A PARABOLIC EQUATION OF THE KPP TYPE IN HIGHER DIMENSIONS*

JEAN-FRANÇOIS MALLORDY† AND JEAN-MICHEL ROQUEJOFFRE‡

Abstract. The aim of this paper is to study the long-time behaviour of the solutions of a semilinear parabolic equation in an infinite cylinder, which generalises a well-known one-dimensional model that was first investigated by Kolmogorov, Petrovskii, and Piskunov (KPP).

It is shown that the asymptotic behaviour of the solutions strongly depends on the asymptotic behaviour of the initial datum at the ends of the cylinder. In particular, the equation admits a continuum of travelling wave solutions, each of them stable with regard to adequate perturbations.

Key words. reaction diffusion, KPP nonlinearity, travelling waves, asymptotic behavior

AMS subject classifications. 35B35, 35K57, 35B40

1. Introduction.

This paper is concerned with the large-time behaviour of the solutions of a class of semilinear parabolic equations in an infinite multidimensional cylinder. Namely, denoting by Σ the cylinder $\Sigma = (x, y) \in \mathbb{R} \times \omega$, ω being a bounded regular domain in $\mathbb{R}^{N-1}$, we consider the following problem:

$$(\mathcal{P}) : \begin{cases} \partial_t u - \Delta u + \alpha(y)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 \quad \text{on } \partial\Sigma, \\ u(t=0) = u_0 & \text{in } \Sigma, \end{cases}$$

Here ν denotes the outward unit normal on $\partial\Sigma$, $\alpha(y)$ is a given continuous function on $\bar{\omega}$, and g is a given source term satisfying $g(0) = g(1) = 0$ with $g > 0$ in $(0,1)$, and $g'(0) > 0 > g'(1)$. The initial datum u_0 is assumed to take its values in $(0,1)$.

Under the above assumptions, $(\mathcal{P})$ has a unique global classical solution, denoted by $S(t)u_0$. These assumptions will always be understood to hold in the rest of the paper.

Our aim is to understand how the asymptotics of u, for large t, depend on the initial datum u_0. Indeed, $(\mathcal{P})$ admits travelling wave solutions of speed $c \geq c_*$, for some c_* depending on the source term g, and it is expected that each travelling wave is stable in some sense.

Such problems have a wide range of applications, such as population dynamics or combustion; quite a few authors have already contributed to the study of the one-dimensional problem

$$u_t - u_{xx} = g(u), \quad u(-\infty, t) = 0, \quad u(+\infty, t) = 1.$$

The first paper dealing with the subject is the celebrated article by Kolmogorov, Petrovskii, and Piskunov [13]. The source term which is taken into account in their paper is $g(u) = u(1-u)$ and $S(t)H$—H being the Heaviside step function—is shown to converge, in some weak sense, towards the travelling front with speed c_*.

Subsequent work was then done by Aronson and Weinberger [2], where, in particular, the set of c's such that $u(x - ct, t)$ goes to 0 (respectively, 1) as $t \to +\infty$ is

characterised. Local exponential stability results were proved by Sattinger [19] for the waves with speed $c > c_*$ in weighted spaces; quite recently, Kirchgässner [12] reached local algebraic stability for the waves with speed c_*. In [10], Hagan investigated fully nonlinear equations of the form $u_t = f(u, u_x, u_{xx})$, with f satisfying suitable assumptions.

Finally, let us mention the work of Uchiyama [21], which covers all the previously mentioned aspects, and which provides a classification of every possible asymptotic behaviour.

In the multidimensional framework, Aronson and Weinberger [3] investigated the unsteady problem in $\mathbb{R}^N$, with $\alpha \equiv 0$. They obtained "hair-trigger effect" type results, i.e., a nonnegative initial datum with even a small compact support that evolves into a solution that tends to 1 on every compact subset.

Our purpose is to extend to $(\mathcal{P})$ some of these results. In particular, we will fully generalise [2], [19], and the global stability results of [21] for the waves with speed $c > c_*$. To do this, we will rely heavily on the results of Berestycki and Nirenberg [8].

The paper is organised as follows. In §2, we recall the existence, uniqueness, and qualitative properties results for the travelling wave solutions $(\mathcal{P})$. In §§3 and 4, we investigate $(\mathcal{P})$ with a source term g such that $g(s)/s$ is decreasing in s. Such a g will be called a KPP source term, and we will see in §§3 and 4 that this additional assumption allows us to produce shorter and more elegant proofs. Section 5 is devoted to exponential local stability results, and no KPP assumption is made unless otherwise stated. Finally, §6 is devoted to the extension of the results of §4 when g is no longer a KPP source term.

2. Travelling waves. All the material in this section comes from the work of Berestycki and Nirenberg [8]. Therefore no proof will be given, apart from the last exponential behaviour result.

When we look for travelling waves solutions of the form $u(x, y, t) = \phi(x + ct, y)$, we have to deal with the elliptic problem

$$(E) : \begin{cases} -\Delta\phi + (\alpha(y) + c)\partial_x\phi = g(\phi) & \text{in } \Sigma, \\ \partial_\nu\phi = 0 & \text{on } \partial\Sigma. \end{cases}$$

We set

$$\beta(y) = \alpha(y) + c, \quad \forall y \in \bar{\omega},$$
$$A_c = -\Delta + \beta(y)\partial_x.$$

The resolution of problem (E) requires the study of the linearised problem around 0, which is presented below.

The linearised problem. Here we are interested in finding positive solutions to the problem

$$(E_L) : \begin{cases} -\Delta z + \beta(y)\partial_x z = g'(0)z & \text{in } \Sigma, \\ \partial_\nu z = 0 & \text{on } \partial\Sigma. \end{cases}$$

It is easy to see that $z = e^{\lambda x}\varphi(y)$, with $\varphi > 0$ on ω, is a solution of (E_L) if and only if

$$\lambda^2 = \mu_1(-\Delta + \lambda\beta(y) - g'(0)),$$

where $\mu_1(B)$ represents the first eigenvalue of the operator B defined on ω with a Neumann condition on the boundary.

LEMMA 2.1. *Let $m \in \mathbb{R}$ and $\mu_1(t) = \mu_1(-\Delta + t\beta(y) + m)$, then the function $t \mapsto \mu_1(t)$ satisfies the following:*

1. *μ_1 is Lipschitz with coefficient $||\beta||_\infty$,*
2. *$\mu_1(0) = m$,*
3. *μ_1 is concave,*
4. *μ_1 is differentiable and $\mu_1'(0) = \frac{1}{|\omega|}\int_\omega \beta(y)dy$,*
5. *$m + t(\inf_\omega \beta) \leq \mu_1(t) \leq m + t(\sup_\omega \beta)$.*

We call $\lambda \in \mathbb{R}$ a principal eigenvalue (p.e.) if $\mu_1(\lambda) = \lambda^2$. An immediate consequence of the lemma is the following theorem (remember $m = -g'(0) < 0$).

THEOREM 2.2. *There exists $c_0 \in \mathbb{R}$ such that*

- *$c < c_0 \Longrightarrow$ there is no positive p.e.*
- *$c = c_0 \Longrightarrow$ there is exactly one positive p.e.*
- *$c > c_0 \Longrightarrow$ there are exactly two positive p.e.*

Notation: we call λ_c the smallest positive principal eigenvalue associated to $c > c_0$ and λ_0 the positive principal eigenvalue associated to c_0. We will also use the notation λ_c^u (u for "usual") instead of λ_c, and then λ_c^a (a for "accidental") will be the other p.e.

Solutions of Problem (E).

THEOREM 2.3. *There exists $c^* \geq c_0$ such that the problem*

$$(E): \begin{cases} -\Delta\phi + (\alpha(y) + c)\partial_x\phi = g(\phi) & \text{in } \Sigma, \\ \partial_\nu\phi = 0 & \text{on } \partial\Sigma. \end{cases}$$

with $\phi(-\infty, y) = 0$, $\phi(+\infty, y) = 1$ uniformly on $\bar{\omega}$, has a solution if and only if $c \geq c^*$. Furthermore the solution is unique (up to the x translations), and increasing in x, more precisely, $\partial_x\phi > 0$ on $\bar{\Sigma}$.

Notation: we call ϕ_c the solution associated to c normalised by the condition $\sup_{y\in\bar{\omega}} \phi_c(0, y) = 1/2$. If we now impose $\phi(-\infty, y) = 1$, $\phi(+\infty, y) = 0$ uniformly on $\bar{\omega}$, we will have solutions if and only if $c \leq c^{**}$, for a real $c^{**} < c^*$, this is obvious by changing x into $-x$. We call $\tilde{\phi}_c$ these decreasing solutions. We call λ_{00} the λ_0 obtained when considering $-\alpha(y)$ instead of $\alpha(y)$ in the linearised problem.

We end this paragraph by examining the asymptotic behaviour of ϕ_c as $|x| \to +\infty$.

LEMMA 2.4.

- *If $c > c^*$ we have, near $-\infty$, and uniformly in $y \in \bar{\omega}$,*

$$\phi_c(x, y) \sim e^{\lambda_- x}\varphi_-(y), \qquad \partial_x\phi_c(x, y) \sim \lambda_- e^{\lambda_- x}\varphi_-(y);$$

  furthermore, if $c^* > c_0$, we have the same at $c = c^*$.
- *If $c \geq c^*$, we have near $+\infty$, and uniformly in $y \in \bar{\omega}$,*

$$1 - \phi_c(x, y) \sim e^{-\lambda_+ x}\varphi_+(y), \qquad \partial_x\phi_c(x, y) \sim \lambda_+ e^{-\lambda_+ x}\varphi_+(y),$$

where $e^{\lambda_- x}\varphi_-(y)$ is a positive solution of the linearised problem around 0 (E_L) with $\lambda_- > 0$, and $e^{-\lambda_+ x}\varphi_+(y)$ is a positive solution of the linearised problem around 1, with $\lambda_+ > 0$.

In the case $c > c^*$, we can be more precise.

LEMMA 2.5. *Let $c > c^*$, then the exponential behaviour of ϕ_c near $-\infty$ is given by λ_c, the smallest principal eigenvalue, i.e.,*

$$\phi_c(x, y) \sim e^{\lambda_c x}\varphi_c(y) \quad \text{as } x \to -\infty,$$

where φ_c is a positive eigenfunction associated to λ_c.

Proof. By the sliding method, as in [7]. Set $\phi_c(x,y) \sim \varphi_-(y)e^{\lambda_- x}$ as $x \to -\infty$, and assume that $\lambda_- > \lambda_c^a$. Then we have

$$\lim_{|x|\to+\infty} \phi_{c^*}/\phi_c = +\infty$$

(this follows from Theorem 4.1 in [8]). Moreover,

$$-\Delta(\phi_{c^*} - \phi_c) + (c + \alpha(y))\partial_x(\phi_{c^*} - \phi_c) + \frac{g(\phi_{c^*}) - g(\phi_c)}{\phi_{c^*} - \phi_c}(\phi_{c^*} - \phi_c)$$
$$= (c - c^*)\partial_x\phi_{c^*} > 0.$$

We choose a translate of ϕ_{c^*} (still denoted by ϕ_{c^*}), such that $\phi_{c^*} \geq \phi_c$, and such that the two functions coincide somewhere. The maximum principle and the Hopf boundary lemma yield $\phi_{c^*} = \phi_c$, which is a contradiction. □

3. Long-time behaviour with rapidly decreasing initial data. Here we consider the problem

$$(\mathcal{P}) : \begin{cases} \partial_t u - \Delta u + \alpha(y)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 & \text{on } \partial\Sigma, \\ u(t=0) = u_0 & \text{in } \Sigma, \end{cases}$$

where u_0 decays faster than any travelling front at one or both ends of the cylinder. We recall that, in this section, g is assumed to be a KPP source term.

3.1. Decay at only one end.

THEOREM 3.1.

- *If* $u_0(x,y) = o(e^{\lambda x})$ *as* $x \to -\infty$ *for every* $\lambda < \lambda^*$, *then for each* $c > c^*$ *we have* $u(x - ct, y, t) \to 0$ *when* $t \to +\infty$ *uniformly on each* $(-\infty, a] \times \bar{\omega}$.
- *If* $\liminf_{x\to+\infty} u_0 > 0$, *then for each* $c < c^*$ *we have* $u(x - ct, y, t) \to 1$ *when* $t \to +\infty$ *uniformly on each* $[a, +\infty) \times \bar{\omega}$.

If we now consider a u_0 that satisfies both conditions of Theorem 3.1, we can obviously define

$$\varphi(t) = \sup\{x \in \mathbb{R}; u(x,y,t) \leq 1/2, \forall y \in \omega\}$$

for sufficiently large values of t. We then have the next corollary.

COROLLARY 3.2. *Under the conditions of Theorem* 3.1, $\varphi(t)/t \to -c^*$ *as* $t \to +\infty$.

We first prove the first part of the theorem, which is much easier. Set $v(x,y,t) = u(x - ct, y, t)$ so that $\partial_t v + A_c v = g(v)$; assume $c > c^*$. Let $c' \in (c^*, c)$ and $e^{\lambda x}\varphi(y)$ a positive solution of the linearised problem $\partial_t v + A_{c'} v = g'(0)v$, with the Neumann boundary condition (such a solution exists since $c > c^*$). Using the condition at $-\infty$, we know $\exists x_0$ such that

$$x < x_0 \Longrightarrow u_0(x,y) < e^{\lambda x}\varphi(y)$$

so, for some large M, $u_0(x,y) < e^{\lambda(x+M)}\varphi(y)$ on Σ; now just apply the maximum principle to see that $v(x,y,t) < e^{\lambda(x+M-(c'-c^*)t)}\varphi(y)$ on Σ, $\forall t \geq 0$, wich yields the first assertion of Theorem 3.1.

Before proving the second part of the theorem, we need a lemma.

LEMMA 3.3. *Let* f *be a* C^1 *function such that* $f(0) = f(1) = 0$, $f'(0) > 0 > f'(1)$, *and* $f > 0$ *on* $(0,1)$; *we suppose that* u *satisfies* $\partial_t u + A_c u = f(u)$ *in* Σ *with*

Neumann boundary conditions, and $\liminf_{t\to+\infty} u(x,y,t) \geq \delta > 0$ *uniformly on each* $[a,+\infty)\times\bar{\omega}$, *then* $u(x,y,t) \to 1$ *when* $t \to +\infty$ *uniformly on each* $[a,+\infty)\times\bar{\omega}$.

Proof. There exists a sequence $t_n \to +\infty$ such that $\forall t \geq t_n$, $u(t) \geq h_n^0$ where

$$h_n^0(x,y) = \begin{cases} \delta/2 & \text{if } x > -n, \\ 0 & \text{if } x < -n, \end{cases}$$

we denote by $h_n(x,y,t)$ the solution of

$$\begin{cases} \partial_t h + A_c h = f(h) & \text{in } \Sigma, \\ \partial_\nu h = 0 & \text{on } \partial\Sigma, \\ h(t=0) = h_n^0 & \text{in } \Sigma. \end{cases}$$

By the maximum principle, we have $u(t+t_n) \geq h_n(t)$ $\forall t \geq 0$. As n increases, h_n^0 increases, and so $h_n(t)$ increases too (another consequence of the maximum principle). Since $h_n(t)$ is bounded by 1, we have $h_n(x,y,t) \to h_\infty(x,y,t)$ as $n \to +\infty$. Using classical parabolic estimates, we get $h_n \to h_\infty$, $\partial_t h_n \to \partial_t h_\infty$, $\partial_x h_n \to \partial_x h_\infty$, and $\Delta h_n \to \Delta h_\infty$, uniformly on each $[-a,+a]\times\bar{\omega}\times[1/T,T]$. This shows $\partial_t h_\infty + A_c h_\infty = f(h_\infty)$ with the Neumann boundary condition. Meanwhile $h_\infty(x,y,t=0) \geq \delta/2 > 0$. Obviously, $h_\infty(x,y,t) \to 1$ uniformly on Σ as $t \to +\infty$.

We conclude that $h_n(x,y,t) \to 1$ uniformly on each $[-a,+a]\times\bar{\omega}$ as n and $t \to +\infty$, but with $h_n(t)$ increasing in x (maximum principle), the convergence is in fact uniform on each $[-a,+\infty)\times\bar{\omega}$. By remembering $u(t+t_n) \geq h_n(t)$, $\forall t \geq 0$, we have our lemma. □

Now we prove the second assertion in Theorem 3.1; first, we suppose that g is concave. Set $g = 0$ outside of $[0,1]$. For $\epsilon > 0$, consider the following problem, with unknown (u,c):

$$(E_\epsilon): \begin{cases} -\Delta u + (\alpha(y)+c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 & \text{on } \partial\Sigma, \\ u(-\infty,y) = -\epsilon \quad \text{and} \quad u(+\infty,y) = 1. \end{cases}$$

Setting $w = (u+\epsilon)/(1+\epsilon)$, we see that (E_ϵ) is equivalent to

$$(E'_\epsilon): \begin{cases} -\Delta w + (\alpha(y)+c)\partial_x w = g_\epsilon(w) & \text{in } \Sigma, \\ \partial_\nu w = 0 & \text{on } \partial\Sigma, \\ w(-\infty,y) = 0 \quad \text{and} \quad w(+\infty,y) = 1, \end{cases}$$

where we have set $g_\epsilon(s) = g((1+\epsilon)s-\epsilon)/(1+\epsilon)$. Using the concavity of g, we find that g_ϵ increases as ϵ decreases. Now, we just do as Berestycki and Nirenberg did when they proved that the existence of c^* (see [8]); this yields that for a given $\epsilon > 0$, there is exactly one solution (u_ϵ, c_ϵ) to problem (E_ϵ) (defined modulo x translations); this solution is increasing in x and c_ϵ increases to c^* as ϵ decreases to 0.

Let $\delta > 0$ such that $\liminf_{x\to+\infty} > \delta$; set $g_\delta(s) = \delta g(s/\delta)$ for $s \in \mathbb{R}$. Still using the concavity of g, we get $g_\delta \leq g$, $\forall \delta \in (0,1]$. Consider the problem

$$(E_{\epsilon,\delta}): \begin{cases} -\Delta v + (\alpha(y)+c)\partial_x v = g_\delta(v) & \text{in } \Sigma, \\ \partial_\nu v = 0 & \text{on } \partial\Sigma, \\ v(-\infty,y) = -\epsilon \quad \text{and} \quad v(+\infty,y) = \delta. \end{cases}$$

Setting $v = \delta u$, we see that problem $(E_{\epsilon,\delta})$ is equivalent to problem $(E_{\epsilon/\delta})$ (defined above); let us call $(v_{\epsilon,\delta}, c_{\epsilon,\delta})$ the solution of problem $(E_{\epsilon,\delta})$; we still have that $c_{\epsilon,\delta}$ increases to c^* as ϵ decreases to 0.

Let $c < c^*$. Let $\epsilon > 0$ such that $c < c_{\epsilon,\delta} < c^*$; we now consider u the solution of

$$(\mathcal{P}_C) : \begin{cases} \partial_t u - \Delta u + (\alpha(y) + c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 \quad \text{on } \partial\Sigma, \\ u(t = 0) = u_0 & \text{in } \Sigma, \end{cases}$$

and we set $z(x, y, t) = v_{\epsilon,\delta}(x + (c_{\epsilon,\delta} - c)t, y)$. We have

$$\begin{cases} -\Delta z + (\alpha(y) + c)\partial_x z = g_\delta(z) \leq g(z) & \text{in } \Sigma, \\ \partial_\nu z = 0 \quad \text{on } \partial\Sigma, \\ z(x, y, t = 0) \leq u_0(x, y) \text{ in } \Sigma \text{ up to some } x \text{ translation}, \end{cases}$$

which implies $z(x, y, t) \leq u(x, y, t), \forall t \geq 0, \forall (x, y) \in \Sigma$. This yields $\liminf_{t\to+\infty} u(x, y, t) \geq \delta$ uniformly on each $[-a, +\infty) \times \bar{\omega}$. An application of Lemma 3.3 ends the proof, in the case where g is KPP and concave.

The result is still available when g is KPP but not concave: for $\eta > 0$, set $c^*(g'(0) - \eta)$ the critical speed obtained when replacing $g'(0)$ by $g'(0) - \eta$. Choose some small $\eta > 0$ such that $c < c^*(g'(0) - \eta) < c^*$; choose g_η as a KPP and concave function smaller than g satisfying $g'_\eta(0) = g'(0) - \eta$. Now just replace g by g_η in $(E_{\epsilon,\delta})$: this provides a subsolution with the same properties as z and completes the proof of the second part of Theorem 3.1. □

3.2. Initial data with compact support.

THEOREM 3.4. *We suppose that u_0 satisfies $u_0(x, y) = o(e^{\lambda x})$ as $x \to -\infty$, uniformly in y for each $\lambda < \lambda^*$ and $u_0(x, y) = o(e^{-\mu x})$ as $x \to +\infty$, uniformly in y for each $\mu < \lambda^{**}$, then u satisfies uniformly on every compact of $\bar{\Sigma}$.*

1. *$u(x - ct, y, t) \to 0$ when $t \to +\infty$ if $c \notin [c^{**}, c^*]$,*
2. *$u(x - ct, y, t) \to 1$ when $t \to +\infty$ if $c \in (c^{**}, c^*)$.*

The first assertion follows directly from Theorem 3.1. As a first step to the second assertion, we prove the following lemma, which was obtained independently by Lachand-Robert [14] in a different context.

LEMMA 3.5. *There exists $c' < c^*$ such that $\forall c \in (c', c^*)$, $\exists \lambda \in \mathbb{C} \setminus \mathbb{R}$ and $\varphi \in C^2(\bar{\omega}, \mathbb{C})$ with $\mathrm{Re}(\varphi) > 0$ in $\bar{\omega}$ which satisfies*

$$\begin{cases} -\Delta\varphi + (\lambda(\alpha(y) + c) - \lambda^2 - g'(0))\varphi = 0 & \text{in } \omega, \\ \partial_\nu\varphi = 0 \quad \text{on } \partial\omega. \end{cases}$$

Proof. Remember that for $\lambda \in \mathbb{R}$, we denote by $\mu_1(-\Delta + \lambda\beta_*)$ the first eigenvalue of the operator $-\Delta + \lambda(\alpha(y) + c^*)$; the eigenspace associated in $L^2(\omega)$ is one-dimensional. The family of operators $-\Delta + \lambda(\alpha(y) + c^*)$ depends analytically on λ, in the sense of Kato (see [16]). From the Kato–Rellich theorem, $\exists V$ a neighbourhood of λ^* in $\mathbb{C}$ such that there exists a simple eigenvalue $\tilde{\mu}_1(-\Delta + \lambda\beta_*)$ continuing μ_1 on all V analytically; there also exists a family of eigenfunctions ψ_λ in $L^2(\omega)$, analytic in λ.

Let us study the zeros of $F_c(\lambda) = \tilde{\mu}_1(-\Delta + \lambda\beta_*) + \lambda(c - c^*) - \lambda^2 - g'(0)$. F_c is analytic and converges locally uniformly to F_{c^*} as $c \to c^*$, λ^* being a zero of F_{c^*}, the Rouché theorem yields the existence, in a neighbourhood of c^*, of a family λ_c such that $F_c(\lambda_c) = 0$ and $\lambda_c \to \lambda^*$ as $c \to c^*$. We then have, for c near c^*: $\tilde{\mu}_1(-\Delta + \lambda_c\beta_*) + \lambda_c(c - c^*) - \lambda_c^2 - g'(0) = 0$; setting $\psi_c = \psi_{\lambda_c}$, we get

$$\begin{cases} -\Delta\psi_c + (\lambda_c(\alpha(y) + c) - \lambda_c^2 - g'(0))\psi_c = 0 & \text{in } \omega, \\ \partial_\nu\psi_c = 0 \quad \text{on } \partial\omega. \end{cases}$$

Notice that $\psi_c \to \psi_{c^*}$ as $c \to c^*$, in $L^2(\omega)$. Writing the equation satisfied by $\psi_c - \psi_{c^*}$, and using classical elliptic estimates, we get

$$||\psi_c - \psi_{c^*}||_{L^2(\omega)} \to 0 \Longrightarrow ||\psi_c - \psi_{c^*}||_\infty \to 0$$

as $c \to c^*$. Without loss of generality, we can assume that ψ_{c^*} is real and positive on $\bar{\omega}$ (since the eigenspace associated to λ^* is generated by a real positive function). We have that $\mathrm{Re}(\psi_c) \to \psi_{c^*}$ in $L^\infty(\omega)$, so $\mathrm{Re}(\psi_c) > 0$ for c near c^*. Now we need only prove that for $c \in \mathbb{R}$, with $c < c^*$ near enough, it is impossible to have $\lambda_c \in \mathbb{R}$; if it were possible, we could write $\mu_1(-\Delta + \lambda_c(\alpha(y) + c) - g'(0)) = \lambda_c^2$; but $c < c^*$ means that this never happens for $\lambda \in \mathbb{R}$ (see the definition of c^*). The lemma is proved with $\lambda = \lambda_c$ and $\varphi = \psi_c$. □

Now we prove Theorem 3.4. Let $\epsilon_0 > 0$ such that $c^{**} < c^* - \epsilon_0$. Let c_δ the c^* obtained when replacing $g'(0)$ by $g'(0) - \delta$, for some $\delta > 0$, in the principal eigenvalue problem. It is not difficult to see that c_δ increases to c^* as δ decreases to 0. So, for δ small enough, $c^* - \epsilon_0 < c_\delta < c^*$. We apply the lemma with $g'(0) - \delta$ instead of $g'(0)$ and c_δ instead of c^*. This provides, for $c < c_\delta$ near c_δ, (λ, φ) such that $\varphi_0 := \mathrm{Re}(e^{\lambda x}\varphi(y))$ is a real-valued solution of

$$\begin{cases} -\Delta\varphi_0 + (\alpha(y) + c)\partial_x\varphi_0 = (g'(0) - \delta)\varphi_0 & \text{in } \Sigma, \\ \partial_\nu\varphi_0 = 0 & \text{on } \partial\Sigma. \end{cases}$$

Since $\mathrm{Re}(\varphi) > 0$ in $\bar{\omega}$ and $\lambda \in \mathbb{C} \setminus \mathbb{R}$, there exist two functions in $C^1(\bar{\omega})$, $x_1(y)$ and $x_2(y)$, such that

$$\forall y \in \bar{\omega}, \ , x_1(y) < x_2(y) \quad \text{and} \quad \varphi_0(x_1(y), y) = \varphi_0(x_2(y), y) = 0,$$
$$\forall y \in \bar{\omega}, \quad \forall x \in (x_1(y), x_2(y)), \quad \varphi_0(x, y) > 0.$$

Set $D = \{(x, y) \in \Sigma; x_1(y) < x < x_2(y)\}$. Since g is C^1, there exists $\eta > 0$ such that $\forall s \in (0, \eta)$, $(g'(0) - \delta)s < g(s)$; so, without loss of generality, we can assume that $\varphi_0 \leq \eta$ on D, which implies

$$-\Delta\varphi_0 + (\alpha(y) + c)\partial_x\varphi_0 = (g'(0) - \delta)\varphi_0 \leq g(\varphi_0) \text{ in } D.$$

Now we follow the idea of Aronson and Weinberger in [2]. Solve the following problem:

$$\begin{cases} \partial_t w - \Delta w + (\alpha(y) + c)\partial_x w = g(w) & \text{in } \Sigma, \\ \partial_\nu w = 0 & \text{on } \partial\Sigma, \\ w(t = 0) = \varphi_0 \text{ in } D, \text{ and } 0 & \text{in } \Sigma - D. \end{cases}$$

Then $w(x, y, t) \geq \varphi_0(x, y)$ in D, $\forall t \geq 0$ (apply the maximum principle in D, taking into account the Neumann condition on $\partial D \cap \partial\Sigma$ and the Dirichlet condition on $\partial D \cap \Sigma$). Considering the function $m(x, y, t) = w(x, y, t + h) - w(x, y, t)$ for $h > 0$, we see that m is positive $\forall t \geq 0$ (maximum principle again), and so w is increasing in t. Then there exists a limit function $w_\infty(x, y)$ to which $w(x, y, t)$ converges as $t \to +\infty$. Using classical parabolic estimates and Ascoli theorem, we get the uniform convergence on every compact subset of $\bar{\Sigma}$, as well as for the derivatives $\partial_x w$, $\partial_t w$, and Δw. This implies

$$-\Delta w_\infty + (\alpha(y) + c)\partial_x w_\infty = g(w_\infty) \text{ in } \Sigma$$

with Neumann boundary conditions.

An argument similar to that of [5], Theorem 1 shows that w_∞ has to go to a constant limit as $|x| \to +\infty$, which can only be 0 or 1. But from the theory of Berestycki and Nirenberg, it follows that w_∞ is monotonic; since $c \in (c^{**}, c^*)$, it must be 0 or 1 identically, so it is 1 identically. To sum up, we have just constructed a function with compact support, with arbitrarily small supremum norm, and such that the solution of the corresponding Cauchy problem goes to 1 uniformly on every compact subset of $\bar{\Sigma}$. Applying the maximum principle, we generalize this result to any u_0 having compact support.

Now proceed similarly with $u(-x, y, t)$; we finally get that $u(x - ct, y, t) \to 1$ for some real $c \in (c^{**}, c^*)$ arbitrarily near c^{**}. The second assertion in Theorem 3.4 is then proved for reals $c \in (c^{**}, c^{**} + \epsilon) \cup (c^* - \epsilon, c^*)$ with any small $\epsilon > 0$. The general result follows from an application of the maximum principle as in Theorem 4.7; see §4. □

NB: For the proof of the second assertion in Theorem 3.4, we needn't suppose that $g(s)/s$ decreases.

4. Global stability of waves. In this section, we show that the travelling waves are stable in some sense, and give criteria for the creation of travelling fronts, as t grows to infinity.

In order to emphasize the main ideas, we first investigate particular cases, then generalize. Recall that g is still assumed to be a KPP term.

LEMMA 4.1. *Let $c \in \mathbb{R}$ and $\beta(y) = \alpha(y) + c$. Consider two solutions u and v of*

$$\begin{cases} \partial_t z - \Delta z + \beta(y)\partial_x z = g(z) & \text{in } \Sigma, \\ \partial_\nu z = 0 & \text{on } \partial\Sigma. \end{cases}$$

Also suppose that $u(t = 0) \leq v(t = 0)$, with values in $[0, 1]$ and that there exists $x_0 \in \mathbb{R}$ such that $u(x, y, 0) = v(x, y, 0)$, $\forall x \leq x_0$, $\forall y \in \omega$; then

$$0 \leq v(t) - u(t) \leq Ce^{\lambda^*[x-(c-c^*)t]} \text{ for some real } C.$$

Proof. The left-hand side follows from the maximum principle. For the right-hand side, we write for some w,

$$(\partial_t + A_c)(v - u) = g'(w)(v - u) \leq g'(0)(v - u)$$

since $v - u \geq 0$ and g is a KPP source term; then let then $e^{\lambda^* x}\varphi^*(y)$ be a positive exponential solution of

$$-\Delta z + (\alpha(y) + c^*)\partial_x z = g'(0)z$$

with the Neumann boundary condition on $\partial\Sigma$; then $h(x, y, t) = e^{\lambda^*[x-(c-c^*)t]}\varphi^*(y)$ satisfies $(\partial_t + A_c - g'(0))h = 0$ with the same boundary condition; we then choose a constant Λ such that $v(0) - u(0) \leq \Lambda h(0)$; the result then follows from the maximum principle. □

THEOREM 4.2. *Let $c > c^*$, $\beta(y) = \alpha(y) + c$, and consider $u(t)$ the solution of the problem*

$$(\mathcal{P}_c) : \begin{cases} \partial_t u - \Delta u + (\alpha(y) + c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 & \text{on } \partial\Sigma, \\ u(t = 0) = u_0 & \text{in } \Sigma, \end{cases}$$

where u_0, with values in $[0,1]$, satisfies

$$u_0(x,y) \sim \phi_c(x,y) \text{ uniformly on } \bar{\omega} \text{ when } x \to -\infty,$$

then

$$u(x,y,t) \to \phi_c(x,y) \text{ when } t \to +\infty, \text{ uniformly on } (-\infty,a] \times \bar{\omega} \quad \forall a \in \mathbb{R}.$$

Proof. Let $a \in \mathbb{R}$ and $\epsilon > 0$. Set $\phi := \phi_c$. Let $\delta > 0$ such that

$$|\phi(x,y) - \phi(x-\delta,y)| < \epsilon/2 \quad \text{on } \Sigma$$

since $\phi_c(x,y) \sim e^{\lambda_c x}\varphi_c(y)$ as $x \to -\infty$, with $\lambda_c > 0$ and $\varphi_c > 0$ on $\bar{\omega}$, we have

$$\phi^\delta(x,y) := \phi(x-\delta,y) \sim e^{-\lambda_c \delta}\phi(x,y) \quad \text{when } x \to -\infty$$

so $\underline{u}_0 := \inf(u_0, \phi^\delta)$ satisfies $\underline{u}_0 \le \phi^\delta$ and $\underline{u}_0(x,y) = \phi^\delta(x,y)$ $\forall x \le x_0$ (for some real x_0); we denote by $\underline{u}$ the solution of the Cauchy problem with $\underline{u}(0) = \underline{u}_0$, and apply Lemma 4.1, which yields

$$0 \le \phi^\delta - \underline{u}(t) \le Ce^{\lambda^*[(x-(c-c^*)t]}.$$

Similar considerations on $\bar{u}_0 := \sup(u_0, \phi^{-\delta})$ provide

$$0 \le \bar{u}(t) - \phi^{-\delta} \le Ce^{\lambda^*[x-(c-c^*)t]}.$$

Now we just have to apply the maximum principle

$$\phi^\delta - Ce^{\lambda^*[x-(c-c^*)t]} \le \underline{u}(t) \le u(t) \le \bar{u}(t) \le \phi^{-\delta} + Ce^{\lambda^*[x-(c-c^*)t]} \qquad \square$$

Under an additional hypothesis, we now obtain uniform convergence in the whole cylinder.

THEOREM 4.3. *Let $c > c^*$, $\beta(y) = \alpha(y) + c$, and consider $u(t)$ the solution of the problem*

$$(\mathcal{P}_c): \begin{cases} \partial_t u - \Delta u + (\alpha(y)+c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 \quad \text{on } \partial\Sigma, \\ u(t=0) = u_0 \quad \text{in } \Sigma, \end{cases}$$

with u_0 (taking its values in $[0,1]$) satisfying

1. *$u_0(x,y) \sim \phi_c(x,y)$ uniformly in ω as $x \to -\infty$*
2. *$\liminf_{x\to+\infty} u_0 > 0$ uniformly in ω, then*

$$\sup_{(x,y)\in\bar{\Sigma}} |u(x,y,t) - \phi_c(x,y)| \to 0 \text{ as } t \to +\infty.$$

We will make use of the following lemma. These kinds of sub- and supersolutions results have been widely used in one space dimension; see [10] and [21].

LEMMA 4.4. *Let $c > c^*$ and $\epsilon_0 \in (0,1)$, then $\exists s, K > 0$ such that $\psi(x,y,t) := h(t)\phi_c(x-m(t),y)$ satisfies $\partial_t\psi + A_c\psi - g(\psi) \le 0$ on Σ, $\forall t \ge 0$, with $h(t) := 1-\epsilon_0 e^{-st}$ and $m(t) := K(1-e^{-st})$.*

Proof. Let $u_1 \in (0,1)$ such that $\forall \epsilon_0 \in (0,1)$, $\exists T > 0$ satisfying

$$(1-\epsilon)g(u) - g((1-\epsilon)u) \le -T\epsilon u, \ \forall u \in [u_1,1], \ \forall \epsilon \in [0,\epsilon_0]$$

(such an u_1 exists as soon as $g'(0) > 0 > g'(1)$).

Set $N[\psi] = \partial_t \psi + A_c \psi - g(\psi)$, and $\varphi(x,y,t) = \phi_c(x - m(t), y)$; we compute

$$N[\psi] = s\epsilon_0 e^{-st}\varphi - hsK\partial_x\varphi + hg(\varphi) - g(h\varphi).$$

There exists X_0 such that $\forall x \geq X_0$, $\forall y \in \omega$, $\phi_c(x,y) \geq u_1$, so if $x - m(t) \geq X_0$, we have $hg(\varphi) - g(h\varphi) \leq -T\epsilon_0 e^{-st}\varphi$ and then $N[\psi] \leq e^{-st}\varphi(s-T)\epsilon_0$; choosing $s = T$, we have $N[\psi] \leq 0$; if $x - m(t) \leq X_0$, notice that there exists a constant $C > 0$ such that $\partial_x\varphi/\varphi \geq C$, because of the asymptotic behaviour of ϕ_c as $x \to -\infty$. Write

$$N[\psi] \leq s\epsilon_0 e^{-st}\varphi - hsCKe^{-st}\varphi + g(\varphi) - g(h\varphi),$$

$$N[\psi] \leq e^{-st}\varphi(s\epsilon_0 - hsCK + C'\epsilon_0).$$

Now choose $K = (s + C')\epsilon_0/(1 - \epsilon_0)sC$, which yields $N[\psi] \leq 0$ as well. □

Here is the proof of Theorem 4.3. In the case where $u_0(x,y) > 0$ in $\bar{\Sigma}$, the hypothesis guarantees there exists some $h_0 \in (0,1)$ and some $x_0 \in \mathbb{R}$, satisfying $h_0\phi_c(x - x_0, y) \leq u_0(x,y)$ in Σ. Apply Lemma 4.4 with $\epsilon_0 = 1 - h_0$. Then $\psi(x,y,t) \leq u(x,y,t)$, $\forall t \geq 0$; this, together with Theorem 4.2, proves that the convergence is uniform on $\bar{\Sigma}$.

If we do not assume $u_0(x,y) > 0$ in $\bar{\Sigma}$, we still have, by the maximum principle, that $u(x,y,t_0) > 0$ as soon as $t_0 > 0$. Notice that condition 1 is preserved at all positive times (use the same arguments as in the proof of Theorem 4.2); condition 2 is in fact also preserved: just compare u_0 to some C^∞ and the increasing function $h_0(x,y)$, which is 0 if $x < M$ and ϵ if $x > M+1$; solve the corresponding Cauchy problem, which gives some $h(x,y,t)$ increasing in x, so that obviously $\liminf_{x\to+\infty} h(x,y,t) > 0$, for each positive t.

Both conditions being preserved,we use the semigroup property and prove Theorem 4.3 in the general case. □

Now we give a more powerful version of this result.

THEOREM 4.5. *Let $c > c^*$, $\beta(y) = \alpha(y) + c$, and consider $u(t)$ the solution of the problem*

$$(\mathcal{P}_c): \begin{cases} \partial_t u - \Delta u + (\alpha(y) + c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 & \text{on } \partial\Sigma, \\ u(t=0) = u_0 & \text{in } \Sigma, \end{cases}$$

with u_0 (taking its values in $[0,1]$) satisfying

1. *$u_0(x,y) \sim a(y)e^{\lambda_c x}$ uniformly on ω as $x \to -\infty$, where $a(y)$ is continuous and not identically zero;*
2. *$\liminf_{x\to+\infty} u_0 > 0$ uniformly on ω,*

then

$$\exists x_0 \in \mathbb{R} \text{ such that } \sup_{(x,y)\in\bar{\Sigma}} |u(x,y,t) - \phi_c(x + x_0, y)| \to 0 \text{ as } t \to +\infty.$$

First, let us state a lemma.

LEMMA 4.6. *Let u be a solution of $(\mathcal{P}_c)$, with $c > c^*$; suppose $u(x,y,0)$ satisfies the first condition in Theorem 4.5. Let $\psi(y,t)$ be the solution of*

$$\begin{cases} \partial_t\psi - \Delta\psi + (\lambda_c\beta(y) - \lambda_c^2)\psi = g'(0)\psi & \text{in } \omega, \\ \partial_\nu\psi = 0 & \text{on } \partial\omega, \\ \psi(y,0) = a(y), \end{cases}$$

then

$$u(x,y,t) \sim \psi(y,t)e^{\lambda_c x} \text{ as } x \to -\infty, \forall t \geq 0, \text{ uniformly in } \omega.$$

Proof. Set $u(x,y,t) = e^{\lambda_c x}v(x,y,t)$. Notice that $v(x,y,t)$ is bounded on every $[0,T]$. To prove it, notice that the hypothesis on u_0 implies the existence of a wave ϕ_c and a real x_0 such that $(u_0 - \phi_c)(x,y) < 0$ for all $x < x_0$; then apply Lemma 4.1:

$$u(x,y,t) < \phi_c(x,y) + Ce^{\lambda^*[x-(c-c^*)t]} \quad \forall t > 0$$

so

$$v(t) < e^{-\lambda_c x}\phi_c(x,y) + Ce^{(\lambda^*-\lambda)x-\lambda^*(c-c^*)t}$$

since $\lambda_c < \lambda^*$, this yields an upper bound for $v(t)$ on $\mathbb{R}^- \times \omega$, $\forall t \in [0,T]$, whereas $v(t)$ is clearly bounded on $\mathbb{R}^+ \times \omega$ (remember that $u \leq 1$).

