ON NONSTATIONARY MOTION OF A COMPRESSIBLE BAROTROPIC VISCOUS CAPILLARY FLUID BOUNDED BY A FREE SURFACE*

W. M. ZAJACZKOWSKI†

Abstract. The author considers the motion of a viscous compressible barotropic fluid in $\mathbb{R}^3$, bounded by a free surface that is under surface tension and constant exterior pressure. Assuming the initial density is sufficiently close to a constant, the initial domain is sufficiently close to a ball, the initial velocity is sufficiently small, and the external force vanishes, the existence of a global-in-time solution is proven, which satisfies, at any moment of time, the properties prescribed at the initial moment.

Key words. free boundary, compressible barotropic viscous fluid, global existence, surface tension, anisotropic Sobolev spaces

AMS subject classifications. 35R35, 35A05, 76N10

1. Introduction.

We consider the motion of a viscous compressible barotropic fluid in a bounded domain $\Omega_t \subset \mathbb{R}^3$, which depends on time $t \in \mathbb{R}^1_+$. The free boundary S_t of Ω_t is governed by the surface tension. Let $v = v(x,t)$ be the velocity of the fluid, $\rho = \rho(x,t)$ the density, $f = f(x,t)$ the external force field per unit mass, $p = p(\rho)$ the pressure, μ and ν the viscosity coefficients, σ the surface tension coefficient, and p_0 the external (constant) pressure. Then the problem is described by the following system (see [7, Chaps. 1, 2, 7]):

$$\rho(v_t + v\cdot\nabla v) + \nabla p(\rho) - \mu\Delta v - \nu\nabla \mathrm{div} v = \rho f \quad \text{in } \tilde{\Omega}^T, \tag{1.1a}$$

$$\rho_t + \mathrm{div}(\rho v) = 0 \quad \text{in } \tilde{\Omega}^T, \tag{1.1b}$$

$$\rho|_{t=0} = \rho_0, \qquad v|_{t=0} = v_0 \quad \text{in } \Omega, \tag{1.1c}$$

$$\mathbb{T}\bar{n} - \sigma H\bar{n} = -p_0\bar{n} \quad \text{on } \tilde{S}^T, \tag{1.1d}$$

$$v\cdot\bar{n} = -\phi_t/|\nabla\phi| \quad \text{on } \tilde{S}^T, \tag{1.1e}$$

where $\phi(x,t) = 0$ describes S_t, $\tilde{\Omega}^T = \bigcup_{t\in(0,T)} \Omega_t \times \{t\}$, Ω_t is the domain of the drop at time t, $\Omega_0 = \Omega$ is its initial domain, $\tilde{S}^T = \bigcup_{t\in(0,T)} S_t \times \{t\}$, $\bar{n}$ is the unit outward vector normal to the boundary ($\bar{n} = \nabla\phi/|\nabla\phi|$), and μ, ν, σ are constant coefficients. Moreover, thermodynamic considerations imply $\nu \geq 1/3\mu > 0$, $\sigma > 0$. The last condition (1.1e) means that the free boundary S_t is built of moving fluid particles. Finally, $\mathbb{T} = \mathbb{T}(v,p)$ denotes the stress tensor of the form

$$T_{ij} = -p\delta_{ij} + \mu\left(\partial_{x^i}v^j + \partial_{x^j}v^i\right) + (\nu - \mu)\delta_{ij}\mathrm{div} v \equiv -p\delta_{ij} + D_{ij}(v), \tag{1.2}$$

where $i, j = 1,2,3$, $\mathbb{D} = \mathbb{D}(v)$ is the deformation tensor and H is the double mean curvature of S_t, which is negative for convex domains and can be expressed in the form

$$H\bar{n} = \Delta_{S_t}(t)x, \qquad x = (x^1, x^2, x^3), \tag{1.3}$$

where $\Delta_{S_t}(t)$ is the Laplace–Beltrami operator on S_t. Let S_t be determined by $x = x(s1, s2, t)$, $(s1, s2) \in U \subset \mathbb{R}^2$, where U is an open set. Then we have

$$\Delta_{S_t}(t) = g^{-1/2}\partial_{s^\alpha}g^{-1/2}\hat{g}_{\alpha\beta}\partial_{s^\beta} = g^{-1/2}\partial_{s^\alpha}g^{1/2}g^{\alpha\beta}\partial_{s^\beta}, \qquad \alpha,\beta = 1,2, \tag{1.4}$$

where the convention summation over the repeated indices is assumed, $g = \det\{g_{\alpha\beta}\}_{\alpha,\beta=1,2}$, $g_{\alpha\beta} = x_\alpha \cdot x_\beta$, where $x_\alpha = \partial_{s^\alpha} x$, $\{g^{\alpha\beta}\}$ is the inverse matrix to $\{g_{\alpha\beta}\}$ and $\{\hat{g}_{\alpha\beta}\}$ is the matrix of algebraic complements for $\{g_{\alpha\beta}\}$.

Let the domain Ω be prescribed. Then, by (1.1e), $\Omega_t = \{x \in \mathbb{R}^3 : x = x(\xi, t), \xi \in \Omega\}$, where $x = x(\xi, t)$ is the solution of the Cauchy problem

$$\frac{\partial x}{\partial t} = v(x,t), \qquad x|_{t=0} = \xi \in \Omega, \quad \xi = (\xi^1, \xi^2, \xi^3). \tag{1.5}$$

Therefore the transformation $x = x(\xi, t)$ connects the Eulerian x and the Lagrangian ξ coordinates of the same fluid particle. Hence

$$x = \xi + \int_0^t u(\xi, s)ds \equiv X_u(\xi, t) \equiv x(\xi, t), \tag{1.6}$$

where $u(\xi, t) = v(X_u(\xi, t), t)$. Moreover, the kinematic boundary condition (1.1e) implies that the boundary S_t is a material surface; so if $\xi \in S = S_0$, then $X_u(\xi, t) \in S_t$ and $S_t = \{x : x = X_u(\xi, t), \xi \in S\}$.

By the continuity equation (1.1b) and the kinematic condition (1.1e) the total mass M is conserved and

$$\int_{\Omega_t} \rho(x,t)dx = M, \tag{1.7}$$

which is a relation between ρ and Ω_t.

Let us define an equilibrium state to be a solution of (1.1a–e) such that $v = 0$, $\Omega_t = \Omega_e$ is a ball for all $t \in \mathbb{R}^1$ and $f = 0$. Then, in view of (1.1a, d), $\rho = \rho_e = \text{const}$, and $p(\rho_e) = (2\sigma/R_e) + p_0$, where $R_e = ((3/4\pi)|\Omega_e|)^{1/3}$, and by (1.7), $\rho_e = M/((4\pi/3)R_e^3)$. By summarizing we have the following.

DEFINITION 1.1. Let M, σ, p_0 and a functional dependence $p = p(\rho)$ be given. Let $f = 0$. Then by the equilibrium state we mean a solution of (1.1a–e) such that

$$v = 0, \quad \rho = \rho_e, \quad \Omega_t = \Omega_e, \quad t \in \mathbb{R}^1_+, \tag{1.8}$$

is a ball of radius R_e that is a solution of the equation

$$p(M/((4\pi/3)R_e^3)) = 2\sigma/R_e + p_0, \tag{1.9}$$

which is also a relation between the total mass M and volume $|\Omega_e|$.

In this paper the existence of such global solutions is proved when the velocity v is small, the density ρ is close to a constant, the domain Ω_t is close to a ball, and the external force vanishes. Hence, we show the stability of the equilibrium state, which means that any motion described by (1.1a–e), which starts from a state sufficiently close to the equilibrium state, remains close to it for all time. However, we are not able to show that it converges to the equilibrium state as t is passing to infinity. To prove the global existence of solutions of (1.1a–e) close to the equilibrium state, the surface tension is important because it controls a shape of the boundary and implies that it is close to a ball. The case without surface tension is considered in [35].

Finally, to prove local existence (see Lemma 5.1) and then to prove global existence (see Theorems 5.5 and 5.6) we need the following compatibility conditions:

$$D_s^\alpha \partial_t^i (\mathbb{T}(v,p)\bar{n} - \sigma H\bar{n} + p_0\bar{n})|_{t=0,s} = 0, \qquad |\alpha| + i \leq 2,$$

where times derivatives of $v, p, \rho, \bar{n}$ at $t = 0$ are calculated from (1.1 a, b) and D_s means tangent derivatives only (see Remark 5.7).

As far as we know this paper and [35] are the first papers that treat global existence of solutions to free boundary problems for compressible viscous fluids in three dimensions. In the one-dimensional case there is a result of Matsumura and Nishida [8], who additionally takes gravitation into account.

Since 1976 Solonnikov has been working in free boundary problems for equations of incompressible viscous fluid [20], [21], [23], [25]–[29]. In a series of papers he showed the existence of global motion of a viscous incompressible fluid bounded by a free boundary, both with surface tension (see [23] and [25]) and without it (see [26]). The latter case is proved for solutions of incompressible Navier–Stokes equations by using the Korn inequality. To prove the existence of solutions of the incompressible version of problem (1.1a–e) with surface tension the existence of solutions of the initial-boundary value problem for the Stokes system with a corresponding boundary condition of type (1.1d) with surface tension has to be shown (linear problem). By using potential theory techniques, this was also accomplished by Solonnikov (see [21]). It should be emphasized that the existence of solutions of the latter problem was shown in anisotropic Sobolev–Slobodetskii spaces $W_2^{l,l/2}$ with noninteger positive l (see definitions at the end of this section). The boundary condition (1.1d) with surface tension contains both first- and second-order derivatives of solutions, so the considered problem is noncoercive. Solonnikov used the spaces $W_2^{l,l/2}$ with noninteger l to prove the existence of solutions of the incompressible version of the problem (1.1a–e) in Sobolev spaces as low as possible to omit compatibility conditions. In the case of compressible fluid we have had to also prove the existence for the linear problem (3.3) which, because of the boundary condition (1.1d) (see also (3.3)), does not follow from the general theory of initial-boundary value problems for Douglis–Nirenberg parabolic systems (see [24]). The existence of solutions of that problem is shown in the same anisotropic Sobolev–Slobodetskii spaces as in the incompressible case (see [34] and [36]). This implies that in this paper the technique of spaces $W_2^{l,l/2}$ has to be used in §3, where the local existence for (1.1a–e) is considered (see [34] and [36]). In these considerations it is convenient to use noninteger l to reduce a number of coefficients of type T^{-a}, $a > 0$, where T is the time of local existence, in the norms used in its proof (see [36]). Such coefficients may imply difficulties in the proof of local existence. However, to prove global existence we need local solvability of (1.1a–e) in such classes that $v \in W_2^{4,2}(\Omega^T)$, $\rho \in W_2^{3,3/2}(\Omega^T) \cap C(0,T;\Gamma_0^{3,3/2}(\Omega))$ (see Remark 3.2 and [37], where existence of local solutions in these classes is shown). Then global existence is proved in class $\mathcal{M}(t), t \in \mathbb{R}_+$ (see definition of $\mathcal{M}(t)$ at the beginning of §5), which is implied by differential inequality (4.195) (see Lemma 5.1).

Now we make some comments on the literature concerning free boundary problems for the nonstationary incompressible Navier–Stokes system. Local existence of solutions in the case without surface tension is proved in Hölder and Sobolev anisotropic space by Solonnikov in [26] and [27] (see also [20]). Potential theory techniques are used to prove the existence of solutions of the corresponding linear problems in Hölder and in Sobolev spaces (see [28] and [29]). In all papers of Solonnikov the Lagrangian coordinates are used. Global existence is also proved by Beale [3], [4], where the free boundary is infinite and gravitation is taken into account. Local existence with surface tension is considered by Allain [2].

Local existence of solutions for compressible fluids without surface tension is proved by Secchi and Valli (see [16]), but with surface tension by Solonnikov and

Tani (see [31]).

Lately, Secchi showed existence and uniqueness of solutions of equations describing the motion of gaseous stars (see [17]–[19]).

References to the literature concerning stationary free boundary problems can be found in [15]. Moreover, in [15] Pileckas and Zajaczkowski proved the existence of stationary motion of viscous, compressible, barotropic fluid bounded by a free surface governed by surface tension. In the proof, one has to assume that the domain and the external force satisfy some extra symmetry conditions. In the present paper the global existence is proved for $f = 0$ and without any symmetry conditions, so there is no connection with the result in [15]. However, similar to the case treated in [15], to prove global existence the necessary a priori estimate is found by the energy method that was also used in papers [8]–[12], [15], [32], [33], and [35].

This paper relies heavily on the following main points. First we study inequality (2.33), which guarantees that variations of the volume of Ω_t (denoted by $|\Omega_t|$) and the surface area of S_t (denoted by $|S_t|$) are as small as we need for all time. This inequality follows from conservation laws for (1.1a–e) (see Lemma 2.1) and a special choice of the parameters of the problem (1.1a–e) $(\mu, \nu, \sigma, p_0, p = p(\rho), |\Omega|, |S|, v_0, \rho_0, f = 0)$ (see Lemma 2.2), which implies that the right-hand side of (2.20) is sufficiently small. This result is crucial for the proof of global existence in the compressible case only, because in the incompressible case $|\Omega_t|$ is constant. We have to underline that the result is shown under the assumption that the considered fluid is barotropic, so $p = A\rho^\kappa$, where A, κ are constants and $\kappa > 1$. Moreover, (2.65) is essential because it ensures that Ω_t is close to a ball. Second, we prove the local-in-time existence of solutions to (1.1 a–e) by employing the Lagrangian coordinates, and we find a suitable a priori estimate (see Theorem 3.1—the proof is shown in [36]). The existence is proved in such classes that $v \in W_2^{l+2,l/2+1}$, $\rho \in W_2^{l+1,l/2+1/2}$, $l/2 - 3/4 - \kappa \in \mathbb{N} \cup \{0\}$, $\kappa \in (0, 1/4)$. However, to prove global existence we need a local solution such that $v \in W_2^{4,2}(\Omega^T)$, $\rho \in W_2^{3,3/2}(\Omega^T) \cap C([0,T]; \Gamma_0^{3,3/2}(\Omega))$ (see [37] and Remark 3.2).

Moreover, to prove global existence we also need a bound for variations of the solution near the equilibrium state in terms of the appropriate norms of v_0, $p(\rho_0) - p_0 - 2\sigma/R_0$, $H(x,0)) + 2/R_0$ (see Remark 3.2, where (3.6) is such an inequality), where the last expression measures the deviation of the initial domain from a ball. From this inequality and imbedding theorems we have the minimum and maximum of the density, which are necessary to find the inequality (2.65). This fact and the use of Lagrangian coordinates, which also exist only locally suggests that the proof of global existence should be done step by step by employing local existence. However, this procedure needs a special a priori estimates because (3.6) is not sufficiently strong. The inequalities are shown in §4 (see (4.195), Theorems 4.13 and 4.14, and (4.197)), whose proofs constitute the most technically difficult part of this paper. It requires the technique of an energy method, which is very close to the methods used in [33] (see also [8]–[12], [15], and [32]). To prove the inequality we need much more regularity of solutions than is needed to show the local existence. This is achieved in Lemma 5.1 under appropriate assumptions on initial data.

The global existence is proved in the case $f = 0$. The main result is formulated in Theorem 5.5. In the case of the external pressure $p_0 = 0$ the proof of Lemma 2.2 essentially simplifies and the necessary relations between parameters of (1.1a–e) may be explicitly formulated (see Lemma 2.8). In this case the global existence result is stated in Theorem 5.6.

In this paper we use the anisotropic Sobolev–Slobodetskii spaces $W_2^{l,l/2}(\Omega^T)$,

$l \in \mathbb{R}_+$ (see [5, Chap. 18]) of functions defined in $\Omega^T = \Omega \times (0,T)$. In fact, $W_2^{l,l/2}$ are Besov spaces for $l \notin \mathbb{Z}$; the equivalence between $W_2^{l,l/2}$, $l \notin \mathbb{Z}$, and Besov spaces follows from considerations in [1, Chap. 7]. In the case of noninteger l we have the norms ($\Omega \subset \mathbb{R}^3$)

(1.10)

$$\|u\|_{W_2^{l,0}(\Omega^T)} = \left(\int_0^T \|u\|^2_{W_2^l(\Omega)} dt \right)^{1/2},$$

$$\|u\|_{W_2^{0,l/2}(\Omega^T)} = \left(\int_\Omega \|u\|^2_{W_2^{l/2}((0,T))} dx \right)^{1/2},$$

$$\|u\|^2_{W_2^l(\Omega)} = \sum_{|\alpha| \le [l]} \|D_x^\alpha u\|^2_{L_2(\Omega)} + \sum_{|\alpha| = [l]} \int_\Omega \int_\Omega \frac{|D_x^\alpha u(x,t) - D_y^\alpha u(y,t)|^2}{|x-y|^{3+2(l-[l])}} dxdy,$$

$$\|u\|^2_{W_2^{l/2}((0,T))} = \sum_{j=0}^{[l/2]} \|D_t^j u\|^2_{L_2((0,T))} + \int_0^T \int_0^T \frac{|D_t^{[l/2]} u(x,t) - D_\tau^{[l/2]} u(x,\tau)|^2}{|t-\tau|^{1+2(l/2-[l/2])}} dtd\tau,$$

$$\|u\|^2_{W_2^{l,l/2}(\Omega^T)} = \sum_{|\alpha|+2\alpha_0 \le [l]} \left(\|D_x^\alpha \partial_t^{\alpha_0} u\|^2_{L_2(\Omega^T)} \right) + \int_0^T dt \int_\Omega \int_\Omega dxdy \frac{|D_x^\alpha \partial_t^{\alpha_0} u(x,t) - D_y^\alpha \partial_t^{\alpha_0} u(y,t)|^2}{|x-y|^{3+2(l-[l])}} + \int_\Omega dx \int_0^T \int_0^T dtdt' \frac{|D_x^\alpha \partial_t^{\alpha_0} u(x,t) - D_x^\alpha \partial_{t'}^{\alpha_0} u(x,t')|^2}{|t-t'|^{1+2(l/2-[l/2])}},$$

where $D_x^\alpha = \partial_{x_1}^{\alpha_1} \dots \partial_{x_n}^{\alpha_n}$, $\partial_x = \partial/\partial x$, $\partial_t = \partial/\partial t$, and we use generalized (Sobolev) derivatives. Similarly, by using local coordinates and a partition of unity we introduce the norm in the space $W_2^{l,l/2}(S^T)$ of functions defined on $S^T = S \times (0,T)$, where $S = \partial\Omega$. We also use $W_2^l(\Omega)$ with the third norm of (1.10) for functions defined in Ω. We do not distinguish norms of scalar and vector-valued functions. To simplify notation we write

$$\|u\|_{l,Q} = \|u\|_{W_2^{l,l/2}(Q)} \quad \text{if } Q = \Omega^T \quad \text{or} \quad Q = S^T, l \ge 0, \|u\|_{l,Q} = \|u\|_{W_2^l(Q)} \quad \text{if } Q = \Omega$$

or $Q = (0,T), l \ge 0$, and $W_2^{0,0}(Q) = W_2^0(Q) = L_2(Q)$. Moreover, $\|u\|_{L_p(Q)} = |u|_{p,Q} 1 \le p \le \infty$ and $\|u\|_{l,p,\Omega^T} = \|u\|_{L_p(0,T;W_2^l(\Omega))}$.

For the proof of global existence we also need the following notation: $H^l(Q) = W_2^l(Q)$, where Q is one of the following expressions: Ω, S, Ω^T, and S^T. We introduce the space $\Gamma_0^{l,l/2}(\Omega)$ with the norm

$$\|u\|_{\Gamma_0^{l,l/2}(\Omega)} = \sum_{0 \le 2i+|\alpha| \le 1} \|\partial_t^i D_x^\alpha u\|_{0,\Omega} \equiv |u|_{l,0,\Omega},$$

and $\Gamma_k^l(\Omega)$ with the norm

$$\|u\|_{\Gamma_k^l(\Omega)} = \sum_{0 \le i \le l-\kappa} \|\partial_t^i u\|_{l-i,\Omega} \equiv |u|_{l,k,\Omega},$$

where $l \geq k$, $k \in \mathbb{Z}_+ \cup \{0\}$, $0 \leq l \in \mathbb{R}$.

We define $L_p(0,T;\Gamma_0^{l,l/2}(\Omega))$ with

$$\|u\|_{L_p(0,T;\Gamma_0^{l,l/2}(\Omega))} \equiv |u|_{l,0,p,\Omega^T},$$

and $C([0,T];\Gamma_0^{l,l/2}(\Omega))$ with the norm

$$\|u\|_{C([0,T];\Gamma_0^{l,l/2}(\Omega))} = \sup_{t\in[0,T]} |u|_{l,0,\Omega}.$$

We also need

$$|u|_{l,k} = \sum_{0\leq i\leq l-\kappa} \sum_{|\alpha|=l-1} |D_x^\alpha \partial_t^i u|,$$

where $||$ is the Euclidean norm either of a vector or a matrix.

Moreover, we shall use the imbedding (see [5] and [13])

$$W_r^\delta(\Omega) \subset L_p^\alpha(\Omega), \qquad \Omega \subset \mathbb{R}^3, \alpha + 3/r - 3/p \leq \delta, \tag{1.11}$$

where $\|u\|_{L_p^\alpha(\Omega)} = |D_x^\alpha u|_{p,\Omega}$ and the corresponding interpolation inequality holds

$$|D_x^\alpha u|_{p,\Omega} \leq \varepsilon^{1-\kappa} |D_x^\delta u|_{r,\Omega} + c\varepsilon^{-\kappa} |u|_{r,\Omega}, \tag{1.12}$$

where $\kappa = \alpha/\delta + (3/\delta)(1/r - 1/p) < 1, \varepsilon \in (0,1)$.

2. Global estimates and relations. We start with conservation laws for problem (1.1a–e).

LEMMA 2.1. *Sufficiently smooth solutions to problem* (1.1a–e) *satisfy*

$$\begin{aligned} &\frac{d}{dt}\left[\int_{\Omega_t} \left(\frac{1}{2}\rho v^2 + \rho h(\rho)\right) dx + p_0|\Omega_t| + \sigma|S_t|\right] \\ &\quad + \frac{\mu}{2} E(v,v) + (\nu - \mu)\|\operatorname{div} v\|_{0,\Omega_t}^2 = \int_{\Omega_t} \rho f \cdot v \, dx, \end{aligned} \tag{2.1}$$

where $|\Omega_t| = \operatorname{vol}\Omega_t$, $|S_t|$ *is the surface area of* S_t, $h(\rho) = \int (p(\rho)/\rho^2) d\rho$,

$$E(v,u) = \int_{\Omega_t} \left(v^i_{x^j} + v^j_{x^i}\right)\left(u^i_{x^j} + u^j_{x^i}\right) dx.$$

Moreover,

$$\frac{d}{dt}\int_{\Omega_t} \rho v \cdot \eta \, dx = \int_{\Omega_t} \rho f \cdot \eta \, dx, \tag{2.2}$$

where $\eta = a + b \times x, a, b$ *are arbitrary constant vectors, and*

$$\frac{d}{dt}\int_{\Omega_t} \rho x \, dx = \int_{\Omega_t} \rho v \, dx. \tag{2.3}$$

Proof. To prove (2.1) we multiply (1.1a) by v, (1.1b) by $v^2/2$, add the results, and integrate over Ω_t to get

$$\int_{\Omega_t} \frac{1}{2}\left[\partial_t(\rho v^2) + \nabla\cdot(\rho v v^2)\right] dx - \int_{S_t} T_{ij} n^i v^j d\tau$$
$$+ \int_{\Omega_t} \left[-p\delta_{ij} + \mu\left(v^i_{x^j} + v^j_{x^i}\right) + (\nu-\mu)\delta_{ij}\ \text{div}\ v\right] v^i_j\, dx = \int_{\Omega_t} \rho f\cdot v\, dx.$$

Using (1.1d) we obtain

$$\frac{d}{dt}\int_{\Omega_t}\frac{1}{2}\rho v^2\, dx - \int_{S_t}(\sigma H - p_0)\bar{n}\cdot v d\tau + \frac{\mu}{2}E(v,v) + (\nu-\mu)\|\text{div}\ v\|^2_{0,\Omega_t}$$
$$- \int_{\Omega_t} p\ \text{div}\ v\, dx = \int_{\Omega_t}\rho f\cdot v\, dx. \tag{2.4}$$

From (1.3) and (1.4), as in [23], one obtains

$$-\int_{S_t} H\bar{n}\cdot v d\tau = -\int_{S_t}\frac{1}{\sqrt{g}}\partial_{s^\alpha}(g^{\alpha\beta}\sqrt{g}x_\beta)x_t d\tau = \int_U g^{\alpha\beta}\sqrt{g}x_\beta x_{\alpha t} ds^1 ds^2$$
$$= \frac{1}{2}\int_U g^{\alpha\beta}\sqrt{g}\partial_t g_{\alpha\beta} ds^1 ds^2 = \int_U \partial_t\sqrt{g} ds^1 ds^2 = \frac{d}{dt}\int_U \sqrt{g} ds^1 ds^2 = \frac{d}{dt}|S_t|. \tag{2.5}$$

By (2.4) and (2.5) we have

$$\frac{d}{dt}\left(\int_{\Omega_t}\frac{1}{2}\rho v^2\, dx + |S_t|\right) + \frac{\mu}{2}E(v,v) + (\nu-\mu)\|\text{div}\ v\|^2_{0,\Omega_t}$$
$$- \int_{\Omega_t}(p-p_0)\text{div}\ v\, dx = \int_{\Omega_t}\rho f\cdot v\, dx. \tag{2.6}$$

Now we consider the term involving the pressure. Using the equation of continuity we have

$$-\int_{\Omega_t}(p-p_0)\text{div}\ v\, dx = \int_{\Omega_t}(p-p_0)(\rho\rho_t + \rho v\cdot\nabla\rho)/\rho^2\, dx$$
$$= \int_{\Omega_t}\left[\rho(h+p_0 h_1)_{,t} + \rho v\cdot\nabla(h+p_0 h_1)\right] dx,$$

where $h_1(\rho) = -\int(d\rho/\rho^2) = 1/\rho$. Since

$$\int_{\Omega_t}\left[\rho_t + \text{div}(\rho v)\right](h+p_0 h_1)\, dx = 0,$$

we get

$$-\int_{\Omega_t}(p-p_0)\text{div}\ v\, dx = \int\left[(\rho(h+p_0 h_1))_{,t} + \text{div}(\rho v(h+p_0 h_1))\right] dx$$
$$= \frac{d}{dt}\int_{\Omega_t}\rho(h+p_0 h_1)\, dx. \tag{2.7}$$

Inserting (2.7) in (2.6) and applying $\rho h_1 = 1$ gives (2.1).

To show (2.2) we pass to Lagrangian coordinates, so we have

$$\frac{d}{dt}\int_{\Omega_t} \rho v \cdot \eta \, dx = \frac{d}{dt}\int_{\Omega} \rho_0(\xi) v(X_u(\xi,t),t) \cdot \eta(X_u(\xi,t)) d\xi,$$

where we used the fact that $\rho = \rho_0/J$ and J is the Jacobian of the transformation (1.6).

Now differentiating the integrand, using (1.1b), and proceeding exactly in the same way as in [23] we get (2.2). Finally,

$$\frac{d}{dt}\int_{\Omega_t} \rho x \, dx = \frac{d}{dt}\int_{\Omega} \rho_0(\xi) X_u(\xi,t) d\xi = \int_{\Omega} \rho_0(\xi) v(X_u(\xi,t),t) d\xi = \int \rho v \, dx,$$

so (2.3) is satisfied. This concludes the proof.

Now we find restrictions on parameters of problem (1.1a–e) which imply that the variation of $|\Omega_t|$ is small for all time. Let us assume that solutions of (1.1a–e) are sufficiently regular. Let

$$\nu - \mu/3 \geq 0. \tag{2.8}$$

Then

$$\begin{aligned}
&\frac{\mu}{2} E(v,v) + (\nu-\mu)\|\operatorname{div} v\|^2_{0,\Omega_t} \\
&\quad = \frac{\mu}{2}\int_{\Omega_t} \left(v^i_{x^j} + v^j_{x^i}\right)^2 dx + (\nu-\mu)\int_{\Omega_t} (\operatorname{div} v)^2 \, dx \\
&\quad \geq \sum_{i=j} \frac{\mu}{2}\int_{\Omega_t} \left(v^i_{x^j} + v^j_{x^i}\right)^2 dx + (\nu-\mu)\int_{\Omega_t} (\operatorname{div} v)^2 \, dx \\
&\quad = 2\mu \sum_i \int_{\Omega_t} \left(v^i_{x^i}\right)^2 dx + (\nu-\mu)\int_{\Omega_t} (\operatorname{div} v)^2 \, dx.
\end{aligned}$$

Since $(\xi_1+\xi_2+\xi_3)^2 \leq 3(\xi_1^2+\xi_2^2+\xi_3^2)$ the above expression is not less than $(\nu - \mu/3)\|\operatorname{div} v\|^2_{0,\Omega_t}$, which by (2.8) is nonnegative.

Hence, assuming $f = 0$, (2.1) implies

$$\begin{aligned}
&\frac{1}{2}\int_{\Omega_t} \rho v^2 \, dx + \int_{\Omega_t} \varphi(\rho) \, dx + p_0|\Omega_t| + \sigma|S_t| \\
&\quad \leq \frac{1}{2}\int_{\Omega} \rho_0 v_0^2 \, dx + \int_{\Omega} \varphi(\rho_0) \, dx + p_0|\Omega| + \sigma|S| \equiv d,
\end{aligned} \tag{2.9}$$

where $p(\rho) = A\rho^\kappa$, so $\varphi(\rho) = (A/(\kappa-1))\rho^\kappa, \kappa > 1$.

Using (1.7) and the Hölder inequality one gets

$$M = \int_{\Omega_t} \rho \, dx \leq |\Omega_t|^{1-1/\kappa} \left(\int_{\Omega_t} \rho^\kappa \, dx\right)^{1/\kappa}.$$

Now from (2.9) one obtains

$$\left(\frac{A}{\kappa-1}\frac{M^\kappa}{d}\right)^{1/(\kappa-1)} \leq |\Omega_t| \leq \frac{d}{p_0}. \tag{2.10}$$

Introducing the mean density $\bar{\rho}_t = M/|\Omega_t|$, one gets

$$\frac{Mp_0}{d} \le \bar{\rho}_t \le \left(\frac{(\kappa-1)d}{AM}\right)^{1/(\kappa-1)}. \tag{2.11}$$

We also obtain

$$\left(\frac{p_0}{d}\right)^{\kappa-1} M^\kappa \le \int_{\Omega_t} \rho^\kappa \, dx \le \frac{(\kappa-1)d}{A}. \tag{2.12}$$

In this way we have shown that $|\Omega_t|$ and $\psi_t = \int_{\Omega_t} \varphi(\rho(x))dx$ are bounded from below and from above.

Multiplying equation (2.9) by $|\Omega_t|^{\kappa-1}$, using the Hölder inequality $(\int_{\Omega_t} \rho \, dx)^\kappa \le |\Omega_t|^{\kappa-1} \int_{\Omega_t} \rho^\kappa \, dx$ and (1.7), we obtain

$$\begin{aligned} y(|\Omega_t|) + |\Omega_t|^{\kappa-1} \frac{1}{2} \int_{\Omega_t} \rho v^2 \, dx + \sigma(|S_t| - 4\pi R_t^2)|\Omega_t|^{\kappa-1} \\ + \frac{A}{\kappa-1} \left(|\Omega_t|^{\kappa-1} \int_{\Omega_t} \rho^\kappa \, dx - \left(\int_{\Omega_t} \rho \, dx \right)^\kappa \right) \le 0, \end{aligned} \tag{2.13}$$

where

$$y(x) = p_0 x^\kappa + c_0 \sigma x^{\kappa-1/3} - dx^{\kappa-1} + \frac{AM^\kappa}{\kappa-1}, \quad \kappa > 1, \quad x \equiv |\Omega_t|, \tag{2.14}$$

and $c_0 = (36\pi)^{1/3}, (4\pi/3)R_t^3 = |\Omega_t|$.

Our aim is to find restrictions on the coefficients of (2.13) $(p_0, \sigma, d, A, \kappa, M)$ that lead to small changes of $|\Omega_t|$ for all $t \ge 0$. For this purpose we have to find a minimum of the left-hand side of (2.13) and to show that for some relations among $p_0, \sigma, d, A, \kappa, M$ (2.13) holds only for small changes of $|\Omega_t|$ near the minimum point. Since the last three terms on the left-hand side of (2.13) are positive, we have

$$y(x) \equiv y(|\Omega_t|) \le 0. \tag{2.15}$$

This inequality holds for all physical drop volumes, and so for all real physical motions governed by (1.1a–e).

Now our aim is to determine minimum points $\{x_0\}$ of $y = y(x)$. In view of (2.15) we must look for such minimum points x_0 that $x_0 > 0, y(x_0) < 0, y'(x_0) = 0, y''(x_0) > 0$. Moreover, the coefficients in $y = y(x)$ must be chosen in such a way that $|x - x_0|$ is small for $x \in \{x : y(x) \le 0\}$. Examining (2.15) instead of (2.13) is justified since $|x - x_0| \le \varepsilon$ for $x \in \{x : y(x) \le 0\}$ (where ε is sufficiently small) implies that $|x - x_0| \le \varepsilon$ also for $x \in \{x : y(x) + a \le 0\}$, where a denotes the sum of the last three terms on the left-hand side of (2.13).

Minimum points of $y = y(x)$ are determined by the equation

$$y'(x) \equiv [p_0 \kappa x + c_0 \sigma(\kappa - 1/3)x^{2/3} - d(\kappa - 1)]x^{\kappa-2} = 0. \tag{2.16}$$

Viete's formulas imply that the solutions x_1, x_2, x_3 of (2.16) satisfy

$$x_1 \cdot x_2 \cdot x_3 = \left(\frac{d(\kappa-1)}{p_0\kappa}\right)^{1/3} > 0, \qquad x_1^{1/3} + x_2^{1/3} + x_3^{1/3} = -\frac{c_0\sigma(\kappa - 1/3)}{p_0\kappa} < 0,$$

so there exists only one positive root of (2.16). Denote it also by x_0. To calculate it we consider the equation which follows from (2.16):

$$\omega^3 + 3p\omega + 2q = 0, \tag{2.17}$$

where $\omega = u + \mu_0$, $u = x^{1/3}$, $p = -\mu_0^2$, $q = \mu_0^3 - \nu_0$, $\mu_0 = (c_0\sigma(\kappa - 1/3))/3p_0\kappa$, $\nu_0 = d(\kappa - 1)/2p_0\kappa$. At a point x_0 of a minimum $y = y(x)$, we have

$$y''(x)\Big|_{x=x_0} = p_0^\kappa x_0^{\kappa-3}\left[-\mu_0 x_0^{2/3} + 2\nu_0\right] = p_0^\kappa x_0^{\kappa-3}\left[x_0 + 2\mu_0 x_0^{2/3}\right] > 0\,, \tag{2.18}$$

because $x_0 > 0$ and the last equality follows from (2.16) expressed in the form $x_0 + 3\mu_0 x_0^{2/3} - 2\nu_0 = 0$.

Now we find restrictions on the variations of $|\Omega_t|$ near the minimum point x_0. Since $\lim_{x\to 0} y(x) = AM^\kappa/(\kappa - 1) > 0$ and $\lim_{x\to\infty} y(x) = \infty$, if we assume that the parameters p_0, σ, κ, and d vary in a bounded set, we find that $x_0 = x_0(p_0, \sigma, \kappa, d)$ belongs to a compact set separated from zero by a positive number, and $y(x) = 0$ has exactly two positive solutions, which also belong to a compact set. Denote them by w_1, w_2, and $0 < w_1 < w_2$. Inequality (2.15) implies that $w_1 \le |\Omega_t| \le w_2$. Expanding $y(x)$ in a Taylor series in a neighborhood of x_0 up to the second order, we obtain

$$y(x) = y(x_0) + \tfrac{1}{2}y''(x_0 + \theta h)h^2,$$

where $\theta \in (0,1)$, $h = x - x_0$. Assume that $(x_0 - h, x_0 + h) \subset (w_1, w_2)$. Since $y(x) \le 0$ for $x \in (x_1, x_2)$, we have

$$h \le \left(\frac{-2y(x_0)}{y''(x_0 + \theta h)}\right)^{1/2}. \tag{2.19}$$

Moreover,

$$0 < y(x) - y(x_0) = \tfrac{1}{2}y''(x_0 + \theta h)h^2;$$

hence for $h > h_* > 0$ we have $y''(x_0 + \theta h) \ge y_* > 0$. For $x_0 + \theta h$ close to x_0 we use the fact that $y''_\alpha = y''_\alpha(x)$, where $\alpha = (p_0, \sigma, \kappa, d) \in B$, which is assumed to be a bounded set, is a continuous function of x. Then, $y''_\alpha(x_0)$, $\alpha \in B$, being separated from zero, so is $y''_\alpha(x)$ for x from a sufficiently small neighborhood of x_0.

By (2.19), $-y(x_0)$ small yields h small. Then (2.13) implies

$$\begin{aligned} &|\Omega_t|^{\kappa-1}\int_{\Omega_t}\frac{1}{2}\rho v^2\,dx + \sigma(|S_t| - 4\pi R_t^2)|\Omega_t|^{\kappa-1} \\ &\quad + \frac{A}{\kappa - 1}\left(|\Omega_t|^{\kappa-1}\int_{\Omega_t}\rho^\kappa\,dx - \left(\int_{\Omega_t}\rho\,dx\right)^\kappa\right) \le -y(x_0). \end{aligned} \tag{2.20}$$

To get $|h|$ small we can also assume that the denominator on the right-hand side of (2.19) is large and $-y(x_0)$ is bounded. In this case the left-hand side of (2.20) is not small. However, it is difficult to find conditions guaranteeing that $y''(x)$ is large.

Now we find the minimum of $y = y(x)$, so we look for solutions to (2.17). Let

$$D = q^2 + p^3 = \nu_0(\nu_0 - \mu_0^3). \tag{2.21}$$

Then we have the following possibilities:

(2.22)

$$D > 0, \nu_0 > 2\mu_0^3, \quad \cosh\varphi := \nu_0/\mu_0^3 - 1 > 1, \quad u = \mu_0(2z - 1) > 0, \quad z = \cosh\varphi/3.$$

(2.23)

$$D \le 0 \quad \text{and } \nu_0 \in (\mu_0^3, 2\mu_0^3], \quad \cos\varphi := \nu_0/\mu_0^3 - 1, \quad u = \mu_0(2z-1) > 0, \quad z = \cos\varphi/3.$$

(2.24)

$$D \le 0 \quad \text{and } \nu_0 \in (0, \mu_0^3], \quad \cos\varphi := 1 - \nu_0/\mu_0^3, \quad u = \mu_0(2z-1), \quad z = \cos(\pi/3 - \varphi/3).$$

Moreover, $x_0 = u^3$.

Using the above notation we have

$$\begin{aligned} y(x_0) = {} & p_0\mu_0^{3(\kappa-1)}(2z-1)^{3(\kappa-1)}[(\kappa-1/3)^{-1}\mu_0^3(2z-1)^2 - 2\nu_0/(\kappa-1)] \\ & + AM^\kappa/(\kappa-1) \end{aligned} \tag{2.25}$$

and $y''(x)_{|x=x_0|} > 0$ yields

$$\mu_0^3(2z-1)^2 - 2\nu_0 < 0. \tag{2.26}$$

Equation (2.26) implies that the first term on the right-hand side of (2.25) is negative. This enables us to make $y(x_0)$ arbitrarily small.

Let (2.22) be satisfied. Then (2.26) is satisfied and (2.25) has the form

$$\begin{aligned} y(x_0) = {} & -(\kappa-1)^{-1}p_0\mu_0^{3\kappa}(2\cosh(\varphi/3) - 1)^{3(\kappa-1)} \\ & \cdot [2(\cosh\varphi + 1) - (\kappa-1)(\kappa-1/3)^{-1}(2\cosh(\varphi/3) - 1)^2\,] \\ & + AM^\kappa/(\kappa-1) \equiv -\Phi_1(\mu_0, \varphi, p_0, \kappa, A, M). \end{aligned} \tag{2.27}$$

The first expression in (2.27) is a decreasing continuous function of $z = \cosh(\varphi/3)$ and μ_0, which vanishes for $z = \frac{1}{2}$. Thus there exists a set of parameters of $\mu_0, \nu_0, p_0, \kappa, A, M$, such that $y(x_0)$ is very small negative.

Let (2.23) be satisfied. Then (2.26) is satisfied and (2.25) yields

(2.28)

$$\begin{aligned} y(x_0) = {} & -(\kappa-1)^{-1}p_0\mu_0^{3\kappa}(2\cos(\varphi/3) - 1)^{3(\kappa-1)}\,[2(\cos\varphi + 1) \\ & -(\kappa-1)(\kappa-1/3)^{-1}(2\cos(\varphi/3) - 1)^2] \\ & + AM^\kappa/(\kappa-1) \equiv -\Phi_2(\mu_0, \varphi, p_0, \kappa, A, M), \end{aligned}$$

where the first expression achieves its minimum at $\varphi = 0$ and increases with φ. Therefore, to guarantee that $y(x_0)$ is negative for some φ we have to assume that

$$(3\kappa - 1/3)(\kappa - 1/3)^{-1}p_0\mu_0^{3\kappa} > AM^\kappa. \tag{2.29}$$

Under this assumption there exists a set of parameters such that $y(x_0)$ given by (2.28) is very small and negative.

Finally, assume that (2.24) is satisfied. Then (2.26) is satisfied for $\varphi \in (0, \pi]$. Moreover, (2.25) gives

(2.30)

$$\begin{aligned} y(x_0) = {} & -(\kappa-1)^{-1}p_0\mu_0^{3\kappa}(2\cos(\pi/3 - \varphi/3) - 1)^{3(\kappa-1)} \\ & \cdot [2(1 - \cos\varphi) - (\kappa-1)(\kappa-1/3)^{-1}(2\cos(\pi/3 - \varphi/3) - 1)^2] + AM^\kappa/(\kappa-1) \\ \equiv {} & -(\kappa-1)^{-1}p_0\mu_0^{3\kappa}\Gamma(\varphi) + AM^\kappa/(\kappa-1) \equiv -\Phi_3(\mu_0, \varphi, p_0, \kappa, A, M), \end{aligned}$$

where $\varphi \in (0,\pi]$, $\Gamma(0)=0$, $\Gamma(\pi/2)=(\sqrt{3}-1)^{3(\kappa-1)}[2-(\kappa-1)(\kappa-1/3)^{-1}(\sqrt{3}-1)^2]$ and $d\Gamma/d\varphi > 0$. Therefore, as in the above case we have to assume that

$$p_0\mu_0^3\Gamma(\varphi) > AM^\kappa, \qquad \varphi \in (0,\pi]. \tag{2.31}$$

The above considerations imply that there exist sets of parameters μ_0, ν_0, p_0, κ, A, M such that conditions (2.22), (2.23), and (2.24) can be satisfied and $y = y(x_0)$ can be determined by (2.27), (2.28), and (2.30), respectively, such that $y(x_0) < 0$ and

$$|y(x_0)| \le \varepsilon, \tag{2.32}$$

where ε may be made arbitrarily small. Then by (2.19) it follows that

$$\sup_t \operatorname{var}|\Omega_t| \le c_1\varepsilon, \qquad t \in \mathbb{R}_+. \tag{2.33}$$

From (2.33) we have $|\int_{\Omega_t}\rho^\kappa\,dx - \int_{\Omega_{t'}}\rho^\kappa\,dx| = |\int_{\Omega_t\setminus\Omega_{t'}}\rho^\kappa\,dx| \le c_2\varepsilon$ (where for convenience we assume that $\Omega_{t'} \subset \Omega_t$) because $\int_{\Omega_t}\rho^\kappa\,dx$ is bounded. Hence

$$\sup \operatorname{var}|\psi_t| \le c_2\varepsilon, \qquad t \in \mathbb{R}_+, \tag{2.34}$$

where $\psi_t = \int_{\Omega_t}\varphi(\rho)\,dx$.

Thus we have proved the following.

LEMMA 2.2. *Let $\varepsilon > 0$ be small. Assume that the parameters $\mu_0, \nu_0, p_0, \kappa, A, M$, where $\mu_0 = c_0\sigma(\kappa-1/3)/(3p_0)$, $\nu_0 = d(\kappa-1)/(2p_0)$, satisfy the relation*

$$\nu_0 \in I_i, \qquad 0 < \Phi_i(\mu_0,\varphi_i,p_0,\kappa,A,M) \le \varepsilon, \tag{2.35}$$

where $i = 1,2,3, \Phi_i, i = 1,2,3$, are determined by (2.27), (2.28), *and* (2.30), *respectively, $I_1 = (2\mu_0^3,\infty)$, $I_2 = (\mu_0^3, 2\mu_0^3]$, $I_3 = (0,\mu_0^3]$, $\cosh\varphi_1 = \nu_0/\mu_0^3 - 1$, $\cos\varphi_2 = \nu_0/\mu_0^3 - 1$, $\cos\varphi_3 = 1 - \nu_0/\mu_0^3$.*

Then there exist constants c_1, c_2 independent of ε (they can depend on the parameters) such that (2.33) *and* (2.34) *hold. Moreover, in the case* (2.35) *we have*

$$\||\Omega_t| - Q_i\| \le c_3\varepsilon \quad \forall t \in \mathbb{R}_+, \tag{2.36}$$

where $i = 1,2,3, Q_1 = \mu_0^3(2\cosh(\varphi_1/3)-1)^3$, $Q_2 = \mu_0^3(2\cos(\varphi_2/3)-1)^3$, and $Q_3 = \mu_0^3(2\cos(\pi/3-\varphi_3/3)-1)^2$.

The condition (2.36) means that for parameters satisfying (2.35) the volume $|\Omega_t|$ of the considered drop does not differ much from the constant value $Q_i, i = 1,2,3$. This means that the initial volume $|\Omega|$ must also be close to $Q_i, i = 1,2,3$.

On the other hand, from physical reasons the drop volume $|\Omega_t|$ should also be close to the volume $|\Omega_e|$ of the drop in the equilibrium state (see Definition 1.1).

For this purpose we show the following.

LEMMA 2.3. *Let the assumptions of Lemma* 2.2 *be satisfied. Then there exists a constant c_4 such that*

$$|Q_i - |\Omega_e|| \le c_4\varepsilon, \qquad i = 1,2,3, \tag{2.37}$$

where ε is sufficiently small.

Proof. Consider the case Q_i, where $i \in \{1,2,3\}$. Recall that $x_0 = Q_i$. Then (2.16) determining x_0 has the form

$$p_0x_0^\kappa + (\kappa-1/3)\kappa^{-1}c_0\sigma x_0^{\kappa-1/3} + (\kappa-1)\kappa^{-1}\,dx_0^{\kappa-1} = 0. \tag{2.38}$$

Moreover, we have

$$0 \le -y(x_0) = -(p_0 x_0^\kappa + c_0 \sigma x_0^{\kappa - 1/3} - d x_0^{\kappa-1} + AM^\kappa/(\kappa-1)) \le \varepsilon^2. \tag{2.39}$$

In the case of the barotropic fluid (1.9) takes the form

$$p_0 |\Omega_e|^\kappa + 2(4\pi/3)^{1/3} \sigma |\Omega_e|^{\kappa - 1/3} - AM^\kappa = 0. \tag{2.40}$$

Employing (2.38) in (2.39) yields

$$0 \le p_0 x_0^\kappa + (2/3) c_0 \sigma x_0^{\kappa - 1/3} - AM^\kappa \le (\kappa - 1)\varepsilon^2. \tag{2.41}$$

Calculating the coefficient in the second term in (2.40) we have

$$2(4\pi/3)^{1/3}\sigma = (2/3)c_0\sigma, \quad \text{because } c_0 = (36\pi)^{1/3}.$$

Hence (2.40) takes the form

$$p_0 |\Omega_e|^\kappa + (2/3) c_0 \sigma |\Omega_e|^{\kappa - 1/3} - AM^\kappa = 0. \tag{2.42}$$

Comparing (2.41) with (2.42) implies (2.37). This concludes the proof.

Considering variations of $|\Omega_t|$ near the volume $|\Omega_e|$ we choose a constant c_5 such that

$$\| |\Omega_e| - |\Omega_t| \| \le c_5 \varepsilon \quad \forall t \in \mathbb{R}_+, \tag{2.43}$$

where comparing (2.33) and (2.36)–(2.38) we have $c_3 + c_4 + c_5 \le c_1$.

Finally, (2.35) and (2.20) imply that for $t \ge 0$ the left-hand side of (2.20) must be smaller than $c_1\varepsilon^2$, so $1/2 \int_{\Omega_t} \rho v^2 \, dx \le c_1 \varepsilon^2$, the considered drop must be close to a ball, and the last term on the left-hand side of (2.20) that vanishes for a constant density is small, too.

To prove the global existence, we assume that Ω_t is diffeomorphic to a ball, so S_t can be described by

$$|x| \equiv r = R(\omega, t), \qquad \omega \in S^1, \tag{2.44}$$

where S^1 is the unit sphere.

LEMMA 2.4 (see the proof of Theorem 3 in [23]). *Let S_t be determined by* (2.44) *and suppose that the origin of coordinates coincides with the barycentre of Ω_t. Let $\rho(x,t)$ be a density defined for $x \in \Omega_t$, and let $t \in (T_1, T_2)$. Assume that there exists a maximum and a minimum of the density for $t \in (T_1, T_2)$ denoted by*

$$\rho_* = \min_{t \in (T_1, T_2)} \min_{\Omega_t} \rho(x,t), \qquad \rho^* = \max_{t \in (T_1, T_2)} \min_{\Omega_t} \rho(x,t). \tag{2.45}$$

Set $|\Omega^*| = M/\rho^*, |\Omega_*| = M/\rho^*, \bar{\rho}_t = M/|\Omega_t|$.

Then there exists a constant $\delta \in (0, 1/2)$ such that if

$$\sup_{S^1} |R(\omega,t) - R_t| + \sup_{S^1} |\nabla R| \le \delta R_t, \qquad t \in (T_1, T_2), \tag{2.46}$$

where $|\nabla R|^2 = R_\theta^2 + (\sin\theta)^{-2} R_\varphi^2$ in spherical coordinates, $R_t = ((3/4\pi)|\Omega_t|)^{1/3}$, then

$$\begin{aligned} &\int_{S^1} (|R(\omega,t) - R_t|^2 + |\nabla R(\omega,t)|^2) d\omega \\ &\qquad \le c_1(|S_t| - 4\pi R_t^2) + c_2 R_t^2 |\Omega_*|^{-2} (|\Omega_t| - |\Omega_*|)^2, \end{aligned} \tag{2.47}$$

where c_1, c_2 are constants that do not depend on δ and R_t.

Proof. To make the barycentre of Ω_t coincide with the origin of coordinates we must have (see Remark 2.6)

$$\int_{\Omega_t} \rho(x,t)x\,dx = \int_{S^1} d\omega \int_0^{R(\omega,t)} \rho(r,\omega,t)r^3\bar{\nu}(\omega)dr = 0, \tag{2.48}$$

where $\bar{\nu}(\omega) = (\cos\varphi\sin\theta, \sin\varphi\sin\theta, \cos\theta)$. We write (2.48) in the form

$$\frac{1}{\bar{\rho}_t}\int_{S^1} d\omega \int_0^{R(\omega,t)} (\rho(r,\omega,t) - \bar{\rho}_t)r^3\bar{\nu}(\omega)dr + \frac{1}{4}\int_{S^1}(R^4(\omega,t) - R_0^4)\bar{\nu}(\omega)d\omega = 0, \tag{2.49}$$

where the first expression can be estimated by

$$\begin{aligned}(\pi/\bar{\rho}_t)(\rho^* - \bar{\rho}_t)R^4(\omega,t) &\le \pi R^4(|\Omega_t|/M)(M/|\Omega_*| - M/|\Omega_t|)\\ &= (\pi R^4/|\Omega_*|)(|\Omega_t| - |\Omega_*|).\end{aligned}$$

From $|\Omega_t| = (4\pi/3)R_t^3$ we have

$$\int_{S^1}(R^3(\omega,t) - R_t^3)d\omega = 0. \tag{2.50}$$

From (2.48)–(2.50) we obtain

$$R_t^2\int_{S^1}(R - R_t)d\omega = -R_t\int_{S^1}(R-R_t)^2d\omega - \frac{1}{3}\int_{S^1}(R-R_t)^3d\omega, \tag{2.51}$$

(2.52)

$$\begin{aligned}R_t^3\int_{S^1}(R-R_t)\bar{\nu}(\omega)d\omega = &-\frac{3}{2}R_t^2\int_{S^1}(R-R_t)^2\bar{\nu}(\omega)d\omega - R_t\int_{S^1}(R-R_t)^3\bar{\nu}(\omega)d\omega\\ &-\frac{1}{4}\int_{S^1}(R-R_t)^4\bar{\nu}(\omega)d\omega + \frac{4}{\bar{\rho}_t}\int_{\Omega_t}(\rho - \bar{\rho}_t)x\,dx.\end{aligned}$$

To estimate $|S_t| - 4\pi R_t^2$ from below we use the formula

$$|S_t| - 4\pi R_t^2 = \int_{S^1}\left(R\sqrt{R^2 + |\nabla R|^2} - R_t^2\right)d\omega,$$

and we write the integrand in the form

(2.53)

$$\begin{aligned}&-R_t^2 + R\sqrt{R^2 + |\nabla R|^2}\\ &\quad = 2R_t(R-R_t) + \frac{1}{2}[2(R-R_t)^2 + |\nabla R|^2]\\ &\qquad + \frac{1}{2}\int_0^1 (1-s)^2\frac{d^3}{ds^3}\left[(R_t + s(R-R_t))\sqrt{R_t^2 + s(R-R_t)^2 + s^2|\nabla R|^2}\right]ds.\end{aligned}$$

Therefore,

$$|S_t| - 4\pi R_t^2 = -\int_{S^1}(R-R_t)^2d\omega + \frac{1}{2}\int_{S^1}|\nabla R|^2d\omega - \frac{2}{3R_t}\int_{S^1}(R-R_t)^3d\omega + I, \tag{2.54}$$

where I is the integral of the last term in (2.53).

Using the inequality

$$\int_{S^1} |f(\omega)|^2 d\omega \le \frac{1}{6} \int_{S^1} |\nabla f|^2 d\omega$$

for $f = a + \bar{b}\cdot\bar{\nu} + R - R_t$, where $a = (1/4\pi)\int_{S^1}(R-R_t)d\omega$, $\bar{b} = (3/4\pi)\int_{S^1}(R-R_t)\bar{\nu}d\omega$, we get

$$\|R - R_t\|^2_{0,S^1} \le (1/6)\|\nabla R\|^2_{0,S^1} + 4\pi(|a|^2 + |\bar{b}|^2) + |\bar{b}|^2\|\nabla\bar{\nu}\|^2_{0,S^1}. \tag{2.55}$$

Using (2.51) and (2.52) we obtain

$$\begin{aligned} &|a| \le c_3\delta\|R - R_t\|_{0,S^1}, \\ &|b| \le c_4\delta\|R - R_t\|_{0,S^1} + c_5(R_t/|\Omega_*|)(|\Omega_t| - |\Omega_*|) \end{aligned} \tag{2.56}$$

and

(2.57)

$$\frac{2}{3R_t}\int_{S^1} |R - R_t|^3 d\omega \le \frac{2}{3}\delta\|R - R_t\|^2_{0,S^1}, \qquad |I| \le c_6\delta(\|R - R_t\|^2_{0,S^1} + \|\nabla R\|^2_{0,S^1}).$$

From (2.55)–(2.57) for sufficiently small δ one gets (2.47). This concludes the proof.

The double mean curvature of S in spherical coordinates has the form

$$\mathcal{H} = \frac{1}{R\sin\theta}\left(\frac{\partial}{\partial\varphi}\frac{R_\varphi}{\sin\theta\sqrt{R^2 + |\nabla R|^2}} + \frac{\partial}{\partial\theta}\frac{\sin\theta R_\theta}{\sqrt{R^2 + |\nabla R|^2}}\right) - \frac{2}{\sqrt{R^2 + |\nabla R|^2}}. \tag{2.58}$$

Now we consider the equation

$$\mathcal{H}(R) + \frac{2}{R_t} = h(\omega), \tag{2.59}$$

where $h(\omega) = \bar{n}\mathbb{T}(v, p_\sigma)\bar{n}|_S$.

From Theorem 4 in [14] we have the following.

THEOREM 2.5. *Let $R \in H_2^{k+5/2}(S^1)$, $k \in \mathbb{Z}_+ \cup \{0\}$ be a solution to* (2.59) *that satisfies* (2.46) *with sufficiently small δ. If $h \in H_2^{k+1/2}(S^1)$, then*

$$\|R - R_t\|_{2+\mu,S^1} \le C_1\|h\|_{\mu,S^1} + c_2\|R - R_t\|_{0,S^1}, \qquad \mu = k + 1/2. \tag{2.60}$$

To guarantee that the barycentre of Ω_t coincides with the origin of coordinates, we need the following.

Remark 2.6. Assume $f = 0$ and

$$\int_\Omega \rho_0 v_0\, dx = 0, \qquad \int_\Omega \rho_0 \xi d\xi = 0. \tag{2.61}$$

Then (2.2) and (2.61) imply $\int_{\Omega_t} \rho v\, dx = 0$, and then (2.3) gives (2.48).

Now we formulate the main result, which is necessary in the proof of global existence.

Remark 2.7. Let the assumptions of Lemma 2.2 be satisfied. Let $|\Omega^{**}| = \max_t |\Omega_t|$, $|\Omega_{**}| = \min_t |\Omega_t|$, $\psi^{**} = \max_t \psi_t$, and $\psi_{**} = \min_t \psi_t$. Let $|S_{**}| = 4\pi R^2_{**}$,

where R_{**} is determined by $(4\pi/3)R_{**}^3 = |\Omega_{**}|$. Then $|S_t| - |S_{**}| \geq 0$. Moreover, by Lemma 2.2 we have $|\Omega^{**}| - |\Omega_{**}| \leq \varepsilon$, $\psi^{**} - \psi_{**} \leq \varepsilon$. Furthermore, by writing (2.1) in the form

$$\frac{d}{dt}\left(\int_{\Omega_t} \frac{1}{2}\rho v^2 dx + \psi_t + p_0|\Omega_t| + \sigma|S_t|\right) \leq 0, \tag{2.62}$$

we obtain

$$\begin{aligned} &\frac{1}{2}\int_{\Omega_t} \rho v^2 dx + \psi_t - \psi_{**} + p_0(|\Omega_t| - |\Omega_{**}|) + \sigma(|S_t| - |S_{**}|) \\ &\quad \leq \frac{1}{2}\int_{\Omega_t} \rho_0 v_0^2 dx + \psi - \psi_{**} + p_0(|\Omega| - |\Omega_{**}|) + \sigma(|S| - |S_{**}|) \leq \kappa_0 \varepsilon_0, \end{aligned} \tag{2.63}$$

where $\psi = \psi_0, \varepsilon_0 = \varepsilon_0(\varepsilon)$ will be made arbitrarily small.

Since the minima of $|\Omega_t|, |S_t|, \psi_t$, for all $t \in \mathbb{R}_+$, exist, we can always obtain (2.63) with an arbitrarily small right-hand side because we can choose ε in Lemma 2.2 so small that the right-hand side of (2.63) is as small as we please. To ensure the last inequality we have to assume

$$\frac{1}{2}\int_{\Omega} \rho_0 v_0^2 dx \leq \varepsilon. \tag{2.64}$$

Moreover, the coefficient κ_0 in (2.63) will be chosen in such a way that Lemma 2.4 yields

$$\frac{1}{2}\int_{\Omega_t} \rho v^2 dx + \|R(\omega, t) - R_t\|_{1,S^1}^2 \leq \varepsilon_0. \tag{2.65}$$

Finally, we consider the case $p_0 = 0$. Then, instead of (2.9), we obtain

$$\begin{aligned} &\frac{1}{2}\int_{\Omega_t} \rho v^2 dx + \int_{\Omega_t} \varphi(\rho) dx + \sigma|S_t| \\ &\quad \leq \frac{1}{2}\int_{\Omega} \rho_0 v_0^2 dx + \int_{\Omega} \varphi(\rho_0) dx + \sigma|S| \equiv d_0. \end{aligned} \tag{2.66}$$

Hence instead of (2.13) we have

$$\begin{aligned} &y_1(|\Omega_t|) + |\Omega_t|^{\kappa-1}\int_{\Omega_t} \frac{1}{2}\rho v^2 dx + \sigma(|S_t| - 4\pi R_t^2)|\Omega_t|^{\kappa-1} \\ &\quad + \frac{A}{\kappa - 1}\left(|\Omega_t|^{\kappa-1}\int_{\Omega_t} \rho^\kappa dx - \left(\int_{\Omega_t} \rho dx\right)^\kappa\right) \leq 0, \end{aligned} \tag{2.67}$$

where

$$y_1(x) = c_0 \sigma x^{\kappa - 1/3} - d_0 x^{\kappa-1} + \frac{A}{\kappa - 1} M^\kappa, \qquad x := |\Omega_t|. \tag{2.68}$$

Inequality (2.67) holds for physical volumes $|\Omega_t|$. Since the last three terms in (2.67) are positive, we have

$$y_1(|\Omega_t|) \leq 0. \tag{2.69}$$

An extremum point x_0 of the function $y_1 = y_1(x)$ calculated from the relation

$$y_1'(x) \equiv c_0\sigma(\kappa - 1/3)x^{\kappa-4/3} - d_0(\kappa-1)x^{\kappa-2} = 0 \tag{2.70}$$

is

$$x_0 = \left(\frac{d_0(\kappa-1}{c_0\sigma(\kappa-1/3)}\right)^{3/2}. \tag{2.71}$$

This is a positive number. From the form of $y_1 = y_1(x)$ we have $y_1(0) = AM^\kappa/(\kappa - 1) > 0$, $y_1(\infty) = \infty$, $y_1'(x)|_{x<x_0} < 0$, $y_1'(x)|_{x>x_0} > 0$, so x_0 is a minimum point. We also have

$$y_1''(x_0) = (2/3)d_0(\kappa-1)x_0^{\kappa-3} > 0. \tag{2.72}$$

From (2.69) it follows that there are two strictly positive solutions of the equation $y_1(x) = 0$. Denote them by w_1, w_2. We have $0 < w_1 < x_0 < w_2 < \infty$.

To guarantee (2.69) we have to require that

$$y_1(x_0) = -\frac{2}{3}\left(\frac{d_0}{\kappa-1/3}\right)^{(3\kappa-1)/2}\left(\frac{\kappa-1}{c_0\sigma}\right)^{3(\kappa-1)/2} + AM^\kappa/(\kappa-1) < 0. \tag{2.73}$$

Using the form of d_0 from (2.66) in (2.73) yields

$$\begin{aligned} y_1(x_0) = &-\frac{2}{3}(\kappa-1)^{3(\kappa-1)/2}(\kappa-1/3)^{(3\kappa-1)/2}(c_0\sigma)^{-3(\kappa-1)/2} \\ &\cdot\left(\frac{1}{2}\int_\Omega \rho_0 v_0^2 dx + \frac{A}{\kappa-1}\int_\Omega \rho_0^\kappa dx + \sigma|S|\right)^{(3\kappa-1)/2} + AM^\kappa/(\kappa-1) < 0. \end{aligned} \tag{2.74}$$

Since $M^\kappa \le |\Omega|^{\kappa-1}\int_\Omega \rho_0^\kappa dx$, we see that (2.74) may hold.

Now we show that for a given $\varepsilon > 0$ there exists a set of parameters κ, d_0, A, M such that meas $X \equiv |X| \le \varepsilon$, where $X = \{x \in \mathbb{R}_+ : y_1(x) < 0, \text{or } w_1 < x < w_2\}$. Moreover, $x_0 \in X$. To calculate meas X in the case of small ε we estimate solutions to the equation

$$y_1(x) = c_0\sigma x^{\kappa-1/3} - d_0 x^{\kappa-1} + AM^\kappa/(\kappa-1) = 0. \tag{2.75}$$

We expand the functions $x^{\kappa-1}$ and $x^{2/3}$ near the minimum point x_0 in the form

$$\begin{aligned} x^{\kappa-1} &= x_0^{\kappa-1} + (\kappa-1)x_0^{\kappa-2}h + (1/2)(\kappa-1)(\kappa-2)x^{\kappa-3}(\tilde{x}_1)h^2, \\ x^{2/3} &= x_0^{2/3} + (2/3)x_0^{-1/3}h - (1/9)\tilde{x}_2^{-4/3}h^2, \end{aligned} \tag{2.76}$$

where $(x_0 - h, x_0 + h) \subset (w_1, w_2)$ and $\tilde{x}_i \in (x_0 - h, x_0 + h)$, $i = 1, 2$.

Assume that h is small. Put (2.76) into (2.75) and take into account terms up to the second-order with respect to h only. Then we obtain

$$\left[c_0\sigma\left(\frac{\kappa^2}{2} - \frac{5}{6}\kappa + \frac{2}{9}\right)x_0 - d_0\frac{(\kappa-1)(\kappa-2)}{2}\right]x_0^{\kappa-3}h^2 \cong -y(x_0). \tag{2.77}$$

Using (2.71) in (2.77) yields

$$|h| \le (-3y(x_0)/(d_0(\kappa-1)x_0^{\kappa-1}))^{1/2}. \tag{2.78}$$

Now we impose restrictions on the parameters $\kappa, \rho_0, v_0, \Omega, A, \sigma, S, M$ such that for a given $\varepsilon > 0$ we have $y_1(x_0) < 0$ and $-y_1(x_0) < \varepsilon^2$. Hence by (2.78) we have $|h| \le (3/(d_0(\kappa-1)x_0^{\kappa-1}))^{1/2}\varepsilon \equiv c_1\varepsilon$, where ε may be assumed to be as small as we need. Thus we have shown the following.

LEMMA 2.8. *Let $\varepsilon > 0$. Then there exists a set of parameters $\kappa, \rho_0, v_0, \Omega, S, \sigma, A, M$ such that $y_1(x_0) < 0, |y_1(x_0)| \le \varepsilon$ and*

$$\sup_t \operatorname{var} |\Omega_t| \le c_1\varepsilon, \qquad t > 0, \tag{2.79}$$

and there exists a constant c_2 such that

$$\sup_t \operatorname{var} \psi_t \le c_2\varepsilon, \qquad t > 0. \tag{2.80}$$

3. Local existence. To prove the local existence of solutions to (1.1a–e) we write it in the Lagrangian coordinates introduced by (1.5) and (1.6):

$$\begin{aligned}
\eta u_t - \mu\nabla_u^2 u - \nu\nabla_u\nabla_u\cdot u + \nabla_u q &= \eta g && \text{in } \Omega^T,\\
\eta_t + \eta\nabla_u\cdot u &= 0 && \text{in } \Omega^T,\\
\mathbb{T}_u(u,q)\bar{n} - \sigma\Delta_{S_t}(t)X_u(\xi,t) &= -p_0\bar{n} && \text{on } S^T,\\
u|_{t=0} &= v_0(\xi) && \text{in } \Omega,\\
\eta|_{t=0} &= \rho_0(\xi) && \text{in } \Omega,
\end{aligned} \tag{3.1}$$

where $u(\xi,t) = v(X_u(\xi,t),t)$, $\eta(\xi,t) = \rho(X_u(\xi,t),t)$, $q(\xi,t) = p(X_u(\xi,t),t)$, $g(\xi,t) = f(X_u(\xi,t),t)$,

$$\nabla_u = \partial_x\xi^i\nabla_{\xi^i}, \quad \nabla_{\xi^i} = \partial_{\xi^i}, \quad \mathbb{T}_u(u,q) = -qI + \mathbb{D}_u(u) \quad \text{and}$$
$$\mathbb{D}_u(u) = \left\{\mu\left(\partial_{x^i}\xi^k\nabla_{\xi^k}u^j + \partial_{x^j}\xi^k\nabla_{\xi^k}u^i\right) + (\nu-\mu)\delta_{ij}\nabla_u\cdot u\right\},$$

$\nabla_u\cdot u = \partial_{x^i}\xi^k\nabla_{\xi^k}u^i$. Let A be the Jacobi matrix of the transformation $x = x(\xi,t) = X_u(\xi,t)$ with elements $a_{ij} = \delta_{ij} + \int_0^t \partial_{\xi^j}u^i(\xi,\tau)d\tau$. Assuming $|\nabla_\xi u|_{\infty,\Omega^T} \le M$, we obtain

$$0 < c_1(1-Mt)^3 \le \det\left\{\partial_{\xi^j}x^i\right\} \le c_2(1+Mt)^3, \qquad t \le T, \tag{3.2}$$

where c_1, c_2 are constants and T is sufficiently small. Moreover, $\det A = \exp(\int_0^t \nabla_u\cdot u\,d\tau) = \rho_0/\eta$.

Let S_t be determined (at least locally) by the equation $\phi(x,t) = 0$. Then S is described by $\phi(x(\xi,t),t)|_{t=0} \equiv \tilde{\phi}(\xi) = 0$. Moreover, we have

$$\bar{n} = \bar{n}(x(\xi,t),t) = \frac{\nabla_x\phi(x,t)}{|\nabla_x\phi(x,t)|}|_{x=x(\xi,t)} \quad \text{and} \quad \bar{n}_0 = \bar{n}_0(\xi) = \frac{\nabla_\xi\tilde{\phi}(\xi)}{|\nabla_\xi\tilde{\phi}(\xi)|}.$$

THEOREM 3.1. *Let $v_0 \in W_2^{l+1}(\Omega)$, $\rho_0 \in W_2^{l+1}(\Omega)$, $f \in C^{l+1}(\mathbb{R}^3\times(0,T))$, $S \in W_2^{l+5/2}$, $l \ge \frac{3}{2}$ and $\frac{l}{2} - \frac{3}{4} - \kappa \in \mathbb{N} \subset \{0\}$, $\kappa \in (0,\frac{1}{4})$. Let $G = G(t, t\tilde{A}, \alpha, \beta, \gamma)$ be an increasing positive function of its arguments (its definition is given by (3.55) in [36]), where $\alpha = \|\rho_0\|_{l+1,\Omega}, \beta = \|f\|_{C^{l+1}(\mathbb{R}^3\times(0,T))}$, $\gamma = |u(0)|_{l+1,0,\Omega}$, which is such*

that $G(0,0,\alpha,\beta,\gamma) > 0$. *Suppose that* $\tilde{A} > G(0,0,\alpha,\beta,\gamma)$. *Let* $|v(0)|_{l+1,0,\Omega} \le \tilde{A}$. *Let* δ_1 *be sufficiently small (see the proof of Lemma* 3.3 *in* [36]). *Let* T_* *be so small that*

$$T_*^a \tilde{A}\varphi_1(T_*, T_*^a\tilde{A}, \tilde{A}, \tilde{A}) \le \delta_1,$$
$$0 < c_1(1-\tilde{A}T_*)^3 \le \det\left\{\frac{\partial x}{\partial \xi}\right\} \le c_2(1+\tilde{A}T_*)^3,$$

where φ_1 *is an increasing positive function which is defined in the assumptions of Lemma* 3.3 *from* [36], $x(\xi,t) = \xi + \int_0^t v_0(\xi,\tau)d\tau$, $t \le T_*$, $G(T_*, T_*^a\tilde{A}, \alpha, \beta, \gamma) \le \tilde{A}$, $a > 0$ *and* $\tilde{v}_0(\xi,t)$ *is defined in the proof of Theorem* 3.6 *from* [36].

Then there exists $T_{**}, 0 < T_{**} \le T_*$ *such that for* $T \le T_{**}$ *there exists a unique solution to problem* (3.1) *such that* $u \in W_2^{l+2,l/2+1}(\Omega^T)$, $\eta \in W_2^{l+1,l/2+1/2}(\Omega^T) \cap C([0,T]; \Gamma_0^{l+1,(l+1)/2}(\Omega))$ *and*

$$\|u\|_{l+2,\Omega^T} \le \tilde{A}, \qquad \|\eta\|_{l+1,\Omega^T} + \|\eta\|_{l+1,\infty,\Omega^T} + \|1/\eta\|_{l+1,\Omega^T} \le (\|\rho_0\|_{l+1,\Omega} + \|1/\rho_0\|_{l+1,\Omega})\,\varphi_2(T, T^a\tilde{A}), \tag{3.3}$$

where φ_2 *is an increasing positive function defined in the theses of Lemma* 3.5 *in* [36].

Having shown the local existence of solutions to (3.1), we find a more appropriate estimate that will be useful in the proof of global existence. Let us recall that $R_t = \left(\frac{3}{4}\pi|\Omega_t|\right)^{1/3}$, $t \ge 0$. In view of Definition 1.1, we shall look for motions of (1.1a–e) which are close to the equilibrium state. Assuming that the initial motion is sufficiently close to the equilibrium state, we introduce the quantity $q_\sigma = q - p_0 - q_0$, where $q_0 = 2\sigma/R_0$. The quantity describes changes of the pressure near the sum of external pressure p_0 and the initial pressure of surface tension in the case when, at the initial moment, our drop is a ball (q_0). Therefore, we consider

$$\begin{aligned}
&\eta u_t - \mu\nabla_u^2 u - \nu\nabla_u\nabla_u\cdot u = -\nabla_u q_\sigma + \eta g,\\
&\Pi_0\Pi\mathbb{D}_u(u)\bar{n} = 0,\\
&\bar{n}_0\mathbb{D}_u(u)\bar{n} - \sigma\Delta_{S_t}(t)\int_0^t u(\tau)d\tau\cdot\bar{n}_0 = \bar{n}_0\cdot\bar{n}q_\sigma + \sigma\bar{n}_0\cdot(\Delta_{S_t}(t) - \Delta_S(0))\,\xi\\
&\qquad\qquad + \sigma\left(H(\xi,0) + \frac{2}{R_0}\right),\\
&u|_{t=0} = v_0,
\end{aligned} \tag{3.4}$$

where $\Pi_0 g = g - g\cdot\bar{n}_0\bar{n}_0$, $\Pi g = g - g\cdot\bar{n}\bar{n}$, and

$$\begin{aligned}
&q_{\sigma t} = -q_\sigma\Psi(\eta)\mathrm{div}_u u - (p_0+q_0)\mathrm{div}_u u,\\
&q_\sigma|_{t=0} = p(\rho_0) - p_0 - q_0,
\end{aligned} \tag{3.5}$$

where $\Psi(\eta) = p_\eta(\eta)\eta/p(\eta)$, $p_\eta = \partial_\eta p$.

By Theorem 3.1 we have the existence of solutions to (3.4) and (3.5). Moreover, we obtain the following.

Remark 3.2. Let u, η be solutions of problem (1.1a–e). Then from (3.4) and (3.5)

for sufficiently small T we obtain the estimate

$$
\begin{aligned}
&\|u\|_{l+2,\Omega^T} + \|q_\sigma\|_{l+1,\Omega^T} + |q_\sigma|_{l+1,0,\infty,\Omega^T} \\
&\quad \le \varphi_3\left(T, \|v_0\|_{l+1,\Omega}, \|\rho_0\|_{l+1,\Omega}, \|f\|_{C^{l+1}(\mathbb{R}^3\times(0,T))}, \|S\|_{W_2^{l+5/2}}\right) \\
&\qquad \left[\|f\|_{C^{l+1}(\mathbb{R}^3\times(0,T))} + \|v_0\|_{l+1,\Omega}\right. \\
&\qquad \left. + \|p(\rho_0) - p_0 - q_0\|_{l+1,\Omega} + \|H(\xi,0) + 2/R_0\|_{l+1/2,S}\right],
\end{aligned} \tag{3.6}
$$

where $1 > \frac{3}{2}$. The existence of solution v, p of (1.1a–e) such that $u \in W_2^{4,2}(\Omega^T)$, $q_\sigma \in W_2^{3,3/2}(\Omega^T) \cap C(0,T;\Gamma_0^{3,3/2}(\Omega))$ and estimate (3.6) for $l = 2$ are proved in [37].

Proof. Applying Lemma 3.3 from [36] to (3.4) yields

$$
\begin{aligned}
\|u\|_{l+2,\Omega^T} \le c\left(T, \tilde{A}, \alpha, \beta, \gamma, \|S\|_{W_2^{l+5/2}}\right) &\left[\|q_\sigma\|_{l+1,\Omega^T} + \|g\|_{l,\Omega^T}\right. \\
&\left. + \|H(\xi,0) + 2/R_0\|_{l+1/2,S}\right].
\end{aligned} \tag{3.7}
$$

Integrating (3.5) implies

$$
\begin{aligned}
q_\sigma(\xi,t) = &-\exp\left[-\int_0^t \Psi(\eta)\mathrm{div}_u u dt'\right] \\
&\cdot \left[\int_0^t \left[(p_0+q_0)\mathrm{div}_u u \exp\int_0^{t'} \Psi(\eta)\mathrm{div}_u u dt''\right] dt' + p(\rho_0) - p_0 - q_0\right].
\end{aligned} \tag{3.8}
$$

From (3.8) we have

$$
\begin{aligned}
&\|q_\sigma\|_{l+1,\Omega^T} + |q_\sigma|_{l+1,0,\infty,\Omega^T} \le c(T, \tilde{A}, \alpha, \beta, \gamma, \|S\|_{W_2^{l+5/2}}) \\
&\quad \cdot (T^a\|u\|_{l+2,\Omega^T} + \|p(\rho_0) - p_0 - q_0\|_{l+1,\Omega}), \qquad a > 0.
\end{aligned} \tag{3.9}
$$

From (3.7) and (3.9) for sufficiently small T we have (3.6). This concludes the proof.

4. Global differential inequality. Assume that we have proved the existence of a sufficiently smooth local solution. First we find a special differential inequality that enables us to prove the existence of a solution by energy estimates and then to prove global existence.

To show it we consider the motion near the equilibrium state $v_e = 0$, $p_e = p_0 + 2\sigma/R_0$, $\rho_e = M/((4\pi/3)R_0^3)$; R_0 is a solution of the equation $p_0(M/((4\pi/3)R_0^3)) = p_0 + 2\sigma/R_0$, $q_0 = 2\sigma/R_0$ and $p_\sigma = p - p_0 - q_0$. Therefore, we examine the following system:

$$
\rho(v_t^i + v\cdot\nabla v^i) - \partial_{x^j} T_{ij}(v, p_\sigma) = \rho f^i \text{ in } \Omega_t, t \in [0,T], \tag{4.1a}
$$

$$
\rho_t + \mathrm{div}(\rho v) = 0 \text{ in } \Omega_t, t \in [0,T], \tag{4.1b}
$$

$$
\mathbb{T}(v, p_\sigma)\bar{n} = \sigma\Delta_{S_t} x\cdot\bar{n}\bar{n} + q_0\bar{n} \text{ on } S_t, t \in [0,T], \tag{4.1c}
$$

where $\mathbb{T} = \{T_{ij}\} = \{\mu(\partial_{x^j} v^i + \partial_{x^i} v^j) + (\nu - \mu)\delta_{ij}\mathrm{div}\, v - p_\sigma\delta_{ij}\}$.

Using the barotropic law $p = p(\rho)$ we write (4.1b) in the form

$$
p_{\sigma t} + v\cdot\nabla p_\sigma + p\Psi(\rho)\mathrm{div}\, v = 0, \tag{4.2}
$$

where $\Psi(\rho) = p_\rho\rho/p$.

Set $\rho_* = \min_{\tilde{\Omega}^T} \rho(x,t)$, $\rho^* = \max_{\tilde{\Omega}^T} \rho(x,t)$.

Now we point out the following facts concerning the estimates in Lemmas 4.1–4.12 and Theorems 4.13 and 4.14.

(1) The numbers δ_i are assumed to be small and are separately numbered in each lemma.

(2) We distinguish absolute constants, denoted by c, which may depend on such parameters of the problem as $\mu, \nu, \kappa, \sigma, A$ and which are coefficients in those terms in the right-hand sides of the inequalities that contain the highest derivatives only, and are finally balanced by the left-hand side main terms after appropriate summing.

(3) We distinguish the coefficients by the lower-order terms, nonlinear terms, and also by the force terms which depend on ρ_*, ρ^*, T,

$$a \equiv \int_0^T \|v\|_{3,\Omega_{t'}} dt', \quad a_0(t) \equiv \left| \int_0^t v_x d\tau \right|_{\infty,\Omega}, \quad b \equiv \|S\|_{4+1/2}, M, p_0,$$

on the parameters that guarantee the existence of the inverse transformation to $x = x(\xi,t)$, and also on the constants of imbedding theorems considered over Ω_t. Generally, the coefficients are increasing functions of the parameters. In the statements of the lemmas, we denote such coefficients by $P_1, P_2, \ldots,$ (common numbering for all lemmas) and independently in each lemma by $a_1, a_2, \ldots$. Moreover, P_i, a_i are positive and increasing functions of a and b.

(4) We have to underline that all estimates in this section are obtained under the assumption that there exists a local solution of (1.1a–e) so that all the quantities ρ_*, ρ^*, T, a, b are estimated by the data functions. Moreover, the local solution guarantees the existence of the inverse transformation to $x = x(\xi,t)$. Generally, the quantities $\rho_*, \rho^*, a, b, M, p_0$ might be large.

LEMMA 4.1. *Let v, p_σ be a sufficiently smooth solution of* (4.1). *Then*

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v^2 + \frac{1}{p\Psi(\rho)}p_\sigma^2\right)dx + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot\int_0^t v_{s^\alpha}d\tau\bar{n}\cdot\int_0^t v_{s^\beta}d\tau\,ds \\ &\quad + \frac{\mu}{2}\|v\|^2_{1,\Omega_t} + (\nu-\mu)\|\operatorname{div} v\|^2_{0,\Omega_t} \\ &\le \varepsilon_1\left(\|p_\sigma\|^2_{0,\Omega_t} + \left\|\int_0^t v_s d\tau\right\|^2_{0,S_t} + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{0,S^1}\right) \\ &\quad + P_1\left(\|v\|^2_{0,\Omega_t} + \|f\|^2_{0,\Omega_t}\right) + P_2 X_1 Y_1, \end{aligned} \tag{4.3}$$

where $\varepsilon_1 \in (0,1)$, $P_i = P_i^*(\rho_*, \rho^*, a_0(t))$, $i = 1,2$, and

$$\begin{aligned} X_1 &= \|v\|^2_{2,\Omega_t} + \|p_\sigma\|^2_{1,\Omega_t}, \\ Y_1 &= X_1 + \left\|\int_0^t v d\tau\right\|^2_{2,S_t}. \end{aligned} \tag{4.4}$$

Proof. Multiplying (4.1a) by v, integrating over Ω_t, and using (4.1b, c) implies

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\rho v^2 dx + \frac{\mu}{2}E_{\Omega_t}(v) + (\nu-\mu)\|\operatorname{div} v\|^2_{0,\Omega_t} - \int_{\Omega_t} p_\sigma \operatorname{div} v\,dx \\ &\quad -\sigma\int_{S_t}\left(\Delta_{S_t}x\cdot\bar{n} + \frac{2}{R_0}\right)\bar{n}\cdot v\,ds = \int_{\Omega_t}\rho f\cdot v\,dx. \end{aligned} \tag{4.5}$$

Equation (4.2) yields

$$-\int_{\Omega_t} p_\sigma \operatorname{div} v\, dx = \int_{\Omega_t} \frac{1}{p\Psi(\rho)}(\partial_t + v\cdot\nabla)\frac{p_\sigma^2}{2}\, dx$$

and

$$[F_t + \operatorname{div}(Fv) + (F_\rho \rho - F)\operatorname{div} v]\frac{p_\sigma^2}{2} = 0, \tag{4.6}$$

where $F = 1/(p(\rho)\Psi(\rho))$; so

$$\begin{aligned}\int_{\Omega_t} p_\sigma \operatorname{div} v\, dx &= -\frac{d}{dt}\int_{\Omega_t}\frac{1}{p\Psi(\rho)}\frac{p_\sigma^2}{2}dx + \int_{\Omega_t}(F - F_\rho\rho)\operatorname{div} v\frac{p_\sigma^2}{2}dx \\ &\le -\frac{d}{dt}\int_{\Omega_t}\frac{1}{p\Psi(\rho)}\frac{p_\sigma^2}{2}dx + \delta_1\|p_\sigma\|^2_{0,\Omega_t} \\ &\quad + a_1(\rho_*,\rho^*,\delta_1)\|p_\sigma\|^2_{1,\Omega_t}\|v\|^2_{2,\Omega_t}.\end{aligned} \tag{4.7}$$

In view of Lemma 5.2 from [35] and the relation $p(\rho) - p_0 = p - p(\rho_e) = p'(\tilde\rho)(\rho - \rho_e)$, $\tilde\rho \in [\rho, \rho_e]$, we have

$$\|v\|^2_{1,\Omega_t} \le c_2(\rho^*)(E_{\Omega_t}(v) + \|p_\sigma\|^2_{0,\Omega_t}\|v\|^2_{2,\Omega_t}). \tag{4.8}$$

By the Hölder and Young inequalities the right-hand side of (4.5) is estimated by

$$\delta_2\|v\|^2_{0,\Omega_t} + c(\delta_2)\rho_*^2\|f\|^2_{0,\Omega_t}. \tag{4.9}$$

Now we consider the boundary term in (4.5). By exploiting the Lagrangian coordinates we express S_t as follows: $x(s^1,s^2,t) = \xi(s^1,s^2) + \int_\sigma^t u(\xi(s^1,s^2),\tau)d\tau$, where $\{s^1,s^2\} \in U \subset \mathbb{R}^2$, so the boundary term takes the form

(4.10)

$$\begin{aligned}-\int_{S_t}\left(\Delta_{S_t}x\cdot\bar n + \frac{2}{R_0}\right)v\cdot\bar n ds &= -\int_U\left(\partial_{s^\alpha}\left(g^{\alpha\beta}\sqrt{g}x_\beta\right)\cdot\bar n + \frac{2}{R_0}\sqrt{g}\right)v\cdot\bar n\, ds^1ds^2 \\ &= -\int_U\left(\partial_{s^\alpha}\left(g^{\alpha\beta}\sqrt{g}\xi_{s^\beta}\right)\cdot\bar n + \frac{2}{R_0}\sqrt{g}\right)u\cdot\bar n\, ds^1ds^2 \\ &\quad -\int_U\partial_{s^\alpha}\left(g^{\alpha\beta}\sqrt{g}\int_0^t u_{s^\beta}d\tau\right)\cdot\bar n u\cdot\bar n\, ds^1ds^2.\end{aligned}$$

The first term we write is the following:

$$\begin{aligned}-\int_U\Big[&(g^{\alpha\beta}\sqrt{g})_{,s^\alpha}\,\xi_{s^\beta}\cdot(\bar n - \bar n_0) + (g^{\alpha\beta} - g^{\alpha\beta}(0))\sqrt{g}\xi_{s^\alpha s^\beta}\cdot\bar n \\ &+ g^{\alpha\beta}(0)\sqrt{g}\xi_{s^\alpha s^\beta}\cdot(\bar n - \bar n_0) + g^{\alpha\beta}(0)\sqrt{g}\xi_{s^\alpha s^\beta}\cdot\bar n_0 + \frac{2}{R_0}\sqrt{g}\Big]u\cdot\bar n\, ds^1ds^2 \\ &= -\int_{S_t}\left(H(0) + \frac{2}{R_0}\right)v\cdot\bar n\, ds + N_1,\end{aligned}$$

where $H(0) = g^{\alpha\beta}(0)\xi_{s^\alpha s^\beta}\cdot\bar n_0$, $\bar n = (x_{s^1}\times x_{s^2})/|x_{s^1}\times x_{s^2}|$, $\bar n_0 = (\xi_{s^1}\times\xi_{s^2})/|\xi_{s^1}\times\xi_{s^2}|$, $g_{\alpha\beta} = x_{s^\alpha}\cdot x_{s^\beta}$, $g_{\alpha\beta}(0) = \xi_{s^\alpha}\cdot\xi_{s^\beta}$ and

$$|N_1| \le \delta_3\|\int_0^t v_s d\tau\|^2_{0,S_t} + \delta_4\|v\|^2_{1,\Omega_t} + a_2\|v\|^2_{0,\Omega_t}.$$

The second term in the right-hand side of (4.10) takes the form

$$\frac{1}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot\int_0^t v_{s^\alpha}\,d\tau\bar{n}\cdot\int_0^t v_{s^\beta}\,d\tau\,ds + N_2,$$

where

$$|N_2| \le \delta_5\left(\left\|\int_0^t v_s d\tau\right\|^2_{0,S_t} + \|v\|^2_{1,\Omega_t}\right) + a_3\|v\|^2_{0,\Omega_t} + a_4\|\int_0^t v d\tau\|^2_{2,S_t}\|v\|^2_{2,\Omega_t}.$$

Hence, taking $\delta_i, i = 1,\dots,5$, sufficiently small and using (4.7) and (4.10) in (4.5) we obtain (4.3). This concludes the proof.

LEMMA 4.2. *For a sufficiently smooth solution of* (4.1) *we have*

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_t^2 + \frac{1}{p\Psi(\rho)}p_{\sigma t}^2\right)dx + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}v_{s^\alpha}\cdot\bar{n}v_{s^\beta}\cdot\bar{n}\,ds \\
&\qquad + \frac{\mu}{4}\|v_t\|^2_{1,\Omega_t} + (\nu-\mu)\|\operatorname{div} v_t\|^2_{0,\Omega_t} \\
&\le \varepsilon_2\left(\|p_{\sigma t}\|^2_{0,\Omega_t} + \|v_{xx}\|^2_{0,\Omega_t}\right) + P_3(\rho_*,\rho^*,\varepsilon_2)X_2Y_2 \\
&\qquad + P_4\left(\|f\|^2_{1,0,\Omega_t} + \|v\|^2_{0,\Omega_t}\right),
\end{aligned} \tag{4.11}$$

where $\varepsilon_2 \in (0,1)$, $P_3(\varepsilon_2)$ *behaves like* ε_2^{-a}, $a > 0$, *and*

$$Y_2 = X_2 = |p_\sigma|^2_{2,1,\Omega_t} + |v|^2_{2,1,\Omega_t}. \tag{4.12}$$

Proof. Differentiating (4.1a) with respect to t, multiplying by v_t, and integrating over Ω_t yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\rho v_t^2 dx + \frac{\mu}{2}E_{\Omega_t}(v_t) + (\nu-\mu)\|\operatorname{div} v_t\|^2_{0,\Omega_t} - \int_{\Omega_t} p_{\sigma t}\operatorname{div} v_t dx \\
&\qquad - \int_{S_t} T(v,p_\sigma)_{,t}\cdot\bar{n}\cdot v_t ds = N_1,
\end{aligned} \tag{4.13}$$

where

$$N_1 \le \delta_1\|v_t\|^2_{0,\Omega_t} + c(\delta_1)[\|f\|^2_{1,\Omega_t} + X_2^2] + c(\delta_1,\rho^*)\|f_t\|^2_{0,\Omega_t}.$$

From (4.2) and (4.6) with $p_{\sigma t}$ in place of p_σ we obtain

$$\begin{aligned}
\int_{\Omega_t} p_{\sigma t}\operatorname{div} v_t dx \le -\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\frac{1}{p\Psi(\rho)}p_{\sigma t}^2\,dx + \delta_2\|p_{\sigma t}\|^2_{0,\Omega_t} \\
+ c(\rho_*,\rho^*,\delta_2)X_2^2.
\end{aligned} \tag{4.14}$$

The boundary term in (4.13) is equal to

$$-\int_{S_t} T(v,p_\sigma)_{,t}\cdot\bar{n}\cdot v_t\,ds = -\sigma\int_{S_t}\Delta_{S_t}v\cdot\bar{n}\,v_t\cdot\bar{n}\,ds + N_2, \tag{4.15}$$

where

$$|N_2| \le \delta_3(\|v_t\|^2_{1,\Omega_t} + \|v_{xx}\|^2_{0,\Omega_t}) + a_1\|v\|^2_{0,\Omega_t}.$$

Next, using the Lagrangian coordinates we have

$$\begin{aligned} -\sigma\int_{\Delta_{S_t}} \Delta_{s_t} v\cdot\bar n\, v_t\cdot\bar n\, ds &= -\sigma\int_U \partial_{s^\alpha}\left(g^{\alpha\beta}\sqrt{g}\partial_{s^\beta} v\right)\cdot\bar n\, v_t\cdot\bar n\, ds^1 ds^2 \\ &= \frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta} v_{s^\alpha}\cdot\bar n\, v_{s^\beta}\cdot\bar n\, ds + N_3, \end{aligned} \tag{4.16}$$

and

$$|N_3| \le \delta_4\left(\|v_t\|^2_{1,\Omega_t} + \|v_{xx}\|^2_{0,\Omega_t}\right) + a_2\|v\|^2_{0,\Omega_t} + a_3 X_2^2.$$

Finally, from (4.13)–(4.16) and Lemma 5.3 from [35] we obtain (4.11) for sufficiently small δ's. This concludes the proof.

From Lemmas 4.1 and 4.2 we have the following.

LEMMA 4.3.

(4.17)

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left[\rho\left(v^2+v_t^2\right) + \frac{1}{p\Psi(\rho)}\left(p_\sigma^2 + p_{\sigma t}^2\right)\right]dx \\ &\quad + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\left[\bar n\cdot\int_0^t v_{s^\alpha} d\tau\,\bar n\cdot\int_0^t v^{s^\beta} d\tau + \bar n\cdot v_{s^\alpha}\bar n\cdot v_{s^\beta}\right]ds \\ &\quad + \frac{\mu}{2}\left(\|v\|^2_{1,\Omega_t} + \|v_t\|^2_{1,\Omega_t}\right) + (\nu-\mu)\left(\|\operatorname{div} v\|^2_{0,\Omega_t} + \|\operatorname{div} v_t\|^2_{0,\Omega_t}\right) \\ &\le \varepsilon_3\left(\|p_{\sigma t}\|^2_{0,\Omega_t} + \|p_\sigma\|^2_{0,\Omega_t} + \left\|\int_0^t v d\tau\right\|^2_{1,S_t} + \|v_{xx}\|^2_{0,\Omega_t} + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{0,S^1}\right) \\ &\quad + P_5(\rho_*,\rho^*,\varepsilon_3)X_3Y_3 + P_6(|f|^2_{1,0,\Omega_t} + \|v\|^2_{0,\Omega_t}), \end{aligned}$$

where $\varepsilon_3 \in (0,1)$ *and*

$$X_3 = X_2, Y_3 = X_2 + \left\|\int_0^t v d\tau\right\|^2_{2,S_t}. \tag{4.18}$$

To obtain an inequality for x-derivatives we write problem (4.1) in Lagrangian coordinates, so we can introduce a partition of unity in the fixed domain Ω. Therefore, we have

$$\begin{aligned} \eta u_t^i - \nabla_{u^j} T_u^{ij}(u,q_\sigma) &= \eta g^i, \\ q_{\sigma t} + q\Psi(\eta)\nabla_u\cdot u &= 0, \\ \mathbb{T}_u(u,q_\sigma)\bar n &= \sigma\Delta_{S_t} x(\xi,t)\cdot\bar n\bar n + q_0\bar n, \end{aligned} \tag{4.19}$$

where $\eta(\xi,t) = \rho(x(\xi,t),t)$, $u(\xi,t) = v(x(\xi,t),t)$, $g(\xi,t) = f(x(\xi,t),t)$, $q(\xi,t) = p(x(\xi,t),t)$, $q_\sigma = q - p_0 - q_0$, $\nabla_{u^j} = \xi^k_{x^j}\partial_{\xi^k}$, $\Psi(\eta) = q_\eta\eta/q$, and

(4.20)

$$\mathbb{T}_u(u,q_\sigma) = \left\{T_u^{ij}(u,q_\sigma)\right\} = \left\{-q_\sigma\delta_{ij} + \mu\left(\nabla_{u^i}u^j + \nabla_{u^j}u^i\right) + (\nu-\mu)\delta_{ij}\nabla_u\cdot u\right\}.$$

Next we introduce a partition of unity $(\{\tilde{\Omega}_i\}, \{\zeta_i\}), \Omega = \cup_i \tilde{\Omega}_i$. Let $\tilde{\Omega}$ be one of the $\tilde{\Omega}_i$, and s and $\zeta(\xi) = \zeta_i(\xi)$ be the corresponding function. If $\tilde{\Omega}$ is an interior subdomain, then let $\tilde{\omega}$ be such that $\bar{\tilde{\omega}} \subset \tilde{\Omega}$ and $\zeta(\xi) = 1$ for $\xi \in \tilde{\omega}$. Otherwise, we assume that $\bar{\tilde{\Omega}} \cap S \neq \phi$, $\bar{\tilde{\omega}} \cap S \neq \phi$, $\bar{\tilde{\omega}} \subset \bar{\tilde{\Omega}}$. Let $\beta \in \bar{\tilde{\omega}} \cap S \subset \bar{\tilde{\Omega}} \cap S$, $\tilde{S} \equiv \tilde{\Omega} \cap S$. Introduce local coordinates $\{y\}$ connected with $\{\xi\}$ by

$$y^k = \alpha^{kl}(\xi^l - \beta^l), \alpha^{3k} = n^k(\beta), k = 1, 2, 3, \tag{4.21}$$

where α^{kl} is a constant orthogonal matrix, such that $\tilde{S}$ is determined by $y^3 = F(y^1, y^2), F \in H^{4+1/2}$, and

$$\tilde{\Omega} = \{y : |y^i| < d, i = 1, 2, F(y') < y^3 < F(y') + d, y' = (y^1, y^2)\}.$$

Next we introduce functions u' and q' by

$$u'^i(y) = \alpha^{ij} u^j(\xi)|_{\xi=\xi(y)}, \qquad q'(y) = q(\xi)|_{\xi=\xi(y)}, \tag{4.22}$$

where $\xi = \xi(y)$ is the inverse transformation to (4.21). Furthermore, we introduce new variables by

$$z^i = y^i, \quad i = 1, 2, \quad z^3 = y^3 - \tilde{F}(y), \quad y \in \tilde{\Omega}, \tag{4.23}$$

which will be denoted by $z = \Phi(y)$, where $\tilde{F}$ is an extension of F to $\tilde{\Omega}$ with $\tilde{F} \in H^5(\tilde{\Omega})$. Let $\hat{\Omega} = \Phi(\tilde{\Omega}) = \{z : |z^i| < d, i = 1, 2, 0 < z^3 < d\}$ and $\hat{S} = \Phi(\tilde{S})$. Define

$$\hat{u}(z) = u'(y)|_{y=\Phi^{-1}(z)}, \qquad \hat{q}(z) = q'(y)|_{y=\Phi^{-1}(z)}. \tag{4.24}$$

We introduce $\hat{\nabla}_k = \xi^l_{x^k}(\xi) z^i_{\xi^l} \nabla_{z^i}|_{\xi=\chi^{-1}(z)}$, where $\chi(\xi) = \Phi(\psi(\xi))$ and $y = \psi(\xi)$ are described by (4.21). We also introduce the following notation:

$$\tilde{u}(\xi) = u(\xi)\zeta(\xi), \quad \tilde{q}_\sigma(\xi) = q_\sigma(\xi)\zeta(\xi), \quad \xi \in \tilde{\Omega}, \quad \tilde{\Omega} \cap S = \phi, \tag{4.25}$$

and

$$\tilde{u}(z) = \hat{u}(z)\hat{\zeta}(z), \quad \tilde{q}_\sigma(z) = \hat{q}_\sigma(z)\hat{\zeta}(z), \quad z \in \hat{\Omega} = \Phi(\tilde{\Omega}), \quad \bar{\hat{\Omega}} \cap S \neq \phi, \tag{4.26}$$

where $\hat{\zeta}(z) = \zeta(\xi)|_{\xi=\chi^{-1}(z)}$.

Under the above notation problem (4.19) has the following form in an interior subdomain:

$$\eta \tilde{u}^i_t - \nabla_{u^j} T^{ij}_u(\tilde{u}, \tilde{q}_\sigma) = \eta \tilde{g}^i - \nabla_{u^j} B^{ij}_u(u, \zeta) - T^{ij}_u(u, q_\sigma)\nabla_{u^j}\zeta \equiv \eta \tilde{g}^i + k^i_1, \tag{4.27a}$$

$$\tilde{q}_{\sigma t} + q\Psi(\eta)\nabla_u \cdot \tilde{u} = q\Psi(\eta) u \cdot \nabla_u \zeta \equiv k_2, \tag{4.27b}$$

and in a boundary subdomain:

$$\hat{\eta}\tilde{u}^i_t - \hat{\nabla}_j \hat{T}^{ij}(\tilde{u}, \tilde{q}_\sigma) = \hat{\eta}\tilde{g}^i - \hat{\nabla}_j \hat{B}^{ij}(\hat{u}, \hat{\zeta}) - \hat{T}^{ij}(\hat{u}, \hat{q}_\sigma)\hat{\nabla}_j\hat{\zeta} \equiv \hat{\eta}\tilde{g}^i + k^i_3, \tag{4.28a}$$

$$\tilde{q}_{\sigma t} + \hat{q}\Psi(\hat{\eta})\hat{\nabla} \cdot \tilde{u} = \hat{q}\Psi(\hat{\eta})\hat{u} \cdot \hat{\nabla}\hat{\zeta} \equiv k_4, \tag{4.28b}$$

$$\hat{\mathbb{T}}(\tilde{u}, \tilde{q}_\sigma)\hat{n} - \sigma\hat{\Delta}_{\hat{S}}\hat{\xi} \cdot \hat{n}\hat{n}\hat{\zeta} - \sigma\hat{\Delta}_{\hat{S}} \int_0^t \tilde{u} d\tau \cdot \hat{n}\hat{n} = \frac{2\sigma}{R_0}\hat{\zeta}\hat{n} + k_5 + k_6, \tag{4.28c}$$

where

$$k^i_5 = \hat{B}^{ij}(\hat{u}, \hat{\zeta})\hat{n}_j, \qquad k_6 = -\sigma\left(2\hat{\nabla}\int_0^t \hat{u} d\tau\, \hat{\nabla}\hat{\zeta} + \int_0^t \hat{u} d\tau\, \hat{\nabla}^2\hat{\zeta}\right) \cdot \hat{n}\hat{n}, \tag{4.29}$$

$$B^{ij}_u(u, \zeta) = \mu(u^i \nabla_{u^j}\zeta + u^j \nabla_{u^i}\zeta) + (\nu - \mu)\delta_{ij} u \cdot \nabla_u \zeta,$$

and $\hat{\mathbb{T}}$, $\hat{B}$ indicate that the operator ∇_u is replaced by $\hat{\nabla}$.

In the next considerations we denote z^1, z^2 by τ and z^3 by n.

LEMMA 4.4. *Let the assumptions of Lemmas* 4.1 *and* 4.2 *be satisfied. Then we have*

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho|v|^2_{1,0}+\frac{1}{p\Psi(\rho)}|p_\sigma|^2_{1,0}\right)dx\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\left[\bar{n}\cdot\int_0^t v_{s^\alpha}d\tau\,\bar{n}\cdot\int_0^t v_{s^\beta}d\tau+\bar{n}\cdot v_{s^\alpha}\bar{n}\cdot v_{s^\beta}\right]ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t v_{ss^\alpha}d\tau\,\bar{n}\cdot\int_0^t v_{ss^\beta}d\tau\,ds+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar{n}\cdot\int_0^t v_{s^1s^2}d\tau\right|^2ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^{2}\left(\frac{1}{2}\bar{n}\cdot\int_0^t v_{s^is^i}d\tau+2\left(H(0)+\frac{2}{R_0}\right)\right)^2ds\\
&\quad+\frac{\mu}{2}|v|^2_{2,1,\Omega_t}+|p_\sigma|^2_{1,0,\Omega_t}\qquad(4.30)\\
&\le\varepsilon_4\left(\|v_t\|^2_{2,\Omega_t}+\|p_{\sigma t}\|^2_{1,\Omega_t}+\left\|\int_0^t v d\tau\right\|^2_{0,\Omega_t}\right.\\
&\qquad\left.+\|H(\cdot,0)+\frac{2}{R_0}\|^2_{0,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{2,S^1}\right)\\
&\quad+P_7\left(\|f\|^2_{0,\Omega_t}+\|v\|^2_{0,\Omega_t}+\|p_\sigma\|^2_{0,\Omega_t}\right)\\
&\quad+P_8\left(X_4Y_4+\|H(\cdot,0)+\frac{2}{R_0}\|^4_{0,S^1}\right),
\end{aligned}
$$

where the summation over the repeated indices $(\alpha,\beta=1,2)$ *and coordinates* $(x, s=(s^1,s^2))$ *is assumed,* P_7 *is a positive increasing function,* $P_7=P_7(a,b)$, *and*

$$
\begin{aligned}
X_4&=X_4(t)=|v|^2_{2,1,\Omega_t}+|p_\sigma|^2_{2,1,\Omega_t},\\
Y_4&=Y_4(t)=X_4(t)+\|v\|^2_{3,\Omega_t}+\int_0^t\|v\|^2_{3,\Omega_\tau}d\tau.
\end{aligned}
\qquad(4.31)
$$

Proof. At first we consider interior subdomains. By differentiating (4.27) with respect to ξ, multiplying the result by $\tilde{u}_\xi A$ (A is the Jacobian of the transformation $x=x(\xi)$), and integrating over $\tilde{\Omega}$, we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}}\eta\tilde{u}^2_\xi Ad\xi+\frac{\mu}{2}\int_{\tilde{\Omega}}(\nabla_{u^i}\tilde{u}^j_\xi+\nabla_{u^j}\tilde{u}^i_\xi)^2Ad\xi\\
&\quad+(\nu-\mu)\|\nabla_u\cdot\tilde{u}_\xi\|^2_{0,\tilde{\Omega}}\\
&\quad-\int_{\tilde{\Omega}}\tilde{q}_{\sigma\xi}\cdot\nabla_u\tilde{u}_\xi Ad\xi\le\delta_1(\|u_{\xi\xi}\|^2_{0,\tilde{\Omega}}+\|q_{\sigma\xi}\|^2_{0,\tilde{\Omega}})\qquad(4.32)\\
&\quad+a_1(\|u\|^2_{1,\tilde{\Omega}}+\|q_\sigma\|^2_{0,\tilde{\Omega}}+\|\tilde{g}\|^2_{0,\tilde{\Omega}})\\
&\quad+a_2\left(\|u\|^2_{2,\tilde{\Omega}}\left\|\int_0^t u d\tau\right\|^2_{3,\tilde{\Omega}}+\|q_\sigma\|^2_{1,\tilde{\Omega}}|u|^2_{2,1,\tilde{\Omega}}\right),
\end{aligned}
$$

where $\|h\|_{0,\tilde{\Omega}}=(\int_{\tilde{\Omega}}|h|^2Ad\xi)^{1/2}$.

By the continuity equation (4.27b), we have

$$-\int_{\tilde{\Omega}} \tilde{q}_{\sigma\xi} \nabla_u \cdot \tilde{u}_\xi A d\xi = \frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \frac{1}{q\Psi(\eta)} \tilde{q}^2_{\sigma\xi} A d\xi + N_1, \tag{4.33}$$

where

$$|N_1| \le \delta_2 \|\tilde{q}_{\sigma\xi}\|^2_{0,\tilde{\Omega}} + a_4 \|u\|^2_{1,\tilde{\Omega}}$$

$$+a_5 \left[|\tilde{q}_\sigma|^2_{2,1,\tilde{\Omega}} (\|u\|^2_{2,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}}) + \|u\|^2_{2,\tilde{\Omega}} \left\| \int_0^t u d\tau \right\|^2_{3,\tilde{\Omega}} \right].$$

Consider the Stokes problem in $\tilde{\Omega}$:

$$\begin{gathered} \mu \nabla^2_u \tilde{u} - \nu \nabla_u \nabla_u \cdot \tilde{u} + \nabla_u \tilde{q}_\sigma = \eta \tilde{g} - \eta \tilde{u}_t + k_1, \\ \nabla_u \cdot \tilde{u} = \nabla_u \cdot \tilde{u}, \\ \tilde{u}|_{\partial\tilde{\Omega}} = 0. \end{gathered} \tag{4.34}$$

Hence, we have

$$\begin{aligned} \|\tilde{u}\|^2_{2,\tilde{\Omega}} + \|\tilde{q}_\sigma\|^2_{1,\tilde{\Omega}} &\le a_6 (\|\tilde{g}\|^2_{0,\tilde{\Omega}} + |u|^2_{1,0,\tilde{\Omega}} + \|q_\sigma\|^2_{0,\tilde{\Omega}}) \\ &+ a_7 (\|u\|^2_{2,\tilde{\Omega}} + \|q_\sigma\|^2_{1,\tilde{\Omega}}) \left\| \int_0^t u d\tau \right\|^2_{3,\tilde{\Omega}} + c \|\nabla_u \cdot \tilde{u}\|^2_{1,\tilde{\Omega}}. \end{aligned} \tag{4.35}$$

Using Lemma 5.1 from [35] in the case $G = \tilde{\Omega}$, $v = \tilde{u}_\xi$, from (4.32), (4.33), and (4.35) for sufficiently small δ_1 and δ_2, we obtain

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \left(\eta \tilde{u}^2_\xi + \frac{1}{q\Psi(\eta)} q^2_{\sigma\xi} \right) A d\xi \\ &\quad + \frac{\mu}{2} \|\tilde{u}_\xi\|^2_{1,\tilde{\Omega}} + (\nu - \mu) \|\nabla_u \cdot \tilde{u}_\xi\|^2_{0,\tilde{\Omega}} + \|\tilde{q}_{\sigma\xi}\|^2_{0,\tilde{\Omega}} \\ &\quad \le \delta_1 (\|u_{\xi\xi}\|^2_{0,\tilde{\Omega}} + \|q_{\sigma\xi}\|^2_{0,\tilde{\Omega}}) \\ &\quad + a_8 (\|\tilde{g}\|^2_{0,\tilde{\Omega}} + |u|^2_{1,0,\tilde{\Omega}} + \|q_\sigma\|^2_{0,\tilde{\Omega}}) + a_9 X_4(\tilde{\Omega}) Y_4(\tilde{\Omega}), \end{aligned} \tag{4.36}$$

where $X_4(\tilde{\Omega}) = |u|^2_{2,1,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}}$, $Y_4(\tilde{\Omega}) = X_2(\tilde{\Omega}) + \|u\|^2_{3,\tilde{\Omega}} + \int_0^t \|u\|^2_{3,\tilde{\Omega}} d\tau$.

Now we consider subdomains near the boundary. Differentiating (4.28a) with respect to τ, multiplying the result by $\tilde{u}_\tau J$, and integrating over $\hat{\Omega}$ yields (J is the Jacobian of the transformation $x = x(z)$)

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}} \hat{\eta} \tilde{u}^2_\tau J dz + \frac{\mu}{2}\int_{\hat{\Omega}} (\hat{\nabla}_i \tilde{u}^j_\tau + \hat{\nabla}_j \tilde{u}^i_\tau)^2 J dz + (\nu - \mu) \|\hat{\nabla} \cdot \tilde{u}_\tau\|^2_{0,\hat{\Omega}} \\ &\quad - \int_{\hat{\Omega}} \tilde{q}_{\sigma\tau} \hat{\nabla} \cdot \tilde{u}_\tau J dz - \int_{\hat{S}} (\hat{n} \hat{\mathbb{T}}(\tilde{u}, \tilde{q}_\sigma))_{,\tau} \tilde{u}_\tau J dz' \\ &\quad \le \delta_3 (\|\hat{u}_{zz}\|^2_{0,\hat{\Omega}} + \|\hat{q}_{\sigma z}\|^2_{0,\hat{\Omega}}) \end{aligned} \tag{4.37}$$

$$+ a_{10}(\|\tilde{g}\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}})$$
$$+ a_{11}\|\hat{u}\|^2_{2,\hat{\Omega}}\left(\|\hat{u}\|^2_{2,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + \left\|\int_0^t u d\tau\right\|^2_{3,\hat{\Omega}}\right),$$

where we have used the inequalities

$$\int_{\hat{\Omega}}[(\hat{\nabla}_j\hat{T}^{ij}(\tilde{u},\tilde{q}_\sigma))_{,\tau} - \hat{\nabla}_j\hat{T}^{ij}(\tilde{u}_\tau,\tilde{q}_{\sigma\tau})]\tilde{u}_\tau J dz' \le \delta_4(\|\tilde{u}_{zz}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}})$$
$$+ a_{12}\|\tilde{u}\|^2_{2,\hat{\Omega}}\left\|\int_0^t u d\tau\right\|^2_{3,\hat{\Omega}} + c(\|\hat{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}}),$$

and

$$\int_{\hat{S}}[(\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,\tau} - \hat{n}\hat{\mathbb{T}}(\tilde{u}_\tau,\tilde{q}_{\sigma\tau})]\tilde{u}_\tau J dz' \le \delta_5(\|\tilde{u}_{zz}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}})$$
$$+ a_{13}\left(\|\tilde{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{2,\hat{\Omega}}\left\|\int_0^t \hat{u} d\tau\right\|^2_{3,\hat{\Omega}}\right),$$

and the fact that ∇F can be expressed in terms of $\int_0^t u_\xi d\tau$. Consider the boundary term in (4.37). Using the boundary condition (4.28c), we obtain

$$-\int_{\hat{S}}(\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma)),_\tau \tilde{u}_\tau J dz' = -\sigma\int_{\hat{S}}\left(\hat{\Delta}_{\hat{s}_t}\hat{\xi}\cdot\hat{n}\hat{n}\hat{\zeta} + \frac{2}{R_0}\hat{n}\hat{\zeta}\right),_\tau \tilde{u}_\tau J dz'$$
$$-\sigma\int_{\hat{S}}\left(\hat{\Delta}_{\hat{S}_t}\int_0^t \tilde{u} d\tau\cdot\hat{n}\hat{n}\right),_\tau \cdot\,\tilde{u}_\tau J dz' + \int_{\hat{S}}(k_5+k_6),_\tau \tilde{u}_\tau J dz'. \tag{4.38}$$

Similarly as in (4.10) the first term on the right-hand side is equal to

$$-\sigma\int_U\left(H(\cdot,0) + \frac{2}{R_0}\right)\bar{n}\zeta\cdot\tilde{u}_{ss}\sqrt{g}ds^1ds^2 + N_2,$$

where

$$|N_2| \le \delta_6\left(\left\|\int_0^t \tilde{u} d\tau\right\|^2_{2,\hat{S}} + \|\hat{u}_{zz}\|^2_{2,\hat{\Omega}} + \left\|\hat{H}(\cdot,0) + \frac{2}{R_0}\right\|^2_{0,\hat{S}} + \|R(\cdot,t) - R(\cdot,0)\|^2_{2,S^1}\right)$$
$$+a_{14}(\|\xi\|_4)\left(\|\tilde{u}\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{2,\hat{\Omega}}\left\|\int_0^t \hat{u} d\tau\right\|^2_{3,\hat{\Omega}}\right).$$

The second term on the right-hand side of (4.38) takes the form

$$\frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{ss^\alpha} d\tau\bar{n}\cdot\int_0^t \tilde{u}_{ss^\beta} d\tau\, ds + N_3,$$

where

$$|N_3| \le \delta_7\left(\left\|\int_0^t \tilde{u} d\tau\right\|^2_{2,\hat{S}} + \|\tilde{u}_{zz}\|^2_{0,\hat{\Omega}}\right) + a_{15}\left(\|\tilde{u}\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{2,\hat{\Omega}}\left\|\int_0^t \tilde{u} d\tau\right\|^2_{3,\hat{\Omega}}\right).$$

Finally, the last term in (4.38) is bounded by

$$\delta_8\left(\left\|\int_0^t \tilde{u}d\tau\right\|_{2,\hat{S}}^2 + \|\hat{u}_{zz}\|_{0,\hat{\Omega}}^2\right) + a_{16}\|\hat{u}\|_{0,\hat{\Omega}}^2.$$

By summarizing, we have proved

(4.39)

$$\begin{aligned}
&\int_{\hat{S}}\left(\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma)\right),\ {}_\tau\tilde{u}_\tau J dz' \\
&\le -\frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{ss^\alpha}d\tau\bar{n}\cdot\int_0^t \tilde{u}_{ss^\beta}d\tau\,ds \\
&\quad -\sigma\int_{S_t}\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\tilde{u}_{ss}\cdot\bar{n}ds \\
&\quad +\delta_9\left(\left\|\int_0^t\tilde{u}d\tau\right\|_{2,\hat{S}}^2 + \|\tilde{u}_{zz}\|_{0,\hat{\Omega}}^2 + \left\|\left(\hat{H}(0)+\frac{2}{R_0}\right)\hat{\zeta}\right\|_{0,\hat{S}}^2 + \|R(\cdot,t)-R(\cdot,0)\|_{2,S^1}^2\right) \\
&\quad +a_{17}\left(\|\hat{u}\|_{0,\hat{\Omega}}^2 + \|\hat{u}\|_{2,\hat{\Omega}}^2\left\|\int_0^t\tilde{u}d\tau\right\|_{3,\hat{\Omega}}^2\right).
\end{aligned}$$

From the continuity equation (4.28b) we get

$$-\int_{\hat{\Omega}}\tilde{q}_{\sigma\tau}\nabla_u\cdot\tilde{u}_\tau J dz = \frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}_{\sigma\tau}^2 J dz + N_4, \tag{4.40}$$

where

$$\begin{aligned}
|N_4| &\le \delta_{10}\|\tilde{q}_{\sigma\tau}\|_{0,\hat{\Omega}}^2 + c\|\hat{u}\|_{1,\hat{\Omega}}^2 \\
&\quad + a_{18}\left[|\hat{q}_\sigma|_{2,1,\hat{\Omega}}^2\left(\|\hat{u}\|_{2,\hat{\Omega}}^2 + |\hat{q}_\sigma|_{2,1,\hat{\Omega}}^2\right) + \|\hat{u}\|_{2,\hat{\Omega}}^2\left\|\int_0^t u dt'\right\|_{2,\hat{\Omega}}^2\right],
\end{aligned}$$

and $P = P(|\int_0^t \hat{u}_z dt'|_{0,\hat{\Omega}}, \|h\|_{0,\hat{\Omega}} = (\int_{\hat{\Omega}}|h|^2 J dz)^{1/2})$. From (4.37)–(4.40) and Lemma 5.1 from [35] in the case $G = \hat{\Omega}$, $v = \tilde{u}_\tau$, we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}_\tau^2 + \frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}_{\sigma\tau}^2\right)Jdz \\
&\qquad +\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}} g^{\alpha\beta}\bar{n}\cdot\int_0^t\tilde{u}_{ss^\alpha}d\tau\bar{n}\cdot\int_0^t\tilde{u}_{ss^\beta}d\tau\,ds' \\
&\qquad +\sigma\int_{\hat{S}}\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\tilde{u}_{ss}\cdot\bar{n}ds' \\
&\qquad +\frac{\mu}{2}\|\tilde{u}_\tau\|_{1,\hat{\Omega}}^2 + (\nu-\mu)\|\hat{\nabla}\cdot\tilde{u}_\tau\|_{0,\hat{\Omega}}^2 \qquad (4.41)\\
&\quad \le \delta_{11}\left(\|\hat{u}_{zz}\|_{0,\hat{\Omega}}^2 + \|\hat{q}_{\sigma z}\|_{0,\hat{\Omega}}^2 + \left\|\int_0^t\tilde{u}d\tau\right\|_{2,\hat{S}}^2 + \|R(\cdot,t)-R(\cdot,0)\|_{2,S^1}^2\right) \\
&\qquad +a_{19}\left(\|\hat{u}\|_{1,\hat{\Omega}}^2 + \|\hat{q}_\sigma\|_{0,\hat{\Omega}}^2 + \|\tilde{q}\|_{0,\hat{\Omega}}^2 + \|H(\cdot,0)+\frac{2}{R_0}\|_{0,\hat{S}}^2\right) \\
&\qquad +a_{20}X_4(\hat{\Omega})Y_4(\hat{\Omega}),
\end{aligned}$$

where $X_4(\hat{\Omega}) = |\hat{u}|^2_{2,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}$, $Y_4(\hat{\Omega}) = X_4(\hat{\Omega}) + \|\hat{u}\|^2_{3,\hat{\Omega}} + \int_0^t \|\hat{u}\|^2_{3,\hat{\Omega}} dt'$.

Applying the operator $(\mu+\nu)\hat{\nabla}$ to (4.28b), dividing the result by $\hat{q}\Psi(\hat{\eta})$, and adding to (4.28a) gives

(4.42)
$$\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\hat{\nabla}_i\tilde{q}_{\sigma t} + \hat{\nabla}_i\tilde{q}_\sigma = \mu(\hat{\nabla}^2\tilde{u}^i - \hat{\nabla}_i\hat{\nabla}\cdot\tilde{u}) - \hat{\eta}\tilde{u}^i_t + \hat{\eta}\tilde{g}^i - \frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\hat{\nabla}(\hat{q}\Psi(\hat{\eta}))\hat{\nabla}\cdot\tilde{u} + \frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\hat{\nabla}(\hat{q}\Psi(\hat{\eta})\hat{u}\cdot\hat{\nabla}\hat{\zeta}) + k_3.$$

Multiplying the normal component of (4.42) by $\tilde{q}_{\sigma n}J$ and integrating over $\hat{\Omega}$ implies

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n}Jdz + \frac{1}{2}\|\tilde{q}_{\sigma n}\|^2_{0,\hat{\Omega}} \\
&\quad\le c\|\tilde{u}_{z\tau}\|^2_{0,\hat{\Omega}} + a_{21}(\|\tilde{u}_t\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}} + \|\tilde{g}\|^2_{0,\hat{\Omega}}) \\
&\qquad + a_{22}\left(\|\tilde{u}\|^2_{2,\hat{\Omega}}\|\int_0^t \hat{u}dt'\|^2_{3,\hat{\Omega}} + (\delta_7' + cd)(\|\tilde{u}_{zz}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}})\right. \\
&\qquad\quad \left. + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}\left(\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^2_{2,\hat{\Omega}} + \|\int_0^t \hat{u}dt'\|^2_{2,\hat{\Omega}}\right)\right).
\end{aligned} \tag{4.43}$$

We write (4.28a) in the form

$$\hat{\eta}\tilde{u}^i_t - \mu\Delta\tilde{u}^i - \nu\nabla_i\nabla\cdot\tilde{u} = \hat{\nabla}_i\tilde{q}_\sigma + \eta\tilde{g}^i + k^i_3 - k^i_7, \tag{4.44}$$

where $k_7 = (\mu\Delta\tilde{u}^i + \nu\nabla_i\nabla\cdot\tilde{u}) - (\mu\hat{\nabla}^2\tilde{u}^i + \nu\hat{\nabla}_i\hat{\nabla}\cdot\tilde{u})$.

Multiplying the third component of (4.44) by $\tilde{u}^3_{nn}J$ and integrating over $\hat{\Omega}$ yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_n|^2Jdz + \frac{\mu+\nu}{2}\|\tilde{u}^3_{nn}\|^2_{0,\hat{\Omega}} \\
&\quad\le c(\|\tilde{u}_{z\tau}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma n}\|^2_{0,\hat{\Omega}}) \\
&\qquad + a_{23}(\|\hat{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}} + \|\tilde{g}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_t\|^2_{0,\hat{\Omega}}) \\
&\qquad + \delta_{12}(\|\tilde{u}^3_{nt}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_{zz}\|^2_{0,\hat{\Omega}}) \\
&\qquad + a_{24}\left(|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}\|\tilde{u}\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^4_{2,\hat{\Omega}} + \|\tilde{u}\|^2_{2,\hat{\Omega}}\left\|\int_0^t \hat{u}dt'\right\|^2_{3,\hat{\Omega}}\right).
\end{aligned} \tag{4.45}$$

To estimate $\tilde{u}^i_{nn}$, $i = 1, 2$, and $\tilde{q}_{\sigma\tau}$ we write (4.44) in the form

$$\begin{aligned}
&-\mu\Delta\tilde{u}^i + \nabla_{z^i}\tilde{q}_\sigma \\
&\quad = \hat{\eta}\tilde{g}^i - \hat{\eta}\tilde{u}^i_t + k^i_3 - k^i_7 + \nabla_{z^i}\tilde{q}_\sigma - \hat{\nabla}_i\tilde{q}_\sigma + \nu\nabla_{z^i}\mathrm{div}\tilde{u} \\
&\quad = \tilde{f}^i + \nu\nabla_{z^i}\mathrm{div}\tilde{u},
\end{aligned} \tag{4.46}$$

and the boundary condition (4.28c) as

$$\frac{\partial\tilde{u}^i}{\partial z^3} = -\frac{\partial\tilde{u}^3}{\partial z^i} + \left(\frac{\partial\tilde{u}^i}{\partial z^3} + \frac{\partial\tilde{u}^3}{\partial z^i} - \frac{1}{\mu}\hat{\tau}_i\hat{\mathbb{T}}\hat{n}\right) + \frac{1}{\mu}k_5\cdot\hat{\tau}_i \equiv \tilde{h}^i, \qquad i = 1, 2, z^3 = 0, \tag{4.47}$$

where we have also used the fact that $\hat{\tau}_i \cdot \hat{n} = 0$, $i = 1, 2$. Considering the problem (4.46) and (4.47) in $\hat{\Omega}$ we have to add the boundary conditions

$$\tilde{u}^i|_{|z'|=d} = 0, \quad \tilde{u}^i|_{z^3=d} = 0, \quad i = 1, 2, \tilde{q}_\sigma|_{|z'|=d} = 0, \quad \tilde{q}_\sigma|_{z^3=d} = 0. \tag{4.48}$$

Multiplying (4.46) by $\tilde{u}^i$, summing over $i = 1, 2$, integrating over $\hat{\Omega}$, and using boundary conditions (4.47) and (4.48) yields

$$\|\nabla \tilde{u}'\|^2_{0,\hat{\Omega}} \le \delta_9 \|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}} + c\left(\|\tilde{f}'\|^2_{0,\hat{\Omega}} + \|\tilde{h}'\|^2_{0,\hat{S}} + \|\operatorname{div} \tilde{u}\|^2_{0,\hat{\Omega}}\right), \tag{4.49}$$

where the prime denotes that only two components ($i = 1, 2$) are taken into account.

We now look for a function $w \in H^1(\hat{\Omega})$ such that

$$\operatorname{div} w = \tilde{q}_\sigma, w^3|_{z^3=0} = \chi(z') \int_{\hat{\Omega}} \tilde{q}_\sigma dz, \quad w|_{\partial\hat{\Omega}\setminus\hat{S}} = 0, \quad w^i|_{z^3=0} = 0, \quad i = 1, 2, \tag{4.50}$$

where $\chi(z')$ is a smooth function such that $\int_{\hat{S}} \chi(z')dz' = 1$, $\chi(z') \ge 0$, $\chi|_{|z'|=d} = 0$. Moreover, $1 \le 4d^2|\chi|_{\infty,\hat{S}}$, so $|\chi|_{\infty,\hat{S}} \ge 1/(4d^2)$. Finally, assuming that χ vanishes only in a neighborhood of the boundary of $\hat{S}$, we require that $\min \chi(z')_{|z'|\le d/2} > 0$. Hence

$$1 = \int_{\hat{S}} \chi(z')dz' \ge \int_{|z'|\le d/2} \chi(z')dz' \ge d^2 \min_{|z'|\le d/2} \chi(z'), \quad \text{so } \min_{|z'|\le d/2} \chi(z') \le 1/d^2.$$

Therefore, we can assume that $\chi(z') \le c/d^2$.

We look for solutions of (4.50) in the form $w = \nabla\varphi + \alpha$, where φ is a solution to the Neumann problem

$$\begin{gathered} \Delta\varphi = \tilde{q}_\sigma, \quad \partial_{z^3}\varphi|_{z^3=0} = \chi(z') \int_{\hat{\Omega}} \tilde{q}_\sigma dz \equiv \varphi_0, \quad \partial_{z^3}\varphi|_{z^3=d} = 0, \\ \partial_{z^i}\varphi|_{|z^i|=d} = 0, \qquad i = 1, 2, \int_{\hat{\Omega}} \varphi dz = 0, \end{gathered} \tag{4.51}$$

and

$$\operatorname{div} \alpha = 0, \quad \alpha|_{\partial\hat{\Omega}\setminus\hat{S}} = -\nabla\varphi|_{\partial\hat{\Omega}\setminus\hat{S}}, \quad \alpha \cdot \bar{n}|_{\hat{S}} = 0, \quad \alpha \cdot \bar{\tau}_i|_{\hat{S}} = -\bar{\tau}_i \cdot \nabla\varphi|_{\hat{S}}, \quad i = 1, 2, \tag{4.52}$$

where $\bar{n}, \bar{\tau}_i$, $i = 1, 2$, are normal and tangent vectors to $\hat{S}$.

Since the compatibility condition for (4.51) is satisfied, there exists a unique solution to (4.51) such that $\varphi \in H^2(\hat{\Omega})$ and

$$\|\varphi\|_{2,\hat{\Omega}} \le c(\|\tilde{q}_\sigma\|_{0,\hat{\Omega}} + \|\varphi_0\|_{0,\hat{S}} + \|\varphi_0\|_{1/2,\hat{S}}) \le c(1 + d^{1/2})\|\tilde{q}_\sigma\|_{0,\hat{\Omega}} \tag{4.53}$$

because

$$\begin{aligned} \|\varphi_0\|_{0,\hat{S}} &\le \left|\int_{\hat{\Omega}} \hat{q}_\sigma dz\right| \left(\int_{\hat{S}} |\chi(z')|^2 dz'\right)^{1/2} \le cd^{1/2}\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}, \\ \|\varphi_0\|_{1/2,\hat{S}} &\le \left|\int_{\hat{\Omega}} \hat{q}_\sigma dz\right| \left(\int_{\hat{S}}\int_{\hat{S}} \frac{|\chi(x') - \chi(y')|^2}{|x' - y'|^3} dx'dy'\right)^{1/2} \\ &\le \frac{c}{d^3} \left|\int_{\hat{\Omega}} \tilde{q}_\sigma dz\right| \left(\int_{\hat{S}}\int_{\hat{S}} |x' - y'|^{-1} dx'dy'\right)^{1/2} \\ &\le cd^{-3/2} \left|\int_{\hat{\Omega}} \tilde{q}_\sigma dz\right| \le c\|\tilde{q}_\sigma\|_{0,\tilde{\Omega}}, \end{aligned}$$

where we have used the fact that $|\nabla\chi| \le c/d^3$.

Similarly, the compatibility condition for (4.52) is satisfied because $\bar{n}\cdot\nabla\varphi|_{\partial\hat{\Omega}\setminus\hat{S}} = 0$. Hence, there exists a solution to (4.52) such that $\alpha \in H^1(\hat{\Omega})$ and

$$\|\alpha\|_{1,\hat{\Omega}} \le c\|\nabla\varphi\|_{1/2,\partial\hat{\Omega}} \le c\|\varphi\|_{2,\hat{\Omega}} \le c\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}. \tag{4.54}$$

By summarizing, there exists a solution of problem (4.50) such that $w \in H^1(\hat{\Omega})$ and

$$\|w\|_{1,\hat{\Omega}} \le c\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}. \tag{4.55}$$

Now we estimate $\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}$. Multiplying (4.46) by w and integrating over $\hat{\Omega}$ yields

$$-\mu\int_{\hat{\Omega}} \Delta\tilde{u}\cdot w dz + \int_{\hat{\Omega}} \nabla\tilde{q}_\sigma \cdot w dz = \int_{\hat{\Omega}} \tilde{f}\cdot w dz + \nu\int_{\hat{\Omega}} \nabla\mathrm{div}\tilde{u}\cdot w dz. \tag{4.56}$$

The boundary term which follows from integration by parts in the first term of (4.56) is estimated in the following way:

$$\left|\mu\int_{\hat{S}} \bar{n}\cdot\nabla\tilde{u}\cdot w dz'\right| \le c\left|\int_{\hat{S}} \tilde{u}^3_{z^3} w^3 dz'\right| \le c\|\tilde{u}^3_{z^3}\|_{-1/2,\hat{S}}\|w^3\|_{1/2,\hat{S}}$$

$$\le c\|\tilde{u}^3_{z^3}\|_{0,\hat{\Omega}}\|w\|_{1,\hat{\Omega}}.$$

The second term on the left-hand side of (4.56) is equal to

$$\int_{\hat{S}} \tilde{q_\sigma}\cdot w^3 dz' - \int_{\hat{\Omega}} \tilde{q}_\sigma \mathrm{div}\, w dz,$$

where

$$\left|\int_{\hat{S}} \tilde{q}_\sigma w^3 dz'\right| = \left|\int_{\hat{\Omega}} \tilde{q}_\sigma dz \int_{\hat{S}} \tilde{q}_\sigma\chi(z')dz'\right| \le c/d^2 \int_{\hat{\Omega}} |\tilde{q}_\sigma| dz \int_{\hat{S}} |\tilde{q}_\sigma| dz'$$

$$\le cd^{-1/2}\|\tilde{q}_\sigma\|_{0,\hat{\Omega}} \int_{\hat{S}} |\tilde{q}_\sigma(z')| dz'$$

$$\le cd^{1/2}\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}\|\tilde{q}_\sigma\|_{0,\hat{S}} \le \delta_{13}^2\|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}} + c(\delta_{13})d\|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}},$$

and

$$\int_{\hat{\Omega}} \tilde{q}_\sigma \mathrm{div}\, w\, dz = \|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}}.$$

Finally, the last term in (4.56) can be expressed in the form

$$\int_{\hat{\Omega}} \nabla\mathrm{div}\, \tilde{u}\cdot w dz = \int_{\hat{S}} \mathrm{div}\, \tilde{u}\, w^3 dz' - \int_{\hat{\Omega}} \mathrm{div}\, \tilde{u}\, \mathrm{div}\, w\, dz,$$

where

$$\left|\int_{\hat{S}} \mathrm{div}\, \tilde{u}\, w^3\, dz'\right| = \left|\int_{\hat{\Omega}} \tilde{q}_\sigma dz \int_{\hat{S}} \mathrm{div}\, \tilde{u}\, \chi(z')dz'\right| \le cd^{-1/2}\|\tilde{q}_\sigma\|_{0,\hat{\Omega}} \int_{\hat{S}} |\mathrm{div}\, \tilde{u}| dz'$$

$$\le cd^{1/2}\|\tilde{q}_\sigma\|_{0,\hat{\Omega}}\|\mathrm{div}\tilde{u}\|_{0,\hat{S}} \le d\|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}} + c\|\mathrm{div}\tilde{u}\|^2_{1,\hat{\Omega}}.$$

By summarizing, we obtain the estimate

$$\|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}} \le \delta_{13}\|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}} + c\left(\|\tilde{f}\|^2_{0,\hat{\Omega}} + \|\tilde{h}'\|^2_{0,\hat{\Omega}} + \|\tilde{u}^3_{z^3}\|^2_{0,\hat{\Omega}} + \|\mathrm{div}\ \tilde{u}\|^2_{1,\hat{\Omega}}\right) \tag{4.57}$$

for sufficiently small d.

Now instead of problems (4.46) and (4.47) we consider the problem

$$\begin{aligned} -\mu\Delta\tilde{u}^i_{z'} + \nabla_{z^i}\tilde{q}_{\sigma z'} &= \tilde{f}^i_{z'} + \nabla_{z^i}\mathrm{div}\ \tilde{u}_{z'}, \qquad i = 1,2,3, \\ \partial_{z^3}\tilde{u}^i_{z'} &= \tilde{h}^i_{z'}, \qquad i = 1,2. \end{aligned} \tag{4.58}$$

Multiplying (4.58) by $\tilde{u}^i_{z'}$, summing over $i = 1,2$, and integrating over $\hat{\Omega}$ yields

$$\|\tilde{u}'_{zz'}\|^2_{0,\hat{\Omega}} \le \delta_{13}\|\tilde{q}_{\sigma z'}\|^2_{0,\hat{\Omega}} + c(\|\tilde{f}'\|^2_{0,\hat{\Omega}} + \|\tilde{h}'_{z'}\|^2_{0,\hat{\Omega}} + \|\mathrm{div}\tilde{u}\|^2_{1,\hat{\Omega}}). \tag{4.59}$$

Finally, let us introduce a function $w_1 \in W^1_2(\hat{\Omega})$ such that

$$\mathrm{div}w_1 = \tilde{q}_{\sigma z'}, \qquad w_1|_{\partial\hat{\Omega}} = 0. \tag{4.60}$$

By $\int_{\hat{\Omega}} \tilde{q}_{\sigma z'}dz = 0$ there exists a solution of (4.60) such that $w_1 \in H^1(\hat{\Omega})$ and

$$\|w_1\|_{1,\hat{\Omega}} \le c\|\tilde{q}_{\sigma z'}\|_{0,\hat{\Omega}}. \tag{4.61}$$

Multiplying the first equation of (4.58) by w_1 and integrating over $\tilde{\Omega}$ gives

$$\|\tilde{q}_{\sigma z'}\|^2_{0,\hat{\Omega}} \le c(\|\tilde{f}\|^2_{0,\hat{\Omega}} + \|\mathrm{div}\ \tilde{u}\|^2_{1,\hat{\Omega}} + \|\tilde{u}_{zz'}\|^2_{0,\hat{\Omega}}). \tag{4.62}$$

From (4.49), (4.57), (4.59), and (4.62) we have

$$\begin{aligned} &\|\tilde{u}'_z\|^2_{0,\hat{\Omega}} + \|\tilde{u}'_{zz'}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z'}\|^2_{0,\hat{\Omega}} \\ &\quad \le c(\|\tilde{f}'\|^2_{0,\hat{\Omega}} + \|\tilde{h}'\|^2_{1,\hat{\Omega}} + \|\mathrm{div}\ \tilde{u}\|^2_{1,\hat{\Omega}} + \|\tilde{u}\|^2_{1,\hat{\Omega}}) \\ &\qquad +\delta_{13}\|\tilde{q}_{\sigma z^3}\|^2_{0,\hat{\Omega}}. \end{aligned} \tag{4.63}$$

From the form of $\tilde{f}'$ and $\tilde{h}'$ we have

$$\begin{aligned} \|\tilde{f}\|^2_{0,\hat{\Omega}} &\le c(\|\tilde{g}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_t\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{1,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}}) \\ &\quad +c\left(\left\|\int_0^t \hat{u}dt'\right\|^2_{3,\hat{\Omega}} + d\right)(\|\tilde{q}_\sigma\|^2_{2,\hat{\Omega}} + \|\tilde{u}\|^2_{2,\hat{\Omega}}), \\ \|\tilde{h}\|^2_{1,\hat{\Omega}} &\le c\left(\|\tilde{u}^3_{z\tau}\|^2_{0,\hat{\Omega}} + \left(\left\|\int_0^t \hat{u}dt'\right\|^2_{3,\hat{\Omega}} + d\right)(\|\tilde{u}\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^2_{1,\hat{\Omega}})\right). \end{aligned} \tag{4.64}$$

Finally, from (4.46) we obtain

$$\|\tilde{u}'_{nn}\|^2_{0,\hat{\Omega}} \le c(\|\tilde{q}_{\sigma\tau}\|^2_{0,\hat{\Omega}} + \|\tilde{f}\|^2_{0,\hat{\Omega}} + \|\mathrm{div}\ \tilde{u}\|^2_{1,\hat{\Omega}} + \|\tilde{u'}_{zz'}\|^2_{0,\hat{\Omega}}). \tag{4.65}$$

Therefore, equations (4.63)–(4.65) imply

$$
\begin{aligned}
&\|\tilde{u}'_{nn}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma\tau}\|^2_{0,\hat{\Omega}} \\
&\quad \le c(\|\tilde{u}^3_{z\tau}\|^2_{0,\hat{\Omega}} + \|\operatorname{div}\tilde{u}\|^2_{1,\hat{\Omega}}) \\
&\quad\quad + a_{25}(\|\tilde{g}\|^2_{0,\hat{\Omega}} + |\tilde{u}|^2_{1,0,\hat{\Omega}} + \|\tilde{q}_\sigma\|^2_{0,\hat{\Omega}}) \\
&\quad\quad + a_{26}\left\|\int_0^t \hat{u}dt'\right\|^2_{3,\hat{\Omega}} (\|\tilde{q}_\sigma\|^2_{2,\hat{\Omega}} + \|\tilde{u}\|^2_{2,\hat{\Omega}}) + \delta_{14}\|\tilde{q}_{\sigma n}\|^2_{0,\hat{\Omega}}.
\end{aligned} \tag{4.66}
$$

Now equations (4.41), (4.43), (4.45), and (4.66) follow:

(4.67)

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left[\hat{\eta}(\tilde{u}^2_\tau + |\tilde{u}^3_n|^2) + \frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma z}\right]dz \\
&\qquad + \frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}} g^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{ss^\alpha}d\tau\,\bar{n}\cdot\int_0^t \tilde{u}_{ss^\beta}d\tau\,ds' \\
&\qquad + \sigma\int_{\hat{S}}\left(H(0) + \frac{2}{R_0}\right)\zeta\tilde{u}_{ss}\cdot\bar{n}\,ds' \\
&\qquad + \frac{\mu}{2}\|\tilde{u}\|^2_{2,\hat{\Omega}} + \|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}} \\
&\quad \le \delta_{15}\left(\left\|\int_0^t \tilde{u}d\tau\right\|^2_{2,\hat{S}} + \|\hat{u}_{zz}\|^2_{0,\hat{\Omega}} + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,\hat{S}} + \|R(\cdot,t) - R(\cdot,0)\|^2_{2,S^1}\right) \\
&\qquad + a_{27}(\|\tilde{g}\|^2_{0,\hat{\Omega}} + |\hat{u}|^2_{1,0,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}}) \\
&\qquad + a_{28}X_4(\hat{\Omega})Y_4(\hat{\Omega}).
\end{aligned}
$$

We also have

$$
\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}\tilde{u}^2_n J dz \le \delta_{16}\|\tilde{u}_{nt}\|^2_{0,\hat{\Omega}} + c\|\tilde{u}\|^2_{1,\hat{\Omega}} + a_{29}X_4(\hat{\Omega})Y_4(\hat{\Omega}). \tag{4.68}
$$

From (4.67) and (4.68) we have

(4.69)

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left[\hat{\eta}\tilde{u}^2_z + \frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma z}\right]dz \\
&\qquad + \frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}\left[g^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{ss^\alpha}d\tau\,\bar{n}\cdot\int_0^t \tilde{u}_{ss^\beta}d\tau + 2\left(H(0) + \frac{2}{R_0}\right)\zeta\bar{n}\cdot\int_0^t \tilde{u}_{ss}d\tau\right]ds' \\
&\qquad + \frac{\mu}{2}\|\tilde{u}\|^2_{2,\hat{\Omega}} + \|\tilde{q}_{\sigma z}\|^2_{0,\hat{\Omega}} \\
&\quad \le \delta_{17}\left(\left\|\int_0^t \tilde{u}d\tau\right\|^2_{2,\hat{S}} + \|\hat{u}_{zz}\|^2_{0,\hat{\Omega}} + \left\|H(0) + \frac{2}{R_0}\right\|^2_{0,\hat{S}} + \|R(\cdot,t) - R(\cdot,0)\|^2_{2,S^1}\right) \\
&\qquad + a_{30}(|\hat{u}|^2_{1,0,\hat{\Omega}} + \|\hat{q}_\sigma\|^2_{0,\hat{\Omega}} + \|\tilde{g}\|^2_{0,\hat{\Omega}}) \\
&\qquad + a_{31}X_4(\hat{\Omega})Y_4(\hat{\Omega}).
\end{aligned}
$$

We examine the second term on the left-hand side of (4.69). By employing the fact that the part of the boundary $S_t \cap \{x : \zeta(x) \neq 0\}$ can be described in the local

coordinates $\{y\}$ by the formula $y^i = s^i, i = 1, 2, y^3 = \bar{F}(s^1, s^2, t)$, we have $g^{\alpha\beta} = \delta^{\alpha\beta} + \varepsilon^{\alpha\beta}$, where $\varepsilon^{\alpha\beta} = \bar{F}_{s^\alpha}\bar{F}_{s^\beta}\left(1 + \bar{F}_{s^1}^2 + \bar{F}_{s^2}^2\right)^{-1}$. Assuming that $\operatorname{supp}\{\zeta\}$ is sufficiently small, we have that $|\bar{F}_s| \le \frac{1}{2}$. Then, performing summation over $s \in \{s^1, s^2\}$, we write the second term in the form

$$
\begin{aligned}
&\frac{\sigma}{2}\frac{d}{dt}\int_U \frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{ss^\alpha}d\tau\,\bar{n}\cdot\int_0^t \tilde{u}_{ss^\beta}d\tau\sqrt{g}\,ds^1ds^2\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_U\left|\bar{n}\cdot\int_0^t \tilde{u}_{s^1s^2}d\tau\right|^2\sqrt{g}ds^1ds^2\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_U\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t \tilde{u}_{s^is^i}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)^2\sqrt{g}ds^1ds^2\\
&\quad-4\sigma\frac{d}{dt}\int_U\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)^2\sqrt{g}ds^1ds^2,
\end{aligned}
\tag{4.70}
$$

where $\tilde{\delta}^{\alpha\beta} = \delta^{\alpha\beta} + 2\varepsilon^{\alpha\beta}$ and $\frac{3}{4}\xi^2 \le \tilde{\delta}^{\alpha\beta}\xi_\alpha\xi_\beta, \xi^2 = \xi_1^2 + \xi_2^2$.

We use (4.70) in (4.69) and then we go back to the variables ξ. Then from the resulting estimate and (4.36), after summing over all neighborhoods of the partition of unity, and going back to the variables x and from using (4.17), we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho|v|_{1,0}^2+\frac{1}{p\Psi(\rho)}|p_\sigma|_{1,0}^2\right)dt\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\left[\bar{n}\cdot\int_0^t v_{s^\alpha}d\tau\bar{n}\cdot\int_0^t v_{s^\beta}d\tau+\bar{n}\cdot v_{s^\alpha}\bar{n}\cdot v_{s^\beta}\right]ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t v_{ss^\alpha}d\tau\bar{n}\cdot\int_0^t v_{ss^\beta}d\tau ds+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar{n}\cdot\int_0^t v_{s^1s^2}d\tau\right|^2ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t v_{s^1s^2}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)\right)^2ds\\
&\quad+\frac{\mu}{2}|v|_{2,1,\Omega_t}^2+|p_\sigma|_{1,0,\Omega_t}^2\\
&\le\delta_{17}\left(\left\|\int_0^t v d\tau\right\|_{2,S_t}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{0,S_t}^2+\|R(\cdot,t)-R(\cdot,0)\|_{2,S^1}^2\right)\\
&\quad+a_{32}(|v|_{1,0,\Omega_t}^2+\|p_\sigma\|_{0,\Omega_t}^2+|f|_{1,0,\Omega_t}^2)+a_{33}X_4Y_4\\
&\quad+4\sigma\frac{d}{dt}\int_{S_t}\left(H(\cdot,0)+\frac{2}{R_0}\right)^2ds.
\end{aligned}
\tag{4.71}
$$

By virtue of the interpolation inequality (1.12), we obtain

$$
\begin{aligned}
\left|\frac{d}{dt}\int_{S_t}\left(H(\cdot,0)+\frac{2}{R_0}\right)^2\right|ds&\le\delta_{18}\|v_{xx}\|_{0,\Omega_t}^2\\
&\quad+a_{34}(\|H(\cdot,0)+\frac{2}{R_0}\|_{0,S^1}^4+\|v\|_{0,\Omega_t}^2).
\end{aligned}
\tag{4.72}
$$

Expressing boundary conditions (4.1c) locally we have

$$
\sigma\hat{\Delta}_{\hat{S}_t}\int_0^t\tilde{u}dt'=-\sigma\left(\hat{\Delta}_{\hat{S}_t}\hat{\xi}+\frac{2}{R_0}\hat{n}\right)\hat{\zeta}-\hat{\mathbb{T}}_u(\tilde{u},\tilde{q}_\sigma)\hat{n}+l_1+l_2,
\tag{4.73}
$$

where

$$l_1^i = -\hat{B}^{ij}(\hat{u},\hat{\zeta})\hat{n}_j, \qquad l_2 = \sigma\left(2\hat{\nabla}\int_0^t \hat{u}d\tau\,\hat{\nabla}\hat{\zeta} + \int_0^t \hat{u}d\tau\,\hat{\nabla}^2\hat{\zeta}\right). \tag{4.74}$$

Multiply (4.73) by $\int_0^t \tilde{u}dt'$, then differentiate with respect to τ and multiply by $\int_0^t \tilde{u}_\tau dt'$. By integrating the result over $\hat{S}$ and summing over all neighborhoods of the partition of unity we obtain

$$\begin{aligned}\left\|\int_0^t v d\tau\right\|^2_{2,S_t} &\le \delta_{19}\left(\|v\|^2_{2,\Omega_t} + \|p_\sigma\|^2_{1,\Omega_t}\right)\\ &\quad + a_{35}\Bigg(\|v\|^2_{0,\Omega_t} + \|p_\sigma\|^2_{0,\Omega_t} + \left\|\int_0^t v d\tau\right\|^2_{0,\Omega_t}\\ &\qquad + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{0,S^1} + \|R(\cdot,t) - R(\cdot,0)\|^2_{2,S^1}\Bigg)\\ &\quad + a_{36}(\|v\|^2_{2,\Omega_t} + \|p_\sigma\|^2_{2,\Omega_t})\int_0^t \|v\|^2_{3,\Omega_\tau} d\tau.\end{aligned} \tag{4.75}$$

From (4.71), (4.72), (4.75), and sufficiently small δ_{17}, δ_{18}, δ_{19} we get (4.30). This concludes the proof.

Now we obtain an inequality for the third derivatives.

LEMMA 4.5. *For a sufficiently smooth solution of the problem* (4.1a–c) *the following inequality holds*:

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_{xx}^2 + \frac{1}{p\Psi(\rho)}p_{\sigma xx}^2\right)dx\\ &\quad + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t v_{s_1s_2s^\alpha}d\tau\bar{n}\cdot\int_0^t v_{s_1s_2s^\beta}d\tau ds\\ &\quad + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar{n}\cdot\int_0^t v_{s^1s^2s}d\tau\right|^2 ds\\ &\quad + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t v_{ss^is^i}d\tau + 2\left(H(\cdot,0)+\frac{2}{R_0}\right),s\right)^2 ds\\ &\quad + \|v\|^2_{3,\Omega_t} + \|p_\sigma\|^2_{2,\Omega_t}\\ &\le \varepsilon_5\left(\|v_{xxt}\|^2_{0,\Omega_t} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{1,S^1} + \|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\right)\\ &\quad + P_9\left(\|f\|^2_{1,\Omega_t} + |v|^2_{2,1,\Omega_t} + |p_\sigma|^2_{1,0,\Omega_t}\right)\\ &\quad + P_{10}\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{1,S^1} + P_{11}X_5(1+X_5)Y_5,\end{aligned} \tag{4.76}$$

where the summation over the repeated indices (α,β) *and coordinates* $x, s_i = (s^1,s^2), i = 1,2, s = (s^1,s^2)$ *is assumed and*

$$X_5 = \|v\|^2_{3,\Omega_t} + |p_\sigma|^2_{2,1,\Omega_t} + \|v_t\|^2_{1,\Omega_t} + \int_0^t \|v\|^2_{3,\Omega_t} d\tau, \tag{4.77}$$

$$Y_5 = \|v\|^2_{4,\Omega_t} + \|p_\sigma\|^2_{3,\Omega_t} + |p_\sigma|^2_{2,1,\Omega_t} + \|v_t\|^2_{1,\Omega_t} + \int_0^t \|v\|^2_{4,\Omega_t} d\tau. \tag{4.78}$$

Proof. We use the introduced partition of unity. First we consider interior subdomains. We differentiate (4.27) twice with respect to ξ, multiply the result by $\tilde{u}_{\xi\xi}A$, and integrate over $\tilde{\Omega}$ to get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \eta \tilde{u}^2_{\xi\xi} A d\xi + \frac{\mu}{2}\int_{\tilde{\Omega}} (\nabla_{u^i}\tilde{u}^j_{\xi\xi} + \nabla_{u^j}\tilde{u}^i_{\xi\xi})^2 A d\xi \\
&\quad + (\nu-\mu)\|\nabla_u \cdot \tilde{u}_{\xi\xi}\|^2_{0,\tilde{\Omega}} - \int_{\tilde{\Omega}} \tilde{q}_{\sigma\xi\xi}\nabla_u \cdot \tilde{u}_{\xi\xi} A d\xi \\
&\le \delta_1(\|\partial^3_\xi u\|^2_{0,\tilde{\Omega}} + \|\partial^2_\xi q_\sigma\|^2_{0,\tilde{\Omega}}) + a_1(\|u\|^2_{2,\tilde{\Omega}} + \|q_\sigma\|^2_{1,\tilde{\Omega}} + \|\tilde{g}\|^2_{1,\tilde{\Omega}}) \\
&\quad + a_2 X_5(\tilde{\Omega})(1 + X_5(\tilde{\Omega}))Y_5(\tilde{\Omega}),
\end{aligned} \tag{4.79}$$

where

$$\begin{aligned}
X_5(\tilde{\Omega}) &= \|u\|^2_{3,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}} + \|u_t\|^2_{1,\tilde{\Omega}} + \int_0^t \|u\|^2_{3,\tilde{\Omega}} dt', \\
Y_5(\tilde{\Omega}) &= \|u\|^2_{4,\tilde{\Omega}} + \|q_\sigma\|^2_{3,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}} + \|u_t\|^2_{1,\tilde{\Omega}} + \int_0^t \|u\|^2_{4,\tilde{\Omega}} dt'.
\end{aligned} \tag{4.80}$$

From the continuity equation (4.27b) we obtain

$$-\int_{\tilde{\Omega}} \tilde{q}_{\sigma\xi\xi}\nabla_u \cdot \tilde{u}_{\xi\xi} A d\xi = \frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \frac{1}{q\Psi(\eta)}\tilde{q}^2_{\sigma\xi\xi} A d\xi + N_1, \tag{4.81}$$

where

$$|N_1| \le \delta_2 \|\tilde{q}_{\sigma\xi\xi}\|^2_{0,\tilde{\Omega}} + c\|u\|^2_{2,\tilde{\Omega}} + a_3 X_5(\tilde{\Omega})(1 + X_5(\tilde{\Omega}))Y_5(\tilde{\Omega}).$$

Using the form of k_1 (see (4.27a)) from (4.34) we obtain

$$\begin{aligned}
\|\tilde{u}\|^2_{3,\tilde{\Omega}} + \|\tilde{q}_\sigma\|^2_{2,\tilde{\Omega}} &\le a_4(\|\tilde{g}\|^2_{1,\tilde{\Omega}} + \|u\|^2_{2,\tilde{\Omega}} + \|q_\sigma\|^2_{1,\tilde{\Omega}} + \|\tilde{u}_t\|^2_{1,\tilde{\Omega}}) \\
&\quad + a_5\Bigg(\|q_\sigma\|^4_{2,\tilde{\Omega}} + \|q_\sigma\|^2_{2,\tilde{\Omega}}\|\tilde{u}_t\|^2_{1,\tilde{\Omega}} \\
&\qquad + \left\|\int_0^t u dt'\right\|^2_{3,\tilde{\Omega}} \left(1 + \left\|\int_0^t u dt'\right\|^2_{3,\tilde{\Omega}}\right)\|u\|^2_{3,\tilde{\Omega}}\Bigg) \\
&\quad + c\|\nabla_u \cdot \tilde{u}\|^2_{2,\tilde{\Omega}}.
\end{aligned} \tag{4.82}$$

Employing Lemma 5.1 from [35] in the case $G = \tilde{\Omega}$, $v = \tilde{u}_{\xi\xi}$, and (4.79), (4.81), and (4.82) we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \left(\eta\tilde{u}^2_{\xi\xi} + \frac{1}{q\Psi(\eta)}\tilde{q}^2_{\xi\xi}\right) A d\xi + \frac{\mu}{2}\|\tilde{u}\|^2_{3,\tilde{\Omega}} + \|\tilde{q}_\sigma\|^2_{2,\tilde{\Omega}} \\
&\le \delta_3(\|\partial^3_\xi u\|^2_{0,\tilde{\Omega}} + \|\partial^2_\xi q_\sigma\|^2_{0,\tilde{\Omega}}) + a_6(\|\tilde{g}\|^2_{1,\tilde{\Omega}} + |u|^2_{2,1,\tilde{\Omega}} + \|\tilde{q}_\sigma\|^2_{1,\tilde{\Omega}}) \\
&\quad + a_7 X_5(\tilde{\Omega})(1 + X_5(\tilde{\Omega}))Y_5(\tilde{\Omega}).
\end{aligned} \tag{4.83}$$

Now we consider a subdomain near the boundary. Differentiating (4.28a) twice with respect to τ, multiplying the result by $\tilde{u}_{\tau\tau}J$, and integrating over $\hat{\Omega}$ yields

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}_{\tau\tau}+\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma\tau\tau}\right)Jdz+\frac{\mu}{2}\|\tilde{u}_{\tau\tau}\|^2_{1,\hat{\Omega}}\\
&\qquad-\int_{\hat{S}}(\hat{n}\hat{T}(\tilde{u},\tilde{q}_\sigma))_{,\tau\tau}\cdot\tilde{u}_{\tau\tau}Jdz'\\
&\leq\delta_4(\|\hat{q}_{\sigma zz}\|^2_{0,\hat{\Omega}}+\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}})\\
&\qquad+a_8(\|\hat{u}\|^2_{2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{1,\hat{\Omega}}+\|\tilde{g}\|^2_{1,\hat{\Omega}})+a_9X_5(\hat{\Omega})(1+X_5(\hat{\Omega})Y_5(\hat{\Omega}),
\end{aligned}
\tag{4.84}
$$

where the $X_5(\hat{\Omega}), Y_5(\hat{\Omega})$ are defined by (4.80) with $\hat{\Omega}$ instead of $\tilde{\Omega}$, and u, q_σ are replaced by $\hat{u}, \hat{q}_\sigma$. We have used Lemma 5.1 from [35] in the case $G=\hat{\Omega}, v=\tilde{u}_{\tau\tau}$, and

$$
-\int_{\hat{\Omega}}\tilde{q}_{\sigma\tau\tau}\hat{\nabla}\cdot\tilde{u}_{\tau\tau}Jdz=\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma\tau\tau}Jdz+N_2,
$$

where

$$
|N_2|\leq\delta_5\|\tilde{q}_{\sigma\tau\tau}\|^2_{0,\hat{\Omega}}+a_{10}\|\hat{u}\|^2_{2,\hat{\Omega}}+a_{11}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
$$

Considering the boundary term in (4.84) we obtain the expression

$$
\begin{aligned}
&\int_{\hat{S}}(\hat{n}\cdot\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,\tau\tau}\cdot\tilde{u}_{\tau\tau}Jdz'\\
&=-\int_{\hat{S}}\left(\hat{\Delta}_{\hat{S}_t}\hat{\xi}\cdot\hat{n}\hat{n}\hat{\zeta}+\frac{2}{R_0}\hat{n}\hat{\zeta}\right)_{,\tau\tau}\tilde{u}_{\tau\tau}Jdz'\\
&\quad-\sigma\int_{\hat{S}}\left(\hat{\Delta}_{\hat{S}_t}\int_0^t\tilde{u}d\tau\cdot\hat{n}\hat{n}\right)_{,\tau\tau}\tilde{u}_{\tau\tau}Jdz'+\int_{\hat{S}}(k_5+k_6)_{,\tau\tau}\tilde{u}_{\tau\tau}Jdz'.
\end{aligned}
\tag{4.85}
$$

Similarly, as in the case of (4.38), the first term on the right-hand side is equal to

$$
\begin{aligned}
&-\sigma\int_U\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\bar{n}\zeta\right)_{,s_1s_2}\tilde{u}_{s_1s_2}\sqrt{g}ds^1ds^2+N_3\\
&=\sigma\int_U\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\bar{n}\zeta\right)_{,s_1}\tilde{u}_{s_1s_2s_2}\sqrt{g}ds^1ds^2+N_4,
\end{aligned}
$$

where the summation over the repeated indices s_1, s_2 is assumed, and where

$$
\begin{aligned}
|N_4|\leq\delta_6&\left(\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{S}}+\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{1,\hat{S}}\right)\\
&+a_{12}(\|\xi\|_4)\|\hat{u}\|^2_{2,\hat{\Omega}}+a_{13}\|\hat{u}\|^2_{3,\hat{\Omega}}\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{S}}.
\end{aligned}
$$

The second term on the right-hand side of (4.85) takes the form

$$
\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\alpha}d\tau\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\beta}d\tau\,ds+N_5,
$$

and

$$|N_5| \le \delta_7 \left(\left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2 + \|\tilde{u}_{zzz}\|_{0,\hat{\Omega}}^2 \right) + a_{14}\|\hat{u}\|_{2,\hat{\Omega}}^2 + a_{15}\|\hat{u}\|_{3,\hat{\Omega}}^2 \left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2.$$

Finally, the last term in (4.85) is estimated by

$$\delta_8 \left(\left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2 + \|\hat{u}_{zzz}\|_{0,\hat{\Omega}}^2 \right) + a_{16}\|\hat{u}\|_{0,\hat{\Omega}}^2.$$

By summarizing, we have

$$\begin{aligned}
&\int_{\hat{S}} (\hat{n}\mathbb{T}(\tilde{u}, \tilde{q}_\sigma))_{,\tau\tau} \tilde{u}_{\tau\tau} J dz' \\
&\quad \le -\frac{\sigma d}{2dt} \int_{\hat{S}} g^{\alpha\beta} \bar{n} \cdot \int_0^t \tilde{u}_{s_1 s_2 s^\alpha} d\tau \bar{n} \cdot \int_0^t \tilde{u}_{s_1 s_2 s^\beta} d\tau J dz' \\
&\quad\quad -\sigma \int_{\hat{S}} \left(\left(H(\cdot, 0) + \frac{2}{R_0} \right) \bar{n}\zeta \right)_{,s_1} \tilde{u}_{s_1 s_2 s_2} J dz' \\
&\quad\quad +\delta_9 \left(\left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2 + \|\hat{u}_{zzz}\|_{0,\hat{\Omega}}^2 + \left\| H(\cdot, 0) + \frac{2}{R_0} \right\|_{1,\hat{S}}^2 \right) \\
&\quad\quad +a_{17}\|\hat{u}\|_{2,\hat{\Omega}}^2 + a_{18}\|\hat{u}\|_{3,\hat{\Omega}}^2 \left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2.
\end{aligned} \tag{4.86}$$

By summarizing, we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt} \int_{\hat{\Omega}} \left(\hat{\eta}\tilde{u}_{\tau\tau}^2 + \frac{1}{\hat{q}\Psi(\hat{\eta})} \tilde{q}_{\sigma\tau\tau}^2 \right) J dz \\
&\quad +\frac{\sigma}{2}\frac{d}{dt} \int_{\hat{S}} g^{\alpha\beta} \bar{n} \cdot \int_0^t \tilde{u}_{s_1 s_2 s^\alpha} d\tau \bar{n} \cdot \int_0^t \tilde{u}_{s_1 s_2 s^\beta} d\tau ds \\
&\quad +\sigma \frac{d}{dt} \int_{\hat{S}} \left(\left(H(\cdot, 0) + \frac{2}{R_0} \right) \zeta \right)_{,s_1} \tilde{u}_{s_1 s_2 s_2} \cdot \bar{n} ds + \frac{\mu}{2} \|\tilde{u}_{\tau\tau}\|_{1,\hat{\Omega}}^2 \\
&\le \delta_{10} \left(\|\hat{u}_{zzz}\|_{0,\hat{\Omega}}^2 + \|\hat{q}_{\sigma zz}\|_{0,\hat{\Omega}}^2 + \left\| \int_0^t \tilde{u} d\tau \right\|_{3,\hat{S}}^2 \right. \\
&\quad \left. + \left\| H(\cdot, 0) + \frac{2}{R_0} \right\|_{1,\hat{S}}^2 + \|R(\cdot, t) - R(\cdot, 0)\|_{3,S^1}^2 \right) \\
&\quad +a_{19}(\|\hat{u}\|_{2,\hat{\Omega}}^2 + \|\hat{q}_\sigma\|_{1,\hat{\Omega}}^2 + \|\tilde{g}\|_{1,\hat{\Omega}}^2) + a_{20} X_5(\hat{\Omega})(1 + X_5(\hat{\Omega})) Y_5(\hat{\Omega}).
\end{aligned} \tag{4.87}$$

Differentiating the third component of (4.42) with respect to τ, multiplying the

result by $\tilde{q}_{\sigma n\tau}J$, and integrating over $\hat{\Omega}$ yields

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n\tau}Jdz+\|\tilde{q}_{\sigma n\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le c\|\tilde{u}_{z\tau\tau}\|^2_{0,\hat{\Omega}}\\
&\qquad+(\delta_{11}+cd)(\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zz}\|^2_{0,\hat{\Omega}})\|\hat{F}\|^2_{4+1/2,\hat{S}}\\
&\qquad+a_{21}(|\hat{u}|^2_{2,1,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{1,\hat{\Omega}}+\|\tilde{g}\|^2_{1,\hat{\Omega}})\\
&\qquad+a_{22}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.88}
$$

Differentiating the third component of (4.44) with respect to τ, multiplying the result by $\tilde{u}^3_{nn\tau}J$ and integrating over $\hat{\Omega}$ gives

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{n\tau}|^2Jdz+\frac{\mu+\nu}{2}\|\tilde{u}^3_{nn\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le c(\|\tilde{u}_{z\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma n\tau}\|^2_{0,\hat{\Omega}})\\
&\qquad+(\delta_{12}+cd)(\|\tilde{u}_{zzz}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zz}\|^2_{0,\hat{\Omega}})\|\hat{F}\|^2_{4+1/2,\hat{S}}\\
&\qquad+a_{23}\|\tilde{u}_t\|^2_{1,\hat{\Omega}}+a_{24}(\|\hat{u}\|^2_{2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{1,\hat{\Omega}}+\|\tilde{g}\|^2_{1,\hat{\Omega}})\\
&\qquad+a_{25}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.89}
$$

By differentiating (4.46) twice with respect to τ, multiplying by $\tilde{u}'_{\tau\tau}J$, integrating over $\hat{\Omega}$, and using the boundary condition (4.47), we get

$$
\begin{aligned}
&\|\tilde{u}'_{z\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma\tau\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{13}+cd)(\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zz}\|^2_{0,\hat{\Omega}})\|\hat{F}\|^2_{4+1/2,\hat{S}}\\
&\qquad+a_{26}(\|\operatorname{div}\tilde{u}_\tau\|^2_{1,\hat{\Omega}}+\|\tilde{u}_t\|^2_{1,\hat{\Omega}}+\|\hat{u}\|^2_{2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{1,\hat{\Omega}}+\|\tilde{g}\|^2_{1,\hat{\Omega}})\\
&\qquad+a_{27}X_5(\hat{\Omega})Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.90}
$$

Moreover, from (4.46) we obtain

$$
\begin{aligned}
\|\tilde{u}'_{nn\tau}\|^2_{1,\hat{\Omega}}\le{}&c(\|\tilde{u}'_{\tau\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma\tau\tau}\|^2_{0,\hat{\Omega}}+\|\operatorname{div}\tilde{u}_{\tau\tau}\|^2_{0,\hat{\Omega}})\\
&+(\delta_{14}+cd)(\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zz}\|^2_{0,\hat{\Omega}})\|\hat{F}\|^2_{4+1/2,\hat{S}}\\
&+a_{28}(\|\tilde{u}_t\|^2_{1,\hat{\Omega}}+\|\tilde{u}\|^2_{2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{1,\hat{\Omega}}+\|\hat{g}\|^2_{1,\hat{\Omega}})\\
&+a_{29}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.91}
$$

By summarizing, inequalities (4.87)–(4.91) we get the following:

(4.92)
$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left[\hat\eta(\tilde u_{\tau\tau}^2+|\tilde u_{n\tau}^3|^2)+\frac{1}{\hat q\hat\Psi(\hat\eta)}\tilde q_{\sigma z\tau}^2\right]Jdz\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde S}g^{\alpha\beta}\bar n\cdot\int_0^t\tilde u_{s_1s_2s^\alpha}d\tau\bar n\cdot\int_0^t\tilde u_{s_1s_2s^\beta}d\tau ds\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde S}\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s_1}\tilde u_{s_1s_2s_2}\cdot\bar n ds\\
&\qquad+\|\tilde u_\tau\|_{2,\hat\Omega}^2+\|\tilde q_{\sigma\tau}\|_{1,\hat\Omega}^2\\
&\quad\le(\delta_{15}+cd)(\|\hat u_{zzz}\|_{0,\hat\Omega}^2+\|\hat q_{\sigma zz}\|_{0,\hat\Omega}^2)\|\hat F\|_{4+1/2,\hat S}^2\\
&\qquad+\delta_{16}\left(\left\|\int_0^t\tilde u d\tau\right\|_{3,\hat S}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{1,S^1}^2+\|R(\cdot,t)-R(\cdot,0)\|_{3,S^1}^2\right)\\
&\qquad+a_{30}(|\hat u|_{2,1,\hat\Omega}^2+\|\hat q_\sigma\|_{1,\hat\Omega}^2+\|\tilde g\|_{1,\hat\Omega}^2)+a_{31}X_5(\hat\Omega)(1+X_5(\hat\Omega))Y_5(\hat\Omega).
\end{aligned}$$

By differentiating the third component of (4.42) with respect to n, multiplying the result by $\tilde q_{\sigma nn}J$, and then integrating over $\hat\Omega$ implies

(4.93)
$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\frac{\mu+\nu}{\hat q\hat\Psi(\hat\eta)}\tilde q_{\sigma nn}^2Jdz+\|\tilde q_{\sigma nn}\|_{0,\hat\Omega}^2\\
&\le c(\|\tilde u_\tau\|_{2,\hat\Omega}^2+(\delta_{16}+cd)(\|\tilde u_{zzz}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma zz}\|_{0,\hat\Omega}^2))\|\hat F\|_{4+1/2,\hat S}^{82}+\delta_{17}\left\|\int_0^t\tilde u d\tau\right\|_{3,\hat S}^2\\
&\quad+a_{32}(\|\tilde u_t\|_{1,\hat\Omega}^2+\|\hat u\|_{2,\hat\Omega}^2+\|\hat q_\sigma\|_{1,\hat\Omega}^2+\|\tilde g\|_{1,\hat\Omega}^2)\\
&\quad+a_{33}X_5(\hat\Omega)(1+X_5(\hat\Omega))Y_5(\hat\Omega).
\end{aligned}$$

We write (4.28a) in the form

$$\begin{aligned}
(\mu+\nu)\nabla_{z^i}\operatorname{div}\tilde u=&-\mu(\Delta\tilde u^i-\nabla_{z^i}\operatorname{div}\tilde u)+\hat\eta\tilde u_t^i-\hat\eta\tilde g^i-k_3^i\\
&-[\mu\nabla^2\tilde u^i+\nu\nabla_{z^i}\operatorname{div}\tilde u-\mu\hat\nabla^2\tilde u^i-\nu\hat\nabla_i\hat{\operatorname{div}}\tilde u]-\hat\nabla_i\tilde q_\sigma.
\end{aligned}\tag{4.94}$$

Differentiating the third component of (4.94) with respect to n gives

$$\begin{aligned}
\|(\operatorname{div}\tilde u)_{nn}\|_{0,\hat\Omega}^2\le&\,c(\|\tilde u_\tau\|_{2,\hat\Omega}^2+\|\tilde q_{\sigma nn}\|_{0,\tilde\Omega}^2)\\
&+(\delta_{18}+cd)\|\tilde u\|_{3,\tilde\Omega}^2\|\hat F\|_{4+1/2,\hat S}^2\\
&+a_{34}(|\hat u|_{2,1,\hat\Omega}^2+\|\hat q_\sigma\|_{1,\hat\Omega}^2+\|\tilde g\|_{1,\hat\Omega}^2)\\
&+a_{35}X_5(\hat\Omega)(1+X_5(\hat\Omega))Y_5(\hat\Omega).
\end{aligned}\tag{4.95}$$

Finally, differentiating (4.46) with respect to n yields

$$\begin{aligned}
\|\tilde u_{nnn}\|_{0,\hat\Omega}^2\le&\,c(\|\tilde u_{\tau\tau}\|_{1,\hat\Omega}^2+\|\tilde q_{\sigma n}\|_{1,\hat\Omega}^2+\|(\operatorname{div}\tilde u)_n\|_{1,\hat\Omega}^2)\\
&+(\delta_{19}+cd)\|\tilde u\|_{3,\hat\Omega}^2\|\hat F\|_{4+1/2,\hat S}^2\\
&+a_{36}(|\hat u|_{2,1,\hat\Omega}^2+\|\hat q_\sigma\|_{1,\hat\Omega}^2+\|\tilde g\|_{1,\hat\Omega}^2)\\
&+a_{37}X_5(\hat\Omega)(1+X_5(\hat\Omega))Y_5(\hat\Omega).
\end{aligned}\tag{4.96}$$

From (4.92), (4.93), (4.95), and (4.96) we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left[\hat{\eta}(\tilde{u}_{\tau\tau}^2+|\tilde{u}_{n\tau}^3|^2)+\frac{\mu+\nu}{\hat{q}\psi(\hat{\eta})}\tilde{q}_{\sigma zz}^2\right]Jdz\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde{S}}g^{\alpha\beta}\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\alpha}d\tau\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\beta}d\tau ds\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde{S}}\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s_1}\tilde{u}_{s_1s_2s_2}\cdot\bar{n}ds+\|\tilde{u}\|_{3,\hat{\Omega}}^2+\|\tilde{q}_\sigma\|_{2,\hat{\Omega}}^2\\
&\qquad\le c(\delta_{20}+cd)(\|\hat{u}_{zzz}\|_{0,\hat{\Omega}}^2+\|\hat{q}_{\sigma zz}\|_{0,\hat{\Omega}}^2)\\
&\qquad+\delta_{21}\left(\left\|\int_0^t\tilde{u}d\tau\right\|_{3,\hat{S}}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{1,S^1}^2+\|R(\cdot,t)-R(\cdot,0)\|_{3,S^1}^2\right)\\
&\qquad+a_{38}(|\hat{u}|_{2,1,\hat{\Omega}}^2+\|\hat{q}_\sigma\|_{1,\hat{\Omega}}^2+\|\tilde{g}\|_{1,\hat{\Omega}}^2)+a_{39}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.97}
$$

To obtain the full second derivative of u under the derivative with respect to time, we examine the expression

$$
\begin{aligned}
\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}\tilde{u}_{zz}^2Jdz&=\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}_{zz}\cdot\tilde{u}_{zzt}J+\frac{1}{2}\hat{\eta}_t\tilde{u}_{zz}^2J+\frac{1}{2}\hat{\eta}\tilde{u}_{zz}^2J_t\right)dz\\
&\le\delta_{22}(\|\tilde{u}_{zzt}\|_{0,\hat{\Omega}}^2+\|\tilde{u}_{zz}\|_{1,\hat{\Omega}}^2)+a_{40}\|\hat{u}\|_{2,\hat{\Omega}}^2\|\tilde{u}\|_{2,\hat{\Omega}}^2,
\end{aligned}
\tag{4.98}
$$

where we have used the relations

$$
\hat{\eta}_t+\hat{\eta}\hat{\nabla}\cdot\hat{u}=0\quad\text{and}\quad J_t=J\hat{\nabla}\cdot\hat{u}.
\tag{4.99}
$$

Employing (4.98) in (4.97) and using the fact that δ_{22} is sufficiently small, we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}_{zz}^2+\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}_{\sigma zz}^2\right)Jdz\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde{S}}g^{\alpha\beta}\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\alpha}d\tau\bar{n}\cdot\int_0^t\tilde{u}_{s_1s_2s^\beta}d\tau\,ds\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{\tilde{S}}\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s_1}\tilde{u}_{s_1s_2s_2}\cdot\bar{n}ds\\
&\qquad+\|\tilde{u}\|_{3,\hat{\Omega}}^2+\|\tilde{q}_\sigma\|_{2,\hat{\Omega}}^2\\
&\qquad\le c(\delta_{23}+cd)(\|\hat{u}_{zzt}\|_{0,\hat{\Omega}}^2+\|\hat{u}_{zzz}\|_{0,\hat{\Omega}}^2+\|\hat{q}_{\sigma zz}\|_{0,\hat{\Omega}}^2)\\
&\qquad+\delta_{24}\left(\left\|\int_0^t\tilde{u}d\tau\right\|_{3,\hat{S}}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{1,S^1}^2+\|R(\cdot,t)-R(\cdot,0)\|_{3,S^1}^2\right)\\
&\qquad+a_{41}(|\hat{u}|_{2,1,\hat{\Omega}}^2+\|\hat{q}_\sigma\|_{1,\hat{\Omega}}^2+\|\tilde{g}\|_{1,\hat{\Omega}}^2)\\
&\qquad+a_{42}X_5(\hat{\Omega})(1+X_5(\hat{\Omega}))Y_5(\hat{\Omega}).
\end{aligned}
\tag{4.100}
$$

Now we examine the second and the third terms in the left-hand side of (4.100). Applying the same considerations as they were used in the case of inequalities (4.69)

and (4.70), we obtain that both terms are equal to

$$
\begin{aligned}
&\frac{\sigma}{2}\frac{d}{dt}\int_U \frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t \tilde{u}_{s_1s_2s^\alpha}d\tau\,\bar{n}\cdot\int_0^t \tilde{u}_{s_1s_2s^\beta}d\tau\sqrt{g}ds^1ds^2\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_U\left|\bar{n}\cdot\int_0^t \tilde{u}_{ss_1s_2}d\tau\right|^2\sqrt{g}ds^1ds^2\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_U\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t \tilde{u}_{ss^is^i}d\tau+2\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s}\right)^2\sqrt{g}ds^1ds^2\\
&\quad-4\sigma\frac{d}{dt}\int_U\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s}^2\sqrt{g}ds^1ds^2,
\end{aligned}
\tag{4.101}
$$

where $\tilde{\delta}^{\alpha\beta}$ is defined in (4.70).

Now, going back to the variables ξ in the inequality (4.101), summing over all neighborhoods of the partition of unity (for the interior neighborhoods we use the inequality (4.83)), and then going back to the variables x, we obtain for sufficiently small δ_1 and d the inequality

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_{xx}^2+\frac{1}{\rho\Psi(\rho)}p_{\sigma xx}^2\right)dx\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde{\delta}^{\alpha\beta}\bar{n}\cdot\int_0^t v_{s_1s_2s^\alpha}d\tau\,\bar{n}\cdot\int_0^t v_{s_1s_2s^\beta}d\tau\,ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar{n}\cdot\int_0^t v_{ss^1s^2}d\tau\right|^2 ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t v_{ss^is^i}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s}\right)^2 ds\\
&\quad+\frac{\mu}{2}\|v\|_{3,\Omega_t}^2+\|p_\sigma\|_{2,\Omega_t}^2\le\delta_{24}\left(\left\|\int_0^t v d\tau\right\|_{3,S_t}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{1,S^1}^2\right)\\
&\quad+a_{42}(|v|_{2,1,\Omega_t}^2+\|\hat{p}_\sigma\|_{1,\Omega_t}^2+\|f\|_{1,\Omega_t}^2)\\
&\quad+a_{43}X_5(1+X_5)Y_5+4\sigma\frac{d}{dt}\int_{S_t}\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s}\right)^2 ds.
\end{aligned}
\tag{4.102}
$$

In virtue of the Young and Hölder inequalities we get

$$
\begin{aligned}
&\left|\frac{d}{dt}\int_{S_t}\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s}\right)^2 ds\right|\\
&\qquad\le\delta_{25}\|v_{xxx}\|_{0,\Omega_t}^2+a_{44}\left(\|v\|_{0,\Omega_t}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{1,S^1}^4\right).
\end{aligned}
\tag{4.103}
$$

Finally, using (4.73) and repeating the considerations following (4.75) gives

$$
\begin{aligned}
\left\| \int_0^t v d\tau \right\|^2_{3,S_t} &\le \delta_{26}(\|v\|^2_{3,\Omega_t} + \|p_\sigma\|^2_{2,\Omega_t}) \\
&\quad + a_{45}\left(\left\| \int_0^t v d\tau \right\|^2_{0,\Omega_t} + \|v\|^2_{0,\Omega_t} + \|p_\sigma\|^2_{0,\Omega_t} \right. \\
&\quad \left. + \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{1,S^1} + \|R(\cdot,t) - R(\cdot,0)\|^2_{3,S^1} \right) \\
&\quad + a_{46}(\|v\|^2_{3,\Omega_t} + \|p_\sigma\|^2_{2,\Omega_t}) \int_0^t \|v\|^2_{4,\Omega_\tau} d\tau.
\end{aligned} \tag{4.104}
$$

Therefore, from (4.102)–(4.104) for sufficiently small δ_{24}, δ_{25}, δ_{26}, we obtain (4.76). This concludes the proof.

To estimate the first term in the right-hand side of (4.77) we need the following result.

LEMMA 4.6. *For sufficiently smooth solutions of problem* (4.1a–c) *we have*

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t} \left(\rho v_{xt}^2 + \frac{1}{\rho \Psi(\rho)} p_{\sigma xt}^2 \right) dx + \frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta} \bar{n} \cdot v_{ss^\alpha} \bar{n} \cdot v_{ss^\beta} ds \\
&\quad + \|v_t\|^2_{2,\Omega_t} + \|p_{\sigma t}\|^2_{1,\Omega_t} \\
&\le \varepsilon_6 \left(\|v_{xtt}\|^2_{0,\Omega_t} + \|v_{xxx}\|^2_{0,\Omega_t} + \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{0,s^1} \right) \\
&\quad + P_{12}(|v|^2_{2,0,\Omega_t} + |p_\sigma|^2_{1,0,\Omega_t} + |f|^2_{1,0,\Omega_t}) \\
&\quad + P_{13} X_6 (1 + X_6) Y_6,
\end{aligned} \tag{4.105}
$$

where

$$
\begin{aligned}
X_6 &= |v|^2_{3,1,\Omega_t} + |p_\sigma|^2_{2,0,\Omega_t} + \int_0^t \|v\|^2_{3,\Omega_\tau} d\tau, \\
Y_6 &= |v|^2_{4,2,\Omega_t} + |p_\sigma|^2_{3,1,\Omega_\tau} + \int_0^t \|v\|^2_{4,\Omega_\tau} d\tau.
\end{aligned} \tag{4.106}
$$

Proof. We use the partition of unity. First we obtain the inequality in an interior subdomain. Differentiating (4.27a) with respect to t and ξ, multiplying the result by $\tilde{u}_{t\xi}$, and integrating over $\tilde{\Omega}$ yields

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \eta \tilde{u}^2_{t\xi} A d\xi + \frac{\mu}{2}\int_{\tilde{\Omega}} (\nabla_{u^i} \tilde{u}^j_{t\xi} + \nabla_{u^j} \tilde{u}^i_{t\xi})^2 A d\xi \\
&\quad + (\nu - \mu)\|\nabla_u \cdot \tilde{u}_{t\xi}\|^2_{0,\tilde{\Omega}} - \int_{\tilde{\Omega}} \tilde{q}_{\sigma t\xi} \nabla_u \cdot \tilde{u}_{t\xi} A d\xi \\
&\le \delta_1 \|\tilde{u}_{t\xi}\|^2_{1,\tilde{\Omega}} + a_1(\|u_t\|^2_{1,\tilde{\Omega}} + \|q_{\sigma t}\|^2_{0,\tilde{\Omega}} + |\tilde{g}|^2_{1,0,\tilde{\Omega}}) \\
&\quad + a_2 X_6(\tilde{\Omega}) Y_6(\tilde{\Omega}),
\end{aligned} \tag{4.107}
$$

where

$$X_6(\tilde{\Omega}) = |u|^2_{3,1,\tilde{\Omega}} + |q_\sigma|^2_{2,0,\tilde{\Omega}} + \left\| \int_0^t u dt' \right\|^2_{3,\tilde{\Omega}},$$

$$Y_6(\tilde{\Omega}) = |u|^2_{4,2,\tilde{\Omega}} + |q_\sigma|^2_{3,1,\tilde{\Omega}} + \left\| \int_0^t u dt' \right\|^2_{4,\tilde{\Omega}}.$$

By the continuity equation (4.27b) we have

$$-\int_{\tilde{\Omega}} \tilde{q}_{\sigma t\xi} \nabla_u \cdot \tilde{u}_{t\xi} A d\xi = \frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \frac{1}{q\Psi(\eta)} \tilde{q}^2_{\sigma t\xi} A d\xi + N_1, \tag{4.108}$$

where

$$|N_1| \le \delta_1 \|\tilde{q}_{\sigma t}\|^2_{1,\tilde{\Omega}} + a_3 |u|^2_{2,1,\tilde{\Omega}} + a_4 X_6(\tilde{\Omega})(1 + X_6(\tilde{\Omega}))Y_6(\tilde{\Omega}).$$

From (4.34) we obtain

$$\begin{aligned} \|\tilde{u}_t\|^2_{2,\tilde{\Omega}} + \|\tilde{q}_{\sigma t}\|^2_{1,\tilde{\Omega}} &\le c\|(\nabla_u \cdot \tilde{u})_t\|^2_{1,\tilde{\Omega}} + a_5(\|\tilde{u}_{tt}\|^2_{0,\tilde{\Omega}} \\ &\quad + |u|^2_{2,1,\tilde{\Omega}} + |q_{\sigma t}|^2_{1,0,\tilde{\Omega}} + |\tilde{g}|^2_{1,0,\tilde{\Omega}}) + a_6 X_6(\tilde{\Omega}) Y_6(\tilde{\Omega}). \end{aligned} \tag{4.109}$$

Employing Lemma 5.1 from [35] in the case $G = \tilde{\Omega}$, $v = \tilde{u}_{\xi\xi}$, and (4.107)–(4.109) we obtain for sufficiently small δ_1 and δ_2,

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \left(\eta \tilde{u}^2_{t\xi} + \frac{1}{q\Psi(\eta)} \tilde{q}^2_{\sigma t\xi} \right) A d\xi + \|\tilde{u}_t\|^2_{2,\tilde{\Omega}} + \|\tilde{q}_{\sigma t}\|^2_{1,\tilde{\Omega}} \\ &\quad \le a_7(\|\tilde{u}_{tt}\|^2_{0,\tilde{\Omega}} + |u|^2_{2,1,\tilde{\Omega}} + |q_\sigma|^2_{1,0,\tilde{\Omega}} + |\tilde{g}|^2_{1,0,\tilde{\Omega}}) \\ &\quad + a_8 X_6(\tilde{\Omega})(1 + X_6(\tilde{\Omega}))Y_6(\tilde{\Omega}). \end{aligned} \tag{4.110}$$

Now we obtain an estimate in a subdomain near the boundary. Differentiating (4.28a) with respect to t and τ, multiplying the result by $\tilde{u}_{t\tau} J$, and integrating over $\hat{\Omega}$ yields

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}} \left(\hat{\eta} \tilde{u}^2_{t\tau} + \frac{1}{\hat{q}\Psi(\hat{\eta})} \tilde{q}^2_{\sigma t\tau} \right) J dz + \frac{\mu}{2}\|\tilde{u}_{t\tau}\|^2_{1,\hat{\Omega}} \\ &\quad - \int_{\hat{S}} (\hat{n}\hat{\mathbb{T}}(\tilde{u}, \tilde{q}_\sigma))_{,t\tau} \cdot \tilde{u}_{t\tau} J dz' \le \delta_3(\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_\sigma\|^2_{1,\hat{\Omega}}) \\ &\quad + a_9(|\hat{u}|^2_{2,0,\hat{\Omega}} + |\hat{q}_\sigma|^2_{1,0,\hat{\Omega}} + |\tilde{g}|^2_{1,0,\hat{\Omega}}) \\ &\quad + a_{10} X_6(\hat{\Omega})(1 + X_6(\hat{\Omega}))Y_6(\hat{\Omega}), \end{aligned} \tag{4.111}$$

where $X_6(\hat{\Omega})$, $Y_6(\hat{\Omega})$ are equal to $X_6(\tilde{\Omega})$, $Y_6(\tilde{\Omega})$ with $\hat{u}$, $\hat{q}_\sigma$, $\hat{\Omega}$ instead of u, q_σ, $\hat{\Omega}$, respectively. Moreover, to obtain (4.111) we have used Lemma 5.1 from [35] in the case $G = \hat{\Omega}$, $v = \tilde{u}_{t\tau}$, and

$$-\int_{\hat{\Omega}} \tilde{q}_{\sigma t\tau} \hat{\nabla} \cdot \tilde{u}_{t\tau} J dz = \frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}} \frac{1}{\hat{q}\Psi(\hat{\eta})} \tilde{q}^2_{\sigma t\tau} J dz + N_2,$$

and

$$|N_2| \le \delta_4 \|\tilde{q}_{\sigma t}\|^2_{1,\hat{\Omega}} + a_{11}|\hat{u}|^2_{2,1,\hat{\Omega}} + a_{12}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).$$

Let us consider the boundary term in (4.111). Using the boundary condition (4.28c) we obtain

$$\begin{aligned} &-\int_{\hat{S}} (\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,t\tau} \cdot \tilde{u}_{t\tau} J dz' \\ &= -\sigma \int_{\hat{S}} \left(\hat{\Delta}_{\hat{S}_t} \hat{\xi} \cdot \hat{n}\hat{n}\hat{\zeta} + \frac{2}{R_0}\hat{n}\hat{\zeta} \right)_{,t\tau} \tilde{u}_{t\tau} J dz' \\ &\quad -\sigma \int_{\hat{S}} \left(\hat{\Delta}_{\hat{S}_t} \int_0^t \tilde{u} d\tau \cdot \hat{n}\hat{n} \right)_{,t\tau} \tilde{u}_{t\tau} J dz' + \int_{\hat{S}} (k_5 + k_6)_{,t\tau} \tilde{u}_{t\tau} J dz'. \end{aligned} \tag{4.112}$$

The first term on the right-hand side of (4.112) is estimated by

$$\begin{aligned} &\delta_5 \left(\|\tilde{u}_t\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{\Omega}} + \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{1,S^1} \right) + a_{13}(\|\hat{u}\|^4_{3,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{\Omega}} \|\hat{u}_t\|^2_{2,\hat{\Omega}}) \\ &\quad + a_{14}(\|\hat{u}\|^2_{0,\hat{\Omega}} + \|\hat{u}_t\|^2_{0,\hat{\Omega}}). \end{aligned}$$

The second term is equal to

$$\frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta} \bar{n} \cdot \tilde{u}_{ss^\alpha} \bar{n} \cdot \tilde{u}_{ss^\beta} ds + N_3,$$

where

$$\begin{aligned} |N_3| \le{}& \delta_6 \left(\|\tilde{u}_t\|^2_{2,\hat{\Omega}} + \|\tilde{u}\|^2_{3,\hat{\Omega}} + \left\| \int_0^t \tilde{u} d\tau \right\|^2_{2,\hat{S}} \right) \\ &+ a_{15} \left(\|\hat{u}\|^2_{3,\hat{\Omega}} \left\| \int_0^t \hat{u} d\tau \right\|^2_{4,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{S}} \left\| \int_0^t \hat{u} d\tau \right\|^2_{3,\hat{\Omega}} \right) + a_{16}\|\hat{u}\|^2_{0,\hat{\Omega}}. \end{aligned}$$

Finally, the last term is bounded by

$$\begin{aligned} &\delta_7 \left(\|\hat{u}_t\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{\Omega}} \right) + a_{17}(\|\hat{u}_t\|^2_{0,\hat{\Omega}} + \|\hat{u}\|^2_{0,\hat{\Omega}}) \\ &\quad + a_{18}(\|\hat{u}\|^4_{2,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{\Omega}} \left\| \int_0^t \hat{u} d\tau \right\|^2_{3,\hat{\Omega}}). \end{aligned}$$

By summarizing, we have

$$\begin{aligned} &\int_{\hat{S}} (\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,t\tau} \tilde{u}_{t\tau} J dz' \\ &\le -\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}} g^{\alpha\beta} \bar{n} \cdot \tilde{u}_{ss^\alpha} \bar{n} \cdot \tilde{u}_{ss^\beta} J dz' \\ &\quad + \delta_8 \left(\|\hat{u}_t\|^2_{2,\hat{\Omega}} + \|\hat{u}\|^2_{3,\hat{\Omega}} + \left\| \int_0^t \tilde{u} d\tau \right\|^2_{2,\hat{S}} + \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{1,S^1} \right) \end{aligned} \tag{4.113}$$

$$+a_{19}\left(\|\hat{u}\|^4_{3,\hat{\Omega}}+\|\hat{u}\|^2_{3,\hat{\Omega}}\|\tilde{u}_t\|^2_{2,\hat{\Omega}}+\|\hat{u}\|^2_{3,\hat{\Omega}}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{\Omega}}+\|\hat{u}\|^2_{3,\hat{S}}\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{\Omega}}\right)$$
$$+a_{20}(\|\hat{u}\|^2_{0,\hat{\Omega}}+\|\hat{u}_t\|^2_{0,\hat{\Omega}}).$$

By exploiting (4.113) in (4.111), it follows that

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}^2_{i\tau}+\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma t\tau}\right)Jdz+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\bar{n}\cdot\tilde{u}_{ss^\alpha}\bar{n}\cdot\tilde{u}_{ss^\beta}Jdz'\\&\quad+\frac{\mu}{4}\|\tilde{u}_{t\tau}\|^2_{1,\hat{\Omega}}\\&\le\delta_9\left(\|\hat{u}_{tzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma tz}\|^2_{0,\hat{\Omega}}+\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\left\|\int_0^t\tilde{u}d\tau\right\|^2_{2,\hat{S}}\right)\\&\quad+a_{21}(|\hat{u}|^2_{2,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{1,0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})+a_{22}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned}\tag{4.114}$$

By differentiating the third component of (4.42) with respect to t, multiplying the result by $\tilde{q}_{\sigma nt}J$, and integrating over $\hat{\Omega}$ yields

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+v}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma nt}Jdz+\|\tilde{q}_{\sigma nt}\|^2_{0,\hat{\Omega}}\\&\le(\delta_{10}+cd)\|\hat{F}\|^2_{4+1/2,\hat{S}}(\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zt}\|^2_{0,\hat{\Omega}})+c\|\tilde{u}_{t\tau}\|^2_{1,\hat{\Omega}}\\&\quad+a_{23}(|\hat{u}|^2_{2,0,\hat{\Omega}}+\|\hat{q}_{\sigma t}\|^2_{0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})\\&\quad+a_{24}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned}\tag{4.115}$$

By differentiating the third component of (4.44) with respect to t, multiplying the result by $\tilde{u}^3_{nnt}J$, and integrating over $\hat{\Omega}$ implies

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{nt}|^2Jdz+\frac{\mu+\nu}{2}\|\tilde{u}^3_{nnt}\|^2_{0,\hat{\Omega}}\\&\le(\delta_{11}+cd)\|\hat{F}\|^2_{4+1/2,\hat{S}}(\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zt}\|^2_{0,\hat{\Omega}})+\delta_{12}\|\tilde{u}_{ztt}\|^2_{0,\hat{\Omega}}\\&\quad+c(\|\tilde{u}_{z\tau t}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma nt}\|^2_{0,\hat{\Omega}})+a_{25}(|\hat{u}|^2_{2,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{1,0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})\\&\quad+a_{26}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned}\tag{4.116}$$

By differentiating (4.46) with respect to t and τ, multiplying by $\tilde{u}'_{t\tau}J$, integrating over $\hat{\Omega}$, and using (4.47) we get the following:

$$\begin{aligned}&\|\tilde{u}'_{zt\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma t\tau}\|^2_{0,\hat{\Omega}}\\&\le(\delta_{13}+cd)\|\hat{F}\|^2_{4+1/2,\hat{S}}(\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zt}\|^2_{0,\hat{\Omega}})\\&\quad+c\|(\operatorname{div}\tilde{u}')_{,\tau t}\|^2_{0,\hat{\Omega}}+a_{27}(|\hat{u}|^2_{2,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{1,0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})\\&\quad+a_{28}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned}\tag{4.117}$$

Moreover, from (4.46) we obtain

(4.118)
$$\begin{aligned}\|\tilde{u}'_{nnt}\|^2_{0,\hat{\Omega}} \le{}& (\delta_{14}+cd)\|\hat{F}\|^2_{4+1/2,\hat{S}}(\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zt}\|^2_{0,\hat{\Omega}})\\ &+c(\|\tilde{u}_{zt\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma t\tau}\|^2_{0,\hat{\Omega}})+a_{29}(|\hat{u}|^2_{2,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{1,0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})\\ &+a_{30}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned}$$

Finally, we have

$$\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}\tilde{u}^2_{zt}Jdz \le \delta_{15}\|\tilde{u}_{ztt}\|^2_{0,\hat{\Omega}}+c(\|\tilde{u}_t\|^2_{1,\hat{\Omega}}+\|\tilde{u}_{zt}\|^2_{0,\hat{\Omega}}\|\hat{u}\|^2_{3,\hat{\Omega}}). \tag{4.119}$$

From (4.113), (4.115)–(4.119) we obtain, for sufficiently small δ's,

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}^2_{zt}+\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma zt}\right)Jdz+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\bar{n}\cdot\tilde{u}_{ss^\alpha}\bar{n}\cdot\tilde{u}_{ss^\beta}Jdz'\\ &\quad+\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zt}\|^2_{0,\hat{\Omega}}\\ &\le \delta_{16}\|\tilde{u}_{ztt}\|^2_{0,\hat{\Omega}}+(\delta_{17}+cd)(\|\hat{u}_{zzt}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zt}\|^2_{0,\hat{\Omega}})\\ &\quad+a_{18}\left(\|\hat{u}_{zzz}\|^2_{0,\hat{\Omega}}+\left\|\int_0^t\tilde{u}d\tau\right\|^2_{2,\hat{S}}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{1,\hat{S}}\right)\\ &\quad+a_{31}(|\hat{u}|^2_{2,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{1,0,\hat{\Omega}}+|\tilde{g}|^2_{1,0,\hat{\Omega}})\\ &\quad+a_{32}X_6(\hat{\Omega})(1+X_6(\hat{\Omega}))Y_6(\hat{\Omega}).\end{aligned} \tag{4.120}$$

By going back to the variables ξ in (4.120), summing over all neighborhoods of the partition of unity (where we use (4.111) for the interior subdomains), then going back to the variables x and using estimate (4.104), we obtain (4.105) for sufficiently small δ's and d. This concludes the proof.

To estimate the first term in the right-hand side of (4.105) we need the following result.

LEMMA 4.7. *For a sufficiently smooth solution of the problem* (4.1), *the following inequality holds*:

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v^2_{tt}+\frac{1}{p\Psi(\rho)}p^2_{\sigma tt}\right)dx+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar{n}\cdot\tilde{v}_{s^\alpha t}\bar{n}\cdot\tilde{v}_{s^\beta t}ds\\ &\quad+\|v_{tt}\|^2_{1,\Omega_t}+\|p_{\sigma tt}\|^2_{0,\Omega_t}\\ &\le c\|v_t\|^2_{1,\Omega_t}+\varepsilon_7\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{0,S^1}\\ &\quad+P_{14}(\|f_{tt}\|^2_{0,\Omega_t}+|f|^2_{1,0,\Omega_t})+P_{15}X_7(1+X_7)Y_7,\end{aligned} \tag{4.121}$$

where

$$X_7=|v|^2_{3,1,\Omega_t}+|p_\sigma|^2_{2,0,\Omega_t},\qquad Y_7=|v|^2_{4,2,\Omega_t}+|p_\sigma|^2_{3,1,\Omega_t}+\int_0^t\|u\|^2_{2,\Omega_t}d\tau. \tag{4.122}$$

Proof. Differentiating (4.1a) twice with respect to t, multiplying by v_{tt}, and integrating over Ω_t yields

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_{tt}^2+\frac{1}{p\Psi(\rho)}p_{\sigma tt}^2\right)dx+\frac{\mu}{2}\|v_{tt}\|_{1,\Omega_t}^2\\ &\quad-\int_{S_t}(n_iT^{ij}(v,p_\sigma))_{,tt}\cdot v_{tt}^i ds\le\delta_1(\|v_{tt}\|_{1,\Omega_t}^2+\|p_{\sigma tt}\|_{0,\Omega_t}^2)\\ &\quad+a_1(|f|_{1,0,\Omega_t}^2+\|f_{tt}\|_{0,\Omega_t}^2)+a_2X_7(1+X_7)Y_7,\end{aligned}\tag{4.123}$$

where we have used

$$\int_{\Omega_t}p_{\sigma tt}\operatorname{div}v_{tt}\,dx=\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\frac{1}{p\Psi(\rho)}p_{\sigma tt}^2dx+N_1,$$

Lemma 5.4 from [35], and

$$|N_1|\le\delta_2\|p_{\sigma tt}\|_{0,\Omega_t}^2+a_3X_7(1+X_7)Y_7.$$

Employing boundary condition (4.1c) we obtain

$$\begin{aligned}\int_{S_t}(\bar n\cdot T(v,p_\sigma))_{,tt}\cdot v_{tt}ds&=\sigma\int_{S_t}\left(g^{\alpha\beta}x_{s^\alpha s^\beta}\cdot\bar n\bar n+\frac{2}{R_0}\bar n\right)_{,tt}\cdot v_{tt}ds\\ &=-\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar n\cdot v_{s^\alpha t}\bar n\cdot v_{s^\beta t}ds+N_2,\end{aligned}\tag{4.124}$$

where

$$\begin{aligned}|N_2|\le\delta_3&\left(\|v_{xtt}\|_{0,\Omega_t}^2+\|v_{xxt}\|_{0,\Omega_t}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{0,S^1}^2\right)+a_4\|v_t\|_{0,\Omega_t}^2\\ &+a_5(\|v\|_{2,\Omega_t}^2+\|v_t\|_{2,\Omega_t}^2)\left(\|v\|_{3,\Omega_t}^2+\left\|\int_0^t v\,d\tau\right\|_{2,\Omega_t}^2\right).\end{aligned}$$

Moreover, by the continuity equation (4.2) we have

$$\|p_{\sigma tt}\|_{0,\Omega_t}^2\le c\|v_t\|_{1,\Omega_t}^2+a_6X_7(1+X_7)Y_7.\tag{4.125}$$

Hence, (4.123) and (4.125) imply (4.121). This concludes the proof.

Summarizing, from Lemmas 4.5–4.7 we obtain the following.

LEMMA 4.8.

(4.126)

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho|D_{x,t}^2u|^2+\frac{1}{p\Psi(\rho)}|D_{x,t}^2p_\sigma|^2\right)dx\\ &\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde\delta^{\alpha\beta}\bar n\cdot\int_0^t v_{s_1s_2s^\alpha}d\tau\bar n\cdot\int_0^t v_{s_1s_2s^\beta}d\tau ds+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar n\cdot\int_0^t v_{ss^1s^2}d\tau\right|^2ds\\ &\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac{1}{2}\bar n\cdot\int_0^t v_{ss^1s^2}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s}\right)^2ds\\ &\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar n\cdot v_{ss^\alpha}\bar n\cdot v_{ss^\beta}ds+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar n\cdot v_{s^\alpha t}\bar n\cdot v_{s^\beta t}ds\end{aligned}$$

$$
\begin{aligned}
&+|v|^2_{3,1,\Omega_t}+|p_\sigma|^2_{2,0,\Omega_t}\\
&\le P_{16}\left(|v|^2_{2,0,\Omega_t}+|p_\sigma|^2_{1,0,\Omega_t}+\left\|\int_0^t v\,d\tau\right\|^2_{0,\Omega_t}\right)\\
&\quad+\varepsilon_8\left(\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{1,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\right)\\
&\quad+P_{17}\left(|f|^2_{1,0,\Omega_t}+\|f_{tt}\|^2_{0,\Omega_t}\right)+P_{18}\left(X_8(1+X_8)Y_8+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{1,S^1}\right),
\end{aligned}
$$

where the summation over repeated indices $(\alpha,\beta=1,2)$ *and coordinates* $(x,s_i=(s^1,s^2),i=1,2,s=(s^1,s^2))$ *is assumed and*

$$
\begin{aligned}
X_8&=|v|^2_{3,1,\Omega_t}+|p_\sigma|^2_{2,0,\Omega_t}+\int_0^t\|v\|^2_{3,\Omega_\tau}d\tau,\\
Y_8&=|v|^2_{4,2,\Omega_t}+|p_\sigma|^2_{3,1,\Omega_t}+\int_0^t\|v\|^2_{4,\Omega_t}d\tau.
\end{aligned}
\tag{4.127}
$$

Finally, we obtain inequalities for the fourth derivatives.

LEMMA 4.9. *For a sufficiently smooth solution of the problem* (4.1a–c) *the following estimate holds:*

(4.128)

$$
\begin{aligned}
&\frac12\frac{d}{dt}\int_{\Omega_t^*}\left(\rho v^2_{xxx}+\frac{1}{p\Psi(\rho)}p^2_{\sigma xxx}\right)dx\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac12\tilde\delta^{\alpha\beta}\bar n\cdot\int_0^t v_{s_1s_2s_3s^\alpha}d\tau\,\bar n\cdot\int_0^t v_{s_1s_2s_3s^\beta}d\tau\,ds\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar n\cdot\int_0^t v_{s_1s_2s^1s^2}d\tau\right|^2ds\\
&\qquad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac12\bar n\cdot\int_0^t v_{s_1s_2s^is^i}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s_1s_2}\right)^2ds\\
&\qquad+\|v\|^2_{4,\Omega_t}+\|p_\sigma\|^2_{3,\Omega_t}\\
&\le\varepsilon_8\left(\|v_{xxxt}\|^2_{0,\Omega_t}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)\\
&\qquad+P_{19}\left(|v|^2_{3,2,\Omega_t}+\|p_\sigma\|^2_{2,\Omega_t}+\left\|\int_0^t v\,d\tau\right\|^2_{0,\Omega_t}\right.\\
&\qquad\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,S^1}+\|f\|^2_{2,\Omega_t}\right)\\
&\qquad+P_{20}\left(X_9(1+X_9^2)Y_9+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{2,S^1}\right.\\
&\qquad\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t v\,d\tau\right\|^2_{4,S_t}\right.
\end{aligned}
$$

$$+\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t v d\tau\right\|^2_{3,S_t}\Bigg),$$

where the summation over repeated indices $(\alpha,\beta=1,2)$ *and coordinates* $(x,s_i=(s^1,s^2),i=1,2,3)$ *is assumed and*

$$\begin{aligned} X_9&=|v|^2_{3,2,\Omega_t}+|p_\sigma|^2_{3,2,\Omega_t}+\int_0^t\|v\|^2_{3,\Omega_t}d\tau,\\ Y_9&=|v|^2_{4,3,\Omega_t}+|p_\sigma|^2_{3,2,\Omega_t}+\int_0^t\|v\|^2_{4,\Omega_t}d\tau. \end{aligned} \tag{4.129}$$

Proof. We use the partition of unity. First, we consider interior subdomains. We differentiate (4.27a) three times with respect to ξ, multiply by $\tilde u_{\xi\xi\xi}A$, and integrate over $\tilde\Omega$ to get

$$\begin{aligned} &\frac12\frac{d}{dt}\int_{\tilde\Omega}\left(\eta\tilde u^2_{\xi\xi\xi}+\frac{1}{q\Psi(\eta)}\tilde q^2_{\sigma\xi\xi\xi}\right)Ad\xi\\ &\qquad+\frac{\mu}{2}\int_{\tilde\Omega}(\nabla_{u^i}\tilde u^j_{\xi\xi\xi}+\nabla_{u^j}\tilde u^i_{\xi\xi\xi})^2Ad\xi+(\nu-\mu)\|\nabla_u\cdot\tilde u_{\xi\xi\xi}\|^2_{0,\tilde\Omega}\\ &\le\delta_1(\|\tilde u_{\xi\xi\xi}\|^2_{1,\tilde\Omega}+\|\tilde q_{\sigma\xi\xi\xi}\|^2_{0,\tilde\Omega})+a_1(\|u\|^2_{3,\tilde\Omega}+\|q_\sigma\|^2_{2,\tilde\Omega}+\|\tilde g\|^2_{2,\tilde\Omega})\\ &\qquad+a_2X_9(\tilde\Omega)(1+X_9^2(\tilde\Omega))Y_9(\tilde\Omega), \end{aligned} \tag{4.130}$$

where

$$\begin{aligned} X_9(\tilde\Omega)&=|u|^2_{3,2,\tilde\Omega}+|q_\sigma|^2_{3,2,\tilde\Omega}+\int_0^t\|u\|^2_{3,\tilde\Omega}dt',\\ Y_9(\tilde\Omega)&=|u|^2_{4,3,\tilde\Omega}+|q_\sigma|^2_{3,2,\tilde\Omega}+\int_0^t\|u\|^2_{4,\tilde\Omega}dt'. \end{aligned}$$

We have also used

$$-\int_{\tilde\Omega}\tilde q_{\sigma\xi\xi\xi}\nabla_u\cdot\tilde u_{\xi\xi\xi}Ad\xi=\frac12\frac{d}{dt}\int_{\tilde\Omega}\frac{1}{q\Psi(\eta)}\tilde q^2_{\sigma\xi\xi\xi}Ad\xi+N_1,$$

where

$$|N_1|\le\delta_2\|\tilde q_{\sigma\xi\xi\xi}\|^2_{0,\tilde\Omega}+a_3\|u\|^2_{3,\tilde\Omega}+a_4X_9(\tilde\Omega)(1+X_9^2(\tilde\Omega))Y_9(\tilde\Omega).$$

Moreover, the following relation has been employed, too:

$$\begin{aligned} &\left|\int_{\tilde\Omega}[(\nabla_u\nabla_u\tilde u)_{\xi\xi\xi}-\nabla_u\nabla_u\tilde u_{\xi\xi\xi}]\cdot\tilde u_{\xi\xi\xi}Ad\xi+\int_{\tilde\Omega}[(\nabla_u\tilde q_\sigma)_{\xi\xi\xi}-\nabla_u\tilde q_{\sigma\xi\xi\xi}]\cdot\tilde u_{\xi\xi\xi}Ad\xi\right|\\ &\quad\le\delta_3\|\tilde u_{\xi\xi\xi}\|^2_{1,\tilde\Omega}+a_5X_9(\tilde\Omega)(1+X_9^2(\tilde\Omega))Y_9(\tilde\Omega). \end{aligned}$$

From the problem (4.34) we obtain

$$\begin{aligned} \|\tilde u\|^2_{4,\tilde\Omega}+\|\tilde q_\sigma\|^2_{3,\tilde\Omega}&\le c\|\nabla_u\cdot\tilde u\|^2_{3,\tilde\Omega}+a_6(|u|^2_{3,2,\tilde\Omega}+\|\tilde q_\sigma\|^2_{2,\tilde\Omega}+\|\tilde g\|^2_{2,\tilde\Omega})\\ &\quad+a_7X_9(\tilde\Omega)(1+X_9^2(\tilde\Omega))Y_9(\tilde\Omega). \end{aligned} \tag{4.131}$$

From (4.130) and (4.131) for sufficiently small δ_1 we have

$$\begin{aligned}(4.132)\quad &\frac{1}{2}\frac{d}{dt}\int_{\tilde\Omega}\left(\eta\tilde u_{\xi\xi\xi}^2+\frac{1}{q\Psi(\eta)}\tilde q_{\sigma\xi\xi\xi}^2\right)Ad\xi+\|\tilde u\|_{4,\tilde\Omega}^2+\|\tilde q_\sigma\|_{3,\tilde\Omega}^2\\ &\le a_8(|u|_{3,2,\tilde\Omega}^2+\|q_\sigma\|_{2,\tilde\Omega}^2+\|\tilde g\|_{2,\tilde\Omega}^2)+a_9X_9(\tilde\Omega)(1+X_9(\tilde\Omega))Y_9(\tilde\Omega),\end{aligned}$$

where Lemma 5.1 from [35] in the case $G=\tilde\Omega$ and $v=\tilde u_{\xi\xi\xi}$ has been used.

Now we consider a neighborhood of the boundary. Differentiating (4.28a) three times with respect to τ, multiplying by $\tilde u_{\tau\tau\tau}J$, and integrating over $\hat\Omega$ yields

$$\begin{aligned}(4.133)\quad &\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left[\hat\eta\tilde u_{\tau\tau\tau}^2+\frac{1}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma\tau\tau\tau}^2\right]Jdz+\frac{\mu}{2}\|\tilde u_{\tau\tau\tau}\|_{1,\hat\Omega}^2\\ &\quad+(\nu-\mu)\|\hat\nabla\cdot\tilde u_{\tau\tau\tau}\|_{0,\hat\Omega}^2-\int_{\hat S}(\hat n\hat{\mathbb{T}}(\tilde u,\tilde q_\sigma))_{,\tau\tau\tau}\cdot\tilde u_{\tau\tau\tau}Jdz'\\ &\le\delta_4(\|\tilde u_{z\tau\tau\tau}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma z\tau\tau}\|_{0,\hat\Omega}^2)+a_{10}(|\hat u|_{3,2,\hat\Omega}^2+\|\hat q_\sigma\|_{2,\hat\Omega}^2+\|\tilde g\|_{2,\hat\Omega}^2)\\ &\quad+a_{11}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega),\end{aligned}$$

where $X_9(\hat\Omega),Y_9(\hat\Omega)$ has the form $X_9(\tilde\Omega),Y_9(\tilde\Omega)$ with $\hat u,\hat q_\sigma,\hat\Omega$ instead of $u,q_\sigma,\tilde\Omega$, respectively. Moreover, we have used

$$-\int_{\hat\Omega}\tilde q_{\sigma\tau\tau\tau}\hat\nabla\cdot\tilde u_{\tau\tau\tau}Jdz=\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\frac{1}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma\tau\tau\tau}^2Jdz+N_2,$$

where

$$|N_2|\le\delta_5\|\tilde q_{\sigma\tau\tau\tau}\|_{0,\hat\Omega}^2+a_{12}\|\hat u\|_{3,\hat\Omega}^2+a_{13}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega).$$

We have also employed the following considerations:

$$\begin{aligned}&\left|\int_{\hat\Omega}[(\hat\nabla\hat\nabla\tilde u)_{,\tau\tau\tau}-\hat\nabla\hat\nabla\tilde u_{\tau\tau\tau}]\cdot\tilde u_{\tau\tau\tau}Jdz+\int_{\hat\Omega}[(\hat\nabla\tilde q_\sigma)_{,\tau\tau\tau}-\hat\nabla\tilde q_{\sigma\tau\tau\tau}]\cdot\tilde u_{\tau\tau\tau}Jdz\right|\\ &\le\delta_6(\|\tilde u_{zz\tau\tau}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma z\tau\tau}\|_{0,\hat\Omega}^2)+a_{12}(\|\hat u\|_{3,\hat\Omega}^2+\|\hat q_\sigma\|_{2,\hat\Omega}^2)\\ &\quad+a_{13}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega),\end{aligned}$$

and

$$\begin{aligned}&\left|\int_{\hat S}[(\hat n\hat{\mathbb{T}}(\tilde u,\tilde q_\sigma))_{,\tau\tau\tau}-\hat n\hat{\mathbb{T}}(\tilde u_{\tau\tau\tau},\tilde q_{\sigma\tau\tau\tau})]\cdot\tilde u_{\tau\tau\tau}Jdz'\right|\\ &\quad\le\delta_7(\|\tilde u_{z\tau\tau\tau}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma z\tau\tau}\|_{0,\hat\Omega}^2)+a_{14}(\|\hat u\|_{3,\hat\Omega}^2+\|\hat q_\sigma\|_{2,\hat\Omega}^2)\\ &\qquad+a_{15}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega),\end{aligned}$$

where δ_6 and δ_7 have been assumed sufficiently small.

Finally, Lemma 5.1 from [35] in the case $G=\hat\Omega$ and $v=\tilde u_{\tau\tau\tau}$ has been used.

Using the Lagrangian coordinates and boundary condition (4.28c) we rewrite the boundary term in (4.133) as follows:

$$
\begin{aligned}
&-\int_{\hat{S}} (\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,\tau\tau\tau}\cdot\tilde{u}_{\tau\tau\tau}Jdz' \\
&= -\sigma\int_{\hat{S}}\left(\hat{\Delta}_{\hat{S}_t}\hat{\xi}\cdot\hat{n}\hat{n}\hat{\zeta}+\frac{2}{R_0}\hat{n}\hat{\zeta}\right)_{,\tau\tau\tau}\tilde{u}_{\tau\tau\tau}Jdz' \\
&\quad -\sigma\int_{\hat{S}}\left(\hat{\Delta}_{\hat{S}_t}\int_0^t\tilde{u}d\tau\cdot\hat{n}\hat{n}\right)_{,\tau\tau\tau}\cdot\tilde{u}_{\tau\tau\tau}Jdz'+\int_{\hat{S}}(k_5+k_6)_{,\tau\tau\tau}\tilde{u}_{\tau\tau\tau}Jdz'.
\end{aligned}
\tag{4.134}
$$

Similarly, as in the cases of (4.38) and (4.85), the first term in the right-hand side of (4.134) is estimated by

$$
\begin{aligned}
&\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,\tau\tau}\hat{\zeta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau_i\tau_i}ds+\delta_8\left(\|\tilde{u}_{\tau\tau\tau}\|^2_{1,\hat{S}}+\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}\right.\\
&\quad\left.+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)\\
&\quad+a_{16}\left(\|\hat{u}\|^2_{3,\hat{\Omega}}+\left\|\int_0^t\hat{u}d\tau\right\|^2_{0,\hat{\Omega}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,\hat{S}}\right)\\
&\quad+a_{17}\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}\\
&\quad+a_{18}\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{S}}.
\end{aligned}
$$

We estimate the second term by

$$
\begin{aligned}
&\delta_9\left(\left\|\int_0^t\tilde{u}d\tau\right\|^2_{4,\hat{S}}+\|\tilde{u}_{\tau\tau\tau}\|^2_{1,\hat{\Omega}}\right)+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\alpha}dt'\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\beta}dt'ds\\
&\quad+a_{19}\|\tilde{u}\|^2_{3,\hat{\Omega}}+a_{20}\|\hat{u}\|^2_{3,\hat{\Omega}}\left\|\int_0^t\tilde{u}d\tau\right\|^2_{4,\hat{S}}.
\end{aligned}
$$

Finally, the last term is bounded by

$$
c\|\hat{u}\|^2_{3,\hat{S}}+\delta_{10}\left(\|\hat{u}_{\tau\tau\tau}\|^2_{1,\hat{\Omega}}+\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}\right).
$$

Summarizing, we have

$$
\begin{aligned}
&\int_{\hat{S}}(\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,\tau\tau\tau}\cdot\tilde{u}_{\tau\tau\tau}Jdz'\le-\frac{\sigma d}{2dt}\int_{\hat{S}}g^{\alpha\beta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\alpha}dt'\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\beta}dt'ds\\
&\quad-\frac{\sigma d}{2dt}\int_{\hat{S}}\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,\tau\tau}\hat{\zeta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau_i\tau_i}dt'ds\\
&\quad+\delta_{11}\left(\|\tilde{u}_{\tau\tau\tau}\|^2_{1,\hat{\Omega}}+\left\|\int_0^t\tilde{u}d\tau\right\|^2_{4,\hat{S}}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,\hat{S}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)
\end{aligned}
\tag{4.135}
$$

$$+a_{21}\left(\|\hat{u}\|^2_{3,\hat{\Omega}}+\left\|\int_0^t\hat{u}d\tau\right\|^2_{0,\hat{\Omega}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,S^1}\right)$$

$$+a_{22}\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,S^1}\right.$$

$$\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{S}}\right)$$

$$+a_{23}\|\hat{u}\|^2_{3,\hat{\Omega}}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}.$$

From (4.133) and (4.135) we obtain

(4.136)

$$\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}^2_{\tau\tau\tau}+\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma\tau\tau\tau}\right)Jdz$$

$$+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\alpha}dt'\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau s^\beta}dt'ds$$

$$+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,\tau\tau}\hat{\zeta}\hat{n}\cdot\int_0^t\tilde{u}_{\tau\tau\tau_i\tau_i}dt'ds$$

$$+\frac{\mu}{4}\|\tilde{u}_{\tau\tau\tau}\|^2_{1,\hat{\Omega}}+(\nu-\mu)\|\hat{\nabla}\cdot\tilde{u}_{\tau\tau\tau}\|^2_{0,\hat{\Omega}}$$

$$\le\delta_{12}\left(\|\hat{u}_{z\tau\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma z\tau\tau}\|^2_{0,\hat{\Omega}}+\left\|\int_0^t\tilde{u}d\tau\right\|^2_{4,\hat{S}}\right.$$

$$\left.+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,\hat{S}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)$$

$$+a_{24}\left(|\hat{u}|^2_{3,2,\hat{\Omega}}+\left\|\int_0^t\tilde{u}d\tau\right\|^2_{0,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,S^1}+\|\tilde{g}\|^2_{2,\hat{\Omega}}\right)$$

$$+a_{25}\left(\|\hat{u}\|^2_{3,2,\hat{\Omega}}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}+\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{4,\hat{S}}\right.$$

$$\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t\hat{u}d\tau\right\|^2_{3,\hat{S}}\right)$$

$$+a_{26}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).$$

Differentiating the third component of (4.42) twice with respect to τ, multiplying the result by $\tilde{q}_{\sigma n\tau\tau}J$, and integrating over $\hat{\Omega}$ gives

(4.137)

$$\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n\tau\tau}Jdz+\frac{1}{2}\|\tilde{q}_{\sigma n\tau\tau}\|^2_{0,\hat{\Omega}}$$

$$\le(\delta_{13}+cd)(\|\hat{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma n\tau\tau}\|^2_{0,\hat{\Omega}})$$

$$+c\|\tilde{u}_{\tau\tau\tau}\|^2_{1,\hat{\Omega}}+a_{27}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|q_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})$$

$$+a_{28}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).$$

Differentiating the third component of (4.44) twice with respect to τ, multiplying the result by $\tilde{u}^3_{nn\tau\tau}J$, and integrating over $\hat{\Omega}$ implies

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{n\tau\tau}|^2 Jdz+\frac{\mu+\nu}{2}\|\tilde{u}^3_{nn\tau\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{14}+cd)(\|\tilde{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma z\tau\tau}\|^2_{0,\hat{\Omega}})+\delta_{15}\|\tilde{u}_{n\tau\tau t}\|^2_{0,\hat{\Omega}}\\
&\qquad+c(\|\tilde{u}_{z\tau\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma n\tau\tau}\|^2_{0,\hat{\Omega}})+a_{29}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\tilde{q}_{\sigma}\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\qquad+a_{30}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}\tag{4.138}$$

Differentiating (4.46) three times with respect to τ, multiplying by $\tilde{u}'_{\tau\tau\tau}J$, integrating over $\hat{\Omega}$, and using the boundary condition (4.47) we obtain

$$\begin{aligned}
&\|\tilde{u}'_{z\tau\tau\tau}\|^2_{0,\hat{\Omega}}+\tilde{q}_{\sigma\tau\tau\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{16}+cd)(\|\hat{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\hat{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\qquad+c\|\mathrm{div}\tilde{u}_{\tau\tau}\|^2_{1,\hat{\Omega}}+a_{31}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\qquad+a_{32}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}\tag{4.139}$$

Moreover, from (4.46) we find

$$\begin{aligned}
\|\tilde{u}'_{nn\tau\tau}\|^2_{0,\hat{\Omega}}&\le(\delta_{17}+cd)\,(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad+c(\|\tilde{u}'_{\tau\tau\tau\tau}\|^2_{0,\hat{\Omega}}+\|(\mathrm{div}\,\tilde{u})_{\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma\tau\tau\tau}\|^2_{0,\hat{\Omega}})\\
&\quad+a_{33}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})+a_{34}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}\tag{4.140}$$

To summarize, from (4.137)–(4.140) we obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}|\tilde{u}^3_{n\tau\tau}|^2+\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n\tau\tau}\right)Jdz+\|\tilde{q}_{\sigma z\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{18}+cd)(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})+\delta_{19}\|\tilde{u}_{n\tau\tau t}\|^2_{0,\hat{\Omega}}\\
&\qquad+c\|\tilde{u}_{z\tau\tau\tau}\|^2_{0,\hat{\Omega}}+a_{35}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_{\sigma}\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\qquad+a_{36}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}\tag{4.141}$$

Differentiating the third component of (4.42) with respect to n and τ, multiplying by $\tilde{q}_{\sigma nn\tau}J$, and integrating over $\hat{\Omega}$ yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma nn\tau}Jdz+\|\tilde{q}_{\sigma nn\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{20}+cd)(\|\tilde{u}_{zzz\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zz\tau}\|^2_{0,\hat{\Omega}})\\
&\qquad+c\|\tilde{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}+a_{37}(|\hat{u}|^2_{3,2,\hat{\Omega}}+|\hat{q}_{\sigma}|^2_{2,1,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\qquad+a_{38}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}\tag{4.142}$$

Differentiating the third component of (4.94) with respect to n and τ gives

$$
\begin{aligned}
\|(\operatorname{div}\tilde{u})_{nn\tau}\|^2_{0,\hat{\Omega}} &\le (\delta_{21}+cd)(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad + c(\|\tilde{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma nn\tau}\|^2_{0,\hat{\Omega}})+a_{39}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\quad + a_{40}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.143}
$$

Next we differentiate (4.46) with respect to n and τ. Hence we get

$$
\begin{aligned}
\|\tilde{u}_{nn\tau\tau}\|^2_{0,\hat{\Omega}} &\le (\delta_{22}+cd)(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad + c(\|\tilde{u}_{zz\tau\tau}\|^2_{0,\hat{\Omega}}+\|(\operatorname{div}\tilde{u})_{zn\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zn\tau}\|^2_{0,\hat{\Omega}})\\
&\quad + a_{41}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})+a_{42}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.144}
$$

From (4.141)–(4.144) we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}|\tilde{u}^3_{n\tau\tau}|^2+\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma zz\tau}\right)Jdz+\|\tilde{u}_{zzz\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zz\tau}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{23}+cd)(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})+\delta_{24}\|\tilde{u}_{n\tau\tau t}\|^2_{0,\hat{\Omega}}\\
&\quad+c\|\tilde{u}_{z\tau\tau\tau}\|^2_{0,\hat{\Omega}}+a_{43}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\quad+a_{44}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.145}
$$

Differentiating the third component of (4.42) twice with respect to n, multiplying the result by $\tilde{q}_{\sigma nnn}J$, and integrating over $\hat{\Omega}$ yields

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma nnn}Jdz+\|\tilde{q}_{\sigma nnn}\|^2_{0,\hat{\Omega}})\\
&\quad\le(\delta_{25}+cd)(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad+c\|\tilde{u}_{zzz\tau}\|^2_{0,\hat{\Omega}}+a_{45}(|\hat{u}|^2_{3,2,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\quad+a_{46}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.146}
$$

Differentiating the third component of (4.94) twice with respect to n implies

$$
\begin{aligned}
\|(\operatorname{div}\tilde{u})_{nnn}\|^2_{0,\hat{\Omega}} &\le (\delta_{26}+cd)\,(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad + c(\|\tilde{u}_{zzz\tau}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma nnn}\|^2_{0,\hat{\Omega}})+a_{47}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})\\
&\quad + a_{48}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.147}
$$

We differentiate (4.46) twice with respect to n. Hence after integrating over $\hat{\Omega}$ we obtain

$$
\begin{aligned}
\|\tilde{u}_{nnnn}\|^2_{0,\hat{\Omega}} &\le (\delta_{27}+cd)\,(\|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzz}\|^2_{0,\hat{\Omega}})\\
&\quad + c(\|\tilde{u}_{zzz\tau}\|^2_{0,\hat{\Omega}}+\|(\operatorname{div}\tilde{u})_{znn}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma znn}\|^2_{0,\hat{\Omega}})\\
&\quad + a_{49}(|\hat{u}|^2_{3,2,\hat{\Omega}}+\|\hat{q}_\sigma\|^2_{2,\hat{\Omega}}+\|\tilde{g}\|^2_{2,\hat{\Omega}})+a_{50}X_9(\hat{\Omega})(1+X_9^2(\hat{\Omega}))Y_9(\hat{\Omega}).
\end{aligned}
\tag{4.148}
$$

Finally, using that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\hat\eta\tilde u_{zzz}^2 J dz &\le \delta_{28}(\|\tilde u_{zzzt}\|_{0,\hat\Omega}^2+\|\tilde u_{zzzz}\|_{0,\hat\Omega}^2)\\ &\quad + c\|\tilde u\|_{3,\hat\Omega}^2 + c(|\hat q_\sigma|_{2,1,\hat\Omega}^2+\|\hat u\|_{3,\hat\Omega}^2)\|\tilde u\|_{3,\hat\Omega}^2,\end{aligned}\tag{4.149}$$

from (4.145)–(4.149), we obtain

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left(\hat\eta\tilde u_{zzz}^2+\frac{\mu+\nu}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma zzz}^2\right)Jdz+\|\tilde u_{zzzz}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma zzz}\|_{0,\hat\Omega}^2\\ &\quad\le \delta_{29}\|\tilde u_{zzzt}\|_{0,\hat\Omega}^2+(\delta_{30}+cd)(\|\hat u_{zzzz}\|_{0,\hat\Omega}^2+\|\hat q_{\sigma zzz}\|_{0,\hat\Omega}^2)\\ &\quad+c\|\tilde u_{z\tau\tau\tau}\|_{0,\hat\Omega}^2+a_{51}(|\hat u|_{3,2,\hat\Omega}^2+|\hat q_\sigma|_{2,1,\hat\Omega}^2+\|\tilde g\|_{2,\hat\Omega}^2)\\ &\quad+a_{52}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega).\end{aligned}\tag{4.150}$$

From (4.136) and (4.150) it follows that

(4.151)

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left(\hat\eta\tilde u_{zzz}^2+\frac{\mu+\nu}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma zzz}^2\right)Jdz\\ &\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}g^{\alpha\beta}\hat n\cdot\int_0^t\tilde u_{\tau\tau\tau s^\alpha}dt'\hat n\cdot\int_0^t\tilde u_{\tau\tau\tau s^\beta}dt'ds\\ &\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,\tau\tau}\hat\zeta\hat n\cdot\int_0^t\tilde u_{\tau\tau\tau_i\tau_i}dt'ds\\ &\quad+\|\tilde u_{zzzz}\|_{0,\hat\Omega}^2+\tilde q_{\sigma zzz}\|_{0,\hat\Omega}^2\\ &\le \delta_{31}\left(\|\tilde u_{zzz\tau}\|_{0,\hat\Omega}^2+\left\|\int_0^t\tilde u d\tau\right\|_{4,\hat S}^2+\|H(\cdot,0)+\frac{2}{R_0}\|_{2,S^1}^2+\|R(\cdot,t)-R(\cdot,0)\|_{4,S^1}^2\right)\\ &\quad+(\delta_{32}+cd)(\|\hat u_{zzzz}\|_{0,\hat\Omega}^2+\|\hat q_{\sigma zzz}\|_{0,\hat\Omega}^2)\\ &\quad+a_{53}\left(|\hat u|_{3,2,\hat\Omega}^2+\left\|\int_0^t\hat u d\tau\right\|_{0,\hat\Omega}^2+|\hat q_\sigma|_{2,1,\hat\Omega}^2\right.\\ &\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|_{0,S^1}^2+\|\tilde g\|_{2,\hat\Omega}^2\right)\\ &\quad+a_{54}\left(\|\hat u\|_{3,\hat\Omega}^2\left\|\int_0^t\hat u d\tau\right\|_{4,\hat S}^2+\|R(\cdot,t)-R(\cdot,0)\|_{3,S^1}^2\left\|\int_0^t\hat u d\tau\right\|_{4,\hat S}^2\right.\\ &\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|_{4+1/2,S^1}^2\left\|\int_0^t\hat u d\tau\right\|_{3,\hat S}^2\right)\\ &\quad+a_{55}X_9(\hat\Omega)(1+X_9^2(\hat\Omega))Y_9(\hat\Omega).\end{aligned}$$

Now we examine the second and the third terms in the left-hand side of (4.151). Applying the same considerations as in the case of (4.69), (4.70), and (4.101) we find

that both terms are equal to

$$
\begin{aligned}
&\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}\frac{1}{2}\tilde\delta^{\alpha\beta}\hat n\cdot\int_0^t \tilde u_{s_1s_2s_3s^\alpha}d\tau\hat n\cdot\int_0^t\tilde u_{s_1s_2s_3s^\beta}dtJdz'\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}\left|\hat n\cdot\int_0^t\tilde u_{s_1s_2s^is^i}d\tau\right|^2Jdz'\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}\sum_{i=1}^2\left(\frac{1}{2}\hat n\cdot\int_0^t\tilde u_{s_1s_2s^is^i}d\tau+2\left(\left(H(\cdot,0)+\frac{2}{R_0}\right)\zeta\right)_{,s_1s_2}\right)^2Jdz'\\
&\quad-4\sigma\frac{d}{dt}\int_{\hat S}\left(H(\cdot,0)+\frac{2}{R_0}\right)^2_{,s_1s_2}Jdz'.
\end{aligned}
\tag{4.152}
$$

Going back to the variable ξ in (4.151) and (4.152), summing the result and (4.132) over all neighborhoods of the partition of unity, using that δ_{32} and d are sufficiently small, and, finally, going back to the variables x we obtain

(4.153)

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_{xxx}^2+\frac{1}{p\Psi(\rho)}p_{\sigma xxx}^2\right)dx\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\frac{1}{2}\tilde\delta^{\alpha\beta}\bar n\cdot\int_0^t v_{s_1s_2s_3s^\alpha}d\tau\,\bar n\cdot\int_0^t v_{s_1s_2s_3s^\beta}d\tau\,ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\left|\bar n\cdot\int_0^t v_{s_1s_2s^1s^2}d\tau\right|^2ds\\
&\quad+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}\sum_{i=1}^2\left(\frac{1}{2}\bar n\cdot\int_0^t v_{s_1s_2s^is^i}d\tau+2\left(H(\cdot,0)+\frac{2}{R_0}\right)_{,s_1s_2}\right)^2ds\\
&\le\delta_{33}\left(\|v_{xxxt}\|^2_{0,\Omega_t}+\left\|\int_0^t vd\tau\right\|^2_{4,S_t}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)\\
&\quad+a_{55}\left(|v|^2_{3,2,\Omega_t}+\|p_\sigma\|^2_{2,\Omega_t}+\left\|\int_0^t vd\tau\right\|^2_{0,\Omega_t}+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,S^1}+\|f\|^2_{2,\Omega_t}\right)\\
&\quad+a_{56}\left(X_9(+X_9^2)Y_9+\|v\|^2_{3,\Omega_t}\left\|\int_0^t vd\tau\right\|^2_{4,S_t}+\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t vd\tau\right\|^2_{4,S_t}\right.\\
&\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t vd\tau\right\|^2_{3,S_t}\right)\\
&\quad+a_{57}\left|\frac{d}{dt}\int_{S_t}\left(H(\cdot,0)+\frac{2}{R_0}\right)^2_{,ss}ds\right|.
\end{aligned}
$$

We have the estimates

$$
\begin{aligned}
\left\|\int_0^t vd\tau\right\|^2_{4,S_t}&\le\delta_{34}(\|v_{xxxx}\|^2_{0,\Omega_t}+\|p_{\sigma xxx}\|^2_{0,\Omega_t})\\
&\quad+a_{58}\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{4,s^1}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\left\|\int_0^t vd\tau\right\|^2_{0,\Omega_t}\right.
\end{aligned}
$$

(4.154)
$$+\|v\|^2_{0,\Omega_t}+\|p_\sigma\|^2_{0,\Omega_t}\Big)$$
$$+a_{59}(\|v\|^2_{3,S_t}+\|p_\sigma\|^2_{2,S_t})\left\|\int_0^t v\,d\tau\right\|^2_{4,\Omega_t}\left(1+\left\|\int_0^t v\,d\tau\right\|^2_{3,\Omega_t}\right),$$

and

$$\left|\frac{d}{dt}\int_{S_t}\left(H(\cdot,0)+\frac{2}{R_0}\right)^2_{,ss}ds\right|\le\delta_{35}\|v\|^2_{3,\Omega_t}+c\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{2,S}. \tag{4.155}$$

Using (4.154) and (4.155) in (4.153) implies (4.128) for sufficiently small δ_{34} and δ_{35}. This concludes the proof.

To estimate the first term in the right-hand side of (4.128) we need the following result.

LEMMA 4.10. *For a sufficiently smooth solution of the problem* (4.1a–c) *the following inequality holds*:

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v^2_{xxt}+\frac{\mu+\nu}{p\Psi(\rho)}p^2_{\sigma xxt}\right)dx+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}v_{s_1s_2s^\alpha}\cdot\bar n v_{s_1s_2s^\beta}\cdot\bar n ds\\&\quad+\|v_{xxxt}\|^2_{0,\Omega_t}+\|p_{\sigma xxt}\|^2_{0,\Omega_t}\\&\le\varepsilon_{10}\left(\|v_{xxxx}\|^2_{0,\Omega_t}+\|v_{xxtt}\|^2_{0,\Omega_t}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{0,S^1}\right)\\&\quad+P_{21}(|v|^2_{3,1,\Omega_t}+|p_\sigma|^2_{2,1,\Omega_t}+|f|^2_{2,1,\Omega_t})+P_{22}X_{10}(1+X^2_{10})Y_{10},\end{aligned} \tag{4.156}$$

where $\varepsilon_{10}\in(0,1)$, *the summation over repeated indices* $(\alpha,\beta=1,2)$ *and coordinates* $(x,s_i=(s^1,s^2),i=1,2)$ *is assumed, and*

$$\begin{aligned}X_{10}&=|v|^2_{3,2,\Omega_t}+|p_\sigma|^2_{3,1,\Omega_t}+\int_0^t\|v\|^2_{3,\Omega_t}d\tau,\\Y_{10}&=|v|^2_{4,3,\Omega_t}+|p_\sigma|^2_{3,1,\Omega_t}+\int_0^t\|v\|^2_{4,\Omega_t}d\tau.\end{aligned} \tag{4.157}$$

Proof. We also use the partition of unity. First we consider the interior subdomains. Differentiating (4.27a) twice with respect to ξ and once with respect to time, multiplying by $\tilde u_{t\xi\xi}A$, and integrating over $\tilde\Omega$ yields

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\int_{\tilde\Omega}\left(\eta\tilde u^2_{i\xi\xi}+\frac{1}{q\Psi(\eta)}\tilde q^2_{\sigma t\xi\xi}\right)Ad\xi\\&\quad+\frac{\mu}{2}\int_{\tilde\Omega}(\nabla_{u^i}\tilde u^j_{t\xi\xi}+\nabla_{u^j}\tilde u^i_{t\xi\xi})^2Ad\xi+(\nu-\mu)\|\nabla_u\cdot\tilde u_{t\xi\xi}\|^2_{0,\tilde\Omega}\\&\le\delta_1(\|\tilde u_{t\xi\xi}\|^2_{1,\tilde\Omega}+\|\tilde q_{\sigma t\xi\xi}\|^2_{0,\tilde\Omega})+a_1(|\tilde u|^2_{3,2,\tilde\Omega}+|\tilde q_\sigma|^2_{2,1,\tilde\Omega}+|\tilde g|^2_{2,1,\tilde\Omega})\\&\quad+a_2X_{10}(\tilde\Omega)(1+X^2_{10}(\tilde\Omega))Y_{10}(\tilde\Omega),\end{aligned} \tag{4.158}$$

where

$$X_{10}(\tilde{\Omega}) = |u|^2_{3,2,\tilde{\Omega}} + |q_\sigma|^2_{3,1,\tilde{\Omega}} + \int_0^t \|u\|^2_{3,\tilde{\Omega}} dt,$$

$$Y_{10}(\tilde{\Omega}) = |u|^2_{4,3,\tilde{\Omega}} + |q_\sigma|^2_{3,1,\tilde{\Omega}} + \int_0^t \|u\|^2_{4,\tilde{\Omega}} dt.$$

Moreover, the following considerations have been used:

$$\begin{aligned} -\int_{\tilde{\Omega}} \tilde{q}_{\sigma t\xi\xi} \nabla_u \cdot \tilde{u}_{t\xi\xi} A d\xi &= \frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \frac{1}{q\Psi(\eta)} \tilde{q}^2_{\sigma t\xi\xi} A d\xi + N_1, \\ &\Big| \int_{\tilde{\Omega}} [(\nabla_u \nabla_u \tilde{u})_{,t\xi\xi} - \nabla_u \nabla_u \tilde{u}_{,t\xi\xi}] \cdot \tilde{u}_{t\xi\xi} A d\xi \\ &\quad + \int_{\tilde{\Omega}} [(\nabla_u \tilde{q}_\sigma)_{,t\xi\xi} - \nabla_u \tilde{q}_{\sigma t\xi\xi}] \cdot \tilde{u}_{t\xi\xi} A d\xi \Big| \\ &\le \delta_2 \|\tilde{u}_{t\xi\xi}\|^2_{1,\tilde{\Omega}} + a_3 X_{10}(\tilde{\Omega})(1 + X^2_{10}(\tilde{\Omega}))Y_{10}(\tilde{\Omega}), \end{aligned}$$

where

$$N_1 \le \delta_3 \|\tilde{q}_{\sigma t\xi\xi}\|^2_{0,\tilde{\Omega}} + a_4 |\tilde{u}|^2_{3,2,\tilde{\Omega}} + a_5 X_{10}(\tilde{\Omega})(1 + X^2_{10}(\tilde{\Omega}))Y_{10}(\tilde{\Omega}).$$

From (4.34) we obtain

(4.159)
$$\begin{aligned} \|\tilde{u}_t\|^2_{3,\tilde{\Omega}} + \|\tilde{q}_{\sigma t}\|^2_{2,\tilde{\Omega}} &\le c\|\nabla_u \cdot \tilde{u}_t\|^2_{2,\tilde{\Omega}} \\ &\quad + a_6(|u|^2_{3,1,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}} + |\tilde{g}|^2_{2,1,\tilde{\Omega}}) \\ &\quad + a_7 X_{10}(\tilde{\Omega})(1 + X^2_{10}(\tilde{\Omega}))Y_{10}(\tilde{\Omega}). \end{aligned}$$

Now, by applying Lemma 5.1 from [35] for $G = \tilde{\Omega}$ and $v = \tilde{u}_{t\xi\xi}$ from (4.158) and (4.159) for sufficiently small δ_1, we have

(4.160)
$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}} \left(\eta \tilde{u}^2_{t\xi\xi} + \frac{1}{q\Psi(\eta)} \tilde{q}^2_{\sigma t\xi\xi}\right) A d\xi + \|\tilde{u}_t\|^2_{3,\tilde{\Omega}} + \|\tilde{q}_{\sigma t}\|^2_{2,\tilde{\Omega}} \\ &\quad \le a_8(|u|^2_{3,1,\tilde{\Omega}} + |q_\sigma|^2_{2,1,\tilde{\Omega}} + |\tilde{g}|^2_{2,1,\tilde{\Omega}}) + a_9 X_{10}(\tilde{\Omega})(1 + X^2_{10}(\tilde{\Omega}))Y_{10}(\tilde{\Omega}). \end{aligned}$$

Now we consider boundary subdomains. Differentiating (4.28a) with respect to t and twice with respect to τ, multiplying by $\tilde{u}_{t\tau\tau} J$, integrating over $\tilde{\Omega}$, and applying Lemma 5.1 from [35] for $G = \hat{\Omega}$ and $v = \tilde{u}_{t\tau\tau}$ gives

(4.161)
$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}} \left[\hat{\eta}\tilde{u}^2_{t\tau\tau} + \frac{1}{\hat{q}\Psi(\hat{\eta})} \tilde{q}^2_{\sigma t\tau\tau}\right] J dz + \|\tilde{u}_{t\tau\tau}\|^2_{1,\hat{\Omega}} \\ &\qquad + (\nu - \mu)\|(\operatorname{div} \tilde{u})_{,t\tau\tau}\|^2_{0,\hat{\Omega}} - \int_{\hat{S}} (\hat{n}\hat{T}(\tilde{u}, \tilde{q}_\sigma))_{,t\tau\tau} \cdot \tilde{u}_{t\tau\tau} J dz' \\ &\quad \le \delta_4(\|\tilde{u}_{zz\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z\tau t}\|^2_{0,\hat{\Omega}}) \\ &\qquad + a_{10}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) \\ &\qquad + a_{11} X_{10}(\hat{\Omega})(1 + X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}), \end{aligned}$$

where we have used the following relations:

$$-\int_{\hat{\Omega}} \tilde{q}_{\sigma\tau\tau t}\hat{\nabla}\cdot\tilde{u}_{\tau\tau t}Jdz = -\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma\tau\tau t}Jdz + N_2,$$

$$\int_{\hat{\Omega}}[(\hat{\nabla}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,\tau\tau t} - \hat{\nabla}\hat{\mathbb{T}}(\tilde{u}_{\tau\tau t},\tilde{q}_{\sigma\tau\tau t})]\tilde{u}_{\tau\tau t}Jdz$$

$$\le \delta_5(\|\tilde{u}_{zz\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z\tau t}\|^2_{0,\hat{\Omega}}) + a_{12}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}})$$

$$+a_{13}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega})$$

and

$$N_2 \le \delta_6\|\tilde{q}_{\sigma\tau\tau t}\|^2_{0,\hat{\Omega}} + a_{14}|\hat{u}|^2_{3,2,\hat{\Omega}} + a_{15}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).$$

Moreover, $X_{10}(\hat{\Omega})$, $Y_{10}(\hat{\Omega})$ are obtained from $X_{10}(\tilde{\Omega})$, $Y_{10}(\tilde{\Omega})$, replacing u, q_σ, $\tilde{\Omega}$, by $\hat{u}$, $\hat{q}_\sigma$, $\hat{\Omega}$, respectively.

In view of the boundary condition (4.28c) the boundary term in (4.161) can be estimated in the following way:

$$-\int_{\hat{S}}(\hat{n}\hat{\mathbb{T}}(\tilde{u},\tilde{q}_\sigma))_{,t\tau\tau}\cdot\tilde{u}_{t\tau\tau}Jdz' = -\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}} g^{\alpha\beta}\tilde{u}_{\tau\tau s^\alpha}\cdot\bar{n}\tilde{u}_{\tau\tau s^\beta}\cdot\bar{n}Jdz' + N_3, \tag{4.162}$$

where

$$|N_3| \le \delta_7\left(\|\hat{u}_{t\tau\tau z}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}} + \left\|\int_0^t \tilde{u}d\tau\right\|^2_{4,\hat{\Omega}} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{0,S^1}\right)$$

$$+ a_{16}|\hat{u}|^2_{3,1,\hat{\Omega}} + a_{17}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).$$

From (4.161) and (4.162) we obtain

(4.163)

$$\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left[\hat{\eta}\tilde{u}^2_{t\tau\tau} + \frac{1}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma t\tau\tau}\right]Jdz + \frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}} g^{\alpha\beta}\tilde{u}_{\tau\tau s^\alpha}\cdot\bar{n}\tilde{u}_{\tau\tau s^\beta}\cdot\bar{n}Jdz'$$

$$+\|\tilde{u}_{t\tau\tau}\|^2_{1,\hat{\Omega}} + (\nu-\mu)\|(\mathrm{div}\tilde{u})_{,t\tau\tau}\|^2_{0,\hat{\Omega}}$$

$$\le \delta_8\left(\|\tilde{u}_{t\tau\tau z}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_{zzzz}\|^2_{0,\hat{\Omega}} + \|\hat{q}_{\sigma t\tau\tau}|^2_{0,\hat{\Omega}} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{0,S^1}\right)$$

$$+a_{18}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) + a_{19}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).$$

Differentiating the third component of (4.42) with respect to τ and t, multiplying the result by $\tilde{q}_{\sigma n\tau t}J$, and integrating over $\hat{\Omega}$ implies

$$\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n\tau t}Jdz + \|\tilde{q}_{\sigma n\tau t}\|^2_{0,\hat{\Omega}}$$

$$\le (\delta_9 + cd)(\|\tilde{u}_{zz\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z\tau t}\|^2_{0,\hat{\Omega}})$$

$$+c\|\tilde{u}_{z\tau\tau t}\|^2_{0,\hat{\Omega}} + a_{20}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\tilde{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}})$$

$$+a_{21}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}). \tag{4.164}$$

Differentiating the third component of (4.44) with respect to τ and t, multiplying the result by $\tilde{u}^3_{nn\tau t}J$, and integrating over $\hat{\Omega}$ gives

(4.165)
$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{n\tau t}|^2 J dz + \frac{\mu+\nu}{2}\|\tilde{u}^3_{nn\tau t}\|^2_{0,\hat{\Omega}} \\
&\quad \le \delta_{10}\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}} \\
&\qquad +(\delta_{10}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z\tau t}\|^2_{0,\hat{\Omega}}) + c(\|\tilde{u}_{z\tau\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma n\tau t}\|^2_{0,\hat{\Omega}}) \\
&\qquad +a_{22}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) + a_{23}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}$$

From the problem (4.46)–(4.48) we have

(4.166)
$$\begin{aligned}
\|\tilde{u}'_{n\tau\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma\tau\tau t}\|^2_{0,\hat{\Omega}} &\le (\delta_{12}+cd)\left(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}}\right) \\
&\quad +c(\|\tilde{u}^3_{nn\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{u}_{z\tau\tau t}\|^2_{0,\hat{\Omega}}) \\
&\quad +a_{24}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) \\
&\quad +a_{25}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}),
\end{aligned}$$

where prim denotes that only components u^1, u^2 are taken into consideration. Moreover, from (4.46) we get

(4.167)
$$\begin{aligned}
\|\tilde{u}'_{nn\tau t}\|^2_{0,\hat{\Omega}} &\le c\,(\,\|(\mathrm{div}\tilde{u})_{,\tau\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma\tau\tau t}\|^2_{0,\hat{\Omega}}) \\
&\quad +(\delta_{13}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}}) \\
&\quad +a_{26}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) \\
&\quad +a_{27}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}$$

Summarizing, from (4.164)–(4.167) we obtain

(4.168)
$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}|\tilde{u}^3_{n\tau t}|^2 + \frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma n\tau t}\right)Jdz + \|\tilde{u}_{nn\tau t}\|^2_{0,\hat{\Omega}} + \|\tilde{q}_{\sigma z\tau t}\|^2_{0,\hat{\Omega}} \\
&\quad \le \delta_{14}\|\tilde{u}_{tt}\|^2_{2,\hat{\Omega}} + c\|\tilde{u}_{\tau\tau t}\|^2_{1,\hat{\Omega}} + (\delta_{15}+cd)(\|\hat{u}_{zzzt}\|^2_{0,\hat{\Omega}} + \|\hat{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}}) \\
&\qquad +a_{28}(|\hat{u}|^2_{3,1,\hat{\Omega}} + |\hat{q}_\sigma|^2_{2,1,\hat{\Omega}} + |\tilde{g}|^2_{2,1,\hat{\Omega}}) \\
&\qquad +a_{29}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}$$

Differentiating the third component of (4.42) with respect to t and n, multiplying the

result by $\tilde{q}_{\sigma nnt}J$, and integrating over $\hat{\Omega}$ yields

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma nnt}Jdz\\
&\quad+\frac{1}{2}\|\tilde{q}_{\sigma nnt}\|^2_{0,\hat{\Omega}}\le c\|\tilde{u}_{zz\tau t}\|^2_{0,\hat{\Omega}}\\
&\quad+(\delta_{16}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}})\\
&\quad+a_{30}(|\hat{u}|^2_{3,1,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}+|\tilde{g}|^2_{2,1,\hat{\Omega}})+a_{31}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}
\tag{4.169}
$$

Differentiating the third component of (4.44) with respect to n and t, multiplying the result by $\tilde{u}^3_{nnnt}J$, and integrating over $\hat{\Omega}$ implies

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{nnt}|^2Jdz+\frac{\mu+\nu}{2}\|\tilde{u}^3_{nnnt}\|^2_{0,\hat{\Omega}}\\
&\quad\le c(\|\tilde{u}_{zz\tau t}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma nnt}\|^2_{0,\hat{\Omega}})\\
&\qquad+\delta_{17}\|\tilde{u}_{tt}\|^2_{2,\hat{\Omega}}+(\delta_{18}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}})\\
&\qquad+a_{32}(|\hat{u}|^2_{3,1,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}+|\tilde{g}|^2_{2,1,\hat{\Omega}})\\
&\qquad+a_{33}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}
\tag{4.170}
$$

Finally, from (4.46) we get

$$
\begin{aligned}
\|\tilde{u}'_{nnnt}\|^2_{0,\hat{\Omega}}&\le c\left((\mathrm{div}\tilde{u})_{,n\tau t}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma n\tau t}\|^2_{0,\hat{\Omega}}\right)\\
&\quad+c(\delta_{19}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}})\\
&\quad+a_{34}(|\hat{u}|^2_{3,1,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}+|\tilde{g}|^2_{2,1,\hat{\Omega}})+a_{35}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}
\tag{4.171}
$$

Hence, from (4.168)–(4.171) it follows that

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}|\tilde{u}^3_{znt}|^2+\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma znt}\right)Jdz+\|\tilde{u}_{znnt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}}\\
&\quad\le\delta_{20}\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+c\|\tilde{u}_{z\tau\tau t}\|^2_{0,\hat{\Omega}}+(\delta_{21}+cd)(\|\tilde{u}_{zzzt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma zzt}\|^2_{0,\hat{\Omega}})\\
&\qquad+a_{36}(|\hat{u}|^2_{3,1,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}}+|\tilde{g}|^2_{2,1,\hat{\Omega}})+a_{37}X_{10}(\hat{\Omega})(1+X^2_{10}(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}
\tag{4.172}
$$

To obtain a full derivative $\tilde{u}_{zzt}$ under the integral over $\hat{\Omega}$ and under derivative with respect to time, we need the following:

$$
\begin{aligned}
\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}\tilde{u}^2_{zzt}Jdz&\le\delta_{22}\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+c\|\tilde{u}_{zzt}\|^2_{0,\hat{\Omega}}\\
&\quad+c(\|\hat{u}\|^2_{3,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,1,\hat{\Omega}})|\hat{u}|^2_{3,2,\hat{\Omega}}.
\end{aligned}
\tag{4.173}
$$

From (4.163), (4.172), and (4.173) we obtain for sufficiently small δ and d,

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\left(\hat{\eta}\tilde{u}_{zzt}^2+\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}_{\sigma zzt}^2\right)Jdz+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat{S}}g^{\alpha\beta}\tilde{u}_{\tau\tau^\alpha}\cdot\bar{n}\tilde{u}_{\tau\tau^\beta}\cdot\bar{n}Jdz'\\
&\qquad+\|\tilde{u}_{zzzt}\|_{0,\hat{\Omega}}^2+\|\tilde{q}_{\sigma zzt}\|_{0,\hat{\Omega}}^2\\
&\qquad\le\delta_{23}\Bigg(\|\hat{u}_{zzzz}\|_{0,\hat{\Omega}}^2+\|\hat{u}_{zztt}\|_{0,\hat{\Omega}}^2+\|\hat{u}_{zzzt}\|_{0,\hat{\Omega}}^2\\
&\qquad+\|\hat{q}_{\sigma zzt}\|_{0,\hat{\Omega}}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{0,S^1}^2\Bigg)\\
&\qquad+a_{38}(|\hat{u}|_{3,1,\hat{\Omega}}^2+|\hat{q}_\sigma|_{2,1,\hat{\Omega}}^2+|\tilde{g}|_{2,1,\hat{\Omega}}^2)\\
&\qquad+a_{39}X_{10}(\hat{\Omega})(1+X_{10}^2(\hat{\Omega}))Y_{10}(\hat{\Omega}).
\end{aligned}
\tag{4.174}
$$

Going back to the variables ξ in (4.174) and using (4.160), we sum the inequalities over all neighborhoods of the partition of unity. Then, going back to the variables x in the followed estimate and using smallness of δ_{23}, we obtain (4.156). This concludes the proof.

To estimate the first term in the right-hand side of (4.156) we need the following result.

LEMMA 4.11. *For a sufficiently smooth solution of the problem* (4.1a–c) *the following inequality holds*:

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v_{xtt}^2+\frac{\mu+\nu}{p\Psi(\rho)}q_{\sigma xtt}^2\right)dx+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar{n}\cdot v_{tss^\alpha}\bar{n}\cdot v_{tss^\beta}ds\\
&\qquad+\|v_{tt}\|_{2,\Omega_t}^2+\|p_{\sigma tt}\|_{1,\Omega_t}^2\\
&\qquad\le\varepsilon_{11}\left(\|v_{xxxt}\|_{0,\Omega_t}^2+\|v_{xttt}\|_{0,\Omega_t}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{0,S^1}^2\right)\\
&\qquad+P_{23}(|v|_{3,0,\Omega_t}^2+|p_\sigma|_{2,0,\Omega_t}^2+|f|_{2,0,\Omega_t}^2)+P_{24}X_{11}(1+X_{11}^2)Y_{11},
\end{aligned}
\tag{4.175}
$$

where

$$
\begin{aligned}
X_{11}&=|v|_{3,0,\Omega_t}^2+|p_\sigma|_{3,0,\Omega_t}^2+\int_0^t\|v\|_{3,\Omega_\tau}^2d\tau,\\
Y_{11}&=|v|_{4,1,\Omega_t}^2+|p_\sigma|_{3,0,\Omega_t}^2+\int_0^t\|v\|_{4,\Omega_t}^2d\tau.
\end{aligned}
\tag{4.176}
$$

Proof. We also use the partition of unity. First we consider interior subdomains. Differentiating (4.27a) twice with respect to t and once with respect to ξ; multiplying

the result by $\tilde{u}_{tt\xi}A$ and integrating over $\hat{\Omega}$ yields

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}}\left(\eta\tilde{u}_{tt\xi}^2+\frac{1}{q\Psi(\eta)}\tilde{q}_{\sigma tt\xi}^2\right)Ad\xi\\
&\quad+\frac{\mu}{2}\int_{\tilde{\Omega}}(\nabla_{u^i}\tilde{u}_{tt\xi}^j+\nabla_{u^j}\tilde{u}_{tt\xi}^i)^2Ad\xi+(\nu-\mu)\|\nabla_u\cdot\tilde{u}_{tt\xi}\|_{0,\tilde{\Omega}}^2\\
&\quad\le\delta_1(\|\tilde{u}_{tt\xi\xi}\|_{0,\tilde{\Omega}}^2+\|\tilde{q}_{\sigma tt\xi}\|_{0,\tilde{\Omega}}^2)+a_1(|u|_{3,1,\tilde{\Omega}}^2+|q_\sigma|_{2,0,\tilde{\Omega}}^2+|\tilde{g}|_{2,0,\tilde{\Omega}}^2)\\
&\qquad+a_2X_{11}(\tilde{\Omega})(1+X_{11}^2(\tilde{\Omega}))Y_{11}(\tilde{\Omega}),
\end{aligned}\tag{4.177}$$

where

$$X_{11}(\tilde{\Omega})=|u|_{3,0,\tilde{\Omega}}^2+|q_\sigma|_{3,0,\tilde{\Omega}}^2+\int_{\tilde{\Omega}}\|u\|_{3,\tilde{\Omega}}^2dt,$$

$$Y_{11}(\tilde{\Omega})=|u|_{4,1,\tilde{\Omega}}^2+|q_\sigma|_{3,0,\tilde{\Omega}}^2+\int_{\tilde{\Omega}}\|u\|_{4,\tilde{\Omega}}^2dt.$$

We have also used the fact that

$$-\int_{\tilde{\Omega}}\tilde{q}_{\sigma tt\xi}\nabla_u\cdot\tilde{u}_{tt\xi}Ad\xi=\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}}\frac{1}{q\Psi(\eta)}\tilde{q}_{\sigma tt\xi}^2Ad\xi+N_1,$$

$$\left|\int_{\tilde{\Omega}}[(\nabla_u\nabla_u\tilde{u})_{,tt\xi}-\nabla_u\nabla_u\tilde{u}_{tt\xi}]\cdot\tilde{u}_{tt\xi}Ad\xi+\int_{\tilde{\Omega}}[(\nabla_u\tilde{q}_\sigma)_{,tt\xi}-\nabla_u\tilde{q}_{\sigma tt\xi}]\cdot\tilde{u}_{tt\xi}Ad\xi\right|$$

$$\le\delta_2\|\tilde{u}_{tt\xi\xi\xi}\|_{0,\tilde{\Omega}}^2+a_3X_{11}(\tilde{\Omega})(1+X_{11}^2(\tilde{\Omega}))Y_{11}(\tilde{\Omega}),$$

where

$$|N_1|\le\delta_3\|\tilde{q}_{\sigma tt\xi}\|_{0,\tilde{\Omega}}^2+a_4|\hat{u}|_{3,1,\hat{\Omega}}^2+a_5X_{11}(\tilde{\Omega})(1+X_{11}^2(\tilde{\Omega}))Y_{11}(\tilde{\Omega}).$$

From (4.34) we obtain

$$\begin{aligned}
\|\tilde{u}_{tt}\|_{2,\tilde{\Omega}}^2+\|\tilde{q}_{\sigma tt}\|_{1,\tilde{\Omega}}^2\le{}&c\|u_{zztt}\|_{0,\tilde{\Omega}}^2\\
&+a_6(|u|_{3,0,\tilde{\Omega}}^2+|q_\sigma|_{2,0,\tilde{\Omega}}^2+|\tilde{g}|_{2,0,\tilde{\Omega}}^2)\\
&+a_7X_{11}(\tilde{\Omega})(1+X_{11}^2(\tilde{\Omega}))Y_{11}(\tilde{\Omega}).
\end{aligned}\tag{4.178}$$

Now from (4.177) and (4.178) for sufficiently small δ_1 and Lemma 5.1 from [35] for $G=\tilde{\Omega}$ and $v=\tilde{u}_{tt\xi}$, we get

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\tilde{\Omega}}\left(\eta\tilde{u}_{tt\xi}^2+\frac{1}{q\Psi(\eta)}\tilde{q}_{\sigma tt\xi}^2\right)Ad\xi+\|\tilde{u}_{tt}\|_{2,\tilde{\Omega}}^2+\|\tilde{q}_{\sigma tt}\|_{1,\tilde{\Omega}}^2\\
&\quad\le a_8(|u|_{3,0,\tilde{\Omega}}^2+|q_\sigma|_{2,0,\tilde{\Omega}}^2+|\tilde{g}|_{2,0,\tilde{\Omega}}^2)+a_9X_{11}(\tilde{\Omega})(1+X_{11}^2(\tilde{\Omega}))Y_{11}(\tilde{\Omega}).
\end{aligned}\tag{4.179}$$

Consider the boundary subdomains. Differentiating (4.28a) twice with respect to t and once with respect to τ, multiplying the result by $\tilde{u}_{tt\tau}J$, and integrating over $\hat{\Omega}$

gives

$$\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left[\hat\eta\tilde u_{tt\tau}^2+\frac{1}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma tt\tau}^2\right]Jdz+\|\tilde u_{tt\tau}\|_{1,\hat\Omega}^2$$

$$+(\nu-\mu)\|(\operatorname{div}\tilde u)_{,tt\tau}\|_{0,\hat\Omega}^2-\int_{\hat S}(\hat n\hat{\mathbb{T}}(\tilde u,\tilde q_\sigma))_{,tt\tau}\cdot\tilde u_{tt\tau}Jdz'$$

$$\le\delta_4(\|\tilde q_{\sigma tt\tau}\|_{0,\hat\Omega}^2+\|\tilde u_{zztt}\|_{0,\hat\Omega}^2) \tag{4.180}$$

$$+a_{10}(|\hat u|_{3,0,\hat\Omega}^2+|q_\sigma|_{2,0,\hat\Omega}^2+|\tilde g|_{2,0,\hat\Omega}^2)$$

$$+a_{11}X_{11}(\hat\Omega)(1+X_{11}^2(\hat\Omega))Y_{11}(\hat\Omega),$$

where we have used Lemma 5.1 from [35] in the case $G=\hat\Omega$, $v=\tilde u_{tt\tau}$, and

$$\left|\int_{\hat\Omega}[(\hat\nabla\hat{\mathbb{T}}(\tilde u,\tilde q_\sigma))_{,tt\tau}-\hat\nabla\hat{\mathbb{T}}(\tilde u_{tt\tau},\tilde q_{\sigma tt\tau})]\tilde u_{tt\tau}Jdz\right|$$

$$\le\delta_5(\|\tilde u_{zztt}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma ztt}\|_{0,\hat\Omega}^2)+a_{12}|\tilde u|_{3,1,\hat\Omega}^2+a_{13}X_{11}(\hat\Omega)(1+X_{11}^2(\hat\Omega))Y_{11}(\hat\Omega),$$

$$\int_{\hat\Omega}\hat\nabla\cdot\tilde u_{tt\tau}\tilde q_{\sigma tt\tau}Jdz=-\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\frac{1}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma tt\tau}^2Jdz+N_2,$$

and

$$|N_2|\le\delta_6\|\tilde q_{\sigma tt\tau}\|_{0,\hat\Omega}^2+a_{14}|\hat u|_{3,1,\hat\Omega}^2+a_{15}X_{11}(\hat\Omega)(1+X_{11}^2(\hat\Omega))Y_{11}(\hat\Omega).$$

Moreover, $X_{11}(\hat\Omega)$, $Y_{11}(\hat\Omega)$ are obtained from $X_{11}(\tilde\Omega)$, $Y_{11}(\tilde\Omega)$, replacing u, q_σ, $\tilde\Omega$, by $\hat u$, $\hat q_\sigma$, $\hat\Omega$, respectively.

Employing the boundary condition (4.28c) the boundary term in (4.180) can be expressed in the following way:

$$\int_{\hat S}(\hat n\hat{\mathbb{T}}(\tilde u,\tilde q_\sigma))_{,tt\tau}\cdot\tilde u_{tt\tau}Jdz'\le-\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}g^{\alpha\beta}\bar n\cdot\tilde u_{tss^\alpha}\bar n\cdot\tilde u_{tss^\beta}Jdz'+N_3, \tag{4.181}$$

where

$$|N_3|\le\delta_7\left(\|\hat u_{ztt\tau}\|_{0,\hat\Omega}^2+\|\hat u_{zzzt}\|_{0,\hat\Omega}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{2,S^1}^2\right)+a_{16}|\hat u|_{3,1,\hat\Omega}^2$$

$$+a_{17}X_{11}(\hat\Omega)(1+X_{11}(\hat\Omega))Y_{11}(\hat\Omega).$$

From (4.180) and (4.181) we obtain for sufficiently small δ_7,

(4.182)

$$\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left(\hat\eta\tilde u_{tt\tau}^2+\frac{1}{\hat q\Psi(\hat\eta)}\tilde q_{\sigma tt\tau}^2\right)Jdz'+\frac{\sigma}{2}\frac{d}{dt}\int_{\hat S}g^{\alpha\beta}\bar n\cdot\tilde u_{tss^\alpha}\bar n\cdot\tilde u_{tss^\beta}Jdz'$$

$$+\|\tilde u_{tt\tau}\|_{1,\hat\Omega}^2+(\nu-\mu)\|(\operatorname{div}\tilde u)_{,tt\tau}\|_{0,\hat\Omega}^2$$

$$\le\delta_8\left(\|\hat u_{ztt\tau}\|_{0,\hat\Omega}^2+\|\hat u_{zzzt}\|_{0,\hat\Omega}^2+\|\tilde q_{\sigma tt\tau}\|_{0,\hat\Omega}^2+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|_{2,S^1}^2\right)$$

$$+a_{18}(|\hat u|_{3,0,\hat\Omega}^2+|\hat q_\sigma|_{2,0,\hat\Omega}^2+|\tilde g|_{2,0,\hat\Omega}^2)+a_{19}X_{11}(\hat\Omega)(1+X_{11}^2(\hat\Omega))Y_{11}(\hat\Omega)).$$

Differentiating the third component of (4.42) twice with respect to t, multiplying the result by $\tilde{q}_{\sigma ntt}J$, and integrating over $\hat{\Omega}$ implies

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\frac{\mu+\nu}{\hat{q}\Psi(\hat{\eta})}\tilde{q}^2_{\sigma ntt}Jdz+\frac{1}{2}\|\tilde{q}_{\sigma ntt}\|^2_{0,\hat{\Omega}}\\
&\quad\le c\|\tilde{u}_{z\tau tt}\|^2_{0,\hat{\Omega}}\\
&\quad\quad+(\delta_9+cd)(\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma ztt}\|^2_{0,\hat{\Omega}})\\
&\quad\quad+a_{20}(|\hat{u}|^2_{3,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,0,\hat{\Omega}}+|\tilde{g}|^2_{2,0,\hat{\Omega}})\\
&\quad\quad+a_{21}X_{11}(\hat{\Omega})(1+X^2_{11}(\hat{\Omega}))Y_{11}(\hat{\Omega}).
\end{aligned}\tag{4.183}$$

Differentiating the third component of (4.44) twice with respect to t, multiplying the result by $\tilde{u}^3_{nntt}J$, and integrating over $\hat{\Omega}$, we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat{\Omega}}\hat{\eta}|\tilde{u}^3_{nnt}|^2Jdz+\frac{\mu+\nu}{2}\|\tilde{u}^3_{nnnt}\|^2_{0,\hat{\Omega}}\\
&\quad\le c(\|\tilde{u}_{z\tau tt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma ntt}\|^2_{0,\hat{\Omega}})+\delta_{10}\|\tilde{u}_{ztttt}\|^2_{0,\hat{\Omega}}\\
&\quad\quad+(\delta_{11}+cd)(\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma ztt}\|^2_{0,\hat{\Omega}})\\
&\quad\quad+a_{22}(|\hat{u}|^2_{3,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,0,\hat{\Omega}}+|\tilde{g}|^2_{2,0,\hat{\Omega}})+a_{23}X_{11}(\hat{\Omega})(1+X^2_{11}(\hat{\Omega}))Y_{11}(\hat{\Omega}).
\end{aligned}\tag{4.184}$$

From the problem (4.46)–(4.48) we have

$$\begin{aligned}
&\|\tilde{u}'_{z\tau tt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma\tau tt}\|^2_{0,\hat{\Omega}}\\
&\quad\le(\delta_{12}+cd)\,(\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma ztt}\|^2_{0,\hat{\Omega}})\\
&\quad\quad+c\|\mathrm{div}\;\tilde{u}_{tt}\|^2_{1,\hat{\Omega}}+a_{24}(|\hat{u}|^2_{3,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,0,\hat{\Omega}}+|\tilde{g}|^2_{2,0,\hat{\Omega}})\\
&\quad\quad+a_{25}X_{11}(\hat{\Omega})(1+X^2_{11}(\hat{\Omega}))Y_{11}(\hat{\Omega}).
\end{aligned}\tag{4.185}$$

Moreover, from (4.46) it follows

$$\begin{aligned}
\|\tilde{u}'_{nntt}\|^2_{0,\hat{\Omega}}&\le c\,(\|(\mathrm{div}\;\tilde{u})_{,\tau tt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma\tau tt}\|^2_{0,\hat{\Omega}})\\
&\quad+(\delta_{13}+cd)(\|\tilde{u}_{zztt}\|^2_{0,\hat{\Omega}}+\|\tilde{q}_{\sigma ztt}\|^2_{0,\hat{\Omega}})\\
&\quad+a_{26}(|\hat{u}|^2_{3,0,\hat{\Omega}}+|\hat{q}_\sigma|^2_{2,0,\hat{\Omega}}+|\tilde{g}|^2_{2,0,\hat{\Omega}})+a_{27}X_{11}(\hat{\Omega})(1+X^2_{11}(\hat{\Omega}))Y_{11}(\hat{\Omega}).
\end{aligned}\tag{4.186}$$

Summarizing from (4.183)–(4.186) we have

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left(\hat\eta|\tilde u^3_{ntt}|^2+\frac{\mu+\nu}{\hat q\Psi(\hat\eta)}\tilde q^2_{\sigma ntt}\right)Jdz+\|\tilde u_{zztt}\|^2_{0,\hat\Omega}+\|\tilde q_{\sigma ztt}\|^2_{0,\hat\Omega}\\
&\quad\le\delta_{14}\|\tilde u_{ttt}\|^2_{1,\hat\Omega}+(\delta_{15}+cd)(\|\tilde u_{zztt}\|^2_{0,\hat\Omega}+\|\tilde q_{\sigma ztt}\|^2_{0,\hat\Omega})\\
&\qquad+c\|\tilde u_{z\tau tt}\|^2_{0,\hat\Omega}+a_{28}(|\hat u|^2_{3,0,\hat\Omega}+|\hat q_\sigma|^2_{2,0,\hat\Omega}+|\tilde g|^2_{2,0,\hat\Omega})\\
&\qquad+a_{29}X_{11}(\hat\Omega)(1+X^2_{11}(\hat\Omega))Y_{11}(\hat\Omega).
\end{aligned}
\tag{4.187}
$$

Finally, using the inequality

$$
\begin{aligned}
\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\hat\eta\tilde u^2_{ztt}Jdz&\le\delta_{16}\|\tilde u_{ttt}\|^2_{1,\hat\Omega}+c\|\tilde u_{tt}\|^2_{1,\hat\Omega}\\
&\quad+c(\|\hat u\|^2_{3,\hat\Omega}+|\hat q_\sigma|^2_{3,2,\hat\Omega})\|u_{ztt}\|^2_{0,\hat\Omega}.
\end{aligned}
\tag{4.188}
$$

From (4.182) and (4.187) we obtain

(4.189)

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\hat\Omega}\left(\hat\eta\tilde u^2_{ztt}+\frac{\mu+\nu}{\hat q\Psi(\hat\eta)}\tilde q^2_{\sigma ztt}\right)Jdz+\|\tilde u_{tt}\|^2_{2,\hat\Omega}+\|\tilde q_{\sigma tt}\|^2_{1,\hat\Omega}\\
&\quad\le\delta_{17}\left(\|\tilde u_{zzzt}\|^2_{0,\hat\Omega}+\|\tilde u_{ztttt}\|^2_{0,\hat\Omega}+\|\hat u_{zztt}\|^2_{0,\hat\Omega}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}\right)\\
&\qquad+a_{30}(|\hat u|^2_{3,0,\hat\Omega}+|\hat q_\sigma|^2_{2,0,\hat\Omega}+|\tilde g|^2_{2,0,\hat\Omega})+a_{31}X_{11}(\hat\Omega)(1+X^2_{11}(\hat\Omega))Y_{11}(\hat\Omega).
\end{aligned}
$$

Going back to the variables ξ in (4.189), then summing the result and (4.180) over all neighborhoods of the partition of unity, we finally obtain (4.175) after going back to the variables x and assuming that δ_{17} is sufficiently small. This concludes the proof.

Finally, to obtain an estimate for the second term in the right-hand side of the inequality (4.175) we have to show the result.

LEMMA 4.12. *For a sufficiently smooth solution of the problem* (4.1a–c) *we have*

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v^2_{ttt}+\frac{1}{p\Psi(\rho)}p^2_{\sigma ttt}\right)dx+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar n\cdot v_{tts^\alpha}\bar n\cdot v_{tts^\beta}ds\\
&\qquad+\|v_{ttt}\|^2_{1,\Omega_t}+\|p_{\sigma ttt}\|^2_{0,\Omega_t}\\
&\quad\le c\|v_{xtt}\|^2_{0,\Omega_t}+P_{25}(|v|^2_{3,0,\Omega_t}+\|f_{ttt}\|^2_{0,\Omega_t}+|f|^2_{2,0,\Omega_t})\\
&\qquad+P_{26}X_{12}(1+X^3_{12})Y_{12},
\end{aligned}
\tag{4.190}
$$

where $X_{12}=|v|^2_{3,0,\Omega_t}+|p_\sigma|^2_{3,0,\Omega_t}$, $Y_{12}=|v|^2_{4,1,\Omega_t}+|p_\sigma|^2_{3,0,\Omega_t}$.

Proof. Differentiating (4.1a) three times with respect to t, multiplying the result by v_{ttt}, integrating over Ω_t and using Lemma 5.5 from [35], we obtain

$$
\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_{\Omega_t}\left(\rho v^2_{ttt}+\frac{1}{p\Psi(\rho)}p^2_{\sigma ttt}\right)dx+\|v_{ttt}\|^2_{1,\Omega_t}\\
&\qquad-\int_{S_t}(n_iT^{ij}(v,p_\sigma))_{,ttt}\cdot v^j_{ttt}ds\le\delta_1\|v_{ttt}\|^2_{0,\Omega_t}\\
&\qquad+c(\|f_{ttt}\|^2_{0,\Omega_t}+|f|^2_{2,0,\Omega_t})+cX_{12}(1+X^3_{12})Y_{12},
\end{aligned}
\tag{4.191}
$$

where by the boundary condition (4.1c) the boundary term has the form

$$-\int_{S_t}(n_iT^{ij}(v,p_\sigma))_{,ttt}\,v^i_{ttt}ds=\frac{\sigma}{2}\frac{d}{dt}\int_{S_t}g^{\alpha\beta}\bar{n}\cdot v_{tts^\alpha}\bar{n}\cdot v_{tts^\beta}ds+N_1, \tag{4.192}$$

where

$$|N_1|\le\delta_2(\|v_{tttx}\|^2_{0,\Omega_t}+\|v_{ttxx}\|^2_{0,\Omega_t})+a_1|v|^2_{3,0,\Omega_t}+a_2X_{12}(1+X_{12}^2)Y_{12}.$$

By (4.2) we have

$$\|p_{\sigma ttt}\|^2_{0,\Omega_t}\le c\|v_{xtt}\|^2_{0,\Omega_t}+cX_{12}(1+X_{12}^2)Y_{12}. \tag{4.193}$$

Therefore, from (4.191)–(4.193) we obtain (4.190). This concludes the proof.

From the above lemmas for sufficiently small ε's we have the following result.

THEOREM 4.13. *Let*

$$\begin{aligned}\varphi(t)\equiv&\frac{1}{2}\int_{\Omega_t}\left(\rho|v|^2_{3,0}+\frac{1}{p\Psi(\rho)}|p_\sigma|^2_{3,0}\right)dx\\&+\frac{\sigma}{2}\int_{S_t}\tilde{\delta}^{\alpha\beta}\sum_{|k|\le2}\bar{n}\cdot\int_0^t\partial_s^kv_{s_1s^\alpha}dt'\bar{n}\cdot\int_0^t\partial_s^kv_{s_1s^\beta}dt'ds\\&+\frac{\sigma}{2}\int_{S_t}\sum_{|k|\le2}\left|\bar{n}\cdot\int_0^t\partial_s^kv_{s^1s^2}dt'\right|^2ds\\&+\frac{\sigma}{2}\int_{S_t}\sum_{|k|\le2}\sum_{i=1}^2\left(\frac{1}{2}\bar{n}\cdot\int_0^t\partial_s^kv_{s^is^i}dt'+2\partial_s^k\left(H(\cdot,0)+\frac{2}{R_0}\right)\right)^2ds\\&+\frac{\sigma}{2}\int_{S_t}g^{\alpha\beta}\left(\bar{n}\cdot\int_0^tv_{s^\alpha}dt'\bar{n}\cdot\int_0^tv_{s^\beta}dt'\right.\\&\qquad\left.+\sum_{|k|\le2}D^k_{t,s}v_{s^\alpha}\cdot\bar{n}D^k_{t,s}v_{s^\beta}\cdot\bar{n}\right)ds,\end{aligned} \tag{4.194}$$

$$\Phi_0(t)\equiv|v|^2_{4,1,\Omega_t}+|p_\sigma|^2_{3,0,\Omega_t},$$

$$\psi(t)\equiv\|v\|^2_{0,\Omega_t}+\|p_\sigma\|^2_{0,\Omega_t}+\|R(\cdot,t)-R(\cdot,0)\|^2_{0,S^1}.$$

For sufficiently smooth solutions of the problem (4.1a–c) *the following estimate holds*:

(4.195)

$$\begin{aligned}&\frac{d}{dt}\varphi+\Phi_0(t)\\&\quad\le c_1P(X)X(1+X^3)Y+c_2F+c_3\psi(t)\\&\qquad+c_4\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{2,S^1}+\delta_1c_5\left(\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}\right)\\&\qquad+c_6\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^tvd\tau\right\|^2_{3,S_t}\right.\\&\qquad\qquad\left.+\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^tvd\tau\right\|^2_{4,S_t}\right),\end{aligned}$$

where $c_1, i = 1\text{–}6$ *depend on* ρ_*, ρ^*, T, a, b, *constants from theorems of imbedding and Korn inequalities* (*see* §5 *in* [35]); δ_1 *then is a small parameter, and*

$$
\begin{aligned}
X &= |v|^2_{3,0,\Omega_t} + |p_\sigma|^2_{3,0,\Omega_t} + \int_0^t \|v\|^2_{3,\Omega_{t'}} dt', \\
Y &= |v|^2_{4,1,\Omega_t} + |p_\sigma|^2_{3,0,\Omega_t} + \int_0^t \|v\|^2_{4,\Omega_{t'}} dt', \\
F &= |f|^2_{2,0,\Omega_t} + \|f_{ttt}\|^2_{0,\Omega_t}.
\end{aligned} \tag{4.196}
$$

Repeating the proof of Theorem 4.13 in the proper way we obtain the following.

THEOREM 4.14. *For sufficiently smooth solutions of the problem* (4.1a–c) *we have*

$$
\begin{aligned}
&\frac{d}{dt}\varphi(t) + \Phi_0(t) \\
&\quad \le c_7 P\left(\varphi_0 + \int_0^t \|v\|^2_{4,\Omega_t} d\tau\right)\left(\varphi_0 + \int_0^t \|v\|^2_{4,\Omega_t} d\tau\right) \\
&\quad \cdot \left[1 + \left(\varphi_0 + \int_0^t \|v\|^2_{4,\Omega_\tau} d\tau\right)^3\right] \Phi_0 + c_8 F + c_9 \psi(t) \\
&\qquad + c_{10} \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^4_{2,S^1} \\
&\qquad + \delta_2 c_{11} \left(\left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{2,S^1} + \|R(\cdot,t) - R(\cdot,0)\|^2_{4,S^1} \right) \\
&\qquad + c_{12} \left(\|R(\cdot,t) - R(\cdot,0)\|^2_{4+1/2,S^1} \left\| \int_0^t v d\tau \right\|^2_{3,S_t} \right. \\
&\qquad\qquad \left. + \|R(\cdot,t) - R(\cdot,0)\|^2_{3,S^1} \left\| \int_0^t v d\tau \right\|^2_{4,S_t} \right),
\end{aligned} \tag{4.197}
$$

where δ_2 *is a small parameter,* c_7–c_{12} *have the same properties as in Theorem* 4.13 *and*

$$
\varphi_0(t) = |v|^2_{3,2,\Omega_t} + |p_\sigma|^2_{3,2,\Omega_t}. \tag{4.198}
$$

5. Global existence. Let us introduce the spaces

$$
\mathcal{M}(t) = \left\{ (v, p_\sigma) : \varphi(t) + \int_0^t \Phi_0(\tau) d\tau < \infty \right\},
$$

and

$$
\mathcal{N}(t) = \{(v, p_\sigma) : \varphi(t) < \infty\},
$$

where $\varphi(t)$ and $\Phi_0(t)$ are defined in (4.194).

In this section, to prove the global existence of the solutions, we assume that the external force vanishes, so that

$$
f = 0. \tag{5.1}
$$

First we prove the following.

LEMMA 5.1. *Let the initial data* $v_0, p_{\sigma 0}, S$ *of* (1.1a–e) *be such that* $(v(0), p_\sigma(0)) \in \mathcal{N}(0)$ *and* $S \in H^{4+1/2}$. *Let*

$$\int_\Omega \rho_0 v_0 \cdot \eta dx = 0, \qquad \int_\Omega \rho_0 x dx = 0,$$

where $\eta = a + b \times x$, *and* a, b *are constant vectors.*

Let the initial data $v_0, p_{\sigma 0}, S$ *and the parameters of* (1.1a–e) $(p_0, \sigma, d, A, \kappa, M)$ *be such that*

$$\begin{aligned} &\varphi(0) \le \varepsilon_1, \qquad \chi(0) \equiv \left\| H(\cdot, 0) + \frac{2}{R_0} \right\|^2_{2+1/2, S^1} \le \varepsilon_2, \\ &\vartheta(t) \equiv \sup_{\tau \le t} \|R(\cdot, \tau) - R_0\|^2_{0, S^1} \le c_0 \varepsilon_0, \qquad t \le T, \end{aligned} \tag{5.2}$$

where $\varepsilon_0, \varepsilon_1, \varepsilon_2$ *are sufficiently small* (ε_0 *appears in Remark* 2.7—*see* (2.65)).

Then there exists a local solution of problem (1.1a–e) *such that* $v, p_\sigma \in \mathcal{M}(t), t \le T$, *where* T *is the time of local existence* (*see Theorem* 3.1) *and*

$$\varphi(t) + \int_0^t \Phi_0(\tau) d\tau \le c_1(\varphi(0) + \chi(0) + \vartheta(t)) \equiv c_1 A \le c_1(\varepsilon_0 + \varepsilon_1 + \varepsilon_2). \tag{5.3}$$

Moreover, we have that $S_t \in H^{4+1/2}$.

Proof. Take

$$v_0, p_{\sigma 0} \in H^3(\Omega), \qquad S \in H^{4+1/2} \tag{5.4}$$

such that the assumptions of the lemma hold. Then, in view of Theorem 3.1 and Remark 3.2 there exists a local solution of (1.1) such that

$$u \in W_2^{4,2}(\Omega^T), \qquad q_\sigma \in W_2^{3,3/2}(\Omega^T) \cap C(0, T; \Gamma_0^{3,3/2}(\Omega)), \tag{5.5}$$

where T is the time of local existence. Next, in view of Theorem 2.5, $S_t \in H^{4+1/2}$. Moreover, (3.6) implies

$$\begin{aligned} &\|u\|_{4,\Omega^T} + \|q_\sigma\|_{3,\Omega^T} + |q_\sigma|_{3,0,\infty,\Omega^T} \\ &\qquad \le c \left(\|v_0\|_{3,\Omega} + \|p_{\sigma 0}\|_{3,\Omega} + \left\| H(\cdot, 0) + \frac{2}{R_0} \right\|_{2+1/2, S^1} \right) \\ &\qquad \le c(\varphi(0) + \chi(0)) \le c(\varepsilon_1 + \varepsilon_2), \end{aligned} \tag{5.6}$$

where the last inequality follows from (5.2) and v, p_σ in (5.6) are written in the Lagrangian coordinates, so $u(\xi, t) = v(x(\xi, t), t)$, $q_\sigma(\xi, t) = p_\sigma(x(\xi, t), t)$.

Integrating the equation of continuity we have

$$\eta(\xi, t) = \rho_0(\xi) \exp\left[- \int_0^t \operatorname{div}_u u \, d\tau \right];$$

so, using (5.6), we have that $\eta_{tt} \in L_\infty(0,T;L_2(\Omega)) \cap L_2(0,T;H^1(\Omega))$, $\eta_t \in L_\infty(0,T;H^2(\Omega)) \cap L_2(0,T;H^3(\Omega))$, and the following estimates are valid:

$$\begin{aligned} &\sup_t (\|\eta_{tt}\|^2_{0,\Omega} + \|\eta_t\|^2_{2,\Omega} + \|\eta\|^2_{3,\Omega}) \\ &\qquad + \|\eta_{tt}\|^2_{1,2,\Omega^T} + \|\eta_t\|^2_{3,2,\Omega^T} \\ &\quad \le \varphi_1(T, \varphi(0) + \chi(0))(\varphi(0) + \chi(0)) \\ &\quad \le c(\varepsilon_1 + \varepsilon_2). \end{aligned} \tag{5.7}$$

Writing (4.2) in the Lagrangian coordinates, we have

$$q_{\sigma t} + q\Psi(\eta)\mathrm{div}_u u = 0;$$

so integration with respect to time yields

$$q_\sigma = q_\sigma(0) - \int_0^t q\Psi(\eta)\mathrm{div}_u u d\tau. \tag{5.8}$$

Using the estimate (5.6) for the local solutions we also obtain that q_σ belongs to the same spaces as η above and the following estimate for solution (5.8) holds:

$$\begin{aligned} N_1 \equiv &\sup_t (\|q_{\sigma tt}\|^2_{0,\Omega} + \|q_{\sigma t}\|^2_{2,\Omega} + \|q_\sigma\|^2_{3,\Omega}) \\ &+ \|q_{\sigma tt}\|^2_{1,2,\Omega^T} + \|q_{\sigma t}\|^2_{3,2,\Omega^T} \\ &\le \varphi_2(T, \varphi(0) + \chi(0))(\varphi(0) + \chi(0)) \\ &\le c(\varepsilon_1 + \varepsilon_2). \end{aligned} \tag{5.9}$$

In the above considerations we have used the imbeddings

$$\begin{aligned} N_2 &\equiv \sup_t (\|u\|^2_{3,\Omega} + \|u_t\|^2_{1,\Omega}) \\ &\le c(\|u\|^2_{4,\Omega^T} + \|u(0)\|^2_{3,\Omega} + |u(0)|^2_{1,0,\Omega}) \\ &\le c(\varphi(0) + \chi(0)) \le c(\varepsilon_1 + \varepsilon_2), \end{aligned} \tag{5.10}$$

and

$$\begin{aligned} \int_0^t |u_x|_{\infty,\Omega} d\tau &\le cT^{1/2} \left(\int_0^t \|u\|^2_{3,\Omega} d\tau \right)^{1/2} \le cT^{1/2} \|u\|_{4,\Omega^T} \\ &\le cT^{1/2}(\varphi(0) + \chi(0)) \le c(\varepsilon_1 + \varepsilon_2). \end{aligned} \tag{5.11}$$

By repeating the proof of Lemma 4.10, we have

$$\begin{aligned} &\frac{d}{dt} \|v_{xxt}\|^2_{0,\Omega_t} + \frac{\sigma}{2} \frac{d}{dt} \int_{S_t} g^{\alpha\beta} \bar{n} \cdot v_{sss^\alpha} \bar{n} \cdot v_{sss^\beta} ds \\ &\quad + \|v_{xxt}\|^2_{1,\Omega_t} \le (\varepsilon_1' + cN) \|v_{xttt}\|^2_{0,\Omega_t} + c \left(N, \int_0^T M(\tau) d\tau \right) M, \end{aligned} \tag{5.12}$$

where $N = N_1 + N_2$ and M is such an expression that

$$\int_0^t M d\tau \le c(\varphi(0) + \chi(0))$$

holds in virtue of the estimates for the local solution.

Similarly, using Lemma 4.11, we have

$$\begin{aligned}
&\frac{d}{dt}\left(\|v_{xtt}\|^2_{0,\Omega_t}+\|p_{\sigma xtt}\|^2_{0,\Omega_t}\right)+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot v_{tss^\alpha}\bar{n}\cdot v_{tss^\beta}ds\\
&\qquad+\|v_{xtt}\|^2_{1,\Omega_t}+\|p_{\sigma xtt}\|^2_{0,\Omega_t}\\
&\quad\le(\varepsilon_2'+cN)(\|v_{xttt}\|^2_{0,\Omega_t}+\|v_{xxtt}\|^2_{0,\Omega_t}+\|v_{xxxt}\|^2_{0,\Omega_t})\\
&\qquad+c\|v_{ttt}\|^2_{0,\Omega_t}+c\left(N,\int_0^T M(\tau)d\tau\right)M.
\end{aligned}\tag{5.13}$$

Finally, Lemma 4.12 implies

$$\begin{aligned}
&\frac{d}{dt}\|v_{ttt}\|^2_{0,\Omega_t}+\frac{\sigma}{2}\frac{d}{dt}\int_{S_t} g^{\alpha\beta}\bar{n}\cdot v_{tts^\alpha}\bar{n}\cdot v_{tts^\beta}ds\\
&\qquad+\|v_{ttt}\|^2_{1,\Omega_t}\le\varepsilon_3'\|v_{xxtt}\|^2_{0,\Omega_t}+cM\|v_t\|^2_{2,\Omega_t}+c(N)M,
\end{aligned}\tag{5.14}$$

where in virtue of the equation of continuity (4.2) we have

$$\|p_{\sigma ttt}\|^2_{0,\Omega_t}\le c\|v_{xtt}\|^2_{0,\Omega_t}+c(N)M.$$

From (5.12)–(5.14) and the last inequality we obtain for sufficiently small $\varepsilon_1',\varepsilon_2',\varepsilon_3'$, N and $\int_0^T Md\tau$ that

$$\begin{aligned}
&\sup_t(\|v_{xxt}\|^2_{0,\Omega_t}+\|v_{xtt}\|^2_{0,\Omega_t}+\|v_{ttt}\|^2_{0,\Omega_t}+\|p_{\sigma xtt}\|^2_{0,\Omega_t}+\|p_{\sigma ttt}\|^2_{0,\Omega_t})\\
&\quad+\sup_t\int_{S_t} g^{\alpha\beta}\left(\bar{n}\cdot v_{sss^\alpha}\bar{n}\cdot v_{sss^\beta}+\bar{n}\cdot v_{tss^\alpha}\bar{n}\cdot v_{tss^\beta}+\bar{n}\cdot v_{tts^\alpha}\bar{n}\cdot v_{tts^\beta}\right)ds\\
&\quad+\int_0^t(\|v_{xxt}\|^2_{1,\Omega_t}+\|v_{xtt}\|^2_{1,\Omega_t}+\|v_{ttt}\|^2_{1,\Omega_t})dt\le c\left(N,\int_0^t Md\tau\right).
\end{aligned}$$

Using (4.104) and (4.154) in (4.195) we have

$$\begin{aligned}
&\frac{d}{dt}\varphi+\Phi_0\\
&\quad\le c_1P(X)X(1+X^3)Y+c_2\psi(t)+c_3\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{2,S^1}\\
&\qquad+\varepsilon c_4\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1}+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}\right)\\
&\qquad+c_5(\|v\|^2_{4,\Omega_t}+\|p_\sigma\|^2_{3,\Omega_t}+\|R(\cdot,t)-R_0\|^2_{0,S^1}\\
&\qquad+\|R(\cdot,0)-R_0\|^2_{4+1/2,S^1})\int_0^t\|v\|^2_{3,\Omega_t}d\tau\\
&\qquad+c_6[\varepsilon(\|v\|^2_{4,\Omega_t}+\|p_\sigma\|^2_{3,\Omega_t})+\|R(\cdot,t)-R_0\|^2_{0,S^1}+\|R(\cdot,0)-R_0\|^2_{3,S^1}]\\
&\qquad\cdot\Bigg[\varepsilon(\|v\|^2_{4,\Omega_t}+\|p_\sigma\|^2_{3,\Omega_t})+\|v\|^2_{0,\Omega_t}+\|p_\sigma\|^2_{0,\Omega_t}+\int_0^t\|v\|^2_{0,\Omega_t}d\tau\\
&\qquad\quad+\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}+\|R(\cdot,t)-R_0\|^2_{0,S^1}+\|R(\cdot,t)-R_0\|^2_{0,S^1}\\
&\qquad\quad+(\|v\|^2_{3,\Omega_t}+\|p_\sigma\|^2_{2,\Omega_t})\left(1+\int_0^t\|v\|^2_{3,\Omega_\tau}d\tau\right)\int_0^t\|v\|^2_{4,\Omega_\tau}d\tau\Bigg].
\end{aligned}\tag{5.15}$$

Integrating (5.15) with respect to t and using the fact that $\varepsilon, \varepsilon_0, \varepsilon_1, \varepsilon_2$ are sufficiently small, we obtain

$$\begin{aligned}\varphi(t) &+ \int_0^t \Phi_0(\tau)d\tau \\ &\le c\int_0^t \psi(\tau)d\tau + c\left(\left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,S^1} + \sup_{\tau\le t}\|R(\cdot,\tau) - R_0\|^2_{0,S^1}\right) + \varphi(0) \\ &\le c(\varepsilon_0 + \varepsilon_1 + \varepsilon_2).\end{aligned}$$

Hence, we have shown that $(v, p_\sigma) \in \mathcal{M}(t), t \le T$ and (5.3) holds. We have to emphasize that to prove the above result the standard technique of mollifiers or differences should be used. This concludes the proof.

LEMMA 5.2. *Assume that there exists a local solution to* (1.1a–e), *which belongs to* $\mathcal{M}(t), t \le T$. *Let the assumptions of Lemma* 2.2 *be satisfied. Then there exists* $\delta = \delta(\delta', \varepsilon) \in (0,1)$ *such that*

$$\|p_\sigma\|^2_{0,\Omega_t} \le c_2\delta, \tag{5.16}$$

where $\delta' \in (0,1), \delta = c_3\varepsilon_1\delta' + c(\delta')\varepsilon_0$, $c(\delta')$ *is a decreasing function of* δ', *and* ε_0 *is taken from Remark* 2.7.

Proof. Let $\bar{p}_{\Omega_t} = (1/|\Omega_t|)\int_{\Omega_t} p dx$ and $p_{\Omega_t} = p - \bar{p}_{\Omega_t}$. Then

$$\|p_\sigma\|_{0,\Omega_t} \le \|p_{\Omega_t}\|_{0,\Omega_t} + \|\bar{p}_{\Omega_t} - p_0 - q_0\|_{0,\Omega_t}. \tag{5.17}$$

We introduce a function ϑ as a solution of the problem

$$\begin{aligned}\operatorname{div}\vartheta &= p_{\Omega_t} \quad \text{in } \Omega_t, \\ \vartheta &= 0 \quad \text{on } S_t.\end{aligned} \tag{5.18}$$

In view of Lemma 2.2 in [6] there exists $\vartheta \in \overset{0}{W}{}^1_2(\Omega_t) = \{u \in W^1_2(\Omega_t) : u_{|S_t} = 0\}$ such that

$$\|\vartheta\|_{1,\Omega_t} \le c\|p_{\Omega_t}\|_{0,\Omega_t}. \tag{5.19}$$

Multiplying (1.1a) written in the form

$$\rho v_t + \rho v\cdot\nabla v + \nabla p_{\Omega_t} - \operatorname{div}\mathbb{D}(v) = 0,$$

by ϑ, integrating the result over Ω_t, and performing integration by parts, we obtain

$$\int_{\Omega_t} p_{\Omega_t}\operatorname{div}\vartheta dx = \int_{\Omega_t}\mathbb{D}(v)\operatorname{div}\vartheta dx + \int_{\Omega_t}\rho(v_t + v\cdot\nabla v)\vartheta dx.$$

Taking (5.19) into account and using the fact that our local solution is such that $|\rho|_{\infty,\Omega_t} + |v|_{\infty,\Omega_t} \le c$, we have

$$\|p_{\Omega_t}\|^2_{0,\Omega_t} \le c(\|v_x\|^2_{0,\Omega_t} + \|v_t\|^2_{0,\Omega_t}). \tag{5.20}$$

To estimate the second term in the right-hand side of (5.17) we use

$$\|\bar{p}_{\Omega_t} - p_0 - q_0\|^2_{0,\Omega_t} = |\Omega_t||\bar{p}_{\Omega_t} - p_0 - q_0|^2 \tag{5.21}$$

and the relation

$$\bar{p}_{\Omega_t} - p_0 - q_0 = \bar{n} \cdot \mathbb{D}(v) \cdot \bar{n} - \sigma \left(H(\cdot, t) + \frac{2}{R_0} \right) - (p - \bar{p}_{\Omega_t}) \quad \text{on } S_t, \tag{5.22}$$

which follows form the boundary condition (1.1d).

From (5.21) and (5.22) we have

(5.23)

$$\begin{aligned} \|\bar{p}_{\Omega_t} - p_0 - q_0\|^2_{0,\Omega_t} &\le c \frac{|\Omega_t|}{|S_t|} \left(\|p - \bar{p}_{\Omega_t}\|^2_{0,S_t} + \|\mathbb{D}(v)\|^2_{0,S_t} + \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{0,S^1} \right) \\ &\le \varepsilon_1' (\|p_x\|^2_{0,\Omega_t} + \|v_{xx}\|^2_{0,\Omega_t}) + c(\varepsilon_1') (\|p - \bar{p}_{\Omega_t}\|^2_{0,\Omega_t} + \|v\|^2_{0,\Omega_t}) \\ &\quad + c \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{0,S^1}, \end{aligned}$$

where $c(\varepsilon_1')$ is a decreasing function of ε_1'.

Inequalities (5.17), (5.20), and (5.23) imply

$$\begin{aligned} \|p_\sigma\|^2_{0,\Omega_t} &\le \varepsilon_1' (\|p_x\|^2_{0,\Omega_t} + \|v_{xx}\|^2_{0,\Omega_t}) \\ &\quad + c(\|v_x\|^2_{0,\Omega_t} + \|v_t\|^2_{0,\Omega_t} + \|v\|^2_{0,\Omega_t}) + c \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{0,S^1} \\ &\le \varepsilon_2' (\|v\|^2_{4,\Omega^T} + \sup_{t \le T} \|p_\sigma\|^2_{1,\Omega_t}) + c \left(\|v\|^2_{0,\Omega_t} + \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{0,S^1} \right). \end{aligned} \tag{5.24}$$

Finally,

$$\begin{aligned} \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{0,S^1} &\le c \|R(\cdot, t) - R_0\|^2_{2,S^1} \\ &\le \varepsilon_3' \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{1,S^1} + c \|R(\cdot, t) - R_0\|^2_{0,S^1}. \end{aligned} \tag{5.25}$$

From (5.24) and (5.25) it follows

$$\begin{aligned} \|p_\sigma\|^2_{0,\Omega_t} &\le \varepsilon_4' \left(\|v\|^2_{4,\Omega^T} + \sup_{t \le T} \|p_\sigma\|^2_{1,\Omega_t} + \left\| H(\cdot, t) + \frac{2}{R_0} \right\|^2_{1,S^1} \right) \\ &\quad + c(\|v\|^2_{0,\Omega_t} + \|R(\cdot, t) - R_0\|^2_{0,S^1}). \end{aligned} \tag{5.26}$$

From (5.6) and Remark 2.7 (see (2.65)), the inequality (5.26) follows (5.16). This concludes the proof.

Now we have the following.

LEMMA 5.3. *Let $(v, p_\sigma) \in \mathcal{M}(t), t \le T$ be a solution of the problem* (1.1a–e). *Then $u(\xi, t) = v(x(\xi, t), t) \in C(t_0 + \lambda, T; H^4(\Omega))$ and the estimate holds*

$$\sup_{t_0 + \lambda < t \le T} \|v\|^2_{4,\Omega_t} \le c(\varphi(0) + \chi(0)) \equiv cA, \tag{5.27}$$

where $t_0 > 0, \lambda > 0, t_0 + \lambda < T$.

Proof. Let $\zeta_\lambda(t) \in C^\infty$ be such that $\zeta_\lambda(t) = 1$ for $t \geq t_0 + \lambda, \zeta_\lambda(t) = 0$ for $t \leq t_0 + \lambda/2, 0 \leq \zeta_\lambda(t) \leq 1, |\dot{\zeta}_\lambda(t)| \leq c/\lambda$, where $\dot{\zeta}_\lambda = (d/dt)\zeta_\lambda$. Let $u_\lambda = u\zeta_\lambda, q_\lambda = q\zeta_\lambda$. Then they are solutions of the problem (see (3.1) and (5.1))

(5.28)

$$
\begin{aligned}
&\eta u_{\lambda t} - \mu\nabla_u^2 u_\lambda - v\nabla_u\nabla_u \cdot u_\lambda = \nabla_u q_\lambda + \eta u\dot{\zeta}_\lambda \quad \text{in } \Omega^T,\\
&\Pi_0 \Pi\mathbb{D}_u(u_\lambda)\bar{n} = 0 \quad \text{on } S^T,\\
&\bar{n}_0\mathbb{D}_u(u_\lambda)\bar{n} - \sigma\bar{n}_0\int_0^t \Delta_{S_\tau}(\tau)u_\lambda(\tau)d\tau\\
&\quad = \int_0^t [\dot{\zeta}_\lambda\bar{n}_0\mathbb{T}(u,q_\sigma)\bar{n} + \sigma\bar{n}_0\zeta_\lambda\dot{\Delta}_{S_\tau}(\tau)\left(\xi + \int_0^\tau u(\tau')d\tau'\right) + \zeta_\lambda\partial_\tau(q_0\bar{n}_0\cdot\bar{n})]d\tau,\\
&+ q_\lambda\bar{n}_0\cdot\bar{n} \equiv \int_0^t B(\tau)d\tau + q_\lambda\bar{n}_0\cdot\bar{n} \quad \text{on } S^T,\\
&u_\lambda|_{t=0} = 0 \quad \text{in } \Omega,
\end{aligned}
$$

where $q_\lambda = q_\sigma\zeta_\lambda$ is treated as a given function, $\Pi_0 g = g - \bar{n}_0(\bar{n}_0\cdot g)$, $\Pi g = g - \bar{n}(\bar{n}\cdot g)$. The second boundary condition (5.28) follows from the following integration by parts:

$$
\begin{aligned}
0 &= \int_0^t \zeta_\lambda(\tau)\partial_\tau\left[\bar{n}_0\mathbb{T}(u,q_\sigma)\bar{n} - \sigma\bar{n}_0\Delta_{S_\tau}(\tau)\left(\xi + \int_0^\tau u(\tau')d\tau'\right) - q_0\bar{n}_0\cdot\bar{n}\right]d\tau\\
&= \int_0^t \partial_\tau[\zeta_\lambda\bar{n}_0\mathbb{T}(u,q_\sigma)\bar{n}]d\tau\\
&\quad - \int_0^t \left[\dot{\zeta}_\lambda\bar{n}_0\mathbb{T}(u,q_\sigma)\bar{n} + \sigma\bar{n}_0\zeta_\lambda\dot{\Delta}_{S_\tau}(\tau)\left(\xi + \int_0^\tau u(\tau')d\tau'\right) + q_\sigma\zeta_\lambda\partial_\tau(\bar{n}_0\cdot\bar{n})\right]d\tau\\
&\quad - \sigma\bar{n}_0\cdot\int_0^t \Delta_{S_\tau}(\tau)u_\lambda(\tau)d\tau.
\end{aligned}
$$

Next we introduce the differences: $u^{(s)}(\xi,t) = u_\lambda(\xi,t) - u'_\lambda(\xi,t), q^{(s)}(t) = q_\lambda(\xi,t) - q'_\lambda(\xi,t)$, where $w'(\xi,t) = w(\xi,t-s)$, $0 < s < t_0$. Therefore, we obtain the following equations:

(5.29)

$$
\begin{aligned}
&\eta u_t^{(s)} - \mu\nabla_u^2 u^{(s)} - \nu\nabla_u\nabla_u\cdot u^{(s)} = \nabla_u q^{(s)} - (\eta-\eta')u'_{\lambda t} + \mu(\nabla_u^2 - \nabla_{u'}^2)u'_\lambda\\
&\quad + \nu(\nabla_u\nabla_u - \nabla_{u'}\nabla_{u'})\cdot u'_\lambda + (\nabla_u - \nabla_{u'})q'_\lambda\\
&\quad + (\eta-\eta')u\dot{\zeta}_\lambda + \eta' u'(\dot{\zeta}_\lambda - \dot{\zeta}'_\lambda) \equiv E \text{ in } \Omega^T,\\
&\Pi_0\Pi\mathbb{D}_u(u^{(s)})\bar{n} = \Pi_0(\Pi\mathbb{D}_u(u'_\lambda)\bar{n} - \Pi'\mathbb{D}_{u'}(u'_\lambda)\bar{n}' \equiv F \quad \text{on } S^T,\\
&\bar{n}_0\mathbb{D}_u(u^{(s)})\bar{n} - \sigma\bar{n}_0\int_0^t \Delta_{S_\tau}(\tau)u^{(s)}(\tau)d\tau = q^{(s)}\bar{n}\cdot\bar{n}_0\\
&\quad + \bar{n}_0(\mathbb{D}_u(u'_\lambda)\bar{n} - \mathbb{D}_{u'}(u'_\lambda)\bar{n}') - \sigma\bar{n}_0\int_0^t (\Delta_{S_\tau}(\tau) - \Delta'_{S_\tau}(\tau))u'_\lambda d\tau\\
&\quad + \sigma\int_0^t (B(\tau) - B'(\tau'))d\tau + q'_\lambda\bar{n}_0\cdot(\bar{n}-\bar{n}') \equiv G_1 + \int_0^t G_2(\tau)d\tau \quad \text{on } S^T,\\
&u^{(s)}|_{t=0} = 0 \quad \text{in } \Omega.
\end{aligned}
$$

Let us introduce the notation: $\lambda \in (0,1), t_0 + \lambda < T, Q_\lambda = \Omega \times (t_0 + \lambda, T), G_\lambda = S \times (t_0 + \lambda, T)$.

From considerations in [34] we get

(5.30)
$$\|u^{(s)}\|_{4,Q_\lambda} \le c\left(\|E\|_{2,Q_{\lambda/2}} + \|F\|_{3-1/2,G_{\lambda/2}} + \|G_1\|_{3-1/2,G_{\lambda/2}} + \|G_2\|_{2-1/2,G_{\lambda/2}}\right).$$

Now we have to estimate the particular terms in the right-hand side of (5.30). Using the explicit form of E, F, G_1, G_2 we have

$$\|u^{(s)}\|_{4,Q_\lambda} \le c(A)As. \tag{5.31}$$

Hence we have

$$\begin{aligned}
&\| \|u(\cdot)\|_{4,\Omega} \|^2_{B^1_{2,\infty}(t_0+\lambda,T)} \\
&\quad = \sup_s \int_{t_0+\lambda}^T \frac{|\,\|u(t)\|_{4,\Omega} - \|u(t-s)\|_{4,\Omega}|^2}{s^2} dt + \int_{t_0+\lambda}^T \|u(t)\|^2_{4,\Omega} dt \\
&\quad \le \sup_s \int_{t_0+\lambda}^T \frac{\|u(t) - u(t-s)\|^2_{4,\Omega}}{s^2} dt + \int_{t_0+\lambda}^T \|u(t)\|^2_{4,\Omega} dt \le c(A)A.
\end{aligned}$$

Therefore, by imbedding theorems for Besov and Nikolskii spaces we have (see [13, Chap. 6.1])

$$B^\beta_{2,\infty}(0,T) \subset C([0,T]) \quad \text{for } \beta > \tfrac{1}{2}.$$

Hence (5.27) is shown. This concludes the proof.

Now we prove a result which guarantees a prolongation of the local solution. The result plays a crucial role in the proof of global existence. A similar result is shown in [33] and [35].

LEMMA 5.4. *Assume that there exists a local solution in $\mathcal{M}(t), t \le T$. Let $\bar{c}_1$ be a positive constant. Assume that*

$$\begin{aligned}
&\varphi(0) \le \gamma/2\bar{c}_1, \qquad \gamma \in (0, \tfrac{1}{2}], \\
&\tilde{\psi}(t) = \sup_{t' \le t} \psi(t') \le \delta_0, \qquad \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{2,S^1} \le d, \delta_0, \ d \in (0,1).
\end{aligned} \tag{5.32}$$

Then for sufficiently small γ, δ_0, and d we have

$$\varphi(t) \le \gamma/2\bar{c}_1, \qquad t \le T. \tag{5.33}$$

Proof. First we have to obtain an appropriate differential inequality which enables us to prove (5.33). Introducing the new quantity

$$\Phi_{00} = \Phi_0 + \left\| \int_0^t v d\tau \right\|^2_{4,S_t}, \tag{5.34}$$

and using (4.154) and (5.1) in (4.195) yields

(5.35)
$$\begin{aligned}\frac{d}{dt}\varphi + \Phi_{00} &\le cP(X)X(1+X^3)Y + c\psi_1(t)\\ &+ c\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}\right)\\ &+ c\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^4_{2,S^1} + c\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\left\|\int_0^t v\,d\tau\right\|^2_{3,S_t}\\ &+ c\|R(\cdot,t)-R(\cdot,0)\|^2_{3,S^1}\left\|\int_0^t v\,d\tau\right\|^2_{4,S_t},\end{aligned}$$

where

(5.36)
$$\begin{aligned}\psi_1(t) = \|v\|^2_{0,\Omega_t} + \|p_\sigma\|^2_{0,\Omega_t} + \int_0^t \|v\|^2_{0,\Omega_\tau}\,d\tau\\ +\|R(\cdot,t)-R_0\|^2_{0,S^1} + \|R(\cdot,0)-R_0\|^2_{0,S^1}.\end{aligned}$$

The inequality (5.35) has been proved for the local solution. Therefore, in view of boundary conditions (4.1c), Lemmas 5.1 and 5.2, we have

(5.37)
$$\begin{aligned}&\|R(\cdot,t)-R(\cdot,0)\|^2_{4+1/2,S^1}\\ &\quad\le \|R(\cdot,t)-R_0\|^2_{4+1/2,S^1} + \|R(\cdot,0)-R_0\|^2_{4+1/2,S^1}\\ &\quad\le c(\|v\|^2_{4,\Omega_t} + \|p_\sigma\|^2_{3,\Omega_t}) + \|R(\cdot,t)-R_0\|^2_{0,S^1} + \|R(\cdot,0)-R_0\|^2_{4+1/2,S^1}\\ &\quad\equiv 0(\varepsilon_0+\varepsilon_1+\varepsilon_2).\end{aligned}$$

Using (5.37) with sufficiently small $\varepsilon_0, \varepsilon_1, \varepsilon_2$ in (5.35) we obtain

(5.38)
$$\begin{aligned}\frac{d}{dt}\varphi + \Phi_{00} &\le cP(X)X(1+X^3)Y + c\psi_1(t)\\ &+c\left(\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1}\right),\end{aligned}$$

where we have used the fact that $\|H(\cdot,0)+(2/R_0)\|^2_{2,S^1}$ is also small.

