}$ as a bounded operator from Y to Z_0. Clearly, when $\epsilon = 0$, the stretching factor $\theta = 1$ and thus $J(0)$ is the identity operator. In the following lemma, we show that $J(0)\,L_0 = L_0$ is invertible.

LEMMA 4.5. *Given any $(f,\vec{g},q)$ in Z_0, there exists a unique solution (u,v,w) in Y that satisfies*

$$u_x + v_{\tilde{y}} + w_z = f, \tag{4.37}$$

$$w_{\tilde{y}} - v_z = g_1, \tag{4.38}$$
$$u_z - w_x = g_2, \tag{4.39}$$
$$v_x - u_{\tilde{y}} = g_3, \tag{4.40}$$

$$w = q \quad on\ z = 1, \tag{4.41}$$

$$w = 0 \quad on\ z = 0, \tag{4.42}$$

and the estimate

$$|\,(u,v,w)\,|_Y \le C\,|\,(f,\vec{g},q)\,|_{Z_0}.$$

Proof. We use the method of Lemma 3.2 and start with the case $q = 0$. With u_n, v_n, w_n, f_n, and g_{in} defined as before, we are led to solve (3.25)–(3.28). According to their symmetries in the x direction, we can expand all functions involved into Fourier series in x. For example, we have

$$u_n = \sum_{m=0}^{+\infty} u_{nm}(\tilde{y})\,\cos mk_1x.$$

Similar to (3.16), (4.34) implies

$$g_{1n,x} + g_{2n,\tilde{y}} - n\pi\, g_{3n} = 0 \quad \text{for } n \ge 1.$$

As in Lemma 3.2, it is sufficient to consider (3.25)–(3.27) when $n \ge 1$. By taking Fourier transform in the $\tilde{y}$ direction, we obtain the algebraic linear system

$$\begin{aligned} -mk_1\,\widehat{u_{nm}} + i\,\xi\,\widehat{v_{nm}} + n\,\pi\,\widehat{w_{nm}} &= \widehat{f_{nm}}, \\ n\pi\,\widehat{v_{nm}} + i\,\xi\,\widehat{w_{nm}} &= \widehat{g^m_{1n}}, \\ -n\pi\,\widehat{u_{nm}} - mk_1\,\widehat{w_{nm}} &= \widehat{g^m_{2n}} \end{aligned} \tag{4.43}$$

for each $m \geq 1$. For $m, n \geq 1$, since $\rho < \rho_* < k_1$, the determinant $n^2\pi^2 + m^2 k_1{}^2 + \xi^2$of the above linear system has no complex roots in the strip $\mid \operatorname{Im} z \mid \leq \rho_*$. Now we can use the Cramer's rule and Lemma 4.3 to solve (4.43).

For $n = 0$ and $m \geq 1$, (3.25) and (3.28) lead to

$$-mk_1 \, \widehat{u_{0m}} + i\xi \, \widehat{v_{0m}} = \widehat{f_{0m}},$$
$$-i\xi \, \widehat{u_{0m}} + mk_1 \, \widehat{v_{0m}} = \widehat{g_{30}^{m}},$$

which can be solved as in the previous paragraph. When $n \geq 0$ and $m = 0$, from (3.28), we are led to solve

$$- i\xi \, \widehat{u_{n0}} = \widehat{g_{3n}^{0}}. \tag{4.44}$$

Note that (4.35) implies $\widehat{g_{3n}^{0}}(0) = 0$ for $n \geq 0$. Thus Lemma 4.3 applies and u_{n0} are determined.

With the help of the extra factor given in (4.36), we can show that

$$\mid u_n \mid_{s+1,\rho} + n \mid u_n \mid_{s,\rho} \leq C \left(|f_n|_{s,\rho} + \sum_{i=1}^{3} |g_{in}|_{s,\rho} \right),$$
$$\mid u_0 \mid_{s+1,\rho} + \mid v_0 \mid_{s+1,\rho} \leq C \mid (f, \vec{g}, 0) \mid_{Z_0}.$$

The rest of the proof is essentially the same as that of Lemma 5 in [1]. □

Now suppose that we are given a η of the form (4.27) in which η^0, $a^{\pm}$, and $\delta^{\pm}$ are within some bounded set. We can regard $J(\epsilon\eta)$ and $\{L_0 + \epsilon L_1(\eta)\}$ as operators, depending smoothly on η^0, $a^{\pm}$, $\delta^{\pm}$, and ϵ. Since $J(0)$ is the identity, $J(\epsilon\eta)$ is invertible for ϵ sufficiently small. Thus solving (4.30) is equivalent to solving

$$J(\epsilon\eta) \{ L_0 + \epsilon L_1(\eta) \} (u^0, v^0, w^0) = (f, \vec{g}, q), \tag{4.45}$$

where

$$(f, \vec{g}, q) = J(\epsilon\eta) \Big((0, \vec{0}, \eta_x) - \{ L_0 + \epsilon L_1(\eta) \} (u^{\pm}, v^{\pm}, w^{\pm}) \Big). \tag{4.46}$$

Here the last term with ± represents a sum of two terms. As a result of Lemma 4.5, $J(\epsilon\eta) \{L_0 + \epsilon L_1(\eta)\}$ is an invertible operator from Y onto Z_0, provided ϵ is sufficiently small. To solve (4.45), it remains to show that $(f, \vec{g}, q)$ defined above is in Z_0. Let

$$\{L_0 + \epsilon L_1(\eta)\}(u^{\pm}, v^{\pm}, w^{\pm}) = (f^{\pm}, g^{\pm}, q^{\pm}).$$

As before, if we apply (3.15) to $g^{\pm}$ and define $\tilde{g}^{\pm}$, then $\tilde{g}^{\pm}$ satisfies (4.32) and, as in (4.33), $\tilde{g}_3^{\pm}$ are divergences with respect to x and $\tilde{y}$. Thus $\vec{g} = -\tilde{g}^{+} - \tilde{g}^{-}$ defined in (4.46) satisfies (4.34). Moreover, from (4.30), we can see that $g^{\pm}$ defined above decay rapidly in the $\tilde{y}$ direction. This implies

$$\int_{-\ell_1}^{+\ell_1} g_3(x, \tilde{y}, z) \, dx = \partial_{\tilde{y}} \, r_1(\tilde{y}, z)$$

for some function r_1 that decays rapidly in the $\tilde{y}$ direction. Consequently, (4.35) and (4.36) hold and we have $(f, \vec{g}, q) \in Z_0$. Now, for ϵ sufficiently close to zero, (u^0, v^0, w^0) can be regarded as a function that depends smoothly on η^0, $a^{\pm}$, $\delta^{\pm}$, and ϵ through

$$(u^0, v^0, w^0) = \big(J(\epsilon\eta) \{ L_0 + \epsilon L_1(\eta) \} \big)^{-1} (f, \vec{g}, q), \tag{4.47}$$

where $(f, \vec{g}, q)$ is given in (4.46).

Now, because of (4.47), it remains to solve Bernoulli's equation (4.26) as a nonlinear equation of the form

$$B(\eta^0, a^\pm, \delta^\pm, \epsilon) + p = 0, \tag{4.48}$$

where

$$B(\eta^0, a^\pm, \delta^\pm, \epsilon) = \eta - \beta \tilde{\nabla} \cdot \frac{\tilde{\nabla}\eta}{[1+\epsilon^2 \mid \tilde{\nabla}\eta \mid^2]^{1/2}} + \gamma u + \frac{\epsilon}{2}(u^2+v^2+w^2). \tag{4.49}$$

Here $\tilde{\nabla} = (\partial_x,\, \theta\,\partial_{\tilde{y}})$; η and (u, v, w) are defined as in (4.27) and (4.28), with (u^0, v^0, w^0) given by (4.47). Let N be any bounded neighborhood of $\vec{0}$ in ${}_\rho H_e^{s+3/2}(\Gamma) \times \mathbf{R}^5$ and regard B as an operator defined on N. First, we point out that B ranges in ${}_\rho H_e^{s-1/2}(\Gamma)$. Let $(\eta^0, a^\pm, \delta^\pm, \epsilon)$ be an arbitrary element in N. Note that

$$\begin{aligned}\tilde{\nabla} \cdot \frac{\tilde{\nabla}\eta}{[1+\epsilon^2 \mid \tilde{\nabla}\eta \mid^2]^{1/2}} &= \frac{1}{\epsilon}\left\{\frac{\epsilon\,\eta_x}{[1+\epsilon^2\,\eta_x{}^2+\epsilon^2\,\theta^2\,\eta_{\tilde{y}}{}^2]^{1/2}}\right\}_x \\ &+ \frac{1}{\epsilon}\left\{\frac{\epsilon\,\theta\,\eta_{\tilde{y}}}{[1+\epsilon^2\,\eta_x{}^2+\epsilon^2\,\theta^2\,\eta_{\tilde{y}}{}^2]^{1/2}}\right\}_{\tilde{y}}.\end{aligned} \tag{4.50}$$

Let f be the C^∞ function

$$f(\tau_1, \tau_2) = \frac{\tau_1}{(1+\tau_1{}^2+\tau_2{}^2)^{1/2}}.$$

Note that

$$f(\tau_1+h_1, \tau_2+h_2) = f(\tau_1, \tau_2) + \int_0^1 \frac{d}{dt} f(\tau_1+th_1, \tau_2+th_2)\,dt.$$

Apply this formula with $\tau_1 = \epsilon\,(\eta_x^+ + \eta_x^-)$, $\tau_2 = \epsilon\,\theta\,(\eta_{\tilde{y}}^+ + \eta_{\tilde{y}}^-)$, $h_1 = \epsilon\,\eta_x^0$ and $h_2 = \epsilon\,\theta\,\eta_{\tilde{y}}^0$. Since $\eta^0 \in {}_\rho H_e^{s+3/2}(\Gamma)$, we have

$$f(\epsilon\,\eta_x, \epsilon\,\theta\,\eta_{\tilde{y}}) = f(\tau_1, \tau_2) + r_2,$$

where $r_2 \in {}_\rho H^{s+1/2}(\Gamma)$. By construction, the term

$$f(\tau_1, \tau_2) - f(\epsilon\,\eta_x^+, \epsilon\,\theta\,\eta_{\tilde{y}}^+) - f(\epsilon\,\eta_x^-, \epsilon\,\theta\,\eta_{\tilde{y}}^-)$$

has compact support in $\tilde{y}$. Hence, the first term in (4.50) can be rewritten as

$$\partial_x\, f(\epsilon\,\eta_x, \epsilon\,\theta\,\eta_{\tilde{y}}) = \partial_x\, f(\epsilon\,\eta_x^+, \epsilon\,\theta\,\eta_{\tilde{y}}^+) + \partial_x\, f(\epsilon\,\eta_x^-, \epsilon\,\theta\,\eta_{\tilde{y}}^-) + r_3,$$

where $r_3 \in {}_\rho H^{s-1/2}(\Gamma)$. We can rewrite the second term in (4.50) in a similar manner. Next, on $z = 1$, we can write

$$(u^2+v^2+w^2) = (u^{+2}+v^{+2}+w^{+2}) + (u^{-2}+v^{-2}+w^{-2}) + r_4,$$

where r_4 is in ${}_\rho H^{s+1/2}(\Gamma)$. Now, since the symmetric doubly periodic waves satisfy Bernoulli's equation, the sum of all the terms with ± sign has compact support in $\tilde{y}$. Hence, we have shown that B ranges in ${}_\rho H_e^{s-1/2}(\Gamma)$.

When $\epsilon = 0$, the y coordinate and the $\tilde{y}$ coordinate are the same since the stretching factor $\theta = 1$. Given phase shifts $\delta^\pm$ such that $\sin k_2(\delta^+ - \delta^-) \neq 0$, η^* and $a_0^\pm$ determined by (4.18) and (4.13) in §4.1 satisfy

$$B(\eta^*,\, a_0^\pm,\, \delta^\pm, 0) + p = 0.$$

Let N be a sufficiently large neighborhood of $(\eta^*, a_0^\pm, \delta^\pm, 0)$ in ${}_\rho H_e^{s+3/2}(\Gamma) \times \mathbf{R}^5$. In what follows, we will apply the implicit function theorem for Banach spaces to solve (4.48) for ϵ close to zero. We will show that the Fréchet derivative A of B with respect to $(\eta^0, a^\pm)$ at $(\eta^*, a_0^\pm, \delta^\pm, 0)$ is an invertible operator from ${}_\rho H_e^{s+3/2}(\Gamma) \times \mathbf{R}^2$ to ${}_\rho H_e^{s-1/2}(\Gamma)$.

When $\epsilon = 0$,

$$B(\eta^0, a^\pm, \delta^\pm, 0) = \eta - \beta \widetilde{\nabla}^2 \eta + \gamma\, u, \tag{4.51}$$

where η is of the form (4.27) and (u, v, w) is determined by (4.2)–(4.6). As is pointed out in (3.43), the terms $\eta^\pm$ in (4.27) now have the form

$$\eta^\pm = a^\pm\, \zeta^\pm(\tilde{y})\, \cos k_1 x\, \cos k_2(\tilde{y} - \delta^\pm)$$

when $\epsilon = 0$. Given any amplitudes $\tilde{a}^\pm$ and $\tilde{\eta}^0$ in${}_\rho H_e^{s+3/2}(\Gamma)$, with $\tilde{\eta}^0$ written as

$$\tilde{\eta}^0 = \sum_{m=0}^{+\infty} \tilde{\eta}_m(\tilde{y})\, \cos m k_1 x,$$

we obtain

$$\begin{aligned} \widehat{A(\tilde{\eta}^0,\, \tilde{a}^\pm)}(x, \xi) = \sum_{m=0}^{+\infty} b(m k_1, \xi)\, \widehat{(\tilde{\eta}_m)}(\xi)\, \cos m k_1 x \\ + \tilde{a}^+\, \partial_{a^+}\, b(k_1, \xi)\, \widehat{(\eta^+)}(x, \xi) \\ + \tilde{a}^-\, \partial_{a^-}\, b(k_1, \xi)\, \widehat{(\eta^-)}(x, \xi). \end{aligned} \tag{4.52}$$

Here $\widehat{\ }$ is the Fourier transform in $\tilde{y}$. We need to show that, for any $g \in {}_\rho H_e^{s-1/2}(\Gamma)$

$$A(\tilde{\eta}^0,\, \tilde{a}^\pm) = g \tag{4.53}$$

has a unique solution depending boundedly on g. Assume that

$$g = \sum_{m=0}^{+\infty} g_m(\tilde{y})\, \cos m k_1 x.$$

From (4.52), the transform of (4.53) leads to

$$\begin{aligned} \Big[b(k_1, \cdot)\, \widehat{(\tilde{\eta}_1)}\Big](\xi)\, \cos k_1 x = \widehat{g_1}(\xi)\, \cos k_1 x \\ - \tilde{a}^+\, \partial_{a^+}\, \Big[b(k_1, \cdot)\, \widehat{(\eta^+)}\Big](x, \xi) \\ - \tilde{a}^-\, \partial_{a^-}\, \Big[b(k_1, \cdot)\, \widehat{(\eta^-)}\Big](x, \xi), \end{aligned} \tag{4.54}$$

and

$$\left[b(mk_1, \cdot)\,\widehat{(\tilde{\eta}_m)} \right](\xi) = \widehat{g_m}(\xi) \quad \text{for } m \neq 1. \tag{4.55}$$

Note that (4.12) and (4.54) are similar. As before, we set $\xi = k_2$ and use

$$\tilde{a}^+ \left[b(k_1, \cdot)\,\widehat{(\eta^+)} \right](x, k_2) + \tilde{a}^- \left[b(k_1, \cdot)\,\widehat{(\eta^-)} \right](x, k_2) = \widehat{g_1}(k_2)\, \cos k_1 x$$

to form a linear system for $\tilde{a}^\pm$. Then by (4.11) and the assumption that $\sin k_2(\delta^+ - \delta^-)$ is nonzero, $\tilde{a}^\pm$ can be determined as in (4.13), and then the right-hand side of (4.54) becomes a function that vanishes at $\xi = k_2$. As in §4.1, the amplitudes $\tilde{a}^\pm$ thus determined guarantee that the right-hand side of (4.54) also vanishes at $\xi = -k_2$. As a result of Corollary 4.2, we can now use Lemma 4.3 to solve (4.54) and (4.55) as in (4.7), (4.15). The solution $(\tilde{\eta}^0, \tilde{a}^\pm)$ thus obtained can be estimated as in (4.14) and (4.19). We obtain, as in (4.21),

$$|\, \tilde{\eta}^0 \,|_{s+3/2,\rho} + |\, \tilde{a}^+ \,| + |\, \tilde{a}^- \,| \le C \,|\, g \,|_{s-1/2,\rho}.$$

The uniqueness of the solution follows as a result of the above estimate.

Now, since the Fréchet derivative A is invertible, the implicit function theorem for Banach spaces applies. As a result, there exists a solution $(\eta^0(\epsilon), a^\pm(\epsilon))$ of (4.48) in ${}_\rho H_e^{s+3/2}(\Gamma) \times \mathbf{R}^2$ for each ϵ sufficiently close to zero, provided the phase shifts at infinity $\delta^\pm$ satisfy $\sin k_2(\delta^+ - \delta^-) \neq 0$.

By examining the above result more closely, we can construct three-dimensional exact steady water waves traveling along a vertical wall located on $y = 0$, generated by a partially localized pressure disturbance. Suppose that the pressure disturbance $p \in {}_\rho H_e^{s-1/2}(\Gamma)$ is an even function of y. Observe that an L^2 function $v(x, y, z)$ is even in y if and only if its Fourier transform $\widehat{v}(x, \xi, z)$ is even in ξ. Similarly, v is odd in y if and only if $\widehat{v}$ is odd in ξ. Note that p is even in y implies that each of the $\widehat{p_m}(\xi)$ in (4.7) is even in ξ. Since the function $b(mk_1, \xi)$ is also even in ξ for each m, the solution η_m of (4.7) is even in y. For this reason, we seek a surface elevation η which is even in y. Given such a η, when we solve (4.2)–(4.6), the resulting (u, v, w) would have u, w even in y and v odd in y. Consequently, we will need to use Sobolev spaces which specify the symmetries in both the x and y direction. Let $H^s(\Omega)$ and $H^s(\Gamma)$ be defined as in §2. A subscript (e, e), (e, o), (o, e), or (o, o) is used to indicate the symmetries in x and y. Similarly, we define subspaces of ${}_\rho H^s(\Omega)$and ${}_\rho H^s(\Gamma)$. In what follows, we will only point out the necessary changes; most of the construction remains the same.

When we carry out the linear calculation as in §4.1, since η is even in y, we should take

$$a^+ = a^- \quad \text{and} \quad \delta^+ = -\delta^- \tag{4.56}$$

in (4.8). As a result, (4.13) is replaced by

$$2i\, a^+ \, \sin k_2 \delta^+ = \widehat{p_1}(k_2) \,/\, c, \tag{4.57}$$

where c is nonzero and pure imaginary. Since p_1 is real-valued and is even in y, we have

$$\overline{\widehat{p_1}(k_2)} = \widehat{p_1}(-k_2) = \widehat{p_1}(k_2).$$

This implies $\widehat{p_1}$ is real-valued. Given δ^+ such that $\sin k_2\delta^+ \neq 0$, we can determine a^+ uniquely from (4.57). The rest of the calculation remains unchanged except that we now have additional symmetry in the y direction. The estimate (4.21) shows that η^* is in ${}_\rho H^{s+3/2}_{e,e}(\Gamma)$. Because of (4.56), (4.17) provides a one-parameter family of solutions of (4.2)–(4.6) with v vanishing along $y = 0$.

As for modifying the construction in §4.2, first we need to replace function spaces Y and Z by

$$\begin{aligned} Y &= \{(u,v,w) \in {}_\rho H^{s+1}_{e,e}(\Omega) \times {}_\rho H^{s+1}_{o,o}(\Omega) \times {}_\rho H^{s+1}_{o,e}(\Omega) : w(x,\tilde{y},0) = 0\}, \\ Z &= {}_\rho H^{s}_{o,e}(\Omega) \times {}_\rho H^{2}_{o,o}(\Omega) \times {}_\rho H^{s}_{e,e}(\Omega) \times {}_\rho H^{s}_{e,o}(\Omega) \times {}_\rho H^{s+1/2}_{e,e}(\Gamma). \end{aligned}$$

Again, let Z_0 be the subspace of Z consisting of $(f, \vec{g}, q)$ that satisfies (4.34)–(4.36). Next, because of the symmetry in the $\tilde{y}$ direction, the function B in (4.49) can be regarded as a function of η^0, a^+, δ^+, and ϵ from a neighborhood N in ${}_\rho H^{s+3/2}_{e,e}(\Gamma) \times \mathbf{R}^3$ to ${}_\rho H^{s-1/2}_{e,e}(\Gamma)$. Amplitude a^- and phase shift δ^- on the other side are determined by (4.56). Consequently, when we solve (4.53), $\tilde{a}^+$ is determined by an equation that is similar to (4.57). Finally, by applying the implicit function theorem, we obtain a one-parameter family of exact solutions of (4.22)–(4.26). Note that these solutions also satisfy

$$v(x,0,z) = 0,$$

which is the boundary condition along the vertical wall. Now, if we accept the assumption that the contact angle of the fluid with the wall is 90° by restricting the solutions we just obtained to the domain $\{(x,y,z) : y > 0,\ 0 < z < 1\}$, we obtain a one-parameter family of exact steady waves traveling along a vertical wall.

5. Appendix.

Proof of Lemma 3.1. Let $f(x) = (1 + \beta x^2)\, x \tanh x$ for $x \geq 0$. From (3.3), it is easy to see that ξ is a real root of $b(k_1, \xi) = 0$ if and only if $\tilde{k} = ({k_1}^2 + \xi^2)^{1/2}$ satisfies

$$f(x) = \gamma\, {k_1}^2. \tag{5.1}$$

Thus we are led to investigate whether (5.1) has a positive root $\geq k_1$.

Clearly, we have $f'(x) > 0$ for any $x > 0$ and $f(0) = 0$. Hence, given any real number $k_1 > 0$, there exists a unique $\tilde{k} > 0$ such that $f(\tilde{k}) = \gamma\, {k_1}^2$. Note that

$$\begin{aligned} f(\tilde{k}) - f(k_1) &= \gamma\, {k_1}^2 - (1 + \beta\, {k_1}^2)\, k_1 \tanh k_1 \\ &= -k_1\, b(k_1, 0) \tanh k_1. \end{aligned} \tag{5.2}$$

From the proof of Lemma 2 in [1], it is not hard to see that

$$\begin{aligned} &b(k_1, 0) < 0 \quad \text{if } k_G < k_1 < k_T, \\ &b(k_1, 0) > 0 \quad \text{if } 0 < k_1 < k_G \ \text{ or } \ k_T < k_1. \end{aligned} \tag{5.3}$$

Thus, when $0 < k_1 < k_G$ or $k_T < k_1$ we have $f(\tilde{k}) < f(k_1)$. This implies that the only positive root of (5.1) is strictly less than k_1 and so $b(k_1, \xi) = 0$ has no real roots. When $k_G < k_1 < k_T$,(5.2) and (5.3) imply (5.1) has a positive root $\tilde{k}$ which is $> k_1$. As a result, $k_2 = (\tilde{k}^2 - {k_1}^2)^{1/2}$ satisfies $b(k_1, k_2) = 0$. The uniqueness of the positive root $\xi = k_2$ follows from that of $\tilde{k}$.

It remains to show that $k_2 > 0$ is a simple root of $b(k_1, \xi) = 0$. For any $\xi > 0$, note that

$$f\left(\sqrt{k_1{}^2 + \xi^2}\right) = \gamma\, k_1{}^2 + b(k_1, \xi)\sqrt{k_1{}^2 + \xi^2}\,\tanh\sqrt{k_1{}^2 + \xi^2}.$$

This implies

$$\left[\partial_\xi\, f\left(\sqrt{k_1{}^2 + \xi^2}\right)\right]_{\xi = k_2} = \left[\tilde{k}\,\tanh \tilde{k} \partial_\xi\, b(k_1, \xi)\right]_{\xi = k_2},$$

where $\tilde{k} = (k_1{}^2 + \xi^2)^{1/2}$. It is easy to see that $[\partial_\xi\, f(\sqrt{k_1{}^2 + \xi^2})]_{\xi = k_2}$ is nonzero. Thus $\partial_\xi\, b(k_1, \xi)$ is also nonzero at $\xi = k_2$. This completes the proof of Lemma 3.1. □

Proof of Corollary 4.2. Let ρ be an arbitrary constant such that $0 < \rho < k_1$. By Lemma 4.1, for each $m \geq 0$, $b(mk_1, z)$ is analytic over the strip $|\operatorname{Im} z| \leq \rho$. Moreover, there exists a positive integer M such that

$$|b(mk_1, z)| \geq C\,(m^2 k_1{}^2 + |\operatorname{Re} z|^2)^o$$

whenever $|\operatorname{Re} z|$ or m is larger than M. Hence, to prove Corollary 4.2, it suffices to consider analytic functions $b(0, z)$, $b(k_1, z), \ldots, b(Mk_1, z)$ over the compact set $\{\xi + i\phi : |\ \xi\ | \leq M,\ |\ \phi\ | \leq \rho\}$. Each of these functions can only have a finite number of zeros in the compact set. Since $\max(k_G, k_T/2) < k_1 < k_T$, among these functions, Lemma 3.1 implies that only $b(k_1, z)$ has two real roots $z = \pm k_2$. Thus there is a small enough $\rho_* > 0$ such that all the roots of $b(0, z)$, $b(k_1, z), \ldots, b(Mk_1, z)$ except $\pm k_2$ lie outside the strip $|\operatorname{Im} z| \leq \rho_* < k_1$. This proves Corollary 4.2. □

Acknowledgment. This paper is based on the results obtained in the author's dissertation. The author would like to thank his thesis advisor, Professor J. Thomas Beale, for his encouragement and advice. The author would also like to thank the referees for their helpful suggestions.

TRAVELLING WAVES IN PREDATOR-PREY SYSTEMS*

KONSTANTIN MISCHAIKOW† AND JAMES F. REINECK‡

Abstract. The existence of travelling wave solutions to reaction-diffusion equations which model predator-prey systems is proven. Bistable waves, Fisher waves, and higher-dimensional analogues of Fisher waves are found. Some of the systems investigated have bistable homoclinic waves. The proofs use the Conley index, continuation, the connection matrix, and bifurcation theory in the Conley index setting.

Key words. travelling wave, reaction-diffusion equation, predator-prey system, Conley index

1. Introduction.

This paper discusses the existence of travelling wave solutions for systems of reaction-diffusion equations which model two-species predator-prey interactions. In particular, the following two questions are addressed.

(Q1) Given general qualitative hypotheses on the nonlinear reaction terms, what travelling waves occur?

(Q2) Given qualitative properties of a travelling wave, can one find nonlinearities for which such a travelling wave exists?

From the very beginning it must be emphasized that we are *far* from being able to give a complete answer to either of these questions. On the other hand, we are able to provide partial solutions to both problems. What is perhaps more important is that our results are obtained in a systematic manner which shows potential for applications in both higher-dimensional and more complicated problems.

In some sense the techniques we use are not new. They are based on careful choices of isolating neighborhoods and applications of the Conley index, a procedure which in a very simple setting (one-species) was outlined by Conley [Co, Chap. IV.2.6]. That these ideas work for more challenging problems has been amply demonstrated by now. For a sampling of these we draw the readers' attention to the work of Conley and Gardner [C-G] (a "simple" two-competing species model), Feinberg and Terman [F-T] (a "complicated" two-competing species model), Mischaikow and Hutson [M-H] (n-mutualist species), Mischaikow [Mi2] (two-mutualist and one-competitor), Gardner and Smoller [G-S] (periodic wave trains via perturbation methods). Of particular note for the problem we consider here is the work of Gardner [Ga], also on a predator-prey system.

Our proof of existence uses techniques similar to those of Conley [Co], Conley and Gardner [C-G], and Gardner [Ga]. As in the earlier work, we deform the original system to a simpler one where the existence of travelling waves is shown by making direct computations using the Conley index and related machinery (Theorem 2.1 and §4). A set is constructed in phase space which is an isolating neighborhood throughout the deformation, and it follows that there is a travelling wave throughout the deformation, and in particular for the original system. The major difference between

our work and that of Conley–Gardner and Gardner is in the computations in the simplified system. We use connected simple system arguments instead of the connection index arguments of [C-G] and [Ga]. Thus we return to the ideas developed in Conley's monograph [Co]. Theorem 2.1 is weaker than the abstract theorem in [C-G] and [Ga], but it suffices to prove existence of travelling waves both in the earlier work and in our setting, and the necessary computations are simpler. In addition, we believe that this is an improvement over previous work, since, as will be demonstrated in §4, we can incorporate the connection matrix and transition matrix theory to obtain travelling waves in a product system which we then continue back to the original system. We believe that the continuation ideas developed in [Co], [C-G], and [Ga], combined with the more powerful computational tools which have been developed, will yield many useful results similar to those obtained in this paper.

Turning to the problem at hand, we will consider the following pair of reaction-diffusion equations

$$\begin{aligned} \frac{\partial u_1}{\partial t} &= \mu_1 \frac{\partial^2 u_1}{\partial x^2} + u_1 f(u_1, u_2), \\ \frac{\partial u_2}{\partial t} &= \mu_2 \frac{\partial^2 u_2}{\partial x^2} + u_2 g(u_1, u_2), \end{aligned} \tag{1.1}$$

where $x, t \in \mathbf{R}$ and the μ_i (assumed > 0) are the diffusion coefficients. It is convenient to state the hypothesis for (1.1) in terms of the *reaction system*

$$\begin{aligned} \dot{u}_1 &= u_1 f(u_1, u_2), \\ \dot{u}_2 &= u_2 g(u_1, u_2). \end{aligned} \tag{1.2}$$

H1. $f, g \in C^2$, $\partial f/\partial u_2 < 0$ and $\partial g/\partial u_1 > 0$.

H2. The zero sets of f and g, i.e., $\{u \mid f(u) = 0\}$ and $\{u \mid g(u) = 0\}$, are as shown in Fig. 1.1. In particular, $\{u \mid f(u) = 0\}$ is given by a smooth curve $p(u_1)$ lying to the right of the y-axis such that $p''(u_1) < 0$ and p has a unique maximum at $u_1 = \xi_1$. Similarly, $\{u \mid g(u) = 0\}$ is given by a smooth curve $q(u_2)$ lying to the right of the y-axis such that $q''(u_2) > 0$ and q has a unique minimum at $u_2 = \xi_2$. Furthermore, we assume that p and q intersect in four points with two intersections on each side of the vertex of either curve.

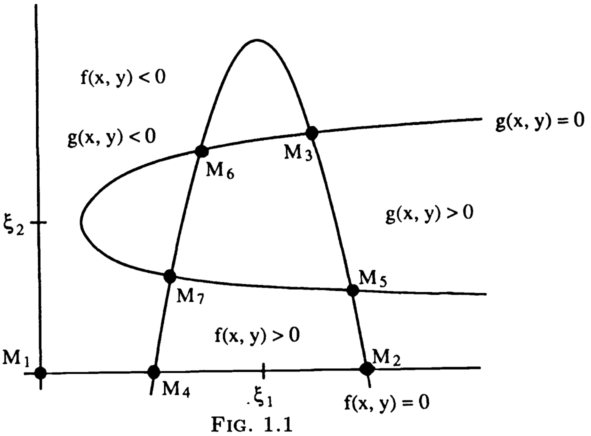

FIG. 1.1

From H1 and H2 it follows that there are seven critical points for (1.2). We label these as $M_i, i = 1, \ldots, 7$ and let (a_i, b_i) denote the coordinates of M_i.

H3. The critical points are hyperbolic.

This implies that M_1, M_2, and M_3 are attractors, M_4, M_5, and M_6 are saddle points, and M_7 is a repeller. Recall that a travelling wave for the system (1.1) is a solution of the form

$$u(x+\theta t) = (u_1(x+\theta t), u_2(x+\theta t)).$$

where θ is called the wave speed. If we set $\tau = x + \theta t$ and let $\dot{} = d/d\tau$, then (1.1) reduces to the four-dimensional system of ordinary differential equations,

$$\begin{aligned} \dot{u}_1 &= v_1, \\ \dot{u}_2 &= v_2, \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 f(u_1, u_2), \\ \mu_2 \dot{v}_2 &= \theta v_2 - u_2 g(u_1, u_2). \end{aligned} \tag{1.3}$$

Notice that the critical points of (1.2) are in 1–1 correspondence with those of (1.3). More precisely, the set of critical points of (1.3) is given by $\{M(i) = (M_i, 0) \in \mathbf{R}^4 \mid i = 1, \dots, 7\}$.

Typically, when one speaks of travelling wave solutions one incorporates the boundary conditions

$$\begin{aligned} \lim_{\tau \to -\infty} (u(\tau), v(\tau)) &= (M_i, 0), \\ \lim_{\tau \to +\infty} (u(\tau), v(\tau)) &= (M_j, 0). \end{aligned} \tag{1.4}$$

We shall refer to such a solution as an $M(i) \to M(j)$ wave. In analogy with the one species problem (see Fife [Fi, pp. 106–109] for example) if $i, j = 1, 2, 3$ we shall refer to these waves as *bistable travelling waves.* From the point of view of stability (under the dynamics of the partial differential equation (1.1)) these solutions are of special interest.[1] Another class of waves which have been extensively studied are *Fisher waves.* For the specific system we are considering here these waves satisfy the boundary conditions (1.4) with $i = 4, 5, 6$ and $j = 1, 2, 3$. Because we are studying a system where the reaction dynamics is nontrivial, "new"[2] types of waves appear. From the point of view of the dynamics of the partial differential equation (1.1) it appears that the most relevant are those that satisfy the boundary conditions (1.4) with $i = 7$ and $j = 1, 2, 3$. We shall refer to these a HDF waves (higher-dimensional Fisher waves).

As will become clear in §8, we can, for high wave speeds, give a fairly complete description of the Fisher waves and HDF waves which occur under only slightly stronger hypotheses than H1–H3. Unfortunately, we cannot treat the bistable waves in this generality.

To motivate the additional hypotheses that we are forced to make consider the existence of an $M(1) \to M(2)$ wave. Observe that $\{(u_2, v_2) = (0, 0)\}$ defines a two–dimensional invariant subspace for (1.3) on which the dynamics are determined by

$$\begin{aligned} \dot{u}_1 &= v_1, \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 f(u_1, 0). \end{aligned} \tag{1.5}$$

[1] This in no way implies that we claim to understand the stability properties of the waves whose existence we are proving. For techniques which might be applicable to some of our results, see [G-J].

[2] In this context new means that we have not seen it addressed in the literature.

Now it is easy to check that transformations $v_1 \mapsto -v_1$, $\theta \mapsto -\theta$, and $\tau \mapsto -\tau$ leaves (1.5) unchanged (in fact it leaves (1.3) unchanged). Thus there is no loss of generality in restricting our attention to $\theta \geq 0$. To simplify the presentation we shall actually search for waves that satisfy the slightly stronger assumption condition that $\theta > 0$.

Define

$$H(u_1, v_1) = \frac{\mu_1}{2} v_1^2 + \int u_1 f(u_1, 0)\, du_1. \tag{1.6}$$

Then along solutions to (1.5),

$$\frac{dH}{d\tau} = \theta v_1^2 \geq 0. \tag{1.7}$$

Thus, a necessary condition for the existence of an $M(1) \to M(2)$ wave is the assumption

$$\int_{a_1}^{a_2} u_1 f(u_1, 0)\, du_1 > 0. \tag{H4}$$

This is also a sufficient condition as the following theorem indicates.

THEOREM 1.1. *Given* H1–H4, *there exists an* $M(1) \to M(2)$ *wave for some wave speed* $\theta_{12} > 0$.

This is by now a classical result (see Fife [Fi], Conley–Gardner [C-G], or Terman [Te], for instance). For a proof in the spirit of the rest of the results of this paper see Conley [Co]. Since it is obvious how to modify the assumptions of this theorem to prove the existence of an $M(2) \to M(1)$ which lies in the $\{u_2 = v_2 = 0\}$ invariant plane we shall not explicitly discuss this problem. This comment holds throughout the rest of the discussion.

Remark. Let $(u(t), v(t))$ be a travelling wave solution, and assume that a maximal interval of monotonicity for $u_1(t)$ is $[t_0, t_1]$. Then we immediately obtain

$$0 = \left.\frac{\mu_1 v_1^2(t)}{2}\right|_{t_0}^{t_1} = \mu_1 \int_{t_0}^{t_1} v_1 \dot{v}_1\, d\tau = \int_{t_0}^{t_1} \theta v_1^2\, d\tau - \int_{t_0}^{t_1} u_1 v_1 f(u_1, u_2)\, d\tau.$$

Using the monotonicity, we observe that this integral can be parameterized by u_1, i.e.,

$$0 = \mu_1 \int_{t_0}^{t_1} \theta v_1^2\, d\tau - \int_{\alpha}^{\beta} u_1 f(u_1, u_2(u_1))\, du_1,$$

where $\alpha = u_1(t_0)$ and $\beta = u_1(t_1)$. For example, using the wave $M(1) \to M(2)$, this reduces to

$$\theta = \frac{\int_{a_1}^{a_2} u_1 f(u_1, 0)\, du_1}{\mu_1 \int_{-\infty}^{\infty} \theta v_1^2\, d\tau},$$

and H4 clearly implies that

$$\theta > 0.$$

Although this argument is trivial, it will be repeated numerous times in various forms to guarantee that the waves considered have positive wave speed.

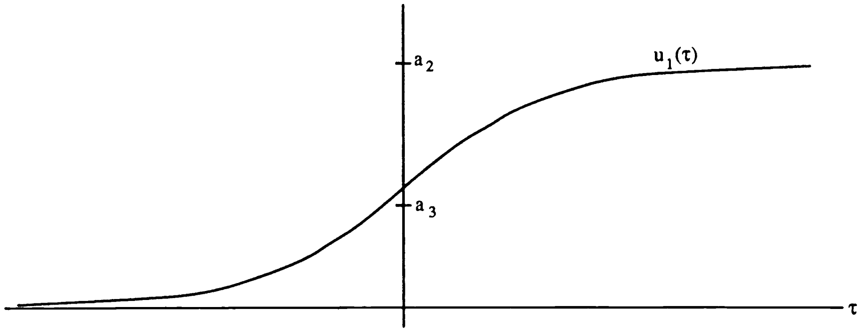

FIG. 1.2. $M(1) \to M(2)$ *wave from Theorem* 1.1.

It is enlightening, perhaps, to consider what the $M(1) \to M(2)$ waves of Theorem 1.5 look like in terms of the function $u_1(\tau)$. See Fig. 1.2.

We now turn to the first new result, namely the existence of an $M(2) \to M(3)$ wave. In this case there does not exist a simple two-dimensional invariant subspace, and hence we are forced to work with (1.3). The strategy in this case involves the following three steps.

1. Homotope the four-dimensional system to a system with an invariant two-dimensional subsystem on which the dynamics are qualitatively the same as (1.5).

2. Use the proof of Theorem 1 to conclude the existence of a wave speed for which the heteroclinic orbit occurs for the two-dimensional system.

3. Homotope back to the original problem and conclude that for some wave speed the travelling wave exists.

Since we will be using Conley index techniques, the key to this procedure is the existence of an isolating neighborhood throughout the homotopy. The following hypotheses will be used to guarantee this. Let α and γ be defined by Fig. 1.3. We assume

$$\text{(H5)} \qquad p(\xi_1) > \alpha,$$

$$\text{(H6)} \qquad \int_0^\gamma sg(a_2, s)\, ds < 0.$$

Finally, we add a hypothesis to guarantee that the wave speed is positive:

$$\text{(H7)} \qquad \int_0^{b_3} sg(a_3, s)\, ds > 0.$$

THEOREM 1.2. *Given* H1–H3, H5–H7, *there exists an* $M(2) \to M(3)$ *wave with wave speed* $\theta_{23} > 0$.

In Fig. 1.4 we indicate what the $M(2) \to M(3)$ wave of Theorem 1.2 looks like. Note that there are two possibilities: (a) where the eigenvalues of $(M_3, 0)$ are real and (b) where the eigenvalues are complex.

The next wave whose existence will be demonstrated is $M(3) \to M(1)$. This result is complicated by the fact that there does not appear to be a natural two-dimensional system towards which one can homotope. Thus instead we will homotope to a simple four-dimensional system for which the nonlinearities decouple. Again we

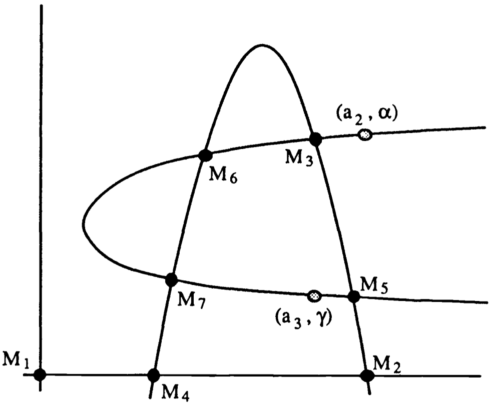

FIG. 1.3

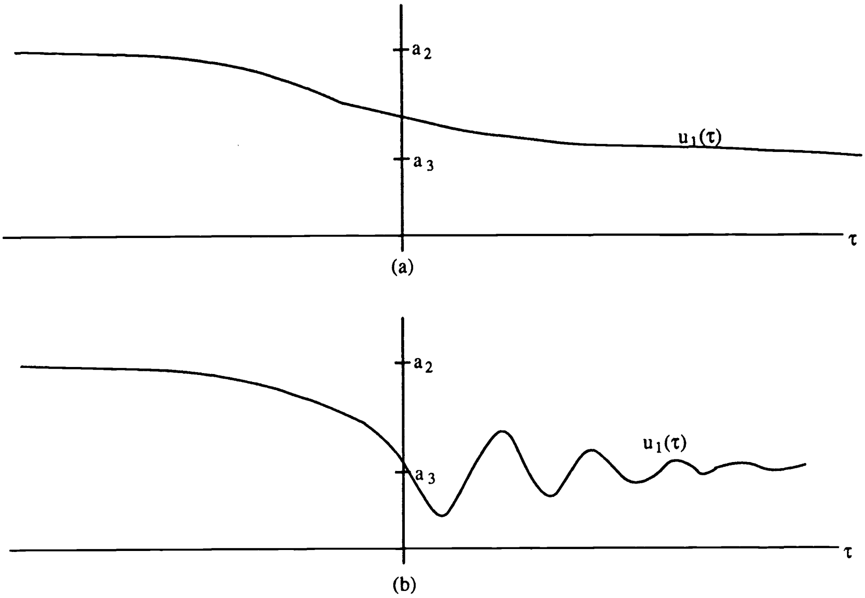

FIG. 1.4. $M(2) \to M(3)$ *wave from Theorem* 1.2.

need hypotheses to guarantee the existence of isolating neighborhoods and a positive wave speed.

$$\text{(H8)} \qquad \int_{a_4}^{a_5} sf(s, b_3)\, ds > 0,$$

$$\text{(H9)} \qquad \int_{0}^{b_3} sg(a_4, s)\, ds > 0.$$

THEOREM 1.3. *Given* H1–H3, H8, *and* H9, *there exists an* $M(3) \to M(1)$ *wave for some wave speed* $\theta_{31} > 0$.

Figure 1.5 indicates what the function $u_1(\tau)$ looks like for the $M(3) \to M(1)$ wave of Theorem 1.3. Again there are two possibilities depending on whether the eigenvalues of $(M_3, 0)$ are real (a) or complex (b).

Theorems 1.1, 1.2, and 1.3 are partial answers to question Q1. We shall now describe our results involving Q2.

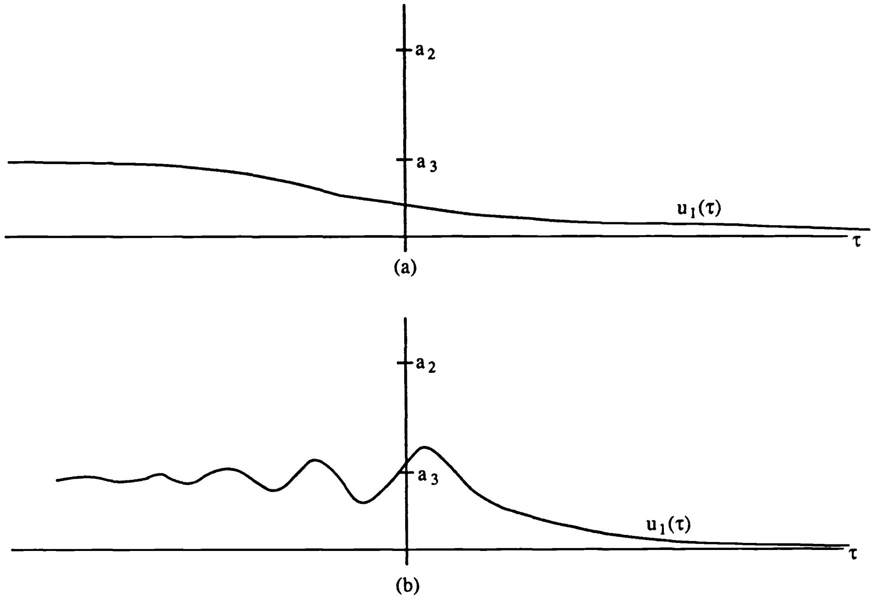

FIG. 1.5. *The* $M(3) \rightarrow M(1)$ *wave of Theorem* 1.3.

We begin by viewing (1.1) as a parameterized family of equations, namely

$$\begin{aligned}\frac{\partial u_1}{\partial t} &= \mu_1 \frac{\partial^2 u_1}{\partial x^2} + u_1 f^\lambda(u_1, u_2),\\ \frac{\partial u_2}{\partial t} &= \mu_2 \frac{\partial^2 u_2}{\partial x^2} + u_2 g^\lambda(u_1, u_2),\end{aligned} \tag{1.8}$$

where $\lambda \in [0,1]$. Furthermore, we assume that the hypothesis H1–H9 are satisfied for all values of λ. In this case Theorems 1.1, 1.2, and 1.3 apply and hence for each $\lambda \in [0,1]$ there exist positive wave speeds, θ^λ_{12}, θ^λ_{23}, and θ^λ_{31}, for which corresponding travelling waves occur. We would like to show that for some choice of nonlinearities additional bistable waves occur; e.g., $M(1) \rightarrow M(3)$, $M(2) \rightarrow M(1)$, $M(3) \rightarrow M(2)$, also with positive wave speed.

Unfortunately, at this point an additional complication arises, namely, the possibility that the wave speeds are not unique. It is well known that the $M(1) \rightarrow M(2)$ waves which satisfy (1.5) occur at a unique positive wave speed θ^λ_{12}, however, there are no corresponding results known regarding θ^λ_{23} and θ^λ_{31}. For each fixed λ, let $\bar{\theta}^\lambda_{23}$ denote the fastest wave speed and $\underline{\theta}^\lambda_{23}$ the slowest wave speed for which an $M(2) \rightarrow M(3)$ travelling wave occurs for (1.8^λ). By our assumptions $0 < \underline{\theta}^\lambda_{23} \leq \bar{\theta}^\lambda_{23} < \infty$. Let $I^\lambda_{23} = [\underline{\theta}^\lambda_{23}, \bar{\theta}^\lambda_{23}] \subset (0,\infty)$ and $I^\lambda_{31} = [\underline{\theta}^\lambda_{31}, \bar{\theta}^\lambda_{31}]$.

THEOREM 1.4. *Assume that for* $\lambda = 0$, *and* $i \neq j \neq k \neq i$, $\underline{\theta}^0_{ik} > \bar{\theta}^0_{kj}$ *and for* $\lambda = 1$, $\bar{\theta}^1_{ik} < \underline{\theta}^1_{kj}$, *there then exists an open interval* $\Lambda \subset [0,1]$, *such that for* $\lambda \in \Lambda$, *there exists an* $M(i) \rightarrow M(j)$ *wave which passes close to* $(M_k, 0)$ *and which has wave speed* $\theta^\lambda_{ij} > 0$.

It should be noted that the proof of this theorem works equally well if we assume that $\bar{\theta}^0_{ik} < \underline{\theta}^0_{kj}$ and $\underline{\theta}^1_{ik} > \bar{\theta}^1_{kj}$.

The implications of this theorem is most easily understood via Fig. 1.6, where the case $i = 2$, $j = 1$, and $k = 3$ is shown. Again there are two cases depending on the nature of the eigenvalues at $(M_3, 0)$. These drawings should be contrasted with that of Fig. 1.2.

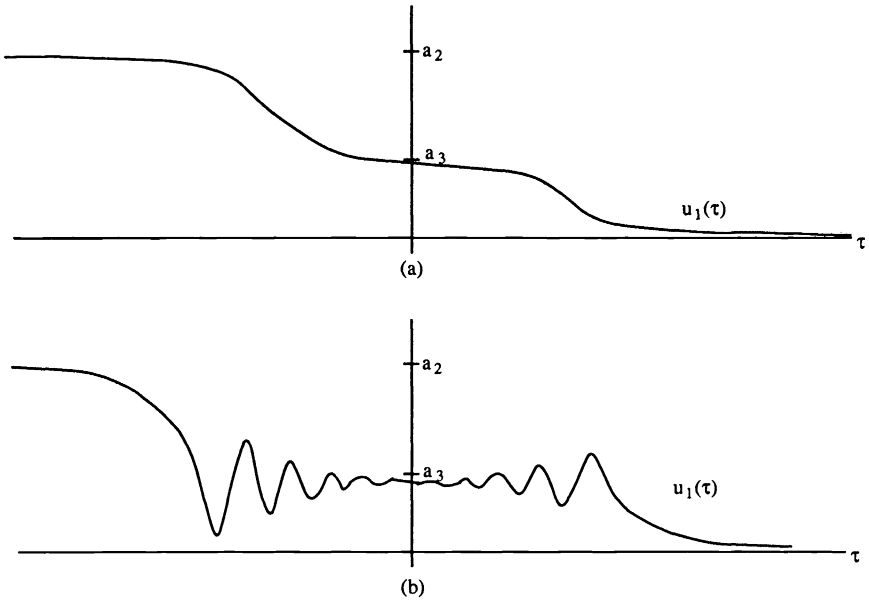

FIG. 1.6. *$M(2) \to M(1)$ wave of Theorem* 1.4.

Finally, we shall prove that for some set of nonlinearities there exist homoclinic pulse waves. Recall the notation of Theorem 1.4. In particular, for $\lambda \in \Lambda$, let θ_{ij}^{λ} denote the wave speed of the $M(i) \to M(j)$ wave of Theorem 1.4 and let θ_{ji}^{λ} denote the wave speed of the $M(j) \to M(i)$ wave of Theorems 1.1, 1.2, and 1.3.

THEOREM 1.5. *Let the interval $[a,b] \subset \Lambda$, and assume that $\underline{\theta}_{ij}^{a} > \bar{\theta}_{ji}^{a}$ and $\bar{\theta}_{ij}^{b} < \underline{\theta}_{ji}^{b}$. Then there exists an open interval $\widetilde{\Lambda} \subset \Lambda$, such that for $\lambda \in \widetilde{\Lambda}$ there exists an $M(i) \to M(i)$ wave which passes close to $(M_j, 0)$ and $(M_k, 0)$ and which has wave speed $\theta_{ii}^{\lambda} > 0$.*

Again, the implications of this result are explained in Fig. 1.7 (where $i = 2$), and depends on the eigenvalues at $(M_3, 0)$.

A large part of this paper is concerned with proving Theorems 1.2–1.5. In §2, the relevant definitions and theorems from the Conley index theory are presented. The proofs of Theorems 1.2 and 1.3 appear in §3 and §5, respectively. However, the latter result depends on understanding a complicated homotopy from a product system to the desired system. This is discussed in §4. In §6 the proofs of Theorems 1.4 and 1.5 are presented. This is followed in the next section by a construction to show that the abstract algebraic results of §6 are realizable for our particular class of predator-prey systems. We include a discussion in an attempt to convince the reader that these techniques are, in fact, applicable to a wide variety of travelling wave problems.

In §8 we return to the question of Fisher waves and HDF waves. The key to the existence proofs are two abstract results, Theorems 8.1 and 8.7. Since the theorems make it trivial to determine the existence of certain waves, the emphasis of this section is on explaining how they can be applied rather than formal existence theorems for the predator-prey system. Finally in §9 the proofs of Theorem 8.1 and Corollary 8.2 are presented.

2. Definitions and notation.

This section presents some of the definitions, notations, ideas, and theorems related to the Conley index theory. However, it is assumed that the reader is already familiar with these ideas (see Conley [Co], Salamon

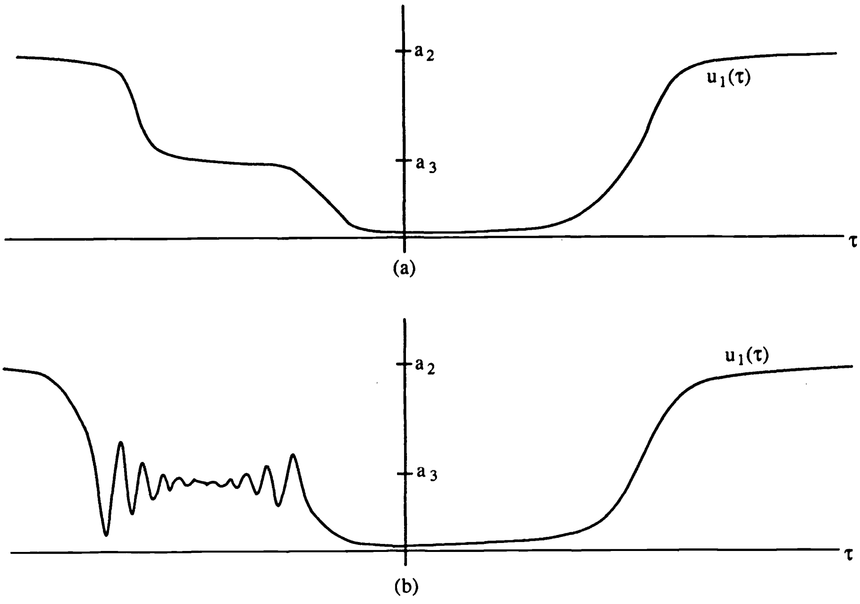

FIG. 1.7. *$M(2) \to M(2)$ wave of Theorem* 1.5.

[Sa], Smoller [Sm], Franzosa [Fr], or Moeckel [Mo]).

Let $\phi : \mathbf{R} \times X \to X$ be a flow on a locally compact space. Given a compact set N, let

$$N^T = \{x \in N \mid \phi([-T, T], x) \subset N\}.$$

N is called an *isolating neighborhood* if there exists $T > 0$ such that $N^T \subset \operatorname{int}(N)$. Let $N^\infty = \bigcap_{T>0} N^T$. It is easy to check that N^∞ is an invariant set, i.e., $\phi(\mathbf{R}, N^\infty) = N^\infty$. Clearly, N is an isolating neighborhood if and only if $x \in N^\infty$ implies $x \notin \partial N$. An invariant set S is called *isolated* if there exists an isolating neighborhood N of S such that $S = N^\infty$. We shall also use $I(N)$ to denote N^∞.

A simple but, as we shall see, useful decomposition of an invariant set S is that of an *attractor-repeller* (A-R) pair. Let $\omega(U)$ and $\omega^*(U)$ denote the omega and alpha limit sets of U, respectively. $A \subset S$ is called an *attractor* in S if there exists a neighborhood U of A such that $\omega(U \cap S) = A$. The *dual repeller* of A, denoted by A^* is defined by $A^* = \{x \in S \mid \omega(x) \cap A = \emptyset\}$. The pair (A, A^*) make up an A-R pair. Notice that given an A-R pair decomposition of S, if $x \in S$ then $x \in A \cup A^*$ or $\omega(x) \subset A$ and $\omega^*(x) \subset A^*$, i.e., S is made up of the attractor A, its dual repeller A^*, and connecting orbits from A^* to A. Thus, if one lets $C(A^*, A)$ denote the set of connecting orbits from A^* to A, then $S = A \cup A^* \cup C(A^*, A)$.

Since in our proof the complicated four-dimensional problem will be homotoped to a simple two- or four-dimensional problem we need to discuss what is meant by continuing isolating neighborhoods and isolated invariant sets. Consider a parameterized family of flows $\phi(t, x, \sigma) = \phi^\sigma(t, x)$, where $\sigma \in [0, 1]$ is the parameter value. Define the parameter flow to be $\Phi : \mathbf{R} \times X \times [0, 1] \to X \times [0, 1]$ by

$$\Phi(t, x, \sigma) = (\phi^\sigma(t, x), \sigma).$$

Let N^σ denote an isolating neighborhood for the flow ϕ^σ. One says that the isolating neighborhood N^1 continues to N^0 if there exists N an isolating neighborhood of Φ, the parameter flow, such that $N|_{X \times \{0\}} = N^0$ and $N|_{X \times \{1\}} = N^1$. Similarly, if S^σ denotes an isolated invariant set under ϕ^σ, then S^0 continues to S^1 if there exist corresponding isolating neighborhoods which continue.

For our applications, the homotopy we have in mind takes the form

$$(TW^{\theta,\sigma}) \qquad \begin{aligned} \dot{u}_1 &= v_1, \\ \dot{u}_2 &= v_2, \\ \mu_1^\sigma \dot{v}_1 &= \theta v_1 - u_1 f^\sigma(u_1, u_2), \\ \mu_2^\sigma \dot{v}_2 &= \theta v_2 - u_2 g^\sigma(u_1, u_2), \end{aligned}$$

where $\sigma \in [0,1]$ is the homotopy parameter. It will always be assumed that at $\sigma = 0$ we have the system of interest, namely, (1.3), and at $\sigma = 1$ we have a simpler system, i.e. one which we can analyze directly. The corresponding family of reaction systems is given by

$$(R^\sigma) \qquad \begin{aligned} \dot{u}_1 &= u_1 f^\sigma(u_1, u_2), \\ \dot{u}_2 &= u_2 g^\sigma(u_1, u_2). \end{aligned}$$

We now state an abstract theorem which will be used in §3 to prove Theorem 1.2, and a modification of which shall be used in §5 to prove Theorem 1.3.

Assumption 1. For the reaction system (R^1) there exists a one-dimensional attracting invariant affine subspace $L \subset \mathbf{R}^n$. Furthermore, the dynamics on L are as in Fig. 2.1, i.e., the set of bounded solutions consist of the hyperbolic critical points $\{A, B, C\}$ and the heteroclinic connections $C \to A$ and $C \to B$.

We now state the assumption concerning the homotopy from $\sigma = 1$ to $\sigma = 0$. Let $A_0^1 = (A^1, 0), B_0^1 = (B^1, 0)$, and $C_0^1 = (C^1, 0)$.

Assumption 2. A^σ and B^σ continue as critical points for (R^σ) and N^σ continue as isolating neighborhoods for $(TW^{c,\sigma})$ such that (B_0^σ, A_0^σ) is an attractor-repeller pair for $(N^{c,\sigma})^\infty$, the invariant set isolated by N^σ under the flow generated by $(TW^{c,\sigma})$. Furthermore, for $\sigma = 1$, if there exists an $A_0^1 \to B_0^1$ solution to $(TW^{c,1})$ for some value of c, then the connecting orbit belongs to $(N^{c,1})^\infty$.

FIG. 2.1 *The dynamics on L.*

THEOREM 2.1 [M-H, Thm. 3.1]. *Given Assumptions* 1 *and* 2, *there exists a bistable travelling wave from* A_0 *to* B_0 *for some wave speed* θ_{AB}.

As will be seen most of §3 is dedicated to verifying Assumption 2.

Assumption 1 is equivalent to finding an invariant two-dimensional subspace for $(TW^{\theta,1})$ on which the dynamics is qualitatively equivalent to that of (1.5). For proving the existence of the $M(3) \to M(1)$ wave, this does not appear to be possible. Thus we need a weaker version of Assumption 1. This will be discussed in §4 and requires connection matrix and transition matrix techniques. For these purposes we shall adopt the following conventions.

The $\mathbf{Z}_2$ homology Conley index of S is denoted and defined by

$$CH_*(S) := H_*(N/L, [L]; \mathbf{Z}_2),$$

where (N, L) is an index pair for S. Given a Morse decomposition of S, $\mathbf{M}(S) = \{M(i) \mid i \in (P, >)\}$, where P is the indexing set for the Morse sets $M(i)$ and $>$ is a strict partial order on P, recall that the connection matrix is a linear map

$$\Delta : \bigoplus_{i \in P} CH_*(M(i)) \longrightarrow \bigoplus_{i \in P} CH_*(M(i)).$$

We shall always take the direct sum according to a nonincreasing order in P. This has the effect of making Δ into a strictly upper triangular matrix.

For (N, L) an index pair for S, the homotopy type of the pointed space $(N/L, [L])$ is usually referred to as the Conley index of S and is denoted $h(S)$. There exists, however, a finer version of the index which will be used in the proof. A *connected simple system* consists of a collection I_o of pointed spaces along with a collection I_m of homotopy classes of maps between these such that:

1. $\hom(X, X') = \{[f] \in [X, X'] \mid [f] \in I_m\}$ is nonempty and consists of a single element for each ordered pair X, X' of spaces in I_o;

2. if $X, X', X'' \in I_o, [f] \in \hom(X, X')$, and $[f'] \in \hom(X', X'')$, then $[f' \circ f] \in \hom(X, X'')$;

3. $\hom(X, X) = \{[1_X]\}$ for all $X \in I_m$.

Recall ([Co], [Sa]) that the Conley index of S forms a connected simple system where $I_o = \{(N/L, [L]) \mid (N, L) \text{ is an index pair for } S\}$ and I_m consists of the flow defined maps between the elements of I_o. The connected simple system of the Conley index of S is denoted by $I(S)$. The following result ([Co], [Sa]) is crucial to our analysis.

PROPOSITION 2.2. *If (A^c, A^{c*}) is an attractor repeller pair for S^c which continues for $c \in \mathbf{R}$ and $S^{c_i} = A^{c_i} \cup A^{c_i*}$ when $i = 0, 1$, but $I(S^{c_0}) \not\cong I(S^{c_1})$, then for some $c \in (c_0, c_1)$ there exists a connecting orbit from A^{c*} to A^c.*

It should be noted that the proof of Theorem 2.1 uses this proposition. In fact, a cursory reading of the proof [M-H, Appen.] shows that if the bistable wave is found via Theorem 2.1 then the connected simple systems at large and small wave speed differ.

3. The $M(2) \to M(3)$ travelling wave.

In this section we prove Theorem 1.2, i.e., we show that there is a $M(2) \to M(3)$ travelling wave provided assumptions H1–H3 and H5–H7 are satisfied. Recall that α and γ are defined in Fig. 1.3. Choose $l > \alpha$ such that $f(\xi_1, \alpha) > 0$ (we can do this by H5). Choose $h > a_2$ such that $\int_0^\gamma sg(h, s)\, ds < 0$ and such that $\{\, (x, l) \mid \xi_1 \le x \le h \,\}$ lies in the region $\{g < 0\}$. We can always do this by the assumptions on g. Choose k and m such that $\{\, (x, k) \mid \xi_1 \le x \le h \,\}$ lies in the region $\{g > 0\}$, and $\{\, (x, y) \mid \xi_1 \le x \le h, 0 \le y \le m \,\}$ lies in the region $\{g < 0\}$.

To prove Theorem 1.2, we use Theorem 2.1 and continue to a system where g is unchanged and $f(x, y)$ is independent of y. See Fig. 3.1. Clearly one can choose a deformation so that the assumptions hold for $(TW^{\theta,\sigma})$ for $\sigma \in [0, 1)$. In particular, the integral in assumption H7 can be bounded throughout the deformation, so by the Remark following Theorem 1.1 the wave speed will be bounded away from zero. For each σ we will construct an isolating neighborhood which contains only the critical points $M(2)$ and $M(3)$, plus any connecting orbits between the points. The construction we make will also construct an isolating neighborhood for $\sigma = 1$, so we can apply Theorem 2.1 and conclude the existence of an $M(2) \to M(3)$ travelling wave.

Let $N_3 = [\xi_1, h] \times [k, l]$, $N_4 = [\xi_1, h] \times [m, l]$, and $N_5 = [\xi_1, h] \times [-e, m]$ for small positive e. These will be the u projections of our isolating neighborhood. For $K, \epsilon > 0$,

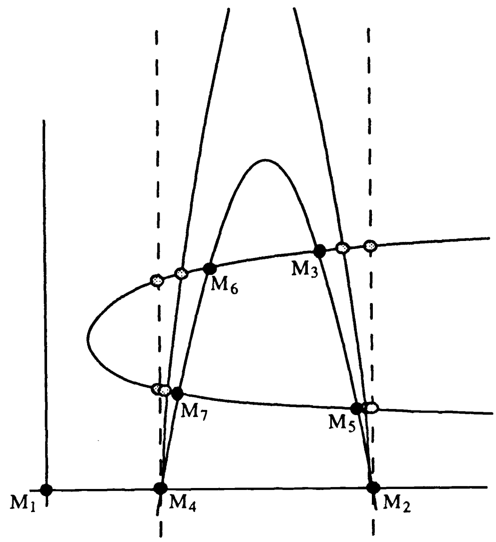

FIG. 3.1

define

$$\bar{N}_3 = N_3 \times [-K, K] \times [-K, K],$$

$$\bar{N}_4 = N_4 \times [-K, 0] \times [0, K],$$

$$\bar{N}_5 = N_5 \times [-K, K] \times [-K, K],$$

$$\bar{N}_{K,\epsilon} = (\bar{N}_3 \cup \bar{N}_4 \cup \bar{N}_5) \setminus B_\epsilon(M(5)).$$

See Fig. 3.2. Via a series of lemmas we will show that for K big enough and ϵ small enough, $\bar{N}_{K,\epsilon}$ is an isolating neighborhood.

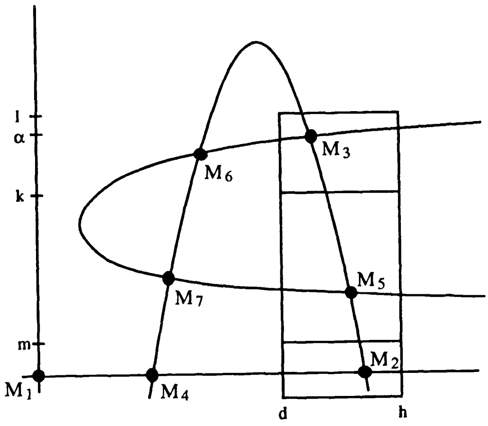

FIG. 3.2

LEMMA 3.1. *For any K, $I(\bar{N}_3) = M(3)$.*

Proof. Suppose there is some nonconstant orbit which stays in $\bar{N}_3$ for all time. Let $B = \{ (u_1, u_2) \mid x_1 \leq u_1 \leq x_2,\ y_1 \leq u_1 \leq y_2 \}$ be the smallest rectangular box containing the u-projection of the orbit. Since B is the smallest such box, somewhere on the top edge there is a point (u_1, y_2) such that when the u-projection of the orbit passes through the point, $v_2 = 0$ and $\dot{v}_2 \leq 0$. At this point we must have $-y_2 g(u_1, y_2) \leq 0$, i.e., $g(u_1, y_2) \geq 0$. It follows that $g(x_2, y_2) \geq 0$. By looking at the other edges of B, we can conclude that $f(x_2, y_1) \geq 0$, $g(x_1, y_1) \leq 0$, and $f(x_1, y_2) \geq 0$. Assumption H5 plus the concavity assumptions on p and q make it impossible for such a closed box to exist, so there is no recurrent orbit, and the only orbit which stays in $\bar{N}_3$ for all time is the critical point $M(5)$. □

LEMMA 3.2. *For any K, $I(\bar{N}_5) = M(2)$.*

Proof. We first show $I(N_5 \times [-K, K] \times [-K, K])$ is contained in the invariant plane $\{u_2 = v_2 = 0\}$. If $v_2 = 0$, then $\mu_2 \dot{v}_2 = -u_2 g(u)$, and since $g(u) < 0$ in N_5, the sign of $\dot{v}_2$ is the same as the sign of u_2 when $v_2 = 0$. Thus if $u_2 > 0$, and $v_2 > 0$, v_2 cannot change sign along the forward orbit and the orbit leaves $\bar{N}_5$ in forward time. If $u_2 > 0$ and $v_2 < 0$, then the orbit leaves $\bar{N}_5$ in backward time. If $u_2 < 0$, then a similar argument shows that the u-projection of the orbit leaves the bottom of N_5 in one direction or the other. Finally, if $u_2 = 0$ and $v_2 \neq 0$, then there are points on the orbit with $u_2 \neq 0$, so the orbit must leave. □

Notice that the proof of Lemma 3.2 actually shows that for an $M(2)$ to $M(3)$ connecting orbit, $v_2 > 0$ in $N_5 \times [-K, K] \times [-K, K]$. By Lemmas 3.1 and 3.2, and the fact that u_1 acts as a Lyapunov function in the region with u-projection in N_4, the only orbits which can stay in $\bar{N}_{K,\epsilon}$ for all time are connecting orbits from $M(2)$ to $M(3)$. To show that $\bar{N}_{K,\epsilon}$ is an isolating neighborhood, we must show that no *connecting* orbit is internally tangent to $\bar{N}_{K,\epsilon}$. For sufficiently large K, if $v_i = K$, then the u-projection of the orbit leaves $N_3 \cup N_4 \cup N_5$, so no internal tangencies can occur at $v_i = K$. Also, no orbit can be internally tangent to the top of N_3, the bottom of N_5, or the left or right side of the N_i. If $u_2 = l$, for example, and $v_2 \neq 0$, then the orbit leaves immediately. If $v_2 = 0$, then $\mu_2 \dot{v}_2 = -u_2 g(u) > 0$ so the orbit is externally tangent. The argument which shows that orbits tangent to the bottom and sides are externally tangent in u-space is similar.

LEMMA 3.3. *If (u, v) is a point on a connecting orbit in $\bar{N}_{K,\epsilon}$ and $u \in N_4$, then $v_i \neq 0$ for $i = 1, 2$.*

Proof. First assume that $u \in \operatorname{int}(N_4)$. If $v_1 = 0$ and $\dot{v}_1 \neq 0$, then the orbit leaves $\bar{N}_K$ immediately in one direction or the other. If $v_1 = 0$ and $\dot{v}_1 = 0$, then $-u_1 f(u) = 0$, and since $u_1 > 0$ in $\bar{N}_K$, we must have $f(u) = 0$. Thus if (u, v) is on a connecting orbit and $v_1 = \dot{v}_1 = 0$, then u must lie on the segment of $\{f = 0\}$ between M_2 and M_3. At this point we have

$$\mu_1 \ddot{v}_1 = \theta \dot{v}_1 - v_1 f(u) - u_1 v_1 f_1(u) - u_1 v_2 f_2(u) = -u_1 v_2 f_2(u).$$

(Here f_1 denotes the partial derivative with respect to the first argument.) If $v_2 > 0$, then $\ddot{v}_1 > 0$ and the orbit leaves in forward time. If $v_2 = 0$, then $\dot{v}_2 \neq 0$ (or else we're at a critical point), so the orbit leaves in one direction or the other. Thus v_1 cannot be zero.

If $v_2 = 0$ and $\dot{v}_2 \neq 0$, then the orbit leaves immediately in one direction or the other as noted above. If $\dot{v}_2 = 0$, then $g(u) = 0$. Parameterize time so that

$(u, v) = (u(0), v(0))$. Since $v_2 \geq 0$ we can parameterize the orbit by u_2. We get

$$\begin{aligned} 0 = \mu_2 v_2^2(0)/2 = \mu_2 \int_{-\infty}^{0} v_2 \dot{v}_2 \, d\tau &= \int_{-\infty}^{0} \theta v_2^2 \, d\tau - \int_{-\infty}^{0} u_2 v_2 g(u_1, u_2) \, d\tau \\ &= \int_{-\infty}^{0} \theta v_2^2 \, d\tau - \int_{0}^{u_2(0)} s g(u_1(s), s) \, ds \\ &\geq \int_{-\infty}^{0} \theta v_2^2 \, d\tau - \int_{0}^{u_2(0)} s g(h, s) \, ds \\ &> 0. \end{aligned}$$

The first inequality follows from the fact that $g_1 > 0$, and the integral in the scond term of that line is negative by assumption H6. This chain of inequalities is impossible, so (u, v) cannot be on a connecting orbit. We have thus proved the lemma for the case $u \in \operatorname{int}(N_4)$.

If u is on the left or right edge of N_4 and $v_1 = 0$, then the orbit leaves $\bar{N}_{K,\epsilon}$ in both directions. If $v_2 = 0$ and $v_1 \neq 0$, then the orbit leaves $\bar{N}_{K,\epsilon}$ in one direction. If $u \in N_4 \cap N_5$, i.e., if $u_2 = m$, and $v_2 = 0$, then $\dot{v}_2 > 0$, so the orbit leaves in backward time. If $u_2 = m$, and $v_1 = 0$, then $\mu_1 \dot{v}_1 = -u_1 f(u)$. If $f(u) < 0$, then the orbit leaves $\bar{N}_{K,\epsilon}$ in forward time (since $v_2 > 0$). Similarly, if $f(u) = 0$, then $\ddot{v}_1 = -u_1 v_2 f_2(u) > 0$ so the orbit leaves. If $f(u) > 0$, then $u_1 < a_2$, and if we follow the backward orbit, it moves in the direction of decreasing u_1 (i.e., $v_1 > 0$). This cannot change unless f changes sign (which can only occur of the backward orbit exits N_5 to the left), or u_1 changes sign, which by the remark following the proof of Lemma 3.2 cannot occur on a connecting orbit. Thus (u, v) is not on a connecting orbit if $u_2 = m$ and $v_1 = 0$. The argument for $u \in N_4 \cap N_3$ is similar. □

We now have shown that the only possible internal tangencies can come from connecting orbits which are close to the rest point $M(5)$. The next lemma states that orbits cannot come too close to $M(5)$.

LEMMA 3.4. *There is an $\epsilon > 0$ such that if γ is a connecting orbit then $\gamma \cap B_\epsilon(M(5)) = \emptyset$.*

Proof. Suppose not. Then there is a sequence $\epsilon_n \to 0$ and points (u_n, v_n) on connecting orbits from $M(2)$ to $M(3)$ such that $(u_n, v_n) \in B_{\epsilon_n}(M(5))$. It follows that there is a connecting orbit $(u(t), v(t))$ from $M(2)$ to $M(5)$ (since u_1 is a Lyapunov function). We can again use u_2 as a parameter along the orbit and we obtain

$$\begin{aligned} 0 = \mu_2 \int_{-\infty}^{\infty} v_2 \dot{v}_2 \, d\tau &= \int_{-\infty}^{\infty} \theta v_2^2 \, d\tau - \int_{-\infty}^{0} u_2 v_2 g(u_1, u_2) \, d\tau \\ &= \int_{-\infty}^{\infty} \theta v_2^2 \, d\tau - \int_{0}^{b_5} s g(u_1(s), s) ds \\ &\geq \int_{-\infty}^{\infty} \theta v_2^2 \, d\tau - \int_{0}^{b_5} s g(h, s) ds \\ &> 0. \end{aligned}$$

This is a contradiction. □

Putting together Lemmas 3.1–3.4, it follows that we have an isolating neighborhood for each σ during the deformation, so by Theorem 2.1, there is a $M(2)$ to $M(3)$ travelling wave, and the proof of Theorem 1.2 is complete. □

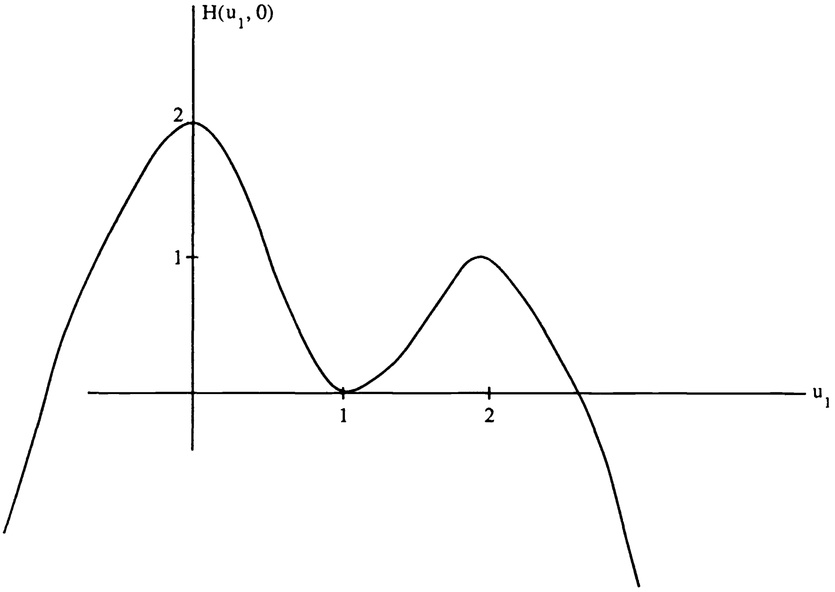

FIG. 4.1

4. The product system. In this section we will analyze the existence of a bistable travelling wave for a very simple system. The purpose of this analysis is to provide a system to which (1.3) can be homotoped in order to prove Theorem 1.3.

Consider the product system

$$(P^\theta) \qquad \begin{aligned} \dot{u}_1 &= v_1 \\ \dot{u}_2 &= v_2 \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 h(u_1) \\ \mu_2 \dot{v}_2 &= \theta v_2 - u_2 h(u_2), \end{aligned}$$

where $\theta > 0$ and define $H : \mathbb{R}^2 \to \mathbb{R}$ by

$$H(u_1, u_2) = \int^{u_1} \xi h(\xi)\, d\xi + \int^{u_2} \xi h(\xi)\, d\xi.$$

Furthermore, assume $H(u_1, 0)$ is as in Fig. 4.1, i.e., it has exactly three nondegenerate critical points at $u_1 = 0, 1, 2$ and it takes the values $H(0,0) = 2, H(1,0) = 0$ and $H(2,0) = 1$.

Observe that if we define

$$\mathcal{H}(u, v) = \tfrac{1}{2} \langle v, v \rangle + H(u),$$

then $d\mathcal{H}/d\tau = \theta \langle v, v \rangle$, i.e., $\mathcal{H}$ acts as a Lyapunov function for (P^θ). Fig. 4.2 indicates the (u_1, u_2) coordinates for the set of critical points of (P^θ) and their respective values under $\mathcal{H}$.

Observe that the u_2-axis defines an invariant two-dimensional subspace for the system (P^θ). Let C_3 equal the set of all bounded orbits lying in the space $u_1 = v_1 = 0$. One can check that C_3 is an isolated invariant set.

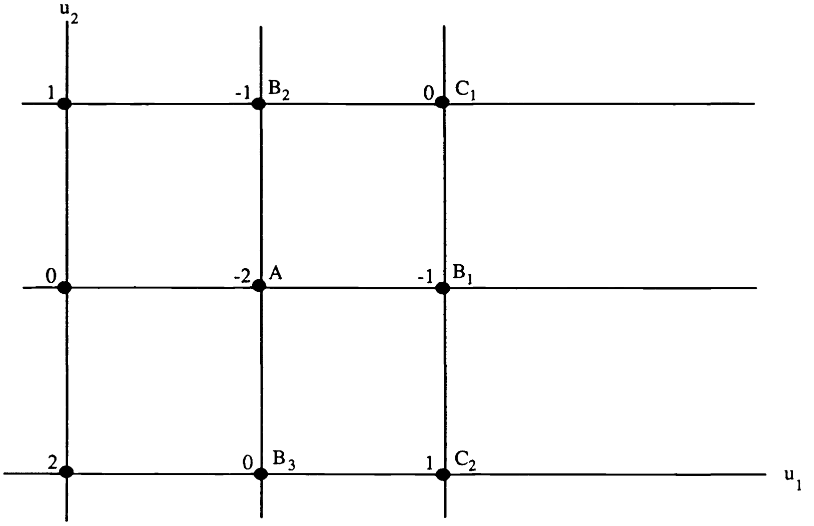

FIG. 4.2

Let S denote the set of bounded solutions to (P^θ), then S is an isolated invariant set and

$$CH_n(S) \approx \begin{cases} \mathbf{Z}_2 & \text{if } n = 2, \\ 0 & \text{otherwise.} \end{cases}$$

A Morse decomposition of S is given by

$$\mathcal{M}(S) = \{A, B_i, C_i \mid i = 1, 2, 3\}.$$

Furthermore, $\mathcal{H}$ and the fact that (P^θ) is a product system implies that the following is an admissible order on $\mathcal{M}(S)$

$$A > B_i > B_3 > C_i > C_3,$$

where $i = 1, 2$. A simple computation leads to the Conley indices of the Morse sets. In particular,

$$CH_n(A) \approx \begin{cases} \mathbf{Z}_2 & \text{if } n = 4, \\ 0 & \text{otherwise,} \end{cases}$$

$$CH_n(B_i) \approx \begin{cases} \mathbf{Z}_2 & \text{if } n = 3, \\ 0 & \text{otherwise,} \end{cases}$$

$$CH_n(C_i) \approx \begin{cases} \mathbf{Z}_2 & \text{if } n = 2, \\ 0 & \text{otherwise.} \end{cases}$$

We now wish to compute the connection matrices of $\mathcal{M}(S)$ for θ small and large. For θ large, the dynamics of (P^θ) are approximated by that of the reaction system (see §8)

$$\dot{u}_i = u_1 h(u_1),$$
$$\dot{u}_2 = u_2 h(u_2).$$

It is left to the reader to check that the appropriate connection matrix in this setting is

$$\Delta^\infty = \begin{array}{c} \\ C_3 \\ C_2 \\ C_1 \\ B_3 \\ B_2 \\ B_1 \\ A \end{array} \begin{array}{c} \begin{array}{ccccccc} C_3 & C_2 & C_1 & B_2 & B_2 & B_1 & A \end{array} \\ \left(\begin{array}{ccccccc} & & & 1 & 1 & 0 & \\ & & & 1 & 0 & 1 & \\ & & & 0 & 1 & 1 & \\ & & & & & & 1 \\ & & & & & & 1 \\ & & & & & & 1 \\ & & & & & & \end{array} \right) \end{array}.$$

For $0 < \theta << 1$, the connection matrix is given by

$$\Delta^0 = \begin{pmatrix} & & & 0 & 0 & 0 & \\ & & & 1 & 0 & 1 & \\ & & & 0 & 1 & 1 & \\ & & & & & & 1 \\ & & & & & & 1 \\ & & & & & & 1 \\ & & & & & & \end{pmatrix}.$$

This is easily obtained by comparing the dynamics of

$$\begin{aligned} \dot{u}_1 &= v_1, \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 h(u_1), \end{aligned}$$

with that of

$$\begin{aligned} \dot{u}_1 &= v_1, \\ \mu_1 \dot{v}_1 &= -u_1 h(u_1). \end{aligned}$$

(For more details see Mischaikow [Mi1].)

Since $\mathcal{H}$ acts as a Lyapunov function for all $\theta \in (0, \infty)$ and since the Morse decomposition is valid for all these values of θ, there exists an upper triangular degree-0 isomorphism

$$T = \begin{pmatrix} 1 & x & y & & & & \\ 0 & 1 & z & & & & \\ 0 & 0 & 1 & & & & \\ & & & 1 & a & b & \\ & & & 0 & 1 & 0 & \\ & & & 0 & 0 & 1 & \\ & & & & & & 1 \end{pmatrix},$$

which satisfies the equation (see Franzosa and Mischaikow [F-M])

$$\Delta^0 T + T \Delta^\infty = 0.$$

This implies that $x = y = 1$. Now a result of McCord and Mischaikow [M-M] implies the following.

PROPOSITION 4.1. *The connected simple system for the attractor repeller pair* (C_3, C_1) *differ at* $\theta \approx \infty$ *and* $\theta \approx 0$.

Observe that because (P^θ) is a product system it is easy to check that $S \subset [0,2] \times [0,2] \times \mathbb{R}^2$. Thus, changing the dynamics outside a neighborhood of $[0,2] \times [0,2] \times \mathbb{R}^2$ will have no effect on Proposition 4.1 as long as one restricts attention to the invariant set inside $[0,2] \times [0,2] \times \mathbb{R}^2$. Therefore, we claim that Proposition 4.1 holds for the following system

$$\begin{aligned}\dot{u}_1 &= v_1,\\ \dot{u}_2 &= v_2,\\ \dot{v}_1 &= \theta v_1 - u_1 h_1(u_1,u_2),\\ \dot{v}_2 &= \theta v_2 - u_2 h_2(u_1,u_2),\end{aligned}$$

where $h_i(u_1,u_2) = h(u_i)$ for (u_1,u_2) in a neighborhood of $[0,2] \times [0,2]$ and the zero sets for the functions are as shown in Fig. 4.3.

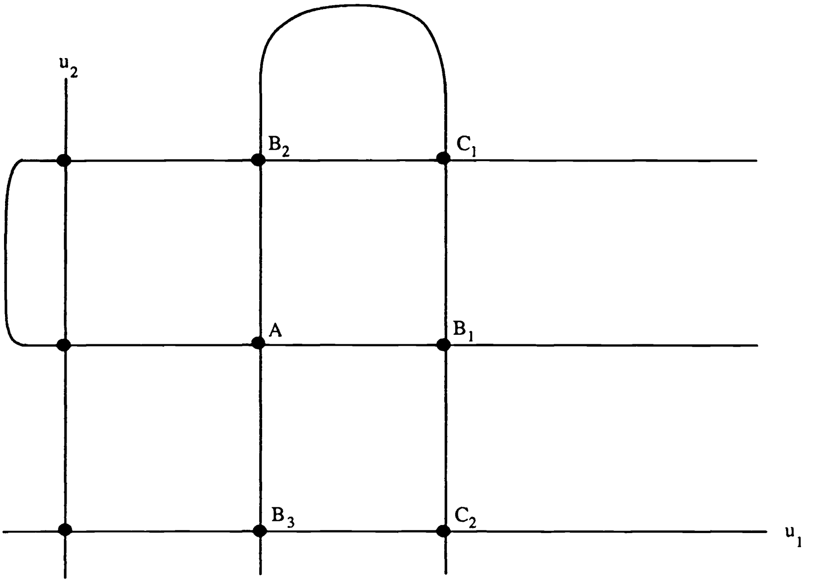

FIG. 4.3

Now recall, that the Conley index is stable under perturbations. Thus Proposition 4.1 holds for the system

$$\begin{aligned}\dot{u}_1 &= v_1,\\ \dot{u}_2 &= v_2,\\ \dot{v}_1 &= \theta v_1 - u_1 f^1(u_1,u_2),\\ \dot{v}_2 &= \theta v_2 - u_2 g^1(u_1,u_2),\end{aligned}$$

where f^1 is a perturbation of h_1 and g^1 is a perturbation of h_2 such that hypothesis H1–H3, H5, H8–H9 are satisfied. The existence of such f^1 and g^1 is clear when one notes that one can choose h such that H5, H8, and H9 are satisfied for system (P^θ).

5. The $M(3) \to M(1)$ travelling wave.

In this section we show that there is a $M(3) \to M(1)$ travelling wave. Choose l, n, d, r, and h as in Fig. 5.1, i.e., the box with corners (d,n), (d,l),(r,n), and (r,l) has its left side in the region $\{f > 0\}$, its right side in the region $\{f < 0\}$, its top in the region $\{g < 0\}$, and its bottom in the region $\{f > 0\}$. Also, choose $r < a_5$, and $n > b_6$. Choose c with $0 < c < a_4$ such that $\int_0^d sg(c,s)ds > 0$, and $\int_c^d sf(s,l)ds > 0$, and choose $h > a_2$.

To prove Theorem 1.3, we use the strengthened version of Theorem 2.1 in which we homotope the system to a product system as discussed in §4. See Fig. 5.2. As usual, we let σ denote the continuation parameter, with $\sigma = 0$ the original system,

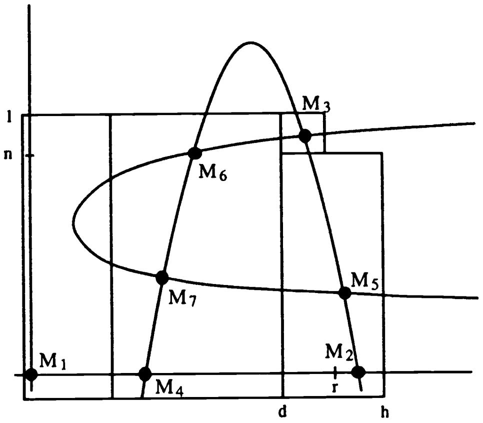

FIG. 5.1

and $\sigma = 1$ the system of Fig. 4.3. Clearly one can choose a deformation so that the assumptions hold for $\sigma \in [0, 1)$. In particular, the integrals in assumptions H8 and H9 can be bounded away from zero, so by the remark following Theorem 1.1, the speeds of any $M(3) \to M(1)$ travelling waves will be positive. For each σ we will construct an isolating neighborhood which contains only the critical points $M(1)$ and $M(3)$, plus any connecting orbits between the points. The construction we make will also construct an isolating neighborhood for $\sigma = 1$, so we can apply Theorem 2.1 and deduce the existence of an $M(3) \to M(1)$ travelling wave.

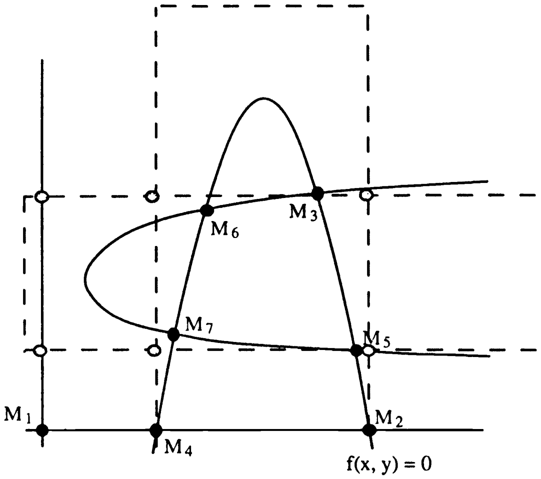

FIG. 5.2

For $e > 0$ define

$$N_1 = [-e, c] \times [-e, l],$$
$$N_2 = [c, d] \times [-e, l],$$
$$N_3 = [d, r] \times [n, l],$$
$$N_4 = [d, h] \times [-e, n].$$

For $K, \epsilon > 0$, define $\bar{N}_1 = N_1 \times [-K, K] \times [-K, K]$, $\bar{N}_2 = N_2 \times [-K, 0] \times [-K, 0]$, $\bar{N}_3 = N_3 \times [-K, K] \times [-K, K]$, $\bar{N}_4 = N_4 \times [-K, K] \times [-K, 0]$, and set

$$\bar{N}_K = \bar{N}_1 \cup \bar{N}_2 \cup \bar{N}_3 \cup \bar{N}_4,$$
$$\bar{N}_{K,\epsilon} = (\bar{N}_1 \cup \bar{N}_2 \cup \bar{N}_3 \cup \bar{N}_4) \setminus (B_\epsilon(2) \cup B_\epsilon(4) \cup B_\epsilon(5) \cup B_\epsilon(6) \cup B_\epsilon(7)).$$

To prove Theorem 1.3, we will show that for K sufficiently large and ϵ sufficiently small, $\bar{N}_{K,\epsilon}$ is an isolating neighborhood for any positive θ. We will use several lemmas in the course of the proof.

LEMMA 5.1. *For any K, $I(\bar{N}_3) = M(3)$.*

Proof. The proof is the same as the proof of Lemma 3.1. □

LEMMA 5.2. *For K sufficiently large, $\bar{N}_1$ is an isolating neighborhood and $I(\bar{N}_1) \subset \{u_1 = v_1 = 0\}$.*

Proof. We first show that every boundary point of $\bar{N}_1$ leaves in forward or backward time. For large K, if $u \in N_1$ and $|v_i| = K$ for $i = 1$ or 2, then the orbit leaves $\bar{N}_1$. If $u_1 = c$ and $v_1 \neq 0$, then the u-projection of the orbit leaves N_1 immediately in forward time if $v_1 > 0$ and in backward time if $v_1 < 0$. If $u_1 = c$ and $v_1 = 0$, then $\mu_1 \dot{v}_1 = -u_1 f(u) > 0$, so the orbit leaves $\bar{N}_1$ in both forward and backward time, i.e., the orbit is externally tangent. A similar argument for the other sides of N_1, i.e., $u_1 = -e$, $u_2 = -e$ and $u_2 = h$, establishes that $\bar{N}_1$ is an isolating neighborhood.

To see that $I(\bar{N}_1) \subset \{u_1 = v_1 = 0\}$, first suppose that $u_1 > 0$ and $v_1 = 0$. Then $\mu_1 \dot{v}_1 = -u_1 f(u) > 0$, i.e., v_1 can only change from negative to positive and in fact, if $v_1 \geq 0$, then v_1 is increasing. So if $u_1 > 0$ and $v_1 \geq 0$, then the u-projection of the forward orbit leaves N_1 to the right (unless it leaves via the top or bottom first). Similarly, if $v_1 < 0$, then v_1 must stay negative in backward time, so the u-projection of the backward orbit leaves N_1. Thus if $u_1 > 0$, the u-projection of the orbit leaves N_1 in one direction or the other. If $u_1 < 0$, a similar argument shows that the orbit exits to the left (in forward time if $v_1 \leq 0$ and in backward time if $v_1 > 0$). Finally if $u_1 = 0$ and $v_1 \neq 0$, then the orbit contains points with nonzero u_1 so the u-projection of the orbit leaves N_1, and it follows that $I(\bar{N}_1) \subset \{u_1 = v_1 = 0\}$. □

The argument used in the second paragraph of this lemma actually shows that if $u_2 < 0$ for any orbit, then $\dot{u}_2$ must stay negative on either the entire forward or entire backward orbit, so any orbit with $u_2 < 0$ somewhere on the orbit cannot be contained in $\bar{N}_{K,\epsilon}$.

Lemmas 5.1 and 5.2, plus the fact that $v_2 \leq 0$ in $\bar{N}_2$ and $\bar{N}_4$, imply that any nonconstant orbit γ which stays in $\bar{N}_{K,\epsilon}$ for all time and is not in the invariant subspace $\{u_1 = v_1 = 0\}$ must have $\omega(\gamma) \subset \{u_1 = v_1 = 0\}$ and $\omega^*(\gamma) = M(3)$. To show that $\bar{N}_{K,\epsilon}$ is an isolating neighborhood, we must show that no connecting orbit in $\bar{N}_{K,\epsilon}$ is internally tangent.

LEMMA 5.3. *Suppose (u, v) is on a connecting orbit in $\bar{N}_K$ (for any K) with $u \in N_2$. Then $v_1 \neq 0$ and $v_2 \neq 0$.*

Proof. To prove this, we will assume $u \in N_2$, $v_i = 0$, and show that (u, v) is not on a connecting orbit. First suppose $u \in \operatorname{int}(N_2)$. If $v_2 = 0$ and $\dot{v}_2 \neq 0$, then the orbit leaves immediately in one direction or the other. If $v_2 = \dot{v}_2 = 0$, then $\mu_2 \ddot{v}_2 = -u_2 v_1 g_1(u)$. If $u_2 \leq 0$ then the orbit cannot be a connection in $\bar{N}_{K,\epsilon}$, so assume $u_2 > 0$. Then $\ddot{v}_2 > 0$, and the orbit leaves immediately in forward time unless $v_1 = 0$. If $v_1 = 0$ and $\dot{v}_1 \neq 0$, then the orbit leaves immediately in one direction or the other, and if $v_1 = \dot{v}_1 = 0$, this combined with $v_2 = \dot{v}_2 = 0$ implies that (u, v) is a critical point. This finishes the case $u \in \operatorname{int}(N_2)$, $v_2 = 0$.

If $u \in \operatorname{int}(N_2)$, $v_1 = 0$ and $\dot{v}_1 = 0$, then $f(u) = 0$ and we may assume $u_2 > 0$. Assume time is parameterized so that $\tau = 0$ at (u, v) and $\tau = t_0 < 0$ when the orbit enters $\bar{N}_2$. If we integrate $\mu_1 v_1 \dot{v}_1$ along the orbit segment in $\bar{N}_2$ we get

$$\begin{aligned} -\mu_1 v_1^2(t_0)/2 = \mu_1 \int_{t_0}^0 v_1\dot{v}_1\,d\tau &= \int_{t_0}^0 \theta v_1^2\,d\tau - \int_{t_0}^0 v_1 u_1 f(u)\,d\tau \\ &= \int_{t_0}^0 \theta v_1^2\,d\tau + \int_{u_1(t_0)}^d u_1 f(u_1, u_2(u_1))\,du_1 \\ &\geq \int_{t_0}^0 \theta v_1^2\,d\tau + \int_{u_1(t_0)}^d sf(s,l)\,ds \\ &> 0. \end{aligned}$$

To get the second line, we parameterize the path by u_1 which we can do since $v_1 < 0$ in $\bar{N}_2$. The inequalities come from the fact that $f_2 > 0$ and H9. The resulting inequality is absurd, so we cannot have $u \in \operatorname{int}(N_2)$, $v_1 = 0$, and $\dot{v}_1 = 0$.

If $u_2 = l$, i.e., u is on the top boundary of N_2, and if $v_2 = 0$, then $\dot{v}_2 > 0$, so the orbit leaves in both directions. If $u_2 = -e$, then the orbit leaves as noted in the remark after the proof of Lemma 5.2. If $u_1 = c$ and $v_1 = 0$, then $\dot{v}_1 < 0$, so the orbit leaves in both directions.

Suppose $u_1 = c$, $u_2 = z$, and $v_2 = 0$. If $\gamma \subset \bar{N}_{K,\epsilon}$, then $v_1 < 0$ as noted above. $\mu_2\dot{v}_2 = -u_2 g(u)$. If $g(u) > 0$, then $\dot{v}_2 < 0$, so the orbit leaves $\bar{N}_{K,\epsilon}$ in backward time. If $g(u) > 0$ and (c,z) lies above the $\{g \geq 0\}$ region, then $\dot{v}_2 > 0$ so v_2 is positive in forward time. In the region $(0,c) \times [z,\infty)$, $g(u) < 0$, so if $v_2 = 0$, then $\dot{v}_2 > 0$, i.e., v_2 cannot change from positive to negative on the forward orbit (unless the orbit crosses $\{u_1 = c\}$ again, in which case it leaves $\bar{N}_{K,\epsilon}$). Since $\omega(\gamma) \subset \{u_1 = v_1 = 0\}$ and the flow on $\{u_1 = v_1 = 0\}$ is gradient-like, $\omega(\gamma)$ must be a critical point. This is impossible since $u_2 \geq z$ on the forward orbit from (c,z). Thus $\gamma \not\subset \bar{N}_{K,\epsilon}$ if γ passes through (c,z) with $v_2 = 0$ for such a z. If z is the larger value in the intersection $\{g = 0\} \cap \{u_1 = c\}$, then $\dot{v}_2 = 0$, but $\ddot{v}_2 = -u_2 v_1 g_1(u) > 0$ so the same argument applies. If $g(c,z) \leq 0$, and (c,z) lies below the $\{g > 0\}$ region, then we integrate $\mu_2 v_2 \dot{v}_2$ along the orbit segment in $\bar{N}_2 \cup \bar{N}_4$. Assume $\tau = 0$ at (c,z), and $\tau = t_0 < 0$ when the orbit enters $\bar{N}_2 \cup \bar{N}_4$. Since $v_2 < 0$ in $\bar{N}_2 \cup \bar{N}_4$, we can parameterize the orbit segment by u_2 and we get

$$\begin{aligned} -\mu_2 v_2^2(t_0)/2 = \mu_2 \int_{t_0}^0 v_2\dot{v}_2\,d\tau &= \int_{t_0}^0 \theta v_2^2\,d\tau - \int_{t_0}^0 v_2 u_2 g(u)\,d\tau \\ &= \int_{t_0}^0 \theta v_2^2\,d\tau + \int_z^{u_2(t_0)} u_2 g(u)\,du_2 \\ &\geq \int_{t_0}^0 \theta v_2^2\,d\tau + \int_z^{u_2(t_0)} sg(c,s)\,ds \\ &\geq \int_{t_0}^0 \theta v_2^2\,d\tau + \int_0^n sg(c,s)\,ds \\ &> 0, \end{aligned}$$

using $g_1 < 0$, the fact that $g(c,y) < 0$ for $y > b_6$, and H9. This can't happen, so v_2 can't be zero when $u_1 = c$ on an orbit lying entirely in $\bar{N}_{K,\epsilon}$. Notice that the same argument using $t = \infty$ instead of $t = 0$ for the upper limit shows that there cannot be an $M(3) \to M(4)$ connection in $\bar{N}_K$.

Finally, if $u_1 = d$ and $v_1 = 0$, $\dot{v}_1 < 0$ so the orbit leaves in both directions, and if $v_2 = 0$, the argument is the same as that for $u_1 = d$. □

LEMMA 5.4. *Suppose (u,v) is on an $M(3) \to M(1)$ connecting orbit in $\bar{N}_K$ (for any K) with $u \in N_4$. Then $v_2 \neq 0$.*

Proof. If $v_2 = 0$ and $v_2 \in \operatorname{int}(N_4)$, then if $\dot{v}_2 \neq 0$, then the orbit leaves $\bar{N}_4$, so assume $v_2 = \dot{v}_2 = 0$. Then either $u_2 = 0$, in whch case (u,v) is in the invariant plane $\{u_2 = v_2 = 0\}$ (and not on a connecting orbit), or $g(u) = 0$. If $g(u) = 0$, then we integrate $\mu_2 v_2 \dot{v}_2$ along the orbit segment in $\bar{N}_4$, setting $\tau = t_0$ as the time when the orbit enters $\bar{N}_4$, and $\tau = 0$ at (u,v). Note that $u_2(t_0) = n$.

$$\begin{aligned}
-\mu_2 v_2^2(t_0)/2 = \mu_2 \int_{t_0}^{0} v_2 \dot{v}_2 \, d\tau &= \int_{t_0}^{0} \theta v_2^2 \, d\tau - \int_{t_0}^{0} v_2 u_2 g(u) \, d\tau \\
&= \int_{t_0}^{0} \theta v_2^2 \, d\tau + \int_{g(0)}^{n} u_2 g(u) \, du_2 \\
&\geq \int_{t_0}^{0} \theta v_2^2 \, d\tau + \int_{g(0)}^{n} s g(c,s) \, ds \\
&\geq \int_{t_0}^{0} \theta v_2^2 \, d\tau + \int_{0}^{n} s g(c,s) \, ds \\
&> 0,
\end{aligned}$$

so we have a contradiction, and there is no such (u,v).

The verification that v_2 cannot be zero on a connecting orbit when $u \in \partial N_4$ is tediously similar to the proof of Lemma 5.3, and hence omitted. □

LEMMA 5.5. *There is no $M(3) \to M(2)$, $M(3) \to M(4)$, $M(3) \to M(5)$, $M(3) \to M(6)$, or $M(3) \to M(7)$ connection in $\bar{N}_K$.*

Proof. Suppose there were an $M(3) \to M(2)$ connection. Then we can parameterize the orbit segment in $\bar{N}_4$ by the u_2 coordinate, and we get the same contradiction as in the proof of Lemma 5.4, so we cannot have a $M(3) \to M(2)$ connection. Similarly, we cannot have a $M(3) \to M(5)$ connection. It was noted in the proof of Lemma 5.3 that there is no $M(3) \to M(4)$ connection. If there were a $M(3) \to M(6)$ connection, parameterize the orbit segment in $\bar{N}_2$ such that $t = 0$ when the orbit enters $\bar{N}_2$, i.e. when $u_1 = d$. Using the fact that u_1 is decreasing along the orbit segment we get

$$\begin{aligned}
-\mu_1 v_1^2(0)/2 = \mu_1 \int_{0}^{\infty} v_1 \dot{v}_1 \, d\tau &= \int_{0}^{\infty} \theta v_1^2 \, d\tau - \int_{0}^{\infty} v_1 u_1 f(u) \, d\tau \\
&= \int_{0}^{\infty} \theta v_1^2 \, d\tau + \int_{a_6}^{d} u_1 f(u) \, du_1 \\
&\geq \int_{-\infty}^{\infty} \theta v_1^2 \, d\tau + \int_{a_4}^{d} s f(s,l) \, ds \\
&> 0,
\end{aligned}$$

with the last inequality following from H8. Thus there is no $M(3) \to M(6)$ connection. Finally, there cannot be a $M(3) \to M(7)$ connection beacuse $M(7)$ is a repeller for $\theta > 0$. □

Proof of Theorem 1.3. The only possible orbits which can stay in $\bar{N}_{K,\epsilon}$ for all time are orbits lying in the invariant plane $\{u_1 = v_1 = 0\}$ and orbits connecting $M(3)$ to a point in the invariant plane. We will show that no such connecting orbit can be internally tangent to the boundary of $\bar{N}_{K,\epsilon}$ for large enough K and small enough ϵ. If K is large enough, then no orbit with $v_i = K$ can stay in $\bar{N}_{K,\epsilon}$ for all time.

It is easy to check that if u lies on the boundary of $N_1 \cup N_2 \cup N_3 \cup N_4$, then using the above arguments the orbit leaves $\bar{N}_{K,\epsilon}$ immediately in one time direction or the other. Lemmas 5.3 and 5.4 show that there cannot be an internal tangency in $\bar{N}_K$ when $v_1 = 0$ or $v_2 = 0$. The only other possile source of internal tangency is around the ϵ balls which are cut out.

Since $M(7)$ is a repeller, we can simply take ϵ such that $\omega^*(B_\epsilon(M(7))) = M(7)$. For the other critical points, suppose that for any $\epsilon > 0$ there is no ϵ-ball around $M(j)$ which can be cut out to give an isolating neighborhood, $j \in \{2,4,5,6\}$. Then there is a sequence $\epsilon_n \to 0$ and a sequence (u^n, v^n), with (u^n, v^n) on an $M(3) \to M(1)$ connection which passes within ϵ_n of $M(j)$. If we parameterize the connecting orbit so that $t = 0$ at (u^n, v^n), then the same integrals which were used to derive a contradiction in the proof of Lemma 4.6 can be used here to derive the same contradiction. Thus no sequence of $\epsilon_n \to 0$ can be found, so for K sufficiently large and ϵ sufficiently small, $\bar{N}_{K,\epsilon}$ is an isolating neighborhood. □

6. Bifurcation results. This section presents the proofs of Theorems 1.4 and 1.5. As will be seen shortly, they follow immediately from work of McCord and Mischaikow [M-M], thus we begin by describing their result.

Let $\Phi : \mathbf{R} \times X \times \Xi \to X$ be a parameter flow (see §2 for a concrete description) where $\Xi = \mathbf{R}^2$, i.e., we are thinking of a system with two independent parameters. Let S be an isolated invariant set under Φ. We need to make several assumptions, the first being the following.

A1. $\mathcal{M}(S) = \{M(p) \mid p = 1,2,3 \text{ and } 3 > 2 > 1\}$ is a Morse decomposition of S. Let $S_\xi = S \cap (X \times \{\xi\})$ and $M_\xi(p) = M(p) \cap (X \times \{\xi\})$. It can be easily checked that S_ξ is an isolated invariant set under φ_ξ and $\mathcal{M}(S_\xi) = \{M_\xi(p) \mid p = 1,2,3,\ 3 > 2 > 1\}$ a corresponding Morse decomposition. We shall also assume the following.

A2. $h(M_\xi(p), \varphi_\xi) \sim \Sigma^n$, $n \geq 1$, $p = 1,2,3$, $\xi \in \Xi$, where Σ^n denotes the pointed n-sphere. Since $\{1,2\}$ and $\{2,3\}$ define intervals in $\{1,2,3\}$ under the ordering on the Morse decomposition,

$$M(i,i+1) = M(i) \cup M(i+1) \cup C(M(i+1),\ M(i))$$

is an isolated invariant set and has an attractor repeller decomposition given by $(M(i),\ M(i+1))$. Let $I_\xi(i,i+1)$ denote the connected simple system associated with $h(M(i,i+1), \varphi_\xi)$. Let $\Xi' \subset \Xi$ such that $M(i,i+1) = M(i) \cup M(i+1)$ *for* $i = 1,2$.

A3. Assume there exist parameter values $\xi_0, \xi_1, \xi_2, \xi_3 \in \Xi'$ for which

$$I_0(1,2), \quad I_1(1,2) \not\cong I_2(1,2), \quad I_3(1,2)$$

and

$$I_0(2,3), \quad I_2(2,3) \not\cong I_1(2,3), \quad I_3(,3);$$

A4.

$$I_0(1,2) \cong I_11,2), \qquad I_2(1,2) \cong I_3(1,2),$$
$$I_0(2,3) \cong I_2(2,3), \qquad I_1(2,3) \cong I_3(2,3).$$

Let $C_{ij} = \{\xi \in \Xi \mid$ there exists a connecting orbit from $M_\lambda(i)$ to $M_\lambda(j)\}$.

THEOREM 6.1 [M-M, Thm. 4.2 and Cor. 4.3]. *Assume* A1–A4, *and assume that* C_{21} *does not separate* ξ_0 *from* ξ_1 *nor* ξ_2 *from* ξ_1 *and that* C_{32} *does not separate* ξ_0 *from* ξ_1 *nor* ξ_2 *from* ξ_3. *Then* $C_{31} \neq \emptyset$. *Furthermore,* $\mathrm{cl}(C_{31}) \cap C_{21} \cap C_{32} \neq \emptyset$.

We shall now show how Theorem 6.1 leads to Theorem 1.4. Hopefully, from the discussion it will become clear why the hypothesis needs to be stated in such a complicated manner.

Proof of Theorem 1.4. Consider Fig. 6.1, which shows $\Xi = [0,1] \times [0,\infty)$. We consider $(\lambda, \theta) = \xi \in \Xi$ where φ_ξ is the flow associated to the ordinary differential equations

$$(6.1^{\lambda,\theta}) \qquad \begin{aligned} \dot{u}_1 &= v_1, \\ \dot{u}_2 &= v_2, \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 f^\lambda(u_1, u_2), \\ \mu_2 \dot{v}_2 &= \theta v_2 - u_2 g^\lambda(u_1, u_2). \end{aligned}$$

The results of Theorems 1.1 and 1.2 guarantee that for each fixed $\lambda \in [0,1]$ there exists θ^λ_{12}, θ^λ_{23} wave speeds at which $M(1) \to M(2)$ and $M(2) \to M(3)$ waves exist. Actually, the proof of Theorem 2.1 tells us more. First, there is an upper and lower bound for θ^λ_{ij}. Second, the existence of these wave speeds is obtained by knowledge that the connected simple systems for $h(M(i,j))$ differ at $\theta \approx \infty$ and $\theta \approx 0$. Thus, Figure 6.1 is the simplest possible diagram of the sets θ^λ_{12} and θ^λ_{23}.

Let $\xi_i = (\lambda_i, \theta_i)$. Chose ξ_0 such that θ_0 is greater than θ^λ_{12} and θ^λ_{23} for all $\lambda \in [0,1]$, where θ^λ_{ij} are determined by Theorems 1.1, 1.2, or 1.3. Similarly, ξ_3 is chosen such that $\theta_3 > 0$ is less than $\underline{\theta}^\lambda_{12}$ and $\underline{\theta}^\lambda_{23}$ for all $\lambda \in [0,1]$. Finally, the hypotheses of Theorem 1.4 allows us to choose ξ_1 and ξ_2 such that $\lambda_2 = 0$, $\bar{\theta}^0_{23} < \theta_2 < \underline{\theta}^0_{12}$, $\lambda_1 = 1$, and $\underline{\theta}^1_{23} > \theta_1 > \bar{\theta}^1_{12}$. Because θ^λ_{ij} was determined by changes in the connected simple system of $h(M(i,j))$ one can immediately conclude that

$$\begin{aligned} I_0(1,2) &\cong I_1(1,2), \\ I_2(1,2) &\cong I_3(1,2), \\ I_0(1,2) &\not\cong I_2(1,2), \\ I_1(1,2) &\not\cong I_3(1,2), \end{aligned}$$

and similarly for $I_\xi(2,3)$. Thus, Theorem 6.1 gives the desired result. The proofs for the other i, j follow similarly. □

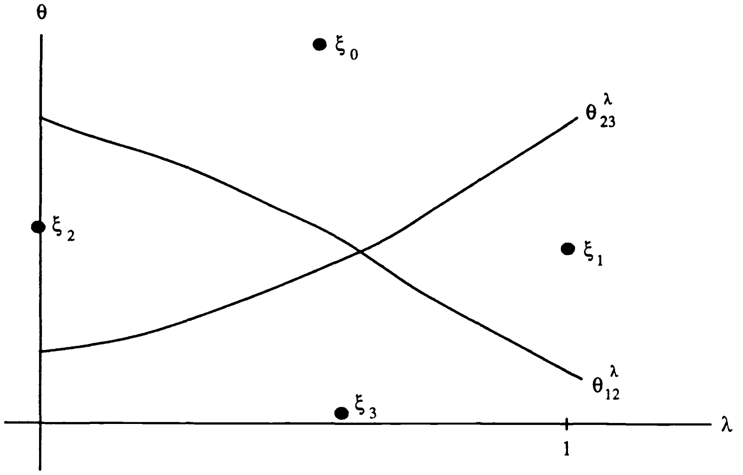

FIG. 6.1

The proof for Theorem 1.5 is similar, if one observes that in the proof of Theorem 6.1 the existence of C_{13} is obtained as the separating set of parameter value for two different connected simple systems for $h(M(13))$.

7. Existence of nonmonotone bistable waves. The results of the previous section were dependent upon knowing that the wave speeds of different bistable waves could be made to cross by changing the nonlinearities. In this section, we intend to show that it is easy to construct parameterized families of nonlinearities for which this phenomenon occurs. One of the implications of our construction is that for a wide class of predator-prey systems of the type being considered here one should expect the existence of nonmonotone travelling waves. It should also be pointed out that the constructions we make are general and applicable to other reaction diffusion systems. To emphasize this latter point we begin with a schematic sketch of the general existence proof (in effect outlining the proof of Theorem 1.4) along with comments of how this will be done for our specific predator-prey system.

Step 1. For a class of reaction terms, one proves the existence of travelling waves $M(i) \rightarrow M(j)$ and $M(j) \rightarrow M(k)$. Furthermore, one obtains the existence results by showing that the connected simple systems of the Conley indices differ; depending on whether the wave speed is large or small.

Comment. This is the content of Theorems 1.1, 1.2, and 1.3 where the reaction terms are assumed to satisfy H1–H9.

Step 2. One parameterizes the class of possible reaction terms. Let Λ denote the set of parameters. Also, let $I^\lambda_{ij} = [\underline{\theta}^\lambda_{ij}, \bar{\theta}^\lambda_{ij}]$ and $I^\lambda_{jk} = [\underline{\theta}^\lambda_{jk}, \bar{\theta}^\lambda_{jk}]$ denote bounded intervals in $\mathbf{R}$ such that if θ^λ_{ij} is a wave speed for which an $M(i) \rightarrow M(j)$ wave occurs, then $\theta^\lambda_{ij} \in I^\lambda_{ij}$.

Comment. In the statement of Theorem 1.4, we chose $\Lambda = [0,1]$ for the sake of simplicity. For more concrete problems there may be a more natural choice for Λ. From a practical point of view the only necessary restrictions on Λ is that it be compact and simply connected.

Furthermore, it is assumed implicitly in the statement of step 2 that the connected simple system of the Conley index for the attractor-repeller pair $(M(j), M(i))$ for wave speeds which lie above I^λ_{ij} differ from the connected simple system for wave speeds which lie below I^λ_{ij}. This will always be the case if the existence of bistable waves were found by an application of Theorem 2.1.

Step 3. One finds parameter values λ_0 and λ_1 such that $\bar{\theta}^{\lambda_0}_{ij} < \underline{\theta}^{\lambda_1}_{ij}$ and $\bar{\theta}^{\lambda_1}_{ij} < \underline{\theta}^{\lambda_0}_{ij}$.

Comment. This of course involves estimates on the wave speeds which may or may not be easy to obtain. In Theorems 7.1, 7.4, and 7.5 we present some general results which allow us to make comparisons of wave speeds between certain nonlinearities. Given these theorems it then becomes a triviality to choose the desired nonlinearities at λ_0 and λ_1.

Step 4. One applies Theorem 6.1.

Comment. See the proof of Theorem 1.4 to see how this is done.

With this outline in mind we now turn to the problem of comparing wave speeds for different nonlinearities. To simplify notation, we consider the one-dimensional problem which has the form

$$\begin{aligned} \dot{u} &= v, \\ \dot{v} &= \theta v - f(u). \end{aligned} \tag{7.1}$$

(Here we have absorbed the diffusion coefficient in θ and f, and we write $f(u)$ instead of $uf(u)$.) The nonlinearity f satisfies $f(0) = f(a) = f(1) = 0$, f is negative between zero and a and positive between a and 1. Let F be such that $F'(u) = f(u)$, $F(0) = 0$, so F has maxima at zero and 1, and a minimum at $u = a$. We assume $F(1) > 0$, so Theorem 1.1 guarantees a positive θ^* so there is bistable wave, i.e., a solution to (7.1) connecting the saddle point (0,0) to the saddle point (1,0). Moreover, it is well known that this connecting orbit satisfies $v > 0$, so we can parameterize the travelling by u instead of t, and (7.1) becomes

$$v\frac{dv}{du} = \theta v - f(u). \tag{7.2}$$

Finally, by integrating (7.2) we get

$$\frac{v^2(u)}{2} = \theta\int_0^u v(\xi)\,d\xi - F(u). \tag{7.3}$$

There are two ways to alter the equation to decrease the wave speed: we can decrease f (near the minimum between zero and a), or we can make the well in F deeper (near $u = a$). Notice that decreasing the well has the effect of decreasing f for $u < a$ and increasing f for $u > a$. We show that either technique can be used to make the wave speed $\theta \to 0$ monotonically.

THEOREM 7.1. *Let $I \subset (0, a)$ be an interval, and let f_2 be a function with wave speed θ_2^*. Then for any $\epsilon > 0$, there is a function f_1 which agrees with f_2 on $[0,1] \setminus I$ and has $0 < \theta_1^* < \epsilon$.*

The proof of this theorem requires two lemmas.

LEMMA 7.2. *Suppose $f_1(u) \leq f_2(u)$ for all u. If $f_1(u) \neq f_2(u)$ for some u, then $\theta_1^* < \theta_2^*$.*

Proof. We have $F_i(u) = \int_0^u f_i(\xi)\,d\xi$ for $i = 1, 2$, and let b denote a point with $f_1(b) < f_2(b)$, so $F_1(u) < F_2(u)$ for $u > b$. Fix $\theta = \theta_2^*$ for both f_1 and f_2. For the f_1 flow, there is a connecting orbit from the $u = 0$ saddle to the $u = 1$ saddle. In the f_2 flow, the corresponding orbit coming from the $u = 0$ saddle will agree with the connecting orbit as long as f_1 and f_2 agree. However, (7.3) implies that for $u > b$, $v_2(u) > v_1(u)$, since $v_1, v_2 \geq 0$, the θ is the same, and $F_1(u) < F_2(u)$. Indeed, (7.3) implies that $v_1 - v_2$ is an increasing function of u, so $v_1(u) > 0$, and $\theta_1^* \neq \theta_2^*$. It is clear from (2) that increasing θ for a fixed f increases $v(u)$, therefore we must have $\theta_1^* < \theta_2^*$. □

As noted in the previous proof, since $F(u) = \int_0^u f(\xi)\,d\xi$, decreasing f causes a corresponding decrease in F, so by decreasing f in some interval we can force $F(1) - F(0)$ to become arbitrarily small. (If the difference becomes nonpositive, θ^* will also become nonpositive.) Since $\theta\int_0^1 v\,du = F(1) - F(0)$, we only need to show that $\int_0^1 v\,du$ is bounded away from zero as f is decreased.

LEMMA 7.3. *Suppose $f_1(u) \leq f_2(u)$ for all u. Then $\int_0^1 v_1\,du \geq \int_0^a \sqrt{-2F_2(\xi)}\,d\xi$.*

Proof. By (7.3), $v_1^2(u)/2 > -F_1(u)$ and by hypothesis $F_1(u) \leq F_2(u)$. For $0 < u < a, F_i(u) < 0$, so we have

$$\begin{aligned}\int_0^1 v_1\,du &\geq \int_0^a v_1\,du \\ &\geq \int_0^a \sqrt{-2F_1(u)}\,du \\ &\geq \int_0^a \sqrt{-2F_2(u)}\,du. \qquad \square\end{aligned}$$

Proof of Theorem 7.1. Theorem 7.1 is an easy consequence of Lemmas 7.2 and 7.3. Start with some f_2, and let $k = \int_0^a \sqrt{-2F_2(u)}\,du$. Now decrease the value of f in

I (this introduces no new critical points), so $F(1) - F(0) < \epsilon/k$. For this f we have $\theta\int_0^1 v_1\,du = F(1) - F(0) < \epsilon/k$ and $\int_0^1 v_1\,du \geq k$ by Lemma 3, so $\theta < \epsilon$. □

The arguments to show that increasing the depth of the well of F can force the wave speed to go to zero are similar. We now state assumptions in terms of F.

THEOREM 7.4. *Let F_2 be a function with wave speed θ_2^*, and let I be an interval containing a with $F_2 < 0$ on I. Then for any $\epsilon > 0$, there is a function F_1 which agrees with F_2 on $[0,1] \setminus I$ and has $0 < \theta_1^* < \epsilon$.*

We use one more lemma.

LEMMA 7.5. *Suppose $F_1(u) \leq F_2(u)$ for all u. If $F_1(u) \neq F_2(u)$ for some u, then $\theta_1^* < \theta_2^*$.*

Proof. The proof is the same as the proof of Lemma 2. □

Proof of Theorem 7.4. Start with F_2, and let $F_2(1) - F_2(0) = k$. Now decrease F in I so that $\int_0^a \sqrt{-2F(u)}\,du > k/\epsilon$. Since $a \in I$, this can be done without introducing new critical points, and since $I \subset (0,1)$ the new F still satisfies $F(1) - F(0) = k$. We have

$$\begin{aligned} k = F(1) - F(0) &= \theta^* \int_0^1 v\,du \\ &\geq \theta^* \int_0^a \sqrt{-2F(u)}\,du \\ &> \theta^* k/\epsilon, \end{aligned}$$

so $\theta^* < \epsilon$. □

We now show that by raising $F(1)$ (or equivalently, lowering $F(0)$), we can force θ^* to go to ∞.

THEOREM 7.6. *Let F_2 be a function with wave speed θ_2^*, and let $b \in (a,1)$ be the point with $F_2(b) = 0$. Then for any $M, \epsilon > 0$, there is a function F_1 which agrees with F_2 on $(b+\epsilon, 1]$ and has $\theta_1^* > M$.*

Proof. Let v be a solution to (7.2) with $\theta = M$, i.e., v satisfies $dv/du = M - f_2(u)/v$, $v(0) = 0$ where $F_2' = f_2$. Let $\gamma = \max\{v(u) \mid 0 \leq u \leq b\}$. Note that $f_2(u) > 0$ for $u \in [b,1]$, so $dv/du \leq M$ for $u \in [b,1]$. It follows that $v(u) \leq \gamma + M(1-b)$ for all u. Make a function $F_3(u)$ which agrees with $F_2(u)$ for $u \in [0,1]$, $F_3' > 0$ in $[b,1]$, (so the bound on $v(u)$ holds for solutions involving F_3 and $\theta = M$), and $F_3(u) = F_2(u) + K$ for $u \in [b+\epsilon, 1]$ where K is a constant to be named later. Equation (7.3) implies $F_3(1) = M\int_0^1 v(\xi)\,d\xi$ if $v > 0$ along the whole orbit. But $M\int_0^1 v(\xi)\,d\xi < M(\gamma + M(1-b)) < F_3(1)$, if K is large enough, so the wave speed for F_3 is greater than M. We now set $F_1(u) = F_3(u) - K$. □

Obviously, these results hold if the critcal points are at points other that zero, a, and 1.

We now show how these one-dimensional results can be applied to the predator-prey systems we have been studying. We will show that there are systems of the form (1.3) which have $M(1) \to M(3)$ travelling waves and homoclinic $M(1) \to M(1)$ travelling waves.

THEOREM 7.7. *There are systems of the form* (1.3) *satisfying* H1–H3 *and* H5–H7 *which have an $M(1) \to M(3)$ travelling wave with $\theta_{13} > 0$.*

Proof. Theorem 1.2 guarantees an $M(2) \to M(3)$ travelling wave of speed $\theta_{23} > 0$. Let $\underline{\theta}_{23}$ be the minimum speed for any $M(2) \to M(3)$ travelling wave. It is easy to see that the set of wave speeds is closed, so $\underline{\theta}_{23} > 0$. Similarly, let $\bar{\theta}_{23}$ be the largest $M(2) \to M(3)$ wave speed. It will be shown in §9 that this is finite. The idea of the proof is to deform f away from this wave to change the speed of the $M(1) \to M(2)$

travelling wave. So start with any system (1.3) satisfying H1–H3, H5–H7. We apply Theorem 7.6 to the one-dimensional problem

$$\begin{aligned} \dot{u}_1 &= v_1 \\ \dot{v}_1 &= \mu_1 \theta v_1 - u_1 f(u_1, 0) \end{aligned}$$

which is the equation governing the $M(1) \to M(2)$ travelling wave. By altering $f(u_1, 0)$ on the segment $\{ (u_1, 0) \mid \epsilon \leq u_1 < b + \epsilon \}$ (where the b is as in Theorem 7.6, and ϵ is small), we can produce a function $\tilde{f}(u_1, 0)$ so that θ_{12}, the speed of the $M(1) \to M(2)$ travelling wave, is greater than $\bar{\theta}_{23}$. Let U be a neighborhood of the segment $\{ (u_1, 0) \mid \epsilon \leq u_1 < b + \epsilon \}$ which misses the (u_1, u_2)-projection of any $M(2) \to M(3)$ travelling wave. Define f^0 to be a function which satisfies H1–H3, H5–H7, $f^0 = f$ outside of U and $f^0(u_1, 0) = \tilde{f}(u_1, 0)$. Similarly, by using Theorem 7.1 we can alter $f(u_1, 0)$ on the segment $\{ (u_1, 0) | \epsilon \leq u_1 < b + \epsilon \}$ to $\hat{f}(u_1, 0)$ so that θ_{12} is less than $\underline{\theta}_{23}$. Let f^1 be a function which satisfies H1–H3, H5–H7, $f^1 = f$ outside of U and $f^1(u_1, 0) = \hat{f}(u_1, 0)$. Finally, for $0 \leq \lambda \leq 1$ define $f^\lambda(u) = (1 - \lambda) f^0(u) + \lambda f^1(u)$.

Now consider the parameterized family

$$\begin{aligned} \dot{u}_1 &= v_1 \\ \dot{u}_2 &= v_2 \\ \mu_2 \dot{v}_2 &= \theta v_2 - u_2 g(u_1, u_2)\,. \end{aligned}$$

For each $\lambda \in [0, 1]$ there is an $M(1) \to M(2)$ travelling wave of speed θ^λ_{12} and an $M(2) \to M(3)$ travelling wave of speed θ_{32}. By the construction of f^λ, $\theta^0_{12} > \bar{\theta}_{32}$, and $\theta^1_{12} < \underline{\theta}_{32}$. Theorem 1.4 implies the existence of a λ so that the system with f^λ has an $M(1) \to M(3)$ travelling wave of speed $\theta_{13} > 0$. □

We remark that the proof of Theorems 7.7 and 1.4 actually imply that the $M(1) \to M(3)$ travelling wave passes close to $M(2)$, and that θ_{13} is close to the speed of some $M(2) \to M(3)$ travelling wave.

Finally, we discuss how to use Theorem 1.5 to construct homoclinic $M(1) \to M(1)$ travelling waves. We first use Theorem 1.4 to construct $M(2) \to M(1)$ travelling waves (via $M(3)$), then apply Theorem 1.5 to the $M(2) \to M(1)$ and $M(1) \to M(2)$ waves, where we control the speed of the $M(1) \to M(2)$ wave as in the proof of Theorem 7.7. We begin by modifying f so that the critical points M_2, M_5, and M_3 all lie in the same vertical line in the (u_1, u_2)-plane, i.e., $a_2 = a_5 = a_3$. See Fig. 7.1.

The proof of Theorem 1.3 implies that there is an $M(3) \to M(1)$ travelling wave with positive wave speed θ_{31}. Let $\underline{\theta}_{31}$ be the minimum $M(3) \to M(1)$ speed, and $\bar{\theta}_{31}$ be the maximum speed. The one-dimensional analysis applies in the set $\{ u_1 = a_2, v_1 = 0 \}$ to allow us to control the speed θ_{23} of the $M(2) \to M(3)$ travelling wave. As in the proof of Theorem 7.7, we can alter g in a neighborhood of the $u_1 = a_2$ line (in particular, away from any $M(3) \to M(1)$ travelling wave) to obtain functions g^0 so that the speed of the $M(3) \to M(2)$ travelling wave for the system using g^0 is $\theta^0_{23} > \bar{\theta}_{31}$. Similarly, we can alter g to get g^1 so the speed of the $M(3) \to M(2)$ travelling wave for the system using g^1 is $\theta^1_{23} < \underline{\theta}_{31}$. Notice that g^0 and g^1 can be constructed so that hypotheses H6, H7, and H9 are still satisfied. We define $g^\lambda(u) = (1 - \lambda) g^0(u) + \lambda g^1(u)$, and consider the parameterized family

$$\begin{aligned} \dot{u}_1 &= v_1, \\ \dot{u}_2 &= v_2, \\ \mu_1 \dot{v}_1 &= \theta v_1 - u_1 f(u_1, u_2), \\ \mu_2 \dot{v}_2 &= \theta v_2 - u_2 g^\lambda(u_1, u_2). \end{aligned} \tag{7.4}$$

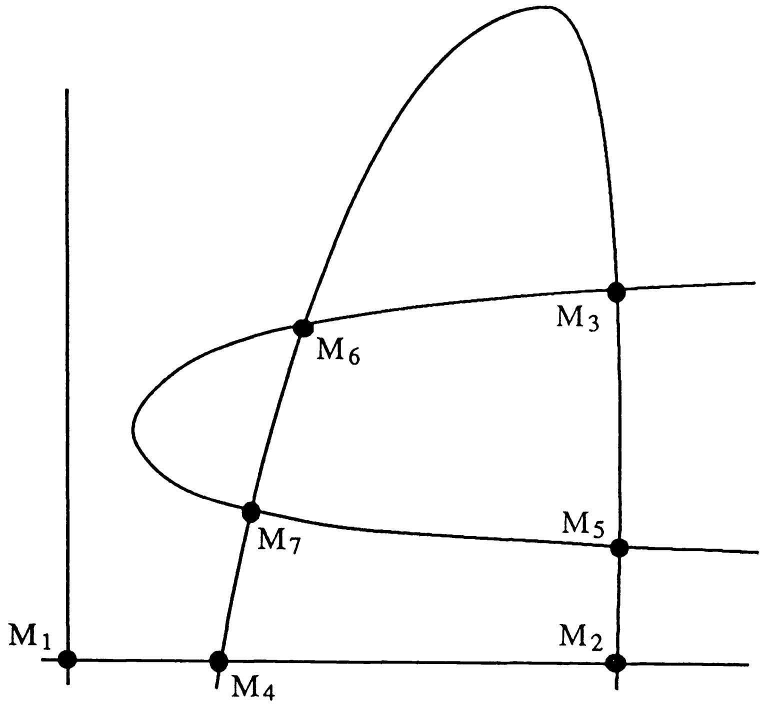

FIG. 7.1

We now argue as in the proof of Theorem 7.7 and obtain a g^λ such that there is an $M(2) \to M(1)$ travelling wave of speed $\theta_{21} > 0$. Note that this wave passes close to $M(3)$.

Now we perturb f slightly so that the points M_2, M_5, and M_3 are no longer in the same line in the (u_1, u_2)-plane, but instead that f satisfies H1–H9. As noted in the proof of Theorem 1.4, because the connected simple systems continue, for a small perturbation the speed of any $M(3) \to M(2)$ travelling wave in the perturbed system will be close to the speed in the system with the vertical line analyzed in the preceeding paragraph. It follows that we can still construct g^0 and g^1 so that $\underline{\theta}^0_{23} > \bar{\theta}_{31}$ and $\bar{\theta}^1_{23} < \underline{\theta}_{31}$, so for the perturbed f there is a g^λ so that system (7.4) has an $M(2) \to M(1)$ travelling wave of speed $\theta_{21} > 0$. We have proved the following.

THEOREM 7.8. *There are systems of the form* (1.3) *satisfying* H1–H9 *which have an* $M(2) \to M(1)$ *travelling wave with* $\theta_{21} > 0$.

Now to show the existence of an $M(1) \to M(1)$ travelling wave, we start with a system from Theorem 7.8, with a $M(2) \to M(1)$ travelling wave of speed $\theta_{21} > 0$. We now repeat the proof of Theorem 7.7 with θ_{21} replacing θ_{32}. Specifically, by changing f near the u_1 axis in the (u_1, u_2)-plane (in particular, away from the $M(2) \to M(1)$ travelling wave), we construct a one-parameter family f^λ so that the system (7.4) satisfies the following.

(i) There is an $M(2) \to M(1)$ travelling wave of speed θ_{21} for all λ (the wave speed is independent of λ since f^λ is unchanged near the wave).

(ii) When $\lambda = 0$, there is an $M(1) \to M(2)$ travelling wave of speed $\theta^0_{12} > \bar{\theta}_{21}$.

(iii) When $\lambda = 1$, there is an $M(1) \to M(2)$ travelling wave of speed $\theta^1_{12} < \underline{\theta}_{21}$.

The conditions of Theorem 1.5 are satisfied, so there is a $\lambda \in (0,1)$ and a homoclinic $M(1) \to M(1)$ travelling wave of speed $\theta^\lambda_{11} > 0$. So we have proved the following.

THEOREM 7.9. *There are systems with $M(1) \to M(1)$ homoclinic travelling waves of speed $\theta_{11} > 0$.*

8. Fisher waves and higher-dimensional analogues. Proving the existence of bistable waves as described in the previous sections was dependent upon careful selections of isolating neighborhoods and homotopies to simpler systems. As will be shown now, for high wave speeds the existence of Fisher waves and their higher-dimensional analogues can be determined directly from the dynamics of the reaction system. In particular we shall state an abstract existence theorem and a simple corollary, followed by a discussion of how they can be applied to the two species predator-prey systems being considered in this paper.

The abstract existence theorem relates, in a general setting, connecting orbits for the reaction system with connecting orbits (i.e., travelling waves) for the travelling wave system. So consider the following n-dimensional system of ordinary differential equations

$$\dot{u} = F(u) \tag{8.1}$$

and the corresponding $2n$-dimensional travelling wave system

$$\begin{aligned} \dot{u} &= v, \\ D\dot{v} &= \theta v - F(u), \end{aligned} \tag{8.2}$$

where D is a diagonal matrix with strictly positive entries and $(u,v) \in \mathbf{R}^n \times \mathbf{R}^n$. For the remainder of this section N will always denote an isolating neighborhood for (8.1) and $S = I(N)$, the maximal invariant set in N. Let ϕ^θ denote the flow on $\mathbf{R}^{2n}$ generated by (8.2). Let $\mathcal{M}(S) = \{M(p) \mid p \in (P,>)\}$ be a Morse decomposition for S and let $\mathcal{CM}(S)$ denote the set of connection matrices for $\mathcal{M}(S)$.

THEOREM 8.1. (i) *There exist positive constants K, Θ such that $N \times [-K,K] \subset \mathbf{R}^n \times \mathbf{R}^n$ is an isolating neighborhood for the flow ϕ^θ when $\theta > \Theta$.*

(ii) *Let $S^\theta = I(N \times [-K,K], \phi^\theta)$. Then, there exists a Morse decomposition of the form*

$$\mathcal{M}(S^\theta) = \{M(p^\theta) \mid p^\theta \in (P,>)\}$$

such that $M(p^\theta)$ and $M(p^{\bar{\theta}})$ are related by continuation for all $\theta, \bar{\theta} > \Theta$.

(iii) *If $\Delta^\theta \in \mathcal{CM}(S^\theta)$, the set of connection matrices for $\mathcal{M}(S^\theta)$, then Δ^θ is a degree n conjugation of Δ for some $\Delta \in \mathcal{CM}(S)$.*

Theorem 8.1 is considerably more general that what we need. For our purposes the following corollary will suffice.

COROLLARY 8.2. *Assume that:*

(i) *For all $p \in P$, $M(p)$ is a hyperbolic fixed point of* (8.1),

(ii) *$\mathcal{CM}(S)$ consists of a unique connection matrix Δ,*

(iii) *$p, q \in P$ are adjacent and $\Delta(p,q) \neq 0$.*

Then there exists Θ such that for $\theta > \Theta$:

(a) *$\mathcal{M}(S) = \{(M(p), 0) \mid p \in (P,>)\}$ is a Morse decomposition for S^θ,*

(b) *Δ^θ, a degree n conjugation of Δ, is the unique connection matrix for $\mathcal{M}(S^\theta)$,*

(c) *there exists a solution* $(u(t), v(t))$ *of* (8.2) *such that*

$$\lim_{t\to\infty}(u(t), v(t)) = (M(q), 0),$$
$$\lim_{t\to-\infty}(u(t), v(t)) = (M(p), 0).$$

The proofs of Theorem 8.1 and Corollary 8.2 can be found in §9. For the moment we concentrate on showing how Corollary 8.2 can be applied to two-species predator-prey systems. In particular, both Theorem 8.1 and Corollary 8.2 suggest that we begin our analysis by investigating the possible connection matrices for the predator-prey system. This has been done by Reineck [Re2] under hypothesis H1, H2, and H3. In particular, $\mathcal{M}(S) = \{M(p) = M_p \mid p = 1, 2, \ldots, 7\}$ forms a Morse decomposition of S, the set of bounded solutions in the positive orthant for the reaction system (8.1). The connection matrix can now be consider as map on

$$CH_0(M_1) \oplus CH_0(M_2) \oplus CH_0(M_3) \oplus CH_1(M_4) \oplus CH_1(M_5) \oplus CH_1(M_6) \oplus CH_2(M_7).$$

Thus it is a 7×7 matrix and since it is degree -1 it must be of the form

$$\Delta = \begin{array}{c|ccccccc} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ \hline M_1 & 0 & 0 & 0 & * & * & * & 0 \\ M_2 & 0 & 0 & 0 & * & * & * & 0 \\ M_3 & 0 & 0 & 0 & * & * & * & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & * \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & * \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & * \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

where $*$ denotes entries which need to be determined. The following theorem provides this information.

THEOREM 8.3 [R2, §3]. *Under the hypothesis* H1, H2, *and* H3, *only the following* 6 *connection matrices can be realized.*

$$B = \begin{array}{c|ccccccc} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ \hline M_1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

$$C = \begin{array}{c|ccccccc} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ \hline M_1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

$$D = \begin{array}{c|ccccccc|} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ M_1 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

$$E = \begin{array}{c|ccccccc|} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ M_1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

$$F = \begin{array}{c|ccccccc|} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ M_1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 1 & 1 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array},$$

$$G = \begin{array}{c|ccccccc|} & M_1 & M_2 & M_3 & M_4 & M_5 & M_6 & M_7 \\ M_1 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ M_2 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\ M_3 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ M_4 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_5 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_6 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ M_7 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{array}.$$

In order to simplify matters we shall make the following assumption.

H10. *The reaction system* (8.1) *is Morse–Smale.*

By Reineck [Re1], H10 implies that the connection matrix is unique. Furthermore, if any entry in the matrix is nonzero then the Morse sets are adjacent, and therefore Corollary 8.2 is applicable. This raises the question, which of the six possible connection matrices correspond to the systems we have been studying. Before providing an answer let us introduce a formal hypothesis. Recall from H2 that $u_2 = \xi_2$ is the point at which $q(u_2)$, the zero set of g, reaches an absolute minimum. Also recall that $M_4 = (a_4, b_4)$.

H11. $q(\xi_2) \leq a_4$

Implicit in the discussion of [Re2] is the following result.

PROPOSITION 8.4. *Assume* H1, H2, H3, *and* H10. *If in addition one assumes*:

(a) H5, *then* $\Delta = E, F,$*or* G;

(b) H11, *then* $\Delta = C, D,$ *or* G;

(c) H5 *and* H10, *then* $\Delta = G$.

Recall that H5 was essential to our construction of an isolating neighborhood for the $M(2) \to M(3)$ bistable wave. From Fig. 5.1 we see that we are assuming H11 in our proof of the existence of the $M(3) \to M(1)$ wave. Therefore, by Proposition 8.4 for hypotheses under which the results of §6 hold, the connection matrix for the reaction system is G. Therefore, as an example of how to apply Propositions 8.2 and 8.4 we state the following result.

PROPOSITION 8.5. *Given* H1–H3, H5, H10, *and* H11, *there exists* $\Theta > 0$ *such that for all* $\theta > \Theta$ *there exist Fisher waves of the form*

$$\begin{aligned} &M(4) \to M(1), &&M(4) \to M(2),\\ &M(5) \to M(2), &&M(5) \to M(3),\\ &M(6) \to M(1), &&M(6) \to M(3). \end{aligned}$$

While Corollary 8.2 is easy to state and easy to apply, its hypotheses are somewhat stronger that desired. In particular, even if 8.2(iii) is violated, i.e., $\Delta(p,q) = 0$, it is possible to have an $M(p) \to M(q)$ travelling wave. As an example consider the following result.

PROPOSITION 8.6. *Assume* H1–H3, H5, H10, *and that* $\Delta = E$. *Then, there exists* $\Theta > 0$ *such that for all* $\theta > \Theta$ *there exists Fisher waves of the form*

$$\begin{aligned} &M(4) \to M(1), &&M(4) \to M(2),\\ &M(5) \to M(2), &&M(5) \to M(3), \end{aligned}$$

and two distinct waves

$$M(6) \to M(3).$$

Proof. For the reaction system (1.2) one can always find an isolating neighborhood which contains an $M_6 \to M_3$ connecting orbit (see [Re2, §3]) and for which, restricted to that neighborhood, the connection matrix entry $\Delta(6,3) = 1$. Since, for $\Delta = E$, $\Delta(6,3) = 0$, there exists another connecting orbit (this follows directly from [McC, Thm. 2.5]). Now apply Theorem 8.1. □

This result should be contrasted with those of one-dimensional systems where the Fisher waves have been most extensively considered. First, for a given wave speed in one species systems there can be at most one Fisher wave connecting two stationary solutions. For two species problems this is no longer the case. Second, in the one species case the minimum wave speed which these Fisher waves occur is associated with the appearance of a bistable wave. This wave speed is known to be unique for the one species problem. In the two species model there is no reason to assume that the minimum wave speed agrees for the two distinct Fisher waves.

We now turn to the question of determining the existence of HDF waves. Recall that for the systems being consider in this paper these take the form $M(7) \to M(j)$ where $j = 1,2,3$. The key to proving the existence of these wave is the following theorem.

THEOREM 8.7 [M-R, Thm. 3.2]. *Let* Δ^θ *be the unique connection matrix for the Morse decomposition* $\mathcal{M}(S^\theta) = \{M(p^\theta) \mid p^\theta \in (P, >^\theta)\}$ *where* $>^\theta$ *is the flow defined order. Let* $\{\alpha, \beta^\pm, \gamma\} \subset P$. *Assume*:

(i) $\gamma >^\theta \beta^\pm >^\theta \alpha$,

(ii) $\{\alpha, \beta^+, \gamma\}$ *and* $\{\alpha, \beta^-, \gamma\}$ *are intervals in* P,

(iii) $\Delta(\beta^\pm, \alpha) \circ \Delta(\gamma, \beta^\pm) \neq 0$,

(iv) $C\check{H}_*(M(p); \mathbf{Z}_2)$ *is finitely generated for* $p \in \{\alpha, \beta^\pm, \gamma\}$.

Then there exists a connected set $\Gamma \subset C(M(\gamma), M(\alpha))$ such that $\mathrm{cl}(\Gamma) \cap M(\beta^{\pm}) \neq \emptyset$.

Obviously, given H1–H3 and H10, Theorems 8.1 and 8.3 determine the possibilities for Δ^{θ}. Now to apply Theorem 8.7 we need only find four element subsets of $\{1,2,3,4,5,6,7\}$ for which the hypotheses apply. As an example of this assume $\Delta^{\theta} = G$. Consider the sets

$$\{\alpha, \beta^{+}, \beta^{-}, \gamma\} = \{7,6,4,1\}, \quad \{7,5,4,2\}, \quad \text{or } \{7,6,5,3\}.$$

It is easy to check that they satisfy hypotheses (i)–(iv), and hence, Theorem 8.7 provides the existence of HDF waves. In fact, since we know that $M(7)$ is a hyperbolic critical point with a four-dimensional unstable manifold and $M(i)$, $i = 1,2,3$, are hyperbolic critical points with two-dimensional unstable manifolds we can conclude that the set of connecting orbits $M(7) \to M(i)$, $i = 1,2,3$, contains open 2-disks. For a more detailed discussion of Theorem 8.7, possible variations, and its applications we refer the reader to [M-R].

Aside from demonstrating how to find Fisher waves, this section serves another purpose, and that is to show how far we are from a general understanding of the existence of travelling waves for predator-prey systems. As was mentioned before, to obtain the types of results presented in §6, it must be that the connection matrix for the reaction system is of the form G. In particular, if the connection matrix for the reaction system is of the form B or D (and Theorem 8.3 guarantees the existence of such systems), then our analysis for the existence of either an $M(2) \to M(3)$ or $M(3) \to M(1)$ travelling wave fails. It is easy to see why this is the case; all our constructions of isolating neighborhoods in §§3 and 5 were based on finding monotone travelling waves. However, the obvious homotopies for the latter two cases suggest the existence of a nonmonotone wave. It seems reasonable to speculate that such waves could be of physical interest if one assumes that the diffusion coefficients are small while the reaction terms are large. If this is indeed the case, then this suggests an important future avenue of research.

9. Proof of Theorem 8.1.

Although it will be clear from the proof, we wish to emphasize that Theorem 8.1 is essentially a corollary of perturbation results due to Conley and Fife [C-F].

Proof of Theorem 8.1. Consider the system of equations

$$(9.1)\qquad \begin{aligned} u' &= \epsilon F(u) + \epsilon w, \\ w' &= D^{-1}w - \epsilon \nabla F(u) \cdot Dw - \epsilon \nabla F(u) \cdot F(u). \end{aligned}$$

For $\epsilon = 0$, (9.1) becomes

$$(9.2)\qquad u' = 0, \qquad w' = D^{-1}w.$$

Since D^{-1} is a diagonal matrix with strictly positive entries, $\{(u,w) \mid w = 0\}$ defines a critical manifold [C-F, p. 160]. The corresponding limit equation [C-F, p. 164] is

$$(9.3)\qquad u' = F(u).$$

If one sets $\epsilon = c^{-2}$, $' = 1/c$ $\dot{}$, and $Dw = \theta v - F(u)$, then (9.1) becomes (8.2), the travelling wave system. One now applies Theorems 3.5A and 3.5B of [C-F] to obtain (i), (ii), and the fact that for every attractor repeller pair of $\mathcal{M}(S^{\theta})$ the connecting maps are n-fold suspensions of the connecting maps for the corresponding attractor-repeller pair in $\mathcal{M}(S)$. (iii) now follows from [Fr2, Thm. 5.7]. □

Proof of Corollary 8.2. An easy eigenvalue computation or [C-F] guarantees that if M_p is a hyperbolic fixed point for (8.1), then so is $(M_p, 0)$ for (8.2) and θ large. Thus (a) follows from Theorems 3.5A and 3.5B of [C-F]. Observe that (b) follows from 8.2(ii) and 8.1(iii), while (c) follows from 8.2(iii) and properties of the connection matrix. □

SINGULARITIES OF THE X-RAY TRANSFORM AND LIMITED DATA TOMOGRAPHY IN $\mathbb{R}^2$ AND $\mathbb{R}^3$*

ERIC TODD QUINTO†

Abstract. Given a function f, the author specifies the singularities of f that are visible in a stable way from limited X-ray tomographic data. This determines which singularities of f can be stably recovered from limited data and which cannot, no matter how good the inversion algorithm. Microlocal analysis is used to determine the relationship between the singularities of a function f and those of its X-ray transform. The results are applied to determine the singularities that are visible for limited angle tomography and the interior and exterior problems. The author also suggests a practical method to use this relationship to reconstruct singularities of f from limited data Rf. The X-ray transform with sources on a curve in $\mathbb{R}^3$ is also analyzed.

Key words. X-ray transform, limited data tomography, microlocal analysis

AMS subject classifications. primary 44A12, 92C55; secondary 35S30, 58G15

1. Introduction. X-ray tomography is an important, noninvasive, practical way of finding the density of objects. In standard tomography, X-rays of the object are taken over an evenly distributed set of lines, so-called *complete tomographic data*, and well-known algorithms are used to recover a good approximation to that object [21]. Inversion is only mildly ill-conditioned (continuous of order $\frac{1}{2}$ in Sobolev norms). However, one often needs to find the density of an object but one cannot get X-ray tomographic data over an evenly spaced set of lines through the object but only some subset; one has *limited tomographic data.* Limited data tomography is important in medical imaging [21], scientific tomography [1], and industrial nondestructive evaluation [28].

In general, reconstruction from limited tomographic data is much more highly ill-posed than reconstruction from complete data [6]. As a result, inversion algorithms using limited data, generally, can create artifacts, blurring or other distortions in their reconstructions. The goal of this article is to classify what singularities can be stably reconstructed from limited data and what singularities cannot be stably reconstructed no matter how good the algorithm. To do this, we will use a precise concept of singularity: *the wavefront set,* and a precise concept of stability: *continuity in microlocal Sobolev norms.* Then we will tell which singularities the X-ray transform "sees" stably and which singularities are not stably detected from limited data. The reason we can do this is because the X-ray transform is an elliptic Fourier integral operator and, therefore, changes wavefront sets in specific ways.

We do not claim that all limited data tomography algorithms will reconstruct the "visible" singularities well. Rather, we claim that, if a singularity is not stably visible from limited data, no algorithm can reconstruct it stably. For "visible" singularities our theorem gives stability estimates of order $\frac{1}{2}$ in Sobolev norms, so one would ex-

pect "visible" singularities to be well constructed by a "good" algorithm even in the presence of noise.

This work is a natural outgrowth of [26], which gave the general principle (3.3) we make more precise and then prove in §3–4. Palamodov stated a closely related idea in [22]. The "tangent casting" effects of [30] is an intuitive way of expressing (3.3) below. One can also understand stability of these problems using singular value decompositions [4], [14], [16], [17], [18]. Lambda tomography [5] is a well developed algorithm that finds singularities of a function from real tomographic data. Their method works quite well with interior data (Example 3.3). Ramm and Zaslavsky [29] have developed a method using Legendre transforms to reconstruct the singularities of a function from knowing the singularities of its Radon transform. They consider functions $f = \psi\chi_D$, where D is a piecewise smooth domain and ψ is smooth—functions with the jump singularities on ∂D, and they use the behavior of Rf at ∂D to find the (jump) singularities of f. Technicians currently use the sinogram, the graph of $Rf(\theta, p)$ in rectangular coordinates, to find boundaries, but this method is subjective.

In Remark 3.2, we propose a method to reconstruct singularities (classified by Sobolev wavefront set) for arbitrary functions from general limited data.

Section 2 of this article provides the definitions of singularity and microlocal Sobolev smoothness. In §3 we give the singularity result for the Radon transform in the plane, Theorem 3.1. We apply this to determining singularities of arbitrary functions from general limited data (Remark 3.2) and to show limitations inherent in the common types of limited data tomography (Examples 3.3–3.5). Reconstructions from exterior data are presented that illustrate our analysis. §4 gives analysis and results for the X-ray transform with sources on a curve in $\mathbb{R}^3$.

2. Microlocal singularities and Sobolev spaces. Our development is valid for distributions as well as functions, so first, we recall some basic definitions. $\mathcal{D}(\mathbb{R}^n)$ is the space of C^∞ functions of compact support. A distribution $f \in \mathcal{D}'(\mathbb{R}^n)$ is a continuous linear functional on $\mathcal{D}(\mathbb{R}^n)$. A distribution f has compact support if there is a compact set $K \subset \mathbb{R}^n$ such that $f(\phi) = 0$ for all functions $\phi \in \mathcal{D}(\mathbb{R}^n)$ with support disjoint from K, that is, f is zero outside of K. The set of distributions of compact support is denoted by $\mathcal{E}'(\mathbb{R}^n)$.

The wavefront set of $f \in \mathcal{D}'(\mathbb{R}^n)$ is a powerful classification of singularities because it involves not only a point x_0 at which f is not smooth, but also a *direction* in which f is not smooth at x_0. To understand this we recall some facts about the Fourier transform. When f has compact support, then f is equal to a C^∞ function almost everywhere if and only if its Fourier transform, $\mathcal{F}f$, decreases rapidly in all directions (for all $N \in \mathbb{N}$, there exists C_N such that for all $\xi \in \mathbb{R}^n$, $|\mathcal{F}f(\xi)| \le C_N(1 + |\xi|)^{-N}$). This relates global smoothness of f to rapid decrease of its Fourier transform. A local version of this at a point $x_0 \in \mathbb{R}^n$ would be obtained by multiplying f by a smooth cut-off function, ϕ (with $\phi(x_0) \neq 0$) and seeing if this Fourier transform is rapidly decreasing in every direction. However, this localized Fourier transform $\mathcal{F}(\phi f)$ gives even more specific information—microlocal information—namely, the *directions* in which $\mathcal{F}(\phi f)$ does not decrease rapidly.

DEFINITION 2.1. Let $f \in \mathcal{D}'(\mathbb{R}^n)$ and let $x_0 \in \mathbb{R}^n$ and $\xi_0 \in \mathbb{R}^n \setminus 0$. Then we say $(x_0, \xi_0) \in \mathrm{WF}f$, the wavefront set of f, if and only if for each cut-off function at x_0, $\phi \in \mathcal{D}(\mathbb{R}^n)$ with $\phi(x_0) \neq 0$, $\mathcal{F}(\phi f)$ does not decrease rapidly in any open conic neighborhood of the ray $\{t\xi_0 | t > 0\}$.

For example, if $D \subset \mathbb{R}^n$ has smooth boundary, then $\mathrm{WF}\chi_D$ is exactly the set of normals to ∂D. One can prove this using the definition and a local coordinate change to flatten ∂D locally. If ψ is a smooth function then $\mathrm{WF}\psi\chi_D \subset \mathrm{WF}\chi_D$, and if ψ is not zero anywhere on ∂D, then these sets are equal [11], [24, Lemma 13.3, p. 279].

As defined, WFf is a closed subset of $\mathbb{R}^n \times (\mathbb{R}^n \setminus 0)$ that is conic in the second variable. The Sobolev space analogue to the concept of microlocal smoothness is as follows (see [24, p. 259]).

DEFINITION 2.2. A distribution f is in the Sobolev space H^s microlocally near (x_0, ξ_0) if and only if there is a cut-off function $\phi \in \mathcal{D}(\mathbb{R}^n)$ with $\phi(x_0) \neq 0$ and function $u(\xi)$ homogeneous of degree zero and smooth on $\mathbb{R}^n \setminus 0$ and with $u(\xi_0) \neq 0$ such that $u(\xi)\mathcal{F}(\phi f)(\xi) \in L^2(\mathbb{R}^n, (1 + |x|^2)^s)$.

First, one localizes near x_0 by multiplying f by ϕ and then one takes Fourier transform. Finally, one *microlocalizes* near ξ_0 by forming $u\mathcal{F}f$ and see if this is in $\mathcal{F}(H^s(\mathbb{R}^n))$. It follows from the definition that, if $(x_0, \xi_0) \notin \mathrm{WF}f$, then for all s, f is H^s near (x_0, ξ_0).

Wavefront set and microlocal smoothness are usually defined on $T^*(\mathbb{R}^n) \setminus 0$, the cotangent space of $\mathbb{R}^n$ with its zero section removed, because such a definition can be extended invariantly to manifolds using local coordinates. For the manifold $[0, 2\pi] \times \mathbb{R}$, choosing a function $\phi(\theta, p)$ with sufficiently small support allows one to use θ and p as local coordinates. We will use these conventions.

3. The X-ray transform in the plane.

In $\mathbb{R}^2$ the microlocal analysis of the X-ray transform is easier to describe if one uses parallel-beam geometry rather than fan-beam geometry. By rebinning—a coordinate change—the results are the same as for fan-beam data for functions supported inside the circle of sources. First, let $\cdot$ denote the standard inner product on $\mathbb{R}^2$; let $|\ |$ be the induced norm. Let $\theta \in [0, 2\pi]$, and let $p \in \mathbb{R}$. Let $\overline{\theta} = (\cos\theta, \sin\theta)$ and $\theta^\perp = (-\sin\theta, \cos\theta)$. Now let $\ell(\theta, p) = \{x \in \mathbb{R}^2 | x \cdot \overline{\theta} = p\}$, the line with normal vector $\overline{\theta}$ and directed distance p from the origin. The points (θ, p) and $(\theta + \pi, -p)$ parameterize the same line $\ell(\theta, p)$. Let ds be arc length, the measure on $\ell(\theta, p)$ induced from Lebesgue measure on $\mathbb{R}^2$. The classical X-ray transform in the plane is defined for an integrable function f on $\mathbb{R}^2$ by

$$Rf(\theta, p) = \int_{y \in \ell(\theta, p)} f(y)\,ds. \tag{3.1}$$

$Rf(\theta, p)$ is the integral of f over the line $\ell(\theta, p)$.

In order to describe the main theorem, we will consider wavefront sets as subsets of cotangent spaces. To this end, let $x_0 \in \mathbb{R}^2$. If $y = (y_1, y_2) \in \mathbb{R}^2$, then we let $y\mathbf{dx} = y_1\mathbf{dx}_1 + y_2\mathbf{dx}_2$ be the cotangent vector corresponding to y in $T^*_{x_0}\mathbb{R}^2$. Now let $(\theta_0, p_0) \in [0, 2\pi] \times \mathbb{R}$. Here we will identify $[0, 2\pi]$ with the unit circle by equating zero with 2π. Then for $(\theta, p) \in [0, 2\pi] \times \mathbb{R}$, we let $\mathbf{d\theta}$ and $\mathbf{dp}$ be the standard basis of $T^*_{(\theta,p)}([0, 2\pi] \times \mathbb{R})$. The theorem follows.

THEOREM 3.1. *Let $f \in \mathcal{E}'(\mathbb{R}^2)$. If $(x; \xi) \in T^*(\mathbb{R}^n) \setminus O$ is not conormal to $\ell(\theta_0, p_0)$, then wavefront set of f at $(x; \xi)$ does not contribute to* WFRf *above (θ_0, p_0). Let $x_0 \in \ell(\theta_0, p_0)$ and let $\eta_0 = \mathbf{dp} - (x_0 \cdot \theta_0^\perp)\mathbf{d\theta}$. Let $a \neq 0$. The correspondence between* WFf *and* WFRf *is:*

$$(x_0; a\overline{\theta}_0\mathbf{dx}) \in \mathrm{WF}f \quad \textit{if and only if } (\theta_0, p_0; a\eta_0) \in \mathrm{WF}Rf. \tag{3.2}$$

Given $(\theta_0, p_0; a\eta_0)$, $(x_0; a\overline{\theta}_0\mathbf{dx})$ is uniquely determined by (3.2). *Moreover, $f \in H^s$ is microlocally near $(x_0; a\overline{\theta}_0\mathbf{dx})$ if and only if $Rf \in H^{s+1/2}$ is microlocally near $(\theta_0, p_0; a\eta_0)$.*

Theorem 3.1 provides an exact correspondence between singularities of f and those of Rf. Moreover, it states that the singularities of Rf that are detected are of Sobolev order $\frac{1}{2}$ smoother than the corresponding singularities of f. For typical singularities of f (jump singularities in $H^{1/2-\epsilon}$) one can realistically expect the corresponding singularities of Rf not to be masked by noise. Reconstructions given in Figs. 1 and 2 will corroborate this.

The theorem has this simple corollary:

(3.3)
The X-ray transform data Rf for (θ, p) arbitrarily near (θ_0, p_0) detects singularities of f perpendicular to the line $\ell(\theta_0, p_0)$ but not in other directions.

This follows because of the correspondence (3.2): $Rf(\theta, p)$ is smooth near (θ_0, p_0) (no wavefront set near this point) if and only if there is no wavefront set of f at points on $\ell(\theta_0, p_0)$ conormal to the line.

As an example, let D be a compact set with smooth boundary and let $f = \psi\chi_D$, where ψ is a smooth function that is not zero anywhere on ∂D. Then, by (3.3), $Rf(\theta, p)$ is smooth near (θ_0, p_0) if and only if $\ell(\theta_0, p_0)$ is not tangent to ∂D. If ∂D is not smooth then more wavefront directions will appear at points where ∂D is not smooth. Remark 3.2 gives a more general observation with practical implications.

Remark 3.2. The correspondence (3.2) gives a way to find WFf from knowing WFRf. Given $(\theta_0, p_0; a\eta_0) \in \mathrm{WF}Rf$, the rule (3.2) determines $(x_0; a\overline{\theta}_0\mathbf{dx})$ uniquely. This method to find singularities of f is easiest to describe in the case f is C^1 except for jump singularities on a collection, E, of C^1 curves. In this case, almost all singularities of f are in $H^{1/2-\epsilon}$ (so corresponding singularities of Rf are in $H^{1-\epsilon}$) for $\epsilon > 0$ but not for $\epsilon = 0$. One can take a local (discrete) Fourier transform of Rf in (θ, p) and find the directions in which the localized transform is not in $\mathcal{F}H^1$. Perhaps this can be efficiently done just by calculating local fast Fourier transforms and looking for directions in which they do not decrease quickly. Then the rule (3.2) gives the covectors $(x_0; a\overline{\theta}_0\mathbf{dx})$ at which f is not $H^{1/2}$. These covectors specify the jump singularities of f, that is the location of E (and $\overline{\theta}_0$ even gives the normal to E at x_0). This method also filters out noise that is H^1 or smoother.

This method can be used for limited data problems: the method is local in the strong sense that singularities of Rf at (θ_0, p_0) (and therefore the corresponding singularities of f on $\ell(\theta_0, p_0)$) are determined by data $Rf(\theta, p)$ for (θ, p) near (θ_0, p_0). This method is being pursued.

Proof of Theorem 3.1. The microlocal correspondence between WFf and WFRf is in the literature (e.g., [8], [25]), but since it is especially straightforward in this case, it will be given here. First, note that the Schwartz kernel of the operator R is the distribution on $\mathbb{R}^2 \times \big([0, 2\pi] \times \mathbb{R}\big)$ that is integration with respect to the weight $dxd\theta$ over the set $Z = \{(x, \theta, p) | x \cdot \overline{\theta} = p\}$. This is a special type of distribution and in [10] it is shown to be a Fourier integral distribution associated with the Lagrangian manifold $\Gamma = N^*Z \setminus 0$ where N^*Z is the conormal bundle of Z in $T^*\big(\mathbb{R}^2 \times ([0, 2\pi] \times \mathbb{R})\big)$. As shown in [8] (see also [25] for details), because the measure of integration $dxd\theta$ is nowhere zero and the projection from Γ to $T^*([0, 2\pi] \times \mathbb{R}) \setminus 0$ is a injective immersion, R is elliptic with elliptic inverse that composes well with R. To understand what R does to wavefront sets, one must calculate the set Γ. Z is defined by the equation $x \cdot \overline{\theta} - p = 0$ and so its differential, $\overline{\theta}\mathbf{dx} + x \cdot \theta^\perp \mathbf{d\theta} - \mathbf{dp}$, is a basis of N^*Z at each point. Therefore,

$$\Gamma = \big\{\big(x, \theta, p; a(\overline{\theta}\mathbf{dx} + x \cdot \theta^\perp \mathbf{d\theta} - \mathbf{dp})\big) \big| (x, \theta, p) \in Z,\ a \neq 0\big\}. \tag{3.4}$$

By the calculus of elliptic Fourier integral operators, there is a simple correspondence between WFf and WFRf: $(x; \xi) \in \mathrm{WF}f$ if and only if there is a $(\theta, p; \eta) \in \mathrm{WF}Rf$

with $(x, \theta, p; \xi, -\eta) \in \Gamma$ [31]. Using (3.4) we see this correspondence is exactly (3.2). Furthermore this correspondence coming from (3.4) shows that if $(x; \xi)$ is not conormal to $\ell(\theta_0, p_0)$, then wavefront set of f at $(x; \xi)$ does not contribute to WFRf above (θ_0, p_0). To see that (3.2) uniquely determines $(x_0; \overline{\theta}_0 \mathbf{dx})$, first note that a is determined by the $\mathbf{dp}$ coordinate of $a\eta_0$. Then as $a \neq 0$, $x_0 \cdot \theta_0^\perp$ is determined by the $\mathbf{d\theta}$ coordinate of $a\eta_0$, and finally $x_0 \cdot \overline{\theta}_0 = p$ determines x_0.

The assertion about H^s will be given because, although it is straightforward, it is not in the elementary literature. We prove one direction and leave the other to the reader. Let Rf be in $H^{s+1/2}$ near $(\theta_0, p_0; a\eta_0)$. Then, by Theorem 6.1 [24, p. 259], $Rf = u_1 + u_2$ where $u_1 \in H_c^{s+1/2} = H^{s+1/2} \cap \mathcal{E}'$, $u_2 \in \mathcal{E}'$, and $(\theta_0, p_0; a\eta_0) \notin \text{WF}u_2$. Because R^{-1} is a Fourier integral operator continuous of order $\frac{1}{2}$ [8] and $u_1 \in H_c^{s+1/2}$, $R^{-1}u_1 \in H_{\text{loc}}^s(\mathbb{R}^2)$ [31]. R^{-1} is a Fourier integral operator associated to Γ (with $\mathbb{R}^2$ and $[0, 2\pi] \times \mathbb{R}$ coordinates reversed) and so the "inverse" relation to (3.2) holds for R^{-1}. Therefore, as $(\theta_0, p_0; a\eta_0) \notin \text{WF}u_2$, $(x_0; a\overline{\theta}_0 \mathbf{dx}) \notin \text{WF}(R^{-1}u_2)$. Therefore, $f = R^{-1}u_1 + R^{-1}u_2$ is the sum of a distribution in H_{loc}^s and one that is smooth near $(x_0; a\overline{\theta}_0 \mathbf{dx})$. Therefore, by Theorem 6.1 [24, p. 259], f is microlocally H^s near $(x_0; a\overline{\theta}_0 \mathbf{dx})$. □

We now apply Theorem 3.1 and (3.3) to three common types of limited data tomography in the plane.

Example 3.3. *Limited angle tomography.* Let $U \subset [0, 2\pi]$ be open, $U = U + \pi$ mod 2π. In limited angle tomography, one knows data $Rf(\theta, p)$ for all p and for $\theta \in U$. One can reconstruct $f(x)$ for all $x \in \mathbb{R}^2$ from limited angle data [21]. However, by (3.3), the only singularities of f that one can detect in a stable way are those with directions in U. To see this, choose $x \in \mathbb{R}^2$ and $\theta \in U$. Any wavefront of f at $(x; \overline{\theta}\mathbf{dx})$ is detected by limited angle data because the line $\ell(\theta, x \cdot \overline{\theta})$ is in this data set. For the same reason, wavefront of f at $(x; \overline{\theta}\mathbf{dx})$ for $\theta \notin U$ will not be stably detected by this limited angle data.

This phenomenon is illustrated by the singular functions in [14]. Those corresponding to large singular values (easy to reconstruct) oscillate generally in directions in U and those corresponding to small singular values (hard to reconstruct) oscillate generally in directions outside of U. This is also seen in the actual reconstructions from limited angle tomography.

Example 3.4. *The interior problem.* Let $M > 1$ and assume supp $f \subset \{x \in \mathbb{R}^2 \big| |x| \leq M\}$. In this problem, one has data $Rf(\theta, p)$ for all θ but only for $|p| < 1$. The goal is to reconstruct $f(x)$ for $|x| < 1$. Simple examples show this is impossible in general. However, according to (3.3), one can detect all singularities of f in $|x| < 1$. To see this, choose a point x inside the unit disk and choose a direction $\theta \in [0, 2\pi]$. Then the line through x and normal to $\overline{\theta}$ is in the data set for interior tomography and so any singularity of f at $(x; \overline{\theta}\mathbf{dx})$ is detected by interior data.

Lambda tomographic reconstructions are local—they use data $Rf(\theta, p)$ only for lines $\ell(\theta, p)$ near x to reconstruct at x. So Lambda tomography is useful for the interior problem. In fact, Lambda tomographic reconstructions for the interior problem clearly show the singularities of f in the unit disk [5]. Maass [18] has developed a singular value decomposition for this problem. See also [16].

Example 3.5. *The exterior problem.* Assume supp $f \subset \{x \in \mathbb{R}^2 \big| |x| \leq M\}$. Here one has data $Rf(\theta, p)$ for all θ but only for $|p| > 1$. By [3] one can reconstruct $f(x)$ for $|x| > 1$. Let $|x| > 1$ and $\theta \in [0, 2\pi]$. Then the only singularities of f at x that are reconstructed in a stable manner are those for θ with $\ell(\theta, x \cdot \overline{\theta})$ in the data set, that is, for $|x \cdot \overline{\theta}| > 1$. Other singularities of f are not stably detected. This can be seen from the reconstructions in Figs. 1 and 2.

Lewitt and Bates [13], Louis [15], and Natterer [20] have developed good reconstruction algorithms that use exterior data. The author has developed an exterior reconstruction algorithm which employs Perry's singular value decomposition [23] and a priori information about the shape of the object to be reconstructed. Reconstructions for "medical" phantoms are in [26] and those for industrial phantoms are in [27], [28]. Exactly those singularities that are supposed to be stably reconstructed are clearly defined. In the author's algorithm, singularities that are not "visible" are smeared; reconstructions will now be given.

Figure 1 shows an object with outer radius $M = 1.5$ on a rectangular grid. The two bigger circles have density 1.5 and the two smaller 1.375. The annulus has density one. The reconstruction in Fig. 1b is gotten using the author's algorithm with noiseless data. The reconstruction in Fig. 1c is from the same algorithm but using data with slightly less than 1% L^∞ noise. Data are taken over lines using 100 values of p and 256 of θ [26]. In both reconstructions, the principle (3.3) is illustrated. However, the reconstruction with noise, Fig. 1c, shows some algorithm limitations as well (and reminds one that algorithm limitations independent of the principle can be important). The slightly darker areas in the background in Fig. 1c are the result of amplified high polar Fourier coefficients due to the noisy data.

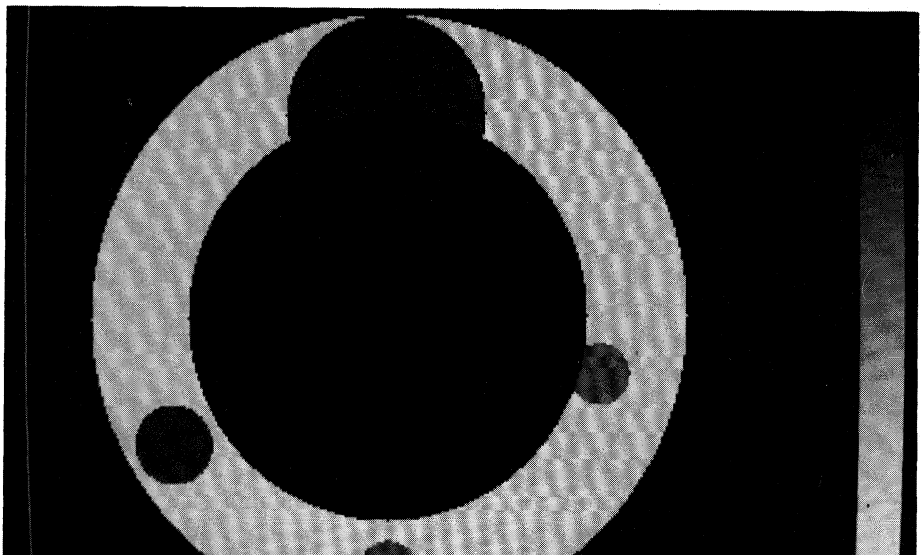

FIG. 1a. *Rectangular coordinate display of the phantom* [26] (*similar to the phantom in* [20]).

Figure 2 shows polar coordinate displays for $x = (r, \theta)$ with $\theta \in [\pi/8, 3\pi/8]$ on the horizontal axis and $r \in [1, 1.10]$ on the vertical axis ($r = 1.10$ at the bottom) [28]. To provide sufficiently fine radial resolution, the scale in r is magnified by a factor of 7.85. The phantom in Fig. 2 is supposed to represent a rocket motor with fuel of density 1.7 inside the circle of radius $r = 1.052$, an insulator of density 1.1 from

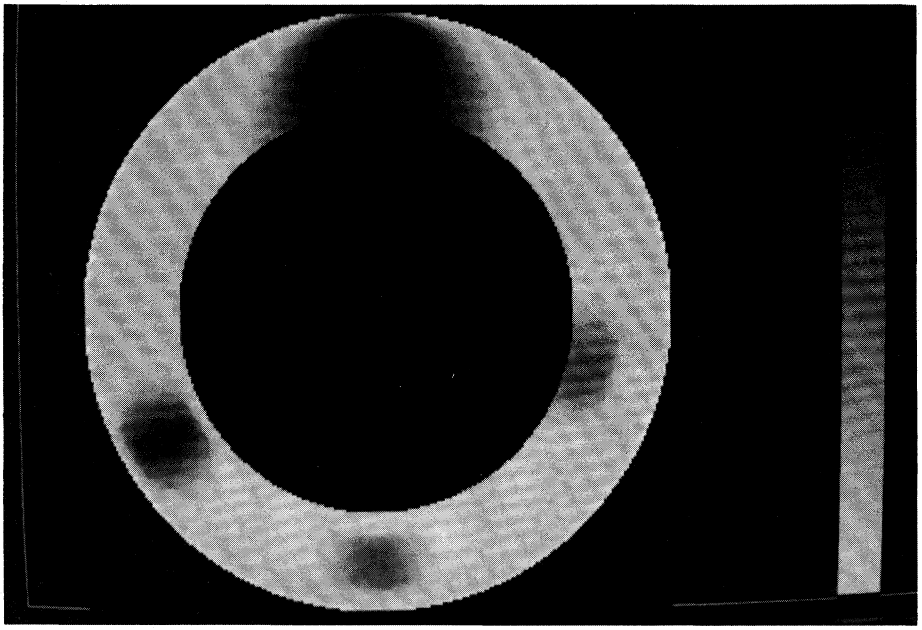

FIG. 1b. *Rectangular coordinate display of the reconstruction without noise of the phantom in Fig.* 1a [26].

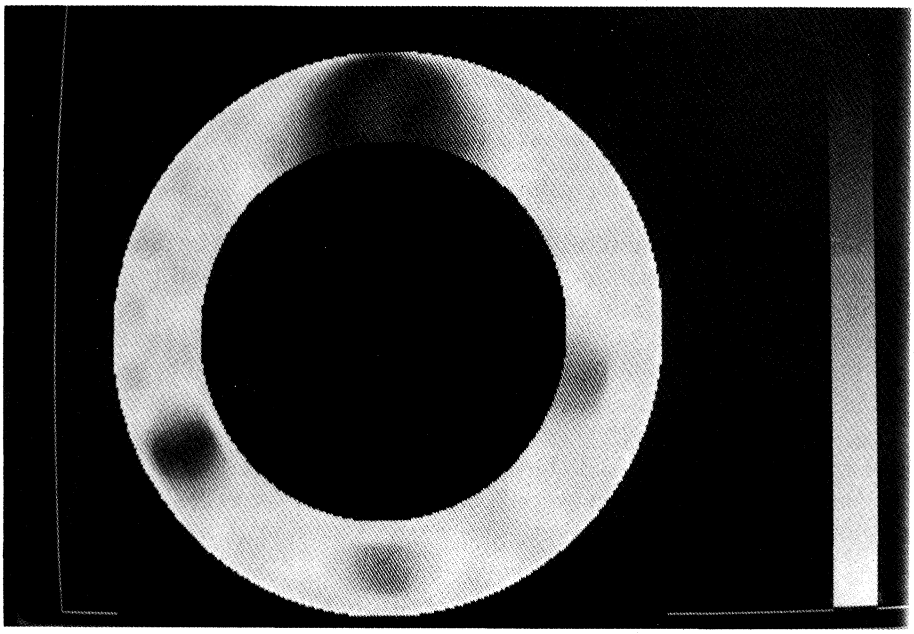

FIG. 1c. *Rectangular coordinate display of the reconstruction with noise of the phantom in Fig.* 1a [26].

$1.052 < r < 1.056$, and a shell of density 1.5 and outer radius $r = 1.093$. The defect rests against the inside boundary of the insulator and extends for 0.06 radians and is 0.0014 units thick (it is seen tangentially by only three detectors). It is centered at $\pi/4$ radians and has density zero. The reconstruction is done with 1% multiplicative L^∞ noise. Data are collected in a fan beam with 200 rays from $p = 1.0$ to $p = 1.10$ that emanate from the source in evenly spaced angles. The source and fan beam rotate around the object in 512 equally spaced angles.

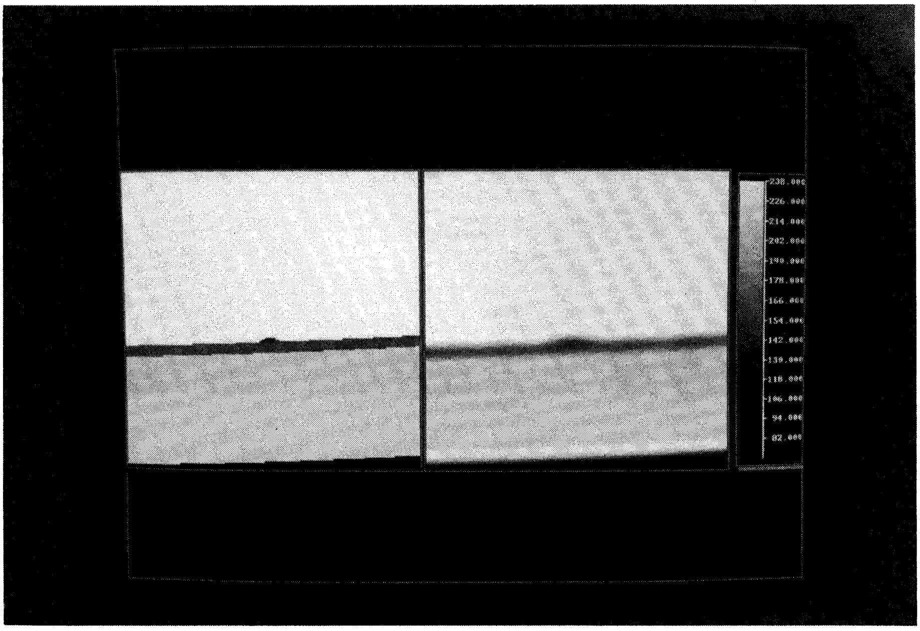

FIG. 2. *Polar coordinate display of rocket motor (phantom left, reconstruction with noise right)* [28]. *The "wedge" near* $r = 1.10$ *(at the bottom of the display) occurs because the center of the rocket is offset slightly from the center of the coordinate system.*

Because some wavefront directions are not stably detectable by limited angle data or by exterior data, inversion for these problems is highly ill-posed (see the example in [6] and the inverse discontinuity result in L^2 of [19]).

Reconstructions in Figs. 1 and 2 illustrate the principle (3.3). In the reconstruction in Fig. 1, the "sides" of the circles are blurred (corresponding to singularities normal to lines *not* in the data set), but the "inside" and "outside" boundaries of the circles are well reconstructed. This occurs despite the fact that only a few lines in the data set are tangent to the inside boundaries. The reconstructions of Fig. 2 are good (even though the problem is, in general, highly ill-posed) because all singularities are perpendicular to lines in the data set. This is true, even though the defect is very thin and short in extent.

4. The X-ray transform with sources on a curve in $\mathbb{R}^3$. The standard parameterization will be used for the divergent beam transform in $\mathbb{R}^3$. Let $\omega \in S^2$ and $x \in \mathbb{R}^3$, then the ray $\mathfrak{r}(\omega, x) = \{x + t\omega | t \geq 0\}$ is the ray parallel to ω and starting at x. The divergent beam transform of $f \in C_c(\mathbb{R}^3)$ is

$$Df(\omega, x) = \int_{t=0}^{\infty} f(x + t\omega)dt, \tag{4.1}$$

the integral of f over the ray $\mathfrak{r}(\omega, x)$. Typically, the sources for the divergent beam transform are points on a smooth closed curve γ. The divergent beam transform is defined for $f \in L^1_c(\mathbb{R}^3 \setminus \gamma)$ (L^1 functions of compact support in $\mathbb{R}^3 \setminus \gamma$) [9] (and even continuous on $\mathcal{E}'(\mathbb{R}^3 \setminus \gamma)$, [7]).

Inversion of the divergent beam transform is a limited data problem because data are given only over rays with sources on γ. Moreover, typically, X-rays are taken only over an open connected set, $\mathfrak{R}$, of rays with sources on γ. In general, as long as some ray in the data set is disjoint from supp f, then the part of f seen by the data (that is, supp $f \cap \left[\cup_{\mathfrak{r}\in\mathfrak{R}} \mathfrak{r}\right]$) is uniquely determined (see [9] and the generalization [2, Thm. 2.2]). Our theorem for the X-ray transform is as follows.

THEOREM 4.1. *Let γ be a smooth curve in $\mathbb{R}^3$ and $f \in \mathcal{E}'(\mathbb{R}^3 \setminus \gamma)$. Let $x_0 \in$ supp f and $\xi_0 \in T^*_{x_0}(\mathbb{R}^3) \setminus 0$. Then any wavefront set of f at $(x_0; \xi_0)$ is stably detected from data Df with sources on γ if and only if*

(4.2) *the plane $\mathcal{P}$, through x_0 conormal to ξ_0, intersects γ transversally.*

If data are taken over an open set of rays with sources on γ, then a ray in $\mathcal{P}$ from γ to x_0 must be in the data set for (4.2) *to apply. In these cases, f is in H^s microlocally near $(x_0; \xi_0)$ if and only if the corresponding singularity of Df is in $H^{s+1/2}$.*

The exact correspondence of singularities analogous to (3.2) can be obtained from the microlocal diagram (3.1.1) and the proof of Proposition 3.1.1 of [2]. Theorem 4.1 follows from [7] as well.

The global version of condition (4.2)—every plane meeting supp f intersects γ transversally—is called the Kirillov–Tuy condition. This condition is required for the inversion methods of Kirillov [12] and Tuy [32]. Under this condition, Finch [6] proves that $f \in H^s$ if $Df \in H^{s+1/2}$ for $s \geq \frac{1}{2}$ (and our theorem implies this fact for all s).

Typically, X-ray sources are placed on a circle surrounding the object to be reconstructed. Theorem 4.1 shows the singularities that are not detected by such data: singularities $(x_0; \xi_0)$ conormal to planes $\mathcal{P}$ not meeting the circle transversally. There are many such singularities—the more undetected singularities, the farther x_0 is from the plane of C. Finch [6] and others have noted that inversion with sources on one circle, C, is highly unstable. By analyzing the singular values, Maass shows that inversion is more stable for nonplanar curves such as two parallel circles or curves oscillating on a cylinder [17]. Condition (4.2) is another way to understand why inversion of data with sources on such nonplanar curves is better posed than for sources on one circle—in general, if the curve is nonplanar, more singularities can be detected stably from the given data.

Proof of Theorem 4.1. The microlocal assertion of Theorem 4.1 is a paraphrase of the comment about "type II complexes" below the statement of Proposition 3.1.1 of [2]. That comment is equivalent to the fact that if $x_0 \in \mathfrak{r}(\omega, y)$ for some $y \in \gamma$ and ξ_0 is conormal to ω then WFf at $(x_0; \xi_0)$ is detected by divergent beam data unless ξ_0 is conormal to γ at y. This is equivalent to condition (4.2). The statement about microlocal Sobolev spaces is valid because D is an elliptic Fourier integral operator of order $-\frac{1}{2}$ and so, if a singularity of f is detected by data Df, then the singularity of Df is $\frac{1}{2}$ order smoother than thę corresponding singularity of f. This can be proven just as the analogous statement in Theorem 3.1 is proven. □

HOMOGENIZATION OF DEGENERATE WAVE EQUATIONS WITH PERIODIC COEFFICIENTS*

YOUCEF AMIRAT[†], KAMEL HAMDACHE[‡], AND ABDELHAMID ZIANI[§]

Abstract. In this paper the authors discuss homogenization of hyperbolic equations involving periodic coefficients which are degenerate relative to a certain direction. The general scheme by which effective equations are obtained is as the reiterated homogenization. The first step of the process leads to equations describing the oscillatory behavior in the direction of the propagation. Next, space averaging in the degenerate direction gives the result. The process in the second step produces nonlocal effects.

Key words. homogenization, hyperbolic, oscillations, periodic media

AMS subject classifications. 35B25, 35B40, 35C10, 35L15

1. Introduction. The main purpose of this report concerns the study of the propagation and the interaction of oscillations for a class of degenerate wave equations in periodic microstructure. Many problems of wave propagation in composite media are modeled by equations of type: $\rho\,\partial_t^2 u - \operatorname{div}(k\,\mathrm{grad}\ u) + \theta\,\partial_t u = f$, where ρ is the fluid density, k is the bulk modulus of the medium, θ is the viscous damping coefficient, f refers to an external force, and u stands for the pressure. The coefficients ρ, k, and θ are highly oscillating, depending on two spatial variables usually referred to as macroscopic and microscopic variables. Let $\varepsilon > 0$ be the length scale which characterizes the heterogeneities of the medium. Under usual assumptions on ρ, k, and θ, discussions about effective equations can be found in Bensoussan, Lions, and Papanicolaou [8] and Sanchez-Palencia [18]. Our interest here is in the case in which the components of the anisotropic matrix k are taken to be negligible, i.e., small compared with ε^2, in certain direction of the domain, so that waves propagate only in the orthogonal direction. The matrix k is, therefore, of degenerate type, the classical homogenization results fail; see [7].

The outline of this paper is as follows. In §2, we discuss the equation

$$\rho\left(\frac{x}{\varepsilon},y,\frac{y}{\varepsilon}\right)\partial_t^2 u^\varepsilon - \operatorname{div}_x\left(k\left(\frac{x}{\varepsilon},y,\frac{y}{\varepsilon}\right)\mathrm{grad}_x u^\varepsilon\right) = f\left(t,x,\frac{x}{\varepsilon},y,\frac{y}{\varepsilon}\right) \tag{1.1}$$

for $t\in]0,T[$, $(x,y)\in\Omega$, where $T>0$, $\Omega=\mathbb{R}^n\times\mathcal{O}$, $\mathcal{O}$ is an open subset of $\mathbb{R}^m$, supplemented with initial conditions

$$u^\varepsilon(0,x,y)=\alpha(x,y),\quad \partial_t u^\varepsilon(0,x,y)=\beta(x,y),\quad (x,y)\in\Omega. \tag{1.2}$$

Here and below points in $\mathbb{R}^n$ are denoted by x and points in $\mathcal{O}$ are denoted by y. We denote by Y_k the unit cube in $\mathbb{R}^k$ and by $L^\infty_{\mathrm{per}}(Y_k)$ (respectively, $L^2_{\mathrm{per}}(Y_k)$) the space

of functions $\phi \in L^\infty(\mathbb{R}^k)$ (respectively, $L^2_{\text{loc}}(\mathbb{R}^k)$) such that ϕ is Y_k-periodic. The local variables related to Y_n-periodicity (respectively, Y_m-periodicity) are denoted by ζ (respectively, η). Assuming some hypotheses regarding the data $\rho = \rho(x, \zeta, y, \eta)$, $k = k(\zeta, y, \eta)$ and $f = f(x, \zeta, y, \eta)$, we want to describe the asymptotic behavior of the solution u^ε of (1.1), (1.2), more precisely to derive the effective equation satisfied by the weak limit u of (u^ε) as ε goes to zero.

The homogenization process we use will be carried out through two distinct steps following the reiterated homogenization principle; see Bensoussan, Lions, and Papanicolaou [8]. The first one gives the behavior when considering oscillations $\zeta \in Y_n$ in the direction x of the propagation. The main tool is the method of oscillatory test functions introduced by Tartar [19], [20]. To a subsequence of solutions (u^ε) of (1.1), (1.2), one can associate a function $U = U(t, x, y, \zeta, \eta)$ which represents its oscillatory behavior. We shall use a characterization in periodic microstructure due to Nguetseng [16]. One can find other developments related to this subject in Allaire [2], E [10], and Nguetseng [17]. The representation $U = U(t, x, y, \eta)$, which does not depend on the microscopic variable ζ thanks to the compactness property in the direction x, is a solution of the family of wave equations, parametrized by (y, η):

$$(1.3) \qquad \tilde{\rho}(y,\eta)\, \partial_t^2 U - \operatorname{div}_x(\tilde{k}(y,\eta)\operatorname{grad}_x U) = \tilde{f}(t,x,y,\eta), \quad t \in]0,T[, \quad x \in \mathbb{R}^n,$$

$$(1.4) \qquad U(0,x,y,\eta) = \alpha(x,y), \quad \partial_t U(0,x,y,\eta) = \beta(x,y), \quad x \in \mathbb{R}^n.$$

Here $\tilde{\rho}(y,\eta) = \int_{Y_n} \rho(\zeta, y, \eta)\, d\zeta$, $\tilde{f}(t,x,y,\eta) = \int_{Y_n} f(t,x,\zeta,y,\eta)\, d\zeta$, and $\tilde{k}(y,\eta)$ is the homogenized matrix with respect to oscillations ζ for fixed y and η.

Since $u(t,x,y) = \int_{Y_m} U(t,x,y,\eta)\, d\eta$, the next step consists of averaging (1.3) with respect to η. By Laplace and Fourier transforms of (1.3), (1.4), we reduce the averaging problem to characterize some weak limits as in the study of parametrized families of hyperbolic problems discussed in [5]. We distinguish two cases. The first one describes the situation where $\tilde{k}$ is an isotropic tensor; we follow the pattern given in [3]. The result is obtained using an integral representation for Nevanlinna–Pick's holomorphic functions; see Ahiezer and Krein [1], Donoghue [9], and Amirat et al. [3]. For an anisotropic tensor $\tilde{k}$, we apply Radon transform to (1.3), (1.4) as discussed in [5]. This reduces the problem for $\mathbb{R}^n$ in a similar problem for $\mathbb{R}$. The resulting one-dimensional equation may be averaged within the framework mentioned above. Integration over the frequency domain together with use of inverse Radon transform give the homogenized problem. We mention here the strong interaction of the oscillations of the coefficients ρ and k as well as the source term f. The lack of compactness produces nonlocal effects described by integro-differential effective equations. Note that the choice of the dependence of the coefficients ρ and k in (1.1) is essential in the second step. To conclude this section, we address the question of existence and uniqueness results for the effective equation.

In §3, we examine the hyperbolic-parabolic equation in $]0,T[\times\Omega$:

$$(1.5) \qquad \rho\left(x, \frac{x}{\varepsilon}\right) \partial_t^2 u^\varepsilon - \operatorname{div}_x\left(k\left(x, \frac{x}{\varepsilon}\right) \operatorname{grad}_x u^\varepsilon\right) + \theta\left(\frac{x}{\varepsilon}, y, \frac{y}{\varepsilon}\right) \partial_t u^\varepsilon = f\left(t, x, \frac{x}{\varepsilon}, y, \frac{y}{\varepsilon}\right),$$

$$(1.6) \qquad u^\varepsilon\big|_{\partial\Omega_x} = 0 \quad \text{in} \quad]0,T[\times\mathcal{O},$$

$$(1.7) \qquad u^\varepsilon(0,x,y) = \alpha(x,y), \quad \sqrt{\rho\left(x, \frac{x}{\varepsilon}\right)}\, \partial_t u^\varepsilon(0,x,y) = \beta(x,y), \qquad (x,y) \in \Omega,$$

where $\Omega = \Omega_x \times \mathcal{O}$, Ω_x is an open bounded set in $\mathbb{R}^n$ with smooth boundary $\partial\Omega_x$, and $\rho \geq 0$ is allowed to vanish. First, averaging in the direction of propagation yields the damped wave equation

$$\tilde{\rho}(x)\,\partial_t^2 U - \operatorname{div}_x(\tilde{k}(x)\operatorname{grad}_x U) + \tilde{\theta}(y,\eta)\,\partial_t U = \tilde{f}(t,x,y,\eta), \tag{1.8}$$

$$U\,\big|_{\partial\Omega_x} = 0 \quad \text{in }]0,T[\times\mathcal{O}, \quad U\,\big|_{t=0} = \alpha, \quad \tilde{\rho}(x)\,\partial_t U\,\big|_{t=0} = \chi(x)\,\beta \quad \text{in } \Omega, \tag{1.9}$$

where $\tilde{\theta}(y,\eta) = \int_{Y_n} \theta(\zeta,y,\eta)\,d\zeta$, $\chi(x) = \int_{Y_n} \sqrt{\rho(x,\zeta)}\,d\zeta$. Next, the effective equation is obtained using the Dunford–Taylor's integral and the characterization of weak limits used in the preceding section. For this problem, there is no interaction between oscillations of the coefficients ρ and k with the damping coefficient θ. The nonlocal effects are due to oscillations of the damping and source terms. The main key results in §§2 and 3 leading to effective equations are valid only for equations where periodicity occurs in coefficients.

The last section is devoted to some similar problems involving the nonperiodic microstructure. We first analyze, for the sake of completeness, the propagation of a parametrized family of acoustic waves in a bounded domain Ω_x:

$$\partial_t^2 u^\varepsilon - a^\varepsilon(y)\,\Delta_x u^\varepsilon = 0, \quad u^\varepsilon\,|_{\partial\Omega_x} = 0, \quad u^\varepsilon\,|_{t=0} = \alpha, \quad \partial_t u^\varepsilon\,|_{t=0} = \beta. \tag{1.10}$$

We end the section by studying the damped wave equation

$$\begin{aligned} &\rho^\varepsilon(x)\,\partial_t^2 u^\varepsilon - \operatorname{div}_x(k^\varepsilon(x)\operatorname{grad}_x u^\varepsilon) + \theta^\varepsilon(y)\,\partial_t u^\varepsilon = 0, \\ &u^\varepsilon\,|_{\partial\Omega_x\times\mathcal{O}} = 0, \quad u^\varepsilon\,|_{t=0} = \alpha, \quad \partial_t u^\varepsilon\,|_{t=0} = \beta. \end{aligned} \tag{1.11}$$

We apply the same argument to show that there is no interaction when the damping coefficient does not depend on the direction x of the propagation.

A part of these results has been announced in [6].

2. A degenerate wave equation.

Let $\mathcal{O}$ be an open subset of $\mathbb{R}^m$ $(m \geq 1)$ and $T > 0$. Setting $\Omega = \mathbb{R}^n \times \mathcal{O}$, $n \geq 1$, we consider the following Cauchy problem in $]0,T[\times\Omega$:

$$\rho^\varepsilon(x,y)\,\partial_t^2 u^\varepsilon - \operatorname{div}_x(k^\varepsilon(x,y)\operatorname{grad}_x u^\varepsilon) = f^\varepsilon(t,x,y), \tag{2.1}$$

$$u^\varepsilon(0,x,y) = \alpha(x,y), \quad \partial_t u^\varepsilon(0,x,y) = \beta(x,y), \quad (x,y) \in \Omega. \tag{2.2}$$

On the data ρ^ε, k^ε, f^ε, α, and β we make the following hypotheses. We suppose

$$\rho^\varepsilon(x,y) = \rho\left(\frac{x}{\varepsilon}, y, \frac{y}{\varepsilon}\right) \quad \text{for almost every } (x,y) \in \Omega, \tag{2.3}$$

where $\rho \in C(\overline{\mathcal{O}}; L^\infty_{\text{per}}(Y_n \times Y_m))$, that is, $\rho \in C(\overline{\mathcal{O}}; L^\infty(\mathbb{R}^n \times \mathbb{R}^m))$ and $\rho(\cdot,y,\cdot)$ is $Y_n \times Y_m$-periodic for every $y \in \mathcal{O}$, and

$$0 < \rho_- \leq \rho(\zeta,y,\eta) \leq \rho_+ \quad \text{a.e. in } Y_n \times \mathcal{O} \times Y_m; \tag{2.4}$$

the tensor k^ε is symmetric and satisfies

$$k^\varepsilon_{i,j}(x,y) = k_{i,j}\left(\frac{x}{\varepsilon}, y, \frac{y}{\varepsilon}\right) \quad \text{for almost every } (x,y) \in \Omega, \tag{2.5}$$

where, for $i,j=1$ to n, the components $k_{i,j}$ belongs to $C(\overline{\mathcal{O}}; L^\infty_{\text{per}}(Y_n \times Y_m))$ and

$$k_- \,|\xi|^2 \leq k(\zeta,y,\eta)\xi\cdot\xi \leq k_+ \,|\xi|^2 \quad \forall \xi \in \mathbb{R}^n, \tag{2.6}$$

for $y \in \mathcal{O}$, almost everywhere for $(\zeta,\eta) \in Y_n \times Y_m$, k_- and k_+ being two strictly positive real numbers. The source term f^ε is assumed to satisfy

$$\begin{aligned} &f^\varepsilon(t,x,y) = c^\varepsilon(x,y)\, f(t,x,y) \quad \text{for almost every } t \in]0,T[, (x,y) \in \Omega,\\ &c^\varepsilon(x,y) = c\left(\frac{x}{\varepsilon},\frac{y}{\varepsilon}\right), \qquad c_- \leq c^\varepsilon(x,y) \leq c_+ \quad \text{for almost every } (x,y) \in \Omega, \end{aligned} \tag{2.7}$$

where $c \in L^\infty_{\text{per}}(Y_n \times Y_m)$, and $f \in L^2(]0,T[\times\Omega)$. Concerning the initial data, we impose

$$\alpha \in L^2(\mathcal{O}; H^1(\mathbb{R}^n)), \qquad \beta \in L^2(\Omega). \tag{2.8}$$

It is well known that problem (2.1), (2.2) admits a unique solution; see Lions–Magenes [13] and Mizohata [14], for instance. Specifically the following assertions hold true:

(2.9) For each $\varepsilon > 0$, there is a unique solution to (2.1), (2.2) satisfying

$$u^\varepsilon \in C^0([0,T]; L^2(\mathcal{O}; H^1(\mathbb{R}^n))) \cap C^1([0,T]; L^2(\Omega)).$$

(2.10) The sequence $(u^\varepsilon)_{\varepsilon>0}$ is uniformly bounded in

$$L^\infty(0,T; L^2(\mathcal{O}; H^1(\mathbb{R}^n))) \cap W^{1,\infty}(0,T; L^2(\Omega)).$$

Let u be a weak limit, as $\varepsilon \to 0$, of a subsequence $(u^\varepsilon)_{\varepsilon>0}$ of solutions of problem (2.1), (2.2). We want to establish an effective equation satisfied by u. The way to construct that equation is like the process of reiterated homogenization. One first homogenizes with respect to ζ, while keeping y and η as fixed parameters, and next with respect to the direction η, which can be seen as a degenerate direction in (2.1).

2.1. Averaging with respect to ζ. A formal expansion for the solution u^ε of (2.1), (2.2) is obtained by the ansatz

$$u^\varepsilon(t,x,y) = U(t,x,\zeta,y,\eta) + \varepsilon\, U_1(t,x,\zeta,y,\eta) + \varepsilon^2\, U_2(t,x,\zeta,y,\eta) + \cdots \tag{2.11}$$

where $U(t,x,\zeta,y,\eta)$ and $U_j(t,x,\zeta,y,\eta)$ $j \geq 1$ are periodic in ζ and η. Following the usual procedure, we substitute (2.11) into the governing equation (2.1) and collect equal powers of ε. The coefficient of ε^{-2} gives

$$\operatorname{div}_\zeta \left(k(\zeta,y,\eta) \operatorname{grad}_\zeta U\right) = 0, \tag{2.12}$$

which implies that U does not depend on ζ. Hence $U = U(t,x,y,\eta)$. Taking (2.12) into account, the order ε^{-1} yields

$$\operatorname{div}_\zeta(k(\zeta,y,\eta)\,(\operatorname{grad}_x U + \operatorname{grad}_\zeta U_1)) = 0. \tag{2.13}$$

For the zero order, we have

$$\begin{aligned} \operatorname{div}_\zeta \left(k(\zeta,y,\eta) \operatorname{grad}_\zeta U_2\right) = &- c(\zeta,\eta)\, f(t,x,y) + \rho(\zeta,y,\eta)\,\partial_t^2 U\\ &- \operatorname{div}_\zeta(k(\zeta,y,\eta)\,(\operatorname{grad}_x U + \operatorname{grad}_\zeta U_1))\\ &- \operatorname{div}_\zeta(k(\zeta,y,\eta)\operatorname{grad}_x U_1). \end{aligned} \tag{2.14}$$

Thus, averaging (2.14) with respect to ζ, one obtains a wave equation for U:

$$\tilde{\rho}(y,\eta)\,\partial_t^2 U - \operatorname{div}_x(\tilde{k}(y,\eta)\operatorname{grad}_x U) = \tilde{c}(\eta)\, f(t,x,y) \tag{2.15}$$

for $t \in]0,T[$, $x \in \mathbb{R}^n$, $y \in \mathcal{O}$, and $\eta \in Y_m$, provided with the initial conditions

$$U(0,x,y,\eta) = \alpha(x,y), \quad \partial_t U(0,x,y,\eta) = \beta(x,y) \quad \text{in } \Omega \times Y_m. \tag{2.16}$$

Here $\tilde{c}(\eta) = \int_{Y_n} c(\zeta,\eta)\, d\zeta$, $\tilde{\rho}(y,\eta) = \int_{Y_n} \rho(\zeta,y,\eta)\, d\zeta$, and $\tilde{k}(y,\eta)$ is the homogenized tensor associated with $(k(x/\varepsilon,y,\eta))_{\varepsilon>0}$, for fixed y and η. Specifically $\tilde{k} = (\tilde{k}_{l,j})$, for $l,j = 1,\dots,n$ with

$$\tilde{k}_{l,j}(y,\eta) = \int_{Y_n} \left[k_{l,j}(\zeta,y,\eta) + \sum_{i=1}^{n} k_{i,j}(\zeta,y,\eta) \frac{\partial}{\partial \zeta_i} \chi_l(\zeta,y,\eta) \right] d\zeta. \tag{2.17}$$

The function $\chi_l = \chi_l(\zeta,y,\eta)$, with mean value $\langle \chi_l(\cdot,y,\eta)\rangle = \int_{Y_n} \chi_l(\zeta,y,\eta)\, d\zeta = 0$ is calculated explicitly by solving the cell problem

$$-\operatorname{div}_\zeta \left(k(\zeta,y,\eta)\,[e_l + \operatorname{grad}_\zeta \chi_l(\zeta,y,\eta)] \right) = 0, \qquad \zeta \in Y_n, \tag{2.18}$$

e_l being the lth vector of the canonical basis of $\mathbb{R}^n$. Notice that as $k(\zeta,y,\eta)$, $\tilde{k}(y,\eta)$ is also a symmetric tensor. To justify the above procedure, we shall pass to the limit in the variational formulation of (2.1), (2.2) with appropriate oscillatory test functions; see Bensoussan, Lions, and Papanicolaou [8], Murat [15], Sanchez-Palencia [18], and Tartar [19], and use the following convergence result due to Nguetseng [16].

THEOREM 2.1. *Let $(v^\varepsilon)_{\varepsilon>0}$ be a uniformly bounded sequence in $L^2_{\text{loc}}(\mathbb{R}^N)$. Then, there is a subsequence, still denoted by $(v^\varepsilon)_{\varepsilon>0}$, and a function V in the space $L^2_{\text{loc}}(\mathbb{R}^N;$ $L^2_{\text{per}}(Y_N))$ such that*

$$\int_{\mathbb{R}^N} v^\varepsilon(x)\,\psi\left(x,\frac{x}{\varepsilon}\right) dx \underset{\varepsilon\to 0}{\longrightarrow} \int_{\mathbb{R}^N\times Y_N} V(x,\zeta)\,\psi(x,\zeta)\, dx\, d\zeta \tag{2.19}$$

for any smooth function $\psi(x,\zeta)$ with compact support in x and periodic with respect to the variable ζ. If in addition $(\partial_{x_i} v^\varepsilon)_{\varepsilon>0}$ is uniformly bounded in $L^2_{\text{loc}}(\mathbb{R}^N)$, then

(i) *the function $V = V(x,\zeta)$ does not depend on the variable ζ_i;*

(ii) *there exists a function V_1, $V_1 = V_1(x,\zeta)$ with V_1 and $\partial_{\zeta_i} V_1$ in $L^2_{\text{loc}}(\mathbb{R}^N;$ $L^2_{\text{per}}(Y_N))$, such that*

$$\int_{\mathbb{R}^N} \partial_{x_i} v^\varepsilon(x)\,\psi\left(x,\frac{x}{\varepsilon}\right) dx \underset{\varepsilon\to 0}{\longrightarrow} \int_{\mathbb{R}^N\times Y_N} (\partial_{x_i} V + \partial_{\zeta_i} V_1)(x,\zeta)\,\psi(x,\zeta)\, dx\, d\zeta. \tag{2.20}$$

Remark 2.2. If $v^\varepsilon(x) = v(x,x/\varepsilon)$ in (2.19), where $v \in L^2_{\text{loc}}(\mathbb{R}^N; L^2_{\text{per}}(Y_N))$, then obviously $V(x,\zeta) = v(x,\zeta)$.