For $\theta \in \mathbb{R}$, set $w(x,y,t) = v(x,y,t) - \theta\psi(y,t)$ and write the partial differential equation satisfied by w:

$$Lw := \partial_t w - \Delta w + \beta(y)\partial_x w + (\lambda_c\beta(y) - \lambda_c^2 - g'(0))w = e^{-\lambda_c x}g(e^{\lambda_c x}v) - g'(0)v,$$

with g being C^2, we can write $g(s) = g'(0)s + (s^2/2)g''(\eta s)$, so $|Lw| \leq Ke^{-\lambda_c x}e^{2\lambda_c x}v^2$, but we know that v is bounded on each $[0,T]$, therefore

$$|Lw| \leq K(T)e^{\lambda_c x} \quad \forall t \in [0,T].$$

Let M be real, and $h(x,t) = e^{\lambda_c x + Mt}$; choose $T > 0$. We have $Lh = (M + 2(\lambda_c\beta(y) - \lambda_c^2) - g'(0))h$, so for some large enough $M > 0$, we have

$$Lh \geq K(T)h = K(T)e^{\lambda_c x + Mt} \geq K(T)e^{\lambda_c x}.$$

If $\theta > 1$, we have $w(x,y,0) < 0$ for $x < x(\theta)$ (a real depending on θ), and since $w(x,y,0)$ is bounded in Σ, we get $w(x,y,0) < Nh(x,0)$ for N large enough. The maximum principle then implies

$$w(x,y,t) < Nh(x,t) \quad \forall t \in [0,T],$$

$$v(x,y,t) < \theta\psi(y,t) + Ne^{\lambda_c x + Mt}.$$

Meanwhile, $a(y)$ being nonnegative and not identically zero, we know that $\psi(y,t) \geq \epsilon(T) > 0$ for all $t \in [1/T, T]$, so

$$v(x,y,t) < (\theta + N(T)e^{\lambda_c x})\psi(y,t) \quad \forall t \in [1/T, T],$$

then $\limsup_{x\to-\infty}(v(x,y,t)/\psi(y,t)) \leq \theta$, uniformly in $\omega \times [1/T, T]$; the same treatment for $\theta < 1$ provides $\liminf_{x\to-\infty}(v(x,y,t)/\psi(y,t)) \geq \theta$, uniformly in $\omega \times [1/T, T]$, which ends the proof of Lemma 4.6. □

We keep the notation of Lemma 4.6 for the proof of Theorem 4.5: Consider the operator $T = -\Delta + (\lambda_c\beta(y) - \lambda_c^2 - g'(0))$, with Neumann boundary condition; T is self-adjoint with 0 as first eigenvalue; then it is classical to see that, in $L^2(\omega)$, $\psi(y,t) \to \varphi_c(y)$, as $t \to +\infty$, where $\varphi_c(y)$ is the only positive eigenfunction satisfying $\int_\omega a\varphi_c = \int_\omega \varphi_c^2$.

Once again, we use the classical parabolic estimates to prove that the convergence happens in $L^\infty(\omega)$.

Let $\epsilon > 0$, so there exists t_0 such that $\forall t \geq t_0$, $(1-\epsilon)\varphi(y) < \psi(y,t) < (1+\epsilon)\varphi(y)$. Let ϕ_c and ϕ'_c the travelling waves, with speed c, satisfying $\phi_c \sim (1-\epsilon)\varphi(y)e^{\lambda_c x}$ and $\phi'_c \sim (1+\epsilon)\varphi(y)e^{\lambda_c x}$ as $x \to -\infty$. We apply Theorem 4.3 with initial data $\inf\{\phi_c(x,y); u(x,y,t_0)\}$ and $\sup\{\phi'_c(x,y); u(x,y,t_0)\}$; $u(x,y,t)$ stays between the solutions of the corresponding Cauchy problems (maximum principle), but these converge uniformly on $\bar{\Sigma}$ to ϕ_c and ϕ'_c, respectively. Just notice now that $||\phi_c - \phi'_c||_{L^\infty(\Sigma)}$ is arbitrarily small when ϵ is. This proves Theorem 4.5. □

Keeping the notation of Theorem 4.5, we denote by ϕ_c the only travelling front such that $\phi_c(x,y) \sim e^{\lambda_c x}\varphi_c(y)$ as $x \to -\infty$. We have an explicit expression for x_0:

$$x_0 = \frac{1}{\lambda_c}\left(\mathrm{Log}\int_\omega a\varphi_c - \mathrm{Log}\int_\omega \varphi_c^2\right).$$

Our last result concerns the creation of fronts at both ends of the cylinder.

THEOREM 4.7. *Let $u(x,y,t)$ be a solution of $(\mathcal{P})$; suppose there exist $\lambda \in (0,\lambda^*)$ and $\tilde{\lambda} \in (0,\lambda^{**})$ satisfying*

$$u_0(x,y) \sim a(y)e^{\lambda x} \text{ near } -\infty \text{ uniformly in } \omega,$$
$$u_0(x,y) \sim b(y)e^{-\tilde{\lambda}x} \text{ near } +\infty \text{ uniformly in } \omega$$

for some continuous, nonidentically zero $a(y)$ and $b(y)$; then if we denote by c and c' the wave speeds associated to λ and $\tilde{\lambda}$, respectively, with $c' < c^{**} < c^* < c$, we have

$$\sup_{(x,y)\in\Sigma} |u(x,y,t) - \inf\{\phi_c(x+ct,y), \tilde{\phi}_c(x+c't,y)\}| \to 0 \quad \text{as } t \to +\infty.$$

Proof. Using Lemma 4.6, and proceeding as in the proof of Theorem 4.5, we have that $u(x-ct,y,t) \to \phi_c(x,y)$, uniformly on each $(-\infty,a]\times\omega$ and $u(x-c't,y,t) \to \tilde{\phi}_{c'}(x,y)$, uniformly on each $[a,+\infty)\times\omega$.

Let $\epsilon > 0$; there exist X_1 and X_2 such that $\phi_c(x,y) \geq (1-\epsilon)$, $\forall x \geq X_1$, $\forall y \in \omega$, and $\tilde{\phi}_{c'}(x,y) \geq (1-\epsilon)$, $\forall x \leq X_2$, $\forall y \in \omega$. Set $D = \{(x,y,t)/X_1 - ct < x < X_2 - c't\}$; choose some large t_0 satisfying $t \geq t_0 \Longrightarrow u(X_1 - ct, y, t) \geq \phi_c(X_1, y) - \epsilon \geq 1 - 2\epsilon$ and $u(X_2 - c't, y, t) \geq \tilde{\phi}_{c'}(X_2, y) - \epsilon \geq 1 - 2\epsilon$. Set $g_\epsilon(s) = ms(1 - 2\epsilon - s)$ with m small enough to have $g_\epsilon \leq g$; we are going to apply the maximum principle on $D \cap \{t \geq t_0\}$: Let $h(t)$ satisfy $\dot{h} = g_\epsilon(h)$ and $h(0) = \inf\{1-2\epsilon; \inf_{D\cap\{t=t_0\}} u(x,y,t_0)\}$; now write

$$(\partial_t + A)(u - h) = g(u) - g_\epsilon(h) \geq g(u) - g(h).$$

Considering the boundary conditions, this shows that $u(t) \geq h(t+t_0)$ in $D \cap \{t = t_0\}$.

Therefore, there exists t_1 such that $\forall t \geq t_1$, $u(x,y,t) \geq 1 - 3\epsilon$ in D. This ends the proof of Theorem 4.7. □

5. Local stability in weighted spaces. In this section, we adopt another point of view, based upon the spectral analysis of operator A_c in a suitable weighted space. This kind of analysis appeared for the first time in the work of Sattinger [19], with a KPP source term. This section generalises [19]; furthermore, we show how to improve very easily the uniform convergence results of the last section in the case of a KPP source term, when the initial datum has a suitable behaviour as $x \to +\infty$. The general case is more intricate and is presented in the next section.

5.1. Framework. We linearise problem $(\mathcal{P}_c)$ near ϕ_c by setting $u_0 = \phi_c + v_0$ and $u(t) = \phi_c + v(t)$, $\forall t > 0$, with $c > c^*$ fixed once and for all. We obtain

$$\partial_t u + A_c u = g(u) \Leftrightarrow \partial_t v + A_c v = g(\phi_c + v) - g(\phi_c).$$

Set $L = A_c - g'(\phi_c)$ and $f(v) = g(\phi_c + v) - g(\phi_c) - vg'(\phi_c)$, which leads to the formulation

$$\begin{cases} \partial_t v + Lv = f(v) & \text{in } \Sigma, \\ \partial_\nu v = 0 & \text{on } \partial\Sigma, \\ v(0) = v_0. \end{cases}$$

Choice of a space. Set $\beta_\eta = \beta + \eta - \bar{\beta}$ ($\bar{\beta}$ denotes the average of β); for $0 < \eta < \bar{\beta}$ sufficiently close to $\bar{\beta}$, the following problem

$$(E_\eta) : \begin{cases} -\Delta_y \varphi - g'(0)\varphi + \lambda \beta_\eta \varphi = \lambda^2 \varphi & \text{in } \omega, \\ \partial_\nu \varphi = 0 & \text{on } \partial\omega, \end{cases}$$

admits exactly two positive principal eigenvalues; we denote by $r = r(\eta)$ the smallest one, and consider an associated eigenfunction ψ, which is positive on ω.

Remark 1. $r > \lambda_c$ and $r(\eta) \searrow \lambda_c$ as $\eta \nearrow \bar{\beta}$.

Let $\Gamma \in C^\infty(\mathbb{R})$ such that $0 \leq \Gamma \leq 1$, $\Gamma = 0$ on $(-\infty, 0]$ and $\Gamma = 1$ on $[1, +\infty)$; let

$$w_1(x,y) = (1 - \Gamma(x))e^{rx}\psi(y) + \Gamma(x+1) \text{ and } w(x,y) = 1/w_1(x,y)$$

set

$$X = \{u \in C_0(\bar{\Sigma}); wu \in C_0(\bar{\Sigma})\},$$

where $C_0(\bar{\Sigma})$ is the set of all bounded uniformly continuous functions on $\bar{\Sigma}$, which tend to 0 as $|x| \to \infty$, uniformly on $\bar{\omega}$.

We equip X with the norm $||u||_X = ||wu||_\infty$, so that

$$M : X \longrightarrow C^0(\bar{\Sigma}),$$

$$u \mapsto wu,$$

is an isometric isomorphism between $(X, ||.||_X)$ and $(C^0(\bar{\Sigma}), ||.||_\infty)$.

Remark 2. $\partial_x \phi_c \notin X$ This is clear from the behaviour of $\partial_x \phi_c$ as $x \to -\infty$.

Transformation of operator L. To the operator L defined on X, we associate $\tilde{L} = MLM^{-1}$ defined in $C^0(\bar{\Sigma})$, in other words $\forall v \in C^0(\bar{\Sigma})$ smooth, $\tilde{L}v = wL(v/w)$; recall that $L = -\Delta + \beta(y)\partial_x - g'(\phi_c)$, therefore we get $\tilde{L}$

$$\tilde{L}v = -\Delta v + B(x,y).\nabla v + C(x,y)v,$$

where

$$B(x,y).\nabla v = \beta(y)\partial_x v + 2\frac{\nabla w}{w}.\nabla v$$

and

$$C(x,y) = \frac{\Delta w}{w} - 2\frac{|\nabla w|^2}{w^2} - \beta(y)\frac{\partial_x w}{w} - g'(\phi_c).$$

Thanks to our choice for w, we get that $B(x,y)$ is bounded, and

$$C(x,y) = \begin{cases} r(\bar{\beta}-\eta) + g'(0) - g'(\phi_c) & \text{for } x < -1, \\ -g'(\phi_c) & \text{for } x > 1. \end{cases}$$

Set $\gamma(x) = r(\bar{\beta}-\eta)(1-\Gamma(x)) - g'(1)\Gamma(x+1)$; notice that $\inf_{I\!R}\gamma > 0$ and that $|C(x,y)-\gamma(x)| \to 0$ as $|x| \to \infty$, uniformly on $\bar{\omega}$; set

$$\tilde{T}v = -\Delta v + B(x,y).\nabla v + \gamma(x)v,$$

$$\tilde{S}v = [C(x,y)-\gamma(x)]v,$$

write $\tilde{L} = \tilde{S} + \tilde{T}$ and $L = S + T$ with $S = M^{-1}\tilde{S}M$ and $T = M^{-1}\tilde{T}M$; finally, define the domains

$$D(\tilde{L}) = D(\tilde{T}) = \left\{ u \in C_0(\bar{\Sigma}) \cap \left(\bigcap_{p\geq 1} W^{2,p}_{loc}(\Sigma) \right) ; \Delta u \in C^0(\bar{\Sigma}) \text{ and } \partial_\nu u = 0 \text{ on } \partial\Sigma \right\},$$

$$D(L) = M^{-1}(D(\tilde{L})) = \left\{ u \in X \cap \left(\bigcap_{p\geq 1} W^{2,p}_{loc}(\Sigma) \right) ; \Delta u \in X \text{ and } \partial_\nu u = 0 \text{ on } \partial\Sigma \right\}.$$

LEMMA 5.1. *$D(L)$ is dense in X.*

5.2. Spectral properties of L.

LEMMA 5.2. *L is sectorial in X, more precisely $\exists a < 0$, $\gamma_0 > 0$, and $\alpha \in [0, \frac{\pi}{2})$ such that*

1. *$\sigma(L)$ (the spectrum of L in X) is contained in the cone*

$$C_{a,\alpha} = \{ z \in \mathbb{C} \, ; |\mathrm{Arg}(z-a)| < \alpha \}.$$

2. *If $\lambda \in \sigma(L)$ and $\mathrm{Re}(\lambda) < \gamma_0$, then λ is an eigenvalue for L.*

The proof is similar to the one given in [17, Thm. 4.1].

THEOREM 5.3. *If λ is an eigenvalue for L in X, then either $\lambda = 0$ or $\mathrm{Re}(\lambda) > 0$.*

Proof. It is nearly the proof of Theorem 1 in [6], and in fact much simpler since there is nothing to prove as $x \to -\infty$.

Let $u \in X$ such that $Lu = \lambda u$; differentiating $A_c\phi_c = g(\phi_c)$ yields $L(\partial_x\phi_c) = 0$; with u being in X, we immediately have

$$\frac{u}{\partial_x\phi_c} \to 0 \quad \text{when } x \to -\infty;$$

the only point is to prove the same as $x \to +\infty$. Indeed, if we denote by λ^+ the exponent which rules the behaviour of ϕ_c at $+\infty$, and then if $\mathrm{Re}(\lambda) \leq 0$ and $\lambda \neq 0$, there exists $\epsilon > 0$ such that $|u(x,y)| \leq e^{-(\lambda^+ + \epsilon)x}$ in Σ. (See Lemmas 5.1, 5.2, 5.3, and 5.6 in [6].)

Finally, the maximum principle applied to the function $\mathrm{Re}(e^{-\lambda t}u(x,y))/\partial_x\phi_c$ shows that we have $u = 0$. □

PROPOSITION 5.4. *$L : D(L) \longrightarrow X$ is one-to-one.*

Proof. Let $u \in D(L)$ such that $Lu = 0$; from [7] and Lemma 2.5, there exist α_-, α_+, such that

$$\frac{u}{\phi_x} \to \alpha_- \text{ as } x \to -\infty,$$
$$\frac{u}{\phi_x} \to \alpha_+ \text{ as } x \to +\infty.$$

Now proceed as in [17], Proposition 3.4: This yields (u/ϕ_x) =constant. Now since u is supposed to decay faster than ϕ_x, $u = 0$. □

Remark 3. This proves that $Lu = 0$, $u \in C_0(\bar{\Sigma})$ implies that u is proportional to $\partial_x \phi_c$.

5.3. Conclusion: Local stability and exponential convergence.

PROPOSITION 5.5. *L is a sectorial operator in X with spectrum $\sigma(L)$ contained in a cone $C_{a,\alpha}$ with $a > 0$ and $\alpha \in [0, \frac{\pi}{2})$.*

In particular, $\mathrm{Re}(\sigma(L)) > a > 0$.

This is an obvious consequence of the above paragraph.

THEOREM 5.6. *$\exists \omega > 0$, $\rho > 0$, and $M \geq 0$ such that, if $||v_0||_X \leq \rho/2M$, then the problem*

$$\begin{cases} dv/dt + Lv = f(v) & \forall t > 0 \\ v(0) = v_0 \end{cases}$$

admits exactly one solution v defined on $(0, +\infty)$ and satisfying $||v(t)||_X \leq 2Me^{-\omega t}||v_0||_X$.

Proof. Just use Theorem 5.1.1 in [11]. □

Now we may use the global stability theorems of §4 to get an exponential global stability result. Assume for simplicity that g is concave.

PROPOSITION 5.7. *Let u_0 be uniformly continuous in $\bar{\Sigma}$ such that $u_0(x, y) = \phi_c(x, y)(1 + O(e^{rx}))$ as $x \to -\infty$, for some positive real r, and $\liminf_{x \to +\infty} u_0 > 0$. Then*

$$||u(t) - \phi_c||_\infty \leq Ke^{-\kappa t},$$

where K and κ are two positive real numbers.

Proof. Let $w(x, y)$ be a positive exponential solution of

$$\begin{cases} -\Delta w + \beta_\eta \partial_x w = g'(0)w & \text{in } \Sigma, \\ \partial_\nu w = 0 & \text{on } \partial\Sigma, \end{cases}$$

with η close enough to $\bar{\beta}$ so that

$$w(x, y)/e^{(\lambda_c + r)x} \to +\infty \text{ as } x \to -\infty.$$

We have

$$\begin{aligned}(-\Delta + \beta\partial_x)(\phi_c + Cw) &= g(\phi) + \eta C \partial_x w + g'(0)Cw \\ &\geq g(\phi) + g'(0)Cw \geq g(\phi + Cw),\end{aligned}$$

for each constant C (here we have used the concavity of g). Symmetrically, we have

$$\begin{aligned}(-\Delta + \beta\partial_x)(\phi_c - Cw) &= g(\phi) - \eta C \partial_x w - g'(0)Cw \\ &\leq g(\phi) - g'(0)Cw \leq g(\phi - Cw).\end{aligned}$$

We infer from the maximum principle that, for C large enough, the following inequalities hold:

$$\phi_c - Cw \leq u(t) \leq \phi_c + Cw.$$

Now we use the global stability theorem and then we are in a position to apply the local exponential stability theorem. □

6. Extensions to non-KPP source terms. We drop here the KPP assumption. The global stability results for the fast waves—i.e., $c > c_*$—are the same as in the preceeding sections, but the proofs are more technical and appeal to some ideas presented in [18]. New stability results are derived when an additional assumption is made on g.

6.1. Global stability for rapid waves. We want to prove a result similar to Theorem 4.5; let us recall it.

THEOREM 6.1. *Let $c > c^*$, $\beta(y) = \alpha(y) + c$, and consider $u(t)$ the solution of problem*

$$(\mathcal{P}_C) : \begin{cases} \partial_t u - \Delta u + (\alpha(y) + c)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 \quad \text{on } \partial\Sigma, \\ u(t=0) = u_0 \quad \text{in } \Sigma, \end{cases}$$

with u_0 (taking its values in $[0,1]$) satisfying

1. *$u_0(x,y) \sim a(y)e^{\lambda_c x}$ uniformly on ω as $x \to -\infty$, where $a(y)$ is continuous and not identically zero;*
2. *$\liminf_{x\to+\infty} u_0 > 0$ uniformly on ω, then*

$$\exists x_0 \in \mathbb{R} \text{ such that } \sup_{(x,y)\in\bar{\Sigma}} |u(x,y,t) - \phi_c(x + x_0, y)| \to 0 \quad \text{as } t \to +\infty.$$

We need only prove this when $a(y) = \varphi_c(y)$ and $u_0(x,y) = \varphi_c(y)e^{\lambda_c x}(1 + O(e^{rx}))$. To see this, one may proceed as in [18, Lemma 2.3]; this is the way we will follow.

Before we start the proofs, notice that, just as in the proof of Theorem 4.5, we can obtain an explicit expression for the asymptotic shift x_0.

Let $\Gamma \in C^\infty(\mathbb{R})$ such that $0 \leq \Gamma \leq 1$, $\Gamma = 0$ on $(-\infty, 0]$ and $\Gamma = 1$ on $[1, +\infty)$.

LEMMA 6.2. *There exist three positive real M, q_0, and s, such that*

$$u(x,y,t) \leq \phi_c(x + M, y) + q_0 e^{-st}\Gamma(x + M).$$

Proof. Just as in [18, Lemma 5.1]. □

Next we need an even sharper control on the decay of the solution $u(x,y,t)$ as $x \to -\infty$.

LEMMA 6.3. *$\forall r' > r$, $\exists C > 0$ such that, $\forall t \geq 0$,*

$$|u(x,y,t) - \phi_c(x,y)| \leq Ce^{(\lambda_c + r')x}.$$

Proof. Let δ and x_0 such that

- $g'(0) < \delta$;
- the equation $\mu_1(-\Delta + \lambda\beta - \lambda^2 - \delta) = 0$ admits solutions; let $w(x,y)$ be a corresponding exponential solution;

- $\forall (x,y,t) \in (-\infty, x_0] \times \omega \times \mathbb{R}^+$, we have

$$\frac{g(u(x,y,t)) - g(\phi_c(x,y))}{u(x,y,t) - \phi_c(x,y)} \leq \delta.$$

Set $v = u - \phi_c$. The function w is an upper solution for the equation on v. So, for C large enough, we have $Cw \geq u - \phi_c$. The same method works if we look for a subsolution; just consider $\phi_c - u$. □

PROPOSITION 6.4. *There exist three positive real numbers M, q_0,and s, such that*

$$u(x,y,t) \geq \phi_c(x - M, y) - q_0 e^{-st}.$$

Proof. Let $\epsilon > 0$ such that the ball with radius ϵ and center ϕ_c (in the norm $1 + e^{-(\lambda_c + r/2)x}$), be in the attraction domain of ϕ_c. Choose $t_0 > 0$ such that $\forall t \geq t_0$, $\lim_{x \to +\infty} u(x,y,t) \geq 1 - \epsilon/2$. We can construct $\underline{u}_0(x,y)$ satisfying the following properties:

- $\underline{u}_0(x,y) = \phi_c(x,y)(1 + e^{2rx/3}(1 + o(1)))$ for $x \leq -M$;
- $\liminf_{x \to +\infty} \underline{u}_0(x,y) \geq 1 - \epsilon/2$;
- $\sup_{(x,y) \in \Sigma} |\underline{u}_0(x,y) - \phi_c(x,y)|.(1 + e^{-(\lambda_c + r/2)x}) \leq \epsilon$.

The solution of the Cauchy problem, with initial datum $\underline{u}_0(x - M, y)$, will converge exponentially to $\phi_c(x - M, y)$. Moreover, for large enough M, $\underline{u}_0(x,y) \leq u_0(x,y)$. □

Now we prove Theorem 6.1. Let

$$X_{\delta,r} = \{u_0 \in \mathrm{UC}(\bar{\Sigma}); u_0 \nearrow, \lim_{x \to +\infty} u_0(x,y) \geq \delta, \text{ and } |u_0(x,y) - \phi_c(x,y)| \leq C e^{(\lambda_c + 2r/3)x}\},$$

where UC is the set of bounded uniformly continuous functions. Also set

$$C_{\delta,r} = \{u_0 \in X; S(t)u_0 \to \phi_c \text{ in the weighted norm } 1 + e^{-(\lambda_c + r/2)x}\}.$$

It is clear from the local stability theorems that $C_{\delta,r}$ is open in $X_{\delta,r}$; in order to prove that it is also closed, we state the following proposition.

PROPOSITION 6.5. *Let $u_{10} \in X_{\delta,r}$. There exists ε_0 such that, for every $\varepsilon < \varepsilon_0$,*

$$\forall u_{20} \in X_{\delta,r}, \quad ||u_{10} - u_{20}||_{X_{\delta,r}} \leq \epsilon \implies \sup_{(x,y) \in \Sigma} (1 + e^{-\lambda_c x/2})|S(t)u_{10} - S(t)u_{20}| \leq C\epsilon.$$

Proof. Just do as in [18, Prop. 5.3]. The proof involves the construction of upper and lower solutions, and the use of parabolic Harnack inequlities "up to the boundary." □

COROLLARY 6.6. *If $u_0 \in X_{\delta,r}$, then $S(t)u_0$ converges towards ϕ_c.*

To end the proof of the theorem, just notice that it is always possible to find $\underline{u}_0 \in X_{\delta,r}$ and $\bar{u}_0 \in X_{\delta',r'}$, such that $\underline{u}_0 \leq u_0 \leq \bar{u}_0$. □

6.2. Stability of the wave with speed c^*. Here we suppose that $c^* > c_0$. Since the results that are stated can be proved by almost the same methods as in the above sections, we will only give the main lines of the proofs, leaving it to the interested reader to check the details.

We first show that the case $c^* > c_0$ is indeed a possible one, and proceed as in as Berestycki and Nirenberg in [8]. We multiply by $\partial_x \phi$ the equality

$$-\Delta\phi + (c^* + \alpha(y))\partial_x \phi = g(\phi)$$

and we integrate on Σ, which yields

$$\int_\Sigma (c^* + \alpha(y))[\partial_x \phi]^2 dxdy = G(1)$$

where $G(s) = \int_0^s g(\sigma)d\sigma$; the multiplication by $1 - \phi$ yields

$$(c^* + < \alpha >) \geq \frac{2}{|\omega|} \int_\Sigma |\nabla \phi|^2 dxdy,$$

$$(c^* + \sup \alpha)^2 \geq \frac{2}{|\omega|} \int_\Sigma |\nabla \phi|^2 (c^* + \sup \alpha) dxdy$$

so we get $(c^* + \sup \alpha)^2 \geq \frac{2}{|\omega|} G(1)$, that is to say

$$c^* \geq \sqrt{\frac{2}{|\omega|} G(1)} - \sup \alpha.$$

Now remember that $c_0(g'(0)) \to 0$ as $g'(0) \to 0$; then we just have to choose $g'(0)$ small and $G(1)$ large enough. □

As for the asymptotic behaviour of ϕ_{c^*} as $x \to -\infty$, we have to take into account the case when ϕ_{c^*} decays at the usual rate, and the case when ϕ_{c^*} decays at the accidental rate.

Case 1. If ϕ_{c^*} decreases at the usual rate, all the results for rapid waves are still available for ϕ_{c^*}. We leave it to the interested reader to check the analogue of Theorem 6.1 for ϕ_{c^*}.

Case 2. If ϕ_{c_*} decreases at the accidental rate, we get the same results as in the "ignition temperature" case: Local stability in weighted spaces with small exponents, and convergence to travelling waves for initial data that are increasing in x (see [18]). Namely, the weight functions that are suitable in this case are not sufficient to kill the translation invariance. Here is the precise result.

THEOREM 6.7. *Let $u(t)$ be the solution of*

$$(\mathcal{P}_*) : \begin{cases} \partial_t u - \Delta u + (\alpha(y) + c_*)\partial_x u = g(u) & \text{in } \Sigma, \\ \partial_\nu u = 0 \quad \text{on } \partial\Sigma, \\ u(t=0) = u_0 \quad \text{in } \Sigma. \end{cases}$$

Assume moreover that the initial datum u_0 satisfies

1. $u_0(x,y) = O(e^{rx})$ *as* $x \to -\infty$, *with* $r > 0$;
2. $\liminf_{x \to +\infty} u_0 > 0$ *uniformly on* ω.

Then the following is true.

1. *If u_0 has the form $u_0(x,y) = \phi_{c_*}(x,y) + \varepsilon v_0(x,y)$ (with v_0 decaying as e^{rx} as $x \to -\infty$), then for $\varepsilon_0 > 0$ small enough there exists $\gamma(\varepsilon) \in C^1(-\varepsilon_0, \varepsilon_0)$ and*

$$\sup_{(x,y)\in\bar{\Sigma}} |u(x,y,t) - \phi_c(x + \varepsilon\gamma(\varepsilon), y)| = O(e^{-\omega t}) \text{ as } t \to +\infty.$$

2. *If u_0 takes its values in $(0,1)$ is increasing in the x direction then $\exists x_0 \in \mathbb{R}$ and $\omega > 0$ such that*

$$\sup_{(x,y)\in\bar{\Sigma}} |u(x,y,t) - \phi_c(x + x_0, y)| = O(e^{-\omega t}) \text{ as } t \to +\infty.$$

Proof. Point 1 may be proved by the same method as in §5 as far as the linear stability is concerned. Nonlinear stability results are then proved in weighted spaces with exponents $< \lambda^a_{c_*}$; therefore one must go through all the steps of the proof of Theorem 1 in [17].

Let us now give the main lines of the proof of 2. Let $X_{r,\delta}$ and $C_{r,\delta}$ be defined as in the above subsection; we want to prove that $C_{r,\delta}$ is closed in $X_{r,\delta}$. One way to do it is as follows.

1. Prove an inequality of the type

$$\phi_{c_*}(x - M, y) - q_1 e^{-st} \leq u(x, y, t) \leq \phi_{c_*}(x + M, y) + q_2 e^{-st}.$$

This may be done as in Proposition 6.4.

2. Prove a uniform estimate as in Proposition 6.5. □

Remark 4. This method yields an extension to the second author's Theorem 1.2 in [18] to initial data having an arbitrary exponential decay as $x \to -\infty$.

Remark 5. The assumption $c_* > c_0$ is less artificial than it seems to be. Indeed, in combustion theory, in the framework of large activation energies, the so-called ZFK source term satisfies this assumption; see [4]. As such, the corresponding model should share many features with the "ignition temperature" model, investigated in [18]. This is exactly what we have just proved.

Acknowledgments. It is our pleasure to thank Prof. H. Berestycki for the kind interest that he always gave to our work, for his helpful advice, and for his useful remarks.

SLOW MOTION IN ONE-DIMENSIONAL CAHN–MORRAL SYSTEMS*

CHRISTOPHER P. GRANT†

Abstract. In this paper one-dimensional Cahn–Morral systems, which are the multicomponent analogues of the Cahn–Hilliard model for phase separation and coarsening in binary mixtures, are studied. In particular, there is an examination of solutions that start with initial data close to the preferred phases except at finitely many transition points where the data has sharp transition layers, and it is shown that such solutions may evolve exponentially slowly, i.e., if ε is the interaction length then there exists a constant C such that in $\exp(C/\varepsilon)$ units of time the change in such a solution is $o(1)$. This corresponds to extremely slow coarsening of a multicomponent mixture after it has undergone fine-grained decomposition.

Key words. Cahn–Hilliard equation, phase separation, transition layers, metastability

AMS subject classifications. 35B30, 35B25, 35K55

1. Introduction. One of the leading continuum models for the dynamics of phase separation and coarsening in a binary mixture is the Cahn-Hilliard equation, which in the one-dimensional case can be written as

$$\begin{aligned} u_t &= (-\varepsilon^2 u_{xx} + W'(u))_{xx}, && x \in (0,1), \\ u_x &= u_{xxx} = 0, && x \in \{0,1\}. \end{aligned} \tag{1.1}$$

Here W represents the bulk free energy density as a function of the concentration u of one of the two components of the mixture. (If, as is typically assumed, the total concentration of the mixture is a constant then the concentration of the second is determined by the concentration of the first.) The parameter ε represents an interaction length and is assumed to be a small positive constant. This equation was derived in [8] based on the free energy functional of van der Waals [29]

$$\mathcal{E}_\varepsilon[u] \equiv \int_0^1 \left(W(u) + \frac{\varepsilon^2}{2} |u_x|^2 \right) dx. \tag{1.2}$$

We will usually work with the scaled energy $E_\varepsilon[u] \equiv \varepsilon^{-1}\mathcal{E}_\varepsilon[u]$. Also, we will write $E_\varepsilon[u; a, b]$ when the integral is over the interval $[a, b]$ instead of $[0, 1]$.

In the early 1970s, Cahn and Morral [24] and DeFontaine [13], [14] initiated the study of systems of partial differential equations that model the phase separation of mixtures of three or more components in essentially the same way that the Cahn-Hilliard equation models the separation of binary mixtures. (See Eyre [20] for a comprehensive survey of these systems.) If the domain is again taken to be $[0, 1]$, then, after a change of variables, such systems can be written in the form

$$\begin{aligned} u_t &= (-\varepsilon^2 u_{xx} + DW(u))_{xx}, && x \in (0,1), \\ u_x &= u_{xxx} = 0, && x \in \{0,1\}, \end{aligned} \tag{1.3}$$

where u is now an n-vector (for a mixture with $n+1$ components), and W maps $\mathcal{D}(W) \subset \mathbf{R}^n$ into $\mathbf{R}$. Again, $\mathcal{E}_\varepsilon$ defined by (1.2) represents the total free energy of

† Center for Dynamical Systems and Nonlinear Studies, Georgia Institute of Technology, Atlanta, Georgia 30332. Present address, Department of Mathematics, Brigham Young University, Provo, Utah 84602.

the mixture, and it is easy to check that it provides a Lyapunov functional for (1.3). Note, also, that the mass $\int_0^1 u\,dx$ of a solution is conserved.

We will make the following assumptions on W.

- $\mathcal{D}(W)$ is open, convex, and connected;
- $W \geq 0$ throughout its domain, and W has only finitely many zeros, call them $\{z_1, z_2, \ldots, z_m\}$, (corresponding to the preferred homogeneous states, or *phases*, of the system);
- W is C^3 on $\mathcal{D}(W)$ and has a continuous extension to its closure $\overline{\mathcal{D}(W)}$;
- the Hessian D^2W is positive definite at each zero of W, and W is bounded away from 0 outside of each neighborhood of these points.

Additionally, we need to require that W increases as the boundary $\partial\mathcal{D}(W)$ of the domain is approached. The precise assumption we shall make is the following:

- For each point $\overline{u}$ in $\partial\mathcal{D}(W)$, there is a closed, convex set $S \subset \overline{\mathcal{D}(W)} \setminus \overline{u}$ such that we have the following.

1. W is nonzero on Ω, the connected component of $\overline{\mathcal{D}(W)} \setminus S$ containing $\overline{u}$;
2. the function φ that maps each point of $\mathbf{R}^n$ to its nearest point in S satisfies $W(\varphi(u)) \leq W(u)$ for all $u \in \Omega$.

This assumption is trivially satisfied when $\mathcal{D}(W) = \mathbf{R}^n$. It also holds whenever W is C^1 on $\overline{\mathcal{D}(W)}$, $\partial\mathcal{D}(W)$ is a locally compact, oriented hypersurface of class C^2, and the (exterior) normal derivative of W is positive. (See, e.g., [21].) However, we state the assumption in this general way because some of the most important examples of $\mathcal{D}(W)$ do not have smooth boundaries. For example, Eyre [20] and Elliott and Luckhaus [18] study situations where $\mathcal{D}(W)$ is a convex polytope and W satisfies the assumptions given above.

Note that any constant is an equilibrium solution to (1.3). A linear analysis of the equation about an unstable constant equilibrium suggests that typical solutions that start near such a constant undergo fine-grained decomposition with a characteristic length scale that is $O(\varepsilon)$. (See [22] for a precise mathematical formulation and rigorous verification of this heuristic concept in the two-component case.) This fine-grained decomposition of initially homogeneous mixtures has also been frequently observed in physical experiments [7], [9]. In this paper we investigate the way solutions evolve after this initial stage of decomposition. We, therefore, confine our attention to solutions to (1.3) with initial data $u(x,0) = u_0(x)$ close to the zeros of W through most of the domain, with sharp transition layers, or *interfaces*, separating the intervals where u is nearly constant.

Consider when $n = 1$ (i.e., the original Cahn–Hilliard equation (1.1)), the case for which the most work has been done. Carr, Gurtin, and Slemrod [10] showed that all of the local minimizers of E_ε with any specified mass are monotone, so, in general, we would expect that the fine-grained structure of u would coarsen as $t \to \infty$. Numerical work by Elliott and French [17] indicates that this evolution occurs very slowly. (Such slowly evolving states are sometimes said to be *dynamically metastable.*) Bronsard and Hilhorst [5] have shown that, in a certain space, this evolution occurs at a rate that is $O(\varepsilon^k)$ for any power k. Using completely different techniques, Alikakos, Bates, and Fusco [1] constructed a portion of the unstable manifold of a two-layer equilibrium that intersects a small neighborhood of a monotone equilibrium and showed that the speed of the flow along this connecting orbit, measured in the H^{-1} norm, is $O(\exp(-C/\varepsilon))$ for some constant C. Recently, Bates and Xun [4] have found exponentially slow motion for the multilayer states of (1.1) by combining the methods of [1] with those used by Carr and Pego [11] to study reaction-diffusion equations.

The results that we present here are similar to those of Bates and Xun in that we also obtain exponentially slow motion, but the methods we use are much simpler, and they are valid not only for the two-component Cahn–Hilliard equation (1.1) but for the multicomponent Cahn–Morral system (1.3), as well. It should be mentioned, however, that our results for the two-component two-layer case are weaker than those of Alikakos, Bates, and Fusco, in the sense that we do not explicitly construct heteroclinic orbits. We deal only with the speed of motion and say nothing about the geometric structure of the attractor.

In this paper, we apply the elementary yet powerful approach introduced by Bronsard and Kohn [6] in their study of slow motion for reaction-diffusion equations. The improvement from superpolynomial to exponential speed is made possible by incorporating some ideas of Alikakos and McKinney [2] about the profile of constrained minimizers of (1.2). Use is also made of techniques of Sternberg [27] for describing the nature of globally stable steady-state solutions of (1.3) in the limit as $\varepsilon \to 0$.

In §2 we present a lower bound on the energy of any function that is sufficiently close to a given simple function whose range is a subset of $W^{-1}(\{0\})$. This result amounts to an error estimate for a convergence result of Baldo [3]. In §3 we show how this estimate yields our main result on slow evolution of solutions with transition layers. As in [6], the only information used about the time-dependent partial differential equation is the time rate of change of the energy along a solution path in phase space. Finally, in §4 we consider what the main result implies about the motion of the transition layers themselves.

The questions of existence and regularity of solutions for (1.1) and (1.3) have been extensively studied, and different authors have obtained various conditions on W that ensure global existence of solutions [15], [16], [18]–[20], [25], [26], [28], [30]. Rather than restricting ourselves to one particular set of such conditions, we shall simply assume that W is such that for sufficiently smooth initial data with range in $\mathcal{D}(W)$ there exists a global solution that is in $C(\mathbf{R}^+; H^2(0,1)) \cap L^2(0,T; H^4(0,1))$. Given that global solutions exist, our goal is to provide some information about how some of them evolve.

2. Error estimates. Fix $v : [0,1] \to W^{-1}(\{0\})$ having (exactly) N jumps located at $\{x_1, x_2, \dots, x_N\} \subset (0,1)$. Fix r so small that $B(x_k, r) \subset [0,1]$ for each k, and

$$B(x_k, r) \cap B(x_\ell, r) = \emptyset$$

whenever $k \neq \ell$. (Here and below, $B(x,r)$ represents the open ball of radius r centered at x in the relevant space.) Let λ_j be the minimum of the eigenvalues of $D^2W(z_j)$, and let

$$\lambda = \min\{\lambda_j : z_j \in W^{-1}(\{0\})\}.$$

For any function z on $[0,1]$ we write $\tilde{z}(x) \equiv \int_0^x z(s)\,ds$. We are interested in solutions corresponding to initial data $u(x,0) = u_0(x)$ such that $\tilde{u}_0$ is close to $\tilde{v}$ in the L^1 norm. To the discontinuous function v we assign an asymptotic energy

$$E_0[v] \equiv \sum_{k=1}^{N} \phi(v(x_k - r), v(x_k + r)),$$

where

$$\phi(\zeta_1, \zeta_2) \stackrel{\text{def}}{=} \inf\{J[z] : z \in AC([0,1]; \mathcal{D}(W)), z(0) = \zeta_1, z(1) = \zeta_2\},$$

and

$$J[z] \stackrel{\text{def}}{=} \sqrt{2} \int_0^1 \sqrt{W(z(s))}|z'(s)|\, ds.$$

It is easy to check that ϕ is a metric on the domain of W. Also, note that Young's inequality and a change of variable imply that

$$E_\varepsilon[z; a, b] \geq \phi(z(a), z(b)).$$

LEMMA 2.1. *Let C be any positive constant less than $r\sqrt{2\lambda}$. Then there are constants $C_1, \delta > 0$ (depending only on W, v and C) such that, for ε sufficiently small,*

$$\int_0^1 |\tilde{u}(x) - \tilde{v}(x)|\, dx \leq \delta \quad \Rightarrow \quad E_\varepsilon[u] \geq E_0[v] - C_1 \exp(-C/\varepsilon).$$

Proof. Let K be a compact set in the domain of W containing $W^{-1}(\{0\})$ in its interior, and set $\kappa = \sup\{\|D^3W(\zeta)\| : \zeta \in K\}$. Choose $\hat{r} > 0$ and ρ_1 so small that $C \leq (r - \hat{r})\sqrt{2\lambda - n\kappa\rho_1}$ and that $B(z_j, \rho_1)$ is contained in K for each $z_j \in W^{-1}(\{0\})$. Choose ρ_2 so small that

$$\begin{aligned} &\inf\left\{\phi(\zeta_1, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_1 \notin B(z_j, \rho_1), \zeta_2 \in B(z_j, \rho_2)\right\} \\ &> \sup\left\{\phi(z_j, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_2 \in B(z_j, \rho_2)\right\}, \end{aligned}$$

and $|z_j - z_\ell| > 2\rho_2$ if z_j and z_ℓ are different zeros of W.