Employing the inequality

(5.39)
$$\begin{aligned}\|R(\cdot,t)-R(\cdot,0)\|^2_{4,S^1} &\le \|R(\cdot,t)-R_0\|^2_{4,S^1} + \|R(\cdot,0)-R_0\|^2_{4,S^1}\\ &\le \varepsilon(\|v\|^2_{4,\Omega_t} + \|p_\sigma\|^2_{3,\Omega_t}) + c\left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S^1} + c\psi_1(t),\end{aligned}$$

and introducing the new quantity

(5.40)
$$\Phi = \Phi_{00} + \left\|H(\cdot,0)+\frac{2}{R_0}\right\|^2_{2,S_t},$$

instead of (5.38), we get

$$\frac{d}{dt}\varphi + \Phi \le cP(X)X(1+X^3)Y + c\tilde{\psi}(t)c\left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,S^1}, \tag{5.41}$$

where we have used the fact that $\psi_1(t) \le c\tilde{\psi}(t)$.

Using $X(t) \le \varphi(t) + \int_0^t \Phi_0(\tau)d\tau$, $Y(t) \le \Phi_0(t) + \int_0^t \Phi_0(\tau)d\tau$,

$$\int_0^t \Phi_0(\tau)d\tau \le c\left(\tilde{\psi}(t) + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,S^1}\right) + \varphi(0) \le cA,$$

where the last inequality follows from (5.3), the first term on the right-hand side of (5.41) yields

$$P(X)X(1+X^3)Y \le cA\Phi + c\varphi(1+\varphi^3)\Phi_0 + cA^2,$$

where we have used that $\varphi(t) \le c\Phi(t)$. Hence, using the form of A, instead of (5.41), we get

$$\frac{d}{dt}\varphi + \frac{1}{2}\Phi \le \bar{c}_1\varphi(1+\varphi^3)\Phi + \bar{c}_1\left(\tilde{\psi}(t) + \left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,S^1}\right) + \bar{c}_1\varphi^2(0), \tag{5.42}$$

where $\bar{c}_1$ is a constant which bounds all previous constants.

Assume that $t_* = \inf\{t \in [0,T] : \varphi(t) > \gamma/2\bar{c}_1\}$. Consider (5.42) in the interval $[0,t_*]$. From the definition of t_* we have that $\varphi(t_*) = \gamma/2\bar{c}_1$. Then for $t \le t_*$ we have

$$\bar{c}_1\tilde{\psi}(t) + \bar{c}_1\left\|H(\cdot,0) + \frac{2}{R_0}\right\|^2_{2,S^1} + \bar{c}_1\varphi^2(0) \le \bar{c}_1\left(\delta_0 + d + \frac{\gamma^2}{4\bar{c}_1^2}\right).$$

Let us assume that γ, δ_0, d are so small that

$$\bar{c}_1\left(\delta_0 + d + \frac{\gamma^2}{4\bar{c}_1^2}\right) \le \frac{\bar{c}_2}{16\bar{c}_1}\gamma, \tag{5.43}$$

where $\bar{c}_2$ is a constant from the inequality

$$\bar{c}_2\varphi(t) \le \Phi(t). \tag{5.44}$$

Therefore, from (5.42) we obtain

$$\varphi_t(t_*) \le -\Phi\left(\frac{1}{2} - \bar{c}_1\left(\frac{\gamma}{2\bar{c}_1} + \frac{\gamma^3}{2\bar{c}_1^3}\right)\right) + \frac{\bar{c}_2}{16\bar{c}_1}\gamma.$$

So, knowing that (5.44) holds, we have

$$\varphi_t(t_*) \le -\frac{\bar{c}_2\gamma}{2\bar{c}_1}\left[\frac{1}{2} - \frac{\gamma}{2} - \frac{\gamma^3}{8}\right] + \frac{\bar{c}_2}{16\bar{c}_1}\gamma \le -\frac{\bar{c}_2\gamma}{2\bar{c}_1}\left(\frac{1}{4} - \frac{1}{64}\right) + \frac{\bar{c}_2\gamma}{16\bar{c}_1} < 0.$$

Hence $\varphi_t(t_*) < 0$, a contradiction. This concludes the proof.

Finally, we prove the main result of this paper.

THEOREM 5.5. *Assume $f = 0$ and relations* (2.35) *among the constant parameters $\mu, \nu, \sigma, M, A, \kappa, |S|, |\Omega|, \int_\Omega \rho_0 v_0^2 dx, \int_\Omega \rho_0^\kappa dx, p_0$ of* (1.1) *such that the quantities*

$$\int_{\Omega_t} \rho v^2 dx, \quad \psi_t - \psi_{t'}, \quad |S_t| - |S_{t'}|, |\Omega_t| - |\Omega_{t'}| \quad \forall t, t' \in \mathbb{R}^1_+, \tag{5.45}$$

and

$$B \equiv \frac{1}{2}\int_\Omega \rho_0 v_0^2 dx + \psi - \psi_* + p_0(|\Omega| - |\Omega_*|) + \sigma(|S| - |S_*|) \le \varepsilon_0$$

are sufficiently small and $\psi_t = (A/(\kappa - 1))\int \rho^\kappa dx, \psi = \psi_0, \psi_* = \min_t \psi_t, |\Omega_*| = \min_t |\Omega_t|, |S_*| = 4\pi R_*^2$, and $(4\pi/3)R_*^3 = |\Omega_*|$ (see also Lemmas 2.1 *and* 2.2 *and Remark* 2.7).

Assume that $\rho_0 \in H^3(\Omega)$, $v_0 \in H^6(\Omega)$ are such that

$$\int_\Omega \rho_0 v_0 \cdot (a + b \times x) dx = 0, \qquad \int_\Omega \rho_0 x dx = 0, \tag{5.46}$$

where a, b are arbitrarily constant vectors, and

$$\varphi(0) \le \alpha_1, \tag{5.47}$$

where $p_\sigma = p(\rho) - p_0 - q_0, q_0 = 2\sigma/R_0, R_0 = ((3/4\pi)|\Omega|)^{1/3}$ and α_1 is sufficiently small.

Assume that S_t is described by $|x| = R(\omega, t), \omega \in S^1$ (unit sphere) and the initial boundary $S = S_0$ belongs to $H^{4+1/2}$ and is very close to a ball, so that

$$\left\| H(\cdot, 0) + \frac{2}{R_0} \right\|^2_{2, S^1} \le \alpha_2, \tag{5.48}$$

where α_2 is sufficiently small.

Assume compatibility conditions (for more explanation see Remark 5.7)

$$D_s^\alpha \partial_t^i (\mathbb{T}(v, p)\bar{n} - \sigma H \bar{n} + p_0 \bar{n})|_{t=0, S} = 0, \qquad |\alpha| + i \le 2.$$

Then there exists a global solution of (1.1a–e) *such that $(v, p_\sigma) \in \mathcal{M}(t), S_t \in H^{4+1/2}, t \in \mathbb{R}^1_+$ and*

$$\varphi(t) \le \alpha_1, \qquad \left\| H(\cdot, t) + \frac{2}{R_0} \right\|_{2, S^1} \le \alpha_2. \tag{5.49}$$

Moreover,

$$\int_\Omega \rho v \cdot (a + b \times x) dx = 0, \qquad \int_{\Omega_t} \rho x dx = 0,$$

and

$$\frac{1}{2}\int_{\Omega_t} \rho v^2 dx + \psi_t - \psi_* + p_0(|\Omega_t| - |\Omega_*|) + \sigma(|S_t| - |S_*|) \le B \le \varepsilon_0.$$

Proof. In view of (5.47) and (5.48) from Lemma 5.1 it follows that there exists a local solution $(v, p_\sigma) \in \mathcal{M}(t), t \le T$, such that

$$\varphi(T) + \int_0^T \Phi_0(\tau)d\tau \le c_1(\alpha_1 + \alpha_2), \tag{5.50}$$

and T is the time of local existence.

Then for $t \le T$ we have

$$\begin{aligned}
|R(\cdot,t) - R_0| &\le |R(\cdot,0) - R_0| + |R(\cdot,t) - R(\cdot,0)| \\
&\le \varepsilon \left\| H(\cdot,0) + \frac{2}{R_0} \right\|^2_{0,S^1} + c\|R(\cdot,0) - R_0\|^2_{0,S^1} + c\left|\int_0^t u d\tau\right| \left(1 + \left|\int_0^t u d\tau\right|\right) \\
&\le c_2(\alpha_1 + \alpha_2),
\end{aligned}$$

where we have used that

$$|R(\cdot,t) - R(\cdot,0)| = ||x| - |\xi|| = |x^2 - \xi^2|/(|x| + |\xi|) \quad \text{and} \quad x = \xi + \int_0^t u d\tau,$$

$$|\nabla R(t)| \le |\nabla R(0)| + |\int_0^t u(\tau)d\tau| + |\int_0^t \nabla u(\tau)d\tau| \le c_3(\alpha_1 + \alpha_2).$$

Assume that $\alpha_1 + \alpha_2$ is so small that (2.46) holds with a sufficiently small δ. Then (2.47) is valid. Next, sufficient smallness of quantities in (5.45) implies assumptions of Lemma 2.2. Thus, in view of Lemma 2.4 and Remark 2.7 there exists small $\delta_3 = c\varepsilon_0$ such that

$$\|v\|^2_{0,\Omega_t} + \|R(\cdot,t) - R_0\|^2_{0,S^1} \le \alpha_3. \tag{5.51}$$

Next in view of Lemma 5.2 we have that

$$\|p_\sigma\|^2_{0,\Omega_t} \le \alpha_4 = c_4[c_1(\alpha_1 + \alpha_2)\delta' + c_5\alpha_3],$$

where $\delta' \in (0,1)$, so $\alpha_4 > \alpha_3$. Therefore,

$$\tilde{\psi}(t) \le c_6(\alpha_3 + \alpha_4) \equiv \alpha_0.$$

Then in view of Lemma 5.3 we have

$$\|v\|^2_{4,\Omega_t} \le c_7(\alpha_1 + \alpha_2), \tag{5.52}$$

so (5.50) and (5.52) imply

$$\|v\|^2_{4,\Omega_t} + \|p_\sigma\|^2_{3,\Omega_t} \le c_8(\alpha_1 + \alpha_2). \tag{5.53}$$

Therefore, from the boundary conditions we get that $S_t \in H^{4+1/2}$ and

$$\left\| H(\cdot,T) + \frac{2}{R_0} \right\|^2_{2,S^1} \le \varepsilon c_8(\alpha_1 + \alpha_2) + c(\varepsilon)\alpha_0, \qquad \varepsilon \in (0,1). \tag{5.54}$$

Knowing that

$$|R_T - R_0| \le c|\Omega_T - \Omega| \le c_9\alpha_0$$

we obtain

$$\left\| H(\cdot,T) + \frac{2}{R_T} \right\|^2_{2,S^1} \leq \varepsilon c_8(\alpha_1+\alpha_2) + c_{10}\alpha_0 \leq \alpha_2, \tag{5.55}$$

where the last inequality imposes a restriction on α_0 (it must be sufficiently small). Finally, Lemma 5.4 yields

$$\varphi(T) \leq \alpha_1. \tag{5.56}$$

Therefore (5.47) and (5.48) are satisfied for $t = T$.

Now we are in a position to extend the considerations for interval $[T, 2T]$. In view of (5.56) and (5.51) for $t = T$, Remark 3.2 implies local existence of solutions for $t \in [T, 2T]$ which is such that

$$\|u\|_{4,\Omega\times(T,2T)} + \|q_\sigma\|_{3,\Omega\times(T,2T)} + |q_\sigma|_{3,0,\infty,\Omega\times(T,2T)} \leq c_{11}(\alpha_1+\alpha_3),$$

where on the right-hand side we generally have the same bound as for $t \in [0,T]$. Therefore,

$$\left| \int_T^{2T} u d\tau \right| \leq c_{12}(\alpha_1+\alpha_3),$$

so the change of the shape of Ω_t is as small as for interval $[0,T]$. Hence the Korn inequalities and imbedding theorems necessary in the proof of (4.195) can be applied with the same constants. This follows that the same inequality (4.195) holds for $t \in [T, 2T]$. Continuing the considerations, we prove global existence. This concludes the proof.

THEOREM 5.6 (case with $p_0 = 0$). *Let the assumptions of Theorem* 5.5 *with* $p_0 = 0$ *be satisfied. Then there exists a global solution*

$$v, p_\sigma = p - 2\sigma/R_0 \in \mathcal{M}(t), \qquad S_t \in H^{4+1/2}t \in \mathbb{R}^1_+$$

such that (5.49) *holds.*

The proof is the same as in Theorem 5.5.

Remark 5.7. We express explicitly the compatibility conditions formulated in assumptions of Theorem 5.5. Let $i = 0$. Then they take the form

$$D_s^\alpha \left(\mathbb{D}(v_0)\bar{n}_0 - \left(p(\rho_0) - p_0 - \frac{2\sigma}{R_0} \right) \bar{n}_0 - \frac{\sigma}{\sqrt{g_0}} \partial_{s_\alpha} \sqrt{g_0} g_0^{\alpha\beta} \xi_\beta \right) |_S = 0, \qquad |\alpha| \leq 2, \tag{5.57}$$

where $\bar{n}_0 = \xi_1 \times \xi_2 / |\xi_1 \times \xi_2|, \xi_1 = \xi_{s_i}, i = 1,2, g_{0\alpha\beta} = \xi_\alpha \cdot \xi_\beta, g_0 = \det\{g_{0\alpha\beta}\}, g_0^{\alpha\beta}$ is the inverse matrix to $g_{0\alpha\beta}$.

For $i = 1$ we have

$$D_s^\alpha \left(\mathbb{D}(v_t(0))\bar{n}_0 + \mathbb{D}(v_0)\bar{n}_t(0) - p_t(0)\bar{n}_0 - \left(p(\rho_0) - p_0 - \frac{2\sigma}{R_0} \right) \bar{n}_t(0) \right.$$
$$\left. - \partial_t(\Delta_{S_t} x)|_{t=0} \right) |_S = 0, \qquad |\alpha| \leq 1,$$

where $v_t(0), p_t(0)$ are calculated from (1.1a, b) at $t = 0$,

$$\bar{n}_t(0) = \frac{v_{01} \times \xi_2 + \xi_1 \times v_{02}}{|\xi_1 \times \xi_2|} - \frac{\xi_1 \times \xi_2}{|\xi_1 \times \xi_2|^3}(v_{01} \times \xi_2 + \xi_1 \times v_{02}) \cdot (\xi_1 \times \xi_2),$$
$$\partial_t(\Delta_{S_t} x)|_{t=0} = \partial_t(\Delta_{S_t})|_{t=0}\xi + \Delta_S v_0$$

and coefficients of $\partial_t(\Delta_{S_t})|_{t=0}$ depend on $g_{0\alpha\beta}, \partial_t g_{\alpha\beta}|_{t=0} = v_{0\alpha} \cdot \xi_\beta + \xi_\alpha \cdot v_{0\beta}$ and their derivatives with respect to $s = (s_1, s_2)$. Finally, the case $i = 2$ gives

$$\Big(\mathbb{D}(v_{tt}(0))\bar{n}_0 + 2\mathbb{D}(v_t(0))\bar{n}_t(0) + \mathbb{D}(v_0)\bar{n}_{tt}(0) - p_{tt}(0)\bar{n}_0 - 2p_t(0)\bar{n}_t(0)$$
$$-\Big(p(\rho_0) - p_0 - \frac{2\sigma}{R_0}\Big)\bar{n}_{tt}(0) - \partial_t^2(\Delta_{S_t} x)|_{t=0}\Big)|_S = 0,$$

where $v_{tt}(0), p_{tt}(0), \bar{n}_{tt}(0)$ are calculated inductively by employing (1.1a, b) at $t = 0$ and

$$\partial_t^2(\Delta_{S_t} x)|_{t=0} = (\partial_t^2 \Delta_{S_t})|_{t=0}\xi + 2(\partial_t \Delta_{S_t})|_{t=0} v_0 + \Delta_S v_t(0),$$

where coefficients of $(\partial_t^2 \Delta_{S_t})|_{t=0}$ depend on $\partial_t^2 g_{\alpha\beta}|_{t=0} = v_{\alpha t}(0) \cdot \xi_\beta + 2v_{0\alpha} \cdot v_{0\beta} + \xi_\alpha \cdot v_{\beta t}, \partial_t g_{\alpha\beta}|_{t=0}$ and $g_{0\alpha\beta}$.

Acknowledgment. The author is very indebted to professor V. A. Solonnikov for very fruitful discussions during the preparation of this paper.

SOLUTIONS FOR TWO-DIMENSIONAL SYSTEM FOR MATERIALS OF KORTEWEG TYPE*

HARUMI HATTORI† AND DENING LI‡

Abstract. Dunn and Serrin [*Arch. Rational Mech. Anal.*, 88 (1985), pp. 95–133] proposed the interstitial working term and modified the system of compressible fluids based on the Korteweg theory of capillarity. This term was introduced to overcome a difficulty: the higher-order terms of density are not compatible with the classical theory of thermodynamics. In this paper the existence of local solutions to the above system in the multidimensional case are discussed.

Key words. Korteweg material, linearization, local solution

AMS subject classifications. primary 35M10, 35Q35, 76N15; secondary 35K30

1. Introduction.

In order to model the capillarity effect of materials, Korteweg [5] formulated a constitutive equation for the Cauchy stress that includes density gradients. Specifically, he proposed a compressible fluid model in which the "elastic" or "equilibrium" portion of the Cauchy stress tensor $\mathbf{T}$ is given by

$$\mathbf{T} = (-p + \alpha\triangle\rho + \beta|\nabla\rho|^2)\mathbf{I} + \delta\nabla\rho\otimes\nabla\rho + \gamma\nabla\otimes\nabla\rho, \tag{1.1}$$

where

- $\rho = \rho(\mathbf{x}, t)$ is the density of the fluid at the point $\mathbf{x}$ at time t;
- $\nabla\rho$ and $\triangle\rho$ are the gradient and Laplacian of ρ with respect to $\mathbf{x}$;
- $(\mathbf{a}\otimes\mathbf{b})_{ij} = a_i b_j$ is the tensor product of $\mathbf{a}$ and $\mathbf{b}$;
- α, β, δ, and γ are functions of density ρ and temperature θ;
- $p = p(\rho, \theta)$ is the pressure.

This form of $\mathbf{T}$ is a special example of an elastic material of grade N ($N = 2$ in this case). The difficulty with these higher-grade models is that they are, in general, incompatible with conventional thermodynamics. In order to remedy this difficulty, Dunn and Serrin [2] proposed the concept of interstitial working w. It turns out that w must have the form

$$w = \mathbf{w}\cdot\mathbf{n},$$

where $\mathbf{n}$ is the outer unit normal to the boundary of the domain in which the usual set of integral balance laws is postulated and $\mathbf{w}$ is called the interstitial work flux representing spatial interactions of longer range.

Employing this interstitial working into the balance of energy equation, they derived the following set of equations for the conservation of mass, the balance of

linear momentum, the balance of energy, and the Clausius–Duhem inequality:

$$\text{(1.2)}\qquad \begin{cases} \rho_t + \nabla \cdot (\rho \mathbf{u}) = 0, \\ \rho \dfrac{D\mathbf{u}}{Dt} = \nabla \cdot \mathbf{T}, \\ \rho \dfrac{D\varepsilon}{Dt} = \mathbf{T} \cdot \mathbf{L} - \nabla \cdot \mathbf{q} + \nabla \cdot \mathbf{w}, \\ \rho\theta \dfrac{D\eta}{Dt} + \nabla \cdot \mathbf{q} - \dfrac{\mathbf{q} \cdot \nabla\theta}{\theta} \geq 0, \end{cases}$$

where $Df/Dt = f_t + \mathbf{u} \cdot \nabla f$ and we have the following:

- $\mathbf{u} = \mathbf{u}(\mathbf{x}, t)$ is the velocity of fluid;
- $\theta = \theta(\mathbf{x}, t)(> 0)$ is the absolute temperature;
- $\varepsilon = \varepsilon(\mathbf{x}, t)$ is the specific internal energy per unit mass;
- $\eta = \eta(\mathbf{x}, t)$ is the specific entropy per unit mass;
- $\mathbf{T} = \mathbf{T}(\mathbf{x}, t)$ is the Cauchy stress tensor;
- $\mathbf{q} = \mathbf{q}(\mathbf{x}, t)$ is the heat flux vector;
- $\mathbf{L} = \nabla \mathbf{u}$.

Remark 1.1. In Dunn and Serrin "∇" denotes differentiation with respect to the particle and "grad" denotes differentiation with respect to the point. We do not make such a distinction in this paper. They both mean the differentiation with respect to the point.

In terms of the Helmholtz free energy $\psi = \varepsilon - \theta\eta$, the last inequality in (1.2) can be rewritten as

$$\text{(1.3)}\qquad \rho\left(\frac{D\psi}{Dt} + \eta\frac{D\theta}{Dt}\right) - \mathbf{T} \cdot \mathbf{L} - \nabla \cdot \mathbf{w} + \frac{\mathbf{q} \cdot \mathbf{g}}{\theta} \leq 0.$$

They consider the materials of Korteweg type in which the constitutive relations are given by

$$\text{(1.4)}\qquad \begin{aligned} \varepsilon &= \varepsilon(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \\ \eta &= \eta(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \\ \mathbf{T} &= \mathbf{T}(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \\ \mathbf{q} &= \mathbf{q}(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \\ \mathbf{w} &= \mathbf{w}(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \\ \psi &= \psi(\rho, \theta, \mathbf{d}, \mathbf{S}, \mathbf{g}, \mathbf{L}), \end{aligned}$$

where $\mathbf{d} = \nabla\rho$, $\mathbf{S} = \mathbf{S}^T = \nabla^2\rho$, and $\mathbf{g} = \nabla\theta$. Using the Clausius–Duhem inequality (1.3), it is shown that $\mathbf{S}$, $\mathbf{g}$, and $\mathbf{L}$ drop out of ε, η, and ψ and indeed that

$$\text{(1.5)}\qquad \begin{aligned} \psi &= \psi(\rho, \theta, \mathbf{d}), \\ \eta &= -\psi_\theta(\rho, \theta, \mathbf{d}), \\ \varepsilon &= \psi(\rho, \theta, \mathbf{d}) - \theta\psi_\theta(\rho, \theta, \mathbf{d}). \end{aligned}$$

Furthermore, they have proved that for a given Helmholtz free energy $\psi(\rho, \theta, \mathbf{d})$ the following forms of $\mathbf{w}$ and $\mathbf{T}$,

$$\text{(1.6)}\qquad \begin{aligned} \mathbf{w} &= \rho\dot{\rho}\psi_{\mathbf{d}} + \bar{\mathbf{w}}, \\ \mathbf{T} &= (-\rho^2\psi_\rho + \rho\mathbf{d} \cdot \psi_{\mathbf{d}} + \rho^2\nabla \cdot \psi_{\mathbf{d}})\mathbf{I} - \rho\mathbf{d} \otimes \psi_{\mathbf{d}}, \end{aligned}$$

are compatible with (1.3). Here $\rho^2\psi_\rho(\rho,\theta,0)$ is the pressure and $\bar{\mathbf{w}}$ is the "static" portion of the interstitial work flux $\mathbf{w}$. They have shown that if the material possesses a center of symmetry, $\bar{\mathbf{w}}=0$. In what follows, we consider the materials that possess the center of symmetry. They also have observed that the classical forms of viscosity and conductivity tensors are compatible.

In this paper we consider the existence of a unique, local, smooth solution in the two-dimensional isothermal motion of the Korteweg type materials, where the viscous effect is also included. The three-dimensional case can be discussed similarly. The restriction to isothermal motions is a special one, and it would be important to remove it in future work. In what follows, we state the assumptions on the Helmholtz free energy and derive the system that we shall discuss. We assume that the Helmholtz free energy is given by

$$\psi = F(\rho) + \frac{\nu}{2\rho}(\rho_x^2+\rho_y^2), \tag{1.7}$$

where F is a smooth function of ρ and ν is a positive constant. This choice is to make the terms appearing in (1.2) as simple as possible, yet reflect the effect of the higher-order terms of ρ.[1]

With the choice of the Helmholtz free energy given in (1.7) and with $\lambda=-\frac{1}{3}\mu$, the system then becomes

$$\begin{cases} \rho_t+(\rho u)_x+(\rho v)_y=0, \\ (\rho u)_t+(\rho u^2)_x+(\rho uv)_y=(T_{11})_x+(T_{12})_y, \\ (\rho v)_t+(\rho uv)_x+(\rho v^2)_y=(T_{21})_x+(T_{22})_y, \end{cases} \tag{1.8}$$

where u and v are the x and y component of the velocity and

$$\begin{aligned} \mathbf{T} &= \begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix} \\ &= \Big\{-p+\frac{\nu}{2}(\rho_x^2+\rho_y^2)+\nu\rho\triangle\rho\Big\}\mathbf{I}-\nu\begin{pmatrix} \rho_x^2 & \rho_x\rho_y \\ \rho_x\rho_y & \rho_y^2 \end{pmatrix}+\mathbf{V}, \end{aligned} \tag{1.9}$$

$$p=\rho^2F'(\rho), \tag{1.10}$$

$$\mathbf{V}=\begin{pmatrix} V_{11} & V_{12} \\ V_{21} & V_{22} \end{pmatrix}=\mu\{(\nabla\mathbf{u})+(\nabla\mathbf{u})^T-\tfrac{2}{3}(\nabla\mathbf{u})\mathbf{I}\}. \tag{1.11}$$

Here $\mathbf{I}$ is the unit rank-two tensor, and superscript T denotes the transpose of a tensor. Since we discuss the existence of a local solution, we do not need the monotonicity of the pressure on ρ. Further computation simplifies the $\nabla\cdot\mathbf{T}$ term

$$\nabla\cdot\mathbf{T}=-\nabla p+\nu\rho\nabla(\triangle\rho)+\nabla\cdot\mathbf{V}. \tag{1.12}$$

In this paper we discuss the local existence for the initial value problem of (1.8) with the initial data given by

$$(\rho,u,v)(x,y,0)=(\rho_0,u_0,v_0)(x,y). \tag{1.13}$$

[1] Another reasonable choice is to change the last term in (1.7) with $(\nu/2)(\rho_x^2+\rho_y^2)$. Although this choice may be physically more realistic, mathematically it is more cumbersome to handle. For example, the expression for $\nabla\cdot\mathbf{T}$ becomes more complicated; therefore, we do not discuss this case.

We assume that the initial data satisfy

$$(\rho_0 - \bar{\rho_0}, u_0, v_0) \in H^k(R^2), \qquad \bar{\rho_0} \geq \delta > 0,$$

where $k \geq 4$ and $\bar{\rho_0} > 0$ is a positive constant. Denote by $\|\cdot\| \equiv \|\cdot\|_0$ the L^2 norm and by $\|\cdot\|_k$ the kth order Sobolev norm. Set

$$|||w|||_{0,T}^2 \equiv \sup_{0\leq t\leq T} \left(\|w(t)\|^2 + \|\nabla\rho(t)\|^2\right) + \int_0^T \left(\|\nabla u(t)\|^2 + \|\nabla v(t)\|^2\right) dt \tag{1.14}$$

and

$$|||w|||_k^2 = \sum_{|j|\leq k} |||\partial_{x,y}^j w|||^2,$$

where $w \equiv (\rho, u, v)$. Then the main theorem of this paper can be stated as follows.

THEOREM 1.1. *For any initial data (ρ_0, u_0, v_0) such that the condition $\rho_0 \geq \delta > 0$ is satisfied and $(\rho_0 - \bar{\rho_0}, u_0, v_0) \in H^k(R^2)$ $(k \geq 4)$, where $\bar{\rho_0} > 0$ is a constant, there exists a $T > 0$ such that in $t \in [0, T]$, the Cauchy problem (1.8) and (1.13) has a unique solution (ρ, u, v) such that $\rho - \bar{\rho_0} \in L^\infty([0,T]; H^{k+1}(R^2))$, $(u, v) \in L^\infty([0,T]; H^k(R^2))$, and*

$$|||w|||_k^2 \leq C_k \|w_0\|_k^2 + \|\rho_0\|_{k+1}^2. \tag{1.15}$$

Since the linearized problem of (1.8) and (1.13) is not of any classical type, the existence of solutions is not known even for the linearized problem. We prove the existence of solutions for the linearized problem by establishing an energy estimate for the dual problem and then using the dual argument.

For one-dimensional problems, the effects of the higher-order derivatives of density (or in the context of elasticity, the higher-order derivatives of strain) have been discussed extensively in phase transition problems where the pressure or the stress is a nonmonotone function of the density or strain. In compressible fluids, Serrin [11], [12] reconsidered the Korteweg theory and has shown the existence of steady profile connecting two different phases. In [13] and [14], Slemrod considered the existence of travelling wave solutions connecting two different phases. In elasticity, Andrews and Ball [1] discussed the existence and the asymptotic behavior of solutions in the hard loading case. Concerning the dynamical aspects of the soft loading case, Hattori and Mischaikow [4] proved the existence of global solutions and a global compact attractor in H^1, examined the dynamic stability and the bifurcations of stationary solutions, and demonstrated the connecting orbit problems in the semiflow. Sprekels and Zheng [15] discussed the existence of solutions to the equations of a Ginzburg–Landau theory for structural phase transition in shape memory alloys. The system that they discussed was derived by Falk [3]. It is interesting to note that his system has the same term as the interstitial working term, although he derived it independently. This motivates our study of multidimensional problems.

In the one space-dimensional case, the problem is solved by introducing Lagrangian coordinates, and the system (1.8) reduces to scalar equations for the velocity u of higher order. However, in the higher-dimensional space, this kind of reduction is not available. The appearance of higher-order derivatives of ρ in the momentum equations of (1.8) makes the system unsymmetric. Therefore, to obtain the a priori

estimate for the linearized problem, we have repeatedly used the first equation in (1.8).

This paper consists of four sections. The second section discusses the linearization of (1.8), (1.13), and the a priori estimate for smooth solutions for the linearized problem. Section 3 establishes the existence of solutions for the linearized problem and in §4 we discuss the existence of local solutions for (1.8) and (1.13) and complete the proof of Theorem 1.1.

2. Linearized problem and a priori estimate. The linearized equations for the perturbation $\dot{w} \equiv (\dot{\rho}, \dot{u}, \dot{v})$ of (1.8) at a given solution $w \equiv (\rho, u, v)$ can be written as follows:

(2.1)
$$\begin{cases} (\partial_t + u\partial_x + v\partial_y)\dot{\rho} + \rho(\dot{u}_x + \dot{v}_y) + \ell_1(\dot{w}) = \dot{f}_1, \\ \rho(\partial_t + u\partial_x + v\partial_y)\dot{u} + p'(\rho)\dot{\rho}_x - \nu\rho\triangle\dot{\rho}_x - \mu\triangle\dot{u} - \frac{\mu}{3}(\dot{u}_{xx} + \dot{v}_{xy}) + \ell_2(\dot{w}) = \dot{f}_2, \\ \rho(\partial_t + u\partial_x + v\partial_y)\dot{v} + p'(\rho)\dot{\rho}_y - \nu\rho\triangle\dot{\rho}_y - \mu\triangle\dot{v} - \frac{\mu}{3}(\dot{u}_{xy} + \dot{v}_{yy}) + \ell_3(\dot{w}) = \dot{f}_3. \end{cases}$$

Here $\ell_j(\cdot)$ $(j = 1, 2, 3)$ denote the linear functions of the arguments with the coefficients of ℓ_1 depending upon ∇w and the coefficients of ℓ_2, ℓ_3 depending upon ∇w and $\nabla^2(u, v)$.

Consider the Cauchy problem of (2.1) with initial data:

$$\dot{\rho}(x, y, 0) = \dot{\rho}_0(x, y), \quad \dot{u}(x, y, 0) = \dot{u}_0(x, y), \quad \dot{v}(x, y, 0) = \dot{v}_0(x, y). \tag{2.2}$$

Equations (2.1) can be rewritten in the following matrix form:

$$\dot{L}(w)\dot{w} \equiv \begin{pmatrix} \dot{L}_1(w)\dot{w} \\ \dot{L}_2(w)\dot{w} \\ \dot{L}_3(w)\dot{w} \end{pmatrix} \equiv \partial_t\dot{w} + A_1\partial_x\dot{w} + A_2\partial_y\dot{w} + (T_1 + T_2)\dot{w} + \ell(\dot{w}) = \dot{f}, \tag{2.3}$$

where A_1, A_2 are coefficient matrices of the first-order space derivative terms and $T_1 + T_2$ is an operator matrix involving derivatives of order two or higher:

$$A_1 = \begin{pmatrix} u & \rho & 0 \\ p'(\rho)\rho^{-1} & u & 0 \\ 0 & 0 & u \end{pmatrix}, \qquad A_2 = \begin{pmatrix} v & 0 & \rho \\ 0 & v & 0 \\ p'(\rho)\rho^{-1} & 0 & v \end{pmatrix}, \tag{2.4}$$

$$T_1\dot{w} = -\nu\triangle \begin{pmatrix} 0 \\ \nabla\dot{\rho} \end{pmatrix}, \qquad T_2\dot{w} = -\mu\rho^{-1} \begin{pmatrix} 0 \\ \triangle\dot{u} + \frac{1}{3}(\dot{u}_{xx} + \dot{v}_{xy}) \\ \triangle\dot{v} + \frac{1}{3}(\dot{u}_{xy} + \dot{v}_{yy}) \end{pmatrix}. \tag{2.5}$$

Let $\langle \cdot, \cdot \rangle$ denote the L^2 inner product in the $(x, y) \in R^2$. Denote $\|\cdot\| \equiv \|\cdot\|_0$, the corresponding norm, and $\|\cdot\|_k$, the kth order Sobolev norm.

Let β_0 be a constant such that the variables $w = (\rho, u, v)$ in the coefficients of (2.3) satisfy

$$\sup_{t,x,y} \left(\rho^{-1} + |\rho_t| + \sum_{|j| \le 2} |D^j_{x,y} w| \right) \le \beta_0. \tag{2.6}$$

Let C_0 denote the constant that depends only upon β_0. Then we have the following zero-order energy estimate.

THEOREM 2.1. *The smooth solution* $\dot{w} \in C_0^\infty([0,T] \times R^2)$ *of* (2.1) *and* (2.2) *satisfies the estimate*

$$\partial_t(\|\dot{w}\|^2 + \|\nabla\dot{\rho}\|^2) + \|\nabla\dot{u}\|^2 + \|\nabla\dot{v}\|^2 \le C_0(\|\dot{w}\|^2 + \|\nabla\dot{\rho}\|^2 + \|\dot{f}\|_0^2 + \|\dot{f}_1\|_1^2) \tag{2.7}$$

and

$$|||\dot{w}|||_{0,T}^2 \le C_0(T)\left(\|\dot{w}_0\|^2 + \|\dot{\rho}_0\|_1^2 + \int_0^T (\|\dot{f}\|^2 + \|\dot{f}_1\|_1^2)dt\right). \tag{2.8}$$

Here the norm $|||\dot{w}|||_{0,T}$ *is defined as follows*:

$$|||\dot{w}|||_{0,T}^2 \equiv \sup_{0\le t\le T}\left(\|\dot{w}(t)\|^2 + \|\nabla\dot{\rho}(t)\|^2\right) + \int_0^T \left(\|\nabla\dot{u}(t)\|^2 + \|\nabla\dot{v}(t)\|^2\right)dt. \tag{2.9}$$

Proof. Define the diagonal matrix

$$A_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \rho & 0 \\ 0 & 0 & \rho \end{pmatrix}.$$

Taking L^2 inner products of (2.3) with vector $A_0\dot{w}$ gives

$$\langle \partial_t\dot{w}, A_0\dot{w}\rangle + \langle (T_1+T_2)\dot{w}, A_0\dot{w}\rangle \le C_0(\|\dot{f}\| + \|\dot{w}\| + \|\nabla\dot{w}\|)\|\dot{w}\|. \tag{2.10}$$

Obviously,

$$\langle \partial_t\dot{w}, A_0\dot{w}\rangle \ge \tfrac{1}{2}\partial_t\|\sqrt{A_0}\dot{w}\|^2 - C_0\|\dot{w}\|^2. \tag{2.11}$$

From the first equation in (2.1),

$$\rho(\dot{u}_x + \dot{v}_y) = -(\partial_t + u\partial_x + v\partial_y)\dot{\rho} - \ell_1(\dot{w}) + \dot{f}_1,$$

and standard integration by parts gives

$$\begin{aligned} \langle T_1\dot{w}, A_0\dot{w}\rangle &= \langle \nu\triangle\dot{\rho}, \rho(\dot{u}_x + \dot{v}_y) + \nabla\rho\cdot(\dot{u},\dot{v})^t\rangle \\ &= \langle \nu\triangle\dot{\rho}, -(\partial_t + u\partial_x + v\partial_y)\dot{\rho} - \ell_1(\dot{w}) + \dot{f}_1 + \nabla\rho\cdot(\dot{u},\dot{v})^t\rangle \\ &\ge \nu\langle\nabla\dot{\rho}, \partial_t\nabla\dot{\rho}\rangle - C_0\|\nabla\dot{\rho}\|(\|\dot{w}\| + \|\nabla\dot{w}\| + \|\dot{f}_1\|_1) \\ &\ge \tfrac{\nu}{2}\partial_t\|\nabla\dot{\rho}\|^2 - C_0\epsilon^{-1}\|\nabla\dot{\rho}\|^2 - \epsilon\|\nabla\dot{w}\|^2 - C_0(\|\dot{w}\|^2 + \|\dot{f}_1\|_1^2) \end{aligned} \tag{2.12}$$

and

$$\begin{aligned} \langle T_2\dot{w}, A_0\dot{w}\rangle &= -\mu\langle\triangle\dot{u} + \tfrac{1}{3}(\dot{u}_{xx} + \dot{v}_{xy}), \dot{u}\rangle - \mu\langle\triangle\dot{v} + \tfrac{1}{3}(\dot{u}_{xy} + \dot{v}_{yy}), \dot{v}\rangle \\ &\ge \mu(\|\nabla\dot{u}\|^2 + \|\nabla\dot{v}\|^2) - C_0\|\nabla\dot{w}\|\|\dot{w}\|. \end{aligned} \tag{2.13}$$

Combining (2.10)–(2.13) and noticing that $\|A_0\dot{w}\| \sim \|\dot{w}\|$, $\|A_0\nabla\dot{w}\| \sim \|\nabla\dot{w}\|$ by (2.6), we obtain the estimate (2.7) by taking $\epsilon \ll 1$.

By the Gronwall theorem, we have from (2.7) that

$$\|\dot{w}(t)\|^2 + \|\nabla\dot{\rho}(t)\|^2 \le e^{C_0t}\left(\|\dot{w}_0\|^2 + \|\nabla\dot{\rho}_0\|^2\right) + \int_0^t e^{C_0(t-s)}(\|\dot{f}(s)\|^2 + \|\dot{f}_1(s)\|_1^2)ds. \tag{2.14}$$

Replacing the terms $\|\dot{w}(t)\|^2 + \|\nabla\dot{\rho}(t)\|^2$ on the right of (2.7) and integrating in t from 0 to T, we obtain (2.8).

To derive higher-order estimates, we denote $\|\cdot\|_k$ the kth-order Sobolev norm in $(x, y) \in R^2$ and

$$\|\dot{w}\|_k^2 \equiv \sum_{|j|\le k} \|\partial_{x,y}^j \dot{w}\|^2.$$

Let β_k be a constant such that the variables $w = (\rho, u, v)$ in the coefficients of (2.3) satisfy

$$\sup_{t,x,y} \left(\rho^{-1} + \sum_{|j|\le 2} |D_{x,y}^j w| + |\rho_t| \right) + \|w\|_k^2 \le \beta_k. \tag{2.15}$$

Let C_k denote the constant that depends only upon β_k. Then we have the following kth order energy estimate.

THEOREM 2.2. *For integer $k \ge 4$, the smooth solution $\dot{w} \in C_0^\infty([0,T] \times R^2)$ of (2.1) and (2.2) satisfies the estimate*

$$\begin{aligned} &\partial_t(\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2) + \|\dot{u}\|_{k+1}^2 + \|\dot{v}\|_{k+1}^2 \\ &\quad \le C_k \left(\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2 + \|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1} \right) \end{aligned} \tag{2.16}$$

and

$$\|\dot{w}\|_k^2 \le C_k(T) \left(\|\dot{w}_0\|_k^2 + \|\dot{\rho}_0\|_{k+1}^2 \right) + C_k(T) \int_0^T (\|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1}^2) dt. \tag{2.17}$$

Proof. Applying the operator ∇^j to (2.3), we have

$$\dot{L}(w)\nabla^j \dot{w} = \nabla^j \dot{f} - [\nabla^j, \dot{L}]\dot{w}. \tag{2.18}$$

Taking the L^2 inner product of (2.18) with $A_0 \nabla^j \dot{w}$, we obtain

$$\begin{aligned} &\partial_t \|\nabla^j \dot{w}\|^2 + \|\nabla^{j+1}\dot{u}\|^2 + \|\nabla^{j+1}\dot{v}\|^2 + \langle A_0 \nabla^j \dot{w}, T_1 \nabla^j \dot{w} \rangle \\ &\quad \le C_j \left(\|\dot{w}\|_j^2 + \|\dot{\rho}\|_{j+1}^2 + \|\dot{f}\|_{j-1}^2 + |\langle A_0 \nabla^j \dot{w}, [\nabla^j, \dot{L}]\dot{w} \rangle| \right). \end{aligned} \tag{2.19}$$

First consider

$$\langle A_0 \nabla^j \dot{w}, T_1 \nabla^j \dot{w} \rangle = \nu \langle \triangle \nabla^j \dot{\rho}, \rho \nabla^j (\dot{u}_x + \dot{v}_y) \rangle + \nu \langle \triangle \nabla^j \dot{\rho}, \nabla \rho \nabla^j (\dot{u}, \dot{v})^t \rangle.$$

From the first equation in (2.18), we have

$$\rho \nabla^j (\dot{u}_x + \dot{v}_y) = -(\partial_t + u\partial_x + v\partial_y)\nabla^j \dot{\rho} - \ell_1(\nabla^j \dot{w}) - \nabla^j \dot{f}_1 - [\nabla^j, \dot{L}_1(w)]\dot{w}.$$

Noticing that $[\nabla^j, \dot{L}_1(w)]$ is an operator of order j, hence

$$\begin{aligned} \langle A_0 \nabla^j \dot{w}, T_1 \nabla^j \dot{w} \rangle \ge &-\nu \langle \triangle \nabla^j \dot{\rho}, \rho \nabla^j \dot{\rho}_t \rangle \\ &- \epsilon \left(\|\nabla^{j+1}\dot{u}\|^2 + \|\nabla^{j+1}\dot{v}\|^2 \right) - C_j \left(\|\nabla^{j+1}\dot{\rho}\|^2 + \|\dot{f}_1\|_{j+1}^2 \right). \end{aligned}$$

Since

$$-\langle \triangle \nabla^j \dot{\rho}, \rho \nabla^j \dot{\rho}_t \rangle \geq \tfrac{1}{2}\partial_t \|\nabla^{j+1}\dot{\rho}\|^2 - C_j \|\nabla^{j+1}\dot{\rho}\| \|\nabla^j \dot{\rho}_t\|$$
$$\geq \tfrac{1}{2}\partial_t \|\nabla^{j+1}\dot{\rho}\|^2 - C_j(\|\nabla^{j+1}\dot{\rho}\|^2 + \|\dot{f}_1\|_j^2) - \epsilon\left(\|\nabla^{j+1}\dot{u}\| + \|\nabla^{j+1}\dot{u}\|\right)$$

by the first equation in (2.3), we have

(2.20)
$$\langle A_0 \nabla^j \dot{w}, T_1 \nabla^j \dot{w} \rangle \geq \tfrac{1}{2}\partial_t \|\nabla^{j+1}\dot{\rho}\|^2$$
$$- \epsilon\left(\|\nabla^{j+1}\dot{u}\|^2 + \|\nabla^{j+1}\dot{v}\|^2\right) - C_j(\|\nabla^{j+1}\dot{\rho}\|^2 + \|\dot{f}_1\|_{j+1}^2).$$

To discuss the terms involving the commutator $[\nabla^j, \dot{L}]$, we notice the structure of the operator $\dot{L}$ in (2.3) and the terms in $[\nabla^j, \dot{L}]\dot{w}$ having the form

$$\nabla^{j-i} F(w) \nabla^{2+i} \dot{w}, \qquad 0 \leq i \leq j-1,$$

where F denotes smooth functions of its argument. According to Nirenberg's inequality [7], [9], we have

$$\|\nabla^{j-i} F(w) \nabla^{2+i} \dot{w}\|_0 \leq C\left(|\nabla F(w)|_{C^0} \|\nabla^2 \dot{w}\|_{j-1} + \|\nabla F(w)\|_{j-1} |\nabla^2 \dot{w}|_{C^0}\right), \tag{2.21}$$

where $|\cdot|_{C^0}$ denotes the usual maximum norm of continuous functions. Consequently,

$$|\langle A_0 \nabla^j \dot{w}, [\nabla^j, \dot{L}]\dot{w} \rangle| \leq C_0 \|\nabla^j \dot{w}\| \|\dot{w}\|_{j+1} + C_j |\nabla^2 \dot{w}|_{C^0} \|\nabla^j \dot{w}\|. \tag{2.22}$$

Replacing $|\langle A_0 \nabla^j \dot{w}, [\nabla^j, \dot{L}]\dot{w} \rangle|$ in (2.19) by (2.22) and summing up for all $j \leq k$, we have

(2.23)
$$\partial_t(\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2) + \|\dot{u}\|_{k+1}^2 + \|\dot{v}\|_{k+1}^2$$
$$\leq C_k\left(\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2 + \|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1} + |\nabla^2 \dot{w}|_{C^0}^2\right).$$

For $k \geq 4$, $H^k(R^2) \subset C^2(R^2)$; therefore, we obtain (2.16).

Applying the Gronwall theorem to (2.16), we find

(2.24)
$$\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2$$
$$\leq C_k\left(\|\dot{w}_0\|_k^2 + \|\dot{\rho}_0\|_{k+1}^2 + \|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1}^2 + \int_0^t e^{C(t-s)}(\|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1}^2) ds\right).$$

Replacing $\|\dot{w}\|_k^2 + \|\dot{\rho}\|_{k+1}^2$ in (2.16) and integrating in t over $[0,T]$, we obtain (2.17). This concludes the proof of Theorem 2.2.

Remark 2.1. From (2.24) and (2.3), it is easy to obtain the corresponding estimates for $\partial_t^j \dot{w}$.

3. Existence of solution for linearized problem. By the energy estimate (2.17) and the continuation method, in order to prove the existence of the solution for the problem (2.1) and (2.2), we need only to show the existence of a solution for $f \in C_0^\infty([0,T] \times R^2)$, $\dot{w}_0 = 0$ with the lower-order terms in (2.1) omitted.

In the following, we use the dual method [6], [10] to prove the existence of the following problem in $[0,T]$:

$$L\dot{w} \equiv \partial_t \dot{w} + B_1' \partial_x \dot{w} + B_2' \partial_y \dot{w} + (T_1 + T_2)\dot{w} = \dot{f}, \tag{3.1}$$

$$\dot{w}(x,y,0)=0. \tag{3.2}$$

In (3.1), the operators T_1, T_2 are defined in (2.5), and the matrices B_1, B_2 are obtained by omitting the lower-order terms of A_1, A_2 in (2.4):

$$B_1=\begin{pmatrix} u & \rho & 0\\ 0 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}, \qquad B_2=\begin{pmatrix} v & 0 & \rho\\ 0 & 0 & 0\\ 0 & 0 & 0\end{pmatrix}. \tag{3.3}$$

The adjoint operator L^* for (5.1) is defined by

$$\langle L\dot{w},\dot{\phi}\rangle=\langle \dot{w},L^*\dot{\phi}\rangle.$$

To prove the existence of weak solution $\dot{w}\in L^2([0,T],H^{k+1})$ for (3.1) and (3.2), we need to establish the energy estimates of negative order for the operator L^*. Since the operator L is not symmetric, we first derive the classical energy estimate for

$$L^*\dot{\phi}=-\partial_t\dot{\phi}-B_1^*\partial_x\dot{\phi}-B_2^*\partial_y\dot{\phi}+(T_1^*+T_2^*)\dot{\phi}=\dot{g}, \tag{3.4}$$

$$\dot{\phi}(x,y,T)=0. \tag{3.5}$$

THEOREM 3.1. *The solutions of* (3.4) *and* (3.5) *satisfy the following estimate*:

$$\|\dot{\phi}(t)\|^2+\|\dot{\phi}_{2,3}(t)\|_2^2\le C\left(\|\dot{g}(t)\|^2+\int_0^T\|\dot{g}(\tau)\|^2d\tau\right). \tag{3.6}$$

Proof. Explicitly, the operator L^* can be written as follows:

$$\begin{cases} -(\partial_t+\partial_x u+\partial_y v)\dot{\phi}_1+\nu\triangle(\partial_x\dot{\phi}_2+\partial_y\dot{\phi}_3)=\dot{g}_1,\\ -\partial_t\dot{\phi}_2-\partial_x(\rho\dot{\phi}_1)-(\mu\triangle+\frac{\mu}{3}\partial_{xx})(\rho^{-1}\dot{\phi}_2)-\frac{\mu}{3}\partial_{xy}(\rho^{-1}\dot{\phi}_3)=\dot{g}_2,\\ -\partial_t\dot{\phi}_3-\partial_y(\rho\dot{\phi}_2)-(\mu\triangle+\frac{\mu}{3}\partial_{xx})(\rho^{-1}\dot{\phi}_3)-\frac{\mu}{3}\partial_{xy}(\rho^{-1}\dot{\phi}_2)=\dot{g}_3. \end{cases} \tag{3.7}$$

Taking the inner product of the second and third equations in (3.7) with $\dot{\phi}_2,\dot{\phi}_3$ and integrating by parts, we have

$$-\partial_t\|\dot{\phi}_{2,3}\|^2+\mu\|\rho^{-\frac{1}{2}}\nabla\dot{\phi}_{2,3}\|^2\le C(\|\dot{\phi}\|^2+\|\dot{g}_{2,3}\|^2). \tag{3.8}$$

Then, taking the inner product of the second and third equations in (3.7) with $-\triangle\dot{\phi}_2,-\triangle\dot{\phi}_3$ and integrating by parts, we have

$$\begin{aligned} &-\tfrac{1}{2}\partial_t\|\nabla\dot{\phi}_{2,3}\|^2+\mu\|\rho^{-\frac{1}{2}}\triangle\dot{\phi}_{2,3}\|^2-\langle\rho\dot{\phi}_1,\triangle(\partial_x\dot{\phi}_2+\partial_y\dot{\phi}_3)\rangle\\ &\quad\le C(\|\dot{\phi}_{2,3}\|^2+\|\nabla\dot{\phi}_{2,3}\|^2+\|\dot{g}_{2,3}\|^2). \end{aligned} \tag{3.9}$$

From the first equation of (3.7),

$$\triangle(\partial_x\dot{\phi}_2+\partial_y\dot{\phi}_3)=\nu^{-1}[(\partial_t+\partial_x u+\partial_y v)\dot{\phi}_1+\dot{g}_1],$$

and

$$-\langle\rho\dot{\phi}_1,\partial_t\dot{\phi}_1\rangle\ge-\tfrac{1}{2}\partial_t\|\rho^{-\frac{1}{2}}\dot{\phi}_1\|^2-C\|\dot{\phi}_1\|^2,$$
$$|\langle\rho\dot{\phi}_1,(\partial_x u+\partial_y v)\dot{\phi}_1\rangle|\le C\|\dot{\phi}_1\|^2;$$

therefore, we obtain the following estimate from (3.9):

$$-\partial_t \left(\|\dot{\phi}_1\|^2 + \|\nabla \dot{\phi}_{2,3}\|^2 \right) + \|\rho^{-\frac{1}{2}} \triangle \dot{\phi}_{2,3}\|^2 \leq C \left(\|\dot{\phi}\|^2 + \|\nabla \dot{\phi}_{2,3}\|^2 + \|\dot{g}\|^2 \right). \tag{3.10}$$

Combining (3.8) and (3.10), we obtain

$$-\partial_t \left(\|\dot{\phi}\|^2 + \|\nabla \dot{\phi}_{2,3}\|^2 \right) + \|\rho^{-\frac{1}{2}} \triangle \dot{\phi}_{2,3}\|^2 \leq C \left(\|\dot{\phi}\|^2 + \|\nabla \dot{\phi}_{2,3}\|^2 + \|\dot{g}\|^2 \right). \tag{3.11}$$

Applying the Gronwall inequality and noticing $\dot{\phi} = 0$ at $t = T$, we get (3.6) in Theorem 3.1.

Next we derive the negative norm estimate for the solution of (3.3) and (3.4). Let Λ denote the operator with symbol

$$\lambda(\xi) = \sqrt{1 + |\xi|^2},$$

where $\xi = (\xi_1, \xi_2)$ is the dual variable of (x, y). Now we are going to establish the following estimate.

THEOREM 3.2. *For any $s \in R$, the solutions of* (3.4) *and* (3.5) *satisfy the following estimate*:

$$\|\Lambda^s \dot{\phi}(t)\|^2 + \|\Lambda^{s+2} \dot{\phi}_{2,3}(t)\|^2 \leq C \left(\|\Lambda^s \dot{g}(t)\|^2 + \int_0^T \|\Lambda^s \dot{g}(\tau)\|^2 d\tau \right). \tag{3.12}$$

Proof. Let $L^*_{2,3}$ denote the second and third components of the operator L^*. Consider the inner product

$$\langle \Lambda^s \dot{\phi}_{2,3}, \Lambda^s \dot{g}_{2,3} \rangle = \langle \Lambda^s \dot{\phi}_{2,3}, L^*_{2,3} \Lambda^s \dot{\phi} \rangle + \langle \Lambda^s \dot{\phi}_{2,3}, [\Lambda^s, L^*_{2,3}] \dot{\phi} \rangle.$$

Similar to (3.8), we have

$$\begin{aligned} &-\partial_t \|\Lambda^s \dot{\phi}_{2,3}\|^2 + \|\rho^{-\frac{1}{2}} \nabla \Lambda^s \dot{\phi}_{2,3}\|^2 \\ &\quad \leq C \left(\|\Lambda^s \dot{\phi}\|^2 + \|\Lambda^s \dot{g}_{2,3}\|^2 + |\langle \Lambda^s \dot{\phi}_{2,3}, [\Lambda^s, L^*_{2,3}] \dot{\phi} \rangle| \right). \end{aligned} \tag{3.13}$$

Since the commutator operator $[\Lambda^s, L^*_{2,3}]$ is of order $s + 1$,

$$|\langle \Lambda^s \dot{\phi}_{2,3}, [\Lambda^s, L^*_{2,3}] \dot{\phi} \rangle| \leq C \|\Lambda^{s+1} \dot{\phi}_{2,3}\| \|\Lambda^s \dot{\phi}\| \leq \epsilon \|\Lambda^{s+1} \dot{\phi}_{2,3}\|^2 + C(\epsilon) \|\Lambda^s \dot{\phi}\|^2.$$

Therefore, we obtain the following from (3.13):

$$-\partial_t \|\Lambda^s \dot{\phi}_{2,3}\|^2 + \|\rho^{-\frac{1}{2}} \nabla \Lambda^s \dot{\phi}_{2,3}\|^2 \leq C \left(\|\Lambda^s \dot{\phi}\|^2 + \|\Lambda^s \dot{g}_{2,3}\|^2 \right). \tag{3.14}$$

Then consider the inner product

$$-\langle \triangle \Lambda^s \dot{\phi}_{2,3}, \Lambda^s \dot{g}_{2,3} \rangle = -\langle \triangle \Lambda^s \dot{\phi}_{2,3}, L^*_{2,3} \Lambda^s \dot{\phi} \rangle - \langle \triangle \Lambda^s \dot{\phi}_{2,3}, [\Lambda^s, L^*_{2,3}] \dot{\phi} \rangle.$$

Similar to (3.9), we have

$$\begin{aligned} &-\tfrac{1}{2} \partial_t \|\nabla \Lambda^s \dot{\phi}_{2,3}\|^2 + \mu \|\rho^{-\frac{1}{2}} \triangle \Lambda^s \dot{\phi}_{2,3}\|^2 - \langle \rho \Lambda^s \dot{\phi}_1, \triangle (\partial_x \Lambda^s \dot{\phi}_2 + \partial_y \Lambda^s \dot{\phi}_3) \rangle \\ &\quad \leq C \left(\|\Lambda^s \dot{\phi}_{2,3}\|^2 + \|\nabla \Lambda^s \dot{\phi}_{2,3}\|^2 + \|\Lambda^s \dot{g}_{2,3}\|^2 + |\langle \triangle \Lambda^s \dot{\phi}_{2,3}, [\Lambda^s, L^*_{2,3}] \dot{\phi} \rangle| \right). \end{aligned} \tag{3.15}$$

From the first equation in (3.7),

$$\triangle\Lambda^s(\partial_x\dot\phi_2+\partial_y\dot\phi_3)=\nu^{-1}\Lambda^s[(\partial_t+\partial_x u+\partial_y v)\dot\phi_1+\Lambda^s\dot g_1],$$

and

$$-\langle\rho\Lambda^s\dot\phi_1,\Lambda^s[(\partial_t+\partial_x u+\partial_y v)\dot\phi_1]\rangle\geq-\tfrac12\partial_t\|\sqrt\rho\Lambda^s\dot\phi_1\|^2-C\|\Lambda^s\dot\phi_1\|^2,$$

hence

(3.16)
$$-\langle\rho\Lambda^s\dot\phi_1,\triangle(\partial_x\Lambda^s\dot\phi_2+\partial_y\Lambda^s\dot\phi_3)\rangle\geq-\frac{1}{2\nu}\partial_t\|\sqrt\rho\Lambda^s\dot\phi_1\|^2-C\left(\|\Lambda^s\dot\phi_1\|^2+\|\Lambda^s\dot g_1\|^2\right).$$

Because $[\Lambda^s,L^*_{2,3}]$ is an operator of order $s+1$ with respect to $\dot\phi_{2,3}$ and an operator of order s with respect to $\dot\phi_1$,

$$|\langle\triangle\Lambda^s\dot\phi_{2,3},[\Lambda^s,L^*_{2,3}]\dot\phi\rangle|\leq\epsilon\|\triangle\Lambda^s\dot\phi_{2,3}\|^2+C(\epsilon)\left(\|\Lambda^{s+1}\dot\phi_{2,3}\|^2+\|\Lambda^s\dot\phi\|^2\right). \tag{3.17}$$

From (3.15)–(3.17), we have

$$\begin{aligned}&-\partial_t\left(\|\nabla\Lambda^s\dot\phi_{2,3}\|^2+\partial_t\|\sqrt\rho\Lambda^s\dot\phi_1\|^2\right)+\|\rho^{-\frac12}\triangle\Lambda^s\dot\phi_{2,3}\|^2\\&\qquad\leq C\left(\|\Lambda^s\dot\phi\|^2+\|\nabla\Lambda^s\dot\phi_{2,3}\|^2+\|\Lambda^s\dot g\|^2\right).\end{aligned} \tag{3.18}$$

Combining (3.14) and (3.18), we obtain

$$\begin{aligned}&-\partial_t\left(\|\Lambda^s\dot\phi\|^2+\|\nabla\Lambda^s\dot\phi_{2,3}\|^2\right)+\|\rho^{-\frac12}\triangle\Lambda^s\dot\phi_{2,3}\|^2\\&\qquad\leq C_s\left(\|\Lambda^s\dot\phi\|^2+\|\nabla\Lambda^s\dot\phi_{2,3}\|^2+\|\Lambda^s\dot g\|^2\right).\end{aligned} \tag{3.19}$$

Applying the Gronwall inequality to (3.19) concludes the proof of the Theorem 3.2.

From Theorem 3.2, it is standard to derive the existence of a differentiable weak solution for (3.1) and (3.2). Since, for any large integer k,

$$\left|\int_0^T\langle\dot f,\dot\phi\rangle dt\right|=\left|\int_0^T\langle\Lambda^k\dot f,\Lambda^{-k}\dot\phi\rangle dt\right|\leq\int_0^T\|\Lambda^k\dot f\|\|\Lambda^{-k}\dot\phi\|dt.$$

Applying (3.12) for $s=-k$, we have

$$\left|\int_0^T\langle\dot f,\dot\phi\rangle dt\right|\leq C\int_0^T\|\Lambda^k\dot f\|dt\int_0^T\|\Lambda^{-k}L^*\dot\phi\|dt.$$

Therefore,

$$\int_0^T\langle\dot f,\dot\phi\rangle dt$$

defines a bounded linear functional of $L^*\dot\phi$ in the space $L^2([0,T],H^{-k}(R^2))$. By the Hahn–Banach extension theorem and the Riesz representation theorem, we obtain a weak solution $w\in L^2([0,T],H^k(R^2))$ such that

$$\int_0^T\langle\dot f,\dot\phi\rangle dt=\int_0^T\langle w,L^*\dot\phi\rangle dt\quad\forall\dot\phi\in C_0^\infty([0,T)\times R^2). \tag{3.20}$$

Since differentiable weak solutions satisfy the equation in the classical sense, we have proved the following existence theorem.

THEOREM 3.3. *For all* $\dot{f} \in C([0,T], H^k(R^2))$, $\dot{f}_1 \in C([0,T], H^{k+1}(R^2))$, $\dot{w}_0 \in H^k(R^2)$ *and* $\dot{\rho}_0 \in H^{k+1}(R^2)$, *the Cauchy problem* (2.1) *and* (2.2) *has a unique solution* $\dot{w}$ *such that its norm* $|||\dot{w}|||$ *is bounded and satisfies the estimate* (2.17).

4. Local existence of solution for the nonlinear problem. In this section, we shall establish the local existence of classical solutions for the Cauchy problem of (1.8) and (1.13). Consider the initial value problem

$$\begin{cases} \rho_t + (\rho u)_x + (\rho v)_y = 0, \\ (\rho u)_t + (\rho u^2 + p)_x + (\rho uv)_y = (T_{11})_x + (T_{12})_y, \\ (\rho v)_t + (\rho uv)_x + (\rho v^2 + p)_y = (T_{21})_x + (T_{22})_y, \end{cases} \tag{4.1}$$

$$\rho(x,y,0) = \rho_0(x,y), \quad u(x,y,0) = u_0(x,y), \quad v(x,y,0) = v_0(x,y). \tag{4.2}$$

We have the following theorem.

THEOREM 4.1. *For any initial data* (ρ_0, u_0, v_0) *such that the condition* $\rho_0 \geq \delta > 0$ *is satisfied and* $(\rho_0 - \bar{\rho}_0, u_0, v_0) \in H^k(R^2)$ $(k \geq 4)$, *where* $\bar{\rho}_0 > 0$ *is a constant, there exists a* $T > 0$ *such that for* $t \in [0,T]$, *the Cauchy problem* (4.1) *and* (4.2) *has a unique solution* (ρ, u, v) *such that* $\rho - \bar{\rho}_0 \in L^\infty([0,T]; H^{k+1}(R^2))$, $(u,v) \in L^\infty([0,T]; H^k(R^2))$, *and*

$$|||w|||_k^2 \leq C_k \|w_0\|_k^2 + \|\rho_0\|_{k+1}^2.$$

Remark 4.1. The solution in Theorem 4.1 is the classical solution, i.e., all the corresponding derivatives in (4.1) and (4.2) exist and are continuous and satisfy (4.1) and (4.2) in the classical sense.

Remark 4.1 is shown as follows. From

$$\rho \in L^\infty(0,T; H^5), \qquad (u,v) \in L^\infty(0,T; H^4), \tag{4.3}$$

we have, by the Sobolev imbedding theorem,

$$\nabla^3 \rho \in L^\infty(0,T; C^0), \qquad \nabla^2(u,v) \in L^\infty(0,T; C^0). \tag{4.4}$$

From (4.1), we obtain

$$\partial_t \rho \in L^\infty(0,T; H^3), \qquad \partial_t^2(u,v) \in L^\infty(0,T; H^2). \tag{4.5}$$

Therefore,

$$\partial_t \nabla^3 \rho \in L^\infty(0,T; H^0), \qquad \partial_t \nabla^2(u,v) \in L^\infty(0,T; H^0). \tag{4.6}$$

Combining (4.4) and (4.6), we have, by the trace theorem [8],

$$\nabla^3 \rho \in C(0,T; C^0), \qquad \nabla^2(u,v) \in C(0,T; C^0). \tag{4.7}$$

Using (4.1) again, we have

$$\partial_t^2 \rho \in L^\infty(0,T; H^1), \qquad \partial_t^2(u,v) \in L^\infty(0,T; H^0). \tag{4.8}$$

Combining (4.5) and (4.8), we have

$$\partial_t \rho \in C(0,T;C^0), \qquad \partial_t(u,v) \in C(0,T;C^0). \tag{4.9}$$

This concludes the proof of the remark.

As in §2, denote the quasilinear differential operator in (4.1) as

$$\mathcal{L}(w)w \equiv \begin{cases} (\partial_t + u\partial_x + v\partial_y)\rho + \rho(u_x + v_y) = 0, \\ (\partial_t + u\partial_x + v\partial_y)u + p'(\rho)\rho^{-1}\partial_x\rho - \nu\triangle\partial_x\rho - \mu\rho^{-1}\triangle u \\ \qquad\qquad - \frac{\mu}{3\rho}(\partial_{xx}u + \partial_{xy}v) = 0, \\ (\partial_t + u\partial_x + v\partial_y)v + p'(\rho)\rho^{-1}\partial_y\rho - \nu\triangle\partial_y\rho - \mu\rho^{-1}\triangle v \\ \qquad\qquad - \frac{\mu}{3\rho}(\partial_{xy}u + \partial_{yy}v) = 0. \end{cases}$$

Let $\tilde{w}_0(x,y,t)$ be the unique bounded solution for the Cauchy problem

$$\partial_t w - \triangle w = 0, \qquad w(x,y,0) = w_0(x,y). \tag{4.10}$$

It is readily checked that the solution $\tilde{w}_0(x,y,t)$ satisfies the following estimate:

$$\int_0^T \|\partial_t \tilde{w}_0\|_k^2 dt + \int_0^T \|\tilde{w}_0\|_{k+2}^2 dt \le C\|w_0\|_k^2. \tag{4.11}$$

Let $w \equiv \tilde{w}_0 + \dot{w}$, the problem (4.1) and (4.2) can be rewritten as the following Cauchy problem for the new unknown functions $\dot{w}$:

$$\begin{cases} \dot{L}(\dot{w})\dot{w} = -\mathcal{L}(\tilde{w}_0)\tilde{w}_0 \equiv \dot{f}, \\ \dot{w}(x,y,0) = 0, \end{cases} \tag{4.12}$$

where $\dot{L}(\dot{w})\dot{w} \equiv \mathcal{L}(\tilde{w}_0 + \dot{w})\dot{w} + (\mathcal{L}(\tilde{w}_0 + \dot{w}) - \mathcal{L}(\tilde{w}_0))\tilde{w}_0$ is the quasilinear differential operator of $\dot{w}$, whose linearization has the same structure as $\dot{L}$ in §2.

Since by (4.11), $\dot{f}_1 \in L^2(0,T;H^{k+1})$, and $\dot{f}_{2,3} \in L^2(0,T;H^k)$, it is obvious that Theorem 4.1 is equivalent to the following.

THEOREM 4.2. *Under the condition of Theorem* 4.1, *for any* $\dot{f}_1 \in L^2(0,T;H^{k+1})$ *and* $\dot{f}_{2,3} \in L^2(0,T;H^k)$, *there exists a* $T > 0$ *such that in* $t \in [0,T]$, *the Cauchy problem* (4.12) *has a unique solution* $\dot{w}$ *such that* $\dot{\rho} \in L^\infty([0,T];H^{k+1}(R^2))$, $(\dot{u},\dot{v}) \in L^\infty([0,T];H^k(R^2))$, *satisfying*

$$|||\dot{w}|||_k^2 \le C_k \int_0^T (\|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1}^2) dt. \tag{4.13}$$

Proof. Theorem 4.2 is proved by iteration. Let $\dot{w}_0(x,y,t) = 0$ and $\dot{w}_j(x,y,t)$ $(j = 1,2,\cdots)$ be defined as the unique solution of the following linear Cauchy problem:

$$\dot{L}(\dot{w}_{j-1})\dot{w}_j = \dot{f}, \qquad \dot{w}_j(x,y,0) = 0. \tag{4.14}$$

Choose $T \ll 1$ such that (2.15) is satisfied for $\tilde{w}_0$ in $[0,T]$. By the Sobolev imbedding theorem [9], we need only to show that for $T, \delta > 0$ sufficiently small, we have the successive solutions $\dot{w}_j (j = 1,2,\ldots)$, satisfying

$$|||\dot{w}_j|||_k^2 \le \delta \le \beta_k, \tag{4.15}$$

$$|||\dot{w}_j - \dot{w}_{j-1}|||_{k-2} \leq \tfrac{1}{2}|||\dot{w}_{j-1} - \dot{w}_{j-2}|||_{k-2}. \tag{4.16}$$

Assume (4.15) and (4.16) to be true for j and smaller indices. From the energy estimate (2.17) for the linearized problem, we have

$$|||\dot{w}_{j+1}|||_k^2 \leq C_k \int_0^T (\|\dot{f}\|_k^2 + \|\dot{f}_1\|_{k+1}^2)dt.$$

On the other hand, $\dot{w}_{j+1} - \dot{w}_j$ satisfies the homogeneous initial data and the following equation:

$$\dot{L}(\dot{w}_j)(\dot{w}_{j+1} - \dot{w}_j) = \left(\dot{L}(\dot{w}_{j-1}) - \dot{L}(\dot{w}_j)\right)\dot{w}_j. \tag{4.17}$$

Applying (2.17) of the order $k-2$, we have

$$|||\dot{w}_{j+1} - \dot{w}_j|||_{k-2}^2 \leq C_{k-2}\delta \int_0^T |||\dot{w}_j - \dot{w}_{j-1}|||_{k-2}^2 dt. \tag{4.18}$$

Choosing δ such that $C_{k-2}\delta < \frac{1}{2}$, we obtain (4.16). This finishes the proof of Theorem 4.2.

INSTABILITY OF PLANAR INTERFACES IN REACTION-DIFFUSION SYSTEMS*

MASAHARU TANIGUCHI† AND YASUMASA NISHIURA‡

Abstract. Instability of planar front solutions to reaction-diffusion systems in two space dimensions is studied. Let ε denote the width of interface. Then the planar front solution—or a solution having an internal transition layer which is flat—loses its stability when the length of interface along the tangential direction exceeds $O(\varepsilon^{1/2})$. The wavelength of the fastest growth is of $O(\varepsilon^{1/3})$ which is inherent in the system and determined by the nonlinearity and diffusion coefficients. Complete asymptotic characterization of these quantities as $\varepsilon \to 0$ is given by the analysis of what is called the singular dispersion relation derived from the linearized eigenvalue problem. The numerical computations also confirm that the theoretically predicted fastest growth wavy pattern actually arises from a randomly perturbed planar front.

Key words. stability, interface, singular perturbation, reaction diffusion system

AMS subject classifications. 35B25, 35B32, 35K57

1. Introduction and main results.

A variety of dissipative structures are created by symmetry breaking through successive bifurcations. The resulting patterns often have a separation boundary (or interfacial region) between two stable physical or chemical states. The simplest geometry of such interfaces is planar, and there is an extensive literature concerning "transition from planar to wavy patterns" in various fields. Especially in solidification problems, the classical Mullins–Sekerka instability is well known [MS], where the main issue is to determine the finite (or infinite) band of unstable wave numbers and find the fastest growth wavelength. They solved a free boundary problem of a Stefan type model where the interface has no thickness. However, there are several drawbacks to this approach, especially in the relation between linearized stability and nonlinear one which is in general unclear in this framework from a mathematical point of view (see, for instance, [St]). This motivates us to take another approach, namely, to adopt reaction-diffusion equations where the interface has small but positive thickness and there are no free boundaries. The phase field model (see, for instance, [Ca]) and activator-inhibitor systems, which we treat here, are the most well-known examples. The main objective of this paper is to describe rigorously the transition from planar to wavy patterns for the reaction-diffusion system (1.1).

Since our model system (1.1) is semilinear parabolic, it has several important advantages: global existence (in time) of solutions is easily obtained and the linearized stability implies a nonlinear one; it is an appropriate framework to study symmetry breaking bifurcations, since dynamical system theory can be applied to it; numerically it is quite easy to track the behavior of interface, since location of an interface is defined as a contour.

Despite this, there are very few rigorous results for asymptotic characterizations of reaction-diffusion systems. The main reason is that it is not an easy task to char-

acterize asymptotic forms as the thickness of an interface tends to zero, since both planar solutions and eigenfunctions of the linearized eigenvalue problem have singularities at the layer position in the above limit. In fact, for some problems, sharp interface models where the width of interface equals zero, are easier to handle; see [Ch], [HNM], and [GGI].

However, as far as the stability problem is concerned, the SLEP method originated in Nishiura and Fujii [NF] turns out to be quite useful to resolve the difficulties mentioned above. They decomposed the linearized eigenvalue problem into singular and nonsingular parts like the Lyapunov–Schmidt reduction in bifurcation theory and gave an asymptotic characterization of the singular part. This method has been developed by [NM], [N1], and [N2], and enables us to control critical eigenvalues which are crucial to the study of stability and bifurcation; see also [Sa] and [GJ].

The aim of this paper is the following. First, we derive a fundamental relation of eigenvalues and wave numbers called the *singular dispersion relation* from the linearized eigenvalue problem at a planar front solution; second, by using this relation, we determine the size of instability region in wave number space; third, we characterize the asymptotic behavior of the fastest growth wavelength as well as the associated eigenvalue when the width of interface tends to zero; finally, we study numerically to what extent the linearized stability analysis is valid to predict qualitatively the final wavy patterns starting from a perturbed planar front.

The idea of [NF] is available to resolve the first two problems. For the third problem, however, a more subtle analysis is necessary to determine such wavelength, because the eigenfunction which characterizes such wavelength has no useful limit when the interface becomes sharp. It should be noted that our theory is based on the analysis of linear stability, thus the theoretically predicted fastest growth wavelength—namely that of $O(\varepsilon^{1/3})$—is valid only when the perturbation is small. Nonetheless, our numerical computations show that this wavelength is dominant even for largely deformed wavy patterns (see Fig. 2).

In [OMK], they obtained interesting bifurcation curves for special activator-inhibitor models. They could solve explicitly the linearized problem, since piecewise-linear nonlinearity was employed. However, they did not treat the third problem mentioned above.

The model system takes the following form:

$$
\begin{aligned}
&\tau \frac{\partial u}{\partial t} = \varepsilon \Delta u + \frac{1}{\varepsilon} f(u,v) && \\
&\qquad\qquad && (t,x,y) \in \mathbb{R}^+ \times \Omega, \\
&\frac{\partial v}{\partial t} = D \Delta v + g(u,v) && \\
&\frac{\partial u}{\partial \nu} = 0 = \frac{\partial v}{\partial \nu} && (t,x,y) \in \mathbb{R}^+ \times \partial\Omega,
\end{aligned}
\tag{1.1}
$$

where Ω is a rectangle in the (x,y)-plane:

$$
\Omega = (0,1) \times (0,\ell), \qquad \ell > 0, \tag{1.2}
$$

τ, ε and D are positive constants, $\Delta = \partial^2/\partial x^2 + \partial^2/\partial y^2$, and ν denotes the unit outer normal vector. Assumptions for f and g will be stated at the end of this section. Let $\mathfrak{U}(\varepsilon) = (u(x,\varepsilon), v(x,\varepsilon))$ be a one-dimensional steady state solution (see Fig. 1), which

is defined in §2; then it is apparent that $\bar{\mathfrak{U}}(\varepsilon)$ defined by

$$\bar{\mathfrak{U}}(\varepsilon) \equiv (\bar{u}(x,y,\varepsilon), \bar{v}(x,y,\varepsilon)), \tag{1.3}$$

$$\begin{cases} \bar{u}(x,y,\varepsilon) \equiv u(x,\varepsilon) \\ \bar{v}(x,y,\varepsilon) \equiv v(x,\varepsilon) \end{cases} \quad \text{for any} \quad (x,y) \in \Omega \tag{1.4}$$

is a two-dimensional stationary solution of (1.1). The location of interface Γ^ε of $\bar{\mathfrak{U}}(\varepsilon)$ defined by

$$\Gamma^\varepsilon \equiv \{(x,y) \in \Omega; \bar{u}(x,y,\varepsilon) = h_0(\bar{v}(x,y,\varepsilon))\} \tag{1.5}$$

forms a straight line through $x = x^\varepsilon$, where x^ε denotes the layer position of $\mathfrak{U}(\varepsilon)$ (see Theorem 2.1).

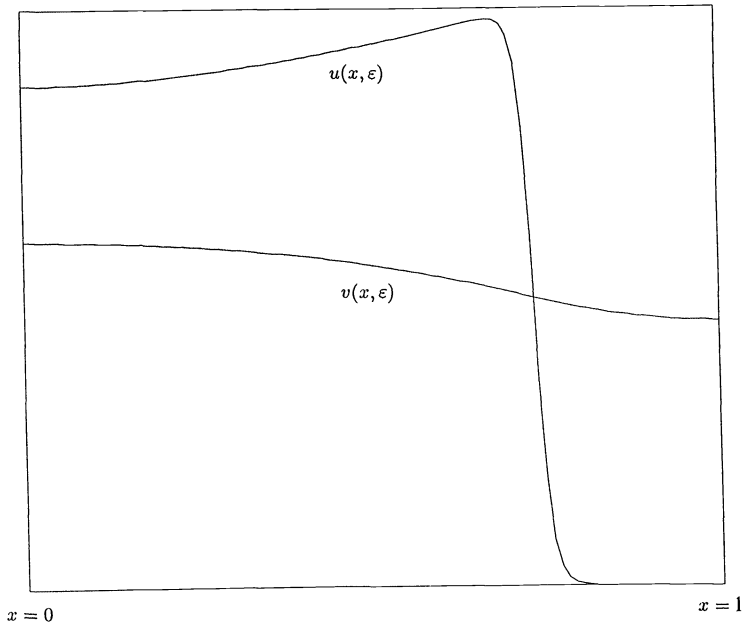

FIG. 1. *The graph of* $\mathfrak{U}(\varepsilon)$.

In order to study the stability properties of $\bar{\mathfrak{U}}(\varepsilon)$, we resort to the linearized principle, namely, we determine the spectral distribution of the following linearized eigenvalue problem at $\bar{\mathfrak{U}}(\varepsilon)$:

$$\begin{aligned} \begin{pmatrix} \mathfrak{L}(\varepsilon) & f_v(\bar{u},\bar{v}) \\ g_u(\bar{u},\bar{v}) & \mathfrak{M}(\varepsilon) \end{pmatrix} \begin{pmatrix} w \\ z \end{pmatrix} &= \lambda \begin{pmatrix} \varepsilon\tau & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} w \\ z \end{pmatrix} \quad \text{in } \Omega, \\ \frac{\partial w}{\partial \nu} = 0 = \frac{\partial z}{\partial \nu} \quad &\text{on } \partial\Omega, \end{aligned} \tag{1.6}$$

where $\mathfrak{L}(\varepsilon) \equiv \varepsilon^2\Delta + f_u(\bar{u},\bar{v})$ and $\mathfrak{M}(\varepsilon) \equiv D\Delta + g_v(\bar{u},\bar{v})$. Under the hypothesis given in Theorem 2.1 for (f,g) and parameters (τ, D), our results can be summarized as follows (more precise statements are given in §4).

MAIN THEOREM. (a) (Instability result.) *There exists* $\varepsilon_1 = \varepsilon_1(f, g, D, \tau) > 0$ *such that the following stability criterion holds for any fixed* $\varepsilon \in (0, \varepsilon_1)$:

$$\bar{\Omega}(\varepsilon) \text{ is stable if } \ell < \omega(\varepsilon)\varepsilon^{\frac{1}{2}}, \text{ and is unstable if } \ell > \omega(\varepsilon)\varepsilon^{\frac{1}{2}}, \tag{1.7}$$

where $\omega(\varepsilon)$ *is a positive function satisfying*

$$\lim_{\varepsilon \downarrow 0} \omega(\varepsilon) = \pi \widehat{\zeta_0}(0)^{-\frac{1}{2}} > 0. \tag{1.8}$$

(b) (The fastest growth wavelength.) *Let* $\lambda_{\max}(\varepsilon)$ *be the eigenvalue of* (1.6) *with the largest real part. Then, for any fixed* $\varepsilon \in (0, \varepsilon_1)$, $\lambda_{\max}(\varepsilon)$ *exists and is a real number satisfying*

$$\lim_{\varepsilon \downarrow 0} \lambda_{\max}(\varepsilon) = \widehat{\zeta_0}(0)/\tau > 0. \tag{1.9}$$

The eigenspace associated with $\lambda_{\max}(\varepsilon)$ *is the linear hull of a finite number of eigenfunctions, each of which can be expressed by*

$$\begin{aligned} w_0(x, y, \varepsilon) &= w_{m_0(\varepsilon)}(x) \cos \frac{m_0(\varepsilon)\pi y}{\ell}, \\ z_0(x, y, \varepsilon) &= z_{m_0(\varepsilon)}(x) \cos \frac{m_0(\varepsilon)\pi y}{\ell}, \end{aligned} \tag{1.10}$$

where $w_{m_0(\varepsilon)}(x)$, $z_{m_0(\varepsilon)}(x)$ *are smooth functions given by* (4.6), *and* $m_0(\varepsilon)$ *is some positive integer that satisfies*

$$\left| \varepsilon^{\frac{1}{3}} m_0(\varepsilon) - \frac{\ell}{\pi} \sqrt[3]{\frac{c_1^* c_2^*}{4D}} \right| < \delta(\varepsilon). \tag{1.11}$$

Here $\delta(\varepsilon)$ *is a positive function satisfying* $\delta(\varepsilon) \to 0$ *as* $\varepsilon \downarrow 0$, *and* c_1^*, c_2^* *are positive constants given by* (2.11). *The associated fastest growth wavelength is thus given by*

$$\mu_0(\varepsilon) = \frac{2\ell}{m_0(\varepsilon)} = 2\pi \sqrt[3]{\frac{4D}{c_1^* c_2^*}} \varepsilon^{\frac{1}{3}} + o(\varepsilon^{\frac{1}{3}}). \tag{1.12}$$

Note that the principal part of the right-hand side does not depend on ℓ.

REMARK 1.1. In the case when f is a piecewise linear function, part (a) was obtained by [OMK].

In the singular dispersion relation (see (3.25)), the term $\varepsilon\kappa^2$ corresponding to surface tension exerted along the tangential direction cannot be negligible, because it becomes dominant for deformations of short wavelengths (large wave numbers). On the other hand, from (1.11), we see that the most unstable wave number (see (4.5)) tends to ∞ as $\varepsilon \downarrow 0$. Dealing with the behavior of eigenfunctions for large wave numbers requires a delicate analysis. Also, it should be noted that although the eigenfunctions $(w_{m_0(\varepsilon)}(x), z_{m_0(\varepsilon)}(x))$ associated with $\lambda_{\max}(\varepsilon)$ have finite limits in appropriate function spaces as $\varepsilon \downarrow 0$, the limit of $z_{m_0(\varepsilon)}(x)$ turns out trivial. Hence it is not an easy task to extract useful information to obtain (1.11) from their limits. In general, when we deal with (1.6) in a multidimensional domain, we cannot expect

any "useful" limits of the eigenfunctions with the largest growth rate as $\varepsilon \downarrow 0$. This makes a sharp contrast with one-dimensional cases, in which the configuration of the limiting eigenfunction gives crucial information about the stability. In this paper, we always study (1.6), keeping ε positive, and get asymptotic expansions of eigenvalues for a small but positive ε.

From the Main Theorem, it is anticipated that a wavy pattern having the wavelength (1.12) starts to grow most rapidly at the first stage when a small perturbation is added to $\bar{\mathfrak{U}}(\varepsilon)$. We check this numerically for the data:

$$\begin{gathered} f(u,v) = u^2(\tfrac{3}{2} - u) - \tfrac{1}{2}uv, \qquad g(u,v) = \tfrac{3}{4}uv - \tfrac{1}{10}v - \tfrac{2}{5}v^2 \\ D = 0.4, \quad \varepsilon = 0.0075, \quad \ell = 2.46, \quad \tau = 1. \end{gathered} \tag{1.13}$$

In view of (A2), (A3), (2.11) and Remark 2.3, this immediately leads to

$$\begin{gathered} v^* = 1, \quad h_-(v^*) = 0, \quad h_0(v^*) = \tfrac{1}{2}, \quad h_+(v^*) = 1, \\ J'(v^*) = -\tfrac{1}{4}, \quad \gamma = \sqrt[4]{72}, \quad c_1^* = \tfrac{1}{4}\gamma, \quad c_2^* = \tfrac{3}{4}\gamma, \\ \Phi(\eta) = 1/\{1 + \exp(-\eta/\sqrt{2})\}. \end{gathered} \tag{1.14}$$

By numerical computation for the one-dimensional solution $\mathfrak{U}(\varepsilon)$, we have

$$\int_0^{x^*} g(U,V)dx = 0.117\ldots,$$

which together with (1.8) and (2.13) implies that $\omega(\varepsilon)\varepsilon^{1/2} = 0.35\ldots$. Hence, it follows from the Main Theorem (a) and (1.13) that $\bar{\mathfrak{U}}(\varepsilon)$ is unstable. Substituting (1.14) into (1.12), we see that the most unstable wavelength is equal to $1.232\ldots$, which implies that 4-mode wavy pattern should in general be selected after a short transition period. Here note that any mode higher than or equal to 8 does not grow from Theorem (a) and $\ell/8 < \omega(\varepsilon)\varepsilon^{1/2}$. Fig. 2 shows the evolution of a planar interface (see (1.5)) after we add a small bump on it (a) or give a random perturbation (b). The predicted wavelength (1.12) is seen to be dominant not only at the initial stage but also at the final stage in which the wavy patterns are fully developed. The final two states coincide almost exactly up to the phase shift.

On the other hand, suppose we put a pure sinusoidal perturbation of 5-mode on the planar front as in Fig. 3(c). The solution settles down to a wavy pattern of 5-mode, not 4-mode. This process is rather robust. In fact, even if we add a small bump to the previous perturbation as in Fig. 3(d), the same final pattern will eventually arise as before. This suggests the coexistence of stable wavy patterns (at least 4- and 5-modes) for the parameter values (1.13). Nevertheless, our numerical computations confirm that in most cases the solutions converge to the 4-mode pattern. Thus the theoretically predicted wavy pattern seems to have quite a large basin of attraction.

Now we state the assumptions for f and g.

(A1) f, g are smooth functions of u, v defined on some open set $\mathcal{O}$ in $\mathbb{R}^2$.

(A2) The nullcline $\{(u,v) \in \mathcal{O}; f(u,v) = 0\}$ is sigmoidal and consists of three curves C_i $(i = -, 0, +)$. We have $C_i \equiv \{(u,v) \in \mathcal{O}; u = h_i(v), v = I_i\}$, where h_i is a smooth function on an interval I_i $(i = -, 0, +)$. Let $\underline{v}$ (respectively, $\overline{v}$) be the minimum (respectively, maximum) of I_- (respectively, I_+), then we have $h_-(v) < h_0(v) < h_+(v)$ for any $v \in I^* \equiv (\underline{v}, \overline{v})$.

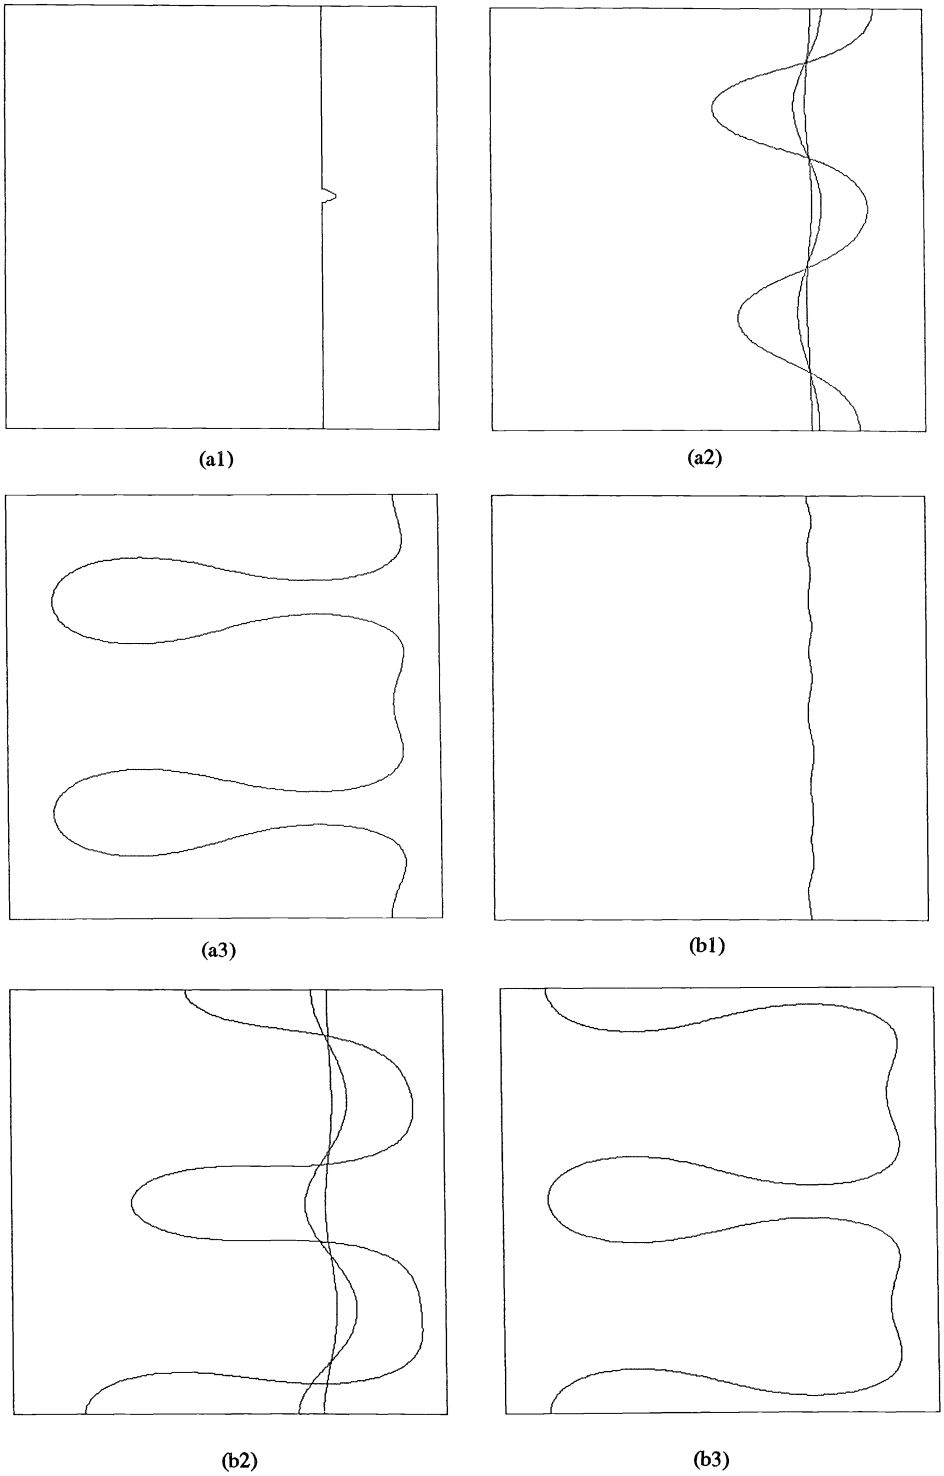

FIG. 2. *The evolution of interfaces from planar ones* I. (a) *A small projection is added to* Γ^ϵ; (b) Γ^ϵ *is perturbed randomly.*

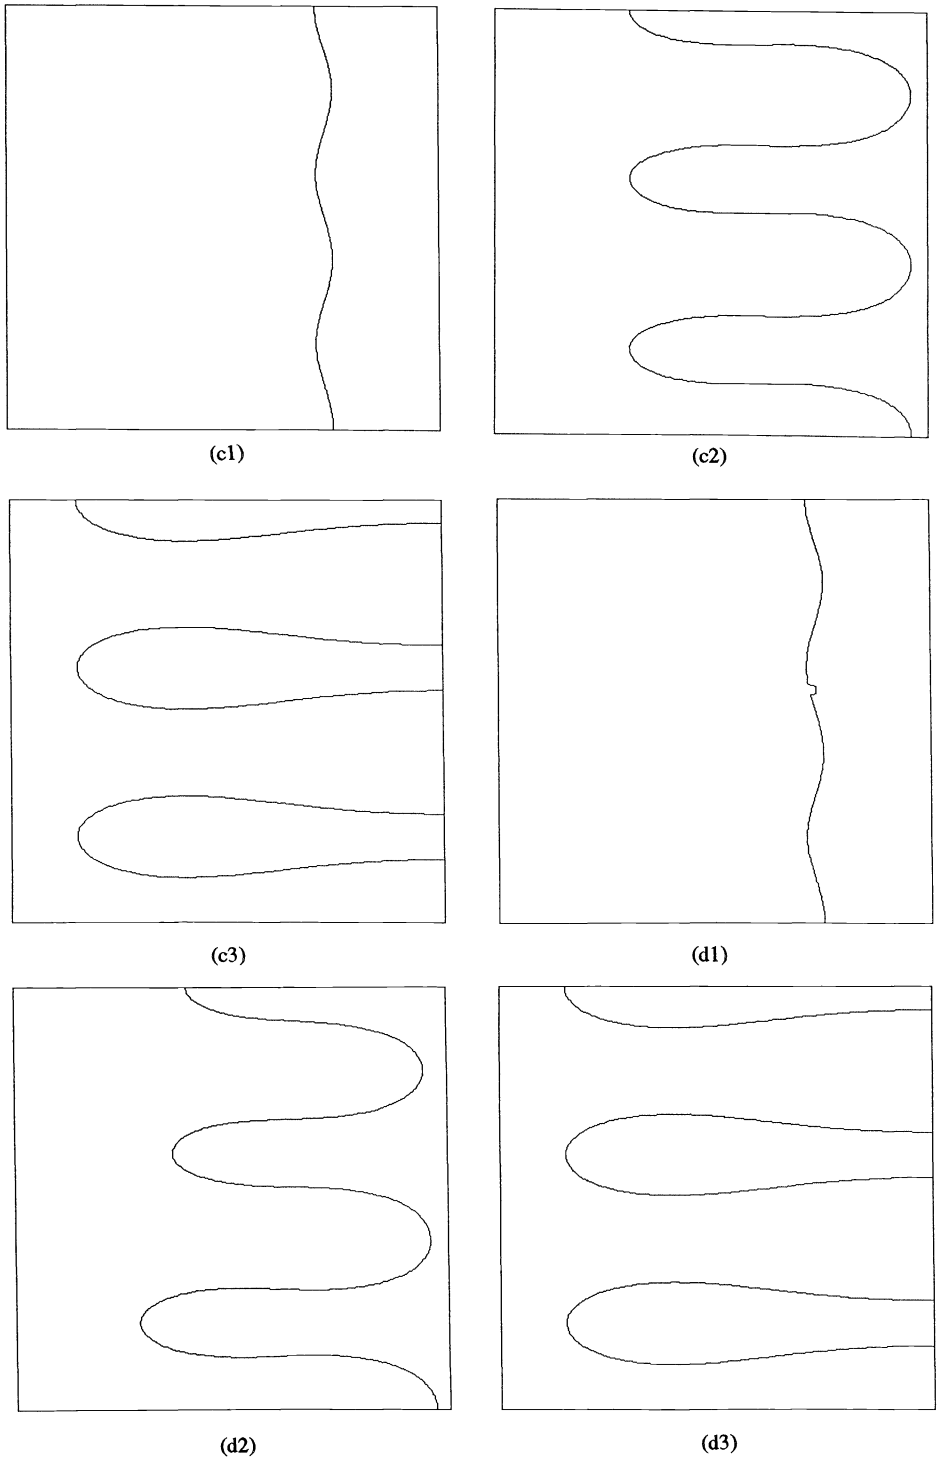

FIG. 3. *The evolution of interfaces from planar ones* II. (a) Γ^{ϵ} *is perturbed by a pure sinusoidal perturbation;* (b) *a small projection is added in addition.*

(A3) Let $J(v) \equiv \int_{h_-(v)}^{h_+(v)} f(s,v)ds$ for $v \in I^*$, then there exists $v^* \in I^*$ such that $J(v^*) = 0$, $J'(v^*) < 0$.

(A4) The nullcline of g intersects transversally with that of f. Let the intersection point on C_i, if it exists, be denoted by $P_i = (h_i(v_i), v_i)$, for $i = -, 0, +$. Then we assume that $v_- < v^* < v_+$.

(A5) (a) $f_u < 0$ on $R_- \cup R_+$, where $R_\pm$ are defined by

$$R_- = \{(h_-(v), v); v_- < v \leq v^*\}, \qquad R_+ = \{(h_+(v), v); v^* \leq v < v_+\};$$

(b) $g|_{R_-} < 0 < g|_{R_+}$;

(c) $(f_u g_v - f_v g_u)|_{R_- \cup R_+} > 0$, $g_v|_{R_- \cup R_+} \leq 0$.

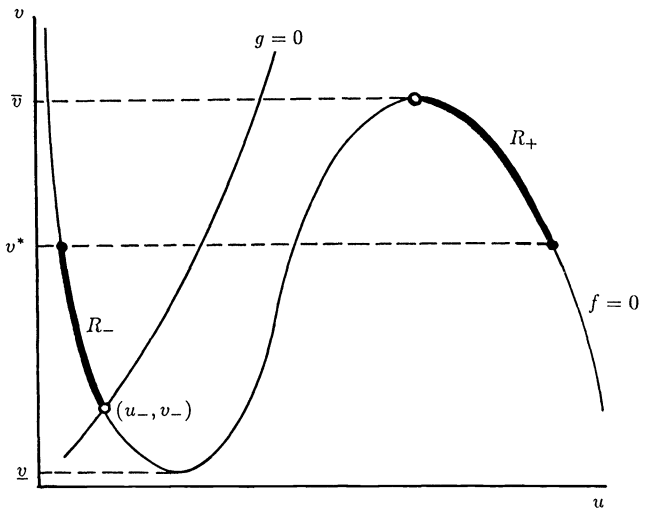

FIG. 4. *The nullclines of f and g.*

Fig. 4 shows typical functional forms of nullclines of f and g. It should be noted that, in order to satisfy (A1)–(A5), it is not necessary to assume that f and g intersect in this manner (*monostable type*).

The outline of this paper is as follows. In §2, we summarize several results for the Sturm–Liouville eigenvalue problem as well as the existence of a one-dimensional layered solution. In §3, we derive the singular dispersion relation (3.25) from the linearized eigenvalue problem at a planar front solution $\bar{\mathfrak{U}}(\varepsilon)$. In §4, we prove the main result Theorem 4.1, and show that the Main Theorem is a direct consequence of this theorem.

We shall use the following notation throughout this paper:

$I = (0,1)$.

$\mathbb{C}_a = \{\lambda \in \mathbb{C}; \Re\lambda \geq -a\}$ for $a > 0$.

$\mathcal{B}(X,Y)$ = the set of bounded linear operators from X to Y, where X and Y are Banach spaces.

$(\cdot,\cdot)_{L^2(I)}$=the inner product in $L^2(I)$.
$H^1(I)$, $H^{-1}(I)$ = the usual Sobolev space and its dual space.
${}_{H^1(I)}\langle\cdot,\cdot\rangle_{H^{-1}(I)}$ = the inner product between the above spaces.
o, O = the usual symbols of Landau.

2. Preliminaries. We start by summarizing the results of existence and stability of monolayered equilibrium solutions to (1.1) on a finite interval I:

$$\begin{aligned} \varepsilon\tau u_t &= \varepsilon^2 u_{xx} + f(u,v), \\ v_t &= Dv_{xx} + g(u,v), \\ u_x &= 0 = v_x, \end{aligned} \qquad \begin{aligned} &x \in I, \quad t > 0, \\ &\\ &x \in \partial I, \quad t > 0. \end{aligned} \tag{2.1}$$

We state the existence and stability of monolayered equilibrium solutions of (2.1) as follows.

THEOREM 2.1. *Assume f, g satisfy* (A1)–(A5). *Then there exists $D_* > 0$ and for any $D > D_*$, there exists $\tau_* > 0$ such that, for any fixed $(D,\tau) \in (D_*,\infty)\times(\tau_*,\infty)$,* (2.1) *has a stable equilibrium solution $\mathfrak{U}(\varepsilon) = (u(x,\varepsilon), v(x,\varepsilon))$ for arbitrary $\varepsilon \in (0,\varepsilon_0)$, where $\varepsilon_0 = \varepsilon_0(f,g,D,\tau) > 0$. $\{\mathfrak{U}(\varepsilon); \varepsilon \in (0,\varepsilon_0)\}$ is bounded in $C(\bar I)\times C^2(\bar I)$. Moreover there exists $x^* \in I$ and $V \in C^1(\bar I)$ which is a monotone decreasing function such that*

$$u(\cdot,\varepsilon) \to U \quad \text{in} \quad C([0,x^*-\iota]\cup[x^*+\iota,1]), \tag{2.2a}$$

$$v(\cdot,\varepsilon) \to V \quad \text{in} \quad C^1(\bar I), \tag{2.2b}$$

as $\varepsilon \downarrow 0$, where ι is an arbitrary positive number and

$$U(x) = \begin{cases} h_+(V(x)) & \text{if} \quad x \in [0,x^*], \\ h_-(V(x)) & \text{if} \quad x \in (x^*,1]. \end{cases} \tag{2.3}$$

Proof. See Appendix 1 in [NF] for the existence; see also [F], [Ito], [MTH], and [Sa]. For the stability, see [NF] and [NM].

REMARK 2.1. D_* is given in [NF, Prop. 1.1], and τ_* is expressed by (4.14) in §4.2.

REMARK 2.2. The location of the *interfacial point* $x = x^\varepsilon$ of $\mathfrak{U}(\varepsilon)$ is defined by

$$u(x^\varepsilon,\varepsilon) = h_0(v(x^\varepsilon,\varepsilon)). \tag{2.4}$$

The upper estimate for the distance between x^ε and x^* is given by $|x^\varepsilon - x^*| = O(\varepsilon)$. (See Sakamoto [Sa] for the proof.)

In order to solve (1.6), it is important to know the spectral behavior of the following Sturm–Liouville problem:

$$L(\varepsilon)[\phi] = \zeta\phi \quad \text{in } I, \qquad \phi_x = 0 \quad \text{on } \partial I, \tag{2.5}$$

where $L(\varepsilon)$ is a selfadjoint operator defined by

$$L(\varepsilon) \equiv \varepsilon^2 \frac{d^2}{dx^2} + f_u(u(x,\varepsilon), v(x,\varepsilon)). \tag{2.6}$$

Let $\{\phi_i(\varepsilon)\}_{i\ge 0}$ be the complete orthonormal set in $L^2(I)$ consisting of the eigenfunctions of $L(\varepsilon)$, and let $\{\zeta_i(\varepsilon)\}_{i\ge 0}$ be the associated eigenvalues. It is clear that $\{\zeta_i(\varepsilon)\}$ are real numbers ($\zeta_0(\varepsilon) > \zeta_1(\varepsilon) \ge \zeta_2(\varepsilon) \ge \cdots$). More precisely we have the following results.

PROPOSITION 2.1. (1) *There exists a constant* $\zeta_* > 0$ *such that*

$$\zeta_i(\varepsilon) < -\zeta_* < 0 < \zeta_0(\varepsilon) \qquad (i = 1, 2, 3, \dots) \tag{2.7}$$

is satisfied for any $\varepsilon \in (0, \varepsilon_0)$, *where* ε_0 *is the same one as in Theorem* 2.1. *Moreover* $\widehat{\zeta}_0(\varepsilon) \equiv \varepsilon^{-1}\zeta_0(\varepsilon)$ *converges to a positive constant* $\widehat{\zeta}_0(0)$ *as* $\varepsilon \downarrow 0$.

(2) $\{\varepsilon^{-1/2}\phi_0(\varepsilon)\}_{0<\varepsilon<\varepsilon_0}$ *is bounded in* $L^1(I)$, *and there exist positive constants* β, B *such that*

$$|\phi_0(x,\varepsilon)| \le B\varepsilon^{-\frac{1}{2}} \exp(-\beta|x - x^*|/\varepsilon) \quad \text{for } x \in I. \tag{2.8}$$

(3) *Let* h_0, h_1 *and* h_2 *be the functions defined by*

$$h_0(x,\varepsilon) = \varepsilon^{-\frac{1}{2}}\phi_0(x,\varepsilon), \tag{2.9a}$$

$$h_1(x,\varepsilon) = -\varepsilon^{-\frac{1}{2}} f_v(u(x,\varepsilon), v(x,\varepsilon))\phi_0(x,\varepsilon), \tag{2.9b}$$

$$h_2(x,\varepsilon) = \varepsilon^{-\frac{1}{2}} g_u(u(x,\varepsilon), v(x,\varepsilon))\phi_0(x,\varepsilon). \tag{2.9c}$$

Then they satisfy

$$h_i(x,\varepsilon) \longrightarrow c_i^*\delta(x - x^*) \quad \text{in } H^{-1}(I), \tag{2.10}$$

as $\varepsilon \downarrow 0$, *where* c_i^* *is a positive constant* $(i = 0, 1, 2)$, *and* $\delta(x - x^*)$ *is Dirac's* δ*-function at* x^*. *We have*

$$c_1^* = -\gamma J'(v^*), \qquad c_2^* = \gamma\{g(h_+(v^*), v^*) - g(h_-(v^*), v^*)\}, \tag{2.11}$$

where γ *is a positive constant* (*see* (2.13)).

Proof. See [NF], [NM], and [Sa] for the proof.

COROLLARY 2.1. *Under the same notation as in Proposition* 2.1, *we have*

$$|h_i(x,\varepsilon)| \le B\varepsilon^{-1} \exp(-\beta|x - x^*|/\varepsilon) \quad \text{for } x \in I, \tag{2.12a}$$

$$\int_I |h_i(x,\varepsilon)|dx \le 2B/\beta, \tag{2.12b}$$

for $i = 0, 1, 2$. *In particular, we have* $\|h_i(x,\varepsilon)\|_{H^{-1}(I)} < B_*$ *for some* $B_* = B_*(f, g, D) > 0$.

Proof of Corollary 2.1. We obtain the conclusions from (2.8), (2.9), and the fact that $\{\mathfrak{U}(\varepsilon); \varepsilon \in (0, \varepsilon_0)\}$ is bounded in $C(\bar{I}) \times C^2(\bar{I})$. We replaced B by a larger one, if necessary. Since $h_i(\varepsilon)$ is bounded in $L^1(I)$ uniformly for ε, it is uniformly bounded also in $H^{-1}(I)$ $(i = 1, 2)$. □

REMARK 2.3. According to [NF], γ and $\widehat{\zeta}_0(0)$ in Proposition 2.1 are explicitly given as follows. Let $\Phi(\eta)$ be a monotone increasing function in $C^\infty(\mathbb{R})$ defined by the unique solution of

$$\frac{d^2\Phi}{d\eta^2} + f(\Phi(\eta), v^*) = 0, \quad \Phi(0) = h_0(v^*), \quad \Phi(\pm\infty) = h_\pm(v^*),$$

then they are given by

$$\begin{aligned} \gamma &= \|d\Phi/d\eta\|_{L^2(I)}^{-1}, \\ \widehat{\zeta}_0(0) &= -\gamma^2 J'(v^*) D^{-1} \int_0^{x^*} g(U(x), V(x))dx. \end{aligned} \tag{2.13}$$

3. Derivation of the singular dispersion relation for the planar front. The aim of this section is to derive the singular dispersion relation (3.25) of eigenvalues and wave numbers for the planar front. Because of the singular nature of the transition layer as $\varepsilon \downarrow 0$, we immediately encounter several difficulties to solve (1.6), namely

(1) The highest order term of $\mathfrak{L}(\varepsilon)$ degenerates when $\varepsilon \downarrow 0$;

(2) $\bar{\mathfrak{U}}(\varepsilon)$ and hence the coefficients of (1.6) become discontinuous at the layer position when $\varepsilon \downarrow 0$.

The method given by Nishiura and Fujii [NF] is one of the useful tools for resolving these difficulties, and in fact we can derive (3.25) with the aid of this. However, we have another subtle problem which is inherent in higher-dimensional case, namely the dependency of eigenvalues on the wave number along the interfacial direction. It turns out that the fastest growth wave number depends on ε and tends to infinity when $\varepsilon \downarrow 0$. A careful analysis is needed to describe this dependency, and will be discussed in §4.

It is convenient to use a complete orthonormal system $\{Y_m\}_{m=0}^{\infty}$ in $L^2(0,\ell)$, where

$$Y_m(y) = \begin{cases} \ell^{-1/2} & \text{for } m = 0, \\ \sqrt{2}\ell^{-1/2}\cos(m\pi y/\ell) & \text{for } m > 0. \end{cases} \tag{3.1}$$

For (w,z) in (1.6), we set

$$w_m(x) = \int_0^\ell w(x,y)Y_m(y)dy, \qquad z_m(x) = \int_0^\ell z(x,y)Y_m(y)dy, \tag{3.2}$$

for $x \in I$, $(m = 0,1,2,\cdots)$. Then (w,z) is expanded as follows:

$$w(x,y) = \sum_{m=0}^{\infty} w_m(x)Y_m(y), \qquad z(x,y) = \sum_{m=0}^{\infty} z_m(x)Y_m(y) \tag{3.3}$$

in $L^2(\Omega)$. This decomposes (1.6) into the following countably many eigenvalue problems for $(w_m(x), z_m(x))$ and $\lambda \in \mathbb{C}$ with $m \in \bar{\mathbb{N}}$:

$$(L(\varepsilon) - \varepsilon^2\kappa^2)w_m + f_v(\bar{u},\bar{v})z_m = \varepsilon\tau\lambda w_m, \tag{3.4a}$$

$$\left(D\frac{d^2}{dx^2} + g_v(\bar{u},\bar{v}) - D\kappa^2\right)z_m + g_u(\bar{u},\bar{v})w_m = \lambda z_m, \tag{3.4b}$$

on I, subject to the zero flux boundary conditions

$$\frac{dw_m}{dx}(0) = 0 = \frac{dw_m}{dx}(1), \qquad \frac{dz_m}{dx}(0) = 0 = \frac{dz_m}{dx}(1), \tag{3.4c}$$

where $\kappa \equiv m\pi/\ell$ and

$$L(\varepsilon) \equiv \varepsilon^2\frac{d^2}{dx^2} + f_u(\bar{u},\bar{v}). \tag{3.5}$$

Since the planar front $\bar{\mathfrak{U}}(\varepsilon) = (\bar{u},\bar{v})$ defined by (1.3) and (1.4) is independent of y, so are $f_v(\bar{u},\bar{v}), g_v(\bar{u},\bar{v}), \ldots$. It is obvious that $L(\varepsilon)$ defined above is the same as (2.6).

REMARK 3.1. If (3.4) has a solution $\lambda \in \mathbb{C}$ and $(w_m(x), z_m(x)) \not\equiv (0,0)$, then $(w_m(x)Y_m(y), w_m(x)Y_m(x))$ satisfies (1.6) with the same λ. On the contrary, if (1.6) has an eigenvalue $\lambda \in \mathbb{C}$ and an eigenfunction (w, z), then $(w_m(x), z_m(x))$ defined by (3.2) satisfies (3.4) with the same λ for any $m \in \bar{\mathbb{N}}$. Moreover, $(w_m(x), z_m(x))$ is nontrivial for some $m \in \bar{\mathbb{N}}$.

This remark allows us to study (3.4) for each $m \in \bar{\mathbb{N}}$ instead of studying the eigenvalues and eigenfunctions of (1.6). Hereafter we regard κ as a continuous valuable in $[0, \infty)$, although κ takes only discrete values. We begin with the following fact.

PROPOSITION 3.1. *Let $\lambda \in \mathbb{C}$ be an eigenvalue of* (3.4) *for some $\kappa \in [0, \infty)$. There exists a positive constant $\lambda_* = \lambda_*(f, g, D)$, and for any given $\delta > 0$, there is $\bar{\varepsilon}(\delta)$ such that either*

$$\Re\lambda < -\lambda_* < 0 \quad \text{or} \quad |\varepsilon^2\kappa^2 + \varepsilon\tau\lambda| < \delta$$

holds for any $\varepsilon \in (0, \bar{\varepsilon}(\delta))$.

Proof. The proof of this lemma can be carried out by the same argument as in [NF,Prop.2.1] with no essential changes. We omit the proof. □

It suffices to study the behavior of eigenvalues in $\mathbb{C}_{\lambda_*}$ because the others have nothing to do with the instability of $\bar{\mathfrak{U}}(\varepsilon)$. Therefore we may assume, by virtue of Proposition 3.1, that there is a positive function $\bar{\delta}(\varepsilon)$ ($\bar{\delta}(\varepsilon) \to 0$ as $\varepsilon \downarrow 0$) such that

$$|\varepsilon^2\kappa^2 + \varepsilon\tau\lambda| < \bar{\delta}(\varepsilon), \tag{3.6}$$

for any $\varepsilon \in (0, \varepsilon_0)$, where $\varepsilon_0 = \varepsilon_0(f, g, D, \tau) > 0$ is the same one as in Theorem 2.1. We note that $\bar{\delta}(\varepsilon)$ is independent of (κ, λ). From (3.6), we have, for small $\varepsilon > 0$,

$$|\zeta_i(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda| \geq \zeta_*/2 > 0 \qquad (i = 1, 2, 3, \cdots), \tag{3.7}$$

which guarantees the existence of (3.9) below. We make some preparations in order to derive the relation (3.25).

First we introduce two operators from $L^2(I)$ to $L^2(I)$ as follows:

$$R(\varepsilon, \kappa, \lambda) \equiv -g_v(\bar{u}, \bar{v}) - g_u(\bar{u}, \bar{v})(L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^\dagger(-f_v(\bar{u}, \bar{v})\cdot), \tag{3.8a}$$

$$S(\varepsilon, \kappa, \lambda) \equiv -g_u(\bar{u}, \bar{v})(L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^{2\dagger}(-f_v(\bar{u}, \bar{v})\cdot), \tag{3.8b}$$

when $\varepsilon > 0$, where

$$(L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^\dagger \equiv \sum_{i=1}^{\infty} \frac{(\cdot, \phi_i(\varepsilon))_{L^2(I)}}{\zeta_i(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda}\phi_i(\varepsilon), \qquad L^2(I) \to L^2(I), \tag{3.9}$$

and when $\varepsilon = 0$, we set

$$R(0, \kappa, \lambda) = (f_u g_v - f_v g_u)/(-f_u)\big|_{\substack{u=U(x)\\v=V(x)}}, \tag{3.10a}$$

$$S(0, \kappa, \lambda) = f_v g_u / {f_u}^2\big|_{\substack{u=U(x)\\v=V(x)}}. \tag{3.10b}$$

Note that the right-hand sides of (3.10) are independent of (κ, λ), and that the right-hand side of (3.10a) is a strictly positive function on I, by virtue of (2.3) and (A5) in §1. Next we define a sesquilinear form $B(\varepsilon, \kappa, \lambda) : H^1(I) \times H^1(I) \to \mathbb{C}$ as follows:

$$B(\varepsilon, \kappa, \lambda)(z^1, z^2) \equiv D\,(z^1_x, z^2_x)_{L^2(I)} + ((R(\varepsilon, \kappa, \lambda) + D\kappa^2 + \lambda)\,z^1, z^2)_{L^2(I)}, \tag{3.11}$$

for $z^1, z^2 \in H^1(I)$. We also define an operator $T(\varepsilon, \kappa, \lambda) : H^1(I) \to H^{-1}(I)$ by

$$T(\varepsilon, \kappa, \lambda)z \equiv -Dz_{xx} + (R(\varepsilon, \kappa, \lambda) + D\kappa^2 + \lambda)z, \tag{3.12}$$

for $z \in H^1(I)$. Applying the standard Lax–Milgram theorem, we have the following lemma.

LEMMA 3.1. *There exist* $\varepsilon_* > 0$, $\delta_* > 0$ $(0 < \delta_* < \zeta_*/2)$ *such that* (i)–(v) *hold true for* $\varepsilon \in [0, \varepsilon_*)$, $\kappa \in [0, \infty)$ *and* $\lambda \in \mathbb{C}_{\lambda_*}$ *which satisfy*

$$|\varepsilon^2\kappa^2 + \varepsilon\tau\lambda| < \delta_*. \tag{3.13}$$

(i) $R(\varepsilon, \kappa, \lambda)$, $S(\varepsilon, \kappa, \lambda)$ *are uniformly bounded linear operators from* $L^2(I)$ *to* $L^2(I)$ *for* $(\varepsilon, \kappa, \lambda)$.

(ii) $B(\varepsilon, \kappa, \lambda)$ *is a bounded and coercive sesquilinear form on* $H^1(I)$.

(iii) $T(\varepsilon, \kappa, \lambda)$ *belongs to* $\mathcal{B}(H^1(I), H^{-1}(I))$, *and has an inverse operator denoted by* $K(\varepsilon, \kappa, \lambda)$. $K(\varepsilon, \kappa, \lambda)$ *is a uniformly bounded linear operator from* $H^{-1}(I)$ *to* $H^1(I)$ *for* $(\varepsilon, \kappa, \lambda)$.

(iv) *If we assume* (3.6) *in addition, we have*

$$K(\varepsilon, \kappa, \lambda) \to K(0, \kappa, \lambda) \quad \text{in} \quad \mathcal{B}(H^{-1}(I), H^1(I)),$$

as $\varepsilon \downarrow 0$. *The convergence is uniform for* (κ, λ) *in any compact subset of* $[0, \infty) \times \mathbb{C}_{\lambda_*}$.

(v) $K(\varepsilon, \kappa, \lambda)$ *depends continuously on* ε, *analytically on* $\lambda \in \overset{\circ}{\mathbb{C}}_{\lambda_*}$ *and real-analytically on* $\kappa > 0$ *in* $\mathcal{B}(H^{-1}(I), H^1(I))$, *respectively, and satisfies*

(3.14a)
$$\frac{\partial K}{\partial \lambda}(\varepsilon, \kappa, \lambda) = -K(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda) - \varepsilon\tau K(\varepsilon, \kappa, \lambda)S(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda),$$

(3.14b)
$$\frac{\partial K}{\partial \kappa}(\varepsilon, \kappa, \lambda) = -2\kappa\left\{D \cdot K(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda) + \varepsilon^2 K(\varepsilon, \kappa, \lambda)S(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda)\right\}.$$

Proof. We first note that $\bar{\mathfrak{U}} = (\bar{u}, \bar{v})$ can be regarded as a function of x, and is uniformly bounded in $C(\bar{I}) \times C^2(\bar{I})$ for ε. Using this fact, (2.7) and (3.13), we can see the right-hand sides of (3.8), (3.10) belong to $\mathcal{B}(L^2(I), L^2(I))$ and satisfy the conclusions of (i). The proofs of (ii)–(v) can be carried out by the same arguments as in [NF, Lemma 3.1] by making use of (3.13). □

We set $\varepsilon_1 = \varepsilon_1(f, g, D, \tau) > 0$ such that we have

$$\varepsilon_1 < \min\{\varepsilon_*, \varepsilon_0\}, \qquad 0 < \bar{\delta}(\varepsilon) < \delta_* \quad \text{for any} \quad \varepsilon \in (0, \varepsilon_1). \tag{3.15}$$

We have, from (3.4a),

$$(L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)w_m = -f_v(\bar{u}, \bar{v})z_m, \tag{3.16}$$

for any fixed $\varepsilon \in (0, \varepsilon_1)$. Multiplying the both sides of (3.16) by $\phi_i(\varepsilon)$, and integrating over I, we obtain

$$(\zeta_i(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)(w_m, \phi_i(\varepsilon))_{L^2(I)} = (-f_v(\bar{u}, \bar{v})z_m, \phi_i(\varepsilon))_{L^2(I)}. \tag{3.17}$$

In view of (3.7), (3.9) and (3.17), we see that it is necessary that $w_m(x)$ should have the form:

$$w_m = \alpha_0\phi_0(\varepsilon) + (L - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^\dagger(-f_v(\bar{u}, \bar{v})z_m) \tag{3.18}$$

for some $\alpha_0 \in \mathbb{C}$. The solvability of (3.16) will be discussed in the proof of Lemma 3.2. In what follows we shall derive necessary conditions so that λ may be an eigenvalue of (3.4). Inserting (3.18) into (3.4b), we obtain from (3.12)

$$T(\varepsilon,\kappa,\lambda)z_m = \alpha_0 g_u(\bar{u},\bar{v})\phi_0(\varepsilon), \tag{3.19}$$

which yields

$$z_m = \alpha_0 K(\varepsilon,\kappa,\lambda)(g_u(\bar{u},\bar{v})\phi_0(\varepsilon)). \tag{3.20}$$

Putting $\alpha = \varepsilon^{1/2}\alpha_0$ and using (2.9), we rewrite (3.18) and (3.20) as follows.

$$z_m = \alpha K(\varepsilon,\kappa,\lambda)h_2(\varepsilon), \tag{3.21a}$$

$$w_m = \alpha\varepsilon^{-\frac{1}{2}}\phi_0(\varepsilon) + (L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^\dagger(-f_v(\bar{u},\bar{v})z_m). \tag{3.21b}$$

Multiplying both sides of (3.4a) by $\phi_0(\varepsilon)$ and integrating over I, we find

$$(\zeta_0(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)(w_m,\phi_0(\varepsilon))_{L^2(I)} = (-f_v(\bar{u},\bar{v})z_m,\phi_0(\varepsilon))_{L^2(I)}. \tag{3.22}$$

From (3.21b), we have $(w_m,\phi_0(\varepsilon))_{L^2(I)} = \alpha\varepsilon^{-1/2}$. Hence we see from (2.9) and (3.21a) that (3.22) can be rewritten as

$$\alpha(\widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - \tau\lambda) = \alpha(K(\varepsilon,\kappa,\lambda)h_2(\varepsilon),h_1(\varepsilon))_{L^2(I)}. \tag{3.23}$$

Without loss of generality, we can assume (w_m,z_m) to be nontrivial, which implies $\alpha \neq 0$. Thus we obtain from (3.23)

$$\widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - \tau\lambda = (K(\varepsilon,\kappa,\lambda)h_2(\varepsilon),h_1(\varepsilon))_{L^2(I)}. \tag{3.24}$$

LEMMA 3.2. *For any fixed $\varepsilon \in (0,\varepsilon_1)$, $\lambda \in \mathbb{C}_{\lambda_*}$ is an eigenvalue of* (3.4) *if and only if, it satisfies*

$$F(\varepsilon,\kappa,\lambda) = 0, \tag{3.25}$$

where

$$F(\varepsilon,\kappa,\lambda) \equiv \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - \tau\lambda - H(\varepsilon,\kappa,\lambda), \tag{3.26}$$

$$H(\varepsilon,\kappa,\lambda) \equiv (K(\varepsilon,\kappa,\lambda)h_2(\varepsilon),h_1(\varepsilon))_{L^2(I)}. \tag{3.27}$$

The associated eigenfunction of (3.4) *is represented by* (3.21). *We call* (3.25) *the singular dispersion relation for the planar front.*

Proof. Tracing back the arguments before Lemma 3.2, we see that all what we have to do is to show the solvability of (3.16) starting from (3.25) and (3.21a). Let us consider the homogeneous equation:

$$(L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)\phi = 0 \quad \text{in } I, \qquad \phi_x = 0 \quad \text{on } \partial I. \tag{3.28}$$

In the case where (3.28) has no nontrivial solution, we can solve (3.16) as follows.

$$\begin{aligned} w_m =& (L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^{-1}(-f_v(\bar{u},\bar{v})z_m) \\ =& \frac{(-f_v(\bar{u},\bar{v})z_m,\phi_0(\varepsilon))_{L^2(I)}}{\zeta_0(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda}\phi_0(\varepsilon) + (L(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda)^\dagger(-f_v(\bar{u},\bar{v})z_m). \end{aligned} \tag{3.29}$$

From (3.21a) and (3.25), we have

$$(\text{The first term of (3.29)}) = \alpha\varepsilon^{-\frac{1}{2}}\phi_0(\varepsilon).$$

Putting together the above two equalities, we obtain (3.18). Next we consider the case where (3.28) has an nontrivial solution. In view of (3.7), we see that it is $\phi_0(\varepsilon)$. We can assume that

$$\zeta_0(\varepsilon) - \varepsilon^2\kappa^2 - \varepsilon\tau\lambda = 0,$$

which, together with (3.25) yields

$$H(\varepsilon, \kappa, \lambda) = 0.$$

Hence we obtain, from (3.21a),

$$\begin{aligned}(-f_v(\bar{u}, \bar{v})z_m, \phi_0(\varepsilon))_{L^2(I)} =& \alpha(K(\varepsilon, \kappa, \lambda)h_2(\varepsilon), -f_v(\bar{u}, \bar{v})\phi_0(\varepsilon))_{L^2(I)} \\ =& \alpha\varepsilon^{\frac{1}{2}}(K(\varepsilon, \kappa, \lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)} \\ =& \alpha\varepsilon^{\frac{1}{2}}H(\varepsilon, \kappa, \lambda) = 0,\end{aligned}$$

which equals to the orthogonality condition in (3.16). This completes the proof. □

4. Proof of the Main Theorem. The aim of this section is to give a proof of the Main Theorem in §1. We first state a key result Theorem 4.1 in §4.1, which immediately leads us to the Main Theorem. In §4.2 and §4.3, we study the precise behaviors of solutions of (3.25) with respect to κ, which are the main ingredients of §4.4, where we present a proof of Theorem 4.1. More precisely, a priori bound for solutions of (3.25) is given in §4.2. In §4.3 we parameterize the eigenvalues by κ of the form $\lambda = \widetilde{\lambda}(\varepsilon, \kappa)$ with the aid of the standard implicit function theorem. We also show in §4.3, that λ associated with sufficiently small κ and sufficiently large κ is negative-valued. In §4.4 we characterize $\kappa(\varepsilon)$ in Theorem 4.1 by $\left(\partial\widetilde{\lambda}/\partial\kappa\right)(\varepsilon, \kappa(\varepsilon)) = 0$. Although it is just a necessary condition for $\kappa(\varepsilon)$, it turns out to be sufficient to control the behavior of $\kappa(\varepsilon)$ when $\varepsilon \downarrow 0$ (see (4.2)).

4.1. Asymptotic behaviors of the fastest growth wave numbers and their eigenvalues. The following is a key result in this section.

THEOREM 4.1. *Under the same assumptions for D and τ as in Theorem 2.1, there exists $\varepsilon_1 = \varepsilon_1(f, g, D, \tau) > 0$ such that (1), (2), and (3) hold true for any fixed $\varepsilon \in (0, \varepsilon_1)$.*

(1) *Let $\lambda \in \mathbb{C}_{\lambda_*}$ satisfy (3.25), then λ is real.*

(2) *There exist $\underline{\kappa}(\varepsilon)$, $\overline{\kappa}(\varepsilon)$ $(0 < 2\underline{\kappa}(\varepsilon) < \overline{\kappa}(\varepsilon) < \infty)$ such that, if $\lambda \in (-\lambda_*, \infty)$ satisfies (3.25) with some $\kappa \notin [\underline{\kappa}(\varepsilon), \overline{\kappa}(\varepsilon)]$, then $\lambda < 0$.*

(3) *Let $\mathcal{S}$ be the set of (κ, λ) satisfying (3.25) and $\lambda \geq 0$, then we have*

$$\mathcal{S} = \{(\kappa, \lambda); \kappa \in [\underline{\kappa}(\varepsilon), \overline{\kappa}(\varepsilon)], \lambda = \widetilde{\lambda}(\varepsilon, \kappa)\},$$

where $\widetilde{\lambda}(\varepsilon, \cdot)$ is a real-valued function that fulfills

(i) $\widetilde{\lambda}(\varepsilon, \cdot) \in C^\infty[\underline{\kappa}(\varepsilon), \overline{\kappa}(\varepsilon)]$;

(ii) $\widetilde{\lambda}(\varepsilon, \underline{\kappa}(\varepsilon)) = 0 = \widetilde{\lambda}(\varepsilon, \overline{\kappa}(\varepsilon))$;

(iii) $\widetilde{\lambda}(\varepsilon, \kappa) > 0$ *for any* $\kappa \in (\underline{\kappa}(\varepsilon), \overline{\kappa}(\varepsilon))$

with the asymptotic limits

$$\lim_{\varepsilon\downarrow 0}\varepsilon\overline{\kappa}(\varepsilon)^2=\widehat{\zeta}_0(0)\quad\text{and}\quad\lim_{\varepsilon\downarrow 0}\underline{\kappa}(\varepsilon)=\underline{\kappa}(0)\in(0,\infty). \tag{4.1}$$

Moreover, let $\kappa(\varepsilon)$ be any local maximizer of $\widetilde{\lambda}(\varepsilon,\cdot)$ in $(\underline{\kappa}(\varepsilon),\overline{\kappa}(\varepsilon))$; then we have, as $\varepsilon\downarrow 0$,

$$\varepsilon\kappa(\varepsilon)^3\to\frac{c_1^*c_2^*}{4D}, \tag{4.2}$$

$$\widetilde{\lambda}(\varepsilon,\kappa)\to\widehat{\zeta}_0(0)/\tau\quad\textit{uniformly for }\kappa\in(\kappa(\varepsilon)-M,\kappa(\varepsilon)+M), \tag{4.3}$$

where M is any positive constant. Note that the asymptotic characterizations (4.2) *and* (4.3) *do not depend on the choice of a local maximizer.*

Proof of Main Theorem (a). Let $\underline{m}(\varepsilon)$, $\overline{m}(\varepsilon)$ be defined by

$$\underline{m}(\varepsilon)=\ell\underline{\kappa}(\varepsilon)/\pi,\qquad\overline{m}(\varepsilon)=\ell\overline{\kappa}(\varepsilon)/\pi.$$

We have $0<2\underline{m}(\varepsilon)<\overline{m}(\varepsilon)<\infty$. By virtue of Remark 3.1, Lemma 3.2, and Theorem 4.1, we have the following alternative.

Case 1. If $[\underline{m}(\varepsilon),\overline{m}(\varepsilon)]$ includes no positive integer, then (1.6) has no eigenvalue whose real part is nonnegative.

Case 2. If $(\underline{m}(\varepsilon),\overline{m}(\varepsilon))$ includes a positive integer, then (1.6) has at least one positive real eigenvalue.

Let us put $\omega(\varepsilon)\equiv\pi\varepsilon^{-1/2}\overline{\kappa}(\varepsilon)^{-1}$. We have

$$\omega(\varepsilon)\varepsilon^{\frac{1}{2}}=\pi\overline{\kappa}(\varepsilon)^{-1}=\ell/\overline{m}(\varepsilon). \tag{4.4}$$

When $\ell<\omega(\varepsilon)\varepsilon^{1/2}$, we have $\overline{m}(\varepsilon)<1$ from (4.4). Hence Case 1 holds in this case, which implies that $\overline{\mathfrak{U}}(\varepsilon)$ is stable. When $\ell>\omega(\varepsilon)\varepsilon^{1/2}$, we have $\overline{m}(\varepsilon)>1$ from (4.4). Putting $\overline{m}(\varepsilon)=N+\nu$ (N is a positive integer; $0<\nu\le 1$), we get

$$\underline{m}(\varepsilon)<\overline{m}(\varepsilon)/2=(N+\nu)/2\le N,$$

which implies that a positive integer N belongs to $(\underline{m}(\varepsilon),\overline{m}(\varepsilon))$. We see that Case 2 holds, and hence $\overline{\mathfrak{U}}(\varepsilon)$ turns out to be unstable in this case. □

Proof of Main Theorem (b). From Main Theorem (a), we see that Case 2 holds and hence $\overline{\mathfrak{U}}(\varepsilon)$ becomes unstable for sufficiently small ε. We set

$$\overline{\lambda}(\varepsilon,m)\equiv\widetilde{\lambda}(\varepsilon,m\pi/\ell),$$

for $m\in\mathbb{N}\cap(\underline{m}(\varepsilon),\overline{m}(\varepsilon))$. In view of Theorem 4.1, we see that there exist a finite number of positive integers which maximize $\overline{\lambda}(\varepsilon,\cdot)$. Let us denote arbitrary one of them by $m_0(\varepsilon)$. Then $\widetilde{\lambda}(\varepsilon,\cdot)$ must have at least one local maximizer in $((m_0(\varepsilon)-1)\pi/\ell,(m_0(\varepsilon)+1)\pi/\ell)$. Let $\kappa(\varepsilon)$ be any one of them. We can apply Theorem 4.1 for this $\kappa(\varepsilon)$. Then it follows that

$$\varepsilon\kappa(\varepsilon)^3\to\frac{c_1^*c_2^*}{4D}\quad(\text{as}\quad\varepsilon\downarrow 0),\qquad|m_0(\varepsilon)-\ell\kappa(\varepsilon)/\pi|<1$$

are satisfied, which yields (1.11). We note here that (1.11) holds true regardless of our way of selecting $m_0(\varepsilon)$. We put

$$\kappa_0(\varepsilon) = m_0(\varepsilon)\pi/\ell. \tag{4.5}$$

Then we have $|\kappa_0(\varepsilon) - \kappa(\varepsilon)| < \pi/\ell$. Using (4.3), we obtain

$$\widetilde{\lambda}(\varepsilon, \kappa_0(\varepsilon)) \to \widehat{\zeta}_0(0)/\tau,$$

as $\varepsilon \downarrow 0$ which, together with $\lambda_{\max}(\varepsilon) = \widetilde{\lambda}(\varepsilon, \kappa_0(\varepsilon))$, yields (1.9). Next, from (3.21), we have

$$z_{m_0(\varepsilon)} = \alpha K(\varepsilon, \kappa_0(\varepsilon), \lambda_{\max}(\varepsilon))h_2(\varepsilon), \tag{4.6a}$$

$$w_{m_0(\varepsilon)} = \alpha\varepsilon^{-\frac{1}{2}}\phi_0(\varepsilon) + (L(\varepsilon) - \varepsilon^2\kappa_0(\varepsilon)^2 - \varepsilon\tau\lambda_{\max}(\varepsilon))^{\dagger}(-f_v(\bar{u}, \bar{v})z_{m_0(\varepsilon)}), \tag{4.6b}$$

where α is an arbitrary constant in $\mathbb{R}$. Since $(w_{m_0(\varepsilon)}, z_{m_0(\varepsilon)})$ satisfies (3.4), the standard bootstrap argument implies that $w_{m_0(\varepsilon)}$ and $z_{m_0(\varepsilon)}$ are C^∞-functions on I. At last we obtain (1.12) immediately from (1.11), which completes the proof of Main Theorem (b). □

REMARK 4.1. Using Lemma 3.1 (iv) and (2.9c), we have the limit of (4.6a) in $H^1(I)$ as $\varepsilon \downarrow 0$. Let the limit be denoted by z^*. From (4.35b) and (2.9c), we obtain

$$\|\text{the right-hand side of (4.6a)}\|_{L^\infty(I)} = O(\kappa_0(\varepsilon)^{-\frac{1}{2}}),$$

which, together with the fact $\kappa_0(\varepsilon) \to \infty$ as $\varepsilon \downarrow 0$, implies that z^* is a trivial function. Hence it follows, from (2.9a), that $w_{m_0(\varepsilon)}(x)$ converges to $\alpha c_0^* \delta(x - x^*)$ in $H^{-1}(I)$ as $\varepsilon \downarrow 0$.

4.2. A priori bound for eigenvalues in $\mathbb{C}_{\lambda_*}$. In this subsection, we show the uniformly boundedness of $\lambda \in \mathbb{C}_{\lambda_*}$ satisfying the singular dispersion relation (3.25).

We introduce a Sturm–Liouville operator:

$$T_0 \equiv -D\frac{d^2}{dx^2} + (f_u g_v - f_v g_u)/(-f_u)|_{\substack{u=U(x)\\v=V(x)}} \tag{4.7}$$

subject to the zero flux boundary condition. Let $\{\psi_n, \gamma_n\}_{n=0}^\infty$ be the complete orthonormal set and the eigenvalues associated with T_0. It is clear from (2.3) and (A.5) in §1 that the eigenvalues are strictly positive. It follows from the general theory of the Sturm–Liouville problems (see for instance [CH]), that $\{\psi_n\}_{n=0}^\infty$ is bounded in $C(\bar{I})$ and $\gamma_n = O(n^2)$ (as $n \uparrow \infty$). In view of Lemma 3.1 and (3.12), we have

$$K(0, \kappa, \lambda)\delta(x - x^*) = \sum_{n=0}^{\infty} \frac{\psi_n(x^*)\psi_n(x)}{\gamma_n + D\kappa^2 + \lambda} \quad \text{in} \quad C(\bar{I}). \tag{4.8}$$

In what follows we assume $\lambda_* < \gamma_0$ with replacing λ_* in Proposition 3.1 by a smaller one, if necessary. In order to treat (3.25), the following properties of H (see (3.27)) are useful.

LEMMA 4.1. *Under the same hypotheses of Lemma* 3.1, *we have* (i)–(iii).

(i) $H(\varepsilon,\kappa,\lambda)$ *is a continuous and uniformly bounded function of* $(\varepsilon,\kappa,\lambda)$ *with*

$$\widehat{\zeta}_0(0) - H(0,0,0) < 0. \tag{4.9}$$

(ii) $H(\varepsilon,\kappa,\lambda)$ *depends analytically on* $\lambda \in \overset{\circ}{\mathbb{C}}_{\lambda_*}$ *and real analytically on* $\kappa > 0$, *respectively. We have*

$$\frac{\partial H}{\partial \lambda}(\varepsilon,\kappa,\lambda) = -I(\varepsilon,\kappa,\lambda) - \varepsilon\tau J(\varepsilon,\kappa,\lambda), \tag{4.10a}$$

$$\frac{\partial H}{\partial \kappa}(\varepsilon,\kappa,\lambda) = -2\kappa\{D\cdot I(\varepsilon,\kappa,\lambda) + \varepsilon^2\cdot J(\varepsilon,\kappa,\lambda)\}, \tag{4.10b}$$

where $I(\varepsilon,\kappa,\lambda), J(\varepsilon,\kappa,\lambda)$ *are uniformly bounded functions defined by*

$$I(\varepsilon,\kappa,\lambda) \equiv (K(\varepsilon,\kappa,\lambda)K(\varepsilon,\kappa,\lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}, \tag{4.11a}$$

$$J(\varepsilon,\kappa,\lambda) \equiv (K(\varepsilon,\kappa,\lambda)S(\varepsilon,\kappa,\lambda)K(\varepsilon,\kappa,\lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}. \tag{4.11b}$$

(iii) *We have*

$$\begin{aligned} H(0,\kappa,\lambda) &= c_1^*c_2^*\cdot {}_{H^1(I)}\langle K(0,\kappa,\lambda)\delta(x-x^*), \delta(x-x^*)\rangle_{H^{-1}(I)} \\ &= \sum_{n=0}^{\infty} \frac{c_1^*c_2^*|\psi_n(x^*)|^2}{\gamma_n + D\kappa^2 + \lambda}, \end{aligned} \tag{4.12}$$

$$\begin{aligned} I(0,\kappa,\lambda) &= c_1^*c_2^*\cdot {}_{H^1(I)}\langle K(0,\kappa,\lambda)K(0,\kappa,\lambda)\delta(x-x^*), \delta(x-x^*)\rangle_{H^{-1}(I)} \\ &= c_1^*c_2^*\cdot (K(0,\kappa,\lambda)\delta(x-x^*), K(0,\kappa,\bar{\lambda})\delta(x-x^*))_{L^2(I)} \\ &= \sum_{n=0}^{\infty} \frac{c_1^*c_2^*|\psi_n(x^*)|^2}{(\gamma_n + D\kappa^2 + \lambda)^2}. \end{aligned} \tag{4.13}$$

Proof. Basically the above properties of H are the consequences from those of K in Lemma 3.1 except (4.9), (4.12), and (4.13). The inequality (4.9) comes from the stability of $\mathfrak{U}(\varepsilon)$ when $\tau = 1/\varepsilon$, which was proved in [NF] (see also [NM, Thm. 2.2]). Next, let $\varepsilon \downarrow 0$ in (3.27) and (4.11a), then by virtue of (2.10), (4.8) and the property of $K(\varepsilon,\kappa,\lambda)$ in Lemma 3.1 (iv), we obtain (4.12) and (4.13), respectively. □

Now we can give τ_*, which appeared in §§2 and 3 and in the assumptions of Theorem 4.1. We put

$$\begin{aligned} \tau_* &= c_1^*c_2^*\,\|K(0,0,-\lambda_*)\delta(x-x^*)\|_{L^2(I)}^2 \\ &= \sum_{n=0}^{\infty} \frac{c_1^*c_2^*|\psi_n(x^*)|^2}{(\gamma_n - \lambda_*)^2}. \end{aligned} \tag{4.14}$$

Here we used (4.8) to get the second equality of (4.14). Since $\lambda_* = \lambda_*(f,g,D)$, we can see that τ_* depends only on f, g and D. Our standing assumption for τ throughout this paper is given by

$$\tau_* < \tau. \tag{4.15}$$

Recalling (3.15), Lemma 4.1 is valid for any $\varepsilon \in (0,\varepsilon_1)$. Then we have the following a priori estimate for λ.

PROPOSITION 4.1. *There exists* $M_1 = M_1(f, g, D) > 0$ *such that, for any fixed* $\varepsilon \in (0, \varepsilon_1)$, *we have*

$$|\lambda| < M_1 \tag{4.16}$$

for any eigenvalue λ *of* (3.25) *in* $\mathbb{C}_{\lambda_*}$.

Proof. We take the real part and imaginary parts of (3.25), respectively,

$$\begin{aligned} \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - \tau\Re\lambda - \Re H(\varepsilon, \kappa, \lambda) = 0, \\ -\tau\Im\lambda - \Im H(\varepsilon, \kappa, \lambda) = 0, \end{aligned}$$

which yields

$$\begin{aligned} \tau\Re\lambda = \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - \Re H(\varepsilon, \kappa, \lambda) \le |\widehat{\zeta}_0(\varepsilon)| + |H(\varepsilon, \kappa, \lambda)|, \\ \tau|\Im\lambda| \le |H(\varepsilon, \kappa, \lambda)|. \end{aligned}$$

The conclusion follows from Proposition 2.1, Lemma 4.1 (i), and (4.15). □

REMARK 4.2. In view of the proof of Proposition 4.1, we see that the assumption (4.15) is too strong to obtain a priori bound, in fact, it suffices to assume that τ is strictly bounded away from zero. However, as we will see in §4.3, we need the condition (4.15) to guarantee that the eigenvalues of (3.25) in $\mathbb{C}_{\lambda_*}$ are real and hence there does not occur the instability of Hopf type.

4.3. Parameterization of eigenvalues in $\mathbb{C}_{\lambda_*}$. The objective of this subsection is to show that the distribution of eigenvalues of singular dispersion relation (3.25) is, as a function of κ, like a parabolic curve qualitatively. More precisely we shall prove the following:

(1) Every eigenvalue in $\mathbb{C}_{\lambda_*}$ must be real.

(2) All the eigenvalues in $\mathbb{C}_{\lambda_*}$ can be parameterized by κ. Especially nonnegative ones, which interest us most, are located on an ε-dependent interval $[\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$ with $\lim_{\varepsilon\downarrow 0} \overline{\kappa}_+(\varepsilon) = \infty$ (see Prop. 4.3). The eigenvalues outside of this interval, namely those for small κ or large κ, are negative.

We begin with the study of the asymptotic behavior of $K(\varepsilon, \kappa, \lambda)$ of (3.25) for large κ, which, combined with the term $-\varepsilon\kappa^2$, determines the behavior of eigenvalues.

We make a decomposition defined by

$$K(\varepsilon, \kappa, \lambda) = \widehat{K}(\kappa) + \overline{K}(\varepsilon, \kappa, \lambda), \tag{4.17}$$

for $\varepsilon \in [0, \varepsilon_*)$, $\kappa > 0$ and $\lambda \in \mathbb{C}_{\lambda_*}$, where the first and the second terms are defined below. We first introduce a sesquilinear form on $H^1(I)$:

$$\widehat{B}(\kappa)(z^1, z^2) \equiv D\,(z^1_x, z^2_x)_{L^2(I)} + D\kappa^2 (z^1, z^2)_{L^2(I)}, \tag{4.18}$$

for $z^1, z^2 \in H^1(I)$ and $\kappa > 0$. We also define an operator given by

$$\widehat{T}(\kappa) z \equiv \left(-D\frac{d^2}{dx^2} + D\kappa^2 \right) z, \tag{4.19}$$

for $z \in H^1(I)$ and $\kappa > 0$. Since $\widehat{B}(\kappa)$ is bounded and coercive, by using Lax–Milgram's theorem again, we see that $\widehat{T}(\kappa)$ has an inverse operator $\widehat{K}(\kappa)$, which is a bounded linear operator from $H^{-1}(I)$ to $H^1(I)$. In a loose way, it can be represented by

$$\widehat{K}(\kappa) = \left(-D\frac{d^2}{dx^2} + D\kappa^2\right)^{-1}, \qquad H^{-1}(I) \to H^1(I). \tag{4.20}$$

The second term of (4.17) is simply defined by

$$\overline{K}(\varepsilon, \kappa, \lambda) \equiv K(\varepsilon, \kappa, \lambda) - \widehat{K}(\kappa). \tag{4.21}$$

It turns out later that $\widehat{K}(\kappa)$ plays a dominant role for the study of the asymptotic behavior of $K(\varepsilon, \kappa, \lambda)$ as $\kappa \uparrow \infty$. The following Green's function for $\widehat{T}(\kappa)$ with the Neumann boundary condition is useful:

$$G(x, \xi, \kappa) = \begin{cases} \dfrac{\cosh \kappa x \cosh \kappa(1-\xi)}{D\kappa \sinh \kappa} & (0 \le x \le \xi \le 1), \\ \dfrac{\cosh \kappa(1-x) \cosh \kappa\xi}{D\kappa \sinh \kappa} & (0 \le \xi < x \le 1). \end{cases} \tag{4.22}$$

The following lemma can be checked by a direct calculation from (4.22).

LEMMA 4.2. *There are positive constants $M_2 = M_2(D)$ and $d = d(D)$ such that we have*

$$\max_{x,\xi \in \bar{I}} |G(x, \xi, \kappa)| < M_2 \cdot \kappa^{-1} \qquad (\kappa > 1), \tag{4.23}$$

$$\max_{x,\xi \in \bar{I}} \left|\frac{\partial G}{\partial \xi}(x, \xi, \kappa)\right| < M_2 \qquad (\kappa > 1), \tag{4.24}$$

$$\max_{x \in \bar{I}} \|G(x, \cdot, \kappa)\|_{L^2(I)} < M_2 \cdot \kappa^{-3/2} \qquad (\kappa > 1), \tag{4.25}$$

$$\max_{x \in \bar{I}} \|G(x, \cdot, \kappa)\|_{H^1(I)} < M_2 \cdot \kappa^{-1/2} \qquad (\kappa > 1), \tag{4.26}$$

$$\|G(x^*, \cdot, \kappa)\|^2_{L^2(I)} = \frac{1}{4D^2\kappa^3} + o(\exp(-d\kappa)) \quad (\text{as } \kappa \uparrow \infty), \tag{4.27}$$

where x^* is the position of the layer (see Theorem 2.1).

Since $H^1(I)$ can be imbedded into $L^2(I)$ or $L^\infty(I)$ continuously, we can regard an element of $\mathcal{B}(H^{-1}(I), H^1(I))$ as that of $\mathcal{B}(H^{-1}(I), L^2(I))$ or $\mathcal{B}(H^{-1}(I), L^\infty(I))$.

LEMMA 4.3. *There exist positive constants $M_i = M_i(D)$ $(i = 3, 4)$ such that we have*

$$\|\widehat{K}(\kappa)\|_{\mathcal{B}(H^{-1}(I), L^2(I))} < M_3 \cdot \kappa^{-1} \qquad (\kappa > 1), \tag{4.28a}$$

$$\|\widehat{K}(\kappa)\|_{\mathcal{B}(H^{-1}(I), L^\infty(I))} < M_3 \cdot \kappa^{-1/2} \qquad (\kappa > 1), \tag{4.28b}$$

and moreover, if $\{\Theta(\kappa)\}_{\kappa > 1}$ is a set of functions satisfying $\|\Theta(\kappa)\|_{L^2(I)} < \kappa^{-1}$, then we have

$$\|\widehat{K}(\kappa)\Theta(\kappa)\|_{L^2(I)} < M_4 \cdot \kappa^{-3} \qquad (\kappa > 1), \tag{4.29a}$$

$$\|\widehat{K}(\kappa)\Theta(\kappa)\|_{L^\infty(I)} < M_4 \cdot \kappa^{-5/2} \qquad (\kappa > 1). \tag{4.29b}$$

Proof. See Appendix 1.

LEMMA 4.4. *Let us assume in addition to the hypotheses of Lemma* 3.1, *that* $|\lambda| < M_1$ *is satisfied, where* M_1 *is the same one as in Proposition* 4.1. *Then there exists* $\kappa_* = \kappa_*(f, g, D) > 1$ *such that we have*

$$\overline{K}(\varepsilon, \kappa, \lambda) = \widehat{K}(\kappa)\overline{R}(\varepsilon, \kappa, \lambda)\widehat{K}(\kappa) \quad \text{for} \quad \kappa > \kappa_*, \tag{4.30}$$

where $\overline{R}(\varepsilon, \kappa, \lambda)$ *is a bounded linear operator in* $L^2(I)$. *There exists* $M_5 = M_5(f, g, D) > 0$ *such that*

$$\|\overline{R}(\varepsilon, \kappa, \lambda)\|_{\mathcal{B}(L^2(I), L^2(I))} < M_5, \tag{4.31}$$

$$\|\overline{K}(\varepsilon, \kappa, \lambda)\|_{\mathcal{B}(H^{-1}(I), L^2(I))} < M_5 \cdot \kappa^{-3}, \tag{4.32a}$$

$$\|\overline{K}(\varepsilon, \kappa, \lambda)\|_{\mathcal{B}(H^{-1}(I), L^\infty(I))} < M_5 \cdot \kappa^{-5/2}, \tag{4.32b}$$

hold for $\kappa > \kappa_*$.

Proof. See Appendix 2.

LEMMA 4.5. *We assume that* $\kappa > \kappa_*$ *in addition to the hypothesis of Lemma* 4.1, *where* κ_* *is the same one as in Lemma* 4.4. *Then there is* $M_6 = M_6(f, g, D) > 0$ *such that we have*

$$|H(\varepsilon, \kappa, \lambda)| < M_6 \cdot \kappa^{-1/2}, \tag{4.33}$$

$$|I(\varepsilon, \kappa, \lambda)| < M_6 \cdot \kappa^{-5/2}, \tag{4.34a}$$

$$|J(\varepsilon, \kappa, \lambda)| < M_6 \cdot \kappa^{-5/2}. \tag{4.34b}$$

Proof. Using (4.28) and (4.32), we obtain, from (4.17),

$$\|K(\varepsilon, \kappa, \lambda)\|_{\mathcal{B}(H^{-1}(I), L^2(I))} < (M_3 + M_5) \cdot \kappa^{-1}, \tag{4.35a}$$

$$\|K(\varepsilon, \kappa, \lambda)\|_{\mathcal{B}(H^{-1}(I), L^\infty(I))} < (M_3 + M_5) \cdot \kappa^{-1/2}, \tag{4.35b}$$

for $\kappa > \kappa_*$. In view of (3.27), we have

$$|H(\varepsilon, \kappa, \lambda)| \le \|K(\varepsilon, \kappa, \lambda)h_2(\varepsilon)\|_{L^\infty(I)} \cdot \|h_1(\varepsilon)\|_{L^1(I)}. \tag{4.36}$$

From Corollary 2.1, $h_i(\varepsilon)$ is uniformly bounded in $L^2(I)$ and also in $H^{-1}(I)$ $(i = 1, 2)$. Using this fact and (4.35b), we obtain (4.33) from (4.36). From (4.35a) and the boundedness of $S(\varepsilon, \kappa, \lambda)$ in Lemma 3.1, we have

$$\|K(\varepsilon, \kappa, \lambda)h_2(\varepsilon)\|_{L^2(I)} = O(\kappa^{-1}), \tag{4.37a}$$

$$\|S(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda)h_2(\varepsilon)\|_{L^2(I)} = O(\kappa^{-1}). \tag{4.37b}$$

Making use of (4.29b) and (4.32b), we obtain, from (4.17),

$$\|K(\varepsilon, \kappa, \lambda)\Theta(\kappa)\|_{L^\infty(I)} = O(\kappa^{-5/2}), \tag{4.38}$$

where $\{\Theta(\kappa)\}$ is a set of functions satisfying $\|\Theta(\kappa)\|_{L^2(I)} < \kappa^{-1}$. Regarding each term of (4.37) to be $\Theta(\kappa)$, we obtain from (4.37) and (4.38)

$$\|K(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda)h_2(\varepsilon)\|_{L^\infty(I)} = O(\kappa^{-5/2}),$$

$$\|K(\varepsilon, \kappa, \lambda)S(\varepsilon, \kappa, \lambda)K(\varepsilon, \kappa, \lambda)h_2(\varepsilon)\|_{L^\infty(I)} = O(\kappa^{-5/2}).$$

In view of the definitions of $I(\varepsilon, \kappa, \lambda)$ and $J(\varepsilon, \kappa, \lambda)$, we obtain (4.34) from the above inequalities and the uniformly boundedness of $h_1(\varepsilon)$ in $L^1(I)$. □

Before studying the κ-parameterization of solutions of (3.25), the following observation is basic in characterizing the behaviors of eigenvalues in $\mathbb{C}_{\lambda_*}$, which allows us to consider only real solutions of (3.25).

PROPOSITION 4.2. *Let* $\lambda \in \mathbb{C}_{\lambda_*}$ *satisfy* (3.25) *with some* $\varepsilon \in (0, \varepsilon_1)$ *and* $\kappa \in [0, \infty)$, *then* λ *must be a real number.*

Proof. See Appendix 3. □

It is crucial to know the location of zero eigenvalues of (3.25) and their dependency on ε to clarify the stability properties of the planar front. In fact, there exist two zeros of (3.25) at $\underline{\kappa}(\varepsilon)$ and $\overline{\kappa}(\varepsilon)$, where $\underline{\kappa}(\varepsilon)$ remains finite and $\overline{\kappa}(\varepsilon) \to \infty$ as $\varepsilon \downarrow 0$. It turns out that instability occurs on the band region $(\underline{\kappa}(\varepsilon), \overline{\kappa}(\varepsilon))$, and outside of this interval the associated eigenvalues become nonpositive. The smaller one $\underline{\kappa}(\varepsilon)$ can be controlled by studying the *reduced problem* of (3.25) (namely the limiting one of (3.25) as $\varepsilon \downarrow 0$). While more careful analysis is needed to handle the larger one $\overline{\kappa}(\varepsilon)$, and hence we will discuss it in §4.4. Nevertheless we can show that the eigenvalues of (3.25) become negative for sufficiently large κ as well as for small κ. Moreover we can parameterize all the nonnegative eigenvalues by κ, which we are most concerned with. Putting $\lambda = 0$ in (3.25), we have

$$F_0(\varepsilon, \kappa) = 0, \tag{4.39}$$

for $\varepsilon \in [0, \varepsilon_1)$ and $\kappa \in [0, \infty)$, where

$$F_0(\varepsilon, \kappa) \equiv F(\varepsilon, \kappa, 0) = \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - H(\varepsilon, \kappa, 0). \tag{4.40}$$

Recalling that (3.26) is well defined up to $\varepsilon = 0$ from Lemma 4.1, we see from (4.40) and the property of H in Lemma 4.1 that

$$\frac{\partial F_0}{\partial \kappa}(0, \kappa) = 2\kappa D \cdot c_1^* c_2^* \cdot \|K(0, \kappa, 0)\delta(x - x^*)\|^2_{L^2(I)} > 0, \tag{4.41}$$

for $\kappa > 0$. On the other hand, by using (4.9) and (4.33), we have, from (4.40),

$$F_0(0, \kappa)|_{\kappa=0} < 0, \qquad F_0(0, \kappa)|_{\kappa=\infty} > 0. \tag{4.42}$$

From (4.41), (4.42) and the continuity of $F_0(0, \cdot)$, we see that there is a unique $\kappa = \underline{\kappa}(0)$ such that

$$F_0(0, \underline{\kappa}(0)) = \widehat{\zeta}_0(0) - H(0, \underline{\kappa}(0), 0) = 0. \tag{4.43}$$

Thanks to (4.43) and (4.41), we can apply the standard implicit function theorem to (4.39) at $(\varepsilon, \kappa) = (0, \underline{\kappa}(0))$ yielding a unique $\underline{\kappa}(\varepsilon)$ with

$$F_0(\varepsilon, \underline{\kappa}(\varepsilon)) = 0, \tag{4.44a}$$

$$\underline{\kappa}(\varepsilon) \to \underline{\kappa}(0) \in (0, \infty) \quad (\text{as} \quad \varepsilon \downarrow 0), \tag{4.44b}$$

$$F_0(\varepsilon, \kappa) < 0 \quad \text{for any} \quad \kappa \in [0, \underline{\kappa}(\varepsilon)), \tag{4.44c}$$

for any $\varepsilon \in (0, \varepsilon_1)$. We replaced ε_1 in Proposition 4.2 by a smaller one, if necessary.

In view of (3.26) and (4.33), we easily see that when $\kappa = O(\varepsilon^{-1/2})$ the term $-\varepsilon\kappa^2$ becomes $O(1)$ and hence it is enough to compete with $\widehat{\zeta}_0(\varepsilon)$ to determine the sign of the eigenvalue λ. This motivates us to take the following special scaling of κ given by

$$\overline{\kappa}_+(\varepsilon) \equiv \sigma \cdot \varepsilon^{-\frac{1}{2}}, \tag{4.45}$$

where σ is a constant satisfying

$$\widehat{\zeta}_0(0) < \sigma^2 < \widehat{\zeta}_0(0) + \tfrac{1}{2}\tau\lambda_*. \tag{4.46}$$

Replacing ε_1 by a smaller one again, we have the following two lemmas.

LEMMA 4.6. *For any fixed* $\varepsilon \in (0, \varepsilon_1)$, *it holds that*

$$\frac{\partial F}{\partial \lambda}(\varepsilon, \kappa, \lambda) < -\frac{1}{2}(\tau - \tau_*) < 0 \tag{4.47}$$

for $(\kappa, \lambda) \in [0, \infty) \times [-\lambda_*, M_1)$ *satisfying* (3.6).

LEMMA 4.7. *We have, for* $\varepsilon \in (0, \varepsilon_1)$ *and* $\kappa \in [\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$,

$$F(\varepsilon, \kappa, \lambda)|_{\lambda=-\lambda_*} \geq \tfrac{1}{2}\lambda_*(\tau - \tau_*) > 0,$$
$$F(\varepsilon, \kappa, \lambda)|_{\lambda=M_1} < 0.$$

Proof of Lemma 4.6. Let us assume the contrary; then we have a sequence $\{(\varepsilon_i, \kappa_i, \lambda_i)\}_{i=1}^{\infty}$ such that $\varepsilon_i \to 0$ as $i \uparrow \infty$, and each $(\varepsilon_i, \kappa_i, \lambda_i)$ satisfies (3.6), (3.25), and

$$\frac{\partial F}{\partial \lambda}(\varepsilon_i, \kappa_i, \lambda_i) \geq -\frac{1}{2}(\tau - \tau_*).$$

Using (3.26) and Lemma 4.1, we rewrite it as follows:

$$-\tau + I(\varepsilon_i, \kappa_i, \lambda_i) + \varepsilon_i \tau J(\varepsilon_i, \kappa_i, \lambda_i) \geq -\tfrac{1}{2}(\tau - \tau_*). \tag{4.48}$$

First, we consider the case in which $\{\kappa_i\}$ is unbounded. Without loss of generality, we can assume that $\kappa_i \to \infty$ as $i \uparrow \infty$. Let $i \uparrow \infty$ in (4.48). Then from (4.34) we obtain the inequality: $-\tau \geq -\frac{1}{2}(\tau - \tau_*)$, which contradicts the positiveness of τ. Next, we consider the case in which $\{\kappa_i\}$ is bounded. Since $\{\lambda_i\}$ is bounded, we can take a subsequence such that $\kappa_i \to \kappa_0 \in [0, \infty)$, and $\lambda_i \to \lambda_0 \in [-\lambda_*, M_1]$. By virtue of Lemma 4.1 and the definition of τ_*, we have

$$\lim_{i \uparrow \infty} \{I(\varepsilon_i, \kappa_i, \lambda_i) + \varepsilon_i \tau J(\varepsilon_i, \kappa_i, \lambda_i)\}$$
$$= \sum_{n=0}^{\infty} \frac{c_1^* c_2^* |\psi_n(x^*)|^2}{(\gamma_n + D\kappa_0^2 + \lambda_0)^2} < \sum_{n=0}^{\infty} \frac{c_1^* c_2^* |\psi_n(x^*)|^2}{(\gamma_n - \lambda_*)^2} = \tau_*.$$

Letting $i \uparrow \infty$ in (4.48) and using the above inequality, we have $-\tau + \tau_* \geq -\frac{1}{2}(\tau - \tau_*)$, which contradicts (4.15). We complete the proof of Lemma 4.6. □

Proof of Lemma 4.7. We can obtain the second inequality from the definition of $F(\varepsilon, \kappa, \lambda)$ and the boundedness of $H(\varepsilon, \kappa, \lambda)$ in Lemma 4.1, and (4.15), if we replace M_1 by a larger one, if necessary. It is enough for us to prove the first inequality. Let us assume the contrary, then there exists $\{(\varepsilon_i, \kappa_i)\}_{i=0}^{\infty}$ such that we have $\varepsilon_i \to 0$ as $i \uparrow \infty$, $\kappa_i \in [\underline{\kappa}(\varepsilon_i), \overline{\kappa}_+(\varepsilon_i))$ and

$$F(\varepsilon_i, \kappa_i, -\lambda_*) < \tfrac{1}{2}\lambda_*(\tau - \tau_*), \tag{4.49}$$

which is equivalent to

$$\widehat{\zeta}_0(\varepsilon_i) - \varepsilon_i \kappa_i^2 + \tau\lambda_* - H(\varepsilon_i, \kappa_i, -\lambda_*) < \tfrac{1}{2}\lambda_*(\tau - \tau_*). \tag{4.50}$$

From $\kappa_i < \overline{\kappa}_+(\varepsilon_i)$, (4.45) and (4.46), we see that the first three terms on the left-hand side of (4.50) can be estimated from below:

$$\varliminf_{i \uparrow \infty} \{\widehat{\zeta}_0(\varepsilon_i) - \varepsilon_i \kappa_i^2 + \tau\lambda_*\} \geq \tfrac{1}{2}\tau\lambda_*. \tag{4.51}$$

First we consider the case in which $\{\kappa_i\}$ is not bounded. By taking a subsequence, we can assume $\kappa_i \to \infty$ as $i \uparrow \infty$. We let $i \uparrow \infty$ in (4.50). Then from (4.33), we have the inequality: $\frac{1}{2}\tau\lambda_* \le \frac{1}{2}\lambda_*(\tau - \tau_*)$, which contradicts the positiveness of τ_*. We next consider the case in which $\{\kappa_i\}$ is bounded. By taking a subsequence, we can assume that $\kappa_i \to \kappa_0 \ge \underline{\kappa}(0)$ as $i \uparrow \infty$. Hence we have

$$\begin{aligned} &\lim_{i\uparrow\infty} F(\varepsilon_i, \kappa_i, -\lambda_*) \\ &\quad = \widehat{\zeta}_0(0) + \tau\lambda_* - H(0, \kappa_0, -\lambda_*) \\ &\quad = H(0, \underline{\kappa}(0), 0) - H(0, \kappa_0, -\lambda_*) + \tau\lambda_* \quad \text{(from (4.43))}. \end{aligned} \tag{4.52}$$

Using (4.12) and (4.14), we obtain

$$\begin{aligned} &H(0, \underline{\kappa}(0), 0) - H(0, \kappa_0, -\lambda_*) \\ &\quad = \{-\lambda_* + D(\kappa_0^2 - \underline{\kappa}(0)^2)\} \sum_{n=0}^{\infty} \frac{c_1^* c_2^* |\psi_n(x^*)|^2}{\{\gamma_n + D\underline{\kappa}(0)^2\}\{\gamma_n + D\kappa_0^2 - \lambda_*\}} \ge -\lambda_*\tau_*. \end{aligned}$$

Putting together (4.52) and the above inequality, we obtain

$$\lim_{i\uparrow\infty} F(\varepsilon_i, \kappa_i, -\lambda_*) \ge -\lambda_*\tau_* + \tau\lambda_* = \lambda_*(\tau - \tau_*).$$

On the other hand, we have from (4.49),

$$\overline{\lim_{i\uparrow\infty}} F(\varepsilon_i, \kappa_i, -\lambda_*) \le \tfrac{1}{2}\lambda_*(\tau - \tau_*).$$

Combining the above two inequalities, we get $\lambda_*(\tau - \tau_*) \le \frac{1}{2}\lambda_*(\tau - \tau_*)$, which contradicts (4.15). Thus we complete the proof of Lemma 4.7. □

PROPOSITION 4.3. *For any fixed $\varepsilon \in (0, \varepsilon_1)$, the statements* (1) *and* (2) *hold true, where $\underline{\kappa}(\varepsilon)$ and $\overline{\kappa}_+(\varepsilon)$ are given in* (4.44) *and* (4.45), *respectively.*

(1) *If $\lambda \in (-\lambda_*, M_1)$ satisfies* (3.25) *with some $\kappa \notin [\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$, then $\lambda < 0$.*

(2) *A unique $\lambda = \widetilde{\lambda}(\varepsilon, \kappa)$ satisfies* (3.25) *for each $\kappa \in [\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$, where $\widetilde{\lambda}(\varepsilon, \kappa)$ is a real-valued function of C^∞-class for κ and the derivative is given by*

$$\frac{\partial\widetilde{\lambda}}{\partial\kappa}(\varepsilon, \kappa) = -\frac{\partial F}{\partial\kappa}(\varepsilon, \kappa, \widetilde{\lambda}(\varepsilon, \kappa)) \Big/ \frac{\partial F}{\partial\lambda}(\varepsilon, \kappa, \widetilde{\lambda}(\varepsilon, \kappa)). \tag{4.53}$$

Moreover, $\widetilde{\lambda}(\varepsilon, \kappa)$ always remains in $(-\lambda_*, M_1)$.

Proof of Proposition 4.3. As for (1), we see, from the assumption, that κ must lie in $[0, \underline{\kappa}(\varepsilon))$ or $[\overline{\kappa}_+(\varepsilon), \infty)$. In view of (4.40) and (4.44c), we have

$$F(\varepsilon, \kappa, 0) < 0 \quad \text{for any} \quad \kappa \in [0, \underline{\kappa}(\varepsilon)),$$

which, combined with (4.47), leads to

$$F(\varepsilon, \kappa, \lambda) < 0 \quad \text{for any } \lambda \ge 0 \text{ and } \kappa \in [0, \underline{\kappa}(\varepsilon)).$$

We have the desired result when $\kappa \in [0, \underline{\kappa}(\varepsilon))$. Next we consider the case in which $\kappa \in [\overline{\kappa}_+(\varepsilon), \infty)$. In view of the definition of $\overline{\kappa}_+(\varepsilon)$, we have the inequality: $\widehat{\zeta}_0(0) < \sigma^2 < \varepsilon\kappa^2$, which combined with (3.26) yields

$$\begin{aligned} \tau\lambda &= \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa^2 - H(\varepsilon, \kappa, \lambda) \\ &< \{\widehat{\zeta}_0(\varepsilon) - \sigma^2\} - H(\varepsilon, \kappa, \lambda). \end{aligned} \tag{4.54}$$

We see that $H(\varepsilon,\kappa,\lambda)$ converges to zero as $\varepsilon \downarrow 0$ because of (4.33) and $\kappa \geq \overline{\kappa}_+(\varepsilon)$, while $\{\widehat{\zeta}_0(\varepsilon) - \sigma^2\}$ converges to a negative value $\widehat{\zeta}_0(0) - \sigma^2$. Hence we have $\lambda < 0$ for $\varepsilon \in (0, \varepsilon_1)$ and $\kappa \geq \overline{\kappa}_+(\varepsilon)$. It suffices to prove (2). Making use of Lemmas 4.6 and 4.7, we have a unique $\lambda \in (-\lambda_*, M_1)$ which satisfies (3.25) for each $\kappa \in [\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$. Let this λ be denoted by $\widetilde{\lambda}(\varepsilon,\kappa)$. Lemma 4.6 allows us to apply the standard implicit function theorem to (3.25) around $(\varepsilon,\kappa,\lambda) = (\varepsilon,\kappa,\widetilde{\lambda}(\varepsilon,\kappa))$. Since $F(\varepsilon,\kappa,\lambda)$ depends continuously on ε and real analytically on κ (in particular, it is of $C^\infty-$class for κ), we see that $\widetilde{\lambda}(\varepsilon,\kappa)$ is continuous for ε, of C^∞-class for κ, and the formula (4.53) holds. □

4.4. Asymptotic characterization of the fastest growth wave number and proof of Theorem 4.1. The singular dispersion relation (3.25) has strictly positive solutions somewhere on the interval $[\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$ of Proposition 4.3. In fact, suppose we take $\kappa = \varepsilon^{-\vartheta}$ $(0 < \vartheta < \frac{1}{2})$, then we see from (3.25) and (4.33)

$$\begin{aligned} \tau\widetilde{\lambda}(\varepsilon,\varepsilon^{-\vartheta}) &= \widehat{\zeta}_0(\varepsilon) - \varepsilon(\varepsilon^{-\vartheta})^2 - H(\varepsilon,\varepsilon^{-\vartheta},\widetilde{\lambda}(\varepsilon,\varepsilon^{-\vartheta})) \\ &\to \widehat{\zeta}_0(0) > 0 \qquad (\text{as} \quad \varepsilon \downarrow 0). \end{aligned} \tag{4.55}$$

Since $\widetilde{\lambda}(\varepsilon,\underline{\kappa}(\varepsilon)) = 0$ and $\widetilde{\lambda}(\varepsilon,\overline{\kappa}_+(\varepsilon)) < 0$, it is clear that a continuous function $\widetilde{\lambda}(\varepsilon,\cdot)$ has a positive maximum in $(\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$.

We study in this subsection the asymptotic behaviors of the largest eigenvalue $\lambda(\varepsilon)$ of (3.25) and the associated wave number $\kappa(\varepsilon)$ when $\varepsilon \to 0$.

There is at least one local maximizer of $\widetilde{\lambda}(\varepsilon,\cdot)$ in $(\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$ for any fixed $\varepsilon \in (0, \varepsilon_1)$. Let $\kappa(\varepsilon)$ be an arbitrary one of them and let us put $\lambda(\varepsilon) \equiv \widetilde{\lambda}(\varepsilon,\kappa(\varepsilon))$. From the definition of $\kappa(\varepsilon)$ and that of $\lambda(\varepsilon)$, it follows that

$$F(\varepsilon,\kappa(\varepsilon),\lambda(\varepsilon)) = 0, \tag{4.56a}$$

$$\frac{\partial\widetilde{\lambda}}{\partial\kappa}(\varepsilon,\kappa(\varepsilon)) = 0. \tag{4.56b}$$

In view of Proposition 4.3, we can rewrite (4.56b) as follows:

$$\frac{\partial F}{\partial\kappa}(\varepsilon,\kappa(\varepsilon),\lambda(\varepsilon)) = 0, \tag{4.57}$$

or equivalently (see (4.10b)),

$$\varepsilon - D \cdot I(\varepsilon,\kappa(\varepsilon),\lambda(\varepsilon)) - \varepsilon^2 \cdot J(\varepsilon,\kappa(\varepsilon),\lambda(\varepsilon)) = 0. \tag{4.58}$$

REMARK 4.3. The relation (4.56b) implies that $\kappa(\varepsilon)$ is a stationary point of $\widetilde{\lambda}(\varepsilon,\cdot)$. Although it is not a sufficient condition for $\kappa(\varepsilon)$ to be a local maximizer, we will be able to obtain enough information to control the asymptotic behaviors of $\kappa(\varepsilon)$ and $\lambda(\varepsilon)$ as ε tends to zero.

PROPOSITION 4.4. $\kappa(\varepsilon)$ $(\in (\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon)))$ *satisfies*

$$\begin{aligned} &\overline{\lim_{\varepsilon\downarrow 0}}\, \varepsilon\kappa(\varepsilon)^2 \leq \sigma^2, \\ &\kappa(\varepsilon) \to \infty \quad \textit{as} \quad \varepsilon \downarrow 0, \end{aligned}$$

while $\lambda(\varepsilon)$ *remains in* $(-\lambda_*, M_1)$ *for any* $\varepsilon \in (0, \varepsilon_1)$. M_1 *is the same constant as in Proposition* 4.1.

Proof. The boundedness of $\lambda(\varepsilon)$ is a direct consequence of that of $\widetilde{\lambda}(\varepsilon, \cdot)$ in Proposition 4.3. We can obtain the first inequality from $\kappa(\varepsilon) < \overline{\kappa}_+(\varepsilon)$ and the definition of $\overline{\kappa}_+(\varepsilon)$. It is enough to prove $\kappa(\varepsilon) \to \infty$ as $\varepsilon \downarrow 0$. Let us assume the contrary; then we have a sequence $\{\varepsilon_n\}_{n=1}^{\infty}$ such that $\varepsilon_n \to 0$ as $n \uparrow \infty$, $\{\kappa(\varepsilon_n)\}_{n=1}^{\infty}$ remains bounded and that

$$\varepsilon_n - D \cdot I(\varepsilon_n, \kappa(\varepsilon_n), \lambda(\varepsilon_n)) - \varepsilon_n^2 \cdot J(\varepsilon_n, \kappa(\varepsilon_n), \lambda(\varepsilon_n)) = 0. \tag{4.59}$$

By taking a subsequence, we can assume

$$\kappa(\varepsilon) \to \kappa_0 \in [\underline{\kappa}(0), \infty), \qquad \lambda(\varepsilon_n) \to \lambda_0 \in [-\lambda_*, M_1],$$

as $n \uparrow \infty$. In view of Lemma 4.1, we have

$$D \cdot I(\varepsilon_n, \kappa(\varepsilon_n), \lambda(\varepsilon_n)) \to D c_1^* c_2^* \| K(0, \kappa_0, \lambda_0) \delta(x - x^*) \|_{L^2(I)}^2 > 0. \tag{4.60}$$

Since $J(\varepsilon_n, \kappa(\varepsilon_n), \lambda(\varepsilon_n))$ remains bounded, the first and the second terms of the right-hand side of (4.59) converge to zero as $n \uparrow \infty$. (4.60) is not consistent with (4.59). This is a contradiction and completes the proof. □

We study the asymptotic behaviors of $\kappa(\varepsilon)$ and $\lambda(\varepsilon)$ more accurately. It turns out that the first and the second terms of (4.58) play a dominant role in the limit of $\varepsilon \downarrow 0$ and $\kappa \uparrow \infty$. Without loss of generality, we can assume $\kappa_* < \kappa(\varepsilon)$ for $\varepsilon \in (0, \varepsilon_1)$. Recall that κ_* is a constant appeared in Lemma 4.4. In view of Lemma 4.5 and Proposition 4.4, we have

$$\varepsilon^2 |J(\varepsilon, \kappa, \lambda)| \le \varepsilon^2 M_6 \kappa(\varepsilon)^{-5/2} \le \sigma^4 M_6 \kappa(\varepsilon)^{-13/2}, \tag{4.61}$$

for $\varepsilon \in (0, \varepsilon_1)$. In order to study the second term of the right-hand side of (4.58), we use the next lemma.

LEMMA 4.8. *We assume that* $0 < \varepsilon < \varepsilon_1$, $\kappa_* < \kappa$, *and* $|\lambda| < M_1$. *Then we have*

$$|I(\varepsilon, \kappa, \lambda) - (\widehat{K}(\kappa) h_2(\varepsilon), \widehat{K}(\kappa) h_1(\varepsilon))_{L^2(I)}| < M_7 \cdot \kappa^{-4}, \tag{4.62}$$

where $M_7 = M_7(f, g, D) > 0$, *and* κ_* *is the same constant as in Lemma* 4.4.

Proof. In view of (4.17) and the definition of $I(\varepsilon, \kappa, \lambda)$, we see that $I(\varepsilon, \kappa, \lambda)$ can be rewritten as follows:

$$I(\varepsilon, \kappa, \lambda) \equiv \sum_{j=1}^{4} I_j(\varepsilon, \kappa, \lambda), \tag{4.63}$$

where

$$\begin{aligned}
I_1(\varepsilon, \kappa, \lambda) &\equiv (\widehat{K}(\kappa) \widehat{K}(\kappa) h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}, \\
I_2(\varepsilon, \kappa, \lambda) &\equiv (\widehat{K}(\kappa) \overline{K}(\varepsilon, \kappa, \lambda) h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}, \\
I_3(\varepsilon, \kappa, \lambda) &\equiv (\overline{K}(\varepsilon, \kappa, \lambda) \widehat{K}(\kappa) h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}, \\
I_4(\varepsilon, \kappa, \lambda) &\equiv (\overline{K}(\varepsilon, \kappa, \lambda) \overline{K}(\varepsilon, \kappa, \lambda) h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}.
\end{aligned}$$

Using (4.30) and the fact that $\widehat{K}(\kappa)$ is a selfadjoint operator, we have

$$I_1(\varepsilon,\kappa,\lambda) = (\widehat{K}(\kappa)h_2(\varepsilon), \widehat{K}(\kappa)h_1(\varepsilon))_{L^2(I)},$$
$$I_2(\varepsilon,\kappa,\lambda) = (\overline{K}(\varepsilon,\kappa,\lambda)h_2(\varepsilon), \widehat{K}(\kappa)h_1(\varepsilon))_{L^2(I)},$$
$$I_3(\varepsilon,\kappa,\lambda) = (\overline{R}(\varepsilon,\kappa,\lambda)\widehat{K}(\kappa)\widehat{K}(\kappa)h_2(\varepsilon), \widehat{K}(\kappa)h_1(\varepsilon))_{L^2(I)},$$
$$I_4(\varepsilon,\kappa,\lambda) = (\overline{R}(\varepsilon,\kappa,\lambda)\widehat{K}(\kappa)\overline{K}(\varepsilon,\kappa,\lambda)h_2(\varepsilon), \widehat{K}(\kappa)h_1(\varepsilon))_{L^2(I)}.$$

By virtue of Schwarz's inequality, the estimates in Lemmas 4.3 and 4.4, and Corollary 2.1, we obtain

$$|I_2(\varepsilon,\kappa,\lambda)| < (B_*)^2 M_3 M_5 \cdot \kappa^{-4},$$
$$|I_3(\varepsilon,\kappa,\lambda)| < (B_*)^2 (M_3)^2 M_4 M_5 \cdot \kappa^{-4},$$
$$|I_4(\varepsilon,\kappa,\lambda)| < (B_*)^2 M_3 M_4 (M_5)^2 \cdot \kappa^{-6}.$$

Substituting these into (4.63), we obtain the desired result. □

Using (4.61) and (4.62), we have, from (4.58),

$$|\varepsilon - D(\widehat{K}(\kappa(\varepsilon))h_2(\varepsilon), \widehat{K}(\kappa(\varepsilon))h_1(\varepsilon))_{L^2(I)}| < M_8 \cdot \kappa(\varepsilon)^{-4}, \tag{4.64}$$

where $M_8 = M_8(f,g,D) > 0$.

In order to obtain the asymptotic form of the left-hand side of (4.64), we need preparations. We introduce two positive constants $\theta_1, \theta_2 \in (0,1)$, which will be specified later, and divide $I = (0,1)$ into two subintervals:

$$I = I^1_{\text{in}}(\varepsilon) \cup I^1_{\text{out}}(\varepsilon), \tag{4.65a}$$

for $\varepsilon \in (0, \varepsilon_1)$, where

$$I^1_{\text{in}}(\varepsilon) = (x^* - \varepsilon^{\theta_1}, x^* + \varepsilon^{\theta_1}), \qquad I^1_{\text{out}}(\varepsilon) = I \setminus I^1_{\text{in}}(\varepsilon), \tag{4.65b}$$

and

$$I = I^2_{\text{in}}(\kappa) \cup I^2_{\text{out}}(\kappa), \tag{4.66a}$$

for $\kappa \in (\kappa_*, \infty)$, where

$$I^2_{\text{in}}(\kappa) = (x^* - \kappa^{-\theta_2}, x^* + \kappa^{-\theta_2}), \qquad I^2_{\text{out}}(\kappa) = I \setminus I^2_{in}(\kappa). \tag{4.66b}$$

Let $c_i(\varepsilon)$ be defined by

$$c_i(\varepsilon) \equiv \int_{I^1_{\text{in}}(\varepsilon)} h_i(x)dx \qquad (i = 1,2). \tag{4.67}$$

LEMMA 4.9. *$c_i(\varepsilon) \to c_i^*$ as $\varepsilon \downarrow 0$, $(i = 1,2)$.*

Proof. For $i = 1,2$, we have

$$\int_{I^1_{\text{in}}(\varepsilon)} h_i(x,\varepsilon)dx = \int_I h_i(x,\varepsilon)dx - \int_{I^1_{\text{out}}(\varepsilon)} h_i(x,\varepsilon)dx. \tag{4.68}$$

Since we see that the first term of the right-hand side of (4.68) converges to c_i^* from (2.10), it suffices to show the second term converges to zero. Using (2.12), we have

$$\begin{aligned}\int_{I^1_{\text{out}}(\varepsilon)} |h_i(x,\varepsilon)|dx &= \left(\int_{\varepsilon^{\theta_1-1}}^{(1-x^*)/\varepsilon} + \int_{-x^*/\varepsilon}^{-\varepsilon^{\theta_1-1}}\right) \varepsilon\,|h_i(\varepsilon\eta + x^*, \varepsilon)|\,d\eta \\ &\le \left(\int_{\varepsilon^{\theta_1-1}}^{\infty} + \int_{-\infty}^{-\varepsilon^{\theta_1-1}}\right) B\exp(-\beta|\eta|)d\eta \\ &\le (2B/\beta)\cdot\exp(-\beta\varepsilon^{\theta_1-1}),\end{aligned} \tag{4.69}$$

which completes the proof. □

LEMMA 4.10. *Under the same hypothesis as in Lemma* 4.8, *we have*

$$(\widehat{K}(\kappa)h_i(\varepsilon))(x) = c_i(\varepsilon)\{G(x,x^*,\kappa) + r_i(\varepsilon,x,\kappa)\} + p_i(\varepsilon,x,\kappa) \tag{4.70}$$

for $x \in I$ $(i = 1,2)$, *where* $r_i(\varepsilon,\cdot,\kappa)$, $p_i(\varepsilon,\cdot,\kappa)$ *are functions with*

$$\|r_i(\varepsilon,\cdot,\kappa)\|_{L^\infty(I)} \le M_2 \cdot \varepsilon^{\theta_1} \qquad (i = 1,2), \tag{4.71a}$$

$$\|p_i(\varepsilon,\cdot,\kappa)\|_{L^\infty(I)} \le M_2 \cdot \exp(-\beta\varepsilon^{\theta_1-1}) \qquad (i = 1,2). \tag{4.71b}$$

Proof. Using (4.65a) and Green's function of $\widehat{T}(\kappa)$, we have

$$(\widehat{K}(\kappa)h_i(\varepsilon))(x) = \left(\int_{I^1_{\text{in}}(\varepsilon)} + \int_{I^1_{\text{out}}(\varepsilon)}\right) G(x,\xi,\kappa)h_i(\xi,\varepsilon)d\xi,$$

for $x \in I$ $(i = 1,2)$. From (4.24), we have

$$|G(x,\xi,\kappa) - G(x,x^*,\kappa)| \le M_2|\xi - x^*| < M_2\varepsilon^{\theta_1},$$

for $x \in I$ and $\xi \in I^1_{in}(\varepsilon)$. We rewrite it as follows:

$$G(x,x^*,\kappa) - M_2\varepsilon^{\theta_1} < G(x,\xi,\kappa) < G(x,x^*,\kappa) + M_2\varepsilon^{\theta_1},$$

for $x \in I$ and $\xi \in I^1_{in}(\varepsilon)$. We multiply each side of the above inequality by $h_i(\xi,\varepsilon)$ and integrate it over $I^1_{in}(\varepsilon)$, then using (4.67), we obtain

$$\begin{aligned} c_i(\varepsilon)\{G(x,x^*,\kappa) - M_2\varepsilon^{\theta_1}\} &< \int_{I^1_{\text{in}}(\varepsilon)} G(x,\xi,\kappa)h_i(\xi,\varepsilon)d\xi \\ &< c_i(\varepsilon)\{G(x,x^*,\kappa) + M_2\varepsilon^{\theta_1}\}, \end{aligned}$$

for $x \in I$ and $i = 1,2$. The above inequality implies that, if we write

$$\int_{I^1_{\text{in}}(\varepsilon)} G(x,\xi,\kappa)h_i(\xi,\varepsilon)d\xi = c_i(\varepsilon)\{G(x,x^*,\kappa) + r_i(\varepsilon,x,\kappa)\},$$

then $r_i(\varepsilon,\cdot,\kappa) \in C(\bar{I})$ satisfies (4.71a) for $i = 1,2$. It suffices to show

$$p_i(\varepsilon,x,\kappa) \equiv \int_{I^1_{\text{out}}(\varepsilon)} G(x,\xi,\kappa)h_i(\xi,\varepsilon)d\xi \tag{4.72}$$

satisfies (4.71b). Indeed we have, from (4.69) and (4.23),

$$|\text{the right-hand side of (4.72)}| \le M_2/\kappa^* \cdot (2B/\beta)\exp(-\beta\varepsilon^{\theta_1-1}),$$

for $\kappa > \kappa^*$. Replacing M_2 with a larger one, if necessary, we obtain the desired result. □

LEMMA 4.11. *Under the same hypothesis as in Lemma* 4.8, *we have*

$$\left|(\widehat{K}(\kappa)h_2(\varepsilon), \widehat{K}(\kappa)h_1(\varepsilon))_{L^2(I)} - \frac{c_1(\varepsilon)c_2(\varepsilon)}{4D^2\kappa^3}\right| < M_9\left\{\varepsilon^{\theta_1}\kappa^{-(1+\theta_2)} + \varepsilon^{2\theta_1} + \exp(-d\kappa)\right\}, \tag{4.73}$$

where d *is the same one as in Lemma* 4.2, *and* $M_9 = M_9(f, g, D) > 0$.

Proof. Making use of (4.70), we have

$$\begin{aligned}(\widehat{K}(\kappa)h_2(\varepsilon))(x) \cdot (\widehat{K}(\kappa)h_1(\varepsilon))(x) \\ = [c_1(\varepsilon)\{G(x, x^*, \kappa) + r_1(\varepsilon, x, \kappa)\} + p_1(\varepsilon, x, \kappa)] \\ \times [c_2(\varepsilon)\{G(x, x^*, \kappa) + r_2(\varepsilon, x, \kappa)\} + p_2(\varepsilon, x, \kappa)],\end{aligned} \tag{4.74}$$

for $x \in I$. Using (4.71b), we obtain

$$\text{(the right-hand side of (4.74))} = c_1(\varepsilon)c_2(\varepsilon)\widehat{g}(\varepsilon, x, \kappa) + p(\varepsilon, x, \kappa),$$

for $x \in I$, where

$$\widehat{g}(\varepsilon, x, \kappa) \equiv \{G(x, x^*, \kappa) + r_1(\varepsilon, x, \kappa)\}\{G(x, x^*, \kappa) + r_2(\varepsilon, x, \kappa)\}$$

and $p(\varepsilon, \cdot, \kappa)$ is a function of x which satisfies

$$\|p(\varepsilon, \cdot, \kappa)\|_{L^\infty(I)} < M_2 \exp(-\beta\varepsilon^{\theta_1 - 1}).$$

We replaced M_2 with a larger one, if necessary. It suffices to show that

$$\int_I \widehat{g}(\varepsilon, x, \kappa)dx - \frac{c_1(\varepsilon)c_2(\varepsilon)}{4D^2\kappa^3}$$

is estimated by the right-hand side of (4.73). We have

$$\int_I \widehat{g}(\varepsilon, x, \kappa)dx = \overline{g}_1(\kappa) + \overline{g}_2(\varepsilon, \kappa) + \overline{g}_3(\varepsilon, \kappa) + \overline{g}_4(\varepsilon, \kappa),$$

where

$$\begin{aligned}\overline{g}_1(\varepsilon, \kappa) &\equiv \int_I |G(x, x^*, \kappa)|^2 dx, \\ \overline{g}_2(\varepsilon, \kappa) &\equiv \int_{I^2_{\text{in}}(\kappa)} G(x, x^*, \kappa)\{r_1(\varepsilon, x, \kappa) + r_2(\varepsilon, x, \kappa)\}dx, \\ \overline{g}_3(\varepsilon, \kappa) &\equiv \int_{I^2_{\text{out}}(\kappa)} G(x, x^*, \kappa)\{r_1(\varepsilon, x, \kappa) + r_2(\varepsilon, x, \kappa)\}dx, \\ \overline{g}_4(\varepsilon, \kappa) &\equiv \int_I r_1(\varepsilon, x, \kappa)r_2(\varepsilon, x, \kappa)dx.\end{aligned}$$

We have, from (4.27),

$$\overline{g}_1(\varepsilon, \kappa) = \frac{1}{4D^2\kappa^3} + o(\exp(-d\kappa)).$$

From (4.23), (4.66b), and (4.71a), we obtain

$$|\overline{g}_2(\varepsilon,\kappa)| < 2\kappa^{-\theta_2}\cdot M_2\kappa^{-1}\cdot 2M_2\varepsilon^{\theta_1} = 4(M_2)^2\varepsilon^{\theta_1}\kappa^{-(1+\theta_2)}.$$

By a direct calculation from (4.22), we have

$$\int_{I^2_{\mathrm{out}}(\kappa)} |G(x,x^*,\kappa)|dx = O(\kappa^{-2}\exp(-\kappa^{1-\theta_2})).$$

Using (4.71a) and the above estimate, we obtain

$$\begin{aligned}|\widehat{g}_3(\varepsilon,\kappa)| &< M_2\varepsilon^{\theta_1}\cdot O(\kappa^{-2}\exp(-\kappa^{1-\theta_2})),\\ |\widehat{g}_4(\varepsilon,\kappa)| &< (M_2)^2\varepsilon^{2\theta_1}.\end{aligned}$$

Putting together the above estimates, we conclude (4.73) for some $M_9 = M_9(f,g,D) > 0$. □

Proof of Theorem 4.1. Since we already showed (1) in Proposition 4.2, it is enough to prove (2) and (3) with the aid of Propositions 4.1 and 4.3. Combining (4.64) and (4.73), we have

$$\left|\varepsilon - \frac{c_1(\varepsilon)c_2(\varepsilon)}{4D\kappa(\varepsilon)^3}\right| < \frac{M_8}{\kappa(\varepsilon)^4} + M_9D\left\{\frac{\varepsilon^{\theta_1}}{\kappa(\varepsilon)^{1+\theta_2}} + \varepsilon^{2\theta_1} + \exp(-d\kappa(\varepsilon))\right\}.$$

Multiplying both sides of the above inequality by $\kappa(\varepsilon)^3$, we obtain

(4.75)
$$\begin{aligned}&\left|\varepsilon\kappa(\varepsilon)^3 - \frac{c_1(\varepsilon)c_2(\varepsilon)}{4D}\right|\\ &\quad< M_8\kappa(\varepsilon)^{-1} + M_9D\left\{\varepsilon^{\theta_1}\kappa(\varepsilon)^{2-\theta_2} + \varepsilon^{2\theta_1}\kappa(\varepsilon)^3 + \kappa(\varepsilon)^3\exp(-d\kappa(\varepsilon))\right\}.\end{aligned}$$

We choose θ_1 and θ_2 appropriately in order to make the right-hand side of (4.75) tends to zero as $\varepsilon \downarrow 0$. Let us set θ_1, θ_2 such that

$$2\theta_1 + \theta_2 - 2 > 0, \qquad 4\theta_1 - 3 > 0. \tag{4.76}$$

For instance, we can take $\theta_1 = 7/8, \theta_2 = 7/8$. Since we have $\kappa(\varepsilon) < \overline{\kappa}_+(\varepsilon)$, we have

$$\varepsilon^{\theta_1}\kappa(\varepsilon)^{2-\theta_2} < \varepsilon^{\theta_1}(\sigma\varepsilon^{-1/2})^{2-\theta_2} = \sigma^{2-\theta_2}\varepsilon^{(2\theta_1+\theta_2-2)/2}, \tag{4.77a}$$

$$\varepsilon^{2\theta_1}\kappa(\varepsilon)^3 < \varepsilon^{2\theta_1}(\sigma\varepsilon^{-1/2})^3 \quad = \sigma^3\varepsilon^{(4\theta_1-3)/2}, \tag{4.77b}$$

which yield (4.2). We note that the convergence of (4.2) is uniform regardless of our way of selecting $\kappa(\varepsilon)$. Now we show the unique existence of a zero solution of (3.25) which goes to ∞ as $\varepsilon \downarrow 0$. We see that $\lambda(\varepsilon) \equiv \widetilde{\lambda}(\varepsilon,\kappa(\varepsilon))$ is positive for small ε. From Proposition 4.3, we also see that $\widetilde{\lambda}(\varepsilon,\overline{\kappa}_+(\varepsilon))$ is negative. Since $\widetilde{\lambda}(\varepsilon,\cdot)$ is continuous, we obtain at least one zero point in $(\kappa(\varepsilon),\overline{\kappa}_+(\varepsilon))$. Let $\overline{\kappa}(\varepsilon)$ be an arbitrary one of them, then by the definition of $\overline{\kappa}(\varepsilon)$, it holds that

$$\begin{aligned}&\overline{\kappa}(\varepsilon) \to \infty \qquad (\text{as} \quad \varepsilon \downarrow 0),\\ &F(\varepsilon,\overline{\kappa}(\varepsilon),0) = \widehat{\zeta}_0(\varepsilon) - \varepsilon\overline{\kappa}(\varepsilon)^2 - H(\varepsilon,\overline{\kappa}(\varepsilon)^2,\lambda(\varepsilon)) = 0.\end{aligned}$$

Using (4.33) and the above equality, we obtain $\varepsilon\overline{\kappa}(\varepsilon)^2 \to \widehat{\zeta}_0(0)$ as $\varepsilon \downarrow 0$, which implies, for any given $\delta' > 0$, $\overline{\kappa}(\varepsilon)$ must lie in the interval

$$\left(\sqrt{\widehat{\zeta}_0(0) - \delta'} \cdot \varepsilon^{-1/2}, \sqrt{\widehat{\zeta}_0(0) + \delta'} \cdot \varepsilon^{-1/2}\right)$$

for small $\varepsilon > 0$. Since the asymptotic characterization (4.2) holds for any stationary point of $\widetilde{\lambda}(\varepsilon, \cdot)$, we see that $\widetilde{\lambda}(\varepsilon, \cdot)$ is monotone in the above interval. Accordingly $\overline{\kappa}(\varepsilon)$ is uniquely determined and satisfies (4.1). There are no other zero points of $\widetilde{\lambda}(\varepsilon, \cdot)$ in $[\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$ besides $\underline{\kappa}(\varepsilon)$ and $\overline{\kappa}(\varepsilon)$. We see that $\underline{\kappa}(\varepsilon)$ remains bounded, while $\overline{\kappa}(\varepsilon)$ goes to infinity as $\varepsilon \to 0$. Hence it holds that $0 < 2\underline{\kappa}(\varepsilon) < \overline{\kappa}(\varepsilon) < \infty$ for small ε. Let us take any $\kappa_1(\varepsilon)$ from $(\kappa(\varepsilon) - M, \kappa(\varepsilon) + M)$. Then it follows that $\kappa_1(\varepsilon) \in [\underline{\kappa}(\varepsilon), \overline{\kappa}_+(\varepsilon))$ for small $\varepsilon > 0$, and $\kappa_1(\varepsilon) = O(\varepsilon^{-1/3})$ as $\varepsilon \downarrow 0$. We have

$$\tau\widetilde{\lambda}(\varepsilon, \kappa_1(\varepsilon)) = \widehat{\zeta}_0(\varepsilon) - \varepsilon\kappa_1(\varepsilon)^2 - H(\varepsilon, \kappa_1(\varepsilon), \widetilde{\lambda}(\varepsilon, \kappa_1(\varepsilon))). \tag{4.78}$$

Making use of (4.33), we see that the right-hand side of (4.78) converges to $\widehat{\zeta}_0(0) > 0$ as $\varepsilon \downarrow 0$ uniformly for $\kappa_1(\varepsilon)$. We obtain (4.3), and this completes the proof of Theorem 4.1. □

Appendix 1 (Proof of Lemma 4.3). Let $z \in H^1(I)$ and $h \in H^{-1}(I)$ satisfy the equation: $\widehat{T}(\kappa)z = h$, which is equivalent to

$$D(z_x, \varphi_x)_{L^2(I)} + D\kappa^2(z, \varphi)_{L^2(I)} = {}_{H^{-1}(I)}\langle h, \varphi\rangle_{H^1(I)} \quad \forall\, \varphi \in H^1(I). \tag{1}$$

Substituting z for φ, we obtain

$$\begin{aligned} &D\|z_x\|^2_{L^2(I)} + D\kappa^2\|z\|^2_{L^2(I)} \\ &\quad = {}_{H^{-1}(I)}\langle h, z\rangle_{H^1(I)} \le |{}_{H^{-1}(I)}\langle h, z\rangle_{H^1(I)}|. \end{aligned} \tag{2}$$

We have

$$|{}_{H^{-1}(I)}\langle h, z\rangle_{H^1(I)}| \le \|h\|_{H^{-1}(I)}\|z\|_{H^1(I)} \le \frac{1}{2D}\|h\|^2_{H^{-1}(I)} + \frac{D}{2}\|z\|^2_{H^1(I)}. \tag{3}$$

Putting (2) and (3) together, we get

$$\frac{D}{2}\|z_x\|^2_{L^2(I)} + D\left(\kappa^2 - \frac{1}{2}\right)\|z\|^2_{L^2(I)} \le \frac{1}{2D}\|h\|^2_{H^{-1}(I)}.$$

In particular, we obtain

$$D\left(\kappa^2 - \frac{1}{2}\right)\|z\|^2_{L^2(I)} \le \frac{1}{2D}\|h\|^2_{H^{-1}(I)},$$

which leads to (4.28a). In order to prove (4.28b), we use the expression by Green's function:

$$\begin{aligned} z(x) &= \int_0^1 G(x, \xi, \kappa)h(\xi)d\xi \\ &= {}_{H^1(I)}\langle G(x, \cdot, \kappa), h\rangle_{H^{-1}(I)}, \end{aligned}$$

for $x \in I$. Making use of the Schwarz inequality, we have

$$
\begin{aligned}
|z(x)| &= |{}_{H^1(I)}\langle G(x,\cdot,\kappa), h\rangle_{H^{-1}(I)}| \\
&\leq \|G(x,\cdot,\kappa)\|_{H^1(I)} \|h\|_{H^{-1}(I)},
\end{aligned} \tag{4}
$$

for $x \in I$. We obtain (4.28b) from (4.26) and (4). Next we prove (4.29). Assume that $z \in H^1(I)$ satisfies $\widehat{T}(\kappa) z = \Theta(\kappa)$. Multiplying both side by $\bar{z}$ and integrating over I, we have

$$
\begin{aligned}
D\|z_x\|^2_{L^2(I)} + D\kappa^2 \|z\|^2_{L^2(I)} &= (\Theta(\kappa), z)_{L^2(I)} \\
&\leq \|\Theta(\kappa)\|_{L^2(I)} \|z\|_{L^2(I)}.
\end{aligned}
$$

In particular, we have

$$
D\kappa^2 \|z\|^2_{L^2(I)} \leq \|\Theta(\kappa)\|_{L^2(I)} \|z\|_{L^2(I)},
$$

which, combined with the assumption for $\Theta(\kappa)$, yields (4.29a). Finally we prove (4.29b). Expressing z by Green's function

$$
z(x) = \int_0^1 G(x,\xi,\kappa)\Theta(\xi,\kappa)d\xi \qquad (x \in I),
$$

and using the Schwarz inequality, we obtain

$$
|z(x)| \leq \|G(x,\cdot,\kappa)\|_{L^2(I)} \cdot \|\Theta(\kappa)\|_{L^2(I)}. \tag{5}
$$

Combining (4.25) with (5), we obtain (4.29b). Thus we complete the proof. □

Appendix 2 (Proof of Lemma 4.4). Since the latter half of this lemma, namely (4.32), can be proved by using the former half and Lemma 4.3, it suffices to show (4.30) and (4.31). By the definition of $T(\varepsilon,\kappa,\lambda)$ (see (3.12)), we have

$$
\begin{aligned}
T(\varepsilon,\kappa,\lambda) &= \widehat{T}(\kappa) + R(\varepsilon,\kappa,\lambda) + \lambda \\
&= \widehat{T}(\kappa)\{I + Z(\varepsilon,\kappa,\lambda)\},
\end{aligned} \tag{6}
$$

where I is the identity operator in $L^2(I)$, and

$$
Z(\varepsilon,\kappa,\lambda) \equiv \widehat{K}(\kappa)\{R(\varepsilon,\kappa,\lambda) + \lambda\}. \tag{7}
$$

In view of Lemma 3.1 and Proposition 4.1, we see that $\{R(\varepsilon,\kappa,\lambda) + \lambda\}$ is uniformly bounded in $\mathcal{B}(L^2(I), L^2(I))$. Since the norm of $\widehat{K}(\kappa)$ in $\mathcal{B}(L^2(I), L^2(I))$ is $O(\kappa^{-1})$ from (4.28a), there exists $\kappa_* = \kappa_*(f,g,D)$ such that

$$
\|Z(\varepsilon,\kappa,\lambda)\|_{\mathcal{B}(L^2(I),L^2(I))} < \tfrac{1}{2} \tag{8}
$$

holds for any $\kappa > \kappa_*$. Since $\mathcal{B}(L^2(I), L^2(I))$ is a Banach space, we see that

$$
W(\varepsilon,\kappa,\lambda) \equiv \sum_{j=0}^{\infty} (-1)^j Z(\varepsilon,\kappa,\lambda)^j
$$

exists in $\mathcal{B}(L^2(I), L^2(I))$ and its norm is less than 2. We have

$$\{I + Z(\varepsilon, \kappa, \lambda)\}^{-1} = W(\varepsilon, \kappa, \lambda) = I - Z(\varepsilon, \kappa, \lambda)W(\varepsilon, \kappa, \lambda). \tag{9}$$

Using (9), we rewrite (6) as

$$K(\varepsilon, \kappa, \lambda) = \{I - Z(\varepsilon, \kappa, \lambda)W(\varepsilon, \kappa, \lambda)\}\widehat{K}(\kappa).$$

In view of (4.17) and the above equality, we obtain

$$\overline{K}(\varepsilon, \kappa, \lambda) = -Z(\varepsilon, \kappa, \lambda)W(\varepsilon, \kappa, \lambda)\widehat{K}(\kappa),$$

which, combined with (7), implies that (4.30) holds true, if we set

$$\overline{R}(\varepsilon, \kappa, \lambda) = -\{R(\varepsilon, \kappa, \lambda) + \lambda\}W(\varepsilon, \kappa, \lambda). \tag{10}$$

We see that both $\{R(\varepsilon, \kappa, \lambda) + \lambda\}$ and $W(\varepsilon, \kappa, \lambda)$ are uniformly bounded operators in $L^2(I)$ for $(\varepsilon, \kappa, \lambda)$, and so is $\overline{R}(\varepsilon, \kappa, \lambda)$. We complete the proof of Lemma 4.4. □

Appendix 3 (Proof of Proposition 4.2). We prove Proposition 4.2 by contradiction. Let us assume that there exists $\{(\varepsilon_n, \kappa_n, \lambda_n)\}_{n=1}^{\infty}$ such that each $(\varepsilon_n, \kappa_n, \lambda_n)$ satisfies (3.25) and

$$\varepsilon_n \to 0 \quad \text{as} \quad n \uparrow \infty, \qquad \Im\lambda_n \neq 0 \quad \text{for any} \quad n. \tag{11}$$

By virtue of Proposition 4.1, we may suppose, without loss of generality, that $\lambda_n \to \lambda_0 \in \mathbb{C}_{\lambda_*}$ as $n \uparrow \infty$. We rewrite the right-hand side of (3.26) by

$$F(\varepsilon, \kappa, \lambda) = \widehat{\zeta_0}(\varepsilon) - \varepsilon\kappa^2 - \tau\Re\lambda - X(\varepsilon, \kappa, \lambda) - i\Im\lambda\{\tau - Y(\varepsilon, \kappa, \lambda)\}, \tag{12}$$

where X, Y are real-valued functions defined by

$$H(\varepsilon, \kappa, \lambda) = X(\varepsilon, \kappa, \lambda) - i\Im\lambda Y(\varepsilon, \kappa, \lambda). \tag{13}$$

Since $(\varepsilon_n, \kappa_n, \lambda_n)$ satisfies (3.25) and (11), we obtain

$$\widehat{\zeta_0}(\varepsilon_n) - \varepsilon_n\kappa_n^2 - \tau\Re\lambda_n - X(\varepsilon_n, \kappa_n, \lambda_n) = 0, \tag{14a}$$

$$\tau - Y(\varepsilon_n, \kappa_n, \lambda_n) = 0. \tag{14b}$$

It is apparent from (11) that (14b) is equivalent to

$$\Im H(\varepsilon_n, \kappa_n, \lambda_n) = -\tau\Im\lambda_n. \tag{15}$$

We have two cases $\Im\lambda_0 \neq 0$ and $\Im\lambda_0 = 0$. First we consider the case $\Im\lambda_0 \neq 0$. We can assume that $\{\kappa_n\}$ remains bounded, because if not, we see that the left-hand side of (15) converges to zero by virtue of (4.33), while the right-hand side of (15) converges to $\tau\Im\lambda_0 \neq 0$, which is a contradiction. Hence we can assume $\kappa_n \to \kappa_0$ as $n \uparrow \infty$ without loss of generality. It follows from Lemma 4.1 that

$$\lim_{n\uparrow\infty} Y(\varepsilon_n, \kappa_n, \lambda_n)$$

$$= -\frac{1}{\Im\lambda_0}\Im H(0, \kappa_0, \lambda_0) = \sum_{n=0}^{\infty} \frac{c_1^* c_2^* |\psi_n(x^*)|^2}{(\gamma_n + D\kappa_0^2 + \Re\lambda_0)^2 + (\Im\lambda_0)^2}.$$

By the definition of τ_* and (4.15), we see that the right-hand side of the above equality is less than τ, which contradicts (14b) as $n \uparrow \infty$.

Next we consider the case $\Im\lambda_0 = 0$. We make some preparations under the hypotheses of Lemma 3.1. From now on, all function spaces are considered as those of real functions. Let $P(\varepsilon, \kappa, \lambda)$ and $Q(\varepsilon, \kappa, \lambda)$ be the operators defined by

$$R(\varepsilon, \kappa, \lambda) = P(\varepsilon, \kappa, \lambda) + i\varepsilon\tau\Im\lambda Q(\varepsilon, \kappa, \lambda). \tag{16}$$

We introduce a bilinear form from $H^1(I) \times H^1(I)$ to $\mathbb{R}$ defined by

$$\widetilde{B}(\varepsilon, \kappa, \lambda)(z^1, z^2) \equiv D(z^1_x, z^2_x)_{L^2(I)} + ((P(\varepsilon, \kappa, \lambda) + D\kappa^2 + \Re\lambda)z^1, z^2)_{L^2(I)},$$

for $z^1, z^2 \in H^1(I)$. We also define an operator from $H^1(I)$ to $H^{-1}(I)$ by

$$\widetilde{T}(\varepsilon, \kappa, \lambda)z \equiv -z_{xx} + (P(\varepsilon, \kappa, \lambda) + D\kappa^2 + \Re\lambda)z, \tag{17}$$

for $z \in H^1(I)$. Then we have

LEMMA A.1. *Under the same hypotheses of Lemma* 3.1, *we have* (i)–(v).

(i) *Both* $P(\varepsilon, \kappa, \lambda)$ *and* $Q(\varepsilon, \kappa, \lambda)$ *are uniformly bounded linear operators from* $L^2(I)$ *to* $L^2(I)$ *for* $(\varepsilon, \kappa, \lambda)$.

(ii) $\widetilde{B}(\varepsilon, \kappa, \lambda)$ *is a bounded and coercive sesquilinear form on* $H^1(I)$.

(iii) $\widetilde{T}(\varepsilon, \kappa, \lambda)$ *belongs to* $\mathcal{B}(H^1(I), H^{-1}(I))$, *and has an inverse operator denoted by* $\widetilde{K}(\varepsilon, \kappa, \lambda)$. $\widetilde{K}(\varepsilon, \kappa, \lambda)$ *is a uniformly bounded linear operator from* $H^{-1}(I)$ *to* $H^1(I)$ *for* $(\varepsilon, \kappa, \lambda)$.

(iv) *If we assume* (3.6) *in addition, we have*

$$\widetilde{K}(\varepsilon, \kappa, \lambda) \to K(0, \kappa, \Re\lambda) \quad \textit{in} \quad \mathcal{B}(H^{-1}(I), H^1(I)),$$

as $\varepsilon \downarrow 0$. *The convergence is uniform for* (κ, λ) *in any compact subset of* $[0, \infty) \times \mathbb{C}_{\lambda_*}$.

(v) *We have, for* $\kappa > \kappa_*$,

$$|(\widetilde{K}(\varepsilon, \kappa, \lambda)\widetilde{K}(\varepsilon, \kappa, \lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}| < M_6 \cdot \kappa^{-5/2}, \tag{18}$$

where M_6, κ_* *are the same constants in Lemma* 4.5.

Proof. By virtue of (3.7), we can obtain (i) by a simple calculation from (3.8a) and (16). The proofs of (ii), (iii), and (iv) can be carried out by the same argument as in [NF, Lemma 3.1]. A similar argument used to obtain (4.34a) is also valid to get (v). □

From the definitions of $T(\varepsilon, \kappa, \lambda)$ and $\widetilde{T}(\varepsilon, \kappa, \lambda)$, we have

$$\begin{aligned} T(\varepsilon, \kappa, \lambda) &= \widetilde{T}(\varepsilon, \kappa, \lambda) + i\Im\lambda\{I + \varepsilon\tau Q(\varepsilon, \kappa, \lambda)\} \\ &= \widetilde{T}(\varepsilon, \kappa, \lambda)\{I + i\Im\lambda\widetilde{Z}(\varepsilon, \kappa, \lambda)\}, \end{aligned} \tag{19}$$

where

$$\widetilde{Z}(\varepsilon, \kappa, \lambda) \equiv \widetilde{K}(\varepsilon, \kappa, \lambda)\{I + \varepsilon\tau Q(\varepsilon, \kappa, \lambda)\}. \tag{20}$$

LEMMA A.2. *Under the same hypotheses of Lemma* 3.1, *there exists* $\nu_* = \nu_*(f, g, D)$ *such that it holds for* $|\Im\lambda| < \nu_*$ *that*

$$K(\varepsilon,\kappa,\lambda) = \{I - i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}\{I - (\Im\lambda)^2\widetilde{W}(\varepsilon,\kappa,\lambda)\}\widetilde{K}(\varepsilon,\kappa,\lambda), \tag{21}$$

where $\widetilde{W}(\varepsilon,\kappa,\lambda)$ *is a uniformly bounded linear operator in* $L^2(I)$ *for* $(\varepsilon,\kappa,\lambda)$.

Proof. In view of (20) and Lemma A.1, we see that $\widetilde{Z}(\varepsilon,\kappa,\lambda)$ is uniformly bounded in $\mathcal{B}(L^2(I), L^2(I))$ for $(\varepsilon,\kappa,\lambda)$. Since $\mathcal{B}(L^2(I), L^2(I))$ is a Banach space, we have

$$\{I + i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}^{-1} = \sum_{n=0}^{\infty}\{-i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}^n, \tag{22}$$

for small $\Im\lambda$. We set

$$\widetilde{W}(\varepsilon,\kappa,\lambda) = \sum_{n=0}^{\infty}(-1)^n(\Im\lambda)^{2n}\{\widetilde{Z}(\varepsilon,\kappa,\lambda)\}^{2n+2}.$$

Then we see that $\widetilde{W}(\varepsilon,\kappa,\lambda)$ is uniformly bounded for $(\varepsilon,\kappa,\lambda)$ in $\mathcal{B}(L^2(I), L^2(I))$ and that from (22),

$$\{I + i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}^{-1} = \{I - i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}\{I - (\Im\lambda)^2\widetilde{W}(\varepsilon,\kappa,\lambda)\} \tag{23}$$

in $\mathcal{B}(L^2(I), L^2(I))$. It follows from (19) that

$$K(\varepsilon,\kappa,\lambda) = \{I + i\Im\lambda\widetilde{Z}(\varepsilon,\kappa,\lambda)\}^{-1}\widetilde{K}(\varepsilon,\kappa,\lambda). \tag{24}$$

Combining (23) and (24), we obtain the desired result. □

From the definition of $Y(\varepsilon,\kappa,\lambda)$,

$$\begin{aligned} &Y(\varepsilon_n,\kappa_n,\lambda_n) \\ &\quad = -\Im H(\varepsilon_n,\kappa_n,\lambda_n)/\Im\lambda_n \\ &\quad = -(\Im K(\varepsilon_n,\kappa_n,\lambda_n)h_2(\varepsilon_n), h_1(\varepsilon_n))_{L^2(I)}/\Im\lambda_n, \end{aligned} \tag{25}$$

which, combined with (21) and (20), leads to

$$\begin{aligned} &Y(\varepsilon_n,\kappa_n,\lambda_n) \\ &\quad = (\widetilde{Z}(\varepsilon,\kappa,\lambda)\{I - (\Im\lambda)^2\widetilde{W}(\varepsilon,\kappa,\lambda\}\widetilde{K}(\varepsilon,\kappa,\lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}\Big|_{\substack{\varepsilon=\varepsilon_n,\kappa=\kappa_n\\ \lambda=\lambda_n}} \\ &\quad = (\widetilde{K}(\varepsilon,\kappa,\lambda)\widetilde{K}(\varepsilon,\kappa,\lambda)h_2(\varepsilon), h_1(\varepsilon))_{L^2(I)}\Big|_{\substack{\varepsilon=\varepsilon_n,\kappa=\kappa_n\\ \lambda=\lambda_n}} + O(\varepsilon_n) + O(|\Im\lambda_n|^2). \end{aligned} \tag{26}$$

If $\{\kappa_n\}$ is unbounded, we may assume that $\kappa_n \to \infty$ as $n \uparrow \infty$ by taking a subsequence. Using Lemma A.1.(v) and the assumption $\Im\lambda_n \to 0$, we see that the right-hand side of (26) converges to zero, which contradicts (14b). Hence $\{\kappa_n\}$ must remain bounded. So we may assume that we have $\kappa_n \to \kappa_0 \in [0,\infty)$ and $\lambda_n \to \lambda_0 \in \mathbb{C}_{\lambda_*}$ as $n \uparrow \infty$. Letting $n \uparrow \infty$ in (26), it follows from Lemma A.1 (iv) and (4.8) that

$$\begin{aligned} &\lim_{n\uparrow\infty} Y(\varepsilon_n,\kappa_n,\lambda_n) \\ &\quad = c_1^*c_2^* \cdot {}_{H^1(I)}\langle K(0,\kappa_0,\Re\lambda_0)K(0,\kappa_0,\Re\lambda_0)\delta(x-x^*), \delta(x-x^*)\rangle_{H^{-1}(I)} \\ &\quad = \sum_{n=0}^{\infty}\frac{c_1^*c_2^*|\psi_n(x^*)|^2}{(\gamma_n + D\kappa_0^2 + \Re\lambda_0)^2} \quad < \tau, \end{aligned}$$

which contradicts (14b) when $n \uparrow \infty$. We complete the proof of Proposition 4.2. □

Acknowledgment. The first author expresses his sincere gratitude to Professor Hiroshi Matano for many stimulating discussions and continuous encouragement. Special thanks go to Professor Masashi Katsurada for useful suggestions on numerical computations.

TIKHONOV REGULARIZATION FOR FINITELY AND INFINITELY SMOOTHING OPERATORS*

B. A. MAIR†

Abstract. The main goal of this paper is to obtain a unified theory of Tikhonov regularization, incorporating explicit asymptotic rates of convergence based on a priori assumptions, which cover both the finitely and infinitely smoothing forward operators, and to extend a classic result of Natterer to this more general framework. More specifically, it is shown that, for a large class of operators, as in the finitely smoothing case obtained by Natterer, the stabilizing functional involved in the minimization process can be determined by larger norms over much smaller classes than those determined by the a priori assumption for the true solution.

Key words. Tikhonov regularization, Hilbert scales, spectral measure

AMS subject classifications. 45L05, 35R25

1. Introduction. The method of Tikhonov regularization is one of the most widely applied methods for solving ill-posed inverse problems that arise in a wide variety of problems in science and engineering. As is well known, the main difficulty in applying this method occurs in the choice of a regularizing parameter, usually denoted by α, depending on the error in the data. Both a priori and a posteriori methods of choosing α have been developed, mainly for the case of finitely smoothing forward operators (cf. [12] and [23]). However, many problems in partial differential equations (cf. [3], [6], [7], [10], [11], [13]–[15], [25]–[27]), linear systems theory (cf. [10] and [18]), statistics (cf. [8]), optics (cf. [4]), and astronomy (cf. [9]), just to mention a few areas, give rise to linear ill-posed problems determined by infinitely smoothing forward operators. The main goal of this paper is to obtain a unified theory, incorporating explicit asymptotic rates of convergence based on a priori assumptions, which covers both the finitely and infinitely smoothing forward operators. We also show that, as in the finitely smoothing case (cf. [22]), the stabilizing functional involved in the minimization process can be determined by larger norms over much smaller classes than those determined by the a priori assumption for the true solution. In other words, it certainly does no harm to "over-regularize." In fact, the application of over-regularization to severely ill-posed inverse heat conduction problems (cf. [3], [15], [26], and [27]) have greatly improved the accuracy of the resulting numerical algorithms.

More specifically, we consider the problem of finding an approximate solution to an operator equation of the form

$$T(x) = y,$$

based on inaccurate data y_δ. Although the results in §2 cover a more general case, for this discussion assume that T is injective with dense range, and that the data satisfies $\|y_\delta - y\| \leq \delta$. As in [19]–[23] and [27], consider approximations obtained by minimizing

$$\|Tx - y_\delta\|^2 + \alpha^2 \|Bx\|^2$$

*Received by the editors October 8, 1992; accepted for publication March 15, 1993. This work was partially supported by National Science Foundation grant DMS 9006308.

over the domain of a suitable constraint operator B, where it is assumed that the true solution x_0 satisfies, $\|Bx_0\| \leq E$.

By using techniques in [20], [21], and [26] and a condition describing the degree of ill-posedness of quite general T in terms of the spectral measure of B^*B, it is shown in §2 that the Tikhonov regularized solution $x_{\alpha,\delta}$ satisfies

$$\|x_{\alpha,\delta} - x_0\| = O\left(\sqrt{\varphi^{-1}(\delta^2)}\right) \quad \text{if } \alpha = \frac{\delta}{E},$$

where φ is a convex function which quantifies the ill-posedness of the operator T.

This generalizes the classical result (cf. [2], [22], and [23]) for finitely smoothing operators, in which $\varphi^{-1}(t)$ is simply a power of t. For the general case considered here, there is no closed form for $\varphi^{-1}(t)$. Explicit convergence rates can only be obtained from estimates of the behavior of $\varphi^{-1}(t)$ as $t \to 0$. The surprising fact is that this basic result enables us to generalize a well-known result of Natterer [22], thus providing a new result for an important class of inverse problems (see §5).

In §3, we specialize this result to the case when the approximation is taking place in a Hilbert scale, $\{X_s : s \in \mathbb{R}\}$, to obtain the usual result (cf. [2], [22], and [23]) for finitely smoothing T and a logarithmic rate of convergence for a general class of infinitely smoothing operators (cf. [2] and [26]).

To demonstrate the significance of the general result, §4 applies it to problems of deconvolution and inversion of dilationally invariant transforms (cf. [1], [2], [4], [5], [7]–[9], [13]–[15], and [24]). There we obtain a convergence rate for a very general class of deconvolution problems that is faster than the classical one obtained in [2] for the special case considered there.

In the final section we show that for a very general class of operators, if approximation is taking place in a Hilbert scale and it is assumed that the true solution $x_0 \in X_q$, then the unique minimizer of $\|Tx - y_\delta\|^2 + \alpha^2\|x\|_p^2$ over $x \in X_p$, for any $p \geq q$, and an appropriate choice of α, produces an approximation of x_0 with the same rate of convergence as when $p = q$. This generalizes the result of Natterer for finitely smoothing operators obtained in [22]. It is interesting to note that the proof here is very different from that in [22]. It simply uses the basic result in §2 and denseness properties of the spaces in a Hilbert scale, avoiding the very involved use of interpolation theorems present in the classical proof.

2. A general error estimate for Tikhonov regularization. Let X, Y be Hilbert spaces and $T : X \longrightarrow Y$ be a bounded, linear operator with nonclosed range $\mathcal{R}(T)$. Then the Moore–Penrose inverse $T^\dagger$ is not continuous and the problem of solving the equation

$$Tx = y$$

is ill-posed, even if $y \in \mathcal{R}(T)$.

In this section we use basic properties of Moore-Penrose inverses contained in [2], [17], [20]. Here, we consider the problem of obtaining an approximate "solution" to the "equation"

$$Tx = y_0, \tag{2.1}$$

based on inaccurate data y_δ, where y_0 is not even assumed to be in $\mathcal{R}(T)$.

We assume y_0 is in the domain, $\mathcal{D}(T^\dagger)$, of the Moore–Penrose inverse $T^\dagger$, which is $\mathcal{R}(T) + \mathcal{R}(T)^\perp$.

For any such y_0, let

$$x_0 = T^\dagger(y_0). \tag{2.2}$$

This is the so-called best approximate solution to (2.1) and is the unique classical solution if T is injective and $y_0 \in \mathcal{R}(T)$.

Since y_0 is usually not known, we need to obtain an approximation to x_0 based on the approximate data y_δ.

Let Q denote the orthogonal projection of Y onto $\overline{\mathcal{R}(T)}$ and assume that the appproximate data y_δ satisfies

$$\|Q(y_\delta - y_0)\| \leq \delta. \tag{2.3}$$

To construct a regularized solution of (2.1), we need a "constraint operator" B that quantifies the smoothness constraints imposed on our solution x_0 (cf. [2], [19]–[21], and [27]).

DEFINITION 2.1. Let B be a closed, densely defined operator on X, mapping its domain $V \subset X$ onto a Hilbert space Z. For each α and $\delta > 0$, define the quadratic functional $L_{\alpha,\delta}$ on V by

$$L_{\alpha,\delta}(x) = \|Tx - y_\delta\|^2 + \alpha^2\|Bx\|^2.$$

Then we seek an approximation to x_0 obtained by minimizing $L_{\alpha,\delta}$ over V.

To guarantee the existence of a unique minimizer, we assume the following.

Assumption 2.2. There exists $\beta > 0$ such that $\|Tx\| \geq \beta\|x\|$ for all $x \in \mathcal{N}(B)$.

Then, by reformulating the minimization as a least squares problem, the following is shown in [20].

THEOREM 2.3. *$L_{\alpha,\delta}$ has a unique minimizer $x_{\alpha,\delta} \in V$. Furthermore, $x_{\alpha,\delta} \in \mathcal{D}(B^*B)$ and is the unique solution of $(T^*T + \alpha^2 B^*B)x_{\alpha,\delta} = T^*y_\delta$.*

Now, to obtain explicit convergence rates for the error in approximating x_0 by $x_{\alpha,\delta}$, assume the following.

Assumption 2.4. T is injective.

The general case can be reduced to this, by considering the restriction of T to $\mathcal{N}(T)^\perp$.

DEFINITION 2.5. *For each $\varepsilon > 0$, $\nu(\varepsilon) = \sup\{\|x\| : x \in V,\ \|Tx\| \leq \varepsilon,\ \|Bx\| \leq 1\}$.*

THEOREM 2.6. *Under Assumption 2.4, for any $\alpha > 0$, $\|x_{\alpha,\delta} - x_0\| \leq \sqrt{(\delta^2/\alpha^2) + \|Bx_0\|^2}\ \nu(\alpha)$.*

Proof. We need to go back to the characterization of $x_{\alpha,\delta}$ as the result of a least squares method. As in [20], for $\alpha > 0$ define $K_\alpha : V \longrightarrow Y \oplus Z$ by $K_\alpha(x) = [Tx, \alpha Bx]$, where $[y, z]$ represents the generic element in $Y \oplus Z$, and the inner product on this space is: $\langle [y, z], [y', z'] \rangle_{Y\oplus Z} = \langle y, y' \rangle_Y + \langle z, z' \rangle_Z$. Then $x_{\alpha,\delta} = K_\alpha^\dagger([y_\delta, 0])$, where $K_\alpha^\dagger$ is the Moore–Penrose inverse of K_α. Hence $x_{\alpha,\delta}$ is characterized as the unique solution in V of the equation

$$K_\alpha x_{\alpha,\delta} = Q_\alpha([y_\delta, 0]), \tag{2.4}$$

where Q_α is the projection of Y onto $\overline{\mathcal{R}(K_\alpha)} = \mathcal{R}(K_\alpha)$.

Now, for any $x \in V$,

$$\langle [y_\delta - Qy_\delta, 0], K_\alpha x \rangle_{Y\oplus Z} = \langle y_\delta - Qy_\delta, Tx \rangle_Y = 0,$$

since $y_\delta - Qy_\delta \in \mathcal{R}(T)^\perp$. Hence,

$$Q_\alpha[y_\delta, 0] - [Qy_\delta, 0] \in \mathcal{R}(K_\alpha)^\perp. \tag{2.5}$$

Now, by (2.4),

$$\begin{aligned} K_\alpha x_0 - [Qy_\delta, 0] &= K_\alpha(x_0 - x_{\alpha,\delta}) + K_\alpha x_{\alpha,\delta} - [Qy_\delta, 0] \\ &= K_\alpha(x_0 - x_{\alpha,\delta}) + Q_\alpha[y_\delta, 0] - [Qy_\delta, 0]. \end{aligned}$$

Hence by (2.5) and (2.3),

$$\begin{aligned} \|K_\alpha(x_0 - x_{\alpha,\delta})\|^2 &\le \|K_\alpha x_0 - [Qy_\delta, 0]\|^2 \\ &= \|Tx_0 - Qy_\delta\|^2 + \alpha^2\|Bx_0\|^2 \\ &= \|Qy_0 - Qy_\delta\|^2 + \alpha^2\|Bx_0\|^2 \\ &\le \delta^2 + \alpha^2\|Bx_0\|^2. \end{aligned}$$

Thus,

$$\|T(x_0 - x_{\alpha,\delta})\| \le \sqrt{\delta^2 + \alpha^2\|Bx_0\|^2},$$

$$\|B(x_0 - x_{\alpha,\delta})\| \le \sqrt{\frac{\delta^2}{\alpha^2} + \|Bx_0\|^2}.$$

The result follows from Definition 2.5.

Now, to obtain an a priori error estimate, assume that the true solution x_0 satisfies the following.

Assumption 2.7. $\|Bx_0\| \le E$, for some fixed constant E.

Then, from Theorem 2.6 we obtain the following.

THEOREM 2.8. *Let $\alpha(\delta) = \delta/E$, and define $x_\delta = x_{\alpha(\delta),\delta}$. Then*

$$\|x_\delta - x_0\| \le \sqrt{2}\, E\, \nu\left(\frac{\delta}{E}\right).$$

This is a slight improvement and generalization of Theorem 3.4 in [2]. To make this result more applicable we need to obtain an estimate of $\nu(\varepsilon)$. To do this, assume the following (cf. [26]).

Assumption 2.9. There exists a continuous function $\varphi : [0,\infty) \to [0,\infty)$ such that: (i) the map $s \mapsto \varphi(s)/s$ is increasing on $(0,\infty)$;

(ii) $\varphi(s) = 0$ if and only if $s = 0$;

(iii) φ is convex on an interval containing $\{1/\lambda : \lambda$ is in the spectrum of $B^*B\}$;

(iv) there exists a constant $m > 0$ such that

$$m^2 \int \varphi\left(\frac{1}{\lambda}\right) \lambda \, d\mathcal{M}_{x,x}(\lambda) \le \|Tx\|^2 \quad \text{for all } x \in \mathcal{D}(B^*B),$$

where $\mathcal{M}$ is the spectral measure of B^*B.

THEOREM 2.10. *Assuming* 2.9, $\nu(\varepsilon) \le \sqrt{\varphi^{-1}(\varepsilon^2/m^2)}$ *for all* $\varepsilon > 0$.

Proof. Let $x \in \mathcal{D}(B^*B)$. Then, by Jensen's inequality and Assumption 2.9,

$$\begin{aligned} \varphi\left(\frac{\|x\|^2}{\|Bx\|^2}\right) = \varphi\left(\frac{\int (1/\lambda)\lambda \, d\mathcal{M}_{x,x}(\lambda)}{\int \lambda \, d\mathcal{M}_{x,x}(\lambda)}\right) &\le \frac{\int \varphi(1/\lambda)\lambda \, d\mathcal{M}_{x,x}(\lambda)}{\|Bx\|^2} \\ &\le \frac{\|Tx\|^2}{m^2\|Bx\|^2}. \end{aligned}$$

Now, the graph of the restriction of B to $\mathcal{D}(B^*B)$ is dense in the graph of B. Hence, the above inequality is valid for $x \in V$.

Now, if $\|Bx\| \leq 1$, then $\|x\| \leq \|x\|/\|Bx\|$; so

$$\frac{\varphi(\|x\|^2)}{\|x\|^2} \leq \frac{\varphi(\|x\|^2/\|Bx\|^2)}{\|x\|^2/\|Bx\|^2} \leq \frac{\|Tx\|^2}{m^2\|x\|^2}.$$

Hence $\varphi(\|x\|^2) \leq \|Tx\|^2/m^2$. The proof is completed by noting that φ^{-1} exists and is increasing.

THEOREM 2.11. *Under Assumptions* 2.4, 2.7, *and* 2.9,

$$\|x_\delta - x_0\| \leq \sqrt{2}E\sqrt{\varphi^{-1}\left(\frac{\delta^2}{m^2E^2}\right)} = O\left(\sqrt{\varphi^{-1}(\delta^2)}\right).$$

3. Approximation in Hilbert scales. In this section we consider the frequently used constraint of assuming that the best approximate solution is in some fixed ball in a Hilbert scale. The case when T is a finitely smoothing operator has been well studied (cf. [2], [22], and [23], and the references therein). Here we obtain the classical result as a special case of Theorem 2.11 and obtain a new result applicable to a general class of infinitely smoothing operators when the Hilbert scale is viewed as Sobolev spaces.

Assumption 3.1. Assume that $\{X_s : s \in \mathbb{R}\}$ is a Hilbert scale generated by a selfadjoint, densely defined, unbounded operator L, on X, with $\|Lx\| \geq \|x\|$, for all $x \in \mathcal{D}(L)$. As usual, $X_0 = X$, and $X_s = \mathcal{D}(L^s)$.

The usual method of regularization by smoothing in a Sobolev space is obtained from the general case by setting $V = Z = X_p$, for some $p > 0$, and B to be the identity on X_p.

Then, the approximation $x_{\alpha,\delta}$ obtained in Theorem 2.3 is the unique minimizer of the quadratic functional

$$x \mapsto \|Tx - y_\delta\|^2 + \alpha^2\|x\|_p^2,$$

where $\|\cdot\|_p$ denotes the norm in X_p. Now, under these assumptions, it is easy to see that $\mathcal{D}(B^*B) = X_{2p}$ and $B^*B = L^{2p}$. Hence, by Theorem 2.3, we obtain

$$(T^*T + \alpha^2L^{2p})x_{\alpha,\delta} = T^*y_\delta.$$

Now, consider the classical choice of $\alpha(\delta) = \delta/E$ (so $x_{\alpha,\delta} = x_\delta$), where it is assumed that the solution x_0 satisfies

$$\|x_0\|_p \leq E.$$

To obtain an estimate on the rate of convergence of x_δ to x_0, it is often assumed that there exist constants $a, m, M > 0$, such that

$$m\|x\|_{-a} \leq \|Tx\| \leq M\|x\|_{-a} \quad \text{for all } x \in X. \tag{3.1}$$

To fit this into the framework of Assumption 2.9, let $\mathcal{L}$ be the spectral measure of L. Then the spectral measure of $B^*B = L^{2p}$ is given by

$$d\mathcal{M}(\lambda) = d\mathcal{L}(\lambda^{1/2p}). \tag{3.2}$$

We now deduce the classical convergence rate (cf. [2] and [22]) from our results in §2.

THEOREM 3.2. *If* $m\|x\|_{-a} \leq \|Tx\|$ *for all* $x \in X_{2p}$, *then*

$$\|x_\delta - x_0\| \leq \sqrt{2}\left(\frac{E^a}{m^p}\right)^{1/(a+p)} \delta^{p/(a+p)}.$$

Proof.

$$\begin{aligned}\|x\|_{-a}^2 &= \int_1^\infty \lambda^{-2a} d\mathcal{L}_{x,x}(\lambda) \\ &= \int_1^\infty \lambda^{-a/p}\, d\mathcal{M}_{x,x}(\lambda) \\ &= \int_1^\infty \left(\frac{1}{\lambda}\right)^{1+a/p} \lambda\, d\mathcal{M}_{x,x}(\lambda).\end{aligned}$$

Hence, setting $\varphi(s) = s^{1+a/p}$, we see that Assumption 2.9 is satisfied.

Clearly, $\varphi^{-1}(s) = s^{p/(a+p)}$ and the result follows from Theorem 2.11.

To deal with a general class of infinitely smoothing operators, we need to investigate properties of functions of the following form.

DEFINITION 3.3. For each $\beta, \gamma > 0$, define the function

$$\psi_{\beta,\gamma}(s) = s \exp\left(-\frac{\beta}{s^\gamma}\right) \quad \text{if } s > 0 \quad \text{and} \quad \psi_{\beta,\gamma}(0) = 0.$$

Then it is easy to see what follows in Lemma 3.4.

LEMMA 3.4.

(i) *The map* $s \mapsto (1/s)\psi_{\beta,\gamma}(s)$ *is increasing on* $(0, \infty)$.

(ii) $\psi_{\beta,\gamma}(s) = 0 \iff s = 0$.

(iii) *If* $\beta \geq 1$, *then* $\psi_{\beta,\gamma}$ *is convex on* $[0, 1]$.

LEMMA 3.5. $\psi_{\beta,\gamma}^{-1}(s) = (\beta/(\log 1/s))^{1/\gamma}\,(1 + o(1)) \quad$ *as* $s \to 0+$.

Proof. Let $t = \psi_{\beta,\gamma}^{-1}(s)$. Then

$$\log s = \log t - \frac{\beta}{t^\gamma}. \tag{3.3}$$

Hence

$$t = \left(\frac{\beta}{\log t - \log s}\right)^{1/\gamma} = \left(\frac{\beta}{|\log s|}\right)^{1/\gamma} G(s),$$

where

$$\begin{aligned}G(s) &= \left|\frac{\log t}{\log s} - 1\right|^{-1/\gamma} \\ &= \left|\frac{\log t}{\log t - \beta t^{-\gamma}} - 1\right|^{-1/\gamma}, \quad \text{by (3.3)} \\ &= \left|\left(1 - \frac{\beta}{t^\gamma \log t}\right)^{-1} - 1\right|^{-1/\gamma}.\end{aligned}$$

Hence $G(s) \to 1$ as $s \to 0+$.

This result (not the proof) is similar to one in [26].

THEOREM 3.6. *If there exist positive constants a, m, and b such that*

$$m^2 \int \exp(-b\lambda^a)\, d\mathcal{L}_{x,x}(\lambda) \le \|Tx\|^2 \quad \textit{for all } x \in X_{2p},$$

then

$$\|x_\delta - x_0\| \le \sqrt{2}E \left(\frac{\max\{b,1\}}{2\log(mE/\delta)} \right)^{p/a} (1 + o(1)) = O\left(\left[\log \frac{1}{\delta} \right]^{-p/a} \right).$$

Proof. From (3.2) it is clear that

$$m^2 \int \varphi\left(\frac{1}{\lambda}\right) \lambda \, d\mathcal{M}_{x,x}(\lambda) \le \|Tx\|^2 \quad \text{for all } x \in X_{2p},$$

where $\varphi(s) = s \exp\left(-\max\{b,1\} s^{-a/2p}\right)$.

Hence, by using Lemma 3.4, it is clear that Assumption 2.9 is satisfied.

It is interesting to note that this convergence rate is obtained for such a wide class of problems by using the classical choice of $\alpha(\delta) = \delta/E$, contrary to results in [2, §10.2], which indicate a different choice for the particular example considered there.

4. Applications. It is well known that inverse problems for the heat equation have important applications in science and engineering. The basic, so-called Inverse Heat Conduction Problem (cf. [3]) gives rise to the problem of solving convolution equations with kernels whose Fourier transforms decrease exponentially fast (cf. [6], [7], and [15]). Our result applies easily to a general class of such deconvolution problems.

For a given kernel $K \in L^2(\mathbb{R})$, consider the problem of solving the convolution equation

$$K * f = g \tag{4.1}$$

for $f, g \in L^2(\mathbb{R})$, given approximate data $g_\delta \in L^2(\mathbb{R})$, satisfying

$$\|g_\delta - g\|_{L^2} \le \delta. \tag{4.2}$$

Assumption 4.1.

(i) There exist constants $a, b, c > 0$ such that the Fourier transform of K satisfies $|\hat{K}(s)| \ge ce^{-b|s|^a}$ for all $s \in \mathbb{R}$.

(ii) For some $p > 0$, the true solution lies in a fixed ball in the usual Sobolev space H^p, i.e., $\|f\|_{H^p} \le E$.

THEOREM 4.2. *Assuming* (4.2) *and Assumption* 4.1, *let f_δ satisfy*

$$\hat{f}_\delta(s) = \frac{\overline{\hat{K}}(s)}{|\hat{K}(s)|^2 + (\delta/E)^2(1+s^2)^p} \, \hat{g}_\delta(s).$$

Then $\|f_\delta - f\|_{L^2} = O([\log(1/\delta)]^{-p/a})$.

Proof. Consider $X = Y = L^2(\mathbb{R})$, $Tf = K * f$, $Sf = f - f''$, and $L = S^{1/2}$.

Then $H^p = \mathcal{D}(L^p) = X_p$, and we are in the framework of §3.

Now, $\|Tf\|_{L^2}^2 = \int_1^\infty |\hat{K}(\sqrt{\lambda^2-1})|^2 d\mathcal{L}_{f,f}(\lambda)$, where $\mathcal{L}$ is the spectral measure of L.

Hence, by Assumption 4.1,

$$\|Tf\|_{L^2}^2 \geq c^2 \int_1^\infty \exp(-2b\lambda^a)\, d\mathcal{L}_{f,f}(\lambda).$$

The result follows from Theorem 3.6, and the representation of $f_\delta = (T^*T + (\delta^2/E^2)L^{2p})^{-1}T^*g_\delta$.

The classical inverse problem of determining initial temperature from later temperature readings (cf. [10]–[14] and [25]) also gives rise to an ill-posed problem with an exponential rate of decrease of its spectral information. Hence, the analysis in [14], which provided only partially explicit convergence rates, can now be modified using Theorem 3.6 in order to obtain a slightly different numerical scheme with completely explicit error bounds.

Many inverse problems in optics and astronomy (cf. [4] and [9]) can be modeled, at least approximately, by the problem of solving an integral equation of the type

$$\int_0^\infty k(st)f(t)dt = g(s), \tag{4.3}$$

given approximate data g_δ.

As in [1] and [4], (4.3) is equivalent to solving the convolution equation

$$G = K * F, \tag{4.4}$$

where

$$K(t) = e^{-t}k(e^{-t}), \quad F(t) = f(e^t), \quad G(t) = e^{-t}g(e^{-t}). \tag{4.5}$$

Thus an approximation to f can be obtained from the regularized solution of (4.4) if $K \in L^2(\mathbb{R})$. Error estimates can be obtained from the classical Theorem 3.2 or from Theorem 3.6.

To state our results here, we will find it useful to introduce the following (cf. [24]).

DEFINITION 4.3.

(i) For any $f : [0,\infty) \to \mathbb{R}$, define $Jf(t) = tf(t)$.

(ii) Define the measure μ on $[0,\infty)$ by $d\mu(t) = dt/t$.

(iii) $H^1(\mu)$ denotes the set of all absolutely continuous functions f on $[0,\infty)$ such that $f(0) = 0$ and $f' \in L^2(\mu)$, with the usual norm.

As noted in [24], μ is the Haar measure of the group $[0,\infty)$ under multiplication (cf. [8]).

Now, consider the problem of Laplace transform inversion. An application of Theorem 3.6 in the special case of $p = 1$ gives the following (cf. [24]).

THEOREM 4.4. *Suppose the data g_δ satisfies $\|J(g_\delta - g)\|_{L^2(\mu)} \leq \delta$, and the true solution, f, to the equation,*

$$\int_0^\infty e^{-st}f(t)dt = g(s),$$

satisfies $\|Jf\|_{H^1(\mu)} \leq E$. Let $f_\delta(t) = F_\delta(\log t)$, where

$$\hat{F}_\delta(s) = \frac{\Gamma(1-is)}{\left(\left|\frac{\pi s}{\sin h\pi s}\right| + \frac{\delta^2}{E^2}(1+s^2)\right)}\hat{G}_\delta(s)$$

and $G_\delta(t) = e^{-t}g_\delta(e^{-t})$. *Then* $\|f_\delta - f\|_{L^2(\mu)} = O([\log(1/\delta)]^{-1})$.

Proof. As in [1], $|\hat{k}(s)|^2 = \pi s/|\sin h\pi s| \geq ce^{-\pi s}$. The result follows by applying Theorem 3.6 with $p = a = 1$.

This same error estimate was obtained in [1].

Now, consider problem (4.3) with the kernel $k(t) = J_1^2(t)/t^2$, where J_1 is the usual Bessel function (cf. [4]). Using formulas in [15], it is easy to see that the Fourier transform of the corresponding kernel K given by (4.5) satisfies

$$|\hat{K}(s)| = \frac{8}{\pi^{1/4}(1+s^2)(9+s^2)^{1/2}}.$$

Hence this problem is not as ill-posed as the Laplace-inversion problem and can be solved by the classical result for finitely smoothing operators. In fact, under the same conditions as in Theorem 4.4, the convergence rate for this problem is $O\left(\delta^{2/5}\right)$.

5. Higher-order regularization. This section combines the general framework in §2 with the basic assumptions for approximation in Hilbert scales (§3) to extend the result in [22] to a more general framework that includes both the finitely and infinitely smoothing operators. Also, the method of proof differs from that in [22] even for the special case considered there.

More specifically, assume (2.3) and Assumptions 2.4 and 3.1. The a priori assumption on the solution x_0 is the following.

Assumption 5.1. There exists $q > 0$ such that $x_0 \in X_q$ and $\|x_0\|_q \leq E$ for some constant E.

The degree of ill-posedness of T is characterized by the following.

Assumption 5.2. There exists a decreasing, continuous function $w : (0, \infty] \longrightarrow [0, \infty)$ such that

(i) $w(s) = 0 \Leftrightarrow s = \infty$;

(ii) the function $s \mapsto s\,w(s^{-\gamma})$ is convex on $[0, 1]$ for each $\gamma > 0$;

(iii) there exist constants m, $M > 0$, and $0 < \rho \leq 1$ such that

$$m^2 \int w \, d\mathcal{L}_{x,x} \leq \|Tx\|^2 \leq M^2 \int w^\rho \, d\mathcal{L}_{x,x} \quad \text{for all } x \in X_{2q},$$

where $\mathcal{L}$ is the spectral measure of L.

DEFINITION 5.3. For each $r > 0$, define the function $\varphi_r : [0, \infty) \longrightarrow [0, \infty)$ by $\varphi_r(\lambda) = \lambda\, w(\lambda^{-1/2r})$.

Since the spectral measure, $\mathcal{M}^{(r)}$, of L^{2r} is given by $d\mathcal{M}^{(r)}(\lambda) = d\mathcal{L}(\lambda^{1/2r})$, then from Assumption 5.2, we see that the following holds.

Remark 5.4. For each $r > 0$, the function φ_r satisfies Assumption 2.9 with $B^*B = L^{2r}$.

The following technical result will be used in the subsequent theorem to compare the convergence rates of two components of the total error.

LEMMA 5.5. *For any* $p \geq q > 0$ *and constant* $C > 0$,

(i) $\varphi_q^{-1}(C\lambda) = O(\varphi_q^{-1}(\lambda))$;

(ii) $\varphi_p^{-1}(C\lambda[\varphi_q^{-1}(\lambda)]^{(p-q)/q}) = O([\varphi_q^{-1}(\lambda)]^{p/q})$, *as* $\lambda \to 0+$.

Proof. Let $C_1 = \max(1, C)$. Then for any $t > 0$, since w is decreasing, $C\varphi_p(t) = Ctw(t^{-1/2p}) \leq C_1 tw\left((C_1 t)^{-1/2p}\right)$. Hence, $\varphi_p^{-1}\left(C\varphi_p(t)\right) \leq C_1 t$.

Part (i) follows easily. To prove (ii), let $t = \varphi_q^{-1}(\lambda)$. Then,

$$\begin{aligned}\varphi_p^{-1}\left(C\varphi_q(t)t^{(p-q)/q}\right) &= \varphi_p^{-1}\left(Cw(t^{-1/2q})t^{p/q}\right) \\ &= \varphi_p^{-1}\left(C\varphi_p(t^{p/q})\right) \leq C_1 t^{p/q}.\end{aligned}$$

THEOREM 5.6. *Assume Assumptions* 5.1, 5.2, $p \geq q$, *and let* $x_{\alpha,\delta} = (T^*T + \alpha^2 L^{2p})^{-1}T^*y_\delta$. *Then*

$$\|x_{\alpha(\delta),\delta} - x_0\| = O\left(\left[\frac{\varphi_q^{-1}(\delta^{2\rho})}{\varphi_q^{-1}(\delta^2)}\right]^{p/2q}\sqrt{\varphi_q^{-1}(\delta^2)}\right), \quad \textit{where}$$

$$\alpha(\delta) = \frac{1+EM}{E}\delta^\rho\left[\varphi_q^{-1}(\delta^2)\right]^{(p-q)/2q}.$$

Proof. The basic idea is quite natural: to use the denseness of X_p to obtain an approximation, x_1 to x_0. Then, use the basic Tikhonov regularization to estimate x_1 in X_p. However, these approximations have to be carefully done to maintain suitable orders of convergence.

It will be essential to observe that for each $\delta > 0$ there exists $\tau(\delta) \uparrow \infty$ as $\delta \downarrow 0$ such that

$$\tau(\delta) = \left[\varphi_q^{-1}(\delta^2)\right]^{-1/2q} \quad \text{and} \quad \tau(\delta)^{-2q}w(\tau(\delta))^\rho \leq \delta^{2\rho}. \tag{5.1}$$

To obtain asymptotic error estimates it suffices to assume δ is so small that $\delta \leq 1$ and $\tau(\delta) \geq 1$.

Let $x_1 = \int_{[1,\tau(\delta)]} d\mathcal{L}_{x_0}$. Then, $\|x_1 - x_0\|^2 = \int_{(\tau(\delta),\infty)} d\mathcal{L}_{x_0,x_0} \leq 1/\tau(\delta)^{2q}\int_{(\tau(\delta),\infty)} \lambda^{2q}\, d\mathcal{L}_{x_0,x_0}(\lambda)$.

Hence, from Assumption 5.1,

$$\|x_1 - x_0\| \leq \frac{E}{\tau(\delta)^q}. \tag{5.2}$$

From Assumption 5.2,

$$\begin{aligned}\|T(x_1 - x_0)\|^2 &\leq M^2\int_{(\tau(\delta),\infty)} w(\lambda)^\rho\, d\mathcal{L}_{x_0,x_0}(\lambda)\\ &\leq M^2 w(\tau(\delta))^\rho\int_{(\tau(\delta),\infty)} d\mathcal{L}_{x_0,x_0}\\ &\leq E^2M^2w(\tau(\delta))^\rho\tau(\delta)^{-2q}\end{aligned}$$

by Assumption 5.1. Hence, by (5.1),

$$\|T(x_1 - x_0)\| \leq EM\delta^\rho. \tag{5.3}$$

By using the triangle inequality, (5.3), and the data error in (2.3), we obtain

$$\|Qy_\delta - Tx_1\| \leq (1+EM)\delta^\rho. \tag{5.4}$$

To use the data y_δ to recover x_1 by minimizing $\|Tx - y_\delta\|^2 + \alpha^2\|x\|_p^2$ over $x \in X_p$, we need an estimate of the size of $\|x_1\|_p$.

$$\|x_1\|_p^2 = \int_{[1,\tau(\delta)]} \lambda^{2p}\, d\mathcal{L}_{x_0,x_0}(\lambda) \leq \tau(\delta)^{2(p-q)}\int_{[1,\tau(\delta)]} \lambda^{2q}\, d\mathcal{L}_{x_0,x_0}\,(\lambda).$$

Thus,

$$\|x_1\|_p \leq E\tau(\delta)^{p-q}. \tag{5.5}$$

By applying Remark 5.4, the error estimate (5.4) and the a priori norm bound (5.5), to Theorem 2.11, it follows that if

$$\alpha(\delta) = \frac{(1+EM)\delta^\rho}{E\tau(\delta)^{p-q}},$$

then, by (5.1) and Lemma 5.5,

$$\|x_{\alpha(\delta),\delta} - x_1\| \le \sqrt{2}E\tau(\delta)^{p-q}\sqrt{\varphi_p^{-1}\left(\left(\frac{(1+EM)\delta^\rho}{E\tau(\delta)^{p-q}}\right)^2\right)}.$$

The result follows from (5.1), Lemma 5.5, and (5.2).

Now, to obtain the result in [22], set $\rho = 1$, and $w(\lambda) = \lambda^{-2a}$, $a > 0$. Then $\varphi_r(\lambda) = \lambda^{1+a/r}$ and Assumption 5.2 reduces to the one in [22]:

$$m\|x\|_{-a} \le \|Tx\| \le M\|x\|_{-a}. \tag{5.6}$$

Since $\varphi_r^{-1}(\lambda) = \lambda^{r/(a+r)}$, the result in Theorem 5.6 says that, under (5.6) and Assumption 5.1,

$$\|x_{\alpha(\delta),\delta} - x_0\| = O(\delta^{a/(a+q)}) \quad \text{where } \alpha(\delta) = O(\delta^{(a+p)/(a+q)}).$$

We now obtain an analogous result for the general class of "infinitely smoothing" operators discussed in §§3 and 4.

COROLLARY 5.7. *Suppose that there exist positive constants a, b, c, m, and M such that*

$$m^2 \int \exp(-b\lambda^a)\, d\mathcal{L}_{x,x}(\lambda) \le \|Tx\|^2 \le M^2 \int \exp(-c\lambda^a)\, d\mathcal{L}_{x,x}(\lambda)$$

for all $x \in X_{2q}$, and the best approximate solution x_0 satisfies

$$\|x_0\|_q \le E.$$

Given data y_δ satisfying $\|Q(y_\delta - y_0)\| \le \delta$, let $x_{\alpha,\delta} = (T^*T + \alpha^2 L^{2p})^{-1}T^*y_\delta$, where $p \ge q$.

Then

$$\|x_{\alpha(\delta),\delta} - x_0\| = O\left(\left[\log\frac{1}{\delta}\right]^{-q/a}\right), \quad \textit{where}$$

$$\alpha(\delta) = O\left(\delta^\rho\left[\log\frac{1}{\delta}\right]^{-(p-q)/a}\right) \quad \textit{and} \quad \rho = \min\left[\frac{c}{\max\{b,1\}}, 1\right].$$

More specifically,

$$\alpha(\delta) = \frac{1+EM}{E}\delta^\rho\,\eta(\delta)^{p-q}, \quad \textit{where}$$

$$\eta(\delta)^{2q}\exp\left(-\max\{b,1\}\eta(\delta)^{-a}\right) = \delta^2.$$

Proof. Let $\beta = \max\{b,1\}$, so $\rho = \min\{c/\beta, 1\}$.

Set $w(\lambda) = \exp(-\beta\lambda^a)$. Then, for all $\lambda > 0$, $w(\lambda) \le \exp(-b\lambda^a)$ and $\exp(-c\lambda^a) \le w(\lambda)^\rho$.

Now, from Definition 3.3, $s\,w(s^{-\gamma}) = \psi_{\beta,a\gamma}(s)$. Hence, by using Lemma 3.4, Assumption 5.2 is satisfied. The result follows from Theorem 5.6 and Lemma 3.5, by noting that $\varphi_q = \psi_{\beta,a/2q}$ and $\varphi_q^{-1}(\delta^{2\rho}) = O(\varphi_q^{-1}(\delta^2))$. □

Preliminary testing indicates that the numerical accuracy of inversion schemes are improved by using this result.

Acknowledgment. The author is indebted to Scott McCullough and Murali Rao for many stimulating discussions.

REGULARIZING MICROSCOPES AND RIVERS*

MARC DIENER†

This paper is dedicated to Professor Jean-Louis Callot, in memoriam.

Abstract. This paper proposes a generalization of the existing geometric studies of resonance. The Riccati equation associated with any second-order linear equation is extended to any C^∞ first-order equation. The Morse-critical point is generalized to any "generic" critical point. The resonant solution becomes a general canard solution. The paper explains how to find the regularizing blowup, and shows how classical special functions become enlarged in *rivers*, i.e., some resurgent solutions of polynomial differential equations. The paper shows a matching principle that connects the slow solutions with these rivers. The method to show the existence of canards is applied for some *Union-Jack equations*, i.e., equations with a critical point where three smooth curves intersect.

Key words. resonance, turning points, singular perturbations, matching, canard, river, Union-Jack, macroscope, microscope, nonstandard analysis, Newton polygon

AMS subject classifications. 34E20, 34E05, 03H10

Introduction. For the problem of turning points of singularly perturbed linear second-order differential equations [21], one is indebted to Kopell [14] for a geometric study of *resonances*, remarkable solutions, discovered by Ackerberg and O'Malley [1], of some boundary value problems in the neighbourhood of the equation's turning points.

At the heart of the proof of the main theorem, Kopell introduces a crucial blowup that turns the singular perturbation problem into a regular one. The first approximation of that new equation is a Hermite equation $\ddot{U} - X\dot{U} + kU = 0$ depending on the real parameter k. It is well known that this equation admits, for noninteger k, a basis of solutions, generally denoted by H_k^+ and H_k^-, with polynomial growth at $+\infty$ and $-\infty$, respectively. When k becomes an integer, these two solutions become equal to each other and turn into a polynomial: the Hermite polynomial. As observed independently by Kopell and Callot [5], it is the "crossing" of these two special functions that makes possible (and necessary) the existence of the resonant solutions. We want to show here that the special functions (or more precisely the inverse of their logarithmic derivatives) admit a generalization, the "rivers," that make it possible to solve this kind of turning point problem for a much more general class of equations.

Let's briefly sketch Callot's approach. One first factors out the invariance of the set of solutions of the second-order differential equation $\varepsilon\ddot{u} - f(x)\dot{u} + g(x,a)u = 0$ by considering the new unknown $y = u/\dot{u}$. So, one considers the slow-fast Riccati equation $\varepsilon dy/dx = -f(x)y + g(x,a)y^2 + \varepsilon$ whose slow curve $\{g(x,a)y^2 - f(x)y = 0\}$ is the union of the two smooth curves $C_1 = \{g(x,a)y = f(x)\}$ and $C_2 = \{u = 0\}$ (see Fig. 1(a)). In those variables, a resonant solution is a slow solution (i.e., infinitely close to the slow curve) staying infinitely close to C_1 on both sides of some "critical point" x_0, i.e., here, of a point such that $f(x_0) = 0$, and such that, near x_0, C_1 is attracting for $x < x_0$ and repelling for $x > x_0$. This is precisely what is usually called a *canard* [3], [10].

Now comes the trick we want to consider here in a general set-up. In order to determine the behaviour of the slow solutions when they come across the halo*[1] of

[1] We use here the methods of nonstandard asymptotics. We recall in the appendix (§4) most nonstandard definitions and results involved here: we indicate by a star * the words defined there.

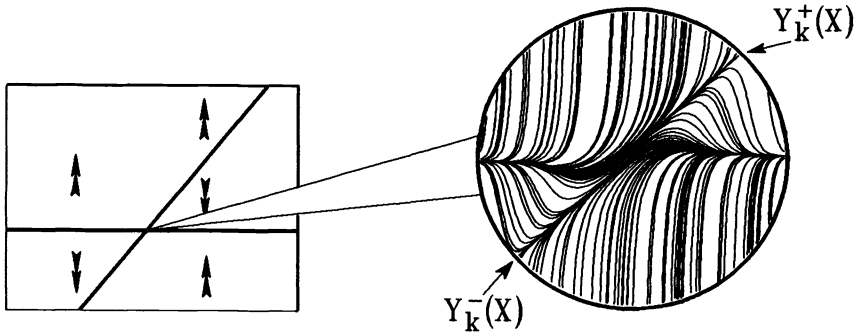

FIG. 1. *Sketch of Callot's proof of the existence of resonant solutions.* (a) *The slow curve of the Riccati equation* $\varepsilon dy/dx = -f(x)y + g(x,a)y^2 + \varepsilon$; (b) *The rivers* $Y^{\pm}(X)$ *of the Riccati–Hermite equation* $dY/dX = -XY + kY^2 + 1$ *for* k *near to* 1. *For larger* k, *the river would have an analogous behaviour at infinity, but would exhibit* $\operatorname{Int} k - 1$ *simple poles.*

the critical point $(x_0, 0)$ (and see how to choose the value of the parameter a in order that such a solution is a canard), one introduces a microscope

$$x - x_0 = \sqrt{\varepsilon}X, \qquad y = \sqrt{\varepsilon}Y$$

that is *regularizing*, in the sense that it turns the singular perturbation of the Riccati equation into a *regular* perturbation of the so-called Riccati–Hermite equation

$$dY/dX = -XY + kY^2 + 1,$$

where $k = k(a) := g(x_0, a)/f'(x_0)$.

Let $Y_k^{\pm} := H_k^{\pm}/H_k^{\pm}$. The function Y_k^+ and Y_k^- can clearly be perceived in Fig. 1(b): they are the only trajectories asymptotic to a (neither horizontal nor vertical) straight line, here $X = kY$. The striking fact about these solutions is that the other nearby solutions depart from it in an "exponential way." This kind of behaviour has been studied since that time for general polynomial differential equations, and these solutions are now called *rivers* (see below).

Let $U \subseteq \mathbb{R}^2$ be a nonempty standard open set, $\varepsilon > 0$ an infinitesimal, and f a function defined on U, with regular ε-shadow expansion*.

In this paper, we consider the general nonlinear singular perturbation problem associated with equation

$$\varepsilon dy/dx = f(x,y) \quad (\varepsilon > 0 \text{ infinitesimal}), \tag{1}$$

where $f(x,y) = f_0(x,y) + \varepsilon f_1(x,y) + \cdots$ with (f_n) a standard sequence of $\mathcal{C}^\infty$ functions of $(x,y) \in U$. One may think of $f(x,y) = F(x,y,\varepsilon)$ for some standard smooth function F, but it could as well be $f(x,y) := G(x,y,\varepsilon,\overline{a})$ with $\overline{a}$ the sum to the smallest term of some diverging series $\sum a_n \varepsilon^n$.

The purpose of this paper is first to show how to associate with any equation (1) one, or if necessary several, *regularizing microscopes* in the neighbourhood of a *critical* point of the slow curve $f_0(x,y) = 0$, one for each growth type of the branches of this curve. This makes it possible to convert the singular perturbation into the regular perturbation of one or more *polynomial* differential equation: the *local models.*

We shall then see that the special functions of the above example are not a "miracle": the local model indeed has rivers; the rivers are solutions that are transcendent, but, as in the case of the special functions of physics such as the Airy function, they have remarkable asymptotic behaviour that lead to efficient numerical approximations. We shall recall the definition and main properties of the rivers at §1.2.

The final problem is to relate the behaviour of the slow solutions of (1) when they are infinitely close to the critical point with the rivers of the local model. This study will lead to Theorem 3.1, a matching principle, which is the central result of this paper. It shows how these rivers generalize the special functions $Y_k^{\pm}$ introduced in the recalled study, and make it possible to specify the behaviour of the slow solutions of (1) near the critical points.

In the introduction to §2, we shall give an example in which the critical point is the intersection of three smooth curves. Using a transversality argument (the "crossing" of two rivers) on the local model, we will show (Corollary 3.2) the existence of canards.

1. Slow-curve branches, Newton polygons, and rivers. The local models near critical points of the slow curve depend strongly on the geometry of this slow curve at that point. We give here some elementary tools that yield crucial information about that geometry from a finite number of terms of the Taylor expansion that give dominant balance near the critical point.

This first section will recall some definitions and define notation that we shall need in the sequel concerning the branches of curves $f(x,y)=0$. Then it will introduce our main tool, the rivers.

1.1. Branches of generic $\mathcal{C}^\infty$ curves.

DEFINITIONS. Let f be a function defined in the neighbourhood of (x_0,y_0). Let φ be a continuous function, whose domain $\mathcal{D}(\varphi)$ is a closed interval with nonempty interior, and having x_0 as one of its ends.We call φ a *branch* at (x_0,y_0) of the curve $\mathcal{C}$ of equation $f(x,y)=f(x_0,y_0)$ if $\varphi(x_0)=y_0$ and $f(x,\varphi(x))=f(x_0,y_0)$ for all $x\in\mathcal{D}(\varphi)$. One specifies that φ is a *positive* or *negative* branch, according to the sign of $x-x_0$ for $x\in\mathcal{D}(\varphi)$, $x\neq x_0$. Let k and r be real numbers, $k\neq 0$ if $r\neq 0$. We say that φ is a branch of type (k,r) at(x_0,y_0) (or, for short, a (k,r)-branch) if $\varphi(x)-y_0\sim k|x-x_0|^r$ when $x\to x_0$ in $\mathcal{D}(\varphi)$ in the case $k\neq 0$, or $\varphi(x)\equiv y_0(=0)$ in the case $k=r=0$.

We denote by $\sim$ the classical relation "is asymptotic to" in the neighbourhood of x_0 or $\pm\infty$, according to the context. In nonstandard words this is equivalent, for standard φ, x_0, $k\neq 0$, and r, to $\varphi(x)=y_0+k|x-x_0|^r(1+\delta)$ with $\delta\simeq 0$ as soon as $x\simeq x_0$ if $x_0\in\mathbb{R}$. If $x_0=\pm\infty$, it means $\varphi(x)=kx^r(1+\delta)$ with $\delta\simeq 0$ as soon as x is unlimited*, of the sign of $\pm\in\{-1,+1\}$.

Puiseux's theory [12], [15] shows that if f is analytic in the neighbourhood of (x_0,y_0), the curve $\mathcal{C}$ is a union of (k,r)-branches with r rational (and possibly the straight line $x=x_0$). The assumption that f is $\mathcal{C}^\infty$ is much too flabby to force an analogous result, as $\mathcal{C}$ could be any closed subset of $\mathbb{R}^2$. Nevertheless one recovers an analogous result if f is not too degenerate; for that purpose, we introduce now what we shall call the *lower* Newton polygon $\mathcal{N}(f\,;x_0,y_0)$. Proposition 1.2 will show how to determine the growth types of the various *branches* of $f=0$ using this lower Newton polygon and the polynomial ${}_rf_0$ that we shall now define (see also Fig. 2).

DEFINITION. Let f be a $\mathcal{C}^\infty$ function on a neighbourhood of $(x_0,y_0)\in\mathbb{R}^2$. We call the *Taylor set* of f at the point (x_0,y_0) the set of couples of integers $\mathcal{T}(f;x_0,y_0):=\{(m,n)\neq(0,0)|f^{(m+n)}_{x^my^n}(x_0,y_0)\neq 0\}$; if $(x_0,y_0)=(0,0)$ we'll just write $\mathcal{T}(f)$ for

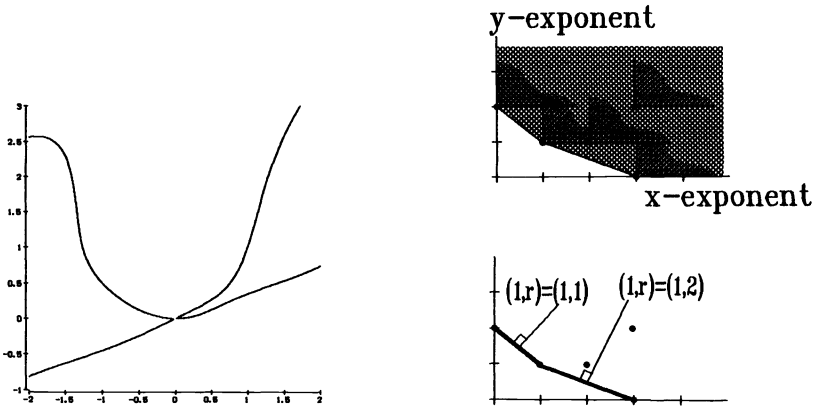

FIG. 2. *The curve $f = 0$ and the lower Newton polygon at $(0,0)$ associated with $f(x,y) = (x-2y)(2y-x^2)+x^3y^2\cos(x-y)$; here ${}_1f(x,y) = 2y(x-2y)$ and ${}_2f(x,y) = x(2y-x^2)$. The curve shows two negative and two positive branches at $(0,0)$, of growth-type $x/2$ and $x^2/2$ at $(0,0)$.*

$\mathcal{T}(f\,;0,0)$. Let $\mathcal{E} = \mathcal{E}(f;x_0,y_0)$ be the convex hull in $\mathbb{R}^2_{mn}$ of the union of all quadrants $m \geq \overline{m}$ and $n \geq \overline{n}$ for all $(\overline{m},\overline{n}) \in \mathcal{T}(f;x_0,y_0)$.

The (*lower*) *Newton polygon* of f at the point (x_0,y_0) is the union $\mathcal{N}(f;x_0,y_0)$ of all oblique segments that build the border of $\mathcal{E}(f;x_0,y_0)$. If $(x_0,y_0) = (0,0)$, we'll just write $\mathcal{N}(f)$ for $\mathcal{N}(f\,;0,0)$.

We call *coslope* of a nonhorizontal segment σ the real number r such that $(1,r)$ is orthogonal to σ. If r is the coslope of some segment σ contained in $\mathcal{N}(f;x_0,y_0)$ we say that r is a coslope of $\mathcal{N}(f;x_0,y_0)$; r is then necessarily a positive rational (see Fig. 2). If there is no point $(m,n) \in \mathcal{N}(f;x_0,y_0)$ such that $n = 0$ (i.e., if $(y-y_0)$ is a factor of $f(x,y)-f(x_0,y_0)$, we shall say that $r = 0$ is (also) a coslope of $\mathcal{N}(f;x_0,y_0)$.

In §1.2 we shall define an *upper* Newton polygon for f any *polynomial.*

DEFINITION. We assume that $\mathcal{T}(f;x_0,y_0) \neq \emptyset$. We define the *r-valuation* of f at the point (x_0,y_0) as the minimum $\mu_r(f;x_0,y_0)$ of all $m+rn$ for $(m,n) \in \mathcal{T}(f;x_0,y_0)$. We'll just write $\mu_r(f)$ when $(x_0,y_0) = (0,0)$. We denote by ${}_rf(X,Y)$ the polynomial, sum of all monomials of the Taylor expansion of f at the point (x_0,y_0) with r-valuation equal to $\mu := \mu_r(f;x_0,y_0)$:

$$ {}_rf(X,Y) := \sum_{m+rn=\mu} \frac{1}{m!n!} f^{(m+n)}_{x^m y^n}(x_0,y_0) X^m Y^n. $$

Remark. The polynomial ${}_rf$ is *r-homogeneous* of *r-degree*$=\mu := \mu_r(f;x_0,y_0)$, that is, ${}_rf(\lambda X,\lambda^r Y) = \lambda^\mu {}_rf(X,Y)$ for any $\lambda > 0$. For $r \neq 0$, its Taylor set is contained in the segment σ of $\mathcal{N}(f;x_0,y_0)$ with coslope r if any and then $\mathcal{N}({}_rf;x_0,y_0) = \sigma$, or is just equal to one point of $\mathcal{N}(f;x_0,y_0)$.

LEMMA 1.1. *Let $f \in \mathcal{C}^\infty$ be a standard function, such that $f(0,0) = 0$ and $\mathcal{T}(f) \neq \emptyset$. Let $\alpha > 0$, $\alpha \simeq 0$, and $r \in \mathbb{R}^+$ standard. Set $\mu = \mu_r(f)$, $x = \alpha X$, and $y = \alpha^r Y$. For all limited (X,Y), one has $f(x,y) = \alpha^\mu({}_rf(X,Y) + \phi)$.*

Proof. As f and r are standard, so* is μ. Let N be a standard integer, $N \geq \mathrm{Max}\{\mu, \mu/r\}$. We write f as $f = T_N f + R_N f$, where $T_N f$ is the Taylor polynomial

of f at $(0,0)$ of degree N, and $R_N f$ is the rest of the Taylor expansion. For all infinitesimal (x,y), one has $R_N f(x,y) = (\mathrm{Max}\{|x|,|y|\})^{N+1}\mathcal{L}$ ($\mathcal{L}$ denoting a generic limited real number), and thus $R_N f(\alpha X, \alpha^r Y) = \alpha^\mu \phi$ as $N+1 \geq \mathrm{Max}\{\mu, \mu/r\}$.

Thus, it suffices to show the lemma in the case where f is a standard polynomial $T_N f(x,y)$; this case is trivial. □

PROPOSITION 1.2. *Let $f \in \mathcal{C}^\infty$ be any function defined on some neighbourhood $(0,0)$, such that $f(0,0) = 0$ and $\mathcal{T}(f) \neq \emptyset$. Let k and r be nonzero numbers. If the curve $f = 0$ admits a negative (k,r)-branch at $(0,0)$, then r is a coslope of $\mathcal{N}(f)$ and ${}_r f(-1,k) = 0$.*

Proof. By transfer*, we may assume that f and the branch φ are standard. Since φ is standard, and as $\varphi(x) \sim k|x|^r$, the real numbers k and r are standard. Let $\alpha > 0$ be any infinitesimal. The hypothesis $\varphi(x) \sim k|x|^r$ for $x < 0$ implies that $\varphi(-\alpha) = k\alpha^r(1+\phi)$. Let $\mu := \mu_r(f\,; 0,0)$. Lemma 1.1 implies that

$$f(-\alpha, \varphi(-\alpha)) = f(-\alpha, k\alpha^r(1+\phi)) = \alpha^\mu({}_r f(-1, k(1+\phi)) + \delta)$$

with $\delta \simeq 0$. Dividing by α^μ the relation $f(\alpha, \varphi(\alpha)) = 0$, one gets ${}_r f(-1, k(1+\phi)) \simeq 0$. Since ${}_r f$ is a standard continuous function, one has

$${}_r f(-1,k) = {}_r f({}^o(-1, k(1+\phi))) = {}^o({}_r f(-1, k(1+\phi))) = 0.$$

Thus ${}_r f(-1,k) = 0$; since $k \neq 0$, the polynomial ${}_r f(X,Y)$ cannot be just equal to one monomial; r is thus a coslope of $\mathcal{N}(f)$. □

Here is a somewhat more general result that we will *not* use here.

PROPOSITION 1.3. *Let $f \in \mathcal{C}^\infty$ be standard such that $f(0,0) = 0$ and $\mathcal{T}(f) \neq \emptyset$. Let $(\alpha, \phi) \simeq (0,0)$, $\alpha > 0$, such that $f(\alpha,\phi) = 0$. Assume that $\phi = \alpha^r$ with r appreciable. Then some standard $k_0 \neq 0$ and some $r_0 = {}^o r$ exist such that $\phi = k_0\alpha^{r_0}(1+\phi)$; r_0 is a coslope of $\mathcal{N}(f; x_0, y_0)$ and ${}_{r_0} f(1, k_0) = 0$.*

Proof. Let $r_0 := {}^o r \neq 0$, and $\mu := \mu_{r_0}(f)$, which is standard, as are f and r_0. Let $N \geq \mathrm{Max}\{\mu, \mu/r\}$. Using the factorization $\alpha^r = \alpha^{r-r_0}\alpha^{r_0}$ and reasoning as in proof of Lemma 1.1, one checks that $f(\alpha,\phi) = \alpha^\mu({}_{r_0} f(1, \alpha^{r-r_0}) + \phi)$. Since $f(\alpha,\phi) = 0$, dividing by α^μ, one sees that ${}_{r_0} f(1, \alpha^{r-r_0}) \simeq 0$. Since $p(K) := {}_{r_0} f(1,K)$ is a nonconstant standard polynomial, thus unlimited for any unlimited K, $k := \alpha^{r-r_0}$ has to be limited, thus near-standard in $\mathbb{R}$. Let $k_0 := {}^o k$. One has $0 = {}^o({}_{r_0} f(1,k)) = {}_{r_0} f(1, {}^o k) = {}_{r_0} f(1, k_0)$. We have to show that $k_0 \neq 0$. If we set $s := 1/r$ and $g(x,y) := f(y,x)$, as $\alpha = \phi^s$, the previous reasoning shows that $l := \alpha^{s-{}^o s}$ is near-standard in $\mathbb{R}$, and $\alpha = l\phi^{s_0}$ with $s_0 := {}^o s$. Thus $\phi = k\alpha^{r_0} = kl^{r_0}\phi^{r_0 s_0} = kl^{r_0}\phi$, with k and l limited. Finally, $1 = kl^{r_0}$ and ${}^o k \neq 0$. □

1.2. Rivers of polynomial differential equations. The polynomial differential equations that occur as local models for the behaviour of the slow solutions near the critical points of the slow curve have a few remarkable solutions called "rivers" that "organize" the qualitative behaviour of the other solutions. These solutions are of polynomial growth and attract or repel exponentially the nearby solutions. These rivers generalize the (logarithmic derivative) of the special functions, the distinguished solutions of (the Riccati equations associated with) the second-order linear differential equations occuring in mathematical physics. We recall here briefly the definition of rivers of a polynomial differential equation and the effective methods to determine the rivers using an *upper* Newton polygon and the polynomials ${}_r P$ associated with P that we also define now. For more details see [11], [7], and [20].

Let us consider the following differential equation:

$$\frac{dY}{dX} = P(X,Y) \tag{2}$$

with $P(X,Y)$ any polynomial with real coefficients.

DEFINITION (see [4]). Let $\overline{Y}$ be any solution of (2), and k and r two real numbers, with $k \neq 0$ if $r \neq 0$. We say that $\overline{Y}$ is a solution of type (k,r) of (2) at $X = +\infty$ (respectively, $X = -\infty$) if there exists a real number X_0 such that $\overline{Y}$ is defined on $[X_0, +\infty)$ (respectively, $(-\infty, X_0]$), and if

$$\overline{Y}(X) \sim k|X|^r \quad \text{at } X = +\infty \quad (\text{respectively, } X = -\infty).$$

We say that $\overline{Y}$ is a *river* of type (k,r) of (2) at $X = +\infty$ (respectively, $X = -\infty$) if $\overline{Y}$ is a solution of type (k,r) of (2) at $X = +\infty$ (respectively, $X = -\infty$) and if

$$\lim_{X \to \pm\infty} X \cdot P'_Y(X, \overline{Y}(X)) = \pm\infty.$$

We shall use the expression "of growth type kX^r at $X = \pm\infty$" as a synonym "of type (k,r) at $X = \pm\infty$."

This last hypothesis suffices to ensure the exponential attracting or repelling of nearby solutions (see [4]). Here come two definitions introducing objects useful to determine the rivers of a polynomial differential equation.

DEFINITION. Let $P := \sum a_{mn} X^m Y^n$, and let $\mathcal{D} = \mathcal{D}(P)$ be the convex hull in $\mathbb{R}^2_+$ of the half-lines $m \leq \overline{m}$ and $n = \overline{n}$, for all $(\overline{m}, \overline{n})$ such that $a_{\overline{mn}} \neq 0$. We call the *upper* Newton polygon of the polynomial P the union $\mathcal{M}(P)$ of all oblique segments of the border of $\mathcal{D}$.

If σ is a segment contained in $\mathcal{M}$ of coslope r, we say that r is a coslope of $\mathcal{M}(P)$. If $(Y - k)$ is a factor of P for some $k \in \mathbb{R}$, we shall say that $r = 0$ is (also) a coslope of $\mathcal{M}(P)$.

DEFINITION. Let $r \in \mathbb{R}$ and $P(X,Y) := \sum a_{mn} X^m Y^n$ for any polynomial. We define the r-degree of P to be the number $\partial_r P := \operatorname{Max}\{m + rn \mid a_{mn} \neq 0\}$. We set

$${}^r P(X,Y) = \sum_{m+rn=\partial_r P} a_{mn} X^m Y^n.$$

Remarks. As we already pointed out, for any smooth function f at (x_0, y_0), the polynomial ${}_r f$ is *r-homogeneous of r-degree=μ* $:= \mu_r(f; x_0, y_0)$, and, if $r \neq 0$, its Taylor set is contained in the segment σ of $\mathcal{N}(f; x_0, y_0)$ with coslope r if any and then $\mathcal{N}({}_r f; x_0, y_0) = \sigma$, or is just equal to one point. Thus $\mathcal{N}({}_r f; x_0, y_0) = \mathcal{M}({}_r f)$, ${}^r({}_r f) = {}_r f = {}_r({}_r f)$ and $\partial_r({}_r f) = \mu_r(f\,; x_0, y_0)$.

By construction of $\mathcal{N}({}_r f; x_0, y_0)$, any of its coslopes r are nonnegative; this was done intentionally, for the sake of simplicity, choosing to define $\mathcal{E}$ as the convex hull of a union of quadrants. Indeed, a curve of type (k,r) at (x_0, y_0) with $r < 0$ would tend to infinity when x goes to x_0; the problem would no longer be local so we would need some rigidity on f, such as "f is a polynomial in y^α" (this is beyond the purpose of this paper); nevertheless, in §3 we give an example on singular deformation to show how curves of type (k,r) with $r < 0$ arise.

As we consider here a river solution of *polynomial* differential equations, it is no longer necessary to exclude the case $r < 0$: this is why the upper Newton polygon was introduced as the convex hull of horizontal half-lines instead of quadrants as in the previous case. So $\mathcal{M}(P)$ may have some negative r as coslope.

There is a result [11], [4] in which (a) and (b) are the analogs, for rivers, of Proposition 1.2 for the branches of the slow curve at a critical point; condition (c) is related to the behaviour of the other solutions with respect to the river: for X unlimited (that is, for $x := \varepsilon X \not\simeq 0$, where $\varepsilon \simeq 0$), the river behaves as a slow solution of a (usually other) slow-fast differential equation. As rivers are concerned with the behaviour of the equation at infinity, it is the *upper* Newton polygon that is of interest here. Proposition 2.1, Theorem 2.2, and finally the matching principle 3.1 will make precise the relation between growth type of a branch at a critical point and rivers of the related local model under the regularizing blowup.

PROPOSITION 1.4. *If* (2) *has a solution of type* (k, r) *at* $X = \pm\infty$, *then* (a) r *is a coslope of the upper Newton polygon* $\mathcal{M}(P)$; (b) ${}^rP(\pm 1, k) = 0$. *Moreover, this solution is a river at* $X = \pm\infty$ *if and only if* (c) $c(r) := 1 - r + \partial_r P > 0$.

Conversly, if beyond properties (a), (b), and (c) above, one has

$$ {}^rP'_Y(1, k) \neq 0, $$

then the *rivers-existence theorem* [11] implies that (2) has indeed a river of type (k, r).

One of the interests of the river solutions lies in the fact that they admit, as most special functions, a (diverging) asymptotic expansion of Gevrey type [7], and that they are resurgent [13], [6] and, in particular, summable in the sense of the summation of diverging series [17]. In practice, in the "good cases," i.e., if ${}^rP'_Y(\pm 1, k) \neq 0$ and for $r = p/q$ with p and $q > 0$ integers, any river has an asymptotic expansion $kx^r \sum_{n\geq 0} a_n x^{-n/q}$ for which it is easy to compute as many terms as desirable, with help, for example, from programs such as *Maple* or *Mathematica*. The fact that the expansion is of Gevrey type, that is, (a_n) grows no faster as $n\,!$, implies among other things [19] that the error committed when truncating the sum is of order equal to the first "neglected" term. So one may compute approximations of the rivers of order of the smallest term $a_n x^{-n/q}$ ("summation up to the smallest term"), or excellent approximation with few terms, as for the diverging expansions of special functions. The fact that the expansion is resurgent is related to its "transasymptotic" expansion (exponential corrections). So rivers lend themselves nicely to numerical computations.

2. Regularizing microscopes and local models.

Examples and definition. Let us consider the following example of slow-fast differential equation (Fig. 3):

$$ \varepsilon dy/dx = (y - ax)(y - bx)(y - cx) + p(x, y), \quad \text{with } abc \neq 0 \tag{3} $$

with $a < b < c$ three standard real numbers, and p a standard $\mathcal{C}^\infty$ function with $\mathcal{T}_3(p) \equiv 0$, i.e., zero Taylor polynomial of degree 3. The slow curve is the union of three smooth curves passing through the origin, and tangent to the three straight lines $y = ax$, $y = bx$, and $y = cx$, respectively, that motivate the name, *Union-Jack* equation, that we give to it; $(0, 0)$ is a more degenerate critical point than in the case of a Riccati equation. Let us perform the following change of variable:

$$ \alpha X = x, \quad \alpha Y = y, \quad \text{with } \alpha = \varepsilon^{1/3}. \tag{4} $$

Since $\varepsilon \simeq 0$, this operates as a microscope on the phase-space, and the image is a blowup of this phase space. The behaviour of the solutions for (X, Y) limited corresponds to the behaviour of solutions of (3) in the α-galaxy of $(0, 0)$. Equation (3) becomes

$$ dY/dX = (Y - aX)(Y - bX)(Y - cX) + \varepsilon^{-1} p(\alpha X, \alpha Y). \tag{5} $$

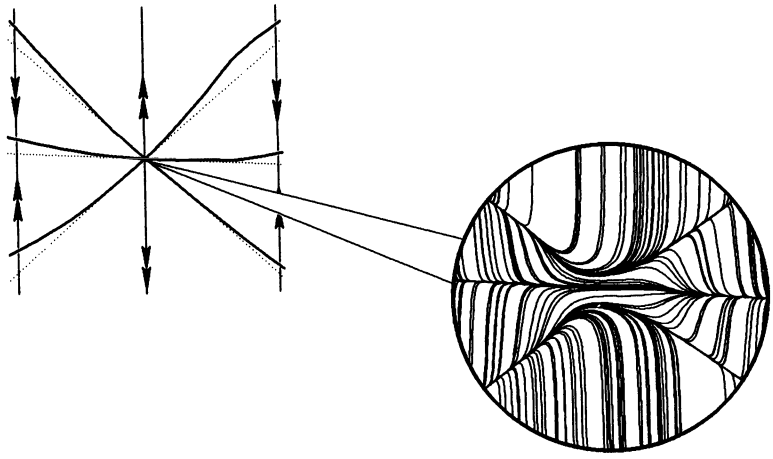

FIG. 3. *Slow-curve of a Union-Jack equation* 3 *and its image under a regularizing blowup.*

Since, by assumption, the Taylor polynomial of degree 3 of p is zero, we see that the term $\varepsilon^{-1}p(\alpha X, \alpha Y)$ is infinitesimal for (X, Y) limited. In other words, the blow up (4) made it possible, in the vicinity (i.e., infinitesimal) of the critical point, to convert the singular perturbed equation (3) into a regular one. The shadow of the solutions of (5) are solutions of the standard differential equation

$$dY/dX = (Y - aX)(Y - bX)(Y - cX). \tag{6}$$

And this is now a polynomial differential equation. An easy study of its rivers shows that this equation has three rivers at $X = +\infty$, and as many at $X = -\infty$, all being asymptotic to kX^r for some $k = a, b, c$, and $r = 1$. Theorem 3.1 will show that any slow solution following $\{y = bx\}$ for $x < 0$ (attracting solution), or $\{y = ax\}$ or $\{y = cx\}$ for $x > 0$ (repelling solution), is infinitely close to the corresponding river at the scale of (X, Y).

In this study, we want to elucidate a double "miracle": how to associate with any critical point of a large class such a desingularizing blowup, and how to approximate the slow solutions in the very vicinity of the critical point by a river of some standard, polynomial, differential equation. As an example of possible application of that method, we shall show how to deduce the existence of *canards* in a one-parameter family of Union-Jack equations.

DEFINITION. Let $\varphi(x) \sim y_0 + k(x - x_0)^r$ be a positive (respectively, negative) branch of the slow curve $\{f_0 = 0\}$ of (1) in the neighbourhood of (x_0, y_0). We call this the *regularizing microscope* of (1) in the neighbourhood of (x_0, y_0) with respect to the branch φ any change of variable $x = x_0 + \alpha X$, $y = y_0 + \beta Y$, with $\alpha > 0$, $\alpha \simeq 0$ and any $\beta > 0$, that converts that equation into $dY/dX = F(X, Y)$, with F of class S^0, ${}^oF \neq 0$, such that the standard equation $dY/dX = {}^oF(X, Y)$ admits a solution asymptotic to kX^r at $X = +\infty$ (respectively, $X = -\infty$). Equation $dY/dX = F(X, Y)$ will be called a *regularizing blowup* of (1) (by the considered regularizing microscope).

Remark. For small enough $\alpha = \beta$ it is always possible to get an infinitesimal F, that is, a regular perturbation of the trivial equation $dY/dX = 0$. This way to "regularize" the singular perturbation is of course of low interest: it is just a way to express the classical theorem of local straightening of locally Lipschitz differential equations' solutions. This is why we ask for ${}^oF \neq 0$; as we shall see, this needs a more

subtle choice of α and β, neither too large nor too small.

2.1. Case $f = f_0$: the simple equation. We first consider the case of the *simple* equation

$$\varepsilon dy/dx = f_0(x,y) \quad (\varepsilon > 0 \text{ infinitesimal}), \tag{7}$$

i.e., the case where f is a standard function. It is easy to see that the microscope

$$x = x_0 + \alpha X, \qquad y = y_0 + \alpha^r Y, \tag{8}$$

centered at a standard point (x_0, y_0) of the slow curve, yields the following blowup of (7):

$$dY/dX = (\alpha^{1-r}/\varepsilon) f(x_0 + \alpha X, y_0 + \alpha^r Y) = (\alpha^{1-r+\mu}/\varepsilon)\,({}_r f_0(X,Y) + \delta)\,,$$

with $\mu = \mu_r(f_0\,; x_0, y_0)$ and $\delta \simeq 0$ for any limited (X,Y). In order to get a regularizing microscope, one has to consider those choices of α such that $\alpha^{1-r+\mu}/\varepsilon$ is appreciable, for example, equal to 1, which means that $\alpha = \varepsilon^{1/(1-r+\mu)}$. The crucial point of this study consists in observing that for some convenient choices of r the shadow of the near-standard equation associated in that way is a *polynomial equation exhibiting rivers.*

PROPOSITION 2.1 (case of the simple equation). *Assume f is standard (i.e., $f = f_0$) and that $(0,0)$ belongs to the slow curve $\{f_0 = 0\}$. Let $r \geq 0$ be any coslope of the lower Newton polygon $\mathcal{N}(f_0)$, $\mu = \mu_r(f_0)$, and k be any root of (the algebraic) equation ${}_r(f_0)(\pm 1, k) = 0$. Let $s = 1/(1-r+\mu)$. In that case $s > 0$, $\alpha := \varepsilon^s$ is infinitesimal, the microscope*

$$x = \varepsilon^s X, \qquad y = \varepsilon^{sr} Y \tag{9}$$

is regularizing for (7), and the resulting blowup is infinitely close to the polynomial equation

$$dY/dX = {}_r f_0(X,Y). \tag{10}$$

If $({}_r f_0)'_Y(\pm 1, k) \neq 0$, this equation has a river of type kX^r at $X = \pm\infty$.

Proof. One has $1/(1-r+\mu) > 0$: let $(m,n) \in \mathcal{N}(f_0)$ be the point of the segment σ of the lower Newton polygon of f_0 of coslope r that has the largest ordinate n; one has $n \geq 1$ and thus

$$1 - r + \mu = 1 - r + \mu_r(f_0) = 1 - r + m + rn = (1+m) + r(n-1) \geq 1.$$

Thus $1 - r + \mu$ is positive and is standard, whence $\alpha := \varepsilon^{1/(1-r+\mu)} \simeq 0$.

The microscope is regularizing: Lemma 1.1 implies that

$$f(x,y) = \alpha^{\mu}({}_r f(X,Y) + \delta),$$

with $\delta \simeq 0$ for all limited (X,Y), whence

$$dY/dX = \alpha^{1-r}\alpha^{\mu}\varepsilon^{-1}\,({}_r f_0(X,Y) + \delta) = {}_r f_0(X,Y) + \delta =: F(X,Y),$$

and ${}^{\circ}F = {}_r f_0$. The *short-shadow lemma** [9] implies that the shadows of the solutions at this scale really are solutions of (10).

Equation $dY/dX = {}^oF(X,Y)$ does have rivers: the polynomial ${}_rf_0$ is r-homogeneous (of r-degree $\mu := \mu_r(f_0)$), and its *upper* Newton polygon $\mathcal{M}({}_rf_0)$ is just equal to the segment σ. Since $({}_rf_0)'_Y(\pm 1, k) \neq 0$, the *rivers-existence theorem* [11] implies the existence of one river of type kX^r at $X = \pm\infty$. □

Examples. Case of a regular point of the slow curve. Assume $f = f_0$, i.e., f is standard, and that $(0,0)$ is a regular point of the slow curve of (1), that is, $f_0(0,0) = 0$ and $f_{0x}'f_{0y}'(0,0) \neq 0$. The implicit-function theorem implies that the slow curve $\{f_0 = 0\}$ is, in the neighbourhood of $(0,0)$, a standard smooth curve tangent to the straight line $\{y = kx\}$, with $k = -A/B$, where $A := f_{0x}'(0,0)$ and $B := f_{0y}'(0,0)$. So, it has two branches (one for $x \geq 0$ and one for $x \leq 0$), of type $(k,1)$.

The microscope $x = \varepsilon X$, $y = \varepsilon Y$ is regularizing and turns (1) into a near-standard equation, the shadows of the trajectories of which being solutions of

$$\frac{dY}{dX} = AX + BY.$$

This equation has the explicit solution $\overline{Y}(X) := -XA/B - A/B^2$, which is a river, both at $X = +\infty$ and at $X = -\infty$, of the same type as the two branches of the slow curve.

Case of a fold point. In [16], Mishchenko and Rosov study the behaviour of the solutions of (1) near a fold point at $(0,0)$, that is, in the case $f_{0x}'(0,0) \neq 0$ and $f_{0y}'(0,0) = 0$, but $f_{0y^2}''(0,0) \neq 0$: the slow curve looks like a horizontal parabola: it has two branches (assumed to be negative) of type $(k, \frac{1}{2})$.

Let $s_0 = \frac{2}{3}$; the microscope $x = \varepsilon^{s_0}X$, $y = \varepsilon^{s_0/2}Y$ is regularizing at such a fold-point. It turns (1) into a near-standard equation, the shadows of the trajectories being solutions of

$$\frac{dY}{dX} = AX + BY^2$$

with $A = f_{0x}'(0,0)$ and $B = \frac{1}{2}f_{0y^2}''(0,0)$. It is a Liouville equation that exhibits [11] two families of rivers (Fig. 4), one containing just one isolated river (asymptotic to $y = +\sqrt{-x}$ on the figure, and that the authors call the "dividing solution," which they are able, in that case, to express in terms of Bessel functions), and the other containing an infinity of rivers, all asymptotic to each other (and to $-\sqrt{-x}$ on the figure). The types of the two families of rivers are equal to those of the two branches of slow curve.

2.2. Regular deformations. We now come back to the general case, where $f = f_0 + \varepsilon f_1 + \cdots$ that we shall consider in different ways, according to whether the microscope (9) used to regularize the simple (or *simplified*) equation (7), obtained by replacing f by f_0, is still regularizing for the *complete* equation (1) or not.

Let us first consider the example of the following equation:

$$\varepsilon dy/dx = \pm(y-x)(y-x^2) + \varepsilon(a+bx), \quad \text{with } a,b \in \mathbb{R}. \tag{11}$$

The slow curve, with equation $(y-x)(y-x^2) = 0$, exhibits some branches at $(0,0)$ of type x^r with $r = 1$ and $r = 2$. Let's consider successively the cases $r = 1$ and $r = 2$.

For $r = 1$, considering the simplified equation leads to selecting $s = \frac{1}{2}$, the microscope $x = \varepsilon^{1/2}X$, $y = \varepsilon^{1/2}Y$ yields the blowup

$$dY/dX = \pm(Y-X)(Y-\varepsilon^{1/2}X^2) + a + \varepsilon^{1/2}bX, \tag{12}$$

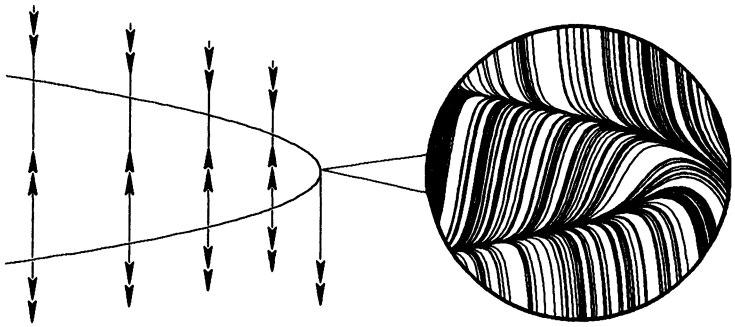

FIG. 4. *Slow-fast equation with slow curve exhibiting a fold point, and its image under a regularizing microscope. This last equation has a unique river asymptotic to* $\sqrt{-x}$, *and an infinity of rivers all asymptotic to* $-\sqrt{-x}$, *and actually with the same asymptotic expansion: they are exponentially close to each other.*

which, for limited a and b, is infinitely close to a standard equation (i.e., is a regular perturbation), namely, $dY/dX = \pm Y(Y - X) + {}^{\circ}a$.

For $r = 2$, considering the simplified equation suggests once more letting $s = \frac{1}{2}$; the microscope $x = \varepsilon^{1/2}X$, $y = \varepsilon Y$ transforms (11) into

$$dY/dX = \mp X(Y - X^2) \pm \varepsilon^{1/2}Y(Y - X^2) + a\varepsilon^{-1/2} + bX. \tag{13}$$

We notice here that if a is standard nonzero, the term $a\varepsilon^{-1/2}$ is unlimited: the microscope that is regularizing for the simplified equation associated with (11) is no longer regularizing for the complete equation (11).

In terms of the following definition, the "deformation term" $\varepsilon(a + bx)$ is a *regular deformation* for the growth-type x^1, and a *singular deformation* for the growth-type x^2 (if ${}^{\circ}a \neq 0$).

DEFINITION. We say that (1) is a *regular deformation at the point* (x_0, y_0) *of the simple equation* (7) *for the growth type* x^r, if, for $s_0 = 1/(1 - r + \mu_r(f_0; x_0, y_0))$, the microscope

$$x = x_0 + \varepsilon^{s_0}X, \qquad y = y_0 + \varepsilon^{s_0 r}Y \tag{14}$$

is regularizing for (1). If not, we call it a *singular deformation at the point* (x_0, y_0) *of* (7) *for the growth type* x^r.

The purpose of the following theorem is first to show that only an explicit finite number of terms of the expansion of $f = \varepsilon f_1 + \varepsilon^2 f_2 + \cdots$ may introduce a singular deformation of the simple equation for a given branch-growth type. Then it establishes a relation existing between the local model of the simple equation and that of the complete equation, in case of regular deformation. This will make it possible to show (Corollary 2.3) that these two models have essentially the "same kind" of rivers.

THEOREM 2.2. *Let* $s_0 = 1/(1 - r + \mu_r(f_0))$. *A necessary and sufficient condition for* (1) *to be a regular deformation at the point* $(0, 0)$ *for the simplified equation for the growth type* x^r *is that, for all* p *such that* $1 \leq p < 1 + s_0(r - 1)$, *the following inequality holds:*

$$p - 1 + s_0\big(1 - r + \mu_r(f_p)\big) \geq 0. \tag{15}$$

If so, the blowup $dY/dX = F(X, Y)$ *of equation* (1) *by the microscope* (14) *is infinitely close to some standard polynomial differential equation*

$$dY/dX = P(X, Y), \quad \text{with } {}^{r}P(X, Y) = {}_{r}f_0,$$

called the local model *of* (1) *at the point* $(x_0, y_0) = (0,0)$ *for branches of growth type* $|x - x_0|^r$.

Proof. Let $p^* > 1 + s_0(r-1)$ be some fixed standard integer and denote $\mu(f_p)$ just by μ_p. One has

$$f(x,y) = f_0(x,y) + \varepsilon f_1(x,y) + \cdots + \varepsilon^{p^*}\left(f_{p^*}(x,y) + \phi\right),$$

for all $(x,y) \simeq (0,0)$; thus, for all limited (X,Y)

$$\begin{aligned} F(X,Y) &= \varepsilon^{-1+s_0(1-r)} f(\varepsilon^{s_0}X, \varepsilon^{rs_0}X) \\ &= \sum_{p<p^*} \varepsilon^{-1+s_0(1-r)+p+s_0\mu_p}\left({}_r f_p(X,Y) + \phi\right) \\ &\quad + \varepsilon^{p^*-1+s_0(1-r)}\left(f_{p^*}(0,0) + \phi\right) \\ &\simeq \sum_{p<p^*} \varepsilon^{-1+s_0(1-r)+p+s_0\mu_p}\left({}_r f_p(X,Y) + \phi\right). \end{aligned}$$

So, the deformation is regular if and only if all the exponents of this later sum are positive or zero, that is, if (15) holds for all $p < 1 + s_0(r-1)$. If so, let $\Pi_* := \{p < p^* \mid p + s_0\mu_p = 1 + s_0(r-1)\}$; so, for any limited (X,Y),

$$F(X,Y) \simeq \sum_{p\in\Pi_*} {}_r f_p(X,Y) =: P(X,Y).$$

Since this defines a standard polynomial P, one finally has ${}^oF = P$.

Still in that case, let $p \geq 1$, $p \leq 1 + s_0(r-1)$, and assume that f_p brings a noninfinitesimal contribution to $F(X,Y)$, that is, assume $-1 + s_0(1-r) + p + s_0\mu_r(f_p) = 0$. By definition of s_0, we thus have $p + s_0\mu_r(f_p) = 0 + s_0\mu_r(f_0)$, whence $\mu_r(f_0) - \mu_r(f_p) = p/s_0$, which is strictly positive, since $p \geq 1$ and $s_0 > 0$ as we saw in Proposition 2.1. Thus $\mu_r(f_0) > \mu_r(f_p)$, and ${}^rP = {}^r({}^oF) = {}_r f_0$. □

Example. If $r \leq 1$, the condition $1 \leq p < 1 + s_0(r-1)$ is never satisfied, and thus any deformation is automatically satisfied for the growth type x^r: at a regular point or at a fold point, or at a Morse point ($f(0,0) = 0$, $\mathrm{Jac}\,(f)(0,0) = (0,0)$, but $\mathrm{hess}\,(f)(0,0) \neq 0$) any deformation is regular for all growth types of the branches that reach such a point. This explains why all the existing studies of canards never came across the problem of singular deformations.

COROLLARY 2.3 (regular deformations). *Assume* $(x_0, y_0) = (0,0)$. *Let* $r \geq 0$ *be a coslope of the lower Newton polygon* $\mathcal{N}(f_0)$, *and* k_0 *any root of the algebraic equation* ${}_r f_0(\pm 1, k)$. *Let* $s_0 = 1/(1 - r + \mu_r(f_0))$. *If* (1) *is, at the point* $(0,0)$, *a regular deformation of the simplified equation* (7) *for the growth type* x^r, *the microscope* (14) $x = \varepsilon^{s_0}X$, $y = \varepsilon^{rs_0}Y$ *is regularizing for* (1), *and the image of equation* (1) *by this microscope* (14) *is infinitely close to the standard polynomial equation*

$$dY/dX = P(X,Y), \tag{16}$$

with ${}^rP(X,Y) = {}_r f_0$. *If* $({}_r f_0)'_Y(\pm 1, k_0) \neq 0$, *this equation has a river of type* k_0X^r *at* $X = \pm\infty$.

Proof. The previous theorem implies that ${}^rP = {}_r f_0$, and the existence of rivers of type (k,r) for $dY/dX = P(X,Y)$ depends only on that polynomial ${}^rP$: so the corollary follows immediately from Theorem 2.2. □

We shall come back to the problem of singular deformations at the end of the study of preresonant solutions.

3. Preresonant trajectories.

3.1. Entrance in the halo of a critical point. The two previous sections were dedicated to the geometric study of (1), that is, in some sense, to the formal solutions of that equation. We can now come to the study of the behaviour of the (slow) *solutions* of that equation, when x becomes infinitely close to a critical point. Actually, to know that the solution is slow for x not infinitely close to the critical point does not always give strong information about its behaviour when x becomes infinitely close to that point. Indeed, consider, for example, the equation $\varepsilon dy/dx = -2xy$, which has a critical point at $(0,0)$, and whose solutions are given, as a function of the initial condition $y_- = \overline{y}(x_-)$, by

$$\overline{y}(x) = y_- e^{x_-^2/\varepsilon} e^{-x^2/\varepsilon}.$$

The hypothesis that the solution is equal to an infinitesimal $y_- = \overline{y}(x_-)$ at some "initial condition" $x_- \not\simeq 0$ does not suffice to give some control on $\overline{y}$ for $x \simeq 0$: for example, for $x_- = -1$ and $x = 0$, y_- may be infinitesimal and $\overline{y}(0) = y_- e^{1/\varepsilon}$ may take, according to the value of y_-, any infinitesimal value, and $\overline{y}(0)$ may even be appreciable or illimited, for some convenient choice of $y_- \simeq 0$. This comes, essentially, from the fact that the slow curve $y = 0$ is repelling for $x < 0$ (or attracting for $x > 0$). In the general case, we can get a good precision on the behaviour of slow solutions in the halo of the critical point (x_0, y_0) and more precisely under a regularizing microscope, only for solutions that follow an attracting curve for $x < x_0$, or a repelling one for $x > x_0$. Such a solution, defined and satisfying that condition on *both* sides of x_0 is a *canard* [10], also called [18] "resonant in the sense of N. Kopell." This is why we shall call any solution satisfying that condition on *one* side (at least) of the critical point *pre*resonant.

DEFINITION. Let $\varphi : \mathcal{D}(\varphi) \longrightarrow \mathbb{R}$ be a (k,r)-branch at the point (x_0, y_0) of the slow-curve $f_0(x,y) = 0$ of (1). We say that φ is a *preresonant branch* at (x_0, y_0) if and only if φ is standard, $(f_0)'_y(x_0, y_0) = 0$, and $(f_0)'_y(x, \varphi(x))$ is nonzero and of the same sign as $(x - x_0)$ for all $x \in \mathcal{D}(\varphi)$ not equal to x_0 (i.e., if and only if (x_0, y_0) is critical, and for $x \neq x_0$, $(x, \varphi(x))$ is attracting if $x < x_0$, or repelling if $x > x_0$).

Let φ be a (k,r)-branch at (x_0, y_0) of the slow curve of (1) and $\overline{y}$ a solution of (1). We say that $\overline{y}$ is a *preresonant solution at* (x_0, y_0) *attached to* φ if and only if φ is preresonant, and for all $x \not\simeq x_0$ in $\mathcal{D}(\varphi)$, $\overline{y}(x)$ is defined and $\overline{y}(x) \simeq \varphi(x)$.

Examples. For a Union-Jack equation (3) (with $a < b < c$) (Fig. 3), the slow-curve at $(0,0)$ has one preresonant branch defined for $x < 0$ which is tangent to $y = bx$, and two preresonant branches defined for $x > 0$, tangent to $y = ax$ and $y = cx$, respectively.

At a fold point (Fig. 4), one of the branches of the slow curve is preresonant and the other is not.

To each preresonant branch there corresponds, on the regularizing blowup, an isolated river that is a shadow of the image by the microscope of any preresonant solution infinitely close to that preresonant branch. Theorem 3.1 shows that this is a general fact.

We shall consider in this main theorem the case of a preresonant branch defined for $x < x_0$, with $x_0 = 0$; one has of course an analogous result for any standard x_0, and also for any preresonant branch defined for $x > x_0$.

THEOREM 3.1 (matching principle). *Let* $k \neq 0$, $r > 0$, $x_- < 0$ *be standard, and* $\varphi : [x_-, 0] \longrightarrow \mathbb{R}$ *be a preresonant* (k,r)*-branch at* $(0,0)$ *of the slow curve of* (1); *Let*

$s_0 := 1/(1 - r + \mu_r(f_0))$. *Assume that* $({}_r f_0)'_y(-1, k) \neq 0$, *and that* (1) *is a regular deformation for the growth type of* φ *of the simplified equation*

$$\varepsilon \frac{dy}{dx} = f_0(x, y).$$

Let $P(X, Y)$ *be the polynomial such that the shadow of the blowup of* (1) *by the regularizing microscope*

$$x = \varepsilon^{s_0} X, \qquad y = \varepsilon^{r s_0} Y \tag{17}$$

is

$$\frac{dY}{dX} = P(X, Y). \tag{18}$$

Let $\overline{y}$ *be any maximal solution of* (1) *such that* $\overline{y}(x_-) \simeq \varphi(x_-)$. *Then*

(1) *There exists some limited* $X_+ \leq 0$ *such that* $\overline{y}$ *is defined and preresonant, attached to* φ *on* $[x_-, x_+]$, *with* $x_+ := \varepsilon^{s_0} X_+ \simeq 0$.

(2) *For all* $x \in [x_-, x_+]$ *such that* $x \simeq 0$, *if* x/ε^{s_0} *is unlimited, then* $\overline{y}(x) = k|x|^r(1 + \phi)$.

(3) *Equation* (18) *has a unique river* $\hat{Y} : (-\infty, a) \longrightarrow \mathbb{R}$ *of type* (k, r) *at* $X = -\infty$; *for any* X *near-standard in* $(-\infty, a)$ *the image* $\overline{Y}(X)$ *of* $\overline{y}(x)$ *by the microscope* (17) *is infinitely close to* $\hat{Y}(X)$. *So for* $x := \varepsilon^{s_0} X$, $\overline{y}(x)$ *is defined and satisfies*

$$\varepsilon^{-r s_0} \overline{y}(\varepsilon^{s_0} X) \simeq \hat{Y}(X).$$

Proof. The proof uses a zoom technique introduced by Callot for the Riccati–Hermite equation [5], and presented in a more general case by Benoit in [2]. It consists of a three-step study, the middle step connecting the scales of the first and the last step using a typically nonstandard technique.

Behaviour of $\overline{y}$ *for* $x \ll 0$ *and for* $x \leq x_0 \simeq 0$. As the branch $y = \varphi(x)$ is negative by assumption and thus attracting, as it is preresonant, the solution $\overline{y}$ is defined and satisfies $\overline{y}(x) \simeq \varphi(x)$ for all x such that $x_- \leq x \ll 0$ and thus, by permanence (Fehrele's principle*), there exists $x_0 \simeq 0$, $x_0 \leq 0$, such that this stays true for all $x \in [x_-, x_0]$.

As φ is asymptotic (tangent) to $k|x|^r$ at $x = 0$ with $k \neq 0$, there exists some standard $x'_- \in [x_-, 0)$ such that $\varphi(x) \neq 0$ for all $x'_- \in [x_-, 0)$. As the result is local, without loss of generality, we may assume that $x_- = x'_-$.

As φ is standard, $\varphi(x)$ is appreciable on $[x_-, 0)$ for all $x \not\simeq 0$, and thus $\overline{y}(x) = \varphi(x) + \phi = \varphi(x)(1 + \phi)$ if $x \not\simeq 0$. By Fehrele's principle, there exists some infinitesimal $x'_0 \leq x_0$ such that this stays true for all $x \leq x'_0$. Possibly choosing a smaller infinitesimal x'_0, we may also assume that x'_0/ε^{s_0} is unlimited (negative). Without loss of generality we now change x_0 into $x_0 := x'_0$.

Behaviour for $x \simeq 0$ *outside the* ε^{s_0}*-galaxy of* 0. We now assume that $x_0 \leq x < 0$, $|x|$ large enough for x/ε^{s_0} to be unlimited. We both have to show that $\overline{y}(x)$ is defined and that $\overline{y}(x) = k|x|^r(1 + \phi)$.

Let $\kappa(x) := \overline{y}(x)/|x|^r$, and choose $k_- < k_+$ standard with the same sign such that $k_- < k < k_+$, and such that $[k_-, k_+]$ contains no other root than k of the algebraic equation ${}_r f_0(-1, K) = 0$. We shall show that it is absurd to assume that $\kappa(x)$ leaves (k_-, k_+) on the external domain under consideration here. This will imply, on one hand, that $\overline{y}(x)$ stays defined, as the compact $\{(x, y) | x_0 \leq x \leq 0, k_-|x|^r \leq \overline{y}(x) \leq$

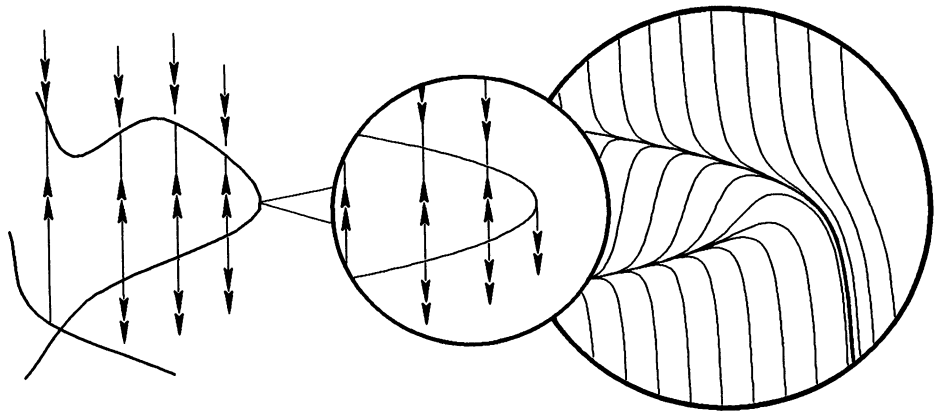

FIG. 5. *The equation* (1), *its image by the microscope* (19), *and its image by the regularizing microscope* (21).

$k_+|x|^r\}(\subseteq \text{hal}\,(0,0))$ is contained in the domain of (1). On the other hand, this implies also that $\kappa(x) \simeq k$ as k_- and k_+ are standard and can be chosen arbitrarily close to k, and so assertion (3.1) will be shown.

So assume that $\kappa(x)$ leaves (k_-, k_+) at $x_1 \geq x_0$, with x_1/ε^{s_0} unlimited, that is, $k_-|x|^r < \overline{y}(x) < k_+|x|^r$ for all $x \in [x_0, x_1)$ and $\overline{y}(x_1) = k_\pm|x|^r$. Let $s_1(< s_0)$ be such that $x_1/\varepsilon^{s_1} = -1$, and consider the microscope

$$x = \varepsilon^{s_1}\xi, \qquad y = \varepsilon^{rs_1}\eta. \tag{19}$$

Let $\overline{\eta}$ be the image of $\overline{y}$ by this microscope; $\overline{\eta}(\xi) = \varepsilon^{rs_1}\overline{y}(\xi/\varepsilon^{s_1})$ and thus $k_-|\xi|^r < \overline{\eta}(\xi) < k_+|\xi|^r$ for all $\xi \leq -1$ limited, and $\overline{\eta}(-1) = k_\pm$.