Remark 2.3. If $(v^\varepsilon)_{\varepsilon>0}$ is a bounded sequence in $L^2(\mathbb{R}^N)$ converging in the sense of equation (2.19) to $V = V(x,\zeta)$, then $(v^\varepsilon)_{\varepsilon>0}$ converges weakly in $L^2(\mathbb{R}^N)$ to $v(x) = \int_{Y_n} V(x,\zeta)\, d\zeta$.

Let us return to problem (2.1), (2.2). We are going to prove the following result.

THEOREM 2.4. *Let $(u^\varepsilon)_{\varepsilon>0}$ be the sequence of solutions of* (2.1), (2.2) *under assumptions* (2.3)–(2.8). *Then $(u^\varepsilon)_{\varepsilon>0}$ converges in the sense of* (2.19) *to a function*

$U = U(t,x,y,\eta)$ solution of the family of equations (2.15) *parametrized by* $(y,\eta) \in \mathcal{O} \times Y_m$ *with prescribed initial conditions* (2.16).

Proof. Let $\mathcal{L}$ denote the Laplace transform in t. We set for $p \in \mathbb{C}$ with $\Re e\, p > 0$

$$v^\varepsilon(p,x,y) = \mathcal{L}(u^\varepsilon(\cdot,x,y))(p), \qquad g(p,x,y) = \mathcal{L}(f(\cdot,x,y))(p) \quad \text{a.e. in } \Omega.$$

Taking the Laplace transform of (2.1), (2.2), one obtains

$$\begin{aligned} p^2\,\rho^\varepsilon(x,y)\,v^\varepsilon - \operatorname{div}_x(k^\varepsilon(x,y)\operatorname{grad}_x v^\varepsilon) &= c^\varepsilon(x,y)\,g(p,x,y) \\ &\quad + \rho^\varepsilon(x,y)\,(p\,\alpha(x,y) + \beta(x,y)). \end{aligned} \tag{2.21}$$

We now fix $p \in \mathbb{C}$ with $\Re e\, p > p_0 > 0$. The variational formulation of (2.21) reads

$$\begin{aligned} &\int_\Omega \left(p^2\,\rho^\varepsilon(x,y)\,v^\varepsilon\,\psi^\varepsilon + k^\varepsilon(x,y)\operatorname{grad}_x v^\varepsilon \cdot \operatorname{grad}_x \psi^\varepsilon\right) dx\,dy \\ &= \int_\Omega \{c^\varepsilon(x,y)\,g(p,x,y) + \rho^\varepsilon(x,y)\,(p\,\alpha(x,y) + \beta(x,y))\}\,\psi^\varepsilon\,dx\,dy \end{aligned} \tag{2.22}$$

for any test function ψ^ε. In the sequel φ stands for a function in $\mathcal{D}(\Omega)$. Choosing $\psi^\varepsilon(x,y) = \varepsilon\,\varphi(x,y)\,w(x/\varepsilon, y/\varepsilon)$ in (2.22), with w a smooth and $Y_n \times Y_m$-periodic function, we have

$$\lim_{\varepsilon\to 0} I^\varepsilon = 0, \quad \text{where } I^\varepsilon = \int_\Omega \varphi\, k^\varepsilon(x,y)\operatorname{grad}_x v^\varepsilon \cdot \operatorname{grad}_x w\left(\frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) dx\,dy.$$

On the other hand, Theorem 2.1 asserts that there is a subsequence (still denoted by $(v^\varepsilon)_{\varepsilon>0}$), $V = V(p,x,y,\eta)$, V in $L^2(\Omega; L^2_{\text{per}}(Y_m))$, $V_1 = V_1(p,x,\zeta,y,\eta)$, V_1, and $\partial_{\zeta_i} V_1$, in $L^2(\Omega; L^2_{\text{per}}(Y_n \times Y_m))$ for $i = 1$ to n, such that

$$\lim_{\varepsilon\to 0} I^\varepsilon = \int_{\Omega\times Y_n\times Y_m} \varphi\, k(\zeta,y,\eta)\,(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1) \cdot \operatorname{grad}_\zeta w\,dx\,dy\,d\zeta\,d\eta.$$

Hence

$$\operatorname{div}_\zeta\big(k(\zeta,y,\eta)\,(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1)\big) = 0 \quad \text{in the sense of distributions.} \tag{2.23}$$

Next we take $\psi^\varepsilon(x,y) = \varphi(x,y)\,w(y/\varepsilon)$ in (2.22), with w a smooth Y_m-periodic function, and pass to the limit as $\varepsilon \to 0$. In view of Theorem 2.1, we get

$$\begin{aligned} &p^2 \int_{\Omega\times Y_n\times Y_m} \rho(\zeta,y,\eta)\,\varphi\,V\,w(\eta)\,dx\,dy\,d\zeta\,d\eta \\ &+ \int_{\Omega\times Y_n\times Y_m} k(\zeta,y,\eta)\,\big(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1\big) \cdot \operatorname{grad}_x \varphi\,w(\eta)\,dx\,dy\,d\zeta\,d\eta \\ &= \int_{\Omega\times Y_n\times Y_m} \big(c(\zeta,\eta)\,g + \rho(\zeta,y,\eta)\,(p\,\alpha + \beta)\big)\,\varphi\,w(\eta)\,dx\,dy\,d\zeta\,d\eta. \end{aligned} \tag{2.24}$$

Relation (2.24) says that V and V_1 satisfy in $\mathcal{D}'(\Omega \times Y_m)$

$$\begin{aligned} &p^2\,\tilde{\rho}(y,\eta)\,V - \operatorname{div}_x\left(\int_{Y_n} k(\zeta,y,\eta)\,(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1)\,d\zeta\right) \\ &\quad = \tilde{\rho}(y,\eta)\,(p\,\alpha(x,y) + \beta(x,y)) + \tilde{c}(\eta)\,g(p,x,y). \end{aligned} \tag{2.25}$$

As in the classical framework of the homogenization theory, one can display from (2.23) V_1 in terms of V, and substituting it into (2.25) leads to

$$\begin{aligned} p^2\,\tilde\rho(y,\eta)\,V - \operatorname{div}_x(\tilde k(y,\eta)\operatorname{grad}_x V) \\ = \tilde\rho(y,\eta)\,(p\,\alpha(x,y)+\beta(x,y)) + \tilde c(\eta)\,g(p,x,y). \end{aligned} \tag{2.26}$$

Taking the inverse Laplace transform in (2.26), which is meaningful, there is a function $U = U(t,x,y,\eta)$ in $L^2(]0,T[\times\mathcal{O}\times Y_m; H^1(\mathbb{R}^n))$ solution of

$$\tilde\rho(y,\eta)\,\partial_t^2 U - \operatorname{div}_x(\tilde k(y,\eta)\operatorname{grad}_x U) = \tilde c(\eta)\,f(t,x,y), \tag{2.27}$$

$$U(0,x,y,\eta) = \alpha(x,y), \qquad \partial_t U(0,x,y,\eta) = \beta(x,y) \tag{2.28}$$

for $t\in]0,T[$, $x\in\mathbb{R}^n$, $y\in\mathcal{O}$, and $\eta\in Y_m$. Since the function U is uniquely determined by (2.27), (2.28), the whole sequence $(u^\varepsilon)_{\varepsilon>0}$ converges weakly in the sense of (2.19) to U. Theorem 2.4 is thereby proved.

2.2. Averaging with respect to η: effective equations. Let u be the zero-order moment of function U defined in Theorem 2.4, i.e.,

$$u(t,x,y) = \int_{Y_m} U(t,x,y,\eta)\,d\eta, \quad t\in]0,T[, \quad (x,y)\in\Omega. \tag{2.29}$$

Thanks to Theorem 2.1 and Remark 2.3, the sequence $(u^\varepsilon)_{\varepsilon>0}$ of solutions of (2.1), (2.2) converges as $\varepsilon\to 0$ to u weakly in $L^2(]0,T[\times\Omega)$. The homogenization of (2.1), (2.2) is now reduced to the averaging of (2.27) and (2.28) in Y_m. We shall then discuss such averaging subsequently. This problem enters in the framework of homogenizing parametrized families of wave equations. In order to be self-contained we summarize here the characterization of a weak* limit, obtained in [3], [4], which will be used throughout this paper.

Let (a^ε) and (b^ε) be two sequences in $L^\infty(\mathcal{O})$, not necessary in the periodic setting, satisfying

$$0 < a_- \le a^\varepsilon(y) \le a_+, \qquad 0 \le b^\varepsilon(y) \le b_+ \quad \text{a.e. in } \mathcal{O}.$$

Let $\Lambda =]a_-, a_+[$. We consider the sequence (ψ^ε) defined by

$$\psi^\varepsilon(y,z) = b^\varepsilon(y)\,(z - a^\varepsilon(y))^{-1} \quad \text{for all } z\in\mathbb{C}\setminus\overline{\Lambda} \quad \text{and for almost every } y\in\mathcal{O}.$$

Suppose

$$a^\varepsilon \overset{\star}{\rightharpoonup} \overline{a}, \quad \text{and} \quad b^\varepsilon \overset{\star}{\rightharpoonup} \overline{b} \quad \text{weakly* in } L^\infty(\mathcal{O}),$$

where $\overline{b}(y) \ge b_- > 0$ for almost every $y\in\mathcal{O}$. Define the coefficient $\overline{d}$ as

$$a^\varepsilon\, b^\varepsilon \overset{\star}{\rightharpoonup} \overline{b}\,\overline{d} \quad \text{weakly* in } L^\infty(\mathcal{O}).$$

The following lemma makes precise the weak* limit for a subsequence of (ψ^ε).

LEMMA 2.5. *There exists a parametrized family of nonnegative measures $d\sigma_y(\cdot)$, supported, for almost every $y\in\mathcal{O}$, in $\overline{\Lambda}$ such that for a subsequence*

$$\psi^\varepsilon(\cdot,z) \overset{\star}{\rightharpoonup} \psi(\cdot,z) \quad \textit{in } L^\infty(\mathcal{O}) \quad \textit{weak* for all } z\notin\overline{\Lambda}, \tag{2.30}$$

with

$$\psi(y,z)=\bar{b}(y)\left(z-\bar{d}(y)-\int_\Lambda (z-\lambda)^{-1}d\sigma_y(\lambda)\right)^{-1}. \tag{2.31}$$

We shall refer to $d\sigma_y$ as the parametrized family of measures associated with sequence $(a^\varepsilon, b^\varepsilon)$. The measure $d\sigma_y$ is defined by its moments $\int_\Lambda \lambda^k\, d\sigma_y(\lambda)$, which are explicitly given in terms of the limits of (a^ε), $(b^\varepsilon\,(a^\varepsilon)^k)$, $k \geq 0$. Let $\tau(y)=\int_\Lambda d\sigma_y(\lambda)$. One has $\tau(y)\geq 0$ and $\tau(y)\equiv 0$ if and only if the sequence $(a^\varepsilon(y))$ converges strongly. Let $d\nu_y$ be the family of Young measures associated with (ψ^ε). The support of $d\nu_y$ is contained in $[0,b_+]\times[a_-,a_+]$ and for all $z\in\mathbb{C}\setminus\overline{\Lambda}$, we have

$$\lim_{\varepsilon\to 0}\psi^\varepsilon(\cdot,z)=\langle d\nu_y(\mu,\lambda),\mu\,(z-\lambda)^{-1}\rangle.$$

We can state the following result.

LEMMA 2.6. *For almost every $y\in\mathcal{O}$, the measure $d\sigma_y$ is related to the measure $d\nu_y$ by*

$$\int_\Lambda d\sigma_y(\lambda)(z-\lambda)^{-1}=z-\bar{d}(y)-\bar{b}(y)\left(\int_{]0,b_+[\times\Lambda}\mu\,(z-\lambda)^{-1}\,d\nu_y(\mu,\lambda)\right)^{-1} \tag{2.32}$$

for all $z\in\mathbb{C}\setminus\overline{\Lambda}$. Furthermore, the family $d\sigma_y$ depends mesurably on y.

Proof. Relation (2.32) is established in [4], [5]. On the other hand, we know from Tartar [20] that the Young measure $d\nu_y$ depends measurably on $y\in\mathcal{O}$. Then, from (2.32), using Cauchy's formula we deduce that $y\mapsto d\sigma_y$ is also weakly measurable.

Let us now return to the averaging problem. According to whether the tensor $\tilde{k}$ defined by (2.17) is isotropic or not, the effective equations are obtained by different ways. We shall distinguish the following situations.

2.2.1. Case of macroscopic isotropy.

In this subsection, we suppose that the tensor $\tilde{k}(y,\eta)$ given by (2.17) is isotropic. For convenience, we denote also by $\tilde{k}(y,\eta)$ the scalar coefficient of the isotropic matrix. Consider the problem

$$\begin{aligned}&\tilde{\rho}(y,\eta)\,\partial_t^2U-\tilde{k}(y,\eta)\,\Delta_xU=\tilde{c}(\eta)\,f(t,x,y),\\ &U(0,x,y,\eta)=\alpha(x,y),\qquad \partial_tU(0,x,y,\eta)=\beta(x,y),\end{aligned} \tag{2.33}$$

for $t\in]0,T[$, $(x,y)\in\Omega$, $\eta\in Y_m$. Let $\widehat{U}(t,\xi,y,\eta)=\int_{\mathbb{R}}\exp(-2i\pi x\xi)\,U(t,x,y,\eta)\,dx$, the Fourier transform in x of U, and $V(p,\xi,y,\eta)=\mathcal{L}(\widehat{U}(\cdot,\xi,y,\eta))(p)$, the Laplace transform in time of $\widehat{U}$. Then for $p\in\mathbb{C}$ with $\Re e\,p>p_0>0$,

$$V(p,\xi,y,\eta)=\psi(p,\xi,y,\eta)\,(p\,\hat{\alpha}(\xi,y)+\hat{\beta}(\xi,y)+b(y,\eta)\,g(p,\xi,y)). \tag{2.34}$$

Here $\psi(p,\xi,y,\eta)=(p^2+4\pi^2|\xi|^2\,a(y,\eta))^{-1}$, $g(p,\xi,y)=\mathcal{L}(\hat{f}(\cdot,\xi,y))(p)$, $a(y,\eta)=\tilde{k}(y,\eta)/\tilde{\rho}(y,\eta)$ and $b(y,\eta)=\tilde{c}(\eta)/\tilde{\rho}(y,\eta)$. Owing to (2.4) and (2.6), one has

$$0<a_-\leq a(y,\eta)\leq a_+\quad\text{a.e. in }\mathcal{O}\times Y_m,\quad\text{with } a_-=\frac{k_-}{\rho_+},\quad a_+=\frac{k_+}{\rho_-}. \tag{2.35}$$

Let $v(p,\xi,y) = \int_{Y_m} V(p,\xi,y,\eta)\,d\eta$. From (2.34), we get

$$v(p,\xi,y) = \overline{\psi}\,(p\,\hat{\alpha}(\xi,y) + \hat{\beta}(\xi,y)) + \overline{b\psi}\,g(p,\xi,y),$$

where the overbar will denote the spatial averaging over the period Y_m. Notice that for fixed $\xi \in \mathbb{R}^n$ and $p \in \mathbb{C}$ with $\Re e\, p > p_0 > 0$, we have

$$\overline{\psi}(p,\xi,y) = \lim_{\varepsilon\to 0} \left(p^2 + 4\pi^2|\xi|^2\, a\left(y, \frac{y}{\varepsilon}\right)\right)^{-1},$$
$$\overline{b\psi}(p,\xi,y) = \lim_{\varepsilon\to 0} b\left(y, \frac{y}{\varepsilon}\right) \left(p^2 + 4\pi^2|\xi|^2\, a\left(y, \frac{y}{\varepsilon}\right)\right)^{-1} \quad \text{in } L^\infty(\mathcal{O}) \text{ weak*}.$$

Since we do not impose any condition on positiveness of coefficient $c^\varepsilon(x,y)$ in (2.7), we must be careful in applying Lemma 2.5, which holds only when c^ε does not change sign. Otherwise, we break up the coefficient c^ε in $c^\varepsilon(x,y) = c^\varepsilon_+(x,y) - c^\varepsilon_-(x,y)$, where c^ε_+ and c^ε_- are, respectively, the positive and negative parts of c^ε. As $\tilde{c}_\pm(\eta) \geq 0$, therefore,

$$\overline{b}_\pm(y) = \int_{Y_m} b_\pm(y,\eta)\,d\eta \geq \frac{\overline{c}_\pm}{\rho_+} > 0 \quad \text{with } \overline{c}_\pm = \int_{Y_m} \tilde{c}_\pm(\eta)\,d\eta > 0.$$

Let $\Lambda =]a_-, a_+[$, $\overline{a}(y) = \int_{Y_m} a(y,\eta)\,d\eta$. Lemma 2.5 asserts that there exist three families of nonnegative measures $d\sigma_y$, $d\sigma_y^+$ and $d\sigma_y^-$ associated, respectively, with sequences $(a(y,y/\varepsilon))_{\varepsilon>0}$, $(a(y,y/\varepsilon)b_+(y,y/\varepsilon))_{\varepsilon>0}$, and $(a(y,y/\varepsilon)b_-(y,\frac{y}{\varepsilon}))_{\varepsilon>0}$, parametrized by $y \in \mathcal{O}$ and supported in $\overline{\Lambda}$, such that

$$\text{(2.36)}\quad \overline{\psi}(p,\xi,y) = \left(p^2 + 4\pi^2|\xi|^2\,\overline{a}(y) - (4\pi^2|\xi|^2)^2 \int_\Lambda (p^2 + 4\pi^2|\xi|^2\,\lambda)^{-1}\,d\sigma_y(\lambda)\right)^{-1},$$

$$\text{(2.37)}\quad \begin{aligned}&\overline{b_\pm\,\psi}(p,\xi,y)\\ &= \overline{b}_\pm(y)\left(p^2 + 4\pi^2|\xi|^2\,\overline{d}_\pm(y) - (4\pi^2|\xi|^2)^2 \int_\Lambda (p^2 + 4\pi^2|\xi|^2\,\lambda)^{-1}\,d\sigma_y^\pm(\lambda)\right)^{-1},\end{aligned}$$

where

$$\overline{d}_\pm(y) = \frac{1}{\overline{b}_\pm(y)} \int_{Y_m} a(y,\eta)\,b_\pm(y,\eta)\,d\eta.$$

Let us now introduce functions $u_1 = u_1(t,x,y)$, $u_+ = u_+(t,x,y)$, and $u_- = u_-(t,x,y)$ such that

$$\text{(2.38)}\qquad \mathcal{L}(\hat{u}_1) = \overline{\psi}\,(p\,\hat{\alpha} + \hat{\beta}), \qquad \mathcal{L}(\hat{u}_\pm) = \overline{b_\pm\,\psi}\,g.$$

Using the inverse Laplace and Fourier transforms, it follows from (2.36), (2.37), and (2.38) that u_1, u_+ and u_- satisfy, respectively,

$$\text{(2.39)}\quad \begin{aligned}&\partial_t^2 u_1 - \overline{a}(y)\,\Delta_x u_1 - \int_0^t \int_{\mathbb{R}^n} M_n(t-s, x-z, y)\,\Delta_z^2 u_1(s,z,y)\,dz\,ds = 0,\\ &u_1\,|_{t=0} = \alpha, \qquad \partial_t u_1\,|_{t=0} = \beta,\end{aligned}$$

$$\begin{aligned}
&\partial_t^2 u_\pm - \overline{d}_\pm(y)\,\Delta_x u_2\\
&\qquad - \int_0^t \int_{\mathbb{R}^n} M_n^\pm(t-s,x-z,y)\,\Delta_x^2 u_\pm(s,z,y)\,dz\,ds = \overline{b}_\pm(y)\,f(t,x,y), \qquad (2.40)\\
&u_\pm\,|_{t=0} = 0, \qquad \partial_t u_\pm\,|_{t=0} = 0.
\end{aligned}$$

Here the kernels M_n, $M_n^\pm$ are given by

$$M_n(t,x,y) = \int_\Lambda d\sigma_y(\lambda)\,\mathcal{E}_n(t,x,\lambda), \qquad M_n^\pm(t,x,y) = \int_\Lambda d\sigma_y^\pm(\lambda)\,\mathcal{E}_n(t,x,\lambda),$$

where $\mathcal{E}_n(\cdot,\cdot,\lambda)$ is the elementary solution in $\mathbb{R}^n$ of the wave operator $\partial_t^2 - \lambda\,\Delta_x$, $\lambda \in \Lambda$.

We have thus proved the following.

THEOREM 2.7. *Let $(u^\varepsilon)_{\varepsilon>0}$ be the sequence of solutions of* (2.1), (2.2) *under assumptions* (2.3)–(2.8). *In the case of macroscopic isotropy, $(u^\varepsilon)_{\varepsilon>0}$ converges weakly in $L^2(]0,T[\times\Omega)$ to $u = u_1 + u_+ - u_-$, where u_1 and $u_\pm$ are characterized by* (2.39) *and* (2.40), *respectively.*

COROLLARY 2.8. *Assume that in* (2.3) *and* (2.6), *respectively, the functions ρ and c do not depend on the η-variable, that is, $\rho = \rho(\zeta,y)$, $c = c(\zeta)$. Hence, as $\varepsilon \to 0$, the sequence $(u^\varepsilon)_{\varepsilon>0}$ of solutions of* (2.1), (2.2) *converges weakly in $L^2(]0,T[\times\Omega)$ to u satisfying*

$$\begin{aligned}
&\tilde{\rho}(y)\,\partial_t^2 u - \overline{k}(y)\,\Delta_x u - \int_0^t \int_{\mathbb{R}^n} M_n(t-s,x-z,y)\,\Delta_x^2 u(s,z,y)\,dz\,ds = \tilde{c}\,f(t,x,y), \qquad (2.41)\\
&u_1\,|_{t=0} = \alpha, \qquad \partial_t u_1\,|_{t=0} = \beta.
\end{aligned}$$

Here $\tilde{\rho}(y) = \int_{Y_n} \rho(\zeta,y)\,d\zeta$, $\tilde{c} = \int_{Y_n} c(\zeta)\,d\zeta$, $\overline{k}(y) = \int_{Y_m} \tilde{k}(y,\eta)\,d\eta$ and $d\sigma_y$ represent the parametrized measure associated with $(\tilde{k}(y,y/\varepsilon))_{\varepsilon>0}$.

Remark 2.9. The one-dimensional case enters in the above pattern. The coefficient $\tilde{k}$ reduces to

$$\tilde{k}(y,\eta) = \int_0^1 \frac{d\zeta}{k(\zeta,y,\eta)}.$$

Remark 2.10. The Dunford–Taylor integral representation allows to extend the result for boundary value problem when the variable $x \in \Omega_x \subseteq \mathbb{R}^n$; see §4.

We establish now the existence and uniqueness result for equations of type (2.39), (2.40), or (2.41). Consider, for instance, (2.39). Introduce the auxiliary function w_1 defined on $]0,T[\,\times\Omega\times\Lambda$ by $w_1(t,x,y,\lambda) = \int_0^t \Delta_x u_1(s,x-\lambda(t-s),y)\,ds$. So (2.39) becomes the system

$$\begin{aligned}
&\partial_t^2 u_1 - \overline{a}(y)\,\Delta_x u_1 + \int_\Lambda \Delta_x w_1(t,x,y,\lambda)\,d\sigma_y(\lambda) = 0,\\
&\partial_t^2 w_1 - \lambda\,\Delta_x w_1 + \Delta_x u_1 = 0, \qquad (2.42)\\
&u_1\,|_{t=0} = \alpha, \quad \partial_t u_1\,|_{t=0} = \beta, \quad w_1\,|_{t=0} = 0, \quad \partial_t w_1\,|_{t=0} = 0.
\end{aligned}$$

We can write (2.42) as an abstract evolution problem in the form

$$\begin{aligned}
&U'' + AU = F, \qquad (2.43)\\
&U\,\Big|_{t=0} = U_0, \qquad U'\,\Big|_{t=0} = U_1.
\end{aligned}$$

The prime sign stands for the derivative with respect to time t, $U = (u, w)$, $U_0 = (\alpha_0, \beta_0)$, and $U_1 = (\alpha_1, \beta_1)$. The operator A is formally defined by

$$A \begin{pmatrix} u \\ w \end{pmatrix} = \begin{pmatrix} -\bar{a}(y)\, \Delta_x u + \int_\Lambda \Delta_x w(t,x,y,\lambda)\, d\sigma_y(\lambda) \\ \Delta_x u - \lambda\, \Delta_x w \end{pmatrix}. \tag{2.44}$$

Let $d\mu(y,\lambda) = dy\, d\sigma_y(\lambda)$. From Lemma 2.6 $d\mu$ is a nonnegative valued measure on $\mathcal{O} \times \Lambda$. Introduce then the Sobolev spaces $L^2_\mu(\mathcal{O} \times \Lambda) = L^2(\mathcal{O} \times \Lambda;\, d\mu(y,\lambda))$, $\mathbb{H} = L^2(\Omega) \times L^2_\mu(\mathcal{O} \times \Lambda; L^2(\mathbb{R}^n))$ and $\mathbb{V} = L^2(\mathcal{O}; H^1(\mathbb{R}^n)) \times L^2_\mu(\mathcal{O} \times \Lambda, H^1(\mathbb{R}^n))$. Relatively to the scalar product associated with a variational formulation of (2.43), one has

$$\begin{aligned}(AU, U) = &\int_\Omega \bar{a}(y)\, |\mathrm{grad}_x u|^2\, dx\, dy + \int_\Omega \int_\Lambda \lambda\, d\sigma_y(\lambda)\, |\mathrm{grad}_x w|^2\, dx\, dy \\ &- 2 \int_\Omega \int_\Lambda \mathrm{grad}_x u \cdot \mathrm{grad}_x w\, d\sigma_y(\lambda)\, dx\, dy.\end{aligned}$$

Let $\gamma > 0$. Since $2\, |\mathrm{grad}_x u \cdot \mathrm{grad}_x w| \le ((1+\gamma)/\lambda)\, |\mathrm{grad}_x u|^2 + (\lambda/(1+\gamma))\, |\mathrm{grad}_x w|^2$, it implies that

$$\begin{aligned}(AU, U) \ge &\int_\Omega |\mathrm{grad}_x u|^2 \left(\bar{a}(y) - (1+\gamma) \int_\Lambda \lambda^{-1} d\sigma_y(\lambda)\right) dx\, dy \\ &+ \frac{\gamma}{1+\gamma} \int_\Omega \int_\Lambda \lambda\, d\sigma_y(\lambda)\, |\mathrm{grad}_x w|^2\, dx\, dy.\end{aligned}$$

Taking (2.32) into account, one observes that

$$\bar{a}(y) - \int_\Lambda \lambda^{-1} d\sigma_y(\lambda) = \left(\lim_{\varepsilon \to 0} \frac{1}{a^\varepsilon(y)}\right)^{-1} = a_{-1}^{-1} \ge a_-.$$

It follows that

$$\bar{a}(y) - (1+\gamma) \int_\Lambda \lambda^{-1} d\sigma_y(\lambda) = -\gamma\, \bar{a}(y) + (1+\gamma)\, \bar{a}_{-1}^{-1}(y) \ge -\gamma\, a_+ + (1+\gamma)\, a_-.$$

Since $a_- > 0$, we can choose $\gamma > 0$ such that

$$\gamma_- = \min\left\{ -\gamma\, a_+ + (1+\gamma)\, a_-, \frac{\gamma}{1+\gamma}\, a_- \right\} > 0.$$

Thus

$$(AU, U) \ge \gamma_- \left(|\mathrm{grad}_x u|^2_{L^2(\Omega)} + |\mathrm{grad}_x w|^2_{L^2_\mu(\mathcal{O} \times \Lambda, L^2(\mathbb{R}^n))} \right). \tag{2.45}$$

Inequality (2.45) says that A is $\mathbb{V}$-elliptic. Hence, following Lions–Magenes [13, Thm. 8.1, p. 287], for U_1 in $\mathbb{H}$, U_0 in $\mathbb{V}$, and F in $L^2(0, T; \mathbb{H})$, there exists a unique function U satisfying (2.43) and such that

$$U \in L^2(0, T; \mathbb{V}) \quad \text{and} \quad U' \in L^2(0, T; \mathbb{H}).$$

Then we have established the following.

THEOREM 2.11. *Problem* (2.42) *admits a unique solution* $U = (u_1, w_1)$ *satisfying*

$$u_1 \in L^2(0,T; L^2(\mathcal{O}; H^1(\mathbb{R}^n))), \qquad w_1 \in L^2(0,T; L^2_\mu(\mathcal{O}\times\Lambda; H^1(\mathbb{R}^n))),$$
$$\partial_t u_1 \in L^2(0,T; L^2(\Omega)), \qquad \partial_t w_1 \in L^2(0,T; L^2_\mu(\mathcal{O}\times\Lambda; L^2(\Omega))).$$

Existence and uniqueness results for (2.40) and (2.41) can be handled in a similar manner. We conclude that the weak limit $u = u_1 + u_+ - u_-$ of sequence (u^ε) of solutions of (2.1), (2.2) is well defined by (2.39), (2.40), and (2.41).

2.2.2. Anisotropic case. The same basic approach as developed in [5] will be applied. First, we split up the solution U of (2.27), (2.28) into the superposition of solutions U_1 and U_2 of the subproblems

$$(2.46)\qquad \begin{aligned} &\tilde\rho(y,\eta)\,\partial_t^2 U_1 - \operatorname{div}_x(\tilde k(y,\eta)\operatorname{grad}_x U_1) = 0 \quad \text{in }]0,T[\times\Omega\times Y_m,\\ &U_1(0,x,y,\eta) = \alpha(x,y), \qquad \partial_t U_1(0,x,y,\eta) = \beta(x,y) \quad \text{in } \Omega\times Y_m, \end{aligned}$$

$$(2.47)\qquad \begin{aligned} &\tilde\rho(y,\eta)\,\partial_t^2 U_2 - \operatorname{div}_x(\tilde k(y,\eta)\operatorname{grad}_x U_2) = \tilde c(\eta)\, f(t,x,y) \quad \text{in }]0,T[\times\Omega\times Y_m,\\ &U_2(0,x,y,\eta) = 0, \qquad \partial_t U_2(0,x,y,\eta) = 0 \quad \text{in } \Omega\times Y_m. \end{aligned}$$

As before, we set $a(y,\eta) = \tilde k(y,\eta)/\tilde\rho(y,\eta)$ and $b(y,\eta) = \tilde c(\eta)/\tilde\rho(y,\eta)$. The tensor $a(y,\eta)$ satisfies

$$a_-\,|\xi|^2 \le a(y,\eta)\xi\cdot\xi \le a_+\,|\xi|^2 \quad \forall\xi\in\mathbb{R}^n, \quad \forall y\in\mathcal{O}, \quad \text{a.e. for } \eta\in Y_m,$$

with a_+ and a_- as in (2.35). To avoid complications in notation, we restrict ourselves to the case $0 \le \tilde c(\eta) \le c_+$. Then, according to the representation formula using Radon transform, we construct equations satisfied by the zero-order moment u_i of U_i, $i = 1, 2$, for which we just describe the procedure and refer to [5] for the details. We essentially use the isometry

$$(2.48)\qquad (-\partial_r^2)^{\frac{n-1}{4}}\mathcal{R}\colon L^2(\mathbb{R}^n) \longrightarrow L^2_o(\mathbb{R}\times S^{n-1}; |c_n|\,dr\,d\omega).$$

Here S^{n-1} denotes the unit sphere in $\mathbb{R}^n$, $c_n = (2i\pi)^{-n+1}/2$, $d\omega$ is the usual measure on S^{n-1}, $\mathcal{R}(\cdot)$ stands for the Radon transform, and the subscript o stands for even functions. Let, for $i = 1, 2$,

$$(2.49)\qquad \tilde u_i(t,r,\omega,y) = (-\partial_r^2)^{\frac{n-1}{4}}\,\mathcal{R}(u_i(t,\cdot,y))\,(r,\omega).$$

One can establish that $\tilde u_i$, $i = 1, 2$, satisfy, respectively,

$$(2.50)\qquad \begin{aligned} &\partial_t^2\tilde u_1 - \bar a(y)\,\omega\cdot\omega\,\partial_r^2\tilde u_1 + \int_\Lambda \partial_r^2\tilde w_1(t,r,\omega,y,\lambda)\,d\sigma^1_{y,\omega}(\lambda) = 0,\\ &\partial_t^2\tilde w_1 - \lambda\,\partial_r^2\tilde w_1 + \partial_r^2\tilde u_1 = 0, \end{aligned}$$

$$(2.51)\qquad \begin{aligned} &\partial_t^2\tilde u_2 - \bar a(y)\,\omega\cdot\omega\,\partial_r^2\tilde u_2 + \int_\Lambda \partial_r^2\tilde w_2(t,r,\omega,y,\lambda)\,d\sigma^2_{y,\omega}(\lambda) = \bar b(y)\,\tilde f(t,r,\omega),\\ &\partial_t^2\tilde w_2 - \lambda\,\partial_r^2\tilde w_2 + \partial_r^2\tilde u_2 = 0, \end{aligned}$$

where

$$\bar{b}(y)=\int_{Y_m} b(y,\eta)\,d\eta,\quad \bar{a}(y)=\int_{Y_m} a(y,\eta)\,d\eta \text{ and } \bar{d}(y)=\frac{1}{\bar{b}(y)}\int_{Y_m} a(y,\eta)\,b(y,\eta)\,d\eta.$$

For all fixed $\omega\in S^{n-1}$, $d\sigma^i_{y,\omega}$, $i=1,2$, are the measures associated, respectively, with the sequences $(a(y,y/\varepsilon)\omega\cdot\omega)_{\varepsilon>0}$ and $(b(y,y/\varepsilon)a(y,y/\varepsilon)\omega\cdot\omega)_{\varepsilon>0}$ in the sense of Lemma 2.5. Moreover, let $d\nu^1_y$ be the Young measure associated with the sequence $(a(y,y/\varepsilon))$. Then one has the relation

$$\begin{aligned}(2.52)\qquad &\langle d\sigma^1_{y,\omega}(\lambda),(z-\lambda)^{-1}\rangle\\ &=(\langle d\nu^1_y(T),(zI+T)\rangle\omega,\omega)-(\langle d\nu^1_y(T),(zI+T)^{-1}\rangle\omega,\omega)^{-1}.\end{aligned}$$

Here T stands for a matrix describing the oscillations of $a(y,y/\varepsilon)$. From (2.52), we deduce that, for any holomorphic function g in $\mathbb{C}$,

$$\langle d\Sigma^1_y(\cdot,\cdot),g(\cdot)\rangle\equiv\int_{S^{n-1}}\langle d\sigma^1_{y,\omega}(\cdot),g(\cdot)\rangle\,d\omega$$

is well defined and $d\Sigma^1_y(\cdot,\cdot)$ is a family of nonnegative measures, with support contained in $\overline{\Lambda}\times S^{n-1}$, parametrized by $y\in\mathcal{O}$. Hence, the inverse Radon transform gives the homogenized equation. Let $d\Sigma^2_y(\cdot,\cdot)$ be the corresponding measure associated with $d\sigma^2_{y,\omega}$.

We summarize this result in the following theorem.

THEOREM 2.12. *Assume that α, β, and f have compact supports in the direction x. Then, there exist two families of nonnegative measures $d\Sigma^i_y(\cdot,\cdot)$, $i=1,2$, parametrized by $y\in\mathcal{O}$, supported in $\overline{\Lambda}\times S^{n-1}$, such that the sequence of solutions $(u^\varepsilon)_{\varepsilon>0}$ of* (2.1), (2.2) *under assumptions* (2.3)–(2.8) *converges to $u=u_1+u_2$ weakly in $L^2(]0,T[\times\Omega)$. The functions u_1 and u_2 are solutions through auxiliary functions $w_1=w_1(t,x,y,\lambda)$, $w_2=w_2(t,x,y,\lambda)$, $(t,x,y)\in]0,T[\times\Omega$, $\lambda\in\Lambda$, of the following systems:*

(2.53)

$$\begin{aligned}&\partial_t^2u_1-\mathrm{div}_x(\bar{a}(y)\mathrm{grad}_x u_1)-c_n\int_{\Lambda\times S^{n-1}}d\Sigma^1_y(\lambda,\omega)\,(-\partial_r^2)^{\frac{n+1}{2}}\mathcal{R}(w_1)\,\big|_{r=x\cdot\omega}=0,\\ &\partial_t^2w_1-\lambda\,\Delta_x w_1+\Delta_x u_1=0,\quad t\in]0,T[,\quad (x,y)\in\mathbb{R}^n\times\mathcal{O},\quad \lambda\in\Lambda,\\ &u_1\,|_{t=0}=\alpha,\quad w_1\,|_{t=0}=0,\quad \partial_t u_1\,|_{t=0}=\beta,\quad \partial_t w_1\,|_{t=0}=0,\end{aligned}$$

$$\begin{aligned}(2.54)\qquad &\partial_t^2u_2-\mathrm{div}_x(\bar{d}(y)\mathrm{grad}_x u_2)\\ &\qquad -c_n\int_{\Lambda\times S^{n-1}}d\Sigma^2_y(\lambda,\omega)\,(-\partial_r^2)^{\frac{n+1}{2}}\mathcal{R}(w_2)\,\big|_{r=x\cdot\omega}=\bar{b}(y)\,f(t,x,y),\\ &\partial_t^2w_2-\lambda\,\Delta_x w_2+\Delta_x u_2=0,\quad t\in]0,T[,\quad (x,y)\in\mathbb{R}^n\times\mathcal{O},\quad \lambda\in\Lambda,\\ &u_2\,|_{t=0}=0,\quad w_2\,|_{t=0}=0,\quad \partial_t u_2\,|_{t=0}=0,\quad \partial_t w_2\,|_{t=0}=0.\end{aligned}$$

COROLLARY 2.13. *Assume that in* (2.3) *and* (2.6), *respectively, the functions* ρ *and* c *do not depend on the* η*-variable. Then, the weak limit* u *satisfies*

$$(2.55)\quad \begin{aligned} &\tilde{\rho}(y)\,\partial_t^2 u - \operatorname{div}_x(\overline{k}(y)\operatorname{grad}_x u) \\ &\qquad - c_n \int_{\Lambda\times S^{n-1}} d\Sigma_y(\lambda,\omega)\,(-\partial_r^2)^{\frac{n+1}{2}}\mathcal{R}(w)\,\big|_{r=x\cdot\omega} = \tilde{c}\, f(t,x,y), \\ &\tilde{\rho}(y)\,\partial_t^2 w - \lambda\,\Delta_x w + \Delta_x u = 0, \quad t \in]0,T[, \quad (x,y) \in \mathbb{R}^n \times \mathcal{O}, \quad \lambda \in \Lambda, \\ &u\,|_{t=0} = \alpha, \quad w\,|_{t=0} = 0, \quad \partial_t u\,|_{t=0} = \beta, \quad \partial_t w\,|_{t=0} = 0, \end{aligned}$$

where $\tilde{\rho}(y) = \int_{Y_n} \rho(\zeta, y)\,d\zeta$, $\tilde{c} = \int_{Y_n} c(\zeta)\,d\zeta$, $\overline{k}(y) = \int_{Y_m} \tilde{k}(y,\eta)\,d\eta$ *and* $d\Sigma_y$ *is the measure associated with* $(\tilde{k}(y, y/\varepsilon))$.

Finally, we state the following.

THEOREM 2.14. *Under hypotheses* (2.3)–(2.8), *problem* (2.53) (*respectively,* (2.54)) *admits a unique solution* $U = (u_1, w_1)$ (*respectively,* $U = (u_2, w_2)$) *satisfying for* $i = 1, 2$

$$\begin{aligned} &u_i \in L^2(0,T;L^2(\mathcal{O};H^1(\mathbb{R}^n))), &&w_i \in L^2(0,T;L^2_\mu(\mathcal{O}\times\Lambda;H^1(\mathbb{R}^n))), \\ &\partial_t u_i \in L^2(0,T;L^2(\Omega)), &&\partial_t w_i \in L^2(0,T;L^2_\mu(\mathcal{O}\times\Lambda;L^2(\Omega))). \end{aligned}$$

Thus, the weak limit $u = u_1 + u_2$ *of sequence* (u^ε) *of solutions of* (2.1), (2.2) *is well defined.*

Proof. Consider, for instance, system (2.53). Thanks to the isometry (2.48), it suffices to prove the existence and uniqueness for system (2.50). We can associate with system (2.50) an abstract formulation of type (2.43). Here the operator A is formally defined by

$$A\begin{pmatrix} u \\ w \end{pmatrix} = \begin{pmatrix} -\overline{a}(y)\omega\cdot\omega\,\partial_r^2 u + \int_\Lambda \partial_r^2 w(t,x,y,\lambda)\,d\sigma^1_{y,\omega}(\lambda) \\ \partial_r^2 u - \lambda\,\partial_r^2 w \end{pmatrix}.$$

Following the proof of Theorem 2.11, we introduce $d\mu(y,\omega,\lambda) = dy\,d\sigma^1_{y,\omega}(\lambda)\,d\omega$ and the Sobolev spaces $L^2_\mu(\mathcal{O}\times S^{n-1}\times\Lambda) = L^2(\mathcal{O}\times S^{n-1}\times\Lambda;\, d\mu(y,\omega,\lambda))$, $\widetilde{\mathbb{H}} = L^2(\widetilde{\Omega})\times L^2_\mu(\mathcal{O}\times S^{n-1}\times\Lambda;L^2(\mathbb{R}_+))$, and $\widetilde{\mathbb{V}} = L^2(\mathcal{O}\times S^{n-1}, H^1(\mathbb{R}_+))\times L^2_\mu(\mathcal{O}\times S^{n-1}\times\Lambda;H^1(\mathbb{R}_+))$, where $\widetilde{\Omega} = \mathbb{R}_+\times S^{n-1}\times\mathcal{O}$. One has

$$\begin{aligned} (AU,U) = &\int_{\widetilde{\Omega}} \overline{a}(y)\omega\cdot\omega\,|\partial_r u|^2\,dr\,dy\,d\omega + \int_{\widetilde{\Omega}}\int_\Lambda \lambda\,d\sigma^1_{y,\omega}(\lambda)\,|\partial_r w|^2\,d\sigma^1_{y,\omega}(\lambda)\,dr\,dy\,d\omega \\ &- 2\int_{\widetilde{\Omega}}\int_\Lambda \partial_r u\,\partial_r w\,d\sigma^1_{y,\omega}(\lambda)\,dr\,dy\,d\omega. \end{aligned}$$

For $\gamma > 0$, one deduces that

$$\begin{aligned} (AU,U) \geq &\int_{\widetilde{\Omega}} \left(\overline{a}(y)\omega\cdot\omega - (1+\gamma)\int_\Lambda \lambda^{-1}\,d\sigma^1_{y,\omega}(\lambda)\right)|\operatorname{grad}_x u|^2\,dr\,dy\,d\omega \\ &+ \frac{\gamma}{1+\gamma}\int_{\widetilde{\Omega}}\int_\Lambda \lambda\,d\sigma^1_{y,\omega}(\lambda)\,|\partial_r w|^2\,dr\,dy\,d\omega. \end{aligned}$$

From (2.52), one observes that

$$\overline{a}(y)\omega\cdot\omega-\int_{\Lambda}\lambda^{-1}\,d\sigma^{1}_{y,\omega}(\lambda)=\left(\lim_{\varepsilon\to 0}a\left(y,\frac{y}{\varepsilon}\right)^{-1}\omega\cdot\omega\right)^{-1}\geq a_{-}.$$

It follows that

$$\begin{aligned}\overline{a}(y)\omega\cdot\omega-(1+\gamma)\int_{\Lambda}\lambda^{-1}d\sigma^{1}_{y,\omega}(\lambda)&\geq-\gamma\,\overline{a}(y)\omega\cdot\omega+(1+\gamma)\,a_{-}\\&\geq-\gamma\,a_{+}+(1+\gamma)a_{-}.\end{aligned}$$

Thus, for some $\gamma_{-}>0$,

$$(AU,U)\geq\gamma_{-}\left(|\partial_{r}u|^{2}_{L^{2}(\widetilde{\Omega})}+|\partial_{r}w|^{2}_{L^{2}_{\mu}(\mathcal{O}\times S^{n-1}\times\Lambda,L^{2}(\mathbb{R}_{+}))}\right).$$

This completes the proof.

3. An hyperbolic-parabolic equation. Let $\mathcal{O}$ be an open subset of $\mathbb{R}^{m}$, $m\geq 1$, $T>0$, and let Ω_{x} be an open bounded set in $\mathbb{R}^{n}$ with smooth boundary $\partial\Omega_{x}$. We set $\Omega=\Omega_{x}\times\mathcal{O}$. We consider the following Dirichlet problem:

$$\rho^{\varepsilon}(x)\,\partial_{t}^{2}u^{\varepsilon}-\operatorname{div}_{x}(k^{\varepsilon}(x)\operatorname{grad}_{x}u^{\varepsilon})+\theta^{\varepsilon}(x,y)\,\partial_{t}u^{\varepsilon}=f^{\varepsilon}(t,x,y)\quad\text{in }]0,T[\times\Omega,\tag{3.1}$$

$$u^{\varepsilon}\big|_{\partial\Omega_{x}}=0\quad\text{in }]0,T[\times\mathcal{O},\tag{3.2}$$

$$u^{\varepsilon}\big|_{t=0}=\alpha\quad\text{in }\Omega,\tag{3.3}$$

$$\sqrt{\rho^{\varepsilon}}\,\partial_{t}u^{\varepsilon}\big|_{t=0}=\beta\quad\text{in }\Omega.\tag{3.4}$$

On the data ρ^{ε}, k^{ε}, θ^{ε}, f^{ε}, α, and β we assume that the following hypotheses hold. Let

$$\rho^{\varepsilon}(x)=\rho\left(x,\frac{x}{\varepsilon}\right)\quad\text{a.e. in }\Omega_{x},\tag{3.5}$$

with the function ρ belonging to $C(\overline{\Omega_{x}};L^{\infty}_{\text{per}}(Y_{n}))$, and satisfying

$$\begin{aligned}&0\leq\rho(x,\zeta)\leq\rho_{+}\quad\forall x\in\Omega_{x}\text{ for almost every }\zeta\in Y_{n},\\&\text{where we impose that }\tilde{\rho}(x)=\int_{Y_{n}}\rho(x,\zeta)\,d\zeta\geq\rho_{-}>0.\end{aligned}\tag{3.6}$$

The matrix k^{ε} is symmetric, with entries

$$k^{\varepsilon}_{i,j}(x)=k_{i,j}\left(x,\frac{x}{\varepsilon}\right)\quad\text{a.e. in }\Omega_{x},\quad i,j=1\text{ to }n,\tag{3.7}$$

where $k_{i,j}\in C(\overline{\Omega_{x}};L^{\infty}_{\text{per}}(Y_{n}))$, and satisfies

$$k_{-}\,|\xi|^{2}\leq k(x,\zeta)\xi\cdot\xi\leq k_{+}\,|\xi|^{2}\quad\forall\xi\in\mathbb{R}^{n}\quad\forall x\in\Omega_{x},\quad\text{a.e. for }\zeta\in\mathbb{R}^{n},\tag{3.8}$$

k_- and k_+ being two strictly positive real numbers. The damping coefficient is defined by

$$\theta^\varepsilon(x,y) = \theta\left(\frac{x}{\varepsilon}, y, \frac{y}{\varepsilon}\right) \quad \text{a.e. in } \Omega, \tag{3.9}$$

where $\theta \in C(\overline{\mathcal{O}}; L^\infty_{\text{per}}(Y_n \times Y_m))$, and

$$0 < \theta_- \le \theta(\zeta, y, \eta) \le \theta_+ \quad \forall y \in \mathcal{O} \quad \text{for almost every } (\zeta,\eta) \in Y_n \times Y_m. \tag{3.10}$$

In the sequel we set $\Lambda =]\theta_-, \theta_+[$. We take the source term f^ε as in (2.7) where we impose for the case of exposition

$$0 \le c\left(\frac{x}{\varepsilon}, \frac{y}{\varepsilon}\right) \le c_+. \tag{3.11}$$

On the initial data, we suppose

$$\alpha \in L^2(\mathcal{O}; H^1_0(\Omega_x)), \qquad \beta \in L^2(\Omega). \tag{3.12}$$

Observe that (3.4) gives a condition on $\partial_t u^\varepsilon \big|_{t=0}$ only on the set where $\rho^\varepsilon(x) \neq 0$. Hence (3.1) is an equation of hyperbolic-parabolic type. In the standard case where there is no dependence on the variable $y \in \mathcal{O}$, this class of equations has been considered in Vragov [21], and the homogenization is carried out in Bensoussan–Lions–Papanicolaou [8]. Under assumptions (3.5)–(3.12) problem (3.1)–(3.4) admits a unique solution in a weak sense; see [13], [14]. More precisely, we have

(3.13) For each $\varepsilon > 0$, there is a unique solution to (3.1)–(3.4) satisfying

$$u^\varepsilon \in L^\infty(0,T; L^2(\mathcal{O}; H^1_0(\Omega_x))) \cap C^0([0,T]; L^2(\Omega)).$$

(3.14) The sequence $(u^\varepsilon)_{\varepsilon>0}$ is uniformly bounded in

$$L^\infty(0,T; L^2(\mathcal{O}; H^1_0(\Omega_x))) \cap H^1(0,T; L^2(\Omega)).$$

Furthermore

$$\sqrt{\rho^\varepsilon}\, \partial_t u^\varepsilon \quad \text{is bounded in } L^2(]0,T[\times\Omega). \tag{3.15}$$

The proof of (3.13)–(3.15) is standard. It relies on the following a priori identity of energy

$$\begin{aligned} &\int_\Omega \rho^\varepsilon(x)|\partial_t u^\varepsilon|^2\,dx\,dy + \int_\Omega k^\varepsilon(x)\operatorname{grad}_x u^\varepsilon \cdot \operatorname{grad}_x u^\varepsilon\,dx\,dy \\ &\quad + \int_0^t \int_\Omega \theta^\varepsilon(x,y)|\partial_t u^\varepsilon|^2\,dx\,dy\,ds \\ &= \int_\Omega |\beta|^2\,dx\,dy + \int_\Omega k^\varepsilon(x)\operatorname{grad}_x \alpha \cdot \operatorname{grad}_x \alpha\,dx\,dy \\ &\quad + \int_0^t \int_\Omega f^\varepsilon(s,x,y)\,\partial_t u^\varepsilon\,dx\,dy\,ds \end{aligned} \tag{3.16}$$

for all $t \in (0,T)$.

Remark 3.1. Since (u^ε) belongs to $C^0([0,T];L^2(\Omega))$, (3.3) has a meaning. From (3.5), (3.6), (3.13), and (3.14) it follows that $\rho^\varepsilon\,\partial_t u^\varepsilon$ belongs to $L^2(0,T;L^2(\Omega))$ and $\partial_t(\rho^\varepsilon\,\partial_t u^\varepsilon)$ belongs to $L^2(0,T;L^2(\mathcal{O};H^{-1}(\Omega_x)))$. Thus

$$\rho^\varepsilon\,\partial_t u^\varepsilon \quad \text{belongs to } C^0([0,T];H^{-1}(\Omega)). \tag{3.17}$$

We know from [13, Lem. 8.1, p. 297] that

$$L^\infty(0,T;L^2(\Omega))\cap C^0([0,T];H^{-1}(\Omega))\subset C_s([0,T];L^2(\Omega)),$$

where $C_s([0,T];L^2(\Omega))$ denotes the space of functions v defined in $[0,T]$ with values in $L^2(\Omega)$, such that for any w in $L^2(\Omega)$ the function $t\longmapsto \int_\Omega v(t)\,w\,dx\,dy$ is continuous on $[0,T]$. Therefore $\rho^\varepsilon\,\partial_t u^\varepsilon$ belongs to $C_s([0,T];L^2(\Omega))$, and consequently the function

$$t\longmapsto \int_\Omega (\sqrt{\rho^\varepsilon}\,w)\,(\sqrt{\rho^\varepsilon}\,\partial_t u^\varepsilon)\,dx\,dy$$

is continuous on $[0,T]$ for any w such that $\sqrt{\rho^\varepsilon}\,w\in L^2(\Omega)$. This implies that the initial condition (3.4) has a meaning. Obviously the condition $\rho^\varepsilon\,\partial_t u^\varepsilon\,\big|_{t=0}=\sqrt{\rho^\varepsilon}\,\beta$ is also well defined.

In order to derive effective equation describing the oscillatory behavior of (u^ε), we shall proceed as in §2.

3.1. Averaging with respect to ζ. Taking $y\in\mathcal{O}$ and $\eta\in Y_m$ as fixed parameters, we define

$$\tilde c(\eta)=\int_{Y_n} c(\zeta,\eta)\,d\zeta,\ \tilde\theta(y,\eta)=\int_{Y_n}\theta(\zeta,y,\eta)\,d\zeta,\quad\text{and}\quad \chi(x)=\int_{Y_n}\sqrt{\rho(x,\zeta)}\,d\zeta. \tag{3.18}$$

Let also $\tilde k(x)$ be the homogenized matrix associated with the sequence $(k(x,x/\varepsilon))_{\varepsilon>0}$.

We now state and prove the following result.

THEOREM 3.2. *Let $(u^\varepsilon)_{\varepsilon>0}$ be the sequence of solutions of* (3.1)–(3.4), *under assumptions* (3.5)–(3.12). *Then, there is a unique function $U=U(t,x,y,\eta)$ in $L^2(]0,T[\times\mathcal{O}\times Y_m;H_0^1(\Omega_x))$ such that $(u^\varepsilon)_{\varepsilon>0}$ converges, as $\varepsilon\to 0$, to U in the sense of* (2.19). *For almost every $(y,\eta)\in\mathcal{O}\times Y_m$, the function $U(\cdot,\cdot,y,\eta)$ is the solution of*

$$\tilde\rho(x)\,\partial_t^2 U-\operatorname{div}_x(\tilde k(x)\operatorname{grad}_x U)+\tilde\theta(y,\eta)\,\partial_t U=\tilde c(\eta)\,f(t,x,y) \tag{3.19}$$

for $t\in]0,T[$, $x\in\Omega_x$,

$$U\,\big|_{t=0}=\alpha\quad \textit{in}\ \Omega_x, \tag{3.20}$$

$$\tilde\rho(x)\,\partial_t U\,\big|_{t=0}=\chi(x)\,\beta\quad \textit{in}\ \Omega_x. \tag{3.21}$$

Remark 3.3. Assume that in (3.5) the function ρ is independent of ζ and $\rho\not\equiv 0$. Then, it follows from (3.21) that $\partial_t U\,\big|_{t=0}$ is given over the whole domain Ω_x. There is some sort of increase of the initial data comparing with (3.4); see [8].

Proof. It is very close to that of Theorem 2.4. Without going into further details, let us outline the procedure. Let $v^\varepsilon(p,x,y)=\mathcal{L}(u^\varepsilon(\cdot,x,y))(p)$, $g(p,x,y)=$

$\mathcal{L}(f(\cdot,x,y))(p)$ and fix $p \in \mathbb{C}$ with $\Re e p > p_0$ for some real $p_0 > 0$. Therefore, by Laplace transform, (3.1)–(3.4) becomes

$$\begin{aligned} &p^2\,\rho^\varepsilon(x)\,v^\varepsilon - \operatorname{div}_x(k^\varepsilon(x)\operatorname{grad}_x v^\varepsilon) + p\,\theta^\varepsilon(x,y)\,v^\varepsilon \\ &= c^\varepsilon(x,y)\,g(p,x,y) + (p\,\rho^\varepsilon(x) + \theta^\varepsilon(x,y))\,\alpha(x,y) + \sqrt{\rho^\varepsilon(x)}\,\beta(x,y), \end{aligned} \tag{3.22}$$

$$v^\varepsilon\,\big|_{\partial\Omega_x} = 0. \tag{3.23}$$

Consider the variational formulation of (3.22), (3.23):

$$\begin{aligned} &\int_\Omega \left((p^2\,\rho^\varepsilon(x) + p\,\theta^\varepsilon(x,y))\,v^\varepsilon\,\psi^\varepsilon + k^\varepsilon(x)\operatorname{grad}_x v^\varepsilon\cdot\operatorname{grad}_x\psi^\varepsilon\right)dx\,dy \\ &= \int_\Omega \left\{(p\,\rho^\varepsilon(x) + \theta^\varepsilon(x,y))\,\alpha(x,y) + \sqrt{\rho^\varepsilon(x)}\,\beta(x,y)\right\}\psi^\varepsilon\,dx\,dy \\ &\quad + \int_\Omega c^\varepsilon(x,y)\,g(p,x,y)\,\psi^\varepsilon\,dx\,dy \end{aligned} \tag{3.24}$$

for any test function ψ^ε. Arguing like before, we take successively in (3.24)

$$\psi^\varepsilon(x,y) = \varepsilon\,\varphi(x,y)\,w\left(\frac{x}{\varepsilon},\frac{y}{\varepsilon}\right) \quad\text{and}\quad \psi^\varepsilon(x,y) = \varphi(x,y)\,w\left(\frac{y}{\varepsilon}\right)$$

with $\varphi \in \mathcal{D}(\Omega)$, w a smooth $Y_n\times Y_m$-periodic function and send $\varepsilon \to 0$. Thanks to Theorem 2.1, there exists a subsequence (still denoted by $(v^\varepsilon)_{\varepsilon>0}$), and $V = V(p,x,y,\eta)$, $V_1 = V_1(p,x,\zeta,y,\eta)$, V in $L^2(\Omega; L^2_{\text{per}}(Y_m))$, V_1 and $\partial_{\zeta_i}V_1$ in $L^2(\Omega; L^2_{\text{per}}(Y_n\times Y_m))$ such that

$$\operatorname{div}_\zeta(k(x,\zeta)\,(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1)) = 0, \tag{3.25}$$

$$\begin{aligned} &p^2\,\tilde\rho(x)\,V - \operatorname{div}_x\left(\int_{Y_n} k(x,\zeta)\,(\operatorname{grad}_x V + \operatorname{grad}_\zeta V_1)\right)d\zeta + p\,\tilde\theta(y,\eta)\,V \\ &= (p\,\tilde\rho(x) + \tilde\theta(y,\eta))\,\alpha(x,y) + \chi(x)\,\beta(x,y) + \tilde c(\eta)\,g(p,x,y). \end{aligned} \tag{3.26}$$

in the sense of distributions. Displaying from (3.25) V_1 in terms of V and introducing the homogenized tensor $\tilde k(x)$ of $(k(x,x/\varepsilon))_{\varepsilon>0}$ gives

$$\begin{aligned} &p^2\,\tilde\rho(x)\,V - \operatorname{div}_x(\tilde k(x)\operatorname{grad}_x V) + p\,\tilde\theta(y,\eta)\,V \\ &= (p\,\tilde\rho(x) + \tilde\theta(y,\eta))\,\alpha(x,y) + \chi(x)\,\beta(x,y) + \tilde c(\eta)\,g(p,x,y). \end{aligned} \tag{3.27}$$

Taking the inverse Laplace transform of (3.27), one deduces that there is a function $U = U(t,x,y,\eta)$ in $L^2(]0,T[\times\mathcal{O}\times Y_m; H^1_0(\Omega_x))$ such that (3.19), (3.20), and (3.21) hold. Moreover, the function U is uniquely determined by (3.19)–(3.21). Hence the whole sequence $(u^\varepsilon)_{\varepsilon>0}$ converges weakly in the sense of (2.19) to U. The proof of Theorem 3.2 is then complete.

3.2. Averaging with respect to η. Nonlocal effective equations. Let u be the zero-order moment of the function U defined in Theorem 3.2

$$u(t,x,y) = \int_{Y_m} U(t,x,y,\eta)\,d\eta, \quad t>0, \quad (x,y)\in\Omega. \tag{3.28}$$

Clearly, the sequence $(u^\varepsilon)_{\varepsilon>0}$ of solutions of (3.1)–(3.4) converges as $\varepsilon \to 0$ to u weakly in $L^2(]0,T[\times\Omega)$. In order to get an equation for u, it remains to average (3.19) with respect to $\eta \in Y_m$. Let $V(p,x,y,\eta) = \mathcal{L}(U(\cdot,x,y,\eta))(p)$, the Laplace transform in time t of U. Then for $p \in \mathbb{C}$ with $\Re e p > 0$, V satisfies (3.27). For fixed $p \in \mathbb{C}$ with $\Re e p > p_0$, introduce the unbounded operator A_p with domain $D(A_p) = \{v \in H_0^1(\Omega_x)\,;\ A_p v \in L^2(\Omega_x)\}$ defined by

$$A_p v = p^2\,\tilde{\rho}(x)\,v - \mathrm{div}_x(\tilde{k}(x)\,\mathrm{grad}_x v). \tag{3.29}$$

For almost every $(y,\eta) \in \mathcal{O}\times Y_m$, $(A_p + p\,\tilde{\theta}(y,\eta))$ is a one-to-one operator from $D(A_p)$ onto $L^2(\Omega_x)$. Then, from (3.27) we deduce

$$V(p,\cdot,y,\eta) = \left(A_p + p\,\tilde{\theta}(y,\eta)\right)^{-1}\left(h(p,x,y,\eta)\right) \tag{3.30}$$

with $h(p,x,y,\eta) = (p\,\tilde{\rho}(x) + \tilde{\theta}(y,\eta))\,\alpha(x,y) + \chi(x)\,\beta(x,y) + \tilde{c}(\eta)\,g(p,x,y)$. According to Dunford–Taylor's integral (see Kato [12]) we can write

$$\left(A_p + p\,\tilde{\theta}(y,\eta)\right)^{-1} = \frac{-1}{2\,i\,\pi}\int_{\Gamma_p}\left(z - p\,\tilde{\theta}(y,\eta)\right)^{-1}(A_p + z)^{-1}\,dz. \tag{3.31}$$

Here

$$\Gamma_p = \left\{z \in \mathbb{C}\,;\, \frac{z}{p} \in \tilde{\Gamma}_p\right\}$$

with $\tilde{\Gamma}_p$ a closed curve in the right half plane $\Re e\, z > 0$ containing the real interval $\overline{\Lambda}$. Thanks to Fubini's lemma and Lemma 2.5, averaging in Y_m of (3.31) is easily obtained. There exist two parametrized families of nonnegative measures $d\sigma_y^1$ and $d\sigma_y^2$ associated, respectively, with the sequences $(\tilde{\theta}(y,y/\varepsilon))_{\varepsilon>0}$ and $(\tilde{c}(y/\varepsilon)\,\tilde{\theta}(y,y/\varepsilon))_{\varepsilon>0}$, with support contained in $\overline{\Lambda}$ such that for all $z \in \Gamma_p$ and almost every $y \in \mathcal{O}$,

$$\int_{Y_m}(z - p\,\tilde{\theta}(y,\eta))^{-1}\,d\eta = \left(z - p\,\overline{\theta}(y) - p^2\int_\Lambda (z - p\,\lambda)^{-1}, d\sigma_y^1(\lambda)\right)^{-1}, \tag{3.32}$$

$$\int_{Y_m}\tilde{c}(\eta)\,(z - p\,\tilde{\theta}(y,\eta))^{-1}\,d\eta = \overline{c}\left(z - p\,\overline{d}(y) - p^2\int_\Lambda (z - p\,\lambda)^{-1}\,d\sigma_y^2(\lambda)\right)^{-1}, \tag{3.33}$$

where $\overline{\theta}(y) = \int_{Y_m}\tilde{\theta}(y,\eta)\,d\eta$, $\overline{c} = \int_{Y_m}\tilde{c}(\eta)\,d\eta$, and $\overline{d}(y) = \frac{1}{\overline{c}}\int_{Y_m}\tilde{\theta}(y,\eta)\,\tilde{c}(\eta)\,d\eta$. Introduce for $i = 1,2$, the functions $V_i = V_i(p,x,y,\eta)$ such that

$$\begin{aligned} V_1(p,x,y,\eta) &= (A_p + p\,\tilde{\theta}(y,\eta))^{-1}\left((p\,\tilde{\rho}(x) + \tilde{\theta}(y,\eta))\,\alpha(x,y) + \chi(x)\,\beta(x,y)\right),\\ V_2(p,x,y,\eta) &= (A_p + p\,\tilde{\theta}(y,\eta))^{-1}\left(\tilde{c}(\eta)\,g(p,x,y)\right). \end{aligned} \tag{3.34}$$

First, it follows from Dunford–Taylor's integral that

$$\begin{aligned} &\int_{Y_m}(A_p + p\,\tilde{\theta}(y,\eta))^{-1}(h(p,\cdot,y))\,d\eta\\ &\quad = \left(A_p + p\,\overline{\theta}(y) - p^2\int_\Lambda (A_p + p\,\lambda)^{-1}\,d\sigma_y^2(\lambda)\right)^{-1}(h(p,\cdot,y)) \end{aligned} \tag{3.35}$$

for any function $h(p,\cdot,y)$ in $L^2(\Omega_x)$. Using the relation

$$p\,\tilde\theta(y,\eta)\,(z-p\,\tilde\theta(y,\eta))^{-1} = -1 + z\,(z-p\,\tilde\theta(y,\eta))^{-1}, \tag{3.36}$$

we also obtain

$$\begin{aligned}&\int_{Y_m}\tilde\theta(y,\eta)\,(A_p+p\,\tilde\theta(y,\eta))^{-1}(h(p,\cdot,y))\,d\eta\\ &\quad= \left(A_p+p\,\bar\theta(y)-p^2\int_\Lambda (A_p+p\,\lambda)^{-1}\,d\sigma_y^2(\lambda)\right)^{-1}(h_*(p,\cdot,y))\end{aligned} \tag{3.37}$$

with $h_*(p,\cdot,y) = (\bar\theta(y) - p\int_\Lambda (A_p+p\,\lambda)^{-1}\,d\sigma_y^1(\lambda))(h(p,\cdot,y))$. Similarly, we deduce from (3.33) that

$$\begin{aligned}&\int_{Y_m}(A_p+p\,\tilde\theta(y,\eta))^{-1}(h(p,\cdot,y)\,\tilde b(y,\eta))\,d\eta\\ &\quad= \bar c\left(A_p+p\,\bar d(y)-p^2\int_\Lambda (A_p+p\,\lambda)^{-1}\,d\sigma_y^2(\lambda)\right)^{-1}(h(p,\cdot,y)).\end{aligned} \tag{3.38}$$

Now let $v(t,x,y)=\int_{Y_m} V(p,x,y,\eta)\,d\eta$ and $v_i(t,x,y)=\int_{Y_m} V_i(p,x,y,\eta)\,d\eta$ for $i=1,2$. The functions $v_i(p,\cdot,y)$, $i=1,2$, belong to $H_0^1(\Omega_x)$ and $v=v_1+v_2$. Also let introduce v_1^* and v_2^* such that

$$v_1^* = (A_p+p\,\lambda)^{-1}(p\,v_1+\alpha), \qquad v_2^* = (A_p+p\,\lambda)^{-1}(p\,v_2).$$

Therefore, from (3.35), (3.37), and (3.38) one easily deduces that (v_1,v_2,v_1^*,v_2^*) satisfy the following system of equations:

$$\begin{aligned}&A_p\,v_1+p\,\bar\theta(y)\,v_1-p\int_\Lambda v_1^*\,d\sigma_y^1(\lambda) = p\,(\tilde\rho(\cdot)+\bar\theta(y))\,\alpha(\cdot,y)+\chi(\cdot)\,\beta(\cdot,y),\\ &A_p\,v_1^*+p\,\lambda\,v_1^*-p\,v_1=\alpha,\\ &A_p\,v_2+p\,\bar d(y)\,v_2-p\int_\Lambda v_2^*\,d\sigma_y^2(\lambda)=\bar c\,g(p,\cdot,y),\\ &A_p\,v_2^*+p\,\lambda\,v_2^*-p\,v_2=0.\end{aligned}$$

The inverse Laplace transform, with the notation $u_i=\mathcal{L}^{-1}(v_i)$, $w_i=\mathcal{L}^{-1}(v_i^*)$, gives

$$\begin{aligned}&\tilde\rho(x)\,\partial_t^2u_1-\operatorname{div}_x(\tilde k(x)\operatorname{grad}_x u_1)+\bar\theta(y)\,\partial_t u_1-\int_\Lambda \partial_t w_1\,d\sigma_y^1(\lambda)=0,\\ &\tilde\rho(x)\,\partial_t^2w_1-\operatorname{div}_x(\tilde k(x)\operatorname{grad}_x w_1)+\lambda\,\partial_t w_1-\partial_t u_1=0,\\ &u_1\,\big|_{\partial\Omega_x\times\mathcal{O}}=0,\\ &u_1\,\big|_{t=0}=\alpha,\qquad \tilde\rho\,\partial_t u_1\,\big|_{t=0}=\chi\cdot\beta\quad\text{in }\Omega,\\ &w_1\,\big|_{t=0}=0,\qquad \partial_t w_1\,\big|_{t=0}=0\quad\text{in }\Omega,\end{aligned} \tag{3.39}$$

$$\begin{aligned}&\tilde\rho(x)\,\partial_t^2u_2-\operatorname{div}_x(\tilde k(x)\operatorname{grad}_x u_2)+\bar d(y)\,\partial_t u_2-\int_\Lambda \partial_t w_2\,d\sigma_y^2(\lambda)=0,\\ &\tilde\rho(x)\,\partial_t^2w_2-\operatorname{div}_x(\tilde k(x)\operatorname{grad}_x w_2)+\lambda\,\partial_t w_2-\partial_t u_2=\bar c\,f(t,x,y),\\ &u_2\,\big|_{\partial\Omega_x\times\mathcal{O}}=0,\\ &u_2\,\big|_{t=0}=0,\qquad \partial_t u_2\,\big|_{t=0}=0\quad\text{in }\Omega,\\ &w_2\,\big|_{t=0}=0,\qquad \partial_t w_2\,\big|_{t=0}=0\quad\text{in }\Omega.\end{aligned} \tag{3.40}$$

Thus we obtain the following.

THEOREM 3.4. *Let* $(u^\varepsilon)_{\varepsilon>0}$ *be the sequence of solutions of* (3.1)–(3.4) *under assumptions* (3.5)–(3.9). *Then,* $(u^\varepsilon)_{\varepsilon>0}$ *converges weakly in* $L^2(]0,T[\times\Omega)$ *to* $u = u_1+u_2$, *where* u_1 *and* u_2 *are, respectively, defined by* (3.39) *and* (3.40).

Remark 3.5. If in (3.11) the function c does not depend on the η-variable, then the corresponding sequence of solutions of (3.1)–(3.4) converges weakly in $L^2(]0,T[\times\Omega)$ to u solution of the following system:

$$\tag{3.41}\begin{aligned}
&\tilde\rho(x)\,\partial_t^2 u - \operatorname{div}_x(\tilde k(x)\operatorname{grad}_x u) + \overline{\theta}(y)\,\partial_t u - \int_\Lambda \partial_t w\, d\sigma_y^1(\lambda) = \tilde c\, f(t,x,y),\\
&\tilde\rho(x)\,\partial_t^2 w - \operatorname{div}_x(\tilde k(x)\operatorname{grad}_x w) + \lambda\,\partial_t w - \partial_t u = 0,\\
&u\,\Big|_{\partial\Omega_x\times\mathcal{O}} = 0,\\
&u\,\Big|_{t=0} = \alpha, \qquad \tilde\rho\,\partial_t u\,\Big|_{t=0} = \chi\beta \quad \text{in } \Omega,\\
&w\,\Big|_{t=0} = 0, \qquad \partial_t w\,\Big|_{t=0} = 0 \quad \text{in } \Omega.
\end{aligned}$$

Remark 3.6. Existence and uniqueness results for (3.39)–(3.41), may be established by the same technique as in Theorem 2.11.

Remark 3.7. If the function c^ε changes sign, we proceed as in §2.

4. Parametrized families in the nonperiodic microstructure. Let $T > 0$ and $\Omega = \Omega_x \times \mathcal{O}$, where Ω_x is an open bounded set in $\mathbb{R}^n$ with smooth boundary $\partial\Omega_x$ and $\mathcal{O}$ is a domain in $\mathbb{R}^m$.

4.1. Parametrized family of acoustic waves. We consider in this section the propagation of a parametrized family of acoustic waves:

$$\tag{4.1}\begin{aligned}
&\partial_t^2 u^\varepsilon - a^\varepsilon(y)\,\Delta_x u^\varepsilon = 0, \quad t\in]0,T[, \quad (x,y)\in\Omega_x\times\mathcal{O},\\
&u^\varepsilon\,|_{\partial\Omega_x\times\mathcal{O}} = 0, \qquad t\in]0,T[,\\
&u^\varepsilon\,|_{t=0} = \alpha, \qquad \partial_t u^\varepsilon\,|_{t=0} = \beta \quad \text{in } \Omega_x\times\mathcal{O}.
\end{aligned}$$

Here (a^ε) is a sequence in $L^\infty(\mathcal{O})$ that satisfies

$$\tag{4.2}\begin{aligned}
&a^\varepsilon(y)\in\overline{\Lambda} \quad \text{a.e. in } \mathcal{O}, \quad \Lambda =]a_-,a_+[, \quad 0 < a_- \le a_+,\\
&a^\varepsilon \overset{\star}{\rightharpoonup} \overline{a} \quad \text{in } L^\infty(\mathcal{O}) \text{ weak*}.
\end{aligned}$$

The initial data are taken such that

$$\tag{4.3} \alpha\in L^2(\mathcal{O}; H_0^1(\Omega_x)), \qquad \beta\in L^2(\mathcal{O}; L^2(\Omega_x)).$$

We state and prove the following result.

THEOREM 4.1. *Suppose* (4.2), (4.3) *hold. Then, along a subsequence, there exists a parametrized family of nonnegative measures* $d\sigma_y$, *with support in* $\overline{\Lambda}$, *such that the sequence* (u^ε) *of solutions of* (4.1) *converges in* $L^\infty(0,T;L^2(\mathcal{O};H_0^1(\Omega_x)))$ *weak* and in* $H^1(0,T;L^2(\mathcal{O};H_0^1(\Omega_x)))$ *weak to* u *solution, in the sense of distributions, of the following system:*

$$\tag{4.4}\begin{aligned}
&\partial_t^2 u - \overline{a}(y)\Delta_x u + \int_\Lambda d\sigma_y(\lambda)\Delta_x w(\lambda) = 0 \quad \text{in }]0,T[\,\times\Omega_x\times\mathcal{O},\\
&\partial_t^2 w - \lambda\Delta_x w + \Delta_x u = 0 \quad \text{in }]0,T[\,\times\Omega\times\Lambda,\\
&u\,|_{\partial\Omega} = 0, \qquad w\,|_{\partial\Omega_x\times\mathcal{O}\times\Lambda} = 0 \quad \text{in }]0,T[,\\
&u\,|_{t=0} = \alpha, \qquad \partial_t u\,|_{t=0} = \beta \quad \text{in } \Omega,\\
&w\,|_{t=0} = 0, \qquad \partial_t w\,|_{t=0} = 0 \quad \text{in } \Omega\times\Lambda.
\end{aligned}$$

Remark 4.2. In the case of the Cauchy problem ($\Omega_x = \mathbb{R}^n$) the function u satisfies in $]0,T[\times\mathbb{R}^n \times \mathcal{O}$ the following nonlocal wave equation:

$$\tag{4.5} \begin{aligned} &\partial_t^2 u - \bar{a}(y)\Delta_x u + \int_0^t \int_{\mathbb{R}^n} ds\, M_n(t-s, x-z, y)\Delta_x^2 u(s,z,y)(x)\, ds\, dz = 0,\\ &u\,|_{t=0} = \alpha, \qquad \partial_t u\,|_{t=0} = \beta. \end{aligned}$$

The kernel $M_n(t,x,y)$ is given by $M_n(t,x,y) = \int_\Lambda d\sigma_y(\lambda)\, \mathcal{E}_n(t,x,\lambda)$, where $\mathcal{E}_n(\cdot,\cdot,\lambda)$ is the elementary solution in $\mathbb{R}^n$ of the wave operator $\partial_t^2 - \lambda\,\Delta_x$, $\lambda \in \Lambda$.

Proof of Theorem 4.1. Let $\mathcal{L}$ denote the Laplace transform in time and $v^\varepsilon(p,x,y) = \mathcal{L}(u^\varepsilon(\cdot,x,y))(p)$. Then, for fixed $p \in \mathbb{C}$ with $\Re e\, p > p_0 > 0$, v^ε is the unique solution of the Dirichlet problem

$$\tag{4.6} p^2\, v^\varepsilon - a^\varepsilon(y)\,\Delta_x v^\varepsilon = F \quad \text{in } \Omega_x \times \mathcal{O}, \quad v^\varepsilon\,|_{\partial\Omega} = 0,$$

where the source term is given by $F(p,x,y) = p\,\alpha(x,y) + \beta(x,y)$. Since the function $F(p,\cdot,\cdot)$ belongs to $L^2(\mathcal{O}; L^2(\Omega_x))$ then, according to the regularity properties of elliptic equations, $v^\varepsilon(p,\cdot,y)$ belongs to $L^2(\mathcal{O}; H_0^1(\Omega_x) \cap H^2(\Omega_x))$. So, let us introduce the unbounded operator A in $L^2(\Omega_x)$ defined by

$$\tag{4.7} A\,u = -\Delta_x u \quad \text{with domain } D(A) = H_0^1(\Omega_x) \cap H^2(\Omega_x).$$

Hence, from (4.6), one deduces that for almost every $y \in \mathcal{O}$,

$$\tag{4.8} v^\varepsilon(p,\cdot,y) = (p^2 + a^\varepsilon(y)A)^{-1} F(p,\cdot,y).$$

Using the Dunford–Taylor integral representation, one has

$$\tag{4.9} v^\varepsilon(p,\cdot,y) = \left(\frac{-1}{2\,\imath\,\pi}\int_{\Gamma_p} (p^2 - a^\varepsilon(y)z)^{-1}\,(z+A)^{-1}\,dz\right)(F(p,\cdot,y)),$$

where

$$\Gamma_p = \left\{ z \in \mathbb{C};\ \frac{p^2}{z} \in \tilde{\Gamma}_p \right\}$$

with $\tilde{\Gamma}_p$ a closed curve in the right half space $\Re e\, z > 0$ containing the real interval $\overline{\Lambda}$. Consider now for fixed z in Γ_p the sequence $(H^\varepsilon(\cdot,p,z))$ defined for almost every $y \in \mathcal{O}$ by $H^\varepsilon(y,p,z) = (p^2 - a^\varepsilon(y)z)^{-1}$. Thanks to Lemma 2.5, there exists a parametrized family of nonnegative measures $d\sigma_y(\cdot)$ supported, for almost every $y \in \mathcal{O}$, in $\overline{\Lambda}$ such that for a subsequence,

$$H^\varepsilon(\cdot,p,z) \overset{\star}{\rightharpoonup} H(\cdot,p,z) \quad \text{in } L^\infty(\mathcal{O}) \text{ weak*},$$

with

$$\tag{4.10} H(y,p,z) = \left(p^2 - z\,\bar{a}(y) - z^2\int_\Lambda (p^2 - \lambda\,z)^{-1}\,d\sigma_y(\lambda)\right)^{-1}.$$

Hence, for a subsequence,

$$v^\varepsilon(p,\cdot,\cdot) \rightharpoonup v(p,\cdot,\cdot) \quad \text{in } L^2(\mathcal{O}; H_0^1(\Omega_x)) \text{ weak},$$

and

$$v(p,\cdot,y) = \frac{-1}{2\imath\pi}\int_{\Gamma_p} H(y,p,z)\,(z+A)^{-1}(F(p,\cdot,y))\,dz \quad \text{a.e. in } \mathcal{O}. \tag{4.11}$$

Plugging (4.10) into (4.11) and using Dunford–Taylor's integral, we find

$$v(p,\cdot,y) = \left(p^2 + \bar{a}(y)\,A - \int_\Lambda A(p^2+\lambda A)^{-1}A\,d\sigma_y(\lambda)\right)^{-1}(F)\,(p,\cdot,y). \tag{4.12}$$

We now introduce the new function $w_*(p,x,y,\lambda)$ defined for $\Re e p > p_0 > 0$, $\lambda \in \Lambda$ and for almost every $y \in \mathcal{O}$ by

$$w_*(p,\cdot,y,\lambda) = (p^2+\lambda A)^{-1}Av(p,\cdot,y). \tag{4.13}$$

Clearly w_* is the unique solution of the Dirichlet problem

$$p^2\,w_* - \lambda\,\Delta_x w_* = -\Delta_x v \quad \text{in } \Omega_x\times\mathcal{O}\times\Lambda, \qquad w_*\,|_{\partial\Omega_x\times\mathcal{O}\times\Lambda} = 0. \tag{4.14}$$

Equations (4.12) and (4.14) imply that (v, w_*) is a solution for $p \in \mathbb{C}$, $\Re e p > p_0$ of the following system:

$$\begin{aligned} &p^2\,v - \bar{a}(y)\Delta_x v + \int_\Lambda d\sigma_y(\lambda)\,\Delta_x w_* = F(p,\cdot,y) \quad \text{in } \Omega,\\ &p^2\,w_* - \lambda\,\Delta_x w_* + \Delta_x v = 0 \quad \text{in } \Omega_x\times\mathcal{O}\times\Lambda,\\ &v\,|_{\partial\Omega_x\times\mathcal{O}} = 0, \qquad w_*\,|_{\partial\Omega_x\times\mathcal{O}\times\Lambda} = 0. \end{aligned} \tag{4.15}$$

Let $w(t,x,y,\lambda)$ be defined in $]0,T[\times\Omega_x\times\mathcal{O}\times\Lambda$ by its Laplace transform w_*:

$$\mathcal{L}(w(\cdot,x,y,\lambda))(p) = w_*(p,x,y,\lambda). \tag{4.16}$$

One deduces from (4.15) and (4.16) that (u,w) is a solution of system (4.4) and proves the theorem.

Remark 4.3. We can study, along lines similar to §§2 and 3, (4.1) with a source term of type

$$\begin{aligned} &f^\varepsilon(t,x,y) = c^\varepsilon(y)\,f(t,x),\\ &\qquad f \in L^2(]0,T[\times\Omega_x), \qquad 0 < c_- \le c^\varepsilon(y) \le c_+ \quad \text{a.e. in } \mathcal{O}. \end{aligned} \tag{4.17}$$

4.2. A damped wave equation. This second part is concerned with the study of some kind of interaction of oscillations by the homogenization process in the damped wave equation for which the damping acts on the transverse variable $y \in \mathcal{O}$. We consider the Dirichlet problem

$$\begin{aligned} &\rho^\varepsilon(x)\,\partial_t^2 u^\varepsilon - \mathrm{div}_x(k^\varepsilon(x)\ \mathrm{grad}_x u^\varepsilon) + \theta^\varepsilon(y)\,\partial_t u^\varepsilon = 0,\\ &u^\varepsilon\,|_{\partial\Omega_x\times\mathcal{O}} = 0, \quad u^\varepsilon\,|_{t=0} = \alpha, \quad \partial_t u^\varepsilon\,|_{t=0} = \beta, \end{aligned} \tag{4.18}$$

where $\alpha \in L^2(\mathcal{O}; H_0^1(\Omega_x))$ and $\beta \in L^2(\mathcal{O}; L^2(\Omega_x))$. We assume that ρ^ε belongs to $L^\infty(\Omega_x)$ and k^ε is a symmetric tensor with components in $L^\infty(\Omega_x)$ satisfying, for almost every $x \in \Omega_x$,

$$0 < \rho_- \le \rho^\varepsilon(x) \le \rho_+, \tag{4.19}$$

$$k_-|\xi|^2 \le k^\varepsilon(x)\xi\cdot\xi \le k_+|\xi|^2 \quad \forall\xi\in\mathbb{R}^n, \tag{4.20}$$

with $0<k_- \le k_+$. Suppose also that

$$\begin{aligned} &\rho^\varepsilon \overset{\star}{\rightharpoonup} \overline{\rho} \quad \text{in } L^\infty(\Omega_x) \text{ weak*},\\ &k^\varepsilon \overset{\mathcal{H}}{\rightharpoonup} \overline{k} \quad \text{in the sense of homogenization [15], [19].}\end{aligned} \tag{4.21}$$

The sequence $(\theta^\varepsilon(y))$ is in $L^\infty(\mathcal{O})$ such that

$$\begin{cases} 0<\theta_- \le \theta^\varepsilon(y) \le \theta_+ \quad \text{a.e. for } y\in\mathcal{O},\\ \theta^\varepsilon \overset{\star}{\rightharpoonup} \overline{\theta} \quad \text{in } L^\infty(\mathcal{O}) \text{ weak*}.\end{cases} \tag{4.22}$$

Let $p\in\mathbb{C}$ with $\Re e\, p>p_0$ for some $p_0>0$. We denote by H_p^ε the unbounded operator in $L^2(\Omega_x)$, with domain $D(H_p^\varepsilon)=\{v\in H_0^1(\Omega_x);\ H_p^\varepsilon v\in L^2(\Omega_x)\}$ defined by

$$H_p^\varepsilon(v)=\rho^\varepsilon(x)\,p^2\,v-\operatorname{div}_x(k^\varepsilon(x)\operatorname{grad}_x v), \qquad v\in D(H_p^\varepsilon). \tag{4.23}$$

Taking the Laplace transform in time of (4.18), the function $v^\varepsilon(p,x,y)=\mathcal{L}(u^\varepsilon(\cdot,x,y))(p)$ is then the unique solution of the equation

$$\left(H_p^\varepsilon+p\,\theta^\varepsilon(y)\right)v^\varepsilon=F^\varepsilon(p,x,y)+\theta^\varepsilon(y)\,\alpha(x,y),$$

where $F^\varepsilon(p,x,y)=\rho^\varepsilon(x)\,(p\,\alpha(x,y)+\beta(x,y))$. Arguing as in the proof of Theorem 3.4, we must pass to the limit in the following two sequences: $(H_p^\varepsilon+p\,\theta^\varepsilon(y))^{-1}(F^\varepsilon)$ and $(H_p^\varepsilon+p\,\theta^\varepsilon(y))^{-1}(\theta^\varepsilon(y)\,\alpha)$. The resolvent operator $(H_p^\varepsilon+p\,\theta^\varepsilon(y))^{-1}$, defined for $\Re e\,p>p_0$, have the following integral representation:

$$\left(H_p^\varepsilon+p\,\theta^\varepsilon(y)\right)^{-1}=\frac{-1}{2\,\imath\,\pi}\int_{\Gamma_p}(z-p\,\theta^\varepsilon(y))^{-1}\,(H_p^\varepsilon+z)^{-1}\,dz.$$

Here

$$\Gamma_p=\left\{z\in\mathbb{C};\frac{z}{p}\in\tilde{\Gamma}_p\right\}$$

with $\tilde{\Gamma}_p$ a closed curve in the right half plane $\Re e\, z>0$ containing the real interval $\overline{\Lambda}$. Thanks to Lemma 2.5, one has, for a subsequence

$$\left(z-p\,\theta^\varepsilon(\cdot)\right)^{-1}\overset{\star}{\rightharpoonup}\left(z-p\overline{\theta}(\cdot)-p^2\int_\Lambda(z-p\lambda)^{-1}\,d\sigma_\bullet(\lambda)\right)^{-1}(F) \tag{4.24}$$

in $L^\infty(\mathcal{O})$ weak*, where $d\sigma_y(\cdot)$ is a parametrized family of nonnegative measures associated with (θ^ε). From (4.21), (F^ε) converges weakly in $L^2(\Omega)$ to F, where $F(p,x,y)=\overline{\rho}(x)\,(p\,\alpha(x,y)+\beta(x,y))$. We claim that, for all $z\in\Gamma_p$,

$$(H_p^\varepsilon+z)^{-1}(F^\varepsilon(p,\cdot,\cdot))\ \to\ (H_p+z)^{-1}(F(p,\cdot,\cdot)) \quad \text{strongly in } L^2(\Omega), \tag{4.25}$$

where H_p is the homogenized operator of H_p^ε given by

$$\begin{aligned} &D(H_p)=\{v\in H_0^1(\Omega_x);\ H_p v\in L^2(\Omega_x)\},\\ &H_p(v)=\overline{\rho}(x)\,p^2\,v-\operatorname{div}_x(\overline{k}(x)\operatorname{grad}_x v) \quad \text{for } v\in D(H_p).\end{aligned} \tag{4.26}$$

For $z \in \Gamma_p$, let χ^ε be the solution of

$$(4.27)\qquad (H_p^\varepsilon + z)\chi^\varepsilon = F^\varepsilon \quad \text{in } \Omega_x \times \mathcal{O}, \quad \chi^\varepsilon|_{\partial\Omega_x \times \mathcal{O}} = 0.$$

The sequence (χ^ε) lies in a bounded set of $L^2(\mathcal{O}; H_0^1(\Omega_x))$. Thus, for a subsequence, (χ^ε) converges weakly in $L^2(\Omega)$ to χ. For a given function φ, defined in Ω, let us denote by $\tilde{\varphi}$ its extension which takes the value zero outside Ω. For h_y given in $\mathbb{R}^m$, we set

$$\delta_{h_y}\tilde{\varphi}(x,y) = \tilde{\varphi}(x, y+h_y) - \tilde{\varphi}(x,y).$$

Clearly, $\delta_{h_y}\tilde{\chi}^\varepsilon(p,\cdot,y)$ is, for almost every $y \in \mathbb{R}^m$, the unique solution of

$$(H_p^\varepsilon + z)\,\delta_{h_y}\tilde{\chi}^\varepsilon(p,\cdot,y) = \rho^\varepsilon(\cdot)\,\delta_{h_y}\tilde{F}(p,\cdot,y) \quad \text{in } \Omega_x,$$

$$\delta_{h_y}\tilde{\chi}^\varepsilon(p,\cdot,y)\,|_{\partial\Omega_x} = 0,$$

and satisfies the standard estimate

$$\|\delta_{h_y}\tilde{\chi}^\varepsilon(p,\cdot,y)\|_{H_0^1(\Omega_x)} \le C\,|\delta_{h_y}\tilde{F}(p,\cdot,y)|_{L^2(\Omega_x)} \quad \text{for almost every } y \in \mathbb{R}^m,$$

where $C > 0$ is independent of ε and h_y. One easily deduces that, for $h_x \in \mathbb{R}^n$, $h_y \in \mathbb{R}^m$, $|h_x|$ small,

$$\int_{\Omega_x \times \mathcal{O}} |\tilde{\chi}^\varepsilon(p, x+h_x, y+h_y) - \tilde{\chi}^\varepsilon(p,x,y)|^2 dx$$
$$\le C\left(|h_x|^2\,|F|^2_{L^2(\Omega_x\times\mathcal{O})} + |\delta_{h_y}\tilde{F}(p,\cdot,\cdot)|^2_{L^2(\Omega_x\times\mathcal{O})}\right),$$

with $C > 0$ independent of ε, h_x, and h_y. Thus the sequence (χ^ε) is compactly imbedded in $L^2(\Omega_x \times \mathcal{O})$. Hence, there exists a subsequence (still denoted by χ^ε) such that $\chi^\varepsilon \to \chi$ strongly in $L^2(\Omega)$. Using the standard arguments of the homogenization theory, see Murat [15] and Tartar [19], one verifies that $\chi(p,\cdot,y)$ is the unique solution in $H_0^1(\Omega_x)$ of the homogenized problem

$$\overline{\rho}(x)\,p^2\,\chi - \mathrm{div}_x(\overline{k}(x)\mathrm{grad}_x\chi) + z\,\chi = F(p,\cdot,y) \quad \text{for almost every } y \in \mathcal{O}.$$

This proves (4.25). Consequently, for all $z \in \Gamma_p$,

$$(z - p\,\theta^\varepsilon(y))^{-1}\,(H_p^\varepsilon + z)^{-1}(F^\varepsilon) \rightharpoonup \left(z - p\overline{\theta} - \int_\Lambda d\sigma_y(\lambda)\,(z - p\,\lambda)^{-1}\right)^{-1}(H_p + z)^{-1}(F)$$

weakly in $L^2(\Omega)$. Let $\psi \in L^2(\Omega)$ fixed and define

$$m^\varepsilon(z) = \int_\Omega \psi(x,y)\,(z - p\,\theta^\varepsilon(y))^{-1}\,(H_p^\varepsilon + z)^{-1}(F^\varepsilon(p,x,y))\,dx\,dy,$$

$$m(z) = \int_\Omega \psi(x,y)\left(z - p\overline{\theta}(y) - \int_\Lambda d\sigma_y(\lambda)\,(z - p\,\lambda)^{-1}\right)^{-1}(H_p + z)^{-1}F(p,x,y)\,dx\,dy.$$

We have proved that $m^\varepsilon(z) \to m(z)$ for all $z \in \Gamma_p$. In order to apply the dominated convergence theorem to the sequence $\left(\int_{\Gamma_p} m^\varepsilon(z)\,dz\right)$, see Folland [11, p. 157] for instance, let us prove that $m^\varepsilon(z)$ is bounded by an integrable function on Γ_p. The strong convergence of the sequence $(H_p^\varepsilon + z)^{-1}(F^\varepsilon)$ in $L^2(\Omega)$, the energy estimate

$$|(H_p^\varepsilon + z)^{-1}(F^\varepsilon)|_{L^2(\Omega)} \leq C\,|F|_{L^2(\Omega)},$$

with C independent of ε and z, and the dominated convergence theorem yield

$$\int_{\Gamma_p} |(H_p^\varepsilon + z)^{-1}(F^\varepsilon)|_{L^2(\Omega)}\,dz \to \int_{\Gamma_p} |(H_p + z)^{-1}(F)|_{L^2(\Omega_x \times \mathcal{O})}\,dz.$$

Since $\tilde{\Gamma}_p$ is a closed curve in $\mathbb{C}$ containing $\overline{\Lambda}$, $\Lambda =]\theta_-, \theta_+[$, there exists $r > 0$ such that

$$(z - p\,\theta^\varepsilon(y)) \geq r > 0 \quad \text{for all } z \in \tilde{\Gamma}_p \quad \text{and for almost every } y \in \mathcal{O}.$$

Using the Cauchy–Schwarz inequality, one gets

$$|m^\varepsilon(z)| \leq \frac{C}{r}|\psi|_{L^2(\Omega)}\,|(H_p^\varepsilon + z)^{-1}(F^\varepsilon)|_{L^2(\Omega)}.$$

From the dominated convergence theorem, it follows that, for all $\psi \in L^2(\Omega)$,

$$\int_{\Gamma_p} m^\varepsilon(z)\,dz \to \int_{\Gamma_p} m(z)\,dz.$$

This convergence means that the sequence $(\int_{\Gamma_p}(z - p\,\theta^\varepsilon(\cdot))^{-1}\,(H_p^\varepsilon + z)^{-1}\,dz\,(F^\varepsilon))$ converges weakly in $L^2(\Omega)$ to

$$\int_{\Gamma_p}\left(z - p\bar{\theta}(\cdot) - \int_\Lambda d\sigma_\bullet(\lambda)\,(z - p\,\lambda)^{-1}\right)^{-1}\,(H_p + z)^{-1}(F)\,dz.$$

We finally use Dunford–Taylor's integral to deduce the following weak convergence in $L^2(\Omega)$:

$$\text{(4.28)}\quad (H_p^\varepsilon + p\,\theta^\varepsilon(\cdot))^{-1}(F^\varepsilon) \rightharpoonup \left(H_p + p\bar{\theta}(\cdot) - p^2\int_\Lambda (H_p + \lambda p)^{-1}\,d\sigma_\bullet(\lambda)\right)^{-1}(F).$$

Consider now the sequence $((H_p^\varepsilon + p\,\theta^\varepsilon(y))^{-1}(\theta^\varepsilon(y)\,\alpha))$. Using (3.36) and Lemma 2.5, one proves that, for a subsequence,

$$\text{(4.29)}\qquad (H_p^\varepsilon + p\,\theta^\varepsilon(\cdot))^{-1}(\theta^\varepsilon(\cdot)\,\alpha) \rightharpoonup \frac{-1}{2\,\imath\,\pi}\int_{\Gamma_p}\frac{1}{p}G(p,z,\cdot)\,(H_p + z)^{-1}(\alpha)\,dz$$

in $L^2(\Omega)$ weak, where

$$G(p,z,y) = -1 + z\left[z - p\bar{\theta}(y) - p^2\int_\Lambda (z - p\,\lambda)^{-1}\,d\sigma_y(\lambda)\right]^{-1}.$$

This can be written also as

$$\frac{1}{p}G(p,z,y) = \left(z - p\bar{\theta}(y) - p^2\int_\Lambda (z - p\lambda)^{-1}d\sigma_y(\lambda)\right)^{-1}\left(\bar{\theta}(y) + p\int_\Lambda (z - p\lambda)^{-1}\,d\sigma_y(\lambda)\right).$$

By using the Dunford–Taylor integral formula, one gets

$$(H^\varepsilon_p + p\theta^\varepsilon(\cdot))^{-1}(\theta^\varepsilon(\cdot)\,\alpha) \rightharpoonup -\frac{1}{p}G(p,-H_p,\cdot)(\alpha) \quad \text{in } L^2(\Omega) \text{ weak},$$

and

$$-\frac{1}{p}\,G(p,-H_p,y) = \left(H_p + p\overline{\theta}(y) - p^2\int_\Lambda (H_p+p\lambda)^{-1}\,d\sigma_y(\lambda)\right)^{-1}(h(p,H_p,y)), \tag{4.30}$$

where $h(p,H_p,y) = \overline{\theta}(y) - p\int_\Lambda (H_p+\lambda p)^{-1}\,d\sigma_y(\lambda)$. From (4.28)–(4.30) we deduce the following result.

THEOREM 4.4. *Let u^ε be the solution of* (4.18), *under assumptions* (4.19)–(4.22). *Then, along a subsequence, there exists a parametrized family of nonnegative measures $d\sigma_y$, with support in $\overline{\Lambda}$, such that the sequence (u^ε) converges, as $\varepsilon \to 0$, weakly* in the space $L^\infty(0,T;L^2(\mathcal{O};H^1_0(\Omega_x)))$ and in $H^1(0,T;L^2(\mathcal{O};H^1_0(\Omega_x)))$ weak to u solution, in the sense of distributions, of the following system:*

$$\begin{aligned}
&\overline{\rho}(x)\,\partial_t^2 u - \operatorname{div}_x(\overline{k}(x)\operatorname{grad}_x u) + \overline{\theta}(y)\partial_t u - \int_\Lambda d\sigma_y(\lambda)\partial_t w(\lambda) = 0,\\
&\overline{\rho}(x)\partial_t^2 w - \operatorname{div}_x(\overline{k}(x)\operatorname{grad}_x w) + \lambda\partial_t w - \partial_t u = 0,\\
&u\,|_{\partial\Omega_x\times\mathcal{O}} = 0, \qquad w\,|_{\partial\Omega_x\times\mathcal{O}\times\Lambda} = 0,\\
&u\,|_{t=0} = \alpha, \quad w\,|_{t=0} = 0, \quad \partial_t u\,|_{t=0} = \beta, \quad \partial_t w\,|_{t=0} = 0,
\end{aligned} \tag{4.31}$$

where $t \in]0,T[$, $x \in \Omega_x$, $y \in \mathcal{O}$, $\lambda \in \Lambda$.

REGIONAL BLOW UP IN A SEMILINEAR HEAT EQUATION WITH CONVERGENCE TO A HAMILTON–JACOBI EQUATION*

VICTOR A. GALAKTIONOV[†] AND JUAN L. VAZQUEZ[‡]

Abstract. The authors investigate the asymptotic behaviour of blowing-up solutions $u = u(x,t) \geqq 0$ to the semilinear parabolic equation with source

$$u_t = u_{xx} + (1+u)\log^2(1+u) \quad \text{for } x \in \mathbf{R},\ t > 0,$$

with nonnegative and radial symmetric initial data $u_0(|x|)$ that are nonincreasing in $|x|$. Any nontrivial solution u to this problem blows up in a finite time $T > 0$. It is remarkable that the blow-up behaviour of u as t approaches T can be described by the exact blow-up solutions of the quasilinear Hamilton–Jacobi equation

$$U_t = \frac{(U_x)^2}{1+U} + (1+U)\log^2(1+U),$$

with the same blow-up time T. These explicit profiles are only approximate solutions for the problem. The authors prove that the blow-up set B of the solution satisfies meas $(B) \geqq 2\pi$, and under some additional hypothesis on the initial function it is shown that B is just the interval $[-\pi, \pi]$ and the rescaled blow-up shape consists of one hump with formula $\cos^2(x/2)$. The proofs rely on the knowledge of a family of explicit solutions, the method of intersection comparison, some dynamical systems ideas, and a stability analysis for solutions of the Hamilton–Jacobi equation.

Key words. semilinear heat equation, regional blow up, asymptotic behaviour, Hamilton–Jacobi equation

1. Introduction.

In this paper we consider the Cauchy problem for the semilinear heat equation

$$u_t = u_{xx} + (\ 1+u)\log^2(1+u) \quad \text{for } x \in \mathbf{R},\ t > 0, \tag{1.1}$$

$$u(x,0) = u_0(x) \quad \text{for } x \in \mathbf{R}. \tag{1.2}$$

We assume that the initial function $u_0 \in L^1_{\text{loc}}(\mathbf{R}) \cap L^\infty(\mathbf{R})$ is radially symmetric, $u_0 = u_0(|x|)$, nonnegative, $u_0 \geqq 0$, and nonconstant. Our main results also assume that u_0 is nonincreasing as a function of $|x| > 0$. The final section deals with periodic solutions.

Problem (1.1)–(1.2) has a unique classical solution $u = u(|x|,t) > 0$ defined in some maximal time interval [Fr1]. Since the heat source $Q(u) = (1+u)\log^2(1+u)$ in the right-hand side of (1.1) satisfies $Q(u) > 0$ for $u > 0$, $Q(u) = u^2 + o(u^2)$ as $u \to 0$ and $\int_1^\infty dz/Q(z) < \infty$, the solution blows up in a finite time T, $0 < T < \infty$ (cf. [Fu]): $u(x,t)$ is a classical solution of (1.1) in $\mathbf{R} \times (0,T)$ and

$$\sup_{x \in \mathbf{R}} u(x,t) \to \infty \quad \text{as } t \to T. \tag{1.3}$$

Much work has been devoted in recent years to understanding finite-time blow up for equations of the form $u_t = u_{xx} + Q(u)$. Four major problems arise in this context and have been studied by different authors; see the books [BE] and [SGKM] for extensive

references. They are: (i) existence of blow up in terms of the initial data, (ii) the form of the *blow-up set*

$$B = B(u_0) \equiv \{x \in \mathbf{R} : \exists x_n \to x \text{ and } t_n \to T \text{ such that } u(x_n, t_n) \to \infty \text{ as } n \to \infty\}, \tag{1.4}$$

(iii) the rate of divergence of $u(x,t)$ as $t \to T$ for points $x \in B$, and (iv) the shape of the solution at $t = T$, after scaling out this rate. The aim of the paper is to answer these questions for the solutions of (1.1) for different choices of initial data.

The simplest form of blow up is *global flat blow up*, i.e., the solution blows up in the whole space with no spatial structure. This blow-up form can always be obtained by starting with a constant initial function, and the precise profile $u = u(t)$ is obtained by integrating the ordinary differential equation (ODE): $u_t = Q(u)$. It is remarkable that precisely the opposite situation occurs for many blow-up equations for suitably concentrated initial data, say when u_0 is bell-shaped with one maximum and compact support: then blow up occurs at an isolated point, *single-point blow up*. Other solutions many blow up at a finite number of points. This happens, for instance, in the most studied cases $Q(u) = u^p$ with $p > 1$ and $Q(u) = \exp(u)$. See, for instance, [FM], [CM], [V].

Since no blow up occurs for $Q(u) = u^p$ with $p = 1$, it is interesting to understand the limit situation $p \approx 1$. In this direction the family of equations

$$u_t = u_{xx} + (1+u)\log^{\beta}(1+u), \qquad \beta > 0 \tag{1.5}$$

was introduced in [GKMS] in 1979 (see also [Sam], generalizations in [G1], and the references of [SGKM, Chap. IV]). The case $\beta = 2$ has a particular interest since it serves as a limit case for the blow-up behaviour as we explain below.

Indeed, qualitative and numerical methods described in the above references had suggested that for suitably concentrated initial data blow up occurs in problem (1.1), (1.2) in a bounded domain, i.e., we have the so-called *regional blow up*. Moreover, these studies pointed out that the behaviour of the solution to (1.1), (1.2) as it approaches blow up should be described by some solution of the quasilinear Hamilton–Jacobi equation

$$U_t = \frac{(U_x)^2}{1+U} + (1+U)\log^2(1+U) \quad \text{for } x \in \mathbf{R},\ t \in (0,T), \tag{1.6}$$

of the form

$$U(x,t) = \exp\left\{(T-t)^{-1}\,\overline{g}(x)\right\} - 1. \tag{1.7}$$

By substituting (1.7) into (1.6) one can obtain that the function $\overline{g} \geqq 0$ solves the first-order quadratic ordinary differential equation

$$(\overline{g}_x)^2 + \overline{g}^2 - \overline{g} = 0 \quad \text{in } \mathbf{R}. \tag{1.8}$$

In this paper we give a rigorous proof of these facts for the class of solutions that are radially symmetric in the space variable x and nonincreasing in $|x| > 0$. Let us briefly describe the main ideas and results: in studying the blow-up behaviour of (1.1) it is convenient to introduce the transformation

$$u(x,t) = e^{v(x,t)} - 1, \tag{1.9}$$

which yields the following equation for the function $v(x,t)$:

$$(1.10) \qquad v_t = v_{xx} + (v_x)^2 + v^2 \quad \text{for } x \in \mathbf{R},\ t > 0.$$

In view of the expected behaviour (1.7), we also introduce the rescaled function

$$(1.11) \qquad \theta(x,\tau) = (T-t)v(x,t),$$

where $\tau = -\log(T-t)$ (so that, in particular, the new time $\tau \to \infty$ as $t \to T$). The function $\theta(x,\tau)$ solves the Cauchy problem

$$(1.12) \qquad \theta_\tau = e^{-\tau}\theta_{xx} + (\theta_x)^2 + \theta^2 - \theta \quad \text{for } x \in \mathbf{R},\ \tau > \tau_0 = -\log T,$$

$$(1.13) \qquad \theta(x,\tau_0) = \theta_0(x) \equiv T\log(1+u_0(x)) \quad \text{for } x \in \mathbf{R}.$$

After describing in §2 a family of 2π-periodic blow-up solutions constructed in [GP3], which satisfy (1.10) but blow up in the whole space and are essential in later comparison arguments, we proceed in §§3–8 to study solutions with radially symmetric and nonincreasing initial data. Thus, in §3 we establish a sharp estimate for the supremum of θ as $\tau \to \infty$: $\sup\theta(\cdot,\tau) \to 1$ (Proposition 3.1 and 3.2). Section 4 is devoted to proving a semiconvexity result, of the form $\theta_{xx} \geqq -C$ for τ large (Proposition 4.1), which together with the previous estimate implies that single point blow up cannot occur.

Regional blow up means that $u(x,t) \to \infty$ as $t \to T$ in a set of nonzero finite measure. We have already introduced the blow-up set, where u diverges. A more precise divergence is obtained on a possible smaller set,

$$(1.14) \qquad \begin{aligned} B_* = B_*(u_0) \equiv \{x \in \mathbf{R} : \exists t_n \to T \text{ such that} \\ u(x,t_n) \to \infty \text{ as } n \to \infty\}. \end{aligned}$$

Obviously, $B_* \subseteq B$. By the monotonicity results of [GP1] and [GP4], B_* can also be defined as follows:

$$(1.15) \qquad B_* \equiv \{x \in \mathbf{R} : u(x,t) \to \infty \text{ as } t \to T\}.$$

B_* is called the *monotone blow-up set*; see [G3]. We establish in §5 that the minimal configuration for blow up corresponds to the particular profile

$$(1.16) \qquad G(x) = \begin{cases} \cos^2\left(\dfrac{x}{2}\right) & \text{if } |x| \leqq \pi, \\ 0 & \text{otherwise.} \end{cases}$$

This implies that the blow-up set consists of an interval of length at least 2π. Moreover, $B_* \supseteq (-\pi,\pi)$. Conversely, we obtain in §6 localization of the blow-up set in terms of the number of intersections of u_0 with respect to the explicit solutions of §2 (Theorem 6.1).

In order to better understand the blow-up phenomenon we have to study the stabilization of the function $\theta(x,\tau)$ as $\tau \to \infty$ to a solution $\bar{g}(x)$ of the stationary equation (1.8). This is done in §§7 and 8 where we prove that under a strict condition (which is satisfied, for instance, by suitably bell-shaped initial functions with support in $(-\pi,\pi)$; see condition (7.26)) the blow-up set is exactly $[-\pi,\pi]$ and θ converges as $\tau \to \infty$ to the function G. In these proofs we consider (1.12) as a perturbation of the Hamilton–Jacobi equations

$$(1.17) \qquad g_\tau = (g_x)^2 + g^2 - g \quad \text{in } \mathbf{R} \times (0,\infty),$$

and apply the asymptotic results for small perturbations of autonomous dynamical systems of [GV] and some stability analysis of the viscosity solutions of (1.17). In fact, we will need an improvement of the result of [GV] which simplifies its application.

Many solutions have nonminimal blow up. Solutions with more than one hump can have a nonconnected blow-up set. As an example we consider in §9 x-periodic solutions with period $2m\pi$, m as integer, since we can use the techniques developed in the radially symmetric case. We construct solutions whose blow up consists of the union of intervals of the form $[(2km-1)\pi,\ (2km+1)\pi]$, $k \in \mathbf{Z}$, with a corresponding union of copies of $G(x)$ as an asymptotic profile. We have refrained in this paper from using more general situations for the sake of brevity. We hope to treat some of them, in particular examples of two-hump blow up, in a forthcoming article.

As a final comment on related equations, let us mention that the exponent $\beta = 2$ of our equation is critical for the blow-up behaviour of (1.5). Thus, the Cauchy–Dirichlet Problem has been studied in [GP2] for $\beta > 2$, and *single-point blow up* is shown to occur using the method of [FM], while [L] shows *global blow up* for $1 < \beta < 2$ for the same problem. This leaves $\beta = 2$ as the only case with *regional blow up*. On the other hand, it is interesting to remark that in the case $\beta \in (0,1)$ studied in [GKS1], though solutions are global in time, the asymptotic profiles as $t \to \infty$ are given as the solutions of the Hamilton–Jacobi equations, $U_t = (U_x)^2/(1+U) + (1+U)\log^{\beta}(1+U)$, which parallels (1.6).

Let us also recall that regional blow up has been observed for several models of quasilinear heat equation, like

$$u_t = (u^m)_{xx} + u^p \tag{1.18}$$

for $m > 1$ and $p = m$; see [SGKM, Chap. IV] and [G3]. The present model seems to be the only known case of a *semilinear* heat equation with regional blow up.

2. Explicit solutions. Equation (1.10) admits an explicit solution, 2π-periodic in x, of the form (cf. [GP3], [G2])

$$v_*(x,t) = \varphi(t)[\psi(t) + \cos(x)], \tag{2.1}$$

where the functions $\varphi(t)$ and $\psi(t)$ satisfy the system of ordinary differential equations

$$\varphi' = -\varphi + 2\varphi^2\psi, \quad \psi' = \varphi + \psi - \varphi\psi^2 \quad \text{for } t > 0. \tag{2.2}$$

There exists a one-parameter family of nonnegative blowing-up solutions (2.1) having a given fixed blow-up time $T \in (0,\infty)$. To see this we observe that system (2.2) is equivalent to the following first-order differential equation

$$\frac{d\psi}{d\varphi} = \frac{\varphi + \psi - \varphi\psi^2}{2\varphi^2\psi - \varphi}, \quad \varphi > 0,\ \psi \geqq 1. \tag{2.3}$$

Equation (2.3) admits a one-parameter family of trajectories with the asymptotic behaviour (see [G2])

$$\psi = 1 + \frac{\log\varphi}{2\varphi} + \frac{\mu}{\varphi} + o\left(\frac{1}{\varphi}\right) \quad \text{as } \varphi \to \infty, \tag{2.4}$$

where $\mu \in \mathbf{R}$ is a parameter describing this family. Given a certain μ, namely, on a given trajectory, fixing the blow-up time $T > 0$ is equivalent to fixing an initial point (φ_0, ψ_0)

on the trajectory, corresponding to $t = 0$. It follows from the detailed study of the system (2.2) that for fixed $T > 0$ there exists a constant μ_T such that for any $\mu \geqq \mu_T$ the explicit solution $v_* = v_*(x, t;\, T, \mu)$ with blow-up time T is well defined and nonnegative in $\mathbf{R} \times (0, T)$, while for $\mu < \mu_T$ the initial value of v_* has changing sign. In terms of the functions $\varphi(t), \psi(t)$ the constant μ_T is such that $\psi_0 = 1$ and $\varphi_0 > 0$. This implies that the corresponding initial function has the form

$$v_*(x, 0;\, T, \mu_T) \equiv \varphi_0[1 + \cos(x)] \geqq 0 \quad \text{in } \mathbf{R}. \tag{2.5}$$

Clearly, for $\mu > \mu_T$ we have $\psi_0 > 1$; hence

$$v_*(x, 0) \equiv \varphi_0[\psi_0 + \cos x] \tag{2.6}$$

is positive in $\mathbf{R}$. In any case $v_*(x, t;\, T, \mu) > 0$ in $\mathbf{R} \times (0, T)$ for $\mu \geqq \mu_T$. Integrating the first equation of (2.2) with the help of expansion (2.4) for $\mu \geqq \mu_T$ we obtain the following asymptotic behaviour of the explicit solutions near a fixed blow-up time $t = T$:

$$\begin{aligned} \varphi(t) &= \tfrac{1}{2}(T-t)^{-1}[1 - \tfrac{1}{2}(T-t)|\log(T-t)|(1+o(1))], \\ \psi(t) &= 1 + (T-t)|\log(T-t)|(1+o(1)) \quad \text{as } t \to T. \end{aligned}$$

Therefore, as $t \to T$,

$$\begin{aligned} v_*(x, t;\, T, \mu) = (T-t)^{-1}\Bigg[&\cos^2\left(\frac{x}{2}\right) + \frac{1}{2}\sin^2\left(\frac{x}{2}\right)(T-t)|\log(T-t)| \\ &+ \left(\frac{1}{4} - \frac{1 + 2\log 2 - 4\mu}{4}\sin^2\left(\frac{x}{2}\right)\right)(T-t)(1+o(1))\Bigg]. \end{aligned} \tag{2.7}$$

At the maxima $x = 2\pi k, k = 0, \pm 1, \ldots$, where $\cos^2(x/2) = 1$, we have as $t \to T$

$$\begin{aligned} \sup_{x \in \mathbf{R}} v_*(x, t;\, T, \mu) &\equiv v_*(2\pi k, t;\, T, \mu) \\ &= (T-t)^{-1}[1 + \tfrac{1}{4}(T-t)(1+o(1))]. \end{aligned} \tag{2.8}$$

At the minima $x = \pi + 2\pi k, k = 0, \pm 1, \ldots$, where $\cos^2(x/2) = 0$, the behaviour as $t \to T$ is quite different:

$$\inf_{x \in \mathbf{R}} v_*(x, t;\, T, \mu) \equiv v_*(\pi(2k+1), t;\, T, \mu)\tfrac{1}{2}|\log(T-t)|(1+o(1)). \tag{2.9}$$

For the rescaled explicit solution

$$\theta_*(x, \tau;\, T, \mu) \equiv (T-t)v_*(x, t;\, T, \mu), \quad \tau = -\log(T-t), \tag{2.10}$$

we have as $\tau \to \infty$

$$\theta_*(x, \tau;\, T, \mu) \equiv \cos^2\left(\frac{x}{2}\right) + \frac{1}{2}\sin^2\left(\frac{x}{2}\right)\tau e^{-\tau} + O(e^{-\tau}), \tag{2.11}$$

$$\theta_*(0, \tau;\, T, \mu) \equiv 1 + \tfrac{1}{4}e^{-\tau}(1+o(1)) \to 1, \tag{2.12}$$

$$\theta_*(\pm\pi, \tau;\, T, \mu) \equiv \tfrac{1}{2}\tau e^{-\tau}(1+o(1)) \to 0. \tag{2.13}$$

Notice that $\theta_*(x, \tau;\, T, \mu)$ converges to $G(x)$ as $\tau \to \infty$ for $|x| \leqq \pi$; cf. [G2].

3. Lower and upper bounds. As a first step in controlling the blow-up behaviour of the solution, we derive in this section upper and lower bounds for the supremum in x of the rescaled solution θ defined by (1.11). We begin with the lower bound.

PROPOSITION 3.1. *For every $\tau > \tau_0$ there holds*

$$\sup_{x\in\mathbf{R}} \theta(x,\tau) \equiv \theta(0,\tau) > 1. \tag{3.1}$$

Proof. Equation (1.10) admits a blowing-up solution of the form

$$\overline{v}(t) = (T-t)^{-1}, \tag{3.2}$$

with the same blow-up time, T, as u. Then for any $t \in [0,T)$, $\overline{v}(t)$ intersects in x the solution $v(x,t)$. Indeed, if for some $t = t_0 \in [0,T)$ we have $\overline{v}(t_0) \geqq v(x,t_0)$ in $\mathbf{R}$, then by using the Strong Maximum Principle [Fr1] we arrive at the conclusion that $\overline{v}$ must blow up before v does. This is in contradiction with our assumption. Hence,

$$\sup_{x\in\mathbf{R}} v(x,t) > \overline{v}(t) \quad \text{for } t \in [0,T), \tag{3.3}$$

thus completing the proof. □

Notice that we do not use any special assumptions on u_0 in proving the result. The proof is based on intersection comparison with a solution which is constant as a function of x, and so (3.3) remains valid in much more general situations, e.g., for any arbitrary nonnegative initial function satisfying $u_0 \to 0$ as $|x| \to \infty$. Then $u(x,t) \to 0$ as $|x| \to \infty$ for any fixed $t \in (0,T)$, and (3.3) yields the lower estimate $\sup_{x\in\mathbf{R}} \theta(x,\tau) > 1$ for $\tau \in [\tau_0, \infty]$.

We proceed now with the upper bound. This estimate is much more difficult to obtain.

PROPOSITION 3.2. *Let u_0 be radially symmetric and nonincreasing as a function of $|x|$. A $\tau \to \infty$ there holds*

$$\sup_{x\in\mathbf{R}} \theta(x,\tau) \equiv \theta(0,\tau) < 1 + 2\tau e^{-\tau}. \tag{3.4}$$

Proof. It consists of several steps. We shall use some ideas of the method of stationary states (cf. [SGKM, Chap. 7] and also [GKS2]).

Step 1. *Stationary solutions.* We begin with some simple properties of the stationary solutions of (1.1). Thus, we look at solutions $U(x;\ \lambda)$ of

$$U_{xx} + (1+U)\log^2(1+U) = 0 \quad \text{for } x > 0 \quad \text{and} \quad x < 0, \tag{3.5}$$

$$U_x(0;\ \lambda) = 0, \qquad U(0;\ \lambda) = \lambda, \tag{3.6}$$

where $\lambda > 0$ is an arbitrary constant. We easily show that a positive solution of (3.5), (3.6) exists in a finite interval $\{|x| < x_0(\lambda)\}$, where the endpoint $x_0(\lambda) > 0$ is the point x at which $U(\pm x;\ \lambda)$ reaches the zero value. We let $U(x;\ \lambda) \equiv 0$ for $|x| \geqq x_0(\lambda)$. Since $U(x,\lambda)$ is monotone for $x > 0$ and $x < 0$, we have the inequality

$$U_{xx} \geqq -(1+U)\log^2(1+U) \geqq -(1+\lambda)\log^2(1+\lambda). \tag{3.7}$$

By integrating twice we obtain the lower bound

$$U(x;\ \lambda) \geqq U_-(x;\ \lambda) \equiv (\lambda - \tfrac{1}{2}(1+\lambda)\log^2(1+\lambda)x^2)_+, \tag{3.8}$$

and, in particular,

$$x_0(\lambda) \geqq x_*(\lambda) \equiv \left(\frac{2\lambda}{(1+\lambda)\log^2(1+\lambda)}\right)^{1/2}. \tag{3.9}$$

Multiplying (3.5) by U_x and integrating over $(0,x), 0 \leqq x < x_0(\lambda)$, yields the identity

$$\begin{aligned}(U_x)^2 = {} & \tfrac{1}{2}(1+\lambda)^2[\log^2(1+\lambda) - \log(1+\lambda) + \tfrac{1}{2}] \\ & -\tfrac{1}{2}(1+U)^2[\log^2(1+U) - \log(1+U) + \tfrac{1}{2}].\end{aligned} \tag{3.10}$$

By integrating (3.10) we obtain that

$$x_0(\lambda) \to 0 \quad \text{as } \lambda \to \infty. \tag{3.11}$$

It also follows from (3.10) that for every fixed $m > 0$ and $x' = x'(\lambda, m) > 0$ on the level set $\{x \in \mathbf{R} : U(x;\ \lambda) = m\}$; then

$$U_x(x';\ \lambda) \to \infty \quad \text{as } \lambda \to \infty. \tag{3.12}$$

Step 2. *Intersection comparison.* The result given below is true for a wide class of quasilinear heat equations with source; see [SGKM, Chaps. 6, 7] and [GKS2].

LEMMA 3.3. *There exists $\lambda_* > 0$ large enough such that for any $\lambda > \lambda_*$,*

$$u(x,t) \geqq U(x;\ \lambda) \quad \textit{in } \mathbf{R} \quad \textit{if } u(0,t) \geqq \lambda. \tag{3.13}$$

Proof. For a fixed $t \in [0,T)$ denote by $N(t;\ \lambda)$ the number of intersections in $\{|x| \leqq x_0(\lambda)\}$ of solutions $u(x,t)$ and $U(x;\ \lambda)$, or, in other words, the number of sign changes in $\{|x| \leqq x_0(\lambda)\}$ of the difference $w(x,t;\ \lambda) \equiv u(x,t) - U(x;\ \lambda)$.

By a standard smoothness result for semilinear heat equations we may conclude that $u(x,t)$ is smooth enough for arbitrarily small $t > 0$. It then follows from (3.11) and (3.12) that for every $\lambda > \lambda_*$ large enough there exist exactly two intersections for $t = t_1$ small enough, i. e.,

$$N(t_1;\ \lambda) = 2 \quad \text{for } \lambda > \lambda_*. \tag{3.14}$$

Since $U(\pm x_0(\lambda);\ \lambda) \equiv 0$ and $u(x,t) > 0$ in $\mathbf{R} \times (0,T)$, by a well-known intersection property we conclude that $N(t;\ \lambda)$ does not increase with time (cf. [A], [GP1], [M], [Sat]). Hence by (3.14) we deduce that

$$N(t;\ \lambda) \leqq 2 \quad \text{for } t \in (t_1, T), \lambda > \lambda_*. \tag{3.15}$$

We now prove that if $t_\lambda \in (t_1, T)$ is such that $u(0, t_\lambda) = \lambda$, then

$$N(t_\lambda;\ \lambda) = 0. \tag{3.16}$$

If on the contrary, $N(t_\lambda;\ \lambda) > 0$ (more exactly, $N(t_\lambda;\ \lambda) \geqq 2$ by symmetry), then one can see that for any small $\delta > 0$ the inequality $N(t_\lambda;\ \lambda - \delta) \geqq 4$ holds, contradicting (3.15).

Thus (3.16) implies that $u(x, t_\lambda) \geqq U(x;\ \lambda)$ in $\mathbf{R}$, and hence (3.13) holds by comparison. □

As a consequence of Lemma 3.3 we obtain a control of the L^1-norm near the blow-up time.

LEMMA 3.4. *As $t \to T$ the integral $\|u(\cdot, t)\|_{L^1(\mathbf{R})}$ diverges. More precisely, we have*

$$\tag{3.17} \begin{aligned} &\|u(\cdot, t)\|_{L^1(\mathbf{R})} \geqq \|U(\cdot; u(0,t))\|_{L^1(\mathbf{R})} \geqq \|U_-(\cdot; u(0,t))\|_{L^1(\mathbf{R})} \\ &\quad = \frac{2}{3}\lambda x_*(\lambda)|_{\lambda=u(0,t)} = \frac{2^{2/3}}{3}\frac{u(0,t)}{\log u(0,t)}(1+o(1)) \to \infty. \end{aligned}$$

Though relation (3.17) is not exact in view of the precise asymptotic results that follow, it gives a correct idea of the relative growth of the L^1 and sup-norms.

Step 3. *Ordinary differential inequality for an energy function.* We now introduce the local weighted energy

$$\tag{3.18} E(t) = \int_{-\pi/2}^{\pi/2} \phi(x)u(x,t)\,dx,$$

where

$$\tag{3.19} \phi(x) = \frac{1}{2}\cos(x) > 0 \quad \text{in } \left(-\frac{\pi}{2}, \frac{\pi}{2}\right),$$

so that $\phi'' \equiv -\phi$ and

$$\tag{3.20} \int_{-\pi/2}^{\pi/2} \phi(x)\,dx = 1.$$

An energy estimate is obtained as follows. We multiply (1.1) by $\phi(x)$ and integrate over $(-\pi/2, \pi/2)$ to obtain

$$\tag{3.21} \frac{dE}{dt} \geqq -E + \int_{-\pi/2}^{\pi/2} \phi(x)(1+u)\log^2(1+u)\,dx,$$

valid for $t \in (0,T)$. Now using Jensen's inequality for the convex function $(1+u)\log^2(1+u)$ and (3.20) we have

$$\tag{3.22} \frac{dE}{dt} \geqq -E + (1+E)\log^2(1+E).$$

(Inequalities of the type (3.22) have been used by many authors for proving global (in time) nonexistence of solutions; see, e.g., the first such result in [K] and references in [SGKM].)

By integrating (3.22) over (t,T) and using the fact that $E(T) = \infty$ (see (3.17)) we arrive at the estimate

$$\tag{3.23} T - t \leqq \int_{E(t)}^{\infty} \frac{dz}{(1+z)\log^2(1+z) - z} \quad \text{as } t \to T.$$

Now using the fact that

$$\int_p^{\infty} \frac{dz}{(1+z)\log^2(1+z) - z} = \frac{1}{\log p}\left[1 + \frac{1}{3}\frac{1}{\log^2 p}(1+o(1))\right]$$

as $p \to \infty$, we obtain the following estimate for E.

LEMMA 3.5. *As $t \to T$ we have*

$$T - t \leqq \frac{1}{\log E(t)} \left[1 + \frac{1}{3} \frac{1}{\log^2 E(t)} (1 + o(1)) \right]. \tag{3.24}$$

Step 4. *End of Proof of Proposition* 3.2. By using (3.13), (3.8), and (3.9) we conclude that as $t \to T$,

$$\begin{aligned} E(t) &\geqq \int_{-\pi/2}^{\pi/2} \phi(x) U(x;\, u(0,t))\, dx \geqq \int_{-x_*(\lambda)}^{x_*(\lambda)} \phi(x) U_-(x;\, u(0,t))\, dx \\ &\geqq \frac{1}{2} \phi(0) \| U_-(\cdot;\, u(0,t)) \|_{L^1(\mathbf{R})}. \end{aligned}$$

It then follows from (3.17) that as $t \to T$,

$$E(t) \geqq \frac{1}{4} \frac{2^{2/3}}{3} \frac{u(0,t)}{\log u(0,t)} (1 + o(1)). \tag{3.25}$$

Together (3.24) and (3.25) yield the following inequality

$$T - t \leqq \frac{1}{\log u(0,t)} \left[1 + \frac{\log \log u(0,t)}{\log u(0,t)} (1 + o(1)) \right] \tag{3.26}$$

as $u(0,t) \to \infty$. This inequality can be transformed into

$$\log u(0,t) \leqq (T-t)^{-1} [1 + (T-t) |\log(T-t)| (1 + o(1))] \tag{3.27}$$

as $t \to T$. The last estimate yields (3.4). □

4. Semiconvexity. In the next five sections u_0 is radially symmetric and nonincreasing in $|x|$. We may also assume that u_0 is not constant. The analysis of the asymptotic behaviour is best done in terms of the variable θ introduced in (1.11). As is usual in Dynamical Systems we introduce the ω-limit set of the solution $\theta(x, \tau)$ as follows:

$$\begin{aligned} \omega(\theta_0) = \{ f \in C(\mathbf{R}) : \exists_{\tau_j \to \infty} \text{ such that } \theta(\cdot, \tau_j) \to f(\cdot) \\ \text{as } j \to \infty \text{ uniformly in any compact subset of } \mathbf{R} \}. \end{aligned} \tag{4.1}$$

A key estimate in controlling the ω-limit and in preventing single-point blow up is the following.

PROPOSITION 4.1. *For any $\varepsilon > 0$ there exists a constant $a_\varepsilon > 0$ such that*

$$\theta_{xx}(x, \tau) \geqq - \left(\frac{1}{2} + \varepsilon \right) - \frac{a_\varepsilon}{(\tau - \tau_1)} \tag{4.2}$$

in $\mathbf{R} \times (\tau_1, \infty)$, where $\tau_1 = \tau_0 + 1$.

Proof. The function $z = \theta_{xx}$ solves a semilinear parabolic equation in $\mathbf{R} \times (\tau_0, \infty)$:

$$z_\tau = e^{-\tau} z_{xx} + 2\theta_x z_x + 2z^2 + (2\theta - 1) z + 2(\theta_x)^2. \tag{4.3}$$

By Proposition 3.2 there exists a constant $\tau_\varepsilon > \tau_1$ such that

$$\| \theta(\cdot, \tau) \|_\infty \leqq 1 + \varepsilon \quad \text{for } \tau > \tau_\varepsilon. \tag{4.4}$$

Then it is easily seen that the function

$$\mathbf{z}(\tau) = -\left(\frac{1}{2} + \varepsilon + \frac{a_\varepsilon}{(\tau - \tau_1)}\right) < 0 \tag{4.5}$$

will be a subsolution of (4.3) in $\mathbf{R} \times (\tau_1, \infty)$, namely,

$$\mathbf{z}' \leqq 2\mathbf{z}^2 + (2\theta - 1)\mathbf{z} \quad \text{for } \tau > \tau_1 \tag{4.6}$$

if

$$\frac{a_\varepsilon(2a_\varepsilon - 1)}{(\tau - \tau_1)^2} - 2\mathbf{z}(1 + \varepsilon - \|\theta(\cdot, \tau)\|_\infty) + (1 + 2\varepsilon)\frac{a_\varepsilon}{\tau - \tau_1} \geqq 0 \tag{4.7}$$

for $\tau > \tau_1$. By using (4.4) we have that (4.7) holds for $\tau > \tau_\varepsilon$, and (4.7) will be also valid for $\tau_1 < \tau \leqq \tau_\varepsilon$ if $a_\varepsilon > 0$ is large enough. □

As a straightforward consequence of Proposition 3.2 and Lemma 4.1 we obtain a control on the derivative θ_x.

COROLLARY 4.2. *There exists a constant $C > 0$ such that*

$$|\theta_x(x, \tau)| \leqq C \quad \textit{in } \mathbf{R} \times (\tau_1, \infty). \tag{4.8}$$

5. Lower bound for the blow-up set and the asymptotic profile. We begin here the analysis of the asymptotic profile of the solution as $t \to T$. This analysis starts with a simple consequence of our semiconvexity result, Proposition 4.1.

LEMMA 5.1. *If $f \in \omega(\theta_0)$, then*

$$f_{xx} \geq -\tfrac{1}{2} \textit{ a.e. in } \mathbf{R}, \tag{5.1}$$

and, in particular,

$$f(x) \geqq \left(1 - \frac{x^2}{4}\right)_+ \quad \textit{a.e. in } \mathbf{R}. \tag{5.2}$$

Notice that, since (5.1) is true for every $f \in \omega(\theta_0)$, then necessarily

$$v(x,t) \geqq (T-t)^{-1}\left[\left(1 - \frac{x^2}{4}\right)_+ + o(1)\right]$$

in $\mathbf{R}$ as $t \to T$. This implies a first lower estimate of the blow-up set:

$$[-2, 2] \subset B, \quad \text{hence meas}(B) \geqq 4. \tag{5.3}$$

Although, according to the Introduction, these estimates will not be optimal in predicting the asymptotic shape, it is interesting to note that exactly (5.3) has been proved in [L] for the initial-boundary value problem by a completely different approach.

A sharp lower estimate is as follows.

THEOREM 5.2. *If $f \in \omega(\theta_0)$, then*

$$f(x) \geqq \cos^2\left(\frac{x}{2}\right) \quad \textit{for } |x| \leqq \pi, \tag{5.4}$$

so that

$$v(x,t) \geqq (T-t)^{-1}\left(\cos^2\left(\frac{x}{2}\right)+o(1)\right) \quad in\ \{|x| \leqq \pi\}. \tag{5.5}$$

It follows that $(-\pi,\pi) \subseteq B_*$, *so that* $\operatorname{meas}(B_*) \geqq 2\pi$.

Proof. Step 1. By the results of §3 we know that the maximum value of the variable $\theta(\cdot,t)$ tends to 1 as $t \to T$. By Lemma 5.1 we also have a first estimate from below for all elements of the ω-limit, namely,

$$f(0)=1,\ f_{xx} \geqq -\frac{1}{2} \quad \text{and} \quad f \geqq \left(1-\frac{x^2}{4}\right)_+ \quad \text{a. e. in } \mathbf{R}.$$

Step 2. *The Hamilton–Jacobi equation.* We next analyze the equation satisfied by the solution θ after some limit process. This turns out to be a Hamilton–Jacobi equation.

Fix an arbitrary sequence $\tau_j \to \infty$ such that $\theta(\cdot,\tau_j) \to f(\cdot) \in \omega(\theta_0)$ as $j \to \infty$. Using Propositions 3.2, 4.1, and Corollary 4.2 in passing to the limit as $\tau = \tau_j + s \to \infty$ in the linear and nonlinear terms of (1.12) we conclude that $\theta(\cdot,\tau_j+s) \to g(\cdot,s)$ as $j \to \infty$ locally in $L^\infty([0,\infty) : (c(\mathbf{R}))$, where $g(x,s)$ satisfies the following nonlinear Hamilton–Jacobi equation

$$g_s = (g_x)^2 + g^2 - g \quad \text{for } x \in \mathbf{R},\ s>0, \tag{5.6}$$

with initial data

$$g(x,0) = f(x) \quad \text{in } \mathbf{R}. \tag{5.7}$$

Step 3. *Explicit solutions.* Equation (5.6) with quadratic nonlinearities admits a family of explicit classical solutions, 2π-periodic in x, given by

$$g_*(x,s;\ \alpha) = \left(2\cos^2\left(\frac{x}{2}\right)+\alpha e^{-s}\right)(2+\alpha e^{-s})^{-1} \tag{5.8}$$

for $x \in \mathbf{R}$, $s>0$, where $\alpha > -2$ is a fixed constant. If $\alpha = 0$, then g_* is the classical stationary solution of (5.6):

$$g_*(x,s;\ 0) = \cos^2\left(\frac{x}{2}\right) \equiv G_*(x), \tag{5.9}$$

where $G_*(x) = G(x)$ for $|x| \leqq \pi$; see (1.16). For $\alpha > 0$ we have $g_*(x,s;\ \alpha) \geqq G_*(x)$ and

$$g_*(x,s;\ \alpha) \to G_*(x) \quad \text{as } s \to \infty \tag{5.10}$$

from above, uniformly in $\mathbf{R}$. On the other hand, it is easy to see that when $\alpha \in (-2,0)$ then $g_*(x,s;\ \alpha) = 0$ for $x = \pm x_*(s;\ \alpha)$ and $g_*(x,s;\ \alpha) > 0$ if $|x| < x_*(s;\ \alpha)$, where

$$x_*(s;\ \alpha) = 2\arccos(|\alpha|^{1/2}2^{-1/2}e^{-s/2}) < \pi$$

and $x_*(s;\ \alpha) \to \pi$ as $s \to \infty$. We also notice that if $\alpha \in (-2,0)$, then $g_*(x,s;\ \alpha) \leqq G_*(x)$ and

$$g_*(x,s;\ \alpha) \to G_*(x) \quad \text{as } s \to \infty \tag{5.11}$$

from below uniformly in $\mathbf{R}$.

Step 4. *Final estimate.* It follows from (5.2) that there exists $\alpha \in (-2, 0)$, which does not depend on f, such that

$$f(x) \geqq g_{-}(x, 0;\ \alpha) \quad \text{in } \mathbf{R}, \tag{5.12}$$

where

$$g_{-}(x, s;\ \alpha) = [g_*(x, s;\ \alpha)]_+ \quad \text{for } |x| \leqq \pi, \tag{5.13}$$

$$g_{-}(x, s;\ \alpha) = 0 \quad \text{for } |x| > \pi,\ s > 0, \tag{5.14}$$

is a viscosity solution of the Hamilton–Jacobi equation (5.6) (cf. [CL], [CEL]), and hence

$$g(x, s) \geqq g_{-}(x, s;\ \alpha) \quad \text{in } \mathbf{R} \times (0, \infty). \tag{5.15}$$

Then by (5.11) we have that for any small $\varepsilon > 0$ there exists $s_\varepsilon > 0$, which is independent for f, such that

$$g(x, s_\varepsilon) \geqq G(x) - \varepsilon \quad \text{for } |x| \leqq \pi \tag{5.16}$$

(recall that $G \equiv G_*$ in the interval $|x| \leqq \pi$). Since $\{\tau_j\}$ is an arbitrary sequence, we conclude that (5.16) holds for arbitrary $f \in \omega(\theta_0)$, whence (5.4) follows.

Remark. The lower estimate (5.4) can be also proved by an analysis similar to one given in §4. This can be done by using, instead of (4.3), the equation for the function $w = \theta_{xx} + \theta$. This equation has the form

$$w_\tau = e^{-\tau} w_{xx} + 2\theta_x w_x + (w - \theta)(2w - 1) + (\theta_x)^2 + \theta^2 - \theta. \tag{5.17}$$

To derive a lower bound of $w(x, \tau)$ as $\tau \to \infty$ we need a special estimate of the term $(\theta_x)^2 + \theta^2 - \theta$ in the right-hand side of (5.17).

6. Localization. In order to obtain upper bounds on the size of the blow-up set we shall make the additional assumption that v_0 has a finite number of intersections with an initial function of the form (2.6): $v_*(x, 0) = v_*(x, 0;\ T, \mu)$, with the same blow-up time $T > 0$ as u and $\mu \geqq \mu_T$ (which means that $v_*(x, 0)$ is nonnegative). It is easily seen that there exists a wide class of initial function with this property, in particular among the functions with compact support (see also Proposition 7.4 below). For a fixed $t \in [0, T)$ we denote by $N(t)$ the number of intersections of the solution $v(x, t)$ and the particular solution $v_*(x, t) = v_*(x, t;\ T, \mu) \geqq 0$ with the above initial data. By symmetry $N(t)$ is an even number. We then get the following estimate.

THEOREM 6.1. *Let T be the blow-up time of a solution u, and, with the above assumptions and notation, let*

$$N(0) = 2k < \infty. \tag{6.1}$$

Then the solution is uniformly bounded in set of the form

$$K = \{(x, t) : |x| \geqq x_1, 0 \leqq t < T\} \textit{ with } x_1 > L_k, \tag{6.2}$$

where $L_k = \pi(k + 2)$ if k is an odd number, and $L_k = \pi(k + 1)$ if k is even (L_k is a precise minimum for the function v_*). Consequently,

$$B \subseteq [-L_k, L_k]. \tag{6.3}$$

Proof. To begin with, we need the following result.

LEMMA 6.2. *Assume that as $t \to T$*

$$v(x,t) \geqq (T-t)^{-1}[1+\vartheta(t)] \tag{6.4}$$

for $|x| \leqq \pi/2$. Then

$$\vartheta(t) < (T-t)^2 \quad \text{as } t \to T. \tag{6.5}$$

Proof. By (3.24) we know that

$$T-t \leqq \frac{1}{\log E(t)}\left[1+\frac{1}{3}\frac{1}{\log^2 E(t)}(1+o(1))\right] \tag{6.6}$$

as $t \to T$. On the other hand, it follows from (6.4) and the definition of E, (3.18), that

$$E(t) \geqq \exp[(T-t)^{-1}(1+\vartheta(t))]-1 \quad \text{as } t \to T. \tag{6.7}$$

Then (6.5) is a direct consequence of (6.6) and (6.7). □

As a consequence of Lemma 6.2 and (2.8) we have the following consequence.

COROLLARY 6.3. *For $t \approx T$ there holds*

$$v(\pm 2\pi, t) < v_*(\pm 2\pi, t). \tag{6.8}$$

We continue the proof of Theorem 6.1 with the following.

LEMMA 6.4. *For $t \approx T$ we have*

$$v(\pm L_k, t) \leqq v_*(\pm L_k, t) \equiv \inf_{x\in\mathbf{R}} v_*(x,t). \tag{6.9}$$

Proof. Hypothesis (6.1) implies that

$$N(t) \leqq 2k \quad \text{for any } t \in (0,T). \tag{6.10}$$

By Corollary 6.3 we have that if $|x| \geqq 2\pi$ and $t \approx T$, then

$$v(x,t) < \sup_{x\in\mathbf{R}} v_*(x,t) \equiv v_*(\pm 2\pi, t). \tag{6.11}$$

We conclude that (6.9) holds. Indeed, if it is not valid and for $t \to T$,

$$v(\pm L_k, t) > v_*(\pm L_k, t), \tag{6.12}$$

then from (6.11) and (6.12) and using the spatial 2π-periodic structure of the explicit solution (2.1) we have the estimate $N(t) \geqq 2(k+1)$, contradicting (6.10). □

We are now ready to consider what happens in the domain $D = \{(x,t) : x > L_k, t_0 < t < T\}$ with $t_0 \approx T$. Observe first that since $v(|x|,t)$ is increasing in $|x|$, estimates (6.9) and (2.9) imply that for $t_0 \approx T$ we have

$$v(x,t) \leqq \tfrac{1}{2}|\log(T-t)|(1+o(1)) \tag{6.13}$$

in D. Consider the function $u(x,t) = e^{v(x,t)}-1$. It solves in D the problem consisting of (1.1) with initial condition

$$u(x,t_0) = a(x) \quad \text{for } x > L_k, \tag{6.14}$$

where a is bounded and nonnegative: $0 \leqq a(x) \leqq C$. It also satisfies a boundary condition for $t_0 \leqq t < T$ of the form

$$u(x_0, t) = h(t) \leqq \frac{1}{T-t} - 1. \tag{6.15}$$

Without loss of generality we may shift the axes and take $L_k = t_0 = 0$. The outer analysis of our solution relies on the following result.

LEMMA 6.5. *Let $u(x,t)$ be a solution of* (1.1) *in $D = \{(x,t) : x > 0, 0 < t < T\}$, which is nonincreasing as a function of x for all $t > 0$. If $u(x,0)$ is bounded for $x \geqq 0$, and there exists a constant $c > 0$ such that*

$$u(0,t) \leqq \frac{c}{T-t} - 1, \tag{6.16}$$

for $0 < t < T$, then $u(x,t)$ is bounded uniformly on sets of the form $K = \{(x,t) : x \geqq x_1, 0 \leqq t < T\}$ with $x_1 > 0$ arbitrary.

Proof. It proceeds via a two-step comparison argument. We obtain a first bound from above for $u(x,t)$ by comparing it with the solution $\overline{u}$ of the equation

$$\overline{u}_1 = \overline{u}_{xx} + \frac{c}{(T-t)} \log^2 \left(\frac{c}{T-t} \right) \tag{6.17}$$

with initial data C, a bound for $u(x,0)$ in $(0,\infty)$, and boundary data $c/(T-t) - 1$. Moreover, we may apply the superposition principle to the linear equation (6.17) and split $\overline{u}$ into $\overline{u}_1 + \overline{u}_2$, where $\overline{u}_1$ is a solution of (6.17) with zero initial and boundary data, and $\overline{u}_2$ solves the homogeneous heat equation $(\overline{u}_2)_t = (\overline{u}_2)_{xx}$ with same initial and boundary data as $\overline{u}$. By comparison with a solution that depends only on t, the function $\overline{u}_1$ can be easily estimated as

$$\overline{u}_1(x,t) \leqq \frac{c}{3} \left\{ \log^3 \left(\frac{c}{T-t} \right) - \log^3 \left(\frac{c}{T} \right) \right\}. \tag{6.18}$$

As for $\overline{u}_2$, by the results of [SGKM, p. 166] we can control the profile near the time T in the form

$$\overline{u}_2(x,t) \leqq C_1 + C_2 x^{-2} \quad \text{for some } C_1, C_2 > 0. \tag{6.19}$$

It follows that for $x \geqq x' > 0$ and as $t \to T$,

$$u(x,t) + 1 < c \log^3 \left(\frac{c}{T-t} \right). \tag{6.20}$$

The second step of the iteration consists in using (6.20) to modify (6.17) for the majorant into

$$\tilde{u}_t = \tilde{u}_{xx} + c \log^3 \left(\frac{c}{T-t} \right) \log^2 \left(c \log^3 \left(\frac{c}{T-t} \right) \right) \tag{6.21}$$

posed in $D' = \{(x,t) : x > x', 0 < t < T\}$ with corresponding initial and boundary conditions. We now get a finite estimate for both components of $\tilde{u}$ defined as before. Indeed, $\tilde{u}_1$ is uniformly bounded in D' since the last term in (6.21) is now integrable; $\tilde{u}_2$ is bounded for $x > x_1$ if $x_1 > x'$ by the same reason as in (6.19). □

With this proof of Theorem 6.1 is complete.

7. Minimal asymptotic behaviour. We are interested in giving a precise description of the shape of the solution at blow up. Under a stricter intersection condition on the data we establish in this section that the blow-up profile of our solution is just the minimal configuration (1.16). Our result is the following.

THEOREM 7.1. *Let as above v_0 be radially symmetric, nonincreasing in $|x|$, and assume moreover that it has two transversal intersections with a member $v_*(x, 0;\ T, \mu) \geqq 0$ of the explicit family* (2.1), *which has the same blow-up time T as v_0. Then as $t \to \infty$,*

$$\theta(x, \tau) \to G(x) = \begin{cases} \cos^2\left(\frac{x}{2}\right) & \textit{for } |x| \leqq \pi, \\ 0 & \textit{for } |x| > \pi, \end{cases} \tag{7.1}$$

uniformly in **R**.

Remark. We will give below in Proposition 7.4 direct conditions on v_0 so that this intersection hypothesis holds.

Proof. Step 1. *Perturbation analysis.* As explained in the Introduction the variable θ introduced in (1.11) satisfies (1.12):

$$\theta_\tau = e^{-\tau}\theta_{xx} + (\theta_x)^2 + \theta^2 - \theta$$

for $x \in \mathbf{R}$, $\tau > \tau_0 = -\log T$. This can be considered as a perturbation of the Hamilton–Jacobi equation

$$g_s = (g_x)^2 + g^2 - g \quad \text{for } x \in \mathbf{R},\ s > 0. \tag{HJ}$$

We want to describe the asymptotic behaviour of our solution of (1.12) in terms of the asymptotic behaviour of (HJ). More precisely, we want to apply Theorem 3 of [GV], which has to be conveniently adapted. [GV]'s result says that if three certain conditions to be discussed below are satisfied, then the ω-limit of the solution θ to (1.12) is contained in some part of the ω-limit of (HJ). In fact, we will need an improvement of that result and will show that, under our assumptions, such part is just the function G.

The first two steps in [GV] consist in proving that the orbits under consideration for (1.12) are compact in an appropriate topology and that, whenever a sequence $\theta(\cdot, \tau_j + s)$ converges locally in s to a function $g(\cdot, s)$ as $\tau_j \to \infty$, this g is a solution of (HJ). By the estimates proved in §4 we conclude that such facts are true and that the convergence takes place in $L^\infty_{\text{loc}}([0, \infty) : C(\mathbf{R}))$.

Step 2. *Stationary ω-limits for* (HJ). The last hypothesis in Theorem 3 of [GV] consists in showing the following:

(i) that the set Ω of all ω-limits of solutions g of (HJ) obtained in this way consists of stationary solutions; and

(ii) that it is nonvoid, compact and uniformly stable in the sense of Lyapunov for the flow generated by (HJ).

We first observe that the solutions of (HJ) we are considering take as initial data

$$g(x, 0) = f(x) \quad \text{in } \mathbf{R}, \tag{7.2}$$

where $f(\cdot) = \lim_{\tau_j \to \infty} \theta(\cdot, \tau_j)$ is an element of $\omega(\theta_0)$ satisfying

$$f = f(|x|) \quad \text{is nonincreasing in } |x|, \tag{7.3}$$

$$|f_x| \leqq C \text{ in } \mathbf{R}, \tag{7.4}$$

$$f(0) = 1, \qquad f_{xx} \geqq -\tfrac{1}{2} \quad \text{in } \mathbf{R}. \tag{7.5}$$

It is easily seen that the whole set of stationary and symmetric solutions $g = g(|x|)$ of (HJ), which are nonincreasing and tend to zero at infinity, is the one-parametric family of functions $S = \{\overline{g}(x;\ a), a \geqq 0\}$, where for a fixed $a \geqq 0$,

$$\tag{7.6} \begin{cases} \overline{g}(x, a) = 1 \quad \text{for } |x| \leqq a, \\ \overline{g}(x;\ a) = \cos^2\left(\dfrac{|x| - a}{2}\right) \quad \text{for } a \leqq |x| \leqq a + \pi, \\ \overline{g}(x;\ a) = 0 \quad \text{for } |x| \geqq a + \pi. \end{cases}$$

Nore that $G(x) \equiv \overline{g}(x;\ 0)$. We have the following.

LEMMA 7.2. *The ω-limit of g, solution of* (HJ), *with initial data f satisfying* (7.3)–(7.5), *consists of stationary solutions, i.e.*,

$$\tag{7.7} w_*(f) \subseteq S = \{\overline{g}(x;\ a), a \geqq 0\},$$

where ω_* denotes the ω-limit along the flow of (HJ).

Proof. We consider an arbitrary solution $g(x, s)$ of problem (HJ), (7.2), where the initial function $f(x)$ satisfies (7.3)–(7.5). Set

$$\tag{7.8} a = \sup\{x | f(x) = 1\} \geqq 0.$$

By Theorem 6.1 we have $a < \infty$, $f(x) = 1$ for $|x| \leqq a$ and $f(x) < 1$ for $|x| > a$. We shall compare $g(x, s)$ with the explicit solutions g_* of the Hamilton–Jacobi equation given in §5.

We now introduce a modification, g_a, of the function g_- given by (5.13), (5.14). It is defined for $a \geqq 0$ and $\alpha \in (-2, 0)$ as

$$\begin{aligned} &g_a(x, s;\ \alpha) = 1 && \text{for } |x| \leqq a, \\ &g_a(x, s;\ \alpha) = [g_*(|x| - a, s;\ \alpha)]_+ && \text{for } a \leqq |x| \leqq a + \pi, \\ &g_a(x, s;\ \alpha) = 0 && \text{for } |x| \geqq a + \pi, s \geqq 0. \end{aligned}$$

For any value of the parameter $\alpha \in (-2, 0)$, the function $g_a(x, t) = g_a(x, t;\ \alpha)$ thus defined is a subsolution of (HJ). By using estimates (7.5), which imply that

$$\tag{7.9} f(x) \geqq [1 - \tfrac{1}{4}(|x| - a)^2]_+ \quad \text{for } |x| \geqq a,$$

we deduce that there exists a value of the parameter $\alpha \in (-2, 0)$, which does not depend on f, such that, fixing this α,

$$\tag{7.10} f(x) \geqq g_a(x, 0) \quad \text{in } \mathbf{R}.$$

Then by comparison (cf. [CEL], [CL])

$$\tag{7.11} g(x, s) \geqq g_a(x, s) \quad \text{in } \mathbf{R} \times (0, \infty).$$

Similarly, we find a strictly positive super-solution g^a of (HJ) of the form

$$\begin{aligned} &g^a(x, s;\ \alpha, \lambda) = 1 && \text{for } |x| \leqq a + \lambda, \\ &g^a(x, s;\ \alpha, \lambda) = g_*(|x| - (a + \lambda), s;\ \alpha) && \text{for } |x| \geqq a + \lambda, s \geqq 0, \end{aligned}$$

with parameters α and $\lambda > 0$. One can see that for any arbitrarily small $\lambda > 0$ there exists $\alpha_+\lambda > 0$ such that

$$f(x) \leqq g^a(x,0) \quad \text{in } \mathbf{R},$$

and, therefore, by comparison

$$g(x,s) \leqq g^a(x,s) \quad \text{in } \mathbf{R} \times (0,\infty).$$

It follows from (5.10) and (5.11) that

$$g_a(x,s) \to \overline{g}(x;\, a), \qquad g^a(x,s) \to \overline{g}(x;\, a+\lambda) \tag{7.12}$$

as $s \to \infty$ uniformly in $\mathbf{R}$. Using the fact that $\overline{g}(x;\, a+\lambda) \to \overline{g}(x;\, a)$ as $\lambda \to 0$ uniformly in $\mathbf{R}$ completes the proof of the lemma. □

Step 3. *The reduced Ω-limit set.* The last condition we still have to check in order to apply Theorem 3 of [GV] is the uniform stability (in the sense of Lyapunov) of the Ω-limit set of (HJ). Unfortunately, such an assertion is false for the set S and the current topology. However, a careful inspection of the proof in [GV] show that we only work with a *reduced Ω-limit set,* which we define as "the set of ω-limits which actually occur as solutions of (HJ), (7.2) when the initial datum f is an ω-limit of (1.12)." Consequently, *we only have to prove that this reduced set has the desired properties.*

LEMMA 7.3. *The reduced Ω-limit set consists only of the special profile G.*

Proof. Let $v_*(x,t) = v_*(x,t;\, T,\mu)$ be the special solution referred to in the statement of the theorem. The proof of this lemma is based on a careful study of the comparison between our solution v and the special solution slightly delayed in time, $v_*(x,t+\varepsilon)$, $\varepsilon > 0$ small. We carefully control the relative situation of both solutions at $x = 0$ and $x = \pm\pi$. If an ω-limit is not G, then we show that the intersection count is violated as $t \to T$.

Let $N(t;\, \varepsilon)$ be the number of intersection in x at time $t \geqq 0$ of the solutions $v(x,t)$ and $v_*(x,t+\varepsilon)$ with initial data $v_0(x)$ and $v_*(x,\varepsilon)$. Our assumption is that $N(0;0) = 2$. By transversality and continuous dependence, the same is valid for the functions $v_0(x)$ and $v_*(x,\varepsilon)$ provided ε is small enough. This means that

$$N(0;\, \varepsilon) = 2 \quad \text{for any small } \varepsilon \geqq 0, \tag{7.13}$$

and hence by the Strong Maximum Principle we have

$$N(t;\, \varepsilon) \leqq 2 \quad \text{for } t \in [0, T-\varepsilon), \tag{7.14}$$

if $\varepsilon > 0$ is small enough. Notice that (7.14) with $\varepsilon = 0$ automatically implies the lower bound

$$v(0,t) > v_*(0,t) \quad \text{for } t \in [0,T). \tag{7.15}$$

Assume now that the assertion of the lemma is not true and that there exists a sequence $t_k \to T$ such that

$$\theta(x,t_k) \equiv (T-t_k)v(x,t_k) \to f(x)$$

as $k \to \infty$ uniformly in $\mathbf{R}$, and the function g, solution of (HJ) starting from f, tends in its turn as $s \to \infty$ to some $h \not\equiv G$. By Lemma 7.2 we have $h = \overline{g}(x;\, a)$ for some

$a > 0$. Therefore, we conclude from a simple triangular argument that there exists another sequence, that we denote by t_j, such that

$$\theta(x,t_j) \equiv (T-t_j)v(x,t_j) \to \overline{g}(x;\, a). \tag{7.16}$$

Notice that the corresponding explicit solution $v_*(x,t)$ satisfies (cf. (2.11))

$$\theta_*(x,t_j) \equiv (T-t_j)v_*(x,t_j) \to \overline{g}(x;\, 0) \tag{7.17}$$

as $j \to \infty$ uniformly in $\mathbf{R}$, and

$$\overline{g}(x;\, a) > \overline{g}(x;\, 0) \quad \text{for } 0 < |x| < a+\pi, \tag{7.18}$$

so that

$$\overline{g}(\pi;\, a) > 0 = \overline{g}(\pi;\, 0), \tag{7.19}$$

and

$$\overline{g}(0;\, a) = \overline{g}(0;\, 0) = 1. \tag{7.20}$$

Fix arbitrary j such that $s = T - t_j > 0$ is small enough and set $\varepsilon = s/2$. Then by (7.17), (7.16), and (7.20) we have that

$$\begin{aligned} v_*(0, t_j+\varepsilon) &\simeq (T-t_j-\varepsilon)^{-1} \equiv 2s^{-1} \\ &> s^{-1} \simeq v(0,t_j). \end{aligned} \tag{7.21}$$

The time displacement ε is used here. Using (7.17), (7.19), and (2.9) we get if $s > 0$ is small enough the inequality in the converse direction at $x = \pm\pi$;

$$\begin{aligned} v_*(\pm\pi, t_j+\varepsilon) &\simeq \frac{1}{2}|\log(T-t_j-\varepsilon)| \equiv \frac{1}{2}\left|\log\frac{s}{2}\right| \\ &< s^{-1}\overline{g}\,(\pm\pi;\, a) \simeq v(\pm\pi, t_j). \end{aligned} \tag{7.22}$$

One can see also that

$$v_*(\pm 2\pi, t_j+\varepsilon) > v(\pm 2\pi, t_j). \tag{7.23}$$

Estimates (7.21)–(7.23) imply that for the choice of $t = t_j$ and $\varepsilon > 0$ given above we have that

$$N(t_j;\, \varepsilon) \geqq 4,$$

which contradicts (7.14) for $t = t_j$. Hence $a = 0$, which completes the proof. □

Step 4. *Stability of G*. To end the proof we have to show that for every $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon) > 0$ such that if $g(\cdot, s)$ is a solution of (HJ), (7.2) such that

$$d(f, G) < \delta, \tag{7.24}$$

then

$$d(g(\cdot,s), G) < \varepsilon \quad \text{for every } s > 0 \tag{7.25}$$

(we denote by $d(\cdot,\cdot)$ the distance associated to $L^\infty(\mathbf{R})$). We can repeat the comparison arguments mentioned in Lemma 7.2, using the subsolution g_a and supersolution g_a. This completes the proof of Theorem 7.1.

To end the section we give explicit conditions under which the intersection assumption of Theorem 7.1 is fulfilled, as promised above.

PROPOSITION 7.4. *Let $v_0 = v_0(|x|)$ be a radially symmetric function, decreasing in $|x|$. Assume, moreover, that there exists a constant $m \in [0, v_0(0))$ such that*

$$v_0'(x) \leqq -\tfrac{1}{2}(v_0(0) - m)\sin x \tag{7.26}$$

for any $x \in [0,\pi]$ such that $v_0(x) > m$. Then the number of intersections of $v_0(x)$ with any positive function $v_*(x,0)$ of the form (2.6) *and satisfying*

$$v_0(0) > \max_x\{v_*(x,0)\} > \min_x\{v_*(x,0)\} \geqq m \tag{7.27}$$

is two and they are transversal. Moreover, if $v_0(0)$ is large and m small enough we can choose the parameters φ_0 and ψ_0 in (2.6) *so that $v_*(x,t)$ has the same blow-up time as v, and* (7.26) *holds.*

Proof. The initial function $\overline{v}_*(x) \equiv v_*(x,0;\,T,\mu)$ has the form (2.6) for $\mu \geqq \mu_T$, i.e.,

$$\overline{v}_*(x) = \varphi_0(\psi_0 + \cos x), \tag{7.28}$$

where $\varphi_0 > 0$, $\psi_0 \geqq 1$ are constants. According to (7.27),

$$M_1 = \inf_x \overline{v}_*(x) \equiv \varphi_0(\psi_0 - 1) \geqq m, \tag{7.29}$$

and

$$M_2 = \sup_x \overline{v}_*(x) \equiv \varphi_0(\psi_0 + 1) < v_0(0), \tag{7.30}$$

where m is as in (7.26). One can see that under hypothesis (7.26) the function $v_0(x)$ intersects an arbitrary function of the family $\overline{v}_*(x)$ exactly at two points. In fact, at any intersection point $x > 0$ we have

$$\overline{v}_*'(x) = -\varphi_0 \sin x > v_0'(x),$$

since $v_0(0) - m > M_2 - M_1 = 2\varphi_0$.

Finally, in order for v_* to have the same blow-up time T as u, and according to the analysis of §2, the data φ_0 and ψ_0 have to satisfy a certain condition, namely, the point (φ_0, ψ_0) must lie on some curve situated in the region $\{0 < \varphi_0 < \infty, 1 < \psi_0 < \infty\}$. This condition is clearly compatible with (7.29), (7.30) if m is small and $v_0(0)$ large. Then there are infinitely many choices. □

8. Minimal blow-up set. We have established minimal asymptotic behaviour in terms of the variable θ in the preceding section. Unfortunately, due to the factor $(T-t)$ in the change of variables (1.11), this does not automatically imply that u remains bounded outside of the minimal set $[-\pi,\pi]$. This section is devoted to establishing such a result.

THEOREM 8.1. *Assume that v_0 satisfies the conditions of Proposition* 7.4. *Then $B \equiv [-\pi,\pi]$.*

Remark. In view of Theorem 5.2, it follows that meas $(B_*) = 2\pi$, so that the solution actually converges to infinity as $t \to T$ at any point of the interval $-\pi < x < \pi$; see (8.1) below. The actual asymptotic behaviour at $x = \pm\pi$ is an open question.

Proof. The proof consists of a preliminary analysis of what happens near $x = \pm\pi$ (*boundary analysis*) plus an analysis of the situation for $|x| > \pi$. This latter outer analysis follows Lemma 6.5. To begin with, by Theorem 7.1 we know that as $t \to T$,

$$\theta(x,t) \equiv (T-t)v(x,t) \to G(x) \tag{8.1}$$

uniformly in **R**. The special solution with the same blow-up time selected as in Proposition 7.4 satisfies

$$\theta_*(x,t) \equiv (T-t)v_*(x,t) \to G_*(x) \tag{8.2}$$

as $t \to T$ uniformly in **R**. For a fixed $t \in [0,T)$ and arbitrary $\lambda \geqq 0$ small enough we denote by $N(t;\ \lambda)$ the number of intersections in x of the solutions $v(x,t)$ and this $v_*(x-\lambda,t)$ having the same blow-up time T as v. Then, since by Proposition 7.4 each intersection of the initial functions $v_0(x)$ and $v_*(x,0)$ is transversal, by continuity of the function $v_*(x-\lambda,0)$ with respect to λ we conclude that there holds (cf. (7.13))

$$N(0;\ \lambda) = 2 \quad \text{for any small } \lambda \geqq 0. \tag{8.3}$$

Hence (cf. (7.14))

$$N(t;\ \lambda) \leqq 2 \quad \text{for } t \in [0,T), \tag{8.4}$$

if $\lambda \geqq 0$ is small enough (notice that (7.26) yields that (8.4) is valid for arbitrary $\lambda \geqq 0$).

We now perform the boundary analysis. We prove that the solution $v(x,t)$ is small enough as $t \to T$ in a right neighborhood of the point $x = \pi$. (By symmetry, the same is true for a left neighborhood of $x = -\pi$).

LEMMA 8.2. *Let* $\lambda_0 > 0$ *be small enough. Then, as* $t \to T$,

$$v(\pi+\lambda_0,t) \leqq v_*(\pi,t) \equiv \tfrac{1}{2}|\log(T-t)|(1+o(1)). \tag{8.5}$$

Proof. We use an interesting technique of intersection comparison with shifting in x. Let $x = x_0(t) > 0$ be the unique positive intersection point of the solutions $v(x,t)$ and $v_*(x,t)$. Notice that since both solutions are analytic functions in the x variable, each intersection point is isolated for $0 < t < T$, [Fr2]. If $x_0(t) \leqq \pi$ as $t \to T$, then using (7.15) and (8.4) with $\lambda = 0$ we deduce that $v(x;\ t) \leqq v_*(x,t)$ for $x \geqq \pi$, and hence (8.5) is valid even with $\lambda_0 = 0$.

Suppose on the contrary that there exists a monotone sequence $t_j \to T$, such that

$$x_0(t_j) > \pi \quad \text{for } j = 1,2,\ldots. \tag{8.6}$$

Then by the Strong Maximum Principle [Fr1] we have that

$$v(x,t_j) > v_*(x,t_j) \quad \text{for } |x| \leqq \pi. \tag{8.7}$$

Hence,

$$\delta_j = \delta(t_j) \equiv \sup\{\lambda > 0 : v(x,t_j) \geqq v_*(x-\lambda,t_j) \text{ for } |x| \leqq \pi\} > 0. \tag{8.8}$$

It follows from (8.1) and (8.2) that $\delta_j \to 0$ as $j \to \infty$.

Compare now for a fixed j large enough the functions $v(x,t_j)$ and $v_*(x-\delta_j,t_j)$. First, we conclude that

$$v(x,t_j) > v_*(x-\delta_j,t_j) \quad \text{for } x \in [0,\pi). \tag{8.9}$$

Otherwise, if (8.9) is not valid so that, by the definition of δ_j, there exists some interior tangency point $x = x_1 \in (0, \pi)$ of these functions, at which

$$\begin{aligned} v(x_1, t_j) &= v_*(x_1 - \delta_j, t_j), \\ v_x(x_1, t_j) &= (v_*)_x(x_1 - \delta_j, t_j); \end{aligned} \tag{8.10}$$

we arrive at the contradiction with (8.4). Indeed, under conditions (8.10) by additionally "shifting to the right in x" the function $v_*(x - \delta_j, t_j)$, we deduce that for arbitrary $0 < \nu \ll \delta_j$ the number of intersections grows,

$$N(t_j;\, \delta_j + \nu) \geqq 3, \tag{8.11}$$

contradicting (8.4) with $t = t_j$, $\lambda = \delta_j + \nu$.

Thus, (8.9) holds. From the definition of δ_j given by (8.8) we conclude then that necessarily

$$v_*(\pi - \delta_j, t_j) = v(\pi, t_j), \tag{8.12}$$

and, therefore, (8.4) implies that

$$v(\pi + \delta_j, t_j) < v_*(\pi, t_j). \tag{8.13}$$

Since $\{t_j\}$ is arbitrary, by using the fact that $\delta(t) \to 0$ as $t \to T$ we have that for any small $\lambda_0 > 0$ there exists $t_0 \in (0, T)$ such that (8.5) holds for $t \in (t_0, T)$. □

It then follows from (2.9) that for $t \to T$,

$$v(x_0, t) \leqq -\tfrac{1}{2}\log(T - t)(1 + o(1)), \tag{8.14}$$

where $x_0 = \pi + \lambda_0$. The proof that u is uniformly bounded on sets of the form $K = \{(x, t) : x \geqq x_1, 0 \leqq t < T\}$ with $x_1 > x_0$ is done by applying Lemma 6.5. Since $\lambda > 0$ is arbitrarily small, the proof of Theorem 9.1 is thus complete. □

9. Periodic solutions. The techniques developed in the preceding sections can be easily adapted to some other situations. We consider in this section the case of periodic initial data with period a multiple of 2π, namely,

$$u_0(x + 2m\pi) = u_0(x), \tag{9.1}$$

with m and integer. Let us take the interval $I_m = [-m\pi, m\pi]$ as the basic period. We also assume that u_0 is symmetric in I_m, nonnegative, and nonincreasing for $0 \leq x \leq m\pi$. We also ask u_0 not to be constant in order to avoid trivial cases whose behaviour is different from the one we want to study here. Notice that we can think of the solution of the Cauchy Problem for (1.1) in $Q = \mathbf{R} \times (0, T)$ under these initial data as the solution of the Neumann Problem posed in $Q_m = I_m \times (0, T)$ with boundary data

$$u_x(\pm m\pi, t) = 0 \quad \text{for } t > 0. \tag{9.2}$$

To begin with, the explicit solutions u_* considered in §2 are still solutions of this problem. Moreover, for any solution of the Neumann Problem we have the following:

(i) If t is fixed the solution $u(x, t)$ is a symmetric function of x, decreasing for $0 < x < m\pi$. Hence, the maximum is always taken at $x = 0$. The Maximum Principle applies and the intersection number in I_m is still a nonincreasing function of time;

(ii) Estimates (3.1) and (3.4) of §3 hold. The proofs are unchanged;

(iii) The same is true for semiconvexity results of §4 and the minimal profiles of §5;

(iv) Theorem 6.1 and the other results of §6 are valid, though statements (6.2), (6.3) are void if $m\pi \leqq L_k$.

Thus, we obtain the next theorem.

THEOREM 9.1. *Let u be a solution of* (1.1), (9.1), (9.2) *with* $m \geqq 4$. *Assume that u_0 satisfies the intersection condition $N(0) = 2$ with some nonnegative initial data $u_*(x, 0;\ T, \mu)$, $\mu \geqq \mu_T$. Then*

$$B \cap I_m \subseteq [-3\pi, 3\pi]. \tag{9.3}$$

Proof. Our assumption is that $v_0 = \log(1 + u_0)$ satisfies

$$N(0) = 2, \tag{9.4}$$

where $N(t)$ denotes number of intersections in I_m of the functions $v(x, t)$ and $v_*(x, t)$. As before it follows that

$$N(t) \leqq 2 \tag{9.5}$$

for every $0 < t < T$. As in Corollary 6.3 we have $v(\pm 2\pi, t) < v_*(\pm 2\pi, t)$ for $t \approx T$. This and (9.5) imply that

$$v(3\pi, t) < v_*(3\pi, t) = \tfrac{1}{2}|\log(T - t)|(1 + o(1)) \tag{9.6}$$

as $t \to T$. Since the solution $v(x, t)$ is nonincreasing in $x > 0$ we conclude that for $t \approx T$ and $3\pi \leqq x \leqq m\pi$,

$$v(x, t) \leqq |\log(T - t)|. \tag{9.7}$$

We now apply Lemma 6.5 to conclude that v is uniformly bounded for $m\pi \geqq x \geqq x_1 > 3\pi$ and $0 < t < T$. □

(v) Under stricter conditions on the initial data we obtain, as in Theorem 7.1, the following.

THEOREM 9.2. *Let $m \geqq 3$ and let $v_0 = \log(1 + u_0)$ satisfy the conditions of Proposition 7.4 in I_m. Then*

$$B \cap I_m = [-\pi, \pi]. \tag{9.8}$$

Proof. We have (9.4) and then (9.5). Arguments similar to those given in §§7 and 8 show that, similar to (9.6) in the preceding result, the inequality $v(\pi, t) \leqq v_*(\pi, t)$ is valid after slightly shifting in x and t the explicit solution $v_*(x, t)$. In this way we can apply the arguments of Theorems 7.1 and 8.1. □

ON THE NODAL SETS OF THE EIGENFUNCTIONS OF CERTAIN HOMOGENEOUS AND NONHOMOGENEOUS MEMBRANES*

CHAO-LIANG SHEN†

Abstract. The author finds conditions for the existence of eigenfunctions whose nodal sets consist of one line segment or two perpendicular line segments. Using nodal sets of eigenfunctions, a sufficient condition is found for the density function of a nonhomogeneous annular membrane that is a radial function. The author also shows how to use the nodal sets of eigenfunctions of some particular type and the corresponding eigenvalues to determine the density function of the annular membrane if its density function is a radial function.

Key words. nonhomogeneous membranes, density functions, eigenvalues, eigenfunctions, nodal sets, nodal domains

AMS subject classifications. 35B05, 35P99

1. Introduction. Suppose Ω is a simply connected plane domain which is symmetric with respect to the x-axis. Does the fixed membrane problem

$$\Delta\varphi + \lambda\varphi = 0 \quad \text{in } \Omega, \qquad \varphi = 0 \quad \text{on } \partial\Omega \tag{1.1}$$

have an eigenfunction whose nodal set is the portion of x-axis in Ω? If Ω is also symmetric with respect to the y-axis, does (1.1) have an eigenfunction whose nodal set consists of the portion of x-axis and the portion of y-axis in the domain Ω? These questions shall be answered in §2.

In §3 we consider the nonhomogeneous membrane problem over an annulus R in $\mathbb{R}^2$:

$$\Delta\varphi + \lambda\rho(x,y)\varphi = 0 \quad \text{in } R, \qquad \varphi = 0 \quad \text{on } \partial\Omega, \tag{1.2}$$

where the density function $\rho(x,y)$ is a positive continuous function. We are interested in the question of determining the density function $\rho(x,y)$ by knowing the nodal sets of sufficiently many eigenfunctions and the corresponding eigenvalues. We prove that if (1.2) has infinitely many nodal sets of the eigenfunctions that are *circular-nested*, then the density function $\rho(x,y)$ must be radial (Theorem 3.1). Furthermore, if the density function ρ in (1.2) is radial, then, using some results in [5], we show that sufficiently many *circular nodal sets* are enough to determine the density function ρ (Theorem 3.3).

2. Existence of eigenfunctions whose nodal sets consist of straight lines. Let $f(x)$ be a continuous function on the interval $a \leqq x \leqq b$, $f(a) = f(b) = 0$, $f(x) > 0$ for $a < x < b$. We shall use the notation Ω_f to denote the region $\{(x,y)\} \in \mathbb{R}^2 : a < x < b,\ -f(x) < y < f(x)\}$. In this paper we shall assume f is nice enough for Ω_f to have smooth boundary. We use the notation $N(\varphi)$ to denote the *nodal set* of an eigenfunction φ of (1.1) on Ω, which is the set $\{(x,y) \in \Omega : \varphi(x,y) = 0\}$. The notation $E_4(\Omega_f)$ is used to denote the four-dimensional domain whose closure is

$$\overline{E_4(\Omega_f)} = \{(x, y_1, y_2, y_3) \in \mathbb{R}^4 : a \leqq x \leqq b, y_1^2 + y_2^2 + y_3^2 \leqq [f(x)]^2\}. \tag{2.1}$$

If the even function $g(x)$ is continuous on the interval $-a \leqq x \leqq a$, strictly positive in the interior, and vanishes at $\pm a$, we shall use the notation $E_6(\Omega_g)$ to denote the six-

† Institute of Mathematics, National Tsing Hua University, Hsinchu, Taiwan 30043, Republic of China.

dimensional domain whose closure is defined as follows:

$$\overline{E_6(\Omega_g)} = \{(x_1, x_2, x_3; y_1, y_2, y_3) \in \mathbb{R}^6 : x_1^2 + x_2^2 + x_3^2 \leqq a^2, \\ y_1^2 + y_2^2 + y_3^2 \leqq [g((x_1^2 + x_2^2 + x_3^2)^{1/2})]^2 \}. \tag{2.2}$$

We shall use the notation $\Delta_{x;y_1,y_2,y_3}$, $\Delta_{x_1,x_2,x_3;y_1,y_2,y_3}$ to denote the four-dimensional and six-dimensional Laplacians, respectively:

$$\Delta_{x;y_1,y_2,y_3} = \frac{\partial^2}{\partial x^2} + \sum_{j=1}^{3} \frac{\partial^2}{\partial y_j^2},$$

$$\Delta_{x_1,x_2,x_3;y_1,y_2,y_3} = \sum_{j=1}^{3} \frac{\partial^2}{\partial x_j^2} + \sum_{j=1}^{3} \frac{\partial^2}{\partial y_j^2}.$$

The following simple results shall be used later. Since they follow easily from calculation, we omit the proof.

LEMMA 2.1. (1) *Suppose the function $v(x; y_1, y_2, y_3)$ depends only on x and $y_1^2 + y_2^2 + y_3^2$. Then*

$$\Delta_{x;y_1,y_2,y_3} v = \Delta_{x,y} v(x, y) + \frac{2v_y(x, y)}{y}, \tag{2.3}$$

where $y^2 = y_1^2 + y_2^2 + y_3^2$, $v(x, y) = v(x; y_1, y_2, y_3)$, $v_y = \partial v/\partial y$, and $\Delta_{x,y}$ is the two-dimensional Laplacian in x, y.

(2) *Suppose the function $w(x_1, x_2, x_3; y_1, y_2, y_3)$ depends only on $x^2 = x_1^2 + x_2^2 + x_3^2$ and $y^2 := y_1^2 + y_2^2 + y_3^2$. Then*

$$\Delta_{x_1,x_2,x_3;y_1,y_2,y_3} w = \Delta_{x,y} w(x, y) + \frac{2w_x}{x} + \frac{2w_y}{y}, \tag{2.4}$$

where $w(x, y) = w(x_1, x_2, x_3; y_1, y_2, y_3)$.

In [4], the author had used a method to compare two eigenvalues by knowing the nodal sets of the corresponding eigenfunctions. One of the key points of the method is to construct a four-dimensional domain from Ω_f by revolving Ω_f about the x-axis. We use the same idea to prove the following theorem.

THEOREM 2.2. *For the region Ω_f, the eigenvalue problem* (1.1) *has an eigenfunction φ whose nodal set is the portion of x-axis in Ω_f, i.e., $N(\varphi) = \{(x, 0) : a < x < b\}$.*

Proof. On the four-dimensional domain $E_4(\Omega_f)$ we consider the following eigenvalue problem:

$$\Delta_{x;y_1,y_2,y_3} v + \mu v = 0 \quad \text{in } E_4(\Omega_f), \qquad v = 0 \quad \text{on } \partial E_4(\Omega_f). \tag{2.5}$$

Let v_1 be the first eigenfunction of the eigenvalue problem (2.5) such that $v_1(0; 0, 0, 0) = 1$. Using the fact that the first eigenvalue of (2.5) is simple, and the fact that $E_4(\Omega_f)$ is axially symmetric, we see that for any three-dimensional rotation $A = [a_{ij}]_{i,j=1}^{3}$, $v_1(x; y_1, y_2, y_3) = v_1(x; \sum_{j=1}^{3} a_{1j} y_j, \sum_{j=1}^{3} a_{2j} y_j, \sum_{j=1}^{3} a_{3j} y_j)$. This implies that v_1 depends only on x and $y_1^2 + y_2^2 + y_3^2$. Let $y^2 = y_1^2 + y_2^2 + y_3^2$. Again we use the notation $v_1(x, y)$ to denote $v_1(x; y_1, y_2, y_3)$. Then Lemma 2.1 tells us that

$$-\Delta_{x,y} v_1 - \frac{2(v_1)_y}{y} = \mu_1 v_1. \tag{2.6}$$

Let $\varphi(x,y) = yv_1(x,y)$. Then it is clear that $\varphi(x,y) = 0$ on $\partial\Omega_f$, $\varphi(x,0) = 0$ for $a < x < b$. Furthermore, by (2.6),

$$\begin{aligned}\Delta\varphi &= y\Delta_{x,y}v_1 + 2(v_1)_y \\ &= -\mu_1 y v_1 \\ &= -\mu_1\varphi,\end{aligned}$$

i. e., μ_1 is an eigenvalue and φ is an eigenfunction of (1.1), which has the stated property. □

Following a similar idea we have the next theorem.

THEOREM 2.3. *Let $g(x)$ be an even function which is continuous on $-a \leqq x \leqq a$, $g(a) = g(-a) = 0$, and $g(x) > 0$ for all $-a < x < a$. Then, for Ω_g, the eigenvalue problem* (1.1) *has an eigenfunction ψ whose nodal set $N(\psi) = \{(x,0) : -a < x < a\} \cup \{(0,y) : -g(0) < y < g(0)\}$.*

Proof. On $E_6(\Omega_g)$ we consider the following eigenvalue problem:

$$\Delta_{x_1,x_2,x_3;y_1,y_2,y_3}w + vw = 0 \quad \text{in } E_6(\Omega_g), w = 0 \quad \text{on } \partial E_6(\Omega_g). \tag{2.7}$$

Let v_1, w_1 denote the first eigenvalue and the first eigenfunction with $w_1(0,0,0;0,0,0) = 1$, respectively. Then, using the simplicity of v_1, we have

$$\begin{aligned}&w_1\left(\textstyle\sum_j a_{1j}x_j, \sum_j a_{2j}x_j, \sum_j a_{3j}x_j; \sum_j b_{1j}x_j, \sum_j b_{2j}x_j, \sum_j b_{3j}x_j\right) \\ &\quad = w_1(x_1,x_2,x_3;y_1,y_2,y_3)\end{aligned}$$

for all three-dimensional rotations $[a_{ij}]$, $[b_{ij}]$. This implies that $w_1(x_1,x_2,x_3;y_1,y_2,y_3)$ depends only on $x^2 = x_1^2 + x_2^2 + x_3^2$, and $y^2 = y_1^2 + y_2^2 + y_3^2$. Denote this w_1 by $w_1(x,y)$. Then, by Lemma 2.1 we have

$$-\Delta_{x,y}w_1 - \frac{2(w_1)_x}{x} - \frac{2(w_1)_y}{y} = v_1 w_1. \tag{2.8}$$

Now we define $\psi(x,y) = xyw_1(x,y)$. Then

$$\begin{aligned}\psi(x,y) &= 0 &&\text{on } \partial\Omega_g, \\ \psi(x,0) &= 0 &&\text{for } -a < x < a, \\ \psi(0,y) &= 0 &&\text{for } -g(0) < y < g(0).\end{aligned}$$

Furthermore, by (2.8) we have

$$\begin{aligned}\Delta_{x,y}\psi &= xy\Delta_{x,y}w_1 + 2x(w_1)_y + 2y(w_1)_x \\ &= -v_1 xyw_1 \\ &= -v_1\psi.\end{aligned}$$

Thus ψ is the desired eigenfunction. □

3. Nonhomogeneous annular membranes with radial density functions. Let R be the annulus $r_0^2 < x^2 + y^2 < r_1^2$, $0 < r_0 < r_1$. Suppose (λ, φ) is an eigenpair of (1.2) such that the nodal set of φ consists of concentric circles centered at the origin $(0,0)$. We shall call the nodal set a *circular nodal set*, φ a *circular eigenfunction*, and λ a *circular eigenvalue*.

If $(\tilde{\lambda}, \tilde{\varphi})$ is an eigenpair of (1.2) such that the nodal set of $\tilde{\varphi}$ is of the form $\{(r\cos\theta, \sin\theta)$: $r = r_{1,\tilde{\varphi}}, \ldots, r_{l(\tilde{\varphi}),\tilde{\varphi}}$, or $r_0 < r < r_1$ and $\theta = \theta_* + k\pi/m(\tilde{\varphi}), k = 1, 2, \ldots, 2m(\tilde{\varphi})\}$, where $r_0 < r_{1,\tilde{\varphi}} < \cdots < r_{l(\tilde{\varphi}),\tilde{\varphi}} < r_1$, θ_* and the integers $l(\tilde{\varphi})$, $m(\tilde{\varphi})$ are determined by the eigenfunction $\tilde{\varphi}$, then we call such an eigenfunction $\tilde{\varphi}$ a *circular-nested eigenfunction*, and the corresponding eigenvalue $\tilde{\lambda}$ a *circular-nested eigenvalue*. For an eigenfunction φ of (1.2), we use mesh (φ) to denote the maximum of the diameters of its nodal domains. Throughout this section we shall assume the density function $\rho(x, y)$ in (1.2) is a positive continuous function. We have the following inverse spectral theorem.

THEOREM 3.1. *If* (1.2) *has infinitely many circular-nested eigenfunction* φ_{n_j} *such that* $\lim_{n_j\to\chi}$ *mesh* $(\varphi_{n_j}) = 0$, *then the density function* $\rho(x, y)$ *is a radial function, i.e.*, $\rho(x, y) = \rho(r), r = (x^2 + y^2)^{1/2}$.

Proof. By assumption, the nodal domains of φ_{n_j} are of the form (in polar coordinate):

$$I^{(n_j)}(i,k) = \left\{(r,\theta) : r_i^{(n_j)} < r < r_{i+1}^{(n_j)}, \theta_{n_j} + \frac{k\pi}{m(n_j)} < \theta < \theta_{n_j} + \frac{(k+1)\pi}{m(n_j)}\right\},$$

where $r_0 = r_0^{(n_j)} < r_1^{(n_j)} < r_{l(nj)}^{(n_j)} = r_1$, $k = 0, 1, \ldots, 2m(n_j) - 1$; the integers $l(n_j)$, $m(n_j)$, the angle θ_{n_j}, and the radii $r_i^{(n_j)}$ are determined by φ_{n_j}.

If the density function ρ is not radial, then there exist an r_*, $r_0 < r_* < r_1$, and θ_*, θ_{**} such that $\rho(r_*\cos\theta_*, r_*\sin\theta_*) > \rho(r_*\cos\theta_{**}, r_*\sin\theta_{**})$. Since $\lim_{\lambda_{n_j}\to\infty}$ mesh $(\varphi_{n_j}) = 0$, there exist indices n_j, i, k_1, k_2, $k_1 \neq k_2$, such that (r_*, θ_*) is in closure of $I^{(n_j)}(i, k_1)$, (r_*, θ_{**}) is in the closure of $I^{(n_j)}(i, k_2)$, and

$$\rho(x_1, y_1) > \rho(x_2, y_2) \quad \text{for all } (x_1, y_1) \text{ in } I^{(n_j)}(i, k_1), \quad \text{all } (x_2, y_2) \text{ in } I^{(n_j)}(i, k_2). \tag{3.1}$$

Let $\lambda_1(I^{(n_j)}(i, k_s))$ be the first eigenvalue of

$$\Delta u + \lambda\rho u = 0, \quad I^{(n_j)}(i, k_s), \quad u = 0 \quad \text{on } \partial I^{(n_j)}(i, k_s).$$

Then (3.1) implies $\lambda_1(I^{(n_j)}(i, k_1)) < \lambda_1(I^{(n_j)}(i, k_2))$, which is absurd, since both of these first eigenvalues are equal to λ_{n_j}, the eigenvalue of (1.2) corresponding to φ_{n_j}. This completes the proof of Theorem 3.1. □

If we know that the density function of (1.2) is radial: $\rho(x, y) = \rho(r)$, $r = (x^2 + y^2)^{1/2}$, then (1.2) has infinitely many eigenfunctions which are radial, and hence, circular. These eigenfunctions are eigenfunctions of the following eigenvalue problem:

$$u''(r) + \frac{u'(r)}{r} + \mu\rho(r)u(r) = 0, \qquad u(r_0) = u(r_1) = 0. \tag{3.2}$$

Let $r = e^t, \alpha = \ln r_0, \beta = \ln r_1, v(t) = u(r)$. Then (3.2) is transformed into the following eigenvalue problem:

$$v''(t) + \mu P(t)v(t) = 0, \qquad v(\alpha) = v(\beta) = 0, \tag{3.3}$$

where $P(t) = e^{2t}\rho(e^t)$. Let $v_n(t)$ be the nth eigenfunction, μ_n be the nth eigenvalue of (3.3). We will denote $x_1^{(n)} < x_2^{(n)} < \cdots < x_{n-1}^{(n)}$, the nodal points of v_n in the open interval (α, β), and we denote $x_0^{(n)} = \alpha$, $x_n^{(n)} = \beta$, $I_{n,j} = [x_{j-1}^{(n)}, x_j^{(n)}]$. Then by the variational formula for μ_n, and the monotonicity principle for the comparison of the eigenvalues, we have

$$\frac{\pi^2}{[\max(P, I_{n,j})|I_{n,j}|^2]} \leqq \mu_n \leqq \frac{\pi^2}{[\min(P, I_{n,j})|I_{n,j}|^2]}, \tag{3.4}$$

where $\max(P,I)$ (respectively, $\min(P,I)$) denotes the maximum (respectively, the minimum) of P on the interval I, and $|I|$ denotes the length of the interval I. The following lemma was proved in [5].

LEMMA 3.2. *For $\delta > 0$, there exists $n_0(\delta)$ such that $|I_{n,k}| < \delta, \quad k = 1,2,\dots,n$ for all $n \geqq n_0$.*

Using Lemma 3.2 we can prove the following theorem.

THEOREM 3.3. *Suppose that R is an annulus as above, and we know the density function ρ in* (1.2) *is radial. If we can "hear" infinitely many circular eigenvalues and we can "see" the circular nodal sets of the corresponding eigenfunctions, then we can determine the density function ρ.*

Proof. By assumption we know infinitely many eigenvalues μ_{n_k} of (3.3) and we know the corresponding nodal points $\alpha < x_1^{(n_k)} < \cdots < x_{n_k-1}^{(n_k)} < \beta$ of v_{n_k}. Then by (3.4), Lemma 3.2, and the fact that $P(t)$ is uniformly continuous on $[\alpha,\beta]$, for $x \in [\alpha,\beta]$, if $I_{n_k,j(x)}$ is the closure of the nodal domain of v_{n_k} which contains x in its interior or has x as its right end point, we then have

$$P(x) = \pi^2 \lim_{k\to\infty} \frac{1}{\mu_{n_k}|I_{n_k,j(x)}|^2}.$$

Hence $P(x)$ is determined, so is $\rho(r)$. □

We note that recently the problem of determining the coefficients of a Sturm–Liouville equation from the nodal sets of the eigenfunctions has attracted some attention (see [2], [3], and [5]). In particular, for the string equation with Neumann boundary condition, $y'' + \lambda\rho(x)y = 0$, $y'(0) = y'(L) = 0$, if the density function $\rho(x)$ has integrable second derivative, then it was shown by Hald and McLaughlin [2] that $\rho(x)$ can be determined uniquely up to a multiplicative constant by a dense set of nodal points of eigenfunctions. Their idea is to transform the string equation via the Liouville transform into an equation of the form $z''+(\lambda-q)z = 0$. Then they use the asymptotic behaviour of the nodal sets of the eigenfunctions of the latter to achieve their goal. Besides, Hald and McLaughlin also developed some interesting numerical methods for the inverse nodal problems. Our approach to the inverse problem of the eigenvalue problem (3.3) is different from theirs. We look at the nodal sets of the eigenfunctions of (3.3) directly, and we need eigenvalues.

Combining Theorems 3.1 and 3.3 we see that the appearance of infinitely many circular-nested eigenvalues such that the meshes of the nodal domains shrink to zero implies the density function ρ is radial. Then the appearance of circular nodal sets determines the density function ρ.

The following example shows that only the appearance of infinitely many circular nodal sets does not guarantee that the density function is radial. That is, to determine a radial density function, we need the appearance of both of circular and circular-nested eigenvalues and nodal sets.

Example. For (x,y), which lies on the circle $x^2 + y^2 = r^2$, $r > 0$, define $z = x + iy$, here $i = (-1)^{1/2}$, and define

$$w = w(z) = \frac{z + z^{-1}}{2} = u + iv, \qquad u = \operatorname{Re} w, \quad v = \operatorname{Im} w. \tag{3.5}$$

Then (u,v) lies on the ellipse E_r defined as follows:

$$E_r = \left\{(u,v) : \frac{u_2}{[(r+1/r)/2]^2} + \frac{v_2}{[(r-1/r)/2]^2} = 1\right\}. \tag{3.6}$$

Note that for $r > 0$, the foci of E_r are $(1,0)$, $(-1,0)$, i.e., E_r are confocal. Conversely, if E is an ellipse with foci $(\pm 1,0)$, then E is of the form E_r. For $1 < a < b$, via the map $w(z)$, the annulus $R(a,b) = \{a^2 < x^2 + y^2 < b\}$ is transformed into the doubly connected domain $E(a,b)$ bounded by two confocal ellipses, E_a and E_b. Via $w(z)$ eigenvalue problem

$$\Delta\varphi + \lambda\varphi = 0 \quad \text{in } E(a,b), \qquad \varphi = 0 \quad \text{on } \partial E(a,b), \tag{3.7}$$

is transformed into the following nonhomogeneous annular membrane problem:

$$\Delta\psi + \lambda\left\{\frac{|1 - 1/z^2|^2}{4}\right\}\psi = 0 \quad \text{in } R(a,b), \qquad \psi = 0 \quad \text{on } \partial R(a,b). \tag{3.8}$$

Suppose ξ_0, ξ_1 are chosen so that

$$\cosh^2\xi_0 = \left[\frac{(a+1/a)}{2}\right]^2, \qquad \cosh^2\xi_1 = \left[\frac{(b+1/b)}{2}\right]^2. \tag{3.9}$$

For $(x,y) \in E(a,b)$ we introduce the *elliptic-coordinate* (ξ,η) by the following formulae: $x = \cosh\xi\cos\eta, y = \sinh\xi\sin\eta$, where $\xi_0 < \xi < \xi_1, 0 \leqq \eta < 2\pi$. Then the functions

$$\Psi(\xi,\eta;q) := \left\{\left[\frac{\mathrm{Ce}_0(\xi,q)}{\mathrm{Ce}_0(\xi_0,q)}\right] - \left[\frac{\mathrm{Fey}_0(\xi,q)}{\mathrm{Fey}_0(\xi_0,q)}\right]\right\}\mathrm{ce}_0(\eta,q), \tag{3.10}$$

where q is determined by the following transcendental equation:

$$\frac{\mathrm{Ce}_0(\xi_1,q)}{\mathrm{Ce}_0(\xi_0,q)} - \frac{\mathrm{Fey}_0(\xi_1,q)}{\mathrm{Fey}_0(\xi_0,q)} = 0 \tag{3.11}$$

are eigenfunctions of (3.7) in elliptic coordinates. ce_0, Ce_0, and Fey_0 are Mathieu functions and modified Mathieu functions of the second kind (for definition and relevant properties; see [1]). Since $\mathrm{ce}_0(\eta,q) > 0$ in the interior of the elliptic annulus for the q determined by (3.11), the nodal set of $\Psi(\xi,\eta;q)$ are those of ξ_* such that

$$\frac{\mathrm{Ce}_0(\xi_*,q)}{\mathrm{Ce}_0(\xi_0,q)} - \frac{\mathrm{Fey}_0(\xi_*,q)}{\mathrm{Fey}_0(\xi_0,q)} = 0.$$

These nodal curves $\xi = \xi_*$ correspond to concentric circles in Euclidean coordinates. Thus the nonhomogeneous annular membrane problem (3.8) has infinitely many circular eigenfunctions, but the density function of (3.8) is not radial.

Thus the appearance of infinitely many circular eigenvalues does not guarantee that the density function of a nonhomogeneous annular membrane is radial.

ON THE ZEROS OF SOLUTIONS TO GINZBURG–LANDAU TYPE SYSTEMS*

PATRICIA BAUMAN†‡, NEIL N. CARLSON†, AND DANIEL PHILLIPS†§

Abstract. The authors consider minimizers of a nonlinear functional whose Euler–Lagrange equation includes the Ginzburg–Landau system. For a certain class of Dirichlet data, it is proved that a minimizer has exactly one zero which necessarily has winding number ±1. Moreover, the same result holds for solutions of the corresponding parabolic system at all sufficiently large, fixed values of time, under certain conditions on the initial and boundary values.

Their result on minimizers supports several theories from physics (concerning interacting bosons, for example). These theories predict that *stable* solutions with isolated zeros (called vortices) exist, and each zero of a stable solution has winding number ±1.

Key words. Ginzburg–Landau system, vortices, zeros

AMS subject classifications. 35J55, 35Q40

1. Introduction.

Let Ω be a bounded simply connected domain in $\mathbb{R}^2$, and let $\mathcal{U}(X) : \Omega \to \mathbb{R}^2$ be a solution to the diagonal system

$$0 = \Delta \mathcal{U} - G'(|\mathcal{U}|^2) \cdot \mathcal{U}. \tag{1.1}$$

If $G'(|\mathcal{U}|^2) = (|\mathcal{U}|^2 - 1)$, this is the Ginzburg–Landau system used in both the theory for interacting bosons [Gr] and the theory of super-conductivity [G–L]. Here the squared modulus $|\mathcal{U}|^2$ plays the role of a density. Denote by $\Gamma(\mathcal{U})$ the set of zeros of $\mathcal{U}$, namely, $\Gamma(\mathcal{U}) = \{X \in \Omega : \mathcal{U}(X) = 0\}$. The above theories predict the existence of solutions for which $\Gamma(\mathcal{U})$ consists of isolated points called *vortices.* Moreover, it is expected that each vortex of a stable solution has winding number ±1.

In this paper we consider the variational problem associated with (1.1), subject to a particular class of Dirichlet data. We prove that an energy-minimizing solution has exactly one zero that necessarily has winding number ±1. This result then supports the theories described above.

To state our results more precisely, assume that Ω is of class $C^{2,\mu}$ for μ fixed with $0 < \mu < 1$. Let $Y(s)$ for $0 \leq s < L$ be a one-to-one parametrization of $\partial\Omega$ with respect to arclength. Consider Dirichlet data, ψ_0, in $C^{2,\mu}(\overline{\Omega}; \mathbb{R}^2)$. Expressing the image, $\psi_0(Y(s))$, of $\partial\Omega$ in polar coordinates, we have

$$\psi_0(Y(s)) = (r(s) \cdot \cos\theta(s), r(s) \cdot \sin\theta(s)).$$

We assume that ψ_0 satisfies

$$r(s) > 0, \theta'(s) \neq 0 \quad \text{for } 0 \leq s < L \quad \text{and} \quad |\theta(L) - \theta(0)| = 2\pi. \tag{1.2}$$

§This author's research was partially supported by National Science Foundation grant DMS-9112471.

Thus the image, $\psi_0(\partial\Omega)$, bounds a starlike region with respect to the origin in $\mathbb{R}^2$ such that $\psi_0(Y(s))$ crosses each ray, $\theta = \theta_0$, exactly once as s increases from zero to L. We assume that the nonlinearity, G, satisfies

$$G \in C^2([0,\infty)), \quad G \geq 0, \quad \text{and} \quad \overline{\lim_{\tau\to\infty}} \frac{|G'(\tau)|}{\tau^\lambda} < \infty \quad \text{for some } \lambda > 0. \tag{1.3}$$

Consider the variational problem of minimizing the functional

$$J(\psi) = \int_\Omega (|\nabla\psi|^2 + G(|\psi|^2))dX \tag{1.4}$$

in the class $\mathcal{M} \equiv \{\psi \in W^{1,2}(\Omega;\mathbb{R}^2) : \psi = \psi_0 \text{ on } \partial\Omega\}$. Our main result is the following.

THEOREM. *If $\mathcal{U}$ is a minimizer of $J(\cdot)$ in $\mathcal{M}$, then $\Gamma(\mathcal{U})$ consists of one point.* (*See Theorem* 2.3.)

In general, the most one can say about $\Gamma(\psi)$ for a given continuous vector field ψ with $\psi = \psi_0$ on $\partial\Omega$ is that its Brouwer degree satisfies $d(\psi,\Omega,0) = \pm 1$. Thus, our result states that a minimizer has the simplest structure of this type possible.

An interesting case is with $\Omega = B_1(0)$ and $\psi_0(X) = X$. It is known that there exists a separable solution of (1.1) with boundary values, ψ_0, namely,

$$\mathcal{U}_R(X) = R(|X|)(X/|X|),$$

with $R(0) = 0$, $R(1) = 1$, and $0 < R(|X|) < 1$ for $|X|$ in $(0,1)$. See [Ab]. It is not known, however, if $\mathcal{U}_R$ is a minimizer of $J(\cdot)$ in all of $\mathcal{M}$. Thus the fact that a minimizer has one zero is new even in this case.

The stationary result can be used to investigate the pattern of the zero set as it evolves with time for the nonlinear heat equation studied in [N]. Consider the system

$$\begin{aligned} \mathcal{U}_t &= \Delta\mathcal{U} - G'(|\mathcal{U}|^2)\mathcal{U} && \text{for } X \in \Omega, \quad t > 0, \\ \mathcal{U}(X,t) &= \psi_0(X) && \text{for } X \in \partial\Omega, \quad t > 0, \\ \mathcal{U}(X,0) &= \mathcal{U}_0(X) && \text{for } X \in \Omega. \end{aligned} \tag{1.5}$$

It is known that if $\mathcal{U}_0 \in \mathcal{M}$, then there is a unique solution $\mathcal{U} = \mathcal{U}(t)$, which is classical for $t > 0$. Setting $m = \inf_{\psi\in\mathcal{M}} J(\psi)$ we have the following.

THEOREM. *There is a constant $\delta > 0$ such that if $J(\mathcal{U}_0) \leq m + \delta$, then $\Gamma(\mathcal{U}(t)) = \{X(t)\}$, where $X(t)$ is a C^1 curve in Ω for all t sufficiently large.* (*See Theorem* 3.3.)

If $G(\tau)$ is real analytic, with Ω and ψ_0 sufficiently smooth, then more can be said. A result of Simon states that there is a constant $\delta_1 > 0$ such that if $J(\mathcal{U}_0) \leq m + \delta_1$, then $\mathcal{U}(t) \to \mathcal{U}^\infty$ in $C^2(\overline{\Omega};\mathbb{R}^2)$ as $t \to \infty$, where $\mathcal{U}^\infty$ is a minimizer. We use this to prove the following.

THEOREM. *$X(t) \to X^\infty$ as $t \to \infty$, where $\{X^\infty\} = \Gamma(\mathcal{U}^\infty)$.* (*See Theorem* 3.6.)

Thus in this setting there is large-time dynamic stability for the pattern of $\Gamma(\mathcal{U}(t))$ near the minimum energy level.

Notation. When the context is clear we use the following abbreviated notation:

$$\begin{gathered} W^{1,2}(\Omega;\mathbb{R}^2) = W^{1,2}(\Omega), \\ C^{2,\mu}(\overline{\Omega};\mathbb{R}^2) = C^{2,\mu}(\overline{\Omega}), \\ \|\mathcal{U}\|_{C^{2,\mu}(\overline{\Omega};\mathbb{R}^2)} = \|\mathcal{U}\|_{C^{2,\mu}}. \end{gathered}$$

2. Minimizers and their zeros. We first summarize the existence and regularity results related to the variational problem.

LEMMA 2.1. *There is at least one minimizer for $J(\cdot)$ in $\mathcal{M}$. A minimizer, $\mathcal{U} = (u,v)$, is a solution of*

$$\begin{aligned} \Delta u - G'(|\mathcal{U}|^2)u &= 0, \\ \Delta v - G'(|\mathcal{U}|^2)v &= 0 \quad \text{in } \Omega, \\ (u,v) &= \psi_0 \quad \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

Any weak solution, $\widetilde{\mathcal{U}}$, of this system in $W^{1,2}(\Omega)$ is of class $C^{2,\mu}(\overline{\Omega})$ and

$$\|\widetilde{\mathcal{U}}\|_{C^{2,\mu}(\overline{\Omega})} \le C\left(\|\widetilde{\mathcal{U}}\|_{W^{1,2}(\Omega)}, \|\psi_0\|_{C^{2,\mu}(\overline{\Omega})}\right). \tag{2.2}$$

Proof. Since G satisfies the conditions in (1.3), the general theory of variational problems implies the existence of a minimizer, $\mathcal{U}$, in $\mathcal{M}$. See [G, Chap. I]. Since $\Omega \subset \mathbb{R}^2$ and $\mathcal{U} \in W^{1,2}(\Omega)$, it follows from the Sobolev imbedding theorem that $\mathcal{U} \in L^p(\Omega)$ for any $p < \infty$. From this and (1.3), $J(\mathcal{U}+\varepsilon\Phi)$ is differentiable in ε for any $\Phi \in C_c^1(\Omega;\mathbb{R}^2)$. Thus $\mathcal{U}$ is a weak solution of (2.1).

Now let $\widetilde{\mathcal{U}} = (\widetilde{u},\widetilde{v})$ be any weak solution of (2.1) in $W^{1,2}(\Omega)$. By (1.3), (2.1), and the Sobolev imbedding theorem $\Delta\widetilde{u}$ and $\Delta\widetilde{v}$ are in $L^q(\Omega)$ for any $q < \infty$. Hence by elliptic estimates,

$$\begin{aligned} \|\widetilde{\mathcal{U}}\|_{C^1(\overline{\Omega})} &\le C(\|\widetilde{\mathcal{U}}\|_{L^q(\Omega)}, \|\psi_0\|_{C^{2,\mu}(\overline{\Omega})}) \\ &\le \widetilde{C}(\|\widetilde{\mathcal{U}}\|_{W^{1,2}(\Omega)}, \|\psi_0\|_{C^{2,\mu}(\overline{\Omega})}) \end{aligned}$$

for all q sufficiently large. Thus $\Delta\widetilde{u}$, $\Delta\widetilde{v} \in C^{\mu}(\overline{\Omega})$, and (2.2) follows. □

For $\alpha \in \mathbb{R}$ and $\mathcal{U} = (u,v)$, a minimizer for $J(\cdot)$ in $\mathcal{M}$, set

$$w_\alpha(X) = -u(X)\cdot\sin\alpha + v(X)\cdot\cos\alpha.$$

Define the *nodal set* of w_α by

$$N_\alpha \equiv \{X \in \overline{\Omega} : w_\alpha(X) = 0\}.$$

Note that for any pair α_1, α_2 with $0 \le \alpha_1 < \alpha_2 < \pi$, the set of zeros of $\mathcal{U}$ is just $\Gamma(\mathcal{U}) = N_{\alpha_1} \cap N_{\alpha_2}$. Thus as α varies, $\Gamma(\mathcal{U})$ is the subset of N_α that remains fixed.