Let

$$\begin{aligned} F(\rho_2) = \inf\{&\phi(\zeta_1, \zeta_2) : z_{j_1}, z_{j_2} \in W^{-1}(\{0\}), z_{j_1} \neq z_{j_2}, \\ &\zeta_1 \in B(z_{j_1}, \rho_2), |(\zeta_2 - z_{j_2}) \cdot (z_{j_2} - z_{j_1})| \leq \rho_2 |z_{j_2} - z_{j_1}|\}. \end{aligned} \tag{2.1}$$

By our assumptions about W, $F(\rho_2) > 0$, so there exists $M \in \mathbf{N}$ such that $MF(\rho_2) > E_0[v]$. Pick such an M, and set $\delta = \hat{r}^2\rho_2/(5M^2)$.

Now assume that $\int_0^1 |\tilde{u}(x) - \tilde{v}(x)|\, dx \leq \delta$, and let us focus our attention on $B(x_k, r)$, a neighborhood of one of the transition points of v. For convenience, let $v_+ = v(x_k + r)$ and $v_- = v(x_k - r)$. Suppose $|u - v| \geq \rho_2$ throughout $(x_k, x_k + \hat{r})$, and let I_M be an open subinterval of $(x_k, x_k + \hat{r})$ of width $\hat{r}/M$. If we assume without loss of generality that $E_\varepsilon[u] \leq E_0[v]$ then for ε sufficiently small there must be some $\hat{x} \in I_M$ such that $u(\hat{x}) \in B(z_{j_1}, \rho_2)$ for some $z_{j_1} \in W^{-1}(\{0\})$. (Otherwise the rescaled bulk free energy would be too high.) If

$$\left|(u - v) \cdot \frac{z_{j_1} - v_+}{|z_{j_1} - v_+|}\right| \geq \rho_2$$

throughout I_M then it is not hard to check that we would have

$$\int_{I_M} |\tilde{u}(x) - \tilde{v}(x)|\, dx \geq \int_{I_M} \left|(\tilde{u}(x) - \tilde{v}(x)) \cdot \frac{z_{j_1} - v_+}{|z_{j_1} - v_+|}\right| dx > \delta,$$

which is a contradiction. Hence,

$$\left|(u - v) \cdot \frac{z_{j_1} - v_+}{|z_{j_1} - v_+|}\right| < \rho_2$$

somewhere on I_M. But then the rescaled energy on I_M must be no less than $F(\rho_2)$. Partitioning $(x_k, x_k + \hat{r})$ into M equal intervals of width $\hat{r}/M$ and using the preceding result, we have $E_\varepsilon[u; x_k, x_k + \hat{r}] \geq MF(\rho_2) > E_0[v]$, contrary to assumption. Hence, there is some $r_+ \in (0, \hat{r})$ such that

$$|u(x_k + r_+) - v_+| < \rho_2.$$

Similarly, there is some $r_- \in (0, \hat{r})$ such that

$$|u(x_k - r_-) - v_-| < \rho_2.$$

Next, consider the unique minimizer $z : [x_k + r_+, x_k + r] \to \mathbf{R}^n$ of the functional $E_\varepsilon[z; x_k + r_+, x_k + r]$ subject to the boundary condition

$$z(x_k + r_+) = u(x_k + r_+).$$

If the range of z is not contained in $B(v_+, \rho_1)$ then

$$\begin{aligned} E_\varepsilon[z; x_k + r_+, x_k + r] &\geq \inf\{\phi(z(x_k + r_+), \zeta) : \zeta \notin B(v_+, \rho_1)\} \\ &\geq \phi(z(x_k + r_+), v_+), \end{aligned} \tag{2.2}$$

by the choice of ρ_2 and the choice of r_+.

Suppose, on the other hand, that the range of z is contained in $B(v_+, \rho_1)$. Then the Euler–Lagrange equation for z is

$$\begin{aligned} z''(x) &= \varepsilon^{-2} DW(z(x)), & x &\in (x_k + r_+, x_k + r), \\ z(x) &= u(x_k + r_+), & x &= x_k + r_+, \\ z'(x) &= 0, & x &= x_k + r. \end{aligned} \tag{2.3}$$

If we define $\psi(x) \equiv |z(x) - v_+|^2$ then $\psi' = 2(z - v_+) \cdot z'$ and

$$\psi'' = 2(|z'|^2 + (z - v_+) \cdot z'') \geq \frac{2}{\varepsilon^2}(z - v_+) \cdot DW(z). \tag{2.4}$$

Now Taylor's theorem and the choice of ρ_1 imply that

$$DW(z) = D^2W(v_+)(z - v_+) + R, \tag{2.5}$$

where $|R| \leq n\kappa|z - v_+|^2/2$. Substituting (2.5) into (2.4) gives

$$\begin{aligned} \psi'' &\geq \frac{2}{\varepsilon^2}(z - v_+) \cdot D^2W(v_+)(z - v_+) - \frac{n\kappa}{\varepsilon^2}|z - v_+|^3 \\ &\geq \frac{2\lambda}{\varepsilon^2}|z - v_+|^2 - \frac{n\kappa\rho_1}{\varepsilon^2}|z - v_+|^2 \\ &\geq \frac{\mu^2}{\varepsilon^2}|z - v_+|^2 \\ &= \frac{\mu^2}{\varepsilon^2}\psi, \end{aligned}$$

where $\mu = C/(r - \hat{r})$.

Thus, ψ satisfies

$$\begin{aligned} \psi''(x) - (\mu/\varepsilon)^2\psi(x) &\geq 0, & x &\in (x_k + r_+, x_k + r), \\ \psi(x) &= |u(x_k + r_+) - v_+|^2, & x &= x_k + r_+, \\ \psi'(x) &= 0, & x &= x_k + r. \end{aligned}$$

Following Alikakos and McKinney [2], we compare ψ to the solution $\hat{\psi}$ of

$$\begin{aligned} \hat{\psi}''(x) - (\mu/\varepsilon)^2 \hat{\psi}(x) &= 0, & x &\in (x_k + r_+, x_k + r), \\ \hat{\psi}(x) &= |u(x_k + r_+) - v_+|^2, & x &= x_k + r_+, \\ \hat{\psi}'(x) &= 0, & x &= x_k + r, \end{aligned}$$

which can be explicitly calculated to be

$$\hat{\psi}(x) = \frac{|u(x_k + r_+) - v_+|^2}{\cosh\left[(\mu/\varepsilon)(r - r_+)\right]} \cosh\left[\frac{\mu}{\varepsilon}(x - (x_k + r))\right].$$

By the maximum principle, $\psi(x) \le \hat{\psi}(x)$, so, in particular,

$$\psi(x_k + r) \le \frac{|u(x_k + r_+) - v_+|^2}{\cosh\left[(\mu/\varepsilon)(r - r_+)\right]} \le 2\rho_2^2 \exp\left[-\frac{C}{\varepsilon}\right].$$

Consequently,

$$|z(x_k + r) - v_+| \le \rho_2 \sqrt{2} \exp(-C/(2\varepsilon)). \tag{2.6}$$

Because W is quadratic at v_+, (2.6) implies that, for some constant C_1,

$$\begin{aligned} E_\varepsilon[z; x_k + r_+, x_k + r] &\ge \phi(z(x_k + r_+), z(x_k + r)) \\ &\ge \phi(z(x_k + r_+), v_+) - \phi(v_+, z(x_k + r)) \\ &\ge \phi(z(x_k + r_+), v_+) - (C_1/(2N)) \exp(-C/\varepsilon). \end{aligned} \tag{2.7}$$

Combining (2.2) and (2.7), we see that the constrained minimizer of the proposed variational problem satisfies

$$E_\varepsilon[z; x_k + r_+, x_k + r] \ge \phi(z(x_k + r_+), v_+) - (C_1/(2N)) \exp(-C/\varepsilon).$$

But the restriction of u to $[x_k + r_+, x_k + r]$ is an admissable function, so it must satisfy the same estimate

$$E_\varepsilon[u; x_k + r_+, x_k + r] \ge \phi(u(x_k + r_+), v_+) - (C_1/(2N)) \exp(-C/\varepsilon).$$

A similar estimate holds for the energy of u on the interval $[x_k - r, x_k - r_-]$. Hence,

$$\begin{aligned} E_\varepsilon[u; x_k - r, x_k + r] &= E_\varepsilon[u; x_k - r, x_k - r_-] + E_\varepsilon[u; x_k - r_-, x_k + r_+] \\ &\quad + E_\varepsilon[u; x_k + r_+, x_k + r] \\ &\ge \phi(v_-, u(x_k - r_-)) - (C_1/(2N)) \exp(-C/\varepsilon) \\ &\quad + \phi(u(x_k - r_-), u(x_k + r_+)) \\ &\quad + \phi(u(x_k + r_+), v_+) - (C_1/(2N)) \exp(-C/\varepsilon) \\ &\ge \phi(v(x_k - r), v(x_k + r)) - (C_1/N) \exp(-C/\varepsilon). \end{aligned}$$

Assembling all of our estimates,

$$E_\varepsilon[u] \ge \sum_{k=1}^{N} E_\varepsilon[u; x_k - r, x_k + r] \ge E_0[v] - C_1 \exp(-C/\varepsilon),$$

as was claimed. □

3. Slow evolution. In this section we will consider a family of solutions $u^\varepsilon(x,t)$ to (1.3), parametrized by the corresponding interaction length ε.

LEMMA 3.1. *Suppose that $C < r\sqrt{2\lambda}$ and the initial data u_0^ε satisfies*

$$\int_0^1 |\tilde{u}_0^\varepsilon(x) - \tilde{v}(x)|\,dx \le \frac{\delta}{2}$$

and

$$E_\varepsilon[u_0^\varepsilon] \le E_0[v] + \frac{1}{g(\varepsilon)}$$

for some function g and for all ε small, where δ is as in Lemma 2.1. Then

$$\lim_{\varepsilon\to 0}\left\{\sup_{0\le t\le \min\{g(\varepsilon),\exp(C/\varepsilon)\}}\int_0^1 |\tilde{u}^\varepsilon(x,t) - \tilde{u}_0^\varepsilon(x)|\,dx\right\} = 0. \tag{3.1}$$

Proof. First note that the scaled total energy $E_\varepsilon[u^\varepsilon(\cdot,t)]$ of the solution of a Cahn-Morral system is nonincreasing in t, since

$$\begin{aligned}\frac{d}{dt}E_\varepsilon[u^\varepsilon(\cdot,t)] &= \varepsilon^{-1}\int_0^1 \left[DW(u^\varepsilon)\cdot u_t^\varepsilon + \varepsilon^2 u_x^\varepsilon \cdot u_{xt}^\varepsilon\right] dx\\ &= \varepsilon^{-1}\int_0^1 \left[(DW(u^\varepsilon) - \varepsilon^2 u_{xx}^\varepsilon)\cdot u_t^\varepsilon\right] dx\\ &= -\varepsilon^{-1}\int_0^1 |\tilde{u}_t^\varepsilon|^2\,dx.\end{aligned}$$

Integrating this equation over $t \in (0,T)$ gives

$$E_\varepsilon[u_0^\varepsilon] - E_\varepsilon[u^\varepsilon(\cdot,T)] = \varepsilon^{-1}\int_0^T\int_0^1 |\tilde{u}_t^\varepsilon|^2\,dx\,dt. \tag{3.2}$$

Next, assume that u_0^ε satisfies the conditions of the lemma and that T is small enough that

$$\int_0^T\int_0^1 |\tilde{u}_t^\varepsilon|\,dx\,dt \le \delta/2.$$

Then

$$\int_0^1 |\tilde{u}_0^\varepsilon(x) - \tilde{u}^\varepsilon(x,T)|\,dx \le \delta/2,$$

so by the triangle inequality,

$$\int_0^1 |\tilde{u}^\varepsilon(x,T) - \tilde{v}(x)|\,dx \le \delta.$$

Applying, Lemma 2.1 to $\tilde{u}^\varepsilon(\cdot,T)$ gives $E_\varepsilon[u^\varepsilon(\cdot,T)] \ge E_0[v] - C_1\exp(-C/\varepsilon)$. In combination with (3.2), this yields

$$\begin{aligned}\int_0^T\int_0^1 |\tilde{u}_t^\varepsilon|^2\,dx\,dt &= \varepsilon(E_\varepsilon[u_0^\varepsilon] - E_\varepsilon[u^\varepsilon(\cdot,T)])\\ &\le C_1\varepsilon\left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right],\end{aligned} \tag{3.3}$$

assuming, without loss of generality, that $C_1 \geq 1$.

Using Hölder's inequality and (3.3) we have

$$\left(\int_0^T \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt\right)^2 \leq \left(\int_0^T \int_0^1 1 \, dx \, dt\right) \cdot \left(\int_0^T \int_0^1 |\tilde{u}_t^\varepsilon|^2 \, dx \, dt\right)$$
$$\leq C_1 T \varepsilon \left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right].$$

Hence,

$$T \geq \frac{1}{C_1 \varepsilon} \left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right]^{-1} \left(\int_0^T \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt\right)^2. \tag{3.4}$$

Now suppos that

$$\int_0^\infty \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt \geq \delta/2.$$

Then we can choose T such that $\int_0^T \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt = \delta/2$. For this choice of T, equation (3.4) yields

$$T \geq \frac{\delta^2}{4C_1 \varepsilon \left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right]} \geq \frac{\delta^2}{8C_1 \varepsilon} \min\left\{g(\varepsilon), \exp(C/\varepsilon)\right\}.$$

Then (3.3) implies that

$$\int_0^{\delta^2 \min\{g(\varepsilon), \exp(C/\varepsilon)\}/(8C_1\varepsilon)} \int_0^1 |\tilde{u}_t^\varepsilon|^2 \, dx \, dt \leq C_1 \varepsilon \left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right]. \tag{3.5}$$

If, on the other hand, $\int_0^\infty \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt < \delta/2$, then (3.3) must hold for every T; therefore, (3.5) is also true for this case.

Using Hölder's inequality and (3.5) we see that for $\varepsilon < \delta^2/(8C_1)$

$$\begin{aligned}
&\sup_{0 \leq t \leq \min\{g(\varepsilon), \exp(C/\varepsilon)\}} \int_0^1 |\tilde{u}^\varepsilon(x,t) - \tilde{u}_0^\varepsilon(x)| \, dx \\
&\leq \int_0^{\min\{g(\varepsilon), \exp(C/\varepsilon)\}} \int_0^1 |\tilde{u}_t^\varepsilon| \, dx \, dt \\
&\leq \left(\min\left\{g(\varepsilon), \exp(C/\varepsilon)\right\} \int_0^{\min\{g(\varepsilon), \exp(C/\varepsilon)\}} \int_0^1 |\tilde{u}_t^\varepsilon|^2 \, dx \, dt\right)^{1/2} \\
&\leq \left(\min\left\{g(\varepsilon), \exp(C/\varepsilon)\right\} C_1 \varepsilon \left[\frac{1}{g(\varepsilon)} + \exp(-C/\varepsilon)\right]\right)^{1/2} \\
&\leq \sqrt{2C_1 \varepsilon}.
\end{aligned}$$

Letting $\varepsilon \to 0$ we get (3.1). □

The strength of estimate (3.1) in Lemma 3.1 depends on the efficiency of the transition layers in the initial data. In Theorem 3.3 below, we show that, in a neighborhood of the step function v, there exist initial data that smooth out the discontinuities of

v in an efficient enough manner that the corresponding solutions of (1.3) evolve in an exponentially slow way. Before we present this theorem, we shall state and prove a technical lemma about the existence and regularity of minimizing geodesics for the degenerate Riemannian metric ϕ.

LEMMA 3.2. (1) *For any two zeros z_i and z_j of W, there is a Lipschitz continuous path γ_{ij} from z_i to z_j, parametrized by a multiple of Euclidean arclength, that realizes the distance $\phi(z_i, z_j)$*; i.e., $\phi(z_i, z_j) = J[\gamma_{ij}]$.

(2) *There exists a positive constant C_2 such that $|\gamma_{ij}(y) - z_i| \geq C_2 y$ for y sufficiently small, and $|\gamma_{ij}(y) - z_j| \geq C_2(1-y)$ for y sufficiently near* 1.

Proof. Recall that outside of a neighborhood of its zeros W is bounded away from 0; therefore, it is possible to find a bounded set $B \subset \mathcal{D}(W)$ such that if $\gamma(0) = z_i$, $\gamma(1) = z_j$, and $J[\gamma] \leq \phi(z_i, z_j) + 1$ then the image of γ is contained in B. Extend W continuously to $\overline{B}$, and consider the problem of minimizing $J[\gamma]$ over all γ satisfying these boundary conditions and having images contained in $\overline{B}$. Now, $J[\gamma]$ is a parametric integral, and it is known that this new minimization problem has an AC global minimizer γ_{ij} [12]. The parameter of this minimizer can be chosen to be proportional to arclength, and then γ_{ij} will be Lipschitz continuous.

We claim that $\gamma_{ij}([0,1])$ is contained in $\mathcal{D}(W)$. Suppose it is not. Then there exists some $y \in (0,1)$ such that $\gamma_{ij}(y) \in \partial\mathcal{D}(W)$. By the assumptions on W, there is a closed, convex set $S \subset \overline{\mathcal{D}(W)} \setminus \gamma_{ij}(y)$ such that W is nonzero on the connected component Ω of $\overline{\mathcal{D}(W)} \setminus S$ containing $\gamma_{ij}(y)$, and the function φ that maps each point of $\mathbf{R}^n$ to its nearest point in S satisfies $W(\varphi(u)) \leq W(u)$ for all u in Ω. Consider the modified path $\bar{\gamma}_{ij}$ from z_i to z_j defined by

$$\bar{\gamma}_{ij}(y) = \begin{cases} \varphi(\gamma_{ij}(y)) & \text{if } \gamma_{ij}(y) \in \Omega, \\ \gamma_{ij}(y) & \text{otherwise.} \end{cases}$$

Note that φ is Lipschitz continuous with Lipschitz constant 1. Because of this and the fact that S separates Ω from the rest of $\overline{\mathcal{D}(W)}$, $\bar{\gamma}_{ij}$ is Lipschitz continuous. It is also easy to check that $J[\bar{\gamma}_{ij}] < J[\gamma_{ij}]$. This contradicts the optimality of γ_{ij}; hence, the claim holds. This verifies that $\phi(z_i, z_j) = J[\gamma_{ij}]$.

We now prove the estimate on γ_{ij} near z_i; the estimate near z_j can be derived similarly. Again, we consider a modification of γ_{ij}, this time the path γ_{ij}^{η} defined by

$$\gamma_{ij}^{\eta}(y) = \begin{cases} z_i + (y/\eta)(\gamma_{ij}(\eta) - z_i) & \text{if } 0 \leq y \leq \eta, \\ \gamma_{ij}(y) & \text{otherwise.} \end{cases}$$

The optimality of γ_{ij} implies that

$$\sqrt{2}\int_0^{\eta} \sqrt{W(\gamma_{ij}(s))}|\gamma_{ij}'(s)|\,ds \leq \sqrt{2}\int_0^{\eta} \sqrt{W(\gamma_{ij}^{\eta}(s))}\frac{|\gamma_{ij}(\eta) - z_i|}{\eta}\,ds. \tag{3.6}$$

Because $D^2W(z_i)$ is positive definite, there are positive constants M_1 and M_2 such that

$$M_1|u - z_i| \leq \sqrt{W(u)} \leq M_2|u - z_i|$$

in a small neighborhood of z_i. Using this in (3.6), we find that

$$|\gamma_{ij}(\eta) - z_i|^2 \geq M_3 \int_0^{\eta} |\gamma_{ij}(s) - z_i|\,ds$$

for some constant M_3. Applying a variant of Gronwall's inequality [23] we obtain the desired estimate. □

THEOREM 3.3. *Given $\delta > 0$, there exist constants $C, \hat{\varepsilon} > 0$ and a family of initial conditions $\{u_0^\varepsilon : 0 \le \varepsilon \le \hat{\varepsilon}\}$ of (1.3) satisfying homogeneous Neumann boundary conditions and the estimate*

$$\int_0^1 |\tilde{u}_0^\varepsilon(x) - \tilde{v}(x)|\, dx \le \frac{\delta}{2}$$

such that the corresponding solutions u^ε of (1.3) satisfy

$$\lim_{\varepsilon \to 0} \left\{ \sup_{0 \le t \le \exp(C/\varepsilon)} \int_0^1 |\tilde{u}^\varepsilon(x,t) - \tilde{u}_0^\varepsilon(x)|\, dx \right\} = 0.$$

Proof. Lemma 3.2 shows that to each discontinuity x_k of v there corresponds an optimal path connecting $v(x_k - r)$ to $v(x_k + r)$. Note that it suffices to prove the present theorem under the assumption that none of these optimal paths passes through any zero of W (except at the endpoints of the path), since if the assumption is not satisfied then v can be perturbed slightly to create a new step function that does satisfy the assumption.

Given ε, set $u_0^\varepsilon = v$ outside of $\cup_{j=1}^m B(x_k, r)$. For fixed x_k, we shall again use the notation $v_\pm$ for $v(x_k \pm r)$ and will show that for ε sufficiently small we can define u_0^ε inside $B(x_k, r)$ in such a way that u_0^ε is very close to v (in the L^1 sense) on $B(x_k, r)$, $E_\varepsilon[u_0^\varepsilon; x_k - r, x_k + r] \le \phi(v_-, v_+) + C_3 \exp(-C/\varepsilon)$ for some C and C_3, and u_0^ε is continuous at the endpoints of $B(x_k, r)$. By taking C slightly smaller and applying Lemma 3.1, the proof of the theorem will then be complete.

Let $\gamma : [0,1] \to \mathbf{R}^n$ be an optimal path from v_- to v_+ as described in Lemma 3.2. Let σ be the Euclidean arclength of γ. Let $y : \mathbf{R} \to [0,1]$ be the solution of

$$\frac{dy}{d\xi} = \sigma^{-1} \sqrt{2W(\gamma(y(\xi)))} \tag{3.7}$$

satisfying $y(0) = 1/2$. (Since $\sqrt{W}$ and γ are Lipschitz continuous, a unique C^1 solution is guaranteed to exist.) Note that $\lim_{\xi \to \infty} y(\xi) = 1$ and $\lim_{\xi \to -\infty} y(\xi) = 0$. Define u_0^ε inside $B(x_k, r)$ by

$$u_0^\varepsilon(x) = \begin{cases} v_- + (\gamma(y(1 - r/\varepsilon)) - v_-)(x - x_k + r)/\varepsilon, & x_k - r < x < x_k - r + \varepsilon, \\ \gamma(y((x - x_k)/\varepsilon)), & x_k - r + \varepsilon \le x \le x_k + r - \varepsilon, \\ v_+ + (v_+ - \gamma(y(r/\varepsilon - 1)))(x - x_k - r)/\varepsilon, & x_k + r - \varepsilon < x < x_k + r. \end{cases}$$

It is easy to see that u_0^ε is continuous and, for ε sufficiently small, will satisfy the L^1 requirement; therefore, we only need to check the energy requirement. Note that

$$\begin{aligned} E_\varepsilon[u_0^\varepsilon; x_k - r, x_k + r] &= \int_{-r}^{-r+\varepsilon} \left[\frac{1}{\varepsilon} W(u_0^\varepsilon(x + x_k)) + \frac{\varepsilon}{2} |u_0^{\varepsilon\prime}(x + x_k)|^2 \right] dx \\ &\quad + \int_{-r+\varepsilon}^{r-\varepsilon} \left[\frac{1}{\varepsilon} W(u_0^\varepsilon(x + x_k)) + \frac{\varepsilon}{2} |u_0^{\varepsilon\prime}(x + x_k)|^2 \right] dx \\ &\quad + \int_{r-\varepsilon}^{r} \left[\frac{1}{\varepsilon} W(u_0^\varepsilon(x + x_k)) + \frac{\varepsilon}{2} |u_0^{\varepsilon\prime}(x + x_k)|^2 \right] dx \\ &\stackrel{\text{def}}{=} I_1 + I_2 + I_3. \end{aligned} \tag{3.8}$$

Now, using (3.7) and the definition of γ we have

$$
\begin{aligned}
I_2 &= \int_{-r+\varepsilon}^{r-\varepsilon} \left[\frac{1}{\varepsilon} W\left(\gamma\left(y\left(\frac{x}{\varepsilon}\right)\right)\right) + \frac{1}{2\varepsilon}\left|\gamma'\left(y\left(\frac{x}{\varepsilon}\right)\right) y'\left(\frac{x}{\varepsilon}\right)\right|^2 \right] dx \\
&= \int_{1-r/\varepsilon}^{r/\varepsilon-1} \left[W(\gamma(y(\xi))) + \frac{1}{2}|\gamma'(y(\xi))y'(\xi)|^2 \right] d\xi \\
&= \int_{1-r/\varepsilon}^{r/\varepsilon-1} \sqrt{2W(\gamma(y(\xi)))}|\gamma'(y(\xi))|y'(\xi)\, d\xi \qquad (3.9) \\
&= \int_{y(1-r/\varepsilon)}^{y(r/\varepsilon-1)} \sqrt{2W(\gamma(y))}|\gamma'(y)|\, dy \\
&\le \phi(v_-, v_+).
\end{aligned}
$$

Next, we estimate I_1 (letting C_3 represent a constant whose value may change from line to line):

$$
\begin{aligned}
I_1 &= \frac{1}{\varepsilon}\int_{-r}^{-r+\varepsilon} W\left(v_- + \frac{\gamma\left(y\left(1-r/\varepsilon\right)\right) - v_-}{\varepsilon}(x+r)\right) dx \\
&\quad + \frac{1}{2}\left|\gamma\left(y\left(1-\frac{r}{\varepsilon}\right)\right) - v_-\right|^2 \qquad (3.10) \\
&\le C_3\left|\gamma\left(y\left(1-\frac{r}{\varepsilon}\right)\right) - v_-\right|^2 \\
&\le C_3\left(y\left(1-\frac{r}{\varepsilon}\right)\right)^2.
\end{aligned}
$$

Now, Lemma 3.2 implies that there exists a constant $C > 0$ such that, for $\xi \ll 0$,

$$
\begin{aligned}
y'(\xi) &= \sigma^{-1}\sqrt{2W(\gamma(y(\xi)))} \\
&\ge \frac{C}{2rC_2}|\gamma(y(\xi)) - v_-| \qquad (3.11) \\
&\ge \frac{C}{2r}(y(\xi)).
\end{aligned}
$$

Applying a simple comparison argument to (3.11) yields

$$
y(\xi) \le C_3 \exp\left(\frac{C\xi}{2r}\right)
$$

for $\xi \ll 0$. Substituting this into (3.10) we have

$$
I_1 \le C_3 \exp(-C/\varepsilon). \qquad (3.12)
$$

Similarly,

$$
I_3 \le C_3 \exp(-C/\varepsilon). \qquad (3.13)
$$

By substituting (3.9), (3.12), and (3.13) into (3.8), we see that u_0^ε satisfies the energy requirement, so we are done. □

Remark. For the standard two-component case with W having two minima, the maximum principle can be used more directly in the proof of Lemma 2.1 (see [2])

and an explicit value of C can be obtained in Theorem 3.3. This C agrees with that obtained in [1] and [4].

Remark. The initial data u_0^ε just constructed are in $W^{1,\infty}(0,1)$. Since E_ε is continuous on this space and elements of this space can be approximated arbitrarily closely by C^p functions (for arbitrarily large p), the initial data in Theorem 3.3 can be assumed to be arbitrarily smooth.

4. Motion of transition layers. From Theorem 3.3, which establishes slow evolution in a certain abstract space, it is natural to infer that the movement of the transition layers themselves is extremely slow. This concept can be made precise in a number of ways, one of which we present here.

Fix some closed subset K of $\mathcal{D}(W) \setminus W^{-1}(\{0\})$, and define the *interface* $I[u]$ of a function u by

$$I[u] \stackrel{\text{def}}{=} u^{-1}(K).$$

This terminology is natural, since the set K is bounded away from the phases of W, where the bulk energy is low. By analyzing how rapidly $I[u]$ changes, we obtain information on how fast the transition layers move.

Let $d(A,B)$ denote the Hausdorff distance between the sets A and B, i.e.,

$$d(A,B) = \max\left\{\sup_{a\in A} d(a,B), \sup_{b\in B} d(b,A)\right\}.$$

We shall show that $d(I[u^\varepsilon(\cdot,t)], I[u_0^\varepsilon])$ grows very slowly in t.

THEOREM 4.1. *Fix $\hat{r} > 0$ and $\hat{\delta} > 0$. Then there exist constants $C, \hat{\varepsilon} > 0$ and a family of initial conditions $\{u_0^\varepsilon : 0 \le \varepsilon \le \hat{\varepsilon}\}$ of (1.3) satisfying homogeneous Neumann boundary conditions and the estimate*

$$\int_0^1 |\tilde{u}_0^\varepsilon(x) - \tilde{v}(x)|\, dx \le \hat{\delta}$$

such that the time $T(\hat{r})$ necessary for $d(I[u^\varepsilon(\cdot,T(\hat{r}))], I[u_0^\varepsilon])$ to exceed $\hat{r}$ satisfies

$$T(\hat{r}) \ge \exp(C/\varepsilon). \tag{4.1}$$

Proof. Assume, without loss of generality, that $\hat{r} \le r$. Choose $\hat{\rho}$ small enough that

$$\begin{aligned}&\inf\left\{\phi(\zeta_1,\zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_1 \in K, \zeta_2 \in B(z_j,\hat{\rho})\right\}\\ &\quad > 4N \sup\left\{\phi(z_j,\zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_2 \in B(z_j,\hat{\rho})\right\}.\end{aligned}$$

Choose $M \in \mathbf{N}$ so large that $MF(\hat{\rho}) > E_0[v]$, where F is defined as in (2.1).

We claim that there exists $\varepsilon_0 > 0$ such that for all $\varepsilon \le \varepsilon_0$ and for all functions $z : [0,1] \to \mathbf{R}^n$ satisfying

$$\int_0^1 |\tilde{z}(x) - \tilde{v}(x)|\, dx \le \frac{\hat{\rho}\hat{r}^2}{17M^2} \tag{4.2}$$

and

$$E_\varepsilon[z] \le E_0[v] + 2N \sup\left\{\phi(z_j,\zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_2 \in B(z_j,\hat{\rho})\right\} \tag{4.3}$$

we have

$$d\left(I[z], \{x_k\}_{k=1}^N\right) < \frac{\hat{r}}{2}.$$

Verification of claim. Note first that if ε is sufficiently small then for each k there exist

$$x_{k-} \in (x_k - \hat{r}/2, x_k)$$

and

$$x_{k+} \in (x_{k+}, x_k + \hat{r}/2)$$

such that $|z(x_{k\pm}) - v(x_{k\pm})| < \hat{\rho}$. This follows as in the proof of Lemma 2.1. Now, suppose the claim is violated. Then, reasoning as before,

$$\begin{aligned} E_\varepsilon[z] &\geq \sum_{k=1}^N E_\varepsilon[z; x_{k-}, x_{k+}] \\ &\quad + \inf\left\{\phi(\zeta_1, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_1 \in K, \zeta_2 \in B(z_j, \hat{\rho})\right\} \\ &\geq E_0[v] - 2N \sup\left\{\phi(z_j, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_2 \in B(z_j, \hat{\rho})\right\} \\ &\quad + \inf\left\{\phi(\zeta_1, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_1 \notin K, \zeta_2 \in B(z_j, \hat{\rho})\right\} \\ &> E_0[v] + 2N \sup\left\{\phi(z_j, \zeta_2) : z_j \in W^{-1}(\{0\}), \zeta_2 \in B(z_j, \hat{\rho})\right\} \\ &\geq E_\varepsilon[z], \end{aligned}$$

which is a contradiction. Thus, the claim is true.

Apply Theorem 3.3 with $\delta = \min\{\hat{\delta}, \hat{\rho}\hat{r}^2/(17M^2)$ to obtain a parametrized set of initial conditions $\{u_0^\varepsilon : 0 \leq \varepsilon \leq \hat{\varepsilon}\}$. Note that $z = u_0^\varepsilon$ satisfies (4.2) and, by the construction in the proof of Theorem 3.3, satisfies (4.3) for ε sufficiently small. Applying the claim we get

$$d\left(I[u_0^\varepsilon], \{x_k\}_{k=1}^N\right) < \frac{\hat{r}}{2},$$

for ε sufficiently small. By Theorem 3.3, the triangle inequality, and the fact that $E_\varepsilon[u^\varepsilon(\cdot, t)]$ is decreasing in t, we see that there is a constant $C > 0$ such that for ε sufficiently small, $z = u^\varepsilon(\cdot, T)$ satisfies (4.2) and (4.3) if $T \leq \exp(C/\varepsilon)$. Thus, for all such T we also have

$$d\left(I[u^\varepsilon(\cdot, T)], \{x_k\}_{k=1}^N\right) < \frac{\hat{r}}{2}.$$

By the triangle inequality we get

$$d\left(I[u_0^\varepsilon], I[u^\varepsilon(\cdot, T)]\right) < \hat{r}.$$

This means that (4.1) must hold. □

Acknowledgments. I am indebted to K. Mischaikow for suggesting this problem and to P. Bates for helping to correct a mistake in the original manuscript. I would also like to thank the referees for their helpful suggestions.

ON A SYSTEM OF INTEGRODIFFERENCE EQUATIONS MODELLING THE PROPAGATION OF GENES*

HWEI-TING LIN†

Abstract. The author considers the gene spread of a certain diploid plant, one of whose gene loci has two alleles. A mathematical model is formulated as a system of integrodifference equations $[N^{(n+1)}, u^{(n+1)}] = Q[N^{(n)}, u^{(n)}]$, where Q is a system of nonlinear convolution integral operators. The dynamics of Q in the heterozygote intermediate case is considered in a one-dimensional habitat. When the initial disadvantageous gene is present only in a finite region of the habitat, the dynamics of Q tends to a constant equilibrium dominated by the advantageous gene. Under certain conditions, the system has traveling wave solutions with speed not less than a minimal wave speed. The method of the Laplace transform is used to determine the minimal wave speed explicitly. The Contraction Mapping Theorem is applied to prove the existence and the uniqueness of the traveling waves. Moreover, it is proved that the minimal wave speed is the asymptotic speed of propagation of the advantageous gene, and the dynamics of the model approaches the traveling waves from suitable initial generations.

Key words. traveling waves, asymptotic stability, integrodifference equations, gene spread

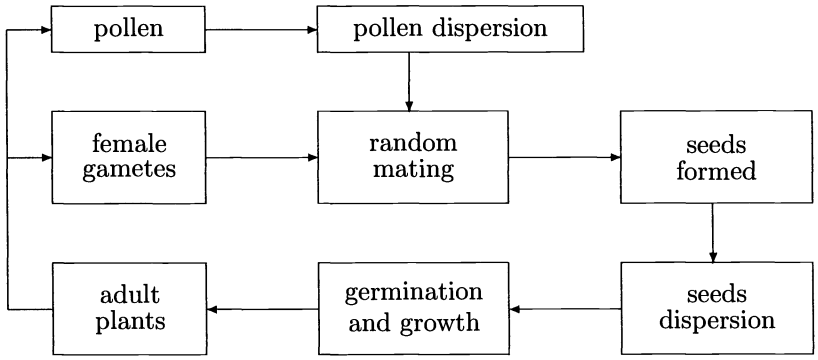
1. Introduction.

We study a discrete dynamical system that models the propagation of mutant genes. This model was proposed in a project by Kareiva et al. [6]. They consider a certain diploid plant, one of whose gene loci has two allelic types: A and a. The pollen disperses throughout the habitat according to some probability distribution function $\mathcal{P}$. Then the pollen randomly mates with female gametes. The seeds thus formed disperse throughout the habitat according to some probability distribution function $\mathcal{S}$. The seeds then settle down in the habitat to germinate and grow into adult plants. The new generation of the adult plants starts another cycle of the spread of alleles A and a. See the following flowchart of this model. We copy this flowchart from Kareiva's project [6].



The complete cycle of the gene spread.

We consider the spread of genes in a one-dimensional habitat. Let $u_1(x)$ and $v_1(x)$ denote, respectively, the local densities of female gametes of types a and A in a certain generation. We assume the local densities of pollen of types a and A are given

* Received by the editors September 14, 1992; accepted for publication (in revised form) May 20, 1993.
† Department of Mathematics, Soo Chow University, Taipei 11102, Taiwan.

by ku_1 and kv_1, where k is a constant. The pollen disperses according to a dispersion probability distribution $\mathcal{P}(x)$. Thus the pollen has the densities $ku_1 * \mathcal{P}$ and $kv_1 * \mathcal{P}$ after dispersion, where

$$u_1 * \mathcal{P}(x) = \int_{-\infty}^{\infty} u_1(x-y)d\mathcal{P}(y), \qquad v_1 * \mathcal{P}(x) = \int_{-\infty}^{\infty} v_1(x-y)d\mathcal{P}(y).$$

Then the pollen randomly mates with the female gametes, and a fraction k' of the female gametes produces seeds.

The diploid seeds of genotypes aa, Aa, and AA thus formed have local densities

$$k'u_1(x)\frac{u_1 * \mathcal{P}(x)}{(u_1+v_1) * \mathcal{P}(x)}, \qquad k'\frac{u_1(x)\, v_1 * \mathcal{P}(x) + v_1(x)\, u_1 * \mathcal{P}(x)}{(u_1+v_1) * \mathcal{P}(x)},$$
$$k'v_1(x)\frac{v_1 * \mathcal{P}(x)}{(u_1+v_1) * \mathcal{P}(x)},$$

respectively. These seeds disperse throughout the habitat according to the dispersion probability distribution $\mathcal{S}(x)$. They then settle down and a fraction d of each genotype grows into adult plants. Thus the adult plants of genotype aa, Aa, and AA have local densities

$$k'd\left(u_1\frac{u_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x), \qquad k'd\left(\frac{u_1(v_1 * \mathcal{P}) + v_1(u_1 * \mathcal{P})}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x),$$
$$k'd\left(v_1\frac{v_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x),$$

respectively. We assume that dk' is a constant that does not depend on the genotypes. Therefore the local population density of adults in the generation is given by

$$N_1(x) = dk'\left(u_1\frac{u_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x) + dk'\left(\frac{u_1(v_1 * \mathcal{P}) + v_1(u_1 * \mathcal{P})}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x)$$
$$+dk'\left(v_1\frac{v_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}(x) \;=\; dk'\,(u_1+v_1) * \mathcal{S}(x).$$

We now assume that each adult plant of type aa produces $\alpha_1(N_1)$ female gametes of type a, each adult plant of type Aa produces $\frac{1}{2}\beta_1(N_1)$ female gametes of type A and the same number of type a, and each adult plant of type AA produces $\gamma_1(N_1)$ female gametes of type A. α_1, β_1, and γ_1 are assumed to depend only on the population density $N_1 = dk'(u_1+v_1)*\mathcal{S}$. Then the densities $\tilde{u}_1(x)$ and $\tilde{v}_1(x)$ of the new generation of female gametes are given by

$$\begin{aligned}
\tilde{u_1} &= \alpha_1(dk'(u_1+v_1) * \mathcal{S})\, dk'\left[\left(u_1\frac{u_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}\right] \\
&\quad +\frac{1}{2}\beta_1(dk'(u_1+v_1) * \mathcal{S})\, dk'\left[\left(\frac{u_1(v_1 * \mathcal{P}) + v_1(u_1 * \mathcal{P})}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}\right], \\
\tilde{v_1} &= \gamma_1(dk'(u_1+v_1) * \mathcal{S})\, dk'\left[\left(v_1\frac{v_1 * \mathcal{P}}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}\right] \\
&\quad +\frac{1}{2}\beta_1(dk'(u_1+v_1) * \mathcal{S})\, dk'\left[\left(\frac{u_1(v_1 * \mathcal{P}) + v_1(u_1 * \mathcal{P})}{(u_1+v_1) * \mathcal{P}}\right) * \mathcal{S}\right].
\end{aligned} \tag{1}$$

The problem is to determine how the genotypes spread in the habitat in the course of many generations. In this paper, we consider a few aspects of this problem in a one-dimensional habitat.

To simplify the equation, we define

$$u_2 = dk'u_1, \quad v_2 = dk'v_1, \quad \alpha_2 = dk'\alpha_1, \quad \beta_2 = dk'\beta_1, \quad \gamma_2 = dk'\gamma_1.$$

Then u_2, v_2 satisfy the same system (1) with α_2, β_2, γ_2 as viability functions and with the constant dk' replaced by 1.