This is absurd; indeed, the image of (1) by the microscope (19) is a slow-fast differential equation

$$\varepsilon^d \frac{d\eta}{d\xi} = g(\xi, \eta) \tag{20}$$

with $d := 1 - s_1(1 - r + \mu_r(f_0)) > 0$ and $g(\xi, \eta) := \varepsilon^{-s_1\mu_r(f_0)} f(\varepsilon^{s_1}\xi, \varepsilon^{rs_1}\eta) \simeq {}_r f_0(\xi, \eta)$, the slow curve of which, for $\xi < 0$, is the union of the branches $y = K|x|^r$ for the various roots K of ${}_r f_0(-1, K) = 0$. The differential equation is thus fast at the point $(-1, \overline{\eta}(-1)) = (-1, k_\pm)$, and oriented towards the branch $k|x|^r$, as by asumption $({}_r f_0)'_y(-1, k) < 0$, which contradicts that $(\xi, \overline{\eta}(\xi))$ is contained in the crescent $\eta \in [k_-\xi^r, k_+\xi^r]$ for $\xi \leq -1$.

Behaviour for x in the ε^{s_0}-galaxy of 0. We just showed that $\overline{y}(x)$ is defined and satifies the inequalities $k_-|x|^r < \overline{y}(x) < k_+|x|^r$ for all $x \in [x_0, 0]$ such that x/ε^{s_0} is unlimited. Thus by Cauchy's permanence principle* there exists some $x_+ < 0$ such that $X_+ := x_+/\varepsilon^{s_0}$ is limited, and such that this internal property stays true for all $x \in [x_0, x_+]$, which implies, in particular, assertion (3.1).

In other words, the image $\overline{Y}$ of the solution $\overline{y}$ by the microscope

$$x = \varepsilon^{s_0}X, \qquad y = \varepsilon^{rs_0}Y \tag{21}$$

keeps contained, for $X \leq X_+$ limited, in the region $k_-|X|^r \leq \overline{Y}(X) \leq k_+|X|^r$ (Fig. 6) as, for $X \leq X_+$ limited, $x := \varepsilon^{s_0}X \geq x_0$; $\overline{Y}(X)$ is thus limited for all limited

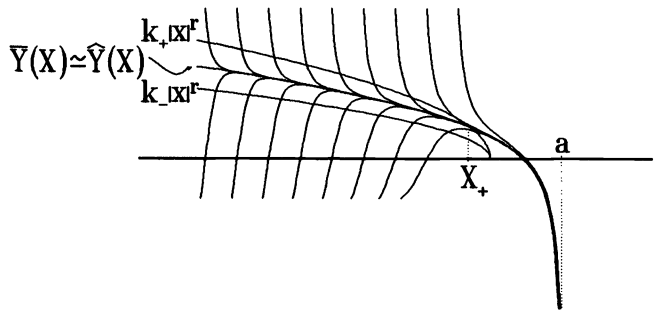

FIG. 6. *The unique river of* (22) *which is contained in the crescent-shaped region* $X < X_+$, $k_-|X|^r \le Y \le k_+|X|^r$ *for all (limited)* X *sufficently negative.*

$X \le X_+$. By the short-shadow lemma, $\overline{Y}$ has thus a shadow $\hat{Y}$, also contained in the close, standard region $k_-|X|^r \le \hat{Y}(x) \le k_+|X|^r$, which is necessarily a solution of the shadow (22) of (1) by the regularizing microscope (21):

$$\frac{dY}{dX} = P(X, Y). \tag{22}$$

But, by Corollary 2.3, one has ${}^rP(X, Y) = {}_rf_0$. As equation ${}^rP(-1, K)$ $(= {}_rf_0(-1, K)) = 0$ has a unique root, k, between k_- and k_+, by Proposition 1.4, $\hat{Y}$ is asymptotic to $k|X|^r$ at $X = -\infty$. As, moreover, $({}^rP)'_Y(-1, k) < 0$, by the rivers-existence theorem [11], $\hat{Y}$ is necessarily the unique river of (22), that is, of type (k, r). As $\hat{Y}$ is the shadow of $\overline{Y}$, one has $\overline{Y}(X) \simeq \hat{Y}(X)$ for all limited X. As k_- and k_+ are standard and of the same sign, $\hat{Y}(X)$ is appreciable for all limited $X \le X_+$, and thus $\overline{Y}(X) = \hat{Y}(X)(1 + \phi)$ for all limited X; hence assertion (3.1). □

Here is, as an example of application, a corollary giving the existence of canards for certain one-parameter famillies of Union-Jack equations. Such canards are not of class S^1 (i.e., the shadow of their image exhibits angles).

COROLLARY 3.2. *Consider a continuous, one-parameter* $d \in \mathbb{R}$ *family of Union-Jack equations*

$$\varepsilon \frac{dy}{dx} = (y - ax)(y - bx)(y - cx) + p(x, y, d) \tag{23}$$

with $a < b < c$ *fixed standard numbers,* p *an internal function with regular* ε*-shadow expansion,* $p(x, y) =: p_0(x, y) + \varepsilon(p_1(x, y, d) + \varepsilon\phi)$*, on some standard neighbourhood of* $\{(0, 0)\} \times [A, C]$*, with* $\mathcal{T}_3(p_0)(x, y) \equiv 0$*,* p_1 *standard continuous such that* $a = p_1(0, 0, A)$*, and* $c = p_1(0, 0, C)$.

Then there exist values $d_a \in (A, B)$ *(respectively,* $d_c \in (B, C)$*) of the parameter* d *for which* (23) *has a canard, that is, more precisely, a slow solution, defined on the halo of* 0 *(and further), following, for* $x < 0$*, the attracting branch of a slow-curve tangent to* $y = bx$*, and following, for* $x > 0$*, the repelling branch tangent to* $y = ax$ *(respectively,* $y = cx$*).*

Proof. As the Taylor polynomial of p_0 of degree 3, $\mathcal{T}_3(p_0)$ is zero, the slow curve of (23) has, at $(0, 0)$, three negative branches, φ_a^-, φ_b^-, φ_c^-, and three positive branches φ_a^+, φ_b^+, φ_c^+, tangent, respectively, to the three straight lines $y = ax$, $y = bx$, and $y = cx$ (Fig. 7(a)); the three preresonant branches are φ_b^-, φ_a^+, and φ_c^+. We shall show the existence of a value $d_c \in (B, C)$ and of a canard, for $d = d_c$, following φ_b^-

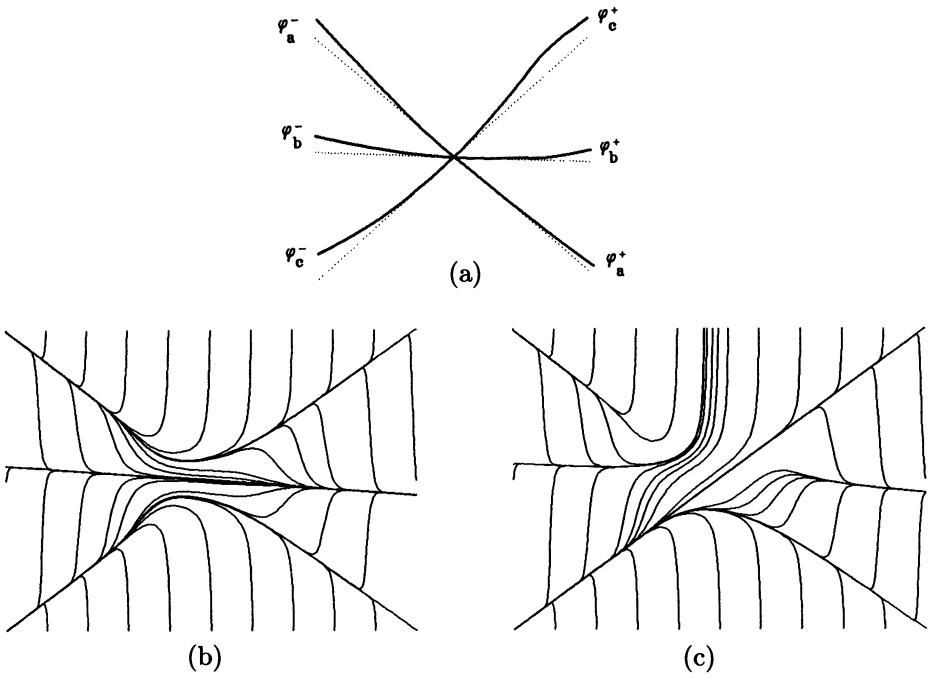

FIG. 7. (a) *the six branches, at* $(0,0)$ *of the (fixed) slow curve of the family* (23); (b) *and* (c) *are some trajectories of* (24), *image by the regularizing microscope of* (23) *for* $d = B$ *and* $d = C$.

and φ_c^+. One would proceed analogously for the existence of a canard following φ_a^+ for some $d = d_a \in (A, B)$.

Let $x_- \ll 0 \ll x_+$ be such that $x_- \in \mathcal{D}(\varphi_b^-)$ and $x_+ \in \mathcal{D}(\varphi_c^+)$. Choose $y_- \simeq \varphi_b^-(x_-)$ and $y_+ \simeq \varphi_c^+(x_+)$; so, (x_-, y_-) and (x_+, y_+) are two "initial conditions" belonging, respectively, to the halo of the two considered branches of slow curve: let $\overline{y}_-$ and $\overline{y}_+$ be the maximal solutions of (23) passing through these two initial conditions; as in (23), $\overline{y}_-$ and $\overline{y}_+$ are dependent continuously on the parameter d.

LEMMA 3.3. *Let* $dY/dX = F(X, Y, d)$ *be a continuous one-parameter* $d \in [D_-, D_+]$ *family of locally Lipschitz differential equations defined for all* $(X, Y) \in [X_-, X_+] \times \mathbb{R}$. *For each* $d \in [D_-, D_+]$, *let* $(X, d) \mapsto \hat{Y}_-$ *and* $(X, d) \mapsto \hat{Y}_+$ *be the maximal solution through* Y_- *and* Y_+ *for* $X = X_-$ *and* $X = X_+$, *respectively* ($Y_\pm$ *may be constant or may depend continuously on the parameter* d). *If there exist* X_0^- *and* X_0^+ *in* $[X_-, X_+]$ *such that* $Y_-(X_0^-, D_-) < Y_+(X_0^-, D_-)$ *and* $Y_-(X_0^+, D_+) > Y_+(X_0^+, D_+)$, *then there exists* $d_c \in [D_-, D_+]$ *such that* $\hat{Y}_-(X, d_c) = Y_+(X, d_c)$ *for all* $X \in [X_-, X_+]$.

Proof. Consider the map $\varphi : [D_-, D_+] \longrightarrow \overline{\mathbb{R}} := \mathbb{R} \cup \{-\infty, +\infty\}$ that to each value of the parameter d associates the value of $\hat{Y}_-(X_+, d)$ if this value is defined, or $\pm\infty$ if $\hat{Y}_-$ stops to be defined because it tends to $\pm\infty$ for some $X_0 < X_+$. By continuity of F and Y_- with respect to d, φ is continuous. By uniqueness $\varphi(D_-) < Y_+$ and $\varphi(D_+) > Y_+$. Thus, by continuity with respect to d of φ and Y_+, there exists d_c such that $\varphi(d_c) = Y_+$. By uniqueness, for $d = d_c$, $\hat{Y}_- = \hat{Y}_+$. □

Here is the principle of the end of the proof.

Looking at the solutions $\overline{y}_-$ and $\overline{y}_+$ on the regularizing blowup, where, by Theorem 3.1, these solutions are infinitely close to the isolated rivers $\overline{Y}_-$ and $\overline{Y}_+$, shows

that for $d = B$ and $d = C$, the solutions $\overline{y}_-$ and $\overline{y}_+$ are defined and slow until $x = 0$, that is, on $[x_-, 0]$ and $[0, x_+]$, respectively, which for $d = B$, one has $\overline{y}_-(0) < \overline{y}_+(0)$, and that for $d = C$, these values at 0 of the solutions are in the inverse order. Thus by Lemma 3.3 there exists some $d_c \in (B, C)$ such that for this value of d, $\overline{y}_- \equiv \overline{y}_+$: this solution is the desired canard. Let us check the various facts stated in this reasoning.

Consider the following regularizing microscope

$$\varepsilon^{1/3} X = x, \qquad \varepsilon^{1/3} Y = y$$

that we already used in example (11). The shadow of the corresponding blowup of (23) is

$$\frac{dY}{dX} = (Y - aX)(Y - bX)(Y - cX) + D, \quad \text{with } D = p_1(0, 0, d). \tag{24}$$

Let $\overline{Y}_\pm(X) := \varepsilon^{-1/3} \overline{y}_\pm(\varepsilon^{1/3} X)$ be the images of the solutions $\overline{y}_\pm(x)$. Theorem 3.1 implies that $\overline{Y}_-(X)$ is defined and infinitely close to the unique river $\hat{Y}_-$ asymptotic to $Y = bX$, if X is near-standard in the domain of $\hat{Y}_-$. Analogously $\overline{Y}_+(X)$ is defined and infinitely close to the unique river $\hat{Y}_+$ asymptotic to $Y = cX$ if X is near-standard in the domain of $\hat{Y}_+$.

An elementary study of the two solutions $\hat{Y}_\pm$ of (24) shows that for $D = b$ and $D = c$, these solutions are well defined on an open interval containing $(-\infty, 0]$ and $[0, +\infty)$, respectively.

For $D = b$, $\hat{Y}_-(X) \equiv bX$ is an obvious solution, and $\hat{Y}_+(X) > bX \equiv \hat{Y}_-(X)$, for X positive and large enough, thus for all $X \in \mathcal{D}\hat{Y}_+$, by uniqueness of solutions (Fig. 7(b)). Moreover, as for large values of $Y > 0$, $dY/dX > 0$, solutions of (24) "above" the obvious solution Y_- have to be defined down to $X = -\infty$. So, in particular, $\hat{Y}_+(0)$ is defined and $\hat{Y}_+(0) > \hat{Y}_-(0)$. Now, still for $D = b$, that is, $d = B$, using that $\hat{Y}_+(0)$ and $\hat{Y}_+(0)$ are standard, one has

$$\varepsilon^{-1/3} \overline{y}_-(0) = \overline{Y}_-(0) \simeq \hat{Y}_-(0) \ll \hat{Y}_+(0) \simeq \overline{Y}_+(0) = \varepsilon^{-1/3} \overline{y}_+(0),$$

and thus $\overline{y}_-(0) < \overline{y}_+(0)$.

One uses an analog way of reasoning for $d = C$ (Fig. 7(c)), that is, $D = c$, observing here that $\hat{Y}_+(X) \equiv cX$ is now an obvious solution of (24), and that $\hat{Y}_+ < \hat{Y}_-$. So, for $d = C$, $\overline{y}_-(0) > \overline{y}_+(0)$, which shows the corollary, as explained above. □

Remark. A consequence of Corollary 3.2 is that there exists, for (24) a value $D(= {}^o d)$ for which the unique river asymptotic to bX at $X = -\infty$, and the unique river asymptotic, for example, to aX at $X = +\infty$, are equal. Figure 8 shows a numerical computation of that value. We would be highly interested in an analytical method to determine this value.

3.2. Exiting a critical point's halo. In Theorem 3.1 we considered the question of the image, on a convenient regularizing blowup of any preresonant slow solution. The example considered in Corollary 3.2 can also be used to illustrate the inverse problem, which will be solved below with Theorem 3.4: to the contrary of the canard behaviour of a solution of (23), the "ordinary" behaviour of a preresonant solution that enters, say, for $x < 0$ in the scope of the regularizing microscope, is to stay infinitely close, on the blowup, to a repelling river (at $X = -\infty$). This river solution may also be (see, for example, the left-hand side of Fig. 8) a river at $X = +\infty$ but *attracting* now, so belonging to a one-parameter family of rivers, all with same asymptotic expansion at $X = +\infty$. Such a slow solution crosses the halo of the critical

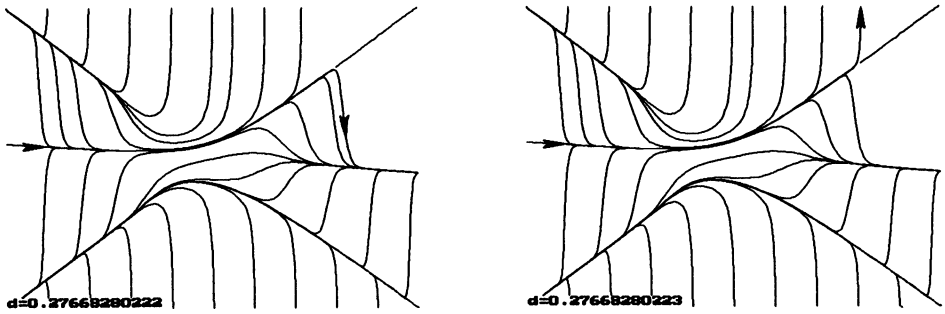

FIG. 8. *Numerical computation of the standard part of the canard value d_c for equation* (23), *in the case* $(a,b,c) = (-1,-0.1,1)$. *The behaviour at* $X = +\infty$ (*"descending" or "ascending" arrow*) *of the river at* $X = -\infty$ *of type* $(b,1)$ (*"left-entering arrow"*) *changes very quickly with the value of d, displayed in the lower left corner.*

point and then follows, for $x > 0$, an attracting branch $\varphi_+ : [0, x_+] \longrightarrow \mathbb{R}$, of type (k_+, r_+), where (k_+, r_+) is precisely the type of the considered river at $X = +\infty$.

Once more, we assume that $(x_0, y_0) = (0,0)$, but that φ is defined on $[0, x_+]$ this time, and is attracting (thus *nonpreresonant*). There is of course an analogous result for any standard (x_0, y_0), and also any repelling branch defined on some "left-interval" $[x_-, x_0]$.

THEOREM 3.4. *Let* $k \neq 0$, $r > 0$, $x_+ > 0$ *be standard numbers, and* $\varphi : [0, x_+] \longrightarrow \mathbb{R}$ *be any attracting* (k,r)*-branch at* $(0,0)$ *of the slow curve of equation* (1); *put* $s_0 := 1/(1-r+\mu_r(f_0))$. *Assume that* $({}_r f_0)'_y(-1,k) \neq 0$, *and that* (1) *is a regular deformation for the growth-type of the branch* φ *of the simplified equation*

$$\varepsilon \frac{dy}{dx} = f_0(x,y).$$

Denote by $P(X,Y)$ *the polynomial such that the shadow of the blowup of* (1) *by the regularizing microscope*

$$x = \varepsilon^{s_0} X, \qquad y = \varepsilon^{r s_0} Y \tag{25}$$

is equal to

$$\frac{dY}{dX} = P(X,Y). \tag{26}$$

Under these assumptions, (26) *has an attracting river* $\hat{Y} : (a, +\infty)$ *of type* (k,r) *at* $X = +\infty$.

Let $\overline{y}$ *be any maximal solution of* (1), *and let* $\overline{Y}(X) := \varepsilon^{-r s_0} \overline{y}(\varepsilon^{s_0} X)$ *be its image by the regularizing microscope* (25). *Let* $X_0 \gg a$ *be limited, and define* $x_0 = \varepsilon^{s_0} X_0$.

(1) *If* $\overline{Y}(X_0) \simeq \hat{Y}(X_0)$, *then for any* X *near-standard in* $]a, +\infty[$ *and for* $x := \varepsilon^{s_0} X$, $\overline{y}(x)$ *is defined and satisfies*

$$\varepsilon^{-r s_0} \overline{y}(\varepsilon^{s_0} X) \ \ (= \overline{Y}(X)) \simeq \hat{Y}(X).$$

(2) *For all* $x \in [0, x_+]$ *such that* $x \simeq 0$, *if* x/ε^{s_0} *is unlimited, then* $\overline{y}(x) = kx^r(1+\not{o})$.

(3) *For any appreciable* $x \in]0, x_+]$, $\overline{y}(x) \simeq \varphi(x)$.

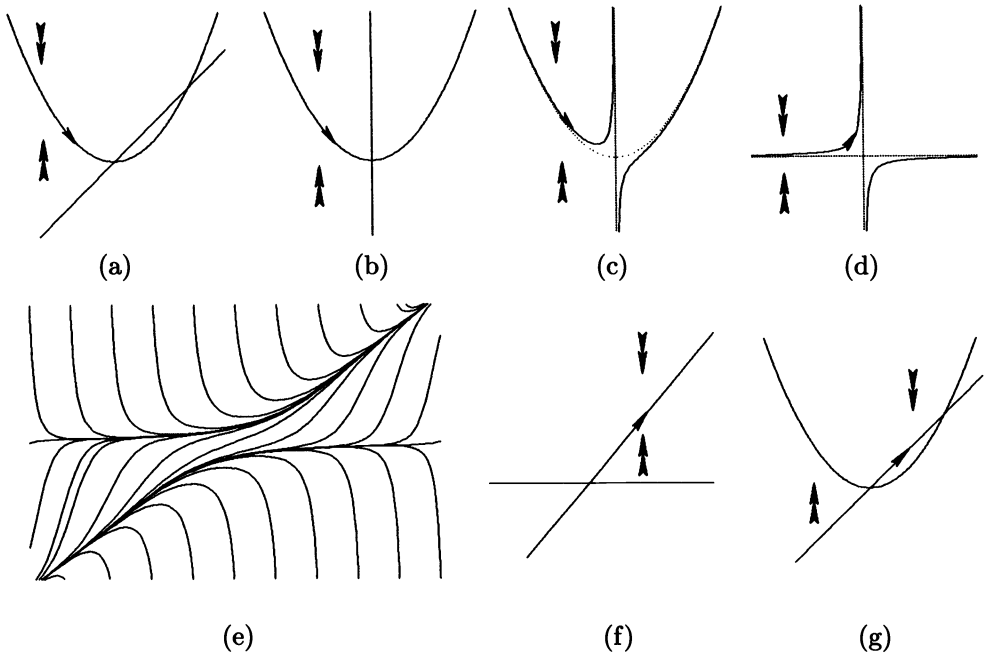

FIG. 9. *The passage through the halo of the critical point of* (27). (a) *and* (g): $\varepsilon^s = 1$, *the initial scale*; (b): $\varepsilon^s \simeq 0$ *and* $\varepsilon/\varepsilon^{3s} \simeq 0$; (c): $\varepsilon^{3s} = \varepsilon$, *one puts* $\eta = \varepsilon^{1/3}$; (c)–(e): *the microscopes of Theorem* 3.1 *in the case* $0 > r \ (= -1)$; (e)–(g): *the microscopes of Theorem* 3.4 *applied to the positive branch* $y = x$.

Proof. By Corollary 2.3, we have ${}^rP(X,Y) = {}_rf_0$. By Proposition 1.2, we have ${}^rP(1,k) = {}_rf_0(1,k) = 0$, and, as the branch φ is attracting, $({}_rf_0)'_y(1,k) < 0$. Thus by the rivers existence theorem, there exists an attracting river $\hat{Y}$: $(a,+\infty) \longrightarrow \mathbb{R}$, of type (k,r). The short-shadow lemma implies that the solution $\overline{Y}$ of blowup of (1) by the regularizing microscope (25) is defined for all X near-standard in $]a,+\infty[$, and that $\overline{Y}(X) \simeq \hat{Y}(X)$; hence assertion (3.4).

Assertions (2) and (3) are obtained by reasoning with the same microscopes as in the proof of Theorem 3.1; the existence of the slow solution up to x_+ follows from the attractivity of the slow curve at each of these scales. □

3.3. Singular deformations. We shall raise the question of equations with singular deformations for some branches of the slow curve on an example, and more precisely on the example of (11) which we already used to introduce that notion. This will also give us the oportunity to sketch how to deal with slow curves at some x_0 with branches of type (k,r), with $r < 0$. For the sake of simplicity, we do not consider here this question in the general case (that is, only relevant $f_0(x,y)$ that are polynomials in y^α).

Recall that (11) is equation

$$\varepsilon\frac{dy}{dx} = (y - x^2)(x - y) + \varepsilon(a + bx) \tag{27}$$

for which the term $\varepsilon(a + bx)$ is a singular deformation for the branch $y = x^2$ for any standard $a \neq 0$. This branch being preresonant for $x < 0$, we shall, more precisely, be interested in the behaviour of any preresonant solution $\overline{y}$ with initial condition

(x_-, y_-) such that x_- is appreciable and negative and $y_- \simeq x_-^2$. The branch $y = x^2$ being attracting, $\overline{y}(x)$ is defined and $\overline{y}(x) \simeq x^2$ for all x such that $x_- \leq x \ll 0$, and thus, by Fehrele's principle, for some $x \simeq 0$. As soon as $x \simeq 0$, we study $\overline{y}$ using the "zoom" (microscope with strengh varying with s)

$$\varepsilon^s X = x, \qquad \varepsilon^{2s} Y = y. \tag{28}$$

Let $\overline{Y}_s$ be the image of $\overline{y}$ by this microscope; thus it is a solution of equation

$$\frac{dY}{dX} = \varepsilon^{-1-s}[\varepsilon^{3s}(Y - X^2)(X - \varepsilon^s Y) + \varepsilon(a + bX)]. \tag{29}$$

As long as $s \ll \frac{1}{3}$, and more precisely as long as $\varepsilon/\varepsilon^{3s} \simeq 0$, (29) is slow-fast, with slow curve $X(Y - X^2)$, which is attracting for $X < 0$ (Fig. 9). Using the same reasoning as in the proof of Theorem 3.1, we see that for all these values of s and all appreciable $X < 0$, $\overline{Y}_s(X) \simeq X^2$, and thus $\varepsilon^{-2s}\overline{y}(\varepsilon^s X) \simeq X^2$.

Increasing the strengh of the zoom, that is, increasing s such that the ratio $\varepsilon^{3s}/\varepsilon$ becomes appreciable, say equal to 1, that is $s = \frac{1}{3}$, then $\overline{Y}_{1/3}$ is a solution of

$$\eta \frac{dY}{dX} = X(Y - X^2) + a + \eta(bX - Y(Y - X^2)), \tag{30}$$

with $\eta := \varepsilon^{1/3}$; this is still a slow-fast equation, but a change occured in the slow curve (Fig. 9(c)): it's no longer a parabola, but the curve $X(Y - X^2) + a = 0$, which, as $a \neq 0$, is now only asymptotic to the parabola $\{Y = X^2\}$ at $X = -\infty$; but at $X = 0$, it is asymptotic to $Y = -a/X$. *This part of the slow curve has to be seen as a (negative) branch φ of type $(a, -1)$ at $(0, 0)$, which means asymptotic to $a|X|^r$, with* $r = -1$.

Notice that now the term ηbX is a *regular* deformation term with respect to the preresonant branch φ, of type $(a, -1)$, for the simplified equation $\eta(dY/dX) = X(Y - X^2) + a$, for which the "microscope" (it is indeed a microscope with respect to X, but it is a *macroscope* with respect to Y)

$$\eta^{\frac{1}{2}} \mathbf{X} = X, \qquad \eta^{-\frac{1}{2}} \mathbf{Y} = Y \tag{31}$$

changes (30) into a regular perturbation for the polynomial differential equation with rivers

$$\frac{d\mathbf{Y}}{d\mathbf{X}} = -\mathbf{Y}^2 + \mathbf{X}\mathbf{Y} + a, \tag{32}$$

which exhibits in particular a river $\hat{\mathbf{Y}}_-$ of type $-a/\mathbf{X}$ at $\mathbf{X} = -\infty$. Observe now that in Theorem 3.1, we assumed that r, the growth type of the branch, is positive; this was done for the sake of simplicity, and also for the sake a generality with respect to the equation (which was assumed to be C^∞ and not only a polynomial), a negative growth type at x_0 making no sense in the C^∞ case. One checks easily that we only used that $r \neq 0$ (and thus $kr \neq 0$). So we come to the same conclusion here and see that for limited $\mathbf{X}$ sufficiently negative,

$$\hat{\mathbf{Y}}_-(\mathbf{X}) \simeq \overline{\mathbf{Y}}_{\frac{1}{3}}(\mathbf{X}),$$

where $\overline{\mathbf{Y}}_{1/3}$ denotes the image of the solution $\overline{Y}_{1/3}$ on the blowup using the microscope (31).

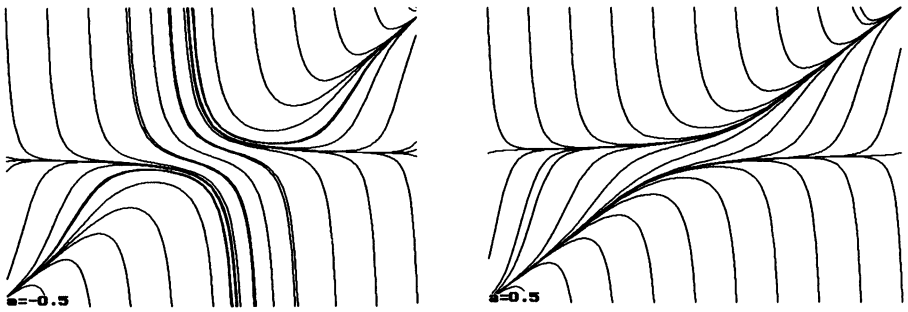

FIG. 10. *The blowup of equation* (27) *by the regularizing microscope* (31) *for some negative and some positive value of the parameter* a.

It is easy to study the behaviour of the rivers of (32) (see Fig. 10). One shows in particular that for $a > 0$, the river $\hat{\mathbf{Y}}_-$ at $\mathbf{X} = -\infty$ is also a river at $\mathbf{X} = +\infty$, but attracting and of type $(1,1)$ this time.

The time has come to express the microscope we obtained by the two successive microscopes we applied, namely, $x = \varepsilon^{1/3}X$, $y = \varepsilon^{2/3}Y$, and $X = \varepsilon^{2/3}\mathbf{X}$, $Y = \varepsilon^{-1/3}\mathbf{Y}$, as $\eta = \varepsilon^{1/3}$. Finally, we have

$$x = \varepsilon^{\frac{1}{2}}\mathbf{X}, \qquad y = \varepsilon^{\frac{1}{2}}\mathbf{Y} :$$

we merely resulted in the regularizing microscope relative to the branch of type $(1,1)$ (with respect to which the complete equation (27) is a regular deformation of the simplified equation). So we can apply Theorem 3.4 for $\mathbf{X} > 0$, and we get (Fig. 9(e)–9(g)) that for $a > 0$ (standard), the solution $\overline{y}$ stays slow for $x > 0$, and follows the attracting curve $y = x$.

Let us observe that for $a < 0$ (standard), Fig. 10(b) suggests what the behaviour of $\overline{y}$ will be for $x \gg 0$: when $\mathbf{X}$ increases, $\hat{\mathbf{Y}}_-$ decreases faster than any linear function and thus, coming back to the initial scale, $\overline{y}$ jumps towards y unlimited negative.So we can deduce that $\overline{y}$ will assume, for some $a \simeq 0$, intermediate behaviours, and especially that for any limited b, there exists some $a(b)$ such that $\overline{y}_{a(b),b}$ is a canard of (27).

This example shows how to reduce a singular deformation problem: r being chosen with respect to the preresonant branch φ followed by the considered solution, one increases gradually the value of s in the zoom (28): for small values of $s > 0$, at that scale the solution follows the slow curve equal to the growth type of φ. For some smallest standard value $s_1 (< s_0$, unless the deformation would just be regular), one or several terms in the deformation get the same size order as those of f_0: Proposition 1.2 shows that such terms can only rise from those f_p such that $1 \leq p < 1 + s_0(r-1)$. One gets a new slow-fast equation ("ε" becomes "η"), the standard part of which being henceforth a polynomial, and the slow curve being an *algebraic curve*, which may exhibit new critical points and which may once more be analysed in branches at these critical points, but also branches at $X = \pm\infty$, or $Y = \pm\infty$ $(r < 0)$. Once the critical points with finite abscissa have been found (this is the only difficult operation), one can study theses branches with convenient Newton polygons. If the slow curve at the initial scale exhibits a preresonant branch of type (k,r) for $\pm(x - x_0) > 0$, the slow curve of the blowup will exhibit a branch of type (k,r) at $X = \pm\infty$ such that the solution will follow up to some new critical point of finite abscissa and finite or infinite ordinate: it suffices to reapply the same process; as already mentioned, the

Theorems 3.1 and 3.4 apply in both cases, and this makes it possible to "follow" the considered solution, at least when no canard situations occur, which would imply an additional canard study. We do not doubt that this process will finally result (if no nonzero occuring function is infinitely flat at some of the critical points, which will not happen if the functions are assumed to be analytic) in a regularizing blowup, but it would of course be interesting to solve this question in an effective manner (symbolic machine computations). We will not consider here this purely algebraic question that involves only the equation, our goal being to show the role played by rivers in the behaviour of the slow *solutions*.

4. Appendix. Let us briefly sketch the nonstandard tools involved in this paper.

The vocabulary of infinitesimals had gradually been forsaken by most mathematicians because of the contradictions that this terminology seemed to introduce. To overcome these contradictions, logicians like Löwenheim and Skolem introduced so-called "nonstandard models," mathematical constructions that would, for example, add "infinitely large elements" to the integers. Abraham Robinson extended these techniques in order to build efficient nonstandard models that contain all of what is needed by mathematical analysis (Banach spaces, measure spaces, etc.) He also pointed out that his construction should indicate how to use safely the infinitesimal terminology within the usual mathematical sets, like $\mathbb{R}$, the main idea being not to apply blindly classical results to "external sets" like the set of standard integers. It is Nelson that achieved this program, in his October 1977 paper in the Bulletin of the American Mathematics Society that indicates what to do (and what *not* to do) using that terminology. Actually, Nelson's Internal Set Theory introduces just one new word, *standard*, and gives the rules for correct use of it.

We use Nelson's approach (and thus the usual real line, not some elaborate model); here is how it works. Every classical object is standard or not: we just need tools to determine which is which. Any uniquely defined object (possibly using other objects that have already been shown to be standard) is standard. So $\emptyset$, 0, 1, π, sin, $\mathbb{R}$, $\mathcal{C}_0(\mathbb{R})$ are standard. An equivalent statement, called *transfer*, asserts that classical-type theorems are true if and only if they are true for standard elements. Things become more interesting with the theorem asserting that any infinite set contains nonstandard elements (infinite means, as usual, in one–one correspondence with one of its proper subsets). So $\mathbb{N}$ has nonstandard elements, and any nonstandard integer, say ω, is larger than any standard one. So we have an infinitely large number ω. Taking its inverse (in $\mathbb{Q}$ or $\mathbb{R}$), we get a nonzero *infinitesimal* $\varepsilon = 1/\omega$, i.e., $|\varepsilon|$ is smaller than $1/n$ for all standard $n > 0$. A number is *limited* if its absolute value is smaller than some standard number (one should keep the word "finite" for questions of cardinality: the set $\{1, \ldots, \omega\} \subset \mathbb{N}$ is finite, but its cardinal is infinitely large, or better: *unlimited*). It is *appreciable* if it is neither infinitesimal nor unlimited. Here are two notations: ϕ (pronounce *zerobar*) will always denote an infinitesimal and $\pounds$ a limited number, but two occurences of ϕ are *not* necessarily equal, and analogously for $\pounds$. Please notice the difference between the empty-set symbol $\emptyset$ and this symbol ϕ. We write $x \simeq y$ if and only if $x - y$ is infinitesimal, and, to the contrary, $x \ll y$ if and only if $x - y$ is not infinitesimal.

As $\mathbb{R}$ is complete, any limited real number l is infinitely close to a standard one, called its standard part, and denoted by ${}^{\circ}l$. This extends easily to any standard finite-dimensional Banach space B. For any standard $C \subseteq B$, if ${}^{\circ}l \in C$, we say that l is near-standard in C. If $\gamma \subseteq B$ has all its limited points near-standard in C, it is *infinitely close to* C. If γ is a curve (think of a trajectory), we also say that γ

follows C. If, moreover, C is standard and any of its standard points is infinitely close to some point of γ, then C is called the *shadow* of γ, and we write ${}^o\gamma = C$ (actually, on any standard compact subset, it *is* a standard part for the Haussdorf metric). A standard function f_0 is the shadow of the function f if their graphs are also. We use this terminology for differential equations, just identifying the equation $y' = f(x,y)$ with the function f. Given a differential equation $y' = f(x,y)$ and its shadow $y' = {}^of(x,y)$, both assumed to be locally Lipschitz, the *short-shadow lemma* [9, Thm. 8.2.2] indicates the relationship existing between the shadow of some segments of solution of the initial equation and a standard solution of the shadow equation. The segment should be short in the sense that the difference between two elements in its domain has to be limited. The lemma also gives existence results for solutions of the initial equation from existence assumptions on the shadow equation.

To make it possible to assume that $\varepsilon > 0$ is a *fixed* infinitesimal is a key point in the use of nonstandard analysis to singular perturbation theory. For example, dealing with the question of *existence*, the fact that solutions have their values in a (finite-dimensional and thus) locally compact space, one can refer to the prolongation theorem, which ensures that the maximal solution leaves any closed subset of the domain of the equation; it might be more cumbersome to deal with an (ad hoc) infinite-dimensional space (of $\mathbb{R}^2$-valued functions, defined for $\varepsilon \in (0, \varepsilon_0)$). A still more important reason is that it makes it easier to let other parameters vary. Expansions involving ε may enter "by themselves" for a *number* a, as, for example, for the necessary value $a = 1 - \frac{1}{8}\varepsilon - \frac{3}{32}\varepsilon^2 + \varepsilon^2\phi$ of some parameter (for the existence of canards [3]).

A number a has an ε-shadow expansion, that we shall write $a = \sum a_n\varepsilon^n$, if $(a_n)_{n\geq 0}$ is a standard sequence of numbers and for any *standard* n, $a = a_0 + a_1\varepsilon + \cdots + a_n\varepsilon^n + \varepsilon^n\phi$ (this formal expansion usually does not converge for any nonzero value of ε). A function f has an ε-shadow expansion, write $f = \sum f_n\varepsilon^n$, if $(f_n)_{n\geq 0}$ is a standard sequence of functions on some domain D, and for any *standard* n, and any x near-standard in D, $f(x) = f_0(x) + f_1(x)\varepsilon + \cdots + f_n(x)\varepsilon^n + \varepsilon^n\phi$. The expansion is *regular* if the functions f_n are C^∞, and for any *standard* p, $f^{(p)} = \sum f_n^{(p)}\varepsilon^n$. For example, if F is standard and C^∞ with respect to (x,e) and if $\varepsilon > 0$ is some infinitesimal, then Taylor's theorem shows that for $f(x) := F(x,\varepsilon)$, one has $f = \sum F_{e^n}^{(n)}(.,\varepsilon)\varepsilon^n/n!$. But there exist useful examples which are not of that kind, for example, $f(x) = \Phi(x,\varepsilon,a)$, $\Phi \in C^\infty$ standard, and a is equal to the sum of the smallest term of some diverging expansion, as for the canard values of the Van der Pol equation [3]. If f has a regular ε-shadow expansion, and $\overline{y}$ is a slow solution of $\varepsilon y' = f(x,y)$ that follows a branch of the slow curve $\{{}^of(x,y) = 0\}$ with no critical point, then $\overline{y}$ has also an ε-shadow expansion, and this expansion is the same for all slow solutions following the same branch [8].

It is possible to deal with external sets, provided one takes care not to apply (blindly) classical theorems to them. We say that a set (i.e., a subcollection defined using the extended language of some classical set) is *external*, if some classical result is wrong for it. The set ${}^{st}\mathbb{N}$ of standard integers is external (it is bounded by ω but has no least upper-bound), and so is the *principal galaxy* $\mathbb{G}$ *of* $\mathbb{R}$, the set of all limited real numbers (the previous example could be deduced from it just by intersecting it with the standard set $\mathbb{N}$), or the α-galaxy $x_0 + \alpha\mathbb{G}$ of any x_0 for any $\alpha \neq 0$. One has specific results for external sets, which can be used as *permanence* principles (or overspill principles). The most obvious one is the "Cauchy principle" (named after Cauchy's original statement on continuity of the limit of a sequence of continuous functions)

that just states that an external set is not internal. So, an internal property cannot hold only on an external set (otherwise this statement would define the external set, and there would be a contradiction in classical mathematics) and the property must overspill to other points. An external set is a *halo* if it is the *intersection* on all standard indices of an internal family of sets (think of $\mathrm{hal}(0) := \bigcap_{st\mathbb{N}}[-\frac{1}{n}, \frac{1}{n}]$), and it is a *galaxy* if it is the *union* on all standard indices of such a family (think of $\mathbb{G} := \bigcup_{st\mathbb{N}}[-n, n]$). So the external domain where a function is limited or appreciable is a galaxy, and the external domain where it is infinitesimal or unlimited is a halo. Fehrele's principle states that no halo is a galaxy, so, for example, two functions cannot be infinitely close to each other only on a galaxy. This is a generalization of an easy but nice result called Robinson's lemma. The typical use of this permanence result is when it is necessary to overspill an "up to an infinitesimal" estimate from all limited values of the variable up to some infinitely large ones: the domain where this type of estimate holds is a halo, whereas the external set of limited numbers is a galaxy; so the halo must be strictly larger than this galaxy.

We refer to [9] for proofs, further results, and bibliography.

A NEW STANDARD ISOMETRY OF DEVELOPABLE SURFACES IN CAD/CAM*

ERWIN KREYSZIG†

Abstract. This paper discusses a recent exact method by Clements and Leon [*Marine Tech.*, 18 (1981), pp. 227–233] for the isometric mapping of developable surfaces into the plane, as needed in computer-aided design and manufacturing (CAD/CAM), and some practical shortcomings of this method. A new exact method for that purpose is then presented that is free of those deficiencies. Of equal practical importance is the fact that, whereas the method by Clements and Leon requires the numerical solution of a second-order nonlinear ordinary differential equation (or of an equivalent first-order system), the present method involves only the evaluation of two single integrals.

Key words. developable surface, isometric mapping into the plane

AMS subject classifications. 53, 65

1. Introduction.

Computer-aided design and manufacturing (CAD/CAM), robotics, computer graphics, and pattern recognition are among the fields that provide various, novel, and practical problems and applications of the differential-geometric theory of curves and surfaces in space [1], [6]. Software reduction calls for standardization to a relatively small number of well-documented portable codes corresponding to fast and efficient algorithms. With respect to curves this means a preference for cubic splines, Bezier curves (named after P. Bezier, of the French Renault Automobile Company), or B-splines, instead of the host of special algebraic and transcendental curves explored during the 18th and 19th centuries. With respect to surfaces the situation is similar, although more complex. For a simple introduction into these matters, see [6].

In construction work, if shape and mechanical stability permit it, one often chooses (portions of) developable surfaces because then the prescribed design surface S can be obtained by cutting a suitable portion S^* from plane material and bending S^* to give it the form of S. Bending is an isometry, a length-preserving mapping [4], and *standardization* here means to design, once and for all, standard isometric mappings $S \to S^*$ and corresponding software applicable to any of the usual practical problems as they arise in ship building, where large steel plates are to be cut, in roof constructions, in airfoil design, and in numerous other tasks; see the references in [2] and [3].

Two not quite satisfactory approximation methods for setting up an isometry $S \to S^*$ into the plane are mentioned in [3]. The paper [3] itself seems to contain the earliest method for that purpose based on an exact differential-geometric theory. In §2 we outline the basics of this method. In §3 we show that it is essentially local and discuss its theoretical and practical limitations. In §4 we present a new method that is free of those limitations. Moreover, our method is numerically much simpler because, instead of the numerical solution of a nonlinear second-order differential equation (or an equivalent first-order system) required in [3], it involves only the (generally numerical) evaluation of two single integrals. A proof of isometry of the mapping given by the algorithm in §4 is provided in the last two sections.

2. Clements–Leon method [3]. An isometry is a geodesic mapping; hence it maps every geodesic on a developable surface S into a straight line in a plane, called the pq-plane. Accordingly, it is natural to determine on a given developable surface

$$S: \quad \mathbf{x}(s,t) = \mathbf{y}(s) + t\mathbf{z}(s),$$

a geodesic $G: t = \tilde{t}(s)$, and map G into a convenient straight line in the pq-plane, say, into a straight-line segment $0 \le p \le P$ on the p-axis.

Theoretically, this is simple. The essential formulas are as follows. First we have

$$G: \quad \tilde{\mathbf{x}}(s) = \mathbf{x}(s, \tilde{t}(s)) = \mathbf{y}(s) + \tilde{t}\mathbf{z}(s).$$

The second derivative with respect to s is

$$\tilde{\mathbf{x}}'' = \mathbf{y}'' + \tilde{t}''\mathbf{z} + 2\tilde{t}'\mathbf{z}' + \tilde{t}\mathbf{z}''.$$

G is geodesic on S if $\kappa_g = 0$, thus $\tilde{\mathbf{x}}'' \cdot \mathbf{w} = 0$, where $\mathbf{w} = \tilde{\mathbf{x}}' \times \tilde{\mathbf{n}}$ and $\tilde{\mathbf{n}}$ is a normal vector of S along G (cf. [4, p. 155]). We thus obtain for $\tilde{t}(s)$ the nonlinear differential equation

$$(\tilde{t}''\mathbf{z} + 2\tilde{t}'\mathbf{z}' + \tilde{t}\mathbf{z}'' + \mathbf{y}'') \cdot \mathbf{w} = 0.$$

Except for the notation in [3], this equation is written in the form

$$\tilde{t}'' = f(s, \tilde{t}(s), \tilde{t}'(s))$$

or as an equivalent first-order system of two differential equations, as usual. For details on differentiability conditions, etc., we refer to [3]. This is the theory. Practically, this equation or system is now solved *numerically*, subject to two suitable initial conditions by which the geodesic G is uniquely determined. Then, using conformality of an isometry, one constructs the plane image S^* of S by means of the images of the generators of S, which are straight-line segments of the same length as their inverse images on S. These are the essential ideas in [3].

3. Restrictions of the method in [3]. In the method just described, one must tacitly impose the condition that on S there exists at least one geodesic that has a point in common with each generator on S. Furthermore, in choosing initial conditions as mentioned in §2, one must be skillful in order to obtain a geodesic of that kind and resulting from it an isometric image of the *entire* given surface S; also, such a geodesic must not meet an edge of regression or any other singularity that S may have.

However, that condition tacitly assumed need not hold even in very simple cases. For instance, think of the surface of a straight circular cone whose plane image (obtained after cutting along a generator) has at the image of the apex an angle $\alpha \ge \pi$. Accordingly, in this sense the method is *local*, and it may be necessary to proceed "piecewise," that is, work with portions of several geodesics; this appears to be a detour. Remarks at the beginning of §4 on p. 970 in [3] seem to indicate that the authors were aware of those practical difficulties.

In the next section we present a method that gives a differential geometrically exact standard mapping that is *global* and makes direct use of the given representation of S in the sense that the auxiliary construction of a geodesic is avoided, and the integration of two single integrals is all that is needed numerically, as was mentioned before.

4. Global standard isometry of a developable surface into the plane. Given a developable surface

$$S: \quad \mathbf{x}(s,t) = \mathbf{y}(s) + t\mathbf{z}(s) \qquad [t_1(s) \le t \le t_2(s),\ a \le s \le b], \tag{1}$$

where

$$\mathbf{z}(s) = \sum_{j=1}^{3} \alpha_j(s)\mathbf{v}_j(s), \quad \sum_{j=1}^{3} \alpha_j^2(s) = 1, \quad \alpha_3(s) \neq 0, \tag{2}$$

$\{\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3\}$ is the trihedron (cf. [4, p. 36] and [5, p. 469]), of the curve $C: \mathbf{y}(s)$ with arc length s and curvature $\kappa(s) > 0$.

Note that $\alpha_3(s) \neq 0$ is no restriction of the geometric shape of S. Geometrically, it means that the representation of S is chosen so that S has no singularities along C, and calls for a change of the representation if it is violated somewhere (or everywhere) along C.

ALGORITHM ISOM(S, $\Pi(\epsilon)$). For a developable surface S given by (1) and (2), this algorithm computes an isometric image S^* in the pq-plane given by (9).

Input. Developable surface S given by (1), (2), partition $\Pi(\epsilon)$ of $[a, b]$ fine enough so that the integration rule chosen (e.g., Simpson's rule) will give values (5) and (7), whose absolute errors do not exceed a given $\epsilon > 0$.

Output. Isometric image S^* of S given by (9) in the pq-plane.

(i) Calculate the curvature $\kappa(s)$ of C, a unit normal vector $\mathbf{n}$ of S along C,

$$\mathbf{n}(s) = \frac{1}{|\mathbf{v}_1 \times \mathbf{z}|}\mathbf{v}_1 \times \mathbf{z} \qquad (a \le s \le b), \tag{3}$$

and the geodesic curvature κ_g of C on S,

$$\kappa_g = \mathbf{v}_3 \cdot \mathbf{n} \qquad (a \le s \le b). \tag{4}$$

(ii) Evaluate the integral

$$L(s) = \int_0^s \kappa_g(u)\, du \qquad [s \in \Pi(\epsilon)]. \tag{5}$$

(iii) Compute

$$\mathbf{v}_1^*(s) = \begin{bmatrix} \cos L(s) \\ \sin L(s) \end{bmatrix}, \quad \mathbf{v}_2^*(s) = \begin{bmatrix} -\sin L(s) \\ \cos L(s) \end{bmatrix} \quad [s \in \Pi(\epsilon)]. \tag{6}$$

(iv) Evaluate the integral

$$\mathbf{y}^*(s) = \int_0^s \mathbf{v}_1^*(\sigma)\, d\sigma \qquad [s \in \Pi(\epsilon)]. \tag{7}$$

(v) Compute

$$\mathbf{z}^*(s) = \alpha_1 \mathbf{v}_1^*(s) + (1 - \alpha_1^2)^{1/2}\mathbf{v}_2^*(s) \qquad [s \in \Pi(\epsilon)]. \tag{8}$$

(vi) Compute the isometric image S^* of S given by

$$\mathbf{x}^*(s,t) = \mathbf{y}^*(s) + t\mathbf{z}^*(s) \qquad [t_1(s) \le t \le t_2(s),\ s \in \Pi(\epsilon)]. \tag{9}$$

End.

5. Auxiliary formulas for the isometry proof. For easy reference, we continue the equation numbering. From (6),

$$|\mathbf{v}_1^*| = |\mathbf{v}_2^*| = 1, \qquad \mathbf{v}_1^* \cdot \mathbf{v}_2^* = 0. \tag{10}$$

From this and (7),

$$|\mathbf{y}^{*\prime}| = 1; \tag{11}$$

hence s is the arc length of the image $C^* : \mathbf{y}^*(s)$ of C. Also, by (8),

$$|\mathbf{z}^*|^2 = \alpha_1^2 + 1 - \alpha_1^2 = 1. \tag{12}$$

For the unit normal vector $\mathbf{n}$ of S along C we get, by (1) and (2),

$$\mathbf{n} = \frac{\mathbf{x}_s \times \mathbf{x}_t}{|\mathbf{x}_s \times \mathbf{x}_t|} = \frac{\mathbf{v}_1 \times \mathbf{z}}{|\mathbf{v}_1 \times \mathbf{z}|} = \frac{\alpha_2 \mathbf{v}_3 - \alpha_3 \mathbf{v}_2}{(1-\alpha_1^2)^{1/2}}. \tag{13}$$

From this we get by the first Frenet formula (cf. [4, pp. 41, 155])

$$\kappa_g = |\mathbf{y}'\ \mathbf{y}''\ \mathbf{n}| = (\mathbf{v}_1 \times \kappa \mathbf{v}_2) \cdot \mathbf{n} = \kappa \mathbf{v}_3 \cdot \mathbf{n} = \frac{\kappa \alpha_2}{(1-\alpha_1^2)^{1/2}}. \tag{14}$$

From (6) we also have

$$\mathbf{v}_1^{*\prime} = \kappa_g \mathbf{v}_2^*, \qquad \mathbf{v}_2^{*\prime} = -\kappa_g \mathbf{v}_1^*. \tag{15}$$

6. Proof that S and S^* are isometric. We have an isometry if and only if corresponding coefficients of the first fundamental forms of S and S^* are equal [4, p. 176]). With the usual notation $E = \mathbf{x}_s \cdot \mathbf{x}_s$, $F = \mathbf{x}_s \cdot \mathbf{x}_t$, $G = \mathbf{x}_t \cdot \mathbf{x}_t$, we have for S by (1), (2), and $\mathbf{z}' \cdot \mathbf{z} = 0$,

$$E = 1 + 2t\mathbf{y}' \cdot \mathbf{z}' + t^2 \mathbf{z}' \cdot \mathbf{z}', \quad F = \mathbf{v}_1 \cdot \mathbf{z}, \quad G = 1.$$

Similarly for S^* by (9), (11), (12),

$$E^* = 1 + 2t\mathbf{y}^{*\prime} \cdot \mathbf{z}^{*\prime} + t^2 \mathbf{z}^{*\prime} \cdot \mathbf{z}^{*\prime}, \quad F^* = \mathbf{v}_1^* \cdot \mathbf{z}^*, \quad G^* = 1.$$

Accordingly, we have to show that

$$\mathbf{v}_1^* \cdot \mathbf{z}^* = \mathbf{v}_1 \cdot \mathbf{z}, \tag{16}$$

$$\mathbf{v}_1^* \cdot \mathbf{z}^{*\prime} = \mathbf{v}_1 \cdot \mathbf{z}', \tag{17}$$

$$\mathbf{z}^{*\prime} \cdot \mathbf{z}^{*\prime} = \mathbf{z}' \cdot \mathbf{z}'. \tag{18}$$

Now (16) follows from (2) and (8):

$$\mathbf{v}_1^* \cdot \mathbf{z}^* = \alpha_1 = \mathbf{v}_1 \cdot \mathbf{z}. \tag{19}$$

We prove (17). Differentiating (19), we first have

$$\mathbf{v}_1^{*\prime} \cdot \mathbf{z}^* + \mathbf{v}_1^* \cdot \mathbf{z}^{*\prime} = \mathbf{v}_1' \cdot \mathbf{z} + \mathbf{v}_1 \cdot \mathbf{z}'$$

and obtain (17) by proving that the first terms on both sides are equal. Now by (15), the first term on the left equals $\kappa_g \mathbf{v}_2^* \cdot \mathbf{z}^*$, which equals $\kappa_g(1-\alpha_1^2)^{1/2}$ by (8) and (10), and this equals $\alpha_2\kappa$ by (14). But the first term on the right equals $\kappa\mathbf{v}_2 \cdot \mathbf{z}$ by the first Frenet formula, hence $\alpha_2\kappa$ by (2).

We prove (18). From $\alpha_3(s) \neq 0$ in (2) we have $|\alpha_1(s)| < 1$; hence $\mathbf{v}_1$ and $\mathbf{z}$ are linearly independent, so that the developability condition $|\mathbf{z}\ \mathbf{z}'\mathbf{v}_1| = 0$ (cf. [4, p. 182]) implies that

$$\mathbf{z}' = \beta_1\mathbf{v}_1 + \beta_2\mathbf{z}, \quad \text{thus } 0 = \mathbf{z} \cdot \mathbf{z}' = \beta_1\alpha_1 + \beta_2$$

(with β_1 and β_2 depending on s), as well as

$$\mathbf{v}_1 \cdot \mathbf{z}' = \beta_1 + \beta_2\alpha_1 = \beta_1(1-\alpha_1^2). \tag{20}$$

By Lagrange's identity and (8), (10), and (12),

$$|\mathbf{v}_1^* \times \mathbf{z}^*|^2 = 1 - \alpha_1^2 \neq 0,$$

so that $\mathbf{v}_1^*$ and $\mathbf{z}^*$ are linearly independent and we can write

$$\mathbf{z}^{*\prime} = \beta_1^*\mathbf{v}_1^* + \beta_2^*\mathbf{z}^*, \quad \text{thus } 0 = \mathbf{z}^* \cdot \mathbf{z}^{*\prime} = \beta_1^*\alpha_1 + \beta_2^*$$

(with β_1^* and β_2^* depending on s), as well as, by (8) and (10),

$$\mathbf{v}_1^* \cdot \mathbf{z}^{*\prime} = \beta_1^* + \beta_2^*\alpha_1 = \beta_1^*(1-\alpha_1^2). \tag{21}$$

But $\mathbf{v}_1 \cdot \mathbf{z}' = \mathbf{v}_1^* \cdot \mathbf{z}^{*\prime}$ by (17), so that (20) and (21) imply that $\beta_1^* = \beta_1$, and then $\beta_2^* = \beta_2$. Together,

$$\mathbf{z}' = \beta_1\mathbf{v}_1 + \beta_2\mathbf{z}, \qquad \mathbf{z}^{*\prime} = \beta_1\mathbf{v}_1^* + \beta_2\mathbf{z}^*,$$

and (18) now follows because of (10) and (12). This proves isometry.

EXISTENCE OF A HOMOCLINIC ORBIT OF THE LORENZ SYSTEM BY PRECISE SHOOTING*

BRIAN HASSARD† AND JIANHE ZHANG†

Abstract. A proof of the existence of a homoclinic orbit of the Lorenz system is given, based on shooting using precise numerical integrations. This makes rigorous an argument given by Sparrow [*Appl. Math. Sci.* 41, Springer-Verlag, New York, 1982], and improves greatly on the accuracy of the estimate of the value R^* for which a homoclinic orbit exists, in the Hastings–Troy proof [*Bull. Amer. Math. Soc.*, 27 (1992), pp. 128–131, and *J. Diff. Eqns.*, 1993, to appear].

Key words. Lorenz system, homoclinic orbit, precise integration

AMS subject classifications. 34A50, 34C37, 65L70

1. Introduction.

The Lorenz system [5]

$$x' = s(y - x), \tag{1.1}$$

$$y' = (R - z)x - y, \tag{1.2}$$

$$z' = xy - qz, \tag{1.3}$$

is often cited as a simple ordinary differential system which exhibits complex dynamical behavior, including chaos. However, remarkably little of this behavior has been actually proven to exist. Our knowledge of the more interesting phenomena in the system, derives from traditional numerical integrations lacking rigorous control of truncation and roundoff error.

Only recently has even existence of a homoclinic orbit for the system been proven. Hastings and Troy [2], [3] show for each (s, q) in some neighborhood of (10,1), there is an R in the range (1,1000) for which (1.1) has a homoclinic orbit.

Here we give a proof which is essentially a rigorous version of the numerical shooting argument in Sparrow [6] that a homoclinic orbit exists. The numerical part of our proof uses a precise numerical integrator which produces true error bounds. As in [2] and [3], the existence of a homoclinic orbit is inferred as a consequence of properties of the just two computed orbits (shots). As in [6], the estimate of a value of R for which a homoclinic orbit exists is sharpened by additional shooting.

Each orbit we compute has one of the following properties.

Property P. As $t \to -\infty, (x, y, z)^T \to (0, 0, 0)^T$. Also, there exist numbers $\tau_1 < s_1 < t_1$ such that

$$\begin{aligned}
&x' > 0 \quad \text{on } (-\infty, \tau_1),\\
&x' < 0 \quad \text{on } (\tau_1, t_1],\\
&x(t_1) = 0,\\
&y' < 0 \quad \text{on } [\tau_1, s_1],\\
&y(s_1) = 0,\\
&y < 0 \quad \text{on } (s_1, t_1],\\
&x > 0 \quad \text{on } (-\infty, t_1).
\end{aligned}$$

*Received by the editors July 27, 1992; accepted for publication February 12, 1993.

†Department of Mathematics, State University of New York at Buffalo, Buffalo, New York, 14214.

Property Q. As $t \to -\infty, (x, y, z)^T \to (0, 0, 0)^T$. There exists a τ_1 such that $x' > 0$ on $(-\infty, \tau_1)$. Also, the orbit $(x, y, z)^T$ does not have Property P.

In §2, we show how the existence of orbits having Properties P and Q leads to the existence of a homoclinic orbit. We incorporate more information about orbits into Property P than in the hypotheses of [2, Lemma 2.2] so that we can separate a central argument (Lemma 2.1) from the body (Lemma 2.2) of the proof, and organize the proofs around the concept of sequences of orbits having Property P.

In §§3 and 4 we construct orbits with Properties P and Q. On $(-\infty, 0]$, orbits are approximated by polynomials in $e^{\lambda_3 t}$, where λ_3 is the positive eigenvalue of the Jacobian at $(0, 0, 0)^T$. Initial conditions for the numerical integrations derive from these approximations at $t = 0$. The origin of t is defined such that on the time interval $(-\infty, 0]$, the orbits are in neighborhood of $(0, 0, 0)^T$ sufficiently small that local theory (Lemma 3.4) applies to show existence and to construct highly accurate approximations. High accuracy at $t = 0$ is necessary to compensate for the large loss of precision during the integrations for $t \geq 0$.

In §4, we describe precise numerical integrations of using an algorithm due to Aberth [1]. The actual code we used is based on Aberth's C++ program called "difsys.cc," which generates precise solutions of initial value problems of ordinary differential systems for which the component functions are elementary. In §4 we first describe the modifications we had to make to Aberth's algorithm to achieve our goals, and then we present the results in the form of Lemma 4.1. Finally, we state Theorem 4.2.

2. Conditions for existence of a homoclinic orbit. We fix $q > 0$, $s > 0$ and restrict our attention to some interval $[R_a, R_b]$ of R values, $R_a > 1$. The Jacobian matrix for (1.1)–(1.3) at the origin has two negative and one positive eigenvalues. The unstable manifold at the origin has components $\gamma^+(R)$, $\gamma^-(R)$, where locally $x > 0$ on γ^+, $x < 0$ on γ^-. We will be concerned only with γ^+.

We let $p^+(R) = (\sqrt{q(R-1)}, \sqrt{q(R-1)}, R-1)^T$ denote the stationary point in the positive octant. Let $p(t; R) = (x(t; R), y(t; R), z(t; R))^T$ denote a family of orbits of the Lorenz system, one for each $R \in [R_a, R_b]$, jointly smooth in t and R, known to exist on the interval $(-\infty, 0]$, and such that $\lim_{t \to -\infty} p(t; R) = (0, 0, 0)^T$ and $x'(t, R) > 0$ on $(-\infty, 0]$. Such orbits will be constructed in §3. Then $p(.; R) \in \gamma^+(R)$. It is well known [5, Appendix C] that for fixed parameters q,R,s, there is a region V, the interior of an ellipse, which contains the origin and is a (forward) invariant set for the flow. Because of the invariant region, each orbit $p(t; R)$ on $(-\infty, 0]$ may be continued to the entire line $(-\infty, \infty)$. Furthermore, the partial derivatives of x, y, and z with respect to t of any fixed order, are bounded for all t and bounds which are uniform in R may be constructed.

The main task in establishing the existence of a homoclinic orbit is to show that for the sequence $\{p(.; R_j)\}$ of orbits with Property P constructed in Lemma 2.2, the sequence $\{t_{1,j}\}$ is unbounded. This will be done using the following lemma.

LEMMA 2.1. *Suppose* $0 < q < 2s$ *and* $1 < R_a < R < R_b$. *Let* $R_j \in (R_a, R_b)$ *and suppose each orbit* $p(.; R_j) = (x(.; R_j), y(.; R_j), z(.; R_j))^T$ *has Property P. Let* $\tau_{1,j} < s_{1,j} < t_{1,j}$ *be from Property P such that* $x'(\tau_{1,j}; R_j) = 0$, $y(s_{1,j}; R_j) = 0$ *and* $x(t_{1,j}; R_j) = 0$. *If the sequences* $\{\tau_{1,j}\}, \{s_{1,j}\}, \{t_{1,j}\}$ *have finite limits* τ_1, s_1, t_1, *then the orbit* $(x(.; R), y(.; R), z(.; R))$ *also has Property P.*

The basic existence result is then Lemma 2.2.

LEMMA 2.2. *Suppose* $0 < q < 2s$ *and* $1 < R_a < R_b$. *Suppose that for* $R = R_b$, *there is an orbit with Property P and for* $R = R_a$ *there is an orbit with Property Q.*

Suppose further that for all $R \in [R_a, R_b]$, $p^+(R)$ *is linearly stable. Then there is a value* R^*, $R_a < R^* < R_b$ *for which there is an orbit* $p(.; R^*) = (x, y, z)^T$ *with the following properties.*

As $t \to \pm\infty$, $(x, y, z)^T \to (0, 0, 0)^T$. *Also, there exist* τ_1, s_1, $-\infty < \tau_1 < s_1 < \infty$ *such that*

$$
\begin{aligned}
&x' > 0 \quad \textit{on } (-\infty, \tau_1),\\
&x' < 0 \quad \textit{on } (\tau_1, \infty),\\
&y' < 0 \quad \textit{on } [\tau_1, s_1],\\
&y(s_1) = 0,\\
&y < 0 \quad \textit{on } (s_1, \infty),\\
&x > 0 \quad \textit{on } (-\infty, \infty).
\end{aligned}
$$

The remainder of this section gives the proofs.

Proof of Lemma 2.1. As τ_1, s_1, t_1 are the limits of $\{\tau_{1,j}\}$, $\{s_{1,j}\}$, $\{t_{1,j}\}$, it follows from Property P that

$$
\begin{aligned}
&\tau_1 \le s_1 \le t_1,\\
&x' \ge 0 \quad \text{on } (-\infty, \tau_1),\\
&x' \le 0 \quad \text{on } (\tau_1, t_1],\\
&x(t_1) = 0,\\
&y' \le 0 \quad \text{on } [\tau_1, s_1],\\
&y(s_1) = 0,\\
&y \le 0 \quad \text{on } (s_1, t_1],\\
&x \ge 0 \quad \text{on } (-\infty, t_1),
\end{aligned}
$$

where $x(t) = x(t; R)$ and $y(t) = y(t; R)$.

To establish that $p(.; R)$ has Property P, we only need to show

(a) $\tau_1 \neq s_1$,

(b) $s_1 \neq t_1$,

(c) $x \neq 0$ on $(-\infty, t_1)$,

(d) $x' \neq 0$ on $(-\infty, \tau_1)$,

(e) $y' \neq 0$ on (τ_1, s_1),

(f) $x' \neq 0$ on (τ_1, t_1),

(g) $y'(\tau_1) \neq 0$,

(h) $y \neq 0$ on (s_1, t_1),

(i) $y'(s_1) \neq 0$,

(j) $y(t_1) \neq 0$,

(k) $x'(t_1) \neq 0$.

We first derive an inequality at τ_1 which shows $p(.;R)$ is nontrivial and will be useful below. Let $Q_j(t) = z(t;R_j) - (x(t;R_j)^2/2s)$. Then

$$\begin{aligned} Q_j' &= -qz(t;R_j) + \left(1 - \frac{q}{2s}\right) x(t;R_j)^2, \\ Q_j'' + qQ_j' &= 2\left(1 - \frac{q}{2s}\right) x(t;R_j)x'(t;R_j), \\ Q_j'(t) &= 2\left(1 - \frac{q}{2s}\right) \int_{-\infty}^{t} e^{q(t-\tau)} x(\tau;R_j)x'(\tau;R_j)d\tau, \end{aligned}$$

and from Property P for $p(.;R_j)$, $Q_j'(\tau_{1,j}) > 0$. Thus $z'(\tau_{1,j};R_j) = Q_j'(\tau_{1,j}) > 0$. From (1.1), $y(\tau_{1,j};R_j) = x(\tau_{1,j};R_j)$ so from (1.3), $x^2(\tau_{1,j};R_j) > qz(\tau_{1,j};R_j)$. By P, $y'(\tau_{1,j};R_j) < 0$ so from (1.2) $(R_j - z(\tau_{1,j};R_j) - 1)x(\tau_{1,j};R_j) < 0$ which implies $z(\tau_{1,j};R_j) > R_j - 1$. Then $x^2(\tau_{1,j};R_j) > q(R_j - 1)$. In the limit $j \to \infty$,

$$x(\tau_1;R) = y(\tau_1;R) \geq (q(R-1))^{\frac{1}{2}} > 0. \tag{2.1}$$

We now establish (a)–(k) in order.

(a) If $\tau_1 = s_1$, then $y(\tau_1) = y(s_1) = 0$, contradicting (2.1). Therefore, $\tau_1 < s_1$.

(b) If $s_1 = t_1$, then $x(t_1) = y(t_1) = 0$ and (1.1), (1.2) imply $x(t) = y(t) = 0$ for all t, contradicting (2.1). Therefore, $s_1 < t_1$.

(c) Suppose there is a $t_0 < t_1$ such that $x(t_0) = 0$. By (2.1), $x(\tau_1) \neq 0$ so either $t_0 < \tau_1$ or $t_0 > \tau_1$. If $t_0 < \tau_1$, then as $x'(t) \geq 0$ on $(-\infty, \tau_0]$, $\int_{-\infty}^{t_0} x'(t)dt = x(t_0) = 0$ and x' is continuous, it follows that $x'(t) = 0$ on $(-\infty, t_0]$. Then $x(t) = 0$ on $(-\infty, t_0]$ and (1.1),(1.2) imply $x(t) = y(t) = 0$ for all t, contradicting (2.1).

If $\tau_1 < t_0 < t_1$, then as $x'(t) \leq 0$ on (τ_1, t_1), $\int_{-\infty}^{t_0} x'(t)dt = x(t_1) = 0$ and x' is continuous, it follows that $x'(t) = 0$ on $[t_0, t_1]$. Then (1.1),(1.2) imply $x(t) = y(t) = 0$ for all t, contradicting (2.1).

It follows that $x > 0$ on $(-\infty, t_1)$.

(d) Suppose there is a $\tau_0 < \tau_1$ such that $x'(\tau_0) = 0$.

We claim that $x''(0) = 0$. For, if $x''(0) \neq 0$, $x'(t)$ changes sign at τ_0 and this is impossible since $x' \geq 0$ on $(-\infty, \tau_1)$. We claim further that $x'''(\tau_0) \geq 0$. For, if $x'''(\tau_0) < 0$, then $x'(t) < 0$ for t near τ_0; again, this is impossible.

So now $x'(\tau_0) = x''(\tau_0) = 0$ and $x'''(\tau_0) \geq 0$. Equation (1.1) gives $y(\tau_0) = x(\tau_0)$, (1.1)$'$ gives $y'(\tau_0) = 0$, (1.1)$''$ gives $y''(\tau_0) = x'''(\tau_0)/s \geq 0$, and (1.2) then implies $(R - z(\tau_0) - 1)x(\tau_0) = 0$. But from (c), $x(\tau_0) > 0$ and so $z(\tau_0) = R - 1$. From (1.2)$'$, $y''(\tau_0) = -x(\tau_0)z'(\tau_0) \geq 0$ which implies $z'(\tau_0) \leq 0$.

Let $Q = z - (x^2/2s)$. Then as above $Q'(\tau_0) = (1 - \frac{q}{2s}) \int_{-\infty}^{\tau_0} 2e^{q(t-\tau)}x(\tau)x'(\tau)d\tau$. Since $x(\tau_0) > 0$, $x'(t) > 0$ for at least some $t < \tau_0$. From (c), $x(t) > 0$ on $(-\infty, \tau_0]$, and so $Q'(\tau_0) > 0$. But then $z'(\tau_0) = Q'(\tau_0) > 0$, and so we have a contradiction.

It follows that $x' > 0$ on $(-\infty, \tau_1)$.

(e) Suppose there is a σ_2, $\tau_1 < \sigma_2 < s_1$ such that $y'(\sigma_2) = 0$. We claim that $y''(\sigma_2) = 0$. For if $y''(\sigma_2) \neq 0$, $y'(t)$ changes sign at σ_2 which is impossible since $y' \leq 0$ on (τ_1, s_1).

We also claim that $y(\sigma_2) > 0$. For if $y(\sigma_2) = -\int_{\sigma_1}^{s_1} y'(\tau)d\tau = 0$, then, since $y' \leq 0$ on $[\tau_1, s_1]$ it follows that $y'(t) = 0$ for all $t \in [\sigma_2, s_1]$, so then $y(t) = 0$ on $[\sigma_2, s_1]$. Then (1.2) and (c) imply $z(t) = R$ on $[\sigma_2, s_1]$, and (1.3) gives $-qR = 0$, a contradiction.

So now $y'(\sigma_2) = y''(\sigma_2) = 0$ and $y(\sigma_2) > 0$. From (1.2), $y'(\sigma_2) = (R - z(\sigma_2))x(\sigma_2) - y(\sigma_2) = 0$. From (c), $x(\sigma_2) > 0$ so $z(\sigma_2) < R$. From (1.2)$'$, $y''(\sigma_2) =$

$(R-z)x'-xz'=0$ and it follows that $z'(\sigma_2)\le 0$. From (1.3)', $z''+qz'=x'y+xy'$, and so for all $t\in(\sigma_2,s_1)$, $e^{qt}z'(t)=e^{q\sigma_2}z'(\sigma_2)+\int_{\sigma_2}^{t}e^{q\tau}(x'y+xy')d\tau\le 0$. Therefore $z(s_1)\le z(\sigma_2)<R$. But at s_1, $y'(s_1)=(R-z)x\le 0$, so $z(s_1)\ge R$ a contradiction.

It follows that $y'<0$ on (τ_1,s_1).

(f) Suppose there is a $\tau_2\in(\tau_1,t_1)$ such that $x'(\tau_2)=0$.

If $\tau_2\in(\tau_1,s_1)$, then by the same argument as in (d), $x''(\tau_2)=0$. Then from (1.1)', $y'(\tau_2)=0$ contradicting (e).

If $\tau_2\in[s_1,t_1)$, $y(\tau_2)\le 0$. From (1.1) and (c), $y(\tau_2)=x(\tau_2)>0$, a contradiction.

If $\tau_2=t_1$, then (1.1), (1.2) imply $x(t)=y(t)=0$ for all t, contradicting (2.1).

It follows that $x'<0$ on (τ_1,t_1).

(g) Suppose $y'(\tau_1)=0$. Then from (1.1)', $x''(\tau_1)=0$.

We claim that $x'''(\tau_1)=0$. For otherwise x' does not change sign at τ_1, which we know happens by (d) and (f).

So now $x'(\tau_1)=x''(\tau_1)=x'''(\tau_1)=0$. From (1.1)'', $y''(t_1)=0$ as well. Then from (1.2)', $z'(\tau_1)=0$. But letting Q be as in (d), $z'(\tau_1)=Q'(\tau_1)=(1-\frac{q}{2s})\int_{-\infty}^{\tau_1}2e^{q(t-\tau)}x(\tau)x'(\tau)d\tau>0$ a contradiction.

Since we have shown that $y'(\tau_1)\neq 0$, and from (e) $y'(t)<0$ for t near τ_1, $t>\tau_1$, it follows that $y'(\tau_1)<0$.

(h) Suppose there is a point s_2, $s_1<s_2<t_1$ such that $y(s_2)=0$.

We claim that $y'(s_2)=0$ and $y''(s_2)\le 0$. For otherwise y changes sign at s_2, contradicting $y\le 0$ on (s_1,t_1).

So now $y(s_2)=y'(s_2)=0$ and $y''(s_2)\le 0$. From (1.2), $(R-z(s_2))x(s_2)=0$. By (c), $x(s_2)>0$ so $z(s_2)=R$. From (1.2)', $y''(s_2)=-z'(s_2)x(s_2)\le 0$ and so $z'(s_2)\ge 0$. But from (1.3), $z'(s_2)=-qz(s_2)=-qR<0$, a contradiction.

It follows that $y<0$ on (s_1,t_1).

(i) Suppose that $y'(s_1)=0$.

We claim that $y''(s_1)=0$. For if $y''(s_1)<0$, then $y'(t)>0$ for t near s_1, $t<s_1$ contradicting (e). If $y''(s_1)>0$, then $y(t)>0$ for t near s_1, $t>s_1$ contradicting (h).

So now $y(s_1)=y'(s_1)=y''(s_1)=0$. From (1.2), $(R-z(s_1))x(s_1)=0$. By (c), $x(s_1)>0$, so $z(s_1)=R$. Then from (1.2)', $z'(s_1)=0$. From (1.3), $z'(s_1)=-qz(s_1)=0$, so $z(s_1)=0$, a contradiction.

It follows that $y'(s_1)<0$.

(j) If $y(t_1)=0$, then since $x(t_1)=0$, (1.1), (1.2) give $x(t)=y(t)=0$ for all t contradicting (2.1). Therefore $y(t_1)\neq 0$.

It follows that $y(t_1)<0$.

(k) We have $x'(t_1)=s(y(t_1)-x(t_1))=sy(t_1)<0$ from (j). □

Proof of Lemma 2.2. First we construct a family of orbits $p(t;R)$, $R\in[R_a,R_b]$. Take $J=1$ in the hypotheses of Lemma 3.4. Then choose $\eta>0$ small enough so that the conditions of Lemma 3.4 are satisfied and furthermore $0<x(0;R)<y(0;R)$ and $z(0;R)<R-1$ for all $R\in[R_a,R_b]$ so the conditions of Lemma 3.5 are satisfied. Then by Lemmas 3.4 and 3.5, there exists a family of orbits $p(t;R), t\in(-\infty,0]$ such that $\lim_{t\to-\infty}p(t;R)=0$ and $x'(0;R)>0$ on $(-\infty,0]$. Furthermore $p(t;R)$ is jointly smooth in t and R.

By uniqueness of the unstable manifold, the hypothesized orbit for $R=R_b$ differs from $p(.;R_b)$ only by a phase shift, so $p(.;R_b)$ has Property P. Similarly, $p(.;R_a)$ has Property Q.

If an orbit $p(.;R), R>1$ has Property P, then we claim that all orbits $p(.;\rho)$ for ρ in some neighborhood of R also have Property P. One establishes this claim by first using the implicit function theorem and $x''(\tau_1(R);R)=sy'(\tau_1(R);R)<0$,

$y'(s_1(R);R) < 0$ and $x'(t_1(R);R) < 0$ to show the existence of $\tau_1(\rho)$, $s_1(\rho)$, and $t_1(\rho)$ such that $x'(\tau_1(\rho);\rho) = y(s_1(\rho);\rho) = x(t_1(\rho);\rho) = 0$. As $x'(t;\rho) > 0$ on $(-\infty, 0]$, $\tau_1(\rho) > 0$ and we may restrict our attention to the bounded set $[0, t_1(R)+1] \times [R_a, R_b]$. We omit further details.

Let

$$R^* = \inf\{R, R_a < R < R_b \text{ such that } p(.;R) \text{ has Property P}\}.$$

Then $p(.;R^*)$ does not have Property P. If $R^* = R_a$ this is immediate. If $R^* > R_a$ and $p(.;R^*)$ has Property P, then so do $p(.;\rho)$ for ρ sufficiently close to R^*,$\rho < R^*$ contradicting the definition of R^*.

Let $\{R_j\}$ be decreasing towards R^* and such that each $p(.;R_j)$ has Property P. Let $\{\tau_{1,j}\}$, $\{s_{1,j}\}$, and $\{t_{1,j}\}$ be the associated values such that $x'(\tau_{1,j};R_j) = y(s_{1,j};R_j) = x(t_{1,j};R_j) = 0$. By construction, $x'(t;R_j) > 0$ on $(-\infty, 0]$ and so $0 < \tau_{1,j} < s_{1,j} < t_{1,j}$ for each j.

We now claim $\{t_{1,j}\}$ is unbounded. For, if $\{t_{1,j}\}$ is bounded, so are $\{\tau_{1,j}\}$ and $\{s_{1,j}\}$ and we may extract convergent subsequences $\{t_{1,k}\}$, $\{\tau_{1,k}\}$, $\{s_{1,k}\}$, and define t_1, τ_1, s_1 as the limits. By Lemma 2.1, the orbit for $R = R^*$ would then have Property P, a contradiction.

So now $\{t_{1,j}\}$ is unbounded. Let $\{t_{1,j'}\}$ be a subsequence such that $t_{1,j'} \to \infty$. We claim that $\{\tau_{1,j'}\}$ is bounded. For suppose not. Then taking the limit $k' \to \infty$ over a subsequence of $\{j'\}$ such that $\tau_{1,k'} \to \infty$, the orbit $p(.;R^*)$ has the property that x is nondecreasing for all t. Since $0 < x(0;R^*)$, $p(.;R^*)$ is nontrivial and the only possibility is that $\lim_{t\to\infty} p(t;R^*) = p^+(R^*)$. By hypothesis, for all $R \in [R_a, R_b]$, $p^+(R)$ is a linearly stable stationary point. If $p(.;R^*)$ is a heteroclinic connection between $(0,0,0)^T$ and $p^+(R^*)$ and $x(t;R^*) > 0$ for all t, then for all R sufficiently close to R^*, $p(.;R)$ is a heteroclinic connection between $(0,0,0)^T$ and $p^+(R)$, and $x(t;R) > 0$ for all t. Then for all sufficiently large k' $p(.;R_{k'})$ does not have Property P. This contradicts the definition of R^*.

So now $\{\tau_{1,j'}\}$ is bounded. Let $\{\tau_{1,j''}\}$ be a subsequence such that

$$\tau_1 = \lim_{j''\to\infty} \tau_{1,j''}$$

exists. As $x'(t,R^*) = \lim_{j''\to\infty} x'(t;R_{j''})$, $x'(t) \le 0$ for $t > \tau_1$. So $x(t,R^*)$ is monotone when $t > \tau_1$ which implies $\lim_{t\to\infty} p(t,R^*) = p_\infty$ exists and is an equilibrum point. As $x(.;R^*) \ge 0$, the only possibilities are $p_\infty = p^+(R^*)$ and $p_\infty = (0,0,0)^T$. If $p_\infty = p^+(R^*)$, then $p(.;R^*)$ is a heteroclinic connection between $(0,0,0)^T$ and $p^+(R^*)$ which contradicts the definition of R^* by the same argument as above. Therefore $\lim_{t\to\infty} p(t,R^*) = (0,0,0)^T$, that is, $p(.;R^*)$ is a homoclinic orbit.

We now claim $\{s_{1,j''}\}$ is bounded. For if not, let $\{s_{1,k''}\}$ be a subsequence such that $s_{1,k''} \to \infty$, then $y'(t,R^*) = \lim_{k''\to\infty} y'(t,R_{k''}) \le 0$ for $t > \tau_1$. On the other hand, $y' = (z-R^*)x - y \ge (z-R^*-1)x$ when $t > \tau_1$. From $\lim_{t\to\infty} p(t,R^*) = (0,0,0)^T$, $z < R^* - 1$ when t is large. So one can find large t such that $y'(t) > 0$, which is a contradiction.

What remains to be shown are:

$$\begin{aligned} x' &\neq 0 \quad \text{on } (-\infty, \tau_1), \\ x' &\neq 0 \quad \text{on } (\tau_1, \infty), \\ y' &\neq 0 \quad \text{on } (\tau_1, s_1], \\ y &\neq 0 \quad \text{on } (s_1, \infty), \\ x &\neq 0 \quad \text{on } (-\infty, \infty). \end{aligned}$$

These inequalities are established the same way as in the proof of Lemma 2.1. □

3. Local approximation of the unstable manifold. Our objective in this section is to construct highly accurate approximations to solutions $p(t)$ of (1.1)–(1.3) with the property $\lim_{t\to-\infty} p(t) = (0,0,0)^T$. The construction also shows existence. The first step is a coordinate transformation.

Let $s' = s - 1$ and $d = ((s')^2 + 4sR)^{\frac{1}{2}}$. The eigenvalues of the Jacobian matrix for (1.1) at the origin are then $\lambda_1 = -q < 0$, $\lambda_2 = ((-(s+1) - d)/2) < 0$, and $\lambda_3 = ((-(s+1) + d)/2) > 0$. Let Λ denote the matrix whose columns are the eigenvectors $(0,0,1)^T$, $(1,c_2,0)^T$, and $(1,c_3,0)^T$ corresponding to λ_1, λ_2, and λ_3. Here $c_2 = ((s'-d)/2s) < 0$ and $c_3 = ((s'+d)/2s) > 0$. Let $c_1 = s/d > 0$. Setting $(x,y,z)^T = \Lambda w$, (1.1)–(1.3) becomes

$$\begin{aligned} \frac{dw_1}{dt} &= \lambda_1 w_1 + f_1 = \lambda_1 w_1 + (c_2 w_2 + c_3 w_3)(w_2 + w_3), \\ \frac{dw_2}{dt} &= \lambda_2 w_2 + f_2 = \lambda_2 w_2 + c_1 w_1 (w_2 + w_3), \\ \frac{dw_3}{dt} &= \lambda_3 w_3 + f_3 = \lambda_3 w_3 - c_1 w_1 (w_2 + w_3). \end{aligned} \tag{3.1}$$

We shall find solutions of (3.1) with the property $\lim_{t\to-\infty} w = (0,0,0)^T$, by solving the system of integral equations

$$\begin{aligned} w_1(t) &= \int_{\tau=-\infty}^{t} e^{\lambda_1(t-\tau)}(c_2 w_2(\tau) + c_3 w_3(\tau))(w_2(\tau) + w_3(\tau))d\tau, \\ w_2(t) &= \int_{\tau=-\infty}^{t} e^{\lambda_2(t-\tau)} c_1 w_1(\tau)(w_2(\tau) + w_3(\tau))d\tau, \\ w_3(t) &= \eta e^{\lambda_3 t} - \int_{\tau=t}^{0} e^{\lambda_3(t-\tau)} c_1 w_1(\tau)(w_2(\tau) + w_3(\tau))d\tau. \end{aligned} \tag{3.2}$$

To start, we define some functionals.

DEFINITION 3.1. For bounded continuous R^3-valued functions $u(t), v(t)$ on $(-\infty, 0]$ and for real η, let $\beta(u,v) = (\beta_1, \beta_2, \beta_3)^T$, $\varphi(u)$ and $\psi(u;\eta)$ denote the functionals

$$\begin{aligned} \beta_1(u,v)(t) &= \int_{-\infty}^{t} e^{\lambda_1(t-\tau)}(c_2 u_2(\tau) + c_3 u_3(\tau))(v_2(\tau) + v_3(\tau))d\tau, \\ \beta_2(u,v)(t) &= \int_{-\infty}^{t} e^{\lambda_2(t-\tau)} c_1 u_1(\tau)(v_2(\tau) + v_3(\tau))d\tau, \\ \beta_3(u,v)(t) &= -\int_{t}^{0} e^{\lambda_3(t-\tau)} c_1 u_1(\tau)(v_2(\tau) + v_3(\tau))d\tau, \end{aligned} \tag{3.3}$$

$$\varphi(u) = \beta(u,u), \tag{3.4}$$

$$\psi(u;\eta) = (0,0,\eta e^{\lambda_3 t})^T + \varphi(u). \tag{3.5}$$

The system (3.2) then becomes simply

$$w = \psi(w;\eta). \tag{3.6}$$

DEFINITION 3.2. Let $W^1 = (0, 0, \eta e^{\lambda_3 t})^T$, and for each $J \geq 2$, let

$$W^J(t) = W^{J-1}(t) + \frac{\eta^J}{J!} \frac{\partial^J \varphi(W^{J-1})(t)}{\partial \eta^J} \Big|_{\eta=0} . \tag{3.7}$$

We use W^J for some fixed J as the approximation to the unstable manifold for (3.1) at the origin. Our objective in the remainder of this section is to establish the error bound in Lemma 3.4. (U^J defined by $U^1 = W^1$, $U^j = \psi(U^{j-1}; \eta)$ for $2 \leq j < J$, has similar approximation properties to W^J but is impractical here since U^J is a polynomial of degree 2^{J-1} in η.)

LEMMA 3.1. *For each $J \geq 1$, the component functions $W_i^J, i = 1, 2, 3$ of W^J have the form*

$$W_i^J = \sum_{j=1}^{J} \eta^j \sum_{k=1}^{j} W_{ijk} \xi^k, \tag{3.8}$$

where $\xi = e^{\lambda_3 t}$ and the coefficients W_{ijk} are constants given recursively by (3.9), (3.10), *and* (3.12) *below.*

Proof. The components of W^1 are of the form (3.8): explicitly,

$$W_{111} = W_{211} = 0 \quad \text{and} \quad W_{311} = 1. \tag{3.9}$$

For $J \geq 2$, assume for induction that W^{J-1} has components of the form (3.8). From (3.1) the components of $f(W^{J-1})$ are then

$$f_i(W^{J-1}) = \sum_{j=1}^{2J-2} \eta^j \sum_{k=1}^{j} \xi^k f_{ijk}^{J-1},$$

where for $1 \leq i \leq 3$, $1 \leq j \leq 2J-2$, and $1 \leq k \leq j$,

$$\begin{aligned} f_{1jk}^{J-1} &= \sum_{j'+j''=j} \sum_{k'+k''=k} (c_2 W_{2j'k'} + c_3 W_{3j'k'})(W_{2j''k''} + W_{3j''k''}), \\ f_{2jk}^{J-1} &= \sum_{j'+j''=j} \sum_{k'+k''=k} c_1 W_{1j'k'} (W_{2j''k''} + W_{3j''k''}), \\ f_{3jk}^{J-1} &= -f_{2jk}^{J-1}, \end{aligned} \tag{3.10}$$

and $1 \leq j', j'', k', k'' \leq J-1$ in the summations and $f_{ijk}^{J-1} = 0$ when no terms are present. From (3.7), (3.4), and (3.2),

$$\begin{aligned} W_i^J &= W_i^{J-1} + \eta^J \int_{-\infty}^{t} e^{\lambda_i (t-\tau)} \sum_{k=2}^{J} e^{k\lambda_3 \tau} f_{iJk}^{J-1} d\tau \\ &= W_i^{J-1} + \eta^J \sum_{k=2}^{J} e^{k\lambda_3 t} \frac{f_{iJk}^{J-1}}{k\lambda_3 - \lambda_i}, \qquad i = 1, 2, \\ W_3^J &= W_3^{J-1} - \eta^J \int_{t}^{0} e^{\lambda_3 (t-\tau)} \sum_{k=2}^{J} e^{k\lambda_3 \tau} f_{3Jk}^{J-1} d\tau \\ &= W_3^{J-1} + \eta^J \sum_{k=2}^{J} (e^{k\lambda_3 t} - e^{\lambda_3 t}) \frac{f_{3Jk}^{J-1}}{k\lambda_3 - \lambda_3}. \end{aligned} \tag{3.11}$$

Replacing $e^{\lambda_3 t}$ with ξ in (3.11) shows that the functions W_i^J are of the form (3.8), where the new coefficients are

$$
\begin{aligned}
W_{iJk} &= \frac{f_{iJk}^{J-1}}{k\lambda_3 - \lambda_i}, \qquad 1 \le i \le 2,\ 1 \le k \le J, \\
W_{3J1} &= -\sum_{k=2}^{J} \frac{f_{3Jk}^{J-1}}{k\lambda_3 - \lambda_3}, \\
W_{3Jk} &= \frac{f_{3Jk}^{J-1}}{k\lambda_3 - \lambda_3}, \qquad 2 \le k \le J.
\end{aligned} \tag{3.12}
$$

This completes the induction. □

It is easy to show that the components of $\psi(W^J;\eta)$ are of the general form

$$\psi_i(W^J;\eta) = \sum_{j=1}^{2J} \eta^j \sum_{k=1}^{j} \xi^k \psi_{ijk}^J.$$

The purpose of the following two lemmas is to show that in fact $\psi_{ijk}^J = W_{ijk}$ for $1 \le j \le J$ and $1 \le k \le j$. The "$O(\eta^{J+1})$" reasoning is simply a quick way to achieve this result. The actual bounding argument does not appear until Lemma 3.4.

LEMMA 3.2. *For each $J \ge 2$, $\psi(W^{J-1};\eta) = W^J + O(\eta^{J+1})$ for any fixed $t \le 0$.*

Proof. For $J = 2$ this is true since $W^2 = \psi(W^1;\eta)$. Consider $J \ge 3$. For each $2 \le j \le J$, since $W^{j-1} = W^{J-1} + O(\eta^j)$,

$$
\begin{aligned}
\varphi(W^{j-1}) &= \beta(W^{J-1} + O(\eta^j), W^{J-1} + O(\eta^j)) = \beta(W^{J-1}, W^{J-1}) + O(\eta^{j+1}) \\
&= \varphi(W^{j-1}) + O(\eta^{j+1}),
\end{aligned}
$$

so

$$\frac{\partial^j}{\partial \eta^j} |_{\eta=0}\, \psi(W^{j-1}) = \frac{\partial^j}{\partial \eta^j} |_{\eta=0}\, \psi(W^{J-1}).$$

Now

$$\psi(W^{J-1};\eta) - W^J = \varphi(W^{J-1}) + W^1 - W^J = \varphi(W^{J-1}) - \sum_{j=2}^{J} \frac{\eta^j}{j!} \frac{\partial^j}{(\partial \eta)^j} |_{\eta=0}\, \varphi(W^{J-1}).$$

Since $W^{J-1} = O(\eta)$ the linear term in the Taylor expansion of $\varphi(W^{J-1})$ about $\eta = 0$ vanishes, and $\psi(W^{J-1};\eta) - W^J = O(\eta^{J+1})$ as desired. □

LEMMA 3.3. *For each $J \ge 2$,$\psi(W^J;\eta) = W^J + O(\eta^{J+1})$ for any fixed $t \le 0$, and the components of $\psi(W^J;\eta)$ are given by* (3.14)–(3.15) *below.*

Proof. Since $W^J = W^{J-1} + O(\eta^J)$,

$$
\begin{aligned}
\psi(W^J;\eta) &= \psi(W^{J-1} + O(\eta^J);\eta) = W^1 + \beta(W^{J-1} + O(\eta^J), W^{J-1} + O(\eta^J)) \\
&= W^1 + \beta(W^{J-1}, W^{J-1}) + O(\eta^{J+1}) = \psi(W^{J-1};\eta) + O(\eta^{J+1})
\end{aligned}
$$

so

$$\psi(W^J;\eta) - W^J = \psi(W^{J-1};\eta) - W^J + O(\eta^{J+1}) = O(\eta^{J+1})$$

follows from Lemma 3.2.

From (3.1) and (3.8) the components of $f(W^J)$ are of the form

$$f_i(W^J) = \sum_{j=1}^{2J} \eta^j \sum_{k=1}^{j} \xi^k f_{ijk}^J,$$

where for $1 \le i \le 3$, $1 \le j \le 2J$ and $1 \le k \le j$, f_{ijk}^J is given by the right sides of (3.10) but with $1 \le j', j'', k', k'' \le J$ in the summations. Using (3.2)–(3.7) and $\psi(W^J;\eta) = W^J + O(\eta^{J+1})$,

$$\begin{aligned}
\psi_i(W^J;\eta) &= \sum_{j=1}^{2J} \eta^j \int_{-\infty}^{t} e^{\lambda_i(t-\tau)} \sum_{k=1}^{j} e^{k\lambda_3\tau} f_{ijk}^J d\tau \\
&= W_i^J + \sum_{j=J+1}^{2J} \eta^j \sum_{k=1}^{j} e^{k\lambda_3 t} \frac{f_{ijk}^J}{k\lambda_3 - \lambda_i}, \qquad i = 1,2, \\
\psi_3(W^J;\eta) &= -\sum_{j=1}^{2J} \eta^j \int_{t}^{0} e^{\lambda_3(t-\tau)} \sum_{k=1}^{j} e^{k\lambda_3\tau} f_{3jk}^J d\tau \\
&= W_3^j + \sum_{j=J+1}^{2J} \eta^j \sum_{k=1}^{j} (e^{k\lambda_3 t} - e^{\lambda_3 t}) \frac{f_{3jk}^J}{k\lambda_3 - \lambda_3}.
\end{aligned} \tag{3.13}$$

Setting $e^{\lambda_3 t} = \xi$ in (3.13) gives

$$\psi_i(W^J;\eta) = W_i^J + \sum_{j=J+1}^{2J} \eta^j \sum_{k=1}^{j} \xi^k \psi_{ijk}^J, \qquad 1 \le i \le 3, \tag{3.14}$$

where for $J+1 \le j \le 2J$,

$$\begin{aligned}
\psi_{ijk}^J &= \frac{f_{ijk}^J}{k\lambda_3 - \lambda_i}, \qquad 1 \le i \le 2, 1 \le k \le j, \\
\psi_{3j1}^J &= -\sum_{k=2}^{J} \frac{f_{3jk}^J}{k\lambda_3 - \lambda_3}, \\
\psi_{3jk}^J &= \frac{f_{3jk}^J}{k\lambda_3 - \lambda_3}, \qquad 2 \le k \le J. \qquad \square
\end{aligned} \tag{3.15}$$

Definition of norms. For $u \in R^3$, we write $|u| = |u_1| + |u_2| + |u_3|$, and for continuous, R^3-valued functions $u(t)$ on $(-\infty, 0]$ we write $\|u\| = \sup_{t \le 0} |u(t)|$.

LEMMA 3.4. *Fix $J \ge 1$. Let $\rho > 0$ be such that $0 < K(\rho) < \frac{1}{2}$, where $K(\rho) = 2\rho((c_3/|\lambda_1|) + (c_1/|\lambda_2|) + (c_1/\lambda_3))$. Choose $\eta_0 > 0$ sufficiently small so that for all $|\eta| \le \eta_0$, the conditions $\|w^0\| \le \frac{\rho}{2}$ and $\|\psi(w^0;\eta) - w^0\| \le \frac{\rho}{4}$ are satisfied, where $w^0 = W^J(t,\eta)$. Then the sequence $w^n = \psi(w^{n-1};\eta)$, $n = 1,2,\ldots$, converges uniformly in t and η to a continuous, bounded solution $w(t)$ of the integral equation $w = \psi(w;\eta)$. Moreover, for each $t \le 0$ and $|\eta| \le \eta_0$,*

$$|w(t) - w^0(t)| \le (1 - K(\rho))^{-1} \sum_{i=1}^{3} \sum_{j=J+1}^{2J} |\eta|^j \sum_{k=1}^{j} \xi^k |\psi_{ijk}^J|, \tag{3.16}$$

where $\xi = e^{\lambda_3 t}$ *and the coefficients* ψ^J_{ijk} *are given by* (3.15).

Proof. If $u, v \in R^3$ obey $|u| \le \rho$ and $|v| \le \rho$, then since $|c_2| < c_3$,

$$\begin{aligned}|f_1(u) - f_1(v)| &= |(u_2+u_3)(c_2u_2+c_3u_3-c_2v_2-c_3v_3)+(u_2+u_3-v_2-v_3)(c_2v_2+c_3v_3)| \\ &\le |u|c_3|u-v| + |u-v|c_3|v| \le 2c_3\rho|u-v|,\end{aligned}$$

and

$$\begin{aligned}|f_2(u) - f_2(v)| = |f_3(u) - f_3(v)| &\le c_1|u_1(u_2+u_3-v_2-v_3)+(u_1-v_1)(v_2+v_3)| \\ &\le c_1(|u_1||u-v| + |u-v||v|) \le 2c_1\rho|u-v|.\end{aligned}$$

Using these inequalities (3.2) and (3.4), if $u(t)$ and $v(t)$ are continuous R^3-valued functions on $(-\infty, 0]$ and obey $\|u\| \le \rho$, $\|v\| \le \rho$, then for each $t \le 0$

$$\begin{aligned}|\varphi_1(u) - \varphi_1(v)| &\le \frac{2c_3\rho}{|\lambda_1|}\|u-v\|, \\ |\varphi_2(u) - \varphi_2(v)| &\le \frac{2c_1\rho}{|\lambda_2|}\|u-v\|, \\ |\varphi_3(u) - \varphi_3(v)| &\le \frac{2c_1\rho}{|\lambda_3|}\|u-v\|,\end{aligned}$$

so

$$\|\varphi(u) - \varphi(v)\| \le K(\rho)\|u-v\|.$$

By hypothesis $\|w^0\| \le \frac{\rho}{2}$ and $\|w^1 - w^0\| \le \frac{\rho}{4}$, so $\|w^1\| \le \|w^0\| + \|w^1 - w^0\| \le \frac{3\rho}{4}$. Then $\|w^2 - w^1\| \le K(\rho)\|w^1 - w^0\| < \frac{\rho}{8}$ which implies $\|w^2\| \le \|w^1\| + \frac{\rho}{8} \le \frac{7\rho}{8}$.

Assume for induction that $\|w^k\| \le \rho(1 - 2^{-(k+1)})$ for $0 \le k \le n$. Then

$$\begin{aligned}\|w^{n+1} - w^n\| = \|\varphi(w^n) - \varphi(w^{n-1})\| &\le K(\rho)\|w^n - w^{n-1}\| \\ &\le K(\rho)^n\|w^1(t) - w^0(t)\| \le 2^{-(n+2)}\rho,\end{aligned}$$

and so $\|w^{n+1}\| \le \rho(1 - 2^{-(n+2)})$ completing the induction. Therefore $\|w^n\| < \rho$ for all n. For any pair $m \ge n$,

$$\|w^m - w^n\| \le \sum_{k=n}^{m-1} \|w^{k+1} - w^k\| \le \sum_{k=n}^{m-1} 2^{-(k+2)}\rho < 2^{-(n+1)}\rho,$$

so the sequence is Cauchy uniformly for $t \le 0$ and $|\eta| \le \eta_0$. Define w as the limit of the sequence. Then $w(t)$ is bounded, continuous in t and η, and

$$\|w^{n+1} - w^0\| \le \sum_{k=0}^{n} \|w^{k+1} - w^k\| \le \sum_{k=0}^{n} K(\rho)^k\|w^1 - w^0\| < (1 - K(\rho))^{-1}\|w^1 - w^0\|$$

so

$$\|w - w^0\| \le (1 - K(\rho))^{-1}\|w^1 - w^0\| \le \frac{\rho}{2}. \tag{3.17}$$

Since $w^{n+1} = \psi(w^n; \rho)$, $\|w^n\| \le \rho$ and $\|w\| \le \|w^0\| + \|w - w^0\| \le \rho$,

$$\|w - \psi(w;\eta)\| \le \|w - w^{n+1}\| + \|\psi(w^n;\eta) - \psi(w)\| \le \|w - w^{n+1}\| + K(\rho)\|w^n - w\|$$

from which $w = \psi(w;\eta)$. Immediately, w solves (3.1), $p = \Lambda w$ solves (1.1)–(1.3) and

$$\lim_{t\to-\infty} p(t) = V(\lim_{t\to-\infty} w(t)) = (0,0,0)^T.$$

Now from (3.14),

$$w_i^1 - w_i^0 = \psi_i(W^J;\eta) - W_i^J = \sum_{j=J+1}^{2J} \eta^j \sum_{k=1}^{j} \xi^k \psi_{ijk}^J, \qquad 1 \le i \le 3, \tag{3.18}$$

where $\xi = e^{\lambda_3 t}$ and the coefficients ψ_{ijk} are given by (3.15). The bound

$$|w - W^J| \le (1 - K(\rho))^{-1} \sum_{i=1}^{3} \sum_{j=J+1}^{2J} |\eta|^j \sum_{k=1}^{j} \xi^k |\psi_{ijk}^J| \tag{3.19}$$

then follows using (3.17). □

To apply Lemma 3.4, J is chosen and the coefficients W_{ijk}, $1 \le i \le 3$, $1 \le j \le J$, $1 \le k \le j$ and ψ_{ijk}^J, $1 \le i \le 3$, $J+1 \le j \le 2J$, $1 \le k \le j$ are computed. Then η is chosen, and the expressions

$$B_0 = \sum_{i=1}^{3} \sum_{j=1}^{J} |\eta|^j \sum_{k=1}^{j} |W_{ijk}|,$$

$$B_1 = \sum_{i=1}^{3} \sum_{j=J+1}^{2J} |\eta|^j \sum_{k=1}^{j} |\psi_{ijk}^J|$$

are computed. These bound $\|w^0\|$ and $\|w^1 - w^0\|$, respectively. Then for $\rho = \max(2B_0, 4B_1)$, $K(\rho)$ is evaluated. If $K(\rho) \ge \frac{1}{2}$, it is necessary to choose a smaller η. Assuming $K(\rho) < \frac{1}{2}$, the expressions

$$W_i^J(0) = \sum_{j=1}^{J} \eta^j \sum_{k=1}^{j} W_{ijk}, \qquad 1 \le i \le 3$$

are evaluated, and then

$$w_i(0) \in \bar{w}_i = \left[W_i^J(0) - \frac{B_1}{1-K(\rho)}, W_i^J(0) + \frac{B_1}{1-K(\rho)} \right], \qquad 1 \le i \le 3.$$

For example, if $s = 10$, $R = 15$, and $q = \frac{8}{3}$, one finds that $\lambda_1 = -2.666667$, $\lambda_2 = -18.548$, $\lambda_3 = 7.548$, $c_1 = 0.3832, c_2 = -0.8548$, and $c_3 = 1.7548$, the numeric values in this example being precise in the sense that the absolute errors do not exceed $\frac{1}{2}$ unit in the last decimal place shown. Then for $J = 2$,

$$w^0 = (0.0988\eta^2\xi^2, 0, \eta\xi)^T$$

$$\psi(w^0;\eta) = w^0 + (0, 0.000919\eta^3\xi^3, 0.00251\eta^3(1-\xi^3))^T.$$

Choosing $\eta = \frac{1}{10}$, we find that $\|w^0\| \le B_0 = 0.10098815$ and $\|w^1 - w^0\| \le B_1 = 0.0000059367$. Then for $\rho = \max(2B_0, 4B_1) = 0.2019763$, $K(\rho) = 0.2947 < \frac{1}{2}$, so Lemma 3.4 applies. Now $w^0(0) = (0.000988, 0, 0.1)^T$, and $w(0)$ obeys $|w(0) - w^0(0)| \le B_1/(1 - K(\rho)) \le 0.0000084171$, from which $x(0) = w_2(0) + w_3(0) \in \bar{x} = [0.0999, 0.1001]$, $y(0) = c_2 w_2(0) + c_3 w_3(0) \in \bar{y} = [0.1754, 0.1756]$ and $z(0) = w_1(0) \in \bar{z} = [0.0009, 0.0011]$.

Lemma 3.4 shows existence of solutions $p(t) = (x, y, z)^T = \Lambda(R)w$ of (1.1)–(1.3), defined on $(-\infty, 0]$ and such that $\lim_{t\to-\infty} p(t) = 0$. Then, thanks to the invariant set V, the solutions $p(t)$ may be continued to $(-\infty, \infty)$. To have Property P or Q, the solutions must also satisfy $x' > 0$ for $t < \tau_1$, where $x'(\tau_1) = 0$. By choosing η sufficiently small positive, we can arrange that $x' > 0$ on $(-\infty, 0]$ as in the following lemma, which implies that any τ_1 such that $x'(\tau_1) = 0$ must be positive.

LEMMA 3.5. *Let* $p(t) = (x(t), y(t), z(t))^T$, $t \in (-\infty, 0]$ *be a solution of* (1.1)–(1.3) *such that* $0 < x(0) < y(0)$, $z(t) < R - 1$ *on* $(-\infty, 0]$ *and* $x(t) \to 0$ *as* $t \to -\infty$. *Then* $x' > 0$ *on* $(-\infty, 0]$.

Proof. From (1.1), $x'(0) = s(y(0) - x(0)) > 0$, so $x' > 0$ for $t < 0$ near 0.

Suppose for contradiction that there exist point(s) $\tau < 0$ at which $x'(\tau) = 0$. At any such point, $x(\tau) \neq 0$, for if $x(\tau) = 0$ the solution of (1.1) and (1.2) would be just $x(t) = y(t) = 0$ for all t and inconsistent with $x(0) < y(0)$. Therefore $x''(\tau) = sy'(\tau) = sx(\tau)(R - 1 - z(\tau)) \neq 0$, $\operatorname{sgn}(x(\tau)) = \operatorname{sgn}(x''(\tau)) \neq 0$, and x' changes sign at τ. Let

$$\tau^* = \sup\{\tau < 0 | x'(\tau) = 0\}.$$

Then x' changes sign at τ^* and is of one sign (positive) on $(\tau^*, 0)$. Since $x''(\tau^*) \neq 0$ and $x'(t) > 0$ for $t > \tau^*$ near τ^*, necessarily $x''(\tau^*) > 0$ and so $x(\tau^*) > 0$. For $t < \tau^*$ near τ^*, $x'(t) < 0$. Now $x'(t)$ must change sign on $(-\infty, \tau^*)$, for otherwise $x(t)$ would be monotone decreasing on $(-\infty, \tau^*)$, inconsistent with $\lim_{t\to-\infty} x(t) = 0$ and $x(\tau^*) > 0$. Let

$$\tau^{**} = \sup\{t < \tau^*, x'(t) = 0\}.$$

Then x' is of one sign (negative) on (τ^{**}, τ^*) and changes sign at τ^{**}. Necessarily $x''(\tau^{**}) < 0$, which implies $x(\tau^{**}) < 0$. This is a contradiction, since one cannot have $x(\tau^{**}) < 0, x(\tau^*) > 0$, and $x'(t) < 0$ on (τ^{**}, τ^*).

We have shown that x' has no zeros on $(-\infty, 0]$. Since $x'(0) > 0$, it follows that $x' > 0$ on $(-\infty, 0]$. □

4. The solutions for $t > 0$. In [1], Aberth describes an algorithm for computing the solutions of initial value problems "precisely." The algorithm is a Taylor series method using interval arithmetic, and applies to ordinary differential systems in which the functions defining the derivatives are elementary. In [1], algorithms and programs are given for first- and second-order systems. The generalization to systems of n first-order equations is more recent and is coded as program difsys.cc; see the discussion. Modifications of difsys were required to obtain the information needed for present purposes. The basic task in difsys to advance the solution to $t_{k'} = t_k + h$ and determine bounds for $x(t_{k'}), y(t_{k'}), z(t_{k'})$. Before a trial interval $[t_k, t_k + h]$ is accepted as a "bounding interval," an associated containment region is constructed. The first two modifications we made to the algorithm were as follows:

M_1: reject a trial interval unless the containment region guarantees
at least one of x, x' is of one sign on the interval, and
at least one of y, y' is of one sign on the interval, and

at least one of z, z' is of one sign on the interval.

M_2: reject a trial interval unless the containment region guarantees
at least one of x', x'' is of one sign on the interval, and
at least one of y', y'' is of one sign on the interval, and
at least one of z', z'' is of one sign on the interval.

We also added code to compute intervals $I_k^0 \supset x(t_k)x(t_{k'})$, $J_k^0 \supset y(t_k)y(t_{k'})$, $K_k^0 \supset z(t_k)z(t_{k'})$, $I_k^1 \supset x'(t_k)x'(t_{k'})$, $J_k^1 \supset y'(t_k)y'(t_{k'})$,and $K_k^1 \supset z'(t_k)z'(t_{k'})$. The last two modifications are

M_3: if $I_k^0 < 0$, print a message "x changes sign,"
if $J_k^0 < 0$, print a message "y changes sign,"
if $K_k^0 < 0$, print a message "z changes sign,"
if I_k^0, J_k^0 or K_k^0 overlaps 0, print a message that this happens.

M_4: if $I_k^1 < 0$, print a message "x' changes sign,"
if $J_k^1 < 0$, print a message "y' changes sign,"
if $K_k^1 < 0$, print a message "z' changes sign,"
if I_k^1, J_k^1 or K_k^1 overlaps 0, print a message that this happens.

Here $I_k^0 > 0$ (respectively, < 0) means every point in I_k^0 is positive (respectively, negative), and "I_k^0 overlaps zero" means $0 \in I_k^0$.

Suppose that the modified code has accepted a bounding interval $[t_k, t_{k'}]$ and has successfully computed an approximate solution on this interval, and no messages from M_3 appear. Then we claim that $x(t)$ is either strictly positive or strictly negative on $[t_k, t_{k'}]$. For, as M_3 issued no message, neither $I_k^0 < 0$ nor I_k^0 overlaps zero, so $I_k^0 > 0$. Therefore, $x(t_k)x(t_{k'}) > 0$ and x does not vanish at either endpoint. Since the interval $[t_k, t_{k'}]$ passed the test M_1, the containment region guarantees that at least one of x, x' is of one sign on the interval. If x is of one sign, then $\operatorname{sgn}(x(t)) = \operatorname{sgn}(x(t_k)) \neq 0$ for all $t \in [t_k, t_{k'}]$ and we are done. If x' is of one sign, so then $x(t)$ is monotonic (increasing or decreasing) from $x(t_k)$ to $x(t_{k'})$, where $x(t_k)$ and $x(t_{k'})$ are of the same sign, and so again $\operatorname{sgn}(x(t)) = \operatorname{sgn}(x(t_k))$ for all $t \in [t_k, t_{k'}]$. Similarly if no messages from M_3 appear, $y(t)$ and $z(t)$ are strictly positive or negative on $[t_k, t_{k'}]$.

If the message "x changes sign" appears, then $x(t_k)x(t_{k'}) < 0$ so $x(t_k)$ and $x(t_{k'})$ are of opposite signs and $x(t)$ has at least one zero in the interval. In this case, since the interval passed the test M_1, necessarily x' is of one sign on the interval and it follows that $x(t)$ changes sign at exactly one point, an interior point, of the interval. Messages "y changes sign" and "z changes sign" are similarly interpreted. If no messages from M_4 appear for a bounding interval $[t_k, t_{k'}]$, by a similar argument $x'(t), y'(t)$ and $z'(t)$ are each of one sign on the interval. If a message "x' changes sign" appears, then x' is strictly monotonic on the interval and has a zero at an interior point. Messages "y' changes sign" and "z' changes sign" are interpreted similarly. If any messages that $I_k^0, J_k^0, K_k^0, I_k^1, J_k^1$ or K_k^1 overlap 0 should appear, it is necessary to repeat the computation at a higher precision.

We now state the numerical results as follows.

LEMMA 4.1. *For each set of values s, q, R in Table 1, the Lorenz system has an orbit $p(t)$ with the Property Q, and for each set of values s, q, R in Table 2, the Lorenz system has an orbit $p(t)$ with Property P.*

$t_f = 1.72$ (exact)

Proof. For each triple (s, q, R) shown in Tables 1 and 2,[1] we chose J and and computed intervals $\bar{x}(0)$, $\bar{y}(0)$, $\bar{z}(0)$ guaranteed by Lemma 3.4 to contain a point $x(0)$, $y(0)$, $z(0)$ of a trajectory of the Lorenz system such that $x(t) \to 0$ as $t \to -\infty$. This was done with a short program in C++ using the Aberth–Schaefer interval arithmetic package. Input data consists of the parameters q, R, s, the integer J, $\eta = w_3(0) > 0$, and an integer determining the precision of the arithmetic. Output consists of the information, whether or not η was chosen sufficiently small for the hypotheses of

[1]The notation "$\sim$" in the tables indicates intervals having midpoint of the given decimal number and half-width one unit of the last decimal place. The absolute error in decimal values given does not exceed $\frac{1}{2}$ unit in the last decimal place.

Lemma 3.4 to be satisfied, and if they are, the initial condition intervals $\bar{x}(0), \bar{y}(0), \bar{z}(0)$ and bounds B_0, B_1 on $\|w^0\|$ and $\|w^1 - w^0\|$. All this data is shown in the tables. Examining $\bar{x}(0)$ and $\bar{y}(0)$, since $x(0) \in \bar{x}(0)$ and $y(0) \in \bar{y}(0)$ it follows that $0 < x(0) < y(0)$. Since $|z(t)| = |w_1(t)|$, it follows that $|z(t)| < \|p(t)\| \leq \rho = \max(2B_0, 4B_1) = 2B_0 < R - 1$ for all $t < 0$. From Lemma 3.5 we conclude that $x'(t) > 0$ on $(-\infty, 0]$, which implies $x(t) > 0$ on $(-\infty, 0]$.

Using Aberth's code difsys with modifications M_1 through M_4 described above, we computed trajectories of the Lorenz system for $t > 0$, taking $\bar{x}(0), \bar{y}(0), \bar{z}(0)$ as interval-valued initial conditions. The integrations were carried out until either

(1) the sign change message showed that the orbit had Property P;

(2) the sign change message showed that the orbit had Property Q;

(3) the computation failed due to determine whether the orbit had Property P or Q.

Data corresponding to successful computations was then entered in the Tables 1 and 2. □

We now state our result concerning a homoclinic orbit for (1.1).

THEOREM 4.2. *For* $s = 10$, $q = \frac{8}{3}$ *and some* R^*, $R_a < R_* < R_b$, *where* $R_a = 13.9265$ *is the maximum of the* R *values in Table* 1 *and* $R_b = 13.927$ *is the minimum of the values in Table* 2, *the Lorenz system has an orbit* $p(t)$ *such that* $\lim_{t\to-\infty} p(t) = \lim_{t\to\infty} p(t) = (0,0,0)^T$, *and there are numbers* $\tau_1 < s_1$ *such that*

$$
\begin{aligned}
&x' > 0 \quad \text{on } (-\infty, \tau_1),\\
&y(\tau_1) < 0,\\
&x' < 0 \quad \text{on } (\tau_1, \infty),\\
&y' < 0 \quad \text{on } [\tau_1, s_1],
\end{aligned}
$$

$$
\begin{aligned}
&y(s_1) = 0,\\
&y < 0 \quad \text{on } (s_1, \infty),\\
&x > 0 \quad \text{on } (-\infty, \infty).
\end{aligned}
$$

Proof. It is easily verified that $p^+(R)$ is linearly stable for all $R \in [R_a, R_b]$. The proof then follows immediately from Lemmas 2.2 and 4.1. □

5. Discussion. The present methods do not obtain an approximation to the homoclinic orbit valid on $(-\infty, \infty)$; to do this, one could approximate trajectories in the stable manifold much as in §3.

We expect that some details of the "homoclinic explosion" in the Lorenz system could be established rigorously by methods similar to those used here.

The present work is ostensibly numerical, while [2] and [3] are analytical. However, this distinction is blurry. Hastings and Troy use calculator computations, and allow margins in their bounds to account for possible roundoff errors. They approximate the unstable manifold, and shoot, generating bounds on the trajectories. Here we do the same, except that we use an interval-arithmetic package and methods of precise numerical analysis to obtain the bounds automatically.

The condition in Lemma 2.2 that $p^+(R)$ is linearly stable could be dropped if we adopted part of the argument in [2,3]. We retain the condition because it simplifies the argument and holds for the present parameter values.

Together with Hastings and Troy [4] we have recently demonstrated the existence of an infinite set of solutions of (1.1) with certain properties of chaos, for $R = 76$, $s = 10$, $q = 9$. The verification of condition A in [4] used the present methods.

Aberth has made the Aberth–Schaefer interval arithmetic package, including the code difsys.cc, publicly available by anonymous ftp from math.tamu.edu, as file pub/range/range.tar.Z.

Acknowledgments. We wish to thank S. P. Hastings for suggesting the problem, O. Aberth for his most useful interval analysis codes, and both for helpful discussions.

THE ADDITION FORMULA FOR CONTINUOUS q-LEGENDRE POLYNOMIALS AND ASSOCIATED SPHERICAL ELEMENTS ON THE $SU(2)$ QUANTUM GROUP RELATED TO ASKEY–WILSON POLYNOMIALS*

H. T. KOELINK†

Abstract. The known interpretation of a two-parameter family of Askey–Wilson polynomials as spherical elements on the $SU(2)$ quantum group is extended to an interpretation of a three-parameter (one discrete parameter) family of Askey–Wilson polynomials as associated spherical elements on the $SU(2)$ quantum group. An abstract addition formula, i.e., an expression involving noncommuting variables, for the two-parameter class of Askey–Wilson polynomials is obtained by this interpretation. Specialization gives an abstract addition formula for the continuous q-Legendre polynomials from which the ordinary Rahman–Verma addition formula for continuous q-Legendre polynomials is obtained.

Key words. quantum group, $SU(2)$, associated spherical elements, Askey–Wilson polynomials, continuous q-Legendre polynomials, addition formula

AMS subject classifications. 33A65, 33A75, 22E70

1. Introduction.

The interpretation of special functions of q-hypergeometric type on quantum groups, cf. [8] for a survey, started with the interpretation of the little q-Jacobi polynomials as matrix elements of irreducible unitary representations of the quantum group $SU_q(2)$; see Vaksman and Soibelman [15], Masuda et al. [11], [12], and Koornwinder [7]. The Schur orthogonality relations for the quantum group $SU_q(2)$ are equivalent to the orthogonality relations for the little q-Jacobi polynomials. Koornwinder [9] then used this quantum group interpretation to obtain an addition formula for the little q-Legendre polynomials which was not known until then. Later Koornwinder [8], [10] gave an interpretation of a two-parameter family of Askey–Wilson polynomials on the quantum group $SU_q(2)$. For a suitable choice of parameters we get a quantum group interpretation of the continuous q-Legendre polynomials for which an addition formula has been proved analytically by Rahman and Verma [14]. The main goal of this paper is to show that this addition formula can also be proved by use of the quantum group $SU_q(2)$.

This paper is closely related to Koornwinder's paper [10], and we assume the reader is familiar with §§2–5 of [10]. In §2 we start with the introduction of so-called associated (σ,τ)-spherical elements in the quantized algebra $\mathcal{A}_q$ of polynomials on $SU(2)$. These elements are invariant under the left action of some fixed element of the quantized universal enveloping algebra $\mathcal{U}_q$, and they transform in some nice ways under the right action of another fixed element of $\mathcal{U}_q$. It is proved that an associated (σ,τ)-spherical element multiplied in $\mathcal{A}_q$ from the right by a (σ,τ)-spherical element, cf. [8] and [10], is again an associated (σ,τ)-spherical element of the same sort. Then we can write an associated (σ,τ)-spherical element as some sort of minimal associated (σ,τ)-spherical element times a polynomial in $\rho_{\sigma,\tau}$, the generator of the algebra of (σ,τ)-spherical elements on $SU_q(2)$. For some suitable choice of associated (σ,τ)-spherical elements these polynomials yield systems of orthogonal polynomials.

*Received by the editors August 8, 1990; accepted for publication February 10, 1993.

†Departement of Mathematics, Catholic University of Leuven, Celestijnenlaan 200B, B-3001 Heverlee, Belgium.

In §3 we determine these polynomials, which turn out to be Askey–Wilson polynomials of two continuous and one discrete parameter. This interpretation of Askey–Wilson polynomials on $SU_q(2)$ is the second main result of this paper. The Haar functional and the Schur orthogonality relations are used to identify the polynomials mentioned in the previous paragraph as these Askey–Wilson polynomials. In this section we also show how to obtain an abstract addition formula, i.e., an identity involving noncommuting variables for a two-parameter class of Askey–Wilson polynomials by application of the comultiplication on such an Askey–Wilson polynomial in $\rho_{\sigma,\tau}$. Actually, we obtain an expansion in terms of associated (σ,τ)-spherical elements and thus in terms of Askey–Wilson polynomials of two continuous and one discrete parameter.

The difficult part is to obtain an addition formula in commuting variables from this abstract addition formula, and until now we can only do this for the special case of the continuous q-Legendre polynomial. In §4 we show how it can be done, by exploiting the fact that the abstract addition formula is essentially a development in associated (σ,τ)-spherical elements. Apart from this, only one-dimensional representations of the algebra $\mathcal{A}_q$ are used, which contrast with the quantum group theoretic proof of the addition formula for the little q-Legendre polynomials (cf. [9]), where only infinite-dimensional representations of the algebra $\mathcal{A}_q$ are used. For the continuous q-Legendre polynomials the addition formula has already been proved analytically by Rahman and Verma [14], where it occurs as a special case of the addition formula for the continuous q-ultraspherical polynomials. Section 5 is devoted to the limit case $q \uparrow 1$ of the proof presented in §4. The proof reduces to evaluation of functions on $SU(2)\times SU(2)$, which is used in [16, Chap. 3.4] to prove the addition formula for Legendre polynomials from a group theoretic point of view.

In this paper a lot of constants have to be calculated, and the reader is urged to skip these straightforward, but sometimes tedious calculations at first reading.

The results contained in §§2 and 3 have also been obtained by Noumi and Mimachi in a slightly different but more general setting. At the end of each section we compare our work with the results of their announcement [13].

Notation: $\mathbf{Z}_+$ denotes the nonnegative integers $\{0,1,2,3,\ldots\}$.

2. Associated (σ,τ)-spherical elements on $SU_q(2)$. In this section associated (σ,τ)-spherical elements on $SU_q(2)$ are defined. These elements can be expressed explicitly in terms of the matrix elements $t^l_{m,n}$ of the irreducible unitary representations of $SU_q(2)$ using dual q-Krawtchouk polynomials. Next we prove that all associated (σ,τ)-spherical elements can be expressed as some minimal associated (σ,τ)-element times a polynomial in $\rho_{\sigma,\tau}$. These polynomials form a system of orthogonal polynomials with respect to some moment functional.

Recall from [10, §4] the definitions

$$X_\sigma = iq^{\frac{1}{2}}B - iq^{-\frac{1}{2}}C - \frac{q^{-\sigma}-q^{\sigma}}{q^{-1}-q}(A-D) \in \mathcal{U}_q, \qquad \sigma \in \mathbf{R},$$

and

$$\begin{aligned}\rho_{\sigma,\tau} =& \tfrac{1}{2}\big(\alpha^2+\delta^2+q\gamma^2+q^{-1}\beta^2+i(q^{-\sigma}-q^{\sigma})(q\delta\gamma+\beta\alpha)\\ &-i(q^{-\tau}-q^{\tau})(\delta\beta+q\gamma\alpha)+(q^{-\sigma}-q^{\sigma})(q^{-\tau}-q^{\tau})\beta\gamma\big),\end{aligned}$$

as well as that for all polynomials p we have

$$X_\sigma.p(\rho_{\sigma,\tau}) = 0 = p(\rho_{\sigma,\tau}).X_\tau.$$

DEFINITION 2.1. *An element $b \in \mathcal{A}_q$ is an associated (σ,τ)-spherical element if there exists $\lambda \in \mathbf{C}$ so that*

$$X_\sigma.b = 0, \qquad b.X_\tau = \lambda b.D. \tag{2.1}$$

For $\lambda = 0$ we obtain the (σ,τ)-spherical elements as defined by Koornwinder [8], and we will first investigate the relation between (σ,τ)-spherical elements and associated (σ,τ)-spherical elements.

PROPOSITION 2.2. *Suppose $b \in \mathcal{A}_q$ satisfies (2.1), and let $a \in \mathcal{A}_q$ be a (σ,τ)-spherical element. Then ba satisfies (2.1) with the same λ.*

Proof. Because of [10, eq. (3.10), Lem. 3.1] and (2.1) we find

$$X_\sigma.(ba) = (A.b)(X_\sigma.a) + (X_\sigma.b)(D.a) = 0.$$

Similarly we find

$$(ba).X_\tau = (b.A)(a.X_\tau) + (b.X_\tau)(a.D) = \lambda(b.D)(a.D),$$

and this equals $\lambda(ba).D$ because of [10, eq. (3.10)] and $\Delta(D) = D \otimes D$. □

PROPOSITION 2.3. *If $b \in \mathcal{A}_q$ is an associated (σ,τ)-spherical element with $\lambda \in \mathbf{R}$, then b^*b is a (σ,τ)-spherical element.*

Proof. To prove this proposition we will first consider $X_\sigma.b^*$ and $b^*.X_\tau$. To do this we need the duality between the Hopf $*$-algebras $\mathcal{A}_q$ and $\mathcal{U}_q$. In particular, we have (cf. [10, eq. (3.6)])

$$\langle X, a^* \rangle = \overline{\langle S(X)^*, a \rangle} \quad \forall\, X \in \mathcal{U}_q \quad \forall\, a \in \mathcal{A}_q. \tag{2.2}$$

It easily follows from [10, eqs. (3.3) and (3.4)] that $S(X_\sigma)^* = -X_\sigma$ and $S(A)^* = D$. If we write

$$\Delta(b) = \sum_{(b)} b_{(1)} \otimes b_{(2)},$$

then we have by [10, eq. (3.8)], (2.2), and (2.1),

$$\begin{aligned} X_\sigma.b^* &= \sum_{(b)} b^*_{(1)} \langle X_\sigma, b^*_{(2)} \rangle = -\sum_{(b)} b^*_{(1)} \overline{\langle X_\sigma, b_{(2)} \rangle} \\ &= -\left(\sum_{(b)} b_{(1)} \langle X_\sigma, b_{(2)} \rangle \right)^* = -(X_\sigma.b)^* = 0. \end{aligned} \tag{2.3}$$

Similarly we find

$$\begin{aligned} b^*.X_\tau &= -(b.X_\tau)^* = -\overline{\lambda}(b.D)^* = -\overline{\lambda} \sum_{(b)} \overline{\langle D, b_{(1)} \rangle} b^*_{(2)} \\ &= -\overline{\lambda} \sum_{(b)} \langle A, b^*_{(1)} \rangle b^*_{(2)} = -\overline{\lambda} b^*.A. \end{aligned} \tag{2.4}$$

Now we are able to prove the proposition. Using [10, eq. (3.10)], (2.1), and (2.3), we have

$$X_\sigma.(b^*b) = (A.b^*)(X_\sigma.b) + (X_\sigma.b^*)(D.b) = 0,$$

and similarly, using (2.4) instead of (2.3), we obtain

$$(b^*b).X_\tau = (b^*.A)(b.X_\tau) + (b^*.X_\tau)(b.D) = (\lambda - \overline{\lambda})(b^*.A)(b.D).$$

This yields zero for $\lambda \in \mathbf{R}$. □

In a moment we will see that there are no nonzero-associated (σ,τ)-spherical elements with nonreal λ in (2.1), so Proposition 2.3 applies to all associated (σ,τ)-spherical elements on $SU_q(2)$.

Now [10, eqs. (3.18) and (3.19)] shows that $X_\sigma.$ and $.X_\tau$ preserve the linear span of the matrix elements $t^l_{n,m}$, $n,m \in \{-l,\dots,l\}$, and hence it is sufficient to look for associated (σ,τ)-spherical elements b of the form

$$\sum_{n,m=-l}^{l} \gamma_{nm} t^l_{n,m}.$$

In this case (2.1) is equivalent to (cf. [10, Lem. 3.4])

$$t^l(X_\sigma)\sum_{m=-l}^{l}\gamma_{nm}e^l_m = 0 \quad \forall n, \qquad t^l(X_\tau A)\sum_{n=-l}^{l}\overline{\gamma_{nm}}e^l_n = \overline{\lambda}\sum_{n=-l}^{l}\overline{\gamma_{nm}}e^l_n \quad \forall m, \tag{2.5}$$

since $(X_\tau A)^* = X_\tau A$. From [10, Lem. 4.6] we know that $\ker(t^l(X_\sigma))$ has dimension zero if $l+\frac{1}{2} \in \mathbf{Z}_+$, while for $l \in \mathbf{Z}_+$ $t^l(X_\sigma)$ it has a one-dimensional null space spanned by $\sum_{m=-l}^{l} q^{-m/2}c^{l,\sigma}_m e^l_m$ with

$$c^{l,\sigma}_m = \frac{i^m q^{-(l+\sigma)m}q^{m^2/2}}{(q^2;q^2)^{1/2}_{l+m}(q^2;q^2)^{1/2}_{l-m}}\,{}_3\varphi_2\left(\begin{matrix} q^{-2l+2m}, q^{-2l}, -q^{-2l-2\sigma} \\ q^{-4l},\ 0 \end{matrix}; q^2, q^2\right). \tag{2.6}$$

The eigenvalues and eigenvectors of $t^l(X_\tau A)$, $l \in \mathbf{Z}_+$, have also been determined in [8] and [10, Thm. 4.3 and Lem. 4.4]. The spectrum of $t^l(X_\tau A)$, $l \in \mathbf{Z}_+$, is simple and consists of $2l+1$ points

$$\lambda_j = \frac{q^{-2j+\tau} - q^{2j-\tau} + q^{-\tau} - q^\tau}{q^{-1}-q}, \qquad j = -l,\dots,l. \tag{2.7}$$

So the eigenspaces of $t^l(X_\tau A)$ are one-dimensional, and the corresponding eigenvectors are given in terms of dual q-Krawtchouk polynomials (cf. [10, Thm. 4.3]),

$$t^l(X_\tau A)\sum_{n=-l}^{l} p_{l-n}(\lambda_j;l)e^l_n = \lambda_j \sum_{n=-l}^{l} p_{l-n}(\lambda_j;l)e^l_n,$$

with

$$p_n(\lambda_j;l) = i^{-n}q^{n\tau}q^{\frac{1}{2}n(n-1)}\left(\frac{(q^{4l};q^{-2})_n}{(q^2;q^2)_n}\right)^{\frac{1}{2}} R_n(q^{-2l-2j}-q^{2j-2l-2\tau};q^{2\tau},2l \mid q^2), \tag{2.8}$$

where R_n is defined in [10, eq. (2.17)]. Note that for $l \le m$ spectrum$(t^l(X_\tau A)) \subset$ spectrum$(t^m(X_\tau A))$.

These results prove the following proposition.

PROPOSITION 2.4. *For $l \in \frac{1}{2} + \mathbf{Z}_+$ the space of associated (σ,τ)-spherical elements in* span $\{t^l_{mn}\}$ *is zero. If $l \in \mathbf{Z}_+$, then λ must be of the form λ_j for $j \in \{-l,\dots,l\}$, and the space of associated (σ,τ)-spherical elements in* span$\{t^l_{nm}\}$ *corresponding to λ_j is one-dimensional and spanned by*

$$\sum_{n,m=-l}^{l} q^{-\frac{m}{2}} c^{l,\sigma}_m \overline{p_{l-n}(\lambda_j;l)} t^l_{n,m}.$$

Note that Proposition 2.4 implies that all possible λ's in (2.1) are real for nonzero-associated (σ,τ)-spherical elements; hence Proposition 2.3 applies to all associated (σ,τ)-spherical elements.

We will renormalize the element spanning the one-dimensional space of associated (σ,τ)-spherical elements in span$\{t^l_{nm}\}$ corresponding to λ_j by

$$b^l_j(\sigma,\tau) = \sum_{n,m=-l}^{l} q^{-\frac{m}{2}} c^{l,\sigma}_m a^{l,j}_n(\tau) t^l_{n,m}, \tag{2.9}$$

with $a^{l,j}_n(\tau) = C^{l,j}(\tau)\overline{p_{l-n}(\lambda_j;l)}$, so that

$$\sum_{n=-l}^{l} a^{l,j}_n(\tau)\overline{a^{l,i}_n(\tau)} = \delta_{ij} = \sum_{n=-l}^{l} a^{l,n}_j(\tau)\overline{a^{l,n}_i(\tau)}. \tag{2.10}$$

From [10, eq. (2.18)] it immediately follows that

(2.11)

$$\begin{aligned} C^{l,j}(\tau) =& q^{-(l+j)} \begin{bmatrix} 2l \\ l+j \end{bmatrix}_{q^2}^{\frac{1}{2}} \left(\frac{(-q^{4l+2\tau};q^{-2})_{l+j}}{(-q^{2-2\tau};q^2)_{l+j}}\right)^{\frac{1}{2}} \\ & \times \left(\frac{1+q^{4j-2\tau}}{1+q^{-4l-2\tau}}\right)^{\frac{1}{2}} - (q^{2\tau};q^2)_{2l}^{-\frac{1}{2}} \\ =& q^{l-j} \begin{bmatrix} 2l \\ l+j \end{bmatrix}_{q^2}^{\frac{1}{2}} \left(\frac{1+q^{4j-2\tau}}{1+q^{-2\tau}}\right)^{\frac{1}{2}} \left(\frac{1}{(-q^{2-2\tau};q^2)_{l+j}(-q^{2+2\tau};q^2)_{l-j}}\right)^{\frac{1}{2}}. \end{aligned}$$

The associated (σ,τ)-spherical element $b^l_j(\sigma,\tau)$, $j \geq 0$, can be related to $b^j_j(\sigma,\tau)$ in a very simple manner. To see this we start with an arbitrary polynomial s_r of degree r, and we consider $b^j_j(\sigma,\tau)s_r(\rho_{\sigma,\tau})$. Now [6, Thm. 3.4] or [18, Thm. 5.11] (cf. [10, Prop. 3.5]) implies that we can write

$$b^j_j(\sigma,\tau)s_r(\rho_{\sigma,\tau}) = \sum_{k=|j-r|}^{j+r} b_k, \tag{2.12}$$

where $b_k \in \text{span}\{t^k_{n,m} : n,m = -k,\dots,k\}$. However, by Proposition 2.2, this is an associated (σ,τ)-spherical element with λ replaced by λ_j in (2.1), and so every b_k in (2.12) must be an associated (σ,τ)-spherical element because $X_\sigma.$ and $.X_\tau$ preserve span$\{t^l_{n,m}\}$. Hence $b_k = 0$ for $k < j$ by Proposition 2.4. Rewriting (2.12) as

$$b^j_j(\sigma,\tau)s_r(\rho_{\sigma,\tau}) = \sum_{k=j}^{j+r} c_k b^k_j(\sigma,\tau),$$

we see that we are left with $r+1$ constants c_k depending on the polynomial s_r of degree r. Application of the one-dimensional representation $\pi^1_{\theta/2}$ shows that the mapping $s_r \mapsto b^j_j s_r(\rho_{\sigma,\tau})$ is injective.

PROPOSITION 2.5. *There exist two systems of orthogonal polynomials p_{l-j}, q_{l-j} of degree $l-j$ so that for $j \geq 0$ we have*

$$b^l_j(\sigma,\tau) = b^j_j(\sigma,\tau)p_{l-j}(\rho_{\sigma,\tau})$$

and

$$b^l_{-j}(\sigma,\tau) = b^j_{-j}(\sigma,\tau)q_{l-j}(\rho_{\sigma,\tau}).$$

Proof. The previous remarks prove that for some polynomial p_{l-j} of degree $l-j$ we have

$$b^l_j(\sigma,\tau) = b^j_j(\sigma,\tau)p_{l-j}(\rho_{\sigma,\tau}). \tag{2.13}$$

To prove that the polynomials p_n form a system of orthogonal polynomials we need the Haar functional h; cf. [17, §4]. For the quantum group $SU_q(2)$ the Schur orthogonality relations [17, Thm. 5.7] have been calculated explicitly (cf. [7, §5] and [10, (3.21)]):

$$h((t^l_{m,n})^* t^k_{r,s}) = \delta_{k,l}\delta_{m,r}\delta_{n,s}q^{2(l-m)}\frac{1-q^2}{1-q^{2(2l+1)}}. \tag{2.14}$$

Now (2.9) and (2.14) imply the orthogonality of the associated (σ,τ)-spherical elements $b^l_j(\sigma,\tau)$ with respect to the Haar functional,

$$h(b^l_j(\sigma,\tau)^* b^k_j(\sigma,\tau)) \begin{cases} = 0, & l \neq k, \\ > 0, & l = k. \end{cases}$$

Because of Proposition 2.3 [8, Thm. 8.2], [10, Prop. 4.7] $b^j_j(\sigma,\tau)^* b^j_j(\sigma,\tau) = P_j(\rho_{\sigma,\tau})$ for some nonzero polynomial P_j of degree smaller or equal to j. Now (2.13) implies

$$h(\overline{p_{l-j}}(\rho_{\sigma,\tau})P_j(\rho_{\sigma,\tau})p_{k-j}(\rho_{\sigma,\tau})) \begin{cases} = 0, & l \neq k, \\ > 0, & l = k, \end{cases}$$

since $\rho_{\sigma,\tau}$ is selfadjoint. Using the explicit form for the Haar functional acting on a polynomial in $\rho_{\sigma,\tau}$ [8, Thm. 8.4], [10, Thm. 5.3] we find that the polynomials p_{l-j} form a system of orthogonal polynomials for the positive-definite moment functional $\mathcal{L}_j$ (cf. [2, Chap. 1]) defined by

$$\mathcal{L}_j[x^n] = \int_{-\infty}^{\infty} x^n P_j(x) dm_{a,b,c,d;\,q^2}(x) < \infty,$$

where $dm_{a,b,c,d;\,q^2}(x)$ denotes the orthogonality measure for the Askey–Wilson polynomials $p_n(x;a,b,c,d \mid q^2)$ with $a = -q^{\sigma+\tau+1}$, $b = -q^{-\sigma-\tau+1}$, $c = q^{\sigma-\tau+1}$, and $d = q^{\tau-\sigma+1}$.

The statements for the polynomials q_{l-j} are proved analogously. □

Remark. In their announcement [13], Noumi and Mimachi obtain results using a similar approach. For a matrix

$$g = \begin{pmatrix} a & -\bar{c} \\ c & \bar{a} \end{pmatrix} \in SU(2) \times \mathbf{R}_{>0}$$

subject to $|a|^2 - |c|^2 q^{2k} \neq 0$ for all $k \in \mathbf{Z}$, they define

$$\theta(g) = \bar{a}cq^{1/2}B + a\bar{c}q^{-1/2}C - \frac{|a|^2 - |c|^2}{q - q^{-1}}(A - D) \in \mathcal{U}_q.$$

Note that for $\bar{a}c = i$ we get $\theta(g) = X_\tau$ with $q^\tau = |a|^2$. For two such matrices g_1, g_2 they obtain matrix elements $\psi^j_{m,n}(g_1, g_2)$ in $\mathcal{A}_q$ satisfying

$$\begin{cases} \theta(g_1).\psi^j_{m,n}(g_1, g_2) = \lambda_n(g_2)A.\psi^j_{m,n}(g_1, g_2), \\ \psi^j_{m,n}(g_1, g_2).\theta(g_2) = \lambda_m(g_1)\psi^j_{m,n}(g_1, g_2).A, \end{cases} \tag{2.15}$$

where $\lambda_n(g_2)$, $\lambda_m(g_1)$ are eigenvalues of $t^l(D\theta(g_2))$, $t^l(D\theta(g_1))$ similar in form to λ_j in (2.7). So their results are more general, since they also take the action from the left into consideration. However, Definition 2.1 does not fit into (2.15) since $\theta(g)D \neq X_\tau A$ for all g. But from (2.3) and (2.4) it is easily seen that b^* fits into (2.15), whenever b is an associated (σ, τ)-spherical element and g_1 and g_2 are chosen properly.

3. Associated (σ, τ)-spherical elements related to Askey–Wilson polynomials. As we saw in the previous section there is a natural way to relate associated (σ, τ)-spherical elements to systems of orthogonal polynomials, and in this section we will show that these polynomials are Askey–Wilson polynomials by investigating the moment functional defined in the proof of Proposition 2.5. These Askey–Wilson polynomials will have two continuous and one discrete parameter. Application of the comultiplication on a (σ, τ)-spherical element in $\operatorname{span}\{t^l_{n,m}\}$ yields an abstract addition formula for a two-parameter class of Askey–Wilson polynomials involving the Askey–Wilson polynomials of two continuous and one discrete variable. From this result an expansion for this two-parameter class of Askey–Wilson polynomials of argument $\cos(\theta + \varphi)$ is obtained.

To find the polynomials p_n and q_m as described in Proposition 2.5, we investigate the corresponding moment functional. In order to do this, we need to know for which polynomials P_j, Q_j we have $b^j_j(\sigma, \tau)^* b^j_j(\sigma, \tau) = P_j(\rho_{\sigma,\tau})$ and $b^j_{-j}(\sigma, \tau)^* b^j_{-j}(\sigma, \tau) = Q_j(\rho_{\sigma,\tau})$. The easiest way is to apply a one-dimensional $*$-representation of $\mathcal{A}_q$ to these equalities and the following lemma gives the heart of the solution. Although this lemma is not stated in its most elegant way, it has the right form for the applications later in this section.

LEMMA 3.1. *For arbitrary real σ, τ we have*

$$\begin{aligned}(q^{-\sigma-\tau+1}e^{i\theta}; q^2)_j(-q^{-\tau+\sigma+1}e^{i\theta}; q^2)_j &= e^{ij\theta}q^{\sigma j}q^{\frac{1}{2}j(j+1)}(q^2; q^2)^{\frac{1}{2}}_{2j} \\ &\times \sum_{n=-j}^{j} e^{-in\theta}q^{-\tau(j-n)}q^{\frac{1}{2}(j-n)(j-n-1)}\left(\frac{(q^{4j}; q^{-2})_{j-n}}{(q^2; q^2)_{j-n}}\right)^{\frac{1}{2}} \frac{q^{-\frac{n}{2}}q^{-(j+\sigma)n}q^{\frac{n^2}{2}}}{(q^2; q^2)^{\frac{1}{2}}_{j-n}(q^2; q^2)^{\frac{1}{2}}_{j+n}} \\ &\times {}_3\varphi_2\left(\begin{matrix} q^{-2(j-n)}, q^{-2j}, -q^{-2j-2\sigma} \\ 0, \ q^{-4j} \end{matrix}; q^2, q^2\right),\end{aligned}$$

$$\begin{aligned}(-q^{\sigma+\tau+1}e^{i\theta}; q^2)_j(q^{\tau-\sigma+1}e^{i\theta}; q^2)_j &= e^{ij\theta}q^{-\sigma j}q^{\frac{1}{2}j(j+1)}(q^2; q^2)^{\frac{1}{2}}_{2j} \\ &\times \sum_{n=-j}^{j} e^{-in\theta}q^{\tau(j-n)}q^{\frac{1}{2}(j-n)(j-n-1)}(-1)^{j-n}\left(\frac{(q^{4j}; q^{-2})_{j-n}}{(q^2; q^2)_{j-n}}\right)^{\frac{1}{2}} \\ &\times \frac{q^{-\frac{n}{2}}q^{-(j-\sigma)n}q^{\frac{n^2}{2}}}{(q^2; q^2)^{1/2}_{j-n}(q^2; q^2)^{\frac{1}{2}}_{j+n}} {}_3\varphi_2\left(\begin{matrix} q^{-2(j-n)}, q^{-2j}, -q^{-2j+2\sigma} \\ 0, \ q^{-4j} \end{matrix}; q^2, q^2\right).\end{aligned}$$

Proof. Recall from [1, eq. (1.15)] and [10, §2] the definition of the Askey–Wilson polynomials

$$p_n(y;a,b,c,d \mid q) = a^{-n}(ab,ac,ad;q)_n {}_4\varphi_3\left(\begin{matrix} q^{-n}, abcdq^{n-1}, az, a/z \\ ab, ac, ad \end{matrix}; q, q\right), \tag{3.1}$$

where $y = \frac{1}{2}(z+z^{-1})$, and let us consider the following generating function for the Askey–Wilson polynomials (cf. [5, eq. (1.9)]):

$$\sum_{n=0}^{\infty} \frac{p_n(y;a,b,c,d \mid q)t^n}{(ab,dc,q;q)_n} = {}_2\varphi_1\left(\begin{matrix} a/z, b/z \\ ab \end{matrix}; q, zt\right) {}_2\varphi_1\left(\begin{matrix} cz, dz \\ cd \end{matrix}; q, t/z\right) \tag{3.2}$$

with $y = \frac{1}{2}(z+z^{-1})$.

To obtain a generating function for the dual q-Krawtchouk polynomials from (3.2) we put $a = iq^{-1/2(N+\sigma)}$, $b = c = 0$, $d = -iq^{1/2(\sigma-N)}$, and $z = iq^{x-1/2(N+\sigma)}$ for $N \in \mathbf{N}$ and $x = 0, 1, \ldots, N$. For $0 \leq n \leq N$ and these choices of a, b, c, and d we get

$$p_n(y;a,b,c,d \mid q) = i^{-n}q^{\frac{n}{2}(N+\sigma)}(q^{-N};q)_n R_n(q^{-x} - q^{x-N-\sigma}; q^{\sigma}, N \mid q).$$

Note that $ad = q^{-N}$, $a/z = q^{-x}$ for $N \in \mathbf{N}$, $x = 0, 1, \ldots, N$ implies $p_n(y;a,b,c,d \mid q) = 0$ for $n > N$. So for these values of a, b, c, d and z the left-hand side of (3.2) reduces to a finite sum involving dual q-Krawtchouk polynomials, whereas the right-hand side yields a product of two ${}_1\varphi_0$'s, which can be summed using the q-binomial theorem; cf. [4, eq. (1.3.14)]. Hence,

$$\begin{aligned} \sum_{n=0}^{N} i^{-n}q^{\frac{n}{2}(N+\sigma)} \frac{(q^{-N};q)_n}{(q;q)_n} R_n(q^{-x} - q^{x-N-\sigma}; q^{\sigma}, N \mid q)t^n \\ = (itq^{-\frac{1}{2}(N+\sigma)};q)_x(-itq^{\frac{1}{2}(\sigma-N)};q)_{N-x}. \end{aligned} \tag{3.3}$$

In this generating function for the dual q-Krawtchouk polynomials we specialize $x = j$, $N = 2j$ and replace q by q^2 and n by $j-n$. Finally, put $t = iq^{2j+2\tau+1}e^{i\theta}$ to obtain the last statement of the lemma. The first statement follows from the last by replacing q^{τ} and σ by $-q^{-\tau}$ and $-\sigma$. □

Recall the definition of $a_n^{l,j}(\tau)$ given immediately after (2.10). It easily follows from [10, eq. (2.17)] that

$$a_n^{j,-j}(\tau) = C^{j,-j}(\tau)i^{j-n}q^{(j-n)\tau}q^{\frac{1}{2}(j-n)(j-n-1)}\left(\frac{(q^{4j};q^{-2})_{j-n}}{(q^2;q^2)_{j-n}}\right)^{\frac{1}{2}}, \tag{3.4}$$

since the dual q-Krawtchouk polynomial reduces to 1. However, in the other extreme case we can evaluate the dual q-Krawtchouk polynomial as well. In this case the ${}_3\varphi_2$ occurring in [10, eq. (2.17)] is actually a ${}_2\varphi_1$, since q^{-4j} appears as upper and lower parameter. This ${}_2\varphi_1$ can be summed by the q-Chu–Vandermonde formula [4, eq. (1.5.3)]. This yields $R_{j-n}(q^{-4j} - q^{-2\tau}; q^{2\tau}, 2j|q^2) = (-q^{-2\tau})^{j-n}$. Hence we find

$$a_n^{j,j}(\tau) = C^{j,j}(\tau)i^{j-n}q^{-(j-n)\tau}(-1)^{j-n}q^{\frac{1}{2}(j-n)(j-n-1)}\left(\frac{(q^{4j};q^{-2})_{j-n}}{(q^2;q^2)_{j-n}}\right)^{\frac{1}{2}}. \tag{3.5}$$

By $\pi^1_{\theta/2}$ we denote the one-dimensional $*$-representation as defined in [10, eq. (3.22)] for $\theta \in \mathbf{R}$. From [7, Thm. 5.3 or p. 108] and [10, eq. (3.23)] it follows that $\pi^1_{\theta/2}(t^j_{n,m})$

$= \delta_{nm}e^{-in\theta}$. Application of $\pi^1_{\theta/2}$ on $b^j_j(\sigma,\tau)$ and $b^j_{-j}(\sigma,\tau)$ reduces the double sum in (2.9) to a single sum of the type considered in Lemma 3.1. Thus we have shown that

$$\begin{aligned}\pi^1_{\theta/2}(b^j_j(\sigma,\tau)) = {} & C^{j,j}(\tau)q^{-\frac{1}{2}j(j+1)}q^{-\sigma j}i^j(q^2;q^2)^{-\frac{1}{2}}_{2j} \\ & \times e^{-ij\theta}(-q^{-\sigma-\tau+1}e^{i\theta};q^2)_j(q^{\sigma-\tau+1}e^{i\theta};q^2)_j\end{aligned} \tag{3.6}$$

and

$$\begin{aligned}\pi^1_{\theta/2}(b^j_{-j}(\sigma,\tau)) = {} & C^{j,-j}(\tau)q^{-\frac{1}{2}j(j+1)}q^{-\sigma j}i^j(q^2;q^2)^{-\frac{1}{2}}_{2j} \\ & \times e^{-ij\theta}(-q^{\sigma+\tau+1}e^{i\theta};q^2)_j(q^{\tau-\sigma+1}e^{i\theta};q^2)_j.\end{aligned} \tag{3.7}$$

From (3.6) and (3.7) it follows immediately that

$$\begin{aligned}P_j(\cos\theta) &= \pi^1_{\theta/2}((b^j_j(\sigma,\tau))^* b^j_j(\sigma,\tau)) \\ &= D_j(-q^{-\sigma-\tau+1}e^{i\theta}, -q^{-\sigma-\tau+1}e^{-i\theta}, q^{\sigma-\tau+1}e^{i\theta}, q^{\sigma-\tau+1}e^{-i\theta};q^2)_j\end{aligned} \tag{3.8}$$

and

$$\begin{aligned}Q_j(\cos\theta) &= \pi^1_{\theta/2}((b^j_{-j}(\sigma,\tau))^* b^j_{-j}(\sigma,\tau)) \\ &= D_{-j}(-q^{\sigma+\tau+1}e^{i\theta}, -q^{\sigma+\tau+1}e^{-i\theta}, q^{-\sigma+\tau+1}e^{i\theta}, q^{-\sigma+\tau+1}e^{-i\theta};q^2)_j\end{aligned} \tag{3.9}$$

for nonzero constants D_j, $j \in \mathbf{Z}$. Now we can give an interpretation of a subclass of Askey–Wilson polynomials (cf. (3.1)) on the quantum group $SU_q(2)$.

THEOREM 3.2. *For $j \geq 0$ we have*

$$\begin{aligned}b^l_{-j}(\sigma,\tau) = {} & C^l_{-j}(\sigma,\tau)b^j_{-j}(\sigma,\tau) \\ & \times p_{l-j}(\rho_{\sigma,\tau}; -q^{\sigma+\tau+1+2j}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{\tau-\sigma+1+2j} \mid q^2)\end{aligned}$$

and

$$\begin{aligned}b^l_j(\sigma,\tau) = {} & C^l_j(\sigma,\tau)b^j_j(\sigma,\tau) \\ & \times p_{l-j}(\rho_{\sigma,\tau}; -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1+2j}, q^{\sigma-\tau+1+2j}, q^{\tau-\sigma+1} \mid q^2)\end{aligned}$$

with

$$C^l_{-j}(\sigma,\tau) = q^{\frac{1}{2}(j-l+j^2-l^2)}i^{l-j}q^{\sigma(j-l)}(q^{4l};q^{-2})^{-\frac{1}{2}}_{2(l-j)}(q^{4l};q^{-2})^{-1}_{l-j}\frac{C^{l,-j}(\tau)}{C^{j,-j}(\tau)},$$

$$C^l_j(\sigma,\tau) = q^{\frac{1}{2}(j-l+j^2-l^2)}i^{l-j}q^{\sigma(j-l)}(q^{4l};q^{-2})^{-\frac{1}{2}}_{2(l-j)}(q^{4l};q^{-2})^{-1}_{l-j}\frac{C^{l,j}(\tau)}{C^{j,j}(\tau)}.$$

Proof. Let us consider general Askey–Wilson polynomials $p_n(x;a,b,c,d|q)$. These polynomials form a system of orthogonal polynomials with respect to the orthogonality measure $dm_{a,b,c,d;\,q}(x)$, which consists of an absolutely continuous part on $[-1,1]$ and possibly a finite number of discrete mass points off $[-1,1]$; see [1, Thm. 2.5] and [4, §7.5]. A straightforward calculation shows that the orthogonality measure $dm_{aq^j,b,c,dq^j;\,q}(x)$ is equivalent to $b(x)dm_{a,b,c,d;\,q}(x)$, where

$$b\left(\frac{y+y^{-1}}{2}\right) = (ay, ay^{-1}, dy, dy^{-1};q)_j.$$

Apart from the constant the theorem now follows from the proof of Proposition 2.5, (3.8), (3.9), and the fact that the Askey–Wilson polynomial is symmetric in its parameters; cf. [1, p. 6].

The fact that the constant is correct remains to be proved. Apply $\pi^1_{\theta/2}$ to the second formula of the theorem and compare the coefficients of $e^{-il\theta}$ on both sides. The coefficient of $e^{-il\theta}$ in the left-hand side is

$$q^{-l/2}c_l^{l,\sigma}a_l^{l,j}(\tau) = C^{l,j}(\tau)q^{-l/2}\frac{i^l q^{-(l+\sigma)l}q^{l^2/2}}{(q^2;q^2)_{2l}^{1/2}}. \tag{3.10}$$

To calculate the coefficient of $e^{-il\theta}$ in the right-hand side we need the coefficient of $e^{-ij\theta}$ in $\pi^1_{\theta/2}(b_j^j(\sigma,\tau))$, which is (3.10) with l replaced by j, and the coefficient of $e^{-i(l-j)\theta}$ of

$$\begin{aligned} &p_{l-j}(\cos\theta;\ -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1+2j}, q^{\sigma-\tau+1+2j}, q^{\tau-\sigma+1}|q^2) \\ &\quad = 2^{l-j}(q^{2l+2j+2};q^2)_{l-j}(\cos\theta)^{l-j} + \text{lower-order terms} \end{aligned}$$

(cf. [1, p. 5]), which is $(q^{2l+2j+2};q^2)_{l-j} = (q^{4l};q^{-2})_{l-j}$. Comparing these coefficients yields $C_j^l(\sigma,\tau)$. The other constant can be calculated similarly. □

In order to formulate the next theorem we have to introduce a map $\Theta\colon \mathcal{A}_q \to \mathcal{A}_q$, which is defined on the generators by

$$\Theta(\alpha) = q^{-\frac{1}{2}}\alpha, \quad \Theta(\beta) = q^{\frac{1}{2}}\gamma, \quad \Theta(\gamma) = q^{-\frac{1}{2}}\beta, \quad \Theta(\delta) = q^{\frac{1}{2}}\delta,$$

and extended to $\mathcal{A}_q$ as an antilinear multiplicative map. It is easily checked that Θ preserves the commutation relations [10, eq. (3.1)] of $\mathcal{A}_q$, so it is well defined.

Now we consider the image of a matrix element $t^l_{n,m}$ under Θ. First we consider the matrix elements $t^l_{n,m} = t^l_{n,m}(\alpha,\beta,\gamma,\delta)$ as polynomials in α, β, γ, and δ. From [7, Thm. 5.3] we not only know that these polynomials have real coefficients, but it also gives

$$\Theta(t^l_{n,m}(\alpha,\beta,\gamma,\delta)) = t^l_{n,m}(q^{-\frac{1}{2}}\alpha, q^{\frac{1}{2}}\gamma, q^{-\frac{1}{2}}\beta, q^{\frac{1}{2}}\delta) = q^m t^l_{n,m}(\alpha,\gamma,\beta,\delta).$$

Proposition 4.1 of [7], which states that interchanging β and γ in $t^l_{n,m}$ is the same as interchanging m and n, now yields $\Theta(t^l_{n,m}) = q^m t^l_{m,n}$. Using this information and (2.9) gives

$$\Theta(b_j^l(\sigma,\tau)) = \sum_{n,m=-l}^{l} q^{m/2}\overline{c_m^{l,\sigma}a_n^{l,j}(\tau)}t^l_{m,n}. \tag{3.11}$$

THEOREM 3.3 (abstract addition formula). *The following identity in $\mathcal{A}_q \otimes \mathcal{A}_q$ is valid*:

$$\begin{aligned} &p_l(\Delta(\rho_{\sigma,\tau});\ -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1}|q^2) \\ &\quad = \sum_{j=1}^{l} A(l,-j)\Theta(b^j_{-j}(\tau,\tau))p_{l-j}(\Theta(\rho_{\tau,\tau});\ -q^{2\tau+1+2j}, -q^{-2\tau+1}, q, q^{1+2j}|q^2) \\ &\qquad \otimes b^j_{-j}(\sigma,\tau)p_{l-j}(\rho_{\sigma,\tau};\ -q^{\sigma+\tau+1+2j}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1+2j}|q^2) \\ &\qquad + A(l,0)p_l(\Theta(\rho_{\tau,\tau});\ -q^{2\tau+1}, -q^{-2\tau+1}, q, q|q^2) \\ &\qquad \otimes p_l(\rho_{\sigma,\tau};\ -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1}|q^2) \\ &\qquad + \sum_{j=1}^{l} A(l,j)\Theta(b_j^j(\tau,\tau))p_{l-j}(\Theta(\rho_{\tau,\tau});\ -q^{2\tau+1}, -q^{-2\tau+1+2j}, q^{1+2j}, q|q^2) \\ &\qquad \otimes b_j^j(\sigma,\tau)p_{l-j}(\rho_{\sigma,\tau};\ -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1+2j}, q^{\sigma-\tau+1+2j}, q^{-\sigma+\tau+1}|q^2), \end{aligned}$$

where the constants $A(l,j)$ are defined for $j \geq 0$ by

$$A(l,j) = q^{j-l}\left(c_j^{j,\sigma}\overline{c_j^{j,\tau}}\right)^{-1}\frac{(q^{2l+2};q^2)_l}{(q^{4l};q^{-2})_{l-j}^2}\frac{|C^{l,j}(\tau)|^2}{|C^{j,j}(\tau)|^2},$$

$$A(l,-j) = q^{j-l}\left(c_j^{j,\sigma}\overline{c_j^{j,\tau}}\right)^{-1}\frac{(q^{2l+2};q^2)_l}{(q^{4l};q^{-2})_{l-j}^2}\frac{|C^{l,-j}(\tau)|^2}{|C^{j,-j}(\tau)|^2}.$$

Proof. Application of the comultiplication on the (σ,τ)-spherical element contained in the span$\{t_{n,m}^l\}$ yields

$$\begin{aligned}
&\frac{c_l^{l,\sigma}\overline{c_l^{l,\tau}}}{(q^{2l+2};q^2)_l}p_l(\Delta(\rho_{\sigma,\tau});\ -q^{\sigma+\tau+1},-q^{-\sigma-\tau+1},q^{\sigma-\tau+1},q^{\tau-\sigma+1}\mid q)\\
&\quad=\Delta\left(\sum_{n,m=-l}^{l}q^{(n-m)/2}c_m^{l,\sigma}\overline{c_n^{l,\tau}}t_{n,m}^l\right)\\
&\quad=\sum_{n,m,k,r=-l}^{l}q^{(n-m)/2}c_m^{l,\sigma}\overline{c_n^{l,\tau}}\delta_{kr}t_{n,r}^l\otimes t_{k,m}^l\\
&\quad=\sum_{j=-l}^{l}\left(\sum_{n,r=-l}^{l}q^{n/2}\overline{c_n^{l,\tau}a_r^{l,j}(\tau)}t_{n,r}^l\right)\otimes\left(\sum_{k,m=-l}^{l}q^{-m/2}c_m^{l,\sigma}a_k^{l,j}(\tau)t_{k,m}^l\right)\\
&\quad=\sum_{j=-l}^{l}\Theta(b_j^l(\tau,\tau))\otimes b_j^l(\sigma,\tau)
\end{aligned}\tag{3.12}$$

by [10, Thm. 5.2, Prop. 4.7], [10, eq. (3.13)], (2.9), (2.10), and (3.11). In (3.12) we use Theorem 3.2 and (2.6). □

Of course we would like to have an addition formula in commuting variables, so let us apply $\pi_{\theta/2}^1\otimes\pi_{\varphi/2}^1$ to this identity in $\mathcal{A}_q\otimes\mathcal{A}_q$. It is easily checked that

$$\begin{aligned}
&\pi_{\theta/2}^1\otimes\pi_{\varphi/2}^1(\Delta(\rho_{\sigma,\tau}))=\cos(\theta+\varphi),\qquad \pi_{\varphi/2}^1(\rho_{\sigma,\tau})=\cos\varphi,\\
&\pi_{\theta/2}^1(\Theta(\rho_{\tau,\tau}))=\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2}.
\end{aligned}\tag{3.13}$$

In view of (3.6) and (3.7) it remains to calculate $\pi_{\theta/2}^1(\Theta(b_{\pm j}^j(\sigma,\tau)))$. From the definition of Θ we see that for $a\in\mathcal{A}_q$ with $\pi_{\theta/2}^1(a)=\sum_k c_k e^{ik\theta}$ we have $\pi_{\theta/2}^1(\Theta(a))=\sum_k\overline{c_k}q^{-k}e^{ik\theta}$. This proves

$$\begin{aligned}
\pi_{\theta/2}^1(\Theta(b_{-j}^j(\sigma,\tau)))&=\overline{C^{j,-j}(\tau)}i^{-j}q^{-\frac{1}{2}j(j-1)}q^{-\sigma j}(q^2;q^2)_{2j}^{-\frac{1}{2}}\\
&\quad\times e^{-ij\theta}(-q^{\sigma+\tau}e^{i\theta};q^2)_j(q^{-\sigma+\tau}e^{i\theta};q^2)_j\\
\pi_{\theta/2}^1(\Theta(b_j^j(\sigma,\tau)))&=\overline{C^{j,j}(\tau)}i^{-j}q^{-\frac{1}{2}j(j-1)}q^{-\sigma j}(q^2;q^2)_{2j}^{-\frac{1}{2}}\\
&\quad\times e^{-ij\theta}(-q^{-\sigma-\tau}e^{i\theta};q^2)_j(q^{-\tau+\sigma}e^{i\theta};q^2)_j.
\end{aligned}\tag{3.14}$$

Now (3.13), (3.14), (3.6), (3.7), and Theorem 3.3 imply the following formula:

$$
\begin{aligned}
&p_l(\cos(\theta+\varphi);\, -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1}|q^2)\\
&\quad=\sum_{j=1}^{l} B(l,-j)e^{-ij\theta}e^{-ij\varphi}(-q^{2\tau}e^{i\theta}, e^{i\theta}, -q^{\sigma+\tau+1}e^{i\varphi}, q^{\tau-\sigma+1}e^{i\varphi}; q^2)_j\\
&\qquad\times p_{l-j}\left(\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2};\, -q^{2\tau+1+2j}, -q^{-2\tau+1}, q, q^{1+2j}|q^2\right)\\
&\qquad\times p_{l-j}(\cos\varphi;\, -q^{\sigma+\tau+1+2j}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1+2j}|q^2)\\
&\qquad+B(l,0)p_l\left(\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2};\, -q^{2\tau+1}, -q^{-2\tau+1}, q, q|q^2\right)\\
&\qquad\times p_l(\cos\varphi;\, -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1}, q^{\sigma-\tau+1}, q^{-\sigma+\tau+1}|q^2)\\
&\qquad+\sum_{j=1}^{l} B(l,j)e^{-ij\theta}e^{-ij\varphi}(-q^{-2\tau}e^{i\theta}, e^{i\theta}, -q^{-\sigma-\tau+1}e^{i\varphi}, q^{\sigma-\tau+1}e^{i\varphi}; q^2)_j\\
&\qquad\times p_{l-j}\left(\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2};\, -q^{2\tau+1}, -q^{-2\tau+1+2j}, q^{1+2j}, q|q^2\right)\\
&\qquad\times p_{l-j}(\cos\varphi;\, -q^{\sigma+\tau+1}, -q^{-\sigma-\tau+1+2j}, q^{\sigma-\tau+1+2j}, q^{-\sigma+\tau+1}|q^2),
\end{aligned}
\tag{3.15}
$$

where for $j \geq 0$,

$$
\begin{aligned}
B(l,j) &= q^{j-l}\frac{(q^{2l+2};q^2)_l}{(q^{4l};q^{-2})^2_{l-j}}|C^{l,j}(\tau)|^2,\\
B(l,-j) &= q^{j-l}\frac{(q^{2l+2};q^2)_l}{(q^{4l};q^{-2})^2_{l-j}}|C^{l,-j}(\tau)|^2.
\end{aligned}
$$

The value for the $B(l,j)$ immediately follows from Theorem 3.3, (3.14), (3.6), (3.7), and the following observation:

$$
\left(c_j^{j,\sigma}\overline{c_j^{j,\tau}}\right)^{-1} = (q^2;q^2)_{2j}q^{j^2}q^{j(\sigma+\tau)}.
$$

Remark. In their announcement [13] Noumi and Mimachi obtained a result similar to Theorem 3.2 in their Theorem 3 for an element $\psi^j_{m,n}(g_1,g_2)$ (cf. remark at the end of the previous section). $\psi^j_{m,n}(g_1,g_2)$ is expressed as an Askey–Wilson polynomial times a minimal element with respect to j, which still satisfies (2.15).

The formula (3.15) can be obtained from their Theorem 4 by putting $z = e^{i\theta}$, $w = qe^{i\varphi}$, $s = u = q^\tau$, $t = q^\sigma$, and replacing q by q^2. The extra parameter u in their Theorem 4 can also be easily obtained in this context if we replace $\overline{a_r^{l,j}(\tau)}a_k^{l,j}(\tau)$ in (3.12) by $\overline{a_r^{l,j}(\mu)}a_k^{l,j}(\mu)$ for some $\mu \in \mathbf{R}$. This also generalizes Theorem 3.3, which can be obtained from Noumi and Mimachi's paper by combining their Theorem 3 and Proposition 2c) for $m = n = 0$.

4. The addition formula for the continuous q-Legendre polynomials. In Theorem 3.3 we obtained an abstract addition formula for a two-parameter family of Askey–Wilson polynomials. In this section we consider the case $\sigma = \tau = 0$, so that we obtain an abstract addition formula for the continuous q-Legendre polynomials. The continuous q-Legendre polynomial is a special case of the continuous q-ultraspherical polynomial for which Rahman and Verma obtained an addition formula; cf. [14]. We show how to prove the result of Rahman and Verma [14, eq. (1.24)], [4, Ex. 8.11]

with $a = q^{1/4}$ from our abstract addition formula using the fact that the right-hand side of (4.6) consists of associated $(0,0)$-spherical elements. Finally, we note that the method we use is quite different from Koornwinder's as used in [9] to obtain an addition formula for the little q-Legendre polynomials, since we only use one-dimensional representations of $\mathcal{A}_q$, whereas Koornwinder uses infinite-dimensional representations. Koornwinder's result is also mentioned in [4, Ex. 7.41].

Formulas (4.1)–(4.5) are just restatements of the results obtained in the previous sections. The calculations involved are straightforward but tedious, so the reader is invited to skip these at first reading.

From [1, eqs. (4.20) and (4.2)] we see that

(4.1)
$$p_{l-j}(x; -q^{1+2j}, -q, q, q^{1+2j} \mid q^2) = p_{l-j}(x; -q, -q^{1+2j}, q^{1+2j}, q \mid q^2)$$
$$= \frac{(q^{4j+4};q^4)_{l-j}(q^4;q^4)_{l-j}}{(q^{4j+2};q^2)_{l-j}} C_{l-j}(x; q^{2+4j} \mid q^4),$$

where $C_n(x;\beta \mid q)$ denotes a continuous q-ultraspherical polynomial defined by

$$C_n(x;\beta \mid q) = \frac{(\beta^2;q)_n}{\beta^{n/2}(q;q)_n} {}_4\varphi_3\left(\begin{matrix} q^{-n}, q^n\beta^2, \beta^{1/2}e^{i\theta}, \beta^{1/2}e^{-i\theta} \\ \beta q^{1/2}, -\beta q^{1/2}, -\beta \end{matrix}; q, q\right)$$

with $x = \cos\theta$; cf. [1, §4]. Note that $C^{l,j}(0) = C^{l,-j}(0)$ (see (2.11)), and if we put for $j \geq 0$,

(4.2)
$$b^l_{\pm j} \overset{\text{def}}{=} i^{-l} q^{l^2/2} \left(\frac{(q^2;q^4)_l (q^{8l};q^{-4})_l}{(-q^2;q^2)_{2l}}\right)^{\frac{1}{2}} b^l_{\pm j}(0,0)$$
$$= q^{\frac{1}{2}(l-j)} \begin{bmatrix} l+j \\ l-j \end{bmatrix}_{q^4}^{-\frac{1}{2}} b^j_{\pm j} C_{l-j}(\rho_{0,0}; q^{2+4j} \mid q^4),$$

by Theorem 3.2 and (4.1); then we have

(4.3)
$$\pi^1_{\theta/2}(b^j_j) = \pi^1_{\theta/2}(b^j_{-j}) = \frac{1}{2}\sqrt{2}\left(\frac{1+q^{4j}}{(-q^2;q^2)_{2j}}\right)^{\frac{1}{2}}$$
$$\times \left(\frac{(q^2;q^4)_j}{(q^4;q^4)_j}\right)^{\frac{1}{2}} q^{-j/2} e^{-ij\theta} (q^2 e^{2i\theta}; q^4)_j$$

and

(4.4)
$$\pi^1_{\theta/2}(\Theta(b^j_j)) = \pi^1_{\theta/2}(\Theta(b^j_{-j})) = \frac{1}{2}\sqrt{2}\left(\frac{1+q^{4j}}{(-q^2;q^2)_{2j}}\right)^{\frac{1}{2}}$$
$$\times \left(\frac{(q^2;q^4)_j}{(q^4;q^4)_j}\right)^{\frac{1}{2}} q^{j/2} e^{-ij\theta} (e^{2i\theta}; q^4)_j$$

by (3.6), (3.7), and (3.14). Use (4.2) in (3.12) to obtain the abstract addition formula for the continuous q-Legendre polynomial:

(4.5)
$$C_l(\Delta(\rho); q^2 \mid q^4)$$
$$= q^l C_l(\Theta(\rho); q^2 \mid q^4) \otimes C_l(\rho; q^2 \mid q^4)$$
$$+ \sum_{j=1}^{l} q^{l-j} \begin{bmatrix} l+j \\ 2j \end{bmatrix}_{q^4}^{-1} \big(\Theta(b^j_j) C_{l-j}(\Theta(\rho); q^{2+4j} \mid q^4) \otimes b^j_j C_{l-j}(\rho; q^{2+4j} \mid q^4)$$
$$+ \Theta(b^j_{-j}) C_{l-j}(\Theta(\rho); q^{2+4j} \mid q^4) \otimes b^j_{-j} C_{l-j}(\rho; q^{2+4j} \mid q^4)\big),$$

where $\rho = \rho_{0,0} = \frac{1}{2}(\alpha^2 + q^{-1}\beta^2 + q\gamma^2 + \delta^2) = \rho^*$. Application of $\pi^1_{\theta/2} \otimes id$ on (4.5) yields

(4.6)
$$\begin{aligned} &C_l(\rho^\theta; q^2 \mid q^4) \\ &\quad = q^l C_l\left(\frac{q^{-1}e^{i\theta} + qe^{-i\theta}}{2}; q^2 \mid q^4\right) C_l(\rho; q^2 \mid q^4) \\ &\quad + \sum_{j=1}^{l} q^{l-j} \begin{bmatrix} l+j \\ 2j \end{bmatrix}_{q^4}^{-1} \frac{1}{2}\sqrt{2}\left(\frac{1+q^{4j}}{(-q^2;q^2)_{2j}}\right)^{\frac{1}{2}} \left(\frac{(q^2;q^4)_j}{(q^4;q^4)_j}\right)^{\frac{1}{2}} q^{j/2} e^{-ij\theta}(e^{2i\theta}; q^4)_j \\ &\quad \times C_{l-j}\left(\frac{q^{-1}e^{i\theta} + qe^{-i\theta}}{2}; q^{2+4j} \mid q^4\right)(b^j_j + b^j_{-j}) C_{l-j}(\rho; q^{2+4j} \mid q^4), \end{aligned}$$

where $\rho^\theta = (\pi^1_{\theta/2} \otimes id) \circ \Delta(\rho) = \frac{1}{2}(e^{i\theta}\alpha^2 + q^{-1}e^{i\theta}\beta^2 + qe^{-i\theta}\gamma^2 + e^{-i\theta}\delta^2) = (\rho^\theta)^*$. The formula (4.6) will be our starting point for the proof of the addition formula for the continuous q-Legendre polynomials.

Put $X = X_0 = iq^{1/2}B - iq^{-1/2}C \in \mathcal{U}_q$, then we have by [10, eq. (3.9)] , (2.1), (2.7), (4.1), Proposition 2.5, and Theorem 3.2,

$$(b^j_j + b^j_{-j}) C_{l-j}(\rho; q^{2+4j} \mid q^4).(XA)^2 = \left(\frac{q^{-2j} - q^{2j}}{q^{-1} - q}\right)^2 (b^j_j + b^j_{-j}) C_{l-j}(\rho; q^{2+4j} \mid q^4).$$

Consequently,

$$\begin{aligned} (b^j_j + b^j_{-j}) C_{l-j}(\rho; q^{2+4j} \mid q^4).\prod_{i=0}^{k-1}(1 - q^{4i}((q-q^{-1})^2(XA)^2 + 2) + q^{8i}) \\ = (q^{-4j}, q^{4j}; q^4)_k (b^j_j + b^j_{-j}) C_{l-j}(\rho; q^{2+4j} \mid q^4). \end{aligned} \tag{4.7}$$

Let us define

(4.8)
$$Y = \sum_{k=0}^{\infty} q^{4k} \frac{\prod_{i=0}^{k-1}(1 - q^{4i}((q-q^{-1})^2(XA)^2 + 2) + q^{8i})(e^{i\theta+i\varphi+i\psi}, e^{i\theta+i\varphi-i\psi}; q^4)_k}{(q^4, q^2, e^{2i\theta}, q^2e^{2i\varphi}; q^4)_k}.$$

Although Y is not defined as an element of the quantized, universal enveloping algebra $\mathcal{U}_q$, we will see that the action of Y on (4.6) from the right is well defined. For the right-hand side this follows directly from (4.7) and for the left-hand side we use a similar argument, which is worked out in more detail in the proof of Proposition 4.2.

If we first apply $.Y$ to the right-hand side of (4.6) and next $\pi^1_{\varphi/2}$, then we find by (4.8), (4.7), and (4.3),

$$\begin{aligned} &q^l C_l\left(\frac{q^{-1}e^{i\theta} + qe^{-i\theta}}{2}; q^2 \mid q^4\right) C_l(\cos\varphi; q^2 \mid q^4) \\ &\quad + \sum_{j=1}^{l} q^{l-j} \begin{bmatrix} l+j \\ 2j \end{bmatrix}_{q^4}^{-1} \frac{1+q^{4j}}{(-q^2;q^2)_{2j}} \frac{(q^2;q^4)_j}{(q^4;q^4)_j} e^{-ij\theta} e^{-ij\varphi} (e^{2i\theta}; q^4)_j (q^2e^{2i\varphi}; q^4)_j \\ &\quad \times C_{l-j}\left(\frac{q^{-1}e^{i\theta} + qe^{-i\theta}}{2}; q^{2+4j} \mid q^4\right) C_{l-j}(\cos\varphi; q^{2+4j} \mid q^4) \\ &\quad \times {}_4\varphi_3\left(\begin{matrix} q^{-4j}, q^{4j}, e^{i\theta+i\varphi+i\psi}, e^{i\theta+i\varphi-i\psi} \\ q^2,\ e^{2i\theta},\ q^2e^{2i\varphi} \end{matrix}; q^4, q^4\right). \end{aligned} \tag{4.9}$$

This ${}_4\varphi_3$ series is an Askey–Wilson polynomial without any factors, which we will denote by $\tilde{p}_j(\cos\psi; e^{i\theta+i\varphi}, q^2e^{-i\theta-i\varphi}, e^{i\theta-i\varphi}, q^2e^{-i\theta+i\varphi} \mid q^4)$.

THEOREM 4.1. *We have*

$$\begin{aligned}
&C_l(\cos\psi; q^2 \mid q^4)\\
&\quad = q^l C_l\left(\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2}; q^2 \mid q^4\right) C_l(\cos\varphi; q^2 \mid q^4)\\
&\qquad + \sum_{j=1}^{l} q^{l-j} \begin{bmatrix} l+j \\ 2j \end{bmatrix}_{q^4}^{-1} \frac{1+q^{4j}}{(-q^2;q^2)_{2j}} \frac{(q^2;q^4)_j}{(q^4;q^4)_j} e^{-ij\theta}e^{-ij\varphi}(e^{2i\theta};q^4)_j(q^2e^{2i\varphi};q^4)_j\\
&\qquad \times C_{l-j}\left(\frac{q^{-1}e^{i\theta}+qe^{-i\theta}}{2}; q^{2+4j} \mid q^4\right) C_{l-j}(\cos\varphi; q^{2+4j} \mid q^4)\\
&\qquad \times \tilde{p}_j(\cos\psi; e^{i\theta+i\varphi}, q^2e^{-i\theta-i\varphi}, e^{i\theta-i\varphi}, q^2e^{-i\theta+i\varphi} \mid q^4).
\end{aligned}$$

Remark. If we replace $e^{i\theta}$ by $qe^{i\theta}$, then we obtain the addition formula of Rahman and Verma [14, eq. (1.24)] for $a = q^{1/4}$ with q replaced by q^4. The general Rahman–Verma addition formula for the continuous q-ultraspherical polynomials, [14, eq. (1.24)], can also be obtained from Theorem 4.1, as suggested by Askey. Application of the divided difference operator δ_{q^4} defined in [1, eq. (5.3)] on the result contained in Theorem 4.1 yields the addition formula for the continuous q-ultraspherical polynomials $C_l(\cos\psi; q^{2+4k} \mid q^4)$ for all $k \in \mathbf{Z}_+$ by [1, eq. (5.6)]. Since the Rahman–Verma addition formula for the continuous q-ultraspherical polynomials $C_l(\cos\psi; \beta \mid q)$ is a rational expression in $\beta^{1/2}$, the addition formula follows for all values of β by analytic continuation.

The theorem is proved if we could show that

$$\pi^1_{\varphi/2}(C_l(\rho^\theta; q^2 \mid q^4).Y) = C_l(\cos\psi; q^2 \mid q^4) \quad \forall\, l \in \mathbf{Z}_+,$$

or equivalently,

$$\pi^1_{\varphi/2}\big(f(\rho^\theta).Y\big) = f(\cos\psi) \quad \forall \text{ polynomials } f, \tag{4.10}$$

or equivalently,

$$\pi^1_{\varphi/2}\big(f_l(\rho^\theta).Y\big) = f_l(\cos\psi) \quad \forall\, l \in \mathbf{Z}_+ \tag{4.11}$$

for some basis f_l of the space of polynomials. By (4.8) the left-hand side of (4.11) is an expansion in the polynomials

$$\cos\psi \mapsto (e^{i(\theta+\varphi)}e^{i\psi}, e^{i(\theta+\varphi)}e^{-i\psi}; q^4)_l.$$

So it is natural to choose these polynomials as a basis for the space of polynomials, and then condition (4.11) is equivalent to

$$\pi^1_{\varphi/2}\left(\left(\prod_{j=0}^{l-1}(1-2e^{i(\theta+\varphi)}q^{4j}\rho^\theta+e^{2i(\theta+\varphi)}q^{8j})\right).Y\right) = (e^{i(\theta+\varphi)}e^{i\psi}, e^{i(\theta+\varphi)}e^{-i\psi}; q^4)_l$$

for all $l \in \mathbf{Z}_+$. Now this is a direct consequence of (4.8) and the following proposition.

PROPOSITION 4.2. *For the polynomial*

$$f_l(\cos\psi) = (e^{i(\theta+\varphi)+i\psi}, e^{i(\theta+\varphi)-i\psi}; q^4)_l = \prod_{j=0}^{l-1}(1 - 2e^{i(\theta+\varphi)}q^{4j}\cos\psi + e^{2i(\theta+\varphi)}q^{8j}),$$

we have

$$\pi^1_{\varphi/2}\left(f_l(\rho^\theta).\left(\prod_{i=0}^{k-1}(1 - q^{4i}((q-q^{-1})^2(XA)^2 + 2) + q^{8i})\right)\right)$$
$$= \delta_{lk}q^{-4k}(q^2, q^4, e^{2i\theta}, q^2e^{2i\varphi}; q^4)_k.$$

To prove this proposition we need two lemmas. The first one is straightforward, using the definitions in [10, §3].

LEMMA 4.3. *For $X = iq^{1/2}B - iq^{-1/2}C \in \mathcal{U}_q$ we have*

$$\alpha^2.(XA) = i(1+q^2)\gamma\alpha,\ \alpha^2.(XA)^2 = (1+q^2)(\alpha^2 - q^{-1}\gamma^2),\ \alpha^2.A^l = q^l\alpha^2,$$
$$\beta^2.(XA) = i(1+q^2)\delta\beta,\ \beta^2.(XA)^2 = (1+q^2)(\beta^2 - q^{-1}\delta^2),\ \beta^2.A^l = q^l\beta^2,$$
$$\gamma^2.(XA) = -iq^{-1}(1+q^2)\gamma\alpha,\ \gamma^2.(XA)^2 = (1+q^2)(q^{-2}\gamma^2 - q^{-1}\alpha^2),\ \gamma^2.A^l = q^{-l}\gamma^2,$$
$$\delta^2.(XA) = -iq^{-1}(1+q^2)\delta\beta,\ \delta^2.(XA)^2 = (1+q^2)(q^{-2}\delta^2 - q^{-1}\beta^2),\ \delta^2.A^l = q^{-l}\delta^2,$$

and

$$(\gamma\alpha).XA = iq^{-1}\gamma^2 - i\alpha^2, \quad (\delta\beta).XA = iq^{-1}\delta^2 - i\beta^2, \quad (\gamma\alpha).A = \gamma\alpha, \quad (\delta\beta).A = \delta\beta.$$

COROLLARY 4.4.

$$\pi^1_{\varphi/2}(2\rho^\theta.A^{2p}XAA^{2r}XAA^{2s}) = e^{-i(\theta+\varphi)}q^{-2-2(p+s)}(1+q^2)(1-q^{4p}e^{2i\theta})(1-q^{2+4s}e^{2i\varphi}).$$

LEMMA 4.5. *For all $l, n \in \mathbf{Z}_+$ and all $a, b, c, d \in \mathbf{C}$, we have*

$$\pi^1_{\varphi/2}\left((a\alpha^2 + b\beta^2 + c\gamma^2 + d\delta^2)^l.(XA)^{2n+1}\right) = 0.$$

Proof. For $l = 0$ this follows directly from $\epsilon(XA) = 0$, and we proceed by induction with respect to l. Since

$$\Delta(XA) = A^2 \otimes XA + XA \otimes 1, \tag{4.12}$$

we find that a general term $\Delta(XA)^{2n+1}$ is of the form $Z \otimes (XA)^m$, where Z consists of $2n+1-m$ terms XA intermingled with terms A^2. If m is odd, then

$$\pi^1_{\varphi/2}\left((a\alpha^2 + b\beta^2 + c\gamma^2 + d\delta^2)^{l-1}.(XA)^m\right) = 0$$

by the induction hypothesis. If m is even, then Z contains an odd number of XA, and by Lemma 4.3 and [10, eq. (3.22)] we find

$$\pi^1_{\varphi/2}\left((a\alpha^2 + b\beta^2 + c\gamma^2 + d\delta^2).Z\right) = 0.$$

Now [10, eq. (3.10)] provides for the induction step. □

Proof of Proposition 4.2. For any polynomial r_l of degree l we have by [6, Thm. 3.4],

$$r_l(\rho^\theta) \in \bigoplus_{k=0}^{l} \operatorname{span}\{t^k_{n,m} \mid n,m = -k, -k+1, \dots, k\}.$$

It follows from §2 that we can write

$$r_l(\rho^\theta) = \sum_{j=0}^{l} z_j, \qquad z_j.(XA)^2 = \left(\frac{q^{-2j} - q^{2j}}{q^{-1} - q}\right)^2 z_j.$$

Consequently,

$$\pi^1_{\varphi/2}\left(r_l(\rho^\theta).\left(\prod_{i=0}^{k-1}(1-q^{4i}((q-q^{-1})^2(XA)^2+2)+q^{8i})\right)\right) = \sum_{j=0}^{l}(q^{-4j}, q^{4j}; q^4)_k \pi^1_{\varphi/2}(z_j),$$

and this equals 0 for $k > l$, which proves the proposition in case $k > l$.

Next we will consider the case $k < l$. We will show that for all k and l with $k < l$ we have

$$\pi^1_{\varphi/2}\Big(f_l(\rho^\theta).(XA)^{2k}\Big) = 0. \tag{4.13}$$

To do this we use induction with respect to k. If $k = 0$, then

$$\pi^1_{\varphi/2}\Big(f_l(\rho^\theta)\Big) = (1, e^{2i(\theta+\varphi)}; q^4)_l = 0$$

for $l \geq 1 > k = 0$. Now we assume (4.13) true for all l, k with $l > k$ and $k < n$. Since

$$\Delta(XA)^{2n} = A^{4n} \otimes (XA)^{2n} + \text{terms of the form } Z \otimes (XA)^p,\ p \leq 2n-1, \tag{4.14}$$

[10, (3.10)], Lemma 4.5 and the induction hypothesis imply, for $l > n$,

$$\begin{aligned}\pi^1_{\varphi/2}\Big(f_l(\rho^\theta).(XA)^{2n}\Big) =& \pi^1_{\varphi/2}\left(\left(\prod_{j=n}^{l-1}(1 - 2e^{i(\theta+\varphi)}q^{4j}\rho^\theta + e^{2i(\theta+\varphi)}q^{8j})\right).A^{4n}\right) \\ &\times \pi^1_{\varphi/2}\left(\left(\prod_{j=0}^{n-1}(1 - 2e^{i(\theta+\varphi)}q^{4j}\rho^\theta + e^{2i(\theta+\varphi)}q^{8j})\right).(XA)^{2n}\right).\end{aligned}$$

Now $.A^{4n}$ is a homomorphism of $\mathcal{A}_q$, and so the first term in this product is

$$\prod_{j=n}^{l-1}(1 - e^{i(\theta+\varphi)}q^{4j}(q^{4n}e^{i(\theta+\varphi)} + q^{-4n}e^{-i(\theta+\varphi)}) + e^{2i(\theta+\varphi)}q^{8j}) = 0.$$

The case $l = k$ remains to be considered. Put

$$\begin{aligned}A_l =& \pi^1_{\varphi/2}\left(f_l(\rho^\theta).\left(\prod_{i=0}^{l-1}(1 - q^{4i}((q-q^{-1})^2(XA)^2 + 2) + q^{8i})\right)\right) \\ =& (-1)^l(q-q^{-1})^{2l}q^{2l(l-1)}\pi^1_{\varphi/2}\Big(f_l(\rho^\theta).(XA)^{2l}\Big),\end{aligned}$$

where we used (4.13). If we work out (4.14) a bit more we find

$$\begin{aligned}\Delta(XA)^{2l} =& A^{4l}\otimes(XA)^{2l}+\sum_{p+r+s=2(l-1)} A^{2p}XAA^{2r}XAA^{2s}\otimes(XA)^{2(l-1)}\\ &+\text{terms of the form } Z\otimes(XA)^{2n},\quad n<l-1\\ &+\text{terms of the form } Z\otimes(XA)^{2m+1},\end{aligned}$$

and thus by [10, eq. (3.10)], Lemma 4.5, and the part of the proposition already proved, we find

$$\begin{aligned}A_l =& (-1)^l(q-q^{-1})^{2l}q^{2l(l-1)}\\ &\times\pi^1_{\varphi/2}\left((1-2e^{i(\theta+\varphi)}q^{4(l-1)}\rho^\theta+e^{2i(\theta+\varphi)}q^{8(l-1)}).A^{4l}\right)\pi^1_{\varphi/2}\left(f_{l-1}(\rho^\theta).(XA)^{2l}\right)\\ &-q^{4(l-1)}(q-q^{-1})^2A_{l-1}\\ &\times\sum_{p+r+s=2(l-1)}\pi^1_{\varphi/2}\left((1-2e^{i(\theta+\varphi)}q^{4(l-1)}\rho^\theta+e^{2i(\theta+\varphi)}q^{8(l-1)}).A^{2p}XAA^{2r}XAA^{2s}\right).\end{aligned}$$

In order to rewrite this equation as a recurrence relation for A_l we use

$$\begin{aligned}&(-1)^l(q-q^{-1})^{2l}q^{2l(l-1)}(XA)^{2l}\\ &\quad=\prod_{i=0}^{l-1}(1-q^{4i}((q-q^{-1})^2(XA)^2+2)+q^{8i})\\ &\qquad+(-1)^l(q-q^{-1})^{2(l-1)}q^{2l(l-1)}\left(\frac{1-q^{-4l}}{1-q^{-4}}-2l+\frac{1-q^{4l}}{1-q^4}\right)(XA)^{2(l-1)}\\ &\qquad+\text{ lower-order terms}\end{aligned}$$

to obtain

(4.15)

$$\begin{aligned}A_l = A_{l-1}\Bigg[&-q^{4(l-1)}\pi^1_{\varphi/2}\left((1-2e^{i(\theta+\varphi)}q^{4(l-1)}\rho^\theta+e^{2i(\theta+\varphi)}q^{8(l-1)}).A^{4l}\right)\\ &\times\left(\frac{1-q^{-4l}}{1-q^{-4}}-2l+\frac{1-q^{4l}}{1-q^4}\right)\\ &+(q-q^{-1})^2q^{8(l-1)}e^{i(\theta+\varphi)}\sum_{p+r+s=2(l-1)}\pi^1_{\varphi/2}\left(2\rho^\theta.A^{2p}XAA^{2r}XAA^{2s}\right)\Bigg].\end{aligned}$$

To make this recurrence relation more explicit some calculations have to be made. First note that

$$\pi^1_{\varphi/2}\left((1-2e^{i(\theta+\varphi)}q^{4(l-1)}\rho^\theta+e^{2i(\theta+\varphi)}q^{8(l-1)}).A^{4l}\right)=(1-q^{-4})(1-q^{8l-4}e^{2i(\theta+\varphi)}).$$

The sum in (4.15) can be evaluated using Corollary 4.4, where we obtain

$$\begin{aligned}&q^{4(l-1)}e^{i(\theta+\varphi)}\sum_{p+r+s=2(l-1)}\pi^1_{\varphi/2}\left(2\rho^\theta.A^{2p}XAA^{2r}XAA^{2s}\right)\\ &=(1+q^{-2})\Bigg[\frac{q^{4l}(1-2lq^{-4l+2}+(2l-1)q^{-4l})+q^{4l-2}e^{2i(\theta+\varphi)}(1-2lq^{4l-2}+(2l-1)q^{4l})}{(1-q^2)^2}\\ &\qquad-\frac{e^{2i\theta}+q^2e^{2i\varphi}}{(1-q^2)(1-q^4)}(1-q^{4l-2}+q^{8l-2}-q^{4l})\Bigg].\end{aligned}$$

Plugging these two identities into (4.15) gives an explicit recurrence relation:

$$\begin{aligned} A_l &= q^{-4}(1-q^{4l})(1-q^{4l-2})(1-q^{4l-4}e^{2i\theta})(1-q^{4l-2}e^{2i\varphi})A_{l-1} \\ &= q^{-4l}(q^2,q^4,e^{2i\theta},q^2e^{2i\varphi};q^4)_l A_0. \end{aligned}$$

Since $A_0 = 1$, the proof of the proposition is complete. □

Remark. The map

$$\pi^1_{\theta/2} \otimes (\pi^1_{\varphi/2} \circ .Y) : \mathcal{A}_q \otimes \mathcal{A}_q \to \mathbf{C},$$

used to obtain Theorem 4.1 from (4.5), is not injective.

5. The limit case $q \uparrow 1$. In the previous section the addition formula for the continuous q-Legendre polynomials was derived from the abstract addition formula (4.5) by use of the map $\pi^1_{\theta/2} \otimes \pi^1_{\varphi/2} \circ .Y$. For $q \uparrow 1$ the abstract addition formula (4.5) can be regarded as an identity for functions on $SL(2,\mathbf{C}) \times SL(2,\mathbf{C})$, and we will show in this section that $\pi^1_{\theta/2} \otimes \pi^1_{\varphi/2} \circ .Y$ reduces to evaluation at some suitable element of $SL(2,\mathbf{C}) \times SL(2,\mathbf{C})$, which brings us back to the group theoretic proof of the addition formula for Legendre polynomials as presented in [16, Chap. 3.4].

We regard $\mathcal{A}_1$ as the commutative algebra of functions on $SL(2,\mathbf{C})$, which are polynomials in the coordinate elements α, β, γ, and δ. In particular, the comultiplication Δ of $\mathcal{A}_1$ is given by the group multiplication on $SL(2,\mathbf{C})$ as follows:

$$(\Delta f)(g,h) = f(gh) \quad \forall\, f \in \mathcal{A}_1 \quad \forall\, g,h \in SL(2,\mathbf{C}). \tag{5.1}$$

The one-dimensional representation $\pi^1_{\theta/2} : \mathcal{A}_1 \to \mathbf{C}$ corresponds to evaluation of functions at a diagonal element of $SL(2,\mathbf{C})$:

$$\pi^1_{\theta/2}(f) = f\left(\begin{pmatrix} e^{i\theta/2} & 0 \\ 0 & e^{-i\theta/2} \end{pmatrix}\right) \quad \forall\, f \in \mathcal{A}_1. \tag{5.2}$$

To take the limit in $\mathcal{U}_q$ we replace A by $e^{((q-1)/2)H}$ and let $q \uparrow 1$; then $\mathcal{U}_q$ tends to the universal enveloping algebra $\mathfrak{U}(\mathfrak{sl}(2,\mathbf{C}))$ with generators H, B, and C and relations

$$[H,B] = 2B, \qquad [H,C] = -2C, \qquad [B,C] = H.$$

Then the right action of $\mathcal{U}_q$ on $\mathcal{A}_q$ corresponds to the action of the universal enveloping algebra $\mathfrak{U}(\mathfrak{sl}(2,\mathbf{C}))$ on functions on $SL(2,\mathbf{C})$ by right invariant differential operators.

First we consider the action of Y from the right as $q \to 1$. Note that $XA \to \tilde{X} = iB - iC$ for $q \uparrow 1$, which we identify with $\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right) \in \mathfrak{sl}(2,\mathbf{C})$. Taking termwise limits in (4.8) formally yields

$$\tilde{Y} \overset{\text{def}}{=} \lim_{q\uparrow 1} Y = {}_2F_1\left(\begin{matrix} \tilde{X}/2, -\tilde{X}/2 \\ 1/2 \end{matrix}; \frac{\cos\psi - \cos\theta\cos\varphi + \sin\theta\sin\varphi}{2\sin\theta\sin\varphi}\right),$$

where the hypergeometric function is defined by

$${}_2F_1\left(\begin{matrix} a,b \\ c \end{matrix}; x\right) = \sum_{k=0}^{\infty} \frac{(a)_n (b)_n}{n!(c)_n} x^k, \qquad (a)_n = a(a+1)\cdots(a+n-1).$$

Pick z so that

$$\cos 2z = \frac{\cos\theta\cos\varphi - \cos\psi}{\sin\theta\sin\varphi}, \tag{5.3}$$

then (cf. [3, 2.8(11)])

$${}_2F_1\left(\begin{matrix}a/2,-a/2\\1/2\end{matrix};\frac{1-\cos 2y}{2}\right) = \cos ay = \frac{e^{iay}+e^{-iay}}{2}$$

implies that formally

$$\tilde{Y} = \lim_{q\uparrow 1} Y = \frac{e^{iz\tilde{X}}+e^{-iz\tilde{X}}}{2}. \tag{5.4}$$

So (4.8) is a q-analogue of (5.4) in combination with (5.3).

From (5.4) it follows that the action of the analogue of $.Y$ on an element $f \in \mathcal{A}_1$ is given by

$$(f.\tilde{Y})(g) = \frac{1}{2}\left(f\left(\begin{pmatrix}\cos z & -\sin z\\ \sin z & \cos z\end{pmatrix}g\right) + f\left(\begin{pmatrix}\cos z & \sin z\\ -\sin z & \cos z\end{pmatrix}g\right)\right), \tag{5.5}$$

for $g \in SL(2,\mathbf{C})$, which could have been defined without using the universal enveloping algebra $\mathfrak{U}(\mathfrak{sl}(2,\mathbf{C}))$. The transition of (4.6) to (4.9) corresponds to the fact that if $f \in \mathcal{A}_1$ satisfies

$$f\left(\begin{pmatrix}\cos z & -\sin z\\ \sin z & \cos z\end{pmatrix}g\right) = e^{ijz}f(g), \qquad g \in SL(2,\mathbf{C}),$$

then $(f.\tilde{Y})(g) = \cos(jz)f(g)$.

The previous paragraph and (5.2) give a clear understanding of the action of the analogue of $\pi^1_{\theta/2}\otimes\pi^1_{\varphi/2}\circ .Y$ on the right-hand side of (4.5) for $q\uparrow 1$. For the left-hand side we consider the action of the analogue of $\pi^1_{\theta/2}\otimes\pi^1_{\varphi/2}\circ .Y$ on an element $\Delta(f)\in\mathcal{A}_1\otimes\mathcal{A}_1$. From (5.1), (5.2), and (5.5) it follows that this action is given by

$$\frac{1}{2}\left(f\begin{pmatrix}e^{i(\varphi+\theta)/2}\cos z & -e^{i(\theta-\varphi)/2}\sin z\\ e^{i(\varphi-\theta)/2}\sin z & e^{-i(\theta+\varphi)/2}\cos z\end{pmatrix} + f\begin{pmatrix}e^{i(\varphi+\theta)/2}\cos z & e^{i(\theta-\varphi)/2}\sin z\\ -e^{i(\varphi-\theta)/2}\sin z & e^{-i(\theta+\varphi)/2}\cos z\end{pmatrix}\right).$$

If f is any polynomial in $\rho = \frac{1}{2}(\alpha^2+\beta^2+\gamma^2+\delta^2)$, say $f = p(\rho)$, we can give an explicit expression for this action. Since evaluation is a homomorphism of $\mathcal{A}_1$ and because of the quadratic terms γ^2 and β^2 in ρ we find that the action of the analogue of $\pi^1_{\theta/2}\otimes\pi^1_{\varphi/2}\circ .Y$ on $\Delta(p(\rho))$ is just

$$p(\rho)\begin{pmatrix}e^{i(\varphi+\theta)/2}\cos z & -e^{i(\theta-\varphi)/2}\sin z\\ e^{i(\varphi-\theta)/2}\sin z & e^{-i(\theta+\varphi)/2}\cos z\end{pmatrix} = p(\cos\psi), \tag{5.6}$$

where z and ψ are related by (5.3). So (5.6) is easily proved, whereas its analogue (4.10) requires a lengthy proof.

Acknowledgment. The author wishes to express his gratitude to Tom Koornwinder for his support and suggestions.

BASIC HYPERGEOMETRIC FUNCTIONS AND THE BOREL–WEIL CONSTRUCTION FOR $U_q(3)$*

M. A. LOHE†‡ AND L. C. BIEDENHARN†

Abstract. The Borel–Weil construction of the irreducible unitary representations of the quantum group $U_q(3)$ is investigated. The representation functions are calculated explicitly and found to be expressible in terms of basic hypergeometric functions; the form of these basis functions verifies previous general results. It is shown that several identities satisfied by basic hypergeometric functions, including a special case of Watson's formula, are implied by properties of the quantum group.

Key words. quantum group, basic hypergeometric functions, irreducible representations, Borel–Weil construction

1. Introduction.

Quantum groups have achieved significance in recent years as algebraic structures, which have appeared in several areas of both mathematics and physics including, for example, knot theory, gauge theories, and statistical mechanical models. Quantum groups are Hopf algebras which are neither commutative nor co-commutative; alternatively, we can regard them as deformations of the universal enveloping algebra of an underlying Lie group, so that in the limit in which the deformation parameter q approaches 1 we regain the Lie algebra. Various aspects of quantum groups, including the fundamental theory and applications to physics, are investigated in [1] (where further references may be found), and for general discussions we mention [2]–[4].

Of particular interest are the irreducible representations (irreps) of quantum groups (for generic real q), for it is through these that the quantum group manifests itself in physical applications. The explicit construction of all representations of $SU_q(2)$, the simplest of the quantum groups, can be carried out in several different ways, one of which is to express the generators in terms of finite difference operators acting in the space of homogeneous polynomials of some fixed degree [5]. For $q \to 1$ one regains the familiar harmonic oscillator representation of $SU(2)$, in which the generators are realized as differential operators, or equivalently, can be expressed in terms of boson creation and annihilation operators. This construction is, unfortunately, difficult to generalize to $U_q(n)$ in such a way as to obtain all representations.

There is, however, another method of constructing representations of $SU_q(2)$ that *does* admit a relatively simple generalization to arbitrary n, the Borel–Weil (BW) construction [6]. This method, which allows us to construct (for generic real q) *all* unitary irreps of $U_q(n)$, is recursive in that one assumes that all irreps of the subgroup $U_q(n-1) \times U(1)$ have already been constructed and is explicit to the extent that the basis vectors spanning an irreducible representation space for $U_q(n)$ are expressed in terms of those for the subgroup $U_q(n-1) \times U(1)$. For $n = 2$ this construction is straightforward and appears in [6]. Our aim in this paper is to provide explicit details of the BW construction, and its q-extension, for the case $n = 3$; this is of

interest for several reasons. First, it is only for $n \geq 3$ that several complexities of the quantum group appear, such as the Serre relations, which define the quantum group (see §2), and the explicit realizations show how these relations are satisfied. Second, it will be seen that q-extensions of classical functions appear naturally in the BW construction, and that general results for the form of the basis vectors imply identities among these functions. This is true even for the simplest case $n = 2$, where we use the q-exponential function to construct q-BW states, with addition properties being related to co-multiplication in $SU_q(2)$. For the case $n = 3$, terminating basic hypergeometric functions, q-analogs of ${}_6F_5$ functions arise in our calculations of the q-BW basis states, and we reduce these to ${}_3\phi_2$ functions by using a special case of the q-analog of Whipple's transformation (Watson's formula), which reduces a ${}_8\phi_7$ basic hypergeometric function to a ${}_4\phi_3$ function. Moreover, since we know from general considerations [6] that the final form of the basis vector *must* involve a ${}_3\phi_2$ function (which is related to a q-Clebsch–Gordan coefficient), we have in effect proved the special case of Watson's formula by using quantum group properties.

It is, of course, well known that many properties of special functions can be understood as group theoretical properties of basis vectors for irreps of Lie groups (see, for example, Vilenkin [7] and [8]–[10]). It is now clear, however, that quantum groups underlie properties of q-extensions to special functions in a similar way; examples of this are the q-Clebsch–Gordan and q-Racah coefficients of $SU_q(2)$, which can be expressed as ${}_3\phi_2$ and ${}_4\phi_3$ functions, and for which properties such as the symmetries and orthogonality relations are implied by the structure of the quantum group [11], [12]. Some of these properties were, of course, derived well before the formulation of quantum groups (by Askey and Wilson [13]), but it is through the quantum group that one achieves a unifying perspective.

The plan of the paper is to first outline in §2 some basic facts about the quantum groups $U_q(2)$ and $U_q(3)$, also including a discussion on q-extensions to classical functions such as the q-exponential function, basic hypergeometric functions, and properties of the finite difference operator. Next, in §3, we show how the BW construction is applied to $U(2)$ and its quantum deformation $U_q(2)$, and then in §4 we explicitly calculate the BW basis states for $n = 3$. This calculation serves more than to merely rederive a certain form for these states, found from previous considerations [6]; the method used here is direct and the explicit calculation demonstrates that hypergeometric functions appear as coefficients of basis vectors. The general form of the basis states therefore implies the existence of identities and transformations that must be satisfied by the hypergeometric functions, including a transformation due to Whipple. In §5 we formulate q-BW states (using slightly different conventions than those of [6]) and show that the $U_q(3)$ algebra is satisfied by the realization of the quantum group generators. Finally, in §6, we present the explicit calculation of the q-BW states, in which the basic hypergeometric functions appear.

2. Quantum groups and q-extensions. The relations which define the quantum group $U_q(n)$ have been given by several authors [2], [3], [15]. In the case of $n = 2$ there are four generators, denoted $E_{ij}(i, j = 1, 2)$, satisfying the commutation relations

$$
\begin{aligned}
&[E_{11}, E_{12}] = E_{12}, \qquad [E_{11}, E_{21}] = -E_{21}, \\
&[E_{22}, E_{12}] = -E_{12}, \qquad [E_{22}, E_{21}] = E_{21},
\end{aligned} \tag{2.1}
$$

and

$$[E_{12}, E_{21}] = \frac{q^{\frac{1}{2}(E_{11}-E_{22})} - q^{-\frac{1}{2}(E_{11}-E_{22})}}{q^{\frac{1}{2}} - q^{-\frac{1}{2}}}, \tag{2.2}$$

where q is a positive real number. We will frequently use the notation

$$\begin{aligned}[n] &= \frac{q^{n/2} - q^{-n/2}}{q^{\frac{1}{2}} - q^{-\frac{1}{2}}} \\ &= q^{(n-1)/2} + q^{(n-3)/2} + \cdots q^{-(n-1)/2},\end{aligned} \tag{2.3}$$

where n is an integer, but we extend this notation so that n can also be an operator; hence (2.2) may be written $[E_{12}, E_{21}] = [E_{11} - E_{22}]$. For $q \to 1$ we have $[n] \to n$, and so in this limit (2.1) and (2.2) reduce to the usual commutation relations for $U(2)$.

The quantum group $U_q(3)$ is generated by the elements $\{e_i, f_i, h_i \mid i = 1, 2\}$, which satisfy the following equations:

$$\begin{aligned}&[h_i, h_j] = 0, \\ &[h_i, e_j] = k_{(i,j)} e_j, \qquad [h_i, f_j] = -k_{(i,j)} f_j, \\ &[e_i, f_j] = \delta_{ij}[2h_i],\end{aligned} \tag{2.4}$$

where

$$k_{(i,j)} = \begin{cases} 1, & i = j, \\ -\frac{1}{2}, & i = j + 1, \\ 0, & \text{otherwise}, \end{cases}$$

together with the $U(1)$ element h_3, which commutes with the other generators. As in [6] we will use the notation

$$\begin{aligned}&E_{12} = e_1, \quad E_{21} = f_1, \quad E_{23} = e_2, \quad E_{32} = f_2, \\ &\tfrac{1}{2}(E_{11} - E_{22}) = h_1, \quad \tfrac{1}{2}(E_{22} - E_{33}) = h_2, \quad E_{11} + E_{22} + E_{33} = h_3.\end{aligned} \tag{2.5}$$

In addition, the definition of quantum group $U_q(3)$ includes the following Serre relations:

$$\begin{aligned}&E_{12}^2 E_{23} - [2] E_{12} E_{23} E_{12} + E_{23} E_{12}^2 = 0, \\ &E_{12} E_{23}^2 - [2] E_{23} E_{12} E_{23} + E_{12} E_{23}^2 = 0,\end{aligned} \tag{2.6}$$

and the conjugate relations

$$\begin{aligned}&E_{21}^2 E_{32} - [2] E_{21} E_{32} E_{21} + E_{32} E_{21}^2 = 0, \\ &E_{21} E_{32}^2 - [2] E_{32} E_{21} E_{32} + E_{21} E_{32}^2 = 0.\end{aligned} \tag{2.7}$$

In general, $U_q(n)$ has the structure of a Hopf algebra with comultiplication Δ: $U_q(n) \to U_q(n) \otimes U_q(n)$ which is defined for the elements $\{e_i, f_i, h_i\}$ by

$$\begin{aligned}\Delta(h_i) &= h_i \otimes I + I \otimes h_i, \\ \Delta(e_i) &= e_i \otimes q^{-h_i/2} + q^{h_i/2} \otimes e_i, \\ \Delta(f_i) &= f_i \otimes q^{-h_i/2} + q^{h_i/2} \otimes f_i.\end{aligned} \tag{2.8}$$

The definition of a Hopf algebra also requires the concepts of a co-unit ε and antipode γ, which are readily defined for the quantum group:

$$\varepsilon(1) = 1, \qquad \varepsilon(e_i) = \varepsilon(f_i) = \varepsilon(h_i) = 0,$$
$$\gamma(e_i) = -q^{-\frac{1}{2}} e_i, \quad \gamma(f_i) = -q^{\frac{1}{2}} f_i, \quad \gamma(h_i) = -h_i.$$

It is well known that we can construct representations of $U(n)$ in which the generators are realized as differential operators acting on polynomials in complex variables [5]–[7] or, equivalently, we can express this construction in the language of boson creation and annihilation operators $a, \bar{a}$ acting on a vacuum state $|0\rangle$, and satisfying $[\bar{a}, a] = 1$ (see [16]). In order to construct representations in a similar way for the quantum groups, we introduce q-boson operators [17], [18] a^q and $\bar{a}^q$, satisfying

$$\bar{a}^q a^q - q^{\frac{1}{2}} a^q \bar{a}^q = q^{-\frac{N}{2}}, \tag{2.9}$$

where N (the number operator) satisfies

$$[N, a^q] = a^q, \qquad [N, \bar{a}^q] = -\bar{a}^q. \tag{2.10}$$

The q-boson vacuum $|0\rangle$ satisfies $\bar{a}^q|0\rangle = 0$, and basis states are constructed by allowing q-boson operators to act on the vacuum $|0\rangle$. Equivalently, we can realize q-boson operators as finite difference operators by defining, for suitable functions $f(z)$,

$$a^q f(z) = z f(z), \tag{2.11a}$$

$$\bar{a}^q f(z) = D_q f(z) \equiv \frac{f(zq^{\frac{1}{2}}) - f(zq^{-\frac{1}{2}})}{z(q^{\frac{1}{2}} - q^{-\frac{1}{2}})},$$

$$N\, f(z) = z\, \frac{\partial f(z)}{\partial z}. \tag{2.11b}$$

The last equation implies that $q^{-\frac{N}{2}} f(z) = f(zq^{-\frac{1}{2}})$ and the relations (2.9) and (2.10) can then be verified. Evidently, D_q acts as a finite difference operator and for $q \to 1$ becomes differentiation $\partial/\partial z$; we can regard the properties of D_q as comprising a "q-calculus."

It follows from (2.11) that

$$D_q z^n = [n] z^{n-1}, \tag{2.12}$$

where $[n]$ is defined by (2.3). Let us define the q-exponential function $\exp_q$ by

$$\exp_q(z) = \sum_{n=0}^{\infty} \frac{z^n}{[n]!}, \tag{2.13}$$

where $[n]! = [n][n-1]\cdots[1]$. Then as a result of (2.12),

$$D_q \exp_q(Az) = A \exp_q(Az), \tag{2.14}$$

where A is a constant, or an operator independent of z. The q-exponential is a q-analog of the classical exponential function, although as such it is not unique; however, it is invariant under $q \leftrightarrow q^{-1}$. The finite difference operator D_q and q-extensions to classical functions are not new to quantum groups; they were studied some time ago by Jackson [19] and the subject has been developed extensively by Askey [13], Andrews [20], and also by Milne [21] and Koornwinder [22]. Many of the results of this q-calculus have been derived by Feinsilver [23] using operator methods, in which operators satisfying (2.9) (or an equivalent relation) are postulated and q-identities are developed from algebraic considerations (see also Cigler [24]).

The q-exponential and the operators $a^q, \bar{a}^q$ appear in the BW construction of $U_q(n)$ states, and several further properties will be used extensively there, in particular the following operator equations:

$$a^q \bar{a}^q = [N], \qquad \bar{a}^q a^q = [N+1] \tag{2.15}$$

(these equations imply (2.9) directly and, with certain assumptions, can be derived from them).

Apart from the q-exponential function, we will use another q-extension of classical functions, the basic hypergeometric function, which can be defined in the following way: Let

$$(a;q)_n = \begin{cases} 1, & n = 0, \\ (1-a)(1-aq)\cdots(1-aq^{n-1}), & n > 0, \end{cases} \tag{2.16}$$

where n is an integer, then the basic hypergeometric function ${}_{p+1}\phi_p$ is defined by

$${}_{p+1}\phi_p\left(\begin{matrix} a_1 a_2 \cdots a_{p+1} \\ b_1 b_2 \cdots b_p \end{matrix}; q, z\right) = \sum_{n=0}^{\infty} \frac{(a_1;q)_n (a_2;q)_n \cdots (a_{p+1};q)_n}{(q;q)_n (b_1;q)_n \cdots (b_p;q)_n} z^n. \tag{2.17}$$

We can express the symbol $(a;q)_n$ in terms of the notation (2.3) by means of the formula

$$(a;q)_n = (q^\alpha;q)_n = (1-q)^n q^{\frac{n}{4}(n+2\alpha-3)} ([\alpha])_n, \tag{2.18}$$

where we have put $a = q^\alpha$ and

$$([\alpha])_n = [\alpha][\alpha+1]\cdots[\alpha+n-1]. \tag{2.19}$$

We can therefore write ${}_{p+1}\phi_p$ in the form

$$\begin{aligned} {}_{p+q}\phi_p\left(\begin{matrix} q^{\alpha_1} q^{\alpha_2} \cdots q^{\alpha_{p+1}} \\ q^{\beta_1} q^{\beta_2} \cdots q^{\beta_p} \end{matrix}; q, z\right) &= \sum_{n=0}^{\infty} \frac{([\alpha_1])_n ([\alpha_2])_n \cdots ([\alpha_{p+1}])_n}{[n]!([\beta_1])_n \cdots ([\beta_p])_n} (q^{\frac{\sigma}{2}} z)^n \\ &= {}_{p+1}\phi_p\left(\begin{matrix} q^{-\alpha_1} q^{-\alpha_2} \cdots q^{-\alpha_{p+1}} \\ q^{-\beta_1} \cdots q^{-\beta_p} \end{matrix}; q^{-1}, z q^\sigma\right), \end{aligned} \tag{2.20}$$

where

$$\sigma = \sum_{i=1}^{p+1} \alpha_i - \sum_{i=1}^{p} \beta_i - 1. \tag{2.21}$$

For $q = 1$ this function reduces to

$$(2.22) \qquad {}_{p+1}F_p\left(\begin{matrix}\alpha_1 \cdots \alpha_{p+1} \\ \beta_1 \cdots \beta_p\end{matrix}; z\right).$$

For the case $\sigma = -2$ and $z = q$ the function ${}_{p+1}\phi_p$ is called *balanced* or *Saalschützian.* If one of the numerator parameters $\alpha_1 \cdots \alpha_{p+1}$ is a negative integer $-m$ the series terminates, and in this case any one of the denominator parameters $\beta_1 \cdots \beta_p$ can also be negative, provided it is less than $-m$. Basic hypergeometric functions occur naturally within quantum group structures, for example, the q-Clebsch–Gordan and q-Racah coefficients can be expressed in terms of ${}_3\phi_2$ and ${}_4\phi_3$ functions, respectively [11], [12]. Basic hypergeometric functions were first introduced by Heine [25] and a recent exposition of their properties has been presented by Gasper and Rahman [26].

Finally, let us mention the q-binomial theorem, from which an addition theorem can be derived for the q-exponential function. An elegant formulation can be written in terms of quantum coordinates a, b, which satisfy

$$(2.23) \qquad ba = q\, ab,$$

and then the q-binomial theorem states, for positive integers n,

$$(2.24) \qquad (a+b)^n = \sum_{j=1}^{n} \frac{q^{j(n-j)/2}[n]!}{[j]![n-j]!} a^j b^{n-j},$$

which can be proved by induction on n. (For a discussion of this theorem and applications using q-calculus see Feinsilver [23].) We will interpret the quantum coordinates a, b as operators to be constructed from quantum group generators.

3. The BW construction for $U(2)$ and $U_q(2)$. The Borel–Weil (BW) construction of irreducible representations of the unitary groups was originally formulated in differential geometric terms as the construction of a line bundle over the homogeneous space $U(n)\backslash(U(n-1) \times U(1))$, in which the fiber carries an irreducible representation of $U(n-1) \times U(1)$ with sections that are holomorphic functions in the homogeneous space. An algebraic version of this construction can be formulated in the framework of vector coherent states (LeBlanc and Biedenharn [14]), and this procedure can be generalized directly to quantum groups [6], unlike the fiber bundle construction for which too little is known of nonplanar quantum manifolds.

Let us outline the construction of vector coherent states, which we refer to as BW states. These are described in more detail in [14]; BW states are formed from the subset of Gel'fand–Weyl basis vectors annihilated by the raising operators $E_{in}, i = 1, \ldots, n-1$ of $U(n)$. This subset is therefore given by

$$(3.1) \qquad \{|(\mu)\rangle\} \equiv \{|(m)_n\rangle : E_{in}|(m)_n\rangle = 0, i = 1, \ldots, n-1\},$$

where $|(m)_n\rangle$ is a basis vector in the irrep space of $U(n)$ labelled by $[\mathbf{m}_n] = [m_{1n}, \ldots, m_{nn}]$ and $(m)_n$ is an n-rowed Gel'fand–Weyl pattern. The linear space spanned by the vectors $\{|(\mu)\rangle\}$ carries the irrep

$$(3.2) \qquad [\mu_{1,n-1}, \mu_{2,n-1}, \ldots, \mu_{n-1,n-1}] \otimes [m_{nn}],$$

where $\mu_{i,n-1} = m_{in}, i = 1, \ldots, n-1$, which is of the subgroup $U(n-1) \times U(1)$. The BW states are vector-valued holomorphic functions defined by

$$(3.3) \qquad |(m)_n\rangle_{BW} = \sum_{(\mu)} \langle(\mu)|e^{z \cdot E}|(m)_n\rangle|(\mu)\rangle,$$

where $z \cdot E = \sum_{i=1}^{n-1} z_i E_{in}$, and $\{z_i\}$ is a set of $(n-1)$ complex variables used as coordinates for the co-set space $U(n)\backslash(U(n-1)\times U(1))$; these complex variables $\{z_i\}$ can be identified with boson creation operators $\{a_i\}$ acting on the vacuum $|0\rangle$, as mentioned in §2. The sum in (3.3) is over all Gel'fand–Weyl patterns (μ) carrying the irrep of $U(n-1)\times U(1)$ shown in (3.2).

The basis $|(m)_n\rangle_{BW}$ carries the $U(n)$ irrep $[\mathbf{m}_n]$, with the group action defined by

$$g \circ |(m)_n\rangle_{BW} \equiv \sum_{(\mu)} \langle(\mu)|e^{z\cdot E} g|(m)_n\rangle|(\mu)\rangle, \tag{3.4}$$

where $g \in U(n)$. This group action can be generalized to the quantum group, provided it is formulated in terms of the Lie algebra; the BW state realization $\Gamma(E_{ij})$ of a generator E_{ij} of $U(n)$ acts on the BW states according to

$$\Gamma(E_{ij})|(m)_n\rangle_{BW} = \sum_{(\mu)} \langle(\mu)|e^{z\cdot E} E_{ij}|(m)_n\rangle|(\mu)\rangle. \tag{3.5}$$

It can be shown [14] that the basis vectors $|(m)_n\rangle_{BW}$ take the form

$$|(m)_n\rangle_{BW} = K\begin{pmatrix}[\mathbf{m}_n]\\ [\mathbf{m}_{n-1}]\end{pmatrix} \sum_{(\mu),(\mu')} C^{[\mu][w\dot{0}][m_{n-1}]}_{(\mu)(\mu')(m_{n-1})} \left(\left| \begin{matrix}[w\ \dot{0}]\\ (\mu')\end{matrix} \right\rangle \otimes \left| \begin{matrix}[\mu]\\ (\mu)\end{matrix} \right\rangle \right), \tag{3.6}$$

where

(i) the numerical constant K depends only on the $U(n)$ irrep labels $[\mathbf{m}_n]$ and the $U(n-1)$ irrep labels $[\mathbf{m}_{n-1}]$, according to the formula

$$K\begin{pmatrix}[\mathbf{m}_n]\\ [\mathbf{m}_{n-1}]\end{pmatrix} = \left(\prod_{i=1}^{n-1} \frac{(p_{in} - p_{nn} - 1)!}{(p_{i,n-1} - p_{nn})!} \right)^{\frac{1}{2}}, \tag{3.7}$$

where $p_{ij} \equiv m_{ij} + j - i$;

(ii) the Wigner–Clebsch–Gordan coefficient $C^{\cdots}_{\cdots}$ effects the tensor coupling: $[w\ \dot{0}] \times [\mu] \to [\mathbf{m}_{n-1}]$;

(iii) The irrep vector $|\begin{smallmatrix}[w\ \dot{0}]\\ (\mu')\end{smallmatrix}\rangle$ is homogeneous and holomorphic in the boson operators $\{z_i\}$ acting on the vacuum with the $U(n-1)$ irrep labels $[w, 0\cdots 0]$, where

$$w = \sum_{i=1}^{n-1} (m_{i,n-1} - \mu_{i,n-1}); \tag{3.8}$$

(iv) the $U(n-1)$ irrep labels of the fiber vector $|\begin{smallmatrix}[\mu]\\ (\mu)\end{smallmatrix}\rangle$ are given by $\mu_{i,n-1} = m_{i,n}$ for $i = 1, 2, \ldots, n-1$. (These fiber vectors are actually tensored with a fixed $U(1)$ vector carrying the irrep $[m_{nn}]$ but this is suppressed to avoid complication.)

Let us illustrate this construction and the rather complicated result (3.6) by writing the $U(2)$ BW states explicitly, and deriving the form (3.6) for this case. It is then straightforward to determine the extension to the quantum group. The $U(2)$ BW states are defined by

$$\left| \begin{matrix} m_{12} & m_{22} \\ m_{11} \end{matrix} \right\rangle_{BW} = \left\langle \begin{matrix} m_{12} & m_{22} \\ m_{12} \end{matrix} \right| \exp(aE_{12}) \left| \begin{matrix} m_{12} & m_{22} \\ m_{11} \end{matrix} \right\rangle |0\rangle \otimes \left| \begin{matrix} m_{12} & m_{22} \\ m_{12} \end{matrix} \right\rangle, \tag{3.9}$$

where we have used the definition (3.1) in which the summation over the patterns (μ) has one term only, and where we have also used the operator notation in which a boson operator a acts on $|0\rangle$. Using the known matrix elements of E_{12},

$$(3.10)\quad E_{12}\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle = \sqrt{(m_{12}-m_{11})(m_{11}+1-m_{22})}\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11}+1 \end{matrix}\right\rangle$$

and orthonormality of the Gel'fand–Weyl basis vectors, we find

(3.11)

$$\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle_{BW} = \left(\frac{(m_{12}-m_{22})!}{(m_{11}-m_{22})!}\right)^{\frac{1}{2}} \frac{a^{m_{12}-m_{11}}}{\sqrt{(m_{12}-m_{11})!}}|0\rangle \otimes \left|\begin{matrix} m_{12} & m_{22} \\ & m_{12} \end{matrix}\right\rangle,$$

where the factors correspond to those shown in (3.6), i.e., the K-factor and the boson polynomial.

Now let us extend this construction to the quantum group $U_q(2)$, defining the q-BW states by

(3.12)

$$\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle_{q,BW} = \left\langle\begin{matrix} m_{12} & m_{22} \\ & m_{12} \end{matrix}\right| \exp_q(a^q E_{12}) \left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle |0\rangle \otimes \left|\begin{matrix} m_{12} & m_{22} \\ & m_{12} \end{matrix}\right\rangle,$$

where the q-boson operator and the q-exponential are defined in (2.9), (2.10), and (2.13), respectively. These states may be evaluated directly from the matrix elements of E_{12}:

$$(3.13)\quad E_{12}\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle = \sqrt{[m_{12}-m_{11}][m_{11}+1-m_{22}]}\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11}+1 \end{matrix}\right\rangle,$$

and we obtain a straightforward analog of (3.11):

(3.14)

$$\left|\begin{matrix} m_{12} & m_{22} \\ & m_{11} \end{matrix}\right\rangle_{q,BW} = \left(\frac{[m_{12}-m_{22}]!}{[m_{11}-m_{22}]!}\right)^{\frac{1}{2}} \frac{(a^q)^{m_{12}-m_{11}}}{\sqrt{[m_{12}-m_{11}]!}}|0\rangle \otimes \left|\begin{matrix} m_{12} & m_{22} \\ & m_{12} \end{matrix}\right\rangle.$$

From the definition of the q-BW states and the action of the algebra given in (3.2), we can calculate the q-BW realization $\Gamma(E_{ij})$ of the generators E_{ij}, as summarized in the following two lemmas.

LEMMA 3.1. *The realization $\Gamma(E_{ij})$ of the $U_q(2)$ generators acting on the basis $|(m)\rangle_{q,BW}$ is given by*

$$(3.15a)\qquad \Gamma(E_{11}) = E_{11} - N,$$

$$(3.15b)\qquad \Gamma(E_{22}) = E_{22} + N,$$

$$(3.15c)\qquad \Gamma(E_{12}) = \bar{a}^q,$$

$$(3.15d)\qquad \Gamma(E_{21}) = a^q[E_{11} - E_{22} - N],$$

where N is the number operator for the q-bosons, satisfying (2.10).

Proof. By using the commutation relations (2.1) we find

$$[E_{11} - N, a^q E_{12}] = 0 = [E_{22} + N, a^q E_{12}], \tag{3.16}$$

from which we obtain $(E_{11}-N)\exp_q(a^qE_{12})\,|\,0\rangle = \exp_q(a^qE_{12})E_{11}\,|\,0\rangle$, which in turn implies (3.15a), and similarly implies (3.15b). Equation (3.15c) follows upon using the q-boson form of (2.14). To obtain (3.15d) we need the relation

$$E_{21}E_{12}^n = E_{12}^n E_{21} - [E_{11} - E_{22} - n + 1][n]E_{12}^{n-1}, \qquad n \in \mathbb{Z} \tag{3.17}$$

which is proved by induction on n (the proof uses the identity

$$[a][b+c] - [b][a+c] = [a-b][c] \tag{3.18}$$

for $a = E_{11} - E_{22} - n$, $b = n$, c $= 1$). From (3.17),

$$\exp_q(a^qE_{12})E_{21}\,|\,0\rangle = (E_{21} + a^q[E_{11} - E_{22} - N])\exp_q(a^qE_{12})\,|\,0\rangle \tag{3.19}$$

follows, and now we use the fact that the state $|(\mu)\rangle$ (shown specifically in (3.12)) is of highest weight in $U(1)$, i.e., $\langle(\mu)|E_{21} = 0$ in order to obtain (3.15d). □

LEMMA 3.2. *The map* $\Gamma : g \to U_q(g)$, *where* g *is a generator of* $U_q(2)$, *given by* (3.15), *is an isomorphism of the algebra* $U_q(2)$.

Proof. The commutation relations (2.1) follow immediately, except

$$[\Gamma(E_{12}), \Gamma(E_{21})] = [\Gamma(E_{11}) - \Gamma(E_{22})] = [E_{11} - E_{22} - 2N], \tag{3.20}$$

which follows from (2.15) and the identity (3.18) for $a = E_{11} - E_{22} - N$, $b = N$, $c = 1$. □

4. Explicit BW states for $U(3)$. For $U(3)$ the BW states defined by (3.1) take the form

$$\left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix}\right\rangle_{BW} = \sum_m E_m((m);z) \left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{13} & m_{23} \\ & & m \end{matrix}\right\rangle, \tag{4.1}$$

where the coefficients are the matrix elements

$$E_m((m);z) = \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{13} & m_{23} \\ & & m \end{matrix} \right| \exp(z_1E_{13} + z_2E_{23}) \left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix}\right\rangle, \tag{4.2}$$

where (m) denotes the array (m_{ij}). We now verify the form (3.6) of these states by explicit calculation, proceeding by determining first the matrix elements in (4.2). This we do by writing the exponential in (4.2) as a product of two exponential factors (using the addition theorem for exponentials), each of which is expanded as an infinite series; however, only one term of each series contributes due to orthonormality of the Gel'fand–Weyl basis. We therefore require the matrix elements of E_{13} and E_{23}, to arbitrary powers, in the Gel'fand–Weyl basis, and then express (4.2) as a sum. We find that this can be written in terms of a hypergeometric ${}_6F_5$ function. Next we use an identity due to Whipple that expresses the ${}_6F_5$ function in terms of a ${}_3F_2$ function, which in turn can be expressed as a Clebsch–Gordan coefficient. This calculation leads us directly to the final form (3.6) that we seek; the fact that the final answer *must* be

of this form in fact implies the existence of Whipple's identity, as well as symmetries of the hypergeometric functions, as noted in the Introduction.

For $n = 3$, (3.6) reads

$$\left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{12} & m_{22} & \\ m_{11} & & \end{matrix} \right\rangle_{BW} = (-1)^{m_{22}-m_{23}} \left[\frac{(m_{13}-m_{33}+1)!(m_{23}-m_{33})!}{(m_{12}-m_{33}+1)!(m_{22}-m_{33})!} \right]^{\frac{1}{2}}$$

(4.3)

$$\times \sum_m \frac{z_1^{m-m_{11}}(-z_2)^{w+m_{11}-m}}{\sqrt{(m-m_{11})!(w+m_{11}-m)!}} C^{j_1 j_2 j}_{m_1 m_2 m_1+m_2} \left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13} & m_{23} & \\ m & & \end{matrix} \right\rangle,$$

where

$$\begin{aligned} w &= m_{13} + m_{23} - m_{12} - m_{22}, \\ j_1 &= \tfrac{1}{2}(m_{13} - m_{23}), \quad j_2 = \tfrac{1}{2} w, \quad j = \tfrac{1}{2}(m_{12} - m_{22}), \\ m_1 &= m - \tfrac{1}{2}(m_{13} + m_{23}), \qquad m_2 = m_{11} - m + \tfrac{1}{2} w. \end{aligned} \tag{4.4}$$

Here we have also substituted from (3.7) for the explicit K-factor, namely,

$$K\begin{pmatrix} [\mathbf{m}_3] \\ [\mathbf{m}_2] \end{pmatrix}^2 = \prod_{i=1}^{2} \frac{(p_{i3} - p_{33} - 1)!}{(p_{i2} - p_{33})!}, \tag{4.5}$$

and have included the phase factor $(-1)^\phi$ (see [14, eq. (2.16)]), where

$$\begin{aligned} \phi &= \phi([\mu]) - \phi([0, -w]) - \phi([\mathbf{m}_2]) \\ &= \phi([m_{13}, m_{23}]) - \phi([0, -w]) - \phi([m_{12}, m_{22}]) \\ &= m_{22} - m_{23}. \end{aligned} \tag{4.6}$$

We now provide details of the calculations, together with properties of the hypergeometric functions used in order to obtain precisely the form (4.3). Apart from its intrinsic interest, this calculation serves as a guide for establishing similar results for the quantum group case.

In order to evaluate the matrix elements (4.2) we first require the matrix elements of E_{13} and E_{23} in the Gel'fand–Weyl basis. Explicit formulas for matrix elements in $U(n)$, first found by Gel'fand and Zetlin [27], are given by Baird and Biedenharn [28], and for the particular case $n = 3$ and for E_{23} these reduce to

(4.7)

$$\left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{12} & m_{22} & \\ m_{11} & & \end{matrix} \right| E_{23}$$

$$= \left[\frac{(m_{12}-m_{11})(m_{13}-m_{12}+1)(m_{12}-m_{23})(m_{12}-m_{33}+1)}{(m_{12}-m_{22}+1)(m_{12}-m_{22})} \right]^{\frac{1}{2}} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{12}-1 & m_{22} & \\ m_{11} & & \end{matrix} \right|$$

$$+ \left[\frac{(m_{11}-m_{22}+1)(m_{13}-m_{22}+2)(m_{23}-m_{22}+1)(m_{22}-m_{33})}{(m_{12}-m_{22}+2)(m_{12}-m_{22}+1)} \right]^{\frac{1}{2}} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{12} & m_{22}-1 & \\ m_{11} & & \end{matrix} \right|.$$

By repeated application of E_{23} we obtain the general form

$$(4.8)\qquad \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} \quad m_{22} & \\ & m_{11} & \end{matrix} \right| (E_{23})^n = \sum_{r=0}^{n} A_r^n(m) \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12}-r \quad m_{22}+r-n & \\ & m_{11} & \end{matrix} \right|,$$

where (m) is the array $\left(\begin{smallmatrix} m_{12} & m_{22} \\ & m_{11} \end{smallmatrix}\right)$, and the coefficients A_r^n are to be determined. This can be done by deriving a recurrence relation for A_r^n using (4.7). We find

(4.9)

$$\begin{aligned} &A_r^{n+1} \\ &= A_{r-1}^n \left[\frac{(m_{12}-m_{11}-r+1)(m_{13}-m_{12}+r)(m_{12}-m_{23}-r+1)(m_{12}-m_{33}-r+2)}{(m_{12}-m_{22}+n-2r+3)(m_{12}-m_{22}+n-2r+2)}\right]^{\frac{1}{2}} \\ &\quad + A_r^n \left[\frac{(m_{11}-m_{22}+n-r+1)(m_{13}-m_{22}+n-r+2)}{(m_{12}-m_{22}+n-2r+2)}\right. \\ &\qquad \left. \times \frac{(m_{23}-m_{22}+n-r+1)(m_{22}-m_{33}-n+r)}{(m_{12}-m_{22}+n-2r+1)}\right]^{\frac{1}{2}} \end{aligned}$$

with $A_0^0 = 1$. Let us merely state the solution of these recurrence relations, as verified by direct substitution:

(4.10)

$$\begin{aligned} A_r^n &= \frac{n!(m_{12}-m_{22}-r)!}{r!(n-r)!(m_{12}-m_{22}+n-r+1)!} \\ &\quad \times \left[\frac{(m_{11}-m_{22}+n-r)!(m_{23}-m_{22}+n-r)!(m_{22}-m_{33})!}{(m_{11}-m_{22})!(m_{23}-m_{22})!(m_{22}-m_{33}-n+r)!}\right. \\ &\qquad \times \frac{(m_{12}-m_{11})!(m_{12}-m_{23})!(m_{12}-m_{33}+1)!(m_{13}-m_{12}+r)!}{(m_{12}-m_{11}-r)!(m_{12}-m_{23}-r)!(m_{12}-m_{33}-r+1)!(m_{13}-m_{12})!} \\ &\qquad \left. \times \frac{(m_{13}-m_{22}+n-r+1)!(m_{12}-m_{22}+1)(m_{12}-m_{22}+n-2r+1)}{(m_{13}-m_{22}+1)!}\right]^{\frac{1}{2}}. \end{aligned}$$

We also need to evaluate the matrix elements of $(E_{13})^\ell$, for arbitrary integers ℓ, but in this case we require the action of $(E_{13})^\ell$ only on those states for which $m_{12} = m_{13}, m_{22} = m_{23}$. Since $E_{13} = [E_{12}, E_{23}]$, the matrix elements of E_{13} are easily found

from those of E_{23}, given in (4.7), and those of E_{12} in (3.10), to give

(4.11)

$$\left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13} & m_{23} \\ & m_{11} \end{matrix} \right| E_{13} = \sqrt{\frac{(m_{13}-m_{33}+1)(m_{11}-m_{23})}{(m_{13}-m_{23}+1)}} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13}-1 & m_{23} \\ & m_{11}-1 \end{matrix} \right| - \sqrt{\frac{(m_{23}-m_{33})(m_{13}-m_{11}+1)}{(m_{13}-m_{23}+1)}} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13} & m_{23}-1 \\ & m_{11}-1 \end{matrix} \right| .$$

From this follows the general form:

$$\left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13} & m_{23} \\ & m_{11} \end{matrix} \right| (E_{13})^{\ell} = \sum_{s=0}^{\ell} B_s^{\ell}(m) \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13}-s & m_{23}-\ell+s \\ & m_{11}-\ell \end{matrix} \right| , \tag{4.12}$$

where (m) is the array $\left(\begin{smallmatrix} m_{13} & m_{23} \\ & m_{11} \end{smallmatrix}\right)$ for some coefficients B_s^{ℓ}. As before, we derive a recurrence relation for B_s^{ℓ}, using (4.11):

(4.13)

$$\begin{aligned} &B_s^{\ell+1} \\ &= B_{s-1}^{\ell} \left[\frac{s(m_{13}-m_{23}-s+1)(m_{13}-m_{33}-s+2)(m_{11}-m_{23}-s+1)}{(m_{13}-m_{23}+\ell-2s+3)(m_{13}-m_{23}+\ell-2s+2)} \right]^{\frac{1}{2}} \\ &- B_s^{\ell} \left[\frac{(m_{13}-m_{23}+\ell-s+2)(\ell-s+1)(m_{23}-m_{33}-\ell+s)(m_{13}-m_{11}+\ell-s+1)}{(m_{13}-m_{23}+\ell-2s+2)(m_{13}-m_{23}+\ell-2s+1)} \right]^{\frac{1}{2}} \end{aligned}$$

with $B_0^0 = 1$. The solution, which again is verified by direct substitution, is

(4.14)

$$\begin{aligned} B_s^{\ell} &= (-1)^{\ell+s}\ell! \\ &\times \left[\frac{(m_{13}-m_{33}+1)!(m_{11}-m_{23})!(m_{13}-m_{23}-s)!(m_{13}-m_{11}+\ell-s)!}{s!(\ell-s)!(m_{13}-m_{23}+\ell+1-s)!(m_{13}-m_{33}+1-s)!(m_{11}-m_{23}-s)!} \right. \\ &\times \left. \frac{(m_{23}-m_{33})!(m_{13}-m_{23}+\ell-2s+1)}{(m_{13}-m_{11})!(m_{23}-m_{33}-\ell+s)!} \right]^{\frac{1}{2}} . \end{aligned}$$

We can now evaluate $E_m((m);z)$ by expanding the exponentials, giving

(4.15)

$$E_m((m);z) = \sum_{\ell,n} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13} & m_{23} \\ & m \end{matrix} \right| \frac{z_1^{\ell} z_2^{n}}{\ell!\, n!} (E_{13})^{\ell} (E_{23})^{n} \left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{12} & m_{22} \\ & m_{11} \end{matrix} \right\rangle$$

$$= \sum_{\ell,n=0}^{\infty} \sum_{s=0}^{\ell} \sum_{r=0}^{n} \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ m_{13}-s-r, & m_{23}-\ell+s+r-n & \\ & m-\ell & \end{matrix} \right| \frac{(z_1)^{\ell}(z_2)^{n}}{\ell!\, n!} B_s^{\ell} \begin{pmatrix} m_{13} & m_{23} \\ & m \end{pmatrix}$$

$$\times A_r^n \begin{pmatrix} m_{13}-s, m_{23}-\ell+s \\ m-\ell \end{pmatrix} \left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix} \right\rangle .$$

Since the Gel'fand–Weyl states are orthonormal, we can eliminate three of the four summations, namely, the sums over ℓ, n, r. We must have

$$\begin{aligned} \ell &= m - m_{11}, \\ r &= m_{13} - m_{12} - s, \\ n &= w - m + m_{11}, \end{aligned} \tag{4.16}$$

where $w = m_{13} + m_{23} - m_{12} - m_{22}$. The matrix element now takes the form

(4.17)

$$\begin{aligned} &E_m((m); z) \\ &\quad = \sum_s \frac{z_1^{m-m_{11}}\, z_2^{w-m+m_{11}}}{(m-m_{11})!(w-m+m_{11})!} B_s^{m-m_{11}} \\ &\qquad \cdot \begin{pmatrix} m_{13} & m_{23} \\ & m \end{pmatrix} A^{w-m+m_{11}}_{m_{13}-m_{12}-s} \begin{pmatrix} m_{13}-s & m_{23}+s-m+m_{11} \\ & m_{11} \end{pmatrix}. \end{aligned}$$

Next, we collect all the factors as given in (4.10) and (4.14) in order to obtain the resulting matrix elements

(4.18)

$$\begin{aligned} E_m((m); z) &= z_1^{m-m_{11}}\, z_2^{w-m+m_{11}} (-)^{m-m_{11}} \\ &\times \left[\frac{(m_{13}-m_{33}+1)!(m_{23}-m_{33})!(m_{11}-m_{22})!(m_{23}-m_{22})!}{(m_{22}-m_{33})!(m_{12}-m_{33}+1)!(m_{12}-m_{11})!(m_{12}-m_{23})!(m_{13}-m_{12})!} \right. \\ &\quad \left. \times \frac{(m_{12}-m_{22}+1)}{(m_{13}-m)!(m-m_{23})!(m_{13}-m_{22}+1)!} \right]^{\frac{1}{2}} \\ &\times \frac{(m_{13}-m_{23})!(m_{12}+m-m_{23}-m_{11})!(m_{13}-m_{11})!}{(m-m_{11})!(m_{13}+m-m_{11}-m_{23})!(m_{11}+m_{23}-m_{22}-m)!} \sum_s R(s), \end{aligned}$$

where $R(s)$ is a product of all those terms containing s-dependent factors, and may be written as

$$R(s) = \frac{(-)^s (1+a/2)_s (a)_s (b)_s (c)_s (d)_s (e)_s}{s!(a/2)_s (a-b+1)_s (a-c+1)_s (a-d+1)_s (a-e+1)_s}, \tag{4.19}$$

where

$$\begin{aligned} a &= m_{11} + m_{23} - m_{13} - m - 1, \qquad b = m_{11} - m, \\ c &= m_{12} - m_{13}, \qquad d = m_{23} - m, \\ e &= m_{22} - m_{13} - 1, \end{aligned} \tag{4.20}$$

and where it can be seen that all square roots have combined to give a rational function of the basis state labels.

The function obtained by summing the terms $R(s)$ over s can be identified as a generalized hypergeometic function with argument -1:

(4.21)
$$\sum_s R(s) = {}_6F_5\left(\begin{matrix} 1+a/2 & a & b & c & d & e \\ a/2 & a-b+1 & a-c+1 & a-d+1 & a-e+1 & \end{matrix}\ ;-1\right).$$

This function can be expressed in a simpler form by means of a special case of Whipple's transformation, which itself transforms a terminating well-poised ${}_7F_6$ into a Saalschützian ${}_4F_3$ (see Bailey [29, §4.3]). This transformation is derived by Bailey (§4.4, eq. (2)), and reads

(4.22)
$$\begin{aligned} &{}_6F_5\left(\begin{matrix} 1+a/2 & a & b & c & d & e \\ a/2 & a-b+1 & a-c+1 & a-d+1 & a-e+1 & \end{matrix}\ ;-1\right) \\ &\quad = (-1)^c \frac{(-a-1)_{-c}}{(a-e+1)_{-c}}\, {}_3F_2\left(\begin{matrix} 1+a-b-d & c & e \\ 1+a-b & 1+a-d & \end{matrix}\right), \end{aligned}$$

where we have used the fact that $-c = m_{13} - m_{12}$ is a positive integer.

We now obtain from (4.17),

(4.23)
$$\begin{aligned} &E_m((m);z) \\ &= \frac{z_1^{m-m_{11}}\, z_2^{w-m+m_{11}}}{\sqrt{(m-m_{11})!(w-m+m_{11})!}}\,(-)^{m-m_{11}+m_{12}-m_{13}}(m_{13}-m_{23})!(m_{13}-m_{11})! \\ &\times \left[\frac{(m_{13}-m_{33}+1)!(m_{23}-m_{33})!(m_{11}-m_{22})!(m_{23}-m_{22})!(m_{12}-m_{22}+1)}{(m_{12}-m_{33}+1)!(m_{22}-m_{33})!(m_{13}-m_{22}+1)!(m_{13}-m)!(m_{12}-m_{11})!(m-m_{23})!}\right. \\ &\quad \left.\times \frac{1}{(m_{12}-m_{23})!(m_{13}-m_{12})!(m-m_{11})!(w+m_{11}-m)!}\right]^{\frac{1}{2}} \\ &\times {}_3F_2\left(\begin{matrix} m-m_{13} & m_{22}-m_{13}-1 & m_{12}-m_{13} \\ & m_{23}-m_{13} & m_{11}-m_{13} \end{matrix}\right). \end{aligned}$$

We expect this expression, from consideration of the general form (3.6), to be proportional to the Clebsch–Gordan coefficient that couples the following states:

(4.24)
$$\left|\begin{matrix} 0 & -w \\ m_{11}-m & \end{matrix}\right\rangle, \qquad \left|\begin{matrix} m_{13} & m_{23} \\ m & \end{matrix}\right\rangle \to \left|\begin{matrix} m_{12} & m_{22} \\ m_{11} & \end{matrix}\right\rangle.$$

The Clebsch–Gordan coefficient that performs this coupling is $C^{j_1 j_2 j}_{m_1 m_2 m_1+m_2}$, where

(4.25)
$$\begin{aligned} &j_1 = \tfrac{1}{2}(m_{13}-m_{23}), \quad j_2 = \tfrac{1}{2}w, \quad j = \tfrac{1}{2}(m_{12}-m_{22}), \\ &m_1 = m - \tfrac{1}{2}(m_{13}+m_{23}), \qquad m_2 = m_{11} - m + \tfrac{1}{2}w. \end{aligned}$$

A standard expression for the Clebsch–Gordan coefficient is given by the van der Waerden form, which can be expressed as an ${}_3F_2$ function as follows (see, for example,

[30, p. 429]):

(4.26)
$$
\begin{aligned}
&C^{j_1 j_2 j}_{m_1 m_2 m_1+m_2} \\
&= \left[\frac{(m_{12}-m_{22}+1)(m_{12}-m_{33})!(m_{23}-m_{22})!(m-m_{23})!(m-m_{11})!}{(m_{13}-m_{22}+1)!(m_{13}-m)!(w+m_{11}-m)!}\right. \\
&\qquad \left.\times \frac{(m_{11}-m_{22})!(m_{12}-m_{11})!}{(m_{13}-m_{12})!}\right]^{\frac{1}{2}} \\
&\times \frac{1}{(m_{12}+m-m_{13}-m_{23})!(m_{12}+m-m_{13}-m_{11})!} \\
&\times {}_3F_2\begin{pmatrix} m_{12}-m_{13} & m-m_{13} & -w-m_{11}+m \\ m_{12}-m_{13}-m_{23}+m+1 & m_{12}-m_{11}+m-m_{13}+1 & \end{pmatrix},
\end{aligned}
$$

where we used the definitions given in (4.25). The ${}_3F_2$ function in (4.23) is not in the form (4.26); however, there is a direct transformation between the two forms, which appears in Bailey [29, p. 85] and may be written

(4.27)
$$
\begin{aligned}
{}_3F_2\begin{pmatrix} a & b & c \\ e & f & \end{pmatrix} &= \frac{(a-f)!(c-f)!(c-e)!(a-e)!}{(-e)!(-f)!(a+c-e)!(a+c-f)!} \\
&\quad \times {}_3F_2\begin{pmatrix} a & c & a+b+c-e-f+1 \\ a+c-f+1 & a+c-e+1 & \end{pmatrix},
\end{aligned}
$$

where c is a negative integer (the parameters a, b, e, f here differ from those defined in (4.20)). Now, if we substitute into (4.27) for the parameters according to

(4.28)
$$
\begin{aligned}
&a = m - m_{13}, \qquad b = m_{22} - m_{13} - 1, \\
&c = m_{12} - m_{13}, \quad e = m_{23} - m_{13}, \quad f = m_{11} - m_{13},
\end{aligned}
$$

then we transform the ${}_3F_2$ function in (4.23) into the form (4.26) for the Clebsch–Gordan coefficient, and consequently express the BW state in precisely the required form (4.3).

5. The BW realization of $U_q(3)$. It is known [31], [32] that (for generic real q) all unitary irreps of the quantum groups $U_q(n)$ are finite-dimensional and in one-to-one correspondence with those of $U(n)$. Similarly, the basis states are in one-to-one correspondence with the Gel'fand–Weyl basis states for the unitary groups, and so the same set of labels (m) can be used to label the quantum group states. In constructing q-BW states, analogous to (4.1) and (4.2) for $U(3)$, we need to determine only the appropriate q-extension of the exponential factor and its argument in (4.2). The algebra (2.4) for $U_q(3)$ is specified in terms of elements corresponding to the simple roots, namely, E_{12} and E_{23}, and we require an appropriate definition of E_{13} in order to generalize (4.2). We choose, as in [6],

$$
E_{13} = q^{-E_{22}/2}(E_{12}E_{23} - q^{-\frac{1}{2}}E_{23}E_{12}); \tag{5.1}
$$

then, as a consequence of the defining relations (2.4) and (2.6), we have

$$
[E_{13}, E_{23}] = 0 = [E_{13}, E_{12}]. \tag{5.2}
$$

(In fact these relations are equivalent to the Serre relations (2.6).) Similarly, we choose the operator E_{31} according to

$$E_{31} = q^{E_{22}/2}(E_{32}E_{21} - q^{\frac{1}{2}}E_{21}E_{32}), \tag{5.3}$$

which satisfies

$$[E_{31}, E_{21}] = 0 = [E_{31}, E_{32}]. \tag{5.4}$$

We can now define the $U_q(3)$ BW states by

$$\left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix} \right\rangle_{q,BW} = \sum_m E_m^q((m); a^q)|0\rangle \otimes \left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{13} & m_{23} \\ & & m \end{matrix} \right\rangle, \tag{5.5}$$

where

$$E_m^q((m); a^q) = \left\langle \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{13} & m_{23} \\ & & m \end{matrix} \right| \exp_q(a_1^q E_{13}) \exp_q(a_2^q E_{23}) \left| \begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix} \right\rangle, \tag{5.6}$$

and where the q-exponential is defined in (2.13). The product of exponentials can be combined using a q-addition formula, which is obtained with the help of the q-binomial theorem (2.24), which we may write as

$$\exp_q(a_1^q E_{13}) \exp_q(a_2^q E_{23})\,|0\rangle = \exp_q\left(q^{-N_2/2} a_1^q E_{13} + q^{N_1/2} a_2^q E_{23}\right)|0\rangle. \tag{5.7}$$

An outline of the proof of this formula is as follows. Define the operators a, b by

$$a = q^{-N_2/2} a_1^q, \qquad b = q^{N_1/2} a_2^q, \tag{5.8}$$

where N_1, N_2 are the number operators for the q-boson operators a_1^q, a_2^q, respectively. Then $ba = qab$, and we may apply the q-binomial theorem (2.24) to each of the series expansions of the q-exponentials on the left-hand side of (5.7) to obtain the right-hand side after applying the number operators to the vacuum $|0\rangle$.

We have now defined q-analogs of the BW states for $n = 3$, and we next establish the $n = 3$ version of Lemma 3.1, i.e., we calculate the realization $\Gamma(E_{ij})$ of the $U_q(3)$ generators and verify that these operators satisfy the algebra of $U_q(3)$. The results are summarized in the following lemmas.

LEMMA 5.1. *The realization $\Gamma(E_{ij})$ of the $U_q(3)$ generators acting on the basis $|(m)\rangle_{q,BW}$ is given by*

$$\begin{aligned}
\Gamma(E_{11}) &= E_{11} - N_1, \\
\Gamma(E_{22}) &= E_{22} - N_2, \\
\Gamma(E_{33}) &= E_{33} + N_1 + N_2, \\
\Gamma(E_{13}) &= \bar{a}_1^q, \\
\Gamma(E_{23}) &= \bar{a}_2^q, \\
\Gamma(E_{12}) &= q^{N_2/2} E_{12} - q^{(E_{22}+1)/2}\, a_2^q\, \bar{a}_1^q, \\
\Gamma(E_{21}) &= q^{-N_1/2} E_{21} - q^{-(E_{11}+1)/2}\, a_1^q\, \bar{a}_2^q, \\
\Gamma(E_{32}) &= q^{-E_{33}/2} a_1^q E_{12} + a_2^q[E_{22} - E_{33} - N_1 - N_2], \\
\Gamma(E_{31}) &= q^{E_{33}/2} a_2^q E_{21} + a_1^q[E_{11} - E_{33} - N_1 - N_2].
\end{aligned} \tag{5.9}$$

Proof. The expressions for $\Gamma(E_{13})$, $i = 1, 2$ are immediate since $\bar{a}_i^q \exp_q(a_i^q E_{i3}) \mid 0\rangle = \exp_q(a_i^q E_{i3}) E_{i3} \mid 0\rangle$ $(i = 1, 2)$, as indicated in (2.14), and $[E_{13}, E_{23}] = 0$. The expressions for $\Gamma(E_{ii})$, $i = 1, 2, 3$ follow in the same way as for $U_q(2)$, using

$$[E_{11} - N_1, a_1^q E_{13}] = 0 = [E_{11} - N_1, a_2^q E_{23}]$$

and

$$[E_{33} + N_1 + N_2, a_1^q E_{13}] = 0 = [E_{33} + N_1 + N_2, a_2^q E_{23}].$$

Next, we require the formula

$$E_{23}^n E_{12} = q^{n/2} E_{12} E_{23}^n - [n] q^{(E_{22}+1)/2} E_{13} E_{23}^{n-1}, \tag{5.10}$$

which is proved by induction on n. From it follows

$$\exp_q(a_2^q E_{23}) E_{12} = E_{12} q^{N_2/2} \exp_q(a_2^q E_{23}) q^{-N_2/2} - q^{(E_{22}+1)/2} E_{13} a_2^q \exp_q(a_2^q E_{23}).$$

We multiply this operator equation on the right by $\exp_q(a_1^q E_{13})$, replace $E_{13} \exp_2(a_2^q E_{23})$ by $\bar{a}_1^q \exp_q(a_2^q E_{23})$, and let the result act on the vacuum to give the required expression for $\Gamma(E_{12})$. Similarly, beginning with the formula

$$E_{13}^n E_{21} = q^{-n/2} E_{21} E_{13}^n - q^{-(E_{11}+1)/2} [n] E_{23} E_{13}^{n-1}, \tag{5.11}$$

we obtain $\Gamma(E_{21})$. In order to calculate $\Gamma(E_{32})$, we first prove

$$E_{13}^n E_{32} = q^{n/2} E_{32} E_{13}^n + q^{-E_{33}/2} [n] E_{12} E_{13}^{n-1} \tag{5.12}$$

by induction on n. Hence

$$\exp_q(a_1^q E_{13}) E_{32} = E_{32} q^{N_1/2} \exp_q(a_1^q E_{13}) q^{-N_1/2} + q^{-E_{33}/2} E_{12} a_1^q \exp_q(a_1^q E_{13}).$$

Next we use

$$\exp_q(a_2^q E_{23}) E_{32} = (E_{32} + a_2^q [E_{22} - E_{33} - N_2]) \exp_q(a_2^q E_{23}),$$

which follows from

$$E_{23}^n E_{32} = E_{32} E_{23}^n + [E_{22} - E_{33} - n + 1][n] E_{23}^{n-1}. \tag{5.13}$$

By combining these formulas, we get $\Gamma(E_{32})$ as required, and $\Gamma(E_{31})$ is obtained by using (5.3). □

LEMMA 5.2. *The map* $\Gamma : g \to U_q(g)$, *where* g *is a generator of* $U_q(3)$, *given by* (5.9), *is an isomorphism of the algebra* $U_q(3)$.

Proof. We first check that the definition (5.1) of E_{13} is preserved under the mapping Γ, i.e., we verify

$$\Gamma(E_{13}) = q^{-\Gamma(E_{22})/2} \left(\Gamma(E_{12}) \Gamma(E_{23}) - q^{-\frac{1}{2}} \Gamma(E_{23}) \Gamma(E_{12}) \right), \tag{5.14}$$

and this follows directly upon using the definition (2.9) for the q-boson operator a_2^q. It is also immediate that

$$[\Gamma(E_{13}), \Gamma(E_{23})] = 0 = [\Gamma(E_{13}), \Gamma(E_{12})]. \tag{5.15}$$

We also find

$$
\begin{aligned}
[\Gamma(E_{12}),\Gamma(E_{21})] &= q^{-(N_1-N_2)/2}[E_{12},E_{21}] - q^{(E_{22}-E_{11})/2}\,[a_1^q\bar{a}_2^q, a_2^q\bar{a}_1^q] \\
&= [\Gamma(E_{11}) - \Gamma(E_{22})],
\end{aligned} \tag{5.16}
$$

as required, and

$$
\begin{aligned}
[\Gamma(E_{23}),\Gamma(E_{32})] &= \bar{a}_2^q a_2^q[E_{22} - E_{33} - N_1 - N_2] - a_2^q\bar{a}_2^q[E_{22} - E_{33} - N_1 - N_2 + 1] \\
&= [E_{22} - E_{33} - N_1 - 2N_2],
\end{aligned} \tag{5.17}
$$

again as required, where we used (2.15) and (3.18) with $a = E_{22} - E_{33} - N_1 - N_2, b = N_2, c = 1$. □

6. Explicit BW states for $U_q(3)$. In this section we undertake the q-analog of the calculation in §4 in order to obtain the $U_q(3)$ BW states explicitly, in a form analogous to (3.6). For this we require various identities satisfied by basic hypergeometric functions, which arise naturally within the calculation. Whereas the required matrix elements can be written in terms of ${}_6F_5$ functions for $U(3)$ (see (4.21)), we find that for $U_q(3)$ they can be expressed as a certain limit of basic hypergeometric functions ${}_8\phi_7$, which are then reduced to ${}_3\phi_2$ functions by using known identities. These ${}_3\phi_2$ functions can in turn be transformed into a standard form recognizable as q-Clebsch–Gordan coefficients, enabling us to express the q-BW states as a product of a K_q-factor and a sum over a polynomial in a_1^q, a_2^q, with a q-Clebsch–Gordan coupling, tensored with the Gel'fand–Weyl states.

The q-BW states are defined by (5.5) and (5.6), and our first task is to evaluate the matrix elements in (5.6). The matrix elements of the simple roots E_{12}, E_{23} of the $U_q(3)$ algebra are identical to those of $U(3)$, but with the parentheses in (3.10) and (4.7) replaced by the square brackets defined in (2.3); compare, for example, (3.10) and (3.13). For general n a proof has been provided by Ueno et al. [33]. Hence we can calculate the matrix elements of E_{13} from those of E_{12}, E_{23} by using (5.1), and we find that

$$
\begin{aligned}
E_{13}\left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix}\right\rangle
&= q^{-m_{22}/2}\sqrt{\frac{[m_{13}-m_{12}][m_{12}-m_{23}+1][m_{12}-m_{33}+2][m_{11}+1-m_{22}]}{[m_{12}-m_{22}+2][m_{12}-m_{22}+1]}} \\
&\quad\times\left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12}+1 & m_{22} \\ & & m_{11}+1 \end{matrix}\right\rangle \\
&\quad - q^{-(m_{12}+1)/2}\sqrt{\frac{[m_{13}-m_{22}+1][m_{23}-m_{22}][m_{22}+1-m_{33}][m_{12}-m_{11}]}{[m_{12}-m_{22}+1][m_{12}-m_{22}]}} \\
&\quad\times\left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22}+1 \\ & & m_{11}+1 \end{matrix}\right\rangle .
\end{aligned} \tag{6.1}
$$

From the matrix elements for E_{23} and E_{13} we can calculate the coefficients $A^n_r(m)$ and $B^\ell_s(m)$, which are defined as in (4.8) and (4.12), respectively. We do this by obtaining recurrence relations analogous to (4.9) and (4.13), and for A^n_r the only change is to replace parentheses $(\ldots)$ by brackets $[\ldots]$ to obtain the solution analogous to (4.10), and the recurrence relations are satisfied upon using the identity (3.18). The coefficients B^ℓ_s involve explicit q-factors, as is apparent from the matrix elements (6.1), and satisfy

(6.2)
$$\begin{aligned} B^{\ell+1}_s &= B^\ell_{s-1} q^{-(m_{23}-\ell+s-1)/2} \\ &\quad \cdot \left(\frac{[s][m_{13}-m_{23}-s+1][m_{13}-m_{33}-s+2][m_{11}-m_{23}-s+1]}{[m_{13}-m_{23}+\ell-2s+3][m_{13}-m_{23}+\ell-2s+2]} \right)^{\frac{1}{2}} \\ &\quad - B^\ell_s q^{-(m_{13}-s+1)/2} \left(\frac{[m_{13}-m_{23}+\ell-s+2][\ell-s+1]}{[m_{13}-m_{23}+\ell-2s+2]} \right. \\ &\qquad \left. \times \frac{[m_{23}-m_{33}-\ell+s][m_{13}-m_{11}+\ell-s+1]}{[m_{13}-m_{23}+\ell-2s+1]} \right)^{\frac{1}{2}}. \end{aligned}$$

The solution is

(6.3)
$$\begin{aligned} B^\ell_s &= q^{-(\ell-s)(m_{13}-s)/2} q^{-s(m_{23}-1)/2} q^{-\ell/2} (-)^{\ell+s} [\ell]! \\ &\quad \times \left(\frac{[m_{13}-m_{33}+1]![m_{11}-m_{23}]![m_{13}-m_{23}-s]![m_{13}-m_{11}+\ell-s]!}{[s]![\ell-s]![m_{13}-m_{23}+\ell+1-s]![m_{13}-m_{33}+1-s]![m_{11}-m_{23}-s]!} \right. \\ &\qquad \left. \times \frac{[m_{23}-m_{33}]![m_{13}-m_{23}+\ell-2s+1]}{[m_{13}-m_{11}]![m_{23}-m_{33}-\ell+s]!} \right)^{\frac{1}{2}}, \end{aligned}$$

which is verified by direct substitution, using (3.18) with $a = \ell+1$, $b = m_{13}-m_{23}+\ell-s+2$, $c = -s$.

The matrix element $E^q_m((m); a^q)$ is therefore given by the q-analog of (4.18) (i.e., replace $(\ldots)$ by $[\ldots]$), together with the multiplicative q-factor

$$q^{-s(s+a)/2-(m_{13}+1)(m-m_{11})/2}, \tag{6.4}$$

which comes from the coefficient B^ℓ_s in (6.3), and where a is defined in (4.20). The terms involving the summation s, analogous to $R(s)$ as given in (4.19), are

$$R(s) = \frac{[a+2s]([a])_s([b])_s([c])_s([d])_s([e])_s(-1)^s q^{-s(a+s)/2}}{[s]![a]([1+a-b])_s([1+a-c])_s([1+a-d])_s([1+a-e])_s}, \tag{6.5}$$

where a, b, c, d, e are given by (4.20).

The function $\sum_s R(s)$ is the q-analog of the ${}_6F_5$ function appearing in (4.21), and is most conveniently expressed as the limit of an ${}_8\phi_7$ function, specifically

(6.6)
$$\begin{aligned} &\sum_s R(s) \\ &= \lim_{N\to\infty} {}_8\phi_7 \left(\begin{matrix} q^a, q^{1+a/2}, -q^{1+a/2}, q^b, q^c, q^d, q^e, q^{-N} \\ q^{a/2}, -q^{a/2}, q^{1+a-b}, q^{1+a-c}, q^{1+a-d}, q^{1+a-e}, q^{1+a+N} \end{matrix} ; q, \frac{q^{2a+2+N}}{q^{b+c+d+e}} \right) \\ &= \lim_{N\to\infty} \sum_s \frac{[a+2s]([a])_s([b])_s([c])_s([d])_s([e])_s([-N])_s}{[s]![a]([1+a-b])_s([1+a-c])_s([1+a-d])_s([1+a-e])_s([1+a+N])_s}, \end{aligned}$$

where we used the definition (2.20) of a basic hypergeometric function, and the identity

$$\frac{(q^{1+a/2};q)_s(-q^{1+a/2};q)_s}{(q^{a/2};q)_s(-q^{a/2};q)_s} = q^s\frac{[a+2s]}{[a]}. \tag{6.7}$$

The limit $N \to \infty$ in (6.6) is taken using

$$\lim_{N\to\infty}\frac{([-N])_s}{([1+a+N])_s} = (-)^s q^{-s(s+a)/2} \qquad (q>1). \tag{6.8}$$

Although $\sum_s R(s)$ can be expressed in a certain way as a ${}_7\phi_6$ function, the form (6.6) is appropriate for our purposes because we can now use a formula due to Watson [34] that reduces a terminating, very well-poised ${}_8\phi_7$ series to a terminating balanced ${}_4\phi_3$ series, and is the q-analog of Whipple's formula, which transforms a well-poised ${}_7F_6$ into a Saalschützian ${}_4F_3$. By using this formula we can reduce $\sum_s R(s)$ to a ${}_3\phi_2$ function, which is identifiable with a q-Clebsch–Gordan coefficient. Watson's formula states (see Bailey [29, p. 69] or Gasper and Rahman [26, p. 35])

(6.9)

$$\begin{aligned}
&{}_8\phi_7\left(\begin{matrix} q^a, & q^{1+a/2}, & -q^{1+a/2}, & q^b, & q^c, & q^d, & q^e, & q^{-N} \\ q^{a/2}, & -q^{a/2}, & q^{1+a-b}, & q^{1+a-c}, & q^{1+a-d}, & q^{1+a-e}, & q^{1+a+N} & \end{matrix}\ ;\ q, \frac{q^{2a+2+N}}{q^{b+c+d+e}}\right) \\
&= \frac{(q^{1+a};q)_N(q^{1+a-d-e};q)_N}{(q^{1+a-d};q)_N(q^{1+a-e};q)_N}\ {}_4\phi_3\left(\begin{matrix} q^d & q^e & q^{1+a-b-c} & q^{-N} \\ & q^{1+a-b} & q^{1+a-c} & q^{e+d-a-N} \end{matrix}\ ;\ q, q\right).
\end{aligned}$$

In Bailey's notation we have replaced a by q^a, c by q^b, d by q^c, e by q^d, f by q^e, and g by q^{-N}, where N is a positive integer. In our notation Watson's formula reads

$$\begin{aligned}
&\sum_s \frac{[a+2s]([a])_s([b])_s([c])_s([d])_s([e])_s([-N])_s}{[s]![a]([1+a-b])_s([1+a-c])_s([1+a-d])_s([1+a-e])_s([1+a+N])_s} \\
&= \frac{([1+a])_N([1+a-c-e])_N}{([1+a-c])_N([1+a-e])_N} \\
&\quad\times \sum_s \frac{([1+a-b-d])_s([c])_s([e])_s([-N])_s}{[s]!([1+a-b])_s([1+a-d])_s([c+e-a-N])_s}.
\end{aligned} \tag{6.10}$$

Watson used this formula to prove the Rogers–Ramanujan identities, by taking suitable limits of the parameters; it also implies a general summation formula due to Jackson (see Gasper and Rahman [26, §§2.6 and 2.7]).

We now let $N \to \infty$ in (6.10) and the left-hand side reduces, according to (6.6), to $\sum_s R(s)$, while the multiplicative factors on the right-hand side become

$$(-)^e q^{-ec/2}\frac{[-a-1]![a-c]!}{[a-c-e]![-a+e-1]!} \qquad (q>1) \tag{6.11}$$

(in which positivity of the factorial arguments follows from the definitions of a, c, e in (4.20) and the inequalities satisfied by the Gel'fand–Weyl labels m_{ij}). We also use the limit

$$\lim_{N\to\infty}\frac{[\alpha-N]_s}{[\beta-N]_s} = q^{(\beta-\alpha)/2} \qquad (q>1) \tag{6.12}$$

and hence find

$$\sum_s R(s) = (-)^e q^{-ec/2} \frac{[-a-1]![a-c]!}{[a-c-e]![-a+e-1]!} \cdot \sum_s \frac{([1+a-b-d])_s([c])_s([e])_s q^{-s(e+c-a)/2}}{[s]!([1+a-b])_s([1+a-d])_s}, \tag{6.13}$$

which is the desired expression relating $\sum_s R(s)$ to a ${}_3\phi_2$ function.

Upon combining all terms, the matrix element $E^q_m((m); a^q)$ is now found to be

$$\begin{aligned}
&\sum_m (a_1^q)^{m-m_{11}} (a_2^q)^{w+m_{11}-m} (-)^{m_{12}-m_{13}+m-m_{11}} \\
&\quad \cdot q^{-(m_{12}-m_{13})(m_{22}-m_{13}-1)/2} q^{-(m_{13}+1)(m-m_{11})/2} \\
&\quad \times \frac{[m_{13}-m_{22}]![m_{13}-m_{11}]!}{[m-m_{11}]![w-m+m_{11}]!} \\
&\quad \times \left(\frac{[m_{13}-m_{33}+1]![m_{23}-m_{33}]![m_{11}-m_{22}]![m_{23}-m_{22}]!}{[m_{22}-m_{33}]![m_{12}-m_{33}+1]![m_{13}-m]![m_{12}-m_{11}]![m_{12}-m_{23}]!} \right. \\
&\qquad \left. \times \frac{[m_{12}-m_{22}+1]}{[m-m_{23}]![m_{13}-m_{12}]![m_{13}-m_{22}+1]!} \right)^{\frac{1}{2}} \\
&\quad \times {}_3\phi_2 \left(\begin{matrix} q^{m-m_{13}} & q^{m_{22}-m_{13}-1} & q^{m_{12}-m_{13}} \\ & q^{m_{23}-m_{13}} & q^{m_{11}-m_{13}} \end{matrix} ; q^{-1}, q^{-1} \right).
\end{aligned} \tag{6.14}$$

We wish to identify the ${}_3\phi_2$ function with that appearing in the q-Clebsch–Gordan coefficients; a standard form for these coefficients, the q analog of the van der Waerden form (4.26), has been calculated in [11], and can be expressed in terms of ${}_3\phi_2$ functions as follows [12].

$$\begin{aligned}
&{}_qC^{j_1 j_2 j}_{m_1 m_2 m} = \delta_{m,m_1+m_2} q^{(j_1+j_2-j)(j_1+j_2+j+1)/4+(j_1 m_2 - j_2 m_1)/2} \\
&\quad \times \left(\frac{[2j+1][j_1+m_1]![j_2-m_2]![j+m]![j-m]!}{[j_1+j_2+j+1]![j_1+j_2-j]![j-j_1+j_2]![j+j_1-j_2]![j_2+m_2]![j_1-m_1]!} \right)^{\frac{1}{2}} \\
&\quad \times ([j-j_2+m_1+1])_{j_1-m_1} ([j-j_1-m_2+1])_{j_2+m_2} \\
&\quad \times {}_3\phi_2 \left(\begin{matrix} q^{-j_1-j_2+j} & q^{-j_1+m_1} & q^{j_2-m_2} \\ & q^{j-j_2+m_1+1} & q^{j-j_1-m_2+1} \end{matrix} ; q, q \right).
\end{aligned} \tag{6.15}$$

We identify the parameters j_1, j_2, j, m_1, m_2 as in (4.25), and we seek to express the coefficients in the form shown in (6.14); in order to do this we require the following transformation [13, eq. (1.30)], [26, eq. (3.2.2)]:

$${}_3\phi_2 \left(\begin{matrix} q^{-n} & \alpha & \beta \\ & \gamma & \delta \end{matrix} ; q, q \right) = \alpha^n \frac{(\delta/\alpha; q)_n}{(\delta; q)_n} {}_3\phi_2 \left(\begin{matrix} q^{-n} & \alpha & \gamma/\beta \\ & \gamma & \alpha q^{1-n}/\delta \end{matrix} ; q, \beta q/\delta \right), \tag{6.16}$$

where n is a positive integer. Putting $\alpha = q^a$, $\beta = q^b$, $\gamma = q^e$, $\delta = q^f$, we can write

this as

(6.17)

$$\begin{aligned}
&\sum_s \frac{q^{-s(a+b-n-e-f+1)/2}([a])_s([b])_s([-n])_s}{[s]!([e])_s([f])_s} \\
&\quad = q^{-an/2}\frac{([f-a])_n}{([f])_n}\sum_s \frac{q^{-s(b-f)/2}([a])_s([e-b])_s[-n])_s}{[s]!([e])_s([a+1-n-f])_s} \\
&\quad = \frac{([f-a])_n([e-a])_n}{([e])_n([f])_n}\sum_s \frac{q^{-sb/2}([a])_s([a+b+1-n-e-f])_s([-n])_s}{[s]!([a+1-n-f])_s([a+1-n-e])_s},
\end{aligned}$$

where we used the identity a second time in the last step. Hence we have

(6.18)

$$\begin{aligned}
&{}_3\phi_2\left(\begin{matrix} q^a & q^b & q^{-n} \\ & q^e & q^f \end{matrix}; q^{-1}, q^{-1}\right) \\
&\quad = \frac{([f-a])_n([e-a])_n}{([e])_n([f])_n}\,{}_3\phi_2\left(\begin{matrix} q^a & q^{a+b+1-n-e-f} & q^{-n} \\ & q^{a+1-n-e} & q^{a+1-n-f} \end{matrix}; q^{-1}, q^{-1}\right).
\end{aligned}$$

This relation is the q-analog of (4.27), with $c = -n$ and, with the parameters identified as in (4.28), enables us to express the ${}_3\phi_2$ function in (6.14) in terms of the ${}_3\phi_2$ function in (6.15), i.e., we can now explicitly identify the q-Clebsch–Gordan coefficients in the matrix elements $E^q_m((m); a^q)$. Upon collecting all factors, we find that

(6.19)

$$\begin{aligned}
\left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{12} & m_{22} \\ & & m_{11} \end{matrix}\right\rangle_{q,BW} &= (-)^{m_{22}-m_{23}} K_q\left(\begin{matrix}[\mathbf{m}_3] \\ [\mathbf{m}_2]\end{matrix}\right)\sum_m \frac{(a_1^q)^{m-m_{11}}(-a_2^q)^{w+m_{11}-m}}{\sqrt{[m-m_{11}]![w+m_{11}-m]!}} \\
&\quad \times q^{\mu/4}{}_{q^{-1}}C^{j_1 j_2 j}_{m_1 m_2 m_2+m_2}\,|0\rangle \otimes \left|\begin{matrix} m_{13} & m_{23} & m_{33} \\ & m_{13} & m_{23} \\ & & m \end{matrix}\right\rangle,
\end{aligned}$$

where the K_q-factor is given by

$$K_q\left(\begin{matrix}[\mathbf{m}_3] \\ [\mathbf{m}_2]\end{matrix}\right)^2 = \frac{[m_{13}-m_{33}+1]![m_{23}-m_{33}]!}{[m_{12}-m_{33}+1]![m_{22}-m_{33}]!} \tag{6.20}$$

and

(6.21)

$$\mu = -(m_{13}-m_{12})(m_{13}-m_{22}+1) - (3m_{13}-m_{23}+2)(m-m_{11}) + w(m_{13}-m).$$

This form for the general $U_q(3)$ basis vector is a special case of general results we have obtained [6] for the form of the BW basis vectors for $U_q(n)$. The origin of the various factors is explained in [6]; however, as discussed in the Introduction, our calculation here explicitly shows how the theory of special functions and their q-analogs is interwoven with properties of the representations of the classical Lie groups and their q-analogs, the quantum groups.

DEDICATION

This special issue of the *SIAM Journal on Mathematical Analysis* is dedicated to our dear friends Richard A. Askey on the occasion of his sixtieth birthday on June 4, 1993, and Frank W. J. Olver on the upcoming occasion of his seventieth birthday on December 15, 1994.

Frank Olver was the Managing Editor of this journal from its inception in 1970 until the end of 1974, and he has been on its Editorial Board ever since. He was on the Editorial Boards for the *SIAM Journal on Numerical Analysis* (1964–69), *NBS Journal of Research* (1966–78) and the Springer-Verlag series *Handbook for Automatic Computation* (1959–73). In addition, he has been an Associate Editor for *Mathematics of Computation* since 1984, and in 1992 he joined the Editorial Board for the new journal *Methods and Applications of Analysis.*

According to his son Peter, Frank's mathematical career started in World War II while he was working for the British Nautical Almanac Office, just after he received his bachelor's degree from the University of London. One day he had finished whatever he was doing and was wandering in the room. He paused behind one of his coworkers who was carefully adding up an infinite series. Frank's eyes widened when he looked at the series and he suddenly remarked "You know, that series diverges!" The other fellow momentarily turned around to say "Yes, that's right..." and then resumed his calculation. Of course, the series was an asymptotic one, and Frank's curiosity on how one could sum a divergent series led directly to his eventual mathematical career. To illustrate Frank's meticulous and rather unusual proofreading technique, Peter contributed the following anecdote. Frank was and is one of the most careful proofreaders of mathematics ever. For his book, he proofread every formula backwards (!) so as not to be lulled into skipping errors. Late at night at home you could hear him mutter unintelligible (to his kids) things like "... zero, zero, equals, equals, x, x, 3, 3, plus, plus ...". He proofread not only the galley proofs and the page proofs this way, but even when the final typeset manuscript was shipped from England to the United States, he spent a day in New York looking for a few final corrections. He once even offered Peter several dollars for any typographical error he could find in his book—more for mathematical ones. Peter has yet to collect a single dollar for this despite having asked a number of friends and colleagues!

Among Frank's most significant contributions are his example of a convergent series expansion which has *twice* itself as its own asymptotic expansion (published in Vol. 1 of this journal, pp. 533–534), rigorous exponential improvement of asymptotic expansions derived from Laplace integrals or ordinary differential equations, error bounds for a great variety of asymptotic expansions, a numerical algorithm for second-order difference equations, a new method for the evaluation of zeros of solutions of second-order differential equations and the development of a new system of computer arithmetic. His book, *Asymptotics and Special Functions*, published in 1974 and translated into Russian in 1978 (shorter version) and 1990 (full version), is considered to be the classic source on these topics. For additional comments on Frank's contributions to mathematics, see the 1990 book *Asymptotic and Computational Analysis*, edited by R. Wong, which contains the proceedings of the *International Symposium on Asymptotic and Computational Analysis* that was held in honor of Frank Olver on the occasion of his sixty-fifth birthday. Although Frank received the rank of Professor Emeritus in 1992 at the University of Maryland (in the Institute for Physical Science and Technology and the Mathematics Department), he has not retired from

his research or editorial work, and he continues to make important contributions to asymptotics, numerical analysis, and special functions.

In asymptotics, it is often not the final result but the method used to obtain the result that is the most important. This is why one will not find many well-known theorems in books on asymptotics, but instead will find methods such as Laplace's method, the principle of stationary phase, the method of steepest descent, saddle-point method, and so forth in almost every book on the subject. What makes Frank's work stand out from others is that Frank not only can come up with powerful methods but he can also formulate the final result into precise and general theorems which can be applied directly to a wide variety of problems. This is certainly evidenced in his earlier work on the construction of globally valid uniform asymptotic solutions to ordinary differential equations, and in his recent work on the exponentially-improved asymptotic solutions of ordinary differential equations. Frank is so thorough that when he finishes his investigation, there may be very little left for someone else to continue.

Dick Askey has been on the Editorial Board of this journal since its first issue in 1970. He is the Szegö Professor at the University of Wisconsin in Madison and an Honorary Fellow of the Indian Academy of Sciences. He was a Guggenheim Fellow (1969–70) and Vice President of the American Mathematical Society (1986–87). During the spring of 1992 he gave the Turán lectures in Budapest. Dick has constantly been on the look-out for areas of research in science generally (not just in mathematics) where special functions might play a significant role. As a result he has interacted with physicists, statisticians, engineers, and others in important ways so that work on special functions has become widely visible.

His research during the 1960s and early 1970s concentrated primarily on harmonic analysis and classical orthogonal polynomials, related positivity questions and inequalities. Perhaps the best testimony to the power and importance of this work lies in the fact that one of the inequalities in a joint paper with one of us (G. G.) (see *American J. Math.*, 98 (1976), p. 713, Theorem 3) plays a central role in Louis de Branges' original proof of the celebrated Bieberbach Conjecture.

In 1974, Dick presented ten lectures at a C.B.M.S. Regional Conference Lecture Series at the Virginia Polytechnic Institute which were published in his book *Orthogonal Polynomials and Special Functions.* This book helped lead to a renewed interest in orthogonal polynomials, a subject area which was more or less dormant during the 1950s and 1960s, but has been one of the liveliest areas in classical analysis ever since. Starting in the late 1960s Dick managed to get together a large group of graduate and postdoctoral students at the University of Wisconsin in Madison, many of whom ended up as internationally recognized specialists in various areas of special functions and orthogonal polynomials. In the late 1970s his work expanded to include those special functions allied with combinatorics and number theory. Recent developments in quantum groups have shown that the same functions arise there. For example, these studies led to the embedding of the "$6-j$ symbols" of physics into the theory of orthogonal polynomials. He unearthed and extended beautiful results of L. J. Rogers; this led to new families of orthogonal polynomials known as the Askey–Wilson polynomials and the "sieved" polynomials. He has also vigorously participated in the renaissance of interest in Ramanujan. In particular, he has been a leader in applying some of Ramanujan's integrals to work in hypergeometric and basic hypergeometric series.

Although Dick proudly and jokingly classifies himself as one of the last breed of 18th-century mathematicians, he is, in fact, very much a 21st-century mathematician.

He helped to keep classical analysis alive and interacting with modern mathematics. He has pursued excellence in every aspect of mathematics, including teaching, libraries and history, and has given never ending encouragement and support to younger colleagues, including those in crises (political, economic, personal, and scientific). Many of us feel that he is a bridge between the great classical analysts such as Hardy, Littlewood, Ramanujan, Pólya, and Szegö, just to name a few, and future mathematics and related areas.

Dick is also well known for his unique mathematical vocabulary which includes "marvellous" (way before Billy Crystal) and "preposterous" so that very few of his letters or recommendations and referee reports can remain truly anonymous. His observation that "a ten minute nap in a colloquium is equivalent to one hour of a good night's sleep" has been put to practice and validated by each of us.

We wish the very best to Dick and Frank in their future personal and professional endeavors.

A HYPERGEOMETRIC ANALYSIS OF THE GENUS SERIES FOR A CLASS OF 2-CELL EMBEDDINGS IN ORIENTABLE SURFACES*

G. E. ANDREWS†, D. M. JACKSON‡, AND T. I. VISENTIN§

Abstract. The genus series for dipoles is used to determine an explicit expression for the number of dipoles of given genus with a given number of edges. The approach uses a hypergeometric argument, which may assist with other classes of maps such as vertex-regular maps. Such maps are of importance in combinatorial theory and appear to have application to two-dimensional quantum gravity.

Key words. hypergeometric function, 2-cell embedding, rooted map, integral representation, genus series

AMS subject classifications. 33C20, 57N37, 05A15

1. Introduction.

A *dipole* is a map on two vertices of the same degree, with loops allowed. It is a generalization of a map consisting of a multiple edge, whose vertices necessarily have the same degree. In a loose sense, dipoles are the next class of maps in order of complexity beyond the one-vertex maps (called *monopoles*), and dipoles with no loops have been an object of study in topological graph theory [6]. A *k-pole* is a map (loops and multiple edges allowed) on k vertices of the same degree. The set of all k-poles is the set of *vertex-regular* maps. The study of poles may therefore lead indirectly to information about important subclasses of regular maps, namely, quadrangulations and triangulations. The former occur, for example, in the ϕ^4-model of two-dimensional quantum gravity [7].

The *genus series* for a class of maps is the generating series for the number of such maps with respect to genus and the number of edges. The genus series for dipoles (technically, they are rooted) has been given by Jackson [9], using integral representations of sums of characters of the symmetric group. If $\nu = (\nu_1, \nu_2, \ldots)$ is a partition of $2n$, let p_ν denote $p_{\nu_1} p_{\nu_2} \ldots$, where $p_k = \lambda_1^k + \cdots + \lambda_N^k$ and N is a positive integer. Let $V(\lambda)$ be the Vandermonde determinant in $\lambda_1, \ldots, \lambda_N$, and let $[x^n] f(x)$ denote the coefficient of x^n in the formal power series f. Let $m_g(n), d_g(n)$ be the numbers of monopoles and dipoles, respectively, of genus g on n edges. Then

$$m_g(n) = [u^{n+1-2g}] A_{[2n]}(u), \tag{1}$$

$$d_g(n) = \frac{1}{n} [u^{n-2g}] \left(A_{[n^2]}(u) - A_{[n]}^2(u) \right), \tag{2}$$

where

$$A_\nu(N) = \frac{\int_{\mathcal{V}_N} e^{-\frac{1}{2}\operatorname{trace} \mathbf{M}^2} \prod_{k \geq 1} \left(\operatorname{trace} \mathbf{M}^k\right)^{a_k} d\mathbf{M}}{\int_{\mathcal{V}_N} e^{-\frac{1}{2}\operatorname{trace} \mathbf{M}^2} d\mathbf{M}}$$

$$= \frac{\sqrt{2}^{N^2-N} 2^n}{\sqrt{\pi}^N \prod_{j=1}^N j!} \int_{\mathbb{R}^N} V^2(\lambda) e^{-p_2} p_\nu d\lambda,$$

and a_j is the number of occurrences of j in the partition ν. Here $\mathcal{V}_N$ is the vector space, of dimension N^2 over $\mathbb{R}$, of all $N \times N$ Hermitian complex matrices and $d\mathbf{M}$ denotes Lesbesgue measure. The integrands with respect to $d\mathbf{M}$ are invariant under adjoint action of the unitary group, and diagonalization under this action gives the transformed integral in $d\lambda$. The constant that appears is related to the volume of the unitary group.

In determining $d_g(u)$, it is necessary first to carry out the integration to exhibit $A_\nu(N)$ as a polynomial in N, and then replace N formally by the indeterminate u. This is shown in the cases of monopoles [8] and dipoles [9], in the following two results.

THEOREM 1.1. *The number of monopoles of genus g on n edges is*

$$m_g(n) = \frac{(2n)!}{2^n n!} [u^{n+1-2g}] \sum_{k=1}^{n+1} \binom{u}{k} \binom{n}{k-1} 2^{k-1}.$$

THEOREM 1.2. *The number of dipoles of genus g with n edges is*

$$d_g(n) = (n-1)! \, [u^{n-2g}] \sum_{j=0}^{\lfloor \frac{1}{2}(n-1) \rfloor} \binom{2j}{j} \sum_{r=0}^{n-2j-1} \binom{n-2j-1}{r} \binom{u+j+r}{n}$$
$$\cdot \sum_{k=0}^{\lfloor \frac{1}{2}(n-2j-1) \rfloor} \frac{1}{4^k} \binom{2k}{k} \binom{n}{2k}.$$

As seen in these results, this procedure typically leads to a representation of $A_\nu(u)$ with respect to bases for the ring of formal power series other than the standard (monomial) basis, and this may be inconvenient for subsequent work.

The approach through integral representations can be applied to other classes of maps, and it is of interest to determine whether any more detailed information can be obtained about the exact number of maps. We carry out this task for dipoles in particular and, in doing so, demonstrate the type of hypergeometric arguments that we believe to be of general value in this context. The key appears to lie in representing the genus series with respect to a basis in which its degree and its parity are manifestly apparent. We call such a form *degree respecting* and *parity respecting*. We show how series can be resolved with respect to a natural basis of odd series that is attuned to hypergeometric series. It can be shown by a combinatorial argument that the representation of the genus series for monopoles and dipoles given in Theorems 1.1 and 1.2 and is degree respecting but *not* parity respecting.

The necessary background of results is given below, but the reader is referred to [10] and [11] for basic definitions about maps since these are not given here. Throughout, we use the usual hypergeometric convention that the Pochhammer symbol is $(x)_k = x(x+1)(x+2)\cdots(x+k-1)$.

Because of the embedding theorem (see, for example, [10]), the question addressed here can be expressed in terms of permutations alone. In this context, we seek the number of permutations in $2n$ symbols, with k cycles, which are expressible as the product of a prescribed permutation with two n-cycles and a fixed point free involution. The reader who is unfamiliar with maps may prefer to think of the question in these terms. We prove the following theorem about dipoles.

THEOREM 1.3. *The number of dipoles of genus $g > 0$ with $2m$ edges and $2m+1$ edges is, respectively,*

$$\text{(i)}\quad \frac{2^{\lfloor \frac{1}{2}g \rfloor}}{(2g+1)!}\binom{2m-1}{m}^2\binom{m}{g+1}\left(m-g+\tfrac{1}{2}\right)_{(\lfloor \frac{1}{2}g \rfloor)} r_g(m),$$

$$\text{(ii)}\quad \frac{2^{\lfloor \frac{1}{2}(g-1) \rfloor}}{(2g+1)!}\binom{2m-1}{m}^2\binom{m}{g}(2m+1)\left(m-g+\tfrac{3}{2}\right)_{(\lfloor \frac{1}{2}(g-1) \rfloor)} s_g(m),$$

where $r_g(x)$ and $s_g(x)$ are polynomials of degrees at most $\lfloor \frac{1}{2}(3g-1) \rfloor$ and $\lfloor \frac{3}{2}g \rfloor$, respectively, in x. Moreover, the polynomials $r_g(x)$ and $s_g(x)$ are given explicitly in (11) and (12).

2. Parity respecting form for the series for odd dipoles. We begin by presenting the genus series for dipoles in a form that is both degree respecting *and* exhibits its parity.

Let E, Δ, I be the successor operator, the forward difference operator, and the identity operator defined on the ring of polynomials by $Ef(x) = f(x+1)$, $\Delta f(x) = (E-I)f(x) = f(x+1) - f(x)$, and $If(x) = f(x)$. Since E and I commute, then for $M \geq 0$,

$$\Delta^M f(x) = \sum_{j=0}^{M} (-1)^j \binom{M}{j} f(x+M-j). \tag{3}$$

The following lemma concerns the representation of a polynomial of odd degree with respect to a convenient basis of upper factorial polynomials of odd degree. We extend it slightly later. It is precisely the central difference operator expansion given by Steffensen [12, p. 13, eq. (19)] in the case of odd polynomials.

LEMMA 2.1. *Let $f(x)$ be an odd polynomial of degree at most $2n-1$. Then*

$$f(x) = \sum_{j=0}^{n-1} \beta_j \frac{(x-j)_{2j+1}}{(2j+1)!}, \quad \text{where } \beta_j = \Delta^{2j+1} f(x)\big|_{x=-j-1}.$$

The next result is used later, and illustrates the use of this device to derive the representation of the sort described above. It is equivalent to a result appearing in [1] and [2] in connection with one of the Bailey-type sums.

LEMMA 2.2.

$$\binom{u+a}{n} - \binom{-u+a}{n} = \sum_{j=0}^{\lfloor \frac{1}{2}(n-1) \rfloor} \binom{a-j}{n-2j-1} \frac{2a-n+1}{a-j} \frac{(u-j)_{2j+1}}{(2j+1)!}.$$

Proof. From Lemma 2.1,

$$\begin{aligned}
\beta_m &= \sum_{k=0}^{2m+1} (-1)^k \binom{2m+1}{k} \left\{ \binom{m-k+a}{n} - \binom{-m+k+a}{n} \right\} \\
&= \binom{m+a}{n} {}_2F_1\left[\begin{matrix} -2m-1 & -m-a+n \\ & -m-a \end{matrix} \,\middle|\, 1 \right] \\
&\quad + \binom{-m+a}{n} {}_2F_1\left[\begin{matrix} -2m-1 & -m+a+1 \\ & -m+a-n+1 \end{matrix} \,\middle|\, 1 \right] \\
&= \frac{2a-n+1}{a-n} \binom{a-m}{n-2m-1}
\end{aligned}$$

by the Chu–Vandermonde theorem, giving the result. □

COROLLARY 2.3.

$$\sum_{r=0}^{2m-2j}\binom{2m-2j}{r}\binom{u+j+r}{2m+1}=\sum_{i=0}^{m}\frac{1}{(2i+1)!}4^{i-j}\binom{m-j}{i-j}(u-i)_{2i+1}.$$

Proof. Let $S(m,j)$ denote the left-hand side. Then

$$S=\binom{2m-2j}{m-j}\binom{u+m}{2m+1}+\sum_{r=0}^{m-j-1}\binom{2m-2j}{r}\left\{\binom{u+j+r}{2m+1}-\binom{-u+j+r}{2m+1}\right\},$$

so S is an odd polynomial in u. Then, by doubling S and using Lemma 2.2,

$$\begin{aligned}2S&=\sum_{r=0}^{2m-2j}\binom{2m-2j}{r}\sum_{\lambda=0}^{m}\binom{j+r-\lambda}{2m-2\lambda}\frac{2j+2r-2m}{j+r-\lambda}\frac{(u-\lambda)_{2\lambda+1}}{(2\lambda+1)!}\\&=\sum_{\lambda=0}^{m}\frac{(u-\lambda)_{2\lambda+1}}{(2\lambda+1)!}\sum_{r=0}^{2m-2j}\binom{2m-2j}{r}\binom{j+r-\lambda}{2m-2\lambda}\frac{2j+2r-2m}{j+r-\lambda},\end{aligned}$$

so

$$\begin{aligned}S&=\sum_{\lambda=0}^{m}\frac{(u-\lambda)_{2\lambda+1}}{(2\lambda+1)!}\binom{j-\lambda}{2m-2\lambda}\frac{j-m}{j-\lambda}\\&\quad\cdot{}_3F_2\left[\begin{matrix}-2m+2j & j-\lambda & j-m+1\\ & j+\lambda-2m+1 & j-m\end{matrix}\,\middle|\,-1\right]\\&=\sum_{\lambda=0}^{m}\frac{(u-\lambda)_{2\lambda+1}}{(2\lambda+1)!}\binom{j-\lambda}{2m-2\lambda}\frac{j-m}{j-\lambda}\\&\quad\cdot\lim_{\substack{a\to-2m+2j\\ c\to\infty}}{}_5F_4\left[\begin{matrix}a & 1+\frac{1}{2}a & b & c & d\\ & \frac{1}{2}a & 1+a-b & 1+a-c & 1+a-d\end{matrix}\,\middle|\,1\right],\end{aligned}$$

where $b=j-\lambda, d=-m+j+\frac{1}{2}$, and the result follows by Dougall's theorem. □

A referee noted that Corollary 2.3 follows from the identity

$${}_2F_1\left[\begin{matrix}-2k & -x\\ & -N\end{matrix}\,\middle|\,2\right]={}_3F_2\left[\begin{matrix}-k & x-N & -x\\ & -\frac{1}{2}N & -\frac{1}{2}(N-1)\end{matrix}\,\middle|\,1\right],$$

connecting Krawtchouk polynomials of even degree with Hahn polynomials. This entails applying the linear transformation formula to our ${}_2F_1(-1)$ to obtain a ${}_2F_1(\frac{1}{2})$, reversing the resulting series to obtain a ${}_2F_1(2)$, and observing by standard arguments that the above identity holds for all real N, rather than just integral N. Corollary 3.1 follows in the same way from the analogous formula for Krawtchouk polynomials of odd degree.

It is useful to observe that Steffensen's expansion is a natural method for expanding an odd polynomial into a series involving rising factorials such that the oddness is evident term-by-term, and has the merit of being applicable generally to the above type of problems.

The next result is given in Bailey (see [3, p. 12, eq. (1)], with $a=-n$).

$$(4)\qquad {}_3F_2\left[\begin{matrix}-n & b & c\\ & e & f\end{matrix}\,\middle|\,1\right]=\frac{(e-b)_n}{(e)_n}{}_3F_2\left[\begin{matrix}-n & b & f-c\\ & 1-n+b-e & f\end{matrix}\,\middle|\,1\right].$$

Thus, from (4),

$$\lim_{e\to -n} {}_3F_2\left[\begin{matrix} -n & b & c \\ & e & f \end{matrix}\,\middle|\, 1\right] = \frac{(b+1)_n}{n!}\,{}_3F_2\left[\begin{matrix} -n & b & f-c \\ & 1+b & f \end{matrix}\,\middle|\, 1\right] = \sum_{j=0}^{n} \frac{(b)_j (c)_j}{j!(f)_j}.$$

We may now give a parity and degree respecting expression for the dipole generating series.

THEOREM 2.4. *Let $n = 2m+1$. Then the number of dipoles of genus g on n edges is*

$$d_g(n) = \binom{2m}{m} n! \left[u^{n-2g}\right] \sum_{i=0}^{m} \frac{(u-i)_{2i+1}}{(2i+1)!} 4^{i-m} \binom{m}{i} \cdot \sum_{k=0}^{m-i} (-1)^k \frac{1}{2k+1} \binom{m-i}{k} \binom{2m-k}{m}.$$

Proof. From Theorem 1.2 and Corollary 2.3,

$$d_g(n) = (n-1)! \left[u^{n-2g}\right] \sum_{i=0}^{m} \frac{(u-i)_{2i+1}}{(2i+1)!} \sum_{k=0}^{m} \sum_{j=0}^{m-k} 4^{i-j-k} \binom{m-j}{i-j} \binom{2j}{j} \binom{2k}{k} \binom{n}{2k}.$$

Now

$$\begin{aligned} &\sum_{j=0}^{m-k} 4^{i-j-k} \binom{m-j}{i-j} \binom{2j}{j} \\ &= 4^{i-k} \binom{m}{i} \lim_{e\to -m+k} {}_3F_2\left[\begin{matrix} \frac{1}{2} & -m+k & -i \\ & e & -m \end{matrix}\,\middle|\, 1\right] \qquad (5) \\ &= 4^{i-m} \binom{m}{i} \frac{(2m-2k+1)!}{(m-k)!^2}\, {}_3F_2\left[\begin{matrix} -m+k & \frac{1}{2} & -m+i \\ & \frac{3}{2} & -m \end{matrix}\,\middle|\, 1\right]. \end{aligned}$$

Substituting this into the sum over k we have

$$\begin{aligned} &\sum_{k=0}^{m} \sum_{j=0}^{m-k} 4^{i-j-k} \binom{m-j}{i-j} \binom{2j}{j} \binom{2k}{k} \binom{n}{2k} \\ &\quad = 4^{i-m} \frac{1}{n} \sum_{k=0}^{m} \frac{(2m+1)!}{k!^2 (m-k)!^2}\, {}_3F_2\left[\begin{matrix} -m+k & \frac{1}{2} & -m+i \\ & \frac{3}{2} & -m \end{matrix}\,\middle|\, 1\right] \\ &\quad = \frac{1}{n} 4^{i-m} \binom{m}{i} (2m+1)! \sum_{r=0}^{m-i} \frac{(-m+i)_r (\frac{1}{2})_r (-1)^r}{r!(\frac{3}{2})_r (-m)_r m!(m-r)!} \\ &\qquad \cdot \sum_{k=0}^{m} \frac{m!(m-r)!}{k!^2 (m-k)!(m-k-r)!} \\ &\quad = 4^{i-m} \binom{m}{i} \frac{(2m)!}{m!^2} \sum_{r=0}^{m-1} (-1)^r \binom{m-i}{r} \frac{1}{2r+1} \binom{2m-r}{m}, \end{aligned}$$

since the sum over k is equal to $\binom{2m-r}{m}$, and this gives the result. □

3. Parity respecting form for the series for even dipoles. We follow the approach of the previous section to give a parity respecting form for the genus series for dipoles on an even number of edges. To do this, we need the following corollary, which corresponds to Corollary 2.3.

COROLLARY 3.1.

$$\sum_{r=0}^{2m-2j-1}\binom{2m-2j-1}{r}\binom{u+j+r}{2m}=\sum_{i=j}^{m-1}\frac{4^{i-j}u}{(2i+1)!(i+1)}\binom{m-j-1}{i-j}(u-i)_{2i+1}.$$

Proof. Replace m by $m+j$ and then i by $i+j$ in the enunciation to obtain the *restatement*

$$\sum_{r=0}^{2m-1}\binom{2m-1}{r}\binom{u+j+r}{2m+2j}=\sum_{i=0}^{m-1}\frac{4^{i}u}{(2i+2j+1)!(i+j+1)}\binom{m-1}{i}(u-i-j)_{2i+2j+1},$$

or, equivalently,

$$\binom{u+j}{2m+2j}{}_2F_1\left[\begin{matrix}-2m+1 & u+j+1\\ & u-2m-j+1\end{matrix}\,\middle|\,-1\right]=\frac{u}{j+1}\binom{u+j}{2j+1}{}_3F_2\left[\begin{matrix}-m+1 & 1+j-u & u+j+1\\ & j+\frac{3}{2} & j+2\end{matrix}\,\middle|\,1\right]. \tag{6}$$

The proof is complete once this is established.

But

$$ {}_2F_1\left[\begin{matrix}a & b\\ & \kappa-b\end{matrix}\,\middle|\,-1\right]=\frac{\Gamma(\kappa-b)\Gamma(\frac{1}{2}\kappa)}{\Gamma(\kappa)\Gamma(\frac{1}{2}\kappa-b)}{}_3F_2\left[\begin{matrix}b & \frac{1}{2}(\kappa-a) & \frac{1}{2}(\kappa-a)+\frac{1}{2}\\ & \kappa-a & \frac{1}{2}(\kappa+1)\end{matrix}\,\middle|\,1\right] \tag{7}$$

from [3, p. 33, eq. (3)]

$$=\frac{\Gamma(\kappa-b)\Gamma(\frac{1}{2}\kappa)}{\Gamma(\kappa)\Gamma(\frac{1}{2}\kappa-b)}\frac{\Gamma(\kappa-a)\Gamma(\frac{1}{2}\kappa-b)}{\Gamma(\kappa-a-b)\Gamma(\frac{1}{2}\kappa)}\cdot{}_3F_2\left[\begin{matrix}b & \frac{1}{2}(a+1) & \frac{1}{2}a\\ & \frac{1}{2}\kappa & \frac{1}{2}(\kappa+1)\end{matrix}\,\middle|\,1\right] \tag{8}$$

from [3, p. 98, ex. 7]

$$=\frac{\Gamma(\kappa-b)\Gamma(\kappa-a)}{\Gamma(\kappa)\Gamma(\kappa-a-b)}{}_3F_2\left[\begin{matrix}b & \frac{1}{2}(a+1) & \frac{1}{2}a\\ & \frac{1}{2}\kappa & \frac{1}{2}(\kappa+1)\end{matrix}\,\middle|\,1\right]. \tag{9}$$

Equation (9) appears in [15]. Then with $a=1-2m, b=u+j+1, \kappa=2u-2m+2$ (so $\kappa-a=2u+1$),

$${}_2F_1\left[\begin{matrix}1-2m & u+j+1\\ & u-2m-j+1\end{matrix}\,\middle|\,-1\right]=\frac{(2u-2m+2)_{2m-1}}{(u-2m-j+1)_{2m-1}}{}_3F_2\left[\begin{matrix}u+j+1 & -m+1 & -m+\frac{1}{2}\\ & u-m+1 & u-m+\frac{3}{2}\end{matrix}\,\middle|\,1\right].$$

Thus, from (6), we must establish that

$$\binom{u+j}{2m+2j}\frac{(2u-2m+2)_{2m-1}}{(u-2m-j+1)_{2m-1}}{}_3F_2\left[\begin{matrix}u+j+1 & -m+1 & -m+\frac{1}{2}\\ & u-m+1 & u-m+\frac{3}{2}\end{matrix}\,\middle|\,1\right]=\frac{u}{j+1}\binom{u+j}{2j+1}{}_3F_2\left[\begin{matrix}-m+1 & 1+j-u & u+j+1\\ & j+\frac{3}{2} & j+2\end{matrix}\,\middle|\,1\right].$$

We now use Sheppard's [14] transformation. This is a generalization of the Pfaff–Saalschutz formula. It is not explicitly stated in [3], but is given without attribution in [4, p. 168].

$$
\begin{aligned}
{}_3F_2\left[\begin{matrix} -n & b & c \\ & e & f \end{matrix}\,\middle|\,1\right] &= \frac{(e-b)_n(f-b)_n}{(e)_n(f)_n} \\
&\cdot {}_3F_2\left[\begin{matrix} -n & b & -n+b+c+1-e-f \\ & -n+b-f+1 & -n+b-e+1 \end{matrix}\,\middle|\,1\right],
\end{aligned} \tag{10}
$$

so

$$
\begin{aligned}
&{}_3F_2\left[\begin{matrix} -m+1 & u+j+1 & 1+j-u \\ & j+\frac{3}{2} & j+2 \end{matrix}\,\middle|\,1\right] \\
&\quad = \frac{(j+\frac{1}{2}-u-j)_{m-1}(j+1-u-j)_{m-1}}{(j+\frac{3}{2})_{m-1}(j+2)_{m-1}} \\
&\quad \cdot {}_3F_2\left[\begin{matrix} -m+1 & u+j+1 & -m+\frac{1}{2} \\ & u-m+1 & u-m+\frac{3}{2} \end{matrix}\,\middle|\,1\right].
\end{aligned}
$$

The identity to be proved is therefore equivalent to

$$
\binom{u+j}{2m+2j}\frac{(2u-2m+2)_{2m-1}}{(u-2m-j+1)_{2m-1}} = \frac{u}{j+1}\binom{u+j}{2j+1}\frac{(-2u+1)_{2m-2}}{(2j+3)_{2m+2}}.
$$

But both sides are equal to

$$
\frac{(u+j)!(2u)!}{(2m+2j)!(u-j-1)!(2u-2m+1)!},
$$

and this therefore establishes the result. □

We may now give a parity and degree respecting expression for the dipole generating series.

THEOREM 3.2. *Let $n = 2m$. Then the number of dipoles of genus g on n edges is*

$$
\begin{aligned}
d_g(n) = \binom{2m}{m} n!\,[u^{n-2g-1}] &\sum_{i=0}^{m-1} \frac{4^{i-m}(u-i)_{2i+1}}{(2i+1)!(i+1)}\binom{m-1}{i} \\
&\cdot \sum_{k=0}^{m-i-1} (-1)^k \frac{1}{2k+1}\binom{m-i-1}{k}\binom{2m-k-1}{m}.
\end{aligned}
$$

Proof. From Theorem 1.2 and from Corollary 3.1,

$$
\begin{aligned}
d_g(n) = (n-1)![u^{n-2g}] &\sum_{j=0}^{m-1}\binom{2j}{j} u \sum_{i=0}^{m-1} \frac{4^{i-j}}{(2i+1)!(i+1)}\binom{m-j-1}{i-j}(u-i)_{2i+1} \\
&\cdot \sum_{k=0}^{m-j-1} \frac{1}{4^k}\binom{2k}{k}\binom{2m}{2k}.
\end{aligned}
$$

From (5), with slight modification,

$$
\sum_{j=0}^{m-k-1} 4^{i-j-k}\binom{m-j-1}{i-j}\binom{2j}{j} = A_{k,n},
$$

where

$$A_{k,n} = 4^{i-m+1}\binom{m-1}{i}\frac{(2m-2k-1)!}{(m-k-1)!^2}\,{}_3F_2\left[\begin{matrix} -m+k+1 & \frac{1}{2} & -m+i+1 \\ & \frac{3}{2} & -m+1 \end{matrix}\,\middle|\, 1\right],$$

so

$$d_g(n) = (2m-1)![u^{n-2g}]\sum_{0\le i\le m-1}\frac{u(u-i)_{2i+1}}{(2i+1)!(i+1)}\sum_{k=0}^{m-1}\binom{2k}{k}\binom{2m}{2k}\binom{m-1}{i}A_{k,n}.$$

But

$$\begin{aligned}
&(2m-1)!\sum_{k=0}^{m-1}\binom{2k}{k}\binom{2m}{2k}\binom{m-1}{i}A_{k,m} \\
&= \frac{4^{i-m+1}}{n}\binom{m-1}{i}\sum_{k=0}^{m}\frac{(2m)!^2}{k!^2(m-k-1)!^2(2m-2k)} \\
&\quad\cdot\sum_{h\ge 0}\frac{(-1)^h}{2h+1}\binom{m-k-1}{h}\frac{(-m+i+1)_h}{(-m+1)_h} \\
&= \frac{4^{i-m+1}}{2n}\binom{m-1}{i}\sum_{h\ge 0}\frac{(2m)!^2(-1)^h(-m+i+1)_h}{h!(2h+1)(-m+1)_h m!(m-h-1)!}
\end{aligned}$$

since

$$\sum_{k\ge 0}\frac{m!(m-h-1)!}{k!^2(m-k)!(m-k-h-1)!} = \binom{2m-h-1}{m-h-1}.$$

The result follows. □

4. The sphere and the torus. As an example of the use of Theorems 2.4 and 3.2, we consider dipoles on the sphere and the torus. In the odd case, when $g = 0$, there is a single term to consider and this gives

$$d_0(2m+1) = \binom{2m}{m}^2.$$

When $g = 1$, we note that $(u-m)_{2m+1} = u^{2m+1} - \frac{1}{6}m(m+1)(2m+1)u^{2m-1} + \cdots$, so

$$\begin{aligned}
d_1(2m+1) &= -\tfrac{1}{6}m(m+1)(2m+1)\binom{2m}{m}^2 \\
&\quad + \tfrac{1}{2}(2m+1)m^2\binom{2m}{m}\sum_{r=0}^{1}\binom{1}{r}\frac{(-1)^r}{2r+1}\binom{2m-r}{m} \\
&= \tfrac{1}{3}\binom{2m-1}{m}^2 m(2m+1)(3m-2).
\end{aligned}$$

In the even case

$$d_0(2m) = \binom{2m}{m}(2m)!\frac{1}{(2m-1)!m}\frac{1}{4}\binom{2m-1}{m} = \binom{2m-1}{m}^2,$$

and

$$d_1(2m) = \binom{2m}{m}(2m)!\left\{\frac{-\sum_{j=1}^{m-1} j^2}{(2m-1)!}\frac{1}{4m}\binom{2m-1}{m}\right.$$
$$\left. + \frac{1}{(2m-3)!}\frac{1}{4^2}\sum_{h=0}^{1}\binom{1}{h}\frac{(-1)^h}{2h+1}\binom{2m-h-1}{m}\right\}$$
$$= \tfrac{1}{6}\binom{2m-1}{m}^2 m(m-1)(3m-1).$$

The number of terms to be considered in the summation increases with genus.

5. The number of dipoles. We are in a position to prove Theorem 1.3 and to obtain full structural information about the polynomials $r_g(m)$ and $s_g(m)$. The following result is needed (the proof is sketched in [13, pp. 234–236]).

PROPOSITION 5.1. *Let* $(u-j)_{2j+1} = \sum_{i=0}^{j}\mu_i(j)u^{2i+1}$. *Then, for* $0 \le k \le j$,

$$\mu_{j-k}(j) = \sum_{\lambda=1}^{k}\alpha_{k,\lambda}\binom{2j+2}{2k+\lambda} = (2j-2k+2)_{2k+1}\hat{\mu}_k(j),$$

where $\alpha_{k,\lambda}$ *is independent of* j *and* $\hat{\mu}_k(j)$ *is a polynomial in* j *of degree* $k-1$.