We shall prove (in Lemma 2.2) that for each α, N_α is a smooth imbedded curve which enters and exits $\overline{\Omega}$ at distinct points of $\partial\Omega$. Following this, we prove that the curves, N_α, have exactly one point in common.

LEMMA 2.2. *For each α, N_α is a C^1 imbedded curve in $\overline{\Omega}$.*

Proof. First consider $N_\alpha \cap \partial\Omega$. From (1.2) we have $N_\alpha \cap \partial\Omega = \{P_1, P_2\}$. Using the notation from (1.2) if $Y(s_1) = P_1$ and $Y(s_2) = P_2$, we can assume without loss of generality that $\theta(s_1) = \alpha + \pi$ and $\theta(s_2) = \alpha$. Now

$$w_\alpha(Y(s)) = r(s)\cdot[-\cos\theta(s)\cdot\sin\alpha + \sin\theta(s)\cdot\cos\alpha].$$

Hence

$$\left.\frac{\partial}{\partial s}w_\alpha(Y(s))\right|_{s_1} = -r(s_1)\cdot\theta'(s_1) \ne 0$$

and

$$\frac{\partial}{\partial s} w_\alpha(Y(s))\bigg|_{s_2} = r(s_2)\cdot\theta'(s_2) \neq 0.$$

Thus there are neighborhoods $\mathcal{O}_1$ and $\mathcal{O}_2$ of P_1 and P_2, respectively, so that $N_\alpha \cap \mathcal{O}_1$ and $N_\alpha \cap \mathcal{O}_2$ are C^1 curves intersecting $\partial\Omega$ at P_1 and P_2.

Next we examine N_α in Ω. Note that w_α is a $C^{2,\mu}$ solution of

$$\Delta w_\alpha - G'(|\mathcal{U}|^2)w_\alpha = 0 \quad \text{in } \Omega,$$

where $G'(|\mathcal{U}|^2)$ is continuous. By Hartman and Wintner's classical results (see [H-W, Thms. 1–2 and Cor. 1]), the set

$$K_\alpha \equiv \{X \in \Omega : w_\alpha(X) = 0 \text{ and } \nabla w_\alpha(X) = 0\}$$

is locally finite. Our previous analysis near $\partial\Omega$ then implies that K_α is either empty or is a finite subset of Ω. It follows from [H-W] and our analysis near $\partial\Omega$ that N_α consists of a finite number of C^1 arcs along which $\nabla w_\alpha \neq 0$ except at their endpoints in Ω; moreover, the arcs may intersect only at these (interior) endpoints. Exactly two endpoints of these arcs are in $\partial\Omega$, and the rest make up K_α.

Finally, we note that at least four distinct arcs in N_α meet at each point in K_α. This follows from Hartman and Wintner's analysis of w_α near X_0 in K_α: Indeed, they show that for some integer n there is a homogeneous harmonic polynomial, H_n, of order n so that

$$w_\alpha(X) - H_n(X - X_0) = o(|X - X_0|^n) \quad \text{and}$$
$$\nabla w_\alpha(X) - \nabla H_n(X - X_0) = o(|X - X_0|^{n-1}).$$

(See (5) and (5′) of §1 in [H-W].) It follows that the nodal set of w_α has the same structure near X_0 as that of the harmonic function, $H_n(X - X_0)$.

We claim that $K_\alpha = \emptyset$. If not, fix X_0 in K_α. Let C_1, C_2, and C_3 be three distinct maximal (piecewise C^1) curves in N_α with endpoints at X_0. If *none* of these curves returns to X_0 or self-intersects or intersects one of the other two curves, then all three curves must reach $\partial\Omega$. But this is impossible by our analysis of N_α near $\partial\Omega$. Thus there exists a nontrivial subdomain $D_\alpha \subset \Omega$ with $\partial D_\alpha \subset N_\alpha$. Using a rotated basis for the image, we can represent $\mathcal{U}$ by $\mathcal{U}(X) = (w_\alpha(X), w_{\alpha+\frac{\pi}{2}}(X))$. Let

$$\widetilde{\mathcal{U}} = \begin{cases} \mathcal{U} & \text{in } \Omega - D_\alpha, \\ (-w_\alpha, w_{\alpha+\frac{\pi}{2}}) & \text{in } \overline{D}_\alpha. \end{cases}$$

Then $\widetilde{\mathcal{U}} \in \mathcal{M}$ and $J(\mathcal{U}) = J(\widetilde{\mathcal{U}})$. Thus $\widetilde{\mathcal{U}}$ is also a minimizer and (by Lemma 2.1) $\widetilde{\mathcal{U}} \in C^{2,\mu}(\overline{\Omega})$. But this is possible only if $\nabla w_\alpha \equiv 0$ on ∂D_α, which contradicts the fact that K_α is a finite set. This proves that $K_\alpha = \emptyset$. The same argument implies N_α does not contain a closed loop. Hence N_α is connected.

It follows that $\nabla w_\alpha \neq 0$ on N_α and N_α can be parametrized by arclength as a smooth imbedded curve in $\overline{\Omega}$ with endpoints $\{P_1, P_2\}$. □

The set, $\Gamma(\mathcal{U})$, is nonempty since $d(\mathcal{U}, \Omega, 0) = \pm 1$. In the following theorem we construct a homotopy from N_0 to N_π, passing through each N_α for $0 \leq \alpha \leq \pi$. By analyzing the points contained in all the N_α we prove that $\Gamma(\mathcal{U})$ has just one element.

THEOREM 2.3. *Let $\mathcal{U}$ be a minimizer for $J(\cdot)$ in $\mathcal{M}$ where ψ_0 satisfies* (1.2). *Then $\Gamma(\mathcal{U}) = \{X_0\}$ for some X_0 in Ω.*

Proof. Let $\{P_1, P_2\} = N_0 \cap \partial\Omega$ and assume without loss of generality that $\mathcal{U}(P_1) = (u(P_1), 0)$ with $u(P_1) < 0$ and $\mathcal{U}(P_2) = (u(P_2), 0)$ with $u(P_2) > 0$. The points, P_1 and P_2, partition $\partial\Omega$ into two arcs, $(\partial\Omega)^- \equiv \{X \in \partial\Omega : v(X) \le 0\}$ and $(\partial\Omega)^+ \equiv \{X \in \partial\Omega : v(X) \ge 0\}$. Starting at P_1 and moving along N_0, let X_0 be the first point reached in $\Gamma(\mathcal{U})$. Since $X_0 \in N_\alpha$ for all α, it follows from Lemma 2.2 that each N_α can be parametrized by arclength, $X = X(\tau, \alpha)$, such that

$$a(\alpha) < \tau < b(\alpha), \quad a(\alpha) < 0, \quad X(a(\alpha), \alpha) \in (\partial\Omega)^-, \quad b(\alpha) > 0, \quad X(b(\alpha), \alpha) \in (\partial\Omega)^+,$$
$$\left|\frac{\partial X}{\partial \tau}\right| = 1 \quad \text{and} \quad X(0, \alpha) = X_0.$$

Set $\mathcal{D} = \{(\tau, \alpha) : a(\alpha) \le \tau \le b(\alpha), 0 \le \alpha \le \pi\}$. We split the proof into three parts.

Part 1. We first show that $X \in C^1(\mathcal{D})$, and that $a(\alpha)$ and $b(\alpha)$ are in $C^1([0, \pi])$. Without loss of generality, assume that

$$\frac{\partial X}{\partial \tau}(0,0) = \left(\frac{\partial w_0}{\partial x_2}(X_0), -\frac{\partial w_0}{\partial x_1}(X_0)\right) \Big/ |\nabla w_0(X_0)|.$$

By Lemma 2.2 and the equicontinuity of $\{\nabla w_\alpha(X) : 0 \le \alpha \le \pi\}$, we have

$$\inf\{|\nabla w_\alpha(X)| : X \in N_\alpha \text{ and } 0 \le \alpha \le \pi\} > 0.$$

Thus from the theory of ordinary differential equations, it follows that $X(\tau, \alpha)$ solves the initial value problem

$$\begin{aligned} \frac{\partial x_1}{\partial \tau} &= \frac{\partial w_\alpha}{\partial x_2}(x_1, x_2) \Big/ |\nabla w_\alpha(x_1, x_2)|, \\ \frac{\partial x_2}{\partial \tau} &= -\frac{\partial w_\alpha}{\partial x_1}(x_1, x_2) \Big/ |\nabla w_\alpha(x_1, x_2)|, \\ (x_1(0,\alpha)&, x_2(0, \alpha)) = X_0. \end{aligned}$$

Since $w_\alpha(X)$ is a C^2 function of α and X it follows that $X(\tau, \alpha) \in C^1(\mathcal{D})$.

To show that $a(\alpha)$ is C^1, let $Q_1 \in \partial\Omega$ with $Q_1 = X(a(\alpha_1), \alpha_1)$. Choose Φ so that the equation, $\Phi(X) = 0$, defines $\partial\Omega$ in a neighborhood of Q_1 and $\nabla\Phi(Q_1) \ne 0$. In the proof of Lemma 2.2 we showed that the tangential component of $\nabla w_\alpha(Q_1)$ does not vanish. It follows that $\nabla\Phi(Q_1) \cdot (\partial X/\partial\tau)(a(\alpha_1), \alpha_1) \ne 0$. Thus the equation $\Phi(X(\tau, \alpha)) = 0$ implicitly determines $\tau = a(\alpha)$ as a C^1 function of α near α_1. Hence $a(\alpha) \in C^1([0, \pi])$. In the same manner, we have $b(\alpha) \in C^1([0, \pi])$. Thus $X(\tau, \alpha)$ is a C^1 homotopy defined on the piecewise smooth domain $\mathcal{D}$.

Part 2. By construction, $X(\tau, 0) \notin \Gamma(\mathcal{U})$ for $\tau < 0$. Here we show that for all α in $[0, \pi]$ and $\tau < 0$, $X(\tau, \alpha) \notin \Gamma(\mathcal{U})$. In particular, $X(\tau, \pi) \notin \Gamma(\mathcal{U})$ for $\tau < 0$.

Set
$$\overline{\alpha} = \sup\{\alpha : X(\tau, \beta) \notin \Gamma(\mathcal{U}) \text{ for } \tau < 0 \text{ and } \beta \le \alpha\}.$$

There are three possibilities. The first is that there exists $\overline{\tau} < 0$ such that $X(\overline{\tau}, \overline{\alpha}) \in \Gamma(\mathcal{U})$. Since $\Gamma(\mathcal{U}) \subset N_\alpha$ for all α, we have $X(\overline{\tau}, \overline{\alpha}) \in N_\alpha$ for all $\alpha < \overline{\alpha}$. By construction, for each $\alpha < \overline{\alpha}$ there exists $\tau(\alpha) \in (0, b(\alpha))$ with $X(\tau(\alpha), \alpha) = X(\overline{\tau}, \overline{\alpha})$. By continuity this implies that for some $\tau^* \in [0, b(\alpha)]$, we have $X(\tau^*, \overline{\alpha}) = X(\overline{\tau}, \overline{\alpha})$. But $N_{\overline{\alpha}}$ does not self-intersect (by the proof of Theorem 2.2). Hence this case is impossible.

The second possibility is that $\overline{\alpha} < \pi$ and $X(\tau, \overline{\alpha}) \notin \Gamma(\mathcal{U})$ for all $\tau < 0$. In this case, there must be a sequence, $\{\tau_n, \alpha_n\}$, with $\alpha_n \downarrow \overline{\alpha}$, $\tau_n \uparrow 0$, and $X(\tau_n, \alpha_n)$ in $\Gamma(\mathcal{U})$. By continuity, $X(\tau_n, \alpha_n) \to X(0, \overline{\alpha}) = X_0$. Moreover, since $\Gamma(\mathcal{U}) \subset N_{\overline{\alpha}}$, there is a sequence $\{t_n\}$ with $t_n > 0$ so that $X(t_n, \overline{\alpha}) = X(\tau_n, \alpha_n)$. Necessarily, $t_n \downarrow 0$. Consider the vectors

$$\frac{X(\tau_n, \alpha_n) - X(0, \alpha_n)}{\tau_n}$$

and

$$\frac{X(t_n, \overline{\alpha}) - X(0, \overline{\alpha})}{t_n}.$$

Since $X \in C^1(\mathcal{D})$ both sequences tend to $(\partial X/\partial \tau)(0, \overline{\alpha})$ as $n \to \infty$. But for each n the angle between the two vectors is π. Hence $(\partial X/\partial \tau)(0, \overline{\alpha}) = 0$. This contradicts the fact that $|\partial X/\partial \tau| = 1$.

The only remaining possibility is that $\overline{\alpha} = \pi$ and $X(\tau, \pi) \notin \Gamma(\mathcal{U})$ for $\tau < 0$.

Part 3. Now $X(\tau, 0)$ and $X(\tau, \pi)$ are each parametrizations of N_0 in opposite directions. Since X_0 is the first point in each direction along N_0 that is in $\Gamma(\mathcal{U})$, we conclude that $\Gamma(\mathcal{U}) = \{X_0\}$. □

Remark. The idea of using a homotopy of nodal curves based on the result of Lemma 2.2 was motivated by an argument of Payne in [P] where he shows that in a convex domain in $\mathbb{R}^2$, an eigenfunction for the first eigenvalue of the Laplacian has one critical point.

COROLLARY 2.4. *Let $\mathcal{U}$ be a minimizer for $J(\cdot)$ in $\mathcal{M}$. The curves $\{u = 0\}$ and $\{v = 0\}$ cross only at $\Gamma(\mathcal{U}) = \{X_0\}$ in Ω. In fact, there is a constant $c > 0$ independent of $\mathcal{U}$ such that $|\det \nabla\mathcal{U}(X_0)| \geq c$.*

Proof. If there is no such lower bound, then there exists a sequence of minimizers $\{\mathcal{U}^n\}$ with $\mathcal{U}^n(X_0^n) = 0$, and $\det \nabla\mathcal{U}^n(X_0^n) \to 0$. From the uniform bound (2.2) for minimizers, it follows that there exists a minimizer, $\widetilde{\mathcal{U}}$, and a subsequence, $\{\mathcal{U}^j\}$, such that $\mathcal{U}^j \to \widetilde{\mathcal{U}}$ in $C^2(\overline{\Omega})$, $X_0^j \to \widetilde{X}_0 \in \Omega$, $\widetilde{\mathcal{U}}(\widetilde{X}_0) = 0$, and $\det \nabla\widetilde{\mathcal{U}}(\widetilde{X}_0) = 0$. Let α be such that $[-\sin\alpha, \cos\alpha] \cdot \nabla\widetilde{\mathcal{U}}(X_0) = 0$. Consider the function $\widetilde{w}_\alpha = -\widetilde{u}\sin\alpha + \widetilde{v}\cos\alpha$. We have $\nabla\widetilde{w}_\alpha(\widetilde{X}_0) = 0$ and $\widetilde{w}_\alpha(\widetilde{X}_0) = 0$. This is impossible by the proof of Lemma 2.2. □

3. The time dependent problem. In this section we consider the set of zeros of solutions to the parabolic problem,

$$\text{(3.1)} \qquad \begin{aligned} \mathcal{U}_t &= \Delta\mathcal{U} - G'(|\mathcal{U}|^2)\mathcal{U} && \text{for } X \in \Omega, \quad t > 0, \\ \mathcal{U}(X,t) &= \psi_0(X) && \text{for } X \in \partial\Omega, \quad t > 0, \\ \mathcal{U}(X,0) &= \mathcal{U}_0(X) && \text{for } X \in \overline{\Omega}, \end{aligned}$$

where $\psi_0 \in C^{2,\mu}(\overline{\Omega}; \mathbb{R}^2)$ and $\mathcal{U}_0 \in \mathcal{M} \equiv \{\psi \in W^{1,2}(\Omega; \mathbb{R}^2) : \psi = \psi_0 \text{ on } \partial\Omega\}$. We prove that for ψ_0 as before and for certain initial data, $\mathcal{U}_0$, the zero set of $\mathcal{U}$, namely, $\Gamma(\mathcal{U}(t)) = \{X \in \Omega : \mathcal{U}(X,t) = 0\}$, consists of exactly one point for all t sufficiently large. (See Theorem 3.3.)

We begin by stating existence, uniqueness, and regularity results for this problem.

THEOREM 3.1. *Assume $\psi_0 \in C^{2,\mu}(\overline{\Omega})$ and $\mathcal{U}_0 \in \mathcal{M}$. There exists a unique solution, $\mathcal{U}(t) \equiv \mathcal{U}(X,t)$, of* (3.1) *in $C([0,\infty); W^{1,2}(\Omega;\mathbb{R}^2))$. The solution is classical for $t > 0$ and*

$$\|\mathcal{U}(t)\|_{C^{2,\mu}(\overline{\Omega})} \le M_1 \quad \text{for } t \ge 1, \tag{3.2}$$

where M_1 depends only on Ω, μ, G, $J(\mathcal{U}_0)$, and $\|\psi_0\|_{C^{2,\mu}(\overline{\Omega})}$. Moreover, if $k \ge 3$, $G \in C^{k+1}([0,\infty))$, Ω is of class $C^{k,\mu}$, and $\psi_0 \in C^{k,\mu}(\overline{\Omega};\mathbb{R}^2)$, then $\mathcal{U}(t) \in C^{k,\mu}(\overline{\Omega};\mathbb{R}^2)$ for each $t > 0$ and

$$\|\mathcal{U}(t)\|_{C^{k,\mu}(\overline{\Omega})} \le M_2 \quad \text{for } t \ge 1. \tag{3.3}$$

The constant, M_2, depends only on Ω, μ, k, G, $J(\mathcal{U}_0)$, and $\|\psi_0\|_{C^{k,\mu}(\overline{\Omega})}$.

Proof. Let $\mathcal{V}$ be the unique solution of $\Delta\mathcal{V} = 0$ in Ω, $\mathcal{V} = \psi_0$ on $\partial\Omega$. Set $\widetilde{\mathcal{U}}(X,t) = \mathcal{U}(X,t) - \mathcal{V}(X)$. By elliptic estimates, $\mathcal{V} \in C^{2,\mu}(\overline{\Omega})$ and $\|\mathcal{V}\|_{C^{2,\mu}(\overline{\Omega})} \le M_1$ for some constant M_1 as above. Moreover, if Ω is $C^{k,\mu}$ and $\psi_0 \in C^{k,\mu}(\overline{\Omega})$ for $k \ge 3$, then $\|\mathcal{V}\|_{C^{k,\mu}(\overline{\Omega})} \le M_2$ for some constant M_2 as above. Thus the theorem follows if we prove that there is a unique solution, $\widetilde{\mathcal{U}}(t) \equiv \widetilde{\mathcal{U}}(X,t)$, in $C([0,\infty); W^{1,2}(\Omega))$ of the boundary value problem

$$\begin{aligned}
\widetilde{\mathcal{U}}_t &= \Delta\widetilde{\mathcal{U}} - G'(|\widetilde{\mathcal{U}} + \mathcal{V}|^2)\cdot(\widetilde{\mathcal{U}} + \mathcal{V}) && \\
&\equiv \Delta\widetilde{\mathcal{U}} + F(\widetilde{\mathcal{U}}), && \text{for } X \in \Omega, \quad t > 0,\\
\widetilde{\mathcal{U}}(X,t) &= 0, && \text{for } X \in \partial\Omega, \quad t > 0,\\
\widetilde{\mathcal{U}}(X,0) &= \mathcal{U}_0(X) - \mathcal{V}(X) && \text{for } X \in \overline{\Omega},
\end{aligned} \tag{3.4}$$

and that $\widetilde{\mathcal{U}}$ is classical and satisfies (3.2) and (3.3).

To prove existence and uniqueness of solutions to (3.4), we apply semigroup theory as in [H]. Fix $p \ge 2$ and note that $F(\psi) \equiv -G'(|\psi + \mathcal{V}|^2)(\psi + \mathcal{V})$ is locally Lipschitz continuous from $W_0^{1,p}(\Omega) \equiv W_0^{1,p}(\Omega;\mathbb{R}^2)$ into $L^p(\Omega) \equiv L^p(\Omega;\mathbb{R}^2)$. Let $A : W_0^{1,p}(\Omega) \cap W^{2,p}(\Omega) \to L^p(\Omega)$ be defined by $A(\psi) = -\Delta\psi$. Then $A = A_p$ is a densely defined, positive, self-adjoint operator on $X \equiv L^p(\Omega)$ and A^{-1} is a compact operator. The operator $A^{1/2}$ is defined on $X^{1/2} \equiv D(A^{1/2}) = W_0^{1,p}(\Omega)$.

Consider the equations

$$\begin{aligned}
\widetilde{\mathcal{U}}_t &= -A\widetilde{\mathcal{U}} + F(\widetilde{\mathcal{U}}) \quad \text{in } L^p(\Omega) \quad \text{for } t > t_0 \ge 0,\\
\widetilde{\mathcal{U}}(t_0) &= \widetilde{\mathcal{U}}_0.
\end{aligned} \tag{3.5}$$

If $\widetilde{\mathcal{U}}_0 \in W_0^{1,p}(\Omega)$, then the existence-uniqueness result of Henry (see Theorem 3.3 of [H]) states that there exists $t_1 > t_0$ such that (3.5) has a unique solution on (t_0, t_1). Here, such a solution is defined as a mapping $\widetilde{\mathcal{U}}$, in $C([t_0,t_1); L^p(\Omega))$ such that $\widetilde{\mathcal{U}}(t) \in W_0^{1,p}(\Omega) \cap W^{2,p}(\Omega) \equiv D(A)$, $\partial\widetilde{\mathcal{U}}/\partial t$ exists, $t \to F(\widetilde{\mathcal{U}}(t))$ is locally Hölder continuous on (t_0, t_1),

$$\int_{t_0}^{t_0+\rho} \|F(\widetilde{\mathcal{U}}(t))\|_{L^p(\Omega)} dt < \infty \quad \text{for some } \rho > 0,$$

$\widetilde{\mathcal{U}}(t_0) = \widetilde{\mathcal{U}}_0$, and $\widetilde{\mathcal{U}}$ satisfies (3.5) in $L^p(\Omega)$ for $t_0 < t < t_1$.

Applying the above result with $p = 2$, $t_0 = 0$, and $\widetilde{\mathcal{U}}_0 = \mathcal{U}_0 - \mathcal{V}$, we obtain a unique solution of (3.5) in $C([0,t_1); L^2(\Omega))$ for some $t_1 > 0$.

We first prove that $t_1 = \infty$. Choose $t_2 \geq t_1$ such that $(0,t_2)$ is the maximal interval of existence-uniqueness of the solution in $L^2(\Omega)$. Fix $p > 2$, and let K_1 denote constants depending only on Ω, p, μ, G, $J(\mathcal{U}_0)$, and $\|\psi_0\|_{C^{2,\mu}(\overline{\Omega})}$. By standard energy estimates (see (3.11)),

$$J(\mathcal{U}(t)) \leq J(\mathcal{U}(0)) \quad \text{for all } t \text{ in } (0,t_2),$$

where $\mathcal{U} = \widetilde{\mathcal{U}} + \mathcal{V}$. Since $W_0^{1,2}(\Omega) \subset L^p(\Omega)$ for all $p \geq 2$, we have

$$\begin{aligned}(3.6)\qquad \|\widetilde{\mathcal{U}}(t)\|_{L^p(\Omega)} &\leq K_1 \cdot \|\widetilde{\mathcal{U}}(t)\|_{W_0^{1,2}(\Omega)}\\ &\leq K_1 \cdot J(\mathcal{U}(t)) + \|\mathcal{V}\|_{W_0^{1,2}(\Omega)}\\ &\leq K_1 \cdot (J(\mathcal{U}(0)) + 1) \leq K_1\end{aligned}$$

for all t in $(0,t_2)$. By (1.3) and the above inequality, we have

$$(3.7)\qquad \|F(\widetilde{\mathcal{U}}(t))\|_{L^p(\Omega)} = \|G'(|(\widetilde{\mathcal{U}} + \mathcal{V})(t)|^2) \cdot (\widetilde{\mathcal{U}} + \mathcal{V})(t)\|_{L^p(\Omega)} \leq K_1$$

for all t in $(0,t_2)$. Now $\widetilde{\mathcal{U}}(T) \in D(A) = W_0^{1,2}(\Omega) \cap W^{2,2}(\Omega) \subset W_0^{1,p}(\Omega)$ for any T in $(0,t_2)$. Thus by the existence-uniqueness result in [H],

$$(3.8)\qquad \widetilde{\mathcal{U}}(t) = e^{-A(t-T)}\widetilde{\mathcal{U}}(T) + \int_T^t e^{-A(t-s)}F(\widetilde{\mathcal{U}}(s))ds$$

in $W_0^{1,p}(\Omega)$ for all t in (T,T_1), where $T < T_1 < t_2$ and T_1 depends on Ω, p, F, T, and $\widetilde{\mathcal{U}}(T)$. By a result of Alikakos (see [Al, p. 285]), it follows from (3.6)–(3.8) that

$$(3.9)\qquad \|\widetilde{\mathcal{U}}(t)\|_{W^{1,p}(\Omega)} \leq K_1 \quad \text{for } T < t < T_1,$$

and we may take $T_1 = t_2 = t_1 = \infty$.

Finally, to show that $\widetilde{\mathcal{U}}$ is classical, we note that by (3.9) with $p = p_0 > 2$,

$$\|\widetilde{\mathcal{U}}(t)\|_{L^\infty(\Omega)} \leq K_1 \quad \text{for all } t > 0,$$

where K_1 is independent of t. It follows from parabolic estimates (see [L-S-U, Chap. 2, Lem. 3.3 and Chap. 4, Thms. 5.2 and 9.1]) that $\widetilde{\mathcal{U}}$ is classical and

$$\|\widetilde{\mathcal{U}}(t)\|_{C^{2,\mu}(\overline{\Omega})} \leq M_1 \quad \text{for } t \geq t_0 > 0,$$

where M_1 depends only on K_1 and t_0. Moreover, if $k \geq 2$, $G \in C^{k+1}([0,\infty))$, Ω is of class $C^{k,\mu}$, and $\psi_0 \in C^{k,\mu}(\overline{\Omega})$, then $\mathcal{U}(t) \in C^{k,\mu}(\overline{\Omega})$ for $t > 0$ and

$$\|\mathcal{U}(t)\|_{C^{k,\mu}(\overline{\Omega})} \leq M_2 \quad \text{for } t \geq t_0,$$

where M_2 depends only on t_0, k, Ω, μ, G, $J(\mathcal{U}_0)$, and $\|\psi\|_{C^{k,\mu}(\overline{\Omega})}$. □

DEFINITION. If $\mathcal{F} \subset C^2(\overline{\Omega}; \mathbb{R}^2)$ and $\varepsilon > 0$, set

$$\mathcal{F}_\varepsilon = \{\mathcal{V} \in C^2(\overline{\Omega}) : \|\mathcal{V} - \mathcal{U}\|_{C^2(\overline{\Omega})} < \varepsilon \text{ for some } \mathcal{U} \in \mathcal{F}\}.$$

Fix ψ_0 in $C^{2,\mu}(\overline{\Omega})$ such that ψ_0 satisfies (1.2). Let $\mathcal{S}$ be the set of all minimizers of J in $\mathcal{M}$. By Theorem 2.1, $\mathcal{S}$ is a bounded subset of $C^2(\overline{\Omega})$. We shall need the following lemma concerning $\mathcal{S}_\varepsilon$.

LEMMA 3.2. *There exists $\varepsilon > 0$ such that if $\mathcal{V} \in \mathcal{S}_\varepsilon$, then $\Gamma(\mathcal{V}) \equiv \{X \in \Omega : \mathcal{V}(X) = 0\}$ is a single point.*

Proof. From (2.2) and Corollary 2.4, there exist positive constants C_1 and C_2 (independent of $\mathcal{U}$) such that if $\mathcal{U} \in \mathcal{S}$ and $\{X_0\} = \Gamma(\mathcal{U})$, then

$$\|\mathcal{U}\|_{C^2(\overline{\Omega})} \leq C_1 \quad \text{and} \quad |\det \nabla\mathcal{U}(X_0)| \geq C_2.$$

It follows that if ε_1 is sufficiently small (depending on C_1 and C_2), $\mathcal{V} \in \mathcal{S}_{\varepsilon_1}$, and $\|\mathcal{V} - \mathcal{U}\|_{C^2(\overline{\Omega})} < \varepsilon_1$, then

$$\|\mathcal{V}\|_{C^2(\overline{\Omega})} \leq 2C_1 \quad \text{and} \quad |\det \nabla\mathcal{V}(X_0)| \geq \frac{C_1}{2}.$$

By the inverse function theorem there are positive constants, r_1 and r_2, independent of $\mathcal{V}$, such that $B_{r_1}(X_0) \subset \Omega$, $\mathcal{V}$ is a diffeomorphism from $B_{r_1}(X_0)$ onto its image, and $B_{r_2}(\mathcal{V}(X_0)) \subset \mathcal{V}(B_{r_1}(X_0))$. Setting $\varepsilon_2 = \min(\varepsilon_1, r_2/2)$, we have

$$0 = \mathcal{U}(X_0) \in B_{r_2}(\mathcal{V}(X_0)) \subset \mathcal{V}(B_{r_1}(X_0)) \quad \text{if } \mathcal{V} \in \mathcal{S}_{\varepsilon_2} \quad \text{and} \quad \|\mathcal{U} - \mathcal{V}\|_{C^2(\overline{\Omega})} < \varepsilon_2.$$

Next we note that there exists $\eta > 0$ such that

$$\inf_{X \in \Omega - B_{r_1}(X_0)} |\mathcal{U}(X)| \geq \eta \quad \text{for all } \mathcal{U} \text{ in } \mathcal{S}, \tag{3.10}$$

where $\{X_0\} = \Gamma(\mathcal{U})$. Indeed, if (3.10) fails then by compactness there is a member of $\mathcal{S}$ with more than one zero.

Now set $\varepsilon = \min(\varepsilon_2, \eta/2)$. If $\mathcal{V} \in \mathcal{S}_\varepsilon$, it follows that $\mathcal{V} \neq 0$ in $\Omega - B_{r_1}(X_0)$ whenever $\mathcal{U} \in \mathcal{S}$, $\|\mathcal{V} - \mathcal{U}\|_{C^2(\overline{\Omega})} < \varepsilon$ and $\{X_0\} = \Gamma(\mathcal{U})$. Moreover, $\mathcal{V}|_{B_{r_1}(X_0)}$ is a diffeomorphism and $0 \in \mathcal{V}(B_{r_1}(x_0))$. □

For the remainder of this section, we assume (in addition to our hypotheses on ψ_0) that $\mathcal{U}_0 \in \mathcal{M}$ and $\mathcal{U}(X,t)$ is a solution of (3.1).

Let $\mathcal{U}(t) = \mathcal{U}(\cdot, t)$. Our next result states that if $J(\mathcal{U}_0)$ is sufficiently close to the minimum energy level, then $\Gamma(\mathcal{U}(t))$ is a single point for all t sufficiently large.

THEOREM 3.3. *Let $m = \inf_{\psi \in \mathcal{M}} J(\psi)$. There exist positive constants δ and T (depending only on Ω, ψ_0, and $\mathcal{U}_0$) such that if $J(\mathcal{U}_0) \leq m + \delta$, then $\Gamma(\mathcal{U}(t)) = \{X(t)\}$ for all $t \geq T$, where $X(t)$ is a C^1 curve from (T, ∞) into Ω.*

Proof. Let

$$\omega = \omega(\mathcal{U}_0) \equiv \{\mathcal{V} : \mathcal{U}(t_n) \to \mathcal{V} \text{ in } C^2(\overline{\Omega}) \text{ for some sequence } t_n \to \infty\}.$$

By Theorem 3.1, $\{\mathcal{U}(t) : t \geq 1\}$ is precompact in $C^2(\overline{\Omega})$. Thus ω is nonempty and for each $\varepsilon > 0$, there exists $T(\varepsilon) > 0$ such that $\{\mathcal{U}(t) : t \geq T(\varepsilon)\} \subset \omega_\varepsilon$. Multiplying (3.1) by $\mathcal{U}_t(t)$ and integrating gives

$$\int_0^t \int_\Omega |\mathcal{U}_t|^2 dX\, dt + \frac{1}{2} J(\mathcal{U}(t)) = \frac{1}{2} J(\mathcal{U}_0). \tag{3.11}$$

From this and the argument of Theorem 1.1 in [L-P], it follows that $\omega(\mathcal{U}_0)$ is made up of solutions to (2.1).

Given $\delta > 0$ assume that $J(\mathcal{U}_0) \leq m + \delta$. From (3.11), $J(\mathcal{V}) \leq m + \delta$ for any $\mathcal{V}$ in $\omega(\mathcal{U}_0)$. By (2.2) and compactness, it follows that for each $\varepsilon > 0$ there exists $\delta_1 > 0$ such that if $\mathcal{V}$ solves (2.1) and $J(\mathcal{V}) \leq m+\delta_1$, then $\mathcal{V} \in \mathcal{S}_\varepsilon$. Consequently, if $J(\mathcal{U}_0) \leq m+\delta_1$, there exists $T = T(\Omega, \mathcal{U}_0, \varepsilon)$ such that if $t \geq T$, then $\mathcal{U}(t) \in \mathcal{S}_{2\varepsilon}$. By Lemma 3.2 if $t \geq T$, we have $\Gamma(\mathcal{U}(t)) = \{X(t)\}$ for some $X(t)$ in Ω and $\det \nabla\mathcal{U}(X(t),t) \neq 0$. Since $\mathcal{U}(X(t),t) = 0$, the implicit function theorem ensures that $X(t)$ is C^1 and

$$\frac{dX}{dt} = -[\nabla\mathcal{U}(X(t),t)]^{-1}\frac{\partial\mathcal{U}}{\partial t}(X(t),t). \qquad \square$$

A result of Simon [S] implies that if $G(\tau)$ is real analytic for $\tau \geq 0$ and if ψ_0 and Ω are sufficiently regular, then $\mathcal{U}(t)$ converges to an equilibrium solution, $\mathcal{U}^\infty$ as $t \to \infty$. We use this result to prove that $X(t) \to X^\infty$ as $t \to \infty$, where $\{X^\infty\} = \Gamma(\mathcal{U}^\infty)$. (See Theorem 3.6.)

Simon's work is done in the Sobolev space $W^{k,2}(\Omega)$, where k is large enough so that

$$\|\mathcal{V}\|_{C^2(\overline{\Omega})} \leq C \cdot \|\mathcal{V}\|_{W^{k-3,2}(\Omega)} \quad \text{for all } \mathcal{V} \text{ in } W^{k-3,2}(\Omega).$$

Since $\Omega \subset \mathbb{R}^2$, it suffices to take $k = 7$.

LEMMA 3.4. *Assume that $G(\tau)$ is real analytic for $\tau \geq 0$, Ω is of class $C^{7,\mu}$, and $\psi_0 \in C^{7,\mu}(\overline{\Omega};\mathbb{R}^2)$. There exists a solution, $\mathcal{U}^\infty$, of* (2.1) *such that $\mathcal{U}(t) \to \mathcal{U}^\infty$ in $C^2(\overline{\Omega})$ as $t \to \infty$.*

Proof. We apply Corollary 1 from [S]. This asserts that $\mathcal{U}(t) \to \mathcal{U}^\infty$ in $W^{7,2}(\Omega)$ as $t \to \infty$, provided it is known that for some sequence, $\{t_n\}$, with $t_n \to \infty$, we have $\mathcal{U}(t_n) \to \mathcal{U}^\infty$ in $W^{7,2}(\Omega)$ and $\mathcal{U}^\infty$ solves (2.1). To prove this condition, note that by Theorem 3.1, $\{\mathcal{U}(t) : t \geq 1\}$ is precompact in $C^7(\overline{\Omega})$; hence it is precompact in $W^{7,2}(\Omega)$. In addition, the proof of Lemma 3.3 ensures that any limit point of this set is a solution of (3.1). □

A further result of Simon is that the only equilibrium solution near a minimizer is another minimizer. From this we obtain the following.

LEMMA 3.5. *Under the hypotheses of Lemma* 3.4, *there exists $\delta > 0$ such that if $\mathcal{U}_0 \in \mathcal{M}$ and $J(\mathcal{U}_0) \leq m + \delta$, then $\mathcal{U}^\infty(X) \equiv \lim_{t\to\infty}\mathcal{U}(X,t)$ is a minimizer.*

Proof. Assume that no such δ exists. Then there are sequences, $\{\mathcal{U}_{n0}(X)\}$ and $\{\mathcal{U}_n(X,t)\}$, such that $\mathcal{U}_{n0} \in \mathcal{M}$, $\mathcal{U}_n(X,t)$ satisfies (3.1) with $\mathcal{U}_0(X) = \mathcal{U}_{n0}(X)$,

$$J(\mathcal{U}_{n0}) \leq m + \frac{1}{n} \quad \text{and} \quad m < J(\mathcal{U}_n^\infty) \quad \text{for } n = 1, 2, \ldots,$$

where $\mathcal{U}_n^\infty(X) \equiv \lim_{t\to\infty}\mathcal{U}_n(X,t)$. By (2.2) and (3.11) we may assume (by considering a subsequence) that $\mathcal{U}_n^\infty \to \mathcal{V}$ in $C^{2,\mu/2}(\overline{\Omega})$, where $\mathcal{V}$ is a minimizer. By Theorem 3 of [S], there exists $\sigma > 0$ such that if

$$\|\mathcal{V} - \mathcal{U}_n^\infty\|_{C^{2,\mu/2}(\overline{\Omega})} < \sigma,$$

then $J(\mathcal{U}_n^\infty) = m$, which is impossible. □

From Theorem 3.3 and the above lemmas, we obtain the following.

THEOREM 3.6. *Assume that Ω is of class $C^{7,\mu}$, G is real analytic in* $[0,\infty)$, *and $\psi_0 \in C^{7,\mu}(\overline{\Omega};\mathbb{R}^2)$. There exists $\delta > 0$ and a point X^∞ in Ω so that if $J(\mathcal{U}_0) \leq m + \delta$, then*

(i) *$\mathcal{U}(t) \to \mathcal{U}^\infty$ in $C^2(\overline{\Omega})$ as $t \to \infty$;*

(ii) *$\Gamma(\mathcal{U}(t)) = \{X(t)\} \subset \Omega$ for all t sufficiently large;*

(iii) $X^\infty = \lim_{t\to\infty} X(t)$ *and* $\Gamma(\mathcal{U}^\infty) = \{X^\infty\}$.

Proof. By Lemmas 3.4 and 3.5, (i) holds for a minimizer, $\mathcal{U}^\infty$. Condition (ii) follows from Theorem 3.3, and then condition (iii) holds by continuity and Theorem 2.3. □

SUBHARMONIC SOLUTIONS FOR SOME SECOND-ORDER DIFFERENTIAL EQUATIONS WITH SINGULARITIES*

ALESSANDRO FONDA[†], RAÚL MANÁSEVICH[‡], AND FABIO ZANOLIN[§]

Abstract. The existence of infinitely many subharmonic solutions is proved for the periodically forced nonlinear scalar equation $u'' + g(u) = e(t)$, where g is a continuous function that is defined on a open proper interval $(A, B) \subset \mathbb{R}$. The nonlinear restoring field g is supposed to have some singular behaviour at the boundary of its domain. The following two main possibilities are analyzed:

(a) The domain is unbounded and g is sublinear at infinity. In this case, via critical point theory, it is possible to prove the existence of a sequence of subharmonics whose amplitudes and minimal periods tend to infinity.

(b) The domain is bounded and the periodic forcing term $e(t)$ has minimal period $T > 0$. In this case, using the generalized Poincaré–Birkhoff fixed point theorem, it is possible to show that for any $m \in \mathbb{N}$, there are infinitely many periodic solutions having mT as minimal period.

Applications are given to the dynamics of a charged particle moving on a line over which one has placed some electric charges of the same sign.

Key words. periodic solutions, subharmonics, repulsive singularities, saddle point theorem, critical levels, twist maps, generalized Poincaré–Birkhoff theorem

AMS subject classifications. 34C15, 34C25, 58E05, 70D05

1. Introduction.

A scalar equation of the form

$$u'' + g(u) = e(t) \tag{1.1}$$

can be viewed as a model for a system with one degree of freedom subject to an internal force given by the nonlinear restoring field $g(u)$ and an external time-dependent perturbation represented by $e(t)$.

In this paper we are interested in situations where $g(u)$ is a field having one or more singularities, all of which are of repelling type, and $e(t)$ will be supposed to be a periodic forcing, with period $T > 0$. We prove the existence of subharmonic solutions of (1.1), i.e., periodic solutions whose periods are integer multiples of T.

A simple physical model for this type of equation can be given by the dynamics of a charged particle moving on a line, over which one has placed some electric charges of the same sign. Since we consider only trajectories which do not collide with the singularity points, we can reduce our study to two different cases: the case of one singularity, with the particle moving on one side, and the case of two singularities, with the particle in between.

In §2 we deal with the one-singularity case. This case has been already considered by Lazer and Solimini in [17] (see also [14], [18]). They proved the existence of at least

one T-periodic solution of (1.1) for the model described above. Under some general assumptions on g, we will show that, besides the T-periodic solutions, there is a whole sequence of subharmonic solutions whose minimal period is an arbitrarily large integer multiple of T. The proofs of the results of this section will use variational arguments providing critical points of saddle type for the action functional.

The forced two-singularities case for (1.1), as far as we know, has not been considered explicitly in the literature. Some work has been done for systems with a potential well (see [2], [1], [4]), but without a forcing term.

In §3, we will consider this case. Using a generalized version of the Poincaré–Birkhoff fixed point theorem we will prove that, for any fixed period which is an integer multiple of T, there are infinitely many periodic solutions with such a minimal period.

To be more specific, we will consider $g(u)$ to be defined on an open interval (A, B), which may be bounded or unbounded. This will permit us to deal simultaneously with various different qualitative situations. Intuitively, we may think of the extreme points A and B of the domain of g as "singularities" for the field g. With this in mind, it is reasonable to look for conditions on g such that g grows faster than linear at the singularities. Such requirement is satisfied when A (respectively, B) is finite, and $\lim_{x\to A^+} g(x) = -\infty$ (respectively, $\lim_{x\to B^-} g(x) = +\infty$) while, for $A = -\infty$ (respectively, $B = +\infty$), we will assume that $g(x)/x \to +\infty$ as $x \to A^+$ (respectively, $x \to B^-$).

In this setting, the search of T-periodic solutions and subharmonic solutions in the case $A = -\infty$ and $B = +\infty$ has already been considered in several papers starting with Morris [19], [20] who proved in [20] the existence of infinitely many subharmonics of any order for e smooth and $g(x) = 2x^3$. Extensions of Morris's result were obtained in [9], [7] for any g continuous and such that $g(x)/x \to +\infty$ for $x \to \pm\infty$, using a generalization of the Poincaré–Birkhoff fixed point theorem due to W. Ding [9]. Namely, the existence of fixed points for the iterates of the Poincaré map associated to (1.1) is obtained in [8], by showing that there are circular annuli in the plane (u, u') where the twist condition at the boundaries (which are circumferences) is satisfied.

In [5] Del Pino and Manásevich considered the case $A \in \mathbb{R}$ and $B = +\infty$ for a variant of (1.1) motivated by a problem in nonlinear elasticity. They proved the existence of infinitely many T-periodic solutions using the more refined version of W. Ding's theorem in [10], where fixed points of an area-preserving homeomorphism twisting the boundaries of an annulus are obtained for annuli with star-shaped boundaries. Note that in this case, the singularity in A modifies the geometry of the planar flow and now the twist property has to be checked on the boundary of some annular regions which are "deformations" of circular annuli through a non-Euclidean metric. For another recent application of the Poincaré–Birkhoff theorem to (1.1), see also [6].

In §4, we apply our results to the dynamics of an electric charge moving in a Coulombian field with one or two singularities.

2. Sublinear case and one singularity.

We consider the equation

$$u'' + g(t, u) = e(t), \tag{2.1}$$

where $g : \mathbb{R} \times (0, +\infty) \to \mathbb{R}$ is a Caratheodory function, T-periodic in its first variable, such that for every positive constants $r < R$ there is a $\nu = \nu_{r,R} \in L^1(0, T)$ with $|g(t, x)| \le \nu(t)$ for almost every $t \in [0, T]$ and all $x \in [r, R]$. Moreover, $e : \mathbb{R} \to \mathbb{R}$ is locally integrable and T-periodic $(T > 0)$. We denote by $\bar{e}$ the mean value of $e(t)$, i.e., $\bar{e} = (1/T) \int_0^T e(t)\, dt$.

THEOREM 2.1. *Let $F : (0,+\infty) \to \mathbb{R}$ be a continuously differentiable function satisfying the following two properties:*

$$\lim_{x\to+\infty} \frac{F(x)}{x^2} = 0, \tag{k$_1$}$$

$$\lim_{x\to 0^+} F(x) = +\infty. \tag{k$_2$}$$

Assume that

$$g(t,x) \le F'(x), \tag{k$_3$}$$

and

$$g(t,x)\operatorname{sgn}(x-1) \ge -h(t), \tag{k$_4$}$$

for all $x > 0$ and almost every $t \in [0,T]$, where $h \in L^1([0,T],\mathbb{R}^+)$. If, moreover,

$$\frac{1}{T}\int_0^T \limsup_{x\to 0^+} g(t,x)\, dt \ < \bar{e} < \frac{1}{T}\int_0^T \liminf_{x\to+\infty} g(t,x)\, dt, \tag{k$_5$}$$

then (2.1) has a sequence $(x_k)_{k\ge 1}$ of positive kT-periodic solutions whose minimal periods tend to infinity.

We first define a truncation function. Thus, for $r > 0$, let us define $g_r : \mathbb{R}\times\mathbb{R} \to \mathbb{R}$ as follows:

$$g_r(t,x) = \begin{cases} g(t,x) & \text{if } x \ge r; \\ g(t,r) & \text{if } x < r. \end{cases}$$

PROPOSITION 2.1. *For every $k \in \mathbb{N}$ there exist positive r_k, R_k such that for any $s \in (0, r_k]$ and any kT-periodic solution u of*

$$u'' + g_s(t,u) = e(t), \tag{2.2}$$

we have that $r_k \le u(t) \le R_k$ for all $t \in \mathbb{R}$. In particular, any kT-periodic solution of (2.2) with $s = r_k$ is a solution of (2.1).

Proof. Without loss of generality, we can assume that $\bar{e} = 0$ (just subtract $\bar{e}$ to both sides of (2.2)).

We argue by contradiction. Fix $k \in \mathbb{N}$ and assume that for every $n \in \mathbb{N}$, there are $s_n \in (0, 1/n)$ and a kT-periodic function u_n that satisfy

$$u_n'' + g_{s_n}(t,u_n) = e(t), \tag{2.3}$$

and such that $\{u_n(t) \mid t \in \mathbb{R}\} \not\subset [1/n, n]$.

In the following, we denote by $||\cdot||_q$ the usual L^q-norm on $(0,kT)$.

We claim there exists a $d \ge 1$ such that for every n there is $t_n^{(1)} \in [0,kT]$ with $u_n(t_n^{(1)}) \in [1/d, d]$.

Indeed, suppose for instance that, for a subsequence, $\max u_n \to c \in [-\infty, 0]$. Since

$$0 = \int_0^{kT} g_{s_n}(t, u_n(t))\, dt, \tag{2.4}$$

by Fatou's lemma we have

$$0 \leq \int_0^{kT} \limsup_{n\to\infty}[g(t,u_n(t))\chi_{[u_n>s_n]} + g(t,s_n)\chi_{[u_n\leq s_n]}]\ dt \ \leq \int_0^{kT} \limsup_{x\to 0^+} g(t,x)\ dt$$

contradicting the Landesman-Lazer like condition (k_5). A similar contradiction is obtained if we let $\min u_n \to +\infty$, and the claim follows.

From now on we fix the constant $d \geq 1$ such that (according to (k_3) and (k_5)), $F'(x) > 0$ for each $x \in [d, +\infty)$.

Next, let us prove that there exists a positive constant R such that $\max u_n \leq R$ for every n. We will use some ideas from [22]. By contradiction, assume there exists a subsequence, still denoted by (u_n) for which $\max u_n \to +\infty$. Then we can find an interval $[\alpha_n, \beta_n]$, containing a point $t_n^{(2)}$ with $u_n(t_n^{(2)}) = \max u_n$, such that $(\beta_n - \alpha_n) \leq kT$ and

$$u_n(\alpha_n) = d = u_n(\beta_n);$$
$$d \leq u_n(t) \leq u_n(t_n^{(2)}) \quad \text{for all } t \in [\alpha_n, \beta_n].$$

For $t \in [\alpha_n, \beta_n]$, we have that (2.3) can be written as

$$\begin{aligned} u_n' &= v_n + \int_{\alpha_n}^t e(s)\ ds \\ v_n' &= -g(t, u_n). \end{aligned} \tag{2.5}$$

Since $v_n(t) - \int_{\alpha_n}^t h(s)\ ds$ is decreasing in this interval, using (2.5) we obtain

$$\max u_n - d \leq kT(v_n(\alpha_n) + ||e||_1 + ||h||_1), \tag{2.6}$$

so that, for n large enough, $v_n(\alpha_n) > ||e||_1$. On the other hand, again from (2.5) we find that $v_n(t_n^{(2)}) \leq ||e||_1$. Thus there exists a $t_n^{(3)} \in (\alpha_n, t_n^{(2)}]$ such that $v_n(t_n^{(3)}) = ||e||_1$. For t in the interval $[\alpha_n, t_n^{(3)}]$ we have

$$\begin{aligned} &\frac{d}{dt}\left[F(u_n(t)) + \frac{1}{2}(v_n(t) - ||e||_1)^2\right] \\ &\quad = F'(u_n(t))\left[v_n(t) + \int_{\alpha_n}^t e(s)\ ds\right] + (v_n(t) - ||e||_1)(-g(t,u_n(t))) \\ &\quad \geq F'(u_n(t))(v_n(t) - ||e||_1) + (v_n(t) - ||e||_1)(-g(t,u_n(t))) \\ &\quad \geq (F'(u_n(t)) - g(t,u_n(t)))[v_n(t) - ||e||_1] \geq 0. \end{aligned}$$

Thus $F(u_n(\cdot)) + \frac{1}{2}(v_n(\cdot) - ||e||_1)^2$ is increasing in this interval and hence

$$F(d) + \tfrac{1}{2}(v_n(\alpha_n) - ||e||_1)^2 \leq F(u_n(t_n^{(3)})).$$

From assumption (k_1) we find that for any $\varepsilon > 0$ there is $C'_\varepsilon > 0$ such that

$$F(u) \leq \varepsilon u^2 + C'_\varepsilon \quad \text{for every} \quad u \geq d.$$

Hence

$$\begin{aligned} F(d) + \tfrac{1}{2}(v_n(\alpha_n) - ||e||_1)^2 &\leq \varepsilon(u_n(t_n^{(3)}))^2 + C'_\varepsilon \\ &\leq \varepsilon(\max u_n)^2 + C'_\varepsilon. \end{aligned}$$

Now choosing ε small enough and calling on (2.6) we obtain a contradiction when $n \to \infty$. Thus, we have proved that there exists $R > 0$ such that $\max u_n \leq R$ for every n.

Next, from (2.4) and $s_n \leq 1/d$ we have

$$\begin{aligned}\int_{[u_n<1/d]} |g_{s_n}(t,u_n(t))|\,dt &\leq \int_{[u_n<1/d]} (-g_{s_n}(t,u_n(t))+h(t))\,dt \;+||h||_1\\ &\leq \int_{[1/d\leq u_n\leq R]} |g(t,u_n(t))|\,dt \;+2||h||_1 \;\leq\; C,\end{aligned}$$

and we obtain that $||g_{s_n}(\cdot,u_n(\cdot))||_1 \leq 2C$; hence

$$||u_n'||_\infty \leq C_1 := 2C + ||e||_1.$$

Now define $\tilde{g}_{s_n}(t,x) := g_{s_n}(t,x) - h(t)$. Then (2.3) can be written as

$$u_n'' + \tilde{g}_{s_n}(t,u_n) = e(t) - h(t). \tag{2.7}$$

Set

$$f_{s_n}(x) = \begin{cases} F'(x) & \text{if } x \geq s_n \\ F'(s_n) & \text{if } x < s_n, \end{cases}$$

and

$$\eta_{s_n}(x) = \min\,\{0, f_{s_n}(x)\}.$$

Since $h(t) \geq 0$, we have that, for $x \leq 1$, $\tilde{g}_{s_n}(t,x) \leq \eta_{s_n}(x)$. Assume next there is a $t_n^{(4)} > t_n^{(1)}$ such that $u(t_n^{(4)}) < 1/n$. Then there are $t_n^{(5)} < t_n^{(6)}$ such that $[t_n^{(5)}, t_n^{(6)}]$ is contained in $[t_n^{(1)}, t_n^{(4)}]$, and such that $u_n(t_n^{(5)}) = 1/d$, $u_n(t_n^{(6)}) = 1/n$ and $1/n \leq u_n(t) \leq 1/d$ for all $t \in [t_n^{(5)}, t_n^{(6)}]$. Note that $t_n^{(6)} - t_n^{(5)} \leq kT$.

Then, multiplying (2.7) by $(u_n' - C_1)$ and integrating over $[t_n^{(5)}, t_n^{(6)}]$, we get

$$\begin{aligned}\frac{1}{2}(u_n'(t_n^{(6)}) - C_1)^2 - \frac{1}{2}(u_n'(t_n^{(5)}) - C_1)^2 + \int_{t_n^{(5)}}^{t_n^{(6)}} \tilde{g}_{s_n}(t,u_n(t))(u_n'(t) - C_1)\,dt&\\ \leq\; 2C_1(||e||_1 + ||h||_1).&\end{aligned}$$

Thus, since $(u_n' - C_1) \leq 0$ and $\eta_{s_n}(u_n(t)) \leq 0$, we obtain

$$\int_{t_n^{(5)}}^{t_n^{(6)}} \eta_{s_n}(u_n(t))u_n'(t)\,dt \leq \int_{t_n^{(5)}}^{t_n^{(6)}} \eta_{s_n}(u_n(t))(u_n'(t) - C_1)\,dt \leq \tilde{C},$$

where $\tilde{C} := 2C_1(C_1 + ||e||_1 + ||h||_1)$. Setting $H_{s_n}(x) = \int_{1/d}^{x} \eta_{s_n}(\xi)\,d\xi$ (a primitive of η_{s_n}), it follows that

$$H_{s_n}(1/n) = H_{s_n}(u_n(t_n^{(6)})) - H_{s_n}(u_n(t_n^{(5)})) \leq \tilde{C}.$$

But

$$H_{s_n}(1/n) \geq \int_{1/d}^{1/n} F'(x)\,dx \geq F(1/n) - F(1/d) \to +\infty \quad \text{as} \quad n \to \infty,$$

and hence we have a contradiction. Thus the proposition is proved. □

Proof of Theorem 2.1. We consider (2.2) with $s = r_k$, i.e.,

$$u'' + g_{r_k}(t,u) = e(t). \tag{2.8}$$

At this point we are in the same situation as in the proof of Theorem 2.5 in [12]. This is why we prefer to give only the main lines of the proof, the details being available from [12]. We take r_k sufficiently small, so that $(1/T)\int_0^T g(t,r_k)\,dt < \bar{e}$, and in such a way that $r_k \to 0$ as $k \to \infty$. Denoting by G_{r_k} a primitive of g_{r_k} with respect to its second variable, we have that for every k we are in the situation of [12, Thm. 2.1]. Thus we can apply the Saddle Point theorem to the functional $\phi_k : H^1_{kT} \to \mathbb{R}$ defined by

$$\phi_k(u) = \int_0^{kT} \left(\frac{1}{2}(u')^2 - G_{r_k}(t,u) + eu\right)\,dt,$$

whose critical points correspond to the kT-periodic solutions of (2.8). We find that for each k there is a $\rho_k > 0$ sufficiently large and a critical point u_k of ϕ_k such that

$$\phi_k(u_k) = \inf_{\gamma\in\Gamma_k}\max_{\xi\in[-\rho_k,\rho_k]} \phi_k(\gamma(\xi)),$$

where $\Gamma_k = \{\gamma \in C([-\rho_k,\rho_k],H^1_{kT}) \mid \gamma(\pm\rho_k) = \pm\rho_k\}$. By Fatou's lemma, we have

$$\liminf_{|x|\to\infty,k\to\infty} \operatorname{sgn}(x)\int_0^T\int_0^1 g_{r_k}(t,xs)\,ds\,dt > \bar{e}\,T,$$

and since $\int_0^T G_{r_k}(t,x)\,dt = x\int_0^T\int_0^1 g_{r_k}(t,xs)\,ds\,dt$,

$$\liminf_{|x|\to\infty,k\to\infty} \int_0^T G_{r_k}(t,x)\,dt \; - \bar{e}xT = +\infty.$$

Reasoning next as in the proof of [12, Thms. 2.1 and 2.5] (see also [11]), we can show that

$$\lim_{k\to\infty} \frac{1}{k}\phi_k(u_k) = -\infty. \tag{2.9}$$

Now we can prove that the minimal periods of the kT-periodic solutions u_k tend to infinity as $k \to \infty$. If not, for a subsequence there would be a subsequence with a common period, say $\bar{k}T$. Noting that from Proposition 2.1 the set of $\bar{k}T$-periodic solutions of (2.8) is bounded in H^1_{kT}, independently of $k \geq \bar{k}$, we get a contradiction with (2.9). □

As a consequence of Theorem 2.1 we have the following (cf. [12, Cor. 2.6]).

COROLLARY 2.1. *Suppose* $g : \mathbb{R} \times (0,+\infty) \to \mathbb{R}$ *to be continuous, and that*

$$\lim_{x\to+\infty} \frac{g(t,x)}{x} = 0, \tag{m$_1$}$$

$$\limsup_{x\to0^+} xg(t,x) \leq c < 0, \tag{m$_2$}$$

uniformly with respect to t. *If moreover*

$$\bar{e} < \frac{1}{T}\int_0^T \liminf_{x\to+\infty} g(t,x)\,dt, \tag{m$_3$}$$

the conclusion of Theorem 2.1 *holds.*

If we substitute (k_4)–(k_5) with the more restrictive sign condition

$$\limsup_{x\to 0^+} g(t,x) \le c_1 < \bar{e} < c_2 \le \liminf_{x\to+\infty} g(t,x), \tag{k$'_5$}$$

uniformly with respect to t, it is possible to get more precise information about the subharmonic solutions of (2.1), as follows.

THEOREM 2.2. *Assume* (k_1), (k_2), (k_3), *and* (k'_5). *Then there exists an integer* $m^* \in \mathbb{N}$ *such that for every* $m \ge m^*$, *equation* (2.10) *has at least one positive periodic solution having minimal period* mT.

The proof of this statement is omitted since it can be achieved via the generalized Poincaré–Birkhoff fixed point theorem arguing as in [8] (proof of Theorem 1.1). On the other hand, we prefer to present a different application of this theorem to the case of two singularities in the next section.

Remark 2.1. It is possible to see that, in Theorem 2.1, we can replace conditions (k_4) and (k_5) by

(k''_4) there is a $d \ge 1$ such that $g(t,x)\mathrm{sgn}(x-1) > \bar{e}$ for all $x \in (0,1/d) \cup (d,+\infty)$;

$$\lim_{x\to+\infty}\int_0^T (G(t,x) - \bar{e}x)\,dt = +\infty; \tag{k$''_5$}$$

where G is a primitive of g with respect to the x variable. We are then led to the following.

COROLLARY 2.2. *Assume that* $g(t,x) = g(x)$ *and that the following conditions hold:*

$$\lim_{x\to+\infty}\frac{G(x)}{x^2} = 0; \tag{j$_1$}$$

(j_2) *There is a* $d \ge 1$ *such that* $g(x)\mathrm{sgn}(x-1) > \bar{e}$ *for all* $x \in (0,1/d) \cup (d,+\infty)$;

$$\lim_{x\to 0^+} G(x) = \lim_{x\to+\infty}(G(x) - \bar{e}x) = +\infty. \tag{j$_3$}$$

Then the same conclusion of Theorem 2.1 *holds.*

Remark 2.2. By a suitable change of variables, we can easily restate the analogous version of the results of this section in the case where $g(t,x)$ is defined on $\mathbb{R}\times(A,+\infty)$ or on $\mathbb{R}\times(-\infty,B)$, the singularity being at $A \in \mathbb{R}$ or at $B \in \mathbb{R}$, respectively.

3. Superlinear case and two singularities. Consider again equation

$$u'' + g(u) = e(t), \tag{3.1}$$

where $g : (A,B) \to \mathbb{R}$ is continuous and $e : \mathbb{R} \to \mathbb{R}$ is T-periodic ($T > 0$), with $e \in L^1_{\mathrm{loc}}$.

Here we suppose that

$$-\infty \le A < B \le +\infty$$

and fix any $c \in (A,B)$.

Our goal is to prove the existence of infinitely many subharmonics of any order for (3.1) with $(u(t), u'(t))$ lying in the open strip

$$\mathcal{S} := (A, B) \times \mathbb{R}$$

and giving a precise statement about the nodal properties of $u(t) - c$.

To this end we consider also the equivalent system

$$u' = v + E(t), \qquad v' = -g(u) + \bar{e}, \tag{3.2}$$

where $E(t) := \int_0^t \left(e(\xi) - \bar{e}\right) d\xi$ and $\bar{e} := (1/T) \int_0^T e(t)\, dt$. Note that $E : \mathbb{R} \to \mathbb{R}$ is continuous and T-periodic with mean value zero. Let G be a primitive of g; e.g., the one defined by

$$G(x) := \int_c^x g(s)\, ds.$$

To describe our result, we assume further the next conditions.

$$\lim_{x \to A^+} G(x) = \lim_{x \to B^-} G(x) = +\infty. \tag{i$_1$}$$

$$\lim_{x \to A^+} \frac{g(x)}{(x - c)} = \lim_{x \to B^-} \frac{g(x)}{(x - c)} = +\infty. \tag{i$_2$}$$

Remark 3.1. Note that condition (i$_2$) reads as follows:

If $A = -\infty$, then $\lim_{x \to -\infty} g(x)/x = +\infty$, while if $A \in \mathbb{R}$, then $\lim_{x \to A^+} g(x) = -\infty$.

If $B = +\infty$, then $\lim_{x \to +\infty} g(x)/x = +\infty$, while if $B \in \mathbb{R}$, then $\lim_{x \to B^-} g(x) = +\infty$.

We also observe that (i$_1$) is always satisfied at $A = -\infty$ or at $B = +\infty$ when (i$_2$) is assumed.

Finally, we remark that (i$_2$) is independent upon the choice of the point $c \in (A, B)$.

We further introduce the following terminology (see, e.g., [15, p.17]).

For $f : \mathcal{O} \to \mathcal{S}$, $\alpha \mapsto f(\alpha)$, with $\alpha \in \mathcal{O}$, where $(\mathcal{O}, \prec)$ is a directed set, we write

$$f(\alpha) \to \partial\mathcal{S}$$

if, for every compact set $\mathcal{K} \subset \mathcal{S}$, there is $\alpha_{\mathcal{K}} \in \mathcal{O}$ such that $f(\alpha) \notin \mathcal{K}$, for all $\alpha \in \mathcal{O}$ with $\alpha \succ \alpha_{\mathcal{K}}$.

The case in which $e(t)$ is a constant, and hence $E(t) \equiv 0$, can be completely analyzed in terms of energy levels arguments. Indeed, we can prove that if $\Gamma(\mathrm{z}_0)$ is the orbit of

$$u' = v, \qquad v' = -g(u) + \bar{e},$$

with $(u(0), v(0)) = \mathrm{z}_0$, then, for $\mathrm{z}_0 \to \partial\mathcal{S}$, $\Gamma(\mathrm{z}_0)$ is a periodic orbit with minimal period tending to zero. Therefore we assume henceforth that $e(t) \not\equiv \bar{e}$ on a set of positive measure, so that $E(t)$ is nonconstant and it has a positive minimal period. Without loss of generality, we can suppose that T is the minimal period of $E(t)$.

Now we are in position to state our main result.

THEOREM 3.1. *Assume* (i$_1$) *and* (i$_2$) *and let* $m \geq 1$ *be any fixed integer. Then* (3.1) *has infinitely many periodic solutions with minimal period* mT. *More precisely, for each* $m \geq 1$, *there is an integer* $\nu_m^* \geq 0$ *such that for every* $p \in \mathbb{N}$ *with* p *prime with* m *and* $p > \nu_m^*$, *equation* (3.1) *has at least one periodic solution* $u = u_{m,p}(\cdot)$, *with minimal period* mT *and such that* $u(t) - c$ *has exactly* $2p$ *simple zeros in the interval* $[0, mT)$. *Moreover,* $(u_{m,p}(t), u'_{m,p}(t)) \to \partial S$, *as* $p \to +\infty$, *uniformly with respect to* $t \in [0, mT]$.

Remark 3.2. Note that if we are interested only in the existence of T-periodic solutions, then we can apply the above theorem taking $m = 1$, and we find ν_1^* such that for every $p \in \mathbb{N}$ with $p > \nu_1^*$ there is at least one T-periodic solution $u_p(\cdot)$ with $u_p(t) - c$ having exactly $2p$ simple zeros in the interval $[0, T)$.

This remark is true even in the case when T is not the minimal period of $E(t)$; however, in such a situation, we cannot guarantee that the periodic solutions we find have T as minimal period.

The proof of Theorem 3.1 is based on W. Ding's generalized Poincaré–Birkhoff fixed point theorem [10] which provides fixed points for the Poincaré map (and its mth iterates) associated to system (3.2). To do this, we need to have such an operator well defined. Hence, a first requirement is to have the uniqueness of the solutions for the Cauchy problems associated to (3.2). This difficulty can be overcome by a standard smoothing of the field g as briefly described in [23]. Of course, then it will be necessary to prove that the fixed points related to the approximating equations are all contained in the same annulus in order to pick up a sequence of these fixed points converging to a fixed point representing the initial value of an mT-periodic solution to (3.2). Here we do not follow such a program which has been already accomplished with all the details in various preceding papers. Accordingly, from now on, *we assume the uniqueness of the solutions for the Cauchy problems associated to system* (3.2) leaving the interested reader to complete the missing details following, e.g., [7].

We also remark that if we assume condition (i$_1$)–(i$_2$) then we have that the same is satisfied for the function $g(x) - \bar{e}$. Hence, calling $g(x)$ what was written before as $g(x) - \bar{e}$ and $e(t)$ instead of $e(t) - \bar{e}$, from now on we can assume, without loss of generality, that

$$\text{(i}_0\text{)} \qquad \frac{1}{T}\int_0^T e(t)dt = 0$$

holds. Notice that system (3.2) takes now the form

$$\text{(3.3)} \qquad u' = v + E(t), \qquad v' = -g(u).$$

Our first step is to prove the global existence in the past and in the future of the solutions to (3.3). In this direction we have the following result which is proved under some more general conditions than in Theorem 3.1.

PROPOSITION 3.1. *Assume* (i$_0$), (i$_1$) *and suppose that there are constants* a, b *with* $A < a < b < B$ *such that*

$$\text{(3.4)} \qquad g(x) < 0 \quad \textit{for } A < x \leq a, \qquad g(x) > 0 \quad \textit{for } b \leq x < B.$$

Then any noncontinuable solution $z = (u, v)$ *of* (3.3) *is defined in* $(-\infty, +\infty)$.

Proof. From (i$_1$) it is clear that $G(x) \geq G_{\min} > -\infty$, for all $x \in (A, B)$.

Let $\eta : (A, B) \to \mathbb{R}$, be a C^1 function defined as follows (cf. [16, p.120]): $\eta(x) = -||E||_\infty$ for $x \in (A, a)$, $\eta(x) = ||E||_\infty$ for $x \in (b, B)$, and η increasing in $[a, b]$. We thus have that $0 \leq \eta'(x) \leq L_\eta$ for all x in (A, B), where L_η is a suitable constant depending on the function η.

Now, define $V : (A, B) \times \mathbb{R} \to \mathbb{R}$ by

$$V(x, y) := \tfrac{1}{2}(y + \eta(x))^2 + G(x) - G_{\min}.$$

It is clear that for any $D > 0$ there is a compact set $\mathcal{B}_D$ contained in $\mathcal{S}$ such that

$$(x, y) \in \mathcal{S} \setminus \mathcal{B}_D \quad \text{implies that} \quad V(x, y) > D.$$

Next, let $z(t) = (u(t), v(t))$ be a solution of (3.3) defined in a maximal interval (α, β), with $\alpha < t_0 < \beta$ and $z(t_0) \in \mathcal{S}$. For $t \in [t_0, \beta)$, we have

$$\begin{aligned}\frac{d}{dt}V(z(t)) =&[\eta'(u)(v + \eta(u)) + g(u)]u' + [v + \eta(u)]v' \\ =&\eta'(u)[v + \eta(u)]^2 + \eta'(u)[v + \eta(u)][-\eta(u) + E(t)] - g(u)[\eta(u) - E(t)].\end{aligned}$$

Noting that $-g(x)[\eta(x) - E(t)] \leq 0$ for all $x \in (A, a) \cup (b, B)$, we find that there is a constant $R_0 > 0$ such that $-g(x)[\eta(x) - E(t)] \leq R_0$ for all $x \in (A, B)$ and $t \in \mathbb{R}$.

Thus

$$\begin{aligned}\frac{d}{dt}V(z(t)) &\leq L_\eta[v + \eta(u)]^2 + 2||E||_\infty L_\eta|v + \eta(u)| + R_0 \\ &\leq \frac{3}{2}L_\eta[v + \eta(u)]^2 + R_1,\end{aligned}$$

where R_1 is a constant depending on $||E||_\infty$ and R_0. We obtain

$$\frac{d}{dt}V(z(t)) \leq 3L_\eta V(z(t)) + R_1.$$

We claim that β must be $+\infty$. Otherwise from the last inequality and Gronwall's lemma,

$$V(z(t)) \leq \left[\frac{R_1}{3L_\eta} + V(z(t_0))\right] \exp(3L_\eta(\beta - t_0)) := \text{constant} := R_2.$$

Then

$$z(t) \in \mathcal{B}_{R_2} \quad \text{for all} \quad t \in [t_0, \beta).$$

But, this contradicts the global continuation theorem and the claim is proved.

Global continuability to the left follows from the above argument and by changing $t - t_0$ for $t_0 - t$ in (3.3). □

According to Proposition 3.1 and the uniqueness assumption for the Cauchy problems, we have that any solution to (3.3) is uniquely defined on $(-\infty, +\infty)$ by its initial conditions.

Remark 3.3. It is obvious that hypothesis (i_2) implies the existence of suitable constants a and b with

$$A < a < c < b < B \tag{3.5}$$

such that (3.4) holds. *Henceforth* (3.4) *and* (3.5) (*as well as* (i_0)) *will be constantly assumed in connection with* (i_2).

We define now the compact set

$$\mathcal{M} := [a,b] \times [-||E||_\infty, ||E||_\infty]$$

and observe that $(c,0) \in \mathcal{M}$. A corollary of Proposition 3.1 is the following.

PROPOSITION 3.2. *Assume* (i_1) *and* (i_2). *Then for every compact set* $\mathcal{K} \subset \mathcal{S}$ *and each* $m \in \mathbb{N}$, *there is a compact set* $\mathcal{B} = \mathcal{B}(\mathcal{K}, m) \subset \mathcal{S}$ *with* $\mathcal{K} \subset \mathcal{B}$ *such that for each solution* $z = (u,v)$ *of system* (3.3), *the following inference holds:*

$$z(0) \notin \mathcal{B} \Rightarrow z(t) \notin \mathcal{K} \quad \forall t \in [-mT, mT].$$

In particular, for each $m \in \mathbb{N}$, *there is a compact set* $\mathcal{R}_m$ *with* $\mathcal{M} \subset \mathcal{R}_m \subset \mathcal{S}$ *such that*

$$z(0) \notin \mathcal{R}_m \Rightarrow z(t) \notin \mathcal{M} \quad \forall t \in [-mT, mT] \tag{3.6}$$

holds for any solution z *to* (3.3).

By the second part of Proposition 3.2 and (3.6) we have that given any solution $z(\cdot) = (u(\cdot), v(\cdot))$ of equation (3.3) with $z(0) \notin \mathcal{R}_m$, it follows that if $t \in [0, mT]$ is such that $u(t) - c = 0$, or, respectively, $v(t) = 0$, then $u'(t) \neq 0$, respectively, $v'(t) \neq 0$. Then, according to [5], we can define the *rotation number* $\psi_m(u)$ as

$$\psi_m(u) = k\pi + \lim_{t \to 0^+} \tan^{-1}\left(\frac{v(t)}{u(t) - c}\right) - \lim_{t \to mT^-} \tan^{-1}\left(\frac{v(t)}{u(t) - c}\right), \tag{3.7}$$

where k is the number of zeros of $u(t) - c$ in $(0, mT)$. Geometrically, $\psi_m(u)$ represents the total angle the vector from the origin to the point $(u(t) - c, v(t))$ describes as t goes from zero to mT, positive angles measured clockwise.

On the other hand, if $z(0) \notin \mathcal{R}_m$, then $z(t) \neq (c,0)$, for all $t \in [0, mT]$ and therefore we can use polar coordinates with center in $(c,0)$ to express $z(t)$ via Prüfer transformation as

$$u(t) = c + \rho(t)\cos\theta(t), \qquad v(t) = \rho(t)\sin\theta(t).$$

By standard facts,

$$-\theta'(t) = \frac{g(u(t))(u(t) - c) + v(t)^2 + E(t)v(t)}{(u(t) - c)^2 + v(t)^2} \tag{3.8}$$

and by the definition of the rotation number, we have

$$\theta(0) - \theta(mT) = \psi_m(u). \tag{3.9}$$

We recall that, from Proposition 3.1 and the uniqueness of the solutions to the Cauchy problems associated to system (3.3), we have that for every $\mathrm{z}_0 = (\mathrm{x}_0, \mathrm{y}_0) \in \mathcal{S}$ there is a unique solution $z(t) = z(t; \mathrm{z}_0) = \big(u(t; \mathrm{z}_0), v(t; \mathrm{z}_0)\big)$ of (3.3) with $z(0) = \mathrm{z}_0$, which is defined on $\mathbb{R}$. Hence the Poincaré map

$$\phi : \mathcal{S} \to \mathcal{S}, \qquad \phi(\mathrm{z}_0) := z(T; \mathrm{z}_0)$$

is defined and it is continuous on $\mathcal{S}$. By the Liouville theorem it follows that ϕ is an area—preserving homeomorpism of the strip $\mathcal{S}$ onto itself. Clearly, all of these properties of ϕ hold true for any of the maps

$$\phi^k : \mathcal{S} \to \mathcal{S}, \quad \phi^k(\mathrm{z}_0) := z(kT; \mathrm{z}_0), \quad k \in \mathbb{Z}.$$

In particular, we note that z_0 is the initial point of a mT-periodic solutions $z(\cdot)$ of (3.3), with $m \in \mathbb{N}$, if and only if z_0 is a fixed point of the mth iterate ϕ^m of the Poincaré map ϕ.

A consequence of Proposition 3.2 which is crucial for the next application of the Poincaré–Birkhoff theorem is given by

$$\phi^{-m}((c,0)) = (\phi^m)^{-1}((c,0)) \in \mathcal{R}_m. \tag{3.10}$$

Finally, we set

$$\Psi_m(\mathrm{z}_0) := \frac{\psi_m(u(\cdot;\mathrm{z}_0))}{2\pi} \quad \text{for } \mathrm{z}_0 \in \mathcal{S} \setminus \mathcal{R}_m$$

and observe that the map

$$\Psi_m : \mathrm{dom}\Psi_m \supset \mathcal{S} \setminus \mathcal{R}_m \to \mathbb{R}$$

is continuous. Notice that if $u(\cdot;\mathrm{z}_0)$ is mT-periodic, then

$$\#_m u = 2\Psi_m(\mathrm{z}_0), \tag{3.11}$$

where $\#_m u$ is the number of zeros of $u(t) - c$ in the interval $[0, mT)$. In this case, the simplicity of the zeros of $u(t) - c$ implies that $\#_m u$ is always an even number.

With the above notation, we can prove the next result.

PROPOSITION 3.3. *Assume* (i$_1$), (i$_2$). *Then*

$$\Psi_m(\mathrm{z}_0) \to +\infty \quad \textit{as } \mathrm{z}_0 \to \partial\mathcal{S}.$$

Proof. In order to simplify the notation in the proof, we choose $c = (a+b)/2$.

From assumption (i$_2$) and (3.5), for any constant $R > 0$ we can find two numbers, d_R^- and d_R^+, with

$$A < d_R^- < a < c < b < d_R^+ < B$$

such that

$$g(x)(x-c) \geq 3R(x-c)^2 \quad \text{for all} \quad x \in (A, d_R^-] \cup [d_R^+, B).$$

Moreover, we can assume without loss of generality, by taking d_R^- smaller and d_R^+ larger, if necessary, that

$$\mathcal{R}_m \subset (d_R^-, d_R^+) \times \mathbb{R}.$$

Thus, for $x \in (A, d_R^-] \cup [d_R^+, B)$, and by choosing $R \geq \frac{1}{2}(2||E||_\infty/b-a)^2$, we have

$$\begin{aligned} g(x)(x-c) + y^2 + E(t)y &\geq 3R(x-c)^2 + \frac{1}{2}y^2 - \frac{1}{2}||E||_\infty^2 \\ &\geq 2R(x-c)^2 + \frac{1}{2}y^2 + R\left(\frac{b-a}{2}\right)^2 - \frac{1}{2}||E||_\infty^2 \\ &\geq 2R(x-c)^2 + \frac{1}{2}y^2. \end{aligned}$$

Now let us take $\gamma_R > 0$ so that

$$g(x)(x-c) \geq 3R(x-c)^2 - \gamma_R \quad \text{for all} \quad x \in (A,B).$$

Thus, for every $x \in [d_R^-, d_R^+]$, we obtain

$$g(x)(x-c) + y^2 + E(t)y \geq 2R(x-c)^2 + \tfrac{1}{2}y^2,$$

provided that $|y| \geq ||E||_\infty + (||E||_\infty^2 + 2\gamma_R)^{\frac{1}{2}} := D_R$.

In conclusion from this last argument, from Proposition 3.2, and from (3.8) we have that for all $m \in \mathbb{N}$, for all $R > 0$, there is a compact set $\mathcal{W}(R,m) \supset [d_R^-, d_R^+] \times [D_R^-, D_R^+]$ such that

$$\mathcal{R}_m \subset \mathcal{W}(R,m) \subset \mathcal{S}$$

and if $z(0) \in \mathcal{S} \setminus \mathcal{W}(R,m)$, then $z(t) \notin [d_R^-, d_R^+] \times [D_R^-, D_R^+]$ for $t \in [-mT, mT]$, and

$$-\theta'(t) \geq \frac{2R(u(t)-c)^2 + \frac{1}{2}v(t)^2}{(u(t)-c)^2 + v(t)^2}.$$

Thus, if $z(0) \notin \mathcal{W}(R,m)$ and $t \in [-mT, mT]$, we obtain

$$\frac{-\theta'(t)}{2R\cos^2\theta(t) + \frac{1}{2}\sin^2\theta(t)} \geq 1,$$

that implies

$$\int_{\theta(mT)}^{\theta(0)} \frac{d\theta}{2R\cos^2\theta + \frac{1}{2}\sin^2\theta} \geq mT$$

(see [3] for analogous computations). Using the fact that

$$\int_0^{2\pi} \frac{d\theta}{2R\cos^2\theta + \frac{1}{2}\sin^2\theta} = \frac{2\pi}{\sqrt{R}}$$

and recalling that

$$\frac{\theta(0) - \theta(mT)}{2\pi} \leq k+1,$$

where k denotes here the integer part of $\Psi_m(z(0))$, we obtain

$$k + 1 \geq mT\sqrt{R}/2\pi$$

and hence

$$\Psi_m(z(0)) \geq \left(mT\sqrt{R}/2\pi\right) - 1.$$

Letting R go to $+\infty$, we end the proof of the proposition. □

At this point we have all the tools to prove Theorem 3.1.

Proof of Theorem 3.1. We define the function

$$W : \mathcal{S} \to \mathbb{R}, \qquad W(x,y) := G(x) + \tfrac{1}{2}y^2$$

and observe that from (i$_1$) and (3.4) it follows that there is a constant $L_m > 0$ such that, for each $L \geq L_m$, the set $W^{-1}(L)$ is a simple closed curve which is star-shaped with respect to the point $(c, 0)$ and it is contained in $\mathcal{S} \setminus \mathcal{R}_m$. Then, for any r_1, r_2 with $L_m \leq r_1 < r_2$, we can consider the annulus

$$\mathcal{A} = \mathcal{A}(r_1, r_2) := \{(x, y) \in \mathcal{S} \mid r_1 \leq W(x, y) \leq r_2\} = W^{-1}\big([r_1, r_2]\big)$$

and the inner disc

$$\mathcal{D} = \mathcal{D}(r_1) := \{(x, y) \in \mathcal{S} \mid W(x, y) < r_1\} = W^{-1}\big((-\infty, r_1)\big).$$

By the choice of r_1 and r_2 we have that the boundary of $\mathcal{A}$ is the union of two simple closed curves $\partial^-\mathcal{A}$ and $\partial^+\mathcal{A}$, named respectively *the inner boundary* and *the outer boundary* of $\mathcal{A}$, such that

$$\partial\mathcal{D} = \partial^-\mathcal{A} = W^{-1}(r_1)$$

is star-shaped around $(c, 0)$. Moreover, as $\mathcal{D} \supset \mathcal{R}_m$, from (3.10) we obtain

$$(c, 0) \in \phi^m(\mathcal{D}).$$

Now we argue as follows.

At first we fix any constant $r = r(m) \geq L_m$ and, using the continuity of Ψ_m, define

$$\nu_m^* := \operatorname{int}\left[\max\{\Psi_m(\mathrm{z}_0) \mid \mathrm{z}_0 \in \partial\mathcal{D}(r)\}\right], \tag{3.12}$$

where $\operatorname{int}[\xi]$ denotes the integer part of the number $\xi \in \mathbb{R}$.

Second, we choose any number $p \in \mathbb{N}$, with p prime with m and

$$p > \nu_m^*. \tag{3.13}$$

Then, using Proposition 3.3 and the continuity of Ψ_m, we can find another constant $R = R(m, p)$ with $R > r$ such that

$$\min\{\Psi_m(\mathrm{z}_0) \mid \mathrm{z}_0 \in W^{-1}(R)\} > p. \tag{3.14}$$

Now we observe that (3.12), (3.13), and (3.14) imply that on the boundaries of the annulus

$$\mathcal{A} = \mathcal{A}(r, R),$$

the twist condition

$$\Psi_m(\mathrm{z}_0) < p \quad \text{for } \mathrm{z}_0 \in \partial^-\mathcal{A}, \qquad \Psi_m(\mathrm{z}_0) > p \quad \text{for } \mathrm{z}_0 \in \partial^+\mathcal{A}$$

is satisfied.

Thus we have met all the conditions in order to apply W. Ding's generalization of the Poincaré–Birkhoff fixed point theorem [10] and hence we can conclude that the map ϕ^m has a fixed point, say $\mathrm{z}_{m,p}^*$, belonging to the annulus $\mathcal{A}$. Furthermore, we also obtain

$$\Psi_m\big(\mathrm{z}_{m,p}^*\big) = p. \tag{3.15}$$

The continuity of Ψ_m implies that $\Psi_m\big(\mathrm{z}_0\big)$ is bounded for z_0 belonging to a compact subset of $\mathcal{S} \setminus \mathcal{R}_m$, thus, as

$$\Psi_m\big(\mathrm{z}_{m,p}^*\big) \to +\infty$$

for $p \to +\infty$, we have

$$\mathrm{z}^*_{m,p} \to \partial\mathcal{S} \quad \text{as} \quad p \to +\infty.$$

This last property, in connection with Proposition 3.2, finally implies that

$$\left(u^*_{m,p}(t), \frac{d}{dt}u^*_{m,p}(t)\right) \to \partial\mathcal{S} \quad \text{as} \quad p \to +\infty,$$

uniformly with respect to $t \in [0, mT]$, where $(u^*, v^*) = z^*$ is the solution to (3.3) starting at $\mathrm{z}^* = \mathrm{z}^*_{m,p}$ at the time $t = 0$.

Our last goal now is to prove that the solution we find does have minimal period mT. To this aim it is sufficient to prove that

$$\phi^k\left(\mathrm{z}^*_{m,p}\right) \neq \mathrm{z}^*_{m,p} \quad \text{for each} \quad 1 \leq k \leq m-1,$$

holds.

Assume by contradiction (cf. [7, §6]) that there is some k with $1 \leq k < m$ such that $\mathrm{z}^* = \mathrm{z}^*_{m,p}$ is a fixed point of ϕ^k. Then, by (3.9), (3.11), and the definition of Ψ_m, we obtain that

$$\exists\, \ell \in \mathbb{N},\ \ell < p: \quad \Psi_k(\mathrm{z}^*) = \ell.$$

Observing now that

$$(\phi^m)^k(\mathrm{z}^*) = (\phi^k)^m(\mathrm{z}^*) = \mathrm{z}^*,$$

we have

$$pk = \Psi_{m\cdot k}(\mathrm{z}^*) = \ell m$$

which yields

$$\frac{m}{p} = \frac{k}{\ell},$$

a contradiction with the assumption that p is prime with m.

In conclusion, we observe that if the local uniqueness of the solutions for the Cauchy problems associated to (3.3) is not guaranteed, we have to repeat the above argument for a sequence of approximating equations of the form

$$u' = v + E(t), \qquad v' = -g_n(u),$$

where $g_n : (A, B) \to \mathbb{R}$ is smooth and $g_n \to g$ uniformly on compact sets. It is possible to check that, for n sufficiently large, all the fixed points of the iterates of the Poincaré operator of the approximating equations belong to the same annulus $\mathcal{A}$ and the rotation number Ψ_m of all these fixed points is the same and equal to p. Hence we can pass to the limit for a subsequence and get a fixed point of ϕ^m (which now could be a multivalued function). For the missing technical details concerning such an approximation approach, we refer the reader to [7, §6].

At this step, all the assertions in Theorem 3.1 are justified and the proof is now complete. □

4. Examples. In this section we consider two examples for the applicability of our main results.

First, we examine the case with one singularity at a point $A \in \mathbb{R}$.

Example 4.1. Let an electric charge Q be placed at the fixed point $A \in \mathbb{R}$ and suppose that $y > A$ (or $y < A$) denotes the position of an electric charge q, having the same sign of Q, which lives in a one-dimensional space.

The Coulombian force h acting on q at time t is given by

$$h(y(t)) = \kappa q Q \frac{y(t) - A}{|y(t) - A|^3} := \kappa_0 \frac{y(t) - A}{|y(t) - A|^3},$$

where κ is a suitable constant and $\kappa_0 = \kappa q Q > 0$.

Let $e : \mathbb{R} \to \mathbb{R}$ be a T-periodic external forcing term acting on the system. We assume that $e \in L^1_{\mathrm{loc}}$ and denote by $\bar{e} = \frac{1}{T} \int_0^T e(s)\, ds$ the mean value of the function e.

Then the Newton law for the dynamics of the charge q yields the following differential equation (unitary mass is assumed).

$$y''(t) = h(y(t)) + e(t). \tag{4.1}$$

Now, from Theorem 2.1, we have the following proposition.

PROPOSITION 4.1. *Equation* (4.1) *has periodic solutions if and only if* $\bar{e} \neq 0$. *If* $\bar{e} < 0$ (*respectively,* $\bar{e} > 0$), *all periodic solutions of* (4.1) *lie in* $(A, +\infty)$ (*respectively,* $(-\infty, A)$), *and besides having at least one T-periodic solution,* (4.1) *also has subharmonic solutions with minimal period mT, for every sufficiently large integer m.*

Proof. We rewrite (4.1) as

$$u''(t) + g(u(t)) = e(t), \tag{4.2}$$

with $u(t) = y(t) - A$ and $g(x) := -h(x + A)$. Let G be a primitive of g, e.g.,

$$G(x) = \frac{\kappa_0}{|x|}.$$

Note that

$$\lim_{|x| \to \infty} g(x) = 0, \qquad \lim_{|x| \to \infty} \frac{G(x)}{x^2} = 0 \tag{4.3}$$

and that

$$\lim_{x \to 0} g(x) \mathrm{sgn}(-x) = \lim_{x \to 0} G(x) = +\infty. \tag{4.4}$$

At first we claim that $\bar{e} \neq 0$ is a necessary condition. This follows from [17]. Namely, assume for instance that (4.2) has a τ-periodic solution $\tilde{u}(t)$, with $\tilde{u}(t) > 0$ for all $t \in \mathbb{R}$. Integrating both sides of (4.2) on the interval $[0, \tau]$, we obtain

$$\frac{1}{\tau} \int_0^\tau g(\tilde{u}(t))\, dt = \frac{1}{\tau} \int_0^\tau e(t)\, dt = \bar{e}.$$

Since $g(x) < 0$ for all $x > 0$, we obtain $\bar{e} < 0$. Analogously, if (4.2) has a negative solution, $\bar{e}$ has to be positive. Thus the claim is achieved.

Now, we suppose $\bar{e} < 0$, According to (4.3) and (4.4) all the assumptions of Theorem 2.2 are satisfied and we conclude with the result. If $\bar{e} > 0$, we can reduce by a change of variables to the previous case (see Remark 2.2). □

Next we present an example with two singularities.

Example 4.2. Let Q_1 and Q_2 be two electric charges placed at the fixed points $A \in \mathbb{R}$ and $B \in \mathbb{R}$ with $A < B$. Suppose that u, with $A < u < B$ denotes the position of an electric charge q where we assume that Q_1, Q_2 and q have all the same sign.

Now the Coulombian force l acting on q at the time t takes the form

$$\begin{aligned} l(u(t)) &= \kappa\frac{qQ_1}{(u(t)-A)^2} - \kappa\frac{qQ_2}{(u(t)-B)^2} \\ &= \frac{\kappa_1}{(u(t)-A)^2} - \frac{\kappa_2}{(u(t)-B)^2}, \end{aligned}$$

where $\kappa_i = \kappa q Q_i > 0$ for $i = 1, 2$.

Let $e : \mathbb{R} \to \mathbb{R}$ be a T-periodic forcing term as above and consider the differential equation

$$u''(t) = l(u(t)) + e(t). \tag{4.5}$$

We assume also that $\int_0^t (e(s) - \bar{e})\, ds$ is not constant. Then from Theorem 3.1 we have the following proposition.

PROPOSITION 4.2. *For every $m \geq 1$, equation* (4.5) *has infinitely many mT-periodic solutions lying in (A, B), all having minimal period mT.*

Proof. We write (4.5) as

$$u''(t) + g(u(t)) = e(t). \tag{4.6}$$

with $g(x) := -l(x)$. Note that

$$\lim_{x\to A^+} g(x) = -\infty, \qquad \lim_{x\to B^-} g(x) = +\infty$$

and

$$\lim_{x\to A^+} G(x) = \lim_{x\to B^-} G(x) = +\infty,$$

where, for a fixed $c \in (A, B)$,

$$G(x) = \int_c^x g(s)\, ds = \frac{\kappa_1}{x-A} + \frac{\kappa_2}{B-x} - \frac{\kappa_1}{c-A} - \frac{\kappa_2}{B-c}.$$

Since $e(t)$ is T-periodic and nonconstant, its minimal period equals to T/γ, for some $\gamma \in \mathbb{N}$. We apply now Theorem 3.1 and have that for every $m \geq 1$ equation (4.6) has at least infinitely many periodic solutions having $mT = m\gamma(T/\gamma)$ as minimal period. □

Remark 4.1. Since the nonlinearities in the above examples are locally Lipschitz continuous, arguing as in [21] we could claim that for any subharmonic solution we found there is a second one with the same minimal period and the same number of zeros, which is not a shift of the previous one.

BOUNDEDNESS OF PRIME PERIODS OF STABLE CYCLES AND CONVERGENCE TO FIXED POINTS IN DISCRETE MONOTONE DYNAMICAL SYSTEMS*

PETER HESS† AND PETER POLÁČIK‡

Abstract. In this paper the boundedness of minimal periods of linearly stable cycles for discrete, strongly order-preserving semigroups $(F_0^n)_{n\in\mathbb{N}}$ in bounded subsets of an ordered Banach space is proved. It is further shown that this bound is not increased by small perturbations of F_0. Of particular interest is the case where the only linearly stable cycles of F_0 are fixed points. Employing a recent result of Poláčik and Tereščák, the typical convergence of relatively compact orbits and for perturbed systems then follow. The results are applied to classes of time-periodic reaction-diffusion equations and give typical convergence to periodic solutions.

Key words. discrete monotone dynamical systems, linearly stable cycles, Lyapunov exponents, center manifold theorem, Krein–Rutman theorem, periodic reaction-diffusion equations, generic convergence

1. Introduction. In the recent paper [PT1], Poláčik and Tereščák address the question of the typical asymptotic behavior of orbits in strongly monotone discrete-time dynamical systems. In contrast to the continuous-time case, where a rather complete description of the typical behavior of trajectories is available (see [Hi1], [Hi3], [Ma], [ST1], [ST2], [Sm], [T2], [P1], [P2], [Mi1], or the introduction of [PT1] for a brief discussion of these results), [PT1] seems to be the first paper that provides an answer to this question for a rather general class of smooth ($C^{1,\alpha}$) discrete systems. The authors prove that a typical trajectory (i.e., a trajectory emanating from a residual set of initial conditions) of such a discrete system converges to a linearly stable cycle. (Here cycle refers to the orbit of a periodic point, and linearly stable means that the spectrum of the linearization of an appropriate iterate of the mapping lies in the closed unit disc in $\mathbb{C}$; see §2 for the precise definition.) This result applies to dynamical systems generated by the period map of many types of periodically forced differential equations, including scalar parabolic equations and cooperative systems of parabolic equations on bounded domains, and to cooperative systems of ODEs.

It is known that, unless severe restrictions (like those in [AH1], [AH2], [AHM], [Hs1], [Hs2], [T1], [T5]) are imposed, the result of [PT1] cannot be improved as to assert typical convergence to fixed points rather than to cycles. Counterexamples can be found in [DH], [T3], [T4]. However, an improvement is possible. We show here that one can establish typical convergence to a fixed point for a certain iterate F_0^m of the mapping F_0 in question. This is true at least for any bounded set in the state space (with m depending on this set). Specifically, we prove that for any bounded set B,

the set of minimal periods of linearly stable cycles contained in B is bounded. This, in conjunction with the result of [PT1], implies the above improvement.

We obtain boundedness of the minimal periods of linearly stable cycles (below such periods are called stable periods) as a by-product in proving a certain perturbation result. Roughly speaking, this result says that for any bounded domain B, the maximal stable period of F_0 in B is not increased by a small perturbation of F_0. More precisely, if $F_\varepsilon, \varepsilon \in \mathbb{R}$, is a family of mappings, satisfying the hypotheses of §2, then the maximal stable period of F_0 (in B) is not less than the maximal stable period of F_ε for any ε sufficiently close to zero.

This result is of particular interest in case F_0 does not have stable periods greater than 1 (i.e., all linearly stable cycles are fixed points of F_0). It is well known (see [Hs2, Prop. 9.4]) that this situation occurs when F_0 is a time-t map of a strongly monotone semiflow. Thus our perturbation result can be applied to small time-periodic perturbations of autonomous equations that generate a strongly monotone semiflow (see §5 for an example). Moreover, there are several different classes of discrete dynamical systems that are known not to have higher stable periods. We discuss two such classes and their perturbations in §5.

Our main results and some immediate consequences are stated in §2. Section 3 gives a preparation for the proofs of the main results which are then carried out in §4.

2. Statement of the main results.

In the whole paper X is a strongly ordered Banach space with norm $\|\cdot\|$ and order cone X_+. By an order cone we mean a closed convex cone such that $X_+ \cap (-X_+) = \{0\}$, and X being strongly ordered requires $\operatorname{int} X_+$, the interior of X_+, to be nonempty. For $x, y \in X$ we write

$$\begin{aligned} x &\le y && \text{if } y - x \in X_+, \\ x &< y && \text{if } x \le y \quad \text{and} \quad x \ne y, \\ x &\ll y && \text{if } y - x \in \operatorname{int} X_+. \end{aligned}$$

The reversed signs are used in the usual way. A mapping $h : X \to X$ is called monotone if $x \le y$ implies $h(x) \le h(y)$.

We can now formulate our hypotheses.

(H) For each $\varepsilon \in J$, where $J = [-\delta, \delta]$ is an interval in $\mathbb{R}, F_\varepsilon : X \to X$ is a compact monotone mapping such that the following properties hold:

(a) $F : (\varepsilon, x) \mapsto F_\varepsilon(x) : J \times X \to X$ is of class C^1;

(b) $F_0 : X \to X$ is of class $C^{1,\theta}$ (C^1 with locally θ-Hölder continuous derivative), $\theta \in (0, 1]$, and it is one-to-one. For any $x \in X$ the differential $d_x F_0 = F_0'(x)$ is a strongly positive operator (i.e., $v > 0$ implies $d_x F_0 v \gg 0$).

Notice that compactness of each F_ε (by which we mean that each bounded set is mapped onto a relatively compact set), in conjunction with (H)(a), implies that $F : J \times X \to X$ is a compact map.

Below, several results of [PT1] are applied to F_0. To justify this, we make a few comments on the hypotheses imposed on F_0.

The standing hypotheses of [PT1], see p. 340, are identical to our (H)(b) without the assumption of F_0 being one-to-one. There is another hypothesis, existence of continuous separation along any compact set invariant under F_0 (see [PT1, p. 344]), which (or whose weaker form) is used at various places in [PT1]. However, as was shown in [PT2], this hypothesis follows from (H)(b)—the injectivity assumption is essential for this. We can thus use the results of [PT1] freely.

For the formulation of our results we need some more definitions. Let $h : X \to X$ be a C^1-map (below we always consider $h = F_0$ or $h = F_\varepsilon$). A point $x \in X$ is a *periodic point of* h if $h^k(x) = x$ for some natural number k, which is then a *period* for x. If it is the minimal period, i.e., if $h^m(x) \neq x$ for $m = 1, \dots, k-1$, we call x *k-periodic.* A k-periodic point x is said to be *linearly stable* if the spectrum of the operator $d_x h^k$ is contained in the closed unit disc in $\mathbb{C}$. Note that "linearly stable" refers only to the location of the spectrum and such a point may be unstable for the dynamical system defined by h. A more precise expression would be "linearly stable or linearly neutrally stable." For brevity, we use the former expression throughout.

Let $B \subset X$. We say that k is a *stable period* for the restriction $h|\hat{B}$ if there is a linearly stable k-periodic point x of h such that the orbit $O(x,h) := \{h^n(x) : n = 0, 1, \dots\} = \{h^n(x) : n = 0, 1, \dots, k-1\}$ is contained in B. If $B = X$ we simply say that k is a stable period for h. Similarly as for the orbits $O(x,h)$, we always indicate to which map the dynamical notions refer. We, e.g., write

$$\omega(x,h) := \{y \in X : \text{ there is a sequence } n_j \to +\infty \text{ such that } h^{n_j}(x) \to y\}$$

for the *ω-limit set* of x with respect to h.

Our main theorems can now be formulated as follows.

THEOREM 1. *Let* (H)(b) *hold. Let $B \subset X$ be a closed bounded set. Then there exists a constant m such that the set of stable periods of $F_{0|B}$ is bounded above by m.*

THEOREM 2. *Let* (H) *hold. Let $B \subset X$ be a closed bounded set. Suppose that all the stable periods of $F_{0|B}$ are bounded above by m. Then there exists a $\delta_0 > 0$ such that for any $\varepsilon \in [-\delta_0, \delta_0]$ all the stable periods of $F_{\varepsilon|B}$ are bounded by m.*

The following result is an important particular case of Theorem 2.

COROLLARY 3. *Let* (H) *hold. Suppose that all linearly stable periodic points of F_0 are fixed points of F_0 (i.e., there are no stable periods for F_0 larger than* 1). *Then, given any closed bounded set B, there exists a $\delta_0 > 0$ such that for any $\varepsilon \in [-\delta_0, \delta_0]$ all linearly stable periodic points of $F_{\varepsilon|B}$ are fixed points of F_ε.*

Of course if it is known a priori that all periodic points of F_ε lie in a fixed bounded set, then the statement of this corollary holds for $B = X$.

Theorem 1 allows for an improvement of the result on generic convergence to cycles proved by Poláčik and Tereščák [PT1, Thm. 5.1]. This result says that in any open bounded set $\mathcal{G}$ positively invariant under F_0, there is an open dense subset of points whose ω-limit sets are linearly stable cycles. This and Theorem 1 (applied to $\overline{\mathcal{G}}$) immediately give the following.

COROLLARY 4. *Let* (H)(b) *hold. Let $\mathcal{G}$ be an open bounded set positively invariant under F_0 (i.e., $F_0\mathcal{G} \subset \mathcal{G}$). Then there is an m such that the set*

$$\{x \in \mathcal{G} : \omega(x, F_0) \textit{ is a cycle of period at most } m\}$$

contains an open and dense subset of $\mathcal{G}$.

Here cycle of period k means the orbit of a k-periodic point.

Finally, we formulate a theorem which implies that in the class of mappings satisfying (H)(b) generic convergence is an open property. A point $x \in X$ is said to be *convergent* for h if $h^n(x)$ converges, as $n \to +\infty$, to a $z \in X$. Another way to say this is that the orbit $O(x,h)$ is relatively compact and $\omega(x,h)$ consists of a single point z, which is necessarily a fixed point of h.

COROLLARY 5. *Let* (H) *hold. In addition suppose that* (H)(b) *holds with F_0 replaced by F_ε for any $\varepsilon \in [-\delta, \delta]$. Let $\mathcal{G}$ be an open bounded set such that for each $\varepsilon \in [-\delta, \delta]$ all the orbits $O(x, F_\varepsilon), x \in \mathcal{G}$, lie in a ball D independent of ε. Finally,* *suppose that all linearly stable periodic points of $F_0|_{\overline{D}}$ are fixed points. Then there exists a $\delta_0 > 0$ such that for any $\varepsilon \in [-\delta_0, \delta_0]$ the set*

$$\{x \in \mathcal{G} : x \textit{ is convergent for } F_\varepsilon\}$$

contains an open and dense subset of $\mathcal{G}$.

This result follows from [PT1, Thm. 5.1] applied to F_ε and from the fact that all stable periods of F_ε for ε near zero equal 1 (cf. Theorem 2).

An important example of F_0 which satisfies the requirement that all linearly stable periodic points are fixed points is the time-one map of a strongly monotone (continuous-time) semiflow [Hs2, Prop. 9.4]). Thus Corollary 5 can be applied to small nonautonomous time-periodic perturbations of an autonomous differential equation generating a strongly monotone semiflow. A different type of application we present in §5 establishes generic convergence for equations which are perturbations of some equations taken in a special class where generic convergence is known to hold. Such perturbations are allowed to fall outside this special class.

The proofs of Theorems 1, 2 consist of the following two steps: (I) localization, (II) local bifurcation.

In the first step, the localization, we prove that any sequence p_n of linearly stable periodic points of $F_{\varepsilon_n|B}$ with $\varepsilon_n \to 0$ (in particular one can take $\varepsilon_n = 0$) contains a subsequence p_{n_j} such that

$$\operatorname{dist}(O(p_{n_j}, F_{\varepsilon_{n_j}}), \qquad O(z, F_0)) \to 0 \quad \text{as } j \to +\infty.$$

Here z is a linearly stable periodic point for F_0 and dist is as in (4.3) below. So for this subsequence, the orbit of p_{n_j} is as close to the orbit $O(z, F_0)$ as we wish if j is large enough.

In the second step, we then consider such a local situation and prove that for large j the minimal period of p_{n_j} cannot be larger than that of z. This will conclude the proof of Theorem 2 and also the proof of Theorem 1 because this shows that there cannot be a sequence of stable periods for $F_{0|B}$ converging to $+\infty$.

In the first step investigation of a "limit set" of $O(p_\varepsilon, F_\varepsilon)$ as $\varepsilon \to 0$ and Lyapunov exponents for points in this limit set are the crucial ingredients.

The second step is just a combination of the center manifold theorem and the Krein–Rutman theorem.

We carry out the two steps after the following preliminary section.

3. Preliminaries. In this section we fix notation and prove or recall some basic assertions needed in the sequel. Let $h : X \to X$ be a C^1-map. If $x \in X$ and the orbit $O(x,h)$ is relatively compact, then the ω-limit set $\omega(x,h)$ is a nonempty, compact set invariant under h. If h has strongly positive differentials, i.e., $d_x hv = h'(x)v \gg 0$ for any $x \in X, v > 0$ (which is the case for $h = F_0$), then $\omega(x,h)$ is an *unordered set.* More precisely, there are no two points $z, y \in \omega(x,h)$ with $z < y$. This is a general property valid for any *strongly monotone* mapping, that is a mapping which takes related points $x < y$ onto strongly relaxed points $h(x) \ll h(y)$ (see [T1], [T5], [Hi2]). A mapping h with strongly positive differentials is strongly monotone. To see this one just observes that for any $x < y$ the curve $\{h(x + s(y-x)) : \ s \in (-1,2)\}$ is at any of its points z tangent to $d_z h(y-x) \gg 0$, hence any two distinct points on this curve are related by $\ll$.

A consequence of this unorderedness property of the ω-limit sets is that if x is a periodic point for a strongly monotone map h, then $O(x,h)$, which equals $\omega(x,h)$, does not contain two related points. This property of periodic points remains valid under the weaker assumption that h is merely monotone (not necessarily strongly). This can be proved as follows; cf. [Hi4, Prop. 0(a)]. Suppose that x is a k-periodic point of h and that $O(x,h)$ contains two related points, i.e.,

$$h^{m+r}x < h^m x$$

for some $m \in \{0,1,\dots\}$ and $r \in \{1,\dots,k-1\}$. Then by [Hi2, Prop. 6.1], $\omega(h^m x, h)$ is a cycle with the minimal period at most r. This is a contradiction because $\omega(h^m x, h) = O(x,h)$ and r is less than k, the minimal period of x.

Unorderedness of cycles will be later used for $h = F_\varepsilon$. We will also use the fact that if h is C^1 and monotone, then $d_x h$ is a positive linear operator for any x. Indeed, for any $v \geq 0$ one has

$$d_x h v = \lim_{s \to 0+} \frac{h(x+sv) - h(x)}{s} \geq 0$$

by monotonicity of h and closedness of the relation $\geq$. This of course implies that $d_x h^n$ is positive for any $x \in X$ and $n = 0,1,2,\dots$.

For any $x \in X, v \in X$ we define

$$\lambda(x,v,h) = \limsup_{n \to +\infty} \frac{\log \|d_x h^n v\|}{n} \tag{3.1}$$

and

$$\lambda_1(x,h) = \sup_{\substack{v \in X \\ v \neq 0}} \lambda(x,v,h).$$

We call $\lambda_1(x,h)$ the first *Lyapunov exponent* of x (with respect to h). This is a slight abuse of language because in general one does not know if $\lambda_1(x,h) = \lambda(x,h,v)$ for some v (which is a Lyapunov exponent in the usual terminology). For $h = F_0$, the hypothesis (H)(b) implies that $\lambda_1(x,F_0) = \lambda(x,v,F_0)$ for any $v > 0$ (see [PT1, §3]; for a general background in Lyapunov exponents see [M1], [M2]).

If x is a k-periodic point of h and h is compact (as is the case for $h = F_\varepsilon$), then

$$\lambda_1(x,h) = \frac{1}{k} \log \operatorname{spr}(d_x h^k), \tag{3.2}$$

where $\operatorname{spr}(d_x h^k)$ is the spectral radius of $d_x h^k$. Moreover,

$$\lambda_1(x,h) = \lambda(x,h,v), \tag{3.3}$$

where v is an eigenvector (or the real part of an eigenvector) corresponding to any eigenvalue μ with $|\mu| = \operatorname{spr}(d_x h^k)$. These properties follow from the equality

$$d_x h^{mk+r} = d_x h^r d_x h^{mk} = (d_x h^r)(d_x h^k)^m \tag{3.4}$$

obtained by the chain rule and periodicity of x. Indeed, substituting (3.4) in (3.1) with $n = km + r, m \in \{0,1,\dots\}, r \in \{0,1,\dots,k-1\}$ and using the fact that r varies in a finite set, we obtain

$$\lambda(x,v,h) \leq \frac{1}{k} \log \operatorname{spr}(d_x h^k) \tag{3.5}$$

for any $v \neq 0$. Therefore, $\lambda_1(x,h)$ is not larger than this logarithm. On the other hand, if v is the real part of an eigenvector as above, then

$$\begin{aligned}\lambda(x,v,h) &\geq \limsup_{m\to\infty} \frac{\log \|(d_x h^k)^m v\|}{km} \\ &\geq \frac{1}{k}\log|\mu| = \frac{1}{k}\log \operatorname{spr}(d_x h^k).\end{aligned}$$

This and (3.5) imply (3.2) and (3.3).

By (3.2), a periodic point x of h is linearly stable if and only if

$$\lambda_1(x,h) \leq 0.$$

Below we consider only compact mappings $h = F_\varepsilon$, and we use the latter equivalent definition of linear stability.

We now introduce the notion of a *regular point* of the strongly monotone compact map F_0. We say that $x \in X$ is regular if

$$\lambda(x,v,F_0) = \lim_{n\to+\infty} \frac{\log \|d_x F_0^n v\|}{n}$$

for any $v > 0$, i.e., $\lambda_1(x,F_0) = \lambda(x,v,F_0)$ is the limit, not just the superior limit, for any $v > 0$.

We conclude this section by proving the following "continuity" property of the first Lyapunov exponent.

LEMMA 3.1. *Let* (H) *hold. Let $K \subset X$ be a compact set invariant under F_0. Suppose that*

$$\lambda_1(z,F_0) > 0 \quad \textit{for each } z \in K. \tag{3.6}$$

Then there exist a $\delta_1 > 0$ and a neighborhood U of K with the following property: If $\varepsilon \in [-\delta_1, \delta_1]$ and $y \in U$ is such that $O(y,F_\varepsilon) \subset U$, then $\lambda_1(y,F_\varepsilon) > 0$.

Proof. Fix a vector $w \gg 0$. By [PT1, Proof of Prop. 4.5] (see formula (4.2) of [PT1]), for any $z \in K$ there is a ν such that

$$d_z F_0^\nu w \gg 2w. \tag{3.7}$$

We now show that (3.7) implies the following claim.

There exist a $\delta_1 > 0$, a neighborhood U of K, and an integer-valued bounded function $y \mapsto \nu(y)$ defined on U such that

$$d_y F_\varepsilon^\nu w \gg 2w \text{ whenever } y \in U, \quad \varepsilon \in [-\delta_1,\delta_1], \text{ and } \quad \nu = \nu(y). \tag{3.8}$$

To prove the claim we first fix a $z \in K$. Let ν be as in (3.7). Since $(\varepsilon, y) \to d_y F_\varepsilon^\nu$ is continuous and (3.7) is an open relation, there is a $\delta(z) > 0$ and a neighborhood $U(z)$ of z such that

$$d_y F_\varepsilon^\nu w \gg 2w \quad \text{for any } y \in U(z), \quad \varepsilon \in [-\delta(z), \delta(z)].$$

Taking a finite cover of K by such neighborhoods and letting U be the union of the cover and δ_1 the minimum of the corresponding $\delta(z)'s$, we find a function $\nu(y)$ on U as desired.

Now we verify that U and δ_1 just constructed have the properties asserted in Lemma 3.1. Fix $\varepsilon \in [-\delta_1, \delta_1]$ and $y \in U$ such that $O(y, F_\varepsilon) \subset U$. Let

$$y_n := F_\varepsilon^n(y), \qquad n = 0, 1, \dots,$$

and define the sequence $n_k, k = 1, 2, \dots$, as follows:

$$\begin{aligned} n_1 &:= \nu(y), \\ n_{k+1} &:= n_k + \nu(y_{n_k}). \end{aligned}$$

This makes sense since $y_n \in U$ for any n. By (3.8) we have

$$d_y F_\varepsilon^{n_1} w \gg 2w. \tag{3.9}$$

Using the chain rule we further obtain

$$d_y F_\varepsilon^{n_{k+1}} w = d_{y_{n_k}} F_\varepsilon^{\nu_k} d_y F_\varepsilon^{n_k} w, \tag{3.10}$$

where $\nu_k = \nu(y_{n_k})$. Since each $d_{y_{n_k}} F_\varepsilon^{\nu_k}$ is positive, from (3.9), (3.10) we obtain by induction with respect to k that

$$d_y F_\varepsilon^{n_k} w \geq 2^k w. \tag{3.11}$$

Let m be an upper bound for $\nu(y)$, $y \in U$. Then

$$n_k = \nu(y) + \nu(y_{n_1}) + \cdots + \nu(y_{n_{k-1}}) \leq mk,$$

and hence

$$k \geq n_k/m.$$

This and (3.11) lead to

$$(e^{-\gamma})^{n_k} d_y F_\varepsilon^{n_k} w \geq w \gg 0, \tag{3.12}$$

where

$$\gamma = \log\left(2^{\frac{1}{m}}\right) > 0.$$

Inequality (3.12) implies that $(e^{-\gamma})^{n_k} \|d_y F_\varepsilon^{n_k} w\|$ stays bounded away from zero (otherwise, by closedness of the relation $\leq$, it would follow that $w = 0$). This implies

$$\lambda(y, w, F_\varepsilon) \geq \gamma > 0,$$

and consequently,

$$\lambda_1(y, F_\varepsilon) \geq \lambda(y, w, F_\varepsilon) > 0,$$

as claimed. □

4. Proofs of Theorems 1 and 2. The proofs have two common steps as outlined in §2. Throughout the section we assume that (H) holds.

I. Localization. Let $B \subset X$ be a closed bounded set. Let $\varepsilon_n, n = 1, 2, \dots$, be a sequence in $J = [-\delta, \delta]$ converging to zero. To minimize the number of indices we shall use the notation

$$F_n = F_{\varepsilon_n}.$$

Suppose that for $n = 1, 2, \ldots$, p_n is a k_n-periodic point of F_n such that

$$O(p_n, F_n) \subset B \tag{4.1}$$

and

$$\lambda_1(p_n, F_n) \leq 0 \quad \text{(i.e., } p_n \text{ is linearly stable).} \tag{4.2}$$

The aim of *localization* is to prove that there exists a linearly stable periodic point z of F_0 and a sequence $n_j \to +\infty$ such that $O(z, F_0) \subset B$ and

$$\operatorname{dist}(O(p_{n_j}, F_{n_j}), \qquad O(z, F_0)) \to 0 \quad \text{as } j \to +\infty, \tag{4.3}$$

where

$$\operatorname{dist}(A, M) = \sup_{a \in A} \inf_{y \in M} \|a - y\|.$$

In order to find such a z, we first study properties of the "limit set" Λ defined by

$$\Lambda := \bigcap_{q \geq 1} cl \bigcup_{n \geq q} O(p_n, F_n). \tag{4.4}$$

LEMMA 4.1. *Under the above assumptions and notation the following properties hold:*

(i) Λ *is a nonempty compact set and* $\Lambda \subset B$;

(ii) Λ *is invariant under* F_0;

(iii) $\operatorname{dist}(O(p_n, F_n), \Lambda) \to 0$ *as* $n \to +\infty$.

Proof. As mentioned in §2, (H)(a) implies that $F : J \times X \to X$ is compact. Therefore, $clF([-\delta, \delta] \times B)$ is a compact set in X. Since $O(p_n, F_n) \subset B$ and, by periodicity, $O(p_n, F_n) = F_n(O(p_n, F_n))$, we have

$$\bigcup_{n \geq 0} O(p_n, F_n) \subset F([-\delta, \delta] \times B).$$

This implies that $cl \bigcup_{n \geq q} O(p_n, F_n), q \geq 1$, is a nested family of compact sets and, as such, it has nonempty compact intersection. Since all the orbits $O(p_n, F_n)$ are contained in B and B is closed, Λ is also contained in B. This proves (i).

To prove (ii), first observe that Λ can be equivalently defined by

(4.5)
$$\Lambda = \{z \in X : \text{there are two sequences } n_j, m_j \text{ of positive integers such that } n_j \to \infty \text{ and } F_{n_j}^{m_j}(p_{n_j}) \to z\}.$$

The verification of (4.5) is left to the reader. (The reader has certainly noticed the analogy to the proof of properties of ω-limit sets of orbits.)

We prove that $F_0(\Lambda) \subset \Lambda$ (positive invariance). Let $z \in \Lambda$, and let n_j, m_j be the sequences as in (4.5). We prove that $F_0(z) \in \Lambda$ by showing that

$$F_{n_j}^{m_j+1}(p_{n_j}) \to F_0(z) \quad \text{as } j \to +\infty.$$

This follows from the triangle inequality and the following convergence properties:

$$F_0 F_{n_j}^{m_j}(p_{n_j}) - F_0(z) \to 0$$

and

$$F_{n_j}^{m_j+1}(p_{n_j}) - F_0 F_{n_j}^{m_j}(p_{n_j}) = F_{n_j} F_{n_j}^{m_j}(p_{n_j}) - F_0 F_{n_j}^{m_j}(p_{n_j}) \to 0.$$

The former convergence is just by continuity of F_0, while the latter one follows from the fact that all points $F_{n_j}^{m_j}(p_{n_j})$ lie in the compact set $clF([-\delta,\delta]\times B)$. Note that it is a straightforward consequence of the continuity of $F : [-\delta,\delta]\times X \to X$ that

$$F_n(z) = F(\varepsilon_n, z) \to F_0(z) \quad \text{as } n \to \infty$$

and that the convergence is uniform for z in a compact set.

To prove that $\Lambda \subset F_0(\Lambda)$ (negative invariance) one proceeds as follows. Given $z \in \Lambda, n_j, m_j$ being the corresponding sequences, one considers the sequence

$$F_{n_j}^{m_j-1}(p_{n_j}).$$

It is well defined since p_{n_j} is periodic. This sequence lies in a compact set, hence passing to a subsequence one may assume that it converges to a $y \in \Lambda$. It is then easy to see that $F_0(y) = z$. This completes the proof of (ii).

Property (iii) follows directly from (4.5) and the fact that $O(p_n, F_n), n = 1, 2, \ldots,$ are contained in a compact set. □

Our next aim is to find a linearly stable periodic point of F_0 in Λ.

First we find a $\tilde{z} \in \Lambda$ with $\lambda_1(\tilde{z}, F_0) \leq 0$. Existence of such a $\tilde{z}$ follows easily by property (iii) of Lemma 4.1 (in case of nonexistence, Lemma 3.1 applied to $K = \Lambda$ would give a contradiction to (4.2)).

Next, consider the orbit $O(\tilde{z}, F_0)$. By invariance of Λ, we have $O(\tilde{z}, F_0) \subset \Lambda$. So $O(\tilde{z}, F_0)$ is relatively compact, and consequently the ω-limit set $\omega(\tilde{z}, F_0)$ is nonempty, compact and invariant under F_0. Moreover,

$$\text{dist}(F_0^n(\tilde{z}), \omega(\tilde{z}, F_0)) \to 0 \quad \text{as } n \to +\infty \tag{4.6}$$

(see, e.g., [Ha]). Obviously,

$$\omega(\tilde{z}, F_0) \subset clO(\tilde{z}, F_0) \subset \Lambda.$$

Now, since

$$\lambda_1(F_0^n(\tilde{z}), F_0) = \lambda_1(\tilde{z}, F_0) \leq 0, \tag{4.7}$$

there is a $z \in \omega(\tilde{z}, F_0)$ with $\lambda_1(z, F_0) \leq 0$ (otherwise Lemma 3.1 applied to $K = \omega(\tilde{z}, F_0)$ gives a contradiction to (4.7)).

In fact, there must be a *regular* point $z \in \omega(\tilde{z}, F_0)$ with $\lambda_1(z, F_0) \leq 0$ (see [PT1, Prop. 4.6]). Proposition 4.4 of [PT1] now yields that $\omega(\tilde{z}, F_0) = O(z, F_0)$ and z is a periodic point of F_0.

We have thus shown that Λ contains a linearly stable periodic point of F_0. To complete the localization we need the following result.

LEMMA 4.2. *Let z be a linearly stable periodic point of F_0. Then for any neighborhood V of $O(z, F_0)$ there exist constants $\rho > 0$ and $\delta_0 > 0$ such that for any $\varepsilon \in [-\delta_0, \delta_0]$ and for any $y \in X$ satisfying $\|y - z\| < \rho$ one of the properties holds:*

(i) *$O(y, F_\varepsilon) \subset V$; or*

(ii) *There are positive integers r, m such that $F_\varepsilon^{r+m} y \gg F_\varepsilon^r y$.*

Before giving the proof we show how this lemma implies localization. Let $z \in \Lambda$ be a linearly stable periodic point of F_0. Then $O(z, F_0) \subset \Lambda$, by invariance of Λ. Further, by (4.5), there are sequences $n_j \to +\infty$ and m_j such that

$$F_{n_j}^{m_j}(p_{n_j}) \to z.$$

Let V be any neighbourhood of $O(z, F_0)$, and let ρ, δ_0 be as in Lemma 4.2. For j sufficiently large (so that $\|F_{n_j}^{m_j}(p_{n_j}) - z\| < \rho$ and $\varepsilon_{n_j} \in [-\delta_0, \delta_0]$) we obtain by Lemma 4.2 that either

$$O(p_{n_j}, F_{n_j}) = O(F_{n_j}^{m_j}(p_{n_j}), F_{n_j}) \subset V \tag{4.8}$$

or else

$$F_{n_j}^{r+m} p_{n_j} \gg F_{n_j}^{r} p_{n_j} \tag{4.9}$$

for some $r, m > 0$. But we know that (4.9) is impossible because the cycle $O(p_{n_j}, F_{n_j})$ cannot contain two related points (cf. §3). Hence (4.8) holds for all j sufficiently large. Since the neighborhood V is arbitrary, this readily completes localization. It remains to prove Lemma 4.2.

Proof of Lemma 4.2. First we show that it is sufficient to consider the case when z is a fixed point of F_0. Indeed, replacing F_ε by F_ε^k, k being the period of z, we still have (H) satisfied and, obviously, z is a linearly stable fixed point of F_0^k. Now, if V is a given neighborhood of $O(z, F_0)$, there exist a $\delta_2 > 0$ and a neighborhood $\tilde{V}$ of z such that $w \in \tilde{V}$ and $\varepsilon \in [-\delta_2, \delta_2]$ imply that $F_\varepsilon^j(w) \in V$ for $j = 0, 1, \dots, k-1$. From this it is clear that if we find $\rho > 0$ and $\tilde{\delta}_0$ corresponding to $\tilde{V}$ as required in Lemma 4.2 with F_ε replaced by F_ε^k, then the same ρ and $\delta_0 = \min\{\delta_2, \tilde{\delta}_0\}$ are the constants required in the original assertion. We thus proceed in the proof assuming that $F_0 z = z$.

Let a neighborhood V of z be given. We want to find constants ρ and δ_0. In order to see how small these constants must be, we first derive an equation for the deviation from z of an orbit $O(y, F_\varepsilon)$ with some fixed y and ε. Denote

$$\begin{aligned} y_0 &= y, \\ y_n &= F_\varepsilon^n y, \\ u_n &= y_n - z. \end{aligned}$$

We have

$$\begin{aligned} u_{n+1} &= F_\varepsilon y_n - F_0 z \\ &= F_0 y_n - F_0 z + F_\varepsilon y_n - F_0 y_n; \end{aligned}$$

hence

$$u_{n+1} = A u_n + g(u_n) + H(\varepsilon, u_n), \tag{4.10}$$

where

$$\begin{aligned} A &= F_0'(z), \\ g(u) &= \int_0^1 [F_0'(z + su) - F_0'(z)] u \, ds, \end{aligned} \tag{4.11}$$

$$H(\varepsilon, u) = F_\varepsilon(u+z) - F_0(u+z). \tag{4.12}$$

The idea of what follows is to show that if u_0 is close to zero and ε is small, then either u_n stays small, so that y_n stays in V, or else the "positive component" of u_n gets so large compared with u_0 that u_n and u_0 are related (hence y_n and y_0 are related). This requires some estimates in the flavor of [PT1, Proof of Prop. 3.5]. First we need some properties of spectral projections corresponding to the Krein–Rutman decomposition of the spectrum of A. By the latter we mean the decomposition

$$\sigma(A) = \{\mu_1\} \cup \sigma_2,$$

where $\mu_1 = \exp(\lambda_1(z, F_0))$ is the principal eigenvalue of (the strongly positive and compact operator) A and $\sigma_2 = \sigma(A)\backslash\mu_1$. The corresponding invariant decomposition of X has the form

$$X = X_1 \oplus X_2, \tag{4.13}$$

where X_1 is spanned by an eigenvector $v \gg 0$, which we further assume to be normalized, $\|v\| = 1$, and $X_2 \cap X_+ = \{0\}$. Moreover, the spectrum of the restriction $A_2 := A|_{X_2}$ is contained inside the unit circle in the complex plane. We can thus find constants $M \geq 1, \beta \in (0,1)$ such that

$$\|A_2^n\| \leq M\beta^n, \qquad n = 0, 1, 2, \ldots. \tag{4.14}$$

Let $P : X \to X_1$ and $Q = I - P : X \to X_2$ be the spectral projections associated with the decomposition (4.13). For $u \in X$ we write

$$u^1 = Pu, \qquad u^2 = Qu.$$

The following property holds true. Let $\mathbb{B}_R$ denote the ball of radius R around zero in X.

SUBLEMMA. *There exist constants $C_1 > 0$ and $\alpha \in (0,1)$ such that for any $u \in X$ and any $R > 0$ the relations*

$$\|u^2\| \leq C_1\|u^1\| \quad \textit{and} \quad \|u\| \geq R \tag{4.15}$$

imply that u is strongly related to $\mathbb{B}_{\alpha R}$, that is, either $u \gg \mathbb{B}_{\alpha R}$ or $u \ll \mathbb{B}_{\alpha R}$.

Here $u \gg \mathbb{B}_{\alpha R}$ means that $u \gg b$ for any $b \in \mathbb{B}_{\alpha R}$ (and similarly for the reversed sign). The proof of the sublemma will be given later.

Equipped with this sublemma, we can now find constants ρ and δ_0 corresponding to the given neighbourhood V of z such that the conclusion of Lemma 4.2 holds.

First we choose a number $R \in (0, 1]$ so small that the following properties hold.

(a) For any $u \in X$ with $\|u\| < R$ one has $z + u \in V$.

(b) There is a constant C_2 such that

$$\left\|\frac{\partial F(\varepsilon, z+u)}{\partial \varepsilon}\right\| \leq C_2 \quad \text{for any } u \text{ with } \|u\| \leq R \quad \text{and} \quad \varepsilon \in [-\delta, \delta]. \tag{4.16}$$

(To achieve this, one just uses the fact that F is C^1 and $[-\delta, \delta]$ is compact.)

(c) Certain estimates (see (4.25) below), which involve only C_1 from the sublemma and certain constants depending only on the operator A and the function g (see 4.11) are satisfied by R. Having such an R we choose a ρ with

$$0 < \rho < \min\{\alpha R, [\|Q\| 3M(1 + C_1^{-1})]^{-1} R\}. \tag{4.17}$$

To define the constant δ_0, we first observe that, by (4.12),

$$h(\varepsilon) := \sup_{\|u\|\le R} \|H(\varepsilon,u)\| \le \varepsilon \sup_{\|u\|\le R} \left\| \frac{\partial F(\varepsilon, z+u)}{\partial \varepsilon} \right\|; \tag{4.18}$$

hence, by (4.16),

$$h(\varepsilon) \to 0 \quad \text{as } \varepsilon \to 0 .$$

Choose $\delta_0 > 0$ so small that $\varepsilon \in [-\delta_0, \delta_0]$ implies

$$h(\varepsilon) M \|Q\| \sum_{k=0}^{\infty} \beta^k < \overline{R}/3. \tag{4.19}$$

Here $M \ge 1$ and $\beta \in (0,1)$ are as in (4.14) and

$$\overline{R} := (1 + C_1^{-1})^{-1} R.$$

With ρ and δ_0 chosen in this way, we claim that if $\varepsilon \in [-\delta_0, \delta_0]$ and $\|u_0\| = \|y - z\| < \rho$, then the following alternative holds (with the notation as above). Either

(i)′ $\|u_n\| < R, n = 0, 1, 2, \ldots$, or else

(ii)′ there is an n such that $\|u_n\| \ge R$ and $\|u_n^2\| \le C_1 \|u_n^1\|$.

By the choice of R, (i)′ implies assertion (i) of Lemma 4.2. Since $\|u_0\| = \|y - z\| < \rho < \alpha R$, (ii)′ implies (ii) (here we use the sublemma). So we are done, provided we prove that the alternative holds. To do that we assume that (ii)′ does not hold, i.e., for any n,

$$\|u_n^1\| < C_1^{-1} \|u_n^2\| \quad \text{or} \quad \|u_n\| < R. \tag{4.20}$$

We prove that (i)′ holds. By (4.20) and the inequality $\|u_n\| \le \|u_n^1\| + \|u_n^2\|$ it is sufficient to prove that

$$\|u_k^2\| < \overline{R} = (1 + C_1^{-1})^{-1} R \tag{4.21}$$

for $k = 0, 1, 2, \ldots$. Observe that (4.21) holds true for $k = 0$ by the choice ρ. Indeed,

$$\|u_0^2\| \le \|Q\| \, \|u_0\| < \|Q\| \rho < (3M)^{-1} \overline{R} < \overline{R}. \tag{4.22}$$

Suppose (4.21) holds for $k = 0, 1, \ldots, n-1$. We prove that it holds for $k = n$. This implies that (4.22) holds for all $n = 0, 1, 2, \ldots$.

Applying the projection Q to both sides of (4.10) we obtain

$$u_{n+1}^2 = A_2 u_n^2 + Q[g(u_n) + H(\varepsilon, u_n)].$$

The variation of constants for this equation gives

$$u_n^2 = A_2^n u_0^2 + \sum_{k=0}^{n-1} A_2^{n-k-1} Q[g(u_k) + H(\varepsilon, u_k)]. \tag{4.23}$$

By (H), the function $\|g(u)\| \, \|u\|^{-1-\theta}$ is bounded on any bounded set. So there is a constant C_3 such that

$$\sup_{\|u\|\le R} \|g(u)\| \le C_3 R^{1+\theta}. \tag{4.24}$$

(Since R is in the bounded interval $[0,1]$, C_3 depends only on g.)

Now we have prepared everything for an estimate of $\|u_n^2\|$. By (4.23) and (4.14)

$$\|u_n^2\| \le M\beta^n\|u_0^2\| + \sum_{k=0}^{n-1} M\beta^{n-k-1}\|Q\|\,(\|g(u_k)\| + \|H(\varepsilon, u_k)\|).$$

By our induction hypotheses (cf. (4.20)) and (4.21) we have $\|u_k\| < R$ for $k = 0, 1, \dots n-1$. We can thus apply (4.18), (4.19), and (4.24), which yield

$$\|u_n^2\| \le M\|u_0^2\| + R^{1+\theta}M\|Q\|C_3\sum_{k=0}^{\infty}\beta^k + \frac{\overline{R}}{3}.$$

Recall that, by the choice of ρ (see (4.22))

$$M\|u_0^2\| < \frac{\overline{R}}{3}.$$

So if R is so small that

$$(1 + C_1^{-1})R^{\theta}M\|Q\|C_3\sum_{k=0}^{\infty}\beta^k < \frac{1}{3}, \tag{4.25}$$

we have the estimate

$$\|u_n^2\| < \overline{R}.$$

This completes the proof of the alternative. It remains to prove the sublemma.

Proof of the sublemma. Define C_1 to be a constant such that

$$v + x \gg \frac{1}{2}v \quad \text{for any } x \quad \text{with } \|x\| \le C_1. \tag{4.26}$$

Such C_1 exists because the eigenvector $\frac{1}{2}v$ is in $\operatorname{int}X_+$. Put $\alpha = C_1(1+C_1)^{-1}$. Observe that if $\|u\| \ge R$ and $\|u^2\| \le C_1\|u^1\|$, then

$$R \le \|u^1 + u^2\| \le (1 + C_1)\|u^1\|;$$

hence

$$\|u^1\| \ge R(1 + C_1)^{-1}.$$

Suppose that (4.15) holds. For definiteness also assume that $u^1 > 0$ (the case $u^1 < 0$ is analogous). Then by (4.15) and (4.26),

$$\begin{aligned} u = u^1 + u^2 &= \|u^1\|v + u^2 = \|u^1\|(v + \|u^1\|^{-1}u^2) \\ &\ge R(1 + C_1)^{-1}\tfrac{1}{2}v. \end{aligned}$$

Now, by (4.26),

$$\tfrac{1}{2}v \gg \mathbb{B}_{C_1}.$$

Therefore,

$$u \ge R(1 + C_1)^{-1}\tfrac{1}{2}v \gg R(1 + C_1)^{-1}\mathbb{B}_{C_1} = \mathbb{B}_{\alpha R}. \qquad \square$$

Having completed localization we pass to the second step.

II. Local bifurcation. Our aim here is to prove the following proposition.

PROPOSITION 4.3. *Let z be a linearly stable k-periodic point of F_0. Then there exist a $\delta_2 > 0$ and a neighborhood V of $O(z, F_0)$ such that for any $\varepsilon \in (-\delta_2, \delta_2)$ all cycles of F_ε contained in V have the minimal period k.*

Proof. By continuity of F, there are $\tilde{\delta}_2 > 0$ and a neighborhood $\tilde{V}$ of $O(z, F_0)$ such that for any $\varepsilon \in (-\tilde{\delta}_2, \tilde{\delta}_2)$ all cycles of F_ε contained in $\tilde{V}$ have the minimal period at least k. Next we prove that such cycles have the minimal period at most k, if $\tilde{\delta}_2$ and $\tilde{V}$ are made sufficiently small.

Similarly as in Lemma 4.2, we reduce the proof to the case when z is a fixed point of F_0. To see that it is sufficient to consider this case, one only has to realize that the following consequence of continuity of F holds: Let $\tilde{V}$ be a given neighborhood of the k-periodic point z such that $F_0^j z \notin cl\tilde{V}$ for $j = 1, 2, \dots, k-1$. Then there exist a $\delta_3 > 0$ and a neighborhood V of $O(z, F_0)$, such that for any $\varepsilon \in (-\delta_3, \delta_3)$ and any cycle $O(y, F_\varepsilon)$ of F_ε contained in V, the set $O(y, F_\varepsilon) \cap \tilde{V}$ is a cycle for F_ε^k. With this observation it is easy to see that the assertion of the lemma follows provided we prove the assertion with F_ε replaced by F_ε^k, assuming that z is a fixed point of F_0^k. Notice that F_ε^k also satisfies (H). Thus we may proceed, assuming that z is a fixed point of F_0.

Consider the spectrum $\sigma(A)$ of the (compact strongly positive) operator $A := F_0'(z)$. We have

$$\sigma(A) = \{\mu_1\} \cup \sigma_2,$$

where $\mu_1 = \exp(\lambda_1(z, F_0))$ and $\sigma_2 \subset \{\mu \in \mathbb{C} : |\mu| < \mu_1\}$. We distinguish between the two cases

$$\mu_1 < 1 \quad \text{and} \quad \mu_1 = 1.$$

(Recall that $\mu_1 \leq 1$, since z is linearly stable.) If $\mu_1 < 1$, there is an equivalent norm $\|\cdot\|_a$ on X such that $\|A\|_a < 1$ (see, e.g., [Io, Chap. I]). Since F is C^1, there exists a ball $\mathbb{B}$ around z in $(X, \|\cdot\|_a)$ such that for all ε sufficiently close to zero, F_ε is a contraction on $\mathbb{B}$. Therefore, all cycles of F_ε in $\mathbb{B}$ are fixed points of F_ε. In the case $\mu_1 < 1$ we are done. Let us now consider the case $\mu_1 = 1$. To prove the assertion, we apply a center manifold theorem. This will give us a neighborhood V of z such that for each ε close to zero, any invariant set of F_ε contained in V lies on a one-dimensional locally invariant manifold of F_ε. Moreover, the restriction of F_ε to this invariant manifold is conjugate to an increasing map on an interval. There are thus no periodic points of F_ε, except for fixed points, on this invariant manifold and consequently there are no periodic points of higher period in the neighborhood V. This implies the assertion.

We give more details concerning the reduction result (which certainly is familiar to experts in the bifurcation theory).

To find the invariant manifolds for all ε, we consider the standard suspension, i.e., the mapping

$$G : (\varepsilon, x) \mapsto (\varepsilon, F(\varepsilon, x)) : (-\delta, \delta) \times X \to (-\delta, \delta) \times X$$

(cf. [He, §8.5]; [Io, Chap. V]).

By (H), G is of class C^1. Obviously, $(0, z)$ is a fixed point of G. The spectrum of the linearized (at $0, z)$) operator $(\eta, w) \mapsto (\eta, d_z F_0 w + \eta d_0 F(\cdot, z))$ is the same as the spectrum of $A = d_z F_0$, except that 1 is now a double eigenvalue (it has geometric multiplicity 2 if $d_0 F(\cdot, z) \in R(I - A)$, the range of $I - A$, otherwise it has geometric multiplicity 1 and algebraic multiplicity 2). The eigenspace corresponding to the eigenvalue 1 has the form $\operatorname{span}\{(1, w), (0, v)\}$, where v is the positive eigenvector of A

and w is a vector in X. By the center manifold theorem (see [He], [Io], [Sh], [MM], [CL]) there exist a $\delta_2 > 0$, a neighborhood V of z, and a C^1 submanifold of $\mathbb{R} \times X$ of the form

$$W := \{(\varepsilon, z + \varepsilon w + sv) + (\sigma_1(\varepsilon, s), \sigma_2(\varepsilon, s)) : \varepsilon, s \in (-\delta_2, \delta_2)\},$$

where σ_1 and σ_2 take values in $\mathbb{R}$ and X, respectively, are of class C^1 and of order $O(|\varepsilon| + |s|)$ as $\varepsilon \to 0, s \to 0$, and the following properties hold: For any $(\varepsilon, x) \in W$ the iterates $G^n(\varepsilon, x), n = 0, 1, \ldots$ stay in W as long as they stay in $(-\delta_2, \delta_2) \times V$. Moreover, any cycle of G contained entirely in $(-\delta_2, \delta_2) \times V$ is contained in W.

Let us be more precise about the references. The center manifold theorem in the form we need is stated in [Io, Chap. V] and [He, §8.5]. In [He] the application of this theorem to parametrized mappings (using the suspension as above) is also described (cf. also [Io, §V.3], where $F(\varepsilon, z) \equiv F(z)$ for any ε is assumed). However, in this references higher regularity of F is required. One has to combine these results with [Sh, Thm. 3.2], where C^1-regularity of the (global) center-unstable manifold (in our case just the center manifold) for a C^1-mapping is provided (see also [CL], which is slightly less general).

Now the special form of G implies that for $\varepsilon \in (-\delta_2, \delta_2)$ the ε-section of W, $W_\varepsilon = \{x : (\varepsilon, x) \in W\} = \{z + \varepsilon w + sv + \sigma_2(\varepsilon, s) : |s| < \delta_2\}$, is a one-dimensional C^1-submanifold of X, which is locally invariant under F_ε (more precisely, $F_\varepsilon(x) \in W_\varepsilon$ if $x \in W_\varepsilon$ and $F_\varepsilon(x) \in V$) and which contains any cycle of F_ε lying in V. Now, since the critical eigenvalue which gives rise to these invariant manifolds (that is, the eigenvalue of $d_z F_0$ on the unit circle) equals 1, by continuous dependence of the eigenvalues on parameters, we may assume (making δ_2 and V smaller if necessary) that the restriction $F_{\varepsilon|W_\varepsilon}$ is orientation preserving. As such, this restriction cannot have periodic orbits, except fixed points. We conclude that for $\varepsilon \in (\delta_2, \delta_2)$, any cycle of F_ε contained in V is a fixed point of F_ε. This completes the proof of Proposition 4.3. □

III. Completion of the proofs. First we complete the proof of Theorem 2. Let B be a closed bounded set. Let m be a bound on stable periods of $F_{0|B}$. Suppose the conclusion of Theorem 2 is not true. Then there exist sequences $\varepsilon_n \in [-\delta, \delta], p_n \in X, k_n \in \{1, 2, \ldots\}$ such that $\varepsilon_n \to 0, p_n$ is a linearly stable k_n-periodic point of $F_n = F_{\varepsilon_n}$ with $O(p_n, F_n) \subset B$ and $k_n > m, n = 1, 2, \ldots$. Using localization and Proposition 4.3 (where z is the k-periodic point found by localization, hence $O(z, F_0) \subset B$ and $k \leq m$ by assumption) we immediately arrive at a contradiction.

Next, suppose that for a given closed bounded set B, the conclusion of Theorem 1 fails. Since there is no bound on stable periods at $F_{0|B}$, there is a sequence p_n of linearly stable periodic points of F_0 with $O(p_n, F_0) \subset B$ such that the minimal period k_n of p_n approaches $+\infty$ as $n \to +\infty$. Using localization (with $\varepsilon_n \equiv 0$) and Proposition 4.3 we again arrive at a contradiction.

5. Applications. There are several standard classes of periodically forced equations whose period maps have the smoothness, compactness, and strong monotonicity properties we require of F_0 (cf. [Hi2], [Hs2]). Moreover, in many cases the backward uniqueness guarantees that the period map is one-to-one. Thus Theorem 1 and Corollary 4 are applicable for a general scalar semilinear or quasilinear equation or a cooperative system of reaction diffusion equations. We do not consider these general classes here. Our concern in this section is to show some applications of Corollaries 3 and 5. We consider three types of problems where nonexistence of linearly stable *subharmonic* solutions (i.e., solutions whose minimal period is a nontrivial multiple of the period of the equation) can be established. All these equations are small perturbations of problems for which the nonexistence is known to hold.

Example 1 (perturbation of an autonomous equation). Consider the parabolic equation

$$u_t = \Delta u + f(x,u) + \varepsilon g(\varepsilon, t, x, u), \qquad t > 0, \quad x \in \Omega, \tag{5.1}$$

where $\Omega \subset \mathbb{R}^N$ is a smooth bounded domain, $\varepsilon \in \mathbb{R}$ a parameter, and the nonlinearities $f : \overline{\Omega} \times \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \times \mathbb{R} \times \overline{\Omega} \times \mathbb{R} \to \mathbb{R}$ satisfy the following assumptions.

(A1) f is of class C^2.

(A2) g is of class C^1.

(A3) g is τ-periodic in t, $\tau > 0$, i.e. $g(\cdot, t+\tau, \cdot, \cdot) \equiv g(\cdot, t, \cdot, \cdot)$.

(A4) There are constants $C_1, C_2 > 0$ such that

$$|g(\varepsilon, t, x, u)| \leq C_1|u| + C_2$$

for any ε, t, x, u.

(A5) $L := \limsup_{|n| \to \infty} f(x,u)/u < \mu_1$, uniformly for $x \in \overline{\Omega}$. Here μ_1 is the first eigenvalue of $-\Delta$ on Ω under the boundary condition

$$\mathcal{B}u = 0, \tag{5.2}$$

where the boundary operator $\mathcal{B}$ is either of Dirichlet type

$$\mathcal{B}u = u|\partial\Omega$$

or of Neumann type

$$\mathcal{B}u = \frac{\partial u}{\partial n} + bu$$

($b : \partial\Omega \to \mathbb{R}^+$ being a C^2-function and n a smooth outward pointing and nowhere tangent vector field on $\partial\Omega$).

We consider the boundary value problem (5.1), (5.2) in the context of analytic semigroups.

Let $Y = L_p(\Omega)$ with $p > N$, and let $Y^\beta, \beta \geq 0$, be the scale of fractional power spaces associated with the L_p-realization of $-\Delta$ and the boundary condition (5.2) (cf. [He]). Choose a β with $(p+N)(2p)^{-1} < \beta < 1$. Then $X := Y^\beta$ is continuously imbedded in $C^1(\overline{\Omega})$; hence it is strongly ordered by the pointwise ordering (see [Hi3], [Hs2]). By [He], (5.1), (5.2) is well posed on X. More specifically, (A1), (A2) imply that for any $u_0 \in X$, (5.1), (5.2) has a unique maximal solution $t \mapsto u(t, \cdot, \varepsilon, u_0)$ in $C([0,s), X) \cap C^1([0,s), X)$ satisfying $u(0, \cdot, \varepsilon, u_0) = u_0(\cdot)$. By (A4), (A5) this solution is global, that is, $s = +\infty$ [Am1], so the period map $F_\varepsilon : u_0 \mapsto F_\varepsilon(u_0) := u(\tau, \cdot, \varepsilon, u_0) : X \to X$ is defined everywhere on X. It is well known (see [He], [Hs2]) that all the smoothness, compactness, and monotonicity properties required in (H) are satisfied by the family $F_\varepsilon; \varepsilon \in [-\delta, \delta]$ (for any $\delta > 0$). Finally, by backward uniqueness, F_ε is one-to-one. Thus (H)(b) is satisfied for F_0 (and also for F_ε if g is assumed more regular, say C^2).

Now fix a $\delta > 0$ such that $\delta C_1 + L < \mu_1$. We want to apply Corollary 3 to the family $F_\varepsilon, \varepsilon \in [-\delta, \delta]$. For any $\varepsilon \in [-\delta, \delta]$ we have

$$\limsup_{|u| \to \infty} (f(x,u) + \varepsilon g(\varepsilon, t, x, u))/u \leq |\varepsilon| C_1 + L \leq \delta C_1 + L < \mu_1,$$

uniformly for $x \in \overline{\Omega}, t \in [0, \tau]$.

This estimate implies that there is a constant $C_3 > 0$ such that for each $\varepsilon \in [-\delta, \delta]$ all periodic solutions of (5.1), (5.2) satisfy the a priori estimate

$$\|u(t, \cdot, \varepsilon, u_0)\|_X \leq C_3.$$

Indeed, using standard comparison arguments (cf. [KW], [Am2]) one constructs a time-independent subsolution in $-\text{int}X_+$ and, similary, a supersolution in $\text{int}X_+$. This can be done in such a way that any multiple by a scalar factor ≥ 1 is again a sub/ supersolution. We thus have unbounded continua of subsolutions and supersolutions. The standard sweeping principle implies a uniform a priori bound on periodic solutions in L_∞. By bootstrap arguments [Am2], we obtain the desired a priori estimate in X.

Thus for $\varepsilon \in [-\delta, \delta]$ all the cycles of F_ε lie in a ball D independent of ε.

Finally, since F_0 is the time-τ map of a C^1-strongly monotone semiflow, all linearly stable periodic points of F_0 are fixed points of F_0 corresponding to equilibria of the autonomous problem (see [Hs2, Prop. 9.4]).

We have thus verified all the hypotheses of Corollary 3. We infer that for $|\varepsilon|$ sufficiently small there are no linearly stable periodic points of F_ε except for fixed points. Consequently, (5.1), (5.2) has no stable subharmonic solutions. If in addition to (A1)–(A5) one assumes that $g(\varepsilon, t, x, u)$ is of class C^2, then the F_ε also satisfy the hypotheses of Corollary 5. As a consequence we obtain that for $|\varepsilon|$ sufficiently small, the following convergence property holds: For any bounded set $\mathcal{G} \subset X$ there is an open dense subset $\tilde{\mathcal{G}}$ of $\mathcal{G}$ such that $O(u_0, F_\varepsilon)$ is convergent for any $u_0 \in \tilde{\mathcal{G}}$.

Various generalizations of this example are possible. Firstly, the Laplacian may be replaced by a general uniformly elliptic operator of second order with C^2 coefficients. Assuming appropriate growth conditions one may allow f and g to depend also on ∇u.

We now mention two further examples. Without going into details, we present periodically time-dependent equations which do not admit linearly stable subharmonic orbits, and discuss admissible perturbations of such equations.

Example 2 (perturbation of a spatially homogeneous equation). Let Ω be a smooth convex domain in $\mathbb{R}^N$. Consider the problem

$$\begin{aligned} &u_t = \Delta u + f(t, u, \nabla u), \qquad t > 0, \quad x \in \Omega, \\ &\frac{\partial u}{\partial n} = 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{5.3}$$

where n is now the unit outward normal vectorfield on $\partial\Omega$. The function $f : \mathbb{R} \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is assumed to be of class C^2 and τ-periodic in t. It has been observed in [PT2] that there are no linearly stable subharmonic solutions. This follows from the fact that any stable $k\tau$-periodic solution, $k \in \{1, 2, \ldots\}$, is spatially homogeneous (see [Hs2, Thm. 23.4]). Therefore, it satisfies the τ-periodic one-dimensional ODE

$$u_t = f(t, u, 0),$$

which does not have subharmonic solutions.

Consider now the perturbed equation

$$u_t = \Delta u + f(t, u, \nabla u) + \varepsilon g(t, x, u, \nabla u) \tag{5.4}$$

with a small spatial inhomogeneity (ε is a small parameter). Under appropriate smoothness and growth conditions one can again check that the period map F_ε on X

(with X as in Example 1) satisfies (H). Thus there are no stable subharmonic solutions of (5.3), (5.4) for small $|\varepsilon|$, and "most" solutions converge to a τ-periodic solution.

Example 3 (perturbation in one space dimension). Consider the one-dimensional problem

$$u_t = u_{xx} + f(t, x, u, u_x), \qquad t > 0, \quad 0 < x < 1, \tag{5.5}$$

$$u_x(t, 0) \equiv u_x(t, 1) \equiv 0, \tag{5.6}$$

where f is of class C^2 and τ-periodic in t (other boundary conditions are also admissible). It has been proved in [BPS] that any bounded solution approaches, as $t \to \infty$, a τ-periodic solution. In particular, there is no subharmonic solution.

We now perturb (5.5) by a nonlocal term,

$$u_t = u_{xx} + f(t, x, u, u_x) + \varepsilon^2 C(x) \int_0^1 \nu(x) u(t, x) dx, \tag{5.7}$$

where $C(x) \geq 0$ and $\nu(x) \geq 0$ are C^1 functions of $x \in [0, 1]$. These sign restrictions assure that the strong comparison principle applies to (5.6) and (5.7). Under appropriate growth conditions the period map of this equation satisfies (H) with $X = H^2(0, 1) \cap H_0^1(0, 1)$ (see [PT2]). Using Corollary 3, one obtains that there are no stable subharmonic solutions of (5.6), (5.7) if ε is sufficiently small. By [PT1] this implies that "most" orbits of the period map are convergent.

STRICTLY NONAUTONOMOUS COOPERATIVE SYSTEM WITH A FIRST INTEGRAL*

BAORONG TANG†§, YANG KUANG†‡, AND HAL SMITH†§

Abstract. The authors consider the nonautonomous cooperative system

$$dx_i/dt = F_i(t, x_1, \dots, x_n) \qquad (i = 1, \dots, n)$$

in the nonnegative orthant in the real n-dimensional Euclidean space, which has the first integral with positive gradient. The authors guess that every solution to such a system either converges to an asymptotic state (for the almost periodic (or periodic) case, this state is an almost periodic (or periodic) solution) or eventually leaves any compact set. They partly prove this conjecture.

Key words. cooperative systems, nonautonomous systems, almost periodic (or periodic) solution, first integral, Lyapunov function, uniformly stable, skew-product flow, ω-limit set

AMS subject classifications. primary 34C27; secondary 34C25, 34D20, 90A16

1. Introduction.

The autonomous gross-substitute system forms a mathematical model for the classical law of supply and demand in economics, which has been studied by many economists [9] and has the property (P_1): *every bounded solution converges to an equilibrium.* Such a system is a special class of cooperative systems.

Cooperative (or competitive) systems are a class of dynamic systems $\dot{x} = F(x)$, $x \in U \subset \mathbf{R}^n$, which satisfy conditions $\partial F_i/\partial x_j \geq 0$ (≤ 0) for $i \neq j$. Recently, systems of this type received much study (see references in [3]–[5] and [15]), since they have wide applications in biology and chemistry (for example, see [6], [17]). In [3]–[5] Hirsch proved many important results about such systems, one of which is that, for systems that are cooperative and irreducible, almost all (with respect to the Lebesgue measure) points whose forward orbits are bounded approach the equilibrium set. But in general, the property (P_1) that every bounded solution converges to an equilibrium or to a closed orbit is not true. A construction of Smale [13] shows that any dynamics is possible for such systems. Hence, one tries to find some special classes of systems of that type for which the property (P_1) is true. In [14] Smillie established a particular class of cooperative systems for which the property (P_1) is true. In [7] Mierczyński found another class of cooperative systems, namely, strictly cooperative systems with a first integral, having the property (P_1) which generalized the result in [9]. Other relevant results can be found in Arino [19] and the references cited therein.

As we know, nonautonomous systems are more realistic and more general in mathematical modelling. For example, if one considers the seasonal effects in economics, it is important to study time-dependent or nonautonomous gross-substitute systems, which are a special class of nonautonomous cooperative systems. For the case of periodic (almost periodic) cooperative systems, the property (P_2) that *every bounded*

§The research of this author was partially supported by National Science Foundation grant DMS 89-22654.

solution converges to a periodic (almost periodic) solution is important. Smith [16] generalized the result in [14] to the periodic case: the property (P_2) holds. Nakajima [8] and Sell and Nakajima [12] studied the nonautonomous gross-substitute systems for which the property (P_2) is true.

In this paper we study the periodic (almost periodic) cooperative systems with a general class of first integrals. For such systems, whether the property (P_2) is true remains unknown. We conjecture here that such a property continued to hold.

We partially answer the above conjecture in this work. Under some conditions, we are able to show that this conjecture is indeed true. Our results generalize those of [8] and [12]. Without loss of generality, we concentrate our study on the almost periodic case.

We adapt the idea similar to that in [12]: by using a Lyapunov function, we show that any "positively compact" solution of the above system (defined in §2) is asymptotically almost periodic. The first integral used in [8] and [12] is $\sum_{i=1}^{n} x_i$, for which there are many properties which played a very important role in [8] and [12]. But since we consider more general first integrals, these properties fail to be true. As we shall see, we introduce a new class of first integrals to construct proper Lyapunov functions and apply the theory of cooperative systems to obtain the desired results. These Lyapunov functions play important roles in this work.

The paper is organized as follows. In the next section, we present some definitions and preliminary lemmas. In §3 we prove the main result, which partly gives an affirmative answer to the conjecture. In the last section we give an example.

2. Definitions and preliminary lemmas. Let $\mathbf{R}^n$ denote the real n-dimensional Euclidean space with norm $|x| = \sum_{i=1}^{n} |x_i|$ for $x = (x_1, \dots, x_n) \in \mathbf{R}^n$ and set $\mathbf{R}_+ = \{x \in \mathbf{R} : x \geq 0\}$, $\mathbf{R}_+^n = \{x \in \mathbf{R}^n : x_i \geq 0\}$, $\partial\mathbf{R}_+^n = \{x \in \mathbf{R}_+^n : x_i = 0 \text{ for some } i\}$ and $\operatorname{Int}\mathbf{R}_+^n = \mathbf{R}_+^n \backslash \partial\mathbf{R}_+^n$.

We denote $x < y$ if $x_i < y_i$ for each i, and $x \leq_i y$ if $x \neq y$, $x_i = y_i$ and $x_j \leq y_j$ for $j \neq i$. By $\langle \cdot, \cdot \rangle$, we mean the usual inner product in $\mathbf{R}^n$.

Let $H : \mathbf{R}_+^n \to \mathbf{R}$ be a C^1 function. We denote grad $H(p)$ as the *gradient* of H at p, which is the vector $((\partial H/\partial x_1)(p), \dots, (\partial H/\partial x_n)(p))$. We denote Int $H^{-1}(h)$ as the set $\{x \in \operatorname{Int}\mathbf{R}_+^n : H(x) = h\}$.

Let $F : \mathbf{R} \times \mathbf{R}_+^n \to \mathbf{R}^n$ be a vector field. A *first integral* for F is a function $H : \mathbf{R}_+^n \to \mathbf{R}_+$, of class C^1, such that grad $H(p) \neq 0$ at each $p \in \mathbf{R}_+^n$ and $\langle \operatorname{grad} H(p), F(t,p) \rangle \equiv 0$.

The system of ordinary differential equations we consider takes the form

$$\frac{dx_i}{dt} = F_i(t, x_1, \dots, x_n) = F_i(t,x), \qquad x \in \mathbf{R}_+^n,\ 1 \leq i \leq n, \tag{2.1}$$

where $F(t,x) = (F_1(t,x), \dots, F_n(t,x))$ is defined and C^1 on $\mathbf{R} \times \mathbf{R}_+^n$. Throughout this paper, we assume that $F(t,x)$ satisfies the following conditions

(A1) If $x \leq_i y$ then $F_i(t,x) < F_i(t,y)$;

(A2) There exists a first integral H for F such that $\operatorname{grad} H(x) > 0$ for $x \in \mathbf{R}_+^n$ and $H(0) = 0$;

(A3) $F(t,x)$ is uniformly almost periodic in t; or

(A3)′ $F(t,x)$ is periodic in t with period $\omega > 0$.

Remark. (A1) implies that (2.1) is cooperative. Also, the assumption that $H(0) = 0$ is not necessary.

Define the translate F_τ by $F_\tau(x,t) = F(x, \tau + t)$, where $\tau \in \mathbf{R}$. By the *hull*, we mean the set $\mathcal{F} = \operatorname{Cl}\{F_\tau : \tau \in \mathbf{R}\}$, where the closure is taken in the topology of uniform convergence on compact sets. It is known that $\mathcal{F}$ is an almost periodic minimal set [2], [11], [18]. It is easy to see that every $G \in \mathcal{F}$ satisfies the conditions (A2), (A3) and that if $x \leq_i y$ then $G(t,x) \leq G(t,y)$.

Recall that a mapping $\pi : W \times \mathbf{R} \to W$ is a flow if π is continuous, $\pi(w,0) = w$ and $\pi(\pi(w,s),t) = \pi(w,s+t)$ for all $w \in W$ and $s,t \in \mathbf{R}$, where W is a topological Hausdorff space. If W is a product space $W = X \times Y$, then a flow π is said to be a *skew-product flow* if π has the form $\pi = (\varphi, \sigma)$, or

$$\pi(x,y,t) = (\varphi(x,y,t), \sigma(y,t)),$$

where $\sigma : Y \times T \to Y$ is itself a flow on Y. For each $x \in \mathbf{R}^n_+$ and $G \in \mathcal{F}$, we denote by $\varphi(x,G,t)$ the maximally defined solution of $x' = G(x,t)$ that satisfies $\varphi(x,G,0) = x$. It is known that

$$\pi(x,G,\tau) = (\varphi(x,G,\tau), G_\tau) \tag{2.2}$$

describes a (local) skew-product flow on $\mathbf{R}^n_+ \times \mathcal{F}$ [10].

A solution $\varphi(x,F,t)$ of (2.1) is said to be *uniformly stable* if it is defined for all $t \geq 0$ and for every $\epsilon > 0$ there is a $\delta = \delta(\epsilon) > 0$ such that

$$|\varphi(x,F,\tau+t) - \varphi(y,F,\tau+t)| \leq \epsilon \quad \text{for all} \quad t \geq 0$$

whenever $\tau \geq 0$ and $|\varphi(x,F,\tau) - \varphi(y,F,\tau)| \leq \delta$ [10].

Let $V(x,y) : \mathbf{R}^n_+ \times \mathbf{R}^n_+ \to \mathbf{R}$ satisfy the following conditions.

(i) $V(x,y) > 0$ for all $x,y \in \mathbf{R}^n$ with $x \neq y$;

(ii) $V(x,y) = 0$ if and only if $x = y$;

(iii) $\lim_{|x-y| \to +\infty} V(x,y) = +\infty$.

Then we say that V is *positively definite.*

We shall use the following lemma, which is easily verified.

LEMMA 2.1. *Let $\varphi(\hat{x},F,t)$ be a positively compact solution, i.e., $\varphi(\hat{x},F,t)$ remains in a compact subset of $\mathbf{R}^n$ for all $t \geq 0$. Assume that there is a positively definite function $V(x,y)$ on $\mathbf{R}^n_+ \times \mathbf{R}^n_+$ such that for all $x,y \in \mathbf{R}^n_+$ and $G \in \mathcal{F}$, one has $D^+V(\varphi(x,G,t),\varphi(y,G,t)) \leq 0$, where D^+ denotes the right-hand derivative. Then $\varphi(\hat{x},F,t)$ is uniformly stable.*

Theorems 2 and 5 in [10] yields the following theorem.

THEOREM 2.1. *Let π be the skew-product flow* (2.2) *on $\mathbf{R}^n_+ \times \mathcal{F}$ generated by system* (2.1). *Let $\varphi(\hat{x},F,t)$ be a positively compact uniformly stable solution of* (2.1) *and let Ω denote the ω-limit set of the motion $\pi(\hat{x},F,t)$. Then Ω is a nonempty compact connected distal minimal set. Furthermore, if for some $G \in \mathcal{F}$ the section*

$$\Omega(G) = \{x \in \mathbf{R}^n_+ : (x,G) \in \Omega\}$$

has only finitely many points, then Ω is an almost periodic minimal set, and for each $(x,G) \in \Omega$ the solution $\varphi(x,G,t)$ is almost periodic in t.

The definition of a distal set can be found in [10].

Recall that a compact invariant set M is minimal if and only if every trajectory is dense in M. If Ω is minimal, then for $x,y \in \Omega(F)$, $(x,F) \in \Omega$, $(y,F) \in \Omega$. There is a sequence $t_n \to +\infty$ such that $\varphi(x,F,t_n) \to y$. $F_{t_n} \to F$. Since $\{\varphi(y,F,t_n)\}$ is compact, without loss of generality, suppose that $\varphi(y,F,t_n) \to z$. Now $F_{t_n} \to F$ and

$(z, F) \in G$. Hence, if Ω is minimal, then for $x, y \in \Omega(F)$, there is a sequence $t_n \to +\infty$ such that $\varphi(x, F, t_n) \to y$ and $\varphi(y, F, t_n) \to z$, where $z \in \Omega(F)$.

Let $x(t) = \varphi(x, G, t)$, $y(t) = \varphi(y, G, t)$ be two solutions of the system $x' = G(t, x)$. Suppose that they are defined on a common interval I. For $t \in I$, we define the following two subsets of $\{i : 1 \leq i \leq n\}$:

$$P_t = \{i : x_i(t) \geq y_i(t)\}, \qquad Q_t = \{i : x_i(t) \leq y_i(t)\}.$$

3. Partial answer.

In this section we study system (2.1) which has $H(x)$ as a first integral.

In the rest of this paper, we make the following assumption:

$$\text{(A4)} \qquad \frac{\partial H}{\partial x_i \partial x_j} \geq 0 \quad \text{for} \quad i \neq j.$$

Define the function $V(x, y) : \mathbf{R}^n_+ \times \mathbf{R}^n_+ \to \mathbf{R}_+$ as follows:

$$V(x, y) = \sum_{i=1}^{n} |H(x_1, \dots, x_{i-1}, x_i, y_{i+1}, \dots, y_n) - H(x_1, \dots, x_{i-1}, y_i, y_{i+1}, \dots, y_n)|.$$

Let

$$V^+(x, y) = \sum_{i \in P_t} [H(x_1, \dots, x_{i-1}, x_i, y_{i+1}, \dots, y_n) - H(x_1, \dots, x_{i-1}, y_i, y_{i+1}, \dots, y_n)],$$

$$V^-(x, y) = \sum_{i \in Q_t} [H(x_1, \dots, x_{i-1}, y_i, y_{i+1}, \dots, y_n) - H(x_1, \dots, x_{i-1}, x_i, y_{i+1}, \dots, y_n)],$$

then $V(x, y) = V^+(x, y) + V^-(x, y)$.

LEMMA 3.1. *Let $x(t) = \varphi(x, F, t)$, $y(t) = \varphi(y, F, t)$ be two solutions of the system* (2.1) *with a common interval I, then for $t_1, t_2 \in I$ with $t_1 < t_2$, we have*

$$V(x(t_2), y(t_2)) \leq V(x(t_1), y(t_1)).$$

Proof. We first prove that

$$\text{(3.1)} \qquad V^+(x(t_2), y(t_2)) \leq V^+(x(t_1), y(t_1)).$$

Let $z_i(t_1) = \max\{x_i(t_1), y_i(t_1)\}$, $z(t_1) = (z_1(t_1), \dots, z_n(t_1))$, then $z(t_1) \geq y(t_1)$ and $z(t_1) \geq x(t_1)$. Let $z(t) = \varphi(z(t_1), F, t - t_1)$ be a solution of (2.1), then (A1) and Kamke's theorem (e.g., see [2]–[4] and [15]) yield that

$$z(t) \geq y(t) \quad \text{and} \quad z(t) \geq x(t) \quad \text{for } t \geq t_1,$$

i.e., $z(t) \geq \max\{x(t), y(t)\} = (\max\{x_1(t), y_1(t)\}, \dots, \max\{x_n(t), y_n(t)\})$ for $t \geq t_1$. Thus, $V^+(z(t), y(t)) = V(z(t), y(t)) = H(z_1(t), \dots, z_n(t)) - H(y_1(t), \dots, y_n(t))$ for $t \geq t_1$. Since H is the first integral for F, we have

$$\text{(3.2)} \qquad V(z(t), y(t)) = V(z(t_1), y(t_1)) = V^+(x(t_1), y(t_1)) \text{ for } t \geq t_1.$$

Since $z(t_2) \geq \max\{x(t_2), y(t_2)\}$, the assumption (A4) implies that

$$\text{(3.3)} \qquad V(z(t_2), y(t_2)) \geq V(\max\{x(t_2), y(t_2)\}, y(t_2)) = V^+(x(t_2), y(t_2)).$$

By (3.2) and (3.3), (3.1) follows.

Similar arguments show that

$$V^-(x(t_2), y(t_2)) \leq V^-(x(t_1), y(t_1))$$

and the proof is thus completed. □

Remark. Clearly, if $V(x, y)$ defined above satisfies that $\lim_{|x-y| \to +\infty} V(x, y) = +\infty$, then V is positively definite.

LEMMA 3.2. *In* (2.1), *in addition to* (A1), (A2), (A3) (*or* (A3)′), *and* (A4), *assume that* $\lim_{|x-y|\to+\infty} V(x,y) = +\infty$ *and for every* $h \in \mathbf{R}_+$, *there is at most one bounded solution which is defined and belongs to* $H^{-1}(h)$ *for all* $t \in \mathbf{R}$. *Then for every positively compact solution* $\hat{x}(t)$, *there exists an almost periodic solution* (*or periodic solution*) *such that*

$$\lim_{t\to+\infty} |\hat{x}(t) - \phi(t)| = 0. \tag{3.4}$$

Proof. Let $\hat{x}(t) = \varphi(\hat{x}, F, t)$ be a positively compact solution and Ω be the ω-limit set of the corresponding motion $\pi(\hat{x}, F, t)$ in $\mathbf{R}^n_+ \times \mathcal{F}$. Let $\Omega(F) = \{x \in \mathbf{R}^n_+ : (x, F) \in \Omega\}$, then Lemma 3.1, combining Lemma 2.1 and Theorem 2.1, implies that $\Omega(F)$ consists of a single point y and the solution $\phi(t) = \varphi(y, F, t)$ is almost periodic.

Now we prove (3.4).

By Lemma 3.1, one has $D^+V(\hat{x}(t), \phi(t)) \leq 0$ for all $t \geq 0$. Thus, the limit $\lim_{t\to+\infty} V(\hat{x}(t), \phi(t))$ exists. Choose a sequence $t_n \to +\infty$ so that $\pi(\varphi(y, F, t_n)) \to (y, F)$ and $\varphi(\hat{x}, F, t_n) \to z$. Since $F_{t_n} \to F$ it follows that $z \in \Omega(F)$ and so $z = y$. Thus $\lim_{t\to+\infty} V(\hat{x}(t), \phi(t)) = 0$ and so $\lim_{t\to+\infty} |\hat{x}(t) - \phi(t)| = 0$. □

For $y = (y_1, \dots, y_n) \in \mathbf{R}^n$, we define

$$S_k(y) = \{x = (x_1, \dots, x_n) \in \mathbf{R}^n : x_i \leq y_i,\ i = 1, \dots, k-1,\ x_k < y_k \text{ and } x_{k+1} > y_{k+1},\ x_i \geq y_i \text{ for } i = k+2, \dots, n\},$$

$$k = 1, \dots, n-1.$$

LEMMA 3.3. *Let* $x(t), y(t)$ *be two solutions of* (2.1). *If* $x(t) \in \cup_{k=1}^{n-1} S_k(y(t))$, *then*

$$\frac{dV(x(t), y(t))}{dt} < 0.$$

Proof. We consider the case $x(t) \in S_1(y(t))$; for the other cases, the proofs are similar.

If $x(t_0) \in S_1(y(t_0))$, then there is a $\delta > 0$ such that $x(t) \in S_1(y(t))$ for $t_0 - \delta < t < t_0 + \delta$. Hence, for $t \in (t_0 - \delta, t_0 + \delta)$,

$$\begin{aligned} V(x(t), y(t)) = {} & H(y_1(t), \dots, y_n(t)) + H(x_1(t), \dots, x_n(t)) \\ & - 2H(x_1(t), y_2(t), \dots, y_n(t)). \end{aligned}$$

Since $H(x_1(t), \dots, x_n(t)) = H(y_1(t), \dots, y_n(t)) = \text{constant}$, we have

$$\begin{aligned} \frac{dV(x(t), y(t))}{dt} = {} & -2\frac{\partial H(x_1(t), y_2(t), \dots, y_n(t))}{\partial x_1} F_1(t, x_1(t), \dots, x_n(t)) \\ & - 2\sum_{i=2}^{n} \frac{\partial H(x_1(t), y_2(t), \dots, y_n(t))}{\partial y_i} F_i(t, y_1(t), \dots, y_n(t)). \end{aligned}$$

Notice that

$$\begin{aligned} & \frac{\partial H(x_1(t), y_2(t), \dots, y_n(t))}{\partial x_1} F_1(t, x_1(t), y_2(t), \dots, y_n(t)) \\ & + \sum_{i=2}^{n} \frac{\partial H(x_1(t), y_2(t), \dots, y_n(t))}{\partial y_i} F_i(t, x_1(t), y_2(t), \dots, y_n(t)) = 0 \end{aligned}$$

and so

$$\begin{aligned}\frac{dV(x(t),y(t))}{dt} = &-2\frac{\partial H(x_1(t),y_2(t),\dots,y_n(t))}{\partial x_1}\\ &\times (F_1(t,x_1(t),x_2(t),\dots,x_n(t)) - F_1(t,x_1(t),y_2(t),\dots,y_n(t)))\\ &-2\sum_{i=2}^{n}\frac{\partial H(x_1(t),y_2(t),\dots,y_n(t))}{\partial y_i}\\ &\times (F_i(t,y_1(t),y_2(t),\dots,y_n(t)) - F_i(t,x_1(t),y_2(t),\dots,y_n(t))).\end{aligned}$$

Now assumption (A1) yields that

$$\frac{dV(x(t),y(t))}{dt} < 0. \qquad \square$$

For any two points $x, y \in \mathbf{R}^n$, which are not related, i.e., that $x \le y$ or $y \le x$ is not true, we always find a map $P : \mathbf{R}^n \to \mathbf{R}^n$ such that $Px \in S_k(y)$ for some $k \in \{1,\dots,n-1\}$.

Let $\mathcal{T}$ be the set of such maps. Since $\mathbf{R}^n$ is finite dimensional, $\mathcal{T}$ is finite. Define

$$V_P(x,y) = V(Px,Py) \quad \text{for} \quad P \in \mathcal{T},$$

and let $W(x,y) = \sum_{P\in\mathcal{T}} V_P(x,y)$, then we have

LEMMA 3.4. *Let $x(t), y(t)$ be two solutions of* (2.1) *with $H(x(t)) = H(y(t))$. Then*

$$\frac{dW(x(t),y(t))}{dt} < 0.$$

Proof. Let $P \in \mathcal{T}$. Consider the system

$$\frac{du}{dt} = F_P(t,u), \tag{3.5}$$

where $u = Px$, $F_P(t,u) = P(F(t,P^{-1}u))$. It is easy to check that system (3.5) satisfies (A1) to (A4). By Lemma 3.1 and Lemma 3.2, we have

$$D^+V(Px(t),Py(t)) \le 0$$

and if $Px(t) \in \cup_{k=1}^{n-1} S_k(Py(t))$, then $\frac{dV(Px(t),Py(t))}{dt} < 0$. Hence

$$D^+V_p(x(t),y(t)) \le 0$$

and

$$\frac{dV_p(x(t),y(t))}{dt} < 0 \quad \text{for} \quad Px(t) \in \bigcup_{k=1}^{n-1} S_k(Py(t)).$$

For $x(t), y(t)$ with $H(x(t)) = H(y(t))$, (A2) implies that $x(t)$ and $y(t)$ are not related and so we can choose $P_0 \in \mathcal{T}$ such that $P_0x(t) \in S_k(P_0y(t))$ for some k, then the above argument shows that

$$\frac{dV_{P_0}(x(t),y(t))}{dt} < 0.$$

Now

$$\frac{dW(x(t),y(t))}{dt} = \sum_{P\in\mathcal{T}} \frac{dV_P(x(t),y(t))}{dt} < 0. \qquad \square$$

We are now in a position to prove our main result.

THEOREM 3.1. *In* (2.1), *in addition to* (A1), (A2), (A3) (*or* (A3)′), *and* (A4), *assume that* $\lim_{|x-y|\to\infty} V(x,y) = +\infty$. *Then for every positively compact solution* $\hat{x}(t)$, *there exists an almost periodic solution* (*or periodic solution*) *such that*

$$\lim_{t\to+\infty} |\hat{x}(t) - \phi(t)| = 0.$$

Proof. Let $\hat{x}(t) = \varphi(\hat{x}, F, t)$ be a positively compact solution and Ω the ω-limit set of the corresponding motion $\pi(\hat{x}, F, t)$ in $\mathbf{R}^n_+ \times \mathcal{F}$. Let $\Omega(F) = \{x \in \mathbf{R}^n_+ : (x, F) \in \Omega\}$. Suppose $\Omega(F)$ contains more than one point. Let $x_0, y_0 \in \Omega(F)$ with $x_0 \neq y_0$ and $x(t) = \varphi(x_0, F, t)$, $y(t) = \varphi(y_0, F, t)$ be the corresponding solution of (2.1).

Since $x(t)$ and $y(t)$ stay in a compact set in $\mathbf{R}^n_+$, they are defined for all $t \in \mathbf{R}$.

By Theorem 2.1, Ω is a distal set. Ellis's theorem [1] implies that the product flow on $\Omega \times \Omega$ is the union of minimal sets. Hence there is a sequence $t_n \to +\infty$ such that $x(t_n) \to x_0$ and $y(t_n) \to y_0$.

Lemma 3.4 implies that there is a $\tau \in \mathbf{R}$ (say $\tau > 0$) such that

$$W(x(t), y(t)) \leq W(x(\tau), y(\tau)) < W(x_0, y_0) \quad \text{for} \quad t \geq \tau.$$

Letting $t_n \to +\infty$, one gets the contradiction

$$W(x_0, y_0) = \lim_{t_n\to+\infty} W(x(t_n), y(t_n)) < W(x_0, y_0).$$

For $\tau \leq 0$, a suitable translation of $x(t)$ and $y(t)$ also yields a contradiction. Thus, the proof follows from Lemma 3.2. □

Remark. If we take $H(x_1, \ldots, x_n) = x_1 + \cdots + x_n$, it is trivial that (A4) is satisfied. Hence the above result generalizes those of [8] and [12].

In the rest of this section, we suppose that (2.1) is periodic, i.e., (A3)′ is true and (A1), (A2) and (A4) hold. Define the Poincaré map $T : \mathbf{R}^n_+ \to \mathbf{R}^n_+$ as follows

$$Tx = \varphi(x, F, \omega).$$

For $x_0 \in \mathbf{R}^n_+$, define $x_0 + \mathbf{R}^n_+ = \{x_0 + x : x \in \mathbf{R}^n_+\}$. Then it is easy to prove the following lemma.

LEMMA 3.5. *Let* $x_0 \in \operatorname{Int} \mathbf{R}^n_+$ *be a periodic point, i.e., the solution* $\varphi(x_0, F, t)$ *is periodic with the period* ω. *Then* $x_0 + \mathbf{R}^n_+$ *is positively invariant under* T, *i.e., for* $x \in (x_0 + \mathbf{R}^n_+) - x_0$, $Tx \in \operatorname{Int}(x_0 + \mathbf{R}^n_+)$. *Thus,* x_0 *is a unique periodic point on* $x_0 + \partial\mathbf{R}^n_+$.

LEMMA 3.6. *Let* $x_0 \in \operatorname{Int} \mathbf{R}^n_+$ *be a periodic point. Then, for every* $\epsilon > 0$ *there exists* $\delta > 0$ *such that for each* $h \in [H(c) - \delta, H(c) + \delta] \cap [0, M)$, *where* M *is the least upper bound of the values of* H, *there is a periodic point* x_h *such that* $H(x_h) = h$, $x_h > x_0$ *for* $h > H(x_0)$ (*respectively,* $x_h < x_0$ *for* $h < H(x_0)$) *and* $|x_h - x_0| < \epsilon$.

Proof. We consider the case $h > H(x_0)$. Let $e_i = (0, \ldots, 0, {}_i1, 0, \ldots, 0)$, then from (A2), we have $H(x_0 + e_i) > H(x_0)$. Let $\delta_1 = \min_{1\leq i\leq n}\{H(x_0 + e_i) - H(x_0)\}$, then (A2) implies that $H^{-1}(h) \cap (x_0 + \rho e_i) \neq \phi$ for all $1 \leq i \leq n$, $\rho \geq 0$, and $h \in [H(x_0), H(x_0) + (\delta_1/2)]$. It is easy to see that $H^{-1}(h) \cap (x_0 + \mathbf{R}^n_+)$ is homeomorphic to the $(n-1)$-dimensional disk. Lemma 3.2 and the definition of H shows that T maps $H^{-1}(h) \cap (x_0 + \mathbf{R}^n_+)$ to itself. The Brouwer fixed-point theorem yields that there is a periodic point $x_h \in H^{-1}(h) \cap (x_0 + \mathbf{R}^n_+)$ for all $h \in [H(x_0), H(x_0) + (\delta_1/2)]$. Also $x_h > x_0$.

Clearly, we can choose a point $x_1 > x_0$ such that for all $x \in H^{-1}(H(x_0) + (\delta_1/2)) \cap (x_0 + \mathbf{R}^n_+)$, $x < x_1$. Then for all $x \in H^{-1}(h) \cap (x_0 + \mathbf{R}^n_+)$ with $h \in [H(x_0), H(x_0) + (\delta_1/2)]$, we have $x_0 \leq x < x_1$. Let $m = \min\{\partial H(x)/\partial x_i : 1 \leq i \leq n,\ x_0 \leq x \leq x_1\}$. If we choose $\delta < \min\{m\epsilon, (\delta_1/2)\}$, then it is easy to conclude that for $h \in [H(x_0), H(x_0) + \delta) \cap [0, M)$, we have

$$|x - x_0| < \epsilon \text{ for } x \in H^{-1}(h),$$

in particular, $|x_h - x_0| < \epsilon$. □

THEOREM 3.2. *In* (2.1) *assume that the assumptions made in Theorem* 3.1 *are true. Then the set of periodic points in* Int $\mathbf{R}^n_+$ *is connected.*

Proof. It follows from Lemma 3.6 and Theorem 3.1. □

4. An example. Consider the following three-dimensional system in $\mathbf{R}^3_+$:

$$\begin{aligned} \dot{x}_1 &= \frac{a(t)x_2 + b(t)x_3 - 2c(t)x_1}{3 + x_2 + x_3}, \\ \dot{x}_2 &= \frac{c(t)x_1 - 2a(t)x_2 + b(t)x_3}{3 + x_1 + x_3}, \\ \dot{x}_3 &= \frac{c(t)x_1 + a(t)x_2 - 2b(t)x_3}{2 + x_1 + x_2}, \end{aligned} \tag{4.1}$$

where $a(t) > 0$, $b(t) > 0$, $c(t) > 0$, $a(t), b(t)$ and $c(t)$ are almost periodic. Clearly, $H(x_1, x_2, x_3) = (Hx_1)(2 + x_2) + (1 + x_1)(1 + x_3) + (1 + x_2)(2 + x_3) - 5$ is the first integral and system (4.1) satisfies (A1), (A2), (A3), and (A4). Also,

$$V(x, y) = |(x_1 - y_1)(3 + y_2 + y_3)| + |(x_2 - y_2)(3 + x_1 + y_3)| + |(x_3 - y_3)(2 + x_1 + x_2)|$$

is positively definite. Hence, we can apply Theorem 3.1 to system (4.1).

ON THE INSTABILITY OF ARBITRARY BIORTHOGONAL WAVELET PACKETS*

A. COHEN[†] AND I. DAUBECHIES[‡]

Abstract. Starting from a multiresolution analysis and the corresponding orthonormal wavelet basis, Coifman and Meyer have constructed wavelet packets, a library from which many different orthonormal bases can be picked. This paper proves that when the same procedure is applied to biorthogonal wavelet bases, not all the resulting wavelet packets lead to Riesz bases for $L^2(\mathbb{R})$.

Key words. wavelet packets, biorthogonal wavelets

AMS subject classifications. 26A16, 26A18, 26A27, 39B12

1. Short review of orthonormal wavelet bases.

An orthonormal basis of wavelets $\psi_{j,k}(x) = 2^{j/2}\psi(2^jx-k)$, $j,k \in \mathbb{Z}$, associated with a multiresolution analysis, is completely determined by a 2π-periodic function $m_0(\xi)$. More precisely,

$$\hat{\psi}(\xi) = e^{-i\xi/2}\overline{m_0\left(\frac{\xi}{2}+\pi\right)}\hat{\phi}\left(\frac{\xi}{2}\right), \tag{1.1}$$

with

$$\hat{\phi}(\xi) = (2\pi)^{-1/2}\prod_{j=1}^{\infty} m_0(2^{-j}\xi). \tag{1.2}$$

Here $^\wedge$ denotes the Fourier transform, normalized by

$$\hat{f}(\xi) = \frac{1}{\sqrt{2\pi}}\int dx e^{-ix\xi} f(x).$$

Conversely, given a 2π-periodic function m_0, one can define (1.1) and (1.2); if m_0 satisfies a few conditions, then the resulting ψ will generate an orthonormal wavelet basis. Which conditions? Let us assume that m_0 is continuous (which is the case in all useful examples). Then in order for (1.2) to converge, we need $m_0(0) = 1$. If moreover $|m_0(\xi) - 1| \leq C|\xi|^\alpha$ for some $\alpha > 0$, then (1.2) converges uniformly on compact sets. (This is not really necessary, but satisfied in all examples of even the remotest interest.) Furthermore, orthonormality of the $\psi_{j,k}$ implies that

$$|m_0(\xi)|^2 + |m_0(\xi+\pi)|^2 = 1 \tag{1.3}$$

(see Mallat [14]). This is not sufficient to ensure orthonormality of the $\psi_{j,k}$, however; to guarantee this orthonormality we need one more (necessary and sufficient) condition on m_0, of a more technical nature: there should exist a compact set K, congruent with $[-\pi,\pi]$ modulo 2π, such that

$$\inf_{\xi\in K}\inf_{n\geq 1}|m_0(2^{-n}\xi)| > 0. \tag{1.4}$$

* Received by the editors April 27, 1992; accepted for publication November 20, 1992.

[‡] Mathematics Department, Hill Center, Busch Campus, Rutgers University, New Brunswick, New Jersey 08930, and AT&T Bell Laboratories, Murray Hill, New Jersey 07974.

If all these conditions on m_0 are verified, then the $\psi_{j,k}$'s do indeed constitute an orthonormal basis for $L^2(\mathbb{R})$. Note that $m_0(0) = 1$ automatically ensures that $|m_0(2^{-n}\xi)| > \frac{1}{2}$ for sufficiently large n and all $\xi \in K$ (because K is compact), so that (1.4) is a constraint for only finitely many values of n. See Cohen [4] or Cohen [5] for a proof of the necessity and sufficiency of this last condition; the condition can also be recast in other forms [13], [5], [6]. A consequence of (1.4) is that (see Cohen [5])

$$\inf_{\xi \in K} |\hat{\phi}(\xi)| > 0. \tag{1.5}$$

The orthonormal basis $\{\psi_{j,k}; j, k \in \mathbb{Z}\}$ generated by ψ can be interpreted within the framework of a *multiresolution analysis* (see Mallat [14], Meyer [15]). Let V_0 be the space spanned by the functions $\phi(x-k)$, $k \in \mathbb{Z}$ (which are also orthonormal). Define V_j to be the space obtained by dilating V_0 by 2^j,

$$f \in V_j \Longleftrightarrow f(2^{-j}\cdot) \in V_0;$$

an orthonormal basis of V_j is given by $\{\phi_{j,k};\ k \in \mathbb{Z}\}$, with $\phi_{j,k}(x) = 2^{j/2}\phi(2^j x - k)$. Then

$$\cdots \subset V_{-2} \subset V_{-1} \subset V_0 \subset V_1 \subset V_2 \subset \cdots,$$

and

$$\bigcap_{j \in \mathbb{Z}} V_j = \{0\}, \qquad \overline{\bigcup_{j \in \mathbb{Z}} V_j} = L^2(\mathbb{R}).$$

Let W_j be the orthogonal complement in V_{j+1} of V_j. Then $\{\psi_{j,k};\ k \in \mathbb{Z}\}$ is an orthonormal basis in W_j, and

$$\bigoplus_{j=-\infty}^{\infty} W_j = L^2(\mathbb{R}). \tag{1.6}$$

This is the standard decomposition of $L^2(\mathbb{R})$ into different "layers" of wavelets with resolution 2^{-j}. One can also choose to use only reasonably fine scale wavelets, and to lump the coarser aspects together into one space, corresponding to the decomposition

$$L^2(\mathbb{R}) = V_0 \oplus \left(\bigoplus_{j=0}^{\infty} W_j \right). \tag{1.7}$$

2. Orthonormal wavelet packets.

Given a 2π-periodic function m_0 which satisfies all the conditions in §1, one can define many other orthonormal bases, corresponding to decompositions of $L^2(\mathbb{R})$ different from (1.6) or (1.7). They are all designated by the name "wavelet packets," first defined by Coifman and Meyer; for a discussion of their properties and some applications, see the two papers by Coifman, Meyer, and Wickerhauser in [16]. Their construction can be understood easily by using the following lemma [8].

LEMMA 2.1 (the "splitting trick"). *Suppose that the functions $f_k(x) = f(x-k)$, $k \in \mathbb{Z}$, are orthonormal. Define f^0, f^1 by*

$$\hat{f}^\sigma(\xi) = m_\sigma(\xi/2)\hat{f}(\xi/2), \qquad \sigma = 0, 1,$$

where m_0 *is as above,* $m_1(\xi) = e^{-i\xi}\,\overline{m_0(\xi+\pi)}$. *Then the functions* $f_k^0(x) = \frac{1}{\sqrt{2}} f^0\left(\frac{x}{2} - k\right)$, $f_k^1(x) = \frac{1}{\sqrt{2}} f^1\left(\frac{x}{2} - k\right)$, $k \in \mathbb{Z}$, *constitute an orthonormal basis for* $E = \overline{\text{Span}\{f_k\}}$.

Remark. Note that with this notation convention, $f_0^\sigma(x) = \frac{1}{\sqrt{2}} f^\sigma\left(\frac{x}{2}\right)$ and not $f^\sigma(x)$.

Proof.

1. Since

$$\begin{aligned}\langle f_k, f_\ell \rangle &= \int d\xi |\hat{f}(\xi)|^2 e^{i(k-\ell)\xi} \\ &= \int_0^{2\pi} d\xi e^{i(k-\ell)\xi} \sum_{m\in\mathbb{Z}} |\hat{f}(\xi + 2\pi m)|^2,\end{aligned}$$

orthonormality of the f_k is equivalent to $\sum_{m\in\mathbb{Z}} |\hat{f}(\xi + 2\pi m)|^2 = \frac{1}{2\pi}$ almost everywhere.

2. Similarly,

$$\begin{aligned}\langle f_k^0, f_\ell^0 \rangle &= 2\int d\xi |\hat{f}^0(2\xi)|^2 e^{2i(k-\ell)\xi} \\ &= 2\int_0^{\pi} d\xi e^{2i(k-\ell)\xi} \sum_{m\in\mathbb{Z}} |\hat{f}^0(2\xi + 2\pi m)|^2.\end{aligned}$$

Splitting the sum over m into even and odd m leads to

$$\begin{aligned}2\sum_{m\in\mathbb{Z}} |\hat{f}^0(2\xi + 2\pi m)|^2 &= 2|m_0(\xi)|^2 \sum_n |\hat{f}(\xi + 2\pi n)|^2 \\ &\quad + 2|m_0(\xi+\pi)|^2 \sum_n |\hat{f}(\xi + \pi + 2\pi n)|^2 = \frac{1}{\pi},\end{aligned}$$

proving that the f_k^0 are orthonormal. Orthonormality of the f_k^1 is proved analogously, as well as orthogonality of f_k^0 and f_ℓ^1.

3. On the other hand, if $\sum_k c_k f_k \perp f_\ell^\sigma$ for all $\ell \in \mathbb{Z}$ $\sigma = 0, 1$, then

$$0 = \left\langle f_\ell^\sigma, \sum_k c_k f_k \right\rangle = \sqrt{2} \sum_k \bar{c}_k \int_0^{2\pi} d\xi e^{i(k-2\ell)\xi} m_\sigma(\xi),$$

i.e. $c(\xi) = \sum_k c_k e^{-ik\xi}$ is orthogonal (in $L^2([0, 2\pi])$) to the $e^{-i2\ell\xi} m_\sigma(\xi), \ell \in \mathbb{Z}$, $\sigma = 0, 1$, implying

$$\overline{c(\xi)} m_\sigma(\xi) + \overline{c(\xi+\pi)} m_\sigma(\xi+\pi) = 0 \quad \text{a.e.}, j = 0, 1.$$

Multiplying with $\overline{m_\sigma(\xi)}$, and adding the two equations gives

$$\begin{aligned}0 &= \overline{c(\xi)}\,\left[|m_0(\xi)|^2 + m_0(\xi+\pi)|^2\right] \\ &\quad + \overline{c(\xi+\pi)}\,\left[m_0(\xi+\pi)\overline{m_0(\xi)} - \overline{m_0(\xi)} m_0(\xi+\pi)\right] = \overline{c(\xi)},\end{aligned}$$

proving that $\sum_k c_k f_k = 0$, so that the $\{f_\ell^\sigma; \ell \in \mathbb{Z}, \sigma = 0, 1\}$ span all of E. □

Modulo appropriate dilations, the splitting trick can of course also be applied to spaces with an orthonormal basis generated by the regularly spaced translates $f(x - ak)$, $k \in \mathbb{Z}$ of a single function, even if $a \neq 1$.

If the splitting trick is applied to V_0, the space with orthonormal basis $\{\phi_{0,k}; k \in \mathbb{Z}\}$, where $f = \phi$, then the corresponding functions f^0, f^1 are exactly $f^0(x) = \phi(x)$ and $f^1(x) = \psi(x)$; it easily follows that the splitting of V_0 into the spaces generated by the f_k^0 on one hand, the f_k^1 on the other hand, is exactly $V_0 = V_{-1} \oplus W_{-1}$. One can, therefore, view the transition from (1.7) to (1.6) as a result of infinitely many successive splittings, where at every step the V_j space with smallest index gets split into two.

Starting with (1.7) one can of course choose to apply the splitting trick to many subspaces other than V_0, leading to many different orthonormal bases. Every one of the functions generated in this way can be labelled by an overall dilation J, a translation k, and a sequence ϵ consisting of only ones and zeros, and ending in a tail of all zeros. Concretely,

$$f_{J,k;\epsilon}(x) = 2^{J/2}\psi_\epsilon(2^J x - k)$$

with

$$\hat{\psi}_\epsilon(\xi) = (2\pi)^{-1/2}\prod_{j=1}^{\infty} m_{\epsilon_j}(2^{-j}\xi);$$

if $j_{\max}$ is the largest index for which $\epsilon_{j_{\max}} = 1$, this can be rewritten as

$$\hat{\psi}_\epsilon(\xi) = \left[\prod_{j=1}^{j_{\max}} m_{\epsilon_j}(2^{-j}\xi)\right] \hat{\phi}(2^{-j_{\max}}\xi).$$

The function $f_{J,k;\epsilon}$ is the result of $j_{\max} - 1$ splittings of $W_{j_{\max}+J-1}$. For every fixed choice of a sequence of splittings the result is an orthonormal wavelet packet basis. In applications to signal analysis, one can use entropy estimates to find the "best" basis (Coifman and Wickerhauser [11]).

An important special case is where each W_j space is split exactly j times. The resulting orthonormal basis functions are the integer translates of all the ψ_ϵ, with ϵ ranging over all possible sequences of zeros and ones, with a tail of all zeros. This orthonormal basis is, of all the wavelet packet bases, the closest to a windowed Fourier transform.

3. Biorthogonal wavelet bases. There exist orthonormal wavelet bases with compactly supported ψ and ϕ. The 2π-periodic function m_0 is then a trigonometric polynomial. By imposing a factorization of the type

$$m_0(\xi) = \left(\frac{1 + e^{-i\xi}}{2}\right)^N Q(\xi),$$

one can construct ϕ and ψ with arbitrarily high degree of smoothness [12]. One inconvenience of these compactly supported orthonormal wavelets is that they are not symmetric. One can restore symmetry by relaxing the orthonormality requirement. In this case one works with *two* 2π-periodic functions, m_0 and $\tilde{m}_0$, satisfying

$$m_0(\xi)\overline{\tilde{m}_0(\xi)} + m_0(\xi + \pi)\overline{\tilde{m}_0(\xi + \pi)} = 1. \tag{3.1}$$

There are similarly two pairs of scaling functions and wavelets, defined by

$$(3.2)\qquad \hat{\phi}(\xi) = (2\pi)^{-1/2}\prod_{j=1}^{\infty} m_0(2^{-j}\xi), \qquad \hat{\tilde{\phi}}(\xi) = (2\pi)^{-1/2}\prod_{j=1}^{\infty} \tilde{m}_0(2^{-j}\xi)$$

$$\hat{\psi}(\xi) = e^{-i\xi/2}\overline{\tilde{m}_0\left(\tfrac{\xi}{2}+\pi\right)}\hat{\phi}\left(\tfrac{\xi}{2}\right), \qquad \hat{\tilde{\psi}}(\xi) = e^{-i\xi/2}\overline{m_0\left(\tfrac{\xi}{2}+\pi\right)}\hat{\tilde{\phi}}\left(\tfrac{\xi}{2}\right).$$

The $\psi_{j,k}$ and $\tilde{\psi}_{j,k}$ now constitute dual Riesz bases; both ψ and $\tilde{\psi}$ can be symmetric (or antisymmetric) and have compact support (Cohen, Daubechies, and Feauveau [9]). (Note that there also exists a different scheme of biorthogonal Riesz bases of wavelets, in which ψ and $\tilde{\psi}$ are symmetric or antisymmetric, and one of them is compactly supported, while the other is not. See Chui and Wang [3] and Chui [1].)

This corresponds to m_0 and $\tilde{m}_0$ which are trigonometric polynomials. We shall restrict ourselves to this case. In order for the whole construction to work, we need, of course, to impose again some conditions on m_0 and $\tilde{m}_0$. First, we need $m_0(0) = 1 = \tilde{m}_0(0)$; the infinite products in (3.2) then converge uniformly on compact sets. We also need more technical conditions. One of them is similar to the orthonormal case; i.e., we need that for some compact set K, congruent to $[-\pi, \pi]$ modulo 2π,

$$(3.3)\qquad \inf_{\xi\in K}\inf_{n>0}|m_0(2^{-n}\xi)| > 0$$

and

$$\inf_{\xi\in K}\inf_{n>0}|\tilde{m}_0(2^{-n}\xi)| > 0.$$

Another condition concerns the spectral radius of two matrices derived from m_0 and $\tilde{m}_0$ (see Cohen and Daubechies [7]). One consequence of (3.3) (the only one we shall use here) is that

$$\inf_{\xi\in K}|\hat{\phi}(\xi)| > 0, \qquad \inf_{\xi\in K}|\hat{\tilde{\phi}}(\xi)| > 0$$

(see Cohen, Daubechies and Feauveau [9]).

The two pairs of scaling functions generate two multiresolution hierarchies,

$$\cdots \subset V_{-2} \subset V_{-1} \subset V_0 \subset V_1 \subset V_2 \subset \cdots$$
$$\cdots \subset \tilde{V}_{-2} \subset \tilde{V}_{-1} \subset \tilde{V}_0 \subset \tilde{V}_1 \subset \tilde{V}_2 \subset \cdots,$$

and the $W_j = \overline{\mathrm{Span}\{\psi_{j,k};\ k \in \mathbb{Z}\}}$, (or $\tilde{W}_j = \overline{\mathrm{Span}\{\tilde{\psi}_{j,k};\ k \in \mathbb{Z}\}}$) are still complement spaces of the V_j in V_{j+1} (or $\tilde{V}_j$ in $\tilde{V}_{j+1}$), though no longer orthogonal complements. The two hierarchies are linked via the property that, for all $j \in \mathbb{Z}$,

$$\tilde{W}_j \perp V_j, W_j \perp \tilde{V}_j.$$

We can again decompose $L^2(\mathbb{R})$ as either

$$(3.4)\qquad L^2(\mathbb{R}) = \bigoplus_{j\in\mathbb{Z}} W_j$$

or

$$(3.5)\qquad L^2(\mathbb{R}) = V_0 \oplus \bigoplus_{j=0}^{\infty} W_j,$$

where the direct sums are not sums of orthogonal spaces. If we define Q_j to be the (nonorthogonal) projection operator onto W_j associated with this expansion, then the L^2-norm $\|u\|^2$ is still equivalent with $\sum_j \|Q_j u\|^2$:

LEMMA 3.1. *Let $\psi_{j,k}$, $\tilde{\psi}_{j,k}$ be biorthogonal wavelet bases, as defined above, with*

$$A\sum_{j,k} |c_{j,k}|^2 \le \left\|\sum_{j,k\in\mathbb{Z}} c_{j,k}\psi_{j,k}\right\|^2 \le B\sum_{j,k} |c_{j,k}|^2.$$

Then for all $u \in L^2(\mathbb{R})$,

$$A/B\sum_{j\in\mathbb{Z}} \|Q_j u\|^2 \le \|u\|^2 \le B/A\sum_{j\in\mathbb{Z}} \|Q_j u\|^2.$$

Proof. We can write $u = \sum_{j,k} c_{j,k}\psi_{j,k}$. It then follows that $Q_j u = \sum_k c_{j,k}\psi_{j,k}$, and

$$\begin{aligned}\|u\|^2 &= \left\|\sum_{j,k\in\mathbb{Z}} c_{j,k}\psi_{j,k}\right\|^2 \le B\sum_{j,k} |c_{j,k}|^2 \\ &= B\sum_j \left(\sum_k |c_{j,k}|^2\right) \le B/A\sum_j \left\|\sum_k c_{j,k}\psi_{j,k}\right\|^2 \le B/A\sum_j \|Q_j\psi\|^2.\end{aligned}$$

The lower bound is proved analogously. □

A similar theorem holds, of course, for the splitting (3.5).

4. The biorthogonal splitting trick. A natural question is now whether wavelet packets can be generalized to the biorthogonal setting. Let us first generalize the "splitting trick."

LEMMA 4.1 (the "biorthogonal splitting trick"). *Suppose that the functions $f_k(x) = f(x-k)$ constitute a Riesz basis for their closed linear span E, with*

$$A|c_k|^2 \le \left\|\sum_k c_k f_k\right\|^2 \le B\sum_k |c_k|^2, \tag{4.1}$$

for all square integrable sequences $(c_k)_{k\in\mathbb{Z}}$. Define f^0, f^1 by

$$\hat{f}^\sigma(\xi) = m_\sigma(\xi/2)\hat{f}(\xi/2), \qquad \sigma = 0, 1,$$

with m_0 as above, and $m_1(\xi) = e^{-i\xi}\overline{\tilde{m}_0(\xi+\pi)}$. Then the functions $f_k^0 = \frac{1}{\sqrt{2}}f^0\left(\frac{x}{2}-k\right)$, $f_k^1(x) = \frac{1}{\sqrt{2}}\, f^1\left(\frac{x}{2}-k\right)$, $k \in \mathbb{Z}$ constitute a Riesz basis for E, with

$$A'\sum_k \left[|a_k|^2 + |b_k|^2\right] \le \left\|\sum_k \left[a_k f_k^0 + b_k f_k^1\right]\right\|^2 \le B'\sum_k \left[|a_k|^2 + |b_k|^2\right], \tag{4.2}$$

where

$$\begin{aligned}B' &= B(\max(M_0, \tilde{M}_0) + \Delta_0) + \frac{B-A}{2}(M_0\tilde{M}_0)^{1/2} \\ A' &= \left[A^{-1}(\max(M_0, \tilde{M}_0) + \Delta_0) + \frac{B-A}{2AB}(M_0\tilde{M}_0)^{1/2}\right]^{-1}\end{aligned}$$

and

$$\begin{aligned}
M_0 &= \sup_\xi \left[|m_0(\xi)|^2 + |m_0(\xi+\pi)|^2\right] \\
\tilde{M}_0 &= \sup_\xi \left[|\tilde{m}_0(\xi)|^2 + |\tilde{m}_0(\xi+\pi)|^2\right] \\
\Delta_0 &= \sup_\xi |m_0(\xi)\tilde{m}_0(\xi+\pi) - m_0(\xi+\pi)\tilde{m}_0(\xi)|\,.
\end{aligned}$$

Remark. If the f_k are orthonormal to start with, and if $\tilde{m}_0 = m_0$ (orthonormal filter case), then $M_0 = \tilde{M}_0 = 1$, $\Delta_0 = 0$, $B = A = 1$, and the new bounds B', A' are also equal to 1. The estimates below can also be used to prove bounds of the type (4.2) where the constants B'', A'' are simply proportional to B and A respectively, namely

$$\begin{aligned}
B'' &= B\left[\max(M_0,\tilde{M}_0) + (M_0\tilde{M}_0)^{1/2}\right] \\
A'' &= A\left[\max(M_0,\tilde{M}_0) + (M_0\tilde{M}_0)^{1/2}\right]^{-1}\,;
\end{aligned} \tag{4.3}$$

these "simpler" bounds are less sharp, in the sense that they do not collapse to 1 if everything is orthonormal.

Proof.

1. For $(c_k)_{k\in\mathbb{Z}} \in \ell^2(\mathbb{Z})$, we denote by $c(\xi)$ the 2π-periodic function $c(\xi) = \sum_k c_k e^{-ik\xi} \in L^2([0,2\pi])$. Then

$$\begin{aligned}
\left\|\sum_k c_k f_k\right\|^2 &= \int_{-\infty}^{\infty} d\xi \left|\sum_k c_k e^{-ik\xi}\hat{f}(\xi)\right|^2 \\
&= \int_0^{2\pi} d\xi |c(\xi)|^2 \sum_k |\hat{f}(\xi+2\pi k)|^2,
\end{aligned}$$

so that (4.1) is seen to be equivalent to $A/2\pi \le \sum_k |\hat{f}(\xi+2\pi k)|^2 \le B/2\pi$.

2. Define $\tilde{f} \in E$ by $\langle \tilde{f}, f_k\rangle = \delta_{0,k}$. Then the $\tilde{f}_\ell(x) = \tilde{f}(x-\ell)$, $\ell \in \mathbb{Z}$ constitute the dual Riesz basis for the f_k. In particular,

$$B^{-1}\sum_k |c_k|^2 \le \left\|\sum_k c_k\tilde{f}_k\right\|^2 \le A^{-1}\sum_k |c_k|^2 \tag{4.4}$$

and

$$\langle \tilde{f}_\ell, f_k\rangle = \delta_{k,\ell}.$$

(Both can easily be derived from $\hat{\tilde{f}}(\xi) = \frac{1}{2\pi}\hat{f}(\xi)[\sum_k |\hat{f}(\xi+2\pi k)|^2]^{-1}$.)