We now assume that there is a positive constant N_0 such that

$$0 \le N\alpha_2(N) \le N_0, \quad 0 \le N\beta_2(N) \le N_0, \quad 0 \le N\gamma_2(N) \le N_0 \tag{2}$$

for $0 \le N \le N_0$. Then we *claim* that, if $0 \le u_2 + v_2 \le N_0$, we also have $0 \le \tilde{u_2} + \tilde{v_2} \le N_0$. To see the claim, we note that

$$\begin{aligned}(\tilde{u_2} + \tilde{v_2})\,[(u_2 + v_2) * \mathcal{S}] \\ \le N_0 \left\{ \left(u_2 \frac{u_2 * \mathcal{P}}{(u_2 + v_2) * \mathcal{P}} \right) * \mathcal{S} + \left(\frac{u_2(v_2 * \mathcal{P}) + v_2(u_2 * \mathcal{P})}{(u_2 + v_2) * \mathcal{P}} \right) * \mathcal{S} \right. \\ \left. + \left(v_2 \frac{v_2 * \mathcal{P}}{(u_2 + v_2) * \mathcal{P}} \right) * \mathcal{S} \right\} = N_0[(u_2 + v_2) * \mathcal{S}].\end{aligned}$$

If $(u_2 + v_2) * \mathcal{S}(x) \neq 0$, then we have $\tilde{u}_2(x) + \tilde{v}_2(x) \le N_0$. If $(u_2 + v_2) * \mathcal{S}(x) = 0$ then

$$\tilde{u}_2(x) + \tilde{v}_2(x) \le \max\{\alpha_2(0), \beta_2(0), \gamma_2(0)\}(u_2 + v_2) * \mathcal{S}(x) = 0.$$

This proves the claim.

We shall assume from now on that the initial gamete population density $u_2 + v_2$, and hence all later densities, satisfy $u_2 + v_2 \le N_0$.

For the convenience of later presentation, we introduce N_0 as a unit of biomass, and renormalize the variables by the following definitions:

$$u = \frac{u_2}{N_0}, \; v = \frac{v_2}{N_0}, \quad \alpha(N) = \alpha_2(N_0 N), \; \beta(N) = \beta_2(N_0 N), \; \gamma(N) = \gamma_2(N_0 N)$$

for $0 \le N \le 1$. Then we still have the system (1) with $k'd = 1$, and the inequalities (2) with $N_0 = 1$. Throughout this paper, we shall use $N(x) = u(x) + v(x) = dk' \frac{N_1(x)}{N_0}$ as the variable of population size. Then $[N, u]$ will be used as our state variables instead of $[u, v]$.

We can now write down the complete cycle as the mapping Q defined in the phase space

$$\Delta = \{[N, u] \mid N, u \in \mathcal{C}(\mathbb{R}), \; 0 \le u(x) \le N(x) \le 1 \text{ for all } x \in \mathbb{R}\},$$

where

$$\mathcal{C}(\mathbb{R}) = \{f \mid f \text{ is a bounded continuous function in } \mathbb{R}.\ f(\pm\infty) \text{ exist}\}.$$

The mapping Q is given by

$$Q[N, u] = [Q_1[N, u], Q_2[N, u]] = [\tilde{N}, \tilde{u}], \qquad [N, u] \in \Delta,$$

where

$$\begin{aligned}\tilde{N} &= Q_1[N,u] \\ &= \alpha(N*\mathcal{S})\left[\left(u\frac{u*\mathcal{P}}{N*\mathcal{P}}\right)*\mathcal{S}\right]+\beta(N*\mathcal{S})\left[\left(u\frac{v*\mathcal{P}}{N*\mathcal{P}}+v\frac{u*\mathcal{P}}{N*\mathcal{P}}\right)*\mathcal{S}\right] \\ &\quad +\gamma(N*\mathcal{S})\left[\left(v\frac{v*\mathcal{P}}{N*\mathcal{P}}\right)*\mathcal{S}\right], \\ \tilde{u} &= Q_2[N,u] \\ &= \alpha(N*\mathcal{S})\left[\left(u\frac{u*\mathcal{P}}{N*\mathcal{P}}\right)*\mathcal{S}\right]+\frac{1}{2}\beta(N*\mathcal{S})\left[\left(u\frac{v*\mathcal{P}}{N*\mathcal{P}}+v\frac{u*\mathcal{P}}{N*\mathcal{P}}\right)*\mathcal{S}\right].\end{aligned}$$

$v = N - u$ in the above equations.

We assume that zero is a point of increase of $\mathcal{P}$ (i.e., $\mathcal{P}(\epsilon) - \mathcal{P}(-\epsilon) > 0$ for all $\epsilon > 0$; see Feller [4]). Thus $N * \mathcal{P}(x) = 0$ will imply $N(x) = 0$. Then we adopt the following convention:

$$u(x)\frac{u*\mathcal{P}(x)}{N*\mathcal{P}(x)} = 0, \quad u(x)\frac{v*\mathcal{P}(x)}{N*\mathcal{P}(x)} = 0, \quad v(x)\frac{u*\mathcal{P}(x)}{N*\mathcal{P}(x)} = 0, \quad v(x)\frac{v*\mathcal{P}(x)}{N*\mathcal{P}(x)} = 0,$$

whenever $N * \mathcal{P}(x) = 0$. Hence Q is well defined in Δ.

The space $\mathcal{C}(\mathbb{R})$ is endowed with the usual sup norm

$$\|f\|_\infty = \sup_{x\in\mathbb{R}} |f(x)|, \qquad f \in \mathcal{C}(\mathbb{R}).$$

We also use the sup norm in Δ unless otherwise stated. Since $\mathcal{P}$ and $\mathcal{S}$ are probability distributions, $f * \mathcal{P} \in \mathcal{C}(\mathbb{R})$ and $f * \mathcal{S} \in \mathcal{C}(\mathbb{R})$ whenever $f \in \mathcal{C}(\mathbb{R})$. This follows from the Lebesgue Dominated Convergence Theorem. Therefore Q maps Δ into itself.

An element of Δ will be called a state of Q. A constant state of Q is a state which is independent of $x \in \mathbb{R}$. Q obviously maps a constant state into a constant state. The corresponding mapping of Q on constant states is the classical one-locus two-allele selection model (see Karlin [7]). α, β, and γ play the roles of the viability fitness matrix elements. However, in contrast with the classical model, α, β, and γ are density dependent. The dynamics of this density-dependent model is presented in Lin [10]. If an advantageous gene is present in a certain generation, the distribution of gene frequencies tends monotonically to the distribution dominated by the advantageous gene, and chaos generically occurs in the evolution of population size due to the density dependence of viability functions.

The modeling of the propagation of an advantageous mutant gene was first introduced by Fisher [5]. He proposed that evolution of the gene frequency $v(x,t)$ of an advantageous gene in a population living in a homogeneous one-dimensional habitat obeys the following nonlinear diffusion equation:

$$v_t = v_{xx} + v(1-v).$$

Fisher [5] and Kolmogorov, Petrovsky, and Piscunoff [8] showed that this model admits traveling waves with speed not less than a minimal speed (which is 2). The wave with minimal speed is an asymptotic state of $v(x,t)$ evolving from some suitable initial conditions. Later work of Aronson and Weinberger [1] went on to show that the minimal wave speed is indeed the asymptotic speed of propagation of the advantageous gene. They also reexamined the modeling process of Fisher's equation, and improved it to take care of both biological realism and mathematical rigor.

One of the recent contributions to the theory of gene spread was a model introduced by Weinberger [15]. He proposed a scalar integrodifference equation of the form

$$v_{n+1}(x) = \int k(x-y)g(v_n(y))dy,$$

where $v_n(x)$ is the gene frequency of the advantageous gene at nth generation, and $k(x)$ is a probability density describing the diffusion process. He showed in [15] that a minimal wave speed c^* exists as

$$c^* = \inf_{\lambda>0}\left\{\frac{1}{\lambda}\log[g'(0)\int e^{\lambda x}k(x)dx]\right\},$$

and it is the asymptotic speed of propagation. He also discussed the connection between his model and Fisher's equation.

In our model, the population density $N(x)$ varies with time and space position. This model is an extension of the model in Weinberger [15], where the population density is assumed to be independent of space position (and hence independent of time). We prove in this paper that a slow selection process enables an advantageous mutant gene to spread throughout the habitat in an asymptotic speed of propagation given by Weinberger's formula. We shall rely on some results in Weinberger [15]. The difficulty in our model is the loss of monotonicity in the system. The use of the comparison principle as presented in Weinberger [16] is limited. The main technique we use is the asymptotic behavior of the solutions of some convolution integral equations as presented in Diekmann and Kaper [2] and Lui [13].

In this paper, $Q^{(n)} = Q \circ \cdots \circ Q$ (n times) denotes the nth iteration of Q. If $[N^{(0)}, u^{(0)}] \in \Delta$ is an initial generation, then $Q^{(n)}[N^{(0)}, u^{(0)}]$ is called the nth iteration state of $[N^{(0)}, u^{(0)}]$ under Q, denoted by $[N^{(n)}, u^{(n)}]$.

2. Basic assumptions and the main results. We state the assumptions for the viability functions and the probability distributions.

(A1) $N\alpha(N)$, $N\beta(N)$, and $N\gamma(N)$ are smooth *concave* functions mapping the interval $0 \le N \le 1$ into itself and $\max\{\alpha(1), \beta(1), \gamma(1)\} < 1$.

(A2) $\alpha(N) \le \beta(N) \le \gamma(N)$ for $0 \le N \le 1$. $\alpha(N)$, $\beta(N)$, and $\gamma(N)$ are not all equal for all $0 \le N < 1$.

(A3) The support of $d\mathcal{S}$ contains a neighborhood of 0, and 0 is a point of increase of $\mathcal{P}$.

The concavity of $N\alpha(N)$ implies that

$$N\frac{d^2}{dN^2}(N\alpha(N)) = N^2\alpha''(N) + 2N\alpha'(N) = \frac{d}{dN}(N^2\alpha'(N)) < 0.$$

Thus $\alpha(N)$, $\beta(N)$, and $\gamma(N)$ are strictly decreasing functions of N. The assumption (A2) is the *heterozygote intermediate* assumption. It shows that the allele A is the advantageous gene. It is then easy to see that

$$Q_1[N,u] \le \gamma(N * \mathcal{S})N * \mathcal{S}$$

for all $[N,u] \in \Delta$. Thus, when $\gamma(0) \le 1$, the dynamics of Q is trivial in the sense that

$$\lim_{n\to\infty} Q^{(n)}[N,u] = [0,0]$$

uniformly in $\mathbb{R}$ for all $[N,u] \in \Delta$. We will always assume the following.

(A4) $\gamma(0) > 1$ and $\gamma'(N^*)N^* + 1 \geq 0$, where N^* satisfies $\gamma(N) = 1$.

Note that N^* is the unique fixed point of the mapping $N\gamma(N)$. It is assumed by (A4) to be a stable fixed point of $N\gamma(N)$ such that any initial condition tends to N^* monotonically under the iteration of $N\gamma(N)$. $[N^*, 0]$ is then a constant fixed point of Q. A straightforward computation shows that the differential of Q at $[N^*, 0]$ is

$$DQ[T, U] = \begin{bmatrix} (\gamma'(N^*)N^* + 1)T * \mathcal{S} + 2(\beta(N^*) - 1)U * \mathcal{J} \\ \beta(N^*)U * \mathcal{J} \end{bmatrix}^t,$$

where $\mathcal{J} = \frac{1}{2}(\mathcal{S} + \mathcal{P} * \mathcal{S})$ and $T,\ U \in \mathcal{C}(\mathbb{R})$. Here the upper index t denotes the transpose operation. Since $\beta(N^*) \leq \gamma(N^*) = 1$ (by (A2)), the Contraction Mapping Theorem shows that the bounded linear operator $DQ : \mathcal{C}(\mathbb{R}) \times \mathcal{C}(\mathbb{R}) \to \mathcal{C}(\mathbb{R}) \times \mathcal{C}(\mathbb{R})$ has a spectrum lying inside the unit disc of the complex plane. Hence $[N^*, 0]$ is a (locally) stable fixed point of the mapping Q whenever (A4) holds. The following result states that $[N^*, 0]$ is in a sense a globally stable fixed point of Q.

THEOREM 2.1. *Let* $[N^{(0)}, u^{(0)}] \in \Delta$ *satisfy* $u^{(0)}(\pm\infty) < N^{(0)}(\pm\infty)$. *Then, under the assumptions* (A1)–(A4), *we have*

$$\lim_{n\to\infty} u^{(n)}(x) = 0, \qquad \lim_{n\to\infty} N^{(n)}(x) = N^*$$

uniformly in $x \in \mathbb{R}$. *Indeed, the rate of convergence is exponential.*

There remains to consider the case where the initial state $[N^{(0)}, u^{(0)}]$ satisfies the equality $u^{(0)}(\pm\infty) = N^{(0)}(\pm\infty)$. We present in this paper several results related to such a case.

We shall impose more assumptions on the viability functions and the distribution functions.

(A2)′ $\alpha(N) < \beta(N) = \gamma(N)$ for $0 \leq N < 1$.

(A3)′ $d\mathcal{P} = \delta$ (the Dirac delta measure). $\mathcal{S}$ has a bounded probability density over $\mathbb{R}$ such that 0 is a point of increase for $\mathcal{S}$ and the Laplace transform

$$K(\lambda) = \int_{-\infty}^{\infty} e^{\lambda x} d\mathcal{S}(x)$$

exists for all $\lambda \in \mathbb{R}$.

(A4)′ $\alpha(0) > 1$ and $\gamma'(N^*)N^* + 1 > 0$.

The assumptions (A2)′ and (A3)′ will simplify the system. The drastic assumption $d\mathcal{P} = \delta$ means that the pollen does not disperse. Although we believe that the following theorems hold even if $d\mathcal{P} \neq \delta$, we are not able to prove them without the restriction. From (A4)′, there exists a unique N_1^* such that $\alpha(N_1^*) = 1$. Then $[N_1^*, N_1^*]$ is also a constant fixed point of Q. It is an unstable constant fixed point of Q. By (A2)′, the strict inequality $N_1^* < N^*$ holds. Define

$$c_1^* = \inf_{\lambda > 0} \frac{1}{\lambda} \log(\gamma(N_1^*)K(\lambda)).$$

The existence of c_1^* is discussed in Weinberger [15], [16]. We then show that c_1^* is the minimal wave speed for a family of traveling waves when the selection is slow.

THEOREM 2.2. *We define* $k(N)$ *such that* $\alpha(N) = k(N)\gamma(N)$ *for* $0 \leq N < 1$. *Then, under assumptions* (A1) *and* (A2)′–(A4)′, *there exist* $\eta > 0$ *such that, whenever* $\max_{0 \leq N \leq N^*}\{|1 - k(N)|, |k'(N)|\} \leq \eta$, *the system* Q *admits a traveling wave profile* $[N(x), u(x)]$ *with speed* c, *which satisfies the system*

$$Q[N, u](x) = [N(x - c), u(x - c)], \qquad x \in \mathbb{R},$$
$$[N(-\infty), u(-\infty)] = [N^*, 0], \qquad [N(\infty), u(\infty)] = [N_1^*, N_1^*]$$

iff $c \geq c_1^*$. *When* $c > c_1^*$, *the wave profile is unique up to translation and is characterized by the positive limit* $\lim_{x\to\infty}(N(x) - N_1^*)e^{\sigma x}$, *where* σ *is the smallest positive root of* $\gamma(N_1^*)e^{-\lambda c}K(\lambda) = 1$.

Furthermore, these waves are the asymptotic state of some initial generation under the evolution of Q. Let us define

$$\Psi(\lambda) = \frac{1}{\lambda}\log(\gamma(N_1^*)K(\lambda)), \qquad \lambda > 0.$$

It is shown in Lemma 4.1 of Weinberger [15, p. 63] that there exists a unique positive value λ^* such that $\Psi(\lambda^*) = c_1^*$. For any $0 < \sigma < \lambda^*$, the value $c = \Psi(\sigma) > c_1^*$ and σ is the smallest positive root of $\gamma(N_1^*)e^{-\lambda c}K(\lambda) = 1$.

THEOREM 2.3. *Under the same assumptions as in Theorem* 2.2, *there exists* $\eta > 0$ *such that the mapping* Q *with the condition* $\max_{0\leq N\leq N^*}\{|1 - k(N)|, |k'(N)|\} \leq \eta$ *has the following asymptotic behavior. Let* $[N^{(0)}(x), u^{(0)}(x)] \in \Delta$ *satisfy* $N^{(0)}(-\infty) > 0$ *and have the asymptotic form for* $x \to \infty$

$$N^{(0)}(x) = L^{(0)} + e^{-\sigma x}\{A^{(0)} + e^{-\epsilon x}R^{(0)}(x)\},$$
$$u^{(0)}(x) = L^{(0)} + e^{-\sigma x}\{C^{(0)} + e^{-\epsilon x}U^{(0)}(x)\}$$

for some $0 < \epsilon < \sigma$, *where* $R^{(0)}(x)$ *and* $U^{(0)}(x)$ *are bounded continuous functions,* $L^{(0)}$, $A^{(0)}$, *and* $C^{(0)}$ *are constants satisfying* $0 < L^{(0)} < 1$, *and* $A^{(0)} \geq C^{(0)}$.

(a) *When* $\sigma \geq \lambda^*$, *then*

$$\lim_{n\to\infty}\max_{x\geq nc}|N^{(n)}(x) - N_1^*| = \lim_{n\to\infty}\max_{x\geq nc}|u^{(n)}(x) - N_1^*| = 0$$

for all $c > c_1^*$.

(b) *When* $0 < \sigma < \lambda^*$ *and* $A^{(0)} = C^{(0)}$, *then*

$$\lim_{n\to\infty}\sup_{x\geq l}|N^{(n)}(x + nc) - N_1^*| = \lim_{n\to\infty}\sup_{x\geq l}|u^{(n)}(x + nc) - N_1^*| = 0,$$

where $c = \Psi(\sigma)$ *and* $l \in \mathbb{R}$ *is arbitrary. Thus*

$$\lim_{n\to\infty}\max_{x\geq nc'}|N^{(n)}(x) - N_1^*| = \lim_{n\to\infty}\max_{x\geq nc'}|u^{(n)}(x) - N_1^*| = 0$$

for all $c' \geq \Psi(\sigma)$.

(c) *When* $0 < \sigma < \lambda^*$ *and* $A^{(0)} > C^{(0)}$, *then*

$$\lim_{n\to\infty}\sup_{x\geq l}|N^{(n)}(x + nc) - N(x)| = \lim_{n\to\infty}\sup_{x\geq l}|u^{(n)}(x + nc) - u(x)| = 0,$$

where $c = \Psi(\sigma)$ *and* $l \in \mathbb{R}$ *is arbitrary.* $[N(x), u(x)]$ *is the traveling wave of* Q *with speed* c, *which is uniquely defined by the limit*

$$\lim_{x\to\infty}(N(x) - N_1^*)e^{\sigma x} = \frac{2(\gamma(N_1^*) - 1)L^{(\infty)}}{\gamma(N_1^*) - (\alpha'(N_1^*)N_1^* + 1)}(A^{(0)} - C^{(0)}),$$

where $L^{(\infty)} = \prod_{n=0}^{\infty}[e^{-\sigma c}K(\sigma)\gamma(L^{(n)})]$ *and* $L^{(n)}$ *is defined by the recursive relation* $L^{(n+1)} = \alpha(L^{(n)})L^{(n)}$ *for* $n = 0, 1, 2, \ldots$. *Thus*

$$\lim_{n\to\infty}\max_{x\geq nc'}|N^{(n)}(x) - N_1^*| = \lim_{n\to\infty}\max_{x\geq nc'}|u^{(n)}(x) - N_1^*| = 0$$

for all $c' > \Psi(\sigma)$.

Theorem 2.3 extends Theorem 1 of Weinberger [15, p. 60] to the system Q. It shows that c_1^* is an asymptotic speed for the spread of the advantageous allele A. Note that the initial state $[N^{(0)}, u^{(0)}] \in \Delta$ in Theorem 2.3 satisfies $N^{(0)}(\infty) = u^{(0)}(\infty) = L^{(0)}$. We will touch upon the cases where $[N^{(0)}(\pm\infty), u^{(0)}(\pm\infty)] = [0, 0]$ in §7.

We now indicate the organization of this paper. Theorem 2.1 is proved in §3. Section 4 covers a key lemma on the asymptotic behavior of the bounded solutions to a linear convolution equation. The techniques used to show such an asymptotic behavior are contained in Diekmann and Kaper [2] and Lui [11]. In §5, we apply the asymptotic representation from §4 along with a (pointwise) Lipschitz estimate of the mapping Q to prove Theorem 2.2 via the Contraction Mapping Theorem. Then Theorem 2.3 is presented in §6 as a direct consequence of the proof of the existence theorem in §5. Finally, in §7, we give some concluding remarks on other traveling wave solutions of Q and their relations to the scalar mapping discussed in Weinberger [15], [16] and Lui [11], [12].

3. The proof of Theorem 2.1. We introduce the gene frequencies

$$m(x) = \frac{u(x)}{N(x)}, \qquad \bar{m}(x) = \frac{u * \mathcal{P}(x)}{N * \mathcal{P}(x)} = \frac{[Nm] * \mathcal{P}(x)}{N * \mathcal{P}(x)}.$$

We rewrite the mapping Q in terms of the variables $[N, m]$. Thus

$$\begin{aligned}\tilde{N} &= \alpha(N * \mathcal{S})\,[Nm\bar{m}] * \mathcal{S} + \beta(N * \mathcal{S})\,[N(m(1-\bar{m}) + \bar{m}(1-m))] * \mathcal{S} \\ &\quad + \gamma(N * \mathcal{S})\,[N(1-m)(1-\bar{m})] * \mathcal{S}, \\ \tilde{m} &= \frac{\alpha(N * \mathcal{S})\,[Nm\bar{m}] * \mathcal{S} + \frac{1}{2}\beta(N * \mathcal{S})\,[N(m(1-\bar{m}) + \bar{m}(1-m))] * \mathcal{S}}{\tilde{N}}.\end{aligned}$$

For each $[N(x), m(x)]$, we define two functions:

$$\begin{aligned}p(x,y) &= \frac{1}{2}N(y)\{\alpha(N * \mathcal{S}(x))[m(y) + \bar{m}(y)] \\ &\qquad + \beta(N * \mathcal{S}(x))[(1 - m(y)) + (1 - \bar{m}(y))]\}, \\ q(x,y) &= N(y)\{\alpha(N * \mathcal{S}(x))m(y)\bar{m}(y) + \beta(N * \mathcal{S}(x))[m(y)(1 - \bar{m}(y)) \\ &\qquad + (1 - m(y))\bar{m}(y)] + \gamma(N * \mathcal{S}(x))(1 - m(y))(1 - \bar{m}(y))\}.\end{aligned}$$

LEMMA 3.1. *Assume that* $\alpha(N) \le \beta(N) \le \gamma(N)$ *for all* $0 \le N < 1$. *Let* $N(x)$, $m(x)$ *be two continuous functions in* $\mathbb{R}$ *such that* $0 \le N(x)$, $m(x) \le 1$ *for all* $x \in \mathbb{R}$. *Then*

(a) $p(x,y) \le q(x,y)$ *for all* $x, y \in \mathbb{R}$,

(b) $\bar{m}(x) \le \|m\|_\infty (\int_{-\infty}^{\infty} p(x, x-y)d\mathcal{S}(y) / \int_{-\infty}^{\infty} q(x, x-y)d\mathcal{S}(y)) \le \|m\|_\infty$ *for all* $x \in \mathbb{R}$.

Proof. (a)

$$\begin{aligned}&q(x,y) - p(x,y) \\ &= \frac{1}{2}N(y)\{2\alpha m(y)\bar{m}(y) + 2\beta[m(y)(1 - \bar{m}(y)) + (1 - m(y))\bar{m}(y)] \\ &\qquad + 2\gamma(1 - m(y))(1 - \bar{m}(y)) - \alpha[m(y) + \bar{m}(y)] \\ &\qquad - \beta[(1 - m(y)) + (1 - \bar{m}(y))]\} \\ &= \frac{1}{2}N(y)\{(1 - \bar{m}(y))[(\beta - \alpha)m(y) + (\gamma - \beta)(1 - m(y))] \\ &\qquad + (1 - m(y))[(\beta - \alpha)\bar{m}(y) + (\gamma - \beta)(1 - \bar{m}(y))]\}.\end{aligned}$$

When $0 \le m(y) \le 1$ for all $y \in \mathbb{R}$, it is clear that $0 \le \bar{m}(y) \le 1$ for all $y \in \mathbb{R}$. Since $\alpha \le \beta \le \gamma$, we get $p(x,y) \le q(x,y)$ for all $x, y \in \mathbb{R}$.

(b) We note that

$$\begin{aligned}
&\alpha(N*\mathcal{S})[Nm\bar{m}]*\mathcal{S} + \frac{1}{2}\beta(N*\mathcal{S})[N(m(1-\bar{m})+\bar{m}(1-m))]*\mathcal{S} \\
&= \frac{1}{2}\{\alpha(N*\mathcal{S})[Nm\bar{m}]*\mathcal{S} + \beta(N*\mathcal{S})[Nm(1-\bar{m})]*\mathcal{S}\} \\
&\quad + \frac{1}{2}\{\alpha(N*\mathcal{S})[Nm\bar{m}]*\mathcal{S} + \beta(N*\mathcal{S})[N\bar{m}(1-m)]*\mathcal{S}\} \\
&\le \frac{1}{2}\|m\|_\infty\{\alpha(N*\mathcal{S})[N\bar{m}]*\mathcal{S} + \beta(N*\mathcal{S})[N(1-\bar{m})]*\mathcal{S}\} \\
&\quad + \frac{1}{2}\|\bar{m}\|_\infty\{\alpha(N*\mathcal{S})[Nm]*\mathcal{S} + \beta(N*\mathcal{S})[N(1-m)]*\mathcal{S}\}.
\end{aligned}$$

By the definition of $\bar{m}(y)$, we have $\|\bar{m}\|_\infty \le \|m\|_\infty$. Therefore

$$\begin{aligned}
&\alpha(N*\mathcal{S})[Nm\bar{m}]*\mathcal{S} + \frac{1}{2}\beta(N*\mathcal{S})[Nm(1-\bar{m}) + N\bar{m}(1-m)]*\mathcal{S} \\
&\le \|m\|_\infty \int_{-\infty}^{\infty} p(x, x-y)d\mathcal{S}(y).
\end{aligned}$$

By the definition of $q(x,y)$, the identity

$$\tilde{N}(x) = \int_{-\infty}^{\infty} q(x, x-y)d\mathcal{S}(y)$$

holds for all $x \in \mathbb{R}$. Thus

$$\tilde{m}(x) \le \|m\|_\infty \frac{\int_{-\infty}^{\infty} p(x, x-y)d\mathcal{S}(y)}{\int_{-\infty}^{\infty} q(x, x-y)d\mathcal{S}(y)}$$

for all $x \in \mathbb{R}$. Then (a) implies (b). □

We start to prove Theorem 2.1. When $m^{(0)}(x) \equiv 0$, $m^{(n)}(x) \equiv 0$ holds for all $n = 1, 2, 3, \ldots$. Then $N^{(n)}(x)$ satisfies

$$N^{(n+1)} = \gamma(N^{(n)} * \mathcal{S})\, N^{(n)} * \mathcal{S}.$$

An application of Theorem 3 of Weinberger [15] proves this theorem. Thus we shall assume that $m^{(0)}(x) \not\equiv 0$.

The rest of the proof will be divided into several steps.

Step 1. $N^{(n)}(\pm\infty) > 0$ and $m^{(n+1)}(\pm\infty) \le m^{(n)}(\pm\infty) < 1$ for each n. Moreover, $\lim_{n\to\infty} m^{(n)}(\pm\infty) = 0$ and $\lim_{n\to\infty} N^{(n)}(\pm\infty) = N^*$.

For convenience, let $r_n = N^{(n)}(\infty)$, $s_n = m^{(n)}(\infty)$. Then $[r_n, s_n]$ satisfies the iteration relations

$$\begin{aligned}
r_{n+1} &= r_n\{\alpha(r_n)s_n^2 + 2\beta(r_n)s_n(1-s_n) + \gamma(r_n)(1-s_n)^2\}, \\
s_{n+1} &= \frac{\alpha(r_n)s_n^2 + \beta(r_n)s_n(1-s_n)}{\alpha(r_n)s_n^2 + 2\beta(r_n)s_n(1-s_n) + \gamma(r_n)(1-s_n)^2}.
\end{aligned}$$

By (A2), we have $r_{n+1} \ge \alpha(r_n)r_n$. Thus $r_n > 0$ by induction. Now

$$s_{n+1} - s_n = s_n(1-s_n)\frac{(\beta(r_n)-\gamma(r_n))(1-s_n) + (\alpha(r_n)-\beta(r_n))s_n}{\alpha(r_n)s_n^2 + 2\beta(r_n)s_n(1-s_n) + \gamma(r_n)(1-s_n)^2}.$$

The assumption (A2) implies that $s_{n+1} \leq s_n \leq s_0 < r_0 \leq 1$. The sequence s_n has a limit. From the iteration relations for $[r_n, s_n]$, it is easy to see that $\lim_{n\to\infty} s_n = 0$ and $\lim_{n\to\infty} r_n = N^*$ (see Lin [10]).

Step 2. $\limsup_{n\to\infty} N^{(n)}(x) \leq N^*$ uniformly in $x \in \mathbb{R}$.

Let $M = \max_{0\leq N\leq 1} N\gamma(N)$. We note that

$$Q_1[N, u] \leq \gamma(N * \mathcal{S})N * \mathcal{S} \leq M.$$

By (A1) and (A4), $N\gamma(N)$ is strictly increasing over $0 \leq N \leq M$. Then an easy induction argument shows that

$$N^{(n)}(x) \leq M_{n-1}, \qquad n = 1, 2, \ldots,$$

where M_n is defined by

$$M_{n+1} = \gamma(M_n)M_n, \quad M_0 = M, \quad n = 0, 1, 2, \ldots.$$

But $\lim_{n\to\infty} M_n = N^*$. This proves Step 2.

Step 3. There exists some integer k such that $N^{(n)}(x) > 0$ and $m^{(n)}(x) < 1$ for all $x \in \mathbb{R}$ and for all $n \geq k$.

We define

$$Z_n = \{x \in \mathbb{R} | N^{(n)}(x) = 0\}, \qquad T_n = \{x \in \mathbb{R} | m^{(n)}(x) = 1\}.$$

Since $N^{(n)}(x)$ and $m^{(n)}(x)$ are continuous, Z_n and T_n are closed subsets of $\mathbb{R}$. By Step 1, Z_n and T_n are bounded subsets of $\mathbb{R}$. Thus they are compact subsets of $\mathbb{R}$. We *claim* that

$$Z_{n+1} \subseteq Z_n, \qquad n = 0, 1, 2, \ldots.$$

Let $x_0 \in Z_{n+1}$. Then $N^{(n+1)}(x_0) = 0$. By

$$N^{(n+1)}(x_0) \geq \alpha(N^{(n)} * \mathcal{S}(x_0))\, N^{(n)} * \mathcal{S}(x_0),$$

we get $N^{(n)} * \mathcal{S}(x_0) = 0$. Thus $N^{(n)}(x_0 - y) = 0$ for all y in the support of $d\mathcal{S}$. Since the support of $d\mathcal{S}$ contains a neighborhood of 0, $N^{(n)}(x_0) = 0$. Thus $x_0 \in Z_n$. This proves the claim. From the claim, we want to deduce that there exists an integer k_1, such that $Z_{k_1} = \emptyset$. Otherwise, $Z_n \neq \emptyset$ for all n. Then $\cap_n Z_n \neq \emptyset$. Let $x_0 \in \cap_n Z_n$. Thus $N^{(n)}(x_0) = 0$ for all n. By the same argument of the proof of the claim, we know that

$$N^{(0)}(x_0 - y_1 - y_2 - \cdots - y_n) = 0$$

for all $y_1, y_2, \ldots, y_n$ in the support of $d\mathcal{S}$. But the support of $d\mathcal{S}$ contains a neighborhood of 0, and we have

$$\cup_n \{x_0 - y_1 - \cdots - y_n | y_1, \ldots, y_n \in \text{ supp}(d\mathcal{S})\} = \mathbb{R}.$$

Therefore $N^{(0)}(x) = 0$ for all x. This contradicts $N^{(0)}(\pm\infty) > 0$. Thus we have proved that $N^{(n)}(x) > 0$ for all $x \in \mathbb{R}$ and $n \geq k_1$.

Now, we *claim* again that

$$T_{n+1} \subseteq T_n, \qquad n = k_1, k_1 + 1, k_1 + 2, \ldots.$$

Let $x_0 \in T_{n+1}$. Then $m^{(n+1)}(x_0) = 1$. From Lemma 3.1 (b), we get

$$1 = m^{(n+1)}(x_0) \le \frac{\int_{-\infty}^{\infty} p^{(n)}(x_0, x_0 - y) d\mathcal{S}(y)}{\int_{-\infty}^{\infty} q^{(n)}(x_0, x_0 - y) d\mathcal{S}(y)},$$

where $p^{(n)}(x, y)$ and $q^{(n)}(x, y)$ are the functions p and q defined by $[N^{(n)}(x), m^{(n)}(x)]$. Since $p^{(n)}(x, y) \le q^{(n)}(x, y)$ for all (x, y), we get

$$\int_{-\infty}^{\infty} [q^{(n)}(x_0, x_0 - y) - p^{(n)}(x_0, x_0 - y)] d\mathcal{S}(y) = 0.$$

Therefore $q^{(n)}(x_0, x_0 - y) - p^{(n)}(x_0, x_0 - y) = 0$ for all y in the support of $d\mathcal{S}$. From the expression for $q^{(n)}(x, y) - p^{(n)}(x, y)$ in the proof of Lemma 3.1 (a) and $N^{(n)}(y) > 0$, we have

$$(1 - m^{(n)}(x_0 - y))\{(\beta - \alpha)\bar{m}^{(n)}(x_0 - y) + (\gamma - \beta)(1 - \bar{m}^{(n)}(x_0 - y))\} = 0.$$

By the assumption (A2), $(\beta - \alpha)\bar{m}^{(n)}(x_0 - y) + (\gamma - \beta)(1 - \bar{m}^{(n)}(x_0 - y)) \neq 0$ for all $y \in \mathbb{R}$. Thus $m^{(n)}(x_0 - y) = 1$ for all y in the support of $d\mathcal{S}$. In particular, we get $m^{(n)}(x_0) = 1$ by putting $y = 0$. This proves the claim. From the claim, we can find $k \ge k_1$ such that $T_k = \emptyset$. Otherwise, if $T_n \neq \emptyset$ for all $n \ge k_1$, then there exists $x_0 \in \cap_{n \ge k_1} T_n$. From $m^{(n)}(x_0) = 1$ for all $n \ge k_1$, we deduce that $m^{(k_1)}(x) = 1$ for all $x \in \mathbb{R}$. This contradicts $m^{(k_1)}(\pm\infty) < 1$. This proves Step 3.

Step 4. $\|m^{(n)}\|_\infty$ decreases to 0.

For convenience, we let $a_n = \|m^{(n)}\|_\infty$. By Lemma 3.1 (b), we have $a_{n+1} \le a_n$. Thus $\lim_{n\to\infty} a_n = a$ exists. By Steps 1 and 3, $0 \le a_n < 1$ for all $n \ge k$. Thus $0 \le a < 1$.

Let us consider the function

$$g(N, m, \bar{m}) = \frac{1}{2} \frac{\alpha(N)(m + \bar{m}) + \beta(N)(2 - m - \bar{m})}{\alpha(N)m\bar{m} + \beta(N)(m + \bar{m} - 2m\bar{m}) + \gamma(N)(1 - m)(1 - \bar{m})},$$

which is defined in $0 \le N,\ m,\ \bar{m} \le 1$. The function g is the ratio of the functions p and q. Note that $g(N, m, \bar{m}) = g(N, \bar{m}, m)$. By the assumption (A2), a computation shows that

$$g(N, m, \bar{m}) \le \max\{g(N, a_n, a_n),\ g(N, a_n, 0),\ g(N, 0, 0)\}$$

for all $0 \le N < 1$, $0 \le m,\ \bar{m} \le a_n$. We define

$$t_n = \max_{0 \le N \le \frac{1}{2}(1+N^*)} \{g(N, a_n, a_n),\ g(N, a_n, 0),\ g(N, 0, 0)\}.$$

Note that, for $0 \le N \le \frac{1}{2}(1 + N^*)$, $g(N, m, \bar{m}) = 1$ only if $m = 1$ or $\bar{m} = 1$. Thus when $0 < a_n < 1$, we have $g(N, m, \bar{m}) \le t_n < 1$ for all $0 \le N \le \frac{1}{2}(1 + N^*)$, $0 \le m,\ \bar{m} \le a_n$. By (A4), Step 2 implies that we can choose k in Step 3 such that $0 < N^{(n)}(x) \le \frac{1}{2}(1 + N^*)$ for all $x \in \mathbb{R}$ and $n \ge k$. Thus, for $n \ge k$, we get

$$g(N^{(n)} * \mathcal{S}(x), m^{(n)}(y), \bar{m}^{(n)}(y)) \le t_n$$

for all $x, y \in \mathbb{R}$. But

$$g(N^{(n)} * \mathcal{S}(x), m^{(n)}(y), \bar{m}^{(n)}(y)) = \frac{p^{(n)}(x, y)}{q^{(n)}(x, y)}.$$

Hence

$$p^{(n)}(x, x-y) \le t_n q^{(n)}(x, x-y)$$

for all $x, y \in \mathbb{R}$. Integrating the above inequality with respect to $d\mathcal{S}(y)$, we get

$$m^{(n+1)}(x) \le \|m^{(n)}\|_\infty \frac{\int_{-\infty}^{\infty} p^{(n)}(x, x-y)d\mathcal{S}(y)}{\int_{-\infty}^{\infty} q^{(n)}(x, x-y)d\mathcal{S}(y)} \le a_n t_n$$

for all $x \in \mathbb{R}$. Therefore $a_{n+1} \le a_n t_n$ for $n \ge k$. We let $n \to \infty$. Then $a \le a\,t$ where

$$t = \max_{0 \le N \le \frac{1}{2}(1+N^*)} \max\{g(N, a, a),\ g(N, a, 0),\ g(N, 0, 0)\}.$$

Since $0 \le a < 1$, we have $0 < t < 1$. Therefore $a = 0$.

We note that this argument shows that $\|m^{(n)}\|_\infty$ decreases to 0 exponentially.

Step 5. Let $b_n = \inf_{x \in \mathbb{R}} N^{(n)}(x)$. Then there exists an $l > 0$ such that $b_n \ge l$ for all $n \ge k$, where k is the integer in Step 3.

We note that, from Steps 1 and 3, $b_n > 0$ for all $n \ge k$. We can rewrite $N^{(n+1)}(x)$ as

$$\begin{aligned} N^{(n+1)}(x) &= \alpha(N^{(n)} * \mathcal{S})\,[N^{(n)} m^{(n)} \bar{m}^{(n)}] * \mathcal{S} \\ &\quad + \beta(N^{(n)} * \mathcal{S})\,[N^{(n)}(m^{(n)}(1-\bar{m}^{(n)}) + \bar{m}^{(n)}(1-m^{(n)}))] * \mathcal{S} \\ &\quad + \gamma(N^{(n)} * \mathcal{S})\,[N^{(n)}(1-m^{(n)})(1-\bar{m}^{(n)})] * \mathcal{S} \\ &\equiv \gamma(N^{(n)} * \mathcal{S}(x))\, N^{(n)} * \mathcal{S}(x) + D_n(x). \end{aligned}$$

Since $\|\bar{m}\|_\infty \le \|m\|_\infty$ and $N^{(n)}(x)$ are uniformly bounded, Step 4 implies that $d_n = \|D_n\|_\infty$ tends to 0 as $n \to \infty$. By (A4), we can choose $\epsilon_0 > 0$ such that $\gamma(N)N \ge \gamma(b)b$ for all $b \le N^*$ and $b \le N \le N^* + \epsilon_0$. Step 2 implies that we can find $k_2 \ge k$ such that $N^{(n)}(x) \le N^* + \epsilon_0$ for all $x \in \mathbb{R}$ and $n \ge k_2$. Therefore, when $n \ge k_2$, $N^{(n+1)}(x) \ge \gamma(b_n)b_n - d_n$ for all $x \in \mathbb{R}$. We deduce that

$$b_{n+1} \ge \gamma(b_n)b_n - d_n \qquad \text{for } n \ge k_2.$$

We *claim* that if there exists a subsequence b_{n_i} such that b_{n_i} has a positive lower bound l, then b_n has a positive lower bound for $n \ge k$. To prove the claim, we may choose the lower bound l such that $0 < l < N^*$. Then $\gamma(l)l - l > 0$. Thus we can choose $k_3 \ge k_2$ such that $d_n < \gamma(l)l - l$ for $n \ge k_3$. We can find an index n_i with $n_i \ge k_3$ and $b_{n_i} \ge l$. Then we will prove by induction that $b_n \ge l$ for $n \ge n_i$. Assume that $b_n \ge l$ for some $n \ge n_i$. Then

$$b_{n+1} \ge \gamma(b_n)b_n - d_n \ge \gamma(l)l - d_n = (\gamma(l)l - l) - d_n + l > l.$$

This proves the claim.