Proof. Let $\mu_i(j)$ be defined by $(u-j)_{2j+1} = \sum_{i=0}^{j} u^{2i+1}\mu_i(j)$. It is readily seen that the $\mu_i(j)$ are determined by $\mu_j(j) = 1, \mu_0(j) = (-1)^j j!^2$, and for $0 < i < j$, $\mu_i(j) = \mu_{i-1}(j-1) - j^2\mu_i(j-1)$. In Riordan's notation [13, p. 213], $x^{[n]} = x(x+\frac{1}{2}n-1)(x+\frac{1}{2}n-2)\cdots(x+\frac{1}{2}n-n+1)$, so $x^{[2j+2]} = x(x+j)(x+j-1)\cdots(x-j)$ and $x^{[2j+2]} = \sum_{k=0}^{2j+2} t(2j+2,k)x^k$, when $\sum_{i=0}^{j} u^{2i+2}\mu_i(j) = u(u-j)_{2j+1} = u^{[2j+2]} = \sum_{k=0}^{2j+2} t(2j+2,k)u^k$, and so $\mu_i(j) = t(2j+2, 2i+2)$. Now [13, pp. 234–236] $4^k t(n, n-2k) = \sum_{j=1}^{k}\alpha_{k,j}\binom{n}{2k+j}$, where the $\alpha_{k,j}$ are rational numbers. Therefore, $\mu_{j-k}(j) = t(2j+2, 2j-2k+2) = 4^{-k}\sum_{\lambda=1}^{k}\alpha_{k,\lambda}\binom{2j+2}{2k+\lambda}$. Thus $\mu_{j-k}(j)$ is a polynomial in j of degree $3k$ and has $(2j-2k+2)_{2k+1}$ as a factor, so $\mu_{j-k}(j) = (2j-2k+2)_{2k+1}\hat{\mu}_k(j)$, where $\hat{\mu}_k(j)$ is a polynomial in j of degree at most $k-1$. □

The $\mu_i(j)$ are more or less the *divided central differences of zero*. The odd and even cases seem to be different, and we treat them separately.

Proof of Theorem 1.3(ii). From Theorem 2.4 with $g > 0$ and $n = 2m+1$,

$$d_g(n) = \binom{2m}{m}n!\,[u^{n-2g}]\sum_{i=0}^{m}\frac{1}{(2i+1)!}\sum_{\lambda=0}^{i}\mu_\lambda(i)u^{2\lambda+1}4^{i-m}\binom{m}{i}$$
$$\cdot\sum_{k=0}^{m-i}\frac{(-1)^k}{2k+1}\binom{m-i}{k}\binom{2m-k}{m}$$
$$= \binom{2m}{m}n!\sum_{i=0}^{g}\frac{\mu_{m-g}(m-i)}{(2m-2i+1)!}4^{-i}\binom{m}{i}\sum_{k=0}^{i}\frac{(-1)^k}{2k+1}\binom{i}{k}\binom{2m-k}{m}$$
$$= 4\binom{2m-1}{m}^2\binom{m}{g}(2m+1)$$
$$\cdot\sum_{0\le k\le i\le g}\frac{(-1)^k\mu_{m-g}(m-i)g!4^{-i}}{k!(i-k)!(2k+1)}\,\frac{(2m-2i+2)_{2i-k-1}m!(m-g)!}{(m-i)!(m-k)!}$$

$$= 4\binom{2m-1}{m}^2\binom{m}{g}(2m+1)(m-g+\tfrac{3}{2})_{\lfloor\frac{1}{2}(g-1)\rfloor}$$
$$\cdot \sum_{0\le k\le i\le g} \frac{(-1)^k g! 4^{-i}}{k!(i-k)!(2k+1)} B_{k,i,g}(m),$$

where

$$B_{k,i,g}(m) = \frac{\hat{\mu}_{g-i}(m-i)(2m-2i+2)_{2i-k-1}(m+1-i)_i}{(m-g+1)_{g-k}(m-g+\frac{3}{2})_{\lfloor\frac{1}{2}(g-1)\rfloor}}(2m-2g+2)_{2g-2i+1}.$$

If $B_{k,i,g}(m)$ is a polynomial in m, then its degree is at most $\lfloor\frac{3}{2}g\rfloor$, and consequently,

$$\frac{2^{\lfloor\frac{1}{2}(g-1)\rfloor}}{(2g+1)!}s_g(m) = \sum_{0\le k\le i\le g} \frac{(-1)^k g! 4^{1-i}}{k!(i-k)!(2k+1)} B_{k,i,g}(m) \tag{11}$$

would produce $s_g(m)$ as a polynomial of degree at most $\lfloor\frac{3}{2}g\rfloor$. All that now remains is to prove the assertion that $B_{k,i,g}(m)$ is indeed a polynomial. Since $(2a)_k = 2^k(a)_{\lfloor\frac{1}{2}(k+1)\rfloor}(a+\frac{1}{2})_{\lfloor\frac{1}{2}k\rfloor}$, we have

$$B_{k,i,g}(m) = \hat{\mu}_{g-i}(m-i)(m-i+1)2^{2g-k}(m+1-i)_i$$
$$\cdot\frac{(m-g+1)_{\lfloor\frac{1}{2}(2g-k)\rfloor}}{(m-g+1)_{g-k}}\frac{(m-g+\frac{3}{2})_{\lfloor\frac{1}{2}(2g-k-1)\rfloor}}{(m-g+\frac{3}{2})_{\lfloor\frac{1}{2}(g-1)\rfloor}}.$$

Now $k \le g$, so $(m-g+\frac{3}{2})_{\lfloor\frac{1}{2}(2g-k-1)\rfloor}/(m-g+\frac{3}{2})_{\lfloor\frac{1}{2}(g-1)\rfloor}$ is a polynomial in m, and since $\lfloor\frac{1}{2}(2g-k)\rfloor \ge g-k$, $(m-g+1)_{\lfloor\frac{1}{2}(2g-k)\rfloor}/(m-g+1)_{g-k}$ is a polynomial in m. This establishes the assertion, and thereby completes the proof. □

We note that (11) gives an explicit expression for the polynomial $s_g(m)$.

Proof of Theorem 1.3(i). From Theorem 3.2 with $g > 0$ and $n = 2m$,

$$d_g(n) = \binom{2m}{m} n! \left[u^{n-2g-1}\right] \sum_{i=0}^{m-1} \frac{(u-i)_{2i+1}}{(2i+1)!(i+1)} 4^{i-m}\binom{m-1}{i}$$
$$\cdot \sum_{k=0}^{m-i-1} \frac{(-1)^k}{2k+1}\binom{m-i-1}{k}\binom{2m-k-1}{m}$$
$$= 2\binom{2m-1}{m} n! \sum_{i=m-g-1}^{m-1} \frac{\mu_{m-g-1}(i)}{(2i+1)!(i+1)} 4^{i-m}\binom{m-1}{i}$$
$$\cdot \sum_{k=0}^{m-i-1} \frac{(-1)^k}{2k+1}\binom{m-i-1}{k}\binom{2m-k-1}{m}$$
$$= 2\binom{2m-1}{m} n! \sum_{i=0}^{g} \frac{\mu_{m-g-1}(m-i-1)}{(2m-2i-1)!(m-i)} 4^{-1-i}\binom{m-1}{i}$$
$$\cdot \sum_{k=0}^{i} \frac{(-1)^k}{2k+1}\binom{i}{k}\binom{2m-k-1}{m}$$
$$= \binom{2m-1}{m}^2\binom{m}{g+1}(g+1)!$$

$$\cdot \sum_{0\le k\le i\le g} \frac{(-1)^k \mu_{m-g-1}(m-i-1)4^{-i}}{k!(i-k)!(2k+1)} \frac{(2m-2i)_{2i-k}(m-k)_k}{(m-g)_{g-i+1}}$$
$$= \frac{2^{\lfloor \frac{1}{2}g\rfloor}}{(2g+1)!}\binom{2m-1}{m}^2\binom{m}{g+1}\left(m-g+\frac{1}{2}\right)_{\lfloor \frac{1}{2}g\rfloor} r_g(m),$$

where

$$r_g(m) = 2^{-\lfloor \frac{1}{2}g\rfloor}(2g+1)!(g+1)! \sum_{0\le k\le i\le g} \frac{(-1)^k 2^{2g-k-2i+1}}{k!(i-k)!(2k+1)}$$
$$\cdot \left\{ \frac{\hat{\mu}_{g-i}(m-i-1)(m-g)_{\lfloor \frac{1}{2}(2g-k+1)\rfloor}(m-g+\frac{1}{2})_{\lfloor \frac{1}{2}(2g-k)\rfloor}(m-k)_k}{(m-g)_{g-i}(m-g+\frac{1}{2})_{\lfloor \frac{1}{2}g\rfloor}} \right\}. \tag{12}$$

Now $r_g(m)$ is a polynomial in m because $g-i \le \lfloor \frac{1}{2}(2g-k+1)\rfloor$, since $0 \le k \le i$ and also $\lfloor \frac{1}{2}(2g-k)\rfloor \le \lfloor \frac{1}{2}g\rfloor$. Therefore, by inspection, $r_g(m)$ is a polynomial of degree at most $\lfloor \frac{1}{2}(3g-1)\rfloor$. □

We note that (12) gives an explicit expression for the polynomial $r_g(m)$.

6. Parity respecting forms for monopoles. We conclude by returning to monopoles and show that they can be treated in a similar way. It is readily seen by symbolic computation that the polynomial

$$\sum_{k=1}^{n+1}\binom{u}{k}\binom{n}{k-1}2^{k-1}$$

has parity $n+1$ mod 2 and is, by Theorem 1.1, up to a numerical factor, the genus series for monopoles. We transform this polynomial to a basis that exhibits the correct parity, and then determine explicit expressions for the number of monopoles.

LEMMA 6.1.

(i) $$\sum_{k=0}^{2m+1}\binom{u}{k+1}\binom{2m+1}{k}2^k = \sum_{j=0}^{m}\frac{4^j}{j+1}\binom{m}{j}\frac{(u-j)_{2j+1}}{(2j+1)!},$$

(ii) $$\sum_{k=0}^{2m}\binom{u}{k+1}\binom{2m}{k}2^k = \sum_{j=0}^{m}4^j\binom{m}{j}\frac{(u-j)_{2j+1}}{(2j+1)!}.$$

Proof. (i) The left-hand side is

$$2^{2m+1}\binom{u}{2m+2}{}_2F_1\left[\begin{matrix}-2m-1 & -2m-2\\ & u-2m-1\end{matrix}\,\middle|\,\frac{1}{2}\right]$$
$$= \binom{u}{2m+2}{}_2F_1\left[\begin{matrix}-2m-1 & u+1\\ & u-2m-1\end{matrix}\,\middle|\,-1\right]$$
$$= \binom{u}{2m+2}\frac{(2u-2m)_{2m+1}}{(u-2m-1)_{2m+1}}{}_3F_2\left[\begin{matrix}u+1 & -m & -m-\frac{1}{2}\\ & u-m & u-m+\frac{1}{2}\end{matrix}\,\middle|\,1\right] \quad \text{by (9)}$$
$$= \binom{u}{2m+2}\frac{(2u)!(u-2m-2)!}{(2u-2m-1)!(u-1)!}\cdot\frac{(-m-1)_m(-m-\frac{1}{2})_m}{(u-m)_m(u-m+\frac{1}{2})_m}$$
$$\cdot {}_3F_2\left[\begin{matrix}-m & u+1 & -u+1\\ & 2 & \frac{3}{2}\end{matrix}\,\middle|\,1\right] \text{ by (10)}$$
$$= u^2\,{}_3F_2\left[\begin{matrix}-m & u+1 & -u+1\\ & 2 & \frac{3}{2}\end{matrix}\,\middle|\,1\right].$$

and this is equivalent to the result.

(ii) The proof is similar. □

Explicit expressions for the numbers of monopoles are given in the next result.

THEOREM 6.2. *Let* $C_n = \frac{1}{n+1}\binom{2n}{n}$, *the nth Catalan number. Then, for* $g > 0$,

$$\text{(i)}\quad m_g(2m+1) = C_{2m+1}\frac{(2m+2)!}{(2m-g+1)!}\sum_{j=0}^{g} 4^{-j}\binom{m}{j}\hat{\mu}_{g-j}(m-j)$$
$$= C_{2m+1}(2m-2g+2)_{2g+1}\sigma_g(m),$$

$$\text{(ii)}\quad m_g(2m) = \frac{(4m)!}{(2m)!(2m-2g+1)!}\sum_{j=0}^{g} 4^{-j}2(m-j+1)\binom{m}{j}\hat{\mu}_{g-j}(m-j)$$
$$= C_{2m}(2m-2g+2)_{2g}\rho_g(m),$$

where $\sigma_g(m)$ *is a polynomial in* m *of degree* $g-1$ *and* $\rho_g(m)$ *is a polynomial in* m *of degree* g.

Proof. (i) From Theorem 1.1 and Lemma 6.1,

$$m_g(2m+1) = C_{2m+1}\frac{(2m+2)!}{2^{2m+1}}\left[u^{2m+1-2g}\right]\sum_{j=0}^{m}\frac{4^j}{j+1}\binom{m}{j}\frac{(u-j)_{2j+1}}{(2j+1)!}$$
$$= C_{2m+1}\frac{(2m+2)!}{4^m}$$
$$\cdot\left[u^{2m+1-2g}\right]\sum_{j=0}^{m}\frac{4^j}{(2j+2)!}\binom{m}{j}\sum_{i=0}^{j}\mu_i(j)u^{2i+1}.$$

From Proposition 5.1,

$$= C_{2m+1}\frac{(2m+2)!}{4^m}\sum_{j=0}^{m}\frac{4^j}{(2j+2)!}\binom{m}{j}\mu_{m-g}(j)$$
$$= C_{2m+1}(2m-2g+2)_{2g+1}\sum_{j=0}^{g}4^{-j}\binom{m}{j}\hat{\mu}_{g-j}(m-j),$$

and this gives the result.

(ii) From Theorem 1.1 and Lemma 6.1,

$$m_g(2m) = \frac{(4m)!}{4^m(2m)!}\left[u^{2m+1-2g}\right]\sum_{j=0}^{m}\frac{4^j}{(2j+1)!}\binom{m}{j}\sum_{i=0}^{j}\mu_i(j)u^{2i+1}.$$

From Proposition 5.1,

$$= \frac{(4m)!}{4^m(2m)!}\sum_{j=0}^{m}\frac{4^j}{(2j+1)!}\binom{m}{j}\mu_{m-g}(j)$$
$$= \frac{(4m)!}{4^m(2m)!}\sum_{j=0}^{g}4^{m-j}\binom{m}{j}\frac{2(m-j+1)}{(2m-2g+1)!}\hat{\mu}_{g-j}(m-j)$$
$$= \frac{(4m)!}{(2m)!(2m-2g+1)!}\sum_{j=0}^{g}4^{-j}\binom{m}{j}2(m-j+1)\hat{\mu}_{g-j}(m-j)$$
$$= C_{2m}(2m-2g+2)_{2g}\rho_g(m),$$

and this gives the result. □

ON CONNECTION COEFFICIENTS FOR q-DIFFERENCE SYSTEMS OF A-TYPE JACKSON INTEGRALS*

KAZUHIKO AOMOTO†

Abstract. General Jackson integrals are formulated. Two different kinds of special Jackson integrals are defined. The explicit relation formulae among them are obtained by the use of theta rational functions.

Key words. connection coefficient, q-difference equation, Jackson integral

1. Introduction. The well-known Ramanujan's $\psi_{1,1}$-sum formula shows that the Jackson integral

$$\int_{[0,\xi\infty]_q} t^{\alpha-1}\frac{(t)_\infty}{(q^\beta t)_\infty}d_qt = (1-q)\sum_{n=-\infty}^{+\infty} q^{n\alpha}\xi^\alpha\frac{(\xi q^n)_\infty}{(q^{\beta+n}\xi)_\infty} \tag{1.1}$$

is equal to the value

$$\left(\frac{\xi}{q}\right)^{\alpha-2}\frac{\theta(q^{\beta+1})\theta(q^{\alpha+\beta-2}\xi)}{\theta(q^{\alpha+\beta-1})\theta(q^\beta\xi)}\int_0^1 t^{\alpha-1}\frac{(t)_\infty}{(q^\beta t)_\infty}d_qt, \tag{1.2}$$

where $\theta(x)$ denotes the Jacobi elliptic theta function $(x)_\infty(q/x)_\infty(q)_\infty$. The equality (1.1) = (1.2) can be explained by saying that in a sense the countable set $[0,\xi]_q$ is homologous to scalar times of the q-interval $[0,1]_q$ with regard to the functions $\Phi = t^\alpha(t)_\infty/(q^\beta t)_\infty$, where the scalar factor

$$\left(\frac{\xi}{q}\right)^{\alpha-2}\frac{\theta(q^{\beta+1})\theta(q^{\alpha+\beta-2}\xi)}{\theta(q^{\alpha+\beta-1})\theta(q^\beta\xi)}$$

is a pseudoconstant, i.e., a constant from the viewpoint of q-difference in the parameters α,β,ξ.

Let $\Phi(t)$ be a q-analog multiplicative function on an n-dimensional algebraic torus $\bar{X}\simeq(\mathbf{C}^*)^n$,

$$\begin{aligned}\Phi(t) &= t_1^{\alpha_1}\cdots t_n^{\alpha_n}\prod_{j=1}^n\prod_{k=1}^m\frac{(t_j/x_k)_\infty}{(t_jq^{\beta_k}/x_k)_\infty},\\ &\prod_{1\le i<j\le n}\frac{(q_j^{\gamma'_{i,j}t_j}/t_i)_\infty}{(q_j^{\gamma_{i,j}t_j}/t_i)_\infty}\quad\text{for } t=(t_1,\dots,t_n)\in\overline{X},\end{aligned} \tag{1.3}$$

where we fix $(x_1,\dots,x_m)\in(\mathbf{C}^*)^m$ and $(\alpha_1,\dots,\alpha_n,\beta_1,\dots,\beta_m,\gamma_{i,j},\gamma'_{i,j})\in\mathbf{C}^{m+n^2}$. $(x)_\infty$ denotes the infinite product $\prod_{\nu=0}^\infty(1-xq^\nu)$. $(x)_k$ denotes $(x)_\infty/(xq^k)_\infty$ for $k\in\mathbf{Z}$.

In this note we consider a general Jackson integral for Φ and give the connection formula for it as a linear combination of a finite number of the fundamental ones giving special asymptotics for $\alpha_j\to+\infty$ (see Theorem in §4). We also give the holonomic

q-difference equations in the parameters $u_j = q^{\alpha_j}$ and x_k, which are satisfied by all Jackson integrals for Φ (see (3.6) and (3.7)).

A holonomic q-difference system has finite-dimensional solutions over the field of pseudoconstants (see [A3]). Given a basis of solutions for the system there arises a problem of expressing a particular solution as a linear combination of them. This problem is generally called a *connection problem.*

We denote by X the subgroup of $\bar{X}$ isomorphic to $\mathbf{Z}^n$, consisting of the elements $q^\chi = (q^{\nu_1}, \dots, q^{\nu_n}) \in \bar{X}$ for $\chi = \sum_{j=1}^n \nu_j \chi_j, \nu_j \in \mathbf{Z}$, $\{\chi_j\}_{1 \le j \le n}$ being a canonical basis of X. In the sequel we put

$$\gamma'_{j,i} = 1 - \gamma_{i,j} \quad \text{and} \quad \gamma_{j,i} = 1 - \gamma'_{i,j} \quad \text{for } i < j \tag{1.4}$$

so that we have $\gamma'_{i,j} + \gamma_{j,i} = 1$ for any pair $i \neq j$.

We do not postulate any further essential condition for $\gamma_{i,j}$. In the case where $\gamma_{i,j} = \gamma$, $\gamma'_{i,j} = \gamma'$, and where $\gamma - \gamma'$ are positive integers, and if Φ reduces to a polynomial, relevant integrals have been investigated in [A6], [K1], and [K2]. But in that case there is no connection problem in our sense.

For an arbitrary permutation σ of the n figures $\{1, 2, \dots, n\}$, i.e., $\sigma \in \mathrm{S}_n$ (the symmetric group of nth degree) we put the operations on the function $\Phi(t) = \Phi(t|\alpha, \gamma)$ depending on t, α, and γ:

$$\sigma\Phi(t|\alpha,\gamma) = \Phi(\sigma^{-1}(t|\alpha,\gamma)), \tag{1.5}$$

where $\sigma^{-1}(t|\alpha,\gamma) = (\tilde{t}|\tilde{\alpha},\tilde{\gamma})$ is defined as

$$\sigma^{-1}(t|\alpha,\gamma) = (\tilde{t}|\tilde{\alpha},\tilde{\gamma}) \tag{1.6}$$

for

$$\tilde{t}_j = t_{\sigma(j)},$$
$$\tilde{\alpha}_j = (\sigma\alpha)_j = \alpha_{\sigma(j)} + \sum_{\substack{k<j \\ \sigma(j)<\sigma(k)}} (\gamma'_{\sigma(j),\sigma(k)} - \gamma_{\sigma(j),\sigma(k)}) - \sum_{\substack{k>j \\ \sigma(j)>\sigma(k)}} (\gamma'_{\sigma(k),\sigma(j)} - \gamma_{\sigma(k),\sigma(j)}).$$

For a canonical system of generators $\{\sigma_r\}_{1 \le r \le n}$ of S_n, with the relations $\sigma_r^2 = 1$ and $\sigma_r\sigma_{r+1}\sigma_r = \sigma_{r+1}\sigma_r\sigma_{r+1}$, $\sigma_r(t|\alpha,\gamma) = (\tilde{t}|\tilde{\alpha},\tilde{\gamma})$ given by $\tilde{t}_j = t_j, \tilde{\alpha}_j = \alpha_j$ for $j \neq r$, $r+1$, and $\tilde{t}_r = t_{r+1}, \tilde{t}_{r+1} = t_r, \tilde{\alpha}_r = \alpha_{r+1} + \gamma_{r,r+1} - \gamma'_{r,r+1}$, $\alpha_{r+1} = \alpha_r + \gamma'_{r,r+1} - \gamma_{r,r+1}$, respectively. Remark that $\tilde{\alpha}_r + \tilde{\alpha}_{r+1} = \alpha_r + \alpha_{r+1}$.

The following associativity holds:

$$\sigma'\sigma\Phi(t|\alpha,\gamma) = \sigma'(\sigma\Phi)(t|\alpha,\gamma) \tag{1.7}$$

for any two elements $\sigma, \sigma' \in \mathrm{S}_n$, i.e., $\sigma^{-1}\sigma'^{-1}(t|\alpha,\gamma) = \sigma^{-1}(\sigma'^{-1}(t|\alpha,\gamma))$. Indeed, to prove (1.7) it is sufficient to show it for $\sigma' = \sigma_r$ only. In this special case $((\sigma^{-1}\sigma_r)(t))_h$ equals $\alpha_{\sigma(h)} + \sum_{\substack{k<h \\ \sigma(h)<\sigma(k)}} (\gamma'_{\sigma(h),\sigma(k)} - \gamma_{\sigma(h),\sigma(k)}) - \sum_{\substack{k>h \\ \sigma(h)>\sigma(k)}} (\gamma'_{\sigma(k),\sigma(h)} - \gamma_{\sigma(k),\sigma(h)})$ if $\sigma(h) \neq r, r+1$, and equals

$$\alpha_{r+1} + (\gamma_{r,r+1} - \gamma'_{r,r+1}) + \sum_{\substack{k<h \\ \sigma(h)>\sigma(k)}} (\gamma'_{\sigma(h),\sigma(k)} - \gamma_{\sigma(h),\sigma(k)}) - \sum_{\substack{k>h \\ \sigma(h)>\sigma(k)}} (\gamma'_{\sigma(k),\sigma(h)} - \gamma_{\sigma(k),\sigma(h)})$$

or

$$\alpha_r + (\gamma_{r,r+1} - \gamma'_{r,r+1}) + \sum_{\substack{k<h \\ \sigma(h)>\sigma(k)}} (\gamma'_{\sigma(h),\sigma(k)} - \gamma_{\sigma(h),\sigma(k)}) - \sum_{\substack{k>h \\ \sigma(h)>\sigma(k)}} (\gamma'_{\sigma(k),\sigma(h)} - \gamma_{\sigma(k),\sigma(h)}),$$

according to whether $\sigma(h) = r$ or $r+1$. Hence (1.7) holds for $\sigma' = \sigma_r$. The functions

$$U_\sigma(t) = \sigma\Phi(t|\alpha,\gamma)/\Phi(t|\alpha,\gamma) \quad \text{for } \sigma \in \mathrm{S}_n, \tag{1.8}$$

are pseudoconstants, i.e.,

$$Q^\chi U_\sigma = U_\sigma(t) \quad \text{for any } \chi \in X, \tag{1.9}$$

where $Q^\chi f(t) = Q_1^{\nu_1} \cdots Q_n^{\nu_n} f(t)$ denotes the shift operator $f(q^\chi t)$ by the element χ. Q_j denotes the partial q-difference operator on the jth coordinate t_j. In particular,

$$U_{\sigma_r}(t) = \left(\frac{t_{r+1}}{t_r}\right)^{\gamma_{r,r+1}-\gamma'_{r,r+1}} \frac{\theta\left(q^{\gamma_{r,r+1}} t_{r+1}/t_r\right)}{\theta\left(q^{\gamma'_{r,r+1}} t_{r+1}/t_r\right)}. \tag{1.10}$$

More generally, $U_\sigma(t)$ can be expressed as

$$U_\sigma(t) = \prod_{\substack{i<j \\ \sigma^{-1}(i)>\sigma^{-1}(j)}} \left(\frac{t_j}{t_i}\right)^{\gamma_{i,j}-\gamma'_{i,j}} \frac{\theta\left(q^{\gamma_{i,j}} t_j/t_i\right)}{\theta\left(q^{\gamma'_{i,j}} t_j/t_i\right)}, \tag{1.11}$$

To prove (1.11) we first remark that $\{U_\sigma(t)\}_{\sigma\in \mathrm{S}_n}$ satisfy the cocycle condition

$$U_{\sigma\sigma'}(t) = U_\sigma(t) \cdot \sigma U_{\sigma'}(t), \tag{1.12}$$

because

$$U_{\sigma\sigma'}(t) = \frac{\sigma\sigma'\Phi(t|\alpha,\gamma)}{\Phi(t|\alpha,\gamma)} = \frac{\sigma\sigma'\Phi(t|\alpha,\gamma)}{\sigma(t|\alpha,\gamma)} \cdot \frac{\sigma\Phi(t|\alpha,\gamma)}{\Phi(t|\alpha,\gamma)} = \sigma U_\sigma(t) \cdot U_{\sigma'}(t).$$

We denote the right-hand side of (1.11) by $\tilde{U}_\sigma(t)$. We must prove that $U_\sigma(t)$ coincides with $\tilde{U}_\sigma(t)$. When $\sigma = \sigma_r$ it is obvious from (1.10). We prove (1.11) by induction on the length of the reduced product expression of σ by the generators σ_r. So we have only to verify (1.12) for $\tilde{U}_\sigma$, $\tilde{U}'_\sigma(t)$ with $\sigma' = \sigma_r$. In this case, first suppose that $\sigma^{-1}(h) = r$ and $\sigma^{-1}(k) = r+1$ for $h < k$. Then

$$\tilde{U}_{\sigma'\sigma_r}(t) = \prod_{\substack{1\le i<j\le n \\ \sigma^{-1}(i)>\sigma^{-1}(j) \\ i\neq h \text{ or } j\neq k}} \left(\frac{t_j}{t_i}\right)^{\gamma_{i,j}-\gamma'_{i,j}} \frac{\theta\left(q^{\gamma_{i,j}} t_j/t_i\right)}{\theta\left(q^{\gamma'_{i,j}} t_j/t_i\right)} \cdot \left(\frac{t_k}{t_h}\right)^{\gamma_{h,k}-\gamma'_{h,k}} \frac{\theta\left(q^{\gamma_{h,k}} t_k/t_h\right)}{\theta\left(q^{\gamma'_{h,k}} t_k/t_h\right)}, \tag{1.13}$$

which is obviously equal to $\tilde{U}_{\sigma'}(t) \cdot \sigma'\tilde{U}_{\sigma_r}(t)$. The case where $h > k$ can be verified similarly. If σ' has a shorter length than σ, by induction hypothesis, $\tilde{U}'_\sigma(t)$ and $\sigma'\tilde{U}_{\sigma_r}(t)$ coincide with $U_{\sigma'}(t)$ and $\sigma'\tilde{U}_{\sigma_r}(t)$, respectively. Hence $\tilde{U}_\sigma(t)$ coincides with $U_\sigma(t)$.

2. Jackson integrals and α-stable cycles. We now want to define α-stable (or α-unstable) cycles giving special asymptotics of Jackson integrals for $\alpha_j \to \pm\infty$.

We assume the following condition, (C).

(C) For an arbitrary sequence of $(r+1)$ different figures $i_0, i_1, \dots, i_r$, the sum $c_{i_0,i_1} + \cdots + c_{i_r,i_0} \notin \mathbf{Z}$, where $c_{i,j}$ denote $\gamma_{i,j}$ or $\gamma'_{i,j}$ for $i,j \geq 1$ and $c_{0,j} = 1 + \log_q x_k$ or $-\beta_k + \log_q x_k$, respectively (we then put $c_{j,0} = -\log_q x_k$ or $1 + \beta_k - \log_q x_k$).

This condition implies that Φ has only simple poles of normal crossings. It is essential in our subsequent argument.

We denote by $[0, \xi\infty]_q$ the countable subset of $\bar{X}$, the X-orbit of a point $\xi \in \bar{X}$: $[0, \xi\infty]_q = \{q^\chi \cdot \xi | \chi \in X\}$. Then the Jackson integral of a function f on $\bar{X}$ over $[0, \xi\infty]_q$ is by definition equal to

$$\int_{[0,\xi\infty]_q} f(t)\tilde{\omega} = (1-q)^n \sum_{\chi \in X} f(q^\chi \cdot \xi) \quad \text{for } \tilde{\omega} = \frac{d_q t_1}{t_1} \wedge \cdots \wedge \frac{d_q t_n}{t_n}, \tag{2.1}$$

provided it exists (see [A2], [A3], and [G1] for various versions of Jackson integrals).

We are now considering the integral (2.1) for $f(t) = \Phi(t)$:

$$J = \int_{[0,\xi\infty]_q} \Phi(t)\tilde{\omega}. \tag{2.2}$$

Since $U_\sigma(t)$ is a pseudoconstant, as an immediate consequence of (2.2), we get the following.

LEMMA 1.

$$\int_{[0,\xi\infty]_q} \Phi\tilde{\omega} = U_\sigma(\xi)^{-1} \int_{[0,\xi\infty]_q} \sigma\Phi\tilde{\omega}, \tag{2.3}$$

provided both sides are convergent.

In fact, the right-hand side of (2.3) equals $U_\sigma(\xi)^{-1} \sum_{\chi \in X} \sigma\Phi(\xi q^\chi) = U_\sigma(\xi)^{-1} \sum_{\chi \in X} U_\sigma(\xi q^\chi)\Phi(\xi q^\chi) = \sum_{\chi \in X} \Phi(\xi q^\chi)$ since $U_\sigma(\xi q^\chi) = U_\sigma(\xi)$.

We are going to define two kinds of special cycles Y_Γ and Y^*_Γ, which are countable subsets of $[0, \xi\infty]_q$ by particular choices of ξ associated with certain forests Γ in graph theoretical sense.

DEFINITION 1. We consider a graph Γ with the following properties. We denote by $V(\Gamma)$ and $E(\Gamma)$ the sets of vertices of Γ and edges of Γ, respectively. (i) The vertices of Γ consist of the variables $t_j, 1 \leq j \leq n$, and parameters $x_k, 1 \leq k \leq m$. They are all labelled, i.e., Γ is a labelled graph. (ii) Γ has n edges. (iii) Γ has neither loops nor proper circuits, i.e., Γ is a forest that is not necessarily connected. (iv) Each connected component T of Γ has only one vertex in $\{x_1, \dots, x_m\}$, i.e., $V(T) \cap \{x_1, \dots, x_m\}$ consists of only one element. We call each of the vertices in $V(\Gamma) \cap \{x_1, \dots, x_m\}$ a root of Γ. We have called these graphs "admissible" in [A2].

It is known, thanks to the matrix tree theorem (see [M3]), that the number of such forests Γ is equal to $\kappa = m(m+n)^{n-1}$.

Each connected component of T of Γ is a tree and has a natural distance function between two vertices of T. For a vertex t_j of Γ, we denote by $t_{p(j)}, 0 \leq p(j) \leq n$, the unique vertex of Γ neighboring t_j and having a shorter distance by one from a root in the same connected component of T of Γ such that $t_j \in T$. We call $t_{p(j)}$ the predecessor of t_j. t_0 denotes a root itself.

If $p(j) < j$ holds for all vertices t_j, we call Γ, Y_Γ, or Y^*_Γ standard.

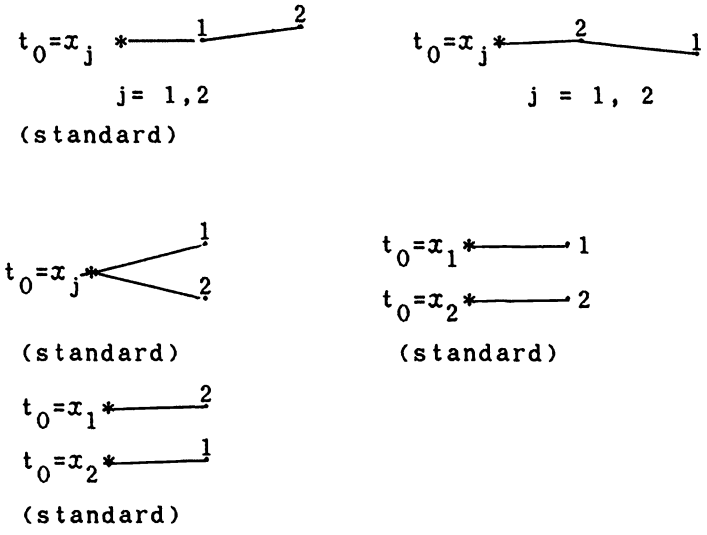

FIG. 1

For example, when $m = 2$ and $n = 2$, κ equals 8. A complete list is given in Fig. 1.

DEFINITION 2. Given an admissible graph Γ, we define a countable subset Y_Γ (or Y_Γ^*) in $\bar{X}$ consisting of the points $t \in \bar{X}$ satisfying the following properties:

(i) $t_j/t_{p(j)}$
$= q^{\gamma_{j,p(j)}}, q^{\gamma_{j,p(j)}+1}, q^{\gamma_{j,p(j)}+2}, \ldots$ (or $q^{-\gamma_{p(j),j}}, q^{-\gamma_{p(j),j}-1}, q^{-\gamma_{p(j),j}-2}, \ldots$);

(ii) $t_0 = qx_k \in V(\Gamma) \cap \{x_1, \ldots, x_m\}$ (or $t_0 = q^{-\beta_k}x_k$) for some $k, 1 \leq k \leq m$.

Likewise we denote by $\eta = (\eta_1, \ldots, \eta_n)$ the point of $\bar{X}$ satisfying the following properties:

(i)' $\eta_j/\eta_{p(j)} = q^{\gamma_{j,p(j)}}$ (or $q^{-\gamma_{p(j),j}}$).

(ii)' $\eta_0 = qx_k$ (or $q^{-\beta_k}x_k$) for some k.

We call this point η the base point of Γ, Y_Γ, and Y_Γ^*.

An admissible graph Γ denoted by Γ_η and the corresponding countable sets Y_Γ and Y_Γ^* are uniquely determined by its base point η. We may denote Y_Γ and Y_Γ^* by Y_η and Y_η^*, respectively, or more simply by $\langle\eta\rangle$. $\langle\eta\rangle$ is the subset of $[0, \eta\infty]_q$. We call the set $\langle\eta\rangle = Y_\eta$ (or Y_η^*) *α-stable* (or *α-unstable*) *cycle*. There are exactly $m(m+n)^{n-1}$ α-stable cycles (or α-unstable cycles).

Now we want to define a regularization of the cycles $[0, \xi\infty]_q$. Assume that $\xi_{j_1}/\xi_{p(j_1)} = q^{-\gamma_{p(j_1),j_1}}, \ldots, \xi_{j_r}/\xi_{p(j_r)} = q^{-\gamma_{p(j_r),j_r}}$ so that $\theta(q^{\gamma_{p(j_1),j_1}}\xi_{j_1}/\xi_{p(j_1)}) = \cdots = \theta(q^{\gamma_{p(j_r),j_r}}\xi_{j_r}/\xi_{p(j_r)}) = 0$ for $j_1 > p(j_1), \ldots, j_r > p(j_r)$. From the genericity of β_k and $\gamma_{i,j}$ stated in condition (C), we can choose the local coordinates $\tau_s = t_{j_s}/t_{p(j_s)}, 1 \leq s \leq n$, of $\bar{X}$ at $t = \xi$. A function

$$f(t) = \frac{g(t)}{\theta\left(q^{\gamma_{p(j_1),j_1}}t_{j_1}/t_{p(j_1)}\right)\cdots\theta\left(q^{\gamma_{p(j_r)j_r}}t_{j_r}/t_{p(j_r)}\right)} \tag{2.4}$$

has the residue at $t = \xi$ along $\tau_1 = q^{-\gamma_{p(j_1),j_1}}, \cdots \tau_r = q^{-\gamma_{p(j_r),j_r}}$ as follows:

$$\operatorname{res}_{t=\xi} f(t) = \frac{q^{-\sum_{s=1}^{r}\gamma_{p(j_s),j_s}}g(\xi)}{\theta'(1)^r} \tag{2.5}$$

for a function $g(t)$ holomorphic at ξ, where $\theta'(1) = -(q)_\infty^3$ (see [G2] for a general definition of residues). This will be denoted by reg $f(\xi)$. For $r = 0$, reg $f(\xi)$ reduces to $f(\xi)$.

When $\langle\eta\rangle$ is standard and α-stable, the Jackson integral of Φ over $\langle\eta\rangle$ is well defined provided it is summable, because Φ is holomorphic along $\langle\eta\rangle$. We have

$$\int_{\langle\eta\rangle} \Phi\tilde{\omega} = \int_{[0,\eta\infty]_q} \Phi\tilde{\omega}, \tag{2.6}$$

seeing that Φ vanishes on the complement $[0,\eta\infty]_q - \langle\eta\rangle$. If $\langle\eta\rangle$ is not standard, then there exists a permutation $\sigma \in \mathrm{S}_n$ such that $\sigma^{-1}\langle\eta\rangle$ is standard. We formally have

$$\begin{aligned}\int_{\langle\eta\rangle} \Phi\tilde{\omega} &= \textstyle\int_{\langle\eta\rangle} U_\sigma(t)^{-1}\sigma\Phi(t|\alpha,\gamma)\tilde{\omega} \\ &= U_\sigma(\eta)^{-1}\int_{\sigma^{-1}\langle\eta\rangle} \hat{\sigma}\Phi(t|\alpha,\gamma)\tilde{\omega},\end{aligned} \tag{2.7}$$

where we denote $\hat{\sigma}\Phi = \Phi(t|\sigma^{-1}(\alpha,\gamma))$. $\sigma^{-1}\langle\eta\rangle$ is also standard for $\hat{\sigma}\Phi(t|\alpha,\gamma)$ when $\int_{\sigma^{-1}\langle\eta\rangle} \hat{\sigma}\Phi(t|\alpha,\gamma)\tilde{\omega}$ is well defined. But $U_\sigma(\eta)^{-1}$ has no meaning because the function $U_\sigma^{-1}(t)$ has poles on $\langle\eta\rangle$. By replacing $U_\sigma^{-1}(\eta)$ by the residue of $U_\sigma^{-1}(t)$ at $t = \eta$ as in (2.5), we have the regularization of (2.6):

$$\mathrm{reg}\int_{\langle\eta\rangle} \Phi\tilde{\omega} = \int_{\sigma^{-1}\langle\eta\rangle} \hat{\sigma}\Phi(t|\alpha,\gamma)\cdot[\mathrm{reg}\, U_\sigma(\eta)^{-1}]. \tag{2.8}$$

This is also equivalent to taking residues with respect to the variables $\tau_1,\dots,\tau_r$ and then doing Jackson integrals with respect to the remaining coordinates $\tau_{r+1},\dots,\tau_n$.

LEMMA 2. *Equation* (2.8) *can be represented by a contour integral avoiding poles of* Φ. *In this sense the corresponding cycle will be denoted by* reg $\langle\eta\rangle$*:*

(2.9)

$$\begin{aligned}\mathrm{reg}\int_{\langle\eta\rangle} \Phi\tilde{\omega} &= \int_{\mathrm{reg}\ \langle\eta\rangle} \Phi\tilde{\omega} \\ &= (1-q)^r \int_{[0,\tilde{\eta}\infty]_q} \frac{d_q\tau_{r+1}\wedge\cdots\wedge d_q\tau_n}{\tau_{r+1}\cdots\tau_n} \sum_{\nu_j\in\mathbf{Z}}{}', \quad \mathrm{res}_{\nu_1,\dots,\nu_r}\left(\frac{\Phi}{t_1\cdots t_n}\right) \\ &\quad / \ [\mathrm{reg}\, U_\sigma(\eta)^{-1}],\end{aligned}$$

where we take the residues at $\tau_1 = q^{-\gamma_{p(j_1),j_1}-\nu_1},\dots,\tau_r = q^{-\gamma_{p(j_r),j_r}-\nu_r}$. $\tilde{\eta}$ *denotes the point* $(\eta_{j_{r+1}}/\eta_{p(j_{r+1})},\dots,\eta_{j_n}/\eta_{p(j_n)}) \in (\mathbf{C}^*)^{n-r}$.

In fact this can be proved by successive applications of the following lemma on a one-dimensional Jackson integral.

LEMMA 3.

$$\begin{aligned} x\ \mathrm{res}_{\xi=x^{-1}} &\int_{[0,\xi\infty]_q} \frac{\theta(txq^\lambda)}{\theta(tx)}\varphi(t)d_qt \\ &= (1-q)\sum_{n=-\infty}^{\infty} \mathrm{res}_{t=x^{-1}q^{-n}}\left[\frac{\theta(txq^\lambda)}{\theta(tx)}\varphi(t)\right] \\ &= x^{-\lambda}\frac{\theta(q^\lambda)}{\theta'(1)}\int_{[0,x^{-1}\infty]_q} t^{-\lambda}\varphi(t)d_qt.\end{aligned} \tag{2.10}$$

In particular, when $\langle\eta\rangle$ is a standard α-unstable cycle, r equals n and we can take as σ the permutation

$$\sigma_0 = \begin{pmatrix} 1,2,\dots,n \\ n,n-1,\dots,1 \end{pmatrix}.$$

The terminologies of α-stable and α-unstable cycles may be justified by the following proposition (see [A2] and [A3]).

PROPOSITION 1. *We put $\alpha_j = \alpha'_j + N\omega_j$ for α'_j and ω_j fixed such that $\omega_j \in \mathbf{Z}^+$. In case of a stable cycle $\langle\eta\rangle$, there exists a $\sigma \in \mathrm{S}_n$ such that $\sigma^{-1}\langle\eta\rangle$ is standard. If $N \in \mathbf{Z}^+$ tends to $+\infty$, then* (2.8) *or* (2.9) *has an asymptotic expansion*

$$\begin{aligned} \operatorname{reg} \int_{\langle\eta\rangle} \Phi\tilde{\omega} &= (1-q)^n \cdot \sigma\Phi(\eta|\alpha,\gamma)\left(1+O\left(\frac{1}{N}\right)\right) \\ &= \eta_1^{\alpha_1}\cdots\eta_n^{\alpha_n} R_+(\eta)\left(1+O\left(\frac{1}{N}\right)\right), \end{aligned} \tag{2.11}$$

where $R_+(\eta)(\neq 0)$ does not depend on α. In particular, if $\langle\eta\rangle$ is itself standard, then

$$\int_{\langle\eta\rangle} \Phi\tilde{\omega} = (1-q)^n \Phi(\eta|\alpha,\gamma)\left(1+O\left(\frac{1}{N}\right)\right). \tag{2.12}$$

Similarly, in case of an α-unstable cycle $\langle\eta\rangle$, for $N \to -\infty$,

$$\operatorname{reg} \int_{\langle\eta\rangle} \Phi\tilde{\omega} = \eta_1^{\alpha_1}\cdots\eta_n^{\alpha_n} R_-(\eta)\left(1+O\left(\frac{1}{N}\right)\right), \tag{2.13}$$

where $R_-(\eta)(\neq 0)$ does not depend on α.

In other words α-stable (or α-unstable) cycles correspond to the simplest asymptotic expansions for $\alpha_j \to +\infty$ (or $-\infty$).

It has been proved in [A2] *and* [A3] *that the α-stable (or α-unstable) cycles give a dual basis of the de Rham cohomology $H^n(\overline{X},\Phi,\nabla_q)$ associated with the Jackson integrals* (2.2). *The dimension of $H^n(\overline{X},\Phi,\nabla_q)$ is equal to $m(m+n)^{n-1}$.*

So an arbitrary cycle $[0,\xi\infty]_q$ can be described as a linear combination of the $m(m+n)^{n-1}\alpha$-stable cycles reg Y_Γ (or α-unstable cycles reg Y^*_Γ) over the field of pseudoconstants in the parameters $u_h, \beta_i, \gamma_{j,k}$, and ξ_ℓ :

$$\int_{[0,\xi\infty]_q} \Phi(t)\tilde{\omega} = \sum c_\Gamma \int_{\operatorname{reg}(Y_\Gamma)} \Phi(t)\tilde{\omega} \tag{2.14}$$

$$= \sum c^*_\Gamma \int_{\operatorname{reg}(Y^*_\Gamma)} \Phi(t)\tilde{\omega} \tag{2.15}$$

for some pseudoconstants c_Γ and c^*_Γ.

We evaluate c_Γ and c^*_Γ explicitly in §4.

3. Holonomic q-difference equations. The notion of holonomic q-difference equations has been investigated in [A1], [A2], [A3], and [S]. In [F] it has been discussed in relation to so-called R-matrices and quantum KZ equations. Here we want to explicitly give the holonomic system satisfied by (2.2) in the parameters u_j and x_k.

We denote by $\tilde{Q}_j (1 \le j \le n)$, and $\tilde{Q}_{n+j} (1 \le j \le m)$ the q-shift operators for functions of $(u,x) = (u_1,\dots,u_n;x_1,\dots,x_m)$ induced by the displacements $u_j \to u_j q$ and $x_k \to x_k q$, respectively. Then we have $\tilde{Q}_j \Phi(t) = u_j \Phi(t)$ and

$$\tilde{Q}_{n+k}\Phi(t) = \prod_{j=1}^{n} \frac{(1-q^{-1}t_j/x_k)}{(1-q^{\beta_k-1}t_j/x_k)}\Phi(t).$$

Now

$$Q^{\chi}\Phi(t) = b_{\chi}(t)\Phi(t), \qquad \chi = \sum_{j=1}^{n} \nu_j \chi_j \in X, \tag{3.1}$$

where $b_{\chi}(t)$ is represented as $u^{\chi} b_{\chi}^{+}(t)/b_{\chi}^{-}(t)$ for $u^{\chi} = u_1^{\nu_1}\cdots u_n^{\nu_n}$, such that $b_{\chi}^{+}(t)$ and $b_{\chi}^{-}(t)$ are Laurent polynomials in $t, \prod_{k=1}^{m}\prod_{\nu_j \ge 0} (t_j q^{\beta_k}/x_k)_{\nu_j} \cdot \prod_{\nu_j<0}(t_j q^{\nu_j}/x_k)_{-\nu_j}$ and $\prod_{k=1}^{m}\prod_{\nu_j\ge 0}(t_j/x_k)_{\nu_j}\cdot\prod_{\nu_j<0}(t_j q^{\beta_k+\nu_j}/x_k)_{-\nu_j}$, respectively. We take as φ the Laurent polynomial $Q^{-\chi}b_{\chi}^{-}(t)$ in t:

$$\varphi(t) = \prod_{k=1}^{m}\prod_{\nu_j\ge 0}\left(t_j q^{-\nu_j}/x_k\right)_{\nu_j} \prod_{\nu_j<0}\left(t_j q^{\beta_k}/x_k\right)_{-\nu_j}. \tag{3.2}$$

Then we get $Q^{\chi}(\Phi(t)\varphi(t)) = b_{\chi}(t)\Phi(t)\cdot Q^{\chi}\varphi(t) = b_{\chi}^{+}(t)\Phi(t)$. Since

$$\int_{[0,\xi\infty]_q} \Phi(t)\varphi(t)\tilde{\omega} = \int_{[0,\xi\infty]_q} Q^{\chi}(\Phi(t)\varphi(t))\tilde{\omega}, \tag{3.3}$$

we have

$$\int_{[0,\xi\infty]_q} \Phi(t)Q^{-\chi}b_{\chi}^{-}(t)\tilde{\omega} - \int_{[0,\xi\infty]_q} \Phi(t)u^{\chi}b_{\chi}^{+}(t)\tilde{\omega} = 0. \tag{3.4}$$

For an arbitrary Laurent polynomial $f(t)$ in t, the equality $f(\tilde{Q}_1,\dots,\tilde{Q}_n)\Phi(t) = f(t_1,\dots,t_n)\Phi(t)$ holds. Hence by the definition of Jackson integrals, (3.4) is equivalent to the equations

$$Q^{-\chi}b_{\chi}^{-}(\tilde{Q})J - u^{\chi}b_{\chi}^{+}(\tilde{Q})J = 0 \tag{3.5}$$

for any $\chi \in X$. Since the set $\{\pm\chi_j, 1 \le j \le n\}$ consists of primitive corner vectors spanning rational polyhedral cones of the fan in the theory of torus embeddings (see [O] for the definition) associated with equation (3.5), (3.5) is equivalent to the following system of q-difference equations:

$$\left(Q_j^{-1}b_{\chi_j}^{-}\right)(\tilde{Q})J - u_j b_{\chi_j}^{+}(\tilde{Q})J = 0, \qquad 1 \le j \le n. \tag{3.6}$$

(See [A3] for more details.) In the same way we have

$$\left\{\prod_{j=1}^{n}\left(1-q^{\beta_k-1}x_k^{-1}\tilde{Q}_j\right)\tilde{Q}_{k+n} - \prod_{j=1}^{n}\left(1-q^{-1}x_k\tilde{Q}_j\right)\right\}J = 0. \tag{3.7}$$

One can prove that the system q-difference equations (3.6) and (3.7) in the parameters u_j and x_k are *holonomic* in the sense that they have only finite-dimensional solutions over the field of pseudoconstants in u_j and x_k. In fact its dimension is equal to $m(m+n)^{n-1}$, which coincides with the dimension of $H^n(\overline{X},\Phi,\nabla_q)$ (see Theorem 2 in [A3]).

4. Main result. We denote by $\Psi_n(\xi,\eta|\alpha)$ the function in the parameters ξ_j,η_j, u_j, and β_k, which is expressed by

$$\Psi_n(\xi,\eta|\alpha)=(1-q)^n\prod_{j=1}^{n}\left\{\left(\frac{\xi_j}{\eta_j}\right)^{\alpha_j}\frac{(q)_\infty^3\theta\left(q^{\alpha_j+\cdots+\alpha_n+1}\xi_j\eta_{j-1}/(\xi_{j-1}\eta_j)\right)}{\theta\left(q^{\alpha_j+\cdots+\alpha_n+1}\right)\theta(q\xi_j\eta_{j-1}/(\xi_{j-1}\eta_j))}\right\},\tag{4.1}$$

where we put $\xi_0=\eta_0=1$. This can be seen to be a pseudoconstant.

We can now state our main theorem.

THEOREM. *For a generic $\xi\in\overline{X}$, we have*

$$\int_{[0,\xi\infty]_q}\Phi\tilde{\omega}=\sum_{\langle\eta\rangle}([0,\xi\infty]_q:\operatorname{reg}\langle\eta\rangle)_\Phi\int_{\operatorname{reg}\langle\eta\rangle}\Phi\tilde{\omega}\tag{4.2}$$

for certain pseudoconstants $([0,\xi\infty]_q:\operatorname{reg}\langle\eta\rangle)_\Phi$, where $\langle\eta\rangle$ ranges over the set of all α-unstable cycles. If $\langle\eta\rangle$ is standard, then $([0,\xi\infty]_q:\langle\eta\rangle)_\Phi$ equals the pseudoconstant $\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)$ defined by the sum

$$\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)=\sum_{\sigma\in S_n}\sigma\Psi_n(\xi,\eta|\alpha)\cdot U_\sigma^{-1}(\xi)U_\sigma(\eta).\tag{4.3}$$

In case of a nonstandard α-unstable cycle $\langle\eta\rangle$, there exists a $\rho\in S_n$ such that $\rho^{-1}\langle\eta\rangle$ is standard and α-unstable. We then have

$$\begin{aligned}([0,\xi\infty]_q:\operatorname{reg}\langle\eta\rangle)_\Phi&=(\rho^{-1}[0,\xi\infty]_q:\rho^{-1}\langle\eta\rangle)_{\hat{\rho}\Phi}U_\rho(\xi)^{-1}\operatorname{reg}[U_\rho(\eta)]\\&=\rho\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)U_\rho(\xi)^{-1}\operatorname{reg}[U_\rho(\eta)],\end{aligned}\tag{4.4}$$

where

$$\int_{\operatorname{reg}\langle\eta\rangle}\Phi\tilde{\omega}=\int_{(\sigma_0\rho)^{-1}\langle\eta\rangle}\hat{\sigma}_0\hat{\rho}\Phi\tilde{\omega}/[\operatorname{reg}U_{\sigma_0\rho}(\eta)^{-1}]\tag{4.5}$$

by definition. $\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)$ is quasi-symmetric, i.e.,

$$\sigma\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)=\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)U_\sigma(\xi)U_\sigma^{-1}(\eta).\tag{4.6}$$

$\operatorname{reg}\langle\eta\rangle$ is not unique and depends on the choice of an element $\rho\in S_n$ such that $\rho^{-1}\langle\eta\rangle$ is standard. We may choose as ρ the unique element having a minimal expression in terms of the generators $\sigma_1,\sigma_2,\dots,\sigma_n$.

$\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)$ can also be written as the quotient of theta polynomials:

$$\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)=\frac{H(\xi,\eta|\alpha,\gamma)}{G(\xi,\eta|\alpha,\gamma)},\tag{4.7}$$

where

$$\begin{aligned}G(\xi,\eta|\alpha,\gamma)=&\prod_{j=1}^{n}\left(\frac{\xi_j}{\eta_j}\right)^{j-1-a_j}\cdot\prod_{0\le k<j\le n}\theta\left(q\xi_j\eta_k/(\xi_k\eta_j)\right)\\&\cdot\prod_{1\le k<j\le n}\left\{\theta\left(q^{\gamma_{k,j}}\xi_j/\xi_k\right)\theta\left(q^{\gamma'_{k,j}}\eta_j/\eta_k\right)\right\}\end{aligned}\tag{4.8}$$

satisfies the quasi skew-symmetric property : $\sigma G(\xi,\eta|\alpha,\gamma) = \operatorname{sgn}\sigma \cdot G(\xi,\eta|\alpha,\gamma)U_\sigma(\xi)^{-1}$ $U_\sigma(\eta)$ for $\sigma \in \mathrm{S}_n$. $H(\xi,\eta|\alpha,\gamma)$ is skew-symmetric:

$$\sigma H(\xi,\eta|\alpha,\gamma) = \operatorname{sgn}\sigma \cdot H(\xi,\eta|\alpha,\gamma). \tag{4.9}$$

From (4.3), $H(\xi,\eta|\alpha,\gamma)$ can be expressed as an alternating sum

$$H(\xi,\eta|\alpha,\gamma) = \sum_{\sigma\in\mathrm{S}_n} \sigma E(\xi,\eta|\alpha,\gamma)\operatorname{sgn}\sigma, \tag{4.10}$$

$$\begin{aligned} E(\xi,\eta|\alpha,\gamma) = (1-q)^n \prod_{j=1}^{n} & \left\{ \frac{\theta\left(q^{\alpha_j+\cdots+\alpha_n+1}\xi_j\eta_{j-1}/(\xi_{j-1}\eta_j)\right)}{\theta\left(q^{\alpha_j+\cdots+\alpha_n+1}\right)} \left(\frac{\xi_j}{\eta_j}\right)^{j-1} \right\} \\ & \cdot \prod_{\substack{0\le k<j\le n \\ j-k\ge 2}} \theta(q\xi_j\eta_k/(\xi_k\eta_j)) \\ & \cdot \prod_{1\le k<j\le n} \left\{ \theta\left(q^{\gamma_{k,j}}\xi_j/\xi_k\right)\theta\left(q^{\gamma'_{k,j}}\xi_k/\xi_j\right)\right\}. \end{aligned} \tag{4.11}$$

LEMMA 4. *As a function of ξ and η in $\overline{X}$, $H(\xi,\eta|\alpha,\gamma)$ is divided out by the product*

$$\prod_{j=1}^{n}\left(\frac{\xi_j}{\eta_j}\right)^{j-1} \prod_{0\le k<j\le n} \theta\left(q\frac{\xi_j\eta_k}{\xi_k\eta_j}\right)$$

in the ring of θ-polynomials on $\bar{X}\times\bar{X}$.

Proof. In fact, as a function of (ξ,η) on $\bar{X}\times\bar{X}$, $G(\xi,\eta) = G(\xi,\eta|\alpha,\gamma)$, and $H(\xi,\eta) = H(\xi,\eta|\alpha,\gamma)$ have the quasi-periodic properties for the q-shift operators $Q_r(\xi), Q_r(\eta)$ induced by the shifts $\xi_r \to \xi_r q$ and $\eta_r \to \eta_r q$, respectively. □

$$\begin{aligned} [Q_r(\xi)G(\xi,\eta)/G(\xi,\eta)] &= [Q_r(\xi)H(\xi,\eta)]/H(\xi,\eta) \\ &= q^{-n+r-\alpha_r+A_r} \cdot \prod_{\substack{k=1 \\ k\ne r}}^{n} \left(\xi_k^2\eta_r/(\xi_r^2\eta_k)\right), \end{aligned} \tag{4.12}$$

$$\begin{aligned} [Q_r(\eta)G(\xi,\eta)]/G(\xi,\eta) &= [Q_r(\eta)H(\xi,\eta)]/H(\xi,\eta) \\ &= q^{-n-r+2+\alpha_r+A'_r} \cdot \prod_{\substack{j=1 \\ j\ne r}}^{n} (\xi_r\eta_j^2/(\xi_j\eta_r^2)) \end{aligned} \tag{4.13}$$

for $A_r = -\sum_{1\le k<r}\gamma_{k,r} + \sum_{r<k\le n}\gamma_{r,k}$ and $A'_r = -\sum_{1\le k<r}\gamma_{r,k} + \sum_{r<k\le n}\gamma_{k,r}$, in view of (1.4). Furthermore, $H(\xi,\eta|\alpha,\gamma)$ vanishes if $\xi_2/\eta_2 = \xi_1/\eta_1$. This can be seen as follows. First we see that $-\sigma_1\sigma' E(\xi,\eta|\alpha,\gamma) + \sigma' E(\xi,\eta|\alpha,\gamma)$ vanishes for any $\sigma' \in \mathrm{S}_n$. Indeed, if $\sigma'(r) = 1$ and $\sigma'(s) = 2$ for some r, s such that $|r-s| > 1$, then $\sigma_1\sigma' E(\xi,\eta|\alpha,\gamma)$ and $\sigma' E(\xi,\eta|\alpha,\gamma)$ both vanish because the factor $\theta(q(\xi_2\eta_1/\xi_1\eta_2))$ or $\theta(q(\xi_1\eta_2/\xi_2\eta_1))$ appears in both. Otherwise we may suppose that $\sigma'(r) = 1$ and $\sigma'(r+1) = 2$. We put $\sigma'^{-1}(\alpha) = \tilde{\alpha}$. Then $\tilde{\alpha}_r = \alpha_1 + \sum_{\substack{1\le k<r \\ \sigma'(k)>r+1}} (\gamma'_{1,\sigma'(k)} - \gamma_{1,\sigma'(k)})$, $\tilde{\alpha}_{r+1} =$

$\alpha_2 + \sum_{\substack{1\le k<r \\ \sigma'(k)>r+1}} (\gamma'_{1,\sigma'(k)} - \gamma_{1,\sigma'(k)})$ and $\tilde{\xi}_r = \xi_1, \tilde{\xi}_{r+1} = \xi_2, \tilde{\eta}_r = \eta_1, \tilde{\eta}_{r+1} = \eta_2$, respectively.

Hence,

(4.14)

$$
\begin{aligned}
&-\sigma_1\sigma' E(\xi,\eta|\alpha,\gamma) + \sigma' E(\xi,\eta|\alpha,\gamma) \\
&= (1-q)^n (q)_\infty^{3n} \prod_{j=1}^{n} \left(\frac{\tilde{\xi}_j}{\tilde{\eta}_j}\right)^{j-1} \cdot \left(\frac{\xi_1\xi_2}{\eta_1\eta_2}\right)^{r-1} \\
&\cdot \prod_{\substack{j=1 \\ j\neq r,r+1,r+2}}^{n} \frac{\theta(q^{\tilde{\alpha}_j+\cdots+\tilde{\alpha}_n+1}\tilde{\xi}_j\tilde{\eta}_{j-1}/(\tilde{\xi}_{j-1}\tilde{\eta}_j))}{\theta(q^{\tilde{\alpha}_j+\cdots+\tilde{\alpha}_n+1})} \prod_{\substack{0\le k<j\le n \\ 2\le j-k, \\ (k,j)\neq(r-1,r+1) \text{ or } (r,r+2)}} \theta\left(q\frac{\tilde{\xi}_k\tilde{\eta}_j}{\tilde{\eta}_k\tilde{\xi}_j}\right) \\
&\cdot \left\{ \frac{\xi_2}{\eta_2} \frac{\theta(q^{\tilde{\alpha}_r+\cdots+\tilde{\alpha}_n+1}\xi_1\tilde{\eta}_{r-1}/(\tilde{\xi}_{r-1}\eta_1))\theta(q^{\tilde{\alpha}_{r+1}+\cdots+\tilde{\alpha}_n+1}\xi_2\eta_1/(\xi_1\eta_2))}{\theta(q^{\tilde{\alpha}_r+\cdots+\tilde{\alpha}_n+1})\,\theta(q^{\tilde{\alpha}_{r+1}+\cdots+\tilde{\alpha}_n+1})} \right. \\
&\cdot \frac{\theta(q^{\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1}\tilde{\xi}_{r+2}\eta_2/(\xi_2\tilde{\eta}_{r+2}))}{\theta(q^{\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1})} \theta\left(q\frac{\tilde{\xi}_{r-1}\eta_2}{\xi_2\tilde{\eta}_{r-1}}\right)\theta\left(q\frac{\xi_1\tilde{\eta}_{r+2}}{\eta_1\tilde{\xi}_{r+2}}\right) \\
&- \frac{\xi_1}{\eta_1} \frac{\theta(q^{\tilde{\alpha}_r+\cdots+\tilde{\alpha}_n+1}\xi_2\tilde{\eta}_{r-1}/(\tilde{\xi}_{r-1}\eta_2))\theta(q^{\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1}\xi_{r+2}\eta_1/(\xi_1\eta_{r+2}))}{\theta(q^{\tilde{\alpha}_r+\cdots+\tilde{\alpha}_n+1})\theta(q^{\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1})} \\
&\left. \cdot \frac{\theta(q^{\tilde{\alpha}_r+\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1+\gamma'_{1,2}-\gamma_{1,2}}\xi_1\eta_2/(\xi_2\eta_1))}{\theta(q^{\tilde{\alpha}_r+\tilde{\alpha}_{r+2}+\cdots+\tilde{\alpha}_n+1+\gamma'_{1,2}-\gamma_{1,2}})} \theta\left(q\frac{\tilde{\xi}_{r-1}\eta_1}{\tilde{\eta}_{r-1}\xi_1}\right)\theta\left(q\frac{\xi_2\tilde{\eta}_{r+2}}{\eta_2\tilde{\xi}_{r+2}}\right) \right\}
\end{aligned}
$$

since $\sigma_1(\tilde{\alpha})_r = \tilde{\alpha}_{r+1} + \gamma_{1,2} - \gamma'_{1,2}, \sigma_1(\tilde{\alpha})_{r+1} = \tilde{\alpha}_r + \gamma'_{1,2} - \gamma_{1,2}$, and $\sigma_1(\tilde{\alpha})_j = \tilde{\alpha}_j$ otherwise. Hence (4.14) and $H(\xi,\eta|\alpha,\gamma)$ vanish for $\xi_1/\eta_1 = \xi_2/\eta_2$. Because $H(\xi,\eta|\alpha,\gamma)$ is symmetric in $(\xi,\eta|\alpha,\gamma)$, it also vanishes if $\xi_j/\eta_j = \xi_k/\eta_k$ for every $j \neq k$ and must be divided out by the factor $\theta(q\xi_j\eta_k/(\eta_j\xi_k))$. Hence the lemma follows.

Remark. Assume that η is standard. If Γ_η (see Definition 2) is a tree and if the vertices of Γ_η are totally ordered, then $U_\sigma(\eta)$ vanishes for all σ different from the identity. Hence $\tilde{\Psi}_n(\xi,\eta|\alpha,\gamma)$ reduces to $\Psi_n(\xi,\eta|\alpha,\gamma)$ itself. On the other hand, if every edge of Γ_η has a root in its ends, then all the terms $\sigma\Psi_\eta(\xi,\eta|\alpha), \sigma \in \mathrm{S}_n$, appear.

To obtain a similar formula to (4.2) with regards to the α-stable cycles Y_Γ in place of Y^*_Γ, we also consider the multiplicative function

$$
\Phi^*(t) = \prod_{j=1}^{n} t_j^{\alpha^*_j} \prod_{j=1}^{n}\prod_{k=1}^{m} \frac{(q^{1-\beta_k}t_jx_k)_\infty}{(qt_jx_k)\infty} \prod_{1\le i<j\le n} \frac{(q^{\gamma'_{j,i}}t_j/t_1)_\infty}{q^{\gamma_{j,i}}t_j/t_i)_\infty} \tag{4.15}
$$

for $\alpha^*_j = -\alpha_j - \beta_1 - \cdots - \beta_m + \sum_{1\le i<j}(\gamma'_{i,j} - \gamma_{i,j}) + \sum_{j<k\le n}(-\gamma'_{j,k} + \gamma_{j,k})$ and $\gamma^*_{i,j} = \gamma_{j,i}$. Then $\Phi(t)$ and $\Phi^*(t^{-1})$ satisfy the same q-difference equations:

$$
Q^\chi\Phi(t)/\Phi(t) = (Q^{-\chi}\Phi^*(t^{-1}))/\Phi^*(t^{-1}), \quad \text{for } \chi \in X. \tag{4.16}
$$

In fact the relation

$$
\Phi(t) = U_0(t)\Phi^*(t^{-1}) \tag{4.17}
$$

holds for the pseudoconstant

$$U_0(t) = \prod_{j=1}^{n}\prod_{k=1}^{m} t_j^{-\beta_k}\frac{\theta(t_j/x_k)}{\theta(q^{\beta_k}t_j/x_k)}\cdot\prod_{1\le i<j\le n}\left(\frac{t_j}{t_i}\right)^{\gamma'_{i,j}-\gamma_{i,j}}\frac{\theta(q^{\gamma'_{i,j}}t_j/t_i)}{\theta(q^{\gamma_{i,j}}t_j/t_i)}. \tag{4.18}$$

(Remark that $\gamma'_{r,s}+\gamma_{s,r}=1$ for $r\neq s$.) Hence, as in Lemma 1, we have the following.

LEMMA 5.

$$\int_{[0,\xi\infty]_q}\Phi(t)\tilde{\omega} = U_0(\xi)\int_{[0,\xi^{-1}\infty]_q}\Phi^*(t)\tilde{\omega}. \tag{4.19}$$

$\langle\eta\rangle$ is an α-stable (or unstable) cycle for Φ according to whether $\langle\eta^{-1}\rangle$ is an α-unstable (or stable) cycle for Φ^*. Hence the following.

PROPOSITION 2. *For an arbitrary α-stable cycle $\langle\eta\rangle$ for Φ,*

$$([0,\xi\infty]_q : \operatorname{reg}\langle\eta\rangle)_\Phi = ([0,\eta^{-1}\infty]_q : \operatorname{reg}\langle\eta^{-1}\rangle)_{\Phi^*}U_0(\xi)U_0(\eta)^{-1}. \tag{4.20}$$

In particular, if $\langle\eta\rangle$ is standard, then $\langle\eta^{-1}\rangle$ becomes a standard α-unstable cycle and we have

$$([0,\xi\infty]_q : \langle\eta\rangle)_\Phi = \tilde{\Psi}_n(\xi^{-1},\eta^{-1}|\alpha^*,\gamma^*)U_0(\xi)U_0(\eta)^{-1}. \tag{4.21}$$

By using these formulae and the theorem, one can also compute connection coefficients for all α-stable cycles.

5. Proof of main result. For $n=1$, Φ reduces to

$$\Phi = t_1^{\alpha_1}\prod_{k=1}^{m}\frac{(t_1/x_k)_\infty}{(t_1q^{\beta_k}/x_k)_\infty}. \tag{5.1}$$

In this case the following lemma, due to Mimachi, will play a central role in the sequel (for similar calculus see [M1] and [M2]).

LEMMA 6.

$$\begin{aligned}\tilde{\Psi}_1(\xi_1,\eta_1|\alpha) &= \Psi_1(\xi,\eta_1|\alpha)\\ &= (1-q)\left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1}\frac{(q)_\infty^3\theta(q^{\alpha_1+1}\xi_1/\eta_1)}{\theta(q^{\alpha_1+1})\theta(q\xi_1/\eta_1)},\end{aligned} \tag{5.2}$$

where η_1 ranges over the set $\{x_1q^{-\beta_1},\dots,x_mq^{-\beta_m}\}$.

Proof. Using Lemma 3, we can express J as

$$J = -\frac{(1-q)(q)_\infty^3}{\theta(q^{\alpha_1+1})}\sum_{\ell=-\infty}^{+\infty}\operatorname{res}_{t_1=\xi_1q^\ell}\left\{\frac{\theta(t_1q^{\alpha_1+1}/\xi_1)}{\theta(t_1/\xi_1)t_1}\prod_{j=1}^{m}\frac{(t_1/x_j)_\infty}{(t_1q^{\beta_j}/x_j)_\infty}\right\}. \tag{5.3}$$

The right-hand side equals

$$\frac{(1-q)(q)_\infty^3}{\theta(q^{\alpha_1+1})}\sum_{j=1}^{n}\left(\frac{\xi_1q^{\beta_j}}{x_j}\right)^{\alpha_1}\frac{\theta(q^{\alpha_1+\beta_j+1}\xi_1/x_j)}{\theta(q^{\beta_j+1}\xi_1/x_j)}\int_{\mathcal{Z}^*_{q^{-\beta_j}x_j}}\Phi\tilde{\omega}, \tag{5.4}$$

where the integral part is, by definition, equal to

$$\sum_{\ell=0}^{+\infty} \operatorname{res}_{t_1=q^{-\beta_j-\ell_{x_j}}} (\Phi/t_1) \quad \text{i.e., reg } \langle \eta_1 \rangle = Z^*_{q^{-\beta_j} x_j}.$$

This means Lemma 6. □

Now we are going to prove the theorem.

Proof of the theorem. By the change of variables $t_1 = \tau_1, t_j = \tau_1 \tau_j$ for $j \geq 2$, (2.2) is rewritten as

$$\begin{aligned} J = & \int_{[0,(\xi_2/\xi_1,\dots,\xi_n/\xi_1)\infty]_q} \frac{d_q\tau_2}{\tau_2} \wedge \cdots \wedge \frac{d_q\tau_n}{\tau_n} \tau_2^{\alpha_2} \cdots \tau_n^{\alpha_n} \\ & \cdot \prod_{2\leq j\leq n} \frac{(q^{\gamma_{1,j}}\tau_j)_\infty}{(q^{\gamma'_{1,j}}\tau_j)_\infty} \prod_{2\leq i<j\leq n} \frac{(q^{\gamma'_{i,j}}\tau_j/\tau_i)_\infty}{(q^{\gamma_{i,j}}\tau_j/\tau_i)_\infty} \int_{[0,\xi_1\infty]_q} \Phi_1 \frac{d_q t_1}{t_1}, \end{aligned} \tag{5.5}$$

where Φ_1 denotes

$$t_1^{\alpha_1+\cdots+\alpha_n} \cdot \prod_{k=1}^{m} \frac{(t_1/x_k)_\infty}{(t_1 q^{\beta_k}/x_k)_\infty} \cdot \prod_{\substack{2\leq j\leq n \\ 1\leq k\leq m}} \frac{(t_1\tau_j/x_k)_\infty}{(t_1\tau_j q^{\beta_k}/x_k)_\infty}. \tag{5.6}$$

We fix $\tau_2, \dots, \tau_n$ for the moment and integrate (5.5) with respect to t_1 over the one-dimensional set $[0, \xi_1\infty]_q$. As a result of Lemma 1,

(5.7)

$$\begin{aligned} & \int_{[0,\xi_1\infty]_q} \Phi_1 \frac{d_q t_1}{t_1} \\ & = (1-q)(q)_\infty^3 \left\{ \sum_{k=1}^{m} \left[\left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1+\cdots+\alpha_n} \frac{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\xi_1/\eta_1\right)}{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\right)\theta\left(q\frac{\xi_1}{\eta_1}\right)} \right.\right. \\ & \qquad \left.\left. \cdot \int_{\text{reg } <\eta_1>} \Phi \frac{d_q t_1}{t_1} \right]_{\eta_1 = x_k q^{-\beta_k}} \right. \\ & \quad + \sum_{j=2}^{n} \sum_{k=1}^{m} \left[\left(\frac{\xi_1}{\eta_1}\tau_j\right)^{\alpha_1+\cdots+\alpha_n} \right. \\ & \qquad \left.\left. \cdot \frac{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\xi_1\tau_j/\eta_1\right)}{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\right)\theta(q\frac{\xi_1}{\eta_1}\tau_j)} \int_{\text{reg } \langle \tau_j^{-1}\eta_1 \rangle} \Phi_1 \frac{d_q t_1}{t_1} \right]_{\eta_1 = x_k q^{-\beta_k}} - \beta_k \right\}. \end{aligned}$$

Since the function (5.2) of ξ_1 and η_1 is pseudoconstant and since τ_j ranges over the set $\xi_j q^{\nu_j}/\xi_1$ for $\nu_j = 0, \pm 1, \pm 2, \dots$, none of the coefficients in the right-hand side depend on either τ_j, i.e., τ_j may be replaced by ξ_j/ξ_1, respectively. By another change of variables, $t_1 = t_1$ and $t_j = t_1\tau_j$ for $j \geq 2, J$ can be expressed as

$$J = \sum_{r=1}^{n} J_r, \tag{5.8}$$

where

$$J_r = (1-q)^n (q)_\infty^{3n} \sum_{k=1}^{m} \left\{ \left[\left(\frac{\xi_r}{\eta_r} \right)^{\alpha_1+\cdots+\alpha_n} \frac{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\xi_r/\eta_r\right)}{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\right)\theta\left(q\frac{\xi_r}{\eta_r}\right)} \right.\right. \tag{5.9}$$
$$\left.\left. \int_{\mathrm{reg}\ [0,\xi\eta_r/\xi_r\infty]_q} \Phi\tilde{\omega} \right]_{\eta_r = x_k q^{-\beta_k}} \right\}, \qquad r \geq 2.$$

We denote by $W_r = \sigma_{r-1}\cdots\sigma_1 \cdot W_1$, where W_1 is the subgroup of S_n consisting of elements leaving the number 1 fixed, and by $\xi^{(r)}$ the $(n-1)$ tuple $(\xi_1,\ldots,\xi_{r-1},\xi_{r+1},\ldots,\xi_n)$ for $\xi \in \overline{X}$. $\tilde{\omega}_r$ will denote the $(n-1)$-difference form

$$(-1)^{r-1} \cdot \frac{d_q t_1}{t_1} \wedge \cdots \wedge \frac{d_q t_{r-1}}{t_{r-1}} \wedge \frac{d_q t_{r+1}}{t_{r+1}} \wedge \cdots \wedge \frac{d_q t_n}{t_n}.$$

Now we start from evaluating J_1. $t_1 = \eta_1 q^{-\nu_1}, \nu_1 \in \mathbf{Z}$, being fixed, by an induction hypothesis we have

(5.10)
$$\int_{[0,\xi^{(1)}\eta_1/\xi_1\infty]_q} \Phi(t)\tilde{\omega}_1 == \sum_{\langle\eta^{(1)}\rangle} \left([0,\xi^{(1)}\eta_1/\xi_1\infty]_q : \mathrm{reg}\ \langle\eta^{(1)}\rangle \right)_\Phi \int_{\mathrm{reg}\ \langle\eta^{(1)}\rangle} \Phi\tilde{\omega}_1,$$

where $\langle\eta^{(1)}\rangle$ ranges over the set of all α-unstable cycles for the function Φ restricted to the variables $t_2,\ldots,t_n$. As for J_r for $r \geq 2$, $t_r = \eta_r q^{-\nu_r}$ being fixed, Lemma 1 shows similarly that

$$\begin{aligned} &\int_{[0,\xi^{(r)}\eta_r/\xi_r\infty]_q} \Phi\tilde{\omega}_r \\ &\quad = U_{\sigma_{r-1}\cdots\sigma_1}(\xi)^{-1} \int_{[0,\xi^{(r)}\eta_r/\xi_r\infty]_q} \sigma_{r-1}\cdots\sigma_1\Phi(t|\alpha,\gamma)\tilde{\omega}_r \\ &\quad = U_{\sigma_{r-1}\cdots\sigma_1}(\xi)^{-1} \sum_{\langle\eta^{(r)}\rangle} ([0,\xi^{(r)}\eta_r/\xi_r\infty]_q : \mathrm{reg}\ \langle\eta^{(r)}\rangle)_{\sigma_{r-1}\cdots\sigma_1\Phi} \\ &\qquad \int_{\mathrm{reg}\ \langle\eta^{(r)}\rangle} \sigma_{r-1}\cdots\sigma_1\Phi\cdot\tilde{\omega}_r, \end{aligned} \tag{5.11}$$

where $\langle\eta^{(r)}\rangle$ ranges over the set of all α-unstable cycles for Φ restricted to the variables $t_1,\ldots,t_{r-1},t_{r+1},\ldots,t_n$. Remark that we have used the fact that $\sigma_{r-1}\cdots\sigma_1\Phi(t)$ can be expressed as

$$\begin{aligned} &\sigma_{r-1}\cdots\sigma_1\Phi(t|\alpha,\gamma) \\ &\quad = \left\{ \prod_{j=1}^{r-1} t_j^{\alpha_j+\gamma'_{j,r}-\gamma_{j,r}} \right\} t_r^{\alpha_r+\sum_{s=1}^{r-1}(\gamma_{s,r}-\gamma'_{s,r})} \\ &\qquad \cdot \left\{ \prod_{j=r+1}^{n} t_j^{\alpha_j} \right\} \prod_{j\neq r} \frac{(q^{\gamma'_{r,j}}t_j/t_r)_\infty}{(q^{\gamma_{r,j}}t_j/t_r)_\infty} \prod_{\substack{1\leq i<j\leq n \\ j\neq r, i\neq r}} \frac{(q^{\gamma'_{i,j}}t_j/t_i)_\infty}{(q^{\gamma_{i,j}}t_j/t_i)_\infty}, \end{aligned} \tag{5.12}$$

and $\theta(q^{\gamma_{r,j}}u) = \theta(q^{\gamma'_{j,r}}u^{-1})$ since $\gamma_{r,j}+\gamma'_{j,r} = 1$ for $j \neq r$. Equations (5.8), (5.10), and (5.11) imply (4.2). Assume now that $\langle\eta\rangle$ is standard. Then $\langle\eta^{(r)}\rangle$ is also standard for the function $\sigma_{r-1}\cdots\sigma_1\Phi(t)$. Hence by induction hypothesis we have

$$
\begin{aligned}
&([0,\xi^{(r)}\eta_r/\xi_r\infty]_q : \operatorname{reg}\langle\eta^{(r)}\rangle)_{\sigma_{r-1}\cdots\sigma_1\Phi} \\
&\quad = \sum_{\sigma\in W_1} \sigma_{r-1}\cdots\sigma_1\left\{\sigma\Psi_{n-1}(\xi^{(r)},\eta^{(r)}|\alpha)U_\sigma(\xi^{(r)})^{-1}U_\sigma(\eta^{(r)})\right\}.
\end{aligned}
\tag{5.13}
$$

Hence the coefficient of the integral of Φ over the cycle $\operatorname{reg}\langle\eta\rangle$ contributed in J_r equals

$$
\begin{aligned}
&(1-q)^n(q)_\infty^{3n}\left(\frac{\xi_r}{\eta_r}\right)^{\alpha_1+\cdots+\alpha_n}\frac{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\xi_r/\eta_r\right)}{\theta\left(q^{\alpha_1+\cdots+\alpha_n+1}\right)\theta(q\xi_r/\eta_r)} \\
&U_{\sigma_{r-1}\cdots\sigma_1}(\xi)^{-1}\sum_{\sigma\in W_1}\sigma_{r-1}\cdots\sigma_1\left\{\sigma\Psi_{n-1}(\xi^{(r)}\eta_r/\xi_r,\eta^{(r)}|\alpha)\right. \\
&\qquad\left.\cdot U_\sigma(\xi^{(r)}\eta_r/\xi_r)^{-1}U_\sigma(\eta^{(r)})\right\}U_{\sigma_{r-1}\cdots\sigma_1}(\eta) \\
&= (1-q)^n(q)_\infty^{3n}\sum_{\sigma\in W_r}\sigma\Psi_n(\xi,\eta|\alpha)U_\sigma(\xi)^{-1}U_\sigma(\eta),
\end{aligned}
\tag{5.14}
$$

because of (4.1) and the cocycle condition for $U_\sigma(t)$:

$$
\sigma_{r-1}\cdots\sigma_1 U_\sigma(t)\cdot U_{\sigma_{r-1}\cdots\sigma_1}(t) = U_{\sigma_{r-1}\cdots\sigma_1\sigma}(t). \tag{5.15}
$$

Hence (5.8) and (5.14) imply (4.3). The theorem has thus been proved. □

6. Examples.

(1) $n = 1$. The formula (5.2) has already been given in [M1] and [A4].

(2) $n = 2$. There are four kinds of admissible graphs:

(i) $\left\langle x_r q^{-\beta_r} * \overset{1}{\frown} 2 \right\rangle$, $\quad 1 \le r \le m$ (standard),

(ii) $\left\langle x_r q^{-\beta_r} * \overset{2}{\frown} 1 \right\rangle$, $\quad 1 \le r \le m$,

(iii) $\left\langle x_r q^{-\beta_r} * \begin{matrix} \nearrow 1 \\ \searrow 2 \end{matrix} \right\rangle$, $\quad 1 \le r \le m$ (standard),

(iv) $\left\langle \begin{matrix} x_r q^{-\beta_r} * & 1 \\ x_s q^{-\beta_s} * & 2 \end{matrix} \right\rangle$, $\quad 1 \le r, s \le m$ (standard).

We put $\gamma = \gamma_{1,2}$ and $\gamma' = \gamma'_{1,2}$, respectively. The corresponding α-stable (or α-unstable) cycles $\langle\eta\rangle$ are given as follows:

(i) $\eta_1 = qx_r, \eta_2 = q^{1-\gamma'}\eta_1$ (or $\eta_1 = x_r q^{-\beta_r}, \eta_2 = q^{-\gamma}\eta_1$);
(ii) $\eta_2 = q^{-\gamma}\eta_1, \eta_2 = qx_r$ (or $\eta_2 = q^{1-\gamma'}\eta_1, \eta_2 = x_r q^{-\beta_r}$);
(iii) $\eta_1 = \eta_2 = qx_r$ (or $\eta_1 = \eta_2 = x_r q^{-\beta_r}$);
(iv) $\eta_1 = qx_r, \eta_2 = qx_s$ (or $\eta_1 = q^{-\beta_r}x_r, \eta_2 = q^{-\beta_s}x_s$).

Moreover, we have

$$
\begin{aligned}
&\tilde{\Psi}_2(\xi,\eta|\alpha,\gamma) \\
&= (1-q)^2(q)_\infty^6 \left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1}\left(\frac{\xi_2}{\eta_2}\right)^{\alpha_2} \\
&\cdot\left\{\frac{\theta\left(q^{\alpha_1+\alpha_2+1}\xi_1/\eta_1\right)\theta\left(q^{\alpha_2+1}\xi_2\eta_1/(\xi_1\eta_2)\right)}{\theta\left(q^{\alpha_1+\alpha_2+1}\right)\theta\left(q^{\alpha_2+1}\right)\theta\left(q\frac{\xi_1}{\eta_1}\right)\theta\left(q\frac{\xi_2\eta_1}{\xi_1\eta_2}\right)}\right. \\
&\qquad + \frac{\theta\left(q^{\alpha_1+\alpha_2+1}\xi_2/\eta_2\right)\theta\left(q^{\alpha_1+\gamma'-\gamma+1}\xi_1\eta_2/(\xi_2\eta_1)\right)}{\theta\left(q^{\alpha_1+\alpha_2+1}\right)\theta(q^{\alpha_1+\gamma'-\gamma+1})\theta\left(q\frac{\xi_2}{\eta_2}\right)\theta\left(q\frac{\xi_1\eta_2}{\xi_2\eta_1}\right)} \qquad (6.1) \\
&\qquad \left.\cdot\frac{\theta\left(q^{\gamma'}\xi_2/\xi_1\right)\theta\left(q^{\gamma}\eta_2/\eta_1\right)}{\theta\left(q^{\gamma}\xi_2/\xi_1\right)\theta\left(q^{\gamma'}\eta_2/\eta_1\right)}\right\} \\
&= (1-q)^2(q)_\infty^6 \left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1}\left(\frac{\xi_2}{\eta_2}\right)^{\alpha_2}\left\{\frac{\theta\left(q^{1+\alpha_1}\xi_1/\eta_1\right)\theta\left(q^{1+\alpha_2}\xi_2/\eta_2\right)}{\theta\left(q^{1+\alpha_1}\right)\theta\left(q^{1+\alpha_2}\right)\theta\left(q\frac{\xi_1}{\eta_1}\right)\theta\left(q\frac{\xi_2}{\eta_2}\right)}\right. \\
&\qquad \left.-q^{\gamma}\frac{\eta_2}{\eta_1}\frac{\theta(q^{\alpha_1+\alpha_2+1}\xi_2/\eta_2)\theta(q^{\gamma'-\gamma})\theta(q^{-\alpha_1+\gamma}\xi_2/\xi_1)\theta(q^{-\alpha_1-\gamma'}\eta_1/\eta_2)}{\theta\left(q^{\alpha_1+\alpha_2+1}\right)\theta\left(q\frac{\xi_2}{\eta_2}\right)\theta\left(q^{\alpha_1+\gamma'-\gamma+1}\right)\theta(q^{\alpha_1+1})\theta\left(q^{\gamma}\frac{\xi_2}{\xi_1}\right)\theta\left(q^{\gamma'}\frac{\eta_2}{\eta_1}\right)}\right\}
\end{aligned}
$$

by the use of the three-term equation for theta functions. Indeed the three-term equation gives the following equality (see [H1]).

LEMMA 7. *For an arbitrary* $\lambda \in \mathbf{C}$,

$$
\begin{aligned}
&\frac{\theta(q^{\lambda+1})\theta(q^{\lambda+1+\gamma'-\gamma}\xi_1\eta_2/(\xi_2\eta_1))\theta(q^{\gamma}\eta_2/\eta_1)\theta(q^{\gamma'}\xi_2/\xi_1)}{\theta(q^{\lambda+1}\xi_1\eta_2/(\xi_2\eta_1))\theta(q^{\lambda+\gamma'-\gamma+1})\theta(q^{\gamma}\xi_2/\xi_1)\theta(q^{\gamma'}\eta_2/\eta_1)} - 1 \\
&\qquad (6.2) \\
&= q^{\gamma}\frac{\xi_2}{\xi_1}\frac{\theta(q^{\gamma'-\gamma})\theta(\xi_1\eta_2/(\xi_2\eta_1))\theta(q^{-\lambda+\gamma}\xi_2/\xi_1)\theta(q^{-\lambda-\gamma'}\eta_1/\eta_2)}{\theta(q^{\lambda+1}\xi_1\eta_2/(\xi_2\eta_1))\theta(q^{\lambda+\gamma'-\gamma+1})\theta(q^{\gamma}\xi_2/\xi_1)\theta(q^{\gamma'}\eta_2/\eta_1)}.
\end{aligned}
$$

Hence

(i) $([0,\xi\infty]_q : \operatorname{reg}\langle\eta\rangle)_\Phi$

$$
\begin{aligned}
&= (1-q)^2\left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1}\left(\frac{\xi_2}{\eta_2}\right)^{\alpha_2}\frac{(q)_\infty^6}{\theta(q^{\alpha_1+\alpha_2+1})\theta(q^{\alpha_2+1})} \\
&\cdot\frac{\theta(q^{\alpha_1+\alpha_2+1}\xi_1/\eta_1)\theta(q^{\alpha_2+\gamma+1}\xi_2/\xi_1)}{\theta(q\xi_1/\eta_1)\theta(q^{1+\gamma}\xi_2/\xi_1)}
\end{aligned}
$$

since $\eta_2 = q^{-\gamma}\eta_1$.

(ii) $([0,\xi\infty]_q : \operatorname{reg}\langle\eta\rangle)_\Phi$

$$= (1-q)^2 \left(\frac{\xi_1}{\eta_1}\right)^{\alpha_1} \left(\frac{\xi_2}{\eta_2}\right)^{\alpha_2}$$

$$\cdot \frac{(q)_\infty^3 \theta(q^{\alpha_1+\alpha_2+1}\xi_2/\eta_2)\theta(q^{\alpha_1-\gamma+2}\xi_1/\xi_2)\theta(q^{\gamma'}\xi_2/\xi_1)\theta(q^{1+\gamma-\gamma'})}{\theta(q^{\alpha_1+\alpha_2+1})\theta(q^{\alpha_1+\gamma'-\gamma+1})\theta(q\xi_2/\eta_2)\theta(q^{\gamma}\xi_2/\xi_1)\theta(q^{2-\gamma'}\xi_1/\xi_2)},$$

by taking the residue of $\tilde{\Psi}(\xi,\eta|\alpha,\gamma)$ for $\eta_2 = q^{1-\gamma'}\eta_1$.

(iii) and (iv) $([0,\xi\infty]_q : \langle\eta\rangle)_\Phi = \tilde{\Psi}_2(\xi,\eta|\alpha,\gamma)$,

which is well defined in view of (6.1).

It is also interesting to consider the case where $q = 1$. A similar formula to our theorem may be possible in view of the result obtained in [G3].

GROUP THEORETICAL INTERPRETATIONS OF SPECIAL FUNCTION IDENTITIES: TWO EXAMPLES*

L. C. BIEDENHARN† AND A. K. ÇIFTÇI‡

Abstract. Two examples, taken from quantum physics, are used to illustrate how group theoretical concepts afford an intuitive understanding of relationships between certain special function identities.

Key words. special functions, symmetry groups, quantal angular momentum group $SU(2)$, group representations, Kronecker product (Wigner product law), group contraction

AMS subject classifications. 33C10, 33C45, 33C55

1. Introduction. The applications of symmetry techniques using group theory have been an important source of special functions [1], [2], and it is only to be expected that quantum physics—with its current strong emphasis on symmetry—has similarly contributed greatly to the supply of special functions [3]. Results in special function theory which stem from group theory are usually rather particular and often lack the generality of analytic results. This situation is characteristic of the group-theoretic approach to special functions [1]. Despite this particularity, results of the group theoretic approach nevertheless have a certain coherence, clarity, and intuitiveness that the analytic approach lacks.

In this contribution we will discuss two examples of the way in which group theoretic concepts can lead to a more transparent and intuitive understanding of certain special function identities and their interrelationships. Both examples are taken from quantum physics and both involve special functions arising from applications of angular momentum techniques. Our first example—the relationship of Gaunt's integral [4] to Sharp's integral [5]—is not new and is possibly well known. Gaunt's integral (see (2.10a) below) involves special functions of the quantal angular momentum group $SU(2)$, whereas Sharp's integral (see (2.19)) involves special functions of the Euclidean group $E(2)$ of the plane. The latter group is a *contraction* of the former (see §3), and it is this asymptotic relationship that we will emphasize and discuss as interrelating the two integrals.

The second example, which we believe is new, concerns integrals involving special functions of the four-dimensional rotation group $SO(4)$ (see (4.10)) and of its contracted group, the Euclidean group in three-space $E(3)$. This latter group is of evident importance in nonrelativistic quantum physics and, in fact, the results we will discuss arose from a recent investigation [6], [7] of the muon-catalyzed fusion process [8], [9].

The interrelationship between the special functions of a symmetry group and those of its contracted (asymptotic) groups is a general feature and can be applied systematically. In our concluding remarks we conjecture the extension of this procedure to quantum groups [10], [11] and their q-analog special functions.

2. First example: Gaunt's integral and Sharp's integral. Angular momentum in quantum physics involves the symmetry group $SU(2)$, whose generators are the three angular momentum operators $\{J_1, J_2, J_3\}$ obeying the commutation rules:

$$[J_i, J_j] = i\varepsilon_{ijk}J_k, \tag{2.1}$$

where $\varepsilon_{ijk} = \pm 1$ for (positive/negative) permutations of 1, 2, 3, and is zero otherwise.

In the standard way [12] one constructs eigenbases (quantal states) for the representations—ket vectors denoted $|jm\rangle$—having sharp total angular momentum $j(2j \in \mathbb{Z}^+)$ and z-component $J_z \to m(-j \leq m \leq j, 2m \in \mathbb{Z}, j-m \in \mathbb{Z})$. The irreducible representations (irreps) are denoted by $\mathcal{D}^{(j)}(g), g \in SU(2)$, with matrix elements: $\langle jm'|\mathcal{D}^{(j)}(g)|jm\rangle \equiv \mathcal{D}^{(j)}_{m',m}(\alpha,\beta,\gamma)$, where α, β, and γ are the Euler angles of the rotation g. The rotation operator matrix elements are special functions, the Jacobi polynomials [12].

The group-theoretical approach to special functions has several characteristic general features [1], [2], [3]. For compact groups, the Peter–Weyl theorem shows that matrix elements of the irreducible representation matrices supply a *complete set of orthonormal special functions over the group manifold.* Similarly, it is characteristic of the group theoretic approach that the *product law* for the group $g_1 \circ g_2 = g_{12}$, when applied to the group representations $\mathcal{D}(g_1)\mathcal{D}(g_2) = \mathcal{D}(g_{12})$, yields an *addition theorem* for the special functions of the group.

A closely related further characteristic of the group theoretic approach—in a certain sense dual to the product law—is the *Kronecker product* [3] for matrix elements of representations involving the *same* group element. This general structure is at present well defined only for multiplicity-free groups [13] or for groups having a canonical resolution of the multiplicity [14]. For angular momentum theory this Kronecker product relation is called the *Wigner product law* [12]:

$$D^{J_1}_{M_1,M_1'}(g)D^{J_2}_{M_2,M_2'}(g) = \sum_{J_3,M_3,M_3'} C^{J_1J_2J_3}_{M_1M_2M_3}C^{J_1J_2J_3}_{M_1'M_2'M_3'}D^{J_3}_{M_3M_3'}(g). \tag{2.2}$$

In this result, the terms $C^{J_1J_2J_3}_{M_1M_2M_3}$ are the *Wigner–Clebsch–Gordan* coefficients [15], which, as group objects, affect the reduction of the direct (Kronecker) product of the irreps J_1 and J_2 into the irreps J_3. Considered as special functions, the Wigner–Clebsch–Gordan coefficients are ${}_3F_2$ generalized hypergeometric functions with the specific relation [12]:

$$C^{abc}_{\alpha\beta\gamma} = \delta_{\alpha+\beta,\tau}\left[(2c+1)(a+\alpha)!(a-\alpha)!(b+\beta)!(b-\beta)!(c+\gamma)!(c-\gamma)!\right]^{\frac{1}{2}}$$

$$\times \frac{(-1)^{a+b+\gamma+\delta_1}\Delta(abc)\,{}_3F_2\left(\begin{matrix}\varepsilon_1-\delta_1, \varepsilon_2-\delta_1, \varepsilon_3-\delta_1 \\ \delta_2-\delta_1+1, \delta_3-\delta_1+1\end{matrix}; 1\right)}{(\delta_2-\delta_1)!(\delta_3-\delta_1)!(\delta_1-\varepsilon_1)!(\delta_1-\varepsilon_2)!(\delta_1-\varepsilon_3)!}. \tag{2.3}$$

Here the parameters $(\delta_1, \delta_2, \delta_3)$ are any permutation of

$$(\alpha+b+\beta, b-\beta+c+\gamma, a+\alpha+c+\gamma), \tag{2.4}$$

except that δ_1 is required to be the smallest integer in this set; the parameters $(\varepsilon_1, \varepsilon_2, \varepsilon_3)$ are any permutation of

$$(a+\alpha, b+\alpha+\tau, c+\tau). \tag{2.5}$$

The *triangle coefficient* $\Delta(abc)$ (which is a special function in its own right in angular momentum theory [12]) is given by

$$\Delta(abc) = \left[\frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}\right]^{\frac{1}{2}}. \tag{2.6}$$

By using the orthonormality relations, we can invert (2.2) and obtain a general integral relation for a triple product of $SU(2)$ special functions:

$$\int dg \left(D^{J_3}_{M_3 M_3'}(g)\right)^* D^{J_1}_{M_1 M_1'}(g) D^{J_2}_{M_2 M_2'}(g) = \left(\frac{8\pi_2}{2J_3+1}\right) C^{J_1 J_2 J_3}_{M_1 M_2 M_3} C^{J_1 J_2 J_3}_{M_1' M_2' M_3'}. \tag{2.7}$$

This result is a special function identity relating an integral over a product of three Jacobi functions to a product of two ${}_3F_2$ special functions.

Gaunt's integral [4] was obtained in the early days of quantum mechanics and involves a special case of this general result, (2.7). For integral angular momenta, denoted by l (orbital angular momenta), the representation functions are related to the spherical harmonics $Y_{lm}(\theta\varphi)$ by

$$Y_{lm}(\theta\varphi) \equiv \langle \theta\varphi | lm \rangle = \left[\frac{2l+1}{4\pi}\right]^{\frac{1}{2}} D^{l*}_{m,0}(\varphi\theta 0). \tag{2.8}$$

Specializing further to $m = 0$ relates the representation functions to the Legendre polynomials

$$D^{l}_{0,0}(0\theta 0) = P_l(\cos\theta). \tag{2.9}$$

Gaunt's integral is an integral over three Legendre polynomials:

$$I_{\text{Gaunt}} = \int_0^\pi \sin\theta d\theta P_{l_1}(\cos\theta) P_{l_2}(\cos\theta) P_{l_3}(\cos\theta), \tag{2.10a}$$

which, using (2.7) and (2.9), can be expressed as

$$I_{\text{Gaunt}} = \left(\frac{2}{2l_3+1}\right) \left(C^{l_1 l_2 l_3}_{000}\right)^2. \tag{2.10b}$$

A more general result is easily obtained from (2.7), using (2.8) rather than (2.9). This is the *generalized Gaunt integral*:

$$\begin{aligned} &\int_0^\pi \sin\theta d\theta \int_0^{2\pi} d\varphi Y^*_{l_3 m_3}(\theta\varphi) Y_{l_1 m_1}(\theta\varphi) Y_{l_2 m_2}(\theta\varphi) \\ &= \left[\frac{(2l_1+1)(2l_2+1)}{4\pi(2l_3+1)}\right]^{\frac{1}{2}} C^{l_1 l_2 l_3}_{000} \cdot C^{l_1 l_2 l_3}_{M_1 M_2 M_3}. \end{aligned} \tag{2.11}$$

Now let us turn to Sharp's integral. This integral involves representation functions of the Euclidean group in two dimensions $E(2)$. This (noncompact) group has three generators: two translation operators $\{T_1, T_2\}$ and a rotation operator M acting in the (1, 2) plane. The commutation relations for these three generators are

$$[T_1, T_2] = 0, \quad [M, T_1] = T_2, \quad [M, T_2] = -T_1. \tag{2.12}$$

The group theoretic results are analogous to the previous case: one constructs the representations (which include as special functions the Bessel functions of integer

order), and uses the $E2$ analog of the Kronecker product law to construct a general threefold Bessel function integral.

The representations $\mathcal{D}(g)$ in which we are interested are labeled by one real parameter p, physically the magnitude of the (nonvanishing) momentum $(0 < p < \infty)$. The irreps $\mathcal{D}^{(p)}(g)$ have the matrix elements [5]

$$\langle m'|\mathcal{D}^{(p)}(g)|m\rangle = e^{i(m-m')\theta} J_{m-m'}(pr) e^{im'\alpha}, \qquad m, m' \in \mathbb{Z}, \tag{2.13}$$

where the basis ket-vectors $|m\rangle$ are eigenfunctions of the rotation operator $M (M \to m, m \in \mathbb{Z})$. In (2.13), the group element g is a translation, parametrized by (r, θ) using polar coordinates, and a rotation by the angle α.

The construction of the Kronecker product law for the $E(2)$ group involves a typical difficulty that occurs for many groups: the existence of multiplicity in the reduction of the Kronecker product [5], [13]. The analog of the Wigner–Clebsch–Gordan coefficients for a nonmultiplicity-free group is not well defined unless there exists a canonical resolution of the multiplicity [14]. For the Euclidean group $E(2)$ the multiplicity is at most 2, and a canonical resolution exists [5]. This resolution adjoins a discrete operation, reflection in the x-axis, yielding the extended Euclidean group $E(2)'$. Denoting the involutary operation by I, we have the additional commutation relations:

$$IM = -MI, \quad IT_1 = T_1 I, \quad IT_2 = -T_2 I. \tag{2.14}$$

The irreducible representations (irreps) are now specified by two labels: p (as before) and $\varepsilon = \pm 1$. The irreps $\mathcal{D}^{(p,\varepsilon)}(g)$ have the same matrix elements as in (2.13) for group elements in $E(2)$, and the additional relation

$$\langle m'|\mathcal{D}^{(p,\varepsilon)}(I)|m\rangle = (-1)^{m+\varepsilon}\delta_{m'}^{-m} \tag{2.15}$$

for the involution I. The extra irrep label ε distinguishes between the two occurrences of the $E(2)$ irreps labelled by p in the reduction of the Kronecker product.

The analog of the Wigner–Clebsch–Gordan (WCG) coefficients for the extended Euclidean group $E(2)'$ have the form [5]

(2.16)

$$C_{m_1 m_2 m_3}^{p_1\varepsilon_1 p_2\varepsilon_2 p_3\varepsilon_3} = \frac{\delta_{m_1+m_2+m_3}}{\sqrt{8\pi A(p_1 p_2 p_3)}} \left(e^{i(m_2\tau_3 - m_3\tau_2)} + (-1)^{\varepsilon_1+\varepsilon_2+\varepsilon_3} e^{-i(m_2\tau_3 - m_3\tau_2)} \right),$$

where $A(p_1 p_2 p_3)$ is the area of the triangle formed by the three momenta $p_i > 0$ and the τ_i are the *exterior* angles of this triangle,

$$\tau_1 + \tau_2 + \tau_3 \equiv 0 \bmod 2\pi. \tag{2.17}$$

If the three momenta do not form a triangle, the coefficient above vanishes, or equivalently, we may define the area of the triangle as infinite.

The general integral [5] for the product of three irreps of the $E(2)'$ group—specialized to have nonzero momenta—is the $E(2)'$ analog of (2.7) and has the form

$$\int dg D_{m_3,m_3'}^{(p_3\varepsilon_3)*}(g)\, D_{m_1,m_1'}^{(p_1\varepsilon_1)}(g)\, D_{m_2,m_2'}^{(p_2\varepsilon_2)}(g) = C_{m_1 m_2 m_3}^{p_1\varepsilon_1 p_2\varepsilon_2 p_3\varepsilon_3}\, C_{m_1' m_2' m_3'}^{p_1\varepsilon_1 p_2\varepsilon_2 p_3\varepsilon_3}. \tag{2.18}$$

Sharp's integral is that special case of (2.18) for which $m_i' = 0$. For this special case, the WCG coefficient ((2.16) with $m_1' = 0$) vanishes unless $\varepsilon_1 + \varepsilon_2 + \varepsilon_3 \equiv 0 \mod 2$.

Using (2.13) and (2.16) in the general relation equation (2.18) and noting the restriction $m_1 = 0$, we obtain *Sharp's integral*:

(2.19)

$$\int_0^\infty r\,dr J_{m_1}(p_1 r) J_{m_2}(p_2 r) J_{m_3}(p_3 r) = \frac{\cos(m_1\tau_2 - m_2\tau_1)}{2\pi A(p_1 p_2 p_3)} \quad \text{if } m_1 + m_2 + m_3 = 0.$$

Sharp pointed out [5] that the integral (2.19) does not appear in the standard compilations by Watson [16] or by Bateman/Erdélyi [17].

3. The contraction relationship. The two integrals above, the generalized Gaunt integral in (2.11) and Sharp's integral in (2.19), have each been obtained by a straightforward application of standard group techniques, and are in consequence similar results differing only in the specific group used. Our objective, however, is not simply to see that the integrals are *analogous* but to show—from group-theoretic concepts—how the particular structures can be understood in such a way that one integral can be *directly* derived from the other.

To do this, let us recall that in physics it is not infrequent that a given theory is subsumed in a larger theory such that the earlier theory may be recovered as a limit. Thus, for example, nonrelativistic physics (Newtonian relativity) is contained in Einsteinian relativity (the physics of special relativity) such that Newtonian relativity is recovered in the limit that the velocity of light (c) becomes infinite. Expressed in group-theoretic terms [18], [19], the Poincaré group of Einsteinian relativistic symmetry *contracts* to the Galilean group of Newtonian relativistic symmetry in the limit where the parameter $c \to \infty$.

A similar relationship exists for the group $SU(2)$, which contracts to $E(2)$. This limit is intuitively understandable as the limit in which the two-sphere S^2 (the space of spherical harmonics) has a "large" radius so that, locally at a specific point, the neighborhood looks flat, becoming the Euclidean two-plane in the limit.

To be more precise let us consider the generators of the $SU(2)$ group: J_1, J_2, J_3, and the commutation rules (2.1):

$$[J_1, J_2] = iJ_3, \quad [J_2, J_3] = iJ_1, \quad \text{and} \quad [J_3, J_1] = iJ_2. \tag{3.1}$$

Multiply J_1 and J_2 in (3.1) by ε so as to obtain

$$[\varepsilon J_1, \varepsilon J_2] = i\varepsilon^2 J_3, \quad [\varepsilon J_2, J_3] = i\varepsilon J_1, \quad \text{and} \quad [J_3, \varepsilon J_1] = i\varepsilon J_2. \tag{3.2}$$

Let J_1 and J_2 become large, and let ε approach zero, such that εJ_i is finite:

$$\varepsilon J_1 \to T_1, \qquad \varepsilon J_2 \to T_2, \tag{3.3}$$

and redefine T_3 to be M. We find that in this contraction limit, the commutation relations become

$$[T_1, T_2] = 0, \quad [M, T_1] = iT_2, \quad [M, T_2] = -iT_1, \tag{3.4}$$

which are precisely the commutation relations of $E(2)$, (2.12).

It is important to note that the contraction process is not necessarily smooth, and the contraction limit can be, and often is, singular. As a result, the importance of the contraction process—considered as a systematic procedure—lies primarily in the *qualitative* insights it affords into the existence, and properties, of asymptotic relationships between special functions.

Let us now apply these ideas to the $SU(2) \to E(2)$ contraction limit. Applied to the representation matrices, the contraction limit is the relation [5]

$$\lim_{j\to\infty} \left(\langle m' | \mathcal{D}^{(j)}(\theta - \tfrac{\pi}{2}, \varepsilon r, \tfrac{\pi}{2} - \theta + \alpha) | m \rangle \right) = \langle m' | \mathcal{D}^{(p)}(r, \theta, \alpha | m \rangle, \tag{3.5}$$

where in the limit j runs over integral values, with $j\varepsilon = p$ (the momentum) fixed. This relation is the well-known asymptotic relation of the Bessel function as a limit of Jacobi polynomials. Accordingly, we can conclude that *the contraction limit of the integrand of the generalized Gaunt integral over three spherical harmonics yields the integrand of Sharp's integral over three Bessel functions*, noting that the orthonormality of both sets of representation matrices determines in each case a well-defined absolute normalization (which is group dependent).

The contraction limit of the two sets of WCG coefficients is a somewhat less straightforward matter because of the multiplicity problem for $E(2)$, which requires the use of the extended Euclidean group $E(2)'$. It is not difficult to adjoin the involution I to the group $SU(2)$. (Note that the group volume is doubled in going from $SU(2)$ to $SU(2)'$, affecting the normalization of the representation functions.) As expected, $E(2)'$ is the contraction limit of $SU(2)'$, but the problem is that this limit is singular. In particular, for $SU(2)'$, there exists a *parity rule*[1] in $SU(2)'$ such that $\varepsilon_1 + \varepsilon_2 + \varepsilon_3 = 0 \bmod 2$. This parity rule is *broken* for $E(2)'$ in the (singular) contraction limit.

In the specific case at hand (the generalized Gaunt integral and Sharp's integral) this problem is *avoided*, since in these two cases the integrals involve representation functions with $m_1' = m_2' = m_3' = 0$, a condition that *enforces* the parity rule even for $E(2)'$. For this special case finds the following the contraction limit of the WCG coefficients:

$$\left(C^{p_1\varepsilon_1 p_2\varepsilon_2 p_3\varepsilon_3}_{m_1 m_2 m_3} \cdot C^{p_1\varepsilon_1 p_2\varepsilon_2 p_3\varepsilon_3}_{0\ 0\ 0} \right)_{E(2)'} = \underset{\text{limit}}{\text{contraction}} \left(C^{l_1 l_2 l_3}_{m_1 m_2 m_3} \cdot C^{l_1 l_2 l_3}_{000} \right)_{SU(2)'}. \tag{3.6}$$

It follows that *the contraction limit carries the generalized Gaunt integral identity into Sharp's integral identity.* This result was first shown by Sharp [5].

4. Second example: $SO(4)$ and $E(3)$. Let us now consider the rotation group in four dimensions: $SO(4)$. This group has six generators, $\vec{L}$ and $\vec{K}$, which obey the commutation relations:

$$[L_i, L_j] = i\varepsilon_{ijk} L_k, \quad [L_i, K_j] = i\varepsilon_{ijk} K_k, \quad \text{and} \quad [K_i, K_j] = i\varepsilon_{ijk} L_k. \tag{4.1a–c}$$

The irreps (for this presentation of the group) are labeled by two invariant operators which may be taken to be $\mathcal{I}_1 \equiv \vec{L}^2 + \vec{K}^2 + 1$ and $\mathcal{I}_2 \equiv \vec{L} \cdot \vec{K}$. For the orbital irreps in which we are most interested these two invariants assume the eigenvalues $\mathcal{I}_1 \to n^2, (n = 1, 2 \ldots)$ and $\mathcal{I}_2 \to 0$. The corresponding irreps are labelled $\mathcal{D}^{(n,0)}(g)$.

[1] To see this, note that the reflection I in the x-axis combines with a rotation by π around the x-axis to yield a central reflection (parity).

It is a fortunate group theoretical "accident" that under the substitution $\vec{L} = \vec{j}_1 + \vec{j}_2, \vec{K} = \vec{j}_1 - \vec{j}_2$ the commutation relations (4.1) take the form

$$\vec{j}_i \times \vec{j}_i = i\vec{j}_i (i = 1, 2) \quad \text{with } [\vec{j}_1, \vec{j}_2] = 0. \tag{4.2}$$

Thus we see that $SO(4)$ is locally the direct product, $SU(2) \times SU(2)$, of two commuting $SU(2)$ groups. This has the important consequence that $SO(4)$ is multiplicity-free and possesses a well-defined Kronecker product law. This basic result is the key to our special function considerations [20], [21].

The general irrep of $SO(4)$, using the realization given in (4.2), may be denoted by $\mathcal{D}^{[j_1,j_2]}(g)$, where the labels j_1, j_2 specify the two $SU(2)$ invariants of the two $SU(2)$ groups. (Note that we use square brackets for these labels to distinguish this choice of invariants from $\mathcal{I}_1, \mathcal{I}_2$ shown earlier.) Here g denotes a generic group element in $SU(2) \times SU(2)$. Matrix elements of the irrep $\mathcal{D}^{[j_1 j_2]}$ are denoted by

$$\langle [j_1 j_2] j' m' | \mathcal{D}^{[j_1 j_2]}(g) | [j_1 j_2] j m \rangle \equiv D^{[j_1,j_2]}_{j'm';jm}(g), \tag{4.3}$$

where the basis ket-vectors $|[j_1 j_2] j m\rangle$ are direct product ket-vectors from $SU(2) \times SU(2)$ coupled to angular momentum j with z-component m. These $SO(4)$ irrep matrices are accordingly vector-coupled $SU(2) \times SU(2)$ rotation matrices [20], [21], [22].

The Kronecker product law for this group [20], [21] has the form

$$\begin{aligned} \mathcal{D}^{[j_1 j_2]}_{j'm';jm}(g) : \mathcal{D}^{[k_1 k_2]}_{k'\kappa';k\kappa}(g) = \sum_{l_1 l_2 l' \lambda' l \lambda} & C\left[\begin{pmatrix} j_1 & j_2 \\ j' & m' \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k' & \kappa' \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l' & \lambda' \end{pmatrix}\right] \\ & \times C\left[\begin{pmatrix} j_1 & j_2 \\ j & m \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k & \kappa \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l & \lambda \end{pmatrix}\right] \mathcal{D}^{[l_1 l_2]}_{l'\lambda';l\lambda}(g). \end{aligned} \tag{4.4}$$

In this result, (4.4), we have used the Wigner–Clebsch–Gordan coefficients for the $SO(4)$ group [20], which are given explicitly by a special function that is the sum of products of five ${}_3F_2$ functions:

$$C\left[\begin{pmatrix} j_1 & j_2 \\ j & m \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k & \mu \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l & \nu \end{pmatrix}\right] \equiv \sum_{\substack{\nu_1 \nu_2 \\ m_1 m_2 \\ \mu_1 \mu_2}} C^{l_1 l_2 l}_{\nu_1 \nu_2 \nu} C^{j_1 j_2 j}_{m_1 m_2 m} C^{k_1 k_2 k}_{\mu_1 \mu_2 \mu} C^{j_1 k_1 l_1}_{m_1 \mu_1 \nu_1} C^{j_2 k_2 l_2}_{m_2 \mu_2 \nu_2}. \tag{4.5}$$

The sum in (4.5) can be put in the more explicit form

$$\begin{aligned} & C\left[\begin{pmatrix} j_1 & j_2 \\ j & m \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k & \kappa \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l & \lambda \end{pmatrix}\right] \\ & = [(2l_1+1)(2l_2+1)(2j+1)(2k+1)]^{\frac{1}{2}} \begin{Bmatrix} j_1 & j_2 & j \\ k_1 & k_2 & k \\ l_1 & l_2 & l \end{Bmatrix} C^{jkl}_{m\kappa\lambda}, \end{aligned} \tag{4.6a}$$

where the term in brackets $\{\ldots\}$ is an angular momentum special function known as the $9-j$ symbol having the definition

(4.6b)
$$\begin{Bmatrix} a & b & c \\ d & e & f \\ h & i & j \end{Bmatrix} \equiv (-1)^{c+f-j} \frac{\Delta(dah)\Delta(bei)\Delta(jhi)}{\Delta(def)\Delta(bac)\Delta(jcf)} \times \sum_{xyz} \frac{(-1)^{x+y+z}}{x!y!z!} \frac{(2f-x)!(2a-z)!}{(2i+1+y)!(a+d+h+1-z)!} \times \frac{(d+e-f+x)!(c+j-f+x)!}{(e+f-d-x)!(c+f-j-x)!} \frac{(e+i-b+y)!(h+i-j+y)!}{(b+e-i-y)!(h+j-i-y)!} \times \frac{(b+c-a+z)!}{(a+d-h-z)!(a+c-b-z)!} \times \frac{(a+d+j-i-y-z)!}{(d+i-b-f+x+y)!(b-f-a+j+x+z)!},$$

where the triangle function $\Delta(abc)$ is given in (2.6).

Using the orthonormality of the irrep matrices, just as in §2, we find an interesting general result for the product of three $SO(4)$ special functions:

(4.7)
$$\left(\frac{(2l_1+1)(2l_2+1)}{64\pi^4}\right) \cdot \int dg D^{[l_1 l_2]*}_{l'\lambda';l\lambda}(g)\, D^{[j_1 j_2]}_{j'm';jm}(g)\, D^{[k_1 k_2]}_{\kappa'\kappa';k\kappa}(g) = C\left[\begin{pmatrix} j_1 & j_2 \\ j & m \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k & n \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l & \lambda \end{pmatrix}\right] C\left[\begin{pmatrix} j_1 & j_2 \\ j & m \end{pmatrix}\begin{pmatrix} k_1 & k_2 \\ k & \kappa \end{pmatrix}\begin{pmatrix} l_1 & l_2 \\ l & \lambda \end{pmatrix}\right].$$

Our interest here is in a special case of (4.7) corresponding to representation matrices which are the spherical harmonics in four dimensions. To obtain this, one specializes $\mathcal{D}^{[j_1 j_2]}(g)$ to have the $SU(2) \times SU(2)$ invariants $j_1 = j_2 \equiv j$, which implies for the realization given by (4.1) that the invariant $\mathcal{I}_1 = (2j+1)^2$—so that $n = 2j+1$—and $\mathcal{I}_2 = 0$. The corresponding irrep, $D^{[j,j]*}_{lm;00}(g)$, will be related to the spherical harmonic $Y_{nlm}(\chi,\theta,\varphi)$ in four dimensions (see (4.8a) below). The group element g will be specified by the angles (χ,θ,φ), which are the polar angles for a point on the surface of the sphere S^3, with $x^2+y^2+z^2+t^2 = 1$ and $t = \cos\chi, z = \sin\chi\cos\theta, y = \sin\chi\sin\theta\sin\varphi, x = \sin\chi\sin\theta\cos\varphi$. All this is in exact analogy with the previous discussion for the spherical harmonics $Y_{lm}(\theta,\varphi)$ in three dimensions.

The spherical harmonics $Y_{nlm}(\chi,\theta,\varphi)$ factorize [20] and [22] into the product of a Gegenbauer polynomial in χ and the usual $SO(3)$ spherical harmonic

(4.8a)
$$\left(\frac{n^2}{2\pi^2}\right)^{\frac{1}{2}} \cdot \mathcal{D}^{(\frac{n-1}{2},\frac{n-1}{2})*}_{lm;00}(g) \equiv Y_{nlm}(\chi,\theta,\varphi) = F_{nl}(\chi)Y_{lm}(\theta\varphi),$$

where

(4.8b)
$$F_{nl}(\chi) = \left(\frac{2n\Gamma(n-l)}{\pi\Gamma(n+l+1)}\right)^{\frac{1}{2}} (l!)(2i\sin\chi)^l C^{l+1}_{n-l-1}(\cos\chi).$$

The function $C^{l+1}_{n-l-1}(\cos\chi)$ in (3.8b) is the special function known as the Gegenbauer polynomial defined in the standard way [17].

For completeness, let us note that the spherical harmonics $Y_{nlm}(\chi,\theta,\varphi)$ are orthogonal and normalized by

(4.9)
$$\int_0^\pi \sin^2\chi d\chi \int_0^\pi \sin\theta d\theta \int_0^\pi d\varphi Y^*_{n'l'm'}(\chi,\theta,\varphi)Y_{nlm}(\chi,\theta,\varphi) = \delta^{n'}_n \delta^{l'}_l \delta^{m'}_m.$$

Introducing these special functions into the general integral, (4.7), we obtain

$$\int dg Y^*_{n_3 l_3 m_3}(g) Y_{n_1 l_1 m_1}(g) Y_{n_2 l_2 m_2}(g) = \left(\frac{n_1 n_2}{2\pi^2 n_3}\right)^{\frac{1}{2}} C\left[\begin{pmatrix} \frac{n_1-1}{2} & \frac{n_1-1}{2} \\ l_1 & m_1 \end{pmatrix}\begin{pmatrix} \frac{n_2-1}{2} & \frac{n_2-1}{2} \\ l_2 & m_2 \end{pmatrix}\begin{pmatrix} \frac{n_3-1}{2} & \frac{m_3-1}{2} \\ l_3 & m_3 \end{pmatrix}\right], \tag{4.10}$$

where the coefficient $C[\ldots]$ is defined in (4.5) and both g and the differential dg are defined implicitly in (4.9). Equation (4.10) is the four-dimensional analog of the generalized Gaunt integral of (2.11).

Using (4.8) this result can be put in the form of an integral over three Gegenbauer polynomials, (evaluating the integral over the $SO(3)$ spherical harmonics by (2.11)), but this explicit result is not necessary for our present purpose.

Remark. The $SO(4)$ spherical harmonic integral, (4.10), implies the restriction (see (4.6a)) that the parameters in two of the three columns of the $9-j$ symbol are *identical.* The $9-j$ symbol has the general symmetry [12] that under the exchange of two columns the symbol is multiplied by the factor: $(-1)^S$, where $S \equiv$ sum of the nine parameters in the $9-j$ symbol. Thus we see that for two identical columns, we must have $(-1)^S = +1$ in order to obtain a nonzero value. This implies that integral in (4.10) is nonzero only for $l_1 + l_2 + l_3 \equiv 0 \bmod 2$. For (4.10) this restriction on the $SO(4)$ WCG coefficient (the right-hand side of (4.10)) is exactly the same restriction as implied by the $SO(3)$ spherical harmonic integral of the left-hand side of (4.10). This integral involves the coefficient $C^{l_1 l_2 l_3}_{000}$, which similarly [12] requires $l_1+l_2+l_3 \equiv 0 \bmod 2$.

Now let us turn to the Euclidean group in three-space, $E(3)$. Rather than proceeding to develop the $E(3)$ analogs to the $SO(4)$ results directly from the $E3$ group itself, let us use the contraction method, applied to the limit $SO(4) \to E(3)$, as more intuitive and illuminating.

The $SO(4) \to E(3)$ contraction limit preserves the diagonal $SO(3)$ group, and hence uses the realization of the commutation relations in (4.1) (where $\vec{L}$ generates the diagonal $SO(3)$ subgroup). These relations are

$$[L_i, L_j] = i\varepsilon_{ijl} L_k, \quad [L_i, K_j] = i\varepsilon_{ijk} K_k, \quad \text{and} \quad [K_i, K_j] = i\varepsilon_{ijk} L_k. \tag{4.11a–c}$$

To obtain the contraction limit we multiply (4.1b,c) by ε^2 on both sides; let $\varepsilon \to 0$ and $K_i \to \infty$, such that $\varepsilon K_i \to T_i =$ finite (momentum) operator. We obtain in this limit the commutation relations

$$[L_i, L_j] = i\varepsilon_{ijl} L_k, \quad [L_i, T_j] = i\varepsilon_{ijk} T_k, \quad [T_i, T_j] = 0, \tag{4.12a–c}$$

which show that $E(3)$ has the structure of a semidirect product group $E(3) \simeq T_3 @ SO3$, with the three-dimensional translation subgroup (T_3) normal.

Consider now the $SO(4)$ irreps $\mathcal{D}^{(n,0)}(g)$ corresponding to the four-dimensional spherical harmonics (cf. (4.8a)). The contraction limit corresponds to taking the radius $\rho = (x^2+y^2+z^2+t^2)^{\frac{1}{2}}$ of a sphere in four dimensions to be "large," and considering the neighborhood about the "origin": $x = y = z = 0$ with $t = \rho$. Rotations R_{tx}, R_{ty}, R_{tz} thus become, for ρ large, translations of this neighborhood, which in the limit becomes planar. For the representation matrix (4.8a), the contraction keeps (θ, φ) fixed. The contraction takes the eigenvalue n of the invariant $\mathcal{I}_1 = \vec{L}^2 + \vec{K}^2 + 1$

to become large (corresponding to $\vec{K}$ becoming large in obtaining (4.12)). The limit $\varepsilon K_3 \to T_3 =$ finite is achieved by defining the rotation operator $e^{-i\chi K_3} \to e^{-irT_3}$, the translation operator with eigenvalue e^{-irk}, ($k = n\varepsilon =$ momentum eigenvalue of $T_3, r =$ displacement). Thus the angle χ in (4.8a) is small, given by $\chi = r\varepsilon$, with $\varepsilon \to 0$. The required asymptotic limit of (4.8a) is found [20], [22] to be

$$\lim_{n\to\infty}\left(\left(\frac{2\pi^2}{n^2}\right)^{\frac{1}{2}} Y_{nlm}(\chi\theta\varphi)\right) = i^l(4\pi)^{\frac{1}{2}} j_l(kr)Y_{lm}(\theta\varphi). \tag{4.12}$$

Put differently, the contraction limit involving the Gegenbauer polynomials is the limit

$$\lim_{n\to\infty}\left(\left(\frac{2\pi^2}{n^2}\right)^{\frac{1}{2}} F_{nl}\left(\frac{kr}{n}\right)\right) = i^l(4\pi)^{\frac{1}{2}} j_l(kr), \tag{4.13}$$

with the Gegenbauer polynomials entering through (4.8b). The special functions of $E(3)$ in (4.14) are the spherical Bessel functions, $j_l(kr)$, using the conventional notation. (It should be noted that these functions are real.)

There is one more detail before we can establish the contraction limit of the left-hand side of (4.10). This concerns the differential dg, which in (4.10) has the value

$$dg = \sin^2\chi d\chi \cdot \sin\theta d\theta d\varphi.$$

Since the angle χ is small ($\chi = \varepsilon \cdot r$ with $\varepsilon \to 0$) we see that $\sin^2\chi d\chi \to \varepsilon^3 r^2 dr$, and the limits of integration become 0 and ∞.

We now use the asymptotic limit given by (4.13) for the left-hand side of (4.10), and note that the ε^3 in dg combines with the terms $n_1n_2n_3$—introduced from using (4.13)—to give $k_1k_2k_3$, that is, $n_i\varepsilon = k_1$. This establishes that the contraction limit of the left-hand side of (4.10) is given by

$$\begin{aligned} & i^{l_1+l_2-l_3}\left(\frac{2}{\pi}\right)^{\frac{3}{2}} k_1k_2k_3\left(\int_0^\infty r^2dr\, j_{l_3}(k_3r)j_{l_1}(k_1r)j_{l_2}(k_2r)\right) \\ & \times\left(\left(\frac{(2l_1+1)(2l_2+1)}{4\pi(2l_3+1)}\right)^{\frac{1}{2}} C^{l_1l_2l_3}_{m_1m_2m_3}C^{l_1l_2l_3}_{0\,0\,0}\right), \end{aligned} \tag{4.14}$$

where the terms in the second bracket (...) use (2.11) to evaluate the ($SO(3)$) spherical harmonic integral.

Let us now consider the contraction limit for the $SO(4)$ WCG coefficients, appearing as the right-hand side of (4.10) and defined in (4.5). This limit will yield new angular special functions, and it is helpful to introduce these functions first and then show that they appear as the contraction limit of (4.5).

These new angular functions were first defined in the context of angular correlation theory [23] for nuclear radiations (for example, gamma rays). The appropriate angle functions for discussing the angular correlation of, say, *two* gamma rays are the Legendre functions of the planar angle defined by the two gamma ray directions, a rotational invariant. The new functions in question are the appropriate angular functions for correlations involving the *three* rotationally invariant angles defined by

three observed directions. Specifically, we have the definition [12], [24]

$$P_{l_1,l_2l_3}(\hat{k}_1\hat{k}_2\hat{k}_3) \equiv (4\pi)^{\frac{3}{2}}\left((2l_1+1)(2l_2+1)(\ldots)^2\right)^{-\frac{1}{2}}$$

$$\cdot i^{l_1+l_2-l_3}\sum_{\alpha,\beta,\gamma}(-1)^{\gamma}C^{l_1l_2l_3}_{\alpha\beta\gamma}Y_{l_1\alpha}(\hat{k}_1)Y_{l_2\beta}(\hat{k}_2)Y_{l_3\gamma}(\hat{k}_3), \tag{4.15}$$

where $\hat{k}_i$ are unit vectors of the directions measured with respect to a fixed, but arbitrary, coordinate frame. Despite the appearance of the (quantal) $SO(3)$ WCG coefficient in (4.16) this is a classical result, for the WCG coefficients appear here as the coefficients of a general vector algebra. For example, the P_{111} function is just the rotationally invariant, antisymmetric combination of three vectors, $\hat{k}_1 \cdot \hat{k}_2 \times \hat{k}_3$ (to within a constant).

The special functions defined by (4.16) are *real* (the factor in i is determined by time reversal invariance in quantum mechanics in order to effect this). Moreover, these functions have the symmetry property

$$P_{l_il_jl_k}(\hat{k}_i\hat{k}_j\hat{k}_k) = (-1)^{l_i+l_j+l_k}P_{l_{i'}l_{j'}l_{k'}}(\hat{k}_{i'}\hat{k}_{j'}\hat{k}_{k'}), \tag{4.16}$$

when $(i'j'k')$ is an odd permutation of (ijk). Note that the normalization is chosen such that $P_{000} = 1$.

We are now in a position to examine the contraction limit of the coefficients (4.5) appearing on the right-hand side of (4.10).

For this limit we find

$$\underset{\text{limit}}{\text{contraction}}\left(i^{l_3-l_1-l_2}\left[(2a+1)(2b+1)(2c+1)\right]^{\frac{1}{2}}\begin{Bmatrix} a & a & l_1 \\ b & b & l_2 \\ c & c & l_3 \end{Bmatrix}\right) = \begin{cases} P_{l_1l_2l_3}(\hat{a}\hat{b}\hat{c}) \\ 0 \end{cases}, \tag{4.18}$$

where the contraction limit and the two alternatives are explained as follows. First note that the $(9-j)$ coefficient appearing in (4.18) has the restriction that two columns are identical. As discussed in the remark above, this implies that $l_1+l_2+l_3 \equiv 0 \bmod 2$ in order to obtain a nonzero value for the $(9-j)$ symbol. Exactly the same restriction also applies, from (4.17), to the $P_{l_1l_2l_3}(\hat{a}\hat{b}\hat{c})$ on the right-hand side of (4.18). To understand the meaning of this restriction, recall our example where $P_{111} = (\text{constant})$ $\hat{k}_1 \cdot \hat{k}_2 \times \hat{k}_3$. Since in this example $(-1)^{l_1+l_2+l_3} = -1, P_{111}$ vanishes, which implies that the three unit vectors $\hat{k}_1, \hat{k}_2, \hat{k}_3$ are *coplanar*. This is the meaning of the restriction on the $9-j$ symbol appearing in (4.18). More precisely, the contraction limit takes the three parameters, a, b, and c large (say, $a = a'/\varepsilon, b = b'/\varepsilon, c = c'/\varepsilon$ with a', b', c' constant as $\varepsilon \to 0$) such that a, b, and c—which form an angular momentum triangle (a condition stemming from (4.5))—continue to form a finite scaled triangle in the limit, with sides a', b', c'. We express this as the statement: *the finite scaled variables a', b', c' form a triangle*, with the unit vectors $\hat{a}, \hat{b}, \hat{c}$ accordingly being coplanar. Note that the angles appearing explicitly in $P_{l_1l_2l_3}(\hat{a}\hat{b}\hat{c})$ are invariant to this scaling and hence well defined.

If the parameters a, b, c in (4.18) do not form a triangle, then both sides of (4.18) vanish.

We can now determine the contraction limit of the right-hand side of (4.10). Using (4.6a) and (4.18) we find

$$\frac{i^{l_1+l_2-l_3}}{(8\pi^2)^{\frac{1}{2}}}\left[(2l_1+1)(2l_2+1)\right]^{\frac{1}{2}} P_{l_1l_2l_3}(\hat{k}_1\hat{k}_2\hat{k}_3)C^{l_1l_2l_3}_{m_1m_2m_3}. \tag{4.19}$$

These results, (4.15), and (4.19) establish the contraction limit of the two sides, independent of (4.10). Equating the two results, and cancelling common factors, we obtain an identity for the special functions of the contracted group, $E(3)$:

$$4k_1k_2k_3\int_0^\infty r^2dr j_{l_1}(k_1r)j_{l_2}(k_2r)j_{l_3}(k_3r)\cdot(2l_3+1)^{-\frac{1}{2}}C^{l_1l_2l_3}_{0\,0\,0} = P_{l_1l_2l_3}(\hat{k}_1\hat{k}_2\hat{k}_3) \tag{4.20}$$

for $l_1+l_2+l_3\equiv 0 \bmod 2$, with k_1, k_2, and k_3 in (4.20) forming a (nondegenerate) triangle.

If the three parameters k_1, k_2, and k_3 in (4.20) form a degenerate triangle (having vanishing area), the result given above must be modified. The contraction limit, as we have noted before, can be singular, and, in fact is singular for a degenerate triangle in the present case. A more careful investigation shows that, for the degenerate case, there is a factor of $\frac{1}{2}$ appearing on the right side of (4.19). (Since the degenerate case implicitly appears in the inversion of (4.4) into (4.7) there is a subtle factor of 2 which renormalizes the limit of the right-hand side of (4.10) also.)

Combining these various cases for the final result we obtain

$$\begin{aligned} &4k_1k_2k_3\int_0^\infty r^2dr j_{l_1}(k_1r)j_{l_2}(k_2r)j_{l_3}(k_3r)\cdot(2l_3+1)^{-\frac{1}{2}}C^{l_1l_2l_3}_{0\,0\,0} \\ &\quad = \Delta\cdot P_{l_1l_2l_3}(\hat{k}_1\hat{k}_2\hat{k}_3) \end{aligned} \tag{4.21a}$$

for $l_1+l_2+l_3\equiv 0 \bmod 2$, with Δ defined by

$$\Delta = \begin{cases} 1 & \text{if } k_1k_2k_3 \text{ forms a triangle,} \\ \frac{1}{2} & \text{if } k_1k_2k_3 \text{ forms a degenerate triangle,} \\ 0 & \text{if not.} \end{cases} \tag{4.21b}$$

The identity given in (4.20) was first established by direct integration, without the use of group theory, by Jackson and Maximon [25]. *The fact that this identity is the contraction limit of the $SO(4)$ identity* (4.10)*—with the interpretation* (4.18)*, for the 9-j contraction limit—is, we believe, new.*

5. Concluding remarks. Within the last few years there has been an almost explosive growth of interest (and new results) from the discovery of a group theoretic basis for q-analog special functions, based on the concept of a *quantum group* [10], [11]. Quantum groups are not actually groups, but rather Hopf algebras, usually of infinite dimension, which are deformations of the universal enveloping algebras of classical Lie groups. Although technically mislabeled, quantum groups do share many group-like properties. The limit $q\to 1$, in which a genuine classical group is attained, is reminiscent of the quantum $\to$ classical limit, which in a sense also justifies the name.

Quantum groups, in particular, permit the construction of unitary irreps (and thereby q-analog special functions), product laws, and the construction (for a suitable classical group) of the q-analog of the Wigner–Clebsch–Gordan coefficients. Thus we see that essentially all of the necessary tools are available for a q-analog version of the

results presented above. It seems evident that such relations must exist, extending to the corresponding q-analog special function identities, the intuitive interrelationships of the contraction limit (which also exists for quantum groups).

It would be interesting to verify whether or not these conjectured q-analog relations actually exist.

Acknowledgment. It is our hope that this contribution to Dick Askey will be of interest not only to him, but also to his many friends and students who have benefitted by his extensive knowledge, highly developed skills, and many contributions to special function theory over the years.

ASYMPTOTIC APPROXIMATIONS FOR SYMMETRIC ELLIPTIC INTEGRALS*

B. C. CARLSON† AND J. L. GUSTAFSON†

Abstract. Symmetric elliptic integrals, which have been used as replacements for Legendre's integrals in recent integral tables and computer codes, are homogeneous functions of three or four variables. When some of the variables are much larger than the others, this paper presents asymptotic approximations with error bounds. In most cases they are derived from a uniform approximation to the integrand. As an application the symmetric elliptic integrals of the first, second, and third kinds are proved to be linearly independent with respect to coefficients that are rational functions.

Key words. elliptic integral, asymptotic approximation, inequalities, hypergeometric R-function

AMS subject classifications. primary 33A25, 41A60, 26D15; secondary 33A30, 26D20

1. Introduction.

A recent table of elliptic integrals [9]–[13] uses symmetric standard integrals instead of Legendre's integrals because permutation symmetry makes it possible to unify many of the formulas in previous tables. Fortran codes for numerical computation of the symmetric integrals, which are homogeneous functions of three or four variables, can be found in several major software libraries as well as in the supplements to [9] and [10]. For analytical purposes it is desirable to know how the homogeneous functions behave when some of the variables are much larger than the others. For all such cases we list in §2 asymptotic approximations (sometimes two or three approximations of different accuracy), always with error bounds. Proofs are discussed in §3. In most cases the approximations are obtained by replacing the integrand by a uniform approximation. Many of the results found by a different method in [16] have been improved by sharpening the error bounds or by finding bounds for incomplete elliptic integrals that are still useful for the complete integrals, which are then not listed separately. Cases not considered in [16] include two for a completely symmetric integral of the second kind and two for a symmetric integral of the third kind in which two variables are much larger than the other two.

We assume that x, y, z are nonnegative and that at most one of them is 0. The symmetric integral of the first kind,

$$R_F(x,y,z) = \frac{1}{2}\int_0^\infty [(t+x)(t+y)(t+z)]^{-1/2}dt, \tag{1}$$

is homogeneous of degree $-\frac{1}{2}$ in x, y, z and satisfies $R_F(x,x,x) = x^{-1/2}$. The symmetric integral of the third kind,

$$R_J(x,y,z,p) = \frac{3}{2}\int_0^\infty [(t+x)(t+y)(t+z)]^{-1/2}(t+p)^{-1}dt, \qquad p>0, \tag{2}$$

is homogeneous of degree $-3/2$ in x, y, z, p and satisfies $R_J(x,x,x,x) = x^{-3/2}$. If $p = z$, R_J reduces to an integral of the second kind,

$$R_D(x,y,z) = R_J(x,y,z,z) = \frac{3}{2}\int_0^\infty [(t+x)(t+y)]^{-1/2}(t+z)^{-3/2}dt, \qquad z>0, \tag{3}$$

† Ames Laboratory and Department of Mathematics, Iowa State University, Ames, Iowa 50011-3020.

which is symmetric in x and y only. If two variables of R_F are equal, the integral becomes an elementary function,

$$R_C(x,y) = R_F(x,y,y) = \frac{1}{2}\int_0^\infty (t+x)^{-1/2}(t+y)^{-1}dt, \qquad y>0. \tag{4}$$

If $x<y$, it is an inverse trigonometric function,

$$R_C(x,y) = (y-x)^{-1/2}\arccos(x/y)^{1/2}, \tag{5}$$

and if $x>y$, it is an inverse hyperbolic function,

$$R_C(x,y) = (x-y)^{-1/2}\operatorname{arccosh}(x/y)^{1/2} = (x-y)^{-1/2}\ln\frac{\sqrt{x}+\sqrt{x-y}}{\sqrt{y}}. \tag{6}$$

If the second argument of R_C is negative, the Cauchy principal value is [18, eq. (4.8)]

$$R_C(x,-y) = \left(\frac{x}{x+y}\right)^{1/2} R_C(x+y,y), \qquad y>0. \tag{7}$$

If the fourth argument of R_J is negative, the Cauchy principal value is given by [18, eq. (4.6)]

$$\begin{aligned}(y+p)R_J(x,y,z,-p) &= (q-y)R_J(x,y,z,q) - 3R_F(x,y,z)\\ &\quad + 3\left(\frac{xyz}{xz+pq}\right)^{1/2} R_C(xz+pq,pq), \qquad p>0,\end{aligned} \tag{8}$$

where $q-y = (z-y)(y-x)/(y+p)$. If we permute the values of x,y,z so that $(z-y)(y-x)\geq 0$, then $q\geq y>0$.

A completely symmetric integral of the second kind is not as convenient as R_D for use in tables because its representation by a single integral is more complicated [7, eq. (9.1-9)]:

$$R_G(x,y,z) = \frac{1}{4}\int_0^\infty [(t+x)(t+y)(t+z)]^{-1/2}\left(\frac{x}{t+x}+\frac{y}{t+y}+\frac{z}{t+z}\right)t\,dt. \tag{9}$$

It is symmetric and homogeneous of degree $\frac{1}{2}$ in x,y,z, and it satisfies $R_G(x,x,x) = x^{1/2}$. It has a nice representation by a double integral that expresses the surface area of an ellipsoid [7, eq. (9.4-6)]. It is related to R_D and R_F by (58) and by

$$R_G(x,y,z) = x(y+z)R_D(y,z,x) + y(z+x)R_D(z,x,y) + z(x+y)R_D(x,y,z), \tag{10}$$

$$R_G(x,y,0) = xy[R_D(0,x,y) + R_D(0,y,x)]. \tag{11}$$

Legendre's complete elliptic integrals K and E are given by

$$K(k) = R_F(0,1-k^2,1), \tag{12}$$

$$\begin{aligned}E(k) &= 2R_G(0,1-k^2,1)\\ &= \frac{1-k^2}{3}[R_D(0,1-k^2,1) + R_D(0,1,1-k^2)],\end{aligned} \tag{13}$$

$$K(k) - E(k) = \frac{k^2}{3}R_D(0,1-k^2,1), \tag{14}$$

$$E(k) - (1-k^2)K(k) = \frac{k^2(1-k^2)}{3}R_D(0,1,1-k^2). \tag{15}$$

Approximations and inequalities for K, E, and some combinations thereof are given in [1]–[3]. If the error terms in (30), (31), and (53) are omitted, the approximations reduce to the leading terms of well-known series expansions of K and E for k near 1 [15, p. 54] [4, eqs. 900.06, 900.10]. If the series for K is truncated after any number of terms, simple bounds for the *relative* error are given in [14, eq. (1.17)]. A generalization of this series to $R_F(x,y,z)$ with $x,y \ll z$ is given in [14, eqs. (1.14)–(1.16)], again with simple bounds for the relative error of truncation.

The various functions designated by R with a letter subscript are special cases of the multivariate hypergeometric R-function,

$$R_{-a}(b_1,\dots,b_n;\, z_1,\dots,z_n),$$

which is symmetric in the indices $1,\dots,n$ and is homogeneous of degree $-a$ in the variables $z_1,\dots,z_n$. Best regarded as the Dirichlet average of x^{-a} [7, §5.9], it is a symmetric variant of the function known as Lauricella's F_D. By the method of Mellin transforms, series expansions that converge rapidly if some of the z's are much larger than the others and if the parameters satisfy $\sum_{i=1}^{n} b_i > a > 0$ are obtained in [8, eqs. (4.16)–(4.19)]. Thus the leading terms of these series provide asymptotic approximations for all except R_G among the functions

$$(16)\quad R_F(x,y,z) = R_{-\frac{1}{2}}(\tfrac{1}{2},\tfrac{1}{2},\tfrac{1}{2};\, x,y,z), \qquad R_C(x,y) = R_{-\frac{1}{2}}(\tfrac{1}{2},1;\, x,y),$$

$$(17)\quad R_J(x,y,z,p) = R_{-\frac{3}{2}}(\tfrac{1}{2},\tfrac{1}{2},\tfrac{1}{2},1;\, x,y,z,p), \qquad R_D(x,y,z) = R_{-\frac{3}{2}}(\tfrac{1}{2},\tfrac{1}{2},\tfrac{3}{2};\, x,y,z),$$

$$(18)\quad R_G(x,y,z) = R_{\frac{1}{2}}(\tfrac{1}{2},\tfrac{1}{2},\tfrac{1}{2};\, x,y,z).$$

However, error bounds for the approximations are more easily derived by the methods of the present paper. Another function that is used repeatedly in obtaining error bounds is [7, Ex. 9.8-5]

$$(19)\quad R_{-1}(\tfrac{1}{2},\tfrac{1}{2},1;\, x,y,z) = \int_0^\infty [(t+x)(t+y)]^{-1/2}(t+z)^{-1}\,dt$$

$$(20)\quad = 2R_C((\sqrt{xy}+z)^2, (\sqrt{x}+\sqrt{y})^2 z).$$

In §4 the asymptotic approximations are applied to show that $R_F(x,y,z)$, $R_D(x,y,z)$, $R_J(x,y,z,p)$, and $(xyz)^{-1/2}$ are linearly independent with respect to coefficients that are rational functions of x,y,z, and p. The appendix contains some elementary inequalities that are used in obtaining error bounds.

The results in this paper provide upper and lower approximations that approach the elliptic integrals as selected ratios of the variables approach zero. Approximations that approach the integrals as all variables approach a common value have been found by other methods. For example, the theory of hypergeometric mean values yields upper and lower algebraic approximations for all the integrals in this paper [5, Thm. 2], while truncation of Taylor series about the arithmetic mean of the variables gives approximations with errors that may be positive or negative. Successive applications of the duplication theorem for R_F, making its three variables approach equality, provide ascending and descending sequences of successively sharper (and successively more complicated) algebraic approximations to R_F and R_C [6]. Transcendental approximations that approach R_F when only two of its variables approach equality are furnished by

$$(21)\quad R_C\left(x, \frac{y+z}{2}\right) \le R_F(x,y,z) \le R_C(x, \sqrt{yz}), \qquad yz \ne 0,$$

which follows from (71). The inequalities can be sharpened by first using Landen or Gauss transformations of R_F [7, §9.5] to make y and z approach equality. If $x = 0$, the Gauss transformation reduces to replacing $\sqrt{y}$ and $\sqrt{z}$ by their arithmetic and geometric means, and each R_C-function becomes $\pi/2$ divided by the square root of its second argument. Therefore, in the complete case the procedure reduces to the algorithm of the arithmetic-geometric mean [7, eqs. (6.10-6), (9.2-3)] and provides ascending and descending sequences of algebraic approximations, of which leading members are shown in (33).

2. Results. We assume throughout that x, y, and z are nonnegative and that at most one of them is 0. The last argument of R_C, R_D, and R_J is assumed to be positive (see (7) and (8)).

C1. $R_C(x,y)$ with $x \ll y$.

$$R_C(x,y) = \frac{\pi}{2\sqrt{y}} - \frac{\sqrt{x}}{y} + \frac{\pi x\theta}{4y^{3/2}}, \tag{22}$$

where $1/(1+\sqrt{x/y}) \le \theta \le 1$ with equalities if and only if $x = 0$.

C2. $R_C(x,y)$ with $y \ll x$. Two approximations of different accuracies are

$$R_C(x,y) = \frac{1}{2\sqrt{x}}\left(\ln\frac{4x}{y} + \frac{y}{2x-y}\ln\frac{\theta_1 x}{y}\right), \tag{23}$$

$$= \frac{1}{2\sqrt{x}}\left[\left(1+\frac{y}{2x}\right)\ln\frac{4x}{y} - \frac{y}{2x} + \frac{3y^2}{4x(2x-y)}\ln\frac{\theta_2 x}{y}\right], \tag{24}$$

where $1 < \theta_i < 4$ for $i = 1, 2$. The first approximation implies

$$R_C(x,y) < \frac{1}{2\sqrt{x}(1-y/2x)}\ln\frac{4x}{y}. \tag{25}$$

F1. $R_F(x,y,z)$ with $x, y \ll z$. Let $a = (x+y)/2$, $g = \sqrt{xy}$, and $\rho = \max\{x,y\}/z$. Then

$$R_F(x,y,z) = \frac{1}{2\sqrt{z}}\left(\ln\frac{8z}{a+g} + \frac{r}{2z}\right), \tag{26}$$

where

$$\frac{g}{1-g/z}\ln\frac{2z}{a+g} < r < \frac{a}{1-a/2z}\ln\frac{8z}{a+g}.$$

The upper bound implies

$$R_F(x,y,z) < \frac{1}{2\sqrt{z}(1-a/2z)}\ln\frac{8z}{a+g}. \tag{27}$$

A sharper lower bound and a higher-order approximation are given by

$$R_F(x,y,z) = \frac{1}{2\sqrt{z}}\left(\ln\frac{8z}{a+g} + \frac{ar_1}{2z}\right) \tag{28}$$

$$= \frac{1}{2\sqrt{z}}\left[\left(1+\frac{a}{2z}\right)\ln\frac{8z}{a+g} - \frac{2a-g}{2z} + \frac{3(3a^2-g^2)r_2}{16z^2}\right], \tag{29}$$

where

$$\ln\frac{z}{2a} < \frac{\ln(1/\rho)}{1-\rho} < r_i < \frac{1}{1-a/2z}\ln\frac{8z}{a+g}, \qquad i=1,2.$$

By (12) this implies (since $4k^2 < 4-k'^2$ if $k^2<1$)

$$K(k) = \ln\frac{4}{k'} + \frac{k'^2}{4-k'^2}\ln\frac{\theta_1}{k'} \tag{30}$$

$$= \left(1+\frac{k'^2}{4}\right)\ln\frac{4}{k'} - \frac{k'^2}{4} + \frac{9k'^4}{16(4-k'^2)}\ln\frac{\theta_2}{k'}, \tag{31}$$

where $0<k'=\sqrt{1-k^2}$ and $1<\theta_i<4$ for $i=1,2$.

F2. $R_F(x,y,z)$ with $z \ll x,y$. Let $a=(x+y)/2$ and $g=\sqrt{xy}$. Then

$$R_F(x,y,z) = R_F(x,y,0) - \frac{\sqrt{z}}{g} + \frac{\pi z\theta}{4g^{3/2}}, \tag{32}$$

where $1/(1+\sqrt{z/g}) < \theta < a/g$. Note that $R_F(x,y,0) = \pi/2\mathrm{AGM}(\sqrt{x},\sqrt{y})$, where AGM denotes Gauss's arithmetic-geometric mean [7, eqs. (6.10-6), (9.2-3)], and hence

$$\frac{1}{\sqrt{a}} \le \sqrt{\frac{2}{a+g}} \le \frac{2}{\sqrt{(a+g)/2}+\sqrt{g}} \le \frac{2}{\pi}R_F(x,y,0) \le \left(\frac{2}{ag+g^2}\right)^{1/4} \le \frac{1}{\sqrt{g}}, \tag{33}$$

with equalities if and only if $x=y$.

D1. $R_D(x,y,z)$ with $x,y \ll z$. Let $a=(x+y)/2$ and $g=\sqrt{xy}$. Then

$$R_D(x,y,z) = \frac{3}{2z^{3/2}}\left(\ln\frac{8z}{a+g} - 2 + \frac{\theta}{z}\ln\frac{2z}{a+g}\right), \tag{34}$$

where

$$\frac{g}{1-g/z} < \theta < \frac{3a}{2(1-a/z)}.$$

D2. $R_D(x,y,z)$ with $z \ll x,y$. Let $a=(x+y)/2$ and $g=\sqrt{xy}$. Then

$$R_D(x,y,z) = \frac{3}{\sqrt{xyz}}\left(1 - \frac{\pi\theta}{2}\sqrt{\frac{z}{g}}\right), \tag{35}$$

where

$$1 - \frac{4}{\pi}\sqrt{\frac{z}{g}} < \theta < \frac{a}{g}.$$

A higher-order approximation is

$$R_D(x,y,z) = \frac{3}{\sqrt{xyz}} - R_D(0,x,y) - R_D(0,y,x) + \frac{3\pi\theta\sqrt{z}}{2g^2(1+\sqrt{z/g})}, \tag{36}$$

where

$$\frac{1}{\sqrt{2/3+\sqrt{z/g}}} < \theta < \frac{3a}{2g(1+\sqrt{z/g})}.$$

An approximation of still higher order is

$$R_D(x,y,z) = \frac{3}{\sqrt{xyz}} - \frac{6}{xy}R_G(x,y,0) + \frac{6a\sqrt{z}}{g^3}\left(1 - \frac{\pi\theta}{4}\sqrt{\frac{z}{a}}\right), \tag{37}$$

where we have used (11) and where

$$\frac{1}{1+\sqrt{z/a}} < \theta < \left(\frac{a}{g}\right)^{3/2}\left(3 - \frac{g^2}{a^2}\right).$$

D3. $R_D(x,y,z)$ with $y,z \ll x$. Let $a = (y+z)/2$ and $g = \sqrt{yz}$. Then

$$R_D(x,y,z) = \frac{3}{\sqrt{x}}\left(\frac{1}{g+z} - \frac{r}{4x}\right), \tag{38}$$

where

$$\frac{1}{1-g/x}\ln\frac{2x}{a+g} - \frac{2z}{g+z} < r < \frac{1}{1-a/2x}\ln\frac{8x}{a+g}.$$

D4. $R_D(x,y,z)$ with $x \ll y,z$. Let $a = (y+z)/2$ and $g = \sqrt{yz}$. Then

$$R_D(x,y,z) = R_D(0,y,z) + \frac{3\sqrt{x}}{gz}\left(-1 + \frac{\pi\theta}{4}\sqrt{\frac{x}{a}}\right), \tag{39}$$

where

$$\frac{1}{1+\sqrt{x/a}} < \theta < \left(\frac{a}{g}\right)^{3/2}\left(1 + \frac{y}{a}\right).$$

J1. $R_J(x,y,z,p)$ with $x,y,z \ll p$. Let $a = (x+y+z)/3$ and $b = (\sqrt{3}/2)(xy+xz+yz)^{1/2}$. Then

$$R_J(x,y,z,p) = \frac{3}{p}R_F(x,y,z) + \frac{3\pi}{2p^{3/2}}(-1+r), \tag{40}$$

where

$$\frac{\sqrt{b/p}}{1+\sqrt{b/p}} < r < \frac{3}{2}\,\frac{\sqrt{a/p}}{1+\sqrt{a/p}}.$$

In the complete case a sharper result is

$$R_J(x,y,0,p) = \frac{3}{p}\left(R_F(x,y,0) - \frac{\pi}{2\sqrt{p}}\right)\left(1 + \frac{\theta/p}{1-\theta/p}\right), \tag{41}$$

where $\sqrt{xy} \le \theta \le (x+y)/2$, with equalities if and only if $x = y$.

J2. $R_J(x,y,z,p)$ with $p \ll x,y,z$. Let $g = (xyz)^{1/3}$, $3h^{-1} = x^{-1}+y^{-1}+z^{-1}$, and $\lambda = \sqrt{xy}+\sqrt{xz}+\sqrt{yz}$. Note that g is the geometric mean and h is the harmonic mean; whence $g \ge h$ with equality if and only if $x = y = z$. Then

$$R_J(x,y,z,p) = \frac{3}{2\sqrt{xyz}}\left(\ln\frac{4g}{p} - 2 + r\right), \tag{42}$$

where

$$-\ln\frac{g}{h} < r < \frac{3p}{2(g-p)}\ln\frac{g}{p}.$$

A higher-order approximation is

$$R_J(x,y,z,p) = \frac{3}{2\sqrt{xyz}}\ln\frac{4xyz}{p\lambda^2} + 2R_J(x+\lambda, y+\lambda, z+\lambda, \lambda) + \frac{3pr}{4\sqrt{xyz}}, \tag{43}$$

where

$$\frac{2}{g-p}\ln\frac{g}{p} < r < \frac{3}{h-p}\ln\frac{h}{p}.$$

The second term in the approximation is independent of p but is otherwise as complicated as the function being approximated. The same is true of an even more accurate approximation [16, Thm. 11] in which the error is of order p instead of $p\ln p$ and the leading term involves R_C.

J3. $R_J(x,y,z,p)$ with $x,y \ll z,p$. Let $a = (x+y)/2$ and $g = \sqrt{xy}$. Then

$$R_J(x,y,z,p) = \frac{3}{2\sqrt{zp}}\left[\ln\frac{8z}{a+g} - 2R_C\left(1,\frac{p}{z}\right) + \frac{\theta}{p}\ln\frac{2p}{a+g}\right], \tag{44}$$

where

$$\frac{g}{1-g/p} < \theta < \frac{a}{1-a/p}\left(1+\frac{p}{2z}\right).$$

J4. $R_J(x,y,z,p)$ with $z,p \ll x,y$. Let $a = (x+y)/2$, $g = \sqrt{xy}$, $b = \sqrt{3p(p+2z)}/2$, and $d = (z+2p)/3$. Then

$$R_J(x,y,z,p) = \frac{3}{g}R_C(z,p) - \frac{3\theta}{g-p}\left[R_C(z,g) - \frac{p}{g}R_C(z,p)\right], \tag{45}$$

where $1 \le \theta \le a/g$ with equalities if and only if $x = y$. Since $z \ll g$, $R_C(z,g)$ can be estimated from (22). In the complete case (45) reduces to

$$R_J(x,y,0,p) = \frac{3\pi}{2\sqrt{xyp}}\left(1 - \frac{\theta\sqrt{p}}{\sqrt{g}+\sqrt{p}}\right), \tag{46}$$

with θ as before. A higher-order approximation is

$$R_J(x,y,z,p) = \frac{3}{g}R_C(z,p) - \frac{6}{xy}R_G(x,y,0) + \frac{3\pi\theta}{2xy}, \tag{47}$$

where we have used (11) and where

$$\frac{\sqrt{b}}{1+\sqrt{b/g}} < \theta < \frac{3a}{2g}\frac{\sqrt{d}}{1+\sqrt{d/g}}.$$

J5. $R_J(x,y,z,p)$ with $x \ll y,z,p$. Let $a = (y+z)/2$ and $g = \sqrt{yz}$. Then

$$R_J(x,y,z,p) = R_J(0,y,z,p) + \frac{3\sqrt{x}}{gp}\left(-1 + \frac{\pi\theta}{4}\sqrt{\frac{x}{g}}\right), \tag{48}$$

where

$$\frac{\sqrt{g/a}}{1+\sqrt{x/a}} < \theta < \frac{a}{g} + \frac{g}{p}.$$

J6. $R_J(x,y,z,p)$ with $y,z,p \ll x$. Let $a = (y+z)/2$ and $g = \sqrt{yz}$. Then

$$R_J(x,y,z,p) = \frac{3}{\sqrt{x}}\left[R_C((g+p)^2, 2(a+g)p) - \frac{r}{4}\right], \tag{49}$$

where

$$\frac{1}{x-g}\ln\frac{2x}{a+g} - \frac{2p}{x}R_C((g+p)^2,2(a+g)p) < r < \frac{1}{x-a/2}\ln\frac{8x}{a+g}.$$

In the complete case this reduces to

$$R_J(x,0,z,p) = \frac{3}{\sqrt{xp}}R_C(p,z) - \frac{3s}{4x^{3/2}}, \tag{50}$$

where

$$\ln\frac{4x}{z} - 2\sqrt{p}R_C(p,z) < s < \frac{1}{1-z/4x}\ln\frac{16x}{z}.$$

G1. $R_G(x,y,z)$ with $x,y \ll z$. Let $a = (x+y)/2$ and $g = \sqrt{xy}$. Then

$$R_G(x,y,z) = \frac{\sqrt{z}}{2}\left(1 + \frac{r}{2z}\right), \tag{51}$$

where

$$\frac{a+g}{2}\ln\frac{2z}{a+g} + 2g - \frac{4a}{3} < r < (3a-g)\ln\frac{2z}{a+g} + 2g - \frac{a}{3}.$$

In the right-hand inequality it is assumed that $5a < z$. A sharper result for the complete case is

$$R_G(0,y,z) = \frac{\sqrt{z}}{2} + \frac{y}{8\sqrt{z}}\left(\ln\frac{16z}{y} - 1 + \frac{ys}{2z}\right), \tag{52}$$

where

$$\frac{3}{4}\ln\frac{z}{y} < s < \frac{1}{1-y/z}\left(\ln\frac{16z}{y} - \frac{13}{6}\right).$$

By (13) this follows from

$$E(k) = 1 + \frac{k'^2}{2}\left(\ln\frac{4}{k'} - \frac{1}{2} + k'^2 r\right), \tag{53}$$

where $0 < k' = \sqrt{1-k^2} \ll 1$ and

$$\frac{3}{8}\ln\frac{1}{k'} < r < \frac{1}{k(1+k)}\left(\ln\frac{4}{k'} - \frac{13}{12}\right).$$

G2. $R_G(x,y,z)$ with $z \ll x,y$. Let $a = (x+y)/2$ and $g = \sqrt{xy}$. Then

$$R_G(x,y,z) = R_G(x,y,0) + \pi\theta z/8, \tag{54}$$

where

$$\frac{1}{\sqrt{a}}\left(1 - \frac{4}{\pi}\sqrt{\frac{z}{a}}\right) < \theta < \left(\frac{2}{ag+g^2}\right)^{1/4} \le \frac{1}{\sqrt{g}}$$

with equality if and only if $x = y$.

3. Proofs. Most of the results in §2 are obtained by replacing an integrand f by an approximation f_a, writing $\int f = \int f_a + \int (f - f_a)$, and finding upper and lower bounds for $\int (f - f_a)$. All integrals are taken over the positive real line. The function f_a is usually chosen to be a uniform approximation $f_a = f_i + f_o - f_m$, where f_i is an approximation in the inner region, f_o is an approximation in the outer region, and f_m is an approximation in the overlap, or matching, region. For instance, if $f(t) = [(t+x)(t+y)(t+z)]^{-1/2}$, with $x, y \ll z$, we get f_i by neglecting t compared to z, f_o by neglecting x and y compared to t, and f_m by doing both. A first example of this process is the proof of Lemma 1.

LEMMA 1. *If $x \geq 0$, $y \geq 0$, and $0 < x + y \ll z$, then*

$$\int_0^\infty \frac{dt}{\sqrt{(t+x)(t+y)}(t+z)} = \frac{1}{z-\theta} \ln \frac{2z}{a+g}, \tag{55}$$

where $\sqrt{xy} = g \leq \theta \leq a = (x+y)/2$ with equalities if and only if $x = y$.

Proof. Let

$$f(t) = \frac{1}{\sqrt{(t+x)(t+y)}(t+z)}, \qquad f_i(t) = \frac{1}{z\sqrt{(t+x)(t+y)}},$$
$$f_o(t) = \frac{1}{t(t+z)}, \qquad f_m(t) = \frac{1}{zt}.$$

Taking $f_a = f_i + f_o - f_m$, we find

$$\int_0^\infty f_a(t)dt = \frac{1}{z} \ln \frac{2z}{a+g}$$

and

$$f - f_a = \frac{t}{z(t+z)} \left(\frac{1}{t} - \frac{1}{\sqrt{(t+x)(t+y)}} \right).$$

Inequality (64) in the appendix implies

$$f - f_a = \frac{\theta}{z\sqrt{(t+x)(t+y)}(t+z)}, \qquad g \leq \theta \leq a,$$

and thus

$$\int f = \int f_a + \int (f - f_a) = \int f_a + \frac{\theta}{z} \int f = \frac{1}{1-\theta/z} \int f_a = \frac{1}{z-\theta} \ln \frac{2z}{a+g}. \qquad \square$$

As a second example, in which Lemma 1 is used, consider $R_F(x,y,z)$ with $x, y \ll z$. Let

$$f(t) = \frac{1}{\sqrt{(t+x)(t+y)(t+z)}}, \qquad f_i(t) = \frac{1}{\sqrt{(t+x)(t+y)z}},$$
$$f_o(t) = \frac{1}{t\sqrt{t+z}}, \qquad f_m(t) = \frac{1}{\sqrt{z}t}.$$

Taking $f_a = f_i + f_o - f_m$, we find (with a and g the same as before)

$$\int_0^\infty f_a(t)dt = \frac{1}{\sqrt{z}} \ln \frac{8z}{a+g}$$

and

$$f - f_a = \left(\frac{1}{\sqrt{z}} - \frac{1}{\sqrt{t+z}}\right)\left(\frac{1}{t} - \frac{1}{\sqrt{(t+x)(t+y)}}\right).$$

Inequalities (61) and (64) imply

$$\frac{g}{2\sqrt{z(t+x)(t+y)}(t+z)} < f - f_a < \frac{a}{2z\sqrt{(t+x)(t+y)(t+z)}}.$$

Hence, by Lemma 1,

$$\frac{g}{2\sqrt{z}(z-g)} \ln\frac{2z}{a+g} < \int (f - f_a) < \frac{a}{2z}\int f < \frac{a/2z}{1-a/2z}\int f_a,$$

where the last inequality follows from the next to last. We complete the proof of (26) by noting that

$$2R_F(x,y,z) = \int f = \int f_a + \int (f - f_a).$$

Equations (28) and (29) are obtained from [14, eqs. (2.15), (3.25)] with $w = \infty$. To derive (32) we construct $f_a = f_i + f_o - f_m$ as usual and find bounds for $\int (f - f_a)$ by using (60) and (65). To simplify the upper bound we note that $R_F(x,y,z) \le R_F(x,y,0)$ and use (33).

Equations (22), (23), (24), and (25) follow from (32), (26), (29), and (27), respectively, by replacing x by y, replacing z by x, and simplifying.

Among the approximations for R_D, we need discuss only (35) and (37) since (34), (36), (38), and (39) follow from (44), (47), (49), and (48), respectively, by putting $p = z$ and simplifying. To prove (35) we let

$$f(t) = \frac{1}{\sqrt{(t+x)(t+y)}(t+z)^{3/2}}, \qquad f_i(t) = \frac{1}{g(t+z)^{3/2}},$$

choose $f_a = f_i$, and apply (65) to get

$$\frac{t}{g(t+g)(t+z)^{3/2}} \le f_a - f \le \frac{at}{g^2\sqrt{(t+x)(t+y)}(t+z)^{3/2}},$$

$$\frac{1}{g(g-z)\sqrt{t+z}}\left(\frac{g}{t+g} - \frac{z}{t+z}\right) \le f_a - f < \frac{a}{g^2\sqrt{t+z}(t+g)},$$

$$\frac{2}{g-z}\left[R_C(z,g) - \frac{\sqrt{z}}{g}\right] \le \int (f_a - f) < \frac{2a}{g^2} R_C(z,g).$$

Use of (22) completes the proof. Approximation (37) follows from applying (39) to two terms on the right side of

$$R_D(x,y,z) = 3(xyz)^{-1/2} - R_D(z,x,y) - R_D(z,y,x), \tag{56}$$

an identity that comes from [7, eqs. (5.9-5) and (6.8-15)].

In discussing approximations for R_J, we define

$$f(t) = \frac{1}{\sqrt{(t+x)(t+y)(t+z)}(t+p)}$$

and construct f_i, f_o, and f_m for each case in the manner described at the beginning of this section. For example, if $x, y, z \ll p$, then f_i is obtained by neglecting t compared to p. Unless otherwise stated, we define $f_a = f_i + f_o - f_m$, take $\int f_a$ as an approximation to $\int f$, and find bounds for $\int(f - f_a)$ by using the inequalities in the appendix.

To prove (40) we use (69). To prove (41) we use (64) and note that $\int(f - f_a) = (\theta/p)\int f$. Before discussing (42), we consider (43), in which the error bounds are easily found by using (70). Finding $\int f_a$ requires an integration by parts and a formula of which we omit the proof,

$$\begin{aligned}(57)\qquad &\int_0^\infty (\ln\, t)\frac{d}{dt}[(t+x)(t+y)(t+z)]^{-1/2}dt \\ &\quad = \frac{1}{\sqrt{xyz}}\ln\frac{\lambda^2}{4xyz} - \frac{4}{3}R_J(x+\lambda, y+\lambda, z+\lambda, \lambda),\end{aligned}$$

where $\lambda = \sqrt{xy} + \sqrt{xz} + \sqrt{yz}$. To have a simpler approximation (42), we define $f_a = f_i + f_o - f_m$ and $\phi_a = f_i + f_s - f_m$, where f_o has been replaced by

$$f_s(t) = \frac{1}{t(t+g)^{3/2}}.$$

Then

$$\int \phi_a = \frac{1}{\sqrt{xyz}}\left(\ln\frac{4g}{p} - 2\right),$$

and an upper bound for $\int(f-\phi_a)$ is found by using $\sqrt{(t+x)(t+y)(t+z)} \geq (t+g)^{3/2}$ and (63). To find a lower bound, we note that $f - f_a > 0$, whence

$$f - \phi_a = f - f_a + f_o - f_s > f_o - f_s.$$

A lower bound for $\int(f_o - f_s)$ follows from (73).

The straightforward proof of (44) uses (64), (67), and Lemma 1. For the elementary approximation (45) we choose $f_a = f_i$ and use (66). For the more accurate approximation (47) we take $f_a = f_i + f_o - f_m$ and evaluate $\int f_a$ by integrating by parts. The error bounds follow from (66) and (69) with two variables equated. To find the error bounds for (48), we use (68), (60), and (71) to prove

$$\frac{\sqrt{t}}{(t+x)(t+a)} < \frac{2gp}{x}(f - f_a) < \left(\frac{a}{g} + \frac{g}{p}\right)\frac{1}{\sqrt{t+z}(t+g)}.$$

After integration, (22) is used to complete the proof. In the case of (49), where $\int(f_o - f_m)$ is infinite, we choose $f_a = f_i$ and evaluate $\int f_a$ by (20). It follows from (61) that

$$\frac{1}{2\sqrt{x(t+y)(t+z)}}\left(\frac{1}{t+x} - \frac{p}{x(t+p)}\right) < f_a - f < \frac{1}{2x\sqrt{(t+x)(t+y)(t+z)}},$$

where we have replaced $t/(t+p)$ by 1 in the upper bound and $x/(x-p)$ by 1 in the lower bound. We then use (20), (55), and (27).

The function R_G can be expressed in terms of R_F and R_D by (17) and [7, Table 9.3-1]:

$$2R_G(x,y,z) = zR_F(x,y,z) - \frac{1}{3}(z-x)(z-y)R_D(x,y,z) + \sqrt{\frac{xy}{z}}. \tag{58}$$

Applying (26) and (34), we obtain (51). The error bounds have been substantially simplified by using the numerical value of $\ln 2$ and assuming $5a < z$ in the upper bound. It is not hard to obtain (53) from a well-known infinite series [15, p. 54] for $E(k)$ by using the inequality

$$1 + \frac{3}{8}k'^2 < {}_2F_1(\tfrac{1}{2}, \tfrac{3}{2}; 2; k'^2) < (1-k'^2)^{-1/2} = 1/k, \qquad 0 < k' < 1,$$

for the hypergeometric function ${}_2F_1$. Unfortunately, (58) does not lead to simple error bounds for (54). Instead, we define $f(z) = R_G(x,y,z)$ and find from [7, eqs. (5.9-9), (6.8-6)] that

$$f'(z) = \frac{1}{8}\int_0^\infty \frac{t\,dt}{\sqrt{(t+x)(t+y)}(t+z)^{3/2}}.$$

Since this is a strictly decreasing function of z, the mean value theorem yields $f(z) = f(0) + zf'(\zeta)$ where

$$f'(z) < f'(\zeta) < f'(0) = \tfrac{1}{4}R_F(x,y,0).$$

By (71) and (5) we see that

$$f'(z) \geq \frac{1}{8}\int_0^\infty \frac{t\,dt}{(t+a)(t+z)^{3/2}} = \frac{1}{4(a-z)}[-\sqrt{z} + aR_C(z,a)].$$

Use of (33) and (22) completes the proof of (54).

4. Application to linear independence. In [7, Thm. 9.2-1] it is shown that $R_F(x,y,z)$, $R_G(x,y,z)$, an integral of the third kind called $R_H(x,y,z,p)$, and the algebraic function $(xyz)^{-1/2}$ are linearly independent with respect to coefficients that are rational functions of x,y,z,p. It then follows [7, §9.2] that every elliptic integral can be expressed in terms of R_F, R_G, R_H, and elementary functions. From (58) and a known relation expressing R_H in terms of R_J and R_F, we may conclude that every elliptic integral can be expressed in terms of R_F, R_D, R_J, and elementary functions. To reach the same conclusion without invoking R_G and R_H, we shall use the results of this paper to prove the linear independence of R_F, R_D, R_J, and $(xyz)^{-1/2}$ with respect to coefficients that are rational functions.

THEOREM 1. *The functions $R_F(x,y,z)$, $R_D(x,y,z)$, $R_J(x,y,z,p)$, and $(xyz)^{-1/2}$ are linearly independent with respect to coefficients that are rational functions of x,y,z, and p.*

Proof. Let α, β, γ, and δ be rational functions of x,y,z, and p. We need to prove that

$$\alpha R_F(x,y,z) + \beta R_D(x,y,z) + \gamma R_J(x,y,z,p) + \delta\,(xyz)^{-1/2} \equiv 0 \tag{59}$$

if and only if α, β, γ, and δ are identically 0. We may assume that these coefficients are polynomials since we can multiply all terms by the denominator of any rational

function. As $p \to 0$, (42) shows that $R_J(x,y,z,p)$ involves $\ln p$, whereas all other quantities are polynomials in p, whence $\gamma \equiv 0$. As $z \to \infty$ we have

$$\alpha = az^m(1+O(1/z)), \qquad \beta = bz^n(1+O(1/z)),$$

where m and n are nonnegative integers and a and b are polynomials in x, y, and p. Using (26) and (34) and multiplying all terms by $2z^{3/2}$, we find

$$az^{m+1}\left[\ln\frac{8z}{a+g}+O\left(\frac{\ln z}{z}\right)\right]+3bz^n\left[\ln\frac{8z}{a+g}-2+O\left(\frac{\ln z}{z}\right)\right]+2\delta\,(xy)^{-1/2}z\equiv 0.$$

Cancellation of the leading terms in $\ln z$ requires $az^{m+1}+3bz^n \equiv 0$, implying that $n = m+1$ and $a \equiv -3b$ and leaving

$$O(z^m \ln z) - 6bz^{m+1} + 2\delta\,(xy)^{-1/2}z \equiv 0.$$

Because the second term is of different order from the first and does not have a square root in common with the third, it follows that $b \equiv 0$, whence also $a \equiv 0$. Since the leading terms of the polynomials α and β are identically 0, so too are α and β. Finally, with only one term remaining in (59), we have $\delta \equiv 0$. □

It is an open question whether Theorem 1 is still true if the coefficients are algebraic functions instead of rational functions. However, polynomial coefficients suffice (see the first paragraph of [7, §9.2]) to prove that every elliptic integral can be expressed in terms of R_F, R_D, R_J, and elementary functions.

Appendix: Elementary inequalities. Assuming x, y, z, and t are positive, we list and prove some inequalities that are used in this paper to obtain error bounds:

$$\frac{x}{2\sqrt{t}(t+x)} < \frac{1}{\sqrt{t}} - \frac{1}{\sqrt{t+x}} < \frac{x}{2t\sqrt{t+x}}, \tag{60}$$

$$\frac{t}{2\sqrt{x}(t+x)} < \frac{1}{\sqrt{x}} - \frac{1}{\sqrt{t+x}} < \frac{t}{2x\sqrt{t+x}}, \tag{61}$$

$$\frac{1}{t^{3/2}} - \frac{1}{(t+x)^{3/2}} = \frac{\theta x}{t^{3/2}(t+x)}, \qquad 1 < \theta < \frac{3}{2}, \tag{62}$$

$$\frac{1}{x^{3/2}} - \frac{1}{(t+x)^{3/2}} = \frac{\theta t}{x^{3/2}(t+x)}, \qquad 1 < \theta < \frac{3}{2}. \tag{63}$$

In the next five inequalities let $a = (x+y)/2$ and $g = \sqrt{xy}$. Inequalities become equalities in (64), (65), and (66) if and only if $x = y$.

$$\frac{1}{t} - \frac{1}{\sqrt{(t+x)(t+y)}} = \frac{\theta}{t\sqrt{(t+x)(t+y)}}, \qquad g \le \theta \le a, \tag{64}$$

$$\frac{t}{g(t+g)} \le \frac{1}{\sqrt{xy}} - \frac{1}{\sqrt{(t+x)(t+y)}} \le \frac{at}{g^2\sqrt{(t+x)(t+y)}}, \tag{65}$$

or, alternatively,

$$\frac{1}{\sqrt{xy}} - \frac{1}{\sqrt{(t+x)(t+y)}} = \frac{\theta t}{g(t+g)}, \qquad 1 \le \theta \le \frac{a}{g}, \tag{66}$$

$$\frac{1}{\sqrt{xy}} - \frac{1}{\sqrt{t+x}(t+y)} = \frac{\theta t}{\sqrt{x}y(t+y)}, \qquad 1 < \theta < 1 + \frac{y}{2x}, \tag{67}$$

$$\frac{1}{\sqrt{xyz}} - \frac{1}{\sqrt{(t+x)(t+y)}(t+z)} = \frac{\theta t}{gz\sqrt{(t+x)(t+y)}}, \qquad 1 < \theta < \frac{a}{g} + \frac{g}{z}. \tag{68}$$

Finally we have

$$\frac{b}{t^{3/2}(t+b)} < \frac{1}{t^{3/2}} - \frac{1}{\sqrt{(t+x)(t+y)(t+z)}} < \frac{3a}{2t^{3/2}(t+a)}, \tag{69}$$

where $a = (x+y+z)/3$ and $b = \sqrt{3(xy+xz+yz)}/2$, and

$$\frac{t}{g^{3/2}(t+g)} < \frac{1}{\sqrt{xyz}} - \frac{1}{\sqrt{(t+x)(t+y)(t+z)}} < \frac{3t}{2g^{3/2}(t+h)}, \tag{70}$$

where $g = (xyz)^{1/3}$ and $3h^{-1} = x^{-1} + y^{-1} + z^{-1}$.

To prove (60) we write

$$\frac{1}{\sqrt{t}} - \frac{1}{\sqrt{t+x}} = \frac{\sqrt{t+x} - \sqrt{t}}{\sqrt{t(t+x)}} = \frac{x}{\sqrt{t(t+x)}(\sqrt{t+x} + \sqrt{t})}$$

and replace the last denominator factor by either $2\sqrt{t}$ or $2\sqrt{t+x}$. Interchange of t and x leads from (60) to (61). To prove (62) let $y = \sqrt{1+x/t}$ and write

$$\frac{t^{3/2}(t+x)}{x}\left(\frac{1}{t^{3/2}} - \frac{1}{(t+x)^{3/2}}\right) = \frac{y^2}{y^2-1}\left(1 - \frac{1}{y^3}\right) = 1 + \frac{1}{y(y+1)},$$

which increases from 1 to 3/2 as t increases from 0 to ∞ and y decreases from ∞ to 1. Interchange of t and x leads from (62) to (63).

If the left side of (64) is put over a common denominator, it suffices to observe that

$$t + g \le \sqrt{(t+x)(t+y)} \le t + a. \tag{71}$$

The left inequality is enough to prove the left inequality in (65). To prove the right inequality in (65), we define

$$\phi(t) = \left(\sqrt{(t+x)(t+y)} - \sqrt{xy}\right)/t$$

and note that $\phi(t)$ tends to a/g as $t \to 0$ and to 1 as $t \to \infty$. Differentiation shows that ϕ decreases monotonically, because

$$t^2\sqrt{(t+x)(t+y)}\phi' = -(ta+g^2) + [(ta+g^2)^2 - t^2(a^2-g^2)]^{1/2} \le 0,$$

with equality if and only if $x = y$. Because of (71), (65) implies (66).

Equation (67) is proved by solving for θ and using (61). Likewise, (68) is proved by solving for

$$\theta = \phi(t) + \frac{t}{t+z}$$

and using the result just established that $1 \le \phi(t) \le a/g$.

To prove (69) we use Maclaurin's inequality [17, Thm. 52] to find that

$$t^3 + 2bt^2 + 4b^2t/3 < (t+x)(t+y)(t+z) \le (t+a)^3,$$

and hence

$$\sqrt{t}(t+b) < \sqrt{(t+x)(t+y)(t+z)} \le (t+a)^{3/2}. \tag{72}$$

Inequality (69) follows from this and (62).

The proof of (70) uses Maclaurin's inequality and the inequality of arithmetic and geometric means to get

$$\frac{t+g}{g} \le \left[\frac{(t+x)(t+y)(t+z)}{xyz}\right]^{1/3} = \left[\left(1+\frac{t}{x}\right)\left(1+\frac{t}{y}\right)\left(1+\frac{t}{z}\right)\right]^{1/3} \le 1+\frac{t}{h},$$

with equalities if and only if $x = y = z$, whence

$$(t+g)^{3/2} \le \sqrt{(t+x)(t+y)(t+z)} \le \left(\frac{g}{h}\right)^{3/2}(t+h)^{3/2}. \tag{73}$$

Two applications of (63) complete the proof of (70).

Acknowledgment. We thank Arthur Gautesen for suggesting the use of uniform approximations.

UNIFORM AIRY-TYPE EXPANSIONS OF INTEGRALS*

A. B. OLDE DAALHUIS† AND N. M. TEMME‡

Abstract. A new method for representing the remainder and coefficients in Airy-type expansions of integrals is given. The quantities are written in terms of Cauchy-type integrals and are natural generalizations of integral representations of Taylor coefficients and remainders of analytic functions. The new approach gives a general method for extending the domain of the saddle-point parameter to unbounded domains. As a side result the conditions under which the Airy-type asymptotic expansion has a double asymptotic property become clear. An example relating to Laguerre polynomials is worked out in detail. How to apply the method to other types of uniform expansions, for example, to an expansion with Bessel functions as approximants, is explained. In this case the domain of validity can be extended to unbounded domains and the double asymptotic property can be established as well.

Key words. uniform asymptotic expansions of integrals, Airy approximation, Bessel function, Laguerre polynomial, Bessel approximation

1. Introduction.

Many problems in mathematical physics and special functions lead to integral representations of the form

$$F(z,\alpha) = \int_{\mathcal{C}} e^{zf(x,\alpha)} g(x)\,dx, \tag{1.1}$$

where $\mathcal{C}$ is a contour in the complex plane, z is a large parameter, and f and g are analytic functions on a neighborhood of $\mathcal{C}$. In Airy-type expansions f depends on a parameter α, the *saddle-point parameter*, that describes the location of the saddle points. For a critical value of α, say, $\alpha = 0$, two saddle points coalesce with each other. With the cubic transformation $x \mapsto w$, given by

$$f(x,\alpha) = \tfrac{1}{3}w^3 - b^2 w + c \tag{1.2}$$

and suggested by Chester, Friedman, and Ursell [3], an asymptotic expansion for large values of z in terms of Airy functions can be obtained, this expansion being uniformly valid with respect to α as α ranges over a connected set containing the critical value 0 in its interior. The parameters b and c are determined explicitly from the requirement that the transformation (1.2) is analytic on a neighborhood of the two saddle points. Transformation (1.2) yields the standard form

$$\frac{1}{2\pi i}\int_{\mathcal{L}} e^{z(\frac{1}{3}w^3 - b^2 w)} h_0(w)\,dw, \tag{1.3}$$

where

$$h_0(w) = g(x(w))\frac{dx}{dw}.$$

The phase function has two saddle points at $w = \pm b$. In the transformed integral (1.3) we call b the saddle-point parameter. The integral (1.3) has a turning-point character: the behavior changes strongly when b varies from real to imaginary values. When $b = 0$, the saddle points coalesce at $w = 0$.

The method for obtaining the Airy-type expansion, based on an integration-by-parts method, is introduced for a different class of integrals in Bleistein [1]. It is described for the Airy case in Bleistein and Handelsman [2, §9.2], in Olver [10, §§9.12, 9.13], and in Wong [19, §7.5].

The purpose of the paper is to present a new method for representing the remainder (and the coefficients) in Airy-type expansions. Two new aspects with respect to the saddle-point parameter are introduced in this way.

(i) A general method is described for extending the domain of this parameter to unbounded domains, by taking into account the singularities of the integrand function (especially the distance between the singularities and the relevant saddle point). The extension is possible since the order estimates of the remainder include information on the behavior of the remainder as the saddle-point parameter tends to infinity.

(ii) The method clearly describes the condition needed for the double asymptotic property of the expansion. That is, under certain conditions, the roles of the large parameter and the saddle-point parameter may be interchanged in describing the asymptotic phenomena. For instance, our analysis shows that the Airy-type expansion of the Laguerre polynomials given in [7] does not have the double asymptotic property, although the domain of uniform validity is indeed unbounded, as is claimed in [7].

Our method is based on a new class of rational functions with which the remainders in the expansions can be represented in a manner that is analogous to the representation of the remainder in the Taylor series of an analytic function. The rational functions do not depend on the integrand function and can be used as a general tool in treating uniform Airy-type expansions. The method is mainly of theoretical interest and delivers only order estimates for the remainders. In §8 we describe a method for obtaining strict error bounds for remainders of Airy-type expansions.

Our methods are not restricted to Airy-type expansions. In §7 we consider some other types of uniform expansions. In particular, a uniform expansion in terms of Bessel functions is considered. In this case the extension of the domain can be obtained, as can the double asymptotic property.

2. Related and earlier results. Airy-type expansions occur in the asymptotic theory of differential equations, for instance in turning-point problems; see [10, chap. 11]. In this case the estimation of remainders in terms of realistic and strict error bounds is well developed. Moreover, Olver extended the domains of the large parameter and the analogue of the saddle-point parameter to large areas in the complex plane.

The situation for integrals is quite different. Although the uniform Airy-type expansions have been extensively studied, a general theory for obtaining computable strict and realistic error bounds is still missing. This problem is more difficult than that for the case of differential equations. In transforming a given integral to a standard form by means of a mapping $x \mapsto w$ as in (1.2), a mapping $\alpha \mapsto b$ is implicitly introduced. Because of these two mappings, the function $h_0(w)$ in (1.3) may be difficult to handle. In corresponding problems in differential equations only the mapping $\alpha \mapsto b$ (or a related one) has to be considered. Another point is that in the theory of differential equations several techniques for bounding the remainders exist, but these techniques cannot be translated to the treatment of remainders of expansions obtained

through integrals. An example is Olver's method that is based on bounding the remainders by using Volterra integral equations.

In [3] the analytical properties of the mapping (1.2) are considered locally around the relevant saddle points; in Friedman [8] another proof is given. Levinson [9] gives a fundamental mapping theorem that generalizes the mapping (1.2) considerably; see also [19, §7.6]. In Qu and Wong [11] an iterative method is used for proving the local analytic property of mappings that are more complicated than those defined by (1.2) (there is a pole in the neighborhood of the coalescing saddle points). The transformation (1.2) is discussed in terms of conformal mappings on unbounded domains for special cases; for instance, in Copson [4] for an integral defining the Bessel function $J_\nu(z)$, in [10] for the Anger function (a function related to the Bessel function), and in [7] for integrals defining the Laguerre polynomials.

Recent examples of the construction of strict bounds in uniform asymptotic expansions of integrals are presented in Shivakumar and Wong [12] and in Frenzen [5] for Legendre-function expansions and in Frenzen and Wong [6] for Jacobi polynomials. The expansions are not of the compound type that follows from the Bleistein method, and a restricted number of terms in the expansions are considered. Another approach is given in Ursell [17] for Legendre functions, where uniform bounds are obtained by applying the maximum-modulus theorem. Ursell's method does not give sharp computable estimates of the remainders, and extension of the bounded domain of z to an unbounded domain is indicated without proof. In Ursell [18] the Airy-type expansion is discussed by using the maximum-modulus principle for complex values of the saddle-point parameter. The possibility of extending the validity to unbounded domains is mentioned again. Earlier, in Ursell [16], the Airy-type expansion is compared with the steepest-descent expansion, giving a continuation to unbounded domains. Qualitative results are obtained for the coefficient functions and the remainders; the Bleistein sequence is not used.

In the Anger function example in [10] the region of the saddle-point parameter is extended to an unbounded real domain by giving order estimates of the remainder. Olver's technique is based on estimating remainders of Taylor series. The expansion is not of the Bleistein type but is obtained by expanding the integrand function at a saddle point inside the interval of integration. The analysis shows that the distance between singular points of the integrand function and that saddle point plays a crucial role, although the singularities are not mentioned explicitly.

In the treatment of Laguerre polynomials in [7] order estimates for the remainders are also given, and there is a claim of uniform validity with respect to the saddle-point parameter in an unbounded real domain. The claim does not follow from investigating the singularities of the integrand function. In the present paper we take into account the singularities, and we show that the claim is indeed correct.

Soni and Soni [14] give new representations of the coefficients and remainders of Airy-type expansions; these representations are based on an expansion of the integrand function in terms of a class of polynomials. The paper is a continuation of earlier papers by Soni and Sleeman [13] and Soni and Temme [15]. The coefficients and remainder are written as contour integrals of the integrand function and rational functions related with the polynomials. New order estimates of the remainder have been derived for a finite domain of the saddle-point parameter.

3. Uniform Airy-type expansion. Let

$$F(z,b) = \frac{1}{2\pi i}\int_{\mathcal{L}} e^{z(\frac{1}{3}w^3 - b^2 w)} h_0(w)\,dw, \tag{3.1}$$

where $h_0(w)$ is an analytic function on a neighborhood of $\mathcal{L}$, with $\mathcal{L}$ a suitable contour that begins at $\infty\exp(-\frac{1}{3}\pi i)$ and ends at $\infty\exp(\frac{1}{3}\pi i)$. When $b \in [0,\infty)$ we take $\mathcal{L}$ the steepest-descent contour through b, which is given by $\mathcal{L} = \{w = x + iy \in \mathbb{C} \mid y^2 = 3x^2 - 3b^2\}$ (see Fig. 3.1), such that $\operatorname{Im}(\frac{1}{3}w^3 - b^2w) = 0$ and $\frac{1}{3}w^3 - b^2w$ attains its maximum on $\mathcal{L}$ at b.

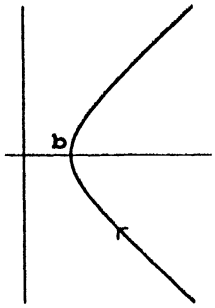

FIG. 3.1. *Steepest-descent curve $\mathcal{L}$ when $b \in [0,\infty)$.*

When $b \in [0, i\infty)$ we take $\mathcal{L} = \{w = x + iy \in \mathbb{C} \mid 3yx^2 = (y \pm ib)^2(y \mp 2ib)\}$, the steepest-descent contour through $\pm b$ (see Fig. 3.2).

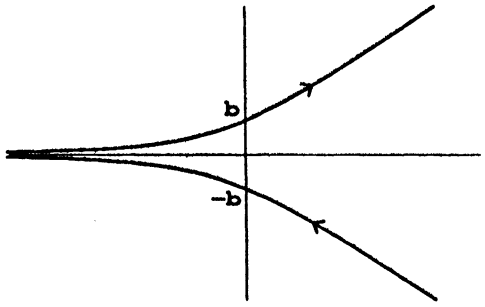

FIG. 3.2. *Steepest-descent curve $\mathcal{L}$ when $b \in [0, i\infty)$.*

It is not necessary to restrict our analysis to these contours of integration, but using these steepest-descent contours makes the following calculations less complicated.

We use Bleistein's method for obtaining an asymptotic expansion, defining $g_n(w)$, $h_{n+1}(w)$, $n = 0, 1, 2, \ldots$, by writing

$$\begin{aligned} h_n(w) &= \alpha_n + \beta_n w + (w^2 - b^2)g_n(w), \\ h_{n+1}(w) &= \frac{d}{dw}g_n(w), \end{aligned} \tag{3.2}$$

with α_n, β_n following from substitution of $w = \pm b$. If we use (3.2) in (3.1) and integrate n times by parts, we obtain

$$F(z,b) = \operatorname{Ai}(z^{2/3}b^2)\sum_{k=0}^{n-1}(-1)^k\alpha_k z^{-k-1/3} - \operatorname{Ai}'(z^{2/3}b^2)\sum_{k=0}^{n-1}(-1)^k\beta_k z^{-k-2/3} + \varepsilon_n, \tag{3.3}$$

where

$$\varepsilon_n = (-1)^n z^{-n}\frac{1}{2\pi i}\int_{\mathcal{L}} e^{z(\frac{1}{3}w^3 - b^2w)}h_n(w)dw \tag{3.4}$$

and where $\mathrm{Ai}(z)$ is the Airy function and $\mathrm{Ai}'(z)$ is its derivative. The functions $h_n(w)$ share, by inheritance, the analytic properties of h_0 on the same neighborhood of $\mathcal{L}$.

Estimates of $|\varepsilon_n|$, for large values of z and for $|b|$ bounded, given in the literature are usually of the form

$$|\varepsilon_n| \leq \frac{M_n}{z^{n+1/3}}\widetilde{\alpha}_n(b)|\widetilde{\mathrm{Ai}}(z^{2/3}b^2)| + \frac{N_n}{z^{n+2/3}}\widetilde{\beta}_n(b)|\widetilde{\mathrm{Ai}}'(z^{2/3}b^2)|, \tag{3.5}$$

where M_n and N_n depend on n and where $\widetilde{\alpha}_n$, $\widetilde{\beta}_n$ are related to the coefficients in (3.2). Furthermore,

$$\begin{aligned} \widetilde{\mathrm{Ai}}\,(u) &= \begin{cases} \mathrm{Ai}\,(u) & \text{if } u \geq 0, \\ \left[\mathrm{Ai}^2(u) + \mathrm{Bi}^2(u)\right]^{1/2} & \text{if } u < 0, \end{cases} \\ \widetilde{\mathrm{Ai}}'\,(u) &= \begin{cases} \mathrm{Ai}'(u) & \text{if } u \geq 0, \\ \left[\mathrm{Ai}'^2(u) + \mathrm{Bi}'^2(u)\right]^{1/2} & \text{if } u < 0. \end{cases} \end{aligned} \tag{3.6}$$

A proof of an estimate like (3.5) is given in [7], with

$$\widetilde{\alpha}_n(b) = \begin{cases} 1 & \text{if } 0 < b < \xi, \\ |\alpha_n| & \text{if } b > \xi, \end{cases} \qquad \widetilde{\beta}_n(b) = \begin{cases} 1 & \text{if } 0 < b < \xi, \\ |\beta_n| & \text{if } b > \xi, \end{cases}$$

where ξ is a fixed positive number.

Notice that the influence of large $|b|$ in (3.5) is not clear. We assume that the function h_0 of (3.1) depends on the saddle-point parameter b. Usually this is a consequence of the transformation to the standard form (3.1) by the mapping defined in (1.2). Also, when h_0 does not depend on b, all functions h_n obtained by recursion from (3.2) do depend on b.

For bounded $|b|$ an estimate like (3.5) holds for rather mild conditions on h_0. However, for obtaining uniformly valid estimates when b runs through an unbounded interval, we need more information on h_0. In the following sections we obtain estimates of $|h_n(w)|$ by formulating conditions on h_0 on discs with centers $\pm b$. These discs have radius $\rho(b)$, which indeed may be a function of b.

For obtaining estimates of ε_n of (3.4) holding in unbounded b-intervals, we now introduce a new class of rational functions.

4. Intermezzo: A new class of rational functions. We introduce a class of rational functions that satisfy the following theorem.

THEOREM 4.1. *Let*

$$R_0(u,w,b) = \frac{1}{u-w}, \tag{4.1.a}$$

$$R_{n+1}(u,w,b) = \frac{-1}{u^2-b^2}\frac{d}{du}R_n(u,w,b), \qquad n = 0,1,2,\ldots, \tag{4.1.b}$$

where $u,w,b \in \mathbb{C}$, $u \neq w$, $u^2 \neq b^2$. Let $h_n(w)$ be defined by the recursive scheme (3.2), *with $h_0(w)$ a given analytic function in a domain G. Then we have*

$$h_n(w) = \frac{1}{2\pi i}\int_C R_n(u,w,b)h_0(u)du, \tag{4.2}$$

where C is a simple closed contour in G that encircles the points w and $\pm b$.

Proof.

$$
\begin{aligned}
h_n(w) &= \frac{1}{2\pi i}\int_C R_0(u,w,b)h_n(u)du = \frac{1}{2\pi i}\int_C R_0(u,w,b)\frac{d}{du}g_{n-1}(u)du \\
&= \frac{1}{2\pi i}\int_C R_1(u,w,b)h_{n-1}(u)du - \frac{1}{2\pi i}\int_C R_1(u,w,b)(\alpha_{n-1}+\beta_{n-1}u)du \\
&=_* \frac{1}{2\pi i}\int_C R_1(u,w,b)h_{n-1}(u)du \\
&\vdots \\
&= \frac{1}{2\pi i}\int_C R_n(u,w,b)h_0(u)du.
\end{aligned}
$$

In * we use the fact that the rational function $R_1(u,w,b)(\alpha_{n-1}+\beta_{n-1}u)$ is $\mathcal{O}(u^{-2})$ as $|u|\to\infty$ and that all the poles of this function are inside C. Thus the integral of this function along C vanishes (use the transformation $u\mapsto u^{-1}$, which is well defined at $u=\infty$ and yields an integral with no singularities inside the contour of integration). □

COROLLARY 4.2. *Let $A_n(u,b)$, $B_n(u,b)$ be defined by the recursion in* (4.1.b), *with initial values*

$$
A_0(u,b) = \frac{u}{u^2-b^2}, \qquad B_0(u,b) = \frac{1}{u^2-b^2}. \tag{4.3}
$$

Then for $n=0,1,2,\ldots$, the coefficients α_n, β_n of (3.2) *can be written as*

$$
\alpha_n = \frac{1}{2\pi i}\int_C A_n(u,b)h_0(u)du, \qquad \beta_n = \frac{1}{2\pi i}\int_C B_n(u,b)h_0(u)du, \tag{4.4}
$$

where C is a simple closed contour in G that encircles the points $\pm b$.

We observe that the rational functions defined by (4.1) are independent of the function h_0 and that representation (4.2) can be considered as the analogue of the Cauchy integral defining the remainder of a Taylor series. An estimate of h_n, the integrand function of (3.4), will be obtained as in Cauchy's inequality for bounding the coefficients of a Taylor series.

By induction with respect to n, it follows that R_n has an expansion of the form

$$
R_n(u,w,b) = \sum_{i=0}^{n-1}\sum_{j=0}^{k_{n,i}} \frac{C_{ij}u^{i-j}}{(u-w)^{n+1-i-j}(u^2-b^2)^{n+i}}, \qquad n=1,2,\ldots, \tag{4.5}
$$

with $k_{n,i}=\min(i,n-1-i)$ and where C_{ij} do not depend on u, w, and b.

We conclude this section by giving estimates for R_n and for integrals of this function; these can be proved easily with (4.5).

(i) Let $w\in\mathbb{C}$ such that $|w-b|=\mathcal{O}(b)$ as $b\to\infty$, and let Γ be a simple closed contour that encircles b and w. Then for $n=1,2,\ldots,$

$$
\frac{1}{2\pi i}\int_\Gamma R_n(u,w,b)du = \mathcal{O}(b^{-3n}) \tag{4.6}
$$

as $b\to\infty$.

(ii) Let $b \in \mathbb{C}$ and $\Omega(b) = \{(u,w) \in \mathbb{C}^2 \mid |u-b| = \rho(b),\ |w-b| \le \frac{1}{2}\rho(b)\}$, such that $\rho(b) = \mathcal{O}(|b|^\theta)$ as $b \to \infty$, where $-\frac{1}{2} < \theta \le 1$. Then we can assign numbers A_n independent of b, such that

$$\sup_{(u,w)\in\Omega(b)} |R_n(u,w,b)| \le A_n |b|^{-(1+2\theta)n-\theta} \quad \text{as} \quad b \to \infty. \tag{4.7}$$

5. Extension of the domain of validity. In this section we prove that, under certain circumstances, expansion (3.3) holds uniformly with respect to the saddle-point parameter b in unbounded domains.

For defining the radius $\rho(b)$ of the discs mentioned at the end of §3, we first define

$$\rho_0(b) = \min\{|w \pm b| \mid w \text{ is a singularity of } h_0(w)\} \tag{5.1}$$

and we assume that, for large $|b|$, we have $\rho_0(b) \ge \delta_0 |b|^\theta$, where the constants δ_0 and θ satisfy $\delta_0 > 0$, $\theta > -\frac{1}{2}$. This is the essential assumption on $h_0(w)$ in the neighborhood of the saddle points.

Now we take $\rho(b) \le \rho_0(b)$ such that $\rho(b) \sim \delta |b|^\theta$ as $b \to \infty$, where the constant $\delta > 0$. We take $\theta \le 1$ as large as possible, and we drop the restriction $\theta \le 1$ after Theorem 5.2. Notice that we concentrate on estimates with $|b| \to \infty$ and that we do not give details for b in compacta.

Next we introduce upper bounds for the $h_n(w)$, $n = 0, 1, 2, \ldots$. Thus let

$$\widetilde{h}_n = \sup_{|w\pm b| \le (1/2)\rho(b)} |h_n(w)|. \tag{5.2}$$

Notice that $h_0(w)$ is analytic on $|w \pm b| < \rho(b)$; thus $\widetilde{h}_0$ is finite.

For obtaining estimates of $\widetilde{h}_n$ in terms of $\widetilde{h}_0$ let Γ be a circle around $\pm b$ with radius $\rho(b)$ and let $|w \mp b| \le \frac{1}{2}\rho(b)$. We require $\theta \le 1$ to ensure that both saddle points are not inside the circle Γ. This is possible by choosing δ appropriately. Then, if we use (4.6), we have

$$\begin{aligned}
h_n(w) &= \frac{1}{2\pi i}\int_\Gamma R_0(u,w,b) h_n(u)\,du \\
&= \frac{1}{2\pi i}\int_\Gamma R_1(u,w,b) h_{n-1}(u)\,du - \frac{1}{2\pi i}\int_\Gamma R_1(u,w,b)(\alpha_{n-1}+\beta_{n-1}u)\,du \\
&=_{(4.6)} \frac{1}{2\pi i}\int_\Gamma R_1(u,w,b) h_{n-1}(u)\,du + \widetilde{h}_{n-1}\mathcal{O}(b^{-3}) \\
&\ \ \vdots \\
&=_{(4.6)} \frac{1}{2\pi i}\int_\Gamma R_n(u,w,b) h_0(u)\,du + \widetilde{h}_{n-1}\mathcal{O}(b^{-3}) + \cdots + \widetilde{h}_0\mathcal{O}(b^{-3n})
\end{aligned}$$

as $b \to \infty$. So by induction and (4.7) we have proved the following theorem.

THEOREM 5.1. *Let $\widetilde{h}_n$, $n = 0, 1, 2, \ldots$, be the upper bound of $h_n(w)$, defined in* (5.2). *Then we have the estimate*

$$\widetilde{h}_n \le C_n |b|^{-(1+2\theta)n} \widetilde{h}_0 \quad \text{as} \quad b \to \infty, \tag{5.3}$$

where C_n does not depend on b.

Now we shall prove that ε_n can be bounded as follows:

$$|\varepsilon_n| \le C_n(|b|+1)^{-(1+2\theta)n}\widetilde{h}_0 z^{-n-1/3}\widetilde{\mathrm{Ai}}(z^{2/3}b^2), \tag{5.4}$$

with a slightly different C_n that does not depend on b and z.

In order to use the preceding estimates, we split up the contour $\mathcal{L}$ into $\mathcal{L}'$ and $\mathcal{L}''$. In the case that $b \in [0,\infty)$ we take $\mathcal{L}' = \{w \in \mathcal{L} \mid |w-b| \le \frac{1}{2}\rho(b)\}$, and in the case that $b \in [0,i\infty)$ we take $\mathcal{L}' = \{w \in \mathcal{L} \mid |w \pm b| \le \frac{1}{2}\rho(b)\}$. We define $\mathcal{L}'' = \mathcal{L} - \mathcal{L}'$ and introduce the corresponding integrals:

$$\begin{aligned}
\varepsilon_{n|_{\mathcal{L}'}} &= (-1)^n z^{-n}\frac{1}{2\pi i}\int_{\mathcal{L}'} e^{z(\frac{1}{3}w^3-b^2w)}h_n(w)dw,\\
\varepsilon_{n|_{\mathcal{L}''}} &= (-1)^n z^{-n}\frac{1}{2\pi i}\int_{\mathcal{L}''} e^{z(\frac{1}{3}w^3-b^2w)}h_n(w)dw.
\end{aligned} \tag{5.5}$$

In the Appendix we formulate conditions on $h_0(w)$ such that when $\theta > -\frac{1}{2}$ the estimate of $|\varepsilon_{n|_{\mathcal{L}''}}|$ is exponentially small compared with the estimate of $|\varepsilon_{n|_{\mathcal{L}'}}|$ as $z \to \infty$ uniformly with respect to b.

The proof of (5.4) for large b is divided into separate cases: (i) $b \in [0,\infty)$ and (ii) $b \in [0,i\infty)$. We first consider case (i). With (5.3) we have

$$\begin{aligned}
|\varepsilon_{n|_{\mathcal{L}'}}| &\le C_n z^{-n}|b|^{-(1+2\theta)n}\widetilde{h}_0\frac{1}{2\pi i}\int_{\mathcal{L}'} e^{z(\frac{1}{3}w^3-b^2w)}dw\\
&\le C_n z^{-n-1/3}|b|^{-(1+2\theta)n}\widetilde{h}_0\mathrm{Ai}(z^{2/3}b^2).
\end{aligned}$$

In case (ii) we write $w = x+iy$ and we define $\mathcal{L}'_+ = \{y > 0 \mid \text{there exists } x \in \mathbb{R} : x+iy \in \mathcal{L}'\}$. Simple transformations give

$$\begin{aligned}
&\frac{1}{2\pi i}\int_{\mathcal{L}'} e^{z(\frac{1}{3}w^3-b^2w)}h_n(w)dw =\\
&\quad\frac{1}{2\pi i}\int_{\mathcal{L}'_+} e^{-z(y+ib)^2f(y)}g(y)(e^{-\frac{2}{3}zb^3}h_n(w) - e^{+\frac{2}{3}zb^3}h_n(\overline{w}))dy\\
&\quad+\frac{1}{2\pi}\int_{\mathcal{L}'_+} e^{-z(y+ib)^2f(y)}(e^{-\frac{2}{3}zb^3}h_n(w) + e^{+\frac{2}{3}zb^3}h_n(\overline{w}))dy,
\end{aligned}$$

where

$$f(y) = \frac{2(2y-ib)^2}{9y}\sqrt{\frac{y-2ib}{3y}}, \qquad g(y) = \sqrt{\frac{y-2ib}{3y}} + \frac{ib(y+ib)}{3y^2}\sqrt{\frac{3y}{y-2ib}}.$$

Note that the functions have real arguments and that $g(y) \ge 0$. Thus with (5.3) we have

$$\begin{aligned}
&\left|\frac{1}{2\pi i}\int_{\mathcal{L}'} e^{z(\frac{1}{3}w^3-b^2w)}h_n(w)dw\right|\\
&\le \frac{1}{2\pi}\int_{\mathcal{L}'_+} e^{-z(y+ib)^2f(y)}(1+g(y))(|h_n(w)| + |h_n(\overline{w})|)dy\\
&\le_{(5.3)} C_n|b|^{-(1+2\theta)n}\widetilde{h}_0\frac{1}{\pi}\int_0^\infty e^{-z(y+ib)^2f(y)}(1+g(y))dy\\
&\le C'_n|b|^{-(1+2\theta)n}\widetilde{h}_0\frac{1}{\sqrt{zb/i}}\\
&\sim_* \pi^{1/2}C'_n|b|^{-(1+2\theta)n}\widetilde{h}_0 z^{-1/3}\widetilde{\mathrm{Ai}}(z^{2/3}b^2),
\end{aligned}$$

as $z \to \infty$. In * we have used the relation $\widetilde{\mathrm{Ai}}(x) \sim \pi^{-1/2}(-x)^{-1/4}$ as $x \to -\infty$; see [10, p. 395].

In the Appendix we prove that

$$|\varepsilon_{n|_{\mathcal{L}''}}| \leq C_n e^{-\lambda(z-\mu)|b|^{2\theta+1}} \widetilde{h}_0 z^{-n-4/3} \widetilde{\mathrm{Ai}}(z^{2/3}b^2), \tag{5.6}$$

where the positive C_n, λ, and μ do not depend on b and z and where $|b| \geq c > 0$. These estimates show that (5.4) is valid. Thus we have proved the following theorem.

THEOREM 5.2. *Let $F(z,b)$ be of the form (3.1), where $h_0(w)$ satisfies the conditions mentioned in the beginning of this section and in the Appendix. Then we have (3.3) as a uniform asymptotic expansion for $F(z,b)$, where (5.4) is an estimate for $|\varepsilon_n|$ as $z \to \infty$ uniformly with respect to $b \in [0,\infty) \cup [0, i\infty)$ and where $\widetilde{h}_0$ is given in (5.2).*

Now we drop the restriction $\theta \leq 1$. In the case that $\theta > 1$, the analysis that leads to Theorem 5.2 is much easier; every time $1 + 2\theta$ occurs it can be replaced with the larger factor 3θ.

Remark 1. With the conditions of Theorem 5.2 it follows that expansion (3.3) has a double asymptotic property: the roles of b and z can be interchanged. The double asymptotic property is lost in the example considered in §6.

Remark 2. An estimate like (5.4) has been derived in [10, p. 360] for a particular example. There the estimate for the remainder of an expansion of the Anger function $\mathrm{A}_{-\nu}(\nu \operatorname{sech} \alpha)$ reads

$$\varepsilon_n(\alpha,\nu) = (1+\xi)^{-\theta(n+1)} \nu^{-\frac{1}{3}(n+1)} \mathrm{Qi}_n(\nu^{\frac{2}{3}}\xi) \mathcal{O}(1),$$

where $\mathrm{Qi}_n(z)$ is a special function, $\frac{2}{3}\xi^{3/2} = \alpha - \tanh\alpha$, and $\theta = -\frac{1}{4}$. This estimate holds as $\nu \to \infty$ uniformly with respect to $\alpha \in [0,\infty)$ or $\xi \in [0,\infty)$. Indeed, the value $\theta = -\frac{1}{4}$ is related to the distance between the relevant saddle point and the nearest singularities of the integrand function, which is of order $\xi^{-1/4}$ as $\xi \to \infty$.

6. Laguerre polynomials: A boundary case. In this section we show that, in certain circumstances, the condition $\theta > -\frac{1}{2}$ of Theorem 5.2 can be replaced with $\theta = -\frac{1}{2}$. We demonstrate this feature by considering a recent expansion for the Laguerre polynomials.

First we summarize the main steps for obtaining an Airy-type expansion of the Laguerre polynomials. More details are given in [7] and [19]. Laguerre polynomials have the following integral representation:

$$(-1)^N 2^\alpha e^{-zt/2} L_N^{(\alpha)}(zt) = \frac{1}{2\pi i} \int_{+\infty}^{(1+)} e^{zf(x,t)} (1-x^2)^{\frac{\alpha-1}{2}} dx, \tag{6.1}$$

where the contour of integration begins and ends at $+\infty$ and encircles 1 in the positive direction and where

$$f(x,t) = \frac{1}{4}\ln\left(\frac{1+x}{1-x}\right) - \frac{1}{2}xt \tag{6.2}$$

and $z = 4N + 2\alpha + 2$, $\alpha > -1$, and $t \geq 1$. Again, we use the transformation

$$f(x,t) = \tfrac{1}{3}w^3 - b^2 w. \tag{6.3}$$

The x-saddle points $\pm\sqrt{1-1/t}$ should correspond with $\pm b$. It follows that

$$b^3 = \tfrac{3}{4}\left(\sqrt{t^2-t} - \operatorname{arccosh}\sqrt{t}\right). \tag{6.4}$$

With transformation (6.3) we have for (6.1)

$$(-1)^N 2^\alpha e^{-zt/2} L_N^{(\alpha)}(zt) = \frac{1}{2\pi i}\int_{\mathcal{L}} e^{z(\frac{1}{3}w^3 - b^2 w)} h_0(w)\,dw, \tag{6.5}$$

where

$$h_0(w) = (1-x^2)^{\frac{\alpha-1}{2}}\frac{dx}{dw} = 2\frac{(1-x^2)^{\frac{\alpha+1}{2}}(w^2-b^2)}{1-t(1-x^2)} \tag{6.6}$$

and $\mathcal{L}$ is given in Fig. 3.1. Again, using (3.2) in (6.5), we obtain

$$\begin{aligned}(-1)^N 2^\alpha e^{-zt/2} L_N^{(\alpha)}(zt) = {}& \operatorname{Ai}(z^{2/3}b^2)\sum_{k=0}^{n-1}(-1)^k \alpha_k z^{-k-1/3} \\ & - \operatorname{Ai}'(z^{2/3}b^2)\sum_{k=0}^{n-1}(-1)^k \beta_k z^{-k-2/3} + \varepsilon_n,\end{aligned} \tag{6.7}$$

where ε_n is as in (3.4).

To apply the analysis of §5, we locate the relevant singular points of $h_0(w)$. Let $x_0 = \sqrt{1-1/t}$ be the positive x-saddle point when $t > 1$. The point x_0 is mapped to $w(x_0) = b$ by the mapping given in (6.3), when the logarithmic function takes its principal value. However, the points x_0 at other sheets of the Riemann surface of the log function are singular points of the mapping (6.3). Then the phase of $1 - x_0$ is, for instance, 2π. When $b = 0$ the singularities $w = S_\pm$ nearest to b satisfy $\frac{1}{3}S_\pm^3 = \pm\frac{1}{2}\pi i$, whereas

$$S_\pm \sim b \pm \sqrt{\frac{\pi i}{2b}} \quad \text{as} \quad b \to \infty. \tag{6.8}$$

Thus $\rho_0(b)$ of (5.1) is of order $b^{-1/2}$ as $b \to \infty$.

As before, we want to split up $\mathcal{L}$ into $\mathcal{L}'$ and $\mathcal{L}''$, and define $\varepsilon_{n|_{\mathcal{L}'}}$, $\varepsilon_{n|_{\mathcal{L}''}}$ similar to (5.5). So define $\mathcal{L}' = \{w \in \mathcal{L} \mid |w-b| \le \delta b^\theta\}$, where the constants δ and θ satisfy $\delta > 0$ and $-\frac{1}{2} < \theta \le 1$, in order that the estimate of $|\varepsilon_{n|_{\mathcal{L}''}}|$ is exponentially small compared with the estimate of $|\varepsilon_{n|_{\mathcal{L}'}}|$ as $z \to \infty$ uniformly with respect to b. We choose θ close to $-\frac{1}{2}$ fixed.

Let Γ_θ be a closed contour which encircles $\mathcal{L}'$ such that

$$\text{length } \Gamma_\theta = \mathcal{O}(b^\theta), \quad \text{distance}(\Gamma_\theta, \mathcal{L}') \sim cb^{-1/2} \quad \text{as} \quad b \to \infty$$

and such that $h_0(w)$ is analytic on $\overline{I(\Gamma_\theta)}$, where $\overline{I(\Gamma_\theta)}$ is the closure of the interior of Γ_θ. Then straightforward calculations give that

$$\sup_{w \in \overline{I(\Gamma_\theta)}} |h_0(w)| \le C_0 b^{(\theta+\frac{1}{2})\alpha}|h_0(b)| \quad \text{as} \quad b \to \infty, \tag{6.9}$$

where C_0 does not depend on b. Further calculations, similar to those in §5 yield, for $n = 1, 2, \ldots$,

$$\sup_{w \in \overline{I(\Gamma_\theta)}} |h_n(w)| \leq C_n b^{(\theta+\frac{1}{2})(\alpha+1)} |h_0(b)| \quad \text{as} \quad b \to \infty, \tag{6.10}$$

where, here and below, C_n denotes a generic quantity that does not depend on b and z. Notice that, in contrast to (5.3), the power of b is positive and does not depend on n. These estimates yield

$$|\varepsilon_{n|_{\mathcal{L}'}}| \leq C_n z^{-n-1/3} b^{(\theta-1)\alpha+(\theta-\frac{1}{2})} \mathrm{Ai}(z^{2/3} b^2). \tag{6.11}$$

In (6.11) we used

$$h_0(b) = t^{\frac{(1-\alpha)}{2}} \frac{\sqrt{2b}}{(t-1)^{1/4} t^{3/4}}.$$

In the Appendix we prove that

$$|\varepsilon_{n|_{\mathcal{L}''}}| \leq C_n' z^{-n-4/3} e^{-\lambda(z-2)b^{2\theta+1}} |h_0(b)| \mathrm{Ai}(z^{2/3} b^2), \tag{6.12}$$

where the positive C_n' and λ do not depend on b and z. It follows that we can assign numbers C_n, independent of z and b, such that

$$|\varepsilon_n| \leq C_n z^{-n-1/3} (b+1)^{(\theta-1)\alpha+(\theta-\frac{1}{2})} \mathrm{Ai}(z^{2/3} b^2), \tag{6.13}$$

as $z \to \infty$ uniformly with respect to $b \in [0, \infty)$. A similar approach can be used for $b \in [0, i\tau]$, where $0 < \tau < (\frac{3}{8}\pi)^{1/3}$, τ fixed.

We can compare this estimate with the estimate given in [7] and [19], which is of the form (3.5). First, we notice that (6.13) is not in the form of the first neglected terms of expansion (6.7). But with (6.10) it easily follows that the first neglected terms can be estimated by the right-hand side of (6.13). Regardless, (6.13) clearly shows why expansion (6.7) holds uniformly with respect to b in an unbounded domain. Secondly, in (6.13) the influence of b is more transparent than in the right-hand side of (3.5).

7. Other uniform expansions generated by the Bleistein method. In this section we show that the methods used for the Airy-type expansions are quite general and can be applied to other uniform expansions of integrals of the form

$$\int_C e^{zf(x,b)} h_0(x) dx \tag{7.1}$$

with coinciding saddle points and singularities. In this section we work out an example of uniform expansions in terms of Bessel functions. In [7] such an expansion of the Laguerre polynomials is given. Let

$$F(z, A) = \frac{1}{2\pi i} \int_{-\infty}^{(0+)} w^{-\alpha-1} h_0(w) e^{\frac{1}{2}z(w-A^2/w)} dw, \tag{7.2}$$

where the contour of integration begins and ends at $-\infty$ and encircles the origin in the positive direction. We assume that $h_0(w)$ is analytic on a neighborhood of the contour of integration, and we let $z > 0$, $iA > 0$, and $\alpha > -1$. Notice that $\pm iA$ are

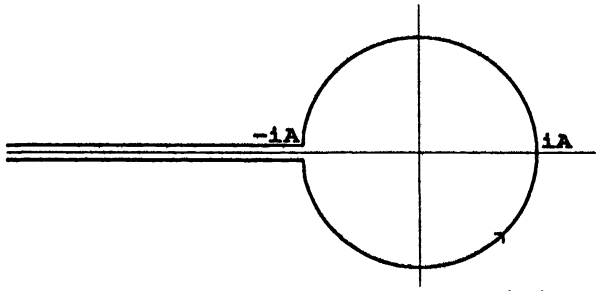

FIG. 7.1. *Steepest-descent curve for integral* (7.2).

the saddle points of the integral. We choose the contour of integration through these saddle points, and the steepest-descent path looks like Fig. 7.1.

The recursion in connection with integral (7.2) is

(7.3)
$$h_n(w) = \alpha_n + \frac{\beta_n}{w} + \left(1 + \frac{A^2}{w^2}\right) g_n(w), \qquad h_{n+1}(w) = w^{\alpha+1} \frac{d}{dw} \left[w^{-\alpha-1} g_n(w)\right],$$

and if we integrate n times by parts, we obtain the expansion

$$F(z, A) = \frac{J_\alpha(zA)}{A^\alpha} \sum_{k=0}^{n-1} (-1)^k \alpha_k \left(\frac{2}{z}\right)^k + \frac{J_{\alpha+1}(zA)}{A^{\alpha+1}} \sum_{k=0}^{n-1} (-1)^k \beta_k \left(\frac{2}{z}\right)^k + \varepsilon_n, \tag{7.4}$$

where

$$\varepsilon_n = (-1)^n \left(\frac{2}{z}\right)^n \frac{1}{2\pi i} \int_{-\infty}^{(0+)} w^{-\alpha-1} h_n(w) e^{\frac{1}{2} z(w - A^2/w)} dw \tag{7.5}$$

and where $J_\alpha(z)$ and $J_{\alpha+1}(z)$ are Bessel functions of the first kind. Since zA is purely imaginary, modified Bessel functions occur in the expansion.

The class of rational functions generated by (7.3) is recursively defined by

$$\begin{aligned} Q_0(u, w, A) &= \frac{1}{u - w}, \\ Q_{n+1}(u, w, A) &= \frac{-1}{1 + A^2/u^2} \left(\frac{\alpha + 1}{u} + \frac{d}{du}\right) Q_n, \qquad n = 0, 1, 2, \ldots. \end{aligned} \tag{7.6}$$

By induction with respect to n it follows that Q_n has an expansion of the form

$$Q_n(u, w, A) = \sum_{i=0}^{n-1} \sum_{j=0}^{n-i} \frac{C_{ij} (A^2/u^2)^i}{(u - w)^{n+1-i-j} u^{i+j} (1 + A^2/u^2)^{n+i}}, \qquad n = 1, 2, \ldots, \tag{7.7}$$

where the C_{ij} do not depend on u, w, and A.

Again, we concentrate on the influence of A on the expansion (7.4), especially when $|A|$ is large.

If Γ is a simple closed contour that encircles iA and w and with $-iA$ in its exterior, then we can prove, just as for (4.6), that

$$\frac{1}{2\pi i} \int_\Gamma Q_n(u, w, A) du = \mathcal{O}(|A|^{-n}) \quad \text{as} \quad |A| \to \infty. \tag{7.8}$$

As before, we want to split up $\mathcal{L}$ into $\mathcal{L}'$ and $\mathcal{L}''$. We assume that, for large $|A|$, the distance from the singularities of $h_0(w)$ to the saddle points $\pm iA$ is at least $\delta|A|^\theta$, where the constants δ, θ satisfy $\delta > 0$, $\frac{1}{2} < \theta \leq 1$. Consequently, we take $\mathcal{L}' = \{w \in \mathcal{L} \mid |w - iA| \leq \frac{1}{2}\delta|A|^\theta\}$ and $\mathcal{L}'' = \mathcal{L} - \mathcal{L}'$ such that the estimate of $|\varepsilon_{n|_{\mathcal{L}''}}|$ is exponentially small compared with the estimate of $|\varepsilon_{n|_{\mathcal{L}'}}|$ as $z \to \infty$ uniformly with respect to $iA \in [c, \infty)$, where $c > 0$ fixed. In fact, we need a growth condition on $h_0(w)$ on a prescribed neighborhood of $\mathcal{L}''$, which is similar to the condition mentioned in the Appendix.

If we set $\Omega(A) = \{(u, w) \in \mathbb{C}^2 \mid |u - iA| = \frac{3}{4}\delta|A|^\theta,\ |w - iA| \leq \frac{1}{2}\delta|A|^\theta\}$, we can prove

$$\sup_{(u,w)\in\Omega(A)} |Q_n(u, w, A)| \leq C_n|A|^{(1-2\theta)n-\theta}, \tag{7.9}$$

where C_n does not depend on A. Finally, we define

$$\widetilde{h}_0 = \sup_{|w\pm iA|\leq(1/2)\delta|A|^\theta} |h_0(w)|. \tag{7.10}$$

With (7.8), (7.9), and straightforward calculations similar to those leading to (5.3), we obtain, for $n = 1, 2, \ldots$,

$$\sup_{|w-iA|\leq(1/2)\delta|A|^\theta} |h_n(w)| \leq C_n|A|^{(1-2\theta)n}\widetilde{h}_0 \quad \text{as} \quad |A| \to \infty, \tag{7.11}$$

where C_n does not depend on A. With the aid of these estimates we obtain as the main result of this section

$$|\varepsilon_n| \leq C_n(|A| + 1)^{(1-2\theta)n-\alpha}\widetilde{h}_0 z^{-n}|J_\alpha(zA)| \tag{7.12}$$

as $z \to \infty$ uniformly with respect to $iA \in [0, \infty)$, where C_n does not depend on A and z.

In the case that $\theta > 1$ we can use the same analysis that leads to (7.12), but every time $1 - 2\theta$ occurs it has to be replaced with $-\theta$.

A similar approach is possible for real values of A.

8. Strict upper bounds of the remainder. In this section we assume that we have quantitative information on the functions $h_n(w)$ and that we can construct upper bounds for the remainders ε_n of (3.4). The simplest case is that we know that $|h_n(w)|$ is bounded on $\mathcal{L}$. If $b \geq 0$, an upper bound for ε_n can be easily expressed in terms of this bound and of the Airy function $\mathrm{Ai}(z^{2/3}b^2)$. When $b^2 < 0$ (the oscillatory case), the bound can be expressed in terms of the modulus function $\left[\mathrm{Ai}^2(z^{2/3}b^2) + \mathrm{Bi}^2(z^{2/3}b^2)\right]^{1/2}$ (see also (3.6)).

When the maximal value of $|h_n(w)|$ occurs at $w = w_0$, with w_0 far away from the saddle point $w = b$, the upper bound obtained in this way may be quite inaccurate. The fact is that the main contributions to the integral (3.4) come from a small neighborhood of b, especially when z is large. To obtain realistic upper bounds of $|\varepsilon_n|$ we describe a different approach in which we also allow unbounded functions $h_n(w)$. We concentrate on the case $b \geq 0$.

The contour $\mathcal{L}$ can be parameterized by writing $w = x + iy$, $3x^2 - y^2 = 3b^2$. By using this and integrating with respect to y, the integral (3.1) can be written in the form

$$\varepsilon_n = (-1)^n z^{-n} \frac{e^{-\frac{2}{3}zb^3}}{2\pi i} \int_{-\infty}^{\infty} e^{-z\phi(y)} H_n(y)\, dy, \tag{8.1}$$

where

$$\phi(y) = (\tfrac{8}{9}y^2 + \tfrac{2}{3}b^2)\sqrt{\tfrac{1}{3}y^2 + b^2} - \tfrac{2}{3}b^3, \qquad H_n(y) = h_n(x+iy)\left[\tfrac{dx}{dy} + i\right],$$

and

$$\frac{dx}{dy} = \frac{\frac{1}{3}y}{\sqrt{\frac{1}{3}y^2 + b^2}}.$$

When $h_0 = 1$ and $n = 0$ we obtain the real representation for the Airy function:

$$\mathrm{Ai}(z^{\frac{2}{3}}b^2) = \frac{z^{\frac{1}{3}}e^{-\frac{2}{3}zb^3}}{2\pi}\int_{-\infty}^{\infty} e^{-z\phi(y)}\,dy. \tag{8.2}$$

To bound ε_n we assume that for fixed b the function $H_n(y)$ is majorized by

$$|H_n(y)| \le M_n e^{\sigma_n \phi(y)}, \qquad -\infty < y < \infty, \tag{8.3}$$

where M_n and σ_n are nonnegative numbers that may depend on b. Observe that, in fact, only the even part of the function $H_n(y)$ needs to be bounded in this way; when $h_n(w)$ is a real function, the even part of $H_n(y)$ equals the imaginary part. The best strategy is to start with M_n and to define it slightly larger than $|H_n(0)| = |h_n(b)|$ (when this quantity vanishes a minor modification is needed), say, $M_n = 1.25|h_n(b)|$. Next we determine the smallest number σ_n that satisfies the upper bound in (8.3). When $|h_n(w)|$ is bounded on $\mathcal{L}$ and assumes its maximal value on $\mathcal{L}$ at $w = w_0 = x_0 + iy_0$, one may take $M_n = |H_n(y_0)|$ and $\sigma_n = 0$. However, as mentioned previously, when y_0 is not close to zero, the resulting bound may be unrealistic. When $\sigma_n > 0$, the argument of the exponential function in the right-hand side of (8.3) is unbounded; thus we accept unbounded functions $|h_n(w)|$. Observe that far away from the origin the estimate (8.3) may be very rough, but there the contribution to the integral (8.1) is negligible, especially when z is large.

Using (8.3) in (8.1) (when $z > \sigma_n$), we obtain with (8.2) the estimate

$$|\varepsilon_n| \le M_n z^{-n}(z-\sigma_n)^{-\frac{1}{3}}\,\mathrm{Ai}\left((z-\sigma_n)^{\frac{2}{3}}b^2\right)e^{-\frac{2}{3}b^3\sigma_n}, \qquad z > \sigma_n, \quad b \ge 0. \tag{8.4}$$

The factor M_n contains the information on the parameter b; especially, it contains the information on whether or not the expansion holds uniformly on unbounded b-domains and has the double asymptotic property.

This bound is computable when the function $h_n(w), w \in \mathcal{L}$ is computable. Representation (4.2) may be helpful in computing $h_n(w)$. We expect that the bound in (8.4) is realistic for a wide class of functions $h_0(w)$.

When the function $h_n(w)$ grows too fast with b, the number σ_n may be an unbounded function of b. In that case the bound in (8.4) loses its uniform character. For example, when $h_0(w) = \exp(-w^2b^2)$ it is easily verified that the minimal value of σ_0 that satisfies (8.3) is $\sigma_0 = (2/243)b$.

When $b \in [0, i\infty)$ a similar approach is possible by majorizing the function $h_n(w)$ on the contour of Fig. 3.2. The analysis and the resulting bounds are slightly more complicated. Details will not be given.

9. An example. We consider the function

$$F(z,b) = \frac{1}{2\pi i}\int_{\mathcal{L}} e^{z(\frac{1}{3}w^3 - b^2w)}\frac{1}{w-b-1}dw, \tag{9.1}$$

where $b \in [0, \infty)$ and $\mathcal{L}$ is the steepest-descent contour shown in Fig. 3.1. $F(z,b)$ can be written as an integral of the Airy function, that is,

$$F(z,b) = e^{(b+1)\zeta}\left[-e^{\frac{1}{3}z(b+1)^3} + z^{-\frac{1}{3}}\int_{\zeta}^{\infty} e^{(b+1)t}\mathrm{Ai}(tz^{-\frac{1}{3}})\,dt\right], \qquad \zeta = zb^2.$$

In this example we have $h_0(w,b) = 1/(w-b-1)$. Thus the quantities introduced in (5.1) and (5.2) are as follows: $\rho_0(b) = 1$, $\theta = 0$, and $\widetilde{h}_0 = 2$. It is easily verified that

$$h_1(w) = \frac{-1}{(2b+1)(w-b-1)^2}, \qquad h_1(b) = \frac{-1}{2b+1},$$
$$h_2(w) = 2\frac{b^2+4b+2-(b+1)w}{(2b+1)^3(w-b-1)^3}, \qquad h_2(b) = -2\frac{3b+2}{(2b+1)^3}.$$

Further calculations show that

$$\begin{aligned} F(z,b) &= \mathrm{Ai}(z^{2/3}b^2)\alpha_0 z^{-1/3} - \mathrm{Ai}'(z^{2/3}b^2)\beta_0 z^{-2/3} + \varepsilon_1 \\ &= \mathrm{Ai}(z^{2/3}b^2)\left(\alpha_0 - \frac{\alpha_1}{z}\right)z^{-1/3} - \mathrm{Ai}'(z^{2/3}b^2)\left(\beta_0 - \frac{\beta_1}{z}\right)z^{-2/3} + \varepsilon_2, \end{aligned} \tag{9.2}$$

with

$$\begin{aligned} \alpha_0 &= -\frac{b+1}{2b+1}, & \beta_0 &= -\frac{1}{2b+1}, \\ \alpha_1 &= -\frac{2b^2+2b+1}{(2b+1)^3}, & \beta_1 &= -2\frac{b^2+b}{(2b+1)^3}, \\ \alpha_2 &= -4\frac{3b^3+5b^2+3b+1}{(2b+1)^5}, & \beta_2 &= -2\frac{6b^2+10b+5}{(2b+1)^5}. \end{aligned} \tag{9.3}$$

We can determine the numbers M_n, σ_n occurring in (8.3), but already for this simple example optimal values have to be computed numerically. Analytical bounds of $\operatorname{Im} H_n(y)$ are easily obtained, however. For example, we have (recall that $x = \sqrt{(1/3)y^2 + b^2}$)

$$\operatorname{Im} H_0(y) = \operatorname{Im}\left[\left(i + \frac{dx}{dy}\right)\frac{1}{x+iy-b-1}\right] = \frac{b^2-(b+1)x}{x[(x-b-1)^2+3x^2-3b^2]}, \qquad x \geq b$$

(changing to x gives better formulas). When $b \geq \frac{1}{2}$ we have $|\operatorname{Im} H_0(y)| \leq |h_0(b)|$; when $b \in [0, \frac{1}{2})$ the maximal value of $|\operatorname{Im} H_0(y)|$ is slightly larger than $|h_0(b)|$. Similar results hold for $n = 1, 2$, where the critical b-values are $b = \frac{1}{3}, b = (\sqrt{7}-1)/6 = 0.27$, respectively. It follows that in this example the remainders can be estimated in terms of the first neglected terms of the asymptotic expansion (note that $h_n(b) = \alpha_n + b\beta_n$):

$$\begin{aligned} |\varepsilon_1| &\leq |h_1(b)|z^{-4/3}\mathrm{Ai}(z^{2/3}b^2), & b &\geq \tfrac{1}{3}, \\ |\varepsilon_2| &\leq |h_2(b)|z^{-7/3}\mathrm{Ai}(z^{2/3}b^2), & b &\geq \tfrac{\sqrt{7}-1}{6}. \end{aligned} \tag{9.4}$$

These estimates may be compared with the order estimates (5.4) obtained from less qualitative information on the functions $h_n(w)$.

Appendix. We formulate conditions on $h_0(w)$ such that the estimate of $|\varepsilon_{n|_{\mathcal{L}''}}|$ is exponentially small compared with the estimate of $|\varepsilon_{n|_{\mathcal{L}'}}|$ as $z \to \infty$ uniformly with respect to b. We take $\mathcal{L}$, $\mathcal{L}'$, $\mathcal{L}''$, $\rho(b)$, δ, θ, $\varepsilon_{n|_{\mathcal{L}'}}$, $\varepsilon_{n|_{\mathcal{L}''}}$, and $\widetilde{h}_n$ as in §5. Define

$$\mathcal{R}(w,b,p,q,r) = r|w^{-q}e^{p(\frac{1}{3}w^3 - b^2w + \frac{2}{3}b^3)}|.$$

We assume that $h_0(w)$ is an analytic function on a neighborhood $\Omega_0(b)$ of $\mathcal{L}''$, such that for every $w \in \mathcal{L}''$ a disc with center w and radius $\mathcal{R}$ is contained in $\Omega_0(b)$, where $r > 0$ and $p,\ q \geq 0$ do not depend on b and w. Note that, since $w \in \mathcal{L}''$, $\mathcal{R}$ may be exponentially small as $|w| \to \infty$. Furthermore, we assume that there are constants $\sigma \geq 0$ and $C_0 > 0$ such that

$$|h_0(w)| \leq C_0 \widetilde{h}_0 |e^{-\sigma(\frac{1}{3}w^3 - b^2 w + \frac{2}{3}b^3)}| \quad \forall w \in \Omega_0(b) \cup \mathcal{L},\ b \in [0, \infty). \tag{A.1}$$

Thus we allow functions $h_0(w)$ to be exponentially large as $|w| \to \infty$.

We define recursively neighborhoods $\Omega_n(b)$ of $\mathcal{L}''$ for $n = 0, 1, 2, \ldots$. Let $\Omega_{n+1}(b)$ be those $w \in \Omega_n(b)$ such that the disc with center w and radius $2^{-(n+1)}\mathcal{R}$ is contained in $\Omega_n(b)$.

Next, let $w \in \Omega_n(b)$ and let Γ be the circle with center w and radius $2^{-n}\mathcal{R}$. The following two weak asymptotic estimates are simply proved with (4.5):

$$\frac{1}{2\pi i}\int_\Gamma R_n(u, w, b) u^m du = \mathcal{O}(|e^{-\frac{1}{3}w^3 + b^2 w - \frac{2}{3}b^3}|), \tag{A.2}$$

$$\sup_{u \in \Gamma} |R_n(u, w, b)| = \mathcal{O}(|e^{-((n+1)p + \frac{1}{2})(\frac{1}{3}w^3 - b^2 w + \frac{2}{3}b^3)}|) \tag{A.3}$$

as $|b| \to \infty$ uniformly with respect to $w \in \Omega_n(b)$ and $m \in \{0, 1\}$.

Now we can estimate $h_n(w)$ on $\Omega_n(b)$.

$$\begin{aligned}
h_n(w) &= \frac{1}{2\pi i}\int_\Gamma R_0(u, w, b) h_n(u) du \\
&= \frac{1}{2\pi i}\int_\Gamma R_1(u, w, b) h_{n-1}(u) du - \frac{1}{2\pi i}\int_\Gamma R_1(u, w, b)(\alpha_{n-1} + \beta_{n-1} u) du \\
&=_{\text{(A.2)}} \frac{1}{2\pi i}\int_\Gamma R_1(u, w, b) h_{n-1}(u) du + \widetilde{h}_{n-1}\mathcal{O}(|e^{-\frac{1}{3}w^3 + b^2 w - \frac{2}{3}b^3}|) \\
&\ \ \vdots \\
&=_{\text{(A.2)}} \frac{1}{2\pi i}\int_\Gamma R_n(u, w, b) h_0(u) du + (\widetilde{h}_{n-1} + \cdots + \widetilde{h}_0)\mathcal{O}(|e^{-\frac{1}{3}w^3 + b^2 w - \frac{2}{3}b^3}|) \\
&=_{\text{(A.3) \& (5.3)}} \widetilde{h}_0 \mathcal{O}(|e^{-(np+1+\sigma)(\frac{1}{3}w^3 - b^2 w + \frac{2}{3}b^3)}|).
\end{aligned}$$

Thus with (5.3) we have proved that

$$|h_n(w)| \leq C_n \widetilde{h}_0 |e^{-(np+1+\sigma)(\frac{1}{3}w^3 - b^2 w + \frac{2}{3}b^3)}| \tag{A.4}$$

for all $w \in \Omega_n(b) \cup \mathcal{L}$ and $b \in [0, \infty) \cup [0, i\infty)$.

For $b \geq c > 0$ it is not difficult to prove that $\mathcal{L}'' = \{\sqrt{(1/3)y^2 + b^2} + iy \,|\, |y| \geq \delta' b^\theta\}$ for a certain positive δ' that does not depend on b. With the notation of §8 we have

$$\varepsilon_{n|\mathcal{L}''} = (-1)^n z^{-n} \frac{e^{-\frac{2}{3}zb^3}}{2\pi i}\int_{\delta' b^\theta}^\infty e^{-z\phi(y)}\big[H_n(y) + H_n(-y)\big]\, dy.$$

We choose $z > np + 2 + \sigma$ and estimate $|\varepsilon_{n|\mathcal{L}''}|$:

$$\begin{aligned}
|\varepsilon_{n|\mathcal{L}''}| &\leq_{(A.4)} C_n'\widetilde{h}_0 e^{-\frac{2}{3}zb^3} z^{-n} \int_{\delta' b^\theta}^{\infty} e^{-(z-np-1-\sigma)\phi(y)}\, dy \\
&\leq C_n'\widetilde{h}_0 e^{-\frac{2}{3}zb^3} z^{-n} \int_{\delta' b^\theta}^{\infty} e^{-(z-np-1-\sigma)by^2}\, dy \\
&\leq C_n'\widetilde{h}_0 e^{-\frac{2}{3}zb^3} z^{-n} \frac{e^{-\delta'^2(z-np-1-\sigma)b^{2\theta+1}}}{2\delta' b^{\theta+1}(z-np-1-\sigma)} \\
&\leq C_n''\widetilde{h}_0\, \mathrm{Ai}(z^{\frac{2}{3}}b^2) z^{-n-\frac{4}{3}} e^{-\delta'^2(z-np-2-\sigma)b^{2\theta+1}}.
\end{aligned}$$

With similar estimates for $b \in [ic, i\infty)$ we have proved

$$|\varepsilon_{n|\mathcal{L}''}| \leq C_n\widetilde{h}_0\, \widetilde{\mathrm{Ai}}(z^{\frac{2}{3}}b^2) z^{-n-\frac{4}{3}} e^{-\delta'^2(z-np-2-\sigma)|b|^{2\theta+1}}, \tag{A.5}$$

where the constants δ' and C_n do not depend on b and z.

Remark. For the boundary case that has been handled in §6 it is not difficult to prove that $p = \sigma = 0$, and (6.10) shows that in (A.4) $\widetilde{h}_0$ can be replaced by $(b+1)^{(\theta+1/2)(\alpha+1)}|h_0(b)|$, and further calculations show that in (A.5) $\widetilde{h}_0$ can be replaced by $|h_0(b)|$.

Acknowledgment. We appreciate the remarks and suggestions of the referees regarding earlier versions of the paper.

UNIFORM ASYMPTOTIC SOLUTIONS OF SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS HAVING A SIMPLE POLE AND A COALESCING TURNING POINT IN THE COMPLEX PLANE*

T. M. DUNSTER†

Abstract. The asymptotic behavior, as a parameter $u \to \infty$, of solutions of second-order linear differential equations having a simple pole and a coalescing turning point is considered. Uniform asymptotic approximations are constructed in terms of Whittaker's confluent hypergeometric functions, which are uniformly valid in a complex domain that includes both the pole and the turning point. Explicit error bounds for the difference between the approximations and the exact solutions are established. These results extend previous real-variable results of F. W. J. Olver and J. J. Nestor to the complex plane.

Key words. turning point theory, differential equations in the complex plane

AMS subject classifications. 34E20, 34A20, 30E10

1. Introduction. In this paper we seek asymptotic solutions, as $u \to \infty$, of second-order linear differential equations of the form

$$\frac{d^2w}{dz^2} = \{u^2 f(a,z) + g(a,z)\}\, w, \tag{1.1}$$

where u and a are real parameters and the independent variable z lies in some complex domain $\mathbf{D}$ (which may be unbounded). The particular case we shall consider is where $f(a,z)$ has a simple zero located on the nonnegative real z-axis at $z = z_t(a)$, with $f(a,z)$ having no other zeros in $\mathbf{D}$. We assume that $(z - z_t(a))^{-1} f(a,z)$ is either real and negative on the positive real axis (we shall call this case I) or real and positive on the positive real axis (case II). These two cases are considered separately in §§2 and 4, respectively.

The position $z = z_t(a)$ of the turning point of the equation is assumed to be a continuous real function of a, which tends to $z = 0$ as a approaches a critical value, say, a_0 . At the point $z = 0$ we assume that $f(a,z)$ has a simple pole, except in the critical case $a = a_0$ when the turning point coalesces with the pole. By an appropriate scaling, we may assume without loss of generality that $a_0 = 0$. We shall then examine (1.1) for a lying in some closed interval $[\,0, A\,]$ (with A a fixed positive number).

Both the pole and the turning point are to lie in $\mathbf{D}$, and both $f(a,z)$ and $g(a,z)$ are to be holomorphic in $\mathbf{D}$ and continuous functions of a and z, simultaneously, except possibly at $z = 0$ (where they may have poles of certain orders). In particular, the function $g(a,z)$ may either be analytic at $z = 0$ or have a simple or double pole there. Moreover, we assume that $\lim_{z\to 0} z^2 g(a,z)$ is independent of a and that

$$\lim_{z\to 0} z^2 g(a,z) \geq -\tfrac{1}{4} \tag{1.2}$$

(see (2.7) in §2). The reason for the restriction (1.2) is that we require the solutions of (1.1) to be monotonic near the regular singularity $z = 0$; they would be oscillatory otherwise.

In the real-variable case Nestor [4] derived uniform asymptotic approximations for solutions of second-order linear ordinary differential equations having a coalescing

turning point and simple pole, in terms of Whittaker functions. In this paper we extend Nestor's results to the complex plane, constructing asymptotic solutions to (1.1) also in terms of Whittaker functions, which are valid in certain subdomains of $\mathbf{D}$, uniformly for $u > 0, a \in [0, A]$. Not only are the present results more general in this regard, but in some instances they are valid for a larger parameter range and include a full set of numerically satisfactory solutions. In particular, for what is equivalent to our case II, Nestor imposes the restriction $m \leq \frac{1}{2}$ and does not construct a uniform asymptotic solution that is always recessive at the pole $z = 0$. By working in the complex plane we are able to overcome both of these restrictions.

It is worth noting that having asymptotic approximations that are valid in the complex plane can be of importance in subsequent identification of standard solutions of (1.1) with the asymptotic solutions. This identification is often greatly facilitated by using complex variables.

Examples of differential equations that are of the form (1.1) are the differential equation satisfied by the Jacobi polynomials and the differential equation satisfied by the Mathieu functions (in their algebraic form). The latter equation is the motivation for the present investigation; having asymptotic solutions in a complex domain containing all the critical points will allow a certain analytic continuation, which in turn should provide asymptotic information on the characteristic exponent of Mathieu's equation.

The new results in this paper in effect unify two current asymptotic theories of a turning point in the complex plane and a simple pole in the complex plane, given in Olver's book [5, Chaps. 11 and 12], and can be regarded as complementary to currently existing uniform asymptotic theories concerning coalescing critical points (see [1], [3], [4], [6]). The first such investigation is in the famous paper of Olver [6], who constructed uniform asymptotic approximations of equations having two coalescing turning points. By an appropriate Liouville transformation Olver arrives at equations of the form

$$d^2W/d\zeta^2 = \left\{\pm u^2(\alpha^2 - \zeta^2) + \psi(u, \alpha, \zeta)\right\} W \tag{1.3}$$

and derives asymptotic solutions in terms of parabolic cylinder functions. These are uniformly valid for $u > 0$ and α lying in some closed interval that contains the critical value $\alpha = 0$ (when the two turning points at $\zeta = \pm\alpha$ coalesce). Olver treats the case for which the principal part of (1.3) is real, that is, for ζ either real or purely imaginary.

In a review paper of 1975 on asymptotics [8], Olver mentions that one of the unsolved problems is an extension of the coalescing turning point theory to the complex plane. The results of this paper partly achieve this goal. To see this, consider (1.3) with ζ now regarded as complex, with $\arg(\zeta) \leq \pi/2$. By the simple Liouville transformation on (1.3)

$$z = \zeta^2, \qquad w(z) = \zeta^{1/2} W(\zeta), \tag{1.4}$$

we arrive at the equation

$$\frac{d^2w}{dz^2} = \left\{\pm u^2\left(\frac{a-z}{4z}\right) - \frac{3}{16z^2} + \frac{\psi(u, \alpha, \zeta)}{4z}\right\} w \qquad (a = \alpha^2), \tag{1.5}$$

where $\arg(z) \leq \pi$. If $\psi(u, \alpha, \zeta)$ is an analytic function of z at $z = 0$, then (1.5) is a special case of the general class of equation we are investigating (satisfying (1.2)),

the $\pm$ corresponding to cases I and II, respectively. Other ranges of $\arg(\zeta)$ can be considered either similarly or by using appropriate connection formulas for the special functions under consideration.

Olver applies his results of [6] to the associated Legendre equation [7] and to Whittaker's equation [9]. The present theory can also be applied to the associated Legendre equation.

2. Case I: $(z - z_t(a))^{-1} f(a, z) < 0$ on the positive real z-axis. Our first step is to make the following Liouville transformation:

$$f(a,z)\left(\frac{dz}{d\xi}\right)^2 = \frac{\alpha - \xi}{\xi}, \tag{2.1a}$$

$$W(\xi) = \left(\frac{d\xi}{dz}\right)^{1/2} w(z), \tag{2.1b}$$

where α is a nonnegative parameter that will be specified shortly, so that $z = 0$ corresponds to $\xi = 0$. Integration of (2.1a) yields the relationship

$$\int_\alpha^\xi \left\{\frac{\tau - \alpha}{\tau}\right\}^{1/2} d\tau = \int_{z_t}^z \{-f(a,t)\}^{1/2} dt, \tag{2.2}$$

the lower limits of integration being chosen so that $z = z_t(a)$ corresponds to $\xi = \alpha$. Explicit integration then gives

$$\xi^{1/2}(\xi - \alpha)^{1/2} - \frac{\alpha}{2}\ln\left(\frac{2\xi - \alpha + 2\xi^{1/2}(\xi - \alpha)^{1/2}}{\alpha}\right) = \int_{z_t}^z \{-f(a,t)\}^{1/2}\, dt. \tag{2.3}$$

Branches for the points $z = 0$ ($\xi = 0$) and $z = z_t(a)$ ($\xi = \alpha$) must be chosen so that $\xi(z)$ is an analytic function of z at both $z = 0$ and $z = z_t(a)$. We temporarily introduce cuts along the real z- and ξ-axes, from $\xi = -\infty$ to $\xi = \alpha$ and from $z = -\infty$ to $z = z_t(a)$. Our choice of branches is such that both sides of (2.2) (and (2.3)) are real and positive when z is lying in the real interval $z > z_t$ and are continuous elsewhere.

We now define α so that $z = 0$ corresponds to $\xi = 0$: from (2.2) we see that this is achieved by specifying

$$\int_0^\alpha \left\{\frac{\alpha - \tau}{\tau}\right\}^{1/2} d\tau = \int_0^{z_t} \{f(a,t)\}^{1/2}\, dt, \tag{2.4}$$

which from (2.3) gives the following definition of α as a continuous nonnegative real function of a:

$$\alpha = \frac{2}{\pi}\int_0^{z_t} \{f(a,t)\}^{1/2}\, dt. \tag{2.5}$$

We shall assume that α is a strictly increasing function of a. Note that α tends to zero as a approaches the critical value 0. In this limiting case the $z - \xi$ relationship is given simply by

$$\xi = \int_0^z \{-f(0,t)\}^{1/2}\, dt. \tag{2.6}$$

We denote by Δ the ξ domain corresponding to the z domain $\mathbf{D}$. Therefore, of course, both the critical points $\xi = 0, \alpha$ lie in Δ. Also, we denote $\alpha = \Lambda$ as the corresponding value of $a = A$.

Let m be a nonnegative real number such that

$$\lim_{z\to 0} z^2 g(a,z) = m^2 - \tfrac{1}{4}. \tag{2.7}$$

Then, the effect of the preceding transformations is to yield the new differential equation

$$\frac{d^2W}{d\xi^2} = \left\{u^2\left(\frac{\alpha-\xi}{\xi}\right) + \frac{m^2-\frac{1}{4}}{\xi^2} + \frac{\psi(\alpha,\xi)}{\xi}\right\} W, \tag{2.8}$$

where, with dots representing differentiation with respect to ξ,

$$\frac{\psi(\alpha,\xi)}{\xi} = \dot{z}^{1/2}\frac{d^2}{d\xi^2}(\dot{z}^{-1/2}) + g\dot{z}^2 - \frac{m^2-\frac{1}{4}}{\xi^2}. \tag{2.9}$$

From (2.1a) and (2.9) we find that

$$\psi(\alpha,\xi) = \frac{\alpha^2 + 4\xi^2 - 16m^2(\alpha-\xi)^2}{16\xi(\alpha-\xi)^2} + \frac{(\alpha-\xi)(4ff'' + 16f^2g - 5f'^2)}{16f^3}, \tag{2.10}$$

where primes represent differentiation with respect to z. If one recalls that $z(\xi)$ is analytic Δ, it is straightforward to show from (2.7) and (2.9) that $\psi(\alpha,\xi)$ is an analytic function in Δ. Moreover, one can show that under the preceding conditions $\psi(\alpha,\xi)$ is continuous for $\xi \in \Delta$ and $\alpha \in [0,\Lambda]$. The proof of this is a fairly straightforward exercise using Cauchy integral representations for z and its ξ-derivatives. The corresponding proof for the real-variable case is considerably more difficult (cf. [6, pp. 142–150]).

If one neglects the term $\psi(\alpha,\xi)/\xi$ in equation (2.8), the resulting "comparison equation" has solutions that can be expressed as a linear combination of any pair of the three Whittaker functions $M_{u\alpha i/2,m}(2u\xi e^{\pi i/2}), W_{\pm u\alpha i/2,m}(2u\xi e^{\pm\pi i/2})$. (The notation we use is the standard one (see, for example, [5, p. 260]).) With this in mind we seek three asymptotic solutions of (2.8) of the form

$$W^{(j)}(u,\alpha,\xi) = \mathcal{U}^{(j)}_{u\alpha/2,m}(2u\xi) + \varepsilon^{(j)}(u,\alpha,\xi) \qquad (j = 0,1,2), \tag{2.11}$$

where we define

$$\mathcal{U}^{(0)}_{k,m}(z) = e^{-k\pi/2}e^{-\pi i(m/2+1/4)}\frac{|\Gamma(m+ik+\frac{1}{2})|}{\Gamma(1+2m)}M_{ik,m}\left(ze^{\pi i/2}\right), \tag{2.12}$$

$$\mathcal{U}^{(1)}_{k,m}(z) = e^{k\pi/2}e^{i\theta}W_{-ik,m}\left(ze^{-\pi i/2}\right), \tag{2.13}$$

and

$$\mathcal{U}^{(2)}_{k,m}(z) = e^{k\pi/2}e^{-i\theta}W_{ik,m}\left(ze^{\pi i/2}\right). \tag{2.14}$$

Here, for convenience, we have introduced the parameter

$$\theta = \arg\Gamma\left(m + ik + \frac{1}{2}\right) - \frac{m\pi}{2} - \frac{\pi}{4}, \tag{2.15}$$

with the principal value taken. The normalizing constants taken in (2.12)–(2.14) are selected to ensure that the three functions form a numerically satisfactory set both for complex values of z and large positive values of k. This is of crucial importance in subsequent construction of error bounds.

We do not attempt to obtain asymptotic expansions. The reason for this is the same as that for the case of two coalescing turning points; see [6, Part D]. In short, error bounds for asymptotic expansions would not be uniformly valid in unbounded domains. This problem was not encountered in the problem of a coalescing turning point and double pole [1], [3].

From the well-known connection and analytic continuation formulas of Whittaker functions (see [5, pp. 261–262]), one easily finds that the three functions are related by

$$\mathcal{U}_{k,m}^{(0)}(z) = \mathcal{U}_{k,m}^{(1)}(z) + \mathcal{U}_{k,m}^{(2)}(z). \tag{2.16}$$

Next, we record the following asymptotic forms of the functions as $z \to 0, \infty$, which we require:

$$\mathcal{U}_{k,m}^{(1)}(z) \sim e^{i\theta} z^{-ik} e^{iz/2} \qquad (z \to \infty, \quad -\pi < \arg z < 2\pi), \tag{2.17}$$

$$\mathcal{U}_{k,m}^{(2)}(z) \sim e^{-i\theta} z^{ik} e^{-iz/2} \qquad (z \to \infty, \quad -2\pi < \arg z < \pi), \tag{2.18}$$

$$\mathcal{U}_{k,m}^{(0)}(z) \sim e^{-k\pi/2} \frac{\left|\Gamma(m+ik+\frac{1}{2})\right|}{\Gamma(1+2m)} z^{m+1/2} \qquad (z \to 0), \tag{2.19}$$

$$\mathcal{U}_{k,m}^{(1,2)}(z) \sim \mp i e^{k\pi/2} \frac{\Gamma(2m)}{\left|\Gamma(m+ik+\frac{1}{2})\right|} z^{1/2-m} \qquad (z \to 0, \quad m > 0), \tag{2.20}$$

$$\mathcal{U}_{k,0}^{(1,2)}(z) \sim \mp i e^{k\pi/2} \frac{1}{\left|\Gamma(ik+\frac{1}{2})\right|} z^{1/2} \ln\left(\frac{1}{z}\right) \qquad (z \to 0). \tag{2.21}$$

An important observation is that $\mathcal{U}_{k,m}^{(0)}(z)$ is recessive at $z = 0$ (with respect to the other solutions), $\mathcal{U}_{k,m}^{(1)}(z)$ is recessive at $z = i\infty$, and $\mathcal{U}_{k,m}^{(2)}(z)$ is recessive at $z = -i\infty$.

We shall use what can now be regarded as a standard method, due to Olver, of obtaining bounds for the error terms $\varepsilon^{(j)}(u, \alpha, \xi)$ in (2.11). First, we find a differential equation for the error terms, and this differential equation is then re-expressed as a Volterra integral equation. A bound for a solution of this integral equation may be found by the method of successive approximations (by using [5, Thm. 10.2, p. 220]). To use this theorem we require suitably defined real-valued auxiliary functions $E_{k,m}^{(j)}(z)$, $M_{k,m}^{(j)}(z)$, and $\theta_{k,m}^{(j)}(z)$, which satisfy[1]

$$\left|\mathcal{U}_{k,m}^{(j+1)}(z)\right| = E_{k,m}^{(j+1)}(z)^{-1} M_{k,m}^{(j)}(z) \sin\theta_{k,m}^{(j)}(z) \tag{2.22}$$

and

$$\left|\mathcal{U}_{k,m}^{(j-1)}(z)\right| = E_{k,m}^{(j-1)}(z)^{-1} M_{k,m}^{(j)}(z) \cos\theta_{k,m}^{(j)}(z). \tag{2.23}$$

[1] In §§2 and 3 we shall suppose j is enumerated modulo 3.

We shall define weight functions $E_{k,m}^{(j)}(z)$ $(j = 0, 1, 2)$ that have an asymptotic behavior that is similar to that of the corresponding functions $|\mathcal{U}_{k,m}^{(j)}(z)|^{-1}$ (with regard to both the complex variable z and the real parameter k). Once these weight functions are prescribed, the modulus and phase functions are implicitly given by (2.22) and (2.23), viz.,

$$M_{k,m}^{(j)}(z) = \left\{ E_{k,m}^{(j-1)}(z)^2 \left| \mathcal{U}_{k,m}^{(j-1)}(z) \right|^2 + E_{k,m}^{(j+1)}(z)^2 \left| \mathcal{U}_{k,m}^{(j+1)}(z) \right|^2 \right\}^{1/2}, \tag{2.24}$$

$$\theta_{k,m}^{(j)}(z) = \tan^{-1} \left\{ \frac{E_{k,m}^{(j+1)}(z) \left| \mathcal{U}_{k,m}^{(j+1)}(z) \right|}{E_{k,m}^{(j-1)}(z) \left| \mathcal{U}_{k,m}^{(j-1)}(z) \right|} \right\}. \tag{2.25}$$

To motivate our choice of weight functions let us briefly examine the general asymptotic behavior of the Whittaker functions $\mathcal{U}_{k,m}^{(j)}(z)$ as $k \to \infty$ and $|z| \to \infty$. The functions $\mathcal{U}_{k,m}^{(j)}(z)$ satisfy the differential equation

$$\frac{d^2U}{dz^2} = \left\{ -\left(\frac{z - 4k}{4z} \right) + \frac{m^2 - \frac{1}{4}}{z^2} \right\} U. \tag{2.26}$$

By an application of [5, Chap. 6, Thm. 11.1], with the identification in [5, Chap. 6, eq. (11.01)], i.e.,

$$f(z) = -\left(\frac{z - 4k}{4z} \right), \qquad g(z) = \frac{m^2 - \frac{1}{4}}{z^2}, \tag{2.27}$$

one establishes the existence of two solutions of (2.26) of the form

$$U_k^{(j)}(z) = \left(\frac{z}{z - 4k} \right)^{1/4} \exp\left\{ i\Phi_k^{(j)}(z) \right\} \left\{ 1 + \varepsilon_k^{(j)}(z) \right\} \qquad (j = 1, 2). \tag{2.28}$$

The functions $\Phi_k^{(j)}(z)$ appearing in (2.28) are given by

$$\Phi_k^{(j)}(z) = \frac{1}{2} \int_{4k}^{z} \left(\frac{t - 4k}{t} \right)^{1/2} dt, \tag{2.29}$$

(cf. [1, eq. (5.7)]). These functions have branch points at $z = 0, 4k$, and their branches will be specified shortly in such a way that Im $\Phi_k^{(1)}(z) \to \infty$, Im $\Phi_k^{(2)}(z) \to -\infty$ as $z \to i\infty$, and Im $\Phi_k^{(1)}(z) \to -\infty$, Im $\Phi_k^{(2)}(z) \to \infty$ as $z \to -i\infty$. We shall also specify branches for a third function $\Phi_k^{(0)}(z)$.

The error terms $\varepsilon_k^{(j)}(z)$ are uniformly bounded by [5, Chap. 6, eq. (11.07)] in a certain domain that contains $z = \pm i\infty$ (but not the points $z = 0, 4k$), and these bounds imply that in this domain

$$\varepsilon_k^{(j)}(z) = o(1) \qquad (k \to \infty \text{ or } |z| \to \infty). \tag{2.30}$$

With the choice of branches for (2.29) just described we see that $U_k^{(1)}(z)$ is recessive at $z = i\infty$ and $U_k^{(2)}(z)$ is recessive at $z = -i\infty$. Consequently, $\mathcal{U}_{k,m}^{(1)}(z)$ is a multiple of $U_k^{(1)}(z)$ and $\mathcal{U}_{k,m}^{(2)}(z)$ is a multiple of $U_k^{(2)}(z)$.

We introduce cuts for the branch points of $\Phi_k^{(j)}(z)$ $(j = 0, 1, 2)$ as follows. With respect to the branch point at $z = 4k$ we introduce a cut along a curve on which Im $\Phi_k^{(j)}(z) = 0$. There are three such curves emanating from $z = 4k$, one in the upper half plane (which we label $\mathcal{C}_2$), its conjugate in the lower half plane (labelled $\mathcal{C}_1$), and one along the positive real axis from $z = 4k$ to $z = \infty$ (labelled $\mathcal{C}_0$). The curves $\mathcal{C}_1$ and $\mathcal{C}_2$ emanate from $z = 4k$ at an angle of $\mp 2\pi/3$ with the positive real axis, respectively, and are asymptotic to the lines Im $z = \mp 2k\pi$ as Re $z \to -\infty$ (see Fig. 1).

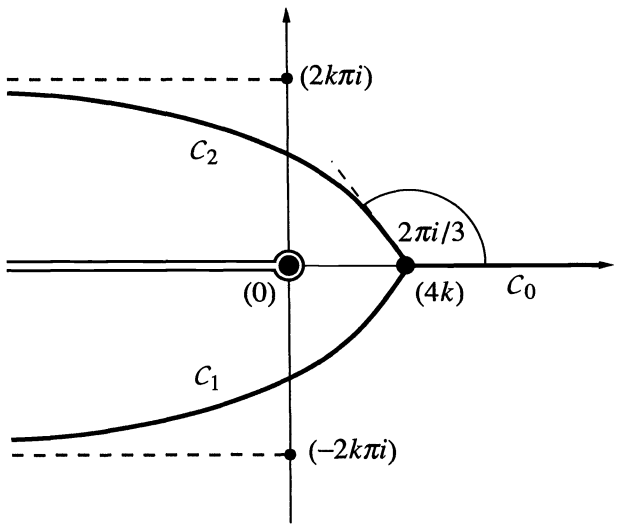

FIG. 1. *z-plane.*

We define $\Phi_k^{(j)}(z)$ $(j = 0, 1, 2)$ to have the branch cut $\mathcal{C}_j$, and with respect to the branch point at $z = 0$ we introduce, for all three functions, a cut along the negative real z-axis from $z = 0$ to $z = -\infty$. The branches in (2.29) are now selected so that the three functions are continuous in their respective cut planes, such that Im $\Phi_k^{(1)}(z) \to \infty$ as $z \to i\infty$, Im $\Phi_k^{(2)}(z) \to \infty$ as $z \to -i\infty$, and Im $\Phi_k^{(0)}(z) \to -\infty$ as $z \to \pm i\infty$.

We now are in a position to define weight functions for $\mathcal{U}_{k,m}^{(j)}(z)(j = 0, 1, 2)$ and we shall use the functions $\Phi_{k+1}^{(j)}(z)$ to do this. The branch cuts associated with these functions emanating from $z = 4k + 4$ divide the z-plane into three regions, which we denote by $\mathcal{S}_k^{(j)}$ (see Fig. 2). Each of the functions $\mathcal{U}_{k,m}^{(j)}(z)$ is recessive in $\mathcal{S}_k^{(j)}$ and dominant in $\mathcal{S}_k^{(j-1)} \cup \mathcal{S}_k^{(j+1)}$. The reason we use $\Phi_{k+1}^{(j)}(z)$ instead of $\Phi_k^{(j)}(z)$ is that the region $\mathcal{S}_k^{(0)}$ as it is now defined does not vanish as $k \to 0$.

We denote by $\mathrm{S}_\alpha^{(j)}(\alpha = 2k/u)$ the regions in the ξ-plane $(\xi = z/(2u))$ corresponding to $\mathcal{S}_k^{(j)}$. The so-called level curves Im $\Phi_{u\alpha/2+1}^{(j)}(2u\xi)$ = constant are important in our asymptotic analysis, and some of these curves are indicated in Fig. 3. In this figure the heavy lines emanating from the point $\xi = \alpha + 2/u$ are the curves Im $\Phi_{u\alpha/2+1}^{(j)}(2u\xi) = 0$, which form the boundaries of $\mathrm{S}_\alpha^{(j)}$.

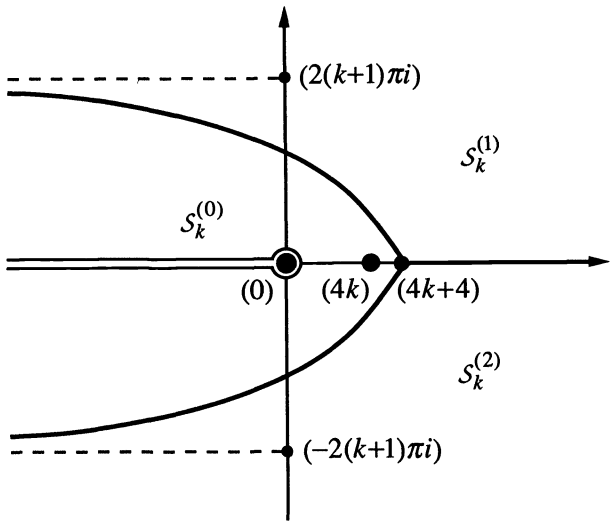

FIG. 2. *z-plane.*

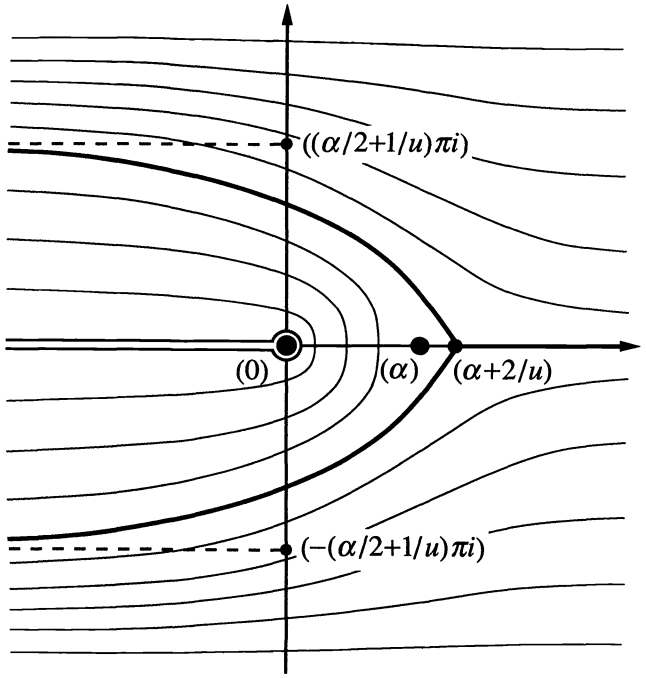

FIG. 3. *ξ-plane: level curves for* $\operatorname{Im} \Phi^{(j)}_{ue/2+1}(2u\xi) = \text{constant}$.

With (2.16) and (2.28) in mind we define

$$E^{(j)}_{k,m}(z) = \left|\exp\left\{-i\Phi^{(j)}_{k+1}(z)\right\}\right| \qquad \left(z \in \mathcal{S}^{(1)}_k \cup \mathcal{S}^{(2)}_k\right) \tag{2.31}$$

for $j = 0, 1, 2$. Note that with our choice of branches $E_{k,m}^{(j)}(z) \geq 1$ for $z \in \mathcal{S}_k^{(j)}$ and $E_{k,m}^{(j)}(z) \leq 1$ for $z \in \mathcal{S}_k^{(j-1)} \cup \mathcal{S}_k^{(j+1)}$.

Unfortunately, (2.31) is not an appropriate definition for the weight functions in $\mathcal{S}_k^{(0)}$ because the Whittaker functions $\mathcal{U}_{k,m}^{(j)}(z)$ have an asymptotic behavior that is different from that of (2.28) near the singularity $z = 0$. Therefore, we must give a different definition for $E_{k,m}^{(j)}(z)$ in $\mathcal{S}_k^{(0)}$. Our choices should reflect both the k-asymptotic behavior $\mathcal{U}_{k,m}^{(j)}(z)$ in $\mathcal{S}_k^{(0)}$ and the behavior of these functions as $z \to 0$ (see (2.19)–(2.21)). Also, bear in mind that $E_{k,m}^{(j)}(z)$ must be continuous for $z > 0$, and so our definitions must be such that $E_{k,m}^{(j)}(z) \to 1$ as z approaches either of the two curves that form the boundary of $\mathcal{S}_k^{(0)}$, i.e., as $\operatorname{Im} \Phi_{k+1}^{(j)}(z) \to 0$.

We begin by defining a positive real-valued radial function $R_k(z)$ having the properties

$$R_k(z) \sim |z| \qquad (z \to 0), \tag{2.32}$$

$$R_k(z) \to \infty \qquad \left(\left|\exp\left\{-i\Phi_{k+1}^{(j)}(z)\right\}\right| \to 1\right). \tag{2.33}$$

The following function satisfies these criteria:

$$R_k(z) = \left(\frac{\left|\exp\left\{-i\Phi_{k+1}^{(0)}(0)\right\}\right| - 1}{\left|\exp\left\{-i\Phi_{k+1}^{(0)}(z)\right\}\right| - 1}\right) \frac{|z|}{1+|z|}. \tag{2.34}$$

Given any point $z \in \mathcal{S}_k^{(0)}$, we define a domain $\mathcal{D}_k^{(0)}(z)$ of a complex t-plane to be the set of points satisfying

$$\operatorname{Im}\Phi_{k+1}^{(0)}(t) > \operatorname{Im}\Phi_{k+1}^{(0)}(z), \tag{2.35}$$

$$|t| < R_k(z), \tag{2.36}$$

$$-\pi < \arg t < \pi \tag{2.37}$$

(see Fig. 4(a)). Note that the level curve $\operatorname{Im} \Phi_{k+1}^{(0)}(t) = \operatorname{Im}\Phi_{k+1}^{(0)}(z)$ forms part of the boundary of $\mathcal{D}_k^{(0)}(z)$.

Similarly, given any point $z \in \mathcal{S}_k^{(0)}$, we define $\mathcal{D}_k^{(1,2)}(z)$ to be the union of the set of points in the t-plane satisfying $\operatorname{Im} \Phi_{k+1}^{(1)}(t) = 0$ with those satisfying

$$\operatorname{Im}\Phi_{k+1}^{(1)}(t) > \operatorname{Im}\Phi_{k+1}^{(1)}(z), \tag{2.38}$$

$$|t| \geq R_k(z), \tag{2.39}$$

$$-\pi < \arg t < \pi \tag{2.40}$$

(see Fig. 4(b)).

Following Olver [6], we introduce so-called balancing functions given by

$$\Omega_d(z) = \begin{cases} |z|^{-d}, & 0 < |z| \leq 1, \\ 1, & |z| > 1, \end{cases} \tag{2.41}$$

where d is real and nonnegative. With the preceding definitions we now can define our weight functions $E_{k,m}^{(j)}(z)$ for $z \in \mathcal{S}_k^{(0)}$. For each $z \in \mathcal{S}_k^{(0)}$ ($|z| > 0$) we define

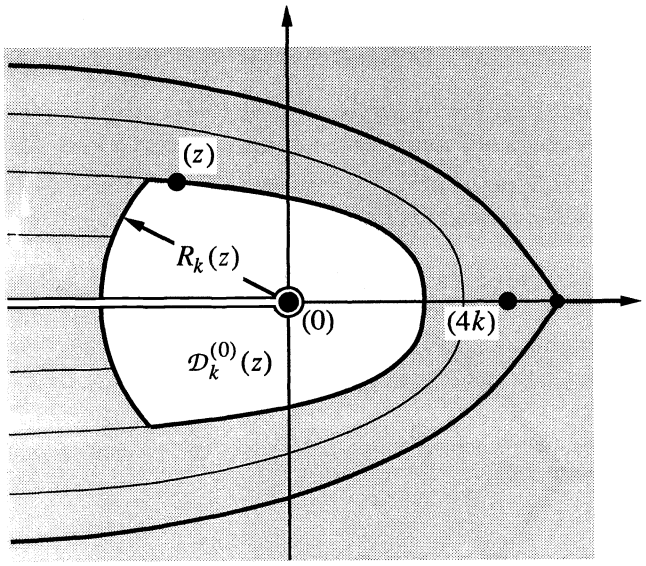

FIG. 4(a). *t-plane.*

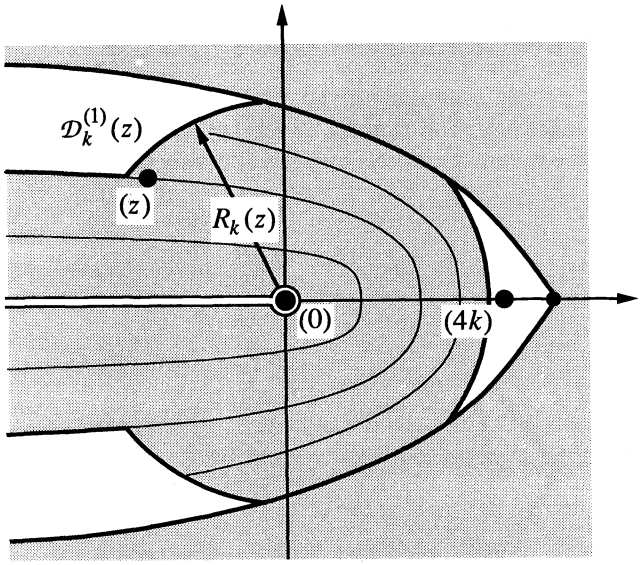

FIG. 4(b). *t-plane.*

$$e_{k,m}^{(j)} E_{k,m}^{(j)}(z)^{-1} = \sup_{t \in D_k^{(j)}(z)} \left\{ \Omega_{1/2}(t) \left| \mathcal{U}_{k,m}^{(j)}(t) \right| \right\} \qquad (j = 0, 1, 2), \tag{2.42}$$

where

$$e_{k,m}^{(0)} = \sup_{t \in D_k^{(0)}(4(k+1))} \left\{ \Omega_{1/2}(t) \left| \mathcal{U}_{k,m}^{(j)}(t) \right| \right\}, \tag{2.43}$$

$$e_{k,m}^{(1)} = e_{k,m}^{(2)} = \sup_{\mathrm{Im}\Phi_{k+1}^{(1)}(t)=0} \left\{ \Omega_{1/2}(t) \left| \mathcal{U}_{k,m}^{(1)}(t) \right| \right\}. \tag{2.44}$$

(The reason for introducing the factor $\Omega_{1/2}(t)$ in (2.42) will be explained shortly.) The coefficients given by (2.43) and (2.44) are introduced so that $E_{k,m}^{(j)}(z) \to 1$ as z approaches any boundary point of $\mathcal{S}_k^{(0)}$. To see this note that as a consequence of the property (2.33) of $R_k(z)$ and the definitions (2.35)–(2.40)

$$\mathcal{D}_k^{(0)}(z^*) = \mathcal{D}_k^{(0)}(4(k+1)), \qquad \mathcal{D}_k^{(1,2)}(z^*) = \left\{ t : \mathrm{Im}\Phi_{k+1}^{(1)}(t) = 0 \right\} \tag{2.45}$$

for any point z^* on the boundary of $\mathcal{S}_k^{(0)}$.

It is straightforward to show from (2.36), (2.39), and (2.42) that

$$e_{k,m}^{(j)} E_{k,m}^{(j)}(z)^{-1} \sim |z|^{-1/2} \left| \mathcal{U}_{k,m}^{(j)}(z) \right| \qquad (z \to 0, j = 0,1,2) \tag{2.46}$$

and hence from (2.24) that

$$M_{k,m}^{(j)}(z) \sim \left\{ \left(e_{k,m}^{(j-1)} \right)^2 + \left(e_{k,m}^{(j+1)} \right)^2 \right\}^{1/2} |z|^{1/2} \qquad (z \to 0). \tag{2.47}$$

The reason for introducing the factor $\Omega_{1/2}(t)$ in (2.42) was to ensure that $\Omega_{1/2}(t)$ $|\mathcal{U}_{k,m}^{(1,2)}(t)| \to \infty$ as $t \to 0$, which would not be true without this factor if $0 \le m \le \frac{1}{2}$ (see (2.20) and (2.21)). The importance of this is that the supremum in (2.42) for $j = 1,2$ is attained on the boundary given by (2.39) when $|t|$ is sufficiently small, which, in turn, is a sufficient condition for (2.46) to hold when $j = 1,2$.

Having defined the weight functions for all values of z ($|z| > 0$), we define modulus and phase functions for the derivatives of $\mathcal{U}_{k,m}^{(j)}(z)$ ($j = 0,1,2$) by

$$\left| \mathcal{U}_{k,m}^{(j+1)'}(z) \right| = E_{k,m}^{(j+1)}(z)^{-1} N_{k,m}^{(j)}(z) \sin \omega_{k,m}^{(j)}(z), \tag{2.48}$$

$$\left| \mathcal{U}_{k,m}^{(j-1)'}(z) \right| = E_{k,m}^{(j-1)}(z)^{-1} N_{k,m}^{(j)}(z) \cos \omega_{k,m}^{(j)}(z). \tag{2.49}$$

We now substitute (2.11) into the differential equation (2.8), yielding the following inhomogeneous differential equation for the error term:

$$\begin{aligned} &\frac{\partial^2 \varepsilon^{(j)}(u,\alpha,\xi)}{\partial \xi^2} - \left\{ u^2 \left(\frac{\alpha - \xi}{\xi} \right) + \frac{m^2 - \frac{1}{4}}{\xi^2} \right\} \varepsilon^{(j)}(u,\alpha,\xi) \\ &\quad = \frac{\psi(\alpha,\xi)}{\xi} \left\{ \mathcal{U}_{u\alpha/2,m}^{(j)}(2u\xi) + \varepsilon^{(j)}(u,\alpha,\xi) \right\}, \end{aligned} \tag{2.50}$$

which by variation of parameters can be re-expressed as the integral equation

$$\varepsilon^{(j)}(u,\alpha,\xi) = \int_{\mathcal{P}^{(j)}} K(\xi,v) \frac{\psi(\alpha,v)}{v} \left\{ \mathcal{U}_{u\alpha/2,m}^{(j)}(2uv) + \varepsilon^{(j)}(u,\alpha,v) \right\} dv. \tag{2.51}$$

The kernel $K(\xi,v)$ is given by

$$K(\xi,v) = \frac{\mathcal{U}_{u\alpha/2,m}^{(j)}(2uv)\mathcal{U}_{u\alpha/2,m}^{(j\pm1)}(2u\xi) - \mathcal{U}_{u\alpha/2,m}^{(j)}(2u\xi)\mathcal{U}_{u\alpha/2,m}^{(j\pm1)}(2uv)}{\mathcal{W}\left(\mathcal{U}_{u\alpha/2,m}^{(j)}(2uv), \mathcal{U}_{u\alpha/2,m}^{(j\pm1)}(2uv) \right)}, \tag{2.52}$$

where $\mathcal{W}$ denotes the Wronskian and the choice of suffix is $j+1$ when $\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j+1)}$ and is $j-1$ when $\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j-1)}$. From well-known results we find that

$$\left|\mathcal{W}\left(\mathcal{U}^{(j)}_{u\alpha/2,m}(2uv), \mathcal{U}^{(j\pm1)}_{u\alpha/2,m}(2uv)\right)\right| = 2u. \tag{2.53}$$

The path of integration $\mathcal{P}^{(j)}$ in (2.51) runs from $v = \tilde{\xi}^{(j)}$ to $v = \xi$, where $\tilde{\xi}^{(0)} = 0$ and $\tilde{\xi}^{(1,2)}$ is some suitably chosen reference point in $\mathrm{S}_\alpha^{(1,2)}$ (possibly at infinity) such that

(i) $\mathcal{P}^{(j)}$ consists of a finite chain of R_2 arcs;

(ii) $\operatorname{Im} \Phi^{(j)}_{u\alpha/2+1}(2uv)$ is nonincreasing as v passes along $\mathcal{P}^{(j)}$ from $\tilde{\xi}^{(j)}$ to ξ;

(iiia) for the segment of $\mathcal{P}^{(0)}$ in $\mathrm{S}_\alpha^{(0)}$, $|v|$ is nondecreasing as v passes along $\mathcal{P}^{(0)}$ from 0;

(iiib) if $\xi \in \mathrm{S}_\alpha^{(0)}$, $|v|$ is nonincreasing as v passes to ξ along the segment of $\mathcal{P}^{(1,2)}$ lying in $\mathrm{S}_\alpha^{(0)}$.

(Here, for simplicity, we identify the region $\mathrm{S}_\alpha^{(0)}$ in the v-plane as being equivalent to $\mathrm{S}_\alpha^{(0)}$ in the ξ-plane.) The reason for these conditions is that $E^{(j)}_{u\alpha/2,m}(2uv)$ is nonincreasing and $E^{(j\pm1)}_{u\alpha/2,m}(2uv)$ is nondecreasing as v passes along $\mathcal{P}^{(j)}$ from $\tilde{\xi}^{(j)}$ to ξ ($\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j\pm1)}$); these monotonicity conditions allow us to apply [5, Thm. 10.2, p. 220]. The subsequent error bounds will be uniformly valid in subdomains $\Delta^{(j)}$ ($j = 0, 1, 2$) defined as the set of points in Δ that can be linked to $\tilde{\xi}^{(j)}$ by a path $\mathcal{P}^{(j)}$ satisfying the conditions (i)–(iii).

Before we state our theorem on error bounds, we introduce some terms that appear. We define

$$F(u, \alpha, \xi) = \int \frac{\psi(\alpha, \xi)}{\xi \Omega_\delta(2u\xi)}\, d\xi \tag{2.54}$$

and assume that this integral converges uniformly with respect to α at $\xi = 0$ for some suitably chosen δ in the interval

$$0 \le \delta < \frac{2}{3}. \tag{2.55}$$

Recall that $\psi(\alpha, \xi)$ is analytic in Δ. If $\psi(\alpha, \xi) = O(\xi)$ as $\xi \to 0$, then, of course, we may prescribe $\delta = 0$ (and hence $\Omega_\delta(2u\xi) \equiv 1$ in (2.54)).

Following [1, eq. (5.13)], we introduce the following constant:

$$\kappa_m = \kappa_{m,1}\kappa_{m,2}, \tag{2.56}$$

where

$$\kappa_{m,1} = \sup\left\{\Omega_\delta(z)(1+k)^{-1/3} \sum_{j=0}^{2} E^{(j)}_{k,m}(z)^2 \left|\mathcal{U}^{(j)}_{k,m}(z)\right|^2\right\} \qquad (m > 0), \tag{2.57}$$

$$\kappa_{m,2} = \sup\left\{E^{(0)}_{k,m}(z)^{-1} E^{(1)}_{k,m}(z)^{-1}\right\} \qquad (m > 0), \tag{2.58}$$

the supremum being taken over all $k \ge 0$ and all $|z| > 0$ for (2.57), and the supremum being taken over all $k \ge 0$ and all $z \in \mathcal{S}_k^{(0)} \setminus \{0\}$ for (2.58).

For the case $m = 0$ we select any δ' satisfying

$$0 < \delta' < \frac{1}{3} \tag{2.59}$$

and then define

$$\kappa_{0,1} = \sup\left\{\Omega_\delta(z)\Omega_{\delta'}(z)(1+k)^{-1/3}\sum_{j=0}^{2} E_{k,0}^{(j)}(z)^2\left|\mathcal{U}_{k,0}^{(j)}(z)\right|^2\right\}, \tag{2.60}$$

$$\kappa_{0,2} = \sup\left\{\Omega_{\delta'}(z)^{-1}E_{k,0}^{(0)}(z)^{-1}E_{k,0}^{(1)}(z)^{-1}\right\}, \tag{2.61}$$

where the suprema are taken over the same ranges as for (2.57) and (2.58), respectively. The factor $(1+k)^{-1/3}$ appearing in (2.57) and (2.60) is needed to ensure that these suprema exist. A consequence of this is that the error bounds are necessarily weakened by a factor of $(\frac{1}{2}u\alpha+1)^{1/3}$ (see (2.63), which follows). An indication of the proof of the existence of the suprema will be given in §3.

We now are in a position to state the main theorem for case I.

THEOREM 1. *With the conditions described in the present section,* (2.8) *has, for each* $u > 0$ *and* $\alpha \in [0, \Lambda]$, *solutions* $W^{(j)}(u,\alpha,\xi)$ $(j = 0,1,2)$ *that are holomorphic in* Δ *except at* $\xi = 0$ *and satisfy*

$$W^{(j)}(u,\alpha,\xi) = \mathcal{U}_{u\alpha/2,m}^{(j)}(2u\xi) + \varepsilon^{(j)}(u,\alpha,\xi), \tag{2.62}$$

where

$$\frac{\left|\varepsilon^{(j)}(u,\alpha,\xi)\right|}{M_{u\alpha/2,m}^{(j\pm1)}(2u\xi)}, \frac{\left|\partial\varepsilon^{(j)}(u,\alpha,\xi)/\partial\xi\right|}{2uN_{u\alpha/2,m}^{(j\pm1)}(2u\xi)}$$

$$\le E_{u\alpha/2,m}^{(j)}(2u\xi)^{-1}\left[\exp\left\{\frac{\kappa_m\left(\frac{1}{2}u\alpha+1\right)^{1/3}}{2u}\mathcal{V}_{\mathcal{P}^{(j)}}(F)\right\}-1\right], \tag{2.63}$$

when $\xi \in \Delta^{(j)}$. *In* (2.63) *the suffix on* M *and* N *is* $j+1$ *when* $\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j-1)}$ *and is* $j-1$ *when* $\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j+1)}$.

The variation of F in (2.63) is given by

$$\mathcal{V}_{\mathcal{P}^{(j)}}(F) = \int_{\mathcal{P}^{(j)}} \frac{|\psi(\alpha,t)|}{|t|\Omega_\delta(2ut)}\,dt. \tag{2.64}$$

Note that the domains $\Delta^{(1,2)}$ depend on the choice of reference points $\tilde{\xi}^{(1,2)}$: these points can be taken at infinity in $\mathrm{S}_\alpha^{(1,2)}$ provided that the variation (2.64) converges at infinity.

It is not difficult to show from (2.64) that $\mathcal{V}_{\mathcal{P}^{(j)}}(F) = O(u^\delta)$ uniformly for $\xi \in \Delta^{(j)}$. For $j = 1,2$ this estimate can be strengthened to $O(1)$ if ξ is bounded away from 0. Consequently, from (2.63) we have the estimates

$$\left|\varepsilon^{(j)}(u,\alpha,\xi)\right| = E_{u\alpha/2,m}^{(j)}(2u\xi)^{-1}M_{u\alpha/2,m}^{(j\pm1)}(2u\xi)O\left((u\alpha+1)^{1/3}u^{-1+\delta}\right) \tag{2.65}$$

as $u \to \infty$ uniformly for $\xi \in \mathrm{S}_\alpha^{(j)} \cup \mathrm{S}_\alpha^{(j\pm1)}$. The number δ can be taken to be zero if $\psi(\alpha,\xi) = O(\xi)$ as $\xi \to 0$; also, for $j = 1,2$ only, δ can be taken to be zero when ξ is bounded away from 0.

3. Existence of the suprema. In this section we establish the existence of the constant κ_m that is defined by (2.56)–(2.61). To do this we require uniform asymptotic approximations for the Whittaker functions $\mathcal{U}_{k,m}^{(j)}(z)$ as $k \to \infty$ and $|z| \to \infty$, which are valid at the turning point $z = 4k$ (in terms of Airy functions) and the pole $z = 0$ (in terms of Bessel functions). In both cases certain Liouville transformations are used, and it is understood that appropriate branches for the branch points are taken so that the transformations are regular at these points.

For the Airy function approximations we use [5, Chap. 11]. The Liouville transformation on (2.26),

$$\frac{2}{3}\zeta^{3/2} = \int_{4k}^{z} \left(\frac{4k-\tau}{\tau}\right)^{1/2} d\tau, \qquad \tilde{W}(\zeta) = \left(\frac{d\zeta}{dz}\right)^{1/2} U(z), \tag{3.1}$$

yields a new differential equation (with $z = 4k, \infty$ corresponding to $\zeta = 0, -\infty$, respectively) of the form

$$\frac{d^2\tilde{W}}{d\zeta^2} = \left\{\zeta + \tilde{\psi}(k,\zeta)\right\}\tilde{W}. \tag{3.2}$$

Here the Schwarzian is given by

$$\tilde{\psi}(k,\zeta) = \frac{\zeta(z^2 + 4k^2 - 4m^2(z-4k)^2)}{z(z-4k)^3} + \frac{5}{16\zeta^2} \tag{3.3}$$

and is analytic at $\zeta = 0$. An application of [5, Chap. 11, Thm. 9.1] (with $u = 1$) yields the solutions

$$\tilde{W}^{(1)}(k,\zeta) = \mathrm{Ai}\left(\zeta e^{2\pi i/3}\right) + \tilde{\varepsilon}^{(1)}(k,\zeta), \tag{3.4}$$

$$\tilde{W}^{(2)}(k,\zeta) = \mathrm{Ai}\left(\zeta e^{-2\pi i/3}\right) + \tilde{\varepsilon}^{(2)}(k,\zeta), \tag{3.5}$$

where the error terms are bounded by [5, Chap. 11, Eq. (9.03)]. In these bounds E and M are auxiliary functions for Airy functions of complex argument satisfying (see [5, Chap. 11, §8.3])

$$\left|\mathrm{Ai}\left(\zeta e^{-2\pi i/3}\right)\right| = \{E_1(\zeta)\}^{-1} M_0(\zeta)\sin\theta_0(\zeta), \tag{3.6a}$$

$$\left|\mathrm{Ai}\left(\zeta e^{2\pi i/3}\right)\right| = \{E_{-1}(\zeta)\}^{-1} M_0(\zeta)\cos\theta_0(\zeta). \tag{3.6b}$$

From the error bounds one can show that

$$\left|\tilde{\varepsilon}^{(1)}(k,\zeta)\right| = \{E_{-1}(\zeta)\}^{-1} M_0(\zeta)O(1), \tag{3.7a}$$

$$\left|\tilde{\varepsilon}^{(2)}(k,\zeta)\right| = \{E_1(\zeta)\}^{-1} M_0(\zeta)O(1), \tag{3.7b}$$

where the $O(1)$ term is uniform for $z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}$ and $0 \le k < \infty$. Moreover, this $O(1)$ term is $o(1)$ if $k \to \infty$ or $|z| \to \infty$ ($z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}$).

The asymptotic solution (3.4) is recessive as $\zeta \to \infty e^{-2\pi i/3}$, which corresponds to $z \to i\infty$, and hence we can claim the existence of a constant $\tilde{c}_{k,m}^{(1)}$ such that

$$\mathcal{U}_{k,m}^{(1)}(z) = \tilde{c}_{k,m}^{(1)} \left(\frac{z\zeta}{4k-z}\right)^{1/4} \left[\mathrm{Ai}\left(\zeta e^{2\pi i/3}\right) + \tilde{\varepsilon}^{(1)}(k,\zeta)\right] \tag{3.8}$$

since both solutions are recessive at $z = i\infty$. This constant can be determined by comparing both sides of (3.8) as $\zeta \to -\infty, z \to +\infty$: one finds by this method

$$\tilde{c}_{k,m}^{(1)} = 2\pi^{1/2} e^{\pi i/6} e^{i\theta} \left(\frac{e}{k}\right)^{ik}. \tag{3.9}$$

Similarly, one finds

$$\mathcal{U}_{k,m}^{(2)}(z) = \overline{\tilde{c}_{k,m}^{(1)}} \left(\frac{z\zeta}{4k-z}\right)^{1/4} \left[\mathrm{Ai}\left(\zeta e^{-2\pi i/3}\right) + \tilde{\varepsilon}^{(2)}(k,\zeta)\right]. \tag{3.10}$$

Consider first the supremum (2.57). From (3.1) a straightforward calculation establishes that

$$\lim_{\zeta\to 0, z\to 4k} \left(\frac{z\zeta}{4k-z}\right)^{1/4} = (2k)^{1/6}, \tag{3.11}$$

and hence, by using this result and (2.16), (2.43), (2.44), (3.4), and (3.5), it can be shown that

$$e_{k,m}^{(j)} = O(k^{1/6}) \qquad (k \to \infty). \tag{3.12}$$

Therefore, from the definition (2.42) we see that[2]

$$E_{k,m}^{(j)}(z)^2 \left|\mathcal{U}_{k,m}^{(j)}(z)\right|^2 \le \left\{\frac{e_{k,m}^{(j)}}{\Omega_{1/2}(z)}\right\}^2 \le K \min\{1,|z|\}(1+k)^{1/3} \tag{3.13}$$

for $z \in \mathcal{S}_k^{(0)}, k \ge 0$. From (2.57) and (3.13) it is now clear that $\kappa_{m,1}$ exists as a supremum over $z \in \mathcal{S}_k^{(0)}, k \ge 0$.

To establish the existence of $\kappa_{m,1}$ it remains to consider $z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}, k \ge 0$. For this range we use (2.16), (3.8), and (3.10) and the following bound ($j = 1, 2$) for Airy functions of complex argument:

$$\left|\mathrm{Ai}(\zeta e^{\pm 2\pi i/3}) + \tilde{\varepsilon}^{(j)}(k,\zeta)\right| \le K \frac{\left|\exp\left\{i\Phi_k^{(j)}(z)\right\}\right|}{1+|\zeta|^{1/4}}. \tag{3.14}$$

To complete the proof of the existence of $\kappa_{m,1}$ we see, from the preceding formulas, that it is sufficient to establish the uniform boundedness of the following function for $z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}, k \ge 0$:

$$\sigma(k,z) = \sigma_1(k,z)\sigma_2(k,z)\sigma_3(k,z), \tag{3.15}$$

[2] Here and throughout, K is used generically as a positive constant (independent of z and k).

where

$$\sigma_1(k,z) = \left|\tilde{c}_{k,m}^{(j)}\right|^2 \Omega_\delta(z), \tag{3.16}$$

$$\sigma_2(k,z) = \left|\frac{z\zeta}{(1+k)^{2/3}(z-4k)}\right|^{1/2} \frac{1}{\left(1+|\zeta|^{1/4}\right)^2}, \tag{3.17}$$

$$\sigma_3(k,z) = \left|\exp\left\{2i\Phi_k^{(j)}(z) - 2i\Phi_{k+1}^{(j)}(z)\right\}\right|. \tag{3.18}$$

The factor $|\tilde{c}_{k,m}^{(j)}|$ on the right-hand side of (3.16) is clearly bounded for $k \geq 0$. On noting that

$$|z| \geq z_0 > 0 \qquad (z \in S_k^{(1)} \cup S_k^{(2)}, \quad k \geq 0), \tag{3.19}$$

where z_0 is some positive constant, it follows that the balancing function in (3.16) is also uniformly bounded on the range of z and k under consideration. Using (3.1) and (3.11), one can show that $\sigma_2(k,z)$ is also uniformly bounded for this range. To prove the same for $\sigma_3(k,z)$ we consider

$$J(k,z) = \int_{4k}^{z} \left(\frac{t-4k}{t}\right)^{1/2} dt - \int_{4(k+1)}^{z} \left(\frac{t-4(k+1)}{t}\right)^{1/2} dt \tag{3.20}$$

and show that the imaginary part of this is uniformly bounded for $z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}, k \geq 0$. To do this we consider separately the cases Z bounded and $1/Z$ bounded, where $Z = z/(k+1)$.

Let Z_0 be an arbitrary positive constant. Then, for the case $0 < Z \leq Z_0$ one can show that

$$J(k,z) = 2\ln\left\{\frac{Z-2+(Z^2-4Z)^{1/2}}{2}\right\} + O\left(\frac{1}{k+1}\right), \tag{3.21}$$

and for the case $0 < 1/Z \leq 1/Z_0$ one can show that

$$J(k,z) = 2\ln\left\{\frac{2-4Z^{-1}+2\left(1-4Z^{-1}\right)^{1/2}}{4Z^{-1}}\right\} + O\left(\frac{1}{|z|}\right). \tag{3.22}$$

Both the O terms in (3.21), (3.22) hold uniformly for $z \in \mathcal{S}_k^{(1)} \cup \mathcal{S}_k^{(2)}, k \geq 0$, and therefore Im $J(k,z)$ is uniformly bounded, as required. The existence of (2.57) is thus assured, and that of (2.60) is proved in essentially the same manner.

For the second supremum $\kappa_{m,2}$ we consider separately the two cases $0 \leq k \leq 1$ and $1 \leq k \leq \infty$. In the former case Im z is bounded in $\mathcal{S}_k^{(0)}$, and hence one need only consider the asymptotic behavior $E_{k,m}^{(0)}(z)^{-1}E_{k,m}^{(1)}(z)^{-1}$ at $z = 0$ (see (2.16)–(2.21) and (2.46))to establish that this product is uniformly bounded for $z \in \mathcal{S}_k^{(0)}, 0 \leq k \leq 1$. Similarly, for the case $m = 0$ note that

$$\Omega_{\delta'}(z)^{-1}E_{k,0}^{(0)}(z)^{-1}E_{k,0}^{(1)}(z)^{-1} = O\left(z^{\delta'}\ln\left(\frac{1}{z}\right)\right) \qquad (z \to 0). \tag{3.23}$$

For the case $k \geq 1$ we consider two subcases: (i) pairs of z and k such that $\operatorname{Im} \Phi_{k+1}^{(0)}(2k) \leq \operatorname{Im} \Phi_{k+1}^{(0)}(z) \leq \operatorname{Im} \Phi_{k+1}^{(0)}(0)$ and (ii) pairs of z and k such that $0 \leq \operatorname{Im} \Phi_{k+1}^{(0)}(z) < \operatorname{Im} \Phi_{k+1}^{(0)}(2k)$. Let us denote the first domain in the z-plane by $\mathbf{Z}_0$ and the second domain by $\mathbf{Z}_1$ (see Fig. 5). Clearly $\mathcal{S}_k^{(0)} = \mathbf{Z}_0 \cup \mathbf{Z}_1$, the pole $z = 0$ lies in $\mathbf{Z}_0$, and the turning point $z = 4k$ lies in $\mathbf{Z}_1$. Moreover, these critical points are bounded away from the common boundary of $\mathbf{Z}_0$ and $\mathbf{Z}_1$ when $k \geq 1$.

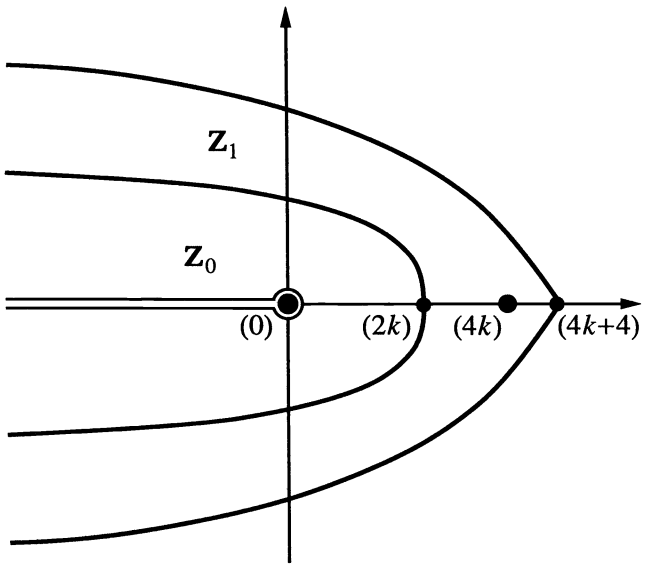

FIG. 5. *z-plane.*

For $z \in \mathbf{Z}_0$ we write $z = 4k\rho$ and consider $\mathcal{U}_{k,m}^{(j)}(4k\rho)$ that satisfy the differential equation

$$\frac{d^2y}{d\rho^2} = \left\{(2k)^2\left(\frac{1-\rho}{\rho}\right) + \frac{(2m)^2-1}{4\rho^2}\right\} y. \tag{3.24}$$

To obtain asymptotic approximations for solutions of (3.24) that are uniformly valid for $z \in \mathbf{Z}_0$ and $k \geq 1$ we use the theory of [5, Chap. 12, §9]. Following this, we make the Liouville transformations

$$\eta^{1/2} = \int_0^\rho \left(\frac{1-t}{t}\right)^{1/2} dt = (\rho-\rho^2)^{1/2} - \frac{i}{2}\ln\left\{1-2\rho+2i(\rho-\rho^2)^{1/2}\right\}, \tag{3.25}$$

$$L = \left(\frac{1-\rho}{\rho}\right)^{1/4} \eta^{1/4} y, \tag{3.26}$$

which transform (3.24) to the form

$$\frac{d^2L}{d\eta^2} = \left\{\frac{(2k)^2}{4\eta} + \frac{(2m)^2-1}{4\eta^2} + \frac{\phi(\eta)}{\eta}\right\} L, \tag{3.27}$$

where

$$\phi(\eta) = \frac{8(1-\rho)}{\rho^4} - \frac{5}{16\rho(1-\rho)^3} - \frac{3}{16\eta} + \frac{\left((2m)^2-1\right)\left(4\rho^2-4\rho+\eta\right)}{16\rho(1-\rho)\eta}. \tag{3.28}$$

The function $\phi(\eta)$ is analytic in the η-domain corresponding to $\mathbf{Z}_0$, in particular at $\eta = 0$ ($z = 0$). Applying [5, Chap. 12, Thm. 9.1] to (3.27) and identifying the solutions that are recessive at $\eta = 0$ ($z = 0$) in the usual manner, we arrive at

$$\begin{aligned} \mathcal{U}_{k,m}^{(0)}(4k\rho) &= l_{k,m}^{(0)} k^{1/2} \left(\frac{\rho\eta}{1-\rho}\right)^{1/4} \\ &\times \left[I_{2m}(2k\eta^{1/2}) + \mathcal{E}_{2m}(2k\eta^{1/2})\mathcal{M}_{2m}(2k\eta^{1/2})O(k^{-1})\right], \end{aligned} \tag{3.29}$$

where

$$l_{k,m}^{(0)} = 2^{1/2}|\Gamma(m + ik + \tfrac{1}{2})|e^{-k\pi/2}k^{-m}. \tag{3.30}$$

Likewise, for solutions that are recessive at $\eta = +\infty$ ($z = i\infty$) we arrive at

$$\begin{aligned} \mathcal{U}_{k,m}^{(1)}(4k\rho) &= l_{k,m}^{(1)} k^{1/2} \left(\frac{\rho\eta}{1-\rho}\right)^{1/4} \\ &\times \left[K_{2m}(2k\eta^{1/2}) + \mathcal{E}_{2m}^{-1}(2k\eta^{1/2})\mathcal{M}_{2m}(2k\eta^{1/2})O(k^{-1})\right], \end{aligned} \tag{3.31}$$

where

$$l_{k,m}^{(1)} = 2\pi^{-1/2}e^{k\pi}e^{i(k+\theta+\pi/4)}k^{-ik}. \tag{3.32}$$

The $O(k^{-1})$ factors in (3.29) and (3.31) hold uniformly for η lying in an unbounded domain whose corresponding z-domain contains all points in the principal z-plane except those on or near the positive real axis from $z = 4k$ to $z = \infty$. Thus, in particular, the identification (3.31) is justified, and (3.29) and (3.31) hold uniformly for $z \in \mathbf{Z}_0$ and $k \geq 1$.

The functions $\mathcal{E}$ and $\mathcal{M}$ are auxiliary functions for Bessel functions of complex argument, defined in [5, Chap. 12, §8]. These have the properties that as $\eta \to 0$

$$\mathcal{M}_{2m}\left(2k\eta^{1/2}\right) \to (2m)^{1/2} \qquad (m > 0), \tag{3.33a}$$

$$\mathcal{E}_{2m}\left(2k\eta^{1/2}\right) \sim \frac{|k\eta^{1/2}|^{2m}}{m^{1/2}\Gamma(2m)} \qquad (m > 0), \tag{3.33b}$$

$$\mathcal{M}_0\left(2k\eta^{1/2}\right) \sim |\ln(1/\eta)|^{1/2}, \tag{3.34a}$$

$$\mathcal{E}_0\left(2k\eta^{1/2}\right) \sim |\tfrac{1}{2}\ln(1/\eta)|^{1/2}, \tag{3.34b}$$

and as $k\eta^{1/2} \to \infty$

$$\mathcal{M}_{2m}\left(2k\eta^{1/2}\right) \sim |k\eta^{1/2}|^{-1/2}, \tag{3.35a}$$

$$\mathcal{E}_{2m}\left(2k\eta^{1/2}\right) \sim \pi^{1/2}\left|\exp\left\{k\eta^{1/2}\right\}\right|, \tag{3.35b}$$

$$\mathcal{E}_{2m}^{-1}\left(2k\eta^{1/2}\right) \leq \pi^{1/2}\left|\exp\left\{-k\eta^{1/2}\right\}\right|\{1=o(1)\}. \tag{3.36}$$

Since $\rho \sim \eta/4$ as $\eta \to 0, \rho \to \infty$ as $\eta \to \infty$, and ρ is bounded away from 1 in the present circumstances, we deduce from [5, Chap. 12, eq. (8.19)] and the preceding results that

$$\begin{aligned}&\Omega_{1/2}(4k\rho)\left|\mathcal{U}_{k,m}^{(0)}(4k\rho)\right| \\ &\leq K l_{k,m}^{(0)} k^{1/2} \frac{|\eta|^{1/2}}{1+|\eta|^{1/4}} \Omega_{1/2}(k\eta)\mathcal{E}_{2m}(2k\eta^{1/2})\mathcal{M}_{2m}(2k\eta^{1/2}),\end{aligned} \tag{3.37}$$

$$\begin{aligned}&\Omega_{1/2}(4k\rho)\left|\mathcal{U}_{k,m}^{(1)}(4k\rho)\right| \\ &\leq K l_{k,m}^{(1)} k^{1/2} \frac{|\eta|^{1/2}}{1+|\eta|^{1/4}} \Omega_{1/2}(k\eta)\mathcal{E}_{2m}^{-1}(2k\eta^{1/2})\mathcal{M}_{2m}(2k\eta^{1/2})\end{aligned} \tag{3.38}$$

for $z \in \mathbf{Z}_0$ and $k \geq 1$.

By virtue of the maximum modulus theorem, it follows from (2.42) that for $k \geq 1$ and $|\rho| > 0$

$$E_{k,m}^{(1)}(4k\rho)^{-1} = \left\{e_{k,m}^{(1)}\right\}^{-1} \Omega_{1/2}(4k\rho_1)\left|\mathcal{U}_{k,m}^{(1)}(4k\rho_1)\right|, \tag{3.39}$$

where ρ_1 lies either on the boundary of $\mathcal{D}_k^{(1)}(4k\rho)$ or on the circle $|\rho| = 1/(4k)$ (on any part of this circle that may lie inside $\mathcal{D}_k^{(1)}(4k\rho)$). Likewise,

$$E_{k,m}^{(0)}(4k\rho)^{-1} = \left\{e_{k,m}^{(0)}\right\}^{-1} \Omega_{1/2}(4k\rho_0)\left|\mathcal{U}_{k,m}^{(0)}(4k\rho_0)\right|, \tag{3.40}$$

where ρ_0 lies either on the boundary of $\mathcal{D}_k^{(0)}(4k\rho)$ or on the part (if any) of the circle $|\rho| = 1/(4k)$ that lies inside $\mathcal{D}_k^{(0)}(4k\rho)$.

Note that $|\rho_0| \leq |\rho_1|$ and that $\rho_j \to 0$ if and only if $\rho \to 0$ $(j = 0, 1)$. Let η_j correspond to ρ_j . Then from (3.37)–(3.40) we can prove that $E_{k,m}^{(0)}(z)^{-1}E_{k,m}^{(1)}(z)^{-1}$ is uniformly bounded for $z \in \mathbf{Z}_0$ and $k \geq 1$ by showing that the following function is uniformly bounded:

$$\left|l_{k,m}^{(0)} l_{k,m}^{(1)}\right| \left\{e_{k,m}^{(0)} e_{k,m}^{(1)}\right\}^{-1} \mathcal{E}_{2m}(2k\eta_0^{1/2})\mathcal{E}_{2m}^{-1}(2k\eta_1^{1/2})\gamma_m(k,\rho_0)\gamma_m(k,\rho_1), \tag{3.41}$$

where

$$\gamma_m(k,\rho) = k^{1/2}\frac{|\eta|^{1/2}\Omega_{1/2}(k\eta)}{\left(1+|\eta|^{1/4}\right)}\mathcal{M}_{2m}(2k\eta^{1/2}). \tag{3.42}$$

Consider first the coefficients in (3.41). By considering the asymptotic behavior of the Gamma function of large complex argument (e.g., see [5, p. 294]), it is straightforward to show that $|l_{k,m}^{(0)} l_{k,m}^{(1)}|$ is bounded as $k \to \infty$. Also, note that $\{e_{k,m}^{(0)} e_{k,m}^{(1)}\}^{-1}$ is bounded for all nonnegative k.

Next, from the definitions of $\mathcal{D}_k^{(0)}(z)$ and $\mathcal{D}_k^{(1)}(z)$ we observe that Re $\{k\eta_1^{1/2}\} \geq$ Re $\{k\eta_0^{1/2}\}$. Therefore, as $k\eta_0^{1/2} \to \infty$ it is clear from (3.35b) that

$$\mathcal{E}_{2m}(2k\eta_0^{1/2})\mathcal{E}_{2m}^{-1}(2k\eta_1^{1/2}) = O(1). \tag{3.43}$$

Furthermore, on recalling that $|\eta_1| \geq |\eta_0|$, we see from (3.33b) that (3.43) is also true when $k\eta_1^{1/2} \to 0$.

It remains to establish that $\gamma_m(k,\rho)$ is uniformly bounded. Essentially, there are three cases to consider, namely,

(i) $k\rho \to \infty$ $(k\eta^{1/2} \to \infty)$ such that $k\eta \to \infty$,
(ii) $k\rho \to \infty$ $(k\eta^{1/2} \to \infty)$ such that $k\eta \to 0$,
(iii) $k\rho \to 0$ $(k\eta^{1/2} \to 0)$.

For case (i) we note that $\Omega_{1/2}(k\eta) \to 1$, and so from (3.35a) we deduce that

$$\gamma_m(k,\rho) = O(1) \qquad \text{(case (i))}. \tag{3.44}$$

For case (ii) we have $\Omega_{1/2}(k\eta) \sim \{k\eta\}^{-1/2}$, and so, again using (3.35a), we find that

$$\gamma_m(k,\rho) = O\left(\frac{1}{k^{1/2}\eta^{1/4}}\right\} \qquad \text{(case (ii))}. \tag{3.45}$$

For case (iii) we use (3.33a) and find (for $m > 0$)

$$\gamma_m(k,\rho) \to (2m)^{1/2} \qquad \text{(case (iii))}. \tag{3.46}$$

To complete the proof of the existence of $\kappa_{m,2}$ one needs to show that $E_{k,m}^{(0)}(z)^{-1}$ $E_{k,m}^{(1)}(z)^{-1}$ is uniformly bounded for $z \in \mathbf{Z}_1$ and $1 \leq k < \infty$. This can be done in a manner similar to that for the case $z \in \mathbf{Z}_0$, by using the uniform asymptotic approximations (3.8) and (3.10) (and the connection formula (2.16)), which are valid in $\mathbf{Z}_1$. Details need not be recorded here. The proof of the existence of the supremum (2.61) (for the case $m = 0$) follows similarly to the preceding.

4. Case II: $(z - z_t(a))^{-1} f(a,z) > 0$ on the positive real z-axis. In this section we construct asymptotic solutions for case II, where $f(a,z)$ is negative on the real axis between the turning point and the pole (when $a > 0$). The appropriate Liouville transformation in this case is given by

$$f(a,z)\left(\frac{dz}{d\xi}\right)^2 = \frac{\xi - \alpha}{\xi}, \tag{4.1a}$$

$$W(\xi) = \left(\frac{d\xi}{dz}\right)^{1/2} w(z), \tag{4.1b}$$

which transforms (1.1) to the form

$$\frac{d^2W}{d\xi^2} = \left\{u^2\left(\frac{\xi - \alpha}{\xi}\right) + \frac{m^2 - \frac{1}{4}}{\xi^2} + \frac{\hat{\psi}(\alpha,\xi)}{\xi}\right\} W, \tag{4.2}$$

where

$$\hat{\psi}(\alpha,\xi) = \frac{\alpha^2 + 4\xi^2 - 16m^2(\xi - \alpha)^2}{16\xi(\xi - \alpha)^2} + \frac{(\xi - \alpha)(4ff'' + 16f^2g - 5f'^2)}{16f^3}. \tag{4.3}$$

We integrate (4.1a) to give

$$\int_\alpha^\xi \left\{\frac{\tau-\alpha}{\tau}\right\}^{1/2} d\tau = \int_{z_t}^z \{f(a,t)\}^{1/2}\, dt, \tag{4.4}$$

which yields the relationship

$$\int_{z_t}^z \{f(a,t)\}^{1/2}\, dt = \xi^{1/2}(\xi-\alpha)^{1/2} - \frac{\alpha}{2}\ln\left\{\frac{2\xi-\alpha+2\xi^{1/2}(\xi-\alpha)^{1/2}}{\alpha}\right\}. \tag{4.5}$$

The choice of branches is such that both sides are real and positive for $z \in (z_t, \infty)$ and $\xi \in (\alpha, \infty)$, with $\xi(z)$ an analytic function of z in $\mathbf{D}$. We denote by $\hat{\Delta}$ the ξ domain corresponding to the z domain $\mathbf{D}$.