3. We start by proving that the f_k^0, f_ℓ^1 span all of E. Assume that $u \in E$ is orthogonal to all the f_ℓ^σ, $\ell \in \mathbb{Z}$, $\sigma = 0, 1$. Since the $\tilde{f}_k$ constitute a Riesz basis for E, we can write $u = \sum_k c_k\tilde{f}_k$. We have then

$$\begin{aligned}
0 = \langle u, f_\ell^\sigma\rangle &= \sqrt{2}\int_{-\infty}^{\infty} d\xi\overline{c(\xi)\hat{\tilde{f}}(\xi)}\hat{f}(\xi)m_\sigma(\xi)e^{-2i\ell\xi} \\
&= \sqrt{2}\int_0^\pi d\xi e^{-2i\ell\xi}\sum_{n\in\mathbb{Z}} m_\sigma(\xi+n\pi)\overline{c(\xi+n\pi)\hat{f}(\xi+n\pi)\hat{\tilde{f}}(\xi+n\pi)}.
\end{aligned}$$

Because m_σ and c are 2π-periodic, and $\sum_\ell \hat{f}(\xi + 2\ell\pi)\overline{\widehat{\tilde{f}}\,(\xi + 2\ell\pi)} = \frac{1}{2\pi}$, this implies

$$m_\sigma(\xi)\overline{c(\xi)} + m_\sigma(\xi + \pi)\overline{c(\xi + \pi)} = 0 \quad \text{a.e.}$$

Multiplying with $\overline{\tilde{m}_\sigma(\xi)}$, and adding the two equations ($\sigma = 0, 1$) leads to (again, almost everywhere)

$$\begin{aligned} 0 = \overline{c(\xi)} &\left[m_0(\xi)\overline{\tilde{m}_0(\xi)} + \overline{\tilde{m}_0(\xi + \pi)}m_0(\xi + \pi)\right] \\ &+ \overline{c(\xi + \pi)}\left[m_0(\xi + \pi)\overline{\tilde{m}_0(\xi)} - \overline{\tilde{m}_0(\xi)}m_0(\xi + \pi)\right] = \overline{c(\xi)}, \end{aligned}$$

which proves that $u = 0$.

4. Next we derive an upper bound on $\sum_k \left[a_k f_k^0 + b_k f_k^1\right]$. With the notation $F(\xi) = \sum_k |\hat{f}(\xi + 2\pi k)|^2$, we have

$$\begin{aligned} &\left\|\sum_k \left[a_k f_k^0 + b_k f_k^1\right]\right\|^2 = 2\int_{-\infty}^{\infty} d\xi |\hat{f}(\xi)|^2 \left|\sum_k a_k e^{-2ik\xi} m_0(\xi) + \sum_k b_k e^{-2ik\xi} m_1(\xi)\right|^2 \\ &\le 2\int_0^\pi d\xi \left[|a(2\xi)|^2 \left(F(\xi)|m_0(\xi)|^2 + F(\xi + \pi)|m_0(\xi + \pi)|^2\right)\right. \\ &\qquad + |b(2\xi)|^2 \left(F(\xi)|\tilde{m}_0(\xi + \pi)|^2 + F(\xi + \pi)|\tilde{m}_0(\xi)|^2\right) \\ &\qquad \left. + 2|a(2\xi)||b(2\xi)||F(\xi)m_0(\xi)\tilde{m}_0(\xi + \pi) - F(\xi + \pi)m_0(\xi + \pi)\tilde{m}_0(\xi)|\right] \\ &\le 2\int_0^\pi d\xi \left[|a(2\xi)|^2 \left(\frac{B}{2\pi}M_0 + \frac{F(\xi) + F(\xi + \pi)}{2}|m_0(\xi)\tilde{m}_0(\xi + \pi) - m_0(\xi + \pi)\tilde{m}_0(\xi)|\right.\right. \\ &\qquad\qquad \left. + \left|\frac{F(\xi) - F(\xi + \pi)}{2}\right| (M_0\tilde{M}_0)^{1/2}\right) \\ &\qquad + |b(2\xi)|^2 \left(\frac{B}{2\pi}\tilde{M}_0 + \frac{F(\xi) + F(\xi + \pi)}{2}|m_0(\xi)\tilde{m}_0(\xi + \pi) - m_0(\xi + \pi)\tilde{m}_0(\xi)|\right. \\ &\qquad\qquad \left.\left. + \left|\frac{F(\xi) - F(\xi + \pi)}{2}\right| (M_0\tilde{M}_0)^{1/2}\right)\right] \\ &\le \left[B(M_0 + \Delta_0) + \frac{B - A}{2}(M_0\tilde{M}_0)^{1/2}\right] \sum |a_k|^2 \\ &\quad + \left[B(\tilde{M}_0 + \Delta_0) + \frac{B - A}{2}(M_0\tilde{M}_0)^{1/2}\right] \sum |b_k|^2, \end{aligned}$$

which implies the upper bound in (4.2).

5. To derive the lower bound in (4.2), we introduce a dual family $\tilde{f}_k^0$, $\tilde{f}_k^1$, defined by $\tilde{f}_k^\sigma(x) = \frac{1}{\sqrt{2}}\tilde{f}^\sigma\left(\frac{x}{2} - k\right)$, with

$$\widehat{\tilde{f}}^{\,\sigma}(\xi) = \tilde{m}_\sigma(\xi/2)\widehat{\tilde{f}}\,(\xi/2),$$

where $\tilde{m}_0(\xi)$ is as above, and $\tilde{m}_1(\xi) = e^{-i\xi}\overline{m_0(\xi + \pi)}$. One easily proves $\langle f_\ell^\sigma, \tilde{f}_m^\tau\rangle = \delta_{\sigma,\tau}\delta_{\ell,m}$. For $\sigma = \tau = 0$, for instance,

$$\langle f_\ell^0, \tilde{f}_m^0\rangle = 2\int d\xi m_0(\xi)\overline{\tilde{m}_0(\xi)}\hat{f}(\xi)\widehat{\tilde{f}}\,(\xi)e^{2i(\ell - m)\xi}$$

$$\begin{aligned}
&= \pi^{-1}\int_0^{2\pi} d\xi m_0(\xi)\overline{\tilde{m}_0(\xi)} e^{2i(\ell-m)\xi} \\
&= \pi^{-1}\int_0^{\pi} d\xi \left[m_0(\xi)\overline{\tilde{m}_0(\xi)} + m_0(\xi+\pi)\overline{\tilde{m}_0(\xi+\pi)}\right] e^{2i(\ell-m)\xi} \\
&= \delta_{\ell,m}.
\end{aligned}$$

6. The same arguments as in point 4, together with (4.4), prove that

$$\begin{aligned}
&\left\|\sum_k a_k\tilde{f}_k^0 + b_k\tilde{f}_k^1\right\|^2 \\
&\quad\le \left[A^{-1}(\max(M_0,\tilde{M}_0)+\Delta_0) + \frac{A^{-1}-B^{-1}}{2}(M_0\tilde{M}_0)^{1/2}\right]\sum_k\left[|a_k|^2+|b_k|^2\right] \\
&\quad= A'^{-1}\sum_k\left[|a_k|^2+|b_k|^2\right].
\end{aligned}$$

The lower bound in (4.2) now follows from a simple duality argument.

$$\begin{aligned}
\sum_k\left[|a_k|^2+|b_k|^2\right] &= \left\langle \sum_k\left[a_kf_k^0+b_kf_k^1\right], \sum_k\left[a_k\tilde{f}_k^0+b_k\tilde{f}_k^1\right]\right\rangle \\
&\le \left\|\sum_k\left[a_kf_k^0+b_kf_k^1\right]\right\| A'^{-1/2}\left(\sum_k\left[|a_k|^2+|b_k|^2\right]\right)^{1/2}. \qquad \square
\end{aligned}$$

An immediate corollary is the following.

COROLLARY 4.2. *We assume the same as in Lemma* 4.1. *If* $u = u_0 + u_1$ *is the unique decomposition of* $u \in E$ *into* $u_\sigma = \sum_k c_k^\sigma f_k^\sigma$, *then*

$$\frac{A'}{B'}\left[\|u_0\|^2+\|u_1\|^2\right] \le \|u\|^2 \le \frac{B'}{A'}\left[\|u_0\|^2+\|u_1\|^2\right].$$

Proof. By the same argument as for Lemma 3.1. □

5. Biorthogonal wavelet packets. We can now apply the biorthogonal splitting trick to the spaces V_0, W_j in the nonorthogonal decomposition (3.5). We start by choosing, among V_0 and all the W_j, an arbitrary subset of spaces to be split, and we apply the biorthogonal splitting trick to all of them. We end up with a different decomposition, in which all the "split" spaces are replaced by their two offspring. We can then repeat the procedure: choose an arbitrary subset, and split again. Every splitting corresponds to a replacement of the basis vectors as well. If, after L splitting steps, the subspace W_j has undergone $J \le L$ splittings, then the $\psi_{j,k}(x) = 2^{j/2}\psi(2^jx-k)$, $k \in \mathbb{Z}$, will have been replaced by $\psi^J_{j;\epsilon_1,\dots,\epsilon_k;\ell(x)} = 2^{(j-J)/2}\psi^J_{\epsilon_1,\dots,\epsilon_J}(2^{j-J}x-\ell)$, $\epsilon_n = 0$ or 1, $\ell \in \mathbb{Z}$, with $\hat{\psi}^J_{\epsilon_1,\dots,\epsilon_J}(\xi) = m_{\epsilon_1}(\xi/2),\dots,m_{\epsilon_J}(2^{-J}\xi)\,\hat{\psi}(2^{-J}\xi)$. The following theorem tells us that as long as we confine ourselves to a finite number of splitting steps, the result is still a Riesz basis.

THEOREM 5.1. *Suppose we start from the decomposition* (3.5), *with*

$$
\begin{aligned}
A\left[\sum_k |\alpha_k|^2 + \sum_{j,k} |\beta_{j,k}|^2\right] &\le \left\| \sum_{k\in\mathbb{Z}} \alpha_k \phi_{0,k} + \sum_{j=0}^{\infty}\sum_{k\in\mathbb{Z}} \beta_{j,k}\psi_{j,k} \right\|^2 \\
&\le B\left[\sum_k |\alpha_k|^2 + \sum_{j,k} |\beta_{j,k}|^2\right] .
\end{aligned}
\tag{5.1}
$$

Let us denote by Ψ^L_λ *the vectors obtained after* L *splitting steps, as described above (the label* λ *stands for* $J, j, \epsilon_1, \dots, \epsilon_K$ *and* ℓ*). Then the* Ψ^L_λ *still constitute a Riesz basis, and*

$$
A_L \sum_\lambda |\gamma_\lambda|^2 \le \left\| \sum_\lambda \gamma_\lambda \Psi^L_\lambda \right\|^2 \le B_L \sum_\lambda |\gamma_\lambda|^2 .
\tag{5.2}
$$

The constants B_L, A_L *are defined recursively by*

$$
B_0 = B, A_0 = A, \beta_0 = B/A, \alpha_0 = A/B,
$$

and

$$
\begin{aligned}
B_L &= \beta_{L-1}\left[B_{L-1}\mu_0 + (B_{L-1} - A_{L-1})\,\nu_0\right] \\
A_L &= \alpha_{L-1}\left[A^{-1}_{L-1}\mu_0 + \left(A^{-1}_{L-1} - B^{-1}_{L-1}\right)\nu_0\right]^{-1}
\end{aligned}
\tag{5.3}
$$

with

$$
\begin{aligned}
\beta_L &= \beta_{L-1}\left[B_{L-1}\mu_0 + (B_{L-1} - A_{L-1})\,\nu_0\right]\left[A^{-1}_{L-1}\mu_0 + \left(A^{-1}_{L-1} - B^{-1}_{L-1}\right)\nu_0\right] \\
\alpha_L &= \alpha_{L-1}\left[A^{-1}_{L-1}\mu_0 + \left(A^{-1}_{L-1} - B^{-1}_{L-1}\right)\nu_0\right]^{-1}\left[B_{L-1}\mu_0 + (B_{L-1} - A_{L-1})\,\nu_0\right]^{-1}
\end{aligned}
\tag{5.4}
$$

and

$$
\begin{aligned}
\mu_0 &= \max(M_0, \tilde{M}_0) + \Delta_0 \\
\nu_0 &= \tfrac{1}{2}(M_0\tilde{M}_0)^{1/2}
\end{aligned}
$$

($M_0, \tilde{M}_0, \Delta_0$ *as defined in Lemma* 4.1).

Proof.

1. We will work by induction on L, the number of splittings. Suppose that we have gone through ℓ splitting steps, resulting in a (nonorthogonal) decomposition of $L^2(\mathbb{R})$, i.e.,

$$
L^2(\mathbb{R}) = \bigoplus_m E_{\ell,m};
$$

in each $E_{\ell,m}$ we have a Riesz basis $F_{\ell,m;k}$, $k \in \mathbb{Z}$. Assume that

$$
A_\ell \sum_{m,k} |c_{m,k}|^2 \le \left\| \sum_{m,k} c_{m,k} F_{\ell,m;k} \right\|^2 \le B_\ell \sum_{m,k} |c_{m,k}|^2
$$

and that for arbitrary $u \in L^2(\mathbb{R})$, $u = \sum_m u_{\ell,m}$, with $u_{\ell,m} \in E_{\ell,m}$, we have

$$\alpha_\ell \sum_m \|u_{\ell,m}\|^2 \leq \|u\|^2 \leq \beta_\ell \sum_m \|u_{\ell,m}\|^2. \tag{5.5}$$

We now choose an arbitrary subset of the $\{E_{\ell,m}; m \in \mathbb{Z}\}$ of spaces to be split, and we apply the biorthogonal splitting trick to each of them. If $E_{\ell,n}$ is a space that gets split into $E^0_{\ell,n} \oplus E^1_{\ell,n}$, then for arbitrary

$$u_{\ell,n} = \sum_k c^0_{n,k} F^0_{\ell,n;k} + \sum_k c^1_{n,k} F^1_{\ell,n;k} = u^0_{\ell,n} + u^1_{\ell,n},$$

applying Lemma 4.1 leads to

$$\begin{aligned}&\left[A_\ell^{-1}\mu_0 + \left(A_\ell^{-1} - B_\ell^{-1}\right)\nu_0\right]^{-1} \sum_{\sigma=0,1} \sum_k |c^\sigma_{n,k}|^2 \\ &\leq \|u_{\ell,n}\|^2 \leq \left[B_\ell\mu_0 + (B_\ell - A_\ell)\nu_0\right] \sum_{\sigma=0,1} \sum_k |c^\sigma_{n,k}|^2.\end{aligned}$$

Bringing all these inequalities together, combining with (5.5), and relabeling the $F^\sigma_{\ell,n;k}$ as $F_{\ell+1,m;k'}$, we obtain

$$\begin{aligned}&\alpha_\ell \left[A_\ell^{-1}\mu_0 + \left(A_\ell^{-1} - B_\ell^{-1}\right)\nu_0\right]^{-1} \sum_k |c_{m,k}|^2 \leq \left\|\sum_{m,k} c_{m,k} F_{\ell+1,m;k}\right\|^2 \\ &\leq \beta_\ell \left[B_\ell\mu_0 + (B_\ell - A_\ell)\nu_0\right] \sum_k |c_{m,k}|^2.\end{aligned} \tag{5.6}$$

2. From Corollary 4.2 and (5.5) we also obtain

$$\alpha_{\ell+1} \sum_m \|u_{\ell+1,m}\|^2 \leq \|u\|^2 \leq \beta_{\ell+1} \sum_m \|u_{\ell+1,m}\|^2, \tag{5.7}$$

with

$$\begin{aligned}\beta_{\ell+1} &= \beta_\ell \left[B_\ell\mu_0 + (B_\ell - A_\ell)\nu_0\right] \left[A_\ell^{-1}\mu_0 + \left(A_\ell^{-1} - B_\ell^{-1}\right)\nu_0\right], \\ \alpha_{\ell+1} &= \alpha_\ell \left[B_\ell\mu_0 + (B_\ell - A_\ell)\nu_0\right]^{-1} \left[A_\ell^{-1}\mu_0 + \left(A_\ell^{-1} - B_\ell^{-1}\right)\nu_0\right]^{-1}.\end{aligned}$$

(5.6) and (5.7) can be used for the next induction step.

3. To start it all (at $L = 0$), we need (5.1), together with Lemma 3.1, which leads to

$$\begin{aligned}A_0 &= A, & B_0 &= B \\ \alpha_0 &= A/B, & B_0 &= B/A.\end{aligned} \qquad \square$$

Remarks.

1. If $A = B = 1$ and $m_0 = \tilde{m}_0$, then $M_0 = \tilde{M}_0 = 1$, $\Delta_0 = 0$, and $A_L = B_L = 1$ for every L; in the orthonormal case we recover the exact estimates for orthonormal wavelet packets.

2. In the nonorthonormal case, B_L and A_L^{-1} increase very rapidly with L: one easily checks that (5.2) and (5.3) imply that $B_L \sim CM^{2^L}$ for large L. In Chui and Li [2] a different technique is used to derive bounds similar to (5.2), with $\log B_L \sim$

const. L, i.e., only exponential growth for B_L. The bounds of Chui and Li do not seem to collapse to the optimal bounds 1 in the orthonormal case, however. They also restrict themselves to the case where one chooses, at every splitting step, to split every available subspace; this is probably not a crucial restriction. The estimates in the next section show that B_L grows at least exponentially with L.

3. For every possible choice of splittings, the dual basis of the resulting Riesz basis can be constructed by applying exactly the same choice of splittings on the original dual decomposition (with the $\tilde{\psi}_{j,k}$ instead of the $\psi_{j,k}$), and using $\tilde{m}_0, \tilde{m}_1$ instead of m_0, m_1 at every splitting step. This follows from the constructions in §4; see also Chui and Li [2].

6. Instability of arbitrary biorthogonal wavelet packets. If we choose to restrict to at most L splittings, then the previous section tells us that we will still have a Riesz basis, even though the constants involved may be large. In the orthonormal case, a very beautiful special wavelet packet basis resulted from splitting every W_j exactly j times. In this decomposition, the total number of splitting steps is not limited, and Theorem 5.1 does not guarantee that the biorthogonal analog leads to a Riesz basis. We shall show in this section that in fact we don't have a Riesz basis (except in the orthonormal case). Define, as in the orthonormal case,

$$\hat{\psi}_\epsilon(\xi) = \left[\prod_{j=1}^{N} m_{\epsilon_j}(2^{-j}\xi)\right] \hat{\phi}(2^{-N}\xi),$$

where $\epsilon = (\epsilon_1, \ldots, \epsilon_N)$ is a sequence of length N ($|\epsilon| = N$) consisting of only zeros and ones. We start by proving several lemmas about the $\hat{\psi}_\epsilon$.

LEMMA 6.1. *There exists a constant $C > 0$ such that*

$$\int d\xi |\hat{\psi}_\epsilon(\xi)|^2 \geq C \int_{|\xi| \leq 2^N \pi} d\xi \prod_{j=1}^{N} |m_{\epsilon_j}(2^{-j}\xi)|^2 \tag{6.1}$$

for all N and ϵ with $|\epsilon| = N$.

Proof.

1. Remember (see §3) that there exists a compact set K, congruent with $[-\pi, \pi]$ modulo 2π, so that $|\hat{\phi}(\xi)| \geq C^2 > 0$ for all $\xi \in K$.

2. We have

$$|\hat{\psi}_\epsilon(\xi)| = \prod_{j=1}^{N} |m_{\epsilon_j}(2^{-j}\xi)| |\hat{\phi}(2^{-N}\xi)|,$$

hence

$$\begin{aligned}\int d\xi |\hat{\psi}_\epsilon(\xi)|^2 &\geq \int_{\xi \in 2^N K} d\xi \prod_{j=1}^{N} |m_{\epsilon_j}(2^{-j}\xi)|^2 |\hat{\phi}(2^{-N}\xi)|^2 \\ &\geq C \int_{\xi \in 2^N K} d\xi \prod_{j=1}^{N} |m_{\epsilon_j}(2^{-j}\xi)|^2 \\ &= C \int_{|\xi| \leq 2^N \pi} d\xi \prod_{j=1}^{N} |m_{\epsilon_j}(2^{-j}\xi)|^2,\end{aligned}$$

where we have used the congruency of K with $[-\pi, \pi]$, and the 2π-periodicity of the m_{ϵ_j}. □

LEMMA 6.2. *Define $p(\xi) = |m_0(\xi)|^2 + |m_1(\xi)|^2$. Then for some $C > 0$,*

$$\sum_{\epsilon \in S_N} \|\psi_\epsilon\|^2 \geq C2^N \int_{|\xi| \leq \pi} d\xi \prod_{j=0}^{N-1} p(2^j\xi), \tag{6.2}$$

where S_N is the set of all sequences $\epsilon = (\epsilon_1, \dots, \epsilon_N)$ of length N and consisting of only zeros and ones.

Proof. The proof follows immediately from (6.1) by summing over the 2^N sequences ϵ with length N, and by changing the integration variable. □

The following lemma will allow us to compute a lower bound for the right-hand side of (6.2).

LEMMA 6.3. *The function $p(\xi) = |m_0(\xi)|^2 + |m_1(\xi)|^2$ satisfies*

$$p(\xi)p(\xi + \pi) \geq 1.$$

Moreover, if $m_0 \neq \tilde{m}_0$ (nonorthogonal case), then

$$p(\xi)p(\xi + \pi) > 1 \quad a.e.$$

Proof.

1. We know (see §4) that

$$m_0(\xi)\overline{\tilde{m}_0(\xi)} + m_0(\xi + \pi)\overline{\tilde{m}_0(\xi + \pi)} = 1. \tag{6.3}$$

By Cauchy–Schwarz, this implies

$$\left[|m_0(\xi)|^2 + |\tilde{m}_0(\xi + \pi)|^2\right] \left[|\tilde{m}_0(\xi)|^2 + |m_0(\xi + \pi)|^2\right] \geq 1 \tag{6.4}$$

or

$$p(\xi)p(\xi + \pi) \geq 1 \left(\text{use } m_\sigma(\xi) = e^{-i\xi}\overline{\tilde{m}_{1-\sigma}(\xi + \pi)}\right).$$

2. Equality in (6.4) is only possible for those ξ for which

$$\tilde{m}_0(\xi) = \alpha(\xi)m_0(\xi), \qquad \overline{m_0(\xi + \pi)} = \alpha(\xi)\overline{\tilde{m}_0(\xi + \pi)}$$

for some $\alpha(\xi)$. For such ξ,

$$\tilde{m}_0(\xi)\overline{\tilde{m}_0(\xi + \pi)} - \overline{m_0(\xi + \pi)}m_0(\xi) = 0. \tag{6.5}$$

3. Suppose that (6.5) were true for all ξ. If we extend the trigonometric polynomials from $z = e^{-i\xi}$ on the torus to all $z \in \mathbb{C}$ (extending $M_0(e^{-i\xi}) = m_0(\xi)$), then the identity (6.5) would still hold for all z,

$$\tilde{M}_0(z)\bar{\tilde{M}}(-z^{-1}) - M_0(z)\bar{M}_0(-z^{-1}) = 0, \tag{6.6}$$

where for $A(z) = \sum_n a_n z^n$, we use the notation $\bar{A}(z) = \sum_n \bar{a}_n z^n$. On the other hand, extension of (6.3) gives

$$M_0(z)\bar{\tilde{M}}_0(z^{-1}) + M_0(-z)\bar{\tilde{M}}_0(-z^{-1}) = 1,$$

which means that $M_0(z)$ and $\bar{\tilde{M}}(-z^{-1})$ share no zeros. It then follows from (6.6) that $\tilde{M}_0(z)$ is zero whenever $M_0(z)$ is. Similarly one concludes that $M_0(z)$ is zero whenever $\tilde{M}_0(z)$ is. Since both are polynomials (up to multiplication by an integer power of z), $M_0 \equiv \tilde{M}_0$ follows.

4. If $\tilde{m}_0 \neq m_0$, one finds therefore that the left-hand side of (6.5) is a nontrivial trigonometric polynomial. It follows that (6.5) can only hold in a finite number of ξ_j. Consequently, (6.4) is a strict inequality except in this finite number of ξ_j, which implies that $p(\xi)p(\xi+\pi) > 1$ almost everywhere. □

We are now ready for the following theorem.

THEOREM 6.4. *There exist $C > 0$, $\lambda > 1$ so that, for all $N \in \mathbb{N}$, $N \geq 1$,*

$$\sum_{\substack{\epsilon \\ |\epsilon|=N}} \|\psi_\epsilon\|^2 \geq C 2^N \lambda^N. \tag{6.7}$$

Proof.

1. By Lemma 6.2, we only need to prove that

$$\int_{-\pi}^{\pi} d\xi \prod_{j=0}^{N-1} p(2^j\xi) \geq C\lambda^N.$$

2. By Jensen's inequality,

$$\log\left[\frac{1}{2\pi}\int_{-\pi}^{\pi} d\xi \prod_{j=0}^{N-1} p(2^j\xi)\right] \geq \frac{1}{2\pi}\int_{-\pi}^{\pi} d\xi \log\left[\prod_{j=0}^{N-1} p(2^j\xi)\right]$$

$$= \frac{1}{2\pi}\sum_{j=0}^{N-1}\int_{-\pi}^{\pi} d\xi \log p(2^j\xi) = \frac{N}{2\pi}\int_{-\pi}^{\pi} d\xi \log p(\xi).$$

3. Since $p(\xi)p(\xi+\pi) > 1$ a.e., it follows that

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} d\xi \log p(\xi) = \frac{1}{2\pi}\int_{0}^{\pi} d\xi \log[p(\xi)p(\xi+\pi)] = \gamma > 0. \qquad \square$$

Consequently,

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} d\xi \prod_{j=0}^{N-1} p(2^j\xi) \geq e^{N\gamma}.$$

Remark. The argument in this proof is borrowed from the proof of Theorem 3 in Coifman, Meyer, and Wickerhauser [10].

This suffices to prove the instability claimed above. If the collection

$$\mathcal{C} = \{\phi(\cdot - k); k \in \mathbb{Z}\} \cup \{\psi_\epsilon(\cdot - k), k \in \mathbb{Z} \text{ and } |\epsilon| = N, \epsilon_N = 1, N \in \mathbb{N}\backslash\{0\}\}$$

were a Riesz basis for $L^2(\mathbb{R})$, then it would follow that the L^2-norms of all these functions could be bounded uniformly by some constant C. (A Riesz basis is the image of an orthonormal basis under a continuous map.) In particular it would follow that, for all $N \in \mathbb{N}$,

$$\sum_{\epsilon \in S_N} \|\psi_\epsilon\|^2 \leq C\#S_N = C2^N.$$

This is contradicted by (6.7); the collection $\mathcal{C}$ does therefore not constitute a Riesz basis.

AN ARITHMETIC CHARACTERIZATION OF THE CONJUGATE QUADRATURE FILTERS ASSOCIATED TO ORTHONORMAL WAVELET BASES*

ALBERT COHEN[†] AND QIYU SUN[‡]

Abstract. Let $h = \{h_n\}$ be a sequence of complex numbers with finite length such that $H(\omega) = \sum h_n \exp(-2\pi in\omega)$ satisfies the identity $|H(\omega)|^2 + |H(\omega + \frac{1}{2})|^2 = 1$ and $H(0) = 1$, i.e., h is the impulse response of a conjugate quadrature filter. In this paper, we give a characterization, by the real roots of $H(\omega)$, of the sequences h that generate an orthonormal wavelet basis in the sense of the theory developed by Meyer and Daubechies. This result leads to a counterexample to Pollen's conjecture.

Key words. wavelet bases, conjugate quadrature filters, Pollen's conjecture

AMS) subject classification. 42C05

1. Introduction and results.

A conjugate quadrature filter (CQF) is a sequence $h = \{h_n\}_{n\in Z}$ of complex numbers with finite length, i.e., there exists a positive integer N such that $h_n = 0$ for $|n| > N$ that satisfies

$$2\sum_m h_m \overline{h}_{m+2n} = \delta(n) \quad \text{for all } n, \tag{1}$$

and

$$\sum_n h_n = 1, \tag{2}$$

or equivalently, whose Fourier transform defined by

$$H(\omega) = \sum h_n \exp(-2\pi in\omega) \tag{3}$$

satisfies

$$|H(\omega)|^2 + |H(\omega + \tfrac{1}{2})|^2 = 1 \tag{4}$$

and

$$H(0) = 1. \tag{5}$$

Here $\delta(m) = 1$ for $m = 0$ and $\delta(m) = 0$ otherwise. Let V denote the set of sequences h that satisfy (1) and (2). For every h in V, following the theory developed in [3], [6], and [7], we construct two functions φ and ψ by

$$\hat{\varphi}(\omega) = \prod_{k=1}^{\infty} H\left(\frac{\omega}{2^k}\right) \tag{6}$$

and

$$\hat{\psi}(\omega) = \exp(-2\pi i\omega)H\left(\omega + \frac{1}{2}\right)\hat{\varphi}\left(\frac{\omega}{2}\right), \tag{7}$$

which represent, respectively, the Fourier transform of a scaling function ϕ and a wavelet function ψ in the sense of tempered distributions. We used the normalization $\hat{f}(\omega) = \int f(x)e^{2i\pi\omega x}dx$ here.

Lawton proved that for h in V, $\{\psi_{j,k}(x) = 2^{-j/2}\psi(2^{-j}x - k)\}_{j,k\in\mathbb{Z}}$ forms a tight frame of $L^2(\mathbb{R})$ [4]. It is known that there exists h in V such that $\{\psi_{j,k}\}_{j,k\in\mathbb{Z}}$ does not form an orthonormal basis of $L^2(\mathbb{R})$. In fact, $\{\psi_{j,k}\}$ is an orthonormal basis if and only if $\{\varphi(x-k)\}_{k\in\mathbb{Z}}$ is orthonomal. By Poisson's summation formula, this is equivalent to

$$(8) \qquad \sum_k |\hat{\varphi}(\omega - k)|^2 = 1 \quad \text{for all } \omega \in \mathbb{R}.$$

We say that h generates an orthonormal wavelet basis if $\{\psi_{j,k}\}_{j,k\in\mathbb{Z}}$ is of that type. Hence to prove that h generates an orthonormal basis it suffices to prove that (8) holds for $\hat{\varphi}$ defined by the infinite product formula (6).

Mallat [6] proved, using the Lebesgue's dominated convergence theorem, that if $H(\omega) \neq 0$ for $|\omega| \leqq \frac{1}{4}$, then (8) holds for all ω in $\mathbb{R}$. A compact subset K of $\mathbb{R}$ is said to be congruous to $\left[-\frac{1}{2}, \frac{1}{2}\right]$ if and only if mes $(K) = 1$ and for almost every ω in $\left[-\frac{1}{2}, \frac{1}{2}\right]$, there exists a β in K such that $\omega - \beta$ is an integer.

Cohen [2] extended Mallat's result and proved that (8) holds if and only if there exists a compact subset K of $\mathbb{R}$ congruous to $\left[-\frac{1}{2}, \frac{1}{2}\right]$ and containing zero in its interior such that $H(2^{-j}\omega) \neq 0$ for all $\omega \in K$ and positive integers j. This result can be expressed in the following way: the identity (8) holds if and only if

$$(9) \qquad \sum_k |\hat{\varphi}(\omega - k)|^2 \neq 0 \quad \text{for all } \omega \in \mathbb{R}.$$

We shall use this important property in the proof of the main theorem of this paper.

Lawton [4], [5] uses an eigenvector relationship between a linear operator on $l^2(\mathbb{Z})$, the set of square summable sequences, to characterize sequences $h \in V$ that generate orthonormal wavelet bases.

Let $R(H)$ be the set of real roots of H in $(0, 1)$. In this paper, we shall characterize these sequences by an arithmetic condition on $R(H)$.

For relatively prime positive odd integers m and n, let $\mathrm{Ind}_2\, n$ be the least positive integer k such that $2^k = 1 \pmod{n}$ and define the number $m_i = 2^i m + n \pmod{2n}$ for $l \leqq i \leqq \mathrm{Ind}_2\, n$. In the next section, we shall prove the following result.

THEOREM 1. *Let $h \in V$. Then the following propositions are equivalent*:

(i) *h generates an orthonormal wavelet basis*;

(ii) *There exist no relatively prime positive odd numbers m and $n \neq 1$ such that $H(m_i/2n) = 0$ for all $1 \leqq i \leqq \mathrm{Ind}_2$ n*;

(iii) *For all ω in* $]0, 1[$, $\lim_{N\to+\infty} \prod_{k=0}^{N} H(2^k\omega) = 0$.

Remarks.

• The proof of Theorem 1 will use the property that the zeros of $H(\omega)$ are isolated points. This result can thus be extended to the case where h is an infinite sequence with exponential decay.

• Pollen [8] conjectured that if h does not generate an orthonormal basis, then there exists an odd integer $n \geqq 3$ and a sequence $\tilde{h}$ in V such that $H(\omega) = \tilde{H}(n\omega)$. Thus, $H(\omega)$ should vanish at all the points $\{m/2n | m \text{ is odd}\} = R_n$. We shall construct counterexamples to this conjecture by taking two relatively prime odd integers m and n, $m \geqq 1$ and $n \geqq 3$ such that the set $\{m_i/2n, 1 - (m_i/2n) | 1 \leqq i \leqq \mathrm{Ind}_2\, n\} \cup \{\frac{1}{2}\}$ is strictly included into R_n. We will then use the following constructive result.

THEOREM 2. *Let m and $n \neq 1$ be two relatively prime positive odd integers. Then there exists an $h \in V$ such that h does not generate an orthonormal basis and $R(H) = \{m_i/2n, 1-(m_i/2n), \frac{1}{2} | 1 \leqq i \leqq \operatorname{Ind}_2 n\}$.*

Observe that $H(\omega) = 0$ implies $H(1-\omega) = 0$ for a sequence $h \in V$ of real numbers. Both of the authors obtained the results above independently at about the same time.

2. Proof of Theorem 1. (a) We start by the assumption that h does not generate an orthonormal wavelet basis and show that $H(\omega)$ vanishes on a set of points of the type $\{m_i/2n | 1 \leqq i \leqq \operatorname{Ind}_2 n\}$.

From (9), we know that for a certain ω_0 in $[0,1]$, $\hat{\varphi}(\omega_0 + l) = 0$ for all l in $\mathbb{Z}$. Consequently, for all l in $\mathbb{Z}$, we can define

$$j(l) = \min\{j > 0 | H(2^{-j}(\omega_0 + l)) = 0\} \tag{10}$$

and

$$\nu(l) = 2^{-j(l)}(\omega_0 + l)(\text{mod } 1), \tag{11}$$

the associated root of $H(\omega)$. Because $H(\omega)$ has a finite number of roots in $[0,1]$, the family $\{\nu(l)\}_{l\in\mathbf{Z}}$ contains only a finite number of points. We shall proceed in four steps to prove that this family contains the announced type of set.

Step 1. There exists a sequence $\{l_k\}_{k \geq 0}$ such that $j(l_{k+1}) > j(l_k)$.

We can construct this sequence recursively: take $l_0 = 0$ and suppose that we have defined the sequence up to l_k. We then write

$$n_k = j(l_k) \tag{12}$$

and

$$\mu_k = \nu(l_k) = 2^{-n_k}(\omega_0 + l_k)(\text{mod } 1). \tag{13}$$

We choose for l_{k+1} the value

$$l_{k+1} = l_k + 2^{n_k - 1}. \tag{14}$$

To check that n_{k+1} is strictly superior to n_k, we remark that for all $n < n_k$,

$$\begin{aligned} H(2^{-n}(\omega_0 + l_{k+1})) &= H(2^{-n}(\omega_0 + l_k) + 2^{n_k - n - 1}) \\ &= H(2^{-n}(\omega_0 + l_k)) \neq 0 \end{aligned}$$

and

$$\begin{aligned} |H(2^{-n_k}(\omega_0 + l_{k+1}))| &= |H(2^{-n_k}(\omega_0 + l_k) + \tfrac{1}{2})| \\ &= |H(\mu_k + \tfrac{1}{2})| = 1 \neq 0. \end{aligned}$$

It follows that $n_{k+1} = j(l_{k+1})$ is strictly superior to $n_k = j(l_k)$, and the sequence $\{j(l)\}_{l\in\mathbf{Z}}$ contains an infinite number of elements. We shall reuse the sequence μ_k, which satisfies

$$\mu_{k+1} = 2^{n_k - n_{k+1}}(\mu_k + \tfrac{1}{2}). \tag{15}$$

Step 2. The family $\{\nu(l)\}_{l\in\mathbf{Z}}$ contains only rational numbers.

It suffices to prove that ω_0 is rational. Since there is an infinite number of $j(l)$ and only finitely many $\nu(l)$, it is possible to find l and l' such that $\nu(l) = \nu(l')$ and $j(l) \neq j(l')$. Consequently, $2^{-j(l)}(\omega_0+l) - 2^{-j(l')}(\omega_0+l')$ is an integer. It follows that ω_0 is a rational number and so are the $\{\nu(l)\}_{l\in\mathbf{Z}}$.

Step 3. $\nu(l)$ can be written in an irreducible form as $\nu(l) = p(l)/2n(l)$, where $p(l)$ and $n(l)$ are odd and $n(l) > 1$.

Let us prove that all the other possibilities are not coherent with the hypotheses.

If $\nu(l)$ was an integer or a half integer, since $\nu(l) = 2^{-j(l)}(\omega_0 + l)$ and $j(l) \geqq 1$, this would imply that ω_0 is an integer. This is impossible since we have

$$\sum_{k\in\mathbf{Z}} |\hat{\varphi}(k)|^2 = |\hat{\varphi}(0)|^2 = 1. \tag{16}$$

Now, let us suppose that the denominator of $\nu(l)$ is a multiple of 4, and let us construct the sequence $\{\mu_k\}_{k\geqq 0}$ as in step 1, with $\mu_0 = \nu(l)$.

We can write μ_0 in an irreducible form:

$$\mu_0 = 2^{-j_0}\frac{p_0}{n}, \tag{17}$$

where p_0 and n are odd and $j_0 \geqq 2$.

By (15), we then have

$$\mu_1 = 2^{n_0-n_1}\left(\mu_0 + \frac{1}{2}\right) = 2^{n_0-n_1-j_0}\left(\frac{p_0 + 2^{j_0-1}n}{n}\right) = 2^{-j_1}\left(\frac{p_1}{n}\right),$$

which is the irreducible form for μ_1 since $p_1 = p_0 + 2^{j_0-1}n$ is odd and prime together with n. It is clear that $j_1 > j_0$ and by iterating this process we have $\mu_k = 2^{-j_k}(p_k/n)$ with $j_k > j_{k-1}$. This clearly contradicts the hypothesis that the $\nu(l)$ are finitely many (modulo 1).

Finally, if $\nu(l)$ had an odd denominator, we could write $\mu_0 = p_0/n$, and this would lead to

$$\mu_1 = 2^{n_0-n_1}\left(\mu_0 + \frac{1}{2}\right) = 2^{n_0-n_1-1}\left(\frac{2p_0 + n}{n}\right) = 2^{-j_1}\left(\frac{p_1}{n}\right)$$

with $j_1 \geqq 2$, which is exactly the previous situation.

The only solution is $\nu(l) = p(l)/2n(l)$.

Step 4. Now we shall construct the set of zero of $H(\omega)$ that has been announced.

First remark that the sequence μ_k can also be generated by taking

$$\mu_{k+1} = 2^{n_k - n_{k+1}}\left(\mu_k - \tfrac{1}{2}\right). \tag{18}$$

For a given $\mu_0 = p_0/2n$ we have $\mu_0 - \frac{1}{2} = (p_0 - n)/2n$ and $\mu_0 + \frac{1}{2} = (p_0 + n)/2n$. Clearly, both $p_0 - n$ and $p_0 + n$ are even, but since their difference is $2n$, one of them cannot be a multiple of 4.

Consequently, to preserve the arithmetic structure imposed by the third step, we shall take

$$\mu_1 = \begin{cases} \dfrac{1}{2}\left(\mu_0 - \dfrac{1}{2}\right) & \text{if } \dfrac{p_0 - n}{2} \text{ is odd,} \\[2ex] \dfrac{1}{2}\left(\mu_0 + \dfrac{1}{2}\right) & \text{if } \dfrac{p_0 + n}{2} \text{ is odd.} \end{cases} \tag{19}$$

By iteration we obtain a sequence of numbers:

$$\mu_k = \frac{p_k}{2n} \quad \text{with } \{p_{k+1}\} = \left\{\frac{p_k+n}{2}, \frac{p_k-n}{2}\right\} \cap 2\mathbb{Z}+1.$$

Remark that by choosing μ_0 in $[-\frac{1}{2}, \frac{1}{2}]$ rather than in $[0, 1]$, the sequence μ_k will stay in $[-\frac{1}{2}, \frac{1}{2}]$. It is thus necessarily a cycle.

Let us now consider the shifted cyclic sequence

$$\gamma_k = \mu_k + \frac{1}{2} = \frac{p_k+n}{2n} = \frac{q_k}{n}. \tag{20}$$

By (19) we obtain

$$\gamma_k = 2\gamma_{k+1} (\text{mod } 1), \tag{21}$$

which shows that γ_k is a cycle for the transformation $\omega \mapsto 2\omega(\text{mod } 1)$. As a consequence, there exists an odd number $m < n$ such that, after reordering the cycle γ_k (in the reverse order), we have

$$\gamma_i = \frac{2^i m}{n} (\text{mod } 1), \quad 0 \leqq i \leqq \text{Ind}_2\, n. \tag{22}$$

It follows that $H(\omega)$ vanishes on the set of point $\{m_i/2n | 1 \leqq i \leqq \text{Ind}_2\, n\}$.

We have thus proved (ii) $\Rightarrow$ (i).

(b) We now prove (iii) $\Rightarrow$ (ii). Suppose that (ii) is not true and that $H(\omega)$ vanish on such a set. Then it follows that $|H(\gamma_i)| = 1$, where $\{\gamma_i\}$ is the cycle given by (22). Consequently, for all $N > 0$,

$$\left| \prod_{k=0}^{N} H(2^k \gamma_0) \right| = 1, \tag{23}$$

and $\gamma_0 = m/n$ is in $]0, 1[$, which contradicts (iii).

(c) Finally, we show that (i) $\Rightarrow$ (iii). Since φ is both compactly supported and square-integrable, it is in $L^1(\mathbb{R})$ by the Cauchy–Schwarz formula. It follows that $\hat{\varphi}(\omega)$ has to go to zero when $\omega \to +\infty$ or $-\infty$.

By (8), for all ω in $]0, 1[$, there exist an integer l such that $\hat{\varphi}(\omega + l) \neq 0$. Let us write $\omega_l = \omega + l \neq 0$.

We have

$$\begin{aligned} \hat{\varphi}(2^N \omega_1) &= \prod_{k=0}^{N-1} H(2^k \omega_l) \hat{\varphi}(\omega_l) \\ &= \prod_{k=0}^{N-1} H(2^k \omega) \hat{\varphi}(\omega_l), \end{aligned}$$

and thus $\prod_{k=0}^{N-1} H(2^k \omega)$ must go to zero when $N \to +\infty$, which implies (iii).

This concludes the proof of Theorem 1.

From this proof we see that the cancellation of $H(\omega)$ at the points $m_i/2n$ is a necessary and sufficient condition for the orthonormality to fail. (In fact one can prove that the numbers $\nu(l)$ are exactly the points $m_i/2n$ modulo 1.)

3. Proof of Theorem 2. Let us define

$$R_n^1 = \left\{\frac{m_i}{2n}, 1 - \frac{m_i}{2n} | 1 \leqq i \leqq \mathrm{Ind}_2\, n\right\}, \tag{24}$$

and let R_n^2 be the complement of $R_n^1 \cup \{\frac{1}{2}\}$ in R_n. Recall that $R_n = \{m/2n | m \text{ is odd}\}$ is the set of all roots of $1 + e^{2\pi i n\omega}$.

In order to construct a trigonometric polynomial $H(\omega)$ that satisfies (4) and (5) and vanished only on the set $R_n^1 \cup \{\frac{1}{2}\}$, we need to define

$$P(\omega) = \prod_{\omega_i \in R_n^1} |e^{4\pi i\omega} - e^{4\pi i\omega_i}|^2, \tag{25}$$

and for each ω_j in R_n^2,

$$Q_j(\omega) = \cos 2\pi\omega_j \cos 2\pi\omega \prod_{\omega_k \in R_n^2 - \{\omega_j, 1-\omega_j\}} |e^{4\pi i\omega} - e^{4\pi i\omega_k}|^2. \tag{26}$$

Consequently, $Q_j(\omega)$ vanishes on $R_n^2 = \{\omega_j, 1 - \omega_j\}$ and we have $Q_j(\omega_j) = Q_j(1 - \omega_j) > 0$. It follows that we can find some strictly positive numbers ε_j such that

$$R(\omega) = |(1 + e^{2\pi i n\omega})/2|^2 + \sin^2 2\pi\omega P(\omega) \sum \varepsilon_j Q_j(\omega) \tag{27}$$

is a nonnegative trigonometric polynomial. Clearly, $R(\omega)$ vanishes only on the set $R_n^1 \cup \{\frac{1}{2}\}$ and one checks easily that it satisfies $R(0) = 1$ and $R(\omega) + R(\omega + \frac{1}{2}) = 1$.

It suffices then to build a trigonometric polynomial H that satisfies $|H(\omega)|^2 = R(\omega)$, which exists by using the Riesz lemma. This concludes the proof of Theorem 2.

From this result we can construct counterexamples to Pollen's conjecture. We can take, for example,

$$R_{15}^1 \cup \left\{\frac{1}{2}\right\} = \left\{\frac{1}{30}, \frac{7}{30}, \frac{11}{30}, \frac{13}{30}, \frac{15}{30}, \frac{17}{30}, \frac{19}{30}, \frac{23}{30}, \frac{29}{30}\right\} \neq R_{15}. \tag{28}$$

Acknowledgment. We are grateful to Professor Daubechies, who brought us in touch with each other. Q. Sun also thanks Professor Z. Guo and D. Huang for their encouragement.

AN ELEMENTARY APPROACH TO SOME ANALYTIC ASYMPTOTICS*

NICHOLAS PIPPENGER[†]

Abstract. Fredman and Knuth have treated certain recurrences, such as $M(0) = 1$ and

$$M(n+1) = \min_{0 \le k \le n} \big(\alpha M(k) + \beta M(n-k)\big),$$

where $\min(\alpha, \beta) > 1$, by means of auxiliary recurrences such as

$$h(x) = \begin{cases} 0 & \text{if } 0 \le x < 1, \\ 1 + h(x/\alpha) + h(x/\beta) & \text{if } 1 \le x < \infty. \end{cases}$$

The asymptotic behavior of $h(x)$ as $x \to \infty$ with α and β fixed depends on whether $\log\alpha/\log\beta$ is rational or irrational. The solution of Fredman and Knuth used analytic methods in both cases, and used in particular the Wiener–Ikehara Tauberian theorem in the irrational case. The author shows that a more explicit solution to these recurrences can be obtained by entirely elementary methods, based on a geometric interpretation of $h(x)$ as a sum of binomial coefficients over a triangular subregion of Pascal's triangle. Apart from Stirling's formula, in the irrational case only the Kronecker–Weyl theorem (which can itself be proved by elementary methods) is needed, to the effect that if ϑ is irrational, the fractional parts of the sequence $\vartheta, 2\vartheta, 3\vartheta, \ldots$, are uniformly distributed in the unit interval.

Key words. asymptotic analysis, recurrence relation

AMS subject classification. 26A12

1. Introduction.

The analysis of algorithms and data structures, as well as of constructions for systems such as sorting and switching networks, often leads to recurrences. Because recursive algorithms, data structures, and constructions often involve choices that should be made in an optimal way, the recurrences often involve minimization. In their paper, Fredman and Knuth [FK] treat a large number of related recurrences by a combination of combinatorial and analytic methods. The goal of the present paper is to show how in many cases it is possible to replace the analytic component of their solutions with elementary arguments. (Here the terms "analytic" and "elementary" are used in accordance with the practice in number theory: "analytic" refers to methods based on properties of analytic functions of a complex variable, especially residues or integral transforms, while "elementary" refers to the absence of such methods. In particular, "elementary" does not refer to either simplicity or brevity.) As a bonus, we shall see that our analysis leads to a more explicit and informative solution in some cases. A preliminary version of our results appears as [P].

Of the recurrences treated by Fredman and Knuth, the one which best illustrates our contribution is $M(0) = 1$ and

$$M(n+1) = \min_{0 \le k \le n} \big(\alpha M(k) + \beta M(n-k)\big), \tag{1.1}$$

*Received by the editors May 4, 1992; accepted for publication (in revised form) December 3, 1992. This research was partially supported by a Natural Sciences and Engineering Research Council of Canada operating grant and a British Columbia Advance Systems Institute Fellowship Award.

where α and β are fixed parameters with $\min(\alpha, \beta) > 1$. (This is the case "$g(n) = \delta_{n0}$," dealt with in their §6.) By straightforward and elementary arguments, Fredman and Knuth reduce the study of (1.1) to that of the function h defined by

$$h(x) = \begin{cases} 0 & \text{if } 0 \le x < 1, \\ 1 + h(x/\alpha) + h(x/\beta) & \text{if } 1 \le x < \infty. \end{cases} \tag{1.2}$$

The analysis of Fredman and Knuth proceeds by considering the integral transform

$$K(s) = \int_1^\infty \frac{h(t)\,dt}{t^{s+1}}$$

of h, which, with the aid of (1.2), can be shown to be $K(s) = 1/s(1 - \alpha^{-s} - \beta^{-s})$. This function is analytic in the open half plane $\mathrm{Re}(s) > \gamma$, where γ is the unique real solution to

$$\alpha^{-\gamma} + \beta^{-\gamma} = 1. \tag{1.3}$$

Furthermore, $K(s)$ has a simple pole at $s = \gamma$ with residue $C = 1/(\alpha^{-\gamma} \log \alpha^\gamma + \beta^{-\gamma} \log \beta^\gamma)$, as is easily calculated. This pole will ultimately give rise to a factor Cx^γ in the asymptotic behavior of $h(x)$.

The behavior of $K(s)$ on the remainder of the critical line $\mathrm{Re}(s) = \gamma$ depends on whether $\log \alpha / \log \beta$ is rational or irrational. If this quotient is irrational, the pole at $s = \gamma$ is the only one on the critical line, and a Tauberian theorem due to Wiener, Ikehara, and Landau (Lemma 4.3 in Fredman and Knuth) leads to the conclusion that

$$h(x) \sim Cx^\gamma \tag{1.4}$$

in this case. If the quotient $\log \alpha / \log \beta$ is rational, $K(s)$ has additional poles periodically disposed along the critical line. Application of Cauchy's residue theorem leads to the conclusion that

$$h(x) \sim D(x)x^\gamma \tag{1.5}$$

in this case, where $D(x)$ is a periodic function of $\log x$ whose period is determined by the spacing between poles along the critical line, and whose Fourier coefficients are determined by the residues at those poles.

In this paper we shall derive (1.4) and (1.5) in an elementary fashion. This new derivation has the merit of giving a simple explicit formula for the function $D(x)$ in (1.5). We shall also want the solution to the related recurrence

$$h'(x) = \begin{cases} 0 & \text{if } 0 \le x < 1, \\ 1 + \alpha h(x/\alpha) + \beta h(x/\beta) & \text{if } 1 \le x < \infty. \end{cases} \tag{1.6}$$

By analogous elementary methods, we shall show that

$$h'(x) \sim C'x^{\gamma+1}, \tag{1.7}$$

where $C' = 1/(\alpha^{-\gamma} \log \alpha^{\gamma+1} + \beta^{-\gamma} \log \beta^{\gamma+1})$ in the irrational case, and

$$h'(x) \sim D'(x)x^{\gamma+1}, \tag{1.8}$$

where $D'(x)$ is a periodic function of $\log x$ which will be determined explicitly in the rational case.

Fredman and Knuth showed that (1.4) implies that

$$M(n) \sim An^{1+1/\gamma}, \tag{1.9}$$

where A is an explicitly determined constant in the irrational case. We shall show that (1.5) and (1.8) together imply

$$M(n) \sim B(n)n^{1+1/\gamma}, \tag{1.10}$$

where $B(n)$ is an explicitly determined periodic function of $\log n$ in the rational case. (Once the form of the functions $D(x)$ and $D'(x)$ are explicitly known, it is possible to go back and derive these results by extending the analysis of Fredman and Knuth. This would involve showing that certain Fourier series converge to certain periodic functions. But since there is no general procedure for identifying a function from its Fourier series, it does not appear to be possible to extend the analysis of Fredman and Knuth without knowing what $D(x)$ and $D'(x)$ are by some other method.)

2. The rational case. Our analysis begins with the observation that $h(x)$ is the number of words over the alphabet $\{\alpha, \beta\}$ having weight at most x, where the *weight* of a word is the product of its letters. (We take the weight of the empty word to be unity.) Indeed, if $0 \le x < 1$, then there are no such words and $h(x) = 0$. If $1 \le x < \infty$, then $h(x) = 1 + h(x/\alpha) + h(x/\beta)$, and any word for which the product of the letters is at most x must either be empty (and there is 1 such word) or consist of an α followed by a word for which the product of the letters is at most x/α (and there are $h(x/\alpha)$ such words), or consist of an β followed by a word for which the product of the letters is at most x/β (and there are $h(x/\beta)$ such words). Since there are exactly $\binom{i+j}{i}$ words that contain i α's and j β's, we have established the following explicit formula for $h(x)$:

$$h(x) = \sum_{\alpha^i \beta^j \le x} \binom{i+j}{i}. \tag{2.1}$$

Taking logarithms in the constraint of the summation, we see that $h(x)$ may be interpreted as the sum of the binomial coefficients $\binom{i+j}{i}$ in Pascal's triangle over the triangular subregion bounded by the inequalities $i \ge 0$, $j \ge 0$, and

$$i \log \alpha + j \log \beta \le \log x. \tag{2.2}$$

Suppose that $\log \alpha / \log \beta$ is the rational number p/q, where p and q are positive integers such that $\gcd(p, q) = 1$. Then $\log_{\alpha\beta} \alpha = p/(p+q)$, $\log_{\alpha\beta} \beta = q/(p+q)$, and if we set

$$\varrho = (\alpha\beta)^{1/(p+q)},$$

then (2.2) becomes

$$pi + qj \le \log_\varrho x.$$

Since p, q, i, and j are integers, we see that $h(x)$ remains constant as x increases except when $\log_\varrho x$ passes through an integer k when it jumps by

$$S(k) = \sum_{pi+qj=k} \binom{i+j}{i}. \tag{2.3}$$

We shall see below that $S(k)$ has the asymptotic formula

$$S(k) \sim (C \log \sigma)\, \sigma^k, \tag{2.4}$$

where

$$\sigma = \varrho^\gamma = (\alpha\beta)^{\gamma/(p+q)}.$$

If we set $S^*(l) = \sum_{0 \le k \le l} S(k)$, it follows that

$$S^*(l) \sim \frac{(C\sigma \log \sigma)\, \sigma^l}{\sigma - 1}.$$

This formula gives the asymptotic value $S^*(l)$ of $h(x)$ when x is a "magic" number of the form $x = \varrho^l$. The asymptotic formula for arbitrary x follows from this and the fact that $h(x)$ remains constant between magic values of x. If we write $\log_\varrho x = l + \lambda$, where $l = \lfloor \log_\varrho x \rfloor$ (the integral part of $\log_\varrho x$) and $\lambda = \{\log_\varrho x\}$ (the fractional part of $\log_\varrho x$), then

$$\begin{aligned} h(x) &\sim \frac{(C\sigma \log \sigma)\, \sigma^l}{\sigma - 1} \\ &\sim \frac{(C\sigma^{1-\lambda} \log \sigma)\, \sigma^{l+\lambda}}{\sigma - 1} \\ &\sim P(\{\log_\varrho x\})\, x^\gamma, \end{aligned}$$

where

$$P(\lambda) = \frac{C\sigma^{1-\lambda} \log \sigma}{\sigma - 1}.$$

This establishes (1.5) with $D(x) = P(\{\log_\varrho x\})$, which is periodic in $\log x$ (with period $\log \varrho$), as claimed.

It remains to establish (2.4). The major steps of the derivation are as follows. First, we approximate the binomial coefficients $\binom{i+j}{i} = (i+j)!/i!j!$ in (2.3) by applying Stirling's formula to their constituent factorials. If we separate the approximation into algebraically varying factors and exponentially varying factors, we see that the exponentially varying factors impart to the summand a peaking reminiscent of the central limit theorem: the greatest contribution to the sum comes when i and j are in the fixed ratio $\alpha^{-\gamma}/\beta^{-\gamma}$. This variation allows the terms of the sum not near the peak to be neglected. The resulting truncated sum is then estimated by an integral; the error in this estimation is at most the total variation of the summand, which (since the summand is unimodal) is at most twice the largest term. The resulting integral can be transformed into the well-known integral $\int_{-\infty}^{+\infty} e^{-y^2}\, dy = \pi^{1/2}$ by adjoining negligible tails. The result is (2.4).

Successive values of i and j differ by q and p, respectively; it will be convenient to have an index whose successive values differ by 1. Thus we introduce the index m satisfying

$$i = qm, \qquad j = k/q - pm, \qquad i + j = k/q - (p - q)m.$$

This index assumes values that are not necessarily integers, but are congruent to $1/q$ modulo 1.

LEMMA 2.1.

$$\binom{i+j}{i} = \left(1 + O\left(\frac{1}{i} + \frac{1}{j}\right)\right) \left(\frac{i+j}{2\pi i j}\right)^{1/2} \exp kE\left(\frac{m}{k}\right),$$

where

$$E(\mu) = F\big(G(\mu)\big), \qquad F(\nu) = \frac{H(\nu)}{p\nu + q(1-\nu)},$$
$$G(\mu) = \frac{q^2\mu}{1-(p-q)q\mu}, \qquad H(\nu) = -\nu\log\nu - (1-\nu)\log(1-\nu).$$

Proof. The estimate

$$\binom{i+j}{i} = \left(1+O\left(\frac{1}{i}+\frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2}\exp(i+j)H\left(\frac{i}{i+j}\right)$$

is an immediate consequence of Stirling's formula

$$n! = \left(1+O\left(\frac{1}{n}\right)\right)(2\pi n)^{1/2}e^{-n}n^n$$

(see Knuth [K1, §1.2.11]). Define ν such that

$$i = \nu(i+j), \qquad j = (1-\nu)(i+j), \qquad k = \big(p\nu + q(1-\nu)\big)(i+j).$$

Then

$$\binom{i+j}{i} = \left(1+O\left(\frac{1}{i}+\frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2}\exp kF\left(\frac{i}{i+j}\right).$$

Define μ such that

$$m = \mu k.$$

Then ν and μ are related by

$$\nu = \frac{q^2\mu}{1-(p-q)q\mu}, \qquad \mu = \frac{\nu}{q^2+(p-q)q\nu}.$$

This yields the assertion of the lemma. □

LEMMA 2.2. *The function $F(\nu)$ assumes its unique maximum (for $0 \le \nu \le 1$) at*

$$N = \sigma^{-p}.$$

At this point

$$F(N) = \log\sigma, \qquad F'(N) = 0, \qquad F''(N) = -\frac{1}{N(1-N)\Delta},$$

where

$$\Delta = pN + q(1-N)$$

and the primes indicate differentiation. Accordingly, $E(\mu)$ assumes its maximum at

$$M = \frac{N}{q\Delta},$$

and at this point

$$E(M) = \log\sigma, \qquad E'(M) = 0, \qquad E''(M) = \frac{\Delta^3}{N(1-N)}.$$

Proof. We shall let $H(0) = H(1) = 0$; this makes $H(\nu)$, and therefore $F(\nu)$, continuous on the closed interval $0 \le \nu \le 1$. These functions are in fact analytic in the open interval $0 < \nu < 1$, and thus $F(\nu)$ can assume its maximum only where its first derivative vanishes or at an endpoint. We compute the first derivatives

$$H'(\nu) = \log(1-\nu) - \log\nu,$$
$$F'(\nu) = -\frac{H(\nu)(p-q)}{\left(p\nu + q(1-\nu)\right)^2} + \frac{H'(\nu)}{p\nu + q(1-\nu)}.$$

Equating $F'(\nu)$ to zero leads to the equation

$$\left(p\nu + q(1-\nu)\right)H'(\nu) = (p-q)H(\nu).$$

This has the unique solution $\nu = N$, where

$$N = \alpha^{-\gamma} = \sigma^{-p},$$

so that

$$1 - N = \beta^{-\gamma} = \sigma^{-q}.$$

This gives

$$F(N) = \log\sigma,$$

which is obviously larger than $F(\nu)$ at either of the endpoints. We compute the second derivatives

$$H''(\nu) = -\frac{1}{\nu(1-\nu)},$$
$$F''(\nu) = \frac{2H(\nu)(p-q)^2}{\left(p\nu + q(1-\nu)\right)^3} - \frac{2H'(\nu)(p-q)}{\left(p\nu + q(1-\nu)\right)^2} + \frac{H''(\nu)}{p\nu + q(1-\nu)}.$$

Since the first two terms of $F''(\nu)$ are a multiple of $F'(\nu)$, they vanish at $\nu = N$, leaving

$$F''(N) = -\frac{1}{N(1-N)\Delta}.$$

This derivation can be carried over to $E(\mu)$, $E'(\mu)$, and $E''(\mu)$ through the derivative

$$G'(\mu) = \frac{q^2}{\left(1 - (p-q)q\mu\right)^2} = \left(p\nu + q(1-\nu)\right)^2$$

and the chain rule. □

LEMMA 2.3.

$$\sum_m \left(1 + O\left(\frac{1}{i} + \frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2} \exp kE\left(\frac{m}{k}\right)$$
$$= \left(1 + O\left(\frac{(\log k)^{3/2}}{k^{1/2}}\right)\right)\frac{\sigma^k}{\Delta}.$$

Here the sum over m, as described above, is over $i \ge 0$ and $j \ge 0$ such that $i + j = k$, with $m = i/q$.

Proof. The major steps of the derivation are as follows. The central peaking of the summand will be exploited, allowing the tails of the summation to be neglected. The decaudated sum can be simplified, since the algebraically varying factors behave like constants in the remaining range of summation. The resulting sum will be estimated with an integral, to which the tails previously removed will be restored. The recaudated integral can be evaluated by standard methods.

Our sum is

$$\sum_m W_m,$$

where

$$W_m = \left(1 + O\left(\frac{1}{i} + \frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2} \exp kE\left(\frac{m}{k}\right).$$

Since $E(\mu)$ is analytic at $\mu = M$, it can be expanded in a Taylor series about this point. The result is

$$E(\mu) = \log\sigma - (\mu - M)^2/\delta^2 + O\big((\mu - M)^3\big),$$

where

$$\delta = \left(\frac{2N(1-N)}{\Delta^3}\right)^{1/2}.$$

We shall break our sum into three parts,

$$\sum_m W_m = \sum_{m<a} W_m + \sum_{a\le m\le b} W_m + \sum_{b<m} W_m,$$

where

$$a = Mk - \left(\frac{6N(1-N)k\log k}{\Delta^3}\right)^{1/2},$$

$$b = Mk + \left(\frac{6N(1-N)k\log k}{\Delta^3}\right)^{1/2}.$$

To estimate the sum over $m < a$, we observe that it comprises $O(k)$ terms, each of which is at most W_a. We have $E(a/k) = \log\sigma - 3(\log k/k) + O\big((\log k/k)^{3/2}\big)$ (by the Taylor expansion). Thus

$$W_a = O\left(\frac{\sigma^k}{k^3}\right),$$

and so

$$\sum_{m<a} W_m = O\left(\frac{\sigma^k}{k^2}\right).$$

Similarly,

$$\sum_{b<m} W_m = O\left(\frac{\sigma^k}{k^2}\right),$$

and thus

$$\sum_m W_m = \sum_{a\le m\le b} W_m + O\left(\frac{\sigma^k}{k^2}\right). \tag{2.5}$$

For any term in the sum over $a \leq m \leq b$,

$$m = Mk\left(1 + O\left(\left(\frac{\log k}{k}\right)^{1/2}\right)\right),$$

from which it follows that

$$i = \frac{Nk}{\Delta}\left(1 + O\left(\left(\frac{\log k}{k}\right)^{1/2}\right)\right),$$

$$j = \frac{(1-N)k}{\Delta}\left(1 + O\left(\left(\frac{\log k}{k}\right)^{1/2}\right)\right),$$

and

$$i + j = \frac{k}{\Delta}\left(1 + O\left(\left(\frac{\log k}{k}\right)^{1/2}\right)\right).$$

Thus

$$W_m = \left(1 + O\left(\frac{(\log k)^{3/2}}{k^{1/2}}\right)\right)\left(\frac{\Delta}{2\pi kN(1-N)}\right)^{1/2} \sigma^k V_m,$$

where

$$V_m = \exp -\left((m - Mk)^2/\delta^2 k\right),$$

and therefore

$$\sum_{a \leq m \leq b} W_m = \left(1 + O\left(\frac{(\log k)^{3/2}}{k^{1/2}}\right)\right)\left(\frac{\Delta^3}{2\pi kN(1-N)}\right)^{1/2} \sigma^k \sum_{a \leq m \leq b} V_m. \tag{2.6}$$

Now,

$$\sum_{a \leq m \leq b} V_m = \int_a^b V_x\,dx + O(1), \tag{2.7}$$

since the total variation of the integrand is $O(1)$. We shall express our integral as the sum of three integrals:

$$\int_a^b V_x\,dx = -\int_{-\infty}^a V_x\,dx + \int_{-\infty}^{+\infty} V_x\,dx - \int_a^{+\infty} V_x\,dx.$$

Integration by parts gives

$$\int_{-\infty}^a V_x\,dx = O\left(\frac{V_a}{a}\right) = O\left(\frac{1}{k^4}\right).$$

Similarly

$$\int_a^{+\infty} V_x\,dx = O\left(\frac{1}{k^4}\right),$$

and thus

$$\int_a^b V_x\,dx = \int_{-\infty}^{+\infty} V_x\,dx + O\left(\frac{1}{k^4}\right). \tag{2.8}$$

Using the transformation

$$x = Mk + \delta k^{1/2} y$$

and the well-known integral

$$\int_{-\infty}^{+\infty} \exp -y^2 \, dy = \pi^{1/2},$$

we obtain

$$\int_{-\infty}^{+\infty} V_x \, dx = \left(\frac{2\pi k N(1-N)}{\Delta^3} \right)^{1/2}.$$

Working backwards through (2.8), (2.7), (2.6), and (2.5) yields the assertion of the lemma. □

The formula (2.4) follows from Lemma 2.3, since $C \log \sigma = 1/\Delta$.

We should mention here that the special cases $p = q = 1$, where $S(k) = 2^k$, and $p = 1$, $q = 2$, where $S(k) = F_{k+1} \sim \phi^{k+1}/\sqrt{5}$ (in which F_n is the nth Fibonacci number and $\phi = (1+\sqrt{5})/2$; see Knuth [K1, §1.2.8, eq. (15) and Exer. 16]) are well known, and the analysis just given can be regarded as a generalization of these cases. Furthermore, that $\sigma = 2$ and $\sigma = \phi$ are algebraic in the examples just cited is not accidental: the rationality of $\log \alpha / \log \beta = p/q$ implies that $\alpha^{-\gamma}$ and $\beta^{-\gamma}$ are roots of the polynomials $(1-z)^p = z^q$ and $z^p = (1-z)^q$, respectively, whence $\sigma = (\alpha\beta)^{\gamma/(p+q)}$ is algebraic.

In §4 we shall also want the solution to the recurrence (1.6) for $h'(x)$ in the rational case. Let us call the product of the letters in a word over the alphabet $\{\alpha, \beta\}$ the *weight* of the word. Then $h'(x)$ is the sum of the weights of all words whose weight is at most x, and thus we have the explicit formula

$$h'(x) = \sum_{\alpha^i \beta^j \le x} \binom{i+j}{i} \alpha^i \beta^j.$$

The treatment of this sum is completely analogous to that of (2.1); the result is

$$h'(x) \sim P'(\{\log_\varrho x\}) \, x^{\gamma+1},$$

where

$$P'(\lambda) = \frac{C' \tau^{1-\lambda} \log \tau}{\tau - 1},$$

in which

$$\tau = \varrho^{\gamma+1} = (\alpha\beta)^{(\gamma+1)/(p+q)}.$$

This establishes (1.8) with $D'(x) = P'(\{\log_\varrho x\})$.

3. The irrational case. When $\log \alpha / \log \beta$ is irrational the analysis of the preceding section is not applicable, for as x increases new binomial coefficients enter the sum one by one, rather than in the regularly spaced platoons of the rational case. Furthermore, the order of their entry is very irregular, with small coefficients near the axes being interspersed with large ones near the main diagonal. The analysis of this section is based on a regularity of averages amid this irregularity of detail, as expressed by the "ergodicity of an irrational rotation of the circle." We shall use in particular the Kronecker–Weyl theorem, to the effect that if ϑ is irrational, then the fractional parts of the sequence $\vartheta, 2\vartheta, 3\vartheta, \ldots$, are uniformly distributed in the unit interval. (This theorem as stated was proved by Weyl [W1]; Kronecker [K2] proved that if ϑ is irrational, then the fractional parts of the sequence $\vartheta, 2\vartheta, 3\vartheta, \ldots$ are dense in the unit interval.) Weyl's orginal proof (which is probably still the simplest proof) of this theorem was based on Fourier series, which by some tastes might not be accepted as elementary. A subsequent proof based on continued fractions (see Nivin [N, Chap. 6, §3]) is incontestably elementary, however.

We shall say that a subset Ξ of the unit interval is an "interval modulo 1" if it is the image modulo 1 of an interval. (Thus $[0, \xi/2) \cup [1-\xi/2, 1)$ is an interval modulo 1 of length ξ.) The Kronecker–Weyl theorem asserts the following.

Let ϑ be irrational. For every $0 < \xi < 1$ and $0 < \eta < 1$, there exists a natural number t such that, if Ξ is an interval modulo 1 of length ξ and T is any set of t consecutive integers, then at least $(1-\eta)\xi t$ and at most $(1+\eta)\xi t$ of the integers i in T are such that $\{i\vartheta\}$ falls in Ξ. (This theorem is often stated in the special case in which $T = \{1, \ldots, t\}$, but shifting T to $T + u$ is equivalent to shifting Ξ to $\Xi - u\vartheta$ modulo 1, so the special case implies the general.)

Let $\varepsilon > 0$ be fixed. Define the function $h_\varepsilon(x)$ by

$$h_\varepsilon(x) = \sum_{xe^{-\varepsilon} < \alpha^i \beta^j \le x} \binom{i+j}{i}. \tag{3.1}$$

Taking logarithms in the constraint of the summation, we see that $h_\varepsilon(x)$ may be interpreted as the sum of the binomial coefficient over the trapezoidal region bounded by the inequalities $i \ge 0$, $j \ge 0$, and

$$\log x - \varepsilon < i \log \alpha + j \log \beta \le \log x. \tag{3.2}$$

We shall see below that $h_\varepsilon(x)$ satisfies the asymptotic inequalities

$$C\gamma\varepsilon(1-\varepsilon)e^{-\gamma\varepsilon}x^\gamma \lesssim h_\varepsilon(x) \lesssim C\gamma\varepsilon(1+\varepsilon)x^\gamma \tag{3.3}$$

as $x \to \infty$ with ε fixed. (Here $f(x) \lesssim g(x)$ means that $\limsup_{x\to\infty} f(x)/g(x) \le 1$.) If we set $l = \lfloor \log x/\varepsilon \rfloor + 1$, then $xe^{-l\varepsilon} < 1$, so we have

$$h(x) = \sum_{0 \le k \le l} h_\varepsilon(xe^{-k\varepsilon}).$$

It follows that

$$\frac{C\gamma\varepsilon(1-\varepsilon)e^{-\gamma\varepsilon}x^\gamma}{1-e^{-\gamma\varepsilon}} \lesssim h(x) \lesssim \frac{C\gamma\varepsilon(1+\varepsilon)x^\gamma}{1-e^{-\gamma\varepsilon}}.$$

Since this holds for every $\varepsilon > 0$, we may let $\varepsilon \to 0$ and obtain (1.4).

It remains to establish (3.3). The proof follows the same general lines as that of (2.4), but is complicated by the fact that the lattice points (i, j) are not equally spaced in the trapezoid (3.2) as they were along the boundary of the triangle (2.2). Our salvation comes from the Kronecker–Weyl theorem, which shows that though they are not "equally spaced," they are "uniformly distributed." This will allow the trapezoid (3.2) to be broken into pieces, each of which is sufficiently large so that it contains a number of lattice points approximately proportional to its area, yet sufficiently small so that the binomial coefficients associated with these lattice points are approximately equal.

Suppose that $\varepsilon < \log\beta$ and set $\vartheta = \log\alpha/\log\beta$, so that ϑ is irrational. Let us say that a natural number i is "lucky" if there exists a j such that i and j satisfy the inequalities (3.2). Clearly there exists such a j if and only if $\{i\vartheta\}$ falls in the interval $\bigl((\log x - \varepsilon)/\log\beta, \log x/\log\beta\bigr]$. (Since the length of this interval is $\varepsilon/\log\beta < 1$, it contains either no integers or one integer.) By the Kronecker–Weyl theorem, with $\xi = \varepsilon/\log\beta$ and $\eta = \varepsilon$, we may choose t such that among any t consecutive natural numbers there are $(1 \pm \varepsilon)\varepsilon t/\log\beta$ lucky values of i.

For lucky i, we shall regard j as a function of i. We shall abbreviate $i\log\alpha + j\log\beta$ by k (which is not necessarily an integer). We shall abbreviate $\log x$ by l (which is not necessarily an integer), and $l - k$ by λ (so that $0 \le \lambda < \varepsilon$).

Since we no longer have the parameters p and q, we shall use $\log\alpha$ and $\log\beta$ in their stead. Thus we introduce m satisfying

$$i = m\log\beta, \quad j = (l-\lambda)/\log\beta - m\log\alpha, \quad i + j = (l-\lambda)/\log\beta - m(\log\alpha - \log\beta).$$

Let us say that a value of m is "lucky" if it corresponds to a lucky value of i. Henceforth, we shall take m to range over lucky values, and regard i, j, k, and λ as functions of m for these lucky values.

By analogy with Lemma 2.1, we have

$$\binom{i+j}{i} = \left(1 + O\left(\frac{1}{i} + \frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2} \exp kE\left(\frac{m}{k}\right),$$

where

$$E(\mu) = F\bigl(G(\mu)\bigr), \qquad F(\nu) = \frac{H(\nu)}{\nu\log\alpha + (1-\nu)\log\beta},$$
$$G(\mu) = \frac{\mu(\log\beta)^2}{1 - (\log\alpha - \log\beta)\log\beta}, \qquad H(\nu) = -\nu\log\nu - (1-\nu)\log(1-\nu).$$

By analogy with Lemma 2.2, the function $F(\nu)$ assumes its unique maximum (for $0 \le \nu \le 1$) at

$$N = \alpha^{-\gamma}, \qquad 1 - N = \beta^{-\gamma}.$$

At this point

$$F(N) = \gamma, \qquad F'(N) = 0, \qquad F''(N) = -\frac{1}{N(1-N)\Delta},$$

where

$$\Delta = N\log\alpha + (1-N)\log\beta.$$

Accordingly, $E(\mu)$ assumes its maximum at

$$M = \frac{N}{\Delta\log\beta},$$

and at this point

$$E(M) = \gamma, \qquad E'(M) = 0, \qquad E''(M) = \frac{\Delta^3}{N(1-N)}.$$

We now seek the analog of Lemma 2.3, which is the following.

LEMMA 3.1.

$$\begin{aligned}&\left(1+O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\frac{(1-\varepsilon)e^{-\gamma\varepsilon}\varepsilon x^{\gamma}}{\Delta}\\ &\leq\sum_m\left(1+O\left(\frac{1}{i}+\frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2}\exp kE\left(\frac{m}{k}\right)\\ &\leq\left(1+O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\frac{(1+\varepsilon)\varepsilon x^{\gamma}}{\Delta}.\end{aligned}$$

In this lemma and all that follows, the constants .implicit in the O-terms may depend on ε. The inequalities involving the O-terms are to be interpreted as follows: for every $\varepsilon > 0$ and every choice of the O-term in the middle expression, there exist choices of the O-terms in the outer expression such that the inequalities are satisfied for all x.

Proof. Since $l-\varepsilon \leq k \leq l$ and $E(\mu) \leq \gamma$, we have

$$e^{-\gamma\varepsilon}\exp lE\left(\frac{m}{k}\right) \leq \exp kE\left(\frac{m}{k}\right) \leq \exp lE\left(\frac{m}{k}\right).$$

Thus it will suffice to prove

$$\begin{aligned}&\left(1+O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\frac{(1-\varepsilon)\varepsilon x^{\gamma}}{\Delta}\\ &\leq\sum_m\left(1+O\left(\frac{1}{i}+\frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2}\exp lE\left(\frac{m}{k}\right)\\ &\leq\left(1+O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\frac{(1+\varepsilon)\varepsilon x^{\gamma}}{\Delta},\end{aligned}\tag{3.4}$$

Choose t using the Kronecker–Weyl theorem so that, for any interval of length $\varepsilon/\log\beta$ modulo 1, among any t consecutive integers i, there are between $(1-\varepsilon)\varepsilon t/\log\beta$ and $(1+\varepsilon)\varepsilon t/\log\beta$ such that $\{i\vartheta\}$ falls in the given interval modulo 1. Set $L = (t\log\beta)/2$. Set

$$Q=\left(\frac{6N(1-N)l\log l}{\Delta^3}\right)^{1/2},$$

and set

$$q=\left\lceil\frac{Q-L}{2L}\right\rceil,$$

so that $(2q+1)L$ is the smallest odd multiple of L that is not less than Q.

Our sum is

$$\sum_m W_m,$$

where

$$W_m=\left(1+O\left(\frac{1}{i}+\frac{1}{j}\right)\right)\left(\frac{i+j}{2\pi ij}\right)^{1/2}\exp lE\left(\frac{m}{k}\right).$$

Since $E(\mu)$ is analytic at $\mu = M$, it can be expanded in a Taylor series about this point. The result is

$$E(\mu)=\gamma-(\mu-M)^2/\delta^2+O\big((\mu-M)^3\big),$$

where

$$\delta = \left(\frac{2N(1-N)}{\Delta^3}\right)^{1/2}.$$

We shall break our sum into three parts,

$$\sum_m W_m = \sum_{m<a} W_m + \sum_{a\le m<b} W_m + \sum_{b\le m} W_m,$$

where

$$a = Ml - (2q+1)L,$$
$$b = Ml + (2q+1)L.$$

We shall need the following approximation property of $E(\mu)$. If m is of the form

$$m = Ml + O\big((l\log l)^{1/2}\big),$$

then (since $|k-l| \le \varepsilon$) we have

$$\left|\frac{m}{k} - \frac{m}{l}\right| = O\left(\frac{1}{l}\right).$$

Furthermore, since $E'(\mu) = O\big(|\mu - M|\big)$ in a fixed neighborhood of M, we have

$$\left|E\left(\frac{m}{k}\right) - E\left(\frac{m}{l}\right)\right| = O\left(\frac{(\log l)^{1/2}}{l^{3/2}}\right).$$

To estimate the sum over $m < a$, we observe that it comprises $O(l)$ terms, each of which is at most W_a. We have $E(a/k) = E(a/l) + O\big((\log l)^{1/2}/l^{3/2}\big)$ (by the approximation property with $m = a$) and $E(a/l) = \gamma - 3(\log l/l) + O\big((\log l/l)^{3/2}\big)$ (by the Taylor series expansion). Thus

$$W_a = O\left(\frac{x^\gamma}{l^3}\right),$$

and so

$$\sum_{m<a} W_m = O\left(\frac{x^\gamma}{l^2}\right).$$

Similarly,

$$\sum_{b\le m} W_m = O\left(\frac{x^\gamma}{l^2}\right),$$

and thus

$$\sum_m W_m = \sum_{a\le m<b} W_m + O\left(\frac{x^\gamma}{l^2}\right). \tag{3.5}$$

For any term in the sum over $a \le m < b$,

$$m = Ml\left(1 + O\left(\left(\frac{\log l}{l}\right)^{1/2}\right)\right),$$

from which it follows that

$$i = \frac{Nl}{\Delta}\left(1 + O\left(\left(\frac{\log l}{l}\right)^{1/2}\right)\right),$$

$$j = \frac{(1-N)l}{\Delta}\left(1 + O\left(\left(\frac{\log l}{l}\right)^{1/2}\right)\right),$$

and

$$i + j = \frac{l}{\Delta}\left(1 + O\left(\left(\frac{\log l}{l}\right)^{1/2}\right)\right).$$

Thus

$$W_m = \left(1 + O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\left(\frac{\Delta}{2\pi l N(1-N)}\right)^{1/2} x^\gamma V_m,$$

where

$$V_m = \exp -\left((m - Mk)^2/\delta^2 k\right).$$

And, therefore,

$$\sum_{a \le m < b} W_m = \left(1 + O\left(\frac{(\log l)^{3/2}}{l^{1/2}}\right)\right)\left(\frac{\Delta^3}{2\pi l N(1-N)}\right)^{1/2} x^\gamma \sum_{a \le m < b} V_m. \tag{3.6}$$

To estimate this sum, we divide the interval $[a, b)$ into $2q + 1$ intervals, each of length $2L$:

$$\sum_{a \le m < b} V_m = \sum_{-q \le r \le q} \sum_{m \in I_r} V_m,$$

where $I_r = \left[Ml + (2r-1)L, Ml + (2r+1)L\right)$ is the half-open interval of length $2L$ centered at $c_r = Ml + 2rL$.

We shall need the following approximation property of V_m. If m and c are each of the form

$$m, c = Ml + O\left((l \log l)^{1/2}\right),$$

and $|m - c| \le L$, then we have

$$\left|\frac{m}{l} - \frac{c}{l}\right| = O\left(\frac{1}{l}\right).$$

Furthermore, since $(d/dm)\log V_m = O\left(|\mu - M|\right)$ in a fixed neighborhood of M, we have

$$V_m = V_c\left(1 + O\left(\frac{(\log l)^{1/2}}{l^{3/2}}\right)\right).$$

Using this approximation property, we may replace the summand V_m by the constant V_{c_r} in the inner sum over $m \in I_r$, so that

$$\sum_{m \in I_r} V_m = \left(1 + O\left(\frac{(\log l)^{1/2}}{l^{3/2}}\right)\right) V_{c_r} \sum_{m \in I_r} 1.$$

By the Kronecker–Weyl theorem, we have

$$(1-\varepsilon)\varepsilon 2L \le \sum_{m\in I_r} 1 \le (1+\varepsilon)\varepsilon 2L$$

for each r, since the lucky values of m in I_r correspond to lucky values of i in an interval of length t. Thus we have

$$(1-\varepsilon)\varepsilon 2L \sum_{-q\le r\le q} V_{c_r} \le \sum_{a\le m<b} V_m \le (1+\varepsilon)\varepsilon 2L \sum_{-q\le r\le q} V_{c_r}. \tag{3.7}$$

The sum $\sum_{-q\le r\le q} V_{c_r}$ may now be approximated by an integral, extended to an infinite range of integration, and evaluated by an appropriate substitution, all as in the proof of Lemma 2.3. The result is

$$\sum_{-q\le r\le q} V_{c_r} = \frac{1}{2L}\left(\frac{2\pi l N(1-N)}{\Delta^3}\right)^{1/2} + O\left(\frac{1}{l^4}\right).$$

Working backwards through (3.7), (3.6), and (3.5) yields (3.4). □

The formula (3.3) follows from Lemma 3.1, since $C\gamma = 1/\Delta$. We observe that the same method works to establish the asymptotic formula (1.7) for $h'(x)$ in the irrational case.

Though we have derived (1.4) and (1.5) by parallel arguments, there is an important difference between these derivations. We could have done the analysis in §2 to obtain an O-estimate for the error in (1.5); the most straightforward way of doing this yields a factor of $\big(1 + O\big((\log\log x)^{3/2}(\log x)^{-1/2}\big)\big)$. No such sharpening is possible for (1.4), however, since the Kronecker–Weyl theorem, in the form we have cited, gives no estimate for the rate of convergence to the uniform distribution. The same phenomenon arises for the analytic proof using the Wiener–Ikehara theorem, for while convergence follows from the behavior of $K(s)$ on the critical line and the right half plane it bounds, the rate of convergence depends on how closely the poles in the left half plane approach the critical line as their imaginary parts grow (see [W2], [I], [L]). With either method, the missing information depends on how well the irrational number $\log\alpha/\log\beta$ can be approximated by rational numbers as the denominators of these rational numbers grow. This is the crux of the difference: all rational numbers are alike, but each irrational number is irrational in its own way.

Since we have not made any quantitative hypothesis concerning the irrationality of $\log\alpha/\log\beta$, we cannot expect to draw any conclusion about the rate of approach in (1.4). If however we assume that $|\log\alpha/\log\beta - p/q|$ is bounded away from zero by a function of q, the elementary method used here (as well as the analytic method used by Fredman and Knuth) can be adapted to yield an explicit O-estimate in (1.4).

4. Conclusion. After deriving (1.4) and (1.5) in a new way, and obtaining explicit descriptions of the functions $D(x)$ and $D'(x)$ appearing in (1.5) and (1.8), we shall exhibit in this section the consequences of these explicit descriptions for the original recurrence (1.1).

Fredman and Knuth show, by elementary arguments, that

$$M(n) = 1 + (\alpha+\beta-1)W(n), \tag{4.1}$$

where $W(n)$ is the sum of the weights of the n words having the smallest weights. (Recall that the weight of a word over $\{\alpha,\beta\}$ is the product of its letters.) By the definitions of $h(x)$ and $h'(x)$, we have $W\big(h(x)\big) = h'(x)$. Let us assume that $\log\alpha/\log\beta$

is rational. Recall that a value of x is "magic" if $x = \varrho^l$ for some natural number l. We have $D(x) = P(0)$ and $P'(x) = P'(0)$ for all magic values of x, and the asymptotic formulas

$$h(x) \sim P(0)\, x^\gamma \tag{4.2}$$

and

$$h'(x) \sim P'(0)\, x^{\gamma+1}, \tag{4.3}$$

valid for magic values of x.

Let us say that a value of n is "magic" if $n = h(x)$ for some magic value of x. Then (4.2) and (4.3) yields the asymptotic formula

$$W(n) \sim P'(0) \left(\frac{n}{P(0)}\right)^{1+1/\gamma}, \tag{4.4}$$

valid for magic values of n.

To extend (4.4) to arbitrary values of n, we observe that as n increases between magic values, $W(n)$ increases by the addition of equal weights. Thus the points of the graph of $W(n)$ between magic values of n lie on the chords joining the points of the graph at successive magic values, and the formula for arbitrary n is obtained by linearly interpolating between the values given by (4.4) for magic values of n. This gives

$$W(n) \sim P'(0) Q\left(\left\{\log_\sigma \left(\frac{n}{P(0)}\right)\right\}\right) \left(\frac{n}{P(0)}\right)^{1+1/\gamma},$$

where $Q(\lambda) = (1 - \lambda + \lambda\tau)\tau^{-\lambda}$, which establishes (1.10) with

$$B(n) = (\alpha + \beta - 1) P'(0) Q\left(\left\{\log_\sigma \left(\frac{n}{P(0)}\right)\right\}\right) \left(\frac{1}{P(0)}\right)^{1+1/\gamma},$$

which is periodic in $\log n$ (with period $\log \sigma$), as claimed.

We have dealt in this paper with particular recurrences, (1.1) and (1.2), taken from Fredman and Knuth. It is possible to extend the analysis straightforwardly to a number of other recurrences of similar form, as, for example, with initial conditions imposed on an initial segment $\{0, 1, \ldots, r\}$ of the domain, rather than just at the point zero, or with three terms on the right-hand side, rather than just two. We see the contribution of this paper, however, as residing more in its methods than in their scope. The Wiener–Ikehara–Landau theorem used by Fredman and Knuth is of an essentially "Tauberian" character, inferring the asymptotics of a sequence from that of its sum. It is virtually equivalent in depth to the prime number theorem, which was in fact the application that motivated Wiener, Ikehara, and Landau. The arguments used in this paper, however, are not only elementary, but also "direct" or "Abelian" in character: they infer the asymptotics of a sum from that of its terms. These arguments are much less delicate than the ones they replace, and they show the phenomena we have studied to be less deep than has hitherto been supposed.

TIME-FREQUENCY LOCALIZATION VIA THE WEYL CORRESPONDENCE*

JAYAKUMAR RAMANATHAN† AND PANKAJ TOPIWALA‡

Abstract. A technique of producing signals whose energy is concentrated in a given region of the time-frequency plane is examined. The degree to which a particular signal is concentrated is measured by integrating the Wigner distribution over the given region. This procedure was put forward by Flandrin, and has been used for time-varying filtering in the recent work of Hlawatsch, Kozek, and Krattenthaler. In this paper, the associated operator is studied. Estimates for the eigenvalue decay and the smoothness and decay of the eigenfunctions are established.

Key words. time frequency localization, Weyl correspondence, Wigner distribution

AMS subject classifications. 45A05, 45C05, 42A60, 94A11

1. Introduction.

It is well known that the time-frequency characteristics of a square integrable signal cannot be arbitrary. For example, no such signal can be both time and band limited. The Heisenberg uncertainty principle provides another quantitive restriction on the joint time-frequency behavior of a square integrable signal. These facts indicate that a signal cannot have all its energy concentrated in a finite region of the time-frequency plane.

Nevertheless, in many applications it is important to use signals whose time-frequency characteristics are highly localized. Among other things, the work of Landau, Pollack, and Slepian [7], [8] produced a rigorous development of band-limited signals that are as concentrated as possible within a prescribed timespan. More recently, there has been interest in finding signals that are localized in general regions of phase space via methods that keep time and frequency on an equal footing (see the papers of Daubechies and Paul [5], [6]).

In this paper, we study a localization technique that uses the Wigner distribution to measure the degree to which a signal is concentrated in a particular region. This leads to a self-adjoint *localization* operator that is easy to study in terms of the Weyl correspondence. Under the Weyl correspondence, a function of two variables—called the *symbol*—is associated with an operator on functions of one variable. The symbol of the localization operator is simply the indicator function of the given region in the time-frequency space. The eigenfunctions of this operator with large eigenvalues span a subspace that can be used to determine the component of a general signal that is concentrated within the given region of the time-frequency plane: one computes the projection of a general signal into this subspace. This procedure was put forward by Flandrin [10], who derived a number of useful results, including Lemma 4 below. It has since been developed in the context of time-varying filtering (see, for example, the

papers of Hlawatsch, Kozek, and Krattenthaler [2], [3]). This paper is devoted to the further study of the localization operator descibed above. The asymptotic properties of the eigenvalues are studied and the fact that they are $\mathcal{O}(k^{-3/4})$ is established. In addition, the eigenfunctions with nonzero eigenvalues are shown to have faster than exponential decay in both the time and frequency domains. This, of course, leads to a statement regarding the smoothness of these eigenfunctions. In particular, we show that they are analytic. In the last section, some numerical examples are provided.

2. The Weyl correspondence.

The basic properties of the Weyl correspondence that we will need are collected in this section; for a thorough treatment, the reader is referred to the book of Folland [1].

Let $f, g \in L^2(\mathbb{R})$. A general time-frequency shift of f is

$$\rho(\tau,\sigma)f(t) = e^{\pi i\tau\sigma}e^{2\pi i\sigma t}f(t+\tau).$$

The cross-ambiguity function of f and g is

$$\begin{aligned} A(f,g)(\tau,\sigma) &= \langle \rho(\tau,\sigma)f, g\rangle \\ &= \int e^{\pi i\tau\sigma}e^{2\pi i\sigma t}f(t+\tau)\overline{g(t)}\,dt \\ &= \int e^{2\pi i\sigma s}f(s+\tau/2)\overline{g(s-\tau/2)}\,ds. \end{aligned}$$

The value of $A(f,g)$ at a particular point is the cross-correlation between a particular time-frequency shift of f against g. The ambiguity function is therefore a time-frequency cross-correlation between two functions. The Wigner distribution is the two-dimensional Fourier transform of the cross ambiguity function, thus giving it the interpretation of a time-varying spectrum. The Wigner distribution can be written as

$$W(f,g)(\xi,t) = \int e^{-2\pi i\tau\xi}f(t+\tau/2)\overline{g(t-\tau/2)}\,d\tau.$$

Several useful properties of the Wigner distribution are catalogued below.

THEOREM 1. *Let $f, g \in L^2(\mathbb{R})$. Then*

(1) $W(f,g)(\xi,t) \in L^2(\mathbb{R}^2)$ *and* $\|W(f,g)\|^2 = \|f\|^2\|g\|^2$,
(2) $W(f,g) \in C_0(\mathbb{R}^2)$ *and* $\|W(f,g)\|_\infty \le \|f\|\|g\|$,
(3) $W(g,f) = \overline{W(f,g)}$,
(4) $W(\hat{f},\hat{g})(\xi,t) = W(f,g)(t,-\xi)$, *and*
(5) $W(\rho(a,b)f, \rho(a,b)g)(\xi,t) = W(f,g)(\xi-b, t+a)$.

The Weyl correspondence uses the Wigner distribution to define a correspondence between functions of two variables and operators on $L^2(\mathbb{R})$. It is defined, via duality, by

$$\langle L_S f, g\rangle = \iint S(\xi,t)W(f,g)(\xi,t)\,d\xi dt,$$

where $f, g \in L^2(\mathbb{R})$ and $S(\xi,t)$ is a function with appropriate decay properties. $S(\xi,t)$ is the symbol of the operator L_S. The following theorem of Pool [9] is useful.

THEOREM 2. *A symbol $S(\xi,t) \in L^2(\mathbb{R}^2)$ gives rise to an operator L_S that is Hilbert–Schmidt on $L^2(\mathbb{R})$. Moreover, the mapping $S \mapsto L_S$ is a unitary operator from $L^2(\mathbb{R}^2)$ to the Hilbert–Schmidt operators on $L^2(\mathbb{R})$.*

LEMMA 3. *L_S is self-adjoint if $S(\xi, t)$ is real valued.*

The following result was derived by Flandrin in [10], based on results of Janssen [11]. We will follow the development in [1].

LEMMA 4. *The eigenfunctions of the operator L_S corresponding to a radially symmetric symbol S are:*

$$h_j(t) = \frac{2^{1/4}}{\sqrt{j!}} \left(\frac{-1}{2\sqrt{\pi}}\right)^j e^{\pi t^2} \frac{d^j}{dt^j} e^{-2\pi t^2}.$$

Proof. Theorem 1.105 in [1] shows that

$$W(h_j, h_k)(\xi, t) = \begin{cases} 2(-1)^k \sqrt{\frac{k!}{j!}} e^{-2\pi|z|^2} (2\sqrt{\pi} z)^{j-k} L_k^{(j-k)}(4\pi|z|^2) & \text{for } j \geq k, \\ 2(-1)^j \sqrt{\frac{j!}{k!}} e^{-2\pi|z|^2} (2\sqrt{\pi}\bar{z})^{k-j} L_j^{(k-j)}(4\pi|z|^2) & \text{for } k \geq j, \end{cases}$$

where $z = t + i\xi$ and $L_k^{(\alpha)}$ is the associated Laguerre polynomial. Set $r = |z|$ and note that

$$\begin{aligned} \langle L_S h_j, h_k \rangle &= \iint S(r) W(h_j, h_k)\, d\xi dt \\ &= \begin{cases} 0 & \text{for } j \neq k, \\ (-1)^j 4\pi \int_0^\infty S(r)\, e^{-2\pi r^2} L_j^{(0)}(4\pi r^2)\, r dr & \text{for } j = k. \end{cases} \end{aligned}$$

Hence

$$\lambda_j = (-1)^j 4\pi \int_0^\infty S(r)\, e^{-2\pi r^2} L_j^{(0)}(4\pi r^2)\, r dr. \tag{1}$$

3. Localization via a cut-off. The localization operator we are concerned with is L_{χ_Ω}, where χ_Ω is the characteristic function of some bounded domain in the $t - \xi$ plane. We will assume that $\Omega \subset [-B, B] \times [-T, T]$. Note that

$$\langle L_{\chi_\Omega} f, g \rangle = \iint_\Omega W(f, g).$$

L_{χ_Ω} is self-adjoint since χ_Ω is real valued. Pool's theorem implies that L_{χ_Ω} is Hilbert–Schmidt. Hence there is an orthonormal basis $\phi_1, \phi_2, \ldots$ of $L^2(\mathbb{R})$ and real numbers $\lambda_1, \lambda_2, \ldots$ such that $L_{\chi_\Omega}\phi_k = \lambda_k \phi_k$. The Hilbert–Schmidt norm of L_{χ_Ω} is $\sum |\lambda_k|^2 = |\Omega|$, the measure of Ω. We will assume that the eigenvalues are arranged in order of decreasing absolute value. It is easy to check that the largest positive eigenvalue corresponds to the maximum energy an L^2 function can have within the domain Ω. The corresponding eigenfunction would then be a time function with energy as concentrated as possible within Ω. Our principal aim in this paper is to study the decay of the eigenvalues of L_{χ_Ω} and the smoothness properties of the eigenfunctions.

Several properties of the associated kernel will be of importance.

LEMMA 5. *The kernel of the operator L_{χ_Ω} is given by the equation*

$$K(s,t) = \int \chi_\Omega\left(\xi, \frac{s+t}{2}\right) e^{2\pi i(s-t)\xi}\, d\xi$$

and has the properties

(1) $K(s,t) \equiv 0$ *if* $|s+t| \geq 2T$; *and*

(2) *if the cross-sections* Ω_t *of* Ω *in the* ξ *direction consist of at most* M *intervals, then* $|K(s,t)| \leq CM/(|s|+1)$.

Proof. The formula for the kernel is well known (see [1]). The kernel can be written as

$$K(s,t) = F\left(t-s, \frac{s+t}{2}\right),$$

where

$$F(\eta,t) = \int_{\Omega_t} e^{-2\pi i\eta\xi}\, d\xi.$$

Item (1) follows from the observation that $\Omega_t = \emptyset$ if $|t| \geq T$. We now verify item (2). By assumption, the cross-section is the union of at most M disjoint intervals: $\Omega_t = \cup_{i=1}^{L}[\alpha_i, \beta_i]$ for some integer $L \leq M$. Therefore, one can estimate that

$$\begin{aligned}|F(\eta,t)| &= \left|\sum e^{-\pi i(\alpha_k+\beta_k)\eta} \frac{\sin(\pi(\beta_k-\alpha_k)\eta)}{\pi\eta}\right| \\ &\leq \sum \left|\frac{\sin(\pi(\beta_k-\alpha_k)\eta)}{\pi\eta}\right| \\ &\leq \frac{2L}{|\eta|+1} \leq \frac{2M}{|\eta|+1}\end{aligned}$$

since $\sin(Ax)/x \leq \max(2,A)/(|x|+1)$. The estimate only needs to be verified when $|s+t| \leq 2T$. In this case,

$$|s-t| + 2T \geq |s-t| + |s+t| \geq 2|s|.$$

Using this and the estimate for $F(\eta,t)$ yields

$$\begin{aligned}|K(s,t)| &\leq \frac{CM}{|s-t|+1} \\ &\leq \frac{CM}{2|s|+1-2T}\end{aligned}$$

for all large s. The estimate in the theorem follows easily by adjusting the constant as necessary.

For domains Ω with piecewise C^1 boundary, we can show that λ_k is $\mathcal{O}(k^{-3/4})$. The proof is a modification of Weyl's classical work on the asymptotics of eigenvalues of integral equations. The following lemma contains some useful standard facts about the Weyl correspondence. Again we refer the reader to [1] for the proofs.

LEMMA 6. (1) *The operators corresponding to $S(\xi,t)$ and $S(\xi-\xi_0,t-t_0)$ are unitarily equivalent.*

(2) *Suppose the symbols $S_1(\xi,t)$ and $S_2(\xi,t)$ are related by an orthogonal change of variables. Then the corresponding operators are unitarily equivalent.*

We will first prove that λ_k is $\mathcal{O}(k^{-3/4})$ for domains Ω of the following form:

$$(*) \qquad \Omega = \{(\xi,t) : \alpha(t) \le \xi \le \beta(t), t \in [-T,T]\},$$

where $\alpha(t),\beta(t)$ are C^1 functions with vanishing endpoint values. The kernel associated to the symbol $\chi_\Omega(\xi,t)$ is

$$K(s,t) = e^{-\pi i(t-s)[\alpha+\beta](\frac{s+t}{2})}\,\frac{\sin(\pi(t-s)[\beta-\alpha](\frac{s+t}{2}))}{\pi(t-s)}.$$

Moreover, it is easy to check that K is a Lipschitz function whose gradient DK exists almost everywhere (a.e.) and satisfies the inequality

$$(2) \qquad |DK| \le C \quad \text{a.e.}$$

LEMMA 7. *If Ω is of the form $(*)$, then there are symmetric finite rank approximations*

$$k_N(s,t) = \sum a_Q\chi_Q,$$

where Q ranges over squares of the form

$$\{(\xi,t) : i/N \le \xi \le (i+1)/N, j/N \le t \le (j+1)/N\}, \qquad -N^2 \le i,j \le N^2-1$$

with the property that

$$(3) \qquad \iint |K(s,t)-k_N(s,t)|^2\,dsdt \quad \textit{is } \mathcal{O}\left(\frac{1}{N}\right).$$

Proof. Set

$$a_Q = \frac{1}{|Q|}\iint_Q K(s,t)\,dsdt.$$

The symmetry of the kernel K forces symmetry of k_N. Let $R = \cup Q$. Then

$$\begin{aligned}\iint_R |K(s,t)-k_N(s,t)|^2\,dsdt &= \sum\iint_Q |K(s,t)-k_N(s,t)|^2\,dsdt \\ &\le \sum |Q|\iint_Q |DK|^2 = \frac{1}{N^2}\iint_R |DK|^2\end{aligned}$$

using Poincaré's inequality [4]. Since $K(s,t)$ is supported within the strip $|s+t| \le 2T$, (2) yields the estimate

$$(4) \qquad \iint_R |K(s,t)-k_N(s,t)|^2\,dsdt \le \frac{C}{N}.$$

The mean square error over the exterior of R can be handled as follows:

$$(5) \qquad \iint_{\mathbb{R}^2-R} |K-k_N|^2 = \iint_{\mathbb{R}^2-R} |K|^2\,dsdt \le \frac{C}{N},$$

in view of Lemma 5. Putting (4) and (5) together yields the estimate in (3).

In view of Satz III of Weyl's paper [4], we have

$$\lambda^2_{4N^2+1} + \cdots \leq \frac{C}{N}.$$

We will apply this inequality to $N/2$, where $N = [\sqrt{k-1}/2]$. (Here [ ] denotes the greatest integer function.) This yields

$$\lambda^2_{4(N/2)^2-1} + \cdots + \lambda^2_{4N^2-1} + \cdots + \lambda^2_k \cdots \leq \frac{2C}{N}.$$

Since the eigenvalues have been arranged in decreasing order, the left-hand side of the above inequality is greater than or equal to $3N^2\lambda^2_k$. This yields an inequality of the form $\lambda^2_k \leq C/N^3$. Clearly $1/N$ is $\mathcal{O}(1/\sqrt{k})$. These remarks imply that λ_k is $\mathcal{O}(k^{-3/4})$ for domains with property (*). We now use a cut and paste argument to derive the result for general Ω with C^1 boundary.

LEMMA 8. *If $K'(s,t)$ and $K''(s,t)$ are two symmetric real kernels in $L^2(\mathbb{R}^2)$ with*

$$|\lambda'_k| \leq \frac{C'}{k^{3/4}} \quad \text{and} \quad |\lambda''_k| \leq \frac{C''}{k^{3/4}},$$

then the eigenvalues of $K(s,t) = K'(s,t) + K''(s,t)$ must satisfy the same estimate: $|\lambda_k| \leq Ck^{-3/4}$ for some constant C.

Proof. Satz I of Weyl's paper [4] implies that

$$|\lambda_{2k}| \leq |\lambda'_k| + |\lambda''_{k+1}|,$$
$$|\lambda_{2k+1}| \leq |\lambda'_{k+1}| + |\lambda''_{k+1}|$$

for all positive integers k. From this it is straightforward to verify that the eigenvalues of $K(s,t)$ have the required decay property.

THEOREM 9. *If Ω is a bounded domain with piecewise C^1 boundary, then λ_k is $\mathcal{O}(k^{-3/4})$.*

Proof. Clearly, such an Ω can be decomposed into a finite union of nonoverlapping subdomains $\Omega = \cup_k \Omega_k$, where each Ω_k can be put into the form (*) after a rigid motion in the plane. By Lemma 6, each $L_{\chi_{\Omega_k}}$ has eigenvalues with the sought-after decay property. Lemma 8 then implies that L_{χ_Ω} also has the same property.

This estimate is in fact sharp, at least for annular regions.

PROPOSITION 10. *Let $\Omega = \{(\xi,t) : \epsilon \leq (\xi^2+t^2)^{1/2} \leq R\}$, where $0 < \epsilon < R$. Then*

$$0 < \limsup_{k\to\infty} k^{3/4}\lambda_k < \infty.$$

Proof. According to Lemma 4, the kth eigenvalue is

$$\lambda_k = (-1)^k 4\pi \int_\epsilon^R \exp(-2\pi r^2) L_k(4\pi r^2)\, r dr.$$

The following classical asymptotic expansion for Laguerre polynomials, valid for $x \in [\epsilon', R']$ with $0 < \epsilon' < R'$, will be essential [12, Thm. 8.22.2]:

$$\pi^{1/2} x^{1/4} k^{1/4} \exp\left(-\frac{x}{2}\right) L_k(x) = \cos\left(2(kx)^{1/2} - \frac{\pi}{4}\right)\left(1 + A_1(x)k^{-1/2} + \mathcal{O}(k^{-1})\right)$$
$$+ \sin\left(2(kx)^{1/2} - \frac{\pi}{4}\right)\left(B_1(x)k^{-1/2} + \mathcal{O}(k^{-1})\right).$$

Applying this formula with $x = 4\pi r^2$ yields

$$|\lambda_k| = k^{-1/4}I_0(k) + k^{-3/4}I_1(k) + \mathcal{O}(k^{-5/4}), \tag{6}$$

where

$$I_0(k) = 2^{3/2}\pi^{1/4}\int_\epsilon^R r^{1/2}\cos\left(4(k\pi)^{1/2}r - \frac{\pi}{4}\right)\,dr$$

and

$$\begin{aligned} I_1(k) =& 2^{3/2}\pi^{1/4}\int_\epsilon^R r^{1/2}A_1(4\pi r^2)\,\cos\left(4(k\pi)^{1/2}r - \frac{\pi}{4}\right)\,dr \\ &+ 2^{3/2}\pi^{1/4}\int_\epsilon^R r^{1/2}B_1(4\pi r^2)\,\sin\left(4(k\pi)^{1/2}r - \frac{\pi}{4}\right)\,dr. \end{aligned}$$

Consider the behavior of $I_0(k)$. Using a double-angle formula, we have

$$I_0(k) = 2^{3/2}\pi^{1/4}\int_\epsilon^R r^{1/2}\cos(4(k\pi)^{1/2}r)\,dr + 2^{3/2}\pi^{1/4}\int_\epsilon^R r^{1/2}\sin(4(k\pi)^{1/2}r)\,dr.$$

These are the Fourier cosine and sine integrals of the smooth function $r^{1/2}$ on the interval $[\epsilon, R]$, evaluated as $4(k\pi)^{1/2}$. As such, both integrals are $\mathcal{O}(k^{-1/2})$. A similar argument shows that the integrals in $I_1(k)$ are $\mathcal{O}(k^{-1/2})$ as well.

Finally, with a little more care one can show that

$$\limsup_{k\to\infty} k^{1/2}I_0(k) > 0.$$

In fact, write the function $r^{1/2} = \ell(r) + (r^{1/2} - \ell(r))$, where $\ell(r)$ is the linear function that interpolates between the endpoint values of $r^{1/2}$ at ϵ and R. The function $r^{1/2} - \ell(r)$ is a Lipschitz function on the real line with support in $[\epsilon, R]$. Consequently, the Fourier sine and cosine integrals of this function evaluated at $4(k\pi)^{1/2}$ are $\mathcal{O}(k^{-1})$. It is therefore enough to show that the integral

$$A_0(k) = \Re\left(e^{i\pi/4}\int_\epsilon^R \ell(y)\exp(4i(k\pi)^{1/2}r)\,dr\right)$$

has the property that

$$\limsup_{k\to\infty} k^{1/2}A_0(k) > 0.$$

This is easy to show directly.

For general domains, we obtain the weaker result that the sequence of eigenvalues is not absolutely summable.

PROPOSITION 11. *The series $\sum \lambda_k$ is not absolutely convergent.*

Proof. It is well known that $\{W(\phi_k, \phi_l)\}$ is an orthonormal basis for $L^2(\mathbb{R}^2)$. The equations $\iint_\Omega W(\phi_k, \phi_l) = \delta_{kl}\lambda_k$ imply that $\chi_\Omega = \sum \lambda_k W(\phi_k, \phi_k)$ in $L^2(\mathbb{R}^2)$. On the other hand, if $\sum |\lambda_k| < \infty$, then $\sum \lambda_k W(\phi_k, \phi_k)$ would have to converge uniformly to an element of $C_0(\mathbb{R}^2)$ (see Theorem 1, part (2)). This is clearly a contradiction.

We now examine the smoothness and decay of the eigenfunctions. We assume that Ω is an open set contained in a rectangle $[-B, B] \times [-T, T]$ of which all cross-sections in the ξ and t directions consist of at most M intervals. We now examine an equation of the form $L_{\chi_\Omega}\phi = \lambda\phi$, where λ is a nonzero real number and $\phi \in L^2(\mathbb{R})$. Fubini's theorem implies that

$$\lambda\phi(s) = \int K(s,t)\phi(t)\,dt$$

holds for all $s \in \mathbb{R}\backslash Z$, where Z is some set of measure zero. Lemma 5 yields the estimate

$$\begin{aligned} |\lambda\phi(s)| &\leq \frac{C}{1+|s|}\int_{-s-2T}^{-s+2T} |\phi(t)|\,dt \\ &\leq \frac{C\sqrt{4T}}{|s|+1}\|\phi\|_{L^2} \leq \frac{C'}{|s|+1} \end{aligned}$$

for all $s \in \mathbb{R}\backslash Z$. This last estimate implies that $\phi \in L^\infty(\mathbb{R})$. Now define

$$\mathcal{E}(s) = \sup_{|s'|\geq|s|} |\phi(s')|.$$

Note that $\mathcal{E}(s)$ is even and decreasing in $|s|$. The quantity $|\lambda\phi(s)|$ can now be estimated as follows:

$$\begin{aligned} |\lambda\phi(s)| &\leq \frac{C}{|s|+1}\int_{-s-2T}^{-s+2T} |\phi(t)|\,dt \\ &\leq \frac{4CT}{|s|+1}\mathcal{E}(|s|-2T) \end{aligned}$$

for all $s \in (\mathbb{R}\backslash Z) \cap \{s' : |s'| > 2T\}$. Therefore, given any $b > 1$, there is an s_0 such that if $|s| \geq |s_0|$ and $s \in \mathbb{R}\backslash Z$, then

$$\mathcal{E}(|s|+2T) \leq \frac{1}{b}\mathcal{E}(|s|).$$

Iterating this estimate yields

$$\mathcal{E}(|s|+2nT) \leq \frac{1}{b^n}\mathcal{E}(|s|).$$

It is straightforward to check that

$$|\phi(s)| \leq Cb^{-|s|/(2T)} \quad \forall s \in \mathbb{R}\backslash Z. \tag{7}$$

As a consequence, $\hat{\phi}$ is smooth and has all its derivatives in L^2.

Now, by Theorem 1, part (4), we have that

$$\iint_{\tilde{\Omega}} W(\hat{\phi}_k, \hat{\phi}_l) = \iint_{\Omega} W(\phi_k, \phi_l) = \lambda_k\delta_{kl},$$

where $\tilde{\Omega} = \{(\xi,t) : (-t,\xi) \in \Omega\}$. Hence $L_{\chi_{\tilde{\Omega}}}\hat{\phi}_k = \lambda_k\hat{\phi}_k$, and by the preceding discussion ϕ is smooth and has all its derivatives in L^2. Now for a given s_1,

$$\left.\frac{d^n\phi}{ds^n}\right|_{s=s_1} = \int \hat{\phi}(\xi)(2\pi i\xi)^n e^{2\pi i s_1\xi}d\xi.$$

Using the estimate analogous to equation (7) for $\hat{\phi}$ with $b >> 1$, one has $|\hat{\phi}(\xi)| \leq Ce^{-4\pi|\xi|}$. Then

$$\left|\frac{1}{n!}\frac{d^n\phi}{ds^n}\right|_{s=s1} \leq \frac{2C}{n!}\int_0^\infty e^{-4\pi\xi}(2\pi\xi)^n\, d\xi$$
$$\leq \frac{C}{n!}\frac{\Gamma(n)}{2^{n+1}} = \frac{C}{2^{n+1}n}.$$

Hence the power series of ϕ at $s = s_1$ converges in some interval around s_1. Because of the symmetry in the role of ϕ and $\hat{\phi}$, the same observations hold for $\hat{\phi}$. The preceding discussion is summarized in the following theorem.

THEOREM 12. *Suppose Ω is an open set contained in the interval $[-B,B] \times [-T,T]$ with the property that all its cross-sections in both the ξ and t directions consist of at most M intervals. Then*

(1) *for any $b > 0$, there is a constant C_b such that*

$$|\phi(s)| \leq C_b e^{-b|s|} \quad \forall s \quad \text{and} \quad |\hat{\phi}(\xi)| \leq C_b e^{-b|\xi|} \quad \forall \xi,$$

and

(2) *ϕ and $\hat{\phi}$ are analytic and have all their derivatives in L^2.*

Note that (1) actually implies (2) in Theorem 12 by the Paley–Wiener theorems [13], although we have chosen to give the elementary argument.

It is instructive to consider the case when Ω is a ball centered at the origin. It is well known that, in this case, the ϕ_k are Hermite functions (see Lemma 4). The Hermite functions $h_j(t)$ in Lemma 4 will satisfy estimates of the form $h_j(t) \leq Ce^{-(\pi-\epsilon)t^2}$ for any $\epsilon > 0$. It is directly evident that they will then satisfy the weaker inequalities in Theorem 12. This theorem states that this weaker decay statement holds for general regions in the time-frequency plane. We do not know whether these estimates can be improved.

4. Numerical examples. For illustration purposes, we provide four numerical examples of time-frequency localization. These examples are obtained by discretizing the kernel in the integral representation of the operator given in Lemma 5. We consider localization on domains of the form of a "zigzag," a disk, a rectangle, and a parallelogram, as indicated in Fig. 1. Note that while the operators here are all Hermitian, so that they have real eigenvalues, they do not generally have real eigenfunctions unless their kernels are real. This is true if the symbol $S(\xi,t)$ satisfies $S(-\xi,t) = S(\xi,t)$. For clarity of eigenfunction representation, projection domains were chosen to allow this symmetry when possible.

Localization on the unusual zigzag domain (Fig. 1a) produces the unfamiliar eigenfunctions in Fig. 2 (as these are complex, we have plotted their magnitude). Eight samples per unit length are used, over the time domain $[-8,8]$. Most of the energy is concentrated in the desired region $[-2,2]$, although there is some leakage. Note that the first three eigenfunctions have one, two, and three peaks, respectively. For the case of the disk (Fig. 1b), a plot of the eigenvalues is shown in Fig. 3. As noted in Lemma 4, the eigenfunctions in this case are the well-known hermite functions. Next, localization on the rectangle (Fig. 1c) allows comparison to the prolate spheroidal wavefunctions. The first nine solutions for the prolate spheroidal and Weyl operator cases are depicted in Figs. 4a and b. Again, eight samples per unit length are used over the time domain $[-8,8]$. While there is energy leakage outside the desired domain

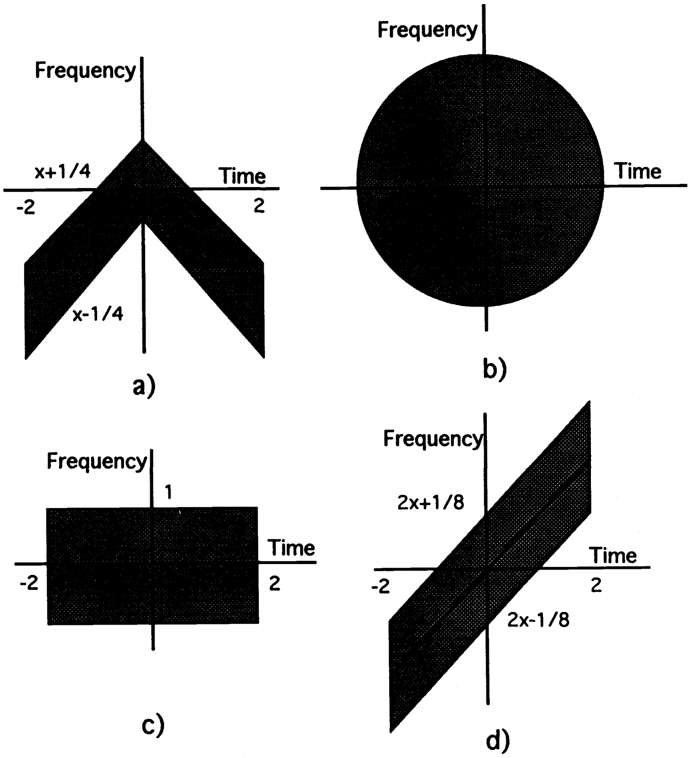

FIG. 1. *Localization Domains:* (a) *zigzag domain*; (b) *disk of area* 50; (c) 4 × 2 *rectangle*; (d) *parallelogram.*

$[-2, 2]$, the amount differs in the two cases. The prolate spheroidal wavefunctions have $1/x$ decay, while the Weyl eigenfunctions have exponential decay. This difference is visible when one compares the last three eigenfunctions in each case. A plot of the eigenvalues is also included.

Finally, we provide a simple illustration of these ideas in the context of filtering Gaussian noise from a corrupted linear FM (chirp) signal. Figures 5a and 6a show, respectively, the Wigner distribution intensity plot and the actual plot of the real part of a linear FM chirp centered at zero frequency. (Although chirp signals used in radar are not centered at zero frequency, that is immaterial for our purposes because of the covariance of the Wigner distribution under time and frequency shifts (Theorem 1, part (5).) In the discretization, 16 samples per unit length are used, over the time domain $[-2, 2]$. No windowing is applied to remove the echo effect in these Wigner plots, although we have found a simple cosine-squared window to be effective. Figures 5b and 6b show this signal after 0 dB Gaussian white noise has been added. To filter the noise, we note that theoretically, the Wigner distribution of a chirp signal is a measure concentrated along a diagonal line corresponding to the slope of the chirp. In particular, a chirp can be localized in any domain containing its time-frequency support. As an elementary example of time-frequency localization, the noisy chirp of Fig. 6b is projected onto the first two eigenfunctions (weighted according to the eigenvalues) for the domain in Fig. 1d. This results in the signal in Fig. 6c, with a Wigner distribution as shown in Fig. 5c. A plot of the eigenvalues for this localization operator is provided in Fig. 6d. In fact, the chirp in Fig. 6a is orthogonal to the second eigenfunction, illustrating an interesting fact. Numerically, the chirp appears to be an exact solution to the problem of localizing onto an infinite diagonal band domain. For

more numerical examples of time-frequency localization, the reader is referred to [2], [3].

It is interesting at this point to remark on a conjecture of Flandrin [10]: for localization onto convex domains, the top eigenvalue is bounded above by 1. This seems to hold (at least numerically) in our examples, even for Fig. 1a, which is not convex. However, something like convexity is certainly necessary in general, since we have nonconvex numerical examples where the top eigenvalue exceeds 4.

SPATIAL DECAY ESTIMATES IN TIME-DEPENDENT STOKES FLOW*

K. A. AMES†, L. E. PAYNE‡, AND P. W. SCHAEFER§

Abstract. This paper considers the time-dependent slow flow of an incompressible viscous fluid in a semi-infinite cylindrical pipe of smooth cross section. An exponential decay estimate in terms of the distance from the finite end of the pipe is obtained from a second-order differential inequality for a weighted energy integral defined on the solutions of the system. The decay constant depends only on the geometry and the first positive eigenvalues for the fixed and free membrane problems for the cross sectional geometry. The paper also indicates how to bound the total weighted energy.

Key words. Stokes flow, decay estimates

1. Introduction.

Although principles of Saint-Venant type, estimating the spatial decay of solutions of various elliptic boundary value problems have been extensively investigated in the literature of the past century (see [5], [8], and the references therein), the study of spatial decay of solutions of time-dependent problems is of relatively recent origin. The first work in this area appears to be that of Boley [3] in 1958. For subsequent investigations on the spatial decay of solutions of parabolic equations, also see the references cited in [5] and [8].

In this paper, we investigate the slow flow of an incompressible viscous fluid in a semi-infinite cylindrical pipe. At the finite end of the pipe, a time-dependent velocity profile is prescribed, adherence is assumed on the lateral surface, and the fluid is assumed to be initially at rest. We derive an explicit inequality which implies exponential decay of a weighted energy expression as a function of the distance from the finite end of the pipe. Of course, the solution will not exhibit spatial decay for each t unless the net flow through the finite end of the pipe is zero for each t. The case of nonzero net entry flow will be considered in a later paper.

The two-dimensional version of the pipe flow problem has been studied by Lin [9]. In this case, he was able to eliminate the troublesome pressure term by introducing a stream function. This feature does not carry over to the pipe flow problem here, so different techniques must be developed for establishing the decay estimate.

It should be remarked that Elcrat and Sigillito [4] actually looked at the question of spatial decay for the dynamical Navier–Stokes equations, but their method required an assumption on an auxiliary function that is not generally satisfied. For decay results in steady pipe flow, see the references cited in Horgan and Knowles [5] and the paper of Ames and Payne [1].

The outline for this paper is as follows. We formulate the boundary value problem, which describes transient Stokes flow in three space, and define the energy function

in §2. After recording in §3 some auxiliary results that we shall use, we determine a second-order differential inequality for the energy expression in §§4 and 5. The exponential decay inequality which follows from the differential inequality is given in (5.34). In §6, we estimate the total weighted energy by techniques developed in the body of this paper, and in §7, we make some concluding remarks.

2. Statement of the problem. Let R denote the interior of a semi-infinite cylindrical pipe of an arbitrary, smooth cross section with generator parallel to the x_3-axis. The end (entrance) of the pipe in the $x_3 = 0$ plane is denoted by D_0 and comprises part of the boundary ∂R of R. We let

$$R_z = \{(x_1, x_2, x_3) \mid (x_1, x_2) \in D_0,\ x_3 > z \geq 0\}$$

denote the subdomain of R for which $x_3 > z$ and let

$$D_z = \{(x_1, x_2, x_3) \mid (x_1, x_2) \in D_0,\ x_3 = z\}$$

denote the part of ∂R_z in the plane $x_3 = z \geq 0$.

The velocity field $u_i(x_1, x_2, x_3, t)$ for $i = 1, 2, 3$ and the pressure $p(x_1, x_2, x_3, t)$ for the time-dependent Stokes flow of an incompressible viscous fluid are assumed to be classical solutions of the initial-boundary value problem:

$$u_{i,t} = \nu \Delta u_i - p_{,i} \quad \text{in } R \times (0, \infty), \tag{2.1}$$

$$u_{i,i} = 0 \quad \text{in } \overline{R} \times (0, \infty), \tag{2.2}$$

$$u_i = 0 \quad \text{on } \partial R \setminus D_0 \times (0, \infty), \tag{2.3}$$

$$u_i = f_i(x_1, x_2, t) \quad \text{in } \overline{D}_0 \times (0, \infty), \tag{2.4}$$

$$u_i = 0 \quad \text{in } R \times \{0\}, \tag{2.5}$$

$$u_i, u_{i,j}, u_{i,t}, p = o\left(x_3^{-1}\right) \quad \text{uniformly in } x_1, x_2, t \quad \text{as } x_3 \to \infty, \tag{2.6}$$

where Δ is the three space Laplace operator, ν is the constant kinematic viscosity, and the comma (partial differentiation) and repeated index (summation) conventions are used. In this work, Latin subscripts range over 1, 2, 3 while Greek subscripts range over 1, 2 unless noted otherwise. We assume that the prescribed functions (entrance profile) f_i are continuously differentiable and vanish on $\partial D_0 \times [0, \infty)$ and that $\nu = 1$ without loss of generality since we can rescale the time variable.

We define a weighted energy integral for solutions u_i of (2.1)–(2.6) by (no summation on τ)

$$E(z, t) = \int_0^t \int_{R_z} (\xi - z)\left[u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}\right] dx d\tau \tag{2.7}$$

and note that

$$\frac{\partial E}{\partial z} = -\int_0^t \int_{R_z} \left[u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}\right] dx d\tau, \tag{2.8}$$

$$\frac{\partial^2 E}{\partial z^2} = \int_0^t \int_{D_z} \left[u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau}\right] dA d\tau, \tag{2.9}$$

where k is a parameter to be chosen. Our aim is to obtain a second-order differential inequality for E from which we can deduce an exponential decay estimate of the form

$$E(z, t) \leq E(0, t) e^{-\sigma z}, \qquad \sigma > 0, \tag{2.10}$$

where $0 \leq z < \infty$.

3. Auxiliary inequalities. We shall make frequent use of the Schwarz inequality and the arithmetic mean-geometric mean (AG) inequality in our derivation of the second-order differential inequality we seek. In addition, we need the following three inequalities.

Let S be a plane domain with sufficiently smooth boundary ∂S, and let v be a sufficiently smooth function defined on the closure $\overline{S}$ of S.

1. If $v = 0$ on ∂S, then

$$\lambda_1 \int_S v^2 dA \leq \int_S v_{,\alpha} v_{,\alpha} dA, \tag{3.1}$$

where λ_1 is the smallest positive eigenvalue of

$$\Delta w + \lambda w = 0 \text{ in } S, \quad w = 0 \quad \text{on } \partial S.$$

2. If $\partial v / \partial n = 0$ on ∂S and $\int_S v dA = 0$, then

$$\mu_2 \int_S v^2 dA \leq \int_S v_{,\alpha} v_{,\alpha} dA, \tag{3.2}$$

where μ_2 is the smallest positive eigenvalue of

$$\Delta w + \mu w = 0 \quad \text{in } S, \quad \frac{\partial w}{\partial n} = 0 \quad \text{on } \partial S, \quad \int_S w dA = 0.$$

3. If g is a continuously differentiable function on $\overline{S}$ and $\int_S g dA = 0$, then there exists a vector function v_α such that

$$v_{\alpha,\alpha} = g \quad \text{in } S, \quad v_\alpha = 0 \quad \text{on } \partial S, \tag{3.3}$$

and a positive constant C depending only on the geometry of S such that

$$\int_S v_{\alpha,\beta} v_{\alpha,\beta} dA \leq C \int_S (v_{\alpha,\alpha})^2 dA. \tag{3.4}$$

The first two inequalities are the result of the variational characterization of the smallest positive eigenvalue of the respective eigenvalue problem, whereas the third inequality is established in [2]. The latter inequality appears to have first been used in [7]. The third implication above asserts the existence of a vector function v_α which is, in fact, not unique. We require only the existence of such a vector function in our derivation and not an explicit solution. We refer the reader to [1] for a brief discussion about the constant C and to [6] for an explicit upper bound for the optimal C when S is a star-shaped domain—an assumption we will make about the domain D_0 (see Lemma 3 in §5).

4. Energy estimation—first part. We are now ready to derive the desired second-order differential inequality for E. Our derivation consists of two parts. In this section, we bound the more easily estimated terms and in the next section, we bound a term complicated by the presence of the pressure function multiplied by the time derivative of u_3 and then determine the exponential decay estimate for the energy expression E.

We consider the energy integral

$$E(z,t) = \int_0^t \int_{R_z} (\xi - z) \left[u_{i,j} u_{i,j} + k u_{i,\tau} u_{i,\tau} \right] dx d\tau, \tag{4.1}$$

where we recall that there is no summation on the τ subscript and k is a parameter to be chosen. On integrating by parts and using (2.1), we have

$$\begin{aligned} E(z,t) = &-\int_0^t \int_{R_z} u_i u_{i,3} dx d\tau - \int_0^t \int_{R_z} (\xi - z) u_i \left[u_{i,\tau} + p_{,i}\right] dx d\tau \\ &+ k \int_0^t \int_{R_z} (\xi - z) u_{i,\tau} \left[\Delta u_i - p_{,i}\right] dx d\tau. \end{aligned}$$

We integrate by parts again and drop two spatial integral terms which are negative to obtain the inequality

$$\begin{aligned} E(z,t) \leq &-\int_0^t \int_{R_z} u_i u_{i,3} dx d\tau - k \int_0^t \int_{R_z} u_{i,\tau} u_{i,3} dx d\tau \\ &+ \int_0^t \int_{R_z} u_3 p dx d\tau + k \int_0^t \int_{R_z} u_{3,\tau} p dx d\tau \\ = &\, I_1 + I_2 + I_3 + I_4. \end{aligned} \tag{4.2}$$

We now proceed to estimate the first three integral terms.

We use the Schwarz inequality, (3.1), and the AG inequality to obtain

$$\begin{aligned} I_1 &\leq \int_0^t \int_z^\infty \left(\int_{D_\xi} u_i u_i dA \int_{D_\xi} u_{i,3} u_{i,3} dA \right)^{\frac{1}{2}} d\xi d\tau \\ &\leq \int_0^t \int_z^\infty \left(\frac{1}{\lambda_1} \int_{D_\xi} u_{i,\alpha} u_{i,\alpha} dA \int_{D_\xi} u_{i,3} u_{i,3} dA \right)^{\frac{1}{2}} d\xi d\tau \\ &\leq \frac{1}{2\sqrt{\lambda_1}} \left\{ \int_0^t \int_{R_z} u_{i,\alpha} u_{i,\alpha} dx d\tau + \int_0^t \int_{R_z} u_{i,3} u_{i,3} dx d\tau \right\}. \end{aligned}$$

Thus we can write

$$I_1 \leq \frac{1}{2\sqrt{\lambda_1}} \left(-\frac{\partial E}{\partial z} \right). \tag{4.3}$$

In a similar manner, it follows that

$$I_2 \leq \frac{k}{2} \left\{ \sigma_1 \int_0^t \int_{R_z} u_{i,\tau} u_{i,\tau} dx d\tau + \frac{1}{\sigma_1} \int_0^t \int_{R_z} u_{i,3} u_{i,3} dx d\tau \right\}.$$

If we let $k = 1/\lambda_1$ and choose $\sigma_1 = 1/\sqrt{\lambda_1}$, then we obtain

$$I_2 \leq \frac{1}{2\sqrt{\lambda_1}} \left(-\frac{\partial E}{\partial z} \right). \tag{4.4}$$

Due to the presence of the pressure function in the I_3 integral, we proceed in a different manner to bound this term. We first note that for any $z^* > 0$, by (2.2) and (2.3),

$$\begin{aligned}\int_{D_z} u_3 dA &= \int_{D_{z^*}} u_3 dA - \int_z^{z^*}\int_{D_\xi} u_{3,3} dA d\xi \\ &= \int_{D_{z^*}} u_3 dA + \int_z^{z^*}\int_{D_\xi} u_{\alpha,\alpha} dA d\xi \\ &= \int_{D_{z^*}} u_3 dA,\end{aligned}$$

and thus the area mean value of u_3 is the same over each section. Since u_3 is assumed to vanish at infinity, we conclude that this value is zero for all $z \geq 0$ and hence requires that f_3 satisfy

$$\int_{D_0} f_3 dA = 0 \quad \text{for all } t \geq 0. \tag{4.5}$$

Under this assumption, there exists a vector function (see (3.3)) ω_α which satisfies

$$\omega_{\alpha,\alpha} = u_3 \quad \text{in } D_\xi, \quad \omega_\alpha = 0 \quad \text{on } \partial D_\xi,$$

for each $\xi \geq 0$ and for which (3.4) holds.

Using the vector function ω_α in I_3, it follows that

$$\begin{aligned}I_3 &= \int_0^t \int_{R_z} \omega_{\alpha,\alpha} p dx d\tau \\ &= -\int_0^t \int_{R_z} \omega_\alpha p_{,\alpha} dx d\tau \\ &= \int_0^t \int_{R_z} \omega_\alpha \left[u_{\alpha,\tau} - \Delta u_\alpha\right] dx d\tau \\ &= \int_0^t \int_{R_z} \omega_\alpha u_{\alpha,\tau} dx d\tau + \int_0^t \int_{D_z} \omega_\alpha u_{\alpha,3} dA d\tau + \int_0^t \int_{R_z} \omega_{\alpha,i} u_{\alpha,i} dx d\tau.\end{aligned}$$

Now by means of Schwarz's inequality, (3.1), and the weighted AG inequality, we have

$$\begin{aligned}I_3 \leq& \frac{1}{2\sqrt{\lambda_1}}\left\{\sigma_2 \int_0^t \int_{R_z} u_{\alpha,\tau} u_{\alpha,\tau} dx d\tau + \frac{1}{\sigma_2}\int_0^t \int_{R_z} \omega_{\alpha,\beta}\omega_{\alpha,\beta} dx d\tau\right\} \\ &+ \frac{1}{2}\left\{\sigma_3 \int_0^t \int_{R_z} u_{\alpha,3} u_{\alpha,3} dx d\tau + \frac{1}{\sigma_3}\int_0^t \int_{R_z} \omega_{\alpha,3}\omega_{\alpha,3} dx d\tau\right\} \\ &+ \frac{1}{2}\left\{\sigma_4 \int_0^t \int_{R_z} u_{\alpha,\beta} u_{\alpha,\beta} dx d\tau + \frac{1}{\sigma_4}\int_0^t \int_{R_z} \omega_{\alpha,\beta}\omega_{\alpha,\beta} dx d\tau\right\} \\ &+ \frac{1}{2\sqrt{\lambda_1}}\left\{\sigma_5 \int_0^t \int_{D_z} u_{\alpha,3} u_{\alpha,3} dA d\tau + \frac{1}{\sigma_5}\int_0^t \int_{D_z} \omega_{\alpha,\beta}\omega_{\alpha,\beta} dA d\tau\right\}.\end{aligned} \tag{4.6}$$

The integrals of the auxiliary function ω_α can be bounded in terms of u_3 by means of (3.1) and (3.4). Thus we can write

$$\begin{aligned}\int_0^t \int_{R_z} \omega_{\alpha,\beta}\omega_{\alpha,\beta} dx d\tau &\leq C \int_0^t \int_{R_z} (u_3)^2 dx d\tau \\ &\leq \frac{C}{\lambda_1}\int_0^t \int_{R_z} u_{3,\beta} u_{3,\beta} dx d\tau,\end{aligned}$$

$$\begin{aligned}\int_0^t\int_{R_z}\omega_{\alpha,3}\omega_{\alpha,3}dxd\tau &\le \frac{1}{\lambda_1}\int_0^t\int_{R_z}\omega_{\alpha,\beta 3}\omega_{\alpha,\beta 3}dxd\tau\\ &\le \frac{C}{\lambda_1}\int_0^t\int_{R_z}(u_{3,3})^2dxd\tau.\end{aligned}$$

We now substitute these estimates into (4.6) and choose

$$\sigma_2=\sqrt{C}/\lambda_1\,,\qquad \sigma_3=\sigma_4=\sigma_5=\sqrt{C}\Big/\sqrt{\lambda_1}\,,$$

so that

$$\begin{aligned}I_3 \le &\frac{1}{2}\sqrt{\frac{C}{\lambda_1}}\left\{\int_0^t\int_{R_z}ku_{\alpha,\tau}u_{\alpha,\tau}dxd\tau+\int_0^t\int_{R_z}u_{3,\beta}u_{3,\beta}dxd\tau\right\}\\ &+\frac{1}{2}\sqrt{\frac{C}{\lambda_1}}\int_0^t\int_{R_z}u_{i,j}u_{i,j}dxd\tau\\ &+\frac{\sqrt{C}}{2\lambda_1}\left\{\int_0^t\int_{D_z}u_{\alpha,3}u_{\alpha,3}dAd\tau+\int_0^t\int_{D_z}u_{3,\beta}u_{3,\beta}dAd\tau\right\}.\end{aligned}$$

Finally, for I_3 we have the estimate

$$I_3\le\sqrt{\frac{C}{\lambda_1}}\left(-\frac{\partial E}{\partial z}\right)+\frac{\sqrt{C}}{2\lambda_1}\frac{\partial^2E}{\partial z^2}. \tag{4.7}$$

The result of estimating the first three integrals in (4.2) is

$$I_1+I_2+I_3\le\frac{1+\sqrt{C}}{\sqrt{\lambda_1}}\left(-\frac{\partial E}{\partial z}\right)+\frac{\sqrt{C}}{2\lambda_1}\frac{\partial^2E}{\partial z^2}. \tag{4.8}$$

We now seek an appropriate estimate for the integral I_4. As this involves a much more complicated calculation, we compute the I_4 bound in the next section.

5. Energy estimation—second part. We need to bound I_4 in terms of $\partial E/\partial z$ and $\partial^2E\big/\partial z^2$ in order to derive the second-order differential inequality for the energy expression E. To accomplish this, we introduce two auxiliary problems for which only the existence of a solution will be required.

Let φ be a solution of the boundary value problem

$$\Delta\varphi=u_{3,t}\quad\text{in } R_z,\qquad \frac{\partial\varphi}{\partial n}=0\quad\text{on }\partial R_z. \tag{5.1}$$

It is clear that

$$\int_{R_z}u_{3,t}dx=\int_z^\infty\int_{D_\xi}u_{3,t}dAd\xi=0, \tag{5.2}$$

and since $u_{3,t}\to 0$ as $x_3\to\infty$, it follows from the Phragmèn–Lindelöf theory that there exists a solution φ which vanishes together with its spatial derivatives as $x_3\to\infty$.

By means of φ, we can write

$$\begin{aligned} I_4 &= k\int_0^t\int_{R_z} p\Delta\varphi dx d\tau = -k\int_0^t\int_{R_z} \varphi_{,i}p_{,i}dx d\tau \\ &= k\int_0^t\int_{R_z} \varphi_{,i}\left[u_{i,\tau} - \left(u_{i,j}-u_{j,i}\right)_{,j}\right]dx d\tau \\ &= k\int_0^t\int_{R_z} \varphi_{,i}u_{i,\tau}dx d\tau + k\int_0^t\int_{D_z}\varphi_{,\alpha}\left(u_{\alpha,3}-u_{3,\alpha}\right)dA d\tau \\ &\quad - k\int_0^t\int_z^\infty\int_{\partial D_\xi}\varphi_{,i}\left(u_{i,j}-u_{j,i}\right)n_j ds d\xi d\tau, \end{aligned}$$

and by Schwarz's inequality, we have
(5.3)

$$\begin{aligned} I_4 \leq & k\left(\int_0^t\int_{R_z}\varphi_{,i}\varphi_{,i}dx d\tau\right)^{\frac{1}{2}}\left(\int_0^t\int_{R_z}u_{i,\tau}u_{i,\tau}dx d\tau\right)^{\frac{1}{2}} \\ &+ k\left(\int_0^t\int_{D_z}\varphi_{,\alpha}\varphi_{,\alpha}dA d\tau\right)^{\frac{1}{2}}\left(\int_0^t\int_{D_z}\left(u_{\alpha,3}-u_{3,\alpha}\right)\left(u_{\alpha,3}-u_{3,\alpha}\right)dA d\tau\right)^{\frac{1}{2}} \\ &+ k\left(\int_0^t\int_z^\infty\int_{\partial D_\xi}\left|\text{grad}_s\varphi\right|^2 ds d\xi d\tau\right)^{\frac{1}{2}}\left(\int_0^t\int_z^\infty\int_{\partial D_\xi}\left(u_{i,j}-u_{j,i}\right)u_{i,j}ds d\xi d\tau\right)^{\frac{1}{2}} \end{aligned}$$

since

$$\varphi_{,i}\left(u_{i,j}-u_{j,i}\right)n_j = \tfrac{1}{2}\left(\varphi_{,i}n_j - \varphi_{,j}n_i\right)\left(u_{i,j}-u_{j,i}\right).$$

In (5.3), $\text{grad}_s\varphi$ denotes the tangential component of the gradient of φ.

We must now determine suitable estimates for the integrals of φ in (5.3). We develop these bounds in the following lemmas. First, we deduce the following.

LEMMA 1. *If $\int_{D_{x_3}}\varphi dA = 0$ as $x_3 \to \infty$, then*

$$\int_{D_z}\varphi dA = 0 \quad \textit{for all } z \geq 0. \tag{5.4}$$

Proof. By (5.1), we have

$$0 = \int_{D_{x_3}} u_{3,t}dA = \int_{D_{x_3}}\varphi_{,ii}dA = \int_{D_{x_3}}\varphi_{,33}dA = \left(\int_{D_{x_3}}\varphi dA\right)_{,33},$$

which implies that

$$\int_{D_{x_3}}\varphi dA = ax_3 + b.$$

Hence by hypothesis, the conclusion follows.

LEMMA 2. *If φ, $\varphi_{,i} \to 0$ uniformly as $x_3 \to \infty$, then*

$$\int_{R_z}\varphi_{,i}\varphi_{,i}dx \leq \frac{1}{\mu_2}\int_{R_z}(u_{3,t})^2 dx, \tag{5.5}$$

$$\int_{D_z}\varphi_{,\alpha}\varphi_{,\alpha}dA \leq \frac{2}{\sqrt{\mu_2}}\int_{R_z}(u_{3,t})^2 dx. \tag{5.6}$$

Proof. For (5.5), we have

$$\begin{aligned}\int_{R_z} \varphi_{,i}\varphi_{,i}dx &= \int_{R_z} \varphi\Delta\varphi dx \\ &= \int_{R_z} \varphi u_{3,t}dx \\ &\leq \left(\int_{R_z} \varphi^2 dx\right)^{\frac{1}{2}} \left(\int_{R_z} (u_{3,t})^2 dx\right)^{\frac{1}{2}} \\ &\leq \left(\frac{1}{\mu_2}\int_{R_z} \varphi_{,i}\varphi_{,i}dx\right)^{\frac{1}{2}} \left(\int_{R_z} (u_{3,t})^2 dx\right)^{\frac{1}{2}},\end{aligned}$$

from which the result follows. We note that we used (5.4) in applying inequality (3.2).

We establish (5.6) by observing that

$$\int_{R_z} \varphi_{,3}\left[\Delta\varphi - u_{3,t}\right] dx = 0$$

implies the identity

$$\frac{1}{2}\int_{D_z} \varphi_{,i}\varphi_{,i}dA = \int_{R_z} \varphi_{,3}u_{3,t}dx.$$

Then by Schwarz's inequality, we can write

$$\frac{1}{2}\int_{D_z} \varphi_{,\alpha}\varphi_{,\alpha}dA \leq \left(\int_{R_z} \varphi_{,i}\varphi_{,i}dx\right)^{\frac{1}{2}} \left(\int_{R_z} (u_{3,t})^2 dx\right)^{\frac{1}{2}},$$

and by applying (5.5), we obtain (5.6).

LEMMA 3. *If φ, $\varphi_{,i} \to 0$ uniformly as $x_3 \to \infty$ and if D_z is star-shaped with respect to a point (origin) in D_z, then*

$$\int_z^\infty \int_{\partial D_\xi} |\text{grad}_s\varphi|^2 ds d\xi \leq \frac{2}{h_0}\left[\frac{1}{\mu_2} + \frac{d^2}{4}\right] \int_{R_z} (u_{3,t})^2 dx, \tag{5.7}$$

where $d =$ diameter D_0 and $h_0 = \min\{x_\alpha n_\alpha\}$ on ∂D_ξ.

Proof. We observe that from

$$\int_{R_z} x_\alpha\varphi_{,\alpha}\left[\Delta\varphi - u_{3,t}\right] dx = 0,$$

one obtains the Rellich-type identity

$$\frac{1}{2}\int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha |\text{grad}_s\varphi|^2 ds d\xi = \int_{R_z} (\varphi_{,3})^2 dx - \int_{R_z} x_\alpha\varphi_{,\alpha}u_{3,t}dx$$

through integrating by parts twice and using the boundary condition on φ. By Schwarz's inequality, the AG inequality, and (5.5), we have

$$\frac{1}{2}\int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha |\text{grad}_s\varphi|^2 ds d\xi \leq \left[\frac{1}{\mu_2} + \frac{d^2}{4}\right] \int_{R_z} (u_{3,t})^2 dx,$$

from which (5.7) follows.

Our next lemma which is needed to estimate the sixth integral in (5.3) does not depend on the auxiliary function φ, but rather on the solutions of the systems (2.1)–(2.6). We assert the following.

LEMMA 4. *For sufficiently smooth functions u_i and p in the system* (2.1)–(2.6), *the following identity holds*:

$$\begin{aligned}\frac{1}{2}\int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha u_{i,j}\left(u_{i,j}-u_{j,i}\right) ds d\xi &= \int_{D_z} x_\alpha u_{\beta,\alpha}\left(u_{\beta,3}-u_{3,\beta}\right) dA \\ &-\frac{1}{2}\int_{R_z} u_{i,j}\left(u_{i,j}-u_{j,i}\right) dx + \int_{R_z} x_\alpha u_{i,\alpha} u_{i,t} dx \\ &+\int_{R_z}\left(x_3-z\right) u_{i,3} u_{i,t} dx + \int_{D_z} x_\alpha u_{3,\alpha} p dA.\end{aligned} \tag{5.8}$$

Proof. By (2.1), we know

$$\int_{R_z}\left(x_k - z\delta_{3k}\right) u_{i,k}\left[\left(u_{i,j}-u_{j,i}\right)_{,j} - u_{i,t} - p_{,i}\right] dx = 0,$$

where δ_{ij} is the Kronecker delta symbol. We integrate by parts in the first and third integrals and obtain

$$\begin{aligned}&\int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,k}\left(u_{i,j}-u_{j,i}\right) n_j ds - \int_{R_z}\left(x_k - z\delta_{3k}\right) u_{i,jk}\left(u_{i,j}-u_{j,i}\right) dx \\ &-\int_{R_z} u_{i,j}\left(u_{i,j}-u_{j,i}\right) dx - \int_{R_z}\left(x_k - z\delta_{3k}\right) u_{i,k} u_{i,t} dx - \int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,k} p n_i ds = 0.\end{aligned}$$

Now since

$$\left(u_{i,j}-u_{j,i}\right) u_{i,jk} = \left(u_{i,j}-u_{j,i}\right)_{,k} u_{i,j},$$

a further integration by parts results in

$$\begin{aligned}&\int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,k}\left(u_{i,j}-u_{j,i}\right) n_j ds \\ &\quad-\frac{1}{2}\int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,j}\left(u_{i,j}-u_{j,i}\right) n_k ds \\ &\quad+\frac{1}{2}\int_{R_z} u_{i,j}\left(u_{i,j}-u_{j,i}\right) dx - \int_{R_z}\left(x_k - z\delta_{3k}\right) u_{i,k} u_{i,t} dx \\ &\quad-\int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,k} p n_i ds = 0.\end{aligned} \tag{5.9}$$

Since $u_{i,k}n_i = u_{i,i}n_k = 0$ on ∂D_ξ for $\xi \geq 0$, the last term in (5.9) can be written

$$\int_{\partial R_z}\left(x_k - z\delta_{3k}\right) u_{i,k} p n_i ds = -\int_{D_z} x_\alpha u_{3,\alpha} p dA.$$

Moreover, by (2.3), the first two integrals in (5.9) on the lateral boundary can be combined so that

$$\begin{aligned}&\int_z^\infty \int_{\partial D_\xi}\left(x_k - z\delta_{3k}\right) u_{i,k}\left(u_{i,j}-u_{j,i}\right) n_j ds d\xi \\ &\quad-\frac{1}{2}\int_z^\infty \int_{\partial D_\xi}\left(x_k - z\delta_{3k}\right) u_{i,j}\left(u_{i,j}-u_{j,i}\right) n_k ds d\xi \\ &=\frac{1}{2}\int_z^\infty \int_{\partial D_\xi} x_\alpha n_\alpha u_{i,j}\left(u_{i,j}-u_{j,i}\right) ds d\xi.\end{aligned} \tag{5.10}$$

Consequently, solving (5.9) for the condensed term obtained in (5.10), we arrive at the identity (5.8).

The appearance of the pressure function p in the identity (5.8) presents a further complication that must now be handled. We define $\overline{p}$ to be the mean value of p over D_z, i.e.,

$$\overline{p} = \frac{1}{|D_z|} \int_{D_z} p dA,$$

where $|D_z| = |D_0|$ is the measure of D_z. It follows that

$$\int_{D_z} [p - \overline{p}]\, dA = 0 \tag{5.11}$$

for each $z \geq 0$. Further, we note that the last term in (5.8) can be replaced by

$$\begin{aligned} \int_{D_z} x_\alpha u_{3,\alpha} p dA &= \int_{D_z} x_\alpha u_{3,\alpha} (p - \overline{p})\, dA + \int_{D_z} x_\alpha u_{3,\alpha} \overline{p} dA \\ &= \int_{D_z} x_\alpha u_{3,\alpha} (p - \overline{p})\, dA, \end{aligned} \tag{5.12}$$

since

$$\int_{D_z} x_\alpha u_{3,\alpha} dA = -2 \int_{D_z} u_3 dA = 0.$$

Since

$$u_{i,j}(u_{i,j} - u_{j,i}) = \tfrac{1}{2}(u_{i,j} - u_{j,i})(u_{i,j} - u_{j,i}),$$

from (5.8), (5.12), and Schwarz's inequality, we have

$$\begin{aligned} \frac{h_0}{2} \int_z^\infty \int_{\partial D_\xi} u_{i,j} (u_{i,j} - u_{j,i})\, ds d\xi &\leq \left(d \int_{D_z} u_{\beta,\alpha} u_{\beta,\alpha} dA \right)^{\frac{1}{2}} \\ &\quad \times \left(d \int_{D_z} (u_{\alpha,3} - u_{3,\alpha})\, (u_{\alpha,3} - u_{3,\alpha})\, dA \right)^{\frac{1}{2}} \\ &\quad + \left(d^2 \int_{R_z} u_{i,t} u_{i,t} dx \right)^{\frac{1}{2}} \left(\int_{R_z} u_{i,\alpha} u_{i,\alpha} dx \right)^{\frac{1}{2}} \\ &\quad + \left(\int_{R_z} (\xi - z)\, u_{i,3} u_{i,3} dx \right)^{\frac{1}{2}} \left(\int_{R_z} (\xi - z)\, u_{i,t} u_{i,t} dx \right)^{\frac{1}{2}} \\ &\quad + \left(d \int_{D_z} u_{3,\alpha} u_{3,\alpha} dA \right)^{\frac{1}{2}} \left(d \int_{D_z} (p - \overline{p})^2\, dA \right)^{\frac{1}{2}}. \end{aligned} \tag{5.13}$$

The need to bound the last integral in (5.13) motivates our second auxiliary problem.

We consider the boundary value problem

$$\begin{cases} \Delta \Psi = 0 & \text{in } R_z, \\ \dfrac{\partial \Psi}{\partial n} = 0 & \text{on } \partial D_\xi, \quad \xi \geq z \geq 0, \\ \dfrac{\partial \Psi}{\partial n} = p - \overline{p} & \text{in } D_z. \end{cases} \tag{5.14}$$

We note by (5.11) that the necessary condition for existence of a solution Ψ is satisfied and recall that Ψ is defined up to an arbitrary constant. We choose the constant such that

$$\lim_{z\to\infty}\int_{D_z}\Psi dA=0.$$

Then from the Phragmèn–Lindelöf theory, we know that there exists a solution Ψ which vanishes exponentially as $x_3\to\infty$. In addition, Ψ has the following properties.

LEMMA 5. *If Ψ is chosen as above, then for all $z\geq 0$,*

$$\int_{D_z}\Psi dA=0, \tag{5.15}$$

$$\int_{D_z}\Psi_{,3}dA=0, \tag{5.16}$$

$$\int_{R_z}\overline{p}_{,3}\Psi_{,3}dx=0. \tag{5.17}$$

Proof. The first property (5.15) follows by an argument similar to Lemma 1. For (5.16), we see that

$$\begin{aligned}\int_{D_z}\Psi_{,3}dA&=-\int_z^\infty\int_{D_\xi}\Psi_{,33}dAd\xi=\int_z^\infty\int_{D_\xi}\Psi_{,\alpha\alpha}dAd\xi\\&=\int_z^\infty\int_{\partial D_\xi}\Psi_{,\alpha}n_\alpha dsd\xi=0.\end{aligned}$$

The third property (5.17) follows from (5.16) since we can write

$$\int_{R_z}\overline{p}_{,3}\Psi_{,3}dx=\int_z^\infty\left(\frac{1}{|D_\xi|}\int_{D_\xi}p_{,3}dA\int_{D_\xi}\Psi_{,3}dA\right)d\xi.$$

By means of the auxiliary problem (5.14) and property (5.17), we have

$$\begin{aligned}\int_{D_z}(p-\overline{p})^2dA&=\int_{\partial R_z}(p-\overline{p})\frac{\partial\Psi}{\partial n}ds\\&=\int_{R_z}(p-\overline{p})_{,i}\Psi_{,i}dx\\&=\int_{R_z}\Psi_{,i}[(u_{i,j}-u_{j,i})_{,j}-u_{i,t}]dx.\end{aligned}$$

Then, in a manner similar to the derivation of (5.3), we can write

$$\begin{aligned}\int_{D_z}(p-\overline{p})^2dA\leq{}&\left(\int_{R_z}\Psi_{,i}\Psi_{,i}dx\right)^{\frac12}\left(\int_{R_z}u_{i,t}u_{i,t}dx\right)^{\frac12}\\&+\left(\int_{D_z}\Psi_{,\alpha}\Psi_{,\alpha}dA\right)^{\frac12}\left(\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})dA\right)^{\frac12}\\&+\left(\int_z^\infty\int_{\partial D_\xi}|\mathrm{grad}_s\Psi|^2dsd\xi\right)^{\frac12}\left(\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}dsd\xi\right)^{\frac12}.\end{aligned}\tag{5.18}$$

We now seek estimates for the integrals involving the function Ψ. These are established in the following lemmas.

LEMMA 6. *The function Ψ satisfies*

$$\int_{D_z} \Psi_{,\alpha}\Psi_{,\alpha} dA = \int_{D_z} (p-\bar{p})^2\, dA, \tag{5.19}$$

$$\int_{R_z} \Psi_{,i}\Psi_{,i} dx \le \frac{1}{\sqrt{\mu_2}} \int_{D_z} (p-\bar{p})^2\, dA. \tag{5.20}$$

Proof. For (5.19), we observe that

$$\int_{R_z} \Psi_{,3}\Delta\Psi dx = 0$$

implies the identity

$$\int_{D_z} (\Psi_{,3})^2 dA - \frac{1}{2}\int_{D_z} \Psi_{,j}\Psi_{,j} dA = 0,$$

and hence

$$\int_{D_z} \Psi_{,\alpha}\Psi_{,\alpha} dA = \int_{D_z} (\Psi_{,3})^2 dA = \int_{D_z} (p-\bar{p})^2\, dA.$$

The second result (5.20) follows from (5.14), (5.15), (5,19), and the calculation

$$\int_{R_z} \Psi_{,i}\Psi_{,i} dx = \int_{D_z} \Psi\,(p-\bar{p})\, dA \le \left(\frac{1}{\mu_2}\int_{D_z} \Psi_{,\alpha}\Psi_{,\alpha} dA\right)^{\frac{1}{2}} \left(\int_{D_z} (p-\bar{p})^2\, dA\right)^{\frac{1}{2}}.$$

LEMMA 7. *If D_z is star-shaped with respect to a point* (*origin*) *in D_z, then*

$$\int_z^{\infty}\int_{\partial D_\xi} |\text{grad}_s \Psi|^2\, ds d\xi \le \frac{2}{h_0}\left[d + \frac{1}{\sqrt{\mu_2}}\right]\int_{D_z} (p-\bar{p})^2\, dA. \tag{5.21}$$

Proof. In a manner similar to the proof of Lemma 3, from

$$\int_{R_z} x_\alpha \Psi_{,\alpha}\Delta\Psi dx = 0$$

we obtain the identity

$$\frac{1}{2}\int_z^{\infty}\int_{\partial D_\xi} x_\alpha n_\alpha\, |\text{grad}_s\Psi|^2\, ds d\xi = \int_{D_z} x_\alpha \Psi_{,\alpha}\,(p-\bar{p})\, dA + \int_{R_z} (\Psi_{,3})^2 dx,$$

and hence the inequality

$$\frac{h_0}{2}\int_z^{\infty}\int_{\partial D_\xi} |\text{grad}_s\Psi|^2\, ds d\xi \le \frac{d}{2}\int_{D_z} \Psi_{,\alpha}\Psi_{,\alpha} dA + \frac{d}{2}\int_{D_z} (p-\bar{p})^2\, dA + \int_{R_z} \Psi_{,i}\Psi_{,i} dx.$$

Now by (5.19) and (5.20), the result follows.

We can use Lemmas 6 and 7 in (5.18) to obtain an estimate for the integral of

$(p-\bar{p})^2$ which is independent of pressure, namely,

$$\begin{aligned}\left(\int_{D_z}(p-\bar{p})^2 dA\right)^{\frac{1}{2}} &\leq \left(\frac{1}{\sqrt{\mu_2}}\int_{R_z} u_{i,t}u_{i,t}dx\right)^{\frac{1}{2}}\\ &+\left(\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})dA\right)^{\frac{1}{2}}\\ &+\left(\frac{2}{h_0}\left[d+\frac{1}{\sqrt{\mu_2}}\right]\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}dsd\xi\right)^{\frac{1}{2}}.\end{aligned} \tag{5.22}$$

We are now ready to complete an estimate for the I_4 integral.

We return to inequality (5.3) and use the weighted AG inequality, Lemma 2, and Lemma 3 to obtain

$$\begin{aligned}I_4 \leq &\frac{\gamma_1}{2\mu_2}\int_0^t\int_{R_z} k(u_{3,\tau})^2 dxd\tau+\frac{1}{2\gamma_1}\int_0^t\int_{R_z} ku_{i,\tau}u_{i,\tau}dxd\tau\\ &+\frac{\gamma_2}{\sqrt{\mu_2}}\int_0^t\int_{R_z} k(u_{3,\tau})^2 dxd\tau+\frac{k}{2\gamma_2}\int_0^t\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})dAd\tau\\ &+\frac{k\gamma_3}{h_0}\left[\frac{1}{\mu_2}+\frac{d^2}{4}\right]\int_0^t\int_{R_z} k(u_{3,\tau})^2 dxd\tau\\ &+\frac{1}{2\gamma_3}\int_0^t\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}dsd\xi d\tau.\end{aligned}$$

Since $k=1/\lambda_1$, we choose

$$\gamma_1=\sqrt{\mu_2},\qquad \gamma_2=1/2\,,\qquad \gamma_3=\lambda_1/\gamma,$$

where γ is a dimensionless constant to be determined, so that

$$\begin{aligned}I_4 \leq &\left(\frac{3}{2\sqrt{\mu_2}}+\frac{1}{\gamma h_0}\left[\frac{1}{\mu_2}+\frac{d^2}{4}\right]\right)\int_0^t\int_{R_z} ku_{i,\tau}u_{i,\tau}dxd\tau\\ &+\frac{1}{\lambda_1}\int_0^t\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})dAd\tau+\frac{\gamma}{2\lambda_1}J,\end{aligned} \tag{5.23}$$

where

$$J=\int_0^t\int_z^\infty\int_{\partial D_\xi}(u_{i,j}-u_{j,i})u_{i,j}dsd\xi d\tau.$$

The first term in (5.23) is estimable in terms of $-\partial E/\partial z$. For the second term, we write

$$\begin{aligned}&\frac{1}{\lambda_1}\int_0^t\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})(u_{\alpha,3}-u_{3,\alpha})dAd\tau\\ &\leq \frac{1}{\lambda_1}(1+\eta)\int_0^t\int_{D_z} u_{\alpha,3}u_{\alpha,3}dAd\tau\\ &+\frac{1}{\lambda_1}\left(1+\frac{1}{\eta}\right)\int_0^t\int_{D_z} u_{3,\alpha}u_{3,\alpha}dAd\tau,\end{aligned} \tag{5.24}$$

where η is a constant to be suitably chosen. To estimate the third term in (5.23), we recall (5.13) and use the weighted AG inequality together with (5.22) on the last term of (5.13) to obtain

$$\begin{aligned}\frac{h_0}{4}\int_z^\infty \int_{\partial D_\xi} (u_{i,j}-u_{j,i})\,u_{i,j}\,ds\,d\xi \le{}& \frac{d\gamma_4}{2}\int_{D_z} u_{\beta,\alpha}u_{\beta,\alpha}dA \\ &+ \frac{d}{2\gamma_4}\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})\,(u_{\alpha,3}-u_{3,\alpha})\,dA \\ &+ \frac{d^2\gamma_5}{2}\int_{R_z} u_{i,t}u_{i,t}dx + \frac{1}{2\gamma_5}\int_{R_z}u_{i,\alpha}u_{i,\alpha}dx \\ &+ \frac{\gamma_6}{2}\int_{R_z}(\xi-z)\,u_{i,3}u_{i,3}dx + \frac{1}{2\gamma_6}\int_{R_z}(\xi-z)\,u_{i,t}u_{i,t}dx \\ &+ \frac{d}{2}(\gamma_7+\gamma_8+\epsilon)\int_{D_z}u_{3,\alpha}u_{3,\alpha}dA + \frac{d}{2\gamma_7\sqrt{\mu_2}}\int_{R_z}u_{i,t}u_{i,t}dx \\ &+ \frac{d}{2\gamma_8}\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})\,(u_{\alpha,3}-u_{3,\alpha})\,dA,\end{aligned}\tag{5.25}$$

where we have set

$$\epsilon = \frac{4d}{h_0^2}\left[d+\frac{1}{\sqrt{\mu_2}}\right].$$

We now integrate (5.25) with respect to τ, multiply by $2\gamma/\lambda_1 h_0$, and then add the resulting inequality to (5.24). Collecting terms, we have

(5.26)

$$\begin{aligned}&\frac{1}{\lambda_1}\int_0^t\int_{D_z}(u_{\alpha,3}-u_{3,\alpha})\,(u_{\alpha,3}-u_{3,\alpha})\,dA\,d\tau + \frac{\gamma}{2\lambda_1}J \\ &\le \frac{1}{\lambda_1}(1+\eta)\left(1+\frac{\gamma d}{h_0}\left[\frac{1}{\gamma_4}+\frac{1}{\gamma_8}\right]\right)\int_0^t\int_{D_z}u_{\alpha,3}u_{\alpha,3}dA\,d\tau \\ &\quad+\frac{1}{\lambda_1}\left(\left[1+\frac{1}{\eta}\right]\left[1+\frac{\gamma d}{h_0}\left(\frac{1}{\gamma_4}+\frac{1}{\gamma_8}\right)\right]+\frac{\gamma d}{h_0}\left[\gamma_7+\gamma_8+\epsilon\right]\right)\int_0^t\int_{D_z}u_{3,\alpha}u_{3,\alpha}dA\,d\tau \\ &\quad+\frac{\gamma d\gamma_4}{\lambda_1 h_0}\int_0^t\int_{D_z}u_{\beta,\alpha}u_{\beta,\alpha}dA\,d\tau + \frac{\gamma d}{\lambda_1 h_0\gamma_7\sqrt{\mu_2}}\int_0^t\int_{R_z}u_{i,\tau}u_{i,\tau}dx\,d\tau \\ &\quad+\frac{\gamma}{\lambda_1 h_0}\left\{\gamma_5 d^2\int_0^t\int_{R_z}u_{i,\tau}u_{i,\tau}dx\,d\tau + \frac{1}{\gamma_5}\int_0^t\int_{R_z}u_{i,\alpha}u_{i,\alpha}dx\,d\tau\right\} \\ &\quad+\frac{\gamma}{\lambda_1 h_0}\left\{\gamma_6\int_0^t\int_{R_z}(\xi-z)\,u_{i,3}u_{i,3}dx\,d\tau + \frac{1}{\gamma_6}\int_0^t\int_{R_z}(\xi-z)\,u_{i,\tau}u_{i,\tau}dx\,d\tau\right\}.\end{aligned}$$

We recall $k = 1/\lambda_1$ and choose

$$\gamma_4=\gamma_8=\frac{d\sqrt{\lambda_1}}{2},\qquad \gamma_5=\frac{1}{d\sqrt{2\lambda_1}},\qquad \gamma_6=\sqrt{\lambda_1},\qquad \gamma_7=\sqrt{\frac{2\lambda_1}{\mu_2}},\qquad \gamma=\frac{h_0\sqrt{\lambda_1}}{2}.$$

Moreover, we choose η to be the positive root of the quadratic equation

$$\eta^2 - c\eta - 1 = 0,\tag{5.27}$$

where

$$c=\frac{d\sqrt{\lambda_1}}{6}\left[\sqrt{\frac{2\lambda_1}{\mu_2}}+\frac{d\sqrt{\lambda_1}}{2}+\frac{4d^2}{h_0^2}+\frac{4d}{h_0^2\sqrt{\mu_2}}\right],$$

so that the coefficients of the first two integrals on the right side of (5.26) are equal. Thus, we can write

(5.28)

$$\frac{1}{\lambda_1}\int_0^t\int_{D_z}\left(u_{\alpha,3}-u_{3,\alpha}\right)\left(u_{\alpha,3}-u_{3,\alpha}\right)dAd\tau+\frac{\gamma}{2\lambda_1}J\le\rho\frac{\partial^2 E}{\partial z^2}+\frac{d}{\sqrt{2}}\left(-\frac{\partial E}{\partial z}\right)+\frac{1}{2}E,$$

where

$$\rho=\max\left\{\frac{d^2}{4},\frac{3}{\lambda_1}(1+\eta)\right\}. \tag{5.29}$$

We combine inequalities (5.23) and (5.28) to obtain our estimate on I_4, namely,

$$I_4\le\left(\frac{3}{2\sqrt{\mu_2}}+\frac{2}{h_0^2\sqrt{\lambda_1}}\left[\frac{1}{\mu_2}+\frac{d^2}{4}\right]+\frac{d\sqrt{2}}{2}\right)\left(-\frac{\partial E}{\partial z}\right)+\rho\frac{\partial^2 E}{\partial z^2}+\frac{1}{2}E. \tag{5.30}$$

Consequently, by combining (4.2), (4.8), and (5.30), we obtain the second-order differential inequality

$$E\le K_1\frac{\partial^2 E}{\partial z^2}-K_2\frac{\partial E}{\partial z}, \tag{5.31}$$

where

$$K_1=\frac{\sqrt{C}}{\lambda_1}+2\rho,$$

$$K_2=2\left(\frac{1+\sqrt{C}}{\sqrt{\lambda_1}}\right)+\frac{3}{\sqrt{\mu_2}}+\frac{4}{\mu_2 h_0^2\sqrt{\lambda_1}}+\frac{d^2}{h_0^2\sqrt{\lambda_1}}+d\sqrt{2}.$$

We can rewrite (5.31) as

$$\frac{\partial^2 E}{\partial z^2}-a\frac{\partial E}{\partial z}-bE\ge 0, \tag{5.32}$$

where $a=K_2/K_1$ and $b=1/K_1$. Furthermore, we can write (5.32) in the form

$$\left(\frac{\partial}{\partial z}-k_1\right)\left(\frac{\partial E}{\partial z}+k_2E\right)\ge 0, \tag{5.33}$$

where

$$k_1=\frac{a}{2}+\frac{1}{2}\sqrt{a^2+4b},\qquad k_2=-\frac{a}{2}+\frac{1}{2}\sqrt{a^2+4b}.$$

Now since

$$\frac{\partial}{\partial z}\left\{e^{-k_1 z}\left(\frac{\partial E}{\partial z}+k_2E\right)\right\}\ge 0,$$

we conclude upon integration from z to ∞ that

$$\frac{\partial E}{\partial z}+k_2E\le 0,$$

and hence that

$$E(z,t)\le E(0,t)\,e^{-k_2 z}. \tag{5.34}$$

This is the exponential decay estimate we set out to obtain.

We note that k_2 depends only on geometry and the eigenvalues λ_1 and μ_2. In fact, using $\lambda_1 = 5.78/r^2$ and $\mu_2 = 3.38/r^2$ for a circular pipe of radius r, we find $k_2 \approx 0.15/r$. We note further that the decay constant k_2 might be improved by a more judicious choice of weights in our derivation above. To complete the energy estimation, we will indicate a procedure for obtaining estimates on the total weighted energy $E\,(0,t)$ in the next section.

6. Bound for $E(0,t)$. We now indicate how one can estimate the total weighted energy. We shall not determine explicit constants in this estimation as we did in the previous sections. Here we let ϵ_i designate positive constants that may be chosen arbitrarily small and let c_i denote computable constants that may depend on the ϵ_i but which remain bounded if any of the ϵ_i tend to zero.

We first note from (5.31),

$$E\,(0,t) \leq K_1 \frac{\partial^2 E}{\partial z^2}\,(0,t) - K_2 \frac{\partial E}{\partial z}\,(0,t)\,. \tag{6.1}$$

Moreover, from (2.9),

$$\begin{aligned} \frac{\partial^2 E}{\partial z^2}\,(0,t) &= \text{data } + \int_0^t \int_{D_0} u_{i,3} u_{i,3} dA d\tau \\ &= \text{data } + \int_0^t \int_{D_0} u_{\alpha,3} u_{\alpha,3} dA d\tau + \int_0^t \int_{D_0} \left(f_{\alpha,\alpha}\right)^2 dA d\tau \end{aligned} \tag{6.2}$$

since $u_{3,3} = -u_{\alpha,\alpha} = -f_{\alpha,\alpha}$ on D_0. Thus we must bound

$$-\frac{\partial E}{\partial z}\,(0,t)\,, \qquad \int_0^t \int_{D_0} u_{\alpha,3} u_{\alpha,3} dA d\tau \tag{6.3}$$

suitably to complete the estimation for $E\,(0,t)$.

Consider the first term in (6.3). On integration by parts, we have

$$\begin{aligned} \int_0^t \int_{R_0} u_{i,j} u_{i,j} dx d\tau &\leq - \int_0^t \int_{D_0} f_i u_{i,3} dA d\tau + \int_0^t \int_{D_0} u_3 p dA d\tau \\ &= - \int_o^t \int_{D_0} f_\alpha u_{\alpha,3} dA d\tau + \int_0^t \int_{D_0} f_3 f_{\alpha,\alpha} dA d\tau \\ &\quad + \int_0^t \int_{D_0} f_3\,(p - \overline{p})\, dA d\tau, \end{aligned} \tag{6.4}$$

and that

$$\begin{aligned} \int_0^t \int_{R_0} u_{i,\tau} u_{i,\tau} dx d\tau &= \int_0^t \int_{R_0} \left[\Delta u_i - p_{,i}\right] u_{i,\tau} dx d\tau \\ &\leq - \int_0^t \int_{D_0} \left[f_{i,\tau} u_{i,3} - u_{3,\tau}\,(p - \overline{p})\right] dA d\tau \\ &= - \int_0^t \int_{D_0} f_{\alpha,\tau} u_{\alpha,3} dA d\tau + \int_0^t \int_{D_0} f_{3,\tau} f_{\alpha,\alpha} dA d\tau \\ &\quad + \int_0^t \int_{D_0} f_{3,\tau}\,(p - \overline{p})\, dA d\tau. \end{aligned} \tag{6.5}$$

Thus, combining (6.4) and (6.5), we find

$$-\frac{\partial E}{\partial z}(0,t) \leq \text{data } + \epsilon_1 \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau + \epsilon_2 \int_0^t \int_{D_0} (p-\overline{p})^2 \, dAd\tau, \tag{6.6}$$

where ϵ_1 and ϵ_1 are constants to be chosen appropriately.

We now observe that from (5.22) and (5.26), we can write

$$\begin{aligned}\int_0^t \int_{D_0} (p-\overline{p})^2 \, dAd\tau \leq & \text{data} + \; c_1 \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau \\ & - c_2 \frac{\partial E}{\partial z}(0,t) + c_3 E(0,t).\end{aligned} \tag{6.7}$$

By means of (6.6) and an appropriate (first restriction on) choice of ϵ_2, we have

$$\int_0^t \int_{D_0} (p-\overline{p})^2 \, dAd\tau \leq \text{data } + c_4 \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau + c_5 E(0,t). \tag{6.8}$$

Substituting (6.8) into (6.6), we obtain

$$-\frac{\partial E}{\partial z}(0,t) \leq \text{data } + (\epsilon_1 + \epsilon_2 c_4) \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau + \epsilon_2 c_5 E(0,t). \tag{6.9}$$

Thus, combining (6.1), (6.2), and (6.9), we can write

$$E(0,t) \leq \text{data } + c_6 \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau + \epsilon_2 c_7 E(0,t), \tag{6.10}$$

and it only remains to bound the middle term on the right side of (6.10).

To establish a bound for the second term of (6.3), we consider the identity

$$\int_0^t \int_{R_0} u_{i,3} \left[(u_{i,j} - u_{j,i})_{,j} - p_{,i} - u_{i,\tau} \right] dxd\tau = 0.$$

On integrating by parts, we are led to

$$\begin{aligned}- \int_0^t \int_{D_0} u_{i,3}(u_{i,3} - u_{3,i}) \, dAd\tau + \frac{1}{2} \int_0^t \int_{D_0} u_{i,j}(u_{i,j} - u_{j,i}) \, dAd\tau \\ + \int_0^t \int_{D_0} u_{3,3} p dAd\tau - \int_0^t \int_{R_0} u_{i,\tau} u_{i,3} dxd\tau = 0.\end{aligned}$$

Since $u_{3,3} = -f_{\alpha,\alpha}$ on D_0, we can now write

$$\begin{aligned}\int_0^t \int_{D_0} \left[u_{\alpha,3}(u_{\alpha,3} - u_{3,\alpha}) - \frac{1}{2} u_{\alpha,3}(u_{\alpha,3} - u_{3,\alpha}) - \frac{1}{2} f_{\alpha,\beta}(f_{\alpha,\beta} - f_{\beta,\alpha}) \right] dAd\tau \\ \leq \int_0^t \int_{D_0} f_{\alpha,\alpha}(p - \overline{p}) \, dAd\tau - c_8 \frac{\partial E}{\partial z}(0,t),\end{aligned}$$

or further,

$$\begin{aligned}\frac{1}{2} \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau \leq \frac{1}{2} \int_0^t \int_{D_0} [f_{3,\alpha}f_{3,\alpha} + f_{\alpha,\beta}(f_{\alpha,\beta} - f_{\beta,\alpha})] \, dAd\tau \\ + \left(\int_0^t \int_{D_0} (f_{\alpha,\alpha})^2 dAd\tau \int_0^t \int_{D_0} (p-\overline{p})^2 \, dAd\tau \right)^{\frac{1}{2}} - c_8 \frac{\partial E}{\partial z}(0,t).\end{aligned}$$

It follows from (6.8) and (6.9) that

$$\int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau$$
$$\leq \text{data } + (\epsilon_3 c_4 + c_8 [\epsilon_1 + \epsilon_2 c_4]) \int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau + (\epsilon_3 c_5 + \epsilon_2 c_9) E(0,t).$$

With an appropriate choice for ϵ_1, ϵ_2, and ϵ_3 (a second restriction on ϵ_2), we have

$$\int_0^t \int_{D_0} u_{\alpha,3}u_{\alpha,3}dAd\tau \leq \text{data } + (\epsilon_3 c_{10} + \epsilon_2 c_{11}) E(0,t). \tag{6.11}$$

We complete our estimation of the total weighted energy by combining (6.10) and (6.11) and putting further restrictions on ϵ_2 and ϵ_3. Thus it follows that

$$E(0,t) \leq \text{data}, \tag{6.12}$$

as we set out to show.

7. Concluding remarks. Instead of considering the slow flow of an incompressible viscous fluid in a semi-infinite cylinder as we did here, one might consider the finite pipe problem. In this case, if one assumes

$$u_i = 0 \quad \text{at } x_3 = \ell,$$

for the pipe of length ℓ, then the analysis of the preceding sections applies with appropriate modifications.

One might also weaken the hypotheses which we imposed in order to obtain sufficient decay at infinity for the semi-infinite pipe. It appears that

$$u_i = o(1), \quad u_{i,t} = o(1), \quad [u_{\alpha,3}u_{\alpha,3}]^{\frac{1}{2}} = o\left(x_3^{-1}\right), \quad p = o\left(x_3^{-1}\right),$$

uniformly in x_1, x_2, t as $x_3 \to \infty$ would be sufficient for the needed convergence.

Finally, the second-order differential inequality (5.31) could be handled differently. Instead of (5.33), suppose we write

$$\left(\frac{\partial}{\partial z} + k_2\right)\left(\frac{\partial E}{\partial z} - k_1 E\right) \geq 0. \tag{7.1}$$

Then

$$\frac{\partial}{\partial z} e^{k_2 z}\left(\frac{\partial E}{\partial z} - k_1 E\right) \geq 0,$$

and integrating from 0 to z, we have

$$\frac{\partial E}{\partial z}(z,t) - k_1 E(z,t) \geq e^{-k_2 z}\left[\frac{\partial E}{\partial z}(0,t) - k_1 E(0,t)\right].$$

Consequently,

$$-\frac{\partial E}{\partial z}(z,t) + k_1 E(z,t) \leq e^{-k_2 z}\left[-\frac{\partial E}{\partial z}(0,t) + k_1 E(0,t)\right], \tag{7.2}$$

and we have established a bound for both $E(z,t)$ and $-\partial E(z,t)/\partial z$. Bounds for the terms on the right side of (7.2) can then be established as in §6.

Acknowledgment. The authors are grateful to a referee who suggested a simpler proof of Lemma 1.

A DEGENERATE PSEUDOPARABOLIC REGULARIZATION OF A NONLINEAR FORWARD-BACKWARD HEAT EQUATION ARISING IN THE THEORY OF HEAT AND MASS EXCHANGE IN STABLY STRATIFIED TURBULENT SHEAR FLOW*

G.I. BARENBLATT[†], M. BERTSCH[‡],
R. DAL PASSO[‡], AND M. UGHI[§]

Abstract. The authors analyze an initial-boundary value problem for the equation

$$u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt},$$

where τ is a positive parameter, $\varphi, \psi : \mathbf{R} \to \mathbf{R}$, φ is nonmonotone, ψ is strictly increasing and uniformly bounded in $\mathbf{R}$, and $|\varphi'(p)| = O(\psi'(p))$ as $p \to \pm\infty$. The equation arises as a (new) model for turbulent heat or mass transfer in stably stratified shear flows, in which case u_x is nonnegative, $\varphi(p) > 0$ for $p > 0$, and $\varphi(0) = \varphi(+\infty) = 0$. Well-posedness is proved and, in the model case, the qualitative behavior of solutions is studied. In particular it is shown that smooth solutions may become discontinuous in finite time, and that such solutions converge to a piecewise constant spatial profile as $t \to \infty$. This behavior is in agreement with experimental observations and numerical computations.

Key words. forward-backward parabolic equation, degenerate pseudoparabolic equation, existence, uniqueness, discontinuous solutions, large-time behavior, turbulent heat and mass diffusion, stratification, shear flow, relaxation time

1. Introduction.

One-dimensional diffusion processes are modeled by the conservation law

$$u_t + q_x = 0, \qquad q = -ku_x, \tag{1.1}$$

where q is the heat or mass flux, x is a spatial coordinate belonging to some real interval, $t > 0$ indicates time, subscripts denote partial differentiations, and k is, by definition, the diffusivity. If k is a given function k_0 of $u(x,t)$, $u_x(x,t)$, x and t, its nonnegativity does not imply the parabolicity of (1.1), since the product $u_x k_0(u, u_x, x, t)$ may be nonmonotone with respect to u_x.

In this paper, we study a mathematical model for heat or mass transfer in a stably stratified turbulent shear flow, where the temperature, respectively concentration u, satisfies an equation of the type (1.1) (we refer to §2 for a brief discussion of the model). Under fixed external conditions the *steady* diffusivity, i.e., the diffusivity in mechanical and thermal equilibrium, depends only on the value of the gradient:

$$k(x,t) = k_0(u_x(x,t)). \tag{1.2}$$

For the stably stratified turbulent shear flow, the effective temperature or mass diffusivity k_0 decreases very quickly at large values of the temperature gradient, respectively concentration gradient, and a typical choice for k_0 is

$$k_0(p) = \frac{A}{B+p^2}, \qquad (A, B > 0), \tag{1.3}$$

and therefore the product

$$\varphi(p) = pk_0(p) \tag{1.4}$$

is nonmonotone: $\varphi(p)$ is increasing for $0 < p < \alpha$ for some critical constant $\alpha > 0$ (in the model u_x is always assumed to be nonnegative), but $\varphi(p)$ is decreasing for $p > \alpha$. More generally, we consider smooth functions φ which satisfy, for some $\alpha > 0$,

$$\begin{cases} \varphi(0) = \varphi(+\infty) = 0 \\ 0 < \varphi(p) \leq \varphi(\alpha) \quad \text{for } p > 0 \end{cases} \tag{1.5}$$

(see Fig. 1).

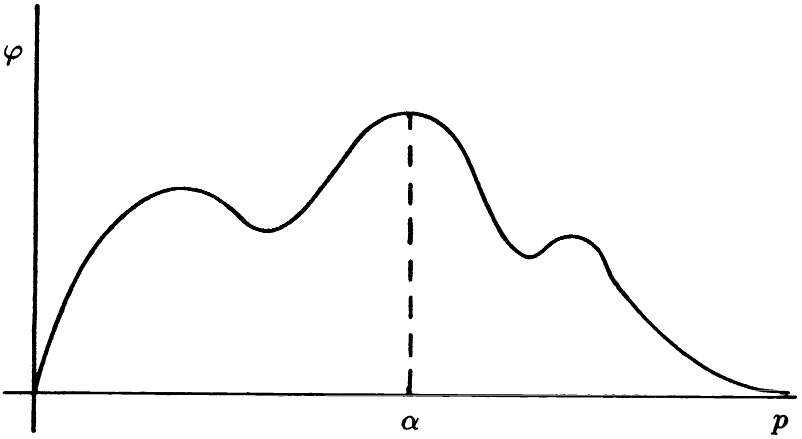

FIG. 1. *The function $\varphi(p)$ for $p \geq 0$.*

If we simply substitute (1.2) into the balance law (1.1), i.e., if we suppose that the turbulence field governing the thermal diffusivity is an equilibrium one, the resulting second-order partial differential equation

$$u_t = \varphi(u_x)_x \tag{1.6}$$

is not of forward parabolic type at points at which $\varphi'(u_x) < 0$.

If φ is not monotone, (1.6) leads to initial-boundary value problems which may be ill-posed. The ill-posedness does not necessarily regard the existence of solutions; for example, Höllig [H] showed that if φ is piecewise linear, decreasing in a bounded interval, and increasing elsewhere, there exist initial functions for which the corresponding Cauchy problem possesses infinitely many solutions.

A natural approach to treat a problem where an equation of the type (1.6) arises is to introduce some regularization which leads to well-posed problems. For example,

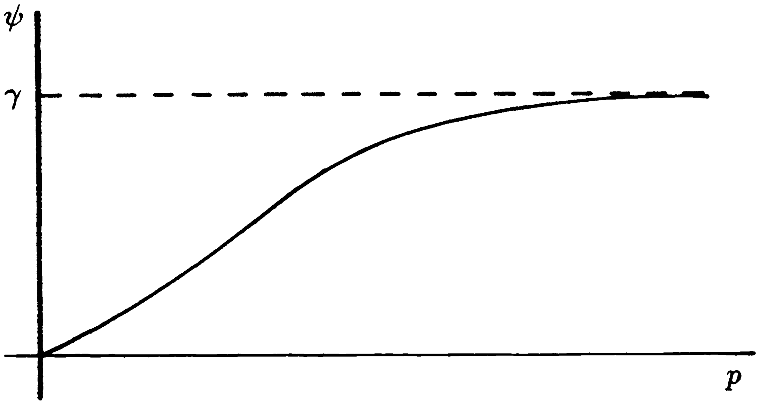

FIG. 2. *The function $\psi(p)$ for $p \geq 0$.*

one might add to the right-hand side of (1.6) the term $\epsilon^2 u_{xxt}$, which yields a pseudoparabolic equation, or $-\epsilon^2 u_{xxxx}$, which leads to a fourth-order parabolic equation. However, an important consequence of Höllig's nonuniqueness result is that the dynamics of the solutions (which will, of course, strongly depend on the type of nonlinear function φ under consideration) may critically depend on the sort of regularization which we introduce. Indeed, in the case of a cubic nonlinearity φ (i.e., φ is decreasing in a bounded interval, increasing elsewhere, and $\varphi(+\infty) = +\infty$), which arises in the context of viscoelasticity, the two regularizations which we mentioned before lead to different dynamics of solutions (we refer to the discussion in [NP]). This strongly suggests that, more than ever, an eventual regularization should be justified at the level of mathematical modeling. In other words, the regularization should be specific for the given physical problem. We observe that also in numerical computations a regularization appears, because difference equations are solved instead of differential equations (cf. the numerical computations in [Po], [Dj] for our model), and also in this context the consistency of the regularization with the physical model should be investigated.

In our model the natural way to modify the problem is to reconsider the assumption that the turbulence, which governs the diffusion coefficient and the flux, is in equilibrium with the temperature gradient. Indeed, in §2 we shall explain that if we take into account a small but positive time τ of the relaxation of the turbulence field to the temperature gradient, we obtain the equation

$$u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt}, \tag{1.7}$$

where ψ is a smooth nonlinear function which is expressed through φ (see Fig. 2). The properties of ψ which are important for us are

$$\begin{cases} \psi'(p) > 0 & \text{for } p > 0, \\ \psi(0) = 0, & \psi(+\infty) = \gamma < +\infty. \end{cases} \tag{1.8}$$

Since $\psi'(+\infty) = 0$, $\psi'(p)$ is not uniformly bounded away from zero, and we call (1.7) of *degenerate pseudoparabolic* type. In addition φ and ψ satisfy the inequality

$$\varphi'(p) \geq -\psi'(p) \quad \text{for } p > 0, \tag{1.9}$$

which will play an important role below since it implies, roughly speaking, that the last term in (1.7) is strong enough to control the possibly negative diffusion coefficient $\varphi'(u_x)$. For the precise hypotheses on the data we refer to §3.

Our main results concern the initial-boundary value problem

$$\text{(I)}\begin{cases} u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt} & \text{in } (0,1)\times\mathbf{R}^+, \\ u_x(0,t) = u_x(1,t) = 0 & \text{for } t > 0, \\ u(x,0) = u_0(x) & \text{for } 0 < x < 1. \end{cases}$$

The lateral boundary conditions in problem (I) are no-flux conditions, but the mathematical analysis which we shall present does not depend strongly on the choice of the boundary conditions; in particular, a similar analysis is possible for the corresponding Cauchy problem in which $-\infty < x < +\infty$.

The main results of this paper regard the well-posedness of problem (I), and both the transient and the large time behavior of its solutions. Below we shall briefly describe these results; for their precise statement we refer again to §3.

The uniqueness and the existence of a (generalized) solution will be proved in, respectively, §§4 and 5.

The qualitative transient behavior of the solutions depends strongly on the properties of the function φ and the threshold α for the gradient u_x. Let us assume for the moment that the initial function u_0 is smooth and nondecreasing in the interval $(0,1)$. In §6 we shall prove that $u_x \geq 0$ in $(0,1)\times\mathbf{R}^+$ and that, given $x_0 \in (0,1)$,

$$u_0'(x_0) \leq \alpha \Rightarrow u_x(x_0,t) \leq \alpha \quad \text{for all } t > 0.$$

In particular, if $u_0' \leq \alpha$ in $(0,1)$, then the gradient u_x is uniformly bounded in $(0,1)\times\mathbf{R}^+$.

The situation changes drastically if u_0' is not bounded by α. In §8 we shall show that there exists a smooth initial function such that the solution becomes *discontinuous within finite time.* Of course this phenomenon is caused by the specific form of φ, but we observe that, due the the strong degeneracy of $\psi(p)$ as $p \to \infty$, the regularizing effect of the third-order term is not sufficient to prevent the formation of discontinuities. In §7 we shall prove that, once a solution is discontinuous at some point x_0, it remains discontinuous at x_0 for all later times t; more precisely we shall show that the jump $u(x_0^+,t)-u(x_0^-,t)$ is nondecreasing with respect to t (actually the growth of the jump is the essential part of the result; the mere preservation of the discontinuity could be guessed from earlier results [NP], [S] on pseudoparabolic equations).

In §9 we shall prove that, given u_0, there exists a function $q \in BV((0,1))$ such that $u(\cdot,t) \to q$ almost everywhere in $(0,1)$ as $t \to \infty$, and the regular part of the derivative q' vanishes almost everywhere in $(0,1)$; the singular part of the measure q' does not necessarily vanish: if u is discontinuous at some point (x_0,t_0), q will also be discontinuous at x_0.

Physically such piecewise constant asymptotic profiles correspond to the formation of stepwise temperature or salinity distributions in, for example, the ocean. On the modeling level it was known for a long time that the nonmonotonicity of φ could explain the formation of steps as $t \to \infty$, but it was always tacitly assumed that $\tau = 0$, without paying attention to the mathematical well-posedness of the problem. As a conclusion we may say that our assumption of positive relaxation time τ guarantees well-posedness of the model and preserves the required qualitative behavior of solutions.

Finally we discuss briefly some of the literature about degenerate and nondegenerate pseudoparabolic equations. For a first introduction to the subject and a list of references to early papers we refer to Chapter 3 in Carroll and Showalter [CS]. Among the more recent papers we mention [BG], [BS], [dBP], [N], [NP], [P], [Pa], [RS], [S], and [SR].

Of particular interest for us is the work of Padron [P], who considered the equation

$$v_t = \varphi(v)_{xx} + \tau v_{xxt}, \tag{1.10}$$

arising in population dynamics. The point is that φ behaves as in our case, and thus (1.10) is the nondegenerate version of our problem if we replace v by u_x. He proved, with techniques different from ours, an existence theorem and a result which suggests the stability of delta-function-type solutions (which correspond to our piecewise constant solutions).

DiBenedetto and Pierre [dBP] have studied a special class of degenerate pseudoparabolic equations which contains the equation

$$(v - \tau\Delta(\varphi(v)))_t = \Delta(\varphi(v)) \tag{1.11}$$

if φ is nondecreasing. Equations of this form arise in the mathematical models of capillary imbibition and were considered by Barenblatt and Gilman [BG]. Similar equations arise in the theory of fluid flows in fissured or fractured porous media [BZK], [BER], [BS], [Pa], [RS]. We observe that (1.11) can also be viewed as the Yoshida regularization of the (possibly degenerate) equation $v_t = \Delta(\varphi(v))$.

Several papers in the literature are devoted to the maximum principle for pseudoparabolic equations [dBP], [S], [SR], [T]. In this context we observe that many of our proofs are based on maximum principle techniques.

Novick-Cohen and Pego [NP] (see also [N]) studied (1.10) (in arbitrary space dimension) as a model for phase-separation in viscous binary mixtures, but in this case the function φ has a cubic type of nonlinearity. The same sort of nonlinearity arises in the context of viscoelasticity, but in this case the derivative with respect to time is of the second order: (1.7), with u_t replaced by u_{tt} and ψ a linear function, has been studied in [D], [AB], [A], [Pe], and [BHJPS].

2. A brief discussion of the model. For the sake of simplicity we shall only consider the case of a thermally stratified fluid; the case of salinity (density) stratification is obtained in a completely analogous way.

It is known (for references we refer to [BBdPPU], where a more detailed physical discussion of the model is presented) that the mean potential temperature $u(x,t)$ in a statistically horizontally homogeneous turbulent shear flow satisfies the equation

$$\rho c_p u_t + \Phi_x = 0. \tag{2.1}$$

Here t is the time, x is the vertical coordinate, Φ is the turbulent heat flux (i.e., we only take into account heat diffusion due to turbulence, which is supposed to be the dominant diffusion process), and ρ and c_p are, respectively, the fluid density and its heat capacity at constant pressure: fluid properties which are assumed constant. Defining the effective temperature diffusivity k by the relation

$$k = -\frac{\Phi}{\rho c_p u_x}, \tag{2.2}$$

we can rewrite (2.1) in the form

$$u_t = (k u_x)_x. \tag{2.3}$$

Under equilibrium (steady state) conditions the turbulent temperature diffusivity k is a function of the temperature gradient:

$$k = k_0(u_x). \tag{2.4}$$

In turbulent shear flows in stably thermally stratified fluids the temperature gradient u_x is positive, and the main characteristic of such flows is that positive temperature gradients suppress turbulence (this effect is caused by the action of buoyancy forces, due to the presence of a strong gravity field). Therefore (see Fig. 3)

$$k_0'(p) < 0 \quad \text{for } p > 0$$

and

$$k_0(p) \to 0 \quad \text{as } p \to +\infty.$$

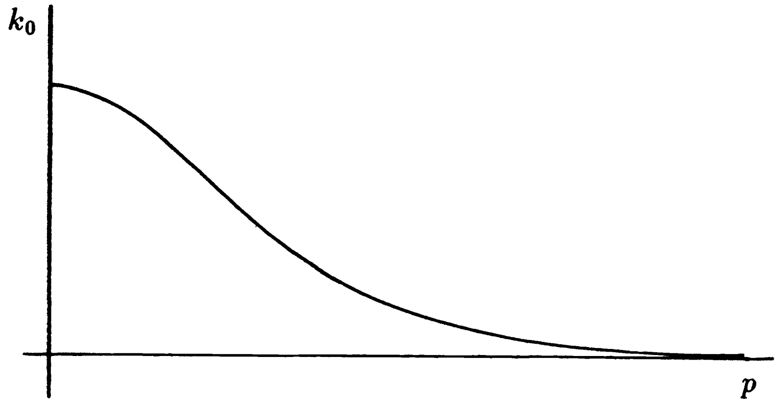

FIG. 3. *The steady heat diffusivity* $k_0(p)$.

Previous investigators have observed that, formally, a sufficiently fast decay of $k_0(p)$ as $p \to +\infty$ may explain the formation of stepwise temperature distributions, a phenomenon which, for example, has been observed in the ocean. Their approach, similar to the traditional derivation of the Fourier heat conduction equation and the Fick diffusion equation, was to use relation (2.4) for closing (2.3), which leads to the following equation for the potential temperature:

$$u_t = \varphi'(u_x)u_{xx}, \tag{2.5}$$

where

$$\varphi(p) = pk_0(p) \quad \text{for } p \geq 0. \tag{2.6}$$

An essential point is that at large values of p the function $k_0(p)$ decreases so rapidly that the function $\varphi(p)$ at a certain value $p = \alpha$ starts to decrease, and, moreover, tends to zero as $p \to +\infty$. Thus, the graph of the function $\varphi(p)$ has the shape which is indicated in Fig. 1 (in the simplest case φ is increasing in $(0, \alpha)$ and decreasing in $(\alpha, +\infty)$), and, for sufficiently large temperature gradients $u_x > \alpha$ the coefficient in (2.5) becomes negative and (2.5) becomes a nonlinear backward heat conduction equation.

Intuitively the negativity of φ' for large values of the temperature gradient might explain the formation of stepwise temperature distributions, and in this direction some numerical experiments were performed [Po], [Dj]. However, as we mentioned in the Introduction, it is plausible that the nonlinear backward-forward heat equation (2.5) leads to ill-posed problems, and therefore the mathematical model should be modified.

To do so we have to take into account that (2.5) is only one of the equations of a system of simultaneous equations governing the turbulence, velocity, and temperature fields. At this moment a generally accepted system of equations to describe these fields is not available. However, it is clear that if in such system the value of the temperature gradient is prescribed at a certain moment, the time τ of adjustment (relaxation) of the turbulence field to this value of the temperature gradient is perhaps small in comparison with the characteristic time of the whole field, but strictly positive. In the present model we average the relaxation time τ over the whole field and consider it as a constant, and we assume that moment t turbulence properties, including the temperature diffusivity k, can be taken as equilibrium values related to the temperature gradient at the moment $t-\tau$.

So, our hypothesis is that the current temperature diffusivity corresponds to the equilibrium temperature gradient at the moment $t-\tau$:

$$k(x,t) = k_0(u_x(x,t-\tau)). \tag{2.7}$$

Bearing in mind that the relaxation time τ is small in comparison with the characteristic time scale of the temperature field we obtain, developing (2.7) in a linear expansion with respect to τ:

$$u_x(x,t-\tau) \approx u_x(x,t) - \tau u_{xt}(x,t)$$

and

$$k \approx k_0(u_x - \tau u_{xt}) \approx k_0(u_x) - \tau k_0'(u_x)u_{xt}. \tag{2.8}$$

Combining (2.5) and (2.8), we obtain the following equation for the temperature:

$$u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt}, \tag{2.9}$$

where the function $\psi : [0,+\infty) \to [0+\infty)$ is defined by

$$\psi(p) = -\int_0^p s k_0'(s)ds = -\varphi(p) + \int_0^p k_0(s)ds \quad \text{for } p \geq 0. \tag{2.10}$$

Since k_0 is strictly decreasing, ψ is strictly increasing in $\mathbf{R}^+$.

In addition we shall assume that

$$\int_0^{+\infty} k_0(s)ds < +\infty,$$

i.e., that k_0 tends to zero sufficiently fast as $p \to +\infty$, which implies that

$$\psi(+\infty) = \gamma < +\infty.$$

A typical graph of ψ is shown in Fig. 2.

We conclude this section with some comments on the hypotheses which we shall use in the mathematical analysis of the model. It follows from (2.10) that $\psi'(0)=0$ if $pk_0'(p) \to 0$ as $p \to 0$, which makes (2.9) degenerate pseudoparabolic at points at which $u_x=0$. In the rest of this paper we shall ignore this degeneracy at zero. We expect that this only leads to a mathematical complication, and we have preferred to focus our attention to what happens for large gradients, for which φ' becomes negative. In addition, for small values of p the precise behavior of $k_0(p)$ is impossible to determine from experimental data, because the measured quantity is the flux and to obtain the diffusivity we have to divide the flux by the gradient. We observe that, once we assume that $\psi'(p) > 0$ for all p and that $\varphi'(p) < 0$ for large values of p, condition (1.9) implies that $|\varphi'(p)| \le k_1\psi'(p)$ for all p and for some constant k_1. Finally we mention that we shall use an additional condition on φ and ψ (see hypothesis (H2a) in §3) to prove the uniqueness of solutions. In the physical model this condition is satisfied for large gradients if, for example, k_0 is given by (1.3).

3. Basic mathematical hypotheses and main results. We use standard notation for the following function spaces (Ω denotes a connected set in $\mathbf{R}^n$): $C(\Omega)$, $C^k(\Omega)$ and $C^\infty(\Omega)$ denote the sets of, respectively, continuous real functions on Ω, k times differentiable real functions on Ω such that $f^{(k)}$ is continuous in Ω, and real functions on Ω which have derivatives of arbitrary order; $L^p(\Omega)$ $(1 \le p < \infty)$ is the set of measurable real functions on Ω such that $|f|^p$ is Lebesgue integrable in Ω; $L^\infty(\Omega)$ is the set of real measurable functions on Ω which are (essentially) bounded in Ω; $H_0^1(\Omega)$ indicates the Sobolev space which, roughly speaking, contains the functions $u \in L^2(\Omega)$ such that the (generalized) first-order derivatives belong to $L^2(\Omega)$ and u vanishes at the boundary of Ω (in the sense of traces); $BV(\Omega)$ is the set of real functions on Ω which have bounded total variation; $L^p(0,T;V)$ (with V a Banach space with norm $\|\cdot\|$) denotes the set of functions $f : [0,T] \to V$ such that $\|f(t)\|$ belongs to $L^p(0,T)$. Supplied with their natural norms, these sets are Banach spaces ($C(\Omega)$, $C^k(\Omega)$ and $C^\infty(\Omega)$ are Banach spaces if Ω is closed and bounded). The subscript *loc* stands for locally; for example, $L^p_{\text{loc}}(\Omega)$ contains the functions u belonging to $L^p(K)$ for any compact subset K of Ω, and $f_k \to f$ in $L^p_{\text{loc}}(\Omega)$ as $k \to \infty$ indicates that $f_k \to f$ in $L^p(K)$ as $k \to \infty$ for every compact subset K of Ω.

First we list the several hypotheses on the data of problem (I), which we shall use in this paper. From a mathematical point of view it turns out to be convenient to define the functions $\varphi(p)$ and $\psi(p)$ also for negative values of p.

(H1) $\psi \in C^3(\mathbf{R})$, $\psi' > 0$ in $\mathbf{R}$, ψ is odd, and $\psi(+\infty) = \gamma$, where $0<\gamma<+\infty$;

(H2) $\varphi \in C^3(\mathbf{R})$, $\varphi(0) = 0$, and there exists a constant $k_1 > 0$ such that

$$|\varphi'| \le k_1\psi' \quad \text{in } \mathbf{R}; \tag{3.1}$$

(H2a) there exists a constant k_2 such that

$$\left| \left(\frac{\varphi'}{\psi'}\right)' \frac{1}{\psi'} \right| \le k_2 \quad \text{in } \mathbf{R}; \tag{3.2}$$

(H3) $u_0 \in BV((0,1))$, and there exists a function $w_0 \in H_0^1((0,1))$ such that

$$\begin{aligned} w_0(x) &= \lim_{h\to 0} \psi\left(\frac{u_0(x+h)-u_0(x^+)}{h}\right) \\ &= \lim_{h\to 0} \psi\left(\frac{u_0(x+h)-u_0(x^-)}{h}\right) \quad \text{for } 0<x<1, \end{aligned} \tag{3.3}$$

where $u_0(x^{\pm})$ denote the one-sided limits of u_0 at the point x;

(A2) $\varphi(+\infty)=0$, $0<\varphi(p)\le\varphi(\alpha)$ for $0<p<+\infty$ for some $\alpha>0$, and $\varphi<0$ in $\mathbf{R}^-$;

(A3) u_0 is nondecreasing in $(0,1)$.

The hypotheses (H1), (H2), and (H3) will ensure the existence of a solution. The more restrictive condition (H2a) on the behavior of $\psi(p)$ as $p\to\infty$ will be used to prove uniqueness; we observe that it is satisfied in the interval $[1,+\infty)$ in the model case in which φ and ψ are determined by (1.3), (1.4), and (2.10). The assumptions (A2) and (A3) are natural in the context of the physical model, and will be used to study the qualitative behavior of the solutions.

Hypotheses (H1) and (H2) imply that $\varphi(+\infty)$ and $\varphi(-\infty)$ exist and are finite. Defining the function $h:[-\gamma,\gamma]\to\mathbf{R}$ by

$$h(p):=\begin{cases}\varphi\circ\psi^{-1}(p) & \text{if } |p|<\gamma,\\ \varphi(\pm\infty) & \text{if } p=\pm\gamma,\end{cases} \tag{3.4}$$

where ψ^{-1} denotes the inverse of ψ and $\varphi\circ\psi^{-1}$ is the composed function $p\mapsto\varphi(\psi^{-1}(p))$, it follows from (H2) and (H2a) that $h\in C^2((-\gamma,\gamma))\cap C^1([-\gamma,\gamma])$ and

$$|h'|\le k_1 \quad\text{and}\quad |h''|\le k_2 \quad\text{in } (-\gamma,\gamma), \tag{3.5}$$

where we have used the formulas

$$h'(p)=\frac{\varphi'}{\psi'}\circ\psi^{-1}(p) \quad\text{and}\quad h''(p)=\left(\frac{\varphi'}{\psi'}\right)'\frac{1}{\psi'}\circ\psi^{-1}(p) \quad\text{for } -\gamma<p<\gamma.$$

We observe that the continuous function $w_0(x)$ in hypothesis (H3) is nothing else than $\psi(u_0'(x))$ at the points where $|u_0'|<\infty$. In a similar way we replace the function $\psi(u_x(x,t))$, which is only defined at points where $u(x,t)$ is smooth, by a continuous function $w(x,t)$ in the definition of a solution. Throughout this paper we shall use the notation

$$Q=(0,1)\times(0,+\infty) \quad\text{and}\quad Q_T=(0,1)\times(0,T],$$

where $T>0$.

DEFINITION. A function $u:\overline{Q}\mapsto\mathbf{R}$ is a solution of problem (I) if for any $T>0$:

(i) $u\in L^\infty(Q_T)\cap L^\infty(0,T;BV((0,1)))$ and $u_t\in L^2(Q_T)$;

(ii) there exists a function $w\in C(\overline{Q})$ such that $|w|\le\gamma$ in Q,

$$\begin{aligned} w(x,t) &= \lim_{h\to0}\psi\left(\frac{u(x+h,t)-u(x^+,t)}{h}\right)\\ &= \lim_{h\to0}\psi\left(\frac{u(x+h,t)-u(x^-,t)}{h}\right) \quad\text{for } 0<x<1 \quad\text{and}\quad t>0,\end{aligned} \tag{3.6}$$

$w\in L^\infty(0,T;H_0^1((0,1)))$ and $w_t\in L^2(0,T;H^1((0,1)))$;

(iii) u and w satisfy the equation

$$u_t=h(w)_x+\tau w_{xt} \quad\text{in } L^2(Q_T), \tag{3.7}$$

where $h:[-\gamma,\gamma]\to\mathbf{R}$ is defined by (3.4), and

$$u(x,0)+\tau w_x(x,0)=u_0(x)+\tau w_0'(x) \quad\text{for almost every } 0<x<1, \tag{3.8}$$

where u_0 and w_0 are determined by (H3).

In (3.8), the words "almost every" indicate that (3.8) holds in the interval $(0,1)$ with the possible exception of a subset of measure zero.

Our first main result concerns the well-posedness of problem (I).

THEOREM 3.1 (existence and uniqueness). *Let hypotheses* (H1), (H2), *and* (H3) *be satisfied. Then problem* (I) *possesses a solution u. If in addition hypothesis* (H2a) *is satisfied, then the solution is unique.*

In Theorem 3.1 we have not required the positivity of u_0'. On the other hand the positivity of u_x was a crucial physical hypothesis in the derivation of the mathematical model. The first part of the following result shows the consistency of this hypothesis.