We know that b_n is a bounded sequence. If Step 5 is false, it follows from the claim that $\lim_{n\to\infty} b_n = 0$. From Step 1, $N^{(n)}(\pm\infty)$ tends to N^* as $n \to \infty$. Thus, for each $n \ge k_2$, we can find $x_n \in \mathbb{R}$ such that $N^{(n)}(x_n) = b_n$. This can be done by taking k_2 larger whenever it is necessary. We call

$$e_n = N^{(n)} * \mathcal{S}(x_{n+1}) \quad \text{for } n \ge k_2.$$

Then

$$\begin{aligned} b_{n+1} &= N^{(n+1)}(x_{n+1}) \\ &= \gamma(N^{(n)} * \mathcal{S}(x_{n+1}))\, N^{(n)} * \mathcal{S}(x_{n+1}) + D_n(x_{n+1}) \\ &= \gamma(e_n)e_n + D_n(x_{n+1}), \qquad n \geq k_2. \end{aligned}$$

Since $D_n(x_{n+1}) = O(\|m^{(n)}\|_\infty)$ as $n \to \infty$, we get $\lim_{n\to\infty} \gamma(e_n)e_n = 0$. But $0 \leq N^{(n)} \leq \frac{1}{2}(1 + N^*)$, $\gamma(e_n) \geq \gamma(\frac{1}{2}(1 + N^*)) > 0$. Thus $\lim_{n\to\infty} e_n = 0$. Now, from the iteration relation for $N^{(n+1)}$, we get

$$\begin{aligned} N^{(n+1)}(x) \geq b_n\{&\alpha(N^{(n)} * \mathcal{S})\,[m^{(n)}\bar{m}^{(n)}] * \mathcal{S} \\ &+ \beta(N^{(n)} * \mathcal{S})\,[m^{(n)}(1 - \bar{m}^{(n)}) + \bar{m}^{(n)}(1 - m^{(n)})] * \mathcal{S} \\ &+ \gamma(N^{(n)} * \mathcal{S})\,[(1 - m^{(n)})(1 - \bar{m}^{(n)})] * \mathcal{S}\} \\ \equiv b_n\{&\gamma(N^{(n)} * \mathcal{S}(x)) + \tilde{D}_n(x)\}, \end{aligned}$$

where $\tilde{D}_n(x) = O(\|m^{(n)}\|_\infty)$. $\tilde{D}_n(x)$ tends to 0 uniformly in $x \in \mathbb{R}$. By putting $x = x_{n+1}$ in the inequality, we have

$$b_{n+1} \geq b_n\{\gamma(e_n) + \tilde{D}_n(x_{n+1})\}, \qquad n \geq k_2.$$

However,

$$\lim_{n\to\infty} \{\gamma(e_n) + \tilde{D}_n(x_{n+1})\} = \gamma(0) > 1.$$

We can find $k_4 \geq k_2$ such that $\gamma(e_n) + \tilde{D}_n(x_{n+1}) > 1$ for all $n \geq k_4$. Thus $b_{n+1} > b_n > 0$ for $n \geq k_4$. This is a contradiction to $\lim_{n\to\infty} b_n = 0$. The proof of Step 5 is complete.

Step 6. $\lim_{n\to\infty} b_n = N^*$. Hence $N^{(n)}(x)$ converges to N^* uniformly in $\mathbb{R}$.

Let $\epsilon > 0$ be given sufficiently small. From Steps 2 and 5, we can find $k_2 \geq k$ such that

$$0 < l \leq b_n \leq N^{(n)}(x) \leq N^* + \epsilon, \qquad b_{n+1} \geq \gamma(b_n)b_n - d_n$$

for $n \geq k_2$ and for all $x \in \mathbb{R}$. Define

$$l_1 = \min_{l \leq N \leq N^* - \epsilon} (\gamma(N)N - N),$$

$l_1 > 0$. Thus we can find $k_5 \geq k_2$ such that $d_n < l_1$ for $n \geq k_5$. We *claim* that there exists $k_6 \geq k_5$ such that $b_{k_6} \geq N^* - \epsilon$. We prove the claim by contradiction. Suppose that $b_n < N^* - \epsilon$ for all $n \geq k_5$. From

$$b_{n+1} \geq \gamma(b_n)b_n - d_n = (\gamma(b_n)b_n - b_n) - d_n + b_n \geq l_1 - d_n + b_n > b_n$$

for all $n \geq k_5$, we know that $\lim_{n\to\infty} b_n = b$ exists. Clearly, $l \leq b \leq N^* - \epsilon$. However, by letting $n \to \infty$ in $b_{n+1} \geq b_n\gamma(b_n) - d_n$, we get $b \geq b\gamma(b)$. Thus $\gamma(b) \leq 1$. But $b < N^*$, and we also have $\gamma(b) > 1$. This is a contradiction, and the claim is proved. From the claim, we can prove by induction that $b_n \geq N^* - \epsilon$ for $n \geq k_6$. Suppose that this inequality holds for some n. Then

$$\begin{aligned} b_{n+1} \geq \gamma(b_n)b_n - d_n &\geq \gamma(N^* - \epsilon)(N^* - \epsilon) - d_n \\ &= [\gamma(N^* - \epsilon)(N^* - \epsilon) - (N^* - \epsilon)] - d_n + (N^* - \epsilon) \\ &\geq l_1 - d_n + (N^* - \epsilon) \geq N^* - \epsilon. \end{aligned}$$

Thus we have proved that $|b_n - N^*| \leq \epsilon$ for all $n \geq k_6$.

The proof of Theorem 2.1 is complete. □

Remark 3.1. From the proof of Step 3, we see that if $N^{(0)}(x) \not\equiv 0$ (without assuming $N^{(0)}(\pm\infty) > 0$), then for any compact subset $K \subseteq \mathbb{R}$, there exists n_0 such that $N^{(n)}(x) > 0$ for all $x \in K$ and $n \geq n_0$.

Remark 3.2. If we assume instead of (A3) that each point of $\mathbb{R}$ is a point of increase for $d\mathcal{S}$, then we can obtain the following conclusion. Let $[N^{(0)}, u^{(0)}] \in \Delta$ satisfy

$$N^{(0)}(x) \not\equiv 0 \quad \text{and} \quad m^{(0)}(\pm\infty) = \lim_{x\to\pm\infty} \frac{u^{(0)(x)}}{N^{(0)}(x)} < 1;$$

then, under assumptions (A1), (A2), and (A4), we have $u^{(n)}(x) \to 0$ uniformly in $\mathbb{R}$ and $N^{(n)}(x) \to N^*$ uniformly on compact subsets of $\mathbb{R}$.

4. A preliminary lemma. In this section, we shall present a lemma on the asymptotic behavior of a positive bounded solution $\varphi(x)$ to the linear convolution equation

$$\varphi(x) = f(x)\,\varphi * F(x),$$

where F is a probability distribution function on $\mathbb{R}$ and $f(x)$ is a given continuous function. This lemma is essential to the proof of the existence of the traveling wave solutions of Q. We shall use several results in Essén [3] and Diekmann and Kaper [2]. A full discussion on the existence and the uniqueness of the bounded solutions to the above convolution equation can be found in Lin [9].

We assume that F has a bounded probability density such that the Laplace transform

$$\hat{F}(\lambda) = \int_{-\infty}^{\infty} e^{\lambda x} dF(x)$$

exists for all $\lambda \geq 0$. We define $F_0 = \min_{\lambda\geq 0} \hat{F}(\lambda)$.

LEMMA 4.1. *Let $f \in C(\mathbb{R})$ satisfy $f(x) \geq 0$ for all $x \in \mathbb{R}$ and $f(\infty) > 1$. Suppose that $\varphi \in C(\mathbb{R})$ satisfies $\varphi(x) \geq 0$, $\varphi(x) \not\equiv 0$, and*

$$\varphi(x) = f(x)\,\varphi * F(x) \quad \textit{for all } x \in \mathbb{R}.$$

We make the following assertions.

(a) *There exists some $k > 0$ such that $\int_{-\infty}^{\infty} e^{\lambda x}\varphi(x)dx < \infty$ for $0 < \lambda < k$.*

(b) *Define $\sigma = \sup\{\lambda | \lambda > 0, \int_{-\infty}^{\infty} e^{\lambda x}\varphi(x)dx < \infty\}$. Then $\varphi(x)e^{\lambda x}$ is uniformly bounded for all $0 \leq \lambda < \sigma$, while $\varphi(x)e^{\lambda x}$ is unbounded for $\lambda > \sigma$.*

(c) *If we assume further that $\frac{1}{F_0} > f(\infty) \geq f(x)$, $f(x)$ is not a constant function, and $f(x) = f(\infty) + O(e^{-\epsilon x})$ as $x \to \infty$ for some $\epsilon > 0$, then $\varphi(x)$ has the asymptotic representation*

$$\varphi(x) = e^{-\sigma x}[A + U(x)e^{-\epsilon' x}],$$

where A, ϵ', and σ are some positive constants. $U(x)$ is a bounded continuous function with $Ue^{-\epsilon' x}$ bounded, and $U(x) \leq 0$ for all $x \in \mathbb{R}$. Moreover, σ is the smallest positive root of the equation $f(\infty)\hat{F}(\lambda) = 1$.

Proof. (a). Let $1 < t < f(\infty)$ and choose $l > 0$ such that $F(l) - F(-l) = \frac{1}{2}(1 + \frac{1}{t})$. Define

$$F_l(x) = \begin{cases} 0 & \text{if } x \le -l, \\ \frac{F(x)-F(-l)}{F(l)-F(-l)} & \text{if } -l \le x \le l, \\ 1 & \text{if } l < x. \end{cases}$$

$F_l(x)$ is again a probability distribution. Now

$$\begin{aligned} &\varphi - \varphi * F_l \\ &\quad = \varphi(x) - \frac{2t}{1+t}\int_{-l}^{l} \varphi(x-y)dF(y) \\ &\quad = \frac{t-1}{t+1}\varphi(x) + \frac{2}{t+1}\varphi(x) - \frac{2t}{t+1}\int_{-l}^{l} \varphi(x-y)dF(y) \\ &\quad = \frac{t-1}{t+1}\varphi(x) + \frac{2}{t+1}\left\{ f(x)\int_{-\infty}^{\infty} \varphi(x-y)dF(y) - t\int_{-l}^{l} \varphi(x-y)dF(y) \right\} \\ &\quad = \frac{t-1}{t+1}\varphi(x) + \frac{2}{t+1}\psi(x), \end{aligned}$$

where $\psi(x)$ can be written as

$$\psi(x) = (f(x) - t)\int_{-l}^{l} \varphi(x-y)dF(y) + f(x)\int_{|y|\ge l} \varphi(x-y)dF(y).$$

Choose x_0 such that $f(x) > t$ for $x \ge x_0$. Then $\psi(x) \ge 0$ for $x \ge x_0$. By integrating the above identity from x to r with $x_0 \le x \le r$, we get

$$\varphi * N_l(r) - \varphi * N_l(x) = \frac{t-1}{t+1}\int_x^r \varphi(y)dy + \frac{2}{t+1}\int_x^r \psi(y)dy, \tag{3}$$

where

$$N_l(x) = \begin{cases} 1 - F_l(x) & \text{if } x \ge 0, \\ -F_l(x) & \text{if } x < 0. \end{cases}$$

Note that $\int_{-\infty}^{\infty} |x|dF_l(x) < \infty$ and $\int_{-\infty}^{\infty} |N_l(x)|dx = \int_{-\infty}^{\infty} |x|dF_l(x)$. Since $f(\infty) > 1$ and $\varphi \in \mathcal{C}(\mathbb{R})$, $\varphi(\infty) = 0$. Thus $\lim_{r\to\infty} \varphi * N_l(r) = 0$. Therefore, using $\varphi \ge 0$ and $\psi \ge 0$ in (3), we have proved that $\int_x^{\infty} \varphi(y)dy$ and $\int_x^{\infty} \psi(y)dy$ exist for all $x \ge x_0$, and they have the relation

$$\int_x^{\infty} \varphi(y)dy = -\frac{t+1}{t-1}\left\{ \varphi * N_l(x) + \frac{2}{t+1}\int_x^{\infty} \psi(y)dy \right\}.$$

We shall generalize this relation as follows.

Define $\varphi^{(n)}$ and $\psi^{(n)}$ inductively as

$$\varphi^{(n+1)}(x) = \int_x^{\infty} \varphi^{(n)}(y)dy, \qquad \varphi^{(0)}(x) = \varphi(x),$$

$$\psi^{(n+1)}(x) = \int_x^{\infty} \psi^{(n)}(y)dy, \qquad \psi^{(0)}(x) = \psi(x),$$

for $n = 0, 1, 2, \ldots$. We *claim* that $\varphi^{(n)}$ and $\psi^{(n)}$ exist for all n and they satisfy the following identities

$$\varphi^{(n)} - \varphi^{(n)} * F_l = \frac{t-1}{t+1}\varphi^{(n)} + \frac{2}{t+1}\psi^{(n)}, \tag{4}$$

$$\varphi^{(n+1)}(x) = -\frac{t-1}{t+1}\left[\varphi^{(n)} * N_l(x) + \frac{2}{t+1}\psi^{(n+1)}(x)\right] \tag{5}$$

for $n = 0, 1, 2, \ldots$, and for all $x \geq x_0$. We have proved the case $n = 0$. Assume that (4) and (5) have been proved in step n; then $\varphi^{(n+1)}$ and $\psi^{(n+1)}$ exist. We integrate (4) from x to ∞, and note that

$$\begin{aligned}
\int_x^\infty \varphi^{(n)} * F_l(y)dy &= \int_x^\infty \left(\int_{-\infty}^\infty \varphi^{(n)}(y-z)dF_l(z)\right)dy \\
&= \int_{-\infty}^\infty \left(\int_x^\infty \varphi^{(n)}(y-z)dy\right)dF_l(z) \\
&= \int_{-\infty}^\infty \left(\int_{x-z}^\infty \varphi^{(n)}(y)dy\right)dF_l(z) \\
&= \int_{-\infty}^\infty \varphi^{(n+1)}(x-z)dF_l(z) \\
&= \varphi^{(n+1)} * F_l(x).
\end{aligned}$$

This proves that (4) holds for step $n+1$. We can now integrate (4) for step $n+1$ from x to r. We get

$$\varphi^{(n+1)} * N_l(r) - \varphi^{(n+1)} * N_l(x) = \frac{t-1}{t+1}\int_x^r \varphi^{(n+1)}(y)dy + \frac{2}{t+1}\int_x^r \psi^{(n+1)}(y)dy.$$

By definition, $\varphi^{(n+1)}(\infty) = 0$, $\varphi^{(n+1)} \geq 0$ and $\psi^{(n+1)} \geq 0$; this implies that $\varphi^{(n+2)}$ and $\psi^{(n+2)}$ exist for $x \geq x_0$ and that the identity (5) holds for step $n+1$.

Since $\psi^{(n)} \geq 0$, we get from (5)

$$\begin{aligned}
\varphi^{(n+1)}(x) &\leq -\frac{t-1}{t+1}\int_{-l}^{l} \varphi^{(n)}(x-y)N_l(y)dy \\
&\leq \frac{t-1}{t+1}\max\{\varphi^{(n)}(y) \,|\, |y-x| \leq l\}\|N_l\|_{L^1} \\
&\leq \frac{t-1}{t+1}\varphi^{(n)}(x-l)\|N_l\|_{L^1} \quad \text{for } x \geq x_0.
\end{aligned}$$

Choose $x \geq x_0 + l$ to get

$$\begin{aligned}
\varphi^{(n+1)}(x-l) = \int_{x-l}^\infty \varphi^{(n)}(y)dy &= \int_{x-l}^x \varphi^{(n)}(y)dy + \varphi^{(n+1)}(x) \\
&\leq \varphi^{(n)}(x-l)l + \frac{t-1}{t+1}\varphi^{(n)}(x-l)\|N_l\|_{L^1} = k^{-1}\varphi^{(n)}(x-l),
\end{aligned}$$

for $n = 1, 2, 3, \ldots$, where

$$k^{-1} = l + \frac{t-1}{t+1}\|N_l\|_{L^1}.$$

Thus

$$\varphi^{(n)}(x) \le k^{-(n-1)}\varphi^{(1)}(x) \quad \text{for } x \ge x_0, \quad n = 1, 2, 3, \ldots.$$

Now, by integration by parts,

$$\varphi^{(n)}(x) = \frac{1}{(n-1)!}\int_x^\infty (y-x)^{n-1}\varphi(y)dy, \qquad n = 1, 2, 3, \ldots.$$

Therefore, for $x \ge x_0$ and $0 < \lambda < k$,

$$\begin{aligned}\int_x^\infty e^{\lambda y}\varphi(y)dy &= e^{\lambda x}\sum_{n=0}^\infty \frac{\lambda^n}{n!}\int_x^\infty (y-x)^n\varphi(y)dy \\ &= e^{\lambda x}\sum_{n=0}^\infty \lambda^n\varphi^{(n+1)}(x) \\ &\le e^{\lambda x}\sum_{n=0}^\infty \lambda^n k^{-n}\varphi^{(1)}(x) < \infty.\end{aligned}$$

This proves (a).

(b) Let $dF(x) = p(x)dx$, where $p(x) \ge 0$ is a bounded measurable function. Let $0 < \lambda < \sigma$. Choose λ_0 and q such that $0 < \lambda < \lambda_0 < \sigma$ and $1 < q < \lambda_0/\lambda$. Let r be the conjugate exponent of q, i.e., $\frac{1}{q} + \frac{1}{r} = 1$. Then

$$\varphi(x)e^{\lambda x} = f(x)\int_{-\infty}^\infty \varphi(x-y)e^{\lambda(x-y)}e^{\lambda y}p(y)dy = f(x)\{A + B\},$$

where

$$A = \int_{-\infty}^x \varphi(x-y)e^{\lambda(x-y)}e^{\lambda y}p(y)dy, \qquad B = \int_x^\infty \varphi(x-y)e^{\lambda(x-y)}e^{\lambda y}p(y)dy.$$

Now

$$\begin{aligned}0 \le B &\le (\sup_{y\le 0}\varphi(y)e^{\lambda y})\int_x^\infty e^{\lambda y}p(y)dy \le \|\varphi\|_\infty \hat{F}(\lambda), \\ A &= \int_{-\infty}^x \varphi(x-y)e^{\frac{\lambda_0}{q}(x-y)}e^{(\lambda-\frac{\lambda_0}{q})(x-y)}e^{\lambda y}p(y)dy \\ &\le \left(\int_{-\infty}^x \varphi(x-y)^q e^{\lambda_0(x-y)}dy\right)^{\frac{1}{q}}\left(\int_{-\infty}^x e^{r(\lambda-\frac{\lambda_0}{q})(x-y)}e^{r\lambda y}p(y)^r dy\right)^{\frac{1}{r}} \\ &\le \|\varphi\|_\infty^{\frac{q-1}{q}}\left(\int_{-\infty}^\infty \varphi(x)e^{\lambda_0 x}dx\right)^{\frac{1}{q}}\|p\|_\infty^{\frac{r-1}{r}}\hat{F}(r\lambda)^{\frac{1}{r}} < \infty.\end{aligned}$$

Therefore $\varphi(x)e^{\lambda x}$ is uniformly bounded. When $\lambda > \sigma$, if $\varphi(x)e^{\lambda x}$ is bounded, $\varphi(x)e^{\frac{1}{2}(\lambda+\sigma)x}$ is integrable, a contradiction to the definition of σ.

(c) We rewrite the equation as

$$\varphi(x) - f(\infty)\,\varphi * F(x) = (f(x) - f(\infty))\varphi * F(x) \equiv h(x).$$

Let $\Phi(\lambda) = \int_{-\infty}^\infty e^{\lambda x}\varphi(x)dx$ and $H(\lambda) = \int_{-\infty}^\infty e^{\lambda x}h(x)dx$ be the Laplace transforms of φ and h, respectively. By (a), $\Phi(\lambda)$ is finite for $0 < \lambda < \sigma$; hence the Laplace transform of $\varphi * F$ is finite for $0 < \lambda < \sigma$. We have the identity

$$[1 - f(\infty)\hat{F}(\lambda)]\Phi(\lambda) = H(\lambda) \quad \text{for } 0 < \lambda < \sigma. \tag{6}$$

Note that $f(\infty)F_0 < 1$. The equation $f(\infty)\hat{F}(\lambda) = 1$ admits at least one positive root. However, $h(x) \leq 0$ and $h(x) \not\equiv 0$ in $\mathbb{R}$. If $\sigma = \infty$, then $\Phi(\lambda)$ and $H(\lambda)$ exist for all $\lambda > 0$ and $H(\lambda) < 0$. Thus the identity (6) can not hold for all $\lambda > 0$. Therefore $0 < \sigma < \infty$. Then $\Phi(\lambda)$ must be singular at $\lambda = \sigma$, i.e., $\Phi(\sigma) = \infty$ (see Widder [17]). Now

$$\begin{aligned}
&\int_{-\infty}^{\infty} |f(x) - f(\infty)| \varphi * F(x) e^{(\sigma + \frac{1}{2}\epsilon)x} dx \\
&= \int_{-\infty}^{\infty} |f(x) - f(\infty)| \left(\int_{-\infty}^{\infty} \varphi(x-y) e^{(\sigma - \frac{1}{2}\epsilon)(x-y)} e^{(\sigma - \frac{1}{2}\epsilon)y} dF(y) \right) e^{\epsilon x} dx \\
&= \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} |f(x) - f(\infty)| e^{\epsilon x} \varphi(x-y) e^{(\sigma - \frac{1}{2}\epsilon)(x-y)} dx \right) e^{(\sigma - \frac{1}{2}\epsilon)y} \, dF(y).
\end{aligned}$$

Since $|f(x) - f(\infty)| e^{\epsilon x}$ is bounded and $\varphi(x) e^{(\sigma - \frac{1}{2}\epsilon)(x-y)}$ is integrable,

$$\int_{-\infty}^{\infty} |f(x) - f(\infty)| e^{\epsilon x} \varphi(x-y) e^{(\sigma - \frac{1}{2}\epsilon)(x-y)} dx < \infty$$

uniformly in y. Thus $H(\sigma + \frac{1}{2}\epsilon)$ is finite. The above argument also implies that $H(\lambda)$ is finite for $0 < \lambda \leq \sigma + \frac{\epsilon}{2}$. This proves that $f(\infty)\hat{F}(\sigma) = 1$. σ is obviously the smallest positive root of $f(\infty)\hat{F}(\lambda) = 1$.

It remains to prove that $\varphi(x)$ has the desired asymptotic representation. Since $\hat{F}(\lambda)$ is convex with $\hat{F}(0) = 1$, $\hat{F}(\lambda)$ is decreasing near σ. Hence we can choose λ such that $\sigma < \lambda < \sigma + \frac{\epsilon}{2}$ and $0 < l = \hat{F}(\lambda) f(\infty) < 1$. We rewrite the equation as

$$\varphi = f(\infty)\, \varphi * F + (f(x) - f(\infty)) \varphi * F.$$

Multiply both sides by $e^{\lambda x}$. Then $\varphi_\lambda = l\, \varphi_\lambda * F_\lambda + g$, where

$$\begin{aligned}
&\varphi_\lambda = \varphi(x) e^{\lambda x}, \qquad dF_\lambda(x) = \frac{1}{\hat{F}(\lambda)} e^{\lambda x} dF(x), \\
&g(x) = (f(x) - f(\infty)) e^{\lambda x}\, \varphi * F.
\end{aligned}$$

Since f and φ are uniformly bounded, g decays exponentially near $x = -\infty$. Near $x = \infty$,

$$g(x) = O(e^{-\epsilon x}) e^{\lambda x}\, \varphi * F(x) = O(\varphi_{\lambda - \epsilon} * F_{\lambda - \epsilon}).$$

But $0 < \lambda - \epsilon < \sigma - \frac{\epsilon}{2} < \sigma$, and by (b), $\varphi_{\lambda - \epsilon}$ is bounded. Thus $g(x)$ is bounded and continuous, and decays exponentially at $\pm\infty$. Therefore, there exists a unique bounded continuous function $U(x)$ satisfying $U = l\, U * F_\lambda + g$. Indeed,

$$U = g + \sum_{j=1}^{\infty} l^j g * F_\lambda^{(j)},$$

where $F_\lambda^{(j)} = F_\lambda * \cdots * F_\lambda$ (j times). Note that $U(x) \leq 0$ for all $x \in \mathbb{R}$, since $g \leq 0$ by assumption. Define

$$\psi(x) = \varphi(x) - U(x) e^{-\lambda x} \geq 0.$$

ψ satisfies

$$\psi = f(\infty)\,\psi * F, \quad 0 \le \psi \le C(1 + e^{-\lambda x}), \qquad C \text{ some constant.}$$

This equation has the general solution

$$\psi(x) = \sum_{\mu} P_\mu(x) e^{-\mu x}, \qquad P_\mu \text{ a polynomial,}$$

where μ is a (real or complex) root of $1 = f(\infty)\hat{F}(\mu)$. Since σ is the smallest positive root of $1 = f(\infty)\hat{F}(\mu)$ and $l < 1$, the equation $f(\infty)\hat{F}(\mu) = 1$ has only one real root σ inside the strip $0 \le Re(\mu) \le \lambda$. This σ is a simple root of $f(\infty)\hat{F}(\mu) = 1$. All other roots inside the strip $0 \le Re(\mu) \le \lambda$ are pairwise complex conjugate. Since, for $\mu = \xi + i\eta$ where ξ and η are real,

$$\hat{F}(\xi + i\eta) = \int_{-\infty}^{\infty} e^{i\eta x} e^{\xi x} dF(x) \to 0 \qquad \text{as } |\eta| \to \infty,$$

$\hat{F}(\mu) f(\infty) = 1$ has only a finite number of roots inside the strip $0 \le Re(\mu) \le \lambda$. Also, roots μ with $Re(\mu) > \lambda$ are excluded by the requirement that $0 \le \psi \le C(1 + e^{-\lambda x})$. Thus an application of Theorem 146 in Titchmarsh [14, p. 305] gives

$$\psi(x) = Ae^{-\sigma x} + \sum_{\mu} P_\mu(x) e^{-\mu x},$$

where the sum is over complex numbers μ such that $f(\infty)\hat{F}(\mu) = 1$ and $0 \le Re(\mu) \le \lambda$. But $\psi(x) \ge 0$ for all x, and we must have $\psi(x) = Ae^{-\sigma x}$ with $A \ge 0$. Therefore

$$\varphi(x) = Ae^{-\sigma x} + U(x)e^{-\lambda x} = e^{-\sigma x}[A + U(x)e^{-\epsilon' x}],$$

where $\epsilon' = \lambda - \sigma$. This A can not be zero, otherwise $\varphi_\sigma = \varphi e^{\sigma x}$ satisfies

$$0 \le \varphi_\sigma \le \varphi_\sigma * F_\sigma, \qquad \varphi_\sigma(\pm\infty) = 0.$$

Theorem 4.1 of Essén [3, p. 126] implies that $\varphi_\sigma(x) \equiv 0$ for all x, a contradiction to $\varphi \not\equiv 0$.

The proof of Lemma 4.1 is complete. □

5. The existence of traveling waves. From now on, we shall assume (A1) and (A2)′–(A4)′. The mapping Q is simplified to

$$\tilde{N} = \alpha(N * \mathcal{S})\left(\frac{u^2}{N} * \mathcal{S}\right) + 2\gamma(N * \mathcal{S})\left(\frac{uv}{N} * \mathcal{S}\right) + \gamma(N * \mathcal{S})\left(\frac{v^2}{N} * \mathcal{S}\right),$$
$$\tilde{u} = \alpha(N * \mathcal{S})\left(\frac{u^2}{N} * \mathcal{S}\right) + \gamma(N * \mathcal{S})\left(\frac{uv}{N} * \mathcal{S}\right).$$

It is more convenient to work with the variable $v = N - u$ instead of u. In terms of $[N, v]$ and $k(N) = \frac{\alpha(N)}{\gamma(N)}$, the mapping Q is

$$\tilde{N} = \gamma(N * \mathcal{S})N * \mathcal{S} + (k(N * \mathcal{S}) - 1)\gamma(N * \mathcal{S})\left(\frac{u^2}{N}\right) * \mathcal{S},$$
$$\tilde{v} = \gamma(N * \mathcal{S})v * \mathcal{S}.$$

We look for a traveling wave solution of Q in the form

$$N^{(n)}(x) = N(x - nc), \quad v^{(n)} = v(x - nc), \quad n = 0, 1, 2, \ldots,$$

where c is the wave speed and $[N(x), v(x)] \in \Delta$ is the wave profile. Thus $[N(x), v(x)]$ is such a wave profile iff it satisfies the following system of convolution equations:

$$N = \gamma(N * \mathcal{S}_c)\, N * \mathcal{S}_c + (k(N * \mathcal{S}_c) - 1)\gamma(N * \mathcal{S}_c) \left(\frac{u^2}{N}\right) * \mathcal{S}_c \equiv Q_{1c}[N, v],$$
$$v = \gamma(N * \mathcal{S}_c) v * \mathcal{S}_c \equiv Q_{2c}[N, v],$$

where $\mathcal{S}_c(x) = \mathcal{S}(x + c)$ is the translated probability distribution. We will denote $[Q_{1c}, Q_{2c}]$ by Q_c. Clearly $[N(\pm\infty), v(\pm\infty)]$ must be constant fixed points of Q. In this section, we look for traveling wave solutions which satisfy the boundary conditions

$$[N(-\infty), v(-\infty)] = [N^*, N^*], \qquad [N(\infty), v(\infty)] = [N_1^*, 0]. \tag{7}$$

We shall discuss other types of traveling wave solutions that connect $[N^*, N^*]$ and $[0, 0]$ in §7.

LEMMA 5.1. *Let $[N(x), u(x)]$ be a traveling wave of the system Q with speed c which satisfies the boundary conditions* (7). *Suppose that $\alpha'(N_1^*)N_1^* + 1 \geq 0$.*

(a) *Then $0 < N(x) \leq N^*$ for all $x \in \mathbb{R}$. Thus $\inf_{x\in\mathbb{R}} N(x) > 0$.*

(b) *If $\alpha(N^*)N^* \geq N_1^*$, then $N_1^* \leq N(x) \leq N^*$ for all $x \in \mathbb{R}$.*

(c) *If $|\alpha'(N^*)N^* + \alpha(N^*)| \leq \alpha'(N_1^*)N_1^* + 1$, then $c \geq c_1^*$. Moreover, when $c > c_1^*$, $N(x)$ and $v(x)$ have a representation of the form*

$$N(x) = N_1^* + e^{-\sigma x}\{A + R(x)e^{-\epsilon x}\},$$
$$v(x) = e^{-\sigma x}\{B + V(x)e^{-\epsilon x}\},$$

where $R(x)$ and $V(x)$ are bounded continuous functions, σ is the smallest positive root of the equation $\gamma(N_1^*)e^{-\lambda c}K(\lambda) = 1$, and $0 < \epsilon < \sigma$. A and B are two constants with the relation

$$A = \frac{2(\gamma(N_1^*) - 1)}{\gamma(N_1^*) - (\alpha'(N_1^*)N_1^* + 1)} B.$$

Proof. (a) By (A2)′, we have

$$N(x) \leq \gamma(N * \mathcal{S}_c(x))\, N * \mathcal{S}_c(x) \leq M,$$

where $M = \max_{0\leq N\leq 1} N\gamma(N)$. But $N\gamma(N)$ is increasing over $0 \leq N \leq M$. Therefore $N(x) \leq M_n$ for all $x \in \mathbb{R}$, where M_n is defined by

$$M_{n+1} = \gamma(M_n)M_n, \quad M_0 = M, \quad n = 0, 1, 2, \ldots,$$

Since $\gamma'(N^*)N^* + 1 \geq 0$, M_n decreases to N^* as $n \to \infty$. Thus $N(x) \leq N^*$. Now $N(x)$ satisfies the inequality

$$N(x) \geq \alpha(N * \mathcal{S}_c(x))\, N * \mathcal{S}_c(x) \geq \alpha(N^*)N * \mathcal{S}_c(x).$$

If $N(x_0) = 0$ for some x_0 in $\mathbb{R}$, then $N * \mathcal{S}_c^{(n)}(x_0) = 0$ for all $n = 1, 2, 3, \ldots$. An argument involving the concept of "the point of increase" of a distribution function

(see Diekmann and Kaper [2]) implies that $N(x) = 0$ for all $x \in \mathbb{R}$. This is a contradiction to the boundary conditions of $N(x)$. Therefore $N(x) > 0$ for all $x \in \mathbb{R}$.

(b) Let $N_0 = \inf_{x\in\mathbb{R}} N(x)$. Define $N_1 = \alpha(N_0)N_0$. We *claim* that $N(x) \geq \min\{N_1, N_1^*\}$ for all $x \in \mathbb{R}$. Let $x \in \mathbb{R}$ be a point where $N * \mathcal{S}_c(x) \leq N_1^*$, and we have

$$N(x) \geq \alpha(N * \mathcal{S}_c(x))N * \mathcal{S}_c(x) \geq \alpha(N_0)N_0 = N_1.$$

On the other hand, let $x \in \mathbb{R}$ be a point where $N * \mathcal{S}_c(x) > N_1^*$. Since $\alpha(N^*)N^* \geq N_1^*$ and $N\alpha(N)$ is concave, we have

$$N(x) \geq \alpha(N * \mathcal{S}_c(x))N * \mathcal{S}_c(x) \geq N_1^*.$$

This proves the claim.

From the claim, $N_0 \geq \min\{N_1, N_1^*\}$. If $N_0 < N_1^*$, then $N_0 \geq N_1$. But $\alpha'(N_1^*)N_1^* + 1 \geq 0$ and $N\alpha(N)$ is concave, we must have $N_0 < \alpha(N_0)N_0 = N_1$. This is a contradiction. Therefore $N_0 \geq N_1^*$.

(c) The equation for $v(x)$ is given by

$$v = \gamma(N * \mathcal{S}_c)v * \mathcal{S}_c, \quad v(-\infty) = N^*, \quad v(\infty) = 0.$$

Let $f(x) = \gamma(N * \mathcal{S}_c(x))$. Then $f(\infty) = \gamma(N_1^*) > 1$. By Lemma 4.1 (a) and (b), $v(x)e^{\lambda x}$ is bounded for all $\lambda > 0$ sufficiently small. We *claim* that $(N(x) - N_1^*)e^{\lambda x}$ is also bounded in $\mathbb{R}$. To prove the claim, we write the N equation as

$$\begin{aligned} N - N_1^* = {} & (\alpha(N * \mathcal{S}_c)N * \mathcal{S}_c - N_1^*) + 2(\gamma(N * \mathcal{S}_c) - \alpha(N * \mathcal{S}_c))v * \mathcal{S}_c \\ & + (\alpha(N * \mathcal{S}_c) - \gamma(N * \mathcal{S}_c)) \left(\frac{v^2}{N} * \mathcal{S}_c\right). \end{aligned}$$

By the Mean Value Theorem,

$$\alpha(N * \mathcal{S}_c(x))N * \mathcal{S}_c(x) - N_1^* = T(x)(N * \mathcal{S}_c(x) - N_1^*),$$

where

$$\begin{aligned} T(x) &= \int_0^1 \{\alpha'(N(t) * \mathcal{S}_c)N(t) * \mathcal{S}_c + \alpha(N(t) * \mathcal{S}_c)\}dt, \\ N(t) &= (1-t)N(x) + tN_1^*. \end{aligned}$$

For convenience, we call $N_\lambda(x) = (N(x) - N_1^*)e^{\lambda x}$. We multiply both sides of the N equation by $e^{\lambda x}$. Then

$$N_\lambda(x) = T(x)e^{-\lambda c}K(\lambda)\, N_\lambda * F(x) + g(x), \tag{8}$$

where

$$g(x) = (\gamma(N * \mathcal{S}_c(x)) - \alpha(N * \mathcal{S}_c(x)))e^{-\lambda c}K(\lambda) \left\{2v_\lambda - \frac{v}{N}v_\lambda\right\} * F(x)$$

with

$$v_\lambda(x) = v(x)e^{\lambda x} \quad \text{and} \quad dF(x) = \frac{1}{e^{-\lambda c}K(\lambda)}e^{\lambda x}d\mathcal{S}_c(x).$$

Since $0 \le v \le N$ and v_λ is bounded, $g(x)$ is bounded in $\mathbb{R}$. By (b), $N_1^* \le N(t) \le N^*$. Note that $\alpha'(N)N+\alpha(N)$ is decreasing in N and $|\alpha'(N^*)N^*+\alpha(N^*)| \le \alpha'(N_1^*)N_1^*+1$. Therefore $|T(x)| \le \alpha'(N_1^*)N_1^* + 1$ for all $x \in \mathbb{R}$. Since

$$\lim_{\lambda \to 0}(\alpha'(N_1^*)N_1^* + 1)e^{-\lambda c}K(\lambda) = \alpha'(N_1^*)N_1^* + 1 < 1,$$

we have $(\alpha'(N_1^*)N_1^* + 1)e^{-\lambda c}K(\lambda) < 1$ for all $\lambda > 0$ small enough. Thus, for such λ, we get

$$|T(x)e^{-\lambda c}K(\lambda)| \le (\alpha'(N_1^*)N_1^* + 1)e^{-\lambda c}K(\lambda) < 1$$

for all $x \in \mathbb{R}$. Therefore the equation

$$\varphi(x) = T(x)e^{-\lambda c}K(\lambda)\,\varphi * F(x) + g(x)$$

has a unique solution which is bounded in $\mathbb{R}$. This proves that $N_\lambda(x)$ is bounded in $\mathbb{R}$ for some $\lambda > 0$.

From the claim, we deduce that

$$f(x) = \gamma(N * \mathcal{S}_c(x)) = \gamma(N_1^*) + O(e^{-\lambda x})$$

as $x \to \infty$ for some $\lambda > 0$. Thus Lemma 4.1 (c) implies that the equation $\gamma(N_1^*)e^{-\lambda c}K(\lambda) = 1$ has a smallest positive root σ. Therefore

$$c = \frac{1}{\sigma}\log(\gamma(N_1^*)K(\sigma)) \ge c_1^*.$$

Moreover, when $c > c_1^*$, $v(x)$ has a representation of the form

$$v(x) = e^{-\sigma x}\{B + V(x)e^{-\epsilon x}\}$$

for some $0 < \epsilon < \sigma$, where $B > 0$ and $V(x)$ is a bounded continuous function with $V(x) \le 0$ for all $x \in \mathbb{R}$. We put this form of $v(x)$ into the N equation. By a similar argument as in the proof of the claim, we get the representation of $N(x)$. Indeed, we will get the relation between A and B as follows. Since $A = \lim_{x\to\infty}(N(x) - N_1^*)e^{\sigma x}$, we get

$$A = (\alpha'(N_1^*)N_1^* + 1)e^{-\sigma c}K(\sigma)A + 2(\gamma(N_1^*) - \alpha(N_1^*))e^{-\sigma c}K(\sigma)B$$

by letting $x \to \infty$ in (8) for $\lambda = \sigma$. Thus (c) is proved. □

LEMMA 5.2. *Let* $[N(x), u(x)] \in \Delta$ *have the asymptotic form*

$$N(x) = L + e^{-\sigma x}\{A + e^{-\epsilon x}R(x)\}, \qquad v(x) = e^{-\sigma x}\{B + e^{-\epsilon x}V(x)\}$$

for some $0 < \epsilon < \sigma$. $R(x)$ *and* $V(x)$ *are bounded continuous functions.* L, A, *and* B *are constants. Assume that* $\inf_{x\in\mathbb{R}} N(x) > 0$. *Then*

$$\tilde{N}(x) = Q_{1c}[N, v](x) = \tilde{L} + e^{-\sigma x}\{\tilde{A} + e^{-\epsilon x}\tilde{R}(x)\},$$
$$\tilde{v}(x) = Q_{2c}[N, v](x) = e^{-\sigma x}\{\tilde{B} + e^{-\epsilon x}\tilde{V}(x)\}.$$

$\tilde{L}$, $\tilde{A}$, *and* $\tilde{B}$ *are computed as*

$$\tilde{L} = \alpha(L)L,$$
$$\tilde{A} = e^{-\sigma c}K(\sigma)[A(\alpha'(L)L + \alpha(L)) + 2B(\gamma(L) - \alpha(L))],$$
$$\tilde{B} = e^{-\sigma c}K(\sigma)\gamma(L)B.$$

$\tilde{R}$ and $\tilde{V}(x)$ are also bounded continuous functions.