Again, we specify α so that the poles $z = 0$ and $\xi = 0$ correspond, which gives the formula

$$\alpha = \frac{2}{\pi}\int_0^{z_t} \{-f(a,t)\}^{1/2}\, dt. \tag{4.6}$$

We assume that α is a strictly increasing function of a, with $\alpha \in [0, \Lambda]$.

The comparison equation this time has as its solutions the Whittaker functions $M_{u\alpha/2,m}(2u\xi)$, $W_{u\alpha/2,m}(2u\xi)$, and $W_{-u\alpha/2,m}(2u\xi e^{\pm\pi i})$. We thus seek asymptotic solutions of (4.2) of the form

$$\hat{W}^{(j)}(u,\alpha,\xi) = \hat{\mathcal{U}}^{(j)}_{u\alpha/2,m}(2u\xi) + \hat{\varepsilon}^{(j)}(u,\alpha,\xi) \qquad (j = 0,1,2,3,4), \tag{4.7}$$

where we define

$$\hat{\mathcal{U}}^{(0)}_{k,m}(z) = \frac{\Gamma(k+m+1/2)}{\gamma(k)\Gamma(1+2m)} M_{k,m}(z), \tag{4.8}$$

$$\hat{\mathcal{U}}^{(1)}_{k,m}(z) = e^{-m\pi i}\gamma(k) W_{-k,m}(ze^{-\pi i}), \tag{4.9}$$

$$\hat{\mathcal{U}}^{(2)}_{k,m}(z) = e^{m\pi i}\gamma(k) W_{-k,m}(ze^{\pi i}), \tag{4.10}$$

$$\hat{\mathcal{U}}^{(3)}_{k,m}(z) = \frac{\gamma(k)\Gamma(m-k+1/2)}{\Gamma(k+m+1/2)} W_{k,m}(z), \tag{4.11}$$

$$\hat{\mathcal{U}}^{(4)}_{k,m}(z) = \frac{e^{(k-m+1/2)\pi i}}{\gamma(k)} W_{k,m}(z), \tag{4.12}$$

introducing, for convenience, the parameter

$$\gamma(k) = k^k e^{-k}. \tag{4.13}$$

The reason that we have introduced $\hat{\mathcal{U}}^{(4)}_{k,m}(z)$, which will become clearer later, is due to the complication that $M_{k,m}(z)$ and $W_{k,m}(z)$ are linearly dependent when $k-m-1/2 \in \mathbf{N}$. When $k-m-1/2 \in \mathbf{N}$ it can be shown from (4.8) and (4.12), by using well-known connection formulas for Whittaker functions, that

$$\hat{\mathcal{U}}^{(4)}_{k,m}(z) = \hat{\mathcal{U}}^{(0)}_{k,m}(z). \tag{4.14}$$

For the time being we assume that $k-m-1/2 \notin \mathbf{N}$.

Further connection formulas for the functions $\hat{\mathcal{U}}_{k,m}^{(j)}(z)$ are given by

$$\hat{\mathcal{U}}_{k,m}^{(0)}(z) = \frac{\Gamma(k-m+\frac{1}{2})\Gamma(k+m+\frac{1}{2})}{2\pi\gamma^2(k)}\left[\hat{\mathcal{U}}_{k,m}^{(1)}(z)+\hat{\mathcal{U}}_{k,m}^{(2)}(z)\right], \tag{4.15}$$

$$\hat{\mathcal{U}}_{k,m}^{(4)}(z) = \frac{\Gamma(k-m+\frac{1}{2})\Gamma(k+m+\frac{1}{2})}{2\pi\gamma^2(k)}\left[\hat{\mathcal{U}}_{k,m}^{(1)}(z)-e^{2(k-m)\pi i}\hat{\mathcal{U}}_{k,m}^{(2)}(z)\right], \tag{4.16}$$

and

$$\hat{\mathcal{U}}_{k,m}^{(4)}(z) = \pm\frac{e^{(k-m)\pi i}\Gamma(k+m+\frac{1}{2})}{\gamma^2(k)\Gamma(m-k+\frac{1}{2})}\hat{\mathcal{U}}_{k,m}^{(1,2)}(z) \mp e^{(k-m)\pi i}e^{\pm(k-m)\pi i}\hat{\mathcal{U}}_{k,m}^{(0)}(z). \tag{4.17}$$

The motivating reason for using the particular Whittaker functions (4.8)–(4.12) is their asymptotic behavior at the singularities, which is given as follows:

$$\hat{\mathcal{U}}_{k,m}^{(0)}(z) \sim \frac{\Gamma(k+m+\frac{1}{2})}{\gamma(k)\Gamma(m-k+\frac{1}{2})}z^{-k}e^{z/2} \qquad \left(z\to\infty, \quad -\frac{\pi}{2}<\arg z<\frac{\pi}{2}\right), \tag{4.18}$$

$$\hat{\mathcal{U}}_{k,m}^{(0)}(z) \sim \frac{ie^{-(k-m)\pi i}}{\gamma(k)}z^{k}e^{-z/2} \qquad \left(z\to\infty, \quad \frac{\pi}{2}<\arg z<\frac{3\pi}{2}\right), \tag{4.19}$$

$$\hat{\mathcal{U}}_{k,m}^{(0)}(z) \sim -\frac{ie^{(k-m)\pi i}}{\gamma(k)}z^{k}e^{-z/2} \qquad \left(z\to\infty, \quad -\pi<\arg z<-\frac{3\pi}{2}\right), \tag{4.20}$$

$$\hat{\mathcal{U}}_{k,m}^{(1)}(z) \sim \gamma(k)e^{(k-m)\pi i}z^{-k}e^{z/2} \qquad \left(z\to\infty, \quad -\frac{\pi}{2}<\arg z<\frac{5\pi}{2}\right), \tag{4.21}$$

$$\hat{\mathcal{U}}_{k,m}^{(2)}(z) \sim \gamma(k)e^{-(k-m)\pi i}z^{-k}e^{z/2} \qquad \left(z\to\infty, \quad -\frac{5\pi}{2}<\arg z<\frac{\pi}{2}\right), \tag{4.22}$$

$$\hat{\mathcal{U}}_{k,m}^{(3)}(z) \sim \frac{\gamma(k)\Gamma(m-k+\frac{1}{2})}{\Gamma(k+m+\frac{1}{2})}z^{k}e^{-z/2} \qquad \left(z\to\infty, \quad -\frac{3\pi}{2}<\arg z<\frac{3\pi}{2}\right), \tag{4.23}$$

$$\hat{\mathcal{U}}_{k,m}^{(4)}(z) \sim -\frac{e^{(k-m-1/2)\pi i}}{\gamma(k)}z^{k}e^{-z/2} \qquad \left(z\to\infty, \quad -\frac{3\pi}{2}<\arg z<\frac{3\pi}{2}\right), \tag{4.24}$$

$$\hat{\mathcal{U}}_{k,m}^{(0)}(z) \sim \frac{\Gamma(k+m+\frac{1}{2})}{\gamma(k)\Gamma(1+2m)}z^{m+1/2} \qquad (z\to 0), \tag{4.25}$$

$$\hat{\mathcal{U}}_{k,m}^{(3)}(z) \sim \frac{\gamma(k)\Gamma(2m)}{\Gamma(k+m+\frac{1}{2})}z^{1/2-m} \qquad (z\to 0, \quad m>0), \tag{4.26}$$

$$\hat{U}_{k,0}^{(3)}(z) \sim \frac{\gamma(k)}{\Gamma(k+\frac{1}{2})} z^{1/2} \ln(1/z) \qquad (z \to 0), \tag{4.27}$$

$$\hat{U}_{k,m}^{(1,2)}(z) \sim \mp i \frac{\gamma(k)\Gamma(2m)}{\Gamma(k+m+\frac{1}{2})} z^{1/2-m} \qquad (z \to 0, \quad m > 0), \tag{4.28}$$

$$\hat{U}_{k,0}^{(1,2)}(z) \sim \mp i \frac{\gamma(k)}{\Gamma(k+\frac{1}{2})} z^{1/2} \ln(1/z) \qquad (z \to 0). \tag{4.29}$$

And so in particular, $\hat{U}_{k,m}^{(0)}(z)$ is recessive at $z = 0, \hat{U}_{k,m}^{(1)}(z)$ is recessive at $z = \infty$ $(\pi/2 < \arg z < 3\pi/2), \hat{U}_{k,m}^{(2)}(z)$ is recessive at $z = \infty$ $(-3\pi/2 < \arg z < -\pi/2)$, and $\hat{U}_{k,m}^{(3)}(z)$ is recessive at $z = \infty$ $(-\pi/2 < \arg z < \pi/2)$. Also, $\hat{U}_{k,m}^{(4)}(z)$ is recessive at $z = \infty$ $(-\pi/2 < \arg z < \pi/2)$ and, in addition, is recessive at $z = 0$ when $k - m - 1/2 \in \mathbf{N}$ (as a result of (4.14)).

Corresponding to (2.29), let us define the functions

$$\hat{\Phi}_k^{(j)}(z) = \frac{1}{2} \int_{4k+1}^{z} \left(\frac{t-4k}{t} \right)^{1/2} dt \qquad (k > 0, \quad j = 1, 2, 3), \tag{4.30}$$

with branches defined as follows. With respect to the branch point $z = 4k$ of $\hat{\Phi}_k^{(j)}(z)$ we introduce a cut along a certain curve $\hat{C}_j$. The curve $\hat{C}_2$ consists of the union of the real segment from $z = 4k$ to $z = 4k+1$, with the curve in the upper half plane on which $\operatorname{Re} \Phi_k^{(j)}(z) = 0$. The curve $\hat{C}_1$ is defined as the conjugate of $\hat{C}_2$, and $\hat{C}_3$ is the finite segment of the positive real axis from $z = 4k+1$ to $z = 0$. The nonreal parts of the curves $\hat{C}_1$ and $\hat{C}_2$ emanate from $z = 4k+1$ at an angle of $\mp\pi/2$ with the positive real axis, respectively, and at infinity are asymptotic to the curves

(4.31a)
$$y = \mp \left[\frac{1}{4}(1+\beta(k))^2 e^{(x-\beta(k))/k} - x^2 \right]^{1/2} \qquad (x = \operatorname{Re} z, \quad y = \operatorname{Im} z, \quad k > 0),$$

where

$$\beta(k) = 2k + (4k+1)^{1/2}. \tag{4.31b}$$

When $k = 0$ the curves $\hat{C}_1$ and $\hat{C}_2$ are the vertical lines $\operatorname{Re} z = 1$.

The three curves $\hat{C}_j$ divide the principle z-plane into three domains, which we call $\mathcal{S}_k^{(j)} (j = 1, 2, 3)$. The regions in the ξ-plane corresponding to these will be labeled $\hat{\mathrm{S}}_\alpha^{(j)}$, respectively; see Fig. 6. In this figure pairs of numerically satisfactory solutions in $\hat{\mathrm{S}}_\alpha^{(j)}$ are indicated.

We define $\hat{\Phi}_k^{(j)}(z)$ $(j = 1, 2, 3)$ to have the branch cut $\hat{C}_j$, and with respect to the branch point at $z = 0$ we introduce, for all three functions, a cut along the negative real z-axis from $z = 0$ to $z = -\infty$. The branches in (2.29) are now selected so that the three functions are continuous in their respective cut planes, such that $\operatorname{Re} \hat{\Phi}_k^{(j)}(z) \to \infty$ for $z \in \hat{\mathcal{S}}_k^{(j)}$ as $|z| \to \infty$.

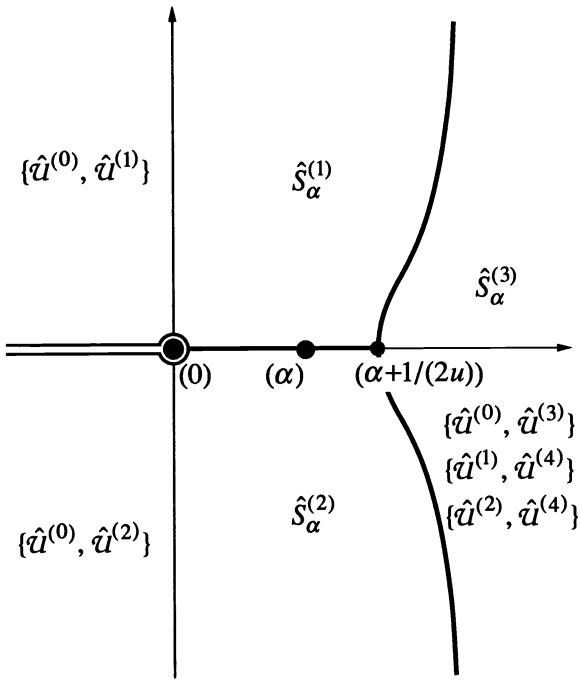

FIG. 6. *ξ-plane.*

We next define

$$\hat{\Phi}_k^{(4)}(z) = \hat{\Phi}_k^{(3)}(z) \qquad (k > 0) \tag{4.32}$$

$$\hat{\Phi}_k^{(0)}(z) = -\hat{\Phi}_k^{(j)}(z) \qquad \left(k > 0, z \in \hat{\mathcal{S}}_k^{(j)}\right), \tag{4.33}$$

so that $\operatorname{Re} \Phi_k^{(0)}(z) \to -\infty$ as $|z| \to \infty$. For the case $k = 0$ we define $\Phi_0^{(j)}(z) = \lim_{k\to 0} \Phi_k^{(j)}(z)$. Thus

$$\hat{\Phi}_0^{(1,2)}(z) = \begin{cases} \frac{1}{2}(z-1) & \left(z \in \hat{\mathcal{S}}_0^{(2,1)}\right), \\ \frac{1}{2}(1-z) & \left(z \in \hat{\mathcal{S}}_0^{(1,2)} \cup \hat{\mathcal{S}}_0^{(3)}\right), \end{cases} \tag{4.34}$$

$$\hat{\Phi}_0^{(4)}(z) = \hat{\Phi}_0^{(3)}(z) = \tfrac{1}{2}(z-1), \tag{4.35}$$

$$\hat{\Phi}_0^{(0)}(z) = -\hat{\Phi}_0^{(j)}(z) \left(z \in \hat{\mathcal{S}}_0^{(j)}\right). \tag{4.36}$$

The level curves in the ξ-plane for case II are defined by $\operatorname{Re} \hat{\Phi}_{u\alpha/2}^{(j)}(2u\xi) =$ constant, some of which are indicated in Fig. 7. In this figure the heavy lines emanating from the point $\xi = \alpha + 1/(2u)$ are the curves $\operatorname{Re} \hat{\Phi}_{u\alpha/2}^{(j)}(2u\xi) = 0$, and those emanating from the turning point $\xi = \alpha$ $(\alpha > 0)$ make an angle $\pm\pi/3$ with the positive

real ξ-axis and satisfy

$$\text{Re } \hat{\Phi}^{(0)}_{u\alpha/2}(2u\xi) = \frac{1}{2}(u\alpha - \beta(u\alpha/2)) + \frac{u\alpha}{2}\ln\left(\frac{1+\beta(u\alpha/2)}{u\alpha}\right). \tag{4.37}$$

When $\alpha = 0$ the level curves are the vertical lines Re ξ = constant.

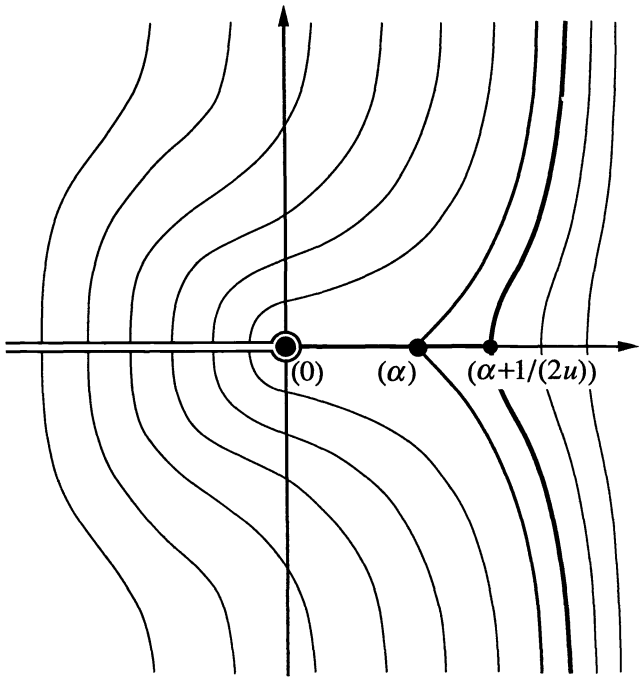

FIG. 7. *ξ-plane.*

We now begin our definitions of the weight functions for $\hat{\mathcal{U}}^{(j)}_{k,m}(z)$. For $z \in \hat{\mathcal{S}}^{(3)}_k$ we define

$$\hat{E}^{(j)}_{k,m}(z) = \left|\exp\left\{\hat{\Phi}^{(j)}_k(z)\right\}\right| \qquad (j = 0, 1, 2, 3, 4), \tag{4.38}$$

and for $j = 4$ only we use the definition (4.38) also for $z \in \hat{\mathcal{S}}^{(1)}_k \cup \hat{\mathcal{S}}^{(2)}_k$.

The definitions of the weight functions for $z \in \hat{\mathcal{S}}^{(1)}_k \cup \hat{\mathcal{S}}^{(2)}_k$ are similar to the corresponding ones for $z \in \hat{\mathcal{S}}^{(0)}_k$ in case I. Given any point $z \in \hat{\mathcal{S}}^{(1)}_k$, we define $\hat{\mathcal{D}}^{(1)}_k(z)(k \geq 0)$ to be the set of points in the t-plane satisfying

$$\text{Re } \hat{\Phi}^{(1)}_k(t) \geq \text{Re } \hat{\Phi}^{(1)}_k(z), \tag{4.39}$$

$$|t| \geq \min\{4k+1, |z|\}, \tag{4.40}$$

$$0 \leq \arg t < \pi; \tag{4.41}$$

see Fig. 8. Given any point $z \in \hat{\mathcal{S}}^{(2)}_k$, we define $\hat{\mathcal{D}}^{(2)}_k(z)$ to be conjugate of $\hat{\mathcal{D}}^{(1)}_k(z)(k \geq 0)$.

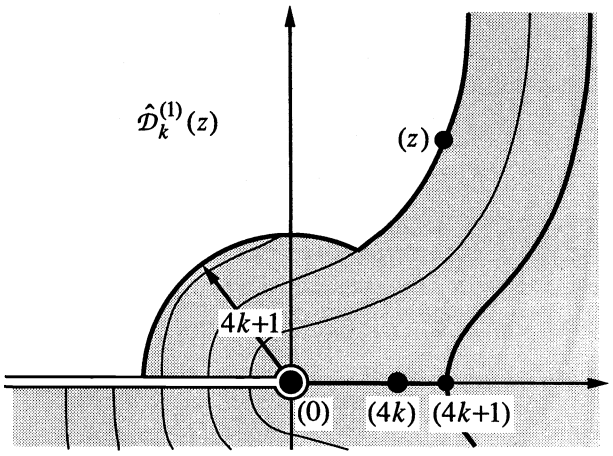

FIG. 8. *t-plane.*

For $k > 0$ choose any point $z \in \hat{\mathcal{S}}_k^{(1)} \cup \hat{\mathcal{S}}_k^{(2)}$ and define $\hat{\mathcal{D}}_k^{(0)}(z)$ to be the set of points in the t-plane satisfying

$$\text{Re } \hat{\Phi}_k^{(0)}(t) \geq \text{Re } \hat{\Phi}_k^{(0)}(z), \tag{4.42}$$

$$|t| \leq |z|, \tag{4.43}$$

$$-\infty < \text{Re } t \leq 4k + 1, \tag{4.44}$$

$$-\pi < \arg t < \pi; \tag{4.45}$$

see Fig. 9(a).

For $k = 0$ we introduce the radial function

$$\hat{R}_0(z) = \frac{|z|}{\min\{1, |1 - \text{Re}(z)|\}}, \tag{4.46}$$

which has the properties

$$\hat{R}_0(z) \sim |z| \qquad (z \to 0), \tag{4.47}$$

$$\hat{R}_0(z) = |z| \qquad (\text{Re}(z) \leq 0), \tag{4.48}$$

$$\hat{R}_0(z) \to \infty \qquad (\text{Re}(z) \to 1). \tag{4.49}$$

Then, given any point $z \in \hat{\mathcal{S}}_0^{(1)} \cup \hat{\mathcal{S}}_0^{(2)}$, we define $\hat{\mathcal{D}}_0^{(0)}(z)$ to be the set of points in the t-plane satisfying

$$-\infty < \text{Re}(t) \leq 1, \tag{4.50}$$

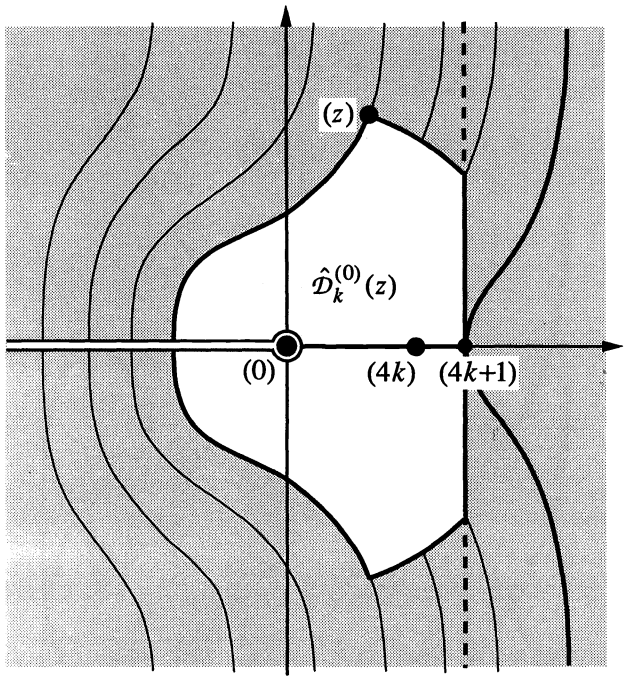

FIG. 9(a). *t-plane.*

$$|\mathrm{Re}(t)| \leq |\mathrm{Re}(z)|, \tag{4.51}$$

$$|t| < \hat{R}_0(z), \tag{4.52}$$

$$-\pi < \arg t < \pi; \tag{4.53}$$

see Fig. 9(b).

For $(j = 0, 1, 2)$ we then define

$$\hat{e}_{k,m}^{(j)} \hat{E}_{k,m}^{(j)}(z)^{-1} = \sup_{t \in \hat{\mathcal{D}}_k^{(j)}(z)} \left\{ \Omega_{1/2}(t) \left| \hat{\mathcal{U}}_{k,m}^{(j)}(t) \right| \right\}, \tag{4.54}$$

with

$$\hat{e}_{k,m}^{(j)} = \sup_{t \in \hat{\mathcal{D}}_k^{(j)}(4k+1)} \left\{ \Omega_{1/2}(t) \left| \hat{\mathcal{U}}_{k,m}^{(j)}(t) \right| \right\}, \tag{4.55}$$

where in (4.54) it is understood that $z \in \hat{\mathcal{S}}_k^{(j)}$ when $j = 1, 2$ and $z \in \hat{\mathcal{S}}_k^{(1)} \cup \hat{\mathcal{S}}_k^{(2)}$ when $j = 0$. By using the uniform asymptotic approximations for Whittaker functions in [2] it can be shown that for all j $\hat{e}_{k,m}^{(j)} = O\left(k^{1/6}\right)$ as $k \to \infty$.[3]

[3] In [2] there are two errors: in equation (4.7) the term -1 should be included in the right-hand side, and in equations (6.17) and (6.20) the term 4 should be replaced by the term e^{-2}.

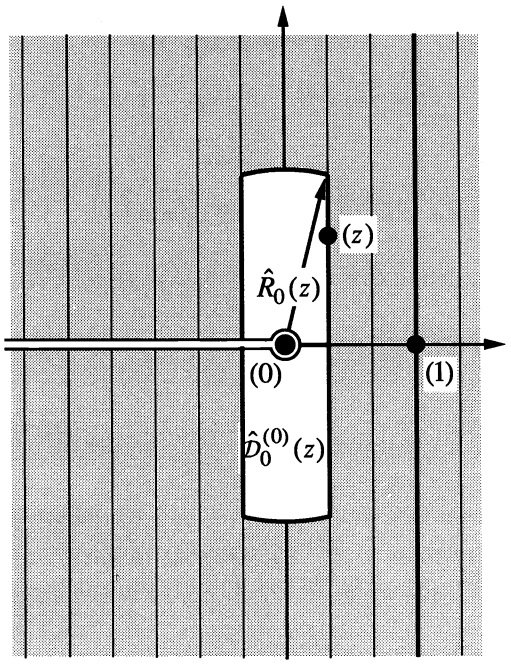

FIG. 9(b). *z-plane.*

The only points in $\hat{\mathcal{S}}_k^{(1)} \cup \hat{\mathcal{S}}_k^{(2)}$ for which we define a weight function for $\hat{\mathcal{U}}_{k,m}^{(3)}(z)$ are those lying in the real interval $0 < z \leq 4k+1$. For these values of z we prescribe

$$\hat{e}_{k,m}^{(3)} \hat{E}_{k,m}^{(3)}(z)^{-1} = \sup_{\substack{\mathrm{Re}(t) \geq z \\ t \in \hat{C}_1 \cup \hat{C}_2 \cup \hat{C}_3}} \left\{ \Omega_{1/2}(t) \left| \hat{\mathcal{U}}_{k,m}^{(3)}(t) \right| \right\}, \tag{4.56}$$

$$\hat{e}_{k,m}^{(3)} = \sup_{\substack{\mathrm{Re}(t) \geq 4k+1 \\ t \in \hat{C}_1 \cup \hat{C}_2}} \left\{ \Omega_{1/2}(t) \left| \hat{\mathcal{U}}_{k,m}^{(3)}(t) \right| \right\}. \tag{4.57}$$

Modulus and phase functions are then defined to satisfy

$$\left| \hat{\mathcal{U}}_{k,m}^{(j)}(z) \right| = \hat{E}_{k,m}^{(j)}(z)^{-1} \hat{M}_{k,m}^{(j,l)}(z) \sin \hat{\theta}_{k,m}^{(j,l)}(z), \tag{4.58}$$

$$\left| \hat{\mathcal{U}}_{k,m}^{(l)}(z) \right| = \hat{E}_{k,m}^{(l)}(z)^{-1} \hat{M}_{k,m}^{(j,l)}(z) \cos \hat{\theta}_{k,m}^{(j,l)}(z), \tag{4.59}$$

where j, l run through the integer values $0 \leq j, l \leq 4, (l \neq j)$, yielding

$$\hat{M}_{k,m}^{(j,l)}(z) = \left\{ \hat{E}_{k,m}^{(j)}(z)^2 \left| \hat{\mathcal{U}}_{k,m}^{(j)}(z) \right|^2 + \hat{E}_{k,m}^{(l)}(z)^2 \left| \hat{\mathcal{U}}_{k,m}^{(l)}(z) \right|^2 \right\}^{1/2}, \tag{4.60}$$

$$\hat{\theta}_{k,m}^{(j,l)}(z) = \tan^{-1} \left\{ \frac{\hat{E}_{k,m}^{(j)}(z) \left| \hat{\mathcal{U}}_{k,m}^{(j)}(z) \right|}{\hat{E}_{k,m}^{(l)}(z) \left| \hat{\mathcal{U}}_{k,m}^{(l)}(z) \right|} \right\}. \tag{4.61}$$

The following asymptotic behavior as $z \to 0$ should be noted (for $0 \le j \le 3$):

$$\hat{e}_{k,m}^{(j)} \hat{E}_{k,m}^{(j)}(z)^{-1} \sim |z|^{-1/2} \left| \hat{\mathcal{U}}_{k,m}^{(j)}(z) \right|, \tag{4.62}$$

$$\hat{M}_{k,m}^{(j,l)}(z) \sim \left\{ \left(\hat{e}_{k,m}^{(j)} \right)^2 + \left(\hat{e}_{k,m}^{(l)} \right)^2 \right\}^{1/2} |z|^{1/2}. \tag{4.63}$$

For the derivatives we define (for $0 \le j, l \le 4, (l \ne j)$)

$$\left| \hat{\mathcal{U}}_{k,m}^{(j)'}(z) \right| = \hat{E}_{k,m}^{(j)}(z)^{-1} \hat{N}_{k,m}^{(j,l)}(z) \sin \hat{\omega}_{k,m}^{(j,l)}(z), \tag{4.64}$$

$$\left| \hat{\mathcal{U}}_{k,m}^{(l)'}(z) \right| = \hat{E}_{k,m}^{(l)}(z)^{-1} \hat{N}_{k,m}^{(j,l)}(z) \cos \hat{\omega}_{k,m}^{(j,l)}(z). \tag{4.65}$$

We next choose reference points $\hat{\xi}^{(j)} (1 \le j \le 4)$, where $\hat{\xi}^{(0)} = 0, \hat{\xi}^{(j)} (j = 1, 2, 3)$ is some suitably chosen point in $\hat{\mathrm{S}}_\alpha^{(j)}$ (possibly at infinity) and $\hat{\xi}^{(4)} = \hat{\xi}^{(3)}$.

We define paths of integration $\hat{\mathcal{P}}^{(j)} (1 \le j \le 4)$ in the v-plane to run from $v = \hat{\xi}^{(j)}$ to $v = \xi$, such that

(i) $\hat{\mathcal{P}}^{(j)}$ consists of a finite chain of R_2 arcs;

(ii) $\operatorname{Re} \hat{\Phi}_{u\alpha/2}^{(j)}(2uv)$ is nonincreasing as v passes along $\hat{\mathcal{P}}^{(j)}$ from $\hat{\xi}^{(j)}$ to ξ, except when $\alpha = 0, j = 0$, in which case $|\operatorname{Re}(v)|$ must be nondecreasing as v passes along $\hat{\mathcal{P}}^{(0)}$;

(iiia) for the segment of $\hat{\mathcal{P}}^{(0)}$ in $\hat{\mathrm{S}}_\alpha^{(1)} \cup \hat{\mathrm{S}}_\alpha^{(2)}$, $|v|$ is nondecreasing as v passes along $\hat{\mathcal{P}}^{(0)}$ from 0;

(iiib) if $\xi \in \hat{\mathrm{S}}_\alpha^{(1,2)}$, $|v|$ is nonincreasing as v passes to ξ along the segment of $\hat{\mathcal{P}}^{(1,2)}$ lying in $\hat{\mathrm{S}}_\alpha^{(1,2)}$;

(iv) the only segment of $\hat{\mathcal{P}}^{(3)}$ that can lie in $\hat{\mathrm{S}}_\alpha^{(1)} \cup \hat{\mathrm{S}}_\alpha^{(2)}$ is the one that consists of the real interval $\xi \le v \le \alpha + 1/(2u)$.

The subsequent error bounds will be uniformly valid in subdomains $\hat{\Delta}_{u\alpha/2,m}^{(j)} (1 \le j \le 4)$, defined as the set of points in $\Xi_{u\alpha/2,m}^{(j)}$ that can be linked to $\tilde{\xi}^{(j)}$ by a path $\mathcal{P}^{(j)}$ in $\Xi_{u\alpha/2,m}^{(j)}$ satisfying the conditions (i)–(iv), where

$$\Xi_{u\alpha/2,m}^{(0)} = \begin{cases} \hat{\Delta} & \left(\frac{1}{2}u\alpha - m - \frac{1}{2} \notin \mathbf{N} \right), \\ \hat{\mathrm{S}}_\alpha^{(1)} \cup \hat{\mathrm{S}}_\alpha^{(2)} & \left(\frac{1}{2}u\alpha - m - \frac{1}{2} \in \mathbf{N} \right), \end{cases} \tag{4.66}$$

$$\Xi_{u\alpha/2,m}^{(1)} = \hat{\mathrm{S}}_\alpha^{(1)} \cup \hat{\mathrm{S}}_\alpha^{(3)}, \tag{4.67}$$

$$\Xi_{u\alpha/2,m}^{(2)} = \hat{\mathrm{S}}_\alpha^{(2)} \cup \hat{\mathrm{S}}_\alpha^{(3)}, \tag{4.68}$$

$$\Xi_{u\alpha/2,m}^{(3)} = \begin{cases} \hat{\mathrm{S}}_\alpha^{(3)} \cup \{\xi : 0 < \xi \le \alpha + 1/(2u)\} & \left(\frac{1}{2}u\alpha - m - \frac{1}{2} \notin \mathbf{N} \right), \\ \emptyset & \left(\frac{1}{2}u\alpha - m - \frac{1}{2} \in \mathbf{N} \right), \end{cases} \tag{4.69}$$

$$\Xi^{(4)}_{u\alpha/2,m} = \hat{S}^{(3)}_{\alpha}. \tag{4.70}$$

Here $\emptyset$ denotes the empty set, and so, for instance, there will be no bounds for $\hat{\varepsilon}^{(3)}(u,\alpha,\xi)$ when $\frac{1}{2}u\alpha - m - \frac{1}{2} \in \mathbf{N}$. We denote the z-domains corresponding to $\Xi^{(j)}_{u\alpha/2,m}$ by $\mathbf{X}^{(j)}_{k,m}$.

As in case I, we choose a δ in the interval

$$0 \le \delta < \frac{2}{3}, \tag{4.71}$$

such that the following integral converges uniformly with respect to α at $\xi = 0$:

$$\hat{F}(u,\alpha,\xi) = \int \frac{\hat{\psi}(\alpha,\xi)}{\xi\Omega_{\delta}(2u\xi)}d\xi. \tag{4.72}$$

Analogously to (2.56), we introduce the following constant:

$$\hat{\kappa}_m = \hat{\kappa}_{m,1}\hat{\kappa}_{m,2}, \tag{4.73}$$

where

$$\hat{\kappa}_{m,1} = \sup\left\{\Omega_{\delta}(z)(1+k)^{-1/3}\sum_{j=0}^{4}\hat{E}^{(j)}_{k,m}(z)^2\left|\hat{\mathcal{U}}^{(j)}_{k,m}(z)\right|^2\right\} \qquad (m>0), \tag{4.74}$$

$$\hat{\kappa}_{m,2} = \sup\left\{\hat{E}^{(0)}_{k,m}(z)^{-1}\hat{E}^{(1)}_{k,m}(z)^{-1}\right\} \qquad (m>0), \tag{4.75}$$

the supremum being taken over all $k \ge 0$ and all $z \in \mathbf{X}^{(j)}_{k,m}$ for (4.74) and the supremum being taken over all $k \ge 0$ and all $z \in \hat{S}^{(1)}_k \cup \hat{S}^{(2)}_k \backslash \{0\}$ for (4.75).

For the case $m = 0$ we select any δ' satisfying

$$0 < \delta' < \frac{1}{3} \tag{4.76}$$

and then define

$$\hat{\kappa}_{0,1} = \sup\left\{\Omega_{\delta}(z)\Omega_{\delta'}(z)(1+k)^{-1/3}\sum_{j=0}^{2}\hat{E}^{(j)}_{k,0}(z)^2\left|\hat{\mathcal{U}}^{(j)}_{k,0}(z)\right|^2\right\}, \tag{4.77}$$

$$\hat{\kappa}_{0,2} = \sup\left\{\Omega_{\delta'}(z)^{-1}\hat{E}^{(0)}_{k,0}(z)^{-1}\hat{E}^{(1)}_{k,0}(z)^{-1}\right\}, \tag{4.78}$$

where the suprema are taken over the same ranges as for (4.74) and (4.75), respectively. The existence of these suprema can be established in a similar manner to the proofs in §3, by using, for example, the uniform asymptotic approximations for Whittaker functions in [2].

We now state our theorem on error bounds for case II.

THEOREM 2. *With the conditions described in the present section,* (4.2) *has, for each* $u > 0$ *and* $\alpha \in [0,\Lambda]$, *solutions* $\hat{W}^{(j)}(u,\alpha,\xi)(j = 0,1,2,3,4)$ *that are holomorphic in* $\hat{\Delta}$ *except at* $\xi = 0$ *and satisfy*

$$\hat{W}^{(j)}(u,\alpha,\xi) = \hat{\mathcal{U}}^{(j)}_{u\alpha/2,m}(2u\xi) + \hat{\varepsilon}^{(j)}(u,\alpha,\xi), \tag{4.79}$$

where

$$\frac{\left|\hat{\varepsilon}^{(j)}(u,\alpha,\xi)\right|}{\hat{M}^{(j,l)}_{u\alpha/2,m}(2u\xi)}, \qquad \frac{\left|\partial\hat{\varepsilon}^{(j)}(u,\alpha,\xi)/\partial\xi\right|}{2u\hat{N}^{(j,l)}_{u\alpha/2,m}(2u\xi)}$$

(4.80)

$$\leq \hat{E}^{(j)}_{u\alpha/2,m}(2u\xi)^{-1}\left[\exp\left\{\frac{\hat{\kappa}_m(\frac{1}{2}u\alpha+1)^{1/3}}{2u}\mathcal{V}_{\hat{\mathcal{P}}^{(j)}}(\hat{F})\right\}-1\right],$$

when $\xi \in \hat{\Delta}^{(j)}_{u\alpha/2,m}$. *In* (4.80) *the suffix* l *accompanying the* j *in* $\hat{M}$ *and* $\hat{N}$ *depends on which region* ξ *lies in, according to Table* 1.

TABLE 1

	$j=0$	$j=1$	$j=2$	$j=3$	$j=4$
$l=0$	—	$\hat{S}^{(1)}_\alpha$	$\hat{S}^{(2)}_\alpha$	$\Xi^{(3)}_{u\alpha/2,m}$	–
$l=1$	$\hat{S}^{(1)}_\alpha$	–	–	–	$\Xi^{(4)}_{u\alpha/2,m}$
$l=2$	$\hat{S}^{(2)}_\alpha$	–	–	–	–
$l=3$	$\hat{S}^{(3)}_\alpha \cap \Xi^{(0)}_{u\alpha/2,m}$	–	–	–	–
$l=4$	–	$\hat{S}^{(3)}_\alpha$	$\hat{S}^{(3)}_\alpha$	–	–

Discussions similar to those for (2.63) lead to the estimates

$$\left|\hat{\varepsilon}^{(j)}(u,\alpha,\xi)\right| = \hat{E}^{(j)}_{u\alpha/2,m}(2u\xi)^{-1}\hat{M}^{(j,l)}_{u\alpha/2,m}(2u\xi)O\Big((u\alpha+1)^{1/3}u^{-1+\delta}\Big) \tag{4.81}$$

as $u \to \infty$ uniformly for $\xi \in \hat{\Delta}^{(j)}_{u\alpha/2,m}$ (with l given by Table 1). As in case I, the constant δ can be taken to be zero if $\hat{\psi}(\alpha,\xi) = O(\xi)$ as $\xi \to 0$; also, for $j \neq 0, \delta$ can be taken to be zero when ξ is bounded away from 0 (which is always true for $j = 4$).

Finally, we remark that the solutions given by Theorem 2 form a numerically satisfactory set in the principal ξ-plane for all ranges of u and α under consideration. The pairs $\{\hat{W}^{(0)}, \hat{W}^{(1)}\}$, $\{\hat{W}^{(0)}, \hat{W}^{(2)}\}$, and $\{\hat{W}^{(1)}, \hat{W}^{(4)}\}$ form sets of numerically satisfactory solutions in $\hat{\mathrm{S}}^{(1)}_\alpha$, $\hat{\mathrm{S}}^{(2)}_\alpha$, and $\hat{\mathrm{S}}^{(3)}_\alpha$, respectively. Moreover, when $u\alpha/2-m-1/2 \notin \mathbf{N}$, the pair $\{\hat{W}^{(0)}, \hat{W}^{(3)}\}$ form a numerically satisfactory set of solutions on the positive real ξ-axis.

ON THE DERIVATIVE WITH RESPECT TO A PARAMETER OF A ZERO OF A STURM–LIOUVILLE FUNCTION*

ÁRPÁD ELBERT† AND MARTIN E. MULDOON‡

Abstract. A formula for the derivative with respect to a parameter ν of a zero of a suitable solution $z(t,\nu)$ of the differential equation $(p(t,\nu)z')' + r(t,\nu)z = 0$ is derived. This provides a kind of quantitative confirmation of the Sturm comparison theorem in that it shows that the zeros are monotonic in ν in the same direction as $p(t,\nu)$ and in a direction opposite to that of $r(t,\nu)$. It is also shown that the derivative of a zero with respect to a parameter is equal to the value at the zero of a function that satisfies a third-order linear nonhomogeneous differential equation. Different methods of solving this equation lead to different formulas for the derivative. The results are applied to get formulas for the derivative with respect to λ of the zeros of the Gegenbauer polynomial $P_n^{(\lambda)}(x)$. The method also yields a generalization to arbitrary cylinder functions of formulas due, respectively, to Schläfli and Schafheitlin for the derivative with respect to order of the zeros of the Bessel functions $J_\nu(x)$ and $Y_\nu(x)$.

Key words. Sturm–Liouville functions, zeros, monotonicity, Bessel function, ultraspherical polynomials

1. Introduction.

The Sturm comparison theorem [21], [22, p. 19] says essentially that if y and Y vanish at a and satisfy

$$(py')' + ry = 0,$$

$$(PY')' + RY = 0,$$

where $0 < P(t) < p(t)$, $R(t) > r(t)$, $a < t < b$, then the next zero of Y to the right of a on (a,b) occurs before the next zero of y. Thus if we have a *family* of functions $y(\nu,t)$ satisfying

$$(p(t,\nu)y')' + r(t,\nu)y = 0, \tag{1.1}$$

where $p(t,\nu)$ increases and $r(t,\nu)$ decreases in ν for each t, and $y(a,\nu) = 0$ for each ν, then the next zero $c = c(\nu)$ of $y(t,\nu)$ to the right of a increases with ν or $dc/d\nu > 0$. This raises the question of whether we can find a formula for $dc/d\nu$ from which its positivity would be obvious. We prove such a formula for suitable functions $p(t,\nu)$ and $r(t,\nu)$:

$$p(c,\nu)[y'(c,\nu)]^2\frac{dc}{d\nu} = \int_a^c \left[-r_\nu(s,\nu)y^2(s,\nu) + p_\nu(s,\nu)[y'(s,\nu)]^2\right] ds. \tag{1.2}$$

(Here and in what follows, the prime indicates partial differentiation with respect to the first place variable, and subscripts denote partial differentiation with respect to the indicated variable.)

In §5 we show also that the derivative of a zero with respect to a parameter is equal to the value at the zero of a function that satisfies a third-order linear nonhomogeneous differential equation.

We apply our results to get formulas for the derivative with respect to λ of the zeros of the Gegenbauer polynomial $P_n^{(\lambda)}(x)$. Our method also yields a generalization to arbitrary cylinder functions $C_\nu(x) = \cos\alpha J_\nu(x) - \sin\alpha Y_\nu(x)$ of formulas due to Schläfli [20], [23, p. 508] and Schafheitlin [19], respectively, for the derivatives with respect to order of the zeros of the Bessel functions $J_\nu(t)$ and $Y_\nu(t)$.

In a later paper [6] we apply some of these results to zeros of Hermite functions.

2. The Richardson formula. We begin by considering the differential equation

$$(p(t,\nu)y')' + r(t,\nu)y = 0, \qquad t \in I, \tag{2.1}$$

for each ν in some interval J. We suppose also that $p^{-1}(t,\nu)$ and $r(t,\nu)$ are of class C^1 in a domain of (t,ν)-space that includes $I \times J$. This implies, in view of [10, Cor. 4.1, p. 101], that the solutions of (2.1) are of class C^1 throughout their domains of existence in the (t,ν) plane. Furthermore, [10, Thm. 3.1, p. 95] shows that $y_\nu(t,\nu)$ satisfies the equation obtained by formally differentiating equation (2.1) with respect to ν, with the implied interchange of orders of differentiation. Thus we get

$$(p_\nu y_t)_t + (py_{\nu t})_t + r_\nu y + ry_\nu = 0. \tag{2.2}$$

Multiplying (2.1) by y_ν and (2.2) by $-y$ and adding, we get, as in [18, p. 293], that

$$D_t\left[py_t y_\nu - pyy_{\nu t} - p_\nu y_t y\right] = r_\nu y^2 - p_\nu y_t^2. \tag{2.3}$$

Now, if we are in a situation where either $y(a,\nu) = 0$ or $y_t(a,\nu) = 0$ for each ν in J, and if $c = c(\nu)$ is another zero of $y(t,\nu)$, we see by integrating (2.3) from a to c that

$$p(c)y_t(c,\nu)y_\nu(c,\nu) = \int_a^c \left[r_\nu y^2 - p_\nu y_t^2\right] ds. \tag{2.4}$$

Also, by differentiating $y(c,\nu) = 0$ we have

$$y_t(c,\nu)\frac{dc}{d\nu} + y_\nu(c,\nu) = 0, \tag{2.5}$$

so that we finally get

$$p(c,\nu)[y'(c,\nu)]^2\frac{dc}{d\nu} = \int_a^c \left[-r_\nu(s,\nu)y^2(s,\nu) + p_\nu(s,\nu)[y'(s,\nu)]^2\right] ds. \tag{2.6}$$

Actually, by a well-known transformation we can reduce the differential equation (2.1) to the case where $p(t,\nu) \equiv 1$. In that case, (2.6) takes the simpler form

$$[y'(c,\nu)]^2\frac{dc}{d\nu} = \int_a^c \left[-r_\nu(s,\nu)y^2(s,\nu)\right] ds. \tag{2.7}$$

We consider now the frequently occurring case where the point a is a singular point of the differential equation. We assume again that $p(t,\nu) \equiv 1$. Then if a is the left-hand endpoint of the interval I, for $c > a$ we get, as before,

$$y_t(c,\nu)y_\nu(c,\nu) + \left[yy_{\nu t} - y_t y_\nu\right]_{t=a+\epsilon} = \int_{a+\epsilon}^c \left[r_\nu y^2\right] ds \tag{2.8}$$

for each $\epsilon > 0$. Thus we get the result (2.7) again, provided that the integral on its right-hand side exists and provided that

$$\lim_{\epsilon \to 0^+} [y(a+\epsilon)y_{\nu t}(a+\epsilon) - y_t(a+\epsilon)y_\nu(a+\epsilon)] = 0. \tag{2.9}$$

The result is modified in an obvious way when $c < a$.

3. Applications of the Richardson formula.

3.1. The Bessel equation. As a first application we consider the equation

$$y'' + \left[1 + \frac{1/4 - \nu^2}{t^2}\right] y = 0, \tag{3.1}$$

with a solution $y(t,\nu) = t^{1/2}J_\nu(t)$ vanishing at $t = 0$. The method of §2 is applicable, with $a = 0$, since $J_\nu(0) = 0$, $\nu > 0$, and we recover Schläfli's formula [20], [23, p. 508]

$$\frac{dj}{d\nu} = \frac{2\nu}{jJ_{\nu+1}^2(j)} \int_0^j s^{-1}J_\nu^2(s)ds, \qquad \nu > 0, \tag{3.2}$$

where $j = j(\nu, k)$ is a positive zero of $J_\nu(x)$. The verification of condition (2.9) for $\nu > 0$ is based on the series expansion of $J_\nu(x)$.

3.2. The generalized Airy equation. Here we consider the differential equation

$$y'' + t^\alpha y = 0, \qquad t \geq 0, \tag{3.3}$$

with the initial conditions

$$y(0) = 0, \qquad y'(0) = 1. \tag{3.4}$$

α is supposed to be a fixed positive number. Using the comparison equation $z''+z = 0$, we see that all the positive zeros of y exceed 1. (Suppose that y has a zero on $(0,1)$. The equation $z'' + z = 0$ is a Sturm majorant of (3.3) on $(0,1)$. Thus its solution $\sin t$, which satisfies $z(0) = 0$, $z'(0) = 1$, would have to have a zero there too, which is impossible.) A well-known transformation [23, p. 96] shows that the solution of (3.3) is given by $y(t,\alpha) = \nu^{-\nu}\Gamma(\nu+1)t^{1/2}J_\nu(2\nu t^{1/(2\nu)})$, where $\nu = 1/(\alpha+2)$. Since $y(t,\alpha)$ vanishes at 0 for each $\alpha > 0$, we find, as in §2, that for every positive zero $a_{\alpha k}$ of $y(t,\alpha)$

$$[y'(a,\alpha)]^2 \frac{da}{d\alpha} = -\int_0^a s^\alpha \log s [y(s,\alpha)]^2\, ds. \tag{3.5}$$

Since the integrand changes sign at $s = 1$, it does not seem to be easy to deduce from (3.5) the fact [9] that $da/d\alpha < 0$, $\alpha > 0$.

3.3. Ultraspherical polynomials. With a usual notation ([22], not [7]) for the ultraspherical or Gegenbauer polynomials, we recall [22] that $y_n(t,\lambda) = (1 - t^2)^{\lambda/2+1/4}P_n^{(\lambda)}(t)$ is a solution of

$$\frac{d^2y}{dx^2} + \left\{\frac{(n+\lambda)^2}{1-x^2} + \frac{1/2 + \lambda - \lambda^2 + x^2/4}{(1-x^2)^2}\right\} y = 0. \tag{3.6}$$

For $\lambda > -\frac{1}{2}$, $y_n(1,\lambda) = 0$ for every n, while for every λ we have $y_n(0,\lambda) = 0$ for n odd and $y_n'(0,\lambda) = 0$ for n even. Applying the results of §2, with $a = 0$, we get for a zero c of $P_n^{(\lambda)}(x)$ the formula

$$\frac{dc}{d\lambda} = -(1-c^2)^{-\lambda-1/2}[P_n^{(\lambda)'}(c)]^{-2}\int_0^c \frac{2n+1-2(n+\lambda)s^2}{(1-s^2)^{-\lambda+3/2}}\left[P_n^{(\lambda)}(s)\right]^2 ds. \tag{3.7}$$

Formula (3.7) shows that a positive zero of $P_n^{(\lambda)}(x)$ is a decreasing function of λ for those values of λ that satisfy $\lambda < (2n+1)/(2c^2) - n$. This covers all the zeros on $(0,1)$ in case $-\frac{1}{2} < \lambda \leq \frac{1}{2}$. On the other hand, when $\lambda > \frac{1}{2}$, the integrand in (3.7) may change sign. But in this situation we can use the formula

$$\frac{dc}{d\lambda} = (1-c^2)^{-\lambda-1/2}[P_n^{(\lambda)'}(c)]^{-2}\int_c^1 \frac{2n+1-2(n+\lambda)s^2}{(1-s^2)^{-\lambda+3/2}}\left[P_n^{(\lambda)}(s)\right]^2 ds \tag{3.8}$$

obtained by using the method described at the end of §2 with $a = 1$ or by using the identity

$$\begin{aligned}(2n+1)&\int_{-1}^1 (1-s^2)^{\lambda-3/2}\left[P_n^{(\lambda)}(s)\right]^2 ds \\ &= 2(n+\lambda)\int_{-1}^1 (1-s^2)^{\lambda-3/2}s^2\left[P_n^{(\lambda)}(s)\right]^2 ds.\end{aligned} \tag{3.9}$$

To prove (3.9) we let A denote the integral on its left-hand side and B the integral on its right-hand side. We have, using [22, eq. (4.7.28)],

$$nP_n^{(\lambda)}(x) = x\frac{d}{dx}\{P_n^{(\lambda)}(x)\} - \frac{d}{dx}\{P_{n-1}^{(\lambda)}(x)\} = x\frac{d}{dx}\{P_n^{(\lambda)}(x)\} - \sum_{k=0}^{n-2} c_k P_k^{(\lambda)}(x),$$

where the c_k are constants. Thus, using the orthogonality property of the ultraspherical polynomials, we get

$$\begin{aligned}&\int_{-1}^1 (1-s^2)^{\lambda-1/2}sP_n^{(\lambda)}(s)\frac{d}{ds}P_n^{(\lambda)}(s)ds \\ &\quad = n\int_{-1}^1 (1-s^2)^{\lambda-1/2}\left[P_n^{(\lambda)}(s)\right]^2 ds = n(A-B).\end{aligned} \tag{3.10}$$

Now

$$(2\lambda-1)B = -\int_{-1}^1 s\left[P_n^{(\lambda)}(s)\right]^2\frac{d}{ds}(1-s^2)^{\lambda-1/2}ds,$$

and so, using integration by parts, we obtain

$$\begin{aligned}(2\lambda-1)B &= \int_{-1}^1 \left[P_n^{(\lambda)}(s)\right]^2(1-s^2)^{\lambda-1/2}ds + \int_{-1}^1 2sP_n^{(\lambda)}(s)\frac{d}{ds}P_n^{(\lambda)}(s)(1-s^2)^{\lambda-1/2}ds \\ &= A - B + 2n(A-B).\end{aligned}$$

From this we get $(2n+1)A = 2(n+\lambda)B$, which is the identity (3.9). To recapitulate, formula (3.7) shows that a positive zero of $P_n^{(\lambda)}(x)$ is a decreasing function of λ for those values of λ that satisfy $\lambda < (2n+1)/(2c^2) - n$, and (3.8) shows it for $\lambda > (2n+1)/(2c^2) - n$. Together, these results recover the known result [22] that all the positive zeros are decreasing functions of λ. We remark that the integral in (3.8) exists only for $\lambda > \frac{1}{2}$. But on considering that $0 < c^2 < 1$, this follows from the condition $\lambda > (2n+1)/(2c^2) - n$.

4. The determinant $Q(t,\nu)$. Here we consider a pair of linearly independent solutions $x(t,\nu)$, $y(t,\nu)$ of the differential equation

$$z'' + q(t,\nu)z = 0, \qquad t \in I, \tag{4.1}$$

satisfying the initial conditions

$$x(a,\nu) = \phi(\nu), \qquad y(a,\nu) = 0, \tag{4.2}$$

$$x_t(a,\nu) = 0, \qquad y_t(a,\nu) = 1/\phi(\nu) \tag{4.3}$$

for each ν in some interval J. The function $\phi(\nu)$ is supposed to be differentiable on J. The Wronskian

$$W = x(t,\nu)y_t(t,\nu) - x_t(t,\nu)y(t,\nu) \equiv 1, \qquad t \in I, \tag{4.4}$$

for each $\nu \in J$. We suppose, as in §2, that $q(t,\nu)$ is of class C^1 in a domain of (t,ν)-space that includes $I \times J$. This implies, as pointed out in §2, that the solutions $x(t,\nu)$, $y(t,\nu)$ and, indeed, any linear combination

$$z(t,\nu) = \cos\alpha\, x(t,\nu) - \sin\alpha\, y(t,\nu) \tag{4.5}$$

are of class C^1 throughout their domains of existence in the (t,ν)-plane. Let $c = c(\nu,\alpha)$ be a zero of $z(t,\nu)$ for some fixed α. Thus

$$\cos\alpha\, x(c,\nu) - \sin\alpha\, y(c,\nu) = 0. \tag{4.6}$$

Proceeding somewhat as in [23, p. 508], we differentiate (4.6) with respect to ν to get

$$\cos\alpha[x_\nu(c,\nu) + x_t(c,\nu)c_\nu] - \sin\alpha[y_\nu(c,\nu) + y_t(c,\nu)c_\nu] = 0. \tag{4.7}$$

In order for (4.6) and (4.7) to hold simultaneously (since $\cos^2\alpha + \sin^2\alpha \neq 0$) we must have (abbreviating the notation)

$$x(y_\nu + y_t c_\nu) - y(x_\nu + x_t c_\nu) = 0, \tag{4.8}$$

or

$$\begin{vmatrix} x & y \\ x_\nu & y_\nu \end{vmatrix} + \begin{vmatrix} x & y \\ x_t & y_t \end{vmatrix} c_\nu = 0. \tag{4.9}$$

Hence, using (4.4), we have

$$\frac{dc}{d\nu} = -Q(t,\nu), \tag{4.10}$$

where

$$Q(t,\nu) = \begin{vmatrix} x(t,\nu) & y(t,\nu) \\ x_\nu(t,\nu) & y_\nu(t,\nu) \end{vmatrix}. \tag{4.11}$$

We will show in §5 that $Q(t,\nu)$ satisfies the third-order nonhomogeneous linear differential equation

$$w''' + 4q(t,\nu)w' + 2q_t(t,\nu)w = 2q_\nu(t,\nu) \tag{4.12}$$

with initial conditions

$$w(a,\nu) = w_{tt}(a,\nu) = 0, \qquad w_t(a,\nu) = -2\phi'(\nu)/\phi(\nu). \tag{4.13}$$

It will then follow that

$$Q(t,\nu) = [-2\phi'(\nu)/\phi(\nu)]x(t,\nu)y(t,\nu) + \int_a^t q_\nu(s,\nu)[z(s,t;\nu)]^2 ds, \tag{4.14}$$

where

$$z(t,s;\nu) = \begin{vmatrix} x(t,\nu) & y(t,\nu) \\ x(s,\nu) & y(s,\nu) \end{vmatrix} \tag{4.15}$$

is the solution of

$$\frac{d^2z}{ds^2} + q(s,\nu)z = 0, \qquad z(t,t;\nu) = 0,\ z_s(t,t;\nu) = 1. \tag{4.16}$$

From (4.14) we get

$$\frac{dc}{d\nu} = [2\phi'(\nu)/\phi(\nu)]x(c,\nu)y(c,\nu) - \int_a^c q_\nu(s,\nu)[z(s,c;\nu)]^2 ds. \tag{4.17}$$

In case $\alpha = 0$ or $\alpha = \pi/2$ the first term on the right-hand side vanishes, and so we see that (4.17) gives a generalization of the Richardson formula (2.7).

5. A third-order differential equation. Our approach here is motivated by what was done in [15] in the case of Bessel functions. There a formula of Watson [23, p. 444],

$$J_\nu(z)\partial Y_\nu(z)/\partial\nu - Y_\nu(z)\partial J_\nu(z)/\partial\nu = -4\pi^{-1}\int_0^\infty K_0(2z\sinh t)e^{-2\nu t}dt, \tag{5.1}$$

and its almost immediate consequence,

$$\frac{dc}{d\nu} = 2c\int_0^\infty K_0(2c\sinh t)e^{-2\nu t}dt, \tag{5.2}$$

were proved by showing that both sides of (5.1) satisfy the same third-order differential equation and have the same asymptotic behavior. Here we prove (4.14) by showing that both sides satisfy (4.12) with initial conditions (4.13). We remark that the product xy of any two solutions x and y of (4.1) satisfies the corresponding homogeneous equation

$$w''' + 4q(t,\nu)w' + 2q_t(t,\nu)w = 0; \tag{5.3}$$

see [1]. Thus the general solution of (4.12) is

$$Q(t,\nu) = k_1(\nu)x^2(t,\nu) + k_2(\nu)x(t,\nu)y(t,\nu) + k_3(\nu)y^2(t,\nu) + S(t,\nu), \tag{5.4}$$

where

$$S(t,\nu) = \int_a^t q_\nu(s,\nu)[z(s,t;\nu)]^2 ds \tag{5.5}$$

is the integral on the right-hand side of (4.14). To show that $Q(t,\nu)$ satisfies (4.12) we find it convenient to introduce also the determinant

$$R(t,\nu) = \begin{vmatrix} x_t(t,\nu) & y_t(t,\nu) \\ x_{\nu t}(t,\nu) & y_{\nu t}(t,\nu) \end{vmatrix}. \tag{5.6}$$

Using the well-known rules for differentiation of determinants, we have

$$R_t(t,\nu) = \begin{vmatrix} x_{tt} & y_{tt} \\ x_{\nu t} & y_{\nu t} \end{vmatrix} + \begin{vmatrix} x_t & y_t \\ x_{\nu tt} & y_{\nu tt} \end{vmatrix}. \tag{5.7}$$

Now, using (4.1) and [10, Thm. 3.1, p. 95], which implies that x_ν and y_ν satisfy the differential equation obtained by formally differentiating (4.1) (with the implied interchange of orders of integration), we get

$$\begin{aligned} R_t(t,\nu) &= -q \begin{vmatrix} x & y \\ x_{\nu t} & y_{\nu t} \end{vmatrix} - q_\nu \begin{vmatrix} x_t & y_t \\ x & y \end{vmatrix} - q \begin{vmatrix} x_t & y_t \\ x_\nu & y_\nu \end{vmatrix} \\ &= -qQ_t + q_\nu. \end{aligned}$$

Similarly,

$$\begin{aligned} Q_{tt}(t,\nu) &= \begin{vmatrix} x_{tt} & y_{tt} \\ x_\nu & y_\nu \end{vmatrix} + 2 \begin{vmatrix} x_t & y_t \\ x_{\nu t} & y_{\nu t} \end{vmatrix} + \begin{vmatrix} x & y \\ x_{\nu tt} & y_{\nu tt} \end{vmatrix} \\ &= -q \begin{vmatrix} x & y \\ x_\nu & y_\nu \end{vmatrix} + 2R + \begin{vmatrix} x & y \\ -q_\nu x - q x_\nu & -q_\nu y - q y_\nu \end{vmatrix} \\ &= -2qQ + 2R. \end{aligned} \tag{5.8}$$

Differentiating this last equation with respect to t and using (5.8), we see that $Q(t,\nu)$ satisfies (4.12). As already remarked, the first term on the right-hand side of (4.14) satisfies the homogeneous equation (5.3). Hence in order to show that $Q(t,\nu)$ satisfies (4.12) it will be enough to show that $S(t,\nu)$, as given by (5.5), satisfies (4.12). We remark, first of all, that

$$z(t,s;\nu) = \begin{vmatrix} x(t,\nu) & y(t,\nu) \\ x(s,\nu) & y(s,\nu) \end{vmatrix} \tag{5.9}$$

since both sides satisfy (4.16). We also have $z(t,s;\nu) = -z(s,t;\nu)$, and hence $z(s,t,\nu)$ satisfies

$$\frac{d^2 z}{dt^2} + q(t,\nu)z = 0, \quad z(s,s;\nu) = 0, \quad z_t(s,s;\nu) = 1. \tag{5.10}$$

Now

$$S_t(t,\nu) = 2\int_a^t q_\nu(s,\nu) z(s,t;\nu) z_t(s,t,\nu)\,ds. \tag{5.11}$$

Differentiating again and using (5.10), we get

$$S_{tt}(t,\nu) = -2q(t,\nu)S(t,\nu) + 2\int_a^t q_\nu(s,\nu)[z_t(s,t;\nu)]^2\,ds. \tag{5.12}$$

A final differentiation and use of (5.10) and (5.11) show that $S(t,\nu)$ satisfies (4.12). Though the verification is easy, we remark that in order to *discover* the form of the

right-hand side of (4.14) we used the method of variation of parameters to solve (4.12) by using the linearly independent solutions x^2, xy, and y^2 of (5.3).

It is clear on using the initial conditions (4.2) and (4.3) that $Q(a,\nu) = 0$ and $R(a,\nu) = 0$. We have

$$Q_t(t,\nu) = \begin{vmatrix} x_t & y_t \\ x_\nu & y_\nu \end{vmatrix} + \begin{vmatrix} x & y \\ x_{\nu t} & y_{\nu t} \end{vmatrix}, \tag{5.13}$$

so that

$$Q_t(a,\nu) = -2\phi'(\nu)/\phi(\nu), \tag{5.14}$$

and from (5.8), $Q_{tt}(a,\nu) = 0$. On the other hand, from (5.10), (5.5), and (5.12), $S(a,\nu) = S_t(a,\nu) = S_{tt}(a,\nu) = 0$. It is clear that choosing $k_1(\nu) = k_3(\nu) = 0, k_2(\nu) = -2\phi'(\nu)/\phi(\nu)$ in (5.4) will make $Q(t,\nu)$ satisfy the initial conditions $Q(a,\nu) = Q_{tt}(a,\nu) = 0$, $Q_t(a,\nu) = -2\phi'(\nu)/\phi(\nu)$. Thus the proof of (4.14) is complete.

6. Application of third-order-equation method to cylinder functions. In the case of cylinder functions,

$$C_\nu(t) = \cos\alpha J_\nu(t) - \sin\alpha Y_\nu(t),$$

the relevant differential equation satisfied by $t^{1/2}C_\nu(t)$ is

$$y'' + \left[1 + \frac{1/4 - \nu^2}{t^2}\right] y = 0. \tag{6.1}$$

For the Bessel function of the first kind, $J_\nu(t)$, we get the Schläfli formula of §3. The discussion of §4, however, enables us to extend this result to all cylinder functions, rather than just $J_\nu(t)$. The approach of §3 does not work because the functions no longer vanish at 0, nor do they have a common finite zero (for all ν). We avoid this problem by choosing, in effect, $a = \infty$.

We suppose that $Q(t,\nu)$ is given by (4.11), where

$$x(t,\nu) = -(t\pi/2)^{1/2}Y_\nu(t), \qquad y(t,\nu) = (t\pi/2)^{1/2}J_\nu(t).$$

We can verify easily that in the present situation (4.12) has a particular solution

$$S(t,\nu) = -\int_t^\infty q_\nu(s,\nu) \begin{vmatrix} x(t,\nu) & y(t,\nu) \\ x(s,\nu) & y(s,\nu) \end{vmatrix}^2 ds, \tag{6.2}$$

so that if we use the considerations leading to (5.4) of §5, its general solution is given by (5.4). With the standard notation [23] for Bessel functions this leads to

$$\begin{aligned} Q(t,\nu) &= k_4(\nu)t[J_\nu^2(t) + Y_\nu^2(t)] + k_5(\nu)t[H_\nu^{(1)}(t)]^2 \\ &\quad + k_6(\nu)t[H_\nu^{(2)}(t)]^2 + (\nu\pi^2/2)t\int_t^\infty s^{-1} \begin{vmatrix} J_\nu(t) & Y_\nu(t) \\ J_\nu(s) & Y_\nu(s) \end{vmatrix}^2 ds. \end{aligned} \tag{6.3}$$

Now from standard asymptotic expansions for the Bessel functions ([23, Chap. 7] or [8, eq. 7.13]) we have (see [17, p. 341] and [15])

$$Q(t,\nu) = -(\pi/2) + O(t^{-1}), \tag{6.4}$$

$$J_\nu^2(t) + Y_\nu^2(t) = (2/\pi)t^{-1} + O(t^{-2}), \tag{6.5}$$

$$t[H_\nu^{(1,2)}(t)]^2 \sim (2/\pi)e^{\pm 2i(t-\nu\pi/2-\pi/4)} \tag{6.6}$$

as $t \to \infty$. It is also clear that

$$\int_t^\infty s^{-1} \begin{vmatrix} J_\nu(t) & Y_\nu(t) \\ J_\nu(s) & Y_\nu(s) \end{vmatrix}^2 ds = O(t^{-2}), \qquad t \to \infty, \tag{6.7}$$

since [23, Chap. 7]

$$\left|t^{1/2}J_\nu(t)\right|, \quad \left|t^{1/2}Y_\nu(t)\right| = O(1), \quad t \to \infty. \tag{6.8}$$

Using these asymptotic estimates in (6.3), we conclude that $k_4(\nu) = -\pi^2/4$, $k_5(\nu) = k_6(\nu) = 0$. Thus we have

$$Q(t,\nu) = -\frac{\pi^2 t}{4}[J_\nu^2(t) + Y_\nu^2(t)] + \frac{\nu\pi^2 t}{2}\int_t^\infty s^{-1} \begin{vmatrix} J_\nu(t) & Y_\nu(t) \\ J_\nu(s) & Y_\nu(s) \end{vmatrix}^2 ds. \tag{6.9}$$

If $c = c(\nu, k, \alpha)$ is a zero of any cylinder function $C_\nu(t) = \cos\alpha J_\nu(t) - \sin\alpha Y_\nu(t)$, we get from (4.10)

$$\frac{dc}{d\nu} = \frac{\pi^2 c}{4}\left[J_\nu^2(c) + Y_\nu^2(c) - 2\nu\int_c^\infty s^{-1} \begin{vmatrix} J_\nu(c) & Y_\nu(c) \\ J_\nu(s) & Y_\nu(s) \end{vmatrix}^2 ds\right]. \tag{6.10}$$

But the determinant in the integrand here is a solution of the Bessel equation (in the variable s), which vanishes at c. Hence it is a constant multiple of $C_\nu(s)$. Differentiating with respect to s, setting $s = c$, and using the Wronskian formula [23, p. 76], we find that this constant is $2/[\pi c C_\nu'(c)]$. Hence (6.10) can be written

$$\frac{dc}{d\nu} = \frac{\pi^2 c}{4}\left[J_\nu^2(c) + Y_\nu^2(c)\right] - \frac{2\nu}{cC_\nu'^2(c)}\int_c^\infty s^{-1}C_\nu^2(s)\,ds. \tag{6.11}$$

In the special case where $\alpha = 0$ and $c = j = j_{\nu k}$, a positive zero of $J_\nu(t)$, this becomes

$$\frac{dj}{d\nu} = \frac{\pi^2 j Y_\nu^2(j)}{4}\left[1 - 2\nu\int_j^\infty s^{-1}J_\nu^2(s)\,ds\right]. \tag{6.12}$$

Using the formula [23]

$$\int_0^\infty s^{-1}J_\nu^2(s)\,ds = 1/(2\nu), \tag{6.13}$$

as well as the Wronskian relation and a recurrence relation for the Bessel function, we see that (6.10) reduces to Schläfli's formula (3.2). Similarly, in the case $\alpha = \pi/2$ we are led to Schafheitlin's formula [19]

$$\frac{dy}{d\nu} = \frac{\pi^2 y J_\nu^2(y)}{4}\left[1 - 2\nu\int_y^\infty s^{-1}Y_\nu^2(s)\,ds\right] \tag{6.14}$$

for the zeros of $Y_\nu(t)$.

Remark 1. A formula that is somewhat more useful than (3.2) for the derivative with respect to order of a zero of a Bessel function is (5.2) (due to Watson [23, p. 508]), which is valid for all zeros of cylinder functions throughout the interval in which they are continuous functions of ν. Because of the simple nature (positive, decreasing, etc.) of $K_0(t)$, the formula (5.2) has been used to remarkable effect in several discussions of monotonicity, convexity, etc., of the zeros; see [2]–[5] and the references therein. In [15] it was shown how to derive (5.2) by a differential-equations method essentially by showing that the corresponding Q (in the notation of the current paper) satisfies (4.12) in the special case involved. It would be interesting to be able to do this for a class of differential equations, that is, to find a method for solving (4.12) that would lead to formulas like (5.2) in much the same way as variation of parameters leads to formulas of the Schläfli type; see [16] for further remarks on this topic.

In contrast to (5.2), there are many approaches to the Schläfli formula (3.2). In addition to the approach in this section, there is an approach based on the Hellmann–Feynman theorem in [14]. A formula for $dj/d\nu$ ([11]; see also [13]) involving infinite sums has been shown [12] to be derivable from the Schläfli formula by using classical results for Bessel functions.

Remark 2. Since we know independently from (5.2) that $dc/d\nu > 0$ and since every positive number can be realized as a zero of some $C_\nu(t)$, we find from (6.10) the inequality

$$J_\nu^2(t) + Y_\nu^2(t) > 2\nu \int_t^\infty s^{-1} \left| \begin{array}{cc} J_\nu(t) & Y_\nu(t) \\ J_\nu(s) & Y_\nu(s) \end{array} \right|^2 ds, \qquad t > 0. \tag{6.15}$$

Acknowledgments. We thank the referees for their constructive comments. We are also grateful to Angelo Mingarelli for drawing our attention to the work of Richardson [18].

REMEZ- AND NIKOLSKII-TYPE INEQUALITIES FOR LOGARITHMIC POTENTIALS*

TAMÁS ERDÉLYI†, XIN LI‡, AND E. B. SAFF§

Abstract. Remez- and Nikolskii-type inequalities on line segments, on circles, and on certain bounded domains of the complex plane are established for exponentials of logarithmic potentials with respect to probability measures on $\mathbb{C}$ having compact support.

Key words. potentials, Remez inequalities, Nikolskii inequalities, logarithmic capacity, Green function

AMS subject classifications. 41A17, 31A15

1. Introduction and notation.

Generalized nonnegative polynomials of the form

$$f(z) = |\omega| \prod_{j=1}^{k} |z - z_j|^{r_j} \qquad (\omega \in \mathbb{C},\ z_j \in \mathbb{C},\ 0 < r_j \in \mathbb{R},\ j = 1, 2, \dots k) \tag{1.1}$$

were studied in a sequence of recent papers [1], [2], [3], [4], [6], [7]. Several important polynomial inequalities were extended to this class by utilizing the generalized degree

$$N := \sum_{j=1}^{k} r_j \tag{1.2}$$

of f in place of the ordinary one. Since

$$\log f(z) = \sum_{j=1}^{k} r_j \log |z - z_j| + \log |\omega|, \tag{1.3}$$

a generalized nonnegative polynomial can be considered as a constant times the exponential of a logarithmic potential with respect to a finite Borel measure on $\mathbb{C}$ that is supported in finitely many points (the measure has mass $r_j > 0$ at each $z_j, j = 1, 2, \dots, k$). This suggests that some of the inequalities holding for generalized nonnegative polynomials may be true for exponentials of logarithmic potentials of the form

$$Q_{\mu,c}(z) = \exp\left(\int_{\mathbb{C}} \log |z - t| d\mu(t) + c \right), \tag{1.4}$$

where μ is a finite, nonnegative Borel measure on $\mathbb{C}$ having compact support and $c \in \mathbb{R}$. The quantity $\mu(\mathbb{C})$ plays the role of the generalized degree N, defined by (1.2). In this paper we extend a number of classical polynomial inequalities for exponentials

of logarithmic potentials. Typically such extensions are not straightforward; indeed our proofs are far from simple density arguments.

Denote by $\mathcal{P}_n^r$ the set of all algebraic polynomials of degree at most n with real coefficients and let $\mathcal{P}_n^c$ be the set of all algebraic polynomials of degree at most n with complex coefficients. Let $\mathcal{M}$ denote the set of all probability measures on $\mathbb{C}$ with compact support. For $\mu \in \mathcal{M}$ and $c \in \mathbb{R}$ we define

$$P_{\mu,c}(z) := \int_{\mathbb{C}} \log|z-t| d\mu(t) + c \qquad (z \in \mathbb{C}) \tag{1.5}$$

and

$$Q_{\mu,c}(z) := \exp(P_{\mu,c}(z)) \qquad (z \in \mathbb{C}). \tag{1.6}$$

Associated with $\mu \in \mathcal{M}$ and $c \in \mathbb{R}$ we introduce the sets

$$\begin{aligned} E_{\mu,c} :&= \{x \in [-1,1] : \ P_{\mu,c}(x) \le 0\} \\ &= \{x \in [-1,1] : \ Q_{\mu,c}(x) \le 1\}. \end{aligned} \tag{1.7}$$

We will denote by $m_1(A)$ and $m_2(B)$ the one-dimensional Lebesgue measure of a set $A \subset \mathbb{R}$, and the two-dimensional Lebesgue measure of a set $B \subset \mathbb{C}$, respectively.

The Remez inequality [12] asserts that

$$\max_{-1\le x\le 1} |p(x)| \le T_n\left(\frac{2+s}{2-s}\right) \tag{1.8}$$

for every $p \in P_n^r$ such that

$$m_1(\{x \in [-1,1] : \ |p(x)| \le 1\}) \ge 2-s \qquad (0 < s < 2), \tag{1.9}$$

where T_n is the Chebyshev polynomial of degree n, defined by $T_n(x) := \cos n\theta, x = \cos\theta$. Proofs of this inequality appear in [9, pp. 119–121] and [5]. In Theorem 2.1 we establish a sharp upper bound for $\max_{-1\le x\le 1} Q_{\mu,c}(x)$ when $m_1(E_{\mu,c}) \ge 2-s$, and (assuming $Q_{\mu,c}(x)$ is continuous) we find all $\mu \in \mathcal{M}$ and $c \in \mathbb{R}$ with $m_1(E_{\mu,c}) \ge 2-s$ for which this sharp upper bound is achieved.

In Theorem 2.2 we establish pointwise upper bounds for $Q_{\mu,c}(x)$ for fixed $x \in [-1,1]$, if $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, and $m_1(E_{\mu,c}) \ge 2-s$. An obvious bound for $Q_{\mu,c}(x)$ follows immediately from Theorem 2.1, but it turns out that for any fixed $-1 < x < 1$ this can be substantially improved. Indeed, Theorem 2.2 establishes essentially sharp upper bounds, which extend the validity of a pointwise Remez-type inequality [4, Thm. 4] proved for generalized nonnegative polynomials.

In Corollary 2.3 we offer another, slightly weaker version of the Remez-type inequality of Theorem 2.1, and in Theorem 2.4 we establish an analogue of Corollary 2.3, where the interval $[-1,1]$ is replaced by the closure of a bounded domain $\Omega \subset \mathbb{C}$ with C^2 boundary, and the one-dimensional Lebesgue measure m_1 is replaced by m_2. Such two-dimensional Remez-type inequalities seem to be new even for ordinary polynomials and for special domains, such as the open unit disk. Therefore we formulate a two-dimensional Remez-type inequality in this special case first, which turns out to be essentially sharp by Theorem 2.6.

Concerning L_p-versions of Remez's inequality, we study the following question: How large can the ratio

$$\frac{\int_{-1}^{1}(Q_{\mu,c}(x))^p dx}{\int_{A}(Q_{\mu,c}(x))^p dx}$$

be if $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, $A \subset [-1,1]$, $m_1(A) \geq 2-s$, $0 < s < 2$, and $p > 0$? We give an essentially sharp answer in Theorem 2.7 for the case when $0 < s \leq \frac{1}{2}$. In Theorem 2.8 we establish an essentially sharp upper bound for the ratio

$$\frac{\int_{\Omega}(Q_{\mu,c}(z))^p dm_2(z)}{\int_{A}(Q_{\mu,c}(z))^p dm_2(z)},$$

when $\Omega \subset \mathbb{C}$ is a bounded domain with C^2 boundary, $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, $A \subset \overline{\Omega}$, $m_2(A) \geq m_2(\Omega) - s, s > 0$ sufficiently small, and $p > 0$. In Theorems 2.9 and 2.10 we give essentially the best possible Remez-type inequalities for exponentials of logarithmic potentials on the unit circle. The Remez-type inequalities of Corollary 2.3 and Theorems 2.4 and 2.9 will play a central role in establishing the Nikolskii-type inequalities for exponentials of potentials on $[-1,1]$, on the unit circle and on bounded domains of $\mathbb{C}$ with C^2 boundary. These Nikolskii-type inequalities are formulated in Theorems 3.1, 3.2, and 3.3.

2. Remez-type inequalities: statement of results. In this section we state our main results concerning Remez-type inequalities for logarithmic potentials on $[-1,1]$, on the unit circle and on bounded domains having smooth boundaries. The proofs of these results will be given in §§6, 7, 8, and 9.

THEOREM 2.1. *Let $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $E_{\mu,c}$ be defined as in* (1.7). *Then*

$$m_1(E_{\mu,c}) \geq 2-s \qquad (0 < s < 2) \tag{2.1}$$

implies

$$\max_{-1\leq x\leq 1} Q_{\mu,c}(x) \leq \frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}}. \tag{2.2}$$

Furthermore, if $Q_{\mu,c}$ restricted to $[-1,1]$ is continuous on $[-1,1]$, then the equality holds in (2.2) *if and only if*

$$\mu = \mu^*_{[-1,1-s]} \quad \text{or} \quad \mu = \mu^*_{[-1+s,1]}$$

and

$$c = -\log\frac{2-s}{4},$$

where μ^*_K denotes the equilibrium measure (cf. [14, §III.2]*) of a compact set $K \subset \mathbb{C}$.*

We remark that $Q_{\mu,c}$ is upper semicontinuous on $\mathbb{C}$, so the maximum on $[-1,1]$ is attained.

Concerning pointwise upper bounds for $Q_{\mu,c}(x)$ we shall prove the following result that extends the validity of Theorem 4 of [4].

THEOREM 2.2. *There is an absolute constant k_1 such that*

$$Q_{\mu,c}(x) \le \exp\left(k_1 \min\left\{\frac{s}{\sqrt{1-x^2}}, \sqrt{s}\right\}\right) \tag{2.3}$$

for every $-1 \le x \le 1, \mu \in \mathcal{M}$ and $c \in \mathbb{R}$ satisfying

$$m_1(E_{\mu,c}) \ge 2 - s \qquad (0 < s \le 1). \tag{2.4}$$

Here we do not examine what happens when $1 < s < 2$; the case $0 < s \le 1$ is more important in applications. The sharpness of Theorem 2.2 (in the corresponding polynomial case) is shown in [4, §12].

Observe that the first assertion of Theorem 2.1 is equivalent to the following.

THEOREM 2.1*. *For every $\mu \in \mathcal{M}, c \in \mathbb{R}$ and $0 < t < 1$,*

$$m_1\left(\left\{x \in [-1,1] : Q_{\mu,c}(x) > \frac{1-\sqrt{t}}{1+\sqrt{t}} \max_{-1\le y\le 1} Q_{\mu,c}(y)\right\}\right) \ge 2t. \tag{2.5}$$

Consequently, we obtain the following.

COROLLARY 2.3. *There is an absolute constant $k_2 > 0$ such that*

$$m_1\left(\left\{x \in [-1,1] : Q_{\mu,c}(x) > \exp(-\sqrt{s}) \max_{-1\le y\le 1} Q_{\mu,c}(y)\right\}\right) \ge k_2 s \tag{2.6}$$

for every $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, and $0 < s < 2$.

In our next theorem we establish the analogue of Corollary 2.3 for the case when $[-1,1]$ is replaced by the closure of a bounded domain $\Omega \subset \mathbb{C}$ with C^2 boundary.

THEOREM 2.4. *Let $\Omega \subset \mathbb{C}$ be a bounded domain with C^2 boundary. Then, there is a constant $k_3 = k_3(\Omega) > 0$ depending only on Ω such that*

$$m_2\left(\left\{z \in \overline{\Omega} : Q_{\mu,c}(z) > \exp(-\sqrt{s}) \max_{w\in\overline{\Omega}} Q_{\mu,c}(w)\right\}\right) \ge k_3 s \tag{2.7}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $0 < s < m_2(\Omega)$.

Actually, in the above theorem it suffices to have a somewhat weaker geometric assumption for the boundary of Ω, namely, the following: there is an $r > 0$ depending only on Ω such that for each $z \in \partial\Omega$ there is an open disk D_z with radius r such that $D_z \subset \Omega$ and $\overline{D}_z \cap \partial\Omega = \{z\}$. It is well known that if $\partial\Omega$ is a C^2 curve, then this property holds.

To prove Theorem 2.4 we will need the following result for polynomials. To formulate this, we introduce the notation

$$D := \{z \in \mathbb{C} : |z| < 1\} \tag{2.8}$$

and

$$\mathcal{P}_n^c(\overline{D}, s) := \{p \in \mathcal{P}_n^c : m_2(\{z \in \overline{D} : |p(z)| \le 1\}) \ge \pi - s\} \qquad (0 < s < \pi), \tag{2.9}$$

along with the analogous definition for $\mathcal{P}_n^r(\overline{D}, s)$.

THEOREM 2.5. *There is an absolute constant $k_4 > 0$ such that*

$$\max_{u\in\overline{D}} |p(u)| \le \exp(k_4 n\sqrt{s}) \tag{2.10}$$

for every $p \in \mathcal{P}_n^c(\overline{D}, s)$ and $0 < s \le \frac{1}{4}$.

Our next theorem shows that the result of Theorem 2.5 is essentially sharp.

THEOREM 2.6. *There is an absolute constant $k_5 > 0$ such that*

$$\sup(\{|p(1)| : p \in \mathcal{P}_{3n}^r(\overline{D}, s)\}) \geq \exp(k_5 n\sqrt{s}) \tag{2.11}$$

for every $0 < s \leq \frac{1}{2}$.

Using Theorems 2.1 and 2.4, we establish Remez-type inequalities in $L_p(0 < p < \infty)$ for exponentials of potentials on both $[-1, 1]$ and bounded domains $\Omega \subset \mathbb{C}$ and C^2 boundary.

THEOREM 2.7. *There is an absolute constant $k_6 > 0$ such that*

$$\begin{aligned} \int_{-1}^{1} (Q_{\mu,c}(x))^p dx &\leq \left(1 + \left(\frac{1+\sqrt{s}}{1-\sqrt{s}}\right)^p\right) \int_A (Q_{\mu,c}(x))^p dx \\ &\leq (1 + \exp(k_6 p\sqrt{s})) \int_A (Q_{\mu,c}(x))^p dx \end{aligned} \tag{2.12}$$

for every $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, $p > 0$, $0 < s \leq \frac{1}{2}$, and $A \subset [-1, 1]$ with $m_1(A) \geq 2 - s$. If $0 < s \leq \frac{1}{4}$, then $k_6 = 4$ is a suitable choice.

THEOREM 2.8. *Let $\Omega \subset \mathbb{C}$ be a bounded domain with C^2 boundary. Then there are constants $0 < k_7 = k_7(\Omega)$ and $0 < k_8 = k_8(\Omega)$ depending only on Ω such that*

$$\int_{\Omega} (Q_{\mu,c}(z))^p dm_2(z) \leq (1 + \exp(k_7 p\sqrt{s})) \int_A (Q_{\mu,c}(z))^p dm_2(z) \tag{2.13}$$

for every $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, $p > 0$, $0 < s \leq k_8$, and $A \subset \overline{\Omega}$ with $m_2(A) \geq m_2(\Omega) - s$.

The following theorem establishes a Remez-type inequality for exponentials of logarithmic potentials on the unit circle, extending a Remez-type inequality for trigonometric polynomials [4, Thm. 3].

THEOREM 2.9. *There is an absolute constant $k_9 > 0$ such that*

$$\max_{-\pi \leq t \leq \pi} Q_{\mu,c}(e^{it}) \leq \exp(k_9 s) \tag{2.14}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$ and $0 < s \leq \pi/2$ whenever

$$m_1(\{t \in [-\pi, \pi) : Q_{\mu,c}(e^{it}) \leq 1\}) \geq 2\pi - s. \tag{2.15}$$

From this we will easily obtain the following.

THEOREM 2.10. *We have*

$$\int_{-\pi}^{\pi} (Q_{\mu,c}(e^{it}))^p dt \leq (1 + \exp(2k_9 ps)) \int_A (Q_{\mu,c}(e^{it}))^p dt$$

for every $\mu \in \mathcal{M}$, $c \in \mathbb{R}$, $p > 0$, $0 < s \leq \pi/4$, and $A \subset [-\pi, \pi)$ with $m_1(A) \geq 2\pi - s$. Here k_9 is the same as in Theorem 2.9.

We have formulated each of our results for *probability* measures on $\mathbb{C}$ with compact support. This was done only for the sake of brevity. As an example, we rewrite the result of Theorem 2.1 for all finite Borel measures on $\mathbb{C}$ with compact support.

COROLLARY 2.11. *Let μ be a finite Borel measure on $\mathbb{C}$ with compact support, and let $c \in \mathbb{R}$ and $E_{\mu,c}$ be defined as in (1.7). Then*

$$m_1(E_{\mu,c}) \geq 2 - s \qquad (0 < s < 2) \tag{2.16}$$

implies

$$\max_{-1\le x\le 1} Q_{\mu,c}(x) \le \left(\frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}}\right)^{\mu(\mathbb{C})}. \tag{2.17}$$

Furthermore, if $Q_{\mu,c}$ restricted to $[-1,1]$ is continuous, then equality holds in (2.17) *if and only if*

$$\mu = \mu(\mathbb{C})\mu^*_{[-1,1-s]} \quad \text{or} \quad \mu = \mu(\mathbb{C})\mu^*_{[-1+s,1]}$$

and

$$c = -\mu(\mathbb{C}) \log \frac{2-s}{4},$$

where μ^*_K denotes the equilibrium measure of a compact set $K \subset \mathbb{C}$.

3. Nikolskii-type inequalities: statement of results. Using Corollary 2.3 and Theorem 2.4 we will prove the following Nikolskii-type inequalities. The proofs will be given in §10.

THEOREM 3.1. *There is an absolute constant $k_{10} > 0$ such that*

$$\|Q_{\mu,c}\|_{L_p(-1,1)} \le (k_{10}(1+q^2))^{1/q-1/p} \|Q_{\mu,c}\|_{L_q(-1,1)} \tag{3.1}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $0 < q < p \le \infty$.

THEOREM 3.2. *Let $\Omega \subset \mathbb{C}$ be a bounded domain with C^2 boundary. There exists a constant $k_{11} = k_{11}(\Omega) > 0$ depending only on Ω such that*

$$\|Q_{\mu,c}\|_{L_p(\Omega)} \le (k_{11}(1+q^2))^{1/q-1/p} \|Q_{\mu,c}\|_{L_q(\Omega)} \tag{3.2}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $0 < q < p \le \infty$.

We remark that Theorem 3.1 is an extension of [7, Thm. 6], where the same inequality was proved when the support of μ is a finite set.

THEOREM 3.3. *There is an absolute constant $k_{12} > 0$ such that*

$$\|Q_{\mu,c}(e^{it})\|_{L_p(-\pi,\pi)} \le (k_{12}(1+q))^{1/q-1/p} \|Q_{\mu,c}(e^{it})\|_{L_q(-\pi,\pi)} \tag{3.3}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $0 < q < p \le \infty$.

For general finite measures μ, Theorem 3.1 yields the following.

COROLLARY 3.4. *There is an absolute constant $k_{10} > 0$ such that*

$$\|Q_{\mu,c}\|_{L_p(-1,1)} \le (k_{10}(1+(q\mu(\mathbb{C}))^2))^{1/q-1/p} \|Q_{\mu,c}\|_{L_q(-1,1)} \tag{3.4}$$

for every finite Borel measure μ on C with compact support, $c \in \mathbb{R}$ and $0 < q < p \le \infty$.

Theorems 3.2 and 3.3 have similar straightforward extensions.

4. Lemmas for Theorem 2.1. To prove Theorem 2.1 we need a series of lemmas, which we state in this section and prove in §5.

For a compact set $K \subset \mathbb{C}$ containing infinitely many points, let $T_{n,K} \in \mathcal{P}^c_n$ be the nth degree monic Chebyshev polynomial with respect to K, i.e.,

$$\|T_{n,K}\|_K = \inf_{p \in \mathcal{P}^c_{n-1}} \|z^n - p(z)\|_K, \tag{4.1}$$

where $\|\cdot\|_K$ denotes the uniform norm on K. We also define the normalized Chebyshev polynomials

$$\widehat{T}_{n,K} := \frac{T_{n,K}}{\|T_{n,K}\|_K}. \tag{4.2}$$

LEMMA 4.1. *Let $0 \le \delta < 2, \delta < s < 2$, and $z \in \mathbb{C}$ with $\operatorname{Re} z \ge 1 - \delta$ fixed. Then*

$$\sup |p(z)| = |\widehat{T}_{n,[-1,1-s]}(z)|, \tag{4.3}$$

where the supremum in (4.3) is taken over all $p \in \mathcal{P}_n^r$ satisfying

$$m_1(\{x \in [-1, 1-\delta] : |p(x)| \le 1\}) \ge 2 - s. \tag{4.4}$$

If $K \subset \mathbb{C}$ is a compact set we denote by $D_\infty(K)$ the unbounded component of the complement $\mathbb{C}\backslash K$. This domain is referred to as the *outer domain* of K and its boundary $\partial D_\infty(K)$ is called the *outer boundary* of K. If K has positive logarithmic capacity [14, p. 55], we denote by $g_{D_\infty(K)}(z, \infty)$ the Green function with pole at ∞ for $D_\infty(K)$. We remark that $g_{D_\infty(K)}(z, \infty)$ is the smallest positive harmonic function in $D_\infty(K)\backslash\{\infty\}$ that behaves like $\log |z| +$ const. near ∞ (cf. [11, p. 333]).

LEMMA 4.2. *Let $K \subset [-1, 1]$ be compact with $m_1(K) \ge 2 - s$ $(0 < s < 2)$. Then the inequality*

$$g_{D_\infty(K)}(z, \infty) \le g_{D_\infty([-1,1-s])}(z, \infty) \tag{4.5}$$

holds for all z such that $\operatorname{Re} z \ge \sup(K)$.

To prove Lemma 4.2 we need the following result of Myrberg and Lega [11, Thm. 11.1, p. 333].

LEMMA 4.3. *Let $K \subset \mathbb{C}$ be compact with* $\operatorname{cap}(K) > 0$, *where* "cap" *denotes the logarithmic capacity. Then*

$$\lim_{n\to\infty} \frac{1}{n} \log \frac{|F_{n,K}(z)|}{\|F_{n,K}\|_K} = g_{D_\infty(K)}(z, \infty) \tag{4.6}$$

for every $z \in D_\infty(K)$, where $F_{n,K}$ denotes an nth *degree monic Fekete polynomial for K. The convergence in (4.6) is locally uniform in $D_\infty(K)$.*

LEMMA 4.4. *Let $\mu \in \mathcal{M}$ and $c \in \mathbb{R}$. If*

$$m_1(E_{\mu,c}) \ge 2 - s \qquad (0 < s < 2), \tag{4.7}$$

then the inequality

$$P_{\mu,c}(z) \le g_{D_\infty([-1,1-s])}(z, \infty) \tag{4.8}$$

holds for all z such that $\operatorname{Re} z \ge \sup(E_{\mu,c})$.

To formulate our last lemma, for $0 < s < 2$ we introduce the notation

$$\mathcal{M}(s) := \{(\mu, c) \in \mathcal{M} \times \mathbb{R} : m_1(E_{\mu,c}) \ge 2 - s\}. \tag{4.9}$$

LEMMA 4.5. *Let $0 < s < 2$ be fixed. Then*

$$\sup\left(\max_{-1\le x\le 1} P_{\mu,c}(x)\right) = \sup(P_{\mu,c}(1)), \tag{4.10}$$

where the supremum on each side of (4.10) is taken over all $(\mu, c) \in \mathcal{M}(s)$.

5. Proofs of the lemmas for Theorem 2.1.

Proof of Lemma 4.1. We prove the lemma only when $\delta = 0$, since the case when $0 < \delta < 2$ can be handled similarly. For the sake of brevity we introduce the classes

$$\mathcal{P}_n^r([-1,1],s) := \{p \in \mathcal{P}_n^r : m_1(\{x \in [-1,1] : |p(x)| \le 1\}) \ge 2 - s\} \quad (n = 0,1,2,\dots;\quad 0 < s < 2). \tag{5.1}$$

It is easy to see that $\mathcal{P}_n^r([-1,1],s)$ is a closed and bounded subset of $\mathcal{P}_n^r$ in the uniform norm on $[-1,1]$; hence it is compact. If $z \in \mathbb{C}$ is fixed, then the map $p \to |p(z)|$ is continuous; therefore, there exists a $p^* \in \mathcal{P}_n^r([-1,1],s)$ such that

$$|p^*(z)| = \sup_{p \in \mathcal{P}_n^r([-1,1],s)} |p(z)|. \tag{5.2}$$

Now we show that $\operatorname{Re} z \ge 1$ implies

$$p^* = \pm \widehat{T}_{n,[-1,1-s]}. \tag{5.3}$$

To see this, we analyze the properties of p^*.

PROPOSITION 5.1. *p^* has only real zeros.*

Proof. Assume to the contrary that p^* has a nonreal zero w. Then

$$p(x) = (1+\eta)p^*(x)\left(1 - \frac{\varepsilon(x-z)(x-\overline{z})}{(x-w)(x-\overline{w})}\right) \in \mathcal{P}_n^r([-1,1],s) \tag{5.4}$$

with sufficiently small $\eta > 0$ and $\varepsilon > 0$ contradicts the maximality of p^*. This proves the proposition. □

PROPOSITION 5.2. *All zeros of p^* are in $[-1,1]$.*

Proof. Assume to the contrary that p^* has a nonreal zero w outside $[-1,1]$, which is real by Proposition 5.1. We now distinguish three cases.

Case 1. $w > \operatorname{Re} z$. Let $w^* \in \mathbb{R}$ be the symmetric image of w with respect to $\operatorname{Re} z$, i.e., $w^* := 2\operatorname{Re} z - w$. Then

$$p(x) := (1+\eta)p^*(x)\frac{x-w^*}{x-w} \in \mathcal{P}_n^r([-1,1],s) \tag{5.5}$$

with a sufficiently small $\eta > 0$ contradicts the maximality of p^*.

Case 2. $1 < w \le \operatorname{Re} z$. Now

$$p(x) := (1+\eta)p^*(x)\frac{x-1}{x-w} \in \mathcal{P}_n^r([-1,1],s) \tag{5.6}$$

with a sufficiently small $\eta > 0$ contradicts the maximality of p^*.

Case 3. $w < -1$. Observe that $(x+1)(x-w)^{-1}$ is strictly increasing in $[-1,\infty)$, and so

$$\left|\frac{\operatorname{Re} z + 1}{\operatorname{Re} z - w}\right| \le \left|\frac{z+1}{z-w}\right|. \tag{5.7}$$

Then

$$p(x) := (1+\eta)p^*(x)\frac{(x+1)(\operatorname{Re} z - w)}{(x-w)(\operatorname{Re} z + 1)} \in \mathcal{P}_n^r([-1,1],s) \tag{5.8}$$

with a sufficiently small $\eta > 0$ contradicts the maximality of p^*.

By considering Cases 1, 2, and 3, Proposition 5.2 is completely proved. □

Now we introduce the notation

$$I := \{x \in [-1,1] : |p^*(x)| \le 1\}. \tag{5.9}$$

Obviously I is the union of pairwise disjoint subintervals of $[-1,1]$ that will be called the components of I. Every component of I contains at least one zero of p^*; otherwise a routine application of Rolle's Theorem, together with Propositions 5.1 and 5.2 would imply that p'^* has at least as many zeros as p^*, a contradiction. Using this observation we prove the following.

PROPOSITION 5.3. *The set I is a single interval; in fact, $I = [-1, 1-s]$.*

Proof. To see that I is an interval, assume to the contrary that I has at least two components, and let I_1 be the component closest to 1. Let η and η' be the left-hand endpoint of I_1 and the right-hand endpoint of the component closest to I_1, respectively. If $w_j (j = 1, 2, \dots, m)$ are the zeros of p^* lying in I_1, then it is easy to check that

$$p(x) := p^*(x) \frac{\prod_{j=1}^{m} (x - w_j + h)}{\prod_{j=1}^{m} (x - w_j)} \in \mathcal{P}_n^r([-1,1], s) \tag{5.10}$$

with $0 < h \le \eta - \eta'$ contradicts the maximality of p^*. Therefore I is an interval with $m_1(I) \ge 2 - s$. Now if $I \ne [-1, 1-s]$, then

$$p(x) := p^*(x + \varepsilon) \in \mathcal{P}_n^r([-1,1], s) \tag{5.11}$$

with sufficiently small $\varepsilon > 0$ contradicts the maximality of p^*, which proves the proposition. □

Now Proposition 5.3 together with a result of Erdős [13, p. 64] yield that $p^* \equiv \widehat{T}_{n,[-1,1-s]}$ and Lemma 4.1 is proved. □

Proof of Lemma 4.2. Let $F_{n,K}$ denote an nth degree monic Fekete polynomial for K and set

$$\widehat{F}_{n,K}(x) := \frac{F_{n,K}(x)}{\|F_{n,K}\|_K} \quad \text{and} \quad \delta := 1 - \sup(K).$$

Then

$$K \subset \{x \in [-1, 1-\delta] : |\widehat{F}_{n,K}(x)| \le 1\}.$$

Therefore,

$$m_1(\{x \in [-1, 1-\delta] : |\widehat{F}_{n,K}(x)| \le 1\}) \ge 2 - s,$$

and Lemma 4.1 implies that

$$|\widehat{F}_{n,K}(z)| \le |\widehat{T}_{n,[-1,1-s]}(z)| \tag{5.12}$$

holds for every $z \in \mathbb{C}$ such that $\operatorname{Re} z \ge \sup(K)$. Since $\operatorname{cap}(K) \ge m_1(K)/4 > 0$ [14, Cor. 4, p. 84], by Lemma 4.3 we have

$$\lim_{n\to\infty} |\widehat{F}_{n,K}(z)|^{1/n} = \exp(g_{D_\infty(K)}(z, \infty)), \qquad z \in D_\infty(K), \tag{5.13}$$

and, as is well known,

$$\lim_{n\to\infty} |\widehat{T}_{n,[-1,1-s]}(z)|^{1/n} = \exp\{g_{D_\infty([-1,1-s])}(z,\infty)\} \tag{5.14}$$

for every $z \in \mathbb{C}$ such that $z \notin [-1, 1-s]$. Now (5.12)–(5.14) yield the lemma except for the point $z_0 = \sup(K) \geq 1-s$. That (4.5) also holds at z_0 can be seen from the limiting argument given in the next proof. □

Proof of Lemma 4.4. For a fixed $0 < \varepsilon < 2-s$ we choose a compact set $K \subset E_{\mu,c}$ such that $\sup(E_{\mu,c}) > \sup(K)$ and

$$m_1(E_{\mu,c}\backslash K) \leq \varepsilon.$$

The last inequality, together with (4.7), yields $m_1(K) \geq 2-s-\varepsilon$. Note that the function

$$g_{D_\infty(K)}(z,\infty) - P_{\mu,c}(z)$$

is superharmonic on $\overline{\mathbb{C}}\backslash K$ and, since $K \subset E_{\mu,c}$,

$$\liminf_{\substack{z\to K \\ z\in D_\infty(K)}} (g_{D_\infty(K)}(z,\infty) - P_{\mu,c}(z)) \geq 0.$$

Therefore the minimum principle for superharmonic functions gives

$$g_{D_\infty(K)}(z,\infty) - P_{\mu,c}(z) \geq 0 \tag{5.15}$$

for all $z \in D_\infty(K)$, and in particular, for all $z \in \mathbb{C}$ with $\operatorname{Re} z \geq \sup(E_{\mu,c}) > \sup(K)$. On the other hand, by the preceding proof,

$$g_{D_\infty(K)}(z,\infty) \leq g_{D_\infty([-1,1-s-\varepsilon])}(z,\infty)$$

for all $z \in \mathbb{C}$ with $\operatorname{Re} z > \sup(K)$. This, together with (5.15) yields

$$P_{\mu,c}(z) \leq g_{D_\infty([-1,1-s-\varepsilon])}(z,\infty) \tag{5.16}$$

for all $z \in \mathbb{C}$ with $\operatorname{Re} z \geq \sup(E_{\mu,c})$. Taking the limit in (5.16) as $\varepsilon \to 0+$, we obtain the desired result. □

Proof of Lemma 4.5. Note that $P_{\mu,c}$ is upper semicontinuous; hence there exists $y \in [-1,1]$ such that

$$P_{\mu,c}(y) = \max_{-1\leq x\leq 1} P_{\mu,c}(x).$$

If $(\mu,c) \in \mathcal{M}(s)$, then either

$$m_1(\{x \in [-1,y] : P_{\mu,c}(x) \leq 0\}) \geq \tfrac{1}{2}(1+y)(2-s) \tag{5.17}$$

or

$$m_1(\{x \in [y,1] : P_{\mu,c}(x) \leq 0\}) \geq \tfrac{1}{2}(1-y)(2-s). \tag{5.18}$$

We may assume that $y > -1$ and that (5.17) holds; otherwise, we study $(\mu(-t),c) \in \mathcal{M}(s)$. Now (5.17) impiles that $(\nu,\hat{c}) \in \mathcal{M}(s)$, where

$$\nu(t) := \mu\left(\frac{y+1}{2}t + \frac{y-1}{2}\right), \qquad \hat{c} := c - \log\left(\frac{2}{y+1}\right),$$

and

$$\max_{-1\leq x\leq 1} P_{\mu,c}(x) = P_{\mu,c}(y) = P_{\nu,\hat{c}}(1),$$

which proves the lemma. □

6. Proofs of Theorems 2.1 and 2.2.

Proof of Theorem 2.1. From Lemmas 4.4 and 4.5 we deduce that

$$\max_{-1\le x\le 1} Q_{\mu,c}(x) \le \exp(g_{D_\infty([-1,1-s])}(1,\infty)), \tag{6.1}$$

whenever $m_1(E_{\mu,c}) \ge 2 - s$. Note that

$$\exp\{g_{D_\infty([-1,1-s])}(1,\infty)\} = \frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}}, \tag{6.2}$$

which, together with (6.1), yields the first part of the theorem.

Now we prove the unicity part of the theorem. Assume that $(\mu, c) \in \mathcal{M}(s)$, $Q_{\mu,c}$ restricted to $[-1, 1]$ is continuous and

$$Q_{\mu,c}(1) = \frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}}. \tag{6.3}$$

Then, by continuity, $\sup(E_{\mu,c}) < 1$. First we show that

$$P_{\mu,c}(z) = g_{D_\infty([-1,1-s])}(z,\infty) \tag{6.4}$$

for all z in the half plane

$$\mathcal{H} := \{z \in \mathbb{C} : \operatorname{Re} z > \sup(E_{\mu,c})\}.$$

Indeed, (6.3) can be written as $h(1) = 0$, where

$$h(z) := g_{D_\infty([-1,1-s])}(z,\infty) - P_{\mu,c}(z).$$

Since h is superharmonic in the domain and $1 \in \mathcal{H}$, Lemma 4.4 and the minimum principle for superharmonic functions imply that $h(z) \equiv 0$ in $\mathcal{H}$. Thus (6.4) holds in $\mathcal{H}$.

Next we show that

$$\operatorname{supp}(\mu) \subset \mathbb{R}.$$

Assume that $\operatorname{supp}(\mu)\backslash\mathbb{R} \ne \emptyset$. If $w \in \operatorname{supp}(\mu)\backslash\mathbb{R}$, then the disk

$$D(w,\varepsilon) := \{z \in \mathbb{C} : |z - w| < \varepsilon\}$$

has positive μ-measure for every $\varepsilon > 0$. Now let

$$A := \operatorname{supp}(\mu) \cap D(w,\varepsilon) \quad \text{with } \varepsilon = \tfrac{1}{3}|\operatorname{Im} w|. \tag{6.5}$$

We define the linear transformation $\varphi : \mathbb{C} \to \mathbb{C}$ by

$$\varphi(z) := 1 + (z-1)\exp(i(\pi - \arg(w-1))). \tag{6.6}$$

Obviously,

$$|1 - \varphi(t)| = |1 - t| \quad \text{for all } t \in \mathbb{C}, \tag{6.7}$$

and there is a $0 < \delta < 1$ depending only on w and $\sup(E_{\mu,c})$ such that

$$|x - \varphi(t)| < \delta|x - t| \quad \text{for all } t \in A \quad \text{and} \quad -1 \le x \le \sup(E_{\mu,c}). \tag{6.8}$$

We denote the restriction of a measure ν on a measurable set B by $\nu|_B$, and define the measure $\sigma(t) := \mu(\varphi^{-1}(t))$. Then (6.7), (6.8), and $\mu \in \mathcal{M}$ imply

$$\begin{aligned}\int_{\mathbb{C}} \log|1-t|d\mu|_A(t) &= \int_A \log|1-\varphi(t)|d\mu(t)\\ &= \int_{\varphi(A)} \log|1-t|d\sigma(t)\end{aligned} \tag{6.9}$$

and

(6.10)

$$\begin{aligned}\int_{\mathbb{C}} \log|x-t|d\sigma|_{\varphi(A)} &= \int_A \log|x-\varphi(t)|d\mu(t)\\ &< \int_A \log|x-t|d\mu(t) + \mu(A)\log\delta \quad \text{for all } -1 \le x \le \sup(E_{\mu,c}).\end{aligned}$$

Now let

$$\hat{\mu}(t) := \mu|_{\mathbb{C}\setminus A}(t) + \sigma|_{\varphi(A)}(t). \tag{6.11}$$

We have $\hat{\mu} \in \mathcal{M}$, since $\mu \in \mathcal{M}$ and

$$\begin{aligned}\int_{\mathbb{C}} d\hat{\mu} &= \int_{\mathbb{C}\setminus A} d\mu + \int_{\varphi(A)} d\sigma\\ &= \int_{\mathbb{C}\setminus A} d\mu + \int_A d\mu = \int_{\mathbb{C}} d\mu = 1.\end{aligned}$$

From (6.9)–(6.11) we obtain

$$\int_{\mathbb{C}} \log|1-t|d\hat{\mu}(t) = \int_{\mathbb{C}} \log|1-t|d\mu(t) \tag{6.12}$$

and, for $-1 \le x \le \sup(E_{\mu,c})$,

$$\int_{\mathbb{C}} \log|x-t|d\hat{\mu}(t) < \int_{\mathbb{C}} \log|x-t|d\mu(t) + \mu(A)\log\delta. \tag{6.13}$$

Now (6.13) and $(\mu, c) \in \mathcal{M}(s)$ imply

$$(\hat{\mu}, c - \mu(A)\log\delta) \in \mathcal{M}(s),$$

while (6.12) and $0 < \delta < 1$ yield

$$P_{\hat{\mu},c-\mu(A)\log\delta}(1) = P_{\mu,c}(1) - \mu(A)\log\delta > P_{\mu,c}(1),$$

which contradicts the extremal property of $P_{\mu,c}$. Therefore $\operatorname{supp}(\mu) \subset \mathbb{R}$.

Let $[\alpha, \beta]$ be the smallest interval containing $\operatorname{supp}(\mu) \cup [-1, 1-s]$. Since the function $g_{D_\infty([-1,1-s])} - P_{\mu,c}$ is harmonic on $\overline{\mathbb{C}}\setminus[\alpha,\beta]$ and vanishes in the half plane $\mathcal{H}$, we have

$$g_{D_\infty([-1,1-s])}(z,\infty) \equiv P_{\mu,c}(z) \tag{6.14}$$

for all $z \in \mathbb{C}\backslash[\alpha,\beta]$. In particular, letting $z \to \infty$ in (6.14),

$$c = -\log\frac{2-s}{4}.$$

Since (6.14) can be written as

$$\int_{\mathbb{C}} \log|z-t|d\mu(t) = \int_{\mathbb{C}} \log|z-t|d\mu^*_{[-1,1-s]}(t)$$

for all $z \in \mathbb{C}\backslash[\alpha,\beta]$, the result of [10, Thm. 1.12′, p. 76] yields $\mu = \mu^*_{[-1,1-s]}$.

Finally, if $(\mu,c) \in \mathcal{M}(s)$ and

$$Q_{\mu,c}(y) = \frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}}, \qquad y \in [-1,1],$$

then, as in the proof of Lemma 4.5, we have either

$$(\hat{\nu},\hat{c}) \in \mathcal{M}(s) \quad \text{or} \quad (\tilde{\nu},\tilde{c}) \in \mathcal{M}(s),$$

where

$$\hat{\nu}(t) := \mu((y+1)t/2 + (y-1)/2), \qquad \hat{c} := c - \log\left(\frac{2}{y+1}\right)$$

and

$$\tilde{\nu}(t) := \mu((1-y)t/2 + (1+y)/2), \qquad \tilde{c} := c - \log\left(\frac{2}{1-y}\right).$$

If $(\hat{\nu},\hat{c}) \in \mathcal{M}(s)$, then

$$Q_{\hat{\nu},\hat{c}}(1) = Q_{\mu,c}(y) = \frac{\sqrt{2}+\sqrt{s}}{\sqrt{2}-\sqrt{s}},$$

and so, by the first part of the proof,

$$\hat{\nu} = \mu^*_{[-1,1-s]} \quad \text{and} \quad \hat{c} = -\log\frac{2-s}{4}.$$

Since $Q_{\hat{\nu},\hat{c}}(1) \geq Q_{\mu,c}(1) = Q_{\hat{\nu},\hat{c}}((3-y)/(1+y))$, it follows that $y = 1$. Hence

$$\mu = \hat{\nu} = \mu^*_{[-1,1-s]} \quad \text{and} \quad c = \hat{c} = -\log\frac{2-s}{4}.$$

If $(\tilde{\nu},\tilde{c}) \in \mathcal{M}(s)$, then in exactly the same way we obtain

$$\mu = \tilde{\nu} = \mu^*_{[-1+s,1]} \quad \text{and} \quad c = \tilde{c} = -\log\frac{2-s}{4},$$

which completes the proof. □

Proof of Theorem 2.2. We assume that $0 < s < 1$, since the case $s = 1$ can be obtained by Theorem 2.1. Let $\mu \in \mathcal{M}$ and $c \in \mathbb{R}$ be such that (2.4) holds. For a fixed $0 < \varepsilon < 1 - s$ we choose a compact set $K \subset E_{\mu,c}$ such that

$$m_1(E_{\mu,c}\backslash K) \leq \varepsilon.$$

Then, as in the proof of Lemma 4.4, we deduce that

$$g_{D_\infty(K)}(z,\infty) - P_{\mu,c}(z) \geq 0 \tag{6.15}$$

for all $z \in D_\infty(K)$. Note that assumption (2.4) and the choice of K imply $m_1(K) \geq 2 - s + \varepsilon$. Applying [4, Thm. 4] to the Fekete polynomials $F_{n,K} \in \mathcal{P}_n^r$, we have

$$\frac{1}{n} \log \frac{|F_{n,K}(x)|}{\|F_{n,K}\|_K} \leq k_1 \min\left\{ \frac{s+\varepsilon}{\sqrt{1-x^2}}, \sqrt{s+\varepsilon} \right\} \tag{6.16}$$

for every $-1 \leq x \leq 1$, where $k_1 > 0$ is an absolute constant. By Lemma 4.3 and $m_1(K) \geq 2 - s - \varepsilon > 0$, the limit of the left-hand side of (6.16), as $n \to \infty$, exists for every $x \in [-1,1]\backslash K$, and equals $g_{D_\infty(K)}(x,\infty)$. Therefore (6.16) and Lemma 4.3 imply

$$g_{D_\infty(K)}(x,\infty) \leq k_1 \min\left\{ \frac{s+\varepsilon}{\sqrt{1-x^2}}, \sqrt{s+\varepsilon} \right\}$$

for every $x \in [-1,1]\backslash K$, and together with (6.15) this yields

$$P_{\mu,c}(x) \leq k_1 \min\left\{ \frac{s+\varepsilon}{\sqrt{1-x^2}}, \sqrt{s+\varepsilon} \right\} \tag{6.17}$$

for every $x \in [-1,1]\backslash K$. Since $P_{\mu,c}(x) \leq 0$ for every $x \in K \subset E_{\mu,c}$, (6.17) holds for every $x \in [-1,1]$. Taking the limit in (6.17) as $\varepsilon \to 0+$, we get the desired result. □

7. Proofs of Theorems 2.4, 2.5, and 2.6. Denote by $\mathcal{T}_n$ the set of all real trigonometric polynomials of degree at most n. Note that $p \in \mathcal{P}_n^c$ implies that $q_r(t) := |p(re^{it})|^2 \in \mathcal{T}_n$ for every $r > 0$. This follows immediately from the identity

$$\begin{aligned} |z - z_j|^2 &= |re^{it} - r_j e^{it_j}|^2 = (re^{it} - r_j e^{it_j})(re^{-it} - r_j e^{-it_j}) \\ &= r^2 + r_j^2 - 2rr_j \cos(t - t_j) \end{aligned} \tag{7.1}$$

$$(z = re^{it}, z_j = r_j e^{it_j}, t, t_j \in \mathbb{R}, r > 0, r_j > 0).$$

In the proof of Theorem 2.5 a Remez-type inequality on the size of trigonometric polynomials will play a central role. To formulate this we introduce the notation

$$\mathcal{T}_n(s) := \{q \in \mathcal{T}_n : m_1(\{t \in [-\pi,\pi) : |q(t)| \leq 1\}) \geq 2\pi - s\} \qquad (0 < s < 2\pi). \tag{7.2}$$

LEMMA 7.1. *There is an absolute constant $k_{13} > 0$ such that*

$$\max_{-\pi \leq t \leq \pi} |q(t)| \leq \exp(k_{13} n s) \qquad (0 < s \leq \pi/2)$$

for every $q \in \mathcal{T}_n(s)$.

Lemma 7.1 is proved in [4, Thm. 3]. Our next lemma is a well-known, simple consequence of the maximum principle for analytic functions.

LEMMA 7.2. *Let $\overline{D} := \{z \in \mathbb{C} : |z| \leq 1\}$. We have*

$$\max_{u \in \overline{D}} |p(u)| \leq (1-r)^{-n} \max_{|u| \leq 1-r} |p(u)|$$

for every $p \in \mathcal{P}_n^c$ and $0 < r < 1$.

Theorem 2.5 will be used in the proof of Theorem 2.4, so we prove Theorem 2.5 first. The proof of Theorem 2.4 will be given at the end of this section.

Proof of Theorem 2.5. Let $p \in \mathcal{P}_n^c(\overline{D}, s)(0 < s \leq \frac{1}{4})$. Observe that if $q_r(t) := |p(re^{it})|^2 \notin \mathcal{T}_n(2\sqrt{s})$ for every $1 - \sqrt{s} \leq r \leq 1$, then

$$m_2(\{z \in \overline{D} : |p(z)|^2 > 1\}) > \int_{1-\sqrt{s}}^{1} 2\sqrt{sr}dr \geq \sqrt{s}2\sqrt{s}(1-\sqrt{s}) \geq s \tag{7.3}$$

($0 < s \leq \frac{1}{4}$ was used in the last inequality), which contradicts the fact that $p \in \mathcal{P}_n^c(\overline{D}, s)$. Thus there exists an $r_0, (1 - \sqrt{s} \leq r_0 \leq 1)$ such that

$$q_{r_0}(t) = |p(r_0 e^{it})|^2 \in \mathcal{T}_n(2\sqrt{s}). \tag{7.4}$$

Then, by Lemma 7.1, we obtain

$$\max_{-\pi \leq t \leq \pi} |p(r_0 e^{it})|^2 = \max_{-\pi \leq t \leq \pi} |q_{r_0}(t)| \leq \exp(2k_{13} n\sqrt{s}). \tag{7.5}$$

Furthermore, Lemma 7.2, together with $1 - \sqrt{s} \leq r_0 \leq 1$ and $0 < s \leq \frac{1}{4}$, yields

$$\begin{aligned} \max_{u \in \overline{D}} |p(u)|^2 &\leq (1-\sqrt{s})^{-2n} \max_{|u| \leq r_0} |p(u)|^2 \\ &\leq \exp(4n\sqrt{s}) \max_{|u| \leq r_0} |p(u)|^2 = \exp(4n\sqrt{s}) \max_{-\pi \leq t \leq \pi} |p(r_0 e^{it})|^2. \end{aligned} \tag{7.6}$$

Now (7.5) and (7.6) give the theorem with $k_4 := k_{13} + 2$. □

Proof of Theorem 2.6. Let $T_n(x) = \cos(n \arccos x)(-1 \leq x \leq 1)$ be the Chebyshev polynomial of degree n. For $0 < s \leq 1$, define the polynomials

$$T_{n,s}(z) := T_n\left(\frac{z}{\cos\sqrt{s}}\right) \tag{7.7}$$

and

$$Q_{3n,s}(z) := z^{2n} T_{n,s}\left(\frac{z + z^{-1}}{2}\right). \tag{7.8}$$

Obviously,

$$\max_{|u| \leq 1} |Q_{3n,s}(u)| = |Q_{3n,s}(1)| = T_n\left(\frac{1}{\cos\sqrt{s}}\right) \geq T_n\left(1 + \frac{s}{2}\right). \tag{7.9}$$

Let

$$\begin{aligned} D_{s,c} := \{z \in \mathbb{C} : |z| \leq 1, \arg z \in [\sqrt{s}, \pi - \sqrt{s}] \cup [\pi + \sqrt{s}, 2\pi - \sqrt{s}]\} \\ \cup \{z \in \mathbb{C} : |z| \leq 1 - c\sqrt{s}\}, \end{aligned} \tag{7.10}$$

where $0 < c \leq 1$ will be chosen later. We examine the maximum of $|Q_{3n,s}|$ on $D_{s,c}$. By the maximum principle, it is sufficient to examine the maximum of $|Q_{3n,s}|$ on the boundary of $D_{s,c}$. For z satisfying $|z| = 1, \arg z \in [\sqrt{s}, \pi - \sqrt{s}] \cup [\pi + \sqrt{s}, 2\pi - \sqrt{s}]$, we have

$$|Q_{3n,s}(z)| \leq \max_{|x| \leq \cos\sqrt{s}} \left| T_n\left(\frac{x}{\cos\sqrt{s}}\right) \right| \leq 1. \tag{7.11}$$

Furthermore, by the maximum principle, we have for $|z| = 1 - c\sqrt{s}$,

(7.12)
$$\begin{aligned} |Q_{3n,s}(z)| &\le (1-c\sqrt{s})^n \max_{|u|\le 1-c\sqrt{s}} \left| u^n T_{n,s}\left(\frac{u+u^{-1}}{2}\right)\right| \\ &\le \exp(-cn\sqrt{s}) \max_{|u|=1} \left| u^n T_{n,s}\left(\frac{u+u^{-1}}{2}\right)\right| = \exp(-cn\sqrt{s}) T_n\left(\frac{1}{\cos\sqrt{s}}\right). \end{aligned}$$

Now let

(7.13) $$z = r(\cos\sqrt{s} + i\sin\sqrt{s}) \quad \text{with } 1 - c\sqrt{s} \le r \le 1.$$

If $c = \frac{1}{8}$ and $0 < s \le 1$ in (7.13), then

(7.14)
$$\begin{aligned} \left|\frac{z+z^{-1}}{2} - \cos\sqrt{s}\right| &= \left|\left(\frac{r+r^{-1}}{2} - 1\right)\cos\sqrt{s} + i\frac{r-r^{-1}}{2}\sin\sqrt{s}\right| \\ &\le \frac{1}{2}\frac{c^2 s}{1-c\sqrt{s}}\cos\sqrt{s} + \frac{c\sqrt{s}}{1-c\sqrt{s}}\sin\sqrt{s} \le \frac{s}{4}\cos\sqrt{s}. \end{aligned}$$

Therefore, using the fact that the zeros of $T_{n,s}$ are in $(-\cos\sqrt{s}, \cos\sqrt{s})$, we easily conclude

(7.15) $$|Q_{3n,s}(z)| \le \left|T_{n,s}\left(\frac{z+z^{-1}}{2}\right)\right| \le T_{n,s}\left(\left(1+\frac{s}{4}\right)\cos\sqrt{s}\right) = T_n\left(1+\frac{s}{4}\right).$$

By the reason of symmetry (7.15) holds when $z = r(\pm\cos\sqrt{s} \pm i\sin\sqrt{s}), 1 - \sqrt{s}/8 \le r \le 1$, and $0 < s \le 1$. We define

(7.16) $$K(n,s) := \max\left\{T_n\left(\frac{1}{\cos\sqrt{s}}\right)\exp\left(-\frac{1}{8}n\sqrt{s}\right), T_n\left(1+\frac{s}{4}\right)\right\}$$

and

(7.17) $$P_{3n,s}(z) := \frac{Q_{3n,s}(z)}{K(n,s)}.$$

By (7.11), (7.12), (7.15)–(7.17) and the maximum principle we can easily deduce that

(7.18) $$|P_{3n,s}(z)| \le 1 \quad \text{for } z \in D_{s,1/8}.$$

Hence

(7.19) $$P_{3n,s} \in \mathcal{P}^r_{3n}(\overline{D}, s) \qquad (0 < s \le 1).$$

Finally, by (7.9), (7.16), and (7.17) we obtain

(7.20)
$$\begin{aligned} P_{3n,s}(1) &= \frac{T_n(1/\cos\sqrt{s})}{K(n,s)} \\ &\ge \min\left\{\exp\left(\frac{1}{8}n\sqrt{s}\right), \frac{T_n(1+s/2)}{T_n(1+s/4)}\right\} = \exp\left(\frac{1}{8}n\sqrt{s}\right), \end{aligned}$$

which completes the proof. □

Proof of Theorem 2.4. Denote the boundary of Ω by Γ. Since Γ is a C^2 curve, there is an $r > 0$ depending only on Ω such that for each $z \in \Gamma$ there is an open disk D_z with radius r such that $D_z \subset \Omega$ and $\overline{D}_z \cap \Gamma = \{z\}$. By the maximum principle for analytic functions, for every $p \in \mathcal{P}_n^c$ there is a $z_0 \in \Gamma$ such that $|p(z_0)| = \max_{u\in\overline{\Omega}} |p(u)|$. It follows from Theorem 2.5, by a linear transformation, that there are constants $k_{14} := k_4\sqrt{1/r^2} = k_4/r > 0$ and $k_{15} := r^2/4 > 0$ depending only on Ω (k_4 is the same as in Theorem 2.5) such that

$$\max_{u\in\overline{\Omega}} |p(u)| = \max_{u\in\overline{D}_{z_0}} |p(u)| \le \exp(k_4 n\sqrt{s/r^2}) = \exp(k_{14} n\sqrt{s}) \qquad (0 < s \le k_{15}) \tag{7.21}$$

for every $p \in \mathcal{P}_n^c$ satisfying

$$m_2(\{z \in \overline{\Omega} : |p(z)| \le 1\}) \ge m_2(\overline{\Omega}) - s. \tag{7.22}$$

Now let $\mu \in \mathcal{M}, c \in \mathbb{R}$,

$$E_{\Omega,\mu,c} := \{z \in \overline{\Omega} : Q_{\mu,c}(z) \le 1\}, \tag{7.23}$$

and assume that

$$m_2(E_{\Omega,\mu,c}) > m_2(\overline{\Omega}) - s. \tag{7.24}$$

For a fixed $0 < \varepsilon < m_2(\overline{\Omega}) - s$ we choose a compact set $K \subset E_{\Omega,\mu,c}$ such that

$$m_2(E_{\Omega,\mu,c}\backslash K) \le \varepsilon. \tag{7.25}$$

This, together with (7.24), gives

$$m_2(K) \ge m_2(\overline{\Omega}) - (s + \varepsilon). \tag{7.26}$$

As in the proof of Lemma 4.4, we obtain that

$$g_{D_\infty(K)}(z, \infty) - P_{\mu,c}(z) \ge 0 \tag{7.27}$$

for all $z \in D_\infty(K)$. Applying (7.21) to the normalized Fekete polynomials

$$\widehat{F}_{n,K} := \frac{F_{n,K}}{\|F_{n,K}\|_K}, \tag{7.28}$$

we obtain

$$\frac{1}{n} \log |\widehat{F}_{n,K}(z)| \le K_{14}\sqrt{s + \varepsilon} \tag{7.29}$$

for every $z \in \overline{\Omega}$ and $0 < s + \varepsilon \le k_{15}$. By Lemma 4.3, the limit of the left-hand side of (7.29), as $n \to \infty$, exists for every $z \in D_\infty(K)$ and equals $g_{D_\infty(K)}(z, \infty)$. Therefore, (7.29) and Lemma 4.3 imply

$$g_{D_\infty(K)}(z, \infty) \le k_{14}\sqrt{s + \varepsilon} \tag{7.30}$$

for every $z \in D_\infty(K) \cap \overline{\Omega}$ and $0 < s + \varepsilon \le k_{15}$, and together with (7.27) this yields

$$P_{\mu,c}(z) \le k_{14}\sqrt{s + \varepsilon} \tag{7.31}$$

for every $z \in D_\infty(K) \cap \overline{\Omega}$ and $0 < s + \varepsilon \le k_{15}$. Since $K \subset E_{\Omega,\mu,c}$ and $P_{\mu,c}(z)$ is subharmonic in $\mathbb{C}$, it follows from the maximum principle that (7.31) holds for all $z \in \overline{\Omega}$. Taking the limit as $\varepsilon \to 0+$, we get

$$Q_{\mu,c}(z) \le \exp(k_{14}\sqrt{s}) \tag{7.32}$$

for every $z \in \overline{\Omega}$ and $0 < s \le k_{15}$, which completes the proof. □

8. Proofs of Theorems 2.7 and 2.8.

Proof of Theorem 2.7. From Theorem 2.1* we can easily deduce that

$$m_1(E_{\mu,c,s,A}) \geq 2s - s = s \tag{8.1}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}, 0 < s < 1$, and $A \subset [-1,1]$ with $m_1(A) \geq 2 - s$, where

$$E_{\mu,c,s,A} = \left\{ x \in A : Q_{\mu,c}(x) > \frac{1-\sqrt{s}}{1+\sqrt{s}} \max_{-1 \leq y \leq 1} Q_{\mu,c}(y) \right\}. \tag{8.2}$$

Hence

$$\begin{aligned} \int_{[-1,1]\setminus A} (Q_{\mu,c}(x))^p dx &\leq s \max_{-1 \leq y \leq 1} (Q_{\mu,c}(y))^p \\ &< \left(\frac{1+\sqrt{s}}{1-\sqrt{s}} \right)^p \int_{E_{\mu,c,s,A}} (Q_{\mu,c}(x))^p dx \\ &< \left(\frac{1+\sqrt{s}}{1-\sqrt{s}} \right)^p \int_A (Q_{\mu,c}(x))^p dx \\ &\leq \exp(k_6 p \sqrt{s}) \int_A (Q_{\mu,c}(x))^p dx \end{aligned} \tag{8.3}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}, 0 < s \leq \frac{1}{2}$ and $A \subset [-1,1]$ with $m_1(A) \geq 2 - s$, where $k_6 = 4$ is a suitable choice. From (8.3) we immediately get (2.12). □

Theorem 2.8 follows from Theorem 2.4 by straightforward modifications of the proof of Theorem 2.7.

9. Proofs of Theorems 2.9 and 2.10.

Proof of Theorem 2.9. Assume that $p \in \mathcal{P}_n^c$ and

$$m_1(\{t \in [-\pi,\pi) : |p(e^{it})| \leq 1\}) \geq 2\pi - s \qquad (0 < s \leq \pi/2). \tag{9.1}$$

Applying Lemma 7.1 to $q(t) := |p(e^{it})|^2 \in \mathcal{T}_n(s)$, we obtain

$$|p(e^{it})| \leq \exp(k_{13} n s) \qquad (t \in \mathbb{R}). \tag{9.2}$$

The above polynomial inequality can be extended to exponentials of logarithmic potentials with compact support by the technique used in the proof of Theorems 2.2 and 2.4; so we omit the details. □

Theorem 2.10 follows immediately from Theorem 2.9 in exactly the same way as Theorem 2.7 was obtained from Theorem 2.1* ; so we omit the details.

10. Proofs of Theorems 3.1, 3.2, and 3.3.

Proof of Theorem 3.1. For the sake of brevity we denote the norm $\|\cdot\|_{L_p(-1,1)}$ by $\|\cdot\|_p$. It is sufficient to prove the theorem when $p = \infty$, and then a simple argument gives the desired result for arbitrary $0 < q < p < \infty$. To see this, assume that

$$\|f\|_\infty \leq M^{1/q} \|f\|_q$$

for an $f \in L_\infty$ and $0 < q < \infty$, with some factor M. Then

$$\|f\|_p^p = \| \, |f|^{p-q+q}\|_1 < \|f\|_\infty^{p-q}\|f\|_q^q$$

$$\leq M^{p/q-1}\|f\|_q^{p-q}\|f\|_q^q,$$

and therefore

$$\|f\|_p \leq M^{1/q-1/p}\|f\|_q$$

for every $0 < q < p < \infty$. Thus, in the sequel let $0 < q < p = \infty$. Applying Corollary 2.3 with

$$s = \min\{1, q^{-2}\}, \tag{10.1}$$

we obtain

$$m_1\left(\left\{x \in [-1,1] : (Q_{\mu,c}(x))^q \geq e^{-1} \max_{-1\leq y\leq 1}(Q_{\mu,c}(y))^q\right\}\right) \geq k_2 s \tag{10.2}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $q > 0$. Now, integrating only on the subset E of $[-1,1]$, where

$$(Q_{\mu,c}(x))^q \geq e^{-1} \max_{-1\leq y\leq 1}(Q_{\mu,c}(y))^q, \tag{10.3}$$

and using (10.1) and (10.2), we conclude that

$$\|Q_{\mu,c}\|_\infty^q \leq \frac{e}{m_1(E)} \int_E (Q_{\mu,c}(x))^q dx \leq \frac{e}{k_2}(1+q^2)\|Q_{\mu,c}\|_q^q \tag{10.4}$$

for every $\mu \in \mathcal{M}, c \in \mathbb{R}$, and $q > 0$, and the theorem follows by taking the qth root. □

Theorems 3.2 and 3.3 follow from Theorems 2.4 and 2.9, respectively, by straightforward modifications of the proof of Theorem 3.1.

ON NECESSARY MULTIPLIER CONDITIONS FOR LAGUERRE EXPANSIONS II*

GEORGE GASPER† AND WALTER TREBELS‡

Abstract. The necessary multiplier conditions for Laguerre expansions derived by Gasper and Trebels [*Canad. J. Math*, 43 (1991), pp. 1228–1242] are supplemented and modified. This allows the authors to place Markett's Cohen-type inequality [*SIAM J. Math. Anal.*, 14 (1983), pp. 819–833] (up to the log case) in the general framework of necessary conditions.

Key words. Laguerre polynomials, necessary multiplier conditions, Cohen-type inequalities, fractional differences, weighted Lebesgue spaces

AMS subject classifications. 33C65, 42A45, 42C10

1. Introduction. The purpose of this sequel to [3] is to obtain a better insight into the structure of Laguerre multipliers on L^p spaces from the point of view of necessary conditions. We recall that in [3] there occurs the annoying phenomenon that, e.g., the optimal necessary conditions in the case $p = 1$ do not give the "right" unboundedness behavior of the Cesàro means. By slightly modifying these conditions we not only remedy this defect but also derive Markett's Cohen-type inequality [6] (up to the log case) as an immediate consequence.

For the convenience of the reader we briefly repeat the notation. We consider the Lebesgue spaces

$$L^p_{w(\gamma)} = \left\{ f : \|f\|_{L^p_{w(\gamma)}} = \left(\int_0^\infty |f(x)e^{-x/2}|^p x^\gamma \, dx \right)^{1/p} < \infty \right\}, \qquad 1 \le p < \infty,$$

denote the classical Laguerre polynomials by $L_n^\alpha(x)$, $\alpha > -1$, $n \in \mathbf{N}_0$ (see Szegö [8, p. 100]), and set

$$R_n^\alpha(x) = L_n^\alpha(x)/L_n^\alpha(0), \qquad L_n^\alpha(0) = A_n^\alpha = \binom{n+\alpha}{n} = \frac{\Gamma(n+\alpha+1)}{\Gamma(n+1)\Gamma(\alpha+1)}.$$

Associate to f its formal Laguerre series

$$f(x) \sim (\Gamma(\alpha+1))^{-1} \sum_{k=0}^\infty \hat{f}_\alpha(k) L_k^\alpha(x),$$

where the Fourier Laguerre coefficients of f are defined by

$$\hat{f}_\alpha(n) = \int_0^\infty f(x) R_n^\alpha(x) x^\alpha e^{-x} \, dx \tag{1}$$

(if the integrals exist). A sequence $m = \{m_k\}$ is called a (bounded) multiplier on $L^p_{w(\gamma)}$, notation $m \in M^p_{w(\gamma)}$, if

$$\left\| \sum_{k=0}^\infty m_k \hat{f}_\alpha(k) L_k^\alpha \right\|_{L^p_{w(\gamma)}} \le C \|f\|_{L^p_{w(\gamma)}}$$

for all polynomials f; the smallest constant C for which this holds is called the multiplier norm $\|m\|_{M^p_{\alpha,\gamma}}$. The necessary conditions will be given in certain smoothness properties of the multiplier sequence in question. To this end we introduce a fractional difference operator of order δ by

$$\Delta^\delta m_k = \sum_{j=0}^{\infty} A_j^{-\delta-1} m_{k+j}$$

(whenever the sum converges), the first-order difference operator Δ_2 with increment 2 by

$$\Delta_2 m_k = m_k - m_{k+2},$$

and the notation

$$\Delta_2 \Delta^\delta m_k = \Delta^{\delta+1} m_k + \Delta^{\delta+1} m_{k+1}.$$

Generic positive constants that are independent of the functions (and sequences) will be denoted by C. Within the setting of the $L^p_{w(\gamma)}$-spaces, our main results now read (with $1/p + 1/q = 1$) as the following theorem.

THEOREM 1.1. *Let α, $a > -1$, and $\alpha + a > -1$. If $f \in L^p_{w(\gamma)}$, $1 \le p < 2$, $\gamma > -1$, then*

$$\left(\sum_{k=0}^{\infty} |(k+1)^{(\gamma+1)/p - 1/2} \Delta_2 \Delta^a \hat{f}_\alpha(k)|^q \right)^{1/q} \le C \|f\|_{L^p_{w(\gamma)}}, \tag{2}$$

provided

$$\frac{\gamma+1}{p} \le \frac{\alpha+a}{p} + 1 \quad \text{if } \alpha + a \le \frac{1}{2},$$

$$\frac{\gamma+1}{p} \le \frac{\alpha+a}{2} + 1 + \frac{1}{2}\left(\frac{1}{p} - \frac{1}{2}\right) \quad \text{if } \alpha + a > \frac{1}{2}.$$

If we note that

$$|m_k| \, \|L^\alpha_k\|_{L^p_{w(\gamma)}} = \|m_k L^\alpha_k\|_{L^p_{w(\gamma)}} \le \|m\|_{M^p_{\alpha,\gamma}} \|L^\alpha_k\|_{L^p_{w(\gamma)}}, \qquad \gamma > -1,$$

implies $M^p_{w(\gamma)} \subset l^\infty$, we immediately obtain, as in [3] (see there the proof of Lemma 2.3), the following theorem.

THEOREM 1.2. *Let $m = \{m_k\} \in M^p_{w(\gamma)}$, $1 \le p < 2$, and let α, γ, and a be as in Theorem 1.1. Then*

$$\sup_n \left(\sum_{k=n}^{2n} |(k+1)^{(2\gamma+1)/p - (2\alpha+1)/2} \Delta_2 \Delta^a m_k|^q \frac{1}{k+1} \right)^{1/q} \le C \|m\|_{M^p_{\alpha,\gamma}} \tag{3}$$

An extension of Theorem 1.2 to $2 < p < \infty$ easily follows by duality

$$M^p_{w(\gamma)} = M^q_{w(\alpha q - \gamma q/p)}, \quad -1 < \gamma < p(\alpha+1) - 1, \quad 1 < p < \infty.$$

In view of the results in [3], [6] and for an easy comparison we want to emphasize the cases $\gamma = \alpha$ and $\gamma = \alpha p/2$. Therefore, we state the following corollary.

COROLLARY 1.3. (a) *Let* $m \in M^p_{w(\alpha)}$, $1 \le p < 2$, $\alpha > -1$, *and let* $\lambda := (2\alpha+1)(1/p - 1/2)$. *Then, with* $\lambda > 0$,

$$\sup_n \left(\sum_{k=n}^{2n} |(k+1)^\lambda \Delta_2 \Delta^{\lambda-1} m_k|^q \frac{1}{k+1} \right)^{1/q} \le C \|m\|_{M^p_{w(\alpha)}}$$

if $\alpha + \lambda \ge 3/2$; *if* $\alpha + \lambda < 3/2$, *it has additionally to be assumed that* $\lambda \ge 2 - p$. *In the case* $\alpha + \lambda < 3/2$ *and* $\lambda < 2 - p$ *an analogous result holds when the difference operator* $\Delta_2 \Delta^{\lambda-1}$ *is replaced by* Δ_2.

(b) *Let* $m \in M^p_{w(\alpha p/2)}$, $1 \le p < \frac{4}{3}$, *and* $(\alpha - 1)(1/p - 1/2) \ge -\frac{1}{2}$. *Then*

$$\sup_n \left(\sum_{k=n}^{2n} |(k+1)^{1/p-1/2} \Delta_2 m_k|^q \frac{1}{k+1} \right)^{1/q} \le C \|m\|_{M^p_{w(\alpha p/2)}}.$$

Remark 1. For polynomial $f(x) = \sum_{k=0}^n c_k L_k^\alpha(x)$ Theorem 1.1 yields, by taking only the $k = n$ term on the left-hand side of (2),

$$|c_n|(n+1)^{(\gamma+1)/p-1/2} \le C \|f\|_{L^p_{w(\gamma)}}, \qquad 1 \le p < 2$$

(under the restrictions on γ of Theorem 1.1). In particular, if we choose $\gamma = \alpha$, this comprises [6, form. (1.13)] for his basic case $\beta = \alpha$. For $\gamma = \alpha p/2$ it even extends [6, form. (1.14)] to negative α's, as described in part (b) of Corollary 1.3. The case $2 < p < \infty$ can be solved by an application of a Nikolskii inequality; see [6].

Remark 2. Analogously, Cohen-type inequalities follow from Theorem 1.2; in particular, Corollary 1.3 yields the following corollary.

COROLLARY 1.4. *Let* $m = \{m_k\}_{k=0}^n$ *be a finite sequence,* $1 \le p < 2$, *and* $\alpha > -1$.

(a) *If* $m \in M^p_{w(\alpha)}$, *then*

$$(n+1)^{(2\alpha+2)(1/p-1/2)-1/2}|m_n| \le C \|m\|_{M^p_{w(\alpha)}}, \qquad 1 \le p < \frac{4\alpha+4}{2\alpha+3}.$$

(b) *If* $m \in M^p_{w(\alpha p/2)}$ *and* $(\alpha - 1)(1/p - 1/2) \ge -\frac{1}{2}$, *then*

$$(n+1)^{2/p-3/2}|m_n| \le C \|m\|_{M^p_{w(\alpha p/2)}}, \qquad 1 \le p < 4/3.$$

With the exception of the crucial log case, i.e., $p_0 = (4\alpha+4)/(2\alpha+3)$ or $p_0 = \frac{4}{3}$, Corollary 1.4 contains [6, Thm. 1] and extends it to negative α's. In particular we obtain for the Cesàro means of order $\delta \ge 0$, represented by its multiplier sequence $m^\delta_{k,n} = A^\delta_{n-k}/A^\delta_n$, the "right" unboundedness behavior (see [4])

$$\|\{m^\delta_{k,n}\}\|_{M^p_{w(\alpha)}} \ge C(n+1)^{(2\alpha+2)(1/p-1/2)-1/2-\delta}, \qquad 1 \le p < \frac{4\alpha+4}{2\alpha+3+2\delta}.$$

Remark 3. There arises the question of how far are necessary conditions of the type given in [3] comparable with the present ones. Let $\lambda > 1$. Since $\Delta_2 m_k = \Delta m_k + \Delta m_{k+1}$, we obviously have

$$\sup_n \left(\sum_{k=n}^{2n} |(k+1)^{(2\gamma+1)/p-(2\alpha+1)/2} \Delta_2 \Delta^{\lambda-1} m_k|^q \frac{1}{k+1} \right)^{1/q} \tag{4}$$

$$\leq C \sup_n \left(\sum_{k=n}^{2n} |(k+1)^{(2\gamma+1)/p-(2\alpha+1)/2} \Delta^\lambda m_k|^q \frac{1}{k+1} \right)^{1/q}.$$

In general, a converse cannot hold, as can be seen by the following example: choose $\gamma = \alpha$, $\lambda = (2\alpha+1)(1/p - 1/2)$, and $m_k = (-1)^k (k+1)^{-\varepsilon}$, $0 < \varepsilon < 1$. Then

$$\sup_n \left(\sum_{k=n}^{2n} |(k+1)\Delta m_k|^q \frac{1}{k+1} \right)^{1/q} = \infty,$$

and hence by the embedding properties of the *wbv*-spaces (see [2]) the right-hand side of (4) cannot be finite for all $\lambda > 1$. But since $\Delta_2 \Delta^{\lambda-1} m_k = \Delta^{\lambda-1} \Delta_2 m_k \sim (k+1)^{-\varepsilon-\lambda}$, the left-hand side of (4) is finite for all $\lambda > 1$.

Theorem 1.1 will be proved in §2 by interpolating between (L^1, l^∞)- and (L^2, l^2)-estimates. The $a \neq 0$ case is an easy consequence of the case $a = 0$ when one uses the basic formula (see [3, form. 3 and Remark 3 preceding §3])

$$(5)\quad \Delta^a R_k^\alpha(x) = \frac{\Gamma(\alpha+1)}{\Gamma(\alpha+a+1)} x^a R_k^{\alpha+a}(x), \qquad x > 0,\ a > -1 - \min\{\alpha, \alpha/2 - 1/4\},$$

where in the case $a > -(2\alpha+1)/4$ the series for the fractional difference converges absolutely. In §3 a necessary (L^1, l^1)-estimate is derived and is compared with a corresponding sufficient (l^1, L^1)-estimate.

2. Proof of Theorem 1.1. Let us first handle the (L^2, l^2)-estimate. Since

$$\Delta_2 \Delta^a \hat{f}_\alpha(k) = \Delta^{1+a} \hat{f}_\alpha(k) + \Delta^{1+a} \hat{f}_\alpha(k+1),$$

it follows from the Parseval formula preceding Corollary 2.5 in [3] that

$$(6)\quad \left(\sum_{k=0}^{\infty} |\sqrt{A_k^{\alpha+1+a}} \Delta_2 \Delta^a \hat{f}_\alpha(k)|^2 \right)^{1/2} \leq C \left(\int_0^\infty |f(t) e^{-t/2} t^{(\alpha+1+a)/2}|^2 \, dt \right)^{1/2}.$$

Concerning the (L^1, l^∞)-estimate, we first restrict ourselves to the case $a = 0$. Define $\mu \in \mathbf{R}$ by

$$2\left(\frac{1}{p} - \frac{1}{2}\right)\mu = \frac{\gamma}{p} - \frac{\alpha+1}{2};$$

with the notation $\mathcal{L}_k^\alpha(t) = (A_k^\alpha/\Gamma(\alpha+1))^{1/2} R_k^\alpha(t) e^{-t/2} t^{\alpha/2}$ it follows that

$$\begin{aligned}
|\Delta_2 \hat{f}_\alpha(k)| &= C \left| \int_0^\infty f(t) \left\{ \mathcal{L}_k^\alpha(t)/\sqrt{A_k^\alpha} - \mathcal{L}_{k+2}^\alpha(t)/\sqrt{A_{k+2}^\alpha} \right\} e^{-t/2} t^{\alpha/2} \, dt \right| \\
&\leq C(k+1)^{-1-\alpha/2} \int_0^\infty |f(t)| |t^{-\mu-1/2} \mathcal{L}_k^\alpha(t)| e^{-t/2} t^{(\alpha+1)/2+\mu} \, dt \\
&\quad + C(k+1)^{-\alpha/2} \int_0^\infty |f(t)| |t^{-\mu-1/2} \{\mathcal{L}_k^\alpha(t) - \mathcal{L}_{k+2}^\alpha(t)\}| \\
&\qquad\qquad e^{-t/2} t^{(\alpha+1)/2+\mu} \, dt \\
&= \mathrm{I} + \mathrm{II}.
\end{aligned}$$

We distinguish the two cases $\alpha \le \frac{1}{2}$ and $\alpha > \frac{1}{2}$ as follows:

First consider the case $\alpha \le \frac{1}{2}$. By the asymptotic estimates for $\mathcal{L}_k^\alpha(t) - \mathcal{L}_{k+2}^\alpha(t)$ in Askey and Wainger [1, p. 699] (see also [6, form. (2.12)]) it follows for $\gamma \le \alpha + p - 1$ that

$$\left\| t^{-\mu-1/2} \{ \mathcal{L}_k^\alpha(t) - \mathcal{L}_{k+2}^\alpha(t) \} \right\|_\infty \le C(k+1)^{-1-\mu},$$

so that

$$\text{(7)} \qquad \text{II} \le C(k+1)^{-1-\mu-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt, \qquad \gamma \le \alpha + p - 1.$$

By [5, Lemma 1, case 4]

$$\left\| t^{-\mu-1/2} \mathcal{L}_k^\alpha(t) \right\|_\infty \le C(k+1)^{-\mu-5/6},$$

so that trivially

$$\text{I} \le C(k+1)^{-1-\mu-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt, \quad \frac{\gamma+1}{p} \le \frac{\alpha+1}{2} - \frac{1}{3p} + \frac{2}{3}.$$

By [5, Lemma 1, case 5]

$$\left\| t^{-\mu-1/2} \mathcal{L}_k^\alpha(t) \right\|_\infty \le C(k+1)^{\mu+1/2},$$

so that

$$\begin{aligned} \text{I} &\le C(k+1)^{\mu-1/2-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt \\ &\le C(k+1)^{-1-\mu-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt, \quad \frac{\gamma+1}{p} > \frac{\alpha+1}{2} - \frac{1}{3p} + \frac{2}{3}, \end{aligned}$$

provided that $\mu - (\alpha+1)/2 \le -1 - \mu - \alpha/2$, which is equivalent to $\mu \le -\frac{1}{4}$ or $\gamma \le 3p/4 - \frac{1}{2} + \alpha p/2$. But this is no further restriction since for $\alpha \le \frac{1}{2}$ there holds $\alpha + p - 1 \le 3p/4 - \frac{1}{2} + \alpha p/2$. Summarizing, for $-1 < \alpha \le \frac{1}{2}$, $\gamma \le \alpha + p - 1$, and $\mu = (\gamma/p - (\alpha+1)/2)/2(1/p - \frac{1}{2})$ we have that

$$\text{(8)} \qquad \sup_k |(k+1)^{1+\mu+\alpha/2} \Delta_2 \hat{f}_\alpha(k)| \le C \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt.$$

Now consider the case $\alpha > 1/2$. Then, by [6, form. (2.12)], (7) is obviously true when $(\gamma+1)/p \le \alpha/2 + 1 + (1/p - 1/2)/2$. Again, the application of [5, Lemma 1] requires $\gamma \le \alpha + p - 1$, which for $\alpha > \frac{1}{2}$ is less restrictive than $(\gamma+1)/p \le \alpha/2 + 1 + (1/p - \frac{1}{2})/2$. Now [5, Lemma 1, case 4] leads to

$$\text{I} \le C(k+1)^{-11/6-\mu-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt, \qquad \frac{\gamma+1}{p} \le \frac{\alpha+1}{2} - \frac{1}{3p} + \frac{2}{3},$$

and [5, Lemma 1, case 5] leads to

$$\text{I} \le C(k+1)^{\mu-1/2-\alpha/2} \int_0^\infty |f(t)| e^{-t/2} t^{(\alpha+1)/2+\mu}\, dt, \qquad (\gamma+1)/p > \frac{\alpha+1}{2} - \frac{1}{3p} + \frac{2}{3}.$$

But $\mu - \frac{1}{2} - \alpha/2 \le -\mu - 1 - \alpha/2$ if $(\gamma+1)/p \le \alpha/2 + 1 + (1/p - \frac{1}{2})/2$, so that, summarizing, (8) also holds under this restriction for $\alpha > \frac{1}{2}$.

Now an application of the Stein and Weiss interpolation theorem (see [7]) with $Tf = \{Tf(k)\}$ and $Tf(k) = \sqrt{A_k^{\alpha+1}}\Delta_2 \hat{f}_\alpha(k)$ gives the assertion of Theorem 1.1 in the case $a = 0$.

If $a \neq 0$, then by (1), the definition of $\Delta_2\Delta^a$, and (5)

$$\Delta_2\Delta^a \hat{f}_\alpha(k) = C\{\Delta \hat{f}_{\alpha+a}(k) + \Delta \hat{f}_{\alpha+a}(k+1)\} = C\Delta_2 \hat{f}_{\alpha+a}(k)$$

since already the condition $\gamma < \alpha + a + 1$ (which implies no new restriction) gives absolute convergence of the infinite sum and integral involved (see the formula following (9) in [3]) and Fubini's theorem can be applied. Hence all the previous estimates remain valid when α is replaced by $\alpha + a$.

3. A variant for integrable functions. Theorem 1.1 gives a necessary condition for a sequence $\{f_k\}$ to generate with respect to L_k^α an $L^1_{w(\gamma)}$-function. But this condition is hardly comparable with the following sufficient one, which is a slight modification of [3, Lemma 2.2].

THEOREM 3.1. *Let $\alpha > -1$ and $\delta > 2\gamma - \alpha + \frac{1}{2} \ge 0$. If $\{f_k\}$ is a bounded sequence with $\lim_{k\to\infty} f_k = 0$ and*

$$\sum_{k=0}^{\infty} (k+1)^{\delta+\alpha-\gamma} |\Delta^{\delta+1} f_k| \le K_{\{f_k\}},$$

then there exists a function $f \in L^1_{w(\gamma)}$ with $\hat{f}_\alpha(k) = f_k$ for all $k \in \mathbf{N}_0$ and

$$\|f\|_{L^1_{w(\gamma)}} \le C\, K_{\{f_k\}}$$

for some constant C independent of the sequence $\{f_k\}$.

The proof follows along the lines of [3, Lemma 2.2] since the norm of the Cesàro kernel

$$\chi_n^{\alpha,\delta}(x) = (A_n^\delta \Gamma(\alpha+1))^{-1} \sum_{k=0}^{n} A_{n-k}^\delta L_k^\alpha(x) = (A_n^\delta \Gamma(\alpha+1))^{-1} L_n^{\alpha+\delta+1}(x)$$

can be estimated with the aid of [5, Lemma 1] by

$$\left\| \chi_k^{\alpha,\delta} \right\|_{L^1_{w(\gamma)}} \le C(k+1)^{\alpha-\gamma}, \qquad \delta > 2\gamma - \alpha + \tfrac{1}{2}.$$

The variant of Theorem 1.1 in the case $p = 1$ is the following theorem.

THEOREM 3.2. *If $\alpha > -1$ and $\gamma > \max\{-\frac{1}{3}, \alpha/2 - \frac{1}{6}\}$, then*

$$\sum_{k=0}^{\infty} (k+1)^{\gamma-2/3} |\Delta^{2\gamma-\alpha+1/3} \hat{f}_\alpha(k)| \le C \|f\|_{L^1_{w(\gamma)}}.$$

A comparison of the sufficient condition and the necessary one nicely shows where the $L^1_{w(\gamma)}$-functions live; in particular, we see that the smoothness gap (the difference of the orders of the difference operators) is just greater than $\frac{7}{6}$. It is clear that Theorem 3.2 can be modified by using the Δ_2 operator. Theorem 3.2 does not follow

from the $p = 1$ case of [3, Lemma 2.1] since that estimate would lead to the divergent sum $\sum_{k=0}^{\infty}(k+1)^{-1}\|f\|_{L^1_{w(\gamma)}}$.

Proof. By formula (5) we have

$$\Delta^{2\gamma-\alpha+1/3}\hat{f}_\alpha(k) = C\int_0^\infty f(t)R_k^{2\gamma+1/3}(t)t^{2\gamma+1/3}e^{-t}\,dt$$
$$= C(k+1)^{-\gamma-1/6}\int_0^\infty f(t)\mathcal{L}_k^{2\gamma+1/3}(t)t^{\gamma+1/6}e^{-t/2}\,dt,$$

and hence

$$\sum_{k=0}^{\infty}(k+1)^{\gamma-2/3}|\Delta^{2\gamma-\alpha+1/3}\hat{f}_\alpha(k)|$$
$$\le C\int_0^\infty |f(t)|\sum_{k=0}^{\infty}(k+1)^{-5/6}|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)|t^\gamma e^{-t/2}\,dt$$

if the right-hand side converges. To show this we discuss for $j \in \mathbf{Z}$

$$\sup_{2^j\le t\le 2^{j+1}}\sum_{k=0}^{\infty}(k+1)^{-5/6}|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)|$$

and prove that this quantity is uniformly bounded in j, whence the assertion.

First consider those $j \ge 0$ for which there exists a nonnegative integer n such that $0 \le k \le 2^n$ implies $3\nu/2 := 3(2k + 2\gamma + 4/3) \le 2^j$ but such that this inequality fails to hold for $k \ge 2^{n+1}$; the latter assumption, in particular, implies that essentially $\nu/2 \ge 2^{j+1}$ for $k \ge 2^{n+4}$. Since $\|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)\|_\infty \le C(k+1)^{-1/6}$ by [5, Lemma 1], we obviously have

$$\sum_{k=0}^{\infty}(k+1)^{-5/6}|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)| \le \left(\sum_{k=0}^{2^n}+\sum_{k=2^{n+4}}^{\infty}\right)+O(1). \tag{9}$$

For $k = 0,\dots,2^n$ we can apply [5, form. (2.5), case 4] to obtain $|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)| \le Ce^{-\mu 2^j}$ for some positive constant μ, and the first sum on the right-hand side of (9) is bounded uniformly in j. In consequence of the choice of n, [5, form. (2.5), case 2] can be used for $k \ge 2^{n+4}$, giving

$$\sum_{k=2^{n+4}}^{\infty}(k+1)^{-5/6}|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)| \le Ct^{-1/12}\sum_{k=2^{n+4}}^{\infty}(k+1)^{-13/12} = O(1)$$

since $2^j \le t \le 2^{j+1}$ and j and n are comparable.

Now consider the remaining j's: We have to split up the sum $\sum_{k=0}^{\infty}\cdots$ into two parts, one where k is such that $2^j\nu \ge 1$ (this contribution has just been seen to be uniformly bounded in j) and the other where k is such that $2^j\nu \le 1$. To deal with the last case again choose n to be the greatest integer such that $2^{n+2} + 4\gamma + 8/3 \le 2^{-j}$; this time, n and $-j$ are comparable and we obtain by [5, form. (2.5), case 1]

$$\sum_{k=0}^{2^n}(k+1)^{-5/6}|t^{1/6}\mathcal{L}_k^{2\gamma+1/3}(t)| \le Ct^{\gamma+1/3}\sum_{k=0}^{2^n}(k+1)^{\gamma-2/3} = O(1)$$

if $2^j \le t \le 2^{j+1}$, $\gamma > -\frac{1}{3}$, which completes the proof. □

SCATTERING THEORY, ORTHOGONAL POLYNOMIALS, AND q-SERIES*

JEFFREY S. GERONIMO†

Abstract. The techniques of scattering theory and Banach algebras are used to study orthogonal polynomials. The coefficients in the three-term recurrence formula are assumed to converge geometrically to their asymptotic limits. The results are used to investigate certain properties of the Askey–Wilson polynomials.

Key words. orthogonal polynomials, scattering theory, Askey–Wilson polynomials, Banach algebras, q-series

AMS subject classification. 42C05

1. Introduction.

Beginning with the three-term recurrence formula

$$\begin{aligned} &a(n+1)p(\lambda,n+1)+b(n)p(\lambda,n)+a(n)p(\lambda,n-1)=\lambda p(\lambda,n),\\ &p(\lambda,0)=1, \qquad p(\lambda,-1)=0, \qquad n=0,1,2,\dots, \end{aligned} \tag{1.1}$$

with $a(n)>0$ and $b(n-1)$ real for $n=1,2,\dots$, one can construct a sequence of polynomials which are, according to a famous result of Favard [7], orthogonal with respect to some (not necessarily unique) probability measure. In [8], [10], and [11] equation (1.1) was studied in the case when $a(n)\to a(\infty)>0$, $b(n)\to b(\infty)$, and

$$\sum_{n=1}^{\infty} n\nu(2n)\left\{\left|1-\frac{a(n)^2}{a(\infty)^2}\right|+|B(n-1)|\right\}<\infty, \tag{1.2}$$

where

$$B(n)=\frac{b(n)-b(\infty)}{a(\infty)} \tag{1.3}$$

and $\nu(n)$ has the following properties:

$$\begin{aligned} &\nu(n)=\nu(-n),\\ &\nu(n)\le\nu(n+1), \qquad n\ge 0,\\ &\nu(n)\le\nu(m)\nu(n-m), \qquad n,m\ge 0,\\ &\nu(0)=1, \qquad \nu(n)\ge 1, \end{aligned} \tag{1.4}$$

and

$$\limsup_{n\to\infty}(\nu(n))^{1/n}=R,$$

with $R=1$. In this case of course the measure $\rho(\lambda)$ is unique and $\{a(n)\}$ and $\{b(n)\}$ are related to $\rho(\lambda)$ by the standard formulas

$$\begin{aligned} a(n)&=\int \lambda p(\lambda,n)p(\lambda,n-1)d\rho(\lambda), && n=1,2,\dots,\\ b(n)&=\int \lambda p(\lambda,n)^2 d\rho(\lambda), && n=0,1,2,\dots, \end{aligned}$$

where the integral is taken over the support of $\rho(\lambda)$.

In Geronimo and Nevai [11] (see also Guseinov [13]) necessary and sufficient conditions were found relating (1.2) to the measure for $R = 1$. Here the case $R \geq 1$ will be investigated. It will be shown that the decay of the coefficients manifests itself in the decay of the Fourier coefficients of the absolutely continuous part (after suitable modifications) of the measure. Another consequence of (1.2) with $R > 1$ is that under certain circumstances one can specify the measure just in terms of the absolutely continuous part and the location of the mass points (see Theorem 4). Note that (1.2) takes into account the exponential decay of the coefficients to their asymptotic values. Thus many of the results obtained here are directly applicable to the q-analogs of some classical orthogonal polynomials, (see [1], [2], and [14]).

We proceed as follows: In §2 the notation is established and some of the analytic consequences of (1.2) are discussed; the techniques of scattering theory and Banach algebras are introduced also. In §3 the addition or removal of mass points is discussed. Also investigated is the addition or removal of polynomial factors (see also [17]) from the measure. Returning in §4 to the absolutely continuous part, the connection between the decay of the coefficients in the recurrence formula and decay of the Fourier coefficients of the absolutely continuous part of the measure is investigated. Finally, in §5 we consider certain examples (the Askey–Wilson polynomials) and obtain some general results on polynomials of this type.

2. Analytic properties. Without loss of generality let

$$a(n) \to \tfrac{1}{2} \quad \text{and} \quad b(n) \to 0. \tag{2.1}$$

Then (1.1) can be written as

$$\Phi(z,n) = C(n)\Phi(z,n-1), \tag{2.2}$$

where

$$\Phi(z,n) = \begin{pmatrix} p(\lambda,n) \\ \psi(z,n) \end{pmatrix},$$

$$C(n) = \frac{1}{2a(n)} \begin{bmatrix} z - 2b(n-1) & 1/z \\ (1-4a(n)^2)z - 2b(n-1) & 1/z \end{bmatrix}, \tag{2.3}$$

$$\lambda = \frac{(z+1/z)}{2},$$

and

$$\Phi(z,0) = \begin{pmatrix} 1 \\ 1 \end{pmatrix}. \tag{2.4}$$

Here we choose the branch

$$z = \lambda - \sqrt{\lambda^2 - 1}. \tag{2.5}$$

To proceed further, it is convenient to introduce the techniques of Banach algebras. Let $\nu(n)$ be given as in (1.4) with $R > 1$. Let A_ν denote the class of functions

$$g(z) = \sum_{n=-\infty}^{\infty} g(n)z^n, \qquad \frac{1}{R} \leq |z| \leq R,$$

with

$$\|g\|_\nu = \sum_{n=-\infty}^{\infty} \nu(n)|g(n)|,$$

and A_ν^+ and A_ν^- denote those functions in A_ν of the form

$$g(z) = \sum_{n=0}^{\infty} g(n)z^n$$

and

$$h(z) = \sum_{n=-\infty}^{0} h(n)z^n,$$

respectively.

If $\|\cdot\|_\nu$ is the norm on A_ν, A_ν^+, and A_ν^-, then A_ν, A_ν^+, and A_ν^- are Banach algebras. We also set $A_\nu = A$, $A_\nu^+ = A^+$, and $A_\nu^- = A^-$ in the case when $v(n) = 1$ for all n.

Note that if (2.1) holds, then (1.2) becomes

$$\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4a(n)^2| + |2b(n-1)|\} < \infty. \tag{2.6}$$

We begin with the following.

LEMMA 1 (Krein [16]). *Suppose $g(z) \in A_\nu^+$ and $g(z_0) = 0$ for $|z_0| < R$. Then $(g(z)/z - z_0) \in A_\nu^+$.*

Proof. Let $g(z) = \sum_{n=0}^{\infty} g_n z^n$ and define $g_n' = g_n R^n$, $z = Rz'$, and $\nu(n) = R^n\nu'(n)$. Then $g(z) = \sum_{n=0}^{\infty} g_n'(z')^n = \sum_{n=0}^{\infty} g_n'(z_0')^n\left(\frac{z'}{z_0'}\right)^n$. Summation by parts gives

$$g(z) = \sum_{n=1}^{\infty}\sum_{m=n}^{\infty} g_m'(z_0')^m\left(\frac{z'}{z_0'}\right)^{n-1}\left(\frac{z'}{z_0'} - 1\right),$$

where the fact that $g(z_0) = \sum_{n=0}^{\infty} g_n'(z_0')^n = 0$ has been used. The above equation shows that

$$\frac{g(z)}{\left(\frac{z}{z_0} - 1\right)} = \sum_{n=1}^{\infty}\left(\frac{z'}{z_0'}\right)^{n-1}\sum_{m=n}^{\infty} g_m'(z_0')^m.$$

Consequently,

$$\begin{aligned}\left\|\frac{g(z)}{\frac{z}{z_0} - 1}\right\|_\nu &\le \sum_{n=1}^{\infty}\frac{\nu'(n-1)}{|z_0'^{n-1}|}\sum_{m=n}^{\infty}|g_m'||z_0'|^m,\\ &\le \sum_{m=1}^{\infty}\nu'(m)|g_m'||z_0'|^m\sum_{n=0}^{m-1}|1/z_0|^n,\\ &\le \frac{|z_0'|}{1 - |z_0'|}\sum_{m=1}^{\infty}\nu(m)|g_m|,\end{aligned}$$

since $|z_0'| < 1$. □

THEOREM 1. *If (2.6) holds then there exists a function $f_+(z)$ such that*

(i) $\lim_{n\to\infty}\|z^n\psi(z,n) - 2zf_+(z)\|_\nu = 0$;

(ii) *Furthermore, the zeros of $f_+(z)$ for $|z| < 1$ are real, simple, finite in number, and the points where the orthogonal polynomials are square summable;*

(iii) *If $f_+(z)$ has zeros on the unit circle they must be at $z = \pm 1$, and they must be simple.*

(iv) $(zf_+(z)/d(z)) \in A_\nu^+$, *where*

$$d(z) = \begin{cases} 1 - z & \text{if } f(1) = 0, \\ 1 + z & \text{if } f(-1) = 0, \\ 1 - z^2 & \text{if } f(1) = f(-1) = 0; \end{cases}$$

(v) $(1 - z^2)(dzf_+(z)/dz) \in A_\nu^+$; *finally, if*

$$\sum_{n=1}^{\infty} n^2\{|1 - 4a(n)^2| + 2|b(n-1)|\} < \infty, \tag{2.7}$$

then

(vi) $(dzf(z)/dz) \in A^+$.

Proof. Parts (ii) and (iii) are proved in Geronimo and Case [10] (see also Chihara and Nevai [6], and Geronimo [9]). For $R > 1$ (iv) follows from Lemma 1 while for $R = 1$ see [10]. Part (v) follows as in Geronimo [8, Thm. 2.3]. To prove (i) first define $\psi^*(z,n) = z^n\psi(z,n)$ and $\alpha(n) = \prod_{i=1}^n (1/2a(i))$, $\alpha(0) = 1$. Multiplying the lower component of (2.2) by z^n, then iterating down yields

$$\frac{\psi^*(z,n)}{\alpha(n)} = 1 + \sum_{i=0}^{n-1} \{(1 - 4a(i+1)^2)z^2 - 2b(i)z\} \frac{z^i p(\lambda,i)}{\alpha(i)}. \tag{2.8}$$

After suitable manipulation of (2.2) (see [10, eq. (B.4)] or [17, Thm. 3]) the following formula can be obtained for $p(\lambda,n)$:

$$\begin{aligned} \frac{z^n p(\lambda,n)}{\alpha(n)} = \frac{1 - z^{2n+2}}{1 - z^2} + \sum_{i=0}^{n-1} \Bigg\{ & (1 - 4a(i+1)^2)z^2 \left(\frac{1 - z^{2n-2i-2}}{1 - z^2}\right) \\ & - 2b(i)z \left(\frac{1 - z^{2n-2i}}{1 - z^2}\right) \Bigg\} z^i \frac{p(\lambda,i)}{\alpha(i)}. \end{aligned} \tag{2.9}$$

To get a bound on $z^n(p(\lambda,n)/\alpha(n))$ note that the above equation yields

$$\begin{aligned} \left\| \frac{z^n p(\lambda,n)}{\alpha(n)} \right\|_\nu \le{}& (n+1)\nu(2n+2) \\ & + \sum_{i=0}^{n-1} \{|1 - 4a(i+1)^2| + 2|b(i)|\} (n-i)\nu(2n-2i) \left\| \frac{z^1 p(\lambda,i)}{\alpha(i)} \right\|. \end{aligned}$$

Since $(n-i)\nu(2n-2i) < (n+1)\nu(2n+2)$ for $i = 0, 1, \ldots, n-1$ we find

$$\|p^*(\lambda,n)\|_\nu \le 1 + \sum_{i=0}^{n-1} \{|1 - 4a(i+1)^2| + 2|b(i)|\}(i+1)\nu(2i+2)\|p^*(\lambda,i)\|_\nu,$$

where $p^*(\lambda,n) = z^n p(\lambda,n)/(n+1)\nu(2n+2)\alpha(n)$. The discrete Gronwall inequality (see Van Assche [21]) now yields

$$\left\|\frac{z^n p(\lambda,n)}{\alpha(n)}\right\|_\nu \le (n+1)\nu(2n+2) \times \exp\sum_{i=1}^{n} i\nu(2i)\left\{|1-4a(i)^2| + |2b(i-1)|\right\}. \tag{2.10}$$

Consequently,

$$\left\|\frac{\psi^*(z,n)}{\alpha(n)}\right\|_\nu \le 1 + \sum_{i=1}^{n} i\nu(2i)\left\{|1-4a(i)^2| + |2b(i-1)|\right\} \times \exp\sum_{j=1}^{n-1} j\nu(2j)\left\{|1-4a(j)^2| + |2b(j-1)|\right\}. \tag{2.11}$$

Furthermore, from (2.8) we find

$$\left\|\frac{\psi^*(z,n)}{\alpha(n)} - \frac{\psi^*(z,m)}{\alpha(m)}\right\|_\nu \le \sum_{i=m}^{n-1} i\nu(2i)\left\{|1-4a(i)^2| + |2b(i-1)|\right\} \times \exp\sum_{j=1}^{i-1} j\nu(2j)\left\{|1-4a(j)^2 + |2b(j-1)|\right\},$$

proving (i). Since $\psi(z,n) \in A_\nu^+$ for all n, $zf(z) \in A_\nu^+$. To prove (vi), differentiate (2.8) and (2.9), then use (2.10) with $v(n) = 1$, for all n, the equation $\|(d/dz)((1-z^{2(n+1)})/(1-z^2))\| = n(n+1)$, and Gronwall's inequality to obtain

$$\left\|\frac{z^n p(\lambda,n)'}{\alpha(n)}\right\| \le (n+1)^2 C \exp C\sum_{i=1}^{n} i^2\left\{|1-4a(i)^2| + 2|b(i-1)|\right\},$$

where C is independent of z and n. This implies

$$\left\|\frac{\psi^*(z,n)'}{\alpha(n)} - \frac{\psi^*(z,m)'}{\alpha(m)}\right\| \le C_1\sum_{i=m}^{n-1} i^2\{|1-4a(i)^2| + 2|b(i-1)|\}, \qquad |z| \le 1;$$

hence $(zf_+(z))' \in A_v^+$ which yields the result. □

This leads to the following.

COROLLARY 1. *If* (2.6) *holds, then* $zf_+(z)$ *is analytic for* $|z| < R \ge 1$ (*see* (1.4)) *and continuous for* $|z| \le R$. *It also follows from* (2.8) *and* (2.9) *that for* $|z| < 1$,

$$z^n p(\lambda,n) - \frac{\psi^*(z,n)}{1-z^2} = o(1). \tag{2.12}$$

So far a consequence of the results above is the extension of the region of analyticity of $zf_+(z)$ to the open disk of radius R. As a function of λ this means f_+ can be continued onto the second Riemann sheet, $(z = \lambda + \sqrt{\lambda^2-1})$. In analogy with scattering theory we shall call the principal sheet $(z = \lambda - \sqrt{\lambda^2-1})$ the physical sheet.

It is possible to include polynomials of the second kind in this scheme by defining

$$\Phi^1(z,n) = \begin{pmatrix} p^1(\lambda,n) \\ \psi^1(z,n) \end{pmatrix}, \qquad n \geq 1, \tag{2.13}$$

satisfying (2.2) with boundary conditions

$$p^1(\lambda,1) = \psi^1(z,1) = 1/a(1).$$

From (2.2) and (2.13) the following equations for $\psi^1(z,n)$ and $p^1(\lambda,n)$ can be derived:

$$\frac{\psi^{*1}(z,n)}{\alpha(n)} = 2z + \sum_{i=1}^{n-1} \{(1-4a(i+1)^2)z^2 - 2b(i)z\} \frac{z^i p^1(\lambda,i)}{\alpha(i)},$$

and

$$\frac{z^n p^1(\lambda,n)}{\alpha(n)} = 2z\left(\frac{1-z^{2n}}{1-z^2}\right) + \sum_{i=1}^{n-1}\left\{(1-4a(i+1)^2)z^2\left(\frac{1-z^{2n-2i-2}}{1-z^2}\right) - 2b(i)z\left(\frac{1-z^{2n-2i}}{1-z^2}\right)\right\}\frac{z^i p^1(\lambda,i)}{\alpha(i)}.$$

Let

$$zf_+^1(z) = \tfrac{1}{2}\lim_{n\to\infty} z^{n-1}\psi^1(z,n). \tag{2.14}$$

Then the above methods show that

$$zf_+^1(z) \in A_\nu. \tag{2.15}$$

Two other useful solutions (see [10]) of (2.2) are

$$\Phi_+(z,n) = \begin{pmatrix} p_+(z,n) \\ \psi_+(z,n) \end{pmatrix} \tag{2.16}$$

and

$$\Phi_-(z,n) = \begin{pmatrix} p_-(z,n) \\ \psi_-(z,n) \end{pmatrix}, \tag{2.17}$$

satisfying the following boundary conditions

$$\lim_{n\to\infty} |z^{-n}p_+(z,n) - 1| = 0, \qquad |z| \leq 1, \tag{2.18a}$$

$$\lim_{n\to\infty} |z^{-n}\psi_+(z,n)| = 0, \qquad |z| \leq 1, \tag{2.18b}$$

and

$$\lim_{n\to\infty} |z^{n}p_-(z,n) - 1| = 0, \qquad |z| \geq 1, \tag{2.19a}$$

$$\lim_{n\to\infty} |z^n\psi_-(z,n) - (1-z^2)| = 0, \qquad |z| \geq 1. \tag{2.19b}$$

THEOREM 2. *If* (2.6) *holds, then* $z^{-n}p_+(z,n)$ *and* $z^{-n}\psi_+(z,n)$ *are elements of* A_ν^+, *which implies that* $\Phi_+(z,n)$ *is analytic for* $|z| < R$. *Likewise* $z^n p_-(z,n)$ *and* $z^n\psi_-(z,n)$ *are elements of* A_ν^-. *Furthermore,* $\Phi_+(z,n)$ *and* $\Phi_-(z,n)$ *are linearly independent for* $1/R \leq |z| \leq R$ *except at* $z = \pm 1$ *and* $p_+(1/z,n) = p_-(z,n)$. *If* (2.7) *holds, then* $p'_+(z,n)$ *is continuous for* $|z| \leq 1$.

Proof. Inverting $C(n)$ we find from (2.2) that

$$p_+(z,n) = \frac{1}{2a(n+1)z}(p_+(z,n+1) - \psi_+(z,n+1)). \tag{2.20}$$

Iterating this equation plus the lower component of (2.2) upwards and using the boundary conditions (2.18) yield a discrete integral equation for $p_+(z,n)$:

$$\begin{aligned}\frac{p_+(z,n)}{\gamma(n+1)} = z^n + \sum_{i=n+1}^{\infty}\sum_{m=i}^{\infty}\left\{\prod_{j=i+1}^{m}(2a(j))^2\right\} \\ \times\{(1-4a(m+1)^2)z - 2b(m)\}\, z^{m-2i+n+1}\frac{p_+(z,m)}{\gamma(m+1)},\end{aligned} \tag{2.21}$$

with $\gamma(n) = \prod_{i=n}^{\infty}(1/2a(i))$. The following bound on $p_+(z,n)$ can be obtained using the discrete Gronwall inequality,

$$\left\|\frac{z^{-n}p_+(z,n)}{\gamma(n+1)}\right\|_\nu \leq \exp\left[C\sum_{m=n+1}^{\infty} m\nu(2m)\left\{|1-4a(m+1)^2| + |2b(m)|\right\}\right], \tag{2.22}$$

with $C = \max_{i,j}\left\{\prod_{k=i+1}^{j}(2a(k))^2\right\}$. Furthermore, using the above equation in (2.21) yields

$$\left\|\frac{z^{-n}p_+(z,n)}{\gamma(n+1)} - 1\right\|_\nu \leq D\sum_{m=n+1}^{\infty} m\nu(2m)\left\{|1-4a(m+1)^2| + |2b(m)|\right\},$$

where D is a constant independent of z and n. Since $p_+(z,n)$ and $p_-(z,n)$ satisfy (1.1) with the boundary conditions (2.18a) and (2.19a), respectively, we see that $p_-(z,n) = p_+(1/z,n)$ for $1/R \leq |z| \leq |R|$, which implies that $z^n p_-(z,n) \in A_\nu^-$. Since the Wronskian of any two solutions Φ_1 and Φ_2, $W[\Phi_1(n),\Phi_2(n)] = \det|\Phi_1(n),\Phi_2(n)|$ is independent of n [10], we find that $W[\Phi_+(n),\Phi_-(n)] = 1 - z^2$, which implies that $\Phi_+(z,n)$ and $\Phi_-(z,n)$ are linearly independent except at $z = \pm 1$.

The properties of ψ_+ follow from (2.20) while those of ψ_- follow an analogous equation. If (2.7) holds, multiply (2.21) by z^{-n}, differentiate, then use (2.22) and Gronwall's inequality to obtain

$$\|(z^{-n}p_+(z,n))'\| \leq \hat{C}\exp C\sum_{m=n+1}^{\infty} m^2|1-4a(m+1)^2| + 2|b(m)|, \tag{2.23}$$

which says that $(z^{-n}p_+(z,n))' \in A$. □

Since Φ_+ and Φ_- are linearly independent except at $z = \pm 1$ we find, using the fact that the Wronskian is independent of n, and the boundary conditions (2.18) and (2.19), the useful equation

$$\Phi(z,n) = \frac{2}{z - 1/z}(f_+(1/z)\Phi_+(z,n) - f_+(z)\Phi_-(z,n)), \quad \frac{1}{R} \le |z| \le R. \tag{2.24}$$

Here we have used (2.18) and (i) of Theorem 1 to make the identification

$$f_+(z) = \frac{1}{2z} W[\Phi_+, \Phi]. \tag{2.25}$$

Now using (2.2) to eliminate ψ_+ and ψ in the above equation yields

$$\begin{aligned} f_+(z) &= a(n+1)[p(\lambda, n+1)p_+(z,n) - p_+(z,n+1)p(\lambda,n)] \\ &= a(0)p_+(z,-1), \qquad |z| \le R. \end{aligned} \tag{2.26}$$

Since Φ and Φ^1 are linearly independent except at $z = 0$, i.e., $W[\Phi, \Phi^1] = 2z$, we also find that

$$\Phi_+(z,n) = f_+^1(z)\Phi(z,n) - f_+(z)\Phi^1(z,n), \qquad |z| \le R, \quad n \ge 1. \tag{2.27}$$

Let

$$\frac{p_+(z,n)}{\gamma(n+1)} = z^n \left(1 + \sum_{i=1}^{\infty} \alpha(n,i) z^i\right). \tag{2.28}$$

Then (2.24) allows us to develop useful asymptotic formulas for $p(\lambda, n)$.

THEOREM 3. *If* (2.6) *holds, then*

$$\begin{aligned} \sin\theta p(\cos\theta, n) = 2|f_+(e^{i\theta})|\gamma(n+1)\{&\sin((n+1)\theta - \arg e^{i\theta} f_+(e^{i\theta})) \\ &+ \sum_{i=1}^{\ell} \alpha(n,i)\sin((n+i+1)\theta - \arg e^{i\theta} f_+(e^{i\theta}))\} \\ + O\left(\sum_{m=[\ell/2]}^{\infty} (2m - \ell + 1)\{|1 - 4a(m+n+1)^2| + 2|b(m+n)|\}\right), \\ &0 \le \theta \le \pi. \end{aligned} \tag{2.29}$$

This implies that the zeros of $p(\cos\theta, n)$ *in* $[-1,1]$ *are located at*

$$\theta = \frac{k\pi}{n+1} + \frac{\arg e^{i\theta} f_+(e^{i\theta})}{n+1} + o(1/n), \qquad k = 1, 2, \ldots, n.$$

If (2.7) *holds, then*

$$\begin{aligned} p(\cos\theta, n) = 2|f_+(e^{i\theta})|\gamma(n+1)\Big\{&\sin((n+1)\theta - \arg e^{i\theta} f_+(e^{i\theta})) \\ &+ \sum_{i=1}^{\ell} \alpha(n,i)\sin((n+i+1)\theta - \arg e^{i\theta} f_+(e^{i\theta}))\Big\}/\sin\theta \\ + O\left(\sum_{k=[\ell/2]}^{\infty} k^2\{|1 - 4a(k+n+1)^2| + 2|b(k+n)|\}\right), &\quad 0 \le \theta \le \pi. \end{aligned} \tag{2.30}$$

Furthermore, from (2.29) *the error term for the zeros of* $p(\cos\theta, n)$ *can be improved to* $O(1/n^2)$.

Proof. Everything in (2.29) but the error term follows from Theorems 1 and 2, (2.28), the upper component of (2.24) and the fact that $f_+(e^{-i\theta}) = \overline{f_+(e^{i\theta})}$. Substituting (2.28) into the left hand side of (2.21) yields

$$\sum_{k=1}^{\infty} \alpha(n,k) z^k = \sum_{i=0}^{\infty} z^{2i+1} \sum_{m=i}^{\infty} C(m+n+1, m-i+n+2) K(m+n+1) \left[1 + \sum_{j=1}^{\infty} \alpha(m+n+1, j) z^j \right],$$

where $C(m,i) = \prod_{j=i+1}^{m} (2a(j))^2$ and $K(m) = (1 - 4a(m+1)^2)z - 2b(m)$. Equating coefficients of z^k we find

$$|\alpha(n,k)| \le C \sum_{i=\left[\frac{k-1}{2}\right]}^{\infty} |K(n+i+1)| + C \sum_{i=n+1}^{\infty} \sum_{j=0}^{\left[\frac{k-2}{2}\right]} |K(i+j)||\alpha(i+j, k-1-2j)|,$$

with $C = \max_{m,i} C(m,i)$. Since $C \sum_{i=n}^{\infty} i|K(i)| < 1$ for all $n \ge n_0$ large enough we find by iterating the above equation that

$$|\alpha(n,k)| \le \frac{C \sum_{i=\left[\frac{k-1}{2}\right]}^{\infty} |K(i+n+1)|}{1 - C \sum_{i=1}^{\infty} i|K(i+n)|}$$

for $n \ge n_0$ large enough. It now follows by induction on n that

$$|\alpha(n,k)| \le O\left(\sum_{m=[(k-1)/2]}^{\infty} |1 - 4a(m+n+2)|^2 + 2|b(m+n+1)| \right). \tag{2.31}$$

Summing the above equation from $k = \ell + 1$ to infinity and using the fact that $p_-(e^{i\theta}, n) = \overline{p_+(e^{i\theta}, n)}$ yields the error term in (2.29). The representation for the zeros of $p(\cos\theta, n)$ now follows from (2.29).

To show (2.30) note that since $p_-(e^{i\theta}, n) = p_+(e^{-i\theta}, n)$, $\frac{p_-(e^{i\theta},n) - p_+(e^{i\theta},n)}{\sin\theta}$ exists for $\theta = 0$ and π by Theorem 1 (vi) and Theorem 2. The same is true for $\frac{f_+(e^{-i\theta}) - f_+(e^{i\theta})}{\sin\theta}$. Thus the error term in (2.30) follows from Theorem 1 (vi), the fact that

$$\left\| \frac{z^{-n} p_+(z,n) - z^n p_-(z,n)}{z - 1/z} \right\| \le \sum_{i=1}^{\infty} |\alpha(n,i)| \left\| \frac{z^i - z^{-i}}{z - 1/z} \right\| \le \sum_{i=1}^{\infty} i|\alpha(n,i)|,$$

and (2.31). □

Estimates for the zeros of $p(\lambda, n)$ for λ near one may be obtained by letting $\theta \to \pi - \theta$.

Equation (2.27) can be used to obtain a useful integral representation for $p_+(z,n)$.

LEMMA 2. *Suppose $p_+(z,n)$ exists for $n = 0,1,2\ldots$, then for $|z| < 1$,*

$$p_+(z,n) = f_+(z)\int \frac{p(\lambda',n)}{\lambda-\lambda'}d\rho(\lambda'), \qquad \lambda = \frac{z+1/z}{2}, \quad n = 0,1,2,\ldots. \tag{2.32}$$

Proof. (This is a modified version of an unpublished proof of Nevai.) Since $p^1(\lambda,n)$ is a polynomial of the second kind,

$$p^1(\lambda,n) = \int \frac{(p(\lambda,n)-p(\lambda',n))}{\lambda-\lambda'}d\rho(\lambda'), \qquad n \geq 1,$$

and from the upper component of (2.27) we find for λ not in the convex hull of the support of $\rho(\lambda)$,

$$\frac{p_+(z,n)}{p(\lambda,n)} = f_+^1(z) - f_+(z)\int \frac{1}{\lambda-\lambda'}d\rho(\lambda') + \frac{f_+(z)}{p(\lambda,n)}\int \frac{p(\lambda',n)}{\lambda-\lambda'}d\rho(\lambda'). \tag{2.33}$$

Since $|z| < 1$ and z is not in the convex hull of the support of $\rho(\lambda)$, $\lim_{n\to\infty}|p(\lambda,n)| = \infty$ and $\lim_{n\to\infty} p_+(z,n) = 0$. These equations, plus the fact that the integral in the last term on the right-hand side of the above equation is uniformly bounded on compact subsets of the unit disk that do not include the support of $\rho(\lambda)$, show that

$$f_+^1(z) = f_+(z)\int \frac{d\rho(\lambda')}{\lambda-\lambda'}, \qquad \lambda = \frac{(z+1/z)}{2}, \qquad |z| < 1, z \notin \text{convex hull supp } \rho.$$

Extending this equation by analytic continuation to $|z| < 1$, using Theorem 4 below, then substituting this result into (2.27) gives the lemma. □

3. The distribution function.

THEOREM 4. *If* (2.6) *holds, then*

$$\int_{-\infty}^{\infty} p(\lambda,n)p(\lambda,m)d\rho(\lambda) = \delta_{n,m}, \tag{3.1}$$

where

$$d\rho(\lambda) = \begin{cases} \sigma(\theta)d\lambda, & \lambda = \cos\theta, \quad 0 \leq \theta \leq \pi, \\ \sum_{i=1}^{N} \rho_i \delta(\lambda-\lambda_i)d\lambda, & \lambda \text{ not as above}, \quad N < \infty, \end{cases}$$

with

$$\sigma(\theta)d\lambda = \frac{\sin\theta}{2\pi|f_+(z)|^2}d\lambda, \qquad \lambda = \cos\theta, \quad z = e^{i\theta}, \tag{3.2}$$

and

$$\rho_i = \frac{p_+(z_i,0)}{f_+'(\lambda_i)}, \qquad \lambda_i = \frac{(z_i+1/z_i)}{2}, \qquad |z_i| < \frac{1}{R}, \tag{3.3}$$

$$\rho_i = \frac{(z_i-1/z_i)}{2}\frac{1}{f_+(1/z_i)f_+'(\lambda_i)}, \qquad \frac{1}{R} \leq |z_i| < 1. \tag{3.4}$$

Here $\{\lambda_i\}$ denote the roots of $f_+(z)$ for $|z| < 1$, and the above differentiation is with respect to λ.

Proof. All but (3.4) has been proved in [10]. Furthermore, it was shown there that (3.3) holds for $|z_i| < 1$. To prove (3.4), note that if (2.6) holds, then (2.24) is valid for all z such that $1/R \le |z| \le R$. Therefore, let $f_+(z_i) = 0$, $1/R \le |z_i| < 1$. Then from (2.24),

$$p(\lambda_i, n) = \frac{2}{z_i - 1/z_i} f_+\left(\frac{1}{z_i}\right) p_+(z_i, n), \qquad n = 0, 1, \ldots,$$

and the result follows by eliminating $p_+(z_i, 0)$ in (3.3). □

If

$$f_+(z) \neq 0, \qquad |z| = R, \tag{3.5}$$

then inside the disk of radius R, $f_+(z)$ has only a finite number of zeros, each having a finite multiplicity. Let $z_0, z_1, z_2, \ldots, z_n$ be the zeros of $f_+(z)$ including multiplicities; then by Lemma 1,

$$\frac{z f_+(z)}{\kappa(z)} \in A_\nu^+, \tag{3.6}$$

where

$$\kappa(z) = \prod_{i=0}^{n} (z - z_i).$$

This leads to the following.

COROLLARY 2. *If* (2.6) *and* (3.5) *hold, then*

$$\ln \frac{\sigma(z)\kappa(z)\kappa(1/z)}{z - 1/z} \in A_\nu.$$

Proof. From (3.2),

$$\sigma(z) = \frac{1}{4\pi i} \frac{z - 1/z}{f_+(z) f_+(1/z)}, \qquad z = e^{i\theta}. \tag{3.7}$$

It follows from (3.6) that $f_+(1/z)/z\kappa(1/z) \in A_\nu^-$. Furthermore, $f_+(1/z)/z\kappa(1/z)$ and $z f_+(z)/\kappa(z)$ are nonzero for $1/R \le |z| \le R$. Thus the result follows from the Wiener–Levy theorem. □

The above result shows that $\sigma(z)$ is a meromorphic function for $1/R < |z| < R$. If $\sigma(z)$ has a pole at $|z_0| < 1$, (3.7) forces $\sigma(z)$ to have a pole at $1/z_0$ and these are the only places $\sigma(z)$ may have poles. Consequently, we need only study the poles of $\sigma(z)$ for $|z| \le 1$, or in terms λ, we can stay on the physical sheet. As seen from (3.7) the poles of $\sigma(z)/(z - 1/z)$ come from the zeros of $f_+(z)$ and $f_-(z)$, and (2.4) prevents $f_+(z)$ and $f_-(z)$ from vanishing at the same value of z for $1/R \le |z| \le R$, $z \neq \pm 1$, since the zeros of $p(\lambda, n)$ alternate with those of $p(\lambda, n+1)$.

The following gives a useful representation of $f_+(z)$ in terms of $\sigma(\theta)$.

COROLLARY 3 (Geronimo and Case [10]). *If* (2.6) *holds with* $\nu(n) = 1$ *for all* n, *then*

$$f_+(z) = \frac{1}{z} \prod_{i=1}^{N} \frac{|z_i|}{z_i} \frac{(z_i - z)}{1 - z_i z} \exp \frac{-1}{4\pi} \int_{-\pi}^{\pi} \left(\frac{e^{i\theta'} + z}{e^{i\theta'} - z}\right) \ln\left(\frac{\sigma(\theta') 2\pi}{\sin\theta'}\right) d\theta', \qquad |z| < 1.$$

What we would like to consider now is the effect of adding or removing the poles (zeros) of $\sigma(z)$ ($f_+(z)$). To this end Geronimo and Nevai [11] have proven the following.

THEOREM 5. *Let $d\rho(\lambda)$ be given as*

$$d\rho(\lambda) = \begin{cases} \sigma(\theta)d\lambda, & \lambda = \cos\theta, \\ \sum_{m=1}^{N} \rho_m \delta(\lambda - \lambda_m)d\lambda, & \lambda \text{ not as above}, \end{cases} \quad N \geq 1,\ |\lambda_i| \geq |\lambda_{i-1}|,$$

and let

$$d\rho^*(\lambda) = \begin{cases} \sigma(\theta)d\lambda, \\ \sum_{m=1}^{N-1} \rho_m \delta(\lambda - \lambda_m)d\lambda. \end{cases}$$

Furthermore let $\{a(n)\}$, $\{b(n)\}$, $\{a^*(n)\}$, and $\{b^*(n)\}$ be the coefficients associated with $d\rho(\lambda)$ and $d\rho^*(\lambda)$, respectively. If $\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4a(n)^2| + |b(n-1)|\} < \infty$, then $\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4a^*(n)^2| + |b^*(n-1)|\} < \infty$.

THEOREM 6. *Let $d\rho(\lambda)$, $\{a(n)\}$, and $\{b(n)\}$ be given as in Theorem 5. Let*

$$d\hat{\rho}(\lambda) = \begin{cases} \sigma(\theta)d\lambda, \\ \sum_{m=1}^{N+1} \rho_m \delta(\lambda - \lambda_m)d\lambda, \end{cases}$$

where $\lambda_{N+1} = (z_{N+1} + 1/z_{N+1})/2$, $|z_{N+1}| < 1/R, |\lambda_{N+1}| \geq |\lambda_N|$. Furthermore, let $\{\hat{a}(n)\}$ and $\{\hat{b}(n)\}$ be the coefficients associated with $d\hat{\rho}(\lambda)$. If

$$\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4a(n)^2| + |b(n-1)|\} < \infty,$$

then $\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4\hat{a}(n)^2| + |\hat{b}(n-1)|\} < \infty$.

Thus from Theorem 5 it is clear that one can remove all the mass points and the rate of convergence of the coefficients associated with the new measure will be at least as fast as the rate of convergence of the coefficients associated with the original measure. Theorem 6 shows that if $|z_{N+1}| < 1/R$, that is, if z_{N+1} is not in the maximal ideal space of A_ν, then one can add a finite number of mass points, the only restrictions being that each one must be positive and of finite magnitude, and the rate of convergence of the new coefficients will be at least as fast as the rate of convergence of the original coefficients. It should be noted that the mass points are added or removed without altering the absolutely continuous part of the distribution function.

LEMMA 3. *If (2.6) holds, then*

$$\sum_{i=1}^{\infty} |z^{-i}\psi_+(z,i)| < \infty, \qquad |z| \leq R, \tag{3.8}$$

$$\sum_{i=1}^{\infty} i\nu(2i)|z^{-2i}(p_+(z,i)^2 - p_+(z,i+1)p_+(z,i-1))| < \infty, \qquad |z| \leq R, \tag{3.9}$$

and

$$\sum_{i=1}^{\infty} i\nu(2i)|z^{-2i}(\lambda p_+(z,i)p_+(z,i+1) - a(i+1)p_+(z,i)^2 - a(i+1)p_+(z,i+1)^2)| < \infty, \qquad |z| \leq R. \tag{3.10}$$

Proof. From (2.2) and the boundary conditions satisfied by $\psi_+(z,n)$ we find

$$\frac{z^{-n}\psi_+(z,n)}{\gamma(n+1)}$$
$$= -\sum_{j=n}^{\infty}\left\{\prod_{k=n+1}^{j}(2a(k))^2\right\}\{(1-4a(j+1)^2)z-2b(j)\}\,z^{2j-2n+1}\frac{z^{-j}p_+(z,j)}{\gamma(j+1)}.$$

To obtain (3.8), multiply the above equation by z^{-n}, take magnitudes, then sum on n and use the fact that $\{\prod_{k=n+1}^{j}(2a(k))^2\}|\frac{z^{-j}p_+(z,j)|}{\gamma(j)}| < c$ (see (2.22)).

To show (3.9) and (3.10) set $\hat{w}(n) = p_+(z,n+1) - zp_+(z,n)$ and $w(n) = p_+(z, n+1) - (1/z)p_+(z,n)$. Then

$$p_+(z,n)^2 - p_+(z,n-1)p_+(z,n+1)$$
$$= \frac{-1}{2\lambda}\left[\left\{\hat{w}(n) - \frac{1}{z}\hat{w}(n-1)\right.\right.$$
$$\left.\left. + w(n) - zw(n-1)\right\}p_+(z,n) - w(n)\hat{w}(n-1) - w(n-1)\hat{w}(n)\right].$$

From (2.6) and (2.22) it is apparent that (3.10) will follow if it can be shown that

$$z^{-2n}\left[\lambda p_+(z,n)p_+(z,n+1) - \frac{p_+(z,n)^2}{2} - \frac{p_+(z,n+1)^2}{2}\right] = -z^{-2n}\frac{w(n)\hat{w}(n)}{2}$$

converges fast enough. Since

$$w(n)\hat{w}(n-1) + w(n-1)\hat{w}(n)$$
$$= w(n)\left[\hat{w}(n-1) - \frac{1}{z}\hat{w}(n)\right]$$
$$+ \hat{w}(n)\left[w(n-1) - zw(n)\right] + \left(z + \frac{1}{z}\right)w(n)\hat{w}(n),$$

the result will follow if it can be shown that

$$\sum_{i=1}^{\infty} i\nu(2i)\left|z^{-2i}\left(\hat{w}(i) - \frac{1}{z}\hat{w}(i-1)\right)p_+(z,i)\right| < \infty, \tag{3.11}$$

$$\sum_{i=1}^{\infty} i\nu(2i)|z^{-2i}(w(i) - zw(i-1))p_+(z,i)| < \infty, \tag{3.12}$$

and

$$\sum_{i=1}^{\infty} i\nu(2i)|z^{-2i}w(i)\hat{w}(i)| < \infty. \tag{3.13}$$

From the definition of w and $\hat{w}$ we find

$$\hat{w}(i) - \frac{1}{z}\hat{w}(i-1) = w(i) - zw(i-1)$$
$$= (1-2a(i+1))p_+(z,i+1) - 2b(i)p_+(z,i)$$
$$+ (1-2a(i))p_+(z,i-1).$$

Combining this with (2.22) gives (3.9) and (3.10). It is a consequence of (3.8) and (2.2) that

$$\sum_{i=1}^{\infty}|z^{-i}\hat{w}(i)| \le C\Big\{\sum_{i=1}^{\infty}|1-2a(i+1)||z^{-i+1}p_+(z,i)| + \sum_{i=1}^{\infty}|2b(i)||z^{-i}p_+(z,i)| + \sum_{i=1}^{\infty}|z^{-i-1}\psi_+(z,i)|\Big\} < \infty.$$

Therefore, with $w^*(n) = z^{-n}w(n)$ we find

$$\sum_{i=1}^{\infty} i\nu(2i)|z^{-i}\hat{w}(i)w^*(i)| \le \sum_{i=1}^{\infty}|z^{-i}\hat{w}(i)| \sum_{j=i+1}^{\infty} j\nu(2j)|w^*(j)-w^*(j-1)| \le \sum_{i=1}^{\infty}|z^{-i}\hat{w}(i)| \sum_{j=2}^{\infty} j\nu(2j)|w^*(j)-w^*(j-1)| < \infty;$$

the result follows from (3.12) and the fact that $\lim_{i\to\infty}(z^{-i}p_+(z,i))/\gamma(i+1) = 1$. □

Theorem 6 deals with mass points whose locations are in the region $0 < |z| < 1/R$. The next theorem demonstrates that if one wants to add mass points whose locations lie in $1/R \le |z| < 1$ and still have the coefficients converge at least as fast as the original coefficients, then the normalizations are strictly determined.

THEOREM 7. *Let*

$$d\rho(\lambda) = \begin{cases} \sigma(\theta)d\lambda, & \lambda = \cos\theta, \quad 0 \le \theta \le \pi, \\ \sum_{i=1}^{N-1}\rho_i\delta(\lambda-\lambda_i)d\lambda, & \lambda_i = \frac{(z_i+1/z_i)}{2}, \quad 1 > |z_i| > 1/R, \end{cases}$$

and

$$d\hat{\rho}(\lambda) = \frac{d\rho(\lambda)}{\lambda_N - \lambda} + \rho_N\delta(\lambda-\lambda_N)d\lambda, \qquad |\lambda_N| > |\lambda_i|, \lambda_N > 0, \quad \lambda_N = \frac{(z_N+1/z_N)}{2}, \quad 1 > z_N \ge 1/R.$$

Let $\{p(\lambda,n)\}$, $\{a(n)\}$, $\{b(n)\}$, $\{\hat{p}(\lambda,n)\}$, $\{\hat{a}(n)\}$, *and* $\{\hat{b}(n)\}$ *be the orthonormal polynomials and coefficients associated with* $d\rho(\lambda)$ *and* $d\hat{\rho}(\lambda)$, *respectively. If*

$$\sum_{n=1}^{\infty} n\nu(2n)\{|1-4a(n)^2| + |b(n-1)|\} < \infty$$

and

$$\rho_N = \frac{-(z_N - 1/z_N)}{2f_+(1/z_N)f_+(z_N)}, \tag{3.14}$$

then $\sum_{n=1}^{\infty} n\nu(2n)\{|1-4\hat{a}(n)^2| + |\hat{b}(n-1)|\} < \infty$.

Proof. Expanding $\hat{p}(\lambda,n)$ in terms of $p(\lambda,n)$ yields

$$\hat{p}(\lambda,n) = \frac{\hat{k}(n)}{k(n)}p(\lambda,n) - \frac{k(n-1)}{\hat{k}(n)}p(\lambda,n-1), \tag{3.15}$$

where $\hat{k}(n)$ and $k(n)$ are the leading coefficients of $\hat{p}(\lambda,n)$ and $p(\lambda,n)$, respectively. Multiplying by $d\hat{\rho}(\lambda)$ and integrating gives

$$\hat{k}(n)^2 = k(n)k(n-1)\frac{\int p(\lambda,n-1)d\hat{\rho}(\lambda)}{\int p(\lambda,n)d\hat{\rho}(\lambda)}, \qquad n>0.$$

Since $\lambda_N > |\lambda_i|$, $i=1,\dots,N-1$ the functions of the second kind associated with $\rho(\lambda)$ evaluated at λ_N are positive. This, plus the fact that $p(\lambda_N,n)>0$ for $n\geq 0$, implies that the above integrals do not vanish. Therefore

$$\hat{a}(n+1)^2 = a(n+1)a(n)\frac{\int p(\lambda,n-1)d\hat{\rho}(\lambda)\int p(\lambda,n+1)d\hat{\rho}(\lambda)}{\left(\int p(\lambda,n)d\hat{\rho}(\lambda)\right)^2}, \qquad n>0. \tag{3.16}$$

Squaring (3.15) then multiplying by $d\rho(\lambda)$ and integrating yields

$$\int \hat{p}(\lambda,n)^2(\lambda_N-\lambda)d\hat{\rho}(\lambda) = \frac{\hat{k}(n)^2}{k(n)^2}+\frac{k(n-1)^2}{\hat{k}(n)^2}.$$

Consequently,

$$\lambda_N - \hat{b}(n) = a(n)\left[\frac{\int p(\lambda,n-1)d\hat{\rho}(\lambda)}{\int p(\lambda,n)d\hat{\rho}(\lambda)}+\frac{\int p(\lambda,n)d\hat{\rho}(\lambda)}{\int p(\lambda,n-1)d\hat{\rho}(\lambda)}\right], \qquad n>0,$$

which gives

$$\begin{aligned}\hat{b}(n) = \Bigg[&\lambda_N\int p(\lambda,n)d\hat{\rho}(\lambda)\int p(\lambda,n-1)d\hat{\rho}(\lambda) - a(n)\left(\int p(\lambda,n-1)d\hat{\rho}(\lambda)\right)^2\\ &- a(n)\left(\int p(\lambda,n)d\hat{\rho}(\lambda)\right)^2\Bigg]\Big/\int p(\lambda,n-1)d\hat{\rho}(\lambda)\int p(\lambda,n)d\hat{\rho}(\lambda), \quad n>0.\end{aligned} \tag{3.17}$$

A consequence of (2.10), (2.22), and (2.32) is that $\int p(\lambda,i)d\hat{\rho}(\lambda) = O(z_N^{-i})$ for large enough i. Thus, from (3.16) and (3.17) the result follows if it can be shown that

$$\sum_{i=1}^{\infty} i\nu(2i)|z_N^{2i}|\left|\int p(\lambda,i)d\hat{\rho}(\lambda)^2 - \int p(\lambda,i-1)d\hat{\rho}(\lambda)\int p(\lambda,i+1)d\hat{\rho}(\lambda)\right| < \infty \tag{3.18}$$

and

$$\begin{aligned}\sum_{i=1}^{\infty} i\nu(2i)|z_N^{2i}|\Bigg|&\lambda_N\int p(\lambda,i)d\hat{\rho}(\lambda)\int p(\lambda,i-1)d\hat{\rho}(\lambda)\\ &- a(i)\left(\int p(\lambda,i-1)d\hat{\rho}(\lambda)\right)^2 - a(i)\left(\int p(\lambda,i)d\hat{\rho}(\lambda)\right)^2\Bigg| < \infty.\end{aligned} \tag{3.19}$$

Since $\int p(\lambda,n)d\hat{\rho}(\lambda) = (p_+(z_N,n)/f_+(z_N)) + \rho_N p(\lambda_N,i)$, the terms between the magnitude signs in (3.18) can be recast as

$$\begin{aligned}&= \left[\frac{p_+(z_N,i)}{f_+(z_N)}+\rho_N p(\lambda_N,i)\right]^2 z_N^{2i}\\ &\quad - \left[\frac{p_+(z_N,i+1)}{f_+(z_N)}+\rho_N p(\lambda_N,i+1)\right]\left[\frac{p_+(z_N,i-1)}{f_+(z_N)}+\rho_N p(\lambda_N,i-1)\right]z_N^{2i},\end{aligned}$$

which can be rewritten as

$$
\begin{aligned}
&= \frac{z_N^{2i}}{f_+(z_N)^2}\left[p_+(z_N,i)^2 - p_+(z_N,i+1)p_+(z_N,i-1)\right] \\
&\quad + \frac{\rho_N}{f_+(z_N)} z_N^{2i}\Big[2p_+(z_N,i)p(\lambda_N,i) - p_+(z_N,i-1)p(\lambda_N,i+1) \\
&\qquad\qquad - p_+(z_N,i+1)p(\lambda_N,i-1)\Big] \\
&\quad + z_N^{2i}\rho_N^2\left[p(\lambda_N,i)^2 - p(\lambda_N,i+1)p(\lambda_N,i-1)\right].
\end{aligned}
$$

From Lemma 3 it is apparent that one need only consider the last two terms in the above equation. Since $1 > |z_N| > 1/R$, equation (2.24) can be used, yielding

(3.20)

$$
\begin{aligned}
&= z_N^{2i}\left[\frac{4\rho_N f_+(1/z_N)}{f_+(z_N)(z_N - 1/z_N)} + \frac{4\rho_N^2 f_+(1/z_N)^2}{(z_N - 1/z_N)^2}\right] \\
&\quad \times \Big[p_+(z_N,i)^2 - p_+(z_N,i-1)p_+(z_N,i+1)\Big] \\
&\quad + \frac{4\rho_N^2 f_+(z_N)^2}{(z_N - 1/z_N)^2}\left[p_-(z_N,i)^2 - p_-(z_N,i-1)p_-(z_N,i+1)\right] z_N^{2i} \\
&\quad - \left[\frac{2\rho_N}{(z_N - 1/z_N)} + \frac{4\rho_N^2 f_+(z_N)f_+(1/z_N)}{(z_N - 1/z_N)^2}\right] \\
&\quad \times \left[2p_+(z_N,i)p_-(z_N,i) - p_+(z_N,i+1)p_-(z_N,i-1) - p_+(z_N,i-1)p_-(z_N,i+1)\right] z_N^{2i}.
\end{aligned}
$$

Thus the convergence of (3.16) follows from Lemma 3, (3.14), the fact that $p_-(z,i) = p_+(1/z,i)$, and the fact that $\nu(n) = \nu(-n)$.

Recast (3.17) as

$$
\begin{aligned}
&= \frac{O(z_N^{2i})}{f_+(z_N)^2}\left[\lambda_N p_+(z_N,i)p_+(z_N,i-1) - a(i)p_+(z_N,i-1)^2 - a(i)p_+(z_N,i)^2\right] \\
&\quad + \frac{\rho_N O(z_N^{2i})}{f_+(z_N)}\left[\lambda_N\left(p_+(z_N,i)p(\lambda_N,i-1) + p_+(z_N,i-1)p(\lambda_N,i)\right)\right. \\
&\qquad\qquad \left. - 2a(i)p_+(z_N,i-1)p(\lambda_N,i-1) - 2a(i)p_+(z_N,i)p(\lambda_N,i)\right] \\
&\quad + \rho_N^2 O(z_N^{2i})\left[\lambda_N p(\lambda_N,i)p(\lambda_N,i-1) - a(i)p(\lambda_N,i-1)^2 - a(i)p(\lambda_N,i)^2\right].
\end{aligned}
$$

The convergence of the first term follows from Lemma 3. The convergence of the last two terms can be demonstrated by using the same manipulations that led to (3.20), then by using Lemma 3, (3.14), the fact that $p_-(z,i) = p_+(1/z,i)$, and the symmetry of $v(n)$. □

An analogous result holds for $\lambda_N < 0$, by letting $d\rho(\lambda)/(\lambda_N - \lambda) \to d\rho(\lambda)/(\lambda - \lambda_N)$.

A consequence of (3.2) is the following.

COROLLARY 4.

$$\hat{f}_+(z) = \frac{(z_N - z)}{\sqrt{2z_N}} f_+(z).$$

The following theorem allows one to eliminate mass points in a fashion that inverts the procedure given in Theorem 7.

THEOREM 8. *Let*

$$
d\rho(\lambda) = \begin{cases} \sigma(\theta)d\lambda, & \lambda = \cos\theta, \quad 0 \le \theta \le \pi, \\ \sum_{i=1}^{N} \rho_i \delta(\lambda - \lambda_i)d\lambda, & \lambda \text{ not as above}, \quad \lambda_N > 0, \lambda_N \ge |\lambda_i|, \end{cases}
$$

and

$$d\rho^*(\lambda) = (\lambda_N - \lambda)d\rho(\lambda).$$

Let $\{p(\lambda,n)\}$, $\{a(n)\}$, $\{b(n)\}$, $\{p^*(n)\}$, *and* $\{b^*(n)\}$ *be the orthonormal polynomials and coefficients associated with* $d\rho(\lambda)$ *and* $d\rho^*(\lambda)$, *respectively. If* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a(i)^2| + |b(i-1)|\} < \infty$, *then* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a^*(i)^2| + |b^*(i-1)|\} < \infty$ *and*

$$f_+^*(z) = \frac{\sqrt{2z_N}}{z_N - z} f_+(z). \tag{3.21}$$

An analogous result holds for $\lambda_N < 0$.

Proof. Expanding $(\lambda_N - \lambda)p^*(\lambda,n)$ in a Fourier series gives

$$(\lambda_N - \lambda)p^*(\lambda,n) = \frac{k(n)}{k^*(n)}p(\lambda,n) - \frac{k^*(n)}{k(n+1)}p(\lambda,n+1), \tag{3.22}$$

where $k^*(n)$ and $k(n)$ are the leading coefficients of $p^*(\lambda,n)$ and $p(\lambda,n)$, respectively. At $\lambda = \lambda_N$ we find

$$\frac{1}{k^*(n)} = \frac{1}{k(n+1)k(n)}\frac{p(\lambda_N,n+1)}{p(\lambda_N,n)}, \tag{3.23}$$

or

$$a^*(n)^2 = a(n)a(n+1)\frac{p(\lambda_N,n+1)p(\lambda_N,n-1)}{p(\lambda_N,n)^2}.$$

Squaring (3.22), then multiplying by $d\rho(\lambda)$ and integrating yields

$$\lambda_N - b^*(n) = \frac{k(n)^2}{k^*(n)^2} + \frac{k^*(n)^2}{k(n+1)^2}.$$

Now, using (3.23) gives

$$\begin{aligned} b^*(n) = (&\lambda_N p(\lambda_N,n)p(\lambda_N,n+1) - a(n+1)p(\lambda_N,n)^2 \\ &- a(n+1)p(\lambda_N,n+1)^2)/p(\lambda_N,n)p(\lambda_N,n+1). \end{aligned} \tag{3.24}$$

Since the mass points occur at the zeros of $f_+(z)$ for $|z| < 1$, we find

$$a^*(n)^2 = a(n)a(n+1)\frac{p_+(z_N,n+1)p_+(z_N,n-1)}{p_+(z_N,n)^2},$$

and

$$\begin{aligned} b^*(n) = (&\lambda_N p_+(z_N,n)p_+(z_N,n+1) - a(n+1)p(z_N,n)^2 \\ &- a(n+1)p_+(z_N,n+1)^2)/p_+(z_N,n)p_+(z_N,n+1). \end{aligned}$$

The convergence of the series now follows from Lemma 3 and the fact that $p_+(z_N,n) \neq 0$ for all finite n. Equation (3.21) follows from (3.2). □

Theorems 7 and 8 demonstrate how to add zeros to $f_+(z)$ for $1 > |z| \geq 1/R$ or remove the zeros of $f_+(z)$ for $1 > |z| > 0$ without decreasing the rate of convergence of the new coefficients. What about the zeros of $f_+(1/z)$ in the region $1 > |z| \geq 1/R$? This breaks down into two cases: the roots of $f_+(1/z)$ that are real and those that are complex. Since the coefficients of $f_+(1/z)$ are real the complex roots of $f_+(1/z)$ come in conjugate pairs. Thus the investigation reduces to considering the effect, on the

coefficients, of multiplying or dividing the distribution function by linear or quadratic polynomials. (For other results in this area see Nevai [17, Chap. 6].)

THEOREM 9. *Given* $d\rho(\lambda)$ *and* $d\hat{\rho}(\lambda) = d\rho(\lambda)/(\lambda_0 - \lambda)$ *with* $\infty > \lambda_0 > 1$, λ_0 *not in the convex hull of the support of* $\rho(\lambda)$, $\lambda_0 = (z_0 + 1/z_0)/2$, $0 < z_0 < 1$. *If* $\sum_{i=1}^{\infty} i\nu(2i)\{|1-4a(i)^2| + |b(i)|\} < \infty$, *then* $\sum_{i=1}^{\infty} i\nu(2i)\{|1-4\hat{a}(i)^2| + |\hat{b}(i)|\} < \infty$ *and*

$$\hat{f}_+(z) = \frac{(1 - z_0 z)}{\sqrt{2z_0}} f_+(z). \tag{3.25}$$

Proof. Use the same procedures that led to (3.16) and (3.17). Then the theorem is a consequence of (2.32), Lemma 3, and (3.2). □

It should be noted that the only restriction on z_0 is that $0 < z_0 < 1$, which may put $1/z_0$ outside the region of analyticity of $zf_+(z)$. However, if $1/z_0$ is within this region or if the region of analyticity can be extended by analytic continuation (see examples) to include the point $1/z_0$, then $\hat{f}_+(z)$ will have a zero there. Analogous results holds for $\lambda_0 < -1$.

THEOREM 10. *Let*

$$d\rho^*(\lambda) = (\lambda_0 - \lambda)d\rho(\lambda),$$

$\lambda_0 > 1$, λ_0 *not in the convex hull of the support of* $\rho(\lambda)$, $\lambda_0 = (z_0 + 1/z_0)/2$ *with* $1 > z_0 \geq 1/R$. *If* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a(i)^2| + |b(i)|\} < \infty$, *and* $f_+(1/z_0) = 0$; *then* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a^*(i)^2| + |b^*(i)|\} < \infty$, *with* $f_+^*(z) = (\sqrt{2z_0}/(1 - z_0 z))f_+(z)$. *Analogous results hold for* $\lambda_0 < -1$.

Proof. Using procedures similar to those of Theorem 8 we find

$$a^*(n)^2 = a(n)a(n+1)\frac{p(\lambda_0, n+1)p(\lambda_0, n-1)}{p(\lambda_0, n)^2},$$

and

$$\begin{aligned} b^*(n) = (\lambda_0 p(\lambda_0, n)p(\lambda_0, n+1) - a(n+1)p(\lambda_0, n+1)^2 \\ - a(n+1)p(\lambda_0, n)^2)/p(\lambda_0, n)p(\lambda_0, n+1). \end{aligned}$$

Substituting (2.24) into the above equations yields

$$a^*(n)^2 = a(n)a(n+1)\frac{p_-(z_0, n+1)p_-(z_0, n-1)}{p_-(z_0, n)^2},$$

and

$$\begin{aligned} b^*(n) = (\lambda_0 p_-(z_0, n)p_-(z_0, n+1) - a(n+1)p_-(z_0, n+1)^2 \\ - a(n+1)p_-(z_0, n)^2)/p_-(z_0, n)p_-(z_0, n+1). \end{aligned}$$

Since λ_0 is not in the convex hull of the support of $\rho(\lambda)$, $p_-(z_0, n) \neq 0$. Thus the convergence of the series is guaranteed by (2.22), the fact that $p_-(z, n) = p_+(1/z, n)$, Lemma 3, and (3.2). □

THEOREM 11. *Given* $d\rho(\lambda)$ *and*

$$d\hat{\rho}(\lambda) = \frac{d\rho(\lambda)}{(\lambda - A)^2 + B^2} = \frac{d\rho(\lambda)}{(\lambda_1 - \lambda)(\lambda_1^* - \lambda)}, \qquad \lambda_1 = A + iB,$$

with $\lambda_1 = (z_1 + 1/z_1)/2$, $0 < |z_1| < 1$ (λ_1 *on the physical sheet*). *If* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a(i)^2| + |b(i-1)|\} < \infty$, *then* $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4\hat{a}(i)^2| + |\hat{b}(i+1)|\} < \infty$ *and* $\hat{f}_+(z) = ((1 - zz_1)(1 - zz_1^*)/2|z_1|)f_+(z)$.

Proof. Expanding $\hat{p}(\lambda, n)$ in terms of $p(\lambda, n)$ gives

$$\begin{aligned}\hat{p}(\lambda, n) = &\frac{\hat{k}(n)}{k(n)} p(\lambda, n) + C(n, n-1) p(\lambda, n-1) \\ &+ \frac{k(n-2)}{\hat{k}(n)} p(\lambda, n-2), \qquad n \geq 2,\end{aligned} \tag{3.26}$$

where $\hat{k}(n)$ and $k(n)$ are the leading coefficients of $\hat{p}(\lambda, n)$ and $p(\lambda, n)$, respectively. To determine $C(n, n-1)$ multiply (3.26) by $\lambda_1 - \lambda$ and integrate with respect $d\hat{\rho}(\lambda)$, then use (2.32) to find

$$C(n, n-1) = \frac{-\hat{k}(n)}{k(n)} \frac{p_+(z_1^*, n)}{p_+(z_1^*, n-1)} - \frac{k(n-2)}{\hat{k}(n)} \frac{p_+(z_1^*, n-2)}{p_+(z_1^*, n-1)}, \qquad n \geq 2.$$

Multiplying (3.26) by $(\lambda_1^* - \lambda) d\hat{\rho}(\lambda)$ and integrating, then using the above equation yields

$$\hat{k}(n)^2 = k(n) k(n-2) \frac{\Delta(n-1)}{\Delta(n)}, \tag{3.27}$$

where $\Delta(n) = [p_+(z_1, n) p_+(z_1^*, n-1) - p_+(z_1^*, n) p_+(z_1, n-1)]$. Therefore

$$\hat{a}(n+1)^2 = a(n+1) a(n-1) \left[\frac{\Delta(n-1)\Delta(n+1)}{\Delta(n)^2} \right]. \tag{3.28}$$

Likewise

$$\hat{b}(n) = \frac{\hat{k}(n, n-1)}{\hat{k}(n)} - \frac{\hat{k}(n+1, n)}{\hat{k}(n+1)},$$

where $\hat{k}(n, n-1)$ is the coefficients of λ^{n-1} in $\hat{p}(\lambda, n)$. From (3.26) we find

$$\frac{\hat{k}(n, n-1)}{\hat{k}(n)} = \frac{k(n, n-1)}{k(n)} - a(n) \frac{p_+(z_1^*, n)}{p_+(z_1^*, n-1)} - \frac{k(n-1)k(n-2)}{\hat{k}(n)^2} \frac{p_+(z_1^*, n-2)}{p_+(z_1^*, n-1)},$$

which, using (3.27), becomes

$$\frac{\hat{k}(n, n-1)}{\hat{k}(n)} = \frac{k(n, n-1)}{k(n)} - a(n) \frac{p_+(z_1^*, n)}{p_+(z_1^*, n-1)} - a(n) \frac{p_+(z_1^*, n-2)}{p_+(z_1^*, n-1)} \frac{\Delta(n)}{\Delta(n-1)}.$$

Therefore,

$$\begin{aligned}\hat{b}(n) = b(n) &- a(n) \frac{p_+(z_1^*, n)}{p_+(z_1^*, n-1)} + a(n+1) \frac{p_+(z_1^*, n+1)}{p_+(z_1^*, n)} \\ &- a(n) \frac{p_+(z_1^*, n-2)}{p_+(z_1^*, n-1)} \frac{\Delta(n)}{\Delta(n-1)} + a(n+1) \frac{p_+(z_1^*, n-1)}{p_+(z_1^*, n)} \frac{\Delta(n+1)}{\Delta(n)}.\end{aligned}$$

Using Lemma 3 we see that the result follows if it can be shown that

$$\sum_{n=2}^{\infty} n \nu(2n) \left| \frac{\Delta(n)^2 - \Delta(n+1)\Delta(n-1)}{\Delta(n)^2} \right| < \infty. \tag{3.29}$$

Since $p_+(z,n)$ satisfies (1.1), it follows that

$$a(n+1)\Delta(n+1) = (\lambda_1 - \lambda_1^*)|p_+(z_1,n)|^2 + a(n)\Delta(n). \tag{3.30}$$

Therefore $\Delta(n) \neq 0$ for finite n and for large n goes as

$$\Delta(n) = O\left(|z_1|^{2n}\left(\frac{1}{z_1^*} - \frac{1}{z_1}\right)\right).$$

Substituting (3.30) in (3.29) we find that the series converges if it can be shown that the following is true:

$$\sum_{n=2}^{\infty} n\nu(2n)|z_1|^{-4n}\big|(\lambda_1 - \lambda_1^*)|p_+(z_1,n)|^2|p_+(z_1,n-1)|^2 - a(n)\Delta(n)(|p_+(z_1,n)|^2 - |p_+(z_1,n-1)|^2)\big| < \infty.$$

If we eliminate $\lambda_1^* p_+(z_1^*,n)$ and $\lambda_1 p_+(z_1,n)$ using (1.1), then the result follows from Lemma 3. □

THEOREM 12. *Given* $d\rho(\lambda)$ *and*

$$d\rho^*(\lambda) = ((\lambda - A)^2 + B^2)d\rho(\lambda) = (\lambda_1 - \lambda)(\lambda_1^* - \lambda)d\rho,(\lambda), \qquad \lambda_1 = A + iB,$$

with $\lambda_1 = (z_1 + 1/z_1)/2$, $1/R \leq |z_1| < 1$.

If $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a(i)^2| + |b(i-1)|\} < \infty$ and

$$f_+(1/z_1) = 0, \tag{3.31}$$

then $\sum_{i=1}^{\infty} i\nu(2i)\{|1 - 4a^*(i)^2| + |b^*(i-1)|\} < \infty$ and

$$f_+^*(z) = 2|z_1|\frac{f_+(z)}{(1 - zz_1)(1 - zz_1^*)}.$$

Proof. Expanding $(\lambda_1 - \lambda)(\lambda_1^* - \lambda)p^*(\lambda,n)$ in terms of $p(\lambda,n)$ gives

$$(\lambda_1 - \lambda)(\lambda_1^* - \lambda)p^*(\lambda,n) = \frac{k^*(n)}{k(n+2)}p(\lambda,n+2) + C(n+1,n)p(\lambda,n+1) + \frac{k(n)}{k^*(n)}p(\lambda,n). \tag{3.32}$$

Therefore setting $\lambda = \lambda_1^*$ and using (3.31) and (2.24) yields

$$C(n+1,n) = -\frac{k^*(n)}{k(n+2)}\frac{p_-(z_1^*,n+2)}{p_-(z_1^*,n+1)} - \frac{k(n)}{k^*(n)}\frac{p_-(z_1^*,n)}{p_-(z_1^*,n+1)}.$$

Now setting $\lambda = \lambda_1$ in (3.32) and using the above equation gives

$$k^*(n)^2 = k(n+2)k(n)\frac{\tilde{\Delta}(n+1)}{\tilde{\Delta}(n+2)},$$

where $\tilde{\Delta}(n) = [p_-(z_1,n)p_-(z_1^*,n-1) - p_-(z_1^*,n)p_-(z_1,n-1)]$. Therefore

$$a^*(n+1)^2 = a(n+3)a(n+1)\left[\frac{\tilde{\Delta}(n+1)\tilde{\Delta}(n+2)}{\tilde{\Delta}(n+2)^2}\right].$$

Equating coefficients of λ^{n+1} in (3.31) yields

$$\frac{k^*(n,n-1)}{k^*(n)} - (\lambda_1 + \lambda_1^*) = \frac{k(n+2,n+1)}{k(n+2)} - \frac{k(n+1)}{k(n+2)}\frac{p_-(z_1^*,n+2)}{p_-(z_1^*,n+1)} - \frac{k(n)}{k^*(n)^2}\frac{p_-(z_1^*,n)}{p_-(z_1^*,n+1)}.$$

Thus

$$\hat{b}(n) = b(n+2) - a(n+2)\frac{p_-(z_1^*,n+2)}{p_-(z_1^*,n+1)} + a(n+2)\frac{p_-(z_1^*,n+3)}{p_-(z_1^*,n+2)} - a(n+2)\frac{p_-(z_z^*,n)}{p_-(z_1^*,n+1)}\frac{\tilde{\Delta}(n+2)}{\tilde{\Delta}(n+1)} + a(n+3)\frac{p_-(z_1^*,n+1)}{p_-(z_1^*,n+2)}\frac{\tilde{\Delta}(n+3)}{\tilde{\Delta}(n+1)}.$$

The result now follows using manipulations similar to those used in the preceding theorem. □

4. The absolutely continuous part. In this section the relation between the decay of coefficients in the recurrence formula and the decay of the Fourier coefficients of the absolutely continuous part of the measure will be investigated. We begin by recalling a result of Baxter.

Let $\sigma(\theta)$ be a real nonnegative periodic function integrable on $[-\pi,\pi]$. Let

$$c_n = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{-in\theta}\sigma(\theta)d\theta, \qquad c_0 \neq 0,$$

and define

$$D_n(\sigma) = \begin{vmatrix} c_0 & c_{-1} & \cdots & c_{-n} \\ c_1 & c_0 & \cdots & c_{-n+1} \\ \vdots & \vdots & & \vdots \\ c_n & c_{n-1} & \cdots & c_0 \end{vmatrix}, \qquad n = 0,1,2,\ldots.$$

(Note that $D_n(\sigma) > 0$.) Let

$$\gamma(n) = \frac{(-1)^n}{D_{n-1}(\sigma)}\begin{vmatrix} c_1 & c_0 & \cdots & c_{-n+2} \\ c_2 & c_1 & \cdots & \\ \vdots & \vdots & & \vdots \\ c_n & c_{n-1} & \cdots & c_1 \end{vmatrix}.$$

LEMMA 4. *Given $\sigma(\theta)$ as above assume (abusing notation) $|\sigma(z)| < \infty$ for $1/R \leq |z| \leq R$, $R \geq 1$. Then $\ln\sigma(z) \in A_\nu$ if and only if $\sum_{n=1}^{\infty}\nu(n)|\gamma(n)| < \infty$. Here $\nu(n)$ is given in* (1.4).

Remark. Baxter proved this theorem for $R = 1$ (see Baxter [3], [4]), and his proof with slight modifications can be carried over to this case.

COROLLARY 5. *Let $\{\phi(z,n)\}$ be the orthonormal polynomials associated with $\sigma(\theta)$ (see* Geronimus [12]). *If $\ln\sigma(z) \in A_\nu$, then $\{z^n\bar{\phi}(1/z,n)\}$ is a Cauchy sequence in A_ν and converges in norm to a nonzero function.*

Proof. See Baxter [3], [4]. □

THEOREM 13. *Let $\rho(\lambda)$ be a bounded, nondecreasing, absolutely continuous function on $[-1,1]$ with*

$$d\rho(\lambda) = \sigma(\theta)d\lambda, \qquad \lambda = \cos\theta, \qquad 0 \le \theta \le \pi.$$

Furthermore, let $\sigma(\theta)/\sin\theta = \sigma(-\theta)/\sin(-\theta)$ and $\ln\sigma(z)/(z-1/z) \in A_\nu$. Suppose $R > 1$ in (1.4). Then

$$\sum_{n=1}^{\infty} n\nu(2n)\{|1-4a(n)^2| + |b(n-1)|\} < \infty \tag{4.1}$$

if and only if

$$\sum_{n=1}^{\infty} n\nu(n)|g(n)| < \infty. \tag{4.2}$$

Here $\sigma(z)/(z-1/z) = \sum_{m=-\infty}^{\infty} g(m)z^m$, $1/R \le |z| \le R$, with $g(m) = g(-m)$.

Proof. Without loss of generality assume $\int_{-1}^{1} d\rho(\lambda) = 1$. From Theorems 1 and 4 we find that (4.1) implies that

$$\frac{\sigma(z)}{z-1/z} = \frac{i}{\pi f_+(z)f_+(1/z)}, \qquad z = e^{i\theta}, \tag{4.3}$$

with $zf_+(z) \in A_\nu^+$. Since $\ln\sigma(z)/(z-1/z) \in A_\nu$, $(zf_+(z))^{-1} \in A_\nu$, which implies that (4.3) holds for $1/R \le |z| \le R$. Differentiating (4.3) with respect to z yields

$$\sum_{m=-\infty}^{\infty} mq(m)z^{m-1} = -\frac{i}{\pi}\left[\frac{(zf_+(z))'}{(zf_+(z))^2 1/zf_+(1/z)} + \frac{(1/zf_+(1/z))'}{zf_+(z)(1/zf_+(1/z))^2}\right].$$

From Lemma 1 and Theorem 1(v) we find that $(zf_+(z))'$ and $(1/zf_+(1/z))' \in A_\nu$ since $R > 1$. Hence (4.1) implies (4.2).

To prove sufficiency note that $\ln\sigma(z)/(z-1/z) \in A_\nu$ and $\sigma(\theta)/\sin\theta = \sigma(-\theta)/\sin(-\theta)$ imply that we can construct $f_+(z)$ such that $zf_+(z) \in A_\nu^+$, $zf_+(z) \ne 0$, $|z| \le R$, $zf_+(z)|_{z=0} > 0$, and

$$\frac{2i\sigma(z)}{z-1/z} = \frac{1}{2\pi z f_+(z) 1/zf_+(1/z)}, \qquad 1/R \le |z| \le R.$$

Differentiating the above equation with respect to z, multiplying by $zf_+(z)(1/z)f_+(1/z)$, applying E_+, the operator that projects A_ν onto A_ν^+, then multiplying by $zf_+(z)$ gives

$$\begin{aligned}(zf_+(z))' = &-zf_+(z)E_+\left\{\frac{(1/zf_+(1/z))'}{1/zf_+(1/z)}\right\} \\ &- 2izf_+(z)E_+\left\{zf_+(z)\frac{1}{z}f_+(1/z)\left(\frac{2i\sigma(z)}{z-1/z}\right)'\right\}.\end{aligned}$$

Thus it follows from (4.2) that $(zf_+(z))' \in A_\nu$. Defining

$$s(z) = \frac{f_+(1/z)}{f_+(z)},$$

we find from above that $(s(z))' \in A_\nu$. The polynomials $\{p(\lambda,n)\}$ orthonormal with respect to $\sigma(\theta)$ can be written as (see Szegö [22])

$$(z-1/z)p(\lambda,n) = \sqrt{\frac{2}{\pi}}\left(1-\frac{\phi(0,2n+2)}{k(2n+2)}\right)^{-1/2} \times [z^{-n-1}\phi(z,2n+2) - z^{n+1}\phi(1/z,2n+2)], \qquad \lambda = \frac{1}{2}(z+1/z),$$

where $\{\phi(z,n)\}$ are polynomials on the unit circle orthonormal with respect to $\sigma(\theta)/\sin\theta$ with leading coefficient $k(n)$. By Corollary 5, $(z-1/z)p(\lambda,n) \in A$ for all n which implies through (2.32) that

$$p_+(z,n) = A(n,n)z^n\left(1+\sum_{i=1}^{\infty}\alpha(n,i)z^i\right) \in A \quad \text{for all } n,$$

since

$$\int \frac{p(\lambda',n)\sigma(\lambda')}{\lambda-\lambda'}d\lambda' = -\frac{1}{2i}\int_{-\pi}^{\pi} p(\cos\theta',n)\sigma(\theta')\left(\frac{e^{i\theta'}+z}{e^{i\theta'}-z}\right)d\theta'.$$

It is known that the Fourier coefficients of $p_+(z,n)$ satisfy the discrete analog of the Marchenko equation [5], [8], [10]:

$$w(2n+m)+\alpha(n,m)+\sum_{i=1}^{\infty}\alpha(n,i)w(i+2n+m) = 0, \qquad m \geq 1, n \geq 0$$

with

$$w(n) = \frac{1}{2\pi i}\oint (1-s(z))z^n\frac{dz}{z}.$$

Therefore

$$\begin{aligned} & nv(2n+2)|\alpha(n,m)-\alpha(n+1,m)| \\ & \quad \leq nv(2n+2)|w(2n+m+2)-w(2n+m)| \\ & \quad\quad + \sum_{i=1}^{\infty} nv(2n+2)|w(2n+i+m+2)-w(2n+m+i)||\alpha(n+1,i)| \\ & \quad\quad + \sum_{i=1}^{\infty} nv(2n+2)|\alpha(n+1,i)-\alpha(n,i)||w(i+2n+m)|. \end{aligned} \tag{4.4}$$

Since $\sum_{n=1}^{\infty}|w(n)| < \infty$ there exists $w_1(n)$ and $\hat{w}(n)$ such that

$$w_1(n) = \begin{cases} w(n)-\hat{w}(n), & w_1(n),\hat{w}(n) \neq 0, \quad n \leq N, \\ w(n), & n > N, \end{cases}$$

and $\sum_{n=1}^{\infty}|w_1(n)| < 1$. Replace $w(n)$ by $w_1(n)+\hat{w}(n)$ in the third term on the right-hand side of (4.4), iterate, then sum n from 1 to infinity. Setting $\gamma = \sup_m \sum_{n=1}^{\infty} nv(2n+2)|\alpha(n,m)-\alpha(n+1,m)|$, and using the fact that $s'(z) \in A_v$ we find

$$\gamma \leq \frac{2c\sup_m \sum_{n=1}^{\infty} nv(2n+2)\{|w(2n+m+2)-w(2n+m)|\}}{1-\sum_{i=1}^{\infty}|w_1(i)|} + \frac{\{\sup_{0\leq m\leq N}\sum_{n=1}^{N} nv(2n+2)|\alpha(n+1,m)-\alpha(n,m)|\}\sum_{i=1}^{N}|\hat{w}(i)|}{1-\sum_{i=1}^{\infty}|w_1(i)|} < \infty.$$

In the above equation $c = \max(\sup_i \sum_{n=1}^{\infty} |\alpha(n,i)| < \infty, 1)$. Thus $\sum_{n=1}^{\infty} nv(2n+2)|\alpha(n,m) - \alpha(n+1,m)| < \infty$ for all m, which implies the result since $\alpha(n,1) - \alpha(n-1,1) = 2b(n)$ and $\alpha(n,2) - \alpha(n-1,\gamma \to 2) = 1 - 4a(n+1)^2 + 2b(n)\alpha(n,n+1)$. □

Remark. We note that the case $R = 1$ does not follow from the above theorem. For $R = 1$, (4.2) needs to be replaced by $\sum_{n=1}^{\infty} nv(n)|g(n) - g(n+2)| < \infty$ (Geronimo[8]* and Guseinov [13]). This is because Lemma 1 does not hold for $z = \pm 1$ in this case; consequently, part (v) in Theorem 1 cannot be strengthened.

Unfortunately, without further hypotheses an analog of Theorem 1 in [11] is unavailable at this time. This is due to the fact that we do not have control on the number of zeros of $zf_+(z)$ for $1 < |z| < R$. Also, although it is clear that one can add or remove a finite number of zeros from $zf_+(z)$ and not decrease the rate of convergence of the coefficients in the recurrence formula, it is not clear whether an infinite number can be added or removed without decreasing the rate of convergence. Some statements about the zeros can be made. First let H_R^2 be the Hilbert space of functions analytic inside and square integrable on the boundary of the disk of radius R, i.e., $g(z) \in H_R^2$ if $g(z) = \sum_{n=0}^{\infty} c(n)z^n$, $|z| < R$ and $(1/2\pi)\int_{-\pi}^{\pi} |g(\mathrm{Re}^{i\theta})|^2 d\theta = \sum_{n=0}^{\infty} |c(n)|^2 R^{2n} < \infty$. Since $zf_+(z)$ is an element of H_R^2 its zeros satisfy the Blaschke condition $\sum_{i=1}^{\infty}(1 - |z_i|/R) < \infty$.

The results of §3, Theorem 13 in §4, and Theorem 6 in [11] can be combined to give the following.

THEOREM 14. *Let $\rho(\lambda)$ be a positive measure with absolutely continuous part $\sigma(\theta), \lambda = \cos\theta, 0 < \theta < \pi$. Set $\sigma(-\theta)/\sin(-\theta) = \sigma(\theta)/\sin(\theta)$, $0 < \theta < \pi$, and suppose $\sigma(z)$ has a meromorphic extension to $\frac{1}{R} < z < R > 1$ such that $|\sigma(z)| < \infty$ for $|z| = R$ and $|z| = 1/R$. Let $\{z_i\}$ denote the singularties of $\sigma(z)/(z - 1/z)$, including multiplicities. Then $\sum_{n=1}^{\infty} n\nu(2n)\{|1 - 4a(n)^2| + |b(n-1)|\} < \infty$ if and only if*

$$d\rho(\lambda) = \begin{cases} \sigma(\theta)d\lambda, & \lambda = \cos\theta, \quad 0 \le \theta \le \pi, \\ \sum_{i=1}^{N} \rho_i \delta(\lambda - \lambda_i)d\lambda, & \lambda \notin [-1,1], \quad N < \infty, \end{cases}$$

$\ln(\sigma(z)d(z)/(z - 1/z)) \in A_v$, and $\sum_{n=-\infty}^{\infty} n\nu(n)|g(n)| < \infty$, where $d(z) = \prod_{i=1}^{M}(z - z_i)((1/z) - z_i), |z_i| \le 1, M < \infty$, with $d(e^{i\theta}) = \overline{d(e^{i\theta})}$, and $\sigma(z)d(z)/(z - 1/z) = \sum_{n=-\infty}^{\infty} g(n)z^n$.

5. Examples—the Askey–Wilson polynomials. We now apply the above theorems to the Askey–Wilson polynomials. These give rise to the q-analogs of many of the classical polynomials [1], [2], [15]. In the examples below the recurrence coefficients $a(n)^2$ and $b(n)$ have the form

$$4a(n)^2 = 1 + \sum_{i=1}^{\infty} q^{ni}\gamma_i(q) \tag{5.1}$$

and

$$b(n) = \sum_{i=1}^{\infty} q^{ni}\beta_i(q), \tag{5.2}$$

*We wish to point out that Theorem 3.1 and its consequence, Lemma 3.1 in Geronimo [8], are incorrect. The correct proof of the sufficiency part of Theorem 1 in [8] is given in Appendix A of [8] (see also Theorem 13 above).

where $\gamma_i(q)$ and $\beta_i(q)$ are rational functions of q independent of n and $0 \le q < 1$. In order for (5.1) and (5.2) to converge we will assume the $\limsup |\gamma_i(q)|^{1/i} < 1/q$ and $\limsup |\beta_i(q)|^{1/i} < 1$. Coefficients having the form (5.1) and (5.2) have analogs in the scattering theory literature of physics and are called Yukawa type potentials [20]. We wish to analyze the structure of $p_+(z,n)$ with coefficients of the form (5.1) and (5.2). To this end let $\hat{p}_+(z,n) = z^{-n}p_+(z,n)/\gamma(n+1)$ with $\gamma(n+1)$ given in the proof of Theorem 2. In this case (1.1) becomes

$$z^2 4a(n+1)^2\hat{p}_+(z,n+1) + 2b(n)z\hat{p}_+(z,n) + \hat{p}_+(z,n-1) = 2z\lambda\hat{p}_+(z,n). \tag{5.3}$$

Using an idea of Martin [18], we make the ansatz $\hat{p}_+(z,n) = 1 + \sum_{i=1}^{\infty} h_i(q,z)q^{ni}$ and substitute this into (5.3). Let $x = q^n$ and note that by varying n [15] we may consider x as an independent variable. Equating powers of x^k in (5.3) we find that

$$h_k = \frac{-zq^k(\gamma_k q^k z + 2\beta_k + \sum_{i=1}^{k-1}(z\gamma_i q^k + 2\beta_i)h_{k-i})}{(1-z^2q^k)(1-q^k)}, \tag{5.4}$$

which implies that $h_k(z)$ is a rational function of z with possible poles located only at the zeros of the function $(z^2q : q)_{k-1}$, where

$$(a : q)_k = \begin{cases} (1-a)(1-aq)\cdots(1-aq^{k-1}), & k \ge 1, \\ 1, & k = 0. \end{cases}$$

In order to show that the equation for $p_+(z,n)$ given above is valid, define $\hat{h}_k = (z^2q : q)_{k-1}(q : q)_{k-1}h_k$; then (5.4) reads as

$$\begin{aligned} \hat{h}_k = -zq^k \Bigg[& (\gamma_k q^k z + 2\beta_k)(z^2q : q)_{k-2}(q : q)_{k-2} \\ & + \sum_{i=1}^{k-1}(z\gamma_{k-i}q^k + 2\beta_{k-i})\frac{(z^2q : q)_{k-1}(q : q)_{k-1}\hat{h}_i}{(z^2q : q)_{i-1}(q : q)_{i-1}} \Bigg]. \end{aligned} \tag{5.5}$$

Let S be a compact subset of the complex plane. Since $|(z^2q : q)_k| \le e^{\sum_{i=1}^{k}|z^2|q^i}$ there exists a constant c depending only upon the set S such that $|(z^2q : q)_k| < c$ and

$$\left|\frac{(z^2q : q)_{k-1}(q : q)_{k-1}}{(z^2q : q)_{i-1}(q : q)_{i-1}}\right| < c$$

for all $k > 0$ and $0 \le i \le k$. Consequently, (5.5) becomes

$$|\hat{h}_k| \le c\left(w_k + \sum_{i=1}^{k-1} w_{k-i}q^i|\hat{h}_i|\right),$$

where $w_k = |z|q^k(|\gamma_k z| + 2|\beta_k|)$. Therefore,

$$\sum_{k=1}^{\infty}|\hat{h}_k| \le c\left(\sum_{k=1}^{\infty} w_k + \sum_{i=1}^{\infty}|\hat{h}_i|q^i\sum_{k=0}^{\infty} w_{k+1}\right).$$

Since $\sum_{k=1}^{\infty}|w_k|<\infty$ there exists an N depending only upon S so that $q^n\sum_{i=1}^{\infty}|w_i|c<1$ for all $n\geq N$. Consequently,

$$\sum_{i=N}^{\infty}|\hat{h}_i|q^i\sum_{k=1}^{\infty}w_k\leq\sum_{i=N}^{\infty}|\hat{h}_i|q^N\sum_{k=1}^{\infty}w_k,$$

which leads to

$$\sum_{k=N}^{\infty}|\hat{h}_k|\leq\frac{c\left(\sum_{k=1}^{\infty}w_k+\sum_{k=1}^{N-1}|\hat{h}_k|+\sum_{k=1}^{N}|\hat{h}_k|q^k\sum_{j=1}^{\infty}w_j\right)}{1-q^Nc\sum_{k=1}^{\infty}|w_k|}<\infty$$

since the above is true for every compact subset of the complex plane, and since $\{\hat{h}_k\}$ is a sequence of polynomials in z we have shown the following.

THEOREM 15. *Suppose that $a(n)$ and $b(n-1)$ have the form* (5.1) *and* (5.2), *respectively, for $n\geq 1$, with $\limsup|\gamma_i|^{1/i}<1/q$ and $\limsup|\beta_i|^{1/i}<1$. Then for each $n\geq -1$, $p_+(z,n)$ is a meromorphic function of z having its possible poles located only at the zeros of $(z^2q:q)_\infty$.*

Remark. It is left as an exercise to show that the above theorem can be extended to the difference equation

$$z^24a(n+1)^2\hat{p}_+(z,n+1)+2b(n)z\hat{p}_+(z,n)+d(n)\hat{p}_+(z,n-1)=2z\lambda e(n)\hat{p}_+(z,n),\quad n\geq 0,$$

where $d(n)=1+\sum_{i=1}^{\infty}d_i(q)q^{ni}$ and $e(n)=1+\sum_{i=1}^{\infty}e_i(q)q^{ni}$ with $\limsup|d_i(q)|^{1/i}<1$ and $\limsup|e_i(q)|^{1/i}<1$.

We now apply our results to the Askey–Wilson polynomials [1], [2], [14], [15], [19]. In this case $a_n^2=\frac{1}{4}A_{n-1}C_n$, $n=1,2,\ldots$, and $b_n=\frac{1}{2}(a+1/a-A_n-C_n)$, $n=0,1,2,\ldots$, where

$$A_n=\frac{a^{-1}(1-abq^n)(1-acq^n)(1-adq^n)(1-abcdq^{n-1})}{(1-abcdq^{2n-1}(1-abcdq^{2n-2})},\qquad n=0,1,2,\ldots,$$

and

$$C_n=\frac{a(1-bcq^{n-1})(1-bdq^{n-1})(1-cdq^{n-1})(1-q^n)}{(1-abcdq^{2n-1}(1-abcdq^{2n-2})},\qquad n=0,1,2,\ldots,$$

where a,b,c,d are chosen so that A_n and C_n are real and $A_{n-1}C_n>0$. Since $1/a-A_n=O(q^n)$, $a-C_n=O(q^n)$ and $1-A_{n-1}C_n=O(q^n)$ the results of the previous section apply when $|q|<1$. Thus the distribution function $\rho(\lambda)$ with respect to which of the polynomials associated with the above recurrence coefficient are orthogonal, satisfies Theorem 4. Furthermore, from Theorem 15 and the remark below it we find that $p_+(z,n)$ is meromorphic with its possible poles located at the zeros of $(z^2q:q)_\infty$. The equation $p_+(z,n)/f_+(z)$ has been computed for these systems by Rahman [19] and Ismail and Rahman [15]. When a,b,c, and d are real or come in complex conjugate pairs and if $\max(|a|,|b|,|c|,|d|)<1$, then Askey and Wilson [2] have shown that $d\rho(\lambda)=\sigma(\lambda)d\lambda$, where

$$\frac{\sigma(\lambda)}{\sin\theta}=\frac{1}{2\pi}\frac{1}{|f_+e^{i\phi}|},\qquad \lambda=\cos\theta,$$

with

$$zf_+(z) = \frac{(az,q)_\infty (bz,q)_\infty (cz,q)_\infty (dz,q)_\infty}{(z^2q:q)_\infty} k(q),$$

where

$$k(q)^2 = \frac{1}{4} \frac{(abcd:q)_\infty}{(ab:q)_\infty (ac:q)_\infty (ad:q)_\infty (bc:q)_\infty (bd:q)_\infty (cd:q)_\infty (q:q)_\infty}.$$

If any of the parameters a, b, c or d become greater than one, then $\rho(\lambda)$ will have an absolutely continuous part and some mass points. This case has been considered by Askey and Wilson [2, Thm. 2.5].

Finally, we note that the error term for the zeros of the polynomials given by Theorem 3 can be improved; in particular, $\theta = k\pi/(n+1) + 1/(n+1) \arg(e^{i\theta} f_+(e^{i\theta})) + O(q^n/n)$. Successive iteration of this equation beginning with $\theta_0 = k\pi/(n+1)$ yields improving estimates for θ. To see this suppose for convenience that a, b, c, and d are real and less than one in magnitude. Then with $\theta_0 = \pi(n-m)/(n+1) = \pi(1 - (m+1)/(n+1))$ we find $\arg(1 - ae^{i\theta_0} q^k) = -a\pi((m+1)/(n+1))(q^k/(1+aq^k)) + O(q^k/n^3)$. Consequently, $\arg(ae^{i\theta_0}, q)_\infty = -a\pi(m+1)/(n+1) \sum_{k=0}^{\infty} q^k/(1+aq^k) + O(1/n^3)$. Set

$$c(a,q) = \sum_{k=0}^{\infty} \frac{aq^k}{1+aq^k}.$$

Applying similar methods to the other factors in the formula for $zf_+(z)$ yields

$$\arg e^{i\theta_0} f_+(e^{i\theta_0}) = \pi \Big[c(a,q) + c(b,q) + c(c,q) + c(d,q) - 2c(q,q) \Big] \frac{m+1}{n+1} + O\left(\frac{1}{n^3}\right).$$

Thus we have proved the following.

THEOREM 16. *Suppose a, b, c, and d are all real and have magnitudes less than one. Then the zeros of $p_n(\cos\theta)$ are given by*

$$\theta = \pi \frac{(n-m)}{n+1} + \pi \Big[c(a,q) + c(b,q) + c(c,q) + c(d,q) - 2c(q,q) \Big] \frac{m+1}{(n+1)^2} + O\left(\frac{1}{n^4}\right).$$

Acknowledgments. The author would like to thank W. Van Assche; without his strong encouragement, this paper may never have seen the light of day.

ON THE ASYMPTOTICS OF THE TRICOMI–CARLITZ POLYNOMIALS AND THEIR ZERO DISTRIBUTION (I)*

WILLIAM M. Y. GOH† AND JET WIMP‡

Abstract. The asymptotic behavior of the Tricomi–Carlitz polynomials in the complex plane is established.

Key words. orthogonal polynomials, zero distribution, Stieltjes transform, uniform convergence, theorem of Grommer and Hamburger

AMS subject classifications. 33A65, 41A60

1. Introduction.

Tricomi [11] studied the polynomials

$$t_n^{(\alpha)}(x) = \sum_{k=0}^{n} (-1)^k \binom{x-\alpha}{k} \frac{x^{n-k}}{(n-k)!}, \tag{1}$$

which satisfy the recurrence

$$\begin{aligned} (n+1)t_{n+1}^{(\alpha)}(x) - (n+\alpha)t_n^{(\alpha)}(x) + xt_{n-1}^{(\alpha)}(x) = 0, \qquad & n \geq 1, \\ t_0^{(\alpha)}(x) = 1, \qquad t_1^{(\alpha)}(x) = \alpha. & \end{aligned} \tag{2}$$

(For a brief treatment of these polynomials, see Chihara's book [3].)

We observe, as did Tricomi himself, that $\{t_n^{(\alpha)}(x)\}$ is not a system of orthogonal polynomials, the recurrence relation failing to have the required form. However, Carlitz [2] discovered that if one sets

$$f_n(x) = x^n t_n^{(\alpha)}(x^{-2}), \tag{3}$$

then $\{f_n(x)\}$ satisfies

$$\begin{aligned} (n+1)f_{n+1}(x) - (n+\alpha)xf_n(x) + f_{n-1}(x) = 0, \qquad & n \geq 1, \\ f_0(x) = 1, \qquad f_1(x) = \alpha x. & \end{aligned} \tag{4}$$

Carlitz proved that for $\alpha > 0$, $\{f_n(x)\}$ satisfies the orthogonality relation

$$\int_{-\infty}^{\infty} f_m(x) f_n(x) d\psi^{(\alpha)}(x) = \frac{2e^{\alpha}}{(n+\alpha)n!}\delta_{mn}, \tag{5}$$

where $\psi^{(\alpha)}(x)$ is a step function whose jumps are

$$d\psi^{(\alpha)}(x) = \frac{(k+\alpha)^{k-1}e^{-k}}{k!} \quad \text{at } x = \pm(k+\alpha)^{-1/2}, \quad k = 0, 1, 2, \ldots. \tag{6}$$

The generating function

$$\exp\left\{\frac{w}{x} + \frac{1-\alpha x^2}{x^2}\log(1-wx)\right\} = \sum_{n=0}^{\infty} f_n(x) w^n \tag{7}$$

follows easily from the recurrence.[1] This series converges for $|w| < |x|$, whenever $x \neq 0$.

For a generalization of the Tricomi–Carlitz polynomials the reader is referred to [1] and [4].

Note that the support of the orthogonality measure is just the set $\{0\} \cup \{\pm(k+\alpha)^{-1/2} : k = 0, 1, 2, \ldots\}$, which has a single accumulation point at 0. To investigate the asymptotic behavior of the zeros of a set of orthogonal polynomials $P_n(x)$ defined on a compact set it is useful to introduce the measures $\{v_n : n = 0, 1, 2, \ldots\}$,

$$\begin{aligned} &v_n(\{x_{j,n}\}) = 1/n, \qquad j = 1, 2, \ldots, n \\ &v_n(A) = 0, \qquad A \text{ contains no zeros of } P_n(x), \end{aligned} \tag{8}$$

where $\{x_{j,n}\}$ are the zeros of $P_n(x)$. Note the measure v_n assigns an equal weight to each zero. The weak limit of v_n (if it exists) is called the distribution of the zeros of $P_n(x)$.

The asymptotic behavior of v_n gives substantial information about how the zeros are distributed in the interval of orthogonality. For an extensive discussion of applications and consequences of this approach, we refer the reader to [6], [7], and [12].

We define the Stieltjes transform of the measure μ:

$$S(\mu; z) = \int_{-\infty}^{\infty} \frac{d\mu}{z - x}. \tag{9}$$

This transform will prove to be a very useful tool in our investigation.

The distribution of the zeros of the Tricomi–Carlitz polynomials can be easily obtained by the following argument:[2] The zeros of f_n are the eigenvalues of the Jacobi matrix J_n (see [13]). Let a_n's be the recurrence coefficients of the orthonormal polynomial $p_n(x) = [(n+\alpha)n!/(2e^{\alpha})]^{1/2} f_n(x)$, i.e.,

$$x p_n(x) = a_{n+1} p_{n+1}(x) + a_n p_{n-1}(x). \tag{10}$$

Here,

$$a_n = \left(\frac{n}{(n+\alpha)(n+\alpha-1)} \right)^{1/2}. \tag{11}$$

We have

$$S(v_n; x) = n^{-1} \operatorname{trace}(xI - J_n)^{-1},$$

whose moments are $\int x^n dv_n = n^{-1} \operatorname{trace} J_n^k$.

Thus the second moment is

$$\frac{2}{n} \sum_{1}^{n-1} a_j^2 = \frac{2}{n} \sum_{1}^{n-1} \frac{j}{(j+\alpha)(j+\alpha-1)} \sim \frac{2 \ln n}{n}. \tag{12}$$

We see that v_n tends towards the δ-distribution as $n \to \infty$.

[1] There is a misprint in this equation in [3].

[2] This procedure was suggested by a referee.

Although the distribution can be worked out with the above approach, it gives no information about the asymptotics of the orthogonal polynomials in the complex plane. Our approach provides this more general information (e.g., see Corollary 2). Note the Jacobi matrix J_n is a compact operator (because $a_n = O(1/n^{1/2})$ here). We mention a theorem by Schwarz [8], which says that for a trace class Jacobi matrix (one for which $\sum_{n=1}^{\infty} a_n < \infty$) there exists a function f analytic in $\mathbf{C}\backslash\{0\}$ such that

$$\lim_{n\to\infty} \frac{p_n(x)}{x^n} = f(x). \tag{13}$$

The above convergence holds uniformly on compact subsets of $\mathbf{C}\backslash\{0\}$. However, for the Tricomi–Carlitz polynomials the Jacobi matrix is not trace class. Therefore it would be interesting to see how the corresponding asymptotic behavior of $p_n(x)$ deviates from what is stated in (13). This question[3] is answered in Proposition 2.

Finally, since v_n converges weakly to the δ function, which is degenerate, we would like to obtain further information about the zero distribution, for example, the "shape" of the δ function. To this end, let $g_n := f_n(\alpha^{-1/2}x)$ so that all zeros are now in $[-1,1]$. We denote them by $r_{j,n}$, $j \le n$. Let X_n be the random variable so that

$$\text{Prob}(X_n = r_{j,n}) = 1/n \quad \text{for } 1 \le j \le n. \tag{14}$$

In order to get substantial information we must normalize correctly. Thus we define

$$\tilde{X}_n := \frac{X_n}{(\alpha/n)^{1/2}}. \tag{15}$$

One can show that the random variable $\tilde{X}_n$ converges in distribution to the distribution function whose density $p(x)$ is defined below:

$$p(x) = \begin{cases} \dfrac{1}{\pi}\left(\dfrac{4\tan^{-1}(x/\sqrt{4-x^2})}{x^3} - \dfrac{\sqrt{4-x^2}}{x^2}\right), & -2 \le x \le 2, \\ \dfrac{2}{|x|^3}, & |x| \ge 2. \end{cases} \tag{16}$$

It is interesting that the graph of $p(x)$ is volcano-like, i.e., with sloping sides and a crater. The proof of (16) requires that the asymptotics of the orthogonal polynomials is in the form $g_n(\sqrt{\frac{\alpha}{n}}z)$. Since it is a continuation of the present work, we intend to publish it elsewhere.

Now let the normalized measure for the zeros of g_n be $\tilde{v}_n$, i.e.,

$$\begin{aligned} &\tilde{v}_n(\{r_{j,n}\}) = 1/n, \qquad j = 1,2,\ldots,n, \\ &\tilde{v}_n(A) = 0, \qquad A \text{ contains no zeros of } g_n(x). \end{aligned} \tag{17}$$

The following proposition is easily proved.

PROPOSITION 1. *Let x in a compact set $K \subseteq \mathbf{C}\backslash[-1,1]$; then*

$$S(\tilde{v}_n : x) = \frac{1}{n}\frac{g_n'(x)}{g_n(x)} = \frac{1}{n}\sum_{j=1}^{n}\frac{1}{x - r_{j,n}}, \tag{18}$$

[3] This question was suggested by a referee.

where $r_{j,n}$'s are the zeros of $g_n(x)$.

Note. This proposition allows us to focus on the asymptotics of $g_n(x)$ for $x \in K \subseteq \mathbf{C}\backslash[-1,1]$.

By Cauchy's theorem we have, for fixed nonzero x,

$$f_n(x) = \frac{1}{2\pi i}\oint_{|w|=\rho} \exp\left\{\frac{w}{x} + \frac{1-\alpha x^2}{x^2}\log(1-wx)\right\} w^{-n-1}dw, \quad \text{where } \rho < |1/x|$$

$$= \frac{1}{2\pi i}\oint_{|w|=|x\rho|} \exp\left\{\frac{w}{x^2} + \frac{1-\alpha x^2}{x^2}\log(1-w)\right\} (w/x)^{-n-1}\frac{dw}{x}, \quad \text{where } |x\rho| < 1.$$

Thus

$$\frac{f_n(x)}{x^n} = \frac{1}{2\pi i}\oint_C \exp\left\{\frac{w}{x^2} + \frac{1-\alpha x^2}{x^2}\log(1-w)\right\} w^{-n-1}dw. \tag{19}$$

Equation (19) holds for all $x \neq 0$, and the integration contour C is any simple closed contour in the open unit disk encircling the origin.

Recall

$$g_n(x) := f_n(\alpha^{-1/2}x). \tag{20}$$

Now all zeros of $g_n(x)$ are in $[-1,1]$; so (19) becomes

$$\frac{g_n(x)}{x^n} = \frac{1}{2\pi i}\oint_C \exp\alpha\left\{\frac{w}{x^2} + \frac{1-x^2}{x^2}\log(1-w)\right\} w^{-n-1}dw. \tag{21}$$

Equation (21) holds for all $x \neq 0$.

The asymptotics of (21) are fairly simple:

$$\frac{g_n(x)}{x^n} = [w^n]\left(\exp\left(\frac{\alpha w}{x^2}\right)(1-w)^{\alpha(1-x^2)/x^2}\right). \tag{22}$$

We emphasize that although one can employ Darboux's method to get the asymptotics of (22) for each *fixed* x (see [16, p. 116]), uniformity is, unfortunately, an issue here, and the Darboux approach does not guarantee uniformity.

Rather, we tackle the problem by using an elementary approach.

PROPOSITION 2.

$$\frac{g_n(x)}{x^n n^{-\alpha(1-x^2)/x^2-1}} \to \frac{e^{\alpha/x^2}}{\Gamma(-\alpha(1-x^2)/x^2)} \quad \text{as } n \to \infty \tag{23}$$

uniformly for all x in a compact set $K \subseteq \mathbf{C}\backslash[-1,1]$.

Proof. To simplify notation we introduce

$$A(x) := \frac{\alpha(1-x^2)}{x^2} \quad \text{and} \quad B(x) := \frac{\alpha}{x^2}. \tag{24}$$

Write the Taylor expansion

$$(1-w)^{A(x)} = \sum_{n=0}^{\infty} a_n w^n, \tag{25}$$

$$(26)\qquad e^{wB(x)} = \sum_{n=0}^{\infty} b_n w^n, \quad \text{where } a_n = (-1)^n \binom{A(x)}{n} \quad \text{and} \quad b_n = \frac{B^n(x)}{n!}.$$

We form the Cauchy product

$$(27)\qquad [w^n]\left(\exp\left(\frac{\alpha w}{x^2}\right)(1-w)^{\alpha(1-x^2)/x^2}\right) = \sum_{j=0}^{n} b_j a_{n-j}.$$

Hence

$$(28)\qquad \frac{g_n(x)}{x^n n^{-A(x)-1}} = \sum_{j=0}^{n} \frac{B^j(x)}{j!} \frac{(-1)^{n-j}}{n^{-A(x)-1}} \binom{A(x)}{n-j}.$$

Using

$$(-1)^{n-j}\binom{A(x)}{n-j} = \frac{\Gamma(n-j-A(x))}{\Gamma(-A(x))\Gamma(n-j+1)},$$

we have

$$(29)\qquad \frac{g_n(x)}{x^n n^{-A(x)-1}} = \frac{1}{\Gamma(-A(x))} \sum_{j=0}^{n} \frac{B^j(x)}{j!} \frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)}.$$

Write

$$(30)\qquad \frac{e^{B(x)}}{\Gamma(-A(x))} = \frac{1}{\Gamma(-A(x))} \sum_{j=0}^{\infty} \frac{B^j(x)}{j!}.$$

Combining (29) and (30) gives

(31)

$$\frac{g_n(x)}{x^n n^{-A(x)-1}} - \frac{e^{B(x)}}{\Gamma(-A(x))} = \frac{1}{\Gamma(-A(x))} \sum_{j=0}^{n} \frac{B^j(x)}{j!} \left(\frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)} - 1\right) - \frac{1}{\Gamma(-A(x))} \sum_{j=n+1}^{\infty} \frac{B^j(x)}{j!}.$$

We now decompose the above sum as follows:

$$(32)\qquad \frac{g_n(x)}{x^n n^{-A(x)-1}} - \frac{e^{B(x)}}{\Gamma(-A(x))} = S_1 + S_2 + S_3,$$

where

$$S_1 = \frac{1}{\Gamma(-A(x))} \sum_{j=0}^{n/\log\log n} \frac{B^j(x)}{j!} \left(\frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)} - 1\right),$$

$$S_2 = \frac{1}{\Gamma(-A(x))} \sum_{j=n/\log\log n}^{n} \frac{B^j(x)}{j!} \left(\frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)} - 1\right),$$

$$S_3 = \frac{-1}{\Gamma(-A(x))} \sum_{j=n+1}^{\infty} \frac{B^j(x)}{j!}. \tag{33}$$

In order to estimate S_i, $i = 1, 2, 3$, we must interrupt our proof for four short lemmas.

LEMMA 1. *Let $x \in K \subseteq \mathbf{C}\backslash[-1,1]$, K compact. Then $A(x)$ is never ≥ 0, and there exists $M > 0$ such that for all $x \in K$ we have $|A(x)| \leq M$.*

Proof. Solving $\alpha(1-x^2)/x^2 = \beta$ for x we have $x = \pm\sqrt{\alpha/(\alpha+\beta)}$. If $\beta \geq 0$, then x would be real and $|x| \leq 1$. This is a contradiction. The second part of the statement is trivial. □

LEMMA 2. *There exists $M > 0$ such that for all $x \in K$ we have $|1/\Gamma(-A(x))| \leq M$, and $|B(x)| \leq M$.*

Proof. The proof is trivial. □

LEMMA 3. *Let j be $\leq n/\log\log n$, and $x \in K \subseteq \mathbf{C}\backslash[-1,1]$. Then as $n \to \infty$ we have*

$$\left(\frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)} - 1\right) = O\left(\frac{1}{\log\log n}\right), \tag{34}$$

where the implicit constant holds uniformly.

Proof. By Lemma 1 there exists $M_1 > 0$ (depending on K) such that for all $x \in K \subseteq \mathbf{C}\backslash[-1,1]$ we have

$$|\mathrm{Im}(n-j-A(x))| \leq M_1. \tag{35}$$

The assumption of the lemma implies $|\mathrm{Re}(n-j-A(x))| \to \infty$, as $n \to \infty$. Hence there exists a $\delta > 0$ (depending on K) such that for all $x \in K$ $|\mathrm{Arg}(n-j-A(x))| \leq \pi/2 - \delta$, provided n is large. Using the asymptotics of $\log\Gamma(z)$ (e.g., [14]), which hold uniformly for all z such that $|\mathrm{Arg}\, z| \leq \pi/2 - \delta$, we have

$$\begin{aligned} &\left(\frac{1}{n^{-A(x)-1}} \frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)}\right) \\ &= \left(1-\frac{j}{n}\right)^{-A(x)-1} \frac{\left(1-\frac{A(x)}{n-j}\right)^{-A(x)-1/2}}{\left(1+\frac{1}{n-j}\right)^{1/2}} \left(1-\frac{A(x)+1}{n-j+1}\right)^{n-j} \\ &\quad e^{A(x)+1}\left(!+O\left(\frac{1}{n-j}\right)\right). \end{aligned} \tag{36}$$

By Lemma 1, $|A(x)|$ is bounded. Hence we may estimate each of the above factors as follows:

$$\left(1-\frac{j}{n}\right)^{-A(x)-1} = 1 + O\left(\frac{j}{n}\right) = 1 + O\left(\frac{1}{\log\log n}\right), \tag{37}$$

$$\left(1-\frac{A(x)}{n-j}\right)^{-A(x)-1/2} = 1 + O\left(\frac{|A(x)|}{n-j}\right), \tag{38}$$

$$\left(1-\frac{A(x)+1}{n-j+1}\right)^{n-j} = e^{-A(x)+1}\left(1+O\left(\frac{1}{n-j}\right)\right). \tag{39}$$

The implicit constants in (36)–(39) hold uniformly for $x \in K$ and for j such that $j \le n/\log\log n$.

Putting (37), (38), and (39) into (36) we get

$$\frac{1}{n^{-A(x)-1}}\,\frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)} - 1 = \left(1+O\left(\frac{1}{\log\log n}\right)\right)\left(1+O\left(\frac{1}{n-j}\right)\right) - 1$$

$$= O\left(\frac{1}{\log\log n}\right). \qquad \square$$

LEMMA 4. *Let $n/\log\log n < j \le n$ and $x \in K \subseteq \mathbf{C}\backslash[-1,1]$. There exists a constant c depending only on K such that*

$$\left|\frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)}\right| \le c^n. \tag{40}$$

Proof. Let $n-j=l$. Thus l is in the interval $[0, n(1-(1/\log\log n))]$.

Now

$$\begin{aligned}\left|\frac{\Gamma(l-A(x))}{\Gamma(l+1)}\right| &= |\Gamma(-A(x))|\left|\binom{A(x)}{l}\right| \\ &= |\Gamma(-A(x))|\left|\frac{A(x)(1-A(x))\cdots(l-1-A(x))}{l!}\right| \\ &= |\Gamma(-A(x))||A(x)|\left|1-\frac{A(x)}{1}\right|\left|1-\frac{A(x)}{2}\right|\cdots\left|1-\frac{A(x)}{l-1}\right|\frac{1}{l}.\end{aligned} \tag{41}$$

By Lemma 1, $A(x)$ is never nonnegative. Hence

$$|\Gamma(-A(x))| \le M \quad \text{(bounded)}.$$

Since $|A(x)|$ is bounded, there is an n_0 depending on K such that for all $j \ge n_0$ we have $|A(x)/j| \le \frac{1}{2}$, and as a consequence

$$\left|\frac{\Gamma(l-A(x))}{\Gamma(l+1)}\right| = M^{n_0}\left(\frac{3}{2}\right)^{l-n_0}. \tag{42}$$

Thus there exists a constant c such that

$$\left|\frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)}\right| \le c^n. \qquad \square$$

With Lemmas (1)–(4) at our disposal we are prepared to estimate S_1, S_2, and S_3 in (32). Thus

$$|S_1| \le \left|\frac{1}{\Gamma(-A(x))}\right| \sum_{j=0}^{n/\log\log n}\left|\frac{B^j(x)}{j!}\left(\frac{1}{n^{-A(x)-1}}\,\frac{\Gamma(n-j-A(x))}{\Gamma(n-j+1)}-1\right)\right|. \tag{43}$$

Using Lemma 3 we have

$$|S_1| \le MO\left(\frac{1}{\log\log n}\right)\sum_{j=0}^{n/\log\log n}\frac{|B^j(x)|}{j!}. \tag{44}$$

The converging series $\sum_{j=0}^{n/\log\log n} |B^j(x)|/j!$ is obviously uniformly bounded. Hence $S_1 \to 0$ uniformly for $x \in K$ as $n \to \infty$.

Next, by Lemma 4 we see that

$$|S_2| \le \left|\frac{1}{\Gamma(-A(x))}\right| \sum_{j=n/\log\log n}^{n} \frac{|B^j(x)|}{j!}\left(\frac{c^n}{n^{-|A(x)|-1}}+1\right). \tag{45}$$

Now

$$j! = \Gamma(j+1) \ge \Gamma\left(\frac{n}{\log\log n}+1\right) \ge K_1 \exp\left(\frac{n\log n}{\log\log n} - \frac{n}{\log\log n}\right). \tag{46}$$

Using (46) in (45) we get

$$|S_2| \le M\left(n - \frac{n}{\log\log n}\right) \frac{|B(x)|^n n^{1+|A(x)|} c^n}{K_1 \exp\left(\frac{n\log n}{\log\log n} - \frac{n}{\log\log n}\right)}. \tag{47}$$

Since $\exp(n\log n/\log\log n)$ is dominant, we have $S_2 \to 0$ uniformly for $x \in K$ as $n \to \infty$. Finally, we observe that the tail of a uniformly converging series $\sum_{j=n+1}^{\infty}(B^j(x)/j!) \to 0$ uniformly for $x \in K$ as $n \to \infty$. Thus $S_3 \to 0$ uniformly. □

PROPOSITION 3.

$$\frac{g_n'(x)}{g_n(x)} - \left(\frac{n}{x} + \frac{2\alpha\log n}{x^3}\right) \to \frac{-2\alpha}{x^3}\left(1 + \frac{\Gamma'(-\alpha(1-x^2)/x^2)}{\Gamma(-\alpha(1-x^2)/x^2)}\right), \tag{48}$$

uniformly for $x \in K \subseteq \mathbf{C}\backslash[-1,1]$.

Proof. Since the convergence in (23) is uniform and both functions

$$\frac{g_n(x)}{x^n} n^{-\alpha(1-x^2)/x^2-1} \quad \text{and} \quad \frac{e^{\alpha/x^2}}{\Gamma(-\alpha(1-x^2)/x^2)}$$

are analytic on $\mathbf{C}\backslash[-1,1]$, by a classical theorem of complex analysis on uniform convergence we can differentiate both sides of (23) with respect to x, still maintaining the uniform convergence. The result follows after a little simplification. □

COROLLARY 1. $\tilde{v}_n \to \delta$ *weakly as* $n \to \infty$.

Proof. Propositions 1 and 3 imply that

$$S(v_n; x) \to \frac{1}{x} \quad \text{uniformly for } x \in K \subseteq \mathbf{C}\backslash[-1,1]. \tag{49}$$

By a theorem of Grommer and Hamburger (see, e.g., [12] and [15]) we conclude that $\tilde{v}_n$ converges weakly to $\delta(x)$, the δ-function at $x = 0$. □

Of course, Corollary 1 implies that for any continuous function $h(x)$ on $[-1,1]$ we have

$$\lim_{n\to\infty} \frac{1}{n} \sum_{j=1}^{n} h(r_{j,n}) = h(0). \tag{50}$$

To have an idea of the rate of convergence of (50) we have the following.

COROLLARY 2. *Let $h(z)$ be analytic in an open set containing $[-1,1]$. Then*

$$n\left(\frac{1}{n}\sum_{j=1}^{n}h(r_{j,n})-h(0)\right) + \alpha h''(0)\ln n \to \frac{1}{2\pi i}\oint_C \frac{-2\alpha}{x^3}\left(1+\frac{\Gamma'(-\alpha(1-x^2)/x^2)}{\Gamma(-\alpha(1-x^2)/x^2)}\right)h(x)dx, \tag{51}$$

where C is a contour in the open set encircling the segment $[-1,1]$.

Proof. Use Proposition 3 and Cauchy's integral formula. □

The existence of a "residual term," $\alpha h''(0)\ln n$ in the above expression (see Theorems 1.11 and 1.14 in [12]), is rather interesting.

WATSON'S BASIC ANALOGUE OF RAMANUJAN'S ENTRY 40 AND ITS GENERALIZATION*

DHARMA P. GUPTA† AND DAVID R. MASSON†

Abstract. The authors generalize Watson's q-analogue of Ramanujan's Entry 40 continued fraction by deriving solutions to a ${}_{10}\phi_9$-series contiguous relation and applying Pincherle's theorem. Watson's result is recovered as a special terminating case, while a limit case yields a new continued fraction associated with an ${}_8\phi_7$-series contiguous relation.

Key words. contiguous relations, continued fractions, Pincherle's theorem, basic hypergeometric series

AMS subject classifications. 33D15, 39A10, 40A15

1. Introduction.

Contiguous relations for hypergeometric functions are an important source for obtaining explicit results for difference equations, continued fractions, Jacobi matrices and their corresponding orthogonal polynomials. At the top of the Askey–Wilson chart of classical orthogonal polynomials [1] one has the ${}_4F_3$ Wilson polynomials. However, the ${}_4F_3$ label is misleading since the properties of these polynomials and their associated case are revealed by two contiguous relations for very well poised ${}_7F_6$ series [8], [14]. These, in turn, can be derived as limits of a contiguous relation for a terminating, very well poised, two-balanced ${}_9F_8$-series [8], [18]. This ${}_9F_8$ contiguous relation is thus fundamental for the classical hypergeometric polynomials. In a previous publication [15] it was shown how this ${}_9F_8$ contiguous relation was also related to Ramanujan's famous Entry 40 continued fraction [3], [16].

All of the above are $q \to 1$ limits of basic hypergeometric analogues. Thus the ${}_4\phi_3$ Askey-Wilson polynomials should be viewed in the light of very well poised ${}_8\phi_7$ series [9] which are limits of terminating, very well poised, balanced ${}_{10}\phi_9$'s. The analogous contiguous relation for ${}_{10}\phi_9$'s is thus fundamental to the whole scheme of classical and basic hypergeometric orthogonal polynomials. In this paper we derive this important contiguous relation and a corresponding continued fraction. A special terminating version of this continued fraction yields the following result of Watson [17], which is the q-analogue of Ramanujan's Entry 40 [3], [16].

THEOREM A (Watson [17]). *Denoting the base by q^2 (instead of more usual q), let*

$$\frac{1}{G(x)} = \prod_{m=0}^{\infty} (1 - xq^{2m+1}), \qquad (|q| < 1),$$

$$\mathcal{P} = G(\alpha\beta\gamma\delta\epsilon)G\Big(\frac{\alpha\beta\gamma}{\delta\epsilon}\Big)G\Big(\frac{\alpha\beta\delta}{\gamma\epsilon}\Big)G\Big(\frac{\alpha\gamma\delta}{\beta\epsilon}\Big)G\Big(\frac{\alpha\beta\epsilon}{\gamma\delta}\Big)G\Big(\frac{\alpha\gamma\epsilon}{\beta\delta}\Big)G\Big(\frac{\alpha\delta\epsilon}{\beta\gamma}\Big)G\Big(\frac{\alpha}{\beta\gamma\delta\epsilon}\Big)$$

$$\mathcal{Q} = G\Big(\frac{\alpha\beta\gamma\delta}{\epsilon}\Big)G\Big(\frac{\alpha\beta\gamma\epsilon}{\delta}\Big)G\Big(\frac{\alpha\beta\delta\epsilon}{\gamma}\Big)G\Big(\frac{\alpha\gamma\delta\epsilon}{\beta}\Big)G\Big(\frac{\alpha\beta}{\gamma\delta\epsilon}\Big)G\Big(\frac{\alpha\gamma}{\beta\delta\epsilon}\Big)G\Big(\frac{\alpha\delta}{\beta\gamma\epsilon}\Big)G\Big(\frac{\alpha\epsilon}{\beta\gamma\delta}\Big).$$

* Received by the editors January 11, 1993; accepted for publication February 9, 1993.

† Department of Mathematics, University of Toronto, Toronto, Canada, M5S 1A1. The work of the second author was partially supported by the Natural Science and Engineering Research Council of Canada.

Then, provided that one of the numbers $\beta, \gamma, \delta, \epsilon$ is of the form $q^{\pm n} (n = 1, 2, \dots)$,

$$\frac{\mathcal{P} - \mathcal{Q}}{\mathcal{P} + \mathcal{Q}} = \frac{A_0}{\beta_0} \frac{\alpha_1}{+\beta_1} \frac{\alpha_2}{+\beta_2} + \cdots,$$

where

$$\begin{aligned}
A_0 &= (q + q^{-1})\Pi(\alpha - \alpha^{-1}) \\
\alpha_m &= (q^{m+1} + q^{-m-1})(q^{m-1} + q^{1-m})\Pi(\alpha^2 + \alpha^{-2} - q^{2m} - q^{-2m}), \\
\beta_m &= (q^{2m+1} - q^{-2m-1}) \\
&\quad \cdot \Big\{ (q^m + q^{-m})(q^{m+1} + q^{-m-1})(\Sigma\alpha^2 + \Sigma\alpha^{-2} + 2) - \Pi(\alpha + \alpha^{-1}) \\
&\qquad - (q + q^{-1})(q^m + q^{-m})(q^{m+1} + q^{-m-1})(q^{2m+1} + q^{-2m-1}) \Big\}
\end{aligned}$$

with the products and sums ranging over the numbers $\alpha, \beta, \gamma, \delta, \epsilon$.

A second special terminating version of the continued fraction obtained here will give the basic analogue of Masson's Proposition 1 in [15], which is described as a "missing companion" of Ramanujan's Entry 40. For the sake of completeness we state Masson's result.

THEOREM B (Masson [15]). *Let $P' = \Pi\Gamma\big((3 + \alpha \pm \beta \pm \gamma \pm \delta \pm \epsilon)/4\big)$ (0, 2 or 4 minus signs) and $Q' = \Pi\Gamma\big((1 + \alpha \pm \beta \pm \gamma \pm \delta \pm \epsilon)/4\big)$ (1 or 3 minus signs). Then if one of the parameters $\beta, \gamma, \delta, \epsilon$ is an odd integer,*

$$\frac{Q'}{P'} = \frac{-1}{a_0} \frac{2b_1}{-a_1} \frac{b_2}{-a_2} \frac{b_3}{-a_3} - \cdots,$$

where

$$\begin{aligned}
b_n &= \Big(\Pi\big((2n-1)^2 - \alpha^2\big)\Big) \Big/ (16)^3 (2n-1)^2, \\
a_n &= \Big\{2n^6 + n^4(5 - \Sigma\alpha^2)/4 + n^2\big(-26 + (1 + \Sigma\alpha^2)^2 - 2\Sigma\alpha^4\big)/64 - a_0\Big\} \Big/ (4n^2 - 1), \\
a_0 &= \big\{2(1 - \Sigma\alpha^4) + (1 - \Sigma\alpha^2)^2 - 8\Pi\alpha\big\} \Big/ (16)^2,
\end{aligned}$$

with these products and sums ranging over the parameters $\alpha, \beta, \gamma, \delta, \epsilon$.

Masson [15] also gave the nonterminating versions of Ramanujan's Entry 40 and Theorem B.

The object of the present study is to obtain the nonterminating versions of Watson's theorem and the q-analogue of Masson's theorem. They are given in §4 by Corollaries 7 and 8, respectively. Our approach is similar to that in several recent papers [5], [6], [12], [13] on the subject where Pincherle's theorem [11] has been used to bring out the connection between several of Ramanujan's Chapter 12 entries and the general theory of hypergeometric orthogonal functions (Askey and Wilson [1], Wilson [18]). For other approaches to explaining some of Ramanujan's continued fraction entries see [3], [10], [19].

2. Contiguous relation. We consider a terminating, very well poised, balanced

${}_{10}\phi_9$ basic hypergeometric function:

$$\begin{aligned}\phi =&\phi(a;b,c,d,e,f,g,h)\\ :=&{}_{10}\phi_9\left(\begin{matrix}a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, f, g, h;\ q, q\\ \sqrt{a}, -\sqrt{a}, \frac{aq}{b}, \frac{aq}{c}, \frac{aq}{d}, \frac{aq}{e}, \frac{aq}{f}, \frac{aq}{g}, \frac{aq}{h}\end{matrix}\right),\\ a^3q^2 =&bcdefgh\,, \qquad |q|<1,\end{aligned} \tag{2.1}$$

with, say, $h = q^{-n}$, $n = 0, 1, \ldots$, $g = sq^{n-1}$, $s := a^3q^3/(bcdef)$. We follow the usual notation for variations of ϕ with respect to the parameters. For example $\phi(b+, c-)$ represents the ϕ with b and c replaced by bq and c/q respectively. ϕ_+ denotes the ${}_{10}\phi_9$ obtained by replacing a by aq^2 and b, c, d, e, f, g, h by $bq, cq, dq, eq, fq, gq, hq$, respectively.

We need a contiguous relation basic analogue to the contiguous relation derived by Wilson [18] for the ${}_9F_8$ hypergeometric function. To work out this contiguous relation, we shall use Wilson's method [18] of using the basic hypergeometric analogues of the relevant formulas.

LEMMA 1. *Let ϕ be given by* (2.1) *(not necessarily terminating). Then*

$$\begin{aligned}&\phi(b-,c+)-\phi\\ &=\frac{\frac{aq}{c}(1-\frac{cq}{b})(1-\frac{bc}{aq})(1-aq)(1-aq^2)(1-d)(1-e)(1-f)(1-g)(1-h)}{(1-\frac{aq}{b})(1-\frac{aq^2}{b})(1-\frac{a}{c})(1-\frac{aq}{c})(1-\frac{aq}{d})(1-\frac{aq}{e})(1-\frac{aq}{f})(1-\frac{aq}{g})(1-\frac{aq}{h})}\\ &\quad\times\phi_+(b-)\,.\end{aligned} \tag{2.2}$$

Proof. A straightforward term by term subtraction on the left side of (2.2) leads to the result. □

LEMMA 2. *If ϕ (given by* (2.1)*) is terminating, then*

$$\begin{aligned}&\frac{b^2(1-h)(1-\frac{aq}{bc})(1-\frac{aq}{bd})(1-\frac{aq}{be})(1-\frac{aq}{bf})(1-\frac{aq}{bg})}{(1-\frac{aq}{b})(1-\frac{aq^2}{b})}\phi_+(b-)\\ &-\frac{h^2(1-b)(1-\frac{aq}{ch})(1-\frac{aq}{dh})(1-\frac{aq}{eh})(1-\frac{aq}{fh})(1-\frac{aq}{gh})}{(1-\frac{aq}{h})(1-\frac{aq^2}{h})}\phi_+(h-)\\ &-\frac{b(1-\frac{h}{b})(1-\frac{aq}{c})(1-\frac{aq}{d})(1-\frac{aq}{e})(1-\frac{aq}{f})(1-\frac{aq}{g})}{(1-aq)(1-aq^2)}\phi=0.\end{aligned} \tag{2.3}$$

Proof. By eliminating $\phi_+(b-)$ from (2.2) and another similar relation written for $\phi(b-, d+) - \phi$ we obtain

$$\begin{aligned}&c(1-c)\left(1-\frac{a}{c}\right)\left(1-\frac{dq}{b}\right)\left(1-\frac{bd}{aq}\right)\phi(b-,c+)\\ &-d(1-d)\left(1-\frac{a}{d}\right)\left(1-\frac{cq}{b}\right)\left(1-\frac{bc}{aq}\right)\phi(b-,d+)\\ &+d\left(1-\frac{b}{q}\right)\left(1-\frac{c}{d}\right)\left(1-\frac{aq}{b}\right)\left(1-\frac{cd}{a}\right)\phi=0.\end{aligned} \tag{2.4}$$

With, say, $h = q^{-n}$, we can apply an iterate of Bailey's transformation 8.5(1) [2, p. 68] to ϕ, $\phi_+(b-)$ and $\phi_+(h-)$ (the transformation [4, ex. 2.19, p. 53] with b, e, g replaced by g, b, e, respectively). The three transformed series are related by (2.4). Reversing the transformations in this relation we arrive at (2.3). □

THEOREM 3. *If ϕ (given by (2.1)) is terminating, then*

$$
\begin{aligned}
&\frac{g(1-h)(1-\frac{a}{h})(1-\frac{aq}{h})(1-\frac{aq}{gb})(1-\frac{aq}{gc})(1-\frac{aq}{gd})(1-\frac{aq}{ge})(1-\frac{aq}{gf})}{(1-\frac{hq}{g})} \\
&\qquad \times [\phi(g-,h+)-\phi] \\
&-\frac{h(1-g)(1-\frac{a}{g})(1-\frac{aq}{g})(1-\frac{aq}{hb})(1-\frac{aq}{hc})(1-\frac{aq}{hd})(1-\frac{aq}{he})(1-\frac{aq}{hf})}{(1-\frac{gq}{h})} \\
&\qquad \times [\phi(h-,g+)-\phi] \\
&-\frac{aq}{h}\left(1-\frac{h}{g}\right)\left(1-\frac{gh}{aq}\right)(1-b)(1-c)(1-d)(1-e)(1-f)\phi = 0.
\end{aligned} \tag{2.5}
$$

Proof. We eliminate $\phi_+(b-)$ and $\phi_+(c-)$ from (2.2), (2.2) with $b \leftrightarrow c$ in (2.2), and with $c \leftrightarrow h$ in (2.3). A final interchange of parameters $b \leftrightarrow g$, $c \leftrightarrow h$ yields the desired result. □

Substituting $h = q^{-n}$, $g = sq^{n-1}$, and renormalizing, the contiguous relation (2.5) becomes the linear second-order difference equation

$$X_{n+1} - a_n X_n + b_n X_{n-1} = 0, \qquad n \geq 0, \tag{2.6}$$

(2.7)

$$
\begin{aligned}
a_n = \Bigg[&\frac{q^{-n+\frac{1}{2}}}{\sqrt{s}}(1-sq^{n-1})(1-\frac{s}{a}q^{n-1})(1-\frac{s}{a}q^{n-2}) \\
&\times \frac{(1-\frac{a}{b}q^{n+1})(1-\frac{a}{c}q^{n+1})(1-\frac{a}{d}q^{n+1})(1-\frac{a}{e}q^{n+1})(1-\frac{a}{f}q^{n+1})}{(1-sq^{2n})} \\
&+ \frac{q^{-n+\frac{3}{2}}}{\sqrt{s}}(1-q^n)(1-aq^n)(1-aq^{n+1}) \\
&\times \frac{(1-\frac{bs}{a}q^{n-2})(1-\frac{cs}{a}q^{n-2})(1-\frac{ds}{a}q^{n-2})(1-\frac{es}{a}q^{n-2})(1-\frac{fs}{a}q^{n-2})}{(1-sq^{2n-2})} \\
&+ \frac{\sqrt{s}}{a}q^{n-\frac{1}{2}}(1-sq^{2n-1})\left(1-\frac{s}{aq^2}\right)(1-b)(1-c)(1-d)(1-e)(1-f)\Bigg] \\
&\Big/\left[(1-sq^{2n-1})(1-\frac{s}{a}q^{n-2})(1-aq^{n+1})\right],
\end{aligned} \tag{2.7}
$$

(2.8)

$$
\begin{aligned}
b_n = &\frac{q^{-2n+3}}{s}(1-q^n)(1-sq^{n-2})\left(1-\frac{a}{b}q^n\right)\left(1-\frac{a}{c}q^n\right)\left(1-\frac{a}{d}q^n\right)\left(1-\frac{a}{e}q^n\right)\left(1-\frac{a}{f}q^n\right) \\
&\times \frac{(1-\frac{bs}{a}q^{n-2})(1-\frac{cs}{a}q^{n-2})(1-\frac{ds}{a}q^{n-2})(1-\frac{es}{a}q^{n-2})(1-\frac{fs}{a}q^{n-2})}{(1-sq^{2n-1})(1-sq^{2n-2})^2(1-sq^{2n-3})},
\end{aligned} \tag{2.8}
$$

$$s = \frac{a^3q^3}{bcdef}$$

with the solution

$$X_n^{(1)} = \frac{q^{-\frac{n^2}{2}+n}}{s^{\frac{n}{2}}} \frac{(sq^{2n-1})_\infty (aq^{n+1})_\infty}{(sq^{n-1})_\infty (\frac{s}{a}q^{n-1})_\infty (\frac{aq^{n+1}}{b}, \frac{aq^{n+1}}{c}, \frac{aq^{n+1}}{d}, \frac{aq^{n+1}}{e}, \frac{aq^{n+1}}{f})_\infty} \times \phi(a; b, c, d, e, f, sq^{n-1}, q^{-n}). \tag{2.9}$$

Here the infinite product $(a)_\infty$ means

$$(a)_\infty = (a; q)_\infty = (1-a)(1-aq)(1-aq^2)\cdots$$

and

$$(a, b, \ldots, k)_\infty = (a)_\infty (b)_\infty \ldots (k)_\infty.$$

For the exceptional values $s = q, q^2$, the a_n, b_n and b_{n+1} in (2.7) and (2.8), and the $X_n^{(1)}, X_{n-1}^{(1)}$ in (2.9) are indeterminate at $n = 0$. We resolve this indeterminancy by taking limits as $n \to 0$.

Next, we proceed to find a second linearly independent solution to the second-order difference equation (2.6). This can be obtained by using a q-analogue of [15]. Thus from (2.6), (2.9), and a symmetry relation ((2.11), which follows) we are able to obtain a second terminating ${}_{10}\phi_9$ solution for the special values $s = q, q^2, \ldots$. For general values of s the second solution will be an appropriate combination of two nonterminating ${}_{10}\phi_9$'s which satisfy a four-term transformation (Gasper and Rahman [4], formula III.39, p. 247). We will consider the case of general s in future work.

Observe that with the replacement

$$(a, b, c, d, e, f, sq^{n-1}, q^{-n}) \to \left(\frac{q}{a}, \frac{q}{b}, \frac{q}{c}, \frac{q}{d}, \frac{q}{e}, \frac{q}{f}, \frac{q^{-n+2}}{s}, q^{n+1}\right) \tag{2.10}$$

we have

$$(a_n, b_n) \to (a_n, b_{n+1}). \tag{2.11}$$

It is easy to check that $b_n \to b_{n+1}$. To check $a_n \to a_n$ we used the "Maple" software on the computer. This meant verifying a polynomial identity in $x = q^{-n}$ of degree 14.

Applying the transformation (2.10) to (2.6) and (2.9) and renormalizing, we obtain the second solution

$$X_n^{(2)} = \frac{q^{-\frac{n^2}{2}+n}}{s^{\frac{n}{2}}} \frac{(\frac{s}{a}q^n)_\infty (sq^{2n-1})_\infty}{(q^{n+1})_\infty (aq^n)_\infty (\frac{bs}{a}q^{n-1}, \frac{cs}{a}q^{n-1}, \frac{ds}{a}q^{n-1}, \frac{es}{a}q^{n-1}, \frac{fs}{a}q^{n-1})_\infty} \times \phi\left(\frac{q}{a}; \frac{q}{b}, \frac{q}{c}, \frac{q}{d}, \frac{q}{e}, \frac{q}{f}, \frac{q^{-n+2}}{s}, q^{n+1}\right), \qquad s = q, q^2, \ldots. \tag{2.12}$$

Note that ϕ is terminating in (2.12) because of the parameter q^{-n+2}/s.

3. Asymptotics and Pincherle's theorem. To obtain a minimal (subdominant) solution for (2.6) we need the large n asymptotics of (2.9) and (2.12). Applying Tannery's theorem to the ${}_{10}\phi_9$'s on the right side of (2.9) and (2.12), we have, as $n \to \infty$,

$$X_n^{(1)} \sim \frac{q^{-\frac{n^2}{2}+n}}{s^{\frac{n}{2}}} W(a; b, c, d, e, f), \qquad \left|\frac{s}{aq}\right| < 1 \tag{3.1}$$

and

$$X_n^{(2)} \sim \frac{q^{-\frac{n^2}{2}+n}}{s^{\frac{n}{2}}} W\left(\frac{q}{a}; \frac{q}{b}, \frac{q}{c}, \frac{q}{d}, \frac{q}{e}, \frac{q}{f}\right), \qquad \left|\frac{aq^2}{s}\right| < 1, \tag{3.2}$$

where

$$W(a; b, c, d, e, f) := {}_8\phi_7\left(\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, f \\ \sqrt{a}, -\sqrt{a}, \frac{qa}{b}, \frac{qa}{c}, \frac{qa}{d}, \frac{qa}{e}, \frac{qa}{f} \end{matrix}; q, \frac{a^2q^2}{bcdef}\right).$$

We write

$$W_1 := W(a; b, c, d, e, f), \qquad |s| < |qa|$$

and its analytic continuation otherwise, and we write

$$W_2 := W\left(\frac{q}{a}; \frac{q}{b}, \frac{q}{c}, \frac{q}{d}, \frac{q}{e}, \frac{q}{f}\right), \qquad |s| > |aq^2|$$

and its analytic continuation otherwise.

Now taking

$$X_n^{(3)} := W_2 X_n^{(1)} - W_1 X_n^{(2)}, \tag{3.3}$$

it follows from (3.1) and (3.2) that

$$\lim_{n\to\infty} \frac{X_n^{(3)}}{X_n^{(1)}} = 0, \qquad \left|\frac{s}{q}\right| < |a| < \left|\frac{s}{q^2}\right|. \tag{3.4}$$

This establishes that $X_n^{(3)}$ is a minimal solution of (2.6). An application of Pincherle's theorem [11] then leads to the following result.

THEOREM 4. *Let* $s = q, q^2, \ldots$. *Then*

$$\frac{1}{a_0} \; \frac{b_1}{-a_1} \; \frac{b_2}{-a_2} \; -\cdots = \lim_{n\to 0} \frac{W_2 X_n^{(1)} - W_1 X_n^{(2)}}{b_n(W_2 X_{n-1}^{(1)} - W_1 X_{n-1}^{(2)})}. \tag{3.5}$$

Proof. From Pincherle's theorem (3.5) is true for $|s/q| < |a| < |s/q^2|$. For other values of a the result follows by analytic continuation. To the left side of (3.5) we can apply the "parabola theorem" (see Jones and Thron [11, p. 99] and Jacobsen [10]) since from (2.6), $b_n/(a_n a_{n-1}) = (q^3/(1+q)^2)(1+O(q^n))$. Hence the left side of (3.5) is a meromorphic function of a. The right side of (3.5) involves convergent infinite products and ${}_8\phi_7$'s that are each expressible in terms of convergent infinite products and convergent ${}_4\phi_3$'s (Gasper and Rahman [4, eq. (2.10.10), p. 43]). Consequently, the right side of (3.5) is also a meromorphic function of a and (3.5) follows by analytic continuation to all values of a. Note that the exceptional cases $s = q, q^2$ that cause indeterminancy are taken care of by the limit $n \to 0$ on the right side of (3.5). □

For the exceptional values $s = q^2, q$ Theorem 4 gives, respectively, the nonterminating versions of Theorem A (Watson[17]) and the basic analogue of Theorem B (Masson [15]). We now demonstrate how to derive the terminating versions of Theorem 4. We shall need to express the ratio W_1/W_2 in terms of infinite products when $b/a = q^N$, N being an integer. We write

$$\widetilde{W}(a; b, c, d, e, f) := \left(\frac{aq}{b}, \frac{aq}{c}, \frac{aq}{d}, \frac{aq}{e}, \frac{aq}{f}\right)_\infty W(a; b, c, d, e, f)$$

and

$$U(a;b,c,d,e,f) := \frac{\widetilde{W}(a;b,c,d,e,f)}{(aq,b,c,d,e,f)_\infty}.$$

LEMMA 5. *If $b/a = q^N$, where N is an integer, then*

$$U(a;b,c,d,e,f) = \left(\frac{s}{aq}\right)^N U\left(\frac{b^2}{a};b,\frac{bc}{a},\frac{bd}{a},\frac{be}{a},\frac{bf}{a}\right). \tag{3.6}$$

Proof. Refer to Bailey's three-term ${}_8\phi_7$ transformation (Gasper and Rahman [4, formula III.37, p. 246]). If we apply the condition $b/a = q^N$, $N = 0, \pm1, \pm2, \dots$ we obtain the desired result. □

LEMMA 6. *If $s = a^3q^3/(bcdef) = q^M$ and $b/a = q^N$, M and N being integers, then*

$$\begin{aligned}&\frac{\widetilde{W}(a;b,c,d,e,f)}{\widetilde{W}\left(\frac{a}{a};\frac{a}{b},\frac{a}{c},\frac{a}{d},\frac{a}{e},\frac{a}{f}\right)}\\ &\quad = \lambda\frac{(aq,c,d,e,f,\frac{aq^2}{s},\frac{aq}{ef},\frac{aq}{df},\frac{aq}{de})_\infty}{(\frac{bc}{a},\frac{bd}{a},\frac{be}{a},\frac{bf}{a},\frac{q^2}{a},\frac{q}{b},\frac{cd}{a},\frac{ce}{a},\frac{cf}{a})_\infty},\end{aligned} \tag{3.7}$$

where

$$\lambda = (-1)^{n+1}\left(\frac{s}{aq}\right)^N\left(\frac{c}{b}\right)^{n+1}q^{n(n+1)/2} \quad \text{for} \quad \frac{aq^3}{bs} = q^{-n},\ n = 0,1,2,\dots, \tag{3.8}$$

and

$$\lambda = (-1)^{n+1}\left(\frac{s}{aq}\right)^N\left(\frac{b}{c}\right)^{n+1}q^{(n+1)(n+2)/2} \quad \text{for} \quad \frac{bs}{aq} = q^{-n},\ n = -1,0,1,2,\dots. \tag{3.9}$$

Proof. We express the left side of (3.7) in terms of appropriate ${}_4\phi_3$'s. To the numerator W in (3.7) we first apply the identity (3.6) and then the three-term transformation [4, formula III.36, p. 246]. To the denominator W we first apply the ${}_8\phi_7$ transformation [4, formula III.24, p. 243] and then formula III.36 [4]. We also make use of the relation

$$\begin{aligned}\lim_{e\to q^{-n}}(e)_\infty\,{}_4\phi_3\left(\begin{matrix}a,b,c,d\\ e,f,g\end{matrix};q,q\right) &= \frac{(a,b,c,d,fq^{n+1},gq^{n+1},q^{n+2})_\infty}{(aq^{n+1},bq^{n+1},cq^{n+1},dq^{n+1},f,g)_\infty}\\ &\quad\times q^{n+1}\,{}_4\phi_3\left(\begin{matrix}aq^{n+1},bq^{n+1},cq^{n+1},dq^{n+1}\\ q^{n+2},fq^{n+1},gq^{n+1}\end{matrix};q,q\right).\end{aligned} \tag{3.10}$$

All this enables us to recognize and cancel a common linear combination of ${}_4\phi_3$'s from the numerator and the denominator yielding the desired result. We note that in the case $bs/aq = q$, $s = q$, the limit (3.10) is not required and there is an exact cancellation. □

4. Exceptional values s = q, q². We now restate Theorem 4 for the exceptional values $s = q, q^2$ and the form they take when the continued fraction terminates:

COROLLARY 7. *If $s = q^2$, then* (3.5) *can be rewritten as*

$$\frac{1}{a_0}\ -\frac{b_1}{a_1}\ -\frac{b_2}{a_2}\ -\cdots = \frac{2a(1-q)}{q^{3/2}(1-\alpha)(1-\beta)(1-\gamma)(1-\delta)(1-\epsilon)}\left(\frac{1-V}{1+V}\right), \tag{4.1}$$

$$
\begin{aligned}
a_n = &\Big[q^{\frac{1}{2}}\Pi(\alpha^{\frac{1}{2}}+\alpha^{-\frac{1}{2}}) + q^{\frac{1}{2}}(q^{\frac{1}{2}}+q^{-\frac{1}{2}})(q^{n+\frac{1}{2}}+q^{-n-\frac{1}{2}}) \\
&\times (q^{\frac{n}{2}}+q^{-\frac{n}{2}})(q^{\frac{n+1}{2}}+q^{-\frac{n+1}{2}}) \\
&- q^{\frac{1}{2}}(\Sigma\alpha+\Sigma\alpha^{-1}+2)(q^{\frac{n}{2}}+q^{-\frac{n}{2}})(q^{\frac{n+1}{2}}+q^{-\frac{n+1}{2}})\Big] \\
&\Big/(q^{\frac{n}{2}}+q^{-\frac{n}{2}})(q^{\frac{n+1}{2}}+q^{-\frac{n+1}{2}}) \,, \qquad (4.2)\\
b_n = &\frac{-q\Pi(\alpha+\alpha^{-1}-q^n-q^{-n})}{(q^{-\frac{n}{2}}+q^{\frac{n}{2}})^2(q^{-n-\frac{1}{2}}-q^{n+\frac{1}{2}})(q^{-n+\frac{1}{2}}-q^{n-\frac{1}{2}})}, \\
V = &\frac{(\frac{q}{a})_\infty(\frac{q^2}{a})_\infty}{(a)_\infty(aq)_\infty}\,\frac{\widetilde{W}_1}{\widetilde{W}_2}\,, \qquad (4.3)\\
a = &(q\alpha\beta\gamma\delta\epsilon)^{\frac{1}{2}},
\end{aligned}
$$

and product Π *and summation* Σ *are taken over the parameters* $\alpha,\beta,\gamma,\delta,\epsilon$. *If one of the parameters* $\beta,\gamma,\delta,\epsilon = q^N$, N *integer,* $(\alpha,\beta,\gamma,\delta,\epsilon) \to (\alpha^2,\beta^2,\gamma^2,\delta^2,\epsilon^2)$ *and the base* q *is changed to* q^2, *then the right side of* (4.1) *becomes*

$$
\frac{2(q^{-1}-q)}{q\Pi(\alpha-\alpha^{-1})}\,\frac{\mathcal{P}-\mathcal{Q}}{\mathcal{P}+\mathcal{Q}}, \qquad (4.4)
$$

with

$$
\begin{aligned}
\frac{1}{\mathcal{P}} &= \Big(\alpha\beta\gamma\delta\epsilon, \frac{\alpha}{\beta\gamma\delta\epsilon}, \frac{\alpha\beta\gamma}{\delta\epsilon}, \frac{\alpha\beta\delta}{\gamma\epsilon}, \frac{\alpha\gamma\delta}{\beta\epsilon}, \frac{\alpha\beta\epsilon}{\gamma\delta}, \frac{\alpha\gamma\epsilon}{\beta\delta}, \frac{\alpha\delta\epsilon}{\beta\gamma}; q^2\Big)_\infty, \\
\frac{1}{\mathcal{Q}} &= \Big(\frac{\alpha\beta\gamma\delta}{\epsilon}, \frac{\alpha\beta\gamma\epsilon}{\delta}, \frac{\alpha\beta\delta\epsilon}{\gamma}, \frac{\alpha\gamma\delta\epsilon}{\beta}, \frac{\alpha\beta}{\gamma\delta\epsilon}, \frac{\alpha\gamma}{\beta\delta\epsilon}, \frac{\alpha\delta}{\beta\gamma\epsilon}, \frac{\alpha\epsilon}{\beta\gamma\delta}; q^2\Big)_\infty,
\end{aligned}
$$

and a_n, b_n *modified accordingly. This reproduces Theorem* A.

Proof. We write $\alpha = a/b$, $\beta = a/c$, $\gamma = a/d$, $\delta = a/e$, $\epsilon = a/f$. After that the proof is straightforward on substituting the values of $X_0^{(1)}$, $X_0^{(2)}$, $b_0X_{-1}^{(1)}$, $b_0X_{-1}^{(2)}$ from (2.9), (2.12) and (2.8) into Theorem 4. A lot of algebra is involved in the simplification. Also, appropriate limits are to be taken whenever indeterminates occur.

To obtain the terminating form (4.4) we need to use Lemma 6 after interchanging, say, b and f. In both cases, viz.,

$$
\frac{aq^3}{fs} = q^{-n}, \quad n = 0,1,2,\ldots \quad \text{and} \quad \frac{fs}{aq} = q^{-n}, \quad n = -1,0,1,2,\ldots
$$

whether the termination is due to one or the other, the result works out to be the same. The above result (4.4) yields Watson's result [17] i.e., Theorem A in §1. □

COROLLARY 8. *If* $s = q$, *then* (3.5) *can be rewritten as*

$$
\frac{1}{a_0} - \frac{b_1}{a_1} - \frac{b_2}{a_2} - \cdots = 2\left(a_0 + \frac{a^2}{q}\,\frac{(\frac{1}{a})_\infty(\frac{1}{a})_\infty}{(aq)_\infty(\frac{a}{q})_\infty}\,\frac{\widetilde{W}_1}{\widetilde{W}_2}\right)^{-1}, \qquad (4.5)
$$

$$
\begin{aligned}
a_n = {} & \frac{q^{\frac{1}{2}}}{(q^{-n-\frac{1}{2}} - q^{n+\frac{1}{2}})(q^{-n+\frac{1}{2}} - q^{n-\frac{1}{2}})} \\
& \cdot \Big\{ (q^{3n} + q^{-3n})(q^{\frac{1}{2}} + q^{-\frac{1}{2}}) \\
& \quad - (q^{2n} + q^{-2n})\Big[q^{\frac{1}{2}} + q^{-\frac{1}{2}} + \Sigma(\alpha^{-\frac{1}{2}} + \alpha^{\frac{1}{2}})\Big] \\
& \quad + (q^n + q^{-n})\Big[- q^{\frac{3}{2}} - q^{-\frac{3}{2}} + (q^{\frac{1}{4}} + q^{-\frac{1}{4}})\Pi(\alpha^{\frac{1}{4}} + \alpha^{-\frac{1}{4}}) \\
& \qquad + (q^{\frac{1}{4}} - q^{-\frac{1}{4}})\Pi(\alpha^{\frac{1}{4}} - \alpha^{-\frac{1}{4}})\Big] \qquad (4.6) \\
& \quad + (q^{-1} + q)(q^{\frac{1}{2}} + q^{-\frac{1}{2}}) + (q^{-1} + q)\Sigma(\alpha^{-\frac{1}{2}} + \alpha^{\frac{1}{2}}) \\
& \quad - (q^{\frac{1}{4}} + q^{-\frac{1}{4}})(q^{\frac{1}{2}} + q^{-\frac{1}{2}})\Pi(\alpha^{\frac{1}{4}} + \alpha^{-\frac{1}{4}}) \\
& \quad + (q^{\frac{1}{4}} - q^{-\frac{1}{4}})(q^{\frac{1}{2}} + q^{-\frac{1}{2}})\Pi(\alpha^{\frac{1}{4}} - \alpha^{-\frac{1}{4}}) \Big\},
\end{aligned}
$$

$$
b_n = q^{\frac{5}{2}} \frac{\Pi(q^{-n} + q^n - \alpha^{\frac{1}{2}}q^{-\frac{1}{2}} - \alpha^{-\frac{1}{2}}q^{\frac{1}{2}})}{(q^{\frac{n}{2}} + q^{-\frac{n}{2}})(q^{\frac{n}{2}-\frac{1}{2}} + q^{-\frac{n}{2}+\frac{1}{2}})(q^{n-\frac{1}{2}} - q^{-n+\frac{1}{2}})^2},
$$

$$
\widetilde{W}_1 = \widetilde{W}\left(a;\ a\sqrt{\frac{q}{\alpha}},\ a\sqrt{\frac{q}{\beta}},\ a\sqrt{\frac{q}{\gamma}},\ a\sqrt{\frac{q}{\delta}},\ a\sqrt{\frac{q}{\epsilon}}\right), \qquad (4.7)
$$

$$
\widetilde{W}_2 = \widetilde{W}\left(\frac{q}{a};\ \frac{\sqrt{\alpha q}}{a},\ \frac{\sqrt{\beta q}}{a},\ \frac{\sqrt{\gamma q}}{a},\ \frac{\sqrt{\delta q}}{a},\ \frac{\sqrt{\epsilon q}}{a}\right),
$$

$$
a = \left(\frac{\alpha\beta\gamma\delta\epsilon}{q}\right)^{\frac{1}{4}},
$$

and product Π *and summation* Σ *are taken over parameters* $\alpha, \beta, \gamma, \delta, \epsilon$. *If one of the parameters* $\beta, \gamma, \delta, \epsilon$ *is* q^N, N *an odd integer,* $(\alpha, \beta, \gamma, \delta, \epsilon) \to (\alpha^4, \beta^4, \gamma^4, \delta^4, \epsilon^4)$ *and the base* q *is changed to* q^4, *then* (4.5) *becomes*

$$
\frac{1}{a_0}\ \frac{b_1}{-a_1}\ \frac{b_2}{-a_2}\ -\cdots = 2\left(a_0 - \frac{q^2}{\alpha^2}\frac{\mathcal{P}'}{\mathcal{Q}'}\right)^{-1}, \qquad (4.8)
$$

where

$$
\begin{aligned}
\frac{1}{\mathcal{Q}'} &= \left(\frac{q\alpha\beta\gamma\delta}{\epsilon}, \frac{q\alpha\gamma\delta\epsilon}{\beta}, \frac{q\alpha\beta\epsilon\delta}{\gamma}, \frac{q\alpha\epsilon\beta\gamma}{\delta}, \frac{q\alpha\beta}{\epsilon\gamma\delta}, \frac{q\alpha\gamma}{\epsilon\beta\delta}, \frac{q\alpha\delta}{\epsilon\beta\gamma}, \frac{q\alpha\epsilon}{\beta\gamma\delta}; q^4\right)_\infty, \qquad (4.9) \\
\frac{1}{\mathcal{P}'} &= \left(q^3\alpha\beta\gamma\delta\epsilon, \frac{q^3\alpha}{\beta\gamma\delta\epsilon}, \frac{q^3\alpha\delta\epsilon}{\beta\gamma}, \frac{q^3\alpha\gamma\epsilon}{\beta\delta}, \frac{q^3\gamma\delta\alpha}{\epsilon\beta}, \frac{q^3\alpha\beta\delta}{\epsilon\gamma}, \frac{q^3\alpha\beta\gamma}{\epsilon\delta}, \frac{q^3\alpha\beta\epsilon}{\gamma\delta}; q^4\right)_\infty,
\end{aligned}
$$

with a_n *and* b_n *modified accordingly.*

Proof. We write $\alpha = a^2q/b^2$, $\beta = a^2q/c^2$, $\gamma = a^2q/d^2$, $\delta = a^2q/e^2$, and $\epsilon = a^2q/f^2$ and make the appropriate substitutions from (2.9), (2.12), and (2.8) into Theorem 4. A considerable amount of algebra is required to reexpress (2.7) as (4.6) for which we used "Maple" software on the computer. We use Lemma 6 after interchanging, say, b and f to arrive at (4.8). The result is the same for either type of termination (3.8) or (3.9). Note that (4.8) can be reexpressed in the form

$$
-\frac{q^2}{\alpha^2}\frac{\mathcal{Q}'}{\mathcal{P}'} = \frac{1}{a_0}\ \frac{2b_1}{-a_1}\ \frac{b_2}{-a_2}\ -\cdots
$$

which is a q-analogue of Theorem B in §1. □

5. Ordinary cases $s = q^3, q^4, \ldots$. By substituting $s = q^m, m$ integer greater than 2, into (3.5) of Theorem 4 we obtain the following corollary.