THEOREM 3.2 (gradient estimates). *Let hypotheses* (H1)–(H3) *and* A2 *be satisfied, and let $u(x,t)$ be the solution of problem* (I).

(i) *If u_0 is nondecreasing in $(0,1)$, then we have $u(x,t)$ nondecreasing with respect to x.*

(ii) *If $u_x(x_0,t_0) \leq \alpha$ for some $x_0 \in (0,1)$ and $t_0 \geq 0$, then $u_x(x_0,t) \leq \alpha$ for all $t > t_0$.*

(iii) *If $u_x(x_0,t_0) \geq \alpha$ for some $x_0 \in (0,1)$ and $t_0 > 0$, then $u_x(x_0,t) \geq \alpha$ for all $0 \leq t < t_0$.*

The interpretation of part (ii) is the following: $\varphi(p)$ has its maximum at $p=\alpha$, and, in the model equation, φ is increasing in $(0,\alpha)$ and decreasing in $(\alpha,+\infty)$, i.e., the diffusion is positive at points where $0 \leq u_x < \alpha$ and negative where $u_x > \alpha$. As we shall see below, the negative diffusion may lead to unboundedness of the spatial gradient, but Theorem 3.2(ii) means that once $u_x \leq \alpha$ at some point x_0, then it remains bounded by α at x_0 for all later times.

Hypothesis (H3) allows discontinuous initial functions. It is a consequence of the following result that the discontinuities only can increase as time evolves.

THEOREM 3.3 (persistence of discontinuities). *Let hypotheses* (H1)–(H3) *and* (A2)–(A3) *be satisfied. Let u be the solution of problem* (I), *and let w be defined by* (3.6). *If for some $0 < x_0 < 1$ and $t_0 \geq 0$,*

$$w(x_0,t_0) = \gamma,$$

then

$$w(x_0,t) = \gamma \quad \textit{for } t > t_0,$$

and

(3.9) $u(x_0^+,t)$ *is nondecreasing in* $(t_0,+\infty), u(x_0^-,t)$ *is nonincreasing in* $(t_0,+\infty)$.

It turns out that also smooth initial functions may lead to discontinuous solutions.

THEOREM 3.4 (formation of discontinuities). *Let hypotheses* (H1)–(H2a) *and* A2 *be satisfied. Then there exist initial functions $u_0 \in C^1([0,1])$ which satisfy hypotheses* (H3) *and* (A3), *such that the corresponding solutions of problem* (I) *are not continuous in Q.*

Finally we consider the large-time behavior of solutions.

THEOREM 3.5 (convergence to stepwise solutions). *Let hypotheses* (H1)–(H3) *and* (A2)–(A3) *be satisfied and let u be the solution of problem* (I). *Then there exists a nondecreasing function $q \in BV((0,1))$ which satisfies*

$$q' = 0 \quad \textit{almost everywhere in } (0,1)$$

such that

$$u(x,t) \to q(x) \quad \textit{as } t \to \infty \textit{ for almost every } 0 < x < 1. \tag{3.10}$$

If $u \notin C(Q)$, then q is nonconstant in $(0,1)$.

4. Uniqueness. In this section we prove the second part of Theorem 3.1, the uniqueness of the solution of problem (I).

Suppose that $\underline{u}$ and $\overline{u}$ are two solutions with corresponding functions $\underline{w}$ and $\overline{w}$ defined by (3.6). It is sufficient to prove local uniqueness, i.e., $\underline{u} = \overline{u}$ almost everywhere in Q_T for some $T > 0$.

The idea of the proof is to subtract the equations for $(\underline{u}, \underline{w})$ and $(\overline{u}, \overline{w})$ and to multiply the resulting equation by a suitable test function in order to obtain an appropriate integral estimate for the difference of the two solutions.

Let $T > 0$ be determined below. We define $\zeta \in L^2(Q_T)$ by

$$\zeta(x,t) = \int_t^T (\underline{w} - \overline{w})_x(x,s)ds,$$

where $(\underline{w} - \overline{w})_x(x,s)$ stands for $\underline{w}_x(x,s) - \overline{w}_x(x,s)$. Subtracting the equations (3.7) for, respectively, $\underline{u}$ and $\overline{u}$, multiplying by ζ, integrating by parts over Q_T, and using (3.8) and the fact that $\zeta(x,T) = 0$ for almost every $0<x<1$, we obtain that

$$\begin{aligned}\iint_{Q_T} (\underline{u} - \overline{u})(\underline{w} - \overline{w})_x dxdt =& \tau \iint_{Q_T} (\underline{w} - \overline{w})_x^2 dxdt \\ &+ \iint_{Q_T} (h(\underline{w}) - h(\overline{w}))_x \left(\int_t^T (\underline{w} - \overline{w})_x(s,t)ds \right) dxdt.\end{aligned}$$

Splitting up the measure $\underline{u}_x$ into its regular part $\underline{u}_x^R \in L^1(Q_T)$ and its singular part $\underline{u}_x^S$ (see [R]), it follows from the nonnegativity of $\iint_{Q_T} (\underline{u}_x^S - \overline{u}_x^S)(\underline{w} - \overline{w})$ that

$$\begin{aligned}&\tau \iint_{Q_T} (\underline{w} - \overline{w})_x^2 dxdt + \iint_{Q_T} (\underline{u}_x^R - \overline{u}_x^R)(\underline{w} - \overline{w}) dxdt \\ &\le - \iint_{Q_T} (h(\underline{w}) - h(\overline{w}))_x \left(\int_t^T (\underline{w} - \overline{w})_x(s,t)ds \right) dxdt \\ &\le \frac{\epsilon}{2} \iint_{Q_T} (h(\underline{w}) - h(\overline{w}))_x^2 \, dxdt + \frac{1}{2\epsilon} \iint_{Q_T} \left(\int_t^T (\underline{w} - \overline{w})_x(s,t)ds \right)^2 dxdt \\ &\equiv I_1 + I_2,\end{aligned} \tag{4.1}$$

where $\epsilon > 0$ is a constant to be chosen below. First we estimate I_1:

$$\begin{aligned}I_1 \le& \epsilon \iint_{Q_T} \left((h'(\underline{w})(\underline{w} - \overline{w})_x)^2 + (h'(\underline{w}) - h'(\overline{w}))^2 \overline{w}_x^2 \right) dxdt \\ \le& \epsilon k_1^2 \iint_{Q_T} (\underline{w} - \overline{w})_x^2 dxdt + \epsilon k_2^2 \sup_{[0,T]} \left(\int_0^1 \overline{w}_x^2(x,t)dx \right) \\ &\cdot \int_0^T \sup_{(0,1)} (\underline{w} - \overline{w})^2 dt,\end{aligned} \tag{4.2}$$

where we have used (3.5). Observe that, for any $t \in [0,T]$,

$$\begin{aligned}\sup_{0<x<1} (\underline{w} - \overline{w})^2(x,t) &= 2 \sup_{0<x<1} \int_0^x (\underline{w} - \overline{w})(\underline{w} - \overline{w})_x(s,t)ds \\ &\le \int_0^1 (\underline{w} - \overline{w})^2(x,t)dx + \int_0^1 (\underline{w} - \overline{w})_x^2(x,t)dx.\end{aligned}$$

We use the second term on the left-hand side of (4.1) to estimate $\underline{w}-\overline{w}$ in $L^2(Q_T)$: since $\underline{w}=\psi(\underline{u}_x^R)$ almost everywhere in Q_T, we have

$$\iint_{Q_T}(\underline{u}_x^R-\overline{u}_x^R)(\underline{w}-\overline{w})dxdt \ge \frac{1}{\sup_{\mathbf{R}}\psi'}\iint_{Q_T}(\underline{w}-\overline{w})^2dxdt,$$

and hence it follows from (4.1) and (4.2) that if we choose $\epsilon>0$ such that

$$\epsilon k_1^2 \le \frac{\tau}{4} \quad\text{and}\quad \epsilon k_2^2\left(\sup_{[0,1]}\int_0^1 \overline{w}_x^2(x,t)dx\right) \le \max\left\{\frac{\tau}{4},\frac{1}{2\sup_{\mathbf{R}}\psi'}\right\},$$

then, for any $T\in(0,1]$,

$$\begin{aligned}
&\frac{1}{2}\tau\iint_{Q_T}(\underline{w}-\overline{w})_x^2dxdt+\frac{1}{2\sup_{\mathbf{R}}\psi'}\iint_{Q_T}(\underline{w}-\overline{w})^2dxdt\\
&\le\frac{1}{2\epsilon}\iint_{Q_T}\left(\int_t^T(\underline{w}-\overline{w})_x(x,s)ds\right)^2dxdt\\
&\le\frac{1}{2\epsilon}\iint_{Q_T}(T-t)\left(\int_t^T(\underline{w}-\overline{w})_x^2ds\right)dxdt\le\frac{T^2}{2\epsilon}\iint_{Q_T}(\underline{w}-\overline{w})_x^2dxdt.
\end{aligned}$$

Choosing $T\in(0,1]$ such that $T^2\le\frac{1}{2}\epsilon\tau$, we find that

$$\frac{1}{4}\tau\iint_{Q_T}(\underline{w}-\overline{w})_x^2dxdt+\frac{1}{2\sup_{\mathbf{R}}\psi'}\iint_{Q_T}(\underline{w}-\overline{w})^2dxdt\le 0,$$

and the proof is complete.

5. Existence. To prove the existence of a solution of problem (I), we proceed in two steps. The first one consists of approximating problem (I) by a nondegenerate problem.

For any $0<\epsilon\le1$ there exist functions φ_ϵ, $\psi_\epsilon\in C^\infty(\mathbf{R})$, and $u_{0\epsilon}\in C^\infty([0,1])$ such that

$$\begin{gathered}
\psi'+\epsilon\le\psi_\epsilon'\le\psi'+2\epsilon \quad\text{in }\mathbf{R},\quad \psi_\epsilon''\in L^\infty(\mathbf{R}),\\
\psi_\epsilon\text{ is odd},\quad \psi_\epsilon\to\psi\quad\text{in }C^3_{\text{loc}}(\mathbf{R})\quad\text{as }\epsilon\to0,
\end{gathered}$$

$$\varphi_\epsilon(0)=0,\quad |\varphi_\epsilon'|\le k_1\psi_\epsilon'\quad\text{in }\mathbf{R},\quad \varphi_\epsilon\to\varphi\quad\text{in }C^3_{\text{loc}}(\mathbf{R})\quad\text{as }\epsilon\to0,$$

where k_1 is defined by (3.1), and

$$\begin{gathered}
\int_0^1\Psi_\epsilon(u_{0\epsilon}'(x))dx\le C,\qquad \int_0^1\left(\psi_\epsilon(u_{0\epsilon}'(x))'\right)^2dx\le C,\\
u_{0\epsilon}'(0)=u_{0\epsilon}'(1)=0,\quad u_{0\epsilon}\to u_0\quad\text{in }L^1(0,1)\quad\text{as }\epsilon\to0
\end{gathered}\tag{5.1}$$

for some $C>0$, which does not depend on ϵ, where we have set

$$\Psi_\epsilon(p)=\int_0^p\psi_\epsilon(s)ds\quad\text{for }p\in\mathbf{R}.\tag{5.2}$$

If condition (A2) is satisfied, we may suppose that

$$\varphi_\epsilon < 0 \quad \text{in } \mathbf{R}^-, \quad 0 \leq \varphi_\epsilon(p) \leq \varphi_\epsilon(\alpha) \quad \text{in } \mathbf{R}^+,$$

and

$$\varphi_\epsilon = 0 \quad \text{in } (\psi_\epsilon^{-1}(\gamma), +\infty). \tag{5.3}$$

We consider the approximate problem

$$(\mathrm{I}_\epsilon)\begin{cases} u_t = \varphi_\epsilon(u_x)_x + \tau\psi_\epsilon(u_x)_{xt} & \text{in } Q, \\ u(x,0) = u_{0\epsilon}(x) & \text{for } 0 < x < 1, \\ u_x(0,t) = u_x(1,t) = 0 & \text{for } t > 0. \end{cases}$$

LEMMA 5.1. *Let $\epsilon > 0$ and $k = 0, 1, 2, \ldots$. Then problem (I_ϵ) has a unique solution*

$$u_\epsilon \in W^{1,\infty}_{\text{loc}}([0,+\infty); C^{2+k}([0,1])).$$

(The notation $u_\epsilon \in W^{1,\infty}_{\text{loc}}$ indicates that, if we set $Y = C^{2+k}([0,1])$ with norm $\|\cdot\|$, the functions $u_\epsilon(t)$ and $u_{\epsilon t}(t)$ belong to Y for all $t \geq 0$ and the scalar functions $\|u_\epsilon(t)\|$ and $\|u_{\epsilon t}(t)\|$ belong to $L^\infty(0,T)$ for any $T > 0$.)

Proof. We introduce the spaces

$$X = \{u \in C^{2+k}([0,1]) : u'(0) = u'(1) = 0\},$$
$$Y = C^k([0,1]),$$

and we define the functionals $G : X \to Y$ and $H : X \to Y$ by

$$G(u) = u - \tau\psi_\epsilon(u')' \quad \text{and} \quad H(u) = \varphi_\epsilon(u')'. \tag{5.4}$$

Clearly these functionals are uniformly Lipschitz continuous. In addition we claim that G is invertible and that its inverse

$$G^{-1} : Y \to X \quad \text{is locally Lipschitz continuous.} \tag{5.5}$$

First, we prove (5.5) for $k=0$.

Let $v_1, v_2 \in Y$ and consider the problem

$$(\mathrm{II}_{\epsilon,i})\begin{cases} u_i - \tau\psi_\epsilon(u_i')' = v_i & \text{in } (0,1), \\ u_i'(0) = u_i'(1) = 0, \end{cases}$$

where $i = 1, 2$. By standard results on quasilinear elliptic equations and by the maximum principle, there exists a unique solution $u_i \in X$ of problem $(\mathrm{II}_{\epsilon,i})$, which satisfies

$$\max_{[0,1]} |u_i| \leq \max_{[0,1]} |v_i| \quad \text{and} \quad \|u_i\|_X \leq C\|v_i\|_Y \tag{5.6}$$

for some constant C that does not depend on v_i.

To prove (5.5), we consider the equation for $z := u_1 - u_2$:

$$z - \tau\psi'_\epsilon(u'_1)z'' - \tau\left(\psi'_\epsilon(u'_1) - \psi'_\epsilon(u'_2)\right)u''_2 = v_1 - v_2,$$

i.e.,

$$z - \tau\psi'_\epsilon(u'_1)z'' - \tau\psi''_\epsilon(\xi)u''_2 z' = v_1 - v_2,$$

where $\xi(x)$ is a number between $u'_1(x)$ and $u'_2(x)$. By the maximum principle

$$\|z\|_Y \leq \|v_1 - v_2\|_Y,$$

and thus

$$|\psi'_\epsilon(u'_1)z'' + \psi''_\epsilon(\xi)u''_2 z'| \leq \frac{2}{\tau}\|v_1 - v_2\|_Y,$$

from which (5.5) follows at once for $k=0$.

If $k \geq 1$, (5.6) remains valid. The remaining part of the proof of (5.5) is based on a standard iteration procedure applied to the equation for the kth-order derivative of $u_1 - u_2$.

We rewrite problem (I_ϵ) as an ordinary differential equation in Y:

$$\begin{cases} \dfrac{d}{dt}w = (H \circ G^{-1})(w) & \text{in } [0, +\infty), \\ w(0) = G(u_{0\epsilon}). \end{cases}$$

The local existence of a unique solution $w_\epsilon \in C^1([0,T];Y)$ (for some $T > 0$) follows from (5.5), and by (5.6) the solution can be extended globally: $w_\epsilon \in C^1([0,+\infty);Y)$. Applying (5.5) a second time, we find that

$$u_\epsilon := G^{-1}(w_\epsilon) \in W^{1,\infty}_{\mathrm{loc}}([0,\infty);X),$$

and u_ϵ is the unique solution of problem (I_ϵ).

The second step in the existence proof is to show several integral estimates for u_ϵ which will enable us to let $\epsilon \to 0$.

LEMMA 5.2. *Let u_ϵ be the solution of problem* (I_ϵ), *and let Ψ_ϵ be defined by* (5.2). *For any $T > 0$ there exists a constant C which does not depend on ϵ such that*

$$\sup_{t\in[0,T]} \int_0^1 \Psi_\epsilon(u_{\epsilon x})dx \leq C, \tag{5.7}$$

$$\sup_{t\in[0,T]} \int_0^1 \psi_\epsilon(u_{\epsilon x})^2_x dx \leq C, \tag{5.8}$$

$$\iint_{Q_T} u^2_{\epsilon t} dxdt \leq C, \tag{5.9}$$

$$\iint_{Q_T} \psi'_\epsilon(u_{\epsilon x})u^2_{\epsilon xt} dxdt \leq C, \tag{5.10}$$

$$\iint_{Q_T} \psi_\epsilon(u_{\epsilon x})^2_{xt} dxdt \leq C, \tag{5.11}$$

$$\sup_{t\in[0,T]} \int_0^1 \psi_\epsilon(u_{\epsilon x})^2 dx \leq C, \tag{5.12}$$

$$\int_0^1 u_\epsilon(x,t)dx = \int_0^1 u_{0\epsilon}(x)dx. \tag{5.13}$$

Proof. Multiplying the equation for u_ϵ by $\psi_\epsilon(u_{\epsilon x})_x$ and integrating by parts, we obtain that for $t \in (0,T]$

$$\int_0^1 \left(\Psi_\epsilon(u_{\epsilon x}) + \frac{1}{2}\tau\psi_\epsilon(u_{\epsilon x})_x^2\right)(x,t)dx - \int_0^1 \left(\Psi_\epsilon(u'_{0\epsilon}) + \frac{1}{2}\tau(\psi_\epsilon(u'_{0\epsilon})')^2\right)(x)dx$$
$$= -\iint_{Q_t} \psi_\epsilon(u_{\epsilon x})_x\varphi_\epsilon(u_{\epsilon x})_x dxdt \le k_1 \iint_{Q_t} \psi_\epsilon(u_{\epsilon x})_x^2 dxdt,$$

where k_1 is defined by (3.1). It follows easily from the conditions on ψ_ϵ and $u_{0\epsilon}$ that the second integral on the left-hand side is uniformly bounded with respect to ϵ, and (5.7) and (5.8) follow at once.

We multiply the equation for u_ϵ by $u_{\epsilon t}$ and integrate by parts:

$$\iint_{Q_T} u_{\epsilon t}^2 dxdt + \tau \iint_{Q_T} \psi'_\epsilon(u_{\epsilon x})u_{\epsilon xt}^2 dxdt = -\int_0^1 \Phi_\epsilon(u_{\epsilon x})(x,T)dx + \int_0^1 \Phi_\epsilon(u'_{0\epsilon}(x))dx,$$

where we have set

$$\Phi_\epsilon(p) = \int_0^p \varphi(s)ds \quad \text{for } p \in \mathbf{R}.$$

Since $|\Phi_\epsilon| \le C\Psi_\epsilon$ in $\mathbf{R}$ for some constant C independent of ϵ, the right-hand side is uniformly bounded, and we obtain (5.9) and (5.10).

Finally (5.11) follows from (5.8), (5.9), and the equation for u_ϵ, (5.12) follows from (5.7) and the inequality $\psi_\epsilon^2 \le C\Psi_\epsilon$ for some C independent of ϵ, and integration of the equation for u_ϵ implies (5.13).

Remark. Except for the estimate (5.11), all estimates of Lemma 5.2 can be obtained if we use, instead of (3.1), the weaker inequality $\varphi' \ge -k_1\psi'$ (cf. (1.9)). In particular it can be shown that this condition is sufficient to prove existence of a solution in the sense of distributions.

Now we are ready to construct a solution u of problem (I). It follows from (5.7) and (5.9) that the set $\{u_\epsilon\}_{0<\epsilon\le 1}$ is bounded in $BV_{\text{loc}}(\overline{Q})$, and it follows from a straightforward diagonal procedure that there exist $u \in L^1_{\text{loc}}(\overline{Q})$ and a sequence $\{\epsilon_n\}$ converging to 0 such that

$$u_{\epsilon_n} \to u \quad \text{in } L^1_{\text{loc}}(\overline{Q}) \quad \text{as } n \to \infty.$$

We observe that (5.13) implies that

$$\int_0^1 u(x,t)dx = \int_0^1 u_0(x)dx \quad \text{for } t \ge 0.$$

Since $u \in L^\infty(0,T; BV((0,1)))$, this implies that $u \in L^\infty(Q_T)$.

In view of (5.8), (5.10)–(5.12), we may assume that there exists $w \in L^\infty_{\text{loc}}((0,+\infty); H^1_0(0,1))$ such that $w_t \in L^2_{\text{loc}}((0,+\infty); H^1(0,1))$ and

$$\psi_{\epsilon_n}(u_{\epsilon_n x}) \to w \quad \text{weakly in } H^1_{\text{loc}}(\overline{Q}) \quad \text{as } n \to \infty.$$

It follows easily from the integral estimates (5.8), (5.10), and (5.11) for $\psi_\epsilon(u_{\epsilon x})$ that these functions are uniformly Hölder continuous with exponent $\frac{1}{2}$ in Q_T; thus $w \in C^{1/2}(Q_T)$ and we may assume that

$$\psi_{\epsilon_n}(u_{\epsilon_n x}) \to w \quad \text{uniformly in } Q_T \quad \text{as } n \to \infty.$$

In addition $|w| \leq \gamma$ in Q_T. Indeed, if $|w| > \gamma + 2\eta$ at some point $(x_0, t_0) \in Q_T$ for some $\eta > 0$, then there exists a neighborhood $U \subset Q_T$ of (x_0, t_0) which does not depend on n such that for all sufficiently large n,

$$|\psi_{\epsilon_n}(u_{\epsilon_n})| > \gamma + \eta \quad \text{in } U;$$

this implies that

$$|u_{\epsilon_n}| > \psi_{\epsilon_n}^{-1}(\gamma + \eta) \quad \text{in } U,$$

and since the term at the right-hand side tends to infinity as $n \to \infty$ we obtain a contradiction with the boundedness of u_{ϵ_n} in $BV_{\mathrm{loc}}(\overline{Q})$.

Property (3.6) follows immediately from the construction and continuity of w.

Using the equation for u_ϵ we obtain for any $\zeta \in C^2(\overline{Q}_T)$ the integral identity

$$\int_0^1 (u\zeta + \tau w\zeta_x)(x, T)dx - \int_0^1 (u_0(x)\zeta(x, 0) + \tau w_0(x)\zeta_x(x, 0))dx$$
$$= \iint_{Q_T} (u\zeta_t + w\zeta_{xt} - h(w)\zeta_x)dxdt,$$

i.e., u and w satisfy (3.7) in the sense of distributions. In view of the regularity of u and w, (3.7) is satisfied in $L^2(Q_T)$.

Next we prove a local regularity result for the limiting function w which we shall use in §8.

THEOREM 5.3. *Let hypotheses* (H1), (H2), *and* (H3) *be satisfied, let* w_0 *be defined as in* (H3), *and let* u *be the solution of problem* (I) *constructed in this section, with the corresponding function* w *defined by* (3.6). *Let* K *be a closed interval contained in* $\{x \in [0,1] : |w_0(x)| < \gamma\}$. *If* $w_0 \in H^2(K)$, *then for every* $\bar{t} > 0$ *such that* $K \times [0, \bar{t}] \subset \{(x,t) : |w(x,t)| < \gamma\}$,

$$w \in L^\infty((0,\bar{t}); H^2(K)) \cap C^{1+\frac{1}{2}}(K \times [0,\bar{t}]).$$

(Here $H^2(K)$ is the Sobolev space containing the functions $u \in L^2(K)$ such that the generalized derivatives of u of first- and second-order belong to $L^2(K)$.)

Proof. Let $\{u_{0\epsilon}\}$ be a sequence of $C^\infty([0,1])$-functions, equibounded in $H^2(K)$, such that $u_{0\epsilon} \to u_0$ in $L^1([0,1])$ as $\epsilon \to 0$. Let u_ϵ be the corresponding solution of problem (I_ϵ), and $w_\epsilon = \psi_\epsilon(u_{\epsilon x}) \to w$ in $C(\overline{Q_T})$ as $\epsilon \to 0$. Thus there exist $\epsilon' > 0$ and $\gamma' \in (0, \gamma)$ such that $|w_\epsilon| \leq \gamma' < \gamma$ in $K \times [0, \bar{t}]$ for every $0 < \epsilon < \epsilon'$. It follows easily from (5.9) and (5.10) that

$$\int_0^{\bar{t}} u_{\epsilon t}^2(x,t)dt \leq \tilde{C}(\gamma') \quad \text{for all } x \in K, \tag{5.14}$$

where $\tilde{C}(\gamma')$ does not depend on $\epsilon \in (0, \epsilon')$.

Multiplying the equation for u_ϵ by $\psi_\epsilon(u_{\epsilon x})_x$ and integrating over $[0, t^*]$, where $t^* \leq \bar{t}$, we obtain for every $x \in K$,

$$\frac{1}{2}\tau\psi_\epsilon(u_{\epsilon x})_x^2(x, t^*) \leq \frac{1}{2}\tau\psi_\epsilon(u_{\epsilon x})_x^2(x, 0) + \left(\frac{1}{2} + k_1\right)\int_0^{t^*} \psi_\epsilon(u_{\epsilon x})_x^2(x,t)dt$$
$$+ \frac{1}{2}\int_0^{\bar{t}} u_{\epsilon t}^2(x,t)dt,$$

where k_1 is defined by (3.1). Combining this integral inequality with (5.14), we find that the functions

$$\psi_\epsilon(u_{\epsilon x})_x \ (0<\epsilon<\epsilon') \quad \text{are uniformly bounded in } K \times [0,\bar{t}]. \tag{5.15}$$

From (5.14) and (5.15) it follows that $\psi_\epsilon(u_{\epsilon x})_x$ are Hölder-continuous with respect to t with exponent $\frac{1}{2}$ uniformly with respect to $x \in K$; indeed, it turns out that

$$\begin{aligned}
&\tau \int_0^{t^*} \psi_\epsilon(u_{\epsilon x})^2_{xt}(x,t)dt \\
&\quad \le \int_0^{t^*} |\varphi_\epsilon(u_{\epsilon x})_x \psi_\epsilon(u_{\epsilon x})_{xt}|(x,t)dt + \int_0^{t^*} |u_{\epsilon t}\psi_\epsilon(u_{\epsilon x})_{xt}|(x,t)dt \\
&\quad \le \frac{1}{2}\tau \int_0^{t^*} \psi_\epsilon(u_{\epsilon x}(x,t))^2_{xt}dt + \frac{1}{\tau}\left(\int_0^{t^*} (\varphi_\epsilon(u_{\epsilon x}(x,t))_x)^2 dt + \int_0^{t^*} (u_{\epsilon t}(x,t))^2 dt\right).
\end{aligned}$$

To complete the proof we derive an estimate for $\psi_\epsilon(u_{\epsilon x})_{xx}$ in $L^2(K)$. For this purpose we consider the equation for $v_\epsilon = u_{\epsilon x}$:

$$v_{\epsilon t} = \varphi_\epsilon(v_\epsilon)_{xx} + \tau\psi_\epsilon(v_\epsilon)_{xxt}. \tag{5.16}$$

Multiplying (5.16) by $\psi_\epsilon(v_\epsilon)_{xx}$ and integrating by parts over $K \times [0,t^*]$, where $0<t^*<\bar{t}$, we have

$$\begin{aligned}
&\tau \int_0^{t^*} \frac{d}{dt}\left(\int_K \tfrac{1}{2}\psi_\epsilon(v_\epsilon)^2_{xx}dx\right) dt \\
&\quad = -\iint_{K\times[0,t^*]} \varphi_\epsilon(v_\epsilon)_{xx}\psi_\epsilon(v_\epsilon)_{xx}dxdt + \iint_{K\times[0,t^*]} v_{\epsilon t}\psi_\epsilon(v_\epsilon)_{xx}dxdt \\
&\quad \le c_1 \iint_{K\times[0,t^*]} \psi_\epsilon(v_\epsilon)^2_{xx}dxdt + c_2 \iint_{K\times[0,\bar{t}]} \psi_\epsilon(v_\epsilon)^4_x dxdt \\
&\qquad + c_3 \iint_{K\times[0,\bar{t}]} \psi'_\epsilon(v_\epsilon)v^2_{\epsilon t}dxdt \\
&\quad \le c_1 \iint_{K\times[0,t^*]} \psi_\epsilon(v_\epsilon)^2_{xx}dxdt + c_4,
\end{aligned}$$

where we have used (5.15), (5.10), and the fact that $\psi'_\epsilon(v_\epsilon)$ is uniformly bounded away from zero in K. It follows at once from this inequality that

$$\psi_\epsilon(v_\epsilon)_{xx} \in L^\infty([0,\bar{t}], L^2(K)),$$

and the proof is complete.

6. Gradient extimates. In this section we shall prove the estimates for u_x given in Theorem 3.2.

Proof of Theorem 3.2(i). It is sufficient to prove that if $u'_{0\epsilon} \ge 0$ in $(0,1)$, the solution u_ϵ of problem (I_ϵ) satisfies the inequality

$$u_{\epsilon x} \ge 0 \quad \text{in } Q_T.$$

The proof is inspired by a method used by Novick-Cohen and Pego [NP]. Let $g : \mathbf{R} \to \mathbf{R}$ be a smooth nondecreasing function such that

$$g(s)\begin{cases} = 0 & \text{if } s \geq 0, \\ < 0 & \text{if } s < 0. \end{cases}$$

Then

$$K_\epsilon(p) := \int_0^p g(\varphi_\epsilon(s))ds\begin{cases} = 0 & \text{if } p \geq 0, \\ > 0 & \text{if } p < 0, \end{cases}$$

and in particular,

$$\int_0^1 K_\epsilon(u'_{0\epsilon})dx = 0.$$

Hence for all $0 < t \leq T$,

$$\begin{aligned}\int_0^1 K_\epsilon(u_{\epsilon x})(x,t)dx &= \iint_{Q_t} g(\varphi_\epsilon(u_{\epsilon x}))u_{\epsilon xt}dxdt \\ &= -\iint_{Q_t} \left(g(\varphi_\epsilon(u_{\epsilon x}) + \tau\psi_\epsilon(u_{\epsilon x})_t) - g(\varphi_\epsilon(u_{\epsilon x}))\right) u_{\epsilon xt}dxdt \\ &\quad + \iint_{Q_t} g(\varphi_\epsilon(u_{\epsilon x}) + \tau\psi_\epsilon(u_{\epsilon x})_t)u_{\epsilon xt}dxdt.\end{aligned}$$

By the mean value theorem, the first term at the right-hand side is nonpositive. Integrating the second integral by parts and using the equation for u_ϵ, we obtain

$$\int_0^1 K_\epsilon(u_{\epsilon x})(x,t)dx \leq -\iint_{Q_t} g'(\varphi_\epsilon(u_{\epsilon x}) + \tau\psi_\epsilon(u_{\epsilon x})_t)u_{\epsilon t}^2 dxdt \leq 0.$$

This implies that $K_\epsilon(u_{\epsilon x}) = 0$ in Q_T and thus $u_{\epsilon x} \geq 0$ in Q_T.

Proof of Theorem 3.2(ii)–(iii). We set

$$z_\epsilon(x,t) = \int_0^x u_\epsilon(y,t)dy, \qquad 0 \leq x \leq 1, t \geq 0, \tag{6.1}$$

where u_ϵ is the solution of problem (I_ϵ). Then

$$z_{\epsilon x} = u_\epsilon \quad \text{in } Q \tag{6.2}$$

and

$$z_{\epsilon t} = \varphi_\epsilon(u_{\epsilon x}) + \tau\psi_\epsilon(u_{\epsilon x})_t \quad \text{in } Q. \tag{6.3}$$

Substituting (6.2) into the latter term of (6.3), we have

$$z_{\epsilon t} - \tau\psi'_\epsilon(u_{\epsilon x})z_{\epsilon txx} = \varphi_\epsilon(u_{\epsilon x}) \quad \text{in } Q. \tag{6.4}$$

By (6.3),

$$z_{\epsilon t}(0,t) = z_{\epsilon t}(1,t) = 0 \quad \text{for } t \geq 0; \tag{6.5}$$

hence, applying for fixed t the maximum principle to the ordinary differential equation (6.4) in x for $z_{\epsilon t}$, we find that

$$z_{\epsilon t} \leq \max_{x\in[0,1]} \varphi_\epsilon(u_{\epsilon x})(x,t) \leq \varphi_\epsilon(\alpha) \quad \text{in } Q.$$

In view of (6.3) this means that

$$\tau\psi_\epsilon(u_{\epsilon x})_t \leq \varphi_\epsilon(\alpha) - \varphi_\epsilon(u_{\epsilon x}) \quad \text{in } Q. \tag{6.6}$$

Fixing $x = x_0$ in (6.6) we obtain an ordinary differential inequality for $u_{\epsilon x}(x_0, t)$, which is uniform with respect to ϵ near the value $u_{\epsilon x} = \alpha$, and Theorem 3.2(ii)–(iii) follows at once.

7. The persistence of discontinuities. In this section we prove that if $u_x(x_0, t_0) = +\infty$ for some (x_0, t_0), then $u_x(x_0, t)$ remains infinite for all $t > 0$. The main idea of the proof is to show that we can reconstruct the solution for $t > t_0$ by solving the problem independently in the sets $(0, x_0) \times (t_0, +\infty)$ and $(x_0, 1) \times (t_0, +\infty)$ if we impose the boundary condition $u_x(x_0, t) = +\infty$ for $t > 0$. This construction reflects the lack of interaction between these two sets across the point $x = x_0$, caused by the strong degeneracy of the equation for infinite gradients; in other words, the vertical line $x = x_0$ is a characteristic of the equation.

Proof of Theorem 3.3. Without loss of generality we may assume that $t_0 = 0$. We consider the problem

$$(\mathrm{III}_\epsilon)\begin{cases} u_t = \varphi_\epsilon(u_x)_x + \tau\psi_\epsilon(u_x)_{xt} & \text{in } (x_0, 1) \times \mathbf{R}^+, \\ u(x, 0) = u_{0\epsilon}(x) & \text{for } x \in (x_0, 1), \\ \psi_\epsilon(u_x(x_0, t)) = \gamma & \text{for } t > 0, \\ \psi_\epsilon(u_x(1, t)) = 0 & \text{for } t > 0. \end{cases}$$

Arguing as in the proof of Theorem 3.1, it follows that problem (III_ϵ) has a unique solution u_ϵ, and that there exists a sequence $\epsilon_n \to 0$ as $n \to \infty$ such that u_{ϵ_n} converges to a solution u of the problem

$$(\mathrm{III})\begin{cases} u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt} & \text{in } (x_0, 1) \times \mathbf{R}^+, \\ u(x, 0) = u_0(x) & \text{for } x_0 < x < 1, \\ \psi(u_x(x_0, t)) = \gamma & \text{for } t > 0, \\ \psi(u_x(1, t)) = 0 & \text{for } t > 0. \end{cases}$$

(The definition of a solution of problem (III) is quite similar to the one of problem (I).)

We claim that the solution of problem (III) has the following property:

$$(7.1) \qquad u(x_0^+, t) \quad \text{is nondecreasing for } t > 0.$$

Before proving this we complete the proof of Theorem 3.3.

In a similar way we solve a corresponding problem for $0 < x < x_0$:

$$(\mathrm{III}')\begin{cases} u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt} & \text{in } (0, x_0) \times \mathbf{R}^+, \\ u(x, 0) = u_0(x) & \text{for } 0 < x < x_0, \\ \psi(u_x(x_0, t)) = \gamma & \text{for } t > 0, \\ \psi(u_x(0, t)) = 0 & \text{for } t > 0, \end{cases}$$

and its solution $\overline{u}(x, t)$ satisfies the property that

$$(7.2) \qquad \overline{u}(x_0^-, t) \quad \text{is nonincreasing in } (0, T].$$

Finally, defining

$$\hat{u}(x, t) = \begin{cases} u(x, t) & \text{if } x_0 < x \le 1, t \ge 0, \\ \overline{u}(x, t) & \text{if } 0 \le x < x_0, t \ge 0, \end{cases}$$

it is easy to show that $\hat{u}$ is the unique solution of problem (I), and the desired result follows from (7.1) and (7.2).

So it remains to prove (7.1).

Let

$$v_\epsilon(x,t) = \int_{x_0}^{x} u_\epsilon(y,t)dy \quad \text{if } x_0 \le x \le 1, t \ge 0 \tag{7.3}$$

and

$$v(x,t) = \int_{x_0}^{x} u(y,t)dy \quad \text{if } x_0 \le x \le 1, t \ge 0. \tag{7.4}$$

Arguing as in the proof of Theorem 3.2(ii)–(iii) and using the boundary conditions at $x=x_0$ and $x=1$, we obtain that $v_{\epsilon t}(\cdot,t)$ satisfies for any $t>0$,

$$\begin{cases} v_{\epsilon t} - \tau\psi_\epsilon'(u_{\epsilon x})v_{\epsilon txx} = \varphi_\epsilon(u_{\epsilon x}) \ge 0 & \text{for } x_0 < x < 1, \\ v_{\epsilon t}(x_0,t) = v_{\epsilon t}(1,t) = 0. \end{cases}$$

Hence $v_\epsilon(x,t)$ and $v(x,t)$ are nondecreasing with respect to t. Since $v(x_0,t)=0$ for $t>0$, this implies that

$$v_x(x_0,t) = u(x_0+,t) \quad \text{is nondecreasing for } t>0,$$

and we have found (7.1).

8. The formation of discontinuities. In this section we shall prove that smooth solutions may develop discontinuities within finite time. The idea of the proof is to start off with a suitable initial function which is discontinuous at some point x_0, to solve the problem backwards in time, and to show that the solution becomes smooth after a finite (negative) time.

Proof of Theorem 3.4. Let $x_0 \in (0, \frac{1}{2})$, and let a, c and δ be small positive parameters such that $c > a\delta$. Then there exists a function u_0 (see Fig. 4) satisfying hypotheses (H3) and (A3) such that

$$\begin{aligned} &u_0 \in C^3([0,1] \setminus \{x_0, 1-x_0\}), \\ &u_0(x_0+) = a, \quad u_0(x_0-) = 0, \quad u(x_0+\delta) = a+c, \\ &u_0(1-x) - u_0(\tfrac{1}{2}) = u_0(\tfrac{1}{2}) - u_0(x) \quad \text{for almost every } 0 < x < 1, \end{aligned}$$

$$u'(x)\begin{cases} > \alpha & \text{if } x_0 < x < x_0+\delta, \\ = \alpha & \text{if } x_0+\delta \le x \le \frac{1}{2}, \end{cases}$$

and

$$u_0''(x) \ge \beta \quad \text{for } 0 \le x < x_0$$

for some $\beta > 0$.

Using the transformation $t \to -t$ and $\varphi(s) \to -\varphi(s)$, we may apply Theorem 3.1 to solve problem (I) backwards in time, i.e., problem (I) has a unique solution $u(x,t)$ for $t<0$. By uniqueness, u has the symmetry of its initial function:

$$u(1-x,t) - u_0(\tfrac{1}{2}) = u_0(\tfrac{1}{2}) - u(x,t) \quad \text{for almost every } 0 < x < 1, t < 0. \tag{8.1}$$

In addition, it easily follows from the continuity of the function w defined by (3.6) and from Theorem 5.3 that there exists a $\underline{t}_0 < 0$ such that $u(x,t)$ is strictly increasing with respect to x in $(0,1) \times [\underline{t}_0, 0)$.

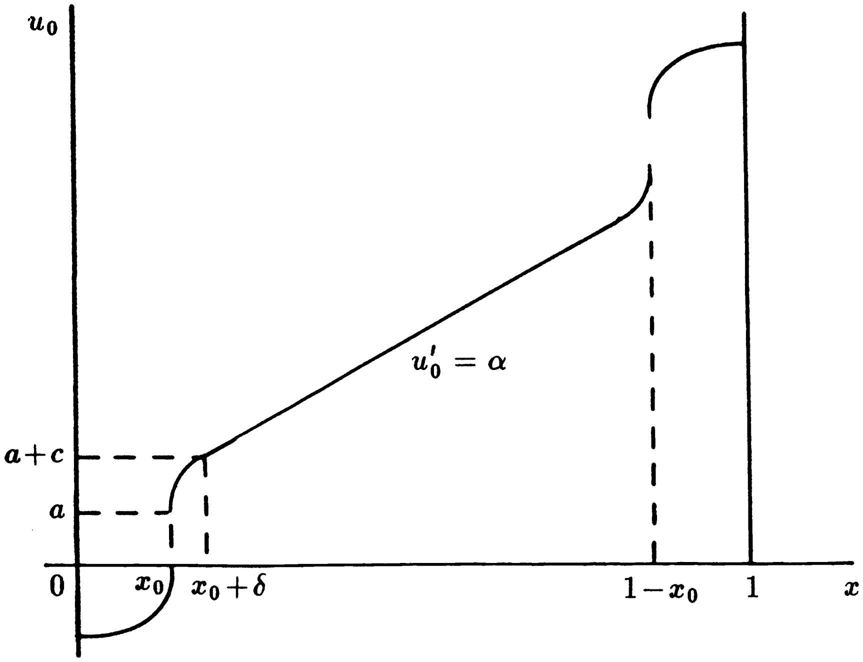

FIG. 4. *The function* u_0 *in the proof of Theorem* 3.4.

We claim that for an appropriate choice of the parameters a, c, and δ, there exists $t_0 \in (\underline{t}_0, 0)$ such that u is smooth at (x_0, t_0). By symmetry, u is also smooth at $(1-x_0, t_0)$; on the other hand it follows from Theorem 3.3 and the smoothness of u_0 that $|u_x(x,t_0)| < +\infty$ in the remaining points (x, t_0). Hence the continuous function $\psi(u_x)$ satisfies $|\psi(u_x)(x,t_0)| < \gamma$ for all $0 \le x \le 1$, and $u(\cdot, t_0) \in C^1([0,1])$. Using $u(\cdot, t_0)$ as the initial function of problem (I) forwards in time, we obtain Theorem 3.4.

It remains to prove our claim. Arguing by contradiction, we may suppose that the function $w(x,t)$, defined in(3.6), satisfies

$$w(x_0,t) = w(1-x_0,t) = \gamma \quad \text{for all } t < 0.$$

Hence the function $u(x,t)$, restricted to the set $[x_0, 1-x_0] \times (-\infty, 0]$, is a solution of the problem

$$\text{(IV)}\begin{cases} u_t = \varphi(u_x)_x + \tau\psi(u_x)_{xt} & \text{for } x_0 < x < 1-x_0, t < 0, \\ \psi(u_x(x_0,t)) = \psi(u_x(1-x_0,t)) = \gamma & \text{for } t < 0, \\ u(x,0) = u_0(x) & \text{for } x_0 < x < 1-x_0. \end{cases}$$

It is not difficult to adapt the proof in §5 to show the uniqueness of the solution of problem (IV).

It follows from Theorem 3.2(iii) that

$$\text{(8.2)} \qquad u_x(x,t) \ge \alpha \quad \text{for almost every } x_0 < x < 1-x_0, t < 0,$$

and Theorem 3.3 implies that

$$\text{(8.3)} \qquad u(x_0+,t) \ge u(x_0-,t) \ge u_0(x_0-) = 0$$

and

$$u((1-x_0)-,t) \le u((1-x_0)+,t) \le u_0((1-x_0)+) \le 2(a+c)+\alpha(1-2x_0). \tag{8.4}$$

Combining (8.2), (8.3), and (8.4) we have that

$$\alpha(x-x_0) \le u(x,t) \le 2(a+c)+\alpha(x-x_0) \quad \text{for almost every } x_0 < x < 1-x_0, t<0. \tag{8.5}$$

The solution of problem (IV) may be approximated by the solution u_ϵ of the problem

$$(\mathrm{IV}_\epsilon)\begin{cases} u_t = \varphi_\epsilon(u_x)_x + \tau\psi_\epsilon(u_x)_{xt} & \text{for } x_0 < x < 1-x_0, t<0, \\ \psi_\epsilon(u_x(x_0,t)) = \psi_\epsilon(u_x(1-x_0,t)) = \gamma & \text{for } t<0, \\ u(x,0) = u_{0\epsilon}(x) & \text{for } x_0 < x < 1-x_0, \end{cases}$$

where $u_{0\epsilon}$ is a smooth function which converges uniformly to u_0 in $(x_0, 1-x_0)$ such that $u'_{0\epsilon} \ge \alpha$ in $(x_0, 1-x_0)$.

Let $v_\epsilon(x,t)$ and $v(x,t)$ be defined by (7.3) and (7.4) for $x_0 \le x \le 1-x_0$ and $t \le 0$. By (8.5) we have that for all $x_0 \le x \le 1-x_0$ and $t \le 0$

$$v(x,t)-v(x,0) = \int_{x_0}^{x} (u(s,t)-u_0(s))ds \ge -2(a+c).$$

Since $v_\epsilon \to v$ uniformly on bounded sets as $\epsilon \to 0$, there exists $\epsilon_0 > 0$ such that for all $0<\epsilon<\epsilon_0$,

$$v_\epsilon(x,t)-v_\epsilon(x,0) \ge -3(a+c) \quad \text{for } x_0 \le x \le 1-x_0, -1 \le t \le 0. \tag{8.6}$$

Arguing as in §7, we obtain that

$$v_{\epsilon t} = \tau\psi_\epsilon(u_{\epsilon x})_t + \varphi_\epsilon(u_{\epsilon x}) \quad \text{in } (x_0, 1-x_0) \times (-\infty, 0).$$

Hence

$$v_\epsilon(x,t)-v_\epsilon(x,0) = \tau\psi_\epsilon(u_{\epsilon x}(x,t)) - \tau\psi_\epsilon(u'_{0\epsilon}(x)) - \int_t^0 \varphi_\epsilon(u_{\epsilon x}(x,s))ds,$$

and, by (8.6), for $0<\epsilon<\epsilon_0$

$$\begin{aligned} \tau\psi_\epsilon(u_{\epsilon x}(x,t)) \ge & \tau\psi_\epsilon(\alpha) + \int_t^0 \varphi_\epsilon(u_{\epsilon x}(x,s))ds - 3(a+c) \\ & \text{for } x_0 \le x \le 1-x_0, -1 \le t \le 0. \end{aligned} \tag{8.7}$$

Since $\varphi_\epsilon(s)$ is uniformly bounded away from zero in a neighborhood of $s=\alpha$ for ϵ small enough, it follows from (8.7) that there exist constants $0<\epsilon_1 \le \epsilon_0$, $\underline{t}_0 \le t_0 < 0$ and $C>0$ which do not depend on a, c, and δ such that

$$u_{\epsilon x}(x,t_0) \ge C+\alpha-3(a+c) \quad \text{for } x_0 < x < 1-x_0.$$

Letting $\epsilon \to 0$, we obtain that

$$u_x(x,t_0) \ge C+\alpha-3(a+c) \quad \text{for almost every } x_0 < x < 1-x_0,$$

and, choosing $a+c$ sufficiently small, we obtain a contradiction with (8.5).

9. The convergence to stepwise solutions. In this section we prove the convergence of the solution to a stepwise steady-state as $t \to +\infty$. The first step is rather elementary: integrating the equation with respect to x, we shall use the maximum principle to prove the existence of an asymptotic profile.

More precisely, let z_ϵ be defined by (6.1), and let

$$z(x,t) = \int_0^x u(y,t)dy \quad \text{for } 0 \le x \le 1, t \ge 0.$$

Since $\varphi_\epsilon(u_{\epsilon x}) \ge 0$ in Q, it follows from (6.4) and (6.5) that $z_{\epsilon t} \ge 0$ in Q, and hence

$$z(x,t) \quad \text{is nondecreasing with respect to } t. \tag{9.1}$$

Since u is nondecreasing with respect to x,

$$z(x,t) \quad \text{is convex with respect to } x, \tag{9.2}$$

and since $z(0,t)=0$ and $z(1,t)=\int_0^1 u_0(x)dx$ for all $t\ge 0$, it follows from (9.1) and (9.2) that the pointwise limit

$$\overline{z}(x) = \lim_{t\to\infty} z(x,t), \qquad 0 \le x \le 1$$

exists, and

$$\overline{z}(x) \quad \text{is convex in } [0,1].$$

Since $u = z_x$ is uniformly bounded in $[0,1]$,

$$\overline{z} \in W^{1,\infty}((0,1)),$$

and it follows from (9.2) that

$$u(x,t) \to q(x) \equiv \overline{z}'(x) \quad \text{as } t \to \infty \quad \text{for almost every } 0 < x < 1. \tag{9.3}$$

To complete the proof of Theorem 3.5 we have to prove that

$$q'(x) = 0 \quad \text{for almost every } 0 < x < 1, \tag{9.4}$$

which is the second step of the proof. The fact that $q(x)$ is nonconstant if u has a discontinuity at some point (x_0, t_0) follows at once from (3.9).

We observe that, formally, (9.4) follows if we prove that $\varphi(q(x))=0$ for all x, i.e., that $q(x)$ is a solution of the steady-state problem

$$\begin{cases} \varphi(q')' = 0 & \text{in } (0,1), \\ q'(0) = q'(1) = 0. \end{cases}$$

Below we shall make this argument precise.

Integrating (6.3) with respect to t, we obtain that for any $t_1 > t_0 \ge 0$ and $0 < x < 1$,

$$z_\epsilon(x,t_1) - \tau\psi_\epsilon(u_{\epsilon x}(x,t_1)) = z_\epsilon(x,t_0) - \tau\psi_\epsilon(u_{\epsilon x}(x,t_0)) + \int_{t_0}^{t_1} \varphi_\epsilon(u_{\epsilon x}(x,t))dt.$$

Since $z_\epsilon \to z$ and $\psi_\epsilon(u_{\epsilon x}) \to w$ uniformly on bounded sets as $\epsilon \to 0$, we have that for any $t_1 > t_0 \geq 0$ and $0 < x < 1$,

$$z(x,t_1) - \tau w(x,t_1) = z(x,t_0) - \tau w(x,t_0) + \int_{t_0}^{t_1} h(w(x,t))dt, \tag{9.5}$$

where h is defined by (3.4).

Since $h(w) \geq 0$, $0 \leq w \leq \gamma$, and $z \to \overline{z}$ as $t \to \infty$, we may define

$$\overline{w}(x) = \lim_{t\to\infty} w(x,t) \quad \text{for } 0 \leq x \leq 1.$$

We observe that this implies that

$$w(\cdot,t) \to \overline{w} \quad \text{in } L^1((0,1)) \quad \text{as } t \to \infty, \tag{9.6}$$

and

$$\int_0^\infty h(w(x,s))ds \quad \text{is uniformly bounded in } (0,1).$$

In particular, since for all $0<x<1$ and $t>0$,

$$\int_t^{t+1} h(w(x,s))ds = z(x,t+1) - z(x,t) - \tau w(x,t+1) + \tau w(x,t),$$

we find in the limit $t \to \infty$ that

$$h(\overline{w}(x)) = 0 \quad \text{for all } 0 < x < 1,$$

which implies that the function $\overline{w}$ assumes only the values 0 or γ.

Let $\epsilon > 0$. Because of (9.6), and since $z(\cdot,t) \to \overline{z}$ uniformly in $(0,1)$, there exists $t_\epsilon > 0$ such that $t_\epsilon \to \infty$ as $\epsilon \to 0$,

$$0 \leq \overline{z} - z(\cdot,t) < \epsilon\tau \quad \text{in } (0,1) \quad \text{for } t \geq t_\epsilon, \tag{9.7}$$

and

$$\text{measure } \{x \in (0,1) : |w(x,t) - \overline{w}(x)| \geq \epsilon\} < \epsilon \quad \text{for } t \geq t_\epsilon. \tag{9.8}$$

We assume for the moment that

$$\overline{w} = 0 \quad \text{almost everywhere in } (0,1). \tag{9.9}$$

Defining the open set

$$U_\epsilon = \{x \in (0,1) : w(x,t_\epsilon) < \epsilon\},$$

it follows from (9.8) and (9.9) that

$$\text{measure } U_\epsilon > 1 - \epsilon.$$

We claim that

$$q' \leq \psi^{-1}(2\epsilon) \quad \text{in } U_\epsilon. \tag{9.10}$$

In view of the arbitrariness of ϵ, this completes the proof of (9.4).

It follows from (9.5) that for all $t > t_\epsilon$ and $0 \le x \le 1$,

$$\tau w(x,t) = \tau w(x,t_\epsilon) + (z(x,t) - \overline{z}(x)) - (z(x,t_\epsilon) - \overline{z}) - \int_{t_\epsilon}^{t} h(w(x,s))ds,$$

and thus, by (9.7), the positivity of $h(w)$ and the definition of U_ϵ,

$$w(x,t) \le 2\epsilon \quad \text{in } U_\epsilon \quad \text{for } t > t_\epsilon.$$

It follows from the relation $w = \psi(u_x)$ in the set where $w < \gamma$ that

$$u_x(x,t) < \psi^{-1}(2\epsilon) \quad \text{for } x \in U_\epsilon \quad \text{and} \quad t > t_\epsilon.$$

Since U_ϵ is an open subset of $(0,1)$, this implies (9.10).

It remains to prove (9.9). We argue by contradiction, and suppose that the set

$$S = \{x \in (0,1) : \overline{w}(x) = \gamma\}$$

has positive measure. Since

$$\tau w(x,t) = \tau \overline{w}(x) + z(x,t) - \overline{z}(x) + \int_{t}^{\infty} h(w(x,s))ds$$

and $z(\cdot,t) \to \overline{z}$ uniformly in $(0,1)$ as $t \to \infty$, for any $\delta > 0$ there exists a $t_\delta > 0$ such that

$$w(x,t) \ge \gamma - \delta \quad \text{for } x \in S \quad \text{and} \quad t > t_\delta.$$

Since

$$w(x,t) = \lim_{\epsilon \to 0} \psi_\epsilon(u_{\epsilon x}) \quad \text{uniformly on bounded sets,}$$

a straightforward integration of $u_{\epsilon x}$ yields that

$$u(1,t) - u(0,t) \ge \psi^{-1}(\gamma - \delta)|S|.$$

Since the choice of $\delta > 0$ is arbitrary and $\psi^{-1}(\gamma - \delta) \to \infty$ as $\delta \to 0$, we obtain a contradiction with the boundedness of u.

To conclude the paper, we observe that it follows easily from Theorem 3.3 about the persistence of discontinuities, that the (infinitely many) piecewise constant steady-states are all locally stable (for example, in $L^\infty(0,1)$ or in $BV(0,1)$), and therefore the asymptotic profile will strongly depend on the initial function u_0.

We conjecture that the asymptotic profile also depends on the value of the relaxation time τ. More precisely, we guess that, given an initial function which has supercritical gradient in some subinterval, the number of discontinuities of the corresponding asymptotic profile may become arbitrarily large as $\tau \to 0$. Some numerical evidence for this conjecture can be found in [BBdPPU].

Acknowledgments. The authors wish to express their sincere thanks to the Institute of Mathematics and its Applications, University of Minnesota, Minneapolis, where this paper was started. The coordinating role of Professor Shoshana Kamin is warmly appreciated.

ON A TRANSMISSION BOUNDARY-VALUE PROBLEM FOR THE TIME-HARMONIC MAXWELL EQUATIONS WITHOUT DISPLACEMENT CURRENTS*

MARTIN REISSEL†

Abstract. This paper considers a transmission boundary-value problem for the time-harmonic Maxwell equations neglecting displacement currents. The usual transmission conditions, which require the continuity of the tangential components of the electric and magnetic fields across boundaries, are slightly modified. For this new problem, it is shown that the uniqueness of the solution depends on the topological properties of the domains under consideration. Finally, existence results are obtained by using a boundary integral equation approach.

Key words. time-harmonic Maxwell equations, existence and uniqueness, integral equation methods

AMS subject classifications. 35Q60, 45F99, 78A25

1. Introduction. Many problems in electrical engineering lead to transmission boundary-value problems for the time-harmonic Maxwell equations. A standard problem of this type is shown in Fig. 1. One considers a bounded domain $G^E \subset \mathbb{R}^3$ of conducting material which is surrounded by an isolator (usually air). In the interior of the unbounded domain $G^L := \mathbb{R}^3 \backslash \bar{G}^E$ a time-harmonic current density $\widetilde{J}_e(x,t) = J_e(x)e^{-i\omega t}$ is given. We are now interested in the currents induced in G^E by $\widetilde{J}_e$. This leads to the classical transmission boundary-value problem for the time-harmonic Maxwell equations

$$
\begin{aligned}
&\left.\begin{aligned}\operatorname{curl} H^L &= J_e - i\omega\varepsilon^L E^L\\ \operatorname{curl} E^L &= i\omega\mu^L H^L\end{aligned}\right\} \quad \text{in } G^L,\\
&\left.\begin{aligned}\operatorname{curl} H^E &= (\sigma^E - i\omega\varepsilon^E)E^E\\ \operatorname{curl} E^E &= i\omega\mu^E H^E\end{aligned}\right\} \quad \text{in } G^E,\\
&\left.\begin{aligned}n \wedge H^L &= n \wedge H^E\\ n \wedge E^L &= n \wedge E^E\end{aligned}\right\} \quad \text{on } \partial G^E,
\end{aligned}
\tag{1}
$$

with the Silver–Müller radiation condition

$$
H^L \wedge \frac{x}{|x|} - E^L = o\left(\frac{1}{|x|}\right)
$$

uniformly for $|x| \to \infty$.

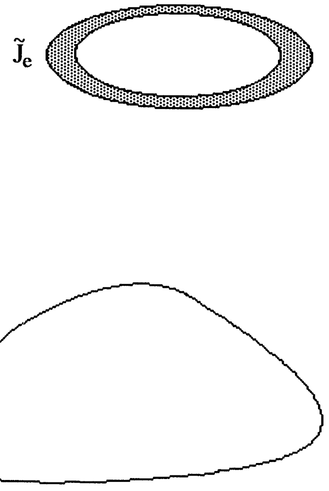

FIG. 1

The different constants have the following meaning:

$\omega \geq 0$	frequency,
$\varepsilon^L, \varepsilon^E > 0$	electric permittivity in G^L, G^E,
$\mu^L, \mu^E > 0$	magnetic permeability in G^L, G^E,
$\sigma^E > 0$	electric conductivity in G^E.

Under certain assumptions on the regularity of J_e and the smoothness of the boundary Γ, which separates the domains G^L and G^E, existence and uniqueness of solutions H^L, E^L, H^E, E^E of (1) can be shown [7], [9].

Dealing with problems in connection with machines working at power frequencies, equations (1) are modified. Since the frequency ω is very small, displacement currents are usually neglected, which means that ε^L and ε^E are set to zero in (1). Moreover, the transmission and radiation conditions are changed. The continuity of the tangential components of the electric field across Γ is substituted by the condition $n \cdot (\mu^L H^L) = n \cdot (\mu^E H^E)$ on Γ, n being the outer normal to G^E. In addition, the Silver–Müller radiation condition is replaced by $H^L(x) = o(1)$, $E^L(x) = o(1)$ uniformly for $|x| \to \infty$. All these modifications together yield our new problem as follows.

$$\left.\begin{aligned} \operatorname{curl} H^L &= J_e \\ \operatorname{curl} E^L &= i\omega\mu^L H^L \end{aligned}\right\} \text{ in } G^L, \qquad \left.\begin{aligned} \operatorname{curl} H^E &= \sigma^E E^E \\ \operatorname{curl} E^E &= i\omega\mu^E H^E \end{aligned}\right\} \text{ in } G^E,$$

$$\text{(2)} \qquad \left.\begin{aligned} n \wedge H^E &= n \wedge H^L \\ n \cdot (\mu^E H^E) &= n \cdot (\mu^L H^L) \end{aligned}\right\} \text{ on } \Gamma,$$

$$H^L(x) = o(1), \qquad E^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty.$$

As we will see, uniqueness results for (2) will strongly depend on the topology of G^L respectively, G^E. In §4 we will show existence for (2), and the set of all possible solutions will be completely characterized.

2. Preliminaries. Before we start with the existence and uniqueness proof, we want to give a detailed description of the problem.

Let $C(G)(C^k(G)$ respectively, $C^{0\alpha}(G)$, $0 < \alpha < 1)$ denote the space of continuous (k times continuously differentiable respectively, Hölder continuous) functions on G.

$G^E \subset \mathbb{R}^3$ is an open, bounded domain with C^2 boundary. The complement $G^L = \mathbb{R}^3 \backslash \bar{G}^E$ should be connected ($\bar{G}^E$ denotes the closure of G^E). G^E is the union of m connected components $G_j^E, j = 1, \dots, m$ having the topological genus p_j. The boundaries $\Gamma_j = \partial G_j^E$ are closed surfaces, which should be disjoint. Setting $\Gamma = \bigcup_{j=1}^m \Gamma_j$ we get $\Gamma = \partial G^E = \partial G^L$.

The topological genus of G^E, respectively G^L, is $p = \sum_{j=1}^m p_j$. There exist p surfaces $\sum_i^E \subset G^E$, respectively, $\sum_i^L \subset G^L$, $i = 1, \dots, p$, such that $G^E \backslash \bigcup_{i=1}^p \sum_i^E$, respectively, $G^L \backslash \bigcup_{i=1}^p \sum_i^L$ are simply connected. The boundary curves $\gamma_i^L = \partial \sum_i^E$ and $\gamma_i^E = \partial \sum_i^L$ lie on Γ.

Example. Let G^E be a torus. In this case we have $m = p = 1$. The surfaces $\sum_1^E, \sum_1^L$ and the curves γ_1^L, γ_1^E are shown in Fig. 2.

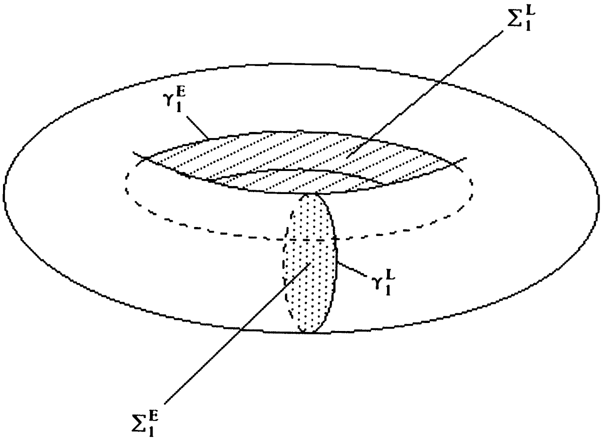

FIG. 2

The problem to be solved is now defined as: for $J_e \in C^1(\mathbb{R}^3)$, div $J_e = 0$, supp$(J_e) \subset G^J$, $\bar{G}^J \subset G^L$ bounded, find $H^L, E^L \in C^1(G^L) \cap C(\bar{G}^L)$, $H^E, E^E \in C^1(G^E) \cap C(\bar{G}^E)$, solving

$$(3) \qquad \begin{array}{c} \operatorname{curl} H^L = J_e \\ \operatorname{curl} E^L = i\omega\mu^L H^L \end{array} \text{ in } G^L, \qquad \begin{array}{c} \operatorname{curl} H^E = \sigma^E E^E \\ \operatorname{curl} E^E = i\omega\mu^E H^E \end{array} \text{ in } G^E,$$

$$\begin{aligned} n \wedge H^E &= n \wedge H^L \\ n \cdot (\mu^E H^E) &= n \cdot (\mu^L H^L) \end{aligned} \qquad \text{on } \Gamma, \tag{4}$$

$$H^L(x) = o(1), \qquad E^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty. \tag{5}$$

3. Uniqueness. Taking a closer look at (3)–(5), it becomes obvious that we cannot expect uniqueness for all four fields because adding the gradient of a suitably chosen function to E^L does not change anything in (3)–(5). Therefore, if we talk about uniqueness in the sequel, we only mean uniqueness of the fields H^L, H^E, and E^E.

THEOREM 1. *For problem* (3)–(5), *together with the additional condition*

$$\int_{\gamma_i^L} \tau \cdot H^L dl = h_i^L, \qquad i = 1, \ldots, p, \tag{6}$$

$h_i^L \in \mathbb{C}$ *given,* τ *being the unit tangent to* γ_i^L, *the fields* H^L, H^E, E^E *are uniquely determined.*

Proof. We consider the homogeneous problem with $J_e = 0$ and $h_i^L = 0, i = 1, \ldots, p$. We show that the fields H^L, H^E, E^E vanish identically.

From the first transmission condition $n \wedge H^E = n \wedge H^L$ on Γ, we get, with the help of the Gaussian theorem,

$$\begin{aligned} \int_\Gamma n \cdot (\bar{H}^L \wedge E^E) ds &= \int_\Gamma n \cdot (\bar{H}^E \wedge E^E) ds \\ &= \int_{G^E} (\sigma^E E^E \cdot \bar{E}^E - i\omega\mu^E H^E \cdot \bar{H}^E) dv, \end{aligned} \tag{7}$$

where $\bar{F}$ denotes the complex conjugate of the field F.

G^E and G^L were defined to have topological genus p. In this case, it is well known [6] that there exist p linear independent Neumann fields Z_i^E respectively, Z_i^L, $i = 1, \ldots, p$, in G^E respectively, G^L, fulfilling

$$\text{curl } Z_i^E = 0, \quad \text{div } Z_i^E = 0 \quad \text{in } G^E, \quad n \cdot Z_i^E = 0 \quad \text{on } \Gamma,$$

$$\text{curl } Z_i^L = 0, \quad \text{div } Z_i^L = 0 \quad \text{in } G^L, \quad n \cdot Z_i^L = 0 \quad \text{on } \Gamma,$$

$$\int_{\gamma_i^L} \tau \cdot Z_j^L dl = \delta_{ij}, \quad \int_{\gamma_i^E} \tau \cdot Z_j^L dl = 0, \quad \int_{\gamma_i^E} \tau \cdot Z_j^E dl = \delta_{ij}, \quad \int_{\gamma_i^L} \tau \cdot Z_j^E dl = 0,$$

and

$$Z_i^L(x) = O\left(\frac{1}{|x|^2}\right),$$

uniformly for $|x| \to \infty$. As a consequence of the regularity assumptions on G^E and G^L we get

$$Z_i^E \in C^\infty(G^E) \cap C^{0\alpha}(\bar{G}^E), \qquad Z_i^L \in C^\infty(G^L) \cap C^{0\alpha}(\bar{G}^L).$$

Using the second transmission condition $n \cdot (\mu^L H^L) = n \cdot (\mu^E H^E)$ on Γ, we conclude that for any surface element $S \subset \Gamma$ we have

$$\int_{\partial S} \tau \cdot (E^E - E^L)dl = \int_S n \cdot \text{curl }(E^E - E^L)ds = i\omega \int_S n \cdot (\mu^E H^E - \mu^L H^L)ds = 0.$$

But this means that the tangential components of $E^E - E^L$ on Γ are of the form

$$(E^E - E^L)\big|_{\text{tan}} = \text{Grad } \varphi + \sum_{j=1}^{p} e_j^L Z_j^L + \sum_{j=1}^{p} e_j^E Z_j^E,$$

where Grad φ denotes the surface gradient of φ on Γ and $e_i^L, e_i^E \in \mathbb{C}, i = 1, \dots, p$, are complex numbers.

In complete analogy, we derive from

$$\text{curl } H^L = 0 \quad \text{in } G^L, \qquad \int_{\gamma_i^L} \tau \cdot H^L dl = 0, \quad i = 1, \dots, p,$$

that we can write the tangential components of H^L as a surface gradient

$$H^L\big|_{\text{tan}} = \text{Grad } \psi.$$

Putting $(E^E - E^L)|_{\text{tan}}$ and $H^L|_{\text{tan}}$ in (7), we arrive at

$$\int_\Gamma n \cdot (\bar{H}^E \wedge E^E)ds = \int_\Gamma n \cdot (\bar{H}^L \wedge E^E)ds$$

$$= \int_\Gamma n \cdot \left(\text{Grad } \bar{\psi} \wedge \left(E^L + \text{Grad } \varphi + \sum_{i=1}^{p} e_i^L Z_i^L + \sum_{i=1}^{p} e_i^E Z_i^E\right)\right) ds.$$

Applying Stokes's theorem to the terms on the right-hand side, we deduce

$$\int_\Gamma n \cdot (\text{Grad } \bar{\psi} \wedge \text{Grad } \varphi)ds = 0,$$

$$\int_\Gamma n \cdot (\text{Grad } \bar{\psi} \wedge Z_i^L)ds = 0,$$

$$\int_\Gamma n \cdot (\text{Grad } \bar{\psi} \wedge Z_i^E)ds = 0,$$

and therefore,

$$\int_\Gamma n \cdot (\bar{H}^E \wedge E^E)ds = \int_\Gamma n \cdot (\bar{H}^L \wedge E^L)ds. \tag{8}$$

Let us now consider $G^R = G^L \cap B^R, B^R := \{x | x \in \mathbb{R}^3, |x| \leq R\}$. For large enough R, we get, by using the Gaussian theorem,

$$\int_{\partial B^R} \frac{x}{|x|} \cdot (\bar{H}^L \wedge E^L)ds - \int_\Gamma n \cdot (\bar{H}^L \wedge E^L)ds = \int_{\partial G^R} n' \cdot (\bar{H}^L \wedge E^L)ds$$

$$= -i\omega\mu^L \int_{G^R} H^L \cdot \bar{H}^L dv,$$

n' being the outer normal to G^R.

Together with (7) and (8) this means

$$\begin{aligned}&-i\omega\mu^L \int_{G^R} H^L \cdot \bar{H}^L dv \\ (9) \qquad &+ \int_{G^E} (\sigma^E E^E \cdot \bar{E}^E - i\omega\mu^E H^E \cdot \bar{H}^E) dv = \int_{\partial B^R} \frac{x}{|x|} \cdot (\bar{H}^L \wedge E^L) ds.\end{aligned}$$

For H^L we have

$$\operatorname{curl} H^L = 0, \quad \operatorname{div} H^L = 0 \quad \text{in } G^L, \quad H^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty.$$

Therefore, H^L is a harmonic vector field in G^L tending to zero for $|x| \to \infty$ and thus [6]

$$H^L(x) = O\left(\frac{1}{|x|^2}\right), \quad \text{uniformly for } |x| \to \infty.$$

From $E^L(x) = o(1)$ uniformly for $|x| \to \infty$ we get

$$\left|\frac{x}{|x|} \cdot (\bar{H}^L \wedge E^L)\right| = o\left(\frac{1}{R^2}\right) \quad \text{on } \partial B^R, \quad R \to \infty$$

and

$$\int_{\partial B^R} \frac{x}{|x|} \cdot (\bar{H}^L \wedge E^L) ds = o(1) \quad \text{for } R \to \infty.$$

Taking the limit $R \to \infty$, (9) yields

$$\sigma^E \int_{G^E} E^E \cdot \bar{E}^E dv - i\omega \left(\mu^E \int_{G^E} H^E \cdot \bar{H}^E dv + \mu^L \int_{G^L} H^L \cdot \bar{H}^L dv\right) = 0.$$

Since $\omega, \sigma^E, \mu^L, \mu^E$ are real and positive constants, we conclude

$$H^L \equiv 0, \quad E^E \equiv 0, \quad H^E \equiv 0. \qquad \square$$

Remark. The free parameters h_i^L in (6), which are the circulations of H^L along the curves γ_i^L, are later on used to characterize the different solutions of (3)–(5).

4. Existence. To establish existence results for (3)–(5) we consider the following auxiliary problem.

Find $H^L \in C^1(G^L) \cap C(\bar{G}^L)$,

$$H^E \in C^2(G^E) \cap C(\bar{G}^E), \quad \operatorname{div} H^E \in C(\bar{G}^E), \quad \operatorname{curl} H^E \in C(\bar{G}^E)$$

solving

$$\left.\begin{aligned}\operatorname{curl} H^L &= 0 \\ \operatorname{div} H^L &= 0\end{aligned}\right\} \text{in } G^L, \qquad \left.\begin{aligned}(\Delta + k^2) H^E &= 0 \\ k^2 &= i\omega\sigma^E\mu^E\end{aligned}\right\} \text{in } G^E,$$

$$(10)\qquad \begin{aligned} n \wedge H^E - n \wedge H^L &= c \\ n \cdot (\mu^E H^E) - n \cdot (\mu^L H^L) &= g \quad \text{on } \Gamma, \\ \operatorname{div} H^E &= d \end{aligned}$$

$$\int_{\gamma_i^L} \tau \cdot H^L dl = 0, \qquad i = 1, \ldots, p,$$

$$H^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty.$$

For k we choose the square root with positive imaginary part.

In this chapter we show that (10) is uniquely solvable for sufficiently smooth data c, g, d. Moreover, we describe how all solutions of (3)–(5) can be constructed by using the solvability of the auxiliary problem (10).

By the following lemma [8], the uniqueness of (10) can be reduced to the uniqueness theorem given in the last chapter.

LEMMA 1. *Let* $H \in C^1(G^L) \cap C(\bar{G}^L)$, $H(x) = O(1/|x|^{1+\beta})$, $|x| \to \infty$, $0 < \beta < 2$, *satisfying* div $H = 0$ *in* G^L. *If we have*

$$\int_{\Gamma_j} n \cdot H \, ds = 0, \qquad j = 1, \ldots, m$$

for any connected component Γ_j *of* Γ, *there exists a field, field* $E \in C^1(G^L) \cap C(\bar{G}^L)$, *such that*

$$\operatorname{curl} E = i\omega\mu^L H, \qquad \operatorname{div} E = 0 \quad \text{in } G^L,$$

$$E(x) = O\left(\frac{1}{|x|^\beta}\right), \quad \text{uniformly for } |x| \to \infty.$$

THEOREM 2. *Problem* (10) *has at most one solution.*

Proof. We consider (10) with homogeneous data $c = 0$, $g = 0$, $d = 0$. Since H^E is a solution of the vector Helmholtz equation with wave number k in G^E, the divergence of H^E solves the scalar Helmholtz equation with the same wave number k in G^E. From div $H^E|_\Gamma = d = 0$ and $\operatorname{Im}(k) > 0$ it follows that div H^E vanishes identically in G^E [1]. Using the identity curl curl = grad div $-\Delta$ and defining E^E by $E^E = 1/\sigma^E$ curl H^E, we conclude that H^E, E^E are solutions of the Maxwell equations in G^E.

On the other hand, H^L is a harmonic vector field in G^L, satisfying $H^L(x) = o(1)$ uniformly for $|x| \to \infty$. Therefore, we immediately get $H^L(x) = O\left(1/|x|^2\right)$ uniformly for $|x| \to \infty$. In addition to this, we deduce from the transmission conditions of (10)

$$\mu^L \int_{\Gamma_j} n \cdot H^L ds = \int_{\Gamma_j} n \cdot (\mu^L H^L) ds = \int_{\Gamma_j} n \cdot (\mu^E H^E) ds$$

$$= \frac{1}{i\omega} \int_{\Gamma_j} n \cdot (i\omega\mu^E H^E) ds = \frac{1}{i\omega} \int_{\Gamma_j} n \cdot \operatorname{curl} E^E ds = 0.$$

Applying Lemma 1 with $\beta = 1$ to H^L proves the existence of a field E^L defined in G^L, having the following properties:

$$\text{curl } E^L = i\omega\mu^L H^L \quad \text{in } G^L,$$

$$E^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty.$$

Thus we have shown that H^L, E^L, H^E, E^E solve the homogeneous equations (3)–(5) with vanishing circulations

$$\int_{\gamma_i^L} \tau \cdot H^L dl = 0.$$

Now, from Theorem 1 we conclude $H^L \equiv 0$, $H^E \equiv 0$. □

Before we start with the existence proof for (10), we have to introduce some notation.

Definition. Let $0 < \alpha < 1$.

$$C^{0\alpha}(G), \qquad \|u\|_{0\alpha,G} = \sup_{x\in G} |u(x)| + \sup_{\substack{x\neq y\\ x,y\in G}} \frac{|u(x)-u(y)|}{|x-y|^\alpha},$$

is the space of Hölder-continuous functions on G.

$$V^{0\alpha}(\Gamma) = (C^{0\alpha}(\Gamma))^3, \qquad \|a\|_{V\alpha,\Gamma} = \max_{i=1,2,3}(\|a_i\|_{0\alpha,\Gamma}),$$

is the space of Hölder-continuous vector fields on Γ.

$$T^{0\alpha}(\Gamma) = \{a \in V^{0\alpha}(\Gamma) | n \cdot a = 0\}, \qquad \|a\|_{T\alpha,\Gamma} = \|a\|_{V\alpha,\Gamma},$$

is the space of Hölder-continuous tangential fields on Γ.

$$T_d^{0\alpha}(\Gamma) = \{a \in T^{0\alpha}(\Gamma) | \text{Div } a \in C^{0\alpha}(\Gamma)\}, \qquad \|u\|_{d\alpha,\Gamma} = \max(\|u\|_{T\alpha,\Gamma}, \|\text{Div } u\|_{0\alpha,\Gamma}),$$

is the space of Hölder-continuous tangential fields on Γ having Hölder-continuous surface divergence.

$$X_d^{0\alpha}(\Gamma) = T_d^{0\alpha}(\Gamma) \times C^{0\alpha}(\Gamma) \times C^{0\alpha}(\Gamma),$$

$$\|u\|_{X_{d\alpha}} = \max(\|u_1\|_{d\alpha,\Gamma}, \|u_2\|_{0\,\alpha\Gamma}, \|u_3\|_{0\alpha,\Gamma}),$$

$$\Phi(x,y) = \frac{1}{4\pi}\frac{e^{ik|x-y|}}{|x-y|}, \qquad \Phi_0(x,y) = \frac{1}{4\pi}\frac{1}{|x-y|}.$$

The spaces $C^{0\alpha}(G)$, $V^{0\alpha}(\Gamma)$, $T^{0\alpha}(\Gamma)$, $T_d^{0\alpha}(\Gamma)$, and $X_d^{0\alpha}$ equipped with the corresponding norms are Banach spaces.

Theorem 3. *For any $c \in T_d^{0\alpha}(\Gamma), g \in C^{0\alpha}(\Gamma), d \in C^{0\alpha}(\Gamma)$, problem* (10) *is uniquely solvable. The solution depends continuously on the given data.*

Proof. The proof will be divided into three parts. In the first part, we use a special ansatz for H^L and H^E to transform the transmission boundary-value problem into a boundary integral equation. In the second step, we show that the integral equation is of second kind. Finally we conclude the proof by showing the injectivity of the corresponding integral operator.

The ansatz. We are looking for solutions H^L, H^E of the form

$$\begin{aligned} & H^L(x) = \operatorname{grad}_x \int_\Gamma \lambda(y)\Phi_0(x,y)ds(y), \\ (11) \qquad & H^E(x) = \operatorname{curl}_x \int_\Gamma a(y)\Phi(x,y)ds(y) + \operatorname{grad}_x \int_\Gamma \lambda(y)\Phi(x,y)ds(y) \\ & \qquad + \int_\Gamma n(y)\delta(y)\Phi(x,y)ds(y), \end{aligned}$$

$a \in T_d^{0\alpha}(\Gamma)$, $\lambda \in C^{0\alpha}(\Gamma)$, $\delta \in C^{0\alpha}(\Gamma)$. For H^L, H^E we get [1] and [9]:

$$\text{(i)} \quad \begin{aligned} & H^L \in C^\infty(G^L) \cap C^{0\alpha}(\bar{G}^L), \qquad H^L(x) = O\left(\frac{1}{|x|^2}\right) \quad \text{uniformly for } |x| \to \infty, \\ & \int_{\gamma_i^L} \tau \cdot H^L dl = 0, \qquad i = 1, \dots, p. \end{aligned}$$

$$\text{(ii)} \quad H^E \in C^2(G^E) \cap C^{0\alpha}(\bar{G}^E), \quad \operatorname{div} H^E \in C^{0\alpha}(\bar{G}^E), \quad \operatorname{curl} H^E \in C^{0\alpha}(\bar{G}^E),$$

$$\text{(iii)} \quad \left.\begin{aligned} \operatorname{curl} H^L &= 0 \\ \operatorname{div} H^L &= 0 \end{aligned}\right. \text{ in } G^L, \qquad \left.\begin{aligned} (\Delta + k^2)H^E &= 0 \\ k^2 &= i\omega\sigma^E\mu^E \end{aligned}\right. \text{ in } G^E,$$

$$\text{(iv)} \quad \begin{aligned} & \|H^L\|_{V\alpha,\bar{G}^L} \le c_\alpha \|\lambda\|_{0\alpha,\Gamma}, \\ & \max(\|H^E\|_{V\alpha,\bar{G}^E}, \|\operatorname{div} H^E\|_{0\alpha,\bar{G}^E}) \le c_\alpha \left\| \begin{pmatrix} a \\ \lambda \\ \delta \end{pmatrix} \right\|_{X_{d\alpha}}, \\ & \|\operatorname{curl} H^E\|_{V\alpha,\bar{G}^E} \le c_\alpha \max(\|a\|_{d\alpha,\Gamma}, \|\delta\|_{0\alpha,\Gamma}). \end{aligned}$$

From (i)–(iv) we see that our ansatz meets all the regularity requirements of (10). H^L and H^E depend continuously on a, λ, and δ and solve the required differential equations. Therefore we only have to adjust the boundary values on Γ corresponding to (10).

Defining $F_\pm(x) = \lim_{h\searrow 0} F(x \pm hn(x))$, $x \in \Gamma$, n outer normal to G^E, we get the following jump conditions for both single and double layer potentials and their derivatives [1]:

$$\mathrm{curl}_x \int_\Gamma a(y)\Phi(x,y)ds(y)\Big|_\pm = \int_\Gamma \mathrm{curl}_x(a(y)\Phi(x,y))ds(y) \mp \frac{1}{2}n(x)\wedge a(x),$$

$$\mathrm{grad}_x \int_\Gamma \lambda(y)\Phi(x,y)ds(y)\Big|_\pm = \int_\Gamma \lambda(y)\mathrm{grad}_x\Phi(x,y)ds(y) \mp \frac{1}{2}n(x)\lambda(x),$$

$$\int_\Gamma n(y)\delta(y)\Phi(x,y)ds(y)\Big|_\pm = \int_\Gamma n(y)\delta(y)\Phi(x,y)ds(y),$$

$$\int_\Gamma \lambda(y)\Phi(x,y)ds(y)\Big|_\pm = \int_\Gamma \lambda(y)\Phi(x,y)ds(y),$$

$$\int_\Gamma \delta(y)\partial_{n_y}\Phi(x,y)ds(y)\Big|_\pm = \int_\Gamma \delta(y)\partial_{n_y}\Phi(x,y)ds(y) \pm \frac{1}{2}\delta(x).$$

The jump conditions do not change if we replace Φ by Φ_0 on both sides. Using

$$\begin{aligned}(\mathrm{div}\ H^E)(x) &= \Delta \int_\Gamma \lambda(y)\Phi(x,y)ds(y) + \int_\Gamma \mathrm{div}_x(n(y)\delta(y)\Phi(x,y))ds(y)\\ &= -k^2\int_\Gamma \lambda(y)\Phi(x,y)ds(y) + \int_\Gamma \delta(y)n(y)\cdot\mathrm{grad}_x\Phi(x,y)ds(y)\\ &= -k^2\int_\Gamma \lambda(y)\Phi(x,y)ds(y) - \int_\Gamma \delta(y)\partial_{n_y}\Phi(x,y)ds(y), \qquad x\in G^E,\end{aligned}$$

we deduce

$$H^L_+(x) = \int_\Gamma \lambda(y)\mathrm{grad}_x\Phi_0(x,y)ds(y) - \frac{1}{2}n(x)\lambda(x),$$

$$\begin{aligned}H^E_-(x) = &\int_\Gamma \mathrm{curl}_x(a(y)\Phi(x,y))ds(y) + \frac{1}{2}n(x)\wedge a(x)\\ &+\int_\Gamma \lambda(y)\mathrm{grad}_x\Phi(x,y)ds(y) + \frac{1}{2}n(x)\lambda(x)\\ &+\int_\Gamma n(y)\delta(y)\Phi(x,y)ds(y),\end{aligned}$$

$$\begin{aligned}(\mathrm{div}\ H^E)_-(x) = &-k^2\int_\Gamma \lambda(y)\Phi(x,y)ds(y)\\ &-\int_\Gamma \delta(y)\partial_{n_y}\Phi(x,y)ds(y) + \frac{1}{2}\delta(x).\end{aligned}$$

Introducing the operators

$$(Ma)(x) = 2n(x) \wedge \int_\Gamma \operatorname{curl}_x(a(y)\Phi(x,y))ds(y),$$

$$(Na)(x) = 2n(x) \cdot \int_\Gamma \operatorname{curl}_x(a(y)\Phi(x,y))ds(y),$$

$$(K\lambda)(x) = 2\int_\Gamma \lambda(y)\partial_{n_y}\Phi(x,y)ds(y),$$

$$(K'\lambda)(x) = 2\int_\Gamma \lambda(y)\partial_{n_x}\Phi(x,y)ds(y),$$

$$(S\lambda)(x) = 2\int_\Gamma \lambda(y)\Phi(x,y)ds(y),$$

$$(P\lambda)(x) = 2n(x) \wedge \int_\Gamma n(y)\lambda(y)\Phi(x,y)ds(y),$$

$$(Q\lambda)(x) = 2n(x) \cdot \int_\Gamma n(y)\lambda(y)\Phi(x,y)ds(y),$$

$$(R\lambda)(x) = 2n(x) \wedge \int_\Gamma \lambda(y)\operatorname{grad}_x\Phi(x,y)ds(y),$$

$$(K_0'\lambda)(x) = 2\int_\Gamma \lambda(y)\partial_{n_x}\Phi_0(x,y)ds(y),$$

$$(R_0\lambda)(x) = 2n(x) \wedge \int_\Gamma \lambda(y)\operatorname{grad}_x\Phi_0(x,y)ds(y),$$

we get the following expressions for the boundary values of H^L and H^E:

$$2n(x) \wedge H_+^L(x) = (R_0\lambda)(x),$$

$$2n(x) \wedge H_-^E(x) = (Ma)(x) - a(x) + (R\lambda)(x) + (P\delta)(x),$$

$$2n(x) \cdot (\mu^L H_+^L(x)) = \mu^L((K_0'\lambda)(x) - \lambda(x)),$$

$$2n(x) \cdot (\mu^E H_-^E(x)) = \mu^E((Na)(x) + (K'\lambda)(x) + \lambda(x) + (Q\delta)(x)),$$

$$2(\operatorname{div} H^E)_-(x) = -k^2(S\lambda)(x) + \delta(x) - (K\delta)(x).$$

Thus, we immediately see that solving (10) is equivalent to solving the following integral equation

$$Av = b, \quad A = \begin{pmatrix} M - I & R - R_0 & P \\ \mu^E N & \mu^E(I + K') + \mu^L(I - K_0') & \mu^E Q \\ 0 & -k^2 S & I - K \end{pmatrix},$$

(12)

$$v = \begin{pmatrix} a \\ \lambda \\ \delta \end{pmatrix}, \quad b = 2\begin{pmatrix} c \\ g \\ d \end{pmatrix}.$$

The integral equation (12) is of second kind in $X_d^{0\alpha}(\Gamma)$. According to [1]–[3] and [9] the operators defined above have the following mapping properties

$$M : T^{0\alpha}(\Gamma) \to T^{0\alpha}(\Gamma) \quad \text{respectively, } T_d^{0\alpha}(\Gamma), \qquad N : T_d^{0\alpha}(\Gamma) \to C^{0\alpha}(\Gamma),$$

$$Q, S, K, K', K_0' : C^{0\alpha}(\Gamma) \to C^{0\alpha}(\Gamma), \qquad P : C^{0\alpha}(\Gamma) \to T_d^{0\alpha}(\Gamma),$$

$$R, R_0 : C^{0\alpha}(\Gamma) \to T^{0\alpha}(\Gamma).$$

N, R, R_0 are continuous; $M, Q, S, K, K', K_0', P, R - R_0$ are compact.

Setting

$$F(x) = 2\int_\Gamma \lambda(y)\operatorname{grad}_x \Phi(x,y)ds(y), \qquad \lambda \in C^{0\alpha}(\Gamma), \quad x \in G^E,$$

we get

$$F \in C^2(G^E) \cap C^{0\alpha}(\bar{G}^E),$$

$$\operatorname{curl} F = 0 \quad \text{in } G^E,$$

$$n \wedge F|_\Gamma = R\lambda.$$

According to [1] we deduce

$$\operatorname{Div}(R\lambda) = \operatorname{Div}(n \wedge F) = -n \cdot \operatorname{curl} F|_\Gamma = 0$$

and therefore

$$\|R\lambda\|_{d\alpha,\Gamma} = \|R\lambda\|_{T\alpha,\Gamma}.$$

In the same way we show $\|R_0\lambda\|_{d\alpha,\Gamma} = \|R_0\lambda\|_{T\alpha,\Gamma}$, so that the continuity of R, R_0 and the compactness of $R - R_0$ carry over to the case where we consider R, R_0 as operators mapping $C^{0\alpha}(\Gamma)$ into $T_d^{0\alpha}(\Gamma)$.

Now A is split up into

$$A = B+C, \quad B = \begin{pmatrix} -I & 0 & 0 \\ \mu^E N & (\mu^E+\mu^L)I & 0 \\ 0 & 0 & I \end{pmatrix}, \quad C = \begin{pmatrix} M & R-R_0 & P \\ 0 & \mu^E K' - \mu^L K_0' & \mu^E Q \\ 0 & -k^2 S & -K \end{pmatrix}.$$

From the above considerations we immediately get

$$B, C : X_d^{0\alpha}(\Gamma) \to X_d^{0\alpha}(\Gamma),$$

where B is continuously invertible and C is compact. Therefore (12) is of second kind.

The operator A is injective. Consider a solution

$$v = \begin{pmatrix} a \\ \lambda \\ \delta \end{pmatrix} \in X_d^{0\alpha}(\Gamma)$$

of the homogeneous equation $Av = 0$. Inserting a, λ, δ in (11), the fields H^L and H^E obtained in this way solve the homogeneous problem (10). Corresponding to Theorem 2, they vanish identically. But H^L was defined as

$$H^L(x) = \operatorname{grad}_x \int_\Gamma \lambda(y)\Phi_0(x,y)ds(y)$$

and therefore

$$0 = 2n \cdot H_+^L = 2\int_\Gamma \lambda \partial_{n_x}\Phi_0 ds - \lambda = -(I - K_0')\lambda.$$

Since $G^L = \mathbb{R}^3 \backslash \bar{G}^E$ is connected and unbounded, we get $N(I - K_0') = \{0\}$ [4], so $\lambda = 0$. Using $\lambda = 0$ we obtain from the last component of $Av = b$, $(I - K)\delta = 0$. According to [1], $N(I - K) = \{0\}$ for $\operatorname{Im}(k) > 0$, and thus $\delta = 0$. From the first component of $Av = b$ we get $(I - M)a = 0$, and again $a = 0$ because $N(I - M) = \{0\}$ for $\operatorname{Im}(k) > 0$ [1].

From the above considerations we conclude that our auxiliary problem (10) is equivalent to the integral equation $Av = b$. Since $c \in T_d^{0\alpha}(\Gamma)$, $g \in C^{0\alpha}(\Gamma)$, $d \in C^{0\alpha}(\Gamma)$, the right-hand side b lies in $X_d^{0\alpha}(\Gamma)$. Now A is injective in $X_d^{0\alpha}(\Gamma)$ and therefore, according to the Riesz theory, continuously invertible in $X_d^{0\alpha}(\Gamma)$. So $Av = b$ is solvable for any $b \in X_d^{0\alpha}(\Gamma)$, with v depending continuously on b. If we use the components of v to define H^L, H^E using (11), we get a solution of (10). By

$$\|H^L\|_{V\alpha,\bar{G}^L} \leq c_\alpha \|\lambda\|_{0\alpha,\Gamma},$$

$$\max(\|H^E\|_{V\alpha,\bar{G}^E}, \|\text{div } H^E\|_{0\alpha,\bar{G}^E}) \leq c_\alpha \left\| \begin{pmatrix} a \\ \lambda \\ \delta \end{pmatrix} \right\|_{X_d\alpha},$$

$$\|\text{curl } H^E\|_{V\alpha,\bar{G}^E} \leq c_\alpha \max(\|a\|_{d\alpha,\Gamma}, \|\delta\|_{0\alpha,\Gamma}),$$

we get the continuous dependence of H^L and H^E on the data c, g, d. □

Up to now we have shown the unique solvability of the auxiliary problem (10) for arbitrary $c \in T_d^{0\alpha}(\Gamma)$, $g \in C^{0\alpha}(\Gamma)$, $d \in C^{0\alpha}(\Gamma)$. With the help of this result, we want to prove existence and uniqueness for (3)–(5) under the additional assumption (6) of prescribed circulations for H^L.

LEMMA 2. (i) *Let $G^J \subset G^L$ be defined as above , $\rho \in C^{0\alpha}(\mathbb{R}^3), \mathrm{supp}(\rho) \subset G^J$. Then*

$$u(x) = \int_{G^J} \rho(y)\Phi_0(x,y)dy \in C^2(\mathbb{R}^3),$$

$$u(x) = O\left(\frac{1}{|x|}\right) \qquad \text{grad } u(x) = O\left(\frac{1}{|x|^2}\right), \quad |x| \to \infty.$$

(ii) *Consider $J_e \in C^1(\mathbb{R}^3)$, div $J_e = 0$, supp$(J_e) \subset G^J$. There exist*

$$H^J \in C^1(\mathbb{R}^3), \qquad E^J \in C^1(G^L) \cap C(\bar{G}^L),$$

$$\text{curl } H^J = J_e, \quad \text{div } H^J = 0, \quad H^J(x) = O\left(\frac{1}{|x|^2}\right), \quad \textit{uniformly for } |x| \to \infty,$$

$$\text{curl } E^J = i\omega\mu^L H^J, \quad \text{div } E^J = 0, \quad E^J(x) = O\left(\frac{1}{|x|}\right), \quad \textit{uniformly for } |x| \to \infty.$$

(iii) *Corresponding to the Neumann fields in G^L we have $E_i^Z \in C^1(G^L) \cap C(\bar{G}^L)$,*

$$\text{curl } E_i^Z = i\omega\mu^L Z_i^L, \quad \text{div } E_i^Z = 0, \quad E_i^Z(x) = O\left(\frac{1}{|x|}\right), \quad \textit{uniformly for } |x| \to \infty.$$

Proof. The first part is an easy consequence of some well-known properties of the Newtonian potentials in $\mathbb{R}^3$ [5].

In (ii), we assume $J_e \in C^1(\mathbb{R}^3)$, supp$(J_e) \subset G^J$. Therefore $J_e \in C^{0\alpha}(\mathbb{R}^3)$ and from (i) we get

$$A = \int_{G^J} J_e(y)\Phi_0(x,y)dy \in C^2(\mathbb{R}^3).$$

Defining H^J as $H^J = \text{curl } A \in C^1(\mathbb{R}^3)$, we see that

$$\text{div } H^J = 0, \qquad \text{curl } H^J = \text{curl curl } A = (\text{grad div } - \Delta)A = J_e.$$

Corresponding to (i), the components of H^J behave as $O(1/|x|^2)$ uniformly for $|x| \to \infty$.

Since

$$\int_{\Gamma_j} n \cdot H^J ds = \int_{\Gamma_j} n \cdot \text{curl } A \, ds = 0, \qquad j = 1, \dots, m,$$

we may apply Lemma 1 to H^J (with $\beta = 1$) and get the existence of E^J.

For the last part, we remark that $Z_i^L \in C^1(G^L) \cap C(\bar{G}^L), i = 1, \dots, p$, are harmonic vector fields in G^L satisfying

$$n \cdot Z_i^L = 0 \quad \text{on } \Gamma, \quad Z_i^L = O\left(\frac{1}{|x|^2}\right), \quad \text{uniformly for } |x| \to \infty.$$

Using Lemma 1 again with $\beta = 1$, the proof is completed. □

With the help of Lemma 2, we obtain the main result of this paper.

THEOREM 4. *Consider $J_e \in C^1(\mathbb{R}^3), \operatorname{div} J_e = 0, \operatorname{supp}(J_e) \subset G^J, \bar{G}^J \subset G^L, G^J$ bounded. Under these assumptions, problem (3)–(6) possesses a solution H^L, E^L, H^E, E^E. H^L, H^E, E^E are uniquely determined.*

Proof. Consider H^J, which is given by Lemma 2. Define h_i^J as $h_i^J = \int_{\gamma_i^L} \tau \cdot H^J dl, i = 1, \ldots, p$, and

$$H^Z = \sum_{j=1}^{p} \left(h_j^L - h_j^J\right) Z_j^L,$$

$$c = n \wedge \left(H^J + H^Z\right)\big|_\Gamma,$$

$$g = n \cdot \left(\mu^L \left(H^J + H^Z\right)\right)|_\Gamma = n \cdot \left(\mu^L H^J\right)\big|_\Gamma.$$

From $H^J \in C^1(\mathbb{R}^3)$ we deduce $H^J|_\Gamma \in C^{0\alpha}(\Gamma)$. For the surface divergence of $n \wedge H^J$ on Γ we get, according to [1],

$$\operatorname{Div}\,(n \wedge H^J) = -n \cdot \operatorname{curl} H^J\,|_\Gamma = -n \cdot J_e|_\Gamma = 0$$

because $\operatorname{supp}(J_e) \subset G^J, \bar{G}^J \subset G^L$.

For the Neumman fields Z_i^L holds [6]

$$n \wedge Z_i^L\big|_\Gamma \in C^{0\alpha}(\Gamma), \qquad \operatorname{Div}\,(n \wedge Z_i^L) = -n \cdot \operatorname{curl} Z_i^L\big|_\Gamma = 0,$$

and therefore $c \in T_d^{0\alpha}(\Gamma)$. On the other hand, $H^J \in C^1(\mathbb{R}^3)$ implies $g \in C^{0\alpha}(\Gamma)$. By Theorem 3 there exist unique fields $\widetilde{H}^L$, $\widetilde{H}^E$,

$$\widetilde{H}^L \in C^1(G^L) \cap C(\bar{G}^L),$$

$$\widetilde{H}^E \in C^2(G^E) \cap C(\bar{G}^E), \quad \operatorname{div} \widetilde{H}^E \in C(\bar{G}^E), \quad \operatorname{curl} \widetilde{H}^E \in C(\bar{G}^E),$$

solving

$$\left.\begin{array}{l} \operatorname{curl} \widetilde{H}^L = 0 \\ \operatorname{div} \widetilde{H}^L = 0 \end{array}\right. \text{ in } G^L, \qquad \left.\begin{array}{c} (\Delta + k^2)\widetilde{H}^E = 0 \\ k^2 = i\omega\sigma^E\mu^E \end{array}\right. \text{ in } G^E,$$

$$\begin{array}{r} n \wedge \widetilde{H}^E - n \wedge \widetilde{H}^L = c \\ n \cdot (\mu^E \widetilde{H}^E) - n \cdot (\mu^L \widetilde{H}^L) = g \\ \operatorname{div} \widetilde{H}^E = 0 \end{array} \quad \text{on } \Gamma,$$

$$\int_{\gamma_i^L} \tau \cdot \widetilde{H}^L dl = 0, \qquad i = 1, \ldots, p,$$

$$\widetilde{H}(x) = o(1), \qquad \text{uniformly for } |x| \to \infty.$$

From div $\widetilde{H}^E = 0$ on Γ and $\mathrm{Im}(k) > 0$ we get, in the same way as in the proof of Theorem 2, that $\widetilde{H}^E$ and $\widetilde{E}^E = (1/\sigma^E)\mathrm{curl}\ \widetilde{H}^E$ solve the time-harmonic Maxwell equations in G^E with coefficients μ^E, σ^E, and ω.

$\widetilde{H}^L$ is harmonic in G^L. From the proof of Theorem 3, we know that for $\widetilde{H}^L$ even the stronger condition $\widetilde{H}^L(x) = O(\frac{1}{|x|^2})$ uniformly holds for $|x| \to \infty$. In addition we have

$$\begin{aligned} i\omega\mu^L \int_{\Gamma_j} n \cdot \widetilde{H}^L ds &= i\omega\mu^E \int_{\Gamma_j} n \cdot \widetilde{H}^E ds - i\omega \int_{\Gamma_j} g ds \\ &= \int_{\Gamma_j} n \cdot \mathrm{curl}\ \widetilde{E}^E ds - i\omega\mu^L \int_{\Gamma_j} n \cdot H^J ds \\ &= \int_{\Gamma_j} n \cdot \mathrm{curl}\ \widetilde{E}^E ds - i\omega\mu^L \int_{\Gamma_j} n \cdot \mathrm{curl}\ A\, ds, \qquad j = 1, \ldots, m, \end{aligned}$$

where A is defined in the proof of Lemma 2. Since Γ_j, $j = 1, \ldots, m$ are closed surfaces, we conclude by Stokes's theorem,

$$\int_{\Gamma_j} n \cdot \widetilde{H}^L ds = 0, \qquad j = 1, \ldots, m.$$

Now Lemma 1 guarantees the existence of $\widetilde{E}^L \in C^1(G^L) \cap C(\bar{G}^L)$ with

$$\mathrm{curl}\ \widetilde{E}^L = i\omega\mu^L \widetilde{H}^L \quad \text{in } G^L, \quad \widetilde{E}^L(x) = O\left(\frac{1}{|x|}\right), \quad \text{uniformly for } |x| \to \infty.$$

Summarizing the results obtained for $\widetilde{H}^L$, $\widetilde{E}^L$, $\widetilde{H}^E$, $\widetilde{E}^E$, we have

$$\widetilde{H}^L, \widetilde{E}^L \in C^1(G^L) \cap C(\bar{G}^L), \qquad \widetilde{H}^E, \widetilde{E}^E \in C^1(G^E) \cap C(\bar{G}^E),$$

$$\left.\begin{aligned} \mathrm{curl}\ \widetilde{H}^L &= 0 \\ \mathrm{curl}\ \widetilde{E}^L &= i\omega\mu^L \widetilde{H}^L \end{aligned}\right\} \text{in } G^L, \qquad \left.\begin{aligned} \mathrm{curl}\ \widetilde{H}^E &= \sigma^E \widetilde{E}^E \\ \mathrm{curl}\ \widetilde{E}^E &= i\omega\mu^E \widetilde{H}^E \end{aligned}\right\} \text{in } G^E,$$

$$\left.\begin{aligned} n \wedge \widetilde{H}^E - n \wedge \widetilde{H}^L &= c \\ n \cdot (\mu^E \widetilde{H}^E) - n \cdot (\mu^L \widetilde{H}^L) &= g \end{aligned}\right\} \text{on } \Gamma,$$

$$\int_{\gamma_i^L} \tau \cdot \widetilde{H}^L dl = 0, \qquad i = 1, \ldots, p,$$

$$\widetilde{H}^L(x) = o(1), \quad \widetilde{E}^L(x) = o(1) \quad \text{uniformly for } |x| \to \infty.$$

But in Lemma 2 the existence of E^J, $E^Z \in C^1(G^L) \cap C(\bar{G}^L)$,

$$\mathrm{curl}\ E^J = i\omega\mu^L H^J, \qquad \mathrm{curl}\ E^Z = i\omega\mu^L H^Z,$$

is shown, both behaving uniformly like $o(1)$ for $|x| \to \infty$.

Defining H^L, E^L, H^E, E^E as

$$H^L = \widetilde{H}^L + H^J + H^Z, \quad E^L = \widetilde{E}^L + E^J + E^Z, \quad H^E = \widetilde{H}^E, \quad E^E = \widetilde{E}^E,$$

and using curl $H^J = J_e$, curl $H^Z = 0$, we get

$$\left.\begin{aligned} \operatorname{curl} H^L &= \operatorname{curl}\,(\widetilde{H}^L + H^J + H^Z) = J_e \\ \operatorname{curl} E^L &= \operatorname{curl}\,(\widetilde{E}^L + E^J + E^Z) = i\omega\mu^L H^L \end{aligned}\right. \quad \text{in } G^L,$$

$$\left.\begin{aligned} \operatorname{curl} H^E &= \sigma^E E^E \\ \operatorname{curl} E^E &= i\omega\mu^E H^E \end{aligned}\right. \quad \text{in } G^E,$$

$$\begin{aligned} n \wedge H^E &= n \wedge \widetilde{H}^E = n \wedge \widetilde{H}^L + c = n \wedge (\widetilde{H}^L + H^J + H^Z) = n \wedge H^L, \\ n \cdot (\mu^E H^E) &= n \cdot (\mu^E \widetilde{H}^E) = n \cdot (\mu^L \widetilde{H}^L) + g = n \cdot (\mu^L(\widetilde{H}^L + H^J + H^Z)) \quad \text{on } \Gamma, \\ &= n \cdot (\mu^L H^L), \end{aligned}$$

and

$$\int_{\gamma_i^L} \tau \cdot H^L dl = \int_{\gamma_i^L} \tau \cdot (\widetilde{H}^L + H^J + H^Z) dl = \int_{\gamma_i^L} \tau \cdot H^J dl + h_i^L - h_i^J = h_i^L, \qquad i = 1, \ldots, p.$$

Therefore, H^L, E^L, H^E, E^E solve (3)–(6). □

COROLLARY. For $J_e \in C^1(\mathbb{R}^3)$, div $J_e = 0$, supp$(J_e) \subset G^J$, $\bar{G}^J \subset G^L$ bounded, problem (3)–(5) is solvable.

In the homogeneous case $J_e = 0$ we get exactly p linear independent solutions H^L, H^E, E^E, where p denotes the topological genus of G^E, respectively, G^L.

E^L is not uniquely determined.

Proof. The first statement follows immediately from the last theorem by choosing the circulations h_i^L, $i = 1, \ldots, p$ arbitrarily.

In the case $J_e = 0$ Theorem 3 shows the existence of p solutions H_j^L, E_j^L, H_j^E, E_j^E, $j = 1, \ldots, p$, of (3), (4), (5), having circulations $h_{ji}^L = \delta_{ij}, i = 1, \ldots, p$. The linear independence of H_j^L, E_j^L, H_j^E is a consequence of the uniqueness results of Theorem 1.

The nonuniqueness of E^L is obvious. □

DETERMINATION OF SCATTERING FREQUENCIES FOR AN ELASTIC FLOATING BODY*

C. HAZARD† AND M. LENOIR†

Abstract. This paper studies the time-harmonic motions of a three-dimensional elastic floating body on the sea, in the case of finite and constant depth. In order to compute the resonant states of such a system, a variational formulation for the determination of the scattering frequencies of the problem is investigated, i.e., the poles of the analytic continuation of the solution operator. A practical method, based on a series expansion of the solution in a vicinity of infinity, is described. The scattering frequencies are shown to be the solutions of a nonlinear eigenvalue problem for a compact operator. Numerical results for a two-dimensional model are presented.

Key words. fluid-structure interaction, scattering frequencies, resonances, series solutions

1. Introduction.

1.1. Motivation. In a previous paper [18], we described two practical methods for the computation of the scattering frequencies of the Helmholtz equation in exterior domains, i.e., the poles of the analytical continuation of the resolvent of the problem. In both cases, we constructed explicitly this analytical continuation by reducing the problem to an equivalent one, set in a bounded domain, using either an integral representation or a series expansion of the solution in the vicinity of infinity. We have shown that the determination of the scattering frequencies then amounts to the solution of a nonlinear and nonselfadjoint eigenvalue problem for a compact operator.

The purpose of the present paper is to show how one of these methods applies to the problem of the linearized motions of an elastic floating body on the sea, in the case of finite and constant depth. The determination of the scattering frequencies, as well as the associated scattering modes, provides a new and especially convenient method for the study of the dynamic stability of ships, in the context of linearized approximation. Indeed, instead of computing the response of the system for numerous cases of external forces (which essentially depend on the frequency and the direction of propagation of the incident wave), our method consists in determining intrinsic quantities of the system : the scattering frequencies, which are characteristic values of the problem. As described in [18], their knowledge allows not only to locate the peaks of the response curve of the floating body, i.e., the (real) frequencies of the incident waves for which the energy transmitted to the body is maximum, but also to obtain an a priori estimate of the response of the system in the vicinity of such frequencies.

Our analysis is based on a stationary approach of scattering frequencies, since the starting point of our study consists in the time-harmonic vibration problem: the scattering frequencies are shown to be the poles of the analytic continuation for complex frequencies of the solution operator associated with this problem. An equivalent approach (see [2], [5], [34]), which is closely related to the time-dependent scattering theory of Lax and Phillips [15], offers another characterization of scattering frequencies:

*Received by the editors December 7, 1992; accepted for publication March 8, 1993.

†Laboratoire de Simulation et Modélisation des Phénomènes de Propagation (associé au Centre National de la Recherche Scientifique et à l'Université Pierre et Marie Curie), Ecole Nationale Supérieure de Techniques Avancées, Chemin de la Hunière, 91120 Palaiseau, France.

they appear as the poles of the analytic continuation of the so-called scattering matrix, which connects the asymptotic behaviours of the incident and scattered waves. The agreement of both approaches is proved in [5] in the case of a rigid floating body. As we will see, the stationary approach is particularly well adapted for a numerical treatment of the problem.

The characterization of scattering frequencies which is proposed in this paper proceeds from the coupling method between variational formulation and series expansion (which leads to the so-called "localized finite element" method; see Richer [28]). It is in fact a generalization to the three-dimensional case and to complex frequencies of the method described by Lenoir and Tounsi [17] (in the two-dimensional case, the extension to complex frequencies is studied in [5]). An alternative approach, which applies in both finite and infinite depth cases, will be presented in [6]: it is based on the coupling method between variational formulation and integral representation introduced by Jami and Lenoir [9] for the sea-keeping problem.

For other fluid structure interaction problems, some asymptotic properties of scattering frequencies are studied by Ohayon and Sanchez-Palencia [23], Sanchez-Hubert and Sanchez-Palencia [29], [30], and Vullierme-Ledard [32]. Also worth mentioning is the work of Joly and Poisson [12], [25], [26], who deal with the scattering of acoustic and elastic waves: they compute the scattering frequencies by means of an integral equation method.

1.2. Description of the method. The general organization of the paper is as follows.

In §2, we introduce the linearized equations describing the small motions of an elastic body floating on the sea and subject to an incident monochromatic wave. These equations involve the velocity potential φ of the scattered wave which is defined in the unbounded fluid domain Ω, and the displacement vector field u of the body. The "stationary problem" then consists of determining the pair (φ, u) for a given frequency (whose square is denoted by ν) and a given incident wave. The purpose of the present paper is to construct explicitly the analytic extension to complex ν of the "solution operator" $\mathcal{R}_\nu$ associated with this problem, i.e., the linear operator which maps the incident wave onto the solution (φ, u). The scattering frequencies actually are the poles of the analytic continuation of $\mathcal{R}_\nu$ in the complex plane $\mathbb{C}$.

In a first step (§2.4), we show how $\mathcal{R}_\nu$ can be easily extended to the upper complex half plane $\mathbb{C}^+ = \{\nu \in \mathbb{C};\ \operatorname{Im} \nu > 0\}$: in fact, the stationary problem extends in this case to a well-posed coercive problem. In order to construct the continuation of $\mathcal{R}_\nu$ in the lower complex half plane $\mathbb{C}^-$, we proceed as in [18] by reducing the initial problem to an equivalent one, which is set in a bounded fluid domain $\hat{\Omega}$ delimited by a fictitious, vertical, cylindrical boundary Σ (§2.5). This reduction is performed by noticing that the only knowledge of the restriction $\varphi_{|\Sigma}$ of φ allows us to determine φ in the whole domain $\check{\Omega}$ outside Σ. We can then define a "reduced problem" by means of a "coupling condition" on Σ which implies the analytical matching between $\varphi_{|\hat{\Omega}}$ and $\varphi_{|\check{\Omega}}$.

The extension of the coupling condition to complex values of ν, which is dealt with in §3, is the backbone of the analytic continuation of $\mathcal{R}_\nu$. To construct this extension, we exhibit an explicit form of the coupling condition by means of a series expansion which follows from the particular choice of the outer domain $\hat{\Omega}$. Indeed, this choice enables us to expand $\varphi_{|\check{\Omega}}$ as a series of functions with separated variables. In the case of real positive ν (§3.1), the application of the method of separation of variables is rather classical: the determination of the solutions with separated variables amounts to solving the so-called dispersion equation $-\zeta \tan \zeta = \nu$, and the completeness of these solutions results from standard arguments of spectral theory. The properties of the series expansion of $\varphi_{|\tilde{\Omega}}$ in terms of solutions with separated variables are studied in Appendix A. The generalization of this method for complex ν (§3.2) causes two difficulties. The first one lies in the solution of the dispersion equation. We make use of an original method for solving some transcendental equations (Henrici [7]), which is based on the properties of Cauchy integrals on arcs. It provides an explicit form of the solutions which actually are branches of an algebraic function having a countable infinity of singularities of order 1. For the sake of clarity, the analysis of the dispersion equation is postponed to Appendix B. The second difficulty is the completeness of the solutions with separated variables, which does not follow any more from classical spectral theory, since it involves the completeness of a nonorthogonal basis. Following Kato [13], we use perturbation techniques for orthonormal families. Finally, we prove in §3.3 that the coupling condition depends analytically on ν in a subset of the complex plane.

This latter property allows us to proceed to the analytic continuation of the reduced problem (§4) by writing it as a Fredholm equation, which requires a sharp study of the series expansion of the coupling condition. Using a theorem due to Steinberg [31], we deduce that its solution depends meromorphically on ν : the poles, which are located in $\mathbb{R}^+$ or $\mathbb{C}^-$, are the solutions of a nonlinear eigenvalue problem. By virtue of the equivalence between the initial and reduced problems, we finally prove that these poles are nothing but the poles of the analytic continuation of the solution operator $\mathcal{R}_\nu$: these are the eigenfrequencies (in $\mathbb{R}^+$) and the scattering frequencies (in $\mathbb{C}^-$) of the problem.

Finally, we present in §5 the outcome of a numerical application for a two-dimensional "catamaran,"i.e., two rigid hulls linked together by an elastic beam. We briefly describe the main stages of the method in this case. Numerical results are shown: they illustrate in particular the connection between the scattering frequencies and the peaks of the response curve of the system.

2. Linearized equations of the coupled problem.

2.1. Notation. Consider an elastic body which floats (without forward motion) on the free surface of an inviscid, incompressible fluid. The motion of the fluid is assumed irrotational. When the system is at rest, the fluid fills an unbounded domain $\Omega \subset \mathbb{R}^3$ whose boundary $\partial\Omega$ consists of the free surface S, the bottom F, which is supposed to be plane and parallel to S, and the immersed surface Γ of the body (see Fig. 2.1). The body fills a bounded connected domain $B \subset \mathbb{R}^3$ with Lipschitz boundary ∂B; the emerged part of ∂B is denoted by Γ_0: it is assumed free. The coordinates (x_1, x_2, x_3) of every point x of the fluid or the body are expressed in an orthonormal system $(O, \vec{x}_1, \vec{x}_2, \vec{x}_3)$ chosen such that $(O, \vec{x}_1, \vec{x}_2)$ contains the free surface S and $(O, \vec{x}_3)$ is the ascending vertical axis. We denote by n either the outer unitary normal to $\partial\Omega$ or the inner normal to ∂B (which coincide on Γ).

All quantities involved in the problem are supposed to be dimensionless. Indeed, we can rescale all physical quantities by means of three independent characteristic constants: the fluid density (which is assumed constant in Ω), the gravitational constant, and the depth. In particular, the equation of the bottom F is $x_3 = -1$.

In the sequel, we will use the following notation. For any open set $D \subset \mathbb{R}^3$, the usual scalar product and the associated norm in $L^2(D)$ (respectively, the Sobolev space $H^s(D)$, for $s \in \mathbb{R}$) are denoted by $(\cdot\,,\cdot)_D$ and $\|\cdot\|_D$ (respectively, $(\cdot\,,\cdot)_{s,D}$ and $\|\cdot\|_{s,D}$). For an unbounded domain Ω, $H^1_{\text{loc}}(\Omega)$ denotes the Frechet space of functions φ such that $\varphi_{|D} \in H^1(D)$ for any bounded domain $D \subset \Omega$. If Σ is the boundary of

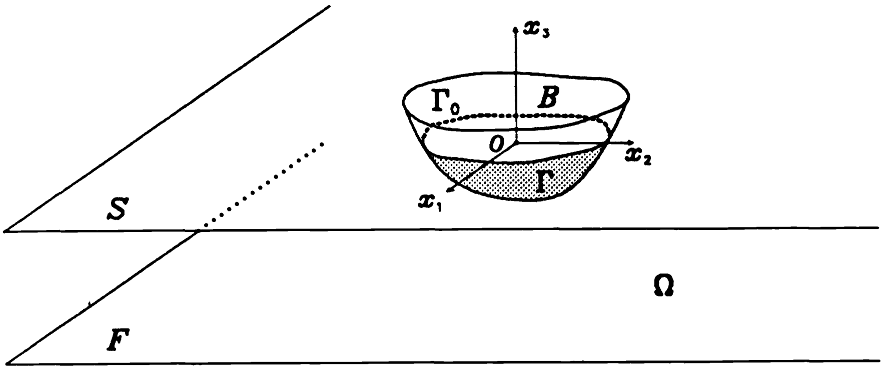

FIG. 2.1

an open set $D \subset \mathbb{R}^3$, the semiduality product between $H^{-s}(\Sigma)$ and $H^s(\Sigma)$ for $s > 0$ is denoted by $\langle \cdot , \cdot \rangle_{s,\Sigma}$.

2.2. The time-dependent problem. In this paper, we are concerned with the linearized approximation of the problem: the amplitudes of the motions of the fluid and the body are assumed small with respect to the dimensions of the body. Let $\Phi(x,t)$ be the velocity potential of the fluid and $U(x,t)$ the displacement field of the body. Let $e_{ij}(U)$ and $\sigma_{ij}(U)$ (for $i,j = 1,3$) be, respectively, the components of the strain and stress tensors given by

$$e_{ij}(U) = \tfrac{1}{2}\left(\partial_{x_j} U_i + \partial_{x_i} U_j\right) \quad \text{and} \quad \sigma_{ij}(U) = a_{ijkh} e_{kh}(U),$$

where $a_{ijkh} \in L^\infty(B)$ are the elastic coefficients. Note that we make use of the classical summation convention for twice-repeated indices in a product. In the case of an isotropic material, we have

$$a_{ijkh} = \lambda\, \delta_{ij}\delta_{kh} + \mu\,(\delta_{ih}\delta_{jk} + \delta_{ik}\delta_{jh}),$$

where λ and μ are the so-called Lamé coefficients. In the sequel, we will only assume that the elastic coefficients satisfy the symmetry and positivity properties

$$a_{ijkh} = a_{jikh} = a_{khij}, \tag{2.1}$$

$$a_{ijkh}(x)\, e_{ij} e_{kh} \geq \alpha\, e_{ij} e_{ij} \quad \forall x \in B \tag{2.2}$$

for any real symmetric tensor e_{ij}, where α is a positive constant. This amounts to saying that $2\mu(x) \geq \alpha$ and $3\lambda(x) + 2\mu(x) > \alpha$ for an isotropic material.

The linearized equations of the time-dependent problem are the following (a mathematical formulation of this problem in terms of semigroups of linear operators, as well as an existence and uniqueness result, are given by Licht [19]) :

$$\Delta\Phi = 0 \quad \text{in } \Omega, \tag{2.3}$$

$$\partial_t^2 \Phi + \partial_n \Phi = 0 \quad \text{on } S, \tag{2.4}$$

$$\partial_n \Phi = 0 \quad \text{on } F, \tag{2.5}$$

$$\rho\, \partial_t^2 U_i - \partial_{x_j} \sigma_{ij}(U) = 0 \quad \text{in } B, \tag{2.6}$$

$$\sigma_{ij}(U)\, n_j = 0 \quad \text{on } \Gamma_0, \tag{2.7}$$

$$\partial_t U.n - \partial_n \Phi = 0 \quad \text{on } \Gamma, \tag{2.8}$$

$$\sigma_{ij}(U)\, n_j - \partial_t \Phi\, n_i = 0 \quad \text{on } \Gamma. \tag{2.9}$$

Laplace equation (2.3) follows from the mass conservation law; the free surface condition (2.4) combines both the kinematic and dynamic relations to be satisfied on S (John [10]); (2.5) expresses that the normal velocity vanishes on the bottom F. Relations (2.6) are the classical dynamic equations in a continuous medium (see, e.g., Nečas and Hlaváček [22]), where $\rho \in L^\infty(B)$ is the (dimensionless) mass density of the body, which is assumed to satisfy

$$\rho(x) \geq \rho_0 \quad \text{in } B \tag{2.10}$$

for some positive constant ρ_0. Equations (2.7) express that the emerged part of ∂B is free. Finally, (2.8) and (2.9) are, respectively, the kinematic and dynamic coupling conditions on Γ (i.e., the continuity of the normal velocity and of the pressure).

In the case of a rigid body (i.e., $e_{ij}(U) = 0$ for $i, j = 1, 3$), the linearized displacement field reads $U = a + b \times x$ (see [22]): the system (2.3)–(2.9) then reduces to the problem studied by John [10].

2.3. The stationary problem. We consider the time-harmonic vibration of the system when it is subject to a monochromatic incident wave of pulsation $\omega > 0$. We are thus led to seek a solution of (2.3) to (2.9) in the form

$$\Phi(x,t) = \mathrm{Re}\left((\varphi(x) + \varphi_I(x))e^{-i\omega t}\right) \quad \text{and} \quad U(x,t) = \mathrm{Re}\left(i\, u(x)e^{-i\omega t}\right), \tag{2.11}$$

where $\varphi_I(x)$ is the velocity potential of the incident wave, that is, a solution of

$$\begin{aligned} &\Delta\varphi_I = 0 \quad \text{in } \{(x_1,x_2,x_3) \in \mathbb{R}^3;\ -1 < x_3 < 0\}, \\ &\partial_n\varphi_I - \nu\,\varphi_I = 0 \quad \text{on } x_3 = 0, \\ &\partial_n\varphi_I = 0 \quad \text{on } x_3 = -1, \end{aligned}$$

where $\nu = \omega^2$. For instance, in the case of a plane wave which propagates in the direction k (unit vector of the plane $(\vec{x}_1, \vec{x}_2)$), we have $\varphi_I(x) = A\cosh(\nu_0(x_3+1))\, e^{i\nu_0 x\cdot k}$, where A is a complex constant and ν_0 is the only positive root of equation

$$\nu_0 \tanh \nu_0 = \nu. \tag{2.12}$$

Substituting the expressions (2.11) of Φ and U in (2.3) to (2.9), we obtain

$$\begin{aligned} &\Delta\varphi = 0 \quad \text{in } \Omega, \\ &\partial_n\varphi - \nu\,\varphi = 0 \quad \text{on } S, \\ &\partial_n\varphi = 0 \quad \text{on } F, \\ &\nu\rho\, u_i + \partial_{x_j}\sigma_{ij}(u) = 0 \quad \text{in } B, \\ &\sigma_{ij}(u)\, n_j = 0 \quad \text{on } \Gamma_0, \\ &\nu^{1/2}\, u.n - \partial_n\varphi = f' \quad \text{on } \Gamma, \\ &\sigma_{ij}(u)\, n_j + \nu^{1/2}\,\varphi\, n_i = n_i f'' \quad \text{on } \Gamma, \end{aligned} \tag{2.13}$$

where $f' = \partial_n\varphi_I$ and $f'' = -\nu^{1/2}\varphi_I$ are given functions on Γ. Note that the complex factor i in the definition (2.11) of u avoids complex coefficients in the boundary conditions on Γ.

In addition, we must specify the asymptotic behaviour of φ by means of the outgoing radiation condition which expresses that the energy (associated with the scattered wave) radiates towards infinity (see [11])

$$\lim_{R\to+\infty} \int_{\Sigma_R} \left|\partial_n\varphi - i\nu_0\,\varphi\right|^2 d\Sigma = 0, \quad \text{with } \Sigma_R = \{x \in \Omega;\ (x_1^2 + x_2^2) = R^2\}, \tag{2.14}$$

where ν_0 still is the only positive root of (2.12). Setting

$$\mathcal{H}_{\mathrm{loc}} = H^1_{\mathrm{loc}}(\Omega) \times H^1(B)^3 \quad \text{and} \quad \mathcal{F} = L^2(\Gamma)^2, \tag{2.15}$$

we thus define the "stationary problem,"denoted by $\mathcal{P}_\nu$ in the sequel:

$$\begin{array}{l} \text{Find } X = (\varphi, u) \in \mathcal{H}_{\mathrm{loc}} \text{ such that} \\ \varphi \text{ and } u \text{ satisfy (2.13) and} \\ \varphi \text{ satisfies the radiation condition (2.14),} \end{array} \tag{2.16}$$

where the datum $f = (f', f'')$ is assumed to belong to $\mathcal{F}$. We will see that $\mathcal{P}_\nu$ has a unique solution, except maybe for a discrete set of $\nu \in \mathbb{R}^+$ (the set of eigenvalues of the problem).

Remark 2.1. If ν is not an eigenvalue of the problem, the solution $X = (\varphi, u)$ of $\mathcal{P}_\nu$ actually provides the asymptotic behaviour when $t \to +\infty$ of the solution $(\Phi(t), U(t))$ of the time-dependent problem (2.3)–(2.9). More precisely, the quantities $\Phi(x,t) - \mathrm{Re}\,((\varphi(x) + \varphi_I(x))e^{-i\omega t})$ and $U(x,t) - \mathrm{Re}\,(i\,u(x)e^{-i\omega t})$ tend to 0: this result, which is called the "limiting amplitude principle," has been proved by Vullierme-Ledard [33] in the case of a fixed rigid body.

In the sequel, we denote by $\mathcal{R}_\nu$ the "solution operator" associated with problem $\mathcal{P}_\nu$, i.e., the linear operator which maps the datum $f \in \mathcal{F}$ onto the solution $X \in \mathcal{H}_{\mathrm{loc}}$ of $\mathcal{P}_\nu$. The aim of the present paper is to construct explicitly the extension of $\mathcal{R}_\nu$ to complex values of ν. We will show that it extends to a meromorphic function of ν whose poles are nothing but the scattering frequencies of the problem, and we will give a characterization of these poles which is well adapted for their numerical computation.

The extension of $\mathcal{R}_\nu$ is performed in two steps. The first one, which consists in extending $\mathcal{P}_\nu$ to the upper complex half plane (i.e., for $\mathrm{Im}\,\nu > 0$) does not raise any difficulty. It is dealt with in §2.4 below. On the other hand, the extension to the lower complex half plane requires a precise control of the asymptotic behaviour of φ when $|x| \to +\infty$ (which becomes exponentially increasing in this case). Following the same idea as in [18], we will reduce problem $\mathcal{P}_\nu$ to an equivalent problem set in a bounded domain (§2.5) in order to carry out this extension (§§3 and 4).

2.4. The solution operator. Let $\nu \in \mathbb{C}^+ = \{\nu \in \mathbb{C};\ \mathrm{Im}\,\nu > 0\}$ and let $(\cdot)^{1/2}$ denote the principal value of the complex square root, i.e.,

$$\nu^{1/2} = r^{1/2}\, e^{i\theta/2} \ \text{ if } \ \nu = r\, e^{i\theta} \quad \text{with } r > 0 \quad \text{and} \quad |\theta| < \pi.$$

Problem $\mathcal{P}_\nu$, defined in (2.16) for real positive ν can be extended to complex values $\nu \in \mathbb{C}^+$ as follows. Let $\mathcal{H}$ denote the Hilbert space

$$\mathcal{H} = H^1(\Omega) \times H^1(B)^3. \tag{2.17}$$

Consider then the problem

$$\begin{array}{l} \text{Find } X = (\varphi, u) \in \mathcal{H} \text{ such that} \\ \varphi \text{ and } u \text{ satisfy (2.13),} \end{array} \tag{2.18}$$

which amounts to replacing the radiation condition by a decay condition at infinity. This problem will also be denoted by $\mathcal{P}_\nu$ in the sequel.

PROPOSITION 2.1. *Let $\nu \in \mathbb{C}^+$. For every $f \in \mathcal{F}$, problem $\mathcal{P}_\nu$ has a unique solution $X = \mathcal{R}_\nu f$ in $\mathcal{H}$. Furthermore, there exists $K(\nu) > 0$ such that*

$$\|\mathcal{R}_\nu f\|_{\mathcal{H}} \le K(\nu) \|f\|_{\mathcal{F}} \quad \forall f \in \mathcal{F}. \tag{2.19}$$

Proof. It is an easy matter to prove that the following variational formulation is equivalent to $\mathcal{P}_\nu$:

$$\text{(2.20)} \qquad \begin{array}{l} \text{Find } X \in \mathcal{H} \text{ such that} \\ a_\nu(X,Y) = l(f;Y) \quad \forall Y \in \mathcal{H}, \end{array}$$

where $a_\nu(\cdot\,,\cdot)$ is the sesquilinear form defined on $\mathcal{H} \times \mathcal{H}$ by

$$a_\nu(X,Y) = k(X,Y) - \nu\, m(X,Y) - \nu^{1/2}\, c(X,Y),$$

with

$$\begin{aligned} k(X,Y) &= \int_\Omega \nabla\varphi.\nabla\bar{\psi}\, d\Omega + \int_B a_{ijkh} e_{ij}(u) e_{kh}(\bar{v})\, dB, \\ m(X,Y) &= \int_S \varphi\bar{\psi}\, dS + \int_B \rho\, u.\bar{v}\, dB, \\ c(X,Y) &= \int_\Gamma (u.n\,\bar{\psi} + \varphi\,\bar{v}.n)\, d\Gamma \end{aligned}$$

for all $X = (\varphi, u)$ and $Y = (\psi, v)$ in $\mathcal{H}$, and $l(f;\cdot)$ is the semilinear form

$$l(f;Y) = -\int_\Gamma (f'\bar{\psi} + f''\bar{v}.n)\, d\Gamma.$$

a_ν and l are of course continuous on $\mathcal{H}$. To see that a_ν is a coercive form, notice that

$$\text{(2.21)} \qquad \operatorname{Im}\left\{\nu^{-1/2}\, a_\nu(X,X)\right\} = -\operatorname{Im}(\nu^{1/2})\,\left(|\nu|^{-1} k(X,X) + m(X,X)\right),$$

from which we deduce

$$\text{(2.22)} \qquad |a_\nu(X,X)| \geq \left|\operatorname{Im}(\nu^{1/2})\right| \operatorname{Min}\left\{|\nu|^{-1/2}, |\nu|^{1/2}\right\} (k(X,X) + m(X,X)).$$

Moreover, $(k(X,X) + m(X,X))^{1/2}$ is a norm in $\mathcal{H}$ equivalent to $\|X\|_{\mathcal{H}}$. This follows on one hand from the assumptions (2.1), (2.2), and (2.10), and from Korn's inequality (see, e.g., Nečas and Hlaváček [22]):

$$\text{(2.23)} \qquad \int_B e_{ij}(u) e_{ij}(\bar{u})\, dB + \int_B |u|^2\, dB \geq \gamma\, \|u\|_{1,B}^2 \quad \forall\, u \in H^1(B).$$

On the other hand, we have

$$\text{(2.24)} \qquad \|\varphi\|_{1,\Omega}^2 \leq \|\nabla\varphi\|_\Omega^2 + \|\varphi\|_S^2 \quad \forall\, \varphi \in H^1(\Omega),$$

which can be proved by the same techniques as for Poincaré's inequality in a strip. The existence and uniqueness of the solution of (2.20) thus results from Lax–Milgram's theorem. Finally, inequality (2.19) is a simple consequence of the continuity of l and of the coerciveness of a_ν. □

Remark 2.2. This new problem actually defines a continuous extension in $\mathbb{C}^+$ of $\mathcal{P}_\nu$ initially constructed for real positive ν : when $\nu \in \mathbb{C}^+ \to \mu \in \mathbb{R}^+$, its solution tends (in $\mathcal{H}_{\text{loc}}$) to the solution of $\mathcal{P}_\mu$. This result, which is called the "limiting absorption principle," may be proved by classical techniques using continuity properties of the Green function with respect to ν (see [5] or [16] for the infinite depth case). In fact, it appears as a straightforward consequence of the analyticity results which will be

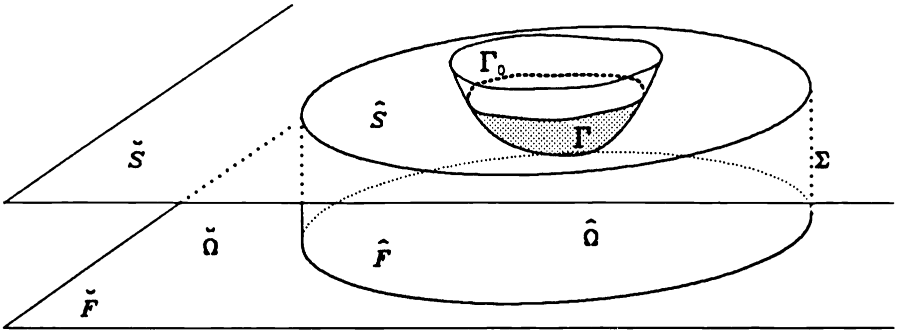

FIG. 2.2. *The inner and outer domains.*

worked out in §4: these results provide far more precise information about the ν-dependence of the solution of $\mathcal{P}_\nu$ than a simple continuity property.

Remark 2.3. If $\nu \in \mathbb{C}^- = \{\nu \in \mathbb{C};\ \operatorname{Im}\nu < 0\}$, problem (2.18) still is well posed: the sign of $\operatorname{Im}\nu$ does not affect the proof of Proposition 2.1. However, we are not concerned with this problem, since it does not define a continuous extension of (2.16). Indeed, if $\nu \in \mathbb{C}^- \to \mu \in \mathbb{R}^+$, the solution of (2.18) has a limit (in $\mathcal{H}_{\text{loc}}$) which satisfies, instead of (2.14), the so-called incoming radiation condition

$$\lim_{R\to+\infty} \int_{\Sigma_R} |\partial_n\varphi + i\nu_0\,\varphi|^2\, d\Sigma = 0,$$

where ν_0 is, here again, the positive root of (2.12) (with $\nu = \mu$).

2.5. Reduction to a bounded domain. In this paragraph, ν denotes either a real positive number or a complex number of $\mathbb{C}^+$. Consider the vertical cylinder $\Sigma = \{x \in \Omega;\ x_1^2 + x_2^2 = r_0^2\}$, where $r_0 > 0$ is chosen large enough so that Σ does not intersect Γ. This boundary Σ splits Ω into an inner bounded part $\hat{\Omega}$ and an outer unbounded part $\check{\Omega}$ (see Fig. 2.2). The parts of S and F which are contained in the boundary $\partial\hat{\Omega}$ of $\hat{\Omega}$ (respectively, $\partial\check{\Omega}$ of $\check{\Omega}$) are denoted by $\hat{S}$ and $\hat{F}$ (respectively, $\check{S}$ and $\check{F}$).

Let us define the outer Dirichlet problem, denoted by $\check{\mathcal{P}}_\nu$ in the sequel:

$$(2.25)\qquad \begin{array}{l} \text{Find } \check{\varphi} \ \text{ in } H^1_{\text{loc}}(\check{\Omega}) \ \text{ if } \nu \in \mathbb{R}^+ \ \text{ or } \ \text{in } H^1(\check{\Omega}) \text{ if } \nu \in \mathbb{C}^+ \ \text{ such that} \\ \Delta\check{\varphi} = 0 \quad \text{in } \check{\Omega}, \\ \partial_n\check{\varphi} - \nu\,\check{\varphi} = 0 \quad \text{on } \check{S}, \\ \partial_n\check{\varphi} = 0 \quad \text{on } \check{F}, \\ \check{\varphi} = \chi \quad \text{on } \Sigma, \\ \check{\varphi} \text{ satisfies the radiation condition (2.14)} \quad \text{if } \nu \in \mathbb{R}^+, \end{array}$$

where χ is a given function defined on Σ.

PROPOSITION 2.2. *For every $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$ and for every datum $\chi \in H^{1/2}(\Sigma)$, problem $\check{\mathcal{P}}_\nu$ has a unique solution $\check{\varphi} = \check{\mathcal{R}}_\nu\,\chi$ which depends continuously on χ, i.e., if $\nu \in \mathbb{R}^+$, for every bounded domain $\mathcal{O} \subset \check{\Omega}$, there exists $K(\nu, \mathcal{O}) > 0$ such that*

$$(2.26)\qquad \left\|\check{\mathcal{R}}_\nu\,\chi\right\|_{1,\mathcal{O}} \le K(\nu,\mathcal{O})\|\chi\|_{1/2,\Sigma}\,;$$

if $\nu \in \mathbb{C}^+$, there exists $K(\nu) > 0$ such that

$$(2.27)\qquad \left\|\check{\mathcal{R}}_\nu\,\chi\right\|_{1,\check{\Omega}} \le K(\nu)\|\chi\|_{1/2,\Sigma}.$$

Proof. (i) If $\nu \in \mathbb{R}^+$, the uniqueness of the solution of $\check{\mathcal{P}}_\nu$ can be worked out by John's method [11]. For the existence proof, we may use some general methods such as the limiting absorption principle (see Remark 2.2) or the "compactness method" (which consists in writing $\check{\mathcal{P}}_\nu$ as a Fredholm equation; see, e.g., [5]). Both methods are based on an integral representation of $\check{\varphi}$ in $\check{\Omega}$. They allow us to deduce the existence of a solution from the uniqueness property. However, for the sake of consistency, we will give in the sequel (see Lemma 3.2 proved in Appendix A) a new proof of the existence and the continuity property (2.26) which is closely related to the method explained in this paper: we will see that the solution can be expressed as the sum of a converging series in $H^1_{\text{loc}}(\check{\Omega})$.

(ii) Now, we deal with the complex case. From classical trace theorems, we know that for every $\chi \in H^{1/2}(\Sigma)$, there exists $\check{\chi} \in H^1(\check{\Omega})$ (which can be chosen with compact support) such that $\check{\chi}_{|\Sigma} = \chi$ and

$$\|\check{\chi}\|_{1,\check{\Omega}} \leq C\|\chi\|_{1/2,\Sigma}, \tag{2.28}$$

where C is a positive constant. Setting $\check{\psi} = \check{\varphi}-\check{\chi}$, we are thus led to consider a problem similar to $\check{\mathcal{P}}_\nu$ with a homogeneous Dirichlet boundary condition on Σ. The end of the proof is similar to that of Proposition 2.1: writing a variational formulation of this problem in the space $\left\{\check{\psi} \in H^1(\check{\Omega});\ \check{\psi}_{|\Sigma} = 0\right\}$, the existence and the uniqueness of the solution follows from Lax–Milgram's theorem, which, moreover, gives the following inequality:

$$\|\check{\psi}\|_{1,\check{\Omega}} \leq K'(\nu)\, \|\check{\chi}\|_{1,\check{\Omega}} \cdot$$

Property (2.27) thus derives from this estimate and (2.28). □

Consider now the so-called coupling operator $\mathcal{Q}_\nu$ from $H^{1/2}(\Sigma)$ into $H^{-1/2}(\Sigma)$ given by

$$\mathcal{Q}_\nu \chi = \partial_n(\check{\mathcal{R}}_\nu \chi)_{|\Sigma}, \tag{2.29}$$

where ∂_n denotes here the exterior normal derivative to $\check{\Omega}$. Proposition 3.1 shows that, for every $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$, $\mathcal{Q}_\nu$ is a continuous operator. We then define the reduced problem, denoted by $\hat{\mathcal{P}}_\nu$:

$$\begin{array}{l}
\text{Find } \hat{X} = (\hat{\varphi}, \hat{u}) \in \hat{\mathcal{H}} \quad \text{such that} \\
\Delta\hat{\varphi} = 0 \quad \text{in } \hat{\Omega}, \\
\partial_n\hat{\varphi} - \nu\hat{\varphi} = 0 \quad \text{on } \hat{S}, \\
\partial_n\hat{\varphi} = 0 \quad \text{on } \hat{F}, \\
\nu\rho\, \hat{u}_i + \partial_{x_j}\sigma_{ij}(\hat{u}) = 0 \quad \text{in } B, \\
\sigma_{ij}(\hat{u})\, n_j = 0 \quad \text{on } \Gamma_0, \\
\nu^{1/2}\, \hat{u}.n - \partial_n\hat{\varphi} = f' \quad \text{on } \Gamma, \\
\sigma_{ij}(\hat{u})\, n_j + \nu^{1/2}\, \hat{\varphi}\, n_i = n_i f'' \quad \text{on } \Gamma, \\
\partial_n\hat{\varphi} = -\mathcal{Q}_\nu\, \hat{\varphi}_{|\Sigma} \quad \text{on } \Sigma,
\end{array} \tag{2.30}$$

where $\hat{\mathcal{H}}$ is the Hilbert space

$$\hat{\mathcal{H}} = H^1(\hat{\Omega}) \times H^1(B)^3. \tag{2.31}$$

This problem is equivalent to problem $\mathcal{P}_\nu$ in the following sense.

PROPOSITION 2.3. *Let $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$; for every $f = (f', f'') \in \mathcal{F}$, problem $\mathcal{P}_\nu$ has at least (respectively, at most) one solution if and only if the same holds for $\hat{\mathcal{P}}_\nu$.*

Moreover, if $\hat{X} = (\hat\varphi, \hat u)$ *is a solution of* $\hat{\mathcal{P}}_\nu$, *then* $X = (\varphi, \hat u)$, *where* φ *is the function given by*

$$(2.32) \qquad \varphi_{|\hat\Omega} = \hat\varphi \quad \text{and} \quad \varphi_{|\check\Omega} = \check{\mathcal{R}}_\nu\, \hat\varphi_{|\Sigma},$$

is a solution of $\mathcal{P}_\nu$. *Conversely, if* $X = (\varphi, u)$ *is a solution of* $\mathcal{P}_\nu$, *then* $\hat X = (\varphi_{|\hat\Omega}, u)$ *is a solution of* $\hat{\mathcal{P}}_\nu$.

Proof. It is enough to prove the equivalence between $\mathcal{P}_\nu$ and $\hat{\mathcal{P}}_\nu$ for the existence property : the equivalence for the uniqueness follows by contraposition from the unique continuation property. Let us first assume that $\hat{\mathcal{P}}_\nu$ admits (at least) one solution $(\hat\varphi, \hat u)$. The coupling condition $\partial_n \hat\varphi = -\mathcal{Q}_\nu\, \hat\varphi_{|\Sigma}$ implies the analytical matching on Σ between $\hat\varphi$ and $\check{\mathcal{R}}_\nu\, \hat\varphi_{|\Sigma}$; according to (2.25) and (2.30) of $\check{\mathcal{P}}_\nu$ and $\hat{\mathcal{P}}_\nu$, the pair $(\varphi, \hat u)$ (where φ is given by (2.32)) actually satisfies the equations of $\mathcal{P}_\nu$. Conversely, if (φ, u) is a solution of $\mathcal{P}_\nu$, the restriction to $\check\Omega$ of φ is nothing but $\check{\mathcal{R}}_\nu\, \varphi_{|\Sigma}$, and thus $\hat\varphi = \varphi_{|\hat\Omega}$ clearly satisfies the coupling condition on Σ. □

Remark 2.4. Note that if $\nu \in \mathbb{C}^+$, Propositions 2.1 and 2.3 show that problem $\hat{\mathcal{P}}_\nu$ is well posed.

3. Diagonalization of the coupling operator. The purpose of this section is to express the coupling operator $\mathcal{Q}_\nu$ (given by (2.29)) by means of an explicit series expansion. We will see that for a suitable choice of a basis of $H^{1/2}(\Sigma)$ (which depends on ν), $\mathcal{Q}_\nu$ becomes diagonal. This result is based on the method of separation of variables which is used here for the outer problem in cylindrical coordinates (r, θ, x_3) (with $r = (x_1^2 + x_2^2)^{1/2}$). In §3.1, we first deal with the case of real positive ν for which the main results follow from spectral theory. In §3.2, we generalize these results to complex $\nu \in \mathbb{C}^+$, using perturbation techniques. We finally show in §3.3 that $\mathcal{Q}_\nu$ actually depends analytically on ν, and has an analytic continuation in the lower complex half plane. This latter property is the basic tool for the analytic extension of the reduced problem (§4).

3.1. The case of real positive ν. The method we use here is quite similar to the one introduced by Lenoir and Tounsi [17] in the two-dimensional case. We first exhibit the solutions of $\check{\mathcal{P}}_\nu$ with separated variables. We then prove that every solution of $\check{\mathcal{P}}_\nu$ can be expanded as a series in terms of solutions with separated variables.

In the following lemma, K_n denotes the modified Bessel function, which is real-valued and exponentially decreasing at infinity for real positive arguments (see, e.g., [1]).

LEMMA 3.1. *Let* $\nu > 0$; *the solutions with separated variables of the outer problem* $\check{\mathcal{P}}_\nu$ *are given (up to a multiplicative complex constant) by*

$$(3.1) \qquad \check\varphi_\nu^{(n,m)}(r, \theta, x_3) = \eta_\nu^{(n,m)}(r)\, \chi_\nu^{(n,m)}(\theta, x_3) \quad \text{for } n \in \mathbb{Z} \quad \text{and} \quad m \geq 0,$$

where the functions $\eta_\nu^{(n,m)}$ *and* $\chi_\nu^{(n,m)}$ *are defined as follows:*

$$(3.2) \quad \eta_\nu^{(n,m)}(r) = \frac{K_n(\zeta_\nu^{(m)} r)}{K_n(\zeta_\nu^{(m)} r_0)}, \qquad \chi_\nu^{(n,m)}(\theta, x_3) = \frac{e^{in\theta}}{\sqrt{2\pi r_0}}\, \tau_\nu^{(m)}(x_3) \quad \text{and}$$

$$(3.3) \quad \tau_\nu^{(m)}(x_3) = \alpha_\nu^{(m)} \cos(\zeta_\nu^{(m)}(x_3 + 1)) \quad \text{with } \alpha_\nu^{(m)} = \left(\frac{\sin 2\zeta_\nu^{(m)}}{4\zeta_\nu^{(m)}} + \frac{1}{2} \right)^{-1/2},$$

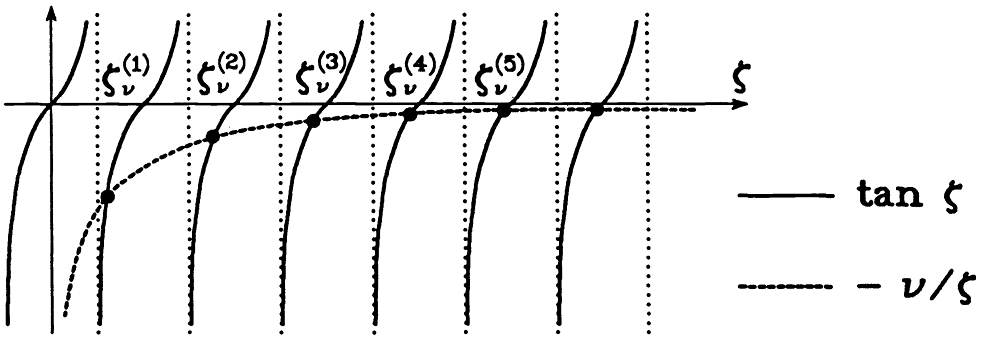

FIG. 3.1. *Real solutions of the dispersion equation.*

and the $\zeta_\nu^{(m)}$, $m \geq 0$, *are the roots of the so-called dispersion equation*

$$-\zeta \tan \zeta = \nu, \tag{3.4}$$

chosen such that $\zeta_\nu^{(0)}$ *is imaginary with negative imaginary part, and* $\zeta_\nu^{(m)}$, *for* $m \geq 1$, *are real, positive, and arranged according to increasing values.*

Remark 3.1. The positive roots $\zeta_\nu^{(m)}$, $m \geq 1$, of (3.4) are represented in Fig. 3.1 ; it may be easily seen that

$$\zeta_\nu^{(m)} \in \,](m - 1/2)\pi, m\pi[\quad \text{for } m \geq 1 \quad \text{and} \quad \zeta_\nu^{(m)} \sim m\pi \quad \text{when } m \to +\infty. \tag{3.5}$$

Notice that (3.4) has only one imaginary root with negative imaginary part. Indeed, setting $\zeta_\nu^{(0)} = -i\nu_0$, we see that ν_0 is the only positive root of (2.12) which appears in the radiation condition (2.14).

Remark 3.2. In this definition of $\check{\varphi}_\nu^{(n,m)}$, the coefficients are chosen so that $\check{\varphi}_\nu^{(n,m)}$ is the (only) solution of $\check{\mathcal{P}}_\nu$ for the Dirichlet datum $\chi_\nu^{(n,m)}$ (which can be considered as a function defined on Σ), and this latter function is a unit vector of $L^2(\Sigma)$. Moreover, setting

$$\Sigma = \mathcal{C} \times \mathcal{I}, \tag{3.6}$$

where $\mathcal{C}$ is a circle of radius r_0 and $\mathcal{I}$ is the vertical segment $]-1, 0[$, we see that functions $\tau_\nu^{(m)}$ and $e^{in\theta}/\sqrt{2\pi r_0}$ are unitary, respectively, in $L^2(\mathcal{I})$ and $L^2(\mathcal{C})$.

Remark 3.3. If $H_n^{(1)}$ denotes the Hankel function of order n of the first kind, we have (see [1])

$$K_n(z) = \frac{i\pi}{2}\, e^{in\pi/2}\, H_n^{(1)}(iz) \quad \text{for } -\pi < \arg z \leq \frac{\pi}{2}. \tag{3.7}$$

Hence, from Remark 3.1, we see that the definitions of $\eta_\nu^{(n,0)}$ and $\chi_\nu^{(n,0)}$ amount to

$$\eta_\nu^{(n,0)}(r) = \frac{H_n^{(1)}(\nu_0 r)}{H_n^{(1)}(\nu_0 r_0)}, \qquad \chi_\nu^{(n,0)}(\theta, x_3) = \frac{e^{in\theta}}{\sqrt{2\pi r_0}}\,\tau_\nu^{(0)}(x_3) \quad \text{and} \tag{3.8}$$

$$\tau_\nu^{(0)}(x_3) = \alpha_\nu^{(0)} \cosh(\nu_0(x_3 + 1)) \quad \text{with } \alpha_\nu^{(0)} = \left(\frac{\sinh 2\nu_0}{4\nu_0} + \frac{1}{2}\right)^{-1/2}. \tag{3.9}$$

These expressions clearly show that the solutions $\check{\varphi}_\nu^{(n,m)}$ of $\check{\mathcal{P}}_\nu$ are divided into two classes. If $m > 0$, $\check{\varphi}_\nu^{(n,m)}$ decreases exponentially when $r \to +\infty$, these solutions are called "evanescent." But if $m = 0$, the functions $\check{\varphi}_\nu^{(n,0)}$ decrease as $r^{-1/2}$ (see (3.14) below), they are called "radiative."

Remark 3.4. Note that, from the relation

$$K_{-n}(z) = K_n(z), \quad n \in \mathbb{Z}, \quad \text{and} \quad |\arg z| < \pi, \tag{3.10}$$

we have the symmetry properties

$$\eta_\nu^{(-n,m)} = \eta_\nu^{(n,m)} \quad \text{and} \quad \chi_\nu^{(-n,m)} = \overline{\chi_\nu^{(n,m)}}. \tag{3.11}$$

Proof of Lemma 3.1. Suppose that a solution $\check{\varphi}$ of $\check{\mathcal{P}}_\nu$ can be written in the form

$$\check{\varphi}(r,\theta,x_3) = \eta(r)\,\tau(x_3)\,\frac{e^{in\theta}}{\sqrt{2\pi r_0}},$$

where $n \in \mathbb{Z}$. According to (2.25) of $\check{\mathcal{P}}_\nu$, functions $\eta(r)$ and $\tau(x_3)$ are solutions of the following problems for some $\lambda \in \mathbb{R}$:

$$\begin{array}{l} r d_r(r d_r \eta) - (n^2 + \lambda r^2)\eta = 0 \quad \text{on }]r_0, +\infty[, \\ \lim_{R\to+\infty} R\,|d_r\eta(R) - i\nu_0\,\eta(R)|^2 = 0, \end{array} \tag{3.12}$$

and

$$\begin{array}{l} d_{x_3}^2\tau + \lambda\tau = 0 \quad \text{on } \mathcal{I}, \\ d_{x_3}\tau(0) - \nu\,\tau(0) = 0, \\ d_{x_3}\tau(-1) = 0 \end{array} \tag{3.13}$$

(where $\mathcal{I}$ denotes the segment $]-1,0[$). Solving the eigenvalue problem (3.13) does not raise any difficulty. If $\lambda > 0$, we obtain the sequence of solutions $(\lambda_\nu^{(m)}, \tau_\nu^{(m)})$ with $\lambda_\nu^{(m)} = {\zeta_\nu^{(m)}}^2$, $m \geq 1$. On the other hand, if $\lambda < 0$, problem (3.13) has a unique solution $(\lambda_\nu^{(0)}, \tau_\nu^{(0)})$, where $\lambda_\nu^{(0)} = -\nu_0^2$.

We can then solve problem (3.12). If $\lambda = {\zeta_\nu^{(m)}}^2$ with $m \geq 1$, the solution can be expressed by means of the modified Bessel function K_n and I_n of order n (see [1]):

$$\eta(r) = \gamma\, K_n(\zeta_\nu^{(m)} r) + \gamma'\, I_n(\zeta_\nu^{(m)} r), \qquad (\gamma,\gamma') \in \mathbb{C}^2,$$

where γ' must be zero, since I_n increases exponentially at infinity. If $\lambda = -\nu_0^2$, the solution is a combination of the Hankel functions $H_n^{(1)}(\nu_0 r)$ and $H_n^{(2)}(\nu_0 r)$; from the asymptotic behaviours of $H_n^{(j)}(z)$ $(j = 1,2)$ and their derivatives for fixed $n \in \mathbb{Z}$ and large $z \in \mathbb{R}^+$ (see [1])

$$H_n^{(j)}(z) = \sqrt{\frac{2}{\pi z}}\, e^{(-1)^{j-1} i(z - n\pi/2 - \pi/4)} + O(z^{-3/2}), \tag{3.14}$$

$$H_n^{(j)\prime}(z) = (-1)^{j-1} i H_n^{(j)}(z) + O(z^{-3/2}), \tag{3.15}$$

we deduce that only $H_n^{(1)}(\nu_0 r)$ satisfies the radiation condition in (3.12). □

PROPOSITION 3.1. *Let $\nu > 0$; the set $\mathcal{X}_\nu = \{\chi_\nu^{(n,m)};\ n \in \mathbb{Z},\ m \geq 0\}$ is an orthonormal basis of $L^2(\Sigma)$ and an orthogonal basis of $H^s(\Sigma)$ for every $s \in\,]0,1]$. Furthermore, the expression*

$$[\chi]_{\nu,s} = \left(\sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (1 + n^2 + m^2)^s \left| (\chi, \chi_\nu^{(n,m)})_\Sigma \right|^2 \right)^{1/2} \tag{3.16}$$

is a norm on $H^s(\Sigma)$ which is equivalent to the usual norm.

Proof. (i) Let us prove that the functions $\chi_\nu^{(m,n)}$ are the eigenvectors of a selfadjoint operator with compact resolvent. First, notice that each function $\chi_\nu^{(n,m)}$ is a solution of the following eigenvalue problem for $\lambda = r_0^{-2}n^2 + (\zeta_\nu^{(m)})^2$:

$$(3.17) \qquad \begin{aligned} &\Delta_\sigma \chi + \lambda \chi = 0 \quad \text{in } \Sigma, \\ &\partial_{x_3}\chi - \nu\chi = 0 \quad \text{on } \mathcal{C}_0, \\ &\partial_{x_3}\chi = 0 \quad \text{on } \mathcal{C}_{-1}, \end{aligned}$$

where Δ_σ denotes the Laplace–Beltrami operator on Σ (i.e., $r_0^{-2}\partial_\theta^2 + \partial_{x_3}^2$), $\mathcal{C}_0$ and $\mathcal{C}_{-1}$ are, respectively, the upper and lower boundaries of Σ (i.e., two circles of radius r_0). A variational formulation of this problem writes as follows:

$$\begin{aligned} &\text{Find } \chi \in H^1(\Sigma) \text{ such that} \\ &t_\nu(\chi,\chi') = \lambda\,(\chi,\chi')_\Sigma \quad \forall \chi' \in H^1(\Sigma), \end{aligned}$$

where $t_\nu(\cdot,\cdot)$ is the following symmetric sesquilinear form on $H^1(\Sigma)$ (∇_σ denotes the tangential gradient on Σ):

$$t_\nu(\chi,\chi') = \int_\Sigma \nabla_\sigma\chi.\overline{\nabla_\sigma\chi'}\,d\Sigma - \nu\int_{\mathcal{C}_0}\chi\overline{\chi'}\,d\mathcal{C}.$$

From Lions's lemmas [20] we know that, for any $\varepsilon > 0$, there exists $K_\varepsilon > 0$ such that

$$C\,\|\chi\|_{\mathcal{C}_0} \le \|\chi\|_{2/3,\Sigma} \le \varepsilon\|\chi\|_{1,\Sigma} + K_\varepsilon\|\chi\|_\Sigma \quad \forall\chi \in H^1(\Sigma),$$

from which we infer that, for sufficiently large $d > 0$, the form

$$t_{d,\nu}(\chi,\chi') = t_\nu(\chi,\chi') + d\,(\chi,\chi')_\Sigma$$

is coercive on $H^1(\Sigma)$. As a consequence, the representation theorem of sesquilinear forms (see, e.g., Reed and Simon [27]) shows that the operator $T_{d,\nu}$ defined on $L^2(\Sigma)$ by

$$\begin{aligned} &D(T_{d,\nu}) = \{\chi \in H^1(\Sigma);\ \exists K > 0,\ \forall\chi' \in H^1(\Sigma),\ t_{d,\nu}(\chi,\chi') \le K\|\chi'\|_\Sigma\}, \\ &(T_{d,\nu}\,\chi,\chi')_\Sigma = t_{d,\nu}(\chi,\chi') \quad \forall\chi \in D(T_{d,\nu}) \quad \forall\chi' \in H^1(\Sigma), \end{aligned}$$

is an unbounded selfadjoint positive operator with compact resolvent. Thus $T_{d,\nu}$ has a countable infinity of positive eigenvalues and the associated eigenvectors can be chosen so as to form an orthonormal basis of $L^2(\Sigma)$.

(ii) To see that the functions $\chi_\nu^{(n,m)}$ are the only eigenvectors of $T_{d,\nu}$, first notice that each of the two families $\{e^{in\theta}/\sqrt{2\pi r_0};\ n \in \mathbb{Z}\}$ and $\{\tau_\nu^{(m)};\ m \ge 0\}$ is, respectively, an orthonormal basis of $L^2(\mathcal{C})$ and $L^2(\mathcal{I})$. The former result is classical. To prove the latter, it suffices to apply the method described in (i) to the eigenvalue problem (3.13) (instead of (3.17)): since we have determined all the solutions of this one-dimensional problem, the completeness of the $\tau_\nu^{(m)}$ follows. Consequently, the products $\tau_\nu^{(m)}(x_3)\,e^{in\theta}/\sqrt{2\pi r_0}$, for $n \in \mathbb{Z}$ and $m \ge 0$, form an orthonormal basis of $L^2(\Sigma)$ (see, e.g., Kato [13, Ex. V.1.10]).

(iii) The set $\{\chi_\nu^{(n,m)};\ n \in \mathbb{Z},\ m \ge 0\}$ is also an orthogonal basis of the domain $D(T_{d,\nu}^r)$ of any power $T_{d,\nu}^r$ (with $r > 0$) of operator $T_{d,\nu}$:

$$\begin{aligned} &D(T_{d,\nu}^r) = \left\{\chi \in L^2(\Sigma);\ \textstyle\sum_{n\in\mathbb{Z}}\sum_{m\ge0}(\lambda_\nu^{(n,m)})^{2r}\left|\left(\chi,\chi_\nu^{(n,m)}\right)_\Sigma\right|^2 < \infty\right\}, \\ &T_{d,\nu}^r\,\chi = \textstyle\sum_{n\in\mathbb{Z}}\sum_{m\ge0}(\lambda_\nu^{(n,m)})^r\left(\chi,\chi_\nu^{(n,m)}\right)_\Sigma\chi_\nu^{(n,m)} \quad \forall\chi \in D(T_{d,\nu}^r), \end{aligned}$$

where $\lambda_\nu^{(n,m)} = d + r_0^{-2}n^2 + \zeta_\nu^{(m)^2}$. By the interpolation theory between Sobolev spaces (see Lions and Magenes [21]), we see that $D(T^r_{d,\nu})$, for $r \in [0, \frac{1}{2}]$, is nothing but the interpolation space $[H^1(\Sigma), L^2(\Sigma)]_{1-2r}$, and thus

$$\mathrm{D}(T^r_{d,\nu}) = H^{2r}(\Sigma) \quad \text{for } 0 \le r \le \tfrac{1}{2}. \tag{3.18}$$

Consequently, $\mathcal{X}_\nu$ is an orthogonal basis of $H^s(\Sigma)$ for $s \in [0,1]$ and the expression

$$\left(\sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\lambda_\nu^{(n,m)})^s \left| \left(\chi, \chi_\nu^{(n,m)} \right)_\Sigma \right|^2 \right)^{1/2}$$

is equivalent to the usual norm of $H^s(\Sigma)$. Moreover, we have from (3.5),

$$C_1 \left(d + r_0^{-2}n^2 + \zeta_\nu^{(m)^2} \right) \le (1 + n^2 + m^2) \le C_2 \left(d + r_0^{-2}n^2 + \zeta_\nu^{(m)^2} \right)$$

for some positive constants C_1 and C_2. The statement of the proposition follows. □

Proposition 3.1 shows that every function $\chi \in H^s(\Sigma)$ (with $0 \le s \le 1$) expands as

$$\chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_\nu^{(n,m)})_\Sigma \, \chi_\nu^{(n,m)}, \tag{3.19}$$

where the series converges in $H^s(\Sigma)$. The following result completes the proof of Proposition 2.2 (existence of a solution of $\check{\mathcal{P}}_\nu$ for real positive ν).

LEMMA 3.2. *Let $\nu > 0$; for every $\chi \in H^{1/2}(\Sigma)$, the outer problem $\check{\mathcal{P}}_\nu$ has a unique solution $\check{\varphi} = \check{\mathcal{R}}_\nu \chi$ which expands as*

$$\check{\varphi} = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_\nu^{(n,m)})_\Sigma \, \check{\varphi}_\nu^{(n,m)}, \tag{3.20}$$

where the series converges in $H^1_{\mathrm{loc}}(\check{\Omega})$ and depends continously on χ.

Proof. Recall that the (only) solution of $\check{\mathcal{P}}_\nu$ for the Dirichlet datum $\chi_\nu^{(n,m)}$ is $\check{\varphi}_\nu^{(n,m)}$ (defined in Lemma 3.1). Consequently, if the series (3.20) converges in $H^1_{\mathrm{loc}}(\check{\Omega})$ and satisfies the radiation condition, it will clearly define the only solution of $\check{\mathcal{P}}_\nu$ for the Dirichlet datum χ. The proof of this statement (which is rather technical) and of the continuity with respect to χ is given in Appendix A. □

Finally, by (2.26) and the continuity of the normal derivative of $\check{\varphi}$ on Σ, we deduce the diagonal form of the coupling operator.

COROLLARY 3.1. *Let $\nu > 0$; the coupling operator $\mathcal{Q}_\nu$ given by (2.29) expands as*

$$\mathcal{Q}_\nu \chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} q_\nu^{(n,m)} \, (\chi, \chi_\nu^{(n,m)})_\Sigma \, \chi_\nu^{(n,m)} \quad \textit{with } q_\nu^{(n,m)} = -\zeta_\nu^{(m)} \frac{K_n'(\zeta_\nu^{(m)} r_0)}{K_n(\zeta_\nu^{(m)} r_0)}, \tag{3.21}$$

where the series converges in $H^{-1/2}(\Sigma)$ for every $\chi \in H^{1/2}(\Sigma)$.

3.2. The case of complex ν. The extension of the results of §3.1 to complex values of ν raises two difficulties. On one hand, we have to solve the dispersion equation (3.4) in the complex plane. On the other hand, the eigenvalue problem (3.17) is no

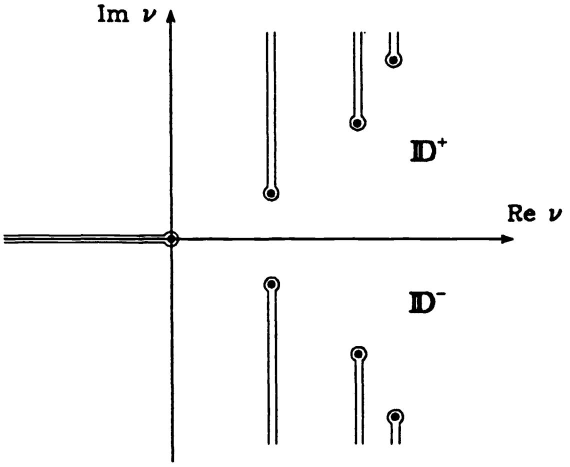

FIG. 3.2. *Analyticity domain of the* $\zeta_\nu^{(m)}$.

longer selfadjoint and therefore the spectral theory results we have used for real ν do not apply any more.

For the sake of clarity, the study of the dispersion equation is postponed to Appendix B. We show that each root $\zeta_\nu^{(m)}$, for $m \geq 0$, actually extends to an analytic function of ν (which will still be denoted by $\zeta_\nu^{(m)}$) in every simply connected domain of $\mathbb{C} \setminus \mathbb{E}$, where $\mathbb{E}$ is the discrete set of $\mathbb{C}$ (with no accumulation point) which consists of the values of ν for which the dispersion equation admits a double root (see §B.1). In the sequel, we will consider the simply connected domain $\mathbb{D}$ of $\mathbb{C} \setminus \mathbb{E}$ which is obtained by cutting the complex plane from each point of $\mathbb{E}$ as shown in Fig. 3.2. This is of course an arbitrary choice, which is justified here by the fact that we are primarily concerned with the analytic continuation of the problem in the vicinity of the positive real axis. We will denote $\mathbb{D}^\pm = \mathbb{D} \cap \mathbb{C}^\pm$.

Since each solution $\zeta_\nu^{(m)}$, for $m \geq 0$, depends analytically on ν in $\mathbb{D}$, each function $\tau_\nu^{(m)}$ given by (3.3) (and thus $\chi_\nu^{(n,m)}$ defined in (3.2)) can be extended to an analytic family on $\mathbb{D}$. Note that the quantity $\sin(2\zeta_\nu^{(m)}) + 2\zeta_\nu^{(m)}$ does not vanish if $\nu \in \mathbb{C} \setminus \mathbb{E}$ (see Proposition B.1), which shows that the normalization coefficient $\alpha_\nu^{(m)}$ is always defined in this domain.

Similarly, each function $\check{\varphi}_\nu^{(n,m)}$can be extended analytically in $\mathbb{D}$ except maybe for the values of ν for which $K_n(\zeta_\nu^{(m)} r_0) = 0$. If $\nu \in \mathbb{D}^+$, this quantity cannot vanish: this results from property (B.34) and the fact that the modified Bessel functions K_n have no zeros in the region $|\arg z| \leq \pi/2$. Thus, $\check{\varphi}_\nu^{(n,m)}$ is defined everywhere in $\mathbb{D}^+$: it is obviously the only solution of $\check{\mathcal{P}}_\nu$ for the Dirichlet datum $\chi_\nu^{(n,m)}$. From (B.34), we see that it is always exponentially decreasing when $r \to +\infty$.

The purpose of this paragraph is to show that Proposition 3.1 and Corollary 3.1 extend as follows.

THEOREM 3.1. *For every $\nu \in \mathbb{D}$ and every $s \in [0,1]$, the set $\mathcal{X}_\nu = \{\chi_\nu^{(n,m)};\ n \in \mathbb{Z}, m \geq 0\}$ is a basis of $H^s(\Sigma)$, and the expression $[\![\chi]\!]_{\nu,s}$ given by* (3.16) *is still a norm on $H^s(\Sigma)$ equivalent to the usual norm. Moreover, the two families $\mathcal{X}_\nu$ and $\mathcal{X}_{\bar\nu}$ are adjoint to each other in $L^2(\Sigma)$, i.e.,*

$$(\chi_\nu^{(n,m)}, \chi_{\bar\nu}^{(n',m')})_\Sigma = \delta_{nn'}\delta_{mm'}. \tag{3.22}$$

In the particular case $\nu \in \mathbb{D}^+$, this statement allows us to extend the diagonal form (3.21) of the coupling operator (which was up to now defined for $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$) as follows.

COROLLARY 3.2. *Let $\nu \in \mathbb{D}^+$; the coupling operator $\mathcal{Q}_\nu$ given by (2.29) expands as*

$$\mathcal{Q}_\nu \chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} q_\nu^{(n,m)} \, (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, \chi_\nu^{(n,m)} \quad \textit{with } q_\nu^{(n,m)} = -\zeta_\nu^{(m)} \frac{K_n'(\zeta_\nu^{(m)} r_0)}{K_n(\zeta_\nu^{(m)} r_0)}, \tag{3.23}$$

where the series converges in $H^{-1/2}(\Sigma)$ for every $\chi \in H^{1/2}(\Sigma)$.

Note that this expression of $\mathcal{Q}_\nu$ agrees with (3.21) if $\nu \in \mathbb{R}^+$, since $\nu = \bar\nu$ in this case.

Proof of Corollary 3.2. Theorem 3.1 shows that every function $\chi \in H^{1/2}(\Sigma)$ expands as

$$\chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, \chi_\nu^{(n,m)}, \tag{3.24}$$

where the series converges in $H^{1/2}(\Sigma)$. Since $\check\varphi_\nu^{(n,m)}$ is the solution of $\check{\mathcal{P}}_\nu$ for the datum $\chi_\nu^{(n,m)}$, we deduce from the continuity of $\check{\mathcal{R}}_\nu$ (Lemma 3.2) that the general solution of $\check{\mathcal{P}}_\nu$ is given by

$$\check\varphi = \check{\mathcal{R}}_\nu \chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, \check\varphi_\nu^{(n,m)}, \tag{3.25}$$

where the series converges in $H^1(\check\Omega)$. The expression of $\mathcal{Q}_\nu$ follows. □

The remainder of the present paragraph is devoted to the proof of Theorem 3.1: it is based on perturbation techniques which consist in comparing the family $\mathcal{X}_\nu$ with the orthogonal basis $\mathcal{X}_\mu$ for some given $\mu > 0$. We begin by proving the completeness of the family $\mathcal{X}_\nu$ in $L^2(\Sigma)$ (Lemma 3.4) which follows from the completeness of the $\tau_\nu^{(m)}$ in $L^2(\mathcal{I})$ (Lemma 3.3) by separation of variables. Lemma 3.5 provides a perturbation result which is used in the proofs of Lemma 3.3 (in the simple case $s = 0$) and Theorem 3.1 (in the general case).

LEMMA 3.3. *For every $\nu \in \mathbb{D}$, the set $\mathcal{T}_\nu = \{\tau_\nu^{(m)};\ m \geq 0\}$ is a basis of $L^2(\mathcal{I})$ and the two families $\mathcal{T}_\nu$ and $\mathcal{T}_{\bar\nu}$ are adjoint to each other, i.e.,*

$$(\tau_\nu^{(m)}, \tau_{\bar\nu}^{(m')})_\mathcal{I} = \delta_{mm'}. \tag{3.26}$$

Remark 3.5. For real positive ν, we defined $\zeta_\nu^{(0)}$ as an imaginary number and $\zeta_\nu^{(m)}$, for $m \geq 1$, as real positive numbers. Consequently, the analyticity property of $\zeta_\nu^{(m)}$ shows that if $\nu \in \mathbb{D}$, we have

$$\zeta_{\bar\nu}^{(0)} = -\overline{\zeta_\nu^{(0)}} \quad \text{and} \quad \zeta_{\bar\nu}^{(m)} = \overline{\zeta_\nu^{(m)}} \quad \text{for } m \geq 1, \tag{3.27}$$

from which we deduce that

$$\tau_{\bar\nu}^{(m)} = \overline{\tau_\nu^{(m)}} \quad \text{for } m \geq 0. \tag{3.28}$$

Proof of Lemma 3.3. (i) Relation (3.26) can be obtained by a direct calculation of the scalar product, noticing that

$$\int_{-1}^{0} \cos^2 \zeta(x_3+1)\,dx_3 = \frac{\sin 2\zeta}{4\zeta} + \frac{1}{2}, \tag{3.29}$$

$$\int_{-1}^{0} \cos\zeta(x_3+1)\cos\zeta'(x_3+1)\,dx_3 = \frac{\cos\zeta\cos\zeta'\ (\zeta\tan\zeta - \zeta'\tan\zeta')}{(\zeta+\zeta')(\zeta-\zeta')}. \tag{3.30}$$

We can also refer to the analyticity of $\tau_\nu^{(m)}$ with respect to ν. As a matter of fact, by the unique continuation property, (3.26) is nothing but the extension to $\mathbb{D}$ of the orthonormality relation of the $\tau_\nu^{(m)}$ for real ν.

(ii) Let μ be a given real positive number, and let $\mathcal{T}_\mu = \{\tau_\mu^{(m)};\ m \geq 0\}$. We have seen in the proof of Proposition 3.1 (point (ii)) that family $\mathcal{T}_\mu$ is an orthonormal basis of $L^2(\mathcal{I})$. To prove that $\mathcal{T}_\nu$ is a basis of $L^2(\mathcal{I})$, we use a perturbation result of orthonormal families (Kato [13, Thm. V-2.20]), by considering $\mathcal{T}_\nu$ as a perturbation of the orthonormal basis $\mathcal{T}_\mu$. We have to verify the two following conditions:

(α) there exists a positive constant C such that

$$\sum_{m\geq 0} \left\| \tau_\nu^{(m)} - \tau_\mu^{(m)} \right\|_{\mathcal{I}}^2 \leq C;$$

(β) for any sequence (a_m; $m \geq 0$) of complex numbers,

$$\tau = \sum_{m\geq 0} a_m \tau_\nu^{(m)} = 0 \ \text{ implies } \ a_m = 0 \quad \forall m \geq 0.$$

Condition (α) follows from Lemma 3.5 below in the case $s = 0$ (the quantity involved in (α) is nothing but $A_{\nu,0}$). Condition (β) is a straightforward consequence of (3.26), since $a_m = (\tau, \tau_{\bar\nu}^{(m)})$. □

LEMMA 3.4. *For every $\nu \in \mathbb{D}$, the set $\mathcal{X}_\nu$ is a basis of $L^2(\Sigma)$, and the two families $\mathcal{X}_\nu$ and $\mathcal{X}_{\bar\nu}$ are adjoint to each other, i.e.,* (3.22).

Remark 3.6. This lemma shows in particular that the scalar product in $L^2(\Sigma)$ can be expressed as follows:

$$(\chi, \chi')_\Sigma = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma\, (\chi_\nu^{(n,m)}, \chi')_\Sigma. \tag{3.31}$$

Proof of Lemma 3.4. Relation (3.22) results from (3.26) by Fubini's theorem. Proceeding as in Kato [13, Ex. V-1.10]), we easily prove that $(\chi, \chi_\nu^{(n,m)})_\Sigma = 0$, for all $n \in \mathbb{Z}$ and $m \geq 0$, implies $\chi = 0$: this derives from Lemma 3.3 and the completeness of the family $\{e^{in\theta}/\sqrt{2\pi r_0};\ n \in \mathbb{Z}\}$ in $L^2(\mathcal{C})$. The completeness of $\mathcal{X}_\nu$ follows. Thus, every $\chi \in L^2(\Sigma)$ expands as

$$\chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} a_{n,m}\, \chi_\nu^{(n,m)},$$

where $a_{n,m} = (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma$ by virtue of (3.22). □

LEMMA 3.5. *Let μ be a given real positive number. Then, for every $s \in [-1,+1]$ and every $\nu \in \mathbb{D}$, the following quantity is finite:*

$$A_{\nu,s} = \sup_{n\in\mathbb{Z}} \sum_{m\geq 0} \sum_{m'\geq 0} \left(\frac{1+n^2+m'^2}{1+n^2+m^2}\right)^s \left|\left(\tau_\nu^{(m)} - \tau_\mu^{(m)}, \tau_\mu^{(m')}\right)_{\mathcal{I}}\right|^2 . \tag{3.32}$$

Proof. This result is based on the asymptotic behaviour of the roots $\zeta_\nu^{(m)}$ of the dispersion equation when $m \to +\infty$. We prove in Appendix B (see Proposition B.6) that

$$\zeta_\nu^{(m)} = m\pi - m^{-1}\nu/\pi + O(m^{-3}) \quad \text{when } m \to +\infty. \tag{3.33}$$

Using the definition (3.3) of $\tau_\nu^{(m)}$ and formula (3.30), we deduce that

$$\left(\tau_\nu^{(m)} - \tau_\mu^{(m)}, \tau_\mu^{(m)}\right)_{\mathcal{I}} = O(m^{-2}), \tag{3.34}$$

$$\left(\tau_\nu^{(m)} - \tau_\mu^{(m)}, \tau_\mu^{(m')}\right)_{\mathcal{I}} = \left(\tau_\nu^{(m)}, \tau_\mu^{(m')}\right)_{\mathcal{I}} = O\left(|m^2 - m'^2|^{-1}\right) \quad \text{if } m \neq m', \tag{3.35}$$

when $m^2 + m'^2 \to +\infty$. In order to prove that $A_{\nu,s}$ is bounded, we split the series into five parts $A_{\nu,s}^{(j)}$, for $j = -2$ to $+2$, which correspond, respectively, to $m' \leq am$, $am < m' < m$, $m' = m$, $m < m' < bm$, and $bm \leq m'$, where a and b are given real positive constants such that $a < 1 < b$. We will assume that $s \geq 0$: the case of negative s can be dealt with similarly. For $A_{\nu,s}^{(-2)}$ to $A_{\nu,s}^{(1)}$, we first notice that

$$\frac{1+n^2+m'^2}{1+n^2+m^2} \leq C,$$

which shows that the convergence does not depend on n and s in these cases. Using (3.34) and (3.35), we deduce

$$A_{\nu,s}^{(-2)} \leq C \sum_{m>0} \sum_{0\leq m'\leq am} (m^2 - m'^2)^{-2} \leq C \sum_{m>0} m^{-3},$$

$$A_{\nu,s}^{(-1)} \leq C \sum_{m>0} \sum_{am<m'<m} (m^2 - m'^2)^{-2} \leq C \sum_{m>0} \sum_{0<p<(1-a)m} p^{-2} m^{-2},$$

$$A_{\nu,s}^{(0)} \leq C \sum_{m>0} m^{-4},$$

and, for $A_{\nu,s}^{(1)}$, the same kind of estimate as for $A_{\nu,s}^{(-1)}$: the convergence of these series follows. It remains to deal with $A_{\nu,s}^{(2)}$. We use in this case the following inequalities (for $m' \geq bm$):

$$\frac{1+n^2+m'^2}{1+n^2+m^2} \leq \frac{m'^2}{m^2},$$

$$m'^2 - m^2 \geq C\, m^{1-\alpha} m'^{1+\alpha},$$

where α can be chosen in the range $[0,1]$. Thus, we deduce

$$A_{\nu,s}^{(2)} \leq C \sum_{m>0} \sum_{m'\geq bm} m^{-2(1-\alpha+s)} m'^{-2(1+\alpha-s)},$$

which converges if $|s-\alpha| < \frac{1}{2}$: for every $s \in [0,1]$, we can choose α such that this condition is satisfied. □

We can now proceed to the proof of Theorem 3.1. As for Lemma 3.3, we consider $\mathcal{X}_\nu$ as a perturbation of the orthogonal family $\mathcal{X}_\mu$ for a given $\mu \in \mathbb{R}^+$. However, the perturbation result we have used in the proof of that lemma does not apply here: condition (α) is not satisfied, since for every $m \geq 0$, the quantity $\sum_{n\in\mathbb{Z}}[\chi_\nu^{(n,m)} - \chi_\mu^{(n,m)}]^2_{\mu,s}$ is infinite. In other words, the perturbation only concerns function $\tau_\nu^{(m)}$ (which does not depend on n) in the expression of $\chi_\nu^{(n,m)}$. Namely, we have

$$\left(\chi_\nu^{(n,m)}, \chi_\mu^{(n',m')}\right)_\Sigma = \delta_{nn'} \left(\tau_\nu^{(m)}, \tau_\mu^{(m')}\right)_{\mathcal{I}}. \tag{3.36}$$

Proof of Theorem 3.1. Consider the linear operators T and S in $H^s(\Sigma)$ given by

$$T\chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} \left(\chi, \chi_\mu^{(n,m)}\right)_\Sigma \chi_\nu^{(n,m)}, \tag{3.37}$$

$$S\chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} \left(\chi, \chi_{\bar\nu}^{(n,m)}\right)_\Sigma \chi_\mu^{(n,m)}. \tag{3.38}$$

(i) Let us first prove that these expressions actually define two bounded operators on $H^s(\Sigma)$. To see that T is bounded, consider the quantity $[T\chi - \chi]^2_{\mu,s}$, for $\chi \in H^s(\Sigma)$, which expands, by (3.16), in the form

$$\sum_{n'\in\mathbb{Z}} \sum_{m'\geq 0} (1+n'^2+m'^2)^s \left| \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_\mu^{(n,m)})_\Sigma \, (\chi_\nu^{(n,m)} - \chi_\mu^{(n,m)}, \chi_\mu^{(n',m')})_\Sigma \right|^2,$$

and simplifies to

$$\sum_{n\in\mathbb{Z}} \sum_{m'\geq 0} (1+n^2+m'^2)^s \left| \sum_{m\geq 0} (\chi, \chi_\mu^{(n,m)})_\Sigma \, (\tau_\nu^{(m)} - \tau_\mu^{(m)}, \tau_\mu^{(m')})_{\mathcal{I}} \right|^2,$$

by virtue of (3.36). Hence, by the Schwarz inequality, we have

$$[T\chi - \chi]^2_{\mu,s} \leq A_{\nu,s}\, [\chi]^2_{\mu,s}, \tag{3.39}$$

where $A_{\nu,s}$ is the bounded quantity defined in Lemma 3.5: the boundedness of T then follows from the triangle inequality. On the other hand, $[S\chi - \chi]^2_{\mu,s}$ expands as follows:

$$\sum_{n'\in\mathbb{Z}} \sum_{m'\geq 0} (1+n'^2+m'^2)^s \left| \left(\chi, \chi_{\bar\nu}^{(n',m')} - \chi_\mu^{(n',m')}\right)_\Sigma \right|^2.$$

Noticing that

$$\begin{aligned}\left(\chi, \chi_{\bar\nu}^{(n',m')} - \chi_\mu^{(n',m')}\right)_\Sigma &= \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} \left(\chi, \chi_\mu^{(n,m)}\right)_\Sigma \left(\chi_\mu^{(n,m)}, \chi_{\bar\nu}^{(n',m')} - \chi_\mu^{(n',m')}\right)_\Sigma, \\ &= \sum_{m\geq 0} \left(\chi, \chi_\mu^{(n',m)}\right)_\Sigma \left(\tau_\mu^{(m)}, \tau_{\bar\nu}^{(m')} - \tau_\mu^{(m')}\right)_{\mathcal{I}},\end{aligned}$$

we deduce as above that $[S\chi - \chi]^2_{\mu,s} \leq B_{\nu,s}\,[\chi]^2_{\mu,s}$, where

$$B_{\nu,s} = \sup_{n\in\mathbb{Z}} \sum_{m\geq 0}\sum_{m'\geq 0} \left(\frac{1+n^2+m^2}{1+n^2+m'^2}\right)^s \left|(\tau_\mu^{(m')}, \tau_{\bar{\nu}}^{(m)} - \tau_\mu^{(m)})_{\mathcal{I}}\right|^2 .$$

From (3.28), we have $B_{\nu,s} = A_{\nu,-s}$. Lemma 3.5 thus shows that S is also bounded on $H^s(\Sigma)$.

(ii) Noticing that $T\chi_\mu^{(n,m)} = \chi_\nu^{(n,m)}$ and conversely $S\chi_\nu^{(n,m)} = \chi_\mu^{(n,m)}$, we infer that T is invertible and S is a left inverse of T, since $\mathcal{X}_\mu$ is an orthogonal basis of $H^s(\Sigma)$. To see that S is also a right inverse of T, it is sufficient to consider T and S as operators defined on $L^2(\Sigma)$ (for they both map $H^s(\Sigma)$ onto itself). In this case, this amounts to showing that the range $R(T)$ of T is the whole space $L^2(\Sigma)$. This latter property readily follows from Lemma 3.4. Indeed, $(\chi, \chi')_\Sigma = 0$ for all $\chi' \in R(T)$ implies, in particular, $(\chi, \chi_{\bar{\nu}}^{(n,m)})_\Sigma = 0$ for all $n \in \mathbb{Z}$ and $m \geq 0$, which shows that $\chi = 0$ since $\mathcal{X}_{\bar{\nu}}$ is a basis of $L^2(\Sigma)$.

As a consequence, T and S are bounded operators on $H^s(\Sigma)$ which are inverse to each other: this clearly shows that $\mathcal{X}_\nu$ is a basis of $H^s(\Sigma)$.

(iii) Finally, noticing that $[S\chi]_{\mu,s} = [\chi]_{\bar{\nu},s}$ (where $[\chi]_{\bar{\nu},s}$ is defined as in (3.16)), we infer that $[\chi]_{\nu,s}$ is a norm on $H^s(\Sigma)$ for every $\nu \in \mathbb{D}$. This completes the proof of Theorem 3.1. □

3.3. Analyticity of the coupling operator. We have seen that every root $\zeta_\nu^{(m)}$ of the dispersion equation (3.4) is analytic in $\mathbb{D}$, and consequently, every term of the series (3.23) is defined at any point of $\mathbb{D}$ provided that $K_n(\zeta_\nu^{(m)} r_0)$ does not vanish. This may happen only in the case $m = 0$: indeed, the set Z_n of zeros of the modified Bessel function K_n is contained in the region $|\arg z| > \pi/2$, and we know from (B.35) that $\zeta_\nu^{(0)}$ is the only root of (3.4) which is located in this domain (if $\nu \in \mathbb{D}^-$). Let $Z = \bigcup_{n\geq 0} Z_n$, and consider the set

$$\mathbb{K} = \{\nu = -z/r_0 \tan(z/r_0) \in \mathbb{C}^-;\ z \in Z\}. \tag{3.40}$$

Lemma 3.6. *For every $\nu \in \mathbb{D}^- \setminus \mathbb{K}$ and every $\chi \in H^{1/2}(\Sigma)$, the series* (3.23) *converges in $H^{-1/2}(\Sigma)$.*

Proof. Let $\nu \in \mathbb{D}^- \setminus \mathbb{K}$. Let us first study the asymptotic behaviour of $q_\nu^{(n,m)}$ when $n^2 + m^2 \to +\infty$. Using the uniform asymptotic expansions (A.20) and (A.21) of K_n, and noticing, from (3.33), that for large enough $n^2 + m^2$, the quantities $\zeta_\nu^{(m)} r_0/n$ lie in a closed subset of the validity domain of these expansions, we deduce, as in the proof of Lemma A.1,

$$\frac{K_n'(\zeta_\nu^{(m)} r_0)}{K_n(\zeta_\nu^{(m)} r_0)} = -\frac{\left(n^2 + \zeta_\nu^{(m)^2} r_0^2\right)^{1/2}}{\zeta_\nu^{(m)} r_0} \left\{1 + O\left(\left(n^2 + \zeta_\nu^{(m)^2} r_0^2\right)^{-1/2}\right)\right\}.$$

Consequently,

$$q_\nu^{(n,m)} = \left(r_0^{-2} n^2 + \zeta_\nu^{(m)^2}\right)^{1/2} + O(1). \tag{3.41}$$

It follows from the asymptotic behaviour (3.33) of $\zeta_\nu^{(m)}$ that

$$\left|q_\nu^{(n,m)}\right| \leq C\,(1 + n^2 + m^2)^{1/2}, \tag{3.42}$$

which shows that for every χ and χ' in $H^{1/2}(\Sigma)$,

$$\left|\langle \mathcal{Q}_\nu \chi, \chi' \rangle_{1/2,\Sigma}\right| = \left| \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} q_\nu^{(n,m)} \, (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, (\chi_\nu^{(n,m)}, \chi')_\Sigma \right| \leq C \, [\chi]_{\bar\nu,1/2} \, [\chi']_{\nu,1/2},$$

by the Schwarz inequality (note that the expression of $\langle \mathcal{Q}_\nu \chi, \chi' \rangle_{1/2,\Sigma}$ results from (3.31)). The conclusion thus follows from Theorem 3.1. □

THEOREM 3.2. *The diagonal form* (3.23) *of the coupling operator* $\mathcal{Q}_\nu$ *defines an analytic family from* $\mathbb{D} \setminus \mathbb{K}$ *into the space* $\mathcal{B}(H^{1/2}(\Sigma), H^{-1/2}(\Sigma))$ *of bounded operators from* $H^{1/2}(\Sigma)$ *to* $H^{-1/2}(\Sigma)$.

Proof. Every term of the series (3.23) is obviously an analytic function of ν. We thus have to prove that the same holds for the sum of this series, which amounts to verifying that $\langle \mathcal{Q}_\nu \chi, \chi' \rangle_{1/2,\Sigma}$ is analytic in $\mathbb{D} \setminus \mathbb{K}$ for every χ and χ' in $H^{1/2}(\Sigma)$ (see Kato [13]). A sufficient condition for this property to be satisfied is, for instance,

$$\lim_{L\to\infty} \left(\sup_{\nu\in K} \sum_{n^2+m^2\geq L} q_\nu^{(n,m)} \, (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, (\chi_\nu^{(n,m)}, \chi')_\Sigma \right) = 0$$

for every compact set $K \subset \mathbb{D} \setminus \mathbb{K}$: this condition expresses that the sequence of partial sums of the series converges locally uniformly on $\mathbb{D} \setminus \mathbb{K}$ (see Henrici [7]). First, notice that the asymptotic expansion (3.33) of $\zeta_\nu^{(m)}$, as well as the estimates which derive from it, are valid uniformly with respect to $\nu \in K$. Consequently, by (3.42) and the Schwarz inequality, it is enough to show that for every $\chi \in H^{1/2}(\Sigma)$,

$$\lim_{L\to\infty} \left(\sup_{\nu\in K} \sum_{n^2+m^2\geq L} (1+n^2+m^2)^{1/2} \left| (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \right|^2 \right) = 0.$$

Let P_L denote the orthogonal projection on the closed linear manifold of $H^{1/2}(\Sigma)$ spanned by $\{\chi_\mu^{(n,m)};\ n^2+m^2 \geq L\}$. We easily obtain

$$\sum_{n^2+m^2\geq L} \left| q_\nu^{(n,m)} \right| \left| (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \right|^2 \leq C \, [P_L S \chi]_{\mu,1/2}^2 ,$$

where S is the bounded operator on $H^{1/2}(\Sigma)$ given by (3.38). We obviously have $[P_L S\chi]_{\mu,1/2} \to 0$ when $L \to +\infty$, locally uniformly with respect to ν. The statement of Theorem 3.2 follows. □

Remark 3.7. The analytic continuation of the roots $\zeta_\nu^{(m)}$ of the dispersion equation also provides the analytic continuation of the solution $\check{\mathcal{R}}_\nu \chi$ of the outer problem $\check{\mathcal{P}}_\nu$ (see Proposition 2.2). Indeed, if $\nu \in \mathbb{R}^+ \cup \mathbb{D}^+$, we have by construction

$$\check{\mathcal{R}}_\nu \chi = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma \, \check\varphi_\nu^{(n,m)} \quad \forall \chi \in H^{1/2}(\Sigma). \tag{3.43}$$

By the same techniques as in §A.1, it may be easily seen that if $\nu \in \mathbb{D}^- \setminus \mathbb{K}$, this series converges in $H^1_{\mathrm{loc}}(\check\Omega)$. Moreover, it depends analytically on ν in $\mathbb{D} \setminus \mathbb{K}$ (same proof as for Theorem 3.2). This expansion thus defines an analytic family from $\mathbb{D} \setminus \mathbb{K}$ to $H^1_{\mathrm{loc}}(\check\Omega)$ (recall that $\check{\mathcal{R}}_\nu \chi \in H^1_{\mathrm{loc}}(\check\Omega)$ is analytic if, for every open bounded set $\mathcal{O} \subset \check\Omega$, the family $(\tilde{\mathcal{R}}_\nu\chi)_{|\mathcal{O}} \in H^1(\mathcal{O})$ is itself analytic). Note that $\tilde{\mathcal{R}}_\nu\chi$ becomes exponentially increasing at infinity when $\nu \in \mathbb{D}^- \setminus \mathbb{K}$, except if $(\chi, \chi_\nu^{(n,0)})_\Sigma = 0$ for all $n \in \mathbb{Z}$.

4. Eigenfrequencies and scattering frequencies.

In §2.4, we have defined problem $\hat{\mathcal{P}}_\nu$ (set on the bounded fluid domain $\hat{\Omega}$) by means of a coupling condition on the fictitious boundary Σ. Theorem 3.2 shows that the coupling operator $\mathcal{Q}_\nu$ actually is an analytic family in $\mathbb{D} \setminus \mathbb{K}$: consequently, we are now able to extend $\hat{\mathcal{P}}_\nu$ to $\mathbb{D}^- \setminus \mathbb{K}$.

4.1. Analytic continuation of the reduced problem.

Let $\nu \in \mathbb{D} \setminus \mathbb{K}$; a variational formulation of problem $\hat{\mathcal{P}}_\nu$ reads (see (2.30)):

$$\text{(4.1)}\qquad \begin{array}{l} \text{Find } \hat{X} = (\varphi, \hat{u}) \in \hat{\mathcal{H}} \text{ such that} \\ \hat{a}_\nu(\hat{X}, \hat{Y}) = \hat{l}(f; \hat{Y}) \quad \forall \hat{Y} \in \hat{\mathcal{H}}, \end{array}$$

where $\hat{a}_\nu(\cdot\,,\cdot)$ is the sesquilinear form defined on $\hat{\mathcal{H}} \times \hat{\mathcal{H}}$ by

$$\text{(4.2)}\qquad \hat{a}_\nu(\hat{X}, \hat{Y}) = \hat{k}(\hat{X}, \hat{Y}) - \nu\,\hat{m}(\hat{X}, \hat{Y}) - \nu^{1/2}\,\hat{c}(\hat{X}, \hat{Y}) + \hat{q}_\nu(\hat{X}, \hat{Y}),$$

with

$$\text{(4.3)}\quad \hat{k}(\hat{X}, \hat{Y}) = \int_{\hat{\Omega}} \nabla\varphi.\overline{\nabla\psi}\, d\hat{\Omega} + \int_B a_{ijkh} e_{ij}(\hat{u}) \overline{e_{kh}(\hat{v})}\, dB,$$

$$\text{(4.4)}\quad \hat{m}(\hat{X}, \hat{Y}) = \int_{\hat{S}} \varphi\overline{\psi}\, d\hat{S} + \int_B \rho\, \hat{u}.\overline{\hat{v}}\, dB,$$

$$\text{(4.5)}\quad \hat{c}(\hat{X}, \hat{Y}) = \int_\Gamma (\hat{u}.n\,\overline{\psi} + \varphi\,\overline{\hat{v}.n})\, d\Gamma,$$

$$\text{(4.6)}\quad \hat{q}_\nu(\hat{X}, \hat{Y}) = <\mathcal{Q}_\nu\varphi, \psi>_{1/2,\Sigma} = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} q_\nu^{(n,m)} \left(\varphi, \chi_\nu^{(n,m)}\right)_\Sigma \left(\chi_\nu^{(n,m)}, \psi\right)_\Sigma$$

for all $\hat{X} = (\varphi, \hat{u})$ and $\hat{Y} = (\psi, \hat{v})$ in $\hat{\mathcal{H}}$. The semilinear form $\hat{l}$, which depends on the datum $f = (f', f'') \in \mathcal{F}$, is given by

$$\text{(4.7)}\qquad \hat{l}(f; \hat{Y}) = -\int_\Gamma (f'\overline{\psi} + f''\overline{\hat{v}.n})\, d\Gamma.$$

Let $\hat{A}_\nu$ and $\hat{L}(f)$ be, respectively, the bounded operator on $\hat{\mathcal{H}}$ and the element of $\hat{\mathcal{H}}$ associated with $\hat{a}_\nu(\cdot\,,\cdot)$ and $\hat{l}(f;\cdot)$, i.e.,

$$\text{(4.8)}\qquad (\hat{A}_\nu\hat{X}, \hat{Y})_{\hat{\mathcal{H}}} = \hat{a}_\nu(\hat{X}, \hat{Y}) \quad\text{and}\quad (\hat{L}(f), \hat{Y})_{\hat{\mathcal{H}}} = \hat{l}(f; \hat{Y}).$$

The variational formulation (4.1) of $\hat{\mathcal{P}}_\nu$ then amounts to $\hat{A}_\nu\hat{X} = \hat{L}(f)$. The object of this paragraph is to prove the following statement.

THEOREM 4.1. *The operators $\hat{A}_\nu$ for $\nu \in \mathbb{D} \setminus \mathbb{K}$ form a holomorphic family of Fredholm operators on $\hat{\mathcal{H}}$. Moreover, $\hat{A}_\nu^{-1}$ is a meromorphic family in $\mathbb{D} \setminus \mathbb{K}$ whose poles are located in $\mathbb{R}^+$ or $\mathbb{D}^- \setminus \mathbb{K}$.*

Remark 4.1. The poles of $\hat{A}_\nu^{-1}$ are the values of ν for which the Fredholm operator $\hat{A}_\nu$ is not invertible. In other words, they are the solutions of the following nonlinear (and nonselfadjoint) eigenvalue problem:

$$\text{(4.9)}\qquad \begin{array}{l} \text{Find } \nu \in \mathbb{R}^+ \cup \mathbb{D}^- \setminus \mathbb{K} \text{ such that there exists } \hat{X} \in \hat{\mathcal{H}} \setminus \{0\} \text{ which satisfies} \\ \hat{k}(\hat{X}, \hat{Y}) - \nu^{1/2}\,\hat{c}(\hat{X}, \hat{Y}) + \hat{q}_\nu(\hat{X}, \hat{Y}) = \nu\,\hat{m}(\hat{X}, \hat{Y}) \quad \forall \hat{Y} \in \hat{\mathcal{H}}. \end{array}$$

Proof. (i) The analyticity of the family $\hat{A}_\nu$ follows readily from Theorem 3.2.

(ii) Let us prove that in every compact subset K of $\mathbb{D}\setminus\mathbb{K}$, $\hat{A}_\nu$ can be written as

$$\hat{A}_\nu = \hat{J}_\nu + \hat{K}_\nu,$$

where $\hat{J}_\nu$ and $\hat{K}_\nu$ are two analytic families of bounded operators on $\hat{\mathcal{H}}$, $\hat{J}_\nu$ is invertible with bounded inverse, and $\hat{K}_\nu$ is compact. The main difficulty arises from the coupling term $\hat{q}_\nu$ which will be rewritten as the sum of two forms such that the real part of the first one is positive, and the second one corresponds to a compact operator on $\hat{\mathcal{H}}$.

Consider the bounded operators $\hat{J}_\nu$ and $\hat{K}_\nu$ defined on $\hat{\mathcal{H}}$ by

$$\begin{aligned}(\hat{J}_\nu\hat{X},\hat{Y})_{\hat{\mathcal{H}}} &= \hat{k}(\hat{X},\hat{Y}) + \hat{m}(\hat{X},\hat{Y}) + \hat{q}_{d,\nu}(\hat{X},\hat{Y}),\\ (\hat{K}_\nu\hat{X},\hat{Y})_{\hat{\mathcal{H}}} &= -(\nu+1)\,\hat{m}(\hat{X},\hat{Y}) - \nu^{1/2}\hat{c}(\hat{X},\hat{Y}) + \hat{q}_\nu(\hat{X},\hat{Y}) - \hat{q}_{d,\nu}(\hat{X},\hat{Y}),\end{aligned}$$

where $\hat{q}_{d,\nu}$ is the sesquilinear form given by

$$(4.10)\qquad \hat{q}_{d,\nu}(\hat{X},\hat{Y}) = \sum_{n\in\mathbb{Z}}\sum_{m\geq 0}\left(d + r_0^{-2}n^2 + \zeta_\nu^{(m)^2}\right)^{1/2} (\hat{\varphi},\chi_\nu^{(n,m)})_\Sigma\,(\chi_\nu^{(n,m)},\hat{\psi})_\Sigma,$$

where d is a real positive parameter. We prove in Lemma 4.1 below that for large enough d, $\hat{q}_{d,\nu}(\hat{X},\hat{X})$ depends analytically on ν in K, and its real part is nonnegative for every $\hat{X}\in\hat{\mathcal{H}}$. Moreover, as in the proof of Proposition 2.1, it may be easily seen that $\hat{k}+\hat{m}$ is a continuous coercive symmetric form on $\hat{\mathcal{H}}\times\hat{\mathcal{H}}$. Consequently, $\hat{J}_\nu$ defines a holomorphic family of bounded invertible operators with bounded inverses, and the inverse family $\hat{J}_\nu^{-1}$ is also holomorphic in K (see Kato [13, §VII-1.1]).

On the other hand, the compactness of $\hat{K}_\nu$ is a straightforward consequence of Lemma 4.2 below and the Rellich theorem.

(iii) Rewriting $\hat{A}_\nu^{-1}$ in the form $(1+\hat{J}_\nu^{-1}\hat{K}_\nu)^{-1}\,\hat{J}_\nu^{-1}$, we can use Steinberg's theorem [31] which states that either $(1+\hat{J}_\nu^{-1}\hat{K}_\nu)$ is nowhere invertible in K, or else $(1+\hat{J}_\nu^{-1}\hat{K}_\nu)^{-1}$ is meromorphic in K. We are of course in the second case, since problem $\hat{\mathcal{P}}_\nu$ is well posed if $\nu\in\mathbb{D}^+$ (see Remark 2.4). Consequently, $\hat{A}_\nu^{-1}$ is a meromorphic family which has no poles in $\mathbb{D}^+$. □

LEMMA 4.1. *For every compact subset K of $\mathbb{D}\setminus\mathbb{K}$, there exists $d>0$ such that*

$$(4.11)\qquad \operatorname{Re}\left(\hat{q}_{d,\nu}(\hat{X},\hat{X})\right)\geq 0\quad \forall\hat{X}\in\hat{\mathcal{H}}\quad\forall\nu\in K.$$

Moreover, $\hat{q}_{d,\nu}(\hat{X},\hat{X})$ depends analytically on ν in K.

Proof. Consider the sesquilinear form $t_{d,\nu}$ introduced in the proof of Proposition 3.1:

$$t_{d,\nu}(\chi,\chi') = \int_\Sigma \nabla_\sigma\chi..\overline{\nabla_\sigma\chi'}\,d\Sigma - \nu\int_{\mathcal{C}_0}\chi\overline{\chi'}\,d\mathcal{C} + d\int_\Sigma\chi\overline{\chi'}\,d\Sigma\quad\forall(\chi,\chi')\in H^1(\Sigma)^2.$$

We know from Lions's lemma that we can choose $d>0$ such that $t_{d,\nu}$ is a strictly m-accretive form for every $\nu\in K$. Consequently, there exists a family of strictly m-accretive unbounded operators $T_{d,\nu}$ on $L^2(\Sigma)$ given by

$$(T_{d,\nu}\chi,\chi')_\Sigma = t_{d,\nu}(\chi,\chi')\quad\forall\chi\in D(T_{d,\nu})\quad\forall\chi'\in H^1(\Sigma).$$

Let $T_{d,\nu}^{1/2}$ be the unique strictly m-accretive operator such that $(T_{d,\nu}^{1/2})^2 = T_{d,\nu}$ (see Kato [13, Thm. V-3.35]). In particular, we have

$$\operatorname{Re}(T_{d,\nu}^{1/2}\chi,\chi)_\Sigma \geq 0 \quad \forall \chi \in D(T_{d,\nu}^{1/2}).$$

We prove below that $D(T_{d,\nu}^{1/2}) = H^1(\Sigma)$ and $T_{d,\nu}^{1/2}$ expands as follows:

$$T_{d,\nu}^{1/2}\chi = \sum_{n\in\mathbb{Z}}\sum_{m\geq 0} \left(d + r_0^{-2}n^2 + \zeta_\nu^{(m)^2}\right)^{1/2} (\chi, \chi_{\bar\nu}^{(n,m)})_\Sigma\, \chi_\nu^{(n,m)}, \tag{4.12}$$

which of course implies (4.11), since $H^1(\Sigma)$ is dense in $H^{1/2}(\Sigma)$.

First, notice that the domain $H^1(\Sigma)$ of the form $t_{d,\nu}$ does not depend on ν, and $t_{d,\nu}(\chi,\chi)$ is holomorphic in K for each fixed $\chi \in H^1(\Sigma)$: the operators $T_{d,\nu}$ associated with such a family of forms (which is called holomorphic of type (a)) define a holomorphic family (Kato [13, Thm. VII-4.2]). Consequently, the family $T_{d,\nu}^{1/2}$ is also holomorphic in K (Kato [13, Rem. VII-4.7]).