Proof. We only prove the representation of $\tilde{N}$. The argument for $\tilde{v}$ is similar. We write

$$(Q_{1c}[N,v]-\tilde{L})e^{\sigma x}=(\alpha(N*\mathcal{S}_c)N*\mathcal{S}_c-\alpha(L)L)e^{\sigma x}+E[N,v]e^{\sigma x},$$

where

$$E[N,v]=(\gamma(N*\mathcal{S}_c)-\alpha(N*\mathcal{S}_c))\left\{2v-\frac{v^2}{N}\right\}*\mathcal{S}_c.$$

But

$$\begin{aligned}&(\alpha(N*\mathcal{S}_c(x))N*\mathcal{S}_c(x)-\alpha(L)L)e^{\sigma x}\\&\quad=T(x)(N*\mathcal{S}_c(x)-L)e^{\sigma x}\\&\quad=T(x)[Ae^{-\sigma c}K(\sigma)+e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon)R*F_1(x)e^{-\epsilon x}]\\&\quad=A(\alpha'(L)L+\alpha(L))e^{-\sigma c}K(\sigma)+B_1(x)+C_1(x)e^{-\epsilon x},\end{aligned}$$

where

$$\begin{aligned}T(x)&=\int_0^1\{\alpha'(N(t)*\mathcal{S}_c)N(t)*\mathcal{S}_c+\alpha(N(t)*\mathcal{S}_c)\}dt,\\N(t)&=(1-t)N(x)+tL,\\B_1(x)&=[T(x)-(\alpha'(L)L+\alpha(L))]e^{-\sigma c}K(\sigma)A,\\C_1(x)&=T(x)e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon)R*F_1(x),\end{aligned}$$

and

$$dF_1(x)=(e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon))^{-1}e^{(\sigma+\epsilon)x}d\mathcal{S}_c(x).$$

Since $N(t)=L+O(e^{-\sigma x})$ as $x\to\infty$, we have

$$T(x)=(\alpha'(L)L+\alpha(L))+O(e^{-\sigma x})$$

as $x\to\infty$. Thus $B_1(x)$ is a bounded continuous function with $B_1(x)=O(e^{-\sigma x})$ as $x\to\infty$. Since $T(x)$ is bounded, $C_1(x)$ is also a bounded continuous function. With a similar computation, we can write

$$E[N,v](x)e^{\sigma x}=2(\gamma(L)-\alpha(L))K(\sigma)e^{-\sigma c}B+B_2(x)+C_2(x)e^{-\epsilon x},$$

where

$$\begin{aligned}B_2(x)&=2(\gamma(N*\mathcal{S}_c(x))-\alpha(N*\mathcal{S}_c(x))-\gamma(L)+\alpha(L))K(\sigma)e^{-\sigma c}B\\&\quad-(\gamma(N*\mathcal{S}_c(x))-\alpha(N*\mathcal{S}_c(x)))\left(\frac{v^2}{N}\right)*\mathcal{S}_c(x)e^{\sigma x},\\C_2(x)&=2(\gamma(N*\mathcal{S}_c(x))-\alpha(N*\mathcal{S}_c(x)))e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon)V*F_1(x).\end{aligned}$$

$C_2(x)$ is obviously bounded. Now

$$\gamma(N*\mathcal{S}_c(x))-\alpha(N*\mathcal{S}_c(x))=\gamma(L)-\alpha(L)+O(e^{-\sigma x}),$$

$v^2(x) = O(e^{-2\sigma x})$ as $x \to \infty$, and $\inf_{x\in\mathbb{R}} N(x) > 0$. We get

$$B_2(x) = O(e^{-\sigma x}) \quad \text{as } x \to \infty.$$

Therefore

$$\begin{aligned}[Q_{1c}[N,v](x) - \tilde{L}]e^{\sigma x} &= A(\alpha'(L)L + \alpha(L))e^{-\sigma c}K(\sigma) \\ &\quad +2(\gamma(L) - \alpha(L))K(\sigma)e^{-\sigma c}B \\ &\quad +(B_1(x) + B_2(x)) + (C_1(x) + C_2(x))e^{-\epsilon x} \\ &= \tilde{A} + e^{-\epsilon x}\tilde{R}(x),\end{aligned}$$

where

$$\tilde{R}(x) = (B_1(x) + B_2(x))e^{\epsilon x} + (C_1(x) + C_2(x)).$$

However, $0 < \epsilon < \sigma$. Hence

$$(B_1(x) + B_2(x))e^{\epsilon x} = O(e^{-(\sigma-\epsilon)x})$$

as $x \to \infty$. Therefore $\tilde{R}(x)$ is bounded. The proof is complete. □

We now establish a key lemma on the Lipschitz estimate of Q.

LEMMA 5.3. *Assume* (A4)′. *Then there exist* $0 < k_0 < 1$ *and* $\eta_0 > 0$ *with the following property. If* $k_0 \le k(N) < 1$ *for all* $0 \le N \le N^*$ *and* $\max_{0\le N\le N^*} |k'(N)| \le \eta_0$, *then for any* $[N_i(x), v_i(x)] \in \Delta$ *with* $N_1^* \le N_i(x) \le N^*$ $(i = 1, 2)$, *we have the following inequalities:*

(a) $|\tilde{v}_1(x) - \tilde{v}_2(x)| \le \gamma(N_1^*) \max\{|u_1 - u_2| * \mathcal{S}_c(x),\ |v_1 - v_2| * \mathcal{S}_c(x)\}$,

(b) $|\tilde{u}_1(x) - \tilde{u}_2(x)| \le \gamma(N_1^*)\ \max\{|N_1 - N_2|, |u_1 - u_2|, |v_1 - v_2|\} * \mathcal{S}_c(x)$

for all x *in* $\mathbb{R}$, *where*

$$\tilde{N}_i = Q_{1c}[N_i, v_i], \quad \tilde{v}_i = Q_{2c}[N_i, v_i], \quad \tilde{u}_i = \tilde{N}_i - \tilde{v}_i$$

for $i = 1, 2$.

Proof. We prove the lemma at each point x in $\mathbb{R}$. Without loss of generality, we may assume that $N_1 * \mathcal{S}_c(x) \ge N_2 * \mathcal{S}_c(x)$ at x. The argument for the case where $N_1 * \mathcal{S}_c(x) \le N_2 * \mathcal{S}_c(x)$ is the same. We divide the proof into several steps.

Step 1. We prove the inequality (a).

By the definition of $\tilde{v}_i$ $(i = 1, 2)$, we have

$$\tilde{v}_1 - \tilde{v}_2 = \gamma(N_1 * \mathcal{S}_c)(v_1 - v_2) * \mathcal{S}_c + (\gamma(N_1 * \mathcal{S}_c) - \gamma(N_2 * \mathcal{S}_c))v_2 * \mathcal{S}_c.$$

Since $N_1 * \mathcal{S}_c(x) \ge N_2 * \mathcal{S}_c(x)$ and γ is decreasing, we get $(\gamma(N_1 * \mathcal{S}_c(x)) - \gamma(N_2 * \mathcal{S}_c(x)))v_2 * \mathcal{S}_c(x) \le 0$. Therefore

$$\tilde{v}_1(x) - \tilde{v}_2(x) \le \gamma(N_1^*)|v_1 - v_2| * \mathcal{S}_c(x).$$

Now we obtain a lower bound for $\tilde{v}_1(x) - \tilde{v}_2(x)$:

$$\begin{aligned}\tilde{v}_1 - \tilde{v}_2 &= \gamma(N_1 * \mathcal{S}_c)(N_1 - u_1) * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)(N_2 - u_2) * \mathcal{S}_c \\ &= (\gamma(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c) \\ &\quad +(\gamma(N_2 * \mathcal{S}_c) - \gamma(N_1 * \mathcal{S}_c))u_1 * \mathcal{S}_c + \gamma(N_2 * \mathcal{S}_c)(u_2 - u_1) * \mathcal{S}_c.\end{aligned}$$

Since $N\gamma(N)$ is increasing and $\gamma(N)$ is decreasing in $N_1^* \le N \le N^*$, we have $\gamma(N_1 * \mathcal{S}_c(x))N_1 * \mathcal{S}_c(x) - \gamma(N_2 * \mathcal{S}_c(x))N_2 * \mathcal{S}_c(x) \ge 0$ and $(\gamma(N_2 * \mathcal{S}_c(x)) - \gamma(N_1 * \mathcal{S}_c(x)))u_1 * \mathcal{S}_c(x) \ge 0$. Then

$$\tilde{v}_1(x) - \tilde{v}_2(x) \ge \gamma(N_2 * \mathcal{S}_c(x))(u_2 - u_1) * \mathcal{S}_c(x) \ge -\gamma(N_1^*)|u_1 - u_2| * \mathcal{S}_c(x).$$

The proof of Step 1 is complete. Note that the inequality (a) for $\tilde{v}$ is independent of k_0 and η_0.

For convenience, we define $\kappa = \min_{0\le N\le N^*} k(N)$ and $\eta = \max_{0\le N\le N^*} |k'(N)|$.

Step 2. There exist $0 < k_1 < 1$ and $0 < \eta_2$ such that whenever $k_1 \le \kappa$ and $0 \le \eta \le \eta_2$, the following inequality holds:

$$\gamma(N_1 * \mathcal{S}_c(x))\tilde{H}(x,\cdot) * \mathcal{S}_c(x) \le \tilde{u}_1(x) - \tilde{u}_2(x) \le \gamma(N_1 * \mathcal{S}_c(x))H(x,\cdot) * \mathcal{S}_c(x)$$

for all x in $\mathbb{R}$, where

$$\begin{aligned} H(x,y) &= (u_1(y) - u_2(y))\left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_1(y) + u_2(y)}{N_1(y)}\right] \\ &\quad + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_2(y)^2}{N_1(y)N_2(y)}(N_2(y) - N_1(y)), \\ \tilde{H}(x,y) &= (v_2(y) - v_1(y))\left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\left(2 - \frac{v_1(y) + v_2(y)}{N_1(y)}\right)\right] \\ &\quad + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(N_2(y) - N_1(y)) \end{aligned}$$

and $H(x,\cdot) * \mathcal{S}_c(x)$ is defined by

$$H(x,\cdot) * \mathcal{S}_c(x) = \int_{-\infty}^{\infty} H(x, x-y)d\mathcal{S}_c(y).$$

$\tilde{H}(x,\cdot) * \mathcal{S}_c(x)$ is similarly defined.

To find the upper bound, we write

$$\begin{aligned} \tilde{u}_1 - \tilde{u}_2 &= (\gamma(N_1 * \mathcal{S}_c)u_1 * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)u_2 * \mathcal{S}_c) \\ &\quad + \left[(k(N_1 * \mathcal{S}_c) - 1)\gamma(N_1 * \mathcal{S}_c)\frac{u_1^2}{N_1} * \mathcal{S}_c\right. \\ &\qquad \left. -(k(N_2 * \mathcal{S}_c) - 1)\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c\right] \\ &= \gamma(N_1 * \mathcal{S}_c)(u_1 - u_2) * \mathcal{S}_c + u_2 * \mathcal{S}_c(\gamma(N_1 * \mathcal{S}_c) - \gamma(N_2 * \mathcal{S}_c)) \\ &\quad + (k(N_1 * \mathcal{S}_c) - 1)\left[\gamma(N_1 * \mathcal{S}_c)\left(\frac{u_1^2}{N_1} - \frac{u_2^2}{N_2}\right) * \mathcal{S}_c\right. \\ &\qquad \left. + (\gamma(N_1 * \mathcal{S}_c) - \gamma(N_2 * \mathcal{S}_c))\frac{u_2^2}{N_2} * \mathcal{S}_c\right] \\ &\quad + (k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c \\ &= \gamma(N_1 * \mathcal{S}_c)\left\{(u_1 - u_2) * \mathcal{S}_c + (k(N_1 * \mathcal{S}_c) - 1)\left[\frac{u_1 + u_2}{N_1}(u_1 - u_2)\right.\right. \\ &\qquad \left.\left. + \frac{u_2^2}{N_1N_2}(N_2 - N_1)\right] * \mathcal{S}_c\right\} \end{aligned}$$

$$+\left[u_2 * \mathcal{S}_c + (k(N_1 * \mathcal{S}_c) - 1)\frac{u_2^2}{N_2} * \mathcal{S}_c\right](\gamma(N_1 * \mathcal{S}_c) - \gamma(N_2 * \mathcal{S}_c))$$
$$+(k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c$$
$$= \gamma(N_1 * \mathcal{S}_c)H(x,\cdot) * \mathcal{S}_c + G,$$

where

$$H(x,y) = (u_1(y) - u_2(y))\left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_1(y) + u_2(y)}{N_1(y)}\right]$$
$$+(k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_2(y)^2}{N_1(y)N_2(y)}(N_2(y) - N_1(y)),$$
$$G = \left[u_2 * \mathcal{S}_c + (k(N_1 * \mathcal{S}_c) - 1)\frac{u_2^2}{N_2} * \mathcal{S}_c\right](\gamma(N_1 * \mathcal{S}_c) - \gamma(N_2 * \mathcal{S}_c))$$
$$+(k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c.$$

We *claim* that there exists $\eta_1 > 0$ such that $G \leq 0$ whenever $0 \leq \eta \leq \eta_1$. We apply the Mean Value Theorem to rewrite G as

$$G(x) = (N_1 - N_2) * \mathcal{S}_c(x)\{\gamma'(\bullet)[u_2 * \mathcal{S}_c(x)$$
$$+(k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_2^2}{N_2} * \mathcal{S}_c(x)]$$
$$+k'(\bullet)\gamma(N_2 * \mathcal{S}_c(x))\frac{u_2^2}{N_2} * \mathcal{S}_c(x)\}$$
$$\leq (N_1 - N_2) * \mathcal{S}_c(x)\left\{\gamma'(\bullet)\left(u_2 - \frac{u_2^2}{N_2}\right) * \mathcal{S}_c(x)\right.$$
$$\left.+\frac{u_2^2}{N_2} * \mathcal{S}_c(x)[\gamma'(\bullet)k(N_1 * \mathcal{S}_c(x)) + \gamma(N_1^*)\eta]\right\}.$$

(Recall that $(N_1 - N_2) * \mathcal{S}_c(x) \geq 0$.) Since $\gamma(N)$ is decreasing in $0 \leq N < 1$, we have

$$\gamma'(\bullet)\left(u_2 - \frac{u_2^2}{N_2}\right) * \mathcal{S}_c(x) \leq 0.$$

When $\kappa \geq \frac{1}{2}$, we choose η_1 such that

$$0 < \eta_1 < \frac{1}{2\gamma(0)}\left(\min_{0 \leq N \leq N^*} |\gamma'(N)|\right).$$

Then, for $0 \leq \eta \leq \eta_1$, we have

$$\gamma'(\bullet)k(N_1 * \mathcal{S}_c(x)) + \gamma(N_1^*)\eta \leq 0.$$

Therefore, $G \leq 0$. Thus

$$\tilde{u}_1(x) - \tilde{u}_2(x) \leq \gamma(N_1 * \mathcal{S}_c(x))H(x,\cdot) * \mathcal{S}_c(x).$$

To find the lower bound, we use $u = N - v$. Then

$\tilde{u}_1 - \tilde{u}_2$

$$
\begin{aligned}
&= \gamma(N_1 * \mathcal{S}_c)(N_1 - v_1) * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)(N_2 - v_2) * \mathcal{S}_c \\
&\quad + (k(N_1 * \mathcal{S}_c) - 1)\left[\gamma(N_1 * \mathcal{S}_c)\frac{(N_1 - v_1)^2}{N_1} * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)\frac{(N_2 - v_2)^2}{N_2} * \mathcal{S}_c\right] \\
&\quad + (k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{(N_2 - v_2)^2}{N_2} * \mathcal{S}_c \\
&= k(N_1 * \mathcal{S}_c)(\gamma(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c) \\
&\quad + [1 + 2(k(N_1 * \mathcal{S}_c) - 1)](\gamma(N_2 * \mathcal{S}_c)v_2 * \mathcal{S}_c - \gamma(N_1 * \mathcal{S}_c)v_1 * \mathcal{S}_c) \\
&\quad + (k(N_1 * \mathcal{S}_c) - 1)\left(\gamma(N_1 * \mathcal{S}_c)\frac{v_1^2}{N_1} * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)\frac{v_2^2}{N_2} * \mathcal{S}_c\right) \\
&\quad + (k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c \\
&= k(N_1 * \mathcal{S}_c)(\gamma(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c)) \\
&\quad + (k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c \\
&\quad + [(1 + 2(k(N_1 * \mathcal{S}_c) - 1))v_2 * \mathcal{S}_c \\
&\qquad + (1 - k(N_1 * \mathcal{S}_c))\frac{v_2^2}{N_2} * \mathcal{S}_c](\gamma(N_2 * \mathcal{S}_c) - \gamma(N_1 * \mathcal{S}_c)) \\
&\quad + \gamma(N_1 * \mathcal{S}_c)[1 + 2(k(N_1 * \mathcal{S}_c) - 1)](v_2 - v_1) * \mathcal{S}_c \\
&\quad + \gamma(N_1 * \mathcal{S}_c)(k(N_1 * \mathcal{S}_c) - 1)\left[(v_1 - v_2)\frac{v_1 + v_2}{N_1} + \frac{v_2^2}{N_1 N_2}(N_2 - N_1)\right] * \mathcal{S}_c \\
&= \tilde{G} + \gamma(N_1 * \mathcal{S}_c)\tilde{H}(x, \cdot) * \mathcal{S}_c,
\end{aligned}
$$

where

$$
\begin{aligned}
\tilde{G} &= k(N_1 * \mathcal{S}_c)(\gamma(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \gamma(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c) \\
&\quad + (k(N_1 * \mathcal{S}_c) - k(N_2 * \mathcal{S}_c))\gamma(N_2 * \mathcal{S}_c)\frac{u_2^2}{N_2} * \mathcal{S}_c \\
&\quad + [(2k(N_1 * \mathcal{S}_c) - 1)v_2 * \mathcal{S}_c \\
&\qquad + (1 - k(N_1 * \mathcal{S}_c))\frac{v_2^2}{N_2} * \mathcal{S}_c](\gamma(N_2 * \mathcal{S}_c) - \gamma(N_1 * \mathcal{S}_c)), \\
\tilde{H}(x, y) &= (v_2(y) - v_1(y))\left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\left(2 - \frac{v_1(y) + v_2(y)}{N_1(y)}\right)\right] \\
&\quad + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(N_2(y) - N_1(y)).
\end{aligned}
$$

We *claim* that there exist $0 < k_1 < 1$ and $0 < \eta_2 \leq \eta_1$ such that $\tilde{G} \geq 0$ whenever $k_1 \leq \kappa$ and $0 \leq \eta \leq \eta_2$. Since $\gamma(N)$ is decreasing and we are assuming that $N_1 * \mathcal{S}_c(x) \geq N_2 * \mathcal{S}_c(x)$, we have $\gamma(N_2 * \mathcal{S}_c(x)) - \gamma(N_1 * \mathcal{S}_c(x)) \geq 0$. If $\frac{1}{2} \leq \kappa$, then

$$
[2k(N_1 * \mathcal{S}_c(x)) - 1]v_2 * \mathcal{S}_c(x) + (1 - k(N_1 * \mathcal{S}_c(x)))\frac{v_2^2}{N_2} * \mathcal{S}_c(x) \geq 0.
$$

Now, by the Mean Value Theorem, we get

$$
\begin{aligned}
\tilde{G}(x) &\geq k(N_1 * \mathcal{S}_c(x))(\gamma'(\xi)\xi + \gamma(\xi))(N_1 - N_2) * \mathcal{S}_c(x) \\
&\quad + \gamma(N_2 * \mathcal{S}_c(x))\frac{u_2^2}{N_2} * \mathcal{S}_c(x)k'(\bullet)(N_1 - N_2) * \mathcal{S}_c(x)
\end{aligned}
$$

for some ξ with $N_1 * \mathcal{S}_c(x) \geq \xi \geq N_2 * \mathcal{S}_c(x)$. Then, when $\kappa \geq \frac{1}{2}$,

$$\begin{aligned}\tilde{G}(x) &\geq \left[\kappa \min_{N_1^* \leq N \leq N^*}(\gamma'(N)N + \gamma(N)) - N^*\eta\right](N_1 - N_2) * \mathcal{S}_c(x) \\ &\geq \left[\frac{1}{2}(\gamma'(N^*)N^* + 1) - N^*\eta\right](N_1 - N_2) * \mathcal{S}_c(x).\end{aligned}$$

By assumption, $\gamma'(N^*)N^* + 1 > 0$. We define

$$\eta_2 = \min\left\{\eta_1, \frac{1}{2N^*}(\gamma'(N^*)N^* + 1)\right\}.$$

Then, for $\kappa \geq \frac{1}{2}$ and $0 \leq \eta \leq \eta_2$, we have $\tilde{G}(x) \geq 0$. This proves the claim and Step 2 by letting $k_1 = \frac{1}{2}$.

Step 3. There exists $1 > k_2 \geq k_1$ such that whenever $k_2 \leq \kappa$, H satisfies

$$H(x, y) \leq \max\{|N_1(y) - N_2(y)|, |u_1(y) - u_2(y)|\}$$

for all $x, y \in \mathbb{R}$.

We note that

$$1 + (\kappa - 1)\frac{2N^*}{N_1^*} \leq 1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_1(y) + u_2(y)}{N_1(y)} \leq 1.$$

When $\kappa \to 1$, $1 + (\kappa - 1)\frac{2N^*}{N_1^*} \to 1$. Thus we can choose $1 > k_2 \geq k_1$ such that

$$0 \leq 1 + (\kappa - 1)\frac{2N^*}{N_1^*} \qquad \text{for } k_2 \leq \kappa.$$

Then, for $\kappa \geq k_2$,

$$\begin{aligned}H(x, y) &\leq |u_1(y) - u_2(y)|\left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{u_1(y) + u_2(y)}{N_1(y)}\right] \\ &\quad + |N_1(y) - N_2(y)|(1 - k(N_1 * \mathcal{S}_c(x)))\frac{u_2(y)^2}{N_1(y)N_2(y)} \\ &\leq \max\{|N_1(y) - N_2(y)|, |u_1(y) - u_2(y)|\} \\ &\quad \times \left[1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\left(\frac{u_1(y)}{N_1(y)} + \frac{u_2(y)v_2(y)}{N_1(y)N_2(y)}\right)\right] \\ &\leq \max\{|N_1(y) - N_2(y)|, |u_1(y) - N_2(y)|\}.\end{aligned}$$

Step 4. There exists $1 > k_4 \geq k_2$ such that whenever $k_4 \leq \kappa$, $\tilde{H}$ satisfies

$$\tilde{H}(x, y) \geq -\max\{|N_1(y) - N_2(y)|, |u_1(y) - u_2(y)|, |v_1(y) - v_2(y)|\}$$

for all $x, y \in \mathbb{R}$.

We consider three cases.

Case a. $N_1(y) \geq N_2(y)$.

We have

$$\frac{v_2(y)}{N_1(y)} \leq \frac{v_2(y)}{N_2(y)}, \quad \text{i.e. } 1 - \frac{v_2(y)}{N_1(y)} \geq \frac{u_2(y)}{N_2(y)} \geq 0.$$

Thus

$$1+(k(N_1*\mathcal{S}_c(x))-1)\left(2-\frac{v_1(y)+v_2(y)}{N_1(y)}\right)$$
$$=1+(k(N_1*\mathcal{S}_c)-1)\left[\left(1-\frac{v_1(y)}{N_1(y)}\right)+\left(1-\frac{v_2(y)}{N_1(y)}\right)\right]\le 1.$$

On the other hand, by $\kappa\ge\frac{1}{2}$,

$$1+(k(N_1*\mathcal{S}_c(x))-1)\left(2-\frac{v_1(y)+v_2(y)}{N_1(y)}\right)$$
$$\ge 1+2(\kappa-1)\left(1-\frac{N_1^*}{N^*}\right)\ge 1-\left(1-\frac{N_1^*}{N^*}\right)\ge 0.$$

Since $N_1(y)\ge N_2(y)$,

$$(k(N_1*\mathcal{S}_c(x))-1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(N_2(y)-N_1(y))\ge 0.$$

Therefore

$$\tilde{H}(x,y)\ge(v_2(y)-v_1(y))\left[1+(k(N_1*\mathcal{S}_c(x))-1)\left(2-\frac{v_1(y)+v_2(y)}{N_1(y)}\right)\right]$$
$$\ge-|v_1(y)-v_2(y)|.$$

Case b. $N_1(y)<N_2(y)$ and $v_1(y)\ge v_2(y)$.
Then $u_1(y)\le u_2(y)$. We write $\tilde{H}$ as

$$\tilde{H}(x,y)=(v_2(y)-v_1(y))\left[1+(k(N_1*\mathcal{S}_c(x))-1)\left(2-\frac{v_1(y)+v_2(y)}{N_1(y)}\right)\right]$$
$$+(k(N_1*\mathcal{S}_c(x))-1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(v_2(y)+u_2(y)-v_1(y)-u_1(y))$$
$$=(v_2(y)-v_1(y))\left\{1+(k(N_1*\mathcal{S}_c(x))-1)\left[\frac{u_1(y)}{N_1(y)}\right.\right.$$
$$\left.\left.+\left(1-\frac{v_2(y)}{N_1(y)}\right)+\frac{v_2(y)^2}{N_1(y)N_2(y)}\right]\right\}$$
$$+(k(N_1*\mathcal{S}_c(x))-1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(u_2(y)-u_1(y)).$$

Similar to the argument in Step 3, we can choose $1>k_3\ge k_2$ such that

$$1+(k(N_1*\mathcal{S}_c(x))-1)\left[\frac{u_1(y)}{N_1(y)}+\left(1-\frac{v_2(y)}{N_1(y)}\right)+\frac{v_2(y)^2}{N_1(y)N_2(y)}\right]\ge 0$$

for $k_3\le\kappa$. By $v_1(y)\ge v_2(y)$, we have

$$0\le 1-\frac{v_1(y)}{N_1(y)}\le 1-\frac{v_2(y)}{N_1(y)}.$$

Hence

$$\tilde{H}(x,y)\ge-\max\{|v_1(y)-v_2(y)|,(u_2(y)-u_1(y))\}$$
$$\times\left\{1+(k(N_1*\mathcal{S}_c(x))-1)\left[\frac{u_1(y)}{N_1(y)}+\left(1-\frac{v_2(y)}{N_1(y)}\right)\right]\right\}$$
$$\ge-\max\{|v_1(y)-v_2(y)|,(u_2(y)-u_1(y))\}.$$

Case c. $N_1(y) < N_2(y)$ and $v_1(y) < v_2(y)$.

By the choice of k_3 in Case b, for $\kappa \geq k_3$, we have

$$1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\left(2 - \frac{v_1(y) + v_2(y)}{N_1(y)}\right)$$
$$\geq 1 + (k(N_1 * \mathcal{S}_c(x)) - 1)\left[\frac{u_1(y)}{N_1(y)} + \left(1 - \frac{v_2(y)}{N_1(y)}\right) + \frac{v_2(y)^2}{N_1(y)N_2(y)}\right] \geq 0.$$

Thus

$$\tilde{H}(x,y) \geq (k(N_1 * \mathcal{S}_c(x)) - 1)\frac{v_2(y)^2}{N_1(y)N_2(y)}(N_2(y) - N_1(y)).$$

Now

$$0 \leq (1 - k(N_1 * \mathcal{S}_c(x)))\frac{v_2(y)^2}{N_1(y)N_2(y)} \leq (1-\kappa)\frac{N^*}{N_1^*} \to 0$$

as $\kappa \to 1$. We can choose $1 > k_4 \geq k_3$ such that $(1-\kappa)\frac{N^*}{N_1^*} < 1$ for $\kappa \geq k_4$. Therefore

$$\tilde{H}(x,y) \geq N_1(y) - N_2(y)$$

for $\kappa \geq k_4$. This proves Step 4.

We define $k_0 = k_4$ and $\eta_0 = \eta_2$. By Steps 2, 3, and 4, we get

$$|\tilde{u}_1(x) - \tilde{u}_2(x)| \leq \gamma(N_1^*) \max\{|N_1 - N_2|, |u_1 - u_2|, |v_1 - v_2|\} * \mathcal{S}_c(x)$$

for all $x \in \mathbb{R}$, whenever $k_0 \leq k(N) < 1$ for all $0 \leq N \leq N^*$ and $0 \leq \eta \leq \eta_0$. □

We are now ready to prove Theorem 2.2.

Proof of Theorem 2.2. We choose k_0 and η_0 such that Lemma 5.3 holds. We can also adjust k_0 and η_0 such that $\alpha'(N^*)N^* + \alpha(N^*) \geq 0$ and $\alpha(N^*)N^* \geq N_1^*$ for $k_0 \leq \kappa = \min_{0 \leq N \leq N^*} k(N)$ and $0 \leq \eta \leq \eta_0$. Then Lemma 5.1 can be applied. The necessity that $c \geq c_1^*$ follows. The desired traveling wave has the exponential decay form at $x = \infty$ when $c > c_1^*$.

We prove the existence for $c > c_1^*$ first. Define σ to be the smallest positive root of the equation

$$\gamma(N_1^*)e^{-\lambda c}K(\lambda) = 1.$$

σ exists due to $c > c_1^*$. Let $0 < \epsilon < \sigma$ be chosen such that

$$0 < \gamma(N_1^*)e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon) < 1.$$

Let $\alpha(N)$ and $\gamma(N)$ be given such that κ and η satisfy $k_0 \leq \kappa$ and $0 \leq \eta \leq \eta_0$. For $B > 0$ fixed, we define the space

$$\begin{aligned}\mathcal{B} = \{[R,V] |\ & R(x) \text{ and } V(x) \text{ are bounded continuous functions} \\ & \text{in } \mathbb{R}.\ N(x) = N_1^* + e^{-\sigma x}[A + e^{-\epsilon x}R(x)] \text{ and} \\ & v(x) = e^{-\sigma x}[B + e^{-\epsilon x}V(x)] \text{ satisfy } 0 \leq v(x) \leq N(x) \\ & \text{and } N_1^* \leq N(x) \leq N^* \text{ for all } x \in \mathbb{R}, \}\end{aligned} \tag{9}$$

where

$$A = \frac{2(\gamma(N_1^*) - 1)}{\gamma(N_1^*) - (\alpha'(N_1^*)N_1^* + 1)}B.$$

Clearly $\mathcal{B} \neq \emptyset$. For $[R, V] \in \mathcal{B}$, define

$$u(x) \equiv N(x) - v(x) = N_1^* + e^{-\sigma x}[(A - B) + e^{-\epsilon x}(R(x) - V(x))].$$

We call $U(x) = R(x) - V(x)$. Then we define a metric on $\mathcal{B}$ by

$$\boldsymbol{d}([R_1, V_1], [R_2, V_2]) = \max\{\|R_1 - R_2\|_\infty, \|V_1 - V_2\|_\infty, \|U_1 - U_2\|_\infty\}. \tag{10}$$

$(\mathcal{B}, \boldsymbol{d})$ is then a complete metric space. We define a mapping Γ on $\mathcal{B}$ by

$$\Gamma([R, V]) = [\tilde{R}, \tilde{V}], \qquad [R, V] \in \mathcal{B}, \tag{11}$$

where

$$\begin{aligned} \tilde{R} &= [(Q_{1c}[N, v] - N_1^*)e^{\sigma x} - A]e^{\epsilon x}, \\ \tilde{V} &= [Q_{2c}[N, v]e^{\sigma x} - B]e^{\epsilon x}. \end{aligned}$$

First, we *claim* that $\Gamma : \mathcal{B} \to \mathcal{B}$. By Lemma 5.2, $\tilde{R}$ and $\tilde{V}$ are bounded continuous functions. Now

$$\begin{aligned} [\tilde{R}(x)e^{-\epsilon x} + A]e^{-\sigma x} + N_1^* &= Q_{1c}[N, v](x) \equiv \tilde{N}(x), \\ [\tilde{V}(x)e^{-\epsilon x} + 1]e^{-\sigma x} &= Q_{2c}[N, v](x) \equiv \tilde{v}(x). \end{aligned}$$

From $0 \leq v(x) \leq N(x)$, we get $0 \leq \tilde{v}(x) \leq \tilde{N}(x)$. We need to show that $N_1^* \leq \tilde{N}(x) \leq N^*$ for all $x \in \mathbb{R}$. By the definition of $Q_{1c}[N, v]$, we get

$$\alpha(N * \mathcal{S}_c)N * \mathcal{S}_c \leq \tilde{N} \leq \gamma(N * \mathcal{S}_c)N * \mathcal{S}_c.$$

Because $\gamma'(N^*)N^* + 1 > 0$ and $\alpha(N^*)N^* \geq N_1^*$, we have (from $N_1^* \leq N(x) \leq N^*$)

$$N_1^* \leq \alpha(N * \mathcal{S}_c)N * \mathcal{S}_c \leq \tilde{N}(x) \leq \gamma(N * \mathcal{S}_c)N * \mathcal{S}_c \leq N^*.$$

This proves the claim.

Now we want to prove that Γ is a contraction mapping when k_0 and η_0 are suitably adjusted. Given $[R_i(x), V_i(x)] \in \mathcal{B}$ $(i = 1, 2)$, we let

$$\begin{aligned} N_i(x) &= N_1^* + e^{-\sigma x}[A + e^{-\epsilon x}R_i(x)], \\ v_i(x) &= e^{-\sigma x}[B + e^{-\epsilon x}V_i(x)] \end{aligned}$$

for $i = 1, 2$. We define

$$\tilde{N}_i = Q_{1c}[N_i, v_i], \quad \tilde{v}_i = Q_{2c}[N_i, v_i] \quad \text{for } i = 1, 2.$$

We estimate $\tilde{N}_1(x) - \tilde{N}_2(x)$ as follows.

$$\begin{aligned} \tilde{N}_1 - \tilde{N}_2 &= (\alpha(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \alpha(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c) \\ &\quad + \left\{\gamma(N_1 * \mathcal{S}_c)(1 - k(N_1 * \mathcal{S}_c))\left(2v_1 - \frac{v_1^2}{N_1}\right) * \mathcal{S}_c\right. \\ &\quad \left. -\gamma(N_2 * \mathcal{S}_c)(1 - k(N_1 * \mathcal{S}_c))\left(2v_2 - \frac{v_2^2}{N_2}\right) * \mathcal{S}_c\right\} \\ &= I + II + III, \end{aligned}$$

where

$$I = \alpha(N_1 * \mathcal{S}_c)N_1 * \mathcal{S}_c - \alpha(N_2 * \mathcal{S}_c)N_2 * \mathcal{S}_c,$$

$$\mathit{II} = [\gamma(N_1 * \mathcal{S}_c)(1 - k(N_1 * \mathcal{S}_c)) - r(N_2 * \mathcal{S}_c)(1 - k(N_2 * \mathcal{S}_c))]\left(2v_1 - \frac{v_1^2}{N_1}\right) * \mathcal{S}_c,$$

$$\mathit{III} = \gamma(N_2 * \mathcal{S}_c)(1 - k(N_2 * \mathcal{S}_c))\left[2(v_1 - v_2) - \left(\frac{v_1^2}{N_1} - \frac{v_2^2}{N_2}\right)\right] * \mathcal{S}_c.$$

By the Mean Value Theorem,

$$|I| \le (\alpha'(N_1^*)N_1^* + 1)|N_2 - N_1| * \mathcal{S}_c.$$

Similarly,

$$|\mathit{II}| \le [(\max_{N_1^* \le N \le N^*} |\gamma'(N)|)(1 - \kappa) + \gamma(N_1^*)\eta](3N^*)|N_1 - N_2| * \mathcal{S}_c,$$

$$|\mathit{III}| \le \gamma(N_1^*)(1 - \kappa)\left[\left(3 + \frac{N^*}{N_1^*}\right)|v_1 - v_2| * \mathcal{S}_c + \frac{N^*}{N_1^*}|N_1 - N_2| * \mathcal{S}_c\right].$$

Thus, for all $x \in \mathbb{R}$,

$$|\tilde{N}_1(x) - \tilde{N}_2(x)| \le \rho_1 \max\{|v_1 - v_2| * \mathcal{S}_c(x), |N_1 - N_2| * \mathcal{S}_c(x)\},$$

where

$$\rho_1 = \rho_1(\kappa, \eta) = (\alpha'(N_1^*)N_1^* + 1) + (3\gamma(N_1^*)N^*)\eta + (1 - \kappa)\left[3N^*\left(\max_{N_1^* \le N \le N^*} |\gamma'(N)|\right) + \gamma(N_1^*)\left(3 + 2\frac{N^*}{N^*}\right)\right].$$

Note that

$$\lim_{\kappa \to 1, \eta \to 0} \rho_1(\kappa, \eta) = \alpha'(N_1^*)N_1^* + 1 < 1.$$

We can choose $k_1 \ge k_0$ and $0 \le \eta_1 \le \eta_0$ such that $\rho_1(\kappa, \eta) < 1$ for $k_1 \le \kappa$ and $0 \le \eta \le \eta_1$. The choice of k_1 and η_1 is independent of c. By the definition of the metric $\boldsymbol{d}$, we have to estimate $\|\tilde{R}_1 - \tilde{R}_2\|_\infty$, $\|\tilde{V}_1 - \tilde{V}_2\|_\infty$ and $\|\tilde{U}_1 - \tilde{U}_2\|_\infty$. By

$$\tilde{R}_1(x) - \tilde{R}_2(x) = (Q_{1c}[N_1, v_1](x) - Q_{2c}[N_2, v_2](x))e^{(\sigma+\epsilon)x},$$

we get

$$\begin{aligned}
|\tilde{R}_1(x) - \tilde{R}_2(x)| &\le \rho_1 \max\{|v_1 - v_2| * \mathcal{S}_c(x), |N_1 - N_2| * \mathcal{S}_c(x)\}e^{(\sigma+\epsilon)x} \\
&\le \rho_1 e^{-(\sigma+\epsilon)c}K(\sigma + \epsilon) \max\{|V_1 - V_2| * F_1(x), |R_1 - R_2| * F_1(x)\} \\
&\le \rho_1 \max\{\|V_1 - V_2\|_\infty, \|R_1 - R_2\|_\infty\} \\
&\le \rho_1 \boldsymbol{d}([R_1, V_1], [R_2, V_2]),
\end{aligned}$$

where

$$dF_1(x) = (e^{-(\sigma+\epsilon)c}K(\sigma + \epsilon))^{-1}e^{(\sigma+\epsilon)x}d\mathcal{S}_c(x).$$

and we have used

$$e^{-(\sigma+\epsilon)c}K(\sigma + \epsilon) < \frac{1}{\gamma(N_1^*)} < 1.$$

Similarly, from Lemma 5.3, we get

$$\begin{aligned}|\tilde{V}_1(x) - \tilde{V}_2(x)| &\le \gamma(N_1^*) \max\{|v_1 - v_2| * \mathcal{S}_c(x), |u_1 - u_2| * \mathcal{S}_c(x)\} e^{(\sigma+\epsilon)x} \\ &= \gamma(N_1^*) e^{-(\sigma+\epsilon)c} K(\sigma+\epsilon) \max\{|V_1 - V_2| * F_1, |U_1 - U_2| * F_1\} \\ &\le \gamma(N_1^*) e^{-(\sigma+\epsilon)c} K(\sigma+\epsilon)\, \boldsymbol{d}([R_1, V_1], [R_2, V_2]),\end{aligned}$$

and

$$\begin{aligned}|\tilde{U}_1(x) - \tilde{U}_2(x)| &\le \gamma(N_1^*) \max\{|v_1 - v_2|, |u_1 - u_2|, |N_1 - N_2|\} * \mathcal{S}_c(x)\, e^{(\sigma+\epsilon)x} \\ &= \gamma(N_1^*) e^{-(\sigma+\epsilon)c} K(\sigma+\epsilon) \max\{|V_1 - V_2|, |U_1 - U_2|, |R_1 - R_2|\} * F_1 \\ &\le \gamma(N_1^*) e^{-(\sigma+\epsilon)c} K(\sigma+\epsilon)\, \boldsymbol{d}([R_1, V_1], [R_2, V_2]).\end{aligned}$$

Therefore

$$\boldsymbol{d}([\tilde{R}_1, \tilde{V}_1], [\tilde{R}_1, \tilde{V}_2]) \le \rho \boldsymbol{d}([R_1, V_1], [R_2, V_2]),$$

where

$$\rho = \max\{\rho_1, \gamma(N_1^*) e^{-(\sigma+\epsilon)c} K(\sigma+\epsilon)\} < 1.$$

Hence, whenever $k_1 \le \kappa$ and $0 \le \eta \le \eta_1$, $\Gamma : \mathcal{B} \to \mathcal{B}$ is a contraction mapping. Thus Γ has a unique fixed point $[R, V]$. The corresponding $[N(x), v(x)]$ satisfies

$$[N(x), v(x)] = Q_c[N, v](x)$$

with $N_1^* \le N(x) \le N^*$, $0 \le v(x) \le N(x)$ for all $x \in \mathbb{R}$, and $N(\infty) = N_1^*$, $v(\infty) = 0$. Since $R(x)$ and $V(x)$ are bounded, $N(x)$ and $v(x)$ are not constant functions. We *claim* that $N(-\infty)$ and $v(-\infty)$ exist with $N(-\infty) = v(-\infty) = N^*$. If the claim is proved, $[N(x), v(x)]$ is the desired traveling wave solution.