COROLLARY 9. *For $s = q^m$, $m = 3, 4, \ldots$*

$$\frac{1}{a_0} \; \frac{b_1}{-a_1} \; \frac{b_2}{-a_2} \; -\cdots = \frac{q^{(m-3)/2}(1-q^{m-1})(1-\frac{a}{q})}{(1-\frac{q}{a}^{m-1})(1-\frac{a}{b})(1-\frac{a}{c})(1-\frac{a}{d})(1-\frac{a}{e})(1-\frac{a}{f})} \tag{5.1}$$

$$\times \left[\phi\Big(\frac{q}{a};\frac{q}{b},\frac{q}{c},\frac{q}{d},\frac{q}{e},\frac{q}{f},q^{-m+2},q\Big) - \frac{\widetilde{W}_2}{\widetilde{W}_1}\,\frac{(a)_\infty(aq)_\infty(q)_\infty}{(\frac{q^m}{a})_\infty(\frac{q^{m-1}}{a})_\infty(q^m)_\infty}\,\frac{1}{(1-q^{m-1})}\right.$$

$$\left.\times\,\frac{(\frac{b}{a}q^{m-1},\ \frac{c}{a}q^{m-1},\ \frac{d}{a}q^{m-1},\ \frac{e}{a}q^{m-1},\ \frac{f}{a}q^{m-1})_\infty}{(\frac{bq}{a},\ \frac{cq}{a},\ \frac{dq}{a},\ \frac{eq}{a},\ \frac{fq}{a})_\infty}\right],$$

where a_n, b_n are given by (2.7) *and* (2.8) *for $s = q^m$, $m \geq 3$.*

Note that if we substitute $s = q (m = 1)$ into (5.1) the right side reduces to

$$\frac{q}{a^2}\,\frac{\widetilde{W}_2}{\widetilde{W}_1}\,\frac{(\frac{a}{q})_\infty(aq)_\infty}{(\frac{1}{a})_\infty(\frac{1}{a})_\infty} \tag{5.2}$$

and (5.1) agrees with (4.5) when the indeterminacy in a_0 and b_1 is taken into account, that is,

$$\begin{aligned} \lim_{s\to q} a_0(s) &= \lim_{n\to 0} a_n(s=q), \\ \lim_{s\to q} b_1(s) &= 2\lim_{n\to 1} b_n(s=q). \end{aligned} \tag{5.3}$$

It is the a_0 and b_1 on the left side of (5.3) that should occur in (5.1) with $s = q$, whereas it is $\lim_{n\to 0} a_n(s=q)$ and $\lim_{n\to 1} b_n(s=q)$ that are the a_0 and b_1 that occur in (4.5).

Similarly, for $s = q^2$ the right side of (5.1) becomes

$$-\frac{a}{q^{\frac{3}{2}}}\,\frac{(1-q)}{(1-\frac{a}{b})(1-\frac{a}{c})(1-\frac{a}{d})(1-\frac{a}{e})(1-\frac{a}{f})}\left[1-\frac{(a)_\infty(aq)_\infty}{(\frac{q^2}{a})_\infty(\frac{q}{a})_\infty}\,\frac{\widetilde{W}_2}{\widetilde{W}_1}\right]. \tag{5.4}$$

This agrees with (4.1) since

$$\lim_{s\to q^2} a_0(s) = \lim_{n\to 0} a_n(s=q^2) + \frac{aq^{\frac{1}{2}}(1-\frac{b}{a})(1-\frac{c}{a})(1-\frac{d}{a})(1-\frac{e}{a})(1-\frac{f}{a})}{2(1-q)},$$

$$\lim_{s\to q^2} b_1(s) = \lim_{n\to 1} b_n(s=q^2).$$

We can also consider the terminating case of (5.1) by taking into account Lemma 6.

Remark 1. If in §2 we make the replacements $a \to \lambda a$, $b \to \lambda q/b$, $c \to \lambda q/c$, $d \to \lambda q/d$, $e \to ae^{i\theta}$, $f \to ae^{-i\theta}$, and let $\lambda \to \infty$, then we obtain solutions to the recurrence for Askey-Wilson polynomials [1] with $s = abcd = q^m$, $m = 1, 2, \ldots$ [7]. By applying the above limit to Corollaries 7, 8, and 9, we recover equations (22), (23), and (24), respectively, of Gupta and Masson [7]. Note that [7, eqs. (22) and (23)] give the q-analogue of Ramanujan's Entries 35 and 39 [3], [13], while Corollaries 7 and 8 are the q-analogues of Corollaries 6 and 7 of [15].

Remark 2. The Corollary 8 case $s = q$ is particularly interesting since the approximants of the continued fraction

$$\frac{1}{a_0} \; \frac{2b_1}{-a_1} \; \frac{b_2}{-a_2} \; -\cdots = \frac{q(aq)_\infty(\frac{a}{q})_\infty}{a^2(\frac{1}{a})_\infty(\frac{1}{a})_\infty} \frac{\widetilde{W}_2}{\widetilde{W}_1}$$

are then given explicitly in terms of $X_n^{(1)}$ and $X_n^{(2)}$. To see this we note that the initial conditions

$$\begin{aligned} 2X_1^{(1)} - a_0 X_0^{(1)} &= 0 \\ X_2^{(2)} - a_1 X_1^{(2)} &= 0 \end{aligned}$$

which follow from (2.7), (2.8), (2.9) and (2.12) when $s = q$, together with the recurrence (2.6), imply that for $s = q$

$$\frac{1}{a_0} \; \frac{2b_1}{-a_1} \; \frac{b_2}{-a_2} \; -\cdots - \frac{b_n}{a_n} = \frac{X_{n+1}^{(2)} X_0^{(1)}}{2X_{n+1}^{(1)} X_1^{(2)}}, \qquad n \geq 0 .$$

Remark 3. In the limit as $m \to \infty$ ($s = q^m \to 0$) Corollary 9 yields a new continued fraction result given by

$$\begin{aligned} \frac{1}{c_0} \; \frac{d_1}{-c_1} \; \frac{d_2}{-c_2} \; -\cdots &= \frac{(1-\frac{a}{q})}{q(1-\frac{a}{b})(1-\frac{a}{c})(1-\frac{a}{d})(1-\frac{a}{e})} \\ &\times \left[W\left(\frac{q}{a}; \frac{q}{b}, \frac{q}{c}, \frac{q}{d}, \frac{q}{e}, q\right) - R \right], \end{aligned} \tag{5.5}$$

$$\begin{aligned} R = \frac{(q, a, \frac{q^2}{a}, \frac{de}{a}, \frac{dc}{a}, \frac{ec}{a})_\infty}{(\frac{dq}{a}, \frac{eq}{a}, \frac{cq}{a}, \frac{dec}{aq}, \frac{aq}{b}, b)_\infty} \\ \times \left\{ {}_3\phi_2\left(\begin{matrix} \frac{q}{d}, \frac{q}{e}, \frac{q}{c} \\ q\frac{b}{a}, \frac{q^2 a}{cde} \end{matrix} ; q, b \right) + \frac{(\frac{q}{d}, \frac{q}{e}, \frac{q}{c}, \frac{bcde}{a^2}, \frac{aq}{b}, \frac{b}{a}, \frac{cde}{a^2}, \frac{a^2 q}{cde}, \frac{dec}{aq})_\infty}{(\frac{ec}{a}, \frac{qb}{a}, \frac{qa}{cde}, \frac{q}{a}, a, \frac{bcde}{qa^2}, \frac{a^2 q^2}{bcde}, \frac{de}{a}, \frac{dc}{a})_\infty} \right. \\ \left. \times {}_3\phi_2\left(\begin{matrix} \frac{de}{a}, \frac{dc}{a}, \frac{ec}{a} \\ \frac{bcde}{a^2}, \frac{dec}{a} \end{matrix} ; q, b \right) \right\} \Bigg/ {}_3\phi_2\left(\begin{matrix} \frac{aq}{bc}, \frac{aq}{bd}, \frac{aq}{be} \\ \frac{aq}{b}, \frac{a^2 q^2}{bcde} \end{matrix} ; q, b \right), \end{aligned}$$

where

$$\begin{aligned} c_n = \Bigg[&- \left(1 - \frac{a}{b}q^{n+1}\right)\left(1 - \frac{a}{c}q^{n+1}\right)\left(1 - \frac{a}{d}q^{n+1}\right)\left(1 - \frac{a}{e}q^{n+1}\right) \\ &- q(1-q^n)(1-aq^n)(1-aq^{n+1})\left(1 - \frac{a^2 q^{n+1}}{bcde}\right) \\ &+ a^2 q^{2n+2} \frac{(1-b)(1-c)(1-d)(1-e)}{bcde} \Bigg] \Big/ (1 - aq^{n+1}), \end{aligned} \tag{5.6}$$

$$d_n = q(1-q^n)\left(1 - \frac{a}{b}q^n\right)\left(1 - \frac{a}{c}q^n\right)\left(1 - \frac{a}{d}q^n\right)\left(1 - \frac{a}{e}q^n\right)\left(1 - \frac{a^2 q^{n+1}}{bcde}\right).$$

A direct proof is obtained by applying our methods to the contiguous relation

$$
\begin{aligned}
&q\left(1-\frac{1}{f}\right)\left(1-\frac{a^2q}{bcdef}\right)\left(1-\frac{a}{f}\right)\left(1-\frac{aq}{f}\right)[W(f+)-W] \\
&+\left(1-\frac{aq}{fb}\right)\left(1-\frac{aq}{fc}\right)\left(1-\frac{aq}{fd}\right)\left(1-\frac{aq}{fe}\right)[W(f-)-W] \\
&+\frac{a^2q^2}{bcdef^2}(1-b)(1-c)(1-d)(1-e)W=0,
\end{aligned} \tag{5.7}
$$

where

$$
\begin{aligned}
W &= W(a;\ b,c,d,e,f) \\
&= {}_8\phi_7\left(\begin{matrix} a, q\sqrt{a}, -q\sqrt{a}, b, c, d, e, f \\ \sqrt{a}, -\sqrt{a}, \frac{aq}{b}, \frac{aq}{c}, \frac{aq}{d}, \frac{aq}{e}, \frac{aq}{f} \end{matrix}\ ;\ q, \frac{a^2q^2}{bcdef}\right).
\end{aligned} \tag{5.8}
$$

The contiguous relation (5.7) is obtained from (2.5) by taking the limit $g \to 0$ with $fg = a^3q^2/(bcdeh)$ and then replacing $h = q^{-n}$ by f. However, the termination of the preceding ${}_8\phi_7$ is not necessary.

SOME q-BETA INTEGRALS ON $SU(n)$ AND $Sp(n)$ THAT GENERALIZE THE ASKEY–WILSON AND NASRALLAH–RAHMAN INTEGRALS*

ROBERT A. GUSTAFSON†

Abstract. $SU(n)$ and $Sp(n)$ generalizations of a q-beta integral of Nasrallah–Rahman are evaluated. Selberg's beta integral can be deduced as a special limiting case of the $Sp(n)$ integral. Extensions of the q-Macdonald–Morris constant term identities for the affine root systems of types $S(BC_n)$, $S(B_n)$, $S(B_n)^v$, $S(C_n)$, $SC(C_n)^v$, and $S(D_n)$ can also be obtained from the $Sp(n)$ integral. There are some additional integral evaluations for $Sp(2)$ and $Sp(3)$.

Key words. multivariate beta integrals, q-beta integrals, Selberg's beta integral, Macdonald–Morris conjecture

AMS subject classifications. 33A15, 33A30, 33A65, 33A75

1. Introduction.

Askey and Wilson [1] evaluated an important integral associated to a family of orthogonal polynomials in five parameters. This integral can be viewed as a q-analog of the classical beta integral. Later, Nasrallah and Rahman [8] and Rahman [9] extended the Askey–Wilson integral by introducing an additional parameter.

Let q be a real number, $0 < q < 1$. For any complex number c define

$$[c]_\infty = [c;q]_\infty = \prod_{k=0}^{\infty}(1 - cq^k).$$

THEOREM 1.1 (Nasrallah–Rahman). *Let $a_i \in \mathbb{C}$, $1 \le i \le 5$, with $|a_i| < 1$. Then*

$$(1.2)\quad \frac{1}{2\pi i}\int_T \frac{\left[z\prod_{i=1}^{5}a_i\right]_\infty \left[z^{-1}\prod_{i=1}^{5}a_i\right]_\infty [z^2]_\infty [z^{-2}]_\infty}{\prod_{i=1}^{5}[a_i z]_\infty [a_i z^{-1}]_\infty}\,\frac{dz}{z} = \frac{2\prod_{k=1}^{5}\left[\prod_{\substack{i=1\\ i\neq k}}^{5}a_i\right]_\infty}{[q]_\infty \prod_{1\le i<j\le 5}[a_i a_j]_\infty},$$

where the unit circle T is taken in the positive direction.

Setting $a_5 = 0$ in (1.2), the identity (1.2) reduces to the Askey–Wilson integral.

In this paper we evaluate integrals associated to the groups $Sp(n)$ and $SU(n)$, which generalize the Nasrallah–Rahman integral. In the $Sp(n)$ case the integrals also generalize the Selberg beta integral [10] (see also [2]) and the Askey–Wilson q-Selberg integral of [2]. In the $SU(n)$ case the integral does not generalize the Selberg beta integral but gives a new kind of $SU(n)$ relative of the $Sp(n)$ q-beta integral. In §4 of this paper some integrals particular to $Sp(2)$ and $Sp(3)$ are also evaluated by a method similar to the general $Sp(n)$ integral evaluation.

There is a theory of multivariate basic hypergeometric series corresponding to the integrals in this paper. If we let the parameter q tend to 1 (at least formally), there are also corresponding multivariate Mellin–Barnes-type integrals and ordinary hypergeometric series. These topics are developed in [5].

Finally, we mention that in the $Sp(n)$ integrals (2.2) that follow the parameters can be specialized to obtain new extensions of the q-Macdonald–Morris constant-term conjectures [6], [7] for the infinite families of affine root systems of types $S(BC_n)$, $S(B_n)$, $S(B_n)^v$, $S(C_n)$, $S(C_n)^v$, and $S(D_n)$, where $n \geq 1$ (when defined) and for arbitrary parameter q. As an illustration of this extension consider the affine root system of type $S(B_n)$ for $n > 1$. Setting $a_3 = -1$, $a_4 = q^{1/2}$, $a_5 = -q^{1/2}$ in (2.2) and using $[c^2]_\infty = [c]_\infty[-c]_\infty[q^{1/2}c]_\infty[-q^{1/2}c]_\infty$ for $c \in \mathbb{C}$, one obtains

$$\begin{aligned}
&\frac{1}{(2\pi i)^n}\int_{T^n}\prod_{1\leq j<k\leq n}\frac{[t_jt_k^{-1}]_\infty[t_j^{-1}t_k]_\infty[t_jt_k]_\infty[t_j^{-1}t_j^{-1}]_\infty}{[bt_jt_k^{-1}]_\infty[bt_j^{-1}t_k]_\infty[bt_jt_k]_\infty[bt_j^{-1}t_k^{-1}]_\infty}\\
&\qquad\cdot\prod_{j=1}^{n}\frac{[t_j]_\infty[t_j^{-1}]_\infty[a_1a_2b^{2n-2}qt_j]_\infty[a_1a_2b^{2n-2}qt_j^{-1}]_\infty}{t_j\prod_{k=1}^{2}[a_kt_j]_\infty[a_kt_j^{-1}]_\infty}dt_j\\
&\qquad=2^nn!\prod_{j=1}^{n}\left\{\frac{[b]_\infty[b^{2n+2j-4}qa_1^2a_2^2]_\infty[qb^{j-1}]_\infty}{[b^j]_\infty[q]_\infty[b^{n+j-2}qa_1a_2]_\infty[a_1a_2b^{j-1}]_\infty[qb^{2j-2}]_\infty}\right.\\
&\qquad\qquad\left.\cdot\prod_{k=1}^{2}\frac{[b^{n+j-2}qa_k]_\infty[a_kb^{j-1}]_\infty}{[a_k^2b^{2j-2}]_\infty}\right\},
\end{aligned}\tag{1.3}$$

where a_1, a_2, $b \in \mathbb{C}$, $\max\{|a_1|, |a_2|, |b|\} < 1$, and T^n is the n-fold direct product of the unit circle traversed in the positive direction. If we set $a_2 = 0$, (1.3) reduces to an identity that is equivalent to the q-Macdonald–Morris constant-term conjecture for B_n (see [2]).

2. A q-beta integral on $Sp(n)$. We give an extension of the q-Selberg integral evaluated in [2]. In the one-dimensional case this reduces to an integral evaluated by Nasrallah and Rahman [8], [9]. The proof of this integral identity is similar to that in [2].

THEOREM 2.1. *Let $n \geq 1$ and $a_1, \ldots, a_5, b, q \in \mathbb{C}$ with $\max\{|a_1|, \ldots, |a_5|, |b|, |q|\} < 1$. Set $A = \prod_{i=1}^{5} a_i$. If T^n is the n-fold direct product of the unit circle $\{t \in \mathbb{C} \mid |t| = 1\}$ traversed in the positive direction, then we have*

$$\begin{aligned}
&\frac{1}{(2\pi i)^n}\int_{T^n}\prod_{1\leq j<k\leq n}\frac{[t_jt_k^{-1}]_\infty[t_j^{-1}t_k]_\infty[t_jt_k]_\infty[t_j^{-1}t_k^{-1}]_\infty}{[bt_jt_k^{-1}]_\infty[bt_j^{-1}t_k]_\infty[bt_jt_k]_\infty[bt_j^{-1}t_k^{-1}]_\infty}\\
&\qquad\cdot\prod_{j=1}^{n}\frac{[t_j^2]_\infty[t_j^{-2}]_\infty[Ab^{2n-2}t_j]_\infty[Ab^{2n-2}t_j^{-1}]_\infty}{\prod_{k=1}^{5}\{[a_kt_j]_\infty[a_kt_j^{-1}]_\infty\}t_j}dt_j\\
&\qquad=2^nn!\prod_{j=1}^{n}\frac{[b]_\infty\prod_{i=1}^{5}[b^{n+j-2}Aa_i^{-1}]_\infty}{[b^j]_\infty[q]_\infty\prod_{1\leq k<\ell\leq 5}[a_ka_\ell b^{j-1}]_\infty}.
\end{aligned}\tag{2.2}$$

Proof. Since the $n = 1$ case of (2.2) is proved in [9], we may assume that $n \geq 2$. Denote the integral on the left-hand side of (2.2) by $I_n(a_1, \ldots, a_5; b; q)$. Let $c_j \in \mathbb{C}$,

$|c_j| < 1$, for $1 \le j \le 2n+3$. Set $C = \prod_{j=1}^{2n+3} c_j$. In [3, Thm. 4.1] we have evaluated the integral

$$\frac{1}{(2\pi i)^n}\int_{T^n} \frac{\prod_{1\le j<k\le n}\{[t_jt_k^{-1}]_\infty[t_j^{-1}t_k]_\infty[t_jt_k]_\infty[t_j^{-1}t_k^{-1}]_\infty\}}{\prod_{i=1}^{2n+3}\prod_{j=1}^{n}[c_it_j]_\infty[c_it_j^{-1}]_\infty}$$

$$\cdot \prod_{j=1}^{n}\left\{[z_j^2]_\infty[z_j^{-2}]_\infty[Cz_j]_\infty[Cz_j^{-1}]_\infty\frac{dz_j}{z_j}\right\} \tag{2.3}$$

$$= \frac{2^n n!\prod_{i=1}^{2n+3}[Cc_i^{-1}]_\infty}{[q]_\infty^n \prod_{1\le j<k\le 2n+3}[c_jc_k]_\infty}.$$

With notation as in the preceding, consider the integral

(2.4)

$$\frac{1}{(2\pi i)^{2n-1}}\int_{T^n}\int_{T^{n-1}} \frac{\prod_{1\le j<k\le n}\{[t_jt_k^{-1}]_\infty[t_j^{-1}t_k]_\infty[t_jt_k]_\infty[t_j^{-1}t_k^{-1}]_\infty\}}{\prod_{j=1}^{n}\prod_{k=1}^{5}[a_kt_j]_\infty[a_kt_j^{-1}]_\infty}$$

$$\cdot \frac{\prod_{j=1}^{n}[t_j^2]_\infty[t_j^{-2}]_\infty \prod_{1\le j<k\le n-1}\{[s_js_k^{-1}]_\infty[s_j^{-1}s_k]_\infty[s_js_k]_\infty[s_j^{-1}s_k^{-1}]_\infty\}}{\prod_{j=1}^{n}\prod_{k=1}^{n-1}\{[b^{1/2}s_kt_j]_\infty[b^{1/2}s_k^{-1}t_j]_\infty[b^{1/2}s_kt_j^{-1}]_\infty[b^{1/2}s_k^{-1}t_j^{-1}]_\infty\}}$$

$$\cdot \prod_{k=1}^{n-1}\frac{[s_k^2]_\infty[s_k^{-2}]_\infty\left[s_kb^{2n-3/2}\prod_{i=1}^{5}a_i\right]_\infty\left[s_k^{-1}b^{2n-3/2}\prod_{i=1}^{5}a_i\right]_\infty}{\left[s_kb^{n-3/2}\prod_{i=1}^{t}a_i\right]_\infty\left[s_k^{-1}b^{n-3/2}\prod_{i=1}^{5}a_i\right]_\infty}\frac{ds_k}{s_k}$$

$$\cdot \prod_{j=1}^{n}\frac{\left[t_jb^{n-1}\prod_{i=1}^{5}a_i\right]_\infty\left[t_j^{-1}b^{n-1}\prod_{i=1}^{5}a_i\right]_\infty}{t_j}dt_j,$$

where $b^{1/2}$ is any fixed square root of b. In the integral (2.4) we may use identity (2.3) to evaluate the interior integral either with respect to the set of variables $\{s_1,\dots,s_{n-1}\}$ or, by changing the order of integration, with respect to the set of variables $\{t_1,\dots,t_n\}$. Equating the resulting integrals, we obtain

$$2^{n-1}(n-1)!\frac{[b^n]_\infty}{[q]_\infty^{n-1}[b]_\infty^n}I_n(a_1,\dots,a_5;b;q)$$

$$= \frac{2^n n!\prod_{i=1}^{5}[b^{n-1}Aa_i^{-1}]_\infty}{[q]_\infty^{n-1}[b]_\infty^{n-1}\prod_{1\le j<k\le 5}[a_ja_k]_\infty}I_{n-1}(a_1b^{1/2},\dots,a_5b^{1/2};b;q). \tag{2.5}$$

We finish the proof of identity (2.2) by doing induction on n, using identity (2.5) and the Nasrallah–Rahman integral for the case $n = 1$. □

3. An analogous q-beta integral on $SU(n)$. We evaluate an $SU(n)$ integral that is analogous to the $Sp(n)$ integral in (2.2). Actually, the $SU(n)$ integral evaluation is slightly different for even n and for odd n, $n > 1$. In the one-dimensional ($SU(2)$) case this integral reduces to the Nasrallah–Rahman integral [8], [9]. In the $SU(3)$ case the integral reduces to one evaluated in [3, Thm. 2.1] (see also [4]).

THEOREM 3.1. *Let $n \ge 1$ and $a, b, c_1, c_2, c_3, d_1, d_2 \in \mathbb{C}$, with $\max\{|a|, |b|, |c_1|, |c_2|, |c_3|, |d_1|, |d_2|, |q|\} < 1$. Then*

(3.2a)

$$\frac{1}{(2\pi i)^{2n-1}}\int_{T^{2n-1}}\frac{\prod_{\substack{i,j=1\\ i\ne j}}^{2n}[z_iz_j^{-1}]_\infty\prod_{j=1}^{2n}\left[z_j(ab)^{2n-2}\prod_{i=1}^{3}c_i\prod_{k=1}^{2}d_k\right]_\infty}{\prod_{1\le i<j\le 2n}[az_iz_j]_\infty[bz_i^{-1}z_j^{-1}]_\infty\prod_{j=1}^{2n}\left\{\prod_{i=1}^{3}[c_iz_j]_\infty\prod_{k=1}^{2}[d_kz_j^{-1}]_\infty\right\}}$$

$$\cdot\frac{dz_1}{z_1}\cdots\frac{dz_{2n-1}}{z_{2n-1}}$$

$$= \frac{(2n)!\prod_{j=1}^{2}\left[a^{2n-2}b^{n-1}d_j\prod_{i=1}^{2}c_i\right]_\infty}{[q]_\infty^{2n-1}[b^{n-1}d_1d_2]_\infty\prod_{1\le i<j\le 3}[a^{n-1}c_ic_j]_\infty[a^n]_\infty[b^n]_\infty}$$

$$\cdot\prod_{j=1}^{n}\left\{\frac{\prod_{1\le i<k\le 3}[(ab)^{n+j-2}c_ic_kd_1d_2]_\infty}{\prod_{i=1}^{3}\prod_{k=1}^{2}[(ab)^{j-1}c_id_k]_\infty}\right\}$$

$$\cdot\prod_{j=1}^{n-1}\left\{\frac{\prod_{k=1}^{2}\left[a^{n+j-2}b^{n+j-1}d_k\prod_{i=1}^{3}c_i\right]_\infty}{[(ab)^j]_\infty[a^jb^{j-1}d_1d_2]_\infty\prod_{1\le i<k\le 3}[a^{j-1}b^jc_ic_k]_\infty}\right\},$$

where $\prod_{j=1}^{2n} z_j = 1$ *and the integral in each variable* $z_1, \dots, z_{2n-1}$ *is over the unit circle* T *taken in the positive direction. We also have*

(3.2b)

$$\frac{1}{(2\pi i)^{2n}} \int_{T^{2n}} \frac{\prod_{\substack{i,j=1 \\ i\neq j}}^{2n+1} [z_i z_j^{-1}]_\infty \prod_{j=1}^{2n+1} \left[z_j (ab)^{2n-1} \prod_{i=1}^{3} c_i \prod_{k=1}^{2} d_k \right]_\infty}{\prod_{1\le i<j\le 2n+1} [a z_i z_j]_\infty [b z_i^{-1} z_j^{-1}]_\infty \prod_{j=1}^{2n+1} \left\{ \prod_{i=1}^{3} [c_i z_j]_\infty \prod_{k=1}^{2} [d_k z_j^{-1}]_\infty \right\}} \cdot \frac{dz_1}{z_1} \cdots \frac{dz_{2n}}{z_{2n}}$$

$$= \frac{(2n+1)! \left[a^{2n-1} b^{n-1} \prod_{i=1}^{3} c_i \prod_{k=1}^{2} d_k \right]_\infty \left[a^{2n-1} b^n \prod_{i=1}^{3} c_i \right]_\infty}{[q]_\infty^{2n} \prod_{i=1}^{3} [a^n c_i]_\infty \prod_{k=1}^{2} [b^n d_k]_\infty \left[a^{n-1} \prod_{i=1}^{3} c_i \right]_\infty}$$

$$\cdot \prod_{j=1}^{n} \left\{ \frac{\prod_{k=1}^{2} \left[a^{n+j-2} b^{n+j-1} d_k \prod_{i=1}^{3} c_i \right]_\infty \prod_{i\le i<k\le 3} [(ab)^{n+j-1} c_i c_k d_1 d_2]_\infty}{[(ab)^j]_\infty [a^j b^{j-1} d_1 d_2]_\infty \prod_{i\le i<k\le 3} [a^{j-1} b^j c_i c_k]_\infty \prod_{i=1}^{3} \prod_{k=1}^{2} [(ab)^{j-1} c_i d_k]_\infty} \right\},$$

where $\prod_{j=1}^{2n+1} z_j = 1$ *and the integral in each variable* $z_1, \dots, z_{2n}$ *is over the unit circle in the positive direction.*

Proof of (3.2a). Since the $n = 1$ case of (3.2a) is proved in [9], we may assume that $n \ge 2$. Let $a_i, b_j \in \mathbb{C}$, $|a_i|, |b_j| < 1$, for $1 \le i \le n$ and $1 \le j \le n+1$. Set $A = \prod_{i=1}^{n} a_i$ and $B = \prod_{j=1}^{n+1} b_j$. Then in [3, Thm. 2.1] we have evaluated the integral

$$\frac{1}{(2\pi i)^{n-1}} \int_{T^{n-1}} \frac{\prod_{k=1}^{n} [ABz_k]_\infty \prod_{\substack{i,j=1 \\ i\neq j}}^{n} [z_i z_j^{-1}]_\infty}{\prod_{k=1}^{n} \left\{ \prod_{i=1}^{n} [a_i z_k^{-1}]_\infty \prod_{j=1}^{n+1} [b_j z_k]_\infty \right\}} \frac{dz_1}{z_1} \cdots \frac{dz_{n-1}}{z_{n-1}}$$

(3.3)

$$= \frac{n! \prod_{j=1}^{n+1} [b_j^{-1} AB]_\infty \prod_{i=1}^{n} [a_i B]_\infty}{[q]_\infty^{n-1} [A]_\infty \prod_{j=1}^{n+1} [b_j^{-1} B]_\infty \prod_{i=1}^{n} \prod_{j=1}^{n+1} [a_i b_i]_\infty},$$

where $\prod_{k=1}^{n} z_k = 1$. With notation as in the preceding, consider the integral

(3.4)

$$\frac{1}{(2\pi i)^{4n-1}}\int_{T^{2n-1}}\int_{T^n}\int_{T^n}\frac{\prod_{\substack{i,j=1\\ i\neq j}}^{2n}[z_iz_j^{-1}]_\infty\prod_{1\le i<j\le n}\{[t_it_j]_\infty[t_it_j^{-1}]_\infty}{\prod_{i=1}^{2n}\prod_{j=1}^{n}\{[a^{1/2}z_it_j]_\infty[a^{1/2}z_it_j^{-1}]_\infty}$$

$$\cdot\frac{[t_i^{-1}t_j]_\infty[t_i^{-1}t_j^{-1}]_\infty[s_is_j]_\infty[s_is_j^{-1}]_\infty[s_i^{-1}s_j]_\infty[s_i^{-1}s_j^{-1}]_\infty\}}{[b^{1/2}z_i^{-1}s_j]_\infty[b^{1/2}z_i^{-1}s_j^{-1}]_\infty\}}$$

$$\cdot\prod_{i=1}^{2n}\frac{\left[z_i(ab)^{2n-2}d_1d_2\prod_{k=1}^{3}c_k\right]_\infty}{\left[z_i(ab)^{n-2}d_1d_2\prod_{k=1}^{3}c_k\right]_\infty}$$

$$\cdot\prod_{j=1}^{n}\left\{\frac{\left[t_ja^{n-3/2}\prod_{k=1}^{3}c_k\right]_\infty}{\prod_{k=1}^{3}[a^{-1/2}c_kt_j]_\infty[a^{-1/2}c_kt_j^{-1}]_\infty}\right.$$

$$\cdot\frac{\left[t_j^{-1}a^{n-3/2}\prod_{k=1}^{3}c_k\right]_\infty\left[s_ja^{n-2}b^{n-3/2}d_1d_2\prod_{k=1}^{3}c_k\right]_\infty}{\left[s_ja^{n-2}b^{-1/2}\prod_{k=1}^{3}c_k\right]_\infty\left[s_j^{-1}a^{n-2}b^{-1/2}\prod_{k=1}^{3}c_k\right]_\infty}$$

$$\left.\cdot\frac{\left[s_j^{-1}a^{n-2}b^{n-3/2}d_1d_2\prod_{k=1}^{3}c_k\right]_\infty[t_j^2]_\infty[t_j^{-2}]_\infty[s_j^2]_\infty[s_j^{-2}]_\infty}{\prod_{i=1}^{2}[b^{-1/2}d_is_j]_\infty[b^{-1/2}d_is_j^{-1}]_\infty}\right\}\frac{dt_jds_j}{t_js_j}\frac{dz_1}{z_1}\cdots\frac{dz_{2n-1}}{z_{2n-1}},$$

where $\prod_{j=1}^{2n}z_j=1$ and $a^{1/2}$, $b^{1/2}$ are any fixed square roots of a, b, respectively. Applying identity (2.3) twice, we evaluate the interior integrals in (3.4) by first integrating

with respect to the set of variables $\{t_1,\dots,t_n\}$ and then integrating with respect to the variables $\{s_1,\dots,s_n\}$. The resulting integral in the variables $\{z_1,\dots,z_{2n-1}\}$ is, up to factors independent of $\{z_1,\dots,z_{2n-1}\}$, just the integral on the left-hand side of (3.2a). On the other hand, by reversing the order of integration we may evaluate (3.4) by applying identity (3.3) to first integrate with respect to the variables $\{z_1,\dots,z_{2n-1}\}$, then applying (2.3) to integrate with respect to the variables $\{s_1,\dots,s_n\}$, and finally applying (2.2) to integrate with respect to the variables $\{t_1,\dots,t_n\}$. The resulting identity is (3.2a). This completes the proof of (3.2a). □

Proof of (3.2b). The proof of identity (3.2b) is entirely similar to that of (3.2a). The only difference is that, instead of the integral (3.4), we consider the integral

(3.5)

$$\frac{1}{(2\pi i)^{4n}}\int_{T^{2n}}\int_{T^n}\int_{T^n}\frac{\displaystyle\prod_{\substack{i,j=1\\ i\neq j}}^{2n+1}[z_iz_j^{-1}]_\infty\prod_{1\le i<j\le n}\{[t_it_j]_\infty[t_it_j^{-1}]_\infty}{\displaystyle\prod_{i=1}^{2n+1}\prod_{j=1}^{n}\{[a^{1/2}z_it_j]_\infty[a^{1/2}z_it_j^{-1}]_\infty}$$

$$\cdot\frac{[t_i^{-1}t_j]_\infty[t_i^{-1}t_j^{-1}]_\infty[s_is_j]_\infty[s_is_j^{-1}]_\infty[s_i^{-1}s_j]_\infty[s_i^{-1}s_j^{-1}]_\infty\}}{[b^{1/2}z_i^{-1}s_j]_\infty[b^{1/2}z_i^{-1}s_j^{-1}]_\infty\}}$$

$$\cdot\prod_{i=1}^{2n+1}\frac{\left[z_j(ab)^{2n-1}d_1d_2\displaystyle\prod_{k=1}^{3}c_k\right]_\infty}{[c_3z_j]_\infty[b^{n-1}d_1d_2z_j]_\infty[a^{n-1}c_1c_2z_j^{-1}]_\infty}$$

$$\cdot\prod_{j=1}^{n}\left\{\frac{[a^nc_1c_2t_j]_\infty[a^nc_1c_2t_j^{-1}]_\infty[b^nd_1d_2s_j]_\infty[b^nd_1d_2s_j^{-1}]_\infty}{\displaystyle\prod_{k=1}^{2}([a^{-1/2}c_kt_j]_\infty[a^{-1/2}c_kt_j^{-1}]_\infty[b^{-1/2}d_ks_j]_\infty[b^{-1/2}d_ks_j^{-1}]_\infty)}\right.$$

$$\left.\cdot\,[t_j^2]_\infty[t_j^{-2}]_\infty[s_j^2]_\infty[s_j^{-2}]_\infty\frac{dt_j}{t_j}\,\frac{ds_j}{s_j}\right\}\frac{dz_1}{z_1}\cdots\frac{dz_{2n}}{z_{2n}},$$

where $\prod_{j=1}^{2n+1}z_j=1$ and the notation is as for (3.4). □

4. Some q-beta integrals on $Sp(2)$ and $Sp(3)$. In $Sp(2)$ and $Sp(3)$ we can evaluate some integrals related to (2.2) that do not generalize to $Sp(n)$. The proofs involve substituting variables in place of the parameters $a_1,\dots,a_4$ in (2.2) and integrating by using Fubini's theorem.

THEOREM 4.1. *With notation as in Theorem* 2.1, *let* $a_1,a_2,b_1,b_2,q\in\mathbb{C}$, *with* $\max\{|a_1|,|a_2|,|b_1|,|b_2|,|q|\}<1$. *Then we have*

$$\frac{1}{(2\pi i)^2}\int_{T^2}\frac{[t_1t_2^{-1}]_\infty[t_1^{-1}t_2]_\infty[t_1t_2]_\infty[t_1^{-1}t_2^{-1}]_\infty}{\prod_{k=1}^{2}[b_kt_1t_2^{-1}]_\infty[b_kt_1^{-1}t_2]_\infty[b_kt_1t_2]_\infty[b_kt_1^{-1}t_2^{-1}]_\infty}$$

$$\cdot\prod_{j=1}^{2}\frac{[t_j^2]_\infty[t_j^{-2}]_\infty dt_j}{\prod_{k=1}^{2}[a_kt_j]_\infty[a_kt_j^{-1}]_\infty t_j} \tag{4.2}$$

$$=\frac{8[(a_1a_2b_1b_2)^2]_\infty[b_1]_\infty[b_2]_\infty}{[q]_\infty^2[a_1a_2]_\infty[b_1b_2]_\infty[a_1a_2b_1b_2]_\infty\prod_{k=1}^{2}[a_k^2b_1b_2]_\infty[a_1a_2b_k]_\infty[b_k^2]_\infty}.$$

Proof. Consider the integral on the left-hand side of (2.2) for $n=2$. Let $a_5=0$, $a_3=b_2^{1/2}z$, $a_4=b_2^{1/2}z^{-1}$, and $b=b_1$. Multiply the integral by $[z^2]_\infty[z^{-2}]_\infty/z$, and integrate with respect to z along the unit circle traversed in the positive direction. We obtain the integral

(4.3)

$$\frac{1}{(2\pi i)^3}\int_T\int_{T^2}\frac{[t_1t_2^{-1}]_\infty[t_1^{-1}t_2]_\infty[t_1t_2]_\infty[t_1^{-1}t_2^{-1}]_\infty}{[b_1t_1t_2^{-1}]_\infty[b_1t_1^{-1}t_2]_\infty[b_1t_1t_2]_\infty[b_1t_1^{-1}t_2^{-1}]_\infty}$$

$$\cdot\prod_{j=1}^{2}\frac{[t_j^2]_\infty[t_j^{-2}]_\infty dt_j}{[b_2^{1/2}zt_j]_\infty[b_2^{1/2}zt_j^{-1}]_\infty[b_2^{1/2}z^{-1}t_j]_\infty[b_2^{1/2}zt_j^{-1}]_\infty\prod_{k=1}^{2}([a_kt_j]_\infty[a_kt_j^{-1}]_\infty)t_j}$$

$$\cdot\frac{[z^2]_\infty[z^{-2}]_\infty}{z}dz.$$

Use identity (2.2) to evaluate the integral (4.3) with respect to the variables t_1 and t_2 first, and then use (2.2) (the Askey–Wilson integral) again to integrate with respect to z. Now reverse the order of integration, and evaluate the integral (4.3) with respect to z first. The resulting identity is (4.2). □

THEOREM 4.4. *With notation as in the preceding, let* $b_1,b_2,b_3,q\in\mathbb{C}$, *with* $\max\{|b_1|,|b_2|,|b_3|,|q|\}<1$. *Then we have*

$$\frac{1}{(2\pi i)^2}\int_{T^2}\frac{[t_1t_2^{-1}]_\infty[t_1^{-1}t_2]_\infty[t_1t_2]_\infty[t_1^{-1}t_2^{-1}]_\infty}{\prod_{k=1}^{3}[b_kt_1t_2^{-1}]_\infty[b_kt_1^{-1}t_2]_\infty[b_kt_1t_2]_\infty[b_kt_1^{-1}t_2^{-1}]_\infty}\prod_{j=1}^{2}\frac{[t_j^2]_\infty[t_j^{-2}]_\infty dt_j}{t_j}$$

$$=\frac{8[qb_1b_2b_3]_\infty}{[q]_\infty^2\prod_{1\le j<k\le 3}[b_jb_k]_\infty}\cdot\prod_{j=1}^{3}\frac{[b_j]_\infty}{[b_j^2]_\infty}. \tag{4.5}$$

Proof. Set $a_1 = b_3^{1/2}z$ and $a_2 = b_3^{1/2}z^{-1}$ in the integral on the left-hand side of (4.2). Multiply the resulting integral by $[z^2]_\infty[z^{-2}]_\infty/z$, and integrate with respect to z along the contour T. Just as before, using (4.2) and (2.2) to evaluate the integrals and reversing the order of integration, we obtain identity (4.5). □

THEOREM 4.6. *With notation as in Theorem* 2.1, *let* $b_1, b_2, q \in \mathbb{C}$ *with* $\max\{|b_1|, |b_2|, |q|\} < 1$. *We have*

(4.7)

$$\frac{1}{(2\pi i)^3}\int_{T^3}\prod_{1\le j<k\le 3}\frac{[t_jt_k^{-1}]_\infty[t_j^{-1}t_k]_\infty[t_jt_k]_\infty[t_j^{-1}t_k^{-1}]_\infty}{\prod_{\ell=1}^{2}[b_\ell t_jt_k^{-1}]_\infty[b_\ell t_j^{-1}t_k]_\infty[b_\ell t_jt_k]_\infty[b_\ell t_j^{-1}t_k^{-1}]_\infty}\prod_{j=1}^{3}\frac{[t_j^2]_\infty[t_j^{-2}]_\infty dt_j}{t_j}$$

$$= 3!2^3\frac{[qb_1^3b_2^3]_\infty}{[b_1b_2]_\infty[b_1b_2^2]_\infty[b_1^2b_2]_\infty[b_1^2b_2^2]_\infty}\prod_{j=1}^{3}\frac{[b_1]_\infty[b_2]_\infty}{[q]_\infty[b_1^j]_\infty[b_2^j]_\infty}.$$

Proof. Set $a_1 = b_2^{1/2}u_1$, $a_2 = b_2^{1/2}u_2$, $a_3 = b_2^{1/2}u_1^{-1}$, $a_4 = b_2^{1/2}u_2^{-1}$, and $a_5 = 0$ in (2.2). Multiply by $[u_1u_2^{-1}]_\infty[u_1^{-1}u_2]_\infty[u_1u_2]_\infty[u_1^{-1}u_2^{-1}]_\infty\prod_{j=1}^{2}[u_j^2]_\infty[u_j^{-2}]_\infty du_j/u_j$, and integrate with respect to the variables u_1 and u_2 along T^2. Using (4.5) and (2.2) to evaluate the integrals and reversing the order of integration, we obtain identity (4.7). □

ON THE STRUVE TRANSFORMATION*

P. HEYWOOD† AND P. G. ROONEY‡

Abstract. The Struve or $\mathcal{H}_\nu$ transformation is defined for suitable functions f by

$$(\mathcal{H}_\nu f)(x) = \int_0^\infty (xt)^{1/2}\mathbb{H}_\nu(xt)f(t)dt,$$

where $\mathbb{H}_\nu$ is the Struve function. It is known to be bounded on weighted L_p spaces with weights $t^{p\mu-1}$ if $1 \le p < \infty$, $\mu \ge \gamma(p)$, and $\nu+\frac{1}{2} < \mu < \nu+\frac{5}{2}$. Inversion formulas have been given for $\mathcal{H}_\nu$ but with the added restriction that $\mu > -(\nu+\frac{1}{2})$. Here inversion formulas are given for $\mu \le -(\nu+\frac{1}{2})$.

Key words. Struve function, Mellin transformation, multiplier

AMS subject classification. 44A15

1. Introduction. The spaces $\mathcal{L}_{\mu,p}$ are defined for $1 \le p \le \infty$ to consist of those Lebesgue-measurable functions f on $(0,\infty)$ such that $\|f\|_{\mu,p} < \infty$, where

$$\|f\|_{\mu,p} = \begin{cases} \left[\int_0^\infty |x^\mu f(x)|^p\, dx/x\right]^{1/p}, & 1 \le p < \infty, \\ \operatorname{ess\ sup}_{x>0} |x^\mu f(x)|, & p = \infty. \end{cases}$$

If X and Y are Banach spaces, we denote by $[X,Y]$ the collection of bounded operators from X to Y, $[X,X]$ being abbreviated to $[X]$. Also, we denote by $\mathcal{C}_0$ the collection of functions, continuous and compactly supported on $(0,\infty)$; clearly, $\mathcal{L}_{\mu,p} = L_p((0,\infty), x^{p\mu-1}\,dx)$, and thus, or from [7, Lemma 2.2], $\mathcal{C}_0$ is dense in $\mathcal{L}_{\mu,p}$ for $1 \le p < \infty$. Furthermore, if $1 \le r \le \infty$, the conjugate index r' is defined by $1/r + 1/r' = 1$.

In earlier papers [4], [9] we considered the Struve transformation $\mathcal{H}_\nu$ defined for $f \in \mathcal{C}_0$ by

$$(\mathcal{H}_\nu f)(x) = \int_0^\infty (xt)^{1/2}\mathbb{H}_\nu(xt)f(t)\,dt,$$

where $\mathbb{H}_\nu(z)$ is the Struve function defined by

$$\mathbb{H}_\nu(z) = \sum_{m=0}^\infty (-1)^m (z/2)^{\nu+2m+1}/(\Gamma(m+\tfrac{3}{2})\Gamma(\nu+m+\tfrac{3}{2})).$$

In [9] it is shown that if $1 < p < \infty$, $\nu+\frac{1}{2} < \mu < \nu+\frac{5}{2}$, and $\mu \ge \gamma(p)$ where $\gamma(p) = \max(1/p, 1/p')$, then $\mathcal{H}_\nu \in [\mathcal{L}_{\mu,p}, \mathcal{L}_{1-\mu,q}]$ for all $q \ge p$ such that $q' \ge 1/\mu$, whereas the boundedness on $\mathcal{L}_{\mu,1}$ is given in [4], being essentially the same range of boundedness, with $\gamma(1) = 1$. Note that if $1 \le p \le \infty$, then $\frac{1}{2} \le \gamma(p) \le 1$,

with equality at the lower endpoint if and only if $p = 2$. Since, for boundedness, $\frac{1}{2} \le \gamma(p) \le \mu < \nu + \frac{5}{2}$, our boundedness result requires that $\nu > -2$.

Inversion formulas for $\mathcal{H}_\nu$ are given in [4] and [9]. The inversion formula given in [4, Thm. 6.1] is valid for $1 \le p < \infty$, $\mu \ge \gamma(p)$, and $\max(\nu+\frac{1}{2}, -(\nu+\frac{1}{2})) < \mu < \nu+\frac{5}{2}$, whereas that given in [9, Thm. 6.3] is valid on a subset of this range of μ and ν. Thus no inversion formulas have been given for $\gamma(p) \le \mu \le -(\nu+\frac{1}{2})$, $\mu < \nu + \frac{5}{2}$, and in this paper we shall find such formulas for this range of μ and ν. Also, when $\mu < 1$ we shall need an inversion formula for $\mathcal{H}_\nu$ that is somewhat different from the one given in [4], and we shall develop it.

It transpires that the case $\mu = -(\nu+\frac{1}{2})$ is a special case. For, as noted in [9, Thm. 5.2], the range of the Struve transformation of order ν on $\mathcal{L}_{\mu,p}$ is the same as that of the Hankel transformation of order $\nu+1$ on $\mathcal{L}_{\mu,p}$, except possibly when $\mu = -(\nu+\frac{1}{2})$, and in order to find inversion formulas for this case we must investigate the range of $\mathcal{H}_\nu$. This causes our program in this paper to divide naturally into three cases. In §2 we deal with the range $\mu \ne -(\nu+\frac{1}{2})$, $\mu < \min(1, \nu+\frac{5}{2})$, and we prove two theorems, one of which is for a part of the range already covered in [4] but which we will need later. Sections 3–5 are devoted to the case $\mu = -(\nu+\frac{1}{2})$. In §3 we show that the range of the Struve transformation in this case is a proper subset of the range of the Hankel transformation of order $\nu+1$, and we characterize that range. In §4 we find an inversion formula for the case $\mu = -(\nu+\frac{1}{2})$, $\mu \ne \frac{1}{2}$, and in §5 we deal with the case $\mu = -(\nu+\frac{1}{2})$, $\mu = \frac{1}{2}$. It seems strange that this last case should be the most elusive since the conditions yield $\nu = -1$, so that the problem is that of inverting $\mathcal{H}_{-1}$ on $\mathcal{L}_{1/2,2} = L^2(0,\infty)$, where one usually expects things to be simpler.

Throughout the paper we use the notation $\int^{\to\infty}$ and $\int_{\to 0}$, which are explained in [11, §1.7]. This causes some of the formulas taken from [1] and [2] to look somewhat different since those formulas are often improper Riemann integrals. In particular, we will have

$$(\mathcal{H}_\nu f)(x) = \int_0^{\to\infty} (xt)^{1/2} \mathbb{H}_\nu(xt) f(t)\, dt$$

whenever this last integral converges. Other notations used include A_ν for

$$\cot(\nu\pi)/\Gamma(\nu+2),$$

and $m_\nu(s)$, which is defined by

$$m_\nu(s) = 2^{s-1/2}\Gamma((\nu+s+\tfrac{1}{2})/2)/\Gamma((\nu-s+\tfrac{3}{2})/2).$$

One of our tools in this work will be the Mellin transformation $\mathcal{M}$, whose properties are summarized in [9, §1].

2. Inversion for $\mu \ne -(\nu+\frac{1}{2})$. In this section we prove two inversion theorems for the range $\mu < \min(1, \nu+\frac{5}{2})$, which are valid when $\mu > \max(-(\nu+\frac{1}{2}), \nu+\frac{3}{2})$ and $\mu < -(\nu+\frac{1}{2})$, respectively. The range of μ and ν in the first theorem is actually within that for which [4, Thm. 6.1] is valid, but the form obtained here is considerably simpler then the form in that theorem, and we shall need the result obtained later.

THEOREM 2.1. *Suppose $f \in \mathcal{L}_{\mu,p}$, where $1 < p < \infty$, $\mu \ge \gamma(p)$, and $\max(-(\nu+\frac{1}{2}), \nu+\frac{3}{2}) < \mu < 1$. Then for almost all $x > 0$*

$$f(x) = x^{-(\nu+1/2)} \frac{d}{dx} x^{\nu+1/2} \int_0^\infty (xt)^{1/2} Y_{\nu+1}(xt)(\mathcal{H}_\nu f)(t) \frac{dt}{t}.$$

Proof. Note that the conditions imply that $-\frac{3}{2} < \nu < -\frac{1}{2}$, and thus $\nu + \frac{5}{2} > 1$, so that $\mu < \nu + \frac{5}{2}$. Fix $x > 0$, and let $g(t) = t^{-1/2}Y_{\nu+1}(xt)$. By [1, eqs. 7.2.1(4) and 7.13.1(4)], $g(t) = O(t^{\nu+1/2}) + O(t^{-\nu-3/2})$ as $t \to 0+$, with a modification when $\nu = -1$, and $g(t) = O(t^{-1})$ as $t \to \infty$. The conditions on μ thus ensure that $g \in \mathcal{L}_{\mu,p'}$, and [9, Thm. 5.3], in which there is a misprint for $\mu \geq \max(\gamma(p), \gamma(q))$, yields

$$\int_0^\infty f(t)(\mathcal{H}_\nu g)(t)\,dt = \int_0^\infty g(t)(\mathcal{H}_\nu f)(t)\,dt \tag{2.1}$$

since $\nu + \frac{3}{2} < \mu < \nu + \frac{5}{2}$.

But then [2, eq. 11.3(2)] gives $\mathcal{H}_\nu g$ since $-\frac{3}{2} < \nu < -\frac{1}{2}$, and by putting this value into (2.1) we have

$$\begin{aligned} -\int_x^\infty t^{\nu+1/2} f(t)\,dt &= x^{\nu+1}\int_0^\infty t^{-1/2}Y_{\nu+1}(xt)(\mathcal{H}_\nu f)(t)\,dt \\ &= x^{\nu+1/2}\int_0^\infty (xt)^{1/2}Y_{\nu+1}(xt)(\mathcal{H}_\nu f)(t)\frac{dt}{t}, \end{aligned} \tag{2.2}$$

and the result follows on differentiation. □

For the inversion when $\mu < -(\nu + \frac{1}{2})$, we first need a lemma.

LEMMA 2.2. *If* $\frac{1}{2} \leq \mu < \min(1, -(\nu + \frac{1}{2}), \nu + \frac{5}{2})$, *then*

$$\begin{aligned} &\lim_{R\to\infty} \frac{1}{2\pi i}\int_{\mu-iR}^{\mu+iR} u^{-s} m_\nu(s) \tan\frac{\pi}{2}(s-\nu-\tfrac{1}{2})/(\nu+\tfrac{3}{2}-s)ds \\ &\quad = u^{-1/2}(Y_{\nu+1}(u) - A_\nu(u/2)^{\nu+1}). \end{aligned}$$

Proof. By integrating around a rectangle with vertices at $\mu \pm iR$ and $\nu + \frac{1}{2} - 2n \pm iR$ and letting R and $n \to \infty$, the limit in the preceding is equal to the sum of the residues of the integrand to the left of the line $\operatorname{Re} s = \mu$. The integrand, fully written out, is

$$\left(u^{-s}2^{s-1/2}\Gamma\left(\left(\nu+s+\tfrac{1}{2}\right)/2\right)\tan\tfrac{\pi}{2}\left(s-\nu-\tfrac{1}{2}\right)\right) / \left(\Gamma\left(\left(\nu+\tfrac{3}{2}-s\right)/2\right)\left(\nu+\tfrac{3}{2}-s\right)\right)$$

$$= \left(u^{-s}2^{s-3/2}\Gamma\left(\left(\nu+s+\tfrac{1}{2}\right)/2\right)\tan\tfrac{\pi}{2}\left(s-\nu-\tfrac{1}{2}\right)\right) / \Gamma\left(\left(\nu+\tfrac{7}{2}-s\right)/2\right).$$

This has two sets of simple poles: at $s_n = -\left(\nu + \frac{1}{2}\right) - 2n$ and at $t_n = \nu + \frac{3}{2} - 2n$, where $n = 0, 1, \ldots$. Note that it follows from the conditions on μ that $-2 < \nu < -1$, from which it follows that the different sets of poles have no members in common. Also, from the hypotheses, $s_0 > \mu$ but $s_n < \mu$, $n = 1, 2, \ldots$, while $t_n < \mu$, $n = 0, 1, \ldots$. The residue at s_n is equal to $u^{-1/2}\cot\pi\nu(-1)^n(u/2)^{\nu+1+2n}/(\Gamma(\nu+n+2)n!)$, and the residue at t_n is equal to $u^{-1/2}\csc\pi\nu(-1)^n(u/2)^{-(\nu+1)+2n}/(\Gamma(n-\nu)n!)$. Hence

$$\begin{aligned} &\lim_{R\to\infty} \frac{1}{2\pi i}\int_{\mu-iR}^{\mu+iR} u^{-s} m_\nu(s) \tan\tfrac{\pi}{2}\left(s-\nu-\tfrac{1}{2}\right) / \left(\nu+\tfrac{3}{2}-s\right)ds \\ &= u^{-1/2}\left(\cot\pi\nu\sum_{n=1}^{\infty}(-1)^n(u/2)^{\nu+1+2n}/(\Gamma(\nu+n+2)n!)\right. \\ &\quad \left. + \csc\pi\nu\sum_{n=0}^{\infty}(-1)^n(u/2)^{-(\nu+1)+2n}/(\Gamma(n-\nu)n!)\right) \\ &= u^{-1/2}(\cot\pi(\nu+1)J_{\nu+1}(u) - A_\nu(u/2)^{\nu+1} - \csc\pi(\nu+1)J_{-(\nu+1)}(u)) \\ &= u^{-1/2}(Y_{\nu+1}(u) - A_\nu(u/2)^{\nu+1}). \qquad \square \end{aligned}$$

THEOREM 2.3. *Suppose that* $f \in \mathcal{L}_{\mu,p}$, *where* $1 < p < \infty$, $\mu \geq \gamma(p)$, *and* $\mu < \min\left(1, -\left(\nu + \frac{1}{2}\right), \nu + \frac{5}{2}\right)$. *Then for almost all* $x > 0$

$$f(x) = x^{-\nu-1/2}\frac{d}{dx}x^{\nu+1/2}\int_0^\infty (xt)^{1/2}\{Y_{\nu+1}(xt) - A_\nu(xt/2)^{\nu+1}\}(\mathcal{H}_\nu f)(t)\frac{dt}{t}.$$

Proof. Note that since $-(\nu + \frac{1}{2}) > \mu \geq \gamma(p) \geq \frac{1}{2}$, $\nu < -1$ and, similarly, $\nu > -2$.

Let $h(u) = u^{-1/2}(Y_{\nu+1}(u) - A_\nu(u/2)^{\nu+1})$. We shall prove that, under the conditions of the theorem,

$$-\int_x^\infty t^{\nu+1/2}f(t)\,dt = x^{\nu+3/2}\int_0^\infty h_\nu(xt)(\mathcal{H}_\nu f)(t)\,dt, \tag{2.3}$$

which on differentiating yields the desired result, and we prove this first on $\mathcal{L}_{1/2,2} = L_2(0,\infty)$.

Suppose then that $f \in \mathcal{L}_{1/2,2}$. Note that if

$$H(s) = m_\nu(s)\tan\left(\frac{\pi}{2}\right)\left(s - \nu - \frac{1}{2}\right)\Big/\left(\nu + \frac{3}{2} - s\right),$$

then $H(\frac{1}{2} + it) \in L_2(\mathbb{R})$, and hence by [12, Thm. 71] and Lemma 2.2, $h \in \mathcal{L}_{1/2,2}$ and $(\mathcal{M}h)(s) = H(s)$. Thus if $h_x(t) = h(xt)$ for $x > 0$ and $h_x \in \mathcal{L}_{1/2,2}$, from elementary considerations $(\mathcal{M}h_x)(s) = x^{-s}H(s)$. Also, from [9], $\mathcal{H}_\nu f \in \mathcal{L}_{1/2,2}$. Hence from [12, Thm. 72]

$$\begin{aligned}
x^{\nu+3/2}\int_0^\infty h(xt)(\mathcal{H}_\nu f)(t)\,dt &= \frac{x^{\nu+3/2}}{2\pi i}\int_{1/2-i\infty}^{1/2+i\infty}(\mathcal{M}h_x)(s)(\mathcal{M}\mathcal{H}_\nu f)(1-s)\,ds \\
&= \frac{x^{\nu+3/2}}{2\pi i}\int_{1/2-i\infty}^{1/2+i\infty} x^{-s}H(s)m_\nu(1-s)\tan\frac{\pi}{2}\left(\nu + \frac{3}{2} - s\right)(\mathcal{M}f)(s)\,ds \\
&= \frac{x^{\nu+3/2}}{2\pi i}\int_{1/2-i\infty}^{1/2+i\infty} x^{-s}(\mathcal{M}f)(s)/\left(\nu + \frac{3}{2} - s\right)ds,
\end{aligned}$$

since $m_\nu(s)m_\nu(1-s) = 1$ and $\tan\frac{\pi}{2}\left(\nu + \frac{3}{2} - s\right) = \cot\frac{\pi}{2}\left(s - \nu - \frac{1}{2}\right)$. Also, if for $x > 0$, $k_x(t) = 0$, $0 < t < x$, and $k_x(t) = t^{\nu+1/2}$, $t > x$, then clearly $k \in \mathcal{L}_{1/2,2}$ and $(\mathcal{M}k_x)(s) = x^{s+\nu+1/2}/(s + \nu + \frac{1}{2})$. Hence from [12, Thm. 72]

$$\begin{aligned}
-\int_x^\infty t^{\nu+1/2}f(t)\,dt &= \frac{1}{2\pi i}\int_{1/2-i\infty}^{1/2+i\infty}(\mathcal{M}k_x)(1-s)(\mathcal{M}f)(s)\,ds \\
&= \frac{x^{\nu+3/2}}{2\pi i}\int_{1/2-i\infty}^{1/2+i\infty} x^{-s}(\mathcal{M}f)(s)/(\nu + \tfrac{3}{2} - s)ds,
\end{aligned}$$

and thus (2.3) holds when $p = 2$ and $\mu = \frac{1}{2}$.

However, under the conditions of the theorem, for each $x > 0$ both sides of (2.3) represent bounded linear functionals on $\mathcal{L}_{\mu,p}$. Clearly, $k_x \in \mathcal{L}_{1-\mu,p'}$ since $\nu + \frac{3}{2} < \frac{1}{2}$ and thus the left-hand side of (2.3) represents such a functional. Also, $h(u) = O(u^{\nu+5/2}) + O^{-(\nu+3/2)})$ as $u \to 0^+$, and $h(u) = O(u^{-1}) + O(u^{\nu+1/2})$ as $u \to \infty$, and thus $h \in \mathcal{L}_{\mu,p'}$. Hence

$$\left|\int_0^\infty h(xt)(\mathcal{H}_\nu f)(t)\,dt\right| \le \left[\int_0^\infty |t^\mu h(xt)|^{p'}\frac{dt}{t}\right]^{1/p'} \|\mathcal{H}_\nu f\|_{1-\mu,p}$$

$$\le Kx^{-\mu}\|h\|_{\mu,p'}\|f\|_{\mu,p},$$

where K is a bound for the norm of $\mathcal{H}_\nu$ and thus the right-hand side of (2.2) also represents a bounded linear functional on $\mathcal{L}_{\mu,p}$. Hence (2.3) holds for the values of μ and ν stated in the theorem, and the theorem is proved. □

The reader should note that $\mathbb{H}_{-3/2}(z) = -J_{3/2}(z)$, so that $\mathcal{H}_{-3/2}$ is just minus the Hankel transformation of order $\frac{3}{2}$, and that then, since $Y_{-1/2}(z) = J_{1/2}(z)$ and $A_{-3/2} = 0$, this gives another inversion of the Hankel transformation of order $\frac{3}{2}$.

3. Range of $\mathcal{H}\nu$ when $\mu = -(\nu + \frac{1}{2})$. In this section we discuss the range of $\mathcal{H}_\nu$ when $\mu = -(\nu + \frac{1}{2})$. To this end we use the properties of the even and odd Hilbert transformations H_+ and H_-, which are summarized in [9, §3], and of the Hankel transformation H_ν, $\nu > -1$, and the extended Hankel transformation H_ν, $\nu < -1$, studied in [4], [5], [7]–[9]; also, M_α, where $\alpha \in \mathbb{R}$, denotes the operator on complex-valued functions on $(0,\infty)$ defined by

$$(M_\alpha f)(t) = t^\alpha f(t).$$

Clearly, M_α is an isometric isomorphism of $\mathcal{L}_{\mu,p}$ onto $\mathcal{L}_{\mu-\alpha,p}$.

In each of the lemmas and theorems of this section we assume that $\gamma(p) \le \mu = -(\nu + \frac{1}{2}) < \nu + \frac{5}{2}$, which gives $\nu > -\frac{3}{2}$. It should be noted that this implies that $\nu \le -1$, with $\nu = -1$ only if $\gamma(p) = \frac{1}{2}$, and thus $p = 2$. Also, it implies that $\nu + \frac{1}{2} \le -\frac{1}{2} < \gamma(p) \le \mu$, and thus μ is in the range for boundedness of $\mathcal{H}_\nu$ on $\mathcal{L}_{\mu,p}$. It further implies that $p > 1$, for since $\nu > -\frac{3}{2}$, $-(\nu + \frac{1}{2}) < 1$, and thus $\gamma(p) < 1$ and hence $p > 1$.

We begin by proving a lemma followed by a theorem that shows immediately that the case in which $\mu = -(\nu + \frac{1}{2})$ is fundamentally different from those cases considered in §2 and from which we immediately obtain, as a corollary, that $\mathcal{H}_\nu(\mathcal{L}_{\mu,p})$ is a proper subset of $H_{\nu+1}(\mathcal{L}_{\mu,p})$.

LEMMA 3.1. *Suppose* $1 < p < \infty$ *and* $\gamma(p) \le \mu = -(\nu + \frac{1}{2}) < \nu + \frac{5}{2}$. *Then on* $\mathcal{L}_{\mu,p}$

$$\mathcal{H}_\nu = H_\nu M_{-(\nu+1/2)} H_- M_{\nu+1/2} \tag{3.1}$$

if $-\frac{3}{2} < \nu < -1$, *and*

$$\mathcal{H}_{-1} = M_{-1/2} H_+ M_{1/2} H_1. \tag{3.2}$$

Proof. Note that $-\frac{3}{2} < \nu \le -1$. It is sufficient to prove the relations when $p = 2$ since $\mathcal{L}_{\mu,2}$ is dense in $\mathcal{L}_{\mu,p}$, $\gamma(p) \ge \gamma(2)$, and each side of (3.1) and (3.2) is a bounded linear transformation from $\mathcal{L}_{\mu,p}$ to $\mathcal{L}_{1-\mu,p}$. From [9, Thm. 5.2] the left-hand side of (3.1) is so bounded. Also, as noted, $M_{\nu+1/2}$ maps $\mathcal{L}_{\mu,p}$ boundedly onto $\mathcal{L}_{\mu-(\nu+1/2),p}$, and from [9, Thm. 3.1], H_- maps $\mathcal{L}_{\mu-(\nu+1/2),p}$ boundedly into itself since $1 \le \mu - (\nu + \frac{1}{2}) < 2$. Further, $M_{-(\nu+1/2)}$ maps $\mathcal{L}_{\mu-(\nu+1/2),p}$ boundedly onto $\mathcal{L}_{\mu,p}$, and finally, from [8, Thm. 1], H_ν maps $\mathcal{L}_{\mu,p}$ boundedly into $\mathcal{L}_{1-\mu,p}$ since the integer m of that theorem is one and our hypotheses ensure that $\gamma(p) \le \mu < \nu + \frac{7}{2}$.

Then by [8, Thm. 1] and [9, eqs. 1.10, 2.3, and Thms. 3.1 and 5.2], if $f \in \mathcal{L}_{\mu,2}$ and Re $s = \frac{1}{2}$, then

$$\begin{aligned}(\mathcal{M}H_\nu M_{-(\nu+1/2)}H_- M_{\nu+1/2}f)(s) &= m_\nu(s)(\mathcal{M}M_{-(\nu+1/2)}H_- M_{\nu+1/2}f)(1-s)\\ &= m_\nu(s)(\mathcal{M}H_- M_{\nu+1/2}f)(1-s-(\nu+\tfrac{1}{2}))\\ &= m_\nu(s)\cot\tfrac{\pi}{2}(1-s-(\nu+\tfrac{1}{2}))(\mathcal{M}M_{\nu+1/2}f)(1-s-(\nu+\tfrac{1}{2}))\\ &= m_\nu(s)\cot\tfrac{\pi}{2}(1-s-(\nu+\tfrac{1}{2}))(\mathcal{M}f)(1-s)\\ &= m_\nu(s)\tan\tfrac{\pi}{2}(s+(\nu+\tfrac{1}{2}))(\mathcal{M}f)(1-s)\\ &= (\mathcal{M}\mathcal{H}_\nu f)(s).\end{aligned}$$

Hence (3.1) holds on $\mathcal{L}_{\mu,2}$ and thus on $\mathcal{L}_{\mu,p}$ for the range of values shown. The proof of (3.2) is similar. □

THEOREM 3.2. *Suppose $f \in \mathcal{L}_{\mu,p}$, where $1 < p < \infty$, $\gamma(p) \le \mu = -(\nu+\frac{1}{2}) < \nu+\frac{5}{2}$. Then the integral*

$$\int_{\to 0}^{\to\infty} t^{\nu+1/2}(\mathcal{H}_\nu f)(t)\,dt$$

converges and equals zero.

Proof. If $\nu < -1$, then from (3.1), $\mathcal{H}_\nu f = H_\nu\phi$, where $\phi = M_{-(\nu+1/2)}H_- M_{\nu+1/2}f$. As noted in the proof of Lemma 3.1, $M_{-(\nu+1/2)}H_- M_{\nu+1/2} \in [\mathcal{L}_{\mu,p}]$, and thus $\mathcal{H}_\nu f \in H_\nu(\mathcal{L}_{\mu,p})$. But from [5, Thm. 6.3], with $l = 1$,

$$\int_{\to 0}^{\to\infty} t^{\nu+1/2}(H_\nu\phi)(t)\,dt$$

converges and equals zero, which is the result to be proved in this case.

If $\nu = -1$, then $\mu = \frac{1}{2}$, so that $p = 2$. But then from (3.2), if $f \in \mathcal{L}_{1/2,2} = L_2(0,\infty)$, $\mathcal{H}_{-1}f = M_{-1/2}H_+\psi$, where $\psi = M_{1/2}H_1 f$. Now by [12, Chap. 8], $H_1 \in [L_2(0,\infty)]$ and thus $\psi \in \mathcal{L}_{0,2}$, and thus by [3, Cor. 4.3]

$$\int_{\to 0}^{\to\infty} (H_+\psi)(t)\frac{dt}{t}$$

converges and equals zero, which is again the result to be proved since $(H_+\psi)(t)/t = t^{-1/2}(\mathcal{H}_{-1}f)(t)$. □

COROLLARY 3.3. *Suppose $1 < p < \infty$, $\gamma(p) \le \mu = -(\nu+\frac{1}{2}) < \nu+\frac{5}{2}$. Then $\mathcal{H}_\nu(\mathcal{L}_{\mu,p})$ is a proper subset of $H_{\nu+1}(\mathcal{L}_{\mu,p})$.*

Proof. In [9, Thm. 5.1] $\mathcal{H}_\nu$ is defined to be $H_{\nu+1}S_\nu$, where S_ν is a transformation that, for the values of μ and ν for which $\mathcal{H}_\nu$ is bounded, maps $\mathcal{L}_{\mu,p}$ boundedly onto itself. Hence, $\mathcal{H}_\nu(\mathcal{L}_{\mu,p}) \subseteq H_{\nu+1}(\mathcal{L}_{\mu,p})$. Let $f(x) = x^{\nu+3/2}/(x^2+1)$. Then $f \in \mathcal{L}_{\mu,p}$, and from [2; eq. 8.5(12)], $(H_{\nu+1}f)(x) = x^{1/2}K_{\nu+1}(x)$. From Theorem 3.2, if $\mathcal{H}_\nu(\mathcal{L}_{\mu,p}) = H_{\nu+1}(\mathcal{L}_{\mu,p})$, then

$$\int_{\to 0}^{\to\infty} t^{\nu+1}K_{\nu+1}(x)\,dx = 0,$$

which is impossible since the integrand is positive! □

Since $\mathcal{H}_\nu(\mathcal{L}_{\mu,p})$ is a proper subset of $H_{\nu+1}(\mathcal{L}_{\mu,p})$, it is of interest to find exactly what subset it is, and the following theorem characterizes it.

THEOREM 3.4. *Suppose* $1 < p < \infty$ *and* $\gamma(p) \le \mu = -(\nu + \frac{1}{2}) < \nu + \frac{5}{2}$. *Then* $g \in \mathcal{H}_\nu(\mathcal{L}_{\mu,p})$ *if and only if*

(a) $g \in H_{\nu+1}(\mathcal{L}_{\mu,p})$,

(b) $\int_{\to 0}^{1} t^{\nu+1/2} g(t)\, dt$ *converges, and*

(c) $\varphi \in H_{\nu+1}(\mathcal{L}_{\mu,p})$, *where* $\varphi(x) = x^{-\nu+1/2} \int_{\to 0}^{x} t^{\nu+1/2} g(t)\, dt$.

Proof. Suppose first that $-\frac{3}{2} < \nu < -1$. If $g \in \mathcal{H}_\nu(\mathcal{L}_{\mu,p})$, then $g = \mathcal{H}_\nu f$, some $f \in \mathcal{L}_{\mu,p}$, and thus from (3.1), $g = H_\nu \psi$, where $\psi = M_\mu H_- M_{-\mu} f$. Now $M_{-\mu} f \in \mathcal{L}_{2\mu,p}$, and thus since $1 < 2\mu < 2$, from [9, Thm. 3.1(b)], $H_- M_{-\mu} f \in \mathcal{L}_{2\mu,p}$, and thus $\psi \in \mathcal{L}_{\mu,p}$. Hence $g \in H_\nu(\mathcal{L}_{\mu,p})$, and it follows from [5, Thm. 6.5], since in this case $l = l_\nu = 1$, that $g \in H_{\nu+2}(\mathcal{L}_{\mu,p})$, (b) holds, and $\varphi \in H_{\nu+2}(\mathcal{L}_{\mu,p})$. But from [10, Thm. 1], since $\nu > -\frac{3}{2}$, $H_{\nu+2}(\mathcal{L}_{\mu,p}) = H_{\nu+1}(\mathcal{L}_{\mu,p})$, and thus (a) and (c) also hold.

Conversely, if g satisfies (a), (b), and (c), then, since from [10, Thm. 1], $H_{\nu+1}(\mathcal{L}_{\mu,p}) = H_{\nu+2}(\mathcal{L}_{\mu,p})$ and since $l_\nu = 1$, g satisfies (a), (b), and (c) of [5, Thm. 6.5], and thus there is a $\psi \in \mathcal{L}_{\mu,p}$, so that $g = H_\nu \psi$. Since from [9, Thm. 3.1(b)], $H_- \in [\mathcal{L}_{2\mu,p}]$, and maps $\mathcal{L}_{2\mu,p}$ one-to-one onto itself, from [11, Thm. 42.-H], H_-^{-1} exists and $H_-^{-1} \in [\mathcal{L}_{2\mu,p}]$. Let $f = M_\mu H_-^{-1} M_{-\mu} \psi$. Then $f \in \mathcal{L}_{\mu,p}$ and $\psi = M_\mu H_- M_{-\mu} f$, and thus, by using (3.1), $g = H_\nu M_\mu H_- M_{-\mu} f = \mathcal{H}_\mu f$, so that $g \in \mathcal{H}_\nu(\mathcal{L}_{\mu,p})$.

Suppose next that $\nu = -1$. Then $\mu = \frac{1}{2}$ and $p = 2$, so that $\mathcal{L}_{\mu,p} = \mathcal{L}_{1/2,2}$. Suppose $g \in \mathcal{H}_{-1}(\mathcal{L}_{1/2,2})$. Then from (3.2), $M_{1/2} g = H_+ M_{1/2} H_1 f = H_+ \psi$, where $\psi = M_{1/2} H_1 f$. But from [6, Thm. 1], since $\mathcal{L}_{1/2,2} = L^2(0,\infty)$, $H_1 f \in \mathcal{L}_{1/2,2}$ and thus $\psi \in \mathcal{L}_{0,2}$. But then, from [3, Thm. 4.4], $M_{1/2} g \in \mathcal{L}_{0,2}$, $\int_{\to 0}^{1} (M_{1/2} g)(t)\, dt/t = \int_{\to 0}^{1} t^{-1/2} g(t)\, dt$ converges, that is, (b) holds, and $k \in \mathcal{L}_{0,2}$, where

$$k(x) = \int_{\to 0}^{x} (M_{1/2} g)(t)\, dt/t = \int_{\to 0}^{x} t^{-1/2} g(t)\, dt.$$

Hence $g \in \mathcal{L}_{1/2,2}$, and since, from [6], $H_0(\mathcal{L}_{1/2,2}) = \mathcal{L}_{1/2.2}$, (a) holds. Also, $\varphi = M_{-1/2} k$, so that $\varphi \in \mathcal{L}_{1/2,2} = H_0(\mathcal{L}_{1/2,2})$ and (c) holds.

Conversely, suppose g satisfies (a), (b), and (c). Then, since $H_0(\mathcal{L}_{1/2,2}) = \mathcal{L}_{1/2,2}$, $M_{1/2} g$ satisfies (i), (ii), and (iii) of [3, Thm. 4.4] with $p = 2$ and thus $M_{1/2} g = H_+ \psi$, where $\psi \in \mathcal{L}_{0,2}$. But then $M_{-1/2} \psi \in \mathcal{L}_{1/2,2} = H_1(\mathcal{L}_{1/2,2})$, and thus there is an $f \in \mathcal{L}_{1/2,2}$, so that $M_{-1/2} \psi = H_1 f$. It follows then that $g = M_{-1/2} H_+ \psi = M_{-1/2} H_+ M_{1/2} H_1 f = \mathcal{H}_{-1} f$ and $g \in \mathcal{H}_{-1}(\mathcal{L}_{1/2,2})$. □

4. Inversion when $\mu = -(\nu + \frac{1}{2})$, $\mu \ne \frac{1}{2}$. Theorem 4.2, which follows, and its corollary give two inversion formulas for $\mathcal{H}_\nu$ in this case. However, we first need a lemma.

LEMMA 4.1. *Suppose that* $f \in \mathcal{L}_{\mu,p}$, *where* $1 < p < \infty$, $-\frac{3}{2} < \nu < -1$, *and* $\mu = -(\nu + \frac{1}{2})$. *Then as* $a \to 0_+$

$$a^{\nu+1} \int_1^\infty t^{-1/2} f(t) \mathbb{H}_{\nu+1}(at)\, dt \to 0. \tag{4.1}$$

Proof. Given $\epsilon > 0$, choose R so large that

$$\left\{ \int_R^\infty |t^u f(t)|^p \frac{dt}{t} \right\}^{1/p} < \epsilon.$$

Since $\mathbb{H}_{\nu+1}(t) \sim t^{\nu+2}/(2^{\nu+1}\pi^{1/2}\Gamma(\nu+\frac{5}{2}))$ as $t \to 0^+$, there is a constant K_R such that $|\mathbb{H}_{\nu+1}(t)| \le K_R t^{\nu+2}$ for $0 \le t \le R$. If $0 < a < 1$, we then have

$$\left| a^{\nu+1} \int_1^R t^{-1/2} \mathbb{H}_{\nu+1}(at) f(t)\, dt \right| \le K_R a^{2\nu+3} \int_1^R t^{\nu+3/2} |f(t)|\, dt.$$

Moreover, by using Hölder's inequality, since $\mu = -(\nu + \frac{1}{2})$,

$$\begin{aligned}
&\left| a^{\nu+1} \int_R^\infty t^{-1/2} \mathbb{H}_{\nu+1}(at) f(t)\, dt \right| \\
&\quad \le a^{\nu+1} \left\{ \int_R^\infty |t^\mu f(t)|^p \frac{dt}{t} \right\}^{1/p} \left\{ \int_R^\infty |t^{1/2-\mu} \mathbb{H}_{\nu+1}(at)|^{p'} \frac{dt}{t} \right\}^{1/p'} \\
&\quad < \epsilon a^{\nu+1} \left\{ \int_{aR}^\infty \left| \left(\frac{u}{a}\right)^{\nu+1} \mathbb{H}_{\nu+1}(u) \right|^{p'} \frac{du}{u} \right\}^{1/p'} \\
&\quad \le \epsilon \left\{ \int_0^\infty |y^{\nu+1} \mathbb{H}_{\nu+1}(u)|^{p'} \frac{du}{u} \right\}^{1/p'} = A\epsilon.
\end{aligned}$$

Here A is finite since $u^{\nu+1}\mathbb{H}_{\nu+1}(u) = O(u^{2\nu+3})$ as $u \to 0^+$ and since $\mathbb{H}_{\nu+1}(u) = O(u^{-1/2}) + O(u^\nu) = O(u^{-1/2})$ as $u \to \infty$, so that $u^{\nu+1}\mathbb{H}_{\nu+1}(u) = O(u^{\nu+1/2})$ as $u \to \infty$.

Combining these estimates, we find that

$$\left| a^{\nu+1} \int_1^\infty t^{-1/2} \mathbb{H}_{\nu+1}(at) f(t)\, dt \right| \le A\epsilon + K_R a^{2\nu+3} \int_1^R t^{\nu+3/2} |f(t)|\, dt,$$

Hence as $a \to 0^+$ the upper limit of the left-hand side is less than $A\epsilon$, and since ϵ is arbitrary, (4.1) follows. □

We now can prove the following inversion theorem and its corollary.

THEOREM 4.2. *Suppose that $f \in \mathcal{L}_{\mu,p}$, where $1 < p < \infty$, $\mu = -(\nu + \frac{1}{2}) \ge \gamma(p)$, and $\nu + \frac{3}{2} < \mu < 1$. Then for almost all $x > 0$*

$$f(x) = x^{-\nu-1/2} \frac{d}{dx} x^{\nu+1/2} \int_{\to 0}^\infty (xt)^{1/2} Y_{\nu+1}(xt) (\mathcal{H}_\nu f)(t) \frac{dt}{t}. \tag{4.2}$$

Proof. It is easy to see that $\mu < \nu + \frac{5}{2}$, so that $\mathcal{H}_\nu f$ exists. Suppose first that $\mu > \gamma(p)$, and choose $\epsilon > 0$ but sufficiently small that $\mu - \epsilon > \max(\gamma(p), \nu + \frac{3}{2})$ and $\mu + \epsilon < \min(1, \nu + 5/2)$. Define f_1 and f_2 by $f_1 = f \cdot \chi_{(1,\infty)}$ and $f_2 = f - f_1$. Then $f_2 \in \mathcal{L}_{\mu+\epsilon,p}$ and $f_1 \in \mathcal{L}_{\mu-\epsilon,p}$, and thus we can apply Theorems 2.1 and 2.3, respectively, and it follows that for almost all $x > 0$

$$f_2(x) = x^{-\nu-1/2} \frac{d}{dx} x^{\nu+1/2} \int_0^\infty (xt)^{1/2} Y_{\nu+1}(xt) (\mathcal{H}_\nu f_2)(t) \frac{dt}{t} \tag{4.3}$$

and

$$f_1(x) = x^{-\nu-1/2} \frac{d}{dx} x^{\nu+1/2} \int_0^\infty (xt)^{1/2} \{ Y_{\nu+1}(xt) - A_\nu (xt/2)^{\nu+1} \} \cdot (\mathcal{H}_\nu f_1)(t) \frac{dt}{t}.$$

In view of Theorem 3.2, we can write this last formula as

$$f_1(x) = x^{-\nu-1/2}\frac{d}{dx}x^{\nu+1/2}\int_{\to 0}^{\to\infty}(xt)^{1/2}Y_{\nu+1}(xt)(\mathcal{H}_\nu f_1)(t)\frac{dt}{t}. \tag{4.4}$$

But for fixed $x > 0$, $(xt)^{1/2}Y_{\nu+1}(xt)$ is bounded for $t \geq 1$, and Hölder's inequality gives

$$\int_1^\infty |(\mathcal{H}_\nu f_1)(t)|\frac{dt}{t} \leq \left[\int_1^\infty |t^{1-\mu}(\mathcal{H}_\nu f_1)(t)|^p\frac{dt}{t}\right]^{1/p}\left[\int_1^\infty t^{(\mu-1)p'}\frac{dt}{t}\right]^{1/p'},$$

and the last two integrals are finite since $\mathcal{H}_\nu f_1 \in \mathcal{L}_{\mu,p}$ and $\mu < 1$. Thus we do not need the arrow on the upper limit of integration in (4.4). Then, adding (4.3) and the modified (4.4), we have the result.

If $\mu = \gamma(p)$, (4.3) still holds but (4.4) does not since now $\mu - \epsilon < \gamma(p)$. Now we apply (2.1) to f_1 and g_x, where

$$g_x(t) = t^{-1/2}\left[Y_{\nu+1}(xt) - A_\nu\left(\frac{xt}{2}\right)^{\nu+1}\chi_{(0,a)}(t)\right],$$

x and a being fixed positive numbers. As in the proof of Theorem 2.3, $g_x(t) = O(t^{\nu+5/2}) + O(t^{-\nu-3/2})$ as $t \to 0^+$ and $g_x(t) = O(1/t)$ as $t \to \infty$, and so the conditions that ensure that $g_x \in \mathcal{L}_{\mu,p'}$ are $\mu + \nu + \frac{5}{2} > 0$, $\mu < \nu + \frac{3}{2}$, and $\mu < 1$. The second and third of these are among our hypotheses, while $\mu = -(\nu + \frac{1}{2})$ yields $\mu + \nu + \frac{5}{2} = 2$. Thus (2.1) yields

$$\int_0^\infty (\mathcal{H}_\nu f_1)(t)g_x(t)\,dt = \int_0^\infty f_1(t)(\mathcal{H}_\nu g_x)(t)\,dt. \tag{4.5}$$

In view of Theorem 3.2, we can write the left-hand side of (4.5) in the form

$$\int_{\to 0}^\infty t^{-1/2}Y_{\nu+1}(xt)(\mathcal{H}_\nu f_1)(t)\,dt - A_\nu\left(\frac{x}{2}\right)^{\nu+1}\int_{\to 0}^a t^{\nu+1/2}(\mathcal{H}_\nu f_1)(t)\,dt,$$

and the second term tends to zero as $a \to 0^+$. We can write the right-hand side of (4.5) in the form

$$\int_0^\infty f_1(t)(\mathcal{H}_\nu h_x)(t)\,dt - A_\nu\left(\frac{x}{2}\right)^{\nu+1}\int_0^\infty f_1(t)(\mathcal{H}_\nu k_a)(t)\,dt, \tag{4.6}$$

where $h_x(t) = t^{-1/2}Y_{\nu+1}(xt)$ and $k_a(t) = t^{\nu+1/2}\chi_{(0,a)}(t)$, provided we show that one of the two integrals exists. From our hypotheses, $-\frac{3}{2} < \nu < -1$. Hence from [2, eq. 11.3(2)] the first integral exists and equals

$$-x^{-\nu-1}\int_x^\infty t^{\nu+1/2}f_1(t)\,dt,$$

this integral existing since Hölder's inequality gives

$$\int_x^\infty t^{\nu+1/2}|f_1(t)|\,dt \leq \left[\int_x^\infty |t^\mu f_1(t)|^p\frac{dt}{t}\right]^{1/p}\left[\int_x^\infty t^{(\nu-\mu+3/2)p'}\frac{dt}{t}\right]^{1/p'} < \infty$$

since $\mu > \nu + \frac{3}{2}$.

By [2, eq. 11.2(2)], $(\mathcal{H}_\nu k)(t) = t^{-\nu-3/2}(at)^{\nu+1}\mathbb{H}_{\nu+1}(at)$ since $\nu > -\frac{3}{2}$, and hence the second term in (4.6) reduces to

$$A_\nu \left(\frac{ax}{2}\right)^{\nu+1} \int_1^\infty t^{-1/2} f_1(t)\mathbb{H}_{\nu+1}(at)\, dt,$$

and as $a \to 0^+$ this tends to zero by Lemma 4.1. Thus if we let a tend to zero in (4.5), we find that

$$\int_{\to 0}^\infty t^{-1/2} Y_{\nu+1}(xt)(\mathcal{H}_\nu f_1)(t)\, dt = -x^{-\nu-1} \int_x^\infty t^{\nu+1/2} f_1(t)\, dt,$$

which, on differentiation, yields

$$x^{\nu+1/2} f_1(x) = \frac{d}{dx} x^{\nu+1/2} \int_{\to 0}^\infty (xt)^{1/2} Y_{\nu+1}(xt)(\mathcal{H}_\nu f_1)(t) \frac{dt}{t}$$

almost everywhere on $(0, \infty)$. Multiplying this by $x^{-\nu-1/2}$ and then adding it to (4.3), we obtain (4.2). □

COROLLARY 4.3. *Under the same hypotheses,*

$$(4.7)\quad f(x) = x^{-\nu-1/2} \frac{d}{dx} x^{\nu+1/2} \int_0^{\to\infty} (xt)^{1/2} \left[Y_{\nu+1}(xt) - A_\nu \left(\frac{xt}{2}\right)^{\nu+1} \right] (\mathcal{H}_\nu f)(t) \frac{dt}{t}$$

almost everywhere on $(0, \infty)$.

Proof. Theorem 3.2 shows that the integrals on the right of (4.2) and (4.7) are equal, and it is easy to see that the integral in (4.7) does not need an arrow at its lower limit. □

5. Inversion of $\mathcal{H}_{-1}$ on $L^2(0, \infty)$. We now consider the problem of inverting $\mathcal{H}_\nu$ on $\mathcal{L}_{\mu,p}$ in the case for which $\mu = \nu + \frac{3}{2}$ and for which the singularity condition, $\mu = -(\nu + \frac{1}{2})$, applies. For the two conditions to hold simultaneously we must have $\nu = -1$ and $\mu = \frac{1}{2}$; thus $\gamma(p) = \frac{1}{2}$, so that $p = 2$ and $\mathcal{L}_{\mu,p}$ is $\mathcal{L}_{1/2,2} = L^2(0, \infty)$. First we prove a lemma.

LEMMA 5.1. *If* $f \in L^2(0, \infty)$, *then as* $a \to \infty$

$$\int_0^\infty t^{-1/2} \mathbb{H}_0(at) f(t)\, dt \to 0.$$

Proof. Let K denote $\left\{\int_0^\infty t^{-1} |\mathbb{H}_0(t)|^2 dt\right\}^{1/2}$, which is finite since $\mathbb{H}_0(t) = O(t)$ as $t \to 0$ and $\mathbb{H}_0(t) = O(t^{-1/2})$ as $t \to \infty$. Given $\epsilon > 0$, choose δ so small that

$$\left[\int_0^\delta |f(t)|^2\, dt\right]^{1/2} < \epsilon.$$

Then, using Schwarz's inequality and the substitution $u = at$, we see that

$$\int_0^\delta |t^{-1/2}\mathbb{H}_0(at) f(t)|\, dt \le \left[\int_0^\infty t^{-1} |\mathbb{H}_0(at)|^2\, dt \cdot \int_0^\delta |f(t)|^2 dt\right]^{1/2} < K\epsilon,$$

while

$$\int_\delta^\infty |t^{-1/2}\mathbb{H}_0(at)f(t)|\,dt \le \|f\|_2 \cdot \left[\int_{a\delta}^\infty u^{-1}|\mathbb{H}_0(u)|^2\,du\right\}^{1/2}.$$

Hence

$$\left|\int_0^\infty t^{-1/2}\mathbb{H}_0(at)f(t)\,dt\right| < K\epsilon + \|f\|_2 \cdot \left[\int_{a\delta}^\infty u^{-1}|\mathbb{H}_0(u)|^2\,du\right]^{1/2},$$

from which it follows that

$$\overline{\lim_{a\to\infty}}\left|\int_0^\infty t^{-1/2}\mathbb{H}_0(at)f(t)\,dt\right| \le K\epsilon,$$

and the result follows. □

THEOREM 5.2. *If $f \in L^2(0,\infty)$, then for almost all $x > 0$*

$$f(x) = x^{1/2}\frac{d}{dx}\int_{\to 0}^\infty t^{-1/2}(Y_0(xt) - Y_0(t))(\mathcal{H}_{-1}f)(t)\,dt.$$

Proof. Let a and x be fixed positive numbers, and let

$$g_a(t) = t^{-1/2}(Y_0(xt) - Y_0(t) - 2\pi^{-1}\log x\chi_{(0,a)}(t)).$$

From [1, eq. 7.2.4(33)],

$$Y_0(xt) = 2\pi^{-1}\left(\gamma + \log\left(\frac{xt}{2}\right)\right) + O(t^2\log t)$$

as $t \to 0^+$, where γ is Euler's constant. Hence $g_a(t) = O(t^{3/2}\log t)$ as $t \to 0^+$; also, from [1, eq. 7.13.1(4)], $g_a(t) = O(t^{-1})$ as $t \to \infty$. Hence $g_a(t) \in L^2(0,\infty)$, and thus if $f \in L^2(0,\infty)$, from [9, eq. (5.9)]

$$\int_0^\infty f(t)(\mathcal{H}_{-1}g_a)(t)\,dt = \int_0^\infty g_a(t)(\mathcal{H}_{-1}f)(t)\,dt. \tag{5.1}$$

Now, from [2, eqs. 11.2(2) and 11.3(2)]

$$(\mathcal{H}_{-1}g_a)(y) = -y^{-1/2}(\chi_{(x,\infty)}(y) - \chi_{(1,\infty)}(y) + (2\pi^{-1}\log x)\mathbb{H}_0(ay))$$

$$= y^{-1/2}(\chi_{(1,x)}(y) - (2\pi^{-1}\log x)\mathbb{H}_0(ay)).$$

Each term of this last line is in $L^2(0,\infty)$, and thus we can write the left-hand side of (5.1) in the form

$$\int_1^x y^{-1/2}f(y)\,dy - 2\pi^{-1}\log x\int_0^\infty y^{-1/2}\mathbb{H}_0(ay)f(y)\,dy,$$

and we can write the right-hand side as

$$\int_{\to 0}^\infty t^{-1/2}(Y_0(xt) - Y_0(t))(\mathcal{H}_{-1}f)(t)\,dt - 2\pi^{-1}\log x\int_{\to 0}^a t^{-1/2}(\mathcal{H}_{-1}f)(t)\,dt$$

since the last integral exists by Theorem 3.2. If we now let $a \to \infty$ in (5.1) and use Lemma 5.1 and Theorem 3.2, it follows that

$$\int_1^x y^{-1/2} f(y)\, dy = \int_{\to 0}^{\infty} t^{-1/2}(Y_0(xt) - Y_0(t))(\mathcal{H}_{-1}f)(t)\, dt,$$

and the result follows on differentiating. □

Finally, we have the following corollary, whose proof is similar to that of Corollary 4.3.

COROLLARY 5.3. *If $f \in L^2(0,\infty)$, then for almost all $x > 0$*

$$f(x) = x^{1/2}\frac{d}{dx}\int_0^{\to\infty} t^{-1/2}(Y_0(xt) - Y_0(t) - 2\pi^{-1}\log x)(\mathcal{H}_{-1}f)(t)\, dt.$$

ASYMPTOTICS OF POLLACZEK POLYNOMIALS AND THEIR ZEROS*

MOURAD E. H. ISMAIL†

Abstract. An asymptotic expression for the large n behavior of Pollaczek polynomials of degree n and argument $\cos(\theta/\sqrt{n})$ is derived. This is applied to find the second term in the asymptotic expansion of the zeros of the Pollaczek polynomials and it also solves a problem of Richard Askey. Some new analytic properties of a confluent Horn function are also proved.

Key words. Pollaczek polynomials, zeros, asymptotics, confluent Horn functions

AMS subject classifications. primary 33A65; secondary 30E15, 41A60

1. Introduction.

The Pollaczek polynomials are generated by [7, VI eq. (5.2)]

$$P_{-1}^{\lambda}(x;a,b) := 0, P_0^{\lambda}(x;a,b) := 1, \tag{1.1}$$

$$\begin{aligned}(n+1)P_{n+1}^{\lambda}(x;a,b) &= 2[x(a+\lambda+n)+b]P_n^{\lambda}(x;a,b)\\ &\quad -(n+2\lambda-1)P_{n-1}^{\lambda}(x;a,b), \qquad n \geq 0.\end{aligned} \tag{1.2}$$

The Pollaczek polynomials are orthogonal when either $\lambda > 0$ and $\lambda + a > 0$ hold or $0 > \lambda > -\frac{1}{2}$ and $0 < 1 + \lambda + a < 1$ are valid. The parameter b is assumed to be real. For a discussion of the nature of the orthogonality see [2] and [6]. The Pollaczek (or Pollaczek–Szegö) polynomials have the explicit representation (see [7, Chap. VI eq. (5.6)] or [10, §10.21])

$$P_n^{\lambda}(\cos\theta;a,b) = \frac{(2\lambda)_n}{n!}e^{in\theta}\,{}_2F_1(-n,\lambda+it(\theta);2\lambda;1-e^{-2i\theta}), \tag{1.3}$$

where

$$t(\theta) := (a\cos\theta + b)/\sin\theta. \tag{1.4}$$

When $a = b = 0$ the Pollaczek polynomials reduce to the familiar ultraspherical (or Gegenbauer) polynomials [21, §4.7], [20, Chap. 17]. Novikoff wrote a dissertation [17] on the Pollaczek polynomials, where he found the main term in the asymptotic development of their zeros. Let $\{x_{n,k}(\lambda,a,b) : 1 \leq k \leq n\}$ be the zeros of a Pollaczek polynomial $\{P_n^{\lambda}(x;a,b)\}$ arranged as

$$1 > x_{n,1}(\lambda,a,b) > x_{n,2}(\lambda,a,b) > \cdots > x_{n,n}(\lambda,a,b) > -1. \tag{1.5}$$

It is more convenient to analyze the θ zeros $\{\theta_{n,k}(\lambda,a,b)\}$,

$$x_{n,k}(\lambda,a,b) = \cos(\theta_{n,k}(\lambda,a,b)). \tag{1.6}$$

Novikoff proved that if $\lambda = \frac{1}{2}$ and $(a,b) \neq (0,0)$, then for any fixed k we have

$$\sqrt{n}\,\theta_{n,k}(\tfrac{1}{2},a,b) \to \sqrt{2(a+b)} \quad \text{as } n \to \infty. \tag{1.7}$$

This is in contrast with the case of ultraspherical polynomials when $a = b = 0$,

$$n\theta_{n,k}(\lambda, 0, 0) \to j_{\lambda-1/2,k} \quad \text{as } n \to \infty,$$

where $j_{\nu,k}$ is the kth positive zero of a Bessell function $J_\nu(z)$. The Pollaczek polynomials are orthogonal with all their zeros in (-1, 1) if and only if $\lambda > 0$ and either $a > |b|$, or $a = b \geq 0$ hold; see Theorems 6.1 and 6.2 in [6]. In both cases the Pollaczek polynomials will be orthogonal with respect to an absolutely continuous measure supported on [-1, 1]. In the other cases of orthogonality we cannot assume that the x zeros can be arranged as in (1.5). This situation will be discussed in §5. One of the reasons for the interest in the Pollaczek polynomials and their zeros is that they do not belong to the Szegö class [2] and as such their θ zeros are not uniform on the semicircle. The spectral properties of the Pollaczek polynomials also proved to be very interesting [2], [6].

It is not clear that Novikoff's methods can be used to extend (1.7) to general $\lambda > 0$. Askey [1] conjectured that the next term in the asymptotic expansion of $\theta_{n,k}$ will involve zeros of a certain transcendental function. The purpose of this paper is to solve Askey's problem. In the process of solving Askey's problem we discovered new properties of a special confluent Horn function ψ_2 [9, p. 225].

Define an even entire transcendental function $F_\lambda(z, c)$ by

$$F_\lambda(z, c) := \int_0^1 (1 - v^2)^{\lambda-1} e^{cv^2} \cos(vz)\, dv. \tag{1.8}$$

THEOREM 1. *Let $\lambda > 0$ and a, b be real and define $\zeta_n > 0$ by*

$$\zeta_n^2 := \frac{2(a+b)}{n} + \sqrt{2(a+b)}\,\xi n^{-3/2} + o(n^{-3/2}). \tag{1.9}$$

Then the asymptotic relationship

$$\begin{aligned} \lim_{n\to\infty} P_n^\lambda(\cos\zeta_n; a, b) \left(\frac{2(a+b)}{n}\right)^{\lambda-1/2} \exp\left(-\pi\sqrt{n(a+b)/2}\right) \\ = \frac{1}{\pi} e^{-a-b} F_\lambda(\zeta, a+b) \end{aligned} \tag{1.10}$$

holds uniformly on compact subsets of the complex ξ plane.

In §2 we will prove Theorem 1. Our proof uses the representation (1.3) and the integral representation [20, §30, p. 47]

$${}_2F_1(a, b; c; z) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)} \int_0^1 u^{b-1}(1-u)^{c-b-1}(1-uz)^{-a}\, du, \tag{1.11}$$

provided $\mathrm{Re}(c) > \mathrm{Re}(b) > 0$. If a is a not a negative integer we need the additional assumption $|z| < 1$.

In §3 we shall prove that the zeros of the function $F_\lambda(z, c)$ are real and either simple or double, if $c \geq 0$ and $\lambda > 0$. This will be stated as Theorem 3. We shall also study some analytic properties of the function $F_\lambda(z, c)$ including differential recurrence relations and a differential equation satisfied by $F_\lambda(z, c)$. We conjecture that all the zeros of $F_\lambda(z, c)$ are simple for $c \geq 0$ and $\lambda > 0$, but we have not been able to prove this conjecture. In §4 we shall prove Theorem 2.

THEOREM 2. *Assume that a and b are real such that either $a > |b|$ or $a = b \geq 0$ hold. If $\lambda > 0$ and $(a,b) \neq (0,0)$, then*

$$\theta_{n,k}(\lambda,a,b) = \sqrt{\frac{2(a+b)}{n}}\left\{1 + \frac{\xi_k(\lambda,a+b)}{\sqrt{2(a+b)n}} + O(n^{-1})\right\} \quad \text{as } n \to \infty \tag{1.12}$$

holds for $k = 1,2,\ldots,$ where

$$0 < \xi_1(\lambda,c) \leq \xi_2(\lambda,c) \leq \cdots \leq \xi_k(\lambda,c) \leq \cdots, \tag{1.13}$$

are the positive zeros of the function $F_\lambda(z,c)$.

In §4 we shall also establish results concerning zeros of functions that are finite Fourier cosine transforms.

Theorem 2 solves a problem of Askey [1] and gives a new derivation of Novikoff's unpublished asymptotic results [17] and extends them from $\lambda = \frac{1}{2}$ to $\lambda > 0$. In §5 we shall give an alternate asymptotic formula when the assumptions of Theorem 2 are not valid but the Pollaczek polynomials are orthogonal. We will also mention several remarks.

2. Proof of Theorem 1. Using (1.3), (1.4), and (1.11) we find

$$P_n^\lambda(\cos\theta;a,b)$$
$$= \frac{e^{in\theta}\Gamma(n+2\lambda)/n!}{\Gamma(\lambda+it(\theta))\Gamma(\lambda-it(\theta))}\int_0^1 u^{\lambda+it(\theta)-1}(1-u)^{\lambda-it(\theta)-1}[1-u(1-e^{-2i\theta})]^n du.$$

We used $\Gamma(2\lambda+n)/\Gamma(2\lambda) = (2\lambda)_n$. Set $u = (1+v)/2$ to obtain the more convenient integral representation

$$\frac{n!|\Gamma(\lambda+it(\theta))|^2}{\Gamma(2\lambda+n)}P_n^\lambda(\cos\theta;a,b)$$
$$= 2^{1-2\lambda}e^{in\theta}\int_{-1}^1 (1-v^2)^{\lambda-1}\left(\frac{1+v}{1-v}\right)^{it(\theta)}\left\{\frac{1}{2}(1+e^{-2i\theta}) - \frac{v}{2}(1-e^{-2i\theta})\right\}^n dv$$
$$= 2^{1-2\lambda}\int_{-1}^1 (1-v^2)^{\lambda-1}\left(\frac{1+v}{1-v}\right)^{it(\theta)}(\cos\theta - iv\sin\theta)^n dv.$$

Thus

$$\frac{n!|\Gamma(\lambda+it(\theta))|^2}{\Gamma(2\lambda+n)(\cos\theta)^n}2^{2\lambda-1}P_n^\lambda(\cos\theta;a,b) = A_n(\theta) + A_n(-\theta), \tag{2.1}$$

with

$$A_n(\theta) := \int_0^1 (1-v^2)^{\lambda-1}\left(\frac{1+v}{1-v}\right)^{it(\theta)}(1-iv\tan\theta)^n dv. \tag{2.2}$$

To determine the large n behavior of $A_n(\theta/\sqrt{n})$, write the integrand in (2.2) after replacing θ by $\theta/\sqrt{n}$ in the form

$$(1-v^2)^{\lambda-1}\left(\frac{1+v}{1-v}e^{-2v}\right)^{it(\theta/\sqrt{n})}\exp[2iv\,t(\theta/\sqrt{n}) + n\log(1-iv\tan(\theta/\sqrt{n}))].$$

Recall the definition of $t(\theta/\sqrt{n})$ in (1.4) and note that

$$2iv\,t(\theta/\sqrt{n}) + n\log[1 - iv\tan(\theta/\sqrt{n})] = iv(n^{1/2}/\theta)[2(a+b) - \theta^2] + v^2\theta^2/2 + O(1/\sqrt{n}), \qquad n \to \infty.$$

Thus we have

$$A_n(\theta/\sqrt{n}) := \int_0^1 (1-v^2)^{\lambda-1} g_n(v)\,dv, \tag{2.3}$$

where

$$g_n(v) := \exp\left\{\frac{1}{2}\theta^2 v^2 + \frac{iv\sqrt{n}}{\theta}[2(a+b) - \theta^2] + it(\theta/\sqrt{n})\log\left(e^{-2v}\frac{1+v}{1-v}\right) + O(1/\sqrt{n})\right\}.$$

If θ in (2.3) is allowed to depend on n but tends to a finite limit other than $[2(a+b)]^{1/2}$ as $n \to \infty$, the the right side of (2.3) will tend to zero. This follows from the Riemann–Lebesgue lemma and the asymptotic method of stationary phase [18]. On the other hand, if $\theta^2 = 2(a+b) + \xi[2(a+b)/n]^{1/2} + \eta_n$ and $\eta_n\sqrt{n} \to 0$ as $n \to \infty$, then there is a chance that $A_n(\theta n^{-1/2})$ will tend to a finite limit. Indeed, with ξ_n as in (1.9) we have

$$A_n(\zeta_n) \to F_\lambda(\xi, a+b) + O(1/\sqrt{n}) \quad \text{as } n \to \infty. \tag{2.4}$$

To prove this, consider the integral

$$I_n(\theta) := \int_0^1 (1-v^2)^{\lambda-1} \exp\left\{(a+b)v^2 + i\xi v + it(\theta/\sqrt{n})\log(e^{-2v}(1+v)/(1-v))\right\} dv.$$

Thus

$$I_n(\theta) = F_\lambda(\xi, a+b) + \int_0^1 (1-v^2)^{\lambda-1} e^{(a+b)v^2 + i\xi v}\left\{\exp[it(\theta/\sqrt{n})\log(e^{-2v}(1+v)/(1-v))] - 1\right\} dv.$$

To determine the large n behavior of I_n we need to change variables and integrate by parts. Define functions $u(v)$ and $w(v)$ by

$$w'(v) := -(1-v^2)^{\lambda-1}\exp\left\{(a+b)v^2 + i\xi v\right\}, \qquad w(1) := 0,$$

$$u(v) := -2v + \ln(1+v) - \ln(1-v).$$

Integrate by parts to get

$$I_n(\theta) - F_\lambda(\xi, a+b) = it(\theta/\sqrt{n})\int_0^1 w(v)\exp[it(\theta/\sqrt{n})u(v)]u'(v)dv.$$

Now apply the method of stationary phase [18, §§13.2 and 13.3, pp. 100–101] to see that

$$I_n(\theta) - F_\lambda(\xi, a+b) \to 0 \quad \text{as } n \to \infty.$$

By adding and subtracting $I_n(\theta)$ to $A_n(\zeta_n)$ and keeping track of the error term in the asymptotic forms that are used, one can establish (2.4). Therefore,

$$\frac{\Gamma(n+1)}{\Gamma(n+2\lambda)}|\Gamma(\lambda + it(\zeta_n))|^2(\cos\zeta_n)^{-n}2^{2\lambda-2}P_n^\lambda(\cos\zeta_n) \to F_\lambda(\xi, a+b) \quad \text{as } n \to \infty. \tag{2.5}$$

But as $n \to \infty, n^{1-2\lambda}\Gamma(n+1)/\Gamma(2\lambda+n) \to 1$ [9, §1.18, eq. (4)], and $\log(\cos\zeta_n)^{-n} \approx -n\log[1-(\zeta_n)^2/2] \to a+b$. Futhermore, if x and y are real, then

$$|\Gamma(x+iy)|e^{\pi|y|/2}|y|^{\frac{1}{2}-x} \to \sqrt{2\pi} \quad \text{as } |y| \to \infty$$

[9, §1.18, eq. (6)]. The substitution of the last three asymptotic forms in (2.5) establishes (1.10) and completes the proof of Theorem 1.

3. Properties of $\mathbf{F}_\lambda$. When $\lambda > 0$ and $c \geq 0$ we can introduce Pollaczek parameters a and b as $a = c$, $b = 0$, so the corresponding polynomials will be orthogonal with respect to a measure supported on [-1, 1]; see Szegö [21]. In this case all the θ zeros are real.

THEOREM 3. *If $\lambda > 0$ and $c \geq 0$, then all the zeros of $F_\lambda(z,c)$ are real and simple or double.*

Proof. Let $\zeta_n = \zeta_n(\lambda, c)$ be as in (1.9). On compact subsets of the complex ξ plane, $F_\lambda(\xi, c)$ is the uniform limit of constant multiples Pollaczek polynomials with parameters $\lambda, c, 0$, and argument $\cos\zeta_n$. But the aforementioned Pollaczek polynomials have real and simple θ zeros, hence also have real and simple ξ zeros. By Hurwitz's theorem, Theorem 14.3.4 in [12, p. 205], the limiting function must have only real zeros. We will see that $F_\lambda(z,c)$ satisfies a third-order differential equation; see (3.12). From (3.12) it follows that if $F_\lambda(z,c)$ and its first two derivatives vanish at $z = z_0$, then all the derivatives of the entire function $F_\lambda(z,c)$ will also vanish at z_0, a contradiction. This completes the proof of Theorem 3.

One can identify $F_\lambda(z,c)$ as a confluent Horn function. To see this replace $\exp(cv^2)$ and $\cos vz$ by their Maclaurin series expansions; then set $u = v^2$ and integrate term by term. The result is

$$\begin{aligned} F(z,c) &= \frac{1}{2}\sum_{m,n=0}^{\infty} \frac{c^n}{n!}\frac{(-1)^m z^{2m}}{(2m)!}\int_0^1 (1-u)^{\lambda-1}u^{m+n-1/2}du \\ &= \frac{1}{2}\sum_{m,n=0}^{\infty} \frac{c^n}{n!}\frac{(-1)^m z^{2m}}{(2m)!}\frac{\Gamma(\lambda)\Gamma(m+n+1/2)}{\Gamma(\lambda+m+n+1/2)} \\ &= \frac{\Gamma(\lambda)\Gamma(3/2)}{\Gamma(\lambda+1/2)}\sum_{m,n=0}^{\infty} \frac{(-1)^m c^n (z/2)^{2m}}{n!m!(1/2)_m}\frac{(1/2)_{m+n}}{(\lambda+1/2)_{m+n}}, \end{aligned}$$

where we used $\Gamma(a+n)/\Gamma(a) = (a)_n$ and $(2m)! = 2^{2m}m!(1/2)_m$. Now set $s := m+n$ to get

$$F_\lambda(z,c) = \frac{\Gamma(\lambda)\Gamma(3/2)}{\Gamma(\lambda+1/2)}\sum_{s=0}^{\infty}\frac{1/2_s c^s}{(\lambda+1/2)_s s!}\,{}_1F_1\left(-s; 1/2; \frac{z^2}{4c}\right). \tag{3.1}$$

Apply the Kummer transformation [20, §69, p. 125]

$${}_1F_1(a;b;z) = e^z\,{}_1F_1(b-a;b;-z) \tag{3.2}$$

to the ${}_1F_1$ in (3.1) to obtain

$$F_\lambda(z,c) = \frac{\Gamma(\lambda)\Gamma(3/2)}{\Gamma(\lambda+1/2)}\exp\left(\frac{z^2}{4c}\right)\sum_{s=0}^{\infty}\frac{(1/2)_s c^s}{(\lambda+1/2)_s s!}\sum_{k=0}^{\infty}\frac{(s+1/2)_k}{k!(1/2)_k}\left(-\frac{z^2}{4c}\right)^k. \tag{3.3}$$

Therefore, F_λ is related to a confluent Horn function ψ_2 [9, §5.7.1, p. 225] via

$$F_\lambda(z,c) = [\Gamma(\lambda)\Gamma(\tfrac{3}{2})/\Gamma(\lambda+\tfrac{1}{2})]\exp(z^2/(4c))\psi_2(\tfrac{1}{2},\lambda+\tfrac{1}{2},\tfrac{1}{2},c,-z^2/(4c)). \tag{3.4}$$

Observe that the expansion (3.1) is a Fourier Hermite expansion, since [10, (10.13.2), (10.12.14)]

$$H_{2n}(x) = (-1)^n 2^{2n} n! L_n^{(-1/2)}(x^2) = (-1)^n 2^{2n}(1/2)_n \ {}_1F_1(-n;1/2;x^2).$$

Therefore (3.1) is equivalent to the Fourier–Hermite expansion

$$F_\lambda(2z\sqrt{c},c) = \frac{\Gamma(\lambda)\Gamma(3/2)}{\Gamma(\lambda+1/2)}\sum_{s=0}^{\infty}\frac{(-c/4)^s}{s!(\lambda+1/2)_s}H_{2s}(z). \tag{3.5}$$

Recall the Poisson integral representation [22, §3.3, (3)]

$$\Gamma(v+1/2)J_\nu(z) = \frac{2}{\sqrt{\pi}}\left(\frac{z}{2}\right)^\nu\int_0^1(1-t^2)^{\nu-1/2}\cos(zt)dt. \tag{3.6}$$

Thus

$$F_\lambda(z,0) = \Gamma(3/2)\Gamma(\lambda)(z/2)^{\lambda-1/2}J_{\lambda-1/2}(z).$$

This suggests expanding $F_\lambda(z,c)$ in terms of Bessel functions. We start with (1.8), replace $\exp(cv^2)$ by $e^c\exp[-c(1-v^2)]$, then expand the latter exponential in powers of $1-v^2$. The resulting integrals can be evaluated by (3.6). The final result is

$$F_\lambda(z,c) = e^c\frac{\sqrt{\pi}}{2}\Gamma(\lambda)\left(\frac{2}{z}\right)^{\lambda-1/2}\sum_{n=0}^{\infty}\frac{(\lambda)_n}{n!}\left(-\frac{2c}{z}\right)^n J_{\lambda+n-1/2}(z). \tag{3.7}$$

The functions $F_\lambda(z,c)$ generalize Bessel functions, so we are guided in our study of $F_\lambda(z,c)$ by properties of Bessel functions. As a first step we derive differential recurrence relations for the function $F_\lambda(z,c)$. The corresponding differential operators raise and lower the parameter λ. Differentiate (1.8) twice with respect to x to get the first differential recurrence relation

$$\frac{d^2}{dx^2}F_\lambda(x,c) = F_{\lambda+1}(x,c) - F_\lambda(x,c). \tag{3.8}$$

The second is

$$2c\frac{d^2}{dx^2}F_\lambda(x,c) - x\frac{d}{dx}F_\lambda(x,c) = (2\lambda-1)F_\lambda(x,c) - 2(\lambda-1)F_{\lambda-1}(x,c). \tag{3.9}$$

To prove (3.9) first assume $\lambda > 2$ and replace $(1-v^2)^{\lambda-1}$ by $(1-v^2)(1-v^2)^{\lambda-2}$ in the integrand in (1.8). Thus

$$F_\lambda(x,c) = F_{\lambda-1}(x,c) + \frac{1}{2}\int_0^1(-2v)(1-v^2)^{\lambda-2}[ve^{cv^2}\cos(vx)]dv.$$

An integration by parts gives

$$2(\lambda-1)F_\lambda(x,c) = 2(\lambda-1)F_{\lambda-1}(x,c) - \int_0^1(1-v^2)^{\lambda-1}\frac{d}{dv}[ve^{cv^2}\cos(vx)]dv,$$

and, after simple manipulations we establish (3.9) for $\lambda > 2$. The latter restriction can be weakened to $\lambda > 1$ by analytic continuation. Set

$$D := \frac{d}{dx}, \quad L_1 := I + D^2, \quad L_2 := 2cD^2 - xD - (2\lambda - 1)I, \tag{3.10}$$

where I is the identity operator. The operators L_1 and L_2 raise and lower the parameter λ. It is interesting to note that I, L_1, and L_2 form a Lie algebra. Let L_3 represent multiplication by x^2. The operators I, L_1, L_2, and L_3 form a Lie algebra isomorphic to $su(1, 1)$. Thus $\{I, L_1, L_2, L_3\}$ provide a new realization for $su(1, 1)$. This is a somewhat surprising fact because the group theoretic results known to date dealt with Horn functions as solutions of second-order partial differential equations and as such missed this connection. Furthermore, this suggests that the Pollaczek polynomials are matrix elements of representations of a larger Lie group that degenerates to $SU(1,1)$ by a group contraction.

The next step is to derive an analog of the Bessel differential equation. Differentiate (1.8); then integrate by parts to obtain the differential recurrence relation

$$2\lambda \frac{d}{dx} F_\lambda(x, c) = 2c \frac{d}{dx} F_{\lambda+1}(x, c) - x F_{\lambda+1}(x, c). \tag{3.11}$$

Now eliminate $F_{\lambda+1}$ between (3.8) and (3.11). The result is the differential equation

$$2c \frac{d^3}{dx^3} F_\lambda(x, c) - x \frac{d^2}{dx^2} F_\lambda(x, c) + 2(c - \lambda) \frac{d}{dx} F_\lambda(x, c) - x F_\lambda(x, c) = 0. \tag{3.12}$$

The differential equation satisfied by $u := {}_1F_1(-; \nu + 1, -x^2/4)$ is [20, (3), p. 109]

$$xu'' + (2\nu + 1)u' + xu = 0.$$

It is clear that (3.12) reduces to the above differential equation when $c \to 0$ and $\lambda = \nu + \frac{1}{2}$.

It is important to note that we treat the function $F_\lambda(z, c)$ as a function of one variable, namely, z. Although a confluent Horn function ψ_2 (a, b, c, x, y) satisfies a homogeneous second-order partial differential equation; $F_\lambda(z, c)$, as a function of z, does not seem to satisfy a homogeneous second-order ordinary differential equation.

4. Zeros of finite Fourier cosine transforms. We first outline a proof of Theorem 2.

Proof of Theorem 2. Hurwitz's theorem, Theorem 14.3.4 in Hille [12, p. 205], asserts that if $\{f_n(z)\}$ is a sequence of holomorphic functions in a domain D and $f_n(z)$ converges to $f(z)$ uniformly in D, then for every $\varepsilon > 0$, there is N_ε such that $f_n(z)$, for $n > N_\varepsilon$, has the same number of zeros in the disc $|z - a| < \varepsilon$ as f has. Theorem 2 follows from the latter fact and Theorem 1.

We follow the notation in Pólya [19] and define

$$U(z) := \int_0^1 f(t) \cos(zt) dt, \qquad V(z) := \int_0^1 f(t) \sin(zt) dt. \tag{4.1}$$

We assume that the integrals in (4.1) exist. Langer [14] denotes $U(z)$ and $V(z)$ by $\Phi_c(z)$ and $\Phi_s(z)$, respectively.

THEOREM 4 (Pólya [19]). *Let $f(t)$ be a nonnegative, nondecreasing function on $[0, 1)$. Then zeros $U(z)$ and $V(z)$ are all real and simple and each interval $(n\pi, (n +$*

$1)\pi$) *contains one and only one zeros of* $V(z)$. *If in addition* $f(t)$ *is convex, then* $U(z)$ *has one and only one zero in each interval* $((n-1/2)\pi, n\pi), n = 1, 2, \ldots$.

To prove Theorem 4, Pólya first noted that $U(z)$ and $V(z)$ are uniform limits, on compact sets, of the trigonometric polynomials

$$\frac{1}{n}\sum_{j=0}^{n-1} f(j/n)e^{j/n^2}\cos(jz/n) \text{ and } \frac{1}{n}\sum_{j=0}^{n-1} f(j/n)e^{j/n^2}\sin(jz/n),$$

respectively, as $n \to \infty$ and used a trigonometric version of Kakeya's theorem and Hurwitz's theorem to establish the reality of the zeros of $U(z)$ and $V(z)$. Pólya proved the positivity of the Wronskian of $U(x)$ and $V(x)$, that is,

$$U(x)V'(x) - U'(x)V(x) > 0 \quad \text{for real } x.$$

The above inequality shows that the zeros of $U(z)$and $V(z)$ are simple.

It is worth mentioning that one can show that $U(z)$ has an odd number of zeros in every interval $((n-1/2)\pi, n\pi), n > 0$ as follows. Let $x = (m + a/2)\pi$, where m is a positive integer and $0 \le a \le 1$. Then

$$U\left(\left(m+\frac{1}{2}a\right)\pi\right) = \frac{1}{2m+a}\int_0^{2m+a} f(u/(2m+a))\cos\left(\frac{1}{2}\pi u\right)du.$$

The above integral may be written in the form

$$\frac{1}{2m+a}\left\{\sum_{k=1}^{m}(-1)^k v_k + (-1)^m w_m\right\},$$

where

$$\begin{aligned} v_k &:= (-1)^k \int_{2k-2}^{2k} f(u/(2m+a))\cos\left(\frac{1}{2}\pi u\right)du, w_m \\ &:= (-1)^m \int_{2m}^{2m+a} f(u/(2m+a))\cos\left(\frac{1}{2}\pi u\right)du. \end{aligned}$$

Now use

$$\int_{2k-2}^{2k} = \int_{2k-2}^{2k-1} + \int_{2k-1}^{2k}$$

and set $u = 2k-1-U$ in the first integral and $u = 2k-1+U$ in the second integral to get

$$v_k = \int_0^1 \left\{f\left(\frac{2k-1+U}{2m+a}\right) - f\left(\frac{2k-1-U}{2m+a}\right)\right\}\sin\left(\frac{1}{2}\pi U\right)dU.$$

It is clear that the integrand of the least integral is positive and increases with k. It is also clear that $w_m \ge 0$. Thus sgn $U((m+a/2)\pi) = (-1)^m$ and the proof is complete. This proof parallels a proof of Lommel's theorem given in Watson [22, §15.2]. Watson

attributes the proof of Lommel's theorem to Lommel and is based on an idea that goes back to Bessel. Pólya [19] used a different agrument to prove the same result.

When $f(t) = (1-t^2)^{\nu-1/2}, U(z)$ will be a constant multiple of $z^{-\nu}J_\nu(z)$ and Theorem 4 is applicable when $-\frac{1}{2} < \nu \leq \frac{1}{2}$. This is Lommel's theorem [22, §15.2]. When $f(t) = (1-t^2)^{\lambda-1}\exp(ct^2), 0 < \lambda \leq 1, c \geq 0$, Theorem 4 is also applicable and in this case $U(z) = F_\lambda(z, c)$. The version of Theorem 4 mention in [14] is Theorem 12 on page 234 and contains an obvious misprint, where "non" is deleted from "nondecreasing."

The next theorem was motivated by problem 6 of §17 in Chapter IX of Dieudonné [8]. Its proof requires the following lemma.

LEMMA 1. *The zeros of the function $A\sin z - B(\cos z)/z$ has infinitely many zeros and they are all real and simple provided that $AB > 0$.*

This is the case $\nu = -\frac{1}{2}$ of a result involving zeros of $AJ_\nu(z) + Bz(J_\nu(z))'$; see [10, §7.9, p. 59].

THEOREM 5. *Let $f(t)$ be a real valued twice continuously differentiable function on [0, 1] such that $f'(1)f(1) < 0$, and let $\{x_n : 1 \leq n < \infty\}$ be the positive zeros of*

$$g(z) := f(1)\sin z + f'(1)(\cos z)/z.$$

Define $U(z)$ as in (4.1) and assume $f'(0) = 0$. Then

(i) *The function $zU(z)$ has infinitely many zeros.*

(ii) *For sufficiently large $R, R \neq x_n$ for any $n, g(z)$ and $zU(z)$ have the same number of zeros in $|z| < R$.*

(iii) *The zeros of $zU(z)$ in the right half plane can be indexed as $\{z_n : 1 \leq n < \infty\}$ such that $z_n - x_n \to 0$ as $n \to \infty$.*

Proof. Integrate by parts twice to get

$$zU(z) = f(1)\sin z + f'(1)(\cos z)/z + G(z),$$

where

$$G(z) := -\frac{1}{z}\int_0^1 f''(t)\cos(zt)dt.$$

Clearly the function $f(1)\sin z + f'(1)(\cos z)/z$ is odd and its zeros coincide with the zeros of

$$zf(1)/f'(1) + \cot z.$$

From the graphs of $zf(1)/f'(1)$ and $\cot z$ it is easy to see that $x_{n+1} > n\pi, n \geq 0$, and $x_{n+1} - n\pi \to 0$ as $n \to \infty$. Given r, it is clear that there is a constant C such that

$$|G(z)| \leq Ce^{|\mathrm{Im}\, z|}/|z| \quad \text{and} \quad |f'(1)(\cos z)/z| \leq Ce^{|\mathrm{Im}\, z|}/|z| \quad \text{for } |z| \geq r. \tag{4.2}$$

It is also clear that

$$|\sin z| = \sin^2 x + \sinh^2 y, \qquad z = x + iy. \tag{4.3}$$

Thus if $|\mathrm{Im}\, z| \geq a$, then $|\sin z| \geq e^{-a}(\sinh a)e^{|\mathrm{Im}\, z|}$. This shows that $|g(z)| \geq |G(z)|$ for sufficiently large z if $|\mathrm{Im}\, z|$ is bounded away from zero. If $|\mathrm{Im}\, z|$ is near zero and x is bounded away from x_n and $n\pi$, then (4.2) and (4.3) show that $|g(z)| \geq |G(z)|$ holds on circles centered at $z = 0$ with sufficiently large radii, provided they are bounded away from the set of zeros of $g(z)$ and the integer multiples of π. Parts (i) and (ii)

now follow from Rouchés' theorem [8, §9.17]. Part (iii) also follows from Rouchés' theorem applied to a square contour centered at x_n with vertices $(x_n \pm \varepsilon, \pm i\varepsilon)$, where ε is positive and none of the point $\pi, 2\pi, \ldots$ is inside or on the boundary of the square.

COROLLARY 1. *Under the assumptions of Theorem* 5 *the zeros of* $zU(z)$ *are all simple, except, possibly, for finitely many zeros.*

Theorem 5 and Corollary 1 are applicable when $f(t) = (1 + \varepsilon - t^2)^{\lambda-1} \exp(ct^2)$, if $\varepsilon > 0, \lambda \geq 3$, and $c\varepsilon < \lambda - 1$.

5. Other cases of orthogonal Pollaczek polynomials. The Pollaczek polynomials are orthogonal with respect to a positive measure if and only if

$$\text{(5.1) (i)} \quad \lambda > 0 \quad \text{and} \quad \lambda + a > 0, \quad \text{or} \quad \text{(ii)} \quad -1/2 < \lambda < 0 \quad \text{and} \quad -1 < \lambda + a < 0.$$

It is then natural to extend Theorems 1 and 2 to the full range of parameters in (5.1) and also to study the large n behavior of $\theta_{n,n-k}$ for fixed k. It is easy to see from (1.2) or (1.3) that

$$P_n^{\lambda}(-x; a, b) = (-1)^n P_n^{\lambda}(x; a, -b). \tag{5.2}$$

Therefore,

$$\theta_{n,n-k}(\lambda, a, b) = \pi - \theta_{n,k}(\pi, a, -b) \tag{5.3}$$

and the asymptotics of $\theta_{n,n-k}(\lambda, a, b)$ follows from Theorem 2 if $a > |b|$ and $\lambda > 0$.

Our methods do not seem be able to treat cases with $\lambda < 0$, so we will focus our attention on case (i) in (5.1). In view of (5.2) there is no loss of generality in assuming $b \geq 0$, so will restrict ourselves to

$$\lambda > 0, \qquad b \geq 0. \tag{5.4}$$

Recall that the measure that the Pollaczek polynomials are orthogonal with respect to is absolutely continuous if and only if $\lambda > 0$ and either $a > |b|$ or $a = b \geq 0$; otherwise it will have a nontrivial discrete part. Thus the cases not covered by Theorem 2 all have discrete spectrum. We will follow the notation in [6] and denote the set of mass points by D^*. The set D^* has been characterized in all cases of orthogonality. Define sequences $\{\Delta_n\}, \{x_n\}$, and $\{y_n\}$ by

(5.5)
$$\Delta_n = (n+\lambda)^2 + b^2 - a^2, \quad x_n = \frac{-ab + (n+\lambda)\sqrt{\Delta_n}}{a^2 - (n+\lambda)^2}, \quad y_n = \frac{-ab - (n+\lambda)\sqrt{\Delta_n}}{a^2 - (n+\lambda)^2}.$$

When (5.4) holds the set D^* can be described as follows:

$$\text{(5.6)} \quad \text{Region I*-(i)} := \{(\lambda, a, b) : 0 \leq a < b, b \geq 0, \lambda > 0\}, \quad D^* = \{x_n : n \geq 0\},$$

(5.7)
$$\text{Region II*-(i)} := \{(\lambda, a, b) : -b \leq a < 0, \lambda > 0, \lambda + a > 0, b \geq 0\}, \quad D^* = \{x_n : n \geq 0\},$$

(5.8)
$$\text{Region II*-(ii)} := \{(\lambda, a, b) : a < -b, \lambda > 0, b > 0\}, \quad D^* = \{x_n : n \geq 0\} \cup \{y_n : n \geq 0\}.$$

In all regions x_n and y_n are as in (5.5) and they satisfy $x_n < x_{n+1} < -1, 1 < y_{n+1} < y_n$ for all n. Since the kth smallest zero $x_{n,n-k}(\lambda, a, b)$ will tend to x_k as $n \to \infty$ and, in

region II*-(ii), $x_{n,k} \to y_k$ as $n \to \infty$, then in order to study the limiting behavior of zeros that remain in [-1, 1] we must restrict ourselves to regions I*-(i) and II*-(i).

THEOREM 6. *Assume that* a, b, *and* λ *satisfy* (5.4) *and either* $0 \le a < b$ *or* $-b \le a < b$. *If* $(a,b) \ne (0,0)$, *then*

$$\theta_{n,k}(\lambda,a,b) = \sqrt{\frac{2(a+b)}{n}} + \frac{\xi_k(\lambda,a+b)}{n} + O(n^{-3/2}) \quad \text{as } n \to \infty \tag{5.9}$$

holds for $k = 1, 2, \dots$, *where the* ξ_k*'s are the zeros of* $F_\lambda(z, a+b)$ *ordered as in* (1.13).

The proof of Theorem 6 is similar to the proof we gave for Theorem 2 and will be omitted.

The Liouville–Green or WKB asymptotic method [18] is a powerful tool for determining the asymptotic behavior of solutions of second-order differential equations. The Pollaczek polynomials satisfy the three-term recurrence relation (1.2), which is a second-order difference equation. It is highly desirable to have a discrete analog of Liouville–Green (WKB) method with uniform error bounds, which can be applied to the Pollaczek polynomials. One difficulty is that the limiting function $F_\lambda(z,c)$ does not seem to satisfy a three-term recurrence relation. It is easy to derive a four-term recursion relation for $F_\lambda(z,c)$ from the differential recurrence relations (3.8) and (3.9). The works [5] and [11] formulated discrete analogs of the Liouville–Green but we still do not have uniform asymptotic estimates for these discrete Liouville–Green approximation methods.

The discrete analogs of the functions $U(z)$ and $V(z)$ of (4.1) are exponential sums. The survey article [14] surveys the results on zeros of exponential sums and integrals up to 1931. For later developments see [3], [15], and [16]. In [4], Boas comments on [19] and provides valuable information and references on zeros of exponential sums and integrals.

It is clear that the function $F_\lambda(z,c)$ has a companion function

$$G_\lambda(z,c) = \int_0^1 (1-v^2)^{\lambda-1} e^{cv^2} \sin(vz)\,dv.$$

This suggests a further study of the functions F_λ and G_λ similar to the Polya's investigations of the U and V functions [19].

Acknowledgments. This paper is dedicated to Richard Askey and Frank Olver in appreciation for the help they have given me over the years and for their immeasurable influence on my professional career.

I am grateful to Richard Askey for proposing the topic of this paper and for his constant help and encouragement. I thank Ruiming Zhang for highly recommending Pólya's collected papers where I found [19] and Boas's very informative comments [4].

ASYMPTOTIC REMAINDERS*

D. S. JONES†

Abstract. It is shown that the remainders in a variety of asymptotic series can be estimated uniformly by the same integral.

Key words. approximation, uniform asymptotics

AMS subject classification. 41A60

1. Introduction. The determination of estimates for the remainders in asymptotic expansions has been the subject of intensive research in the last few years. It may be said to have originated in the book by Dingle (1973), in which divergent series were summed by Borel integrals. It has come to the fore recently because of the desire to improve the uniform validity of asymptotic formulae and, in particular, to provide smooth transitions across Stokes lines. Berry (1989), following Dingle, suggested that the transition could always be accomplished by a suitable error function but did not furnish a rigorous derivation.

Most attempts to supply a rigorous foundation have centered on specific integral representations. For instance, Boyd (1990) used Stieltjes transforms, Jones (1990) and Olver (1990), (1991a), (1991b) used Laplace transforms, Ursell (1990) discussed Watson's lemma, and Paris (1991), (1992) found profit in Mellin–Barnes integrals. The transition functions that have been discovered to have the widest validity are not error functions themselves but are the incomplete gamma function and related functions. However, all of these functions turn out to behave like an error function near a Stokes line, so that the universality suggested by Berry and Dingle does appear to be justified.

In the meantime, Berry (1990), (1991a), (1991b) continued to find more and more places where the remainder of a series can be estimated by an error function in the neighborhood of a Stokes line. One of his papers (1991a), in particular, considers some highly divergent series. Series that are solutions of certain differential equations have been examined by Paris (1992) (see also Paris and Wood (1985)), but, on the whole there have been few investigations that deal directly with series, as opposed to integral representations, especially those of the type that Berry has looked at.

Therefore, it seemed appropriate to see what progress could be made by starting from a series representation, and some results are given in this paper. The method is flexible and is capable of many generalizations, but here we shall limit the theorems to the more straightforward applications and leave the generalizations to another paper (Jones (1993)).

In some of the proofs simplification is achieved by nonstandard analysis. In this context the symbol $\simeq$ is used between quantities that differ by an infinitesimal. Also, $\mathcal{I}$ will denote a generic infinitesimal and is not necessarily the same whenever it occurs. Thus it is legitimate to write

$$2\mathcal{I} = \mathcal{I}, \quad \ln(1+\mathcal{I}) = \mathcal{I}, \quad b\mathcal{I} = \mathcal{I}$$

* Received by the editors April 1, 1992; accepted for publication (in revised form) February 12, 1993.

† Department of Mathematics and Computer Science, University of Dundee, Dundee DD1 4HN, Scotland, U. K.

when b is limited. However, if ω is unlimited, $\omega\mathcal{I}$ must be retained unaltered since it may be anything from infinitesimal to unlimited.

The nonstandard analysis is based on the set theory of Nelson (1977). Nelson provides an algorithm that reduces a nonstandard statement to a classical one. In essence, the argument goes like this in our context. Suppose that for all infinitesimal ε, $f(\varepsilon) \simeq 0$, where f is a standard function. Then, for any standard $\eta > 0$,

$$(*) \qquad |f(\varepsilon)| < \eta$$

for all infinitesimal ε. Hence for all standard $\eta > 0$ there is $\delta > 0$ such that (*) holds for all $|\varepsilon| \leq \delta$. Since this statement contains no free parameters other than the standard f and η, the transfer principle permits the classical statement that for all $\eta > 0$ there is $\delta > 0$ such that (*) is valid for all $|\varepsilon| \leq \delta$.

For the convenience of the reader the nonstandard results used most frequently in subsequent sections are collected in Appendices A and B.

Estimates of the remainder in a series have been considered for many years, and some early formulae did not involve the error function. Nevertheless, it is shown in §2 that both the early estimate and the error function are different ways of approximating a certain integral. It is conjectured, therefore, that this integral is the real universal character in the assessment of remainders. Supporting evidence is supplied in §§3 and 4, where power series are studied under fairly weak conditions on the coefficients.

Asymptotic series are introduced in §5, and a key theorem concerning them is proved. This permits the demonstration in §6 that many asymptotic power series have remainders that can be expressed in terms of the integral just described. One or two extensions are mentioned, but further details are deferred to another paper.

2. A universal link. The aim of this section is to reconcile what appear, at first sight, to be two totally different ways in which the series $\sum_{n=0}^{\infty} a_n z^n$ performs. A classical result due to Izumi (1927) (see also Titchmarsh (1939)) states that if $a_n/a_{n+1} \to 1$ as $n \to \infty$,

$$\frac{\sum_{m=0}^{n} a_m z^m}{a_n z^n} \to \frac{z}{z-1},$$

provided that $|z| \geq 1+\delta > 1$. Similar behavior was obtained by Olver (1974) for some divergent series when $|z|$ was small. One conjectures that $(z-1)^{-1}$ might represent a characteristic way for power series to behave. On the other hand, the research of Berry suggests that the error function has a universal role. It is not immediately clear how this apparent conflict is resolved.

Our proposal for the reconciliation between these seemingly different points of view is to regard them as aspects of the integral

$$(1) \qquad J(\mu, \varepsilon) = \int_0^{\infty} \frac{t^{\mu} e^{-t}}{1+\varepsilon t} dt$$

and to suggest that J is the proper universal function to adopt. For simplicity, μ will be taken to be real and positive in the following.

When ε is small, the integral in (1) has the following asymptotic representation (see Olver (1991b) and Jones (1990)) for $0 \geq \text{ph}\, \varepsilon \geq -3\pi/2$ $(0 \leq \text{ph}\, (1/\varepsilon) \leq 3\pi/2)$:

$$J(\mu,\varepsilon) \sim \frac{\pi i}{\varepsilon}\left(\frac{e^{-\pi i}}{\varepsilon}\right)^{\mu} e^{1/\varepsilon}\left[2H(-\text{ph }\varepsilon-\pi)-\text{erfc}\left\{ir_0\left(\frac{\mu}{2}\right)^{1/2}\right\}\right]$$
$$+(2\pi\mu)^{1/2}e^{\mu\ln\mu-\mu}\left(\frac{1}{1+\mu\varepsilon}+\frac{1}{\varepsilon\mu r_0}\right), \tag{2}$$

where

$$\text{erfc }(w)=\frac{2}{\pi^{1/2}}\int_w^{\infty} e^{-y^2}\,dy$$

and $H(x)$ is the Heaviside step function. Also,

$$\frac{1}{2}r_0^2=-1-\frac{1}{\mu\varepsilon}-\ln\left(\frac{e^{-\pi i}}{\mu\varepsilon}\right). \tag{3}$$

The sign of r_0 is determined first when ph $\varepsilon=-\pi$, being negative when $\mu|\varepsilon|>1$ and positive when $\mu|\varepsilon|<1$. For other values of ph ε the sign of r_0 is fixed by continuity. Thus when ph ε becomes less than $-\pi$, with $\mu|\varepsilon|>1$, r_0 moves into the second quadrant and Im $(r_0)>0$; in fact, Im $(r_0)>0$ when ph $\varepsilon<-\pi$. Likewise, when ph $\varepsilon>-\pi$, Im $(r_0)<0$. Although (2) refers to one range of ph ε, another can be covered easily by taking a complex conjugate. For example, when $0<\text{ph }\varepsilon\leq 3\pi/2$,

$$J(\mu,\varepsilon) \sim \frac{\pi i}{\varepsilon}\left(\frac{e^{-\pi i}}{\varepsilon}\right)^{\mu} e^{1/\varepsilon}\left[\text{erfc}\left\{-ir_2\left(\frac{\mu}{2}\right)^{1/2}\right\}-2H(\text{ph }\varepsilon-\pi)\right]$$
$$+(2\pi\mu)^{1/2}e^{\mu\ln\mu-\mu}\left(\frac{1}{1+\mu\varepsilon}+\frac{1}{\varepsilon\mu r_2}\right),$$

where

$$\frac{1}{2}r_2^2=-1-\frac{1}{\mu\varepsilon}-\ln\left(\frac{e^{\pi i}}{\mu\varepsilon}\right)$$

and Im $(r_2)>0$ for ph $\varepsilon<\pi$, whereas Im $(r_2)<0$ for ph $\varepsilon>\pi$.

While (2) reveals the relation of (1) to the error function, the connection with the Izumi kind of behavior is provided by the following theorem.

LINK THEOREM. *Let $\varepsilon\simeq 0$ and $|\text{ph }\varepsilon|<\pi-\delta$, where δ is a positive standard number. Then*

$$J(\mu,\varepsilon)=\frac{\mu!(1+\mathcal{I})}{1+\mu\varepsilon}$$

for limited $\mu\varepsilon$.

Before proceeding to the proof, we observe that if ph $\varepsilon>-\pi$ and $|r_0\mu^{1/2}|\gg 1$, the error function in (2) can be replaced by its conventional asymptotics because Im $(r_0)<0$. The net result is that

$$J(\mu,\varepsilon)\sim(2\pi\mu)^{1/2}\frac{e^{\mu\ln\mu-\mu}}{1+\mu\varepsilon}.$$

If Stirling's formula for large μ

$$\mu!=(1+\mathcal{I})(2\pi)^{1/2}\exp\left\{\left(\mu+\frac{1}{2}\right)\ln\mu-\mu\right\}, \tag{4}$$

is invoked, a formula similar to that in the Link Theorem is obtained. Consequently, there are circumstances in which the estimates of J in the Link Theorem and (2) agree. In fact, (2) continues to reproduce the same formula when ph $\varepsilon < -\pi$ because the change in the asymptotic behavior of the error function caused by Im $(r_0) > 0$ is canceled by the contribution from the Heaviside step function. A numerical comparison is provided in Appendix C.

Proof. Consider first the case in which μ is limited. When t is limited, $t\varepsilon$ is infinitesimal and $1 + \varepsilon t \simeq 1$. Moreover, there is a finite K for any t such that

$$\left|\frac{t^\mu e^{-t}}{1+\varepsilon t}\right| < Kt^\mu e^{-t}$$

since $|1 + \varepsilon t| \geq \sin\delta$. It follows from Lemma A.2 that

$$J(\mu,\varepsilon) = \mu!(1+\text{I}) = \frac{\mu!}{1+\mu\varepsilon}(1+\text{I})$$

since $\mu\varepsilon \simeq 0$ when μ is limited.

Next, suppose that μ is unlimited but that $\mu\varepsilon$ is limited. Make the substitution $t = \mu u$, so that the integral becomes

$$\mu^{\mu+1}\int_0^\infty \frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du.$$

Let $\theta = 1/\mu^{1/4}$, so that θ is, in fact, infinitesimal. For $u \geq 1+\theta$, $-1 + 1/u \leq -\theta/(1+\theta)$ and hence

$$\ln u - u \leq \ln(1+\theta) - 1 - \theta - \frac{\theta(u-1-\theta)}{1+\theta}.$$

Also, because μ is unlimited, Stirling's formula (4) gives

(5)
$$\left|\frac{\mu^{\mu+1}}{\mu!}\int_{1+\theta}^\infty \frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du\right| \leq \frac{K\mu^{\mu+1}}{\mu!}\exp\{(\mu+1)\ln(1+\theta) - \mu(1+\theta) - \ln(\mu\theta)\}$$
$$\leq K\exp\left(-\frac{1}{2}\ln\mu + \theta - \ln\theta\right) \leq \frac{K}{\mu^{1/4}} \simeq 0,$$

K being adjusted as necessary to absorb finite constants.

For $u \leq 1-\theta$, $-1 + 1/u \geq \theta/(1-\theta)$, so that

$$\ln u - u \leq \ln(1-\theta) - 1 + \theta - \frac{\theta(1-\theta-u)}{1-\theta}.$$

Consequently,

(6)
$$\left|\frac{\mu^{\mu+1}}{\mu!}\int_0^{1-\theta} \frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du\right| \leq K\exp\left(-\frac{1}{2}\ln\mu - \theta - \ln\theta\right) \simeq 0.$$

From (5) and (6) we can deduce

$$\mu^{\mu+1}\int_0^\infty \frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du = \mu^{\mu+1}\int_{1-\theta}^{1+\theta} \frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du + \mu!\,\text{I}.$$

Now, in the integrand on the right $1/(1+\mu\varepsilon u) = (1+\mathcal{I})/(1+\mu\varepsilon)$ because u never differs from unity by more than θ and because

$$\left|\frac{\mu\varepsilon\theta}{1+\mu\varepsilon}\right| < \frac{\theta}{\sin\delta} \simeq 0.$$

Moreover, the interval of integration is limited, and so, by Lemma A.1,

$$\mu^{\mu+1}\int_{1-\theta}^{1+\theta}\frac{\exp\{\mu(\ln u - u)\}}{1+\mu\varepsilon u}du = \frac{1+\mathcal{I}}{1+\mu\varepsilon}\mu^{\mu+1}\int_{1-\theta}^{1+\theta}\exp\{\mu(\ln u - u)\}\,du$$
$$= \frac{1+\mathcal{I}}{1+\mu\varepsilon}\left[\mu^{\mu+1}\int_0^\infty \exp\{\mu(\ln u - u)\}\,du + \mu!\mathcal{I}\right]$$

by repetition of the arguments leading to (5) and (6). The proof of the theorem is concluded. □

It is evident that the proof can be adapted to more general integrands so long as they enjoy properties similar to those of the theorem. Without trying to look for the most general statement it is transparent that the following theorem can be proved by repeating the preceding steps.

THEOREM 1. *If* $|f(\varepsilon t)| < K$ *for all* t, *if* $f(\varepsilon) = (1+\mathcal{I})f(0)$ *for all* $\varepsilon \simeq 0$ *and if*

$$f(\mu\varepsilon u) = (1+\mathcal{I})f(\mu\varepsilon)$$

for $1-\theta \le u \le 1+\theta$, *then*

$$\int_0^\infty f(\varepsilon t)t^\mu e^{-t}dt = \mu! f(\mu\varepsilon)(1+\mathcal{I})$$

for limited $\mu\varepsilon$.

Formula (2) demonstrates that $J(\mu,\varepsilon)$ has the error-function behavior expected by Berry, whereas the Link Theorem shows the sort of function obtained by Izumi. Thus $J(\mu,\varepsilon)$ acts as an intermediary between the two kinds of behavior and has the ability to encompass both. It would appear, therefore, that $J(\mu,\varepsilon)$ offers a better choice as the universal function for estimating asymptotic remainders than does either of the other two. Against that it must be said that the other two are, in general, much easier to compute than is $J(\mu,\varepsilon)$. But, given $J(\mu,\varepsilon)$, there is no reason why it should not be replaced by either of the approximations when that is appropriate. It is also of interest that, in circumstances in which both approximations are sharp, the combination of (2) and the Link Theorem offers a good approximation to the error function.

We turn now to the consideration of series in which $J(\mu,\varepsilon)$ arises naturally in the estimation of remainders.

In all subsequent sections δ will denote a positive standard number, which is not necessarily the same in all places.

3. Behavior of series for lower values of z. The series to be discussed in the first place have the form $\sum_{n=0}^\infty a_n z^n/n!$, where the sequence $\{a_n\}$ is standard. Let

$$s_m(z) = \sum_{n=0}^m \frac{a_n z^n}{n!}, \qquad \sigma_m(z) = \sum_{n=m}^\infty \frac{a_n z^n}{n!}.$$

For our purposes it will be sufficient to assume that

$$\frac{a_{n+1}}{a_n} = 1 + \mathcal{I}/n^{1/2}$$

for unlimited n. This condition is not so restrictive as it might appear at first sight. If z were replaced by z/c it could be changed to

$$\frac{a_{n+1}}{a_n} = c + \mathfrak{I}/n^{1/2}.$$

If, then, c is taken to be e, it is permissible to have a_n growing exponentially by, say, picking $a_n = n^n/n!$

THEOREM 2. *Let $a_{n+1}/a_n = 1 + \mathfrak{I}/n^{1/2}$ when n is unlimited. Let ω be an unlimited positive integer and let $\delta < \operatorname{ph} z < 2\pi - \delta$, where δ is a standard positive number. Then there is an unlimited Δ such that*

$$\sigma_\omega(z) = \frac{1+\mathfrak{I}}{1 - z/\omega} \cdot \frac{a_\omega z^\omega}{\omega!}$$

for $|z| < \omega + \Delta\omega^{1/2}$.

Proof. Write

$$\frac{\omega!\sigma_\omega(z)}{a_\omega z^\omega} = \sum_{n=\omega}^{\infty} \frac{\omega! a_n}{n! a_\omega} z^{n-\omega} = \sum_{n=0}^{\infty} b_n \left(\frac{z}{\omega}\right)^n,$$

where

$$b_n = \frac{\omega!\omega^n a_{\omega+n}}{(\omega+n)! a_\omega}.$$

On account of (4) and Lemma B.1,

$$(7) \qquad b_n = \exp\left[\mathfrak{I}\left\{(\omega+n)^{1/2} - \omega^{1/2}\right\} + n - \left(\omega + n + \frac{1}{2}\right)\ln\left(1 + \frac{n}{\omega}\right) + \mathfrak{I}\right].$$

Suppose now that $|z| \le \omega + d\omega^{1/2}$, where d is positive limited. It is convenient to denote $d/\omega^{1/2}$ by D. The series will be split now into two parts, that in which $n \ge \omega'$ and that in which $n \le \omega' - 1$, where ω' is the next integer above $\omega^{7/12}$.

When $n \ge \omega'$,

$$\left|b_n \left(\frac{z}{\omega}\right)^n\right| \le 2\exp\left\{n + nD - \left(\omega + n + \frac{1}{2}\right)\ln\left(1 + \frac{n}{\omega}\right)\right\}$$

after Lemma B.2 is invoked and an infinitesimal in d is absorbed. The function

$$D - \ln\left(1 + \frac{t}{\omega}\right) - \frac{1/2}{t+\omega}$$

diminishes steadily as t increases from 0; since $\ln(1 + \omega'/\omega) > \omega'/\omega - 1/2(\omega'/\omega)^2$ it is less than $-\omega'/2\omega$ when $t = \omega'$ because of the magnitude of ω' and d being limited. Consequently,

$$\begin{aligned} &n + nD - \left(\omega + n + \frac{1}{2}\right)\ln\left(1 + \frac{n}{\omega}\right) \\ &< -\frac{1}{2}\frac{\omega'}{\omega}(n - \omega') - \left(\omega + \omega' + \frac{1}{2}\right)\ln\left(1 + \frac{\omega'}{\omega}\right) + D\omega' + \omega' < -\frac{\omega' n}{4\omega} \end{aligned}$$

since all other terms are dominated by $\omega' n/4\omega$ on using the logarithmic inequality again. Hence

$$\sum_{n=\omega'}^{\infty} \left| b_n \left(\frac{z}{\omega}\right)^n \right| < \frac{2\exp(-\omega'^2/4\omega)}{1-\exp(-\omega'/4\omega)} < \omega^{5/12} \exp\left(-\frac{\omega^{1/6}}{2}\right) \simeq 0. \tag{8}$$

Now

$$\left(1-\frac{z}{\omega}\right) \sum_{n=0}^{\omega'-1} b_n \left(\frac{z}{\omega}\right)^n = b_0 - b_{\omega'-1}\left(\frac{z}{\omega}\right)^{\omega'} - \sum_{n=0}^{\omega'-2} (b_n - b_{n+1}) \left(\frac{z}{\omega}\right)^{n+1}.$$

Since $b_0 = 1$ and it has been established already that $b'_{\omega'-1}(z/\omega)^{\omega'}$ is infinitesimal,

$$\left(1-\frac{z}{\omega}\right) \sum_{n=0}^{\omega'-1} b_n \left(\frac{z}{\omega}\right)^n = 1 + \mathcal{I} - \sum_{n=0}^{\omega'-2} (b_n - b_{n+1}) \left(\frac{z}{\omega}\right)^{n+1}. \tag{9}$$

To estimate the series on the right of (9) note that

$$b_n - b_{n+1} = b_n \left\{ 1 - \frac{\omega a_{\omega+n+1}}{(\omega+n+1)a_{\omega+n}} \right\} = b_n \left\{ \frac{n+1}{\omega+n+1} + \frac{\mathcal{I}}{(\omega+n)^{1/2}} \right\}.$$

Recalling (7), we have

$$\left| \sum_{n=0}^{\omega'-2} (b_n - b_{n+1}) \left(\frac{z}{\omega}\right)^{n+1} \right| \leq \sum_{n=0}^{\omega'-2} \left(\frac{2}{\omega^{1/2}} + \frac{n}{\omega} \right) \exp\left(\frac{nd}{\omega^{1/2}} - \frac{n^2}{4\omega} \right). \tag{10}$$

From (10) it is clear that when n is limited, a term is infinitesimal. As regards the sum, we take advantage of the definition of the Riemann integral, namely,

$$\int_a^b f(x)dx = \operatorname{st} \sum_{a \leq nh < b} f(nh)h, \tag{11}$$

with h infinitesimal (st means standard part). The selection $h = 1/\omega^{1/2}$ ensures that the sum in (10) is bounded by

$$\int_0^{\infty} (2+t) \exp\left(td - \frac{t^2}{4} \right) dt.$$

Invoking Lemma A.4 we see that the sum of the series on the right of (9) is infinitesimal and that

$$\left(1-\frac{z}{\omega}\right) \sum_{n=0}^{\omega'-1} b_n \left(\frac{z}{\omega}\right)^n = 1 + \mathcal{I}.$$

The combination of this result and (8) demonstrates the theorem when $|z| \leq \omega + d\omega^{1/2}$ with d limited.

Consider now the set of integers $n \in \mathbb{N}$ for which

$$\left| \frac{\omega!(1-z/\omega)\sigma_\omega(z)}{a_\omega z^\omega} - 1 \right| \leq \frac{1}{n}$$

for $(|z| - \omega)/\omega^{1/2} < n$. By what has been proved, this set contains all standard integers n. Since there is no set consisting solely of all the standard integers, there must be an unlimited Δ for which these relations hold with Δ in the place of n. Since $1/\Delta$ is infinitesimal, the proof of the theorem is finished. □

Another way of stating Theorem 2 is

$$\sum_{n=0}^{\infty} \frac{a_n z^n}{n!} = s_{\omega-1}(z) + \frac{1+\mathcal{I}}{1-z/\omega} \cdot \frac{a_\omega z^\omega}{\omega!}. \tag{12}$$

This may also be rewritten, by means of the Link Theorem, as

$$\sum_{n=0}^{\infty} \frac{a_n z^n}{n!} = s_{\omega-1}(z) + (1+\mathcal{I}) \frac{a_\omega z^\omega}{(\omega!)^2} J\left(\omega, \frac{ze^{-\pi i}}{\omega^2}\right). \tag{13}$$

Thus there are two ways of expressing the remainder in the series.

It should also be noted that the condition $\delta < \text{ph } z < 2\pi - \delta$ can be relaxed in Theorem 2. It is required only to prevent z/ω from approaching to within an infinitesimal distance of 1. Therefore, if the condition that $|z/\omega - 1|$ be greater than some positive standard number is imposed, the phase of z can be left unrestricted.

4. Behavior of series for higher z. In this section we consider the series of §3, when $|z| \geq \omega + d\omega^{1/2}$, with d a limited positive number.

THEOREM 3. *With the same conditions on a_n, ω, and* ph z *as in Theorem* 2,

$$s_{\omega-1}(z) = -\frac{1+\mathcal{I}}{1-z/\omega} \cdot \frac{a_\omega z^\omega}{\omega!}$$

for $|z| > \omega + d\omega^{1/2}$, d being standard positive.

Proof. Set

$$\frac{(\omega-1)! s_{\omega-1}(z)}{a_{\omega-1} z^{\omega-1}} = \sum_{n=0}^{\omega-1} C_n \left(\frac{z}{\omega}\right)^{n-\omega+1},$$

where

$$C_n = \frac{(\omega-1)! \omega^{n-\omega+1} a_n}{n! a_{\omega-1}}.$$

When n is a standard integer, (4) and Lemma B.2 supply

$$\left| C_n \left(\frac{z}{\omega}\right)^{n-\omega+1} \right| \leq \frac{|a_n|}{n!} \exp\left\{ \left(n + \frac{1}{2}\right) \ln \omega - \omega + \mathcal{I}\omega^{1/2} \right\} \leq \frac{|a_n|}{n!} \exp\left(-\frac{1}{2}\omega\right) \simeq 0$$

since $|z/\omega| > 1$ and $n + 1 < \omega$. Hence, for standard m

$$\sum_{n=0}^{m} C_n \left(\frac{z}{\omega}\right)^{n-\omega+1} \simeq 0.$$

By Robinson's lemma there is an unlimited M such that $M/\omega \simeq 0$ and

$$\sum_{n=0}^{M} C_n \left(\frac{z}{\omega}\right)^{n-\omega+1} \simeq 0. \tag{14}$$

As in Theorem 2,

$$\left(1-\frac{z}{\omega}\right)\sum_{n=M+1}^{\omega-1}C_n\left(\frac{z}{\omega}\right)^{n-\omega+1}=\not{1}-\frac{z}{\omega}-\sum_{n=M+1}^{\omega-2}(C_n-C_{n+1})\left(\frac{z}{\omega}\right)^{n-\omega+2}$$

since $C_{\omega-1}=1$. Moreover,

$$\sum_{n=M+1}^{\omega-2}(C_n-C_{n+1})\left(\frac{z}{\omega}\right)^{n-\omega+2}=\sum_{m=0}^{\omega-M-3}(C_{\omega-2-m}-C_{\omega-1-m})\left(\frac{z}{\omega}\right)^{-m}. \tag{15}$$

From (4) and Lemma B.1

$$\left|C_{\omega-2-m}\left(\frac{z}{\omega}\right)^{-m}\right|$$
$$\leq \exp\left\{\not{1}\frac{m+1}{(\omega-1)^{1/2}}-\frac{2m}{\omega}-m-\left(\omega-m-\frac{3}{2}\right)\ln\left(1-\frac{m}{\omega}\right)-m\ln\left|\frac{z}{\omega}\right|\right\}.$$

Since $|z/\omega|\geq 1+d/\omega^{1/2}$ and since $\ln(1-x)>-x/(1-x)$, we infer that

$$\left|C_{\omega-2-m}\left(\frac{z}{\omega}\right)^{-m}\right|\leq \exp\left\{-\frac{md}{2\omega^{1/2}}+\frac{3}{2}\ln\left(1-\frac{m}{\omega}\right)\right\}. \tag{16}$$

Furthermore,

$$|C_{\omega-2-m}-C_{\omega-1-m}|\leq |C_{\omega-2-m}|\left(\frac{m}{\omega}+\frac{1}{\omega^{\frac{1}{2}}}\right)\left(\frac{\omega}{\omega-1-m}\right)^{3/2}$$

from Lemma B.1 in Appendix B. Combining this with (16), we have

$$\left|(C_{\omega-2-m}-C_{\omega-1-m})\left(\frac{z}{\omega}\right)^{-m}\right|\leq\left(\frac{m}{\omega}+\frac{1}{\omega^{1/2}}\right)\exp\left(-\frac{md}{4\omega^{1/2}}\right).$$

This shows, on the one hand, that terms in (15) with limited m are infinitesimal and, on the other hand, that the sum of the series is less than

$$\int_0^\infty (1+t)e^{-td/4}\,dt$$

by (11). Lemma A.4 now reveals that the series in (15) is infinitesimal.

Bringing together all the estimates, we obtain

$$\left(1-\frac{z}{\omega}\right)\sum_{n=0}^{\omega-1}C_n\left(\frac{z}{\omega}\right)^{n-\omega+1}=\not{1}-\frac{z}{\omega}.$$

By drawing on $a_\omega\simeq a_{\omega-1}$, the statement of the theorem is confirmed and the proof is complete. □

Again, the constraint on the phase of z can be dropped so long as z/ω differs from unity by a standard positive quantity.

Although both Theorems 2 and 3 indicate a singularity at $z=\omega$, it cannot be inferred that there is a simple pole there. For instance, e^z has $a_n=1$, which meets the conditions of the theorems, but e^z has no singularity at $z=\omega$.

To conclude this section we give a proof of Izumi's result along these lines.

THEOREM 4. *If* $|z| > 1 + \delta$, δ *positive standard,*

$$\sum_{n=0}^{\omega-1} a_n z^n = -\frac{1+\mathcal{I}}{1-z} a_\omega z^\omega.$$

Proof. Let

$$\frac{1}{a_{\omega-1} z^{\omega-1}} \sum_{n=0}^{\omega-1} a_n z^n = \sum_{n=0}^{\omega-1} d_n z^{n-\omega+1},$$

where $d_n = a_n / a_{\omega-1}$. As in Theorem 3, there is an unlimited M such that the terms for $n \leq M$ give an infinitesimal contribution. Also,

$$\sum_{n=M+1}^{\omega-1} d_n z^{n-\omega+1} = \sum_{m=0}^{\omega-M-2} d_{\omega-1-m} z^{-m}.$$

For limited m, $d_{\omega-1-m} \simeq 1$, whereas for any m

$$|d_{\omega-1-m} z^{-m}| \leq \left(\frac{1+\mathcal{I}}{1+\delta}\right)^m.$$

Since $(1+\mathcal{I})/(1+\delta) < 1$, this is a convergent sequence and, by Lemma A.4,

$$\sum_{m=0}^{\omega-M-2} d_{\omega-1-m} z^{-m} = \frac{1+\mathcal{I}}{1-1/z}\left(1 - \frac{1}{z^{\omega-M-1}}\right) = \frac{(1+\mathcal{I})z}{z-1}.$$

The proof of the theorem is now complete. □

5. Asymptotic series. Denote the series $\sum_{m=0}^{\infty} C_m z^m$, C_m being standard, by $F(z)$, and denote a typical remainder by $R_n(z)$, so that

$$R_n(z) = F(z) - \sum_{m=0}^{n} C_m z^m.$$

If

$$R_{n-1}(z) = (C_n + \mathcal{I}) z^n \tag{17}$$

for all standard n when $z \simeq 0$, it will be said that $\sum C_m z^m$ is an asymptotic series for F as $z \to 0$ and the usual notation,

$$F(z) \sim \sum_{m=0}^{\infty} C_m z^m,$$

will be used. Restrictions on ph z may be imposed, and then the series will be asymptotic only for the relevant phases of z.

On this basis, the Maclaurin series of any function with derivatives continuous at the origin is asymptotic. For

$$F(\varepsilon) - \sum_{m=0}^{n} \frac{F^{(m)}(0)}{m!} \varepsilon^m = \frac{F^{(n+1)}(\theta'\varepsilon)}{(n+1)!} \varepsilon^{n+1},$$

with $0 < \theta' < 1$. Since $F^{(n+1)}(\theta'\varepsilon) = (1 + \text{Ł})F^{(n+1)}(0)$, the assertion is confirmed.

THEOREM 5. *Let* $\sum_{m=0}^{\infty} C_m z^m$ *be an asymptotic series as* $z \to 0$ *when* ph $z = \alpha$, *and suppose that*

$$|F(\gamma e^{i\alpha})| < Ae^{\gamma r}$$

with A *and* γ *standard for* $r > 0$. *Then*

$$\sum_{m=0}^{\infty} m! C_m \varepsilon^m$$

is an asymptotic series as $\varepsilon \to 0$ *for* $|\text{ph } \varepsilon - \alpha| \leq \pi/2 - \delta$, *with* δ *standard and positive.*

Proof. Let ε be infinitesimal, and let ph $\varepsilon = \alpha - \beta$, where $|\beta| \leq \pi/2 - \delta$. Define

$$\mathcal{F}(\varepsilon) = \int_0^{\infty e^{i\beta}} e^{-t} F(\varepsilon t) dt.$$

The integral exists by virtue of the hypothesis on the growth of F and $\gamma|\varepsilon|$ being less than $\sin\delta$, because γ is standard, whereas ε is infinitesimal. Furthermore,

$$\mathcal{F}(\varepsilon) = \sum_{m=0}^{n-1} m! C_m \varepsilon^m + \int_0^{\infty e^{i\beta}} e^{-t} R_{n-1}(\varepsilon t) dt. \tag{18}$$

It is necessary to show now that the integral in (18) can be expressed as $(n! C_n + \text{Ł})\varepsilon^n$ when n is standard. For t limited, $\varepsilon t \simeq 0$, and so by (17)

$$\frac{R_{n-1}(\varepsilon t)}{\varepsilon^n} \simeq C_n t^n.$$

The required result now follows from Lemma A.2 provided that the integrand can be bounded suitably.

Set $t = ue^{i\beta}$. When $t\varepsilon \simeq 0$, invoke (17), and then

$$\left| \frac{e^{-t} R_{n-1}(\varepsilon t)}{\varepsilon^n} \right| < (1 + |C_n|) u^n \exp(-u \cos\beta).$$

When $t\varepsilon$ is not infinitesimal u must be unlimited and

$$\begin{aligned} \left| \frac{e^{-t} R_{n-1}(\varepsilon t)}{\varepsilon^n} \right| &= \left| \frac{e^{-t}}{\varepsilon^n} \left\{ F(\varepsilon t) - \sum_{m=0}^{n-1} C_m (\varepsilon t)^m \right\} \right| \\ &\leq (Ae^{\gamma u|\varepsilon|} + A_n u^n) \exp(-u\cos\beta - n \ln|\varepsilon|) \end{aligned}$$

because n is limited. It is now evident that for all u

$$\left| \frac{e^{-t} R_{n-1}(\varepsilon t)}{\varepsilon^n} \right| \leq A' u^n \exp\left(-\frac{1}{4} u \cos\beta \right),$$

and Lemma A.2 can be applied. The proof of the theorem is terminated. □

6. Uniform remainders. The series examined in §§3 and 4 is now discussed further. The formula for the remainder in Theorem 2, coupled with the Link Theorem, suggests that

$$\sigma_\omega(ze^{\pi i}) = \frac{a_\omega(-z)^\omega}{(\omega!)^2} J\left(\omega, \frac{z}{\omega^2}\right) \tag{19}$$

for $|z| < \omega + \Delta\omega^{1/2}$. If (19) is true, it is of wider validity than is the estimate of Theorem 2 for the remainder; it furnishes a transition that is uniform with respect to variations for ph z. Similar remarks can be made for Theorems 3 and 4. However, it is not transparent that (19) is uniformly valid. It is tempting to try verification by analytic continuation, but that course is not open without more knowledge of the analytical properties of the infinitesimals, though some progress might be achieved, within certain limitations, with standard parts. Therefore, uniform remainders will be derived by a different procedure.

Let

$$f(z) = \sum_{n=0}^{\infty} \frac{a_n}{n!}(-z)^n, \qquad F(z) = \sum_{n=0}^{\infty} a_n(-z)^n.$$

The properties of the a_n ensure that $f(z)$ is an entire function and that $F(z)$ has a standard radius of convergence of unity. Indeed, $f(z)$ is of exponential type. More can be said when $F(z)$ is regular at a point of its circle of convergence and can be continued beyond it. For then it is known (see Titchmarsh (1939)) that, if F is regular in crossing the circle of convergence in the direction of $e^{i\alpha}$,

$$|f(te^{i\alpha})| < Me^{\eta t} \tag{20}$$

for any nonnegative t with η standard and $\eta < 1$. One consequence of (20) is that

$$F(z) = \int_0^\infty e^{-t} f(zt)dt \tag{21}$$

for $|z| < 1/\eta$ and ph $z = \alpha$. Let δ_0 be standard positive and such that $1/\eta > 1 + \delta_0$.

THEOREM 6. *Suppose that* $|F(te^{i\alpha})| < Ae^{\gamma t}$ *for all nonnegative* t *and some* α *such that* $|\alpha| \leq \pi - \delta$. *Then, when* $|z| \leq 1/\eta - \delta_0$ *and* ph $z = \alpha$,

$$\begin{aligned} F(z) &= \sum_{n=0}^{\omega-1} a_n(-z)^n + (1+\mathit{I})\frac{a^\omega}{\omega!}(-z)^\omega J\left(\omega, \frac{z}{\omega}\right) \\ &= \sum_{n=0}^{\omega-1} a_n(-z)^n + \frac{1+\mathit{I}}{1+z} a_\omega(-z)^\omega. \end{aligned}$$

Proof. By virtue of (21)

$$F(z) = \sum_{n=0}^{\omega-1} a_n(-z)^n + \int_0^\infty e^{-t} \sum_{n=\omega}^{\infty} \frac{a_n}{n!}(-zt)^n dt.$$

On account of Theorems 2 and 3, the integral can be written as

$$\frac{a_\omega}{\omega!}(-z)^\omega \int_0^\infty \frac{(1+\mathit{I})e^{-t}t^\omega}{1+zt/\omega}dt + \int_{(\omega+\Delta\omega^{1/2})/|z|}^\infty e^{-t} f(zt)dt.$$

The second integral is infinitesimal from (20) and the assumption on $|z|$. The first integral leads to the first statement of the theorem by means of Lemma A.2. The

second statement can be inferred from the Link Theorem. There is nothing more to prove. □

Actually, the exponential growth of F has not been used in the proof; it would have been sufficient to assume that F could be continued analytically across its circle of convergence in the direction of $e^{i\alpha}$. However, for the purposes of the next theorem it is convenient to make just one assumption about F.

THEOREM 7. *If F satisfies the conditions of Theorem 6, then for infinitesimal ε*

$$\sum_{m=0}^{\infty} m!a_m(-\varepsilon)^m = \sum_{m=0}^{n-1} m!a_m(-\varepsilon)^m + a_n(-\varepsilon)^n(1+\text{ɬ}) \cdot \left[J(n,\varepsilon) + \frac{2\pi i}{\varepsilon^{n+1}} e^{1/\varepsilon} \left\{e^{\pi i n} H(\text{ph } \varepsilon - \pi) H(\text{ph } \varepsilon - \alpha) - e^{-\pi i n} H(-\text{ph } \varepsilon - \pi) H(\alpha - \text{ph } \varepsilon)\right\}\right]$$

for every $n \in \mathbb{N}$ and $|\text{ph } \varepsilon - \alpha| \leq \pi/2 - \delta$.

Proof. Define $\mathcal{F}(\varepsilon)$ as in Theorem 5, so that it represents the asymptotic series on the left of the equation in the theorem.

When n is limited, Theorem 5 shows that the remainder is $(n!a_n + \text{ɬ})(-\varepsilon)^n$. Since $n\varepsilon$ is infinitesimal, $J(n,\varepsilon)$ is effectively $n!$ (see §2) and the terms involving the Heaviside step functions are infinitesimal when they are present. Accordingly, there is agreement with the statement of the theorem.

When n is unlimited, Theorem 4 and the second statement of Theorem 6 indicate that

$$\mathcal{F}(\varepsilon) = \sum_{m=0}^{n-1} m!a_m(-\varepsilon)^m + a_n(-\varepsilon)^n(1+\text{ɬ}) \int_0^{\infty e^{i\beta}} \frac{e^{-t}t^n}{1+\varepsilon t} dt + \int_{(1+\delta)e^{i\beta}/|\varepsilon|}^{\infty e^{i\beta}} e^{-t}F(\varepsilon t)dt.$$

The final integral is infinitesimal, as in Theorem 6. In the second term the contour of integration can be deformed into the real axis, possibly capturing a pole in the process. The net result is the formula of the theorem, and the proof has been completed. □

Theorems 6 and 7 reveal how the remainders in certain series may be represented in the same universal manner by means of the function J. In many practical cases one may expect F to comply with the conditions of Theorem 6 for a continuum of values of α, so that the conclusions of the two theorems will hold for wider ranges of ph z and ph ε than they may appear to at first sight. Also, analytic continuation may permit less restriction on β than has been implemented in Theorem 5, with consequent relaxation of the constraint on ph ε.

Other series can give rise to remainders that can be expressed in terms of J. For instance, suppose that

$$F(z) = \sum_{n=0}^{\infty} a_n(-z^2)^n$$

and that F is still of exponential growth at infinity. The argument of Theorem 7 can be repeated, and the remainder will entail

$$\int_0^{\infty} \frac{t^{\mu}e^{-t}}{1+\varepsilon^2 t^2} dt = \frac{1}{2}\{J(\mu, i\varepsilon) + J(\mu, -i\varepsilon)\}.$$

Thus the error function will have an important role in the transition through a Stokes line for the associated asymptotic series.

Another type of series in which the error function comes in has terms originating from logarithms. For example, let $\mathcal{F}(\varepsilon)$ in Theorem 7 be redefined as

$$\mathcal{F}(\varepsilon) = \int_0^{\infty e^{i\beta}} e^{-t} F(\varepsilon t) \ln t \, dt.$$

The terms in the asymptotic series are calculated easily, and the remainder will contain the factor

$$\frac{\partial}{\partial \mu} J(\mu, \varepsilon).$$

It is plain from (2) that the partial derivative will not eliminate the error function nor introduce any new transcendental functions. Clearly, more complicated definitions of $\mathcal{F}$ could be used, but the details are left to the paper, Jones (1993), already referred to.

Appendix A. In this appendix are derived some approximations that are required in the main text.

The first is a simple result, but it is quoted so frequently that it is worth a reference.

LEMMA A.1. *If $f(x) \simeq 0$ for all x of an interval, then*

$$\sup |f(x)| \simeq 0.$$

Proof. For any standard $b > 0$, $|f(x)| < b$ for every x of the interval by hypothesis. Hence $\sup |f(x)| < b$, and, since b is any positive standard number, the lemma follows. □

LEMMA A.2. *Let $f(x) \simeq g(x)$ for all limited x. Suppose there is an $h(x) \in L(0, \infty)$ such that $|f(x)| \leq h(x)$, $|g(x)| \leq h(x)$ for all $x \in \mathbb{R}$. Then*

$$\int_0^\infty f(x)dx \simeq \int_0^\infty g(x)dx.$$

Proof. Let n be a positive limited integer. Then

$$\left| \int_0^n \{f(x) - g(x)\} dx \right| \leq \int_0^n \text{ł} \, dx \leq \text{ł} n$$

by Lemma A.1. The right-hand side is infinitesimal since n is limited. Therefore, by Robinson's lemma there is an unlimited ν such that

$$\int_0^\nu f(x)dx \simeq \int_0^\nu g(x)dx.$$

Furthermore,

$$\left| \int_\nu^\infty \{f(x) - g(x)\} dx \right| \leq 2 \int_\nu^\infty h(x)dx \simeq 0$$

since $h \in L(0, \infty)$. Addition of these formulas completes the proof. □

A slight variant of Lemma A.2 is sometimes useful.

LEMMA A.3. *If $f(x) = \dagger h(x)$ for all limited x, $h(x) \in L(0,\infty)$ and $|f(x)| \leq h(x)$ for all $x \in \mathbb{R}$, then*

$$\int_0^\infty f(x)dx = \dagger \int_0^\infty h(x)dx.$$

Proof. The argument goes along the same lines as that of Lemma A.2, but it starts from

$$\int_0^n f(x)dx = \dagger \int_0^n h(x)dx. \qquad \square$$

Infinite series can be handled in the same way. Since the principle of proof is virtually unchanged, only the lemmas themselves will be stated.

LEMMA A.4. *Let $a_n \simeq b_n$ for all limited integers n. Suppose that $\sum_{n=0}^\infty C_n$ is a standard convergent series such that $|a_n| \leq C_n$, $|b_n| \leq C_n$ for all $n \in \mathbb{N}$. Then*

$$\sum_{n=0}^\infty a_n \simeq \sum_{n=0}^\infty b_n.$$

LEMMA A.5. *Let $a_n = \dagger C_n$ for all limited integers n, $\sum_{n=0}^\infty C_n$ convergent and $|a_n| \leq C_n$ for all $n \in \mathbb{N}$, then*

$$\sum_{n=0}^\infty a_n = \dagger \int_{n=0}^\infty C_n.$$

Appendix B. Here some of the properties of a_n when $a_{n+1}/a_n = 1 + \dagger/n^{1/2}$ for unlimited n are elucidated.

With n unlimited and m a positive integer,

(B.1)

$$\ln \frac{a_{n+m}}{a_n} = \sum_{p=n}^{n+m-1} \ln \frac{a_{p+1}}{a_p} = \sum_{p=n}^{n+m-1} \ln\left(1 + \frac{\dagger}{p^{1/2}}\right) = \sum_{p=n}^{n+m-1} \frac{\dagger}{p^{1/2}} = \dagger \sum_{p=n}^{n+m-1} \frac{1}{p^{1/2}}$$

on account of Lemma A.1. Now

$$\int_n^{n+m} \frac{dt}{t^{1/2}} < \sum_{p=n}^{n+m-1} \frac{1}{p^{1/2}} < \int_{n-1}^{n+m-1} \frac{dt}{t^{1/2}},$$

so that

$$(n+m)^{1/2} - n^{1/2} < \sum_{p=n}^{n+m-1} \frac{1}{2p^{1/2}} < (n+m-1)^{1/2} - (n-1)^{1/2}.$$

Since the two sides of the inequality differ by an infinitesimal multiple, it can be asserted that

$$\sum_{p=n}^{n+m-1} \frac{1}{2p^{1/2}} = \{(n+m)^{1/2} - n^{1/2}\}(1+\dagger).$$

Inserting this result into (B.1), we have the following lemma.

LEMMA B.1. *If n is unlimited and if m is a positive integer,*

$$\frac{a_{n+m}}{a_n} = \exp[\cancel{I}\{(n+m)^{1/2} - n^{1/2}\}]$$

and

$$\left|\frac{a_{n+m}}{a_n}\right| \leq \exp\left(\frac{\cancel{I}m}{n^{1/2}}\right).$$

The second statement is a consequence of the inequality

$$(n+m)^{1/2} - n^{1/2} \leq \frac{m}{2n^{1/2}}.$$

The expression for a_{n+m}/a_n in Lemma B.1 suggests that $a_n = \exp(\cancel{I}n^{1/2})$ for unlimited n. That this is true can be proved as follows.

If n is unlimited and q is a standard integer, $q/n \simeq 0$ and $(\ln a_q)/n^{1/2} \simeq 0$. Therefore, by Robinson's lemma there is an unlimited Q such that $Q/n \simeq 0$ and that $(\ln a_Q)/n^{1/2} \simeq 0$. Therefore,

$$\ln a_n = \ln\left(\frac{a_n}{a_Q}\right) + \ln a_Q = \cancel{I}(n^{1/2} - Q^{1/2}) + \ln a_Q$$

from Lemma B.1. By virtue of the definition of Q, the conjectured expression for a_n is confirmed.

LEMMA B.2. *If n is unlimited*

$$a_n = \exp(\cancel{I}n^{1/2}).$$

Appendix C. This appendix gives a couple of comparisons of the numerical values of the two approximations for J. The parameters chosen are $\mu = 3$, $|\varepsilon| = 0.5$ and $\mu = 6$, $|\varepsilon| = 0.1$, with the phase of ε going from 0 to $-6\pi/5$ in steps of $\pi/10$. These are relatively moderate values of the parameters and offer a severe test for the formulae. In particular, ε is nowhere near the infinitesimal specified in the Link Theorem. Nevertheless, the performance of the formulas can be regarded as very satisfactory.

The first column under each pair of parameters in Table 1 shows the ratio of relation (2) to the function in the Link Theorem. The second column gives the ration of (2) to J, but no effort was made to evaluate J by analytic continuation when $\text{ph}\,\varepsilon = -\pi$. As can be seen from the table, the agreement of the Link Theorem prediction worsens as $\text{ph}\,\varepsilon$ diminishes, whereas that of (2) improves. Yet, at the smaller value of $|\varepsilon|$ the two do not vary by much, the main difference being in the phase predicted. Overall, it can be concluded that (2) is always reliable and that the simpler result of the Link Theorem should be perfectly adequate for ballpark estimates so long as $|\varepsilon|$ is not too large.

TABLE 1

Phase of ε	$\mu = 3$, $\lvert\varepsilon\rvert = 0.5$		$\mu = 6$, $\lvert\varepsilon\rvert = 0.1$

APPLICATION OF SZEGÖ POLYNOMIALS TO FREQUENCY ANALYSIS*

WILLIAM B. JONES†, OLAV NJÅSTAD‡, AND HAAKON WAADELAND§

Abstract. This paper is concerned with the frequency analysis problem of determining unknown frequencies ω_j from a sample of N observed values of a time signal $x_{N,I}$, that is, the superposition of I sinusoidal waves. In recent work [Jones, Njåstad, Thron, and Waadeland, Journal CAM, 46 (1993), pp. 217–228], [Pan and Saff, J. Approx. Theory, 71 (1992), pp. 239–251] it has been shown that, for $1 \le I < \infty$ and $k \ge 2I(+1)$, $\lim_{N\to\infty} z_j(k,\psi_{N,I}) = e^{i\omega_j}$ for $2I(+1)$ zeros $z_j(k,\psi_{N,I})$ of the kth degree Szegö polynomials $\rho_k(\psi_{N,I};z)$ orthogonal on the unit circle with respect to a distribution function $\psi_{N,I}(\theta)$ determined by the signal $x_{N,I}$. Hence the ω_j can be approximated by computing Arg $z_j(k,\psi_{N,I})$. In the present paper the Szegö polynomial method is extended to apply to signals $x_{N,I}$ with $1 \le I \le \infty$. It is shown that as the amplitudes $|\alpha_j|$ of high-order sinusoidal waves approach zero and as $N \to \infty$, $z_j(k,\psi_{N,I}) \to e^{i\omega_j}$ is obtained. It is proved that the sequence of distribution functions $\{\psi_{N,I}(\theta)/N\}$ converges in the weak star sense to a function $\psi_{\infty,I}(\theta)$ as $N \to \infty$. That result is used to establish the convergence of a sequence of two-point Padé approximants to a Carathéodory function $F_{\infty,I}(z)$. The significance of this for frequency analysis lies in the fact that $\rho_k(\psi_{N,I};z)$ is the polynomial denominator of a two-point Padé approximant, and the critical points $e^{i\omega_j}$ are the poles of $F_{\infty,I}(z)$. Results from numerical examples are given to illustrate the use of the method.

1. Introduction.

Recently, attention has been focused on the study of Szegö polynomials $\rho_k(\psi_{N,I};z)$ associated with discrete time signals $x_{N,I} = \{x_{N,I}(m)\}_{m=-\infty}^{\infty}$ of the form

$$x_{N,I}(m) = \begin{cases} \displaystyle\sum_{j=-I}^{I} \alpha_j e^{i\omega_j m}, & 0 \le m < N, \quad (x_{N,I}(o) \ne 0), \\ 0 \quad \text{elsewhere}, \end{cases} \tag{1.1a}$$

where

$$1 \le N \le \infty, \tag{1.1b}$$

$$\omega_0 = 0, \quad 0 < \omega_j = -\omega_{-j} < \pi, \quad \omega_j \ne \omega_k \quad \text{for } j \ne k, \tag{1.1c}$$

$$0 \le \alpha_0 \le r_0, \quad 0 < |\alpha_1| \le r_1, \quad 0 \le |\alpha_j| \le r_j, \quad \alpha_j = \overline{\alpha}_{-j}, \quad r_j = r_{-j} \quad \text{for } j \ge 1 \tag{1.1d}$$

(see, e.g., [3], [4], [8], [9], [10], [18], [19]). In those papers "I" was taken to be a natural number. In the present paper we consider all I such that $1 \le I \le \infty$; hence

this additional requirement is imposed:

$$\sum_{\substack{j=-I \\ j\neq -k}}^{I} \sum_{k=-I}^{I} r_j r_k \left|\csc\left(\tfrac{\omega_j+\omega_k}{2}\right)\right| < \infty, \tag{1.1e}$$

which itself implies

$$\sum_{j=-I}^{I} r_j < \infty. \tag{1.2}$$

We denote by $\rho_n(\psi_{N,I}; z)$ the monic nth degree Szegö polynomial orthogonal on the unit circle with respect to the distribution function $\psi_{N,I}(\theta)$ defined as follows.

(a) If $1 \leq N < \infty$ and $1 \leq I \leq \infty$, then $\psi_{N,I}(\theta)$ is an absolutely continuous function on $[-\pi, \pi]$, such that

$$\psi'_{N,I}(\theta) := \frac{1}{2\pi}|X_{N,I}(e^{i\theta})|^2, \qquad X_{N,I}(z) := \sum_{m=0}^{N-1} x_{N,I}(m) z^{-m}, \tag{1.3}$$

which implies

$$\psi'_{N,I}(-\theta) = \psi'_{N,I}(\theta) \quad \text{for } -\pi \leq \theta \leq \pi. \tag{1.4}$$

(b) For $N = \infty$ and $1 \leq I \leq \infty$,

$$\psi_{\infty,I}(\theta) := \sum_{\substack{j \\ \omega_j \leq \theta}} |\alpha_j|^2, \qquad -\pi \leq \theta \leq \pi. \tag{1.5}$$

Thus, if $1 \leq I < \infty$, $\psi_{\infty,I}(\theta)$ is a step function with jumps $|\alpha_j|^2$ at the points $\theta = \omega_j$.

Determination of the unknown normalized frequencies ω_j from the values of the signal $x_{N,I}(m)$ is called the frequency analysis problem. It arises in the study of physical phenomena described by functions $G(t)$ of time t (seconds) of the form

$$G(t) = \sum_{j=-I}^{I} \alpha_j e^{i2\pi f_j t}, \quad f_j = -f_{-j} > 0, \quad \alpha_j = \overline{\alpha}_{-j} \in \mathbf{C} \quad \text{for } j \geq 1, f_o = 0, \alpha_o \geq 0. \tag{1.6}$$

Using equally spaced instants of time $t_m = m\Delta t$, $m = 0, 1, 2, \ldots$, we obtain from (1.1a) and (1.6) that

$$x_{N,I}(m) = G(t_m) \quad \text{for } 0 \leq m < N \quad \text{and} \quad \omega_j = 2\pi f_j \Delta t \quad \text{for } j \geq 1. \tag{1.7a}$$

Since our study restricts ω_j to $0 < \omega_j < \pi$ for $j \geq 1$, we must have

$$0 < \Delta t < \frac{1}{2f_j} \left(\text{i.e., } 0 < f_j < \frac{1}{2\Delta t}\right) \quad \text{for } j \geq 1. \tag{1.7b}$$

Thus the choice of a sampling interval Δt imposes a limit on the frequencies f_j that can be found. Frequency analysis problems arise from phenomena such as human speech [14], ocean tides [20], and radar.

The following related conjecture on the asymptotics of Szegö polynomial zeros was introduced in [4]: For $1 \le I < \infty$, as n and N tend to infinity (in a manner to be determined), the $n_0(I) := 2I + L$ zeros $z_j(n, \psi_{N,I})$ of $\rho_n(\psi_{N,I}; z)$ of largest moduli approach the critical points $e^{i\omega_j}$, $j = \pm 1, \pm 2, \dots, \pm I$ and also $e^{i0} = 1$ if $L = 1$. Here $L := 1$ if $\alpha_0 > 0$ and $L := 0$ if $\alpha_0 = 0$.

This conjecture has recently been verified by results of two papers [8] and [19] for n fixed, $n \ge n_0(I)$, and $N \to \infty$. In both papers it is shown that for each $n \ge n_0(I)$ there exists an arrangement of the zeros $z_j(n, \psi_{N,I})$ such that

$$\lim_{N\to\infty} z_j(n, \psi_{N,I}) = e^{i\omega_j}, \qquad j = \pm 1, \pm 2, \dots, \pm I, \tag{1.8a}$$

$$\lim_{N\to\infty} z_0(n, \psi_{N,I}) = e^{i0} = 1 \quad \text{if } L = 1 \,(i.e., \alpha_0 > 0). \tag{1.8b}$$

It can be easily seen from the proof in [19] that for each $n \ge n_0(I)$, there exists a number λ_n, with $0 < \lambda_n < 1$, such that for all of the remaining $n - n_0(I)$ zeros $z_j(n, \psi_{N,I})$ of $\rho_n(\psi_{N,I}; z)$, we have

$$|z_j(n, \psi_{N,I})| \le \lambda_n < 1 \quad \text{for all } 1 \le N < \infty. \tag{1.9}$$

Thus, for N large enough, those zeros of $\rho_n(\psi_{N,I}; z)$ which can be used to find the unknown frequencies can be distinguished from the other zeros. The Szegö polynomial method of solving frequency analysis problems (FAP) consists of computing the polynomials $\rho_n(\psi_{N,I}; z)$ and its zeros $z_j(n, \psi_{N,I})$, or at least the ones nearest the unit circle $|z| = 1$. This method has been shown [3], [4] to be a reformulation of the Wiener–Levinson method [13], [24] based on linear prediction and digital filters. Other methods for solving the FAP are discussed in [1], [12], [20], and [21].

In the present paper we assume that $1 \le I \le \infty$ and that $\{\omega_j\}$ and $\{r_j\}$ are sequences of numbers satisfying (1.1c, d, e). The results we obtain apply to all signals $x_{N,I}$ in (1.1a), where $\{\alpha_j\}_{-I}^{I}$ satisfies (1.1d). Although one cannot expect to determine infinitely many frequencies by a polynomial method, it is shown (§4) that under certain conditions one can approximate frequencies ω_j associated with relatively large amplitudes $|\alpha_j|$. More specifically we show (Theorem 4.1) that for each K, with $1 \le K < I \le \infty$, the zeros $z_j(n_0(K), \psi_{N,I})$ of $\rho_{n_0(K)}(\psi_{N,I}; z)$ can be arranged so that

$$\lim_{\substack{N\to\infty \\ \alpha(K,I)\to 0}} z_j(n_0(K), \psi_{N,I}) = e^{i\omega_j}, \qquad j = \pm 1, \pm 2, \dots, \pm K, \quad \alpha(K, I) := \sum_{j=K+1}^{I} |\alpha_j|. \tag{1.10}$$

Therefore, for $\alpha(K, I)$ small enough and N large enough, $\operatorname{Arg} z_j(n_0(K), \psi_{N,I})$ is an approximation of ω_j for each $j = \pm 1, \pm 2, \dots, \pm K$.

Computational results are considered in §5 for an example where $I = 4$ and $|\alpha_1|$ is much larger than other amplitudes. The first four rows of the table — Table 2a — ($k = 2, 4, 6, 8$, corresponding to $K = 1, 2, 3, 4$) illustrate (1.10) for $j = \pm 1$. Further evidence supporting the applicability of the Szegö polynomial method is described in §3. It is shown (Theorem 3.2) that, for $1 \le I \le \infty$,

$$\lim_{\substack{N\to\infty \\ k\to\infty}} \frac{1}{N} \frac{P_{2k+1}(\psi_{N,I}; z)}{Q_{2k+1}(\psi_{N,I}; z)} = F_{\infty,I}(z) = \sum_{j=-I}^{I} |\alpha_j|^2 \frac{e^{i\omega_j} + z}{e^{i\omega_j} - z} \quad \text{for } |z| > 1, \tag{1.11}$$

where $P_{2k+1}(\psi_{N,I};z)/Q_{2k+1}(\psi_{N,I};z)$ is the $(2k+1)$th (two-point Padé) approximant of a positive PC-continued fraction (3.8) associated with the signal $x_{N,I}$. The significance of this result for frequency analysis lies in the fact that

$$\rho_k(\psi_{N,I};z) = Q_{2k+1}(\psi_{N,I};z), \tag{1.12}$$

and hence (1.11) suggests that, under suitable conditions, zeros $z_j(k,\psi_{N,I})$ of $\rho_k(\psi_{N,I};z)$ approach singularities of the Carathéodory function $F_{\infty,I}(z)$. This result is of interest for its own sake since, together with Theorem 4.1, it provides information on the location of the poles of two-point Padé approximants for a large class of Carathéodory functions. Our proof of Theorem 3.2 makes use of a weak star convergence result (Theorem 2.1): $\psi_{N,I}/N \overset{*}{\to} \psi_{\infty,I}$ as $N \to \infty$ for all $1 \le I \le \infty$. This result extends a similar theorem given in [4, Thm. 7] for $1 \le I < \infty$.

In the remainder of this introduction we summarize known properties of Szegö polynomials that are subsequently used. Further results of Szegö polynomials can be found in [5], [7], [15], [17], and [23].

The mth moments $\mu_m^{(N,I)}$ with respect to $\psi_{N,I}$ are defined by

$$\mu_m^{(N,I)} := \int_{-\pi}^{\pi} e^{-im\theta} d\psi_{N,I}(\theta), \qquad m = 0, \pm 1, \pm 2, \ldots, \quad 1 \le N, I \le \infty. \tag{1.13}$$

They can be computed by the following formulas valid for $1 \le I \le \infty$:

$$\mu_m^{(N,I)} = \begin{cases} \displaystyle\sum_{k=0}^{N-m-1} x_{N,I}(k)x_{N,I}(k+m), & m \ge 0 \\ \mu_{-m}^{(N,I)}, & m < 0 \end{cases} \qquad \text{for } 1 \le N < \infty, \tag{1.14a}$$

$$\mu_m^{(\infty,I)} = \sum_{j=-I}^{I} |\alpha_j|^2 e^{i\omega_j m} \qquad m = 0, \pm 1, \pm 2, \ldots \quad \text{for } N = \infty. \tag{1.14b}$$

For $[1 \le N < \infty, 1 \le I \le \infty]$ and for $[N = \infty, I = \infty]$ the bisequence $\{\mu_m^{(N,I)}\}_{m=-\infty}^{\infty}$ is positive definite, that is,

$$\mu_{-n}^{(N,I)} = \mu_n^{(N,I)} \quad \text{and} \quad \Delta_n^{(N,I)} := T_{n+1}^{(0)}(N,I) > 0, \qquad n = 0, 1, 2, \ldots, \tag{1.15}$$

where the Toeplitz determinants $T_k^{(m)}(N,I)$ are defined by

$$T_0^{(m)}(N,I) := 1, \; T_k^{(m)}(N,I) := \det(\mu_{m+j-n}^{(N,I)})_{j,n=0}^{k-1}, \qquad k = 1, 2, 3, \ldots, 1 \le N, I \le \infty.$$

For $[N = \infty, 1 \le I < \infty]$, $\{\mu_m^{(\infty,I)}\}_{m=-\infty}^{m=\infty}$ is positive $n_0(I)$-definite, since

$$\begin{aligned} &\mu_{-n}^{(\infty,I)} = \mu_n^{(\infty,I)}, \qquad \Delta_n^{(\infty,I)} := T_{n+1}^{(0)}(\infty,I) > 0 \quad \text{for } 0 \le n \le n_0(I) - 1, \\ &\Delta_{n_0(I)}^{(\infty,I)} := T_{n_0(I)+1}^{(0)}(\infty,I) = 0. \end{aligned} \tag{1.16}$$

For $1 \le N$, $I \le \infty$ we define

$$\langle f, g \rangle_{\psi_{N,I}} := \int_{-\pi}^{\pi} f(e^{i\theta}) \overline{g(e^{i\theta})} d\psi_{N,I}(\theta).$$

The monic Szegö polynomials $\rho_n(\psi_{N,I};z)$ and reciprocal (reversed) polynomials $\rho_n^*(\psi_{N,I};z) := z^n\overline{\rho_n(\psi_{N,I};1/\bar{z})} = z^n\rho_n(\psi_{N,I};z^{-1})$ are defined by $\rho_0(\psi_{N,I};z) = \rho_0^*(\psi_{N,I};z) = 1$ and, for $1 \le n < n_0(I)+1$ where $n_0(\infty) := \infty$, by

$$\rho_n(\psi_{N,I};z) := \frac{1}{\Delta_{n-1}^{(N,I)}} \begin{vmatrix} \mu_0^{(N,I)} & \mu_{-1}^{(N,I)} & \cdots & \mu_{-n}^{(N,I)} \\ \mu_1^{(N,I)} & \mu_0^{(N,I)} & \cdots & \mu_{-n+1}^{(N,I)} \\ \vdots & \vdots & & \vdots \\ \mu_{n-1}^{(N,I)} & \mu_{n-2}^{(N,I)} & \cdots & \mu_{-1}^{(N,I)} \\ 1 & z & \cdots & z^n \end{vmatrix},$$

(1.17)

$$\rho_n^*(\psi_{N,I};z) := \frac{1}{\Delta_{n-1}^{(N,I)}} \begin{vmatrix} \mu_0^{(N,I)} & \mu_1^{(N,I)} & \cdots & \mu_n^{(N,I)} \\ \mu_{-1}^{(N,I)} & \mu_0^{(N,I)} & \cdots & \mu_{n-1}^{(N,I)} \\ \vdots & \vdots & & \vdots \\ \mu_{-n+1}^{(N,I)} & \mu_{-n+2}^{(N,I)} & \cdots & \mu_1^{(N,I)} \\ z^n & z^{n-1} & \cdots & 1 \end{vmatrix}.$$

They satisfy orthogonality relations, for $1 \le n < n_0(I)+1$,

$$\text{(1.18a)} \quad \langle \rho_n(\psi_{N,I};z), z^m\rangle_{\psi_{N,I}} = \begin{cases} 0, & 0 \le m \le n-1, \\ \Delta_n^{(N,I)}/\Delta_{n-1}^{(N,I)}, & m = n, \end{cases}$$

$$\text{(1.18b)} \quad \langle \rho_n^*(\psi_{N,I};z), z^m\rangle_{\psi_{N,I}} = \begin{cases} \Delta_n^{(N,I)}/\Delta_{n-1}^{(N,I)}, & m = 0, \\ 0, & 1 \le m \le n. \end{cases}$$

These yield the recurrence relations

$$\text{(1.19a)} \quad \rho_n(\psi_{N,I};z) = z\rho_{n-1}(\psi_{N,I};z) + \delta_n^{(N,I)}\rho_{n-1}^*(\psi_{N,I};z), \qquad 1 \le n < n_0(I)+1,$$

$$\text{(1.19b)} \quad \rho_n^*(\psi_{N,I};z) = \delta_n^{(N,I)}z\rho_{n-1}(\psi_{N,I};z) + \rho_{n-1}^*(\psi_{N,I};z), \qquad 1 \le n < n_0(I)+1,$$

where the reflection coefficients $\delta_n^{(N,I)} := \rho_n(\psi_{N,I};0)$ satisfy

$$\text{(1.20)} \quad \delta_n^{(N,I)} = \frac{(-1)^n T_n^{(-1)}(N,I)}{T_n^{(0)}(N,I)} = -\frac{\sum_{j=0}^{n-1} q_j^{(n-1,N,I)}\mu_{-j-1}^{(N,I)}}{\sum_{j=0}^{n-1} q_j^{(n-1,N,I)}\mu_{-j+1-n}^{(N,I)}}, \qquad 1 \le n < n_0(I)+1,$$

where $\sum_{j=0}^{n-1} q_j^{(n-1,N,I)} z^j := \rho_{n-1}(\psi_{N,I};z)$. Levinson's algorithm utilizes (1.18) and (1.19) to compute successively the $\delta_n^{(N,I)}$ and $q_j^{(n-1,N,I)}$.

2. Weak star convergence. Before giving the main results of this section (Theorems 2.1 and 2.2), we describe a family of signals $x_{N,I}$ satisfying conditions (1.1) with $I = \infty$ and with $\omega_0 = 0$ being the limit of an infinite sequence of frequencies ω_j.

Example 2.1. Let $\{r_j\}$ and $\{\omega_j\}$ be defined by

$$r_0 := 0,\ r_j = \frac{1}{|j|^3} \quad \text{and} \quad \omega_j = \frac{1}{j} \quad \text{for} \quad j = \pm 1, \pm 2, \ldots . \tag{2.1}$$

We show that $\{r_j\}$ and $\{\omega_j\}$ satisfy (1.1e). Since $\frac{2}{\pi}x < \sin x$ for $0 < x < \frac{\pi}{2}$, it follows that for all integers m and n such that $0 \neq m \neq -n \neq 0$,

$$\left| \frac{\frac{1}{m} \cdot \frac{1}{n}}{\sin(\frac{1}{2m} + \frac{1}{2n})} \right| < \frac{|\frac{1}{mn}|}{\frac{2}{\pi}|\frac{1}{2m} + \frac{1}{2n}|} = \frac{\pi}{|m+n|} \leq \pi.$$

Therefore,

$$\sum_{0 \neq m \neq -n \neq 0}^{\infty} \sum^{\infty} \left| \frac{\frac{1}{m^3} \cdot \frac{1}{n^3}}{\sin(\frac{\frac{1}{m} + \frac{1}{n}}{2})} \right| < 4\pi \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{1}{m^2} \cdot \frac{1}{n^2} \leq 4\pi \sum_{m=1}^{\infty} \frac{1}{m^2} \sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{\pi^5}{9}.$$

Additional examples can be verified in a similar manner.

THEOREM 2.1 (weak star convergence). *For each* $1 \leq I \leq \infty$, *as* $N \to \infty$,

$$\frac{1}{N}\psi_{N,I}(\theta) \overset{*}{\to} \psi_{\infty,I}(\theta) = \sum_{j:\omega_j \leq \theta} |\alpha_j|^2, \qquad -\pi \leq \theta \leq \pi. \tag{2.2}$$

To prove (2.2) it suffices to show that for every function $f(\theta)$ continuous on $-\pi \leq \theta \leq \pi$,

$$\lim_{N\to\infty} \frac{1}{N} \int_{-\pi}^{\pi} f(\theta) d\psi_{N,I}(\theta) = \int_{-\pi}^{\pi} f(\theta) d\psi_{\infty,I}(\theta) = \sum_{j=-I}^{I} |\alpha_j|^2 f(\omega_j). \tag{2.3}$$

For use in our proof we recall a few well-known results and prove one basic lemma. From [22], e.g., it is known that, for $\omega \in [-\pi, \pi]$ and $N = 1, 2, 3, \ldots$

$$\int_{-\pi}^{\pi} \left[\frac{\sin N(\frac{\theta-\omega}{2})}{\sin(\frac{\theta-\omega}{2})} \right]^2 d\theta = 2\pi N\ . \tag{2.4}$$

Hence, by Schwarz's inequality,

$$\int_{-\pi}^{\pi} \left| \frac{\sin N(\frac{\theta-\omega}{2})}{\sin(\frac{\theta-\omega}{2})} \right| d\theta \leq \left[\int_{-\pi}^{\pi} \left[\frac{\sin N(\frac{\theta-\omega}{2})}{\sin(\frac{\theta-\omega}{2})} \right]^2 d\theta \right]^{\frac{1}{2}} \left[\int_{-\pi}^{\pi} 1^2 d\theta \right]^{\frac{1}{2}} = 2\pi\sqrt{N}. \tag{2.5}$$

Furthermore (also from [22]),

$$\lim_{N\to\infty} \frac{1}{2\pi N} \int_{\omega-\varepsilon_1}^{\omega+\varepsilon_2} \left[\frac{\sin N(\frac{\theta-\omega}{2})}{\sin(\frac{\theta-\omega}{2})} \right]^2 f(\theta) d\theta = f(\omega), \qquad \varepsilon_1 > 0,\ \varepsilon_2 > 0. \tag{2.6}$$

From $|\sin\varphi| = 2|\sin\varphi/2 \cos\varphi/2| \leq 2|\sin\varphi/2|$, one obtains

$$|\sin\tfrac{\varphi}{2}| \geq \tfrac{1}{2}|\sin\varphi|. \tag{2.7}$$

For convenience we introduce the notation

$$S_N(\theta,\alpha,\beta) := \frac{\sin N(\frac{\alpha-\theta}{2})\sin N(\frac{\beta-\theta}{2})}{\sin(\frac{\alpha-\theta}{2})\sin(\frac{\beta-\theta}{2})}. \tag{2.8}$$

LEMMA 2.2. *There exists a number $K > 0$ such that for all $-\pi < \alpha < \beta < \pi$ and $N = 1, 2, 3, \ldots$*

$$\int_{-\pi}^{\pi} |S_N(\theta,\alpha,\beta)|d\theta \le \frac{K\sqrt{N}}{\sin(\frac{\beta-\alpha}{2})}. \tag{2.9}$$

Proof. Since the integrand is a periodic function of θ with period 2π, we have

$$\int_{-\pi}^{\pi} |S_N(\theta,\alpha,\beta)|d\theta = \int_{-\pi+v}^{\pi+v} |S_N(\theta,\alpha,\beta)|d\theta \quad \text{for all } v \in \mathbf{R}.$$

We set $\gamma := \beta - \alpha$ so that $0 < \gamma < 2\pi$ and consider the change of variables $\theta = \varphi + \alpha$. Then it suffices to prove that there exists $K > 0$ such that for all $0 < \gamma < 2\pi$, $N = 1, 2, 3, \ldots$,

$$\int_{-\pi}^{\pi} |S_N(\varphi,0,\gamma)|d\varphi \le \frac{K\sqrt{N}}{\sin(\frac{\gamma}{2})}. \tag{2.10}$$

From (2.5) we know that one can find a $K_0 > 0$ such that for $N \ge 1$ and $\gamma \in \mathbf{R}$,

$$\int_{-\pi}^{\pi} \left|\frac{\sin N(\frac{\varphi}{2})}{\sin(\frac{\varphi}{2})}\right| d\varphi \le K_0\sqrt{N} \text{ and } \int_{-\pi}^{\pi} \left|\frac{\sin N(\frac{\gamma-\varphi}{2})}{\sin(\frac{\gamma-\varphi}{2})}\right| d\varphi \le K_0\sqrt{N}. \tag{2.11}$$

We divide the interval $[-\pi,\pi]$ into two parts $[-\pi,\pi] = A \cup B$, $A := [-\gamma/2, \gamma/2]$, $B := [-\pi,\pi]\backslash A$. First we consider the part of the integral (2.10) over the set B. Since

$$B = [\varphi : \tfrac{\gamma}{2} < |\varphi| < \pi] = [\varphi : \tfrac{\gamma}{4} < |\tfrac{\varphi}{2}| < \tfrac{\pi}{2}],$$

we obtain by (2.7)

$$|\sin\tfrac{\gamma}{2}| > \sin\tfrac{\varphi}{4} > \tfrac{1}{2}\sin\tfrac{\gamma}{2} \quad \text{for all } \varphi \in B,$$

and hence

$$\int_{\beta} |S_N(\varphi,0,\gamma)|d\varphi \le \frac{2K_0\sqrt{N}}{\sin(\frac{\gamma}{2})}. \tag{2.12}$$

To deal with the part of the integral (2.10) over A we consider two cases.

Case 1. Suppose $0 < \gamma \le \pi$. Then $(3\gamma/4) \le \pi - (\gamma/4)$; hence

$$A := [\varphi : -\tfrac{\gamma}{2} \le \varphi \le \tfrac{\gamma}{2}] = [\varphi : \tfrac{\gamma}{4} \le \tfrac{\gamma-\varphi}{2} \le \tfrac{3\gamma}{4}] \subseteq [\varphi : \tfrac{\gamma}{4} \le \tfrac{\gamma-\varphi}{2} \le \pi - \tfrac{\gamma}{4}]$$

and, for all $\varphi \in A$,

$$|\sin(\tfrac{\gamma-\varphi}{2})| \ge \min[\sin\tfrac{\gamma}{4}, \sin(\pi - \tfrac{\gamma}{4})] = \sin\tfrac{\gamma}{4} > \tfrac{1}{2}\sin\tfrac{\gamma}{2}.$$

Then for all $N \ge 1$ and $0 < \gamma \le \pi$,

$$\int_A |S_N(\varphi,0,\gamma)|d\varphi \le \frac{1}{\sin\frac{\gamma}{4}} \int_A \left|\frac{\sin N(\frac{\varphi}{2})}{\sin(\frac{\varphi}{2})}\right| d\theta \le \frac{2K_0\sqrt{N}}{\sin\frac{\gamma}{2}}. \tag{2.13}$$

Case 2. Suppose $\pi < \gamma < 2\pi$. We set

$$\gamma' := 2\pi - \gamma \quad \text{so that } 0 < \gamma' < \pi.$$

Then by (2.13), for all $N \geq 1$ and $\pi < \gamma < 2\pi$, there exists a $K_1 > 0$ such that (with $\psi := -\varphi$)

$$\begin{aligned} \int_A |S_N(\psi, 0, \gamma)| d\psi &= \int_A |S_N(\varphi, 0, -\gamma)| d\varphi = \int_A |S_N(\varphi, 0, \gamma')| d\varphi \\ &\leq \frac{2K_0\sqrt{N}}{\sin\frac{\gamma'}{2}} = \frac{2K_0\sqrt{N}}{\sin\frac{\gamma}{2}}. \end{aligned} \tag{2.14}$$

Combining (2.12), (2.13), and (2.14) yields (2.10). □

Proof of Theorem 2.1. By (1.1), (1.3), and (2.8), we have for all $1 \leq N < \infty$ and $1 \leq I \leq \infty$,

$$\begin{aligned} \psi'_{N,I}(\theta) &= \frac{1}{2\pi}\left|\sum_{m=0}^{N-1} x_{N,I}(m) e^{-im\theta}\right|^2 = \frac{1}{2\pi}\left|\sum_{m=0}^{N-1}\left(\sum_{j=-I}^{I} \alpha_j e^{i\omega_j m}\right) e^{-im\theta}\right|^2 \\ &= \frac{1}{2\pi}\left|\sum_{j=-I}^{I} \alpha_j \frac{1 - e^{-iN(\omega_j-\theta)}}{1 - e^{-i(\omega_j-\theta)}}\right|^2 = \frac{1}{2\pi}\left|\sum_{j=-I}^{I} \alpha_j \frac{e^{iN(\frac{\omega_j-\theta}{2})}\sin N(\frac{\omega_j-\theta}{2})}{e^{i(\frac{\omega_j-\theta}{2})}\sin(\frac{\omega_j-\theta}{2})}\right|^2 \\ &= \frac{1}{2\pi}\sum_{j=-I}^{I}\sum_{k=-I}^{I} \alpha_j\overline{\alpha}_k \frac{e^{iN(\frac{\omega_j-\omega_k}{2})}}{e^{i(\frac{\omega_j-\omega_k}{2})}} S_N(\theta, \omega_j, \omega_k). \end{aligned} \tag{2.15}$$

Therefore,

$$\frac{1}{N}\int_{-\pi}^{\pi} f(\theta) d\psi_{N,I}(\theta) = \frac{1}{2\pi N}\int_{-\pi}^{\pi} f(\theta) \sum_{j,k=-I}^{I} \alpha_j\overline{\alpha}_k \frac{e^{iN(\frac{\omega_j-\omega_k}{2})}}{e^{i(\frac{\omega_j-\omega_k}{2})}} S_N(\theta, \omega_j, \omega_k) d\theta. \tag{2.16}$$

We first show that the order of integration and summation in (2.16) can be interchanged (even if $I = \infty$). Let j and k be any to integers such that $\omega_j < \omega_k (j, k \in [-I, I])$. Let M be chosen such that $|f(\theta)| \leq M$ for $\theta \in [-\pi, \pi]$. Then by Lemma 2.2 there exists a $K > 0$ such that

$$\int_{-\pi}^{\pi} |f(\theta) S_N(\theta, \omega_j, \omega_k)| d\theta \leq \frac{MK\sqrt{N}}{\sin(\frac{\omega_k-\omega_j}{2})} \quad \text{for } N = 1, 2, 3 \ldots. \tag{2.17}$$

Therefore by condition (1.1e) and the assumption $r_j = r_{-j}$ and $\omega_j = -\omega_{-j}$

$$\begin{aligned} &\frac{1}{2\pi N}\left|\sum_{j=-I_{j\neq k}}^{I}\sum_{k=-I}^{I} \alpha_j\overline{\alpha}_k \int_{-\pi}^{\pi} f(\theta) \frac{e^{iN(\frac{\omega_j-\omega_k}{2})}}{e^{i(\frac{\omega_j-\omega_k}{2})}} S_n(\theta, \omega_j, \omega_k) d\theta\right| \\ &\quad \leq \frac{MK}{\sqrt{2\pi N}} \sum_{j=-I_{j\neq k}}^{I}\sum_{k=-I}^{I} r_j r_k |\csc(\tfrac{\omega_k-\omega_j}{2})| \longrightarrow 0 \text{ as } N \to \infty. \end{aligned} \tag{2.18}$$

(Note that the double sum is equal to the double sum in (1.1e).) By (2.4)

$$\begin{aligned}(2.19)\qquad &\frac{1}{2\pi N}\left|\sum_{j=-I}^{I}|\alpha_j|^2\int_{-\pi}^{\pi}f(\theta)\left[\frac{\sin N(\frac{\omega_j-\theta}{2})}{\sin(\frac{\omega_j-\theta}{2})}\right]^2 d\theta\right| \\ &\quad\le\frac{M}{2\pi N}\sum_{j=-I}^{I}|\alpha_j|^2\int_{-\pi}^{\pi}\left[\frac{\sin N(\frac{\omega_j-\theta}{2})}{\sin(\frac{\omega_j-\theta}{2})}\right]^2 d\theta = M\sum_{j=-I}^{I}|\alpha_j|^2<\infty.\end{aligned}$$

It follows from (2.18) and (2.19) and an application of Fubini's theorem [16] that the order of integration and summation in (2.16) can be interchanged. From this we obtain, for $N\ge 1$,

(2.20)

$$\begin{aligned}\frac{1}{N}\int_{-\pi}^{\pi}f(\theta)d\psi_{N,I}(\theta) &= \frac{1}{2\pi N}\sum_{j=-I}^{I}|\alpha_j|^2\int_{-\pi}^{\pi}f(\theta)\left[\frac{\sin N(\frac{\omega_j-\theta}{2})}{\sin(\frac{\omega_j-\theta}{2})}\right]^2 d\theta \\ &\quad+\frac{1}{2\pi N}\sum_{j=-I_{j\ne k}}^{I}\sum_{k=-I}^{I}\alpha_j\overline{\alpha}_k\int_{-\pi}^{\pi}f(\theta)\frac{e^{iN(\frac{\omega_j-\omega_k}{2})}}{e^{i(\frac{\omega_j-\omega}{2})}}S_N(\theta,\omega_j,\omega_k)d\theta.\end{aligned}$$

By (2.18) the second sum on the right side of (2.20) tends to zero as $N\to\infty$. By (2.6) the first sum on the right side of (2.20) approaches, as $N\to\infty$,

$$\sum_{j=-I}^{I}|\alpha_j|^2 f(\omega_j)=\int_{-\infty}^{\infty}f(\theta)d\psi_{\infty,I}(\theta),$$

from which we can conclude that (2.3) holds. □

THEOREM 2.3 (uniform convergence). *For each* $1\le N\le\infty$,

$$(2.21)\qquad \psi_{N,I}(\theta)\longrightarrow\psi_{N,\infty}(\theta)\quad -\pi\le\theta\le\pi,\quad \textit{as } I\to\infty,\ \textit{uniformly.}$$

Proof. First we consider $N=\infty$. Let $\varepsilon>0$ be given. By (1.2) there exists a number $I_0(\varepsilon)$ such that

$$(2.22)\qquad \sum_{|j|>I_0(\varepsilon)}r_j^2<\varepsilon.$$

Then for all I, $I_0(\varepsilon)\le I<\infty$,

$$(2.23)\qquad |\psi_{\infty,\infty}(\theta)-\psi_{\infty,I}(\theta)|=\sum_{\substack{\omega_j\le\theta\\ j>I}}|\alpha_j|^2\le\sum_{j>I}|\alpha_j|^2\le\sum_{j>I_0(\varepsilon)}|\alpha_j|^2<\varepsilon.$$

Thus (2.21) holds for $N=\infty$.

Next we consider $1\le N<\infty$. Then by (2.15), the triangle inequality, and

$$\left|\frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right|=\left|\sum_{m=0}^{N-1}e^{im(\omega_j-\theta)}\right|\le N,$$

it can be seen that

(2.24)

$$\psi'_{N,\infty}(\theta) - \psi'_{N,I}(\theta) = \left[\sqrt{\psi'_{N,\infty}(\theta)} + \sqrt{\psi'_{N,I}(\theta)}\right] \cdot \left[\sqrt{\psi'_{N,\infty}(\theta)} - \sqrt{\psi'_{N,I}(\theta)}\right]$$

$$= \frac{1}{2\pi}\left\{\left|\sum_{j=-\infty}^{\infty} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right| + \left|\sum_{j=-I}^{I} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right|\right\}$$

$$\cdot\left\{\left|\sum_{j=-\infty}^{\infty} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right| - \left|\sum_{j=-I}^{I} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right|\right\}$$

$$\leq \frac{1}{\pi}\left\{\sum_{j=-\infty}^{\infty} |\alpha_j| \cdot \left|\frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right|\right\}$$

$$\cdot\left|\sum_{j=-\infty}^{\infty} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}} - \sum_{j=-I}^{I} \alpha_j \frac{1-e^{iN(\omega_j-\theta)}}{1-e^{i(\omega_j-\theta)}}\right|$$

$$\leq \frac{N^2}{\pi}\left(\sum_{j=-\infty}^{\infty} |\alpha_j|\right)\left(\sum_{|j|>I} |\alpha_j|\right) \leq \frac{N^2}{\pi}\left(\sum_{j=-I}^{I} r_j\right)\left(\sum_{|j|>I} r_j\right).$$

Let $\varepsilon > 0$ be given. By (1.2) there exists a number $I_0(\varepsilon)$ such that

$$\sum_{|j|>I} r_j < \frac{\varepsilon\pi}{N^2 \sum_{j=-\infty}^{\infty} r_j} \quad \text{for all } I \geq I_0(\varepsilon).$$

It follows from (2.24) that for all $I \geq I_0(\varepsilon)$,

$$|\psi'_{N,\infty}(\theta) - \psi'_{N,I}(\theta)| < \varepsilon$$

for all $\theta \in [-\pi, \pi]$. From this result the uniform convergence of $\psi_{N,I}(\theta)$ follows for $N < \infty$. □

3. Moment generating functions. In this section we consider the function of a complex variable

$$F_{N,I}(z) := \int_{-\pi}^{\pi} \frac{e^{i\theta}+z}{e^{i\theta}-z} d\psi_{N,I}(\theta), \quad 1 \leq N, I \leq \infty, \quad |z| \neq 1, \tag{3.1}$$

where $\psi_{N,I}(\theta)$ is a distribution function of the form (1.3) or (1.5). Each such function $F_{N,I}(z)$ belongs to the class of normalized Carthéodory functions (see, e.g., [5] and [7]). For completeness some properties of the functions (3.1) are summarized in Theorem 3.1. In view of (3.4) we refer to $F_{N,I}(z)$ as the moment generating function for $\psi_{N,I}(\theta)$. A related convergence result is described by Theorem 3.2.

THEOREM 3.1. (a) *For each N and I such that $1 \leq N$, $I \leq \infty$, $F_{N,I}(z)$ is holomorphic for $|z| \neq 1$ and satisfies the following properties*:

$$F_{N,I}(0) = \mu_0^{(N,I)} > 0, \tag{3.2}$$

(3.3) $\quad \operatorname{Re} F_{N,I}(z) \geq 0 \quad \textit{for} \quad |z| < 1 \quad \textit{and} \quad \operatorname{Re} F_{N,I}(z) \leq 0 \quad \textit{for} \quad |z| > 1,$

$$\text{(3.4)} \qquad F_{N,I}(z) = \begin{cases} L_0^{(N,I)}(z) := \mu_0^{(N,I)} + 2\sum_{k=1}^{\infty} \mu_k^{(N,I)} z^k & \textit{for} \quad |z| < 1, \\ L_\infty^{(N,I)}(z) := -\mu_0^{(N,I)} - 2\sum_{k=1}^{\infty} \mu_k^{(N,I)} z^{-k} & \textit{for} \quad |z| > 1, \end{cases}$$

$$\text{(3.5)} \qquad F_{N,I}\left(\frac{1}{z}\right) = -F_{N,I}(z) \quad \textit{for} \quad |z| \neq 1.$$

(b) *For each I such that $1 \leq I \leq \infty$,*

$$\text{(3.6)} \qquad F_{\infty,I}(z) = \sum_{j=-I}^{I} |\alpha_j|^2 \frac{e^{i\omega_j} + z}{e^{i\omega_j} - z} \quad \textit{for} \quad |z| \neq 1.$$

Proof. It is readily seen that

$$\text{(3.7a)} \qquad \left|\frac{e^{i\theta} + z}{e^{i\theta} - z}\right| \leq \frac{1 + |z|}{|1 - |z||} \quad \text{for} \quad |z| \neq 1, \ \theta \in [-\pi, \pi],$$

$$\text{(3.7b)} \qquad \operatorname{Re}\left(\frac{e^{i\theta} + z}{e^{i\theta} - z}\right) > 0 \quad \text{for} \quad |z| < 1 \quad \text{and} \quad \operatorname{Re}\left(\frac{e^{i\theta} + z}{e^{i\theta} - z}\right) < 0 \quad \text{for} \quad |z| > 1.$$

First suppose that N and I satisfy $1 \leq N < \infty$ and $1 \leq I \leq \infty$. It follows from (1.3), (3.1), and well known properties of functions defined by integrals that $F_{N,I}(z)$ is holomorphic for $|z| \neq 1$. Equation (3.2) is an immediate consequence of (1.3) and (1.13). Assertion (3.3) follows from (1.3), (3.1), and (3.7b). The power series expansions in (3.4) are obtained from (1.13), substitution of

$$\frac{e^{i\theta} + z}{e^{i\theta} - z} = \begin{cases} 1 + 2\sum_{k=1}^{\infty} e^{-ik\theta} z^k, & |z| < 1, \\ -1 - 2\sum_{k=1}^{\infty} e^{ik\theta} z^{-k}, & |z| > 1, \end{cases}$$

into (3.1) and then term-by-term integration. To verify (3.5) we use (1.4), (3.1), and $\varphi := -\theta$ to obtain

$$F_{N,I}\left(\frac{1}{z}\right) = \int_{-\pi}^{\pi} \frac{e^{i\theta} + z^{-1}}{e^{i\theta} - z^{-1}} d\psi_{N,I}(\theta) = \int_{-\pi}^{\pi} \frac{z + e^{-i\theta}}{z - e^{-i\theta}} \psi'_{N,I}(\theta) d\theta$$

$$= -\int_{-\pi}^{\pi} \frac{e^{i\varphi} + z}{e^{i\varphi} - z} \psi'_{N,I}(\varphi) d\varphi = -F_{N,I}(z).$$

Next we consider $N = \infty$ and $1 \leq I \leq \infty$. The series representation (3.6) follows from (1.5) and (3.1). If $1 \leq I \leq \infty$, then (3.2), (3.3), (3.4), and (3.5) can be deduced from (1.14b), (3.6), and (3.7). □

For each N and I such that $[1 \le N < \infty$ and $1 \le I \le \infty]$ or $[N = \infty$ and $I = \infty]$, we consider the positive PC fraction (Perron–Carathéodory continued fraction)

(3.8a)
$$\delta_0^{(N,I)} - \frac{2\delta_0^{(N,I)}}{1} + \frac{1}{\delta_1^{(N,I)} z} + \frac{(1-|\delta_1^{(N,I)}|^2)z}{\delta_1^{(N,I)}} + \frac{1}{\delta_2^{(N,I)} z} + \frac{(1-|\delta_2^{(N,I)}|^2)z}{\delta_2^{(N,I)}} + \cdots,$$

where

(3.8b)
$$\delta_0^{(N,I)} := \mu_0^{(N,I)} = \sum_{m=0}^{N-1} [x_{N,I}(m)]^2 > 0.$$

The nth numerator $P_n(\psi_{N,I}; z)$ and denominator $Q_n(\psi_{N,I}; z)$ of (3.8) are defined by

(3.9a)
$$P_0(\psi_{N,I}; z) := -P_1(\psi_{N,I}; z) := \delta_0^{(N,I)}, \qquad Q_0(\psi_{N,I}; z) := Q_1(\psi_{N,I}; z) := 1,$$

(3.9b)
$$\begin{bmatrix} P_{2n}(\psi_{N,I}; z) \\ Q_{2n}(\psi_{N,I}; z) \end{bmatrix} = \delta_n^{(N,I)} z \begin{bmatrix} P_{2n-1}(\psi_{N,I}; z) \\ Q_{2n-1}(\psi_{N,I}; z) \end{bmatrix} + \begin{bmatrix} P_{2n-2}(\psi_{N,I}; z) \\ Q_{2n-2}(\psi_{N,I}; z) \end{bmatrix}, \qquad n \ge 1,$$

(3.9c)
$$\begin{bmatrix} P_{2n+1}(\psi_{N,I}; z) \\ Q_{2n+1}(\psi_{N,I}; z) \end{bmatrix} = \delta_n^{(N,I)} \begin{bmatrix} P_{2n}(\psi_{N,I}; z) \\ Q_{2n}(\psi_{N,I}; z) \end{bmatrix} + (1-|\delta_1^{(N,I)}|^2) z \begin{bmatrix} P_{2n-1}(\psi_{N,I}; z) \\ Q_{2n-1}(\psi_{N,I}; z) \end{bmatrix}, \qquad n \ge 1.$$

The close connection between Szegö polynomials and PC fractions (3.8) can be seen from

(3.10)
$$\rho_n(\psi_{N,I}; z) = Q_{2n+1}(\psi_{N,I}; z), \qquad \rho_n^*(\psi_{N,I}; z) = Q_{2n}(\psi_{N,I}; z), \quad n \ge 0,$$

which can be deduced by means of (1.19) and (3.9).

If $N = \infty$ and $1 \le I < \infty$, the corresponding PC fraction is the terminating one

(3.11a)
$$\delta_0^{(\infty,I)} - \frac{2\delta_0^{(\infty,I)}}{1} + \frac{1}{\delta_1^{(\infty,I)} z} + \frac{(1-|\delta_1^{(\infty,I)}|^2)z}{\delta_1^{(\infty,I)}} + \cdots + \frac{1}{\delta_{n_0(I)-1}^{(\infty,I)} z} + \frac{(1-|\delta_{n_0(I)-1}^{(\infty,I)}|^2)z}{\delta_{n_0(I)-1}^{(\infty,I)}} + \frac{1}{\delta_{n_0(I)}^{(\infty,I)} z},$$

where

(3.11b)
$$\delta_0^{(\infty,I)} := \mu_0^{(\infty,I)} = \sum_{j=-I}^{I} |\alpha_j|^2, \quad \delta_n^{(\infty,I)} := \rho_n(\psi_{\infty,I}; 0), \quad 1 \le n \le n_0(I), \quad |\delta_{n_0}^{(\infty,I)}| = 1.$$

The nth numerators and denominators of (3.11) are defined by (3.9) with $N = \infty$, $1 \le n \le 2n_0(I) + 1$. We recall [8, eq. (2.11)] that

(3.12)

$$\rho_{n_0(I)}(\psi_{\infty,I};z) = Q_{2n_0(I)+1}(\psi_{\infty,I};z) = (z-1)^L \prod_{j=1}^{I}(z-e^{i\omega_j})(z-e^{-i\omega_j})$$
$$= (-1)^L \rho^*_{n_0(I)}(\psi_{\infty,I};z) = (-1)^L Q_{2n_0(I)}(\psi_{\infty,I};z).$$

THEOREM 3.2. *For each I such that $1 \le I \le \infty$,*

$$\lim_{\substack{N\to\infty \\ k\to\infty}} \frac{1}{N}\frac{P_{2k}(\psi_{N,I};z)}{Q_{2k}(\psi_{N,I};z)} = F_{\infty,I}(z) = \sum_{j=-I}^{I} |\alpha_j|^2 \frac{e^{i\omega_j}+z}{e^{i\omega_j}-z} \quad \text{for } |z|<1, \tag{3.13a}$$

$$\lim_{\substack{N\to\infty \\ k\to\infty}} \frac{1}{N}\frac{P_{2k+1}(\psi_{N,I};z)}{Q_{2k+1}(\psi_{N,I};z)} = F_{\infty,I}(z) = \sum_{j=-I}^{I} |\alpha_j|^2 \frac{e^{i\omega_j}+z}{e^{i\omega_j}-z} \quad \text{for } |z|>1. \tag{3.13b}$$

Proof. From results given in [7, Thm. 3.2] and [11, Thm. 3.1] we know that for each z with $|z|<1$,

$$\left|\frac{P_{2k}(\psi_{N,I};z)}{Q_{2k}(\psi_{N,I};z)} - F_{N,I}(z)\right| \le \frac{4\delta_0^{(N,I)}|z|^{k+1}}{1-|z|^2}, \quad 1 \le N < \infty,\ 1 \le I \le \infty,\ k \ge 1. \tag{3.14}$$

By (1.1) and (3.8b) there exists a constant $A>0$, such that

$$0 < \delta_0^{(N,I)} \le AN \quad \text{for } 1 \le N < \infty \quad \text{and} \quad 1 \le I \le \infty. \tag{3.15}$$

It follows from (3.14) and (3.15) that, for $1 \le N < \infty$ and $1 \le I \le \infty$,

$$\left|\frac{1}{N}\frac{P_{2k}(\psi_{N,I};z)}{Q_{2k}(\psi_{N,I};z)} - F_{\infty,I}(z)\right| \le \frac{4A|z|^{k+1}}{1-|z|^2} + \left|\frac{1}{N}F_{N,I}(z) - F_{\infty,I}(z)\right|, \quad |z|<1. \tag{3.16}$$

By weak star convergence (Theorem 2.1) we have, for $1 \le I \le \infty$,

$$\lim_{N\to\infty}\frac{1}{N}F_{N,I}(z) = \lim_{N\to\infty}\frac{1}{N}\int_{-\pi}^{\pi}\frac{e^{i\theta}+z}{e^{i\theta}-z}d\psi_{(N,I)}(\theta) = \int_{-\pi}^{\pi}\frac{e^{i\theta}+z}{e^{i\theta}-z}d\psi_{(\infty,I)}(\theta) \tag{3.17}$$
$$= F_{\infty,I}(z), \qquad |z| \ne 1.$$

Now the assertion (3.13a) follows from (3.16) and (3.17). We can obtain (3.13b) from (3.13a), (3.5), and

$$\frac{P_{2k}(\psi_{N,I};z)}{Q_{2k}(\psi_{N,I};z)} = -\frac{P_{2k+1}(\psi_{N,I};z^{-1})}{Q_{2k+1}(\psi_{N,I};z^{-1})} \qquad \text{(see, e.g., [6]).} \qquad \square$$

4. Asymptotics of zeros.

THEOREM 4.1. *Let I be such that $2 \le I \le \infty$ and let $\{r_j\}_{-I}^{I}$ and $\{\omega_j\}_{-I}^{I}$ be sequences of real numbers satisfying* (1.1c, d, e). *For every discrete time signal $x_{N,I}$ of the form* (1.1) *let $\rho_n(\psi_{N,I};z)$ denote the monic nth degree Szegö polynomial* (1.17) *associated with $x_{N,I}$. Then for each K with $1 \le K < I$ the zeros $z_j(n_0(K),\psi_{N,I})$ of $\rho_{n_0(K)}(\psi_{N,I};z)$ can be arranged so that*

$$\lim_{\substack{N\to\infty \\ \alpha(K,I)\to 0}} z_j(n_0(K),\psi_{N,I}) = e^{i\omega_j}, \qquad j = \pm1, \pm2, \ldots, \pm K, \tag{4.1a}$$

and

$$\lim_{\substack{N\to\infty \\ \alpha(K,I)\to 0}} z_0(n_0(K),\psi_{N,I}) = e^{i0} = 1 \quad \text{if } L = 1 (\textit{i. e., } \alpha_0 > 0), \tag{4.1b}$$

where

$$\alpha(K,I) := \sum_{j=K+1}^{I} |\alpha_j|. \tag{4.1c}$$

Our proof of Theorem 4.1 makes use of the following lemmas.

LEMMA 4.2. *For each* $1 \le N < \infty$ *and* $1 \le I \le \infty$,

$$\mu_m^{(N,I)} = N\mu_m^{(\infty,I)} + M_m(N,I), \qquad m = 0, \pm 1, \pm 2, \ldots, \tag{4.2a}$$

where

$$M_m(N,I) := \sum_{\substack{j,n=-I \\ j\neq -n}}^{I} c_{j,n}(m,N)\alpha_j\alpha_n - m\mu_m^{(\infty,I)}, \tag{4.2b}$$

$$c_{j,n}(m,N) := e^{i\left[\frac{N-m-1}{2}\omega_j + \frac{N+m-1}{2}\omega_n\right]} \sin[(N-m)(\tfrac{\omega_j+\omega_n}{2})] \csc(\tfrac{\omega_j+\omega_n}{2}), \tag{4.2c}$$

and

$$|M_m(N,I)| \le M_m(I) := |m| \sum_{j=-I}^{I} r_j^2 + \sum_{j=-I}^{I} \sum_{\substack{n=-I \\ j\neq -n}}^{I} r_j r_n |\csc(\tfrac{\omega_j+\omega_n}{2})|, \tag{4.3}$$

$$M_m(I) \le M_m(I+1) \le M_m(\infty) < \infty, \qquad 1 \le I \le \infty, \quad m = 0, \pm 1, \pm 2, \ldots. \tag{4.4}$$

Proof. Substitute (1.1a) into (1.14a) and interchange the order of summation. Rearranging the terms and using (1.14b) gives (4.2). Equation (4.3) is a consequence of

$$c_{j,n}(m,N) = c_{n,j}(m,N), |c_{-j,-n}(m,N)| = |c_{j,n}(m,N)| \le c_{j,n} := |\csc(\tfrac{\omega_j+\omega_n}{2})|, \tag{4.5}$$

and (4.4) follows from (4.3) and (1.1e). □

LEMMA 4.3. *For* $2 \le I < \infty$,

$$\mu_m^{(\infty,I)} = \mu_m^{(\infty,I-1)} + 2|\alpha_I|^2 \cos(\omega_I m), \qquad m = 0, \pm 1, \pm 2, \ldots. \tag{4.6}$$

Proof. Apply (1.14b). □

LEMMA 4.4. *For* $1 \le N < \infty, 2 \le I < \infty$, *and* $m = 0, \pm 1, \pm 2, \ldots$,

$$\mu_m^{(N,I)} = \mu_m^{(N,I-1)} + |\alpha_I| U_m(N,I), \tag{4.7a}$$

where

$$U_m(N,I) = 2(N-m)|\alpha_I| \cos(\alpha_I m) + V_m(N,I), \tag{4.7b}$$

$$V_m(N,I) := 4 \sum_{j=-I+1}^{I} c_{j,I}(m,N)|\alpha_j| \cos(\varphi_I + \varphi_j) \quad (\varphi_0 := 0, \varphi_j := \operatorname{Arg} \alpha_j \text{for } j \neq 0), \tag{4.7c}$$

$$(4.8a)\quad |V_m(N,I)| \le 4 \sum_{j=-I+1}^{I} c_{j,I} r_j =: V(I) \le V(I+1) \le \lim_{I\to\infty} V(I) =: V(\infty) < \infty,$$

$$(4.8b)\quad |U_m(N,I)| \le \hat{U}_m(N,I) := 2(N+|m|)r_I + V(I),$$

$$(4.8c)\quad \hat{U}_m(N,I) \le 2(N+|m|) \max_{1\le j<\infty} r_j + V(\infty) =: \hat{U}_m(N,\infty) < \infty.$$

Proof. Apply (4.5) and Lemmas 4.2 and 4.3 to obtain (4.7). Then use (1.1e) and (4.7) to obtain (4.8). □

LEMMA 4.5. *For* $1 \le N < \infty$, $1 \le I < \infty$, $k \ge 1$, $m = 0, \pm 1, \pm 2, \ldots$, *let* $G_k^{(m)}(N,I)$ *be defined by*

$$(4.9)\qquad \frac{T_k^{(m)}(N,I)}{N^k} = T_k^{(m)}(\infty, I) + \frac{G_k^{(m)}(N,I)}{N}.$$

Then for each $k \ge 1$ *and* $m \in \mathbf{Z}$, *there exist numbers* $G_k^{(m)}(I)$ *and* $G_k^{(m)}(\infty)$ *such that, for all* $1 \le N < \infty$ *and all sequences* $\{\alpha_j\}_{-I}^{I}$ *satisfying* (1.1 c, d, e),

$$(4.10)\qquad |G_k^{(m)}(N,I)| \le G_k^{(m)}(I) \le G_k^{(m)}(\infty) < \infty.$$

Proof. Substituting (4.2a) into $T_k^{(m)}(N,I) := \det(\mu_{m+j-n}^{(N,I)})_{j,n=0}^{k-1}$, we see that $G_k^{(m)}(N,I)$ is a sum of terms, each a product of $(k-j)$ factors of the form $M_m(N,I)/N$ and j factors of the form $\mu_p^{(\infty,I)} = \sum_{j=-I}^{I} |\alpha_j|^2 e^{i\omega_j p}, 0 \le j \le k-1$. Since

$$|\mu_p^{(\infty,I)}| \le \sum_{j=-I}^{I} |\alpha_j|^2 \le \sum_{j=-\infty}^{\infty} |\alpha_j|^2,$$

it follows from Lemma 4.2 that each such product is of the form

$$H_{k,j}^{(m)}(N,I)/N^{k-j}, \quad \text{where } |H_{k,j}^{(m)}(N,I)| \le H_k^{(m)}(I) \le H_k^{(m)}(\infty),$$

$H_k^{(m)}(I)$ (and $H_k^{(m)}(\infty)$) being a number independent of j and N (and I). Summing these products yield (4.10). □

LEMMA 4.6. *For* $1 \le N < \infty$, $2 \le I < \infty$, $k \ge 1, m = 0, \pm 1, \pm 2, \ldots$, *let* $W_k^{(m)}(N,I)$ *be defined by*

$$(4.11)\qquad \frac{T_k^{(m)}(N,I)}{N^k} = \frac{T_k^{(m)}(N,I-1)}{N^k} + |\alpha_I| W_k^{(m)}(N,I).$$

Then for each $k \ge 1$ *and* $m \in \mathbf{Z}$, *there exist numbers* $W_k^{(m)}(I)$ *and* $W_k^{(m)}(\infty)$ *such that for all* $1 \le N < \infty$ *and all sequences* $\{\alpha_j\}_{-I}^{I}$ *satisfying* (1.1c, d, e),

$$(4.12)\qquad |W_k^{(m)}(N,I)| \le W_k^{(m)}(I) \le W_k^{(m)}(\infty) < \infty.$$

Proof. By substituting (4.7a) into $T_k^{(m)}(N,I) := \det(\mu_{m+j-n}^{(N,I)})_{j,n=0}^{k-1}$, one can show that $W_k^{(m)}(N,I)$ is a sum of terms, each a product of $(k-j)$ factors of the form

$|\alpha_I|U_p(N,I)/N$ and j factors of the form $\mu_p^{(N,I-1)}/N = \mu_p^{(\infty,I-1)} + M_p(N,I-1)/N$. By Lemmas 4.2 and 4.4 each such product is of the form

$$|\alpha_I|^{k-j}Y_{k,j}^{(m)}(N,I), \quad \text{where } |Y_{k,j}^{(m)}(N,I)| \le Y_k^{(m)}(I) \le Y_k^{(m)}(\infty),$$

$Y_k^{(m)}(I)$ (and $Y_k^{(m)}(\infty)$) being a number independent of j and N (and I). Summing these products yields (4.12). □

LEMMA 4.7. *For $1 \le N < \infty$ and $1 \le I < \infty$ let $\hat{\delta}_n(N,I)$ be defined by*

$$\delta_n^{(N,I)} = \delta_n^{(\infty,I)} + \frac{\hat{\delta}_n(N,I)}{N}, \qquad 1 \le n \le n_0(I). \tag{4.13}$$

Then there exist numbers $\hat{\delta}_n(I)$ and $\hat{\delta}_n(\infty)$ such that for all $1 \le N < \infty$ and all $\{\alpha_j\}$ satisfying (1.1c, d, e) *with α_1 fixed and $|\alpha_1| > 0$,*

$$|\hat{\delta}_n(N,I)| \le \hat{\delta}_n(I) \le \hat{\delta}_n(\infty) < \infty, \qquad 1 \le n \le n_0(I). \tag{4.14}$$

Proof. By (1.20), (4.13), and (4.9) with $k = n$

$$\begin{aligned}\frac{\hat{\delta}_n(N,I)}{N} &= \delta_n^{(N,I)} - \delta_n^{(\infty,I)} = (-1)^n\left[\frac{T_n^{(-1)}(N,I)}{T_n^{(0)}(N,I)} - \frac{T_n^{(-1)}(\infty,I)}{T_n^{(0)}(\infty,I)}\right] \\ &= \frac{(-1)^n}{N}\frac{T_n^{(0)}(\infty,I)G_n^{(-1)}(N,I) - T_n^{(-1)}(\infty,I)G_n^{(0)}(N,I)}{N^{-n}T_n^{(0)}(N,I)T_n^{(0)}(\infty,I)} \\ &= \frac{(-1)^n}{N}\frac{T_n^{(0)}(\infty,I)G_n^{(-1)}(N,I) - T_n^{(-1)}(\infty,I)G_n^{(0)}(N,I)}{(T_n^{(0)}(\infty,I) + \frac{G_n^{(0)}(N,I)}{N})T_n^{(0)}(\infty,I)}.\end{aligned}$$

The denominator is positive.

Furthermore, $T_n^{(0)}(\infty,I)$ has a positive lower bound for all $0 \le |\alpha_j| \le r_j$, $j = 2,3,\ldots$ and all $1 \le I \le \infty$ (continuity and compactness).

Thus, by Lemma 4.5 we get

$$|\hat{\delta}_n(N,I)| \le \frac{T_n^{(0)}(\infty,I)G_n^{(-1)}(I) + |T_n^{(-1)}(\infty,I)|G_n^{(0)}(I)}{T_n^{(0)}(\infty,I)\inf_{N\ge1}(T_n^{(0)}(\infty,I) + \frac{G_n^{(0)}(N,I)}{N})} =: \hat{\delta}_n(I)$$

and

$$\begin{aligned}\hat{\delta}_n(I) &\le \frac{G_n^{(-1)}(\infty)\sup_{I\ge\frac{n-L}{2}} T_n^{(0)}(\infty,I) + G_n^{(0)}(\infty)\sup_{I\ge\frac{n-L}{2}}|T_n^{(-1)}(\infty,I)|}{\inf_{\substack{I\ge\frac{n-L}{2}\\ N\ge1}}\left[T_n^{(0)}(\infty,I)(T_n^{(0)}(\infty,I) + \frac{G_n^{(0)}(N,I)}{N})\right]} \\ &:= \hat{\delta}_n(\infty) < \infty.\end{aligned}$$

(Remark: The I-condition is equivalent to the condition $n_0(I) \ge n$.)

LEMMA 4.8. *For $1 \le N < \infty$, $2 \le I < \infty$ and $n \ge 1$, let $\tilde{\delta}_n(N,I)$ be defined by*

$$\delta_n(N,I) = \delta_n^{(N,I-1)} + |\alpha_I|\tilde{\delta}_n(N,I). \tag{4.15}$$

Then there exist numbers $\tilde{\delta}_n(I)$ and $\tilde{\delta}_n(\infty)$ such that for all $1 \le N < \infty$ and all $\{\alpha_j\}$ satisfying (1.1c, d, e) *with α_1 fixed and $|\alpha_1| > 0$,*

$$|\tilde{\delta}_n(N,I)| \le \tilde{\delta}_n(I) \le \tilde{\delta}_n(\infty), \qquad n = 1,2,3,\ldots. \tag{4.16}$$

An argument for proving Lemma 4.8 can be given that it is completely analogous to that given for Lemma 4.7. Hence it is omitted.

LEMMA 4.9. *For* $1 \le N < \infty$, $1 \le I < \infty$, $1 \le n \le n_0(I)$, $0 \le j \le n$, *let* $\hat{q}_j^{(n,N,I)}$ *be defined by*

(4.17)
$$q_j^{(n,N,I)} = q_j^{(n,\infty,I)} + \frac{\hat{q}_j^{(n,N,I)}}{N} \qquad \left(\rho_n(\psi_{N,I}; z) := \sum_{j=0}^{n} q_j^{(n,N,I)} z^j,\ 1 \le N \le \infty\right).$$

Then there exist numbers $\hat{q}_j(n,I)$ *and* $\hat{q}_j(n,\infty)$ *such that for all* $1 \le N < \infty$ *and all* $\{\alpha_j\}$ *satisfying* (1.1 c, d, e) *with* α_1 *fixed and* $|\alpha_1| > 0$,

$$|\hat{q}_j^{(n,N,I)}| \le \hat{q}_j(n,I) \le \hat{q}_j(n,\infty), \quad 0 \le j \le n, \quad 1 \le n \le n_0(I), \quad 1 \le I < \infty. \tag{4.18}$$

Proof. From the recurrence relations (1.19) we obtain the recurrence relations

$$q_0^{(n,N,I)} = \delta_n^{(N,I)}, \quad q_j^{(n,N,I)} = q_{j-1}^{(n-1,N,I)} + \delta_n^{(N,I)} q_{n-1-j}^{(n-1,N,I)} \quad \text{for } 1 \le j \le n-1,\ q_n^{(n,N,I)} = 1, \tag{4.19}$$

valid for all $1 \le N < \infty$, $n \ge 1$. The relations (4.19) are also valid for $n = \infty, 1 \le I < \infty$, $1 \le n \le n_0(I)$. Our proof is by induction on n. First we have, since $\delta_n^{(N,I)} = \rho_n(\psi_{N,I}; 0)$,

$$q_0^{(n,N,I)} = \delta_n^{(N,I)} = \delta_n^{(\infty,I)} + \frac{\hat{\delta}_n(N,I)}{N} = q_0^{(n,\infty,I)} + \frac{\hat{q}_0^{(n,N,I)}}{N},$$

where $\hat{q}_0^{(n,N,I)} = \hat{\delta}_n(N,I)$, hence by Lemma 4.7,

$$|\hat{q}_0^{(n,N,I)}| \le |\hat{\delta}(N,I)| \le \hat{\delta}_n(I) =: \hat{q}_0(n,I) \le \hat{\delta}_n(\infty) =: \hat{q}_0(n,\infty).$$

Therefore, for $j = 0$ Lemma 4.9's assertions hold for all $n \ge 1$. For $n = 1$ the assertion in (4.18) also holds for $j = 1$, since $q_1^{(1,N,I)} = q_1^{(1,\infty,I)} = 1$.

We assume (induction hypothesis) that for some integer $n \ge 1$, there exist numbers $\hat{q}_j(m,I)$ and $\hat{q}_j(m,\infty)$ such that for all $1 \le N < \infty$ and $\{\alpha_j\}$ satisfying (1.1c, d, e) and α_1 fixed $|\alpha_1| > 0$,

$$|\hat{q}_j^{(m,N,I)}| \le \hat{q}_j(m,I) \le \hat{q}_j(m,\infty), \qquad 1 \le j \le m, \quad 1 \le m \le n-1. \tag{4.20}$$

Then, by (4.19), (4.20), (4.17), and (4.13),

$$q_j^{(n,N,I)} = \left(q_{j-1}^{(n-1,\infty,I)} + \frac{\hat{q}_j^{(n-1,N,I)}}{N}\right) + \left(\delta_n^{(\infty,I)} + \frac{\hat{\delta}_n(N,I)}{N}\right)\left(q_{n-1-j}^{(n-1,\infty,I)} + \hat{q}_{n-1-j}^{(n-1,N,I)}\right)$$

$$= q_j^{(n,\infty,I)} + \frac{\hat{q}_j^{(n,N,I)}}{N},$$

where

$$|\hat{q}_j^{(n,N,I)}| = \left|\hat{q}_j^{(n-1,N,I)} + \delta_n^{(\infty,I)}\hat{q}_{n-1-j}^{(n-1,N,I)} + \hat{\delta}_n(N,I)q_{n-1-j}^{(n-1,\infty,I)} + \frac{1}{N}\hat{\delta}_n(N,I)\hat{q}_{n-1-j}^{(n-1,N,I)}\right|$$

$$\leq |\hat{q}_j^{(n-1,N,I)}| + |\delta_n^{(\infty,I)}\hat{q}_{n-1-j}^{(n-1,N,I)}| + |\hat{\delta}_n(N,I)|\left[|q_{n-1-j}^{(n-1,\infty,I)}| + \frac{|\hat{q}_{n-1-j}^{(n-1,N,I)}|}{N}\right]$$

$$\leq \hat{q}_j(n-1,I) + |\delta_n^{(\infty,I)}|\hat{q}_{n-1-j}(n-1,I)$$

$$+\hat{\delta}_n(I)\left[|q_{n-1-j}^{(n-1,\infty,I)}| + \hat{q}_{n-1-j}(n-1,I)\right] =: \hat{q}_j(n,I)$$

$$\leq \hat{q}_j(n-1,\infty) + \hat{q}_{n-1-j}(n-1,\infty)$$

$$+\hat{\delta}_n(\infty)\left[\sup_{1\leq I<\infty} q_{n-1-j}^{(n-1,\infty,I)}| + \hat{q}_{n-1-j}(n-1,\infty)\right] =: \hat{q}_j(n,\infty).$$

Here we have used the fact that $|\delta_n^{(n,\infty)}| \leq 1$ and $\lim_{I\to\infty}\hat{q}_{n-1-j}^{(n-1,\infty,I)} = \hat{q}_{n-1-j}^{(n-1,\infty,\infty)}$ exists and hence $\sup_{1\leq I<\infty}|q_{n-1-j}^{(n-1,\infty,I)}| < \infty$. It follows that (4.20) also holds for $m = n$. □

LEMMA 4.10. *For $1 \leq N < \infty$, $2 \leq I < \infty$ and $n \geq 1$, let $\tilde{q}_j^{(n,N,I)}$ be defined by*

$$q_j^{(n,N,I)} = q_j^{(n,N,I-1)} + |\alpha_I|\,\tilde{q}_j^{(n,N,I)}, \qquad 0 \leq j \leq n. \tag{4.21}$$

Then there exist numbers $\tilde{q}_j(n,I)$ and $\tilde{q}_j(n,\infty)$ such that for all $1 \leq N < \infty$ and all $\{\alpha_j\}$ satisfying (1.1 c, d, e) *with α_1 fixed, $|\alpha_1| > 0$,*

$$|\tilde{q}_j^{(n,N,I)}| \leq \tilde{q}_j(n,I) \leq \tilde{q}_j(n,\infty), \qquad 0 \leq j \leq n, \quad 1 \leq I < \infty. \tag{4.22}$$

A proof for this lemma can be given that it is completely analogous to that given for Lemma 4.9. Hence it is omitted.

LEMMA 4.11. *Let $x_{N,I}$ denote a discrete time signal of the form* (1.1), *where $1 \leq N < \infty$ and $1 \leq I \leq \infty$. Let $\rho_n(\psi_{N,I};z)$ denote the monic nth degree Szegö polynomial* (1.11) *associated with $x_{N,I}$. Let $\hat{\rho}_n(\psi_{N,I};z)$ and $\tilde{\rho}_n(\psi_{N,I};z)$ be defined, for $1 \leq N < \infty, 2 \leq I < \infty, 1 \leq n \leq n_0(I)$, by*

$$\begin{aligned}\rho_n(\psi_{N,I};z) &= \rho_n(\psi_{\infty,I};z) + \tfrac{\hat{\rho}_n(\psi_{N,I};z)}{N},\\ \rho_n(\psi_{N,I};z) &= \rho_n(\psi_{N,I-1};z) + |\alpha_I|\,\tilde{\rho}_n(\psi_{N,I};z).\end{aligned} \tag{4.23}$$

(a) *Then for all $0 < R < \infty$ there exist numbers $\hat{\rho}_n(I,R), \hat{\rho}_n(\infty,R), \tilde{\rho}_n(I,R)$, and $\tilde{\rho}_n(\infty,R)$ such that for all $1 \leq N < \infty$ and all $\{\alpha_j\}$ satisfying* (1.1 c, d, e) *with α_1 fixed, $|\alpha_1| > 0$,*

$$|\hat{\rho}_n(\psi_{N,I};z)| \leq \hat{\rho}_n(I,R) \leq \hat{\rho}_n(\infty,R), \qquad |\tilde{\rho}_n(\psi_{N,I};z)| \leq \tilde{\rho}_n(I,R) \leq \tilde{\rho}_n(\infty,R) \tag{4.24}$$

for $2 \leq I < \infty$, $1 \leq n \leq n_0(I)$, $|z| \leq R$.

(b) *For all I, K, and R such that $2 \leq I \leq \infty, 1 \leq K < I$, there exist positive numbers $\hat{\rho}_{n_0(K)}(R)$ and $\tilde{\rho}_{n_0(K)}(R)$ such that for $1 \leq N < \infty$ and $|z| \leq R$,*

$$\left|\rho_{n_0(K)}(\psi_{N,I};z)-(z-1)^L\prod_{j=1}^{K}(z-e^{i\omega_j})(z-e^{-i\omega_j})\right| \tag{4.25}$$
$$\le \tilde{\rho}_{n_0(K)}(\infty,R)\sum_{j=K+1}^{I}|\alpha_j|+\frac{1}{N}\hat{\rho}_{n_0(K)}(R).$$

Remark. The assertion involving $\hat{\rho}_n(\psi_{N,I};z)$ holds also for $I=\infty$. This can be seen by letting $I\to\infty$ in the first part of (4.23) and (4.24) and using the fact that $\lim_{I\to\infty}\rho_n(\psi_{N,I};z)=\rho_n(\psi_{N,\infty};z)$.

Proof. (a) By Lemma 4.9 we have for $|z|\le R$ and $1\le N<\infty$, $1\le n\le n_0(I)$,

$$|\rho_n(\psi_{N,I};z)-\rho_n(\psi_{\infty,I};z)|=\left|\sum_{j=0}^{n}(q_j^{(n,N,I)}-q_j^{(n,\infty,I)})z^j\right|\le\frac{1}{N}\sum_{j=0}^{n}|\hat{q}_j^{(n,N,I)}|R^j$$
$$\le\frac{1}{N}\sum_{j=0}^{n}\hat{q}_j(n,I)R^j=:\frac{\hat{\rho}_n(I,R)}{N}$$
$$\le\frac{1}{N}\sum_{j=0}^{n}\hat{q}_j(n,\infty)R^j=:\frac{\hat{\rho}_n(\infty,R)}{N}.$$

A similar proof for the second part of (a) can be given and hence is omitted.

(b) First we assume that $2\le I<\infty$. By Lemma 4.11(a) we obtain for $|z|\le R$ and $1\le N<\infty$,

$$\left|\rho_{n_0(K)}(\psi_{N,I};z)-(z-1)^L\prod_{j=1}^{K}(z-e^{i\omega_j})(z-e^{-i\omega_j})\right|$$
$$=\left|\rho_{n_0(K)}(\psi_{N,I};z)-\rho_{n_0(K)}(\psi_{\infty,K};z)\right|$$
$$\le\sum_{j=K+1}^{I}\left|\rho_{n_0(K)}(\psi_{N,j};z)-\rho_{n_0(K)}(\psi_{N,j-1};z)\right|$$
$$+\left|\rho_{n_0(K)}(\psi_{N,K};z)-\rho_{n_0(K)}(\psi_{\infty,K};z)\right|$$
$$=\sum_{j=K+1}^{I}|\alpha_j|\,|\tilde{\rho}_{n_0(K)}(\psi_{N,j};z)|+\frac{1}{N}|\hat{\rho}_{n_0(K)}(\psi_{N,K};z)|$$
$$\le\sum_{j=K+1}^{I}|\alpha_j|\tilde{\rho}_{n_0(K)}(j,R)+\frac{1}{N}\hat{\rho}_{n_0(K)}(K,R)$$
$$\le\tilde{\rho}_{n_0(K)}(\infty,R)\sum_{j=K+1}^{I}|\alpha_j|+\frac{1}{N}\hat{\rho}_{n_0(K)}(\infty,R).$$

To see that this result also holds for $I=\infty$ we let $I\to\infty$ in (4.25) and use the fact that $\lim_{I\to\infty}\rho_{n_0(K)}(\psi_{N,I};z)=\rho_{n_0(K)}(\psi_{N,\infty};z)$. □

Proof of Theorem 4.1. By Lemma 4.11(b) the functions $\rho_{n_0(K)}(\psi_{N,I}; z)$ converge to $(z-1)^L \prod_{j=1}^{K}(z - e^{i\omega_j})(z - e^{-i\omega_j})$ uniformly on each compact set $|z| \leq R$ as $N \to \infty$ and $\alpha(K, I) \to 0$. The assertions (4.1) follow from this and an application of Hurwitz's theorem [2, Thm. 14.3.4]. □

5. Computional results. To illustrate the approximations given by the Szegö polynomial method, we consider signals $x_{N,4}$ of the form (1.4), where $I = 4$ and the α_j and ω_j are as follows in Table 1.

TABLE 1

j	0	1	2	3	4
ω_j	0	$\frac{\pi}{4}$	$\frac{\pi}{6}$	$\frac{\pi}{2}$	$\frac{5\pi}{6}$
α_j	0	100	1	1	1

We let $z_1(k, \psi_{N,4})$ denote the zero of $\rho_k(\psi_{N,4}; z)$ nearest to $e^{i\omega_1}$, where $\rho_k(\psi_{N,4}; z)$ is the Szegö polynomial (1.17) associated with $x_{N,4}$. Values of $z_1(k, \psi_{N,4})$ were computed for the degrees $k = 2, 4, 6, 8, 10, 20, 30, 40, 50$ and for various sample sizes N ranging from $N = 100$ to $N = 3000$. Values of Arg $z_1(k, \psi_{N,4})$ used to approximate $\omega_1 = \pi/4 \doteq 0.785398164$ (for $k \leq 8$ *not* meaning convergence) are given in Table 2a and values of the number of significant digits of these approximations are given in Table 2b. Values of $|z_1(k, \psi_{N,4}) - e^{i\omega_1}|$ are given in Table 3. For these examples $n_0(I) = n_0(4) = 8$, since $L = 0$ (i.e., $\alpha_0 = 0$). By the convergence results (1.8) stated in §1, for all $k \geq n_0(4) = 8$, $z_1(k, \psi_{N,4}) \to e^{i\omega_1}$ and hence Arg $z_1(k, \psi_{N,4}) \to \pi/4$ as $N \to \infty$. The numerical results in Tables 2 and 3 are consistent with this. For degree $k < n_0(4) = 8$ the method gives approximations of $\omega_1 = \pi/4$ with significant digits ranging from 1 to 4 depending on the choices of k and N. For each fixed N, as k takes on the values 2, 4, 6, the significant digits (Table 2b) are nondecreasing. Moreover, for each fixed $k(= 2, 4, 6)$ the significant digits in Table 2b are nondecreasing as N increases from 100 to 1000, with one exception at $k = 6$ and $N = 401$. These results are all consistent with the assertions of Theorem 4.1.

TABLE 2a

MODELS OF Q-ALGEBRA REPRESENTATIONS: THE GROUP OF PLANE MOTIONS*

E. G. KALNINS†, W. MILLER, JR.‡, AND S. MUKHERJEE§

Abstract. This paper continues a study of one- and two-variable function space models of irreducible representations of q-analogs of Lie enveloping algebras, motivated by recurrence relations satisfied by q-hypergeometric functions. The algebra considered is the Lie algebra $m(2)$ of the group of plane motions. It is shown that various q-analogs of the exponential function can be used to mimic the exponential mapping from a Lie algebra to its Lie group, and the corresponding matrix elements of the group operators are computed on these representation spaces. This local approach applies to more general families of special functions, e.g., those with complex arguments and parameters, than does the quantum group approach. A simple one-variable model of the infinite-dimensional irreducible representations is used to compute the Clebsch–Gordan coefficients for $m(2)$ considered as a true quantum algebra. The authors derive a generalization of Koelink's addition formula for Hahn–Exton q-Bessel functions. It is interpreted here as the expansion of the matrix elements of a group operator in a tensor product basis in terms of the matrix elements in a reduced basis.

Key words. basic hypergeometric functions, q-algebras, quantum groups, motion group, Clebsch–Gordan series

1. Introduction.

This paper continues the study of function space models of irreducible representations of q-algebras [8]. These algebras and models are motivated by recurrence relations satisfied by q-hypergeometric functions [2], [9]. Here, we consider the irreducible representations of the Lie algebra $m(2)$ of the group $M(2)$ of plane motions. We replace the usual exponential-function mapping from the Lie algebra to the Lie group by the q-exponential mappings E_q and e_q. In place of the usual matrix elements on the group (arising from an irreducible representation), which are expressible in terms of Bessel functions of integer order, we find four types of matrix elements expressible in terms of the Jackson and the Hahn–Exton q-Bessel functions. These q-matrix elements do not satisfy group homomorphism properties, and so they do not lead to addition theorems in the usual sense. However, they do satisfy orthogonality relations. (This was shown earlier by Koornwinder and Swarttouw [15].) Furthermore, in analogy with true group representation theory, we can show that each of the four families of matrix elements determines a two-variable model for irreducible representations of $m(2)$. By q-exponentiating these models we get q-analogs of addition theorems for Bessel functions.

In §3 we use the definition of $m(2)$ as a true quantum algebra and take the tensor product of two infinite-dimensional unitary irreducible representations of this quantum algebra. The tensor product decomposes into a direct sum of irreducible

representations (rather than a direct integral, as in the $q = 1$ case), and the decomposition is nonunique. Focusing our attention on the two simplest decompositions of the infinite-parameter family of choices, we compute the corresponding Clebsch–Gordon coefficients. Special cases of the unitarity relations for the Clebsch–Gordon coefficients are the q-Hankel orthogonality relations. Moreover, expressing the matrix elements of the group operators in the tensor-product basis as a linear combination of the matrix elements in the basis adapted to the direct sum decomposition, by means of the Clebsch–Gordon coefficients, we obtain a generalization of Koelink's addition theorem for Hahn–Exton q-Bessel functions.

Our approach to the derivation and understanding of q-series identities is based on the study of q-algebras as q-analogs of Lie algebras [7]. Essentially, we are attempting to find q-analogs of the theory relating Lie algebra and local Lie transformation groups. A similar approach has been adopted by Floreanini and Vinet [3]–[5]. This is an alternative to the elegant papers [10]–[17] that are based primarily on the theory of quantum groups. The main justification of the local approach is that it is more general; it applies to more general families of special functions than does the quantum group approach.

The notation used for q-series in this paper follows that of Gasper and Rahman [6]. We wish to thank the referee for suggestions that considerably improved the exposition and accuracy of §2.

2. Matrix elements of $m(2)$ representations. The three-dimensional Lie algebra $m(2)$ is determined by its generators H, E_+, E_-, which obey the commutation relations

$$[H, E_+] = E_+, \qquad [H, E_-] = -E_-, \qquad [E_+, E_-] = 0. \tag{2.1}$$

The irreducible representations $Q(\omega, m_0)$ are characterized by the complex numbers ω and m_0, with $\omega \neq 0$ and $0 \leq \Re\, m_0 < 1$. The spectrum of H corresponding to $Q(\omega, m_0)$ is the set $S = \{m_0 + n : n \in Z\}$, and the complex representation space has basis vectors f_m, $m \in S$, such that

$$E_\pm f_m = \omega f_{m\pm 1}, \quad Hf_m = mf_m, \quad E_+E_-f_m = \omega^2 f_m, \tag{2.2}$$

where $C \equiv E_+E_-$ is an invariant operator. Note that the representations $Q(\omega, m_0)$ and $Q(-\omega, m_0)$ are equivalent.

A simple realization of $Q(\omega, m_0)$ is given by the operators

$$H = m_0 + z\frac{d}{dz}, \quad E_+ = \omega z, \quad E_- = \frac{\omega}{z} \tag{2.3}$$

acting on the space of all linear combinations of the functions z^n, z a complex variable, $n \in Z$, with basis vectors $f_m(z) = z^n$, where $m = m_0 + n$.

The representations $(\omega) \cong Q(\omega, 0)$ with $\omega > 0$ are of special interest. In this case we can introduce an inner product such that $\langle f_n, f_{n'} \rangle = \delta_{nn'}$, $n, n' \in Z$. On the dense subspace $\mathcal{K}$ of all finite linear combinations of the basis vectors we have

$$\langle E_+f, f' \rangle = \langle f, E_-f' \rangle, \quad \langle Hf, f' \rangle = \langle f, Hf' \rangle \tag{2.4}$$

for all $f, f' \in \mathcal{K}$, so that $H = H^*$ and $E_+^* = E_-$. In terms of the operators (2.3) we can obtain a realization of (ω) and its Hilbert-space structure by setting $z = e^{i\theta}$:

$$
\begin{aligned}
&H = -i\frac{d}{d\theta}, \quad E_+ = \omega e^{i\theta}, \quad E_- = \omega e^{-i\theta}, \\
&f_n(z) = e^{in\theta}, \qquad \langle f, f' \rangle = \frac{1}{2\pi}\int_0^{2\pi} f(e^{i\theta})\overline{f'(e^{i\theta})}\, d\theta.
\end{aligned} \tag{2.5}
$$

Matrix elements $T_{m'm}$ of the complex motion group in the representation $Q(\omega, m_o)$ are typically defined by the expansions

$$
e^{\beta E_+} e^{\alpha E_-} e^{\tau H} f_m = \sum_{m'=-\infty}^{\infty} T_{m'm}(\alpha, \beta, \tau) f_{m'}, \tag{2.6}
$$

with $m, m' \in S$ [3], [5], [19]. The group multiplication property of the operators on the left-hand side of (2.6) leads to addition theorems for the matrix elements. For convenience in the computations to follow we shall limit ourselves to the case in which $\tau = 0$ and ω is real. For this case we have $T_{m'm}(\alpha, \beta) \equiv T_{m'm}(\alpha, \beta, 0) \equiv T_{n'n}(\alpha, \beta)$, where $m = m_0 + n$, $m' = m_0 + n'$, i.e., the representations $Q(\omega, m_0)$ and (ω) have exactly the same matrix elements. (The extension of the matrix elements to complex ω will usually be obvious.)

With the q-analogs of the exponential function

$$
\begin{aligned}
e_q(x) &= \sum_{k=0}^{\infty} \frac{x^k}{(q;q)_k} = \frac{1}{(x;q)_\infty}, \qquad |x| < 1, \\
E_q(x) &= \sum_{k=0}^{\infty} \frac{q^{k(k-1)/2} x^k}{(q;q)_k} = (-x;q)_\infty
\end{aligned} \tag{2.7}
$$

we use the model (2.3) to define the following q-analogs of matrix elements of (ω):

$$
e_q(\beta E_+) e_q(\alpha E_-) f_n = \sum_{n'=-\infty}^{\infty} T_{n'n}^{(e,e)}(\alpha, \beta) f_{n'}, \qquad |\omega\alpha|, |\omega\beta| < 1, \tag{2.8a}
$$

$$
e_q(\beta E_+) E_q(\alpha E_-) f_n = \sum_{n'=-\infty}^{\infty} T_{n'n}^{(e,E)}(\alpha, \beta) f_{n'}, \qquad |\omega\beta| < 1, \tag{2.8b}
$$

$$
E_q(\beta E_+) e_q(\alpha E_-) f_n = \sum_{n'=-\infty}^{\infty} T_{n'n}^{(E,e)}(\alpha, \beta) f_{n'}, \qquad |\omega\alpha| < 1, \tag{2.8c}
$$

$$
E_q(\beta E_+) E_q(\alpha E_-) f_n = \sum_{n'=-\infty}^{\infty} T_{n'n}^{(E,E)}(\alpha, \beta) f_{n'}. \tag{2.8d}
$$

Here, $0 < q < 1$ and $\alpha, \beta \in \mathbb{C}$. Since $E_+^* = E_-$, we have

$$
\begin{aligned}
T_{n'n}^{(e,e)}(\alpha, \beta) &= \langle e_q(\beta E_+) e_q(\alpha E_-) f_n,\ f_{n'} \rangle \\
&= \langle f_n,\ e_q(\overline{\alpha} E_+) e_q(\overline{\beta} E_-) f_{n'} \rangle \\
&= \overline{T_{nn'}^{(e,e)}(\overline{\beta}, \overline{\alpha})},
\end{aligned} \tag{2.9}
$$

$$T^{(e,E)}_{n'n}(\alpha,\beta) = \overline{T^{(E,e)}_{nn'}(\overline{\beta},\overline{\alpha})}, \tag{2.10}$$

$$T^{(E,E)}_{n'n}(\alpha,\beta) = \overline{T^{(E,E)}_{nn'}(\overline{\beta},\overline{\alpha})}. \tag{2.11}$$

Furthermore, since $e_q(x)E_q(-x) = 1$, we have the identities

$$\sum_{\ell=-\infty}^{\infty} T^{(e,e)}_{n\ell}(\alpha,\beta)T^{(E,E)}_{\ell n'}(-\alpha,-\beta) = \delta_{nn'}, \qquad |\omega\alpha|, |\omega\beta| < 1, \tag{2.12}$$

$$\sum_{\ell=-\infty}^{\infty} T^{(e,E)}_{n\ell}(\alpha,\beta)T^{(E,e)}_{\ell n'}(-\alpha,-\beta) = \delta_{nn'}, \qquad |\omega\alpha|, |\omega\beta| < 1. \tag{2.13}$$

(Note that our operator derivations of these formulas and of many formulas to follow lead automatically to formal power series identities in the group parameters. These identities must then be examined case by case to determine when the series are convergent as analytic functions of the group parameters.) Using the model (2.3) to treat (2.8) as generating functions for the matrix elements and computing the coefficients of $z^{n'}$ in the resulting expressions, we obtain the explicit results:

$$\begin{aligned} T^{(e,e)}_{n'n}(\alpha,\beta) &= \frac{(q^{n-n'+1};q)_\infty(\alpha\omega)^{n-n'}}{(q;q)_\infty} {}_2\phi_1\left(\begin{matrix}0, & 0\\ q^{n-n'+1}\end{matrix}; q, \alpha\beta\omega^2\right) \\ &= \frac{(q^{n-n'+1};q)_\infty(\alpha\omega)^{n-n'}}{(q;q)_\infty(\alpha\beta\omega^2;q)_\infty} {}_0\phi_1\left(\begin{matrix}-\\ q^{n-n'+1}\end{matrix}; q, \alpha\beta\omega^2 q^{n-n'+1}\right), \end{aligned} \tag{2.14}$$

$$\begin{aligned} T^{(e,E)}_{n'n}(\alpha,\beta) &= \frac{(q^{n-n'+1};q)_\infty(\alpha\omega)^{n-n'}}{(q;q)_\infty} q^{(n-n')(n-n'-1)/2} \\ &\quad \times {}_1\phi_1\left(\begin{matrix}0\\ q^{n-n'+1}\end{matrix}; q, -\alpha\beta\omega^2 q^{n-n'}\right) \\ &= \frac{(q^{n'-n+1};q)_\infty(\beta\omega)^{n'-n}}{(q;q)_\infty} {}_1\phi_1\left(\begin{matrix}0\\ q^{n'-n+1}\end{matrix}; q, -\alpha\beta\omega^2\right), \end{aligned} \tag{2.15}$$

$$T^{(E,e)}_{n'n}(\alpha,\beta) = T^{(e,E)}_{nn'}(\beta,\alpha), \tag{2.16}$$

$$\begin{aligned} T^{(E,E)}_{n'n}(\alpha,\beta) &= \frac{(q^{n-n'+1};q)_\infty(\alpha\omega)^{n-n'}}{(q;q)_\infty} q^{(n-n')(n-n'-1)/2} \\ &\quad \times {}_0\phi_1\left(\begin{matrix}-\\ q^{n-n'+1}\end{matrix}; q, \alpha\beta\omega^2 q^{n-n'}\right). \end{aligned} \tag{2.17}$$

If $\alpha\beta \neq 0$, we can express these results in terms of the Jackson q-Bessel functions [6, p. 25],

$$J^{(1)}_\nu(z;q) = \frac{(q^{\nu+1};q)_\infty}{(q;q)_\infty}\left(\frac{z}{2}\right)^\nu {}_2\phi_1\left(\begin{matrix}0, & 0\\ q^{\nu+1}\end{matrix}; q, -\frac{z^2}{4}\right),$$

$$J_\nu^{(2)}(z;q) = \frac{(q^{\nu+1};q)_\infty}{(q;q)_\infty}\left(\frac{z}{2}\right)^\nu {}_0\phi_1\left(\begin{matrix}-\\ q^{\nu+1}\end{matrix};q,-\frac{z^2q^{\nu+1}}{4}\right), \tag{2.18}$$

$$J_\nu^{(2)}(z;q) = (-z^2/4;q)_\infty J_\nu^{(1)}(z;q),$$

and the Hahn–Exton q-Bessel function [15],

$$J_\nu(z;q) = \frac{(q^{\nu+1};q)_\infty}{(q;q)_\infty} z^\nu {}_1\phi_1\left(\begin{matrix}0\\ q^{\nu+1}\end{matrix};q,qz^2\right). \tag{2.19}$$

Indeed, setting $\alpha = ire^{i\psi}$, $\beta = ire^{-i\psi}$, we see that in terms of the new complex coordinates $[r, e^{i\psi}]$ we have

$$\begin{aligned}
T_{n'n}^{(e,e)}(\alpha,\beta) \equiv T_{n'n}^{(e,e)}[r,e^{i\psi}] &= \frac{e^{i(\frac{\pi}{2}+\psi)(n-n')}}{(-r^2\omega^2;q)_\infty} J_{n-n'}^{(2)}(2r\omega;q),\\
T_{n'n}^{(e,E)}[r,e^{i\psi}] &= e^{i(\frac{\pi}{2}-\psi)(n'-n)} q^{(n'-n)/2} J_{n'-n}(r\omega q^{-\frac{1}{2}};q),\\
T_{n'n}^{(E,e)}[r,e^{i\psi}] &= e^{i(\frac{\pi}{2}+\psi)(n-n')} q^{(n-n')/2} J_{n-n'}(r\omega q^{-\frac{1}{2}};q),\\
T_{n'n}^{(E,E)}[r,e^{i\psi}] &= e^{i(\frac{\pi}{2}+\psi)(n-n')} q^{(n-n')^2/2} J_{n-n'}^{(2)}(2r\omega q^{-\frac{1}{2}};q).
\end{aligned} \tag{2.20}$$

(Note that $J_{-n}(z;q) = (-1)^n q^{n/2} J_n(zq^{n/2};q)$, $J_{-n}^{(2)}(z;q) = (-1)^n J_n^{(2)}(z;q)$ for integer n.)

The matrix elements $T_{n'n}(\alpha,\beta)$ themselves define models of the representations (ω). We can see this directly from the commutation relations (2.1). It is a simple consequence of these relations and $e_q(x) = (x;q)_\infty^{-1}$, $E_q(x) = (-x;q)_\infty$ that

$$\begin{aligned}
e_q(\beta E_+)e_q(\alpha E_-)E_+ &= \frac{1}{\beta}(I - T_\beta)e_q(\beta E_+)e_q(\alpha E_-),\\
e_q(\beta E_+)e_q(\alpha E_-)E_- &= \frac{1}{\alpha}(I - T_\alpha)e_q(\beta E_+)e_q(\alpha E_-),
\end{aligned} \tag{2.21}$$

where I is the identity operator and $T_\beta g(\alpha,\beta) = g(\alpha,\beta q)$ for a function $g(\alpha,\beta)$. Thus

$$\begin{aligned}
\omega T_{n',n+1}^{(e,e)}(\alpha,\beta) &= \langle e_q(\beta E_+)e_q(\alpha E_-)E_+ f_n, f_{n'}\rangle\\
&= \frac{1}{\beta}(I - T_\beta)T_{n'n}^{(e,e)}(\alpha,\beta),\\
\omega T_{n',n-1}^{(e,e)}(\alpha,\beta) &= \frac{1}{\alpha}(I - T_\alpha)T_{n'n}^{(e,e)}(\alpha,\beta).
\end{aligned} \tag{2.22}$$

Similarly, the relations

$$\begin{aligned}
e_q(\beta E_+)E_q(\alpha E_-)E_+ &= \frac{1}{\beta}(I - T_\beta)e_q(\beta E_+)E_q(\alpha E_-),\\
e_q(\beta E_+)E_q(\alpha E_-)E_- &= \frac{q}{\alpha}(T_\alpha^{-1} - I)e_q(\beta E_+)E_q(\alpha E_-)
\end{aligned} \tag{2.23}$$

yield

$$\begin{aligned}
\omega T_{n',n+1}^{(e,E)}(\alpha,\beta) &= \frac{1}{\beta}(I - T_\beta)T_{n'n}^{(e,E)}(\alpha,\beta),\\
\omega T_{n',n-1}^{(e,E)}(\alpha,\beta) &= \frac{q}{\alpha}(T_\alpha^{-1} - I)T_{n'n}^{(e,E)}(\alpha,\beta).
\end{aligned} \tag{2.24}$$

In the same way we find

$$\begin{aligned}\omega T^{(E,e)}_{n',n+1}(\alpha,\beta) &= \frac{q}{\beta}(T_\beta^{-1} - I)T^{(E,e)}_{n'n}(\alpha,\beta),\\ \omega T^{(E,e)}_{n',n-1}(\alpha,\beta) &= \frac{1}{\alpha}(I - T_\alpha)T^{(E,e)}_{n'n}(\alpha,\beta)\end{aligned} \tag{2.25}$$

and

$$\begin{aligned}\omega T^{(E,E)}_{n',n+1}(\alpha,\beta) &= \frac{q}{\beta}(T_\beta^{-1} - I)T^{(E,E)}_{n'n}(\alpha,\beta),\\ \omega T^{(E,E)}_{n',n-1}(\alpha,\beta) &= \frac{q}{\alpha}(T_\alpha^{-1} - I)T^{(E,E)}_{n'n}(\alpha,\beta).\end{aligned} \tag{2.26}$$

Furthermore, induction with respect to $k+\ell$ yields $[H, \alpha^\ell\beta^k E_+^k E_-^\ell] = (k-\ell)\alpha^\ell\beta^k E_+^k E_-^\ell$, and this implies

$$[H, e_q(\beta E_+)e_q(\alpha E_-)] = (\beta\partial_\beta - \alpha\partial_\alpha)e_q(\beta E_+)e_q(\alpha E_-),$$

so that

$$\begin{aligned}(n'-n)T^{(e,e)}_{n'n}(\alpha,\beta) &= \langle e_q(\beta E_+)e_q(\alpha E_-)f_n, Hf_{n'}\rangle - \langle e_q(\beta E_+)e_q(\alpha E_-)Hf_n, f_{n'}\rangle\\ &= \langle [H, e_q(\beta E_+)e_q(\alpha E_-)]f_n, f_{n'}\rangle = (\beta\partial_\beta - \alpha\partial_\alpha)T^{(e,e)}_{n'n}(\alpha,\beta).\end{aligned}$$

Similarly,

$$(n'-n)T_{n'n}(\alpha,\beta) = (\beta\partial_\beta - \alpha\partial_\alpha)T_{n'n}(\alpha,\beta) \tag{2.27}$$

for all the remaining cases.

Thus, denoting operators

$$\tilde{E}^x = \frac{1}{x}(I - T_x), \quad \hat{E}^x = \frac{q}{x}(T_x^{-1} - I), \quad \tilde{H} = \alpha\partial_\alpha - \beta\partial_\beta, \tag{2.28}$$

we see that the following sets of operators and basis functions each define a two-variable realization of relations (2.2) and hence a realization of the representation (ω):

$$\tilde{E}_+^\beta, \tilde{E}_-^\alpha, \tilde{H}, \qquad f_{-n'+n} = T^{(e,e)}_{n'n}(\alpha,\beta), \tag{2.29a}$$

$$\tilde{E}_+^\beta, \hat{E}_-^\alpha, \tilde{H}, \qquad f_{-n'+n} = T^{(e,E)}_{n'n}(\alpha,\beta), \tag{2.29b}$$

$$\hat{E}_+^\beta, \tilde{E}_-^\alpha, \tilde{H}, \qquad f_{-n'+n} = T^{(E,e)}_{n'n}(\alpha,\beta), \tag{2.29c}$$

$$\hat{E}_+^\beta, \hat{E}_-^\alpha, \tilde{H}, \qquad f_{-n'+n} = T^{(E,E)}_{n'n}(\alpha,\beta). \tag{2.29d}$$

Moreover, from the explicit expressions (2.14) for the matrix elements $T_{n'n}(\alpha,\beta)$ it is easy to verify that relations (2.2) remain valid for $-n' = m_0$, a complex number with $0 \le \Re\, m_0 < 1$, ω a nonzero complex number, and n an integer. Thus the four families (2.29) provide realizations of all the representations $Q(\omega, m_0)$, although for $m_0 \neq 0$ the basis functions are no longer matrix elements. (Indeed, each of the families (2.29a)–(2.29d) defines two realizations of $Q(\omega, m_0)$ for $m_0 \neq 0$, one where

the q-Bessel functions are expressed in terms of the subscript $n - n'$ and one where they are expressed in terms of $n' - n$. For $m_0 = 0$ these expressions coincide.)

Before passing on to a deeper consideration of these models we note that the identities (2.12) and (2.13) for $\alpha\beta \neq 0$ are essentially the following identities for q-Bessel functions [15, eqs. (2.14), (2.10)]:

$$\sum_{\ell=-\infty}^{\infty} J^{(2)}_{\ell-n}(r;q) q^{\ell^2/2} J^{(2)}_{\ell}(rq^{-\frac{1}{2}};q) = \delta_{n0}(-r^2/4;q)_\infty, \tag{2.30a}$$

$$\sum_{\ell=-\infty}^{\infty} q^{\ell} J_{\ell+n}(r;q) J_{\ell+n'}(r;q) = \delta_{nn'} q^{-n}, \qquad |r| < q^{-\frac{1}{2}}. \tag{2.30b}$$

The identities (2.30a) can be further generalized by considering matrix element relations of the form

$$S_{n'n}(\beta,\gamma) = \sum_{\ell=-\infty}^{\infty} T^{(e,e)}_{n'\ell}(\alpha,\beta) T^{(E,E)}_{\ell n}(-\alpha,\gamma), \tag{2.12'}$$

where

$$\begin{aligned} S_{n'n}(\beta,\gamma) &= \langle E_q(\gamma E_+) e_q(\beta E_+) f_n, f_{n'} \rangle \\ &= \begin{cases} 0 & \text{if } n' - n < 0, \\ \frac{(\omega\beta)^{n'-n}}{(q;q)_{n'-n}} (-\frac{\gamma}{\beta};q)_{n'-n} & \text{otherwise.} \end{cases} \end{aligned}$$

(There are relations of a similar type for the E_- operator.) These identities yield a q-analog of the Hansen–Lommel orthogonality relations [10], [11]. Indeed, if we set $\alpha = \beta = ir, \gamma = -irq^{n'-n-1}$ in (2.12'), we see that the left-hand side of this equation vanishes unless $n = n'$. Furthermore, with the choice $2r\omega = zq^{n'/2}, m = -\ell$ the expression becomes Koelink's formula:

$$\begin{aligned} &\sum_{m=-\infty}^{\infty} J^{(2)}_{m+n'}(zq^{n'/2};q) q^{(m+n')(m+n'-1)/4} J^{(2)}_{m+n}(zq^{n/2};q) q^{(m+n)(m+n-1)/4} \\ &\qquad = \delta_{nn'}(-z^2 q^n/4;q)_\infty. \end{aligned}$$

As additional examples the identities

$$T^{(E,E)}_{n'n}(\gamma,\alpha) = \sum_{\ell=-\infty}^{n'} S_{n'\ell}(-\beta,\alpha) T^{(E,E)}_{\ell n}(\gamma,\beta),$$

$$T^{(e,E)}_{n'n}(\alpha,\beta) = \sum_{\ell=-\infty}^{n'} S_{n'\ell}(\beta,\gamma) T^{(e,E)}_{\ell n}(\alpha,-\gamma)$$

yield q-analogs of the Lommel relations:

$$x^{-m} J^{(2)}_m(xz;q) = \sum_{j=0}^{\infty} \left(\frac{q^m z}{2}\right)^j q^{j(j+1)/2} \frac{(x^2;q)_j}{(q;q)_j} J^{(2)}_{m+j}(z;q),$$

$$x^m J_m\left(\frac{z}{x} q^{m/2};q\right) = \sum_{j=0}^{\infty} \left(-\frac{zq^{1/2}}{x^2}\right)^j \frac{(x^2;q)_j}{(q;q)_j} J_{m+j}(zq^{(m+j)/2};q),$$

where m is an integer.

We can use the relations (2.22), (2.24)–(2.26) to derive addition theorems for the basis functions $T_{n'n}(\alpha,\beta)$, including the cases in which $n' = -m_0$ is a complex number. First of all, note that (for m, s complex numbers)

$$(2.31)\qquad e_q(\gamma\hat{E}^x)x^m = x^m\frac{(-q^{-m+1}\gamma/x;q)_\infty}{(-q\gamma/x;q)_\infty}, \qquad E_q(\xi\tilde{E}^x)x^s = x^s\frac{(-\xi/x;q)_\infty}{(-q^s\xi/x;q)_\infty}.$$

Now consider the operator $e_q(\gamma\hat{E}_+^\beta)E_q(\xi\tilde{E}_-^\alpha)$ applied to the basis function $f_{m_0} = T^{(E,e)}_{-m_0,0}(\alpha,\beta) = T^{(e,E)}_{0,-m_0}(\beta,\alpha)$:

(2.32)

$$\begin{aligned} &e_q(\gamma\hat{E}_+^\beta)E_q(\xi\tilde{E}_-^\alpha)T^{(E,e)}_{-m_0,0}(\alpha,\beta)\\ &\quad= (\alpha\omega)^{m_0}\frac{(q^{m_0+1};q)_\infty}{(q;q)_\infty}\sum_{k=0}^{\infty}\frac{q^{k(k-1)/2}\omega^{2k}\alpha^k\beta^k(-q^{-k+1}\gamma/\beta;q)_\infty(-\xi/\alpha;q)_\infty}{(q^{m_0+1};q)_k(q;q)_k(-q\gamma/\beta;q)_\infty(-q^{m_0+k}\xi/\alpha;q)_\infty}\\ &\quad= (\alpha\omega)^{m_0}\frac{(q^{m_0+1};q)_\infty(-\xi/\alpha;q)_\infty}{(q;q)_\infty(-q^{m_0}\xi/\alpha;q)_\infty}{}_2\phi_1\left(\begin{matrix}-q^{m_0}\xi/\alpha, & -\beta/\gamma\\ q^{m_0+1}\end{matrix};q,\alpha\gamma\omega^2\right), \end{aligned}$$

convergent for $|q^{m_0}\xi/\alpha| < 1$, $|\alpha\gamma\omega^2| < 1$. Since

$$(2.33)\qquad e_q(\gamma\hat{E}_+^\beta)E_q(\xi\tilde{E}_-^\alpha)T^{(E,e)}_{-m_0,0}(\alpha,\beta) = \sum_{n=-\infty}^{\infty} T^{(e,E)}_{n0}(\xi,\gamma)T^{(E,e)}_{-m_0,n}(\alpha,\beta)$$

from (2.8b), or

$$(2.33')\qquad \begin{aligned} &\frac{x^{m_0}(q^{m_0+1};q)_\infty(qz/xy;q)_\infty}{(q;q)_\infty(q^{m_0+1}z/xy;q)_\infty}{}_2\phi_1\left(\begin{matrix}q^{m_0+1}z/xy, & qx/yz\\ q^{m_0+1}\end{matrix};q,xyz\right)\\ &\quad= \sum_{n=-\infty}^{\infty} y^nJ_n(z;q)J_{m_0+n}(x;q), \qquad |q^{m_0+1}z/xy| < 1, \qquad |xyz| < 1, \end{aligned}$$

this can be considered as an addition theorem for the $T^{(E,e)}_{-m_0,n}$ basis functions that generalizes the Lommel and Graf addition theorems for ordinary Bessel functions, [15, eq. (4.5)], [18], [20], [22]. In [15, eq. (4.10)] (for integer m_0) and in [5] (for complex m_0) the addition theorem corresponding to

$$(2.34)\qquad E_q(\gamma\tilde{E}_+^\beta)E_q(\xi\tilde{E}_-^\alpha)T^{(e,e)}_{-m_0,0}(\alpha,\beta) = \sum_{n=-\infty}^{\infty} T^{(E,E)}_{n0}(\xi,\gamma)T^{(e,e)}_{-m_0,n}(\alpha,\beta)$$

is worked out. The result is

(2.34′)

$$\begin{aligned} &\left(\frac{x}{2}\right)^{m_0}\frac{(qz/xy;q)_\infty(q^{m_0+1};q)_\infty}{(q^{m_0+1}z/xy;q)_\infty(q;q)_\infty}{}_2\phi_1\left(\begin{matrix}q^{m_0+1}z/xy, & yz/x\\ q^{m_0+1}\end{matrix};q,-\frac{x^2}{4}\right)\\ &\quad= \sum_{n=-\infty}^{\infty} q^{n(n-1)/2}y^nJ_n^{(2)}(z;q)J^{(1)}_{m_0+n}(x;q), \qquad |q^{m_0+1}z/xy| < 1, \qquad |x^2| < 4. \end{aligned}$$

To better understand and to extend identities (2.33) we note that, formally at least, the operators $e_q(\gamma\hat{E}_+^\beta)$, $E_q(\xi\tilde{E}_-^\alpha)$, and H are symmetry operators for the q-difference equation

$$\hat{E}_+^\beta \tilde{E}_-^\alpha \Psi(\alpha,\beta) = \ell^2 \Psi(\alpha,\beta). \tag{2.35}$$

That is, these operators map solutions of the equations to new solutions. Thus if $\Psi(\alpha,\beta)$ is a solution, then so are $e_q(\gamma\hat{E}_+^\beta)E_q(\xi\tilde{E}_-^\alpha)\Psi(\alpha,\beta) = \Psi'(\alpha,\beta)$ and $H\Psi(\alpha,\beta)$. It is easy to check that the only solution Ψ_λ of (2.35) and $H\Psi_\lambda = \lambda\Psi_\lambda$ for complex (noninteger) λ, such that $r^{-\lambda}\Psi_\lambda$ is analytic in r at $r = 0$, is $\Psi_\lambda(\alpha,\beta) \equiv \Psi_\lambda[r,t] = t^\lambda J_\lambda(r\omega q^{-1/2};q)$, unique up to multiplication by a constant. Here, $\alpha = irt$, $\beta = ir/t$. (For $\lambda = n$, an integer, the only solution Ψ_λ analytic in r at $r = 0$ is $\Psi_n = t^n J_n(r\omega q^{-1/2};q)$.) Thus if $\Psi'_\lambda(\alpha,\beta)$ is analytic in the variables $R = r$, $S = rt$ at $R = 0$, then it must have an expansion of the form [2]

$$\Psi' = \sum_\lambda c_\lambda t^\lambda J_\lambda(r\omega q^{-1/2};q), \tag{2.36}$$

where the c_λ are complex constants. Expression (2.33) is a special case of this expansion.

It is easy to see from (2.31) that the operators $e_q(\gamma\hat{E}_+^\beta)$, $E_q(\xi\tilde{E}_-^\alpha)$ do commute with $\hat{E}_+^\beta$ and $\tilde{E}_-^\alpha$ when acting on monomials $\beta^m\alpha^s$, and so modulo convergence problems are symmetry operators mapping analytic solutions of $\hat{E}_+^\beta\tilde{E}_-^\alpha\Psi = \ell^2\Psi$ to analytic solutions. Now, instead of the definition $E_q(\xi\tilde{E}^x)x^s = x^s(-\xi/x;q)_\infty/(-q^s\xi/x;q)_\infty$, let us adopt the definition ($\xi \neq 0$)

$$E_q(\xi\tilde{E}_-^x)'x^s = \xi^s q^{s(s-1)/2}\frac{(-q^{-s+1}x/\xi;q)_\infty}{(-qx/\xi;q)_\infty}. \tag{2.37}$$

For s an integer these definitions coincide, but they are distinct for s complex. It is again easy to verify that

$$E_q(\xi\tilde{E}_-^\alpha)'\tilde{E}_-^\alpha\alpha^s = \tilde{E}_-^\alpha E_q(\xi\tilde{E}_-^\alpha)'\alpha^s,$$

so that $E_q(\xi\tilde{E}_-^\alpha)'$ is also a symmetry operator. As an example of the use of this observation consider

(2.38)

$$\begin{aligned}\Psi' &= E_q(\xi\tilde{E}_-^\alpha)'T_{-m_0,0}^{(E,e)}(\alpha,\beta)\\ &= \frac{(\xi\omega)^{m_0}(q^{m_0+1};q)_\infty q^{m_0(m_0-1)/2}(-q^{-m_0+1}\alpha/\xi;q)_\infty}{(q;q)_\infty(-q\alpha/\xi;q)_\infty}\,{}_1\phi_1\left(\begin{matrix}-q^{m_0}\xi/\alpha\\ q^{m_0+1}\end{matrix};q,-\alpha\beta\omega^2\right),\\ &\qquad |q\alpha/\xi| < 1.\end{aligned}$$

Thus we have

$$\frac{(-q^{-m_0+1}irt/\xi;q)_\infty}{(-qirt/\xi;q)_\infty}\,{}_1\phi_1\left(\begin{matrix}-q^{m_0}\xi/irt\\ q^{m_0+1}\end{matrix};q,r^2\omega^2\right) = \sum_{n=-\infty}^{\infty} c_n t^n J_n(r\omega q^{-1/2};q). \tag{2.39}$$

Now set $t = s/r$ and let $r \to 0$ in (2.39). We obtain $c_n = (-iq^{3/2}/\xi\omega)^n (q^{-m_0};q)_\infty/(q^{-m_0+n};q)_\infty$ for $n = 0, 1, \dots$. Similarly, if we set $t = sr$ and let $r \to 0$, we find the same expression for c_n with $-n = 0, 1, \dots$. Thus

$$\frac{(q^{-m_0}x;q)_\infty}{(x;q)_\infty} {}_1\phi_1\left(\begin{matrix} q^{m_0+1}/x \\ q^{m_0+1}\end{matrix}; q, qz^2\right) = \sum_{n=-\infty}^{\infty} \left(\frac{qx}{z}\right)^n \frac{(q^{-m_0};q)_\infty}{(q^{-m_0+n};q)_\infty} J_n(z;q), \tag{2.40}$$
$$0 < |x| < 1.$$

Similarly, applying the symmetry operator $E_q(\xi \tilde{E}_-^\alpha)'$ to the basis function $T^{(e,e)}_{-m_0,0}$, we obtain the identity

(2.41)
$$\frac{(q^{-m_0}ry;q)_\infty}{(ry;q)_\infty} {}_2\phi_1\left(\begin{matrix} q^{m_0+1}/ry, & 0 \\ q^{m_0+1}\end{matrix}; q, -r^2\right) = \sum_{n=-\infty}^{\infty} y^n \frac{(q^{-m_0};q)_\infty}{(q^{-m_0+n};q)_\infty} J_n^{(1)}(2r;q),$$
$$0 < |y|, \quad |r^2| < 1, \quad |ry| < 1.$$

Also, we can apply the symmetry operator

$$e_q(\gamma \hat{E}_+^\beta)' \beta^m = \gamma^m q^{-m(m-1)/2} \frac{(-\beta/\gamma;q)_\infty}{(-q^m\beta/\gamma;q)_\infty},$$

rather than $e_q(\gamma \hat{E}_+^\beta)$, to obtain new identities.

3. Tensor products. In addition to the standard definition of the tensor product of two irreducible representations (ω_1) and (ω_2) of $m(2)$, there is a definition given by the nontrivial Hopf algebra structure in which the coproduct is [1], [4], [11]

$$\begin{aligned} F_+ &= \Delta(E_+) = E_+ \otimes q^{-\frac{1}{2}H} + q^{\frac{1}{2}H} \otimes E_+, \\ F_- &= \Delta(E_-) = E_- \otimes q^{-\frac{1}{2}H} + q^{\frac{1}{2}H} \otimes E_-, \\ L &= \Delta(H) = H \otimes I + I \otimes H. \end{aligned} \tag{3.1}$$

The operators $F_\pm$, L satisfy the same commutation relations as the operators $E_\pm$, H:

$$[L, F_\pm] = \pm F_\pm, \quad [F_+, F_-] = 0. \tag{3.2}$$

The standard definition is obtained by letting $q \to 1$ in (3.1). Each irreducible representation (ω_1), (ω_2) is defined on $L_2[0, 2\pi]$ by the prescription (2.5). To make sense of the operators (3.1) on a dense subspace of the tensor-product space $L[0, 2\pi] \otimes L[0, 2\pi]$ we proceed as follows. The Hilbert-space inner product is

$$\langle f, g \rangle = \frac{1}{(2\pi)^2} \int_0^{2\pi} \int_0^{2\pi} f(\theta_1, \theta_2) \overline{g(\theta_1, \theta_2)}\, d\theta_1 d\theta_2.$$

An orthonormal basis is $\{f_{n_1 n_2} = e^{i(n_1\theta_1 + n_2\theta_2)}, n_j = 0, \pm 1, \pm 2, \dots\}$. In terms of this basis a general element f of the Hilbert space can be expanded as

$$f(\theta_1, \theta_2) \sim \sum_{n_1, n_2 = -\infty}^{\infty} a_{n_1 n_2} e^{i(n_1\theta_1 + n_2\theta_2)} = \sum_{n,k=-\infty}^{\infty} A_{nk} e^{i(n\Theta + k\Phi)}, \tag{3.3}$$

where $\sum |a_{n_1n_2}|^2 < \infty$, $k = n_1 + n_2$, $n = n_1$, $\Theta = \theta_1 - \theta_2$, $\Phi = \theta_2$, and $A_{nk} = a_{n_1n_2}$. Now set $z = e^{i\Theta}$, $t = e^{i\Phi}$. Since $L = \Delta(H) = -i\partial_\Phi = t^{-1}\partial_t$, it is clear that the eigenvalues of L are $k_0 = 0, \pm 1, \pm 2, \ldots$ and that the corresponding eigenspace of $L[0, 2\pi] \otimes L[0, 2\pi]$ consists of those square integrable functions f for which $A_{nk} = 0$ if $k \neq k_0$. The operators (3.2) make sense on the dense subspace $\mathcal{K}$ of the Hilbert space consisting of finite sums of functions $f[z,t] = \sum f_k[z]t^k$, $(z,t) \in \mathcal{C}_2$, ($f[e^{i\Theta}, e^{i\Phi}] = f(\theta_1, \theta_2)$ belongs to the Hilbert space) such that each $f_k[z]$ is analytic except possibly for an essential singularity at $z = 0$ and a countable number of poles in the complex plane (not on the unit circle $|z| = 1$). Then

$$
\begin{aligned}
F_+f[z,t] &= \omega_1 ztf[zq^{1/2}, tq^{-1/2}] + \omega_2 tf[zq^{1/2}, t], \\
F_-f[z,t] &= \frac{\omega_1}{zt} f[zq^{1/2}, tq^{-1/2}] + \frac{\omega_2}{t} f[zq^{1/2}, t], \\
Lf[z,t] &= \frac{1}{t}\partial_t f[z,t].
\end{aligned} \tag{3.4}
$$

We further require that $F_\pm f[e^{i\Theta}, e^{i\Phi}]$ and $F_+F_-f[e^{i\Theta}, e^{i\Phi}]$ are square integrable. Formally, the invariant operator $\Delta(E_+E_-) = F_+F_-$ takes the form

$$
F_+F_-f[z,t] = \left(\omega_1^2 T_t^{-1} + \omega_1\omega_2\left(zq^{1/2} + \frac{1}{zq^{1/2}}\right)T_t^{-1/2} + \omega_2^2 I\right) T_z f[z,t].
$$

Thus if f satisfies

$$
F_+F_-f = \lambda f, \quad Lf = kf, \tag{3.5}
$$

it should have the form $f[z,t] = g_k[z]t^k$, where

$$
(\omega_1 q^{-k/2} + \omega_2 zq^{1/2})\left(\omega_1 q^{-k/2} + \frac{\omega_2}{zq^{1/2}}\right) g_k[zq] = \lambda g_k[z]. \tag{3.6}
$$

To decompose the tensor-product representation into irreducible representations it is sensible to require that the domain of definition of the preceding operators be adjusted so that on this domain F_+ is the adjoint of F_- and L, $K = F_+F_-$ are symmetric. Then we extend the domain to make K self-adjoint. Let us consider the restriction K_k of K to the subspace of functions of the form $f_k[z,t] = g_k[z]t^k$, so that $Lf_k = kf_k$. Then

$$
K_k = (\omega_1 q^{-k/2} + \omega_2 zq^{1/2})\left(\omega_1 q^{-k/2} + \frac{\omega_2}{zq^{1/2}}\right) T_z \tag{3.7}
$$

and the induced Hilbert-space inner product is

$$
(g, g') = \frac{1}{2\pi i}\oint_{|z|=1} g[z]\overline{g}'[z^{-1}]\,\frac{dz}{z}, \tag{3.8}
$$

where $\overline{g[z]} = \overline{g}[\overline{z}]$. It follows that

$$
(K_k g, g') = (g, K_k g') + R(g, g'), \tag{3.9}
$$

where $R(g, g')$ is the sum of residues of the function $z^{-1}(\omega_1 q^{-k/2} + \omega_2 zq^{-1/2})(\omega_1 q^{-k/2} + \omega_2 q^{1/2}/z)g[z]\overline{g}'[q/z]$ in the annulus $q < |z| < 1$. Thus K_k will be symmetric on

a domain $\mathcal{D}$ such that $R(g,g')=0$ for all $g,g'\in\mathcal{D}$. This shows that the role of boundary conditions for symmetric operators is played here by the placement of zeros and poles for the elements of $\mathcal{D}$.

There is an infinite parameter family of self-adjoint operators associated with the symbol (3.7). We shall focus on those two of the self-adjoint operators (and their spectral resolutions) that are the simplest in structure. The first corresponds to the orthonormal basis of eigenvectors

$$h_p^{(1)}[z]=\frac{(-q^{(1+k)/2}\omega_2 z/\omega_1;q)_\infty}{(-q^{(1+k)/2}\omega_2/\omega_1 z;q)_\infty}z^{p+k},\qquad p=0,\pm1,\dots, \tag{3.10}$$

with eigenvalues $\lambda_p^{(1)}=\omega_1^2q^p$. The second has an orthonormal basis of eigenvectors

$$h_p^{(2)}[z]=\frac{(-q^{(1-k)/2}\omega_1 z/\omega_2;q)_\infty}{(-q^{(1-k)/2}\omega_1/\omega_2 z;q)_\infty}z^{p},\qquad p=0,\pm1,\dots, \tag{3.11}$$

with eigenvalues $\lambda_p^{(2)}=\omega_2^2q^p$. Setting $f_{pk}^{(j)}[z,t]=h_p^{(j)}[z]t^k$, $j=1,2$, we have

$$\begin{aligned}F_\pm f_{pk}^{(j)}&=\omega_j q^{p/2}f_{p,k\pm1}^{(j)},\\ Lf_{pk}^{(j)}&=kf_{pk}^{(j)},\qquad Kf_{pk}^{(j)}=\omega_j^2q^pf_{pk}^{(j)}.\end{aligned} \tag{3.12}$$

Thus

$$(\omega_1)\otimes_q^j(\omega_2)\equiv\sum_{p=-\infty}^{\infty}\oplus(\omega_jq^{p/2}), \tag{3.13}$$

i.e., in each case the tensor product decomposes into a direct sum of irreducible representations. (This is dramatically different from the case $q=1$ in which the tensor-product representation is unique and the spectrum of K is continuous [22, p. 224].)

As an indication of the multiplicity of possible self-adjoint operators and resulting spectral decompositions, consider the function

$$S_\lambda[z]=\frac{(-q^{1/2}\lambda/z;q)_\infty(-q^{1/2}z/\lambda;q)_\infty}{(-q^{1/2}\lambda z;q)_\infty(-q^{1/2}/\lambda z;q)_\infty} \tag{3.14}$$

for λ a nonzero real constant. Note that $|S_\lambda[z]|=1$ for $|z|=1$. Now $S_\lambda[zq]=\lambda^2S_\lambda[z]$ so the sets $\{S_\lambda[z]f_{pk}^{(j)}\}$, $j=1,2$, are each orthonormal bases of $L_2[0,2\pi]\otimes L_2[0,2\pi]$ consisting of eigenvectors of K with eigenvalues $\lambda^2\omega_j^2q^p$. Furthermore, the sets $\{f_{pk}^{(j)\prime}=S_\lambda[z^2]f_{pk}^{(j)}\}$ satisfy relations (3.12) with ω_j replaced by $\omega_j\lambda^2$.

The Clebsch–Gordan coefficients for the tensor product corresponding to the spectral resolution (3.10) are defined by

$$f_{pk}^{(1)}[z,t]=f_{pk}^{(1)}(\theta_1,\theta_2)=\sum_{n_1,n_2=-\infty}^{\infty}\begin{bmatrix}\omega_1&\omega_2&p\\ n_1&n_2&k\end{bmatrix}^{(1)}f_{n_1}^{\omega_1}(e^{i\theta_1})\otimes_q^1 f_{n_2}^{\omega_2}(e^{i\theta_2}). \tag{3.15}$$

Clearly, these coefficients vanish unless $k=n_1+n_2$. The orthogonality of the two bases implies the identities

$$\sum_{n_1,n_2}\begin{bmatrix}\omega_1&\omega_2&p\\ n_1&n_2&k\end{bmatrix}^{(1)}\begin{bmatrix}\omega_1&\omega_2&p'\\ n_1&n_2&k\end{bmatrix}^{(1)}=\delta_{pp'}, \tag{3.16}$$

$$\sum_p \begin{bmatrix} \omega_1 & \omega_2 & p \\ n_1 & n_2 & k \end{bmatrix}^{(1)} \begin{bmatrix} \omega_1 & \omega_2 & p \\ n_1' & n_2' & k \end{bmatrix}^{(1)} = \delta_{n_1 n_1'},$$

where $n_1 + n_2 = n_1' + n_2' = k$. Explicitly,

$$\begin{bmatrix} \omega_1 & \omega_2 & p \\ n_1 & n_2 & k \end{bmatrix}^{(1)} = (-1)^{p+n_2} q^{(p+n_2)/2} J_{p+n_2}(q^{-1/2} b_k; q) - \sum_{\ell=0}^{s_k-1} \frac{(q^\ell b_k^2; q)_\infty q^{\ell(\ell+1)/2} (-q^\ell b_k)^{p+n_2} (-1)^\ell}{(q;q)_\infty (q;q)_\ell}, \tag{3.17}$$

where $k = n_1 + n_2$, $b_k = q^{(1+k)/2}\omega_2/\omega_1$, and $s_k \geq 0$ is the smallest integer such that $q^{s_k} b_k < 1$. (We assume that $b_k \neq q^n$ for any integer n.) Indeed, the case $s_k = 0$ of (3.17) follows from (3.15), and this result can be written as a complex contour integral. The case $s_k > 0$ can be obtained from this result by shifting the contour.

Similarly, the Clebsch–Gordan coefficients for the tensor product corresponding to the spectral resolution (3.11) are defined by

$$f_{pk}^{(2)}[z,t] = f_{pk}^{(2)}(\theta_1, \theta_2) = \sum_{n_1, n_2 = -\infty}^{\infty} \begin{bmatrix} \omega_1 & \omega_2 & p \\ n_1 & n_2 & k \end{bmatrix}^{(2)} f_{n_1}^{\omega_1}(e^{i\theta_1}) \otimes_q^2 f_{n_2}^{\omega_2}(e^{i\theta_2}).$$

They satisfy orthogonality relations analogous to (3.16) and are given explicitly by (3.17), where now $b_k = q^{(1-k)/2}\omega_1/\omega_2$ and n_2 is replaced by $-n_1$.

With respect to the tensor-product basis $\{f_{n_1}^{\omega_1} \otimes f_{n_2}^{\omega_2}\}$ the operator $e_q(\beta F_+)E_q(\alpha F_-)$ has matrix elements

$$\begin{aligned} T_{m_1 m_2; n_1 n_2}(\alpha, \beta) &= \langle e_q(\beta\Delta(E_+))E_q(\alpha\Delta(E_-)) f_{n_1}^{\omega_1} \otimes f_{n_2}^{\omega_2}, f_{m_1}^{\omega_1} \otimes f_{m_2}^{\omega_2} \rangle \\ &= (\beta\omega_1)^{m_1 - n_1} (\beta\omega_2)^{m_2 - n_2} \frac{(q^{m_1 - n_1 + 1}; q)_\infty (q^{m_2 - n_2 + 1}; q)_\infty}{(q;q)_\infty^2 q^{(m_1 m_2 + n_1 n_2 - 2n_1 m_2)/2}} \\ &\quad \times {}_1\phi_1\left(\begin{matrix} 0 \\ q^{m_1 - n_1 + 1} \end{matrix}; q, -\alpha\beta\omega_1^2 q^{-m_2} \right) {}_1\phi_1\left(\begin{matrix} 0 \\ q^{m_2 - n_2 + 1} \end{matrix}; q, -\alpha\beta\omega_2^2 q^{n_1} \right), \end{aligned}$$

or, in coordinates $[r,t]$,

$$T_{m_1 m_2; n_1 n_2}[r,t] = (-q^{-1/2} it)^{n_1 + n_2 - m_1 - m_2} J_{m_1 - n_1}(r\omega_1 q^{-(m_2+1)/2}; q) J_{m_2 - n_2}(r\omega_2 q^{(n_1 - 1)/2}; q). \tag{3.18}$$

To see this most simply, recall that if X and Y are linear operators such that $YX = qXY$, then [6, p. 28],

$$(Y + X)^k = \sum_{\ell=0}^{k} \frac{(q;q)_k}{(q;q)_\ell (q;q)_{k-\ell}} X^\ell Y^{k-\ell},$$

$$e_q(X + Y) = e_q(X) e_q(Y), \qquad E_q(X + Y) = E_q(Y) E_q(X).$$

Thus, using the facts that $E_+ q^{\frac{1}{2}H} = q^{-\frac{1}{2}} q^{\frac{1}{2}H} E_+$, $E_- q^{\frac{1}{2}H} = q^{\frac{1}{2}} q^{\frac{1}{2}H} E_-$ for these representations, we have

$$\begin{aligned} &e_q(\beta F_+)E_q(\alpha F_-) \\ &\quad = e_q(\beta E_+ \otimes q^{-\frac{1}{2}H}) E_q(\alpha E_- \otimes q^{-\frac{1}{2}H}) e_q(\beta q^{\frac{1}{2}H} \otimes E_+) E_q(\alpha q^{\frac{1}{2}H} \otimes E_-), \end{aligned}$$

so that the matrix elements with respect to the tensor-product basis are given by

$$T_{m_1m_2;n_1n_2}(\alpha,\beta) = \langle e_q(\beta q^{-m_2/2}E_+)E_q(\alpha q^{-m_2/2}E_-)f_{n_1}^{\omega_1}, f_{m_1}^{\omega_1}\rangle \times \langle e_q(\beta q^{n_1/2}E_+)E_q(\alpha q^{n_1/2}E_-)f_{n_2}^{\omega_2}, f_{m_2}^{\omega_2}\rangle.$$

From the definition of the Clebsch–Gordan coefficients we see immediately that the identities

(3.19)
$$T_{m_1m_2;n_1n_2}(\alpha,\beta) = \sum_{p=-\infty}^{\infty} \begin{bmatrix} \omega_1 & \omega_2 & p \\ n_1 & n_2 & n_1+n_2 \end{bmatrix}^{(j)} T^{(e,E),\omega_j q^{p/2}}_{m_1+m_2,n_1+n_2}(\alpha,\beta) \times \begin{bmatrix} \omega_1 & \omega_2 & p \\ m_1 & m_2 & m_1+m_2 \end{bmatrix}^{(j)}, \qquad j=1,2$$

must hold. Choosing $j=1$ and taking the special case for which $q^{(1+m_1+m_2)/2}\omega_2/\omega_1 < 1$ and $q^{(1+n_1+n_2)/2}\omega_2/\omega_1 < 1$, we obtain the identity

(3.20)
$$(-q)^n J_{x-n}(Sq^{-y};q^2)J_n(RSq^n;q^2) = \sum_{k=-\infty}^{\infty} q^{2k} J_{k-n}(Rq^y;q^2)J_x(Sq^{k-y};q^2)J_k(Rq^{y+x};q^2),$$

which is valid for $0 < Rq^{y+x+1} < 1$, $0 < Rq^{y+1} < 1$, $0 \le S$, and n, x, y integers. The case $S = q^z$ of this formula for z an integer is the addition theorem for Hahn–Exton q-Bessel functions derived by Koelink by using the theory of quantum groups, [10], [21]. For an analytic proof of Koelink's formula, see [20].

Acknowledgment. Willard Miller, Jr. has worked with both Dick Askey and Frank Olver, in an editorial capacity and as a friend and colleague, for some 25 years and respectfully dedicates this paper to them.

SOME RESULTS ON CO-RECURSIVE ASSOCIATED LAGUERRE AND JACOBI POLYNOMIALS*

JEAN LETESSIER†

Abstract. The author presents results on co-recursive associated Laguerre and Jacobi polynomials which are of interest for the solution of the Chapman–Kolmogorov equations of some birth and death processes with or without absorption. Explicit forms, generating functions, and absolutely continuous parts of the spectral measures are given. Fourth-order differential equations satisfied by the polynomials with a special attention to some simple limiting cases are derived.

Key words. orthogonal polynomials, birth and death processes, hypergeometric functions

AMS subject classifications. 33A65, 60J80, 33A30

1. Introduction. Starting from a sequence of orthogonal polynomials $\{P_n\}_{n\geq 0}$ defined by the recurrence relation

$$P_{n+2}(x) = (x-\beta_{n+1})P_{n+1}(x) - \gamma_{n+1}P_n(x), \qquad n \geq 0, \tag{1.1}$$

and the initial conditions

$$P_0(x) = 1, \qquad P_1(x) = x - \beta_0, \tag{1.2}$$

with β_n, $\gamma_n \in \mathbb{C}$, and $\gamma_n \neq 0$, several modifications were considered:

(i) Associated polynomials arise when we replace n by $n+c$ in the coefficients β_n and γ_n (keeping $\gamma_n \neq 0$). If c is an integer k these polynomials are called associated of order k. The associated polynomials of order one are the numerator polynomials;

(ii) Co-recursive polynomials arise when we replace β_0 by $\beta_0 + \mu$;

(iii) Perturbed polynomials arise when we replace γ_1 by $\lambda\gamma_1$, $(\lambda > 0)$;

(iv) Co-recursive polynomials of these perturbed polynomials arise when the two previous modifications are made together;

(v) Generalized co-recursive and perturbed polynomials arise when we change β_n and/or γ_n at any level n.

In the study of birth and death processes, orthogonal polynomials, in particular all the hypergeometric families of the Askey scheme [1], [19] and their corresponding associated families, play a primordial role in the Karlin–McGregor solution of the Chapman–Kolmogorov equation [11], [16]

$$p_{mn}(t) \sim \int_0^\infty e^{-xt}P_m(x)P_n(x)d\phi(x). \tag{1.3}$$

In certain birth and death processes, zero-related polynomials [12], [13], [14] arise in a natural way. Zero-related polynomials are special co-recursive associated polynomials.