On the other hand, we have seen in the proof of Proposition 3.1 that for real positive ν, the expansion (4.12) of $T_{d,\nu}^{1/2}\chi$ is valid for every $\chi \in D(T_{d,\nu}^{1/2}) = H^1(\Sigma)$. Moreover, using exactly the same techniques as for Theorem 3.2, we easily prove that the series in (4.12) defines a holomorphic family of unbounded operators on $L^2(\Sigma)$ (with domain $H^1(\Sigma)$). By virtue of the unique continuation property (Kato [13, Rem. VII-1.6]), this family is nothing but $T_{d,\nu}^{1/2}$, which completes the proof. □

LEMMA 4.2. *Let K be a compact subset of $\mathbb{D}\setminus\mathbb{K}$ and $d > 0$; then, for every $\nu \in K$, we have*

$$\left|\hat q_\nu(\hat X,\hat Y) - \hat q_{d,\nu}(\hat X,\hat Y)\right| \leq C\, \|\hat\varphi\|_\Sigma \left\|\hat\psi\right\|_\Sigma, \tag{4.13}$$

for all $\hat X = (\hat\varphi,\hat u)$ and $\hat Y = (\hat\psi,\hat v)$ in $\hat{\mathcal{H}}$.

Proof. We deduce from the asymptotic behaviour (3.41) of $q_\nu^{(n,m)}$ that

$$\left|\hat q_\nu(\hat X,\hat Y) - \hat q_{d,\nu}(\hat X,\hat Y)\right| \leq C\sum_{n\in\mathbb{Z}}\sum_{m\geq 0}\left|(\hat\varphi,\chi_{\bar\nu}^{(n,m)})_\Sigma\,(\chi_\nu^{(n,m)},\hat\psi)_\Sigma\right|.$$

Relation (4.13) thus results from Theorem 3.1 by the Schwarz inequality. □

4.2. Singularities of the reduced problem. The purpose of this paragraph is to study how the poles of $\hat A_\nu^{-1}$ affect the solution of the reduced problem. Indeed, it may happen that for a datum $f \in \mathcal{F}$, the solution $\hat A_\nu^{-1}\hat L(f)$ of $\hat{\mathcal{P}}_\nu$ is regular in a vicinity of a pole ν_* of $\hat A_\nu^{-1}$: this situation may occur if the datum f is such that $\hat L(f)$ belongs to the range $\mathrm{R}(\hat A_{\nu_*})$ of $\hat A_{\nu_*}$. The question is whether there exists some datum such that the solution of $\hat{\mathcal{P}}_\nu$ becomes singular in the vicinity of ν_*. We first prove the following result which concerns the nonreal poles of $\hat A_\nu^{-1}$.

PROPOSITION 4.1. *Let $\nu_* \in \mathbb{D}^-\setminus\mathbb{K}$. Then, ν_* is a pole of $\hat A_\nu^{-1}$ if and only if there exists at least a datum $f \in \mathcal{F}$ such that ν_* is a pole of $\hat A_\nu^{-1}\hat L(f)$.*

Proof. (i) If ν_* is a pole of $\hat A_\nu^{-1}\hat L(f)$ for some $f \in \mathcal{F}$, it is clearly a pole of $\hat A_\nu^{-1}$: a singularity of the solution can only proceed from a singularity of $\hat A_\nu^{-1}$.

(ii) Conversely, assume that ν_* is a pole of $\hat A_\nu^{-1}$. Let us prove by contradiction that ν_* is a pole of $\hat A_\nu^{-1}\hat L(f)$ for some $f \in \mathcal{F}$. Suppose that

$$\hat L(f) \in \mathrm{R}(\hat A_{\nu_*}) = \left(\operatorname{Ker}(\hat A_{\nu_*}^*)\right)^\perp \quad \forall f \in \mathcal{F}.$$

Let $\hat{X} = (\hat{\varphi}, \hat{u}) \in \operatorname{Ker}(\hat{A}^*_{\nu_*})$. From the definition (4.7), (4.8) of $\hat{L}(f)$, the relation $(\hat{L}(f), \hat{X})_{\hat{\mathcal{H}}} = 0$ yields

$$\int_\Gamma (f' \overline{\hat{\varphi}} + f'' \overline{\hat{u}.n})\, d\Gamma = 0 \quad \forall f = (f', f'') \in \mathcal{F},$$

which shows that

$$\hat{\varphi} = 0 \text{ and } \hat{u}.n = 0 \quad \text{on } \Gamma. \tag{4.14}$$

On the other hand, it may be easily seen that $\hat{A}^*_{\nu_*}$ is given by

$$(\hat{A}^*_{\nu_*} \hat{X}, \hat{Y})_{\hat{\mathcal{H}}} = \hat{k}(\hat{X}, \hat{Y}) - \overline{\nu_*}\, \hat{m}(\hat{X}, \hat{Y}) - \overline{\nu_*^{1/2}}\, \hat{c}(\hat{X}, \hat{Y}) + \overline{\hat{q}_\nu(\hat{Y}, \hat{X})}.$$

As $\hat{X}$ is assumed to belong to $\operatorname{Ker}(\hat{A}^*_{\nu_*})$ and $\hat{c}(\hat{X}, \hat{Y}) = 0$ by virtue of (4.14), we infer that

$$\hat{k}(\hat{X}, \hat{Y}) - \overline{\nu_*}\, \hat{m}(\hat{X}, \hat{Y}) + \overline{\hat{q}_\nu(\hat{Y}, \hat{X})} = 0 \quad \forall \hat{Y} \in \hat{\mathcal{H}}.$$

This implies in particular that $\hat{\varphi}$ and $\hat{u}$ satisfy, respectively, the equations

$$\begin{aligned} &\Delta\hat{\varphi} = 0 \quad \text{in } \hat{\Omega}, \\ &\partial_n \hat{\varphi} = 0 \quad \text{on } \Gamma, \end{aligned} \tag{4.15}$$

and

$$\begin{aligned} &\overline{\nu_*} \rho\, \hat{u}_i + \partial_{x_j} \sigma_{ij}(\hat{u}) = 0 \quad \text{in } B, \\ &\sigma_{ij}(\hat{u})\, n_j = 0 \quad \text{on } \Gamma_0 \cup \Gamma. \end{aligned} \tag{4.16}$$

Equations (4.15) together with (4.14) show that $\hat{\varphi} = 0$ in $\hat{\Omega}$. From (4.16), we readily deduce that $\hat{u} = 0$ in B, since $\operatorname{Im} \nu_* \neq 0$. As a consequence, $\operatorname{Ker}(\hat{A}^*_{\nu_*}) = \{0\}$, which is inconsistent with the fact that ν_* is a pole of $\hat{A}_\nu^{-1}$. □

Assume now that ν_* is a real positive pole of $\hat{A}_\nu^{-1}$. In this case, the arguments of the proof of Proposition 4.1 are still valid, except that (4.16) does not imply $\hat{u} = 0$ in B. Indeed, (4.16) is a classical eigenvalue problem which has a countable infinity of real positive eigenvalues, and ν_* may be one of them. In fact, from (4.14), the problem to be dealt with is the following:

$$\begin{aligned} &\nu_* \rho\, \hat{u}_i + \partial_{x_j} \sigma_{ij}(\hat{u}) = 0 \quad \text{in } B, \\ &\sigma_{ij}(\hat{u})\, n_j = 0 \quad \text{on } \Gamma_0 \cup \Gamma, \\ &\hat{u}.n = 0 \quad \text{on } \Gamma. \end{aligned} \tag{4.17}$$

A real positive number ν_* such that (4.17) has a nonzero solution $\hat{u}$ is referred to as an exceptional eigenvalue. Hargé [4] has proved that for almost every elastic body B with regular boundary ∂B, there is no exceptional eigenvalue. This means that these values may exist only for very particular shapes of the body. The axisymmetrical bodies provide the simplest example of exceptional eigenvalues. Indeed, the revolution motions about the axis of symmetry are obviously solutions of problem (4.17) associated with the value $\nu_* = 0$. But even in this case, it is not clear whether there exists a nonzero exceptional eigenvalue.

An exceptional eigenvalue ν_* is always a pole of $\hat{A}_\nu^{-1}$, since we can find $\hat{u} \neq 0$ such that $\hat{A}_\nu(0, \hat{u}) = 0$. Nevertheless, we cannot assert that there exists a datum f such that it is a pole of $\hat{A}_\nu^{-1} \hat{L}(f)$: indeed, if $\operatorname{Ker}(\hat{A}^*_{\nu_*})$ reduces to the pairs $(0, \hat{u})$ where $\hat{u}$

is a solution of (4.17), then $\hat{L}(f) \in R(\hat{A}_{\nu_*})$ for all $f \in \mathcal{F}$. As a consequence, for real poles of $\hat{A}_\nu^{-1}$, the statement of Proposition 4.1 becomes the following.

PROPOSITION 4.2. *Let $\nu_* \in \mathbb{R}^+$. Then, ν_* is a pole of $\hat{A}_\nu^{-1}$ if and only if there exists at least a datum $f \in \mathcal{F}$ such that ν_* is a pole of $\hat{A}_\nu^{-1}\hat{L}(f)$, except maybe when ν_* is an exceptional eigenvalue of the body.*

4.3. Analytic continuation of the initial problem. We are now able to proceed to the extension to the lower complex half plane of the solution operator $\mathcal{R}_\nu$ associated with the initial problem $\mathcal{P}_\nu$. This operator was defined in §§2.3 and 2.4 for $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$, and the equivalence between $\mathcal{P}_\nu$ and the reduced problem $\hat{\mathcal{P}}_\nu$ (Proposition 2.3) provides in this case a convenient expression for $\mathcal{R}_\nu$. Indeed, for a given $f \in \mathcal{F}$, let $\hat{X} = (\hat{\varphi}, \hat{u})$ denote the solution of $\hat{\mathcal{P}}_\nu$ (i.e., $\hat{X} = \hat{A}_\nu^{-1}\hat{L}(f)$). We know from Proposition 2.3 that the solution of $\mathcal{P}_\nu$ for the same datum f reads

$$\mathcal{R}_\nu f = (\varphi, u), \quad \text{where } (\varphi_{|\hat{\Omega}}, u) = (\hat{\varphi}, \hat{u}) \text{ and } \varphi_{|\check{\Omega}} = \check{\mathcal{R}}_\nu \hat{\varphi}_{|\Sigma}. \tag{4.18}$$

This identity actually defines the analytic continuation of $\mathcal{R}_\nu f$ to $\mathbb{D} \setminus \mathbb{K}$, since $\hat{A}_\nu^{-1}$ is a meromorphic family in $\mathbb{D} \setminus \mathbb{K}$ (Theorem 4.1) and $\check{\mathcal{R}}_\nu \hat{\varphi}_{|\Sigma}$ is analytic in this domain (Remark 3.7). As a consequence, for every $f \in \mathcal{F}$, the family $\nu \to \mathcal{R}_\nu f \in \mathcal{H}_{\text{loc}}$ is meromorphic in $\mathbb{D} \setminus \mathbb{K}$ and its poles coincide with those of $\hat{A}_\nu^{-1} f$. By virtue of Propositions 4.1 and 4.2, we can then state the main result of this paper.

THEOREM 4.2. *The solution operators $\mathcal{R}_\nu$, from $\mathcal{F}$ onto $\mathcal{H}_{\text{loc}}$, form a meromorphic family on $\mathbb{D} \setminus \mathbb{K}$. Its poles coincide with those of $\hat{A}_\nu^{-1}$, i.e., the solutions of the nonlinear eigenvalue problem* (4.9), *except the exceptional eigenvalues defined by* (4.17) *which may be removable singularities of $\mathcal{R}_\nu$. These poles are located in $\mathbb{R}^+$ or $\mathbb{D}^- \setminus \mathbb{K}$, and are referred to as "eigenfrequencies" in the first case, and "scattering frequencies" in the second one.*

Recall that the family $\mathcal{R}_\nu$ is said to be meromorphic near $\nu_* \in \mathbb{C}$ if there exists a vicinity $\mathcal{V}$ of ν_* and a sequence $\{\mathcal{R}^{(p)};\ p \geq -P\}$ (with $P \geq 0$) of operators from $\mathcal{F}$ to $\mathcal{H}_{\text{loc}}$ such that

$$\mathcal{R}_\nu f = \sum_{p \geq -P} (\nu - \nu_*)^p \mathcal{R}^{(p)} f, \tag{4.19}$$

where the series converges in $\mathcal{H}_{\text{loc}}$ for every $f \in \mathcal{F}$ and every $\nu \in \mathcal{V} \setminus \{\nu_*\}$. By (4.18), the $\mathcal{R}^{(p)}$ may be easily obtained from the series expansions of $\hat{A}_\nu^{-1}$ and $\check{\mathcal{R}}_\nu$.

Remark 4.2. The distinction between the real positive poles of $\mathcal{R}_\nu$ and the complex ones seems artificial, since they both are solutions of the same nonlinear eigenvalue problem. This difference actually results from the associated eigenvectors. Let $(\hat{\varphi}, \hat{u})$ be an eigenvector associated with a solution ν_* of problem (4.19), and let φ denote the analytic continuation of $\hat{\varphi}$ in the whole domain Ω, i.e., $\varphi_{|\hat{\Omega}} = \hat{\varphi}$ and $\varphi_{|\breve{\varphi}} = \check{\mathcal{R}}_{\nu_*} \hat{\varphi}_{|\Sigma}$. The asymptotic behaviour of φ at infinity depends on the location of ν_*: if ν_* is real, $\check{\mathcal{R}}_{\nu_*} \hat{\varphi}_{|\Sigma} \to 0$ at infinity (see §3.1), whereas it increases exponentially if $\nu_* \in \mathbb{D}^- \setminus \mathbb{K}$ (see Remark 3.7).

Remark 4.3. The points of $\mathbb{K}$ (defined by (3.40)), which are poles of the coupling operator, were left out for the analytic continuation of the reduced problem. In fact, these singularities are not intrinsic quantities of the initial problem, since they depend on the choice of the fictitious boundary Σ. This means that $\mathcal{R}_\nu$ actually defines a meromorphic family in $\mathbb{D}$. From a practical point of view, it is necessary to decide whether a point of $\mathbb{K}$ is a scattering frequency or not: a convenient criterion is given in [18, §4.3].

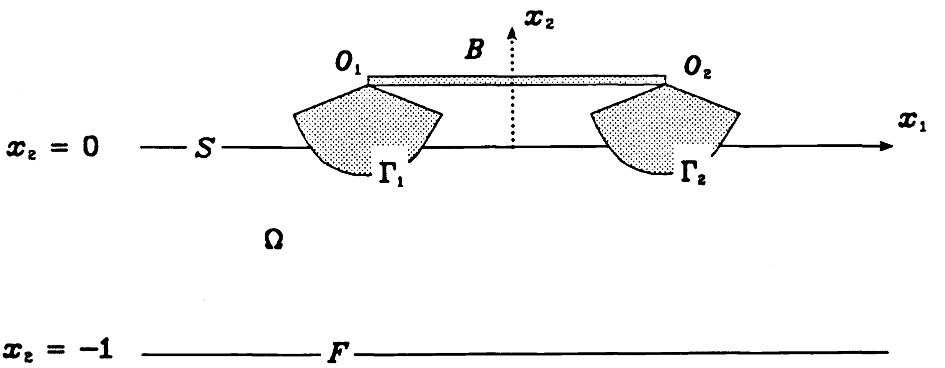

FIG. 5.1

Remark 4.4. On the other hand, the branch points of the solutions of the dispersion equation, which led us to introduce cuts in the complex plane, are clearly intrinsic singularities of the problem, for they do not depend on the method we used to construct the analytic continuation of $\mathcal{R}_\nu$. These are characteristic quantities of the asymptotic behaviour of the system at infinity.

Remark 4.5. The connection between scattering frequencies and resonant states (i.e., the peaks of the response curve of the system for real frequencies) has been circumstantially studied in [18]: for an internal approximation of the problem, we show how to construct explicitly the first terms of the Laurent series of the solution of $\hat{\mathcal{P}}_\nu$ in the vicinity of a scattering frequency. The same results apply to the present problem. A concrete example is given in §5.5 below.

5. Numerical application. We present in this last paragraph the outcome of a numerical application of our method for a two-dimensional problem. We are concerned here with the small motions of an elastic "catamaran" constituted of two rigid floating bodies linked together by an elastic beam. The characterization of the scattering frequencies associated with this problem is performed along the same lines as in the preceding sections: we will restrict ourselves to mention the basic stages of the method, as well as the main differences from the three-dimensional case (a more detailed study may be found in [5]). Except where otherwise stated, the notation previously introduced are retained.

5.1. Equations of the stationary problem. Consider a floating elastic "catamaran" as shown in Fig. 5.1. Let $\Omega \subset \mathbb{R}^2$ denote the domain filled by the fluid at rest, and $\partial\Omega$ its boundary which consists of the free surface S (located at $x_2 = 0$), the bottom F ($x_2 = -1$) and the immersed parts Γ_k, $k = 1, 2$, of the two hulls. The elastic beam B, which is parallel to S, is embedded in the bodies B_k at points O_k, $k = 1, 2$. For the sake of simplicity, it is assumed unstrained when the system is at rest. We denote by φ the (complex) velocity potential of the fluid, $u = (u_1, u_2)$ the displacement field of the beam (i.e., the horizontal and vertical displacements of each point of the beam), and s_k, $k = 1, 2$, the 3-components vectors which characterize the motions of the bodies with respect to O_k (displacement of O_k and rotation of the bodies):

$$s_k = (u_1(O_k), u_2(O_k), d_{x_1}u_2(O_k)). \tag{5.1}$$

The time-harmonic vibrations of the system are described by the following set of equations (where ν still denotes the frequency squared):

$$\Delta\varphi = 0 \quad \text{in } \Omega, \tag{5.2}$$

$$\partial_n\varphi - \nu\,\varphi = 0 \quad \text{on } S, \tag{5.3}$$

$$\partial_n\varphi = 0 \quad \text{on } F, \tag{5.4}$$

$$\nu\rho\, u_1 + d_{x_1}(\alpha\, d_{x_1} u_1) = 0 \quad \text{on } B, \tag{5.5}$$

$$\nu\rho\, u_2 - d^2_{x_1}(\beta\, d^2_{x_1} u_2) = 0 \quad \text{on } B, \tag{5.6}$$

$$\nu^{1/2}\, s_k.n_g - \partial_n\varphi = f'_k \quad \text{on } \Gamma_k, \quad k = 1,2, \tag{5.7}$$

$$(\nu\,\mathbb{M}_k - \mathbb{K}_k)s_k + \nu^{1/2}\int_{\Gamma_k} \varphi\, n_g\, d\Gamma_k + g_k = f''_k, \qquad k = 1,2. \tag{5.8}$$

Equations (5.2)–(5.4) are the same as in problem (2.13). Relations (5.5) and (5.6) are the dynamic equations of an elastic beam which model, respectively, the longitudinal and transverse vibrations of B. The mechanical data ρ, α, and β are assumed to belong to $L^\infty(B)$ and to be bounded from below by a positive constant (ρ is the mass of the beam per unit length, $\alpha = EA$ where E is the Young's modulus and A is the measure of each section of the beam, $\beta = EI$ where I is the geometrical inertia of each section). Equation (5.7) stands for the continuity of the normal velocity on the hulls: n_g denotes the so-called "generalized normal" defined by

$$n_g = (n_1, n_2, x_1 n_2 - x_2 n_1),$$

where $n = (n_1, n_2)$ is the unitary normal to Γ_k at point (x_1, x_2) measured with respect to O_k. Finally, (5.8) expresses the dynamic equations of the two rigid bodies (see John [10]). $\mathbb{M}_k$, which is referred to as the "generalized mass matrix," is the 3×3 positive matrix given by

$$\mathbb{M}_k = \begin{pmatrix} m_k & 0 & -m_k x_{2G_k} \\ 0 & m_k & m_k x_{1G_k} \\ -m_k x_{2G_k} & m_k x_{1G_k} & I_k \end{pmatrix},$$

where m_k is the mass of the body, (x_{1G_k}, x_{2G_k}) is the location of its centre of gravity with respect to O_k, and I_k is its inertia at point O_k. The "hydrostatic stiffness matrix" $\mathbb{K}_k$ is defined by

$$\mathbb{K}_k = \begin{pmatrix} 0 & 0 & 0 \\ 0 & \int_{S_k} dS_k & \int_{S_k} x_1\, dS_k \\ 0 & \int_{S_k} x_1\, dS_k & (x_{2C_k} - x_{2G_k})\int_{\Omega_k} d\Omega_k + \int_{S_k} x_1^2\, dS_k \end{pmatrix},$$

where S_k and Ω_k are represented in Fig. 5.2, and C_k is the geometrical centre of gravity of Ω_k. The 3-components vector g_k is the torque of the force exerted on the body by the beam, which expresses as follows:

$$g_k = (-1)^k\,(-\alpha\, d_{x_1} u_1(O_k), d_{x_1}(\beta\, d^2_{x_1} u_2(O_k), -\beta\, d^2_{x_1} u_2(O_k))). \tag{5.9}$$

In Equations (5.7) and (5.8), the right-hand members depend on the incident wave: f'_k is a function defined on Γ_k, and $f''_k \in \mathbb{C}^3$. More precisely, if φ_I denotes the velocity potential of the incident wave, we have

$$f'_k = \partial_n\varphi_I \quad \text{and} \quad f''_k = -\nu^{1/2}\int_{\Gamma_k} \varphi_I\, n_g\, d\Gamma_k.$$

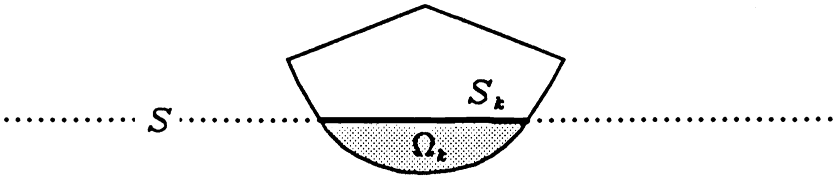

FIG. 5.2

As in §2.3, the asymptotic behaviour at infinity of the scattered wave is specified by means of the outgoing radiation condition

$$\lim_{x_1 \to \pm\infty} \int_{-1}^{0} \left|\partial_{x_1}\varphi \mp i\nu_0\,\varphi\right|^2 dx_2 = 0, \tag{5.10}$$

where ν_0 is, here again, the only positive root of

$$\nu_0 \tanh \nu_0 = \nu. \tag{5.11}$$

For every $\nu \in \mathbb{R}^+$, the stationary problem, denoted by $\mathcal{P}_\nu$ in the sequel, is then defined as follows:

$$\begin{array}{l} \text{Find } X = (\varphi, u) \in \mathcal{H}_{\text{loc}} \text{ such that} \\ \varphi \text{ and } u \text{ satisfy (5.2)–(5.8),} \\ \varphi \text{ satisfies the radiation condition (5.10),} \end{array} \tag{5.12}$$

where $\mathcal{H}_{\text{loc}}$ denotes the Frechet space

$$\mathcal{H}_{\text{loc}} = H^1_{\text{loc}}(\Omega) \times (H^1(B) \times H^2(B)), \tag{5.13}$$

and the datum $f = ((f_1', f_1''), (f_2', f_2''))$ is assumed to belong to

$$\mathcal{F} = (L^2(\Gamma_1) \times \mathbb{C}^3) \times (L^2(\Gamma_2) \times \mathbb{C}^3). \tag{5.14}$$

Following the same idea as in §2.4, problem $\mathcal{P}_\nu$ can be extended to the upper complex half plane by replacing the radiation condition by a decay condition at infinity. For every $\nu \in \mathbb{C}^+$, consider the problem (also denoted by $\mathcal{P}_\nu$)

$$\begin{array}{l} \text{Find } X = (\varphi, u) \in \mathcal{H} \text{ such that} \\ \varphi \text{ and } u \text{ satisfy (5.2)–(5.8),} \end{array} \tag{5.15}$$

where $\mathcal{H}$ is the Hilbert space

$$\mathcal{H} = H^1(\Omega) \times (H^1(B) \times H^2(B)). \tag{5.16}$$

PROPOSITION 5.1. *Let $\nu \in \mathbb{C}^+$. For every $f \in \mathcal{F}$, problem $\mathcal{P}_\nu$ has a unique solution $X = \mathcal{R}_\nu f$ in $\mathcal{H}$. Moreover, $\mathcal{R}_\nu$ is a continuous operator from $\mathcal{F}$ to $\mathcal{H}$.*

Proof. A variational formulation of $\mathcal{P}_\nu$ reads

$$\begin{array}{l} \text{Find } X \in \mathcal{H} \text{ such that} \\ a_\nu(X, Y) = l(f; Y) \quad \forall Y \in \mathcal{H}, \end{array}$$

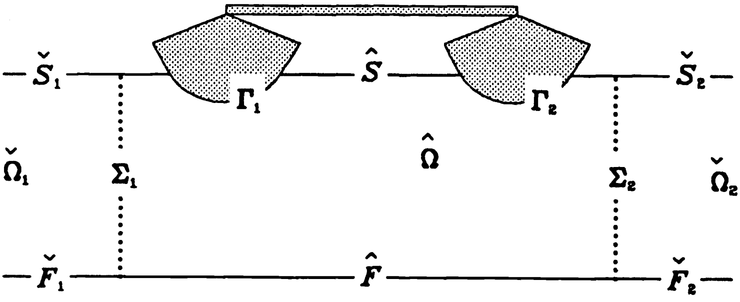

FIG. 5.3. *The inner and outer domains.*

where $a_\nu(\cdot\,,\cdot)$ is the sesquilinear form

$$\begin{aligned}a_\nu(X,Y) = &\int_\Omega \nabla\varphi.\nabla\bar\psi\, d\Omega + \int_B \alpha\, d_{x_1}u_1\, d_{x_1}\bar v_1\, dB + \int_B \beta\, d^2_{x_1}u_2\, d^2_{x_1}\bar v_2\, dB\\ &+\sum_{k=1}^{2}(\mathbb{K}_k s_k).\bar t_k - \nu\left(\int_S \varphi\bar\psi\, dS + \int_B \rho\, u.\bar v\, dB + \sum_{k=1}^{2}(\mathrm{M}_k s_k).\bar t_k\right)\\ &-\nu^{1/2}\sum_{k=1}^{2}\int_{\Gamma_k}(s_k.n_g\,\bar\psi + \varphi\,\bar t_k.n_g)\, d\Gamma_k,\end{aligned}$$

and $l(f;\cdot)$ is the semilinear form

$$l(f;Y) = -\sum_{k=1}^{2}\left(\int_{\Gamma_k} f'_k\bar\psi\, d\Gamma_k + f''_k.\bar t_k\right),$$

where $Y = (\psi, v) \in \mathcal{H}$ and t_k is defined as in (5.1) by

$$t_k = (v_1(O_k), v_2(O_k), d_{x_1}v_2(O_k)).$$

Using the same techniques as in the proof of Proposition 2.1, it may be easily seen that a_ν is a continuous and coercive form on $\mathcal{H}\times\mathcal{H}$. The statement of Proposition 5.1 then follows from Lax–Milgram's theorem. □

5.2. Reduction to a bounded domain. Let $\hat\Omega \subset \Omega$ be the bounded domain delimited by two vertical segments Σ_1 and Σ_2 (located, respectively, at $x_1 = a_1$ and $x_1 = a_2$) chosen such that the hulls Γ_1 and Γ_2 are contained in the boundary $\partial\hat\Omega$ of $\hat\Omega$ (see Fig. 5.3). We denote by $\hat S$ and $\hat F$ the parts of S and F which are included in $\partial\hat\Omega$, and by $\check\Omega_j$, $\check S_j$, and $\check F_j$ (for $j = 1, 2$) the left and right connected components of $\Omega\setminus\hat\Omega$, $S\setminus\hat S$ and $F\setminus\hat F$, respectively.

As in § 2.5, we define, for $j = 1, 2$ and $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$, the coupling operator $\mathcal{Q}_{j,\nu}$ from $H^{1/2}(\Sigma_j)$ to $H^{-1/2}(\Sigma_j)$ by

$$\mathcal{Q}_{j,\nu}\,\tau = \partial_n(\check{\mathcal{R}}_{j,\nu}\,\tau)_{|\Sigma_j}, \tag{5.17}$$

where $\check{\mathcal{R}}_{j,\nu}\,\tau = \check\varphi$ is the solution of the following outer Dirichlet problem $\check{\mathcal{P}}_{j,\nu}$:

$$\left\{\begin{array}{l}\text{Find } \check\varphi \text{ in } H^1_{\text{loc}}(\check\Omega_j) \text{ if } \nu\in\mathbb{R}^+ \text{ or } H^1(\check\Omega_j) \text{ if } \nu\in\mathbb{C}^+ \text{ such that}\\ \Delta\check\varphi = 0 \quad\text{in } \check\Omega_j,\\ \partial_n\check\varphi - \nu\,\check\varphi = 0 \quad\text{on } \check S_j,\\ \partial_n\check\varphi = 0 \quad\text{on } \check F_j,\\ \check\varphi = \tau \quad\text{on } \Sigma_j,\\ \check\varphi \text{ satisfies the radiation condition (5.10)} \quad\text{if } \nu\in\mathbb{R}^+.\end{array}\right. \tag{5.18}$$

The well-posedness of this latter problem, as well as the continuity of the solution operator $\check{\mathcal{R}}_{j,\nu}$, may be proved by the same method as for Proposition 2.2. Consequently, $\mathcal{Q}_{j,\nu}$ is continuous from $H^{1/2}(\Sigma_j)$ to $H^{-1/2}(\Sigma_j)$.

Consider then the reduced problem $\hat{\mathcal{P}}_\nu$, set in the bounded fluid domain $\hat{\Omega}$:

$$\begin{array}{l}\text{Find } \hat{X} = (\hat{\varphi}, \hat{u}) \in \hat{\mathcal{H}} \text{ such that} \\ \Delta\hat{\varphi} = 0 \quad \text{in } \hat{\Omega}, \\ \partial_n\hat{\varphi} - \nu\,\hat{\varphi} = 0 \quad \text{on } \hat{S}, \\ \partial_n\hat{\varphi} = 0 \quad \text{on } \hat{F}, \\ \nu\rho\,\hat{u}_1 + d_{x_1}(\alpha\, d_{x_1}\hat{u}_1) = 0 \quad \text{on } B, \\ \nu\rho\,\hat{u}_2 - d^2_{x_1}(\beta\, d^2_{x_1}\hat{u}_2) = 0 \quad \text{on } B, \\ \nu^{1/2}\,\hat{s}_k.n_g - \partial_n\hat{\varphi} = f'_k \quad \text{on } \Gamma_k, \\ (\nu\,\mathbb{M}_k - \mathbb{K}_k)\hat{s}_k + \nu^{1/2}\int_{\Gamma_k}\hat{\varphi}\, n_g\, d\Gamma_k + \hat{g}_k = f''_k, \\ \partial_n\hat{\varphi} = -\mathcal{Q}_{j,\nu}\,\hat{\varphi}_{|\Sigma_j} \quad \text{on } \Sigma_j,\end{array} \tag{5.19}$$

where $\hat{s}_k$ and $\hat{g}_k$ are defined as in (5.1) and (5.9), and $\hat{\mathcal{H}}$ denotes the Hilbert space

$$\hat{\mathcal{H}} = H^1(\hat{\Omega}) \times (H^1(B) \times H^2(B)). \tag{5.20}$$

The equivalence between $\hat{\mathcal{P}}_\nu$ and the initial problem $\mathcal{P}_\nu$, which is expressed in Proposition 5.2 below, follows from the same arguments as for Proposition 2.3.

PROPOSITION 5.2. *Let $\nu \in \mathbb{R}^+ \cup \mathbb{C}^+$; for every $f \in \mathcal{F}$, problem $\mathcal{P}_\nu$ has at least (respectively, at most) one solution if and only if the same holds for $\hat{\mathcal{P}}_\nu$. Moreover, if $\hat{X} = (\hat{\varphi}, \hat{u})$ is a solution of $\hat{\mathcal{P}}_\nu$, then $X = (\varphi, \hat{u})$, where φ is the function given by*

$$\varphi_{|\hat{\Omega}} = \hat{\varphi} \quad \textit{and} \quad \varphi_{|\check{\Omega}} = \check{\mathcal{R}}_\nu\,\hat{\varphi}_{|\Sigma},$$

is a solution of $\mathcal{P}_\nu$. Conversely, if $X = (\varphi, u)$ is a solution of $\mathcal{P}_\nu$, then $\hat{X} = (\varphi_{|\hat{\Omega}}, u)$ is a solution of $\hat{\mathcal{P}}_\nu$.

5.3. Analytic continuation. The analytic extension of the reduced problem $\hat{\mathcal{P}}_\nu$ is based on the explicit series expansion of the coupling operators $\mathcal{Q}_{j,\nu}$ which is achieved, here again, by the method of separation of variables.

In the case of real positive ν, it is an easy matter to check that the solutions with separated variables of the outer problem $\check{\mathcal{P}}_{j,\nu}$ are given (up to a multiplicative complex constant) by

$$\check{\varphi}^{(m)}_{j,\nu}(x_1, x_2) = \tau^{(m)}_\nu(x_2)\; e^{(-1)^{j+1}\zeta^{(m)}_\nu(x_1 - a_j)} \quad \text{for } m \geq 0, \tag{5.21}$$

where the functions $\tau^{(m)}_\nu$ and the complex numbers $\zeta^{(m)}_\nu$ are defined as in Lemma 3.1. Note that $\check{\varphi}^{(0)}_{j,\nu}$ is the only radiative solution: the others are evanescent, since they decrease exponentially at infinity.

Using some classical results of the spectral theory of selfadjoint operators (see the proof of Proposition 3.1), we readily prove the following.

PROPOSITION 5.3. *Let $\nu > 0$; the set $\mathcal{T}_\nu = \{\tau^{(m)}_\nu;\ m \geq 0\}$ is an orthonormal basis of $L^2(\Sigma_j)$ and an orthogonal basis of $H^s(\Sigma_j)$ for every $s \in \,]0, 1]$. Furthermore, the expression*

$$[\tau]_{\nu,s} = \left(\sum_{m \geq 0} (1 + m^2)^s \left| (\tau, \tau^{(m)}_\nu)_{\Sigma_j} \right|^2 \right)^{1/2} \tag{5.22}$$

is a norm on $H^s(\Sigma_j)$ equivalent to the usual norm.

As a consequence, every function $\tau \in H^{1/2}(\Sigma_j)$ expands as

$$\tau = \sum_{m\geq 0} (\tau, \tau_\nu^{(m)})_{\Sigma_j}\, \tau_\nu^{(m)}.$$

Noticing that $\check{\varphi}_{j,\nu}^{(m)}$ (given by (5.21)) is nothing but the solution of $\check{\mathcal{P}}_{j,\nu}$ for the Dirichlet datum $\tau_\nu^{(m)}$, we infer that the general solution of $\check{\mathcal{P}}_{j,\nu}$ reads

$$\check{\mathcal{R}}_{j,\nu}\,\tau = \sum_{m\geq 0} (\tau, \tau_\nu^{(m)})_{\Sigma_j}\, \check{\varphi}_{j,\nu}^{(m)},$$

where the series converges in $H^1_{\text{loc}}(\check{\Omega}_j)$. The diagonal form of the coupling operator for $\nu \in \mathbb{R}^+$ follows:

$$Q_{j,\nu}\,\tau = \sum_{m\geq 0} \zeta_\nu^{(m)}\, (\tau, \tau_\nu^{(m)})_{\Sigma_j}\, \tau_\nu^{(m)} \quad \forall \tau \in H^{1/2}(\Sigma_j). \tag{5.23}$$

The case of complex ν is dealt with as described in §3.2. We have seen that each solution $\zeta_\nu^{(m)}$ of the dispersion equation extends analytically in the simply connected domain $\mathbb{D} \subset \mathbb{C}$. The same holds for the functions $\tau_\nu^{(m)}$ and $\check{\varphi}_{j,\nu}^{(m)}$ (which are defined everywhere in $\mathbb{D}$). Note that if $\nu \in \mathbb{D} \setminus \mathbb{R}^+$, each solution $\check{\varphi}_{j,\nu}^{(m)}$ decreases exponentially at infinity except in the case $m = 0$ and $\nu \in \mathbb{D}^-$, where it becomes exponentially increasing (see Proposition B.5). Proposition 5.3 extends as follows.

PROPOSITION 5.4. *For every $\nu \in \mathbb{D}$ and every $s \in [0,1]$, the set $\mathcal{T}_\nu = \{\tau_\nu^{(m)};\ m \geq 0\}$ is a basis of $H^s(\Sigma_j)$ and the expression $[\tau]_{\nu,s}$ given by (5.22) is still a norm on $H^s(\Sigma_j)$ equivalent to the usual norm. Moreover, the two families $\mathcal{T}_\nu$ and $\mathcal{T}_{\bar{\nu}}$ are adjoint to each other in $L^2(\Sigma_j)$.*

The proof of this statement is simpler than Theorem 3.1. We use directly the perturbation result given in the proof of Lemma 3.3. Indeed, it may be easily seen that for every $\nu \in \mathbb{D}$ and $\mu \in \mathbb{R}^+$, we have

$$\sum_{m\geq 0} \frac{\left[\tau_\nu^{(m)} - \tau_\mu^{(m)}\right]^2_{\mu,s}}{\left[\tau_\mu^{(m)}\right]^2_{\mu,s}} < \infty.$$

We readily deduce from Proposition 5.4 that if $\nu \in \mathbb{D}^+$, the coupling operator $Q_{j,\nu}$ expands as

$$Q_{j,\nu}\,\tau = \sum_{m\geq 0} \zeta_\nu^{(m)}\, (\tau, \tau_{\bar{\nu}}^{(m)})_{\Sigma_j}\, \tau_\nu^{(m)} \quad \forall \tau \in H^{1/2}(\Sigma_j). \tag{5.24}$$

This expansion actually defines the analytic continuation of $Q_{j,\nu}$: it appears as an analytic family from $\mathbb{D}$ to $\mathcal{B}(H^{1/2}(\Sigma_j), H^{-1/2}(\Sigma_j))$.

We can then proceed to the analytic extension of the reduced problem $\hat{\mathcal{P}}_\nu$ by writing it in variational form:

$$\begin{aligned} &\text{Find } \hat{X} = (\hat{\varphi}, \hat{u}) \in \hat{\mathcal{H}} \text{ such that} \\ &\hat{a}_\nu(\hat{X}, \hat{Y}) = \hat{l}(f; \hat{Y}) \quad \forall \hat{Y} \in \hat{\mathcal{H}}, \end{aligned} \tag{5.25}$$

where $\hat{a}_\nu$ is the sesquilinear form defined on $\hat{\mathcal{H}} \times \hat{\mathcal{H}}$ by

$$\hat{a}_\nu(\hat{X},\hat{Y}) = \hat{k}(\hat{X},\hat{Y}) - \nu\, \hat{m}(\hat{X},\hat{Y}) - \nu^{1/2}\, \hat{c}(\hat{X},\hat{Y}) + \hat{q}_\nu(\hat{X},\hat{Y}), \tag{5.26}$$

with

$$\hat{k}(\hat{X},\hat{Y}) = \int_{\hat{\Omega}} \nabla\hat{\varphi}.\overline{\nabla\hat{\psi}}\, d\hat{\Omega} + \int_B \alpha\, d_{x_1}\hat{u}_1\overline{d_{x_1}\hat{v}_1}\, dB + \int_B \beta\, d^2_{x_1}\hat{u}_2\overline{d^2_{x_1}\hat{v}_2}\, dB + \sum_{k=1}^{2}(\mathbb{K}_k\hat{s}_k).\overline{\hat{t}_k}, \tag{5.27}$$

$$\hat{m}(\hat{X},\hat{Y}) = \int_{\hat{S}} \hat{\varphi}\overline{\hat{\psi}}\, d\hat{S} + \int_B \rho\, \hat{u}.\overline{\hat{v}}\, dB + \sum_{k=1}^{2}(\mathbb{M}_k\hat{s}_k).\overline{\hat{t}_k}, \tag{5.28}$$

$$\hat{c}(\hat{X},\hat{Y}) = \sum_{k=1}^{2}\int_{\Gamma_k} (\hat{s}_k.n_g\,\overline{\hat{\psi}} + \hat{\varphi}\,\overline{\hat{t}_k.n_g})\, d\Gamma_k, \tag{5.29}$$

$$\hat{q}_\nu(\hat{X},\hat{Y}) = \sum_{j=1}^{2}\sum_{m\geq 0} \zeta_\nu^{(m)}\, (\hat{\varphi}, \tau_{\bar{\nu}}^{(m)})_{\Sigma_j}\, (\tau_\nu^{(m)}, \hat{\psi})_{\Sigma_j} \tag{5.30}$$

for all $\hat{X} = (\hat{\varphi}, \hat{u})$ and $\hat{Y} = (\hat{\psi}, \hat{v})$ in $\hat{\mathcal{H}}$. The semilinear form $\hat{l}$ is given by

$$\hat{l}(f;\hat{Y}) = -\sum_{k=1}^{2}\left(\int_{\Gamma_k} f'_k\overline{\hat{\psi}}\, d\Gamma_k + f''_k.\overline{\hat{t}_k}\right). \tag{5.31}$$

Let $\hat{A}_\nu$ denote the bounded operator on $\hat{\mathcal{H}}$ associated with $\hat{a}_\nu$, i.e., defined by the relation $(\hat{A}_\nu\hat{X},\hat{Y})_{\hat{\mathcal{H}}} = \hat{a}_\nu(\hat{X},\hat{Y})$. As in Theorem 4.1, a characterization of the eigenvalues and scattering frequencies of the problem is as follows.

THEOREM 5.1. *The operators $\hat{A}_\nu$ for $\nu \in \mathbb{D}$ form a holomorphic family of Fredholm operators on $\hat{\mathcal{H}}$. Moreover, $\hat{A}_\nu^{-1}$ is a meromorphic family in $\mathbb{D}$ whose poles are located in $\mathbb{R}^+$ or $\mathbb{D}^-$. These poles are the solutions of the following nonlinear* (*and nonselfadjoint*) *eigenvalue problem:*

$$\begin{aligned}&\textit{Find } \nu \in \mathbb{R}^+ \cup \mathbb{D}^- \textit{ such that there exists } \hat{X} \in \hat{\mathcal{H}} \setminus \{0\}, \textit{ which satisfies}\\ &\hat{k}(\hat{X},\hat{Y}) - \nu^{1/2}\, \hat{c}(\hat{X},\hat{Y}) + \hat{q}_\nu(\hat{X},\hat{Y}) = \nu\, \hat{m}(\hat{X},\hat{Y}) \quad \forall \hat{Y} \in \hat{\mathcal{H}}.\end{aligned} \tag{5.32}$$

5.4. Numerical implementation. The discretization of the problem involves two steps. We first truncate the series expansion of the sesquilinear form $\hat{q}_\nu$ (we denote by M the order of truncation of the series). We then define a finite-dimensional subspace of $\hat{\mathcal{H}}$ by means of a standard conforming element method. For the fluid domain $\hat{\Omega}$, we use classical quadrangular Lagrange finite elements (see, e.g., Ciarlet [3]), i.e., a piecewise polynomial interpolation of partial order 1 (class $\mathcal{C}^0$) for $\hat{\varphi}$. For the beam, we use standard beam elements, i.e., a polynomial interpolation of order 1 (class $\mathcal{C}^0$) for $\hat{u}_1$, and of order 3 (class $\mathcal{C}^1$) for $\hat{u}_2$. Let $\mathcal{H}_h$ denote the approximation space resulting from this finite element discretization, and let $(\cdot \mid \cdot)_h$ be the scalar product in $\mathcal{H}_h$. Consider then the matrices $\mathbb{M}_h$, $\mathbb{K}_h$, $\mathbb{C}_h$, and $\mathbb{Q}^{(M)}_{\nu,h}$ given by

$$\begin{aligned}(\mathbb{M}_h X_h \mid Y_h)_h &= \hat{m}(X_h, Y_h),\\ (\mathbb{K}_h X_h \mid Y_h)_h &= \hat{k}(X_h, Y_h),\\ (\mathbb{C}_h X_h \mid Y_h)_h &= \hat{c}(X_h, Y_h),\\ (\mathbb{Q}^{(M)}_{\nu,h} X_h \mid Y_h)_h &= \sum_{j=1}^{2}\sum_{m=0}^{M} \zeta_\nu^{(m)}\, (\varphi_h, \tau_{\bar{\nu}}^{(m)})_{\Sigma_j}\, (\tau_\nu^{(m)}, \psi_h)_{\Sigma_j}\end{aligned}$$

for all $X_h = (\varphi_h, u_h)$ and $Y_h = (\psi_h, v_h)$ in $\mathcal{H}_h$. Note that $\mathbb{M}_h$, $\mathbb{K}_h$, and $\mathbb{C}_h$ are real symmetric matrices, and $\mathbb{Q}_{\nu,h}^{(M)}$ is complex symmetric (but not selfadjoint). These matrices are computed by classical assembly techniques. For the sake of simplicity, we omit the index "h" in the sequel.

The numerical application concerns three points: the usual approach which consists in computing the response curve of the body for real frequencies, the present method of determination of scattering frequencies, and finally, a comparison between both approaches, by means of the series expansion of the response in the vicinity of the scattering frequencies.

(i) The computation of the response curve of the floating body is performed as follows. Consider a monochromatic incident wave of frequency $\nu^{1/2} \in \mathbb{R}^+$ given by

$$\varphi_I(x_1, x_2) = \frac{\cosh \nu_0(x_2+1)}{\nu^{1/2} \cosh \nu_0}\, e^{i\nu_0 x_1},$$

where ν_0 is the positive root of (5.11) (the amplitude of this wave is 1, since the free surface elevation is defined by $\eta(x_1) = i\,\nu^{1/2}\varphi_I(x_1, 0)$; see [10]). From (5.25), the approximate response of the system is then the solution $X = (\varphi, u)$ of the following linear problem:

$$(\mathbb{K} - \nu\mathbb{M} - \nu^{1/2}\mathbb{C} + \mathbb{Q}_\nu^{(M)})\, X = F_\nu, \tag{5.33}$$

where the right-hand member is defined by

$$(F_\nu \mid Y) = -\sum_{k=1}^{2} \int_{\Gamma_k} (\partial_n \varphi_I\, \bar{\psi} - \nu^{1/2}\varphi_I\, \bar{t}_k.n_g)\, d\Gamma_k. \tag{5.34}$$

The total energy of the catamaran follows:

$$E_\nu = \tfrac{1}{2}((\nu\mathbb{M} + \mathbb{K})\dot{X} \mid \dot{X}), \quad \text{where } \dot{X} = (0, u). \tag{5.35}$$

By computing this quantity step by step over a given frequency range, we obtain the response curve of the catamaran: its peaks are the resonant states of the system.

(ii) On the other hand, consider now the matrix nonlinear eigenvalue problem associated with (5.32),

$$(\mathbb{K} - \nu^{1/2}\mathbb{C} + \mathbb{Q}_\nu^{(M)})\, X = \nu\mathbb{M}\, X, \tag{5.36}$$

whose solutions are the approximate scattering frequencies. Solving this problem amounts to determining the solutions of the fixed-point equation $\lambda_k(\nu) = \nu$, where $\lambda_k(\nu)$ denotes any eigenvalue of the problem

$$(\mathbb{K} - \nu^{1/2}\mathbb{C} + \mathbb{Q}_\nu^{(M)})\, X = \lambda_k(\nu)\, \mathbb{M}\, X. \tag{5.37}$$

This latter equation is solved as described in [18, §6.3] by an iterative Newton method.

(iii) As for the continuous problem, the solution of (5.33) is a meromorphic function of ν. In the vicinity of an approximate scattering frequency ν_*, it expands as

$$X = \sum_{p \geq -P} (\nu - \nu_*)^p X^{(p)}, \qquad P \geq 0.$$

We described in [18] how to calculate the first terms of this expansion. In particular, if ν_* is a nonsingular simple scattering frequency (i.e., $\lambda_k(\nu_*) = \nu_*$ is a simple eigenvalue of (5.37) and $d_\nu \lambda_k(\nu_*) \neq 1$), we have $P = 1$ and

$$X^{(-1)} = (\varphi^{(-1)}, u^{(-1)}) = \frac{(F^{(0)} \mid \bar{X}_{\nu_*})}{((\frac{1}{2}\,\nu_*^{-1/2}\mathbb{C} + d_\nu \mathbb{Q}_{\nu_*}^{(M)} - \mathbb{M})X_{\nu_*} \mid \bar{X}_{\nu_*})}\, X_{\nu_*}, \tag{5.38}$$

where $F^{(0)}$ is the first term of the expansion of F_ν near ν_* (F_ν depends analytically on ν), and X_{ν_*} is a scattering mode associated with ν_* (i.e., an eigenvector of (5.37) for $\nu = \nu_*$ associated with the eigenvalue $\lambda_k(\nu_*) = \nu_*$). In this case, the total energy of the catamaran expands as

$$E_\nu = \frac{|\nu - \nu_*|^{-2}}{2}\, ((\nu_* \mathbb{M} + \mathbb{K})\dot{X}^{(-1)} \mid \dot{X}^{(-1)}) + O(|\nu - \nu_*|^{-1}), \tag{5.39}$$

where $\dot{X}^{(-1)} = (0, u^{(-1)})$. For the scattering frequencies which are close enough to the positive real axis, we will see that the only first term of this expansion provides a good approximation of the response curve of the catamaran.

5.5. Numerical results. We present a typical numerical application which is related to the following data. The hulls of the two rigid bodies are parabolic curves defined by

$$x_2 = 2(x_1 \pm 1)^2 - 0.2\,.$$

The centres of gravity of the bodies are $G_k = (\pm 1, 0)$, and the embedding points are $O_k = (\pm 1, 0.3)$. The inertia of each body at point O_k is 0.2. The mechanical data of the beam are assumed constant: $\rho = 0.04$, $\alpha = 0.7$, and $\beta = 0.35$.

The discretizetion of the fluid domain is shown in Fig. 5.4 (770 degrees of freedom for φ). For the beam, we use 38 elements (117 degrees of freedom for u).

The upper part of Fig. 5.5 shows the response curve of the catamaran (i.e., function E_ν defined in (5.35)) in the frequency range $[0.7, 3.0]$. In the lower part of the same figure, the locations of the computed scattering frequencies in the lower complex half plane (solutions of (5.36)) are displayed. All these scattering frequencies are simple; their numerical values are

	(a)	(b)	(c)	(d)	(e)	(f)	(g)
real part	1.028	1.306	1.636	1.776	2.186	2.530	2.723
imag. part	0.175	0.015	0.191	0.011	0.143	0.043	0.010.

As expected, their real parts agree with the resonant states of the catamaran, i.e. the peaks of the response curve. Note that the sharp peaks correspond to the scattering frequencies which are very close to the positive real axis (imaginary part about 10^{-2} for (b), (d), and (g)).

Figs. 5.6(a)–5.6(e) show the scattering modes associated with the scattering frequencies (a)–(e). Only the strain of the catamaran and the free surface elevation are represented. The location of the system at rest is indicated by the dotted line.

Case (a) is nearly a rigid motion of the catamaran (very slight strain of the beam): it is essentially a "rool" motion coupled with a small "sway" (displacement in the x_1 direction).

Case (b) shows, on the other hand, an important bending strain of the beam with nearly no global motion of the catamaran. In fact, this mode is almost an eigenmode

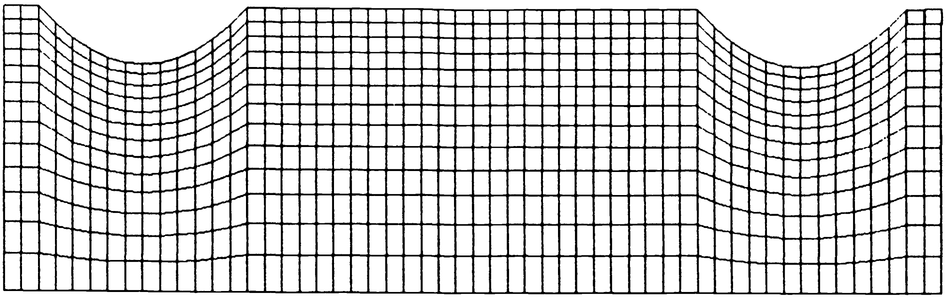

FIG. 5.4. *Discretization of the fluid domain.*

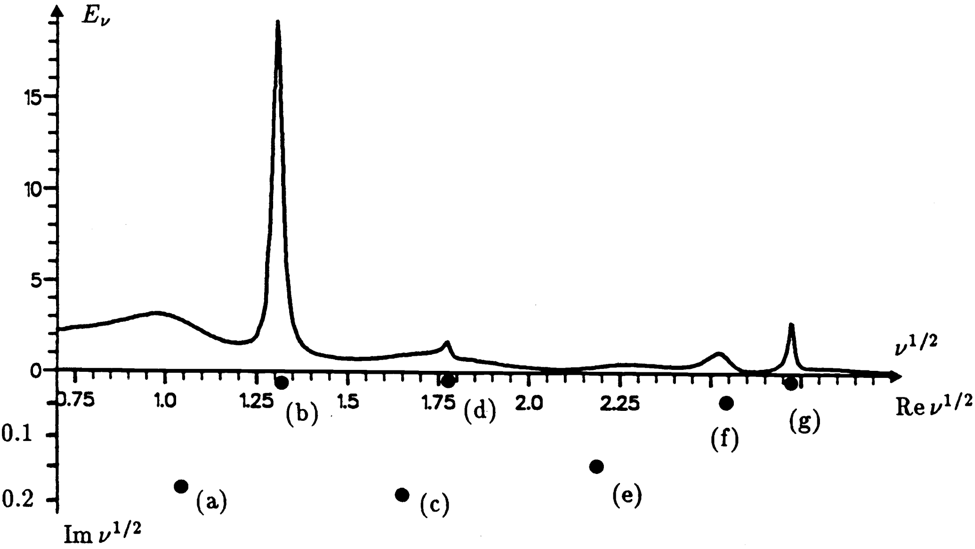

FIG. 5.5. *Response curve and scattering frequencies.*

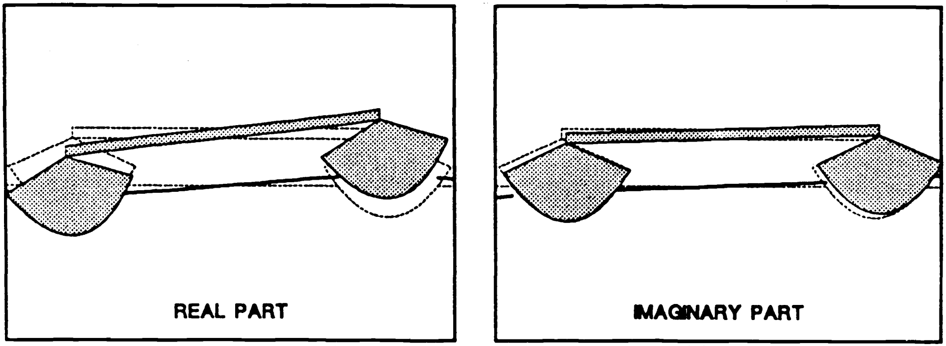

FIG. 5.6(a). *Scattering mode associated with* (a).

of the body uncoupled with the fluid, since the free surface elevation is small with respect to the displacement of the beam.

Case (c) is a symmetric "heave" motion (vertical global displacement) together with a slight longitudinal and bending strain of the beam. As in case (a), this is clearly a coupled mode between the fluid and the floating body.

Case (d) shows a large free surface elevation compared with the motion of the catamaran. In fact, this elevation is nearly zero outside the two hulls: the wave is "trapped" between them. Contrary to (b), this mode is almost a scattering mode (or a "trapped mode") of the fluid uncoupled with the floating body. This explains in particular why the associated peak of the response curve is low.

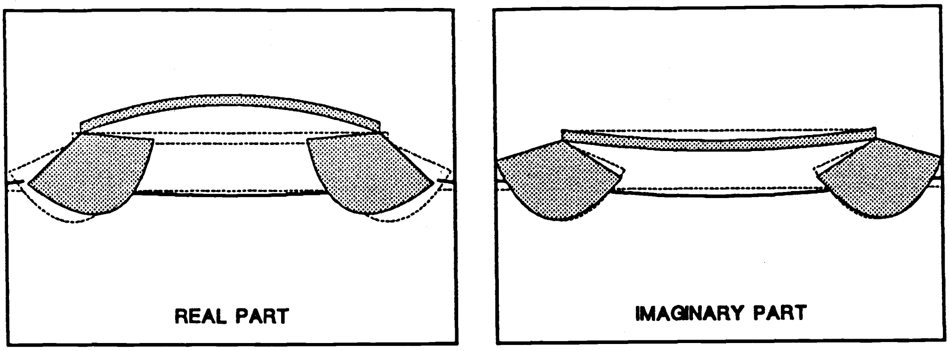

FIG. 5.6(b). *Scattering mode associated with* (b).

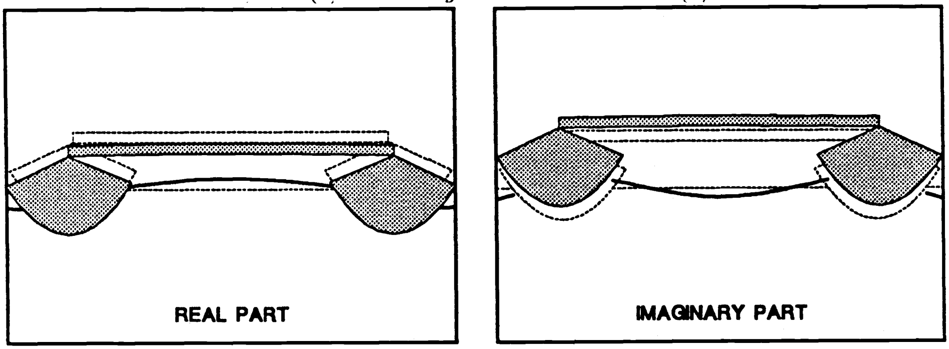

FIG. 5.6(c). *Scattering mode associated with* (c).

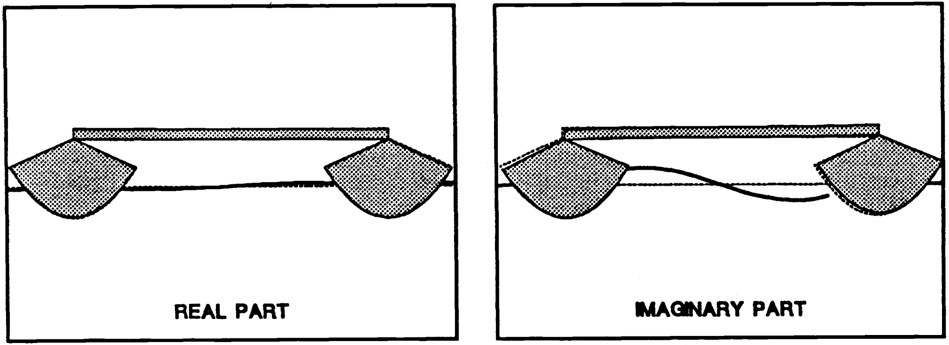

FIG. 5.6(d). *Scattering mode associated with* (d).

Case (e) is a coupled scattering mode of the system: as in case (c), it essentially consists in a global heave motion and a longitudinal strain of the beam.

Fig. 5.7 compares the response curve of the catamaran (i.e., the curve of Fig 5.5, reproduced here in dotted line, with the approximation of resonant states which follows from the first term of the expansion of the response (order -1) in the vicinity of the scattering frequency (i.e., formulas (5.38) and (5.39) applied for real frequencies). This approximation is rather good for (b) and (g) (relative error about 10^{-2} for the maximum). In case (d), the location of the peak is correct but not its height: intuitively, this may be accounted for by the fact that the energy of the catamaran in the scattering mode (d) is low. For the other resonant states, we notice a sensible shift between the peak and its approximation: the only first term of the expansion of the response is not sufficient to provide a precise location of the peak (an estimate of this shift using the second term of the expansion is given in [18]).

Appendix A. Series expansion of the solution of the outer problem. This

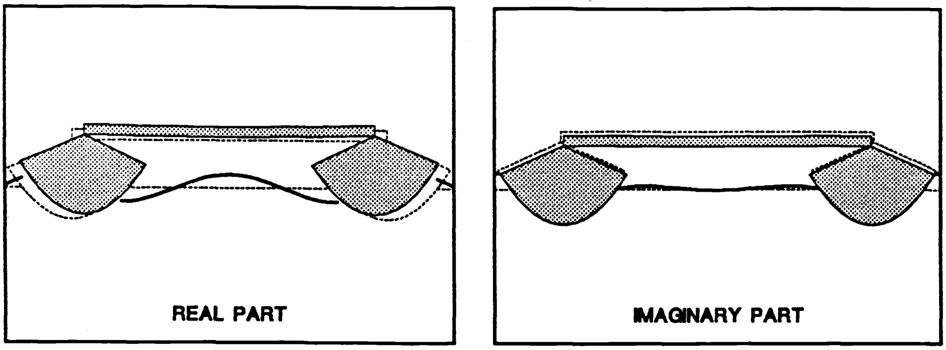

FIG. 5.6(e). *Scattering mode associated with* (e).

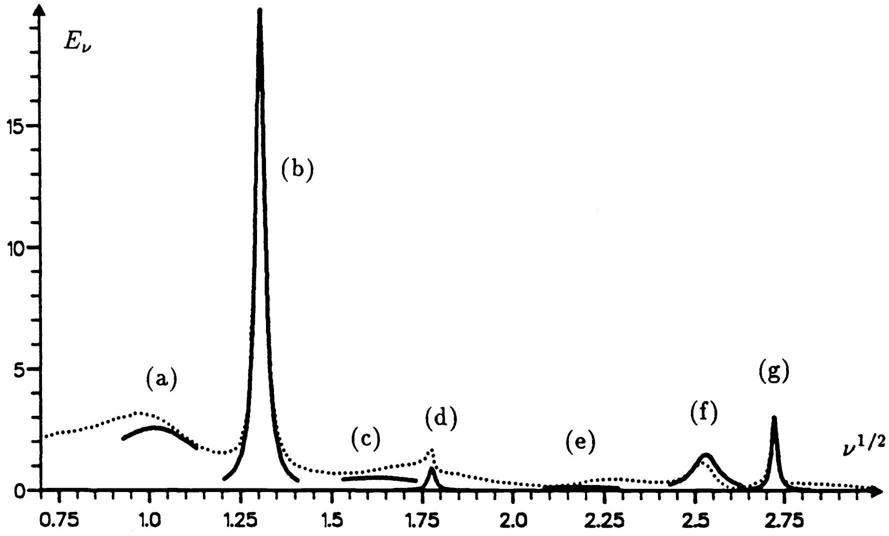

FIG. 5.7. *Approximation of resonant states.*

appendix is devoted to the proof of Lemma 3.2. We show that the series constructed in §3.1 for $\nu \in \mathbb{R}^+$ (see (3.20))

$$\check{\varphi} = \sum_{n\in\mathbb{Z}} \sum_{m\geq 0} (\chi, \chi_\nu^{(n,m)})_\Sigma \, \check{\varphi}_\nu^{(n,m)} \tag{A.1}$$

converges in $H^1_{\text{loc}}(\check{\Omega})$ for every $\chi \in H^{1/2}(\Sigma)$, depends continuously on χ and satisfies the radiation condition (2.14). These results are based on asymptotic properties of the modified Bessel functions K_n which are collected in §A.3.

Let us point out that the method we present below can be used similarly for the two-dimensional acoustic scattering problem, in order to prove that the Fourier series expansion of the scattered wave outside a circle satisfies the Sommerfeld radiation condition. This answers the question raised by Hochstadt [8].

A.1. Convergence of the series. Consider, for a given $R > r_0$, the bounded domain $\check{\Omega}_R \subset \check{\Omega}$ delimited by the vertical cylinder $\Sigma_R = \{x \in \check{\Omega};\ x_1^2 + x_2^2 = R^2\}$; we denote by $\check{S}_R$ the part of $\check{S}$ which is contained in the boundary of $\check{\Omega}_R$. The proof of the convergence of the series (A.1) in $H^1(\check{\Omega}_R)$ is based on a suitable choice of a scalar product for which the solutions with separated variables become orthogonal.

As in the proof of Proposition 3.1, it may be easily seen that the expression

$$N_{d,R}(\check\varphi) = \left(\|\nabla\check\varphi\|^2_{\check\Omega_R} + d\,\|\check\varphi\|^2_{\check\Omega_R} - \nu\,\|\check\varphi\|^2_{\check S_R}\right)^{1/2} \tag{A.2}$$

is, for sufficiently large $d > 0$, a norm on $H^1(\check\Omega_R)$ equivalent to the usual norm. Let $P_{d,R}(\cdot\,,\cdot)$ denote the associated scalar product. Noticing that if $\check\varphi$ is a solution of $\check{\mathcal{P}}_\nu$, we have

$$(\nabla\check\varphi,\nabla\psi)_{\check\Omega_R} - \nu\,(\check\varphi,\psi)_{\check S_R} = \langle\partial_n\check\varphi,\psi\rangle_{1/2,\Sigma\cup\Sigma_R} \quad \forall\psi\in H^1(\check\Omega_R),$$

where $\langle\cdot\,,\cdot\rangle_{1/2,\Sigma\cup\Sigma_R}$ denotes the duality product between $H^{-1/2}(\Sigma\cup\Sigma_R)$ and $H^{1/2}(\Sigma\cup\Sigma_R)$, we deduce from the definition (3.1) of $\check\varphi_\nu^{(n,m)}$ that

(A.3)
$$\begin{aligned}P_{d,R}(\check\varphi_\nu^{(n,m)},\check\varphi_\nu^{(n',m')}) =&(\chi_\nu^{(n,m)},\chi_\nu^{(n',m')})_\Sigma\\ &\times\left(d\int_{r_0}^{R}\eta_\nu^{(n,m)}\overline{\eta_\nu^{(n',m')}}\,\frac{r}{r_0}\,dr + \left[\frac{r}{r_0}\,d_r\eta_\nu^{(n,m)}\overline{\eta_\nu^{(n',m')}}\right]_{r_0}^{R}\right),\end{aligned}$$

which shows that functions $\check\varphi_\nu^{(n,m)}$ form an orthogonal family in $H^1(\check\Omega_R)$ for $P_{d,R}$. Consequently, the norm of (A.1) reads

$$N_{d,R}(\check\varphi) = \left(\sum_{n\in\mathbb{Z}}\sum_{m\geq 0}\left|(\chi,\chi_\nu^{(n,m)})_\Sigma\right|^2 N^2_{d,R}(\check\varphi_\nu^{(n,m)})\right)^{1/2}. \tag{A.4}$$

By Proposition 3.1, if there exists $C > 0$, independent of n and m, such that

$$N^2_{d,R}(\check\varphi_\nu^{(n,m)}) \leq C\,(1+n^2+m^2)^{1/2}, \tag{A.5}$$

then $N_{d,R}(\check\varphi)$ is bounded and satisfies the following inequality:

$$N_{d,R}(\check\varphi) \leq \sqrt{C}\ [\chi]_{\nu,1/2}, \tag{A.6}$$

which is nothing but the required continuity property (2.26). From (A.3), we thus have to estimate the asymptotic behaviour, when $n^2+m^2\to+\infty$, of

$$N^2_{d,R}(\check\varphi_\nu^{(n,m)}) = d\int_{r_0}^{R}\left|\eta_\nu^{(n,m)}\right|^2\frac{r}{r_0}\,dr + \left[\frac{r}{r_0}\,d_r\eta_\nu^{(n,m)}\overline{\eta_\nu^{(n,m)}}\right]_{r_0}^{R}, \tag{A.7}$$

where

$$\eta_\nu^{(n,m)}(r) = \frac{K_n(\zeta_\nu^{(m)}r)}{K_n(\zeta_\nu^{(m)}r_0)} \quad\text{and}\quad d_r\eta_\nu^{(n,m)}(r) = \frac{\zeta_\nu^{(m)}K_n'(\zeta_\nu^{(m)}r)}{K_n(\zeta_\nu^{(m)}r_0)}. \tag{A.8}$$

Note that, from the symmetry property (3.10), it is enough to consider the case $n\geq 0$.

First, assume that $m > 0$. In this case, the roots $\zeta_\nu^{(m)}$ of the dispersion equation are real and positive, and their asymptotic behaviour is given by (see §3.1):

$$\zeta_\nu^{(m)} \sim m\pi \quad\text{when } m\to+\infty. \tag{A.9}$$

The arguments of K_n and K_n' in (A.8) are thus real and positive. Setting $x = \zeta_\nu^{(m)} r$ and $x_0 = \zeta_\nu^{(m)} r_0$ in (A.24), we derive

(A.10)
$$\left|\frac{K_n'(\zeta_\nu^{(m)} r)}{K_n(\zeta_\nu^{(m)} r)}\right| \leq C\,\frac{(n^2+m^2)^{1/2}}{m} \quad \text{and} \quad \left|\frac{K_n(\zeta_\nu^{(m)} r)}{K_n(\zeta_\nu^{(m)} r_0)}\right| \leq C \quad \text{for } n \geq 0,\ m > 0.$$

These inequalities show that the first term of the right-hand side of (A.7) is bounded by a constant, and the second one, by $C(n^2+m^2)^{1/2}$. Relation (A.5) is thus proved.

Suppose now that $m = 0$. In this case, the arguments of K_n and K_n' in (A.8) are imaginary (for $\zeta_\nu^{(0)} = -i\nu_0$; see §3.1). Setting $y = \nu_0 r$ in (A.29) and (A.30), we see that

$$\text{(A.11)} \qquad \left|\frac{K_n'(-i\nu_0 r)}{K_n(-i\nu_0 r)}\right| \leq Cn \quad \text{and} \quad \left|\frac{K_n(-i\nu_0 r)}{K_n(-i\nu_0 r_0)}\right| \leq C \quad \text{for } r \in \,[r_0, R]\,,\quad n > 0.$$

These estimates show that inequality (A.5) is still valid for $m = 0$. The convergence of the series (A.1) follows.

A.2. The radiation condition. By construction, each term of the series (A.1) satisfies the radiation condition (2.14): the aim of this paragraph is to show that this property holds for the sum φ of the series. First, note that for $R > r_0$,

(A.12)
$$\int_{\Sigma_R} |\partial_r\varphi - i\nu_0\varphi|^2\, d\Sigma = \frac{R}{r_0}\sum_{n\in\mathbb{Z}}\sum_{m\geq 0}\left|(\chi, \chi_\nu^{(n,m)})_\Sigma\right|^2 \left|d_r\eta_\nu^{(n,m)}(R) - i\nu_0\eta_\nu^{(n,m)}(R)\right|^2,$$

since $\{\chi_\nu^{(n,m)};\ n\in\mathbb{Z},\ m\geq 0\}$ forms an orthonormal basis of $L^2(\Sigma)$. We prove below that

$$\text{(A.13)} \qquad \lim_{R\to+\infty} R\sum_{n\in\mathbb{Z}}\sum_{m\geq 0}\left|d_r\eta_\nu^{(n,m)}(R) - i\nu_0\eta_\nu^{(n,m)}(R)\right|^2 = 0,$$

which of course implies the convergence to 0 of (A.12) when $R \to +\infty$ for every $\chi \in H^{1/2}(\Sigma)$. Note that, here again, it is enough to deal with the case $n \geq 0$.

(i) In a first step, we consider the part of the series in (A.13) which corresponds to $m > 0$: the exponential decay of $\eta_\nu^{(n,m)}(r)$ actually leads to a stronger property than (A.13), namely,

$$\text{(A.14)} \qquad \lim_{R\to+\infty} R^\beta\sum_{n\geq 0}\sum_{m>0}\left|\eta_\nu^{(n,m)}(R)\right|^2 = 0 \quad \forall\beta > 0,$$

as well as the same property for $d_r\eta_\nu^{(n,m)}(R)$. We restrict ourselves to the proof of the former statement; the latter is obtained similarly. In order to prove (A.14), we study separately the two quantities:

$$\text{(A.15)} \qquad A_1(R) = R^\beta\sum_{m>0}\sum_{n=0}^{n_m(R)}\left|\eta_\nu^{(n,m)}(R)\right|^2,$$

$$\text{(A.16)} \qquad A_2(R) = R^\beta\sum_{m>0}\sum_{n>n_m(R)}\left|\eta_\nu^{(n,m)}(R)\right|^2,$$

where $n_m(R)$ denotes the greatest integer such that $n_m(R) \leq \zeta_\nu^{(m)} R$. If $n \leq n_m(R)$, we deduce from (A.25) that

$$\left|\eta_\nu^{(n,m)}(R)\right| = \left|\frac{K_n(\zeta_\nu^{(m)} R)}{K_n(\zeta_\nu^{(m)} r_0)}\right| \leq C\, e^{-\zeta_\nu^{(m)}(R-r_0)/3},$$

whence we infer, from (A.9), that for every $\gamma > 0$, there exists $C_\gamma > 0$ such that

$$\left|\eta_\nu^{(n,m)}(R)\right| \leq C_\gamma\ (mR)^{-\gamma} \quad \text{for } \ n \leq n_m(R).$$

Noticing that $n_m(R) \leq C\, mR$, we thus have

$$A_1(R) \leq C'_\gamma\ R^\beta \sum_{m>0} (mR)^{-2\gamma+1}.$$

By choosing, for instance, $\gamma = \beta + 1$, we deduce that $A_1(R) \to 0$ when $R \to +\infty$. On the other hand, if $n > n_m(R)$, inequality (A.26) shows that

$$\left|\eta_\nu^{(n,m)}(R)\right| \leq C \left(\frac{R}{2r_0}\right)^{-n}.$$

Noticing that $n_m(R)$ is an increasing function of m, we can rewrite the series (A.16) in the form

$$A_2(R) = R^\beta \sum_{n>n_1(R)} \ \sum_{m<m_n(R)} \left|\eta_\nu^{(n,m)}(R)\right|^2,$$

where $m_n(R)$ is the greatest value of m such that $\zeta_\nu^{(m)} R \leq n$. By (A.9), we see that $m_n(R) \leq C\, n/R$; consequently

$$A_2(R) \leq C'\, R^\beta \sum_{n>n_1(R)} \frac{n}{R} \left(\frac{R}{2r_0}\right)^{-2n}.$$

Hence, we easily deduce that $A_2(R) \to 0$, which completes the proof of (A.14).

(ii) Consider now the case $m = 0$ in the series (A.13): it remains to prove that

$$\text{(A.17)} \qquad \lim_{R\to+\infty} R \sum_{n>0} \left| d_r \eta_\nu^{(n,0)}(R) - i\nu_0 \eta_\nu^{(n,0)}(R)\right|^2 = 0,$$

where

$$\left| d_r \eta_\nu^{(n,0)}(R) - i\nu_0 \eta_\nu^{(n,0)}(R)\right| = \nu_0 \left| \frac{K'_n(-i\nu_0 R) + K_n(-i\nu_0 R)}{K_n(-i\nu_0 r_0)}\right|.$$

Let ε be an arbitrary small (but fixed) positive number. We split the series in (A.17) into three parts:

(A.18)

$$B_1(R) = R \sum_{n<n^-(R)} (...), \quad B_2(R) = R \sum_{n=n^-(R)}^{n^+(R)} (...), \quad B_3(R) = R \sum_{n>n^+(R)} (...),$$

where $n^-(R)$ and $n^+(R)$ denote, respectively, the greatest integers such that

$$n^{\pm}(R) \le \frac{\nu_0 R}{1 \mp \varepsilon}. \tag{A.19}$$

If $n < n^-(R)$, (A.35) shows that there exists some positive constants C and c such that

$$\left| d_r \eta_\nu^{(n,0)}(R) - i\nu_0 \eta_\nu^{(n,0)}(R) \right| \le \frac{C}{R^{3/4}} \left(\frac{n}{c} \right)^{-n}, \qquad c < n < n^-(R),$$

from which we deduce that $B_1(R) \to 0$ when $R \to +\infty$. If $n^-(r) \le n \le n^+(R)$, the estimates given in (A.33) yield

$$\left| d_r \eta_\nu^{(n,0)}(R) - i\nu_0 \eta_\nu^{(n,0)}(R) \right| \le C \left(\frac{n}{c} \right)^{-n},$$

whence we infer that

$$B_2(R) \le C \sum_{n \ge n^-(R)} n \left(\frac{n}{c} \right)^{-2n},$$

since $R \le n(1+\varepsilon)/\nu_0$. The convergence of $B_2(R)$ to 0 follows. Finally, if $n > n^+(R)$, we see from (A.29) and (A.31) that

$$\left| d_r \eta_\nu^{(n,0)}(R) - i\nu_0 \eta_\nu^{(n,0)}(R) \right| \le \frac{Cn}{R} \left(\frac{R}{c} \right)^{-n},$$

from which we easily deduce that $B_3(R) \to 0$. Property (A.17) is thus proved.

A.3. Some properties of the modified Bessel functions. We prove here some asymptotic properties of K_n and K_n' which are used in the two preceding paragraphs. The main tools are the following uniform asymptotic expansions (see Olver [24, Chap. 10, §§7 and 8]):

$$K_n(nz) = \left(\frac{\pi}{2n} \right)^{1/2} \frac{e^{-n\xi(z)}}{(1+z^2)^{1/4}} (1 + \varepsilon_0(z,n)), \tag{A.20}$$

$$K_n'(nz) = -\left(\frac{\pi}{2n} \right)^{1/2} \frac{(1+z^2)^{1/4} e^{-n\xi(z)}}{z} (1 + \varepsilon_1(z,n)), \tag{A.21}$$

where

$$\xi(z) = (1+z^2)^{1/2} + \ln \frac{z}{1 + (1+z^2)^{1/2}}. \tag{A.22}$$

These expansions are valid for $n > 0$ and z in a complex domain such as the one shown in Fig. A.1, which excludes in particular the singular points $\pm i$ of $\xi(z)$. In this domain, $\xi(z)$ is an analytic function, the branch being chosen such that $\xi(z)$ takes its principal value when $z \in \mathbb{R}^+$. Outside a vicinity of the singular points $\pm i$, the bounds for the error terms ε_0 and ε_1 are given by

$$|\varepsilon_k(z,n)| \le C \frac{1}{n \mid 1 + z^2 \mid^{1/2}}, \qquad k = 0, 1. \tag{A.23}$$

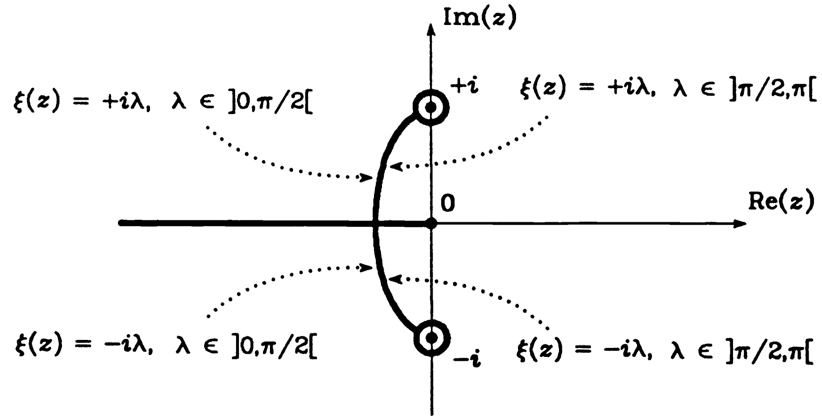

FIG. A.1. *Validity domain of the expansions of K_n and K_n'.*

We begin with the case of real positive arguments.

LEMMA A.1. *Let x_0 be a given real positive number. Then, there exist some positive constants (all denoted by C) such that*

$$\left|\frac{K_n'(x)}{K_n(x)}\right| \le C\frac{(n^2+x^2)^{1/2}}{x} \quad \textit{and} \quad \left|\frac{K_n(x)}{K_n(x_0)}\right| \le C \quad \textit{for } n \ge 0, \quad x \ge x_0. \tag{A.24}$$

Moreover, we have the more precise estimates

$$\left|\frac{K_n(x)}{K_n(x_0)}\right| \le Ce^{-(x-x_0)/3} \quad \textit{for } 0 < x_0 < x \quad \textit{and} \quad 0 \le n \le x, \tag{A.25}$$

$$\left|\frac{K_n(x)}{K_n(x_0)}\right| \le C\left(\frac{x}{2x_0}\right)^{-n} \quad \textit{for } 0 < 2x_0 < x < n. \tag{A.26}$$

Proof. First, assume that $n > 0$. Setting $z = x/n$ in (A.20) and (A.21), we derive

$$\frac{K_n'(x)}{K_n(x)} = -\frac{(n^2+x^2)^{1/2}}{x}\left(1 + O\left((n^2+x^2)^{-1/2}\right)\right),$$

which implies the first inequality in (A.24). On the other hand, we have

$$\frac{K_n(x)}{K_n(x_0)} = \left(\frac{1+x_0^2n^{-2}}{1+x^2n^{-2}}\right)^{1/4} e^{-a_n(x_0,x)}\left(1 + O\left((n^2+x_0^2)^{-1/2}\right)\right), \tag{A.27}$$

where

$$\begin{aligned} a_n(x_0,x) &= n\left(\xi(x/n) - \xi(x_0/n)\right), \\ &= \frac{x^2-x_0^2}{(n^2+x^2)^{1/2}+(n^2+x_0^2)^{1/2}} + n\ln\left(\frac{x_0^{-1}+(n^{-2}+x_0^{-2})^{1/2}}{x^{-1}+(n^{-2}+x^{-2})^{1/2}}\right). \end{aligned}$$

Since $x \ge x_0$, this latter quantity is the sum of two positive terms: the second inequality in (A.24) follows. If $n \le x$, by neglecting the second term of the right-hand side, we easily obtain

$$a_n(x_0,x) \ge (x-x_0)/3,$$

from which we deduce (A.25). If $n > x$, we neglect the first term in the expression of $a_n(x_0, x)$, which yields

$$a_n(x_0, x) \geq n \ln \frac{x}{2x_0}.$$

Inequality (A.26) follows.

Finally, if $n = 0$, we simply use the following asymptotic expansions of $K_0(x)$ and $K_0'(x)$ for large $x > 0$ (see [1]):

$$K_0(x) = \sqrt{\frac{\pi}{2x}} e^{-x}(1 + O(x^{-1})) \quad \text{and}$$
$$K_0'(x) = -K_1(x) = -\sqrt{\frac{\pi}{2x}} e^{-x}(1 + O(x^{-1})),$$

which shows that (A.24) and (A.25) hold for $n = 0$. □

We now deal with the case of imaginary arguments. The results depend on the relative positions of the order n and the modulus of the argument iy (y real): in the three following lemmas, we distinguish the three cases

$$\text{(A.28)} \qquad \frac{|y|}{n} \leq 1 - \varepsilon, \quad \frac{|y|}{n} \geq 1 - \varepsilon \quad \text{and} \quad \frac{|y|}{n} \geq 1 + \varepsilon,$$

where $\varepsilon > 0$ is an arbitrary small (but fixed) constant. All proofs are given for positive imaginary parts: the case of negative imaginary parts follows from the symmetry property

$$K_n(\bar{z}) = \overline{K_n(z)}, \qquad z \in \mathbb{C}.$$

LEMMA A.2. *Let y_0 and y_1 be two given real numbers such that $0 < |y_0| < |y_1|$. Then, there exist some positive constants (denoted by C or c) such that*

$$\text{(A.29)} \qquad \left|\frac{K_n'(iy)}{K_n(iy)}\right| \leq C \frac{n}{|y|} \quad \textit{for } 0 < |y| \leq (1-\varepsilon)n,$$

$$\text{(A.30)} \qquad \left|\frac{K_n(iy)}{K_n(iy_0)}\right| \leq C \quad \textit{for } |y_0| \leq |y| \leq |y_1| \leq (1-\varepsilon)n,$$

$$\text{(A.31)} \qquad \left|\frac{K_n(iy)}{K_n(iy_0)}\right| \leq C \left(\frac{|y|}{c}\right)^{-n} \quad \textit{for } c < |y| < (1-\varepsilon)n.$$

Proof. Setting $z = iy/n$, we see that z belongs to the validity domain of (A.20) and (A.21) shown in Fig. A.1; consequently,

$$\frac{K_n'(iy)}{K_n(iy)} = -\left(\frac{n^2}{y^2} - 1\right)^{1/2} \left(1 + O\left((n^2 - y^2)^{-1/2}\right)\right).$$

Since $n - y \geq \varepsilon n$, the error term is bounded: relation (A.29) follows. On the other hand, we have, instead of (A.27),

$$\text{(A.32)} \qquad \frac{K_n(iy)}{K_n(iy_0)} = \left(\frac{n^2 - y_0^2}{n^2 - y^2}\right)^{1/4} e^{-a_n(iy_0, iy)} \left(1 + O\left((n^2 - y^2)^{-1/2}\right)\right),$$

where

$$a_n(iy_0, iy) = \frac{-(y^2 - y_0^2)}{(n^2 - y^2)^{1/2} + (n^2 - y_0^2)^{1/2}} + n \ln \left(\frac{y_0^{-1} + (y_0^{-2} - n^{-2})^{1/2}}{y^{-1} + (y^{-2} - n^{-2})^{1/2}}\right).$$

The first term in the expression of $a_n(iy_0, iy)$ is negative, but the second one is positive and becomes dominant for large n and y bounded: inequality (A.30) is thus proved.

We obtain the more precise estimate (A.31) by noticing that, if $y \leq (1-\varepsilon)n$,

$$\frac{y^2 - y_0^2}{(n^2-y^2)^{1/2} + (n^2-y_0^2)^{1/2}} \leq Cn \quad \text{and} \quad \frac{y_0^{-1} + (y_0^{-2} - n^{-2})^{1/2}}{y^{-1} + (y^{-2}-n^{-2})^{1/2}} \geq \frac{y}{2y_0},$$

from which we deduce that, for some $c > 0$, $a_n(iy_0, iy) \geq n \ln(y/c)$ when $y > c$. □

LEMMA A.3. *Let $y_0 \neq 0$ be a given real number. There exist some positive constants (denoted by C or c) such that*

$$\text{(A.33)} \qquad \left|\frac{K_n(iy)}{K_n(iy_0)}\right| \leq C\left(\frac{n}{c}\right)^{-n} \quad \textit{and} \quad \left|\frac{K_n'(iy)}{K_n(iy_0)}\right| \leq C\left(\frac{n}{c}\right)^{-n} \quad \textit{for } c < n \leq \frac{|y|}{1-\varepsilon}.$$

Proof. In the "transition region" $y/n \in [1-\varepsilon, 1+\varepsilon]$, we cannot use the asymptotic expansions (A.20) and (A.21). However, we have the following estimate (Olver [24, Chap. 7, ex. 13.4]):

$$|K_n(iy)| \leq \left(\frac{\pi}{2y}\right)^{1/2} e^{n^2/y} \quad \text{for } n \geq 1, \quad y > 0,$$

and thus

$$|K_n(iy)| \leq \left(\frac{\pi}{2y}\right)^{1/2} e^{n/(1-\varepsilon)} \quad \text{for } y > (1-\varepsilon)n.$$

Furthermore, from the asymptotic behaviour of $K_n(iy_0)$ for fixed $y_0 > 0$ (see [1]),

$$\text{(A.34)} \qquad |K_n(iy_0)| \sim \left(\frac{\pi}{2n}\right)^{1/2} \left(\frac{2n}{ey_0}\right)^n \quad \text{when } n \to +\infty,$$

we infer that for large enough n and $y > (1-\varepsilon)n$,

$$\left|\frac{K_n(iy)}{K_n(iy_0)}\right| \leq C\, e^{n(1-\varepsilon-\ln(2n/ey_0))},$$

which implies the first inequality in (A.33). Finally, from the recurrence relation

$$K_n'(z) = -\tfrac{1}{2}\left(K_{n+1}(z) + K_{n-1}(z)\right), \qquad z \in \mathbb{C},$$

we deduce in the same way the second inequality of (A.33). □

LEMMA A.4. *Let $y_0 \neq 0$ be a given real number. There exist some positive constants C and c such that*

$$\text{(A.35)} \qquad \left|\frac{K_n'(iy) + K_n(iy)}{K_n(iy_0)}\right| \leq \frac{C}{|y|^{3/4}}\left(\frac{n}{c}\right)^{-n} \quad \textit{for } c < n \leq \frac{|y|}{1+\varepsilon}.$$

Proof. Setting $z = iy/n$, we clearly have $|z| \geq 1+\varepsilon$, and thus we can use the asymptotic expansions (A.20) and (A.21) with the error bounds (A.23). Hence

$$K_n(iy) = \left(\frac{\pi}{2}\right)^{1/2} \frac{e^{-n\xi(iy/n) - i\pi/4}}{(y^2-n^2)^{1/4}} \left(1 + O\left((y^2-n^2)^{-1/2}\right)\right),$$

$$K_n'(iy) = -\left(\frac{\pi}{2}\right)^{1/2} \frac{(y^2-n^2)^{1/4} e^{-n\xi(iy/n) - i\pi/4}}{y} \left(1 + O\left((y^2-n^2)^{-1/2}\right)\right).$$

From (A.22), we easily verify that for $y/n > 1$,

$$\xi(iy/n) = i\left((y^2n^{-2} - 1)^{1/2} + \arcsin\frac{n}{y}\right),$$

which is purely imaginary, and thus

$$K_n(iy) = \left(\frac{\pi}{2}\right)^{1/2} \frac{e^{-n\xi(iy/n)-i\pi/4}}{(y^2-n^2)^{1/4}} + O\left((y^2-n^2)^{-3/4}\right),$$
$$K_n'(iy) = -\left(\frac{\pi}{2}\right)^{1/2} \frac{(y^2-n^2)^{1/4}e^{-n\xi(iy/n)-i\pi/4}}{y} + O\left(y^{-1}(y^2-n^2)^{-1/4}\right).$$

Noticing that $y^2 - n^2 \geq \varepsilon\, ny$, we see that the error terms is these expressions are bounded by $C\,(ny)^{-3/4}$; then

$$|K_n'(iy) + K_n(iy)| = \left(\frac{\pi}{2}\right)^{1/2} \frac{n^2}{y\,(y^2-n^2)^{1/4}\left(y+(y^2-n^2)^{1/2}\right)} + O((ny)^{-3/4}),$$

which shows that

$$|K_n'(iy) + K_n(iy)| \leq C\; n^{1/4}y^{-3/4}.$$

As in the proof of Lemma A.3, using the asymptotic behaviour (A.34) of $K_n(iy_0)$, we thus deduce (A.35). □

Appendix B. Solution of the dispersion equation in the complex plane. The purpose of this section is to show a method which provides an explicit form of the roots $\zeta \in \mathbb{C}$ of the "dispersion equation" (see (3.4))

$$f(\zeta) = \nu, \quad \text{where } f(\zeta) = -\zeta\tan\zeta \tag{B.1}$$

for any complex number ν. This method, which is based on the properties of Cauchy integrals on arcs, is widely described in Henrici [7, Vol. III, Chap. 14]: some results will be stated here without proof.

B.1. Some general properties of the roots. Let ν_0 be a given complex number; suppose that (B.1) admits a solution $\zeta_0 \in \mathbb{C}$ for $\nu = \nu_0$. Function f is analytic in a vicinity of ζ_0 and can thus be represented by a series

$$f(\zeta) = \nu_0 + \sum_{m\geq 1} a_m(\zeta - \zeta_0)^m.$$

Let $m_0 \geq 1$ be the smallest value of m such that $a_m \neq 0$. We know (see, e.g., Henrici [7, Thm. 2.4f]) that in a vicinity of ν_0 (B.1) admits exactly m_0 solutions which tend to ζ_0 when $\nu \to \nu_0$: these are the m_0 branches of an analytic function having an algebraic singularity of order $m_0 - 1$ at point ν_0 (Knopp [14]). Since $a_m = d_\zeta^m f(\zeta_0)/m!$, we have

$$a_1 = -\frac{\sin 2\zeta_0 + 2\zeta_0}{2\cos^2\zeta_0} \quad \text{and} \quad a_2 = a_1\tan\zeta_0 - 1. \tag{B.2}$$

The first coefficient a_1 vanishes if $\sin 2\zeta_0 + 2\zeta_0 = 0$. In this case, $a_2 \neq 0$, which shows that ζ_0 is a double root of (B.1).

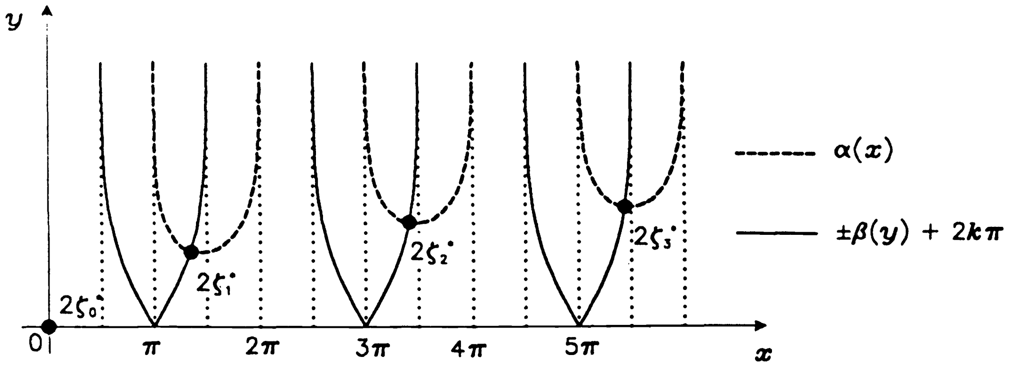

FIG. B.1. *Solutions of equation* $\sin 2\zeta + 2\zeta = 0$.

LEMMA B.1. *The roots of the following equation*

$$\sin 2\zeta + 2\zeta = 0, \tag{B.3}$$

which are such that $\operatorname{Re}\zeta \geq 0$ *and* $\operatorname{Im}\zeta \geq 0$ *form a sequence* (ζ_n^*; $n \in \mathbb{N}$)*, where* $\zeta_0^* = 0$ *and* $\operatorname{Re}\zeta_n^* \in](n-1/2)\pi, (n-1/4)\pi[$. *Their asymptotic behaviour is given by*

$$\zeta_n^* = (n-1/4)\pi + \frac{i}{2}\operatorname{Log}((4n-1)\pi) + o(1) \quad \textit{when } n \to +\infty. \tag{B.4}$$

The other roots of (B.3) *are obtained by symmetry with respect to the real and imaginary axes.*

Proof. First, notice that if ζ is a solution of (B.3), then $-\zeta$ and $\bar{\zeta}$ are ones too; moreover, $\zeta = 0$ is the only solution located on the axes $\operatorname{Re}\zeta = 0$ and $\operatorname{Im}\zeta = 0$. Consequently, setting $2\zeta = x + iy$ (x and y real), we can restrict ourselves to the case $x > 0$ and $y > 0$. Equation (B.3) is thus equivalent to

$$y = \alpha(x) = \operatorname{Arccosh}\frac{-x}{\sin x} \quad \text{and} \tag{B.5}$$

$$x = \pm\beta(y) + 2n\pi = \pm\operatorname{Arccos}\frac{-y}{\sinh y} + 2n\pi, \qquad n \in \mathbb{N}. \tag{B.6}$$

These functions are represented in Fig. B.1: the two families of curves intersect at one point $x_n^* + iy_n^* = 2\zeta_n^*$ in every strip $x \in](2n-1)\pi, (2n-1/2)\pi[$. It may be easily seen that $\operatorname{Min}\alpha(x)$ on each interval $]n\pi, (n+1)\pi[$ tends to $+\infty$ when $n \to +\infty$, when we infer that

$$x_n^* = (2n-1/2)\pi + o(1) \quad \text{when } n \to +\infty.$$

Substituting this expression in (B.5) yields

$$y_n^* = \operatorname{Log}((4n-1)\pi) + o(1).$$

The asymptotic behaviour (B.4) of ζ_n^* follows. □

Let $\mathbb{E}$ denote the set of ν which correspond to the solutions ζ of (B.3), i.e.,

$$\nu = -\zeta\tan\zeta = \sin^2\zeta. \tag{B.7}$$

In other words, $\nu \in \mathbb{E}$ means that (B.1) admits a double root ζ (which is a solution of (B.3)). Note that ζ and $-\zeta$ are the only double roots of (B.1) for such a ν : indeed, it is a easy matter to verify that

$$f(\zeta_1) = f(z_2) \quad \text{and} \quad \sin 2\zeta_1 + 2\zeta_1 = \sin 2\zeta_2 + 2\zeta_2 = 0$$

implies $\zeta_1 = \pm\zeta_2$. The locations of the points of $\mathbb{E}$ are represented in Fig. 3.2: $\mathbb{E}$ is symmetrical with respect to the real axis. Moreover, we have from (B.4)

$$\text{(B.8)} \qquad \nu_n^* = f(\zeta_n^*) = -i\pi(n - 1/4)(1 + o(1)) \quad \text{when } n \to +\infty.$$

These results may be summarized as follows.

PROPOSITION B.1. *rm (i) If $\nu \in \mathbb{C}\backslash\mathbb{E}$, then every root of the dispersion equation* (B.1) *is simple. If $\nu \in \mathbb{E}$,* (B.1) *has exactly two double roots ζ and $-\zeta$, solutions of* (B.3); *the others are simple.*

(ii) *If ζ_0 is a simple root of* (B.1) *for $\nu = \nu_0$, then there exists a vicinity of ν_0 in which* (B.1) *has only one root ζ_ν which tends to ζ_0 when $\nu \to \nu_0$: this root is simple and depends analytically on ν.*

(iii) *If ζ_0 is a double root of* (B.1) *for $\nu = \nu_0$, then there exists a vicinity of ν_0 in which* (B.1) *has exactly two simple roots ζ_ν^+ and ζ_ν^-, for $\nu \neq \nu_0$, which tend to ζ_0 when $\nu \to \nu_0$: these are the two branches of an analytic function of ν which has an algebraic singularity of order* 1 *at point ν_0.*

B.2. Other formulation of the dispersion equation. Let us first note some symmetry properties. For a given ν, if ζ is a solution of (B.1), then $-\zeta$ is also a solution for the same ν and $\bar{\zeta}$ is a solution of (B.1) for $\bar{\nu}$. We can thus restrict ourselves to the case

$$\text{(B.9)} \qquad \operatorname{Re}\zeta \geq 0 \quad \text{and} \quad \operatorname{Im}\nu \geq 0.$$

Let $\operatorname{Arctan} z$ denote the principal value of the inverse of $\tan z$, i.e.,

$$\operatorname{Arctan} z = \int_0^z \frac{dt}{1+t^2},$$

where the path of integration must not cross the two cuts $\{iy; y \in \mathbb{R} \text{ and } |y| \geq 1\}$. If ν/ζ is assumed not to belong to one of these cuts, (B.1) (with the restriction (B.9)) is equivalent to

$$\text{(B.10)} \qquad \zeta = -\operatorname{Arctan}(\nu/\zeta) + k\pi, \qquad k \geq 0.$$

Note that for a given k, the roots of (B.10), if any, are such that

$$\text{(B.11)} \qquad \operatorname{Re}\zeta \in \left](k - \tfrac{1}{2})\pi, \quad (k + \tfrac{1}{2})\pi\right[.$$

It may happen that ν/ζ belongs to one of the cuts of function $\operatorname{Arctan} z$. Indeed, suppose that $\zeta = -i\nu t$ is a solution of (B.1), where t is a real number such that $0 < |t| \leq 1$. From the symmetry properties stated above, we can assume $t > 0$. Equation (B.1) is thus equivalent to $t\tanh(\nu t) = 1$, which yields

$$\text{(B.12)} \qquad \nu = \frac{1}{t}\left[\frac{1}{2}\operatorname{Log}\frac{1+t}{1-t} + i\pi\left(n + \frac{1}{2}\right)\right], \qquad t \in]0,1[, \quad n \geq 0.$$

This expression defines a family of curves ($C_n \subset \mathbb{C}$; $n \geq 0$) which are represented in Fig. B.2.

For every $n > 0$, we denote by D_n the open set located between C_{n-1} and C_n ; D_0 is the domain of $\mathbb{C}^+ \setminus \{0\}$ situated below C_0. We define D and C by

$$\text{(B.13)} \qquad D = \bigcup_{n\geq 0} D_n \quad \text{and} \quad C = \bigcup_{n\geq 0} C_n.$$

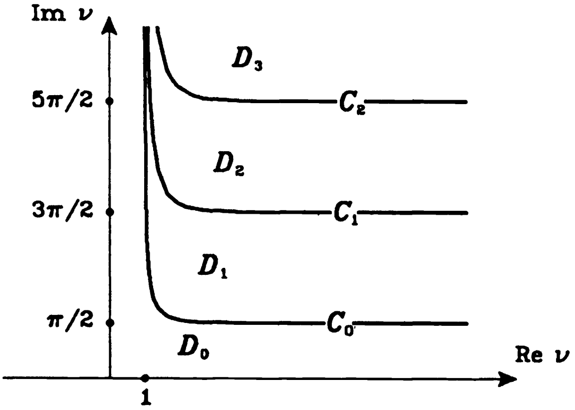

FIG. B.2. *Definition of D_n and C_n.*

In the following paragraph, we will assume that $\nu \in D$. The case $\nu \in C$ will be dealt with at the end of §B.4. Note that this distinction is not specific to (B.1): it results from the choice of the cuts which are necessary for the definition of function $\operatorname{Arctan} z$.

B.3. The Privalov problem. Using the change of variable

$$x = \zeta/(i\nu); \tag{B.14}$$

(B.10) amounts to determining the zeros of functions $f_\nu^{(k)}(x)$ defined as follows

$$f_\nu^{(k)}(x) = \nu x + ik\pi + \frac{1}{2}\operatorname{Log}\frac{x-1}{x+1}, \tag{B.15}$$

where Log is the principal value of the logarithm, and k is a nonnegative integer. Let I denote the segment $[-1,+1]$ oriented from -1 to $+1$. For every $\nu \in D$ and every $k \geq 0$, function $f_\nu^{(k)}$ is analytic on $\mathbb{C} \setminus I$. Let t be a point on I different from the endpoints ± 1 : such a point will be called an interior point of I. If $B(t)$ is a sufficiently small disk centered at t, the set $B(t) \setminus I$ has two separated components

$$B^+(t) = B(t) \cap \{x \in \mathbb{C};\ \operatorname{Im} x > 0\},$$
$$B^-(t) = B(t) \cap \{x \in \mathbb{C};\ \operatorname{Im} x < 0\},$$

and we can define the "one-side limits" of $f_\nu^{(k)}$ at t by

$$f_\nu^{(k)\pm}(t) = \lim_{x \in B^\pm(t) \to t} f_\nu^{(k)}(x).$$

It may be easily verified that at every interior point t of I these limits exist and read

$$f_\nu^{(k)\pm}(t) = t\nu + i\pi(k \pm 1/2) + \frac{1}{2}\operatorname{Log}\frac{1-t}{1+t}. \tag{B.16}$$

Note that the assumption $\nu \in D$ implies that $f_\nu^{(k)+}$ and $f_\nu^{(k)-}$ do not vanish at any interior point of I.

Consider then the function $a_\nu^{(k)}(t)$ defined for every interior point of I by

$$a_\nu^{(k)}(t) = f_\nu^{(k)+}(t)\ \left(f_\nu^{(k)-}(t)\right)^{-1}. \tag{B.17}$$

The so-called (homogeneous) Privalov problem associated with $a_\nu^{(k)}$ consists in finding a function $F_\nu^{(k)}(x)$ which is analytic in $\mathbb{C}\setminus I$, has at most a pole at ∞, and has one-side limits $F_\nu^{(k)+}$ and $F_\nu^{(k)-}$ (at every interior point of I) which satisfy the relation

$$a_\nu^{(k)}(t) = F_\nu^{(k)+}(t)\ \left(F_\nu^{(k)-}(t)\right)^{-1}.$$

Function $f_\nu^{(k)}(x)$ is a particular solution of the Privalov problem. Indeed, it has a pole of order 1 at ∞, since

$$f_\nu^{(k)}(x) = \nu x + ik\pi - x^{-1} + O(x^{-2}). \tag{B.18}$$

The following result provides a general expression for any solution of the Privalov problem (see Henrici [7, §14.8]).

PROPOSITION B.2. *Let $\nu \in D$; all the solutions of the homogeneous Privalov problem are given by*

$$F_\nu^{(k)}(x) = r_\nu^{(k)}(x)\ q_\nu^{(k)}(x), \quad \textit{where} \tag{B.19}$$

$$q_\nu^{(k)}(x) = \exp\left(\frac{1}{2i\pi}\int_I \frac{\log a_\nu^{(k)}(t)}{t-x}\,dt\right), \tag{B.20}$$

(*where* log *denotes any continuous logarithm*) *and $r_\nu^{(k)}(x)$ is an analytic function in $\mathbb{C}\setminus\{\pm 1\}$ which has at most a pole at ∞.*

Proof. First, consider the expression (B.20) of $q_\nu^{(k)}$. Since $f_\nu^{(k)+}$ and $f_\nu^{(k)-}$ are differentiable functions and do not vanish at any interior point of I, the same holds for $a_\nu^{(k)}$. Moreover,

$$\lim_{t\to\pm 1} a_\nu^{(k)}(t) = 1, \tag{B.21}$$

which shows that $a_\nu^{(k)}$ does not vanish on I. For any continuous logarithm, $\log a_\nu^{(k)}$ is a continuous function on I, and we can then define the Cauchy integral

$$\ell_\nu^{(k)}(x) = \frac{1}{2\pi i}\int_I \frac{\log a_\nu^{(k)}(t)}{t-x}\,dt, \qquad x \in \mathbb{C}\setminus I. \tag{B.22}$$

Function $\log a_\nu^{(k)}$ is differentiable on every closed segment of I which does not contain ± 1. Consequently, the one-side limits $\ell_\nu^{(k)+}(t)$ et $\ell_\nu^{(k)-}(t)$ exist at every interior point of I and satisfy the following relation (Sokhotskyi formulas; see Henrici [7, Thm. 14.1c]):

$$\ell_\nu^{(k)+}(t) = \ell_\nu^{(k)-}(t) + \log a_\nu^{(k)}(t).$$

Thus, function $q_\nu^{(k)}(x)$ given by (B.20) is a particular solution of the Privalov problem (it is obviously analytic at ∞), and every function of the form (B.19) is also a solution.

Conversely, let $F_\nu^{(k)}(x)$ denote any solution of the Privalov problem. Since $q_\nu^{(k)}$ vanishes neither on $\mathbb{C}\setminus I$ nor at ∞, function

$$r_\nu^{(k)}(x) = F_\nu^{(k)}(x)\left(q_\nu^{(k)}(x)\right)^{-1}$$

is analytic in $\mathbb{C} \setminus I$ and has at most a pole at ∞. Moreover, $r_\nu^{(k)+}(t) = r_\nu^{(k)-}(t)$ at every interior point of I : $r_\nu^{(k)}$ is thus analytic in $\mathbb{C} \setminus \{\pm 1\}$, which completes the proof. □

Proposition B.2 shows that $f_\nu^{(k)}$ can be written in the form (B.19). From now on, $r_\nu^{(k)}$ will denote the following function:

$$\text{(B.23)} \qquad r_\nu^{(k)}(x) = f_\nu^{(k)}(x)\ \left(q_\nu^{(k)}(x)\right)^{-1} = f_\nu^{(k)}(x)\ \exp\left(-\ell_\nu^{(k)}(x)\right),$$

whose zeros coincide with the ones of $f_\nu^{(k)}$ (if they differ from ± 1). By studying its behaviour in the vicinity of the endpoints ± 1, as well as at ∞, we prove below that $r_\nu^{(k)}$ actually is a rational function.

We first have to precise the definition of $\log a_\nu^{(k)}$ which was so far defined up to a multiple of $2i\pi$. From (B.21), we can choose, for instance,

$$\text{(B.24)} \qquad \lim_{t \to -1} \log a_\nu^{(k)}(t) = 0,$$

which selects a particular branch of the logarithm. According to this choice, we have the following result.

LEMMA B.2. *When $t \to +1$, the limit of $\log a_\nu^{(k)}(t)$ is given by*

$$\text{(B.25)} \qquad \lim_{t \to +1} \log a_\nu^{(k)}(t) = \begin{cases} -2i\pi & \textit{if } k = 0 \quad \textit{and} \quad \nu \notin D_0, \\ 0 & \textit{if } k \neq 0 \quad \textit{and} \quad \nu \notin D_k, \\ +2i\pi & \textit{if } \nu \in D_k. \end{cases}$$

Proof. $a_\nu^{(k)}(I)$ is a curve of the complex plane which is continuous, closed (from (B.21)), and does not pass through 0. We thus have to determine the index of this curve with respect to 0 :

$$\mathcal{I}_\nu^{(k)} = \frac{1}{2i\pi} \int_{a_\nu^{(k)}(I)} \frac{dx}{x} = \frac{1}{2i\pi} \int_{-1}^{+1} d\left[\log a_\nu^{(k)}(t)\right].$$

It may be easily verified that for a given $k \geq 0$, $\mathcal{I}_\nu^{(k)}$ is a continuous (in fact, analytic) function of ν in every domain D_n. Since it is always an integer, we deduce that it is constant in D_n. In order to calculate it, we study below the shape of $a_\nu^{(k)}(I)$ for the particular point $\nu = \varepsilon^{-1} + in\pi$ of D_n, where ε is an arbitrary small positive number. We have, from (B.17),

$$\operatorname{Re} a_\nu^{(k)}(t) = \frac{(g_\varepsilon(t))^2 + ((tn+k)^2 - \frac{1}{4})\pi^2}{(g_\varepsilon(t))^2 + (tn+k-\frac{1}{2})^2\pi^2},$$

$$\operatorname{Im} a_\nu^{(k)}(t) = \frac{\pi\, g_\varepsilon(t)}{(g_\varepsilon(t))^2 + (tn+k-\frac{1}{2})^2\pi^2},$$

where

$$g_\varepsilon(t) = t\varepsilon^{-1} + \frac{1}{2} \operatorname{Log} \frac{1-t}{1+t}.$$

By studying the variations of this function, we see that the sign of $\operatorname{Im} a_\nu^{(k)}(t)$ is given by

t	-1		$-t_\varepsilon^*$		0		$+t_\varepsilon^*$		$+1$
$\operatorname{Im} a_\nu^{(k)}(t)$	0	+	0	−	0	+	0	−	0

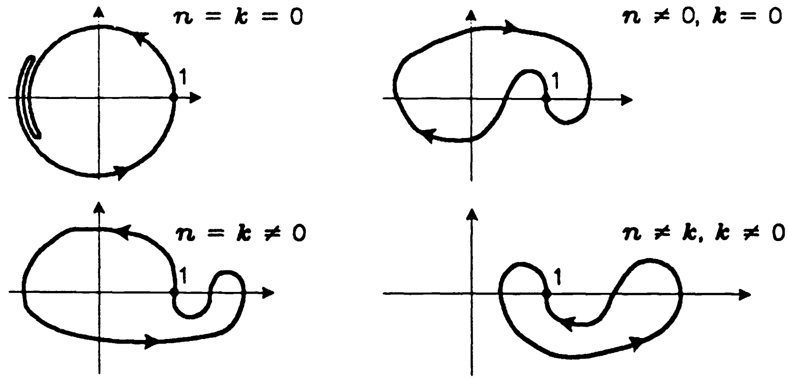

FIG. B.3. *Representation of* $a_\nu^{(k)}(I)$.

where t_ε^* is a real number such that $\sqrt{1-\varepsilon} < t_\varepsilon^* < 1$. Therefore, the curve $a_\nu^{(k)}(I)$ crosses successively the real axis at the four points

$$1 = a_\nu^{(k)}(\pm 1), \quad x_\varepsilon^- = a_\nu^{(k)}(-t_\varepsilon^*), \quad \frac{k+1/2}{k-1/2} = a_\nu^{(k)}(0) \text{ and } x_\varepsilon^+ = a_\nu^{(k)}(+t_\varepsilon^*).$$

Noticing that t_ε^* can be chosen arbitrarily close to 1, we infer that

$$x_\varepsilon^\pm \sim \frac{\pm n + k + 1/2}{\pm n + k - 1/2} \quad \text{when } \varepsilon \to 0.$$

We thus deduce the shape of $a_\nu^{(k)}(I)$ according to k and n (see Fig. B.3), which shows that

$$\mathcal{I}_\nu^{(k)} = \begin{cases} -1 & \text{if } k = 0 \text{ and } \nu \notin D_0, \\ 0 & \text{if } k \neq 0 \text{ and } \nu \notin D_k, \\ +1 & \text{if } \nu \in D_k. \end{cases}$$

Consequently, the variation of the argument of $a_\nu^{(k)}(t)$ when t moves along I is -2π in the first case, 0 in the second one, and $+2\pi$ in the last one. The statement of the lemma follows. □

PROPOSITION B.3. *Function* $r_\nu^{(k)}$ *given by* (B.23) *is a rational function which has a pole of order* 1 *at* ∞ *and a removable singularity at* -1. *At point* $+1$, *the singularity is a pole of order* 1 *if* $\nu \in D_k$, *and is removable if* $\nu \in D \setminus D_k$.

Proof. Using the same techniques as the ones described by Henrici [7, §§14.7 and 14.8], we deduce from (B.24) and (B.25) that $r_\nu^{(k)}(x) = O(1)$ in the vicinity of $x = -1$, and

$$r_\nu^{(k)}(x) = \begin{cases} O((x-1)^{-1}) & \text{if } \nu \in D_k, \\ O(1) & \text{if } \nu \in D \setminus D_k, \end{cases}$$

in the vicinity of $x = +1$. Moreover, at ∞, the singularities of $f_\nu^{(k)}$ and $r_\nu^{(k)}$ are the same (i.e., a pole of order 1, from (B.18)), since $q_\nu^{(k)}$ is analytic. Consequently, $r_\nu^{(k)}$ has at most a pole at $+1$ and ∞, and is analytic elsewhere: it is thus a rational function. □

B.4. Explicit form of the solutions. The Laurent series of $r_\nu^{(k)}$ in the vicinity of ∞ can be constructed explicitly. From (B.22), we have

$$\ell_\nu^{(k)}(x) = \frac{-1}{2\pi i} x^{-1} \int_I \frac{\log a_\nu^{(k)}(t)}{1 - tx^{-1}} dt = -\sum_{p=0}^{\infty} m_{\nu,p}^{(k)} \, x^{-p-1},$$

where

$$m_{\nu,p}^{(k)} = \frac{1}{2\pi i}\int_I t^p \log a_\nu^{(k)}(t)\,dt, \qquad p \geq 0. \tag{B.26}$$

Consequently,

$$\exp(-\ell_\nu^{(k)}(x)) = 1 + \left[m_{\nu,0}^{(k)}\right]x^{-1} + \left[m_{\nu,1}^{(k)} + \tfrac{1}{2}m_{\nu,0}^{(k)^2}\right]x^{-2} + O(x^{-3}).$$

Using the Laurent series (B.18) of $f_\nu^{(k)}(x)$ at ∞, we deduce

$$r_\nu^{(k)}(x) = \nu x + \beta_\nu^{(k)} + \gamma_\nu^{(k)}x^{-1} + O(x^{-2}), \tag{B.27}$$

where

$$\beta_\nu^{(k)} = ik\pi + \nu\, m_{\nu,0}^{(k)}, \tag{B.28}$$

$$\gamma_\nu^{(k)} = -1 + ik\pi m_{\nu,0}^{(k)} + \nu\left(m_{\nu,1}^{(k)} + \tfrac{1}{2}m_{\nu,0}^{(k)^2}\right). \tag{B.29}$$

On the other hand, Proposition B.3 shows that $r_\nu^{(k)}(x)$ has the form $ax + b + c(x-1)^{-1}$, where $c = 0$ if $\nu \in D \setminus D_k$. Comparing the Laurent series of this function with (B.27), we deduce that $a = \nu$, $b = \beta_\nu^{(k)}$, and $c = \gamma_\nu^{(k)}$. The roots of $r_\nu^{(k)}$, which coincide with the ones of $f_\nu^{(k)}$ if they differ from ± 1, are thus given by

$$\begin{aligned} x_\nu^{(k)} &= -\beta_\nu^{(k)}/\nu \quad \text{if } \nu \in D \setminus D_k, \\ x_\nu^{(k)\pm} &= \left(\nu - \beta_\nu^{(k)} \pm \sqrt{(\beta_\nu^{(k)} + \nu)^2 - 4\nu\gamma_\nu^{(k)}}\right)\Big/ 2\nu \quad \text{if } \nu \in D_k. \end{aligned}$$

In the particular case $k = 0$, it may be easily seen that $m_{\nu,0}^{(0)} = 1$, which shows that $\beta_\nu^{(0)} = \nu$. Consequently, if $\nu \in D \setminus D_0$, we have $x_\nu^{(0)} = -1$ which is not acceptable, and if $\nu \in D_0$, the two roots $x_\nu^{(0)\pm}$ are opposite to each other (see the symmetry properties in §B.2): they differ from ± 1 since 1 is a pole of $r_\nu^{(0)}$ when $\nu \in D_0$.

Finally, according to the change of variable (B.14) and property (B.11), we have the following.

PROPOSITION B.4. *The roots of the dispersion equation* (B.1) *are distributed as follows:*

(i) *if $\nu \in D_n$ for $n \neq 0$, no root in the strip $]-\pi/2, \pi/2[\, \times i\mathbb{R}$, one root $z_\nu^{(k)}$ in each strip $](k-\frac{1}{2})\pi, (k+\frac{1}{2})\pi[\, \times i\mathbb{R}$ for $k \neq n$, and two roots $z_\nu^{(n)\pm}$ in the strip $](n-\frac{1}{2})\pi, (n+\frac{1}{2})\pi[\, \times i\mathbb{R}$, where*

$$z_\nu^{(k)} = -i\beta_\nu^{(k)} = k\pi - i\nu m_{\nu,0}^{(k)}, \tag{B.30}$$

$$z_\nu^{(k)\pm} = \frac{i}{2}\left(\nu - \beta_\nu^{(k)} \pm \sqrt{(\beta_\nu^{(k)} + \nu)^2 - 4\nu\gamma_\nu^{(k)}}\right); \tag{B.31}$$

(ii) *if $\nu \in D_0$, two opposite roots $z_\nu^{(0)\pm}$ in the strip $]-\pi/2, \pi/2[\, \times i\mathbb{R}$ given by* (B.31) *with $\beta_\nu^{(0)} = \nu$, and one root $z_\nu^{(k)}$ in each strip $](k-\frac{1}{2})\pi, (k+\frac{1}{2})\pi[\, \times i\mathbb{R}$ for $k \neq 0$, where $z_\nu^{(k)}$ is still given by* (B.30).

Remark B.1. The two roots located in the strip $](n-\frac{1}{2})\pi,(n+\frac{1}{2})\pi[\times i\mathbb{R}$ (for $\nu\in D_n$) may coincide: more precisely, there exists one (and only one) value of $\nu\in D_n$ such that $x_\nu^{(n)+}=x_\nu^{(n)-}$ is a double root of the dispersion equation. Indeed, we know from Lemma B.1 that there is one possible double root ζ_n^* of (B.1) in each strip $](n-\frac{1}{2})\pi,(n+\frac{1}{2})\pi[\times i\mathbb{R}$: this root corresponds to the exceptional point $\nu_n^*=f(\zeta_n^*)=\sin^2\zeta_n^*\in\mathbb{E}$. Consequently, each domain D_n contains one (and only one) point of $\mathbb{E}$.

Consider finally the case $\nu\in C$. By virtue of the definition (B.12) of the curves C_n, this means that there exists $n\geq 0$ and $t\in]0,1[$ such that

$$\nu=\frac{1}{t}\left[\frac{1}{2}\operatorname{Log}\frac{1+t}{1-t}+i\pi\left(n+\frac{1}{2}\right)\right]. \tag{B.32}$$

Moreover,

$$\zeta_{n,t}=-i\nu t=\pi\left(n+\frac{1}{2}\right)-\frac{i}{2}\operatorname{Log}\frac{1+t}{1-t} \tag{B.33}$$

is a simple root of the dispersion equation (B.1). In fact, by Remark B.1, all the roots of (B.1) are simple in this case. Proposition B.1 thus shows that there exists a vicinity of ν in which these roots are analytic. Consequently, their expressions are obtained by going to the limit ($\nu\longrightarrow\nu_n\in C_n$) in (B.30) and (B.31). For some of them, a singular integral appears. Indeed, if $\nu\in C_n$, functions $f_\nu^{(n)+}$ and $f_\nu^{(n+1)-}=f_\nu^{(n)+}$ vanish on I at point $-t$, where t is the parameter which corresponds ν in (B.32). On the other hand, $f_\nu^{(k)+}$ (respectively, $f_\nu^{(k)-}$) does not vanish on I if $k\neq n$ (respectively, $k\neq n+1$). We finally deduce from Proposition B.4 the following:

(i) if ν passes from D_0 to D_1 across C_0, the only root of (B.1) located in the strip $]0,\pi/2[\times i\mathbb{R}$ crosses the line $\operatorname{Re}\zeta=\pi/2$ at point $\zeta_{0,t}$ given in (B.33);

(ii) if ν passes from D_n to D_{n+1} ($n>0$) across C_n, one of the two roots of (B.1) located in the strip $](n-1/2)\pi,(n+1/2)\pi[\times i\mathbb{R}$ crosses the line $\operatorname{Re}\zeta=(n+1/2)\pi$ at point $\zeta_{n,t}$ given in (B.33).

B.5. Further properties of the roots. We consider in this last paragraph the roots $\zeta_\nu^{(m)}$, $m\geq 0$, of the dispersion equation defined in Lemma 3.1 for real positive ν: $\zeta_\nu^{(0)}$ is imaginary with negative imaginary part and $\zeta_\nu^{(m)}$, for $m\geq 1$, are real, positive and arranged according to increasing values. The results of §B.4 together with Proposition B.1 show that each $\zeta_\nu^{(m)}$ extends to an analytic function of ν in any simply connected domain of $\mathbb{C}\setminus\mathbb{E}$. We state below some properties of these roots.

PROPOSITION B.5. *If* $\operatorname{Im}\nu>0$, *the roots* $\zeta_\nu^{(m)}$ *of the dispersion equation* (B.1) *are such that*

$$\operatorname{Re}\zeta_\nu^{(m)}>0 \quad \textit{and} \quad \operatorname{Im}\zeta_\nu^{(m)}<0 \quad \forall m\geq 0. \tag{B.34}$$

If $\operatorname{Im}\nu<0$, *we have*

$$\begin{aligned}&\operatorname{Re}\zeta_\nu^{(0)}<0 \quad \textit{and} \quad \operatorname{Im}\zeta_\nu^{(0)}<0,\\ &\operatorname{Re}\zeta_\nu^{(m)}>0 \quad \textit{and} \quad \operatorname{Im}\zeta_\nu^{(m)}>0 \quad \forall m>0.\end{aligned} \tag{B.35}$$

Proof. First, notice that if ν lies in a simply connected domain of $\mathbb{C}\setminus\mathbb{E}$ which does not cross the real axis, then the signs of $\operatorname{Re}\zeta_\nu^{(m)}$ and $\operatorname{Im}\zeta_\nu^{(m)}$ (for a given $m\geq 0$) are constant. This follows from the fact that a root ζ of (B.1) may be located on the real or imaginary axes only if ν is real (since $\nu = -\zeta \tan \zeta$). In order to find these signs, we simply have to study $d_\nu \zeta_\nu^{(m)}$ when $\nu \in \mathbb{R}^+$. Deriving (B.1) with respect to ν yields

$$d_\nu \zeta_\nu^{(m)} = \frac{-2\cos^2(2\zeta_\nu^{(m)})}{\sin 2\zeta_\nu^{(m)} + 2\zeta_\nu^{(m)}}.$$

If $\zeta_\nu^{(m)}$ is imaginary (i.e., $m = 0$), this quantity is imaginary too, and its imaginary part is positive. Similarly, if $\zeta_\nu^{(m)}$ is real and positive, it is real and negative. (B.34) and (B.35) follow. □

PROPOSITION B.6. *The asymptotic behaviour of $\zeta_\nu^{(m)}$ when $m \to +\infty$ is given by*

$$\zeta_\nu^{(m)} = m\pi - m^{-1}\nu/\pi + O(m^{-3}). \tag{B.36}$$

Proof. We know from Proposition B.4 that for large enough m, $\zeta_\nu^{(m)}$ is nothing but the root $z_\nu^{(m)}$ given by (B.30). We thus have from (B.26),

$$\zeta_\nu^{(m)} = m\pi - \frac{\nu}{2\pi}\int_I \log a_\nu^{(m)}(t)\, dt,$$

where log is here the principal branch Log of the logarithm (see (B.24) and Fig. B.3 in the case $n \neq k$ and $k \neq 0$). Recall that $a_\nu^{(m)}(t)$ reads

$$a_\nu^{(m)}(t) = \frac{t\nu + i\pi(m+\frac{1}{2}) + \frac{1}{2}\operatorname{Log}\frac{1-t}{1+t}}{t\nu + i\pi(m-\frac{1}{2}) + \frac{1}{2}\operatorname{Log}\frac{1-t}{1+t}}.$$

For every $t \in]-1,+1[$, this quantity expands as follows:

$$a_\nu^{(m)}(t) = 1 + m^{-1} + m^{-2}\left(\frac{1}{2} - \frac{1}{i\pi}\left(\nu t + \operatorname{Log}\frac{1-t}{1+t}\right)\right) + O(m^{-3}).$$

Consequently,

$$\operatorname{Log} a_\nu^{(m)}(t) = m^{-1} - m^{-2}\left(\frac{1}{i\pi}\left(\nu t + \operatorname{Log}\frac{1-t}{1+t}\right)\right) + O(m^{-3}).$$

This expansion is valid uniformly with respect to t in every closed segment $[a,b] \subset]-1,+1[$: we can thus integrate it over I. Noticing that

$$\int_I \left(\nu t + \operatorname{Log}\frac{1-t}{1+t}\right) dt = 0,$$

the expansion (B.36) of $\zeta_\nu^{(m)}$ follows. □

We end this section by a remark about the role of the exceptional points of $\mathbb{E}$. We show in Fig. B.5 the path followed by each root $\zeta_\nu^{(m)}$ when ν describes the closed curve around the "first" exceptional point represented in Fig. B.4 (the dots in Fig. B.5 are the possible double roots of the dispersion equation, i.e., the solutions of (B.3)). More generally, it may be easily seen that when ν describes a closed path around the nth exceptional point, every root returns to its initial value, except $\zeta_\nu^{(0)}$ and $\zeta_\nu^{(n)}$ which

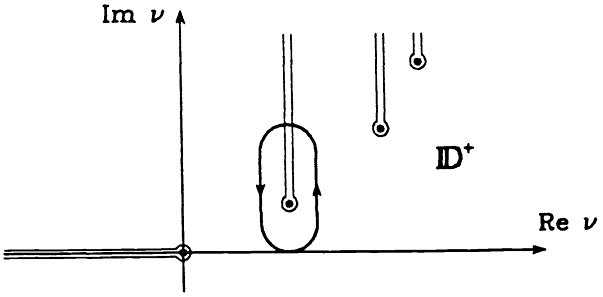

FIG. B.4. *Closed path for ν around an exceptional point.*

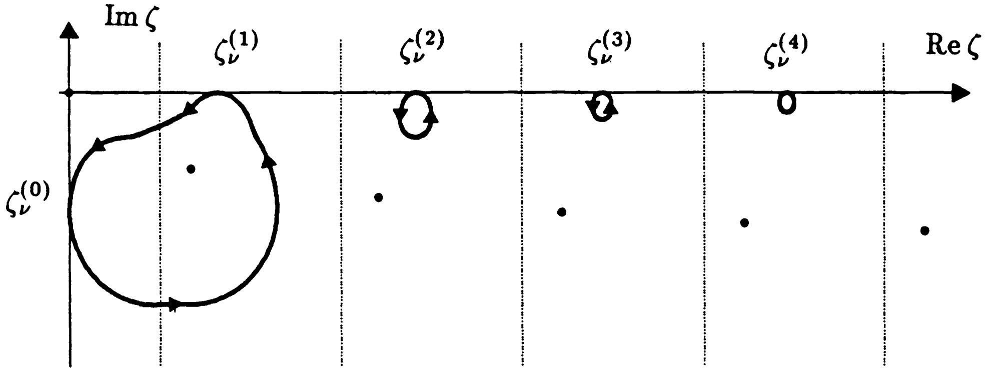

FIG. B.5. *Corresponding path of each $\zeta_\nu^{(m)}$.*

undergo a permutation. This illustrates the fact that the points of $\mathbb{E}$ are branch points of order 1.

GLOBAL EXISTENCE AND BLOW-UP PROBLEMS FOR QUASILINEAR PARABOLIC EQUATIONS WITH NONLINEAR BOUNDARY CONDITIONS*

MINGXIN WANG[†‡] AND YONGHUI WU[†]

Abstract. This paper deals with the solutions of nonlinear parabolic equations $u_t = \nabla(a(u)\nabla u)$ with nonlinear boundary conditions $\partial u/\partial n = b(u)$ on $\partial\Omega\times(0,T)$, where $a(u)$ and $b(u)$ are positive and nondecreasing C^1 functions for $u > 0$. It is shown that if $\int^{+\infty} ds/b(s) < +\infty$ or $\int^{+\infty} ds/b(s) = +\infty$ and $\int^{+\infty} ds/(a(s)b(s)b'(s) + a(s)b(s) + a'(s)b^2(s)) < +\infty$, then the solution blows up in finite time, and the solution exists globally if $\int^{+\infty} ds/b(s) = +\infty$ and $\int^{+\infty} ds/(a(s)b(s)b'(s) + a(s)b(s) + a'(s)b^2(s)) = +\infty$.

Key words. nonlinear parabolic equations, nonlinear boundary conditions, global solutions, blowup, upper and lower solutions

AMS subject classifications. 35K55, 35K60, 35B40

1. Introduction.

The global existence or blow-up problems for parabolic equations are studied by many authors. Papers [1] and [2] studied the following equations:

$$\begin{aligned} &u_t = \Delta u, && x\in\Omega, \quad t>0, \\ &\frac{\partial u}{\partial n} = b(u), && x\in\partial\Omega, \quad t>0, \\ &u(x,0) = u_0(x) > 0, && x\in\bar\Omega, \end{aligned} \tag{1}$$

where n is the outer normal vector.

In [1] Levine and Payne proved that, for the special case $b(u) = |u|^{1+\epsilon}h(u)$, $\epsilon > 0$, $h(u)$ is increasing, problem (1) has no global solution. Later, Walter dealt with the generalized nonlinear boundary conditions and he obtained that if $b(u)$ and $b'(u)$ are continuous, positive, and increasing, then $\int^{+\infty} ds/b(s)b'(s) < +\infty$ implies that the solution of (1) blows up in finite time; $\int^{+\infty} ds/b(s)b'(s) = +\infty$ implies that the solution of (1) is bounded on $\bar\Omega \times [0,T]$ for any $T < +\infty$.

Recently, [3] considered the similar problem from another point of view, i.e., the nonlinear diffusion term.

$$\begin{aligned} &u_t = \nabla(a(u)\nabla u), && x\in\Omega, \quad t>0, \\ &\frac{\partial u}{\partial n} = 1, && x\in\partial\Omega, \quad t>0, \\ &u(x,0) = u_0(x) > 0, && x\in\bar\Omega. \end{aligned} \tag{2}$$

Let $a(u)$ and $a'(u)$ be continuous and positive; there exists $M > 0$ such that $\lim_{u\to+\infty}\sup a'(u)/a(u) \le M$. The author in [3] proved that if $\int^{+\infty} ds/a(s) < +\infty$,

[†] Institute of Systems Science, Academia Sinica, Beijing 100080, People's Republic of China.

[‡] The work of this author was supported by the National Natural Science Foundation of China.

then the solution of (2) blows up in finite time; if $\int^{+\infty} ds/a(s) = +\infty$, then the solution of (2) is bounded on $\bar{\Omega} \times [0,T]$ for any $T < +\infty$.

Because $\lim_{u\to+\infty} \sup a'(u)/a(u) \le M$, it is obvious that the convergence of $\int^{+\infty} ds/a(s)$ is equivalent to that of $\int^{+\infty} ds/(a(s)+a'(s))$.

In this paper, we combine the two nonlinear cases by considering the following nonlinear parabolic equations with nonlinear boundary conditions:

$$(3)\qquad \begin{aligned} &u_t = \nabla(a(u)\nabla u), && x\in\Omega,\quad t>0,\\ &\frac{\partial u}{\partial n} = b(u), && x\in\partial\Omega,\quad t>0,\\ &u(x,0) = u_0(x) > 0, && x\in\bar{\Omega}. \end{aligned}$$

Our approach depends heavily upon the upper and lower solution method which was first introduced by Walter in [2] to deal with nonlinear boundary problems. We obtain similar results of (1) and (2) and can deduce the results of (1) and (2) as our special cases.

2. Main results and an example. Throughout this section we suppose that $\Omega \subset \mathbb{R}^N$ is a smooth bounded domain, and the initial data $u_0(x)$ is a positive C^1 function. Moreover, we assume the following:

(H) $a(s)$ and $b(s)$ are positive and nondecreasing C^1 functions for $s > 0$.

Under the above assumptions, it is well known that (3) has a unique local solution $u(x,t)$ and it is positive on $\bar{\Omega} \times [0, T_{\max})$.

Before giving our main results, we first state a comparison theorem, which is a special case in [4, Thm. 31.IV].

PROPOSITION (comparison principle). Let u, v be two positive smooth functions satisfying

$$\begin{aligned} &u_t - \nabla(a(u)\nabla u) \le v_t - \nabla(a(v)\nabla v), && x\in\Omega,\quad t\in[0,T],\\ &\frac{\partial u}{\partial n} - b(u) \le \frac{\partial v}{\partial n} - b(v), && x\in\partial\Omega,\quad t\in[0,T],\\ &u(x,0)\le v(x,0), && x\in\bar{\Omega}. \end{aligned}$$

Then $u(x,t) \le v(x,t)$ for all $x \in \bar{\Omega}$, $t \in (0,T)$.

We state our main theorems and compare them with the previous results.

THEOREM 1. *Let* (H) *hold. If* $\int^{+\infty} ds/b(s) < +\infty$, *then the solution* $u(x,t)$ *of* (3) *blows up in finite time.*

THEOREM 2. *Let* (H) *hold,* $a(s) + a(s)b'(s) + a'(s)b(s)$ *be nondecreasing, and* $\int^{+\infty} ds/b(s) = +\infty$.

(i) If $\int^{+\infty} ds/(b(s)(a(s)+a(s)b'(s)+a'(s)b(s))) < +\infty$, then the solution $u(x,t)$ of (3) blows up in finite time.

(ii) If $\int^{+\infty} ds/(b(s)(a(s)+a(s)b'(s)+a'(s)b(s))) = +\infty$, then the solution $u(x,t)$ of (3) exists globally.

From Theorems 1 and 2, we see easily that if $a'(s)$ and $b'(s)$ are nondecreasing, then $a(s) + a(s)b'(s) + a'(s)b(s)$ is nondecreasing. Hence the solution $u(x,t)$ of (3) exists globally if and only if $\int^{+\infty} ds/b(s) = +\infty$ and $\int^{+\infty} ds/(b(s)(a(s) + a(s)b'(s) + a'(s)b(s))) = +\infty$.

COROLLARY 1. *Let $b(s) = 1$ and $a(s), a'(s)$ be continuous, positive, and nondecreasing. Then if $\int^{+\infty} ds/(a(s) + a'(s)) < +\infty$, the solution of* (3) *blows up in finite time; if $\int^{+\infty} ds/(a(s) + a'(s)) = +\infty$, the solution of* (3) *exists globally.*

This is the case of [3].

COROLLARY 2. *Let $a(s) = 1, b(s)$ and $b'(s)$ be continuous, positive, and nondecreasing. Then, $\int^{+\infty} ds/b(s)b'(s) < +\infty$ implies that the solution of* (3) *blows up in finite time; $\int^{+\infty} ds/b(s)b'(s) = +\infty$ implies that the solution of* (3) *exists globally.*

This is the case of [2].

Example. Let $a(u) = u^p, b(u) = u^q, p, q \geq 0$. If $q > 1$, the solution of (3) blows up in finite time. If $q \leq 1$, then $p + q > 1$ implies that the solution of (3) blows up in finite time; $p + q = 1$ implies that the solution of (3) exists globally; $p + q < 1$ implies $q < 1$; by a similar method to the proof of (ii) of Theorem 2, it can be proved that the solution of (3) exists globally.

3. Proofs of the main results. Now we are in the position to prove the results of §2. In this section we denote d as the diameter of the bounded domain $\Omega \subset \mathbb{R}^N$. Our steps are just the same as those of [2] and [3]. The basic idea is to construct a lower solution $\underline{u}(x,t)$ or an upper solution $\bar{u}(x,t)$ of (3).

Proof of Theorem 1. By the comparison principle, it is easy to prove that the solution $u(x,t)$ of (3) satisfies $u(x,t) \geq \epsilon_0 = \min_{\bar{\Omega}} u_0(x) > 0$. We first assume that there exists a constant $c_0 > 0$ such that $b'(u) \geq c_0$ for $u \geq \epsilon_0/4$. Let $\psi(s)$ be the solution of the following ordinary differential equation

$$\psi'(s) = b(\psi(s)), \qquad s > 0, \tag{4}$$

$$\psi(0) = \psi_0 = \tfrac{1}{4}\epsilon_0.$$

Then $\psi''(s) = b'(\psi(s))\psi'(s)$. Since $b(s)$ is continuous and $\int^{+\infty} ds/b(s) < +\infty$, it is easy to deduce that $\psi(s)$ exists locally and blows up in finite time. Because $b(u) > 0$ for $u > 0$, we find that there exists a unique $s_1 > 0$ such that

$$\psi(s_1) = \epsilon_0/2.$$

Now we construct a lower solution $\underline{u}(x,t)$ of (3) as follows.

$$\underline{u}(x,t) = \psi(\epsilon t + c_1(h^*(x) + A)),$$

$$h^*(x) = x_1 + \cdots + x_N, \qquad c_1 = \frac{1}{2}\min\left\{\frac{s_1}{2Nd+1}, \frac{1}{N}\right\},$$

$$\epsilon = \frac{1}{2}Na(\psi(0))c_0c_1^2, \qquad A = Nd + 1.$$

Then

$$\frac{\partial \underline{u}}{\partial n} = c_1\psi'(s)\frac{\partial h^*}{\partial n} = b(\psi(s))c_1\frac{\partial h^*}{\partial n} \leq \frac{1}{2}b(\underline{u}).$$

Since

$$|\nabla h^*|^2 = N \quad \text{and} \quad \Delta h^* = 0,$$

direct computations show that

$$\begin{aligned}
\underline{u}_t &= \epsilon\psi'(s),\\
\nabla(a(\underline{u})\nabla\underline{u}) &= c_1^2 a(\psi(s))\psi''(s)|\nabla h^*|^2 + c_1^2 a'(\psi(s))\psi'^2(s)|\nabla h^*|^2\\
&> c_1^2 a(\psi(s))\psi''(s)|\nabla h^*|^2\\
&= c_1^2 a(\psi(s))b'(\psi(s))\psi'(s)N.
\end{aligned}$$

Because $\psi(s)$ is increasing, we know that $\underline{u} = \psi(\epsilon t + c_1(h^*(x) + A)) > \psi(0) = \frac{1}{4}\epsilon_0$, $\underline{u}(x,0) = \psi(c_1(h^*(x) + A)) \le \psi(c_1(2Nd + 1)) \le \psi(s_1) = \frac{1}{2}\epsilon_0$. And hence

$$b'(\underline{u}) = b'(\psi(s)) \ge c_0,$$

so that

$$\nabla(a(\underline{u})\nabla\underline{u}) > c_1^2 c_0 N a(\psi(0))\psi'(s).$$

Therefore, we have that

$$\begin{aligned}
&\underline{u}_t \le \nabla(a(\underline{u})\nabla\underline{u}), && x \in \Omega, \quad t > 0,\\
&\frac{\partial \underline{u}}{\partial n} < b(\underline{u}), && x \in \partial\Omega, \quad t > 0,\\
&\underline{u}(x,0) < u_0(x), && x \in \bar{\Omega}.
\end{aligned}$$

This shows that $\underline{u}(x,t)$ is a lower solution of (3); therefore, $u(x,t) \ge \underline{u}(x,t)$. Since $\underline{u}(x,t) \ge \psi(\epsilon t), \psi(\epsilon t)$ blows up in finite time. So does $u(x,t)$.

If $b'(u)$ has no positive lower bound for $u \ge \epsilon_0/4$, we can construct a new function $b_1(u)$ having this property and satisfying the same conditions of $b(u)$ and $b_1(u) \le b(u)$.

In fact, let $\epsilon_1 = \frac{1}{8}\epsilon_0$. Since $b'(u) \ge 0, b(u) > 0$ and $\int^{+\infty} ds/b(s) \le c < +\infty$, we know that

$$\frac{1}{b(u)}(u - \epsilon_1) \le \int_{\epsilon_1}^{u} \frac{ds}{b(s)} \le c.$$

Hence $b(u) \ge (1/c)(u - \epsilon_1) \ge u/2c$ for $u \ge 2\epsilon_1 = \frac{1}{4}\epsilon_0$. Let

$$b_1(u) = \frac{1}{2\epsilon_1}\int_{u-\epsilon_1}^{u}\left(b(s) + \frac{1}{2c}s\right)ds,$$

then

$$\begin{aligned}
b_1(u) &\le \frac{1}{2}b(u) + \frac{1}{8c\epsilon_1}(2\epsilon_1 u - \epsilon_1^2)\\
&\le \frac{1}{2}\left(b(u) + \frac{1}{2c}u\right) \le b(u) \quad \text{for} \quad u \ge \epsilon_0/4,\\
b_1(u) &\ge \frac{1}{2\epsilon_1}\int_{u-\epsilon_1}^{u} b(s)ds \ge \frac{1}{2}b(u - \epsilon_1),\\
b_1'(u) &= \frac{1}{2\epsilon_1}(b(u) - b(u - \epsilon_1)) + \frac{1}{4c} \ge \frac{1}{4c}.
\end{aligned}$$

These facts show that $b_1(u)$ and $b_1'(u)$ are continuous, positive on $[\epsilon_0/4, +\infty)$ and $\int^{+\infty} ds/b_1(s) < +\infty$.

By the above proof, we know that the solution $u_1(x,t)$ of (3), corresponding to $b_1(u)$, blows up in finite time. Since $u_1(x,t)$ and $u(x,t)$ are both greater than or equal to $\epsilon_0(= 8\epsilon_1)$, we infer that $u(x,t) \geq u_1(x,t)$ from the comparison principle. And hence $u(x,t)$ blows up in finite time, which completes our proof.

Proof of Theorem 2. Let $h(x)$ be the solution of the following problem:

$$(5)\qquad \begin{aligned} &\Delta h(x) = k = \frac{|\partial\Omega|}{|\Omega|}, \qquad x \in \Omega,\\ &\frac{\partial h}{\partial n} = 1, \qquad x \in \partial\Omega. \end{aligned}$$

If $h(x) \in C^2(\bar{\Omega})$ is a solution of (5), it is easy to see that $h(x) + c$ is also a solution of (5) for any constant $c > 0$. Hence we assume that $h(x) > 0$ on $\bar{\Omega}$, and there exists a constant $L > 0$ such that

$$\max_{\bar{\Omega}}(h(x) + |\nabla h(x)|) \leq L.$$

(i) If $\int^{+\infty} ds/(b(s)(a(s) + a(s)b'(s) + a'(s)b(s))) < +\infty$. Let $\psi(s)$ be the solution of (4). At this time $\psi(s)$ exists for all s since $\int^{+\infty} ds/b(s) = +\infty$. It follows from $b(u) > 0$ and $b'(u) \geq 0$ that $\lim_{s\to+\infty} \psi(s) = +\infty$.

Let $g(t)$ be the solution of the ordinary differential equation

$$(6)\qquad \begin{aligned} &g'(t) = c_3[a(\psi(g)) + a(\psi(g))b'(\psi(g)) + a'(\psi(g))b(\psi(g))], \qquad t > 0,\\ &g(0) = g_0 = \tfrac{1}{3}s_1, \end{aligned}$$

where

$$c_2 = \min\left\{\frac{s_1}{3(2Nd+1)}, \frac{1}{4Nd}\right\},$$

$$\lambda = \min\left\{\frac{c_2}{2L}, \frac{1}{2}, \frac{s_1}{3L}\right\}, \qquad c_3 = \min\left\{k\lambda, \left(\frac{c_2}{2}\right)^2\right\},$$

$$s_1 > 0 \quad \text{such that} \quad \psi(s_1) = \tfrac{1}{2}\epsilon_0.$$

Since $\int^{+\infty} ds/(b(s)(a(s) + a(s)b'(s) + a'(s)b(s))) < +\infty$, we have that $g(t)$ exists locally and blows up in finite time.

Let

$$\underline{u}(x,t) = \psi(g(t) + \lambda h(x) + c_2(h^*(x) + A)),$$

where $h^*(x) = x_1 + \cdots + x_N, A = Nd + 1$. Denote

$$s = g(t) + \lambda h(x) + c_2(h^*(x) + A).$$

Then we have that

$$\underline{u}_t = \psi'(s)g'(t),$$

$$\begin{aligned}\nabla(a(\underline{u})\nabla\underline{u}) &= a(\underline{u})[\lambda\psi'(s)\Delta h+\psi''(s)|\lambda\nabla h+c_2\nabla h^*|^2]\\ &\quad +a'(\underline{u})\psi'^2(s)|\lambda\nabla h+c_2\nabla h^*|^2\\ &= k\lambda a(\underline{u})\psi'(s)+(a(\underline{u})b'(\underline{u})\psi'(s)+a'(\underline{u})\psi'^2(s))|\lambda\nabla h+c_2\nabla h^*|^2\\ &\geq \left[k\lambda a(\underline{u})+\left(\frac{c_2}{2}\right)^2(a(\underline{u})b'(\underline{u})+a'(\underline{u})b(\underline{u}))\right]\psi'(s)\\ &\geq c_3[a(\psi(g))+a(\psi(g))b'(\psi(g))+a'(\psi(g))b(\psi(g))]\psi'(s)\end{aligned}$$

since $\psi(s)>\psi(g)$ and $a(s)+a(s)b'(s)+a'(s)b(s)$ is nondecreasing.

Because $\psi'(s)=b(\psi(s))>0$, it follows from (6) that

$$\underline{u}_t\leq\nabla(a(\underline{u})\nabla\underline{u}).$$

Moreover,

$$\frac{\partial\underline{u}}{\partial n}=\psi'(s)\left(\lambda\frac{\partial h}{\partial n}+c_2\frac{\partial h^*}{\partial n}\right)\leq\psi'(s)(\lambda+c_2Nd)<b(\underline{u}),$$

$$\begin{aligned}\underline{u}(x,0) &= \psi(g_0+\lambda h(x)+c_2(h^*(x)+A))\\ &< \psi\left(\frac{1}{3}s_1+\lambda L+c_2(2Nd+1)\right)\\ &< \psi(s_1)=\frac{1}{2}\epsilon_0<u_0(x).\end{aligned}$$

Therefore, by the comparison principle we obtain that

$$u(x,t)\geq\underline{u}(x,t).$$

Since $g(t)$ blows up in finite time and $\lim_{s\to+\infty}\psi(s)=+\infty$, we get that $\underline{u}(x,t)$ blows up in finite time. So does $u(x,t)$.

(ii) If $\int^{+\infty}ds/(b(s)(a(s)+a(s)b'(s)+a'(s)b(s)))=+\infty$. Let $\psi(s)$ be the solution of the following ordinary differential equation:

$$\begin{aligned}&\psi'(s)=b(\psi(s)), \qquad s>0,\\ &\psi(0)=\psi_0=\max_{\Omega}u_0(x).\end{aligned}\tag{7}$$

Then $\psi(s)$ is global solution of (7) because of $\int^{+\infty}ds/b(s)=+\infty$.

Let $g(t)$ be the solution of the following problem:

$$\begin{aligned}g'(t) &= (k+L^2)(a(\psi(g+L))+a(\psi(g+L))b'(\psi(g+L))\\ &\qquad +a'(\psi(g+L))b(\psi(g+L))), \qquad t>0,\\ g(0) &= 1.\end{aligned}$$

$\int^{+\infty} ds/(b(s)(a(s) + a(s)b'(s) + a'(s)b(s))) = +\infty$ implies that $g(t)$ exists globally. We construct $\bar{u}(x,t)$ as follows:

$$\overline{u}(x,t) = \psi(g(t) + h(x)).$$

Through direct computations, it is easy to see that

$$\begin{aligned} &\bar{u}_t \geq \nabla(a(\overline{u})\nabla\bar{u}), && x \in \Omega, \quad t > 0, \\ &\frac{\partial\bar{u}}{\partial n} > b(\bar{u}), && x \in \partial\Omega, \quad t > 0, \\ &\bar{u}(x,0) > u_0(x), && x \in \bar{\Omega}. \end{aligned}$$

This shows that $\bar{u}(x,t)$ is an upper solution of (3). Since ψ and g exist globally, we know that $\bar{u}(x,t)$ exists for all $t > 0$. So does $u(x,t)$. This concludes the proof of Theorem 2.

HIGHER-ORDER REGULARITY FOR THE SOLUTIONS OF SOME DEGENERATE QUASILINEAR ELLIPTIC EQUATIONS IN THE PLANE*

W. B. LIU[†] AND JOHN W. BARRETT[†]

Abstract. Local $C^{k,\beta}$ and $W^{2+k,v}$ ($k \geq 1, \beta > 0$, and $v \geq 1$) regularity is established for the solutions of a class of degenerate quasilinear elliptic equations, which include the p-Laplacian. Unlike the known local regularity results for such equations, k is larger than 2 in many notable cases. These results generalize those in [13], which were established only for the p-Laplacian. Furthermore, local results are extended to obtain a global regularity result in some cases. Global results of this type are essential in proving optimal error bounds for the finite element approximation of such equations.

1. Introduction.

Let Ω be a bounded open set in R^2 with a Lipschitz boundary $\partial\Omega$. Let φ be a positive continuous function on $(0, \infty)$. Many mathematical models from physical processes have the following form: given ρ, find u such that

$$-\nabla \cdot (\varphi(|\nabla u|)\nabla u) = \rho \quad \text{in } \Omega \tag{1.1}$$

plus some boundary conditions. Such models arise in fluid mechanics (see [4] and [5]), nonlinear diffusion (see [24]), and nonlinear elasticity (see [3]). An example of the latter is the mode III problem, longitudinal shear, for a power law material (see [3]). This leads to (1.1) with $\varphi(t) = t^{p-2}$ ($1 < p \leq 2$), which is usually referred to as the p-Laplacian.

There is much work on the regularity of the solutions of (1.1) if $\varphi > 0$ is smooth on $[0, \infty)$ and satisfies certain coercivity and growth conditions. In this case the solutions of (1.1) will generally be smooth in any open set $G \subset\subset \Omega$. As key references, one can refer to [11], [12], [15], and [23]. These results are generally true for (1.1) when $\Omega \subset R^n$.

However, as seen above, in some physically relevant models φ may not be smooth on $[0, \infty)$ or may not satisfy the coercivity and growth conditions. Equations of this type are usually referred to as degenerate. A typical example is the p-Laplacian with $p \neq 2$. The well established regularity results for nondegenerate equations are generally not applicable to such cases (see [29] for some counterexamples). The regularity theory for these degenerate equations is much more complicated and until quite recently very little was known (see [31]).

Since the publication of [30], extensive work has been done on the regularity of the solutions of (1.1) and more general degenerate quasilinear equations and systems. One can find such work, for example, in [1], [2], [9], [10], [13], [17]–[19], [20]–[22], and [26]–[29]. Generally speaking, local and global $C^{1,\alpha}$ regularity has been established for the solutions of (1.1) and more general systems (for example, see [9], [18], [19], and [29]). In addition, some local H^2 regularity results have been established; for example, see [26] and [29]. These results remain true for (1.1) when $\Omega \subset R^n$. It should be noted that it is usually quite difficult to extend a local regularity result to a

global one due to the degenerate nonlinearity. In the plane there exist more powerful methods to study (1.1); for example, complex function theory. In the case $\varphi(t) = t^{p-2}$ and $\rho = 0$ a local $W^{2,2+\eta}(\Omega)$ regularity result, where $\eta(p) > 0$ has been proved, using the theory of quasi-regular mappings, firstly for $p \geq 2$ in [7] and then for $p > 1$ in [22]. In [20] global H^2 regularity results have been established for (1.1), for $\rho \in L^r(\Omega)$, $r > 2$, when $p \in (1, 2]$ and for $\rho = 0$ when $p > 2$, by using an a priori estimate for the solutions of a linear elliptic equation in the plane with only $L^\infty(\Omega)$ coefficients.

These global H^2 regularity results have been used in the error analysis of the finite element approximation of (1.1) in [6], [20], and [21]. From this work it is seen that the regularity of the solutions has a considerable influence on the order of convergence that can be proved for their finite element approximation. Taking the p-Laplacian $(1 < p < 2)$ as an example, if $u \in W^{2,p}(\Omega)$ one can prove that the error for the continuous piecewise linear finite element approximation converges at the rate $h^{p/2}$ in $W^{1,p}(\Omega)$, whereas one can prove that it converges at the optimal rate h if $u \in C^{2,2/p-1}(\bar{\Omega}) \cap W^{3,1}(\Omega)$, see [6], or $u \in W^{3,p}(\Omega)$. With some restrictions on ρ and the boundary data, the global regularity $u \in W^{1+2/p,p}(\Omega)$ is shown in [21] to be sufficient to ensure the optimal convergence rate h. Thus one can see that it is important to establish some global higher-order regularity results in order to obtain optimal error bounds in $W^{1,p}(\Omega)$ for the continuous piecewise linear finite element approximation of (1.1).

A first step in this direction was taken in [13], where $C^{k,\alpha}$ and $W^{2+k,q}$ regularity has been established, using the theory of quasi-regular mappings for the solutions of the p-Laplacian in the plane with $\rho = 0$, although the results are only local. Unlike most known results, k is larger than 2 in many interesting cases; for example, the p-Laplacian with $1 < p \leq 2$. From this result it was pointed out in [21] that global $W^{3,p}(\Omega)$, $C^{2,2/p-1}(\bar{\Omega})$, and $W^{1+2/p,p}(\Omega)$ regularity can indeed be achieved for solutions of the p-Laplacian in some physically relevant cases, though this result is only applicable to a limited class of boundary data. It should be noted that the results in [13] are sharp and such high-order regularity (local or global) is not generally true for the case $\rho \neq 0$; see, for example, [17].

The purpose of this paper is to generalize the results in [13] to a class of degenerate quasilinear elliptic equations, which includes the p-Laplacian. Furthermore, we show that this local result can be extended to a global one in some cases.

Throughout this paper, we adopt the standard notation $W^{s,v}(\Omega)(s \geq 0,\ v \in [1, \infty])$ for Sobolev spaces on Ω with norm $\|\cdot\|_{W^{s,v}(\Omega)}$; see [14], for example. We denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$ for nonnegative integers m and the spaces $W^{s,v}_{\mathrm{loc}}(\Omega)$ consist of all functions which are in $W^{s,v}(D)$ for all open sets $D \subset\subset \Omega$ (that is, $\bar{D} \subset \Omega$). For the definitions of the spaces $C^{k,\beta}(\Omega)$ (k a nonnegative integer and $0 \leq \beta \leq 1$) and domains with $C^{k,\beta}$ boundaries; see [12], for example.

2. Preliminaries.

Let Ω be a bounded open set in R^2 with a Lipschitz boundary $\partial\Omega$. Let φ satisfy the following conditions:

(A1) The function $t \rightarrow \varphi(t)t$ belongs to $C^0[0, \infty) \cap C^\infty(0, \infty)$.

(A2) There exist constants $q > 1$, $q \neq 2$, and $C_i, \kappa > 0$ such that for all $t \geq 0$

$$C_1 t \min\{t^{q-2}, (1+t)^{q-2}\} \leq \varphi(t)t \leq C_2 t \max\{t^{q-2}, (1+t)^{q-2}\}, \tag{2.1a}$$

and $\Gamma(t) \equiv \varphi'(t)t/\varphi(t)$ is such that for all $t \geq 0$,

$$\kappa \leq \Gamma(t)/(q-2) \leq 1. \tag{2.1b}$$

(A3) The function $\Gamma(t)$ is analytic at $t = 0$; that is, in an interval about $t = 0$,

$$\Gamma(t) \equiv \sum_{i=0}^{\infty} \gamma_i t^i. \tag{2.2a}$$

In addition we assume that there is a $\eta > 0$ such that

$$|\gamma_i| \leq |\gamma_0|\eta^i \quad \text{for all } i \geq 1, \tag{2.2b}$$

where we note from (2.1a) that $\Gamma(0) \equiv \gamma_0 \neq 0$.

We note that the regularity requirement $C^{\infty}(0, \infty)$ in (A1) can be appropriately relaxed and the results in this paper remain valid.

In this paper we will study the local and global regularity of the weak solutions $u \in W^{1,q}_{\text{loc}}(\Omega)(q > 1)$ of the following equation:

$$\nabla \,.\, (\varphi(|\nabla u|)\nabla u) = 0 \quad \text{in } \Omega. \tag{2.3}$$

Example 2.1. For example, it is easy to see that $\varphi(t) \equiv t^{q-2}$ or $\varphi(t) \equiv [t(1 + t)]^{(q-2)/2}$ or $\varphi(t) \equiv [t(1 + t^2)]^{(q-2)/3}(q > 1)$ satisfies the conditions (A1)–(A3). It is also easy to show that if φ satisfies the conditions (A1) and (A2), then it satisfies the structural conditions (1.2)–(1.5) in [27] and (1.3)–(1.5) in [29].

Remark 2.1. We note that if $\varphi(t)$ satisfies the conditions (A1)–(A3) and u satisfies (2.3), then for any constant $\lambda > 0$, $\equiv \lambda^{-1}u$ is such that $\nabla \,.\, (\hat{\varphi}(|\nabla \hat{u}|)\nabla \hat{u}) = 0$ in Ω with $\hat{\varphi}(t) \equiv \varphi(\lambda t)$. Therefore $\hat{\varphi}(t)$ satisfies (A1)–(A3) with $\hat{\Gamma}(t) \equiv \hat{\varphi}'(t)t/\hat{\varphi}(t) \equiv \Gamma(\lambda t)$, $\hat{\Gamma}(t) \equiv \sum_{i=0}^{\infty} \hat{\gamma}_i t^i$, and $|\hat{\gamma}_i| \leq |\hat{\gamma}_0|(\lambda\eta)^i$ for all $i \geq 1$. Therefore without loss of generality we can assume that $\eta > 0$ in (2.2b) is as small as we please throughout this paper.

In [8], [19], [27], and [29] the existence of solutions, $u \in W^{1,q}_{\text{loc}}(\Omega)$, to the weak formulation of (2.3) is established. It follows from [9] and [29] that $u \in C^{1,\alpha}(\Omega)$ for an $\alpha > 0$. Furthermore, if some suitable boundary conditions are imposed, the weak solution $u \in W^{1,q}(\Omega)$ is unique.

Let u be a weak solution of (2.3), and let $f \equiv u_x - iu_y$ be the complex gradient of u. It turns out that regularity of f, and hence u, can be more easily examined if we view it as a function of a complex variable. To this end we first express (2.3) in the form of a complex equation. Let us recall for $z \equiv x + iy$, $(x, y) \in R^2$ that $\partial/\partial z \equiv (\partial/\partial x - i\partial/\partial y)/2$ and $\partial/\partial \bar{z} \equiv (\partial/\partial x + i\partial/\partial y)/2$.

LEMMA 2.1. *The mapping $f \equiv u_x - iu_y$ is K-quasi-regular with $K = \max\{q - 1, 1/(q - 1)\}$. Hence $f \in [W^{1,2+\eta}_{\text{loc}}(\Omega)]^2$ for a $\eta > 0$ and $f^{-1}(0) \equiv \{z \in \Omega : \nabla u(z) = 0\}$ is discrete provided that u is not identically constant.*

Let $p \equiv 2 + \Gamma(0)$; then

$$p \in [q, 2) \quad \text{if } q \in (1, 2) \quad \text{and} \quad p \in (2, q] \quad \text{if } q > 2. \tag{2.4}$$

On setting $G(t) \equiv \Gamma(t)/\Gamma(0)$ and $F(t) \equiv pG(t)/(2 + (p - 2)G(t))$, it follows that f satisfies for almost every $z \in \Omega$,

$$\partial f/\partial \bar{z} = (1/p - \tfrac{1}{2})[(\bar{f}/f)(\partial f/\partial z) + (f/\bar{f})(\overline{\partial f/\partial z})]F(|f|). \tag{2.5}$$

Proof. We will show that f is a quasi-regular mapping by generalizing the approach given in [22] for the p-Laplacian. Firstly we prove that $u \in H^2_{\text{loc}}(\Omega)$.

Let $\varphi^\varepsilon(t) \equiv \varphi((t^2+\varepsilon)^{1/2})$ and u^ε be the unique solution of the following problem:

$$(2.6) \qquad \nabla \cdot (\varphi^\varepsilon(|\nabla u^\varepsilon|)\nabla u^\varepsilon) = 0 \quad \text{in } B \quad \text{and} \quad u^\varepsilon = u \quad \text{on } \partial B,$$

where B is an open ball in Ω. As $u \in C^1(\bar{B})$, it follows from [12] and [15] that $u^\varepsilon \in H^2_{\text{loc}}(B) \cap C^1(B)$ (actually $u^\varepsilon \in C^{2,\beta}(B)$ for a $\beta > 0$). Noting that our Assumptions (A1) and (A2) are equivalent to (1.2)–(1.5) in [27], it follows that $u_\varepsilon \to u$ in $W^{1,q}(B)$ as $\varepsilon \to 0$. On the other hand, (2.6) can be restated as

$$(2.7)\ a^\epsilon\partial^2 u^\epsilon/\partial x^2 + 2b^\epsilon\partial^2 u^\epsilon/\partial x\partial y + c^\epsilon\partial^2 u^\epsilon/\partial y^2 = 0 \quad \text{in } B \quad \text{and} \quad u^\epsilon = u \quad \text{on } \partial B,$$

where $v \equiv (\epsilon + |\nabla u^\epsilon|^2)^{1/2}, v_1 \equiv \partial u^\epsilon/\partial x, v_2 \equiv \partial u^\epsilon/\partial y, a^\epsilon \equiv [1 + [\varphi'(v)v/\varphi(v)](v_1/v)^2]$, $b^\epsilon \equiv [\varphi'(v)v/\varphi(v)](v_1v_2/v^2)$, and $c^\epsilon \equiv [1 + [\varphi'(v)v/\varphi(v)](v_2/v)^2]$. Setting $d^\epsilon \equiv a^\epsilon c^\epsilon - (b^\epsilon)^2 \equiv 1 + [\varphi'(v)v/\varphi(v)][\{(v_1)^2 + (v_2)^2\}/v^2]$, we have from (2.1b) that

$$(2.8) \qquad \min\{1, q-1\} \le a^\epsilon, c^\epsilon, d^\epsilon \le \max\{1, q-1\} \quad \text{and} \quad |b^\epsilon| \le |q-2|;$$

that is, the equation is uniformly (with respect to ϵ) elliptic with bounded coefficients.

We now apply the inequality (17.20) in [15, p. 228]. For any $B'' \subset\subset B' \subset\subset B$ this yields that $|u^\epsilon|_{H^2(B'')} \le C\|u^\epsilon\|_{H^1(B')}$, where C is independent of ϵ. In [27] it has been shown that $|u^\epsilon| + |\nabla u^\epsilon|$ is bounded on B' as $\epsilon \to 0$ since $u \in C^0(\bar{B})$. This implies that $\|u^\epsilon\|_{H^2(B'')}$ is uniformly bounded. Hence $u \in H^2(B'')$ so that $u \in H^2_{\text{loc}}(\Omega)$, since u^ϵ will converge to u weakly in $H^2(B'')$ as $\epsilon \to 0$. Since the proof of the uniform boundedness of $|u^\epsilon| + |\nabla u^\epsilon|$ in [27] is quite complicated, we now give a simpler proof. Let $u_0 = \min_{x\in\partial B} u(x)$ and $u_1 = \max_{x\in\partial B} u(x)$. Note that u_0 and u_1 are constants so that one can apply Lemma 3 in [27] to (2.6). This shows that $u_0 \le u^\epsilon \le u_1$ for any $\epsilon > 0$. Then by applying Theorem 12.4 in [12] with $f = 0$ and the interpolation inequality (12.23)[(6.82)] in [12] one can see that $|u^\epsilon| + |\nabla u^\epsilon|$ is bounded on B' as $\epsilon \to 0$. Of course for $q > 2$, $\|u^\epsilon\|_{H^1(B)}$ is uniformly bounded since $\|u^\epsilon\|_{W^{1,q}(B)}$ is. Therefore, we have that $u \in H^2_{\text{loc}}(\Omega)$, which implies that $f \in [H^1_{\text{loc}}(\Omega)]^2$.

Let $f^\epsilon \equiv (v_1, -v_2)$. Adopting the same notation as in Theorem 1 in [22] we have from (2.8) that for all $z \in B$,

$$
\begin{aligned}
(2.9)\quad & \\
&\|Df^\epsilon(z)\|^2/Jf^\epsilon(z)\\
&\quad \equiv [(\partial v_1/\partial x)^2 + (\partial v_1/\partial y)^2 + 2(\partial v_1/y)^2](z)/[(\partial v_1/\partial y)^2 - (\partial v_1/\partial x)(\partial v_2/\partial y)](z)\\
&\quad \le [(a^\epsilon)^2 + 2(b^\epsilon)^2 + (c^\epsilon)^2](z)/[a^\epsilon c^\epsilon - (b^\epsilon)^2](z)\\
&\quad = [1 + (d^\epsilon)^2](z)/d^\epsilon(z) \le 2K,
\end{aligned}
$$

where $K = \max\{q-1, 1/(q-1)\}$. Hence f^ϵ is a K-quasi-regular mapping; see [13] and [22]. As $|u^\epsilon| + |\nabla u^\epsilon|$ is bounded on B' as $\epsilon \to 0$, we can apply the argument in Theorem 1 in [22] and let $\epsilon \to 0$ in the above to yield that f is K-quasi-regular with $K = \max\{q-1, 1/(q-1)\}$.

It follows immediately from the theory of quasi-regular maps, see [15], that $f \in [W^{1,2+\eta}_{\text{loc}}(\Omega)]^2$ for a $\eta > 0$ and $f^{-1}(0) \equiv \{z \in \Omega : \nabla u(z) = 0\}$ is discrete, provided that u is not identically constant.

The result (2.4) follows immediately from Assumption (A2), which in turn implies that G and F are well defined. Finally we note that if $|\nabla u(z)| > 0$, then (2.3) yields that

(2.10)
$$2\partial f(z)/\partial \bar{z} \equiv \Delta u(z) = -\Gamma(|\nabla u(z)|)[(u_x)^2 u_{xx} + 2u_x u_y u_{xy} + (u_y)^2 u_{yy}](z)/|\nabla u(z)|^2$$
$$= (2-p)G(|\nabla u(z)|)[(u_x)^2 u_{xx} + 2u_x u_y u_{xy} + (u_y)^2 u_{yy}](z)/|\nabla u(z)|^2.$$

In addition, if $|\nabla u(z)| > 0$, then $2\partial f/\partial z \equiv u_{xx} - u_{yy} - 2iu_{xy}$, and so

$$(2.11)\qquad \begin{aligned}&[(\bar{f}/f)(\partial f/\partial z) + (f/\bar{f})(\overline{\partial f/\partial z})](z)\\ &\equiv -\Delta u(z) + 2[(u_x)^2 u_{xx} + 2u_x u_y u_{xy} + (u_y)^2 u_{yy}](z)/|\nabla u(z)|^2.\end{aligned}$$

Combining (2.10), (2.11), and noting that $\{z \in \Omega : \nabla u(z) = 0\}$ is discrete yields the desired result (2.5). □

We note that in the case $\varphi(t) = t^{q-2}, q \in (1, \infty)$, it was first proved in [7] for $q > 2$ and then in [22] for $q > 1$ that the corresponding map f was quasi regular.

It follows from classical regularity theory that the solution u of (2.3), and the corresponding f, is C^∞ outside the set $\{z \in \Omega : \nabla u(z) = 0\}$ (see, for example, [12]). Therefore it is sufficiently general to examine the regularity of u (or f) near one of the zero points of f, which one may assume is the origin. From now on, we will assume that $0 \in \Omega$ and $f(0) = 0$.

We now consider the regularity of local solutions of (2.5). We generalize the approach for the p-Laplacian given in [13]. From the theory of quasi-regular mappings, see [16], and as $f(0) = 0$ with $0 \in \Omega$ is an isolated zero of f, there exists a quasi-conformal homeomorphism χ defined in a neighborhood of $z = 0$ and a positive integer n such that $\chi(0) = 0$ and

$$(2.12)\qquad f(z) \equiv [\chi(z)]^n.$$

From (2.5) and (2.12) we have that

$$\partial\chi/\partial\bar{z} = (1/p - \tfrac{1}{2})[(\bar{\chi}^n/\chi^n)(\partial\chi/\partial z) + (\chi/\bar{\chi})(\overline{\partial\chi/\partial z})]F(|\chi|^n).$$

Let $H(\xi)$ be the inverse of $\chi(z)$ in a neighborhood of $z = 0$. It follows that H is quasi-conformal in a neighborhood B of $\xi = 0$, and hence $H \in C(B) \cap H^1(B)$ and $H \in C^\infty(B - \{0\})$. Then we have that

$$(2.13)\qquad \partial H/\partial\bar{\xi} = (\tfrac{1}{2} - 1/p)[(\bar{\xi}^n/\xi^n)(\overline{\partial H/\partial\xi}) + (\xi/\bar{\xi})(\partial H/\partial\xi)]F(|\xi|^n).$$

Let $\xi = re^{i\theta}$ and $H(r, \theta) \equiv H(re^{i\theta})$. Proceeding as in [13] one obtains that

$$(2.14)\qquad 2rH_r = -i(2 + (p-2)G(r^n))H_\theta + i(p-2)G(r^n)e^{-2in\theta}\overline{H_\theta}.$$

Expanding $H(r, \theta)$ into Fourier series with respect to θ, $0 \le \theta < 2\pi$,

$$(2.15)\qquad H(r, \theta) \equiv \sum_{k=-\infty}^{\infty} h_k(r)e^{i(k-n)\theta},$$

where $h_k \in C[0, \delta] \cap C^\infty(0, \delta]$ for $\delta > 0$. It follows from (2.14) and (2.15) that for all integers k,

$$(2.16a)\qquad 2rh_k'(r) = -(n-k)(2 + (p-2)G(r^n))h_k(r) - (n+k)(p-2)G(r^n)\overline{h_{-k}(r)}$$

and

$$(2.16\text{b}) \quad 2r\overline{h'_{-k}(r)} = -(n+k)(2+(p-2)G(r^n))\overline{h_{-k}(r)} - (n-k)(p-2)G(r^n)h_k(r).$$

Setting $X_k(r) \equiv (h_k(r), \overline{h_{-k}(r)})^T$, this system of equations can be restated as follows: Let n be a positive integer and $p \in (1,2) \cup (2,\infty)$. Then for any integer k find $X_k(r)$ such that

$$(2.17\text{a}) \qquad 2rX'_k(r) = -[A(k) + \hat{g}(r)B(k)]X_k(r),$$

where

(2.17b)

$$A(k) \equiv \begin{pmatrix} (n-k)p & (n+k)(p-2) \\ (n-k)(p-2) & (n+k)p \end{pmatrix}, \qquad B(k) \equiv \begin{pmatrix} (n-k) & (n+k) \\ (n-k) & (n+k) \end{pmatrix},$$

and

$$(2.17\text{c}) \qquad \hat{g}(r) \equiv (p-2)(G(r^n)-1).$$

The advantage of this reformulation is that the structure of the general solutions for the system $2rW'_k(r) = -A(k)W_k(r)$ is easily established when $k \neq -n$ and the function $\hat{g}(r)B(k)/r$ is regular.

Therefore, to study the regularity of local solutions of (2.5) we need to study the structure of the general solutions about $r = 0$ to the system (2.17). This we do in the next section.

3. Series expansion for $H(\xi)$. We will analyze the system (2.17) by developing a series solution about $r = 0$. In fact, we analyze a more general system: (2.17a, b) with $\hat{g}(r)$ being any real analytical function at $r = 0$ satisfying $\hat{g}(0) = 0$, instead of the specific choice (2.17c). First, we need a lemma.

LEMMA 3.1. *Let m be a positive integer and let $M \in R$ be such that $M \geq 1 + 2^m$. Then for any integer $k \in [0, m]$ and any integer $i \geq 1$,*

$$(3.1) \qquad \sum_{j=0}^{i-1} (i-j)^k M^j \leq M^i.$$

Proof. Simple calculations yield that (3.1) is true for (i) $k = 0$ for any integer $i \geq 1$, and (ii) $i = 1$ for any integer $k \in [0, m]$. Now assume (3.1) holds for all $k \in [0, \hat{m}]$ and any integer $i \geq 1$ with $0 \leq \hat{m} < m$. Suppose that for $k = \hat{m}+1$ it is also true for any integer $i \in [1, \hat{\imath}]$ with $\hat{\imath} \geq 1$. Then we have that

$$\begin{aligned} \sum_{j=0}^{\hat{\imath}} (\hat{\imath}+1-j)^{\hat{m}+1} M^j &= (\hat{m}+1)! \sum_{j=0}^{\hat{\imath}} M^j \sum_{k=0}^{\hat{m}+1} (\hat{\imath}-j)^k \Big/ [k!(\hat{m}+1-k)!] \\ &= M^{\hat{\imath}} + \sum_{k=0}^{\hat{m}+1} \{(\hat{m}+1)!/[k!(\hat{m}+1-k)!]\} \sum_{j=0}^{\hat{\imath}-1} (\hat{\imath}-j)^k M^j \\ &\leq \left[1 + \sum_{k=0}^{\hat{m}+1} \{(\hat{m}+1)!/[k!(\hat{m}+1-k)!]\}\right] M^{\hat{\imath}} \\ &\leq (1+2^{\hat{m}+1})M^{\hat{\imath}} \leq (1+2^m)M^{\hat{\imath}} \leq M^{\hat{\imath}+1}. \end{aligned}$$

Therefore, (3.1) also holds for $k = \hat{m}+1$ and $i = \hat{i}+1$. Hence by induction (3.1) holds for any integer $k \in [0, m]$ and any integer $i \geq 1$. □

THEOREM 3.1. *Let $p \in (1,2) \cup (2,\infty)$ and n be a positive integer. Suppose that $\hat{g}(r) \equiv \sum_{i=1}^{\infty} g_i r^i$ near $r = 0$ and that there exist $\mathcal{G} \in R^+$ and a positive integer m such that $|g_i| \leq \mathcal{G} i^m$ for all $i \geq 1$. Then for any integer k, except $k = -n$, the general solution $X_k(r)$ of* (2.17 a, b) *near $r = 0$ is of the form*

$$X_k(r) \equiv C_k^+ r^{\lambda_k^+} X_k^+(r) + C_k^- r^{\lambda_k^-}[X_k^-(r) + cr^{\rho_k}\ln(r)X_k^+(r)], \tag{3.2a}$$

where $C_k^{\pm}$ are general constants,

$$\lambda_k^{\pm} \equiv \{-pn \pm [4k^2(p-1) + n^2(p-2)^2]^{1/2}\}/2, \tag{3.2b}$$

$$\rho_k \equiv (\lambda_k^+ - \lambda_k^-) \equiv [4k^2(p-1) + n^2(p-2)^2]^{1/2}, \tag{3.2c}$$

$$\epsilon_k^{\pm} \equiv [(n-k)p + 2\lambda_k^{\pm}]/[(n+k)(2-p)]. \tag{3.2d}$$

The constant c is zero if ρ_k is not an integer, but possibly nonzero otherwise,

$$X_k^{\pm}(r) \equiv \begin{pmatrix} \hat{a}_k^{\pm}(r) + \hat{b}_k^{\pm}(r) \\ \epsilon_k^+ \hat{a}_k^{\pm}(r) + \epsilon_k^- \hat{b}_k^{\pm}(r) \end{pmatrix}, \tag{3.2e}$$

where $\hat{a}_k^{\pm}(0) + \hat{b}_k^{\pm}(0) = 1$ and

$$\hat{a}_k^{\pm}(r) \equiv \sum_{i=0}^{\infty} a_i^{\pm}(k) r^i, \qquad \hat{b}_k^{\pm}(r) \equiv \sum_{i=0}^{\infty} b_i^{\pm}(k) r^i. \tag{3.2f}$$

In addition there exist constants $C(k)$ and $M \geq 1 + 2^m$, dependent on p and n such that $|a_i^{\pm}(k)|, |b_i^{\pm}(k)| \leq C(k) M^i$ for all $i \geq 0$.

Proof. Let $\mathcal{X}(r)$ be a fundamental solution to the system $2rW_k'(r) = -A(k)W_k(r)$ when $k \neq n$; that is,

$$\mathcal{X}_k(r) \equiv \begin{pmatrix} r^{\lambda_k^+} & r^{\lambda_k^-} \\ \epsilon_k^+ r^{\lambda_k^+} & \epsilon_k^- r^{\lambda_k^-} \end{pmatrix},$$

where $\lambda_k^{\pm}$ are the eigenvalues of $-A(k)/2$ and $(1, \epsilon_k^{\pm})^T$ the corresponding eigenvectors; see (3.2b, d). We now seek two linearly independent solutions of (2.17a, b) of the form $\mathcal{X}_k(r)Y_k(r)$. Inserting $\mathcal{X}_k(r)Y_k(r)$ into (2.17a) one obtains

$$2rY_k'(r) = -\hat{g}(r)\mathcal{X}_k^{-1}(r)B(k)\mathcal{X}_k(r)Y_k(r)$$

and hence

$$Y_k'(r) = [\hat{g}(r)/r]D_k(r)Y_k(r), \tag{3.3}$$

where

$$D_k(r) \equiv \begin{pmatrix} d_1(k) & d_2(k)r^{-\rho_k} \\ d_3(k)r^{\rho_k} & d_4(k) \end{pmatrix}$$

$$\equiv (\epsilon_k^- - \epsilon_k^+)^{-1} \begin{pmatrix} (\epsilon_k^- - 1)\tau_k^+ & (\epsilon_k^- - 1)\tau_k^- r^{-\rho_k} \\ (1-\epsilon_k^+)\tau_k^+ r^{\rho_k} & (1-\epsilon_k^+)\tau_k^- \end{pmatrix}$$

with

$$\tau_k^\pm \equiv (n-k) + \epsilon_k^\pm(n+k).$$

It follows that there exists a $\mathcal{D} > 1$, independent of p, n, and k, such that

$$|d_j(k)| \le \mathcal{D}(|k|+n), \qquad j = 1 \to 4. \tag{3.4}$$

From our assumptions we have that $\hat{g}(r)/r \equiv \sum_{i=0}^{\infty} g_{i+1}r^i$. We now look for two linearly independent solutions $Y_k^\pm$ to (3.3) of the form

$$Y_k^\pm(r) \equiv \begin{pmatrix} r^{\alpha_k^\pm}\, \hat{a}_k^\pm(r) \\ r^{\beta_k^\pm}\, \hat{b}_k^\pm(r) \end{pmatrix} \equiv \begin{pmatrix} \sum\limits_{i=0}^{\infty} a_i^\pm(k) r^{\alpha_k^\pm + i} \\ \sum\limits_{i=0}^{\infty} b_i^\pm(k) r^{\beta_k^\pm + i} \end{pmatrix}. \tag{3.5}$$

Inserting (3.5) into (3.3) and equating coefficients one obtains the following linearly independent solutions:

$Y_k^+(r)$ by choosing $\alpha_k^+ \equiv 0, \beta_k^+ \equiv \rho_k, a_0^+(k) \equiv 1, b_0^+(k) \equiv 0$ and for $i \ge 0$,

$$\text{(3.6a)} \qquad \begin{aligned} a_{i+1}^+(k) &\equiv \left[\sum_{j=0}^{i} g_{i+1-j}(d_1(k)a_j^+(k) + d_2(k)b_j^+(k))\right] \Big/ (i+1), \\ b_{i+1}^+(k) &\equiv \left[\sum_{j=0}^{i} g_{i+1-j}(d_3(k)a_j^+(k) + d_4(k)b_j^+(k))\right] \Big/ (i+1+\rho_k); \end{aligned}$$

if ρ_k is not an integer:

$Y_k^-(r)$ by choosing $\alpha_k^- \equiv -\rho_k$, $\beta_k^- \equiv 0$, $a_0^-(k) \equiv 0$, $b_0^-(k) \equiv 1$ and for $i \ge 0$,

$$\text{(3.6b} \qquad \begin{aligned} a_{i+1}^-(k) &\equiv \left[\sum_{j=0}^{i} g_{i+1-j}(d_1(k)a_j^-(k) + d_2(k)b_j^-(k))\right] \Big/ (i+1-\rho_k), \\ b_{i+1}^-(k) &\equiv \left[\sum_{j=0}^{i} g_{i+1-j}(d_3(k)a_j^-(k) + d_4(k)b_j^-(k))\right] \Big/ (i+1). \end{aligned}$$

Then we obtain two linearly independent solutions $r^{\lambda_k^+}X_k^+(r)$ and $r^{\lambda_k^-}X_k^-(r)$ to (2.17a, b), where $r^{\lambda_k^\pm}X_k^\pm(r) \equiv \mathcal{X}_k(r)Y_k^\pm(r)$. Hence the general solution is given by (3.2a) with $c = 0$ and $X_k^{\pm}(r)$ defined by (3.2e) with $\hat{a}_k^{\pm}(0) + \hat{b}_k^{\pm}(0) \equiv 1$. Furthermore, if $C(k)$ and M are such that $M \geq 1 + 2^m$ and $|a_i^{\pm}(k)|$, $|b_i^{\pm}(k)| \leq C(k)M^i$ for all $i < 2\mathcal{G}\mathcal{D}(|k| + n) + \rho_k$ it follows from (3.6), (3.5), and Lemma 3.1 that $|a_i^{\pm}(k)|$, $|b_i^{\pm}(k)| \leq C(k)M^i$ for all $i \leq 0$.

If ρ_k is an integer, say $l \geq 1$, then the solution (3.6b) is no longer valid. Taking $Y_k^{+}(r)$ as in (3.6a) to be one solution to (3.3), a routine calculation yields that a second solution, linearly independent to $Y_k^{+}(r)$, is $Y_k^{-}(r) + c\ln(r)Y_k^{+}(r)$, where

$$c \equiv \sum_{j=0}^{l-1} g_{l-j}(d_1(k)a_j^{+}(k) + d_2(k)b_j^{+}(k))$$

and $Y_k^{-}(r)$ is given by (3.5) with $\alpha_k^{-} \equiv -\rho_k \equiv -l$, $\beta_k^{-} \equiv 0$, $a_0^{-}(k) \equiv 0$, $b_0^{-}(k) \equiv 1$. For $i = 0 \rightarrow l-2$, $a_{i+1}^{-}(k)$ is defined by (3.6b), $a_{l-1}^{-}(k) \equiv 0$, for $i = 0 \rightarrow l-1$, $b_{i+1}^{-}(k)$ is defined by (3.6b), and finally for $i \geq l$,

(3.7)
$$\begin{aligned} a_{i+1}^{-}(k) &\equiv \left[-ca_{i+1-l}^{+}(k) + \sum_{j=0}^{i} g_{i+1-j}(d_1(k)a_j^{-}(k) + d_2(k)b_j^{-}(k)) \right] \Big/ (i+1-l), \\ b_{i+1}^{-}(k) &\equiv \left[-cb_{i+1-l}^{+}(k) + \sum_{j=0}^{i} g_{i+1-j}(d_3(k)a_j^{-}(k) + d_4(k)b_j^{-}(k)) \right] \Big/ (i+1). \end{aligned}$$

We obtain two linearly independent solutions $r^{\lambda_k^{+}}X_k^{+}(r)$ and $r^{\lambda_k^{-}}[X_k^{-}(r) + cr^{\rho_k} \ln(r)X_k^{+}(r)]$ to (2.17 a, b) with c possibly nonzero, by setting $r^{\lambda_k^{\pm}}X_k^{\pm}(r) \equiv \mathcal{X}_k(r)Y_k^{\pm}(r)$. It follows that $X_k^{\pm}(r)$ are given by (3.2e) with $\hat{a}_k^{\pm}(0) + \hat{b}_k^{\pm}(0) \equiv 1$. Similarly to the above we can choose constants $C(k)$ and $M \geq 1 + 2^m$, dependent on p and n, such that $|a_i^{\pm}(k)|$, $|b_i^{\pm}(k)| \leq C(k)M^i$ for all $i \geq 0$. □

With the help of Lemma 3.1 and the following corollary to Theorem 3.1 we will establish our main regularity result for (2.3) in the next section.

COROLLARY 3.1. *Let $p \in (1,2) \cup (2,\infty)$ and n be a positive integer. Suppose that $\hat{g}(r) \equiv \sum_{i=1}^{\infty} g_i r^i$ near $r = 0$ and that $|g_i| \leq \eta^i$ for all $i \geq 1$, where $\eta \leq 1$. Then for any integer k, except $k = -n$, the general solution $X_k(r)$ of* (2.17 a, b) *near $r = 0$ is of the form* (3.2). *In addition for $k \geq n$ and for $\eta \leq 1/(8\mathcal{D})$ we have that*

(3.8a)
$$|a_i^{+}(k)|, |b_i^{+}(k)| \leq (8\mathcal{D}\eta k)^i/i!, \qquad i = 0 \rightarrow k,$$

(3.8b)
$$|a_i^{+}(k)|, |b_i^{+}(k)| \geq (8\mathcal{D}\eta k)^k/k!, \qquad i \geq k,$$

where $\mathcal{D} > 1$ is the constant, independent of p, n, and k, appearing in (3.4).

Proof. Clearly Theorem 3.1 applies with the given assumptions on $\hat{g}$. Let $M \equiv 8\mathcal{D}\eta k$. Firstly, we note that for any integer $j \in [1,k]$,

(3.9)
$$I_j \equiv \sum_{i=0}^{j-1} \eta^{j-i}M^i/i! \leq M^j/j!.$$

Equation (3.9) holds for $j = 1$ as $\eta \leq 1$. Assume it is true for $1 \leq j \leq l < k$, then $I_{l+1} \equiv \eta(I_l + M^l/l!) \leq 2\eta M^l/l! \leq M^{l+1}/(l+1)!$. Hence, by induction (3.9) holds for $1 \leq j \leq k$.

We now show that the improved bounds on the coefficients, (3.8), hold. (3.8a) holds for $i = 0$. Assume it is true for $0 \leq i \leq l < k$; then from (3.6a), (3.4), and (3.9) we have that

$$|a_{l+1}^{+}(k)|, |b_{l+1}^{+}(k)| \leq 4\mathcal{D}k \left[\sum_{j=0}^{l} \eta^{l+1-j} M^j / j! \right] \Big/ (l+1)$$

$$\leq M \left[I_{l-1} + M^l/1! \right] / \, 2(l+1) \leq M^{l+1}/(l+1)!.$$

Hence, by induction (3.8a) holds. Inequality (3.8b) holds for $i = k$. Assume it is true for $k \leq i \leq l$. Then as $M \leq k$ we have from (3.6a), (3.4), (3.9), and (3.8a) that

$$|a_{l+1}^{+}(k)|, |b_{l+1}^{+}(k)| \leq [8\mathcal{D}\eta k/(l+1)] \left[\sum_{j=0}^{k-1} \eta^{l-j} M^j/j! + M^k/k! \sum_{j=k}^{l} \eta^{l-j} \right] \Big/ 2$$

$$\leq \left[\eta^{l-k} + \sum_{j=0}^{l-k} \eta^j \right] (M^k/k!)/2 \leq (M^k/k!).$$

Hence, by induction (3.8b) holds. □

4. The main regularity result.

THEOREM 4.1. *Let $u \in W_{\text{loc}}^{1,q}(\Omega)$, $1 < q < \infty$, be a local weak solution of* (2.3) *with φ satisfying* (A1)–(A3). *Then*

$$u \in C^{k,\beta}(\Omega) \cap W_{\text{loc}}^{k+2,v}(\Omega), \tag{4.1}$$

where the integer $k \geq 1$ and exponents $\beta \in (0,1]$ and $v \in [1,2]$ are determined uniquely from

$$\begin{aligned} &6(k+\beta) = 7 + 1/(p-1) + [1 + 14/(p-1) + 1/(p-1)^2]^{1/2} \\ &\text{and} \quad 1 \leq v < 2/(2-\beta), \end{aligned} \tag{4.2}$$

where $p \equiv 2 + \Gamma(0)$.

Proof. Let $\hat{g}$ be defined as in (2.17c). From the definition of G in Lemma 2.1, Assumption (A3), and Remark 2.1 we can assume that $\hat{g}(r) \equiv \sum_{i=1}^{\infty} g_i r^i$ near $r = 0$ with $|g_i| \leq \eta^i$ for all $i \geq 1$ with $\eta > 0$ as small as we please. Hence we can apply Corollary 3.1 to the system (2.17), yielding that the general solution has the form (3.2a) about $r = 0$ if $k \neq -n$. We note that in this case one can obtain $X_{-n}(r)$ directly from $X_n(r)$. For all integers k the constant C_k^- in (3.2a) must be set equal to zero since $\lambda_k^- < 0$, $\hat{a}_k^{\pm}(0) + \hat{b}_k^{\pm}(0) \equiv 1$ and we know that $X_k \in C[0,\delta]^2$; see (2.15) and (2.17). For the same reason $C_k^+ \equiv 0$ when $|k| < n$ since $\lambda_k^+ < 0$. In addition, as $H(0) = 0$, $\lambda_n^+ = 0$, $\hat{a}_n^+(0) = 1$, and $\hat{b}_n^+(0) = 0$ it follows that $C_n^+ = 0$. Therefore we have from (3.6) and (2.17) that

$$\begin{aligned} H(r,\theta) &\equiv \sum_{k\geq|n+1|} C_k^+ r^{\lambda_k^+}(\hat{a}_k^+(r)+\hat{b}_k^+(r))e^{i(k-n)\theta} \\ &\equiv \sum_{k=n+1}^{\infty}\Big[\Big(C_k^+e^{ik\theta}+\varepsilon_k^+\overline{C_k^+}e^{-ik\theta}\Big)\hat{a}_k^+(r) \\ &\qquad +(C_k^+e^{ik\theta}+\varepsilon_k^-\overline{C_k^+}e^{-ik\theta})\hat{b}_k^+(r)\Big]r^{\lambda_k^+}e^{-in\theta} \end{aligned} \tag{4.3a}$$

or equivalently,

$$\begin{aligned} H(\xi) \equiv \sum_{k=n+1}^{\infty}&\Big[\Big(C_k^+\xi^k+\varepsilon_k^+\overline{C_k^+}\bar{\xi}^k\Big)\hat{a}_k^+(|\xi|) \\ &+\Big(C_k^+\xi^k+\varepsilon_k^-\overline{C_k^+}\bar{\xi}^k\Big)\hat{b}_k^+(|\xi|)\Big]|\xi|^{\lambda_k^++n-k}\xi^{-n}. \end{aligned} \tag{4.3b}$$

Since $H\in L^2(B)$ we have from (4.3) that for R sufficiently small,

$$\begin{aligned} &\int_0^R r\int_0^{2\pi}|H(r,\theta)|^2 d\theta dr \\ &\equiv 2\pi\sum_{k=n+1}^{\infty}|C_k^+|^2\int_0^R r^{2\lambda_k^++1}[(\hat{a}_k^+(r)+\hat{b}_k^+(r))^2 \\ &+(\varepsilon_k^+\hat{a}_k^+(r)+\varepsilon_k^-\hat{b}_k^+(r))^2]dr<\infty. \end{aligned} \tag{4.4}$$

In the analysis that follows M_i denotes a constant dependent only on $R<1$ and p. We set $\sigma_i\equiv a_i^+(k)+b_i^+(k)$, $t=1/r$ and note from (3.2b) that $\lambda_k^+\leq k(p-1)^{1/2}$. In addition we note that the L^1 norm over an interval of length 2 of a polynomial of degree k with leading coefficient 1 is bounded below by 2^{1-k}; see, for example, p. 80 in [25]. Then for $k\geq n+1$ we have from (3.8) that

$$\begin{aligned} &R\left[\int_0^R r^{2l_k^++1}[\hat{a}_k^+(r)+\hat{b}_k^+(r)]^2dr\right]^{1/2} \\ &\geq\int_0^R r^{\lambda_k^++1}|\hat{a}_k^+(r)+\hat{b}_k^+(r)|dr \\ &\geq\int_0^R r^{\lambda_k^++1}\left[\left|\sum_{i=0}^{k}\sigma_i r^i\right|-2[(8\mathcal{D}\eta k)^k/k!]\sum_{i=k+1}^{\infty}{}' r^i\right]dr \\ &\geq\int_{1/R}^{\infty}t^{-(\lambda_k^++k+3)}\left|\sum_{i=0}^{k}\sigma_i t^{k-i}\right|dt-(M_1\eta k)^k/k! \end{aligned} \tag{4.5}$$

$$\geq M_2^k \int_{1/R}^{(2R+1)/R} \left| \sum_{i=0}^{k} \sigma_i t^{k-i} \right| dt - (M_1 \eta k)^k / k!$$

$$\geq M_3^k - (M_1 \eta k)^k / k! \geq M_3^k - (M_1 \eta e)^k,$$

since $\sigma_1 \equiv 1$ and $(k/e)^k/k! \leq e^{-1}$. Combining (4.4) and (4.5) we have that by choosing η sufficiently small there exists an M, dependent only on R and p, such that

$$|C_k^+| \leq M^k \quad \text{for all } k \geq n+1. \tag{4.6}$$

Let δ be such that δ, $Me\delta^{(p-1)^{1/2}} \in (0, R)$. As $\lambda_k^+ \geq k(p-1)^{1/2} - pn/2$ we have that $\sum_{k=n+1}^{\infty} (Me)^k \delta^{\lambda_k^+} < \infty$. It then follows from (4.3b), (4.6), (3.2d), and (3.8) that for $|\xi| \leq \delta$,

$$\begin{aligned} |H(\xi)| &\leq \sum_{k=n+1}^{\infty} |C_k^+| \left[(1 + |\varepsilon_k^+|)|\hat{a}_k^+(|\xi|)| + (1 + |\varepsilon_k^-|)|\hat{b}_k^+(|\xi|)| \right] |\xi|^{\lambda_k^+} \\ &\leq C(|\xi|/\delta)^{\lambda_{n+1}^+} \sum_{k=n+1}^{\infty} [|\hat{a}_k^+(|\xi|)| + |\hat{b}_k^+(|\xi|)|] M^k \delta^{\lambda_k^+} \\ &\leq C|\xi|^{\lambda_{n+1}^+} \sum_{k=n+1}^{\infty} (Me)^k \delta^{\lambda_k^+} \leq C|\xi|^{\lambda_{n+1}^+}. \end{aligned} \tag{4.7}$$

Therefore the upper bound of (41) in [13] holds. In addition, we see from (4.7) that the series (4.3b) is uniformly and absolutely convergent for $|\xi| \leq \delta$.

As H is a one-to-one mapping near $\xi = 0$ it follows that $|C_{n+1}^+| \neq 0$. Noting from (3.2d) that $|\varepsilon_{n+1}^+| < 1$, it follows from (4.3b), (4.7), and (3.8) that there exist positive constants M_i such that for $|\xi|$ sufficiently small,

$$\begin{aligned} |H(\xi)| &\geq |C_{n+1}^+||\xi|^{\lambda_{n+1}^+} \left[M_1 |\hat{a}_{n+1}^+(|\xi|)| - M_2 |\hat{b}_{n+1}^+(|\xi|)| \right] - M_3 |\xi|^{\lambda_{n+2}^+} \\ &\geq |C_{n+1}^+| M_1 |\xi|^{\lambda_{n+1}^+} \left[1 - M_4|\xi| - M_5 |\xi|^{\lambda_{n+2}^+ - \lambda_{n+1}^+} \right] \geq |C_{n+1}^+| M_6 |\xi|^{\lambda_{n+1}^+}. \end{aligned}$$

Hence, the lower bound of (41) in [13] holds. Similarly, one can prove that the bounds (42) and (43) in [13] hold. The remainder of the proof of (4.1) is then identical to that in [13]; that is, apply Lemmas 1 and 2 and Corollary 2 in [13]. □

Note that the conclusion of Theorem 4.1 is not necessarily true for (1.1) for $\rho \neq 0$ (even if ρ is a constant); see [29].

Example 4.1. For the examples considered in Example 2.1 we have with $q > 1$ that the local weak solutions of (2.3) are such that (4.1) and (4.2) hold with $p \equiv 2 + \Gamma(0)$ given as follows: (i) $\varphi(t) \equiv t^{q-2} \Rightarrow p = q$; (ii) $\varphi(t) \equiv [t(1+t)]^{(q-2)/2} \Rightarrow p = (q+2)/2$; and (iii) $\varphi(t) \equiv [t(1+t^2)]^{(q-2)/3} \Rightarrow p = (q+4)/3$. Therefore we see that the solutions of (2.3) with φ defined by (ii) and (iii) are as regular as those of (2.3) with $\varphi(t) \equiv t^{p-2}$, which is nothing other than the singular part of φ in (ii) and (iii). In other words, it is the singular part of φ that determines the regularity of the local solutions of (2.3).

5. A global regularity result. As mentioned in §1, in order to obtain explicit error bounds for the finite element approximation of (2.3) it is necessary to extend the local regularity results obtained in the last section into global results. Apart from those global $C^{1,\alpha}$ and H^2 results mentioned in the introduction, there appear to be no other global results in the literature. We derive in this section a global regularity result from Theorem 4.1 under some restrictions on the boundary data.

Consider the following mechanics problem. Suppose a plane Ω, which is made of a power law material, is undergoing longitudinal shear (the mode III problem; see [3]). In this case the only nonvanishing component of displacement is the z-component $u(x,y)$, which satisfies (2.3) with $\varphi(t) \equiv t^{p-2}$ and $p \in (1,2)$. Physically one expects that the tangential strain of the plane along $\partial\Omega$ will vary strictly monotonically except at those points where the displacement $u(x,y)$ achieves its extreme values. Motivated by this observation we will suppose that (2.3) is supplemented by the boundary condition

$$u|_{\partial\Omega} = g|_{\partial\Omega}, \tag{5.1}$$

where g has a nonvanishing tangential derivative, g_τ, on $\partial\Omega$ except at those points where g achieves its global extrema on $\partial\Omega$. We have the following result.

THEOREM 5.1. *Let φ satisfy* (A1) *with $C^\infty(0,\infty)$ replaced by $C^{1,1}(0,\infty)$,* (A2) *and* (A3) *with $p \equiv 2 + \Gamma(0) \in (1,2)$. Let $\partial\Omega \in C^{2,1}$ and $g \in C^1(\bar{\Omega})$ be such that $|g_\tau(x,y)| > 0$ if $(x,y) \in \partial\Omega$ and $g(x,y)$ is not a global extremum of g on $\partial\Omega$. Let $u \in W^{1,q}(\Omega)$ be the unique solution of* (2.3) *with the boundary condition* (5.1). *Then*

$$\text{(i)} \qquad g \in C^{2,\gamma}(\bar{\Omega}), \qquad \gamma > 0, \Rightarrow u \in C^{2,\mu}(\bar{\Omega}),$$

$$\text{(ii)} \qquad g \in C^{2,\gamma}(\bar{\Omega}) \cap W^{3,r}(\Omega), \qquad \gamma > 0 \text{ and } r \in (1,p], \Rightarrow u \in C^{2,\mu}(\bar{\Omega}) \cap W^{3,r}(\Omega),$$

where $\mu = \gamma$ for $p \in (1,1.3), \mu = \min(\gamma,\beta)$ for $p \in [1.3,2)$, and

$$\beta = \{-5 + 1/(p-1) + [1 + 14/(p-1) + 1/(p-1)^2]^{1/2}\}/6. \tag{5.2}$$

Proof. From [19] we have that $g \in C^{1,\alpha}(\bar{\Omega}) \Rightarrow u \in C^{1,\alpha}(\bar{\Omega})$ for some $\alpha > 0$, so that $|\nabla u|$ is continuous on $\bar{\Omega}$. We first show that $|\nabla u|_{\partial\Omega}| \geq \delta > 0$. If $(x,y) \in \partial\Omega$ and $g_\tau(x,y) \neq 0$, then $|\nabla u(x,y)| > 0$ as $(u-g)|_{\partial\Omega} = 0$. Let $g_\tau(x_0,y_0) = 0$ and (without loss of generality) let $g(x,y) \geq g(x_0,y_0)$ for all $(x,y) \in \partial\Omega$. Let $u_0 \equiv g(x_0,y_0)$. Then $u - u_0$ is such that $\nabla.(\varphi(|\nabla(u-u_0)|)\nabla(u-u_0)) \equiv \nabla.(\varphi(|\nabla u|)\nabla u) = 0$ in Ω and $(u-u_0)_{\partial\Omega} \geq 0$ because u_0 is a constant. If u is constant, then the desired regularity result holds. Therefore we can assume that u is not constant. From the strong maximum principle in §3 of [28], it follows that $u > u_0$ in Ω. (This result also holds from the proof of the strong comparison principle in [22].) From the Hopf maximum principle, see [28] and Lemma 3.4 in [12], we have that $|\partial u/\partial n(x_0,y_0)| > 0$, where $\underline{n}$ is the outward unit normal to $\partial\Omega$. Consequently, $|\nabla u|_{\partial\Omega}| > 0$ and from the continuity of $|\nabla u|$, there exists a domain $S \subset\subset \Omega$ such that $\partial S \in C^{2,1}$ and $|\nabla u|_{\bar{\Omega}\setminus S}| \geq \delta > 0$.

Let $S \subset\subset S_1 \subset\subset \Omega$. Then from Theorem 4.1 we have that

$$p \in (1, 1.3) \Rightarrow k \geq 3 \Rightarrow u \in C^3(\overline{S_1}), \tag{5.3a}$$

$$p \in [1.3, 2) \Rightarrow k = 2 \Rightarrow u \in C^{2,\beta}(\overline{S_1}) \cap W^{3,p}(S_1) \quad \text{with } \beta\text{given by (5.2).} \tag{5.3b}$$

Rewriting (2.3), we have for $Q \equiv \Omega \backslash S$ and $g \in C^{2,\gamma}(\bar{\Omega})$ that

$$\Delta u + \Gamma(|\nabla u|) \left[(u_x)^2 u_{xx} + 2u_x u_y u_{xy} + (u_y)^2 u_{yy}\right] / |\nabla u|^2 = 0 \quad \text{in } Q,$$

$$u|_{\partial Q} \in C^{2,\mu}(\partial Q).$$

As $\Gamma(t) \equiv [(\varphi(t)t)'/\phi(t)] - 1 \geq q - 2$, it follows from our assumptions that $\Gamma \in C^{0,1}(0, \infty)$ and hence the coefficients $\Gamma(|\nabla u|)(u_x)^2/|\nabla u|^2$, $\Gamma(|\nabla u|)(u_x u_y)/|\nabla u|^2$, and $\Gamma(|\nabla u|)(u_y)^2/|\nabla u|^2 \in C^{0,\alpha}(\bar{Q})$. It then follows from Theorem 9.19 in [12], for example, that $u \in C^{2,\sigma}(\bar{Q})$, $\sigma = \min(\alpha, \mu)$. This yields that the above coefficients then belong to $C^{0,1}(\bar{Q})$ and hence $u \in C^{2,\mu}(\bar{Q})$. Combining this with (5.3) yields that $u \in C^{2,\mu}(\bar{\Omega})$. If $g \in C^{2,\alpha}(\bar{\Omega}) \cap W^{3,r}(\Omega)$, $r \in (1, p]$ it follows in a similar manner that $u \in C^{2,\alpha}(\bar{\Omega}) \cap W^{3,r}(\Omega)$. □

It is of great interest to know if the conclusion of Theorem 5.1 is true or not for more general bounary conditions. Of course, it would be even better if Theorem 4.1 could be extended to a global result. Nevertheless, the above result shows that the global regularity on u required to guarantee the optimal rate of convergence in $W^{1,p}(\Omega)$ of the continuous piecewise linear finite element approximation of (2.3) does hold for suitable data. Another unsolved problem is extending the sharp local regularity results in [13] to higher dimensions.

GLOBAL OPTIMALITY CRITERION AND A DUALITY WITH A ZERO GAP IN NONCONVEX OPTIMIZATION[*]

PHAN THIEN THACH[†]

Abstract. This paper presents a relation between geometrical criteria for optimality and a duality in two nonconvex problems: a quasi-convex maximization over a convex set, and a general minimization over the complement of a convex set. A connection between the duality by Toland, the global optimality criterion by Hiriart-Urruty, and the author's result is also given. Several applications are presented.

Key words. geometrical criteria, nonconvex duality

AMS subject classifications. 49N15, 49J52, 90C26

1. Introduction.

Duality theories have provided important relationships in both analytical and algorithmic studies on optimization problems. Primal-dual pairs allow us to construct primal-dual algorithms whose efficiency and nice economic interpretation have attracted many researchers. There are several approaches used to obtain dual problems of a given mathematical program. For example, in convex duality theory we can find dual problems by either the Lagrangian functional approach or the perturbation functional approach. These approaches have a common starting point, the Kuhn–Tucker condition. A Kuhn–Tucker vector provides optimal Lagrange multipliers in the first approach and it is a minimizer of the conjugate of the perturbation functional in the second approach.