To prove the claim, we note that $\gamma(N * \mathcal{S}_c) \ge 1$ for all $x \in \mathbb{R}$. Thus $v(x) \ge v(x) * \mathcal{S}_c(x)$ for $x \in \mathbb{R}$. Since $v(x)$ is bounded, Theorem 4.1 of Essén [3, p. 126] implies that $v(-\infty)$ exists and $v(-\infty) \ne 0$. However,

$$\gamma(N * \mathcal{S}_c(x)) = \frac{v(x)}{v * \mathcal{S}_c(x)} \quad \text{for } x \in \mathbb{R}.$$

We have the limit $\lim_{x\to-\infty} \gamma(N * \mathcal{S}_c(x)) = \frac{v(-\infty)}{v(-\infty)} = 1$. Since $\gamma(N)$ is strictly decreasing in N, we have $\lim_{x\to-\infty} N * \mathcal{S}_c(x) = N^*$. By the General Tauberian Theorem of Wiener [18], we deduce that

$$\lim_{x\to\infty} N * h(x) = N^* \int_{-\infty}^{\infty} h(x)\, dx$$

for all $h(x) \in L^1(\mathbb{R})$. Thus Theorem 9 in Chapter V of Widder [17] implies that $N(-\infty)$ exists and $N(-\infty) = N^*$. From the N equation, we get (by letting $x \to -\infty$)

$$N^* = \gamma(N^*)N^* - (1 - \alpha(N^*)) \frac{(N^* - v(-\infty))^2}{N^*}.$$

Therefore $v(-\infty) = N^*$. This proves the claim.

The uniqueness of this traveling wave for $c > c_1^*$ follows from Lemma 5.1 (c) and the uniqueness of the fixed point of Γ.

We now prove the existence of a traveling wave for $c = c_1^*$. Define

$$c_n = c_1^* + \frac{1}{n}, \qquad n = 1, 2, 3, \ldots.$$

For each c_n, there exists a unique traveling wave $[N_n(x), v_n(x)]$ of the system Q with speed c_n, which satisfies the following conditions:

$$\begin{aligned} &N_n(-\infty) = N^*, \quad N_n(\infty) = N_1^*, \quad N_1^* \le N_n(x) \le N^*, \\ &v_n(-\infty) = N^*, \quad v_n(\infty) = 0, \quad 0 \le v_n(x) \le N_n(x), \end{aligned}$$

for all $x \in \mathbb{R}$. And we normalize (by translation) each wave such that

$$v_n(0) = \frac{1}{2}N^*, \qquad \frac{1}{2}N^* \le v_n(x) \le N^*$$

for all $x \le 0$. The sequence of functions $[N_n(x+c_n), v_n(x+c_n)]$ is uniformly bounded. Since $\mathcal{S}$ has a bounded probability density, the sequence of functions $[N_n(x + c_n) * \mathcal{S}(x), v_n(x + c_n) * \mathcal{S}(x)]$ is equicontinuous on every compact subset of $\mathbb{R}$. But

$$N_n(x + c_n) * \mathcal{S}(x) = \int_{-\infty}^{\infty} N_n(x - y + c_n) d\mathcal{S}(y) = N_n * \mathcal{S}_{c_n}(x).$$

Thus $[N_n * \mathcal{S}_{c_n}, v_n * \mathcal{S}_{c_n}]$ are equicontinuous on every compact subset of $\mathbb{R}$. By $N_1^* \le N_n(x)$, $v_n(x)^2/N_n(x)$ are uniformly bounded in $\mathbb{R}$. Therefore $(v_n^2/N_n) * \mathcal{S}_{c_n}(x)$ are equicontinuous on compact subsets of $\mathbb{R}$ also. Since

$$\begin{aligned} N_n &= \alpha(N_n * \mathcal{S}_{c_n}) N_n * \mathcal{S}_{c_n} + (\gamma(N_n * \mathcal{S}_{c_n}) - \alpha(N_n * \mathcal{S}_{c_n})) \left\{ 2v_n - \frac{v_n^2}{N_n} \right\} * \mathcal{S}_{c_n}, \\ v_n &= \gamma(N_n * \mathcal{S}_{c_n}) v_n * \mathcal{S}_{c_n}, \end{aligned}$$

it follows that $[N_n, v_n]$ are equicontinuous on compact subsets of $\mathbb{R}$. Thus we can extract a subsequence of $[N_n, v_n]$ which converges to a limit $[N, v]$ uniformly on every compact subset of $\mathbb{R}$. For convenience, we may assume that $\lim_{n\to\infty} N_n(x) = N(x)$ and $\lim_{x\to\infty} v_n(x) = v(x)$. Since this convergence is uniform on compact subsets of $\mathbb{R}$ and c_n is a bounded sequence, the limits

$$\lim_{n\to\infty} N_n(x + c_n) = N(x + c_1^*), \qquad \lim_{n\to\infty} v_n(x + c_n) = v(x + c_1^*)$$

hold for all $x \in \mathbb{R}$. Thus, by the Lebesgue Dominated Convergence Theorem,

$$\lim_{n\to\infty} N_n * \mathcal{S}_{c_n}(x) = N * \mathcal{S}_{c_1^*}(x), \qquad \lim_{n\to\infty} v_n * \mathcal{S}_{c_n}(x) = v * \mathcal{S}_{c_1^*}(x)$$

for all $x \in \mathbb{R}$. Then $[N(x), v(x)]$ satisfies

$$[N(x), v(x)] = Q_{c_1^*}[N, v](x), \quad N_1^* \le N(x) \le N^*, \quad 0 \le v(x) \le N(x)$$

for all $x \in \mathbb{R}$. Moreover, $v(0) = \frac{1}{2}N^*$ and $\frac{1}{2}N^* \le v(x) \le N^*$ for all $x \le 0$. It remains to show that $[N, v]$ is the desired traveling wave, i.e., $[N(\pm\infty), v(\pm\infty)]$ exist and they satisfy the boundary conditions (7).

By using $\gamma(N * \mathcal{S}_{c_1^*}(x)) \ge 1$ for all $x \in \mathbb{R}$ and the v equation, we get

$$v(x) \ge v * \mathcal{S}_{c_1^*}(x) \quad \text{for all } x \in \mathbb{R}.$$

Since $v(x)$ is bounded, Theorem 4.1 of Essén [3, p. 126] implies that $v(\pm\infty)$ exist. If $v(\infty) = v(-\infty)$, then $v(x)$ is a constant which must be $\frac{1}{2}N^*$. From the v equation, we get $\gamma(N * \mathcal{S}_{c_1^*}(x)) = 1$ for all $x \in \mathbb{R}$. Thus $N(x) = N^*$ for all $x \in \mathbb{R}$. But $[N^*, \frac{1}{2}N^*]$ can not satisfy the N equation. This contradiction establishes that $v(\infty) \neq v(-\infty)$. Now, from $\frac{1}{2}N^* \leq v(x) \leq N^*$ for $x \leq 0$, we get $v(-\infty) \geq \frac{1}{2}N^*$. Hence

$$\lim_{x\to-\infty} \gamma(N * \mathcal{S}_{c_1^*}(x)) = \lim_{x\to\infty} \frac{v(x)}{v * \mathcal{S}_{c_1^*}(x)} = \frac{v(-\infty)}{v(-\infty)} = 1.$$

We find as before that $N(-\infty) = N^*$. Because $[N(-\infty), v(-\infty)]$ is a constant fixed point of Q, the N equation implies that $v(-\infty) = N^*$. Thus $v(\infty) \neq N^*$. If $v(\infty) > 0$, then the same argument implies that $N(\infty) = N^*$, and hence $v(\infty) = N^*$. This is a contradiction. Therefore we have proved that $v(\infty) = 0$. Finally, we need to show that $N(\infty)$ exists and is N_1^*. For this purpose, we define $a = \limsup_{x\to\infty} N(x)$, $N_1^* \leq a \leq N^*$. We recall that the N equation has the form

$$N = \alpha(N * \mathcal{S}_{c_1^*})N * \mathcal{S}_{c_1^*} + E[N, v],$$

where

$$|E[N,v]| = \left|(\gamma(N * \mathcal{S}_{c_1^*}) - \alpha(N * \mathcal{S}_{c_1^*}))\left(2v - \frac{v^2}{N}\right) * \mathcal{S}_{c_1^*}\right| \leq \gamma(N_1^*)\left(2 + \frac{N^*}{N_1^*}\right) v * \mathcal{S}_{c_1^*}.$$

Thus $\lim_{x\to\infty} E[N,v](x) = 0$. By taking the limit sup in the N equation as $x \to \infty$, we get $a \leq \alpha(a)a$. Hence $\alpha(a) \geq 1$. However, $N_1^* \leq a$, $\alpha(a) \leq \alpha(N_1^*) = 1$. Therefore $\alpha(a) = 1$, i.e., $a = N_1^*$. But $N_1^* \leq N(x) \leq N^*$, we have $\liminf_{x\to\infty} N(x) \geq N_1^* = \limsup_{x\to\infty} N(x)$. Thus $N(\infty)$ exists and $N(\infty) = N_1^*$. This proves Theorem 2.2. □

We remark that the above proof used the following facts from simple analysis. Let $f(x)$ be a bounded continuous function and g be a continuous nondecreasing function. Suppose that F is a probability distribution over $\mathbb{R}$. Then

$$\limsup_{x\to\infty} f * F(x) \leq \limsup_{x\to\infty} f(x), \qquad \limsup_{x\to\infty} g(f(x)) = g(\limsup_{x\to\infty} f(x)).$$

These are easily proved by using the definition of limit superior.

6. The proof of Theorem 2.3. We will modify the proof of Theorem 2.2 to show the asymptotic behavior in Theorem 2.3. As in §5, we will use $[N, v]$ instead of $[N, u]$. The mapping Q_c is defined in §5.

Let $v^{(0)}(x) = N^{(0)}(x) - u^{(0)}(x) = e^{-\sigma x}\{B^{(0)} + e^{-\epsilon x}V^{(0)}(x)\}$ where $B^{(0)} = A^{(0)} - C^{(0)}$ and $V^{(0)}(x) = R^{(0)}(x) - U^{(0)}(x)$. Define the sequence $[\bar{N}^{(n)}(x), \bar{v}^{(n)}(x)]$ as follows:

$$[\bar{N}^{(n+1)}(x), \bar{v}^{(n+1)}(x)] = Q_c[\bar{N}^{(n)}, \bar{v}^{(n)}](x), \qquad n = 0, 1, 2, \ldots,$$
$$[\bar{N}^{(0)}(x), \bar{v}^{(0)}(x)] = [N^{(0)}(x), u^{(0)}(x)].$$

Then we prove by induction that

$$[\bar{N}^{(n)}(x), \bar{v}^{(n)}(x)] = [N^{(n)}(x + nc), v^{(n)}(x + nc)] \quad \text{for } x \in \mathbb{R},\ n = 0, 1, 2, \ldots.$$

Moreover, by Lemma 5.2, we have

$$\bar{N}^{(n)}(x) = L^{(n)} + e^{-\sigma x}\{A^{(n)} + e^{-\epsilon x}R^{(n)}(x)\},$$
$$\bar{v}^{(n)}(x) = e^{-\sigma x}\{B^{(n)} + e^{-\epsilon x}V^{(n)}(x)\}.$$

$L^{(n)}$, $A^{(n)}$, and $B^{(n)}$ satisfy the recursive relations in Lemma 5.2. $R^{(n)}(x)$ and $V^{(n)}(x)$ are bounded continuous functions.

We choose η_1 such that, when $\max_{0\le N\le N^*}\{|1-k(N)|, |k'(N)|\} \le \eta_1$, we have $\alpha'(N^*)N^*+\alpha(N^*) > 0$ (due to (A4)'). Then, since $0 < L^{(0)} < 1$, we get $\lim_{n\to\infty} L^{(n)} = N_1^*$. The rate of convergence is exponential in n. If σ and c satisfy the relation $e^{-\sigma c}K(\sigma)\gamma(N_1^*) = 1$, then the infinite product

$$L^{(\infty)} = \prod_{n=0}^{\infty}[e^{-\sigma c}K(\sigma)\gamma(L^{(n)})]$$

converges and $L^{(\infty)} > 0$. The sequences $B^{(n)}$ and $A^{(n)}$ converge to the limits $B^{(\infty)}$ and $A^{(\infty)}$, respectively, where

$$B^{(\infty)} = L^{(\infty)}B^{(0)}, \qquad A^{(\infty)} = \frac{2(\gamma(N_1^*)-1)L^{(\infty)}}{\gamma(N_1^*)-(\alpha'(N_1^*)N_1^*+1)}B^{(0)}.$$

The rate of convergence is also exponential.

We *claim* that

$$N_1^* \le \liminf_{n\to\infty} \bar{N}^{(n)}(x) \le \limsup_{n\to\infty} \bar{N}^{(n)}(x) \le N^* \tag{12}$$

uniformly in $x \in \mathbb{R}$. That $\limsup_{n\to\infty} \bar{N}^{(n)}(x) \le N^*$ follows from Step 2 of the proof of Theorem 2.1. Due to the choice of η_1, there exists $\delta > 0$ and n_0 such that $\sup_{x\in\mathbb{R}} \bar{N}^{(n)}(x) \le N^* + \delta$ for all $n \ge n_0$, and $N\alpha(N)$ is strictly increasing in $0 \le N \le N^* + \delta$. We define the sequence $\hat{N}^{(n)}(x)$ as follows:

$$\hat{N}^{(n+1)} = \alpha(\hat{N}^{(n)} * \mathcal{S}_c)\hat{N}^{(n)} * \mathcal{S}_c, \qquad n = n_0, n_0+1, n_0+2, \dots,$$
$$\hat{N}^{(n_0)}(x) = \bar{N}^{(n_0)}(x).$$

By (A2)', $Q_{1c}[N,u] \ge \alpha(N * \mathcal{S}_c)N * \mathcal{S}_c$. An induction argument gives that $\bar{N}^{(n)}(x) \ge \hat{N}^{(n)}(x)$ for $n \ge n_0$ and $x \in \mathbb{R}$. If $N^{(0)}(\pm\infty) > 0$, Step 1 of the proof of Theorem 2.1 implies that $\bar{N}^{(n)}(\pm\infty) > 0$ for all n. But $\alpha'(N_1^*)N_1^* + 1 > 0$ (due to the choice of η_1), and Theorem 3 of Weinberger [15] implies that

$$\lim_{n\to\infty} \hat{N}^{(n)}(x) = N_1^* \quad \text{uniformly in } \mathbb{R}.$$

Hence

$$\liminf_{n\to\infty} \bar{N}^{(n)}(x) \ge N_1^* \quad \text{uniformly in } \mathbb{R}.$$

The claim is proved.

We prove Theorem 2.3 (b), (c) first. By the assumption, $0 < \sigma < \lambda^*$. Let $c = \Psi(\sigma)$. Then $e^{-\sigma c}K(\sigma)\gamma(N_1^*) = 1$. Thus $L^{(\infty)}$, $A^{(\infty)}$ and $B^{(\infty)}$ are finite numbers. We can choose $0 < \eta_2 \le \eta_1$ and $\delta_1 > 0$ such that, when $\max_{0\le N\le N^*}\{|1-k(N)|, |k'(N)|\} \le \eta_2$, we have

$$\gamma(N_1^*-\delta)e^{-(\sigma+\epsilon)c}K(\sigma+\epsilon) < 1, \qquad \alpha'(N_1^*-\delta)(N_1^*-\delta)+\alpha(N_1^*-\delta) < 1$$

for all $0 < \delta \le \delta_1$. The space $\mathcal{B}$ in the proof of Theorem 2.2 is modified as follows:

$$\mathcal{B} = \{[L, A, B, R(x), V(x)] \mid |L-N_1^*| \le \delta,\ |A-A^{(\infty)}| \le \delta,\ |B-B^{(\infty)}| \le \delta.$$
$R(x)$ and $V(x)$ are bounded continuous functions in $\mathbb{R}$. Let
$N(x) = L + e^{-\sigma x}[A + e^{-\epsilon x}R(x)]$ and $v(x) = e^{-\sigma x}[B + e^{-\epsilon x}V(x)]$.
$0 \le v(x) \le N(x)$ and $N_1^* - \delta \le N(x) \le N^* + \delta$ for all $x \in \mathbb{R}\}$.

For $[L_i, A_i, B_i, R_i, V_i] \in \mathcal{B}$, $i = 1, 2$, the metric $\boldsymbol{d}$ is defined as

$$\begin{aligned}&\boldsymbol{d}([L_1, A_1, B_1, R_1, V_1], [L_2, A_2, B_2, R_2, V_2])\\&\quad = \max\{|L_1 - L_2|, |A_1 - A_2|, |B_1 - B_2|, \|R_1 - R_2\|_\infty, \|V_1 - V_2\|_\infty, \|U_1 - U_2\|_\infty\},\end{aligned}$$

where $U_i = R_i - V_i$, $i = 1, 2$. $(\mathcal{B}, \boldsymbol{d})$ is again a complete metric space. The mapping Q_c now corresponds to a mapping Γ defined by

$$\Gamma[L, A, B, R, V] = [\tilde{L}, \tilde{A}, \tilde{B}, \tilde{R}, \tilde{V}],$$

where the image is given as in Lemma 5.2. Since $\alpha'(N_1^*)N_1^* + 1 > 0$, $\delta > 0$ can be chosen such that $\Gamma : \mathcal{B} \to \mathcal{B}$ is assured. A Lipschitz estimate on $R(x)$ and $V(x)$ similar to Lemma 5.3 establishes the contraction property of Γ. Indeed, $0 < \eta \le \eta_2$ can be chosen such that, whenever $\max_{0 \le N \le N^*}\{|1 - k(N)|, |k'(N)|\} \le \eta$, the following estimate holds:

$$\begin{aligned}&\boldsymbol{d}(\Gamma[L_1, A_1, B_1, R_1, V_1], \Gamma[L_2, A_2, B_2, R_2, V_2])\\&\quad \le \rho\, \boldsymbol{d}([L_1, A_1, B_1, R_1, V_1], [L_2, A_2, B_2, R_2, V_2]),\end{aligned}$$

where

$$\rho = \max\{\gamma(N_1^* - \delta)e^{-(\sigma+\epsilon)c}K(\sigma + \epsilon),\ \ \alpha'(N_1^* - \delta)(N_1^* - \delta) + \alpha(N_1^* - \delta)\}.$$

Therefore Γ has a unique fixed point in $\mathcal{B}$. We shall identify this fixed point in cases (b) and (c), respectively.

By the claim (12), we can find n_1 such that $N_1^* - \delta \le \bar{N}^{(n)}(x) \le N^* + \delta$ for $x \in \mathbb{R}$, $|L^{(n)} - N_1^*| \le \delta$, $|A^{(n)} - A^{(\infty)}| \le \delta$, and $|B^{(n)} - B^{(\infty)}| \le \delta$ for all $n \ge n_1$. Thus $[L^{(n)}, A^{(n)}, B^{(n)}, R^{(n)}(x), V^{(n)}(x)] \in \mathcal{B}$ for $n \ge n_1$.

(b) When $A^{(0)} = C^{(0)}$, we have $B^{(n)} = B^{(0)} = 0$ for all n. Hence $A^{(\infty)} = B^{(\infty)} = 0$. Then $[N_1^*, 0, 0, 0, 0] \in \mathcal{B}$ and is the fixed point of Γ. That is,

$$\begin{aligned}&\lim_{n\to\infty} \sup_{x \ge l} |\bar{N}^{(n)}(x) - N_1^*|\\&= \lim_{n\to\infty} \sup_{x \ge l} |(L^{(n)} - N_1^*) + e^{-\sigma x}A^{(n)} + R^{(n)}(x)e^{-(\sigma+\epsilon)x}| = 0,\end{aligned}$$

and

$$\lim_{n\to\infty} \sup_{x \in \mathbb{R}} \bar{v}^{(n)}(x)e^{(\sigma+\epsilon)x} = \lim_{n\to\infty} \sup_{x \in \mathbb{R}} V^{(n)}(x) = 0.$$

By $\bar{N}^{(n)}(x) = N^{(n)}(x + nc)$ and $\bar{v}^{(n)}(x) = v^{(n)}(x + nc)$, (b) is proved.

(c) When $A^{(0)} > C^{(0)}$, then $A^{(\infty)} > 0$. There exists a unique traveling wave $[N(x), v(x)]$ with speed c such that $\lim_{x\to\infty}(N(x) - N_1^*)e^{\sigma x} = A^{(\infty)}$. Define $R(x)$ and $V(x)$ as

$$N(x) = N_1^* + e^{-\sigma x}[A^{(\infty)} + R(x)e^{-\epsilon x}], \qquad v(x) = e^{-\sigma x}[B^{(\infty)} + V(x)e^{-\epsilon x}].$$

Then $[N_1^*, A^{(\infty)}, B^{(\infty)}, R(x), V(x)] \in \mathcal{B}$ and is the fixed point of Γ. Therefore

$$\lim_{n\to\infty} \|R^{(n)} - R\|_\infty = \lim_{n\to\infty} \|V^{(n)} - V\|_\infty = 0.$$

Hence

$$\lim_{n\to\infty}\sup_{x\geq l}|\bar{N}^{(n)}(x)-N(x)| = \lim_{n\to\infty}\sup_{x\geq l}|(L^{(n)}-N_1^*)+e^{-\sigma x}(A^{(n)}-A^{(\infty)}) + e^{-(\sigma+\epsilon)x}(R^{(n)}(x)-R(x))| = 0,$$

and

$$\lim_{n\to\infty}\sup_{x\geq l}|\bar{v}^{(n)}(x)-v(x)|e^{\sigma x} = \lim_{n\to\infty}\sup_{x\geq l}|(B^{(n)}-B^{(\infty)})+e^{-\epsilon x}(V^{(n)}(x)-V(x))| = 0.$$

Let $c' > c = \Psi(\sigma)$ be a larger wave speed. Then

$$\max_{x\geq nc'}|N^{(n)}(x)-N_1^*| = \sup_{y\geq n(c'-c)}|\bar{N}^{(n)}(y)-N_1^*| \leq \sup_{y\geq 0}|\bar{N}^{(n)}(y)-N(y)| + \sup_{y\geq n(c'-c)}|N(y)-N_1^*|.$$

But $\lim_{n\to\infty}\sup_{y\geq n(c'-c)}|N(y)-N_1^*| = 0$; therefore,

$$\lim_{n\to\infty}\max_{x\geq nc'}|N^{(n)}(x)-N_1^*| = 0.$$

(c) is proved.

(a) When $\sigma \geq \lambda^*$, then, for any $0 < \sigma_1 < \lambda^*$, we can write

$$N^{(0)}(x) = L^{(0)} + e^{-\sigma_1 x}\hat{R}(x)e^{-\epsilon_1 x}, \qquad u^{(0)}(x) = L^{(0)} + e^{-\sigma_1 x}\hat{U}(x)e^{-\epsilon_1 x},$$

where $0 < \epsilon_1 < \sigma - \sigma_1$. $\hat{R}$ and $\hat{U}$ are bounded continuous functions. Let $c_1 = \Psi(\sigma_1)$. Then (b) implies that

$$\lim_{n\to\infty}\max_{x\geq nc_1}|N^{(n)}(x)-N_1^*| = \lim_{n\to\infty}\max_{x\geq nc_1}|u^{(n)}(x)-N_1^*| = 0.$$

Since σ_1 can be chosen arbitrarily in $0 < \sigma_1 < \lambda^*$, $c_1 > c_1^*$ is arbitrary also. This proves (a).

The proof of Theorem 2.3 is complete. □

Remark. When $L^{(0)} = N_1^*$ and

$$A^{(0)} = \frac{2(\gamma(N_1^*)-1)}{\gamma(N_1^*)-1+\alpha'(N_1^*)N_1^*}C^{(0)}$$

in Theorem 2.3, the rate of convergence in (b) and (c) is exponential. If $C^{(0)} = 0$, then

$$\lim_{n\to\infty}\sup_{x\in\mathbb{R}}|N^{(n)}(x+nc)-N_1^*|e^{(\sigma+\epsilon)x} = \lim_{n\to\infty}\sup_{x\in\mathbb{R}}|u^{(n)}(x+nc)-N_1^*|e^{(\sigma+\epsilon)x} = 0.$$

On the other hand, if $C^{(0)} > 0$, then

$$\lim_{n\to\infty}\sup_{x\in\mathbb{R}}|N^{(n)}(x+nc)-N(x)|e^{(\sigma+\epsilon)x} = \lim_{n\to\infty}\sup_{x\in\mathbb{R}}|u^{(n)}(x+nc)-u(x)|e^{(\sigma+\epsilon)x} = 0.$$

7. Concluding remarks. We have shown some special cases of the dynamics of Q in Theorems 2.1–2.3 when the initial generation has positive local population density $N^{(0)}(x)$ at $x = \pm\infty$. In this section, we shall make a few remarks related to the case when $N^{(0)}(\pm\infty) = 0$ (for example, when $N^{(0)}(x)$ has compact support) and to the heterozygote superior case.

(a) *Traveling waves connecting* $[N^*, 0]$ *and* $[0, 0]$. We assume (A1)–(A4). $[N^*, 0]$ and $[0, 0]$ are always constant fixed points of Q. Define

$$c^* = \inf_{\lambda>0} \frac{1}{\lambda} \log(\gamma(0)K(\lambda)).$$

It is shown in Weinberger [15], [16] that the traveling wave equation

$$N = \gamma(N * \mathcal{S}_c)N * \mathcal{S}_c, \quad N(-\infty) = N^*, \quad N(\infty) = 0 \tag{13}$$

of the mapping $\gamma(N * \mathcal{S})N * \mathcal{S}$ admits a solution iff $c \geq c^*$. When $c > c^*$, the traveling wave is unique up to translation. Then, as a direct consequence of Remarks 3.1 and 3.2, *the system of the traveling wave equations*

$$[N(x - c), u(x - c)] = Q[N, u](x),$$
$$[N(-\infty), u(-\infty)] = [N^*, 0], \qquad [N(\infty), u(\infty)] = [0, 0]$$

admits a solution $[N(x), u(x)]$ *with* $\lim_{x\to\infty} \frac{u(x)}{N(x)} < 1$ *iff* $c \geq c^*$, *and the profile is given by* $[N(x), 0]$ *where* $N(x)$ *satisfies* (13). *When* $c > c^*$, *the wave* $[N(x), u(x)]$ *with* $\lim_{x\to\infty} \frac{u(x)}{N(x)} < 1$ *is also unique up to translation.* We note that, when $u(x) = 0$, the system of the traveling wave equations for Q becomes (13).

We try to remove the condition $\lim_{x\to\infty} \frac{u(x)}{N(x)} < 1$. Indeed, *if* $d\mathcal{P} = \delta$ *and* $\mathcal{S}$ *has a probability density of type* PF_2 (see Lui [11]), *then* $[N(x), 0]$, *where* $N(x)$ *satisfies* (13), *is the unique (up to translation) traveling wave of* Q *when* $c > c^*$.

The proof is as follows. Let $[\bar{N}, \bar{u}] \in \Delta$ be a traveling wave solution of the system with wave speed $c > c^*$. Define the sequence of functions $N^{(n)}(x)$ by

$$N^{(n+1)}(x) = \gamma(N^{(n)} * \mathcal{S}(x))\, N^{(n)} * \mathcal{S}(x), \quad N^{(0)}(x) = \bar{N}(x), \quad n = 0, 1, 2, \ldots.$$

By (A2), an induction argument shows that

$$0 \leq \bar{N}(x - nc) \leq N^{(n)}(x), \qquad n = 1, 2, 3, \ldots.$$

Since $\mathcal{S}$ has a probability density of type PF_2, $N^{(n)}(x)$ tends asymptotically to $N(x - nc + \xi)$ as $n \to \infty$ where ξ is some real number (see Lui [11]). Thus $0 \leq \bar{N}(x) \leq N(x + \xi)$ for all $x \in \mathbb{R}$. Let σ be the smallest positive root of $\gamma(0)e^{-\lambda c}K(\lambda) = 1$. Then $N(x)e^{\sigma x}$ is bounded, and so is $\bar{N}(x)e^{\sigma x}$. Since $0 \leq \bar{u}(x) \leq \bar{N}(x)$, $\bar{u}(x)e^{\sigma x}$ is also bounded.

We denote $R(x) = \bar{N}(x)e^{\sigma x}$ and $W(x) = \bar{u}(x)e^{\sigma x}$. By multiplying both sides of the traveling wave equations by $e^{\sigma x}$, we get

$$\begin{aligned} R = {} & \frac{\gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} R * F + \frac{\alpha(\bar{N} * \mathcal{S}_c) - \gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} \left(\frac{W^2}{R} * F\right) \\ & + 2\frac{\beta(\bar{N} * \mathcal{S}_c) - \gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} \left(\frac{W(R - W)}{R} * F\right), \\ W = {} & \frac{\gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} W * F + \frac{\alpha(\bar{N} * \mathcal{S}_c) - \gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} \left(\frac{W^2}{R} * F\right) \\ & + \frac{\beta(\bar{N} * \mathcal{S}_c) - \gamma(\bar{N} * \mathcal{S}_c)}{\gamma(0)} \left(\frac{W(R - W)}{R} * F\right), \end{aligned} \tag{14}$$

where $dF(x) = \gamma(0)e^{\sigma x}d\mathcal{S}_c(x)$. By (A2) and $\gamma(\bar{N} * \mathcal{S}_c) \le \gamma(0)$, we have

$$0 \le R(x) \le R * F(x), \qquad 0 \le W \le W * F(x) \quad \text{for all } x \in \mathbb{R}.$$

Then Theorem 4.1 of Essén [3] implies that $R(\pm\infty)$ and $W(\pm\infty)$ exist. Since $R(-\infty) = 0$ and $R \not\equiv 0$, $R(\infty) > 0$. For convenience, let $A_1 = R(\infty)$ and $A_2 = W(\infty)$. Then, by taking $x \to \infty$ in (14), we get

$$A_1 = A_1 + \frac{(\alpha(0) - \gamma(0))}{\gamma(0)}\frac{A_2^2}{A_1} + \frac{2(\beta(0) - \gamma(0))}{\gamma(0)}\frac{A_2(A_1 - A_2)}{A_1},$$
$$A_2 = A_2 + \frac{(\alpha(0) - \gamma(0))}{\gamma(0)}\frac{A_2^2}{A_1} + \frac{(\beta(0) - \gamma(0))}{\gamma(0)}\frac{A_2(A_1 - A_2)}{A_1}.$$

By (A2), $\alpha(0) < \gamma(0)$. Thus $A_2 = 0$. We have shown that $W(\pm\infty) = 0$. Since $W(x) \le W * F(x)$ for all $x \in \mathbb{R}$, Theorem 4.1 of Essén [3] implies that $W(x) \equiv 0$. Thus $\bar{u}(x) \equiv 0$. Therefore

$$\bar{N}(x) = \gamma(\bar{N} * \mathcal{S}_c(x))\,\bar{N} * \mathcal{S}_c(x), \quad \bar{N}(-\infty) = N^*, \quad \bar{N}(\infty) = 0.$$

But $c > c^*$, and there exists some t such that $\bar{N}(x) = N(x + t)$.

The asymptotic behavior and the stability of the traveling waves of the scalar mapping $\gamma(N * \mathcal{S})N * \mathcal{S}$ are studied extensively in Weinberger [15], [16] and Lui [11]–[13]. They show that when the initial generation $N^{(0)}(x)$ satisfies $N^{(0)}(\infty) = 0$ in a certain sense, the nth generation $N^{(n)}(x)$ tends asymptotically to a traveling wave. If the initial generation $[N^{(0)}(x), u^{(0)}(x)]$ of the system Q satisfies $N^{(0)}(\infty) = 0$, we think that a similar form of Theorem 2.3 should hold when N_1^* is replaced by 0, and the traveling wave $[N(x), u(x)]$ is the wave connecting $[N^*, 0]$ and $[0, 0]$. In other words, c^* should be characterized as the asymptotic speed for the spread of the advantageous gene when $N^{(0)}(x)$ has compact support.

(b) *The degenerate system Q where $\alpha(N) = \beta(N) = \gamma(N)$ for all $0 \le N \le 1$.* The system decouples into

$$\tilde{N} = \gamma(N * \mathcal{S})N * \mathcal{S}, \qquad \tilde{u} = \frac{1}{2}\gamma(N * \mathcal{S})\left\{\left(u + N\frac{u * \mathcal{P}}{N * \mathcal{P}}\right) * \mathcal{S}\right\}.$$

Suppose that (A1), (A3), and (A4) hold. The constant fixed points consist of $[0, 0]$ and $[N^*, u^*]$ for all $0 \le u^* \le N^*$. If $[N^{(0)}(x), u^{(0)}(x)] \in \Delta$ satisfies $N^{(0)}(\pm\infty) > 0$, then $N^{(n)}(x)$ tends to N^* uniformly in $\mathbb{R}$, and $u^{(n)}(x)$ tends to u^* uniformly on compact subsets of $\mathbb{R}$. u^* is given by

$$u^* = N^*\left\{(1 - j)\frac{u^{(0)}(-\infty)}{N^{(0)}(-\infty)} + j\frac{u^{(0)}(\infty)}{N^{(0)}(\infty)}\right\}, \qquad j = \lim_{n\to\infty} \underbrace{\mathcal{J} * \mathcal{J} * \cdots * \mathcal{J}}_{n \text{ times}},$$

where $\mathcal{J} = \frac{1}{2}(\mathcal{S} + \mathcal{P} * \mathcal{S})$. The system admits a traveling wave $[N(x), u(x)]$ with speed c, which satisfies the boundary conditions

$$[N(-\infty), u(-\infty)] = [N^*, u^*], \quad [N(\infty), u(\infty)] = [0, 0], \quad 0 \le u^* \le N^*$$

iff $c \ge c^*$. The wave is uniquely given by $u(x) = \frac{u^*}{N^*}N(x)$ where $N(x)$ satisfies (13). These waves are also the asymptotic states of some initial generations. These results will be published elsewhere, where the condition (A4) can be relaxed to include some cases of $-1 < \gamma'(N^*)N^* + 1 < 0$.

(c) *The heterozygote superior case.* When $\beta(N) > \max\{\alpha(N), \gamma(N)\}$ for all $0 \leq N < 1$, there exists the interior constant fixed point of Q, i.e., the so-called polymorphism, where two alleles coexist in equilibrium. The dynamics of Q restricted to constant states is already nontrivial. When the viability functions are density independent, the complete dynamics is known (for example, Karlin [6]). However, the mapping Q has density-dependent viability functions. One can show (see Lin [10]) that the dynamics of Q (restricted to constant states) tends asymptotically to the dynamics of the scalar mapping $NG(N)$, where

$$G(N) = \frac{\beta(N)^2 - \alpha(N)\gamma(N)}{2\beta(N) - \alpha(N) - \gamma(N)}.$$

The chaos occurs generically. In general, the relation between the system Q and the scalar mapping $G(N * \mathcal{S})N * \mathcal{S}$ is yet to be explored. Only some special cases where α, β, and γ satisfy certain relations are known. These results will be published elsewhere.

Acknowledgments. Most of the contents of this paper were part of the author's Ph.D. thesis [9]. The author would like to thank her advisor, Professor H. F. Weinberger, for his guidance. She also wishes to thank Professor W.-M. Ni for his concern and encouragement.

BLOW-UP SOLUTIONS OF QUASI-LINEAR DEGENERATE PARABOLIC EQUATIONS WITH CONVECTION *

RYUICHI SUZUKI†

Abstract. The Cauchy problem of the quasi-linear degenerate parabolic equations with convection term is considered. Under some conditions, the existence of single-point blow-up solutions is shown; it is also shown that the blow-up point is bounded. In addition, the asymptotic behavior of interfaces of blow-up solutions is studied.

Key words. blow-up solution, single-point blow-up, quasi-linear degenerate parabolic equation, convection, asymptotic behaviors of interfaces, Cauchy problem

AMS subject classifications. 35B40, 35K15, 35K55, 35K65

0. Introduction.

In this paper we shall consider the Cauchy problem in $\mathbb{R}$:

$$\partial_t \beta(u) - u_{xx} + g(u)_x = f(u), \qquad (x,t) \in \mathbb{R} \times (0,T), \tag{0.1}$$

$$u(x,0) = \varphi(x), \qquad x \in \mathbb{R}, \tag{0.2}$$

where $\beta(v), g(v)$, and $f(v)$ with $v \geq 0$ and $\varphi(x)$ are nonnegative continuous functions.

Equation (0.1) describes the combustion process with convection in a stationary medium in which the thermal conductivity $\beta'(u)^{-1}$, the volume heat source $f(u)$, and convection $g(u)$ depend in a nonlinear way on the temperature $\beta(u) = \beta(u(x,t))$ of the medium.

Throughout this paper we assume

(A1) $\beta(v), f(v), g(v) \in C^\infty(\mathbb{R}_+) \cap C(\bar{\mathbb{R}}_+), \beta(v) > 0, \beta'(v) > 0, \beta''(v) \leq 0$, and $f(v), g(v), g'(v) > 0$ for $v > 0$; $\lim_{v\to\infty} \beta(v) = \infty$; $f \circ \beta^{-1}$ and $g \circ \beta^{-1}$ are locally Lipschitz continuous in $[\beta(0), \infty)$.

(A2) $\{g \circ \beta^{-1}\}'(u) \leq C\sqrt{\{\beta^{-1}\}'(u)}$ in the neighborhood of $u = 0$ for some positive constant C.

(A3) $\varphi(x) \geq 0, \not\equiv 0$, and $\in \mathbb{B}(\mathbb{R})$ (bounded continuous in $\mathbb{R}$).

With these conditions the above Cauchy problem has a unique local solution $u(x,t)$ (in time), which satisfies (0, 1) in $\mathbb{R} \times (0,T)$ in the following weak sense, where $T > 0$ is assumed to be sufficiently small (see, e.g., Oleinik et al. [8], [11], [15]).

DEFINITION 0.1. *Let G be an open interval in $\mathbb{R}$. By a weak solution of equation* (0.1) *in $G \times (0,T)$ we mean a function $u(x,t)$ such that*

(1) *$u(x,t) \geq 0$ in $\bar{G} \times [0,T)$ and $\in \mathbb{B}(\bar{G} \times [0,\tau])$ for each $0 < \tau < T$.*

(2) *For any bounded open interval $\Omega = (x_1, x_2) \subset G, 0 < \tau < T$ and $\varphi(x,t) \in C^2(\bar{\Omega} \times [0,T))$, which vanishes on $x = x_1, x_2$, the following identity holds:*

$$\begin{aligned} &\int_\Omega \beta(u(x,\tau))\varphi(x,\tau)\,dx - \int_\Omega \beta(u(x,0))\varphi(x,0)\,dx \\ &\quad = \int_0^\tau \int_\Omega \{\beta(u)\varphi_t + u\varphi_{xx} + g(u)\varphi_x + f(u)\varphi\}\,dx\,dt - \int_0^\tau u\varphi_x\,dt|_{x=x_1}^{x=x_2}. \end{aligned} \tag{0.3}$$

* Received by the editors August 24, 1992; accepted for publication (in revised form) September 14, 1993.

† Department of Mathematics, Tokyo Metropolitan College of Aeronautical Engineering, 8-52-1 Minamisenju, Arakawa-ku, Tokyo, 116 Japan.

Remark 0.2. If $2q \geq m+1$,

$$(u^{1/m})_t = u_{xx} - (u^{q/m})_x + u^{p/m} \qquad (m,p,q \geq 1) \tag{0.4}$$

satisfies (A1), (A2), and (A3).

If $u(x,t)$ does not exist globally in time, its existence time $T < \infty$ is defined by

$$T = \sup\{\tau > 0; u(x,t) \text{ is bounded in } \mathbb{R} \times [0,\tau]\}, \tag{0.5}$$

and we see that

$$\limsup_{t \uparrow T} \sup_{x \in \mathbb{R}} u(x,t) = \infty. \tag{0.6}$$

In this case we say that u is a blow-up solution and T is a blow-up time.

The main purpose of the present paper is the study of blow-up solutions. We are especially interested in the shape of the blow-up set which locates the "hot-spots" at the blow-up time. In addition, since our quasi-linear equation (0.1) has a property of the finite propagation of an interface, there are some interesting subjects such as asymptotic behavior of the interface near the blow-up time. These problems have been studied for (0.1) without convection term in [5], [6], [7], and [16], and by Mochizuki and Suzuki in [14].

First, we consider the finite propagation of interfaces of solutions of (0.1), (0.2). To deal with this we require the additional conditions:

(A4) $\varphi(x) > 0$ for $x \in (-a_1, a_1)$ and $= 0$ for $x \notin (-a_1, a_1)$,

(A5) $\lim_{v \to 0} \dfrac{g'}{\beta'}(v) = 0$,

(A6) $\beta(0) = f(0) = 0, \qquad \displaystyle\int_0^1 \frac{dv}{\beta(v)} < \infty.$

Remark 0.3. If $q > 1$ and $m > 1$, equation (0.4) satisfies (A5) and (A6).