More generally, co-recursive and generalized co-recursive polynomials are involved in the solution of the Chapman–Kolmogorov equation of birth and death processes with absorption or killing [11], [17], [18].

The purpose of this paper is to present some results on co-recursive, associated Laguerre and Jacobi polynomials which are of special interest in the study of birth and

† Laboratoire de Physique Théorique et Hautes Energies, Unité associée au Centre National de la Recherche Scientifique, Université Paris 7, Tour 24, 5è ét., 2 Place Jussieu, F-75251 Cedex 05.

death processes with linear and rational rates, respectively. The Laguerre polynomial families are involved in processes for which the birth and death rates are of the form [12]

$$\lambda_n = n+\alpha+c+1, \quad \mu_{n+1} = n+c+1, \quad n \geq 0, \quad \mu_0 = c-\mu. \tag{1.4}$$

The Jacobi polynomial families are involved when the rates are of the form

$$\lambda_n = \frac{2(n+c+\alpha+\beta+1)(n+c+\beta+1)}{(2n+2c+\alpha+\beta+1)(2n+2c+\alpha+\beta+2)}, \qquad n \geq 0, \tag{1.5a}$$

$$\mu_n = \frac{2(n+c)(n+c+\alpha)}{(2n+2c+\alpha+\beta)(2n+2c+\alpha+\beta+1)}, \qquad n > 0, \tag{1.5b}$$

$$\mu_0 = \frac{2c(c+\alpha)}{(2c+\alpha+\beta)(2c+\alpha+\beta+1)} - \mu. \tag{1.5c}$$

In both cases $\mu_0 = 0$ correspond to the "honest" [24] linear processes (i.e., processes for which the sum of the probabilities $p_{mn}(t)$ is equal to 1). Cases $\mu_0 = \text{Const.} \neq 0$ correspond to processes with absorption and are not "honest." However, if $\mu_0 = c$ in the Laguerre case or $\mu_0 = 2c(c+\alpha)/(2c+\alpha+\beta)(2c+\alpha+\beta+1)$ in the Jacobi case, the corresponding processes are simply solved using associated polynomials.

In §2 we explain the method used by applying it to the Laguerre case. In §2.1 we give an explicit expression for the co-recursive associated Laguerre (CAL) polynomials. In §2.2 we derive a generating function of them and we find the absolutely continuous part of the spectral measure. Section 2.3 is devoted to the derivation, using the Orr's method, of a fourth-order differential equation satisfied by the CAL polynomials. In §2.4 we present results obtained in some limiting cases, among which is a new simple case of associated Laguerre polynomials.

In §3 we briefly present some results corresponding to the Jacobi case. In §3.1 we give an explicit expression for the co-recursive associated Jacobi (CAJ) polynomials. In §3.2 we present a generating function and in §3.3 we give the absolutely continuous component of the spectral measure. Section 3.5 is devoted to some limiting cases of CAJ polynomials for which we give fourth-order differential equations that they satisfy. In §3.6 we give some concluding remarks.

We use the notation of [7] for the special functions used in this work. We do not give validity conditions on the parameters of the used hypergeometric functions, analytic continuations, or limiting processes giving, in general, valid formulas. We use Slater's notation [29] for the product of Γ functions:

$$\Gamma\left(\begin{matrix}\alpha_1,\ldots,\alpha_p\\ \beta_1,\ldots,\beta_q\end{matrix}\right) = \prod_{i=1}^{p}\Gamma(\alpha_i)\Big/\prod_{i=1}^{q}\Gamma(\beta_i). \tag{1.6}$$

2. The case of Laguerre polynomials. Replacing n by $n+c$ in the recurrence relation of the Laguerre polynomials we obtain the recurrence relation satisfied by the associated Laguerre polynomials $L_n^{\alpha}(x;c)$:

$$(2n+2c+\alpha+1-x)p_n = (n+c+1)p_{n+1} + (n+c+\alpha)p_{n-1}. \tag{2.1}$$

To complete the definition of the polynomials $L_n^{\alpha}(x;c)$ the initial condition

$$L_{-1}^{\alpha}(x;c) = 0, \qquad L_0^{\alpha}(x;c) = 1 \tag{2.2}$$

has to be imposed. These polynomials are orthogonal with respect to a positive measure when $(n+c)(n+\alpha+c) > 0$, for all $n > 0$. (See [2] for details.)

Note that if we consider the monic polynomials $\mathbf{L}_n^\alpha(x;c)$ defined by

$$\mathbf{L}_n^\alpha(x;c) = (-1)^n(c+1)_n L_n^\alpha(x;c), \tag{2.3}$$

they satisfy the recurrence relation

$$(x-2n-2c-\alpha-1)\mathbf{L}_n^\alpha(x;c) = \mathbf{L}_{n+1}^\alpha(x;c) + (n+c)(n+c+\alpha)\mathbf{L}_{n-1}^\alpha(x;c), \tag{2.4}$$

We can see that this recurrence is invariant in the transformation $\mathcal{T}$ defined by

$$\mathcal{T}(c,\alpha) = (c+\alpha, -\alpha). \tag{2.5}$$

2.1. Explicit representation of the CAL polynomials. Equations (2.1) and (2.2) give for $L_1^\alpha(x;c)$,

$$L_1^\alpha(x;c) = -\frac{1}{c+1}(x-2c-\alpha-1). \tag{2.6}$$

The CAL polynomials $L_n^\alpha(x;c,\mu)$ satisfy the same recurrence relation (2.1) with a shift μ on the monic polynomial of first degree, i.e.,

$$L_1^\alpha(x;c,\mu) = -\frac{1}{c+1}(x+\mu-2c-\alpha-1). \tag{2.7}$$

To obtain $L_1^\alpha(x;c,\mu)$ with (2.1) we have to impose the initial condition for the CAL polynomials

$$L_{-1}^\alpha(x;c,\mu) = \frac{\mu}{c+\alpha}, \qquad L_0^\alpha(x;c,\mu) = 0. \tag{2.8}$$

Even for $c+\alpha \to 0$ this initial condition in the recurrence relations (2.1) leads to (2.7).

We know two linearly independent solutions of (2.1) in terms of confluent hypergeometric functions:

$$u_n = \frac{(c+\alpha+1)_n}{(c+1)_n} {}_1F_1\left(\begin{matrix}-n-c\\1+\alpha\end{matrix};x\right) \quad \text{and} \quad v_n = {}_1F_1\left(\begin{matrix}-n-c-\alpha\\1-\alpha\end{matrix};x\right). \tag{2.9}$$

Writing the polynomials $L_n^\alpha(x;c,\mu)$ as a linear combination

$$L_n^\alpha(x;c,\mu) = Au_n + Bv_n \tag{2.10}$$

and using the initial condition (2.8) we obtain

$$A = \frac{1}{\Delta}\left[\frac{\mu}{c+\alpha}v_0 - v_{-1}\right] \quad \text{and} \quad B = -\frac{1}{\Delta}\left[\frac{\mu}{c+\alpha}u_0 - u_{-1}\right], \tag{2.11}$$

where Δ may be calculated using contiguous relations of confluent hypergeometric functions [7, pp. 253–254]

$$\Delta = u_{-1}v_0 - u_0v_{-1} = -\frac{\alpha}{c+\alpha}e^x. \tag{2.12}$$

With the help of the relation

$$\gamma_1 F_1\left(\begin{matrix}1-\gamma\\ \alpha\end{matrix};x\right)-\beta_1 F_1\left(\begin{matrix}-\gamma\\ \alpha\end{matrix};x\right)=(\gamma-\beta)_2F_2\left(\begin{matrix}-\gamma,\beta-\gamma+1\\ \alpha,\beta-\gamma\end{matrix};x\right), \tag{2.13}$$

we can write the CAL polynomials as

(2.14)

$$L_n^\alpha(x;c,\mu)=\frac{e^{-x}}{(c+1)_n}(1+\mathcal{T})\times\frac{\mu-c}{\alpha}(c+1)_n{}_2F_2\left(\begin{matrix}-c,\mu-c+1\\ 1+\alpha,\mu-c\end{matrix};x\right){}_1F_1\left(\begin{matrix}-n-c-\alpha\\ 1-\alpha\end{matrix};x\right).$$

This representation is the one we use to derive the fourth-order differential equation in §2.3. It is valid only for $\alpha\neq 0,\pm1,\pm2,\ldots$ but these restrictions can be removed by limiting processes.

Following the method in [2] we can find an explicit representation. We first transform the ${}_1F_1$ in (2.11) using Kummer's transformation [7, p. 253]

$${}_1F_1\left(\begin{matrix}a\\ c\end{matrix};x\right)=e^x{}_1F_1\left(\begin{matrix}c-a\\ c\end{matrix};-x\right). \tag{2.15}$$

Then we use the formula

$${}_1F_1\left(\begin{matrix}a\\ b\end{matrix};x\right){}_1F_1\left(\begin{matrix}c\\ d\end{matrix};-x\right)=\sum_{k=0}^{\infty}\frac{(a)_kx^k}{k!(b)_k}{}_3F_2\left(\begin{matrix}-k,1-k-b,c\\ 1-k-a,d\end{matrix};1\right) \tag{2.16}$$

for the four products in (2.10).

Applying the three-term relation [4, eq. (2), p. 15] to the four resulting ${}_3F_2(1)$ gives a sum of two terms that we can group to obtain the explicit form

$$L_n^\alpha(x;c,\mu)=\frac{(c+\alpha+1)_n}{n!}\sum_{k=0}^{n}\frac{(-n)_k}{(c+1)_k(c+\alpha+1)_k}\times{}_4F_3\left(\begin{matrix}k-n,c,c+\alpha,G+1\\ c+k+1,c+\alpha+k+1,G\end{matrix};1\right)x^k, \tag{2.17}$$

where

$$G=\frac{c(c+\alpha)}{\mu}. \tag{2.18}$$

Take care of the limiting processes when $n=k$ and when c or $c+\alpha=0$. The representation (2.17) can also be proved using the generating function (2.22).

2.2. Generating function, spectral measure. Let $F(x,w)$ be a generating function of the CAL polynomials $L_n^\alpha(x;c,\mu)$,

$$F(x,w)=\sum_{n=0}^{\infty}w^nL_n^\alpha(x;c,\mu). \tag{2.19}$$

The recurrence relation (2.1) and the initial condition (2.8) lead to the following differential equation for $F(x,w)$,

$$w(1-w)^2\frac{\partial}{\partial w}F(x,w)+[(1-w)(c-(c+\alpha+1)w)+xw]F(x,w)=c-\mu w. \tag{2.20}$$

The function $F(x,w)$ is normalized by the condition $F(x,0) = 1$ and due to the orthogonality of the $L_n^{\alpha}(x;c,\mu)$ we have the boundary condition

$$\int_0^{\infty} F(x,w)d\phi(x) = 1, \tag{2.21}$$

where $d\phi(x)$ is the spectral measure.

The solution of the differential equation (2.20) which is bounded at $w = 0$ is easily obtained, for $c > 0$, following the same method as in [12]:

$$\begin{aligned} F(x,w) &= w^{-c}(1-w)^{-\alpha-1}\exp\left[-\frac{x}{1-w}\right] \\ &\quad \times \int_0^w u^{c-1}(1-u)^{\alpha-1}(c-\mu u)\exp\left[\frac{x}{1-u}\right]du. \end{aligned} \tag{2.22}$$

Changing variables according to

$$u = \frac{\tau}{1+\tau}, \qquad w = \frac{z}{1+z}, \tag{2.23}$$

and integrating both sides of (2.22) with respect to $d\phi(x)$, taking (2.21) into account, leads to

$$\begin{aligned} z^c(1+z)^{-1-\alpha-c} &= \int_0^{\infty}\int_0^z \tau^{c-1}(1+\tau)^{-1-\alpha-c} \\ &\quad \times [c+\tau(c-\mu)]\exp[-x(z-\tau)]d\tau d\phi(x). \end{aligned} \tag{2.24}$$

Taking the Laplace transform of the above identity we obtain, for the Stieltjes transform of the measure $d\phi(x)$, the relationship

$$s(p) = \int_0^{\infty} \frac{d\phi(x)}{x+p} = \frac{\Psi(c+1,1-\alpha;p)}{\Psi(c,-\alpha;p) + (c-\mu)\Psi(c+1,1-\alpha;p)}, \tag{2.25}$$

which we can rewrite formaly, using the expression of the Tricomi function Ψ in terms of generalized hypergeometric functions [7, p. 257], on the form

$$s(p) = p^c\Psi(c+1,1-\alpha;p)\,{}_3F_1\left(\begin{matrix} c, c+\alpha, \frac{c(c+\alpha)}{\mu}+1 \\ \frac{c(c+\alpha)}{\mu} \end{matrix}; -\frac{1}{p}\right)^{-1}, \tag{2.26}$$

where the principal branch of the ${}_3F_1$ is considered one of the Ψ functions. The function $\Psi(a,b;p)$ having no zeros for $|\arg p| \le \pi$ the denominator of (2.25) has no zeros in this region at least for $\mu \le c$.

The CAL polynomials belong to the Laguerre–Hahn family of orthogonal polynomials and are of class zero [22]. It is easily verified that the Stieltjes transform $s(p)$ of the measure, calculated in (2.25), is a solution of the Riccati equation

$$ps'(p) = [\mu p - (c-\mu)(\alpha+c-\mu)]\,s^2(p) + [p+\alpha+2(c-\mu)]\,s(p) - 1. \tag{2.27}$$

The absolutely continuous part of the measure $d\phi(x)$ can be computed using the Perron–Stieltjes inversion formula. Details of the method are in [10] and we obtain

$$\phi'(x) = \frac{1}{\Gamma(c+1)\Gamma(c+\alpha+1)} \frac{x^{\alpha}e^{-x}}{|\Psi(c,-\alpha;xe^{i\pi}) + (c-\mu)\Psi(c+1,1-\alpha;xe^{i\pi})|^2}. \tag{2.28}$$

We can formally write

$$\phi'(x) = \frac{x^{\alpha+2c}e^{-x}}{\Gamma(c+1, c+\alpha+1)} \left| {}_3F_1\left(\begin{matrix} c, c+\alpha, \frac{c(c+\alpha)}{\mu}+1 \\ \frac{c(c+\alpha)}{\mu} \end{matrix}; -\frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{2.29}$$

The CAL polynomials $L_n^\alpha(x; c, \mu)$ satisfy the orthogonality relation, valid at least for $\mu \leq c$, $c \geq 0$, $\alpha + c > -1$,

$$\int_0^\infty L_n^\alpha(x; c, \mu) L_m^\alpha(x; c, \mu) d\phi(x) = \frac{(c+\alpha+1)_n}{(c+1)_n}\delta_{mn}. \tag{2.30}$$

2.3. Fourth-order differential equation. The CAL polynomials verify a differential equation of fourth order [3], [22]. One way to obtain this fourth-order differential equation is to start from their explicit form (2.14). The right-hand side of (2.14) is a sum of two products of a ${}_1F_1$ times a ${}_2F_2$. The ${}_1F_1$ are solutions of a second-order differential equation, but for the ${}_2F_2$ a third-order equation is expected. In fact, the ${}_2F_2$ involved in (2.14) are of the form

$$y(x) = {}_2F_2\left(\begin{matrix} b, e+1 \\ d, e \end{matrix}; x\right), \tag{2.31}$$

which can be shown with little effort to be a solution of the second-order differential equation

$$\begin{aligned} x[(b-e)x + e(d-e-1)]y''(x) - \{(b-e)x^2 + [e(2d-e-2) + b(1-d)]x \\ - ed(d-e-1)\}y'(x) - b[(b-e)x \\ + (e+1)(d-e-1)]y(x) = 0. \end{aligned} \tag{2.32}$$

So we can use the Orr method to obtain the differential equation satisfied by the products involved in (2.14) [23]. Let us notice that because of the second product being obtained by the transformation $\mathcal{T}$ of the first product, the fourth-order differential equation will have to be invariant under this transformation.

The function

$$y = e^{-x}{}_1F_1\left(\begin{matrix} -n-c-\alpha \\ 1-\alpha \end{matrix}; x\right)$$

is a solution of

$$xy'' + (1-\alpha+x)y' + (1+n+c)y = 0, \tag{2.33}$$

and the function

$$z = {}_2F_2\left(\begin{matrix} -c, \mu-c+1 \\ 1+\alpha, \mu-c \end{matrix}; x\right)$$

of

$$\begin{aligned} x[\mu x + (c-\mu)(c+\alpha-\mu)]z''(x) - \{\mu x^2 + [(c-\mu)(c+\alpha-\mu) - \alpha\mu]x \\ - (\alpha+1)(c-\mu)(c+\alpha-\mu)\}z'(x) \\ + c[\mu x + (c-\mu+1)(c+\alpha-\mu)]z(x) = 0. \end{aligned} \tag{2.34}$$

Changing the functions y and z to $y = fv$ and $z = gw$ with

$$f = x^{\frac{\alpha-1}{2}} e^{\frac{x}{2}}, \tag{2.35a}$$

$$g = [(c-\mu)(c+\alpha-\mu)+\mu x]^{\frac{1}{2}} x^{-\frac{\alpha+1}{2}} e^{\frac{x}{2}}, \tag{2.35b}$$

we obtain the normal form of the differential equations (2.33) and (2.34):

$$v'' + Iv = 0, \qquad w'' + Jw = 0. \tag{2.36}$$

The product $u = vw$ is a solution of the fourth-order differential equation (see [30, p. 146])

$$\frac{d}{dx}\left[\frac{u''' + 2(I+J)u' + (I'+J')u}{I-J}\right] = -(I-J)u. \tag{2.37}$$

Finally, we obtain the needed equation for the CAL polynomials setting $y(x) = fgu$.

Details of these calculations are very difficult to write explicitly and were achieved with the help of the MAPLE computer algebra [6]. Although with this help the fourth-order differential equation for the CAL polynomials is not easy to find. We give it as a *curiosity*:

$$c_4 y^{(4)}(x) + c_3 y^{(3)}(x) + c_2 y^{(2)}(x) + c_1 y^{(1)}(x) + c_0 y(x) = 0, \tag{2.38}$$

with

$$c_4 = x^2(2Ax^2 + Bx + 2C), \tag{2.39a}$$

$$c_3 = 2x(3Ax^2 + 2Bx + 5C), \tag{2.39b}$$

$$c_2 = -2Ax^4 + Dx^3 + Ex^2 + Fx + G, \tag{2.39c}$$

$$c_1 = -4Ax^3 + Hx^2 - 4Ax^3 + Ix + J, \tag{2.39d}$$

$$c_0 = n(n+1)(2Ax^2 + Kx + 2L), \tag{2.39e}$$

where

$$\begin{aligned}
A &= \mu^2(1+2n),\\
B &= \mu(2(1+4n)\mu^2 - (4(1+2n)(2c+\alpha)-1)\mu + 2c(3+4n)(c+\alpha)),\\
C &= (c-\mu)(c+\alpha-\mu)(2n\mu^2 - ((1+2n)(2c+\alpha)+1)\mu + 2c(n+1)(c+\alpha)),\\
D &= -\mu(2(1+4n)\mu^2 - (2(1+2n)(8c+4\alpha+1+2n)-1)\mu + 2c(3+4n)(c+\alpha)),\\
E &= -4n\mu^4 + ((1+4n)(4n+12c+6\alpha+3)+3)\mu^3\\
&\quad -2(1+2n)((2c+\alpha)(4n+12c+6\alpha+2) - 2c(c+\alpha)-1)\mu^2\\
&\quad +c(c+\alpha)((3+4n)(4n+12c+6\alpha+1)+3)\mu - 4c^2(c+\alpha)^2(n+1),\\
F &= 8n(2c+\alpha+n+1)\mu^4\\
&\quad -((1+4n)((2c+\alpha)(4n+12c+6\alpha+3) - 8c(c+\alpha) - 1/2) + 10c + 5\alpha + 5/2)\mu^3\\
&\quad +((1+4n)((\alpha^2 + 6c(c+\alpha)(2n+8c+4\alpha+3/2) - (2c+\alpha)(12c(c+\alpha)+1/2))\\
&\qquad +(2\alpha^2 + 6c(c+\alpha) - 1/4)(4c+2\alpha+23/6) - 25/6\alpha^2 + 71/24)\mu^2\\
&\quad -2c(c+\alpha)((1+4n)((2c+\alpha)(2n+4c+2\alpha+3/2) + 2\alpha^2 - 1/4)\\
&\quad +(2c+\alpha)(8c+4\alpha+5/2) + 2\alpha^2 - 7/4)\mu\\
&\quad +8c^2(c+\alpha)^2(n+1)(n+2c+\alpha),
\end{aligned}$$

$$
\begin{aligned}
G &= -2(\alpha-2)(\alpha+2)(c-\mu)(c+\alpha-\mu)(2(c-\mu)(c+\alpha-\mu)n \\
&\quad -(2c+\alpha+1)\mu+2c(c+\alpha)), \\
H &= 2\mu(-2(5n+1)\mu^2+((1+2n)(n+12c+6\alpha+1/2)-3/2)\mu-2c(c+\alpha)(5n+4)), \\
I &= -12n\mu^4+2((n+1/5)(8n+40c+20\alpha+7/5)+93/25)\mu^3 \\
&\quad +2(-(1+2n)((2c+\alpha)(4n+12c+6\alpha+2)+10c(c+\alpha)-1)-6c-3\alpha)\mu^2 \\
&\quad +2c(c+\alpha)((4/5+n)(8n+40c+20\alpha+33/5)+93/25)\mu-12c^2(c+\alpha)^2(n+1), \\
J &= 4(\mu-c)(\mu-c-\alpha)(3n(n+2c+\alpha+1)\mu^2+(-1/4(1+2n)((2c+\alpha)(6n+8c \\
&\quad +4\alpha+3)+8c(c+\alpha)+8)-9/2c-9/4\alpha)\mu+3c(c+\alpha)(n+1)(n+2c+\alpha)), \\
K &= \mu(2(4n-1)\mu^2-(4(1+2n)(2c+\alpha)-3)\mu+2c(4n+5)(c+\alpha)), \\
L &= (c-\mu)(c+\alpha-\mu)(2(n-1)\mu^2-((1+2n)(2c+\alpha)+6)\mu+2c(n+2)(c+\alpha)).
\end{aligned}
$$

Note the invariance of the differential equation (2.38) by the transformation $\mathcal{T}$ defined in (2.5).

2.4. Particular cases. We now give the different results corresponding to limiting cases of special interest.

2.4.1. Limit $c = 0$. In this limit we obtain from (2.14) the co-recursive Laguerre polynomials.

(2.40)
$$
L_n^{\alpha}(x;0,\mu) = \frac{e^{-x}}{\alpha}\left\{\frac{(\alpha-\mu)(\alpha+1)_n}{n!}\,{}_2F_2\left(\begin{matrix}-\alpha,\mu-\alpha+1\\ 1-\alpha,\mu-\alpha\end{matrix};x\right)\,{}_1F_1\left(\begin{matrix}-n\\ 1+\alpha\end{matrix};x\right)\right.
$$
$$
\left.+\mu\,{}_1F_1\left(\begin{matrix}-n-\alpha\\ 1-\alpha\end{matrix};x\right)\right\}.
$$

The limit $\mu = 0$ in (2.40) leads back to the classical Laguerre polynomials. An explicit form is

(2.41)
$$
L_n^{\alpha}(x;0,\mu) = \frac{(\alpha+1)_n}{n!}\sum_{k=0}^{n}\frac{(-n)_k}{k!(1+\alpha)_k}
$$
$$
\times\left[1+\frac{\mu(k-n)}{(1+k)(1+\alpha+k)}\,{}_3F_2\left(\begin{matrix}1+k-n,1+\alpha,1\\ k+\alpha+2,k+2\end{matrix};1\right)\right]x^k,
$$

and the corresponding absolutely continuous part of the measure is given for $\mu \le 0$, $\alpha > -1$, by

(2.42)
$$
\phi'(x) = \frac{x^{\alpha}e^{-x}}{\Gamma(1+\alpha)}\left|1-\mu\Psi(1,1-\alpha;xe^{-i\pi})\right|^{-2},
$$

where the limit $\mu = 0$ is also straightforward.

It is easy to see that the differential equation (2.38) satisfied by the co-recursive Laguerre polynomials can be factorized in the limit $c = 0$ to obtain the fourth-order factorized (2+2) differential equation

(2.43)
$$
\begin{aligned}
&[xA(x)\mathrm{D}^2+\{(2+\alpha-x)A(x)-xB(x)\}\mathrm{D} \\
&\quad +(n-1)A(x)+(x-\alpha-1)B(x)+C(x)] \\
&\times\left[x\mathrm{D}^2+(x+1-\alpha)\mathrm{D}+n+1\right]L_n^{\alpha}(x;0,\mu)=0,
\end{aligned}
$$

where $\mathrm{D} \equiv d/dx$ and

$$A(x) = 3x + 2(x - \alpha + \mu)\{2n(x - \alpha + \mu) + x - \alpha - 1\}, \tag{2.44a}$$

$$B(x) = 1 + 2x - 2\alpha + 2(1 + 4n)(x - \alpha + \mu), \tag{2.44b}$$

$$C(x) = (1 + 2x - 2\alpha)\{1 + \alpha - x - 2n(x - \alpha + \mu)\} + 3x(1 + 4n). \tag{2.44c}$$

The comparison with the differential equation given in [27, eq. 34–35] requires some attention because of a few misprints.

2.4.2. Limit $c = -\alpha$. In this limit we obtain a special class of CAL polynomials corresponding to the associated Laguerre polynomials for which

$$L_n^{\alpha}(x; -\alpha) = \frac{n!}{(1-\alpha)_n} L_n^{-\alpha}(x). \tag{2.45}$$

We can write the $L_n^{\alpha}(x; -\alpha, \mu)$ as

(2.46)

$$L_n^{\alpha}(x; -\alpha, \mu) = \frac{n!}{(1-\alpha)_n} \frac{e^{-x}}{-\alpha} \left\{ \frac{(-\alpha - \mu)(1-\alpha)_n}{n!} {}_2F_2\left(\begin{matrix}\alpha, \mu + \alpha + 1 \\ 1 + \alpha, \mu + \alpha\end{matrix}; x\right) \right.$$
$$\left. \times {}_1F_1\left(\begin{matrix}-n \\ 1 - \alpha\end{matrix}; x\right) + \mu {}_1F_1\left(\begin{matrix}-n + \alpha \\ 1 + \alpha\end{matrix}; x\right) \right\},$$

which gives (2.45) in the limit $\mu = 0$. Except for the global factor $n!/(1-\alpha)_n$, (2.46) is obtained from (2.40) changing α to $-\alpha$. The corresponding measure and differential equation are obtained in the same way as §2.4.1. An explicit form is

(2.47)

$$L_n^{\alpha}(x; -\alpha, \mu) = \sum_{k=0}^{n} \frac{(-n)_k}{k!(1-\alpha)_k}$$
$$\times \left[1 + \frac{\mu(k-n)}{(1+k)(1-\alpha+k)} {}_3F_2\left(\begin{matrix}1 + k - n, 1 - \alpha, 1 \\ k - \alpha + 2, k + 2\end{matrix}; 1\right) \right] x^k.$$

2.4.3. Limit $\mu = 0$. In this limit we obtain the associated Laguerre polynomials studied in [2] and [12]:

$$L_n^{\alpha}(x, c) = \frac{e^{-x}}{(c+1)_n} (1 + \mathcal{T}) \frac{(c+\alpha)_{n+1}}{\alpha} {}_1F_1\left(\begin{matrix}1 - c - \alpha \\ 1 - \alpha\end{matrix}; x\right) {}_1F_1\left(\begin{matrix}-n - c \\ 1 + \alpha\end{matrix}; x\right), \tag{2.48}$$

with the measure

$$\phi'(x) = \frac{x^{\alpha} e^{-x}}{\Gamma(1 + c, 1 + c + \alpha)} \left| \Psi(c, 1 - \alpha; x e^{-i\pi}) \right|^{-2}. \tag{2.49}$$

An explicit form is

$$L_n^{\alpha}(x; c) = \frac{(c + \alpha + 1)_n}{n!} \sum_{k=0}^{n} \frac{(-n)_k}{(c+1)_k (c + \alpha + 1)_k}$$
$$\times {}_3F_2\left(\begin{matrix}k - n, c, c + \alpha \\ c + k + 1, c + \alpha + k + 1\end{matrix}; 1\right) x^k, \tag{2.50}$$

The limit $c = 0$ leads back to the Laguerre polynomial case. The coefficients of the differential equation (2.38) satisfied by the associated Laguerre polynomials are now very simple:

$$c_4 = x^2,\quad c_3 = 5x,\quad c_2 = -x(x-2F) - \alpha^2 + 4,\quad c_1 = 3(F-x),\quad c_0 = n(n+2), \tag{2.51}$$

with $F = n + 2c + \alpha$. This differential equation was first given by Hahn [9, eq. 22]. See [25] and [27] for the special factorizable case $c = 1$ and [5] and [26] when c is an integer.

2.4.4. Limit $\mu = c$. In this limit we obtain the so-called *zero-related* Laguerre polynomials studied in [12]. Note the symmetry $\mathcal{T}$ of the monic polynomials is now broken:

$$\mathcal{L}_n^{\alpha}(x,c) = e^{-x}\left\{\frac{(c+\alpha+1)_n}{(c+1)_n}\,{}_1F_1\left(\begin{matrix}-c-\alpha\\ -\alpha\end{matrix};x\right){}_1F_1\left(\begin{matrix}-n-c\\ 1+\alpha\end{matrix};x\right)\right.$$
$$\left. -\frac{c}{\alpha(\alpha+1)}\,x\,{}_1F_1\left(\begin{matrix}1-c\\ 2+\alpha\end{matrix};x\right){}_1F_1\left(\begin{matrix}-n-c-\alpha\\ 1-\alpha\end{matrix};x\right)\right\}, \tag{2.52}$$

and the measure

$$\phi'(x) = \frac{x^{\alpha}e^{-x}}{\Gamma(1+c,1+c+\alpha)}\left|\Psi(c,-\alpha;xe^{-i\pi})\right|^{-2}. \tag{2.53}$$

Again the limit $c = 0$ leads back to the Laguerre polynomial case.

The explicit form (2.17) simplifies into

$$\mathcal{L}_n^{\alpha}(x,c) = \frac{(c+\alpha+1)_n}{n!}\sum_{k=0}^{n}\frac{(-n)_k}{(c+1)_k(c+\alpha+1)_k}$$
$$\times{}_3F_2\left(\begin{matrix}k-n,c,c+\alpha+1\\ c+k+1,c+\alpha+k+1\end{matrix};1\right)x^k. \tag{2.54}$$

The coefficients of the differential equation satisfied by the zero-related Laguerre polynomials are

$$c_4 = x^2(2(2n+1)x + D),\qquad c_3 = 2x(3(2n+1)x + 2D), \tag{2.55a}$$
$$c_2 = -2(2n+1)x^3 + (8n(F+1) + 8c + D)x^2$$
$$- (4(\alpha^2-1)n - 2\alpha^2 - D(4c+1) - 1)x - 1/4D(D^2-9), \tag{2.55b}$$
$$c_1 = 8(2n+1)x^2 - 4(2n(F+1) + 2c - D)x - 2D(n(D+3) + 6c + 2D), \tag{2.55c}$$
$$c_0 = n(n+1)(2(2n+1)x + 3D), \tag{2.55d}$$

with

$$F = n + 2c + \alpha,\qquad D = 1 + 2\alpha, \tag{2.56}$$

and are no longer invariant under the transformation $\mathcal{T}$.

2.4.5. Limit $\mu = c + \alpha$. This is a new simple case of CAL polynomials lacking in [12]:

$$\mathcal{L}_n^{\alpha}(x,c) = e^{-x}\left\{{}_1F_1\left(\begin{matrix}-c\\ \alpha\end{matrix};x\right){}_1F_1\left(\begin{matrix}-n-c-\alpha\\ 1-\alpha\end{matrix};x\right)\right.$$
$$\left. + \frac{(c+\alpha)(c+\alpha+1)_n}{\alpha(1-\alpha)(c+1)_n}x\,{}_1F_1\left(\begin{matrix}1-c-\alpha\\ 2-\alpha\end{matrix};x\right){}_1F_1\left(\begin{matrix}-n-c\\ 1+\alpha\end{matrix};x\right)\right\}, \tag{2.57}$$

and using [7, (10), p. 258] the measure is obtained:

$$\phi'(x) = \frac{x^{\alpha-1}e^{-x}}{\Gamma(1+c,1+c+\alpha)} \left|\Psi(c+1,2-\alpha;xe^{-i\pi})\right|^{-2}. \tag{2.58}$$

In this case the limit $c = 0$ does not lead back to the Laguerre polynomial case but to the co-recursive Laguerre one with $\mu = \alpha$.

The explicit form is

$$\mathfrak{L}_n^{\alpha}(x,c) = \frac{(c+\alpha+1)_n}{n!} \sum_{k=0}^{n} \frac{(-n)_k}{(c+1)_k(c+\alpha+1)_k} \times {}_3F_2\left(\begin{matrix} k-n, c+1, c+\alpha \\ c+k+1, c+\alpha+k+1 \end{matrix}; 1\right) x^k. \tag{2.59}$$

The coefficients of the differential equation (2.38) satisfied by the polynomials $\mathfrak{L}_n^{\alpha}(x,c)$ are obtained from (2.55), (2.56), changing only $D = 1+2\alpha$ by $D = 1-2\alpha$.

3. The case of Jacobi polynomials. We now present some results on the CAJ polynomials. The recurrence relation of the associated Jacobi polynomials $P_n^{\alpha,\beta}(x;c)$ is [31]

(3.1)
$$\begin{aligned}(2n+2c+\alpha+\beta+1)&[(2n+2c+\alpha+\beta+2)(2n+2c+\alpha+\beta)x+\alpha^2-\beta^2]p_n \\ &= 2(n+c+1)(n+c+\alpha+\beta+1)(2n+2c+\alpha+\beta)p_{n+1} \\ &\quad +2(n+c+\alpha)(n+c+\beta)(2n+2c+\alpha+\beta+2)p_{n-1}.\end{aligned}$$

We can note the invariance of the recurrence relation (3.2) under the transformation $\mathcal{T}'$ defined by

$$\mathcal{T}'(c,\alpha,\beta) = (c+\alpha+\beta,-\alpha,-\beta). \tag{3.2}$$

All polynomials satisfying (3.2), for which the initial conditions are symmetric in α and β and invariant under $\mathcal{T}'$ have the property

$$p_n^{-\alpha,-\beta}(x,c+\alpha+\beta) = p_n^{\alpha,\beta}(x,c). \tag{3.3}$$

As in [31] we use the more convenient shifted polynomials defined as

$$R_n^{\alpha,\beta}(x;c) = P_n^{\alpha,\beta}(2x-1;c). \tag{3.4}$$

Due also to the properties of the recurrence relation (3.2) we have

$$R_n^{\alpha,\beta}(x;c) = (-1)^n R_n^{\beta,\alpha}(1-x;c). \tag{3.5}$$

3.1. Explicit representation for the CAJ polynomials. A solution of the recurrence relation satisfied by the $R_n^{\alpha,\beta}(x;c)$ in terms of the hypergeometric function is [21, p. 280]

$$u_n = \frac{(c+\alpha+1)_n}{(c+1)_n} {}_2F_1\left(\begin{matrix} -n-c, n+c+\alpha+\beta+1 \\ 1+\alpha \end{matrix}; 1-x\right), \tag{3.6}$$

and another linearly independent solution is given by

$$v_n = \mathcal{T}' u_n = \frac{(c+\beta+1)_n}{(c+\alpha+\beta+1)_n} {}_2F_1\left(\begin{matrix}-n-c-\alpha-\beta, n+c+1 \\ 1-\alpha\end{matrix}; 1-x\right). \tag{3.7}$$

The functions u_n and $x^{-\beta}(1-x)^{-\alpha}v_n$ are two independent solutions of the second-order differential equation

$$\begin{aligned} x(1-x)y''(x) + [1+\beta-(\alpha+\beta+2)x]y'(x) \\ + (n+c)(n+c+\alpha+\beta+1)y(x) = 0. \end{aligned} \tag{3.8}$$

The associated Jacobi polynomials are defined by (3.2) and the initial condition

$$P_{-1}^{\alpha,\beta}(x;c) = 0, \qquad P_0^{\alpha,\beta}(x;c) = 1. \tag{3.9}$$

For $P_1^{\alpha,\beta}(x;c)$, this gives

$$\begin{aligned} P_1^{\alpha,\beta}(x;c) = \frac{(2c+\alpha+\beta+1)(2c+\alpha+\beta+2)}{2(c+1)(c+\alpha+\beta+1)} \\ \times \left[x + \frac{\alpha^2-\beta^2}{(2c+\alpha+\beta)(2c+\alpha+\beta+2)}\right]. \end{aligned} \tag{3.10}$$

The CAJ polynomials $P_n^{\alpha,\beta}(x;c,\mu)$ satisfy the recurrence relation (3.2) with a shift μ on the first monic polynomial. This corresponds to the initial condition on the shifted CAJ polynomials $R_n^{\alpha,\beta}(x;c,\mu)$:

$$R_{-1}^{\alpha,\beta}(x;c,\mu) = D = -\frac{(2c+\alpha+\beta)(2c+\alpha+\beta+1)}{2(c+\alpha)(c+\beta)}\mu, \qquad R_0^{\alpha,\beta}(x;c,\mu) = 1. \tag{3.11}$$

If $c+\alpha \to 0$ or $c+\beta \to 0$ this initial condition in (3.2) nevertheless leads to a shift μ on the value of x in $P_1^{\alpha,\beta}(x;c)$.

As in §2.1 writing

$$R_n^{\alpha,\beta}(x;c,\mu) = Au_n + Bv_n \tag{3.12}$$

and using (3.11) we obtain

$$A = \frac{1}{\Delta}[Dv_0 - v_{-1}] \quad \text{and} \quad B = -\frac{1}{\Delta}[Du_0 - u_{-1}], \tag{3.13}$$

where Δ is easily calculated using the fact that u_n and $x^{-\beta}(1-x)^{-\alpha}v_n$ are two independent solutions of (3.8),

$$\Delta = u_{-1}v_0 - u_0 v_{-1} = -\frac{\alpha(2c+\alpha+\beta)}{(c+\alpha)(c+\beta)}. \tag{3.14}$$

The condition $\Delta \neq 0$ leads to $\alpha \neq 0$ and $2c+\alpha+\beta \neq 0$. We can note the invariance of D under $\mathcal{T}'$ and can note that $B = \mathcal{T}'A$.

Grouping the two ${}_2F_1$ involved in the expression (3.13) of A gives

$$A = \frac{c+\alpha+\beta-D(c+\beta)}{\alpha(2c+\alpha+\beta)} {}_3F_2\left(\begin{matrix}-c-\alpha-\beta, c, F+1 \\ 1-\alpha, F\end{matrix}; 1-x\right), \tag{3.15}$$

with

$$F = \frac{c[D(c+\beta) - c - \alpha - \beta]}{D(c+\beta) + c}, \tag{3.16}$$

and the CAJ polynomials could be written as

(3.17)

$$R_n^{\alpha,\beta}(x;c,\mu) = (1+\mathcal{T}')\frac{c+\alpha+\beta-D(c+\beta)}{\alpha(2c+\alpha+\beta)}(c+\alpha)\frac{(c+\alpha+1)_n}{(c+1)_n}$$
$$\times {}_3F_2\left(\begin{matrix}-c-\alpha-\beta, c, F+1\\ 1-\alpha, F\end{matrix}; 1-x\right) {}_2F_1\left(\begin{matrix}-n-c, n+c+\alpha+\beta+1\\ 1+\alpha\end{matrix}; 1-x\right).$$

We will use this expression of the CAJ polynomials in §3.4 to obtain a fourth-order differential equation of them.

Transforming the ${}_2F_1(1-x)$ in (3.12) by [7, eq. 1, p. 108] one obtains, with little algebra,

(3.18)

$$R_n^{\alpha,\beta}(x;c,\mu) = (1+\mathcal{T}')\frac{(-1)^n c(c+\alpha)}{\beta(2c+\alpha+\beta)}$$
$$\times \frac{(c+\alpha+1)_n}{(c+\alpha+\beta+1)_n} {}_2F_1\left(\begin{matrix}-n-c-\alpha-\beta, n+c+1\\ 1-\beta\end{matrix}; x\right)$$
$$\times \left[\frac{c+\beta}{c} D\,{}_2F_1\left(\begin{matrix}-c, c+\alpha+\beta+1\\ 1+\beta\end{matrix}; x\right) - {}_2F_1\left(\begin{matrix}1-c, c+\alpha+\beta\\ 1+\beta\end{matrix}; x\right)\right].$$

This formula generalizes the formula of [31, eq. 28] to the case of the CAJ polynomials. As the explicit form of the CAL polynomials (2.14) the representation (3.17) and (3.18) are valid only for $\alpha \neq 0, \pm 1, \pm 2\ldots$ and $\beta \neq 0, \pm 1, \pm 2\ldots$ but can be extended by limiting processes.

We obtain an explicit formula following the method in [31]. We first use [7, eq. 14, p. 87] for each product of ${}_2F_1$ in (3.18) to obtain four series involving gamma functions and a ${}_4F_3$. For two of them we use [4, eq. 1, p. 56]. The next step is to use [4, eq. 3, p. 62] twice for each ${}_4F_3$. After numerous cancellations only two series of ${}_4F_3$ remain. We can group to obtain the following explicit form:

(3.19)

$$R_n^{\alpha,\beta}(x;c,\mu) = 7(-1)^n \frac{(2c+\alpha+\beta+1)_n(\beta+c+1)_n}{n!(c+\alpha+\beta+1)_n} \sum_{k=0}^{n} \frac{(-n)_k(n+2c+\alpha+\beta+1)_k}{(c+1)_k(c+\beta+1)_k}$$
$$\times {}_5F_4\left(\begin{matrix}k-n, n+k+2c+\alpha+\beta+1, c, c+\beta, G+1\\ c+k+1, c+\beta+k+1, 2c+\alpha+\beta+1, G\end{matrix}; 1\right) x^k,$$

where

$$G = \frac{2c(c+\beta)(2c+\alpha+\beta)}{2c(c+\beta)+\mu(2c+\alpha+\beta)(2c+\alpha+\beta+1)}. \tag{3.20}$$

3.2. Generating function. One can obtain a generating function of the CAJ polynomials following the same strategy as in [31] for the associated one. Let $\mathcal{G}(x,w)$ be a generating function of $R_n^{\alpha,\beta}(x;c,\mu)$:

$$\mathcal{G}(x,w) = \sum_{n=0}^{\infty} \frac{(c+1)_n(c+\alpha+\beta+1)_n}{n!(2c+\alpha+\beta+2)_n} w^n R_n^{\alpha,\beta}(x;c,\mu). \tag{3.21}$$

Starting from the form (3.17) for the $R_n^{\alpha,\beta}(x;c,\mu)$ it follows that

$$\begin{aligned}\mathcal{G}(x,w)&=(1+\mathcal{T}')\frac{c+\alpha+\beta-D(c+\beta)}{\alpha(2c+\alpha+\beta)}(c+\alpha)_3F_2\left(\begin{matrix}-c-\alpha-\beta,c,F+1\\1-\alpha,F\end{matrix};1-x\right)\\&\quad\times\sum_{n=0}^{\infty}\frac{(c+\alpha+1)_n(c+\alpha+\beta+1)_n}{n!(2c+\alpha+\beta+2)_n}w^n{}_2F_1\left(\begin{matrix}-n-c,n+c+\alpha+\beta+1\\1+\alpha\end{matrix};1-x\right),\end{aligned}$$

and using [31, Thm. 4] we obtain

(3.22)

$$\begin{aligned}\mathcal{G}(x,w)&=(1+\mathcal{T}')\frac{c+\alpha+\beta-D(c+\beta)}{\alpha(2c+\alpha+\beta)}\\&\quad\times(c+\alpha)\left[\frac{2}{w(Z_2+1)}\right]^{c+\alpha+\beta+1}{}_3F_2\left(\begin{matrix}-c-\alpha-\beta,c,F+1\\1-\alpha,F\end{matrix};1-x\right)\\&\quad\times{}_2F_1\left(\begin{matrix}-c,c+\alpha+\beta+1\\1+\alpha\end{matrix};\frac{1-Z_1}{2}\right){}_2F_1\left(\begin{matrix}c+\alpha+1,c+\alpha+\beta+1\\2c+\alpha+\beta+2\end{matrix};\frac{2}{1+Z_2}\right),\end{aligned}$$

where

$$Z_1=\frac{1-\sqrt{(1+w)^2-4wx}}{w},\qquad Z_2=\frac{1+\sqrt{(1+w)^2-4wx}}{w},\tag{3.23}$$

which generalize the already exotic generating function [31, eq. 75].

3.3. Spectral measure. The Stieltjes transform of the measure of the shifted associated Jacobi polynomials $R_n^{\alpha,\beta}(x;c)$ is [31, eqs. 63–64]

$$s(p)=\frac{1}{p}{}_2F_1\left(\begin{matrix}c+1,c+\beta+1\\2c+\alpha+\beta+2\end{matrix};\frac{1}{p}\right){}_2F_1\left(\begin{matrix}c,c+\beta\\2c+\alpha+\beta\end{matrix};\frac{1}{p}\right)^{-1}.\tag{3.24}$$

The CAJ polynomials $R_n^{\alpha,\beta}(x;c,\mu)$ satisfy the same recurrence relations as the $R_n^{\alpha,\beta}(x;c)$ with a shift μ on the first monic polynomials

$$R_1^{\alpha,\beta}(x;c,\mu)-R_1^{\alpha,\beta}(x;c)=\frac{(2c+\alpha+\beta+1)(2c+\alpha+\beta+2)}{2(c+1)(c+\alpha+\beta+1)}\mu.\tag{3.25}$$

Using continued J-fractions [14], [8], [28] whose denominators are $R_n^{\alpha,\beta}(x;c,\mu)$ and $R_n^{\alpha,\beta}(x;c)$, we can derive the following for the Stieltjes transform of the measure of the CAJ polynomials:

$$\begin{aligned}s(p;\mu)&=s(p)\left(1+\frac{\mu}{2}s(p)\right)^{-1}\\&=\frac{{}_2F_1\left(\begin{matrix}c+1,c+\beta+1\\2c+\alpha+\beta+2\end{matrix};\frac{1}{p}\right)}{p\,{}_2F_1\left(\begin{matrix}c,c+\beta\\2c+\alpha+\beta\end{matrix};\frac{1}{p}\right)+\frac{\mu}{2}{}_2F_1\left(\begin{matrix}c+1,c+\beta+1\\2c+\alpha+\beta+2\end{matrix};\frac{1}{p}\right)},\end{aligned}\tag{3.26}$$

which using contiguous relations we can also write as

(3.27)

$$s(p;\mu) = {}_2F_1\left(\begin{matrix}c+1, c+\beta+1\\ 2c+\alpha+\beta+2\end{matrix}; \frac{1}{p}\right) \times \left[\left(\frac{c+\alpha}{2c+\alpha+\beta} - \frac{2c+\alpha+\beta+1}{2c}\mu\right) {}_2F_1\left(\begin{matrix}c, c+\beta\\ 2c+\alpha+\beta+1\end{matrix}; \frac{1}{p}\right) + \left(\frac{c+\beta}{2c+\alpha+\beta} + \frac{2c+\alpha+\beta+1}{2c}\mu\right) {}_2F_1\left(\begin{matrix}c, c+\beta+1\\ 2c+\alpha+\beta+1\end{matrix}; \frac{1}{p}\right)\right]^{-1}.$$

Grouping the ${}_2F_1$ in (3.28) gives the compact formula

$$s(p;\mu) = {}_2F_1\left(\begin{matrix}c+1, c+\beta+1\\ 2c+\alpha+\beta+2\end{matrix}; \frac{1}{p}\right) \left[{}_3F_2\left(\begin{matrix}c, c+\beta, G+1\\ 2c+\alpha+\beta+1, G\end{matrix}; \frac{1}{p}\right)\right]^{-1}, \tag{3.28}$$

where G is given by (3.20). A sufficient condition for the positivity of the denominator in (3.28) on $(1,\infty)$ is

$$c \geq 0, \quad c > -\beta, \quad \alpha > -1, \quad \mu \geq -\frac{2c(c+\beta)}{(2c+\alpha+\beta)(2c+\alpha+\beta+1)}, \tag{3.29}$$

but other conditions are possible.

To obtain the absolutely continuous part of the spectral measure we need to evaluate $s^+(p;\mu) - s^-(p;\mu)$, where $s^\pm$ are the values of s above and below the cut [0,1]. Using the analytic continuation [7, eq. 2, p. 108] for each ${}_2F_1$ in (3.26) we find, for the spectral measure of the CAJ polynomials,

(3.30)

$$\begin{aligned}\phi'(x) &= (1-x)^\alpha x^{\beta+2c} \left| {}_2F_1\left(\begin{matrix}c, c+\beta\\ 2c+\alpha+\beta\end{matrix}; \frac{e^{i\pi}}{x}\right) + \frac{\mu}{2x} {}_2F_1\left(\begin{matrix}c+1, c+\beta+1\\ 2c+\alpha+\beta+2\end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2} \\ &= (1-x)^\alpha x^{\beta+2c} \left| {}_3F_2\left(\begin{matrix}c, c+\beta, G+1\\ 2c+\alpha+\beta+1, G\end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2},\end{aligned}$$

valid at least under the conditions (3.29).

3.4. Fourth-order differential equation. The method used to obtain the differential equation satisfied by the $R_n^{\alpha,\beta}(x;c,\mu)$ is the same as in §2.3. In (3.17) the hypergeometric function ${}_2F_1$ is solution of (3.8) and the ${}_3F_2$ is of the form

$${}_3F_2\left(\begin{matrix}a, b, e+1\\ d, e\end{matrix}; x\right),$$

which is also a solution of the second-order differential equation

(3.31)

$$\begin{aligned}&x(x-1)\left[(a-e)(b-e)x + e(d-e-1)\right] y''(x) \\ &+ \left\{(a-e)(b-e)(a+b+1)x^2 + \left[e(a+b+1)(2d-e-2) - d(ab+e^2) + ab\right] x \right. \\ &\left. + de(e-d+1)\right\} y'(x) + ab\left[(a-e)(b-e)x + (e+1)(d-e-1)\right] y(x) = 0.\end{aligned}$$

We don't write the fourth-order differential equation hardly obtained by symbolic MAPLE computation. The coefficients are at most of degree eight in x, and it would take several pages to write them. We give the results only in the following limiting cases.

3.5. Particular cases.

3.5.1. Laguerre case limit. The limit giving the CAL polynomial case is obtained by the replacement

$$\left.\begin{array}{rcl} x & \to & 1-\frac{2x}{\beta} \\ \mu & \to & +\frac{2\mu}{\beta} \end{array}\right\} \qquad \beta \to \infty, \tag{3.32}$$

in $P_n^{\alpha,\beta}(x;c,\mu)$. The representation (3.17) is the more suitable to obtain the form of the CAL polynomials (2.14) using Kummer's transformation (2.15) for one of the confluent hypergeometric functions and his generalization

$$ {}_2F_2\left(\begin{matrix}a, e+1\\ c, e\end{matrix};x\right) = e^x\, {}_2F_2\left(\begin{matrix}c-a-1, \frac{e(c-a-1)}{e-a}+1\\ c, \frac{e(c-a-1)}{e-a}\end{matrix};-x\right) \tag{3.33}$$

for one of the ${}_2F_2$. Note that (3.33) gives (2.15) in the limit $e \to \infty$.

3.5.2. Limit $c = 0$. In this limit we obtain the co-recursive Jacobi polynomials. An explicit form is

(3.34)

$$R_n^{\alpha,\beta}(x;\mu) = (-1)^n \frac{(\beta+1)_n}{n!} \sum_{k=0}^{n} \frac{(-n)_k (n+\alpha+\beta+1)_k}{k!(\beta+1)_k} x^k$$
$$\times \left\{1 + \frac{\mu(k-n)(n+k+\alpha+\beta+1)}{2(k+1)(\beta+k+1)} {}_4F_3\left(\begin{matrix}k-n+1, n+k+\alpha+\beta+2, \beta+1, 1\\ k+2, \beta+k+2, \alpha+\beta+2\end{matrix};1\right)\right\},$$

and the spectral measure is given by

$$\phi'(x) = (1-x)^\alpha x^\beta \left|1 + \frac{\mu}{2x} {}_2F_1\left(\begin{matrix}1, \beta+1\\ \alpha+\beta+2\end{matrix};\frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{3.35}$$

The limit $\mu = 0$ leads back to the Jacobi polynomials.

The fourth-order differential equation satisfied by the co-recursive Laguerre polynomials can be factorized in the limit $c = 0$ to obtain, as in [27], the factorized (2+2) differential equation

$$\begin{aligned} 0 = &\left[(1-x^2)A(x)\mathrm{D}^2 + \left\{(\beta-\alpha-(\alpha+\beta+4)x)A(x) - (1-x^2)B(x)\right\}\mathrm{D}\right. \\ &+ \left\{n(n+\alpha+\beta+1) - (\alpha+\beta+2)\right\}A(x) \\ &\left. + \left\{\beta-\alpha-(\alpha+\beta+2)x\right\}B(x) + C(x)\right] \\ &\times \left[(1-x^2)\mathrm{D}^2 + \{(\alpha+\beta-2)x + \alpha - \beta\}\mathrm{D}\right. \\ &\left. + n(n+\alpha+\beta+1) + \alpha + \beta\right] R_n^{\alpha,\beta}(x;\mu), \end{aligned} \tag{3.36}$$

where

$$\begin{aligned} A(x) = {} & 2(\alpha+\beta)^2(2n+1)(n+\alpha+\beta+1/2)x^2 + 2(\alpha+\beta)(4n(n+\alpha+\beta+1) \\ & \times(-\mu(1+\alpha+\beta)+\alpha-\beta) + (1+\alpha+\beta)(-\mu(\alpha+\beta+2)+2\alpha-2\beta))x \\ & +4n(n+\alpha+\beta+1)(-\mu(1+\alpha+\beta)+\alpha-\beta)^2 \\ & -(\alpha+\beta)(-2\mu(1+\alpha+\beta)\times(\beta-\alpha) - 2(\beta-\alpha)^2 - 3\alpha - 3\beta) \\ B(x) = {} & -(\alpha+\beta)((\alpha+\beta)(8n(n+\alpha+\beta+1)+3\alpha+3\beta)x + 8n(n+\alpha+\beta+1) \end{aligned}$$

$$\times(-\mu(1+\alpha+\beta)+\alpha-\beta)-2(\alpha+\beta+2)(1+\alpha+\beta)\mu+(\alpha-\beta)(3\alpha+3\beta+4))$$
$$C(x)=-(\alpha+\beta)((\alpha+\beta)(\alpha+\beta+2)(2n(n+\alpha+\beta+1)+\alpha+\beta-1)x^2$$
$$+2(n(n+\alpha+\beta+1)(-\mu(\alpha+\beta+1)(\alpha+\beta-4)+2(\alpha-\beta)(\alpha+\beta-2))$$
$$+(\alpha+\beta)(\alpha-\beta)(\alpha+\beta-1))x-2n(n+\alpha+\beta+1)(-\mu(\alpha+\beta+1)(\beta-\alpha)$$
$$-(\alpha-\beta)^2+6\alpha+6\beta)+(\alpha+\beta)((\alpha-\beta)^2-3\alpha-3\beta-6)).$$

3.5.3. Limit $c=-\alpha-\beta$. Due to the T' invariance of (3.2) we obtain in this limit the special case of CAJ polynomials for which

$$R_n^{\alpha,\beta}(x;-\alpha-\beta,\mu)=R_n^{-\alpha,-\beta}(x;\mu). \tag{3.37}$$

All the results are obtained from §3.5.2 by changing α to $-\alpha$ and β to $-\beta$.

3.5.4. Limit $c=-\beta$. The explicit form (3.19) simplifies in the same way as in the case $c=0$. One obtains

$$R_n^{\alpha,\beta}(x;-\beta,\mu)=(-1)^n\frac{(\alpha-\beta+1)_n}{(\alpha+1)_n}\sum_{k=0}^{n}\frac{(-n)_k(n+\alpha-\beta+1)_k}{k!(1-\beta)_k}x^k$$
$$\times\left\{1+\frac{\mu(k-n)(n+k+\alpha-\beta+1)}{2(k+1)(1-\beta+k)}\right.$$
$$\left.\times{}_4F_3\left(\begin{matrix}k-n+1,n+k+\alpha-\beta+2,1-\beta,1\\k+2,2-\beta+k,\alpha-\beta+2\end{matrix};1\right)\right\}. \tag{3.38}$$

Comparing this form with the explicit form of the co-recursive Jacobi polynomials (3.34) one sees that

$$R_n^{\alpha,\beta}(x;-\beta,\mu)=\frac{n!(\alpha-\beta+1)_n}{(\alpha+1)_n(1-\beta)_n}R_n^{\alpha,-\beta}(x;\mu). \tag{3.39}$$

Of course, the spectral measure and the fourth-order differential equation are obtained from (3.35) and (3.36), changing β to $-\beta$.

3.5.5. Limit $c=-\alpha$. This case is the T' transform of the preceding case. All the results are obtained from §3.5.4 by changing α to $-\alpha$ and β to $-\beta$.

3.5.6. Limit $\mu=0$. In this limit we obtain the associated Jacobi polynomials studied in [31]. The form [31, eq. 28] is obtain directly using (3.18) but a slightly different form is

$$R_n^{\alpha,\beta}(x;c)=(1+T')\frac{(c+\alpha)(c+\alpha+\beta)}{\alpha(2c+\alpha+\beta)}\frac{(c+\alpha+1)_n}{(c+1)_n}$$
$$\times{}_2F_1\left(\begin{matrix}1-c-\alpha-\beta,c\\1-\alpha\end{matrix};1-x\right){}_2F_1\left(\begin{matrix}-n-c,n+c+\alpha+\beta+1\\1+\alpha\end{matrix};1-x\right). \tag{3.40}$$

The explicit form [31, eq. 19] is easily obtained starting from (3.19) with $G=2c+\alpha+\beta$, the ${}_5F_4$ reducing to a ${}_4F_3$. Obviously the limit $c=0$ leads back to the Jacobi polynomials.

The coefficients of the differential equation (2.38) satisfied by the associated Jacobi polynomials are

$$c_4=x^2(x-1)^2,\qquad c_3=5x(x-1)(2x-1), \tag{3.41a}$$

$$c_2 = \left(24 - (n+1)^2 - A\right) x(x-1) - Bx - \beta^2 + 4, \tag{3.41b}$$

$$c_1 = -3/2\left((3A + (n+3)(n-1))(2x-1) + B\right), \tag{3.41c}$$

$$c_0 = n(n+2)A, \tag{3.41d}$$

with

$$A = (C+n+1)(C+n-1), \quad B = (\alpha-\beta)(\alpha+\beta), \quad C = 2c+\alpha+\beta. \tag{3.42}$$

This result was first given by Hahn [9, eq. 20]. Note the T' invariance of A, B, and C leading to the invariance of the c_i, more obvious than in [31, eq. 47–48].

3.5.7. Limit $\mu = 2c(c+\alpha)/(2c+\beta+\alpha)(2c+\beta+\alpha+1)$. In this limit the symmetry T' is broken. We obtain the zero-related Jacobi polynomials studied in [15]. An explicit form is

(3.43)

$$\mathcal{R}_n^{\alpha,\beta}(x;c) = (-1)^n \frac{(2c+\alpha+\beta+1)_n(\beta+c+1)_n}{n!(c+\alpha+\beta+1)_n} \sum_{k=0}^{n} \frac{(-n)_k(n+2c+\alpha+\beta+1)_k}{(c+1)_k(c+\beta+1)_k} \times {}_4F_3\left(\begin{matrix} k-n, n+k+2c+\alpha+\beta+1, c, c+\beta+1 \\ c+k+1, c+\beta+k+1, 2c+\alpha+\beta+1 \end{matrix}; 1\right) x^k.$$

The limit $c = 0$ leads back to the Jacobi polynomials and the limit defined in (3.32) gives the zero-related Laguerre polynomials (2.4.4), using Kummer's transformations. The spectral measure is

$$\phi'(x) = (1-x)^\alpha x^{\beta+2c} \left| {}_2F_1\left(\begin{matrix} c, c+\beta+1 \\ 2c+\alpha+\beta+1 \end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{3.44}$$

The coefficients of the differential equation (2.38) satisfied by the polynomials $\mathcal{R}_n^{\alpha,\beta}(x;c)$ are

$$c_4 = x^2(x-1)^2(Ax+D), \tag{3.45a}$$

$$c_3 = x(x-1)\left(8Ax^2 - 3(A-3D)x - 4D\right), \tag{3.45b}$$

$$c_2 = -1/2A(A+2C^2-29)x^3 + \left(1/2A(A+2C^2-2B-23) - D(C^2-19)\right)x^2 - 1/4\left(A(D+1)(D-3) - 2D(2C^2-2B+D-35)\right)x - 1/4D(D^2-9), \tag{3.45c}$$

$$c_1 = -A(A+2C^2-5)x^2 + 1/4\left(A(A+2C^2-2B-5D-5) - 3D(4C^2-11)\right)x + 1/4D\left((D+3)A + 6C^2 - 6B + 3D - 15\right), \tag{3.45d}$$

$$c_0 = 2n(n+1)(C+n)(C+n+1)(Ax+3D), \tag{3.45e}$$

where B and C are defined in (3.42) and

$$A = (2n+1)(1+2C+2n), \qquad D = 1+2\beta. \tag{3.46}$$

3.5.8. Limit $\mu = 2(c+\beta)(c+\alpha+\beta)/(\beta+\alpha+2c)(\beta+\alpha+2c+1)$. This case is the T' transform of the case in §3.5.7. The explicit form is

(3.47)

$$\mathfrak{R}_n^{\alpha,\beta}(x;c) = (-1)^n \frac{(2c+\alpha+\beta+1)_n(\alpha+c+1)_n}{n!(c+1)_n} \sum_{k=0}^{n} \frac{(-n)_k(n+2c+\alpha+\beta+1)_k}{(c+\alpha+\beta+1)_k(c+\alpha+1)_k} \times {}_4F_3\left(\begin{matrix} k-n, n+k+2c+\alpha+\beta+1, c+\alpha+\beta, c+\alpha+1 \\ c+\alpha+\beta+k+1, c+\alpha+k+1, 2c+\alpha+\beta+1 \end{matrix}; 1\right) x^k.$$

The limit (3.32) leads back to the Laguerre case in §2.4.5 and the limit $c = 0$ to the co-recursive Jacobi polynomials with $\mu = 2\beta/(\alpha+\beta+1)$. The spectral measure is

$$\phi'(x) = (1-x)^{\alpha} x^{\beta+2c} \left| {}_2F_1\left(\begin{matrix} c+1, c+\beta \\ 2c+\alpha+\beta+1 \end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{3.48}$$

The coefficients of the differential equation (2.38) satisfied by the polynomials $\mathfrak{R}_n^{\alpha,\beta}(x;c)$ are obtained from (3.45), (3.46), changing only $D = 1+2\beta$ by $D = 1-2\beta$.

3.5.9. Limit $\mu = -2c(c+\beta)/(2c+\alpha+\beta)(2c+\alpha+\beta+1)$. The symmetry $\mathcal{T}'$ is also broken. We obtain a new simple case of CAJ polynomials. An explicit form is

(3.49)

$$\widetilde{\mathcal{R}}_n^{\alpha,\beta}(x;c) = (-1)^n \frac{(2c+\alpha+\beta+1)_n (\beta+c+1)_n}{n!(c+\alpha+\beta+1)_n} \sum_{k=0}^{n} \frac{(-n)_k (n+2c+\alpha+\beta+1)_k}{(c+1)_k (c+\beta+1)_k} \times {}_4F_3\left(\begin{matrix} k-n, n+k+2c+\alpha+\beta+1, c, c+\beta \\ c+k+1, c+\beta+k+1, 2c+\alpha+\beta+1 \end{matrix}; 1\right) x^k$$

and the spectral measure is

$$\phi'(x) = (1-x)^{\alpha} x^{\beta+2c} \left| {}_2F_1\left(\begin{matrix} c, c+\beta \\ 2c+\alpha+\beta+1 \end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{3.50}$$

The coefficients of the differential equation (2.38) satisfied by the polynomials $\widetilde{\mathcal{R}}_n^{\alpha,\beta}(x;c)$ are

$$c_4 = x^2(x-1)^2\left(A(x-1) - D\right), \tag{3.51a}$$

$$c_3 = x(x-1)\left(8Ax^2 - (13A+9D)x + 5A + 5D\right), \tag{3.51b}$$

$$\begin{aligned} c_2 = {} & -1/2A(A+2C^2-29)x^3 + \left(A(A+2C^2-B-32) + D(C^2-19)\right)x^2 \\ & -1/2\left(A(A+2C^2+2\beta^2-2B-43) + D(2C^2-2B-D-41)\right)x \\ & +(\beta^2-4)(A+D), \end{aligned} \tag{3.51c}$$

$$\begin{aligned} c_1 = {} & -2A(A+2C^2-5)x^2 \\ & +1/2\left(A(7A+14C^2-2B+5D-35) + D(3C^2-33)\right)x \\ & -A(3/2A+3C^2-B-2\alpha^2-7) - 3D(C^2-B-1/2D-3), \end{aligned} \tag{3.51d}$$

$$c_0 = n(n+1)(C+n)(C+n+1)(A(x-1) - 3D), \tag{3.51e}$$

where B and C are defined in (3.42) and

$$A = (2n+1)(1+2C+2n), \qquad D = 1+2\alpha. \tag{3.52}$$

3.5.10. Limit $\mu = -2(c+\alpha)(c+\alpha+\beta)/(2c+\alpha+\beta)(2c+\alpha+\beta+1)$. This case is the $\mathcal{T}'$ transform of the case in §3.5.9. The explicit form is

(3.53)

$$\widetilde{\mathfrak{R}}_n^{\alpha,\beta}(x;c) = (-1)^n \frac{(2c+\alpha+\beta+1)_n (\alpha+c+1)_n}{n!(c+1)_n} \sum_{k=0}^{n} \frac{(-n)_k (n+2c+\alpha+\beta+1)_k}{(c+\alpha+\beta+1)_k (c+\alpha+1)_k} \times {}_4F_3\left(\begin{matrix} k-n, n+k+2c+\alpha+\beta+1, c+\alpha+\beta, c+\alpha \\ c+\alpha+\beta+k+1, c+\alpha+k+1, 2c+\alpha+\beta+1 \end{matrix}; 1\right) x^k$$

and the spectral measure

$$\phi'(x) = (1-x)^{\alpha-2}x^{\beta+2c+2}\left|{}_2F_1\left(\begin{matrix}c+1, c+\beta+1\\ 2c+\alpha+\beta+1\end{matrix}; \frac{e^{i\pi}}{x}\right)\right|^{-2}. \tag{3.54}$$

The coefficients of the differential equation (2.38) satisfied by the polynomials $\widetilde{\mathfrak{R}}_n^{\alpha,\beta}(x;c)$ are obtained from (3.51), (3.52) by changing only $D = 1+2\alpha$ by $D = 1-2\alpha$.

3.6. Conclusion. We end with brief remarks. In this article we have studied properties of the co-recursive associated Laguerre and Jacobi polynomials that are of interest in the resolution of some birth and death processes with and without absorption. For a few values of the co-recursivity parameter we obtain polynomial families for which the results are of the same complexity as the corresponding associated polynomials. For the CAL polynomials we find the two expected cases corresponding to $\mu = \mu_0$ (zero-related polynomials) and the new dual case $\mu = \lambda_{-1}$ [20]. For the CAJ polynomials, due to the properties (3.3) and (3.5), we have two more cases corresponding to $\mu = -\mathcal{T}''\mu_0$ and $\mu = -\mathcal{T}''\lambda_{-1}$, where the transformation $\mathcal{T}''$ is defined by

$$\mathcal{T}''(c,\alpha,\beta) = (c+\alpha+\beta, -\beta, -\alpha). \tag{3.55}$$

In some cases the fourth-order differential equations satisfied by the polynomials studied above are factorizable (co-recursive and associated of order one), but we do not find factorization either for the co-recursive associated polynomials or for the associated one. Of course, this is not a proof that the conjectures on this factorizability made in [27] are wrong.

Acknowledgments. The author thanks Galliano Valent and Pascal Maroni for stimulating discussions during the preparation of this article.

BOUNDS AND MONOTONICITIES FOR THE ZEROS OF DERIVATIVES OF ULTRASPHERICAL BESSEL FUNCTIONS*

LEE LORCH† AND PETER SZEGO‡

Abstract. The positive zeros $p_{\nu k}^{(\ell)}$ of $[x^{-\nu+1}J_{\nu+\ell-1}(x)]'$, $\nu+\ell>0$, where $J_\nu(x)$ denotes the standard Bessel function, arise in the study of the eigenvalues of Neumann Laplacians in N dimensions [M. S. Ashbaugh and R. D. Benguria, *SIAM J. Math. Anal.*, 24 (1993), pp. 557–570]. The case $\ell=1$ is particularly relevant. To pave the way for these applications, the authors present here inter alia (i) lower and upper bounds for $p_{\nu 1}^{(\ell)}$ and (ii) an explicit representation for $dp_{\nu k}^{(\ell)}/d\nu$. The latter implies that $p_{\nu k}^{(\ell)}$ is increasing in ν for fixed k,ℓ, provided $\nu+\ell>1$.

Key words. eigenvalues, Bessel functions, zeros, monotonicity

AMS subject classification. 33C40

1. Background and statement of results. In the course of their study [1] of eigenvalues of Neumann Laplacians in higher dimensions, Ashbaugh and Benguria require information concerning the zeros of $[x^{-\nu+1}J_{\nu+\ell-1}(x)]'$, where $J_\nu(x)$ is the usual Bessel function of the first kind and order ν; ℓ is independent of ν. For convenience of reference, they propose calling $x^{-\nu+1}J_{\nu+\ell-1}(x)$ an "ultraspherical Bessel function," since this function becomes (apart from the multiplicative factor $\sqrt{2/\pi}$) the standard spherical Bessel function when $\nu=\frac{3}{2}$ and $\ell=0,1,2,3,\ldots$. We adopt their nomenclature here [1].

The purpose of this note is to establish results that Ashbaugh and Benguria have found relevant to their work. They have particular use for the case $\ell=1$, $\nu=\frac{1}{2}n$, $n=1,2,3,\ldots$, and so we provide explicit statements below for this case.

By $p_{\nu k}^{(\ell)}$ we mean the kth positive zero of $[x^{-\nu+1}J_{\nu+\ell-1}(x)]'$; $p_{\nu k}^{(1)}$ will be simply denoted by $p_{\nu k}$. Furthermore, we note that $p_{\nu k}^{(0)}=j_{\nu,k}$, where $j_{\nu,k}$ is the kth positive zero of $J_\nu(x)$, since [3, §3.2, p. 45] $[x^{-\nu}J_\nu(x)]'=-J_{\nu+1}(x)/x^\nu$.

We shall establish the following properties:

$$(1)\qquad \frac{2\ell(\nu+\ell)(\nu+\ell+1)}{\nu+2\ell+1}<\left[p_{\nu 1}^{(\ell)}\right]^2<2\ell(\nu+\ell),\qquad \ell>0,\ \nu>-1,\ \nu+\ell>0;$$

in particular,

$$(1')\qquad 2\nu+\frac{4}{\nu+3}<p_{\nu 1}^2<2\nu+2,\qquad \nu>-1.$$

We need (2) and (3) as an alternative lower bound for $[p_{\nu 1}^{(\ell)}]^2$. It is weaker than the lower bound provided in (1) for the case ($\ell=1$) required by Ashbaugh and Benguria, but stronger when $\ell>2$ and ν is sufficiently large.

$$(1'')\qquad \left[p_{\nu 1}^{(\ell)}\right]^2>2\nu\ell+\ell^2-2\ell,\quad \nu+\ell>0,\quad \ell>0.$$

‡ 75 Glen Eyrie Avenue, Apt. 19, San Jose, California 95125.

This inequality will show that the denominators in (2) and a fortiori in (2′) are positive.

With $p^{(\ell)} = p_{\nu k}^{(\ell)}$, $\nu + \ell > 1$, we have

$$\frac{dp^{(\ell)}}{d\nu} = \frac{p^{(\ell)}}{\left[p^{(\ell)}\right]^2 - ((2\nu-2)\ell + \ell^2)} \frac{1}{J_{\nu+\ell-1}^2(p^{(\ell)})} \cdot \left\{ 2(\nu - 1 + \ell) \int_0^{p^{(\ell)}} \frac{J_{\nu-1+\ell}^2(t)}{t} dt - J_{\nu-1+\ell}^2(p^{(\ell)}) \right\}, \tag{2}$$

when, with $p = p_{\nu k}$, $\nu > 0$,

$$\frac{dp}{d\nu} = \frac{p}{p^2 - (2\nu - 1)} \frac{1}{J_\nu^2(p)} \left\{ 2\nu \int_0^p \frac{J_\nu^2(t)}{t} dt - J_\nu^2(p) \right\}. \tag{2′}$$

From (1″) and (2) it follows, for each $k = 1, 2, \ldots$, that

$$\frac{dp_{\nu k}^{(\ell)}}{d\nu} > 0, \qquad \nu + \ell > 1. \tag{3}$$

From (1′) and (2′) it follows, for each $k = 1, 2, \ldots$, that

$$\frac{dp_{\nu k}}{d\nu} > 0, \qquad \nu > 0. \tag{3′}$$

As a consequence of (3), which establishes that $p_{\nu k}^{(\ell)}$ is an increasing function of ν for each fixed $k = 1, 2, 3, \ldots$, Ashbaugh and Benguria [1] can infer that each Neumann eigenvalue of the unit ball in n dimensions ($n \geq 2$) increases with the dimension.

2. A preliminary result. Common to the proofs of (1), (1′), (2), and (2′) will be the equation

$$p_{\nu k}^{(\ell)} J'_{\nu+\ell-1}\left(p_{\nu k}^{(\ell)}\right) = (\nu - 1) J_{\nu+\ell-1}\left(p_{\nu k}^{(\ell)}\right) \tag{4}$$

and the special case $\ell = 1$

$$p_{\nu k} J'_\nu(p_{\nu k}) = (\nu - 1) J_\nu(p_{\nu k}). \tag{4′}$$

This is an immediate consequence of the differentiation formula

$$x^\nu \frac{d}{dx} \left\{ \frac{J_{\nu+\ell-1}(x)}{x^{\nu-1}} \right\} = x J'_{\nu+\ell-1}(x) - (\nu - 1) J_{\nu+\ell-1}(x)$$

and the definition of $p_{\nu k}^{(\ell)}$.

3. Proof of (1) and (1′). First we establish the lower bounds in (1) and (1′). To do so, we consider (i) $J'_{\nu+\ell+1}(p_{\nu 1}^{(\ell)}) > 0$, a case which occurs whenever $\nu > 1$, as is clear from (4), and (ii) $J'_{\nu+\ell+1}(p_{\nu 1}^{(\ell)}) \leq 0$.

To case (i) we apply the unnumbered formula following [3, §15.3 (2), p. 486] with $x = p_{\nu 1}^{(\ell)}$. Taking (4) into account, this becomes

$$0 < p_{\nu 1}^{(\ell)} J'_{\nu+\ell+1}\left(p_{\nu 1}^{(\ell)}\right) = 2(\nu+\ell)\left\{1 - \frac{(\nu+\ell-1)(\nu+\ell+1)}{\left[p_{\nu 1}^{(\ell)}\right]^2}\right\} J_{\nu+\ell-1}\left(p_{\nu 1}^{(\ell)}\right)$$
$$- \left\{1 - \frac{2(\nu+\ell)(\nu+\ell+1)}{\left[p_{\nu 1}^{(\ell)}\right]^2}\right\} (\nu-1) J_{\nu+\ell-1}\left(p_{\nu 1}^{(\ell)}\right).$$

Recalling that $p_{\nu 1}^{(\ell)} < j_{\nu+\ell-1,1}$, so that $J_{\nu+\ell-1}\left(p_{\nu 1}^{(\ell)}\right) > 0$, this verifies the first inequality in (1) in case (i).

In case (ii), we have $p_{\nu 1}^{(\ell)} \geq j'_{\nu+\ell+1,1}$. But [3, §15.3 (3), p. 486] $(j'_{\nu 1})^2 > \nu^2 + 2\nu$, so that

$$\left[p_{\nu 1}^{(\ell)}\right]^2 > (\nu+\ell+1)(\nu+\ell+3),$$

which exceeds the lower bound stated in (1). This completes case (ii).

The upper bound in (1) can be inferred from the unnumbered formula immediately above [3, §15.3 (4), p. 486] with ν replaced by $\nu+\ell-1$, x by $p_{\nu 1}^{(\ell)}$, and then using (4), this gives

$$\frac{J_{\nu+\ell+1}\left(p_{\nu 1}^{(\ell)}\right)}{J_{\nu+\ell-1}\left(p_{\nu 1}^{(\ell)}\right)} = -1 + \frac{2(\nu+\ell-1)(\nu+\ell)}{\left[p_{\nu 1}^{(\ell)}\right]^2} - \frac{2(\nu-1)(\nu+\ell)}{\left[p_{\nu 1}^{(\ell)}\right]^2}.$$

The left member is positive, since $p_{\nu 1}^{(\ell)} < j_{\nu+\ell-1,1}$, when $\nu+\ell-1 > -1$, i.e., when $\nu+\ell > 0$.

The upper bounds in (1) and (1′) follow immediately.

Remark 1. From the upper bound in (1) we find that

$$\lim_{\ell \to 0} p_{\nu 1}^{(\ell)} = 0 \neq j_{\nu 1} = p_{\nu 1}^{(0)}, \qquad \nu > -1.$$

Thus, $p_{\nu 1}^{(\ell)}$ is not continuous at $\ell = 0$ for any fixed $\nu > -1$. From (1′) we see that $p_{\nu 1} \to 0$ as $\nu \to -1^+$, and, more generally, from (1) we see that $p_{\nu 1}^{(\ell)} \to 0$ as $\nu \to -\ell^+$.

Remark 2. Equation (4) implies that $J_{\nu+\ell-1}(p_{\nu k}^{(\ell)}) \neq 0$, $k = 1, 2, \ldots$, since the Bessel differential equation has a finite singularity only at $x = 0$, so that $J_{\nu+\ell-1}(x)$ and $J'_{\nu+\ell-1}(x)$ can vanish simultaneously only at $x = 0$.

4. Proof of (1″). The lower bound given by (1″) will be obtained from the differential equation, satisfied by $y = J_{\nu+\ell-1}(x)/x^{\nu-1}$:

$$x^2 y'' + (2\nu - 1) x y' + (x^2 - \ell^2 - 2\nu\ell + 2\ell) y = 0. \tag{5}$$

This is the form to which [3, §4.31(19), p. 98] specializes when in the latter $\psi(x)$ is taken to be x, μ to be $1-\nu$, and the ν occurring in [3] is replaced by $\nu+\ell-1$.

In the course of the proof, we shall use a simple and presumably already recorded property of a class of differential equations to which (5) belongs. We state and prove it here for completeness.

LEMMA. *Let $x = \xi$ yield a positive maximum of the function $y(x)$ that satisfies the differential equation*

$$a_0(x)y'' + a_1(x)y' + a_2(x)y = 0,$$

where $a_0(x), a_1(x), a_2(x)$ are differentiable functions such that $a_0(\xi) > 0$ and $a_2'(\xi) > 0$. Then $y''(\xi) < 0$.

Proof. Clearly, $y''(\xi) \leq 0$. Suppose, *par impossible*, that $y''(\xi) = 0$. Differentiating the given differential equation and then putting $x = \xi$ would give rise to the equation

$$a_0(\xi)y'''(\xi) + a_2'(\xi)y(\xi) = 0.$$

This equation shows, in the light of the lemma's hypotheses, that $y'''(\xi) < 0$. Thus, there exists $\delta > 0$ such that $y''(x)$ decreases in $\xi - \delta < x \leq \xi$ to 0. Hence $y''(x) > 0$, $\xi - \delta < x < \xi$, so that $y'(x)$ increases to 0, $\xi - \delta < x \leq \xi$, i.e., $y'(x) < 0$, $\xi - \delta < x < \xi$. But this implies that $y(x)$ *decreases* to its maximum $y(\xi)$, a manifest impossibility. This proves the lemma.

Now we revert to the special case (5) and note that its solution $y(x) = J_{\nu+\ell-1}(x)/x^{\nu-1} > 0$, $0 < x < j_{\nu+\ell-1,1}$, since (as assumed for (1″)) $\nu + \ell > 0$. Thus, $p_{\nu 1}^{(\ell)}$, the first positive zero of $y'(x)$, yields a positive maximum. From the lemma, $y''(p_{\nu 1}^{(\ell)}) < 0$. Putting $x = p_{\nu 1}^{(\ell)}$ in (5) concludes the proof of (1″), since $y(p_{\nu 1}^{(\ell)}) > 0$.

Remark 3. The lemma, which would otherwise be unnecessary, establishes *strict* inequality in (1″). This is required to permit the division in (2) and (2′) and the positivity asserted in (3) and (3′).

Remark 4. There are equations of type (5) possessing nontrivial solutions y having positive maxima $y(\xi)$ for which $y''(\xi) = 0$. With twice differentiable coefficients $a_0(x), a_1(x), a_2(x)$ such that $a_0(\xi) > 0$ as in the lemma, but with $a_2(\xi) = a_2'(\xi) = 0$ and $a_2''(\xi) > 0$, it follows that $y''(\xi) = y'''(\xi) = 0$ and $y^{(4)}(\xi) < 0$. Thus, it suffices to select the solution for which $y(\xi) = 1$, $y'(\xi) = 0$.

One such example is a special case of a transformation, due to Lommel [see 3, §4.31(9), p. 97], of Bessel's differential equation. This case gives the equation $y'' + 4x^2y = 0$. The initial conditions $y(0) = 2^{1/4}/\Gamma(\frac{3}{4})$, $y'(0) = 0$ yield the unique solution $y = |x|^{1/2}J_{-1/4}(x^2)$. Here $y''(0) = y'''(0) = 0$, $y^{(4)}(0) = -8 < 0$, so that $x = 0$ yields a positive maximum at $x = 0$ but with $y''(0) = 0$.

5. Proof of formulae (2) and (2′). Formula (2) was put in the form stated to facilitate the specialization into (2′) for which applications are at hand [1]. To simplify the notation employed in the proof of (2), we put

$$\mu = \nu - 1, \qquad q = p_{\nu k}^{(\ell)}$$

so that (2) can be stated, since $q^2 \neq 2\mu\ell + \ell^2$, $\mu + \ell > 0$, as

$$(2'') \qquad \frac{dq}{d\mu} = \frac{q}{q^2 - (2\mu\ell + \ell^2)} \frac{1}{J_{\mu+\ell}^2(q)} \left\{ 2(\mu + \ell) \int_0^q \frac{J_{\mu+\ell}^2(t)}{t}\, dt - J_{\mu+\ell}^2(q) \right\}.$$

Thus, (4) becomes

$$(4'') \qquad -\mu J_{\mu+\ell}(q) + qJ_{\mu+\ell}'(q) = 0.$$

Differentiating this with respect to μ yields

$$-J_{\mu+\ell}(q) - \mu \frac{\partial J_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} + q \frac{\partial J'_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} + (1-\mu)J'_{\mu+\ell}(q)\frac{dq}{d\mu} + q\frac{dq}{d\mu}J''_{\mu+\ell}(q) = 0,$$

or, collecting terms,

$$\frac{dq}{d\mu}\left\{(1-\mu)J'_{\mu+\ell}(q) + qJ''_{\mu+\ell}(q)\right\} = J_{\mu+\ell}(q) + \mu \frac{\partial J_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} - q\frac{\partial J'_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q}. \tag{6}$$

In the left member of (6), we replace $J''_{\mu+\ell}(q)$ in terms of $J_{\mu+\ell}(q)$ and $J'_{\mu+\ell}(q)$ via Bessel's differential equation and then with $J'_{\mu+\ell}(q)$ in terms of $J_{\mu+\ell}(q)$ by means of (4″). Thus,

$$\frac{dq}{d\mu}\left\{(1-\mu)J'_{\mu+\ell}(q) + qJ''_{\mu+\ell}(q)\right\} = \frac{dq}{d\mu}\left\{\frac{2\mu\ell + \ell^2 - q^2}{q}J_{\mu+\ell}(q)\right\}. \tag{7}$$

The right member of (6) can be transformed via the identity [2, p. 247]

$$\frac{x}{2(\mu+\ell)}\left\{J_{\mu+\ell}(x)\frac{\partial J'_{\mu+\ell}(x)}{\partial \mu} - J'_{\mu+\ell}(x)\frac{\partial J_{\mu+\ell}(x)}{\partial \mu}\right\} = \int \frac{J^2_{\mu+\ell}(x)}{x}dx,$$

which we may evaluate between the limits of 0 and q. The lower limit on the left vanishes since $\mu + \ell > 0$. Hence,

$$\frac{q}{2(\mu+\ell)}\left\{J_{\mu+\ell}(q)\frac{\partial J'_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} - J'_{\mu+\ell}(q)\frac{\partial J_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q}\right\} = \int_0^q \frac{J^2_{\mu+\ell}(x)}{x}\,dx.$$

In this equation, the factor $J'_{\mu+\ell}(q)$ can be expressed in terms of $J_{\mu+\ell}(q)$ by (4″). Hence, since $J_{\mu+\ell}(q) \neq 0$,

$$\mu \frac{\partial J_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} - q\frac{\partial J'_{\mu+\ell}(x)}{\partial \mu}\bigg|_{x=q} = -\frac{2(\mu+\ell)}{J_{\mu+\ell}(q)}\int_0^q \frac{J^2_{\mu+\ell}(x)}{x}\,dx.$$

This evaluation, together with (6) and (7), establishes (2″) and also (2) and (2′).

6. Proof of (3) and (3′). Now that (1″), (2), and (2′) have been demonstrated, the signs in (3) and (3′) readily follow. The transition is accomplished with the use of the identity [3, §5.51 (5), p. 152], valid for $\nu + \ell - 1 > 0$,

$$2(\nu - 1 + \ell)\int_0^{p^{(\ell)}} \frac{J^2_{\nu+\ell-1}}{x}dx - J^2_{\nu+\ell-1}(p^{(\ell)}) = 2\sum_{n=1}^{\infty} J^2_{\nu+\ell-1+n}(p^{(\ell)}).$$

This is positive, so that the sign of $dp^{(\ell)}/d\nu$ is, according to (2), the same as the sign of $[p^{(\ell)}]^2 - ((2\nu-2)\ell + \ell^2)$, when $\nu + \ell > 1$, i.e., positive, from (1″).

Acknowledgment. We are grateful to a conscientious referee whose careful attention to detail corrected the erroneous value we had ascribed to the coefficient in (2), along with related slips. In addition, we thank M. S. Ashbaugh and R. D. Benguria for a preprint of [1].

BEST WEIGHTED POLYNOMIAL APPROXIMATION VIA JACOBI EXPANSIONS*

DORON S. LUBINSKY† AND VILMOS TOTIK‡

Abstract. Freud's method is modified to prove the Jackson–Favard estimate for weighted algebraic polynomials with Jacobi weights. This approach uses only classical results from the theory of orthogonal polynomials.

Key words. weighted polynomial approximation, orthogonal expansion, Jacobi polynomials

AMS subject classifications. 41A10, 42C10

1. Introduction.

Let f be a function on $[-1,1]$, and

$$E_n(f)_p = \inf_{\deg P_n \le n} \|f - P_n\|_{L^p[-1,1]}$$

be its best approximation by polynomials of degree at most n in the L^p metric. One of the central questions in the constructive theory of approximation is to characterize $E_n(f)_p$ in terms of structural properties of the function f. Even though the analogous problem for trigonometric approximation has been classical for a long time, the characterization problem for algebraic polynomial approximation was only solved in the eighties [15], [16], [17], [11] due to the complex nature of the behavior of the best approximating polynomials around the endpoints ± 1. Eventually, as the complete analogue of the trigonometric case, the following result was proved [11, Chap. 8]: let $\varphi(x) = \sqrt{1-x^2}$, and

$$\omega_\varphi^r(f,\delta)_p = \sup_{0\le h\le\delta} \|\Delta_{h\varphi}^r f\|_p,$$

where

$$\Delta_t^r f(x) = \sum_{k=0}^{r} (-1)^k \binom{r}{k} f\left(x + \left(\frac{r}{2} - k\right)t\right)$$

is the rth symmetric difference of f with increment t ($= h\varphi(x)$ in the definition of ω_φ^r) and where we set $\Delta_t^r f(x) = 0$ if any of the arguments in its defining expression does not belong to $[-1,1]$. Then for a positive integer r we have

$$E_n(f)_p \le C\omega_\varphi^r\left(f, \frac{1}{n}\right)_p$$

and its converse

$$\omega_\varphi^r\left(f, \frac{1}{n}\right)_p \le Cn^{-r}\sum_{k=1}^{n} k^{r-1}E_k(f)_p.$$

In particular, for $0 < \alpha < r$,

$$E_n(f)_p = O(n^{-\alpha}) \Leftrightarrow \omega_\varphi^r(f,\delta)_p = O(\delta^\alpha).$$

The situation is even more complicated if we discuss weighted polynomial approximation:

$$E_n(f)_{w,p} = \inf_{\deg P_n \le n} \|w(f-P_n)\|_p,$$

namely the problem has only been solved for Jacobi-like weights ([11, Thms. 8.2.1 and 8.2.4]) with a weighted modulus of smoothness that is similar in spirit to the ω_φ^r above.

Let us only discuss the case of Jacobi weights

$$w(x) = (1-x)^\alpha (1+x)^\beta$$

with $\alpha, \beta > 0$. We set for $n = 1, 2, \dots$

$$w_n(x) = \left(\sqrt{1-x} + \frac{1}{n}\right)^{2\alpha} \left(\sqrt{1+x} + \frac{1}{n}\right)^{2\beta}$$

and

$$\varphi_n(x) = \sqrt{1-x^2} + \frac{1}{n}.$$

The crux of the matter is the Jackson–Favard type estimate

$$E_n(f)_{w,p} \le C\frac{1}{n^r}\|w_n \varphi_n^r f^{(r)}\|_p \tag{1}$$

with a matching converse Markov–Bernstein inequality

$$\|w_n \varphi_n^r P_n^{(r)}\|_p \le C n^r \|w_n P_n\|_p, \qquad \deg P_n \le n. \tag{2}$$

The rest belongs to the theory of interpolation spaces and to characterizations of weighted K-functionals (see [11, Chap. 8]). By now there are several different procedures known for proving (2) (see [21], [18], [19], and [11, Thm. 8.4.7]), but the only existing way to get to (1) is by transforming the problem to the trigonometric case and to use quite complicated estimates based on Riesz's interpolation formula [11, Chap. 8].

In the present paper we offer an alternative approach to (1). The method was developed by Freud [13], [14] in connection with exponential weights on the whole real line, in which case he based his approach on the orthogonal polynomials that now carry his name. We shall use Jacobi expansions in our method with respect to the weight w^2. Many steps will be the same as Freud's case, but, unlike Freud, we have to overcome the additional difficulty of the weight φ entering our formulas.

A crucial step in Freud's method is the boundedness of $(C,1)$ means of the expansions in question in the appropriate weighted spaces, which is also valid for Jacobi expansions for all parameter values $\alpha, \beta \ge 0$. This is where our work gets connected with the research of Askey, who has many remarkable discoveries concerning Cesaro means of Jacobi expansions (see [1]–[10]).

2. Some facts concerning Jacobi polynomials. Let

$$w(x) = (1-x)^{\alpha}(1+x)^{\beta}$$

be a Jacobi weight with $\alpha,\ \beta > -\frac{1}{2}$. We consider the Jacobi polynomials

$$p_n(x) = \gamma_n x^n + \cdots, \qquad \gamma_n > 0$$

associated with w^2 (sic!), i.e., for which

$$\int_{-1}^{1} p_n p_m w^2 = \delta_{nm}, \qquad n, m = 0, 1, \ldots.$$

We shall need a few classical results for them, all taken from Szegő's book [22].

In what follows we shall write $A \prec B$ if $A = O(B)$ and $A \sim B$ if $A = O(B)$ and $B = O(A)$.

First of all, uniformly in n and $x \in [-1, 1]$,

$$p_n(x) \prec 1 \Big/ \left(w_n(x)\varphi_n(x)^{1/2}\right) \tag{3}$$

(see [22, Thm. 7.32.2] and recall that $P_n^{(2\alpha,2\beta)}$ in [22] has to be normalized by the factor $h_n^{(2\alpha,2\beta)}$ of [22, eq. (4.3.3)] to get p_n). For any fixed $c > 0$,

$$p_n(\cos\theta) = b_n \left(\sin\frac{\theta}{2}\right)^{-2\alpha-1/2} \left(\cos\frac{\theta}{2}\right)^{-2\beta-1/2} \left\{\cos(N\theta+\gamma) + O((n\sin\theta)^{-1})\right\} \tag{4}$$

for

$$\frac{c}{n} \le \theta \le \pi - \frac{c}{n},$$

where

$$N = n + (2\alpha + 2\beta + 1)/2, \qquad \gamma = -\left(2\alpha + \frac{1}{2}\right)\frac{\pi}{2},$$

and b_n tends to a finite and positive limit as $n \to \infty$ (see [22, Thm. 8.21.13]); furthermore, say around $+1$,

$$p_n(\cos\theta) \sim n^{2\alpha+1/2}, \qquad 0 \le \theta \le \frac{c}{n} \tag{5}$$

for sufficiently small c (see [22, Thm. 8.21.12]).

These easily imply for the so-called Christoffel function

$$\lambda_n(w^2, x) := \lambda_n(x) := \left\{\sum_{k=0}^{n-1} p_k(x)^2\right\}^{-1} \tag{6}$$

the uniform estimate

$$\lambda_n(x) \sim \frac{w_n^2(x)\varphi_n(x)}{n} \tag{7}$$

(cf. also [20]).

We shall also need that for $\alpha,\ \beta > -1$,

$$\lambda_n(w_n,x) \sim \frac{w_n(x)\varphi_n(x)}{n}. \tag{8}$$

To prove this we have to recall (see [12]) that for any weight v on $[-1,1]$,

$$\lambda_n(v,x) = \inf_{\deg P_n \le n-1} \frac{1}{P_n^2(x)} \int_{-1}^{1} P_n^2 v.$$

Since $w \le w_n$, this formula immediately gives

$$\lambda_n(w_n,x) \ge \lambda_n(w,x) \ge c\frac{w_n(x)\varphi_n(x)}{n},$$

where, at the last step we applied (7) for w rather than w^2.

Equation (7) also shows that if $\{p_k^{**}\}$ are the orthonormal Jacobi polynomials with respect to the weight

$$w(x)^{1/2}/\varphi(x) = (1-x)^{(\alpha-1)/2}(1+x)^{(\beta-1)/2},$$

then

$$R_{n/2}(x) = \frac{1}{n}\sum_{k=0}^{n/4} p_k^{**}(x)^2$$

is a polynomial of degree at most $n/2$ with

$$R_{n/2}^2(x) \sim \frac{1}{w_n(x)}.$$

Hence

$$\begin{aligned}
\lambda_n(w_n,x) &\prec \inf_{\deg Q_{n/2}<n/2} \frac{1}{R_{n/2}^2(x)Q_{n/2}^2(x)} \int_{-1}^{1} (R_{n/2}Q_{n/2})^2 w_n \\
&\sim w_n(x) \inf_{\deg Q_{n/2}<n/2} \frac{1}{Q_{n/2}^2(x)} \int_{-1}^{1} Q_{n/2}^2 \\
&\sim w_n(x)\lambda_{n/2}(1,x) \sim w_n(x)\frac{\varphi_n(x)}{n},
\end{aligned}$$

where at the very last step we again used (7) for the Legendre weight

$$1 = (1-x)^0(1+x)^0.$$

Finally, it easily follows from the formula [22, eq. (4.5.5)] that

$$\begin{aligned}
p_{k-1}(x) - p_{k+1}(x) = d_k(1-x^2)p_{k-1}^*(x) \\
+ O\left(\frac{1}{k}(|p_{k-1}(x)| + |p_k(x)| + |p_{k+1}(x)|)\right)
\end{aligned}$$

uniformly in n and $x \in [-1,1]$, where $\{d_k\}$ is a positive sequence converging to 1, and $p_{k-1}^*(x)$ is the $(k-1)$st Jacobi polynomial associated with the weight

$$w^2(x)\varphi^2(x) = (1-x)^{2\alpha+1}(1+x)^{2\beta+1}.$$

This formula immediately implies

$$\sum_{k=1}^{n}(p_{k-1}(x)-p_{k+1}(x))^2 \prec (1-x^2)^2\lambda_n^*(x)^{-1}+\sum_{k=0}^{n+1}\frac{1}{(k+1)^2}p_k^2(x), \tag{9}$$

where λ_n^* is the Christoffel function associated with the system $\{p_k^*(x)\}$. The first term on the right is (see (7))

$$(1-x^2)^2\lambda_n^*(x)^{-1} \prec \frac{n\varphi_n(x)}{w_n^2(x)}, \tag{10}$$

while for the second term we easily get from (3) that it is

$$\prec \sum_{k=1}^{n+1}\frac{1}{k^2w_k^2(x)\varphi_k(x)}.$$

For $0 \le x < 1$ we break the last sum into two parts with the ranges $1 \le k \le \varphi_n^{-1}(x)$ and the rest. When $0 < \alpha \le \frac{1}{4}$ this yields

$$\sum_{k=1}^{n+1}\frac{1}{k^2w_k^2(x)\varphi_k(x)} \prec \sum_{k=1}^{\varphi_n^{-1}(x)}\frac{1}{k^{1-4\alpha}}\frac{1}{(k\sqrt{1-x}+1)^{4\alpha+1}}+\sum_{k>\varphi_n^{-1}(x)}\frac{1}{k^2}\frac{1}{w_n^2(x)\varphi_n(x)}$$

because for $n+1 \ge k > \varphi_n^{-1}(x)$ we have

$$\sqrt{1-x}+\frac{1}{k} \sim \sqrt{1-x}+\frac{1}{n},$$

and so $w_k^2(x)\varphi_k(x) \sim w_n^2(x)\varphi_n(x)$. Finally, both sums on the right are of the order

$$\sum_{k=1}^{\varphi_n^{-1}(x)}\frac{1}{k^{1-4\alpha}} \sim \frac{1}{w_n^2(x)\varphi_n(x)}\sum_{k>\varphi_n^{-1}(x)}\frac{1}{k^2} \sim w_n^{-2}(x).$$

When $\alpha > \frac{1}{4}$ similar consideration gives

$$\begin{aligned}\sum_{k=1}^{n+1}\frac{1}{k^2w_k^2(x)\varphi_k(x)} &\prec \frac{1}{(\sqrt{1-x}+\frac{1}{n})^{4\alpha-1}}\sum_{k=1}^{\varphi_n^{-1}(x)}1+\frac{1}{w_n^2(x)\varphi_n(x)}\sum_{k>\varphi_n^{-1}(x)}\frac{1}{k^2}\\ &\prec \frac{1}{w_n^2(x)}.\end{aligned}$$

The argument is similar when $-1 \le x \le 0$.

Our estimates proved so far show that

$$\sum_{k=0}^{n+1}\frac{1}{(k+1)^2}p_k^2(x) \prec \frac{1}{w_n^2(x)}. \tag{11}$$

This, (9), and (10) finally yield

$$\sum_{k=1}^{n}(p_{k-1}(x)-p_{k+1}(x))^2 \prec \frac{n\varphi_n(x)}{w_n^2(x)}. \tag{12}$$

The last fact we need on the Jacobi polynomials is that the leading coefficients γ_n satisfy

$$\left|\frac{\gamma_k}{\gamma_{k+1}} - \frac{1}{2}\right| \prec \frac{1}{k^2} \tag{13}$$

(see [22, eq. (4.5.1), eq. (3.2.2)]).

3. Boundedness of $(C,1)$ means in weighted norms. Let f be a function such that the integrals for the Fourier coefficients

$$c_n(f) = \int_{-1}^{1} fw^2$$

exist. These give rise to the expansion

$$f(x) \sim \sum_{n=0}^{\infty} c_n(f)p_n(x)$$

with partial sums

$$S_k(f,x) = \sum_{j=0}^{k} c_j(f)p_j(x).$$

The $(C,1)$ means are then defined as

$$\sigma_n(f,x) = \frac{1}{n}\sum_{k=1}^{n} S_k(f,x).$$

We shall need the following in the proof of (1).

STATEMENT 3.1. *If $w(x) = (1-x)^\alpha(1+x)^\beta$ with $\alpha, \beta > 0$, then for any $1 \le p \le \infty$*

$$\|w_n\sigma_n(f)\|_p \le C\|wf\|_p \tag{14}$$

with a constant C depending only on α and β.

Proof. First we consider the case $p = \infty$. From here the Statement for $p = 1$ will follow by standard duality argument, although it causes some difficulty that on the left of (14) not the weight w but w_n appears. The case $1 < p < \infty$ follows then by interpolation.

3.1. The case $p = \infty$. Suppose that $\|wf\|_{[-1,1]} \le 1$, and $x \in [-1,1]$ is arbitrary. We write

$$f_n(t) = f_{n,x}(t) = \begin{cases} f(t) & \text{if } |x-t| \le \varphi_n(x)/n, \\ 0 & \text{otherwise,} \end{cases}$$

and

$$F_n(t) = F_{n,x}(t) = \begin{cases} f(t)/(x-t) & \text{if } |x-t| > \varphi_n(x)/n, \\ 0 & \text{otherwise.} \end{cases}$$

If

$$K_k(x,t) = \sum_{j=0}^{k} p_j(x)p_j(t) = \frac{\gamma_k}{\gamma_{k+1}}\frac{p_{k+1}(x)p_k(t) - p_k(x)p_{k+1}(t)}{x-t}$$

is the reproducing kernel for the system $\{p_j\}$, then

$$S_k(f,x) = \int f_n(t)K_k(x,t)w^2(t)dt + \frac{\gamma_k}{\gamma_{k+1}}(c_k(F_n)p_{k+1}(x) - c_{k+1}(F_n)p_k(x)) = I_k(x) + J_k(x),$$

where

$$c_k(F_n) = \int F_n(t)p_k(t)w^2(t)dt$$

are the Fourier coefficients of F_n with respect to $\{p_k\}$. We estimate the two terms in the expression of S_k separately.

For $I_k(x)$ we can write in view of $\|wf\| \le 1$

$$\begin{aligned} |I_k(x)| &\le \int_{|t-x|\le\varphi_n(x)/n} |K_k(x,t)|w(t)dt \\ &\le 2\left(\frac{\varphi_n(x)}{n}\right)^{1/2}\left(\int K_k^2(x,t)w^2(t)dt\right)^{1/2} \\ &= 2\left(\frac{\varphi_n(x)}{n}\right)^{1/2}\lambda_{k+1}^{-1/2}(x) \prec \frac{1}{w_n(x)}, \end{aligned} \tag{15}$$

provided $k \le n$, where in the last step we used (7).

For γ_k/γ_{k+1} in J_k we use (13) to obtain

$$J_k(x) = \frac{1}{2}(c_k(F_n)p_{k+1}(x) - c_{k+1}(F_n)p_k(x)) + O\left(|c_k(F_n)|\frac{|p_{k+1}(x)|}{(k+1)^2} + |c_{k+1}(F_n)|\frac{|p_k(x)|}{(k+1)^2}\right) = J_k^{(1)}(x) + J_k^{(2)}(x).$$

In

$$\sigma_n(f,x) = \frac{1}{n}\sum_{k=1}^{n} S_k(f,x)$$

the sum of the "errors" $J_k^{(2)}(x)$ can be estimated as

$$\sum_{k=1}^{n}|J_k^{(2)}(x)| \le \left(\sum_k c_k(F_n)^2\right)^{1/2}\left(\sum_{k=1}^{n+1}\frac{p_k^2(x)}{k^4}\right)^{1/2}.$$

Making use of Bessel's inequality, $\|wf\| \le 1$ and (11), this can be continued as

$$\begin{aligned} &\prec\left(\int F_n(t)^2w(t)^2dt\right)^{1/2}\frac{1}{w_n(x)} \\ &= \left(\int_{|x-t|\ge\varphi_n(x)/n}\frac{1}{|x-t|^2}dt\right)^{1/2}\frac{1}{w_n(x)} \\ &\le 2\left(\frac{n}{\varphi_n(x)}\right)^{1/2}\frac{1}{w_n(x)}. \end{aligned} \tag{16}$$

The sum of the first terms in $J_k(x)$ is half of

$$2\sum_{k=1}^{n} J_k^{(1)}(x) = c_1(F_n)p_2(x) - c_{n+1}(F_n)p_n(x) + \sum_{k=2}^{n} c_k(F_n)(p_{k+1}(x) - p_{k-1}(x)).$$

For the last expression we obtain from the Schwarz inequality, Bessel inequality, and (12)

$$\left|\sum_{k=2}^{n} c_k(F_n)(p_{k+1}(x) - p_{k-1}(x))\right| \prec \left(\int F_n(t)^2 w(t)^2 dt\right)^{1/2} \frac{(n\varphi_n(x))^{1/2}}{w_n(x)} \prec \frac{n}{w_n(x)}.$$

A similar argument gives that

$$|c_1(F_n)p_2(x)| \prec \frac{n}{w_n(x)}.$$

As for the term $|c_{n+1}(F_n)||p_n(x)|$, we write with (3)

$$\begin{aligned} |c_{n+1}(F_n)||p_n(x)| &\prec \frac{\|wf\|}{w_n(x)\varphi_n^{1/2}(x)} \left(\int_{|x-t|\geq\varphi_n(x)/n} \frac{|p_{n+1}(t)|w(t)}{|x-t|}\, dt\right) \\ &\prec \frac{1}{w_n(x)\varphi_n^{1/2}(x)} \int_{|x-t|>\varphi_n(x)/n} \frac{1}{|x-t|\varphi_n^{1/2}(t)}\, dt, \end{aligned} \tag{17}$$

and so the inequality

$$\int_{|x-t|>\varphi_n(x)/n} \frac{1}{|x-t|\varphi_n^{1/2}(t)}\, dt \prec n\varphi_n^{1/2}(x), \tag{18}$$

which we prove in a short while, gives the estimate

$$|c_{n+1}(F_n)||p_n(x)| \prec \frac{n}{w_n(x)}.$$

Collecting our estimates we finally arrive at

$$|\sigma_n(f;x)| \prec \frac{1}{w_n(x)} \tag{19}$$

provided $\|wf\| \leq 1$, by which the inequality

$$\|w_n\sigma_n(f)\|_\infty \leq C\|wf\|_\infty \tag{20}$$

has been verified.

It remains to show (18) to complete the case $p = \infty$. Suppose for example that $0 \leq x < 1$. If $x > 1 - 4/n^2$, then the integral is obviously bounded by

$$\prec \int_0^{1-n^{-2}} \frac{1}{(1-t)^{5/4}}\, dt \prec n^{1/2} \prec n\varphi_n^{1/2}(x).$$

If, however, $0 \le x < 1 - 4/n^2$, then we write for the the integral

$$\int_{\varphi_n(x)/n \le |x-t| \le (1-x)/2} + \int_{t-x>(1-x)/2} + \int_{x-t>(1-x)/2}$$
$$\prec \frac{1}{\varphi_n^{1/2}(x)} \int_{\varphi_n(x)/n \le |x-t| \le (1-x)/2} \frac{1}{|x-t|} dt + \frac{1}{(1-x)} \int_{t-x>(1-x)/2} \frac{1}{(1-t)^{1/4}}\, dt$$
$$+ \int_{x-t>(1-x)/2} \frac{1}{(1-t)^{5/4}}\, dt \prec \frac{1}{\varphi_n^{1/2}(x)} \log \frac{n(1-x)}{2\varphi_n(x)} + \frac{(1-x)^{3/4}}{(1-x)} + \frac{1}{(1-x)^{1/4}}$$
$$\prec n\varphi_n^{1/2}(x),$$

where we used that $n\varphi_n(x) \ge 1$, and $(\log u)/u$ is bounded for $u \in [1, \infty)$.

We shall also need that

$$\|w_n \varphi_n \sigma_n(f)\|_\infty \le C \|w\varphi_n f\|_\infty. \tag{21}$$

If we go through the preceding proof we can see that there are three places where the assumption $\|wf\|_\infty \le 1$ is used, and these are when we estimated the integrals

$$I_k(x) = \int_{|x-t| \le \varphi_n(x)/n} f(t) K_k(x,t) w^2(t) dt,$$
$$B_n(x) := \left(\int_{|x-t| > \varphi_n(x)/n} \frac{f(t)^2 w(t)^2}{(x-t)^2} dt \right)^{1/2},$$

and

$$R_n(x) := \int_{|x-t| \ge \varphi_n(x)/n} \frac{|f(t) p_{n+1}(t)| w^2(t)}{|x-t|}\, dt,$$

and for these we got the estimates

$$|I_k(x)| \prec \|wf\| \left(\frac{\varphi_n(x)}{n} \right)^{1/2} \lambda_{k+1}^{-1/2}(x), \tag{22}$$

$$|B_n(x)| \prec \|wf\| \left(\frac{n}{\varphi_n(x)} \right)^{1/2}, \tag{23}$$

and

$$R_n(x) \prec \|wf\| n\varphi_n^{1/2}(x) \tag{24}$$

(see (15)–(18)).

Since

$$\varphi_n(x) \sim \varphi_n(t) \quad \text{when } |x-t| < \frac{\varphi_n(x)}{n},$$

together with the first one we can also get

$$\varphi_n(x) |I_k(x)| \prec \|w_n \varphi_n f\| \left(\frac{\varphi_n(x)}{n} \right)^{1/2} \lambda_{k+1}^{-1/2}(x). \tag{25}$$

To prove the analogue of (23) we write

$$\varphi_n(x)B_n(x) \le \|w_n\varphi_n f\| \left(\int_{|x-t|>\varphi_n(x)/n} \frac{1}{(x-t)^2\varphi_n(t)^2} dt \right)^{1/2} \varphi_n(x). \tag{26}$$

Here the estimate of the integral is similar to that of (18). In fact, suppose $0 \le x < 1$. Then the integral can be restricted to $0 \le t \le 1$, because the integral over this range majorizes that of over the range $-1 \le t \le 0$. If $x > 1 - 4/n^2$, then the integral is bounded by

$$2\frac{n}{\varphi_n(x)}n^2 \le 2\frac{n}{\varphi_n(x)}\frac{1}{\varphi_n^2(x)}.$$

Similarly, for all $0 \le x < 1$,

$$\int_{\substack{1-4/n^2\le t\le 1\\ |x-t|\ge\varphi_n(x)/n}} \frac{1}{(x-t)^2\varphi_n(t)^2}\, dt \prec \frac{1}{n^2}\frac{1}{\varphi_n^4(x)}n^2 \prec \frac{n}{\varphi_n(x)}\frac{1}{\varphi_n^2(x)}$$

(check this separately for $x > 1 - 8n^{-2}$ and for $x \le 1 - 8n^{-2}$). If, however, $0 \le x < 1 - 4/n^2$, then for the rest of the integral we write

$$\begin{aligned} &= \int_{\substack{\varphi_n(x)/n\le|x-t|\le(1-x)/2\\ 0\le t\le 1-4/n^2}} + \int_{\substack{t-x>(1-x)/2\\ 0\le t\le 1-4/n^2}} + \int_{\substack{x-t>(1-x)/2\\ 0\le t\le 1-4/n^2}} \\ &\prec \frac{1}{\varphi_n^2(x)} \int_{\varphi_n(x)/n\le|x-t|\le(1-x)/2} \frac{1}{(x-t)^2}\, dt + \frac{1}{(1-x)^2}\int_{\substack{t-x>(1-x)/2\\ 0\le t\le 1-4/n^2}} \frac{1}{1-t}dt \\ &\quad + \int_{\substack{x-t>(1-x)/2\\ 0\le t\le 1-4/n^2}} \frac{1}{(1-t)^3}dt \prec \frac{n}{\varphi_n(x)}\frac{1}{\varphi_n^2(x)} + \frac{1}{(1-x)^2}\log(n^2(1-x)) + \frac{1}{(1-x)^2}. \end{aligned}$$

Since $0 \le x \le 1 - 4/n^2$, we have

$$\frac{1}{(1-x)^2}\log(n^2(1-x)) \prec \frac{1}{\varphi_n(x)^4}\log(n^2\varphi_n^2(x)) \prec \frac{n}{\varphi_n(x)}\frac{1}{\varphi_n^2(x)}$$

because $n\varphi_n(x) \ge 1$, and $(\log u)/u$ is bounded for $u \in [1, \infty)$.

Thus, we get

$$\varphi_n(x)B_n(x) \le \|w_n\varphi_n f\| \left(\frac{n}{\varphi_n(x)}\right)^{1/2}. \tag{27}$$

Finally, the analogue of (24), namely, that

$$\varphi_n(x) \int_{|x-t|\ge\varphi_n(x)/n} \frac{|f(t)p_{n+1}(t)|w^2(t)}{|x-t|}\, dt \prec \|w\varphi_n f\| n\varphi_n^{1/2}(x), \tag{28}$$

can be verified with the method that we used in the proof of (18).

Using (25), (27), and (28) instead of (22)–(24) we can prove (21) with the same argument that we used for (20). In fact, the rest of the proof is the same, word for word, as before.

3.2. The case $p = 1$. To obtain (14) for $p = 1$ from the same inequality with $p = \infty$, we use a standard duality argument. But first we need the following: if P_m is a polynomial of degree at most m, then for every $c > 0$ there is a constant C such that

$$\|w_m P_m\|_p \le C\|w_m P_m\|_{L^p[-1+cm^{-2},1-cm^{-2}]}. \tag{29}$$

Actually we shall need this inequality only for some $c > 0$, but once it is verified with a $c > 0$, we can get it for larger and larger c's (and eventually for all c) by dilation and iteration. Thus, let $c > 0$ be a small number.

The Chebyshev–Markov inequality (2) implies

$$\|w_m P_m'\|_p \le C_1 m^2 \|w_m P_m\|_p. \tag{30}$$

We write

$$Q_m(x) := P_m(x) - P_m(x(1 - cm^{-2})) = \int_{x(1-cm^{-2})}^{x} P_m'(t)\, dt,$$

and use the fact that

$$\left|\frac{w_m(x)}{w_m(y)} - 1\right| \le \eta(c) \quad \text{if } |x - y| \le \frac{c}{m^2}, \tag{31}$$

where $\eta(c) \to 0$ as $c \to 0$. We can easily get from this and (30) combined with Hölder's inequality, that

$$\|w_m Q_m\|_p \le \varepsilon(c)\|w_m P_m\|_p,$$

where $\varepsilon(c) \to 0$ as $c \to 0$. This, together with (31), implies

$$\left\|w_m(x(1 - cm^{-2}))P_m(x(1 - cm^{-2}))\right\|_p > \tfrac{1}{2}\|w_m P_m\|_p$$

for sufficiently small c, and this is the same as (29).

Let us now return to (14) with $p = 1$. We use (29), and observe that on the interval $[-1 + c/n^2, 1 - c/n^2]$ we have $w(x) \sim w_n(x)$. Hence

$$\begin{aligned}\|w_n\sigma_n(f)\|_1 &\le C\int_{-1+c/n^2}^{1-c/n^2} w(t)|\sigma_n(f,t)|dt \\ &= C\sup_{\|wg\|_\infty \le 1}\int_{-1}^{1}\sigma_n(f,t)g(t)w^2(t)dt,\end{aligned}$$

where the supremum is taken for all g that vanish outside the interval

$$[-1 + c/n^2, 1 - c/n^2]$$

and satisfy $\|wg\|_\infty \le 1$. Continuing this inequality, we get from (14) with $p = \infty$

$$\begin{aligned}\|w_n\sigma_n(f)\|_1 &\le C\sup_g \int_{-1}^{1} f(t)\sigma_n(g,t)w^2(t)dt \\ &\le C\sup_g \|w\sigma_n(g)\|_\infty \left(\int w|f|\right) \\ &\le C\sup_g \|wg\|_\infty \|wf\|_1 \le C\|wf\|_1.\end{aligned}$$

3.3. Completion of the proof. From the cases $p = 1$ and $p = \infty$ we get (14) for all $1 \le p \le \infty$ by the Riesz–Thorin theorem. □

We shall also need the delayed arithmetic means of the Jacobi expansion of a function f defined as

$$\rho_n(f,x) = 2\sigma_{2n}(f,x) - \sigma_n(f,x). \tag{32}$$

For any polynomial P_n of degree at most n we have

$$\rho_n(P_n,x) \equiv P_n(x), \tag{33}$$

and for any f the function $\rho_n(f,x)$ is a polynomial of degree at most $2n$. Furthermore, we get from (14)

$$\|w_n\rho_n(f)\|_p \le C\|wf\|_p \tag{34}$$

for all f and p.

4. Proof of the Jackson–Favard type estimate (1). We closely follow the method of Freud [13], [14]. This consists of the following steps built on one another.

Step 1. Weighted approximation in L^1 metric of a piecewise constant function with a single jump.

Step 2. Approximation of functions of bounded variation in L^1 metric.

Step 3. A Bohr-type inequality.

Step 4. The L^∞ case of (1), and a similar estimate for some linear means.

Step 5. Interpolation of the L^1 and L^∞ cases, and iteration of the obtained estimate.

The individual steps are not too long, and they go as follows.

4.1. Step 1. Approximation of Γ_ξ in L^1. Let

$$\Gamma_\xi(t) = \begin{cases} 0 & \text{if } -1 \le t \le \xi, \\ 1 & \text{if } \xi < t < 1. \end{cases}$$

It is well known (see [12]) that

$$E_n(\Gamma_\xi)_{w_n,1} \le \lambda_{[n/2]+2}(w_n,\xi) = \int \lambda_{[n/2]+2}(w_n,t)d\Gamma_\xi(t). \tag{35}$$

4.2. Step 2. Approximation of functions of bounded variation in L^1. If f is a right continuous function of bounded variation, and

$$f_m(x) = f(-1) + \sum_{k=1}^{2m}\left[f\left(-1+\frac{k}{m}\right) - f\left(-1+\frac{k-1}{m}\right)\right]\Gamma_{-1+k/m}(x),$$

then $f_m \to f$ in $L^1[-1,1]$ and

$$\int \lambda_{[n/2]+2}(w_n,t)|df_m(t)| \to \int \lambda_{[n/2]+2}(w_n,t)|df(t)|$$

as $m \to \infty$. By (35),

$$\begin{aligned} E_n(f_m)_{w_n,1} &\le \sum_{k=1}^{2m}\left|f\left(-1+\frac{k}{m}\right) - f\left(-1+\frac{k-1}{m}\right)\right| E_n(\Gamma_{-1+k/m})_{w_n,1} \\ &\le \int \lambda_{[n/2]+2}(w_n,t)|df_m(t)|, \end{aligned}$$

and for $m \to \infty$ we obtain

$$E_n(f)_{w_n,1} \le \int \lambda_{[n/2]+2}(w_n,t)|df(t)| \prec \frac{1}{n}\int w_n(t)\varphi_n(t)|df(t)|, \tag{36}$$

where, at the very last step we made use of (8).

4.3. Step 3. A Bohr-type inequality. We show that if

$$\int_{-1}^{1} gP_n w^2 = 0$$

for every polynomial P_n of degree at most n, then

$$w_n(x)\left|\int_0^x g(t)dt\right| \prec \frac{1}{n}\|w_n\varphi_n g\|_\infty. \tag{37}$$

Without loss of generality let $0 \le x < 1$, and consider first the case $0 \le x \le 1 - 1/n^2$. Let

$$\phi_x(t) = \begin{cases} w^{-2}(t) & \text{if } t \in [0,x], \\ 0 & \text{otherwise.} \end{cases}$$

With an appropriate polynomial P_n of degree at most n

$$\left|\int_0^x g(t)dt\right| = \left|\int g(t)(\phi_x(t) - P_n(t))w^2(t)dt\right| \le \|w\varphi_n g\|_\infty E_n(\phi_x)_{w_n/\varphi_n,1},$$

and if we use (36) for the weight $w_n/\varphi_n \sim (w/\varphi)_n$ rather than for w_n, then we can continue this as

$$\prec \|w\varphi_n g\|_\infty \frac{1}{n}\int w_n(t)|d\phi_x(t)|$$

$$\prec \|w\varphi_n g\|_\infty \frac{1}{n}\left(\frac{1}{w_n(x)} + \frac{1}{w_n(0)} + \int_0^x w_n(t)|(w^{-2}(t))'|dt\right).$$

Here

$$\left|\left(\frac{1}{w^2(t)}\right)'\right| \prec \frac{1}{w^2(t)\varphi^2(t)};$$

hence for $0 \le x \le 1 - 1/n^2$,

$$\int_0^x w_n(t)|(w^{-2}(t))'|dt \prec \int_0^x \frac{1}{w(t)\varphi^2(t)}dt \prec \int_0^x \frac{1}{(1-t)^{\alpha+1}}dt \prec \frac{1}{w(x)} \prec \frac{1}{w_n(x)}.$$

Since $w_n(x) \prec w_n(0)$, (37) follows from the previous computations.

To prove (37) for the case $1 - 1/n^2 \le x \le 1$, as well, we write

$$\left|\int_0^x g(t)dt\right| \prec \left|\int_0^{1-1/n^2} + \int_{1-1/n^2}^1\right| \prec \frac{1}{n}\frac{\|w_n\varphi_n g\|_\infty}{w_n(1-1/n^2)} + \|w_n\varphi_n g\|_\infty \int_{1-1/n^2}^1 n^{2\alpha+1}$$
$$\prec \frac{1}{n}\|w_n\varphi_n g\|\frac{1}{w_n(x)},$$

which is what we needed to prove.

4.4. Step 4. The L^∞ case of (1). Set

$$g = f' - \rho_{[n/2]-1}(f', x),$$

where the $\rho_k(f;x)$'s are the means defined in (32). We obtain from (33) that the preceding lemma can be applied to g with n replaced by $[n/2]-1$. This yields

$$E_n(f)_{w_n,\infty} \le \|w_n(x)\int_0^x g(t)dt\|_\infty$$
$$\prec \frac{1}{n}\|w_n\varphi_n(f' - \rho_{[n/2]-1}(f', x))\|_\infty$$
$$\prec \frac{1}{n}\|w_n\varphi_n f'\|_\infty,$$

where at the last step we used (21).

Since $\rho_n(P_n) \equiv P_n$ for every polynomial of degree at most n, we also get from the preceding estimate with some appropriate P_n that

$$\|w_n(f-\rho_n(f))\|_\infty = \|w_n\left((f-P_n) - \rho_n(f-P_n)\right)\|_\infty \tag{38}$$
$$\prec E_n(f)_{w_n,\infty} \prec \frac{1}{n}\|w_n\varphi_n f'\|_\infty,$$

where in the last but one step we applied the main result of §3, namely (14).

4.5. Step 5. Interpolation of the L^1 and L^∞ cases and iteration of the estimate obtained. We know from Step 2 that with some appropriate P_n,

$$\|w_n(f-\rho_n(f))\|_1 = \|w_n\left((f-P_n) - \rho_n(f-P_n)\right)\|_1 \tag{39}$$
$$\prec E_n(f)_{w_n,1} \prec \frac{1}{n}\|w_n\varphi_n f'\|_1,$$

where we once more utilized (14).

From (38) and (39) we get for any $1 \le p \le \infty$ by interpolation,

$$\|w_n(f-\rho_n(f))\|_p \prec \frac{1}{n}\|w_n\varphi_n f'\|_p;$$

apply interpolation to the operator defined for $h = w_n\varphi_n f'$ as

$$Th(x) = (f(x) - \rho_n(f,x))w_n(x)$$
$$= \left(\int_0^x \frac{h(t)}{w_n(t)\varphi_n(t)}dt - \rho_n\left(\int_0 \frac{h(t)}{w_n(t)\varphi_n(t)}dt; x\right)\right)w_n(x).$$

This yields

$$E_{2n}(f)_{w_n,p} \prec \frac{1}{n}\|w_n\varphi_n f'\|_p,$$

and hence

$$E_n(f)_{w_n,p} \le E_{2[n/2]}(f)_{w_{[n/2],p}} \prec \frac{1}{n}\|w_{[n/2]}\varphi_{[n/2]}f'\| \prec \frac{1}{n}\|w_n\varphi_n f'\|,$$

which in turn implies by subtracting an appropriate polynomial of degree at most $n-1$ from f that

$$E_n(f)_{w_n,p} \prec \frac{1}{n}E_{n-1}(f')_{w_n\varphi_n,p}.$$

This is already in a form that can be iterated (note that $w_n(x) \sim w_{n-1}(x)$), and we obtain

$$E_n(f)_{w_n,p} \prec \frac{1}{n^m}E_{n-m}(f^{(m)})_{w_n\varphi_n^m,p}$$

for every $m \ge 1$, which shows that

$$E_n(f)_{w_n,p} \prec \frac{1}{n^m}\|w_n\varphi_n^m f^{(m)}\|_p,$$

as we claimed in (1).

THE C_ℓ ROGERS–SELBERG IDENTITY*

STEPHEN C. MILNE†

Abstract. In this paper the classical Rogers–Selberg identity is extended to the setting of multiple basic hypergeometric series very well poised on symplectic C_ℓ groups. The C_ℓ Rogers–Selberg identity is deduced from the C_ℓ q-Whipple transformation. Schur functions and q-Kostka polynomials are then used to simplify the balanced "sum side" of these identities. A study of several special limiting cases then provides an elegant generalization of how the classical Rogers–Selberg identity is simplified termwise in the standard analytical proofs of the Rogers–Ramanujan identities. For C_2, explicit Rogers–Ramanujan-type identities are obtained. One of these gives a new expansion, involving q-Kostka polynomials, of the product side of one of Bressoud's (mod 6) Rogers–Ramanujan identities. It is also found that a similar analysis applied to the C_ℓ terminating ${}_6\phi_5$ summation theorem leads to a C_ℓ extension of Sylvester's identity. Special limiting C_2 and C_3 cases of this identity give new expansions of the products in the simplest classical Kac–Peterson identities. The work in this paper is motivated by the unitary A_ℓ case and the classical case corresponding to A_1 or, equivalently, to $U(2)$.

Key words. multiple basic hypergeometric series, very well poised on symplectic groups C_ℓ, C_ℓ terminating ${}_6\phi_5$ summation theorem, C_ℓ q-Whipple transformation, Rogers–Ramanujan identities, Kac–Peterson identities, Schur functions, q-Kostka polynomials

AMS subject classifications. primary 33D70, 05A19; secondary 05E05, 05A17

1. Introduction.

The purpose of this paper is to extend the classical Rogers–Selberg identity to the setting of multiple basic hypergeometric series very well poised on symplectic C_ℓ groups [Gus89], [LM91], [ML92a], [ML92b], and then to study several special limiting cases. The motivation for this work was to extend the analysis in Watson's [Wat29a] proof of the Rogers–Ramanujan identities to the C_ℓ case. This program depends on the C_ℓ q-Whipple transformation from [ML92b], which we stated in Theorem A.3 of Appendix A. Our analysis provides an elegant C_ℓ generalization of how the classical Rogers–Selberg identity is simplified termwise in the standard analytical proofs of the Rogers–Ramanujan identities. For C_2 we are able to obtain explicit Rogers–Ramanujan-type identities. One of these gives a new expansion, involving q-Kostka polynomials, of the product side of one of Bressoud's (mod 6) Rogers–Ramanujan identities [Bre80].

Our work on the C_ℓ case is motivated by the previous analysis of the unitary A_ℓ or, equivalently, the $U(\ell+1)$ case from [Mil88b], [Mil89], [Mil92]. The classical case of this work corresponds to A_1 or, equivalently, to $U(2)$. The ordinary ($q=1$) case of some of the multiple series in [Mil88a], [Mil88b], [Mil89] first appeared in certain applications of mathematical physics and the unitary groups $U(n+1)$ or, equivalently, A_n. This earlier work on the theory of Wigner coefficients for $SU(n)$ was due to Biedenharn, Holman, and Louck [BL68], [BL81a], [BL81b], [Hol80], [HBL76]. They showed in [Hol80], [HBL76] how the classical work on ordinary hypergeometric series is intimately related to the irreducible representations of the compact group $SU(2)$.

At this point it is useful to recall the classical Rogers–Selberg identity. Let q be a complex number such that $|q| < 1$. Define

$$(\alpha)_\infty \equiv (\alpha;q)_\infty := \prod_{k\geq 0}(1-\alpha q^k), \tag{1.1a}$$

$$(\alpha)_n \equiv (\alpha;q)_n := (\alpha)_\infty / (\alpha q^n)_\infty . \tag{1.1b}$$

For products of q-shifted factorials we use the more compact notation

$$(a_1,a_2,\dots,a_m;q)_\infty = (a_1;q)_\infty (a_2;q)_\infty \cdots (a_m;q)_\infty . \tag{1.2}$$

We then have the classical Rogers–Selberg identity [GR90, p. 37, eq. (2.7.6)] in

$$\begin{aligned} &1+\sum_{k=1}^{\infty} \frac{(aq;q)_{k-1}\,(1-aq^{2k})}{(q;q)_k}\,(-1)^k\,a^{2k}\,q^{k(5k-1)/2} \\ &\qquad = (aq;q)_\infty \sum_{k=0}^{\infty} \frac{a^k q^{k^2}}{(q;q)_k}. \end{aligned} \tag{1.3}$$

Most of the standard analytical proofs [And76], [And86], [Bai35], [GR90], [HW79], [Sla66], [Wat29a] of the Rogers–Ramanujan identities first established (1.3). Watson [Wat29a] obtains (1.3) as a special limiting case of his q-analog of Whipple's [Whi24], [Whi26] classical transformation of a very well poised ${}_7F_6(1)$ into a balanced ${}_4F_3(1)$. Setting $a=1$ or $a=q$ in (1.3), they next observe that the left side of (1.3) simplifies termwise into a theta function, which can be summed by Jacobi's [Jac29] well-known triple-product identity in Theorem A.5 of Appendix A. They then immediately obtain the classical Rogers–Ramanujan identities [And76, Chap. 7], [Rog94]

$$\sum_{k=0}^{\infty} \frac{q^{k^2}}{(q;q)_k} = \frac{1}{(q;q^5)_\infty\,(q^4;q^5)_\infty} \tag{1.4}$$

and

$$\sum_{k=0}^{\infty} \frac{q^{k^2+k}}{(q;q)_k} = \frac{1}{(q^2;q^5)_\infty\,(q^3;q^5)_\infty}, \tag{1.5}$$

respectively.

In Theorem 2.1 of §2 we obtain the C_ℓ Rogers–Selberg identity from a limiting case of the C_ℓ q-Whipple transformation in Theorem A.3. The single parameter a in (1.3) becomes the parameters $x_1,\dots,x_\ell$ in Theorem 2.1. We then appeal to the symmetric function and q-difference-equation techniques of [Mil92] to rewrite the balanced multiple sum (2.2c) on the right side of Theorem 2.1 as the sum of products of q-Kostka polynomials $K_{\mu(2^m)}(q)$ and Schur functions $s_\mu(x_1,\dots,x_\ell)$ in Corollary 2.21. This facilitates specializing the $x_1,\dots,x_\ell$ in Theorem 2.1.

The $q\mapsto q^\ell$, $x_k \mapsto q^{k-1}$ specialization of the C_ℓ Rogers–Selberg identity in §3 generalizes what happens to (1.3) when $a=1$. The resulting termwise simplification of (2.22a) is given by Lemma 3.2. Keeping in mind the standard formula for

the specialized Schur function $s_\mu(1, q, \dots, q^{\ell-1})$, we then arrive at the specialized C_ℓ Rogers–Selberg identity in Theorem 3.23. For $\ell = 2$ we are able to express (3.24a) as a double Laurent series, which is then factored into the product of two one-dimensional theta functions. Each of these is then summed by the Jacobi triple-product identity (A.6). That is, for C_2 we obtain the explicit Rogers–Ramanujan-type identity in Theorem 3.26. The sum in (3.27a) gives a new expansion, involving q-Kostka polynomials $K_{(2m-y,y)(2^m)}(q^2)$, of one of Bressoud's (mod 6) Rogers–Ramanujan identities [Bre80]. Theorem 3.26 is the C_2 generalization of the first Rogers–Ramanujan identity in (1.4). Other specializations of the $\ell = 2$ case of (2.22a), such as $\{q \mapsto q^2, x_1 \mapsto q, x_2 \mapsto q^2\}$ and $\{q \mapsto q, x_1 = x_2 = q\}$, do not factor into a single, simple infinite product. Thus (1.5) does not extend to the C_2 case. Moreover, the multiple sum (3.24a) does not appear to factor into a single, simple infinite product when $\ell \geq 3$.

We find in §4 that a limiting case of the C_ℓ terminating ${}_6\phi_5$ summation in Theorem A.1 gives the C_ℓ Sylvester identity in Theorem 4.1. The same calculation that is performed in the proof of Lemma 3.2 then specializes Theorem 4.1 into the C_ℓ Euler pentagonal-number theorem in (4.4). The $\ell = 2$ and $\ell = 3$ cases of Theorem 4.3 lead to new expansions of the infinite products $(q;q)_\infty$, $(q^2;q^2)_\infty$, and $(q;q)_\infty^2$, which appear in the simplest classical Kac–Peterson identities [Rog94], [Hec59], [KP80], [And84a], [Bre86].

In §5 we show that the $\{q \mapsto q, x_1 = x_2 = 1\}$ specialization of the $\ell = 2$ case of (2.22a) can be transformed into the one-dimensional Laurent series (5.13), which is then summed by appealing to the derivative of the quintuple-product identity (A.8). We then have the $x_1 = x_2 = 1$ C_2 Rogers–Ramanujan identity in Theorem 5.15. Just as for (3.24a), the $x_1 = \cdots = x_\ell = 1$ case of (2.22a) does not appear to factor into a single, simple infinite product when $\ell \geq 3$. However, as illustrated by Corollary 5.20, this specialization of (2.22a) should be equivalent to multiple Laurent series similar to those in [Mac72, Appendix I].

2. C_ℓ Rogers–Selberg identities. Motivated by Watson's [Wat29a] proof of the Rogers–Ramanujan identities, we begin this section with the following theorem.

THEOREM 2.1 (first version of C_ℓ Rogers–Selberg identity). *Let $x_1, \dots, x_\ell$ be indeterminate, $\ell \geq 1$, $0 < |q| < 1$, and suppose that none of the denominators in* (2.2) *vanishes. Then*

$$\begin{aligned}
&\sum_{\substack{y_k \geq 0 \\ k=1,2,\dots,\ell}} \left\{ \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \, \frac{1 - x_r x_s q^{y_r + y_s}}{1 - x_r x_s} \right] \right. \\
&\qquad \times \prod_{k=1}^{\ell} \left[\frac{1 - x_k^2 q^{2y_k}}{1 - x_k^2} \right] \prod_{r,s=1}^{\ell} \left[\frac{(x_r x_s)_{y_r}}{\left(q \frac{x_r}{x_s}\right)_{y_r}} \right] \\
&\qquad \times \left[(-1)^{\ell(y_1 + \cdots + y_\ell)} \prod_{k=1}^{\ell} x_k^{(\ell+4)y_k - (y_1 + \cdots + y_\ell)} \right] \\
&\qquad \left. \times \left[q^{y_2 + 2y_3 + \cdots + (\ell-1)y_\ell} \, q^{((\ell+4)/2)(y_1^2 + \cdots + y_\ell^2) - (\ell/2)(y_1 + \cdots + y_\ell)} \right] \right\} \qquad \text{(2.2a)} \\
&\qquad = \left\{ \prod_{k=1}^{\ell} (q x_k^2)_\infty \prod_{1 \leq r < s \leq \ell} (q x_r x_s)_\infty \right\} \qquad \text{(2.2b)}
\end{aligned}$$

$$\times \sum_{\substack{m_k \geq 0 \\ k=1,2,\dots,\ell}} \left\{ \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{m_r - m_s}}{1 - \frac{x_r}{x_s}} \right] \prod_{r,s=1}^{\ell} \left(q \frac{x_r}{x_s} \right)_{m_r}^{-1} \right.$$

$$\times \left[(-1)^{(\ell+1)(m_1+\cdots+m_\ell)} \prod_{k=1}^{\ell} x_k^{(\ell+2)m_k - (m_1+\cdots+m_\ell)} \right]$$

$$\times \left[q^{m_2+2m_3+\cdots+(\ell-1)m_\ell} \, q^{(\ell+2)\left[\binom{m_1}{2}+\cdots+\binom{m_\ell}{2}\right]} \right]$$

$$\left. \times \left[q^{m_1+\cdots+m_\ell} \, q^{-\binom{m_1+\cdots+m_\ell}{2}} \right] \right\}. \tag{2.2c}$$

Proof. Apply the relation $(a)_n = (-a)^n q^{\binom{n}{2}} (a^{-1}q^{1-n})_n$ to the appropriate factors in (A.4), simplify, and then take the limits $b \to 0$, $\beta \to 0$, $a \to \infty$, $\alpha \to \infty$, and $N_1 \to \infty, \dots, N_\ell \to \infty$ in Theorem A.3, while appealing to the dominated convergence theorem. To check the convergence of (2.2a), first observe that by using the product formula for a Vandermonde determinant and some algebra,

$$\prod_{1 \leq r < s \leq \ell} \left[1 - \frac{x_r}{x_s} q^{y_r - y_s} \right]$$

$$= \prod_{k=1}^{\ell} x_k^{1-k} \sum_{\sigma \in \mathcal{S}_\ell} \varepsilon(\sigma) \prod_{k=1}^{\ell} x_{\sigma(k)}^{k-1} \prod_{k=1}^{\ell} q^{(\sigma^{-1}(k)-k)y_k}. \tag{2.3}$$

Then, interchange summation and apply the multiple power-series-ratio test [AK26], [Hor89], [MS73] to each of the resulting $\ell!$ inner multiple sums.

For (2.2c) we use the comparison test and the same argument applied to the dominating multiple series determined by replacing

$$q^{(\ell+2)\left[\binom{m_1}{2}+\cdots+\binom{m_\ell}{2}\right]} \, q^{-\binom{m_1+\cdots+m_\ell}{2}} \tag{2.4a}$$

by

$$q^{(m_1^2+\cdots+m_\ell^2)-((\ell+1)/2)(m_1+\cdots+m_\ell)}. \tag{2.4b}$$

This last step depends on the identity

$$(\ell+2)\left[\binom{m_1}{2}+\cdots+\binom{m_\ell}{2}\right] - \binom{m_1+\cdots+m_\ell}{2}$$

$$= (m_1^2+\cdots+m_\ell^2) - \tfrac{(\ell+1)}{2}(m_1+\cdots+m_\ell) + \tfrac{1}{2} \sum_{1 \leq r < s \leq \ell} (m_r - m_s)^2. \qquad \square \tag{2.5}$$

Remark. The $\ell = 1$ case of (2.2) is the classical Rogers–Selberg identity in (1.3), in which $a = x_1^2$.

The analytical and combinatorial techniques in [Mil92] lead to a substantial simplification of the multiple sum in (2.2c), once we sum over the diagonals

$$m_1 + \cdots + m_\ell = m \quad \text{for} \quad m \geq 0. \tag{2.6}$$

For convenience, we work with the slightly more general diagonal sum determined by

(2.7)

$$
\begin{aligned}
&[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell)\\
&\quad:=\left[(-1)^{(\ell+1)m}\,(x_1\cdots x_\ell)^{-m}\,q^m\,q^{-\binom{m}{2}}\right]\\
&\qquad\times\sum_{\substack{m_k\geq 0\\ k=1,2,\dots,\ell\\ m_1+\cdots+m_\ell=m}}\left\{\prod_{1\leq r<s\leq\ell}\left[\frac{1-\frac{x_r}{x_s}q^{m_r-m_s}}{1-\frac{x_r}{x_s}}\right]\prod_{r,s=1}^{\ell}\left(q\frac{x_r}{x_s}\right)_{m_r}^{-1}\right.\\
&\qquad\qquad\left.\times\left[q^{m_2+2m_3+\cdots+(\ell-1)m_\ell}\,q^{(\ell+b)\left[\binom{m_1}{2}+\cdots+\binom{m_\ell}{2}\right]}\prod_{k=1}^{\ell}x_k^{(\ell+b)m_k}\right]\right\}.
\end{aligned}
$$

It is clear that (2.2c) equals

$$
\sum_{m=0}^{\infty}[G]_m^{(\ell)}(q;2;x_1,\dots,x_\ell). \tag{2.8}
$$

The first step in simplifying (2.8) is to show that $[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell)$ satisfies the q-difference equation in the following lemma.

LEMMA 2.9. *Let $[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell)$ be determined by* (2.7), *with $\ell\geq 1$ and $m\geq 1$. We then have*

$$
\begin{aligned}
&[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell) \qquad\qquad (2.10a)\\
&\quad=\sum_{p=1}^{\ell}\left[(-1)^{\ell-1}\,\frac{q}{1-q^m}\,x_p^{\ell+b-1}\prod_{\substack{r=1\\ r\neq p}}^{\ell}(x_r-x_p)^{-1}\right]\\
&\qquad\times[G]_{m-1}^{(\ell)}(q;b;x_1q^{\delta_{1,p}},\dots,x_\ell q^{\delta_{\ell,p}}), \qquad\qquad (2.10b)
\end{aligned}
$$

where $\delta_{r,s}$ is 1 if $r=s$ and is 0 otherwise.

Proof. The analysis is identical to that in [Mil92, §3]. Substitute (2.7) into (2.10b), and simplify. Group together all terms such that $(m_1,\dots,m_p+1,\dots,m_\ell)$ is the same ℓ-tuple as $(w_1,\dots,w_p,\dots,w_\ell)$ for some p. We then obtain the double sum

(2.11a)

$$
\begin{aligned}
&\left[(-1)^{(\ell+1)m}\,(x_1\cdots x_\ell)^{-m}\,q^m\,q^{-\binom{m}{2}}\,\frac{1}{1-q^m}\right]\\
&\qquad\times\sum_{\substack{w_k\geq 0\\ k=1,2,\dots,\ell\\ w_1+\cdots+w_\ell=m}}\left\{\prod_{1\leq r<s\leq\ell}\left[\frac{1-\frac{x_r}{x_s}q^{w_r-w_s}}{1-\frac{x_r}{x_s}}\right]\prod_{r,s=1}^{\ell}\left(q\frac{x_r}{x_s}\right)_{w_r}^{-1}\right.
\end{aligned}
$$

(2.11b)

$$
\left.\times\left[q^{w_2+2w_3+\cdots+(\ell-1)w_\ell}\,q^{(\ell+b)\left[\binom{w_1}{2}+\cdots+\binom{w_\ell}{2}\right]}\prod_{k=1}^{\ell}x_k^{(\ell+b)w_k}\right]\right\}
$$

(2.11c)

$$\times \sum_{p=1}^{\ell}(1-q^{w_p}) \prod_{\substack{k=1\\k\neq p}}^{\ell}\left[\frac{1-\frac{x_k}{x_p}q^{w_k}}{1-\frac{x_k}{x_p}}\right].$$

It is immediate that the sum in (2.11c) is the $y_i = q^{w_i}$ case of

$$1-y_1y_2\cdots y_\ell = \sum_{p=1}^{\ell}(1-y_p) \prod_{\substack{k=1\\k\neq p}}^{\ell}\left[\frac{x_p-x_ky_k}{x_p-x_k}\right], \tag{2.12}$$

where the $\{x_i\}$ are distinct. Direct, elementary proofs of (2.12) appear in [Mil88a, §8]. Hence the sum in (2.11c) equals

$$1-q^{w_1+\cdots+w_\ell} = 1-q^m,$$

and the proof of Lemma 2.9 is complete. □

We next use [Mil92] to write the solution of the q-difference equation (2.10) in terms of Schur functions $s_\lambda(x_1,\dots,x_\ell)$ and q-Kostka polynomials $K_{\lambda\mu}(q)$.

Let $\lambda = (\lambda_1,\lambda_2,\dots,\lambda_r,\dots)$ be a partition of nonnegative integers in decreasing order, $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_r \cdots$, such that only finitely many of the λ_i are nonzero. The sum of the nonzero parts λ_i is denoted by $|\lambda|$, and the length $\ell(\lambda)$ is the number of nonzero parts of λ. If $|\lambda| = n$, we write $\lambda \vdash n$. The partition with exactly m parts, each equal to b, is (b^m). The conjugate partition to λ is denoted by λ', where $\lambda' = (\lambda_1',\lambda_2',\dots,\lambda_{(\lambda_1)}')$ and λ_i' is the number of parts λ_j in λ that are $\geq i$.

Given a partition $\lambda = (\lambda_1,\dots,\lambda_\ell)$ of length $\leq \ell$,

$$s_\lambda(x) \equiv s_\lambda(x_1,\dots,x_\ell) := \frac{\det(x_i^{\lambda_j+\ell-j})}{\det(x_i^{\ell-j})} \tag{2.13}$$

is the Schur function [Mac79] corresponding to the partition λ. (Here, $\det(a_{ij})$ denotes the determinant of an $\ell\times\ell$ matrix with (i,j)th entry a_{ij}). The Schur function $s_\lambda(x)$ is a symmetric polynomial in $x_1,\dots,x_\ell$ with nonnegative integer coefficients.

The q-Kostka polynomials $K_{\lambda\mu}(q)$ are the entries of the connection coefficient matrix $K(q)$ between Schur functions $s_\lambda(x)$ and Hall–Littlewood polynomials $P_\lambda(x;q)$. The matrix $K(q)$ is strictly upper unitriangular with rows and columns indexed by partitions in reverse lexicographic order, so that (n) comes first and (1^n) comes last. The entries $K_{\lambda\mu}(q)$ of $K(q)$ are polynomials in q with nonnegative integer coefficients. We have

$$s_\lambda(x) = \sum_{\mu\vdash|\lambda|} K_{\lambda\mu}(q)P_\mu(x;q). \tag{2.14}$$

It turns out that $K(0)$ is the identity matrix and that $K(1) \equiv K$ is the Kostka connection coefficient matrix between Schur functions and monomial symmetric functions. Many additional properties of $K(q)$ can be found in [Mac79, Chap. 3].

If (2.10) is kept in mind, it follows that the $\lambda = (b^m)$, $n = \ell$, $z_i = x_i$, $\gamma_i = 0$ case of [Mil92, Thms. 4.29 and 4.34] applied to

$$[F]_m^{(\ell)}(q;b;x_1,\dots,x_\ell) := q^{-m}\ (q)_m\ [G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell), \tag{2.15}$$

leads to the following lemma.

LEMMA 2.16. *Let* $[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell)$ *be determined by* (2.7), *with* $\ell \geq 1$ *and* $m \geq 1$. *We then have*

$$[G]_m^{(\ell)}(q;b;x_1,\dots,x_\ell) = \frac{q^m}{(q)_m} \sum_{\substack{\mu \geq (b^m) \\ |\mu| = bm \\ \ell(\mu) \leq \ell}} K_{\mu(b^m)}(q)\, s_\mu(x_1,\dots,x_\ell), \tag{2.17}$$

where $\mu \geq (b^m)$ *denotes the dominance of the partial sums of the parts of* μ *over those of* (b^m).

Remark. If $\ell(\mu) > \ell$, then $s_\mu(x_1,\dots,x_\ell) = 0$. Also note that $\{K_{\mu(b^m)}(q)\}$ is a column of $K(q)$ corresponding to (b^m).

Remark. By equation (4.37b) and [Mil92, Thm. 4.34], combined with [Mac79, Ex. 1, p. 18], we have

$$[F]_m^{(\ell)}(1;b;1,\dots,1) = (h_b(1,\dots,1))^m = \binom{\ell+b-1}{b}^m, \tag{2.18}$$

where $h_b(x_1,\dots,x_\ell)$ is the bth homogeneous symmetric function of $x_1,\dots,x_\ell$.

Remark. If $\ell = 1$, then the sum in (2.17) is taken over the single partition $\mu = (bm)$. From of [Mac79, ex. 1, p. 130] we have

$$K_{(bm)(b^m)}(q) = q^{b\binom{m}{2}}, \tag{2.19}$$

and, consequently,

$$[G]_m^{(1)}(q;b;x_1) = \frac{q^{m+b\binom{m}{2}}}{(q)_m}\, x_1^{bm}. \tag{2.20}$$

Relation (2.8) and the $b = 2$ case of Lemma 2.16 now immediately give the following corollary.

COROLLARY 2.21 (second version of C_ℓ Rogers–Selberg identity). *Let* $x_1,\dots,x_\ell$ *be indeterminate,* $\ell \geq 1$, $0 < |q| < 1$, *and suppose that none of the denominators in* (2.22) *vanishes. Then*

$$\begin{aligned}
&\sum_{\substack{y_k \geq 0 \\ k=1,2,\dots,\ell}} \left\{ \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \, \frac{1 - x_r x_s q^{y_r + y_s}}{1 - x_r x_s} \right] \right. \\
&\qquad \times \prod_{k=1}^{\ell} \left[\frac{1 - x_k^2 q^{2y_k}}{1 - x_k^2} \right] \prod_{r,s=1}^{\ell} \left[\frac{(x_r x_s)_{y_r}}{\left(q \frac{x_r}{x_s}\right)_{y_r}} \right] \\
&\qquad \times \left[(-1)^{\ell(y_1+\cdots+y_\ell)} \prod_{k=1}^{\ell} x_k^{(\ell+4)y_k - (y_1+\cdots+y_\ell)} \right] \\
&\qquad \left. \times \left[q^{y_2+2y_3+\cdots+(\ell-1)y_\ell}\, q^{((\ell+4)/2)(y_1^2+\cdots+y_\ell^2) - (\ell/2)(y_1+\cdots+y_\ell)} \right] \right\} \qquad \text{(2.22a)} \\
&= \left\{ \prod_{k=1}^{\ell} (q x_k^2)_\infty \prod_{1 \leq r < s \leq \ell} (q x_r x_s)_\infty \right\} \qquad \text{(2.22b)}
\end{aligned}$$

$$\times \sum_{m=0}^{\infty} \frac{q^m}{(q)_m} \sum_{\substack{\mu \geq (2^m) \\ |\mu|=2m \\ \ell(\mu)\leq \ell}} K_{\mu(2^m)}(q)\; s_\mu(x_1,\dots,x_\ell), \tag{2.22c}$$

where $\mu \geq (2^m)$ *denotes the dominance of the partial sums of the parts of* μ *over those of* (2^m).

Remark. It is clear from (2.20), with $b=2$, that the $\ell = 1$ case of (2.22) is also the classical Rogers–Selberg identity in (1.3) in which $a = x_1^2$.

For illustration purposes we conclude this section with the $m = 0,1,2,3$ cases of the inner sum in (2.22c). That is, we give $[F]_m^{(\ell)}(q;2;x)$ for $m = 0,1,2,3$. We use the notation $s_\mu(x) \equiv s_\mu(x_1,\dots,x_\ell)$ and the tables of the q-Kostka polynomials $K_{\mu\lambda}(q)$ from [Mac79, pp. 126–127]. We have the following:

$$[F]_0^{(\ell)}(q;2;x) = 1, \tag{2.23a}$$

$$[F]_1^{(\ell)}(q;2;x) = s_2(x), \tag{2.23b}$$

$$[F]_2^{(\ell)}(q;2;x) = \big\{q^2 s_4(x) + q s_{3,1}(x) + s_{2^2}(x)\big\}, \tag{2.23c}$$

$$\begin{aligned}[F]_3^{(\ell)}(q;2;x) = \big\{&q^6 s_6(x) + (q^4+q^5)s_{5,1}(x) \\ &+ (q^2+q^3+q^4)s_{4,2}(x) + q^3 s_{4,1^2}(x) \\ &+ q^3 s_{3^2}(x) + (q+q^2)s_{3,2,1}(x) + s_{2^3}(x)\big\}.\end{aligned} \tag{2.23d}$$

By [Mil92, Thm. 4.34], $[F]_m^{(\ell)}(q;b;x_1,\dots,x_\ell)$ is the $\lambda = (b^m)$ case of $H_\lambda(x;\emptyset,q)$, which is a natural q-analog of the complete homogeneous symmetric function $h_\lambda(x)$.

3. The specialized C_ℓ Rogers–Selberg identity. Motivated by [Mil92, Thms. 1.19 and 1.21] we rewrite the

$$q \mapsto q^\ell \quad \text{and} \quad x_k \mapsto q^{k-1} \quad \text{for } k = 1,2,\dots,\ell \tag{3.1}$$

case of Corollary 2.21. This generalizes a key simplification of the Rogers–Selberg identity in the standard analytical proof of the Rogers–Ramanujan identities. We first simplify (2.22a) and then deal with (2.22b) and (2.22c).

We begin with the following lemma.

LEMMA 3.2 (C_ℓ Rogers–Selberg product-side simplification). *Let* $0 < |q| < 1$ *and* $\ell \geq 1$. *Then the* (3.1) *case of* (2.22a) *can be termwise rewritten as*

$$\begin{aligned}\sum_{\substack{y_2,\dots,y_\ell \geq 0 \\ -\infty < y_1 < \infty}} \Bigg\{ &\prod_{k=1}^{\ell-1} (q;q)_{2k}^{-1} \prod_{k=2}^{\ell} (1+q^{k-1+\ell y_k}) \\ &\times \prod_{1\leq r<s\leq \ell} \left[(q^{\ell y_r} - q^{s-r+\ell y_s})\,(1-q^{r+s-2+\ell y_r+\ell y_s})\right] \\ &\times \left[(-1)^{\ell(y_1+\cdots+y_\ell)}\, q^{(\ell+4)(y_2+2y_3+\cdots+(\ell-1)\,y_\ell)}\right] \\ &\times \left[q^{(\ell(\ell+4)/2)(y_1^2+\cdots+y_\ell^2)}\, q^{(\frac{\ell}{2}-\ell^2)(y_1+\cdots+y_\ell)+\ell y_1}\right]\Bigg\}.\end{aligned} \tag{3.3}$$

Proof. We first find that the (3.1) case of the $y_1, \dots, y_\ell > 0$ term in (2.22a) simplifies to

$$\begin{aligned}(3.4)\qquad &\Bigg\{\prod_{k=1}^{\ell-1}(q;q)_{2k}^{-1}\prod_{k=1}^{\ell}(1+q^{k-1+\ell y_k})\\ &\times\prod_{1\le r<s\le\ell}\left[(q^{\ell y_r}-q^{s-r+\ell y_s})\,(1-q^{r+s-2+\ell y_r+\ell y_s})\right]\\ &\times\left[(-1)^{\ell(y_1+\cdots+y_\ell)}\,q^{(\ell+4)(y_2+2y_3+\cdots+(\ell-1)\,y_\ell)}\right]\\ &\times\left[q^{(\ell(\ell+4)/2)(y_1^2+\cdots+y_\ell^2)}\,q^{(\frac{\ell}{2}-\ell^2)(y_1+\cdots+y_\ell)}\right]\Bigg\}.\end{aligned}$$

Before applying (3.1), we used

$$(3.5)\qquad \frac{(x_1^2)_{y_1}}{(1-x_1^2)}=(qx_1^2)_{y_1-1}$$

and noted that

$$(3.6)\qquad q^{y_2+2y_3+\cdots+(\ell-1)\,y_\ell}\prod_{1\le r<s\le\ell}\left[\frac{1-\frac{x_r}{x_s}q^{y_r-y_s}}{1-\frac{x_r}{x_s}}\right]=\prod_{1\le r<s\le\ell}\left[\frac{q^{y_r}-\frac{x_s}{x_r}q^{y_s}}{1-\frac{x_s}{x_r}}\right].$$

We then used, in the following order, the relations

$$(3.7)\qquad \prod_{1\le r<s\le\ell}(1-q^{s-r})^{-1}=\prod_{k=1}^{\ell-1}(q;q)_k^{-1};$$

$$(3.8)\qquad \prod_{1\le r<s\le\ell}(1-q^{r+s-2})^{-1}=\prod_{k=1}^{\ell-1}(q^k;q)_k^{-1};$$

$$(3.9)\qquad \prod_{r,s=1}^{\ell}(q^{\ell+r-s};q^\ell)_{y_r}^{-1}=\prod_{k=1}^{\ell}(q^k;q)_{\ell y_k}^{-1};$$

$$(3.10a)\qquad (q^\ell;q^\ell)_{y_1-1}\prod_{s=2}^{\ell}(q^{s-1};q^\ell)_{y_1}=(q;q)_{\ell y_1-1};$$

$$(3.10b)\qquad \prod_{s=1}^{\ell}(q^{k+s-2};q^\ell)_{y_k}=(q^{k-1};q)_{\ell y_k}\quad\text{if } k=2,3,\dots,\ell;$$

$$(3.11)\qquad \prod_{k=1}^{\ell}(1-q^{2k-2+2\ell y_k})=\prod_{k=1}^{\ell}\left[(1+q^{k-1+\ell y_k})\,(1-q^{k-1+\ell y_k})\right].$$

At this point a crucial simplification was provided by

$$(3.12a)\qquad \left[(1-q^{\ell y_1})\,(q;q)_{\ell y_1-1}\right]/(q;q)_{\ell y_1}=1$$

and

$$\left[(1-q^{k-1+\ell y_k})\,(q^{k-1};q)_{\ell y_k}\right] / (q^k;q)_{\ell y_k} = (1-q^{k-1}) \tag{3.12b}$$

if $k = 2, 3, \ldots, \ell$. The classical case of (3.12) just amounts to setting $\ell = 1$ in (3.12a).

Finally, we arrived at (3.4) by observing that

$$\frac{(1-q^k)}{(q;q)_k\,(q^k;q)_k\,(1-q^{2k})} = (q;q)_{2k}^{-1} \tag{3.13}$$

for $k = 1, 2, \ldots, \ell - 1$.

A similar calculation shows that (3.4) also holds for $y_2, \ldots, y_\ell \geq 0$ and $y_1 > 0$.

If $y_1 = 0$, we do not need (3.5). In this case, we obtain (3.4) multiplied by $\frac{1}{2}$.

Let $(1 + q^{\ell y_1})T(y_1, \ldots, y_\ell)$ be given by (3.4). Then the (3.1) case of (2.22a) becomes

$$\sum_{y_2,\ldots,y_\ell \geq 0} T(0, y_2, \ldots, y_\ell) + \sum_{\substack{y_2,\ldots,y_\ell \geq 0 \\ y_1 > 0}} (1 + q^{\ell y_1})\, T(y_1, \ldots, y_\ell). \tag{3.14}$$

It is not hard to see that

$$q^{-\ell y_1} T(-y_1, y_2, \ldots, y_\ell) = T(y_1, \ldots, y_\ell). \tag{3.15}$$

Thus (3.14) equals

$$\sum_{\substack{y_2,\ldots,y_\ell \geq 0 \\ -\infty < y_1 < \infty}} q^{\ell y_1} T(y_1, y_2, \ldots, y_\ell), \tag{3.16}$$

and the proof is complete. □

We now consider the products in (2.22b). An elementary calculation shows that

$$\prod_{k=1}^{\ell} (q^{\ell+2k-2};q^\ell)_\infty \prod_{1 \leq r < s \leq \ell} (q^{\ell+r+s-2};q^\ell)_\infty \tag{3.17a}$$

$$= \begin{cases} \displaystyle\prod_{k=m}^{2m} (q^{1+2k};q)_\infty & \text{for } \ell = 1+2m,\ m \geq 0, \\ \displaystyle (q^{2m};q^2)_\infty \prod_{k=m}^{2m-1} (q^{1+2k};q)_\infty & \text{for } \ell = 2m,\ m \geq 1. \end{cases} \tag{3.17b}$$

To simplify the (3.1) case of (2.22c) we need an explicit formula for the specialized Schur function $s_\lambda(1, q, \ldots, q^{\ell-1})$, which appears in [Mac79], [Sta71].

Consider the Ferrers diagram of λ in which the rows and columns are arranged as in a matrix with the ith row consisting of λ_i cells. For a given cell $x = (i,j) \in \lambda$ we define the hook length $h(x)$ and content $c(x)$ as follows:

$$h(x) \equiv h(i,j) := (\lambda_i - i) + (\lambda'_j - j) + 1, \tag{3.18}$$

where λ' is the partition conjugate to λ and

$$c(x) := j - i. \tag{3.19}$$

Note that $h(x)$ is the number of cells to the right of, on, or below the cell in the (i,j) position and that $c(x)$ measures how far the cell (i,j) is from the main diagonal.

Given (3.18) and (3.19), we have

$$s_\lambda(1,q,\dots,q^{\ell-1}) = q^{n(\lambda)} \prod_{x\in\lambda} \frac{(1-q^{\ell+c(x)})}{(1-q^{h(x)})}, \tag{3.20}$$

where

$$n(\lambda) = \sum_{i\geq 1}(i-1)\lambda_i. \tag{3.21}$$

We are now ready to rewrite the (3.1) case of Corollary 2.21, in which we have multiplied both sides by

$$\prod_{k=1}^{\ell-1} (q;q)_{2k}\,. \tag{3.22}$$

Lemma 3.2 and equations (3.17) and (3.20) immediately imply that (2.22) is transformed into the following theorem.

THEOREM 3.23 (specialized C_ℓ Rogers–Selberg identity). *Let* $0<|q|<1$ *and* $\ell\geq 1$. *We then have*

$$\begin{aligned}
&\sum_{\substack{y_2,\dots,y_\ell\geq 0\\ -\infty<y_1<\infty}} \Bigg\{ \prod_{k=2}^{\ell}(1+q^{k-1+\ell y_k}) \\
&\qquad \times \prod_{1\leq r<s\leq \ell} \left[(q^{\ell y_r}-q^{s-r+\ell y_s})\,(1-q^{r+s-2+\ell y_r+\ell y_s})\right] \\
&\qquad \times \left[(-1)^{\ell(y_1+\cdots+y_\ell)}\, q^{(\ell+4)(y_2+2y_3+\cdots+(\ell-1)\,y_\ell)}\right] \\
&\qquad \times \left[q^{(\ell(\ell+4)/2)(y_1^2+\cdots+y_\ell^2)}\, q^{(\frac{\ell}{2}-\ell^2)(y_1+\cdots+y_\ell)+\ell y_1}\right]\Bigg\}. \qquad \text{(3.24a)} \\
&\quad = P(\ell;q) \sum_{m=0}^{\infty} \frac{q^{\ell m}}{(q^\ell;q^\ell)_m} \sum_{\substack{\mu\geq(2^m)\\ |\mu|=2m\\ \ell(\mu)\leq\ell}} q^{n(\mu)}\, K_{\mu(2^m)}(q^\ell) \\
&\qquad\qquad \times \prod_{x\in\mu} \frac{(1-q^{\ell+c(x)})}{(1-q^{h(x)})}, \qquad \text{(3.24b)}
\end{aligned}$$

where

$$P(\ell;q) = \begin{cases} (q;q)_\infty^{m+1} \displaystyle\prod_{k=1}^{m-1} (q;q)_{2k} & \text{for } \ell = 1+2m,\ m\geq 0, \\ (q^2;q^2)_\infty\ (q;q)_\infty^m \displaystyle\prod_{k=1}^{m-1} (q;q)_{2k-1} & \text{for } \ell = 2m,\ m\geq 1. \end{cases} \tag{3.25}$$

Remark. The products in (3.25) are the product side of the specialized C_ℓ Euler pentagonal number theorem 4.3 in §4.

Remark. The $\ell=1$ case of (3.24a) is [GR90, eq. (2.7.7), p. 37], which is summed by the Jacobi triple-product identity in (A.6) in Appendix A to complete one of the standard proofs of the first Rogers–Ramanujan identity in (1.4).

The $\ell=2$ case of (3.24) leads to the following theorem.

THEOREM 3.26 ($q \mapsto q^2$, $x_1 \mapsto 1$, $x_2 \mapsto q$ C_2 Rogers–Ramanujan identity). *Let* $0 < |q| < 1$. *We then have*

$$1 + \sum_{m=1}^{\infty} \frac{q^{2m}}{(q^2;q^2)_m} \sum_{y=0}^{m} \frac{q^y(1-q^{2m-2y+1})}{(1-q)} K_{(2m-y,y)(2^m)}(q^2) \tag{3.27a}$$

$$= \prod_{\substack{n=1 \\ n\not\equiv 0,\pm 1 \pmod 6}}^{\infty} (1-q^n)^{-1}. \tag{3.27b}$$

Proof. The sum in (3.27a) is immediate from the $\ell = 2$ case of (3.24b) once we note that the set of $m+1$ partitions in the inner sum of (3.24b) is given by

$$\{(2m,0),(2m-1,1),\ldots,(m,m)\}. \tag{3.28}$$

The $m = 1$ case of (3.28) works since $K_{(1^2)(2)}(q) = 0$.

The product in (3.27b) is a consequence of

$$(-q^3,-q^9,q^{12};q^{12})_\infty = \frac{(q^6;q^6)_\infty}{(q^3;q^6)_\infty} \tag{3.29}$$

and the simplification in the following lemma.

LEMMA 3.30. *The* $\ell = 2$ *case of* (3.24a) *can be factored into the infinite product*

$$(-q^3,-q^9,q^{12};q^{12})_\infty\,(q;q)_\infty\,. \tag{3.31}$$

Proof. Write the $\ell = 2$ case of (3.24a) as

$$\sum_{\substack{y_2\geq 0 \\ -\infty<y_1<\infty}} (1+q^{1+2y_2})S(y_1,y_2) \tag{3.32}$$

$$= \sum_{\substack{y_2>0 \\ -\infty<y_1<\infty}} S(y_1,y_2) + \sum_{\substack{y_2>0 \\ -\infty<y_1<\infty}} q^{1+2y_2}S(y_1,y_2) + \sum_{-\infty<y_1<\infty} (1+q)S(y_1,0). \tag{3.33}$$

It is not hard to see that

$$S(y_1,-y_2-1) = q^{1+2y_2}S(y_1,y_2) \quad \text{for } y_2 \geq 0. \tag{3.34}$$

Thus, applying (3.34) to (3.33) gives

$$\sum_{-\infty<y_1,y_2<\infty} S(y_1,y_2),$$

which, in turn, is equal to

$$\sum_{-\infty<y_1,y_2<\infty} q^{6y_1^2+6y_2^2+y_1+3y_2} - \sum_{-\infty<y_1,y_2<\infty} q^{6y_1^2+6y_2^2+3y_1+5y_2+1} \tag{3.35a}$$

$$+ \sum_{-\infty<y_1,y_2<\infty} q^{6y_1^2+6y_2^2+y_1+7y_2+2} - \sum_{-\infty<y_1,y_2<\infty} q^{6y_1^2+6y_2^2-y_1+5y_2+1}. \tag{3.35b}$$

The two double Laurent series in (3.35b) cancel termwise under the transformation

$$y_1 \mapsto -y_1 \quad \text{and} \quad y_2 \mapsto -y_2 - 1,$$

leaving us with (3.35a). Interchanging y_1 and y_2 in the first series in (3.35a) enables us to factor (3.35a) into the product

$$\left\{ \sum_{y_1=-\infty}^{\infty} q^{6y_1^2+3y_1} \right\} \left\{ \sum_{y_2=-\infty}^{\infty} q^{6y_2^2+y_2}(1-q^{1+4y_2}) \right\}. \tag{3.36}$$

The first factor in (3.36) can be summed by the $q \mapsto q^{12}$ and $z \mapsto -q^3$ case of the Jacobi triple product identity in (A.6) in Appendix A to give

$$(-q^3, -q^9, q^{12}; q^{12})_\infty . \tag{3.37}$$

The second factor in (3.36) is just the sum side of the Euler pentagonal number theorem in which the terms are grouped into even or odd index of summation. That is, the $q \mapsto q^3$ and $z \mapsto q^{1/2}$ case of (A.6) implies that the second factor in (3.36) is

$$(q;q)_\infty . \tag{3.38}$$

Gordon [Gor61] has observed that the second factor in (3.36) can also be summed directly by the $q \mapsto q^4$ and $z \mapsto -q$ case of the quintuple-product identity in (A.8) of Appendix A.

Multiplying (3.37) and (3.38) completes the proof. □

The proof of Theorem 3.26 is also complete. □

The product in (3.27b) also appears in the $r = 1$ and $k = 3$ case of Bressoud's multisum Rogers–Ramanujan identity in [Bre80, eq. (3.4)]. This case of Bressoud's identity is

$$\prod_{\substack{n=1 \\ n\not\equiv 0,\pm 1 \pmod 6}}^{\infty} (1-q^n)^{-1} = \sum_{m_1,m_2 \geq 0} \frac{q^{(m_1+m_2)^2+m_2^2+m_1+2m_2}}{(q;q)_{m_1}\,(q^2;q^2)_{m_2}}. \tag{3.39}$$

Clearly, the sums in (3.27a) and (3.39) are equal. It is also possible that the mth diagonal sum in (3.39) over $m_1 + m_2 = m$ equals the inner sum in (3.27a). We have verified this equality for $m = 1, 2, 3$. If true, it appears to be nontrivial. For future reference we note the following conjecture.

CONJECTURE 3.40. *Let m be any positive integer. We then have*

$$q^{2m^2} \sum_{y=0}^{m} q^{-my+\binom{y}{2}}\, (-q^{-m};q)_y \begin{bmatrix} m \\ y \end{bmatrix}_q \tag{3.41a}$$

$$= \sum_{y=0}^{m} \frac{q^y(1-q^{2m-2y+1})}{(1-q)}\, K_{(2m-y,y)(2^m)}(q^2), \tag{3.41b}$$

where $\begin{bmatrix} m \\ y \end{bmatrix}_q$ is the polynomial in q known as the q-binomial coefficient

$$\begin{bmatrix} m \\ y \end{bmatrix}_q = \frac{(q;q)_m}{(q;q)_y\,(q;q)_{m-y}}. \tag{3.42}$$

Equation (3.41) is quite striking in view of Kirillov's formula [Kir88, Thm. 3.1] for the general q-Kostka polynomial $K_{\lambda\setminus\rho,\mu|\eta}(q)$ as a multiple sum of products of q-binomial coefficients. A special case of Kirillov's formula gives $K_{(2m-y,y)(2^m)}(q^2)$ as a sum over the set of partitions $\{\lambda\,|\lambda\vdash y,\ 2\lambda_1\le m\}$, where the term corresponding to λ is a suitable power of q times a product of $\ell(\lambda)$ q-binomial coefficients, each in base q^2.

It is not hard to see that the limit as $q\to 1^-$ of both sides of (3.41) is 3^m.

Bressoud also provided an elegant combinatorial interpretation of his general Rogers–Ramanujan identity in [Bre80, eq. (3.4)]. The special case corresponding to (3.39) is as follows:

For all positive integers n, the partitions of n into parts not congruent to $0,\pm1$ (mod 6) on the product side are equinumerous with the partitions of n into parts, say, $b_1+\cdots+b_s$, such that $b_i\ge b_{i+1}$, $b_i-b_{i+2}\ge 2$; if $b_i-b_{i+1}\le 1$, then b_i+b_{i+1} is even and all parts are ≥ 2 on the sum side.

The same combinatorial interpretation holds for (3.27).

Just as in the classical A_1 case [And84b] it should be possible to iterate the C_2 Bailey lemma in [ML92a] and embed Theorem 3.26 into an infinite family of such identities.

For $\ell\ge 3$ it is not possible to write (3.24a) as an ℓ-dimensional Laurent series. After multiplying out

$$\prod_{k=2}^{\ell}(1+q^{k-1+\ell y_k}),$$

we do have the termwise symmetry determined by

$$y_k\mapsto -y_k-\frac{2(k-1)}{\ell}\quad\text{for } k=1,2,\dots,\ell \tag{3.43}$$

in (3.24a), but (3.43) gives all integer shifts only for $\ell=1$ and 2.

The multiple sum (3.24a) does not appear to factor into a single, simple infinite product when $\ell\ge 3$. We have found, for $\ell=3$ and 4, that Euler's infinite-product-representation algorithm (EIPRA) [And86, p. 104] applied to the power series in q determined by (3.24a) yields an infinite product

$$\prod_{n=1}^{\infty}(1-q^n)^{-a_n} \tag{3.44}$$

in which the a_n's have no simple pattern and $|a_n|\to\infty$. Any power series with constant term 1 and integer coefficients can be uniquely expressed by (3.44). It is still possible that (3.24a) can by written as a finite linear combination of simple infinite products when $\ell\ge 3$.

A further combinatorial examination of (3.24a) should be facilitated by applying the $x_k=-q^{k-1+\ell y_k}$ case of the Weyl denominator formula [Bre87], [Mac79, pp. 46–47] for the root system B_ℓ to expand the product

$$\prod_{k=1}^{\ell}(1+q^{k-1+\ell y_k})\prod_{1\le r<s\le\ell}\left[(q^{\ell y_r}-q^{s-r+\ell y_s})\,(1-q^{r+s-2+\ell y_r+\ell y_s})\right] \tag{3.45}$$

into an alternating sum of $2^\ell\ell!$ monomials.

4. The C_ℓ Euler pentagonal number theorem. In this section we study C_ℓ generalizations of the classical Euler pentagonal number theorem. We also consider the C_2 cases of these general identities.

In the same way that we derived Theorem 2.1 from Theorem A.3 in Appendix A we find that taking the limit $b \to 0$, $a \to \infty$, and $N_1 \to \infty, \dots, N_\ell \to \infty$ in Theorem A.1 leads to the following theorem.

THEOREM 4.1 (the unspecialized C_ℓ Sylvester's identity). *Let $x_1, \dots, x_\ell$ be indeterminate, $\ell \geq 1$, $0 < |q| < 1$, and suppose that none of the denominators in* (4.2) *vanishes. Then*

$$\begin{aligned}\sum_{\substack{y_k \geq 0 \\ k=1,2,\dots,\ell}} \Bigg\{ & \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \, \frac{1 - x_r x_s q^{y_r + y_s}}{1 - x_r x_s} \right] \\ & \times \prod_{k=1}^{\ell} \left[\frac{1 - x_k^2 q^{2y_k}}{1 - x_k^2} \right] \prod_{r,s=1}^{\ell} \left[\frac{(x_r x_s)_{y_r}}{\left(q \frac{x_r}{x_s}\right)_{y_r}} \right] \\ & \times \left[(-1)^{\ell(y_1 + \cdots + y_\ell)} \prod_{k=1}^{\ell} x_k^{(\ell+2)y_k - (y_1 + \cdots + y_\ell)} \right] \\ & \times \left[q^{y_2 + 2y_3 + \cdots + (\ell-1)\, y_\ell} \, q^{((\ell+2)/2)(y_1^2 + \cdots + y_\ell^2) - (\ell/2)(y_1 + \cdots + y_\ell)} \right] \Bigg\} \end{aligned} \tag{4.2a}$$

$$= \prod_{k=1}^{\ell} (q x_k^2)_\infty \prod_{1 \leq r < s \leq \ell} (q x_r x_s)_\infty . \tag{4.2b}$$

Remark. The $\ell = 1$ case of (4.2) is Sylvester's identity in [And76, Thm. 9.2, p. 140] in which we take $x = x_1^2 q^{-1}$.

The same calculation that was performed in the proof of Lemma 3.2, followed by (3.17), enables us to transform the (3.1) case of (4.2) into the following lemma.

THEOREM 4.3 (first C_ℓ Euler pentagonal number theorem). *Let $0 < |q| < 1$ and $\ell \geq 1$. We then have*

$$\begin{aligned}\sum_{\substack{y_2, \dots, y_\ell \geq 0 \\ -\infty < y_1 < \infty}} \Bigg\{ & \prod_{k=2}^{\ell} (1 + q^{k-1+\ell y_k}) \\ & \times \prod_{1 \leq r < s \leq \ell} \left[(q^{\ell y_r} - q^{s-r+\ell y_s}) \, (1 - q^{r+s-2+\ell y_r + \ell y_s}) \right] \\ & \times \left[(-1)^{\ell(y_1 + \cdots + y_\ell)} \, q^{(\ell+2)(y_2 + 2y_3 + \cdots + (\ell-1)\, y_\ell)} \right] \\ & \times \left[q^{(\ell(\ell+2)/2)(y_1^2 + \cdots + y_\ell^2)} \, q^{(\frac{\ell}{2} - \ell^2)(y_1 + \cdots + y_\ell) + \ell y_1} \right] \Bigg\}. \end{aligned} \tag{4.4a}$$

$$= \begin{cases} (q;q)_\infty^{m+1} \prod_{k=1}^{m-1} (q;q)_{2k} & \text{for } \ell = 1 + 2m, \ m \geq 0, \\ (q^2;q^2)_\infty \, (q;q)_\infty^m \prod_{k=1}^{m-1} (q;q)_{2k-1} & \text{for } \ell = 2m, \ m \geq 1. \end{cases} \tag{4.4b}$$

Remark. The $\ell = 1$ case of (4.4) is Euler's pentagonal number theorem in [And76, Cor. 1.7, p. 11].

Remark. The B_ℓ Weyl denominator formula can also be used to expand the products in the sum in (4.4a).

For $\ell = 2$ we are able to write (4.4a) as an alternating sum of four double Laurent series. Two of these series cancel termwise. This is the same analysis that was performed in the proof of Lemma 3.30 that expresses (3.24a) as the difference of two double Laurent series. Keeping in mind the $\ell = 2$ case of (4.4b), we then obtain the following corollary.

COROLLARY 4.5 (second C_2 Euler pentagonal number theorem). *Let* $0 < |q| < 1$. *We then have*

$$(q;q)_\infty (q^2;q^2)_\infty = \sum_{-\infty<y_1,y_2<\infty} q^{4y_1^2+4y_2^2+y_1+y_2} - q \sum_{-\infty<y_1,y_2<\infty} q^{4y_1^2+4y_2^2+3y_1+3y_2}. \tag{4.6}$$

Each double Laurent series in (4.6) is the square of a theta function, which can be summed by the Jacobi triple-product identity (A.6) in Appendix A. It is then clear that (4.6) becomes the following corollary.

COROLLARY 4.7. *Let* $0 < |q| < 1$. *Then*

$$(q,q^2,q^3,q^4,q^5,q^6,q^7;q^8)_\infty (q^2,q^4,q^6;q^8)_\infty \tag{4.8a}$$

$$= (-q^3,-q^5;q^8)_\infty^2 - q(-q,-q^7;q^8)_\infty^2. \tag{4.8b}$$

The product side of Corollary 4.5 also appears in the Kac–Peterson-type identities

$$(q;q)_\infty (q^2;q^2)_\infty = \sum_{\substack{y_1,y_2=-\infty \\ y_2\geq 3|y_1|}}^{\infty} (-1)^{y_2} q^{(y_2^2-8y_1^2+y_2)/2}, \tag{4.9a}$$

$$(q;q)_\infty (q^2;q^2)_\infty = \sum_{\substack{y_1,y_2=-\infty \\ y_2\geq 2|y_1|}}^{\infty} (-1)^{y_1+y_2} q^{(y_2^2-2y_1^2+y_2)/2}, \tag{4.9b}$$

$$(q;q)_\infty (q^2;q^2)_\infty = \sum_{\substack{y_1,y_2=-\infty \\ y_2\geq |y_1|}}^{\infty} (-1)^{y_2} q^{(2y_2^2-y_1^2+2y_2+y_1)/2}. \tag{4.9c}$$

Equation (4.9a) is the original Kac–Peterson identity in [KP80, final equation]. Andrews [And84a] derived (4.9a) and (4.9b) by computing the constant term in the series expansion of a certain infinite product by two very different methods. Bressoud [Bre86] used q-Hermite polynomial expansion techniques of L. J. Rogers to prove (4.9b) and (4.9c). The sums in (4.9a) and (4.9b) are termwise transformed into each other in [And84a, §4]. This is useful since (4.9b) is much easier to prove than is (4.9a).

We give much simpler termwise transformations between the sums in (4.9a) and (4.9b), and those in (4.9b) and (4.9c).

We first transform (4.9b) into (4.9a) by considering a suitable mapping T_1 of one index of summation set into the other.

If $y_1 \geq 0$ is even, then T_1 maps the vertical half-line $\{(y_1, \alpha+2y_1) \,|\alpha \geq 0\}$ onto the vertical half-line $\{(y_1/2, \alpha+2y_1) \,|\alpha \geq 0\}$, and if $y_1 > 0$ is odd, then T_1 maps the vertical half-line $\{(y_1, \alpha+2y_1) \,|\alpha \geq 0\}$ onto the half-line $\{(\alpha+(1+y_1)/2, 3\alpha+1+2y_1) \,|\alpha \geq 0\}$ of slope 3. Moreover, T_1 preserves symmetry with respect to the y_2-axis.

It is not hard to see that T_1 maps $\{(y_1,y_2)\,|y_2 \geq 2|y_1|\}$ one-to-one onto $\{(y_1,y_2)\,|y_2 \geq 3|y_1|\}$.

An explicit formula for T_1 is given by

$$T_1(y_1,y_2) := \begin{cases} \left(\frac{y_1}{2}, y_2\right) & \text{if } y_1 \geq 0 \text{ is even,} \\ \left(y_2 - \frac{3}{2}y_1 + \frac{1}{2}, 3y_2 - 4y_1 + 1\right) & \text{if } y_1 > 0 \text{ is odd,} \end{cases} \tag{4.10a}$$

and

$$T_1(-y_1,y_2) := (-w_1,w_2) \quad \text{if} \quad T_1(y_1,y_2) = (w_1,w_2). \tag{4.10b}$$

By checking the same cases and symmetry needed to define T_1, it is not hard to see that

$$F_2(y_1,y_2) = F_3(T_1(y_1,y_2)), \tag{4.11}$$

where the general terms in the sums in (4.9b) and (4.9a) are denoted by $F_2(y_1,y_2)$ and $F_3(y_1,y_2)$, respectively. That is, the sums in (4.9b) and (4.9a) are termwise equivalent.

We next transform (4.9b) into (4.9c). If $y_1 > 0$, let T_2 map the vertical half-line $\{(y_1,\alpha+2y_1)\,|\alpha \geq 0\}$ onto the half-line $\{(\alpha+1,\alpha+y_1)\,|\alpha \geq 0\}$, and if $y_1 \leq 0$, let T_2 map the vertical half-line $\{(y_1,\alpha-2y_1)\,|\alpha \geq 0\}$ onto the half-line $\{(-\alpha,\alpha-y_1)\,|\alpha \geq 0\}$.

It is clear that T_2 maps $\{(y_1,y_2)\,|y_2 \geq 2|y_1|\}$ one-to-one onto $\{(y_1,y_2)\,|y_2 \geq |y_1|\}$.

The transformation T_2 is given explicitly by

$$T_2(y_1,y_2) := \begin{cases} (1+y_2-2y_1, y_2-y_1) & \text{if } y_1 > 0, \\ (-2y_1-y_2, y_1+y_2) & \text{if } y_1 \leq 0. \end{cases} \tag{4.12}$$

Just as for T_1, it easily follows that

$$F_2(y_1,y_2) = F_1(T_2(y_1,y_2)), \tag{4.13}$$

where the general terms in the sums in (4.9b) and (4.9c) are $F_2(y_1,y_2)$ and $F_1(y_1,y_2)$, respectively. Thus the sums in (4.9b) and (4.9c) are termwise equivalent.

The collection of all the terms in the sum side of (4.6), before any cancellation, is not a subset of all of the terms in any of (4.9a)–(4.9c), and vice versa. This is quite a contrast to the fact that the sums in (4.9a)–(4.9c) are termwise equivalent to one another. The equality of the sum side of (4.6) with the sums in (4.9) is not trivial.

The $\ell = 3$ case of Theorem 4.3 gives an expansion of $(q;q)_\infty^2$ that is not termwise equivalent to the sum in the identity

$$(q;q)_\infty^2 = \sum_{\substack{y_1,y_2=-\infty \\ y_2 \geq 2|y_1|}}^{\infty} (-1)^{y_1+y_2} q^{(y_2^2-3y_1^2+y_2+y_1)/2}. \tag{4.14}$$

Equation (4.14) was first stated and proved by Rogers in [Rog94, p. 323], and was subsequently re-proved in different ways by Hecke [Hec59, eq. (7), p. 425], Kac and Peterson [KP80], Andrews [And84a], and Bressoud [Bre86].

5. The $x_1 = x_2 = 1$ C_2 Rogers–Ramanujan identity. In this section we consider the $x_1 = x_2 = 1$ and $\ell = 2$ specialization of Corollary 2.21 and Theorem 4.1 and the $x_1 = x_2 = x_3 = 1$ and $\ell = 3$ specialization of Corollary 2.21.

It is useful to first observe that the limit as $x_1, x_2 \to 1$ of

$$q^{y_2}(1 - x_1x_2)[1 - (x_1/x_2)q^{y_1-y_2}]/(1 - (x_1/x_2))$$

is $(q^{y_1} - q^{y_2})$, provided that $y_1, y_2 > 0$ and $y_1 \neq y_2$. It is then not hard to see that we have the following lemma.

LEMMA 5.1. *Let $R(y_1, \dots, y_\ell)$ be the general term in either* (2.22a) *or* (4.2a), *where $\ell \geq 2$. If $y_1, y_2 > 0$, let*

$$L(y_1, y_2) = \lim_{x_1, x_2 \to 1} R(y_1, \dots, y_\ell), \tag{5.2}$$

where the notation $L(y_1, y_2)$ suppresses dependence on $y_3, \dots, y_\ell$, as well as $x_3, \dots, x_\ell$. Then $L(y_1, y_2)$ exists, $L(y_1, y_1) = 0$, and

$$L(y_1, y_2) = (q^{y_1} - q^{y_2})Q(y_1, y_2) \quad \text{if} \quad y_1 \neq y_2, \tag{5.3}$$

where $Q(y_1, y_2)$ is symmetric in y_1 and y_2. Thus we also have

$$L(y_1, y_2) + L(y_2, y_1) = 0 \quad \text{if} \quad y_1 \neq y_2. \tag{5.4}$$

It is clear from Lemma 5.1 that if $R(y_1, \dots, y_\ell)$ is the general term in either (2.22a) or (4.2a), with $\ell \geq 2$, then

$$\lim_{\substack{x_k \to 1 \\ k=1,2,\dots,\ell}} \sum_{\substack{y_k \geq 0 \\ k=1,2,\dots,\ell}} R(y_1, \dots, y_\ell) = \lim_{\substack{x_k \to 1 \\ k=1,2,\dots,\ell}} \sum_{\substack{y_1 \text{ or } y_2 = 0 \\ y_3, \dots, y_\ell \geq 0}} R(y_1, \dots, y_\ell). \tag{5.5}$$

As the first application of (5.5) we have the following lemma.

LEMMA 5.6. *The $x_1 = x_2 = 1$ and $\ell = 2$ case of* (2.22a) *can be factored into the infinite product*

$$(q^2; q^2)_\infty^3 \, (q^2; q^4)_\infty^2 . \tag{5.7}$$

Proof. By (5.5) we have to consider only the terms $R(y_1, y_2)$ of (2.22a) in which $y_1 = y_2 = 0$, $y_1 = 0$, or $y_2 = 0$. That is, we can start with

$$1 + \sum_{y \geq 1} [R(y, 0) + R(0, y)], \tag{5.8}$$

with $x_1 = 1$. Simplifying (5.8) gives

$$1 + \sum_{y \geq 1} \left[\frac{(qx_2)_y}{(q)_y} \frac{q^{3y^2 - y}}{(q/x_2)_{y-1} \, (qx_2)_{y-1}} \right] \tag{5.9a}$$

$$\times \left\{ \frac{1}{(x_2 - 1)} \left[(q)_{y-1} \, (qx_2)_{y-1} \, (1 - q^{2y}) \, x_2^{1-y} \right. \right.$$

$$\left. \left. - (qx_2^2)_{y-1} \, (q/x_2)_{y-1} \, (1 - x_2^2 q^{2y}) \, x_2^{5y} \right] \right\}. \tag{5.9b}$$

The limit as $x_2 \to 1$ of the factors in (5.9a) is

$$\frac{q^{3y^2-y}}{(q)_{y-1}^2}. \tag{5.10}$$

An elementary calculation involving l'Hôpital's rule and log differentiation shows that the limit as $x_2 \to 1$ of the factors in (5.9b) is

$$(q)_{y-1}^2\,(1-q^{2y})\left[(1-6y)+\frac{2q^{2y}}{(1-q^{2y})}\right]. \tag{5.11}$$

Thus, multiplying (5.10) and (5.11), we see that the limit of the term in (5.9) is

$$(6y+1)q^{3y^2+y}+(-6y+1)q^{3y^2-y}. \tag{5.12}$$

It is now clear that the $x_1 = x_2 = 1$ and $\ell = 2$ case of (2.22a) is the Laurent series

$$\sum_{y=-\infty}^{\infty}(6y+1)q^{3y^2+y}. \tag{5.13}$$

Taking $q \mapsto q^2$ in the quintuple product identity (A.8) in Appendix A, differentiating both sides with respect to z, setting $z=-1$, and simplifying yields

$$\sum_{y=-\infty}^{\infty}(6y+1)q^{3y^2+y} = (q^2;q^2)_\infty^3\,(q^2;q^4)_\infty^2. \tag{5.14}$$ □

Remark. Equation (5.14), with $q^2 \mapsto q$, was proved, substantially as in the preceeding, by Gordon in [Gor61, eq. (11)]. A more recent exposition appears in [BB87, pp. 306–307]. The $q^2 \mapsto q$ case of (5.14) is also equivalent to Macdonald's BC_1 identity in [Mac72, p. 93 and Appendix I, Type BC_1, eq. 6(a)].

It is now not hard to see that the $x_1 = x_2 = 1$ and $\ell = 2$ case of Corollary 2.21 can be written as the following theorem.

THEOREM 5.15 (the $x_1 = x_2 = 1$ C_2 Rogers–Ramanujan identity). *Let* $0 < |q| < 1$. *We then have*

$$\frac{(-q;q^2)_\infty^2}{(q;q^2)_\infty} = 1+\sum_{m=1}^{\infty}\frac{q^m}{(q)_m}\sum_{y=0}^{m}(2m-2y+1)\,K_{(2m-y,y)(2^m)}(q). \tag{5.16}$$

Proof. Apply Lemma 5.6 to (2.22a), recall (3.28), note the $q=1$ and $\ell=2$ case of (3.20), and then simplify. □

The product side of (5.16) also arises in $(q;q)_\infty^{-1}$ times the simple specialization of the Jacobi triple-product identity, (A.6) of Appendix A in which $q \mapsto q^2$ and $z=-1$. We have

$$\frac{(-q;q^2)_\infty^2}{(q;q^2)_\infty} = \frac{1}{(q;q)_\infty}\sum_{m=-\infty}^{\infty}q^{m^2}. \tag{5.17}$$

Equation (5.17) is just equivalent to a classical identity of Gauss in [And76, eq. (2.2.12), p. 23].

Equating the sum sides of (5.16) and (5.17) immediately gives

$$1+2\sum_{m=1}^{\infty}q^{m^2}=(q)_\infty\left\{1+\sum_{m=1}^{\infty}\frac{q^m}{(q)_m}\sum_{y=0}^{m}(2m-2y+1)\,K_{(2m-y,y)(2^m)}(q)\right\}. \tag{5.18}$$

The $x_1=x_2=1$ and $\ell=2$ specialization of Theorem 4.1 turns out to be

$$(q)_\infty^3=1+\sum_{y\geq 1}(4y+1)q^{2y^2+y}+\sum_{y\geq 1}(-4y+1)q^{2y^2-y}, \tag{5.19}$$

which is equivalent to both Jacobi's [HW79, Thm. 357, p. 285] expansion for $(q)_\infty^3$ and also to Macdonald's [Mac72, Eq. (0.7), p. 93]. The derivation of (5.19) from Theorem 4.1 is exactly the same as the analysis, up to (5.13), in the proof of Lemma 5.6.

The $x_1=\cdots=x_\ell=1$ case of Theorem 4.1 provides an expansion for $(q)_\infty^{\binom{\ell+1}{2}}$. It should be possible to show directly that such expansions are equivalent to the $C_\ell^\vee$ or $B_\ell^\vee$ identities in [Mac72, Appendix I].

We conclude this section with the $x_1=x_2=x_3=1$ and $\ell=3$ specialization of Corollary 2.21 in the following corollary.

COROLLARY 5.20 (the $x_1=x_2=x_3=1$ C_3 Rogers–Selberg identity). *Let* $0<|q|<1$. *We then have*

$$\sum_{-\infty<y_1,y_2<\infty}(-1)^{y_1+y_2}q^{(7y_1^2+7y_2^2-3y_1-y_2)/2}$$

$$\times\left[\frac{(7y_1-1)(7y_1-2)}{2}-\frac{7y_2(7y_2-1)}{2}\right] \tag{5.21a}$$

$$=(q)_\infty^6\sum_{m=0}^{\infty}\frac{q^m}{(q)_m}\sum_{\substack{\mu\geq(2^m)\\ |\mu|=2m\\ \ell(\mu)\leq 3}}K_{\mu(2^m)}(q)\;s_\mu(1,1,1). \tag{5.21b}$$

Proof. Equation (5.21b) is immediate. To establish (5.21a) we carry out a very long elementary calculation that is analogous to the proof of Lemma 5.6, up to (5.13).

First, by Lemma 5.1 we only need to look at the terms in (2.22a) corresponding to the following cases:

$$y_1=0 \quad\text{and}\quad y_2,y_3>0, \tag{5.22a}$$

$$y_2=0 \quad\text{and}\quad y_1,y_3>0. \tag{5.22b}$$

$$y_1>0 \quad\text{and}\quad y_2=y_3=0, \tag{5.23a}$$

$$y_2>0 \quad\text{and}\quad y_1=y_3=0, \tag{5.23b}$$

$$y_3>0 \quad\text{and}\quad y_1=y_2=0. \tag{5.23c}$$

$$y_1=y_2=y_3=0. \tag{5.24}$$

We compute the limit as $x_1,x_2,x_3\to 1$ of each of the cases (5.22)–(5.24) separately. First, relabel the terms in (5.22a) and (5.22b) by $y_2\mapsto y_1$, $y_3\mapsto y_2$, and $y_1\mapsto y_1$, $y_3\mapsto y_2$, respectively. We then compute the limit of the sum of the terms in (5.22). Set $x_1=1$ and then calculate the limit as $x_2\to 1$. We obtain an expression depending on x_3, where $0<y_1\leq y_2$. At this point we can just set $x_3=1$ whenever

$0 < y_1 = y_2$. We obtain four terms, which correspond to (5.21a) with $y_1 = y_2 \neq 0$ or $y_1 = -y_2 \neq 0$. Otherwise, if $0 < y_1 \neq y_2$, we compute the limit as $x_3 \to 1$ of the sum of our expressions corresponding to (y_1, y_2) and (y_2, y_1). After a lengthly calculation we obtain eight terms, each indexed by $0 < y_1 < y_2$, which account for all the terms in (5.21a) except those in which $y_1 = 0$, $y_2 = 0$, or $y_1 = \pm y_2$.

Next, consider the limit of the sum of the three terms in (5.23), once we have relabeled each by $y_i \mapsto y$. Set $x_1 = 1$, and then compute the limit as $x_2, x_3 \to 1$. We end up with four terms, indexed by $0 < y$, which account for the terms in (5.21a) in which $y_1 = 0$, or $y_2 = 0$, but $(y_1, y_2) \neq (0, 0)$.

Finally, just note that the $y_1 = y_2 = y_3 = 0$ case of (2.22a) is 1. □

Just as for (3.24a), the double Laurent series (5.21a) does not factor into a simple infinite product. We obtain (3.44) in which the a_n's alternate in sign, they have no simple pattern, and $|a_n| \to \infty$. A similar situation probably holds when $\ell \geq 3$.

Nonetheless, the $x_1 = \cdots = x_\ell = 1$ case of (2.22a) should be multiple Laurent series similar to those in [Mac72, Appendix I].

Appendix A: Background information. The main results in this paper depend on the C_ℓ terminating very well poised ${}_6\phi_5$ summation theorem from [Gus89], [LM91] and the C_ℓ q-Whipple transformation from [ML92b].

We start with the following theorem.

THEOREM A.1 (the C_ℓ terminating ${}_6\phi_5$ summation theorem). *Let a, b and $x_1, \ldots, x_\ell$ be indeterminate, let N_i be nonnegative integers for $i = 1, 2, \ldots, \ell$, with $\ell \geq 1$, and suppose that none of the denominators in* (A.2) *vanishes. Then*

$$\sum_{\substack{0 \leq y_k \leq N_k \\ k=1,2,\ldots,\ell}} \left\{ \prod_{k=1}^{\ell} \left[\frac{1 - x_k^2 q^{2y_k}}{1 - x_k^2} \right] \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \, \frac{1 - x_r x_s q^{y_r + y_s}}{1 - x_r x_s} \right] \right.$$

$$\times \prod_{r,s=1}^{\ell} \left[\frac{\left(\frac{x_r}{x_s} q^{-N_s}\right)_{y_r} (x_r x_s)_{y_r}}{\left(q \frac{x_r}{x_s}\right)_{y_r} (q x_r x_s q^{N_s})_{y_r}} \right] \prod_{k=1}^{\ell} \left[\frac{(a x_k)_{y_k} (q x_k b^{-1})_{y_k}}{(b x_k)_{y_k} (q x_k a^{-1})_{y_k}} \right]$$

$$\left. \times \, q^{(N_1 + \cdots + N_\ell)(y_1 + \cdots + y_\ell)} \, q^{y_2 + 2y_3 + \cdots + (\ell-1) y_\ell} \left(\frac{b}{a}\right)^{y_1 + \cdots + y_\ell} \right\} \tag{A.2a}$$

$$= \prod_{k=1}^{\ell} \left[\frac{(q x_k^2)_{N_k}}{(b x_k)_{N_k} (q a^{-1} x_k)_{N_k}} \right] \prod_{1 \leq r < s \leq \ell} \left[\frac{(q x_r x_s)_{N_r}}{(q x_r x_s q^{N_s})_{N_r}} \right]$$

$$\times \left(\frac{b}{a}\right)_{N_1 + \cdots + N_\ell}. \tag{A.2b}$$

Proof. We derive (A2) in [LM91] from Gustafson's C_ℓ ${}_6\psi_6$ summation theorem [Gus89, Thm. 5.1]. Specializations serve to terminate Gustafson's C_ℓ ${}_6\psi_6$ summation from below and then from above. These yield the C_ℓ ${}_6\phi_5$ summation theorem and then (A2), respectively.

A summary of the substitutions that transform Gustafson's C_ℓ ${}_6\psi_6$ into Theorem A.1 is given by

$$a_i \mapsto a_i q^{-z_i} \mapsto q^{-N_i} q^{-z_i} \mapsto q^{-N_i} x_i^{-1} \qquad \text{for} \quad i = 1, 2, \ldots, \ell;$$
$$a_{\ell+1} \mapsto a;$$

$$b_i \mapsto b_i q^{-z_i} \mapsto q^{1-z_i} \mapsto q x_i^{-1} \qquad \text{for} \quad i = 1, 2, \dots, \ell;$$
$$b_{\ell+1} \mapsto b;$$
$$q^{z_i} \mapsto x_i. \qquad \square$$

Remark. The $\ell = 1$ case of (A2) is the classical terminating ${}_6\phi_5$ summation in [GR90, eq. (II.21), p. 238] in which $a \mapsto x_1^2$, $n \mapsto N_1$, $b \mapsto a x_1$, and $c \mapsto q x_1 b^{-1}$. That is, they are equivalent.

See [LM91, §2] for the detailed proof of Theorem 2.5.

The unspecialized C_ℓ Sylvester identity in Theorem 4.1 of §4 is a special limiting case of Theorem A.1.

One of the most important applications of Theorem A.1 and the C_ℓ Bailey pair inversion theorem of [LM91], [ML92a] is the following theorem.

THEOREM A.3 (The C_ℓ q-Whipple transformation). *Let a, b, α, β, and $x_1, \dots, x_\ell$ be indeterminate, let N_i be nonnegative integers for $i = 1, 2, \dots, \ell$, with $\ell \geq 1$, and suppose that none of the denominators in* (A.4) *vanishes. Then*

$$\begin{aligned}
&\sum_{\substack{0 \leq y_k \leq N_k \\ k=1,2,\dots,\ell}} \left\{ \prod_{k=1}^{\ell} \left[\frac{1 - x_k^2 q^{2y_k}}{1 - x_k^2} \right] \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{y_r - y_s}}{1 - \frac{x_r}{x_s}} \, \frac{1 - x_r x_s q^{y_r + y_s}}{1 - x_r x_s} \right] \right. \\
&\quad \times \prod_{k=1}^{\ell} \left[\frac{(a x_k)_{y_k} (q x_k b^{-1})_{y_k}}{(b x_k)_{y_k} (q x_k a^{-1})_{y_k}} \, \frac{(\alpha x_k)_{y_k} (q x_k \beta^{-1})_{y_k}}{(\beta x_k)_{y_k} (q x_k \alpha^{-1})_{y_k}} \right] \\
&\quad \times \prod_{r,s=1}^{\ell} \left[\frac{\left(\frac{x_r}{x_s} q^{-N_s}\right)_{y_r} (x_r x_s)_{y_r}}{\left(q \frac{x_r}{x_s}\right)_{y_r} (q x_r x_s q^{N_s})_{y_r}} \right] q^{(N_1 + \cdots + N_\ell)(y_1 + \cdots + y_\ell)} \\
&\quad \left. \times \left[q^{y_2 + 2y_3 + \cdots + (\ell-1) y_\ell} \left(\frac{b\beta}{a\alpha} \right)^{y_1 + \cdots + y_\ell} \right] \right\} \qquad \text{(A.4a)} \\
&= \prod_{k=1}^{\ell} \left[\frac{(q x_k^2)_{N_k}}{(b x_k)_{N_k} (q a^{-1} x_k)_{N_k}} \right] \prod_{1 \leq r < s \leq \ell} \left[\frac{(q x_r x_s)_{N_r}}{(q x_r x_s q^{N_s})_{N_r}} \right] \left(\frac{b}{a} \right)_{N_1 + \cdots + N_\ell} \\
&\quad \times \sum_{\substack{0 \leq m_k \leq N_k \\ k=1,2,\dots,\ell}} \left\{ \prod_{1 \leq r < s \leq \ell} \left[\frac{1 - \frac{x_r}{x_s} q^{m_r - m_s}}{1 - \frac{x_r}{x_s}} \right] q^{m_1 + 2m_2 + \cdots + \ell m_\ell} \right. \\
&\quad \times \prod_{r,s=1}^{\ell} \left[\frac{\left(\frac{x_r}{x_s} q^{-N_s}\right)_{m_r}}{\left(q \frac{x_r}{x_s}\right)_{m_r}} \right] \prod_{k=1}^{\ell} \left[\frac{(a x_k)_{m_k} (q x_k b^{-1})_{m_k}}{(\beta x_k)_{m_k} (q x_k \alpha^{-1})_{m_k}} \right] \\
&\quad \left. \times \left[\left(\frac{\beta}{\alpha} \right)_{m_1 + \cdots + m_\ell} \left(\frac{a}{b} q^{1 - (N_1 + \cdots + N_\ell)} \right)_{m_1 + \cdots + m_\ell}^{-1} \right] \right\}. \qquad \text{(A.4b)}
\end{aligned}$$

Proof. We establish [ML92b, eq. (A.4)] by extending the analysis of the classical ($\ell = 1$) case of [Wat29a], [GR90]. First, apply the C_ℓ Bailey pair inversion theorem of [Lil91], [LM91], [ML92a] to the C_ℓ Bailey pair determined by Theorem A.1. This gives the C_ℓ terminating balanced ${}_3\phi_2$ summation in [ML92b, Thm. 4.4].

The rest of the proof is very similar to the A_ℓ case. Multiply each term in (A.2a) by a suitable rewriting of the product side of [ML92b, Thm. 4.4]. The resulting sum is rewritten as (A.4a). Then use [ML92b, Thm. 4.4] to replace the factors just added by the corresponding sum. At this point, interchange summation and manipulate the resulting inner multiple sum termwise until a shifted C_ℓ very well poised ${}_6\phi_5$ sum is obtained. Use Theorem A.1 to sum this inner sum. Finally, simplify the resulting single multiple sum termwise to obtain (A.4b). □

Remark. The $\ell = 1$ case of (A.4) is [GR90, eq. (III.18), p. 242], in which $a \mapsto x_1^2$, $n \mapsto N_1$, $b \mapsto \alpha x_1$, $c \mapsto q x_1 \beta^{-1}$, $d \mapsto a x_1$, and $e \mapsto q x_1 b^{-1}$. That is, they are equivalent.

The first version of the C_ℓ Rogers–Selberg identity in Theorem 2.1 of §2 is a special limiting case of Theorem A.3.

The derivation of the first C_2 Rogers–Ramanujan identity in Theorem 3.26 and the theta-function identity in Corollary 4.7 require Jacobi's [Jac29] well-known triple product identity.

THEOREM A.5 (Jacobi triple product identity). *Let* $|q| < 1$ *and* $z \neq 0$. *Then*

$$\left(zq^{\frac{1}{2}}, q^{\frac{1}{2}}/z, q; q\right)_\infty = \sum_{m=-\infty}^{\infty} (-1)^m q^{m^2/2} z^m. \tag{A6}$$

See [GR90, p. 12] for an analytical proof of (A.6), and see [And76], [And86], [Bai35], [GR90], [HW79], [Sla66], [Wat29a] for applications of (A.6) to classical Rogers–Ramanujan-type identities.

The final part of the proof of the $x_1 = x_2 = 1$ C_2 Rogers–Ramanujan identity in Theorem 5.15 relies on the following theorem.

THEOREM A.7 (quintuple-product identity). *Let* $0 < |q| < 1$ *and* $z \neq 0$. *Then*

$$\begin{aligned} &\sum_{m=-\infty}^{\infty} (-1)^m q^{m(3m-1)/2} z^{3m} (1 + zq^m) \\ &\qquad = (q, -z, -q/z; q)_\infty \, (qz^2, q/z^2; q^2)_\infty . \end{aligned} \tag{A.8}$$

The identity (A.8) was discovered by Watson [Wat29b] and was rediscovered by Gordon [Gor61], and an equivalent identity is explicitly given by Ramanujan in [Ram88, p. 207]. A more recent exposition can be found in [BB87], [GR90]. The identity (A.8) is also the BC_1 Macdonald identity [Mac72].

Equation (A.8) is the formulation given by [GR90, Ex. 5.6, p. 134].

POSITIVITY OF INTEGRALS OF BESSEL FUNCTIONS*

JOLANTA K. MISIEWICZ† AND DONALD ST. P. RICHARDS‡

Abstract. Using results on multiply monotone functions, we establish the positivity of integrals of Bessel functions of the form

$$\int_0^x (x^\mu - t^\mu)^\lambda t^\alpha J_\beta(t)dt, \qquad x > 0,$$

where $0 < \mu \leq 1 \leq \lambda$ and α, β satisfy various conditions. In particular, the result holds if $-\frac{1}{2} \leq \alpha = \beta \leq \frac{3}{2}$ or if $\frac{3}{2} = \alpha \leq \beta$.

Key words. Bessel functions, characteristic functions, fractional integration, multiply monotone functions, Pólya's criterion, Riesz means

AMS subject classifications. primary 33A45; secondary 60E10

1. Introduction.

The problem of proving positivity of the Bessel function integrals,

$$\int_0^x (x^\mu - t^\mu)^\lambda t^\alpha J_\beta(t)dt, \qquad x > 0, \tag{1.1}$$

is an old one. We refer to Askey [1] and Gasper [5] for reviews of the techniques developed for these problems, and for references to applications of those results. For our purposes it is enough to say that much is known about the positivity of (1.1) when $\mu = 1$ or 2, but that very little seems to be available for other values of μ. In particular, the explicit formulas for the classical hypergeometric series that proved to be extremely useful when $\mu = 1$ or 2 do not appear to be as helpful for noninteger values of μ. This has, perhaps, been the main difficulty in the analysis of (1.1), despite the need (cf. [1, p. 90]) for positivity results when $0 < \mu < 1$.

Here, we obtain positivity results for (1.1) when $0 < \mu < 1$. Our starting point is the observation of Wintner [13, pp. 126 *bis, tre*], that if t_+^λ is t^λ or 0 according as $t > 0$ or $t \leq 0$, respectively, then for $0 < \mu \leq 1$, the function $\phi_\mu : \mathbf{R} \to \mathbf{R}$ given by $\phi_\mu(t) = (1 - |t|^\mu)_+$ is a characteristic function; that is, ϕ_μ is the Fourier transform of a probability measure. (As Loren Pitt reminded us, the fact that ϕ_μ is a characteristic function follows immediately from Pólya's criterion [4]: If a function $\phi : \mathbf{R} \to \mathbf{R}$ is symmetric, convex, and satisfies $\phi(0) = 1$, then ϕ is a characteristic function.)

Since ϕ_μ is integrable on $\mathbf{R}$, then its inverse Fourier transform exists and is nonnegative. Therefore if $0 < \mu \leq 1$, then by the symmetry of ϕ_μ,

$$\int_0^1 (1 - t^\mu) \cos xt \; dt \geq 0, \qquad x > 0, \tag{1.2}$$

---

or

$$\int_0^x (x^\mu - t^\mu) \cos t \, dt \geq 0, \qquad x > 0.$$

Wintner actually proves that ϕ_μ is a characteristic function by directly establishing (1.2). Moreover, he proves that if $\mu > 1$ then (1.2) fails for some $x > 0$. His proof is so simple that we cannot resist the temptation to reproduce it: After an integration by parts, we find that (1.2) is equivalent to

$$\int_0^x t^{\mu-1} \sin t \, dt \geq 0, \qquad x > 0. \tag{1.3}$$

Decompose the interval $(0, x)$ into subintervals $((n-1)\pi, n\pi)$, $n = 1, 2, \ldots$. Then the absolute value of the contribution of the nth interval to the integral in (1.3) is an increasing or decreasing function of n according to whether the function $t^{\mu-1}$ is increasing or decreasing; that is, as $\mu > 1$ or $0 < \mu < 1$, respectively. Since $(-1)^{n-1} \sin t$ is positive if $(n-1)\pi < t < n\pi$, then the nth contribution has the same sign as $(-1)^{n-1}$ and is therefore positive for $n = 1$. Consequently, the integral (1.3) is negative for some $x > 0$ if $\mu > 1$, and is positive for all $x > 0$ if $0 < \mu < 1$. If $\mu = 1$, then (1.3) is easily seen to be valid, so that (1.3) holds for all $0 < \mu \leq 1$.

We also note that (1.3) (and hence (1.2)) can be derived from an expansion as a sum of squares, obtained by applying the expansion formula of Gasper [5, eq. (3.2)] to a special case (with $\lambda = 0$) of [5, eq. (2.20)].

2. Results. In our first extension of (1.2), we replace the function ϕ_μ by more general convex functions.

PROPOSITION 2.1. *Suppose that $\phi : (0, \infty) \to \mathbf{R}$ is nonnegative, nonincreasing, convex, and satisfies $\phi(1) = 0$. Then*

$$\int_0^1 \phi(t) \cos xt \, dt \geq 0, \qquad x > 0. \tag{2.1}$$

Proof. We use the results of Williamson [12], on multiply monotone functions, to derive (2.1). In the terminology of [12], the function ϕ is 2-monotone. By [12], Theorem 1, there exists a unique, nondecreasing function, F, which is bounded from below, such that

$$\phi(t) = \int_0^\infty (1 - ut)_+ \, dF(u), \qquad t > 0. \tag{2.2}$$

Since $\phi(1) = 0$, then it follows from (2.2) that

$$0 = \int_0^\infty (1-u)_+ \, dF(u) = \int_0^1 (1-u)_+ \, dF(u).$$

Therefore $dF(u) = 0$ for $u \leq 1$.

Substituting (2.2) into the integral in (2.1), using Fubini's theorem to reverse the

order of integration, and denoting $u^{-1}dF(u^{-1})$ by $dG(u)$, we have

$$\begin{aligned}\int_0^1 \phi(t)\cos xt\ dt &= \int_0^1 \int_1^\infty (1-ut)_+ \cos xt\ dF(u)\ dt \\ &= \int_0^1 \int_0^1 \left(1-\frac{t}{u}\right)_+ \cos xt\ dF(u^{-1})\ dt \\ &= \int_0^1 \int_0^1 (u-t)_+ \cos xt\ dG(u)\ dt \\ &= \int_0^1 \int_t^1 (u-t)\cos xt\ dG(u)\ dt \\ &= \int_0^1 \int_0^u (u-t)\cos xt\ dt\ dG(u).\end{aligned}$$

Since

$$\int_0^u (u-t)\cos xt\ dt = x^{-2}(1-\cos(ux)) \geq 0, \qquad u>0, x>0,$$

then (2.1) is immediately seen to be nonnegative. □

The proof of Proposition 2.1 has the advantage of explicitly representing the integral (2.1) as a nonnegative function. By choosing $\phi(t) = (1-t^\mu)_+^\lambda$, where $0 < \mu \leq 1 \leq \lambda$, we get the following (portion of a) result of Kuttner [8].

COROLLARY 2.2 (Kuttner [8]). *For* $0 < \mu \leq 1 \leq \lambda$,

$$\int_0^x (x^\mu - t^\mu)^\lambda \cos t\ dt \geq 0, \qquad x>0. \tag{2.3}$$

Note that (2.3) also follows from Pólya's criterion, since the function $\phi(t) = (1-t^\mu)_+^\lambda$ is convex for $0 < \mu \leq 1 \leq \lambda$. When $0 < \mu < 2$, in which case the function ϕ may no longer be convex, Kuttner [8] proved that there exists a continuous, strictly increasing function $k(\mu)$ such that (2.3) is valid if $\lambda \geq k(\mu)$ and invalid for $\lambda < k(\mu)$. He also proved that $k(\mu) \to \infty$ as $\mu \to 2$; $k(1) = 1$; $k(\mu) > \mu$, $\mu \neq 1$; and $0 < k(0+) < 1$.

Substituting for $\cos t$ in terms of the Bessel function $J_{-1/2}(t)$, (2.3) is clearly equivalent to

$$\int_0^x (x^\mu - t^\mu)^\lambda t^{1/2} J_{-1/2}(t)\ dt \geq 0, \qquad x>0. \tag{2.4}$$

We now extend (1.2) and (2.4) by replacing the Bessel function $J_{-1/2}(t)$ by Bessel functions of a more general index.

PROPOSITION 2.3. *If* ϕ *satisfies the hypotheses of Proposition* 2.1, *and* α, β *are such that*

$$\int_0^x (x-t)t^\alpha J_\beta(t)\ dt \geq 0, \qquad x>0, \tag{2.5}$$

then

$$\int_0^1 \phi(t)t^\alpha J_\beta(xt)\ dt \geq 0, \qquad x>0.$$

Proof. We again apply Williamson's integral representation for ϕ. Then it follows as before that

$$\int_0^1 \phi(t)t^\alpha J_\beta(xt)\ dt = \int_0^1 \int_0^u (u-t)t^\alpha J_\beta(xt)\ dt\ dG(u).$$

Since (2.5) is equivalent to

$$\int_0^u (u-t)t^\alpha J_\beta(xt)\,dt \geq 0, \qquad u>0, x>0,$$

then the result follows. □

There appear to be numerous conditions under which (2.5) is valid. We list all conditions known to us in the following result.

COROLLARY 2.4. *For* $0<\mu\leq 1\leq\lambda$,

$$\int_0^x (x^\mu - t^\mu)^\lambda t^\alpha J_\beta(t)\,dt \geq 0, \qquad x>0,$$

if α *and* β *satisfy any of the following conditions*:

(i) $\frac{3}{2}=\alpha\leq\beta$;
(ii) $-\frac{1}{2}\leq\alpha=\beta\leq 3/2$;
(iii) $\alpha=0$, $\beta>-1$;
(iv) $\frac{1}{2}=\alpha<\beta$;
(v) $-1-\beta<\alpha<\alpha(\beta)$, $-1<\beta<\frac{1}{2}$, *where* $\alpha(\beta)$ *is defined by*

$$\int_0^{j_{\beta,2}} t^{\alpha(\beta)}J_\beta(t)\,dt = 0,$$

and $j_{\beta,2}$ *denotes the second positive zero of* $J_\beta(t)$.

(vi) $\alpha=\alpha_0-\delta$, $\beta=\beta_0+\delta$, $\delta\geq 0$, *where* (α_0,β_0) *satisfy any of* (i)–(v).

Proof. In all six cases, the conclusion is obtained by proving that (2.5) is valid under the corresponding restriction on α and β, and then substituting $\phi(t)=(1-t^\mu)_+^\lambda$.

That (2.5) holds under (i) follows from the result of Moak [10], and (ii) follows from Gasper [5, eq. (1.5)]. Next, (iii)–(v) all follow from the identity

$$\int_0^x (x-t)t^\alpha J_\beta(t)\,dt = \int_0^x\int_0^t u^\alpha J_\beta(u)\,du,$$

and then noting that

$$\int_0^t u^\alpha J_\beta(u)\,du \geq 0, \qquad t\geq 0, \tag{2.6}$$

under the corresponding conditions on α and β. In particular, (iii) implies (2.6) by Cooke's inequality (cf. [5, eq. (1.1)]); (iv) implies (2.6) by [5, eq. (1.5)]; and (v) implies (2.6) by the results of Askey and Steinig [3] and Makai [9]. Finally, (vi) follows from [5, eq. (3.17)]. □

Another way to extend (2.1) is to use the fractional integration methods of Askey [1], [2] and Gasper [5], [6].

PROPOSITION 2.5. *If* ϕ *is as before and* $\gamma>-1$, *then*

$$\int_0^1 \phi(t)t^{-(\gamma+\frac{1}{2})}J_{\gamma+\frac{1}{2}}(xt)\,dt \geq 0, \qquad x>0. \tag{2.7}$$

In particular, for $0<\mu\leq 1\leq\lambda$,

$$\int_0^x (x^\mu-t^\mu)^\lambda t^{-(\gamma+\frac{1}{2})}J_{\gamma+\frac{1}{2}}(t)\,dt \geq 0, \qquad x>0. \tag{2.8}$$

Proof. By Poisson's integral [11, §12.11(1)],

$$t^{-(\gamma+\frac{1}{2})}J_{\gamma+\frac{1}{2}}(t) = c_\gamma \int_0^1 (1-u^2)^\gamma \cos tu \, du, \tag{2.9}$$

where the positive constant c_γ depends only on γ. In (2.1), replace x by ux, multiply both sides by $(1-u^2)^\gamma$, and integrate with respect to u over $(0,1)$; then we obtain (2.7) after interchanging the order of integration and applying (2.9). Finally, (2.8) follows from (2.7) in the usual way. □

From the results of [6], we know that the assumption $\mu \leq \lambda$ is necessary for positivity of integrals of the form considered here. In particular, the proof that $k(\mu) > \mu$ ($\mu \neq 1$) follows from the asymptotic behavior of the integral (2.3) as $x \to \infty$. In the following result we show that, even for small x, the assumption $\mu \leq \lambda$ cannot be dispensed with completely.

PROPOSITION 2.6. *Suppose that μ is fixed, $0 < \mu < 1$. Then there exists λ_0, $0 < \lambda_0 < 1$, such that*

$$\int_0^1 (1-t^\mu)^\lambda \cos(3\pi t/2)\, dt \quad \begin{cases} < 0, & 0 < \lambda < \lambda_0, \\ > 0, & \lambda_0 < \lambda < 1. \end{cases} \tag{2.10}$$

Proof. Denote the integral (2.10) by $\psi(\lambda)$. It is simple to check that the kernel $(\lambda, t) \mapsto (1-t^\mu)^\lambda$, $0 \leq \lambda, t \leq 1$, is strictly reverse rule of order 2 (Karlin [7, p. 12]). Further, the function $t \mapsto \cos(3\pi t/2)$, $0 \leq t \leq 1$, has one sign change. By the fundamental theorem of variation diminishing transformations [7, p. 233], it follows that $\psi(\lambda)$ changes sign at most once on $[0,1]$.

By a calculation we have $\psi(0) < 0$; and by Corollary 2.2, $\psi(1) > 0$; hence ψ changes sign at least once. Therefore ψ changes sign exactly once on $[0,1]$. □

The proof also shows that (2.10) remains valid if the function $\cos(3\pi t/2)$ is replaced by $\cos xt$, where $\pi/2 < x \leq 3\pi/2$. More generally, we can get similar results for the situation when $\cos xt$ is replaced by $t^\alpha J_\beta(xt)$ for suitably chosen α and β.

We conjecture that, in (2.10), λ_0 is a strictly increasing function of μ. Evidence supporting this conjecture is based on extensive calculation of λ_0, the results of which are presented partially in Table 1. The values of λ_0 were generated iteratively through Romberg integration of the integral in (2.10).

TABLE 1

μ	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
λ_0	0.409	0.434	0.461	0.489	0.519	0.551	0.583	0.618	0.654	0.692

Acknowledgments. We wish to thank Richard Askey and a referee for their comments on an earlier version of this manuscript, and especially for noting that results like (2.10) should be valid.

GENERALIZED JACOBI WEIGHTS, CHRISTOFFEL FUNCTIONS, AND JACOBI POLYNOMIALS*

PAUL NEVAI†, TAMÁS ERDÉLYI‡, AND ALPHONSE P. MAGNUS§

Abstract. The authors obtain upper bounds for Jacobi polynomials which are uniform in all the parameters involved and which contain explicit constants. This is done by a combination of some results on generalized Christoffel functions and some estimates of Jacobi polynomials in terms of Christoffel functions.

Key words. orthogonal polynomials, Christoffel functions, Jacobi weights, Jacobi polynomials

AMS subject classifications. primary 33A65; secondary 26C05, 42C05

1. Introduction.

DEFINITION. *Orthogonal Polynomials.* Given $w(\geq 0) \in L^1(\mathbb{R})$, $p_n(w)$ denotes the corresponding orthonormal polynomial of precise degree n with leading coefficient $\gamma_n(w) > 0$.

DEFINITION. *Jacobi Weights and Jacobi Polynomials.* Given $\alpha > -1$ and $\beta > -1$, w is called a Jacobi weight if $\operatorname{supp}(w) = [-1, 1]$ and $w(x) = (1-x)^\alpha(1+x)^\beta$ for $x \in [-1, 1]$. The corresponding orthogonal polynomials (for historical reasons with various normalizations) are called Jacobi polynomials.

For a wide class of orthogonal polynomials associated with weight functions supported in $[-1, 1]$, the expression

$$\sqrt{\sqrt{1-x^2}w(x)}p_n(w, x)$$

asymptotically equioscillates between $\pm\sqrt{2/\pi}$ for $x \in (-1, 1)$ when n tends to ∞ (cf. [22, Chaps. VIII and X–XII]). Therefore it is natural to seek inequalities for $\sqrt{1-x^2}w(x)p_n^2(w, x)$ for $x \in [-1, 1]$.

Such inequalities for Jacobi polynomials involving optimal constants are truly fascinating. They are easy to prove for the first and second (and third and fourth) kinds of Chebysev polynomials since they are related to simple trigonometric functions. For Legendre polynomials this is somewhat more complicated, and the appropriate inequality was proved by Bernstein (cf. [22, eq. (7.3.8), p. 165] for Bernstein's result and [1] and [14] for a sharper version of it). Bernstein's results can be extended to Jacobi (i.e., ultraspherical or Gegenbauer) polynomials with parameters $-\frac{1}{2} < \alpha = \beta < \frac{1}{2}$ (cf. [22, eq. (7.33.4) and eq. (7.33.5), p. 171] and also [15] for a refinement). In addition, for a wider range of the parameters, similar inequalities have been proved in [13] ($\alpha = \beta > -\frac{1}{2}$) and [7] ($\alpha = \beta > \frac{1}{2}$).

§ Institut de Mathématique Pure et Appliquée, Université Catholique de Louvain, Chemin du Cyclotron, 2, Louvain-la-Neuve, B-1348, Belgium (magnus@anma.ucl.ac.be).

For instance, Lorch [15, form. (10), p. 115] proved[1]

$$\max_{x\in[-1,1]}\left|(1-x^2)^{\frac{\lambda}{2}}P_n^{(\lambda)}(x)\right| \le \frac{2^{1-\lambda}(n+\lambda)^{\lambda-1}}{\Gamma(\lambda)}$$

for $n = 0, 1, \ldots$ and $0 < \lambda < 1$, which, in terms of the orthonormal Jacobi polynomials, can be stated as

$$\max_{x\in[-1,1]}\left|\sqrt{\sqrt{1-x^2}w(x)}\,p_n(w,x)\right| \le \sqrt{\frac{2\Gamma(n+1)}{\pi\Gamma(n+2\alpha+1)}}\left(n+\alpha+\frac{1}{2}\right)^{\alpha}$$

for $n = 0, 1, \ldots$, and $-\frac{1}{2} < \alpha < \frac{1}{2}$, where $w(x) = (1-x^2)^{\alpha}$.

For nonsymmetric Jacobi weights much less is known. In 1988, Gatteschi [10] extended Bernstein's results to Jacobi polynomials with $-\frac{1}{2} < \alpha, \beta < \frac{1}{2}$. For instance, he proved that if $-\frac{1}{2} < \alpha, \beta < \frac{1}{2}$, and $\alpha + \beta > 0$, then[2]

$$\max_{\theta\in[0,\frac{\pi}{2}]}\left|(\sin\theta/2)^{\alpha+\frac{1}{2}}(\cos\theta/2)^{\beta+\frac{1}{2}}P_n^{(\alpha,\beta)}(\cos\theta)\right| \le \frac{\Gamma(\beta+1)}{\Gamma\left(\frac{1}{2}\right)\left(n+\frac{\alpha+\beta+1}{2}\right)^{\beta+\frac{1}{2}}}\binom{n+\beta}{n}$$

for $n = 0, 1, \ldots$.[3] Again, in terms of the orthonormal Jacobi polynomials, this can be stated as

$$\max_{x\in[0,1]}\left|\sqrt{\sqrt{1-x^2}w(x)}\,p_n(w,x)\right| \le \sqrt{\frac{2^{2\beta+1}\Gamma(n+\alpha+\beta+1)\Gamma(n+\beta+1)}{\pi\Gamma(n+1)\Gamma(n+\alpha+1)}}\,(2n+\alpha+\beta+1)^{-\beta}$$

for $n = 0, 1, \ldots$, where $w(x) = (1-x)^{\alpha}(1+x)^{\beta}$ with $-\frac{1}{2} < \alpha, \beta < \frac{1}{2}$, and $\alpha + \beta > 0$.

In a sense our goal is less ambitious than the previously mentioned inequalities in that we do not expect to be able to obtain sharp constants with our techniques. On the other hand, our techniques enable us to extend these Jacobi polynomial inequalities with very explicit constants for all parameters $\alpha \ge -\frac{1}{2}$ and $\beta \ge -\frac{1}{2}$.

DEFINITION. *Generalized Polynomials.* The function f given by

$$f(z) \stackrel{\text{def}}{=} |\omega|\prod_{j=1}^{k}|z-z_j|^{r_j}, \qquad \omega \neq 0,\ z_j \in \mathbb{C},\ z \in \mathbb{C},\ r_j > 0,$$

is called a *generalized* (*nonnegative*) *algebraic polynomial* of (*generalized*) degree

$$N \stackrel{\text{def}}{=} \sum_{j=1}^{k} r_j\,,$$

and we will write $f \in |\,\mathrm{GCAP}\,|_N$.

If $w(x) = (1-x)^{\alpha}(1+x)^{\beta}$ is a Jacobi weight, then $\sqrt{1-x^2}w(x)p_n^2(w,x)$ is a generalized polynomial (of degree $2n+\alpha+\beta+1$), and as such the framework of generalized polynomials is (one of) the perfect setting for studying Jacobi polynomials. As

[1] Here $P_n^{(\lambda)}$ is the standard normalization of the Gegenbauer polynomials, that is, $P_n^{(\lambda)}(1) = \binom{n+2\lambda-1}{n}$ and Γ denotes the gamma function.

[2] Here $P_n^{(\alpha,\beta)}$ is the standard normalization of the Jacobi polynomials, that is, $P_n^{(\alpha,\beta)}(1) = \binom{n+\alpha}{n}$ and Γ again denotes the gamma function.

[3] For $\theta \in [\frac{\pi}{2}, \pi]$, one can use $P_n^{(\alpha,\beta)}(-x) = (-1)^n P_n^{(\beta,\alpha)}(x)$ to obtain an analogous inequality.

a matter of fact, this was the primary reason for introducing generalized polynomials in the first place (cf. [6] and [5]).

This paper is a modest attempt to demonstrate the applicability of generalized polynomials to problems which have not yet been settled in a satisfactory way despite more than a hundred years of undiminished interest in them.

Our method consists of two steps. First, in §2, we use *generalized polynomials* to estimate the *Christoffel function* $\sum_{k=0}^{n} p_k^2(w)$, and then, in §3, we obtain a Riccati equation which yields estimates for the ratio $p_n^2(w)/\sum_{k=0}^{n} p_k^2(w)$. The reason that we have to limit ourselves to considering $\alpha \geq -\frac{1}{2}$ and $\beta \geq -\frac{1}{2}$ is that the function $\sqrt{1-x^2}w(x)$ for either $\alpha < -\frac{1}{2}$ or $\beta < -\frac{1}{2}$ is no longer a generalized polynomial.

Our main result is the following.

THEOREM 1. *For all Jacobi weight functions* $w(x) = (1-x)^\alpha(1+x)^\beta$ *with* $\alpha \geq -\frac{1}{2}$ *and* $\beta \geq -\frac{1}{2}$, *the inequalities*

$$\max_{x\in[-1,1]} \frac{p_n^2(w,x)}{\sum_{k=0}^{n} p_k^2(w,x)} \leq \frac{4\left(2+\sqrt{\alpha^2+\beta^2}\right)}{2n+\alpha+\beta+2} \tag{1}$$

and

$$\max_{x\in[-1,1]} \sqrt{1-x^2}w(x)p_n^2(w,x) \leq \frac{2e\left(2+\sqrt{\alpha^2+\beta^2}\right)}{\pi} \tag{2}$$

hold for $n = 0, 1, \ldots$.

Our method is therefore able to give $O((\alpha^2+\beta^2)^{1/2})$ estimates for large $\alpha^2+\beta^2$. It is natural to ask how a sharp bound should behave. Numerically computed examples of the actual maximum of $\sqrt{1-x^2}w(x)p_n^2(w,x)$ suggest that small values of n give relevant information. For instance, with $\alpha = 10$ and $\beta = 2$,

n	0	1	2	3	4	5	6	7	8	9	10
max	1.478	1.251	1.191	1.161	0.845	0.747	1.123	0.727	1.112	0.703	0.685.

For $n = 0$, explicit calculation yields

$$\max_{x\in[-1,1]} \sqrt{1-x^2}w(x)p_0^2(w,x) = \frac{\Gamma(\alpha+\beta+2)}{2^{\alpha+\beta+1}\Gamma(\alpha+1)\Gamma(\beta+1)} \max_{x\in[-1,1]} (1-x)^{\alpha+1/2}(1+x)^{\beta+1/2},$$

that is,[4]

$$\max_{x\in[-1,1]} \sqrt{1-x^2}w(x)p_0^2(w,x) = \frac{(\alpha+1/2)^{\alpha+1/2}(\beta+1/2)^{\beta+1/2}\Gamma(\alpha+\beta+2)}{(\alpha+\beta+1)^{\alpha+\beta+1}\Gamma(\alpha+1)\Gamma(\beta+1)},$$

which behaves like $[(\alpha+\beta)/(2\pi)]^{1/2}$ for α and β large. We expect $O((\alpha^2+\beta^2)^{1/4})$ bound to be valid for all $n \geq 1$.

2. Generalized Christoffel functions and generalized polynomials.

DEFINITION. *Generalized Christoffel Functions.* Given $w(\geq 0) \in L^1(\mathbb{R})$ and $p \in (0,\infty)$,

$$\lambda_n^*(w,p,z) \stackrel{\text{def}}{=} \inf_{f\in|\,\mathrm{GCAP}\,|_{n-1}} \int_{\mathbb{R}} \frac{f^p(t)}{f^p(z)}\, w(t)\, dt, \qquad z \in \mathbb{C}, \tag{3}$$

[4] The maximum is taken at $x = (\beta-\alpha)/(\alpha+\beta+1)$.

where $n \geq 1$ is *real*, that is, n is not necessarily an integer.

Remark 2. Of course, $\lambda_n^*(w,p) \equiv \lambda_{np-p+1}^*(w,1)$. As a matter of fact, this is one of the underlying reasons for the usefulness of the concept of *generalized polynomials*. The notation $\lambda_n^*(w,p)$ was kept for historical reasons. Eventually, the parameter p may disappear from it.

DEFINITION. *Generalized Jacobi Weights.* Given a nonnegative integer m, the function w satisfying $\operatorname{supp}(w) = [-1,1]$ and

$$w(x) \stackrel{\text{def}}{=} (1-x)^{\tau_0} \prod_{k=1}^{m} |x-a_k|^{\tau_k} (1+x)^{\tau_{m+1}}, \qquad a_k \in \mathbb{R}, \quad \tau_k \in \mathbb{R}, \tag{4}$$

for $x \in [-1,1]$, is called a *generalized Jacobi weight*, and its *degree* is denoted by $\deg(w) \stackrel{\text{def}}{=} \sum_{k=0}^{m+1} \tau_k$.

We start with the following.

THEOREM 3. *Let w be a generalized Jacobi weight of the form* (4) *such that $a_k \neq a_j$ for $k \neq j$, $a_k \neq \pm 1$ for $k = 1,2,\dots,m$, $\tau_0 \geq -\frac{1}{2}$, $\tau_k > 0$ for $k = 1,2,\dots,m$, and $\tau_{m+1} \geq -\frac{1}{2}$. Then, for all $0 < p < \infty$ and $n \geq 1$, the generalized Christoffel functions $\lambda_n^*(w,p)$ satisfy the inequality*

$$\max_{x\in[-1,1]} \sqrt{1-x^2} w(x) \left[\lambda_n^*(w,p,x)\right]^{-1} \leq \frac{(2+pn-p+\deg(w))\, e}{2\pi}.$$

Since the reciprocal of $\sum_{k=0}^{n-1} p_k^2(w,z)$ equals the right-hand side of (3) with the infimum (that is, *minimum*) taken for all ordinary polynomials of degree at most $n-1$,

$$\sum_{k=0}^{n} p_k^2(w,x) \leq \left[\lambda_{n+1}^*(w,2,x)\right]^{-1}, \qquad n = 0,1,\dots,$$

and thus we have the following.

COROLLARY 4. *For all Jacobi weights $w(x) = (1-x)^\alpha (1+x)^\beta$ with $\alpha \geq -\frac{1}{2}$ and $\beta \geq -\frac{1}{2}$,*

$$\max_{x\in[-1,1]} \sqrt{1-x^2} w(x) \sum_{k=0}^{n} p_k^2(w,x) \leq \frac{(2n+\alpha+\beta+2)\, e}{2\pi}, \qquad n = 0,1,\dots, \tag{5}$$

holds.

Remark 5. We point out the uniformity of (5) in all parameters.

Remark 6. The corresponding lower estimates are essentially the same with a proper interpretation of the word "essentially" (cf. [6, Thms. 2.1 and 2.2, p. 113]).

Remark 7. Of course, given $\epsilon > 0$, for all Jacobi weights we have

$$\lim_{n\to\infty} \frac{\sqrt{1-x^2} w(x) \sum_{k=0}^{n} p_k^2(w,x)}{n} = \frac{1}{\pi}$$

uniformly for $-1+\epsilon \leq x \leq 1-\epsilon$ (cf. [19, Thm. 6.2.35, p. 94]).

Question 8. It remains to be seen how to extend (5) for all Jacobi weights, with parameters $\alpha > -1$ and $\beta > -1$.

Proof of Theorem 3. We start out as in the proof of [16, Thm. 6, p. 149], and we follow closely the proof of [6, Thm. 3.2, p. 126]. If h is analytic in the unit disk, then

$$(1-|rz|^2) h(rz) = \frac{1}{2\pi i} \int_{|u|=1} h(u) \frac{1-r\bar{z}u}{u-rz} du, \qquad |z| \leq 1, \quad 0 \leq r < 1.$$

Hence, if P is a polynomial and $0 < p < \infty$, then

$$(1-|r|^2)|P^*(rz)|^p \le \frac{1}{2\pi}\int_{|u|=1}|P^*(u)|^p|du|, \qquad |z|=1, \quad 0\le r\le 1,$$

where P^* is obtained from P by replacing all the zeros z^* of P which are inside the unit disk by $\bar{z^*}^{-1}$.

Since

$$\frac{1+r}{2}|z-\sigma| \le |rz-\sigma|, \qquad |\sigma|\ge 1, \quad |z|=1, \quad 0\le r\le 1,$$

we have

$$(1-|r|^2)\left(\frac{1+r}{2}\right)^{p\deg(P)}|P^*(z)|^p \le \frac{1}{2\pi}\int_{|u|=1}|P^*(u)|^p|du|, \qquad |z|=1, \quad 0\le r\le 1.$$

Maximizing the left-hand side here for $0 \le r \le 1$ and using $|P^*(z)| = |P(z)|$ for $|z| = 1$, the inequality

$$|P(z)|^p \le \frac{(2+p\deg(P))\,e}{8\pi}\int_{-\pi}^{\pi}|P(e^{i\theta})|^p\,d\theta, \qquad |z|=1,$$

follows.

For every real trigonometric polynomial R_n of degree at most n there is an algebraic polynomial $P_{2n} \in \Pi_{2n}$ such that $R_n^2(\theta) = |P_{2n}(e^{i\theta})|^2$. Therefore,

$$\|R_n\|^p_{L^\infty(\mathbb{R})} \le \frac{(1+pn)\,e}{4\pi}\int_{-\pi}^{\pi}|R_n(\theta)|^p\,d\theta \tag{6}$$

for every such trigonometric polynomial R_n.

If the multiplicity of each zero of $g \in |\,\mathrm{GCAP}\,|_N$ is rational, then there is $q > 0$ such that $g^q(\cos\cdot)$ is a nonnegative trigonometric polynomial, so that applying (6) with $R_{Nq} = g^q$ and $p = \frac{1}{q}$ yields

$$\|g(\cos\cdot)\|_{L^\infty(\mathbb{R})} \le \frac{(1+N)\,e}{4\pi}\int_{-\pi}^{\pi}g(\cos\theta)\,d\theta. \tag{7}$$

Once (7) holds for all $g \in |\,\mathrm{GCAP}\,|_N$ such that the multiplicity of each zero of g is rational, by continuity it remains valid for all $g \in |\,\mathrm{GCAP}\,|_N$. Hence,

$$\|G(\cos\cdot)\|_{L^\infty(\mathbb{R})} \le \frac{(1+N)\,e}{4\pi}\int_{-\pi}^{\pi}G(\cos\theta)\,d\theta \quad \forall\, G \in |\,\mathrm{GCAP}\,|_N \tag{8}$$

for every $N \ge 0$.

Thus,

$$\left\|\sqrt{1-(\cdot)^2}F\right\|_{L^\infty([-1,1])} \le \frac{(2+N)\,e}{2\pi}\int_{-1}^{1}F(t)\,dt \quad \forall\, \sqrt{1-(\cdot)^2}F \in |\,\mathrm{GCAP}\,|_{N+1},$$

$N \ge 0$. Applying this inequality with $F = f^p w$, Theorem 3 follows immediately. □

3. Christoffel Functions and Jacobi Polynomials.

"I've tried A! I've tried B! I've tried C!"

Tom Wolfe, *The Right Stuff.*

If we want to find upper bounds for p_n^2 from upper bounds for $\sum_0^n p_k^2$, then we must have upper bounds for $p_n^2/\sum_0^n p_k^2$, and that is precisely what is attempted here.

THEOREM 9. *Given $n = 1, 2, \ldots$, and a Jacobi weight $w(x) = (1-x)^\alpha(1+x)^\beta$ with $\alpha > -1$ and $\beta > -1$, let $x_{nn}(w) < x_{1n}(w)$ be the extreme zeros of the corresponding nth-degree Jacobi polynomial. Then the inequalities*

$$(9)\qquad \frac{p_n^2(w,x)}{\sum_{k=0}^n p_k^2(w,x)} \le \begin{cases} \frac{(2n+\alpha+\beta+1)(\beta+1)}{(n+\alpha+\beta+1)(n+\beta+1)}, & -1 \le x \le 2x_{nn}(w)+1, \\ \frac{4(2n+\alpha+\beta+1)}{(2n+\alpha+\beta+2)^2 - \frac{2\alpha^2}{1-x} - \frac{2\beta^2}{1+x}}, & \xi_1 \le x \le \xi_2, \\ \frac{(2n+\alpha+\beta+1)(\alpha+1)}{(n+\alpha+\beta+1)(n+\alpha+1)}, & 2x_{1n}(w)-1 \le x \le 1, \end{cases}$$

hold provided $-1 < \xi_1 \le \xi_2 < 1$ are such that $(2n+\alpha+\beta+2)^2 - 2\alpha^2/(1-x) - 2\beta^2/(1+x)$ on the right-hand side of the second inequality of (9) is positive in $[\xi_1, \xi_2]$.

Remark 10. The inequality

$$\frac{p_n^2(w,x)}{\sum_{k=0}^n p_k^2(w,x)} \le \frac{\text{const}}{n}, \qquad -1 \le x \le 1,$$

is well known [19, Lem. 6.2.17, p. 82] (see [18, Lem. 2.1, p. 336] for the necessary Christoffel function estimates) but its proof is rather cumbersome. Theorem 1 of the present paper yields a new proof with an explicit formula for the constant which depends on α and β.

Proof of Theorem 9. By Christoffel–Darboux's formula

$$\begin{aligned}\sum_{k=0}^n p_k^2(w,x) &= \frac{\gamma_n(w)}{\gamma_{n+1}(w)}\left[p'_{n+1}(w,x)p_n(w,x) - p'_n(w,x)p_{n+1}(w,x)\right] \\ &= \frac{\gamma_n(w)}{\gamma_{n+1}(w)} p_n^2(w,x)\frac{d}{dx}\left[\frac{p_{n+1}(w,x)}{p_n(w,x)}\right].\end{aligned}$$

Hence, we need to find an appropriate lower bound for r' in $[-1,1]$, where

$$r(x) = \frac{\gamma_n(w)}{\gamma_{n+1}(w)}\frac{p_{n+1}(w,x)}{p_n(w,x)}.$$

Here r is a rational function with simple poles at the zeros $\{x_{kn}(w)\}_{k=1}^n$ of $p_n(w)$. It has an asymptotic behavior $x+c$ for $x \to \infty$, where c is a constant. Since r' is positive everywhere, r must have negative residues at its poles, so that we obtain

$$r(x) = x + c - \sum_{k=1}^n \frac{A_k}{x - x_{kn}(w)} \quad \text{and} \quad r'(x) = 1 + \sum_{k=1}^n \frac{A_k}{(x - x_{kn}(w))^2}$$

with $A_k > 0$, $k = 1, 2, \ldots, n$. See the graphs of r and r' (solid thick line) on upper and lower parts of Fig. 1 as an example. When $-1 \le x < x_{nn}(w)$, r' is the sum of increasing functions of x, and therefore it is greater than $r'(-1)$. When x is slightly greater than $x_{1n}(w)$, r' is decreasing but it is still greater or equal than $r'(-1)$ as long as each term $A_k/(x - x_{kn}(w))^2$ is greater or equal than the corresponding term at -1, that is, $(x - x_{kn}(w))^2 \le (-1 - x_{kn}(w))^2$ for $k = 1, \ldots, n$ or $(x+1)(x - 2x_{kn}(w) - 1) \le 0$, which holds if $-1 \le x \le 2\min x_{kn}(w) + 1 = 2x_{nn}(w) + 1$. A similar argument shows that $r'(x) \ge r'(1)$ if $x \ge 2\max x_{kn}(w) - 1 = 2x_{1n}(w) - 1$. This will prove the first and third inequalities of (9) as soon as we get the actual values of $r'(-1)$ and $r'(1)$.

The bottom part of Fig. 1 shows a graph of r' for $-1 \le x \le 1$ when $\alpha = 3/2$, $\beta = -3/10$, and $n = 3$. A short-dashed horizontal line has been drawn between -1 and $2x_{nn}(w)+1$ at the ordinate $r'(-1)$. One can see that this horizontal line segment

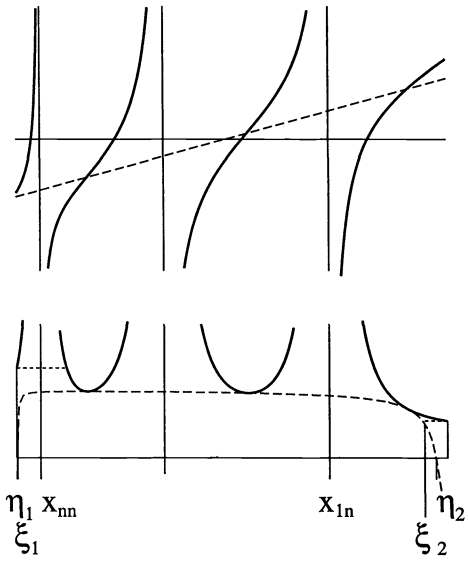

FIG. 1

lies indeed under the graph of r'. As $r'(1)$ is a lower bound of r' on the whole interval $[-1,1]$ in the present case, only a part of the horizontal line of the ordinate $r'(1)$ has been drawn. Other features of this figure will be explained later.

In order to establish the second inequality of (9) and to compute $r'(\pm 1)$, we need the following formulas for the orthonormal Jacobi polynomials.

(i) The recurrence relation:

$$\frac{\gamma_n(w)}{\gamma_{n+1}(w)}p_{n+1}(w,x) = (x - b_n(w))p_n(w,x) - \frac{\gamma_{n-1}(w)}{\gamma_n(w)}p_{n-1}(w,x), \tag{10}$$

where

$$b_n(w) = \frac{\beta^2 - \alpha^2}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)},$$

and

$$\frac{\gamma_n(w)}{\gamma_{n+1}(w)} = 2 \times \sqrt{\frac{(n+1)(n+\alpha+\beta+1)(n+\alpha+1)(n+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)^2(2n+\alpha+\beta+3)}},$$

$n = 1, 2, \ldots$ (cf. [22, form. (4.5.1), p. 71] or [3, Table III.11, p. 220]).

(ii) The differential relation:

$$\begin{aligned}(1-x^2)p_n'(w,x) &= n\left(\frac{\alpha-\beta}{2n+\alpha+\beta} - x\right)p_n(w,x) + (2n+\alpha+\beta+1)\frac{\gamma_{n-1}(w)}{\gamma_n(w)}p_{n-1}(w,x) \\ &= (n+\alpha+\beta+1)\left(\frac{\alpha-\beta}{2n+\alpha+\beta+2} + x\right)p_n(w,x) \\ &\quad - (2n+\alpha+\beta+1)\frac{\gamma_n(w)}{\gamma_{n+1}(w)}p_{n+1}(w,x),\end{aligned} \tag{11}$$

$n = 1, 2, \ldots$ (cf. [22, form. (4.5.7), p. 72]). Of course, each one of these formulas can be deduced from the other one by the three-term recurrence formula.

The combination of (i) and (ii) yields (iii).

(iii) The differential equation:

$$(12)\quad (1-x^2)p_n''(w,x) + [\beta - \alpha - (\alpha+\beta+2)x]p_n'(w,x) + n(n+\alpha+\beta+1)p_n(w,x) = 0$$

(cf. [22, form. (4.2.1), p. 60] or [3, form. (2.20), p. 149]).

In order to compute $r'(\pm 1)$, we proceed as follows. From (11),

$$\frac{\gamma_n(w)}{\gamma_{n+1}(w)}\frac{p_{n+1}(w,\pm 1)}{p_n(w,\pm 1)} = r(\pm 1) = \frac{(n+\alpha+\beta+1)[\alpha-\beta\pm(2n+\alpha+\beta+2)]}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)},$$

and from (12),

$$\frac{p_n'(w,\pm 1)}{p_n(w,\pm 1)} = \frac{n(n+\alpha+\beta+1)}{\pm(\alpha+\beta+2)+\alpha-\beta},$$

so that we have

$$r'(\pm 1) = \frac{\gamma_n}{\gamma_{n+1}}\frac{p_{n+1}(w,\pm 1)}{p_n(w,\pm 1)}\left(\frac{p_{n+1}'(w,\pm 1)}{p_{n+1}(w,\pm 1)} - \frac{p_n'(w,\pm 1)}{p_n(w,\pm 1)}\right),$$

which allows the computation of the requested special values as given in the following table.

(13)

$\boxed{f}$	$\boxed{f(-1)}$	$\boxed{f(1)}$
r	$-\frac{2(n+\alpha+\beta+1)(n+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)}$	$\frac{2(n+\alpha+\beta+1)(n+\alpha+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)}$
p_n'/p_n	$-\frac{n(n+\alpha+\beta+1)}{2(\beta+1)}$	$\frac{n(n+\alpha+\beta+1)}{2(\alpha+1)}$
r'	$\frac{(n+\alpha+\beta+1)(n+\beta+1)}{(2n+\alpha+\beta+1)(\beta+1)}$	$\frac{(n+\alpha+\beta+1)(n+\alpha+1)}{(2n+\alpha+\beta+1)(\alpha+1)}$

The values of $1/r'(-1)$ and $1/r'(1)$ are used in the right-hand sides of the first and third inequalities of (9).

Now, we come to the second inequality. This one will be established through a *Riccati* equation for r. Use the differential relations (11) for eliminating p_n' and p_{n+1}' in $p_{n+1}'p_n - p_n'p_{n+1}$. This gives an equation in terms of p_{n+1}^2, p_np_{n+1}, and p_n^2, so that after some rather tedious calculations,

$$r'(x) = \frac{A + B(x)r(x) + Cr(x)^2}{1-x^2}$$

with

$$A = (2n+\alpha+\beta+3)\left(\frac{\gamma_n(w)}{\gamma_{n+1}(w)}\right)^2 = 4\frac{(n+1)(n+\alpha+\beta+1)(n+\alpha+1)(n+\beta+1)}{(2n+\alpha+\beta+1)(2n+\alpha+\beta+2)^2},$$

$$B(x) = -(2n+\alpha+\beta+2)x - \frac{\alpha^2-\beta^2}{2n+\alpha+\beta+2}, \qquad C = 2n+\alpha+\beta+1.$$

The idea is that whatever the actual value of r is, $A+Br+Cr^2$ will always be greater than the absolute minimum of this trinomial, that is,

$$r'(x) \geq \frac{4AC - B(x)^2}{4C(1-x^2)} .$$

Equality will occur whenever $r(x)$ is equal to $-B(x)/(2C)$, which happens once between any pair of consecutive zeros of p_n, as can be seen in Fig. 1, where the graphs of r and $-B/(2C)$ are shown in the upper part, and the graphs of r' and its lower bound (dashed line) in the lower part. Working out the numerator yields

$$r'(x) \geq \frac{(2n+\alpha+\beta+2)^2 - \frac{2\alpha^2}{1-x} - \frac{2\beta^2}{1+x}}{4(2n+\alpha+\beta+1)} , \qquad -1 < x < 1,$$

and, thus the theorem follows, as long as x is restricted to an interval $[\xi_1, \xi_2]$ where the above lower bound is positive. □

Combining Theorem 3 (that is, Corollary 4) and Theorem 9, we obtain the following pointwise estimate for the Jacobi polynomials.

THEOREM 11. *For all Jacobi weight functions* $w(x) = (1-x)^\alpha(1+x)^\beta$ *with* $\alpha \geq -\frac{1}{2}$ *and* $\beta \geq -\frac{1}{2}$, *we have*

$$p_n^2(w,x) \leq \frac{2}{\pi\sqrt{1-x^2}w(x)} \frac{e\,(2n+\alpha+\beta+2)(2n+\alpha+\beta+1)}{(2n+\alpha+\beta+2)^2 - \frac{2\alpha^2}{1-x} - \frac{2\beta^2}{1+x}} , \qquad n = 1, 2, \ldots,$$

for $-1 < x < 1$, *as long as the denominator* $(2n+\alpha+\beta+2)^2 - 2\alpha^2/(1-x) - 2\beta^2/(1+x)$ *on the right-hand side is positive. In particular, given* $0 < \epsilon < 1$,

$$p_n^2(w,x) \leq \frac{2}{\pi\sqrt{1-x^2}w(x)} \frac{e}{1 - \frac{2(\alpha^2+\beta^2)}{(2n+\alpha+\beta+2)^2\,\epsilon}}$$

for $-1+\epsilon \leq x \leq 1-\epsilon$ *and* $n > \sqrt{2(\alpha^2+\beta^2)/\epsilon} - (\alpha+\beta)/2 - 1$.

For fixed $x \in (-1,1)$ and $n \to \infty$, this is no more than $e \times (1+o(1))$ times worse than an optimal inequality could be. However, when x is close to ± 1, the parameter n needs to be sufficiently large so that the estimate would become useful. The quest for estimates valid for every $n > 0$ is the subject of the following investigations.

First, we deal with the first and third inequalities in (9).

LEMMA 12. *When* $\alpha \geq -\frac{1}{2}$, $\beta \geq -\frac{1}{2}$, *and* $n > 0$, *we have*

$$\begin{aligned} &\max\left[\frac{(2n+\alpha+\beta+1)(\beta+1)}{(n+\alpha+\beta+1)(n+\beta+1)} , \frac{(2n+\alpha+\beta+1)(\alpha+1)}{(n+\alpha+\beta+1)(n+\alpha+1)} \right] \\ &\qquad \leq \frac{4(1+\max(\alpha,\beta))}{2n+\alpha+\beta+2} . \end{aligned} \tag{14}$$

This is the first instance showing how the right-hand sides of (9) behaves. The factor $2n+\alpha+\beta+2$ has been chosen because it will reappear when (5) is used.

Proof of Lemma 12. First of all, since $t/(n+t)$ is an increasing function for $t > -n$, we only have to consider

$$\frac{(2n+\alpha+\beta+1)(\gamma+1)}{(n+\alpha+\beta+1)(n+\gamma+1)} ,$$

where $\gamma = \max(\alpha,\beta)$. Let $\delta = \min(\alpha,\beta)$. Then, we have to show

$$(2n+\gamma+\delta+2)(2n+\gamma+\delta+1) \leq 4(n+\gamma+1)(n+\gamma+\delta+1),$$

when $\gamma \geq \delta \geq -\frac{1}{2}$ and $n > 0$. This is quite elementary and amounts to

$$2n(2\gamma+1)+(\gamma+\delta+1)(3\gamma-\delta+2) \geq 0,$$

which holds since $\gamma \geq \delta$ and $2\gamma+1 \geq 0$. □

In order to use the second inequality of (9), we must find a valid interval $[\xi_1, \xi_2]$ containing $[2x_{nn}(w)+1, 2x_{1n}(w)-1]$, so that then we would have upper bounds of $p_n^2(w)/\sum_0^n p_k^2(w)$ in the whole interval $[-1,1]$. Since no simple formulas for $x_{nn}(w)$ and $x_{1n}(w)$ are known, we will now find a lower bound η_1 for $x_{nn}(w)$ large enough for allowing $\xi_1 = 2\eta_1 + 1$ to be a valid choice in (9), and, similarly, a sufficiently small upper bound η_2 for $x_{1n}(w)$.

There is much literature on bounds for the zeros of Jacobi polynomials (see, e.g., [22, §§6.2 and 6.21, p. 116–123]), but most are useful only when α and β are between $-\frac{1}{2}$ and $\frac{1}{2}$. For large n, the extreme zeros behave like $-1+j_\beta^2/(2n^2)$ and $1-j_\alpha^2/(2n^2)$, where j_κ denotes the smallest positive zero of the Bessel function J_κ [22, § 8.1, p. 192].

The next theorem gives reasonably satisfactory lower and upper estimates for the zeros of the Jacobi polynomials.

THEOREM 13. *Given $n = 1, 2, \ldots$, the zeros $\{x_{kn}(w)\}_{k=1}^n$ of the nth-degree Jacobi polynomial corresponding to a Jacobi weight $w(x) = (1-x)^\alpha(1+x)^\beta$ with $\alpha \geq -\frac{1}{2}$ and $\beta \geq -\frac{1}{2}$ satisfy*

$$\eta_1 = -1 + \frac{2\beta^2}{N^2} \leq x_{kn}(w) \leq \eta_2 = 1 - \frac{2\alpha^2}{N^2}, \tag{15}$$

$k = 1, 2, \ldots, n$, where $N = 2n+\alpha+\beta+1$.

The proof of this theorem requires the following lemma on oscillations of solutions of differential equations.

LEMMA 14. *Let Y, Z, Y', Z', Y'', Z'', K, and L be continuous functions in the open interval (a,b), with $Y \not\equiv 0$, such that*

$$Y''(x)+K(x)Y(x)=0, \qquad Z''(x)+L(x)Z(x)=0, \qquad x \in (a,b).$$

If

$$\text{(i)} \qquad K(x) \leq L(x), \qquad x \in (a,b),$$

$$\text{(ii)} \qquad Y'(x)Z(x)-Y(x)Z'(x) \to 0, \qquad x \to x_0,$$

where x_0 is one of the endpoints of (a,b), and if $Z(x)$ has no zero in (a,b), then Y has no zero in (a,b) either.

Proof of Lemma 14. The lemma is a variant of the Sturmian comparison theorems for solutions of second-order linear differential equations. It is almost the same as *Szegő's comparison theorem* in #16.626 of the 1980 edition of Gradshteyn and Ryzhik's book [11], coming from Theorem 1.82.1 of Szegő [22 §1.82 p. 19], known as "Sturm's theorem for open intervals"; see also the introduction of [9].[5] Here is a self-contained proof.

Suppose that $Y(x_1) = 0$ for some $x_1 \in (a,b)$. Since the equations are homogeneous, we may assume that $Z(x) > 0$ on (a,b), and $(x_0 - x_1)Y'(x_1) > 0$.[6] Therefore, $Y(x) = \int_{x_1}^x Y'(t)dt > 0$ when x is between x_1 and x_0 and it is sufficiently close to x_1,

[5] We thank our dear friend Luigi Gatteschi for drawing our attention to [9].

[6] N.B. $Y'(x_1)$ must be different from zero, otherwise $Y \equiv 0$.

and

$$Y'(x)Z(x) - Y(x)Z'(x) = Y'(x_1)Z(x_1) + \int_{x_1}^{x} [L(t) - K(t)]Y(t)Z(t)\,dt$$

keeps the sign of $x_0 - x_1$ with an increasing absolute value when x varies from x_1 to x_0 (since $Y(x) = Z(x)\int_{x_1}^{x}(Z(t))^{-2}[Y'(t)Z(t) - Y(t)Z'(t)]dt$ keeps its positive sign), and it cannot vanish when $x \to x_0$. □

Proof of Theorem 13. First, one uses the fact that if all the zeros of a polynomial p_n are real and are contained in an interval (a, b), a smaller interval containing all the zeros is $a - p_n(a)/p_n'(a), b - p_n(b)/p_n'(b)$. This is a well known theorem of the numerical analysis of the Newton–Raphson iteration method (see, for instance, [21, Chap. 9, p. 55]). Hence, by (13),

$$-1 + \frac{2(\beta+1)}{n(n+\alpha+\beta+1)} \le x_{kn}(w) \le 1 - \frac{2(\alpha+1)}{n(n+\alpha+\beta+1)}, \tag{16}$$

$k = 1, 2, \ldots, n$, is valid for every $\alpha > -1$, $\beta > -1$, and $n \ge 1$ (and is *exact* if $n = 1$). However, considering only the upper bound, it behaves like $1 - 2(\alpha+1)/n^2$ for large n, instead of $1 - j_\alpha^2/(2n^2)$, and j_α behaves like $\alpha + (1.855757\ldots)\alpha^{1/3}$ for large α (Tricomi's formula; see [4, p. 60]). Thus, we need better estimates when either n, α, or β are large.

Since $Y(x) = (1-x)^{(\alpha+1)/2}(1+x)^{(\beta+1)/2}p_n(w, x)$ is a solution of $Y'' + KY = 0$ with

$$K(x) = \frac{1-\alpha^2}{4(1-x)^2} + \frac{1-\beta^2}{4(1+x)^2} + \frac{2n(n+\alpha+\beta+1) + (\alpha+1)(\beta+1)}{2(1-x^2)},$$

(cf. [22, form. (4.24.1), p. 67]), we take $Z(x) = (1-x)^{(\widetilde{\alpha}+1)/2}(1+x)^{(\widetilde{\beta}+1)/2}$ (cf. Lemma 14), so that

$$L(x) = \frac{1-\widetilde{\alpha}^2}{4(1-x)^2} + \frac{1-\widetilde{\beta}^2}{4(1+x)^2} + \frac{(\widetilde{\alpha}+1)(\widetilde{\beta}+1)}{2(1-x^2)},$$

and

$$L(x) - K(x) = \frac{\alpha^2 - \widetilde{\alpha}^2}{4(1-x)^2} + \frac{\beta^2 - \widetilde{\beta}^2}{4(1+x)^2} + \frac{(\widetilde{\alpha}+1)(\widetilde{\beta}+1) - (\alpha+1)(\beta+1) - 2n(n+\alpha+\beta+1)}{2(1-x^2)}.$$

Now we turn to the upper bound in (15). Since $L - K$ must be positive in a neighborhood of 1, $\widetilde{\alpha}^2 < \alpha^2$, and since $Y'Z - YZ'$ behaves like $(1-x)^{(\alpha+\widetilde{\alpha})/2}$ near 1, one must have $\widetilde{\alpha} > -\alpha$. This implies that the method will work only when $\alpha > 0$. Let us choose $\widetilde{\alpha} = 0$ and $\widetilde{\beta} = \beta$ so that

$$L(x) - K(x) = \frac{1}{4(1-x^2)}\left[\alpha^2\frac{1+x}{1-x} - 2\alpha(\beta+1) - 4n(n+\alpha+\beta+1)\right],$$

which is positive between $1 - (2\alpha^2/(2n+\alpha)(2n+\alpha+2\beta+2)) < 1 - (2\alpha^2/N^2)$ and 1. Finally, considering that the first upper bound in (16) satisfies $1 - (2(\alpha+1)/n(n+\alpha+\beta+1)) \le 1 - 8(\alpha+1)/N^2$ when α and $\beta \ge -\frac{1}{2}$, and that $8(\alpha+1) > 2\alpha^2$ when $-\frac{1}{2} \le \alpha \le 0$, we conclude that $1 - (2\alpha^2/N^2)$ is a valid upper bound.

For the lower bound in (15) one can use the symmetry property of the Jacobi polynomials $P_n^{(\alpha,\beta)}$ given by $P_n^{(\alpha,\beta)}(-x) = (-1)^n P_n^{(\beta,\alpha)}(x)$. □

It is interesting to compare (15) with formulas given in [17, p. 160] (which is also quoted in [2, p. 1448]) stating that, when α, β, and n tend to ∞ in such a way that $\lim_{n\to\infty} \alpha/N = A$ and $\lim_{n\to\infty} \beta/N = B$, then the zeros remain smaller than $B^2 - A^2 + [(1 - A^2 - B^2)^2 - 4A^2B^2]^{1/2}$, which is indeed smaller than $1 - 2A^2$ (for an alternative proof see [12, Thm. 8, p. 137]).

We will also need the following estimates for the second inequality of (9).

LEMMA 15. *For real α, β, and $N \geq [2(\alpha^2 + \beta^2)]^{1/2}$, the inequality*

$$(N+1)^2 - \frac{2\alpha^2}{1-x} - \frac{2\beta^2}{1+x} \geq CN(N+1), \qquad -1 + \frac{4\beta^2}{N^2} \leq x \leq 1 - \frac{4\alpha^2}{N^2},$$

holds with

$$C = \min\left(\frac{1}{2}, \frac{3}{\sqrt{8(\alpha^2+\beta^2)}}\right).$$

Proof of Lemma 15. First, since $(N+1)^2 - 2\alpha^2/(1-x) - 2\beta^2/(1+x)$ is a concave function of x in $[-1,1]$, we only have to check its values at $-1+4\beta^2/N^2$ and $1-4\alpha^2/N^2$, which are $(N+1)^2 - \alpha^2/(1-2\beta^2/N^2) - N^2/2$ and $(N+1)^2 - N^2/2 - \beta^2/(1-2\alpha^2/N^2)$, respectively. Let $\gamma = \max(|\alpha|, |\beta|)$ and $\delta = \min(|\alpha|, |\beta|)$.[7] Since $\gamma^2/(1-2\delta^2/N^2) \geq \delta^2/(1-2\gamma^2/N^2)$, we have to find a lower bound for

$$F(N) \stackrel{\text{def}}{=} \frac{(N+1)^2 - \dfrac{N^2}{2} - \dfrac{\gamma^2 N^2}{N^2 - 2\delta^2}}{N(N+1)}$$

when $N \geq [2(\alpha^2+\beta^2)]^{1/2}$. Note that

$$F(N) \geq \frac{\dfrac{N^2}{2} + 2N - \dfrac{\gamma^2 N^2}{N^2 - 2\delta^2}}{N(N+1)} = \frac{1}{2} + \frac{\dfrac{3}{2} - \dfrac{\gamma^2 N}{N^2 - 2\delta^2}}{N+1},$$

so that $F(N) \geq \frac{1}{2}$ when $N \to \infty$. $F(N)$ is greater than $\frac{1}{2}$ for all $N \geq [2(\gamma^2+\delta^2)]^{1/2}$ if

$$G(N) \stackrel{\text{def}}{=} \frac{3}{2} - \frac{\gamma^2 N}{N^2 - 2\delta^2} \geq 0$$

for all these values of N, that is, if γ^2 is smaller than the values of the increasing function $3N/2 - 3\delta^2/N$, so that the least value is taken at $N = [2(\gamma^2+\delta^2)]^{1/2}$. This happens when $\alpha^2 + \beta^2 = \gamma^2 + \delta^2 \leq 9/2$, and, hence, the minimum of $F(N)$ is $\frac{1}{2}$ in this case.

When $\alpha^2 + \beta^2 = \gamma^2 + \delta^2 > 9/2$, we only have to search for the negative values of $G(N)$ in $F(N) \geq \frac{1}{2} + G(N)/(N+1)$. We will show that $G(N)/(N+1)$ is an increasing function of N, that is, $-G(N)/(N+1)$ is a positive decreasing function of N. Indeed, $-G(N) = \gamma^2/(N - 2\delta^2/N) - \frac{3}{2}$ is a decreasing function itself, as $N - 2\delta^2/N$ is increasing. Thus, the minimum of $F(N)$ is not smaller than $\frac{1}{2} + G(N)/(N+1) \geq \frac{1}{2} + G(N)/N$ at $N = [2(\gamma^2+\delta^2)]^{1/2}$. This gives $G(N) = \frac{3}{2} - \frac{N}{2}$ and $F(N) \geq 3/\{2[2(\gamma^2+\delta^2)]^{1/2}\} = 3/[8(\alpha^2+\beta^2)]^{1/2}$. □

Now we are ready for the following.

Proof of Theorem 1. First we prove formula (1). Since it is obvious for $n = 0$, we can assume that $n \geq 1$. Let $N = 2n + \alpha + \beta + 1$. If $x \in [-1, -1 + 4\beta^2/N^2] \cup [1 - 4\alpha^2/N^2, 1]$, then (1) follows from Theorem 9, Lemma 12, and Theorem 13. If

[7] N.B. these values γ and δ are not the same as in Lemma 12 if α or β is negative.

$N < [2(\alpha^2+\beta^2)]^{1/2}$, then $[-1+4\beta^2/N^2, 1-4\alpha^2/N^2]$ is empty. If $N \geq [2(\alpha^2+\beta^2)]^{1/2}$ and $x \in [-1+4\beta^2/N^2, 1-4\alpha^2/N^2]$, then (1) follows from Theorem 9 and Lemma 15. Finally, Corollary 4 and (1) yield (2). □

REGULARIZATION OF NONLINEAR DIFFERENTIAL-ALGEBRAIC EQUATIONS*

ROBERT E. O'MALLEY, JR.† AND LEONID V. KALACHEV‡

Abstract. This paper illustrates how initial value problems for nonlinear differential-algebraic equations can be regularized, i.e., converted to tractable singularly perturbed problems, by appropriate introduction of a small positive parameter ϵ. The corresponding outer limit provides the desired solution, including consistent initial conditions. Examples are given for problems with indices one, two, and three.

1. Introduction: The index-one problem.

Consider the initial value problem

$$\begin{cases} \dot{u} = f(u,v,t), \quad u(0) \text{ prescribed}, \\ 0 = g(u,v,t) \end{cases} \tag{1.1}$$

on some interval $t \geq 0$ consisting of a differential equation for the m-vector u, a corresponding initial value $u(0)$, and an n-dimensional algebraic constraint $g = 0$ corresponding in dimension to the unknown n-vector v. Such semiexplicit differential-algebraic equations (DAEs) naturally arise in describing constrained mechanical systems, electrical circuits, and, indeed, a wide variety of other significant applications. The initial value $u(0)$ may be restricted to be consistent with the constraint, though users and computations typically do not enforce this. Such problems have received considerable attention recently in the numerical literature (cf. [4] and [10]), because they cannot generally be readily integrated using standard codes for ordinary differential equations.

The simplest situation occurs when the Jacobian matrix g_v is nonsingular for *all* arguments. Then, the implicit function theorem implies that $g = 0$ can be locally solved for, say,

$$v = h(u,t). \tag{1.2}$$

Presuming appropriate smoothness and stability hypotheses, a solution of the initial value problem (1.1) then becomes specified through the unique solution of the initial value problem

$$\dot{u} = f(u,h(u,t),t), \qquad u(0) \text{ prescribed}. \tag{1.3}$$

An alternative solution procedure results if we first differentiate $g = 0$ to obtain

$$g_u\dot{u} + g_v\dot{v} + g_t = 0.$$

Solving for $\dot{v}$ then shows that (1.1) is equivalent to integrating the initial value problem for the $m+n$-dimensional system

$$\begin{cases} \dot{u} = f(u,v,t), \\ \dot{v} = -g_v^{-1}(u,v,t)[g_u(u,v,t)f(u,v,t) + g_t(u,v,t)], \end{cases} \tag{1.4}$$

*Received by the editors February 18, 1992; accepted for publication (in revised form) February 12, 1993. This research was supported in part by National Science Foundation grant DMS 9107197.

with any $u(0)$ prescribed and with $v(0)$ being obtained as a solution of the nonlinear equation

$$g(u(0), v(0), 0) = 0 \tag{1.5}$$

at $t = 0$. We observe that the constraint manifold $g = 0$ is invariant during an exact integration of (1.4)–(1.5), although numerical errors may in practice result in a drift away from the manifold. Since $\dot{u}$ and $\dot{v}$ are obtained as functions of u, v, and t after one differentiation of the constraint equation (because g_v remains nonsingular), we say the problem then has index one (cf. [8]).

Another simple way of solving (1.1) when g_v remains nonsingular is to consider the "nearby" singularly perturbed system

$$\begin{cases} \dot{u} = f(u, v, t), \\ -\epsilon g_v(u(0), v(0), 0)\dot{v} = g(u, v, t) \end{cases} \tag{1.6}$$

for small positive values of ϵ. Note that this generalizes the pencil regularization that was classically used for linear problems (cf. [8]). The Tikhonov–Levinson theory (cf. [17]) for singularly perturbed initial value problems states when the unique solution of (1.6) with the prescribed initial vector $u(0)$ and *any* $v(0)$ will have the asymptotic form

$$\begin{cases} u(t, \epsilon) = U_0(t) + O(\epsilon), \\ v(t, \epsilon) = V_0(t) + \beta_0(\tau) + O(\epsilon) \end{cases} \tag{1.7}$$

on bounded subintervals of $t \geq 0$, where $\binom{U_0}{V_0}$ satisfies the reduced problem

$$\begin{cases} \dot{U}_0 = f(U_0, V_0, t), \qquad U_0(0) = u(0), \\ 0 = g(U_0, V_0, t) \end{cases} \tag{1.8}$$

(i.e., the DAE (1.1)), and where the initial layer corrector $\beta_0(\tau)$ will satisfy the layer problem

$$\begin{aligned} -g_v(u(0), v(0), 0)\frac{d\beta_0}{d\tau} &= g(u(0), V_0(0) + \beta_0(\tau), 0), \\ \beta_0(0) &= v(0) - V_0(0) \end{aligned} \tag{1.9}$$

on the stretched interval $\tau = t/\epsilon \geq 0$. A sufficient hypothesis is that the Jacobian

$$-g_v^{-1}(u(0), v(0), 0)g_v(u(0), v, 0) \tag{1.10}$$

will remain a stable matrix for *any* v. Then the solution β_0 of (1.9) will decay to zero as $\tau \to \infty$. If $v(0)$ is consistent with the constraint, i.e., $g(u(0), v(0), 0) = 0$, we will take $V_0(0) = v(0)$, so $\beta_0(\tau) \equiv 0$. Otherwise, the solution (1.7) of (1.6) features an $O(\epsilon)$ thick initial t-layer of nonuniform convergence within which the solution converges to a solution of the DAE (1.1) as $\epsilon \to 0$. We note that the numerical integration of (1.6) for any such $v(0)$ is tractable (cf. [16], [20], and [1]). Our artificial introduction of the parameter ϵ is an example of a Tikhonov regularization (cf. [22]). We note that Rubin and Ungar [18] introduced an analogous approach for constrained mechanical

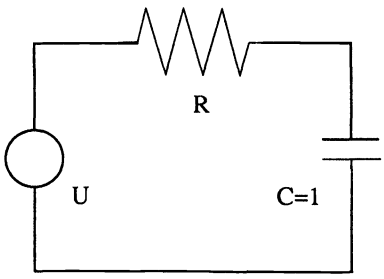

FIG. 1

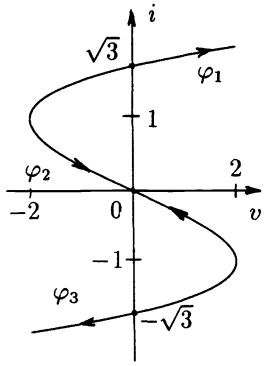

FIG. 2

systems with tangential initial velocities and that Boggs [2] and Boggs and Tolle [3] develop similar approaches for optimization problems. In many physical contexts, such ε parameters can be given natural concrete interpretations (cf. the linear examples in [12] and the circuit theory problem immediately following). Readers are referred to [15] for a survey of related approximate methods to find consistent initial conditions for DAEs. Kopell [14] also presents a related analytic method.

Example. Consider the RC circuit pictured in Fig. 1, with a DC voltage source and a nonlinear resistor in series with a capacitor (see [6] for a discussion of this and more general circuit models). Let i be the current flowing, U be the constant voltage provided, and $3i - i^3$ be the voltage drop across the resistor. Then $U = 3i - i^3 + V$ and $i = \dot{V}$ for a one unit capacitance. Setting $v = V - U$ yields the DAE

$$\begin{cases} \dot{v} = i, \\ 0 = v + 3i - i^3. \end{cases} \tag{1.11}$$

To have a positive voltage drop across the resistor, we'll have to restrict the current so that $0 < i < \sqrt{3}$.

A natural way to solve the DAE is to first solve the constraint for i as a function of v. Graphically, or by use of the implicit function theorem, we'll have one of three possibilities (as shown in Fig. 2):

$$i = \begin{cases} \varphi_1(v) > 1 & \text{if } v \geq -2, \\ \varphi_2(v) & \text{if } -2 \leq v \leq 2, \\ \varphi_3(v) < -1 & \text{if } v \leq 2. \end{cases} \tag{1.12}$$

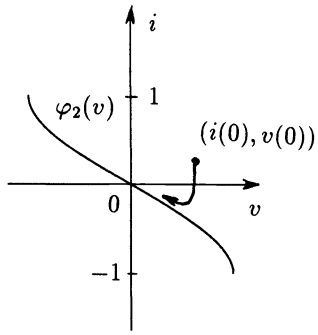

FIG. 3

The sign of $\dot{v}$ in the remaining differential equation

$$\dot{v} = \varphi_j(v) \tag{1.13}$$

implies that $|v(t)|$ will increase monotonically according to the implicit solution

$$t = \int_{v(0)}^{v(t)} \frac{dr}{\varphi_j(r)} \tag{1.14}$$

for $j = 1$ or 3 if $|v(0)| > 2$. Otherwise, for $|v(0)| < 2$, $v \to 0$ monotonically as $t \to \infty$.

Let us, instead, introduce the singular perturbation

$$\begin{cases} \dot{v} = i, \\ -3\epsilon(1 - i^2(0))\dfrac{di}{dt} = v + 3i - i^3 . \end{cases} \tag{1.15}$$

We note that the parameter ϵ corresponds to the introduction of a small inductance of magnitude $3\epsilon(1 - i^2(0))$ into the circuit (cf. [6] or [19]). If $i^2(0) < 1$, the Tikhonov–Levinson result will apply as long as $i^2(t) < 1$, guaranteeing the existence of a limiting solution $\binom{V_0}{I_0}$ for finite t, which satisfies the DAE (1.11). We naturally take

$$I_0 = \varphi_2(V_0), \tag{1.16}$$

for $|V_0| < 2$, so the limiting solution will be determined through the initial value problem

$$\dot{V}_0 = \varphi_2(V_0), \qquad V_0(0) = v(0). \tag{1.17}$$

Because of asymptotic stability, $V_0(t)$ will actually be appropriate for all $t > 0$ (cf. [11]) and the solution will have the asymptotic form

$$\begin{cases} v(t, \epsilon) = V_0(t) + O(\epsilon), \\ i(t, \epsilon) = I_0(t) + \beta_0(\tau) + O(\epsilon), \end{cases} \tag{1.18}$$

where the initial layer correction β_0 is a decaying solution of

$$\frac{d\beta_0}{d\tau} = -\frac{(1 - I_0^2(0))}{1 - i^2(0)}\beta_0 + \frac{\beta_0^2}{3(1 - i^2(0))}(3I_0(0) + \beta_0), \tag{1.19}$$

on $\tau \geq 0$ (cf. Fig. 3). Note that working with the limiting inner solution $\alpha_0(\tau) = I_0(0) + \beta_0(\tau)$ would actually be more convenient to verify the continued existence of $\alpha_0(\tau)$ and $\beta_0(\tau)$.

If instead we had $i(0) > 1$, the Tikhonov–Levinson theory would apply as long as $i^2 > 1$, yielding a limiting solution with current $I_0 = \varphi_1(V_0(t))$ and voltage $V_0(t)$ defined by $\dot{V}_0 = \varphi_1(V_0) > 1$, $V_0(0) = v(0) > -2$. Then, we will have to limit our approximation to finite t intervals to keep solutions bounded. Likewise, a solution can be obtained when $i(0) < -1$ and $v(0) < 2$.

2. The index-two problem. Consider the DAE

$$\begin{cases} \dot{u} = f(u, v, t), \\ 0 = g(u, v, t) \end{cases} \tag{2.1}$$

when the $n \times n$ matrix g_v is singular with constant *positive* rank $r < n$. By possibly reordering the constraints $g = 0$ as

$$g_1(u, v, t) = 0 \quad \text{and} \quad g_2(u, v, t) = 0, \tag{2.2}$$

we can assume that the $r \times n$ matrix g_{1v} has rank r. If we then order the components of v appropriately as

$$v = \begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \tag{2.3}$$

we can even assume that the $r \times r$ matrix

$$\frac{\partial g_1}{\partial v_1} \quad \text{is nonsingular.} \tag{2.4}$$

Then, we will be able to locally solve $g_1 = 0$ for

$$v_1 = h_1(u, v_2, t), \tag{2.5}$$

leaving us the constrained differential system

$$\begin{cases} \dot{u} = \mathcal{F}(u, v_2, t) \equiv f\left(u, \begin{pmatrix} h_1(u, v_2, t) \\ v_2 \end{pmatrix}, t\right), \\ 0 = G(u, t) \equiv g_2\left(u, \begin{pmatrix} h_1(u, v_2, t) \\ v_2 \end{pmatrix}, t\right), \end{cases} \tag{2.6}$$

with the remaining $n - r$ constraints $g_2 = 0$ expressed as $G = 0$. It is important to realize that G is indeed *independent* of v_2, i.e., $\partial G / \partial v_2 \equiv 0$, since otherwise the rank of g_v would exceed its constant rank r. Of course, now we cannot solve the constraint $G = 0$ for v_2, nor can we let $u(0)$ be inconsistent with $G(u(0), 0) = 0$ without expecting an initial discontinuity.

If we now differentiate the constraint in (2.6) and use the differential equation for u, we get the constrained differential system

$$\begin{cases} \dot{u} = \mathcal{F}(u, v_2, t), \\ 0 = G_u(u, t)\mathcal{F}(u, v_2, t) + G_t(u, t). \end{cases} \tag{2.7}$$

If we further assume that the $(n - r) \times (n - r)$ matrix

$$G_u(u, t)\mathcal{F}_{v_2}(u, v_2, t) \quad \text{remains } \textit{nonsingular} \tag{2.8}$$

everywhere (cf., e.g., [7]), (2.7) is an index-one problem since its $n-r$ constraints can be locally uniquely solved for

$$v_2 = h_2(u,t), \tag{2.9}$$

and (2.7) reduces simply to the constrained differential equation

$$\begin{cases} \dot{u} = F(u,t) \equiv \mathcal{F}(u, h_2(u,t), t), \\ 0 = G(u,t), \end{cases} \tag{2.10}$$

consisting of m differential equations and the $n-r$ constraints defined in (2.6). Since we differentiated the constraint $G = 0$ once to get the index-one problem (2.7), we naturally say that the DAE (2.1) has index-two whenever (2.8) holds. We will now further assume that $m > n - r > 0$.

We will now regularize the constrained differential system (2.10) by introducing a small positive parameter ϵ to scale a Lagrange multiplier λ as a slack variable to obtain

$$\begin{cases} \dot{u} = F(u,t) + G_u^T(u,t)\lambda, \\ -\epsilon\lambda = G(u,t)\,. \end{cases} \tag{2.11}$$

Note that Gear [7] effectively uses the Lagrange multiplier λ for $\epsilon = 0$. Introducing ϵ, however, allows us to use inconsistent initial values $u(0)$. If we eliminate λ in (2.11), we obtain

$$\epsilon\dot{u} = -G_u^T(u,t)G(u,t) + \epsilon F(u,t), \tag{2.12}$$

which is a singular singular-perturbation problem (cf. [9] and [23]). Nonetheless we naturally seek an asymptotic solution to the initial value problem for (2.12) in the form

$$u(t,\epsilon) = U(t,\epsilon) + \alpha(\tau,\epsilon), \tag{2.13}$$

where the initial layer correction $\alpha(\tau,\epsilon) \to 0$ as $\tau = t/\epsilon \to \infty$ (cf. [23] or [17]).

Alternatively, we could seek an outer solution

$$U(t,\epsilon) \sim \sum_{j=0}^{\infty} U_j(t)\epsilon^j \tag{2.14}$$

of (2.12) for $t > 0$ and an inner solution

$$\beta(\tau,\epsilon) \equiv U(\epsilon\tau,\epsilon) + \alpha(\tau,\epsilon) \sim \sum_{j=0}^{\infty} \beta_j(\tau)\epsilon^j \tag{2.15}$$

that satisfies (2.12) for all finite τ and coincides asymptotically with $U(\epsilon\tau,\epsilon)$ as $\tau \to \infty$.

To obtain the outer solution, we successively equate coefficients of like powers of ϵ in (2.12). Thus, U_0 must satisfy the limiting equation

$$G_u^T(U_0,t)G(U_0,t) = 0.$$

Because the $m \times (n-r)$ matrix G_u^T has rank $n-r$, multiplication by $G_u(U_0,t)$ implies that U_0 must satisfy the expected constraint

$$G(U_0,t) = 0. \tag{2.16}$$

This determines a locally unique solution $U_0(t)$ when $m = n-r$. For $m > n-r$, it only restricts U_0 to a manifold. The coefficient of ϵ implies that U_1 must satisfy the linear equation

$$-G_u^T(U_0,t)G_u(U_0,t)U_1 = \dot{U}_0 - F(U_0,t) \tag{2.17}$$

(since U_0 satisfies (2.16)). Multiplying (2.17) from the left by $G_u(U_0,t)$ provides $G_u(U_0,t)U_1$ in terms of U_0. Since differentiation of (2.16) implies that $G_u(U_0,t)\dot{U}_0 = -G_t(U_0,t)$, (2.17) finally provides a differential equation

$$\begin{aligned}\dot{U}_0 =& [I - G_u^T(U_0,t)(G_u(U_0,t)G_u^T(U_0,t))^{-1}G_u(U_0,t)]F(U_0,t) \\ & - G_u^T(U_0,t)(G_u(U_0,t)G_u^T(U_0,t))^{-1}G_t(U_0,t)\end{aligned} \tag{2.18}$$

for the desired solution $U_0(t)$ of the DAE (2.1). We note that a differential equation for U_1 will follow analogously using the $O(\epsilon^2)$ terms in (2.12). Equation (2.18) must be solved subject to an initial condition that satisfies the constraint $G = 0$ at $t = 0$. We will get the initial value $U_0(0)$ by matching the limiting inner and outer solutions, i.e., by taking

$$U_0(0) = \lim_{\tau \to \infty} \beta_0(\tau) \tag{2.19}$$

presuming this limit exists.

The leading term of the inner solution $\beta_0(\tau)$ must naturally satisfy the m-dimensional nonlinear initial value problem

$$\frac{d\beta_0}{d\tau} = -G_u^T(\beta_0,0)G(\beta_0,0), \qquad \beta_0(0) = u(0). \tag{2.20}$$

If $G(u(0),0) = 0$, we naturally take $\beta_0(\tau) \equiv u(0)$, so we obtain the consistent initial value $U_0(0) = u(0)$. More generally, any rest point $\beta_0(\infty) = U_0(0)$ will lie on the constraint $G(\beta_0(\infty),0) = 0$, presuming β_0 exists for all $\tau \geq 0$. The equation for β_1 will be a linearized version of (2.20).

Observe that the limiting Jacobian matrix $G_u^T(\beta_0(\infty),0)G_u(\beta_0(\infty),0)$ for (2.20) has $n-r$ stable eigenvalues and $m-(n-r)$ trivial eigenvalues. Reordering the components of β_0, if necessary, let us partition β_0 after its first $n-r$ rows as

$$\beta_0 = \begin{pmatrix} \beta_{01} \\ \beta_{02} \end{pmatrix} \tag{2.21}$$

and *assume* that the $(n-r)$-dimensional stable manifold for (2.20) can be described in the form

$$\beta_{02} = \gamma(\beta_{01}) \tag{2.22}$$

(cf. the analogous use of a *dynamic* manifold in [13] and of invariant manifolds in [5]). Obtaining an explicit representation (2.22) is, admittedly, a difficult problem in

general. If we let $H_1(\beta_{01})$ represent the first $n-r$ components of $-G_u^T G$ evaluated along the stable manifold, (2.20) and (2.22) imply that β_{01} will necessarily have to satisfy the initial value problem

$$\frac{d\beta_{01}}{d\tau} = H_1(\beta_{01}), \qquad \beta_{01}(0) = u_1(0). \tag{2.23}$$

Here, the representation (2.22) restricts the initial value $u(0)$ to lie on the corresponding $(n-r)$-dimensional stable manifold. Since the motion of β_0 is restricted to this stable manifold during integration, the limit at infinity, $\beta_0(\infty) = U_0(0)$ will necessarily satisfy both the $m-(n-r)$-dimensional restriction

$$\beta_{02}(\infty) = \gamma(\beta_{01}(\infty))$$

and the $(n-r)$-dimensional outer constraint

$$G\begin{pmatrix} \beta_{01}(\infty) \\ \gamma(\beta_{01}(\infty)) \end{pmatrix} = 0.$$

The specific limit $\beta_{01}(\infty)$ might be obtained through numerical integration of (2.23) on $\tau \geq 0$ or by solving the last $n-r$ equations. This matching procedure thereby defines a consistent initial m-vector $U_0(0)$.

Example. Consider the DAE

$$\begin{cases} \dot{u} = f_1(u,v,w) + uz, \\ \dot{v} = f_2(u,v,w) + vz, \\ \dot{w} = f_3(u,v,w) + wz, \\ u^2 + v^2 + w^2 = 1, \end{cases} \tag{2.24}$$

consisting of three scalar differential equations and a scalar algebraic constraint. Though this particular problem is unmotivated, similar examples result from constrained mechanics. If we differentiate the constraint with respect to t, we obtain

$$2u(f_1 + uz) + 2v(f_2 + vz) + 2w(f_3 + wz) = 0.$$

This allows us to eliminate

$$z = -uf_1 - vf_2 - wf_3 \tag{2.25}$$

and obtain the vector system

$$\begin{cases} \dot{p} = A(p)f(p), \\ 0 = p^T p - 1 \end{cases} \tag{2.26}$$

for

$$p = \begin{pmatrix} u \\ v \\ w \end{pmatrix}, \qquad f = \begin{pmatrix} f_1 \\ f_2 \\ f_3 \end{pmatrix},$$

$$A(p) = \begin{pmatrix} 1-u^2 & -uv & -uw \\ -uv & 1-v^2 & -vw \\ -uw & -vw & 1-w^2 \end{pmatrix}.$$

To solve the constrained system (2.26), we might use the Lagrange multiplier $\lambda = -\frac{1}{\epsilon}(p^T p - 1)$ as in (2.11) or directly consider the regularized problem

$$\epsilon \dot{p} = \epsilon A(p) f(p) - 2p(p^T p - 1). \tag{2.27}$$

We naturally seek an asymptotic solution of the corresponding initial value problem in the form

$$p(t, \epsilon) = P(t, \epsilon) + \alpha(\tau, \epsilon), \tag{2.28}$$

where $\alpha \to 0$ as $\tau = t/\epsilon \to \infty$. Necessarily, the outer solution $P(t, \epsilon)$ will satisfy the equation

$$2P(P^T P - 1) = \epsilon(A(P) f(P) - \dot{P}) \tag{2.29}$$

as a power series in ϵ. Thus, the leading term must satisfy the equation $P_0(P_0^T P_0 - 1) = 0$. We reject the trivial solution since it does not satisfy the expected constraint $P_0^T P_0 = 1$. Note that the latter implies that $\dot{P}_0^T P_0 = 0$. The coefficient of ϵ in (2.29) then implies that $4P_0 P_0^T P_1 = A(P_0) f(P_0) - \dot{P}_0$. Multiplying by P_0^T allows us to eliminate P_1 and to finally obtain the differential equation

$$\dot{P}_0 = (I - P_0 P_0^T) A(P_0) f(P_0) \tag{2.30}$$

for the solution P_0 of the DAE (2.26). The constraint will be an invariant manifold for solutions of (2.30).

The corresponding inner solution

$$\Pi(\tau, \epsilon) = P(\epsilon\tau, \epsilon) + \alpha(\tau, \epsilon) \tag{2.31}$$

will necessarily satisfy the initial value problem

$$\frac{d\Pi}{d\tau} = -2\Pi(\Pi^T \Pi - 1) + \epsilon A(\Pi) f(\Pi), \qquad \Pi(0, \epsilon) = p(0) \tag{2.32}$$

as a power series in ϵ. Its leading term Π_0 will satisfy the vector equation

$$\frac{d\Pi_0}{d\tau} = -2\Pi_0(\Pi_0^T \Pi_0 - 1) \tag{2.33}$$

so the squared norm $D_0 = \Pi_0^T \Pi_0$ will satisfy the scalar equation

$$\frac{dD_0}{d\tau} = -4D_0(D_0 - 1).$$

An explicit integration yields

$$D_0(\tau) = 1 + \frac{e^{-4\tau}(\|p(0)\|^2 - 1)}{\|p(0)\|^2 + e^{-4\tau}(1 - \|p(0)\|^2)}$$

and, through the resulting linear equation for Π_0,

$$\Pi_0(\tau) = \sqrt{D_0(\tau)}\ \frac{p(0)}{\|p(0)\|}. \tag{2.34}$$

Thus, we obtain the consistent initial vector

$$P_0(0) = \Pi_0(\infty) = \frac{p(0)}{\|p(0)\|}. \tag{2.35}$$

This allows the DAE (2.24) to be solved by integrating the vector system (2.30) for P_0 using a unit initial vector in the direction of the arbitrary $p(0)$. The resulting initial impulse corresponds to an initial boundary layer.

3. Some index-three examples.

(i) Consider the initial value problem

$$\begin{cases} \dot{u} = u(w^2-1) + v, u(0) = 1, \\ \dot{v} = v(w^2-1) - u, v(0) = 2, \\ \dot{w} = u + v - z, w(0) = 2, \\ \text{with} \quad u^2 + v^2 = 1. \end{cases} \tag{3.1}$$

Since the initial conditions are inconsistent with the constraint, the solution is expected to exhibit an initial impulse. Differentiating the constraint provides a *hidden* constraint

$$w^2 = 1, \tag{3.2}$$

since $u\dot{u} + v\dot{v} = (u^2+v^2)(w^2-1) = w^2 - 1 = 0$. (Such hidden constraints are common in higher index problems; cf. [12].) Then $\dot{w} = 0$ implies that we also have the second hidden constraint

$$u + v - z = 0\,. \tag{3.3}$$

Eliminating z and using (3.2), we shall now consider the constrained differential system

$$\begin{cases} \dot{u} = v, \\ \dot{v} = -u, \\ \dot{w} = 0, \\ \text{with } u^2 + v^2 = 1, \quad w^2 = 1, \end{cases} \tag{3.4}$$

together with the prescribed initial conditions, which are inconsistent with both constraints.

We'll now introduce scalars λ and μ as Lagrange multipliers and a small positive parameter ϵ to scale them as slack variables to provide us with the regularized problem

$$\begin{cases} \begin{pmatrix} \dot{u} \\ \dot{v} \end{pmatrix} = \begin{pmatrix} v \\ -u \end{pmatrix} + \begin{pmatrix} 2u \\ 2v \end{pmatrix} \lambda + 0\mu, \\ \dot{w} = 0\lambda + 2w\mu, \\ -\epsilon\lambda = u^2 + v^2 - 1, \\ -\epsilon\mu = w^2 - 1. \end{cases} \tag{3.5}$$

Alternatively, eliminating the multipliers implies the singularly perturbed initial value problem

$$\begin{cases} \epsilon\dot{u} = -2u(u^2+v^2-1)+\epsilon v, & u(0)=1, \\ \epsilon\dot{v} = -2v(u^2+v^2-1)-\epsilon u, & v(0)=2, \\ \epsilon\dot{w} = -2w(w^2-1), & w(0)=2. \end{cases} \tag{3.6}$$

It is elementary to solve this system directly by first solving the equations for w and for $r=\sqrt{u^2+v^2}$. Since $\dot{w}=O(1/\epsilon)$ is negative for $w>1$, it follows that

$$w = 1+\gamma_0(\tau), \tag{3.7}$$

where γ_0 is the unique monotonically decreasing solution of the initial value problem

$$\frac{d\gamma_0}{d\tau} = -2\gamma_0(1+\gamma_0)(2+\gamma_0), \qquad \gamma_0(0)=1.$$

(An implicit solution is easily obtained by separating variables.) Clearly, γ_0 decays exponentially to zero as $\tau\to\infty$. Likewise, the initial value problem

$$\epsilon\frac{dr}{dt} = -2r(r^2-1), \qquad r(0)=\sqrt{5} \tag{3.8}$$

has a unique solution of the form

$$r(t,\epsilon) = 1+\beta_0(\tau), \tag{3.9}$$

where β_0 also decays exponentially to zero as $\tau\to\infty$. Since $-2(u^2+v^2-1)=\frac{\epsilon}{r}\dot{r}$, the equations for u and v can be rewritten as $\left(\frac{u}{r}\right)^{\cdot}=\frac{v}{r}$ and $\left(\frac{v}{r}\right)^{\cdot}=-\frac{u}{r}$. Thus,

$$\frac{u}{r} = \frac{u(0)}{r(0)}\cos t + \frac{v(0)}{r(0)}\sin t \tag{3.10}$$

and (3.9) yields

(3.11)
$$u(t,\epsilon)=\frac{1}{\sqrt{5}}(1+\beta_0(\tau))(\cos t+2\sin t) \quad \text{and} \quad v(t,\epsilon)=\frac{1}{\sqrt{5}}(1+\beta_0(\tau))(2\cos t-\sin t).$$

Thus, u and v have the asymptotic form

$$u(t,\epsilon)=U_0(t)+\alpha(\tau,\epsilon), \qquad v(t,\epsilon)=V_0(t)+\delta(\tau,\epsilon) \tag{3.12}$$

with the outer solution

$$U_0(t)=\frac{1}{\sqrt{5}}(\cos t+2\sin t), \qquad V_0(t)=\frac{1}{\sqrt{5}}(2\cos t-\sin t) \tag{3.13}$$

and an initial layer correction

$$\begin{pmatrix}\alpha(\tau,\epsilon)\\ \delta(\tau,\epsilon)\end{pmatrix}$$

that decays exponentially to zero like $\beta_0(\tau)$. Without the regularization (3.5), it would be quite difficult to predict the appropriate initial vector $(U_0(0), V_0(0), W_0(0)) = \frac{1}{\sqrt{5}}(1, 2, \sqrt{5})$ with which to begin a numerical integration of the original DAE.

(ii) The motion of a spherical pendulum with unit mass and length is described by the DAE

$$\begin{cases} \ddot{x} = \lambda x, \\ \ddot{y} = \lambda y, \\ \ddot{z} = \lambda z - g, \\ x^2 + y^2 + z^2 = 1, \end{cases} \tag{3.14}$$

where λ represents the tension and g is acceleration of gravity (cf. [21]). We obtain the additional hidden constraints

$$\begin{gathered} x\dot{x} + y\dot{y} + z\dot{z} = 0, \\ \dot{x}^2 + \dot{y}^2 + \dot{z}^2 + x\ddot{x} + y\ddot{y} + z\ddot{z} = v^2 + \lambda(x^2 + y^2 + z^2) - gz = 0, \end{gathered} \tag{3.15}$$

by differentiating the constraint twice. Introducing v^2 as the square of the speed, we use the latter equation to eliminate

$$\lambda = gz - v^2. \tag{3.16}$$

Thus, there remains the constrained differential system

$$\begin{cases} \ddot{x} = (gz - v^2)x, \\ \ddot{y} = (gz - v^2)y, \\ \ddot{z} = -g(1 - z^2) - v^2 z, \\ x^2 + y^2 + z^2 = 1, \\ x\dot{x} + y\dot{y} + z\dot{z} = 0. \end{cases} \tag{3.17}$$

Note that one might attempt to solve this problem subject to arbitrary initial position and velocity vectors that could fail to satisfy either constraint.

The geometry suggests that it would be natural to introduce spherical coordinates using

$$x = r\cos\varphi\sin\theta, \quad y = r\sin\varphi\sin\theta, \quad \text{and} \quad z = r\cos\theta. \tag{3.18}$$

After some nontrivial manipulations, we are able to express (3.17) as the equivalent problem

$$\begin{cases} \ddot{r} = (r^2 - 1)(g\cos\theta - r\dot{\theta}^2 - r\dot{\varphi}^2\sin^2\theta) - \dot{r}^2 r, \\ r\sin\theta\ddot{\varphi} = 2\dot{\varphi}(\dot{r}\sin\theta + r\dot{\theta}\cos\theta), \\ r\ddot{\theta} = r\dot{\varphi}^2\sin\theta\cos\theta - 2\dot{r}\dot{\theta} + g\sin\theta, \\ r(t) = 1, \\ \dot{r}(t) = 0. \end{cases} \tag{3.19}$$

To allow arbitrary initial values for r and $\dot{r}$, we could naturally write the second-order equation for r as a first-order system for r and $u = \dot{r}$. If we then introduced scaled slack variables/Lagrange multipliers as $-\varepsilon\xi = r - 1$ and $-\varepsilon\eta = u$, we'd get the regularized problem

$$\text{(3.20)} \qquad \begin{cases} \varepsilon\dot{r} = -(r-1) + \varepsilon u, \\ \varepsilon\dot{u} = -u - \varepsilon(r^2-1)(g\cos\theta - r\dot{\theta}^2 - r\dot{\varphi}^2\sin^2\theta) - \varepsilon r u^2, \\ r\sin\theta\ddot{\varphi} = 2\dot{\varphi}(u\sin\theta + r\dot{\theta}^2\cos\theta), \\ r\ddot{\theta} = r\dot{\varphi}^2\sin\theta\cos\theta - 2u\dot{\theta} + g\sin\theta. \end{cases}$$

We'll solve this system as a singularly perturbed initial value problem with $r(0)$, $u(0) = \dot{r}(0)$, $\varphi(0)$, $\dot{\varphi}(0)$, $\theta(0)$, and $\dot{\theta}(0)$ *arbitrarily* prescribed except that $r(0)\sin\theta(0) \neq 0$. We naturally seek an asymptotic solution in the form

$$\text{(3.21)} \qquad \begin{cases} r(t,\varepsilon) = 1 + \alpha(\tau,\varepsilon), \\ u(t,\varepsilon) = \beta(\tau,\varepsilon), \\ \varphi(t,\varepsilon) = \Phi(t,\varepsilon) + \varepsilon^2\gamma(\tau,\varepsilon), \\ \theta(t,\varepsilon) = \Theta(t,\varepsilon) + \varepsilon^2\delta(\tau,\varepsilon), \end{cases}$$

where we ask that the functions of $\tau = t/\varepsilon$ decay to zero as $\tau \to \infty$ in order to provide an initial layer within which the solution of the regularized problem moves rapidly toward the constraint manifold where $r \equiv 1$. This ansatz follows from the usual Tikhonov–Levinson theory (cf. [17]) once one notes that $R(t,\varepsilon) \equiv 1$ in the outer solution for r, to which $U(t,\varepsilon) \equiv 0$ corresponds.

The consistent outer solution

$$\text{(3.22)} \qquad (R(t,\varepsilon), U(t,\varepsilon), \Phi(t,\varepsilon), \Theta(t,\varepsilon)) \equiv (1, 0, \Phi(t,\varepsilon), \Theta(t,\varepsilon))$$

must satisfy the system (3.20) as a power series in ε. Thus, $\Theta(t,0) = \Theta_0(t)$ and $\Phi(t,\varepsilon) = \Phi_0(t)$ must satisfy the coupled system

$$\text{(3.23)} \qquad \begin{cases} \sin\Theta_0\ddot{\Phi}_0 = 2\cos\Theta_0\dot{\Theta}_0\dot{\Phi}_0, \\ \ddot{\Theta}_0 = \left[\dot{\Phi}_0^2\cos\Theta_0 + g\right]\sin\Theta_0, \end{cases}$$

with $\Phi_0(0) = \varphi(0)$, $\dot{\Phi}_0(0) = \dot{\varphi}(0)$, $\Theta_0(0) = \theta(0)$, and $\dot{\Theta}_0(0) = \dot{\theta}(0)$. Multiplying the first equation by $\sin\Theta_0$ and integrating implies that

$$\text{(3.24)} \qquad \dot{\Phi}_0\sin^2\Theta_0 = \dot{\phi}(0)\sin^2\theta(0) \equiv C.$$

Physically, this means that the angular momentum about the z axis is conserved. Substituting for $\dot{\Phi}_0$ in the second equation and integrating the resulting equation for Θ_0 implies the conservation of energy statement

$$\text{(3.25)} \qquad \dot{\Theta}_0^2 = -\frac{C^2}{\sin^2\Theta_0} - 2g\cos\Theta_0 + E_0,$$

where the constant E_0 is specified by the initial conditions. More explicit results follow, as usual, in terms of elliptic integrals.

The stretched system satisfied by the initial layer correction $(\alpha, \beta, \varepsilon^2\gamma, \varepsilon^2\delta)$ follows in a straightforward fashion. In particular, its initial terms must be decaying solutions of the limiting problem

$$\begin{cases} \dfrac{d\alpha_0}{d\tau} = -\alpha_0, \qquad \alpha_0(0) = r(0) - 1, \\ \dfrac{d\beta_0}{d\tau} = -\beta_0, \qquad \beta_0(0) = \dot{r}(0), \\ (1 + \alpha_0(\tau)) \sin\theta(0) \dfrac{d^2\gamma_0}{d\tau^2} = 2\dot{\varphi}(0) \left[\beta_0 \sin\theta(0) + \alpha_0 \dot{\theta}^2(0) \cos\theta(0)\right], \\ (1 + \alpha_0(\tau)) \dfrac{d^2\delta_0}{d\tau^2} = \alpha_0 \dot{\varphi}^2(0) \sin\theta(0) \cos\theta(0) - 2\beta_0 \dot{\theta}(0). \end{cases} \tag{3.26}$$

Thus

$$\alpha_0(\tau) = e^{-\tau}(r(0) - 1) \tag{3.27}$$

will provide an initial impulse for $r(t)$ if $r(0) \neq 1$;

$$\beta_0(\tau) = e^{-\tau}\dot{r}(0) \tag{3.28}$$

will provide an initial impulse for $\dot{r}(t)$ if $\dot{r}(0) \neq 0$; and they together determine the less important terms

$$\begin{cases} \gamma_0(\tau) = 2\dot{\varphi}(0) \displaystyle\int_\tau^\infty \int_r^\infty e^{-s} \left[(r(0) - 1)\dot{\theta}^2(0) \cos\theta(0) + \dot{r}(0) \sin\theta(0)\right] \\ \qquad\qquad \Big/ (1 + e^{-s}(r(0) - 1)) \, ds \, dr \text{ and} \\ \delta_0(\tau) = \displaystyle\int_\tau^\infty \int_r^\infty e^{-s} \left[(r(0) - 1)\dot{\varphi}^2(0) \sin\theta(0) \cos\theta(0) - 2\dot{r}(0)\dot{\theta}(0)\right] \\ \qquad\qquad \Big/ (1 + e^{-s}(r(0) - 1)) \, ds \, dr. \end{cases} \tag{3.29}$$

We note that the asymptotic structure (3.21) of the solution in spherical coordinates directly determines that in the original Cartesian coordinates as well.

Acknowledgment. This work is written in appreciation of Professors Frank W. J. Olver and Richard A. Askey, especially for their valuable and ongoing contributions to this journal.

A GENERALIZATION OF PEARCEY'S INTEGRAL*

R. B. PARIS†

Abstract. This paper considers the special case of a cuspoid canonical diffraction integral consisting of only two parameters X, Y in the form

$$\int_{-\infty}^{\infty} \exp[i(u^{2m} + Xu^m + Yu)]du,$$

where m is a positive integer with $m \geq 2$. This integral is a reduced form of the general cuspoid canonical diffraction integral involving $2m-1$ stationary phase points, and represents a generalization of the familiar Pearcey integral with $m = 2$. The analytic continuation of this integral to arbitrary complex values of X, Y is considered, and its asymptotic behavior when either $|X|$ or $|Y| \to \infty$ is determined.

Key words. asymptotic expansions, Pearcey integral, caustics

AMS subject classifications. 41A60, 30E15, 33A70

1. Introduction.

We consider a generalization of the Pearcey integral defined by

$$P'_m(X,Y) = \int_{-\infty}^{\infty} \exp[i(u^{2m} + Xu^m + Yu)]du, \tag{1.1}$$

where X and Y are real variables and m is an integer with $m \geq 2$. The particular case $m = 2$, corresponding to the familiar Pearcey integral, arises in many physical problems involving short wavelength phenomena, such as wave propagation and optical diffraction; we refer to [4], [9], [12], and the references therein for a summary of the recent literature on Pearcey's integral.

The Pearcey integral belongs to the family of canonical oscillatory integrals that are classified according to the hierarchy introduced to describe the types of singularities arising in catastrophe theory. For one-dimensional integrals, the exponents are the polynomial transformations associated with the so-called cuspoid catastrophes [3]. The general cuspoid canonical diffraction integral has the form

(1.2)

$$I_n(X_1, X_2, \ldots, X_{n-2}) = \int_{-\infty}^{\infty} \exp[if_n(u; \underline{X})]du, \qquad f_n(u; \underline{X}) = u^n + \sum_{k=1}^{n-2} X_k u^k,$$

where $\underline{X} = (X_1, X_2, \ldots, X_{n-2})$ with the parameters X_k being real, and is associated with $n-1$ stationary phase or saddle points. The simplest case $n = 3$ corresponds to the fold catastrophe and involves two stationary points whose positions depend on the single parameter X_1. The canonical integral in this case is the well-known Airy function. The next integral in the hierarchy has $n = 4$ and corresponds to the cusp catastrophe, which involves three coalescing stationary points and two real parameters, X_1 and X_2. The canonical form of this integral is Pearcey's integral. The cases $n = 5$ and $n = 6$ correspond to the so-called swallowtail and butterfly integrals and involve, respectively, four and five stationary points.

Comparison with (1.2) shows that $P'_m(X,Y)$ is a reduced case of $I_{2m}(X_1, X_2, \ldots, X_{2m-2})$, with $X_1 = Y$, $X_m = X$ and all other parameters equal to zero. In particular, when $m = 3$, we have the reduced butterfly integral $P'_3(X,Y) \equiv I_6(Y,0,X,0)$. The utility of integrals of the type (1.2) is hampered by the lack of detailed information concerning the numerical values of these functions and the complexity of their large parameter behavior. A considerable effort has been made over the last decade in an attempt to rectify these deficiencies. Extensive work concerning the numerical evaluation of the Pearcey and the swallowtail integrals has been described by Connor and Curtis [4], [5] and Connor, Curtis, and Farelly [6]. Recent asymptotic investigations have been undertaken by Stamnes and Spjelkavik [15], Kaminski [9], Paris [12] for the Pearcey integral, and Kaminski [10] for the swallowtail integral (see also [17, p. 389]).

In this paper we shall be concerned with the analytic continuation of $P'_m(X,Y)$ to complex values of X and Y. This is achieved by rotation of the path of integration in (1.1) through an angle of $\pi/4m$ and appeal to Jordan's lemma to obtain

$$P'_m(X,Y) \equiv P_m(x,y) = e^{\pi i/4m} \int_{-\infty}^{\infty} \exp[-t^{2m} - xt^m + iyt]dt, \tag{1.3}$$
$$x = Xe^{-\pi i/4}, \qquad y = Ye^{\pi i/4m},$$

where we have put $u = t\exp(\pi i/4m)$. We consider the case of even and odd m separately and define the integrals

$$\left\{ \begin{array}{c} I_m(x,y) \\ J_m(x,y) \end{array} \right\} = \int_0^{\infty} e^{-t^{2m}-xt^m} \left\{ \begin{array}{c} \cos yt \\ \sin yt \end{array} \right\} dt \tag{1.4}$$

so that

$$P_m(x,y) = 2e^{\frac{\pi i}{4m}} I_m(x,y) \qquad (m \text{ even}), \tag{1.5}$$

$$P_m(x,y) = e^{\frac{\pi i}{4m}} [\{I_m(x,y) + iJ_m(x,y)\} + \{I_m(-x,y) - iJ_m(-x,y)\}] \qquad (m \text{ odd}). \tag{1.6}$$

It is readily established from (1.3) that $P_m(x,y)$ satisfies the symmetry and conjugacy relations

$$P_m(x,y) = P_m((-)^m x, -y),$$
$$e^{\pi i/4m}\overline{P_m(x,y)} = e^{-\pi i/4m} P_m((-)^m \overline{x}, \overline{y}), \tag{1.7}$$

where the bar denotes the complex conjugate.

Following the method described in [12] for the Pearcey integral, we shall obtain the asymptotic behavior of $P_m(x,y)$ for complex variables when $|x|$ or $|y| \to \infty$ by means of an integral representation involving a Weber parabolic cylinder function. This approach permits the determination of the asymptotics without reference to the above-mentioned stationary points. We remark that this approach has also recently been employed by Janssen [8], who has considered a different generalization of Pearcey's integral in the form

$$\int_0^{\infty} \exp[i(u^4 + Xu^2)] J_v(uY) u^{v+1} du \qquad (-1 < v < 5/2),$$

where J_v denotes the Bessel function of order v. This integral, which equals a multiple of Pearcey's integral when $v = -\frac{1}{2}$, occurs in the problem of image formation in high resolution electron microscopes when $v = 0$.

2. Preliminaries. If we denote the phase function in (1.1) by $f(u;X,Y) \equiv u^{2m} + Xu^m + Yu$, then the $2m-1$ stationary points are given by $\partial f/\partial u = 0$, or

$$u^{2m-1} + \frac{1}{2}Xu^{m-1} + \frac{Y}{2m} = 0. \tag{2.1}$$

For real X, Y, application of Descartes's rule shows that there cannot be more than three real roots of (2.1), the remaining roots being complex conjugate pairs (although when $Y = 0$ one of these roots is a multiple root of order $m-1$ at $u = 0$). For certain values of X and Y two of these real roots can coalesce to form a double root. This occurs when $\partial f/\partial u = \partial^2 f/\partial u^2 = 0$ and corresponds to values of X, Y lying on the caustic

$$Y^m + m\left(\frac{m-1}{2}\right)^{m-1}\left(\frac{mX}{2\mu}\right)^{2\mu} = 0, \qquad \mu = m - \frac{1}{2} \quad (m = 2,3,\ldots). \tag{2.2}$$

In the case $m = 2$, this yields the familiar cusped caustic $Y^2 + (\frac{2}{3}X)^3 = 0$ for the Pearcey integral. For m even the caustic in (2.2) is cusped and symmetrical about the negative X-axis, while for m odd the caustic is asymmetrical (see Fig. 1). Inside the shaded domain in the X,Y-plane bounded by the caustic (and, in the case m odd, by the line $Y = 0$) there are three real, distinct stationary points which will contribute to the asymptotic behavior of $P'_m(X,Y)$. Outside of this domain there is only one real stationary point, but some complex stationary points may also contribute (cf. the case $m = 2$).