In convex programs local optimality criteria are also global. In nonconvex programs the local information such as subdifferentials and tangent cones are not enough to provide a global optimality criterion. However, by using the ε-subdifferentials Hiriart-Urruty has provided a global optimality criterion for a problem of minimizing the difference of two convex functions [5]. Since the minimization of the difference of two convex functions can be converted into a convex maximization over a convex set or a convex minimization over the complement of a convex set, a natural question is how to extend the optimality criterion to more general problems. In this paper we present geometrical criteria for global optimality in two problems: a quasi-convex maximization over a closed set and a general minimization over the complement of an open convex set. For constructing optimality criteria the separation theorem (or its variant) is a basic instrument. We say that criterion A is reducible to criterion B if we can obtain criterion B from criterion A by a transformation where the separation theorem is not used. Criterion A is equivalent to criterion B if A is reducible to B and B is reducible to A, i.e., in the proof for the equivalence we do not use the separation theorem. With this definition our geometrical criterion will be equivalent to the criterion in [5] if we consider a problem of minimizing the difference of two convex functions as a particular case of reverse convex constraint problems.

We also present a connection between the optimality criteria and a nonconvex duality. These criteria involve the polars of level sets of the objective functions, and there is a polarity correspondence between the level sets of the objective functions in

[*] Received by the editors October 10, 1991; accepted for publication (in revised form) March 8, 1993. The first manuscript of this paper was prepared when the author was visiting the Department of Mathematics, University of Trier as a fellow of the Alexander von Humboldt Foundation.

a primal-dual pair. By our approach we can obtain dual problems given in Toland [25], and Hiriart-Urruty [4].

The paper consists of six sections. In §2 we present geometrical criteria for global optimality in general nonconvex problems. In §3 we show a polarity correspondence between the level sets of a function and level sets of its quasi conjugate. In §4 we present a duality scheme. Several applications are given in §5. Finally we draw some conclusions in §6.

2. Geometrical criteria for global optimality in nonconvex problems.

Let X be a closed convex set in R^n. It is well known that a vector x does not belong to X if and only if there is a hyperplane strictly separating x and X. The direction "if" is straightforward, and the direction "only if" is a separation theorem. Now let X_1, X_2 be closed convex sets containing 0. Denote by X_1^0, X_2^0 the polars of X_1, X_2, respectively:

$$X_1^0 = \{v : \langle v, x\rangle \leq 1 \;\; \forall x \in X_1\}, \qquad X_2^0 = \{v : \langle v, x\rangle \leq 1 \;\; \forall x \in X_2\}.$$

From the definition of the polar sets it is straightforward that

$$X_1 \subseteq X_2 \Rightarrow X_2^0 \subseteq X_1^0.$$

Since X_1, X_2 are closed convex and contain zero, by the separation theorem we can prove that

$$(X_1^0)^0 = X_1, \qquad (X_2^0)^0 = X_2.$$

Therefore, we have the inverse direction:

$$X_2^0 \subseteq X_1^0 \Rightarrow X_1 \subseteq X_2.$$

Thus in the equivalent relation

$$X_1 \subseteq X_2 \Leftrightarrow X_2^0 \subseteq X_1^0, \tag{1}$$

the separation theorem plays a crucial role in the direction "$\Leftarrow$". Similarly by the strict separation we can prove (1) if X_1, X_2 are open convex sets containing 0. If X_1 and X_2 are neither closed nor open, then generally speaking we do not have (1) (more precisely, the direction "$\Leftarrow$" in (1)). This is quite reasonable, because we will lose the information of irregular points on the boundary of a convex set if we pass to its polar.

In this section we use relation (1) to interpret, in the dual space, the optimality for a solution of a primal problem. Throughout this paper the terms "normal cone," "polar set," "conjugate function," and others have the meanings as in Rockafellar [14].

We start from a very simple convex program

$$\max\{\langle c, x\rangle : x \in D\}, \tag{2}$$

where c is a nonzero vector in R^n, and D is a closed convex set in R^n such that $0 \in \text{int}D$. It is well known that a vector $x^* \in D$ is optimal if and only if c belongs to the normal cone of D at x^*:

$$c \in N(x^*, D). \tag{3}$$

This is equivalent to $(1/\langle c, x^*\rangle)c \in D^0$. Since $0 \in D^0$, this is equivalent to

$$\begin{aligned}&\left\{\frac{\lambda}{\langle c, x^*\rangle}c : 0 \leq \lambda \leq 1\right\} \subseteq D^0\\ \Leftrightarrow &\left\{\frac{\lambda}{\langle c, x^*\rangle}c : 0 \leq \lambda \leq 1\right\}^0 \supseteq D^{00}\\ \Leftrightarrow &\, D \subseteq \{x : \langle c, x\rangle \leq \langle c, x^*\rangle\}.\end{aligned}$$

Thus, criterion (3) can be interpreted as the use of the relation (1) to problem (2).

We consider now more general problems. The first type of nonconvex problems is

$$(4) \qquad \sup\{f(x) : x \in D\},$$

where f is a quasi-convex function, D is a closed subset such that $0 \in \mathrm{conv}D$ (conv$D$ stands as the convex hull of D). Since f is quasi-convex, the supremum value of f over D is equal to the supremum of f over conv$D$. However, in (4) we do not replace D by conv$D$, because in order to find an optimal solution (sometimes called briefly "solution") we do not need to handle the convex hull of D (see Example 4.1 in §4). By setting $\overline{f}(x) = \max\{f(x), f(0)\}$ we see that a maximizer of $\overline{f}$ on D is also a maximizer of f on D. Therefore, we can assume that

$$f(0) = \min\{f(x) : x \in R^n\}.$$

Using relation (1) we have the following geometrical criterion for the optimality in problem (4).

THEOREM 2.1. *Let $z \in D$. The condition*

$$(5) \qquad \{x : f(x) \leq f(z)\}^0 \subseteq D^0$$

is necessary for the optimality of z. If

$$(6) \qquad \sup\{f(x) : x \in D\} = \sup\{f(x) : x \in \mathrm{int}(\mathrm{conv}D)\},$$

then (5) *is sufficient for the optimality of z.*

Proof. If $z \in D$ is optimal, then $D \subseteq \{x : f(x) \leq f(z)\}$. By definition of the polar one has (5). Now suppose that (6) is satisfied and $z \in D$ is not optimal. Then there is vector x^* such that

$$x^* \in D \setminus \mathrm{cl}\{x : f(x) \leq f(z)\},$$

where cl stands as the closure. Since $0 \in \{x : f(x) \leq f(z)\}$, this implies that there is vector $y \in R^n$ such that

$$\langle y, x^*\rangle > 1 \geq \langle y, x\rangle \quad \forall x : f(x) \leq f(z).$$

The second inequality implies $y \in \{x : f(x) \leq f(z)\}^0$. However, $y \notin D^0$ because

$$\sup\{\langle y, x\rangle : x \in D\} \geq \langle y, x^*\rangle > 1.$$

Thus (5) is not satisfied. □

Criterion (5) is rather straightforward, but it can be used later to obtain a nonconvex duality. If f is lower semicontinuous (lsc) and $\mathrm{int}(\mathrm{conv}D) \neq \emptyset$, then we can check that condition (6) is satisfied. In general cases relation (5) is not sufficient for the optimality because optimal solutions could be irregular points on the boundary of a level set of the objective function. We shall say that problem (4) is *regular* if condition (6) is satisfied.

The second type of nonconvex problems under our consideration is

$$\inf\{f(x) : x \notin \operatorname{int} D\}, \tag{7}$$

where f is an arbitrary function and D is a closed convex set containing 0 in its interior.

THEOREM 2.2. *Let $z \notin \operatorname{int} D$. The following condition*

$$D^0 \subseteq \{x : f(x) < f(z)\}^0 \tag{8}$$

is necessary for the optimality of z. If

$$\inf\{f(x) : x \notin \operatorname{int} D\} = \inf\{f(x) : x \notin D\}, \tag{9}$$

then condition (8) *is sufficient for the optimality of z.*

Proof. Suppose that z is optimal to problem (7). Condition (8) follows immediately from $\{x : f(x) < f(z)\} \subseteq \operatorname{int} D \subseteq D$. Suppose now that $z \notin \operatorname{int} D$ is not optimal and condition (9) is satisfied. Then there is $u \notin D$ such that $f(z) > f(u)$. Since $u \notin D$ and D is closed and contains 0, there is a vector $v \in D^0$ such that $\langle u, v\rangle > 1$. Since $f(u) < f(z)$, this implies $v \notin \{x : f(x) < f(z)\}^0$. Therefore, $D^0 \not\subseteq \{x : f(x) < f(z)\}^0$. □

We shall say that problem (7) is regular if condition (9) is satisfied. It is easy to see that if f is upper semicontinuous (usc), then problem (7) is regular.

An important particular case of problem (7) is

$$\inf_{x \in R^n} \{h_0(x) - g_0(x)\}, \tag{10}$$

where $h_0(\cdot)$ is an extended real valued function and g_0 is finite convex function. Using the ε-subdifferentials Hiriart-Urruty [5] proved the following criterion for the optimality of a vector z:

$$\partial_\varepsilon g_0(z) \subseteq \partial_\varepsilon h_0(z) \quad \forall \varepsilon > 0. \tag{11}$$

We know that by an additional variable we can convert problem (10) into a minimization over the complement of a convex set. Therefore, it is natural to study the connection between criteria (8) and (11). In the sequel we prove that these criteria are equivalent for the same problem.

Set

$$h_1(x) = h_0(z + x) - h_0(z), \qquad g_1(x) = g_0(z + x) - g_0(z).$$

Problem (10) is converted into

$$\inf\{f(x, t) : (x, t) \notin \operatorname{int} D\}, \tag{12}$$

where

$$f(x, t) = h_1(x) - t, \qquad D = \{(x, t) : g_1(x) - t \leq 0\}.$$

Problem (12) is regular because

$$\inf\{h_1(x) - t : g_1(x) - t \geq 0\} = \inf\{h_1(x) - t : g_1(x) - t > 0\}.$$

Vector z is optimal to problem (10) if and only if vector $(0, g_1(0)) \in R^n \times R$ is optimal to problem (12). Since $f(0, g_1(0)) = 0$, criterion (8) at $(0, g_1(0))$ is

$$\{(x,t) : g_1(x) \leq t\}^0 \subseteq \{(x,t) : h_1(x) < t\}^0. \tag{13}$$

PROPOSITION 2.3. *Let h be an arbitrary function defined on R^n. For every $\alpha \in R$, one has*

$$\begin{aligned}&\{(x,t) : h(x) - t - \alpha < 0\}^0\\ &\quad = \{(x,t) : h(x) - t - \alpha \leq 0\}^0\\ &\quad = \{(y,\lambda) : \lambda < 0, h^*(-y/\lambda) + \alpha \leq -1/\lambda\} \cup \{(y,0) : y \in (\operatorname{dom} h)^0\}.\end{aligned}$$

Proof. By definition,

$$\begin{aligned}&(y,\lambda) \in \{(x,t) : h(x) - t - \alpha < 0\}^0\\ &\quad \Leftrightarrow \sup\{\langle y, x\rangle + \lambda.t : h(x) - t - \alpha < 0\} \leq 1\\ &\quad \Leftrightarrow s(y,\lambda) := \sup\{\langle y, x\rangle + \lambda.t : h(x) - t - \alpha \leq 0\} \leq 1\\ &\quad \Leftrightarrow (y,\lambda) \in \{(x,t) : h(x) - t - \alpha \leq 0\}^0.\end{aligned}$$

If $\lambda > 0$ then $s(y,\lambda) = +\infty$. If $\lambda = 0$, $y \notin (\operatorname{dom} h)^0$, then $s(y,\lambda) > 1$. If $\lambda = 0$, $y \in (\operatorname{dom} h)^0$, then $s(y,\lambda) \leq 1$. If $\lambda < 0$, then

$$\begin{aligned}s(y,\lambda) &= \sup_{x \in R^n}\{\langle y, z\rangle + \lambda.(h(x) - \alpha)\} \leq 1\\ &\Leftrightarrow \sup_{x \in R^n}\{\langle -y/\lambda, x\rangle - h(x) + \alpha\} \leq -1/\lambda\\ &\Leftrightarrow h^*(-y/\lambda) + \alpha \leq -1/\lambda.\end{aligned}$$

This completes the proof. □

From Proposition 2.3 one has

$$\{(x,t) : g_1(x) \leq t\}^0 = \{(y,\lambda) : \lambda < 0, g_1^*(-y/\lambda) \leq -1/\lambda\} \cup \{0\} \tag{14}$$

$$\begin{aligned}\{(x,t) : h_1(x) < t\}^0 = \{(y,\lambda) : \lambda < 0, h_1^*(-y/\lambda) \leq -1/\lambda\}\\ \cup\{(y,0) : y \in (\operatorname{dom} h)^0\}.\end{aligned} \tag{15}$$

From (14)–(15) it follows that criterion (13) is equivalent to

$$\begin{aligned}&\{y : g_1^*(0) \leq \varepsilon\} \subseteq \{y : h_1^*(0) \leq \varepsilon\} \quad \forall\varepsilon > 0\\ &\quad \Leftrightarrow \partial_\varepsilon g_1^*(0) \subseteq \partial_\varepsilon h_1^*(0) \quad \forall\varepsilon > 0\\ &\quad \Leftrightarrow \partial_\varepsilon g_0(z) \subseteq \partial_\varepsilon g_1(z) \quad \forall\varepsilon > 0.\end{aligned}$$

Thus, we arrive at criterion (11). Note that in the above arguments we do not use the separation theorem.

3. Quasi-conjugate functionals. We know that any function can be defined via its level sets. Let f be a function. If we denote

$$L(f, \leq, \alpha) = \{x : f(x) \leq \alpha\},$$
$$L(f, <, \alpha) = \{x : f(x) < \alpha\},$$

then f can be defined as follows:

$$\begin{aligned} f(x) &= \inf\{\alpha : x \in L(f, \leq, \alpha)\} \\ &= \sup\{\alpha : x \notin L(f, <, \alpha)\}. \end{aligned}$$

By condition (5) we see that $z \in D$ is optimal to problem (4) if

$$\{L(f, \leq, \alpha)\}^0 \subseteq D^0, \tag{16}$$

where $\alpha = f(z)$. Since $\{L(f, \leq, \alpha)\}^0$ and D^0 are closed, convex sets, if they have nonempty interiors, then (16) is equivalent to

$$\operatorname{int}\{L(f, \leq, \alpha)\}^0 \subseteq \operatorname{int} D^0. \tag{17}$$

If $\operatorname{int}\{L(f, \leq, \alpha)\}^0$ is a level set $L(g, <, \beta)$ of a function g, then (17) implies that

$$g(v) \geq \beta \quad \forall v \notin \operatorname{int} D^0. \tag{18}$$

Therefore, we see intuitively that the problem of finding the smallest level set $L(f, \leq, \alpha)$ containing D (in the primal space) can be interpreted as the problem of finding the biggest level set $L(g, <, \beta)$ contained in $\operatorname{int} D^0$ (in the dual space). In this section we prove that the relationship between f and g is nothing but the quasi conjugation presented in [19].

Now for a given function f we set

$$L_\alpha := (L(f, <, -\alpha))^0, \qquad U_\alpha := \operatorname{int}(L(f, \leq, -\alpha))^0.$$

L_α is closed, convex and U_α is open, convex. If $\alpha \leq \beta$, then $-\alpha \geq -\beta$; hence $L(f, \leq, -\beta) \subseteq L(f, \leq, -\alpha)$ and $L(f, <, -\beta) \subseteq L(f, <, -\alpha)$. This implies

$$L_\alpha \subseteq L_\beta, \qquad U_\alpha \subseteq U_\beta \quad (\alpha \leq \beta). \tag{19}$$

Define f^L and f^U as follows:

$$f^L(y) = \inf\{\alpha : y \in L_\alpha\},$$
$$f^U(y) = \sup\{\alpha : y \notin U_\alpha\}.$$

It is easy to check that

$$\{y : f^L(y) \leq \alpha\} = L_\alpha;$$
$$\{y : f^U(y) < \alpha\} = U_\alpha.$$

Since L_α is closed, convex and U_α is open, convex, function f^L is lsc, quasi-convex and function f^U is usc, quasi-convex. In the sequel, we give an analytical formula for f^L and f^U.

Denote by G^L the set of lsc functions $f : R^n \to R \cup \{\pm\infty\}$ such that $L(f, \leq, \alpha)$ is either a compact set or the whole space R^n, by Q^L the set of functions $f \in G^L$ such that $f(0) = \inf\{f(x) : x \in R^n\}$. The property "$L(f, \leq, \alpha)$ is either a bounded set or the whole space R^n" is equivalent to

$$f(x) \to \sup\{f(x) : x \in R^n\} \quad \text{as} \quad \| x \| \to \infty.$$

Denote by Q^U the set of usc functions $f : R^n \to R \cup \{\pm\infty\}$ such that $f(0) = \inf\{f(x) : x \in R^n\}$.

We call the quasi conjugate of a function $f : R^n \to R \cup \{\pm\infty\}$ the function $f^H : R^n \to R \cup \{\pm\infty\}$ defined as follows:

$$f^H(y) = \begin{cases} -\inf\{f(x) : \langle y, x\rangle \geq 1\} & \text{if } y \neq 0 \\ -\sup\{f(x) : x \in R^n\} & \text{if } y = 0. \end{cases}$$

By definition, it is easy to see that f^H is quasi-convex and

$$f^H(0) = \inf\{f^H(y) : y \in R^n\}.$$

THEOREM 3.1. (i) *If $f \in Q^U$ then $f^L \in Q^L$ and $f^L(y) = f^H(y)$ for all $y \neq 0$;*
(ii) *If $f \in G^L$ then $f^U \in Q^U$ and $f^U(y) = f^H(y)$ for all y.*

Proof. (i) Let $f \in Q^U$. For α such that $L(f, <, \alpha)$ is nonempty one has

$$0 \in L(f, <, \alpha) = \text{int}(L(f, <, \alpha))$$

because $f(0) = \inf\{f(x) : x \in R^n\}$. This implies that $L_{-\alpha} = (L(f, <, \alpha))^0$ is compact. For α such that $L(f, <, \alpha)$ is empty, $L_{-\alpha} = \{\emptyset\}^0 = R^n$. Therefore, $f^L \in G^L$. Since $0 \in (L(f, <, \alpha))^0 = L_{-\alpha}$ (for all α), one has

$$f^L(0) = \inf\{\alpha : 0 \in L_{-\alpha}\} = -\infty \leq f^L(y) \quad \forall y.$$

So $f^L \in Q^L$. In order to prove $f^L(z) = f^H(z)$ for all $z \neq 0$ we shall prove that

$$\{y : f^L(y) \leq f^H(z)\} = \{y : f^H(y) \leq f^H(z)\} \tag{20}$$

for all $z \neq 0$. Set $\alpha = f^H(z)$. One has

$$\begin{aligned} f^L(y) \leq \alpha \Leftrightarrow y \in L_\alpha \; &\Leftrightarrow \; y \in (L(f, <, -\alpha))^0 \\ &\Leftrightarrow \sup\{\langle y, x\rangle : f(x) < -\alpha\} \leq 1 \end{aligned} \tag{21}$$

and

$$\begin{aligned} f^H(y) \leq \alpha &\Leftrightarrow -\inf\{f(x) : \langle y, x\rangle \geq 1\} \leq \alpha \\ &\Leftrightarrow \inf\{f(x) : \langle y, x\rangle \geq 1\} \geq -\alpha. \end{aligned} \tag{22}$$

We prove first (21)⇒(22). If (22) is not satisfied then there is vector u such that $\langle y, u\rangle \geq 1$, $f(u) < -\alpha$. Since $\{x : f(x) < -\alpha\}$ is open, one has

$$\sup\{\langle y, x\rangle : f(x) < -\alpha\} > \langle y, u\rangle \geq 1.$$

This conflicts with (21). We prove now (22)⇒(21). If (21) is not satisfied, then there is vector u such that $f(u) < -\alpha$ and $\langle y, u\rangle > 1$. This implies that

$$\inf\{f(x) : \langle y, x\rangle \geq 1\} \leq f(u) < -\alpha.$$

We arrive at the contradiction with (22). Thus, (21) is equivalent to (22) and hence we obtain (20). We would mention that from (22) we obtain (21) without the assumption $f \in Q^U$, and this statement can be regarded as a particular case of more general results in Crouzeix [2].

(ii) Let $f \in G^L$. For every α such that $L(f, \leq, \alpha)$ is compact one has

$$\{y : f^U(y) < -\alpha\} = U_{-\alpha} = \operatorname{int}(L(f, \leq, \alpha))^0 \ni 0. \tag{23}$$

For α such that $L(f, \leq, \alpha) \equiv R^n$ one has

$$\{y : f^U(y) < -\alpha\} = U_{-\alpha} = \operatorname{int}(L(f, \leq, \alpha))^0 = \emptyset. \tag{24}$$

Therefore, f^U is usc and $f^U(0) \leq f^U(y)$ for all $y \in R^n$, i.e., $f^U \in Q^U$. From (23) and (24) it follows that

$$\begin{aligned} f^U(0) &= \sup\{\alpha : 0 \notin U_\alpha\} \\ &= \sup\{\alpha : L(f, \leq, -\alpha) \equiv R^n\} \\ &= -\inf\{\alpha : L(f, \leq, \alpha) \equiv R^n\} \\ &= -\sup\{f(x) : x \in R^n\} \\ &= f^H(0). \end{aligned}$$

In order to prove $f^U(z) = f^H(z)$ for all $z \neq 0$ we shall prove that

$$\{y : f^U(y) < f^H(z)\} = \{y : f^H(y) < f^H(z)\} \tag{25}$$

for all $z \neq 0$. Set $\alpha := f^H(z)$. One has

$$\begin{aligned} f^U(y) < \alpha &\Leftrightarrow y \in U_\alpha \\ &\Leftrightarrow y \in \operatorname{int}(L(f, \leq, -\alpha))^0. \end{aligned} \tag{26}$$

This implies that $L(f, \leq, -\alpha)$ is not the hull space. Since $f \in G^L$, it follows that $L(f, \leq, -\alpha)$ is compact. Therefore, (26) is equivalent to

$$\max\{\langle y, x\rangle : f(x) \leq -\alpha\} < 1. \tag{27}$$

On the other hand,

$$\begin{aligned} f^H(y) &< \alpha \\ &\Leftrightarrow -\inf\{f(x) : \langle y, x\rangle \geq 1\} < \alpha \\ &\Leftrightarrow \inf\{f(x) : \langle y, x\rangle \geq 1\} > -\alpha. \end{aligned} \tag{28}$$

We shall see the equivalence between (27) and (28). First we prove (27)⇒(28). Suppose that (28) is not satisfied, i.e.,

$$\inf\{f(x) : \langle y, x\rangle \geq 1\} \leq -\alpha. \tag{29}$$

Since $f \in G^L$, there is vector u such that $\langle u, x\rangle \geq 1$ and [19]

$$f(u) = \inf\{f(x) : \langle y, x\rangle \geq 1\}.$$

From (29) it follows that $f(u) \leq -\alpha$. Therefore,

$$\sup\{\langle y, x\rangle : f(x) \leq -\alpha\} \geq \langle u, x\rangle \geq 1.$$

This conflicts with (27). Now we prove (28)⇒(27). Suppose that (27) is not satisfied, i.e.,

$$\sup\{\langle y,x\rangle : f(x) \le -\alpha\} \ge 1. \tag{30}$$

Since $L(f,\le,-\alpha)$ is compact, from (30) it follows that there is vector u such that $\langle y,u\rangle \ge 1$ and $f(u) \le -\alpha$. Then,

$$\inf\{f(x) : \langle y,x\rangle \ge 1\} \le f(u) \le -\alpha.$$

This conflicts with (28). Thus, (27)⇔(28) and hence we obtain (25). □

The biquasi-conjugate function $(f^H)^H$ will be denoted by f^{HH}. In [19] we prove that if $f \in Q^U$, then $f^{HH} \in Q^U$ and

$$\{x : f^{HH}(x) < \alpha\} = \operatorname{conv}\{x : f(x) < \alpha\} \quad (\forall\alpha),$$

and that if $f \in Q^L$, then $f^{HH} \in Q^L$ and

$$\{x : f^{HH}(x) \le \alpha\} = \operatorname{conv}\{x : f(x) \le \alpha\} \quad (\forall\alpha).$$

The later relation can be generalized in the following theorem.

THEOREM 3.2. *If $f \in G^L$, then $f^{HH} \in Q^L$ and*

$$\{x : f^{HH}(x) \le \alpha\} = \operatorname{conv}(\{x : f(x) \le \alpha\} \cup \{0\})$$

for all $\alpha > \inf\{f(x) : x \in R^n \setminus \{0\}\}$.

Proof. Let $f \in G^L$. Then, by Theorem 3.1 (ii), $f^H = f^U$ and $f^H \in Q^U$. By Theorem 3.1 (i), $f^{HH}(x) = (f^H)^L(x)$ for all $x \neq 0$ and $(f^H)^L \in Q^L$. This together with the fact that

$$f^{HH}(0) = \inf\{f^{HH}(x) : x \in R^n\}$$

implies $f^{HH} \in Q^L$. By definition,

$$\begin{aligned} f^{HH}(0) &= -\sup\{f^H(y) : y \in R^n\} \\ &= -\sup_{y\in R^n}\{-\inf\{f(x) : \langle y,x\rangle \ge 1\}\} \\ &= \inf_{y\in R^n}\inf_{x}\{f(x) : \langle y,x\rangle \ge 1\} \\ &= \inf_{x}\inf_{y\in R^n}\{f(x) : \langle y,x\rangle \ge 1\} \\ &= \inf\{f(x) : x \in R^n \setminus \{0\}\}. \end{aligned} \tag{31}$$

For $\alpha > \inf\{f(x) : x \in R^n \setminus \{0\}\} = f^{HH}(0)$ one has

$$\begin{aligned} \{x : f^{HH}(x) \le \alpha\} &= \{x : (f^H)^L(x) \le \alpha\} \\ &= \{y : f^H(y) < -\alpha\}^0 \\ &= \{y : f^U(y) < -\alpha\}^0 \\ &= \{\operatorname{int}\{x : f(x) \le \alpha\}^0\}^0. \end{aligned} \tag{32}$$

Since $f \in G^L$, $\{x : f(x) \le \alpha\}$ is either a compact set or the hull space. If $\{x : f(x) \le \alpha\}$ is compact, from (32) it follows that

$$\begin{aligned} \{x : f^{HH}(x) \le \alpha\} &= \{\operatorname{int}\{x : f(x) \le \alpha\}^0\}^0 \\ &= \{x : f(x) \le \alpha\}^{00} \\ &= \operatorname{conv}(\{x : f(x) \le \alpha\} \cup \{0\}). \end{aligned}$$

If $\{x : f(x) \le \alpha\} = R^n$, from (32) it follows that

$$\begin{aligned}\{x : f^{HH}(x) \le \alpha\} &= \{\operatorname{int}\{x : f(x) \le \alpha\}^0\}^0 \\ &= \{\emptyset\}^0 = R^n \\ &= \operatorname{conv}(\{x : f(x) \le \alpha\} \cup \{0\}). \qquad \square\end{aligned}$$

4. Dual problems. Denote by Q the set of functions f such that $f^{HH} = f$. Since f^{HH} is quasi-convex and $f^{HH}(0) = \inf\{f^{HH}(x) : x \neq 0\}$ [19], if $f \in Q$ then f is quasi-convex and

$$(33) \qquad f(0) = \inf\{f(x) : x \neq 0\}.$$

Denote by G the class of quasi-convex functions satisfying (33). Obviously, $Q \subseteq G$. However the difference between Q and G is not very big, because $f \in G$ will be in Q if f is either usc or lsc [19], [22]. For $f \in Q$ we define

$$\begin{aligned}\operatorname{dom} f &= \{x : f(x) < \sup_{x \in R^n} f(x)\}, \\ \ker f &= \{x : f(x) = f(0)\}.\end{aligned}$$

From (33) it follows that $\ker f = \{x : f(x) \le f(0)\}$. Therefore, $\operatorname{dom} f$ and $\ker f$ are convex sets. If f is nonconstant and convex, then $\operatorname{dom} f$ has the usual meaning:

$$\operatorname{dom} f = \{x : f(x) < +\infty\},$$

because $\sup\{f(x) : x \in R^n\} = +\infty$ [14].

Consider the following primal problem:

$$(34) \qquad \sup\{f(x) : x \in D\},$$

where $f \in Q$ and D is a compact set. We call the dual problem of problem (34) the following problem:

$$(35) \qquad \inf\{f^H(y) : y \notin \operatorname{int} D^0\}.$$

THEOREM 4.1. (i) $\sup(34) = -\inf(35)$.

(ii) *If the primal* (34) *is regular then the dual* (35) *is regular.*

(iii) *If y is an optimal solution to the dual* (35) *then every vector $x \in D$ such that $\langle y, x\rangle \ge 1$ is optimal to the primal* (34).

Proof. (i) One has

$$\begin{aligned}&\sup\{f(x) : x \in D\} \\ &\quad = \sup\{f^{HH}(x) : x \in D\} \quad (\text{since } f^{HH} = f) \\ &\quad = \sup_{x \in D}\{-\inf_{y}\{f^H(y) : \langle y, x\rangle \ge 1\}\} \\ &\quad = -\inf_{x \in D}\inf_{y}\{f^H(y) : \langle y, x\rangle \ge 1\} \\ &\quad = -\inf_{y}\inf_{x \in D}\{f^H(y) : \langle y, x\rangle \ge 1\} \\ &\quad = -\inf_{y \notin \operatorname{int} D^0} f^H(y) \quad \left(\text{since } y \in \operatorname{int} D^0 \Leftrightarrow \sup_{x \in D}\langle y, x\rangle < 1\right).\end{aligned}$$

(ii) Suppose that the primal (34) is regular, i.e.,

$$\sup\{f(x) : x \in D\} = \sup\{f(x) : x \in \operatorname{int} D\}.$$

Let $\{x_n\}$ be a sequence in $\operatorname{int} D$ such that

$$f(x_n) \to \sup\{f(x) : x \in D\}. \tag{36}$$

Since $f^{HH} = f$, one has

$$f(x_n) = f^{HH}(x_n) = -\inf\{f^H(y) : \langle y, x_n\rangle \geq 1\}.$$

Let y_n be a vector such that $\langle y_n, x_n\rangle \geq 1$ and

$$| f^H(y_n) + f(x_n) |\leq 1/n. \tag{37}$$

Then, $y_n \notin D^0$ because

$$1 = \langle y_n, x_n\rangle < \sup_{x\in D}\langle y_n, x\rangle \quad (\text{since } x_n \in \operatorname{int} D).$$

Furthermore, from (36) and (37) it follows that

$$-f^H(y_n) \to \sup_{x\in D}\{f(x) : x \in D\} = -\inf_{y\notin \operatorname{int} D^0} f^H(y) \quad \text{as } n \to \infty.$$

Therefore,

$$\inf\{f^H(y) : y \notin D^0\} = \inf\{f^H(y) : y \notin \operatorname{int} D^0\}.$$

So the dual (35) is regular.

(iii) Let y be an optimal solution to the dual (35). Since $y \notin \operatorname{int} D^0$ and D is compact, there is $x \in D$ such that $\langle y, x\rangle \geq 1$. Then,

$$f(x) \geq \inf\{f(z) : \langle y, z\rangle \geq 1\} = -f^H(y) = -\inf(35) = \sup(34).$$

Therefore, x is optimal to the primal (34). □

If the primal problem (34) is nontrivial, i.e., f is nonconstant on D, then

$$\inf(35) = -\sup(34) < -f(0) = -f^{HH}(0) = \sup\{f^H(y) : y \in R^n\}.$$

Therefore,

$$\inf\{f^H(y) : y \notin \operatorname{int} D^0\} \Leftrightarrow \inf\{f^H(y) : y \notin \operatorname{int} D^0, y \in \operatorname{dom} f^H\}.$$

If f is usc, then

$$\begin{aligned}
\operatorname{dom} f^H &= \cup_{\alpha<\sup_{u\in R^n} f^H(u)}\{v : f^H(v) \leq \alpha\}\\
&= \cup_{\alpha<-f(0)}\{v : f^H(v) \leq \alpha\}\\
&= \cup_{\alpha<f(0)}\{x : f(x) < -\alpha\}^0\\
&= \cup_{\beta>f(0)}\{x : f(x) < \beta\}^0\\
&\subseteq (\ker f)^0 \quad (\text{because } \ker f \subseteq \{x : f(x) < \beta\}\ \forall \beta > f(0)).
\end{aligned}$$

This implies that the dual problem can be embedded into a k-dimensional space if $\ker f$ contains an $(n-k)$-dimensional subspace.

Example 4.1 (Burkard, Oettli, and Thach [1]). In a three-dimensional space we are given n vectors $v_i = (a_i, b_i, c_i) \in R^3$, $i = 1, \ldots, n$. Each vector v_i is associated with a weight w_i. We wish to find vectors $v_{i_1}, \ldots, v_{i_k}$ such that the sum of their weights $w_{i_1} + \cdots + w_{i_k}$ is less than or equal to 1, and the vector $v = v_{i_1} + \cdots + v_{i_k}$ has maximum length. This is a generalized knapsack problem. Let $a = (a_1, \ldots, a_n)$, $b = (b_1, \ldots, b_n)$, $c = (c_1, \ldots, c_n)$. If there is a vector $z \in R^n$ such that $a = \alpha z$; $b = \beta z$; $c = \gamma z$, then $a + b + c = (\alpha + \beta + \gamma)z$ and this problem is nothing but the one-dimensional knapsack problem. So, we assume that a, b, c are linearly independent. By using Boolean variables $x_i \in \{0, 1\}$ $i = 1, \ldots, n$ we can formulate the problem as

$$\max\{f(x) : x \in D\},$$

with

$$f(x) := \left(\sum_{i=1}^{n} a_i x_i\right)^2 + \left(\sum_{i=1}^{n} b_1 x_i\right)^2 + \left(\sum_{i=1}^{n} c_i x_i\right)^2$$

$$D := \left\{x = (x_1, ..., x_n) \in \{0, 1\}^n : \sum_{i=1}^{n} w_i x_i \le 1\right\}.$$

Since ker$f$ is the following $(n - 3)$-dimensional subspace

$$C := \left\{x : \sum_{i=1}^{n} a_i x_i = 0, \sum_{i=1}^{n} b_i x_i = 0, \sum_{i=1}^{n} c_i x_i = 0\right\},$$

its dual problem can be embedded into a three-dimensional space as follows:

$$\min\left\{f^H(y) : y \in C^\perp, y \notin \operatorname{int}(D^0)\right\},$$

where

$$C^\perp = \{\alpha a + \beta b + \gamma c : (\alpha, \beta, \gamma) \in R^3\},$$

$$f^H(\alpha a + \beta b + \gamma c) = -\inf\left\{f(x) : \sum_{i=1}^{n} x_i(\alpha a_i + \beta b_i + \gamma c_i) \ge 1\right\}.$$

Since $f(\cdot)$ is convex quadratic, the value $f^H(\alpha a + \beta b + \gamma c)$ can be immediately computed:

$$f^H(\alpha a + \beta b + \gamma c) = -\frac{1}{\alpha^2 + \beta^2 + \gamma^2}.$$

Furthermore, the constraint $(\alpha a + \beta b + \gamma c) \notin \operatorname{int}(D^0)$ is equivalent to

$$\max\left\{\sum_{i=1}^{n} x_i(\alpha a_i + \beta b_i + \gamma c_i) : x \in \{0, 1\}^n\right\} \ge 1.$$

Hence the dual problem can be rewritten as

$$\min\left\{-\frac{1}{\alpha^2 + \beta^2 + \gamma^2} : \max\left\{\sum_{i=1}^{n} x_i(\alpha a_i + \beta b_i + \gamma c_i) : x \in \{0, 1\}^n\right\} \ge 1\right\}$$

$$\Leftrightarrow \min\left\{\alpha^2 + \beta^2 + \gamma^2 : \max\left\{\sum_{i=1}^{n} x_i(\alpha a_i + \beta b_i + \gamma c_i) : x \in \{0, 1\}^n\right\} \ge 1\right\},$$

which is a convex minimization over the complement of a convex set in R^3.

We present now a dual problem for a general minimization over the complement of a convex set:

$$\inf\{f(x) : x \notin \operatorname{int} D\}, \tag{38}$$

where f is an arbitrary function and D is a closed convex set such that $0 \in \operatorname{int} D$. It is well known that $D^{00} = D$. We call the dual problem of problem (38) the following problem:

$$\sup\{f^H(y) : y \in D^0\}. \tag{39}$$

THEOREM 4.2. (i) $\inf(38) = -\sup(39)$;

(ii) *If the primal* (38) *is regular and D is bounded then the dual* (39) *is regular*;

(iii) *If y is an optimal solution to the dual* (39) *then every minimizer of the function f on the half-space $\{x : \langle y, x\rangle \geq 1\}$ is an optimal solution to the primal* (38).

Proof. (i) One has

$$\begin{aligned}
&-\sup\{f^H(y) : y \in D^0\}\\
&\quad = -\sup_{y\in D^0}\{-\inf_x\{f(x) : \langle y, x\rangle \leq 1\}\}\\
&\quad = \inf_{y\in D^0}\inf_x\{f(x) : \langle y, x\rangle \geq 1\}\\
&\quad = \inf_x \inf_{y\in D^0}\{f(x) : \langle y, x\rangle \geq 1\}\\
&\quad = \inf_{x\notin \operatorname{int} D} f(x) \quad \left(\text{since } x \in \operatorname{int} D = \operatorname{int} D^{00} \Leftrightarrow \sup_{y\in D^0}\langle y, x\rangle < 1\right).
\end{aligned}$$

(ii) Suppose that D is bounded and the primal problem (38) is regular, i.e.,

$$\inf\{f(x) : x \notin \operatorname{int} D\} = \inf\{f(x) : x \notin D\}.$$

Let $\{x_n\}$ be a sequence such that $x_n \notin D$ and

$$f(x_n) \to \inf(38) \quad \text{as} \quad n \to \infty. \tag{40}$$

Let $\langle y_n, \cdot\rangle$ be a linear function such that

$$1 = \langle y_n, x_n\rangle > \sup_{x\in D}\langle y_n, x\rangle. \tag{41}$$

Since D is bounded, y_n belongs to $\operatorname{int} D^0$. Furthermore,

$$\sup(39) \geq f^H(y_n) = -\inf\{f(x) : \langle y_n, x\rangle \geq 1\} \geq -f(x_n).$$

This together with (40) and assertion (i) implies

$$f^H(y_n) \to \sup(39).$$

Since $y_n \in \operatorname{int} D^0$, this means that the dual (39) is regular.

(iii) Let y be an optimal solution to the dual (39) and z be a minimizer of f on the half-space $\{x : \langle y, x\rangle \geq 1\}$. Then,

$$\begin{aligned}
f(z) &= \inf\{f(x) : \langle y, x\rangle \geq 1\} = -f(y)\\
&= -\sup(39) = \inf(38).
\end{aligned}$$

Since $y \in D^0$ and $\langle y, z\rangle \geq 1$, z does not belongs to $\operatorname{int} D$. Therefore z is optimal to the primal (38). $\square$

Example 4.2 (Burkard, Oettli, and Thach [1]). As in Example 4.1 we are given n vectors $T_i = (a_i, b_i, c_i) \in R^3$ $i = 1, \ldots, n$. Each vector T_i is associated with an weight w_i. This time we wish to find vector $T_{i_1}, T_{i_2}, \ldots, T_{i_k}$ such that the length of the vector $T = T_{i_1} + \cdots + T_{i_k}$ is greater than or equal to 1 and the sum of their weights $w_{i_1} + \cdots + w_{i_k}$ is minimized. By using a Boolean variable $x \in \{0,1\}^n$ we formulate the problem as follows:

$$\min\{\langle w, x\rangle : \langle a, x\rangle^2 + \langle b, x\rangle^2 + \langle c, x\rangle^2 \geq 1, x \in \{0,1\}^n\}, \tag{42}$$

where $w = (w_1, \ldots, w_n), a = (a_1, \ldots, a_n), b = (b_1, \ldots, b_n)$, and $c = (c_1, \ldots, c_n)$. By setting

$$f(x) = \begin{cases} \langle w, x\rangle & \text{if } x \in \{0,1\}^n \\ +\infty & \text{otherwise,} \end{cases}$$

$$D \;= \{x : \langle a, x\rangle^2 + \langle b, x\rangle^2 + \langle c, x\rangle^2 \leq 1\},$$

the problem is rewritten as follows:

$$\inf\{f(x) : x \notin \operatorname{int} D\}.$$

Then the dual is

$$\sup\{f^H(y) : y \in D^0\}.$$

Since $\{x : \langle a, x\rangle = 0, \langle b, x\rangle = 0, \langle c, x\rangle = 0\} \subseteq D$, D^0 can be embedded into the three-dimensional space:

$$D^0 = \{\alpha.a + \beta.b + \gamma.c : \alpha^2 + \beta^2 + \gamma^2 \leq 1\}.$$

Therefore the dual is a quasi-convex maximization in the three-dimensional space:

$$\sup\{f^H(\alpha.a + \beta.b + \gamma.c) : \alpha^2 + \beta^2 + \gamma^2 \leq 1\}.$$

Note that for each (α, β, γ) we can compute

$$f^H(\alpha.a + \beta.b + \gamma.c) = -\min\{\langle w, x\rangle : \langle \alpha.a + \beta.b + \gamma.c, x\rangle \geq 1, x \in \{0,1\}^n\}$$

by a pseudopolynomial dynamic programming algorithm.

As presented above, a dual of a quasi-convex maximization over a compact set is a quasi-convex minimization over the complement of a convex set and a dual of a general minimization over the complement of a convex set is a quasi-convex maximization over a compact convex set. In the remainder of this section we discuss the duality in another class of nonconvex programs:

$$\inf_{x \in R^n} \{h_1(x) - h_2(x)\}, \tag{43}$$

where h_1 is an arbitrary function and h_2 is a finite convex function. In Toland [25], and Hiriart-Urruty [4] a dual of problem (43) is

$$\inf_{y \in \operatorname{dom} h_2^*} \{h_2^*(y) - h_1^*(y)\}. \tag{44}$$

In the sequel we shall see that if problem (43) is regarded as a particular case of problem (38), then the dual (44) can be obtained by our duality scheme. By adding a variable t we transform problem (43) into the following problem:

$$\inf\{h_1(x) - t : h_2(x) - t - h_2(0) - 1 \geq 0\}. \tag{45}$$

By setting

$$f(x,t) = h_1(x) - t,$$
$$D = \{(x,t) : h_2(x) - t - \alpha \leq 0\},$$

where $\alpha = h_2(0) + 1$, problem (45) has the form (38). Note that $0 \in \operatorname{int} D$, since $\alpha = h_2(0) + 1$.

PROPOSITION 4.3. *Let h be an arbitrary function on R^n. Set $g(x,t) = h(x) - t$, $Y = \{y \in R^n : \langle y, x\rangle < 1$ for all $x \in \operatorname{dom} h\}$. Then,*

$$g^H(y,\lambda) = \begin{cases} (1/\lambda) + h^*(-y/\lambda) & \text{if } \lambda < 0 \\ -\infty & \text{if } y \in Y \text{ and } \lambda = 0 \\ +\infty & \text{otherwise.} \end{cases}$$

Proof. By definition of the quasi conjugate, it is easy to see that $g^H(y) = -\infty$ if $y \in Y$ and $\lambda = 0$, and $g^H(y,\lambda) = +\infty$ if either $\lambda > 0$ or $y \notin Y$ and $\lambda = 0$. If $\lambda < 0$ then

$$\begin{aligned} g^H(y,\lambda) &= -\inf\{h(x) - t : \langle y,x\rangle + \lambda.t \geq 1\} \\ &= -\inf\left\{h(x) - t : -t \geq \left\langle \frac{y}{\lambda}, x\right\rangle - \frac{1}{\lambda}\right\} \\ &= -\inf_{x\in R^n}\left\{h(x) + \left\langle \frac{y}{\lambda}, x\right\rangle - \frac{1}{\lambda}\right\} \\ &= \sup\left\{\left\langle -\frac{y}{\lambda}, x\right\rangle - h(x) + \frac{1}{\lambda}\right\} \\ &= h^*\left(-\frac{y}{\lambda}\right) + \frac{1}{\lambda}. \end{aligned}$$

This completes the proof. □

Setting $Y_1 = \{y \in R^n : \langle y,x\rangle < 1 \text{ for all } x \in \operatorname{dom} h_1\}$, by Propositions 2.3 and 4.3, one has

$$f^H(y,\lambda) = \begin{cases} 1/\lambda + h_1^*(-\frac{y}{\lambda}) & \text{if } \lambda < 0, \\ -\infty & \text{if } y \in Y_1 \text{ and } \lambda = 0, \\ +\infty & \text{otherwise.} \end{cases}$$

$$D^0 = \left\{(y,\lambda) : \lambda < 0, h_2^*\left(-\frac{y}{\lambda}\right) + \alpha \leq -\frac{1}{\lambda}\right\} \cup \{0\}.$$

The dual of problem (45) is maximizing f^H on D^0. Since $f^H(0,0) = -\infty$, maximizing f^H on D^0 is equivalent to maximizing f^H on $D^0 \setminus \{0\}$:

$$\begin{aligned} &\sup\left\{h_1^*\left(-\frac{y}{\lambda}\right) + \frac{1}{\lambda} : \lambda < 0, h_2^*\left(-\frac{y}{\lambda}\right) + \alpha \leq -\frac{1}{\lambda}\right\} \\ &= \sup\left\{h_1^*\left(-\frac{y}{\lambda}\right) - h_2^*\left(-\frac{y}{\lambda}\right) - \alpha : \lambda < 0, y \in \operatorname{dom} h_2^*\right\} \\ &= \sup\{h_1^*(y) - h_2^*(y) : y \in \operatorname{dom} h_2^*\} - \alpha \\ &= -\inf\{h_2^*(y) - h_1^*(y) : y \in \operatorname{dom} h_2^*\} - \alpha. \end{aligned}$$

Thus, we obtain the dual (44).

5. Applications.

Application 5.1. We are given a convex maximization program

$$\sup\{f(x) : h(x) \leq 1\}, \tag{46}$$

where f and h are the Minkowski functionals of the compact convex sets C and D such that $0 \in C$ and $0 \in D$. It is well known that

$$\begin{aligned} f(x) &= \sup\{\langle y, x\rangle : y \in C^0\}, \\ h(x) &= \sup\{\langle y, x\rangle : y \in D^0\}. \end{aligned}$$

Consider a perturbation of program (46):

$$(A(z)) \qquad \sup\{f(x) : h(x) \leq 1 + \langle z, x\rangle\}.$$

It is obvious that program $(A(z))$ is program (46) when $z = 0$. We wish to solve the following parametric problem:

$$s(z) := \sup(A(z)) \rightarrow \inf, \qquad \text{such that } z \in R^n. \tag{47}$$

If $z \notin \operatorname{int} D^0$ then there is vector x such that

$$1 = \langle z, x\rangle \geq \sup\{\langle y, x\rangle : y \in D^0\} = h(x) > 0.$$

So,

$$h(\lambda.x) = \lambda.h(x) \leq \lambda.\langle z, x\rangle < \langle z, \lambda.x\rangle + 1 \quad \forall\lambda \geq 0.$$

Therefore, the half line $\{\lambda.x : \lambda \geq 0\}$ is contained in the feasible domain of program $(A(z))$. This implies $s(z) = +\infty$. If $z \in \operatorname{int} D^0$, then $0 \in \operatorname{int}(D^0 - z)$. Since

$$\begin{aligned} (D^0 - z)^0 &= \left\{x : \sup_{y \in D^0} \langle y - z, x\rangle \leq 1\right\} \\ &= \{x : h(x) \leq 1 + \langle z, x\rangle\}, \end{aligned}$$

the dual of $(A(z))$ is

$$\inf\{f^H(y) : y \notin \operatorname{int}(D^0 - z)\}. \tag{48}$$

It is easy to check that

$$f^H(y) = -1/\sup\{\langle y, x\rangle : x \in C\}.$$

The dual (48) is equivalent to

$$\inf\{g(y) : y \notin \operatorname{int}(D^0 - z)\},$$

where $g(y) = \sup\{\langle y, x\rangle : x \in C\}$, or equivalently,

$$\inf\{g(y - z) : y \notin \operatorname{int} D^0\}. \tag{49}$$

Set $r(z) = \inf(49)$. By the duality, $s(z) = -\inf(48)$, and hence $s(z) = 1/\inf(49) = 1/r(z)$. Therefore, the parametric problem (47) is equivalent to

$$(50) \qquad r(z) \to \sup \quad \text{such that } z \in \operatorname{int} D^0.$$

Since $g(.)$ is the Minkowski functional of the convex set C^0, $r(z)$ is a concave function on D^0 [18] and hence problem (50) is a concave maximization over a convex set, i.e., a convex program. If $f(x) =\| x \|$ then $g(y) =\| y \|$ and program (50) is used to find the biggest ball contained in D^0.

Application 5.2. We are given a convex minimization over the complement of a convex set:

$$(51) \qquad \inf\{f(x) : h(x) \geq 1\},$$

where f and h are functions as in Application 5.1. We assume additionally that $0 \in \operatorname{int} D$. Consider a perturbation of program (51):

$$(B(z)) \qquad \inf\{f(x) : h(x) \geq 1 + \langle z, x\rangle\},$$

and we wish to solve the following parametric problem

$$(52) \qquad s(z) := \inf(B(z)) \to \sup \quad \text{such that } z \in R^n.$$

For every $z \in R^n$, one has

$$\begin{aligned}(D^0 - z)^0 &= \left\{x : \sup_{y \in D^0} \langle y - z, x\rangle \leq 1\right\} \\ &= \{x : h(x) \leq 1 + \langle z, x\rangle\}\end{aligned}$$

and hence

$$\{x : h(x) \leq 1 + \langle z, x\rangle\}^0 = (D^0 - z)^{00} = \operatorname{conv}\{(D^0 - z) \cup \{0\}\}.$$

The dual of (B(z)) is

$$\begin{aligned}(53) \qquad & \sup\{f^H(y) : y \in \operatorname{conv}\{(D^0 - z) \cup \{0\}\}\} \\ & \Leftrightarrow \sup\{f^H(y) : y \in D^0 - z\} \\ & \Leftrightarrow \sup\{f^H(y - z) : y \in D^0\} \\ (54) \qquad & \Leftrightarrow \sup\{g(y - z) : y \in D^0\},\end{aligned}$$

where $g(y) = \sup\{\langle y, x\rangle : x \in C\}$. Set $r(z) = \sup(54)$. By the duality, $s(z) = -\sup(53)$ and hence $s(z) = 1/\sup(54) = 1/r(z)$ because $f^H(y) = -1/g(y)$. Therefore, the parametric problem (52) is equivalent to

$$(55) \qquad r(z) \to \inf \quad \text{such that } z \in R^n.$$

Since $g(.)$ is convex, $r(.)$ is convex. So problem (55) is a convex program. If $f(x) = \| x \|$ then $g(y) =\| y \|$ and problem (55) is used to find the smallest ball containing D^0.

Application 5.3 (Konno, Thach, and Yokota [7]). We consider a multi-objective problem:

$$\langle c_i, x\rangle \to \max \ i = 1, \ldots, p \quad \text{such that } x \in X,$$

where $\langle c_i, \cdot \rangle, i = 1, \dots, p$ are p objectives and X is a polyhedral convex set of feasible solutions. We denote by X^* the set of nondominated solutions and we wish to find a solution in X^* which minimizes an additional objective function $f : R^n \mapsto R$:

$$(56) \qquad f(x) \to \min \quad \text{such that } x \in X^*.$$

For each $s > 0$ we define

$$\begin{aligned} c_i^s &= c_i + \frac{1}{s} \sum_{i=1}^{p} c_i, \\ C^s &= \{x \in R^n : \langle c_i, x \rangle \le 0 \; i = 1, \dots, p\}, \\ X^s &= \cup_{(t_1, \dots, t_p) \ge 0, \sum_{i=1}^{p} t_i = 1} \operatorname{argmax} \left\{ \sum_{i=1}^{p} t_i c_i^s : x \in X \right\}. \end{aligned}$$

Then X^s can be represented as follows:

$$X^s = X \setminus \operatorname{int}\{X + C^s\}$$

and $X^* = X^s$ for sufficiently large enough s (Yu [29], Sawaragi, Nakayama, and Tanino [15]). Therefore, problem (56) is equivalent to

$$(57) \qquad f(x) \to \min \quad \text{such that } x \in X \setminus \operatorname{int}\{X + C^s\}.$$

The constraint in (57) is a reverse convex constraint. By translating the original into $\operatorname{int}\{X + C^s\}$, if necessary, we can assume that $0 \in \operatorname{int}\{X + C^s\}$. The dual of (57) is

$$(58) \qquad f^H(y) \to \max \quad \text{such that } y \in (X + C^s)^0.$$

Since C^s contains the subspace $\{x : \langle c_i^s, x \rangle = 0 \text{ for all } i = 1, \dots, p\}$, the dual (58) can be embedded into the p-dimensional space:

$$(59) \; F(t_1, \dots, t_p) \to \max$$

$$\text{such that} \quad \sup \left\{ \left\langle \sum_{i=1}^{p} t_i c_i^s, x \right\rangle : x \in X \right\} \le 1, \quad \sum_{i=1}^{p} t_i = 1, \quad t_1 \ge 0, \dots, t_p \ge 0,$$

where

$$(60) \qquad F(t_1, \dots, t_p) = -\inf \left\{ f(x) : \left\langle \sum_{i=1}^{p} t_i c_i, x \right\rangle \ge 1, x \in X \right\}.$$

If f is convex, then (60) is a convex program. The dual (59) is a quasi-convex maximization over a compact convex set in R^p. In practice the number of objective functions, p, is often very small compared with the number of variables, n. Therefore the dual problem is much easier to handle than the primal by the existing solution methods (Horst and Tuy [6]).

6. Discussions. Let us discuss on the following classes of multi-extremal problems:

(QMIN) Quasi-convex MINimization over a convex set;
(QMINR) Quasi-convex MINimization over the complement of a convex set;
(QMAX) Quasi-convex MAXimization over a convex set.

Since these classes contain convex programs, it would be interesting if we could find connections between optimality criteria, duality schemes in these classes and convex programs. There have been many significant results for extending the conjugation and convex duality to QMIN problems (see, e.g., Greenberg and Pierskalla [3], Crouzeix [2], Oettli [10], [11], Tind and Wolsey [26], Passy and Prisman [12], Singer [6], [7], Martinez-Legaz [8], Penot and Volle [13]). For a survey we refer to Penot and Volle [13]. Since the class of quasi-convex functions is much bigger than that of convex functions, we have to use an extra parameter in the extensions. More recently, in [23], we have proved that if we restrict quasi-convex functions to a reasonable class, then we can obtain generalizations, which involve no extra parameter. In [24] we present a generalized Kuhn–Tucker condition and a variational inequality for QMIN, and show that the path-following methods could, in principle, be applied to QMIN. Thus QMIN problems are multi-extremal, but they are reasonably closer to convex problems.

A duality scheme for QMINR and QMAX was presented in [19]. We have proved that this duality could be obtained from convex duality and the minimax principles, and if we consider a convex problem as a particular case of convex maximization problems under convex constraints; then the dual problems by convex duality and by the generalized duality are essentially equivalent [22]. In this paper we show a connection between the nonconvex duality and geometrical optimality criteria by using the polar relationships of functions and their quasi conjugates. As we have seen, the optimality criteria and duality in QMINR and QMAX are quite different from those in convex programs. By conjugations we cannot reduce QMINR or QMAX problems to solving equations (or generalized equations). This might be a reason that explains why the algorithms for QMINR and QMAX problems have so far been constructed on the basis of enumeration and branch-and-bound methods, which are completely different from path-following methods and whose complexity is exponential with resepct to the problem dimension. However, we can use the nonconvex duality to reduce the dimension of certain large-scale nonconvex problems and hence to obtain practical algorithms for solving them [1], [7], [20], [21], [27], [28].

Acknowledgments. The author expresses his thanks to Professor W. Oettli for helpful remarks on the relations between the optimality criterion and the duality in optimization problems. The author thanks the referees for many valuable comments and suggestions.

MAXIMUM ENTROPY REGULARIZATION FOR FREDHOLM INTEGRAL EQUATIONS OF THE FIRST KIND*

P. P. B. EGGERMONT†

Abstract. The regularization of Fredholm integral equations of the first kind is considered with positive solutions by means of maximum entropy. The regularized solution is the minimizer of a functional analogous to the case of Phillips–Tikhonov regularization. The regularized solution is shown to converge to the solution of the maximum entropy least squares problem, assuming it exists. Under additional regularity conditions akin to those for Phillips–Tikhonov regularization error estimates are obtained as well. In addition it is shown that the regularity conditions are necessary for these estimates to hold. Approximation from finite-dimensional subspaces are also considered, as well as exact and approximate moment problems for the integral equations. The basic tools in the analysis are the weak compactness of subsets of L^1 consisting of functions of bounded entropy, and an inequality for convex optimization problems with Bregman functionals.

Key words. Fredholm integral equation of the first kind, ill-posed problem, regularization, maximum entropy, Bregman functional

1. Introduction.

We consider the regularization of ill-posed problems by the maximum entropy method. We are interested in stability and error estimates, and in the convergence of the method as the error in the data tends to zero. There are two basic versions of the maximum entropy method. In the older version the entropy of the unknown density distribution is maximized subject to the equality constraints imposed by the data, while the newer version closely resembles the classical Phillips–Tikhonov regularization of ill-posed least squares problems. Our aim is to get estimates similar to the Philips–Tikhonov theory with positivity constraints; see Butler, Reeds, and Dawson [4] and Groetsch [12]. The sensible modification of the older version in which the data are interpreted as providing inequality constraints was considered by Amato and Hughes [1]. This is also the usual interpretation in the statistical treatment; see Skilling [22]. For the maximum entropy method applied to some classical moment problems Borwein and Lewis [2] have obtained strong results. The maximum entropy method has a rich history: we mention Larkin [17], Gordon and Herman [13], Frieden [10], and quite recently Smith and Zoltani [23] and Amato and Hughes [1]. For a guide to the lively recent literature on the statistical aspects of maximum entropy, see the conference proceedings [22]. Here we do not consider such statistical aspects as these.

As the prototypical example of an ill-posed problem we consider the Fredholm integral equation of the first kind. So let $\Omega, \Sigma \subset I\!R^N$ be bounded closed domains, and let $k \in C(\Sigma \times \Omega)$. Define the (compact) operator $\mathcal{K} : L^1(\Omega) \longrightarrow L^2(\Sigma)$ by

$$\mathcal{K}f(x) = \int_\Omega k(x,y)f(y)\,d\mu(y), \quad x \in \Sigma, \tag{1.1}$$

†Department of Mathematical Sciences, University of Delaware, Newark, Delaware 19716 (eggermon@brahms.udel.edu).

where $d\mu(y)$ denotes Lebesgue measure on $I\!R^N$. We note that the operator $\mathcal{K}$ is also compact as mapping from $L^1(\Omega)$ into $C(\Sigma)$. We consider the equation

$$\mathcal{K}f(x) = g(x), \quad x \in \Sigma, \tag{1.2}$$

with given $g \in L^2(\Sigma)$, possibly subject to error. In general this is an ill-posed problem; see Groetsch [12]: solutions may not exist, or the solution f may not depend continuously on the data g. In typical applications, the solution f is nonnegative, e.g., because it represents a density or intensity. Formulating the problem as a constrained least squares problem, viz.

$$\begin{aligned} &\text{mimimize } \|\mathcal{K}f - g\|^2_{L^2(\Sigma)} \\ &\text{subject to } f \geq 0, \end{aligned} \tag{1.3}$$

does not essentially change the difficulty, though. In this paper we study variations of Phillips–Tikhonov regularization of (1.2) or (1.3), i.e., we consider

$$\begin{aligned} &\text{mimimize} \quad \|\mathcal{K}f - g\|^2_{L^2(\Sigma)} + \alpha^2 D(f, \varphi) \\ &\text{subject to} \quad f \geq 0, \end{aligned} \tag{1.4}$$

where α is a regularization parameter, φ is the choice for f in the absence of any data, and $D(f, \varphi)$ is the smoothing term. The case

$$D(f, \varphi) = \|\mathcal{L}(f - \varphi)\|^2_{L^2(\Omega)}, \tag{1.5}$$

with $\mathcal{L}$ a differential operator, e.g., the Laplacian, corresponds to classical Phillips–Tikhonov regularization; see Groetsch [12]. Here we are interested in the *cross-entropy* functional

$$D(f, \varphi) = \int_\Omega \left\{ f(y) \log \frac{f(y)}{\varphi(y)} + \varphi(y) - f(y) \right\} d\mu(y), \tag{1.6}$$

which is defined for all nonnegative f and φ (but its value could be $+\infty$). Note that the integrand in (1.6) is nonnegative. To get a feel for the relation between (1.5) and (1.6) we quote the inequalities (see Kemperman [15] and also [2])

$$\|f - \varphi\|^2_{L^1(\Omega)} \leq (\tfrac{4}{3}F + \tfrac{2}{3}\Phi)\, D(f, \varphi), \tag{1.7}$$

where $F = \int_\Omega f$, $\Phi = \int_\Omega \varphi$, and

$$D(f, \varphi) \leq \int_{\operatorname{supp} \varphi} \frac{|f(y) - \varphi(y)|^2}{\varphi(y)}\, d\mu(y), \tag{1.8}$$

where we assume that f vanishes almost everywhere where φ vanishes. This last inequality arises from the usual convexity inequality for $D(f, \varphi) - D(f, f) \leq \langle D_\varphi(f, \varphi), \varphi - f \rangle$.

Volumes have been and are being written to justify the scheme (1.4)–(1.6) from a statistical point of view; see [22]. In this paper we are concerned with justifying it as a regularization method, as follows. Suppose that $f \geq 0$ and g satisfy $\mathcal{K}f = g$ and that we are given some $\delta \geq 0$ and g_δ with $\|g_\delta - g\| \approx \delta$. Let $f_{\alpha\delta}$ denote the solution of (1.4) with g replaced by g_δ, i.e., $f_{\alpha\delta}$ solves

$$\begin{aligned} &\text{mimimize} \quad \|\mathcal{K}f - g_\delta\|^2_{L^2(\Sigma)} + \alpha^2 D(f, \varphi) \\ &\text{subject to} \quad f \geq 0. \end{aligned} \tag{1.9}$$

Can we get estimates for $\|f_{\alpha\delta} - f\|$, and does the estimate tend to zero as α, $\delta \longrightarrow 0$ (in some way)? And what is the appropriate norm to use here? In the same vein we may ask about the dependence of $f_{\alpha\delta}$ on g_δ and φ for fixed $\alpha > 0$. Partial qualitative answers to this were obtained by Klaus and Smith [16], *complete* quantitative answers were obtained under very strong technical conditions by Engl and Landl [9]. Essentially the same answers to the above questions but without any such technical conditions derive from the following inequalities for (1.4). If f_α solves (1.4), then for all nonnegative f,

$$\|\mathcal{K}(f - f_\alpha)\|^2_{L^2(\Sigma)} + \alpha^2 D(f, f_\alpha) \leq \ell(f) - \ell(f_\alpha), \tag{1.10}$$

where $\ell(f) = \|\mathcal{K}f - g\|^2_{L^2(\Sigma)} + \alpha^2 D(f, \varphi)$, the objective function in (1.4), and if F_α solves (1.4) with g replaced by G, then

$$\|\mathcal{K}(F_\alpha - f_\alpha)\|^2_{L^2(\Sigma)} + \alpha^2 D(F_\alpha, f_\alpha) \leq 4\,\|G - g\|^2_{L^2(\Sigma)}. \tag{1.11}$$

These inequalities contain all the required information. Note that (1.11) shows a well-posedness aspect of the problem (1.4): the quantity $\mathcal{K}f_\alpha$ is well behaved uniformly in α, whereas for fixed $\alpha > 0$ the solution f_α itself is well behaved. The inequality (1.10) is actually quite well known. Note that $\|Kf - g\|^2_{L^2(\Sigma)}$ and $D(f, \varphi)$ as given by (1.6) may be written as

$$\|\mathcal{K}f - g\|^2_{L^2(\Sigma)} = N(\mathcal{K}f) - N(g) - \langle N'(g), \mathcal{K}f - g\rangle, \tag{1.12}$$

$$D(f, \varphi) = d(f) - d(\varphi) - \langle d'(\varphi), f - \varphi\rangle, \tag{1.13}$$

where $N(f) = \|f\|^2_{L^2(\Sigma)}$, and $d(f) = \int_\Omega f(y) \log f(y)\, d\mu(y)$, and $\langle \cdot\,, \cdot\rangle$ denotes the inner product on $L^2(\Omega)$ and $L^2(\Sigma)$. Here $N'(f)$ and $d'(f)$ are the Gateaux derivatives of $N(f)$ and $d(f)$ with respect to f. The inequality (1.10) is now nothing more than the statement that N and d are *convex* functions; see Bregman [3] and also [5]. Recently Chen and Teboulle [6] have made use of this as well. In the entropy context Csiszår and Tusnàdy [7] have a similar inequality. We reproduce the proof in §3. The inequality (1.11) is a corollary to (1.10). All this suggests that we consider more than just maximum entropy regularization, i.e., consider (1.4) with D any function satisfying (1.13) for some convex d. Besides (1.5) and (1.6) there are also

$$D(f, \varphi) = \int_\Omega \left\{ \log \frac{\varphi(y)}{f(y)} + \frac{f(y)}{\varphi(y)} - 1 \right\} d\mu(y), \tag{1.14}$$

which is known as Burg's entropy (see [24] for some applications) and

$$D(f, \varphi) = \int_\Omega \left\{ \log \frac{\cosh f(y)}{\cosh \varphi(y)} - (f(y) - \varphi(y)) \tanh \varphi(y) \right\} d\mu(y), \tag{1.15}$$

which arises from $d(f) = \int_\Omega \log\cosh(f(y))\,d\mu(y)$. This choice, or rather a discrete approximation to $\Sigma_j D(h\partial_{x_j} f, \mathbf{0}_\Omega)$, with h a stepsize, is suggested by Green [11]. However, meaningful results can be obtained only if an inequality like (1.7) holds.

Maximum entropy regularization of Fredholm integral equations of the first kind has been the subject of some recent studies. Klaus and Smith [16] study a discrete version of (1.9) in the $L^2(\Omega)$-setting, and prove weak convergence. Engl and Landl [9] study (1.9) (with a slightly different cross-entropy functional) by translating (1.9) into a Phillips–Tikhonov regularization problem for a nonlinear equation, and then applying their general theory of such problems. The translated problem of Engl and Landl [9] reads

$$\text{(1.16)}\qquad \begin{aligned} &\text{mimimize} && \|\mathcal{K}T(u) - g_\delta\|^2_{L^2(\Sigma)} + \alpha^2 \|\, u\,\|^2_{L^2(\Omega)} \\ &\text{subject to} && u \geq 0, \end{aligned}$$

where $T : \mathcal{D}(T) \subset L^1(\Omega) \longrightarrow L^2(\Omega)$ is an explicitly determined bijective *nonlinear* operator such that if $f = T(u)$ then

$$\text{(1.17)}\qquad \|\, u\,\|^2_{L^2(\Omega)} = \int_\Omega \left\{ f(y) \log \frac{f(y)}{\varphi(y)} + \frac{\varphi(y)}{e} \right\} d\mu(y).$$

(So the operator T depends on φ.) However, their general theory requires that the operator T is weakly closed, which is an annoying technical condition. In our direct approach via the inequalities (1.10) and (1.11), no such extra conditions are necessary.

In this paper we work out the above in detail. In §2 we prove that the minimization problem (1.4) has a solution in $L^1(\Omega)$; in §3 we prove the inequalities (1.10) and (1.11). In §4 we derive the error and stability estimates, which imply that the method converges. Under some additional smoothness conditions on $\mathcal{K}$ we get asymptotic rates of convergence, and we prove a saturation result. In §5 we discuss the maximum entropy optimization problem (1.4) for finite-dimensional subspaces. In §6 we consider the maximum entropy method for approximate moment problems, and in §7 we discuss the (older) version of the maximum entropy problem for exact moment problems associated with integral equations in the style of Borwein and Lewis [2].

We finish the introduction with a remark on notation. In the remanider we let $\|\cdot\|$ denote the norm on the space $L^2(\Sigma)$ rather than the more cumbersome $\|\cdot\|_{L^2(\Sigma)}$, so for all $g \in L^2(\Sigma)$

$$\text{(1.18)}\qquad \|\, g\,\| = \left\{ \int_\Sigma |g(x)|^2\, d\mu(x) \right\}^{1/2}.$$

Norms on other $L^p(S)$ spaces are denoted explicitly as $\|\cdot\|_{L^p(S)}$.

2. Existence of regularized solutions.

For good measure we show that the maximum entropy problem (1.4)–(1.6) has a unique solution in $L^1(\Omega)$ for every $\alpha > 0$. The uniqueness follows from the strict convexity of $\|\mathcal{K}f - g\|^2 + \alpha^2 D(f, \varphi)$ as function of f. The essential ingredient in the existence proof is the weak compactness of sets of bounded entropy. Our proof is different from Borwein and Lewis [2] in that we avoid using the Kadec property of $D(\,\cdot\,, \varphi)$, but it is identical in spirit to that of Amato and Hughes [1] for the problem of minimizing the entropy functional $\int_\Omega f(y) \log f(y)\, dy$ subject to the constraint $\|\mathcal{K}f - g\| \leq \delta$. However, in the process we also prove that the solution is essentially positive, which is useful later on.

LEMMA 2.1. *The sets $\mathcal{E}_M$ defined as*

$$\mathcal{E}_M = \{\, f \in L^1(\Omega) \;:\; f \text{ nonnegative},\; D(f,\varphi) \le M \,\}, \tag{2.1}$$

are weakly closed, convex subsets of $L^1(\Omega)$.

Proof. The convexity of $\mathcal{E}_M$ follows from the convexity of $D(f,\varphi)$ as function of f. We show the closedness of $\mathcal{E}_M$ in the norm topology on $L^1(\Omega)$. Suppose that $\{f_n\}_n \subset \mathcal{E}_M$ converges strongly to $f_o \in L^1(\Omega)$. Then $f_n \longrightarrow f_o$ almost everywhere on Ω, and so $f_n \log(f_n/\varphi)+\varphi-f_n \longrightarrow f_o \log(f_o/\varphi)+\varphi-f_o$ almost everywhere on Ω. Since these are nonnegative functions, Fatou's lemma implies that $D(f_o,\varphi) \le \liminf_n D(f_n,\varphi) \le M$, so that $f_o \in \mathcal{E}_M$. Thus $\mathcal{E}_M$ is closed in $L^1(\Omega)$. The lemma now follows since closed convex sets are weakly closed; see Holmes [14, §12, Cor. 1]. □

COROLLARY 2.2. *For nonnegative $\varphi \in L^1(\Omega)$ the functional $f \longmapsto D(f,\varphi)$ is lower semicontinuous in the weak topology on $L^1(\Omega)$.*

Proof. Let $\{f_n\}_n \subset \mathcal{E}_M$ converge weakly to $f_o \in L^1(\Omega)$, and let $\{f_n'\}_n$ be a subsequence with $\lim_n D(f_n',\varphi) = \liminf_n D(f_n,\varphi)$. By Lemma 2.1 we have that $D(f_o,\varphi) \le \sup_n D(f_n',\varphi)$, and since this also holds for any subsequence of $\{f_n'\}_n$, it follows that $D(f_o,\varphi) \le \limsup_n D(f_n',\varphi) = \liminf_n D(f_n,\varphi)$, which shows the weak lower semicontinuity of $D(f,\varphi)$. □

Remark. Amato and Hughes [1] prove the weak lower semicontinuity of the functional $f \longmapsto \int_\Omega f \log f$ by appealing to Fatou's lemma, as in the proof of Lemma 2.1 above, but without explicit recourse to the convexity of this functional.

LEMMA 2.3. *For fixed nonnegative $\varphi \in L^1(\Omega)$, the sets $\mathcal{E}_M$ are weakly compact subsets of $L^1(\Omega)$.*

Proof. The compactness follows from the Dunford–Pettis criterion, combined with the criterion of De La Vallée–Poussin (see [8, Chap. 8, Thm. 3.1]) as follows. Assume without loss of generality that $\varphi(y) > 0$ almost everywhere on Ω. Define $m(y) = f(y)/\varphi(y)$. Then $f \in \mathcal{E}_M$ is equivalent with $m \in \mathcal{F}_M$, where $\mathcal{F}_M$ is defined as

$$\mathcal{F}_M = \left\{ m \in L^1(\Omega, \varphi(y)d\mu(y)) \;:\; \int_\Omega \Phi(m(y))\,\varphi(y)\,d\mu(y) \le M \right\}.$$

in which $\Phi(t) = t\log t + 1 - t$. Obviously, $\Phi(t)/t \longrightarrow \infty$ as $t \longrightarrow \infty$. Now the Dunford–Pettis–De La Vallée–Poussin criterion applies in the $L^1(\Omega,\varphi(y)dy)$-setting, and gives us the relative compactness of $\mathcal{F}_M$ in the weak topology on $L^1(\Omega,\varphi(y)d\mu(y))$. This is equivalent to the relative compactness of $\mathcal{E}_M$ in the weak topology on $L^1(\Omega)$. By Lemma 2.1, $\mathcal{E}_M$ is closed in the weak topology on $L^1(\Omega)$, so that the relative compactness of $\mathcal{E}_M$ implies its compactness. □

The above Corollary 2.2 and Lemma 2.3 immediately prove the existence of solutions to (1.4)–(1.6).

THEOREM 2.4. *For $\alpha > 0$, nonnegative $\varphi \in L^1(\Omega)$ and $g \in L^2(\Sigma)$ the maximum entropy problem* (1.4)–(1.6) *has a unique solution $f_\alpha \in L^1(\Omega)$. Moreover, the ratio f_α/φ is bounded away from zero.*

Proof. The functional $\ell(f) = \|\mathcal{K}f - g\|^2 + \alpha^2 D(f,\varphi)$ is weakly lower semicontinuous by Corollary 2.2 and the compactness of $\mathcal{K} : L^1(\Omega) \longrightarrow L^2(\Sigma)$. When minimizing $\ell(f)$ we may restrict attention to those f for which $\ell(f) \le \ell(\varphi)$, so that then $D(f,\varphi) \le M$ with $M = \alpha^{-1}\ell(\varphi)$. In other words, we may take $f \in \mathcal{E}_M$ as in (2.1). Thus we are considering a weakly lower semicontinuous functional on a weakly compact subset of $L^1(\Omega)$, and the existence of a solution follows. Note that f_α vanishes almost everywhere where φ vanishes.

Now suppose that $f_\alpha/\varphi \le \delta$ on some set $E \subset \Omega$ with positive measure (on which φ is positive almost everywhere), let $\mathbf{1}_E$ be the indicator function of the set E, and let $f_\lambda = f_\alpha + \lambda \mathbf{1}_E$. Consider the function $L(\lambda) = \|\mathcal{K} f_\lambda - g\|^2 + \alpha^2 D(f_\lambda, \varphi)$ for $\lambda \ge 0$. Then $L(\lambda)$ is differentiable, and

$$L'(0) = \int_E \left[\mathcal{K}^*(\mathcal{K} f_\alpha - g) + \alpha^2 \log \frac{f_\alpha}{\varphi}\right] \le \{\|\mathcal{K}^*(\mathcal{K} f_\alpha - g)\|_{C(\Omega)} + \alpha^2 \log \delta\}\, |E|.$$

So, if, $\delta < \exp\left(-\alpha^{-2}\|K^*(\mathcal{K} f_\alpha - g)\|_{C(\Omega)}\right)$, then $L'(0) \ge 0$, so that $L(\lambda)$ is not the minimum of $L(\lambda)$ for $\lambda \ge 0$. But, obviously, $L(\lambda)$ is minimal for $\lambda = 0$, so we have a contradiction, and f_α/φ is bounded away from 0. □

We note that it is not clear whether the solution f_α actually is in $L^2(\Omega)$ as well. The above analysis suggests a negative answer: the fact that $D(f, \varphi) \le M$ does not imply that $f \in L^2(\Omega)$.

3. Inequalities for constrained regularized least squares. In this section we prove the inequalities (1.10) and (1.11) for the regularized least squares problem (1.4), where $D(f, \varphi)$ has the representation (1.13). Since the nonnegativity constraint in (1.4) may appear rather special, we replace it with an abstract constraint $f \in \mathcal{C}$, where $\mathcal{C}$ is some closed convex set. Since the proper setting of the minimization problem (1.4) depends on the particular choice for D (e.g., for $D(f, \varphi) = \|f - \varphi\|^2_{L^2(\Omega)}$ the setting is the Hilbert space $L^2(\Omega)$, but for the entropy functional $D(f, \varphi)$ given by (1.6) the setting is $L^1(\Omega)$ as shown in §2), we let the setting be any Banach space X of integrable functions on Ω, and assume that $\mathcal{K} : X \longrightarrow L^2(\Sigma)$ is at least bounded. We now consider the problem (1.4) in slightly more abstract setting, i.e., we consider the problem

$$(3.1) \qquad \mathcal{P}_\alpha(g, \varphi): \quad \begin{array}{ll} \text{mimimize} & \ell(f) \overset{\text{def}}{=} \|\mathcal{K} f - g\|^2 + \alpha^2 D(f, \varphi), \\ \text{subject to} & f \in \mathcal{C}, \end{array}$$

where $\alpha > 0$, $g \in L^2(\Sigma)$, $\varphi \in \mathcal{C}$ and D given as

$$(3.2) \qquad D(f, \varphi) = d(f) - d(\varphi) - \langle d'(\varphi), f - \varphi \rangle.$$

Here $\langle \cdot, \cdot \rangle$ denotes the duality pairing between X and X^*, the dual of X, and d is a strictly convex, Gateaux differentiable function on $\mathcal{C}$, with $d'(f) \in X^*$ for each $f \in \mathcal{C}$. The following theorem is a result of Bregman [3] slightly modified. The corollary is vintage (varietal?) Bregman [3]. We remind the reader that $\|\cdot\|$ denotes the norm on $L^2(\Sigma)$.

THEOREM 3.1 (Bregman [3]). *Assuming that $\mathcal{P}_\alpha(g, \varphi)$ has a solution $f_\alpha \in \mathcal{C}$, we have for all $f \in \mathcal{C}$,*

$$\|\mathcal{K}(f - f_\alpha)\|^2 + \alpha^2 D(f, f_\alpha) \le \ell(f) - \ell(f_\alpha).$$

COROLLARY 3.2 (Bregman [3]). *Assuming that the problem*

$$(3.3) \qquad \textit{miminize} \quad D(f, \varphi) \quad \textit{subject to} \quad f \in \mathcal{C}$$

has a solution $f_\alpha \in \mathcal{C}$, we have for all $f \in \mathcal{C}$,

$$D(f, f_\alpha) \le D(f, \varphi) - D(f_\alpha, \varphi).$$

Proof of Corollary 3.2. In the theorem take $\mathcal{K} = \mathcal{O}$, the zero operator, and $g = 0$, the zero function. □

Proof of Theorem 3.1. We note that the representation (3.2) implies that

$$D(f,\varphi) - D(f_\alpha,\varphi) - D(f,f_\alpha) = \langle d'(f_\alpha) - d'(\varphi), f - f_\alpha\rangle = \langle D'(f,\varphi), f - f_\alpha\rangle.$$

A similar relation holds for $\|\mathcal{K}f - g\|^2$. Putting these two relations together results in

$$\ell(f) - \ell(f_\alpha) - \|\mathcal{K}(f - f_\alpha)\|^2 - \alpha^2 D(f,f_\alpha) = \langle \ell'(f_\alpha), f - f_\alpha\rangle,$$

which by the (necessary) Karash–Kuhn–Tucker conditions for a solution of $\mathcal{P}_\alpha(g,\varphi)$ is nonnegative for all $f \in \mathcal{C}$. □

It is possible to derive a continuity result for $\mathcal{P}_\alpha(g,\varphi)$, as follows.

THEOREM 3.3. *Let g, $G \in L^2(\Sigma)$. Let $f_\alpha \in \mathcal{C}$ solve the problem $\mathcal{P}_\alpha(g,\varphi)$, and let $F_\alpha \in \mathcal{C}$ solve the problem $\mathcal{P}_\alpha(G,\varphi)$. Then*

$$\|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha, F_\alpha) \le 4\,\|g - G\|^2.$$

Proof. From Theorem 3.1 we get that

$$\begin{aligned}(3.4)\quad &\|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha,F_\alpha)\\ &\qquad \le \|\mathcal{K}f_\alpha - G\|^2 + \alpha^2 D(f_\alpha,\varphi) - \|\mathcal{K}F_\alpha - G\|^2 - \alpha^2 D(F_\alpha,\varphi).\end{aligned}$$

A Taylor expansion in G around g gives

$$\|\mathcal{K}f_\alpha - G\|^2 - \|\mathcal{K}F_\alpha - G\|^2 = \|\mathcal{K}f_\alpha - g\|^2 - \|\mathcal{K}F_\alpha - g\|^2 + 2\langle \mathcal{K}(f_\alpha - F_\alpha), G - g\rangle,$$

so that from (3.4) we get that

$$\begin{aligned}(3.5)\quad &\|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha,F_\alpha) \le 2\,\|\mathcal{K}(f_\alpha - F_\alpha)\|\,\|g - G\|\\ &\qquad + \|\mathcal{K}f_\alpha - g\|^2 + \alpha^2 D(f_\alpha,\varphi) - \{\|\mathcal{K}F_\alpha - g\|^2 + \alpha^2 D(F_\alpha,\varphi)\}.\end{aligned}$$

Since f_α solves $\mathcal{P}_\alpha(g,\varphi)$, the expression on the second line of (3.5) is negative (nonpositive) so that

$$(3.6)\qquad \|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha,F_\alpha) \le 2\,\|\mathcal{K}(f_\alpha - F_\alpha)\|\,\|g - G\|.$$

Ignoring the $\alpha^2 D$ term on the left of (3.6) we get a quadratic inequality for $\|\mathcal{K}(f_\alpha - F_\alpha)\|$ with the result that

$$(3.7)\qquad \|\mathcal{K}(f_\alpha - F_\alpha)\| \le 2\,\|g - G\|.$$

Using (3.7) in the right-hand side of (3.6) then gives us the required result. □

For the general problem (3.3) an inequality as in Theorem 3.3 does not seem to be available, nor for the problem $\mathcal{P}_\alpha(g,\varphi)$ if we keep g fixed but allow φ to vary, let alone if we vary both g and φ. Note though that Theorem 3.3 in combination with inequality (1.7) already shows for the entropy case that

$$\|f_\alpha - F_\alpha\|_{L^1(\Omega)} \le c\,\|g - G\|,$$

for an appropriate c. For the entropy functional (1.6) we have the following result regarding continuous dependence on φ, but the type of variation allowed in φ is quite limited.

THEOREM 3.4. *Let D be given by (1.6). Let $g \in L^2(\Sigma)$, and let $\varphi \in L^1(\Omega)$ be nonnegative. Then there exists a constant c such that for all $G \in L^2(\Sigma)$ and $\Phi \in L^1(\Omega)$ for which $\|g - G\| + \|\log(\varphi/\Phi)\|_{L^\infty(\Omega)}$ is small enough*

$$\|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha, F_\alpha) \leq c \left(\| g - G \|^2 + \alpha^2 \| \log(\varphi/\Phi)\|^2_{L^\infty(\Omega)}\right),$$

where f_α solves $\mathcal{P}_\alpha(g, \varphi)$ and F_α solves $\mathcal{P}_\alpha(G, \Phi)$.

Proof. Since F_α solves $\mathcal{P}_\alpha(G, \Phi)$ it follows from Theorem 3.1 that

$$\begin{aligned}(3.8)\quad \|\mathcal{K}(f_\alpha - F_\alpha)\|^2 &+ \alpha^2 D(f_\alpha, F_\alpha) \\ &\leq \|\mathcal{K} f_\alpha - G\|^2 + \alpha^2 D(f_\alpha, \Phi) - \|\mathcal{K} F_\alpha - G\|^2 - \alpha^2 D(F_\alpha, \Phi),\end{aligned}$$

which leads to the following variation of (3.5):

$$\begin{aligned}\|\mathcal{K}(f_\alpha - F_\alpha)\|^2 + \alpha^2 D(f_\alpha, F_\alpha) &\leq 2\,\|\mathcal{K}(f_\alpha - F_\alpha)\|\,\|g - G\| \\ &+ \|\mathcal{K} f_\alpha - g\|^2 + \alpha^2 D(f_\alpha, \varphi) - \{\|\mathcal{K} F_\alpha - g\|^2 + \alpha^2 D(F_\alpha, \varphi)\} \\ &+ \alpha^2[D(f_\alpha, \Phi) - D(f_\alpha, \varphi) + D(F_\alpha, \varphi) - D(F_\alpha, \Phi)].\end{aligned} \tag{3.9}$$

Since f_α solves $\mathcal{P}_\alpha(g, \varphi)$ the second line of (3.9) is negative (nonpositive). The expression in the last line equals

$$\int_\Omega (f_\alpha - F_\alpha) \log \frac{\varphi}{\Phi} \leq \|f_\alpha - F_\alpha\|_{L^1(\Omega)}\, \|\log(\varphi/\Phi)\|_{L^\infty(\Omega)}.$$

By means of inequality (1.7) we may estimate

$$\|f_\alpha - F_\alpha\|_{L^1(\Omega)} \leq c\sqrt{D(f_\alpha, F_\alpha)},$$

for some constant c, so that

$$\int_\Omega (f_\alpha - F_\alpha) \log \frac{\varphi}{\Phi} \leq c\, \|\log(\varphi/\Phi)\|_{L^\infty(\Omega)}\, \sqrt{D(f_\alpha, F_\alpha)}.$$

Substituting this into (3.9) results in

$$E^2 + \alpha^2 D \leq 2\,E\,\|g - G\| + c\,\alpha^2 D^{1/2}\, \|\log(\varphi/\Phi)\|_{L^\infty(\Omega)},$$

where $E = \|\mathcal{K}(f_\alpha - F_\alpha)\|$, and $D = D(f_\alpha, F_\alpha)$. After the usual manipulations, as in the proof of Theorem 3.3, the estimate of the theorem follows. □

4. Convergence results and error estimates for maximum entropy. In this section we consider the convergence of the regularization method, and provide error estimates for maximum entropy. We will be using the results from §3 with $D(f, \varphi)$ the cross entropy given by (1.6). To motivate the following theorem it should be noted that for equations $\mathcal{K} f = g$ which admit nonnegative solutions its proof is rather straight forward; this suggests that (constrained) least squares solutions be admitted as well, and that is what we do. So we state first the *constrained least squares* (LS) problem:

$$\begin{aligned}(4.1)\qquad \text{LS:}\qquad &\text{minimize} \quad \|\mathcal{K} f - g\|^2 \\ &\text{subject to} \quad f \in L^1(\Omega), \quad f \geq 0,\end{aligned}$$

and then consider the *maximum entropy least squares* (MELS) problem

$$\text{(4.2)} \qquad \text{MELS:} \quad \begin{array}{ll} \text{minimize} & D(f,\varphi) \\ \text{subject to} & f \text{ solves LS.} \end{array}$$

The insistence on $L^1(\Omega)$ solutions to the LS problem is a nontrivial regularity condition. By way of example, we consider the case where k is bounded away from zero on $\Sigma \times \Omega$, i.e. $k(x,y) \geq k_{\min}$ for all x,y, for some positive constant $k_{\min}$. Then it follows for nonnegative $f \in L^1(\Omega)$ that

$$k_{\min} |\Sigma|^{1/2} \|f\|_{L^1(\Omega)} \leq \|\mathcal{K}f\| \leq \|g\| + \|\mathcal{K}f - g\|,$$

so that a minimizing sequence for (4.1) is bounded in $L^1(\Omega)$. Unfortunately, this does not rule out the possibility that the solution of (4.1) be a nonnegative measure on Ω which is not absolutely continuous with respect to Lebesgue measure. In order for (4.2) to have a solution we need to require even more than mere $L^1(\Omega)$-solvability of (4.1); cf. inequality (1.7).

THEOREM 4.1. *Assume that the* MELS *problem* (4.2) *has a solution* $f_o \in L^1(\Omega)$. *Let* $f_{\alpha\delta}$ *solve the problem* $\mathcal{P}_\alpha(g_\delta, \varphi)$, *with* $\|g_\delta - g\| \leq \delta$. *Then if* $\delta, \alpha \longrightarrow 0$, *with* $\delta/\alpha \longrightarrow 0$, *the regularized solutions* $f_{\alpha\delta}$ *converge strongly to* f_o, *i.e.,*

$$\|f_{\alpha\delta} - f_o\|_{L^1(\Omega)} \longrightarrow 0 \quad \textit{as } \delta \longrightarrow 0.$$

Proof. Applying Theorem 3.1 to $\mathcal{P}_\alpha(g_\delta, \varphi)$ we get that

$$\text{(4.3)} \quad \begin{aligned} &\|\mathcal{K}(f_o - f_{\alpha\delta})\|^2 + \alpha^2 D(f_o, f_{\alpha\delta}) \\ &\qquad \leq \|\mathcal{K}f_o - g_\delta\|^2 + \alpha^2 D(f_o, \varphi) - \|\mathcal{K}f_{\alpha\delta} - g_\delta\|^2 - \alpha^2 D(f_{\alpha\delta}, \varphi). \end{aligned}$$

By Taylor expansion (in g_δ around g) we get that

$$\|\mathcal{K}f_o - g_\delta\|^2 - \|\mathcal{K}f_{\alpha\delta} - g_\delta\|^2 = \|\mathcal{K}f_o - g\|^2 - \|\mathcal{K}f_{\alpha\delta} - g\|^2 + 2\langle \mathcal{K}(f_o - f_{\alpha\delta}), g_\delta - g\rangle.$$

The sum of the first two terms on the right is negative since f_o is a least squares solution. Straight forward estimation then gives that

$$\text{(4.4)} \qquad \|\mathcal{K}f_o - g_\delta\|^2 - \|\mathcal{K}f_{\alpha\delta} - g_\delta\|^2 \leq 2\delta E,$$

where $E = \|\mathcal{K}(f_{\alpha\delta} - f_o)\|$. Then we may write (4.3) as

$$\text{(4.5)} \qquad E^2 + \alpha^2 D(f_o, f_{\alpha\delta}) \leq 2\delta E + \alpha^2 \left[D(f_o, \varphi) - D(f_{\alpha\delta}, \varphi)\right].$$

Ignoring $\alpha^2 D$ term on the left-hand side of this inequality, as well as ignoring the term $-\alpha^2 D(f_{\alpha\delta}, \varphi)$ on the right, we get that $E^2 \leq 2\delta E + c\alpha^2$, where $c = D(f_o, \varphi)$. It follows that

$$\text{(4.6)} \qquad E \leq \delta + \sqrt{c\alpha^2 + \delta^2}.$$

For later use we note that from (4.6) it follows that E/α is bounded as α, $\delta \longrightarrow 0$, with $\delta/\alpha \longrightarrow 0$, and

$$\text{(4.7)} \qquad \|\mathcal{K}(f_{\alpha\delta} - f_o)\| \longrightarrow 0 \quad \text{for } \alpha, \delta \longrightarrow 0,$$

regardless of whether $\delta/\alpha \longrightarrow 0$ or not. Replacing the left-hand side of (4.5) by zero we get that

$$D(f_{\alpha\delta}, \varphi) \leq D(f_o, \varphi) + \frac{2\delta E}{\alpha^2}. \tag{4.8}$$

Since $\delta/\alpha \longrightarrow 0$ it follows from (4.6) that $\delta E/\alpha^2 \longrightarrow 0$, and so from (4.8) that

$$\limsup_{\alpha,\delta} D(f_{\alpha\delta}, \varphi) \leq D(f_o, \varphi). \tag{4.9}$$

Consequently, we have that the $f_{\alpha\delta}$ belong to a set of bounded entropy, so that by Lemma 2.3 the $f_{\alpha\delta}$ belong to a weakly compact subset of $L^1(\Omega)$. Now let $\alpha_n, \delta_n \longrightarrow 0$, with $\delta_n/\alpha_n \longrightarrow 0$ as $n \longrightarrow \infty$, let $g_n = g_{\delta_n}$, and $f_n = f_{\alpha_n\delta_n}$. Then $\{f_n\}_n$ has a weakly convergent subsequence, say with limit ψ_o. For notational convenience assume that the whole sequence converges weakly. Since $\mathcal{K} : L^1(\Omega) \longrightarrow L^2(\Sigma)$ is compact then $\mathcal{K}\psi_o = \lim_n \mathcal{K}f_n$ (strong limit in $L^2(\Sigma)$). From (4.7) we also have that $\mathcal{K}f_o = \lim_n \mathcal{K}f_n$ so that $\mathcal{K}\psi_o = \mathcal{K}f_o$. Since f_o solves the LS problem, then so does ψ_o. By the weak lower semicontinuity of $D(\,\cdot\,, \varphi)$ (see Corollary 2.2, and (4.9)) we also have that

$$D(\psi_o, \varphi) \leq \liminf_n D(f_n, \varphi) \leq \limsup_n D(f_n, \varphi) \leq D(f_o, \varphi).$$

Since f_o is the unique solution of MELS, and ψ_o solves LS, then $\psi_o = f_o$, and

$$\lim_n D(f_n, \varphi) = D(f_o, \varphi). \tag{4.10}$$

From (4.5), ignoring the E^2 term on the left, we obtain that

$$D(f_o, f_n) \leq \frac{2\delta_n E}{\alpha_n^2} + D(f_o, \varphi) - D(f_n, \varphi).$$

Since $\delta_n E/\alpha_n^2 \longrightarrow 0$ as discussed before, we get with (4.10) that $D(f_o, f_n) \longrightarrow 0$. The inequality (1.7) then shows that $\|f_n - f_o\|_{L^1(\Omega)} \longrightarrow 0$. This shows that every convergent subsequence of $\{f_{\alpha_n,\delta_n}\}_n$ converges to f_o. Consequently, the $f_{\alpha\delta}$ have only one accumulation point as $\alpha \longrightarrow 0$, $\delta/\alpha \longrightarrow 0$, and the theorem follows. □

The above shows that the regularized solutions converge, but a *rate of convergence* is not provided. Inspection of the above proof reveals that in order to get rates we need to estimate the term $\alpha^2[D(f_o, \varphi) - D(f_{\alpha\delta}, \varphi)]$ in (4.5). From the easily checked identity

$$D(f_o, \varphi) - D(f_{\alpha\delta}, \varphi) = -D(f_{\alpha\delta}, f_o) + \int_\Omega (f_o - f_{\alpha\delta}) \log(f_o/\varphi),$$

which holds provided f_o/φ is nonzero almost everywhere, we see that the assumption

$$\log(f_o/\varphi) = \mathcal{K}^* \varrho_o, \tag{4.11}$$

for some $\varrho_o \in L^2(\Sigma)$ would go a long way towards this goal. At the end of this section we will address the question whether this assumption is at all reasonable.

THEOREM 4.2. *Assume that f_o solves the* MELS *problem and satisfies* (4.11). *Let $f_{\alpha\delta}$ solve the problem $\mathcal{P}_\alpha(g_\delta,\varphi)$, with $\|g_\delta - g\| \leq \delta$. Then for $\delta \longrightarrow 0$ with $\alpha = \delta^{1/2}$, the regularized solutions $f_{\alpha\delta}$ converge to f_o, and*

$$\|f_{\alpha\delta} - f_o\|_{L^1(\Omega)} = \mathcal{O}(\delta^{1/2}), \quad \delta \longrightarrow 0.$$

Proof. Our starting point is (4.5) in the proof of Theorem 4.1. For the relevant terms in the right-hand side of (4.5) we get by convexity that

$$D(f_o,\varphi) - D(f_{\alpha\delta},\varphi) \leq \int_\Omega (f_o - f_{\alpha\delta}) \log \frac{f_o}{\varphi},$$

so that by (4.11)

$$D(f_o,\varphi) - D(f_{\alpha\delta},\varphi) \leq \int_\Omega (f_o - f_{\alpha\delta})\mathcal{K}^* \varrho_o = \int_\Sigma \varrho_o \mathcal{K}(f_o - f_{\alpha\delta}).$$

It follows that for some constant c (depending on f_o!),

$$\alpha^2 \left[D(f_o,\varphi) - D(f_{\alpha\delta},\varphi)\right] \leq c\,\alpha^2 E. \tag{4.12}$$

Substituting the estimate (4.12) into the right-hand side of (4.5) gives for some (other) constant c,

$$E^2 + \alpha^2 D(f_o, f_{\alpha\delta}) \leq c\,(\delta + \alpha^2)E. \tag{4.13}$$

Ignoring the $\alpha^2 D$ term on the left yields $E \leq c\,(\delta + \alpha^2)$, so that now ignoring the E^2 on the left in (4.13) gives $D(f_o, f_{\alpha\delta}) \leq [c\,(\alpha + \delta/\alpha)]^2$. The choice $\alpha = \delta^{1/2}$ minimizes the right-hand side, and finally (1.7) gives the required result. □

We have an analogous result for exact data (i.e., $\delta = 0$)

THEOREM 4.3. *Assume that f_o solves the* MELS *problem* (4.1) *and satisfies* (4.11). *Let f_α solve $\mathcal{P}_\alpha(g,\varphi)$. Then as $\alpha \longrightarrow 0$ the regularized solution f_α converges to f_o and*

$$D(f_\alpha, f_o) = \mathcal{O}(\alpha^2), \qquad \|\mathcal{K}(f_\alpha - f_o)\| = \mathcal{O}(\alpha^2),$$

as well as

$$\|f_\alpha - f_o\|_{L^1(\Omega)} = \mathcal{O}(\alpha).$$

Proof. As in the proof of the previous theorem we get the inequality (4.13) for $E = \|\mathcal{K}(f_\alpha - f_o)\|$, but now with $\delta = 0$, so that

$$E^2 + \alpha^2 D(f_o, f_\alpha) \leq c\,\alpha^2 E,$$

from which it follows that $E \leq c\,\alpha^2$, and then $D(f_o, f_\alpha) \leq c^2\alpha^2$, and (1.7) does the trick. □

We now show the converse of Theorem 4.3. Although this does not show the reasonableness per se of condition (4.11), it does show that the above error estimates are possible *only* if (4.11) holds. This type of theorem is known as a *saturation* result; cf. Groetsch [12].

THEOREM 4.4. *Let $\varphi \in L^1(\Omega)$ be nonnegative, and let $g \in L^2(\Sigma)$. Let f_o be the solution of the* MELS *problem, and assume that $\mathcal{K}^*(\mathcal{K}f_o - g) = 0$. Let f_α be the solution of $\mathcal{P}_\alpha(g, \varphi)$, and suppose that*

$$D(f_\alpha, f_o) = \mathcal{O}(\alpha^2), \qquad \|\mathcal{K}(f_\alpha - f_o)\| = \mathcal{O}(\alpha^2).$$

Then condition (4.11) *holds.*

Proof. Since f_α solves $\mathcal{P}_\alpha(g, \varphi)$, and since f_α is bounded away from zero (see Theorem 2.4) it follows that the gradient of the objective function vanishes, so

$$2\mathcal{K}^*\mathcal{K}(f_\alpha - f_o) + \alpha^2 \log \frac{f_\alpha}{\varphi} = 0 \quad \text{a.e. on } \Omega, \tag{4.14}$$

where we used the assumption that $\mathcal{K}^*g = \mathcal{K}^*\mathcal{K}f_o$. Let $r_\alpha = -2\mathcal{K}(f_\alpha - f_o)/\alpha^2$, then $\|r_\alpha\|$ is bounded as $\alpha \longrightarrow 0$, by our assumptions. Then for a sequence $\{\alpha_n\}_n$, with $\alpha_n \longrightarrow 0$, we have that $\{r_{\alpha_n}\}_n$ converges weakly to some element $r_o \in L^2(\Sigma)$. Then $\{\mathcal{K}^*r_{\alpha_n}\}_n$ converges strongly to $\mathcal{K}^*r_o$ in the $C(\Omega)$-topology. It follows from (4.14) that then $\log(f_o/\varphi) = \mathcal{K}^*r_o$, and the theorem follows. □

5. Finite-dimensional approximation of maximum entropy problems. In this section we consider the convergence of the solutions of the maximum entropy problems when the maximization is done over finite-dimensional subspaces. So we let $V_1 \subset V_2 \subset \cdots \subset V_n \subset \cdots$ be a nested sequence of subspaces of $L^1(\Omega)$, such that $\bigcup_n V_n$ is dense in $L^1(\Omega)$. We consider the convergence of the solution f_n of the problem

$$\begin{array}{ll} \text{mimimize} & \ell(f) \overset{\text{def}}{=} \|\mathcal{K}f - g\|^2 + \alpha^2 D(f, \varphi), \\ \text{subject to} & f \in V_n, \ f \geq 0, \end{array} \tag{5.1}$$

for fixed $\alpha > 0$ to the solution f_α of the regularized least squares problem (1.4)–(1.6), as well as the convergence for $\alpha = \alpha_n . \longrightarrow 0$ to the solution f_o to the MELS problem (4.2). We need a suitable, possibly nonlinear projector mapping nonnegative $L^1(\Omega)$ functions into nonnegative elements of V_n. We denote this projector by q_n. We require q_n to satisfy the following approximation property:

$$\begin{array}{l} q_n \text{ maps nonnegative } L^1(\Omega) \text{ functions into nonnegative functions in } V_n \\ \text{such that } \lim\limits_{n \longrightarrow \infty} D(q_n f, f) = 0 \text{ for all nonnegative } f \in L^1(\Omega). \end{array} \tag{5.2}$$

Later we will discuss the existence of such q_n.

THEOREM 5.1. *Let $\alpha > 0$ be fixed, let $\varphi \in L^1(\Omega)$ be nonnegative, and let $g \in L^2(\Sigma)$. Let f_n denote the solution of* (5.1). *Then $\{f_n\}_n$ converges to the solution f_α of* (3.1) *and*

$$\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha) \leq \|\mathcal{K}(q_n f_\alpha - f_\alpha)\|^2 + \alpha^2 D(q_n f_\alpha, f_\alpha).$$

Proof. Theorem 3.1 is the starting point as always. Since f_α solves $\mathcal{P}_\alpha(g, \varphi)$, we get that

$$\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha) \leq \ell(f_n) - \ell(f_\alpha). \tag{5.3}$$

Using the identities

$$-\|\mathcal{K}f_\alpha - g\|^2 = -\|\mathcal{K}q_n f_\alpha - g\|^2 + 2\langle \mathcal{K}f_\alpha - g, \mathcal{K}(q_n f_\alpha - f_\alpha)\rangle + \|\mathcal{K}(q_n f_\alpha - f_\alpha)\|^2,$$

and

$$-D(f_\alpha, \varphi) = -D(q_n f_\alpha, \varphi) + D(q_n f_\alpha, f_\alpha) - \langle D'(f_\alpha, \varphi), f_\alpha - q_n f_\alpha\rangle,$$

we get that

$$\begin{aligned} &\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha) \leq \ell(f_n) - \ell(q_n f_\alpha) \\ &\qquad + \|\mathcal{K}(f_\alpha - q_n f_\alpha)\|^2 + \alpha^2 D(q_n f_\alpha, f_\alpha) \\ &\qquad + 2\langle \mathcal{K}^*(\mathcal{K} f_\alpha - g), q_n f_\alpha - f_\alpha\rangle + \alpha^2\langle D'(f_\alpha, \varphi), q_n f_\alpha - f_\alpha\rangle. \end{aligned} \tag{5.4}$$

The expression on the right in the first line of (5.4) is negative (nonpositive) since f_n solves (3.1), and $q_n f_\alpha \in V_n$ as well. The expression on the third line of (5.4) equals $\langle \ell'(f_\alpha), q_n f_\alpha - f_\alpha\rangle$. Now note that the fact that $D(q_n f_\alpha, f_\alpha)$ is finite implies that $q_n f_\alpha$ vanishes on the set where f_α itself vanishes. Since $\ell'(f_\alpha)$ and f_α cannot both be positive on the same sets of positive measure, it follows that the same holds for $\ell'(f_\alpha)$ and $q_n f_\alpha$. Consequently

$$\langle \ell'(f_\alpha), q_n f_\alpha - f_\alpha\rangle = 0,$$

so that from (5.4) the result follows. □

The inequality of the theorem is quite satisfactory, since the error is related to how well f_α can be approximated by elements from V_n. We are also interested in the case $\alpha = \alpha_n \longrightarrow 0$. To quantify the choice of α_n we need the quantity ε_n defined as

$$\varepsilon_n^2 = \|\mathcal{K}(q_n f_\alpha - f_\alpha)\|^2 + \alpha^2 D(q_n f_\alpha, f_\alpha). \tag{5.5}$$

By the assumption (5.2) and inequality (1.7) we have that $\varepsilon_n \longrightarrow 0$ as $n \longrightarrow \infty$.

THEOREM 5.2. *Let $\varphi \in L^1(\Omega)$ be nonnegative, let $g \in L^2(\Sigma)$, and let $\alpha = \alpha_n$ with $\alpha_n = \varepsilon_n^{1/2}$. Assume that the solution f_o of the* MELS *problem satisfies the condition* (4.11). *Then $\{f_n\}_n$ converges to the solution f_o, and*

$$\|f_n - f_o\|_{L^1(\Omega)} \leq c\,\varepsilon_n^{1/2},$$

for some constant c.

Proof. Let ψ_n denote the solution of (3.1) for $\alpha = \alpha_n$. So $\psi_n = f_{\alpha_n}$. By Theorem 5.1 and inequality (1.7) we have that $\|f_n - \psi_n\|_{L^1(\Omega)} \leq c\,\varepsilon_n/\alpha_n$, and by Theorem 4.3 we have that $\|\psi_n - f_o\|_{L^1(\Omega)} \leq c\,\alpha_n$, so that by the triangle inequality

$$\|f_n - f_o\|_{L^1(\Omega)} \leq c\,(\alpha_n + \varepsilon_n/\alpha_n),$$

for some (other) constant c. Since $\alpha_n = \varepsilon_n^{1/2}$ the result follows. □

We finish this section with a discussion of the nonlinear projection operator q_n and the associated approximation number ε_n, see (5.5). The best choice (to produce the smallest ε_n) would be to define $q_n f$ as the solution ψ of the minimization problem

$$\begin{aligned} &\text{mimimize} \quad \|\mathcal{K}(\psi - f)\|^2 + \alpha^2 D(\psi, f) \\ &\text{subject to} \quad \psi \in V_n\,,\ \psi \geq 0. \end{aligned} \tag{5.6}$$

Theorem 5.1 implies that the optimal ψ for $f = f_\alpha$ is precisely equal to f_n, the solution of (5.1), and so implies the commutativity of the diagram

$$\begin{tikzcd}
(g,\varphi) \arrow[r, "(3.1)"] \arrow[dr, "(5.1)"'] & f_\alpha \arrow[d, "(5.6)"] \\
& f_n
\end{tikzcd}$$

So to show that $\varepsilon_n \longrightarrow 0$ it suffices to indicate a $\psi_n \in V_n$ such that $\eta_n \longrightarrow 0$, where

$$\eta_n = \|\mathcal{K}(\psi_n - f)\|^2 + \alpha^2 D(\psi_n, f). \tag{5.7}$$

By inequality (1.7) all we need to do is show that $D(\psi_n, f) \longrightarrow 0$ as $n \longrightarrow \infty$. We will show this for one special choice of the subspaces V_n. Let $\{\sigma_{in}\}_i$ be a nested sequence of triangulations of Ω, with maximum diameter tending to zero as $n \longrightarrow \infty$, i.e., with $\operatorname{diam}(\sigma) = \sup\{|x-y| \,:\, x, y \in \sigma\}$ we require that

$$\max_i \operatorname{diam}(\sigma_{in}) \longrightarrow 0 \quad (n \longrightarrow \infty). \tag{5.8}$$

Let p be a positive natural number. We let V_n be the space of $C^{(-1)}$ piecewise polynomial functions of degree p or less. So $\psi \in V_n$ if and only if ψ restricted to σ_{in} is a polynomial of degree p or less. No continuity conditions across boundaries of the σ_{in} are imposed.

We proceed to construct the ψ_n for given nonnegative $f \in L^1(\Omega)$. Let $p_n : L^1(\Omega) \longrightarrow V_n$ be a projection operator, e.g., the choice

$$p_n f(y) = \tfrac{1}{|\sigma_{in}|} \int_{\sigma_{in}} f(z)\, d\mu(z) \quad \text{for } y \in \sigma_{in}, \tag{5.9}$$

would do. Set $\zeta_n = \|f - p_n f\|_{L^1(\Omega)}$, then $\zeta_n \longrightarrow 0$ as $n \longrightarrow 0$. Define the sets A_n, B_n by

$$A_n = \{\, y \in \Omega \,:\, f(y) < \zeta_n \,\}, \quad B_n = \{\, y \in \Omega \,:\, |f(y) - p_n f(y)| > \zeta_n^{2/3} \,\}. \tag{5.10}$$

Then $|B_n|$, the measure of B_n, tends to zero as $n \longrightarrow \infty$. Now define $\psi_n(y)$ for $y \in \sigma_{in}$ as

$$\psi_n(y) = \begin{cases} 0, & \text{if } \sigma_{in} \cap (A_n \cup B_n) \neq \emptyset, \\ p_n f(y) - m_{in}, & \text{otherwise,} \end{cases} \tag{5.11}$$

where $m_{in} = 0$ if $p_n f(y)$ is nonnegative on σ_{in}, and $m_{in} = \min\{p_n f(y) \,:\, y \in \sigma_{in}\}$ otherwise. So ψ_n is nonnegative everywhere. Also note that $|m_{in}| \le \zeta_n^{2/3}$. We now estimate the quantity

$$\int_\Omega \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y) = \left[\int_{A_n} + \int_{B_n} + \int_{C_n}\right] \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y), \tag{5.12}$$

where $C_n = \Omega \setminus (A_n \cup B_n)$. First we have that

$$\int_{A_n} \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y) = \int_{A_n} f(y)\, d\mu(y) \le \zeta_n\, |A_n| \le \zeta_n\, |\Omega| \longrightarrow 0 \quad (n \longrightarrow \infty),$$

as well as

$$\int_{B_n} \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y) = \int_{B_n} f(y)\, d\mu(y) \longrightarrow 0,$$

since $|B_n| \longrightarrow 0$ as $n \longrightarrow \infty$.

Secondly, on C_n we have that $f(y) \geq \zeta_n$ and $|\psi_n(y) - f(y)| \leq |p_n f(y) - f(y)| + |m_{in}|$, so that

$$\int_{C_n} \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y) \leq \int_{C_n} \frac{(\zeta_n^{2/3} + |m_{in}|)^2}{\zeta_n} \leq 4\,\zeta_n^{1/3}\,|\Omega| \longrightarrow 0 \quad (n \longrightarrow \infty).$$

Putting the above together shows that

$$\int_{\Omega} \frac{|\psi_n(y) - f(y)|^2}{f(y)}\, d\mu(y) \longrightarrow 0 \quad (n \longrightarrow \infty),$$

and then from (1.8) we have that $D(\psi_n, f) \longrightarrow 0$ as desired.

The above argument becomes a bit more involved if continuity/differentiability conditions are imposed on the elements of V_n across the boundaries of the triangulations. It seems reasonable to assume that the conclusion would remain the same.

6. Convergence results for moment problems I. In this section we consider maximum entropy regularization for approximate moment problems, i.e., we assume that we have available for some nonnegative $f_o \in L^1(\Omega)$ the data g_{in} with

$$g_{in} = [\mathcal{K} f_o](x_i) + d_{in}, \qquad i = 1, 2, \ldots, n, \tag{6.1}$$

where d_{in} represents noise. The *exact* moment problem in the style of Borwein and Lewis [2] is considered in §7. Here we regularize (6.1) by means of the minimization problem

$$\begin{array}{ll} \text{minimize} & \displaystyle\sum_{i=1}^{n} w_{in} \left|[\mathcal{K} f](x_i) - g_{in}\right|^2 + \alpha^2 D(f, \varphi) \\ \text{subject to} & f \in L^1(\Omega), \quad f \geq 0, \end{array} \tag{6.2}$$

for appropriate weights w_{in}, about which more later on. In this setting we run into trouble with the point evaluation functionals $\mathcal{K} f \longmapsto [\mathcal{K} f](x_i)$, which are not bounded in the $L^2(\Sigma)$ setting, viz. there is no constant c such that

$$\left|[\mathcal{K} f](x_i)\right| \leq c\,\|\mathcal{K} f\| \quad \text{for all } f \in L^1(\Omega). \tag{6.3}$$

When $D(f, \varphi) = \|f - \varphi\|_{\mathcal{H}}^2$, where $\mathcal{H}$ is a reproducing kernel Hilbert space (RKHS) there are quite elegant solutions to this; see Natterer [20] and Lukas [18]. A similar case arises when we assume that g and $\mathcal{K} f$ themselves lie in some RKHS; see Nashed and Wahba [19], and (much) more recently Nychka and Cox [21]. Here we fudge the issue by considering approximations to the point evaluations in the form

$$r_n F(i) = \int_{\Sigma} F(x) r_{in}(x)\, d\mu(x), \quad i = 1, 2, \ldots, n \tag{6.4}$$

for all $F \in C(\Sigma)$, and we require an (approximate) interpolation operator p_n such that

$$\|F - p_n r_n F\|_{C(\Sigma)} \longrightarrow 0 \quad \text{as } n \longrightarrow \infty \tag{6.5}$$

for all $F \in C(\Sigma)$. We set $P_n = p_n r_n$ and we define the weights w_{in} by means of

$$\sum_{i=1}^{n} w_{in}\,[r_n F](i) = \int_\Sigma [P_n F](x)\,d\mu(x) \quad \text{for all } F \in C(\Sigma). \tag{6.6}$$

We now rephrase (6.2) as

$$\begin{array}{ll} \text{minimize} & \ell_n(f) \overset{\text{def}}{=} \|P_n(\mathcal{K}f - g_n)\|^2 + \alpha^2 D(f,\varphi) \\ \text{subject to} & f \in L^1(\Omega),\ f \geq 0, \end{array} \tag{6.7}$$

with $g_n = p_n(\{g_{in}\}_{i=1}^n)$.

In the analysis below it is helpful to have the following quantities available,

$$\begin{aligned} \varepsilon_n &= \sup\{\|(I - P_n^*)\mathcal{K}f\| + \|(I - P_n)\mathcal{K}f\| \;:\; \|f\|_{L^1(\Omega)} \leq 1\}, \\ \eta_n &= \|(I - P_n^*)g\| + \|(I - P_n)g\|, \\ \delta_n &= \|P_n(g - g_n)\|. \end{aligned} \tag{6.8}$$

We assume that $\varepsilon_n, \eta_n \longrightarrow 0$ as $n \longrightarrow \infty$. Note the occurence of the operator $I - P_n^*$, so that this requires more than just (6.5). We also assume that $\delta_n \longrightarrow 0$.

We begin the analysis with a boundedness result.

LEMMA 6.1. *Let f_n be the solution of* (6.7), *and f_α the solution of* (3.1). *Then*

$$\begin{aligned} D(f_n,\varphi) &\leq D(f_o,\varphi) + \delta_n^2/\alpha^2, \\ D(f_\alpha,\varphi) &\leq D(f_o,\varphi). \end{aligned}$$

Proof. Since f_n solves (6.7) we have that $\ell_n(f_n) \leq \ell_n(f_o)$, so that ignoring the term $\|P_n(\mathcal{K}f_n - g_n)\|$ on the left we get

$$\alpha^2 D(f_n,\varphi) \leq \alpha^2 D(f_o,\varphi) + \|P_n(\mathcal{K}f_o - g_n)\|^2.$$

Since $\mathcal{K}f_o = g$, this proves the inequality. The argument for f_α proceeds in the same way. □

COROLLARY 6.2. *There exists a constant c such that*

$$\|f_n\|_{L^1(\Omega)} \leq c\left(1 + \frac{\delta_n}{\alpha}\right), \qquad \|f_\alpha\|_{L^1(\Omega)} \leq c.$$

Proof. The proof follows from the previous lemma, inequality (1.7), and Lemma 2.3. □

We are now ready to consider the convergence of the entropy method.

THEOREM 6.3. *Let $\varphi \in L^1(\Omega)$ be nonnegative, let g, $g_n \in L^2(\Sigma)$. Let f_n denote the solution of* (6.7). *Then $\{f_n\}_n$ converges to the solution f_α of* (3.1) *and*

$$\|f_n - f_\alpha\|_{L^1(\Omega)} \leq c\,\alpha^{-1}\left(1 + \frac{\delta_n}{\alpha}\right)(\eta_n + \delta_n + \varepsilon_n).$$

Proof. Since f_n solves (6.7) we have that $0 \leq \ell_n(f_\alpha) - \ell_n(f_n)$, and since f_α solves (3.1) we have again by Theorem 3.1 that

$$\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha) \leq \ell(f_n) - \ell(f_\alpha).$$

Adding both inequalities results in

$$\begin{aligned}&\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha)\\ &\quad\le \|P_n(\mathcal{K}f_\alpha - g_n)\|^2 - \|\mathcal{K}f_\alpha - g\|^2 + \|\mathcal{K}f_n - g\|^2 - \|P_n(\mathcal{K}f_n - g_n)\|^2.\end{aligned}$$

In the following we let $F_\alpha = \mathcal{K}f_\alpha - g$, $F_n = \mathcal{K}f_n - g$, and $\gamma_n = P_n(g_n - g)$, as well as $Q_n = P_n - I$. Then the above may be rewritten as

$$\begin{aligned}&\|\mathcal{K}(f_n - f_\alpha)\|^2 + \alpha^2 D(f_n, f_\alpha)\\ &\quad\le \|P_nF_\alpha - \gamma_n\|^2 - \|F_\alpha\|^2 + \|F_n\|^2 - \|P_nF_n - \gamma_n\|^2.\end{aligned}$$

By Taylor expansion of the right-hand side this results in

$$\begin{aligned}&\le 2\langle F_\alpha, Q_nF_\alpha - \gamma_n\rangle + \|Q_nF_\alpha - \gamma_n\|^2 - 2\langle F_n, Q_nF_n - \gamma_n\rangle - \|Q_nF_n - \gamma_n\|^2\\ &\le 2\langle F_\alpha, Q_n\mathcal{K}(f_\alpha - f_n)\rangle - 2\langle \mathcal{K}(f_n - f_\alpha), Q_nF_n - \gamma_n\rangle\\ &\quad + \|Q_nF_\alpha - \gamma_n\|^2 - \|Q_nF_n - \gamma_n\|^2.\end{aligned}$$

Writing $\langle F_\alpha, Q_n\mathcal{K}(f_\alpha - f_n)\rangle = \langle Q_n^*F_\alpha, K(f_\alpha - f_n)\rangle$, this results in the inequality

$$E^2 + \alpha^2 D(f_n, f_\alpha) \le 2\,E\,A_n + B_n^2, \tag{6.9}$$

where $E = \|\mathcal{K}(f_n - f_\alpha)\|$, and

$$\begin{aligned}B_n &= \|Q_nF_\alpha - \gamma_n\|,\\ A_n &= \|Q_n^*F_\alpha\| + \|Q_nF_n\| + \|\gamma_n\|.\end{aligned} \tag{6.10}$$

We may rewrite (6.9) as $(E - A_n)^2 + \alpha^2 D(f_n, f_\alpha) \le A_n^2 + B_n^2$, so that, ignoring the first term on the left we get that

$$\alpha^2 D(f_n, f_\alpha) \le A_n^2 + B_n^2.$$

Since we may estimate A_n and B_n as

$$\begin{aligned}B_n &\le \varepsilon_n\|f_n\|_{L^1(\Omega)} + \eta_n + \delta_n,\\ A_n &\le (\|f_\alpha\|_{L^1(\Omega)} + \|f_n\|_{L^1(\Omega)})\,\varepsilon_n + \eta_n + \delta_n\ .\end{aligned}$$

Corollary 6.2 and inequality (1.7) then provide us with the required estimate. □

We now have a result analogous to Theorem 4.2.

THEOREM 6.4. *Assume that* $\mathcal{K}f_o = g$ *and that* f_o *satisfies condition* (4.11). *Let* $e_n = \varepsilon_n + \eta_n + \delta_n$. *Let* f_n *solve* (6.2) *with* $\alpha = \alpha_n$, *where* $\alpha_n = e_n^{1/2}$. *Then*

$$\|f_n - f_\alpha\|_{L^1(\Omega)} \le c\,e_n^{1/2}.$$

Proof. We have that $\|f_n - f_o\| \le \|f_n - f_\alpha\| + \|f_\alpha - f_o\|$. By Theorem 6.3 and Theorem 4.3 we then have that

$$\|f_n - f_o\|_{L^1(\Omega)} \le c\left(\alpha_n + \frac{e_n}{\alpha_n}\left(1 + \frac{\delta_n}{\alpha_n}\right)\right) \le \tilde{c}\left(\alpha_n + \frac{e_n}{\alpha_n}\right),$$

the last inequality owing to the fact that $\delta_n/\alpha_n \longrightarrow 0$. The theorem follows. □

Specific error estimates follow once the operators r_n, p_n and P_n have been chosen, along the lines of Lukas [18], Nychka and Cox [21], or Nashed and Wahba [19]. It should be noted that here these operators play a crucial part in the method, as opposed to the operator q_n in §5, which played a *theoretical* part only. At this point we also mention that we *can* avoid the introduction of the approximate point evaluation functionals r_n (see (6.4)), but at the price of an extra factor α^{-1} in the estimate of Theorem 6.3, similar to the proof of Theorem 7.2 below. We omit the details.

7. Convergence results for moment problems II. In this section we consider the convergence of the maximum entropy method for the moment problem for $\mathcal{K}f = g$, inspired by Borwein and Lewis [2],

$$\begin{aligned} &\text{mimimize} \quad D(f,\varphi) \\ &\text{subject to} \quad f \geq 0, \quad [\mathcal{K}f](x_i) = g_i, \quad i = 1,2,\dots,n, \end{aligned} \tag{7.1}$$

where the $x_i \in \Sigma$ are given, and the data consists of the $g_i = g(x_i)$ and $\varphi \in L^1(\Omega)$. We are interested in the behavior of the solution f_n as $n \longrightarrow \infty$. Borwein and Lewis [2] obtain uniform convergence for some classical moment problems under quite natural conditions. Here we will be satisfied with obtaining $L^1(\Omega)$ convergence. It should be noted that as a regularization method the method (7.1) is rather suspect, the biggest problem being that the constraints with noisy data

$$[\mathcal{K}f](x_i) = g(x_i) + \delta_i, \qquad i = 1,2,\dots,n, \tag{7.2}$$

might easily be *inconsistent.* For consistent problems we have the following result.

THEOREM 7.1. *Let $\varphi \in L^1(\Omega)$ be nonnegative, and let $\{g_i\}_i$ be a bounded sequence of real numbers. Suppose that there exists a nonnegative $f_o \in L^1(\Omega)$ such that $D(f_o,\varphi) < \infty$, and*

$$[\mathcal{K}f_o](x_i) = g_i, \quad i = 1,2,\dots. \tag{7.3}$$

Let $f_n \in L^1(\Omega)$ be the solution of (7.1)*. Then $\{f_n\}_n$ converges strongly to the solution of*

$$\begin{aligned} &\textit{mimimize} \quad D(f,\varphi) \\ &\textit{subject to} \quad f \geq 0, \ [\mathcal{K}f](x_i) = g_i, \quad i = 1,2,\dots. \end{aligned} \tag{7.4}$$

Proof. Let $\mathcal{C}_n \subset L^1(\Omega)$ be the set of nonnegative $f \in L^1(\Omega)$, which satisfy

$$[\mathcal{K}f](x_i) = g_i, \quad i = 1,2,\dots,n.$$

Note that $f_o \in \mathcal{C}_n$ so that $\mathcal{C}_n$ is nonempty, and obviously the $\mathcal{C}_n$ are closed and convex subsets of $L^1(\Omega)$, and $\mathcal{C}_m \subset \mathcal{C}_n$ if $m > n$. Then the solution f_n to (7.1) exists by Theorem 2.4, and for $m > n$ we have $f_m \in \mathcal{C}_n$. By Corollary 3.2 we have that

$$D(f_m,f_n) \leq D(f_m,\varphi) - D(f_n,\varphi) \quad \text{for all } m > n. \tag{7.5}$$

Since $f_o \in \mathcal{C}_n$ then $D(f_n,\varphi) \leq D(f_o,\varphi)$, so it follows that $\{D(f_n,\varphi)\}_n$ is a bounded increasing sequence, hence it has a finite limit. Then the right-hand side of (7.5) tends to zero as $n, m \longrightarrow \infty$, and we then have that $D(f_m,f_n) \longrightarrow 0$ as n, $m \longrightarrow \infty$ (with $m \geq n$). From the inequality (1.7) we then get that $\{f_n\}_n$ is Cauchy in $L^1(\Omega)$, and thus is convergent, say with limit ψ_o. It is obvious that ψ_o satisfies (7.3). Since $f_o \in \mathcal{C}_n$ it follows from Corollary 3.2 that

$$0 \leq D(f_o,f_n) \leq D(f_o,\varphi) - D(f_n,\varphi),$$

and so $D(\psi_o,\varphi) = \lim_n D(f_n,\varphi) \leq D(f_o,\varphi)$. Since this holds for all f_o which satisfy (7.3), this shows that ψ_o solves (7.4). □

It is clear that we are a long way from uniform convergence, and we will not try to recreate such results. See Borwein and Lewis [2]. However, under the usual conditions (4.11) it is possible to get L^1-error estimates. So we assume that $\{x_i\}_i$ is dense in Σ, with

$$\sup_{y\in\Sigma}\min_{1\leq i\leq n}|y-x_i|\longrightarrow 0,\quad n\longrightarrow\infty. \tag{7.6}$$

It follows that $\mathcal{K}f(x_i)=g(x_i)$ for all i implies that $\mathcal{K}f(x)=g(x)$ for all $x\in\Sigma$, e.g., if $g\in C(\Sigma)$, and $f\in L^1(\Omega)$. We let $r_n : C(\Sigma)\longrightarrow I\!R^n$ be the restriction operator, defined by

$$r_ng(i)=g(x_i),\quad i=1,2,\ldots,n, \tag{7.7}$$

and let $\pi_n : I\!R^n\longrightarrow C(\Sigma)$ be a prolongation operator, e.g., by means of spline interpolation of some appropriate order. We let $\Pi_n=\pi_nr_n$, and we assume that for all $F\in C(\Sigma)$,

$$\|F-\Pi_nF\|_{C(\Sigma)}\longrightarrow 0\quad\text{as } n\longrightarrow\infty; \tag{7.8}$$

cf. (6.5). This should not be too much of a requirement in view of (7.6). We need the following approximation number for the operator $\mathcal{K}$, viz.

$$\kappa_n=\sup\{\|(I-\Pi_n)\mathcal{K}f\| : \|f\|_{L^1(\Omega)}\leq 1\}, \tag{7.9}$$

which provides a measure of how well the data $[\mathcal{K}f](x_i)$, $i=1,2,\ldots,n$, describe the function $[\mathcal{K}f](x)$, $x\in\Sigma$. By (7.8) we have $\kappa_n\longrightarrow 0$ as $n\longrightarrow\infty$.

THEOREM 7.2. *Let $\varphi\in L^1(\Omega)$ be nonnegative, let $g\in C(\Sigma)$, and $g_i\equiv g(x_i)$ for all i. Suppose that f_o is bounded away from zero, and that f_o solves* (7.4). *Assume that f_o satisfies condition* (4.11). *Let f_n solve* (7.1). *Then $\{f_n\}_n$ converges to the solution of* (7.4), *and for some constant c depending on g and φ,*

$$\|f_n-f_o\|_{L^1(\Omega)}\leq c\kappa_n.$$

Proof. From Corollary 3.2 we get that

$$D(f_o,f_n)\leq D(f_o,\varphi)-D(f_n,\varphi)\leq\int_\Omega(f_o-f_n)\log\frac{f_o}{\varphi}.$$

By the assumption (4.11) the right-hand side may be written as $\int_\Sigma\varrho_o\mathcal{K}(f_o-f_n)$, and since $\Pi_n\mathcal{K}(f_o-f_n)=\Pi_n(g-\mathcal{K}f_n)=0$, this equals

$$\int_\Sigma\varrho_o[(I-\Pi_n)\mathcal{K}(f_n-f_o)]\leq\|\varrho_o\|\cdot\kappa_n\,\|f_n-f_o\|_{L^1(\Omega)}. \tag{7.10}$$

In the proof of the previous theorem (see (7.5)), it was shown that $D(f_n,\varphi)\leq D(f_o,\varphi)$, so that $\{f_n\}_n$ is bounded in $L^1(\Omega)$, see Lemma 2.3. Applying (1.7) to the left-hand side of (7.9) then results in the required estimate. □

Actual estimates follow from the theorem once the precise setting is specified, as in §6.

BIFURCATION FROM A PERIODIC ORBIT FOR A STRONGLY RESONANT REVERSIBLE AUTONOMOUS VECTOR FIELD*

MARIE-CHRISTINE PÉROUÈME[†]

Abstract. The author considers a reversible system admitting a symmetric periodic orbit such that the Jordan block belonging to the Floquet exponent zero is four-dimensional, nonsemisimple. Using the normal form theory around closed orbits, it is shown that, generically, such a solution is part of a one-parameter family of symmetric periodic orbits. The existence in such a system of two one-parameter families of symmetric solutions homoclinic to some periodic orbits is also proven. Finally, the author shows how this problem is related to the perturbed reversible 1-1 resonance vector fields, and allows its study to be completed.

Key words. reversible systems, Floquet exponents, normal form theory, integrable systems, homoclinic solutions, 1-1 resonance, Eckhaus instability

1. Introduction.

Let us consider a four-dimensional reversible system $du/dt = F(u)$ with a symmetry S such that $F(Su) = -SF(u)$, and let us assume that this system admits a *reversible or symmetric* T-periodic solution $u_0(t)$ such that $Su_0(t) = u_0(-t)$. It is proved in [6] that u_0 belongs to a one-parameter family of periodic solutions, and, therefore, the Floquet exponent zero attached to the solution u_0 is nonsemisimple. In [6], the author studied the case when the Jordan block belonging to the Floquet exponent zero of the operator $du/dt - DF\big(u_0(t)\big)u$ is two-dimensional; because of the reversibility the other exponents are $\pm\lambda$ with $\lambda \neq 0$ generically. He proved the persistence of the family of periodic solutions under small reversible perturbations as well as the existence of branches of subharmonic solutions when $\exp \lambda T$ is a root of unity. (A complete analysis was made in the case when $\exp \lambda T = -1$.)

In the present work we study the case when the Floquet exponent $\lambda \to 0$. More precisely, if we consider a family (parametrized by ν) of reversible systems with a reversible periodic orbit, the reversibility implies that for each value ν this system admits the Floquet exponents zero (nonsemisimple) and $\pm\lambda(\nu)$. Then, we only need ν to be a one-dimensional parameter to impose the value of λ to be zero at a prescribed value, say $\nu = 0$. As two eigenvalues collapse in a nonsimple way generically, the Jordan block belonging to the Floquet exponent zero is then of the type

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

So this singularity of a vector field is a priori of codimension one. Using the normal form theory for flows near closed orbits for an autonomous vector field as developed in [4], we shall give below a proof that it is in fact of codimension zero.

In §2, we compute *a reversible normal form around the periodic orbit.* It turns out that this four-dimensional normal form admits two first integrals and, therefore,

*Received by the editors January 20, 1992; accepted for publication (in revised form) January 5, 1993.

is *integrable*. We study extensively the reduced system, focusing on *periodic and homoclinic* solutions.

In §3, we prove that our original system admits in fact a family of symmetric periodic solutions, u_{ψ_0}, which stability changes type [semi-elliptic ↔ semihyperbolic] precisely at the solution u_0. Moreover, we prove that two symmetric homoclinic orbits are associated to each periodic solution of semihyperbolic type.

In §4, we study a small reversible perturbation of our system and prove that generically the solution u_0 is stable. It follows that the families of periodic and homoclinic orbits are also stable and that our singularity was in fact of codimension zero.

Finally, we give an example where such a situation occurs: in [5], studying the reversible 1-1 resonance, the authors proved the existence, in the supercritical case, of a point E, *the Eckhaus point*, where periodic solutions change type (elliptic ↔ hyperbolic). In §5, we prove that at the point E, *the Jordan block belonging to the Floquet exponent zero is four-dimensional.* We then compute the first coefficient of the expansion of the normal form to prove that generically the study of the neighborhood of the Eckhaus point falls within the scope of §§3 and 4. So our Fig. 1 is just the same as Fig. 3 of [5], but here we look at a different scaling. Finally, the present study completes the study of the neighborhood of the point E of [5].

2. The "reversible normal form."

2.1. The derivation of the reduced equation. Consider a four-dimensional differential equation

$$\frac{dx}{dt} = F(x), \tag{2.1}$$

where $x \in \mathbb{R}^4$ and F is a *reversible* vector field. That is, we assume that there exists a symmetry S in $GL(\mathbb{R}^4)$ such that $S^2 = \mathrm{Id}_{\mathbb{R}^4}$, and

$$F(Sx) = -SF(x). \tag{2.2}$$

This implies that if $x(t)$ is a solution of (2.1), so is $\tilde{x}(t) =: Sx(-t)$. A solution such that $x = \tilde{x}$ will be called *a reversible solution.*

Let us make the following assumptions.

(H_1) Equation (2.1) admits a reversible solution, periodic of period T, say $u_0(t)$. We shall denote by

$*L(t) =: D_xF\big(u_0(t)\big)$, the linearized operator around the periodic solution,

$*\mathcal{S}(t)$, the fundamental linear operator, solution of the equation

$$\begin{aligned} \frac{d}{dt}\mathcal{S}(t) &= L(t)\mathcal{S}(t), \\ \mathcal{S}(0) &= Id_{\mathbb{R}^4}, \end{aligned} \tag{2.3}$$

$*\mathcal{S}(T)$, the monodromy operator.

It can be easily proved that, as (2.1) is autonomous, $\dot{u}_0(t) = \mathcal{S}(t)\dot{u}_0(0)$ and that, as a consequence, $\dot{u}_0(0)$ is an eigenvector of $S(T)$ belonging to the eigenvalue 1.

Our next assumption is as follows.

(H_2) The Jordan block belonging to the eigenvector $\dot{u}_0(0)$ is four-dimensional, i.e., as

$$\begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

According to [4], we can find a system of independent T-periodic vector-functions satisfying

$$\left(-\frac{d}{dt}+L(t)\right)\zeta_i(t)=\zeta_{i-1}(t), \qquad i=0\cdots 3, \quad \text{with the convention } \zeta_{-1}\equiv 0. \tag{2.4}$$

Note that $\zeta_0(t)=\dot{u}_0(t)$ and satisfies $\tilde{\zeta}_0=-\zeta_0$. It follows that $\tilde{\zeta}_1$ is a solution of the same equation as ζ_1. Then, we have $\tilde{\zeta}_1-\zeta_1=\alpha\zeta_0$ and replacing ζ_1 by $\zeta_1+(\alpha/2)\zeta_0$, we can assume that $\tilde{\zeta}_1=\zeta_1$. This now implies that $-\tilde{\zeta}_2$ is a solution of the same equation as ζ_2, i.e., that $\tilde{\zeta}_2+\zeta_2=\beta\zeta_0$. Applying $\tilde{}$, we can deduce that $\tilde{\zeta}_2+\zeta_2=\beta\tilde{\zeta}_0=-\beta\zeta_0$, i.e., that $\tilde{\zeta}_2=-\zeta_2$. Using the same argument, we finally prove that we can find the ζ_i's such that

$$S\zeta_i(-t)=(-1)^{i+1}\zeta_i(t). \tag{2.5}$$

It is proved in [4] that there exists a nonlinear change of variables (normal form) in the neighborhood of the periodic orbit $\Gamma =: \{u_0(t),\ t\in\mathbb{R}\}$:

$$x(t)=u_0(\tau)+\psi\zeta_1(\tau)+A\zeta_2(\tau)+B\zeta_3(\tau)+\Phi(\tau,y), \tag{2.6}$$

such that *at any arbitrary order* (2.1) becomes an autonomous system:

$$\begin{aligned}\frac{d\tau}{dt} &= 1+\psi+\mathrm{n}\,(y),\\ \frac{dy}{d\tau} &= L_0y+N(y),\end{aligned} \tag{2.7}$$

where

$$y=:\begin{pmatrix}\psi\\ A\\ B\end{pmatrix} \quad\text{and}\quad L_0=:\begin{pmatrix}0&1&0\\0&0&1\\0&0&0\end{pmatrix},$$

Φ is T-periodic and smooth in y, n is a polynomial, N is a polynomial vector function, Φ, n, and N are $O(|y|^2)$.

The normal form theory developed in [4] shows that n and N have to commute with $e^{\tau L_0^*}$; hence, it is proved in [2] that a good choice of n and N is as follows:

$$\begin{aligned}\mathrm{n}\,(y)&=n(\psi,A^2-2\psi B),\\ N(y)&=\begin{pmatrix}\psi P_1(\psi,A^2-2\psi B)\\ AP_1(\psi,A^2-2\psi B)+\psi P_2(\psi,A^2-2\psi B)\\ BP_1(\psi,A^2-2\psi B)+AP_2(\psi,A^2-2\psi B)+\psi P_3(\psi,A^2-2\psi B)\end{pmatrix},\end{aligned}$$

where P_j are polynomial in their arguments. In our case, as the system is reversible and as the ζ_i's satisfy (2.5), Φ can be choosen so that it respects the symmetry:

$$S':\begin{pmatrix}\psi\\ A\\ B\end{pmatrix}\mapsto\begin{pmatrix}\psi\\ -A\\ B\end{pmatrix}, \tag{2.8}$$

and N can be chosen so that the new system in (y,τ) is reversible with respect to S', i.e.,

$$\Phi(-\tau,S'y)=S\Phi(\tau,y), \qquad N(S'y)=-S'N(y), \tag{2.9}$$

which implies that $P_1 \equiv P_3 \equiv 0$.

Finally, up to *any arbitrary order* (2.1) can be written as

$$\tag{2.10}\begin{cases} \dfrac{d\tau}{dt} = 1 + \psi + n(\psi, A^2 - 2\psi B), \\ \dfrac{d\psi}{d\tau} = A, \\ \dfrac{dA}{d\tau} = B + \psi P(\psi, A^2 - 2\psi B), \\ \dfrac{dB}{d\tau} = AP(\psi, A^2 - 2\psi B). \end{cases}$$

By the expression *at an arbitrary order* we mean that (2.1) writes

$$\tag{2.11}\begin{cases} \dfrac{d\tau}{dt} = 1 + \psi + n(\psi, A^2 - 2\psi B) + \text{h.o.t}, \\ \dfrac{d\psi}{d\tau} = A + \text{h.o.t}, \\ \dfrac{dA}{d\tau} = B + \psi P(\psi, A^2 - 2\psi B) + \text{h.o.t}, \\ \dfrac{dB}{d\tau} = AP(\psi, A^2 - 2\psi B) + \text{h.o.t}, \end{cases}$$

where h.o.t stands for T-periodic functions which are $O(\|y\|^{N+1})$, with an arbitrary N.

The solution $u_0(t)$ of (2.1) now corresponds to the solution $y = 0$ of (2.10), and the linearized equation around the basic periodic solution for the transverse dynamics is

$$\tag{2.12}\frac{dy}{d\tau} = L_0 y.$$

We can sum up these results saying that we have found *a reversible normal form for* (2.1) *around the periodic orbit* Γ. For more results about reduction of vector fields with a periodic orbit, see [1].

2.2. Properties of the reduced equations. It is easy to check that (2.10) admits two first integrals:

$$\tag{2.13}\begin{cases} K = A^2 - 2\psi B, \\ H = B - G(\psi, K), \end{cases} \quad \text{where } G(\psi, K) =: \int_0^\psi P(s, K)ds.$$

As a consequence, (2.10) is integrable and can be written as

$$\tag{2.14}\begin{cases} \left(\dfrac{d\psi}{d\tau}\right)^2 = 2\psi\big(G(\psi, K) + H\big) + K, \\ \dfrac{dA}{d\tau} = G(\psi, K) + H + \psi P(\psi, K), \\ B = G(\psi, K) + H, \\ \dfrac{d\tau}{dt} = 1 + \psi + n\big(\psi, K\big). \end{cases}$$

Let us define $f(\psi, K, H) =: 2\psi\bigl(G(\psi, K) + H\bigr) + K$, in such a way that the equations satisfied by y are

$$\left\{\begin{aligned} \frac{d\psi}{d\tau} &= \varepsilon\sqrt{f(\psi, K, H)}, \\ \frac{dA}{d\tau} &= f'_\psi(\psi, K, H)/2, \qquad\qquad \text{with } \varepsilon = \operatorname{sgn} A. \\ \frac{dB}{d\tau} &= \varepsilon\sqrt{f(\psi, K, H)}P(\psi, K), \end{aligned}\right. \tag{2.15}$$

We can notice that fixed points of (2.15) are of the type

$$y = \begin{pmatrix} \psi_0 \\ 0 \\ B \end{pmatrix},$$

where (i) ψ_0 is a double root of the polynomial f, i.e., satisfies

$$\left\{\begin{aligned} 2\psi_0\bigl(G(\psi_0, K) + H\bigr) + K = 0, \\ G(\psi_0, K) + H + \psi_0 P(\psi_0, K) = 0, \end{aligned}\right. \tag{2.16}$$

and (ii) taking account of $A = dA/d\tau = 0$, B satisfies

$$B + \psi_0 P(\psi_0, -2\psi_0 B) = 0. \tag{2.17}$$

For ψ_0 small enough, it is possible to solve (2.17) with respect to B using the implicit function theorem. And finally, fixed points of (2.15) write

$$y = \begin{pmatrix} \psi_0 \\ 0 \\ B(\psi_0) \end{pmatrix},$$

where ψ_0 satisfies (2.16) and $B(\psi_0)$ (2.17). Now, letting ψ_0 be a double root of f, the linearized operator in y around the corresponding fixed point is

$$L(\psi_0) = \begin{pmatrix} 0 & 1 & 0 \\ P_0 + \psi_0 P'_{\psi_0} - 2\psi_0 B(\psi_0) P'_K & 0 & 1 - 2\psi_0{}^2 P'_K \\ 0 & P_0 & 0 \end{pmatrix}, \tag{2.18}$$

where $P_0 = P\bigl(\psi_0, -2\psi_0 B(\psi_0)\bigr)$. Its eigenvalues are zero, due to the existence of a family of fixed points, and $\pm\lambda$, where

$$\lambda^2 = 2P_0 + \psi_0 P'_{\psi_0}. \tag{2.19}$$

2.3. Fixed points and homoclinic solutions of the reduced equations in the generic case. Let us present the expansions we use below:

$$P(\psi, K) = \alpha\psi + \beta K + \cdots, \tag{2.20}$$

$$f(\nu\psi, K, H) = \alpha\psi^3 + 2\beta K\psi^2 + 2H\psi + K + \cdots. \tag{2.21}$$

By "generic case" we mean the case $\alpha \neq 0$. The principal part, for small ψ_0, of the set where we find double roots for f is then given by (see Fig. 1)

$$\left\{\begin{aligned} K &= 2\alpha\psi_0{}^3, \\ H &= -3\alpha\psi_0{}^2/2, \end{aligned}\right. \tag{2.22}$$

and

$$\lambda^2 = 3\alpha\psi_0 + O(\psi_0{}^2). \tag{2.23}$$

The origin is a singular point, corresponding to a triple root of f, where all the eigenvalues vanish in a nonsimple way. The Jordan block corresponding to the eigenvalue zero is then three-dimensional.

If we complete our figure, adding the form of the graph of f and the eigenvalues of $L(\psi_0)$, it appears that there exists a one-parameter family of hyperbolic fixed points along the arc OG. This family can be parametrized by $\psi_0 > 0$, and we shall denote it by

$$y_{\psi_0} =: \begin{pmatrix} \psi_0 \\ 0 \\ B(\psi_0) \end{pmatrix}. \tag{2.24}$$

Let us also denote by $H(\psi_0), K(\psi_0)$, and λ_{ψ_0} the corresponding values of H, K, and λ. For each $\psi_0 > 0$ there exist orbits homoclinic to y_{ψ_0} which are of the type

$$h_{\psi_0}(\tau,\tau_0) =: \begin{pmatrix} \psi_0(\tau-\tau_0) \\ A(\psi_0(\tau-\tau_0)) \\ B(\psi_0(\tau-\tau_0)) \end{pmatrix} \quad \underset{\text{as } \tau\ \rightarrow\ \pm\infty}{\longrightarrow} \quad \begin{pmatrix} \psi_0 \\ 0 \\ B(\psi_0) \end{pmatrix}, \tag{2.25}$$

where (i) the function $\psi_0(\tau)$ is defined implicitly by the formula

$$|\tau| = \operatorname{sgn}\alpha \int_{\psi_0{}'}^{\psi_0(\tau)} \frac{ds}{\sqrt{f(s, K(\psi_0), H(\psi_0))}}, \tag{2.26}$$

(ii) $\psi_0{}'$ is the other root of f which is simple,

(iii) $A(\psi) = \operatorname{sgn}(\alpha(\psi - \psi_0{}'))\sqrt{f(\psi, K(\psi_0), H(\psi_0))}$, $B(\psi) = G(\psi, K(\psi_0)) + H(\psi_0)$.

It follows from the definition that $\psi_0(.)$ is an even function of τ and that $\psi_0(0) = \psi_0{}'$. As a consequence, $A(\psi_0(0)) = 0$, and among the homoclinic orbits one is reversible: the one corresponding to the choice $\tau_0 = 0$. We shall denote it by $h_{\psi_0}(\tau)$.

3. Solution homoclinic to a periodic orbit in the generic case. In the same way as (2.10) leads to (2.15), which can be written as

$$\frac{dy}{d\tau} = F'(y), \tag{3.1}$$

(2.11) leads to

$$\frac{dy}{d\tau} = F'(y) + G'(y,\tau), \quad \text{with } G'(y,\tau) = O(\|y\|^{N+1}). \tag{3.2}$$

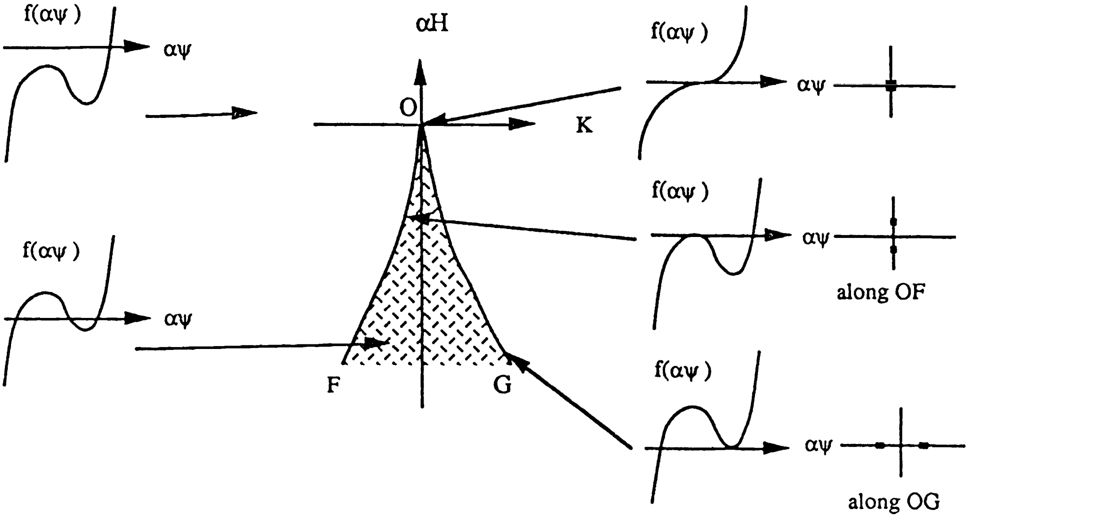

FIG. 1. *Different shapes of the graph of the function f and Floquet exponents of periodic orbits.*

Moreover, G' is T-periodic and reversible:

$$G'(S'y,-\tau) = -S'G'(y,\tau). \tag{3.3}$$

In the previous section, we proved that (3.1) admits reversible fixed points and homoclinic orbits. Our aim is now to prove their persistence for (3.2).

Each solution $y(\tau)$ of (3.2) leads to a one-parameter family of solutions of (2.1):

$$\begin{aligned} x(t) &= u_0(\tau) + \psi(\tau)\zeta_1(\tau) + A(\tau)\zeta_2(\tau) + B(\tau)\zeta_3(\tau) + \Phi(\tau, y(\tau)), \\ t &= \int_{\tau_0}^{\tau} \frac{d\tau}{1+\psi(\tau)+n(\psi(\tau),K)}. \end{aligned} \tag{3.4}$$

Note that $S\zeta_i(T/2) = (-1)^{i+1}\zeta_i(T/2)$. So, if $y(\tau)$ is a reversible solution of (3.2) among the corresponding family of solutions of (2.1) two are reversible: the one corresponding to the choice $\tau_0 = 0$ or $\tau_0 = T/2$.

3.1. Existence of periodic solutions. The proof of the existence of reversible periodic orbits of (3.2) will go in two steps.

The first step consists in controlling the size of the perturbed solutions close to some fixed point of (3.1). We shall follow in that part the proof of [5], that is, we shall show that such perturbed orbits are solutions of a functional equation, and solving this equation will give us, at the same time, the size of these solutions.

The second step will look for periodic reversible solutions. Our approach here will be different from the one of [5]: we shall not involve geometrical arguments but we shall show that the previous functional equation admits a solution in the space of periodic reversible functions.

Let us look for a solution of (3.2) of the form $y(\tau) = y_{\psi_0} + z(\tau)$, $\|z\| \ll \|y_{\psi_0}\| = O(\psi_0)$. Note that ψ_0 appears here as an additional free parameter. This allows us to choose $z(0)$ in any convenient direction transverse to $dy_{\psi_0}/d\psi_0$. And z has to satisfy

$$\frac{dz}{d\tau} - L(\psi_0)z = N(z) + R(z,\tau), \tag{3.5}$$

where $N(z) = F(y_{\psi_0} + z) - F(y_{\psi_0}) - L(\psi_0)z$, and $R(z,\tau) = G(y_{\psi_0} + z, \tau)$, or equivalently,

$$z(\tau) = e^{\tau L(\psi_0)}\xi + \int_0^\tau e^{(\tau - s)L(\psi_0)}\Big(N\big(z(s)\big) + R\big(z(s), s\big)\Big)ds, \tag{3.6}$$

with $\xi = z(0)$. We can notice that

$$\begin{aligned} N(z) &= O(\|z\|^2), \\ N(z) - N(z') &= O\big((\|z\| + \|z'\|) \cdot \|z - z'\|\big), \\ R(z,\tau) &= O({\psi_0}^{N+1}), \\ R(z,\tau) - R(z',\tau) &= O({\psi_0}^N \|z - z'\|). \end{aligned} \tag{3.7}$$

Then, if we denote by Θ_ξ the right-hand side of (3.6), and if we let z and z' in $\mathcal{C}_d$, the set of continuous functions $[-T/2, T/2] \rightarrow \mathrm{IR}^4$ such that $\|z\|_T =: \sup_{\tau \in [-T/2,T/2]} \|z(\tau)\| \leq d$, there exists M such that

$$\begin{aligned} \|\Theta_\xi z\|_T &\leq M\left(\|\xi\| + (d^2 + {\psi_0}^{N+1})\right), \\ \|\Theta_\xi z - \Theta_\xi z'\|_T &\leq M(d + {\psi_0}^N)\ \|z - z'\|. \end{aligned} \tag{3.8}$$

We see that one can always find ψ_0, d, and $\|\xi\|$ small enough for Θ_ξ to be a contraction on $\mathcal{C}_d$. Now, it is a classical result that, when Θ_ξ is a contraction, (3.6) admits an unique solution in $\mathcal{C}_d$, say z_ξ.

Moreover, due to the reversibility, $S'z_\xi(-t)$ is another solution of (3.6) starting at $S'\xi$ at $t = 0$, i.e.,

$$S'z_\xi(-t) = z_{S'\xi}(t).$$

It follows that if we choose $\xi \in \Pi =: \{y/\ S'y = y\}$, the corresponding z_ξ is reversible. And z_ξ will lead to a T-periodic solution of (3.2) if and only if it satisfies the additional condition $z_\xi(-T/2) = z_\xi(T/2) = S'z_\xi(T/2)$, i.e., if and only if

$$\begin{aligned} \Lambda_{\psi_0}\xi = &- \int_0^{T/2} e^{(T/2 - s)L(\psi_0)}\Big(N\big(z_\xi(s)\big) + R\big(z_\xi(s), s\big)\Big)ds \\ &- \int_{-T/2}^{0} e^{-(T/2 + s)L(\psi_0)}\Big(N\big(z_\xi(s)\big) + R\big(z_\xi(s), s\big)\Big)ds, \end{aligned} \tag{3.9}$$

where $\Lambda_{\psi_0} =: e^{(T/2)L(\psi_0)} - e^{-(T/2)L(\psi_0)}$. Notice that Λ_{ψ_0} is a linear operator mapping Π onto the one-dimensional subspace $\Delta =: \{y/\ S'y = -y\}$, and which nullspace is generated by $dy_{\psi_0}/d\psi_0$. Moreover, one can easily show that $S'L(\psi_0) = -L(\psi_0)S'$ and deduce that

$$S'e^{\tau L(\psi_0)} = e^{-\tau L(\psi_0)}S'.$$

So, for each $\xi \in \Pi$,

$$\begin{aligned}\int_{-T/2}^{0} & e^{-(T/2+s)L(\psi_0)}\Big(N\big(z_\xi(s)\big) + R\big(z_\xi(s), s\big)\Big)ds \\ &= -\int_{-T/2}^{0} S' e^{(T/2+s)L(\psi_0)}\Big(N\big(S' z_\xi(s)\big) + R\big(S' z_\xi(s), -s\big)\Big)ds \\ &= -S' \int_{0}^{T/2} e^{(T/2-s)L(\psi_0)}\Big(N\big(z_\xi(s)\big) + R\big(z_\xi(s), s\big)\Big)ds.\end{aligned}$$

It follows that the right-hand side of (3.9) belongs to Δ and (3.9) reduces in fact to a scalar equation. More precisely, let us denote by $\xi_{\lambda_{\psi_0}}$ and $\xi_{-\lambda_{\psi_0}} =: S'\xi_{\lambda_{\psi_0}}$ the eigenvectors of $L(\psi_0)$ belonging to the eigenvalues $\pm\lambda_{\psi_0}$. Then, $\xi \in \Pi$ writes

$$\xi = \mathsf{a}\frac{dy_{\psi_0}}{d\psi_0} + \mathsf{b}\left(\xi_{\lambda_{\psi_0}} + \xi_{-\lambda_{\psi_0}}\right).$$

As a consequence of our remark on the choice of $z(0)$, we can impose the transversality condition $\mathsf{a} = 0$, and (3.9) can be reformulated as

$$g(\mathsf{b}, \psi_0) = 0, \quad \text{with } g(0,0) = 0. \tag{3.10}$$

Noting that $e^{\tau L(\psi_0)}\xi_{\lambda_{\psi_0}} = e^{\lambda_{\psi_0}\tau}\xi_{\lambda_{\psi_0}}$ and $e^{\tau L(\psi_0)}\xi_{-\lambda_{\psi_0}} = e^{-\lambda_{\psi_0}\tau}\xi_{-\lambda_{\psi_0}}$, one can compute

$$\Lambda_{\psi_0}(\xi_{\lambda_{\psi_0}} + \xi_{-\lambda_{\psi_0}}) = 2\sinh\frac{T\lambda_{\psi_0}}{2}(\xi_{\lambda_{\psi_0}} - \xi_{-\lambda_{\psi_0}}).$$

So, applying (3.7) once again, (3.9) leads to

$$\mathsf{b}\sinh\frac{T\lambda_{\psi_0}}{2} + O(\mathsf{b}^2 + {\psi_0}^{N+1}) = 0, \tag{3.11}$$

or equivalently,

$$\mathsf{b} + O\left(\frac{\mathsf{b}^2 + {\psi_0}^{N+1}}{\lambda_{\psi_0}}\right) = 0. \tag{3.12}$$

This equation can be solved with respect to b provided that ${\psi_0}^{N+1}/\lambda_{\psi_0}^2$ is small enough. We then have $\|\xi\| = \mathsf{b} = O({\psi_0}^{N+1}/\lambda_{\psi_0})$. From (2.23), $\lambda_{\psi_0} = O({\psi_0}^{1/2})$, and, therefore, $\|\xi\| = O({\psi_0}^{2N+1/2})$. Now coming back to (3.8), provided that ${\psi_0}^{2N+1/2} \ll 1$, one can choose $d = O({\psi_0}^{2N+1/2})$. It means that if $N \geq 2$, for each value of $\psi_0 > 0$, small enough, (3.2) admits a reversible periodic solution, say $y_{\psi_0}(\tau)$. Remark that the bigger N is, the smaller one can choose d. This means that increasing the value of N, one improves the distance between the periodic solutions of (3.1) and (3.2).

Remark. Notice that the same analysis applies to prove the persistence of the family of fixed points of (2.1) occuring along the curve OF. The eigenvalues are then: zero, double, and two pure imaginary complex numbers, $\pm\iota\lambda'_{\psi_0}$ $[\psi_0 < 0, \lambda_{\psi_0} \in \mathbb{R}]$. All the calculations are the same except that we now choose $-\iota(\xi_{\lambda'_{\psi_0}} + \xi_{-\lambda'_{\psi_0}})$ as basis vector instead of $\xi_{\lambda_{\psi_0}} + \xi_{-\lambda_{\psi_0}}$, and we have to replace $\sinh(T\lambda_{\psi_0}2)$ by $\sinh(\iota T\lambda'_{\psi_0}/2) = -\sin(T\lambda'_{\psi_0}/2)$.

THEOREM. *The original solution u_0 is in fact part of a family of reversible periodic solutions, say u_{ψ_0}, which are of semi-elliptic type for $\psi_0 < 0$ and of semihyperbolic type for $\psi_0 > 0$.*

3.2. Existence of reversible homoclinic solutions. Here again, we shall follow the proof of [5]. However, in putting our system into a normal form, we have factored out the phase in our equations, we then have a quite simple way to express that we are looking for reversible homoclinic solutions.

Let us look for a solution of (3.2) of the form $y(\tau) = h_{\psi_0}(\tau) - y_{\psi_0} + y_{\psi_0}(\tau) + z(\tau)$. Then z has to satisfy

$$\frac{dz}{d\tau} - DF\big(h_{\psi_0}(\tau)\big)z = N'(z,\tau) + R'(z,\tau), \tag{3.13}$$

where

$$\begin{aligned}N'(z,\tau) =: &F\big(h_{\psi_0}(\tau) - y_{\psi_0} + y_{\psi_0}(\tau) + z(\tau)\big)\\ &- F\big(h_{\psi_0}(\tau)\big) - F\big(y_{\psi_0}(\tau)\big) - DF\big(h_{\psi_0}(\tau)\big)z,\end{aligned}$$

and

$$R'(z,\tau) =: G\big(h_{\psi_0}(\tau) - y_{\psi_0} + y_{\psi_0}(\tau) + z(\tau),\tau\big) - G\big(y_{\psi_0}(\tau),\tau\big).$$

We can prove estimations similar to estimations (3.7):

$$\begin{aligned}\|N'(z,\tau)\| &= O\left(\|z\|^2 + d\,\|z\| + d\,\|h_{\psi_0} - y_{\psi_0}\|\right),\\ \|N'(z,\tau) - N'(z',\tau)\| &= O\big((\|z\| + \|z'\| + d)\,\|z - z'\|\big),\\ \|R'(z,\tau)\| &= O\big({\psi_0}^{N+1}\,(\|z\| + \|h_{\psi_0} - y_{\psi_0}\|)\big),\\ \|R'(z,\tau) - R'(z',\tau)\| &= O\big({\psi_0}^{N}\,\|z - z'\|\big),\end{aligned} \tag{3.14}$$

where d is such that $\|y_{\psi_0}(\tau) - y_{\psi_0}\| \leq d$ and is assumed to be $\ll \psi_0$.

Notice that if z is a solution of (3.13) going to zero as $\tau \to \pm\infty$, the corresponding y a homoclinic solution of (3.2), we look for solutions of (3.11) in

$$E_\mu =: \left\{ z \Big/ \sup_{\tau\,\in\,\mathbb{R}} \|z(\tau)\| e^{\mu|\tau|} < +\infty \right\}, \qquad 0 < \mu < \lambda_{\psi_0},\ \mu \text{ close to } \lambda_{\psi_0}.$$

In order to solve (3.13), we need some information about the linearized equation around $h_{\psi_0}(\tau)$ which reads

$$\frac{dz}{d\tau} - DF\big(h_{\psi_0}(\tau)\big)z = 0. \tag{3.15}$$

Let $p_{\psi_0}(\tau) =: (\partial h_{\psi_0}/\partial\tau)(\tau)$, and $r_{\psi_0}(\tau) =: (\partial h_{\psi_0}/\partial\psi_0)(\tau)$, then one can easily check that both p_{ψ_0} and r_{ψ_0} are solutions of (3.15), such that

$$\begin{aligned}&\|p_{\psi_0}(\tau)\| \simeq e^{-\lambda_{\psi_0}\tau} \quad \text{as} \quad \tau \to +\infty, \quad S'p_{\psi_0}(-\tau) = -p_{\psi_0}(\tau),\\ &r_{\psi_0}(\tau) \to \frac{dy_{\psi_0}}{d\psi_0} \quad \text{as} \quad \tau \to +\infty, \quad S'r_{\psi_0}(-\tau) = r_{\psi_0}(\tau).\end{aligned}$$

Now, looking for instance at the Wronskian, one can see that (3.15) admits a solution $q_{\psi_0}(\tau)$ such that

$$S'q_{\psi_0}(-\tau) = q_{\psi_0}(\tau), \qquad \|q_{\psi_0}(\tau)\| \simeq e^{\lambda_{\psi_0}\tau} \quad \text{as} \quad \tau \to +\infty.$$

Let us denote by $(p^*_{\psi_0}, q^*_{\psi_0}, r^*_{\psi_0})$ the adjoint basis of $(p_{\psi_0}, q_{\psi_0}, r_{\psi_0})$. Then one can check that if z is a solution of the functional equation

$$\begin{aligned}z(\tau) = &\int_0^\tau \langle N'(z(s),s) + R'(z(s),s) \mid p^*_{\psi_0}(s)\rangle ds\; p_{\psi_0}(\tau)\\ &- \int_\tau^{+\infty} \langle N'(z(s),s) + R'(z(s),s) \mid q^*_{\psi_0}(s)\rangle ds\; q_{\psi_0}(\tau)\\ &- \int_\tau^{+\infty} \langle N'(z(s),s) + R'(z(s),s) \mid r^*_{\psi_0}(s)\rangle ds\; r_{\psi_0}(\tau),\end{aligned} \tag{3.16}$$

z is a solution of (3.13) lying in Π at $\tau = 0$, therefore a reversible solution. If we denote by Θ' the right-hand side of (3.16), and by $\|z\|_\mu =: \sup_{\tau \in \mathbb{R}} \|z(\tau)\| e^{\mu|\tau|}$ for $z \in E_\mu$, we now obtain, as for (3.8),

$$\begin{aligned}\|\Theta' z\|_\mu &\le \frac{M'}{\lambda_{\psi_0}} \left(\|z\|^2_\mu + (d + {\psi_0}^{N+1}) \frac{\lambda_{\psi_0}}{\lambda_{\psi_0} - \mu} \right)\\ \|\Theta' z - \Theta' z'\|_\mu &\le \frac{M'}{\lambda_{\psi_0}} \left(\|z\|_\mu + \|z'\|_\mu + (d + {\psi_0}^{N}) \frac{\lambda_{\psi_0}}{\lambda_{\psi_0} - \mu} \right) \|z - z'\|_\mu.\end{aligned} \tag{3.17}$$

We now recall that $\lambda_{\psi_0} = O({\psi_0}^{1/2})$ and that $d = O({\psi_0}^{2N+1/2})$, according to §3. Let us also set $\mu = \lambda_{\psi_0}(1-\epsilon)$. Then, provided that ${\psi_0}^{2N-1/2} \ll \epsilon$, we can find d' such that Θ' is a contraction on the ball of radius d' of E_μ. For instance, one can choose $d' = O({\psi_0}^N/\epsilon)$. So, if $N \ge 2$ and $\psi_0 > 0$ is small enough, (3.2) admits a reversible solution homoclinic to $y_{\psi_0}(\tau)$ and (2.1) admits two reversible solutions homoclinic to $u_{\psi_0}(t)$. Notice that the bigger N is, the smaller one can choose ϵ; it means that increasing the value of N, we can improve the exponential tendency of these homoclinic solutions towards the periodic orbit.

THEOREM. *Equation* (2.1) *admits two reversible solutions homoclinic to each periodic orbit of semihyperbolic type.*

4. Roughness.

We are now interested in proving that these families of periodic and homoclinic solutions of (2.1) are generically stable under small reversible perturbations. From the results of §3 it is enough to prove the persistence of a reversible periodic solution such that the Jordan block belonging to the Floquet exponent zero is of the same type as the one attached to u_0. The method we shall use derives from the implicit function theorem and will give at the same time a shorter proof of the existence of a family of periodic solutions of (2.1). But this method does not allow us to reach homoclinic orbits. Anyway, as we pointed out, the part in §3 where we compute explicitly the distance between periodic orbits of (3.1) and (3.2) is essential in proving the persistence of homoclinic orbits. This is the reason why we include the two proofs.

Let us consider a reversible perturbation of (2.1):

$$\frac{dx}{dt} = F(\nu, x), \qquad F(0,x) = F(x), \quad F(\nu, Sx) = -SF(\nu, x). \tag{4.1}$$

We wonder on which conditions (4.1) admits periodic reversible solutions of period close to T, say $T/(1+\psi)$ with $\psi \simeq 0$. Let us make the change on the time $\tau = (1+\psi)t$, so that we now look for T-periodic reversible solutions of

$$\frac{dx}{d\tau} = \frac{F(\nu, x)}{1+\psi}. \tag{4.2}$$

We can look for solutions of (4.2) of the form $x = u_0 + z$. Then z has to satisfy

$$\begin{aligned}\frac{dz}{d\tau} - D_xF(u_0)z &= \frac{F(\nu, u_0+z)}{1+\psi} - F(u_0) - D_xF(u_0)z \\ &= \nu D_\nu F(0,u_0) - \psi\zeta_0 + o(\|z\| + \nu + \psi).\end{aligned} \tag{4.3}$$

To solve this equation we need some information about the linearized operator

$$\mathcal{A} : z \mapsto -\frac{dz}{d\tau} + D_xF(u_0)z. \tag{4.4}$$

PROPOSITION. *Let C^0_T (respectively, C^1_T) the space of continuous (respectively, continuously derivable) vector T-periodic functions $\mathbb{R} \to \mathbb{R}^4$. Then $\mathcal{A} : C^1_T \to C^0_T$ is a Fredholm operator of index zero. His kernel is generated by ζ_0, and his image is the orthogonal of the space generated by ζ_3^* for the standard scalar product on C^0_T:*

$$\langle z \mid z'\rangle_T =: \frac{1}{T}\int_0^T \langle z(t) \mid z'(t)\rangle\, dt.$$

It follows that if we denote by C^+ (respectively, C^-) the space of vector functions such that $Sz(t) = z(-t)$ (respectively, $Sz(t) = -z(-t)$), $\mathcal{A}$ is an inversible operator $C^1_T{}^+ \to C^0_T{}^-$.

Proof. Let $\big(\zeta_0^*(t), \zeta_1^*(t), \zeta_2^*(t), \zeta_3^*(t)\big)$ be the adjoint basis of $\big(\zeta_0(t), \zeta_1(t), \zeta_2(t), \zeta_3(t)\big)$ for the standard scalar product on $\mathbb{R}^4$, and ${}^t\mathcal{A}$ the adjoint operator of $\mathcal{A}$:

$${}^t\mathcal{A} : z \mapsto \frac{dz}{d\tau} + {}^tD_xF(u_0)z. \tag{4.5}$$

Then one can easily check that

$${}^t\mathcal{A}\zeta_i^* = \zeta_{i+1}^*, \qquad i = 0\cdots 3, \quad \text{with the convention } \zeta_4^* \equiv 0. \tag{4.6}$$

Moreover, let $z \in C^1$ and $f \in C^0_T$. Then

$$\mathcal{A}z = f \text{ and } z \in C^1_T \text{ iff } \quad \begin{array}{lclcl} \dfrac{d\langle z \mid \zeta_3^*\rangle}{d\tau} &=& -\langle f \mid \zeta_3^*\rangle & \text{and} & \int_0^T \dfrac{d\langle z \mid \zeta_3^*\rangle}{d\tau} = 0, \\ \dfrac{d\langle z \mid \zeta_2^*\rangle}{d\tau} &=& -\langle f \mid \zeta_2^*\rangle + \langle z \mid \zeta_3^*\rangle & \text{and} & \int_0^T \dfrac{d\langle z \mid \zeta_2^*\rangle}{d\tau} = 0, \\ \dfrac{d\langle z \mid \zeta_1^*\rangle}{d\tau} &=& -\langle f \mid \zeta_1^*\rangle + \langle z \mid \zeta_2^*\rangle & \text{and} & \int_0^T \dfrac{d\langle z \mid \zeta_1^*\rangle}{d\tau} = 0, \\ \dfrac{d\langle z \mid \zeta_0^*\rangle}{d\tau} &=& -\langle f \mid \zeta_0^*\rangle + \langle z \mid \zeta_1^*\rangle & \text{and} & \int_0^T \dfrac{d\langle z \mid \zeta_0^*\rangle}{d\tau} = 0. \end{array} \tag{4.7}$$

It is easy to see that provided that $\langle f \mid \zeta_3^*\rangle_T = 0$, these equations admit a solution which is unique up to adding a multiple of ζ_0 and that this solution satisfies

$$\langle z \mid \zeta_{i+1}^*\rangle_T = \langle f \mid \zeta_i^*\rangle_T, \qquad i = 0, 1, 2. \tag{4.8}$$

This proves the first part of the proposition. The other is a consequence of the fact that $\mathcal{A}$ maps C^{1-} into C^{0+}, C^{1+} into C^{0-}, and $\zeta_0 \in C^{1-}, \zeta_3^* \in C^{1+}$.

Then, using the implicit function theorem, (4.3) can be solved with respect to $z \in \mathcal{C}_T^{1+}$ provided that ν and ψ are small enough. Let us denote by $z(\nu, \psi, \tau)$ this solution. The linearized equation around the corresponding T-periodic orbit of (4.3) writes

$$\frac{dz}{d\tau} = D_xF(\nu, u_0 + z(\nu, \psi))z/(1+\psi). \tag{4.9}$$

We shall denote by $\mathcal{S}(\nu, \psi, \tau)$ its fundamental matrix. Due to the existence of a family of periodic solutions, 1 is a Floquet multiplier of $\mathcal{S}(\nu, \psi, T)$ at least double nonsemisimple. Moreover, one can easily check that

$$\det \mathcal{S}(\nu, \psi, T) = \exp \int_0^T \operatorname{trace} D_xF(\nu, u_0 + z(\nu, \psi))/(1+\psi),$$

and that, due to the reversibility, $\det \mathcal{S}(\nu, \psi, T) = 1$. So, the other Floquet multipliers are, a priori, $\exp \pm T\lambda_{\nu,\psi}$, with $\lambda_{\nu,\psi} \in \mathbb{R}$ or $\iota\mathbb{R}$, and $\operatorname{trace} \mathcal{S}(\nu, \psi, T) = 2(1 + \cosh(T\lambda_{\nu,\psi}))$.

(All assertions concerning Floquet theory are proved in [3], and the way they are modified by reversibility is extensively studied in [6].)

For a given value of (ν, ψ) all the Floquet multipliers are 1 if and only if

$$\operatorname{trace} \mathcal{S}(\nu, \psi, T) = 4. \tag{4.10}$$

We then have $(\mathcal{S}(\nu, \psi, T) - \mathrm{Id}_{\mathbb{R}^4})^4 = 0_{\mathbb{R}^4}$, and, as $(\mathcal{S}(T) - \mathrm{Id}_{\mathbb{R}^4})^3 \neq 0_{\mathbb{R}^4}$, we still have $(\mathcal{S}(\nu, \psi, T) - \mathrm{Id}_{\mathbb{R}^4})^3 \neq 0_{\mathbb{R}^4}$. It follows that if (4.10) is satisfied the Jordan block belonging to the Floquet multiplier 1 is of the same type as the one attached to u_0. Now equation (4.10) can be solved with respect to ψ provided that

$$\operatorname{trace} \frac{\partial \mathcal{S}}{\partial \psi}(0, 0, T) \neq 0. \tag{4.11}$$

For the normal form, the Floquet exponents are computed in (2.23), and

$$\begin{aligned} \operatorname{trace} \mathcal{S}(\psi_0, T) &= 2(1 + \cosh(T\lambda_{\psi_0})), \\ \operatorname{trace} \frac{\partial \mathcal{S}}{\partial \psi_0}(\psi_0, T) &= 2T \sinh(T\lambda_{\psi_0}) \frac{d\lambda_{\psi_0}}{d\psi_0}. \end{aligned}$$

From (2.23), $2\lambda d\lambda/d\psi_0 \to 3\alpha$ as $\psi_0 \to 0$, and we can deduce that

$$\operatorname{trace} \frac{\partial \mathcal{S}}{\partial \psi_0}(0, T) = 3\alpha T^2. \tag{4.12}$$

We are now going to prove that (4.12) still holds for the complete equation (4.1).

Note that, from (4.3), $\partial z/\partial \psi(0, 0, \tau) \in \mathcal{C}_T^{1+}$ and is a solution of

$$-\frac{dz}{d\tau} + D_xF(u_0)z = \zeta_0.$$

It follows that

$$\frac{\partial z}{\partial \psi}(0, 0, \tau) = \zeta_1(\tau). \tag{4.13}$$

In the same way, from (4.9) and (4.13), $\partial\mathcal{S}/\partial\psi$ is a solution of

$$-\frac{dZ}{d\tau}+D_xF(u_0)Z=\big(D_xF(u_0)-D_{xx}F(u_0)\zeta_1\big)\mathcal{S},\qquad Z(0)=0.$$

It follows that

$$\frac{\partial\mathcal{S}}{\partial\psi}(0,0,\tau)=\mathcal{S}(\tau)\int_0^T\mathcal{S}^{-1}(s)\Big(D_{xx}F\big(u_0(s)\big)\zeta_1(s)-D_xF\big(u_0(s)\big)\Big)\mathcal{S}(s)ds. \tag{4.14}$$

Let $\Delta =: \big(D_{xx}F(u_0)\zeta_1-D_xF(u_0)\big)$. Then

$$\begin{aligned}\operatorname{trace}\frac{\partial\mathcal{S}}{\partial\psi}(0,0,T)&=\sum_{i=0}^{3}\int_0^T\langle\mathcal{S}(T)\mathcal{S}^{-1}(s)\Delta(s)\mathcal{S}(s)\zeta_i(0)\mid\zeta_i^*(0)\rangle\,ds\\&=\sum_{i=0}^{3}\int_0^T\langle\Delta(s)\mathcal{S}(s)\zeta_i(0)\mid{}^t\mathcal{S}^{-1}(s){}^t\mathcal{S}(T)\zeta_i^*(0)\rangle\,ds.\end{aligned}$$

One can easily check that $\mathcal{S}(s)\mathcal{S}^{-1}(T)=\mathcal{S}(s-T)$, and that ${}^t\mathcal{S}^{-1}(s)$ is the fundamental matrix of the adjoint equation ${}^t\mathcal{A}z=0$. As a consequence,

$$\begin{aligned}\mathcal{S}(s)\zeta_0(0)&=\zeta_0(s),\\\mathcal{S}(s)\zeta_1(0)&=\zeta_1(s)+T\zeta_0(s),\\\mathcal{S}(s)\zeta_2(0)&=\zeta_2(s)+T\zeta_1(s)+T^2\zeta_0(s)/2,\\\mathcal{S}(s)\zeta_3(0)&=\zeta_3(s)+T\zeta_2(s)+T^2\zeta_1(s)/2+T^3\zeta_0(s)/6,\\{}^t\mathcal{S}(s)^{-1}\zeta_0^*(0)&=\zeta_0^*(s)-T\zeta_1^*(s)+T^2\zeta_2^*(s)/2-T^3\zeta_3^*(s)/6,\\{}^t\mathcal{S}(s)^{-1}\zeta_1^*(0)&=\zeta_1^*(s)-T\zeta_2^*(s)+T^2\zeta_3^*(s)/2,\\{}^t\mathcal{S}(s)^{-1}\zeta_2^*(0)&=\zeta_2^*(s)-T\zeta_3^*(s),\\{}^t\mathcal{S}(s)^{-1}\zeta_3^*(0)&=\zeta_3^*(s).\end{aligned}$$

And we obtain

$$\begin{aligned}\operatorname{trace}\frac{\partial\mathcal{S}}{\partial\psi}(0,0,T)=&\,T^4\langle\Delta\zeta_0\mid\zeta_3^*\rangle_T/6+T^3\big(\langle\Delta\zeta_0\mid\zeta_2^*\rangle_T+\langle\Delta\zeta_1\mid\zeta_3^*\rangle_T\big)/2\\&+T^2\big(\langle\Delta\zeta_0\mid\zeta_1^*\rangle_T+\langle\Delta\zeta_1\mid\zeta_2^*\rangle_T+\langle\Delta\zeta_2\mid\zeta_3^*\rangle_T\big)\\&+T\big(\langle\Delta\zeta_0\mid\zeta_0^*\rangle_T+\langle\Delta\zeta_1\mid\zeta_1^*\rangle_T+\langle\Delta\zeta_2\mid\zeta_2^*\rangle_T+\langle\Delta\zeta_3\mid\zeta_3^*\rangle_T\big).\end{aligned}$$

Due to the reversibility, the scalar product in factor of T^3 and T are zero, and it remains that

$$\begin{aligned}\operatorname{trace}\frac{\partial\mathcal{S}}{\partial\psi}(0,0,T)=&\,T^4\langle\Delta\zeta_0\mid\zeta_3^*\rangle_T/6\\&+T^2\big(\langle\Delta\zeta_0\mid\zeta_1^*\rangle_T+\langle\Delta\zeta_1\mid\zeta_2^*\rangle_T+\langle\Delta\zeta_2\mid\zeta_3^*\rangle_T\big).\end{aligned}\tag{4.15}$$

Now, let us compute the coefficient α of the normal form.

Let $x=u_0+\psi\zeta_1+A\zeta_2+B\zeta_3+\Phi(\tau,y)$, then up to the order 2

$$\begin{aligned}F(x)=&\,\zeta_0+\psi D_xF(u_0)\zeta_1+AD_xF(u_0)\zeta_2+BD_xF(u_0)\zeta_3\\&+D_xF(u_0)\Phi+D_{x,x}F(u_0)(y,y)/2\end{aligned}\tag{4.16}$$

$$\begin{aligned}\frac{dx}{d\tau}=&\,\zeta_0+\psi\big(D_xF(u_0)\zeta_1-\zeta_0\big)+AD_xF(u_0)\zeta_2+BD_xF(u_0)\zeta_3\\&+\alpha\psi^2\zeta_2+\alpha A\psi\zeta_3+\frac{\partial\Phi}{\partial\tau}+A\frac{\partial\Phi}{\partial\psi}+B\frac{\partial\Phi}{\partial A}.\end{aligned}\tag{4.17}$$

If we expand

$$n(y) = \sum n_{i,j,k}\psi^i A^j B^k, \qquad \Phi(\tau, y) = \sum \Phi_{i,j,k}(\tau)\psi^i A^j B^k,$$

the identification of the terms of order ψ^2 in the equation

$$\big(1+\psi+n(y)\big)\frac{dx}{d\tau} = F(x), \tag{4.18}$$

leads to

$$\begin{aligned} -\Phi'_{2,0,0} + D_xF(u_0)\Phi_{2,0,0} =& n_{2,0,0}\zeta_0 - \zeta_0 + \alpha\zeta_2 + D_xF(u_0)\zeta_1 \\ & - D_{x,x}F(u_0)(\zeta_1,\zeta_1)/2. \end{aligned} \tag{4.19}$$

The solvability condition of this equation reads

$$\langle D_xF(u_0)\zeta_1 - D_{x,x}F(u_0)(\zeta_1,\zeta_1)/2 \mid \zeta_3^*\rangle_T = 0,$$

and is satisfied due to the reversibility. In the same way, the identification of the terms of order $A\psi$ leads to

$$\begin{aligned} -\Phi'_{1,1,0} + D_xF(u_0)\Phi_{1,1,0} =& n_{1,1,0}\zeta_0 + \alpha\zeta_3 + D_xF(u_0)\zeta_2 \\ & - D_{x,x}F(u_0)(\zeta_1,\zeta_2) + 2\Phi_{2,0,0}. \end{aligned} \tag{4.20}$$

The solvability condition now reads

$$\alpha + \langle D_xF(u_0)\zeta_2 - D_{x,x}F(u_0)(\zeta_1,\zeta_2) \mid \zeta_3^*\rangle_T + 2\,\langle \Phi_{2,0,0} \mid \zeta_3^*\rangle_T = 0.$$

From (4.8) and (4.19), we get

$$\langle \Phi_{2,0,0} \mid \zeta_3^*\rangle_T = \alpha + \langle D_xF(u_0)\zeta_1 - D_{x,x}F(u_0)(\zeta_1,\zeta_1)/2 \mid \zeta_2^*\rangle_T,$$

and compute

$$\begin{aligned} 3\alpha =& \langle D_{x,x}F(u_0)(\zeta_1,\zeta_1) - 2D_xF(u_0)\zeta_1 \mid \zeta_2^*\rangle_T \\ & + \langle D_{x,x}F(u_0)(\zeta_1,\zeta_2) - D_xF(u_0)\zeta_2 \mid \zeta_3^*\rangle_T. \end{aligned} \tag{4.21}$$

It follows that

$$\begin{aligned} \operatorname{trace}\frac{\partial\mathcal{S}}{\partial\psi}(0,0,T) - 3\alpha T^2 =& T^4\big(\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_3^*\rangle_T - \langle D_xF(u_0)\zeta_0 \mid \zeta_3^*\rangle_T\big)/6 \\ & + T^2\big(\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_1^*\rangle_T - \langle D_xF(u_0)\zeta_0 \mid \zeta_1^*\rangle_T \\ & \quad + \langle D_xF(u_0)\zeta_1 \mid \zeta_2^*\rangle_T\big). \end{aligned}$$

Moreover, writing that $\zeta_2^* = {}^t\mathcal{A}\zeta_1^*$, one gets

$$\begin{aligned} \langle D_xF(u_0)\zeta_1 \mid \zeta_2^*\rangle_T =& \left\langle D_xF(u_0)\zeta_1 \;\middle|\; \frac{d\zeta_1^*}{d\tau} + {}^tD_xF(u_0)\zeta_1^* \right\rangle_T \\ =& -\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_1^*\rangle_T - \left\langle D_xF(u_0)\frac{d\zeta_1}{d\tau} \;\middle|\; \zeta_1^* \right\rangle_T \\ & + \langle D_xF(u_0)\zeta_1 \mid {}^tD_xF(u_0)\zeta_1^*\rangle_T \\ =& -\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_1^*\rangle_T \\ & + \left\langle -\frac{d\zeta_1}{d\tau} + D_xF(u_0)\zeta_1 \;\middle|\; \zeta_1^* \right\rangle_T \\ =& -\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_1^*\rangle_T \\ & + \langle D_xF(u_0)\zeta_0 \mid \zeta_1^*\rangle_T, \end{aligned}$$

i.e.,

$$\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_1^*\rangle_T - \langle D_xF(u_0)\zeta_0 \mid \zeta_1^*\rangle_T + \langle D_xF(u_0)\zeta_1 \mid \zeta_2^*\rangle_T = 0.$$

Writing that $\zeta_3^* = {}^t\mathcal{A}\zeta_2^*$, we obtain similarly

$$\langle D_{x,x}F(u_0)(\zeta_1,\zeta_0) \mid \zeta_3^*\rangle_T = \langle D_xF(u_0)\zeta_0 \mid \zeta_3^*\rangle_T\,.$$

As a consequence,

$$\text{trace}\,\frac{\partial\mathcal{S}}{\partial\psi}(0,0,T) = 3\alpha T^2. \tag{4.22}$$

We finally have stated the following.

THEOREM. *Generically if* $[\alpha \neq 0]$, *the solution* u_0 *and, therefore, the families of periodic and homoclinic orbits of* (2.1), *are stable under small reversible perturbations.*

5. Application to the reversible 1:1 resonance. Let us consider a four-dimensional differential equation

$$\frac{dX}{dt} = \mathcal{F}(\mu, X), \tag{5.1}$$

with a fixed point at the origin such that the linearized operator for $\mu = 0$ has a 1:1 resonance, i.e., such that

$$D_X\mathcal{F}(0,0) = \begin{pmatrix} 0 & -\omega_0 & 1 & 0 \\ \omega_0 & 0 & 0 & 1 \\ 0 & 0 & 0 & -\omega_0 \\ 0 & 0 & \omega_0 & 0 \end{pmatrix}. \tag{5.2}$$

In [5], the authors showed that if in addition the system is reversible, (5.1) can be put into *a normal form* that writes

$$\frac{dX}{dt} = \mathcal{F}'(\mu, X), \tag{5.3}$$

with

$$X = \begin{pmatrix} A \\ B \end{pmatrix}, \qquad A, B \in \mathbb{C},$$

$$\mathcal{F}'(\mu,X) = \begin{pmatrix} i\omega_0 A + B + iA\mathcal{P}\left(\mu, |A|^2, \frac{i}{2}(A\bar{B} - \bar{A}B)\right) \\ i\omega_0 B + iB\mathcal{P}\left(\mu, |A|^2, \frac{i}{2}(A\bar{B} - \bar{A}B)\right) + A\mathcal{Q}\left(\mu, |A|^2, \frac{i}{2}(A\bar{B} - \bar{A}B)\right) \end{pmatrix},$$

and $\mathcal{P}$, $\mathcal{Q}$ polynomial in their arguments such that $\mathcal{P}(0,0,0) = \mathcal{Q}(0,0,0) = 0$.

The system (5.3) is rotationally invariant, i.e.,

$$\mathcal{F}'(\mu, R_\phi X) = R_\phi \mathcal{F}'(\mu, X), \quad \text{where } R_\phi = e^{\phi L}, \quad \text{and} \quad L\begin{pmatrix} A \\ B \end{pmatrix} = \begin{pmatrix} iA \\ iB \end{pmatrix},$$

and admits two first integrals:

$$\begin{cases} \mathcal{K} = \frac{i}{2}(A\bar{B} - \bar{A}B), \\ \mathcal{H} = |B|^2 - \mathcal{G}(\mu, |A|^2, \mathcal{K}), \end{cases} \quad \text{where } \mathcal{G}(\mu, u, \mathcal{K}) =: \int_0^u \mathcal{Q}(\mu, s, \mathcal{K})ds. \tag{5.4}$$

If we define

$$x =: \Re e A e^{-i\omega_0 t} \quad y =: \Im m A e^{-i\omega_0 t}, \qquad \bar{X} = \begin{pmatrix} x \\ y \\ z \\ \mathcal{T} \end{pmatrix},$$
$$z =: \Re e B e^{-i\omega_0 t} \quad \mathcal{T} =: \Im m B e^{-i\omega_0 t},$$

then X is a solution of (5.3) if and only if $\bar{X}$ is a solution of

$$\frac{d\bar{X}}{dt} = \bar{\mathcal{F}}(\mu, \bar{X}), \tag{5.5}$$

with

$$\bar{\mathcal{F}}(\mu, \bar{X}) = \mathcal{F}'(\mu, \bar{X}) - \omega_0 L\bar{X} = \begin{pmatrix} - & y\mathcal{P}(\mu, u, \kappa) + z \\ & x\mathcal{P}(\mu, u, \kappa) + \mathcal{T} \\ - & \mathcal{T}\mathcal{P}(\mu, u, \kappa) + x\mathcal{Q}(\mu, u, \kappa) \\ & z\mathcal{P}(\mu, u, \kappa) + y\mathcal{Q}(\mu, u, \kappa) \end{pmatrix},$$

and $u = x^2 + y^2$, $\kappa = x\mathcal{T} - yz$.

It is proved in [5] that the system (5.5) admits periodic solutions of type

$$\bar{X}_\kappa(t) = R_{\alpha_\kappa t}\bar{X}_\kappa, \tag{5.6}$$

where

$$\bar{X}_\kappa = \begin{pmatrix} r_0 \\ 0 \\ 0 \\ r_1 \end{pmatrix}$$

satisfies

$$\mathcal{F}'(\mu, \bar{X}_\kappa) = (\omega_0 + \alpha_\kappa)L\bar{X}_\kappa. \tag{5.7}$$

The linearized equation around the periodic orbit $\mathcal{O} =: \{\bar{X}_\kappa(t)/t \in \mathbb{R}\}$ is

$$\frac{dZ}{dt} - \mathcal{L}_\kappa(t)Z = 0, \tag{5.8}$$

with $\mathcal{L}_\kappa(t) = D_{\bar{X}}\bar{\mathcal{F}}\big(\mu, \bar{X}_\kappa(t)\big) = D_X\mathcal{F}'\big(\mu, \bar{X}_\kappa(t)\big) - \omega_0 L$. If we let Z_λ be an eigenvector of $\mathcal{L}_\kappa =: D_X\mathcal{F}'(\mu, \bar{X}_\kappa) - (\omega_0 + \alpha_\kappa)L$, belonging to the eigenvalue λ, then $Z_\lambda(t) =: R_{\alpha_\kappa t}Z_\lambda$ is a solution of

$$\frac{dZ}{dt} - \mathcal{L}_\kappa(t)Z = \lambda Z.$$

This proves that the Floquet exponents of (5.8) are mod. $\iota\alpha_\kappa$, the eigenvalues of $\mathcal{L}_\kappa$. Moreover, one can compute

$$\mathcal{L}_\kappa = \begin{pmatrix} 0 & \frac{r_1}{r_0} & 1 & 0 \\ a + c & 0 & 0 & \frac{r_0}{r_1}c \\ \lambda^2 - \frac{r_1}{r_0}(a - b + c) & 0 & 0 & b - c \\ 0 & -\left(\frac{r_1}{r_0}\right)^2 & -\frac{r_1}{r_0} & 0 \end{pmatrix}, \tag{5.9}$$

where

$$a = 2\left(\mathcal{P}'_u r_0^2 - \frac{r_1}{r_0}\right), \qquad b = \mathcal{Q}'_\kappa r_0^2 + 2\frac{r_1}{r_0},$$

$$c = \mathcal{P}'_\kappa r_0 r_1 + \frac{r_1}{r_0}, \qquad \lambda^2 = \mathcal{Q}'_u r_0^2 - 2\left(\frac{r_1}{r_0}\right)^2.$$

When $\lambda \neq 0$, the eigenvectors of $\mathcal{L}_{\mathcal{K}}$ are

$$X_{\pm\lambda} = \begin{pmatrix} \lambda \\ \pm a \\ \pm\lambda^2 \mp \frac{r_1}{r_0} a \\ \frac{r_1}{r_0}\lambda \end{pmatrix} \begin{matrix} \text{belonging to} \\ \text{the eigenvalue } \pm\lambda \end{matrix}, \quad LX_{\mathcal{K}} = \begin{pmatrix} 0 \\ r_{0_{\mathcal{K}}} \\ -r_{1_{\mathcal{K}}} \\ 0 \end{pmatrix} \begin{matrix} \text{belonging to} \\ \text{the eigenvalue zero.} \end{matrix}$$

Notice that the eigenvenvalue zero is not semisimple because, differentiating (5.7) with respect to $\mathcal{K}$, one obtains

$$\mathcal{L}_{\mathcal{K}} \frac{dX_{\mathcal{K}}}{d\mathcal{K}} = \frac{d\alpha_{\mathcal{K}}}{d\mathcal{K}} LX_{\mathcal{K}}. \tag{5.10}$$

According to (16) and (17) of [5] we have

$$u_{\mathcal{K}}^2 \mathcal{Q}(\mu, u_{\mathcal{K}}, \mathcal{K}) + \mathcal{K}^2 = 0, \qquad \alpha_{\mathcal{K}} = \mathcal{P}(\mu, u_{\mathcal{K}}, \mathcal{K}) + \frac{\mathcal{K}}{u_{\mathcal{K}}}. \tag{5.11}$$

We can deduce that

$$\frac{du_{\mathcal{K}}}{d\mathcal{K}} = \frac{-2\mathcal{K}}{\lambda^2 u_{\mathcal{K}}}, \qquad \frac{d\alpha_{\mathcal{K}}}{d\mathcal{K}} = \frac{1}{u_{\mathcal{K}}}\left(1 - \frac{a\mathcal{K}}{\lambda^2 u_{\mathcal{K}}}\right). \tag{5.12}$$

It is proved in [5] that in the supercritical case $[(\partial\mathcal{Q}/\partial u)(0,0,0) > 0]$, when $\mu > 0$, there exists a point (the Eckhaus point E of Fig. 3 in [5]), where $\lambda = 0$. As we get to this point, $\lambda \to 0$, $d\alpha_{\mathcal{K}}/d\mathcal{K} \to -\infty$ and all eigenvectors $X_{\pm\lambda}$ tend towards $LX_E =: LX_{\mathcal{K}_E}$. Moreover, when $\lambda = 0$ $[\mathcal{K} = \mathcal{K}_E]$, one can check that all eigenvalues of $\mathcal{L}_E =: \mathcal{L}_{\mathcal{K}_E}$ vanish and that, as $ab \neq 0$, $\mathrm{Ker}(\mathcal{L}_E)$ is one-dimensional, i.e., *the Jordan block belonging to the eigenvalue zero is four-dimensional.*

We are now going to define a rescaling so that all these "critical" periodic orbits we found for $\mu > 0$ appear for $\nu = 0$. Using the same notation, as in [5], we expand

$$\begin{aligned} \mathcal{P}(\mu, u, \mathcal{K}) &= \quad p_1\mu + p_2 u + p_3\mathcal{K} + \cdots \\ \mathcal{Q}(\mu, u, \mathcal{K}) &= -q_1\mu + q_2 u + q_3\mathcal{K} + \cdots \quad [q_1, q_2 > 0]. \end{aligned}$$

After the change of parameter $\nu^2 =: q_1\mu/3$, we get at the first order,

$$\begin{gathered} \mathcal{K}_E = \frac{2}{q_2}\left(\frac{q_1\mu}{3}\right)^{3/2} + \cdots = \frac{2}{q_2}\nu^3 + \cdots, \\ u_E = \frac{2}{q_2}^{1/3} \mathcal{K}_E^{2/3} + \cdots = \frac{2}{q_2}\nu^2 + \cdots, \\ a = -2\nu + \cdots, \ b = 2\nu + \cdots, \ c = \nu + \cdots, \end{gathered}$$

and

$$\mathcal{L}_E = \begin{pmatrix} 0 & \nu & 1 & 0 \\ -\nu & 0 & 0 & 1 \\ 3\nu^2 & 0 & 0 & \nu \\ 0 & -\nu^2 & -\nu & 0 \end{pmatrix}. \tag{5.13}$$

If we make the rescaling,

(5.14)

$$\hat{X} = \begin{pmatrix} \hat{x} \\ \hat{y} \\ \hat{z} \\ \hat{\tau} \end{pmatrix} = \begin{pmatrix} \frac{1}{\nu}x \\ \frac{1}{\nu}y \\ \frac{1}{\nu^2}z \\ \frac{1}{\nu^2}\tau \end{pmatrix}, \quad \hat{t} =: \nu t, \quad \hat{\mathcal{F}}(\nu, \hat{X}) = \begin{pmatrix} \frac{1}{\nu^2}\left(-y\mathcal{P}(\mu, u, \mathcal{K}) + z\right) \\ \frac{1}{\nu^2}\left(x\mathcal{P}(\mu, u, \mathcal{K}) + \tau\right) \\ \frac{1}{\nu^3}\left(-\tau\mathcal{P}(\mu, u, \mathcal{K}) + x\mathcal{Q}(\mu, u, \mathcal{K})\right) \\ \frac{1}{\nu^3}\left(z\mathcal{P}(\mu, u, \mathcal{K}) + y\mathcal{Q}(\mu, u, \mathcal{K})\right) \end{pmatrix},$$

then $\bar{X}$ is a solution of (5.5) if and only if $\hat{X}$ is a solution of

$$\frac{d\hat{X}}{d\hat{t}} = \hat{\mathcal{F}}(\nu, \hat{X}). \tag{5.15}$$

Note that

$$X_E = \begin{pmatrix} r_{0_E} \\ 0 \\ 0 \\ r_{1_E} \end{pmatrix}, \qquad \hat{X}_E = \sqrt{\frac{2}{\mathcal{Q}_2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix},$$

$$\mathcal{Q}(\mu, \mathcal{U}, \kappa) = \nu^2(\mathcal{Q}_2\hat{\mathcal{U}} - 3) + O(\nu^3), \quad \mathcal{P}(\mu, \mathcal{U}, \kappa) = O(\nu^2), \quad \alpha_\kappa = \nu + O(\nu^2), \tag{5.16}$$

$$\hat{\mathcal{F}}(0, \hat{X}) = \begin{pmatrix} \hat{\mathcal{Z}} \\ \hat{\mathcal{T}} \\ \hat{\mathcal{X}}(\mathcal{Q}_2\hat{\mathcal{U}} - 3) \\ \hat{\mathcal{Y}}(\mathcal{Q}_2\hat{\mathcal{U}} - 3) \end{pmatrix}.$$

So now the solutions $\bar{X}_E(t)$ of (5.5) correspond to the solution $\hat{X}_E(\hat{t}) = R_{\hat{t}}\hat{X}_E$ of (5.13), when $\nu = 0$. Moreover, our rescaling has been chosen in such a way that

$$\hat{\mathcal{L}}_E = \begin{pmatrix} 0 & 1 & 1 & 0 \\ -1 & 0 & 0 & 1 \\ 3 & 0 & 0 & 1 \\ 0 & -1 & -1 & 0 \end{pmatrix}. \tag{5.17}$$

The matrix $\hat{\mathcal{L}}_E$ is nilpotent of order 4, and a good choice of a Jordan basis for $\hat{\mathcal{L}}_E$ is as follows:

$$\hat{X}_0 = \frac{1}{\sqrt{2\mathcal{Q}_2}} \begin{pmatrix} 0 \\ 2 \\ -2 \\ 0 \end{pmatrix}, \qquad \hat{X}_1 = \frac{1}{\sqrt{2\mathcal{Q}_2}} \begin{pmatrix} -1 \\ 0 \\ 0 \\ 1 \end{pmatrix},$$

$$\hat{X}_2 = \frac{1}{\sqrt{2\mathcal{Q}_2}} \begin{pmatrix} 0 \\ 0 \\ -1 \\ 0 \end{pmatrix}, \qquad \hat{X}_3 = \frac{1}{\sqrt{2\mathcal{Q}_2}} \begin{pmatrix} -\frac{1}{4} \\ 0 \\ 0 \\ -\frac{1}{4} \end{pmatrix}.$$

If we let $\zeta_i(\hat{t}) = R_{\hat{t}}\hat{X}_i$, the relations $\hat{\mathcal{L}}_E\hat{X}_i = \hat{X}_{i-1}$ lead to

$$\begin{gathered} \zeta_0(\hat{t}) = \frac{dR_{\hat{t}}\hat{X}_E}{d\hat{t}}(\hat{t}), \\ \left(-\frac{d}{d\hat{t}} + \hat{\mathcal{L}}_E(\hat{t})\right)\zeta_i(\hat{t}) = \zeta_{i-1}(\hat{t}), \qquad i = 1, 2, 3. \end{gathered} \tag{5.18}$$

The adjoint basis of $(\hat{X}_0, \hat{X}_1, \hat{X}_2, \hat{X}_3)$ is

$$\hat{X}_0^* = \sqrt{2\mathcal{Q}_2} \begin{pmatrix} 0 \\ \frac{1}{2} \\ 0 \\ 0 \end{pmatrix}, \qquad \hat{X}_1^* = \sqrt{2\mathcal{Q}_2} \begin{pmatrix} -\frac{1}{2} \\ 0 \\ 0 \\ \frac{1}{2} \end{pmatrix},$$

$$\hat{X}_2^* = \sqrt{2\mathcal{Q}_2} \begin{pmatrix} 0 \\ -1 \\ -1 \\ 0 \end{pmatrix}, \qquad \hat{X}_3^* = \sqrt{2\mathcal{Q}_2} \begin{pmatrix} -2 \\ 0 \\ 0 \\ -2 \end{pmatrix}.$$

If we let $\zeta_i^*(\hat{t}) = R_{-\hat{t}}\hat{X}_i^*$, one can check that

$$\left(\frac{d}{d\hat{t}} + {}^t\hat{\mathcal{L}}_E(\hat{t})\right)\zeta_i^*(\hat{t}) = \zeta_{i+1}^*(\hat{t}), \qquad i = 0 \cdots 3. \tag{5.19}$$

Due to the expression of the ζ_i and ζ_i^* and the rotational invariance of $\hat{F}$, (4.21) takes the "simpler" form

$$\begin{aligned} 3\alpha = &\left\langle D_{\hat{x},\hat{x}}\hat{F}(\hat{X}_E)(\hat{X}_1,\hat{X}_1) - 2D_{\hat{x}}\hat{F}(\hat{X}_E)\hat{X}_1 \mid \hat{X}_2^*\right\rangle, \\ &\left\langle D_{\hat{x},\hat{x}}\hat{F}(\hat{X}_E)(\hat{X}_1,\hat{X}_2) - D_{\hat{x}}\hat{F}(\hat{X}_E)\hat{X}_2 \mid \hat{X}_3^*\right\rangle, \end{aligned}$$

with, according to (5.16),

$$D_{\hat{x}}\hat{F}(\hat{X}_E)\bar{X} = \begin{pmatrix} \hat{z} \\ \hat{T} \\ 3\hat{x} \\ -\hat{y} \end{pmatrix}, \qquad D_{\hat{x},\hat{x}}\hat{F}(\hat{X}_E)(\hat{X}_1,\hat{X}) = \begin{pmatrix} 0 \\ 0 \\ -3\hat{x} \\ -\hat{y} \end{pmatrix}.$$

This allows us to compute

$$\alpha = -4. \tag{5.20}$$

So, the study of the reversible 1:1 resonance enters into the frame of §§3 and 4 with $\alpha = -4$: in our problem the origin in the (H, K) plane is just the same as the point E in [5].

Acknowledgments. The author would like to thank André Vanderbauwhede for the attention he has paid to this work, and the referee for suggesting a great improvement to an earlier result.

CONTINUED FRACTION REPRESENTATIONS OF MAXIMAL AND MINIMAL SOLUTIONS OF A DISCRETE MATRIX RICCATI EQUATION*

CALVIN AHLBRANDT[†]

Abstract. Explicit constructions are given for the "maximal" solution W_n^+ and the "minimal" solution W_n^- of the discrete matrix Riccati equation

$$W_{n+1} = A_n + W_n(W_n + C_{n-1})^{-1}C_{n-1}$$

given "disconjugacy" of the associated self-adjoint linear difference equation

$$-\Delta(C_{n-1}\Delta x_{n-1}) + A_n x_n = 0.$$

These constructions provide characterizations of the recessive solutions at $-\infty$ and ∞ of the linear equation. In the special case where A_n and C_n are positive definite, the solutions W_n^+ and W_n^- have the simple continued fraction representations (using $D_n \equiv C_n^{-1}$)

$$W_n^+ = \lim_{M\to-\infty} \quad A_{n-1} + \frac{I}{D_{n-2}} + \frac{I}{A_{n-2}} + \frac{I}{D_{n-3}} + \cdots + \frac{I}{A_{M+1}} + \frac{I}{D_M}$$

and

$$-\frac{I}{W_n^-} = \lim_{N\to\infty} \quad D_{n-1} + \frac{I}{A_n} + \frac{I}{D_n} + \frac{I}{A_{n+1}} + \cdots + \frac{I}{A_{N-1}} + \frac{I}{D_{N-1}},$$

respectively. The periodic coefficient case provides a matrix extension of a result of Galois. Matrix extensions are also provided for continued fraction results of Euler and Pincherle.

AMS subject classifications. 39A10, 30B70, 11Y65

1. Introduction.

As in Ahlbrandt and Hooker, [5] and [6], consider a vector difference equation

$$-\Delta(C_{n-1}\Delta x_{n-1}) + A_n x_n = 0, \tag{1.1}$$

where A_n and C_n are $r \times r$ real symmetric matrices with C_n nonsingular for all integers n. The associated matrix difference equation is

$$-\Delta(C_{n-1}\Delta X_{n-1}) + A_n X_n = 0. \tag{1.2}$$

By expanding the forward differences, $(\Delta u_k = u_{k+1} - u_k)$, these equations have the form of symmetric, three term recurrence relations

$$-C_n x_{n+1} - C_{n-1}x_{n-1} + B_n x_n = 0 \tag{1.3}$$

*Received by the editors January 31, 1990; accepted for publication (in revised form) September 21, 1992.

[†]Department of Mathematics, University of Missouri, Columbia, Missouri 65211.

and

$$-C_nX_{n+1} - C_{n-1}X_{n-1} + B_nX_n = 0 \tag{1.4}$$

with $B_n = C_n + C_{n-1} + A_n$.

The corresponding discrete Riccati equation is

$$W_{n+1} = A_n + W_n(W_n + C_{n-1})^{-1}C_{n-1}. \tag{1.5}$$

Solutions X_n of (1.2) and W_n of (1.5) are related by

$$W_n = (C_{n-1}\Delta X_{n-1})X_{n-1}^{-1}. \tag{1.6}$$

In previous joint work with Hooker [6] it was shown that a hypothesis of "eventual disconjugacy"of (1.1) implies existence of a recessive solution of (1.2) at ∞ and a corresponding "eventually minimal" Hermitian solution, W_n^-, of the Riccati equation (1.5). An analogous treatment will now be given for the recessive solution at $-\infty$ and the corresponding "primordial maximal" solution, W_n^+, of (1.5). This language is chosen because solutions which start outside the "interval" $[W_n^-, W_n^+]$ can be extensible. This contrasts with the continuous case where no solution can extend to the right if it starts below $W^-(t)$ nor extend to the left if it starts above $W^+(t)$. However, as a consequence of results of [6] and Theorem 6.1, below, it follows that under the disconjugacy hypothesis, any Hermitian solution W_n of (1.5) on $(-\infty, \infty)$ can violate the condition $W_n^- \leq W_n \leq W_n^+$ a finite number of times at most. The Riccati interpretation of the Reid constructions [36] of the recessive solutions will prove convergence of generalized, continued fraction representations for W_n^+ and W_n^-. These results for W_n^- also improve the previous results given in [6]. The general theory is then applied to special cases of periodic coefficients, positive-definite coefficients, and constant positive-definite coefficients. The latter case adds perspective to the results of [6], where the constant coefficient results were obtained by time-reversal methods. The results in the periodic case are related to a study of periodic and reverse periodic continued fractions by Merkes and Scott [28]. In particular, the result of Galois [18] cited there [28, Cor. 1, p. 26] suggested the aesthetic notational relationship of W_n^+ to W_n^- given in the abstract. Furthermore, it shows the dependence of the "minimal" solution upon present and future coefficients, whereas the "maximal" solution depends upon all past coefficients. Ryde [38, Chap. V, pp. 67–82] discussed relationships between finite continued fractions and their reciprocals (he called them "inverse" continued fractions).

Arscott [7], [8] also used the type of construction used by Reid [36] and Gautschi [19] in the study of the recessive solution of three term recursions arising in eigenvalue problems for periodic solutions of Mathieu's differential equation. Noncommutative continued fractions have been studied by Fair [15]–[17], and by Denk and Riederle [13]. Reference [13] includes an extensive bibliography. The question of "oscillation" of (1.2) was recently investigated by Chen and Erbe [10] and by Peterson and Ridenhour [32]. Peterson and Ridenhour [32, eq. (8)] point out that the Riccati equation can also be written in the form

$$\Delta W_n = A_n - W_n(W_n + C_{n-1})^{-1}W_n. \tag{1.7}$$

This shows that the iteration (1.5) carries Hermitian W_n to Hermitian W_{n+1}.

This work was motivated by more complicated Riccati equations arising in the discrete regulator problem; see, for example, Vaughan [44].

Theorem 8.1 makes possible an "analytic theory" formulation of matrix continued fractions. A theory of "symplectic continued fractions" is introduced in §13. That theory allows extensions of theorems of Euler and Pincherle to the matrix case. Theorem 13.1 equates convergence of a matrix continued fraction with convergence of an associated series. Theorem 13.2 establishes equivalence of existence of a recessive solution at ∞ with convergence of a continued fraction. It is to be noted that §13 requires no sign conditions on the coefficients, other than C_n nonsingular, and assumes no Sturmian theory. The experienced reader should start by reading §13.

2. Terminology and basic propositions.

The notation U' denotes the conjugate transpose of U.

PROPOSITION 2.1. *If U_n and V_n are solutions of* (1.2), *then the bracket function*

$$\begin{aligned}\{U_n, V_n\} &= U_n' C_{n-1}\Delta V_{n-1} - [C_{n-1}\Delta U_{n-1}]'V_n \\ &= U_{n-1}' C_{n-1} V_n - U_n' C_{n-1} V_{n-1}\end{aligned} \tag{2.1}$$

has $\Delta\{U_n, V_n\} = 0$; i.e., $\{U_n, V_n\}$ is constant. Also,

$$\{U_n, V_n\}' = -\{V_n, U_n\}. \tag{2.2}$$

Proposition 2.1 also holds for vector solutions. Vector solutions u and v are called *conjoined* [35] if $\{u_n, v_n\} = 0$. A vector solution u is called *self-conjoined* if $\{u_n, u_n\} = 0$. A matrix solution X is called *prepared* [23] (or self-conjoined) if $\{X_n, X_n\} \equiv 0$.

PROPOSITION 2.2 (variation of parameters). *If X_n is a solution of a homogeneous equation $\Delta X_{n-1} + F_n X_n = 0$ with X_n nonsingular for $M < n \leq N$, then Y_n is a solution of the nonhomogeneous equation $\Delta Y_{n-1} + F_n Y_n = G_n$ if and only if Y_n has the form $Y_n = X_n V_n$, $M < n \leq N$ with V_n a solution of the first-order equation*

$$\Delta V_{n-1} = X_{n-1}^{-1} G_n, \qquad M < n - 1 \leq N. \tag{2.3}$$

PROPOSITION 2.3 (reduction of order). *If X_n is any prepared solution of* (1.2) *with X_n nonsingular for $M < n \leq N$, then Y_n is a solution of* (1.2) *if and only if it has the form*

$$Y_n = X_n[P - S_{n,N}(X)Q], \qquad M < n \leq N \tag{2.4}$$

where

$$P = X_N^{-1} Y_N, \qquad Q = \{X_n, Y_n\} \tag{2.5}$$

and

$$S_{n,N}(X) = \begin{cases} 0, & n = N, \\ \sum_{k=n+1}^{N} (X_k' C_{k-1} X_{k-1})^{-1}, & n < N. \end{cases} \tag{2.6}$$

Furthermore, Y_n is prepared if and only if

$$P'Q = Q'P. \tag{2.7}$$

PROPOSITION 2.4. *If U_n is any solution of (1.2), then each of the $2r \times r$ matrices*

$$\mathcal{U}_n = \begin{bmatrix} U_n \\ C_{n-1}\Delta U_{n-1} \end{bmatrix}$$

has the same rank. In particular, if $\mathcal{U}_n$ has full column rank r at one point n, then $\mathcal{U}_n$ has rank r for all n.

A prepared solution U_n such that $\mathcal{U}_n$ has full rank is called a *prepared basis.*

3. Sturmian theory. Jerry Ridenhour and Allan Peterson have pointed out to the author that the definition of conjugate intervals used in [3]–[6] is not appropriate for Theorem 3.1 of [5]. The definition should be as follows: For integers p and q with $p < q$, the intervals $[p, p+1]$ and $[q, q+1]$ are *conjugate* if there exists a self-conjoined vector solution x_n of (1.1) such that

$$x_p' C_p x_{p+1} \le 0 \quad \text{and} \quad x_q' C_q x_{q+1} \le 0 \tag{3.1}$$

with $x_{p+1} \ne 0$ and $x_q \ne 0$. Equation (1.1) is called *disconjugate* on $[M-1, N]$ if the interval $[M-1, N]$ contains no pair of conjugate intervals.

THEOREM 3.1 (see [5]). *Assume A_n and C_n are real symmetric and C_n is nonsingular for all n. Let M and N be integers with $M < N-1$. Then the following conditions are equivalent.*

(i) *If u is a real vector solution of (1.1) on $[M, N]$ with $u_{M-1}' C_{M-1} u_M \le 0$ and $u_M \ne 0$, then*

$$u_n' C_n u_{n+1} > 0 \quad \textit{for } n = M, \ldots, N-1.$$

(ii) *If v is a real vector solution of (1.1) on $[M, N]$ with $v_{N-1}' C_{N-1} v_N \le 0$ and $v_{N-1} \ne 0$, then*

$$v_n' C_n v_{n+1} > 0 \quad \textit{for } n = M-1, \ldots, N-2.$$

(iii) *Equation (1.1) is disconjugate on $[M-1, N]$.*

(iv) *There exists a prepared matrix solution X_n of (1.2) on $[M, N]$ with real entries such that*

$$X_{n-1}' C_{n-1} X_n > 0 \quad \textit{for } n = M, \ldots, N.$$

(v) *There exists a sequence W_n of real symmetric matrices, defined for $n = M, \ldots, N+1$, with $W_n + C_{n-1} > 0$ for $n = M, \ldots, N$ satisfying the matrix Riccati equation (1.5) for $n = M, \ldots, N$.*

(vi) *The quadratic form $\mathcal{J}_2$ defined by*

$$\mathcal{J}_2[\eta] = \sum_M^N (\Delta\eta_{n-1})' C_{n-1} \Delta\eta_{n-1} + \eta_n' A_n \eta_n$$

is positive definite on the class of real vector sequences η with $\eta_{M-1} = 0 = \eta_N$.

Since the quadratic form $\mathcal{J}_2$ has a matrix representation, we have the following.

COROLLARY 3.1. *Disconjugacy on $(-\infty, \infty)$ is equivalent to the condition that the block tridiagonal matrix*

$$\begin{bmatrix} B_M & -C_M & \\ -C_M & \ddots & \ddots \\ & -C_{N-2} & B_{N-1} \end{bmatrix}$$

is positive definite for every M, N, with $M < N - 1$.

Hence this work is conceptually related to Wall's positive-definite continued fractions [45, Chap. IV]. Indeed, this condition will make all inverses exist in our matrix continued fractions. (The referee has pointed out that there is a "related but distinct" paper of MacNerney [27]. That paper extends many of the results of Wall's text [45, Chap. IV] on positive-definite continued fractions to continued fractions of operators.)

THEOREM 3.2 (Sturm separation theorem [6]). *Assume A_n and C_n are real symmetric matrices of order r with C_n nonsingular. If (1.1) is disconjugate on $[M-1, N]$ and U_n is any prepared basis, then the following applies:*

(i) *There exist at most r points m in $[M, N]$ such that U_m is singular; and*

(ii) *There exist at most r points m in $[M, N]$ for which there exist unit vectors $\pi(m)$ such that*

$$(\pi(m))' U_m' C_m U_{m+1} \pi(m) < 0.$$

COROLLARY 3.2. *Suppose (1.1) is disconjugate on $(-\infty, N]$ and U_n is a prepared basis. Then there exists an integer P in $(-\infty, N)$ such that*

$$U_n' C_n U_{n+1} > 0 \quad \text{on } (-\infty, P]. \tag{3.2}$$

In particular, U_n is nonsingular in some neighborhood of $-\infty$.

4. A Hartman-type construction of the recessive solution at $-\infty$.

We assume that (1.1) is disconjugate on some neighborhood of $-\infty$, say $(-\infty, N+1]$. Let X_n be the solution of (1.2) with

$$X_N = I, \qquad X_{N+1} = 0. \tag{4.1}$$

Then $X_n' C_n X_{n+1} > 0$, for $n \le N - 1$, by condition (ii) of Theorem 3.1. Apply Proposition 2.3 with $P = I$ and $Q = -I$ in order to define Y_n by (2.4). Then Y_n is prepared and

$$Y_n = X_n[I + S_{n,N}(X)] \quad \text{for } \le N, \tag{4.2}$$

where $S_{N,N}(X) = 0$ and $S_{n,N}(X) > 0$ for $n < N$. Furthermore, $S_{n,N}(X)$ increases as n decreases. Thus Y_n is nonsingular for $n \le N$ and the roles of X_n and Y_n can be reversed for the identity

$$X_n = Y_n[I - S_{n,N}(Y)] \quad \text{for } n \le N, \tag{4.3}$$

since the Q in this case is $\{Y_n, X_n\} = -\{X_n, Y_n\}' = -(-I)' = I$. Compare (4.2) and (4.3) for the identity

$$I = (I - S_{n,N}(Y))(I + S_{n,N}(X)), \qquad n \le N. \tag{4.4}$$

Since the second factor is increasing as n decreases and exceeds I for $n < N$, the first factor must be decreasing as n decreases and satisfy $0 < I - S_{n,N}(Y) < I$ for $n < N$. Thus $S_{n,N}(Y)$ is bounded above, Hermitian and increasing as n decreases; hence it has a positive-definite limit $S_{-\infty,N}(Y)$. (The solution Y is dominant at $-\infty$.) The *recessive solution* at $-\infty$ is formed as in [23], [2], and [6] (for the recessive solution at ∞) by defining a new solution by

$$Z_n = Y_n[S_{-\infty,N}(Y) - S_{n,N}(Y)], \qquad n \le N. \tag{4.5}$$

Then $Y_n^{-1}Z_n \to 0$ as $n \to -\infty$. Also, Z_n is nonsingular for $n \leq N$ and Z_n is prepared. Reverse the roles for

$$Y_n = Z_n[(S_{-\infty,N}(Y))^{-1} + S_{n,N}(Z)]. \tag{4.6}$$

Let μ be the maximum eigenvalue of $(S_{-\infty,N}(Y))^{-1}$. Then $Z_n^{-1}Y_n \leq \mu I + S_{n,N}(Z)$ and all eigenvalues of $S_{n,N}(Z)$ must go to ∞ as $n \to -\infty$. Thus

$$[S_{n,N}(Z)]^{-1} \to 0 \quad \text{as } n \to -\infty. \tag{4.7}$$

THEOREM 4.1. *Suppose A_n and C_n are real symmetric with C_n nonsingular for all n. Assume that* (1.1) *is disconjugate on* $(-\infty, N+1]$. *Then there exists a solution Z_n of* (1.2) *which is recessive at $-\infty$. It has the following properties*:

(i) *Z_n is nonsingular for $n \leq N$*;

(ii) *Z_n is prepared*;

(iii) *$Z_n'C_{n-1}Z_{n-1} > 0$ for $n < N$*;

(iv) *$[S_{n,N}(Z)]^{-1} \to 0$ as $n \to -\infty$*;

(v) *If Y_n is any prepared solution with $\{Y_n, Z_n\}$ nonsingular, then Y_n is nonsingular for n near $-\infty$ and $Y_n^{-1}Z_n \to 0$, as $n \to -\infty$.*

The proof of condition (v) is immediate from the proof of part (iii) of Theorem 4.1 of [6], given on pp. 19–20.

5. A Reid-type construction of the recessive solution at $-\infty$. Assume that (1.1) is disconjugate on $(-\infty, N+1]$. For $M < N$, let $U_n(M,N)$ denote the solution of (1.2) which satisfies the boundary conditions

$$U_M(M,N) = 0, \qquad U_N(M,N) = I. \tag{5.1}$$

Assume that Z_n is constructed as in the previous section. Without loss of generality, assume $Z_N = I$. Then there exists a matrix Q_M such that

$$U_n(M,N) = Z_n(I - S_{n,N}(Z)Q_M), \qquad n \leq N. \tag{5.2}$$

In particular, $n = M$ gives

$$Q_M = [S_{M,N}(Z)]^{-1} \to 0 \quad \text{as } M \to -\infty \tag{5.3}$$

and hence

$$Z_n = \lim_{M \to -\infty} U_n(M,N) \quad \text{for } n \leq N. \tag{5.4}$$

Thus there can be only one solution Z_n with $Z_N = I$ and property (iv) of Theorem 4.1.

Reid [36] used variational methods to establish that the recessive ("principal") solution at ∞ of a self-adjoint disconjugate linear matrix differential equation was generated as a limiting case of a two-point boundary-value problem. The author, while a student under Professor Reid, once asked him how he knew to use that construction. He replied that he was motivated by Sansone's discussion of the Thomas–Fermi equation. See Sansone [39, pp. 445–450] for a summary of the literature and a proof of existence and uniqueness of a solution of the boundary-value problem

$$x^{1/2}y'' = y^{3/2}, \quad y(0) = 1, \quad \lim_{x \to +\infty} y(x) = 0.$$

Reid's variational proof is patterned after the construction of Sansone. However, as done here, it requires less variational understanding to use Hartman's construction for existence and Reid's construction for uniqueness.

Gautschi [19] credits the analogous backward recurrence construction for the recessive solution of scalar difference equations to J.C.P. Miller. This method was also used by Olver and Sookne [29].

THEOREM 5.1. *Suppose A_n and C_n are real symmetric, C_n is nonsingular, and* (1.1) *is disconjugate on* $(-\infty, N+1]$. *Then the recessive solution Z_n of* (1.2) *with $Z_N = I$ is given by* (5.4) *for $U_n(M,N)$ the unique solution of* (1.2) *which satisfies the boundary conditions* (5.1).

6. Definition, properties, and construction of W_n^+.

Assume that (1.1) is disconjugate on $(-\infty, N+1]$ and Z_n is the recessive solution at $-\infty$ with $Z_N = I$. Then

$$Z_n' C_{n-1} Z_{n-1} > 0 \quad \text{for } n \le N, \tag{6.1}$$

and W_n^+ may be defined by

$$W_n^+ = (C_{n-1}\Delta Z_{n-1}) Z_{n-1}^{-1} \quad \text{for } n \le N+1. \tag{6.2}$$

Then

$$\begin{aligned} W_n^+ + C_{n-1} &= C_{n-1} Z_n Z_{n-1}^{-1} \\ &= (Z_{n-1}^{-1})'(Z_{n-1}' C_{n-1} Z_n) Z_{n-1}^{-1} > 0 \end{aligned} \tag{6.3}$$

for $n \le N$ and W_n^+ is a real symmetric solution of the Riccati equation

$$W_{n+1} = A_n + W_n (W_n + C_{n-1})^{-1} C_{n-1}. \tag{6.4}$$

Suppose that W_n is any other Hermitian solution of (6.4) which is left extensible. We now show that

$$W_n \le W_n^+ \tag{6.5}$$

for n in some neighborhood of $-\infty$. Let N be chosen so that $W_n + C_{n-1}$ is nonsingular for $n \le N$. Furthermore, it is possible to choose N so that $W_n + C_{n-1}$ is positive definite for $n \le N$. This is possible because of the corollary to the Sturm theorem, Theorem 3.2, applied to the solution X_n of (1.2) defined by $X_N = I$ and

$$X_{n-1} = (W_n + C_{n-1})^{-1} C_{n-1} X_n, \qquad n \le N, \tag{6.6}$$

which necessarily has

$$X_{n-1}'(W_n + C_{n-1}) X_{n-1} = X_{n-1}' C_{n-1} X_n > 0 \tag{6.7}$$

for n in some neighborhood of $-\infty$. Then, for N chosen as above, we have

$$Z_n = X_n (I - S_{n,N}(X) Q) \quad \text{for } n \le N. \tag{6.8}$$

For $U_n(M,N)$ as in (5.1), there exists a matrix Γ_M such that

$$U_n(M,N) = X_n (I - S_{n,N}(X)\Gamma_M), \qquad n \le N. \tag{6.9}$$

In particular, $\Gamma_M = (S_{M,N}(X))^{-1}$ and

$$Q = \lim_{M\to-\infty} \Gamma_M = \lim_{M\to-\infty} (S_{M,N}(X))^{-1}, \tag{6.10}$$

where

$$Q = \{X_n, Z_n\} = X'_{n-1}C_{n-1}Z_n - X'_nC_{n-1}Z_{n-1} = C_NZ_{N+1} - X'_{N+1}C_N \tag{6.11}$$

by using $n = N + 1$. Since we wish to compare W_n to W_n^+, note that

$$W_n^+ - W_n = C_{n-1}Z_nZ_{n-1}^{-1} - C_{n-1}X_nX_{n-1}^{-1}, \qquad n \le M + 1. \tag{6.12}$$

But $n = N + 1$ and $X'_{N+1}C_NX_N = X'_NC_NX_{N+1}$ give

$$W_{N+1}^+ - W_{N+1} = Q = \lim_{M\to-\infty} (S_{M,N}(X))^{-1} \ge 0 \tag{6.13}$$

with equality if and only if X is recessive at $-\infty$. Since N can be chosen arbitrarily close to $-\infty$ we have the "maximality" of W_n^+ stated in the following theorem.

THEOREM 6.1. *Suppose A_n and C_n are real symmetric, C_n is nonsingular and* (1.1) *is disconjugate on* $(-\infty, N + 1]$. *Then W_n^+, the solution of the Riccati equation* (6.4) *corresponding to any solution Z of* (1.2) *which is recessive at $-\infty$ has representation*

$$W_n^+ = \lim_{M\to-\infty} C_{n-1}(\Delta U_{n-1}(M, N))U_{n-1}^{-1}(M, N) \tag{6.14}$$

for $n \le N$. This solution W_n^+ has the "primordial maximality" property: For any left extensible Hermitian solution W_n of (6.4), *the inequality*

$$W_n \le W_n^+ \tag{6.15}$$

is satisfied on some neighborhood of $-\infty$.

7. Continued fraction representations of W_n^+.

The result of Theorem 6.1 could be restated in terms of any solution $U_n(M)$ with

$$U_M(M) = 0, \qquad U_{M+1}(M) \text{ nonsingular.} \tag{7.1}$$

Then $W_n(M)$, defined for $M + 2 \le n \le N$ by

$$W_n(M) = (C_{n-1}\Delta U_{n-1}(M))U_{n-1}^{-1}(M), \tag{7.2}$$

satisfies the Riccati equation

$$W_{n+1}(M) = A_n + W_n(M)[W_n(M) + C_{n-1}]^{-1}C_{n-1}, \qquad n = M + 2, \dots, N - 1. \tag{7.3}$$

If we wish to approximate W_N^+, then we need to know $W_{M+2}(M)$ in order to start the iteration (7.3). Rewrite (1.2) as

$$\begin{aligned} 0 &= -\Delta(C_{n-1}\Delta U_{n-1}(M)) + A_nU_n(M) \\ &= [-(C_n\Delta U_n)U_n^{-1} + (C_{n-1}\Delta U_{n-1})U_n^{-1} + A_n]U_n \\ &= [-W_{n+1}(M) + C_{n-1}(I - U_{n-1}U_n^{-1}) + A_n]U_n \end{aligned}$$

and choose n as $M+1$, for the starting value

$$W_{M+2}(M) = A_{M+1} + C_M \tag{7.4}$$

for the iteration (7.3).

THEOREM 7.1. *Suppose that N is such that* (1.1) *is disconjugate on* $(-\infty, N+1]$. *Then, for any positive real number ϵ, there exists an M in* $(-\infty, N-1)$ *such that the value of $W_N(M)$ defined by the iteration* (7.4), (7.3) *has*

$$||W_N^+ - W_N(M)||_2 < \epsilon. \tag{7.5}$$

This shows that computation of W_n^+ requires knowledge of all "previous" coefficients, namely, A_{n-1}, C_{n-2}, A_{n-2}, C_{n-3}, ... If the coefficients are periodic, then these computations are possible; results for the K-periodic case are given in §9.

8. Approximants as iterates of linear fractional transformations.

Define matrix linear fractional transformations T_n by

$$T_n(W) = A_n + W(W + C_{n-1})^{-1}C_{n-1} \ . \tag{8.1}$$

The approximant $W_N(M)$ of W_N^+ given in Theorem 7.1 can then be expressed in terms of these linear fractional transformations. Recall the iteration

$$W_{M+2}(M) = A_{M+1} + C_M \ , \tag{8.2}$$

$$W_{n+1}(M) = A_n + W_n(M)[W_n(M) + C_{n-1}]^{-1}C_{n-1}, \quad n = M+2, \dots, N-1. \tag{8.3}$$

Then

$$W_N(M) = T_{N-1} \circ T_{N-2} \circ \cdots \circ T_{M+3} \circ T_{M+2}(A_{M+1} + C_M). \tag{8.4}$$

Given an initial Hermitian matrix $\mathcal{Z}$, define the function $\mathcal{T}(\mathcal{Z})$ by

$$\mathcal{T}(\mathcal{Z}) = T_{N-1} \circ T_{N-2} \circ \cdots \circ T_{M+3} \circ T_{M+2}(\mathcal{Z}). \tag{8.5}$$

Then $\mathcal{T}(\mathcal{Z})$ is the result of starting the solution of the Riccati recurrence with $W_{M+2} = \mathcal{Z}$ and following it to the right to W_N. It will be shown that this expression can be written in terms of a linear fractional transformation involving $\mathcal{Z}$ and two solutions of the linear equation. These "analytic" methods are being developed for the treatment of the case of periodic coefficients of the next section.

The prototype for this construction is that of Wall [45, pp. 13–16]. We first summarize the relevant points of his definition of continued fractions as compositions of Möbius transformations.

Wall defines t_p by

$$t_0(w) = b_0 + w, \quad t_p(w) = \frac{a_p}{b_p + w}, \quad p = 1, 2, 3, \dots.$$

The associated continued fraction generated by

$$\lim_{n\to\infty} t_0 t_1 \cdots t_n(0), \quad \text{i.e.,} \quad \lim_{n\to\infty} t_0 t_1 \cdots t_{n+1}(\infty),$$

is

$$b_0 + \cfrac{a_1}{b_1 + \cfrac{a_2}{b_2 + \ddots}}.$$

The quantity

$$t_0 t_1 \cdots t_n(0) = b_0 + \cfrac{a_1}{b_1 + \cfrac{a_2}{b_2 + \ddots + (a_n/b_n)}}$$

is called the nth *approximant.* The 0th approximant is $t_0(0) = b_0$.

Composition of the linear fractional transformations gives

$$t_0 t_1 \cdots t_n(w) = \frac{A_{n-1}w + A_n}{B_{n-1}w + B_n},$$

where the quantities A_{n-1}, A_n, B_{n-1}, B_n satisfy the *fundamental recurrence formulas:*

$$\begin{aligned} A_{-1} &= 1, \quad A_0 = b_b, \quad B_{-1} = 0, \quad B_0 = 1; \\ A_{p+1} &= b_{p+1}A_p + a_{p+1}A_{p-1}, \\ B_{p+1} &= b_{p+1}B_p + a_{p+1}B_{p-1}, \end{aligned}$$

for $p = 0, 1, 2, \ldots$.

Finally, Wall inductively computes the determinant of the composite transformation $t(w) = t_0 t_1 \cdots t_n(w)$ by

$$\begin{vmatrix} A_{n-1} & A_n \\ B_{n-1} & B_n \end{vmatrix} = \begin{vmatrix} A_{n-1} & b_n A_{n-1} + a_n A_{n-2} \\ B_{n-1} & b_n B_{n-1} + a_n B_{n-2} \end{vmatrix} = -a_n \begin{vmatrix} A_{n-2} & A_{n-1} \\ B_{n-2} & B_{n-1} \end{vmatrix},$$

so that

$$A_{n-1}B_n - A_n B_{n-1} = (-1)^n a_0 a_1 \cdots a_n, \qquad n = 0, 1, 2, \ldots,$$

where a_0 must be taken equal to unity.

Note that in our case all the a_p are 1, so the determinants are all ±1. Since we are taking only every other approximant, we expect constancy of these determinants as functions of n.

The essential idea which we now emulate is that *the corresponding solution of the linear system gives "projective coordinates" for the approximants.* Given any two linearly independent matrix solutions U_n and V_n of the linear system (1.2), any other solution X_n may be expressed uniquely in terms of U_n and V_n. Corresponding to the initial-value problem

$$W_{M+2} = \mathcal{Z}, \quad W_{n+1} = T_n(W_n), \quad n \geq M + 2,$$

let X_n be defined as the corresponding solution of the linear equation defined by $X_{M+1} = I$ and

$$X_n = C_{n-1}^{-1}(W_n + C_{n-1})X_{n-1}, \qquad M + 2 \leq n \leq N. \tag{8.6}$$

Then $X_{M+2} = C_{M+1}^{-1}\mathcal{Z} + I$. Let U_n and V_n be the solutions of (1.2) which satisfy the initial conditions $U_{M+1} = I = U_{M+2}$ and $V_{M+1} = 0$, $V_{M+2} = C_{M+1}^{-1}$, respectively.

Then U_n and V_n are prepared with $\{U_n, V_n\} = I$. Thus, $X_n = U_n\Gamma_1 + V_n\Gamma_2$ for some constant matrices Γ_1 and Γ_2, namely, $\Gamma_1 = I$ and $\Gamma_2 = \mathcal{Z}$, i.e.,

$$X_n = U_n + V_n\mathcal{Z}. \tag{8.7}$$

Then

$$W_n = \{C_{n-1}(\Delta V_{n-1})\mathcal{Z} + C_{n-1}\Delta U_{n-1}\}\{V_{n-1}\mathcal{Z} + U_{n-1}\}^{-1}, \tag{8.8}$$

and we have shown the following.

THEOREM 8.1. *For N larger than $M+2$, the composite transformation $\mathcal{T}(\mathcal{Z})$ defined by* (8.5)*, which carries the solution starting at $W_{M+2} = \mathcal{Z}$ to $W_N = \mathcal{T}(\mathcal{Z})$, is the matrix linear fractional transformation of $\mathcal{Z}$ given by*

$$\mathcal{T}(\mathcal{Z}) = \{E\mathcal{Z} + F\}\{G\mathcal{Z} + H\}^{-1}, \tag{8.9}$$

where

$$\begin{aligned} &E = C_{N-1}\Delta V_{N-1}, \qquad F = C_{N-1}\Delta U_{N-1}, \\ &G = V_{N-1}, \qquad H = U_{N-1} \end{aligned} \tag{8.10}$$

for solutions U_n and V_n of (1.2) *with initial conditions*

$$U_{M+1} = I = U_{M+2} \quad \text{and} \quad V_{M+1} = 0, \quad V_{M+2} = C_{M+1}^{-1}, \tag{8.11}$$

respectively. Furthermore, the "determinant" of this transformation is

$$\begin{vmatrix} E & F \\ G & H \end{vmatrix} = E'H - G'F = I, \tag{8.12}$$

and we also have the remaining "symplectic" conditions

$$E'G - G'E = 0 \quad \text{and} \quad F'H - H'F = 0. \tag{8.13}$$

The concepts of symplectic matrices and associated linear fractional transformations will be discussed in §13.

9. K-periodic coefficients.

Suppose (1.1) is disconjugate on $(-\infty,\infty)$. Assume that the coefficients are K-periodic, i.e., for some positive integer K,

$$A_{n+K} = A_n, \quad C_{n+K} = C_n \qquad \text{for all } n. \tag{9.1}$$

Then as in [6, p. 2] or [37] maximality implies that $W_n^+ \geq W_{n\pm K}^+$ and hence W_n^+ is K-periodic. The iteration of Theorem 7.1 can be continued until convergence with only a finite number of coefficients. Indeed, set $M+2 = N-K$ in (7.4) and iterate by setting $W_{M+2} = W_N$.

THEOREM 9.1. *Suppose that* (1.1) *is disconjugate on $(-\infty,\infty)$ and K-periodic. In the following algorithm, W_N converges to W_N^+.*

(1) *Initialize by setting $W_{N-K} = A_{N-1} + C_{N-2}$. Then iterate by the following.*

(2) *For $n = N-K,\ldots,N-1$, set $W_{n+1} = A_n + W_n[W_n + C_{n-1}]^{-1}C_{n-1}$.*

(3) *Compare W_{N-K} with W_N. If they "agree," stop; else, set $W_{N-K} = W_N$ and return to* (2)*.*

Theorem 8.1 allows us to step from W_{N-K} to W_N by using the composite function $\mathcal{T}$. Then the problem is reduced to finding a fixed point for the linear fractional transformation $\mathcal{T}(\mathcal{Z})$. Other values of W_n can then be found by iterating the Riccati equation. This role of the linear equation is somewhat like the corresponding Floquet theory in linear ordinary differential equations with periodic coefficients.

THEOREM 9.2. *The algorithm of Theorem* 9.1 *can be replaced by the following: As above, set* $M+2=N-K$.

(1) *Initialize by setting* $\mathcal{Z}=A_{N-1}+C_{N-2}$.

(2) *For* $n=M+2,\ldots,N$ *compute the solutions* U_n *and* V_n *of* (1.2) *which satisfy the initial conditions* (8.11).

(3) *Compute* E, F, G, *and* H *by* (8.10).

(4) *Iterate by replacing* $\mathcal{Z}$ *by* $\mathcal{T}(\mathcal{Z})$ *of* (8.9) *until convergence.*

(5) *Replace* W_{N-K} *by* $\mathcal{Z}$.

(6) *For* $n=N-K,\ldots,N-1$, *set* $W_{n+1}=A_n+W_n[W_n+C_{n-1}]^{-1}C_{n-1}$.

The fact that, for our setting, a convergent periodic continued fraction converges to a solution of a quadratic equation

$$\mathcal{Z}\{G\mathcal{Z}+H\}=E\mathcal{Z}+F \tag{9.2}$$

is a generalization of Theorem 176 of Hardy [22]. (The converse of that result, Theorem 177 of Hardy [22], says that the continued fraction which represents a quadratic surd is periodic. According to Hardy [22, p. 152] that result is "Lagrange's most famous contribution to the theory.")

The special case of $K=1$ is the constant coefficient case.

COROLLARY 9.1. *Suppose* A_n *and* C_n *are constant and* (1.1) *is disconjugate on* $(-\infty,\infty)$. *Then* W_n^+ *is constant and satisfies the discrete algebraic Riccati equation*

$$W=A+W[W+C]^{-1}C. \tag{9.3}$$

Initialize by $W=A+C$ *and iterate by overwriting* W *with* $A+W[W+C]^{-1}C$ *repeatedly in order to obtain* W^+. *Furthermore, for any choice of the integer* K, *the algorithm of Theorem* 9.2 *can also be used on the constant coefficient case.*

We have shown that the periodic case can also be solved by reducing the problem to the solving of a matrix quadratic equation (9.2).

For noniterative solution methods for matrix quadratic equations of Hamiltonian form, see the papers of Potter [34], Vaughan [44], Hewer [24], Laub [26], and Byers [9], as well as the references contained therein.

10. Positive definite coefficients.

One case where we know that (1.1) is disconjugate on $(-\infty,\infty)$ is the case where

$$A_n>0,\qquad C_n>0\quad\text{for all } n. \tag{10.1}$$

Indeed, condition (vi) of Theorem 3.1 is immediate. (The tridiagonal matrix of the Corollary to Theorem 3.1 has a property which can be thought of as a generalization of diagonal dominance.) In this case the approximants $W_N(M)$ of Theorem 7.1 are positive definite and satisfy

$$W_{n+1}(M)=A_n+[C_{n-1}^{-1}+W_n^{-1}(M)]^{-1},\qquad n=M+2,\ldots,N-1. \tag{10.2}$$

This is because (7.4) makes $W_{M+2}(M) > 0$ and (7.3) inductively makes $W_{n+1}(M)$ positive definite if $W_n(M)$ is positive definite. Set $D_n = C_n^{-1}$ for the iteration:

$$\begin{aligned} &(10.3) \qquad W_{M+2}(M) = A_{M+1} + [D_M]^{-1} = A_{M+1} + \frac{I}{D_M}, \\ &\qquad\qquad W_{n+1}(M) = A_n + \frac{I}{D_{n-1} + \frac{I}{W_n(M)}}, \qquad n = M+2, \dots, N-1. \end{aligned}$$

Thus, in modern continued fraction notation,

$$(10.4) \qquad W_N(M) = A_{N-1} + \frac{I}{D_{N-2}\,+}\,\frac{I}{A_{N-2}\,+}\,\frac{I}{D_{N-3}\,+}\,\cdots\,+\,\frac{I}{A_{M+1}\,+}\,\frac{I}{D_M}$$

for $M + 2 \leq N$.

THEOREM 10.1. *Suppose A_n and C_n are positive definite on $(-\infty, \infty)$. Then* (1.1) *is disconjugate on $(-\infty, \infty)$ and for any n the approximants* ($D_n \equiv C_n^{-1}$)

$$(10.5) \qquad W_n(M) = A_{n-1} + \frac{I}{D_{n-2}\,+}\,\frac{I}{A_{n-2}\,+}\,\cdots\,+\,\frac{I}{A_{M+1}\,+}\,\frac{I}{D_M}$$

converge monotonically from above to W_n^+ as $M \to -\infty$. Furthermore, the approximants

$$(10.6) \qquad D_{n-1} + \frac{I}{A_n\,+}\,\frac{I}{D_n\,+}\,\frac{I}{A_{n+1}\,+}\,\cdots\,+\,\frac{I}{A_{N-1}\,+}\,\frac{I}{D_{N-1}}$$

converge monotonically from below to $-(W_n^-)^{-1}$ as $N \to \infty$, where W_n^- is the unique minimal solution of (1.5).

The unique, eventually minimal solution W_n^- corresponds to the recessive solution at ∞. It follows readily from Theorem 4.1 of [6] that the approximants are generated by

$$(10.7) \qquad W_n(N) = (C_{n-1}\Delta U_{n-1}(N))U_{n-1}^{-1}(N), \qquad n \leq N,$$

where $U_n(N)$ satisfies $U_N(N) = 0$ and $U_{N-1}(N)$ nonsingular. Then

$$W_N(N) = C_{N-1}(0 - U_{N-1}(N))U_{N-1}^{-1}(N) = -C_{N-1}$$

and

$$W_{n+1}(N) = A_n + W_n(N)[W_n(N) + C_{n-1}]^{-1}C_{n-1}, \qquad n < N.$$

Inducting to the left, $W_{n+1}(N)$ negative definite implies that

$$0 > W_{n+1}(N) - A_n = W_n(N)[W_n(N) + C_{n-1}]^{-1}C_{n-1}, \qquad n < N.$$

Hence, if $W_{n+1}(N)$ is negative definite, then $W_n(N)$ is nonsingular and satisfies

$$W_{n+1}(N) - A_n = [C_{n-1}^{-1} + W_n^{-1}(N)]^{-1} < 0.$$

Thus, for $n \leq N$,

$$W_n^{-1}(N) + D_{n-1} = -[A_n - W_{n+1}(N)]^{-1},$$

$W_n(N)$ is negative definite, and

$$-W_n^{-1}(N) = D_{n-1} + \frac{I}{A_n - W_{n+1}(N)} \tag{10.8}$$

for $n = N-1, N-2, \ldots$. Since $-W_N(N) = D_{N-1}^{-1}$, relation (10.6) follows by iterating (10.8). Convergence to $(W_n^-)^{-1}$ follows since the approximants $W_n(N)$, i.e.,

$$W_n(N) = -\left[D_{n-1} + \frac{I}{A_n} + \frac{I}{D_n} + \cdots + \frac{I}{D_{N-1}}\right]^{-1}$$

are known to converge to W_n^- as $N \to \infty$ [6, Thm. 4.1, part (v)].

COROLLARY 10.1. *Suppose A_n and C_n are positive definite and K-periodic. Then the iteration which starts with $W_n = A_{n-1} + C_{n-2}$ and iterates by*

$$W_n = A_{n-1} + \frac{I}{D_{n-2}} + \frac{I}{A_{n-2}} + \cdots + \frac{I}{A_{n-K}} + \frac{I}{D_{n-K-1}} + \frac{I}{W_n} \tag{10.9}$$

converges montonically from above to W_n^+. Convergence may be accelerated by using Theorem 9.2. The corresponding iteration which starts with $V_n = D_{n-1}$ and iterates by

$$V_n = D_{n-1} + \frac{I}{A_n} + \frac{I}{D_n} + \cdots + \frac{I}{D_{n+K-2}} + \frac{I}{A_{n+K-1}} + \frac{I}{V_n} \tag{10.10}$$

converges monotonically from below to $-(W_n^-)^{-1}$.

Note that (10.10) could be rewritten as

$$V_n = D_{n-K-1} + \frac{I}{A_{n-K}} + \frac{I}{D_{n-K}} + \cdots + \frac{I}{D_{n-2}} + \frac{I}{A_{n-1}} + \frac{I}{V_n}, \tag{10.11}$$

which generates the "reverse" periodic continued fraction to (10.9). Hence the above corollary provides a matrix interpretation of the scalar result of Galois [18] cited in [28, Cor. 1, p. 26]. Indeed, the results of §9 establish that for each n, there exists a matrix quadratic equation for which W_n^+ is a solution.

It is important to *not* write the continued fraction representation of W_n^+ of Theorem 10.1 as

$$W_n^+ = A_{n-1} + \frac{I}{D_{n-2}} + \frac{I}{A_{n-2}} + \frac{I}{D_{n-3}} + \cdots$$

since W_n^+ is obtained as a contraction (Perron [31, Chap. I, §4, pp. 10–16]) of this continued fraction. Indeed, these continued fractions can diverge even though their even and odd approximants converge. Wall has the following result [45, p. 28, Thm. 6.1]: If the series $\sum |b_p|$ converges, then the continued fraction

$$\frac{1}{b_1} + \frac{1}{b_2} + \frac{1}{b_3} + \cdots$$

diverges. The sequences of its even and odd numerators and denominators, A_{2p}, A_{2p+1}, B_{2p}, B_{2p+1}, converge to finite limits F_0, F_1, G_0, G_1, respectively, where

$$F_1G_0 - F_0G_1 = 1.$$

11. Positive-definite constant coefficients. In the case where A and C are positive-definite constant matrices, W_n^+ and W_n^- are of period 1, hence constant. The existence and uniqueness of W^+ and the relationship with W^- were obtained in [6, Thm. 8.1] by the method of time reversal. We summarize the known facts in light of the above continued fraction representations.

THEOREM 11.1. *Suppose A and C are positive definite. Then for $D = C^{-1}$,*

$$W^+ = \lim \quad A + \frac{I}{D} + \frac{I}{A} + \frac{I}{D} + \cdots + \frac{I}{D} \tag{11.1}$$

and

$$-W^- = \lim \quad \frac{I}{D} + \frac{I}{A} + \frac{I}{D} + \cdots + \frac{I}{D}. \tag{11.2}$$

In particular, $W^+ = A - W^-$. Furthermore, if W is any Hermitian solution of

$$W = A + W[W+C]^{-1}C, \quad i.e., \ WC^{-1}W - AC^{-1}W - A = 0, \tag{11.3}$$

then

$$W^- \leq W \leq W^+.$$

Also W^+ and W^- are the only solutions which are positive definite and negative definite, respectively.

The estimates $W^- > -C$ and $A < W^+ < A + C$ obtained in [6] are immediate from these continued fraction representations.

The two forms in (11.3) are equivalent since both are equivalent to

$$(W - A)C^{-1}(W + C) = W. \tag{11.4}$$

Indeed, if W is a solution of (11.4) and u is a vector with $(W + C)u = 0$, then $0 = (W - A)C^{-1}(W + C)u = Wu = -Cu$ and therefore $u = 0$. Thus, any solution W of (11.4) has $W + C$ nonsingular.

An example where additional Hermitian solutions of (11.3) exist is obtained by taking A and C as scalar matrices $A = aI_n$ and $C = cI_n$, with a and c positive. For w^+ and w^-, the positive and negative roots of

$$w^2 - aw - ac = 0,$$

we have $W^+ = w^+ I_n$ and $W^- = w^- I_n$. But (11.3) and (11.4) have 2^n solutions consisting of diagonal matrices W with diagonal entries chosen from w^+ and w^-.

12. Numerical methods. Numerical experiments with Matlab show that convergence of these continued fraction representations can be quite slow, although they are stable and preserve symmetry. In the variable coefficient case, one is faced with the difficult choice of how many "terms" are necessary. The continued fraction must be computed from "tail to head." A second try with more terms gives a feeling for how many significant digits have been achieved. If more terms are needed for a good estimate, then a completely new calculation must be carried out. This does give an idea of the rate of convergence and some feel for how far one is from convergence to machine precision. This difficulty of knowing how many terms and successively recomputing was addressed in the scalar case by Gautschi's "second" and "third" algorithms; see [19, §4, pp. 42–46].

Attention is now focused on the constant coefficient case. A few terms of the continued fraction representations of Theorem 10.1 can be used to provide starting values for the more rapidly convergent Newton's method. Consider the matrix function F defined by

$$F(W) = WDW - ADW - A, \tag{12.1}$$

where $D = C^{-1}$ and A are positive definite. Then

$$F(W + H) = F(W) + WDH + HDW - ADH + HDH. \tag{12.2}$$

If we neglect the "quadratic" term HDH and choose H so that $F(W + H) = 0$, then Newton's method is to replace W by $W + H$, where H satisfies

$$(A - W)DH - HDW = F(W). \tag{12.3}$$

If A and D are positive definite and $W > A$, then $A - W$ and W have no eigenvalues in common and (12.3) has exactly one solution H; furthermore, H is real symmetric. Indeed, use the numerically stable Cholesky decomposition of D, $D = LL'$, for L lower triangular with positive diagonal entries [20, p. 89] in order to rewrite (12.3) as

$$L'(A - W)LX - XL'WL = L'F(W)L$$

for $X = L'HL$ in order to obtain an equation of the form

$$XP + QX = R, \tag{12.4}$$

where P and Q are the negative-definite matrices $P = -L'WL$, $Q = L'(A - W)L$, and $R = L'F(W)L$. If we choose $q = (||P||_2 + ||Q||_2)/2$ in Smith's Algorithm [43], then (12.4) can be written in the form

$$(qI - Q)X(qI - P) - (qI + Q)X(qI + P) = -2qR. \tag{12.5}$$

Rewrite this equation as

$$X - UXV = S \tag{12.6}$$

for $U = (qI-Q)^{-1}(qI+Q)$, $V = (qI+P)(qI-P)^{-1}$, $S = -2q(qI-Q)^{-1}R(qI+P)^{-1}$. Then the solution X is given by

$$X = \sum_{k=1}^{\infty} U^{k-1}SV^{k-1}, \tag{12.7}$$

which converges since U and V have 2-norm less than 1 (see Smith [43, p. 199]). The solution X is obtained as the limit of the iteration $Y_0 = S$, $Y_{\nu+1} = Y_\nu + U^{2^\nu}Y_\nu V^{2^\nu}$. That is, Smith speeds up the convergence by repeatedly squaring U and V. Thus X gives H and W is replaced by $W + H$. The iteration can by started with W as any of the approximants of W^+ of (11.1). Then H can be obtained by Smith's algorithm. One step of the iteration (10.2) or Theorem 9.2 can be used to stabilize and symmetrize the iterations in between using the Newton method. It is to be noted that if $D^{1/2}$ were used instead of L, the Newton iteration would be unstable. While it is not obvious from (12.4) that H is symmetric, it is true that this solution H is also a solution of the Newton iteration for

$$G(W) = WDW - \tfrac{1}{2}ADW - \tfrac{1}{2}WDA - A.$$

That is,

$$(\tfrac{1}{2}A - W)DH + HD(\tfrac{1}{2}A - W) = G(W) = F(W).$$

For L as before, rewrite this as

$$L'(\tfrac{1}{2}A - W)DHL + L'HD(\tfrac{1}{2}A - W)L = L'F(W)L,$$

i.e., as

$$PK + KP = R$$

for $K = L'HL$, $P = L'(\frac{1}{2}A - W)L$, and $R = L'F(W)L$. Since P is negative definite if $W > A$, this equation has one and only one solution K, which must be symmetric since K also satisfies

$$K'P + PK' = R.$$

Furthermore, K and H are positive definite if $F(W)$ is positive definite. (See Hale [21, Lemma 1.5, p. 315].)

For A and D positive definite, W^+ must agree with the unique positive-definite solution of the symmetric equation, $G(W) = 0$ (see [6, pp. 33, 34] and Coppel [12]).

13. Pincherle's theorem for symplectic continued fractions.

A famous theorem due to Pincherle [33, Chap. III, §15, pp. 228–230] says that a three term recurrence relation has a recessive solution if and only if the associated continued fraction converges. See Jones and Thron [25, Appen. B] for a statement of this result. Jones and Thron call such a solution *minimal.* Pincherle used the terminology *integrale distinto.* (W. T. Reid later used the term *distinguished* for the corresponding solution of the Riccati differential equation.)

We now construct a theory of symplectic continued fractions in order to investigate the corresponding theorem for the self-adjoint case. We already know that under a disconjugacy hypothesis, we have a recessive solution at ∞, and the corresponding solution of the Riccati equation, W_n^-, has a continued fraction representation. The Fibonacci recurrence, $y_{n+1} = y_n + y_{n-1}$, when written in self-adjoint form

$$-(-1)^n y_{n+1} - (-1)^{n-1} y_{n-1} + (-1)^n y_n = 0, \tag{13.1}$$

where $c_n = (-1)^n$ and $b_n = (-1)^n = a_n$, has the recessive solution $y_n = r_2^n$, for r_2 the negative root of $r^2 = r + 1$, but it fails to be disconjugate on any neighborhood of ∞. Indeed, the sequence $\{c_n r_2^n r_2^{n+1}\}$ changes sign and the Sturm separation theorem (Theorem 3.2) implies that no real solution y_n can have $c_n y_n y_{n+1}$ positive in any neighborhood of ∞. (This can also be seen from the Legendre necessary condition given in [4]. For minimization problems, b_n must be nonnegative and for maximization problems, b_n must be nonpositive. Since $b_n = (-1)^n$, the Jacobi condition cannot be satisfied and every neighborhood of ∞ must contain conjugate intervals.) This example contrasts with differential equations where eventual disconjugacy is equivalent to existence of a recessive solution. Thus, for discrete problems, the question of criteria for existence of recessive solutions is more interesting than in the corresponding continuous theory. The purpose of this section is to investigate the question of extension of Pincherle's theorem to systems. Additional insight is provided for scalar self-adjoint recurrence relations.

As noted in Theorem 8.1, we are led to a class of linear fractional transformations of the form

$$T(Z) = (EZ + F)(GZ + H)^{-1} \tag{13.2}$$

whose coefficients satisfy

$$E'G = G'E, \quad F'H = H'F, \quad E'H - G'F = I. \tag{13.3}$$

Associated with the transformation T are the matrices $\mathcal{M}$ and $\mathcal{J}$ defined by

$$\mathcal{M} = \begin{bmatrix} E & F \\ G & H \end{bmatrix}, \quad \mathcal{J} = \begin{bmatrix} 0 & I \\ -I & 0 \end{bmatrix}. \tag{13.4}$$

The matrix $\mathcal{M}$ is called a *symplectic matrix* (Siegel [42]) if conditions (13.3) are satisfied, i.e., $\mathcal{M}'\mathcal{J}\mathcal{M} = \mathcal{J}$. Since this condition is equivalent to $\mathcal{M}^{-1} = -\mathcal{J}\mathcal{M}'\mathcal{J}$, the inverse of the symplectic matrix $\mathcal{M}$ is given by

$$\mathcal{M}^{-1} = \begin{bmatrix} H' & -F' \\ -G' & E' \end{bmatrix}. \tag{13.5}$$

Since $\mathcal{M}^{-1}$ is a two-sided inverse, conditions (13.3) are equivalent to

$$EF' = FE', \quad GH' = HG', \quad EH' - FG' = I. \tag{13.6}$$

Note that the symplectic matrices of order $2r$ form a group under multiplication. Associated with a symplectic matrix $\mathcal{M}$ is the *symplectic transformation* $T_{\mathcal{M}}$. It follows that

$$T_{\mathcal{M}_1} \circ T_{\mathcal{M}_2} = T_{\mathcal{M}_1\mathcal{M}_2}. \tag{13.7}$$

Hence, the symplectic transformations form a transformation group. We also write T_n for the transformation associated with a symplectic matrix $\mathcal{M}_n$. Note that $\mathcal{M}$ and $-\mathcal{M}$ give the same transformation T. (Seigel identifies these matrices.) Symplectic transformations are of special interest not only because the transformation $\mathcal{T}$ of §8 is symplectic, but because the transformations T_n defined by (8.1) are symplectic. Indeed, if we set $D_{n-1} = C_{n-1}^{-1}$, then the transformation

$$T_n(Z) = A_n + Z(Z + C_{n-1})^{-1}C_{n-1} \tag{13.8}$$

can be rewritten as

$$T_n(Z) = A_n + Z[D_{n-1}Z + I]^{-1} = \{A_n(D_{n-1}Z + I) + Z\}\{D_{n-1}Z + I\}^{-1},$$

i.e., in symplectic form,

$$T_n(Z) = (E_nZ + F_n)(G_nZ + H_n)^{-1}, \tag{13.9}$$

with associated symplectic matrix

$$\mathcal{M}_n = \begin{bmatrix} E_n & F_n \\ G_n & H_n \end{bmatrix} = \begin{bmatrix} A_nD_{n-1} + I & A_n \\ D_{n-1} & I \end{bmatrix}. \tag{13.10}$$

However, those transformations run the wrong direction since they were designed to approximate W_n^+. Thus we need to take a fresh start to compare with the usual Pincherle theorem.

Since Pincherle's theorem concerns the recessive solution at ∞, our continued fractions are motivated from the representation

$$(13.11)\quad -W_n^- = \lim_{N\to\infty} \frac{I}{D_{n-1}} + \frac{I}{A_n} + \frac{I}{D_n} + \frac{I}{A_{n+1}} + \cdots + \frac{I}{A_{N-1}} + \frac{I}{D_{N-1}},$$

which is valid when the A_n and D_n are positive definite.

Recall the definition of $\mathcal{T}$ given in (8.5), i.e.,

$$(13.12)\qquad \mathcal{T}(\mathcal{Z}) = T_{N-1} \circ T_{N-2} \circ \cdots \circ T_{M+3} \circ T_{M+2}(\mathcal{Z}).$$

In the statement of Pincherle's theorem given in Jones and Thron [25, p. 403], the continued fraction considered is

$$\frac{a_1}{b_1} + \frac{a_2}{b_2} + \cdots.$$

Thus, we will start with $\mathcal{M}_n$ for $n = 1$. Hence we set $M + 2 = 1$, i.e., $M = -1$, and replace $N - 1$ of (13.12) by N in order to define $\mathcal{T}_N$, for $N \geq 1$, by

$$(13.13)\qquad \mathcal{T}_N(\mathcal{Z}) = T_N \circ T_{N-1} \circ \cdots \circ T_1(\mathcal{Z}).$$

For each positive integer N define a transformation $\mathcal{S}_N$ by

$$\mathcal{S}_N(\mathcal{W}) = \mathcal{Z} \quad \text{provided } \mathcal{W}^{-1} = \mathcal{T}_N(-\mathcal{Z}).$$

Since all the matrices $\mathcal{M}_n$ are symplectic, they are invertible, and the transformation $\mathcal{S}_N$ is remarkably easy to invert, namely, $\mathcal{Z} = \mathcal{S}_N(\mathcal{W}) = -\mathcal{T}_N^{-1}(\mathcal{W}^{-1})$ is given by

$$(13.14)\qquad \mathcal{Z} = -T_1^{-1} \circ T_2^{-1} \circ \cdots \circ T_N^{-1}(\mathcal{W}^{-1}).$$

Let us denote T_n^{-1} by s_n. Then

$$(13.15)\qquad \mathcal{S}_N(\mathcal{W}) = -s_1 \circ s_2 \circ \cdots \circ s_N(\mathcal{W}^{-1}),$$

where, because of (13.5) applied to (13.10), s_n has coefficient matrix

$$(13.16)\qquad \mathcal{M}_n^{-1} = \begin{bmatrix} I & -A_n \\ -D_{n-1} & D_{n-1}A_n + I \end{bmatrix}.$$

Application of Theorem 8.1 with $N - 1$ replaced by N gives the alternative representation of $\mathcal{T}_N$

$$(13.17)\qquad \mathcal{T}_N(\mathcal{Z}) = \{C_N \Delta V_N \mathcal{Z} + C_N \Delta U_N\}\{V_N \mathcal{Z} + U_N\}^{-1},$$

for solutions U_n and V_n of (1.2) with initial conditions

$$(13.18)\qquad U_0 = I = U_1 \quad \text{and} \quad V_0 = 0, \quad V_1 = C_0^{-1},$$

respectively. Since the coefficient matrix is symplectic, we have

$$\mathcal{S}_N(\mathcal{W}) = -\{U_N'\mathcal{W}^{-1} - (C_N\Delta U_N)'\}\{-V_N'\mathcal{W}^{-1} + (C_N\Delta V_N)'\}^{-1},$$

i.e.,

$$\mathcal{S}_N(\mathcal{W}) = \{-(C_N\Delta U_N)'\mathcal{W} + U_N'\}\{-(C_N\Delta V_N)'\mathcal{W} + V_N'\}^{-1}. \tag{13.19}$$

The relevant transformations involving s_n are given by

$$\begin{aligned} s_n(\mathcal{W}^{-1}) &= \{I - A_n\mathcal{W}\}\{-D_{n-1} + (D_{n-1}A_n + I)\mathcal{W}\}^{-1}, \\ s_n(\Theta) &= \{\Theta - A_n\}\{-D_{n-1}\Theta + (D_{n-1}A_n + I)\}^{-1}. \end{aligned} \tag{13.20}$$

We are now prepared to define the continued fraction approximants associated with the sequences of matrices A_n and D_n. We say that $\mathcal{S}_N(0)$ is the Nth *approximant.* For solutions U_n and V_n of (1.2) defined by the initial conditions (13.18) we have the characterization $\mathcal{S}_N(0) = U_N'(V_N')^{-1}$. But each of the T_n and s_n take Hermitian matrices to Hermitian matrices; hence $\mathcal{S}_N(0)$ is Hermitian and

$$\mathcal{S}_N(0) = V_N^{-1}U_N. \tag{13.21}$$

The corresponding *continued fraction* is the sequence of approximants $\{\mathcal{S}_N(0)\}$. We will say that the continued fraction *converges* if V_n is nonsingular for large n and the sequence of approximants has a (finite) matrix limit.

This compares favorably with the relation for $-W_1^-$ given in (13.11) when the coefficients are positive definite. Indeed, in that case

$$\mathcal{S}_1(0) = D_0^{-1} \tag{13.22}$$

and

$$\mathcal{S}_2(0) = \frac{I}{D_0} + \frac{I}{A_1} + \frac{I}{D_1}. \tag{13.23}$$

The iteration in this case, namely, $s_N(\mathcal{W}^{-1})|_{\mathcal{W}=0} = -D_{N-1}^{-1}$ and

$$s_n(\Theta) = -\{D_{n-1} + (A_n - \Theta)^{-1}\}^{-1},$$

allows one to see that (13.15) does yield approximants $\mathcal{S}_N(0)$ corresponding to the right-hand side of (13.11).

The above matrix approach to continued fractions depends heavily on the application of matrix representations of Möbius transformations to scalar continued fractions given by Schwerdtfeger [40], [41].

Another representation of the approximants results from a series interpretation of convergence. The following is related to Theorem 2.1 of Wall [45, pp. 17–18]. However, it is more closely related to the original paper of Pincherle [33, pp. 228–229].

From the bracket function identity, $\{U_n, V_n\} = I$, and relation (2.1) we have

$$U_{n-1}'C_{n-1}V_nV_{n-1}^{-1} - U_n'C_{n-1} = V_{n-1}^{-1}. \tag{13.24}$$

Since V_n is prepared, we may use $C_{n-1}V_nV_{n-1}^{-1} = (V_{n-1}')^{-1}V_n'C_{n-1}$ in (13.24) for the identity

$$U_{n-1}'(V_{n-1}')^{-1}V_n'C_{n-1} - U_n'C_{n-1} = V_{n-1}^{-1}.$$

Therefore,

$$U_{n-1}'(V_{n-1}')^{-1} - U_n'(V_n')^{-1} = V_{n-1}^{-1}C_{n-1}^{-1}(V_n')^{-1}. \tag{13.25}$$

Define R_n by $R_n = (V_{n+1}'C_nV_n)^{-1}$. Then R_n is Hermitian and for $p \geq 1$,

$$\mathcal{S}_{n+p}(0) = \mathcal{S}_n(0) - \sum_{k=0}^{p-1} R_{n+k}. \tag{13.26}$$

Hence, the continued fraction converges if and only if V_n is nonsingular for large n and the series

$$\sum_{k=n}^{\infty} R_k, \quad \text{i.e.,} \quad \sum_{k=n}^{\infty}(V_{k+1}'C_kV_k)^{-1}, \tag{13.27}$$

converges; furthermore, in case the continued fraction converges to a matrix Ω, then Ω is Hermitian and, for n chosen sufficiently large, we have

$$\Omega = V_n^{-1}U_n - \sum_{k=n}^{\infty}(V_{k+1}'C_kV_k)^{-1}. \tag{13.28}$$

These results are summarized as follows.

THEOREM 13.1 (Euler [14]). *Suppose that A_n and C_{n-1} are Hermitian with C_{n-1} nonsingular for $n \geq 1$. Let $D_n = C_n^{-1}$. For U_n and V_n the solutions of* (1.2) *which satisfy the initial conditions*

$$U_0 = I = U_1 \quad \textit{and} \quad V_0 = 0, \quad V_1 = C_0^{-1}, \tag{13.29}$$

assume that V_n is nonsingular for $n \geq M$. Then the approximants $\mathcal{S}_N(0)$, i.e., $V_N^{-1}U_N$, converge if and only if the series $\sum_{k=M}^{\infty}(V_{k+1}'C_kV_k)^{-1}$ converges. Furthermore, if the continued fraction converges to a matrix Ω, then Ω is Hermitian and is given by (13.28) *for $n \geq M$.*

For the history of the equivalence between convergence of continued fractions and convergence of series, see Perron [30, p. 18] and [31, pp. 16–20], and the original paper of Euler [14, p. 63].

We are now prepared to investigate the problem of generalizing Pincherle's theorem. Unfortunately, the development of the theory of recessive solutions given in §§4 and 5 depended upon disconjugacy and the resulting Sturm theorem. A prototype definition for our purposes might be that used by the author in [1, pp. 172–173]. That definition did not use the reduction of order formula. However, we can carry out a reduction of order formula here by using the solution V_n.

We generalize our definition of a recessive solution at ∞ to the following.

A solution Y_n of (1.2) is said to be *recessive at* ∞ if it satisfies the following conditions:

(i) Y_n is a prepared basis;

(ii) If X_n is any solution with $\{X_n, Y_n\}$ nonsingular, then X_n is nonsingular for large n and

$$X_n^{-1}Y_n \to 0 \quad \text{as } n \to \infty. \tag{13.30}$$

Hence, the right-hand counterpart of conclusion (v) of the above Theorem 4.1 is taken as a definition. Also, compare with condition (iv) of Theorem 4.1 of [6, p. 14].

THEOREM 13.2 (Pincherle [33]). *Assume the hypotheses of Theorem* 13.1. *If there exists a recessive solution of* (1.2) *with* Y_0 *nonsingular, then the partial denominators,* V_n*, are nonsingular for large* n *and the continued fraction converges. Conversely, suppose that the denominators* V_n *are nonsingular for large* n *and the continued fraction converges to* Ω*. Then there exists a recessive solution* Y_n *of* (1.2) *with* $Y_0 = I$*. Furthermore,* $\Omega = -C_0\Delta Y_0 = -W_1^-$.

Proof. Assume that (1.2) has a recessive solution Y_n with Y_0 nonsingular. Then, there exist constant matrices P and Q such that

$$Y_n = U_nP + V_nQ \quad \text{for } n = 0, 1, \ldots.$$

Indeed, $P = Y_0$ and $Q = (C_0)(Y_1 - P)$. Also $\{V_n, Y_n\} = -Y_0 = -P$ is nonsingular. Hence V_n is nonsingular for large n,

$$V_n^{-1}Y_nP^{-1} = V_n^{-1}U_n + QP^{-1},$$

and $V_n^{-1}U_n$ has a limit. Hence the continued fraction converges.

Conversely, assume that the continued fraction converges to Ω. Let Y_n be the solution defined by

$$Y_n = U_n - V_n\Omega. \tag{13.31}$$

We will show that Y_n is recessive at ∞. Since V_n is nonsingular for large n, we write

$$V_n^{-1}Y_n = V_n^{-1}U_n - \Omega$$

and observe that $V_n^{-1}Y_n \to 0$ as $n \to \infty$. From the initial conditions $Y_0 = I$, and $Y_1 = I - C_0^{-1}\Omega$, we see that $Y_0'C_0Y_1$ is Hermitian, hence Y_n is a prepared basis. Equation (13.28) gives the identity

$$U_n = V_n\Omega + V_n\sum_{k=n}^{\infty}(V_{k+1}'C_kV_k)^{-1}. \tag{13.32}$$

Substitution of this value of U_n in (13.31) gives

$$Y_n = V_n\sum_{k=n}^{\infty}(V_{k+1}'C_kV_k)^{-1}. \tag{13.33}$$

Now use V_n and Y_n as a basis. Suppose that X_n is a solution with $\{X_n, Y_n\}$ nonsingular. We first establish that there exist constant matrices P and Q such that

$$X_n = V_nP + Y_nQ. \tag{13.34}$$

Indeed, use $n = 0$ and $n = 1$ to conclude that $Q = X_0$ and $P = C_0X_1 + (C_0 - \Omega)X_0$. Then $\{X_1, Y_1\} = -P'$ and P is nonsingular. But the form of Y_n given in (13.33) implies that

$$X_n = V_n\left[P + \sum_{k=n}^{\infty}(V'_{k+1}C_kV_k)^{-1}Q\right]. \tag{13.35}$$

Since the series converges to 0 as $n \to \infty$, we conclude that $V_n^{-1}X_n \to P$ and consequently X_n is nonsingular for large n. Finally,

$$X_n^{-1}Y_n = [V_nP + Y_nQ]^{-1}Y_n = (P + V_n^{-1}Y_nQ)^{-1}V_n^{-1}Y_n \to 0.$$

Thus Y_n is recessive.

The computational value of these results is illustrated by the scalar example of the Fibonacci recurrence (13.1), where the recessive solution is $y_n = r_2^n$, for r_2 the negative root of $r^2 = r + 1$. The solution u_n of the initial-value problem $u_{n+1} = u_{n-1} + u_n$ with $u_0 = 1$, $u_1 = 1$, is the nth Fibonacci number; let us denote it by f_n. Then $v_n = f_{n-1}$ and $c_n = (-1)^n$. Thus (13.28) becomes

$$-w^- = \frac{f_n}{f_{n-1}} - \sum_{k=n}^{\infty}\frac{(-1)^k}{f_{k-1}f_k}.$$

Since the series is alternating with terms decreasing in magnitude to 0, the ratio of successive Fibonacci numbers f_n/f_{n-1} approximates $-w^-$ within $1/(f_{n-1}f_n)$. Furthermore, successive approximants provide a nest for the true value.

We now give the continued fraction representation of W_M^-. Let $U_{M,n}$ and $V_{M,n}$ be the solutions of (1.2) which satisfy the initial conditions

$$U_{M-1} = I = U_M \quad \text{and} \quad V_{M-1} = 0, \quad V_M = C_{M-1}^{-1}. \tag{13.36}$$

Make the definition

$$\mathcal{S}_{M,N}(\mathcal{W}) = -s_M \circ s_{M+1} \circ \cdots \circ s_N(\mathcal{W}^{-1}). \tag{13.37}$$

Then the approximants satisfy

$$\mathcal{S}_{M,N}(0) = V_{M,N}^{-1}U_{M,N} \tag{13.38}$$

and the following corollary gives a continued fraction representation of W_M^-.

COROLLARY 13.1. *Suppose that A_n and C_{n-1} are Hermitian with C_{n-1} nonsingular for $n \geq M$. If* (1.2) *has a recessive solution Y_n at ∞ with Y_{M-1} nonsingular, then the approximants $\mathcal{S}_{M,N}(0)$ are defined for large N and converge to $-W_M^-$.*

The above result extends Theorem 1.1 of Gautschi [19, p. 31]; see also part B of Theorem B.4 of Jones and Thron [25, p. 403]. Gautschi used continued fractions to estimate the Bessel functions $J_n(x)$, which (for fixed x) are recessive solutions of a self-adjoint three term recurrence relation. By doing so, he avoided the inherit instability in calculation of the recessive solution from an initial-value problem for a three term recurrence relation.

Finally, because eventual disconjugacy implies the existence of a recessive solution [6, Thm. 4.1], we have the following sufficient condition for convergence.

COROLLARY 13.2. *Suppose that A_n and C_{n-1} are Hermitian with C_{n-1} nonsingular for $n \geq M-2$. Assume that* (1.2) *is disconjugate on* $[M-2,\infty)$. *Then* (1.2) *has a recessive solution Y_n at ∞ with Y_n nonsingular for $n \geq M-1$, and the approximants $\mathcal{S}_{M,N}(0)$ are defined for $N \geq M$ and converge to $-W_M^-$.*

Note added September 22, 1992. In the time since this paper was written continued fraction representations have been obtained for more general Riccati equations than those considered here. Those equations are variable coefficient versions of those of Vaughan [44]. The paper by the author which contains those results is entitled "Geometric, analytic, and arithmetic aspects of symplectic continued fractions." That paper is to appear in a special volume entitled *Analysis, Geometry and Groups: A Riemann Legacy Volume* edited by T. M. Rassias and H. M. Srivastava, and published by Hadronic Press, Palm Harbor, Florida.

Acknowledgment. The author wishes to express his thanks to the referee for constructive comments and for pointing out the work of MacNerney [27]. The author wishes to thank his colleague, L. J. Lange, for sharing his knowledge of the literature on the subject of continued fractions.

MORE BOUNDS ON EIGENVALUE RATIOS FOR DIRICHLET LAPLACIANS IN N DIMENSIONS*

MARK S. ASHBAUGH[†] AND RAFAEL D. BENGURIA[‡]

Abstract. The authors investigate bounds for various combinations of the low eigenvalues of the Laplacian with Dirichlet boundary conditions on a bounded domain $\Omega \subset \mathbb{R}^n$. These investigations continue and expand upon earlier work of Payne, Pólya, Weinberger, Brands, Chiti, and the authors of this present paper. In particular, the authors generalize and extend to the n-dimensional setting various bounds of Payne, Pólya, Weinberger, Brands, and Chiti and examine their consequences and interrelationships in detail. This includes comparing the asymptotic forms of the various bounds as the dimension n becomes large. The authors also present various extensions and consequences of their recent proof of the Payne–Pólya–Weinberger conjecture, including the proof of a second conjecture of Payne, Pólya, and Weinberger under an added symmetry condition.

Key words. eigenvalues of Dirichlet Laplacians, universal eigenvalue inequalities, zeros of Bessel functions

AMS subject classifications. 35P15, 49Gxx, 35J05, 33A40

1. Introduction.

In this paper we go beyond our work in [6] to investigate such quantities as λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$ for a bounded domain $\Omega \subset \mathbb{R}^n$. Here the quantity λ_i (for $i = 1, 2, \ldots$) denotes the ith eigenvalue of the Laplacian on Ω with zero Dirichlet boundary conditions imposed on $\partial\Omega$. In [6] (see also the announcement in [5]) we proved the Payne–Pólya–Weinberger conjecture in general dimension n, which says that

$$\lambda_2/\lambda_1\Big|_{\Omega} \leq \lambda_2/\lambda_1\Big|_{n\text{-dimensional ball}}, \tag{1.1}$$

with equality if and only if Ω is an n-dimensional ball. This bound had been conjectured by Payne, Pólya, and Weinberger (PPW) in [34] and [35], where they had proved that $\lambda_2/\lambda_1 \leq 3$ in the two-dimensional case (by contrast, (1.1) above gives approximately 2.5387 in this case). Thompson [47] made the natural extension of the results and conjecture of Payne, Pólya, and Weinberger to the n-dimensional setting. Between the papers of PPW and our own, several authors managed to lower the bound 3 in the PPW result for λ_2/λ_1 in two dimensions. These include Brands [12] who obtained 2.686 in 1964, de Vries [18] who obtained 2.658 in 1967, and Chiti [17] who obtained 2.586 in 1983. Only Chiti gave an n-dimensional version of his inequality, and even then he did not evaluate certain integrals of Bessel functions that occur in his bounds (except when $n = 2$). In this paper (§5) we reduce Chiti's n-dimensional result to its simplest form and compare his result with our own. We also extend

the basic result of Brands to the n-dimensional setting, recovering as a by-product a bound on λ_2/λ_1 which was given by Hile and Protter [23] (and which is a moderate improvement upon the general bound $\lambda_2/\lambda_1 \leq 1 + 4/n$ of PPW/Thompson).

In their original paper [35], Payne, Pólya, and Weinberger also formulated conjectures concerning λ_{m+1}/λ_m for $m = 2, 3, 4, \ldots$, and $(\lambda_2 + \lambda_3)/\lambda_1$ in two dimensions. These conjectures were that

(A) Among all bounded domains Ω and for all $m = 1, 2, 3, \ldots$, λ_{m+1}/λ_m is maximized by $\Omega =$ disk and $m = 1$ with equality only in this case, i.e.,

$$\lambda_{m+1}/\lambda_m \leq \lambda_2/\lambda_1\Big|_{\Omega=\text{disk}} \approx 2.5387; \tag{1.2}$$

(B) Among all bounded domains Ω, $(\lambda_2 + \lambda_3)/\lambda_1$ is maximized by $\Omega =$ disk, i.e.,

$$(\lambda_2 + \lambda_3)/\lambda_1 \leq (\lambda_2 + \lambda_3)/\lambda_1\Big|_{\Omega=\text{disk}} \approx 5.077. \tag{1.3}$$

These and related questions have been called attention to recently by Shubin in [3]. In our recent work [7], [8], we have extended our proof of the PPW conjecture to prove the $m = 2$ and $m = 3$ cases of (A) and even to prove that $\lambda_4/\lambda_2 < \lambda_2/\lambda_1$ (disk) ≈ 2.5387. However, the cases for $m > 3$ are still left open. In this paper, we concentrate on (B) and, while we do not prove it, we prove a special case of it for domains with 4-fold rotational symmetry. We also formulate n-dimensional generalizations of it, prove certain related but weaker inequalities, and examine the relations between our inequalities and the conjectured inequalities particularly in the limit as the dimension n goes to infinity.

The original papers of Payne, Pólya, and Weinberger have spawned a large collection of papers on "universal inequalites" between eigenvalues. A relatively complete set of references to this literature is contained in [6]. In the meantime we have become aware of a paper by Anghel [2] and of recent work of Harrell [20]. Particularly relevant to the present paper are the review articles by Protter [39], [41] (see also Payne's review article [32] for a more general overview as of 1967). Finally, we cannot leave our historical summary without at least mentioning the work on λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$ in two dimensions which was begun by Payne, Pólya, and Weinberger and continued by Brands [12], Hile and Protter [23], and Marcellini [27]. Marcellini's result $\lambda_3/\lambda_1 \leq 7(15 + \sqrt{345})/60 \approx 3.9170$ is the best bound on λ_3/λ_1 to date (Brands found $\lambda_3/\lambda_1 \leq (7 + 2\sqrt{7})/3 \approx 4.097$ while Hile and Protter found $\lambda_3/\lambda_1 \leq 4.014$). Similarly, Marcellini's bound $(\lambda_2 + \lambda_3)/\lambda_1 \leq (15 + \sqrt{345})/6 \approx 5.5957$ is the best general bound on $(\lambda_2 + \lambda_3)/\lambda_1$ to date (Brands found $(\lambda_2 + \lambda_3)/\lambda_1 \leq 3 + \sqrt{7} \approx 5.646$ while Hile and Protter found $(\lambda_2 + \lambda_3)/\lambda_1 \leq 5.622$). These bounds improve upon the bound $(\lambda_2 + \lambda_3)/\lambda_1 \leq 6$ proved by Payne, Pólya, and Weinberger [35] (who also observed from this that $\lambda_3/\lambda_1 < 5$ but could easily have obtained $\lambda_3/\lambda_1 \leq 13/3 \approx 4.333$ by using $(\lambda_2 + \lambda_3)/\lambda_1 \leq 6$ in combination with another of their results, $\lambda_3 \leq \lambda_1 + 2\lambda_2$). The work of these authors was largely confined to the two-dimensional case though certain of the results of Brands and Payne, Pólya, and Weinberger do generalize fairly easily (see inequalities (6.2) and (6.10) in §6 below). In addition, many of the results of Hile and Protter are obtained for general dimension n. Work on λ_3/λ_1 is made more difficult by the fact that no reasonable guess exists as to the precise shape of the domain which maximizes it.

We also examine various consequences of our proof of the PPW conjecture for λ_2/λ_1. *In particular, we show that it leads to optimal inequalities for quantities* considered by Pólya [36] and to an improved upper bound in an inequality for the gap $\lambda_2 - \lambda_1$ due to Singer, Wong, Yau, and Yau [45]. These results are in our §§4 and 7, respectively.

2. Notational preliminaries. In this section we summarize our notation and recall from [6] some of the more useful formulas for our present considerations. We deal always with the Dirichlet eigenvalue problem for the Laplacian on a bounded domain $\Omega \subset \mathbb{R}^n$,

$$-\Delta u = \lambda u \quad \text{on } \Omega \tag{2.1}$$

with boundary condition

$$u = 0 \quad \text{on } \partial\Omega. \tag{2.2}$$

We list the eigenvalues (with multiplicity) as

$$0 < \lambda_1 < \lambda_2 \leq \lambda_3 \leq \cdots \to \infty \tag{2.3}$$

and a corresponding complete orthonormal set of eigenfunctions will be denoted by $\{u_i\}_{i=1}^{\infty}$. The Rayleigh–Ritz characterization of the eigenvalues will be an ever-present tool. One has

$$\lambda_i = \min_{\substack{\varphi \in H_0^1(\Omega)\setminus\{0\} \\ \varphi \perp W_{i-1}}} \frac{\int_\Omega |\nabla\varphi|^2 dx}{\int_\Omega \varphi^2 dx}, \tag{2.4}$$

where $W_i =$ span $\{u_1, \dots, u_i\}$ (with $W_0 = \{0\}$). Here dx represents the n-dimensional Lebesgue measure in $\mathbb{R}^n$. For our purposes no harm will be done by restricting consideration to real-valued functions; thus we shall dismiss all complex conjugations from our inner products. We shall be particularly concerned with trial functions φ of the form Pu_1. For these it is useful to formulate (2.4) as

$$\lambda_i - \lambda_1 \leq \min_{\substack{\varphi = Pu_1 \neq 0 \\ \varphi \in W_{i-1}^{\perp}}} \frac{\int_\Omega |\nabla P|^2 u_1^2 dx}{\int_\Omega P^2 u_1^2 dx}. \tag{2.5}$$

There is also a trace version of the Rayleigh–Ritz principle which we refer to as the extended Rayleigh–Ritz principle:

$$\sum_{k=1}^{m} \lambda_k \leq Tr\ A(\varphi_1, \dots, \varphi_m), \tag{2.6}$$

where $A(\varphi_1, \dots, \varphi_m)$ denotes the matrix whose (i, j)th entry is $(\varphi_i, (-\Delta)\varphi_j)$ and $\{\varphi_i\}_{i=1}^{m}$ is any orthonormal set of m vectors from the underlying Hilbert space.

We shall be particularly concerned with trial functions

$$P_i = g(r)x_i/r \quad \text{for } i = 1, 2, \dots, n, \tag{2.7}$$

where the x_i's are the standard Cartesian coordinates and $r = |x|$. A simple topological argument based on the Brouwer fixed point theorem guarantees that the origin can be chosen so that $P_i u_1 \perp u_1$ for all $i = 1, \dots, n$ if g is nonnegative. This argument is due originally to Weinberger [49] who used it in an analogous situation for the Neumann eigenvalue problem. A further topological argument based on the Borsuk–Ulam theorem will be developed below. It will allow us to rotate axes so that various higher orthogonality constraints are satisfied for at least some of the P_i's (in particular, it will guarantee $P_k u_1 \in W_k^\perp$ for $k = 1, 2, \dots, n$ if the axes are ordered appropriately). Often we take $g(r) = r$. In that case $P_i = x_i$ and the Rayleigh quotients in (2.5) become simply

$$\frac{\int_\Omega u_1^2 dx}{\int_\Omega x_i^2 u_1^2 dx}. \tag{2.8}$$

In this case the Brouwer fixed point theorem argument can be replaced simply by a center of mass argument. When we can sum the inequalities arising from all the P_i's (where $P_i = g(r)x_i/r$ again) it is useful to note that

$$\sum_{i=1}^n P_i^2 = g(r)^2 \tag{2.9}$$

and

$$\sum_{i=1}^n |\nabla P_i|^2 = g'(r)^2 + (n-1)\frac{g(r)^2}{r^2}. \tag{2.10}$$

In particular, when $P_i u_1 \in W_1^\perp$ for all $i = 1, \dots, n$ this gives the basic gap inequality

$$\lambda_2 - \lambda_1 \le \frac{\int_\Omega \left[g'(r)^2 + (n-1)g(r)^2/r^2\right] u_1^2 dx}{\int_\Omega g(r)^2 u_1^2 dx}. \tag{2.11}$$

We shall also need Bessel functions and their zeros. We use the standard notation of Abramowitz and Stegun [1]. The standard Bessel function of the first kind of order p will be denoted $J_p(x)$, and its kth positive zero will be denoted $j_{p,k}$. For an n-dimensional ball of radius R the low Dirichlet eigenvalues are $\lambda_1 = j_{n/2-1,1}^2/R^2$ and $\lambda_2 = \cdots = \lambda_{n+1} = j_{n/2,1}^2/R^2$. Corresponding (unnormalized but orthogonal) eigenfunctions are $u_1 = r^{1-n/2}J_{n/2-1}(j_{n/2-1,1}r/R)$ and $u_{i+1} = r^{1-n/2}J_{n/2}(j_{n/2,1}r/R)x_i/r$ for $i = 1, 2, \dots, n$. In particular, the bound in (1.1) is $(j_{n/2,1}/j_{n/2-1,1})^2$.

Rearrangement results will be used as needed. For most of the technical details for these and related matters we refer to [6] and the references therein. A sampling of these references includes [11], [19], and [38]; in particular, [38] is largely devoted to applying rearrangement results to the eigenvalue problems of mathematical physics (see also Bandle's book [11] for much useful information on rearrangement inequalities and eigenvalue problems). Chavel's book [14] also contains related material, particularly with reference to generalizing various results to Riemannian manifolds (usually with constraints of some sort on their curvature).

3. A second conjecture of Payne, Pólya, and Weinberger: Proof for domains with symmetry of order 4. A second conjecture of Payne, Pólya, and Weinberger, contained in [35], is that for the Dirichlet Laplacian on a bounded domain $\Omega \subset \mathbb{R}^2$,

$$(\lambda_2 + \lambda_3)/\lambda_1 \le 2j_{1,1}^2/j_{0,1}^2 \tag{3.1}$$

with equality if and only if Ω is a disk. In [35], the bound 6 was established for $(\lambda_2 + \lambda_3)/\lambda_1$, whereas the conjectured bound given above has a numerical value of approximately 5.077. Various authors have brought the constant here down as follows: Brands [12] 5.646, Hile and Protter [23] 5.622, and Marcellini [27] 5.596. Here we show how our method of proof for the first PPW conjecture can be extended to prove (3.1) in the case that Ω has a center of symmetry of order 4. That is, we establish the following.

THEOREM 3.1. *Let Ω be a bounded domain in $\mathbb{R}^2$ with 4-fold rotational symmetry about a point. Then inequality* (3.1) *holds between the first three eigenvalues of the Laplacian on this domain with Dirichlet boundary conditions. Equality occurs if and only if Ω is a disk.*

Proof. The proof proceeds much like our proof [5], [6] of the Payne–Pólya–Weinberger conjecture for λ_2/λ_1. We start from the extended Rayleigh–Ritz inequality

$$\lambda_2 + \lambda_3 - 2\lambda_1 \leq \frac{\int_\Omega |\nabla P_1|^2 u_1^2 dx}{\int_\Omega P_1^2 u_1^2 dx} + \frac{\int_\Omega |\nabla P_2| u_1^2 dx}{\int_\Omega P_2^2 u_1^2 dx}, \tag{3.2}$$

where now P_1 and P_2 must be nontrivial functions such that $P_1 u_1$ and $P_2 u_1$ are both orthogonal to u_1 and to each other. Taking P_1 and P_2 as in the prior proof (i.e., of the form given by (2.7) with $g(r)$ chosen to be a particular ratio of Bessel functions), orthogonality to u_1 is assured by the symmetry of Ω (which is shared by u_1). To establish orthogonality to each other note that

$$\int_\Omega P_1 P_2 u_1^2 dx = \int_\Omega g^2(r) \left[\frac{1}{2}\sin 2\theta\right] u_1^2 dx = 0 \tag{3.3}$$

since rotation by 90° leaves $g(r)$ and u_1 alone, whereas $\sin 2\theta$ is changed to its negative. A second (crucial) fact deriving from the 4-fold symmetry of Ω is

$$\int_\Omega P_1^2 u_1^2 dx = \int_\Omega P_2^2 u_1^2 dx \tag{3.4}$$

(the numerators in (3.2) above are equal also). This follows by considering the behavior of $\int_\Omega (P_1^2 - P_2^2) u_1^2 dx = \int_\Omega g^2(r) \cos 2\theta u_1^2 dx$ under rotation by 90°. This allows us to replace the right-hand side in (3.2) by

$$\frac{2\int_\Omega \left[g'(r)^2 + \frac{1}{r^2} g(r)^2\right] u_1^2 dx}{\int_\Omega g(r)^2 u_1^2 dx}$$

and then proceed through to the conclusion of the proof exactly as in [5] and [6], except now we have the extra factor of 2 on the right-hand side. □

Remark. One could also have proceeded by arguing from the Rayleigh–Ritz inequality in a slightly different fashion. We can obtain the two inequalities

$$\lambda_2 - \lambda_1 \leq \frac{\int_\Omega |\nabla P_1|^2 u_1^2 dx}{\int_\Omega P_1^2 u_1^2 dx} \tag{3.5}$$

and

$$\lambda_3 - \lambda_1 \leq \frac{\int_\Omega |\nabla P_2|^2 u_1^2 dx}{\int_\Omega P_2^2 u_1^2 dx} \tag{3.6}$$

if we choose P_1 and P_2 as before and also use rotational freedom to fix our coordinate axes so that P_2u_1 is orthogonal to u_2. This is possible because under 180° rotation u_2 can be taken to be either even or odd. In the even case orthogonality is automatic (i.e., no choice of axes is required). In the odd case we observe that if $\int_\Omega P_2u_1u_2dx \neq 0$, then after a 180° rotation of axes this quantity will change signs and hence, by continuity, for some intermediate rotation orthogonality will obtain. Having established (3.5) and (3.6) we can sum them and proceed as before. The 4-fold rotational symmetry is needed to establish (3.4); thus, in a certain sense the consequence (3.4) of the 4-fold rotational symmetry is more crucial to establishing (3.1) than the orthogonality condition (3.3).

In fact, from the alternative approach presented in the preceding remark we can actually obtain the separate inequalities given by the following.

THEOREM 3.2. *With hypotheses as in Theorem* 3.1,

$$\lambda_i/\lambda_1 \leq j_{1,1}^2/j_{0,1}^2 \quad \textit{for } i = 2,3. \tag{3.7}$$

For the proof one simply observes that

$$\int_\Omega |\nabla P_i|^2 u_1^2 dx = \frac{1}{2}\int_\Omega \left[|\nabla P_1|^2 + |\nabla P_2|^2\right] u_1^2 dx \quad \text{for } i = 1,2 \tag{3.8}$$

and

$$\int_\Omega P_i^2 u_i^2 dx = \frac{1}{2}\int_\Omega \left[P_1^2 + P_2^2\right] u_1^2 dx \quad \text{for } i = 1,2. \tag{3.9}$$

The results above have a connection to a celebrated conjecture concerning the nodal line of the second eigenfunction for the Dirichlet problem in two dimensions. The conjecture states that the nodal line of u_2 must cross Ω, i.e., that u_2 cannot have a closed nodal line not touching $\partial\Omega$ (for statements and discussion see [32], [40], [50], and [51]). Throughout our discussion of the nodal line conjecture and its implications for our problem we shall assume that Ω has a C^1 boundary, i.e., that each component of the boundary is given by a simple, closed curve having a continuously turning unit tangent vector. Though partial results have been obtained for this problem they have all required additional assumptions of symmetry and/or convexity [24], [25], [29], [33], [42]. Examples of these results are that u_2 cannot have a closed interior nodal line if Ω is convex and symmetric with respect to a line (Payne [33]) or if Ω is convex and has a discrete rotational symmetry (Lin [25]). Other results relating to this conjecture are contained in the papers of Shen [42] and Jerison [24]. Very recently, Melas [29] has obtained the strongest result to date, requiring only convexity. His work is based on the prior work of Lin [25] and Payne [33].

Based on Lin's result (now a special case of Melas' result [29]) and an observation of Weinberger (made in connection with our work on Neumann eigenvalues in [9]) we can prove

THEOREM 3.3. *Let $\Omega \subset \mathbb{R}^2$ be a bounded convex domain with a smooth boundary and having k-fold rotational symmetry with $k \geq 3$. Then $\lambda_2 = \lambda_3$ and hence inequalities* (3.1) *and* (3.7) *also hold.*

Proof. Aside from the condition $k \geq 3$, the hypotheses here are those of Lin [25]. Therefore, u_2 must have a nodal line which touches the boundary at exactly two points. This shows that u_2 cannot be invariant under rotation by $2\pi/k$ radians and hence that λ_2 is at least doubly degenerate (since u_2 rotated by $2\pi/k$ radians must be an independent eigenfunction for λ_2). □

We note that Theorem 3.3 renders Theorems 3.1 and 3.2 somewhat trivial for the cases that it covers (and also that it goes beyond these theorems in the respect that it allows k's not divisible by 4). On the other hand, Theorems 3.1 and 3.2 are more general in that Ω is allowed to be nonconvex and even nonsimply connected. In addition, one can go beyond what we have done above in the following way, which might actually be of use in establishing the nodal line conjecture for all domains with 4-fold rotational symmetry.

THEOREM 3.4. *Let $\Omega \subset \mathbb{R}^2$ have 4-fold rotational symmetry and suppose that u_2 is even, i.e., $u_2(-x) = u_2(x)$ for all $x \in \Omega$. Then*

$$\lambda_i/\lambda_1 \leq j_{1,1}^2/j_{0,1}^2 \quad \textit{for } i = 3, 4 \tag{3.10}$$

and hence also $(\lambda_3 + \lambda_4)/\lambda_1 \leq 2j_{1,1}^2/j_{0,1}^2$.

Note. This theorem makes no assumptions concerning the connectivity of Ω or the smoothness of its boundary.

Proof. One simply observes that if u_2 is even, then both P_1u_1 and P_2u_1 will be orthogonal to it (see, in particular, the arguments given in the remark following Theorem 3.1). Then all the estimates given above are seen to apply to P_1u_1 and P_2u_1 as trial functions for u_3 and u_4 (the latter by virtue of a rotation, if necessary). In particular, (3.5) and (3.6) can be applied, with λ_3 and λ_4 replacing λ_2 and λ_3 in their left-hand sides, and together with (3.8) and (3.9) these yield (3.10) of our theorem. □

Therefore, if there were a domain with 4-fold symmetry for which the nodal line conjecture were false we would have $\lambda_4/\lambda_1 \leq j_{1,1}^2/j_{0,1}^2$ (since in this context it is clear that if u_2 has a closed interior nodal line, then u_2 can be taken to be even). This may perhaps be a useful result to have in working to show that u_2 cannot have a closed interior nodal line (and hence must be odd). In fact, it seems reasonable to believe that u_2 for a nonconvex domain would be more likely to have a crossing nodal line than u_2 for a convex domain. This certainly suggests that the nodal line conjecture should hold for all domains with 4-fold rotational symmetry but we repeat that this has not yet been proved. It seems that we are in the somewhat paradoxical situation that the harder (convex) case is proved while the nonconvex case remains unproved. If the nodal line conjecture turns out to be true, then for simply connected domains having 4-fold rotational symmetry and smooth boundaries our Theorem 3.4 above would hold vacuously.

The n-dimensional analog of Theorem 3.1 concerns the quantity

$$(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1})/\lambda_1$$

(but see also our comments near the end of §5) and deals with bounded domains $\Omega \subset \mathbb{R}^n$ for which there is a choice of Cartesian coordinates such that Ω is invariant with respect to 90° rotation in each of the $\binom{n}{2}$ coordinate planes. We have the following.

THEOREM 3.5. *Let Ω be a bounded domain in $\mathbb{R}^n$ and suppose Ω is invariant with respect to 90° rotations in the coordinate planes spanned by each pair of (Cartesian) coordinate axes. Then*

$$(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1})/\lambda_1 \leq n\left(j_{n/2,1}/j_{n/2-1,1}\right)^2 \tag{3.11}$$

holds and, furthermore, equality obtains if and only if Ω is an n-dimensional ball.

Proof. The proof here is essentially identical to our previous one. One takes $P_i = g(r)x_i/r$, where x_i is a Cartesian coordinate. Orthogonality of each of the functions $P_i u_1$ $(1 \le i \le n)$ to u_1 is assured by the symmetry of Ω. Pairwise orthogonality of the $P_i u_1$'s $(1 \le i \le n)$ follows as for (3.3) above by making a 90° rotation in the $x_i x_j$-plane, where i and j are the indices of the relevant P's. Finally,

$$\int_\Omega P_1^2 u_1^2 dx = \int_\Omega P_2^2 u_1^2 dx = \cdots = \int_\Omega P_n^2 u_1^2 dx,$$

the analog of (3.4) above, also follows from the 4-fold rotational symmetry of Ω in each coordinate plane.

By the extended Rayleigh–Ritz inequality one then has

$$\begin{aligned}(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1}) - n\lambda_1 &\le \sum_{i=1}^{n} \frac{\int_\Omega |\nabla P_i|^2 u_1^2 dx}{\int_\Omega P_i^2 u_1^2 dx} \\ &= \frac{n \int_\Omega \sum_{i=1}^{n} |\nabla P_i|^2 u_i^2 dx}{\int_\Omega \sum_{i=1}^{n} P_i^2 u_1^2 dx} \\ &= n\frac{\int_\Omega \left[g'(r)^2 + (n-1)g(r)^2/r^2\right] u_1^2 dx}{\int_\Omega g(r)^2 u_1^2 dx},\end{aligned} \tag{3.12}$$

and, as in our previous papers [5], [6], this ultimately yields

$$(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1}) - n\lambda_1 \le n\lambda_1 \left[\left(j_{n/2,1}/j_{n/2-1,1}\right)^2 - 1\right],$$

which is equivalent to (3.11). Characterization of the cases of equality also follows our prior work. □

For weaker inequalities than (3.11) but which hold for general domains (i.e., no symmetry hypothesis required) see §5. There we discuss the relations between these weaker inequalities, the conjectured inequality (3.11) for arbitrary domains $\Omega \subset \mathbb{R}^n$, and an intermediate inequality (also conjectural except under our 4-fold symmetry hypothesis, at this point). Also, in §6 we obtain (nonoptimal) bounds on $(\lambda_2 + \cdots + \lambda_{n+1})/\lambda_1$ which are the n-dimensional analogs of the two-dimensional results $(\lambda_2 + \lambda_3)/\lambda_1 \le 6$ of PPW and $(\lambda_2 + \lambda_3)/\lambda_1 \le 5 + \lambda_1/\lambda_2$ of Brands and investigate some of their consequences.

The results of this section have obvious extensions to the case of Schrödinger operators and quite general second-order elliptic equations (as discussed in §4 of [6]) under suitable symmetry conditions, i.e., if all the coefficient functions share the 4-fold symmetries of Ω.

4. Other isoperimetric results implied by our result.

In this section we give two isoperimetric inequalities which follow from our main result and previously known results. These have been discussed in the previous literature as conjectures. In particular, we recommend the article of Hersch [21] and also his comments and updates to Pólya's papers in [22] (see the comments to papers 202 and 203, specifically).

In [36], Pólya asked for the least upper bound for the quantity

$$\lambda_2 \dot{r}^2$$

and for the shape of domain for which this bound is attained or approximated (see question 5(c) on p. 336 of [36]). Here $\dot{r}$ denotes the maximum inner conformal radius of the domain $\Omega \subset \mathbb{R}^2$, which is here supposed to be a simply connected domain (we use our notation for λ_2 here rather than Pólya's). By virtue of our bound on λ_2/λ_1 and the Pólya–Szegö bound [38, pp. 97–98]

$$\lambda_1 \dot{r}^2 \leq j_{0,1}^2 \approx 5.7832 \tag{4.1}$$

(which is isoperimetric, with equality only for disks), the isoperimetric inequality

$$\lambda_2 \dot{r}^2 \leq j_{1,1}^2 \approx 14.6820 \tag{4.2}$$

follows directly (with equality if and only if Ω is a disk), thus answering Pólya's question in its entirety. Pólya himself only explicitly gave the bound $j_{0,2}^2 \approx 30.4713$. With the PPW result $\lambda_2/\lambda_1 \leq 3$ this value could be reduced to $3j_{0,1}^2 \approx 17.3496$, and obviously the improvements in the bound for λ_2/λ_1 as found by Brands, de Vries, and Chiti all lead to further reductions. One can even do slightly better each time if instead of using the bound for λ_2/λ_1 with the Pólya–Szegö bound (4.1) above one uses it with the isoperimetric bound (equality if and only if Ω is a disk)

$$\left(\frac{1}{\lambda_1} + \frac{1}{\lambda_2}\right)\frac{1}{\dot{r}^2} \geq \frac{1}{j_{0,1}^2} + \frac{1}{j_{1,1}^2} \tag{4.3}$$

of Pólya and Schiffer [37], a fact which appears to have first been utilized by Hersch [21]. Hersch, using $\lambda_2/\lambda_1 \leq 3$, then derived the bound $\lambda_2 \dot{r}^2 \leq 16.5957$. Using Chiti's bound, $\lambda_2/\lambda_1 \leq 2.585965$, the constant here would improve to 14.8779, which is the best value derivable prior to our proof of the PPW conjecture. Of course, our isoperimetric bound (4.2) follows by combining our bound $\lambda_2/\lambda_1 \leq j_{1,1}^2/j_{0,1}^2$ with either of the bounds (4.1) or (4.3).

A second result of this nature which follows from our proof of Payne, Pólya, and Weinberger's second conjecture for the case of domains possessing symmetry of order 4 (see §3 above) is the bound

$$(\lambda_2 + \lambda_3)\dot{r}^2 \leq 2j_{1,1}^2 \approx 29.3639. \tag{4.4}$$

This holds for any simply connected domain in the plane having symmetry of order 4. The best general result of this type (i.e., without symmetry assumptions) known at present is

$$(\lambda_2 + \lambda_3)\dot{r}^2 \leq 32.36095^+, \tag{4.5}$$

which follows from Marcellini's bound $(\lambda_2 + \lambda_3)/\lambda_1 \leq (15 + \sqrt{345})/6 \approx 5.5957$. Obviously, (4.5) is not expected to be isoperimetric.

In addition, for convex domains in $\mathbb{R}^2$ having smooth boundary and k-fold rotational symmetry with $k \geq 3$ one has, by Theorem 3.3 above, $\lambda_2 = \lambda_3$ so that (4.4) and also the stronger inequalities

$$\lambda_i \dot{r}^2 \leq j_{1,1}^2 \approx 14.6820 \quad \text{for } i = 2, 3 \tag{4.6}$$

hold in this case. From Theorem 3.2 one sees that the inequalities (4.6) also hold for any simply connected domain having 4-fold rotational symmetry, whether or not it is convex with a smooth boundary.

Further inequalities with $\dot{r}$ replaced by d, where d is defined as the radius of the largest disk contained in Ω, follow from the inequality $d \leq \dot{r} \leq 4d$ of Koebe. Another useful inequality for such considerations is $\dot{r}^2 \leq A/\pi \leq \overline{r}^2$ [38, p.8], where $\overline{r}$ is the outer conformal radius of Ω and A is its area.

Note that the entire discussion in this section is confined to the two-dimensional case.

5. Large n asymptotics and Chiti's bound. In this section we give an asymptotic expansion for our bound $\left(j_{n/2,1}/j_{n/2-1,1}\right)^2$ for large dimension n and compare it with the bounds of PPW/Thompson [34], [35], [47] and Chiti [17]. We also prove some (nonisoperimetric) bounds which are extensions of Chiti's bound and examine various ramifications with respect to certain further conjectures of Payne, Pólya, and Weinberger (see §3 also).

Using the asymptotic development for $j_{p,1}$ for large p as given by Abramowitz and Stegun [1, p. 371, eq. 9.5.14] it is easy to work out that

$$\left(\frac{j_{n/2,1}}{j_{n/2-1,1}}\right)^2 = 1 + \frac{4}{n} - \frac{4}{3}(1.8557571)\frac{2^{5/3}}{n^{5/3}} + \frac{12}{n^2} + O\left(n^{-7/3}\right). \tag{5.1}$$

(The value 1.8557571 appearing here represents $|a_1|/2^{1/3}$, where a_1 is the first negative zero of the Airy function $Ai(x)$; see Olver [31, p. 408, Ex. 6.4] or Abramowitz and Stegun [1, p. 371, eq. 9.5.22 and p. 368, eq. 9.3.39].) Incidentally, this shows that the PPW/Thompson bound $1 + 4/n$ is the best possible of the form $1 + c/n$: that is, if one seeks a constant c (independent of n) such that $\lambda_2/\lambda_1 \leq 1 + c/n$ holds for all dimensions n, then the value $c = 4$ of PPW/Thompson is the best possible.

In arbitrary dimension n the bound of Chiti is

$$\lambda_2 \leq \left(1 + \frac{n}{2}\frac{J^2_{n/2}(j_{n/2-1,1})}{j^2_{n/2-1,1}\int_0^1 r^3 J^2_{n/2-1}(j_{n/2-1,1}r)\,dr}\right)\lambda_1 \tag{5.2}$$

as given in [17] and reproduced in [41]. The integral occurring here is not too difficult to work out (see Appendix A), and one finds that (5.2) takes the much simpler form

$$\lambda_2/\lambda_1 \leq 1 + \frac{6n}{2j^2_{n/2-1,1} + n(n-4)}. \tag{5.3}$$

Again, the asymptotics of the right-hand side of this inequality may be worked out, yielding

$$1 + \frac{6n}{2j^2_{n/2-1,1} + n(n-4)} = 1 + \frac{4}{n} - \frac{4}{3}(1.8557571)\frac{2^{5/3}}{n^{5/3}} + \frac{16}{n^2} + O(n^{-7/3}). \tag{5.4}$$

A comparison with the best bound as given by (5.1) shows that Chiti's bound gets the next term beyond $4/n$ in the asymptotic expansion "right."

It is clear from the asymptotic formulas that

$$\left(\frac{j_{n/2,1}}{j_{n/2-1,1}}\right)^2 < 1 + \frac{6n}{2j^2_{n/2-1,1} + n(n-4)} < 1 + \frac{4}{n} \tag{5.5}$$

for large dimension n. Indeed, the first of these inequalities holds for all n as follows from Chiti's bound. The second would hold for all n if the inequality

$$j_{p,1} > \sqrt{(p+1)(p+5)} \tag{5.6}$$

were to hold for $p = -1/2, 0, 1/2, 1, 3/2, \ldots$. This inequality has recently been shown to hold by Lorch [26] for all $p > -1$. Watson's book gives only

$$j_{p,1} > \sqrt{p(p+2)}$$

[48, p. 486, ineq. (5)]. Lorch in fact shows that $j_{p,1}^2 - (p+1)(p+5)$ increases from zero to infinity as p runs from -1 to infinity. Lorch also has shown that the bound $(n+3+\sqrt{n^2+10n+9})/2n$ due to Brands [12] (for $n = 2$) and Hile and Protter [23] (for general dimension n) is intermediate between Chiti's bound and the bound $1+4/n$ of Payne, Pólya, and Weinberger (cf. (5.5)). We discuss the Brands/Hile–Protter bound and Lorch's result concerning it in more detail in §6 below.

Finally, we observe that the arguments of Chiti in [16] and [17] as used in this paper allow one to prove the bound

$$\frac{1}{\lambda_2-\lambda_1}+\frac{1}{\lambda_3-\lambda_1} \geq \frac{j_{0,1}^2-2}{3\lambda_1}. \tag{5.7}$$

This is an improvement upon the two-dimensional case of (5.2) and also upon Chiti's bound

$$\frac{1}{\lambda_2-\lambda_1}+\frac{1}{\lambda_3-\lambda_1} \geq \frac{1}{\lambda_1} \tag{5.8}$$

which follows directly from [16] and rearrangement inequalities (since $\lambda_1 \geq \lambda_1^\star$ where $\lambda_1^\star$ is defined as the Rayleigh quotient for $-\Delta$ on Ω^* with $u_1^\star$ as trial function; here Ω^* denotes the disk of the same volume as Ω and $u_1^\star$ denotes the "spherical decreasing rearrangement" of u_1; see [5] and [6] for more details and references) because $\left(j_{0,1}^2-2\right)/3 \approx 1.2611 > 1$. The lower bounds of Chiti [16], $1/\lambda_1^\star$ and $\int_\Omega u_1^2 dx/2\pi u_M^2$, where $u_M^2 = (\text{max of } u_1^2)$, are not directly comparable to the bound in (5.7) above, though in any event they are less accessible as they require knowledge of u_1 or $u_1^\star$.

If the second conjecture (see §3 above),

$$(\lambda_2+\lambda_3)/\lambda_1 \leq 2j_{1,1}^2/j_{0,1}^2, \tag{5.9}$$

of Payne–Pólya–Weinberger were to hold, then (5.7) could be improved to

$$\frac{1}{\lambda_2-\lambda_1}+\frac{1}{\lambda_3-\lambda_1} \geq \frac{2j_{0,1}^2}{\left(j_{1,1}^2-j_{0,1}^2\right)\lambda_1} = \frac{2}{\left[\left(j_{1,1}/j_{0,1}\right)^2-1\right]\lambda_1}, \tag{5.10}$$

where now the constant on the right-hand side has the value $2/\left[\left(j_{1,1}/j_{0,1}\right)^2-1\right] \approx 1.2998$. The inequalities (5.9) and (5.10), if true, would be isoperimetric with equality only for the disk. In any event, (5.9) would imply (5.10) but not conversely so (5.10) is of intermediate strength between the known result (5.7) and the second inequality (5.9) conjectured by Payne, Pólya, and Weinberger. Note that either of the inequalities (5.9) or (5.10) would imply our result (1.1), i.e., the (first) PPW conjecture. Similarly, the bound (5.7) implies the two-dimensional bound that Chiti gave explicitly in [17] for λ_2/λ_1.

We now show how we arrive at (5.7) and then go on to its analog in higher dimensions. As in [12], [16], and [27] we observe that we can choose coordinate axes so that

$$\int_\Omega x u_1^2 dx = \int_\Omega y u_1^2 dx = \int_\Omega x u_1 u_2 dx = 0 \tag{5.11}$$

by suitable translation and rotation of our axes. It then follows by the Rayleigh–Ritz inequality with xu_1 and yu_1 as trial functions for u_3 and u_2 that

$$\lambda_2 - \lambda_1 \leq \frac{\int_\Omega u_1^2 dx}{\int_\Omega y^2 u_1^2 dx}$$

and

$$\lambda_3 - \lambda_1 \leq \frac{\int_\Omega u_1^2 dx}{\int_\Omega x^2 u_1^2 dx}.$$

From these,

$$\frac{1}{\lambda_2 - \lambda_1} + \frac{1}{\lambda_3 - \lambda_1} \geq \frac{\int_\Omega (x^2 + y^2) u_1^2 dx}{\int_\Omega u_1^2 dx} = \frac{\int_\Omega r^2 u_1^2 dx}{\int_\Omega u_1^2 dx} \tag{5.12}$$

follows immediately and then rearrangement inequalities and Chiti's comparison result (see [5] and [6], including Appendix A of [6], for more on this) do the rest to yield (5.7).

In higher dimensions the analog of (5.7) is

$$\frac{1}{\lambda_2 - \lambda_1} + \frac{1}{\lambda_3 - \lambda_1} + \cdots + \frac{1}{\lambda_{n+1} - \lambda_1} \geq \frac{2j_{n/2-1,1}^2 + n(n-4)}{6\lambda_1}, \tag{5.13}$$

where n denotes the dimension. This inequality follows in exact analogy to the two-dimensional case once one shows that by a proper choice of origin and axes one can arrange for the orthogonality conditions

$$\int_\Omega x_i u_1 u_j dx = 0 \quad \text{for } i = 1, 2, \ldots, n \quad \text{and} \quad j = 1, \ldots, n + 1 - i \tag{5.14}$$

to be simultaneously satisfied. That this is possible follows in stages. First, that

$$\int_\Omega x_i u_1^2 dx = 0 \quad \text{for } i = 1, \ldots, n$$

can be satisfied by an appropriate choice of origin follows from the Brouwer fixed point theorem as alluded to in §2; or, more simply, one can view this as choosing the origin to lie at the center of mass of a mass distribution in Ω having mass density u_1^2. Next, one considers

$$\int_\Omega x_1 u_1 u_j dx \qquad \text{for } j = 2, \ldots, n$$

as a function on S^{n-1}, the unit sphere in $\mathbb{R}^n$, where the variable $\sigma \in S^{n-1}$ represents the direction of the positive x_1 axis. This is a mapping f_1 from S^{n-1} to $\mathbb{R}^{n-1}$ (the index j gives the component) which is antipode preserving, i.e., $f_1(-\sigma) = -f_1(\sigma)$. It now follows from the Borsuk–Ulam theorem (see [46, p. 266], [28, p. 170], or [30, p. 361]) that there is a $\sigma_1 \in S^{n-1}$ at which f_1 vanishes (f_1 also vanishes at $-\sigma_1$). We can, therefore, fix the x_1 axis in the direction of σ_1 to guarantee that $\int_\Omega x_1 u_1 u_j dx = 0$ for $j = 2, \ldots, n$. Having achieved this we now repeat the process by considering

$$\int_\Omega x_2 u_1 u_j dx \quad \text{for } j = 2, \ldots, n-1$$

as a function on the sphere S^{n-2}, which is the equator of S^{n-1} consisting of those vectors in S^{n-1} that are perpendicular to the (now fixed) direction of the x_1 axis, i.e., to σ_1. Again, this gives a mapping $f_2 : \; S^{n-2} \to \mathbb{R}^{n-2}$ which is antipode-preserving, and the Borsuk–Ulam theorem tells us that there is a $\sigma_2 \in S^{n-2}$ at which $f_2(\sigma_2) = 0$. If we take the x_2 axis to lie in this direction, then $\int_\Omega x_2 u_1 u_j dx = 0$ for $j = 2, \ldots, n-1$. Obviously, this process may be continued until we have fixed the directions of all the coordinate axes such that all the orthogonality conditions (5.14) hold. Using the Rayleigh–Ritz inequality with $x_i u_1$ as a trial function for u_{n+2-i} one finds easily that

$$\lambda_i - \lambda_1 \le \frac{\int_\Omega u_1^2 dx}{\int_\Omega x_{n+2-i}^2 u_1^2 dx} \quad \text{for } i = 2, 3, \ldots, n+1, \tag{5.15}$$

and then (5.13) follows directly as in the two-dimensional case.

If one computes the large n asymptotic expansion of the bound (5.13) and compares it to that of the conjectured bound

$$\frac{1}{\lambda_2 - \lambda_1} + \frac{1}{\lambda_2 - \lambda_1} + \cdots + \frac{1}{\lambda_{n+1} - \lambda_n} \ge \frac{n}{\left[\left(j_{n/2,1}/j_{n/2-1,1}\right)^2 - 1\right] \lambda_1} \tag{5.16}$$

(the extension to n dimensions of (5.10); all comments above following (5.10) apply to (5.16) as well if generalized to the n-dimensional setting; see also §3 on the second Payne–Pólya–Weinberger conjecture), one finds

$$\left[2j_{n/2-1,1}^2 + n(n-4)\right] \Big/ 6 \sim \frac{n^2}{4} \left[1 + \frac{2}{3}(1.8557571)\frac{2^{2/3}}{n^{2/3}} - \frac{4}{n} + O(n^{-4/3})\right], \tag{5.17}$$

whereas

$$\frac{n}{\left[\left(j_{n/2,1}/j_{n/2-1,1}\right)^2 - 1\right]} \sim \frac{n^2}{4} \left[1 + \frac{2}{3}(1.8557571)\frac{2^{2/3}}{n^{2/3}} - \frac{2}{n} + O(n^{-4/3})\right]. \tag{5.18}$$

From this it seems that the Chiti bound has a relative error of only $O(1/n)$ for large n (assuming that (5.16) is indeed true).

Of course, any of the bounds (5.13), (5.16), or

$$\left(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1}\right) / \lambda_1 \le n \left(j_{n/2,1}/j_{n/2-1,1}\right)^2 \tag{5.19}$$

(the last two of which are only conjectures, in general, at this point) implies a corresponding bound for the eigenvalues $\lambda_2, \ldots, \lambda_k$ for any integer k, $2 \le k \le n+1$. In particular, (5.13) leads to

$$\frac{1}{\lambda_2 - \lambda_1} + \frac{1}{\lambda_3 - \lambda_1} + \cdots + \frac{1}{\lambda_k - \lambda_1} \ge \frac{k-1}{n} \frac{2j_{n/2-1,1}^2 + n(n-4)}{6\lambda_1}, \tag{5.20}$$

(5.16) would lead to

$$\frac{1}{\lambda_2 - \lambda_1} + \frac{1}{\lambda_3 - \lambda_1} + \cdots + \frac{1}{\lambda_k - \lambda_1} \ge \frac{k-1}{\left[\left(j_{n/2,1}/j_{n/2-1,1}\right)^2 - 1\right] \lambda_1}, \tag{5.21}$$

and (5.19) would lead to

$$(5.22)\qquad (\lambda_2+\cdots+\lambda_k)/\lambda_1 \le (k-1)\left[j_{n/2,1}/j_{j/2-1,1}\right]^2$$

for $2 \le k \le n+1$. These follow by just using the obvious facts that

$$\frac{1}{\lambda_k-\lambda_1} \le \frac{1}{k-2}\left(\frac{1}{\lambda_2-\lambda_1}+\frac{1}{\lambda_3-\lambda_1}+\cdots+\frac{1}{\lambda_{k-1}-\lambda_1}\right)$$

and

$$\lambda_k \ge (\lambda_2+\lambda_3+\cdots+\lambda_{k-1})/(k-2),$$

and by working inductively. For $k=2$ the inequalities (5.20), (5.21), and (5.22) reduce to the known inequalities for λ_2/λ_1. The second conjecture of Payne, Pólya, and Weinberger concerning $(\lambda_2+\lambda_3)/\lambda_1$ in two dimensions could be considered to generalize to either (5.19) or the $k=3$ case of (5.22) in n dimensions; we prefer to think of (5.19) as the proper generalization since it seems the more natural of the two (nevertheless, in our next section we work to bound $(\lambda_2+\lambda_3)/\lambda_1$ in all dimensions n).

Finally, we remark that every bound developed above holds unchanged for the Schrödinger operator $H=-\Delta+V(x)$ acting on a bounded domain $\Omega\subset\mathbb{R}^n$ with Dirichlet boundary conditions and with a positive potential V. With minor changes (see §4 of [6]) these bounds also extend to rather general elliptic eigenvalue problems. There are also many Schrödinger problems on unbounded domains to which our bounds apply (see [4] for a discussion in one dimension which applies without change here; see also Simon [43], [44] and Ashbaugh–Exner [10] for some more exotic problems where this extension has interesting applications).

6. Bounds on $(\lambda_2+\lambda_3+\cdots+\lambda_{n+1})/\lambda_1$ and their implications for λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$ in n dimensions.

In this section we return to consideration of bounds for $(\lambda_2+\lambda_3)/\lambda_1$ and, most especially, to their extension to n dimensions. We shall begin by looking at bounds on $(\lambda_2+\lambda_3+\cdots+\lambda_{n+1})/\lambda_1$ in n dimensions and then turn to their implications for λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$. We again examine asymptotics in n as n goes to infinity to help judge the effectiveness of our bounds.

We begin by remarking that the bound

$$(6.1)\qquad (\lambda_2+\lambda_3)/\lambda_1 \le 6$$

of Payne, Pólya, and Weinberger [35] readily extends to n dimensions as

$$(6.2)\qquad (\lambda_2+\lambda_3+\cdots+\lambda_{n+1})/\lambda_1 \le n+4 = n(1+4/n).$$

This is easily arrived at by using trial functions $P_i=x_i$ with the adjustments using the Brouwer fixed point (or simply a center of mass argument) and Borsuk–Ulam theorems already effected so that

$$(6.3)\qquad \lambda_{i+1} \le \lambda_1 + \frac{\int_\Omega u_1^2\,dx}{\int_\Omega x_i^2u_1^2\,dx} \quad \text{for } i=1,2,\dots,n$$

(this is just (5.15) with the order of the x_i's reversed) and hence, by summing,

$$(6.4)\qquad \sum_{i=1}^n \lambda_{i+1} \le n\lambda_1 + \sum_{i=1}^n \frac{\int_\Omega u_1^2\,dx}{\int_\Omega x_i^2u_1^2\,dx}.$$

One then uses integration by parts

$$-2\int_\Omega x_i u_1 u_{1x_i}dx = -\int_\Omega x_i(u_1^2)_{x_i}dx = \int_\Omega u_1^2 dx \tag{6.5}$$

and the Cauchy–Schwarz inequality

$$\left(\int_\Omega u_1^2 dx\right)^2 = 4\left(\int_\Omega x_i u_1 u_{1x_i}dx\right)^2 \le 4\left(\int_\Omega x_i^2 u_1^2 dx\right)\left(\int_\Omega u_{1x_i}^2 dx\right) \tag{6.6}$$

to arrive at

$$\frac{\int_\Omega u_1^2 dx}{\int_\Omega x_i^2 u_1^2 dx} \le \frac{4\int_\Omega u_{1x_i}^2 dx}{\int_\Omega u_1^2 dx}. \tag{6.7}$$

Substituting this into (6.4) yields

$$\lambda_2 + \cdots + \lambda_{n+1} \le n\lambda_1 + 4\frac{\int_\Omega |\nabla u_1|^2 dx}{\int_\Omega u_1^2 dx} = (n+4)\lambda_1, \tag{6.8}$$

and (6.2) is proved. This is essentially the route used by Payne, Pólya, and Weinberger in the two-dimensional case except that rather than obtaining the individual inequalities (6.3) they used the extended Rayleigh–Ritz principle to bound the sum $\lambda_2 + \lambda_3$ by the trace of a 2×2 matrix with matrix elements $(\varphi_i, -\Delta\varphi_j)$, where the φ_i's are chosen to be orthonormal and also orthogonal to u_1. Of course, their φ_i's are nothing but $x_i u_1$, and the required orthogonality conditions are obtained via translation and rotation of the coordinate axes as in the argument above.

Similarly, the bound

$$(\lambda_2 + \lambda_3)/\lambda_1 \le 5 + \lambda_1/\lambda_2 \tag{6.9}$$

of Brands [12] extends easily to n dimensions as

$$(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1})/\lambda_1 \le n + 3 + \lambda_1/\lambda_2. \tag{6.10}$$

To obtain this one follows Brands or PPW (as given above) to (6.4), but then one estimates the sum on the right-hand side via

$$\sum_{i=1}^{n} \frac{\int_\Omega u_1^2 dx}{\int_\Omega x_i^2 u_1^2 dx} \le \frac{(\alpha+1)^2}{2\alpha - 1}\lambda_1 A(\alpha), \tag{6.11}$$

where

$$A(\alpha) = \frac{\left(\int_\Omega u_1^{2\alpha} dx\right)\left(\int_\Omega u_1^2 dx\right)}{\left(\int_\Omega u_1^{\alpha+1} dx\right)^2} \tag{6.12}$$

with α a parameter larger than $\frac{1}{2}$ (setting $\alpha = 1$ recovers the argument of PPW). Brands then finds, with $\nu \equiv \lambda_2/\lambda_1$, that

$$A(\alpha) \le \frac{(2\alpha - 1)(\nu - 1)}{(2\alpha - 1)\nu - \alpha^2} \tag{6.13}$$

if $1 < \alpha < \nu + \sqrt{\nu^2 - \nu}$. Therefore we have

$$(\lambda_2 + \lambda_3 + \cdots + \lambda_{n+1})/\lambda_1 \le n + \frac{(\alpha+1)^2(\nu-1)}{(2\alpha-1)\nu - \alpha^2}, \tag{6.14}$$

and since the minimum of the right-hand side occurs at $\alpha = 2\nu/(\nu+1)$ (which is between 1 and $\nu + \sqrt{\nu^2 - \nu}$) (6.10) follows. It is clear from their remarks [23, p. 538] that Hile and Protter knew of the generalization (6.10) of Brands' bound (6.9).

We turn now to deriving the consequences of the Brands bound (6.10) for λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$. We obtain the following theorem.

THEOREM 6.1. *The eigenvalue ratios λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$ for the n-dimensional Dirichlet Laplacian on a bounded domain $\Omega \subset \mathbb{R}^n$ $(n \geq 2)$ obey*

$$\lambda_3/\lambda_1 \leq \frac{2}{n} + \frac{(n+2)\left(n^2+n+2+\sqrt{n^4+6n^3+13n^2-4n+4}\right)}{2n(n^2+2n-2)} \tag{6.15}$$

and, for $n \geq 3$,

$$(\lambda_2+\lambda_3)/\lambda_1 \leq 1 + \frac{3+\sqrt{n^2+10n+9}}{n}. \tag{6.16}$$

Proof. Brands' bound (6.10) yields

$$(\lambda_2+(n-1)\lambda_3)/\lambda_1 \leq n+3+\lambda_1/\lambda_2, \tag{6.17}$$

which, with $x \equiv \lambda_2/\lambda_1$ and $y \equiv \lambda_3/\lambda_1$, becomes

$$y \leq (n+3+1/x-x)/(n-1). \tag{6.18}$$

We shall use this bound in conjunction with the bound $\lambda_3 - \lambda_2 \leq 2(\lambda_1+\lambda_2)/n$ of Payne, Pólya, and Weinberger [35], which, in our new notation, reads

$$y \leq \frac{2}{n} + \left(1+\frac{2}{n}\right)x. \tag{6.19}$$

(While this bound has been improved upon by Hile and Protter [23] their bound would lead to much additional complication; (6.19) is more than adequate for our purposes here.) We shall examine what the region in the xy-plane satisfying (6.18) and (6.19), along with the two trivial inequalities $x > 1$ and $y \geq x$, says about λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$. First we observe that since the right-hand side of (6.18) is decreasing in x while that of (6.19) is increasing, the maximum value of y for this region is the y corresponding to the intersection of the right-hand sides. The point (x_0, y_0) of intersection has

$$x_0 = \frac{n^2+n+2+\sqrt{n^4+6n^3+13n^2-4n+4}}{2(n^2+2n-2)}, \tag{6.20}$$

and so

$$\frac{\lambda_3}{\lambda_1} = y \leq y_0 = \frac{2}{n} + \frac{n+2}{n}x_0 \tag{6.21}$$

for all points in the region, i.e., (6.15) holds. Note that the $n=2$ case of this gives the bound $\lambda_3/\lambda_1 \leq (7+2\sqrt{7})/3 \approx 4.097$, found originally by Brands.

For (6.16) we begin by observing that the largest value of x in the region occurs at the intersection of (6.18) with $y = x$. Solving for x yields the value

$$x_1 = \left(n+3+\sqrt{n^2+10n+9}\right)/2n, \tag{6.22}$$

so that we obtain the bound

$$\frac{\lambda_2}{\lambda_1} \leq \frac{n+3+\sqrt{n^2+10n+9}}{2n}. \tag{6.23}$$

This bound was derived earlier from Brands' work by Hile and Protter [23, p. 538]. Next observe from (6.18) that

$$x + y \leq [n + 3 + 1/x + (n - 2)x]/(n - 1) \tag{6.24}$$

and that to find an upper bound to $x + y$ on the region of interest we only need to find the maximum of the right-hand side for $x_0 \leq x \leq x_1$. This latter fact is obvious from the fact that, aside from intersections with the boundary determined by (6.18), none of the other boundary curves $x = 1, y = x$, or $y = x + 2(1 + x)/n$ can contain a point in the region with maximal value of $x + y$. Since the right-hand side of (6.24) has a minimum at $x = 1/\sqrt{n-2}$ (for $n \geq 3$; for $n = 2$ it is decreasing for all $x > 0$) and this number is less than or equal to 1 for $n \geq 3$ it is clear that for $n \geq 3$ the right-hand side of (6.24) is increasing for all x's of interest. Thus, an upper bound for $(\lambda_2 + \lambda_3)/\lambda_1$ will be given by evaluating the right-hand side of (6.24) at x_1 and, since at the point of our region that this singles out we also have $y = x$, this leads to $(\lambda_2 + \lambda_3)/\lambda_1 = x + y \leq 2x_1 = 1 + (3 + \sqrt{n^2 + 10n + 9})/n$, which is (6.16). □

Remarks. (1) If $n = 2$, then the completion of the argument for $x+y$ would yield $(\lambda_2 + \lambda_3)/\lambda_1 = x + y \leq x_0 + y_0 = 3 + \sqrt{7} \approx 5.646$, the result found earlier by Brands.

(2) Our result (6.16) shows that the result (6.23) of Hile and Protter found by generalizing Brands' argument to n dimensions is actually true in the stronger form that twice the bound on λ_2/λ_1 is in fact a bound on $(\lambda_2 + \lambda_3)/\lambda_1$, except perhaps in two dimensions. This same duplication effect and more also holds for the PPW upper bound of $1 + 4/n$ even beginning at two dimensions, i.e., $(\lambda_2 + \cdots + \lambda_{k+1})/\lambda_1 \leq k(1 + 4/n)$ for $n \geq 2$ and $1 \leq k \leq n$. In two dimensions Brands' argument yields only $(\lambda_2 + \lambda_3)/\lambda_1 \leq 5.646$, whereas for λ_2/λ_1 he obtains $\lambda_2/\lambda_1 \leq (5 + \sqrt{33})/4 \approx 2.686$, and $2(2.686) \approx 5.372 < 5.646$.

(3) Arguments similar to those in our proof above can be made by replacing the bound (6.17) with the bound

$$(\lambda_2 + (n - 1)\lambda_3)/\lambda_1 \leq n + 4, \tag{6.25}$$

which derives from the PPW bound (6.2). The analogous, but slightly weaker, results are then

$$\lambda_3/\lambda_1 \leq \frac{2}{n} + \frac{(n+2)(n^2 + 2n + 2)}{n(n^2 + 2n - 2)} \quad \text{for } n \geq 2 \tag{6.26}$$

and

$$(\lambda_2 + \lambda_3)/\lambda_1 \leq 2(1 + 4/n) \quad \text{for } n \geq 2. \tag{6.27}$$

(The second of these, of course, follows directly from the PPW bound (6.2) and even generalizes as in the previous remark.)

(4) The bound (6.16) could even be improved further by including the inequality $\lambda_2/\lambda_1 = x \leq \left(j_{n/2,1}/j_{n/2-1,1}\right)^2 \equiv K_n$ (from our proof of the Payne–Pólya–Weinberger conjecture [5], [6]) as a boundary curve for our region. This gives

$$(\lambda_2 + \lambda_3)/\lambda_1 = x + y \leq [n + 3 + K_n^{-1} + (n - 2)K_n]/(n - 1) \tag{6.28}$$

for $n \geq 3$ in place of (6.16) (with (6.25) as in Remark (3) we would obtain only $[n+4+(n-2)K_n]/(n-1)$ as the upper bound). Similarly, by taking into account the inequality

$$y \leq 1 + \frac{(n-1)(x-1)}{C_n(x-1)-1} \quad \text{for } x > 1 + C_n^{-1}, \tag{6.29}$$

where $C_n \equiv [2j_{n/2-1,1}^2 + n(n-4)]/6$, which derives from (5.13) above, and finding the point of intersection of its right-hand side with (6.17) or (6.25) and with the boundary curve $y = x$ or $x = K_n$, we could get further improvements, though at the expense of more complication (see Theorems 6.2 and 6.3 below).

We now turn to comparison of the large n asymptotics of our various upper bounds for λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$. We begin with λ_3/λ_1. One finds that the right-hand side of (6.15) behaves like

$$1 + \frac{4}{n} + \frac{4}{n^2} - \frac{4}{n^3} + O(n^{-4}), \tag{6.30}$$

while that of (6.26) behaves like

$$1 + \frac{4}{n} + \frac{4}{n^2} + O(n^{-4}). \tag{6.31}$$

These bear comparison to the large n asymptotics of the bounds on λ_2/λ_1 found here and in the previous section. In order of accuracy we have the bounds $1+4/n$ (Payne, Pólya, and Weinberger/Thompson), $1 + 4/n - 4/n^2 + 20/n^3 + O(1/n^4)$ (Brands as generalized by Hile and Protter (6.23)), $1 + 4/n - c/n^{5/3} + 16/n^2 + O(n^{-7/3})$ (Chiti, as evaluated by us (5.3)), and $1 + 4/n - c/n^{5/3} + 12/n^2 + O(n^{-7/3})$ (Ashbaugh and Benguria (1.1)). Here $c = 2^{10/3}|a_1|/3 \approx 7.85555$, where a_1 = first negative zero of the Airy function $Ai(x)$ as discussed in §5 (for even more details, see our discussion following (6.53) below).

At this point we could obtain, via combination of our separate results for λ_3/λ_1 and λ_2/λ_1, a bound for $(\lambda_2+\lambda_3)/\lambda_1$ having asymptotic form $2 + 8/n - c/n^{5/3} + 16/n^2 + O(n^{-7/3}) = 2(1 + 4/n - c/2n^{5/3} + 8/n^2) + O(n^{-7/3})$. Using only bounds deriving from Brands' work we would get only $2 + 8/n + 16/n^3 + O(1/n^4) = 2(1 + 4/n + 8/n^3) + O(1/n^4)$. However, we can get better bounds out of our work above since it dealt directly with the combination $(\lambda_2+\lambda_3)/\lambda_1$. In particular, (6.16) behaves like $2 + 8/n - 8/n^2 + 40/n^3 + O(1/n^4) = 2(1 + 4/n - 4/n^2 + 20/n^3) + O(1/n^4)$, which gives a better result than combining the separate Brands-type bounds for λ_2/λ_1 and λ_3/λ_1, though it still falls short of the result which made use of our bound $\lambda_2/\lambda_1 \leq (j_{n/2,1}/j_{n/2-1,1})^2$, at least asymptotically. To beat the bound that goes as $2+8/n-c/n^{5/3}+16/n^2$ we need to investigate the asymptotics of the bound in (6.28). This gives the somewhat better asymptotic form

$$2 + 8/n - c/n^{5/3} + 8/n^2 + O(n^{-7/3}). \tag{6.32}$$

While this is still not the last word on the large n asymptotics of bounds for $(\lambda_2 + \lambda_3)/\lambda_1$, we defer further discussion until after our next two theorems. These theorems take into account the additional bound (6.29). We give these theorems in a form that would be of use for any dimension n and also in their asymptotic form for large n.

THEOREM 6.2. *With hypotheses as given previously, the eigenvalue ratio* $(\lambda_2 + \lambda_3)/\lambda_1$ *obeys the bound*

(6.33)

$$(\lambda_2+\lambda_3)/\lambda_1 \le \max\{[n+4+(n-2)x_1']/(n-1),\ 1+K_n+(n-1)(K_n-1)/[C_n(K_n-1)-1]\},$$

where $C_n = [2j_{n/2-1,1}^2 + n(n-4)]/6$, $K_n = (j_{n/2,1}/j_{n/2-1,1})^2$, *and*

$$x_1' = 1 + \{4C_n - n^2 + 2n - [(4C_n - n^2 + 2n)^2 - 16C_n]^{1/2}\}/2C_n. \tag{6.34}$$

Moreover, for sufficiently large n the second expression on the right-hand side of (6.33) *prevails, and hence*

$$(\lambda_2 + \lambda_3)/\lambda_1 \le 2 + 8/n - 2c/n^{5/3} + 28/n^2 + O(n^{-7/3}) \tag{6.35}$$

for large n.

Note. If it occurs that $x_1' > K_n$, then (6.33) can be replaced by $(\lambda_2 + \lambda_3)/\lambda_1 \le [n + 4 + (n-2)K_n]/(n-1)$. However, we do not think this possibility ever actually occurs, so we have chosen not to clutter the theorem with additional cases. The theorem is, of course, correct without this extra case.

Proof. The approach is as in the proof of Theorem 6.1. We consider the region determined by the inequalities $x > 1$, $y \ge x$, (6.19), (6.25), (6.29), and $x \le K_n$ and show that the maximum of $x + y$ must occur at one of two vertices of this region. These two vertices are (1) the vertex where the boundary curves determined by (6.25) and (6.29) meet and (2) the vertex where the boundary curves determined by (6.29) and $x \le K_n$ meet. To see this one observes that the curves

$$y = 1 + \frac{(n-1)(x-1)}{C_n(x-1)-1} \quad \text{for } x > 1 + C_n^{-1} \tag{6.36}$$

and

$$y = \frac{n+4-x}{n-1} \tag{6.37}$$

have points of intersection for

$$x_\pm = \{6C_n - n^2 + 2n \pm [(4C_n - n^2 + 2n)^2 - 16C_n]^{1/2}\}/2C_n.$$

To see that these roots are real one uses a recent result of Lorch [26] which says that Chiti's bound for λ_2/λ_1, $1 + n/C_n$, is less than the PPW/Thompson bound, $1 + 4/n$, for all n (i.e., $C_n > n^2/4$ for all $n = 1, 2, 3, \ldots$; cf. (5.5) and (5.6)). From this it follows that (6.37) intersects $y = x$ farther out along $y = x$ than does (6.36), and then the asymptotics of the two curves tell us that they must cross at the values $x_\pm$ as determined above. Hence the curve determined by (6.36) lies above that determined by (6.37) for $1 + C_n^{-1} < x < x_-$ and for $x > x_+$ while the opposite is true on the intermediate interval $x_- < x < x_+$. To continue it is enough to observe as before that the maximum value of $x + y$ attained on the allowed region must occur either along (6.36) or (6.37). Since (6.33) yields the PPW bound of 6 for $n = 2$ we can assume henceforth that $n > 2$. From (6.36) and (6.37) we define the related functions

$$F(x) = x + \frac{n+4-x}{n-1} = \frac{n+4+(n-2)x}{n-1} \tag{6.38}$$

and

$$G(x) = 1 + x + \frac{(n-1)(x-1)}{C_n(x-1)-1}. \tag{6.39}$$

As in our previous proof we note that $F(x)$ is an increasing function. Hence the maximum of $x+y$ on the interval $[1, x_-]$ must be $F(x_-)$ which is the first expression found in our bound (6.33) (even if $x_- > K_n$ this expression will serve as an upper bound).

For the other part of the bound we concentrate on $G(x)$ on the interval $[x_-, K_n]$ (where we admit for the time being the possibility that this set vanishes if $x_- > K_n$ in which case the second expression on the right in (6.33) can be dropped). We compute easily that $G'(x) = 0$ at

$$x_2 = 1 + C_n^{-1}(1 + \sqrt{n-1}) \tag{6.40}$$

and that this gives a relative minimum with G decreasing on $(1 + C_n^{-1}, x_2]$ and increasing on $[x_2, \infty)$. Thus, no matter where x_2 is located with respect to K_n the maximum value of $G(x)$ (hence $x+y$) on the interval $[x_-, K_n]$ is given by $\max\{G(x_-), G(K_n)\}$, and this is the conclusion of the theorem (note that $F(x_1') = G(x_1')$ since $x_1' = x_-$ gives a point of intersection of the graphs of F and G).

The proof thus far is a little unsatisfying in that we haven't pinned down where x_-, x_+, x_2, and K_n lie with respect to each other and hence the thought may linger that our bound could be improved if we were to investigate the locations of these points in greater detail. We now do this in the large n regime, where we show that $x_2 < x_- < K_n < x_+$, and hence that, at least for large n, the bound $G(K_n)$ is the best to be had within the context of our argument. (That $K_n < x_+$ for all n already follows from the result of Lorch used above.)

Asymptotic formulas for x_2, x_-, K_n, and x_+ are as follows:

$$x_2 = 1 + \frac{4}{n^{3/2}} + \frac{4}{n^2} + O(n^{-5/2}), \tag{6.41}$$

$$x_- = 1 + \frac{16}{cn^{4/3}} + \frac{128}{c^2 n^{5/3}} + O(n^{-2}), \tag{6.42}$$

$$K_n = 1 + \frac{4}{n} - \frac{c}{n^{5/3}} + \frac{12}{n^2} + O(n^{-7/3}), \tag{6.43}$$

and

$$x_+ = 1 + \frac{c}{n^{2/3}} - \frac{8}{n} + O(n^{-4/3}). \tag{6.44}$$

These show that the relevant bound for $(\lambda_2 + \lambda_3)/\lambda_1$ in the large n regime is $G(K_n)$ and asymptotically we have

$$G(K_n) = 2 + \frac{8}{n} - \frac{2c}{n^{5/3}} + \frac{28}{n^2} + O(n^{-7/3}),$$

which proves the last part of our theorem. □

Remark. One could add to the statement of the theorem the fact that if $x_2 \leq x_1'(= x_-)$ then one has immediately the bound $(\lambda_2 + \lambda_3)/\lambda_1 \leq G(K_n)$.

A slight, additional improvement to Theorem 6.2 can be obtained by using the bound (6.18) instead of (6.25) to define the allowed region. When solving for the intersection points of $G(x)$ and $\tilde{F}(x) \equiv [n+3+x^{-1}+(n-2)x]/(n-1)$ one encounters a cubic of which the second and third roots play the roles of x_- and x_+, respectively (the first root is less than $1+C_n^{-1}$ and, therefore, is of no relevance here). Specifically, one encounters the cubic

$$C_n(x-1)^3 - (2C_n - n^2 + 2n)(x-1)^2 - (4C_n - n^2 + 2n - 3)(x-1) + 4 = 0, \tag{6.45}$$

and since $C_n = n^2/4 + cn^{4/3}/16 - n + O(n^{2/3})$ the roots r_1, r_2, and r_3 $(r_1 \leq r_2 \leq r_3)$ behave asymptotically for large n as

$$r_1 \sim -1, \quad r_2 \sim 1 + 16/cn^{4/3}, \quad r_3 \sim 1 + c/2n^{2/3}.$$

That these three roots are real for all $n = 1, 2, 3, \ldots$ follows from a second result of Lorch [26] which says that Chiti's bound for λ_2/λ_1 is less than the Brands/Hile–Protter bound as given in (6.23) above, i.e., that $1 + n/C_n < (n + 3 + \sqrt{n^2 + 10n + 9})/2n$ for $n = 1, 2, 3, \ldots$. Just as Lorch's first result could be stated as the lower bound (5.6) for the Bessel function zero $j_{p,1}$, we can state this result as

$$j_{p,1}^2 > (p+1)\left[3\sqrt{4p^2 + 28p + 33} - 2p + 5\right]/4.$$

Again, this is valid for all $p > -1$ though we only use it for $p = n/2 - 1$ with $n = 2, 3, 4, \ldots$. Conclusions analogous to Theorem 6.2 can now be drawn by following the same approach (again, asymptotically it is $G(K_n)$ that matters, not $G(r_2)$ $(= \tilde{F}(r_2))$, and therefore the asymptotic result is that of (6.35) in Theorem 6.2 and will not be repeated). This proves the following.

THEOREM 6.3. *With hypotheses and notation as before, for $n \geq 3$ the eigenvalue ratio $(\lambda_2 + \lambda_3)/\lambda_1$ obeys the bound*

$$(\lambda_2 + \lambda_3)/\lambda_1 \leq \max\{[n + 3 + r_2^{-1} + (n-2)r_2]/(n-1),\ G(K_n)\}, \tag{6.46}$$

where r_2 is the intermediate root of the cubic (6.45).

Remark. For $n = 2$ our approach above yields again the result of Brands $(\lambda_2 + \lambda_3)/\lambda_1 \leq 3 + \sqrt{7}$. This is because in that one case $\tilde{F}(x)$ is decreasing across the entire interval of interest instead of increasing as happens for all other cases. (Note that when $n = 2$, $F(x)$ is constantly 6. This explains why the bound in Theorem 6.2 worked even for $n = 2$.)

The asymptotic expansion for our bound (see (6.35)) begins like that of $2K_n$, the conjectured best possible bound. This can be taken as additional evidence in support of this conjecture. Moreover, if one replaces the bound $G(K_n)$ by $G(1+n/C_n)$ (which is certainly permissible for large n since G will then be increasing over the interval of interest and $K_n < 1 + n/C_n$ is true for all n; $1 + n/C_n$ here is the constant occurring in Chiti's bound for λ_2/λ_1), then one gets $(\lambda_2 + \lambda_3)/\lambda_1 \leq 2(1 + n/C_n)$. That is, Chiti's bound has the duplication property for n sufficiently large that $G(1 + n/C_n)$ is greater than or equal to either of $G(x_-)$ or $G(r_2)$. The asymptotic expansion of $2(1 + n/C_n)$ differs from (6.35) only in terms $O(n^{-2})$ and beyond; in particular (see

(5.4)), the term $28/n^2$ in (6.35) gets replaced by $32/n^2$, while the conjectured best bound has $24/n^2$ (see (5.1)).

If one applies the arguments we use in this section to the conjectured bound $(\lambda_2 + \cdots + \lambda_{n+1})/\lambda_1 \le nK_n$, then $(\lambda_2 + \lambda_3)/\lambda_1 \le 2K_n$ of course follows as well as

$$\begin{aligned} \lambda_3/\lambda_1 \le & \frac{2}{n} + \frac{(n+2)[n^2K_n - 2(n-1)]}{n(n^2+2n-2)} \\ = & 1 + \frac{4}{n} - \frac{c}{n^{5/3}} + \frac{16}{n^2} + \frac{k_1}{n^{7/3}} - \frac{17c}{3n^{8/3}} + \frac{k_2}{n^3} + O(n^{-10/3}). \end{aligned} \tag{6.47}$$

Here the constant c has already been defined, while k_1 and k_2 are positive constants which will be explained more fully in connection with (6.52) and (6.53) below. A comparison with (6.30) (or (6.31)) shows that the bound (6.15) that we have proved here is only slightly worse than this for large n (cf. also (6.55) below).

There is one more improvement that we can make to some of the results in this section. That is to incorporate the bound $\lambda_3/\lambda_2 < K_n$ (i.e., $y < K_n x$) which was recently proved by us [7] (see also [8]) into our constraints on the allowed region. It turns out that this bound effectively supersedes the bound (6.19) of Payne, Pólya, and Weinberger at least in the matter of bounding λ_3/λ_1 for large dimension n (and probably for all $n = 2, 3, 4, \dots$). We begin by examining the intersection point of the lines $y = K_n x$ and $y = 2/n + (1 + 2/n)x$. This point is

$$\overline{x}_0 = \frac{2}{nK_n - (n+2)} = 1 + \frac{c}{2n^{2/3}} - \frac{6}{n} + O(n^{-4/3}). \tag{6.48}$$

At least asymptotically, this point is larger than

$$x_0 = \{n^2 + n + 2 + [n^4 + 6n^3 + 13n^2 - 4n + 4]^{1/2}\}/2(n^2 + 2n - 2),$$

corresponding to the point of intersection of $y = 2/n + (1 + 2/n)x$ and $y = (n + 3 + x^{-1} - x)/(n-1)$, which behaves as $1 + 4/n^2 - 12/n^3 + O(n^{-4})$. Since at $x = 1$ $K_n x < 2/n + (1+2/n)x$, this means that $K_n x$ is the controlling bound in the region of interest for $\max \lambda_3/\lambda_1$. Thus we go back and find the points of intersection of $y = K_n x$ with $y = (n + 3 + x^{-1} - x)/(n-1)$ and $y = (n + 4 - x)/(n-1)$, and proceeding in the now familiar way we arrive at the following theorem.

THEOREM 6.4. *With hypotheses and notation as above the ratio* λ_3/λ_1 *obeys*

$$\lambda_3/\lambda_1 < K_n \frac{n + 3 + [(n+3)^2 + 4(n-1)K_n + 4]^{1/2}}{2(n-1)K_n + 2}. \tag{6.49}$$

This is a better bound than (6.15) *if and only if* $x_0 < \overline{x}_0$, *where* $\overline{x}_0 = 2/[nK_n - (n+2)]$ *and* x_0 *is given by* (6.20). *In particular,* (6.49) *is better than* (6.15) *for sufficiently large* n.

Proof. The relevant point of intersection of $y = K_n x$ with $y = (n + 3 + x^{-1} - x)/(n-1)$ is easily found to be

$$x_0' = \frac{n + 3 + [(n+3)^2 + 4(n-1)K_n + 4]^{1/2}}{2(n-1)K_n + 2} \tag{6.50}$$

and that with $y = (n + 4 - x)/(n-1)$ is

$$x_0'' = \frac{n+4}{(n-1)K_n + 1}. \tag{6.51}$$

These have the asymptotic expansions

$$x_0' = 1 + \frac{c}{n^{5/3}} - \frac{8}{n^2} - \frac{k_1}{n^{7/3}} - \frac{c}{3n^{8/3}} + \frac{52 - k_2}{n^3} + O(n^{-10/3}) \tag{6.52}$$

and

$$x_0'' = 1 + \frac{c}{n^{5/3}} - \frac{8}{n^2} - \frac{k_1}{n^{7/3}} + \frac{2c}{3n^{8/3}} + \frac{44 - k_2}{n^3} + O(n^{-10/3}), \tag{6.53}$$

where c is a positive constant as defined above and k_1 and k_2 are higher coefficients in the asymptotic expansion of K_n; specifically, we have $K_n = 1 + 4/n - c/n^{5/3} + 12/n^2 + k_1/n^{7/3} - 17c/3n^{8/3} + k_2/n^3 + O(n^{-10/3})$ with k_1 and k_2 being positive constants with values $k_1 \approx 9.256$, $k_2 \approx 25.31$, which are determined from the coefficients in the asymptotic expansion of the Bessel function zero $j_{p,1}$ for large p as given by Abramowitz and Stegun [1, p. 371, eq. 9.5.14]. (These coefficients can all be related to the first negative zero $a_1 \approx -2.33810741$ of the Airy function $Ai(x)$; in particular, $c = -2^{10/3}a_1/3 \approx 7.85555$, $k_1 = 2^{14/3}a_1^2/15$, and $k_2 = 16(16a_1^3 + 1035)/525$.) Equations (6.52) and (6.53) show already that asymptotically $x_0 < x_0' < x_0'' < \bar{x}_0$. (It is also clear that for sufficiently large n, x_0'' is less than both x_- and r_2 so the bound $y < K_n x$ will not give improvements to the bounds for $(\lambda_2 + \lambda_3)/\lambda_1$ found previously, at least for large n.) By the same arguments used previously one now has $\lambda_3/\lambda_1 < K_n x_0'$ and $K_n x_0''$, with $K_n x_0'$ being a slightly better bound (for all n; the only advantage that x_0'' has to recommend it over x_0' is its relative simplicity). □

Remarks. (1) The condition for when (6.49) is better than (6.15) can be given in other equivalent terms. We have $x_0 < \bar{x}_0 \Leftrightarrow x_0' < \bar{x}_0 \Leftrightarrow x_0 < x_0'$ (so that either $x_0 < x_0' < \bar{x}_0$, $\bar{x}_0 < x_0' < x_0$, or $x_0 = x_0' = \bar{x}_0$).

(2) The quantity $K_n x_0'$ (the bound for λ_3/λ_1 in (6.49)) has asymptotic behavior

$$1 + \frac{4}{n} + \frac{4}{n^2} - \frac{2c}{n^{8/3}} + \frac{20}{n^3} + O(n^{-10/3}), \tag{6.54}$$

which is slightly better than the asymptotic form (6.30) found for our best previous bound.

(3) If one uses $y < K_n x$ to improve the conjectured result (6.47) for the bound on λ_3/λ_1 that would follow from the conjecture $(\lambda_2 + \cdots + \lambda_{n+1})/\lambda_1 \le nK_n$, one obtains

(6.55)

$$\lambda_3/\lambda_1 \le \frac{nK_n^2}{(n-1)K_n + 1} = 1 + \frac{4}{n} - \frac{c}{n^{5/3}} + \frac{16}{n^2} + \frac{k_1}{n^{7/3}} - \frac{20c}{3n^{8/3}} + \frac{k_2 + 12}{n^3} + O(n^{-10/3}).$$

As can be seen, this would be marginally better than (6.47). Equations (6.47) and (6.55) give us something to shoot for in trying to improve upon (6.49) and its asymptotic form (6.54), though it is by no means clear that even (6.55) could not be improved upon.

It might also be noted that our best bounds on $(\lambda_2 + \lambda_3)/\lambda_1$ for large n, at least, depended on the inequality (5.13) through $y \le 1 + (n-1)(x-1)/[C_n(x-1) - 1]$. One can consider the consequences if (5.13) could be replaced by the stronger inequality (5.16) which is itself weaker than (5.19) (see our discussion in §5). This would amount to replacing the constant C_n by $n/(K_n - 1)$ in the operative inequalities and would imply that $(\lambda_2 + \lambda_3)/\lambda_1 \le 2K_n$ for all sufficiently large n. Thus the relatively weak but optimal conjectured inequality (5.16) would imply the best possible bound on $(\lambda_2 + \lambda_3)/\lambda_1$ for large dimensions (perhaps this approach could be made to yield $(\lambda_2 + \lambda_3)/\lambda_1 \leq 2K_n$ for all dimensions higher than three; it cannot work in two dimensions because $5 + 1/x$ is decreasing and also x_2, the point where $G(x)$ reaches its minimum, is larger than K_2).

We conclude by briefly summarizing what we have accomplished in this section and by applying our work to obtain numerical bounds in the three- and four-dimensional cases. We also make some final observations concerning the two-dimensional case. For $n \geq 2$ the boundary curves that matter for λ_3/λ_1 are $y = [n + 3 + x^{-1} - x]/(n - 1)$ and whichever of $y = K_n x$ or $y = 2/n + (1 + 2/n)x$ gives a lower intersection point with the first. This is because the first function is decreasing while the latter two are increasing. Theorems 6.1 and 6.4 cover the two possibilities. For $(\lambda_2 + \lambda_3)/\lambda_1$ the boundary curves that matter for $n \geq 3$ are $x+y = [n+3+x^{-1}+(n-2)x]/(n-1)$ again, $x+y = 1+x+(n-1)(x-1)/[C_n(x-1)-1]$, and $x = K_n$, and hence the bounds that we obtain are the values of $x+y$ corresponding to certain points of intersection of these curves (at most two of these points of intersection ever matter at the same time). The relevant facts are now that the right-hand side of the first equation is an increasing function of x (for $n \geq 3$ and $x \geq 1$) while that of the second is convex. Thus if the second equation matters its endpoint values over the interval on which it matters determine an upper bound for $(\lambda_2 + \lambda_3)/\lambda_1$ and if it does not, then $[n+3+K_n^{-1}+(n-2)K_n]/(n-1)$ is an upper bound. This information is included in (6.28) and Theorem 6.3. In all cases for both λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$, except that of $(\lambda_2 + \lambda_3)/\lambda_1$ when $n = 2$, the boundary curve $y = [n + 4 - x]/(n - 1)$ can replace $y = [n+3+x^{-1} - x]/(n - 1)$ without changing this qualitative picture; it will give slightly worse results but the expressions giving them may be somewhat simpler. This explains the origins of our results concerning $(\lambda_2 + \lambda_3)/\lambda_1$ in Theorems 6.1 (which used only $y = x$ and not $x = K_n$ as one of the boundary curves) and 6.2.

It may in fact be true that of all the bounds derived above for λ_3/λ_1, Theorem 6.4 is always the best for $n \geq 2$ and that for $(\lambda_2 + \lambda_3)/\lambda_1$, $G(K_n)$ is always the best bound for $n \geq 4$. Certainly for large enough n this is what happens. It only remains to determine at what value of n this occurs. It is because this matter is not easy to settle that we stated our theorems in terms of the various contingencies that we did. However, indications from low order cases (see below for the cases $n = 2, 3$, and 4) are that already by $n = 4$ these bounds predominate.

For $n = 3$ our work above gives the numerical results

$$\lambda_3/\lambda_1 < \frac{K_3(3 + \sqrt{2K_3 + 10})}{2K_3 + 1} \approx 2.7137 \tag{6.56}$$

and

$$(\lambda_2 + \lambda_3)/\lambda_1 \leq 4.1499. \tag{6.57}$$

We also note the bounds

$$\lambda_2/\lambda_1 \leq K_3 \approx 2.0457, \tag{6.58}$$

which is best possible, and

$$(\lambda_2 + \lambda_3 + \lambda_4)/\lambda_1 \leq 7. \tag{6.59}$$

The conjectured best possible bounds for $(\lambda_2 + \lambda_3)/\lambda_1$ and $(\lambda_2 + \lambda_3 + \lambda_4)/\lambda_1$ are $2K_3 \approx 4.0915$ and $3K_3 \approx 6.1372$, respectively. There is no reasonable guess as to what the best bound for λ_3/λ_1 might be. The bound in (6.56) derives from the point of intersection of $y = K_3x$ and $y = (6+x^{-1}-x)/2$ while that in (6.57) comes from the intersection point of $y = (6+x^{-1}-x)/2$ and $y = 1+2(x-1)/[C_3(x-1)-1]$ which has x coordinate ≈ 1.717614 (specifically, this value of x is the middle root of the cubic $C_3x^3 - (5C_3 - 3)x^2 + 3C_3x + (C_3 + 1) = 0$ with $C_3 = (2\pi^2 - 3)/6 \approx 2.789868$). To see how close $G(K_3)$ comes to taking over in (6.46) (and hence in (6.57)) we note that $G(K_3) \approx 4.1365$, which is only slightly smaller than the value 4.1499 found in (6.57). For $n = 4$, $G(K_4) \approx 3.6209$ does in fact prevail and it is likely that this trend continues so that $G(K_n)$ prevails for all $n \geq 4$. Also for $n = 4$ one finds $\lambda_2/\lambda_1 \leq K_4 \approx 1.7964$ and $\lambda_3/\lambda_1 < K_4(7 + \sqrt{12K_4 + 53})/2(3K_4 + 1) \approx 2.1979$, the latter coming from the point of intersection of $y = K_4x$ and $y = (7 + 1/x - x)/3$.

For $n = 2$ our work in this section gives only the bounds

$$\lambda_3/\lambda_1 < K_2(5 + \sqrt{4K_2 + 29})/2(K_2 + 1) \approx 4.0381$$

(better than PPW and Brands, not as good as Hile and Protter or Marcellini) and

$$(\lambda_2 + \lambda_3)/\lambda_1 \leq (5 + \sqrt{4K_2 + 29})/2 \approx 5.6287$$

(which has the same position relative to the bounds of the others). Hile and Protter [23] and Marcellini [27] both went beyond our results by working with an additional inequality which takes the place of $y \leq 1+2x$ (as used by Brands) or $y < K_2x$ (as used in our work here). For Hile and Protter it is the bound $y \leq 1 + x + \sqrt{1 - x + x^2}$ and for Marcellini it is $y \leq \{1 + 3x + 4x^2 - [(1 + 3x + 4x^2)^2 - 58x^3 - 4x^2 + 2x]^{1/2}\}/2x$. While Hile and Protter's inequality has the n-dimensional generalization

$$y \leq \left\{(n + 2)(1 + x) + [(n + 2)^2x^2 - 2(n^2 + 4n - 4)x + (n + 2)^2]^{1/2}\right\} \Big/ 2n, \tag{6.60}$$

it seems to be less effective than $y < K_nx$ for higher dimensions than two (at least this is so for $n = 3$ and $n = 4$; it is also significantly more complicated than $y < K_nx$). Similarly, while we have obtained

$$y \leq \frac{A - [A^2 - 4n(n-1)x\{(n^2 + 7n + 11)x^2 + 2x - 1\}]^{1/2}}{2n(n-1)x}, \tag{6.61}$$

where

$$A \equiv (n^2 + 4n - 4)x^2 + n(n + 1)x + n \tag{6.62}$$

as the n-dimensional generalization of Marcellini's bound, the bounds we have developed above would appear to yield better bounds for λ_3/λ_1 in four and more dimensions (in three dimensions the generalized Marcellini bound yields $\lambda_3/\lambda_1 \leq 2(3 + \sqrt{14})/5 \approx 2.6967$, a modest improvement upon (6.56)). All bounds in two dimensions for both λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$ correspond to the vertex point of the allowed region at the left end of the interval of validity of $y \leq 5 + x^{-1} - x$ (or $y \leq 6 - x$ for the PPW bound); when $n \geq 3$ this is still the case for λ_3/λ_1 but not for $(\lambda_2 + \lambda_3)/\lambda_1$.

We summarize the best results for λ_3/λ_1 and $(\lambda_2 + \lambda_3)/\lambda_1$ found to date in Table 1. Note that for $n \geq 3$ the bounds for $(\lambda_2 + \lambda_3)/\lambda_1$ are already in very good agreement

TABLE 1

Best upper bounds to date for λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$ in dimensions 2, 3, and 4 (rounded to 4 places beyond the decimal).

n	bound for λ_3/λ_1	bound for $(\lambda_2+\lambda_3)/\lambda_1$	$(\lambda_2+\lambda_3)/\lambda_1$ for an n-ball
2	3.9170	5.5957	5.0775
3	2.6967	4.1499	4.0915
4	2.1979	3.6209	3.5928

with the conjectured optimal bound of $2K_n$ (which is the value of $(\lambda_2+\lambda_3)/\lambda_1$ for an n-ball).

An analysis similar to that for general n above could be employed to bound λ_4/λ_1 and $(\lambda_2+\lambda_3+\lambda_4)/\lambda_1$ in three and more dimensions. One would then have to study the allowed region in xyz-space for $x \equiv \lambda_2/\lambda_1$, $y \equiv \lambda_3/\lambda_1$, and $z \equiv \lambda_4/\lambda_1$, much as we have done above for λ_2/λ_1 and λ_3/λ_1. In such an analysis one would use the natural analogs of the inequalities we used above; our recently proved bound $\lambda_4/\lambda_2 < K_n$ (see [8]) would replace $\lambda_3/\lambda_2 < K_n$.

7. Improvements to the upper bound of Singer, Wong, Yau, and Yau.

In [45], Singer, Wong, Yau, and Yau considered the problem of bounding the fundamental gap $\lambda_2-\lambda_1$ for a Schrödinger operator $-\Delta+V(x)$ acting on $L^2(\Omega)$ for bounded domains $\Omega \subset \mathbb{R}^n$ with Dirichlet boundary conditions imposed on $\partial\Omega$. They were able to find natural upper and lower bounds to $\lambda_2-\lambda_1$. For their lower bound they impose convexity on both Ω and V, while their upper bound, which is just the PPW/Thompson bound $1+4/n$ generalized to Schrödinger operators and viewed as an upper bound on the difference $\lambda_2-\lambda_1$, applies under much less stringent hypotheses. In its most general form their upper bound reads

$$\lambda_2-\lambda_1 \le \frac{4}{n}(\lambda_1-m) \le \frac{4}{n}(\mu_1+M-m), \tag{7.1}$$

where m and M are lower and upper bounds for the potential V, i.e., $m \le V(x) \le M$ for all $x \in \Omega$, and μ_1 represents the first Dirichlet eigenvalue of $-\Delta$ on Ω. This bound follows immediately by observing that the original argument of Payne, Pólya, and Weinberger carries over essentially unchanged to Schrödinger operators with $V \ge 0$ on Ω. Thus the operator $-\Delta+V-m$ has eigenvalues λ_1-m and λ_2-m satisfying

$$(\lambda_2-m) \le \left(1+\frac{4}{n}\right)(\lambda_1-m)$$

so that the first part of (7.1) holds. To improve upon (7.1) it suffices to note (see Theorem 4.2 of [6]) that our upper bound for λ_2/λ_1 also carries over intact to Schrödinger operators with nonnegative potentials. We therefore obtain

$$\lambda_2-\lambda_1 \le \left[(j_{n/2,1}/j_{n/2-1,1})^2-1\right](\lambda_1-m) \le \left[(j_{n/2,1}/j_{n/2-1,1})^2-1\right](\mu_1+M-m) \tag{7.2}$$

as a better upper bound than (7.1). In two dimensions, for example, the multiplicative factor 2 from (7.1) is improved to approximately 1.539.

One can obtain more explicit upper bounds by using estimates for μ_1. One such bound is simply

$$\mu_1 \le 4j_{n/2-1,1}^2/D^2, \tag{7.3}$$

where D is the diameter of the largest ball that can be inscribed within Ω. As noted by Singer, Wong, Yau, and Yau, Cheng [15] gave the further bound

$$\mu_1 \leq 4j^2_{n/2-1,1}/D^2 < n^2\pi^2/D^2. \tag{7.4}$$

This comes from considering the first eigenvalue of the n-cube inscribed in the ball of diameter D, which has sides of length $D/\sqrt{n}$. Certainly for large n this bound loses a lot with respect to (7.3), specifically, $n^2\pi^2/D^2$ is worse by a factor of π^2 as n goes to infinity. To do somewhat better (for $n \geq 2$) one can employ the inequality

$$j^2_{p,1} < 2(p+1)(p+3) \tag{7.5}$$

(see Watson [48, p. 486, ineq. (5)]). This gives

$$\mu_1 < 2n(n+4)/D^2, \tag{7.6}$$

which is still high by a factor of 2 in the large n limit. With reference to the subject matter of this paper it is perhaps worth noting that (7.5) follows for $p = -\frac{1}{2}, 0, \frac{1}{2}, 1, \ldots$ from the fact that

$$\begin{aligned} 1 + \frac{3}{n} &= [\lambda_2/\lambda_1 \text{ for the } n\text{-cube }] < [\text{ Chiti's bound for } \lambda_2/\lambda_1] \\ &= 1 + \frac{6n}{2j^2_{n/2-1,1} + n(n-4)} \end{aligned} \tag{7.7}$$

(see (5.3) in §5 above).

Beyond (7.5), there is the bound of Chambers [13]

$$j^2_{p,1} < (p+1)[p+3+2\sqrt{p+2}] \tag{7.8}$$

which is both better than (7.5) for all $p > -1$ and asymptotically correct to leading order as p goes to infinity. This yields

$$\mu_1 < n\left(n+4+2\sqrt{2n+4}\right)/D^2 \tag{7.9}$$

as an improvement to the last part of (7.4) for all $n \geq 2$.

8. Concluding remarks. As mentioned in our previous paper, our results and techniques can probably be used to obtain improved results for related problems from differential geometry and possibly for the other problems considered in the original paper of Payne, Pólya, and Weinberger.

Mention might also be made of the fact that our upper bound for λ_2/λ_1 can be used to provide lower bounds on λ_1 provided λ_2 or a lower bound for λ_2 is known. This observation is a key ingredient in finding lower bounds to λ_1 for bent tubes [10].

Improvements in the constant in Marcellini's bound [27] for λ_3/λ_1 in two dimensions,

$$\lambda_3/\lambda_1 \leq 3.917, \tag{8.1}$$

or in his inequality $(\lambda_2+\lambda_3)/\lambda_1 \leq 5.596$ might well follow from some of our techniques, our extension (5.7) of Chiti's bound, and other known results. We intend to make a more extensive investigation of bounds on λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$ in two dimensions and report on them elsewhere.

Finally, we mention that all our bounds can be extended to operators (Dirichlet Laplacians, Schrödinger operators, or general elliptic operators as discussed in §4 of [6]) on unbounded domains $\Omega \subset \mathbb{R}^n$ so long as the operator has a form core of compactly supported functions, for in that case we can approximate all eigenvalues (defined via the Min-Max principle) in terms of appropriate Rayleigh quotients of compactly supported functions and then our known bounds for bounded domains Ω apply (see our discussion on p. 412 of [4] for more details on this). For example, our results apply to the n-dimensional isotropic harmonic oscillator, $H = -\Delta + |x|^2$ in $\mathbb{R}^n$, where one can also compute explicitly that $\lambda_2/\lambda_1 = 1 + 2/n$.

Recently we have successfully applied many of the ideas used in this paper and its predecessors to the Neumann eigenvalues of $-\Delta$ (we admit $|\Omega|$, the volume of Ω, into our formulas, however). These results will be presented in [9].

Appendix A: Some integrals of Bessel functions. We present here the antidifferentiation formula necessary for the explicit evaluation of the integral occurring in (5.2) and certain closely related antidifferentiation formulas.

We have, where $Z_p(x)$ represents any solution to Bessel's equation of order p,

$$\int xZ_p(x)^2dx = \frac{1}{2}(x^2-p^2)Z_p(x)^2 + \frac{1}{2}x^2Z_p'(x)^2 + c, \tag{A.1}$$

$$\begin{aligned}\int x^3Z_p(x)^2dx = \frac{1}{6}\big[&\left(x^4+p^2x^2-2p^2(p^2-1)\right)Z_p(x)^2 - 2x^3Z_p(x)Z_p'(x)\\ &+ (x^4+2(p^2-1)x^2)Z_p'(x)^2\big] + c,\end{aligned} \tag{A.2}$$

(A.3)
$$\begin{aligned}\int x^5Z_p(x)^2dx = \frac{1}{30}\big[&(3x^6+(p^2+8)x^4+4p^2(p^2-4)x^2\\ &-8p^2(p^2-1)(p^2-4))Z_p(x)^2 - 4(3x^5+2(p^2-4)x^3)Z_p(x)Z_p'(x)\\ &+(3x^6+4(p^2-4)x^4+8(p^2-1)(p^2-4)x^2)Z_p'(x)^2\big] + c.\end{aligned}$$

Of these, only (A.2) is needed for simplifying (5.2). Equation (A.1) is well known and was in fact already employed by Chiti in arriving at (5.2). We include (A.3) simply to indicate that further explicit antidifferentiation formulas can be found. In fact, one can obtain explicit formulas for $\int x^{2m+1}Z_p(x)^2dx$ for $m = 0, 1, 2, \ldots$ as well as related integrals involving $Z_p(x)Z_p'(x)$ or $Z_p'(x)^2$ via a recursive procedure.

Acknowledgments. Mark S. Ashbaugh would like to thank the Physics Department and others at the Universidad de Chile for their hospitality during his visit in April 1990 when this research was initiated. We thank Fritz Gesztesy for general comments and encouragement. In addition, it is a pleasure to thank Larry Payne and Gérard Philippin for supplying us with several of the references to the nodal line conjecture and for interesting conversations and correspondence regarding the problems considered here. Finally, we are grateful to Martin E. Muldoon for much useful information concerning Bessel function zeros, and especially to Lee Lorch for proving certain inequalities which we used above and communicating them to us prior to publication.

Note added in proof (July 19, 1993). Since completing this paper we have improved upon Marcellini's bounds for λ_3/λ_1 and $(\lambda_2+\lambda_3)/\lambda_1$ in the two-dimensional case (as alluded to in §8 above). Marcellini's bounds were 3.9170 and 5.5957, respectively, while ours are 3.9051 and 5.5249. The derivations of these bounds and other inequalities of interest will appear in our forthcoming paper, "The Range of Values of λ_2/λ_1 and λ_3/λ_1 for the Fixed Membrane Problem."

SIMULTANEOUS POLYNOMIAL APPROXIMATION*

Z. DITZIAN†, D. JIANG†, AND D. LEVIATAN‡

Abstract. A recent result (see [*Canad. J. Math.*, 44 (1992), pp. 924–940]) has bridged the gap between the Timan-type pointwise estimate and the norm estimate for polynomial approximation in $C[-1,1]$. Here, the authors show that for $f \in C^{(s)}[-1,1]$ the function and its derivatives of order j, $0 \le j \le s$, can be simultaneously approximated by polynomials of degree n and their derivatives in the appropriate manner.

Key words. simultaneous approximation, algebraic polynomial approximation

AMS subject classifications. 41A28, 41A10

1. Introduction. It is known (see [6]) that for $f \in C[-1,1]$, $0 \le \lambda \le 1$ and an integer r there exists a polynomial $P_n \in \Pi_n$, where Π_n is the class of polynomials of degree n, such that

$$|f(x) - P_n(x)| \le C\omega^r_{\varphi^\lambda}(f, n^{-1}\delta_n(x)^{1-\lambda}), \tag{1.1}$$

where $\varphi(x) = \sqrt{1-x^2}$, $\delta_n(x) = n^{-1} + \varphi(x)$, and $\omega^r_\psi(f,t)$ is given by

$$\omega^r_\psi(f,t) = \sup_{x\in I} |\Delta^r_{h\psi(x)} f(x)|, \qquad I = [-1,1]. \tag{1.2}$$

This measure of smoothness related to the step-weight function ψ was introduced and investigated in [8]. (For the case treated here $\omega^r_\psi(f,t)$ was already introduced in [5, §3].) We note that when $\lambda = 0$, (1.1) yields the Timan-type estimate for polynomial approximation and when $\lambda = 1$, (1.1) yields the norm estimate (only for $L_\infty[-1,1]$) for best polynomial approximation (see [8, Chap. 7] for the result in $L_p[-1,1]$, $1 \le p \le \infty$).

For $r = 2$ it was shown (see [7]) that $P_n \in \Pi_n$ can be found such that

$$|f(x) - P_n(x)| \le C\omega^2_{\varphi^\lambda}(f, n^{-1}\varphi(x)^{1-\lambda}). \tag{1.3}$$

In this paper we investigate the situation in which $f^{(s)} \in C[-1,1]$. We will show the following.

THEOREM 1.1. *Suppose s, r, and k are integers, $s \ge 0$, $r \ge 1$, $0 \le \lambda \le 1$ $f^{(s)}(x) \in C[-1,1]$, and $\varphi(x) = \sqrt{1-x^2}$. Then, for $n \ge s+1$ there exists $P_n \in \Pi_n$ for which*

$$|f^{(j)}(x) - P^{(j)}_n(x)| \le C\big(n^{-1}\varphi(x)\big)^{s-j} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big), \qquad 0 \le j \le s, \tag{1.4}$$

and

$$|P^{(s+k)}_n(x)| \le Cn^k\delta_n(x)^{-k}\omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big), \qquad k \ge r. \tag{1.5}$$

The construction used for Theorem 1.1 can be refined to prove the following sharper result for $r = 1, 2$.

THEOREM 1.2. *Under the assumptions of Theorem* 1.1, *for $n \geq s+1$ there exists a polynomial $P_n \in \Pi_n$ such that*

$$|f^{(j)}(x) - P_n^{(j)}(x)| \leq C\big(n^{-1}\varphi(x)\big)^{s-j}\omega_{\varphi^\lambda}^{\ell}\big(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\big) \tag{1.6}$$

for $\ell = 1, 2$ and $0 \leq j \leq s$, and

$$|P_n^{(s+k)}(x)| \leq Cn^k\delta_n(x)^{-k}\omega_{\varphi^\lambda}^{\ell}\big(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\big) \tag{1.7}$$

for $k \geq \ell$.

Remark 1.3. In the preceding theorem it is sufficient to prove the result for $\ell = 2$ in (1.6) and (1.7) since

$$\omega_{\varphi^\lambda}^2(g,t) \leq M\omega_{\varphi^\lambda}(g,t) \quad \text{for } 0 \leq t \leq t_0 \tag{1.8}$$

(see [7, Thm. 4.1.3]). The remaining case, i.e., $k = \ell = 1$ can be treated similarly (see also the remark after (3.13)).

For the special case $\lambda = 0$ a great part (but not all) of the above theorems were proved in a series of articles spread out from the early fifties to the last decade. For $\lambda > 0$ the results are new. The earlier investigation of this type of estimate seems to go back to Timan [17] in 1951, and his work was extended in the sixties by Trigub [18] and Brudnyĭ [1] who achieved a special case of (1.4) for $\lambda = 0$. Improving the estimates by replacing $\delta_n(x)$ by $\varphi(x)$ is due to Teljakovskiĭ [16] and Gopengauz [11] who got (1.6) with $\ell = 1$ and $\lambda = 0$. Gopengauz [12] made an attempt at (1.6) for $\lambda = 0$ and other ℓ but he claimed that the result is valid for all ℓ which is known to be incorrect for $\ell \geq 3$. It seems that the first proof of (1.6) for $\ell = 2$ (under the conditions $\lambda = 0$ and $s = 0$) is due to DeVore [3], [4]. This result was further extended by Gonska and Hinnemann [10] who proved (1.6) for $\lambda = 0$, $\ell = 1, 2, \ldots$, and $0 \leq j \leq s - \ell$; and finally, independently, by Dahlhaus [2] and Li [14], who showed that for $\lambda = 0$, (1.6) holds for some $\ell = 1, 2, \ldots$ if and only if $0 \leq j \leq \min\{s-\ell+2, s\}$. In our proof of (1.6) we rely heavily on our previous construction in [7], which is valid only for $\ell = 1, 2$. Therefore, we have to limit ourselves to $\ell = 1, 2$, but we do get the full range of j, namely, $0 \leq j \leq s$. Note that we also obtain (1.7), which provides estimates on higher derivatives of the approximating polynomials. We would like to thank the referee for bringing to our attention references [2] and [14].

2. Some preliminary lemmas.

We will prove here some lemmas needed for the proof of the main result.

LEMMA 2.1. *Suppose $P_n \in \Pi_n$, $m \geq 0$, $0 \leq \lambda \leq 1$, and $\delta_n(x) = \frac{1}{n} + \sqrt{1-x^2}$ and that the increasing function $\omega(t)$ satisfies*

$$0 < \omega(\mu t) \leq M_r(\mu^r + 1)\omega(t) \tag{2.1}$$

for some positive integer r. Then

$$|P_n(x)| \leq A\big(n^{-1}\delta_n(x)\big)^m\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big), \qquad -1 \leq x \leq 1, \tag{2.2}$$

implies for $k \geq 0$

$$|P_n^{(k)}(x)| \leq C\big(n^{-1}\delta_n(x)\big)^{m-k}\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big), \qquad -1 \leq x \leq 1. \tag{2.3}$$

Proof. For $k \geq m + r(1-\lambda)$, (2.3) follows from Theorem 4.1 of [6]. For $0 < k < m + r(1-\lambda)$ we apply Lemma 2.1 of [5] and ideas from [6] or ideas from the proof of Theorem 5.3 of [15] applied to $t^m\omega(n^{-\lambda}t^{1-\lambda})$. We leave details to the reader. □

We now prove what will constitute the crucial step in the inductive proof of our main result.

LEMMA 2.2. *Suppose ℓ is an integer, $\ell \geq -1$, $0 \leq \lambda \leq 1$, $\omega(t)$ is an increasing function satisfying* (2.1) *for some integer r, $\delta_n(x) = n^{-1} + \sqrt{1-x^2}$, and g_n satisfies*

$$|g_n'(x)| \leq C\big(n^{-1}\delta_n(x)\big)^{\ell}\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big). \tag{2.4}$$

Then there exists a polynomial $Q_n \in \Pi_n$ satisfying

$$|g_n(x) - Q_n(x)| \leq M\big(n^{-1}\delta_n(x)\big)^{\ell+1}\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big) \tag{2.5}$$

and

$$|Q_n'(x)| \leq M\big(n^{-1}\delta_n(x)\big)^{\ell}\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big) \tag{2.6}$$

with $M \equiv M(C, \ell, r, \lambda)$ independent of n and g_n.

Proof. We construct the algebraic polynomial $Q_n \in \Pi_n$ by

$$Q_n(x) \equiv \int_{-\pi}^{\pi} g_n\big(\cos((\arccos\ x) - t)\big)T_n(t)dt, \tag{2.7}$$

where $T_n(t)$ is the trigonometric polynomial of order n given by

$$\begin{gathered} T_n(t) \equiv L_{[n/m],m}(t), \qquad L_{k,m}(t) = \lambda_k\left(\frac{\sin\ kt/2}{\sin\ t/2}\right)^{2m}, \\ \int_{-\pi}^{\pi} L_{k,m}(t)dt = 1 \quad \text{and} \quad m = \ell + r + 2. \end{gathered} \tag{2.8}$$

To prove (2.5) we write

$$I_n(x) = |g_n(x) - Q_n(x)| = \left| \int_{-\pi}^{\pi} \left[\int_{\cos\big((\arccos\ x) - t\big)}^{x} g_n'(u)du \right] T_n(t)dt \right|.$$

We denote the interval between $\cos\big((\arccos\ x) - t\big)$ and x by $J(x,t)$ and its length by $m\big(J(x,t)\big)$. Using straightforward computation, we have (see [8, p. 80])

$$m\big(J(x, \pm t)\big) = |x - \cos\big((\arccos\ x) \pm t\big)| \leq \Delta_{1/t}(x) \equiv |t| \ \Big(|t| + \sqrt{1-x^2}\Big). \tag{2.9}$$

Hence,

$$\begin{aligned} I_n(x) &\leq \int_{-\pi}^{\pi} \left\{ \frac{1}{m\big(J(x,t)\big)} \int_{J(x,t)} \Delta_{1/t}(x)|g_n'(u)|du \right\} T_n(t)dt \\ &\leq Cn^{-\ell} \int_{-\pi}^{\pi} \left\{ \frac{1}{m\big(J(x,t)\big)} \int_{J(x,t)} \Delta_{1/t}(x)\delta_n(u)^{\ell}\omega\big(n^{-1}\delta_n(u)^{1-\lambda}\big)du \right\} T_n(t)dt. \end{aligned}$$

Obviously,

$$\Delta_{1/t}(x) \leq |t|(n|t| + 1)\delta_n(x).$$

Using (2.1), we have

$$\omega\big(f,n^{-1}\delta_n(u)^{1-\lambda}\big)\le C_1\left(\left(\frac{\delta_n(u)}{\delta_n(x)}\right)^{r(1-\lambda)}+1\right)\omega\big(f,n^{-1}\delta_n(x)^{1-\lambda}\big).$$

Some computations following [8, Chap. 7] and the proof of Theorem 2.1 of [6] imply for $m\ge r+\ell+2$

$$I_n(x)\le C_2\big(n^{-1}\delta_n(x)\big)^{\ell+1}\omega^r\big(f,n^{-1}\delta_n(x)^{1-\lambda}\big).$$

We now follow [9, pp. 127–128] to prove (2.6). Using (2.7), $T_n(u)=T_n(-u)$, and [9, p. 128], we have

$$Q_n'(x)=-\int_0^\pi g_n'(\cos\xi)2\sin u\,T_n'(u)du,$$

with $\cos\xi\in J(x,u)$. Following [8, p. 128], we have

$$|Q_n'(x)|\le C_3\int_0^\pi |g_n'(\cos\xi)|L_{[n/m],m-1}(u)du. \tag{2.10}$$

Earlier considerations in this proof yield

$$\begin{aligned}|g_n'(\cos\xi)|&\le C\big(n^{-1}\delta_n(\cos\xi)\big)^{\ell}\omega\big(n^{-1}\delta_n(\cos\xi)^{1-\lambda}\big)\\&\le C_4\big(n^{-1}\delta_n(x)\big)^{\ell}\omega\big(n^{-1}\delta_n(x)^{1-\lambda}\big)\big((nu)^2+1\big)^{\ell}\big(((nu)^2+1)^{r(1-\lambda)}+1\big).\end{aligned}$$

Since

$$\int_{-\pi}^{\pi}|t|^\gamma L_{[n/m],m-1}(t)dt\le L_1n^{-\gamma}\quad\text{for }\gamma<2m-3,$$

the result is valid if $2\ell+2r<2m-3$, which is evident from (2.8). □

Remark 2.3. Examining the proof of Lemma 2.2, we can replace the integer ℓ satisfying $\ell\ge-1$ by any real number satisfying $\beta\ge-1$. In this case the choice $m=[\beta]+r+3$ in (2.8) will do.

LEMMA 2.4 (Trigub). *For any two integers $\ell>0$ and $m>0$ we have a polynomial $P_n\in\Pi_n$ such that*

$$\|(1-x^2)^\ell-(1-x^2)^{\ell+m}P_n(x)\|_{C[-1,1]}\le C(\ell,m)n^{-2\ell}. \tag{2.11}$$

This lemma is a corollary of Lemma 2″ of [18]. The proof in [18] is computational and long (via Lemma 2 and Lemma 2′ there). We will give a different, more accessible and, we hope, more transparent, proof below.

Proof of Lemma 2.4. For $f(x)=\sqrt{1-x^2}$ we have $\omega_\varphi(f,t)\sim t$ (see [8, p. 109(1)]). Hence (see [8, Thm. 7.2.1]), there is $Q_n\in\Pi_n$ for which

$$\left\|\sqrt{1-x^2}-Q_n(x)\right\|_{C[-1,1]}\le Cn^{-1}.$$

Writing

$$Q_{n,1}(x)=Q_n(x)-\frac{(1-x)}{2}Q_n(-1)-\frac{(1+x)}{2}Q_n(1),$$

we have $Q_{n,1}(\pm 1) = 0$, $Q_{n,1}(x) = (1-x^2)Q_{n,2}(x)$ and therefore,

$$\left\| \sqrt{1-x^2} - (1-x^2)Q_{n,2}(x) \right\|_{C[-1,1]} \le 3Cn^{-1}. \tag{2.12}$$

For $-1+n^{-2} \le x \le 1-n^{-2}$,

$$|(1-x^2)^{1/2}Q_{n,2}(x)| \le 1 + 3Cn^{-1}(1-x^2)^{-1/2} \le 1+3C.$$

Using [8, Thm. 8.4.8], we have

$$\|(1-x^2)^{1/2}Q_{n,2}(x)\|_{C[-1,1]} \le A\|(1-x^2)^{1/2}Q_{n,2}(x)\|_{C[-1+(1/n^2),1-(1/n^2)]} \le A(1+3C).$$

We now use (2.12) $2m$ times to obtain

$$\begin{aligned} &\left\| \sqrt{1-x^2} - \sqrt{1-x^2}\,(1-x^2)^m Q_{n,2}^{2m}(x) \right\| \\ &\le \left\| \sqrt{1-x^2} - (1-x^2)^m Q_{n,2}^{2m-1}(x) \right\| \\ &\quad + \left\| \left(\sqrt{1-x^2} - (1-x^2)Q_{n,2}(x)\right)(1-x^2)^{m-1/2}Q_{n,2}^{2m-1}(x) \right\| \\ &\le 3Cn^{-1}\left(1+\cdots+(A(1+3C)^{2m-1})\right). \end{aligned}$$

The desired estimate is that of $\left(\sqrt{1-x^2} - \sqrt{1-x^2}\,(1-x^2)^m Q_{n,2}^{2m}(x)\right)^{2\ell}$. The fact that the polynomial

$$P(x) = \sum_{j=1}^{2\ell} (-1)^{j-1} \binom{2\ell}{j} (1-x^2)^{m(j-1)} Q_{n,2}^{2mj}(x)$$

is not of degree n but rather of degree $4\ell m(n-1) - 2m$ does not matter since ℓ and m are fixed. □

3. The main result.

In this section we will prove Theorems 1.1 and 1.2, which together constitute our main result. It turns out that it is advantageous to prove both theorems simultaneously.

Proof of Theorems 1.1 *and* 1.2. We use Theorem 2.1 of [6] applied to $f^{(s)}(x)$ to ascertain the existence of a polynomial $q_n \in \Pi_n$ satisfying

$$|f^{(s)}(x) - q_n(x)| \le C\omega^r_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\right). \tag{3.1}$$

We also use Theorem 1.1 of [7] to obtain a polynomial $q_n(x) \in \Pi_n$ satisfying

$$|f^{(s)}(x) - q_n(x)| \le C\omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\right). \tag{3.2}$$

In the construction of P_n it will make no difference whether we choose $q_n(x)$ to satisfy (3.1) or (3.2) as

$$\omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\right) \le \omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\right).$$

The difference will emerge in the proofs of (1.4), (1.5), (1.6), and (1.7) as a result of that construction. Our construction will yield a polynomial P_n such that $P_n \in \Pi_{Ln}$

with some fixed integer L. This will not change the result as, in the right-hand side of $(1.4),\dots,(1.7)$, replacing n by Ln would just change the constant.

With no loss of generality we may assume that

$$f(x)=\int_0^x\int_0^{u_{s-1}}\cdots\int_0^{u_1} f^{(s)}(u)du,$$

as $f(x)$ may differ from the above only by a polynomial of degree $s-1$, which can be absorbed by $P_n(x)$.

We recall from [8, Thm. 4.1.2] that $\omega^r_{\varphi^\lambda}(f,t)$ satisfies condition (2.1). This follows from the equivalence

$$\omega^r_{\varphi^\lambda}(f,t)\sim K_{\varphi^\lambda,r}(f,t^r),$$

where

$$K_{\varphi^\lambda,r}(f,t^r)=\inf_g\left(\|f-g\|+t^r\|\varphi^{\lambda r}g^{(r)}\|\right),$$

and the basic properties of any K-functional, i.e., $K(f,t)$ is increasing and $K(f,t^r)\le a^{-r}K(f,(at)^r)$ for $0<a<1$. Hence, using Lemma 2.2 with $\ell=0$ and

$$g_n(x)\equiv\int_0^x\big(f^{(s)}(u)-q_n(u)\big)du=f^{(s-1)}(x)-\int_0^x q_n(u)du,$$

we have a polynomial $q_{n,1}(u)\in\Pi_n$ such that

$$\left|f^{(s-1)}(x)-\int_0^x q_n(u)du-q_{n,1}(x)\right|\le C_1\big(n^{-1}\delta_n(x)\big)\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-1}\delta_n(x)^{1-\lambda}\big)$$

and

$$|q'_{n,1}(x)|\le C_1\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-1}\delta(x)^{1-\lambda}\big).$$

This implies

$$|f^{(s)}(x)-q_n(x)-q'_{n,1}(x)|\le(C+C_1)\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-1}\delta_n(x)^{1-\lambda}\big).$$

We now proceed (in case $s>1$), using Lemma 2.2, with $\ell=1$ and

$$g_n(x)=f^{(s-2)}(x)-\int_0^x\int_0^{u_1}q_n(u)du\,du_1-\int_0^x q_{n,1}(u)du.$$

In general we assume by induction that for some $j<s$ we have already constructed $q_{n,0}(x),q_{n,1}(x),\dots,q_{n,j}(x)\in\Pi_n$ $\quad(q_{n,0}\equiv q_n)$ such that for $0\le i\le j$,

$$\begin{aligned}&\Bigg|f^{(s-i)}(x)-\int_0^x\int_0^{u_{i-1}}\cdots\int_0^{u_1}q_n(u)du\,du_1\cdots du_{i-1}-\cdots\\ (3.3)\qquad&\qquad-\int_0^x q_{n,i-1}(u)du-q_{n,i}(x)-\cdots-q_{n,j}^{(j-i)}(x)\Bigg|\\ &\le C\big(n^{-1}\delta_n(x)\big)^i\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-1}\delta_n(x)^{1-\lambda}\big).\end{aligned}$$

We now use Lemma 2.2 with $\ell=j$ and with $g_n(x)$ given by

$$g_n(x)=f^{(s-j-1)}(x)-\int_0^x\int_0^{u_j}\cdots\int_0^{u_1}q_n(u)du\,du_1\dots du_j-\cdots-\int_0^x q_{n,j}(u)du$$

to obtain $q_{n,j+1}$ that satisfies (3.3) for $f^{(s-j-1)}$ and $i = j + 1$. Moreover, Lemma 2.2 implies

$$|q'_{n,j+1}(x)| \le M\big(n^{-1}\delta_n(x)\big)^j \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big).$$

Using Lemma 2.1 with $m = j$ and $P_n(x) = q'_{n,j+1}(x)$, we have

$$(3.4) \qquad |q^{(k+1)}_{n,j+1}(x)| \le M_1\big(n^{-1}\delta_n(x)\big)^{j-k} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big).$$

Hence, (3.3) is valid for $j + 1$ and $0 \le i \le j + 1$, and by induction we construct $q_n, q_{n,1}, \ldots, q_{n,s}$. We define

$$(3.5) \qquad Q_{n,0}(x) = \int_0^x \int_0^{u_{s-1}} \cdots \int_0^{u_1} q_n(x)du$$

and

$$(3.6) \qquad Q_{n,1}(x) = \int_0^x \int_0^{u_{s-2}} \cdots \int_0^{u_1} q_{n,1}(x)du\, du_1 \cdots du_{s-2} + \cdots + q_{n,s}(x).$$

The construction above yields

$$(3.7) \qquad |f^{(i)}(x) - Q^{(i)}_{n,0}(x) - Q^{(i)}_{n,1}(x)| \le A\big(n^{-1}\delta_n(x)\big)^{s-i} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big)$$

for $0 \le i \le s$, $Q^{(s)}_{n,0}(x) = q_n(x)$ for $q_n(x)$ given in (3.1) or (3.2), and

$$(3.8) \qquad |Q^{(s+k)}_{n,1}(x)| \le A(k)\big(n^{-1}\delta_n(x)\big)^{-k} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda}\big) \quad \text{for } k = 0, 1, \ldots.$$

We follow Gopengauz [11] (see also [13]) with some changes and construct a polynomial $Q_{n,2}(x)$,

$$(3.9) \qquad Q_{n,2}(x) = \sum_{i=0}^{s} (1 - x^2)^i \big(\alpha_i(1 - x) + \beta_i(1 + x)\big),$$

such that

$$(3.10) \qquad Q^{(i)}_{n,2}(\pm 1) = f^{(i)}(\pm 1) - Q^{(i)}_{n,0}(\pm 1) - Q^{(i)}_{n,1}(\pm 1) \quad \text{for } 0 \le i \le s.$$

The fact that n^{-2s+2i} is increasing in i,

$$|f^{(i)}(\pm 1) - Q^{(i)}_{n,0}(\pm 1) - Q^{(i)}_{n,1}(\pm 1)| \le C n^{-2s+2i} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-2+\lambda}\big)$$

for $0 \le i \le s$, and induction imply

$$(3.11) \qquad |\alpha_i| + |\beta_i| \le C_1 n^{-2s+2i} \omega^r_{\varphi^\lambda}\big(f^{(s)}, n^{-2+\lambda}\big) \quad \text{for } 0 \le i \le s.$$

We now use (2.11) (Trigub's lemma) to write

$$(3.12) \qquad \|(1 - x^2)^\ell - (1 - x^2)^{\ell+m} P_{n,\ell}(x)\| \le \frac{C(m, \ell)}{n^{2\ell}}, \qquad \ell, m = 1, 2, \ldots.$$

We construct

$$(3.13)\qquad Q_{n,3}(x)=\sum_{i=1}^{s}(1-x^2)^{i+m}\big(\alpha_i(1-x)+\beta_i(1+x)\big)P_{n,i}(x)$$

with some m, $m\geq s+1$. Showing that $P_n(x)$, given by

$$P_n(x)=Q_{n,0}(x)+Q_{n,1}(x)+Q_{n,2}(x)-Q_{n,3}(x),$$

satisfies both (1.4) and (1.5) when q_n (which defines $Q_{n,0}$) is given by (3.1) and both (1.6) and (1.7) when q_n is given by (3.2) will complete the proof. (Slight modifications are needed for (1.7) and $\ell=1$, i.e., $\omega^1_{\varphi^\lambda}$ should replace $\omega^2_{\varphi^\lambda}$ in (3.2).)

We now prove Theorem 1.1. Using (3.11) and (3.12), we have

$$(3.14)\qquad \|Q_{n,3}(x)-Q_{n,2}(x)\|\leq Cn^{-2s}\omega^r_{\varphi^\lambda}(f^{(s)},n^{-2+\lambda}).$$

Using the Markov inequality, we deduce from (3.14) that

$$(3.15)\qquad \|Q^{(i)}_{n,3}(x)-Q^{(i)}_{n,2}(x)\|\leq Cn^{-2s+2i}\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-2+\lambda}\big).$$

For $-1+n^{-2}\leq x\leq 1-n^{-2}$, (1.4) is valid. For $-1\leq x\leq -1+n^{-2}$ (or $1-n^{-2}\leq x\leq 1$) we use $f^{(i)}(-1)-P^{(i)}_n(-1)=0$ for $0\leq i\leq s$ (or $f^{(i)}(+1)-P^{(i)}_n(+1)=0$) and the Taylor formula to obtain

$$(3.16)\quad f^{(i)}(x)-P^{(i)}_n(x)=\frac{(1+x)^{s-i}}{(s-i)!}\big(f^{(s)}(\xi)-P^{(s)}_n(\xi)\big)\quad\text{for } -1\leq\xi<x\leq -1+n^{-2}.$$

Hence, (3.7) and (3.15) for $i=s$ imply

$$|f^{(i)}(x)-P^{(i)}_n(x)|\leq C(1+x)^{s-i}\omega^r_{\varphi^\lambda}\big(f^{(s)},n^{-2+\lambda}\big)\quad\text{for } -1\leq x\leq -1+n^{-2},$$

which in turn implies (1.4) as $(1+x)\leq\varphi(x)/n$ for $-1\leq x\leq -1+n^{-2}$. Using the Markov–Bernstein inequality, that is,

$$|P^{(i)}_n(x)|\leq Cn^i\delta_n(x)^{-i}\|P_n\|_{C[-1,1]},\qquad P_n\in\Pi_n,$$

we now deduce from (3.14) the inequality

$$|Q^{(i)}_{n,3}(x)-Q^{(i)}_{n,2}(x)|\leq Cn^{-2s+i}\delta_n(x)^{-i}\omega^r_{\varphi^\lambda}(f^{(s)},n^{-2+\lambda}).$$

This inequality together with (3.8) implies that we have to prove (1.5) only for $Q^{(s+k)}_{n,0}=q^{(k)}_n$. For $k=r$ we recall that the estimate of $q^{(r)}_n$ is given by Theorem 6.3 of [5], that is, we have

$$(3.17)\qquad |q^{(r)}_n(x)|\leq Cn^r\delta_n(x)^{-r}\omega^r_{\varphi^\lambda}(f^{(s)},n^{-1}\delta_n(x)^{1-\lambda}).$$

The estimate of $|q^{(k)}_n(x)|$ for $k>r$ follows the same method. For $k>r$ we use the Bernstein and the Markov inequalities on the intervals $[(-1-x)/2,(1+x)/2]$, observing that

$\delta_n(u)^{-m}\omega^r_{\varphi^\lambda}(f^{(s)}, n^{-1}\delta_n(u)^{1-\lambda})$ is bounded by $C(m)\delta_n(x)^{-m}\omega^r_{\varphi^\lambda}(f^{(s)}, n^{-1}\delta_n(x)^{1-\lambda})$ for u in that interval.

For the proof of (1.6) we may use (3.2) and hence $f^{(s)}(\pm 1) = q_n(\pm 1)$. Furthermore, $Q^{(s)}_{n,3}(\pm 1) = 0$, and therefore (3.10) reduces to

$$Q^{(s)}_{n,1}(\pm 1) + Q^{(s)}_{n,2}(\pm 1) = 0. \tag{3.18}$$

We can now prove the inequality (1.6). Note that for $-1 + n^{-2} < x < 1 - n^{-2}$, (1.6) has already been proved as in this case; there is no difference between (1.4) and (1.6) but the constant. For $-1 \le x \le -1 + n^{-2}$ (or $1 - n^{-2} < x \le 1$) we use both (3.16) and (3.17) and write

$$\begin{aligned} f^{(i)}(x) - P^{(i)}_n(x) &= \frac{(1+x)^{s-i}}{(s-i)!}\left(f^{(s)}(\xi) - P^{(s)}_n(\xi)\right) \\ &= \frac{(1+x)^{s-i}}{(s-i)!}\left(f^{(s)}(\xi) - q_n(\xi)\right) \\ &\quad + \frac{(1+x)^{s-i}}{(s-i)!}(1+\xi)\big(- Q^{(s+1)}_{n,1}(\eta) \\ &\qquad\qquad - Q^{(s+1)}_{n,2}(\eta) + Q^{(s+1)}_{n,3}(\eta)\big) = I_1 + I_2 \end{aligned}$$

for $-1 < \eta < \xi < x \le -1 + n^{-2}$. Using (3.2) and $\varphi(\xi) \le \varphi(x)$, we conclude that I_1 is smaller than the right-hand side of (1.6). Using (3.8) for $k = 1$ and (3.15) for $i = s + 1$, we have

$$\begin{aligned} |I_2| &\le C(1+x)^{s-i+1} n^2 \omega^2_{\varphi^\lambda}(f^{(s)}, n^{-2+\lambda}) \\ &\le C\left(n^{-1}\varphi(x)\right)^{s-i}(1+x) n^2 \omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-2+\lambda}\right). \end{aligned}$$

We now note that for any F, $\omega^r_{\varphi^\lambda}(F, t)$ satisfies

$$\omega^2_{\varphi^\lambda}(F, t) \le C_1 a^{-2} \omega^2_{\varphi^\lambda}(F, at)$$

for $a < 1$. Setting $F = f^{(s)}$, $t = n^{-2+\lambda}$, and $a = \left(n\varphi(x)\right)^{1-\lambda}$, we have

$$\begin{aligned} |I_2| &\le C_1\left(n^{-1}\varphi(x)\right)^{s-i}(1+x) n^2 \left(n\varphi(x)\right)^{-2+2\lambda} \omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\right) \\ &\le C_1\left(n^{-1}\varphi(x)\right)^{s-i} \omega^2_{\varphi^\lambda}\left(f^{(s)}, n^{-1}\varphi(x)^{1-\lambda}\right). \end{aligned}$$

This completes the proof of (1.6). The estimate (1.7) follows that of Theorem 6.3 of [6] almost word for word. □

A NOTE ON THE GENERALISED KATZENELSON'S METHOD FOR PIECEWISE LINEAR RESISTIVE NETWORKS*

V. C. PRASAD† AND P. B. L. GAUR‡

Abstract. Ohtsuki, Fijisawa, and Kumagai [*SIAM J. Math. Anal.*, 8 (1977), pp. 69–99] proposed a generalisation of Katzenelson's method that is useful for a large class of piecewise linear resistive networks. In this note, errors are pointed out and the correct proof is presented.

Key words. generalised Katzenelson's method, piecewise linear resistive networks, nonlinear equations, numerical methods

1. Introduction.

Katzenelson [1] proposed an algorithm which is guaranteed to converge to a solution starting from any initial point, provided that the corresponding piecewise linear resistive network has a unique solution. In a significant paper, Ohtsuki, Fujisawa, and Kumagai [3] extended this method to a large class of piecewise linear resistive networks, particularly those containing diodes, especially tunnel diodes, Ebers–Moll transistors, etc. Their method chooses an initial point satisfying what is called the "1-degree condition." Starting from such an initial point, they showed that their generalisation of the Katznelson's method (they called it the "generalised Katzendson's method") is guaranteed to converge to a solution. It is the purpose of this paper to correct some errors in their paper.

2. Deficiencies in the proof of the generalised Katzenelson's method.

The reader is referred to [3] for notation and other details not given here. Let $x^{(o)}$ be an initial point satisfying the 1-degree condition. (This essentially means that $x^{(o)}$ is the only solution of the $y^{(o)} \triangleq f(x^{(o)})$, where $f(x) = y$, $x \in R^n$, $y \in R^n$ and f is a continuous piecewise linear function.) Let $y^{(f)}$ be a point whose solution is required. Starting from $x^{(o)}$, trace the inverse image (i.e., the solution curve L^{-1}), of the line L, joining $y^{(o)}$ and $y^{(f)}$ using "generalised Katzenelson's method" [3]. In Theorem 6 of [3] Ohtsuki et al. stated that this method always converges to a solution. The proof of this theorem is wrong as explained in the following.

(1) Whenever the solution curve hits a corner point, it may or may not be extendable into a new region. To overcome this, they used Theorem 2 (page 81, last line of [3]). In the proof of Theorem 2 they stated that "The degree preserves a constant value, say d." This is incorrect. It is possible to show through an example that even though f is norm-coercive, the restriction of this function at a corner point may not be norm-coercive [4]. Consequently, although the degree is a constant value globally, it is not so locally at a corner point. Thus the assumption that the degree is a constant locally in the proof of their Theorem 2 is wrong. Since Theorem 2 is incorrect, it cannot be used in the proof of Theorem 6.

(2) They have not considered the following possibilities.

(a) In Fig. 1(a), the solution curve ends abruptly at a corner point. Even if their Theorem 2 is assumed to be correct, their Remark 8 cannot guarantee that the

solution curve can be extended into a new region. (They used Remark 8 on page 82 to prove Theorem 6.)

(b) The solution curve shown in Fig. 1(b) satisfies their Remark 8. Similarly, Fig. 1(c) is another possibility. But their arguments do not consider these situations.

(c)

FIG. 1. *Some theoretically possible situations of the solution curve. The solution curve is shown in thick lines. Its perturbation is shown in dotted lines.*

3. Correct proof of Theorem 6. The above situations do not occur if the initial point $x^{(o)}$ satisfies the 1-degree condition and an additional condition (to be explained later) is satisfied. This can be proved using the perturbation technique of Fujisawa and Kuh [2]. For this purpose we need the following definitions. A point, $Z \in R^n$, is said to be a point at infinity if and only if there exists at least one $i, 1 \leq i \leq n$, such that Z_i is arbitrarily large. The line segment of a solution curve in a region R is said to be an end segment if there is a point at infinity on the line segment.

Let $L : y = y^{(o)} + \lambda(y^{(f)} - y^{(o)}, -\infty < \lambda < \infty$ be the doubly infinite line joining $y^{(o)}$ to $y^{(f)}$. Trace the solution curve starting from $x^{(o)}$. Let $x^{(o)}$ lie in a region R_1. If L^{-1} lies entirely in R_1, then a solution of $y^{(f)}$ is obtained anyway and there is nothing to prove (case A of [3]). The solution curve being traced from $x^{(o)}$ in R_1 may eventually come back to $x^{(o)}$, i.e., the solution curve containing $x^{(o)}$ is a loop. This is not possible if $x^{(o)}$ satisfies the 1-degree condition (case B of [3]). This leaves us with only one possibility.

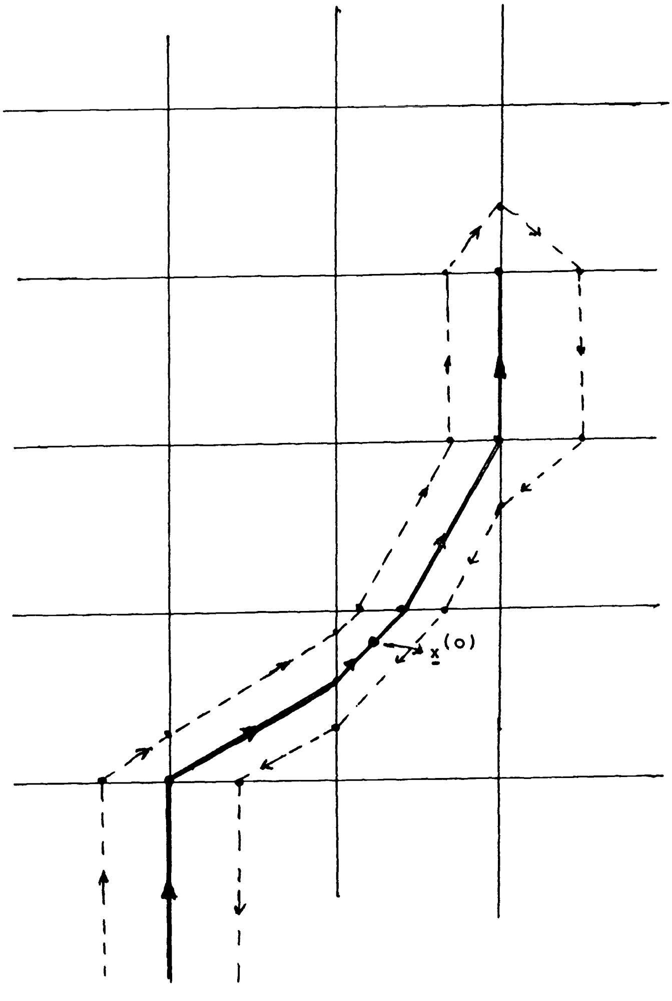

FIG. 2. *A situation in which the generalised Katzenelson's method may not give a solution: $x^{(o)}$ satisfies 1-degree condition.*

The solution curve being traced from $x^{(o)}$ has one end segment in some regions but does not eventually terminate in another unbounded region having another end segment. (The possibilities in Fig. 1 depict this.) In such a case L is perturbed. As explained in Fujisawa and Kuh [2], it is always possible to find a perturbation of L such that the perturbed solution curve does not hit a corner point. Therefore the perturbed solution curve must have two end segments. If the original solution curve has only one end segment (as $\lambda \to -\infty$), say, in the interior of the region R, then the two end segments of the perturbed solution curve also lie in R. If R contains $x^{(o)}$, then its Jacobian is nonsingular. Therefore there cannot be two parallel line segments in a region mapped on to the same line segment in the y-space. Even if $x^{(o)}$ does not lie in R, this statement is still true. This is because the Jacobian of R must be nonsingular as f is norm-coercive.

As $\lambda \to -\infty$, if the end segment of the solution curve starting from $x^{(o)}$ does not lie in the interior of a region, then the generalised Katzenelson's method may not give a solution, at least in theory. Fig. 2 depicts such a possibility. From a practical point of view, since every point in a small open neighborhood of a point satisfying the 1-degree condition also satisfies the 1-degree condition, it is, in general, possible to choose an initial point in that neighborhood such that as $\lambda \to -\infty$, the end segment of L^{-1} lies in the interior of a region. Thus Fig. 2, even if it is true, can be avoided in practice.