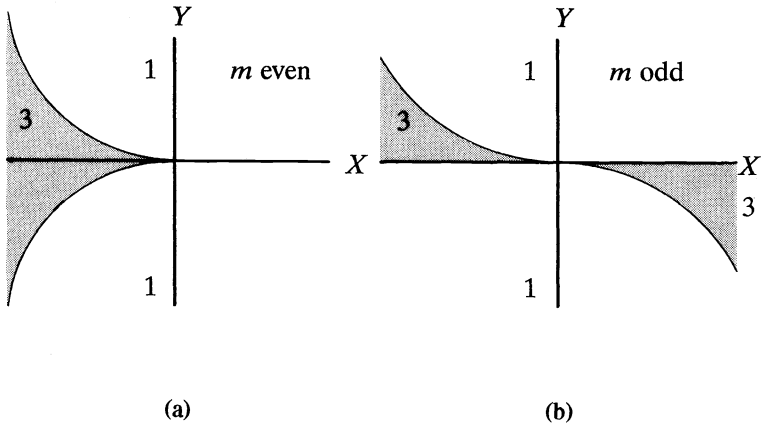

FIG. 1. *The caustic* (2.2) *in the* X,Y*-plane for* (a) m *even and* (b) m *odd. The figures indicate the number of real, distinct stationary points.*

For large values of X, Y inside the caustic the asymptotic behavior of $P'_m(X,Y)$ can be obtained by the method of stationary phase as a sum of three terms. Explicit formulation of these terms, however, is rendered difficult by the fact that the real roots of (2.1) for general m do not seem to be expressible in closed form. The situation for large $|X|$ on the caustic (2.2) is more tractable since the double root can be expressed simply as $u_0 = [(m-1)|X|/4\mu]^{1/m}$. With the new integration variable $\tau = u/u_0$, we then have, on the caustic (when $X < 0$),

$$P'_m(X,Y) = u_0 \int_{-\infty}^{\infty} \exp[iX^{*2}F(\tau)]d\tau, \qquad X^* = \frac{(m-1)}{4\mu}|X|,$$

where

$$F(\tau) = \tau^{2m} - \frac{4\mu}{m-1}\tau^m + \frac{2m^2}{m-1}\tau.$$

The phase function $F(\tau)$ possesses a double positive stationary point at $\tau = 1$ and one negative stationary point, which we define by $\tau = -k$, $k > 0$. Straightforward application of the method of stationary phase (see [11, p. 96] and [17, p. 79]) then shows that for large $|X|$ on the caustic

(2.3)

$$P'_m(X,Y) = \frac{\pi^{1/2}}{m}\alpha(k)(X^*)^{\frac{1}{m}-1}\exp i\left[\beta(k)X^{*2} + \frac{\pi}{4}\right]\left\{1 + O(X^{*-1})\right\}$$
$$+ 3^{-\frac{1}{6}}(2m^2\mu)^{-\frac{1}{3}}(X^*)^{\frac{1}{m}-\frac{2}{3}}\exp\left[2i\mu X^{*2}\right]\left\{\Gamma\left(\frac{1}{3}\right) - \frac{i(3m-5)\Gamma\left(\frac{2}{3}\right)}{(144m^2\mu)^{\frac{1}{3}}}X^{*-\frac{2}{3}} + O\left(X^{*-\frac{4}{3}}\right)\right\},$$

where

$$\alpha(k) \equiv \left[\frac{F''(-k)}{2m^2}\right]^{-\frac{1}{2}} = \frac{k}{\sqrt{k+k^{2m}}}, \qquad \beta(k) \equiv F(-k) = -(2mk + k^{2m}).$$

It does not appear possible to determine the negative stationary point $\tau = -k$ in a simple closed form, except when $m = 2$ and $m = 3$, when $k = 2$ and $k = \frac{2}{3}\left(\frac{5}{4}\right)^{1/3}\left[\left(\frac{5}{4}\right)^{1/3} + \left(\frac{5}{4}\right)^{-1/3} - 1\right] = 0.7221199\ldots$, respectively. Values of k, together with the corresponding values of $\alpha(k)$ and $\beta(k)$, are tabulated in Table 1 for $m = 2$ to $m = 10$. When $m = 2$, equation (2.3) reduces to the asymptotic form obtained in [9] and [12] for the Pearcey integral on the caustic $Y^2 + \left(\frac{2}{3}X\right)^3 = 0$.

In this paper, we shall not be concerned with the asymptotic form of $P'_m(X,Y)$ in the neighborhood of the caustic (2.2), but with the asymptotics of $P_m(x,y)$ for large $|x|$ or $|y|$. We follow the procedure described in [12] for the Pearcey integral to transform the integrals for $I_m(x,y)$ and $J_m(x,y)$ in (1.4) into loop integrals involving a Weber function. To do this, we employ the Mellin–Barnes integral representations, valid for all arg$z$:

$$\left\{ \begin{array}{c} \cos z \\ \sin z \end{array} \right\} = \frac{1}{2\pi i} \int_C \Gamma(s) \left\{ \begin{array}{c} \cos \frac{1}{2}\pi s \\ \\ \sin \frac{1}{2}\pi s \end{array} \right\} z^{-s} ds \qquad (z \neq 0), \tag{2.4}$$

where throughout C will denote a loop that starts and finishes at $-\infty$ and encircles $s = 0$ in the positive sense. Upon reversal of the order of integration, when $\mathrm{Re}(s) < 1$, we then find

$$I_m(x,y) = \frac{1}{2\pi i} \int_C \Gamma(s) \cos \tfrac{1}{2}\pi s \, y^{-s} \left\{ \int_0^\infty e^{-t^{2m} - xt^m} t^{-s} dt \right\} ds \qquad (y \neq 0).$$

The inner integral (with $\tau = t^m$) can be evaluated in terms of the parabolic cylinder function $D_v(z)$, which admits the integral representation [7, p. 119]

$$D_v(z) = \frac{e^{-z^2/4}}{\Gamma(-v)} \int_0^\infty \exp\left(-\tfrac{1}{2}\tau^2 - z\tau\right) \tau^{-v-1} d\tau, \qquad \mathrm{Re}(v) < 0.$$

Similar arguments applied to $J_m(x,y)$ lead to the representations when $\mathrm{Re}(s) < 1$,

$$\left\{ \begin{array}{c} I_m(x,y) \\ J_m(x,y) \end{array} \right\} = \frac{2^{-\frac{1}{2m}}}{m} e^{x^2/8} \frac{1}{2\pi i} \int_C \Gamma(s) \Gamma\left(\frac{1}{m} - \frac{s}{m}\right) \cdot \left\{ \begin{array}{c} \cos \frac{1}{2}\pi s \\ \\ \sin \frac{1}{2}\pi s \end{array} \right\} D_{\frac{s}{m} - \frac{1}{m}}\left(\frac{x}{\sqrt{2}}\right) \left(y 2^{-\frac{1}{2m}}\right)^{-s} ds, \tag{2.5}$$

where the loop C described above separates the poles of $\Gamma(s)$ and $\Gamma(1/m - s/m)$. These representations will form the basis of the present investigation.

From the asymptotic behavior of $D_v(z)$ for fixed z and large $|v|$ (see (4.4)), the convergence of the integrals in (2.5) is seen to be controlled by the quotient of gamma functions $\Gamma(s)\Gamma(1/m - s/m)\Gamma(1/2m + \frac{3}{4} - s/2m)$. Application of Stirling's formula then shows that as $|s| \to \infty$ on C the integrands in (2.5) are dominated by the term $\exp[-(1 - 1/2m)\ln|s|]$, so that the right-hand sides of (2.5) converge for all finite complex values of x and y ($\neq 0$).

We remark that when $m = 2$, use of the properties of the gamma function, followed by replacement of the variable s by $2s$, shows that (1.5) and (2.5) reduce to the alternative representation for Pearcey's integral given in [12]:

$$P_2(x,y) = 2^{-\frac{1}{4}} \pi^{\frac{1}{2}} e^{\frac{x^2}{8} + \frac{\pi i}{8}} \frac{1}{2\pi i} \int_C \Gamma(s) D_{s-\frac{1}{2}}\left(\frac{x}{\sqrt{2}}\right) (y^2/4\sqrt{2})^{-s} ds.$$

3. Asymptotics of $P_m(x,y)$ for large $|x|$. We derive the asymptotic expansions of $I_m(x,y)$ and $J_m(x,y)$ for large $|x|$, y finite. The analysis we present is formal, since no attempt is made here to discuss the asymptotic nature of the various expansions; this has been seen for the Pearcey integral case $m = 2$ in [12]. We substitute the expansion for large $|z|$ of the parabolic cylinder function [16, p. 347], [12]

$$D_v(z) \sim z^v e^{-z^2/4} \sum_{r=0}^\infty \frac{(-v)_{2r}}{r!} (-2z^2)^{-r}, \qquad |\arg z| < \frac{1}{2}\pi, \tag{3.1}$$

where $(a)_r = \Gamma(a+r)/\Gamma(a)$, into (2.5a), to find, when $|\arg x| < \frac{1}{2}\pi$,

$$I_m(x,y) \sim \frac{x^{-\frac{1}{m}}}{m}\frac{1}{2\pi i}\int_C \Gamma(s)\cos\frac{1}{2}\pi s\left(yx^{-\frac{1}{m}}\right)^{-s}\sum_{r=0}^{\infty}\frac{\Gamma\left(\frac{1}{m}-\frac{s}{m}+2r\right)}{r!(-x^2)^r}ds$$

$$= \pi^{\frac{1}{2}}\frac{x^{-\frac{1}{m}}}{m}\sum_{r=0}^{\infty}\frac{(-x^2)^{-r}}{r!}E_r(\chi;m). \tag{3.2}$$

The coefficient functions $E_r(\chi;m)$ $(r=0,1,2,\ldots)$ are defined by

(3.3)

$$E_r(\chi;m) = \frac{\pi^{-1/2}}{2\pi i}\int_C 2^{-s}\Gamma(s)\Gamma\left(\frac{1}{m}-\frac{s}{m}+2r\right)\cos\frac{1}{2}\pi s\,\chi^{-s/m}ds, \qquad \chi \equiv (y/2)^m/x,$$

where, as in (2.5), C is a loop with endpoints at $-\infty$ enclosing the poles of $\Gamma(s)$. Straightforward evaluation of the residues at $s = 0, -2, -4, \ldots$ then leads to the result

$$E_r(\chi;m) = \pi^{-1/2}\sum_{k=0}^{\infty}\frac{(-)^k}{(2k)!}\Gamma\left(\frac{1}{m}+\frac{2k}{m}+2r\right)\left(2\chi^{\frac{1}{m}}\right)^{2k}$$

$$= \sum_{k=0}^{\infty}\frac{(-)^k}{k!}\frac{\Gamma\left(\frac{1}{m}+\frac{2k}{m}+2r\right)}{\Gamma\left(k+\frac{1}{2}\right)}\chi^{2k/m}. \tag{3.4}$$

In a similar manner, we find from (2.5b)

$$J_m(x,y) \sim \frac{\pi^{1/2}}{m}x^{-\frac{1}{m}}\sum_{r=0}^{\infty}\frac{(-x^2)^{-r}}{r!}F_r(\chi;m), \qquad |\arg x| < \tfrac{1}{2}\pi, \tag{3.5}$$

where the coefficient functions $F_r(\chi;m)$ are defined as at (3.3) with the term $\cos\frac{1}{2}\pi s$ replaced by $\sin\frac{1}{2}\pi s$, so that

$$F_r(\chi;m) = \sum_{k=0}^{\infty}\frac{(-)^k}{k!}\frac{\Gamma\left(\frac{2}{m}+\frac{2k}{m}+2r\right)}{\Gamma\left(k+\frac{3}{2}\right)}\chi^{(2k+1)/m}. \tag{3.6}$$

An alternative representation involving derivatives of the coefficient function corresponding to $r=0$ can be found in the form

$$E_r(\chi;m) = \chi^{1-\frac{1}{m}}\frac{d^{2r}}{d\chi^{2r}}\left\{\chi^{2r-1+\frac{1}{m}}E_0(\chi;m)\right\}, \qquad r = 1,2,\ldots$$

with an analogous expression for $F_r(\chi,m)$. The coefficient functions $E_r(\chi;m)$ and $F_r(\chi;m)$ are generalized hypergeometric functions, uniformly and absolutely convergent for all finite values of χ. We note at this point that as $|x| \to \infty$, $\chi \to 0$ and

$$E_r(\chi;m) = \pi^{-\frac{1}{2}}\Gamma\left(2r+\frac{1}{m}\right)\left[1+O\left(x^{-\frac{2}{m}}\right)\right],$$

$$F_r(\chi;m) = \pi^{-\frac{1}{2}}\Gamma\left(2r+\frac{2}{m}\right)yx^{-\frac{1}{m}}\left[1+O\left(x^{-\frac{2}{m}}\right)\right].$$

We remark that in the case of Pearcey's integral when $m = 2$, the coefficients $E_r(\chi; m)$ reduce to a particularly simple form since, from (3.4),

$$E_0(\chi; 2) = e^{-\chi}, \qquad \chi \equiv y^2/4x.$$

The coefficients in this case are then given by

$$E_r(\chi; 2) = \chi^{1/2} \frac{d^{2r}}{d\chi^{2r}} \left[\chi^{2r-1/2} e^{-\chi}\right] \equiv a_r(\chi) e^{-\chi},$$

where $a_r(\chi)$ can be expressed as a Hermite polynomial

$$a_r(\chi) = \pi^{-1/2}\Gamma\left(2r + \frac{1}{2}\right) {}_1F_1\left(-2r; \frac{1}{2}; \chi\right) = 2^{-4r} H_{4r}(\sqrt{\chi}).$$

The domain of validity (in the Poincaré sense) of the expansions (3.2) and (3.5) can be extended to the wider sector $|\arg x| < \frac{3}{4}\pi$ by applying a further transformation to the integrals in (2.5) to make the specific dependence on the parameter group $\chi = (\frac{1}{2}y)^m/x$ apparent; cf. [12, §4a]. We employ the Mellin–Barnes representation of $D_v(z)$ [1, p. 688]

$$D_v(z) = \frac{z^v e^{-z^2/4}}{\Gamma(-v)} \frac{1}{2\pi i} \int_{-\infty i}^{\infty i} \Gamma(t)\Gamma(-2t - v)(2z^2)^t dt, \qquad |\arg z| < \frac{3}{4}\pi,$$

where, provided v is not a nonnegative integer, the path of integration is indented at $t = 0$ to separate the poles of $\Gamma(t)$ from those of $\Gamma(-2t - v)$. Substitution of this result in (2.5a), followed by reversal of the order of integration, then yields the alternative representation of $I_m(x, y)$ in the form

$$I_m(x, y) = \frac{\pi^{\frac{1}{2}}}{m} x^{-1/m} \frac{1}{2\pi i} \int_{-\infty i}^{\infty i} \Gamma(t) E_{-t}(\chi; m) x^{2t} dt. \tag{3.7}$$

where $E_{-t}(\chi; m)$ is defined as in (3.3) and (3.4) (with r replaced by t) and the path is indented at $t = 0$ in order to lie to the right of the poles of $\Gamma(t)$. It can be established that as $t \to \pm i\infty$, $|E_{-t}(\chi, m)| = e^{-\pi|t|} \exp[O(|\chi t|^{1/m})]$ (we omit the details), so that (3.7) defines $I_m(x, y)$ only in the sector $|\arg x| < \frac{3}{4}\pi$. Application of the standard method for asymptotically evaluating Mellin–Barnes integrals [14, p. 143] then yields the expansion given in (3.2), valid in the wider sector $|\arg x| < \frac{3}{4}\pi$.

By means of similar arguments applied to $J_m(x, y)$, we consequently obtain the results

$$I_m(x, y) \sim \frac{\pi^{\frac{1}{2}}}{m} x^{-\frac{1}{m}} S_1^{(c)}(x, y), \qquad J_m(x, y) \sim \frac{\pi^{\frac{1}{2}}}{m} x^{-\frac{1}{m}} S_1^{(s)}(x, y) \tag{3.8}$$

as $|x| \to \infty$ in $|\arg x| < \frac{3}{4}\pi$, where the formal asymptotic sums $S_1^{(c,s)}(x, y)$ are defined by

$$S_1^{(c)}(x, y) = \sum_{r=0}^{\infty} \frac{(-x^2)^{-r}}{r!} E_r(\chi; m), \qquad S_1^{(s)}(x, y) = \sum_{r=0}^{\infty} \frac{(-x^2)^{-r}}{r!} F_r(\chi; m). \tag{3.9}$$

When $|\arg(-x)| < \frac{1}{2}\pi$, we use the connection formula

$$D_v(-z) = e^{\pm\pi i v} D_v(z) \pm i \frac{(2\pi)^{1/2}}{\Gamma(-v)} e^{\pm\pi i v/2} D_{-v-1}(\pm iz), \tag{3.10}$$

where, in order to apply (3.1), the signs will be chosen such that both arguments of the parabolic cylinder functions lie between $\pm\frac{1}{2}\pi$. This means that we select the upper sign in (3.10) when $\frac{1}{2}\pi < \arg x < \pi$ and the lower sign when $-\pi < \arg x < -\frac{1}{2}\pi$. Substitution of (3.10) in (2.5a) then yields

$$I_m(x,y) = e^{\mp\frac{\pi i}{m}} I_m\left(e^{\mp\pi i}x, e^{\mp\frac{\pi i}{m}}y\right) + \frac{2^{-\frac{1}{2m}}}{m} e^{\frac{x^2}{8}} K, \tag{3.11}$$

where, according to the above ranges of $\arg x$,

$$K = \pm i(2\pi)^{1/2}\frac{e^{\mp\frac{\pi i}{2m}}}{2\pi i}\int_C \Gamma(s)\cos\frac{1}{2}\pi s D_{\frac{1}{m}-\frac{s}{m}-1}\left(e^{\mp\pi i/2}\frac{x}{\sqrt{2}}\right)\left(e^{\mp\frac{\pi i}{2m}}y2^{-\frac{1}{2m}}\right)^{-s} ds.$$

The expansion of the first term on the right-hand side of (3.11) in $|\arg(-x)| < \frac{1}{2}\pi$ follows from (3.8) and (3.9) as

$$I_m\left(e^{\mp\pi i}x, e^{\mp\frac{\pi i}{m}}y\right) \sim \frac{\pi^{1/2}}{m}\left(e^{\mp\pi i}x\right)^{-\frac{1}{m}} S_1^{(c)}(x,y). \tag{3.12}$$

The expansion of the second term can be obtained by substitution of (3.1) into the integral for K, as at (3.2), to find

$$K \sim (2\pi)^{1/2}e^{x^2/8}\left(e^{\mp\pi i}\frac{x}{\sqrt{2}}\right)^{\frac{1}{m}-1}\sum_{r=0}^{\infty}\frac{x^{-2r}}{r!}c_r(\xi),$$

where the coefficients $c_r(\xi)$ are defined by

$$\begin{aligned} c_r(\xi) &= \frac{1}{2\pi i}\int_C \Gamma(s)\cos\frac{1}{2}\pi s\left(1+\frac{s}{m}-\frac{1}{m}\right)_{2r}\xi^{-\frac{s}{m}}ds, \qquad \xi \equiv \frac{1}{2}y^m(e^{\mp\pi i}x) \\ &= \xi^{2r+1-\frac{1}{m}}\frac{d^{2r}}{d\xi^{2r}}\left(\frac{1}{2\pi i}\int_C \Gamma(s)\cos\frac{1}{2}\pi s\,\xi^{-\frac{s}{m}+\frac{1}{m}-1}ds\right) \\ &= \xi^{2r+1-\frac{1}{m}}\frac{d^{2r}}{d\xi^{2r}}\left(\xi^{\frac{1}{m}-1}\cos\xi^{\frac{1}{m}}\right) \qquad (r=0,1,2,\ldots) \end{aligned}$$

upon making use of (2.4). We write

$$C_r(\xi) = (-)^r m^{2r}\xi^{-2r/m}c_r(\xi),$$

so that $C_r(\xi)$ involves a finite series of descending powers of $\xi^{1/m}$ to find

$$C_r(\xi) = P_r(\xi)\cos\xi^{\frac{1}{m}} - Q_r(\xi)\sin\xi^{\frac{1}{m}}, \tag{3.13}$$

where the coefficients $P_r(\xi)$ and $Q_r(\xi)$ are given by

$$\begin{aligned} &P_0(\xi) = 1, \qquad Q_0(\xi) = 0, \\ &P_1(\xi) = 1-(m-1)(2m-1)\xi^{-\frac{2}{m}}, \qquad Q_1(\xi) = 3(m-1)\xi^{-\frac{1}{m}}, \\ &P_2(\xi) = 1-5(m-1)(7m-5)\xi^{-\frac{2}{m}} + (m-1)(2m-1)(3m-1)(4m-1)\xi^{-\frac{4}{m}}, \\ &Q_2(\xi) = 10(m-1)\xi^{-\frac{1}{m}} - 5(m-1)(2m-1)(5m-3)\xi^{-\frac{3}{m}}, \ldots. \end{aligned}$$

Then, as $|x| \to \infty$ in $|\arg(-x)| < \frac{1}{2}\pi$, we have

$$K \sim (2\pi)^{1/2}e^{x^2/8}\left(e^{\mp\pi i}\frac{x}{\sqrt{2}}\right)^{\frac{1}{m}-1} S_2^{(c)}(x,y),$$

where the formal asymptotic sum $S_2^{(c)}(x,y)$ is defined by

$$S_2^{(c)}(x,y) = \sum_{r=0}^{\infty} \frac{(-)^r}{r!} \left(2^{-\frac{1}{m}} \frac{y}{m}\right)^{2r} \left(e^{\mp \pi i} x\right)^{-2r\left(1-\frac{1}{m}\right)} C_r(\xi). \tag{3.14}$$

Collecting together the results in (3.5), (3.12), and (3.14), we then have the expansions for $|x| \to \infty$, y finite:

$$\begin{aligned} I_m(x,y) &\sim \frac{\pi^{1/2}}{m} x^{-\frac{1}{m}} S_1^{(c)}(x,y) \quad \text{in } |\arg x| < \frac{3}{4}\pi \\ &\sim \frac{\pi^{1/2}}{m} x^{-\frac{1}{m}} S_1^{(c)}(x,y) + \frac{\pi^{1/2}}{m} \left(\frac{1}{2} x e^{\mp \pi i}\right)^{\frac{1}{m}-1} e^{x^2/4} S_2^{(c)}(x,y) \\ &\qquad \text{in } |\arg(-x)| < \frac{1}{2}\pi, \end{aligned} \tag{3.15}$$

where the upper or lower sign is chosen according as $\frac{1}{2}\pi < \arg x < \pi$ or $-\pi < \arg x < -\frac{1}{2}\pi$, respectively.[1]

In a similar manner, the expansion of $J_m(x,y)$ for $|x| \to \infty$ is given by

$$\begin{aligned} J_m(x,y) &\sim \frac{\pi^{1/2}}{m} x^{-\frac{1}{m}} S_1^{(s)}(x,y) \quad \text{in } |\arg x| < \frac{3}{4}\pi \\ &\sim \frac{\pi^{1/2}}{m} x^{-\frac{1}{m}} S_1^{(s)}(x,y) + \frac{\pi^{1/2}}{m} \left(\frac{1}{2} x e^{\mp \pi i}\right)^{\frac{1}{m}-1} e^{x^2/4} S_2^{(s)}(x,y) \\ &\qquad \text{in } |\arg(-x)| < \frac{1}{2}\pi, \end{aligned} \tag{3.16}$$

where the formal asymptotic sum $S_2^{(s)}(x,y)$ is defined by

$$S_2^{(s)}(x,y) = \sum_{r=0}^{\infty} \frac{(-)^r}{r!} \left(2^{-\frac{1}{m}} \frac{y}{m}\right)^{2r} \left(e^{\mp \pi i} x\right)^{-2r\left(1-\frac{1}{m}\right)} S_r(\xi) \tag{3.17}$$

with

$$\begin{aligned} S_r(\xi) &= (-)^r m^{2r} \xi^{-2r/m} s_r(\xi), \\ s_r(\xi) &= \xi^{2r+1-\frac{1}{m}} \frac{d^{2r}}{d\xi^{2r}} \left(\xi^{\frac{1}{m}-1} \sin \xi^{\frac{1}{m}}\right) \quad (r = 0, 1, 2, \ldots), \end{aligned}$$

so that

$$S_r(\xi) = P_r(\xi) \sin \xi^{\frac{1}{m}} + Q_r(\xi) \cos \xi^{\frac{1}{m}}. \tag{3.18}$$

The expansion of $P_m(x,y)$ can then be constructed from (1.5), (1.6), (3.15), and (3.16). In the special case $y = 0$, we see from (1.4) that $J_m(x,0) \equiv 0$ and

$$I_m(x,0) = \frac{2^{-1/m}}{m} \Gamma(1/m) e^{x^2/8} D_{-1/m}(x/\sqrt{2}).$$

The expansion of $I_m(x,0)$ in (3.15) can be shown to agree with the large-x asymptotics of the parabolic cylinder function, when the sum $S_2^{(c)}(x,0)$ is evaluated by a limiting process as $y \to 0$.

[1] The statement of this result in the case $m = 2$ in [12, eq. (3.16)] is incorrect; the lower sign should be taken when $\pi < \arg x < \frac{3}{2}\pi$ and not as stated.

In terms of the original variables X and Y, we see that negative real X corresponds to the anti-Stokes line $\arg x = \frac{3}{4}\pi$. Thus, for $X \to -\infty$, $P'_m(X,Y)$ will consist of an algebraic and an exponentially oscillatory expansion, while for $X \to +\infty$, $P'_m(X,Y)$ will either consist of a single algebraic expansion or a mixed algebraic and exponentially oscillatory expansions according as m is even or odd. From (1.5), (1.6), (3.15), and (3.16) we then find (upon taking the upper signs) the leading asymptotic behavior

(3.19)

$$P'_m(X,Y) = \frac{2}{m}X^{-\frac{1}{m}}e^{\frac{\pi i}{2m}}\Gamma\left(\frac{1}{m}\right)\left\{1+O\left(X^{-\frac{2}{m}}\right)\right\}, \qquad X \to +\infty$$

$$= \frac{2}{m}|X|^{-\frac{1}{m}}e^{-\frac{\pi i}{2m}}\Gamma\left(\frac{1}{m}\right)\left\{1+O\left(X^{-\frac{2}{m}}\right)\right\} + \frac{2\pi^{1/2}}{m}\left(\frac{|X|}{2}\right)^{\frac{1}{m}-1}$$

$$\cdot \exp\left[i\left(\frac{\pi}{4}-\frac{X^2}{4}\right)\right]\cos\left[Y\left(\frac{|X|}{2}\right)^{\frac{1}{m}}\right]\left\{1+O\left(X^{-2(m-1)/m}\right)\right\}, \qquad X \to -\infty$$

when m is even, and

$$P'_m(X,Y) = \frac{2}{m}X^{-\frac{1}{m}}\left\{\Gamma\left(\frac{1}{m}\right)\cos\frac{\pi}{2m} - X^{-\frac{1}{m}}Y\Gamma\left(\frac{2}{m}\right)\sin\frac{\pi}{m} + O\left(X^{-\frac{2}{m}}\right)\right\}$$

$$+\frac{\pi^{1/2}}{m}\left(\frac{X}{2}\right)^{\frac{1}{m}-1}\exp\left[i\left\{\frac{\pi}{4}-\frac{X^2}{4}-Y\left(\frac{X}{2}\right)^{\frac{1}{m}}\right\}\right] \tag{3.20}$$

$$\cdot\left\{1+O\left(X^{-2(m-1)/m}\right)\right\}, \qquad X \to +\infty$$

when m is odd, the behavior for $X \to -\infty$ being given by $P'_m(-X,Y)$; cf. (1.7a).

The above leading behavior when m is even can be seen to correspond to a single ($X \to +\infty$) and three ($X \to -\infty$) stationary point contributions discussed in §2. In the case $m = 2$, the asymptotic behavior in (3.19) for $X \to \pm\infty$ agrees with that of the Pearcey integral [12].

4. Asymptotics of $P_m(x,y)$ for $|y| \to \infty$. From the symmetry property in (1.7) it is sufficient to consider only the sector $|\arg y| \le \frac{1}{2}\pi$. We first discuss the case of even $m = 2p$. Using the connection formula (3.10) in the form

$$D_v(z) = (2\pi)^{-1/2}\Gamma(1+v)\left\{e^{\pi v i/2}D_{-v-1}(iz) + e^{-\pi v i/2}D_{-v-1}(-iz)\right\} \tag{4.1}$$

together with the new variable σ given by $s = m\sigma + 1$, we find from (1.5) and (2.5), when m is even, that

$$P_m(x,y) = e^{(x^2/8)+(\pi i/4m)}\left\{e^{-\frac{\pi i}{2m}}K_p\left(x, ye^{-\frac{\pi i}{2m}}\right) + e^{\frac{\pi i}{2m}}K_p\left(-x, ye^{\frac{\pi i}{2m}}\right)\right\}, \tag{4.2}$$

where

$$K_p(x,y) = \frac{(2\pi)^{1/2}}{2\pi i}\int_C 2^{\sigma/2}\Gamma(m\sigma+1)\frac{\sin\pi p\sigma}{\sin\pi\sigma}D_{-\sigma-1}\left(\frac{ix}{\sqrt{2}}\right)y^{-m\sigma-1}d\sigma. \tag{4.3}$$

Here C is a loop in the σ-plane with endpoints at $-\infty$, which encircles $\sigma = -1/m$. As the parabolic cylinder function is an entire function of σ and the integrand has no

poles in $\mathrm{Re}(\sigma) \geq 0$, the restriction $\mathrm{Re}(\sigma) < 0$ imposed in the derivation of (2.5) can be removed by analytic continuation.

We now deform C such that $|\sigma|$ is large everywhere on C. On the expanded loop we may employ the asymptotic expansion of the parabolic cylinder function for large order and finite argument (cf. [12, eq. (A.10)])

$$D_{-\sigma-1}(z) \sim \frac{\pi^{1/2} \exp\left(-z\sqrt{\sigma+\frac{1}{2}}\right)}{2^{\sigma/2+1/2}\Gamma\left(\frac{1}{2}\sigma+1\right)} \sum_{r=0}^{\infty} (-)^r A_r \sigma^{-r/2}, \tag{4.4}$$

valid for $|\sigma| \to \infty$ in $|\arg\sigma| < \pi$, where

$$A_0 = 1, \quad A_1 = \frac{z^3}{24}, \quad A_2 = \frac{z^2}{48}\left(\frac{z^2}{24} - 3\right), \ldots.$$

The integral $K_p(x,y)$ then (formally) becomes

$$K_p(x,y) \sim \frac{2\pi m}{y} \sum_{r=0}^{\infty} (-)^r A_r \frac{1}{2\pi i} \int_C \frac{\Gamma(m\sigma)}{\Gamma(\frac{1}{2}\sigma)} \left(\frac{\sin p\pi\sigma}{\sin \pi\sigma}\right) e^{-ix(\sigma/2+1/4)^{1/2}} y^{-m\sigma} \sigma^{-\frac{1}{2}r} d\sigma.$$

We now express the quotient of gamma functions in terms of a single gamma function [2, p. 260]

$$\frac{\Gamma(m\sigma)}{\Gamma\left(\frac{1}{2}\sigma\right)} = \frac{(\pi m)^{-1/2}}{2} \left(\frac{\mu^\mu}{2^{1/2} m^m}\right)^{-\sigma} \Gamma\left(\mu\sigma + \frac{1}{2}\right) \left\{1 + O(\sigma^{-1})\right\}, \tag{4.5}$$
$$\mu = m - \frac{1}{2},$$

valid for $|\sigma| \to \infty$ in $|\arg\sigma| < \pi$, and employ the result

$$\frac{\sin p\pi\sigma}{\sin \pi\sigma} = \sum_{r=1}^{p} e^{\pi i\sigma(p+1-2r)}$$

to obtain

$$K_p(x,y) = \frac{(\pi m)^{\frac{1}{2}}}{y} \sum_{r=1}^{p} \frac{1}{2\pi i} \int_C \Gamma\left(\mu\sigma + \frac{1}{2}\right) e^{-ix\left(\frac{1}{2}\sigma+\frac{1}{4}\right)^{1/2}} (\omega_r y^*)^{-\mu\sigma} \tag{4.6}$$
$$\cdot \left[1 - A_1\sigma^{-\frac{1}{2}} + O\left(\sigma^{-1}\right)\right] d\sigma$$

where

$$\omega_r = \exp[\pi i(2r - p - 1)/\mu], \qquad y^* = 2\mu(y/2m)^{m/\mu}. \tag{4.7}$$

The integrals appearing in (4.6) can be evaluated asymptotically for large $|y|$ by means of the lemma given in [12], which we write in the following, slightly modified form. For arbitrary complex α, b, c and real a (> 0) and v, the integral

$$\frac{1}{2\pi i} \int_C \Gamma(at+b) e^{\alpha(at+c)^{\frac{1}{2}}} z^{-at} t^v dt$$
$$\sim \left(z^{v+b}/a^{v+1}\right) \exp\left[-z + \alpha z^{\frac{1}{2}} - \alpha^2/8\right] \sum_{r=0}^{\infty} B_r z^{-r/2},$$
$$B_0 = 1, \qquad B_1 = \frac{1}{8}\alpha\left[1 - 4(v+b-c) - \alpha^2/12\right], \ldots,$$

for $|z| \to \infty$ in $|\arg z| < \pi$. Application of this lemma with successively $v = 0, -\frac{1}{2}$ and $\alpha = -ix/(2\mu)^{\frac{1}{2}}$, $c = \mu/2$ to $K_p(x,y)$ then yields the expansion for $|y| \to \infty$ (in the sense of Poincaré)

$$
\begin{aligned}
e^{(x^2/8)+(\pi i/4m)}K_p(x,y) &\sim \sum_{r=1}^{p} E_r^{(p)}(x,y), \quad |\arg y| \le \frac{3\pi}{4m} \\
&\sim E_p^{(p)}(x,y), \quad \frac{3\pi}{4m} < \arg y < \frac{\pi}{2m}(m+1) \\
&\sim E_1^{(p)}(x,y), \quad \frac{-\pi}{2m}(m+1) < \arg y < -\frac{3\pi}{4m},
\end{aligned} \tag{4.8}
$$

where

(4.9)

$$
\begin{aligned}
&E_r^{(p)}(x,y) \\
&\quad = (\pi\omega_r/\mu)^{\frac{1}{2}}\left[y^{1-m}/(2m)^{\frac{1}{2}}\right]^{1/2\mu}\exp\left[\pi i/4m - \omega_r y^* - ix(\omega_r y^*/2\mu)^{\frac{1}{2}} + mx^2/8\mu\right] \\
&\qquad \cdot\left\{1 - \frac{ix(m-1)}{4(2\mu\omega_r y^*)^{\frac{1}{2}}}(1 - mx^2/12\mu) + O(y^{*-1})\right\}, \qquad (r = 1,2,\ldots,p).
\end{aligned}
$$

For odd $m = 2p+1$, we find, from (1.6), (2.5), and (4.1), that

(4.10)

$$
\begin{aligned}
P_m(x,y) &= e^{(x^2/8)+(\pi i/4m)}\frac{i}{2\pi i}\int_C 2^{\sigma/2}\Gamma(m\sigma+1)\Gamma(-\sigma) \\
&\qquad \cdot\left\{e^{(1/2)\pi i m\sigma}D_\sigma\left(\frac{x}{\sqrt{2}}\right) - e^{(-1/2)\pi i m\sigma}D_\sigma\left(\frac{-x}{\sqrt{2}}\right)\right\}y^{-m\sigma-1}d\sigma \\
&= e^{(x^2/8)+(\pi i/4m)}\frac{(2\pi)^{1/2}}{2\pi i}\int_C 2^{\sigma/2}\Gamma(m\sigma+1) \\
&\qquad \cdot\left\{\frac{\sin\pi p\sigma}{\sin\pi\sigma}D_{-\sigma-1}\left(\frac{-ix}{\sqrt{2}}\right) + \frac{\sin\pi(p+1)\sigma}{\sin\pi\sigma}D_{-\sigma-1}\left(\frac{ix}{\sqrt{2}}\right)\right\}y^{-m\sigma-1}d\sigma.
\end{aligned}
$$

It is clear that the only poles of the integrand in (4.10) are those resulting from $\Gamma(m\sigma+1)$, which are enclosed by C. The restriction $\mathrm{Re}(\sigma) < 0$ can again be removed by analytic continuation and the loop C can consequently be expanded as in the case m even. We therefore find

$$
P_m(x,y) = e^{(x^2/8)+(\pi i/4m)}\{K_p(-x,y) + K_{p+1}(x,y)\} \qquad (m \text{ odd}). \tag{4.11}
$$

Then, from (4.2), (4.11), and (4.8), the expansion of $P_m(x,y)$ for $|y| \to \infty$, x finite, when $m = 2p$ is even, is then (in the Poincaré sense) given by

$$
\begin{aligned}
P_m(x,y) &\sim e^{-\pi i/2m}\sum_{r=1}^{p} E_r^{(p)}\left(x, ye^{-\pi i/2m}\right) \\
&\quad + e^{\pi i/2m}\sum_{r=1}^{p} E_r^{(p)}\left(-x, ye^{\pi i/2m}\right) \quad |\arg y| \le \frac{\pi}{4m} \\
&\sim e^{\pi i/2m}E_p^{(p)}\left(-x, ye^{\pi i/2m}\right), \qquad \frac{\pi}{4m} < \arg y < \frac{1}{2}\pi \\
&\sim e^{-\pi i/2m}E_1^{(p)}\left(x, ye^{-\pi i/2m}\right), \qquad -\frac{1}{2}\pi < \arg y < -\frac{\pi}{4m},
\end{aligned} \tag{4.12}
$$

and when $m = 2p+1$ is odd,

$$
\begin{aligned}
P_m(x,y) &\sim \sum_{r=1}^{p} E_r^{(p)}(-x,y) + \sum_{r=1}^{p+1} E_r^{(p+1)}(x,y) \qquad |\arg y| \le \frac{\pi}{4m} \\
&\sim E_{p+1}^{(p+1)}(x,y), \qquad \frac{\pi}{4m} < \arg y < \frac{1}{2}\pi \\
&\sim E_1^{(p+1)}(x,y), \qquad -\frac{1}{2}\pi < \arg y < -\frac{\pi}{4m}.
\end{aligned} \tag{4.13}
$$

In the sectors $|\arg(\pm y)| < \pi/4m$, $P_m(x,y)$ is exponentially small as $|y| \to \infty$, while outside of these sectors $P_m(x,y)$ is exponentially large.

In terms of the original variables X and Y, we see that large positive Y corresponds to the upper boundary of the exponentially small sector $|\arg y| < \pi/4m$. Here, $E_p^{(p)}(-x, ye^{\pi i/2m})$ (m even) or $E_{p+1}^{(p+1)}(x,y)$ (m odd) possesses oscillatory behavior, with the other $m-1$ expansions in (4.12) and (4.13) exponentially small and of different degrees of subdominance. Thus, up to exponentially small terms, the behavior of $P_m'(X,Y)$ for $Y \to +\infty$, X finite, is given by

(4.14)

$$
\begin{aligned}
P_m'(X,Y) &= (\pi/\mu)^{\frac{1}{2}}(2m)^{-1/4\mu Y(1-m)/2\mu}\exp i\left[\pi/4 - Y^* + \frac{(-)^m XY^{*\frac{1}{2}}}{(2\mu)^{\frac{1}{2}}} - mX^2/8\mu\right] \\
&\quad \cdot\left\{1 + \frac{(-)^m(m-1)XY^{*-\frac{1}{2}}}{4(2\mu)^{\frac{1}{2}}}\left(1 + \frac{imX^2}{12\mu}\right) + O\left(Y^{*-1}\right)\right\},
\end{aligned}
$$

where

$$
Y^* = 2\mu(Y/2m)^{m/\mu}, \qquad \mu = m - \tfrac{1}{2}.
$$

This behavior can be seen to correspond to the single real stationary point discussed in §2, with the $m-1$ subdominant contributions (not stated in (4.14)) arising from half of the $2(m-1)$ complex stationary points. When $m = 2$, the expansion (4.14) reduces to that of the Pearcey integral.

The approximations in (4.12) and (4.13) describe the asymptotic behavior of $P_m(x,y)$ for $|y| \to \infty$ in the sense of Poincaré. As noted in §5 of [12], the method adopted in this section is not sufficiently precise to determine the domains of validity

of the subdominant exponentially small terms in the above expansions and their associated Stokes lines. This deficiency results from the manner of approximation of the quotient of gamma functions in (4.5), which does not correctly take into account the appearance of exponentially small terms in the large $|z|$ behavior of $\Gamma(z)$ across its Stokes lines $\arg z = \pm\frac{1}{2}\pi$ (see [13]).

To deal with this situation, and the case $\arg y = \pm\frac{1}{2}\pi$, we revert to consideration of the saddle points of the integrand in (1.3). We omit the detailed description of the nature of the paths of steepest descent through the saddle points, which resembles that in the case $m = 2$ [12]. It is found that as $|y| \to \infty$ there is a sequence of Stokes lines given by $\arg(\pm y) = \theta_1, \theta_2, \ldots, \theta_{m-1}$, where $\theta_r = \pi(2r+1)/4m$, across which the coefficients of the exponentially small subdominant expansions in (4.12) and (4.13) change to become zero (the Stokes phenomenon). When m is even, the expansions $E^{(p)}_{p-r}(x, ye^{\pi i/2m})$ and $E^{(p)}_{p-r+1}(x, ye^{-\pi i/2m})$ "switch off" as one crosses (in the sense of increasing $|\arg y|$) $\theta_{2r}(r = 1, 2, \ldots, p-1)$ and $\theta_{2r-1}(r = 1, 2, \ldots, p)$, respectively. When m is odd, a similar pattern of behavior emerges with the expansions $E^{(p+1)}_{p-r+1}(x, y)$ and $E^{(p)}_{p-r+1}(x, y)$ "switching off" across the rays θ_{2r} and $\theta_{2r-1}(r = 1, 2, \ldots, p)$, respectively. A conjugate behavior applies by virtue of (1.7b) in the sector $-\frac{1}{2}\pi \le \arg y < 0$. In this manner the above expansions for $P_m(x, y)$ can be shown to extend to $|\arg y| \le \frac{1}{2}\pi$, with (4.12a) and (4.13a) holding in the wider sector $|\arg y| < 3\pi/4m$ bounded by the first pair of Stokes lines $\arg y = \pm\theta_1$.

Rather than state the complete expansion in the general case, we present, as an illustrative example, only the specific case $m = 3$. The Stokes lines in $\mathrm{Re}(y) > 0$ in this case are $\arg y = \pm\frac{1}{4}\pi$ and $\arg y = \pm 5\pi/12$, and we find that

$$
\begin{aligned}
P_3(x, y) &\sim E^{(1)}_1(-x, y) + \sum_{r=1}^{2} E^{(2)}_r(x, y), \qquad |\arg y| < \frac{1}{4}\pi \\
&\sim \sum_{r=1}^{2} E^{(2)}_r(x, y), \qquad \frac{1}{4}\pi < |\arg y| < \frac{5\pi}{12}, \\
&\sim E^{(2)}_2(x, y), \qquad \frac{5\pi}{12} < \arg y \le \frac{1}{2}\pi, \\
&\sim E^{(2)}_1(x, y), \qquad -\frac{1}{2}\pi \le \arg y < \frac{5}{12}\pi,
\end{aligned}
\tag{4.15}
$$

where, from (4.9),

$$
E^{(p)}_r(x, y) = (2\pi\omega_r/5)^{\frac{1}{2}} \left(6^{\frac{1}{4}} y\right)^{-2/5} \exp\left[-5\omega_r(y/6)^{6/5} - ix\omega_r^{\frac{1}{2}}(y/6)^{3/5} + 3x^2/20 + \pi i/12\right]
$$

$$
\cdot \left\{1 - \frac{ix\omega_r^{-\frac{1}{2}}}{10}(y/6)^{-3/5}(1 - x^2/10) + O\left(y^{-6/5}\right)\right\},
$$

$$
\omega_r = \exp[2\pi i(2r - p - 1)/5].
$$

The different sectorial behavior for $P_3(x, y)$ is summarized in Fig. 2. We note that the above asymptotic approximations satisfy the conjugacy property (1.7b) and, for real x, to correctly predict real values of $\exp(-\pi i/12)P_3(x, y)$ when $\arg y = \pm\frac{1}{2}\pi$.

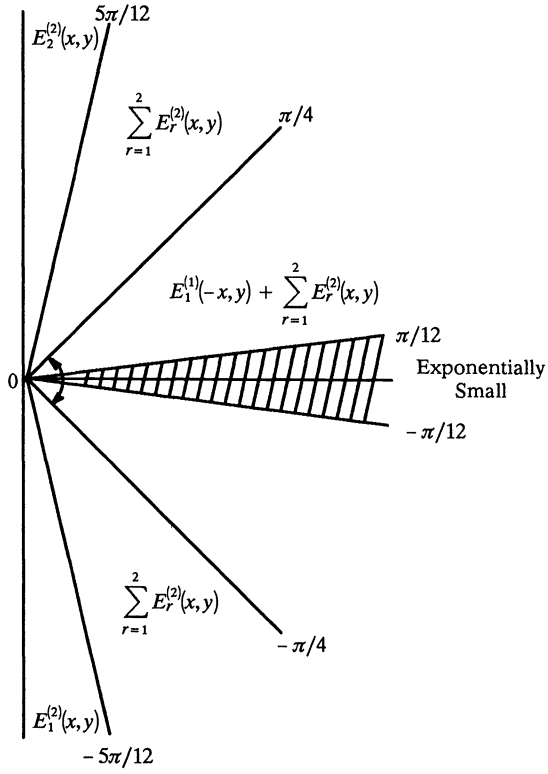

FIG. 2. *The sectorial behavior of* $P_m(x,y)$ *when* $m = 3$ *in the* y*-plane as* $|y| \to \infty$ *in* $|\arg y| \leq \frac{1}{2}\pi$.

THE PEARSON EQUATION AND THE BETA INTEGRALS*

MIZAN RAHMAN† AND SERGEI K. SUSLOV‡

Abstract. An alternate proof of the classical beta integral is given by using the Pearson equation whose solution converts the hypergeometric equation into a self-adjoint equation. A generalization of this idea to difference equations on linear lattices enables a proof of Barnes's second lemma by using his first lemma and gives extensions of some of Ramanujan's formulas. Similar analysis on q-quadratic lattices gives an extension of Askey's integral on the real line and the corresponding basic bilateral sum of Gosper. Another q-quadratic lattice gives an extension of the Askey–Wilson integral. A quadratic lattice is used to evaluate a principal value integral on the real line, whose q-analogue is shown to be equivalent to the Askey integral extension. A list of various beta integrals is also presented.

Key words. beta integrals of Euler, Barnes and Ramanujan, q-beta integrals of Askey and Wilson, Pearson equation, very well poised sums and integrals

AMS subject classifications. primary 33A15; secondary 33A10

1. Introduction.

One of the most basic formulas in all of classical analysis is Euler's beta integral

$$B(\alpha,\beta)=\int_0^1 x^{\alpha-1}(1-x)^{\beta-1}dx=\frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}, \tag{1.1}$$

Re $(\alpha,\beta)>0$; the integrand $\rho(x)=x^{\alpha-1}(1-x)^{\beta-1}$ is the weight function associated with the differential equation for the Jacobi polynomials (see [54]):

$$x(1-x)y''+[\alpha-(\alpha+\beta)x]y'-n(n+\alpha+\beta-1)y=0, \tag{1.2}$$

which becomes self-adjoint when multiplied by $\rho(x)$. The function $\rho(x)$ is the solution of the Pearson equation (see, e.g., [17]):

$$[\rho(x)\sigma(x)]'=\rho(x)\tau(x), \tag{1.3}$$

with $\sigma(x)=x(1-x)$, $\tau(x)=\alpha-(\alpha+\beta)x$ for (1.2).

There are quite a few proofs of (1.1), the earliest one by Euler dating back to 1772 (see [58]) and the latest ones by Knuth [35] in 1973 and Askey [3] in 1981. We shall give another one in §2, not because there is any reason to believe it to be any more elegant than the others (in fact, our proof is very similar to the one given by Askey), but because we want to make the point that a similar technique can be applied to other extensions of (1.1). The observation we wish to make here, and which will be a central theme throughout the paper, is that (1.3), being a first-order linear equation in

$\rho(x)$, not only yields the solution in a very elementary manner but also enables one to compute the integral over $\rho(x)$, like the one in (1.1), provided there is at least one free parameter in $\sigma(x)$ and/or $\tau(x)$. We shall find that with appropriate generalizations of (1.2) and (1.3), the same procedures lead us to alternate proofs of some old extensions of (1.1) as well as to discovering new ones. But first, let us give a short list of some known extensions of the beta integral.

First is Cauchy's extension [19]:

$$\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}\frac{dt}{(1+at)^x(1-bt)^y}=\frac{\Gamma(x+y-1)}{\Gamma(x)\Gamma(y)}a^{y-1}b^{x-1}(a+b)^{1-x-y}, \tag{1.4}$$

Re $(a,b)>0$, Re $(x+y)>1$, which does not resemble (1.1) but looks closer to one of its variants:

$$\int_0^\infty\frac{t^{\alpha-1}dt}{(1+t)^{\alpha+\beta}}=B(\alpha,\beta). \tag{1.5}$$

Then there is Barnes's first lemma [15],

$$\begin{aligned}\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}&\Gamma(a+s)\Gamma(b+s)\Gamma(c-s)\Gamma(d-s)ds\\&=\frac{\Gamma(a+c)\Gamma(a+d)\Gamma(b+c)\Gamma(b+d)}{\Gamma(a+b+c+d)},\end{aligned} \tag{1.6}$$

and his second lemma [16],

$$\begin{aligned}\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}&\frac{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(1-d-s)\Gamma(-s)}{\Gamma(e+s)}ds\\&=\frac{\Gamma(a)\Gamma(b)\Gamma(c)\Gamma(1+a-d)\Gamma(1+b-d)\Gamma(1+c-d)}{\Gamma(e-a)\Gamma(e-b)\Gamma(e-c)},\end{aligned} \tag{1.7}$$

where $e=a+b+c-d+1$. In (1.6) the assumption is that none of the poles of $\Gamma(a+s)\Gamma(b+s)$ coincide with any of the poles of $\Gamma(c-s)\Gamma(d-s)$. In (1.7) the line of integration is the imaginary axis or a line parallel to it with indentations, if necessary, so that the decreasing sequences of poles lie to the left, and the increasing sequences of poles lie to the right of the contour. Askey and Roy [8] showed, by using Stirling's formula, how to deduce (1.1) from (1.6) in a limiting process, and hence called (1.6) Barnes's beta integral. It has been pointed out in [10] and [7] that the integrand in (1.6) is the weight function for the continuous Hahn polynomials. Barnes's second lemma (1.7), an extension of (1.6), may likewise be considered a further extension of (1.1), and corresponds to the continuous biorthogonality of the ${}_4F_3$ rational functions introduced in [46].

A different kind of extension was given by Ramanujan [50]:

$$\begin{aligned}\int_{-\infty}^{\infty}&\frac{dx}{\Gamma(a+x)\Gamma(b+x)\Gamma(c-x)\Gamma(d-x)}\\&=\frac{\Gamma(a+b+c+d-3)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(b+c-1)\Gamma(b+d-1)},\end{aligned} \tag{1.8}$$

where Re $(a+b+c+d) > 3$. The integral on the left is along the real line in contrast to (1.6) where the integral is along the imaginary axis. This is an important difference whose significance will become clearer in later sections. Also, the integrand in (1.8) is the reciprocal of that in (1.6) as is the expression on the right side except for a shift in the Γ-functions. The system of Hahn polynomials that corresponds to the measure in (1.8), was discussed in [4]. For other integrals of Ramanujan similar to (1.8), see [50] and [22].

Among the formulas that we shall prove in this article is a generalization of (1.8):

$$\int_{-\infty}^{\infty} \frac{\Gamma(1-f-x)}{\Gamma(a+x)\Gamma(b+x)\Gamma(c-x)\Gamma(d-x)\Gamma(e-x)}dx \tag{1.9}$$
$$= \frac{\Gamma(2-c-f)(\Gamma(2-d-f)\Gamma(2-e-f)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(b+e-1)},$$

provided

$$\begin{aligned} &\text{(i)} && a+b+c+d+e+f=5,\\ &\text{(ii)} && \operatorname{Im} f \neq 0,\\ &\text{(iii)} && \operatorname{Re}(2-f) > \operatorname{Re}(c,d,e),\\ &\text{(iv)} && \text{a "regularizing" condition, to be stated in §5, is}\\ & && \text{also satisfied by the parameters.} \end{aligned} \tag{1.10}$$

There is also a generalization of Barnes's formula (1.6) due to de Branges [18] and Wilson [59]:

$$\frac{1}{2\pi i}\int_{-i\infty}^{i\infty} \frac{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)}{\Gamma(2s)} \cdot \frac{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)}{\Gamma(-2s)}ds \tag{1.11}$$
$$= 2\frac{\Gamma(a+b)\Gamma(a+c)\Gamma(a+d)\Gamma(b+c)\Gamma(b+d)\Gamma(c+d)}{\Gamma(a+b+c+d)},$$

provided that any pairwise sum of the four parameters a, b, c, d (including $2a, 2b, 2c, 2d$) is not a nonpositive integer. It is understood that the contour of integration is the imaginary axis suitably indented to separate the increasing sequence of poles from the decreasing one.

Askey mused in [4] whether the integral in (1.11) could be modified in the same way as Barnes's integral (1.6) was modified into the Ramanujan integral (1.8), and he wished for a Ramanujan to look at this problem. Askey's instincts were correct, of course, for we shall prove in this paper that the desired analogue is

$$\int_{-\infty}^{\infty} \frac{\Gamma(1+2s)\Gamma(1-2s)ds}{\Gamma(a+s)\Gamma(a-s)\Gamma(b+s)\Gamma(b-s)\Gamma(c+s)\Gamma(c-s)\Gamma(d+s)\Gamma(d-s)} \tag{1.12}$$
$$= \frac{\Gamma(a+b+c+d-3)}{\Gamma(a+b-1)\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(c+d-1)},$$

but Askey was wrong about the need for a Ramanujan. Far lesser individuals like the authors could handle the problem thanks to the ideas buried in [4] and in some of Askey's other works on beta integrals.

There is a third family of beta integral extensions that are not integrals at all, rather sums, finite, infinite, or doubly infinite (commonly called bilateral series). An important member of this family is Dougall's sum [21]:

$$\sum_{n=-\infty}^{\infty} \frac{1}{\Gamma(a+n)\Gamma(b+n)\Gamma(c-n)\Gamma(d-n)} = \frac{\Gamma(a+b+c+d-3)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(b+c-1)\Gamma(b+d-1)}, \tag{1.13}$$

with Re $(a+b+c+d) > 3$. The connection between the formulas (1.8) and (1.13), which are strikingly similar, was made clear by Osler's [45] extension of (1.13):

$$\sum_{n=-\infty}^{\infty} \frac{\alpha}{\Gamma(a+\alpha n)\Gamma(b+\alpha n)\Gamma(c-\alpha n)\Gamma(d-\alpha n)} = \frac{\Gamma(a+b+c+d-3)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(b+c-1)\Gamma(b+d-1)}, \tag{1.14}$$

$0 < \alpha \leq 1$, which approaches Ramanujan's integral formula (1.8) in the limit $\alpha \to 0$, and to (1.13) when $\alpha = 1$. Another Ramanujan-type extension of (1.13) is

$$\sum_{n=-\infty}^{\infty} \frac{\alpha+n}{\Gamma(a+\alpha+n)\Gamma(a-\alpha-n)\Gamma(b+\alpha+n)\Gamma(b-\alpha-n)} \cdot \frac{1}{\Gamma(c+\alpha+n)\Gamma(c-\alpha-n)\Gamma(d+\alpha+n)\Gamma(d-\alpha-n)} = \frac{\sin 2\pi\alpha}{2\pi} \frac{\Gamma(a+b+c+d-3)}{\Gamma(a+b-1)\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(c+d-1)}, \tag{1.15}$$

where Re $(a+b+c+d) > 3$, which is just the ${}_5H_5$ summation formula due to Dougall [21]; see also Slater [52, III.29]. The sum in (1.15) may be considered as a discrete version of the integral in (1.12).

Among the other discrete extensions of the beta integral are the well-known sums due to Vandermonde, Gauss, Pfaff–Saalschütz, Dixon, Dougall, and Bailey, for which we refer the reader to Bailey [14] and Slater [52].

Important as all these formulas are, the sums and integrals of current interest involve a further generalization—the so-called q-extension. The additional parameter q enters all the formulas through the so-called q-shifted factorial

$$(a;q)_n = \begin{cases} 1, & n = 0 \\ (1-a)(1-aq)\dots(1-aq^{n-1}), & n = 1,2,\dots, \end{cases}$$

$$(a;q)_\infty = \prod_{n=0}^{\infty}(1-aq^n), \qquad |q| < 1, \tag{1.16}$$

$$(a_1, a_2, \dots, a_r; q)_n = \prod_{j=1}^{r}(a_j;q)_n;$$

the q-gamma function introduced by Thomae [55] and Jackson [31], [32]:

$$\Gamma_q(x) = \frac{(q;q)_\infty}{(q^x;q)_\infty}(1-q)^{1-x}, \qquad 0<q<1, \ \operatorname{Re} x>0; \tag{1.17}$$

the q-beta function

$$B_q(x,y) = \frac{\Gamma_q(x)\Gamma_q(y)}{\Gamma_q(x+y)}; \tag{1.18}$$

Thomae [55], [56] and Jackson's [32] q-integrals

$$\int_0^a f(t)d_qt = a(1-q)\sum_{n=0}^{\infty} f(aq^n)q^n, \tag{1.19}$$

$$\int_0^\infty f(t)d_qt = (1-q)\sum_{n=-\infty}^{\infty} f(q^n)q^n; \tag{1.20}$$

and the q-binomial formula

$$\sum_{n=0}^{\infty}\frac{(a;q)_n}{(q;q)_n}z^n = \frac{(az;q)_\infty}{(z;q)_\infty}, \qquad |z|<1, \ |q|<1, \tag{1.21}$$

due to Cauchy [20] and Heine [30]. Using (1.18) and (1.19) one can show that the q-binomial formula leads to

$$B_q(x,y) = \int_0^1 t^{x-1}\frac{(tq;q)_\infty}{(tq^y;q)_\infty}d_qt, \tag{1.22}$$

$\operatorname{Re} x>0, \ y\neq 0, \ -1,-2,\ldots$. It is easy to show that

$$\lim_{q\to 1^-} B_q(x,y) = \int_0^1 t^{x-1}(1-t)^{y-1}dt = B(x,y), \tag{1.23}$$

so that the q-beta integral in (1.22) can be treated as a q-analogue of the classical beta integral in (1.1). See Gasper and Rahman [25] for a detailed analysis of the q-analogues of some of the classical functions.

A q-analogue of the beta integral in the form (1.5), however, does not come directly from the q-binomial formula but from an extension of it, due to Ramanujan [29], which, in the present context, can be expressed in the form

$$\begin{aligned}\int_0^\infty t^{x-1}\frac{(-atq^{x+y};q)_\infty}{(-at;q)_\infty}d_qt \\ = a^{-x}q^{-\binom{x}{2}}\theta(aq^x)B_q(x,y)/\theta(a),\end{aligned} \tag{1.24}$$

where $\operatorname{Re}(x,y)>0$, $\operatorname{Re} a>0$, $|q|<1$, and $\theta(aq^x)$ is a periodic function of x of unit period

$$\theta(aq^x) = q^{-\binom{x+1}{2}}(aq^x)^x(-aq^x,-q^{1-x}/a;q)_\infty. \tag{1.25}$$

Closely related to (1.24) is another q-analogue of (1.5), again due to Ramanujan [29]:

$$\int_0^\infty t^{x-1}\frac{(-tq^{x+y};q)_\infty}{(-t;q)_\infty}dt = \frac{\Gamma(x)\Gamma(1-x)}{\Gamma_q(x)\Gamma_q(1-x)}B_q(x,y), \tag{1.26}$$

Re $(x,y)>0$. If x is a positive integer then a limit needs to be taken. As $q\to 1^-$ this approaches the formula (1.5), but it lacks the symmetry that is self-evident in (1.5), so Askey and Roy [8] and, independently Gasper [23], [24], found an extension of it:

$$\int_0^\infty t^{c-1}\frac{(-tq^{x+c},-q^{1+y-c}/t;q)_\infty}{(-t,-q/t;q)_\infty}dt = \frac{\Gamma(c)\Gamma(1-c)}{\Gamma_q(c)\Gamma_q(1-c)}B_q(x,y), \tag{1.27}$$

Re $(x,y)>0$, that restores the symmetry. There are a number of other q-beta integrals that are important but will be of no particular interest for our purposes, so we refer the reader to Andrews and Askey [2], and to Askey [3]–[6]. We shall, however, be interested in Watson's [57] q-analogue of Barnes's first lemma:

$$\begin{aligned}\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}&\Gamma_q(a+s)\Gamma_q(b+s)\Gamma_q(c-s)\Gamma_q(d-s)\phi(s)q^s ds\\ &= \frac{q^c\Gamma(c-d)\Gamma(1+d-c)}{\Gamma_q(d-c)\Gamma_q(1+c-d)}\cdot\frac{\Gamma_q(a+c)\Gamma_q(a+d)\Gamma_q(b+c)\Gamma_q(b+d)}{\Gamma_q(a+b+c+d)},\end{aligned} \tag{1.28}$$

where

$$\phi(s)=\pi^2[\sin\pi(c-s)\sin\pi(d-s)\Gamma_q(c-s)\Gamma_q(1-c+s)\Gamma_q(d-s)\Gamma_q(1-d+s)]^{-1}, \tag{1.29}$$

so that $\phi(s+1)=q^{2(s+1)-c-d}\phi(s)$, and in Agarwal's [1] q-analogue of Barnes's second lemma:

$$\begin{aligned}\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}&\frac{\Gamma_q(a+s)\Gamma_q(b+s)\Gamma_q(c+s)\Gamma_q(1-d-s)\Gamma_q(-s)}{\Gamma_q(e+s)}\phi_1(s)q^s ds\\ &= \frac{\Gamma(d)\Gamma(1-d)}{\Gamma_q(d)\Gamma_q(1-d)}\,\frac{\Gamma_q(a)\Gamma_q(b)\Gamma_q(c)\Gamma_q(1+a-d)\Gamma_q(1+b-d)\Gamma_q(1+c-d)}{\Gamma_q(e-a)\Gamma_q(e-b)\Gamma_q(e-c)},\end{aligned} \tag{1.30}$$

where $d+e=a+b+c+1$, and

$$\phi_1(s)=\pi^2[\sin\pi s\sin\pi(d+s)\Gamma_q(s+1)\Gamma_q(-s)\Gamma_q(d+s)\Gamma_q(1-d-s)]^{-1}, \tag{1.31}$$

so that $\phi_1(s+1)=q^{2s+1+d}\phi_1(s)$. For the conditions that the parameters must satisfy in order that (1.28) and (1.30) are valid, see the original references or [25]. For a recent proof of (1.28) that is very similar to the technique used in this paper see Kalnins and Miller [34].

A q-analogue of (1.11) is the Askey–Wilson integral [9]:

$$\begin{aligned}\frac{1}{2\pi i}\int_K&\frac{(z^2,z^{-2};q)_\infty}{(az,az^{-1},bz,bz^{-1},cz,cz^{-1},dz,dz^{-1};q)_\infty}\frac{dz}{z}\\ &= \frac{2(abcd;q)_\infty}{(q,ab,ac,ad,bc,bd,cd;q)_\infty},\end{aligned} \tag{1.32}$$

where K is a deformation of the positively oriented unit circle so that the zeros of $(az, bz, cz, dz; q)_\infty$ lie outside the contour and those of $(az^{-1}, bz^{-1}, cz^{-1}, dz^{-1}; q)_\infty$ lie inside. Such a contour always exits if the pairwise products of the parameters a, b, c, d (their squares included) are not of the form q^{-n}, $n = 0, 1, 2, \ldots$, $|q| < 1$. In the case $\max(|a|, |b|, |c|, |d|) < 1$, Askey and Wilson [9] reduced it to a real integral formula:

$$\int_{-1}^{1} \frac{h(x; 1, -1, q^{\frac{1}{2}}, -q^{\frac{1}{2}})}{h(x; a, b, c, d)} \frac{dx}{\sqrt{1-x^2}} = \frac{2\pi(abcd; q)_\infty}{(q, ab, ac, ad, bc, bd, cd; q)_\infty}, \tag{1.33}$$

where

$$\begin{aligned} h(x; a_1, a_2, \ldots, a_r) &= h(x; a_1) \ldots h(x; a_r), \\ h(x; a) &= \prod_{n=0}^{\infty} (1 - 2axq^n + a^2 q^{2n}) \\ &= (ae^{i\theta}, ae^{-i\theta}; q)_\infty \quad \text{if } x = \cos\theta. \end{aligned} \tag{1.34}$$

This is a remarkable formula that has sparked a great deal of research in q-extensions of special functions generally, and of orthogonal polynomials, in particular; for references see [25]. By specializing the parameters $a = q^{1/2}$, $b = q^{\alpha-(1/2)}$, $c = -q^{\beta-1/2}$, $d = -q^{1/2}$, it was shown in [47] that (1.33) approaches (1.1) in the limit $q \to 1^-$.

In [38] and [48] formula (1.33) was extended even further:

$$\begin{aligned} &\int_{-1}^{1} \frac{h(x; 1, -1, q^{\frac{1}{2}}, -q^{\frac{1}{2}}, g)}{h(x; a, b, c, d, f)} \frac{dx}{\sqrt{1-x^2}} \\ &\quad = \frac{2\pi(g/a, g/b, g/c, g/d, g/f; q)_\infty}{(q, ab, ac, ad, af, bc, bd, bf, cd, cf, df; q)_\infty}, \end{aligned} \tag{1.35}$$

where $g = abcdf$, and $\max(|a|, |b|, |c|, |d|, |f|, |q|) < 1$. See Askey [5] for an alternate proof of (1.35). We shall give another proof of (1.35) as an illustration of the methods of this paper.

Askey's name seems to be attached to most of the interesting modern extensions of the beta integral, so it is hardly surprising, but remarkable nonetheless, that he came along, once again, to offer the following q-extension [6] of the Cauchy-form of the beta integral:

$$\begin{aligned} &\int_{-\infty}^{\infty} \frac{h(i\sinh u; a, b, c, d)}{h(i\sinh u; q^{\frac{1}{2}}, -q^{\frac{1}{2}}, q, -q)} du \\ &\quad = (\log q^{-1}) \frac{(ab/q, ac/q, ad/q, bc/q, bd/q, cd/q, q; q)_\infty}{(abcd/q^3; q)_\infty}, \end{aligned} \tag{1.36}$$

provided $|abcdq^{-3}| < 1$ and $|q| < 1$. This is a Ramanujan-type integral in contrast to the Barnes-type integral (1.32). It is not difficult to apply the methods of this paper to give an alternate proof of (1.36), but for considerations of length we will instead give an extension of it in §9, in the same spirit as (1.35) is an extension of (1.33). We shall see, however, that the extension is not quite as straightforward as (1.35) would lead us to believe.

In a beautiful piece of work Gustafson [27] gave multidimensional extensions of many of the beta integrals mentioned above, including (1.11), (1.32), and (1.36). Interested readers should work through this paper as well as the references therein.

The plan of the paper is as follows. In §2 we give a proof of the classical beta integral to set the tone of the basic method that we are going to use throughout the paper. Section 3 is a recapitulation of the finite difference schemes described in [12], [40], [42]–[44], and [53], to point out the role that a Pearson equation type difference equation plays in computing sums and integrals. In §4 we give an alternate proof of Barnes's second lemma to give the readers a taste of what our methods can do for a formula that is less familiar than the beta integral (1.1). Section 5 is devoted to extending the same technique to a Ramanujan-type integral on the real line. In §6 we describe some general properties of a q-quadratic lattice and find possible solutions of the Pearson equation for certain choices of the input function. In §7 we give a proof of (1.35) different from the ones that have appeared before. In §8 we deal with the basic bilateral series ${}_8\psi_8$, which is both very well poised and balanced. We give an extension of Askey's integral (1.36) in §9. An evaluation of the integral in (1.12) as well as an extension is given in §10. Finally we give a q-extension of the formulas of §10 in §11 and point out the connection between these results and those in §9. The paper is concluded by giving a summary of beta integrals, old and new, arising out of solutions of Pearson equations on various types of lattices and different kinds of boundary conditions.

2. An evaluation of the beta integral. Let us rewrite the Pearson equation (1.3) as

$$[x^\alpha(1-x)^\beta]' = \alpha x^{\alpha-1}(1-x)^{\beta-1} - (\alpha+\beta)x^\alpha(1-x)^{\beta-1} \tag{2.1}$$

and integrate from 0 to 1. Since $\operatorname{Re}(\alpha,\beta) > 0$, the left side vanishes at both ends and so the right side gives

$$I(\alpha) = \frac{\alpha+\beta}{\alpha} I(\alpha+1), \tag{2.2}$$

where we are denoting the beta integral in (1.1) by $I(\alpha)$, regarded as a function of α. By iterating this formula n times we get

$$\begin{aligned} I(\alpha) &= \frac{(\alpha+\beta)(\alpha+\beta+1)\dots(\alpha+\beta+n-1)}{\alpha(\alpha+1)\dots(\alpha+n-1)} I(\alpha+n) \\ &= \frac{\Gamma(\alpha)}{\Gamma(\alpha+\beta)} f(\alpha+n,\beta), \end{aligned} \tag{2.3}$$

where

$$f(\alpha+n,\beta) = \frac{\Gamma(\alpha+\beta+n)}{\Gamma(\alpha+n)} \int_0^1 x^{\alpha+n-1}(1-x)^{\beta-1}dx. \tag{2.4}$$

By Stirling's formula, $\Gamma(\alpha+\beta+n)/\Gamma(\alpha+n) \sim n^\beta$ for large n, which suggests a transformation of the integral by $x \to 1-x$ followed by $x \to x/n$. So we have

$$\begin{aligned} &\lim_{n\to\infty} f(\alpha+n,\beta) \\ &= \lim_{n\to\infty} \int_0^n x^{\beta-1}\Big(1-\frac{x}{n}\Big)^{\alpha+n-1} dx = \int_0^\infty x^{\beta-1}e^{-x}dx = \Gamma(\beta). \end{aligned} \tag{2.5}$$

This completes the proof of (1.1), which is almost identical to the proof given in [3]. Observe that this very elementary proof brings out the point quite clearly that the

Pearson equation not only provides the solution $\rho(x)$ but also helps set up a functional equation that eventually leads to an evaluation of the integral of $\rho(x)$ between the zeros of $\sigma(x)$ through a knowledge of an integral of lower order. By lower order in this particular instance means evaluating Euler's beta integral with two parameters from a knowledge of Euler's gamma integral that has one parameter.

3. A finite-difference analogue of the Pearson equation. We shall start with a discrete analogue of a hypergeometric differential equation, of which (1.2) is an example:

$$\tilde{\sigma}(x(s))\frac{\nabla}{\nabla x_1(s)}\left[\frac{\triangle y(s)}{\triangle x(s)}\right]+\frac{\tilde{\tau}(x(s))}{2}\left[\frac{\triangle y(s)}{\triangle x(s)}+\frac{\nabla y(s)}{\nabla x(s)}\right]+\lambda y(s)=0, \tag{3.1}$$

where $x(s)$ is generally a nonuniform lattice, $x_k(s)=x(s+k/2)$, $k=1,2,\dots,\triangle f(s)=f(s+1)-f(s)$, $\nabla f(s)=\triangle f(s-1)$; $\tilde{\sigma}(x(s)),\tilde{\tau}(x(s))$ are polynomials in $x(s)$ of degrees at most 2 and 1, respectively, and λ is a constant. The idea of difference equations on nonuniform lattices seems a very natural one (see, e.g., the standard Russian textbook [51]), but a complete analysis of the solutions, particularly the polynomial solutions, of equations like (3.1) for linear and quadratic lattices as well as their q-analogues, was made by Soviet mathematicians Nikiforov and Uvarov [42]–[44], Nikiforov and Suslov [41], and Nikiforov, Suslov, and Uvarov [39], [40]. See also Suslov [53], and Atakishiyev and Suslov [11] for nonpolynomial solutions of homogeneous and nonhomogeneous forms of (3.1).

Denoting

$$v_1(s)=\frac{\triangle y(s)}{\triangle x(s)},\quad v_2(s)=\frac{\triangle v_1(s)}{\triangle x_1(s)}, \tag{3.2}$$

(3.1) can be written in a more compact form:

$$\sigma(s)v_2(s-1)+\tau(s)v_1(s)+\lambda y(s)=0, \tag{3.3}$$

where

$$\begin{aligned}\tau(s)&=\tilde{\tau}(x(s)),\\ \sigma(s)&=\tilde{\sigma}(x(s))-\tfrac{1}{2}\tau(s)\nabla x_1(s).\end{aligned} \tag{3.4}$$

If $\rho(s)$ satisfies the Pearson-type equation

$$\nabla[\rho_1(s)]=\rho(s)\tau(s)\nabla x_1(s), \tag{3.5}$$

with $\rho_1(s)=\rho(s+1)\sigma(s+1)$, then (3.3) can be expressed in a self-adjoint form:

$$\frac{\nabla}{\nabla x_1(s)}[\rho_1(s)v_1(s)]+\lambda\rho(s)y(s)=0. \tag{3.6}$$

In principle, there is no difficulty in writing down a formal solution of (3.5) in terms of $\tau(s)$ and $\sigma(s)$, but first we have to decide what sort of a lattice we have and what kind of problems we are interested in. If one is concerned about preserving the hypergeometric character of (3.3), namely, that the successive difference-derivatives of $y(s)$, like the ones in (3.2), also satisfy equations of the same type, then, as was shown

in [12], the necessary and sufficient condition for that to happen is that $x(s)$ be of the form

$$x(s) = \begin{cases} C_1 q^{-s} + C_2 q^s & \text{if } q \neq 1, \\ C_1 s^2 + C_2 s & \text{if } q = 1, \end{cases} \tag{3.7}$$

where C_1 and C_2 are arbitrary constants, not both zero. Hence

$$\nabla x_1(s) = \begin{cases} q^{-\frac{1}{2}}(1-q)(C_1 q^{-s} - C_2 q^s), & q \neq 1, \\ 2C_1 s + C_2, & q = 1, \end{cases} \tag{3.8}$$

implying that $\nabla x_1(s)$ is odd in s if $x(s)$ is even, and vice versa. In [12] we used the polynomial types of $\tilde{\sigma}(x(s))$ and $\tilde{\tau}(x(s))$ to define the family of classical orthogonal polynomials and to classify them according to the lattice type. In this paper we shall still restrict ourselves to lattice type (3.7) but relax the requirement of $\tilde{\sigma}(x(s))$ and $\tilde{\tau}(x(s))$ being polynomials of degrees 2 and 1, respectively, by allowing simple poles in addition to the zeros that we already had. This type of Pearson equation plays a crucial role, in the theory of biorthogonal rational functions [49].

There are two possible situations: (i) s is a discrete variable varying in unit steps from $s = a$ to $s = b - 1$ (it is permissible for a to be $-\infty$ and/or b to be $+\infty$); (ii) s is a continuous complex variable in some domain of the complex plane.

In case (i) the Pearson equation (3.5) provides a telescoping situation, so we get the formula

$$\rho(b)\sigma(b) - \rho(a)\sigma(a) = \sum_{s=a}^{b-1} \rho(s)\tau(s) \nabla x_1(s). \tag{3.9}$$

If a and b are finite, then usually they are both zeros of $\rho(s)\sigma(s)$, so the left side vanishes and we get

$$\sum_{s=a}^{b-1} \rho(s)\tau(s) \nabla x_1(s) = 0. \tag{3.10}$$

This can be used to prove most of the finite summation formulas (e.g., Vandermonde, Dixon, and Dougall) and their q-analogues, but that will be of no interest to us here. We shall instead be concerned with the situation when neither a nor b is finite and the expression on the left side of (3.9) is not necessarily zero. We shall deal with this case in later sections.

In the continuous case (ii) we may find a suitable contour C in the complex s-plane that does not go through any singularities of the integrands so that (3.5) gives

$$\int_C \nabla[\rho_1(s)]ds = \int_C \rho(s)\tau(s) \nabla x_1(s)ds. \tag{3.11}$$

If C has the property that

$$\int_C \rho_1(s)ds = \int_{C'} \rho_1(s')ds', \tag{3.12}$$

where C' is the contour obtained from C by the shift $s' = s - 1$, then (3.11) gives

$$\int_C \rho(s)\tau(s) \bigtriangledown x_1(s)ds = 0. \tag{3.13}$$

Note that, by Cauchy's theorem, (3.12) implies that there are no singularities of $\rho_1(s)$ between C and C'.

4. Barnes's second lemma: linear lattice $x(s) = s$. Since $\bigtriangledown x_1(s) = 1$, (3.5) takes the form

$$\frac{\rho(s+1)}{\rho(s)} = \frac{\sigma(s)+\tau(s)}{\sigma(s+1)}, \tag{4.1}$$

so we want $\sigma(s)$ and $\tau(s)$ to be such that both $\sigma(s+1)$ and $\sigma(s)+\tau(s)$ are rational functions of s with simple linear factors. We take

$$\begin{aligned} \sigma(s) &= (s_1 - s)(s_2 - s), \\ \tau(s) &= \frac{(1 - s_3 - s_6)(1 - s_5 - s_6)(s + s_4)}{1 + s - s_6} - (s_1 + s_4)(s_2 + s_4), \end{aligned} \tag{4.2}$$

where s_i, $i = 1, \dots, 6$, are some complex parameters. It is easy to verify that if these parameters satisfy the "balance" condition

$$s_1 + s_2 + s_3 + s_4 + s_5 + s_6 = 1, \tag{4.3}$$

then

$$\sigma(s) + \tau(s) = \frac{(s + s_3)(s + s_4)(s + s_5)}{1 + s - s_6}, \tag{4.4}$$

and hence

$$\frac{\rho(s+1)}{\rho(s)} = \frac{(s + s_3)(s + s_4)(s + s_5)}{(s_1 - 1 - s)(s_2 - 1 - s)(1 + s - s_6)}. \tag{4.5}$$

This has infinitely many solutions, all differing by a periodic factor of period 1. The solution that is appropriate for our purposes is

$$\rho(s) = \frac{\Gamma(s_1 - s)\Gamma(s_2 - s)\Gamma(s_3 + s)\Gamma(s_4 + s)\Gamma(s_5 + s)}{\Gamma(1 + s - s_6)}. \tag{4.6}$$

Since

$$\begin{aligned} \rho_1(s) &= [\sigma(s) + \tau(s)]\rho(s) \\ &= \frac{\Gamma(s_1 - s)\Gamma(s_2 - s)\Gamma(s_3 + 1 + s)\Gamma(s_4 + 1 + s)\Gamma(s_5 + 1 + s)}{\Gamma(2 + s - s_6)}, \end{aligned} \tag{4.7}$$

we find that there are no poles of $\rho_1(s)$ between C, the imaginary axis, and C', the line one unit to the left of C, provided (4.3) holds and

$$\operatorname{Re} s_i > 0, \qquad i = 1, \dots, 5. \tag{4.8}$$

Assuming this to be the case we then have

$$\int_C \nabla[\rho_1(s)]ds = 0. \tag{4.9}$$

So, by (3.13) and (4.2) we get

$$\int_C \rho(s)ds = \frac{(1-s_3-s_6)(1-s_5-s_6)}{(s_1+s_4)(s_2+s_4)} \int_C \frac{s+s_4}{1+s-s_6}\rho(s)ds. \tag{4.10}$$

Let us fix the parameters s_1, s_2, s_3, and s_5, and think of $\rho(s)$ as a function of s and s_4. Note that, by (4.3), s_6 decreases by 1 if s_4 increases by 1. So, denoting

$$\frac{1}{2\pi i}\int_C \rho(s)ds = I(s_4), \tag{4.11}$$

we find that

$$\frac{1}{2\pi i}\int_C \frac{s+s_4}{1+s-s_6}\rho(s)ds = I(s_4+1). \tag{4.12}$$

So, (4.10) becomes a 2-term recurrence relation

$$I(s_4) = \frac{(1-s_3-s_6)(1-s_5-s_6)}{(s_1+s_4)(s_2+s_4)} I(s_4+1), \tag{4.13}$$

which, on iteration, gives

$$I(s_4) = \frac{\Gamma(s_1+s_4)\Gamma(s_2+s_4)}{\Gamma(1-s_3-s_6)\Gamma(1-s_5-s_6)}A, \tag{4.14}$$

where

$$\begin{aligned} A &= \lim_{n\to\infty} \frac{\Gamma(1-s_3-s_6+n)\Gamma(1-s_5-s_6+n)}{\Gamma(s_1+s_4+n)\Gamma(s_2+s_4+n)} I(s_4+n) \\ &= \lim_{n\to\infty} \frac{1}{2\pi i}\int_C \Gamma(s_1-s)\Gamma(s_2-s)\Gamma(s_3+s)\Gamma(s_5+s) \\ &\quad \cdot \frac{\Gamma(1-s_3-s_6+n)\Gamma(1-s_5-s_6+n)\Gamma(s_4+s+n)}{\Gamma(s_1+s_4+n)\Gamma(s_2+s_4+n)\Gamma(1+s-s_6+n)}ds. \end{aligned} \tag{4.15}$$

By Stirling's formula and (4.3),

$$\begin{aligned} &\frac{\Gamma(1-s_3-s_6+n)\Gamma(1-s_5-s_6+n)\Gamma(s_4+s+n)}{\Gamma(s_1+s_4+n)\Gamma(s_2+s_4+n)\Gamma(1+s-s_6+n)} \\ &\quad \sim n^{1-(s_1+s_2+s_3+s_4+s_5+s_6)} = 1 \quad \text{for large } n. \end{aligned} \tag{4.16}$$

Also, by Barnes's first lemma (1.6),

$$\begin{aligned} &\frac{1}{2\pi i}\int_C \Gamma(s_1-s)\Gamma(s_2-s)\Gamma(s_3+s)\Gamma(s_5+s)ds \\ &\quad = \frac{\Gamma(s_1+s_3)\Gamma(s_1+s_5)\Gamma(s_2+s_3)\Gamma(s_2+s_5)}{\Gamma(s_1+s_2+s_3+s_5)}. \end{aligned} \tag{4.17}$$

(Incidentally, an alternate proof of (1.6) based on somewhat similar ideas was given by Miller [37] and Kalnins and Miller [34].) Combining (4.6), (4.11), (4.14)–(4.17), we find that

$$\frac{1}{2\pi i}\int_{-i\infty}^{i\infty}\frac{\Gamma(s_1-s)\Gamma(s_2-s)\Gamma(s_3+s)\Gamma(s_4+s)\Gamma(s_5+s)}{\Gamma(s_1+s_2+s_3+s_4+s_5+s)}ds \tag{4.18}$$
$$=\frac{\Gamma(s_1+s_3)\Gamma(s_1+s_4)\Gamma(s_1+s_5)\Gamma(s_2+s_3)\Gamma(s_2+s_4)\Gamma(s_2+s_5)}{\Gamma(s_1+s_2+s_3+s_4)\Gamma(s_1+s_2+s_3+s_5)\Gamma(s_1+s_2+s_4+s_5)},$$

which is essentially the same as (1.7). (It would be the same if one of s_1, s_2 were zero and the contour were indented around the origin.)

5. Extension of Ramanujan's integral: linear lattice $x(s)=s$. Here we start with the same lattice and the same expressions for $\sigma(s)$ and $\tau(s)$ as in §4 so that the formulas (4.1)–(4.5) all hold. But now that the line of integration is the whole real line instead of the imaginary axis, the asymptotics are entirely different, so the appropriate solution of (4.5) is

$$\rho(s)\equiv\rho(s,s_4) \tag{5.1}$$
$$=\frac{\Gamma(s_6-s)}{\Gamma(1+s-s_1)\Gamma(1+s-s_2)\Gamma(1-s_3-s)\Gamma(1-s_4-s)\Gamma(1-s_5-s)}.$$

From (4.2) and (5.1) we have

$$\rho_1(s-1)=\rho(s)\sigma(s) \tag{5.2}$$
$$=\frac{\Gamma(s_6-s)}{\Gamma(s-s_1)\Gamma(s-s_2)\Gamma(1-s_3-s)\Gamma(1-s_4-s)\Gamma(1-s_5-s)}.$$

To investigate the behaviour of $\rho_1(s-1)$ as $s\to-\infty$ let us first split it into two factors:

$$\rho_1(s-1)=\mu_1(s)g_1(s), \tag{5.3}$$

where

$$g_1(s)=\frac{\Gamma(1+s_1-s)\Gamma(1+s_2-s)\Gamma(s_6-s)}{\Gamma(1-s_3-s)\Gamma(1-s_4-s)\Gamma(1-s_5-s)}, \tag{5.4}$$

and

$$\mu_1(s)=\pi^{-2}\sin\pi(s-s_1)\sin\pi(s-s_2). \tag{5.5}$$

Clearly, $\mu_1(s\pm1)=\mu_1(s)$ and $|\mu_1(s)|\le\pi^{-2}$ for all real s. Also, by (4.3) and Stirling's formula,

$$\lim_{s\to-\infty}g_1(s)=1. \tag{5.6}$$

For s near $+\infty$ we take

$$\rho_1(s-1)=\mu_2(s)g_2(s) \tag{5.7}$$

with

$$g_2(s)=\frac{\Gamma(s_3+s)\Gamma(s_4+s)\Gamma(s_5+s)}{\Gamma(s-s_1)\Gamma(s-s_2)\Gamma(1+s-s_6)} \tag{5.8}$$

and

$$\mu_2(s) = \pi^{-2}\frac{\sin\pi(s+s_3)\sin\pi(s+s_4)\sin\pi(s+s_5)}{\sin\pi(s_6-s)}. \tag{5.9}$$

Once again,

$$\lim_{s\to\infty} g_2(s) = 1 \tag{5.10}$$

and $\mu_2(s \pm 1) = \mu_2(s)$. But now $\mu_2(s)$ is not bounded for all real s unless Im $s_6 \neq 0$.

By defining

$$\int_{-\infty}^{\infty} f(s)ds = \lim_{M,N\to\infty}\int_{-N-\epsilon_1}^{M+\epsilon_2} f(s)ds, \tag{5.11}$$

where M, N are positive integers and ϵ_1, ϵ_2 are some real constants with $0 \leq \epsilon_1, \epsilon_2 < 1$, we will now compute the integral $\int_{-\infty}^{\infty} \nabla[\rho_1(s)]ds$. Since

$$\int_a^b \nabla[\rho_1(s)]ds = \int_b^{b+1} \rho_1(s-1)ds - \int_a^{a+1} \rho_1(s-1)ds, \tag{5.12}$$

we have

$$\begin{aligned}
&\int_{-N-\epsilon_1}^{M+\epsilon_2} \nabla[\rho_1(s)]ds \\
&= \int_{M+\epsilon_2}^{M+\epsilon_2+1} \mu_2(s)g_2(s)ds - \int_{-N-\epsilon_1}^{1-N-\epsilon_1} \mu_1(s)g_1(s)ds \\
&= \int_{\epsilon_2}^{\epsilon_2+1} \mu_2(M+s)g_2(M+s)ds - \int_{-\epsilon_1}^{1-\epsilon_1} \mu_1(s-N)g_1(s-N)ds \\
&= \int_{\epsilon_2}^{\epsilon_2+1} \mu_2(s)g_2(M+s)ds - \int_{-\epsilon_1}^{1-\epsilon_1} \mu_1(s)g_1(s-N)ds,
\end{aligned} \tag{5.13}$$

because of the periodicity of μ_1 and μ_2. So, by (5.6) and (5.10) we get

$$\begin{aligned}
\int_{-\infty}^{\infty} \nabla[\rho_1(s)]ds &= \int_{\epsilon_2}^{\epsilon_2+1} \mu_2(s)ds - \int_{-\epsilon_1}^{1-\epsilon_1} \mu_1(s)ds \\
&= \int_0^1 [\mu_2(s) - \mu_1(s)]ds = \mu, \quad \text{say.}
\end{aligned} \tag{5.14}$$

From (5.5) and (5.9) it is clear that the value of μ remains unchanged if we move s_4 one unit up or down as long as (4.3) holds. We now replace $s_1, s_2, s_3, s_4, s_5, s_6$ by $1-a, 1-b, 1-c, 1-d, 1-e$, and $1-f$, respectively, and find that (3.11) leads to the nonhomogeneous recurrence relation

$$I(d) = \frac{(a+d-1)(b+d-1)}{(2-c-f)(2-e-f)}I(d+1) + \frac{\mu}{(2-c-f)(2-e-f)}, \tag{5.15}$$

where the balance condition (4.3) now reads

$$a+b+c+d+e+f = 5, \tag{5.16}$$

and

$$I(d) = \int_{-\infty}^{\infty} \rho(s)ds = \int_{-\infty}^{\infty} \frac{\Gamma(1-f-s)ds}{\Gamma(a+s)\Gamma(b+s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)}. \tag{5.17}$$

It can be shown that, if $\operatorname{Im} f \neq 0$, then

$$|\rho(s)| \sim \begin{cases} (-s)^{-2} & \text{as } s \to -\infty, \\ s^{-2} & \text{as } s \to \infty, \end{cases} \tag{5.18}$$

so that the improper integral in (5.17) converges. Iterating (5.15) n times and then proceeding to the limit $n \to \infty$, we find that

$$I(d) = \frac{\Gamma(2-c-f)\Gamma(2-e-f)}{\Gamma(a+d-1)\Gamma(b+d-1)}B + \frac{\mu}{(2-c-f)(2-e-f)}\, {}_3F_2\left[\begin{matrix} a+d-1, b+d-1, 1 \\ 3-c-f, 3-e-f \end{matrix}; 1\right], \tag{5.19}$$

where

$$B = \lim_{n\to\infty} \int_{-\infty}^{\infty} \frac{\Gamma(a+d+n-1)\Gamma(b+d+n-1)\Gamma(1-f-s+n)}{\Gamma(2-c-f+n)\Gamma(2-e-f+n)\Gamma(d-s+n)} \cdot \frac{ds}{\Gamma(a+s)\Gamma(b+s)\Gamma(c-s)\Gamma(e-s)}, \tag{5.20}$$

provided

$$\operatorname{Re}(2-f) > \max\{\operatorname{Re}(c,d,e)\}. \tag{5.21}$$

By Stirling's formula and Ramanujan's integral (1.8), we have

$$B = \frac{\Gamma(2-d-f)}{\Gamma(a+c-1)\Gamma(a+e-1)\Gamma(b+c-1)\Gamma(b+e-1)}. \tag{5.22}$$

We thus have the formula

(5.23)

$$\int_{-\infty}^{\infty} \frac{\Gamma(1-f-x)dx}{\Gamma(a+x)\Gamma(b+x)\Gamma(c-x)\Gamma(d-x)\Gamma(e-x)} = \frac{\Gamma(2-c-f)\Gamma(2-d-f)\Gamma(2-e-f)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(b+e-1)} + \frac{\mu}{(2-c-f)(2-e-f)}\, {}_3F_2\left[\begin{matrix} a+d-1, b+d-1, 1 \\ 3-c-f, 3-e-f \end{matrix}; 1\right],$$

where the parameters a, b, c, d, e, f satisfy the conditions (i)–(iii) in (1.10), and, by (5.5), (5.9), and (5.14),

$$\mu = \frac{1}{\pi^2}\int_0^1 \Big[\frac{\sin\pi(c-x)\sin\pi(d-x)\sin\pi(e-x)}{\sin\pi(f+x)} - \sin\pi(a+x)\sin\pi(b+x)\Big]dx. \tag{5.24}$$

If the parameters are such that $\mu = 0$, then we have the integration formula (1.9) subject to all four conditions stated in (1.10).

By defining

$$\sum_{-\infty}^{\infty} g(s) = \lim_{k,\ell\to\infty} \sum_{s=\alpha-k}^{\alpha+\ell-1} g(s), \tag{5.25}$$

we obtain, by a similar analysis, that

(5.26)

$$\sum_{n=-\infty}^{\infty} \frac{\Gamma(1-f-\alpha-n)}{\Gamma(a+\alpha+n)\Gamma(b+\alpha+n)\Gamma(c-\alpha-n)\Gamma(d-\alpha-n)\Gamma(e-\alpha-n)}$$
$$= \frac{\Gamma(2-c-f)\Gamma(2-d-f)\Gamma(2-e-f)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(b+e-1)}$$
$$+ \frac{\mu_2(\alpha)-\mu_1(\alpha)}{(2-c-f)(2-e-f)}\,{}_3F_2\left[\begin{matrix} a+d-1, b+d-1, 1 \\ 3-c-f, 3-e-f \end{matrix}; 1\right],$$

with

$$\mu_1(\alpha) = \sin\pi(a+\alpha)\sin\pi(b+\alpha)/\pi^2, \tag{5.27}$$
$$\mu_2(\alpha) = \sin\pi(c-\alpha)\sin\pi(d-\alpha)\sin\pi(e-\alpha)/\pi^2\sin\pi(f+\alpha),$$

and the parameters satisfying the same balance condition (5.16).

Note that the sum on the left side of (5.26) and the first term on the right are symmetrical in c, d, e but the ${}_3F_2$ series is apparently not. This can be rectified by use of the identity [14, Ex. 7, p.98] which, along with (5.16), gives

$$\begin{aligned} &{}_3F_2\left[\begin{matrix} a+d-1, b+d-1, 1; \\ 3-c-f, 3-e-f; \end{matrix} 1\right] \\ &= \frac{2-e-f}{2-d-f}\,{}_3F_2\left[\begin{matrix} a+e-1, b+e-1, 1; \\ 3-c-f, 3-d-f; \end{matrix} 1\right] \\ &= \frac{2-c-f}{2-d-f}\,{}_3F_2\left[\begin{matrix} a+c-1, b+c-1, 1; \\ 3-d-f, 3-e-f; \end{matrix} 1\right], \end{aligned} \tag{5.28}$$

all three ${}_3F_2$'s being convergent because of (5.21). One may deduce from (5.26) the summation formula

$$\sum_{n=-\infty}^{\infty} \frac{(1+\alpha-c)_n(1+\alpha-d)_n(1+\alpha-e)_n}{(\alpha+a)_n(\alpha+b)_n(1+\alpha-a-b-d-e)_n} \tag{5.29}$$
$$= \frac{\Gamma(\alpha+a)\Gamma(\alpha+b)\Gamma(c-\alpha)\Gamma(d-\alpha)\Gamma(e-\alpha)}{\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)\Gamma(a+b+c+d+e-4-\alpha)}$$
$$\cdot \frac{\Gamma(a+b+c+d-3)\Gamma(a+b+c+e-3)\Gamma(a+b+d+e-3)}{\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(b+e-1)},$$

provided

$$\sin\pi(c-\alpha)\sin\pi(d-\alpha)\sin\pi(e-\alpha) \tag{5.30}$$
$$= \sin\pi(a+\alpha)\sin\pi(b+\alpha)\sin\pi(a+b+c+d+e-\alpha).$$

This is a bilateral extension of the Saalschütz formula [52, III. 2, p. 243]. A q-extension is given in §12.

It may be pointed out that by appropriate shift of the parameters we may set $\alpha = 0$ in (5.26), (5.27), (5.29), and (5.30), without any loss of generality.

6. The q-quadratic lattice $x(s) = C_1q^{-s} + C_2q^s$. It would appear that the q-quadratic lattice is far more complicated than the simple linear lattices considered in the previous two sections. However, there is a symmetry in the quadratic case that makes the analysis just as simple as in the linear cases. If we denote $\alpha = C_2/C_1$, $C_1 \neq 0$, then it follows from (3.7) and (3.8) that

$$x(s) = \begin{cases} x(-s-\nu) & \text{if } q \neq 1, \\ x(-s-\alpha) & \text{if } q = 1, \end{cases} \tag{6.1}$$

$$\nabla x_1(s) = \begin{cases} -\nabla x_1(t)|_{t=-s-\nu} & \text{if } q \neq 1, \\ -\nabla x_1(t)|_{t=-s-\alpha} & \text{if } q = 1, \end{cases} \tag{6.2}$$

where $\nu = \log\alpha/\log q$, that is, $\alpha = q^\nu$ when $q \neq 1$, it being understood that the constants C_1, C_2 are not the same in the two cases. Because of (3.4) we are then led to the property

$$\sigma(s) + \tau(s)\nabla x_1(s) = \begin{cases} \sigma(-s-\nu), & q \neq 1, \\ \sigma(-s-\alpha), & q = 1, \end{cases} \tag{6.3}$$

so that the Pearson equation (3.5) takes the form

$$\frac{\rho(s+1)}{\rho(s)} = \sigma^{-1}(s+1)\begin{cases} \sigma(-s-\nu), & q \neq 1, \\ \sigma(-s-\alpha), & q = 1, \end{cases} \tag{6.4}$$

which means that we only need $\sigma(s)$, and not $\tau(s)$ as well, to determine $\rho(s)$. Following the usual structure of the Pearson-type equations discussed in [49] we take

$$\sigma(s) = q^{-2s}\prod_{k=1}^{5}(q^s - s_k)/(q^s - q/s_6), \qquad q \neq 1, \tag{6.5}$$

where $s_1, \dots, s_6$ are six complex parameters that satisfy the balance condition

$$\alpha^2 s_1 s_2 s_3 s_4 s_5 s_6 = q, \qquad \alpha = C_2/C_1 = q^\nu. \tag{6.6}$$

In the $q = 1$ case, the most important quadratic lattice is $x(s) = s^2$, in which case $\alpha = 0$, and

$$\sigma(s) = \frac{(s - s_1)(s - s_2)(s - s_3)(s - s_4)(s - s_5)}{(s - s_1 - s_2 - s_3 - s_4 - s_5)}. \tag{6.7}$$

For now we shall restrict our analysis to the $q \neq 1$ case and return to the $q = 1$ case later. Using (6.2), (6.3), (6.5), and (6.6) we find that

$$\tau(s) = A + B\frac{x(s_0) - x(s)}{x(s_\infty) - x(s)}, \tag{6.8}$$

where

$$q^{s_0} = s_1, \qquad q^{s_\infty} = q/s_6 = \alpha^2 s_1 s_2 s_3 s_4 s_5, \tag{6.9}$$

$$A = \frac{q^{\frac{1}{2}}}{C_1 \alpha^2 s_1 (1 - q)(1 - \alpha q s_1/s_6)} \prod_{k=2}^{5} (1 - \alpha s_1 s_k), \tag{6.10}$$

$$B = \frac{q^{\frac{1}{2}} s_6}{C_1 \alpha^2 q (1 - q)(1 - \alpha q s_1/s_6)} \prod_{k=2}^{5} (1 - q/s_k s_6). \tag{6.11}$$

Clearly, we could have chosen any one of the five parameters $s_1, \dots, s_5$ as q^{s_0} (with corresponding changes in A and B), so this symmetry must be reflected in the final results. We justify the notation s_0 and s_∞ by pointing out that $\sigma(s_0) = 0$ and $\sigma(s_\infty) = \infty$.

Equations (6.4) and (6.5) give

$$\frac{\rho(s+1)}{\rho(s)} = q^{4s+2\nu+2} \frac{1 - s_6 q^s}{1 - s_6 q^{-s-\nu-1}} \prod_{k=1}^{5} \frac{(1 - q^{-s-\nu}/s_k)}{(1 - q^{s+1}/s_k)} \tag{6.12}$$

or

$$\frac{\rho(s+1)}{\rho(s)} = q^{-4s-2\nu-2} \frac{1 - q^{-s}/s_6}{1 - q^{s+\nu+1}/s_6} \prod_{k=1}^{5} \frac{(1 - s_k q^{s+\nu})}{(1 - s_k q^{-s-1})}. \tag{6.13}$$

As we shall see later the expression in (6.12) is suitable for summations and integrations along the real line, while that in (6.13) is more suitable for integration along the imaginary axis.

The general solution of (6.12) is

$$\rho(s) = \rho_0(s) \frac{\prod_{k=1}^{5} (q^{s+1}/s_k, q^{1-s-\nu}/s_k; q)_\infty}{(s_6 q^s, s_6 q^{-s-\nu}; q)_\infty}, \tag{6.14}$$

with

$$\frac{\rho_0(s+1)}{\rho_0(s)} = q^{4s+2\nu+2} \quad \forall\, s \in \boldsymbol{C}, \tag{6.15}$$

while the appropriate solution of (6.13) is

$$\rho(s) = p(s)\frac{(q^{s+\nu+1}/s_6, q^{1-s}/s_6; q)_\infty}{\prod_{k=1}^{5}(s_k q^{s+\nu}, s_k q^{-s}; q)_\infty}, \tag{6.16}$$

with

$$\frac{p(s+1)}{p(s)} = q^{-4s-2\nu-2} \quad \forall\, s \in \boldsymbol{C}. \tag{6.17}$$

Since

$$\begin{aligned}\frac{x(s_0)-x(s)}{x(s_\infty)-x(s)} &= \frac{s_1 s_6}{q}\frac{(1-q^s/s_1)(1-q^{-s-\nu}/s_1)}{(1-s_6 q^{s-1})(1-s_6 q^{-s-\nu-1})} \\ &= \frac{q}{s_1 s_6}\frac{(1-s_1 q^{s+\nu})(1-s_1 q^{-s})}{(1-q^{s+\nu+1}/s_6)(1-q^{1-s}/s_6)},\end{aligned} \tag{6.18}$$

we have

$$\begin{aligned}&\frac{x(s_0)-x(s)}{x(s_\infty)-x(s)}\rho(s) \\ &\quad = \begin{cases} \dfrac{s_1 s_6}{q}\rho_0(s)\dfrac{(q^s/s_1, q^{-s-\nu}/s_1; q)_\infty \prod_{k=2}^{\infty}(q^{s+1}/s_k, q^{1-s-\nu}/s_k; q)_\infty}{(s_6 q^{s-1}, s_6 q^{-s-\nu-1}; q)_\infty}, \\ \dfrac{q}{s_1 s_6}p(s)\dfrac{(q^{2-s}/s_6, q^{s+\nu+2}/s_6; q)_\infty}{(s_1 q^{s+\nu+1}, s_1 q^{1-s}; q)_\infty \prod_{k=2}^{5}(s_k q^{s+\nu}, s_k q^{-s}; q)_\infty}, \end{cases}\end{aligned} \tag{6.19}$$

for the solutions (6.14) and (6.16), respectively.

To emphasize the fact that $\rho(s)$ depends on all 5 parameters $s_1, \ldots, s_5$, and that we have chosen s_1 to be q^{s_0} let us denote

$$\rho(s) = \rho(s; s_1). \tag{6.20}$$

Use of (3.5), (3.8), (6.8)–(6.11), and (6.19) then gives

$$\begin{aligned}\nabla[\rho(s+1)\sigma(s+1)] &= \tau(s)\rho(s; s_1) \nabla x_1(s) \\ &= \frac{\prod_{k=2}^{5}(1-q^\nu s_1 s_k)}{s_1(1-q^{\nu+1}s_1/s_6)} q^{-s-2\nu}(1-q^{\nu+2s})\rho(s; s_1) \\ &\quad + D q^{-s-2\nu}(1-q^{\nu+2s})\rho(s; q s_1),\end{aligned} \tag{6.21}$$

where

$$D = \begin{cases} -\dfrac{s_1 s_6^2}{q^2}\dfrac{\prod_{k=2}^{5}(1-q/s_k s_6)}{(1-q^{\nu+1}s_1/s_6)}, \\ \dfrac{q^{\nu+2}}{s_1 s_6^2}\dfrac{\prod_{k=2}^{5}(1-s_k s_6/q)}{(1-s_6 q^{-\nu-1}/s_1)}, \end{cases} \tag{6.22}$$

the first line of (6.22) corresponding to the first two lines of (6.18) and (6.19), and the second line to the second two lines. In either case, the sum or integral of (6.21) sets up a 2-term recurrence relation for the sum or integral over $q^{-s-2\nu}(1-q^{\nu+2s})\rho(s; s_1)$

as a function of s_1. It is homogeneous or nonhomogenous depending on whether or not the sum or integral of the left side of (6.21) produces a zero.

7. Proof of formula (1.35): lattice $x(s) = \frac{1}{2}(q^{-s} + q^{s})$. In this section we shall consider the integral over $\rho(s)$ along a line parallel to the imaginary axis for the symmetric lattice $x(s) = \frac{1}{2}(q^{-s} + q^{s})$ with $\nu = 0$ in (6.16). We take

$$s_1 = a, \quad s_2 = b, \quad s_3 = c, \quad s_4 = d, \quad s_5 = f \tag{7.1}$$

so that (6.6) gives

$$s_6 = \frac{q}{abcdf}, \tag{7.2}$$

and (6.21) gives

$$\begin{aligned} \nabla\,[\rho(s+1)\sigma(s+1)] &= a^{-1}\frac{(1-ab)(1-ac)(1-ad)(1-af)}{(1-a^2bcdf)}q^{-s}(1-q^{2s})\rho(s;a) \\ &\quad - a^{-1}\frac{(1-abcd)(1-abcf)(1-abdf)(1-acdf)}{(1-a^2bcdf)}q^{-s}(1-q^{2s})\rho(s;aq), \end{aligned} \tag{7.3}$$

with

$$\begin{aligned} \rho(s) &= \rho(s;a) \\ &= p(s)\frac{(abcdfq^{s}, abcdfq^{-s};q)_\infty}{(aq^{s}, aq^{-s}, bq^{s}, bq^{-s}, cq^{s}, cq^{-s}, dq^{s}, dq^{-s}, fq^{s}, fq^{-s};q)_\infty}, \end{aligned} \tag{7.4}$$

$$\frac{p(s+1)}{p(s)} = q^{-4s-2}. \tag{7.5}$$

Let

$$p(s) = \frac{\wp(s)}{q^{-s} - q^{s}}, \tag{7.6}$$

so that

$$\begin{aligned} \frac{\wp(s+1)}{\wp(s)} &= -\frac{(1+q^{-s-1})(1-q^{-s-1})}{(1+q^{s})(1-q^{s})}q^{-2s-1} \\ &= \frac{(1+q^{-s-\frac{1}{2}})(1+q^{-s-1})(1-q^{-s-\frac{1}{2}})(1-q^{-s-1})}{(1+q^{s})(1+q^{s+\frac{1}{2}})(1-q^{s})(1-q^{s+\frac{1}{2}})} \end{aligned} \tag{7.7}$$

with solution

$$\begin{aligned} \wp(s) &= (q^{s}, -q^{s}, q^{-s}, -q^{-s}, q^{s+\frac{1}{2}}, -q^{s+\frac{1}{2}}, q^{\frac{1}{2}-s}, -q^{\frac{1}{2}-s};q)_\infty \\ &= (q^{2s}, q^{-2s};q)_\infty, \end{aligned} \tag{7.8}$$

unique, to within a unit-periodic multiplicative factor. Equations (7.4), (7.6), and (7.8) then give

$$\rho(s;a) = (q^{-s} - q^{s})^{-1}\frac{(q^{2s}, q^{-2s}, abcdfq^{s}, abcdfq^{-s};q)_\infty}{(aq^{s}, aq^{-s}, bq^{s}, bq^{-s}, cq^{s}, cq^{-s}, dq^{s}, dq^{-s}, fq^{s}, fq^{-s};q)_\infty}, \tag{7.9}$$

which agrees with the integrand of (1.33) when $f = 0$, so we may set that multiplicative factor equal to 1.

We now assume that

$$\max(|a|, |b|, |c|, |d|, |f|) < 1, \qquad 0 < q < 1 \tag{7.10}$$

and choose the contour C as $-\pi/(\log q^{-1}) \leq \operatorname{Im} s \leq \pi/\log q^{-1}$, and consider the boundary of the parallelogram defined by

$$0 \leq \operatorname{Re} s \leq 1, \qquad -\frac{\pi}{\log q^{-1}} \leq \operatorname{Im} s \leq \frac{\pi}{\log q^{-1}}. \tag{7.11}$$

Since

$$\rho(s)\sigma(s) = q^{3s}\frac{(q^{s+1}, -q^{s+1}, q^{-s}, -q^{-s}, q^{\frac{1}{2}+s}, -q^{\frac{1}{2}+s}; q)_\infty}{(aq^s, aq^{1-s}, bq^s, bq^{1-s}, cq^s, cq^{1-s}; q)_\infty} \cdot \frac{(q^{\frac{1}{2}-s}, -q^{\frac{1}{2}-s}, abcdfq^s, abcdfq^{1-s}; q)_\infty}{(dq^s, dq^{1-s}, fq^s, fq^{1-s}; q)_\infty}, \tag{7.12}$$

there are no poles inside the basic parallelogram in (7.11). So the integral over $\nabla[\rho(s+1)\sigma(s+1)]$ along the boundary of this parallelogram vanishes and hence, due to the $2\pi i/\log q^{-1}$ periodicity of this integrand, we obtain from (7.3) the recurrence relation

$$I(a) = \frac{(1-abcd)(1-abcf)(1-abdf)(1-acdf)}{(1-ab)(1-ac)(1-ad)(1-af)} I(aq), \tag{7.13}$$

where

$$I(a) = \frac{1}{2\pi i}\int_C \frac{(q^s, -q^s, q^{-s}, -q^{-s}, q^{\frac{1}{2}+s}, -q^{\frac{1}{2}+s}, q^{\frac{1}{2}-s}, -q^{\frac{1}{2}-s}; q)_\infty}{(aq^s, aq^{-s}, bq^s, bq^{-s}, cq^s, cq^{-s}, dq^s, dq^{-s}; q)_\infty} \cdot \frac{(abcdfq^s, abcdfq^{-s}; q)_\infty}{(fq^s, fq^{-s}; q)_\infty} ds. \tag{7.14}$$

By the symmetry of the integrand in (7.14) and the transformation

$$q^s = e^{i\theta}, \qquad 0 \leq \theta \leq \pi, \tag{7.15}$$

we may convert (7.13) into a recurrence relation for the real integral

$$J(a) = \int_0^\pi \frac{h(\cos\theta; 1, -1, q^{\frac{1}{2}}, -q^{\frac{1}{2}}, abcdf)}{h(\cos\theta; a, b, c, d, f)} d\theta, \tag{7.16}$$

namely,

$$J(a) = \frac{(1-abcd)(1-abcf)(1-abdf)(1-acdf)}{(1-ab)(1-ac)(1-ad)(1-af)} J(aq). \tag{7.17}$$

Iterating (7.17) n times and then taking the limit $n \to \infty$ we find that

$$J(a) = \frac{(abcd, abcf, abdf, acdf; q)_\infty}{(ab, ac, ad, af; q)_\infty} J(0), \tag{7.18}$$

where

$$J(0) = \int_0^\pi \frac{h(\cos\theta; 1, -1, q^{\frac{1}{2}}, -q^{\frac{1}{2}})}{h(\cos\theta; b, c, d, f)} d\theta \tag{7.19}$$
$$= \frac{2\pi(bcdf; q)_\infty}{(q, bc, bd, bf, cd, cf, df; q)_\infty}, \quad \text{by (1.33).}$$

Combining (7.18) and (7.19) completes the proof of (1.35).

It may be mentioned that a similar method can also be applied to compute the Askey–Wilson integral (1.33). The idea is to reduce the number of parameters down to zero by successive recursions and then compute the simple parameter-free integral $\int_0^\pi h(\cos\theta; 1, -1, q, -q^{1/2})d\theta$, which can be done in a very elementary manner. See [13] and [33] for details. See also [36] for a similar proof.

8. A very well poised bilateral sum: lattice $x(s) = \frac{1}{2}(q^{-s} + q^s)$. We shall now consider the sum over $\rho(s)$ along the real line for the symmetric lattice $x(s) = \frac{1}{2}(q^{-s} + q^s)$ with $\nu = 0$ in (6.14). We replace the parameters $s_1, \ldots, s_6$ by

$$s_1 = q/a, \quad s_2 = q/b, \quad s_3 = q/c, \quad s_4 = q/d, \quad s_5 = q/e, \quad s_6 = q/f, \tag{8.1}$$

so that the balance condition now reads

$$abcdef = q^5. \tag{8.2}$$

Use of (8.1) in (6.14) gives

$$\rho(s) = \rho(s; a)$$
$$= \rho_0(s) \frac{(aq^s, aq^{-s}, bq^s, bq^{-s}, cq^s, cq^{-s}, dq^s, dq^{-s}, eq^s, eq^{-s}; q)_\infty}{(q^{1+s}/f, q^{1-s}/f; q)_\infty}. \tag{8.3}$$

Defining a bilateral sum by the same limit as in (5.25), where the complex parameter α is not the same as the one used in §6, we find, by summing over (6.21) (after replacing a by aq), that

$$\epsilon(\alpha; aq) = \frac{f}{qa^2} \frac{(1 - ab/q)(1 - ac/q)(1 - ad/q)(1 - ae/q)}{1 - f/qa} I(aq)$$
$$- \frac{q^2}{af^2} \frac{(1 - bf/q^2)(1 - cf/q^2)(1 - df/q^2)(1 - ef/q^2)}{1 - f/qa} I(a), \tag{8.4}$$

where $I(a)$ is the bilateral sum

$$I(a) = \lim_{k,\ell\to\infty} \sum_{\alpha-k}^{\alpha+\ell-1} (1 - q^{2s}) q^{-s} (aq^s, aq^{-s}, bq^s, bq^{-s}, cq^s, cq^{-s}; q)_\infty$$
$$\cdot \frac{(dq^s, dq^{-s}, eq^s, eq^{-s}; q)_\infty}{(q^{1+s}/f, q^{1-s}/f; q)_\infty} \rho_0(s) \tag{8.5}$$

and

$$\epsilon(\alpha; aq) = \lim_{\ell\to\infty} \Big\{ \rho_0(\alpha + \ell) q^{-2\alpha-2\ell} (aq^{\alpha+\ell-1}, aq^{-\alpha-\ell}, bq^{\alpha+\ell-1}, bq^{-\alpha-\ell}; q)_\infty$$
$$\cdot \frac{(cq^{\alpha+\ell-1}, cq^{-\alpha-\ell}, dq^{\alpha+\ell-1}, dq^{-\alpha-\ell}, eq^{\alpha+\ell-1}, eq^{-\alpha-\ell}; q)_\infty}{(q^{\alpha+\ell}/f, q^{1-\alpha-\ell}/f; q)_\infty} \Big\} \tag{8.6}$$
$$- \lim_{k\to\infty} \Big\{ \rho_0(\alpha - k) q^{2k-2\alpha} (aq^{\alpha-k-1}, aq^{-\alpha+k}, bq^{\alpha-k-1}, bq^{-\alpha+k}; q)_\infty$$
$$\cdot \frac{(cq^{\alpha-k-1}, cq^{-\alpha+k}, dq^{\alpha-k-1}, dq^{-\alpha+k}, eq^{\alpha-k-1}, eq^{-\alpha+k}; q)_\infty}{(q^{\alpha-k}/f, q^{1-\alpha+k}/f; q)_\infty} \Big\},$$

provided the limits in (8.5) and (8.6) exist. It can be easily verified that

$$\epsilon(\alpha; aq) = \frac{q}{af}\epsilon(\alpha; a), \tag{8.7}$$

so we may write (8.4) as

$$\begin{aligned} I(a) = {} & \frac{(1-ab/q)(1-ac/q)(1-ad/q)(1-ae/q)}{(1-q^2/bf)(1-q^2/cf)(1-q^2/df)(1-q^2/ef)} I(aq) \\ & + \frac{a(1-aq/f)}{(1-q^2/bf)(1-q^2/cf)(1-q^2/df)(1-q^2/ef)} \left(\frac{q}{af}\right) \epsilon(\alpha; a). \end{aligned} \tag{8.8}$$

Before proceeding any further we have to decide what $\rho_0(s)$ must be in order that the limits indicated above exist. Since $\rho_0(s)$ must satisfy (6.15) (with $\nu = 0$), it suffices to take

$$\rho_0(s) = q^{2s^2}. \tag{8.9}$$

We may now split $\rho(s)\sigma(s)$ into two factors, one that converges as $s \to \infty$ and the other that is periodic of unit period in much the same way as in §5, and find that

$$\begin{aligned} \epsilon(\alpha; a) = q^{2\alpha(\alpha-1)} \Big\{ & (aq^{-\alpha}, q^{\alpha+1}/a, bq^{-\alpha}, q^{\alpha+1}/b, cq^{-\alpha}, q^{\alpha+1}/c; q)_\infty \\ & \cdot \frac{(dq^{-\alpha}, q^{\alpha+1}/d, eq^{-\alpha}, q^{\alpha+1}/e; q)_\infty}{(fq^\alpha, q^{1-\alpha}/f; q)_\infty} \\ & - (aq^{\alpha-1}, q^{2-\alpha}/a, bq^{\alpha-1}, q^{2-\alpha}/b, cq^{\alpha-1}, q^{2-\alpha}/c; q)_\infty \\ & \cdot \frac{(dq^{\alpha-1}, q^{2-\alpha}/d, eq^{\alpha-1}, q^{2-\alpha}/e; q)_\infty}{(fq^{1-\alpha}, q^\alpha/f; q)_\infty} \Big\}. \end{aligned} \tag{8.10}$$

Because of (8.2) the limit in (8.5) also exists, giving us a very well poised bilateral balanced ${}_8\psi_8$ series

$$\begin{aligned} I(a) = {} & q^{2\alpha^2-\alpha}(1-q^{2\alpha})(aq^\alpha, aq^{-\alpha}, bq^\alpha, bq^{-\alpha}, cq^\alpha, cq^{-\alpha}; q)_\infty \\ & \cdot \frac{(dq^\alpha, dq^{-\alpha}, eq^\alpha, eq^{-\alpha}; q)_\infty}{(q^{\alpha+1}/f, q^{1-\alpha}/f; q)_\infty} \\ & \cdot {}_8\psi_8 \left[\begin{matrix} q^{\alpha+1}, -q^{\alpha+1}, q^{\alpha+1}/a, q^{\alpha+1}/b, q^{\alpha+1}/c, q^{\alpha+1}/d, q^{\alpha+1}/e, q^{\alpha+1}/f \\ q^\alpha, -q^\alpha, aq^\alpha, bq^\alpha, cq^\alpha, dq^\alpha, eq^\alpha, fq^\alpha \end{matrix} ; q, q \right]. \end{aligned} \tag{8.11}$$

For the definitions, notation, and properties of various types of basic hypergeometric series see [25].

The limit of $I(a)$, as $a \to 0$, exists provided $|bcde| < q^3$. This limit is

$$\begin{aligned} I(0) = {} & q^{2\alpha^2-\alpha}(1-q^{2\alpha})(bq^\alpha, bq^{-\alpha}, cq^\alpha, cq^{-\alpha}, dq^\alpha, dq^{-\alpha}, eq^\alpha, eq^{-\alpha}; q)_\infty \\ & \cdot {}_6\psi_6 \left[\begin{matrix} q^{\alpha+1}, -q^{\alpha+1}, q^{\alpha+1}/b, q^{\alpha+1}/c, q^{\alpha+1}/d, q^{\alpha+1}/e \\ q^\alpha, -q^\alpha, bq^\alpha, cq^\alpha, dq^\alpha, eq^\alpha \end{matrix} ; q, \frac{bcde}{q^3} \right] \\ = {} & q^{2\alpha^2-\alpha}(q^{2\alpha}, q^{1-2\alpha}; q)_\infty \\ & \cdot \frac{(q, bc/q, bd/q, be/q, cd/q, ce/q, de/q; q)_\infty}{(bcde/q^3; q)_\infty}, \end{aligned} \tag{8.12}$$

by the ${}_6\psi_6$ summation formula [25, eq. (5.3.1), p. 128]. (It is also easy to give an alternate proof of this formula by using the method of this paper.)

We now iterate (8.8) n times, take the limit $n \to \infty$, and use (8.12) to obtain the bilateral extension to Jackson's summation formula; see, for example, [25]:

$$
\begin{aligned}
(8.13)\quad {}_8\psi_8 &\left[\begin{matrix} q^{\alpha+1}, -q^{\alpha+1}, q^{\alpha+1}/a, q^{\alpha+1}/b, q^{\alpha+1}/c, q^{\alpha+1}/d, q^{\alpha+1}/e, q^{\alpha+1}/f \\ q^{\alpha}, -q^{\alpha}, aq^{\alpha}, bq^{\alpha}, cq^{\alpha}, dq^{\alpha}, eq^{\alpha}, fq^{\alpha} \end{matrix}; q, q\right] \\
&= \frac{(q^{1+2\alpha}, q^{1-2\alpha}, q^{\alpha+1}/f, q^{1-\alpha}/f; q)_\infty}{(aq^{\alpha}, aq^{-\alpha}, bq^{\alpha}, bq^{-\alpha}, cq^{\alpha}, cq^{-\alpha}, dq^{\alpha}, dq^{-\alpha}, eq^{\alpha}, eq^{-\alpha}; q)_\infty} \\
&\quad \cdot \frac{(q, ab/q, ac/q, ad/q, ae/q, bc/q, bd/q, be/q, cd/q, ce/q, de/q; q)_\infty}{(q^2/af, q^2/bf, a^2/cf, q^2/df, q^2/ef; q)_\infty} \\
&\quad + \frac{q}{f} \frac{(1 - aq/f)(q^{\alpha+1}/f, q^{1-\alpha}/f; q)_\infty}{(1 - q^{2\alpha})(1 - q^2/bf)(1 - q^2/cf)(1 - q^2/df)(1 - q^2/ef)} \\
&\quad \cdot \frac{q^{\alpha - 2\alpha^2} \epsilon(\alpha; a)}{(aq^{\alpha}, aq^{-\alpha}, bq^{\alpha}, bq^{-\alpha}, cq^{\alpha}, cq^{-\alpha}, dq^{\alpha}, dq^{-\alpha}, eq^{\alpha}, eq^{-\alpha}; q)_\infty} \\
&\quad \cdot {}_8\phi_7 \left[\begin{matrix} aq/f, q(aq/f)^{\frac{1}{2}}, -q(aq/f)^{\frac{1}{2}}, ab/q, ac/q, ad/q, ae/q, q \\ (aq/f)^{\frac{1}{2}}, -(aq/f)^{\frac{1}{2}}, q^3/bf, q^3/cf, q^3/df, q^3/ef, aq/f \end{matrix}; q, bcde/q^3\right],
\end{aligned}
$$

provided

$$
(8.14)\qquad \max(|abcd|, |abce|, |abde|, |acde|, |bcde|) < q^3.
$$

If the parameters satisfy the "regularizing" condition $\epsilon(\alpha; a) = 0$, which, from (8.10), means

$$
\begin{aligned}
(8.15)\quad &\frac{(aq^{-\alpha}, q^{\alpha+1}/a, bq^{-\alpha}, q^{\alpha+1}/b, cq^{-\alpha}, q^{\alpha+1}/c, dq^{-\alpha}, q^{\alpha+1}/d; q)_\infty}{(aq^{\alpha-1}, q^{2-\alpha}/a, bq^{\alpha-1}, q^{2-\alpha}/b, cq^{\alpha-1}, q^{2-\alpha}/c, dq^{\alpha-1}, q^{2-\alpha}/d; q)_\infty} \\
&\quad \cdot \frac{(eq^{-\alpha}, q^{\alpha+1}/e, fq^{1-\alpha}, q^{\alpha}/f; q)_\infty}{(eq^{\alpha-1}, q^{2-\alpha}/e, fq^{\alpha}, q^{1-\alpha}/f; q)_\infty} = 1,
\end{aligned}
$$

then the second term on the right side of (8.13) drops out and we obtain the summation formula due to Gosper [26], see also [25, Ex. 5.12, p. 135].

Clearly, (8.13) is a generalization of (5.26).

9. An extension of Askey's integral (1.36): lattice $x(s) = \frac{1}{2}(q^{-s} - q^{s})$. In this section we find an integral analogue of (8.13) in the same sense as (5.23) is an integral analogue of (5.26). Since the integral is from $-\infty$ to ∞ we have to avoid an integrand that is odd in s, so we take $x(s) = \frac{1}{2}(q^{-s} - q^{s})$ with

$$
(9.1)\qquad \nabla x_1(s) = \frac{1 - q}{2q^{\frac{1}{2}}}(q^{-s} + q^{s}).
$$

The parameter α of §6 is then -1 so that $\nu = \pi i / \log q$. In order to preserve the same basic character of the factors in the first term on the right side of (8.13) corresponding

to $\nu = 0$, we must take all of the parameters $a, \dots, f$ purely imaginary. We choose $\sigma(s)$ and $\tau(s)$ exactly the same as in §8, but replace $s_1, \dots, s_6$ by

$$s_1 = q/ia, \quad s_2 = q/ib, \quad s_3 = q/ic, \quad s_4 = q/id, \quad s_5 = q/if, \quad s_6 = q/ig \tag{9.2}$$

so that the balance condition (6.6) now becomes

$$abcdfg = -q^5. \tag{9.3}$$

We have avoided the symbol e for a parameter since we are going to use it for the standard exponential base a little later. Solution of the Pearson equation now has the form

$$\begin{aligned}\rho(s) &= \rho(s;a) \\ &= \rho_0(s)\frac{(iaq^s, -iaq^{-s}, ibq^s, -ibq^{-s}, icq^s, -icq^{-s}; q)_\infty}{(-iq^{s+1}/g, iq^{1-s}/g; q)_\infty} \\ &\quad \cdot (idq^s, -idq^{-s}, ifq^s, -ifq^{-s}; q)_\infty,\end{aligned} \tag{9.4}$$

with

$$\frac{\rho_0(s+1)}{\rho_0(s)} = q^{4s+2}, \tag{9.5}$$

and

$$\begin{aligned}\rho(s)\sigma(s) &= \rho_0(s)q^{-2s}(iaq^{s-1}, -iaq^{-s}, ibq^{s-1}, -ibq^{-s}; q)_\infty \\ &\quad \cdot \frac{(icq^{s-1}, -icq^{-s}, idq^{s-1}, -idq^{-s}, ifq^{s-1}, -ifq^{-s}; q)_\infty}{(-iq^s/g, iq^{1-s}/g; q)_\infty}.\end{aligned} \tag{9.6}$$

As in (5.12),

$$\begin{aligned}\int_{-\infty}^{\infty} \nabla[\rho_1(s)]ds &= \lim_{M,N\to\infty} \int_{-N-\epsilon_1}^{M+\epsilon_2} \nabla[\rho_1(s)]ds \\ &= \lim_{M\to\infty} \int_{M+\epsilon_2}^{M+\epsilon_2+1} \rho(s)\sigma(s)ds - \lim_{N\to\infty} \int_{-N-\epsilon_1}^{-N-\epsilon_1-1} \rho(s)\sigma(s)ds,\end{aligned} \tag{9.7}$$

where M, N are positive integers and $0 \le \epsilon_1, \epsilon_2 < 1$. Note that

$$\rho(s)\sigma(s) = \mu_2(s)g_2(s), \tag{9.8}$$

where

$$g_2(s) = \frac{(iaq^{s-1}, ibq^{s-1}, icq^{s-1}, idq^{s-1}, ifq^{s-1}, -igq^s; q)_\infty}{(iq^{s+1}/a, iq^{s+1}/b, iq^{s+1}/c, iq^{s+1}/d, iq^{s+1}/f, -iq^s/g; q)_\infty}, \tag{9.9}$$

and

$$\begin{aligned}\mu_2(s) &= \rho_0(s)q^{-2s}(-iaq^{-s}, iq^{s+1}/a, -ibq^{-s}, iq^{s+1}/b; q)_\infty \\ &\quad \cdot \frac{(-icq^{-s}, iq^{s+1}/c, -idq^{-s}, iq^{s+1}/d, -ifq^{-s}, iq^{s+1}/f; q)_\infty}{(iq^{1-s}/g, -igq^s; q)_\infty},\end{aligned} \tag{9.10}$$

so that

$$\mu_2(s+1) = \mu_2(s) \quad \text{by (9.5)} \quad \text{for all } s \in \boldsymbol{C}. \tag{9.11}$$

Hence

$$\lim_{M\to\infty} \mu_2(s+M) = \mu_2(s), \qquad M \text{ an integer.} \tag{9.12}$$

From (9.9) it is also clear that $\lim_{M\to\infty} g_2(s+M) = 1$, so we have

$$\lim_{M\to\infty} \int_{M+\epsilon_2}^{M+\epsilon_2+1} \rho(s)\sigma(s)ds = \int_{\epsilon_2}^{\epsilon_2+1} \mu_2(s)ds = \int_0^1 \mu_2(s)ds, \tag{9.13}$$

by (9.11). Similarly we can show that

$$\lim_{N\to\infty} \int_{-N-\epsilon_1}^{1-N-\epsilon_1} \rho(s)\sigma(s)ds = \int_{-\epsilon_1}^{1-\epsilon_1} \mu_1(s)ds = \int_0^1 \mu_1(s)ds, \tag{9.14}$$

where

$$\begin{aligned}\mu_1(s) = \rho_0(s)q^{-2s}&(iaq^{s-1}, -iq^{2-s}/a, ibq^{s-1}, -iq^{2-s}/b; q)_\infty \\ &\cdot \frac{(icq^{s-1}, -iq^{2-s}/c, idq^{s-1}, -iq^{2-s}/d, ifq^{s-1}, -iq^{2-s}/f; q)_\infty}{(-iq^s/g, iq^{1-s}g; q)_\infty},\end{aligned} \tag{9.15}$$

so that

$$\mu_1(s+1) = \mu_1(s). \tag{9.16}$$

Using (6.8)–(6.11) as well as (9.1)–(9.4) we now find that

$$\begin{aligned}\tau(s)\rho(s;a) \bigtriangledown x_1(s) &= \frac{ia}{q}(q^{-s}+q^s)\rho_0(s)\frac{(1-q^2/ab)(1-q^2/ac)(1-q^2/ad)(1-q^2/af)}{(1+gq/a)} \\ &\cdot (iaq^s, -iaq^{-s}, ibq^s, -ibq^{-s}, icq^s, -icq^{-s}; q)_\infty \\ &\cdot \frac{(idq^s, -idq^{-s}, ifq^s, -ifq^{-s}; q)_\infty}{(-iq^{s+1}/g, iq^{1-s}/g; q)_\infty} \\ &- \frac{iq}{ag^2}(q^{-s}+q^s)\rho_0(s)\frac{(1+bg/q)(1+cg/q)(1+dg/q)(1+fg/q)}{(1+gq/a)} \\ &\cdot (iaq^{s-1}, -iaq^{-s-1}, ibq^s, -ibq^{-s}, icq^s, -icq^{-s}; q)_\infty \\ &\cdot \frac{(idq^s, -idq^{-s}, ifq^s, -ifq^{-s}; q)_\infty}{(-iq^s/g, iq^{-s}/g; q)_\infty}.\end{aligned} \tag{9.17}$$

We now have to choose $\rho_0(s)$ so that (9.5) holds, the integrals on the whole real line over the two expressions on the right side of (9.17) converge, and such that the integral over the first term tends to an Askey integral of the type (1.36) when $a \to 0$. This last requirement eliminates the possibility of $\rho_0(s)$ being of the form (8.9), so we

must look for a unit-periodic function in which powers of q^s occur inside the infinite products only. So let us take

$$\rho_0(s) = \frac{\wp(s)}{q^{-s}+q^s}, \tag{9.18}$$

so that, by (9.5),

$$\begin{aligned} q^{4s+2} &= \frac{\wp(s+1)}{\wp(s)}\frac{q^{-s}+q^s}{q^{-s-1}+q^{s+1}} \\ &= \frac{\wp(s+1)}{\wp(s)}q\frac{1+q^{2s}}{1+q^{2s+2}} \\ &= \frac{\wp(s+1)}{\wp(s)}q\frac{(1+iq^s)(1-iq^s)}{(1+iq^{s+1})(1-iq^{s+1})}, \end{aligned} \tag{9.19}$$

i.e.,

$$\begin{aligned} \frac{\wp(s+1)}{\wp(s)} &= \frac{(1+iq^{s+1})(1-iq^{s+1})}{(1+iq^s)(1-iq^s)}q^{4s+1} \\ &= \frac{(1+iq^{s+1})(1-iq^{s+1})(1+iq^{s+\frac{1}{2}})(1-iq^{s+\frac{1}{2}})}{(1+iq^{-s})(1-iq^{-s})(1+iq^{-s-\frac{1}{2}})(1-iq^{-s-\frac{1}{2}})} \end{aligned} \tag{9.20}$$

with solution

$$\begin{aligned} \wp(s) &= \left[(iq^{\frac{1}{2}+s},-iq^{\frac{1}{2}+s},iq^{\frac{1}{2}-s},-iq^{\frac{1}{2}-s},iq^{s+1},-iq^{s+1},iq^{1-s},-iq^{1-s};q)_\infty\right]^{-1} \\ &= (-q^{1+2s},-q^{1-2s};q)_\infty^{-1}, \end{aligned} \tag{9.21}$$

which is unique to within a periodic factor that we may now take to be unity. Note that (9.21) agrees with the denominator of the integrand in (1.36). Denoting

$$\mu(a) = \int_0^1 [\mu_2(s)-\mu_1(s)]ds \tag{9.22}$$

and

$$\begin{aligned} I(a) = \int_{-\infty}^{\infty} &\frac{(iaq^s,-iaq^{-s},ibq^s,-ibq^{-s},icq^s,-icq^{-s};q)_\infty}{(-q^{1+2s},-q^{1-2s};q)_\infty} \\ &\cdot\frac{(idq^s,-idq^{-s},ifq^s,-ifq^{-s};q)_\infty}{(-iq^{s+1}/g,iq^{1-s}/g;q)_\infty}ds, \end{aligned} \tag{9.23}$$

and then replacing a, g by aq and g/q, respectively, we find that (3.11) in this case leads to the nonhomogeneous recurrence relation

$$\begin{aligned} I(a) = &-\frac{qa^3}{g}\frac{(1-q/ab)(1-q/ac)(1-q/ad)(1-q/af)}{(1+q^2/bg)(1+q^2/cg)(1+q^2/dg)(1+q^2/fg)}I(aq) \\ &-\frac{ai(1+aq/g)}{(1+q^2/bg)(1+q^2/cg)(1+q^2/dg)(1+q^2/fg)}\mu(aq). \end{aligned} \tag{9.24}$$

From (9.10), (9.15), (9.18), and (9.21) it can be verified that

$$\mu(aq) = -\frac{q}{ag}\mu(a). \tag{9.25}$$

Iterating (9.24) n times and then taking the limit $n \to \infty$, we obtain

$$\begin{aligned} I(a) = {} & \frac{(ab/q, ac/q, ad/q, af/q; q)_\infty}{(-q^2/bg, -q^2/cg, -q^2/dg, -q^2/fg; q)_\infty} \lim_{n\to\infty} I(aq^n) \\ & - \frac{iq}{g} \frac{(1+aq/g)\mu(a)}{(1+q^2/bg)(1+q^2/cg)(1+q^2/dg)(1+q^2/fg)} \\ & \cdot {}_8\phi_7\left[\begin{matrix} -aq/g, q(-aq/g)^{\frac{1}{2}}, -q(-aq/g)^{\frac{1}{2}}, ab/q, ac/q, ad/q, \\ (-aq/g)^{\frac{1}{2}}, -(-aq/g)^{\frac{1}{2}}, -q^3/bg, -q^3/cg, -q^3/dg, \end{matrix} \right. \\ & \qquad \left.\begin{matrix} af/q, q \\ -q^3/fg, -aq/g \end{matrix}; q, -q^2/ag\right], \end{aligned} \tag{9.26}$$

provided the limit in (9.26) exists and the integral in (9.23) as well as the infinite series in (9.26) converge. By (9.3), this last requirement implies that

$$|bcdf| < q^3. \tag{9.27}$$

It can be shown that if, in addition, Re $(abcdf) \neq 0$ and

$$\max(|abcd|, |abcf|, |abdf|, |acdf|) < q^3, \tag{9.28}$$

then the integral in (9.23) converges and that

$$\begin{aligned} & \lim_{n\to\infty} I(aq^n) \\ & = \int_{-\infty}^{\infty} \frac{(ibq^s, -ibq^{-s}, icq^s, -icq^{-s}, idq^s, -idq^{-s}, ifq^s, -ifq^{-s}; q)_\infty}{(-q^{1+2s}, -q^{1-2s}; q)_\infty} ds \\ & = \frac{(q, bc/q, bd/q, bf/q, cd/q, cf/q, df/q; q)_\infty}{(bcdf/q^3; q)_\infty}, \end{aligned} \tag{9.29}$$

by (1.36), exists. Thus we have the extension of Askey's formula, with $q^s = e^u$,

$$\begin{aligned} & \int_{-\infty}^{\infty} \frac{h(i\sinh u; a, b, c, d, f)}{h(i\sinh u; q^{\frac{1}{2}}, -q^{\frac{1}{2}}, q, -q, -q/g)} du \\ & = (\log q^{-1}) \frac{(q, ab/q, ac/q, ad/q, af/q, bc/q, bd/q, bf/q, cd/q, cf/q, df/q; q)_\infty}{(abcd/q^3, abcf/q^3, abdf/q^3, acdf/q^3, bcdf/q^3; q)_\infty} \\ & \quad - \frac{iq}{g} \frac{(\log q^{-1})(1+aq/g)\mu(a)}{(1-abcd/q^3)(1-abcf/q^3)(1-abdf/q^3)(1-acdf/q^3)} \\ & \quad \cdot {}_8\phi_7\left[\begin{matrix} -aq/g, q(-aq/g)^{\frac{1}{2}}, -q(-aq/g)^{\frac{1}{2}}, ab/q, ac/q, ad/q, \\ (-aq/g)^{\frac{1}{2}}, -(-aq/g)^{\frac{1}{2}}, -q^3/bg, -q^3/cg, -q^3/dg, \end{matrix} \right. \\ & \qquad \left.\begin{matrix} af/q, q \\ -q^3/fg, -aq/g \end{matrix}; q, bcdf/q^3\right]. \end{aligned} \tag{9.30}$$

By (9.10) and (9.15) $\mu(a)$ can be expressed as a single integral

$$\mu(a) = \int_0^1 \frac{q^{-s}}{(-q^{2s}, -q^{1-2s}; q)_\infty (igq^{s+1}, igq^{1-s}, -iq^s/g, -iq^{-s}/g; q)_\infty} \cdot \left\{ \begin{array}{l} (-iaq^{-s}, iq^{s+1}/a, -ibq^{-s}, iq^{s+1}/b, -icq^{-s}, iq^{s+1}/c; q)_\infty \\ \cdot(-idq^{-s}, iq^{s+1}/d, -ifq^{-s}, iq^{s+1}/f, igq^{s+1}, -iq^{-s}/g; q)_\infty \\ -(iaq^{s-1}, -iq^{2-s}/a, ibq^{s-1}, -iq^{2-s}/b, icq^{s-1}, -iq^{2-s}/c; q)_\infty \\ \cdot(idq^{s-1}, -iq^{2-s}/d, ifq^{s-1}, -iq^{2-s}/f, igq^{1-s}, -iq^s/g; q)_\infty \end{array} \right\} ds. \tag{9.31}$$

It is clear from (9.30) and (9.31) that if any one of the five parameters vanishes, then the second term on the right side of (9.30) drops out leaving us with Askey's formula (9.29).

In concluding this section we would like to remark that while it would not be too difficult to prove (8.13) by using the transformation theory of basic hypergeometric series (see [25]), we do not know how one could discover (9.30) by the same procedure. Formulas (5.23) and (9.30) are of the same basic character, in fact, it is not too hard to show that (5.23) is a special limiting case of (9.30). The appearance of the second term on the right sides of (5.23) and (9.30) is a characteristic of Ramanujan-type integrals of higher order.

10. Proof of (1.12) and an extension: lattice $x(s) = s^2$. In this section we will not only give a rigorous proof of (1.12) but also prove the following extension:

$$\begin{aligned} &\int_{-\infty}^{\infty} \frac{\Gamma(1-2s)\Gamma(1+2s)}{\Gamma(a-s)\Gamma(a+s)\Gamma(b-s)\Gamma(b+s)\Gamma(c-s)\Gamma(c+s)\Gamma(d-s)\Gamma(d+s)} \\ &\quad \cdot \frac{\Gamma(1-f-s)\Gamma(1-f+s)}{\Gamma(e-s)\Gamma(e+s)} ds \\ &= \frac{\Gamma(2-f-a)\Gamma(2-f-b)\Gamma(2-f-c)}{\Gamma(a+b-1)\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)\Gamma(b+c-1)} \\ &\quad \cdot \frac{\Gamma(2-f-d)\Gamma(2-f-e)}{\Gamma(b+d-1)\Gamma(b+e-1)\Gamma(c+d-1)\Gamma(c+e-1)\Gamma(d+e-1)} \\ &\quad + \lambda \frac{1+a-f}{(2-f-b)(2-f-c)(2-f-d)(2-f-e)} \\ &\quad \cdot {}_7F_6\left[\begin{matrix} 1+a-f, 1+\frac{1+a-f}{2}, a+b-1, a+c-1, a+d-1, a+e-1, 1 \\ \frac{1+a-f}{2}, 3-f-b, 3-f-c, 3-f-d, 3-f-e, 1+a-f \end{matrix} ; 1 \right], \end{aligned} \tag{10.1}$$

where

$$a+b+c+d+e+f = 5, \quad \mathrm{Re}\,(2-f) > \mathrm{Re}\,(a,b,c,d,e), \quad \mathrm{Im}\, f < 0, \tag{10.2}$$

and

$$\lambda = \pi \int_0^1 \frac{\lambda(s) - \lambda(-s)}{\sin 2\pi s} ds, \tag{10.3}$$

with

$$\lambda(s) = \frac{\sin\pi(a-s)\sin\pi(b-s)\sin\pi(c-s)\sin\pi(d-s)\sin\pi(e-s)}{\pi^4\sin\pi(f+s)}. \tag{10.4}$$

The symmetry of the second term on the right side of (10.1) can be demonstrated by using a transformation formula for the ${}_7F_6$ series (see [14]) as was done in §5.

It is true, as Askey mentioned in [4], that there is the "immediate problem" of poles of the gamma functions in the numerator of the integrand of (1.12), but they are simple poles and so the problem is immediately resolved by interpreting the integral as a Cauchy principal value integral. The same is true for the integral in (10.1). All we need to do is to find conditions so that these principal value integrals exist and then try to evaluate them.

For the Pearson equation (6.4) we have a very simple relation with the symmetric lattice $x(s) = s^2$:

$$\frac{\rho(s+1)}{\rho(s)} = \frac{\sigma(-s)}{\sigma(s+1)}. \tag{10.5}$$

For Askey's integral (1.12) we take

$$\sigma(s) = (a-1+s)(b-1+s)(c-1+s)(d-1+s), \tag{10.6}$$

and for (10.1) we take

$$\sigma(s) = \frac{(a-1+s)(b-1+s)(c-1+s)(d-1+s)(e-1+s)}{s-f}, \tag{10.7}$$

with $a+b+c+d+e+f = 5$. Clearly, (10.7) reduces to (10.6) in the limit $e \to \infty$. The solution of (10.5) that is appropriate for our purposes is

$$\rho(s) = \frac{\pi}{\sin 2\pi s}\frac{\Gamma(1-f-s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)} \cdot \frac{\Gamma(1-f+s)}{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)\Gamma(e+s)}, \tag{10.8}$$

while the corresponding formula in the Askey case is

$$\rho_A(s) = \frac{\pi}{\sin 2\pi s}[\Gamma(a-s)\Gamma(a+s)\Gamma(b-s)\Gamma(b+s)\Gamma(c-s)\Gamma(c+s)\Gamma(d-s)\Gamma(d+s)]^{-1}, \tag{10.9}$$

where the suffix A is used to indicate the limiting case of (10.8). Since $\nabla x_1(s) = 2s$ and $\Gamma(2s)\Gamma(1-2s) = \pi/\sin 2\pi s$, we find that

$$\rho(s) \nabla x_1(s) = \frac{\Gamma(1-2s)\Gamma(1-f-s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)} \cdot \frac{\Gamma(1+2s)\Gamma(1-f+s)}{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)\Gamma(e+s)} \tag{10.10}$$

and

$$\rho_A(s) \bigtriangledown x_1(s) = \frac{\Gamma(1-2s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)} \cdot \frac{\Gamma(1+2s)}{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)}. \tag{10.11}$$

From (10.7) and (10.8) we also have

$$\begin{aligned}\rho_1(s-1) &= \rho(s)\sigma(s) \\ &= \frac{\pi}{\sin 2\pi s} \frac{\Gamma(1-f-s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)} \\ &\quad \cdot \frac{\Gamma(s-f)}{\Gamma(a-1+s)\Gamma(b-1+s)\Gamma(c-1+s)\Gamma(d-1+s)\Gamma(e-1+s)}.\end{aligned} \tag{10.12}$$

So, in order to investigate the asymptotic behaviour of $\rho_1(s-1)$ near $\pm\infty$ we split $\rho_1(s-1)$ as follows:

$$\rho_1(s-1) = \begin{cases} \dfrac{\pi}{\sin 2\pi s} g(-s)\lambda(-s) & \text{for Re } s < 0, \\ \dfrac{\pi}{\sin 2\pi s} g(s-1)\lambda(s) & \text{for Re } s > 0, \end{cases} \tag{10.13}$$

where $\lambda(s)$ is defined in (10.4) and

$$g(-s) = \frac{\Gamma(1-f-s)\Gamma(2-a-s)\Gamma(2-b-s)\Gamma(2-c-s)\Gamma(2-d-s)\Gamma(2-e-s)}{\Gamma(a-s)\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)\Gamma(1+f-s)}. \tag{10.14}$$

It is clear that $\lambda(s)$ is a periodic function of period 1 and that, by Stirling's formula and (10.2),

$$\lim_{s\to-\infty} g(-s) = \lim_{s\to\infty} g(s-1) = 1, \tag{10.15}$$

the limits being valid along the real line as well as along any line parallel to it.

The factor $\Gamma(1-2s)\Gamma(1+2s)$ has poles at $s = \pm(n+1)/2$, $n = 0, 1, 2, \ldots$. In order to avoid these poles on the real line we first use the following definition of the doubly infinite integral:

$$\int_{-\infty}^{\infty} f(s)ds = \lim_{\substack{N_1,N_2\to\infty, \\ \operatorname{Im}(\epsilon_1+\epsilon_2)=0}} \int_{-N_1-\epsilon_1}^{N_2+\epsilon_2} f(s)ds, \tag{10.16}$$

where N_1, N_2 are positive integers and ϵ_1, ϵ_2 are complex numbers such that $-\operatorname{Im}\,\epsilon_1 = \operatorname{Im}\,\epsilon_2 < |\operatorname{Im}\, f|$ and $0 < \operatorname{Re}\,\epsilon_1, \operatorname{Re}\,\epsilon_2 < \frac{1}{2}$. It means that we are replacing the integral along the real line by an integral along a parallel line just above the real axis. By using the symmetry of the location of the poles on the real line we will eventually prove that the limit on the right side of (10.16) is indeed equal to the integral on the left side interpreted as a principal value integral for (1.12) and (10.1).

As before, we can show that

$$\begin{aligned}(10.17)\qquad &\int_{-N_1-\epsilon_1}^{N_2+\epsilon_2} \nabla\rho_1(s)ds \\ &= \int_{N_2+\epsilon_2}^{N_2+\epsilon_2+1} \rho_1(s-1)ds - \int_{-N_1-\epsilon_1}^{1-N_1-\epsilon_2} \rho_1(s-1)ds \\ &= \int_{\epsilon_2}^{\epsilon_2+1} \frac{\pi}{\sin 2\pi t}\lambda(t)g(t-1+N_2)dt \\ &\quad - \int_{-\epsilon_1}^{1-\epsilon_1} \frac{\pi}{\sin 2\pi t}\lambda(-t)g(N_1-t)dt,\end{aligned}$$

so that

$$\begin{aligned}(10.18)\qquad \int_{-\infty}^{\infty} \nabla\rho_1(s)ds &= \int_{\epsilon_2}^{\epsilon_2+1} \frac{\pi\lambda(t)}{\sin 2\pi t}dt - \int_{-\epsilon_1}^{1-\epsilon_1} \frac{\pi\lambda(-t)}{\sin 2\pi t}dt \\ &= \pi \int_{i\ Im\ \epsilon_2}^{1+i\ Im\ \epsilon_2} \frac{\lambda(t)-\lambda(-t)}{\sin 2\pi t}dt.\end{aligned}$$

For $0 \le t \le 1$ the integrand on the right side of (10.18) has no singularities since the zeros of $\sin 2\pi t$ at $t = 0, \frac{1}{2}, 1$ cancel out with those of $\lambda(t)-\lambda(-t)$. Since by assumption Im $f < 0$, the poles of $\lambda(s)$ are in the lower half plane, so the unit-periodicity of this integrand allows us to reduce it to an integral along a parallel segment of the real line. Thus we have

$$\int_{-\infty}^{\infty} \nabla\rho_1(s)ds = \lambda,$$

where λ is defined in (10.3).

Let us denote

$$(10.19)\qquad I(a) = \int_{-\infty}^{\infty} \rho(s) \nabla x_1(s)ds,$$

where the integral is defined by (10.16), so that Im s = Im ϵ_2. By the procedure outlined in §§6 and 8 it can be easily shown that $I(a)$ satisfies the recurrence relation

$$\begin{aligned}(10.20)\qquad I(a) &= \frac{(a+b-1)(a+c-1)(a+d-1)(a+e-1)}{(2-f-b)(2-f-c)(2-f-d)(2-f-e)}I(a+1) \\ &\quad + \lambda\frac{1+a-f}{(2-f-b)(2-f-c)(2-f-d)(2-f-e)}.\end{aligned}$$

Iterating this formula n times and then taking the limit $n \to \infty$ we find that

$$\begin{aligned}(10.21)\qquad I(a) &= \frac{\Gamma(2-f-b)\Gamma(2-f-c)\Gamma(2-f-d)\Gamma(2-f-e)}{\Gamma(a+b-1)\Gamma(a+c-1)\Gamma(a+d-1)\Gamma(a+e-1)}I_0(b,c,d,e) \\ &\quad + \lambda\frac{1+a-f}{(2-f-b)(2-f-c)(2-f-d)(2-f-e)} \\ &\quad \cdot {}_7F_6\left[\begin{matrix}1+a-f, 1+\frac{1+a-f}{2}, a+b-1, a+c-1, a+d-1, a+e-1, 1 \\ \frac{1+a-f}{2}, 3-f-b, 3-f-c, 3-f-d, 3-f-e, 1+a-f\end{matrix}; 1\right],\end{aligned}$$

where

(10.22)

$$I_0(b,c,d,e) = \lim_{n\to\infty} \int_{-\infty}^{\infty} \left\{ \frac{\Gamma(a+b-1+n)\Gamma(a+c-1+n)\Gamma(a+d-1+n)\Gamma(a+e-1+n)}{\Gamma(2-f-b+n)\Gamma(2-f-c+n)\Gamma(2-f-d+n)\Gamma(2-f-e+n)} \right.$$
$$\left. \cdot \frac{\Gamma(1-f-s+n)\Gamma(1-f+s+n)}{\Gamma(a-s+n)\Gamma(a+s+n)} \right\} \frac{\Gamma(1-2s)}{\Gamma(b-s)\Gamma(c-s)\Gamma(d-s)\Gamma(e-s)}$$
$$\cdot \frac{\Gamma(1+2s)}{\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)\Gamma(e+s)} ds.$$

By (10.2) and Stirling's formula, the expression within the curly brackets is $1+O(1/n)$ as $n \to \infty$. So

(10.23)

$$I_0(b,c,d,e) = \int_{-\infty}^{\infty} \frac{\Gamma(1-2s)\Gamma(1+2s)ds}{\Gamma(b-s)\Gamma(b+s)\Gamma(c-s)\Gamma(c+s)\Gamma(d-s)\Gamma(d+s)\Gamma(e-s)\Gamma(e+s)},$$

which is the same as the integral in (1.12). Gustafson [28] recently found a multidimensional version of this formula, so (1.12) is essentially a special case of his. Gustafson's method, however, is entirely different from ours.

Let us first give a formal evaluation of this integral. The recurrence formula for this integral is

$$I_0(b,c,d,e) = \frac{(b+c-1)(b+d-1)(b+e-1)}{b+c+d+e-3} I_0(b+1,c,d,e), \tag{10.24}$$

which is obtained in a manner similar to (10.20). Since $I_0(b,c,d,e)$ is invariant with respect to a permutation of b,c,d,e it follows that

(10.25)

$$I_0(b,c,d,e) = \frac{\Gamma(b+c+d+e-3)}{\Gamma(b+c-1)\Gamma(b+d-1)\Gamma(b+e-1)\Gamma(c+d-1)\Gamma(c+e-1)\Gamma(d+e-1)} \cdot M(b,c,d,e),$$

where M is invariant under any permutation of b,c,d,e and is unit-periodic in all four parameters. So, iterating the recurrence relation obtained from (10.25) by taking $b \to b+1$, one can show by Stirling's formula that M must be independent of b, and hence must be a numerical constant. Thus,

$$M = \Gamma(c+d-1)\Gamma(c+e-1)\Gamma(d+e-1) \cdot \int_{-\infty}^{\infty} \frac{\Gamma(1-2s)\Gamma(1+2s)ds}{\Gamma(c-s)\Gamma(c+s)\Gamma(d-s)\Gamma(d+s)\Gamma(e-s)\Gamma(e+s)}. \tag{10.26}$$

Setting $c = d = 1$, $e = \frac{1}{2}$, we find that

$$M = \pi \int_{-\infty}^{\infty} \frac{\sin \pi s}{\pi^2 s} ds = 1. \tag{10.27}$$

This completes a formal proof of (1.12) provided that the integral is not along the real line but along a parallel line in the upper half plane. The evaluation of $M(b, c, d, e)$ based on symmetry considerations is a reflection of the influence of the elegant work of Miller [37]. See also [33].

Let us now return to the harder question of how to justify the statement we made prior to (10.17). Let us go back to (3.11), take $N_1 = N_2$ in (10.16) (which we can do without any loss of generality), and define the contour C to be a partially indented rectangular curve as follows:

$$\begin{aligned}
&C_0: && -N - \operatorname{Re} \epsilon_1 \leq s \leq N + \operatorname{Re} \epsilon_2,\ s \text{ real, indented at } s = \\
&&& \pm\frac{n+1}{2},\ n = 0, 1, \ldots, 2N-1 \text{ with semicircles of radius} \\
&&& \delta < \operatorname{Im} \epsilon_2 \text{ in the upper half plane;} \\
&C_R: && \operatorname{Re} s = N + \operatorname{Re} \epsilon_2,\ 0 \leq \operatorname{Im} s \leq \operatorname{Im} \epsilon_2 < |\operatorname{Im} f|; \\
&C_N: && \text{a line segment parallel to the real line from } N + \epsilon_2 \text{ to} \\
&&& -N - \epsilon_1; \\
&C_L: && \operatorname{Re} s = -N - \operatorname{Re} \epsilon_1,\ \operatorname{Im} s \text{ from } \operatorname{Im}(-\epsilon_1) \text{ to } 0.
\end{aligned} \tag{10.28}$$

There are no singularities of $\rho_A(s) \bigtriangledown x_1(s)$ or $\rho(s) \bigtriangledown x_1(s)$ on or inside the contour C, so the integrals along C over both of them vanish.

Since both integrands are symmetric in s we need only to consider their asymptotic behaviour at $+\infty$. On C_R, C_N, and C_L

$$\begin{aligned}
&\rho_A(s) \bigtriangledown x_1(s) \\
&\quad = \frac{\sin \pi(a-s) \sin \pi(b-s) \sin \pi(c-s) \sin \pi(d-s)}{\pi^3 \sin 2\pi s} \\
&\qquad \cdot \frac{\Gamma(1-a+s)\Gamma(1-b+s)\Gamma(1-c+s)\Gamma(1-d+s)}{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)} 2^{2s} \\
&\qquad \sim 2^{2s} s^{5-2(a+b+c+d)},
\end{aligned} \tag{10.29}$$

and

$$\begin{aligned}
&\rho(s) \bigtriangledown x_1(s) \\
&\quad = \frac{\sin \pi(a-s) \sin \pi(b-s) \sin \pi(c-s) \sin \pi(d-s) \sin \pi(e-s)}{\pi^3 \sin 2\pi s \sin \pi(f+s)} \\
&\qquad \cdot \frac{\Gamma(1-a+s)\Gamma(1-b+s)\Gamma(1-c+s)\Gamma(1-d+s)\Gamma(1-e+s)\Gamma(1-f+s)}{\Gamma(a+s)\Gamma(b+s)\Gamma(c+s)\Gamma(d+s)\Gamma(e+s)\Gamma(f+s)} 2^{2s} \\
&\qquad \sim s^{-3},
\end{aligned} \tag{10.30}$$

as $s \to +\infty$. So the three integrals over $\rho_A(s)\nabla x_1(s)$ converge if $2(a+b+c+d)-5 > 1$, i.e., $a+b+c+d > 3$ while the ones over $\rho(s) \nabla x_1(s)$ converge due to the conditions (10.2). Having thus established the convergence of these integrals it is easy to see that

$$\lim_{N\to\infty} \int_{C_R} f(s)ds = \lim_{N\to\infty} \int_{C_L} f(s)ds = 0, \tag{10.31}$$

where $f(s) = \rho_A(s) \nabla x_1(s)$ in one and $\rho(s) \nabla x_1(s)$ in the other. Finally, since $f(s)$ in either case has only simple poles on the real line, the contribution from a typical pole s_k and a semicircle C_δ around it has the form $-i\pi$ Res $f(s)|_{s=s_k}$. However, $f(-s) = f(s)$, so the contributions from s_k and $-s_k$ cancel out. Thus we have the result that

$$\lim_{\delta\to 0} \int_{C_0} f(s)ds = -\lim_{N\to\infty} \int_{C_N} f(s)ds, \tag{10.32}$$

where $f(s) = \rho(s) \nabla x_1(s)$ or $\rho_A(s) \nabla x_1(s)$. This completes the proof of both (1.12) and (10.1).

11. A q-analogue of (10.1): lattice $x(s) = \frac{1}{2}(q^{-s} + q^s)$. We shall now prove that a q-analogue of (10.1) is

$$\int_{-\infty}^{\infty} \frac{(aq^{-s}, aq^s, bq^{-s}, bq^s, cq^{-s}, cq^s, dq^{-s}, dq^s, eq^{-s}, eq^s; q)_\infty}{(q^{1-s}/f, q^{1+s}/f, q^{1-2s}, q^{1+2s}; q)_\infty} ds \tag{11.1}$$

$$= \frac{(q, ab/q, ac/q, ad/q, ae/q, bc/q, bd/q, be/q, cd/q, ce/q, de/q; q)_\infty}{(q^2/af, q^2/bf, q^2/cf, q^2/df, q^2/ef; q)_\infty}$$

$$+ \frac{q\lambda_q}{f} \frac{(1-aq/f)}{(1-q^2/bf)(1-q^2/cf)(1-q^2/df)(1-q^2/ef)}$$

$$\cdot {}_8\phi_7 \left[\begin{matrix} aq/f, q(aq/f)^{\frac{1}{2}}, -q(aq/f)^{\frac{1}{2}}, ab/q, ac/q, ad/q, ae/q, q \\ (aq/f)^{\frac{1}{2}}, -(aq/f)^{\frac{1}{2}}, q^3/bf, q^3/cf, q^3/df, q^3/ef, aq/f \end{matrix} ; q, q^2/af \right],$$

where

$$abcdef = q^5, \quad |q^2/f| < \min(|a|, |b|, |c|, |d|, |e|), \quad \text{Im } f \neq 0 \tag{11.2}$$

and

$$\lambda_q = \int_0^1 \frac{\lambda_q(s) - \lambda_q(-s)}{(q^{2s}, q^{1-2s}; q)_\infty} q^s ds \tag{11.3}$$

with

$$\lambda_q(s) = q^{-2s} \frac{(aq^{-s}, bq^{-s}cq^{-s}, dq^{-s}, eq^{-s}; q)_\infty}{(q^{1-s}/f; q)_\infty} \cdot \frac{(q^{s+1}/a, q^{s+1}/b, q^{s+1}/c, q^{s+1}/d, q^{s+1}/e; q)_\infty}{(fq^s; q)_\infty}. \tag{11.4}$$

The integrand on the left side of (11.1) has simple poles at $s = \pm\frac{n+1}{2}$ on the real line, with n a nonnegative integer, so the integral must be interpreted as a principal

value integral whose existence can be proved in much the same way as in §10. We shall also show, as in §10, that this integral has exactly the same value as the nonsingular integral

$$\int_{-\infty}^{\infty} \frac{(aq^{-s}, aq^{s}, bq^{-s}, bq^{s}, cq^{-s}, cq^{s}, dq^{-s}, dq^{s}, eq^{-s}, eq^{s}; q)_\infty}{(q^{1-s}/f, q^{1+s}/f, q^{1-2s}, q^{1+2s}; q)_\infty} ds, \tag{11.5}$$

where $-\infty < \operatorname{Re} s < \infty, \operatorname{Im} s = s_0 > 0$; s_0 and $|\arg f|$ are so related that there are no poles of the integrand in the strip $0 < \operatorname{Im} s \leq s_0$. In particular, if we take $s_0 = \pi/2 \log q^{-1}$, then $q^{is_0} = e^{-is_0 \log q^{-1}} = e^{-\pi i/2} = -i$. This implies that we must take $|\arg f| > \pi/2$ to ensure that the above integral is nonsingular.

A very interesting thing happens when we transform the integral (11.5) by the substitution $s = i\pi/2 \log q^{-1} - t$, t real. It becomes

$$\int_{-\infty}^{\infty} \frac{(iaq^{t}, -iaq^{-t}, ibq^{t}, -ibq^{-t}, icq^{t}, -icq^{-t}, idq^{t}, -idq^{-t}, ieq^{t}, -ieq^{-t}; q)_\infty}{(iq^{1+t}/f, -iq^{1-t}/f, -q^{1+2t}, -q^{1-2t}; q)_\infty} dt \tag{11.6}$$

which is precisely the same as the integral in (9.23) with e and f replaced by f and $-g$, respectively. So, once it is proved that the integrals in (11.1) and (11.5) are the same we have shown that

$$Pv \int_{-\infty}^{\infty} \frac{(aq^{-s}, aq^{s}, bq^{-s}, bq^{s}, cq^{-s}, cq^{s}, dq^{-s}, dq^{s}, eq^{-s}, eq^{s}; q)_\infty}{(q^{1-s}/f, q^{1+s}/f, q^{1-2s}, q^{1+2s}; q)_\infty} ds \tag{11.7}$$
$$= \text{ the integral (11.6)},$$

provided the parameters satisfy (11.2) and $|\arg f| > \pi/2$. In the limit $e \to 0$ this leads to the formula

$$Pv \int_{-\infty}^{\infty} \frac{(aq^{-s}, aq^{s}, bq^{-s}, bq^{s}, cq^{-s}, cq^{s}, dq^{-s}, dq^{s}; q)_\infty}{(q^{1-2s}, q^{1+2s}; q)_\infty} ds \tag{11.8}$$
$$= \int_{-\infty}^{\infty} \frac{(iaq^{t}, -iaq^{-t}, ibq^{t}, -ibq^{-t}, icq^{t}, -icq^{-t}, idq^{t}, -idq^{-t}; q)_\infty}{(-q^{1-2t}, -q^{1+2t}; q)_\infty} dt.$$

The right side is Askey's integral (1.36) and the left side is a q-analogue of an integral that Askey wrote down in [4] but wished for a Ramanujan to evaluate!

Let us consider the integral

$$I = \int_C \frac{(aq^{-s}, aq^{s}, bq^{-s}, bq^{s}, cq^{-s}, cq^{s}, dq^{-s}, dq^{s}, eq^{-s}, eq^{s}; q)_\infty}{(q^{1-s}/f, q^{1+s}/f, q^{1-2s}, q^{1+2s}; q)_\infty} ds, \tag{11.9}$$

where C is the same contour as described in (10.28) except that we now take $\operatorname{Im} \epsilon_2 = s_0 > 0$ and $|\arg f| > s_0 \log q^{-1}$. If we denote by $h(s)$ the integrand of (11.9) then it can be shown that

$$\lim_{N\to\infty} \int_{C_R} h(s) ds = \lim_{N\to\infty} \int_{C_L} h(s) ds = 0 \tag{11.10}$$

and that $\lim_{N\to\infty}\int_{C_N} h(s)ds$ exists because of (11.2) when $e \neq 0$, and, provided $|abcd/q^3| < 1$ when $e = 0$. Since there are no poles on or inside the contour C, the integral in (11.9) vanishes, by Cauchy's theorem. Therefore, analogous to (10.32) we have the result

$$\lim_{\delta\to 0}\int_{C_0} h(s)ds = -\lim_{N\to\infty}\int_{C_N} h(s)ds. \tag{11.11}$$

Because of the symmetry of $h(s)$, the contributions from the symmetrically located poles $s = \pm(k+1)/2$, $k = 0, 2, \ldots, 2N-1$, to the integral over C_0 cancel out. So we have the formula

$$\begin{aligned}\int_{-\infty}^{\infty} &\frac{(aq^{-t-is_0}, aq^{t+is_0}, bq^{-t-is_0}, bq^{t+is_0}, cq^{-t-is_0}, cq^{t+is_0}; q)_\infty}{(q^{1-is_0-t}/f, q^{1+is_0+t}/f; q)_\infty}\\ &\cdot\frac{(dq^{-t-is_0}, dq^{t+is_0}, eq^{-t-is_0}, eq^{t+is_0}; q)_\infty}{(q^{1-2t-2is_0}, q^{1+2t+2is_0}; q)_\infty}dt\\ &= Pv\int_{-\infty}^{\infty}\frac{(aq^{-t}, aq^t, bq^{-t}, bq^t, cq^{-t}, cq^t, dq^{-t}, dq^t, eq^{-t}, eq^t; q)_\infty}{(q^{1-t}/f, q^{1+t}/f, q^{1-2t}, q^{1+2t}; q)_\infty}dt,\end{aligned} \tag{11.12}$$

provided (11.2) holds and $|\arg f| > s_0 \log q^{-1} > 0$. The integral on the left side can now be calculated in exactly the same way as was done in §9, which corresponds to taking $s_0 = \pi/(2\log q^{-1})$ and replacing e, f by f and $-g$, respectively. Using the same arguments as in §9 it is easy to show that the integral on the left side of (11.12) is independent of s_0 except for the restriction that $0 < s_0 < |\arg f|/\log q^{-1}$. It is also easy to see that $\lambda_q = i\mu(a)$, where $\mu(a)$ is defined in (9.31) (with e, f replaced by $f, -g$). Formula (11.1) then follows by use of (11.12) via (9.26) and (9.29). The special case

$$\begin{aligned}Pv\int_{-\infty}^{\infty}&\frac{(aq^{-t}, aq^t, bq^{-t}, bq^t, cq^{-t}, cq^t, dq^{-t}, dq^t; q)_\infty}{(q^{1-2t}, q^{1+2t}; q)_\infty}\\ &= \frac{(q, ab/q, ac/q, ad/q, bc/q, bd/q, cd/q; q)_\infty}{(abcd/q^3; q)_\infty}, \qquad |abcd/q^3| < 1,\end{aligned} \tag{11.13}$$

then follows by taking $e = 0$, which is clearly a q-analogue of (1.12).

12. Summary of results. In this article we have dealt with only a small subset of the beta integrals. Readers who are interested in knowing all about them must go through some of Askey's papers as well as some of Ramanujan's. The point of view that we have taken here is that all of these formulas originate from the same source—the Pearson equation. They vary according to the underlying lattice types, and whether we are talking about a sum or an integral, along the real line or the imaginary axis, but most importantly it is the asymptotic properties of the summands and integrands near infinity that determine the final structure of the formulas. We have illustrated these ideas with a few examples in the previous sections but there are many more (old and new) formulas that can be proved by the same technique. For the benefit of the readers who would like to see the whole list of formulas in one place we are adding a few more pages to this paper.

We will classify the beta and q-beta integrals into four broad classes according to their lattice types: Table 1: $x(s) = s$ (linear); Table 2: $x(s) = C_1 s^2 + C_2$ (quadratic); Table 3: $x(s) = C_1 q^{-s} + C_2 q^s$ (q-quadratic); Table 4: $x(s) = q^{-s}$ (q-linear). The corresponding formulas will be subdivided into a polynomial-type formula, indicated by a suffix P, and a rational function-type formula, indicated by a suffix R, according to whether $\sigma(s)$ and/or $\tau(s)$ are polynomials or rational functions.

TABLE 1
Lattice $x(s) = s$.

Polynomial type	Rational function type
$\sigma(s) = (s - s_1)(s - s_2)$, $\sigma(s) + \tau(s) = (s + s_3)(s + s_4)$.	$\sigma(s) = (s - s_1)(s - s_2)$, $\sigma(s) + \tau(s) = \frac{(s + s_3)(s + s_4)(s + s_5)}{1 + s - s_6}$, $\sum_1^6 s_k = 1$.

$$(2_R) \qquad {}_3F_2\left[\begin{matrix} s_1 + s_3, s_1 + s_4, s_1 + s_5; \\ 1 + s_1 - s_2, 2s_1 + s_2 + s_3 + s_4 + s_5; \end{matrix} 1\right]$$
$$= \frac{\Gamma(1 + s_1 - s_2)\Gamma(1 - s_1 - s_2 - s_3 - s_4)\Gamma(2s_1 + s_2 + s_3 + s_4 + s_5)}{\Gamma(1 - s_2 - s_3)\Gamma(1 - s_2 - s_4)\Gamma(s_1 + s_2 + s_3 + s_5)\Gamma(s_1 + s_2 + s_4 + s_5)}$$
$$- \frac{\Gamma(1 + s_1 - s_2)\Gamma(2s_1 + s_2 + s_3 + s_4 + s_5)}{\Gamma(s_1 + s_3)\Gamma(s_1 + s_4)\Gamma(s_1 + s_5)}$$
$$\cdot \frac{1}{(s_1 + s_5)(s_2 + s_5)}\,{}_3F_2\left[\begin{matrix} s_1 + s_2 + s_3 + s_5, s_1 + s_2 + s_4 + s_5, 1; \\ 1 + s_1 + s_5, 1 + s_2 + s_5; \end{matrix} 1\right],$$
$$\operatorname{Re}(s_1 + s_2 + s_3 + s_4) < 1.$$

(3_P)

$$\sum_{n=-\infty}^{\infty} \frac{1}{\Gamma(a_1+n)\Gamma(a_2+n)\Gamma(a_3-n)\Gamma(a_4-n)}$$
$$= \frac{\Gamma(a_1+a_2+a_3+a_4-3)}{\Gamma(a_1+a_3-1)\Gamma(a_1+a_4-1)\Gamma(a_2+a_3-1)\Gamma(a_2+a_4-1)}, \qquad \operatorname{Re}\left(\sum_1^4 a_k\right) > 3;$$

(3_R)

$$\sum_{n=-\infty}^{\infty} \frac{\Gamma(1-\alpha-a_6-n)}{\Gamma(a_1+\alpha+n)\Gamma(a_2+\alpha+n)\Gamma(a_3-\alpha-n)\Gamma(a_4-\alpha-n)\Gamma(a_5-\alpha-n)}$$
$$= \frac{\Gamma(2-a_6-a_3)\Gamma(2-a_6-a_4)\Gamma(2-a_6-a_5)}{\Gamma(a_1+a_3-1)\Gamma(a_1+a_4-1)\Gamma(a_1+a_5-1)\Gamma(a_2+a_3-1)\Gamma(a_2+a_4-1)\Gamma(a_2+a_5-1)}$$
$$+ \frac{\mu_2(\alpha)-\mu_1(\alpha)}{(2-a_6-a_3)(2-a_6-a_4)}\, {}_3F_2\left[\begin{matrix} a_1+a_5-1, a_2+a_5-1, 1; \\ 3-a_6-a_3, 3-a_6-a_4; \end{matrix} 1\right],$$

$$\mu_1(\alpha) = \pi^{-2}\sin\pi(a_1+\alpha)\sin\pi(a_2+\alpha),$$
$$\mu_2(\alpha) = \pi^{-2}\sin\pi(a_3-\alpha)\sin\pi(a_4-\alpha)\sin\pi(a_5-\alpha)/\sin\pi(a_6+\alpha),$$
$$\sum_{k=1}^{6} a_k = 5, \ \operatorname{Im}(\alpha+a_6) \neq 0, \ \operatorname{Re}(2-a_6) > \max[\operatorname{Re}(a_3,a_4,a_5)].$$

(4_P)

$$\int_{-\infty}^{\infty} \frac{ds}{\Gamma(a_1+s)\Gamma(a_2+s)\Gamma(a_3-s)\Gamma(a_4-s)}$$
$$= \frac{\Gamma(a_1+a_2+a_3+a_4-3)}{\Gamma(a_1+a_3-1)\Gamma(a_1+a_4-1)\Gamma(a_2+a_3-1)\Gamma(a_2+a_4-1)}, \qquad \operatorname{Re}\left(\sum_1^4 a_k\right) > 3;$$

(4_R)

$$\int_{-\infty}^{\infty} \frac{\Gamma(1-a_6-s)ds}{\Gamma(a_1+s)\Gamma(a_2+s)\Gamma(a_3-s)\Gamma(a_4-s)\Gamma(a_5-s)}$$
$$= \frac{\Gamma(2-a_6-a_3)\Gamma(2-a_6-a_4)\Gamma(2-a_6-a_5)}{\Gamma(a_1+a_3-1)\Gamma(a_1+a_4-1)\Gamma(a_1+a_5-1)\Gamma(a_2+a_3-1)\Gamma(a_2+a_4-1)\Gamma(a_2+a_5-1)}$$
$$+ \frac{\mu}{(2-a_6-a_3)(2-a_6-a_4)}\, {}_3F_2\left[\begin{matrix} a_1+a_5-1, a_2+a_5-1, 1 \\ 3-a_6-a_3, 3-a_6-a_4 \end{matrix} ; 1\right],$$

$$\sum_{k=1}^{6} a_k = 5, \quad \operatorname{Im}\ a_6 \neq 0, \quad \operatorname{Re}(2-a_6) > \max[\operatorname{Re}(a_3,a_4,a_5)], \quad \text{and}$$
$$\mu = \frac{1}{\pi^2}\int_0^1 \Big[\frac{\sin\pi(a_3-s)\sin\pi(a_4-s)\sin\pi(a_5-s)}{\sin\pi(a_6+s)} - \sin\pi(a_1+s)\sin\pi(a_2+s)\Big]ds.$$

The readers may notice a lack of symmetry on the right sides of (2_R), (3_R), and (4_R) as well as the fact that the ${}_3F_2$ series on the right side of (2_R) does not appear to be balanced (i.e., Saalschützian). This can be easily rectified by applying the standard transformation formulas for the ${}_3F_2$ series; see [14]. The purpose of leaving the formulas in this apparent asymmetric form is to emphasize the appearance of 1 as a numerator parameter in each of these cases, a feature that will keep repeating itself in the formulas to follow. The inquisitive reader will also observe the striking similarity between the formulas (3_P) and (4_P) as well as between (3_R) and (4_R), and may wonder if there are no integral analogues for the summation formulas (2_P) and (2_R). The answer is yes and we will report on those formulas in a subsequent paper.

$$= \frac{(\alpha^2, q/\alpha^2, s_3s_4, q/s_3s_4, q/s_1s_3, q/s_1s_4, q/s_2s_3, q/s_2s_4, q; q)_\infty}{(\alpha s_3, q/\alpha s_3, \alpha s_4, q/\alpha s_4, q/\alpha s_1, q/\alpha s_2, \alpha q/s_3, \alpha q/s_4, q/s_1s_2s_3s_4; q)_\infty}$$

$$+ \alpha^2 \frac{(\alpha q/s_1, \alpha q/s_2, s_3/\alpha, s_4/\alpha; q)_\infty}{(q/\alpha s_1, q/\alpha s_2, \alpha s_3, \alpha s_4; q)_\infty}\ {}_2\psi_2\left[\begin{matrix} s_1/\alpha, s_2/\alpha \\ q/\alpha s_3, q/\alpha s_4 \end{matrix}; q, q/s_1s_2s_3s_4\right],$$

$$|q/s_1s_2s_3s_4| < 1,$$

$$(15_R)$$

$${}_3\psi_3\left[\begin{matrix} \alpha s_1, \alpha s_2, \alpha s_3 \\ \alpha q/s_4, \alpha q/s_5, \alpha q/s_6 \end{matrix}; q, q\right]$$

$$- \alpha^2 \frac{(\alpha q/s_1, \alpha q/s_2, \alpha q/s_3, s_4/\alpha, s_5/\alpha, s_6/\alpha; q)_\infty}{(q/\alpha s_1, q/\alpha s_2, q/\alpha s_3, \alpha s_4, \alpha s_5, \alpha s_6; q)_\infty}\ {}_3\psi_3\left[\begin{matrix} s_1/\alpha, s_2/\alpha, s_3/\alpha \\ q/\alpha s_4, q/\alpha s_5, q/\alpha s_6 \end{matrix}; q, q\right]$$

$$= \frac{(\alpha^2, q/\alpha^2, s_4s_5, q/s_4s_5, q/s_1s_4, q/s_1s_5; q)_\infty}{(\alpha s_4, q/\alpha s_4, \alpha s_5, q/\alpha s_5, q/\alpha s_1, q/\alpha s_2; q)_\infty}$$

$$\cdot \frac{(q/s_2s_4, q/s_2s_5, q/s_3s_4, q/s_3s_5, s_6/\alpha, q; q)_\infty}{(q/\alpha s_3, \alpha q/s_4, \alpha q/s_5, s_1s_6, s_2s_6, s_3s_6; q)_\infty}$$

$$+\alpha^{-1}\frac{(\alpha s_1,\alpha s_2,\alpha s_3;q)_\infty}{(\alpha q/s_4,\alpha q/s_5,\alpha q/s_6;q)_\infty}$$
$$\cdot\left[1-\alpha^4\frac{(s_1/\alpha,q\alpha/s_1,s_2/\alpha,\alpha q/s_2,s_3/\alpha,\alpha q/s_3;q)_\infty}{(\alpha s_1,q/\alpha s_1,\alpha s_2,q/\alpha s_2,\alpha s_3,q/\alpha s_3;q)_\infty}\right.$$
$$\left.\cdot\frac{(s_4/\alpha,\alpha q/s_4,s_5/\alpha,\alpha q/s_5,s_6/\alpha,\alpha q/s_6;q)_\infty}{(\alpha s_4,q/\alpha s_4,\alpha s_5,q/\alpha s_5,\alpha s_6,q/\alpha s_6;q)_\infty}\right]$$
$$\cdot\frac{s_6}{(1-s_2s_6)(1-s_3s_6)}\,{}_3\phi_2\left[\begin{matrix}q/s_1s_4,q/s_1s_5,q\\ qs_2s_6,qs_3s_6\end{matrix};q,s_1s_6\right].$$

As before, the ${}_3\phi_2$ series in (14_R) and (15_R) can be transformed to balanced ${}_3\phi_2$ series so that (14_R) is essentially the well-known q-Saalschütz formula [25, eq. (2.10.12)]. However, (15_R) appears to be new, although we believe it can be derived from the general basic bilateral transformation formula [25, eq. (5.4.3)], as can the simpler formula (15_P).

It would be natural to expect that the q-linear case is much easier to handle than the q-quadratic case. One might be tempted to argue that the formulas for the q-linear case should be derived from those for the q-quadratic case by a limiting process. A comparison between the formulas 11_P and 15_P or between 11_R and 15_R should convince the reader that this is not necessarily so. In fact, the formulas for the q-linear case are much harder to derive than the q-quadratic case, especially for the bilateral series. There are two main reasons for this unexpected difficulty. First, the asymptotics for the summands and integrands at $\pm\infty$ are much more delicate when $x(s)=q^{-s}$. Second, the task of taking the limit $n\to\infty$ after n iterations is no longer as straightforward as is the case for the other lattices—instead of one series one may end up with as many as four series! This is what we believe may happen in (16_P) and (16_R) that we have left as open problems. We have some ideas about (16_P) but almost none for (16_R). This is probably the time we could use a helping hand from Ramanujan. A little nudge from Richard Askey, with his near-prophetic feeling for formulas, would also be helpful.

Acknowledgment. We would like to thank the referee for pointing out the important reference [28]. Many helpful comments from Professors R. Askey and M.E.H. Ismail are also appreciated.

THE CLASSICAL UMBRAL CALCULUS*

G.-C. ROTA†‡ AND B. D. TAYLOR†§

Abstract. A rigorous presentation of the umbral calculus, as formerly applied heuristically by Blissard, Bell, Riordan, and others is given. As an application, the basic identities for Bernoulli numbers, as well as their generalizations first developed by Nörlund are derived.

Key words. umbral calculus, Bernoulli numbers, special functions

AMS subject classifications. 05, 33

1. Introduction. It is seldom recognized that the algebraic notation that we use today in mathematics is not the only possible one, nor perhaps even the best. The history of mathematics is littered with abandoned notation, some of which did not deserve such neglect. In this paper we consider one such notation, one that somehow has managed to survive in a no man's land and that has refused to die altogether because of its usefulness. In computing with sequences of numbers a_n, indexed by the nonnegative integers $n = 0, 1, 2, \ldots$, it is often convenient to treat the subscripts as if they were powers. This requires a_0 to equal 1 but is not otherwise a great strain. It was realized early in the development of combinatorics that this simple device would yield insight into quite a number of formulas and, what is more, that it would often suggest the right proofs.

To the best of our knowledge, the first mathematicians who extensively used such a device were Edouard Lucas, in the first volume of his *Théorie des nombres* [L] (the second volume never appeared), and the Rev. John Blissard, in a series of nine papers that appeared in the *Quarterly Journal of Mathematics* between 1862 and 1868 [Bl1]–[Bl9]. The editors of the *Quarterly Journal* must be given credit for publishing papers that thoroughly lacked in rigor but relied on a suggestive and often powerful notation.

Since that time, the umbral calculus, as it came to be called, has not been accepted in mathematical society. Sylvester held the umbral calculus in high esteem but made no attempt to present it; he simply used it. Only Eric Temple Bell [Be1] among mathematicians early in this century had the daring to show public appreciation for this notation. In a book and several papers he attempted to display the full power of the method and at the same time to give it a presentation that would meet the standards of algebraic rigor of the twentieth century. The last of his papers, written in 1940 [Be2], purports to give an explicit axiomatic basis of the umbral calculus. As happens with some writings of E. T. Bell, it is not quite clear whether these axioms make any sense, much less whether they are rigorous at all. Nonetheless, umbral calculus has managed to eke out a meager existence. John Riordan used it extensively in *An Introduction to Combinatorial Analysis* [Ri], the first modern textbook of combinatorics, and although he gives no justification of the method, every formula he displays is correct, though at times his proofs have an air of witchcraft about them. As a matter of fact, the feeling of witchcraft that has hovered over umbral calculus is probably what has kept it from dying out altogether.

To the best of our knowledge, it was one of the present authors [Ro] who first pointed out explicitly what nowadays had become completely obvious, namely, that the shift from a^n to a_n can be "explained" as the application of a linear functional on the space of polynomials in the variable a. Unfortunately, it took the same author another twenty years to realize that this simple truth could not alone explain the stunts of calculations performed by the umbral mathematicians. At long last, it was realized that umbral calculus could be made entirely rigorous by using the language of Hopf algebras, and this was done in a lengthy treatment [RR]. However, although the notation of Hopf algebra satisfied the most ardent advocate of spic-and-span rigor, the translation of "classical" umbral calculus into the newly found rigorous language made the method altogether unwieldy and unmanageable. Not only was the eerie feeling of witchcraft lost in the translation, but, after such a translation, the use of calculus to simplify computation and sharpen our intuition was lost by the wayside. In retrospect, what the authors should have done is to translate the language of Hopf algebra into classical umbral language, a feat that was logically impossible at the time since it was not known whether classical umbral language made any sense.

In the present paper we have finally decided to bite the bullet and give a rigorous, simple presentation of umbral calculus as it was meant by the founders. We have kept new notation both minimal and indispensable to avoid the misunderstandings of the past. Our basic construct is a polynomial ring in several variables, on which no less than three equivalence relations are defined (the "classics" blithely denoted all three of these equivalence relations by the same symbol $=$, not realizing that this was the beginning of the end). The peculiarity of two of these three equivalence relations is that they are not invariant under substitution of variables, nor under multiplication. In fact, one of them is not even invariant under addition. More precisely, they are invariant under addition or multiplication provided that the variables involved are distinct, a fact that should make some algebraists slightly uncomfortable. Moreover, relative to one of these equivalence relations, the equivalence classes form something like an Abelian group, where, however, every element has an infinite set of inverses, all "equivalent" to each other, an unheard-of phenomenon in algebra. In fact, if one extracts a representative from each equivalence class and is willing to restrict oneself to sums of distinct representatives, then the resulting group is easily seen to be isomorphic to the group of formal power series in a single variable with constant coefficient 1, under multiplication. Weirdest of all, there are two ways of multiplying an element of the ring by a "scalar" integer, one of which is defined in a way that defies the current tenets of algebraic sobriety.

But whoever is willing to swallow this strange but (at last) correct definition, and to realize, after a little training, that the calculus is quite manageable, may find it rewarding to start performing combinatorial computations using umbral calculus without fear. Or else he or she may wish to reread the classics with the present key in hand and to realize that these writings make complete sense in retrospect.

We give only one example of computation with umbral calculus: by developing the theory of Bernoulli numbers in umbral notation. All classical identities relating to these numbers are found to have one-line proofs, which, we would like to believe, are the natural ones.

We hope to present other simplifications by the use of umbral calculus in forthcoming publications.

2. Foundations of umbral calculus. An umbral calculus consists of the following data:

(1) A set A, called the *alphabet*, whose elements are called letters or *umbrae*;

(2) A commutative integral domain D, whose quotient field is of characteristic zero;

(3) A linear functional **eval**, called the *evaluation*, defined on the polynomial ring $D[A]$ and taking values in D, such that

(a) $\mathbf{eval}(1) = 1$, where 1 is the identity of D;

(b) if $\alpha, \beta, \ldots, \gamma$ are *distinct* umbrae and if $i, j, \ldots, k$ are nonnegative integers, then

$$\mathbf{eval}(\alpha^i \beta^j \cdots \gamma^k) = \mathbf{eval}(\alpha^i)\mathbf{eval}(\beta^j) \cdots \mathbf{eval}(\gamma^k);$$

(4) A distinguished element ε of the alphabet A, called the *augmentation*, such that

$$\mathbf{eval}(\varepsilon^n) = \delta_{n,0},$$

where δ is the Kronecker delta.

Elements of the polynomial ring $D[A]$ are called *umbral polynomials*. When an umbral polynomial p is written as a linear combination of distinct monomials with nonzero coefficients, the *support* of p is defined to be the set of all umbrae that occur in some such monomial with a positive power. If $\{\alpha, \beta, \ldots, \gamma\}$ is the support of an umbral polynomial p, we may write p as $p(\alpha, \beta, \ldots, \gamma)$.

A set of umbral polynomials such that the supports of any two of them are disjoint is said to be *unrelated*.

A sequence $a_0, a_1, a_2, \ldots$, denoted (a_i), is said to be *umbrally represented* by an umbra α when

$$\mathbf{eval}(\alpha^n) = a_n$$

for $n = 0, 1, 2, \ldots$. Note that if the sequence (a_n) is umbrally represented by an umbra α, then we necessarily have $a_0 = 1$.

If p and q are umbral polynomials, we shall say that p and q are *umbrally equivalent*, in symbols $p \simeq q$, when $\mathbf{eval}(p) = \mathbf{eval}(q)$. For example, if the umbra α represents the sequence (a_n), then we have $\alpha^n \simeq a_n$ for all n, as well as

$$(\alpha + 1)^n \simeq \sum_{i \geq 0} \binom{n}{i} a_i.$$

Two umbral polynomials p and q are said to be *exchangeable*, in symbols $p \equiv q$, when $\mathbf{eval}(p^n) = \mathbf{eval}(q^n)$ for $n = 0, 1, 2, \ldots$. Two equal polynomials are exchangeable, and two exchangeable polynomials are umbrally equivalent, but neither converse holds.

Two umbrae α and β are said to be *inverse* to each other when $\alpha + \beta \equiv \varepsilon$; we say that α is an inverse of β. The inverse of an umbra is not unique, but any two inverse umbrae to the umbra α are exchangeable.

We note that ε behaves much like 0, namely, if p is any umbral polynomial, then $\varepsilon + p \equiv p$ and $\varepsilon \cdot p \equiv \varepsilon$.

By judicious use of the equivalence relations of umbral equivalence and exchangeability, one can dispense with explicit mention of the linear functional **eval**, as we shall do whenever possible.

Suppose the umbral polynomials p and q are exchangeable with the umbral polynomials f and g, respectively. It is true that $p + q$ is umbrally equivalent to $f + g$ but

not that pq is umbrally equivalent to fg. Neither such property holds for exchangeability. Let α and β be exchangeable umbrae representing the sequence a_n; then $(\alpha+\alpha)^3 \simeq 8a_3$ but $(\alpha+\beta)^3 \simeq 2a_3+6a_1a_2$. In other words, umbral polynomials with respect to the equivalence relations of umbral equivalence and exchangeability are not invariant under substitution of exchangeable variables. This failure of the substitution property, which is usually taken for granted in dealing with ordinary equality, has in the past been the stumbling block to a rigorous presentation of umbral calculus.

We have, however, the following proposition, which is easily verified.

PROPOSITION 2.1. *Let $p(x,y,\dots,z)$ be a polynomial in the variables $x,y,\dots,z$ with coefficients in D, and let $f,g,\dots,h,r$ be umbral polynomials, where f and r are exchangeable. If f is unrelated to each of $g,\dots,h$ and if r is also unrelated to each of $g,\dots,h$, then the polynomials $p(f,g,\dots,h)$ and $p(r,g,\dots,h)$ are exchangeable.*

In particular, we have the following corollary.

COROLLARY 2.2. *If the umbral polynomial f is exchangeable with an umbral polynomial g, if the umbral polynomial r is exchangeable with the umbral polynomial s, if f and r are unrelated, and if g and s are unrelated, then $f+r$ is exchangeable with $g+s$ and fr is exchangeable with gs.*

3. Saturated umbral calculi. We come now to one of the problems that vitiated the validity of umbral notation in the past. Briefly, one would like to write a sum of the form

$$\alpha' + \alpha'' + \cdots + \alpha''',$$

(where $\alpha', \alpha'', \dots, \alpha'''$ are any set of n distinct umbrae, each of them exchangeable with a given umbra α) in the form of the integer n multiplied by α, in some sense or other. However, the element $n\alpha \in D[A]$ is in no way exchangeable with $\alpha' + \alpha'' + \cdots + \alpha'''$. For example, if $\mathbf{eval}(\alpha^k) = a_k$, we have

$$\mathbf{eval}\Big((2\alpha)^k\Big) = 2^k\mathbf{eval}(\alpha^k) = 2^k a_k,$$

whereas

$$\mathbf{eval}\Big((\alpha'+\alpha'')^k\Big) = \sum_{i\geq 0}\binom{k}{i}(\alpha')^i(\alpha'')^{k-i} \simeq \sum_{i\geq 0}\binom{k}{i}a_i a_{k-i}.$$

Thus $\alpha'+\alpha''$, though umbrally equivalent to the expression 2α, is neither equal to nor exchangeable with 2α for general α. This puzzling phenomenon was, to the best of our knowledge, first explicitly pointed out by E. T. Bell, who was not able to provide a consistent notation.

What is needed, we believe, is a new notion of multiplication of an umbra by an integer, accompanied by the systematic use of the three kinds of equivalence relations introduced in the preceeding. We shall shortly give a rigorous definition of this concept of multiplication, but a few words of motivation may be in order.

We shall denote by the symbol $n\,.\,\alpha$ an umbra, often called an *auxiliary umbra*, that is exchangeable with the sum

$$\alpha' + \alpha'' + \cdots + \alpha''',$$

where $\alpha', \alpha'', \dots, \alpha'''$ are a set of n distinct umbrae, each of which is exchangeable with the given umbra α. Similarly, for every umbra α and for every positive integer n,

we introduce an umbra, written as $-n.\alpha$, that is exchangeable with $\beta'+\beta''+\cdots+\beta'''$, where $\beta', \beta'', \ldots, \beta'''$ is any set of n distinct umbrae exchangeable with β, and where β and α are inverse umbrae. Finally, we shall denote by $0 \,.\, \alpha$ an umbra exchangeable with the augmentation ε.

A similar notation $n \,.\, p$ is introduced for any umbral polynomial p whose support does not contain auxiliary umbrae. However, we have chosen not to allow such expressions as $m \,.\, (n \,.\, \alpha)$.

When all is said and done, it turns out that the "scalar multiplication," $n \,.\, \alpha$, satisfies the expected properties, stated in Proposition 3.2, which follows.

This motivation, together with the requirement that the alphabet shall be endowed with sufficiently many umbrae exchangeable with any expression whatsoever, leads us to the following definition.

DEFINITION 3.1. *A* saturated umbral calculus *with base alphabet A is an umbral calculus on an alphabet $A \cup B$, where the letters of the alphabet B (the auxiliary alphabet) are denoted by $n.p$ as p ranges over all the polynomials in $D[A]$ and n ranges over all integers. Further, a saturated umbral calculus shall satisfy the following:*

(1) *For every umbral polynomial q in $D[A \cup B]$, there exists an infinite set of umbrae α in A exchangeable with q.*

(2) *For every umbra α in A and for every positive integer n, the umbra $n.\alpha$ in B is exchangeable with $\alpha' + \alpha'' + \cdots + \alpha'''$, where $\alpha', \alpha'', \ldots, \alpha'''$ is any set of n distinct umbrae in A, each of them exchangeable with α.*

(3) *For every umbra α in A and for every positive integer n, the umbra $-n \,.\, \alpha$ in B is exchangeable with $\beta' + \beta'' + \cdots + \beta'''$, where $\beta', \beta'', \ldots, \beta'''$ is any set of n distinct umbrae in A, each of them inverse to α.*

(4) *For every umbra α in A, the umbra $0 \,.\, \alpha$ is exchangeable with the augmentation ε.*

(5) *For every umbral polynomial p in $D[A]$, for every integer n, and for every umbra α in A exchangeable with p, the umbra $n.p$ in B is exchangeable with the umbra $n \,.\, \alpha$.*

We shall hereafter assume that the umbral calculus we are dealing with is saturated. It can be shown that saturated umbral calculi exist and that every umbral calculus can be embedded in a saturated umbral calculus, but we shall spare the reader such proof.

In dealing with a saturated umbral calculus, the term "umbra" will denote an element of the alphabet A and not an element of the auxiliary alphabet B, unless otherwise specified.

The following statements are easily proved.

PROPOSITION 3.2.

(1) $(n+m).\alpha \equiv n.\alpha' + m.\alpha''$ *for any two integers n and m and any two distinct umbra α' and α'' exchangeable with α.*

(2) *If $n \,.\, \alpha \equiv n \,.\, \beta$ for some integer $n \neq 0$, then $\alpha \equiv \beta$.*

(3) *If c is any element of D, then $n \,.\, (c\alpha) \equiv c(n \,.\, \alpha)$.*

(4) *If c is any element of D, then $n \,.\, (c) \equiv nc$ for any integer n.*

The following proposition lists two other useful identities applicable in a saturated umbral calculus.

PROPOSITION 3.3.

(1) *If α and β are inverse umbrae, then $-\beta p(\alpha + \beta) \simeq \alpha p(\alpha + \beta)$ for any polynomial p in one variable with coefficients in D.*

(2) *If α and β are inverse umbrae and if p is a polynomial in one variable over*

D, then for all $n \in \mathbb{Z}$,

$$(n \,.\, \beta)p(n \,.\, \alpha + n \,.\, \beta) \simeq n\Big(\beta p(\alpha + \beta)\Big).$$

Proof (sketch). The left-hand side of the equation in the first part of the proposition may be subtracted from both sides of the identity, preserving umbral equivalence. Then it may be seen that the resulting right-hand side is actually *equal* to a polynomial in $\alpha + \beta$ with zero constant term. But this is equivalent to ε, thus proving the statement.

The key point to proving the second part involves observing that $n \,.\, \beta$ is by definition exchangeable with a sum of n distinct umbrae each exchangeable with β and that to effect a substitution *both* occurrences of $n \,.\, \beta$ in $(n \,.\, \beta)p(n \,.\, \alpha + n \,.\, \beta)$ must be replaced with this sum. Distributing yields a sum of n exchangeable terms, a representative one being $\beta' p\big((\beta' + \beta'' + \cdots + \beta''') + n \,.\, \alpha\big)$, the inner summation containing n umbrae exchangeable with β. But this is exchangeable with $\beta' p(\beta' + \alpha)$. The result follows for n greater than 0. For n negative, the result is an easy consequence of the positive version and the first part of the proposition. □

Umbral calculus leads naturally to certain sequences of polynomials. A sequence $p_k(x)$ of polynomials is termed an *Appell sequence* if for all k, $p_k(x) \simeq (x + \alpha)^k$ for some umbra α.

It can be shown that any sequence satisfying both the relation $p_k'(x) = kp_{k-1}(x)$ and $p_0(x) = 1$ may be defined as $(x + \alpha)^k$ for some umbra α. In fact, the following proposition characterizes Appell sequences.

PROPOSITION 3.4. *Suppose* $p_0(x), p_1(x), p_2(x), \ldots$ *is a sequence of polynomials with* $p_k(x)$ *being of degree* k *and* $p_0(x) = 1$. *Then* $p_k(x) \simeq (x + \alpha)^k$ *for some* α *if and only if* $p_k'(x) = kp_{k-1}(x)$.

Proof. The following calculation proves the proposition in the *only if* direction:

$$Dp_k(x) \simeq D(x + \alpha)^k = k(x + \alpha)^{k-1} \simeq kp_{k-1}(x).$$

The converse is omitted. □

We may define a linear operator T on polynomials in the variable x, over the integral domain of umbral polynomials, by setting $T(x^k) = (x + \alpha)^k$. One verifies that $T = e^{\alpha D}$. Thus $e^{\alpha D}(x^k) = (x + \alpha)^k$. Furthermore, one easily verifies that if $F(t)$ is the exponential generating function for the sequence (a_i), then $F(D)x^n = p_n(x)$.

For the remainder of the present exposition, we shall assume that we are dealing with a saturated umbral calculus. The quotient field of the integral domain D will always contain the complex numbers as a subfield.

4. The Bernoulli umbra. A useful heuristic principle, widely used since the eighteenth century, views Bernoulli numbers as a device for transforming differences into derivatives. We shall now give a precise meaning to such a principle. An umbra β will be said to be a *Bernoulli umbra* if for every polynomial $p(x)$ we have

$$\Delta p(\beta) = p(\beta + 1) - p(\beta) \simeq p'(\varepsilon). \tag{1}$$

Here the operator Δ is the forward difference operator, defined as

$$\Delta f(x) = f(x + 1) - f(x).$$

PROPOSITION 4.1. *A Bernoulli umbra exists and is unique up to exchangeability.*

Indeed, setting $p(x) = x^n$, we obtain the recurrence

$$(\beta + 1)^n \simeq \beta^n, \qquad n > 1,$$

and $\beta^0 \simeq 1$.

Thus the umbra β umbrally represents a unique sequence of complex numbers. Such a sequence (B_n) is the sequence of *Bernoulli numbers.* In other words, for $n > 1$ we have

$$\sum_{k\geq 0} \binom{n}{k} B_k = B_n \quad \text{or} \quad \sum_{k=0}^{n-1} \binom{n}{k} B_k = 0.$$

These results are trivially valid for $n = 0$.

Let $f(x, \beta)$ be a formal power series in the variable x, whose coefficients are umbral polynomials in the Bernoulli umbra β (and possibly other umbrae as well). By comparing coefficients we see that (1) generalizes to

$$f(x, \beta + 1) - f(x, \beta) \simeq f'(x, \varepsilon), \tag{2}$$

where the derivative is taken relative to the second variable. Here, the symbol $\simeq$ is to be understood as coefficientwise equivalence for the coefficients of two formal power series in x.

Setting $f(x, \beta) = e^{\beta x}$, the latter being, of course, interpreted as a formal power series, we obtain

$$(e^x - 1)e^{\beta x} \simeq xe^{\varepsilon x} \simeq x,$$

or, equivalently,

$$e^{\beta x} \simeq \frac{x}{e^x - 1},$$

which gives the exponential generating function of the Bernoulli numbers.

We come now to the main property of the Bernoulli umbra, which is expressed in the following theorem.

THEOREM 4.2. *The Bernoulli umbra satisfies the following umbral equation:*

$$\beta + 1 \equiv -\beta.$$

Proof. In (1) set

$$p(x) = \frac{-(-x + \beta' + 1)^{n+1}}{n+1},$$

where β' is an umbra exchangeable with β, thereby obtaining $p(\beta + 1) - p(\beta) \simeq (\beta' + 1)^n$. The left-hand side of the preceding may be rewritten as

$$\frac{-(-\beta + \beta')^{n+1} + (-\beta + \beta' + 1)^{n+1}}{n+1}. \tag{3}$$

Now let $q(x)$ be the polynomial

$$q(x) = \frac{(x - \beta)^{n+1}}{n+1}$$

and apply (1) again with $q(x)$ in place of $p(x)$ and β' in place of β, thereby obtaining $q(\beta'+1)-q(\beta') \simeq (-\beta')^n$. But observe that the left side of the previous equation is identical to (3). We infer that

$$(\beta'+1)^n \simeq (-\beta')^n$$

for all $n \in \mathbb{N}$; hence the conclusion follows after we replace β' by the exchangeable umbra β. □

It must be remarked that the Bernoulli umbra is not the only umbra α satisfying the umbral equation $\alpha+1 \equiv -\alpha$.

From Theorem 4.2 we infer that for $n>1$, $\beta^n \simeq (\beta+1)^n \simeq (-1)^n\beta^n$ and hence $B_{2n+1}=0$ for $n \geq 1$.

Recall that the operator J, sometimes called the *Bernoulli operator*, is defined as

$$Jp(x) = \int_x^{x+1} p(t)dt.$$

We have now the following proposition.

PROPOSITION 4.3. *Equation* (1) *can be equivalently rewritten in either of the forms*

$$Jp(\beta) \simeq p(\varepsilon) \quad \textit{or} \quad Jp(\varepsilon) \simeq p(\gamma),$$

where γ *is an inverse umbra of* β.

Proof. Indeed, suppose $p(x) = Dq(x)$ for some polynomial $q(x)$, where D is the ordinary derivative. Since $JD = \Delta$, we have $Jp(x) = \Delta q(x)$ and thus

$$Jp(\beta) = \Delta q(\beta) \simeq Dq(\varepsilon) = p(\varepsilon).$$

But every polynomial $p(x)$ can be written in the form $Dq(x)$ for some polynomial $q(x)$; hence the first conclusion. Applying D to both sides (by recalling that J and D commute) yields the converse. To show that the second equation is equivalent to the first, set $p(x) = q(\gamma+x)$, where $q(x)$ is any univariate polynomial. Applying the result just proved to this choice of $p(x)$, we obtain

$$Jq(\gamma+\beta) \simeq q(\gamma+\varepsilon) \simeq q(\gamma).$$

But $Jq(\gamma+\beta) \simeq Jq(\varepsilon)$, as desired. □

COROLLARY 4.4. *For any polynomial* $q(x)$ *we have*

(1) $\Delta q(x+\beta) \simeq Dq(x)$,

(2) $Jq(x+\beta) \simeq q(x)$,

(3) $Jq(x) \simeq q(x+\gamma)$.

Proof. Set $p(x) = q(x+c)$, where c is any constant. Now apply (1), thereby obtaining

$$\Delta q(c+\beta) \simeq Dq(c+\varepsilon) \simeq Dq(c).$$

This equality holds for all constants c; hence the first assertion. The remaining two assertions follow similarly. □

In other words, given the difference equation

$$\Delta f(x) = q'(x),$$

where $q(x)$ is an arbitrary polynomial and a polynomial solution $f(x)$ is desired, that solution is determined up to an additive constant and is given by the polynomial

$$q(x+\beta).$$

This explicit formula for the solution of a difference equation can be extended to a far more general class of functions $q(x)$.

For example, we obtain the classical formula

$$0^n + 1^n + 2^n + \cdots + (x-1)^n \simeq \frac{(x+\beta)^{n+1} - \beta^{n+1}}{n+1}.$$

The preceding formula is (up to a constant) an immediate consequence of the preceding remarks concerning difference equations. To determine the added constant $-\beta^{n+1}/(n+1)$, let the expression on the left-hand side be denoted by the function $s(x)$, taking its arguments from the positive integers. Note that in order for $\Delta s(x) = x^n$ to hold at $x = 0$ we have $s(0) = 0$. So it suffices to perform the obvious check that the constant term in the umbral polynomial on the right-hand side is 0.

As an application of Corollary 4.4, we obtain what is perhaps the simplest proof of the Euler–Maclaurin summation formula.

PROPOSITION 4.5 (Euler–Maclaurin). *For any polynomial $p(x)$ we have the identity*

$$p(x) \simeq Jp(x) + \beta\Delta p(x) + \frac{\beta^2}{2!}\Delta Dp(x) + \frac{\beta^3}{3!}\Delta D^2 p(x) + \cdots.$$

Proof. Again, let γ be an inverse to the Bernoulli umbra β. By Taylor's formula we have

$$p(x) \simeq p(\beta + x + \gamma) = \sum_{k\geq 0} \frac{\beta^k}{k!} D^k p(x+\gamma).$$

By Corollary 4.4 we have $D^k p(x+\gamma) \simeq D^k Jp(x) = D^{k-1}\Delta p(x)$ for $k > 0$. Expanding this relation yields the conclusion. □

5. The Nörlund umbra. A great many sequences occurring in combinatorics and number theory can be represented by sums or differences of umbrae exchangeable with the Bernoulli umbra. Such sequences are often obtained by specializing the following doubly indexed sequence.

DEFINITION 5.1. *Let n be any integer and let k be a nonnegative integer. The number $B_k^{(n)}$ defined as*

$$B_k^{(n)} \simeq (n\,.\,\beta)^k$$

will be called the kth Nörlund number of order n. *Correspondingly, any umbra exchangeable with $n\,.\,\beta$ for some integer n is called a* Nörlund umbra.

For $n = 1$ we may omit the superscript since $B_k^{(1)} \simeq \beta^k \simeq B_k$.

Recall that the operator Δ on polynomials of one variable may be written as $D + D^2/2! + D^3/3! + \cdots$. We denote the invertible operator $(\sum_{i\geq 1} D^{i-1}/i!)$ by Δ/D. It is easily verified that $J = \Delta/D$. The following is a generalization of (1).

THEOREM 5.2.

$$f\Big((n+j)\,.\,\alpha\Big) \simeq \left(\frac{\Delta}{D}\right)^{-n} f(j\,.\,\alpha) = J^{-n} f(j\,.\,\alpha)$$

holds for all polynomials f in one variable and all integers j, n, where the umbra α is a Bernoulli umbra. Conversely, if the equation holds for every polynomial f and some fixed integers $n \neq 0$ and j, then α is a Bernoulli umbra.

Proof. Assume $\alpha \equiv \beta$. Then Proposition 4.3 shows that $f(\beta) \simeq (\Delta/D)^{-1} f(\varepsilon)$. It suffices to assume $n > 0$ and $j = 0$. By induction on n we have

$$\begin{aligned} f(n\,.\,\beta) &\simeq \left(\frac{\Delta}{D}\right)^{-1} f\Big((n-1)\,.\,\beta\Big) \\ &\simeq \left(\frac{\Delta}{D}\right)^{-1} \left(\frac{\Delta}{D}\right)^{-(n-1)} f(\varepsilon). \end{aligned}$$

Replacing the polynomial $f(t)$ by $f(t + j\,.\,\beta)$ yields the result

$$f\Big((n+j)\,.\,\beta\Big) \simeq \left(\frac{\Delta}{D}\right)^{-n} f(j\,.\,\beta).$$

Conversely, the validity of the theorem both for the Bernoulli umbra β and some arbitrary umbra α for fixed $n \neq 0$ and j will enable us to prove that $n\,.\,\alpha \equiv n\,.\,\beta$. By Proposition 3.2 the conclusion follows.

Thus it suffices to show that if $p(t)$ is any polynomial in one variable then $p(n.\beta) \simeq p(n\,.\,\alpha)$. But

$$p(n\,.\,\beta) \simeq \left(\frac{\Delta}{D}\right)^{n} p(n\,.\,\alpha + n\,.\,\beta) \simeq p(n\,.\,\alpha). \qquad \square$$

It is worth stating several corollaries implicit in some of the preceding arguments.

COROLLARY 5.3.

(1) $\Delta^n f(n\,.\,\beta) \simeq D^n f(\varepsilon)$,
(2) $\Delta^n f(\varepsilon) \simeq D^n f(-n\,.\,\beta)$,
(3) $f(1) - f(0) \simeq f'(-1\,.\,\beta)$.

The third property allows the inverse umbra $-1\,.\,\beta$ to be immediately evaluated. Again, let γ be an umbra exchangeable with $-1\,.\,\beta$. Then

$$1^{n+1} - 0^{n+1} \simeq (n+1)(\gamma)^n,$$

so that

$$\gamma^n \simeq \frac{1}{n+1}.$$

6. Nörlund sequences. The Appell polynomial sequence associated with the Bernoulli numbers is the sequence of Bernoulli polynomials. We now concern ourselves with sequences of polynomials associated with the Nörlund umbrae. In particular, the Bernoulli polynomials form such a sequence.

DEFINITION 6.1. *Associated to the Nörlund umbra $n\,.\,\beta$ (for any integer n) is a sequence $(B_k^{(n)}(x))$ of* Nörlund polynomials of order n *and defined by*

$$B_k^{(n)}(x) \simeq (n\,.\,\beta + x)^k \simeq \sum_{i \geq 0} \binom{k}{i} B_i^{(n)} x^{k-i}.$$

The zeroth-order Nörlund polynomials are $B_k^{(0)}(x) = x^k$. The first-order sequence of Nörlund polynomials is the sequence of Bernoulli polynomials.

Applying Theorem 5.2 to $f(t) = (t+x)^k$, we obtain

$$\Delta^n B_k^{(i)}(x) = D^n B_k^{(i-n)}(x).$$

In particular,

$$\Delta^n B_k^{(n)}(x) = (k)_n x^{k-n}, \tag{4}$$

an identity that may be successfully used in the solution of difference equations.

COROLLARY 6.2. *Let $\phi^{(n)}(x)$ be the nth derivative of a polynomial $\phi(x)$ of degree d. Then the difference equation*

$$\Delta^n f(x) = \phi^{(n)}(x)$$

has $f(x) \simeq \phi(x + n \,.\, \beta)$ as a solution.

Observe that

$$\int_0^1 B_k^{(n)}(x)dx = B_k^{(n-1)}$$

since $JB_k^{(n)}(x)|_{x=0} \simeq (x + n \,.\, \beta + \gamma)^k|_{x=0} \simeq \big((n-1) \,.\, \beta\big)^k$.

Since the generating function for the Bernoulli numbers is $e^{\beta t} \simeq t/(e^t - 1)$ and since $e^{(n.\beta)t}e^{(m.\beta')t} \simeq e^{((n+m).\beta)t}$ for integers n and m, we have $e^{(n.\beta)t} \simeq (t/(e^t-1))^n$ and $e^{(x+n.\beta)t} \simeq e^{xt}\,(t/(e^t-1))^n$. These are the exponential generating functions for the Nörlund numbers and Nörlund polynomials each of order n, respectively.

7. Nörlund polynomials. We prove a number of facts concerning Nörlund polynomials that follow solely from the fact that the Nörlund polynomials of order n form an Appell sequence.

PROPOSITION 7.1. *If $n, n_1, n_2, \ldots, n_s$ are integers such that $\sum_{i=1}^s n_i = n$, then*

$$B_k^{(n)}(x_1 + \cdots + x_s) = \sum_{i_1,\ldots,i_s} \binom{k}{i_1,\ldots,i_s} B_{i_1}^{(n_1)}(x_1) \cdots B_{i_s}^{(n_s)}(x_s).$$

Proof. In umbral notation, the preceding identity is

$$(x_1 + \cdots + x_s + n \,.\, \beta)^k \simeq \Big((x_1 + n_1 \,.\, \beta') + \cdots + (x_s + n_s \,.\, \beta'')\Big)^k,$$

where $\beta', \ldots, \beta''$ are distinct umbrae, each exchangeable with β. □

Setting all $x_i = 0$ and all $n_i = 1$, we find

$$B_k^{(n)} = \sum_{i_1,\ldots,i_n} \binom{k}{i_1,\ldots,i_n} B_{i_1} \cdots B_{i_n}.$$

Nörlund polynomials of order n are an Appell sequence; hence the following proposition.

PROPOSITION 7.2. *For any integer n and for $k \geq 1$*

$$D_x\Big(B_k^{(n)}(x)\Big) \simeq D_x(x + n \,.\, \beta)^k = k(x + n \,.\, \beta)^{k-1} \simeq kB_{k-1}^{(n)}(x).$$

PROPOSITION 7.3 (inversion formula). *Suppose* $(r_i)_{i\in\mathbf{N}}$ *and* $(s_i)_{i\in\mathbf{N}}$ *are sequences of complex numbers such that* $r_0 = s_0 = 1$. *Then for* $n > 0$

$$r_k = \sum_{j=0}^{k} s_j \binom{k}{j} B_{k-j}^{(n)} \quad \text{if and only if} \quad s_k = \sum_{j=0}^{k} r_j \binom{k}{j} B_{k-j}^{(-n)}.$$

The coefficients $B_{k-j}^{(-n)}$ *of the sum on the right are all positive.*

Proof. Let ρ and σ be umbrae representing $(r_i)_{i\in\mathbf{N}}$ and $(s_i)_{i\in\mathbf{N}}$, respectively. Then $\rho \equiv \sigma + n \,.\, \beta$ if and only if $\rho + -n \,.\, \beta \equiv \sigma$, which is the desired conclusion. □

We conclude with an example of how the preceding techniques readily combine with facts particular to the Nörlund polynomials. Let k be greater than 0, and let n be any integer. Then

$$\Delta B_k^{(n)}(x) = D B_k^{(n-1)}(x) = k B_{k-1}^{(n-1)}(x).$$

8. Applications. We now prove some of the less trivial properties of Nörlund polynomials. Again, the proofs are, we believe, as short as they can be.

PROPOSITION 8.1. *For all integers* n *and for* $k \geq 0$

$$B_k^{(n)}(n - x) = (-1)^k B_k^{(n)}(x).$$

Proof.

$$\begin{aligned}(n - x + n \,.\, \beta)^k &\simeq \Big(- x + n \,.\, (\beta + 1)\Big)^k \\ &\simeq \Big(- x + n \,.\, (-\beta)\Big)^k \\ &\simeq (-1)^k (x + n \,.\, \beta)^k.\end{aligned}$$

The second line follows from Theorem 4.2, and the first and third results are from Proposition 3.2. □

As a further application of umbral techniques, apply Theorem 5.2 to $\sum_{j=0}^{m-1} B_k(x + j)$ to yield a telescoping sum.

LEMMA 8.2.

$$\begin{aligned}\sum_{j=0}^{m-1} (x + j + -1 \,.\, \beta)^k &\simeq \sum_{j=0}^{m-1} \frac{(x + j + 1)^{k+1} - (x + j)^{k+1}}{k + 1} \\ &= \frac{(x + m)^{k+1} - x^{k+1}}{k + 1} \simeq m^{k+1} (x/m + -1 \,.\, \beta)^k.\end{aligned}$$

This result forms the basis for another classical result.

PROPOSITION 8.3.

$$\sum_{j=0}^{m-1} B_k(x + (j/m)) = m^{-k+1} B_k(mx).$$

Proof. Let β, β' be exchangeable umbrae, and let $\gamma \equiv -1 \,.\, \beta$. Then

$$\sum_{j=0}^{m-1}\Big((x+\beta)+(j/m)\Big)^k \simeq m^{-k}\sum_{j=0}^{m-1}\Big(m(x+\beta)+\beta'+j+\gamma\Big)^k$$
$$\simeq m^{-k+1}\Big(mx+m\beta+\beta'+m\gamma\Big)^k$$
$$\simeq m^{-k+1}(mx+\beta')^k,$$

where the second umbral equality is by Lemma 8.2. □

Just as the Euler–Maclaurin summation formula was immediate from a computation with the Bernoulli umbra, we may easily derive a generalization of this formula by using the Nörlund umbrae.

We start with Taylor's formula,

$$f(x+y)=\sum_{k\geq 0}\frac{x^k}{k!}f^{(k)}(y), \tag{5}$$

and set $x = n\,.\,\beta$ and $y = x + n\,.\,\gamma$ to obtain

$$f(x)\simeq f(n\,.\,\beta+x+n\,.\,\gamma)\simeq\sum_{k\geq 0}\frac{(n\,.\,\beta)^k}{k!}f^{(k)}(x+n\,.\,\gamma).$$

Rewriting this by using Theorem 5.2 yields the following proposition.

PROPOSITION 8.4 (general Euler–Maclaurin summation formula). *Given a polynomial $f(x)\in D[x]$, the quotient field of D, as usual, containing $\mathbb{C}$, is*

$$f(x)\simeq\sum_{k=0}^{n-1}\frac{(n\,.\,\beta)^k}{k!}f^{(k)}(x+n\,.\,\gamma)+\sum_{k\geq n}\frac{(n\,.\,\beta)^k}{k!}\Delta^n f^{(k-n)}(x)$$

for $n\geq 0$.

Similarly, for any integer n we make use of Proposition 3.2 and expand

$$f(x+n)\simeq f\Big(n\,.\,(\beta+1)+x+n\,.\,\gamma\Big)\simeq f\Big(-1(n\,.\,\beta)+x+n\,.\,\gamma\Big)$$

to derive Proposition 8.5.

PROPOSITION 8.5 (Euler–Maclaurin second form). *For any integer $n\geq 0$*

$$f(x+n)\simeq\sum_{k=0}^{n-1}(-1)^k\frac{(n\,.\,\beta)^k}{k!}f^{(k)}(x+n\,.\,\gamma)+\sum_{k\geq n}(-1)^k\frac{(n\,.\,\beta)^k}{k!}\Delta^n f^{(k-n)}(x).$$

Setting $n = 1$ and summing the two preceding formulas as x ranges through $x, x+1,\dots,x+m$ and $x, x+1,\dots,x+m-1$, respectively, yields classical versions of the Euler–Maclaurin summation formula, to wit:

$$\sum_{i=0}^{m}f(x+i)=\int_x^{x+m+1}f(t)dt+\sum_{k\geq 1}\frac{B_k}{k!}\Big[f^{(k-1)}(x+m+1)-f^{(k-1)}(x)\Big]$$

and

$$\sum_{i=0}^{m}f(x+i)=\int_x^{x+m}f(t)dt+\frac{1}{2}\Big[f(x+m)+f(x)\Big]+\sum_{k\geq 2}(-1)^k\frac{B_k}{k!}\Big[f^{(k-1)}(x+m)-f^{(k-1)}(x)\Big].$$

The term $f(x)$ has been added to both sides in the second formula.

We next prove a theorem designed to simplify expressions of the form $(n.\beta)p(n.\beta)$ and examine some consequences. We begin with a basic result for the inverse Bernoulli umbra γ.

PROPOSITION 8.6. *If γ is exchangeable with $-1.\beta$, where β is a Bernoulli umbra, then for any polynomial p*

$$\gamma p'(\gamma) \simeq p(1) - p(\gamma) \simeq p(0) + p'(\gamma) - p(\gamma).$$

Proof. For $n \geq 0$ we have

$$n\gamma^n \simeq \frac{n}{n+1} \simeq 1 - \frac{1}{n+1} \simeq 1^n - \gamma^n.$$

The first identity follows by linearity, and the second is an application of the defining relation (1) of Bernoulli umbra. □

Let γ' be exchangeable with γ. Recall that $q'(\gamma) \simeq q(1) - q(0)$. Letting $q(t) = p(1 - t\gamma')$, we obtain $-\gamma p'(1 - \gamma\gamma') \simeq p(1 - \gamma) - p(1) \simeq p(\gamma) - p(1)$, the last equivalence coming from Theorem 4.2. By Proposition 8.6 this is equivalent to $-\gamma p'(\gamma)$. Evaluating at $p(t) = t^n$, we obtain the elegant identity

$$\sum_{k\geq 0} \binom{n-1}{k} (-1)^k \frac{1}{(k+1)(k+2)} = \frac{1}{n+1}.$$

By recalling Proposition 3.3, Proposition 8.6 may be rewritten as

$$\beta p'(\gamma + \beta) \simeq -\gamma p'(\gamma + \beta) \simeq -\Big[p(\beta) + p'(\varepsilon) - p(\varepsilon)\Big]. \tag{6}$$

We thereby obtain the following theorem.

THEOREM 8.7.

$$(n\,.\,\beta)p'(n\,.\,\beta + n\,.\,\gamma) \simeq -n\Big[p(\beta) + p'(\varepsilon) - p(\varepsilon)\Big].$$

Proof. By Proposition 3.3 the left-hand side in Theorem 8.7 is equivalent to $n[\beta p'(\beta + \gamma)]$. By (6) this is equivalent to the right-hand side. □

Now we use Theorem 8.7 to find an alternative formula for $(x + n\,.\,\beta)^k$, with $n \neq 0$.

$$\begin{aligned}
(x + n\,.\,\beta)^k &= (x + n\,.\,\beta)(x + n\,.\,\beta)^{k-1} \\
&= n\,.\,\beta(x + n\,.\,\beta)^{k-1} + x(x + n\,.\,\beta)^{k-1} \\
&\simeq -\frac{n}{k}\left[\Big(x + (n+1)\,.\,\beta\Big)^k + k(x + n\,.\,\beta)^{k-1} - (x + n\,.\,\beta)^k\right] \\
&\quad + x(x + n\,.\,\beta)^{k-1} \\
&\simeq -\frac{n}{k}\left[\Big(x + (n+1)\,.\,\beta\Big)^k + \frac{k}{n}(n - x)(x + n\,.\,\beta)^{k-1} - (x + n\,.\,\beta)^k\right].
\end{aligned}$$

Rewriting this as a recursion in the Nörlund polynomials, we obtain Corollary 8.8.

COROLLARY 8.8. *For $n \neq 0$ and $k \geq 1$*

$$B_k^{(n+1)}(x) = \frac{k}{n}(x - n)B_{k-1}^{(n)} + \left(1 - \frac{k}{n}\right) B_k^{(n)}(x).$$

Making the appropriate substitutions yields Corollary 8.9.

COROLLARY 8.9. *For $n \neq 0$ and $k \geq 0$*

$$B_k^{(n+1)}(n) = (-1)^k \left(1 - \frac{k}{n}\right) B_k^{(n)}.$$

Proof. By Corollary 8.8 the left-hand side in Corollary 8.9 is umbrally equivalent to $(1-k/n)(n+n\,.\,\beta)^k$. But since $(n+n\,.\,\beta) \equiv n\,.\,(1+\beta) \equiv n\,.\,(-\beta)$, this is umbrally equivalent to the right-hand side. □

9. Stirling numbers. Recall that the Stirling numbers of the second kind $S(n,k)$ are defined as the number of partitions of a set of n elements into k parts. An easy computation shows that

$$k!S(n,k) = [\Delta^k x^n]_{x=0}.$$

Remarkably, the Stirling numbers are very simply related to the Nörlund sequence.

PROPOSITION 9.1. *If $n \geq k \geq 0$, then*

$$\binom{n}{k} B_{n-k}^{(-k)} = S(n,k).$$

Proof. Suppose $n \geq k \geq 0$, and let p be the polynomial $p(t) = t^n$. Then by Theorem 5.2

$$(n)_k (x + -k\,.\,\beta)^{n-k} \simeq D^k p(x + -k\,.\,\beta) \simeq \Delta^k p(x).$$

Setting $x = 0$ and rewriting yields

$$B_{n-k}^{(-k)} \simeq \frac{\Delta^k \varepsilon^n}{(n)_k} \simeq \frac{k!S(n,k)}{(n)_k},$$

where $(n)_k = (n)(n-1)\cdots(n-k+1)$ denotes n falling factorial k. □

PROPOSITION 9.2. *For $n > 0$*

$$B_n^{(n+1)}(x) = (x-1)_n \quad \text{and} \quad B_n^{(n+1)} = (-1)^n n!. \tag{7}$$

Proof. The second half of the proposition is immediate from setting $x = 0$ in the first half.

To prove the first half, it suffices to show that for $n > 1$, $B_n^{(n+1)}(x) = (x - n)B_{n-1}^{(n)}(x)$. But this is precisely Corollary 8.8 for $k = n$. □

Now from Proposition 9.2 we obtain

$$(x-1)\cdots(x-n) \simeq (x + (n+1)\,.\,\beta)^n \simeq \sum_{k=0}^{n} \binom{n}{k} x^k \Big((n+1)\,.\,\beta\Big)^{n-k}. \tag{8}$$

By replacing x by $-x$ and n by $n-1$, this may be rewritten as

$$(-1)^n x(x+1)\cdots(x+n-1) = \sum_{k=1}^{n} \binom{n-1}{k-1} (-1)^k x^k B_{n-k}^{(n)}.$$

We have $x(x+1)\cdots(x+n-1) = \sum_{k=0}^{n} s(n,k)x^k$. The coefficients $s(n,k)$ are called the Stirling numbers of the first kind, which have numerous combinatorial interpretations. We have thus expressed the Stirling numbers of the first kind in terms of the Nörlund sequence.

PROPOSITION 9.3. *For $n \geq k \geq 1$*

$$(-1)^{n-k}s(n,k) = \binom{n-1}{k-1} B_{n-k}^{(n)}.$$

This relationship between Stirling numbers and higher-order Bernoulli numbers allows easy results on the one to be transformed into results on the other.

PROPOSITION 9.4. *If $n \geq k \geq 0$, then*

$$\sum_{i=0}^{k} \binom{k}{i} (-1)^i (k-i)^n = (n)_k B_{n-k}^{(-k)}.$$

Proof. The left-hand side in Proposition 9.4 is equivalent to $\Delta^k f(k \,.\, \beta')$, where $f(t) = (-k \,.\, \beta + t)^n$. Since the right-hand side is equivalent to $f^{(k)}(t)$, the result follows by Theorem 5.2. □

In terms of Stirling numbers, if $n \geq k \geq 0$, we have proved the classical identity

$$\sum_{i=0}^{k} \binom{k}{i} (-1)^i (k-i)^n = k!S(n,k).$$

Recall Newton's formula, namely, for any polynomial f

$$f(x) = \sum_{k \geq 0} \binom{x}{k} \Delta^k f(0). \tag{9}$$

Applying Newton's formula to the polynomial $f(t) = (t + n \,.\, \beta)^d$, for any integer n, yields

$$\begin{aligned}(x + n \,.\, \beta)^d &= \sum_{k \geq 0} \binom{x}{k} \Delta^k (n \,.\, \beta)^d \\ &\simeq \sum_{k \geq 0} \binom{x}{k} D^k \Big((n-k) \,.\, \beta\Big)^d \\ &\simeq \sum_{k \geq 0} \binom{x}{k} (d)_k \Big((n-k) \,.\, \beta\Big)^{d-k}.\end{aligned}$$

From the preceding computation we obtain the expansion of the Nörlund polynomials as linear combinations of the lower factorials $(x)_k$.

PROPOSITION 9.5. *For any integer n*

$$B_d^{(n)}(x) = \sum_{k=0}^{d} \binom{d}{k} (x)_k B_{d-k}^{(n-k)}.$$

Recalling Proposition 9.1, for $n = 0$, we obtain a classical identity for the Stirling numbers of the second kind.

Since $D^{n-k}\big(x+(n+1).\beta\big)^n \simeq (n)_{n-k}\big(x+(n+1).\beta\big)^k$, differentiating the left-hand side of equation (7) $n-k$ times yields the following corollary.

COROLLARY 9.6. *For* $n \geq k \geq 0$

$$B_k^{(n+1)}(x) = \frac{k!}{n!} D^{n-k}(x-1)(x-2)\cdots(x-n).$$

Corollary 9.6 has the following elegant consequence.

PROPOSITION 9.7.

$$B_{n-1}^{(n+1)}(x) = \frac{1}{n}(x-1)(x-2)\cdots(x-n)\left(\frac{1}{x-1}+\frac{1}{x-2}+\cdots+\frac{1}{x-n}\right),$$

in which setting n *to* $n+1$ *and* x *to* 0 *yields*

$$B_n^{(n+2)} = (-1)^n n!\left(\frac{1}{1}+\frac{1}{2}+\cdots+\frac{1}{n+1}\right).$$

Finally, Proposition 9.2 yields the following proposition.

PROPOSITION 9.8.

$$B_n^{(n)}(x) = \int_x^{x+1}(t-1)(t-2)\cdots(t-n)dt$$

and

$$B_n^{(n)} = \int_0^1 (t-1)(t-2)\cdots(t-n)dt.$$

Proof. The first equation in Proposition 9.8 clearly implies the second. To prove the first, rewrite the equation in umbral form by using Corollary 9.6 to produce

$$\begin{aligned}\int_x^{x+1}(t-1)(t-2)\cdots(t-n)dt &= \int_x^{x+1} B_n^{(n+1)}(t)dt \\ &\simeq \Big(x+(n+1)\,.\,\beta+\gamma\Big)^n \\ &\simeq B_n^{(n)}(x),\end{aligned}$$

where the second line is from Corollary 4.4. □

SPECIALIZATIONS OF GENERALIZED LAGUERRE POLYNOMIALS*

R. SIMION† AND D. STANTON‡

Abstract. Three specializations of a set of orthogonal polynomials with "8 different q's" are given. The polynomials are identified as q-analogues of Laguerre polynomials, and the combinatorial interpretation of the moments gives infinitely many new Mahonian statistics on permutations.

Key words. Laguerre polynomials, permutation statistics

AMS subject classifications. 05E35, 33C45

1. Introduction.

The Laguerre polynomials $L_n^{\alpha}(x)$ have been extensively studied, analytically [3] and combinatorially [5], [9]. There is also a classical set of q-Laguerre polynomials [7]. Recently, a set of orthogonal polynomials generalizing the Laguerre polynomials has been studied [8]. These polynomials in some sense have "8 different q's." Various specializations of them give orthogonal polynomials associated with many types of combinatorial objects. The purpose of this paper is to present the specializations that are true q-analogues of $L_n^0(x)$. By this we mean that the nth moments, instead of being $n!$, are basically $n!_q$.

Here we present three specializations whose moments lead to new Mahonian statistics on permutations (Theorems 2, 3, and 4). In fact, infinitely many Mahonian statistics can be derived from those presented here. Moreover, the theorems obtained from our specializations follow easily from classical analytic facts, but are combinatorially nontrivial.

We shall use the terminology and notation found in [6], and let

$$[n]_q = \frac{1-q^n}{1-q}, \qquad [n]_{r,s} = \frac{r^n - s^n}{r-s}.$$

2. The polynomials and their moments.

Any set of monic orthogonal polynomials satisfies the three-term recurrence relation

$$p_{n+1}(x) = (x - b_n)p_n(x) - \lambda_n p_{n-1}(x). \tag{2.1a}$$

For the set of orthogonal polynomials with 8 different "q's" considered in [8], the coefficients are

$$b_n = a[n+1]_{r,s} + b[n]_{t,u}, \qquad \lambda_n = ab[n]_{p,q}[n]_{v,w}. \tag{2.1b}$$

We refer to the polynomials defined by (2.1) as the *octabasic Laguerre polynomials.* They generalize the Laguerre polynomials and are the polynomials whose specializations we consider in this paper.

The fundamental combinatorial fact (Theorem 1) that we need here concerns the moments for these polynomials. They are generating functions for permutations according to certain statistics.

For the definition of these statistics, it is convenient to represent a permutation σ as a word $\sigma(1)\sigma(2)\cdots\sigma(n)$ consisting of increasing runs, separated by the descents of the permutation. For example, the permutation $\sigma = 26|357|4|189$ has 4 runs separated by 3 descents, and we write $\mathrm{run}(\sigma) = 4$. The runs of length 2 or more will be called *proper runs* and those of length 1 will be called *singleton runs.*

The elements $\sigma(i)$ of σ fall into four classes: the elements that begin proper runs (openers), the elements that close proper runs (closers), the elements that form singleton runs (singletons), and the elements that continue runs (continuators). We shall abbreviate these classes of elements "op," "clos," "sing," and "cont," respectively. In the example, $\mathrm{op}(\sigma) = \{3,2,1\}$, $\mathrm{clos}(\sigma) = \{6,7,9\}$, $\mathrm{sing}(\sigma) = \{4\}$, and $\mathrm{cont}(\sigma) = \{5,8\}$.

DEFINITION 1. For $\sigma \in S_n$, the statistics $\mathrm{lsg}(\sigma)$ and $\mathrm{rsg}(\sigma)$ are defined by

$$\mathrm{lsg}(\sigma) = \sum_{i=1}^{n} \mathrm{lsg}(i), \qquad \mathrm{rsg}(\sigma) = \sum_{i=1}^{n} \mathrm{rsg}(i),$$

where $\mathrm{lsg}(i)$ = the number of runs of σ strictly to the left of i which contain elements smaller and greater than i, and $\mathrm{rsg}(i)$ = the number of runs of σ strictly to the right of i which contain elements smaller and greater than i.

We also define the lsg and rsg on the openers of σ

$$\mathrm{lsg(op)}(\sigma) = \sum_{i\in\mathrm{op}(\sigma)} \mathrm{lsg}(i), \qquad \mathrm{rsg(op)}(\sigma) = \sum_{i\in\mathrm{op}(\sigma)} \mathrm{lsg}(i).$$

The statistics lsg and rsg have analogous definitions on each of the remaining three classes of elements.

For example, if $\sigma = 26|357|4|189$, then $\mathrm{lsg}(7) = 0$, $\mathrm{rsg}(7) = 1$, $\mathrm{lsg(op)}(\sigma) = 0+1+0 = 1$, $\mathrm{rsg(op)}(\sigma) = 1+1+0 = 2$, $\mathrm{lsg(clos)}(\sigma) = 0$, $\mathrm{rsg(clos)}(\sigma) = 2+1+0 = 3$, etc.

THEOREM 1. *The* n*th moment* μ_n *for the octabasic Laguerre polynomials is*

$$\mu_n = \sum_{\sigma\in S_n} r^{\mathrm{lsg(sing)}(\sigma)} s^{\mathrm{rsg(sing)}(\sigma)} t^{\mathrm{lsg(cont)}(\sigma)} u^{\mathrm{rsg(cont)}(\sigma)} p^{\mathrm{lsg(op)}(\sigma)} q^{\mathrm{rsg(op)}(\sigma)} v^{\mathrm{lsg(clos)}(\sigma)} w^{\mathrm{rsg(clos)}(\sigma)} a^{\mathrm{run}(\sigma)} b^{n-\mathrm{run}(\sigma)}.$$

Proof. The Viennot theory [9],[10] gives μ_n as a generating function for Motzkin paths from $(0,0)$ to $(n,0)$. From (2.1b) the paths have four types of edges (or steps):

(1) northeast (NE) edges starting at level k with weight in $a[k+1]_{p,q}$,
(2) southeast (SE) edges starting at level k with weight in $b[k]_{v,w}$,
(3) east (E solid) edges starting at level k with weight in $a[k+1]_{r,s}$,
(4) east (E dotted) edges starting at level k with weight in $b[k]_{t,u}$,

where "weight in $\alpha[m]_{c,d}$" means that the weight of the edge is one of the monomials $\alpha c^{m-1}, \alpha c^{m-2}d, \ldots, \alpha d^{m-1}$, which appear in $\alpha[m]_{c,d}$.

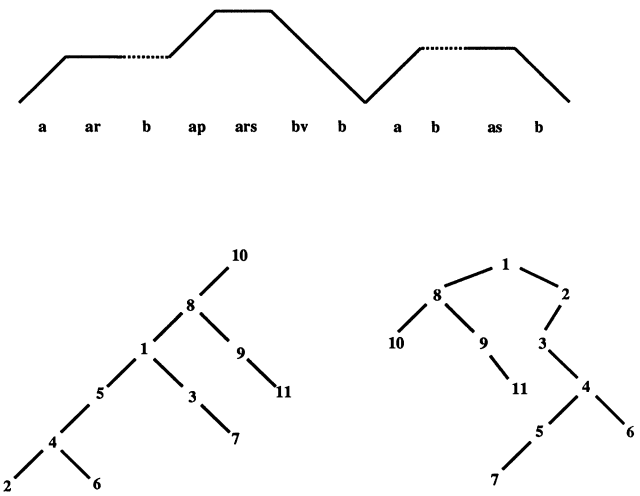

FIG. 1. *The permutation* 10 8 9 11 1 3 7 5 4 6 2 *as a weighted Motzkin path, runs, and a binary tree.*

The weight of a Motzkin path is then the product of the weights of its edges. An example of such a weighted path is given in Fig. 1.

In the statement of Theorem 1 we claim that μ_n is the sum over all permutations in S_n of monomial weights defined in terms of our permutation statistics. To prove the theorem we construct a bijection between the weighted Motzkin paths of length n and permutations in S_n, so that the weight of a path is equal to the weight of its corresponding permutation.

Given a weighted Motzkin path of length n, its corresponding permutation will be constructed in n stages. We begin at the origin and with the empty permutation. We traverse the path from left to right, and the ith step will determine where to insert i in the current (partial) permutation $\sigma_{i-1} \in S_{i-1}$. The end result will be a permutation $\sigma_n = \sigma \in S_n$. Depending on the type of the ith step of the path, i will belong to one or another of the four classes of elements of σ:

(1) NE: $i \in \text{op}(\sigma)$,
(2) SE: $i \in \text{clos}(\sigma)$,
(3) E solid: $i \in \text{sing}(\sigma)$,
(4) E dotted: $i \in \text{cont}(\sigma)$.

The weight $\alpha c^j d^k$ of the ith step of the path determines, as described below, the exact position in σ_{i-1} where we insert i as a point in the appropriate class of elements.

A run in σ_{i-1} will be called an *active run* if its maximum is a (future) opener or continuator in σ. Notice that the first step of the path starts at level 0 and that σ_0, being the empty permutation, has no active runs. Inductively, assume that the level h at which the ith step starts is equal to the number of active runs in σ_{i-1}, and recall the relation between the weight $\alpha c^j d^k$ of a step and its starting level h: for NE and E solid steps we have $j + k = h$, while for other steps we have $j + k = h - 1$.

If the ith step is E dotted or SE, then the element i is adjoined to the $(j+1)$st active run of σ_{i-1}, as a continuator or closer, respectively. This is well defined since, as discussed above, $j + k$ is one unit less than the number of active runs in σ_{i-1}. It follows as well that the new partial permutation, σ_i, will have as many active runs as the starting level of the $(i+1)$st step of the path.

If the ith step is NE or E solid, then $j+k$ is equal to the number of active runs in σ_{i-1}, and we insert i in the leftmost position possible such that it will have j of the *active* runs of σ_{i-1} strictly to its left and k of the *active* runs of σ_{i-1} strictly to its right. The position where i is inserted in this case ensures that i will be the initial element of a run, and it is again true that σ_i will have as many active runs as the starting level of the $(i+1)$st step of the path.

Note that in the final permutation σ the values of $\mathrm{lsg}(i)$ and $\mathrm{rsg}(i)$ are completely determined by the runs that were active in σ_{i-1} and the position, relative to these runs, where i was inserted. So, if the ith step has weight $\alpha c^j d^k$, then $\mathrm{lsg}(i) = j$ because each of the j open runs of σ_{i-1} that remain to the left of i upon its insertion will eventually be extended by at least one element greater than i. Similarly, $\mathrm{rsg}(i) = k$. Finally, $\alpha = a$ in the weight of the ith step corresponds precisely to i being the initial (possibly the only) element of a run. Consequently, the weight of a Motzkin path is equal to our intended weight for the corresponding permutation σ.

It remains to verify that this correspondence is bijective. We claim that, given $\sigma \in S_n$, we can reconstruct its associated Motzkin path, step by step, beginning at the right end of the path, $(n,0)$, since each stage of our construction is reversible.

Using our rules (1)–(4), each permutation in S_n will produce a Motzkin path of length n (not yet weighted), since $|\mathrm{op}(\sigma)| = |\mathrm{clos}(\sigma)|$ and each closer is larger than its corresponding opener. We must check that the weight $\alpha c^{\mathrm{lsg(i)}} d^{\mathrm{rsg(i)}}$ (where $\alpha = a$ if i is the initial element of a run, and $\alpha = b$ otherwise) is a valid weight for the ith step of the path. This follows immediately from the equality $\mathrm{lsg}(i) + \mathrm{rsg}(i) =$ the level of the left endpoint e_{i+1} of the partial path reconstructed from the values $n, n-1, \ldots, i+1$. The equality holds for $i = n$ since $\mathrm{lsg}(n) = \mathrm{rsg}(n) = 0$ in all permutations of S_n, and the left endpoint of the one-point path consisting just of $(n,0) = e_{n+1}$ is at level 0. Suppose the equality holds for $i+1$ and we will prove it for i. Observe that the level of e_{i+1} is equal to the number of SE steps minus the number of NE steps in the partial path from e_{i+1} to $(n,0)$. That is, the level of e_{i+1} is equal to the number of proper runs in σ whose maximum is larger than i, minus the number of proper runs in σ whose minimum is larger than i. But this is equal in turn with the number of proper runs in σ with maximum larger than i and minimum smaller than i, i.e., it is equal to $\mathrm{lsg}(i) + \mathrm{rsg}(i)$. It now becomes clear that our map from weighted Motzkin paths to permutations is indeed invertible. □

Figure 1 shows the weighted Motzkin path that corresponds with the permutation $\sigma = 10|89\,11|137|5|46|2$. We have also included a binary tree representation of the permutation, deeming it of possible interest to the readers familiar with [9]. The bijection constructed in the proof above is related to Viennot's correspondence between Motzkin paths and permutations [9]. As an intermediate step in Viennot's correspondence, Motzkin paths and permutations are encoded by increasingly labeled binary trees.

We will be concerned with specializations of the 8 q's under which the moments in Theorem 1 become multiples of $n!_q = [n]_q[n-1]_q \cdots [1]_q$. It is clear that the parameter b can be rescaled to 1. Also, in considering specializations, we can take advantage of the property — obvious from (2.1) — that the moments are fixed under the interchange of $\{r,s\}$, $\{t,u\}$, $\{p,q\}$, and $\{v,w\}$, and also fixed if p and q are interchanged with v and w.

3. The specializations. In this section we state three different specializations of the polynomials defined by (2.1). The polynomials that arise are monic little q-Jacobi, sums of two little q-Jacobi, and classical q-Laguerre. Each of these three cases

will have moments that are basically $n!_q$.

First we choose the parameters so that the polynomials coincide with the monic form of the little q-Jacobi polynomials [6], $p_n(xq(1-q);q^\alpha,0;q)$, which have

$$b_n = q^{n-1}[n+1+\alpha]_q + q^{n+\alpha-1}[n]_q, \qquad \lambda_n = q^{2n-3+\alpha}[n]_q[n+\alpha]_q. \tag{3.1}$$

The appropriate specialization occurs only for $\alpha = 0$, $p_n(xq(1-q);1,0;q)$, and is $r = t = p = v = q^2$, $s = u = q = w$, $a = 1/q$, $b = 1$. The explicit formula for the polynomials, which is just the definition of the little q-Jacobi polynomials, is

$$p_n(x) = \sum_{k=0}^{n} \begin{bmatrix} n \\ k \end{bmatrix}_q [n]_q \cdots [n-k+1]_q (-1)^k x^{n-k} q^{\binom{k-1}{2}-1}. \tag{3.2}$$

The measure for $p_n(x;q^\alpha,q^\beta;q)$ is purely discrete, with masses of

$$\frac{q^{(\alpha+1)i}(q^{\beta+1};q)_i(q^{\alpha+1};q)_\infty}{(q;q)_i(q^{\alpha+\beta+2};q)_\infty}$$

at $x = q^i$. An easy calculation shows that the moments are given by $\mu_n = (q^{\alpha+1};q)_n/(q^{\alpha+\beta+2};q)_n$. Thus for $p_n(xq(1-q);1,0;q)$, we have $\mu_n = q^{-n}n!_q$. Based upon these remarks, Theorem 1 becomes the following theorem. An equivalent theorem has been given in [2, Prop. 5.2].

THEOREM 2. *For $\sigma \in S_n$, let*

$$s(\sigma) := n - \mathrm{run}(\sigma) + 2\mathrm{lsg}(\sigma) + \mathrm{rsg}(\sigma).$$

Then

$$\sum_{\sigma \in S_n} q^{s(\sigma)} = n!_q.$$

Moreover, we see from the symmetry of (2.1) with respect to the 4 pairs of "q's" that Theorem 2 holds for 16 statistics related to $s(\sigma)$. These 16 are obtained by choosing the coefficients 1 and 2 for lsg and rsg independently for the four types of elements of σ. This means, for example, that

$$\begin{aligned} s'(\sigma) = n - \mathrm{run}(\sigma) &+ \mathrm{lsg(sing)} + 2\mathrm{rsg(sing)} + \mathrm{lsg(op)} + 2\mathrm{rsg(op)} \\ &+ 2\mathrm{lsg(cont)} + \mathrm{rsg(cont)} + 2\mathrm{lsg(clos)} + \mathrm{rsg(clos)} \end{aligned}$$

also satisfies Theorem 2. We will see later that in fact there are infinitely many equidistributed statistics related to $s(\sigma)$.

For our second specialization we consider

$$b_n = q^{n+1}[n+1]_q + q^{n-1}[n]_q, \qquad \lambda_n = q^{2n-1}[n]_q[n]_q. \tag{3.3}$$

The appropriate values are $r = t = p = v = q^2$, $s = u = q = w$, $a = q$, $b = 1$. The polynomials turn out to be a sum of two little q-Jacobi polynomials,

$$\begin{aligned} p_n(x) = n!_q q^{\binom{n}{2}}(-1)^n \Bigg[{}_2\phi_1 \left(\begin{matrix} q^{-n} & 0; \\ & q \end{matrix} \; q, \; xq(1-q) \right) \\ - (1-q^n)\,{}_2\phi_1 \left(\begin{matrix} q^{1-n} & 0; \\ & q^2 \end{matrix} \; q, \; xq(1-q) \right) \Bigg], \end{aligned}$$

or equivalently,

(3.4)
$$p_n(x) = x^n + \sum_{k=1}^{n} \begin{bmatrix} n \\ k \end{bmatrix}_q [n]_q \cdots [n-k+2]_q ([n-k]_q + q^n)(-1)^k x^{n-k} q^{\binom{k}{2}} + (-1)^n q^{\binom{n+1}{2}} n!_q.$$

We omit the proof of these formulas. It is a verification of the recurrence relation (2.1) from the recurrence relation for the little q-Jacobi polynomials.

Since these polynomials do not explicitly appear in the literature, we cannot compute the moments by quoting the relevant facts about their measure. Nonetheless, the moments and measure are easily determined.

PROPOSITION 1. *The moments for the polynomials in* (3.3) *are* $\mu_0 = 1$, *and* $\mu_n = q\, n!_q, n > 0$. *The measure is purely discrete, with masses of* $q^i(q;q)_\infty/(q;q)_{i-1}$ *at* $q^{i-1}/(1-q)$, $i \geq 1$, *and a mass of* $1-q$ *at* 0.

Proof. The q-binomial theorem clearly shows that the total mass $\mu_0 = (1-q)+q = 1$. It also implies

$$\begin{aligned} \mu_n &= \sum_{i=1}^{\infty} \frac{q^{(i-1)n} q^i (q;q)_\infty}{(1-q)^n (q;q)_{i-1}} + (1-q)\delta_{n,0} \\ &= q n!_q + (1-q)\delta_{n,0}. \end{aligned}$$

Thus the stated measure has the right moments. To show that the polynomials are orthogonal with respect to this measure, note that it is easy to check, from the explicit formula (3.4), that the moments annihilate $p_1, p_2, \ldots$. Hence, the linear functional defined by the measure annihilates $p_1, p_2, \ldots$. Finally, the three-term recurrence now shows that the polynomials are indeed orthogonal. □

We then get a companion theorem to Theorem 2. As in the case of Theorem 2, we have 16 equivalent versions of the statistic $s(\sigma)$, by assigning coefficients 1 and 2 to lsg and rsg independently on openers, continuators, closers, and singletons.

THEOREM 3. *For* $\sigma \in S_n$, *let*

$$s(\sigma) := \mathrm{run}(\sigma) - 1 + 2\mathrm{lsg}(\sigma) + \mathrm{rsg}(\sigma).$$

Then

$$\sum_{\sigma \in S_n} q^{s(\sigma)} = n!_q.$$

We remark that Theorems 2 and 3 are valid for an infinite number of variations of the statistic $s(\sigma)$. It is easy to verify that for each $\sigma \in S_n$,

(3.5) $$\mathrm{lsg(op)}(\sigma) + \mathrm{rsg(op)}(\sigma) = \mathrm{lsg(clos)}(\sigma) + \mathrm{rsg(clos)}(\sigma).$$

(In fact there is a specialization of $\{r, s, t, u, p, q, v, w\}$ with one free parameter giving (3.5).) Therefore the value of $s(\sigma)$ remains the same if the coefficients $\{1, 2\}$ are replaced on the openers with $\{1+c, 2+c\}$, and on the closers with $\{1-c, 2-c\}$. This provides a variation of Theorems 2 and 3 for each choice of the real parameter c. For example, $c = 1$ gives the unusual choice of coefficients $\{2, 3\}$ and $\{0, 1\}$.

Our third choice for specialization is the set of the classical q-Laguerre polynomials $L_n^\alpha(x(1-q);q)$ [7], [6, p. 194], whose monic form has

(3.6) $$b_n = q^{-2n-\alpha}[n]_q + q^{-2n-1-\alpha}[n+1+\alpha]_q, \qquad \lambda_n = q^{1-4n-2\alpha}[n]_q[n+\alpha]_q.$$

The appropriate values are $r = t = p = v = q^{-2} = b$, $s = u = q = w := q^{-1} = a$ for $L_n^0(x(1-q), q)$. The explicit formula for the monic form of $L_n^\alpha(x(1-q); q)$ is

$$p_n(x) = \sum_{k=0}^{n} \begin{bmatrix} n \\ k \end{bmatrix}_q [n+\alpha]_q \cdots [n+\alpha-k+1]_q (-1)^k x^{n-k} q^{k(k-\alpha-2n)}. \tag{3.7}$$

Again a measure of these polynomials is explicitly known [7, Thm. 1], and the moments for $L_n^\alpha(x(1-q); q)$ can be found as

$$\mu_n = (q^{\alpha+1}; q)_n q^{-n\alpha-\binom{n+1}{2}}/(1-q)^n.$$

For $\alpha = 0$ this is $q^{-\binom{n+1}{2}} n!_q$. However, the combinatorial version of this theorem is equivalent to Theorem 2, if q is replaced with $1/q$. Thus no new combinatorial theorem results.

4. The "odd" polynomials. If $r = p$, $s = q$, $t = v$, and $u = w$, then the polynomials defined by (2.1) are the "even" polynomials for the polynomials defined by (see [1, p. 41])

$$b_n = 0, \quad \lambda_{2n} = b[n]_{t,u}, \quad \lambda_{2n+1} = a[n+1]_{r,s}.$$

The "odd" polynomials have the coefficients

$$b_n = a[n+1]_{r,s} + b[n+1]_{r,s}, \qquad \lambda_n = ab[n+1]_{r,s}[n]_{t,u}. \tag{4.1}$$

The moments for these "odd" polynomials satisfy $\mu_n(\text{odd}) = \mu_{n+1}(\text{even})/\mu_1(\text{even})$. Since all of our specializations in §3 satisfied $r = p$, $s = q$, $t = v$, and $u = w$, these "odd" polynomials also have moments that are multiples of $(n+1)!_q$. There is a version of Theorem 1 for the "odd" polynomials that yields more statistics related to $s(\sigma)$. We do not state this combinatorial theorem here; rather, in this section we state what these "odd" polynomials are, give their moments, and state in Theorem 4 what the statistics related to $s(\sigma)$ are. Clearly the "odd" polynomials are analogues of the Laguerre polynomials $L_n^1(x)$.

We keep the parameters r, s, t, and u. This specialization gives the "even" and "odd" polynomials a combinatorial interpretation as weighted versions of injective maps (see [5], $L_n^0(x)$, and $L_n^1(x)$). This family with "4 q's" also contains other families of orthogonal polynomials of combinatorial interest that are discussed in [8].

Here we list the "odd" polynomials for the three cases in §3, and the respective moments. In each case the polynomials are monic forms of the given polynomials.

(1) little q-Jacobi $p_n(xq(1-q); q, 0; q)$, $\mu_n = q^{-n}(n+1)!_q$;
(2) little q-Jacobi $p_n(x(1-q); q, 0; q)$, $\mu_n = (n+1)!_q$;
(3) q-Laguerre $L_n^1(x(1-q); q)$, $\mu_n = q^{-(n^2+3n)/2}(n+1)!_q$.

The combinatorial theorem that results is Theorem 4 below. To describe the suitable statistic $s(\sigma)$ we shall need an auxillary statistic, $n(\sigma)$, defined as follows. For a given permutation $\sigma \in S_n$, let d be the largest element in the same run as 1, $d \geq 1$. Now partition the elements of σ into three classes: elements to the left of 1, elements in the same run as 1, and those to the right of d. Suppose that over the portion of σ to the right of d no left-to-right minimum constitutes a singleton run. Put $n(\sigma) = 0$. Otherwise, let c be the last (rightmost, smallest) singleton, which is a left-to-right minimum on the portion of σ to the right of d. Let $\text{nleft}(\sigma) := \#\{i : i <$

$\sigma^{-1}(1),\ c < \sigma(i) < d\}$. In this case put $n(\sigma) = 2(d-c) - \text{nleft}(\sigma)$. For example, $n(9 \mid 1\ 5\ 7 \mid 2\ 6 \mid 4 \mid 3\ 8) = 0$, while for $\sigma = 7\ 12 \mid 1\ 6\ 9 \mid 3 \mid 2\ 10\ 11 \mid 5 \mid 4\ 8$ we have $d = 9$, $c = 3$, $\text{nleft}(\sigma) = 1$ (from the element 7), and we get $n(\sigma) = 2(9-3) - 1 = 11$.

We also need variations lsg^* and rsg^* on the statistics lsg and rsg. These differ from the original statistics in two respects. For closers and singletons (the maxima of the runs), the run containing the element 1 is ignored in the calculation of lsg^* and rsg^*. For openers and continuators, the run containing 1 is always counted in lsg^* (if it is to the left) or in rsg^* (if it is to the right).

For example, if $\sigma = 7\ 12 \mid 1\ 6\ 9 \mid 3 \mid 2\ 10\ 11 \mid 5 \mid 4\ 8$, then $\text{lsg}^*(5) = 1$, $\text{lsg}^*(10) = 2$, $\text{lsg}^*(\sigma) = 10$, and $\text{rsg}^*(\sigma) = 8$.

THEOREM 4. *For $\sigma \in S_n$, let*

$$s(\sigma) := \text{run}(\sigma) - 1 + 2\text{lsg}^*(\sigma) + \text{rsg}^*(\sigma) + n(\sigma).$$

Then

$$\sum_{\sigma \in S_n} q^{s(\sigma)} = n!_q.$$

Theorem 4 also holds if $\text{run}(\sigma) - 1$ is replaced by $n - \text{run}(\sigma)$. Moreover, the role of closers and openers can be interchanged in Theorem 4, and there are also 16 variations, although complicated ones.

A version of Theorem 4 holds for permutations in S_{n+1} that satisfy the following condition: 1 and $n+1$ belong to the same run, and no left-to-right minimum to the right of $n+1$ constitutes a singleton run. There are $n!$ such permutations in S_{n+1}.

Finally, we remark that these specializations are the only ones we have found for which the moments factor into an analogue of $n!$. They are also the only specializations that give the three sets of polynomials that were considered. A more extensive study of the specializations of (2.1) appears in [8].

DISCRETE AND CONTINUOUS LIOUVILLE–GREEN–OLVER APPROXIMATIONS: A UNIFIED TREATMENT VIA VOLTERRA–STIELTJES INTEGRAL EQUATIONS*

RENATO SPIGLER† AND MARCO VIANELLO‡

Abstract. A unified treatment of the Liouville–Green–Olver approximation theory for linear second-order differential *and* difference equations is presented. This is based on reduction to Volterra–Stieltjes integral equations with respect to *complex* measures. The present approach embodies and improves several previous results. Moreover, error bounds are obtained for *recessive* solutions of certain difference equations, for which only qualitative results were known. The theory can be applied, for instance, to the asymptotics of certain families of orthogonal polynomials.

Key words. Volterra–Stieltjes integral equations, complex-valued measures, Liouville–Green (WKBJ) approximation, linear difference equations, linear differential equations

AMS subject classifications. 39A12, 34E20, 45D05, 28A10

1. Introduction.

The well-known and widely used Liouville–Green (or WKBJ) approximations for solutions to linear second-order *differential* equations, to which F. W. J. Olver has been able to associate precise estimates for the error terms since 1961 [10], have been recently extended to the case of *difference* equations [4], [12], [13]. Olver's analysis was based on integral equations of the Volterra type satisfied by the relevant error terms. In this paper we proceed similarly, using Volterra integral equations with respect to *complex* Lebesgue–Stieltjes measures to treat both differential equations (absolutely continuous measures) *and* difference equations (discrete measures) at the same time.

As an application, *error bounds* are obtained for *recessive* solutions to a class of linear difference equations of the second order. Only qualitative results were known for this class. Our results can be applied, for instance, to the asymptotics of certain orthogonal polynomials off their essential spectrum.

The paper is organized as follows. In §2 we prove some theorems on existence, uniqueness, and estimates for the solutions of certain types of Volterra–Stieltjes integral equations with respect to complex-valued measures. In §3 these results are related to the Liouville–Green approximation for the solutions of both differential *and* difference equations and several examples and applications are presented.

2. The main theorems.

In this section we prove some theorems yielding existence, uniqueness, and estimates for the solutions to certain linear Volterra integral equations with respect to Lebesgue–Stieltjes complex-valued measures (for generalities on complex-valued measures, we refer the reader to [16, Chap. 11]). These results will be related to the asymptotic theory of *differential* as well as *difference* equations. Throughout the paper we stipulate, for convenience, that

$$\int_x^{+\infty} f\,d\mu \equiv \int_{[x,+\infty)} f\,d\mu$$

for the general (complex) measure μ.

THEOREM 2.1. *Consider the linear integral equation*

$$\varepsilon(x) = \int_x^{+\infty} K(x,t)[\phi(x,t) + \varepsilon(t)]d\mu, \qquad x \in [a, +\infty), \tag{1}$$

of the Volterra type, where $a \in (-\infty, +\infty)$ *and* μ *is a complex (finite) measure. Suppose that for each fixed* $x \in [a, +\infty)$

(i) $K(x,\cdot)$, $\phi(x,\cdot)$ *are* μ*-measurable complex-valued functions*;

(ii) $|K(x,t)|$, $|K(x,t)\phi(x,t)| \le h(x,t)$ $|\mu|$*—almost everywhere for* $t \ge x$, *where* $h(x,\cdot) \in L^1([x,+\infty);\mu)$, *and, moreover,*

$$V(x) := \int_x^{+\infty} h(x,t)d|\mu| \tag{2}$$

is nonincreasing and $\lim_{x\to+\infty} V(x) < 1$.

Then there exists a unique solution $\varepsilon(x)$ *of* (1) *for* $x > x_1$, *where*

$$x_1 := \inf\{x : x \ge a,\ V(x) < 1\}, \tag{3}$$

and the estimate

$$|\varepsilon(x)| \le \frac{V(x)}{1 - V(x)}, \qquad x > x_1 \tag{4}$$

holds.

Proof. Consider the sequence

$$\begin{aligned} \varepsilon_0(x) &\equiv 0, \\ \varepsilon_{s+1}(x) &= \int_x^{+\infty} K(x,t)[\phi(x,t) + \varepsilon_s(t)]d\mu, \qquad s = 0,1,2,\ldots, \end{aligned} \tag{5}$$

that is well defined since it is easily proved, by induction on s, that

$$|\varepsilon_s(x)| \le C_s, \quad C_0 = 0, \quad C_s = (C_{s-1} + 1)V(a), \quad s = 1,2,3,\ldots. \tag{6}$$

Define, formally,

$$\varepsilon(x) := \sum_{s=0}^{\infty} [\varepsilon_{s+1}(x) - \varepsilon_s(x)]. \tag{7}$$

Now,

$$|\varepsilon_1(x)| \le V(x) \tag{8}$$

holds, and, assuming as an inductive hypothesis that

$$|\varepsilon_s(x) - \varepsilon_{s-1}(x)| \le [V(x)]^s, \tag{9}$$

we obtain

$$|\varepsilon_{s+1}(x) - \varepsilon_s(x)| \le \int_x^{+\infty} |K(x,t)|[V(t)]^s d|\mu| \le [V(x)]^s \int_x^{+\infty} |K(x,t)|d|\mu|$$

$$\leq [V(x)]^s \int_x^{+\infty} h(x,t)d|\mu| = [V(x)]^{s+1}. \tag{10}$$

From (8), (9) then (4) follows, where x_1 is given in (3). The estimates (8) and (9) also show that the series in (7) converges uniformly with respect to x for $x \geq \xi$ and for every fixed $\xi > x_1$. Therefore,

$$\begin{aligned} \varepsilon(x) &= \varepsilon_1(x) + \sum_{s=1}^{\infty} \int_x^{+\infty} K(x,t)[\varepsilon_s(t) - \varepsilon_{s-1}(t)]d\mu \\ &= \varepsilon_1(x) + \int_x^{+\infty} K(x,t) \sum_{s=1}^{\infty} [\varepsilon_s(t) - \varepsilon_{s-1}(t)]d\mu, \end{aligned} \tag{11}$$

and hence $\varepsilon(x)$ given by (7) solves (1) for $x > x_1$. It is finally immediately proved that uniqueness holds for $x \geq \xi$, ξ being any fixed number with $\xi > x_1$. □

Remark 2.2. When $V(x_1) < 1$, i.e., "inf" can be replaced by "min" in (3), all results hold up to and include x_1. When h in (2) is *continuous* as a function of x *and* μ is *absolutely continuous*, then if $x_1 > a$, it follows that $V(x_1) = 1$ (and thus, if $V(x_1) < 1$, it is necessary that $x_1 = a$), $V(x)$ being a *continuous* function in this case.

When μ is absolutely continuous, a variant of Theorem 2.1 that has some interest for differential equations can be proved.

THEOREM 2.3. *Suppose that in Theorem* 2.1 μ *is absolutely continuous with density* $p(x)$ *and condition* (ii) *is replaced by*

(ii′) $|K(x,t)|$, $|K(x,t)\phi(x,t)| \leq M_0(t)N_0(x)$ *almost everywhere for* $t \geq x$, *where* $M_0 \in L^1((a,+\infty);\mu)$, *and* N_0 *is* nondecreasing *for* $x \geq a$.

Then, if we set

$$U_0(x) := \int_x^{+\infty} M_0(t)|p(t)|dt, \tag{12}$$

there exists a unique bounded solution $\varepsilon(x)$ *of* (1) *for* $x \geq a$, *with*

$$|\varepsilon(x)| \leq \exp\{N_0(x)U_0(x)\} - 1. \tag{13}$$

Proof. The proof follows the lines of the previous one, the only difference being that (9) and (10) are replaced with

$$|\varepsilon_s(x) - \varepsilon_{s-1}(x)| \leq \frac{[N_0(x)U_0(x)]^s}{s!}, \qquad s = 1,2,\ldots, \tag{14}$$

and

$$\begin{aligned} |\varepsilon_{s+1}(x) - \varepsilon_s(x)| &\leq N_0(x) \int_x^{+\infty} M_0(t) \frac{[N_0(t)U_0(t)]^s}{s!} |p(t)|dt \\ &\leq -[N_0(x)]^{s+1} \int_x^{+\infty} \frac{[U_0(t)]^s}{s!} U_0'(t)dt = \frac{[N_0(x)U_0(x)]^{s+1}}{(s+1)!}, \end{aligned} \tag{15}$$

where (12) has been used. Therefore, (7) leads to the exponential estimate in (13). Moreover, there is a *unique* solution to (1). In fact, suppose that $\varepsilon(x)$ and $\eta(x)$ are

two such solutions. Then, if we define $\delta(x) := \varepsilon(x) - \eta(x)$, there is a constant C such that $|\delta(x)| \le C$ for $x \ge a$, and $\delta(x)$ can be estimated as

$$
\begin{aligned}
|\delta(x)| &\le \int_x^{+\infty} |K(x,t)|\,|\delta(t)|\,|p(t)|dt \\
&\le CN_0(x)\int_x^{+\infty} M_0(t)|p(t)|dt = CN_0(x)U_0(x),
\end{aligned} \tag{16}
$$

and again, by successive resubstitutions (see [11, p. 141]),

$$
|\delta(x)| \le C\frac{[N_0(x)U_0(x)]^s}{s!} \quad \text{for } s \ge 1 \text{ and } x \ge a, \tag{17}
$$

and hence $\delta(x) \equiv 0$ for $x \ge a$. □

3. Applications to differential and difference equations. As is well known, the measure μ appearing in Theorem 2.1, being finite and complex-valued on $\mathbf{R}$ (and thus Lebesgue–Stieltjes), can be represented as the sum of *three* (complex) measures, the first being *absolutely continuous*, the second being *discrete*, and the third being *singular*. When μ reduces merely to the first one, one is led to integral equations that can be related to linear *differential equations*; when μ reduces to the second one, one is led to integral equations that can be related to linear *difference equations*. In this section we analyze these two special cases in detail.

3.1. Differential equations. In this case some regularity results are needed for the solution $\varepsilon(x)$. These can be estabilished by requiring some additional properties on $K(x,t)$, $\phi(x,t)$ and on the density of μ.

THEOREM 3.1. *Suppose that* (1) *is given, the measure* μ *being absolutely continuous with density* $p(x)$. *Moreover, assume that for* $r \in \mathbf{N}$

(i) K, $\phi \in C^r(T)$, T *being the sector* $x \in [a,+\infty)$, $t \ge x$;

(ii) $p \in C^{r-1}([a,+\infty))$ *when* $r > 0$;

(iii) *there exist* $2r+2$ *nonnegative functions* $M_j(t)$, $N_j(x)$, $j = 0,1,\dots,r$, *with* $M_j \in L^1((a,+\infty);\mu)$, $N_j \in C^0([a,+\infty))$, *and*

$$
\left|\frac{\partial^j K}{\partial x^j}\right|, \ \left|\frac{\partial^j (K\phi)}{\partial x^j}\right| \le M_j(t)N_j(x), \quad j = 0,1,\dots,r, \quad \text{a.e. for } t \ge x. \tag{18}
$$

Then the solution $\varepsilon(x)$ *to equation* (1) *is of class* $C^r([a,+\infty))$.

Proof. We notice first that (18) with $j = 0$ ensures that there is *a unique bounded* solution to (1) by Theorem 2.3.

It is then easy to derive from (1) the representation

$$
\begin{aligned}
\varepsilon^{(r)}(x) = &\int_x^{+\infty} \left[\frac{\partial^r (K\phi)}{\partial x^r}(x,t) + \frac{\partial^r K}{\partial x^r}(x,t)\varepsilon(t)\right] p(t)dt \\
&- \sum_{j=0}^{r-1} \frac{d^j}{dx^j}\left\{\left[\frac{\partial^{r-1-j}(K\phi)}{\partial x^{r-1-j}}(x,x) + \varepsilon(x)\frac{\partial^{r-1-j}K}{\partial x^{r-1-j}}(x,x)\right] p(x)\right\}
\end{aligned} \tag{19}
$$

for the rth derivative of $\varepsilon(x)$. The proof of this can be based essentially on legitimate differentiations under the sign of integral, in view of the dominated convergence theorem, which also shows that $\varepsilon \in C^r$. Details are left to the reader. □

Remark 3.2. Observe that Theorem 3.1 for $r = 0$ ensures uniqueness of solutions to (1) *without* requiring their boundedness a priori. In fact, all solutions would be continuous and thus locally bounded while uniqueness holds in a neighborhood of $+\infty$ since by (12) the integral operator in (1) is a contraction for x sufficiently large.

The following variant of Theorem 3.1 may be useful.

THEOREM 3.3. *Theorem* 3.1 *holds if assumption* (ii) *is replaced by*

$$\text{(ii')} \qquad \frac{\partial^j K}{\partial x^j}(x,x) \equiv 0 \quad \textit{for } j = 1,2,\dots,r,$$

when $r > 0$. *Moreover, if* $N_0(x)$ *is also nondecreasing for* $x \geq a$, *the following estimates hold for the derivatives of* $\varepsilon(x)$:

$$|\varepsilon^{(j)}(x)| \leq N_j(x)U_j(x)\exp\{N_0(x)U_0(x)\}, \qquad x \geq a, \tag{20}$$

$$U_j(x) := \int_x^{+\infty} M_j(t)|p(t)|dt, \qquad j = 1,2,\dots,r. \tag{21}$$

Proof. The first part of the theorem can be proved immediately by observing that (19) still holds true with all terms in the sum equal to zero. As for the second part, similarly to (19), from (5) the following is obtained:

$$\begin{aligned} &\varepsilon_0(x) \equiv 0, \\ &\varepsilon_{s+1}^{(j)}(x) = \int_x^{+\infty} \left[\frac{\partial^j (K\phi)}{\partial x^j}(x,t) + \frac{\partial^j K}{\partial x^j}(x,t)\varepsilon_s(t)\right] p(t)dt, \qquad s = 0,1,2,\dots. \end{aligned} \tag{22}$$

Therefore, by using the monotonicity of $U_0(x)$ (and of $N_0(x)$) it can be proved by induction on s and (14) that

$$|\varepsilon_{s+1}^{(j)}(x) - \varepsilon_s^{(j)}(x)| \leq N_j(x)U_j(x)\frac{[N_0(x)U_0(x)]^s}{s!} \quad \text{for } s = 0,1,2,\dots, \tag{23}$$

and thus (20) follows. In fact, exchanging series and derivatives in (7) is permissible because (23) shows the *uniform* convergence of $\sum_{s=0}^{\infty}[\varepsilon_{s+1}^{(j)}(x) - \varepsilon_s^{(j)}(x)]$ for each j since $N_0(x)U_0(x) \leq N_0(a)U_0(a)$ for $x \geq a$. □

Moreover, we have the following theorem.

THEOREM 3.4. *Under all hypotheses of Theorem* 3.1, *with condition* (ii') *replacing* (ii), *and the additional estimates*

$$\left|\frac{\partial^j K}{\partial x^j}\right|, \left|\frac{\partial^j (K\phi)}{\partial x^j}\right| \leq P_j(x,t), \qquad j = 1,2,\dots,r, \quad \textit{a.e. for } t \geq x, \tag{24}$$

where $P_j(x,\cdot) \in L^1((x,+\infty);\mu)$ *and*

$$W_j(x) := \int_x^{+\infty} P_j(x,t)|p(t)|dt \tag{25}$$

is nonincreasing, then

(I) *if the assumptions of Theorem* 2.1 *are also satisfied, we obtain*

$$|\varepsilon^{(j)}(x)| \leq \frac{W_j(x)}{1 - V(x)} \quad \textit{for } x > x_1, \tag{26}$$

$V(x)$ *being defined in* (2) *and* x_1 *in* (3), *whereas,*

(II) *if* $N_0(x)$ (*see Theorem* 3.1) *is nonincreasing, we obtain*

$$|\varepsilon^{(j)}(x)| \le W_j(x)\exp\{V(x)\} \quad \textit{for } x \ge a. \tag{27}$$

Proof. The proof is similar to that of Theorem 3.3, with inequality (23) being replaced by

$$|\varepsilon_{s+1}^{(j)}(x) - \varepsilon_s^{(j)}(x)| \le W_j(x)[V(x)]^s, \qquad s = 0,1,2,\dots \tag{28}$$

in case (I) and by

$$|\varepsilon_{s+1}^{(j)}(x) - \varepsilon_s^{(j)}(x)| \le W_j(x)\frac{[V(x)]^s}{s!}, \qquad s = 0,1,2,\dots \tag{29}$$

in case (II). □

Theorems 3.1, 3.3, and 3.4 turn out to be useful in the framework of linear differential equations. Here we consider linear second-order differential equations like

$$y'' + [f(x) + g(x)]y = 0, \qquad x \ge 1, \quad f, g \in C^0([1,+\infty)), \tag{30}$$

where f is real valued, g is complex valued, and

(a) $f(x) \ne 0$ in $[1,+\infty)$, $f \in C^2$, and

$$\mathcal{V}(x) = \int_x^{+\infty} |f^{-1/4}(f^{-1/4})'' - gf^{-1/2}|dt < \infty, \tag{31}$$

or

(b) $f(x) \equiv 0$ in $[1,+\infty)$ and

$$\mathcal{M}_k(x) = \int_x^{+\infty} t^k|g(t)|dt < \infty \quad \text{for } k = 1 \text{ or } 2. \tag{32}$$

Case (a) is the typical case considered by F. W. J. Olver in connection with the Liouville–Green approximation theory (see [11, Chap. 6]). If $f(x) > 0$ (oscillatory case), when we look for solutions to (30) of the form

$$y_j(x) = f^{-1/4}(x)\exp\left\{(-1)^j i\int^x f^{1/2}(t)dt\right\}[1 + \varepsilon_j(x)], \qquad j = 1,2, \tag{33}$$

it turns out that the error term, $\varepsilon_j(x)$, must be a C^2-solution to an integral equation like (1), with $K(x,t) = (1/2i)[1 - \exp\{(-1)^j 2i\int_x^t f^{1/2}(s)ds\}]$, $\phi(x,t) \equiv 1$, $d\mu = [f^{-1/4}(f^{-1/4})'' - gf^{-1/2}]dt$. Choosing in (ii′) of Theorem 2.3, $M_0(t) \equiv 1$, $N_0(x) \equiv 1$, one gets $U_0(x) = \mathcal{V}(x)$ and hence Olver's result [11, Thm. 2.1, Chap. 6],

$$|\varepsilon_j(x)| \le \exp\{\mathcal{V}(x)\} - 1, \tag{34}$$

holds. As for the derivatives, one can choose, in Theorem 3.3, $M_1(t) \equiv 1$, $N_1(x) = f^{1/2}(x)$, and thus $U_1(x) = U_0(x)$ and $|\varepsilon_j'(x)| \le f^{1/2}(x)U_0(x)\exp\{U_0(x)\}$. The latter implies that $f^{-1/2}(x)\varepsilon_j'(x) = O(U_0(x))$, as in Olver's theorem [11, Thm. 2.1, Chap. 6].

Alternatively, one could apply Theorem 2.1 (and Theorem 3.4). In this case the estimates hold, in general, only for $x > x_1$ (x_1 being defined in (3)). However, $\varepsilon_j(x) = O(V(x))$ and $V(x) \le U_0(x)$ when $h = |K| = |K\phi| = |\sin(\int_x^t f^{1/2}(s)ds)|$ is

chosen. Moreover, the geometric estimate (4) *may* provide better estimates for fixed x, with respect to certain parameters. This fact can be related to the *double asymptotic* nature of the Liouville–Green approximations with respect to both the independent variable and the parameters entering $f+g$. Here is a simple example, for the purpose of illustration, in which all calculations can be carried out explicitly. Let $f(x) \equiv 1$, $g(x) = x^{-\gamma}$, $\gamma > 2$ on $x \geq 1$. Then $|K| = |K\phi| = |\sin(t-x)|$ and $|p| = x^{-\gamma}$. Choosing $h(x,t) = t-x$ and $M_0(t) \equiv 1$, $N_0(x) \equiv 1$, we get $V(x) = x^{2-\gamma}/(\gamma-1)(\gamma-2)$ and $U_0(x) = x^{1-\gamma}/(\gamma-1)$. Now, the fact that the geometric estimate (4) yields an error of order of $O(\gamma^{-2})$ for fixed x while the exponential estimate (13) gives an order of $O(\gamma^{-1})$ suggests that the former may be better. Indeed, if we compare the two estimates for x such that, e.g., $V(x) \leq \frac{1}{2}$, clearly $V/(1-V) \leq 2V < U_0 < \exp\{U_0\} - 1$ as long as $[2/(\gamma-1)(\gamma-2)]^{1/(\gamma-2)} \leq x < \gamma/2 - 1$, and thus the geometric estimate performs better. Case (a) with $f(x) < 0$ (nonoscillatory case) can be handled in a similar way, and Olver's results are recovered again.

Case (b) has been studied, for instance, in [6], [13]. If (32) holds for $k = 1$, when one looks for a (recessive) solution of the form

$$y_1(x) = 1 + \varepsilon_1(x), \tag{35}$$

$\varepsilon_1(x)$ turns out to be a C^2-solution of (1) with $K(x,t) = t-x$, $\phi(x,t) \equiv 1$, $d\mu = g\,dt$. In this case it is known that a second (dominant) solution $y_2(x) \sim x$ as $x \to +\infty$ exists. If (18) holds for $k = 2$, in addition, when one looks for a (dominant) solution like

$$y_2(x) = x + \varepsilon_2(x), \tag{36}$$

one finds that $\varepsilon_2(x)$ must be a C^2-solution of (1) with $K(x,t) = t-x$, $\phi(x,t) = t$, and $d\mu$ as before. As in case (a), choosing in (ii′) of Theorem 2.3 $M_0(t) = t^k$, $N_0(x) \equiv 1$ (see [6]), we obtain $U_0(x) = \mathcal{M}_k(x)$. Concerning the derivatives, Theorem 3.3 can be applied with $M_1(t) = t^{k-1}$, $N_1(x) \equiv 1$.

It is also possible to apply Theorems 2.1 and 3.4 with $h(x,t) = t^{k-1}(t-x)$, $P_1(x,t) = t^{k-1}$ (see [13]). The advantage obtainable by using the geometric versus the exponential estimates is more pronounced here. In fact, for $g(x) = x^{-\gamma}$, $\gamma > 2$, we get (for $k = 1$) $V(x) = U_0(x)/(\gamma-1)$ for all x. Therefore, comparing the two estimates, (4) and (13), for x such that, e.g., $V(x) \leq \frac{1}{2}$, we find that the geometric estimate is certainly sharper for $\gamma > 3$. Such an estimate is of the order of $O(\gamma^{-2})$, whereas the exponential one is of the order of $O(\gamma^{-1})$, as in case (a), but this holds now without any further limitation on x.

3.2. Difference equations. When the measure μ in Theorem 2.1 is merely discrete, with discrete support $\mathbf{Z}_\nu := \{n \in \mathbf{Z} : n \geq \nu\}$, ν being a given integer, the integral equation (1) plays a role in studying linear difference equations. Hereafter we shall be concerned with the asymptotic solution of second-order difference equations like

$$\Delta^2 y_n + (\alpha + g_n) y_n = 0, \qquad n \in \mathbf{Z}_\nu, \tag{37}$$

$\Delta y_n := y_{n+1} - y_n$, where we consider the following.

(A) $\alpha > 0$ and $\sum_{n=\nu}^{\infty} |g_n| < \infty$;

(B) $\alpha = 0$ and $\sum_{n=\nu}^{\infty} n^k |g_n| < \infty$, $k = 1$ or 2;

(C) $\alpha < 0$, $\alpha \neq -1$, and $\sum_{n=\nu}^{\infty} |g_n| < \infty$.

It is worth noting that the importance of equations of the type

$$\Delta^2 y_n + q_n y_n = 0 \tag{38}$$

stems from the fact that they represent a kind of canonical form for all difference equations like

$$Y_{n+2} + A_n Y_{n+1} + B_n Y_n = 0. \tag{39}$$

Indeed, the transformation

$$Y_n = \alpha_n y_n, \quad \alpha_n := \alpha_{\nu+1} \prod_{k=\nu}^{n-2} \left(-\frac{A_k}{2}\right), \quad n \geq \nu + 2, \tag{40}$$

α_ν and $\alpha_{\nu+1} \neq 0$ being arbitrary constants, takes (39) into (38) with a suitable q_n, provided that $A_k \neq 0$ (at least for k sufficiently large); see [12], [13].

Case (A), in which all real solutions turn out to be *oscillatory*, was studied in some detail in [12]. If one looks for a solution of the form $y_n = \lambda^n(1 + \varepsilon_n)$, λ being one of the roots of the characteristic equation of (37) with $g_n \equiv 0$, $\lambda = 1 \pm i\sqrt{\alpha}$, the "integral equation"

$$\varepsilon_n = \frac{1}{2\lambda(\lambda - 1)} \sum_{k=n}^{\infty} \left(1 - (\lambda/\overline{\lambda})^{k-n+1}\right) g_k(1 + \varepsilon_k) \tag{41}$$

for the error term ε_n is obtained. In [12] it was proved *directly* that such an equation has a solution estimated as

$$|\varepsilon_n| \leq \frac{V_n}{1 - V_n}, \tag{42}$$

$$V_n := \frac{1}{[\alpha(\alpha + 1)]^{1/2}} \sum_{k=n}^{\infty} |g_k|. \tag{43}$$

Both the existence of the solution and the estimate (42), (43) hold for $n \geq n_1 := \min\{n \in \mathbf{Z}_\nu : V_n < 1\}$. This result represents an extension to the discrete domain of the Liouville–Green–Olver approximation theorem for oscillatory-type differential equations (see [11, Thm. 2.2, p. 196]).

Note the formal analogy of (37) with (30) when we take $f(x) \equiv \text{const.} > 0$ (case (a), §3.1). In fact, the unified treatment presented in this paper leads to (42), (43) when we choose in Theorem 2.1 $\phi(x,t) \equiv 1$, $K(x,t) = (1/2\lambda(\lambda - 1))(1 - (\lambda/\overline{\lambda})^{t-x+1})$, and $\mu = \sum_{k=\nu}^{\infty} g_k \delta_k$, where δ_k is the Dirac measure centered in $t = k$. The function $h(x,t)$ estimating K, $K\phi$ in (ii) of Theorem 2.1 can be chosen equal to the constant $1/|\lambda(\lambda - 1)| = [\alpha(\alpha + 1)]^{-1/2}$. It is easily seen that $V(x)$ is left-continuous and piecewise constant and that $x_1 = n_1$; also, $a = \nu$, $V_n = V(n)$. Finally, observe that the solution to (1) restricted to the integers $n \geq n_1$ also solves (41) and that the estimate (42), (43) holds.

Case (B) represents the discrete analogue of case (b) of §3.1 and was studied in [13]. In [13] a unified approach was followed; it was based, however, on a special *subclass* of integral equations like those in (1). Indeed, when one looks for solutions to (37) with $\alpha = 0$ of the form $y_n = n^{k-1} + \varepsilon_n$, with $k = 1$ or 2, an "integral equation"

of type (1) is obtained, with $K(x,t) = x - t + 1$, $\phi(x,t) = t^{k-1}$, and $\mu = \sum_{k=\nu}^{\infty} g_k \delta_k$ ($\nu = 1$). If one takes $h(x,t) = t^{k-1}(t - x + 1)$, estimates are obtained for the error terms corresponding to the *recessive* and the *dominant* solution ($k = 1$ *or* 2 also refers to the finiteness of the first *or* the second moment of $|g_n|$: When $\sum^{\infty} n^2|g_n| = +\infty$ but $\sum^{\infty} n|g_n| < \infty$ the estimate for the recessive solution still holds true).

A Liouville–Green–Olver approximation result for case (C) seems to be missing so far. Note that, unlike in the previous cases, *qualitative* asymptotics for the solutions to (37) with $\alpha < 0$ could be obtained here by Poincaré's or Perron's theorems [9]. Deriving *precise error bounds*, however, is our goal, in the spirit of Olver's approach. This problem represents a discrete analogue of the differential case with solutions of the exponential type in [11, Thm. 2.1, p. 193]. We state our result as a theorem.

THEOREM 3.5. *Suppose that* (37) *is given with* $\alpha = -\beta < 0$, $\beta \neq 1$, *and* $\sum^{\infty} |g_n| < \infty$ (*see case* (*C*)). *Then there exist* $n_1 \in \mathbf{Z}_\nu$ *and two linearly independent solutions to* (37), $y_n^{\pm}$, *such that*

$$y_n^- = (\lambda_-)^n[1 + \varepsilon_n], \quad n \geq n_1; \qquad y_n^+ \sim (\lambda_+)^n, \quad n \to \infty, \tag{44}$$

where $\lambda_\pm = 1 \pm \sqrt{\beta}$ *are the roots of the characteristic equation associated to* (37) *with* $g_n \equiv 0$. *For the error term* ε_n *the estimate*

$$|\varepsilon_n| \leq \frac{V_n}{1 - V_n}, \quad V_n := \frac{1}{2\sqrt{\beta}(\sqrt{\beta} - 1)} \sum_{k=n}^{\infty} |g_k|, \quad n \geq n_1 \tag{45}$$

holds and

$$n_1 = \min\{n \in \mathbf{Z}_\nu : V_n < 1\}. \tag{46}$$

Moreover, when g_n *is real,* $y_n^{\pm}$ *are real.*

Remark 3.6. In view of (45), y_n^- and y_n^+ are *recessive* and *dominant* solutions, respectively. Note that, unlike the corresponding case for differential equations, while $y_n^+ \sim (1 + \sqrt{\beta})^n$ grows exponentially, $y_n^- \sim (1 - \sqrt{\beta})^n$ and thus decays exponentially when $0 < \beta < 1$, but it exhibits *oscillations* exponentially growing (when $\beta > 4$) *or* exponentially decreasing (when $1 < \beta < 4$); when $\beta = 4$, $y_n^- \sim (-1)^n$. The case $\beta = 1$ is pathological in that the unperturbed equation (see (37) with $g_n \equiv 0$) degenerates, having the lowest-order coefficient vanishing (see [8] and [9]), and *cannot* be treated by the present approach.

Remark 3.7. The qualitative behavior $y_n^{\pm} \sim (\lambda_\pm)^n$, $n \to \infty$, *cannot* be obtained directly from Poincaré's or Perron's theorems, despite the fact that such theorems can be applied, since $\lambda_+ \neq \lambda_-$ [8, §5.3, p. 221].

Remark 3.8. Observe even here the *double asymptotic nature* of the Liouville–Green–Olver approximations with respect to both n and β (as $n \to \infty$, and as $\beta \to +\infty$); see (45). In particular, $V_n = O(\beta^{-1})$, whereas the corresponding quantity for the analogous differential equation, $y'' + (-\beta + g(x))y = 0$, $g \in L^1(1, +\infty)$, is $O(\beta^{-1/2})$; see [11] and [12].

Proof of Theorem 3.5. Looking for a solution of the form $y_n^- = (\lambda_-)^n[1 + \varepsilon_n]$, one is led to the difference equation

$$(\lambda_-)^2 \Delta^2 \varepsilon_n + 2\lambda_-(\lambda_- - 1)\Delta\varepsilon_n + g_n(1 + \varepsilon_n) = 0 \tag{47}$$

for the error term. It is then easily proved that any solution of the linear discrete Volterra-type "integral" equation

$$\varepsilon_n = \sum_{k=n}^{\infty} (1 - \rho^{k-n+1}) g_k \sigma(1 + \varepsilon_k), \tag{48}$$

$$\rho = \frac{\lambda_-}{\lambda_+} = \frac{1-\sqrt{\beta}}{1+\sqrt{\beta}}, \qquad \sigma = \frac{1}{2\lambda_-(\lambda_- - 1)} = \frac{1}{2\sqrt{\beta}(\sqrt{\beta}-1)}, \tag{49}$$

also solves (47). The easy but lengthy verification is left to the reader; see [12]. At this point, consider equation (1), with $\phi(x,t) \equiv 1$, $K(x,t) = \sigma(1-\rho^{t-x+1})$, $x \geq a = \nu$, $\mu = \sum_{k=\nu}^{\infty} g_k \delta_k$, and choose $h(x,t) \equiv |\sigma|$, since $|\rho| < 1$. Then we use Theorem 2.1 to obtain (45) since it is clear that the solution to (1), restricted to the integers $\geq n_1$, also solves (48) and $V_n = V(n)$. Note that uniqueness of solutions to (48) does *not* follow immediately from Theorem 2.1 but can be proved directly for $n \geq n_1$.

As for the second (dominant) solution, we consider a solution of the form

$$z_n := y_n^- \sum_{k=n^*}^{n-1} \frac{C_k}{y_k^- y_{k+1}^-} \tag{50}$$

(see [8, §3.5, Thm. 3.9, p. 94]), n^* being the smallest integer $\geq n_1$ such that $y_n^- \neq 0$ for $n \geq n^*$, and C_k denoting the *Casoratian* of y_k^- and z_k. The latter is [8, §3.5]

$$C_k = C_{n^*} \prod_{j=n^*}^{k-1} (1 - \beta + g_j), \tag{51}$$

where C_{n^*} is a nonzero constant that we shall choose. Now,

$$\frac{z_n}{(\lambda_+)^n} \sim \left(\frac{\lambda_+}{\lambda_-}\right)^{-n} \sum_{k=n^*}^{n-1} \frac{C_k}{(\lambda_-)^{2k+1}[1+o(1)]}, \qquad n \to \infty. \tag{52}$$

When $0 < \beta < 1$, using *Cesaro's* theorem, we get

$$\frac{z_n}{(\lambda_+)^n} \sim \frac{C_n/(\lambda_-)^{2n+1}}{(\lambda_+/\lambda_-)^{n+1} - (\lambda_+/\lambda_-)^n} = \frac{(1-\beta)^{-n^*}}{2\sqrt{\beta}} C_{n^*} \prod_{j=n^*}^{n-1} \left(1 + \frac{g_j}{1-\beta}\right), \quad n \to \infty. \tag{53}$$

In fact, $(\lambda_+/\lambda_-)^n \uparrow +\infty$ as $n \to \infty$, and the product in (53) converges in view of the fact that $\sum^{\infty} |g_j| < \infty$. When $\beta > 1$, the same condition holds true, although the classical Cesaro's theorem cannot be invoked. Such a generalized version of Cesaro's theorem is contained in [14]. Finally, choosing the constant C_{n^*} in such a way that the limit of the right-hand side of (53) is equal to 1, one obtains $z_n = y_n^+$. □

Remark 3.9. When one looks for a dominant solution of the form $y_n^+ = (\lambda_+)^n(1+\eta_n)$, an error equation for η_n similar to (48) is obtained, with $\rho = \lambda_+/\lambda_-$, $\sigma = 1/2\lambda_+(\lambda_+ - 1)$. However, $|\rho| > 1$ prevents proving, in general, the existence itself of such a solution, as was done for ε_n. A noteworthy case, however, occurs when $g_n = \rho^{-n}u_n$, with $\sum^{\infty} |u_n| < \infty$, e.g., $g_n = c^{-n}$, with $|c| > |\rho|$. Here Theorem 2.1 can be applied with $\phi(x,t) \equiv 1$, $K(x,t) = \rho^{-t}(1-\rho^{t-x+1})$, $\mu = \sum_{k=\nu}^{\infty} u_k \delta_k$, and $h(x,t) \equiv 1$ for $x \geq 1$. The estimate

$$|\eta_n| \leq \frac{W_n}{1-W_n}, \qquad n \geq n_2 = \min\{n \in \mathbf{Z}_\nu : W_n < 1\},$$
$$W_n := \frac{1}{2\sqrt{\beta}|\sqrt{\beta}-1|} \sum_{k=n}^{\infty} |u_k| \tag{54}$$

is then obtained.

It may be useful, in closing, to reformulate the hypotheses of Theorem 3.5 in terms of the coefficients of (39). Since in (38) one obtains

$$q_n = -1 + \frac{4B_n}{A_n A_{n-1}} \tag{55}$$

for $n \geq \nu + 1$ (see [12] and [13]), they become

$$\lim_{n\to\infty} \frac{B_n}{A_n A_{n-1}} =: L, \qquad \text{with } L < \frac{1}{4}, \quad L \neq 0, \tag{56}$$

$$\sum_{k=\nu+1}^{\infty} \left| \frac{B_n}{A_n A_{n-1}} - L \right| < \infty. \tag{57}$$

We conclude with two simple applications.

Example 3.10 (perturbed Fibonacci equation). Consider

$$f_{n+2} - (1+\sigma_n) f_{n+1} - (1+\tau_n) f_n = 0, \qquad n \geq 0, \tag{58}$$

where

$$\sum_{n=0}^{\infty} (|\sigma_n| + |\tau_n|) < \infty, \tag{59}$$

and $\sigma_n \neq -1$ for $n \geq 0$. The latter restriction can be removed by confining ourselves to $n \geq \nu$ with ν sufficiently large. Then, setting $f_n = \alpha_n y_n$, with

$$\alpha_n = \prod_{k=0}^{n-2} \left(\frac{1+\sigma_k}{2} \right) \tag{60}$$

(cf. (40)) leads to (38) with

$$q_n = -1 - 4 \frac{1+\tau_n}{(1+\sigma_n)(1+\sigma_{n-1})}. \tag{61}$$

Now, $q_n \to -5$ as $n \to \infty$, and then (56) and (57) are satisfied with $L = -1$ and owing to (59). Since $\beta = 5$,

$$g_n = 4 \frac{(\sigma_n + \sigma_{n-1} + \sigma_n \sigma_{n-1} + \tau_n)}{(1+\sigma_n)(1+\sigma_{n-1})} \tag{62}$$

and $\lambda_\pm = 1 \pm \sqrt{5}$, we obtain a *recessive* solution to (58) like

$$f_n^- = \left(\frac{1-\sqrt{5}}{2} \right)^n \left(\prod_{k=0}^{n-2} (1+\sigma_k) \right) (1+\varepsilon_n) \quad \text{for } n \geq n_1, \tag{63}$$

with

$$|\varepsilon_n| \leq \frac{V_n}{1-V_n}, \qquad V_n := \frac{2}{\sqrt{5}(\sqrt{5}-1)} \sum_{k=n}^{\infty} \left| \frac{\sigma_n + \sigma_{n-1} + \sigma_n \sigma_{n-1} + \tau_n}{(1+\sigma_n)(1+\sigma_{n-1})} \right| \quad \text{for } n \geq n_1, \tag{64}$$

with n_1 defined in (46) (cf. Theorem 3.5). Moreover, a *dominant* solution f_n^+ exists, with

$$f_n^+ \sim \left(\frac{1+\sqrt{5}}{2}\right)^n \prod_{k=0}^{\infty}(1+\sigma_k), \qquad n \to \infty. \tag{65}$$

Note that the convergence of the infinite product in (65) is guaranteed by (59).

Example 3.11 (orthogonal polynomials). A field in which asymptotic representations of solutions to three-term recurrent equations is important is that of orthogonal polynomials. In [5] an application is made of the discrete WKB theory developed in [4] to a class of orthogonal polynomials obeying a recurrence with regularly and slowly varying coefficients. Here we show that Theorem 3.5 can be applied to obtain qualitative asymptotics for a well-known class of orthogonal polynomials, on the real line off their essential spectrum. Consider, in fact, the linear recurrence

$$P_{n+2}(x) - (x-\gamma_n)P_{n+1}(x) + \delta_n P_n(x) = 0, \tag{66}$$

with γ_n real, $\delta_n > 0$, $\gamma_n \to \gamma$ and $\delta_n \to \delta$, γ and δ both finite, which defines along with the initial conditions $P_{-1}(x) \equiv 0$, $P_0(x) \equiv 1$, a family of orthogonal polynomials having as essential spectrum the interval $[\gamma - 2\sqrt{\delta}, \gamma + 2\sqrt{\delta}]$; see, e.g., [2]. In this case we obtain from (56)

$$L = \frac{\delta}{(x-\gamma)^2}, \tag{67}$$

and thus $L < 1/4$ for x *off* the essential spectrum. Note then that $x \neq \gamma$. In view of the fact that $\gamma_n \to \gamma$ we see that also $x - \gamma_n \neq 0$ for all n sufficiently large ($n \geq \nu(x)$). This ensures that the transformation in (40),

$$\alpha_n(x) = \prod_{k=\nu(x)}^{n-2}\left(\frac{x-\gamma_k}{2}\right), \tag{68}$$

is applicable and the previous theory can be used. Notice also that a *uniform* lower bound for $\nu(x)$ can be found for x off the essential spectrum. Condition (47) becomes

$$\sum_{n=\nu(x)+1}^{\infty}\left|\frac{\delta_n}{(x-\gamma_n)(x-\gamma_{n-1})} - \frac{\delta}{(x-\gamma)^2}\right| < \infty. \tag{69}$$

Observe that the assumption $\sum^{\infty}(|\gamma_n - \gamma| + |\delta_n - \delta|) < \infty$, which, incidentally, ensures the orthogonality measure to be absolutely continuous in the essential spectrum, *implies* (69) and appears, e.g., in [7] as a key condition for the asymptotic analysis of the linear recurrence (66). Such a condition also appears, for instance, in [15]. Apart from having a weaker condition in (69), asymptotic results obtainable through Theorem 3.5 off the essential spectrum *coincide* with those reported in [7], where completely different techniques were adopted. Our theory, however, yields a precise *error estimate* for a *recessive* solution. This occurrence may be useful in connection to certain well-known numerical algorithms (see [3]).

TRUNCATION ERROR FOR LIMIT PERIODIC SCHUR ALGORITHMS*

W. J. THRON†

Abstract. The Schur algorithm arises in connection with the approximation of functions bounded in the unit disk. For a limit periodic Schur algorithm $\{T_n(z,w)\}$ it is shown that the truncation error is

$$|T_n(z,0) - T(z)| < c(R')^n,$$

where c depends on R' but is independent of n, and

$$1 > R' > \left|\frac{1+\bar{\gamma}zw_1}{1+\bar{\gamma}zw_2}\right|.$$

Here w_1 and w_2 are the fixed points of the limit transformation $t(z,w) = (\gamma + zw)/(1+\bar{\gamma}zw)$, $0 < |\gamma| < 1$. In the proof use is made of the facts

$$\lim_{n\to\infty} T_n^{-1}(\infty) = w_1, \qquad \lim_{n\to\infty} T^{(n)}(w) = w_2,$$

which are proved here.

Key words. Schur algorithm, limit periodic, truncation error

1. Introduction.

The algorithm to be studied here was introduced by Schur [8] in 1917 to investigate functions holomorphic and bounded in the unit disk. For convenience the bound is taken to be 1. We are thus led to consider the family

$$U := [f : f(z) \text{ is holomorphic and } |f(z)| \le 1 \text{ for } |z| < 1].$$

Define

$$t_n(z,w) := \frac{\gamma_n + zw}{1+\bar{\gamma}_n zw}, \qquad n \ge 0, \tag{1,1}$$

and

$$t_n^{-1}(z,u) := \frac{1}{z}\,\frac{\gamma_n - u}{\bar{\gamma}_n u - 1}. \tag{1.2}$$

In terms of the sequence $\{t_n\}$ we define the sequence $\{T_n\}$ inductively as follows:

$$T_0(z,w) := t_0(z,w), \qquad T_n(z,w) := T_{n-1}(z, t_n(z,w)), \quad n \ge 1. \tag{1.3}$$

This can be expressed informally as

$$T_n(z,w) = t_0 \circ \cdots \circ t_n(z,w).$$

In the following we will frequently not indicate the dependence of the t_k and the T_n on z. Since the t_n are linear fractional transformations in w, so is T_n. Hence it can be written as

$$T_n(z,w) := \frac{C_n(z)zw + D_n(z)}{E_n(z)zw + F_n(z)}, \tag{1.4}$$

where the C_n, D_n, E_n, F_n are polynomials in z satisfying the recursion relationships

$$C_0 = 1, \quad D_0 = \gamma_0, \quad E_0 = \bar{\gamma}_0, \quad F_0 = 1,$$

$$\begin{pmatrix} C_n \\ E_n \end{pmatrix} = z \begin{pmatrix} C_{n-1} \\ E_{n-1} \end{pmatrix} + \bar{\gamma}_n \begin{pmatrix} D_{n-1} \\ F_{n-1} \end{pmatrix}, \qquad n \geq 1, \tag{1.5}$$

$$\begin{pmatrix} D_n \\ F_n \end{pmatrix} = \begin{pmatrix} D_{n-1} \\ F_{n-1} \end{pmatrix} + \gamma_n z \begin{pmatrix} C_{n-1} \\ E_{n-1} \end{pmatrix}, \qquad n \geq 1.$$

Schur showed that for every $f \in U$ one can determine a sequence of functions $\{f_n\}$, $f_n \in U$, and a sequence of complex numbers $\{\gamma_n(f)\}$, $|\gamma_n(f)| \leq 1$ inductively, by the rule

$$f_0 =: f, \qquad f_n(z) := t_{n-1}^{-1}(z, f_{n-1}(z)), \quad n \geq 1, \qquad \gamma_n(f) := f_n(0), \quad n \geq 0.$$

The process terminates if a $\gamma_n(f)$ satisfies $|\gamma_n(f)| = 1$. Schur then showed that for the sequence $\{T_n\}$, where $\gamma_n = \gamma_n(f)$, $n \geq 0$,

$$\lim_{n\to\infty} T_n(z, 0) = f(z) \quad \text{for } |z| < 1.$$

It is also true that for any sequence $\{\gamma_n\}$, with $|\gamma_n| < 1$, $n \geq 0$, as the only restriction, $\{T_n(z, 0)\}$ converges uniformly on compact subsets of $|z| < 1$ to a function in U; see [3, Thm. 4].

In what follows we shall assume that

$$|\gamma_n| < 1, \qquad n \geq 0.$$

For any such sequence $\{\gamma_n\}$ we call the mapping $\{\gamma_n\} \to \{T_n\}$ a *Schur algorithm*. If $\gamma_n \to \gamma$, then we speak of a *limit periodic Schur algorithm* (lpS). Frequently we use this expression also for $\{T_n\}$. Schur referred to his algorithm as "kettenbruchartig," that is, as being closely related to the continued-fraction algorithm. Thus it is not unreasonable to look for results for lpS analogous to those found for limit periodic continued fractions. Since all Schur algorithms and thus, in particular, all lpS converge, we will here be concerned with the truncation error $T_n(z, 0) - T$ for lpS.

In §§2 and 3 we derive some preliminary results. In §4 we use the concept "invariance of the cross ratio under linear fractional transformations" to obtain a formula for the truncation error $T_n(0) - T$ as well as an expression for the ratio $(T - T_n(w_2))/(T - T_n(0))$, from which it can be deduced that $\{T_n(w_2)\}$ converges faster to T than does $\{T_n(0)\}$. In these formulas the sequences $\{T_n^{-1}(\infty)\}$ and the "tail" sequence $\{T^{(n)}\}$ play important roles. The convergence of $\{T_n^{-1}(\infty)\}$ to w_1 is proved in §5. In §6 we show that the tail sequence converges to w_2. The truncation error takes the form $K(R')(R')^n$, where

$$\left| \frac{1 + \bar{\gamma} z w_1}{1 + \bar{z} w_2} \right| < R' < 1.$$

Let

$$\delta_n = \gamma_n - \gamma, \qquad d_n = \max_{k \geq n} |\delta_k|. \tag{1.6}$$

Our results here are based on the assumption $d_n \to 0$. In another paper we shall study lpS under the stronger assumption $\sum d_n < \infty$ and obtain results on "separate convergence."

Some aspects of the Schur algorithm have previously been investigated [1], [5], [6], [9]. The algorithm can also be approached by way of *Schur fractions* (see [2] and the references therein). Truncation errors have been obtained for Schur fractions and the closely related positive PC fractions [1], [6].

2. The transformation $T(z,w)$. In our study the "limit" transformation

$$t(z,w) = \frac{\gamma + zw}{1 + \bar{\gamma} zw} \tag{2.1}$$

plays an important role. Frequently, the three cases

$$\gamma = 0, \quad 0 < |\gamma| < 1, \quad |\gamma| = 1$$

have to be treated separately. For the limit transformation we have

$$t(z,w) = zw \quad \text{if } \gamma = 0, \qquad t(z,w) \equiv e^{i\theta}, \quad w \neq -e^{i\theta} \quad \text{if } \gamma = e^{i\theta}. \tag{2.2}$$

If $0 < |\gamma| < 1$, the fixed points w_i of $t(z,w)$ are given by

$$w_i = \frac{\gamma + zw_i}{1 + \bar{\gamma} zw_i}, \tag{2.3}$$

or

$$\bar{\gamma} z w_i^2 + (1 - z) w_i - \gamma = 0. \tag{2.4}$$

Hence

$$w_i(z) := \frac{z - 1 + (-1)^i \sqrt{(z-1)^2 + 4|\gamma|^2 z}}{2\bar{\gamma} z}, \qquad \operatorname{Re} \sqrt{\ } > 0. \tag{2.5}$$

The case $|\gamma| = 1$ can be subsumed under the case $0 < |\gamma| < 1$ if we understand by $w_i(z)$ the quantities given by (2.5). From (2.2) we see that $w_2 = e^{i\theta}$ is indeed the attractive fixed point of the singular transformation $t(z,w) = e^{i\theta}$. The other solution of (2.4), that is, $-e^{i\theta}/z$, is not a fixed point but the exceptional point for which $t(z,w)$ is undefined. The fixed points of $t(z,w) = zw$ are 0 and ∞, and thus that case needs to be considered separately and will be excluded in the rest of this paper.

For the two cases $0 < |\gamma| < 1$ and $|\gamma| = 1$ the identities

$$w_1 w_2 = -\frac{\gamma}{\bar{\gamma} z}, \tag{2.6a}$$

$$w_i(1 + \bar{\gamma} z w_i) = \gamma + z w_i, \tag{2.6b}$$

$$z\bar{\gamma}(w_1 + w_2) = z - 1 \tag{2.6c}$$

are valid and will be useful in what follows.

Since for $0 < |\gamma| < 1$ and $|z| < 1$ the mapping $v = t(z,w)$ maps $|w| \leq 1$ into $|v| < 1$, it follows from the fixed-point theorem that one fixed point, which we shall see is w_2, satisfies $|w_2| < 1$. From the first identity in (2.6) it follows that

$$|w_1| = \frac{1}{|w_2 z|} > 1.$$

Thus for $0 < |\gamma| < 1$, $|z| < 1$, the transformation (2.1) cannot be parabolic.

Next, we explore when the transformation is elliptic. Since for $|\gamma| = 1$, $t(z, w)$ is singular, we consider only $0 < |\gamma| < 1$. It is known (see, for example, [4, p. 52]) that in this case the transformation is elliptic if and only if

$$\left|\frac{1+\bar{\gamma}zw_1}{1+\bar{\gamma}zw_2}\right| = 1, \qquad w_1 \neq w_2. \tag{2.7}$$

We set

$$Q(\gamma, z) := \left|\frac{1+\bar{\gamma}zw_1}{1+\bar{\gamma}zw_2}\right| \quad \text{if } z \neq 0, \quad Q(\gamma, 0) := 0.$$

One easily derives

$$Q(\gamma, z) = \left|\frac{1+z-\sqrt{(1+z)^2-(1-|\gamma|^2)4z}}{1+z+\sqrt{(1+z)^2-(1-|\gamma|^2)4z}}\right|.$$

Now either $z = -1$, in which case $Q(\gamma, -1) = 1$ and hence $t(-1, w)$ is elliptic, or $z \neq -1$ and one can write

$$Q(\gamma, z) = \left|\frac{1-\sqrt{1-(1-|\gamma|^2)\frac{4z}{(1+z)^2}}}{1+\sqrt{1-(1-|\gamma|^2)\frac{4z}{(1+z)^2}}}\right|.$$

The condition for $Q(\gamma, z)$ to equal 1 is then easily seen to be

$$\operatorname{Im} \frac{4z}{(1+z)^2} = 0 \qquad \operatorname{Re} \frac{4z}{(1+z)^2} > \frac{1}{1-|\gamma|^2}. \tag{2.8}$$

Now

$$\operatorname{Im} \frac{z}{(1+z)^2} = \frac{\operatorname{Im} z(1+\bar{z})^2}{|1+z|^4} = \frac{\operatorname{Im}(z+2|z|^2+\bar{z}|z|^2)}{|1+z|^4} = \frac{1-|z|^2}{|1+z|^4} \operatorname{Im} z.$$

Hence $\operatorname{Im}(z/(1+z)^2) = 0$ if and only if either $|z| = 1$ or $z \in \mathbf{R}$. If $z \in \mathbf{R}$, the function $4z/(1+z)^2$ assumes its maximum value at $z = 1$ and the maximum is 1, which is less than $1/(1-|\gamma|^2)$. Thus there is no real value of z for which (2.8) is satisfied. If $|z| = 1$, set $z = e^{i\varphi}$. Then

$$\begin{aligned}\frac{4z}{(1+z)^2} &= \frac{4e^{i\varphi}(1+e^{-i\varphi})^2}{|1+e^{i\varphi}|^4} \\ &= \frac{4e^{i\varphi}+8+4e^{-i\varphi}}{((1+\cos\varphi)^2+\sin^2\varphi)^2} \\ &= \frac{8(1+\cos\varphi)}{4(1+\cos\varphi)^2} = \frac{2}{1+\cos\varphi}.\end{aligned}$$

Hence (2.8) is satisfied if and only if

$$|z| = 1 \quad \text{and} \quad \cos(\arg z) < 1 - 2|\gamma|^2. \tag{2.9}$$

One reaches the conclusion that for $0 < |\gamma| < 1$ the transformation $t(z, w)$ is elliptic for all z on the interior of the arc A of the unit circle for which $\cos(\arg z) \leq 1 - 2|\gamma|^2$.

At the endpoints z_1, z_2 of the arc A the transformation is parabolic. The two points z_1, z_2 are also the branch points of the functions $w_1(z)$, $w_2(z)$. Both functions are holomorphic for

$$z \in D := \mathbf{C} \sim A, \qquad z \neq 0. \tag{2.10}$$

Moreover, $Q(\gamma, z) < 1$ for $z \in D$, because we have $z = 0 \in D$ and $Q(\gamma, 0) = 0$. Since $Q(\gamma, z) = 1$ only on A, our assertion follows.

It will now be useful to introduce

$$u_i(z) := (1 + \bar{\gamma} z w_i), \qquad z \neq 0, \quad u_1(1) := 0, \quad u_2(0) := 1. \tag{2.11}$$

Then it follows from (2.7) that

$$Q(\gamma, z) = \left| \frac{u_1(z)}{u_2(z)} \right|.$$

Set

$$r := r(z) = \frac{u_1(z)}{u_2(z)}.$$

Then for $z \in D$

$$\frac{u_1}{u_2} = r, \qquad |r| =: R < 1. \tag{2.12}$$

3. Two lemmas. From (1.5), (1.6), (2.10), and (2.6b) we obtain

$$\begin{aligned} C_n z w_i + D_n &= z C_{n-1} z w_i + (\bar{\gamma} + \bar{\delta}_n) D_{n-1} z w_i + D_{n-1} + (\gamma + \delta_n) z C_{n-1} \\ &= u_i (C_{n-1} z w_i + D_{n-1}) + \bar{\delta}_n D_{n-1} z w_i + \delta_n z C_{n-1} \\ &= u_i^n (C_0 z w_i + D_0) + \sum_{\nu=0}^{n-1} u_i^\nu (\bar{\delta}_{n-\nu} z w_i D_{n-\nu-1} + \delta_{n-\nu} z C_{n-\nu-1}) \\ &= u_i^n \left(z w_i + \gamma_0 + \sum_{\mu=0}^{n-1} \left(\bar{\delta}_{\mu+1} z w_i \frac{D_\mu}{u_i^{\mu+1}} + \delta_{\mu+1} \frac{z C_\mu}{u_i^{\mu+1}} \right) \right). \end{aligned}$$

Analogous formulas are known from continued-fraction theory (see, for example, [11], [13]). Now set

$$\frac{C_m}{u_2^{m+1}} =: \Gamma_m, \quad \frac{D_m}{u_2^{m+1}} =: \Delta_m, \quad \frac{E_m}{u_2^{m+1}} =: H_m, \quad \frac{F_m}{u_2^{m+1}} =: \Phi_m. \tag{3.1}$$

Then, if $u_1 \neq 0$,

$$u_2(\Gamma_n z w_1 + \Delta_n) = r^n \left(z w_i + \gamma_0 + \sum_{\mu=0}^{n-1} \left(\bar{\delta}_{\mu+1} z w_1 r^{-(\mu+1)} \Delta_\mu + \delta_{\mu+1} z r^{-(\mu+1)} \Gamma_\mu \right) \right),$$