Put

$$\Omega(t) = \{x \in \mathbb{R}; u(x,t) > 0\}, \qquad \Gamma(t) = \partial\Omega(t) \tag{0.7}$$

for each $t \in (0,T)$. Then the interface Γ is given by

$$\Gamma = \bigcup_{0 \leq t \leq T} \Gamma(t) \times \{t\}, \tag{0.8}$$

and under assumptions (A1)–(A6) we can show that $\Omega(t)$ is bounded and nondecreasing in $t \in [0,T)$ (see Theorem 1.7). Moreover, $\Omega(t)$ is represented by continuous functions $\xi_i(t) : [0,T) \to \mathbb{R}\,(i = 1,2)$ like $\Omega(t) = \{x | x \in (\xi_1(t), \xi_2(t))\}$. For the case without convection term in (0.1), these results have been shown by Knerr [11], Suzuki [16], and Mochizuki and Suzuki [14].

Next, we restrict ourselves to the blow-up solution of (0.1), (0.2) and shall study the shape of the blow-up set and the behavior of the interface of u near the blow-up time. The existence and nonexistence of a blow-up solution of (0.1), (0.2) is discussed in Friedman and Lacey [4], Imai and Mochizuki [9], and Imai, Mochizuki, and Suzuki

[10]. We assume the following condition, as given in [10], as a "necessary" condition to raise a blow-up:

$$\text{(A7)} \qquad \int_1^\infty \frac{\beta'(v)}{f(v)}\,dv < \infty.$$

Furthermore, we assume that $f(u)$ grows more rapidly than $g(u)$ and u (see (A10) in §3), and, for the initial data $\varphi(x)$, that

$$\text{(A8)} \qquad \varphi'' - \{g(\varphi)\}' + f(\varphi) \geq 0 \quad \text{in } \mathcal{D}',$$

$$\text{(A9)} \qquad \text{the lap-number of } \varphi(x) \text{ in } [a_1, a_2] \text{ is two.}$$

Here, we define the lap-number of $\varphi(x)$ in the following way.

DEFINITION 0.4 (see [13]). *Let $\bar{I} = [a, b]$ be a closed interval and $w = w(x)$ be a real-valued function on $[a, b]$. We say w is piecewise monotone if $\bar{I}$ can be divided into a finite number of nonoverlapping subintervals $J_1, J_2, \ldots, J_m (\cup_{i=1}^m J_i = \bar{I})$, on each of which w is monotone. Then there is the least value of the numbers m for which we can find a division $\{J_i\}$ as above. This value is called the lap-number of w on $[a, b]$ and is denoted by $l(w)$.*

Then, for the semilinear case $\beta(u) = u$, Friedman and Lacey [4] have shown the existence of single-point blow-up solutions of (0.1) for the Dirichlet problem. In this paper we extend this result to the Cauchy problem of a degenerate quasi-linear equation. Moreover, we can also get that the left side interfaces stay bounded as t tends to the blow-up time T. To state these results exactly, we need the definition of a blow-up set.

DEFINITION 0.5. *The blow-up set of u is defined as*

$$S = \{x \in \mathbb{R};\ \textit{there is a sequence } (x_i, t_i) \in \mathbb{R} \times (0, T) \\ \textit{such that } x_i \to x, t_i \to T,\ \textit{and } u(x_i, t_i) \to \infty \textit{ as } i \to \infty\},$$

and each $x \in S$ is called a blow-up point of u.

Our second result is that, if we add the assumption (A10) in §3, then we obtain $S = \{\eta_0\}$ for some $-\infty < \eta_0 \leq \infty$ and $-\infty < \lim_{t \uparrow T} \xi_1(t)$ (see Theorem 3.4).

The final question we consider is whether $\eta_0 < \infty$ or $\eta_0 = \infty$ holds. Our answer is that $\eta_0 < \infty$ (see Theorem 4.4) if we add another condition on f such that $f(u)$ grows more rapidly than $g(u)$ and u (see (A11) in §4), and if we choose a special initial data φ corresponding to (A11) (see (A12) in §4).

Remark 0.6. $p > \max\{m, 2q - m, m + q - 1\}$ and $2q \geq m + 1$; (0.4) satisfies (A10), (A11).

Remark 0.7. Condition (A2) is needed to show the uniqueness of weak solutions of (0.1). If uniqueness of weak solutions to (0.1) holds, the above results are valid without (A2).

The methods of proving these results are essentially the same as those in Friedman and Lacey [4] and Suzuki [16]. We use the smoothness and comparison principle and a property of the zero set of $u_x(x, t)$.

This paper is structured as follows. In §1 we summarize the above two principles and show the finite propagation of the interfaces of the solutions (see Theorem 1.7). In §2 we study the property of the zero set of $u_x(x, t)$, where the lap-number of the initial data of the solution $u(x, t)$ is 2. Using this property we prove the existence of single-point blow-up solutions in §3. Finally, adding some assumptions, we show that the blow-up point is bounded in §4.

1. A comparison principle and finite propagation of interfaces. In this section we begin with two propositions that will be fundamental tools in our study of the interfaces and the blow-up sets.

PROPOSITION 1.1 (smoothness principle). *Assume* (A1)–(A3). *Let G be an open interval and let u be a solution of* (0.1) *in $G \times (0,T)$ in the sense of Definition* 0.1. *If $u(\bar{x},\bar{t}) > 0$ for some $(\bar{x},\bar{t}) \in G \times (0,T)$, then u is a classical solution in a neighborhood W of $(\bar{x},\bar{t})$, and hence $u \in C^\infty(W)$.*

Proof. Note that $\beta(v), f(v), g(v) \in C^\infty(\mathbb{R}_+)$ and $\beta'(v) > 0$ for $v > 0$. Then the above proposition follows from the usual parabolic regularization method (see, e.g., Ladyzenskaja, Solonnikov, and Ural'ceva [12]). □

DEFINITION 1.2. *For each open interval $G \subset \mathbb{R}$, a supersolution (or subsolution) of* (0.1) *in $G \times (0,T)$ is defined by* (1) *and* (2) *of Definition* 0.1 *with equality in* (0.3) *replaced by $\geq$ (or $\leq$).*

PROPOSITION 1.3 (comparison principle). *Assume* (A1)–(A3). *Let u (or v) be a superposition (or subsolution) of* (0.1) in $G \times (0,T)$. *If $u \geq v$ on the parabolic boundary of $G \times (0,T)$, then we have $u \geq v$ in the whole $\bar{G} \times (0,T)$.*

Proof. See, e.g., Gilding [8]. □

Remark 1.4. Condition (A2) is required in the proof of Proposition 1.3. But this condition could have been replaced by a weaker condition if we added some regularity conditions on $\varphi(x)$ (see Diaz and Kersner [3]).

In the rest of this section, based on these principles, we shall show finite propagation of the interface in $t < T$. First, we prove several lemmas.

LEMMA 1.5 (positivity). *Assume* (A1)–(A3) *and* (A5). *Let u be a weak solution of* (0.1), (0.2). *If $u(\bar{x},\bar{t}) > 0$ for some $(\bar{x},\bar{t}) \in \mathbb{R} \times (0,T)$, then*

$$u(\bar{x},t) > 0 \quad \text{for } t \geq \bar{t}. \tag{1.1}$$

Proof. (cf. Suzuki [16] and Friedman and Lacey [4]). Without loss of generality we can assume $\bar{x} = 0$. Since u is continuous in $\mathbb{R} \times [0,T)$, there exist $a_0 > 0$ and $\delta > 0$ such that

$$u(x,t) \geq a_0 \quad \text{in } [-2\delta, 2\delta] \times [\bar{t}, \bar{t} + 2\delta).$$

Let $\rho(t)$ be the solution to

$$\rho'(t) = -\frac{\lambda\rho}{\beta'(\rho)} \quad \text{in } (\bar{t},\infty) \qquad \text{with } \rho(\bar{t}) = a, \tag{1.2}$$

where $\lambda = (\pi/2\delta)^2$ and $0 < a < a_0$. Integrating this, we have

$$\rho(t) = W^{-1}(W(a) - \lambda(t - \bar{t})), \quad \text{where } W(s) = \int_1^s \frac{\beta'(v)}{v}\, dv. \tag{1.3}$$

Note that $\beta'(v) > 0$ and $\beta''(v) \leq 0$ in $v > 0$. Then, as is easily seen, $W(s)$ is increasing in $s > 0$ and $W(s) \to -\infty$ as $s \downarrow 0$. Thus $\rho(t) > 0$ for each $t > \bar{t}$.

Now we put

$$v(x,t) = \rho(t) \sin \frac{\pi}{2\delta}(x - \delta). \tag{1.4}$$

Then, since $\beta'(\rho) \leq \beta'(v)$, we see

$$\beta(v)_t \leq v_{xx}, \qquad (x,t) \in (-\delta,\delta) \times (\bar{t},T). \tag{1.5}$$

Next we put

$$r(t) = \int_0^t \sup_{0\le\xi\le\rho(t)} \frac{g'}{\beta'}(\xi)\,dt. \tag{1.6}$$

Set

$$R_1 = \{0 < x < \delta, 0 < t < T\},$$
$$R_2 = \{r(t) - r(T) < x < 0, 0 < t < T\},$$

and

$$R_3 = \{r(t) - r(T) - \delta < x < r(t) - r(T), 0 < t < T\}.$$

In addition, we define a function $w(x,t)$ in the following way:

$$\begin{aligned} w(x,t) &= v(x,t) \quad \text{in } R_1,\\ w(x,t) &= \rho(t) \quad \text{in } R_2\\ w(x,t) &= v(x - r(t) + r(T), t) \quad \text{in } R_3\\ w(x,t) &= 0 \quad \text{otherwise.} \end{aligned}$$

Since

$$r(T) \le T \sup_{0\le\xi\le a} \frac{g'}{\beta'}(\xi), \tag{1.7}$$

then, from (A5), if $a > 0$ is small enough, we have

$$0 < r(T) < \delta.$$

Hence we obtain

$$\begin{aligned} w(x,\bar t) &= 0 \quad \text{in } x \le -2\delta, \quad x \ge 2\delta,\\ w(x,\bar t) &\le a \quad \text{in } -2\delta \le x \le 2\delta, \end{aligned}$$

and

$$w(x,\bar t) \le u(x,\bar t), \qquad x \in \mathbb{R}. \tag{1.8}$$

On the other hand, we compute

$$\begin{aligned} \beta(w)_t - w_{xx} + g(w)_x &= \beta(v)_t - v_{xx} + g'(v)v_x\\ &\le g'(v)v_x \le 0 \quad \text{in } R_1 \quad (\text{since } v_x \le 0 \text{ in } R_1),\\ \beta(w)_t - w_{xx} + g(w)_x &= \beta'(\rho(t))\rho'(t) \le 0 \quad \text{in } R_2 \quad (\text{since } \rho'(t) \le 0), \end{aligned}$$

and

$$\begin{aligned} \beta(w)_t - w_{xx} + g(w)_x &= \beta' v_t - \beta' r' v_x - v_{xx} + g'(v)v_x\\ &\le (g'(v) - r'\beta')v_x\\ &= \beta'(v)\left\{\frac{g'}{\beta'}(v) - \sup_{0\le\xi\le\rho(t)} \frac{g'}{\beta'}(\xi)\right\} v_x\\ &\le 0 \quad \text{in } R_3 \quad (\text{since } v \le \rho, v_x \ge 0 \text{ in } R_3 \text{ and (A5)}). \end{aligned}$$

By this computation we can see that $w(x,t)$ is a subsolution of (0.1) in $\mathbb{R}\times[0,T)$. Applying the comparison principle (Proposition 1.3) to w and u, we get

$$u(x,t)\geq w(x,t),\qquad (x,t)\in\mathbb{R}\times[\bar{t},T), \tag{1.9}$$

namely,

$$u(0,t)\geq\rho(t)>0,\qquad t\in[\bar{t},T). \tag{1.10}$$

□

This lemma and the comparison principle imply the existence of the interface; that is, if we put

$$\xi_1(t)=\inf\{x|u(x,t)>0\}, \tag{1.11}$$

$$\xi_2(t)=\sup\{x|u(x,t)>0\}, \tag{1.12}$$

and assume (A4), then we have

$$\{x|u(x,t)>0\}=(\xi_1(t),\xi_2(t))\quad\text{for each } t\in[0,T). \tag{1.13}$$

Furthermore, if we assume (A6), then we can obtain the finite propagation of the interface in $t<T$ using the following lemma.

LEMMA 1.6. *Assume* (A1)–(A6). *Let* $u(x,t)$ *be a weak solution of* (0.1), (0.2). *Suppose that there exist* $(a,t_1)\in\mathbb{R}\times[0,T)$ *and* $M>0$ *such that*

$$u(x,t_1)=0\quad \textit{for } x\geq a, \tag{1.14}$$

$$u(a,t)\leq M\quad \textit{for } t\in[t_1,T). \tag{1.15}$$

Then, there exist $l>0$ *and* $h>0$ *depending only on* M *such that*

$$u(x,t)=0\quad \textit{for } (x,t)\in[a+l,\infty)\times[t_1,t_1+h]\cap[t_1,T). \tag{1.16}$$

Furthermore, if $M>0$ *is small enough, we can take* $l>0$ *small enough.*

Proof. (cf. Lemma 2.2 in this paper, Lemma 2.3 of Mochizuki and Suzuki [14], and Knerr [11]). We construct a supersolution $w(x,t)$ of (0.1) in the form

$$w(x,t)=\psi^{-1}([\rho(t)-(x-a)]^+), \tag{1.17}$$

where $[g]^+=\max\{g,0\}$, $\psi(u)=\int_0^u dv/\beta(v)$, $\rho(t)=C(M)(t-t_1)+\psi(M)$, and $C(M)=1+\sup_{0\leq v\leq 2M}\{g'/\beta'+f/\beta\beta'\}$ (these functions are well defined since we have assumed (A5) and (A6)).

In fact, in the domain $\{\{x\geq a\}\times[t_1,t_1+k]\}\cap\{\rho(t)\geq x-a\}$, where $k=C(M)^{-1}\{\psi(2M)-\psi(M)\}$, we have $w=\psi^{-1}(\rho(t)-x+a)\leq\psi^{-1}(\rho(t_1+k))=2M$, and hence

$$\begin{aligned}&\frac{1}{\beta'(w)}\psi(w)_{xx}+|\psi(w)_x|^2-\frac{g'(w)}{\beta'(w)}\psi(w)_x+\frac{f(w)}{\beta(w)\beta'(w)}\\&\quad\leq 1+\frac{g'(w)}{\beta'(w)}+\frac{f(w)}{\beta(w)\beta'(w)}\leq C(M)=\partial_t\psi(w).\end{aligned} \tag{1.18}$$

Therefore, this w is extended by 0 to the whole $\{x \geq a\} \times [t_1, t_1 + k]$ as a supersolution of (0.1). To achieve this, we have only to note that $f(0) = 0$ and $\partial_x w(\rho(t) + a, t) = (\psi^{-1})'(0) = \beta(0) = 0$.

Moreover, we have

$$w(x, t_1) \geq 0 = u(x, t_1) \quad \text{on } x \geq a,$$
$$w(x, t) \geq \psi^{-1}(\rho(t)) \geq \psi^{-1}(\psi(M)) = M \geq u(x, t) \quad \text{on } x = a, \quad t \geq t_1.$$

Thus, Proposition 1.3 implies that

$$w(x, t) \geq u(x, t) \quad \text{in } \{x \geq a\} \times [t_1, t_1 + k'), \tag{1.19}$$

where $k' = \min\{k, T - t_1\}$.

By the property of $w(x, t)$, choosing $h = k'$ and $l = \rho(t_1 + h)$, we conclude the assertion of (1.16). Since $\psi(M) \to 0$ as $M \to 0$, we can choose k small if $M > 0$ is small enough. Hence we can choose $l > 0$ small enough also. □

THEOREM 1.7. *Assume* (A1)–(A6). *Let $u(x, t)$ be a weak solution to* (0.1), (0.2). *Then $\Omega(t)$ forms a bounded set in $\mathbb{R}$ and is nondecreasing in t:*

$$\Omega(t_1) \subset \Omega(t_2) \quad \text{if } t_1 < t_2,$$

and there exist continuous functions $\xi_i(t)\colon [0, T) \to \mathbb{R}$ $(i = 1, 2)$ such that

$$\Omega(t) = \{x | x \in (\xi_1(t), \xi_2(t))\}.$$

Proof. Proposition 1.3 and Lemmas 1.5 and 1.6 are reduced to Theorem 1.7 easily. □

2. The property of the zero set of $u_x(x, t)$. Throughout this section, we assume (A1)–(A6). Furthermore, we assume that the lap-number of the initial data $\varphi(x)$ is 2 (see (A9)). In this section we prove the next proposition.

PROPOSITION 2.1. *Let $u(x, t)$ and $\xi_i(t)$ be as in Theorem* 1.7. *If we assume* (A9), *then there exists a C^1-function $\eta(t)\colon (0, T) \to \mathbb{R}$ such that*

$$\{x \in (\xi_1(t), \xi_2(t)); u_x(x, t) = 0\} = \{\eta(t)\} \tag{2.1}$$

for each $t \in (0, T)$ and for some $\delta > 0$

$$-a_1 + \delta \leq \eta(t) \quad \text{for all } t \in (0, T). \tag{2.2}$$

First we give the following lemma.

LEMMA 2.2. *Let $\varphi_n(x)$ be a C^∞-function such that $\varphi_n(x) \geq 1/n, \varphi_n(\pm n) = 1/n$, and $\varphi_n(x)$ converges to $\varphi(x)$ as n goes to ∞ locally uniformly with respect to x. Furthermore, assume that the maximum point of $\varphi_n(x)$ is unique and $\sigma_a \varphi_n(x) \geq \varphi_n(x)$ in $x \leq a$ if $a \leq -a_1 + \delta$, and in $x \geq a$ if $a \geq a_1$ for some $\delta > 0$. Here we note that $(\sigma_a x + x)/2 = a$ and $\sigma_a u(x) = u(\sigma_a x)$. Let $u_n(x, t)$ be a classical solution of the initial boundary value problem*

$$\begin{aligned} &\partial_t \beta(u) - u_{xx} + g(u)_x = f(u), && (x, t) \in [-n, n] \times (0, T), \\ &u(x, 0) = \varphi_n(x), && x \in [-n, n], \\ &u(\pm n, t) = 1/n, && t > 0. \end{aligned} \tag{2.3}$$

Then $u_n(x,t) \geq 1/n$ *for* $(x,t) \in [-n,n] \times (0,T)$, *and* $u_n(x,t) \to u(x,t)$ *as* $n \to \infty$ *locally uniformly in* $\mathbb{R} \times [0,T)$.

Proof. See Gilding [8]. □

Remark 2.3. The existence of the above $\varphi_n(x)$ is guaranteed by assumptions (A4) and (A9).

LEMMA 2.4. *Let* $u_n(x,t)$ *be as in Lemma* 2.2. *Then for each* $T' \in (0,T)$ *there exists a* C^1*-function* $\eta_n(t) : (0,T') \to \mathbb{R}$ *with large* n *such that*

$$\{x \in (-n,n);\ u_{n,x}(x,t) = 0\} = \{\eta_n(t)\} \quad \text{for each } t \in (0,T'). \tag{2.4}$$

Furthermore,

$$-a_1 + \delta \leq \eta_n(t) \quad \text{for } t \in (0,T'), \tag{2.5}$$

where $\delta > 0$ *is as in Lemma* 2.2.

Before we show this lemma, we need some notation and definitions (cf. Chen and Matano [2] and Suzuki [16]).

Notation 2.5. Let $w(x)$ be a continuous real-valued function on K where K is a bounded closed interval in $\mathbb{R}$. We define the nodal number of w by

$$\nu_K(w) = \text{ the number of points } x \in K \text{ with } w(x) = 0.$$

DEFINITION 2.6. *We say that* $w \in C^1(K)$ *poses only simple zeros if* $w'(x) \neq 0$ *for any* $x \in K$ *such that* $w(x) = 0$. *The set of all such functions is denoted by* $\Sigma(K)$.

LEMMA 2.7 (see Angenent [1] and note Suzuki [16]). *Let* $p(x,t), q(x,t)$, *and* $r(x,t)$ *be locally bounded continuous functions on* $[a,b] \times (t_0,T)$ *with* $p_{xx}, p_{xt}, p_{tt}, p_x, p_t$, q_x, q_t *all locally bounded continuous. Furthermore, let* $p(x,t) > 0$ *and let* $w(x,t)$ *be a classical solution of*

$$w_t = p(x,t)w_{xx} + q(x,t)w_x + r(x,t)w, \qquad (x,t) \in [a,b] \times (t_0,T). \tag{2.6}$$

Assume that $w(a,t) \neq 0$ *and* $w(b,t) \neq 0$ *for any* $t \in (t_0,T)$. *Then*

(i) $\nu(w(\cdot,t))$ *is finite for any* $t \in (t_0,T)$ *and is monotone nonincreasing in* t;

(ii) *If* x_0 *is a multiple zero of* $w(\cdot,t_1)$, *then* $\nu(w(\cdot,t_2)) > \nu(w(\cdot,t_3))$ *for all* $t_0 < t_2 < t_1 < t_3 < T$;

(iii) *There exists a strictly decreasing sequence of points* $\{t_k\}$ *such that* $\{t_k\} \downarrow t_0$ *and* $w(x,t) \in \Sigma([a,b])$ *for any* $t \in (t_0,T) \setminus \{t_k\}$.

On the other hand, we have the following lemma about lap-number (see Matano [13]).

LEMMA 2.8 (Matano). *Let* $u(x,t)$ *be a solution of the following Dirichlet problem:*

$$\begin{aligned} &u_t = a(x,t)u_{xx} + b(x,t)u_x + f(t,u) && \text{in } [a,b] \times (0,T), \\ &u(x,0) = u_0(x) && \text{in } [a,b], \\ &u(a,t) = u(b,t) = 0 && \text{in } (0,T), \end{aligned}$$

where $u_0(x) \in C([a,b] \times [0,T)), a \in C^1([a,b] \times [0,T)), b \in C^\alpha([a,b] \times [0,T))$ *for some* $0 < \alpha < 1, f \in C^1([0,T) \times \mathbb{R})$, *and* $a(x,t) \geq \delta$ *in* $[a,b] \times [0,T)$ *for some* $\delta > 0$. *Then if we assume that* $u(x,t) \geq 0$ *in* $[a,b] \times [0,T)$ *and* $l(u(\cdot,0)) \neq 0$, *the lap-number* $l(u(\cdot,t))$ *is nonincreasing in* $t \in [0,T)$.

Proof of Lemma 2.4. Applying the maximum principle to $u_n(x,t)$, we obtain

$$u_n(x,t) \geq 1/n \quad \text{in } x \in [-n,n], \quad t > 0 \tag{2.7}$$

and

$$\pm u_x(\pm n, t) < 0 \quad \text{for } t > 0. \tag{2.8}$$

Note that the lap-number $l(u_n(\cdot, t)) = l(u_n(\cdot, t) - 1/n)$ for $t > 0$ is equal to two by Lemma 2.8. Hence, since the nodal number $\nu_{[-n,n]}(u(\cdot, t)) = 1$, it follows from Lemma 2.7 (ii) that there exists a C^1-function $\eta_n(t)$ such that

$$\{x \in (-n, n); u_{n,x}(x, t) = 0\} = \{\eta_n(t)\} \quad \text{for } t > 0. \tag{2.9}$$

Next we prove (2.5) (see Friedman and Lacey [4]). Choose $a \in [-n, -a_1 + \delta]$ and set

$$w = u(x, t) - v(x, t) \quad \text{in } [-n, a]$$

where $u = u_n$ and $v = \sigma_a u_n$. Then w satisfies

$$\beta'(u)w_t - w_{xx} + Cw = -\{g'(u) + g'(v)\}u_x + g'(v)w_x, \tag{2.10}$$

where

$$C = C(x, t) = -\frac{f(u) - f(v)}{u - v} + \frac{\beta'(u) - \beta'(v)}{u - v} v_t.$$

Furthermore, if we set $h(x, t) = e^{-\gamma t}w$, where γ is chosen later, then $h(x, t)$ satisfies the following equation:

$$\beta'(v)h_t - h_{xx} + \{\gamma\beta' + C\}h = -\{g'(u) + g'(v)\}e^{-\gamma t}u_x + g'(v)h_x. \tag{2.11}$$

Since $\beta'(v) > 0$ and $C < \infty$ for each $t \in [0, T']$ and $x \in [-n, n]$, if γ is large enough, then

$$\gamma\beta'(v) + C > 0.$$

Further, we note that

$$\begin{aligned} &h(a, t) = 0, \\ &h(-n, t) = e^{-\gamma t}\{u(-n, t) - v\} = e^{-\gamma t}\{1/n - v\} \le 0 \quad \text{for } t > 0, \\ &h(x, 0) = \varphi_n - \sigma_a\varphi_n \le 0 \quad \text{for } x \in [-n, a]. \end{aligned} \tag{2.12}$$

We shall claim that $h \le 0$ in $[-n, a] \times [0, T']$. Indeed, otherwise we take the positive maximum value of $h(x, t)$ at some point $(\bar{x}, \bar{t})$ in $(-n, a) \times (0, T']$. Then we have

$$h(\bar{x}, \bar{t}) > 0, h_x(\bar{x}, \bar{t}) = 0, h_t(\bar{x}, \bar{t}) \ge 0, \text{ and } h_{xx}(\bar{x}, \bar{t}) \le 0, \tag{2.13}$$

and for $u(x, t)$, we also have

$$u(\bar{x}, \bar{t}) > v(\bar{x}, \bar{t}), \tag{2.14}$$

$$u_x(\bar{x}, \bar{t}) = v_x(\bar{x}, \bar{t}). \tag{2.15}$$

Suppose $\bar{x} \le \eta_n(\bar{t})$. Then $u_x(\bar{x}, \bar{t}) \ge 0$. Noting this and (2.13), we see

$$\beta'(v)h_t - h_{xx} + \{\gamma\beta'(v) + C\}h > -\{g'(u) + g'(v)\}e^{-\gamma t}u_x + g'(v)h_x$$

at $(x,t)=(\bar{x},\bar{t})$. This contradicts (2.11).

Next suppose $\eta_n(\bar{t})<\bar{x}$. Then $u_x(\bar{x},\bar{t})<0$ and $v_x(\bar{x},\bar{t})>0$. These results contradict (2.15).

Hence we obtain $h\le 0$ in $[-n,a]\times[0,T')$, that is,

$$u_n(x,t)\le \sigma_a u_n(x,t) \quad \text{for } (x,t)\in[-n,a]\times\{0,T'\}. \tag{2.16}$$

Therefore,

$$u_{n,x}(a,t)\ge 0 \quad \text{for } t\in[0,T']. \tag{2.17}$$

Since $a\in[-n,a_1+\delta]$ is chosen arbitrarily, we get

$$\eta_n(t)\ge -a_1+\delta.$$

This shows (2.5). The proof is complete. □

Proof of Proposition 2.1. Using Lemmas 2.4 and 2.7 and the limit procedure of an approximate solution u_n, we can prove Proposition 2.1. Indeed, by Theorem 1.7 there exist continuous functions $\xi_i(t):[0,T)\to\mathbb{R}$ such that

$$\xi_1(0)=-a_1, \qquad \xi_2(0)=a_1 \quad \text{for } t\in[0,T) \tag{2.18}$$

and

$$\{x;u(x,t)>0\}=(\xi_1(t),\xi_2(t)) \quad \text{for each } t\in(0,T). \tag{2.19}$$

Hence, for each $t_1\in(0,T)$, there exist sequences $\{x_j^{\pm}\}$ and $\{\delta_j\}$ $(\delta_j>0)$ such that

$$x_j^-\to\xi_1(t_1) \quad \text{and} \quad x_j^+\to\xi_2(t_2) \quad \text{as } j\to\infty, \tag{2.20}$$

$$\xi_1(t)<x_j^-<x_j^+<\xi_2(t) \quad \text{for } t\in(t_1-\delta_j,t_1+\delta_j) \tag{2.21}$$

and

$$\pm u_x(x_j^{\pm},t)<0 \quad \text{for each } t\in(t_1-\delta_j,t_1+\delta_j). \tag{2.22}$$

Now we shall show that the nodal number of $u_x(\cdot,t_1)$ on $[x_j^-,x_j^+]$ is 1, namely,

$$\nu_{[x_j^-,x_j^+]}(u_x(\cdot,t_1))=1. \tag{2.23}$$

Applying Lemma 2.7 to $u_x(\cdot,t_1)$ in $[x_j^-,x_j^+]$, we can see that $\nu_{[x_j^-,x_j^+]}(u_x(\cdot,t))$ is finite for each $t\in(t_1-\delta_j,t_1+\delta_j)$ and is nonincreasing in $t\in(t_1-\delta_j,t_1+\delta_j)$, and we see that $u_x(\cdot,t_2)\in\Sigma([x_j^-,x_j^+])$ for some $t_2\in(t_1-\delta_j,t_1)$. Then we get that if n is large enough,

$$\{\eta_n(t)\}\subset(x_j^-,x_j^+) \quad \text{for } t\in(t_1-\delta_j,t_1+\delta_j). \tag{2.24}$$

In fact, assume that there exists a subsequence $\{\eta_{n_k}(t)\}\subset\{\eta_n(t)\}$ such that $x_j^+\le\eta_{n_k}(t)$. Then, by Lemma 2.4, we obtain that $u_{n_k}(x,t)$ is increasing in $x\in[x_j^-,x_j^+]$. Therefore, since $u_{n_k}(x,t)$ converges to $u(x,t)$ as $n_k\to\infty$ by Lemma 2.2, we can see

that $u(x,t)$ has the same property as $u_{n_k}(x,t)$ and so $u_x(x_j^+,t) \geq 0$. This contradicts (2.22). On the other hand assume that there exists a subsequence $\{\eta_{n_k}(t)\} \subset \{\eta_n(t)\}$ such that $\eta_{n_k}(t) \leq x_j^-$; we can also show the same contradiction.

For each $t \in (t_1 - \delta_j, t_1 + \delta_j)$ let $\eta_0(t)$ be an accumulating point of $\{\eta_n(t)\}$. Then, since $u(\cdot,t)$ is decreasing in $x \in [x_j, \eta_0(t)]$ and $u(\cdot,t)$ is nonincreasing in $x \in [\eta_0(t), x_j^+]$, namely, $u_x(x,t) \geq 0$ in $x \in [x_j^-, \eta_0(t)]$ and $u_x(x,t) \leq 0$ in $x \in [\eta_0(t), x_j^+]$, we obtain $u_x(\eta_0(t),t) = 0$ and $\eta_0(t) \in (x_j^-, x_j^+)$.

Take $t = t_2$ and assume that there is a point $x_1 \in (x_j^-, x_j)$ but η_0 such that $u_x(x_1,t_2) = 0$. It follows from $u_x(\cdot,t_2) \in \Sigma([x_j^-, x_j^+])$ that x_1 is a simple zero point of $u_x(x,t_2)$ in $[x_j^-, x_j^+]$, namely, $u_{xx}(x_1,t_2) \neq 0$. This contradicts the fact that $u_x(x,t_2) \geq 0$ (or ≤ 0) in the neighborhoods of x_1. Hence the zero points of $u_x(x,t_2)$ in $[x_j^-, x_j^+]$ coincide with $\eta_0(t_2)$, that is, $\nu_{[x_j^-, x_j^+]}(u_x(\cdot,t_2)) = 1$.

Since the nodal number of $u_x(\cdot,t)$ in $[x_j^-, x_j^+]$ is nonincreasing in t, we get (2.23). Furthermore, noting that the accumulating point is only $\eta_0(t_1)$, we see that $\eta_n(t_1) \to \eta_0(t_1)$ as $n \to \infty$.

Therefore, if $j \to \infty$ in (2.23), then we get

$$\nu_{(\xi_1(t_1), \xi_2(t_2))}(u_x(\cdot,t_1)) = 1$$

and

$$\{x \in (\xi_1(t_1), \xi_2(t_1)); u_x(x,t) = 0\} = \{\eta_0(t_1)\}.$$

Noting that $t_1 \in (0,T)$ is chosen arbitrarily and $u_x(\cdot,t_1) \in \Sigma(\xi_1(t_1), \xi_2(t_1))$ by Lemma 2.7 (ii), and setting $\eta(t) = \eta_0(t)$, we have that $\{x \in (\xi_1(t), \xi_2(t)); u_x(x,t) = 0\} = \{\eta(t)\}$ for each $t \in (0,T)$, $\eta(t)$ is C^1-function, and

$$\eta_n(t) \to \eta(t) \ (n \to \infty) \quad \text{for each } t \in (0,T). \tag{2.25}$$

(2.5) is reduced by (2.2) easily. The proof is complete. □

3. Single-point blow-up. In this section we assume (A1)–(A6) and (A9), we show the existence of single-point blow-up solutions of (0.1), (0.2), and we study the asymptotic behavior of interfaces of the blow-up solutions. To accomplish this, we also need (A7) and (A8) and the following assumptions:

(A10) There exists a C^2-function $F(v)$ such that

(i) $F(v), F'(v), F''(v) > 0$ for $v > 0$,

(ii) $\int_1^\infty d\xi/F(\xi) < \infty$, and

(iii) there are constants $c > 0$ and $v_0 > 0$ such that

$$f'F - F'f - \tfrac{1}{2}(g')^2 F \geq c(F^2 g'' + F'F) \quad \text{for } v \geq v_0.$$

Condition (A10) shows that $f(u)$ grows more rapidly than $g(u)$ and u.

Remark 3.1. (A10) is satisfied by (0.4) if $p > \max\{m, 2q - m\}$. In this case we can put $F(\xi) = \xi^{\tilde{p}/m}$ for $m < \tilde{p} < \min\{p, p + m - q\}$.

Condition (A8) is required to ensure that $u(x,t)$ is increasing in t for each $x \in \mathbb{R}$. Namely, we have the following lemma.

LEMMA 3.2. *Assume* (A1)–(A3) *and* (A8). *Let* $u(x,t)$ *be a weak solution of* (0.1), (0.2) *in* $\mathbb{R} \times (0,T)$. *Then* $u(x,t)$ *is nondecreasing in* t. *If* $u(x_0,t_0) > 0$ *for some* $(x_0,t_0) \in \mathbb{R} \times (0,T)$, *then* $\partial_t u(x,t) \geq 0$ *in the neighborhood of* (x_0,t_0).

Further, if we add (A7) and (A10), then we can get the following lemma.

LEMMA 3.3 (cf. Chen and Matano [2] and Suzuki [16]). *Assume* (A1)–(A3), (A7), (A8), *and* (A10). *Let* $\Omega = (a,b)$ *be a bounded open interval and let* $u(x,t)$ *be a positive weak solution of* (0.1) *in* $Q_T = \Omega \times (0,T)$. *Furthermore, suppose that*

$$u_x(x,t) > 0 \,[\text{or } u_x(x,t) < 0] \quad \text{in } (x,t) \in [c-\delta, c+\delta] \times (\tau, T) \tag{3.1}$$

for some $c \in (a,b)$ *and* $\delta > 0$ *with* $(c-\delta, c+\delta) \subset (a,b)$ *and some* $\tau \in (0,T)$. *Then there are no blow-up points in* $(c-\delta, c+\delta)$.

Proof. We shall prove this lemma in the case when

$$u_x(x,t) > 0 \quad \text{in } (x,t) \in (c-\delta, c+\delta) \times (\tau, T). \tag{3.2}$$

Assume $x_0 \in (c-\delta, c+\delta)$ is a blow-up point of $u(x,t)$. Then, by (3.2) and Lemma 3.2 we soon see that

$$\lim_{t \uparrow T} u(x,t) = \infty \quad \text{for } x \in (x_0, c+\delta). \tag{3.3}$$

Choose $d \in (x_0, c+\delta)$ and set

$$J = u_x - \varepsilon \rho(x) F(u(x,t)), \qquad (x,t) \in Q = (d, c+\delta) \times (\tau, T) \tag{3.4}$$

and

$$\rho(x) = \left[\sin \frac{\pi(x-d)}{c+\delta-d}\right]^2, \tag{3.5}$$

where $\varepsilon > 0$ and $t_1 \in (\tau, T)$ is chosen later. We compute

$$\begin{aligned}(\beta' J)_t - J_{xx} = {} & \varepsilon \rho A(x,t) + B(x,t) J - g' J_x \\ & - \varepsilon \beta' F u_t + \varepsilon \rho F''(u_x)^2,\end{aligned} \tag{3.6}$$

where

$$A(x,t) = f'F - F'f + \left\{-\frac{\rho'}{\rho} g' + \frac{\rho''}{\rho}\right\} F - \varepsilon\{\rho F^2 g'' + 2\rho' F' F\}$$

and

$$B(x,t) = f' + \varepsilon \rho F' g' + 2\varepsilon \rho' F' - \varepsilon g' \rho F' - g'' J - 2\varepsilon g'' \rho F.$$

Here we used the relations

$$u_{xx} = J_x + \varepsilon \rho' F + \varepsilon \rho F' J + \varepsilon^2 \rho^2 F' F$$

and

$$(u_x)^2 = J^2 + 2\varepsilon \rho F J + \varepsilon^2 \rho^2 F^2.$$

If we note that

$$\rho' = 2\lambda \sin \lambda(x-d) \cdot \cos \lambda(x-d)$$

and

$$\rho'' = 2\lambda^2 (1 - 2\rho) \quad \text{where } \lambda = \frac{\pi}{c+\delta-d},$$

then we get

$$-\frac{\rho'}{\rho}g' + \frac{\rho''}{\rho} = \frac{-2g' \sin\lambda(x-d)\cdot\cos\lambda(x-d) + 2\lambda^2(1-2\rho)}{\{\sin\lambda(x-d)\}^2}$$
$$= -4\lambda^2 + \frac{2\lambda\{\lambda - \cos\lambda(x-d)\cdot\sin\lambda(x-d)\cdot g'\}}{\{\sin\lambda(x-d)\}^2}$$
$$\geq -4\lambda^2 + \frac{2\lambda\{\lambda - \sin\lambda(x-d)\cdot|g'|\}}{\{\sin\lambda(x-d)\}^2}.$$

Hence, putting $\theta = \sin\lambda(x-d)$, we get:

$$-\frac{\rho'}{\rho}g' + \frac{\rho''}{\rho} \geq -4\lambda^2 + \frac{2\lambda(\lambda - \theta|g'|)}{\theta^2},$$

where $0 \leq \theta \leq 1$.

Set

$$h(\theta) = -4\lambda + \frac{2\lambda(\lambda - \theta|g'|)}{\theta^2}$$

and assume that θ is independent of g'. Then we see that $h(\theta)$ takes the minimum value

$$h\left(\frac{2\lambda}{|g'|}\right) = -4\lambda^2 - \frac{1}{2}(g')^2 \quad \text{at } \theta = \frac{2\lambda}{|g'|},$$

since $h'(\theta) = -4\lambda^2\theta^{-3} + 2\lambda\theta^{-2}g'$, and $h(\theta) = 0$ is reduced to $\theta = 2\lambda/|g'|$. Therefore, we have

$$-\frac{\rho'}{\rho}g' + \frac{\rho''}{\rho} \geq -4\lambda^2 - \frac{1}{2}(g')^2. \tag{3.7}$$

Thus, we get the lower bound estimate of $A(x,t)$:

$$A(x,t) \geq f'F - F'f + (4\lambda^2 + \tfrac{1}{2}(g')^2)F - \varepsilon\{\rho F^2 g'' + 2|\rho'|F'F\}. \tag{3.8}$$

Considering (A10), Lemma 3.2, and the fact that $F'(u)$ goes to infinity as $u \to \infty$, if t_1 is close enough to T we have

$$(\beta' J)_t - J_{xx} \geq B(x,t)J - g'J_x. \tag{3.9}$$

On the other hand,

$$J(d,t) = u_x(d,t) > 0, \qquad J(c+\delta,t) = u_x(c+\delta,t) > 0, \tag{3.10}$$

and

$$J(x,t_1) > 0 \quad \text{(by (3.2))} \quad \text{for small enough } \varepsilon > 0. \tag{3.11}$$

Applying the maximum principle to $J(x,t)$, we obtain

$$J(x,t) > 0 \quad \text{in } (t_1,T)\times(d,c+\delta),$$

namely,

$$\frac{u_x}{F} > \varepsilon\rho \quad \text{in } (t_1,T)\times(d,c+\delta). \tag{3.12}$$

Integrating this inequality over $d \leq x \leq c+\delta$ yields

$$\int_{u(d,t)}^{u(c+\delta,t)} \frac{du}{F(u)} > \varepsilon \int_d^{c+\delta} \rho(x)dx \quad \text{in } t_1 < t < T. \tag{3.13}$$

The right-hand side of (3.13) is a positive constant, while the left-hand side tends to zero as $t \uparrow T$ by virtue of condition (A10)(ii) and equation (3.3). This contradiction shows that x_0 is not a blow-up point of $u(x,t)$. The proof is complete. □

THEOREM 3.4. *Let $u(x,t)$ and $\xi_i(t)$ be as in Theorem* 1.7, *and let S be the blow-up set of $u(x,t)$. Furthermore, assume* (A7)–(A10). *Then*

$$S = \{\eta_0\} \tag{3.14}$$

for some $\eta_0 \in [-a_1+\delta, \infty]$ with a small $\delta > 0$ and

$$-\infty < \lim_{t\uparrow T} \xi_1(t). \tag{3.15}$$

Proof (see Friedman and Lacey [4]). By Proposition 2.1, there exists a C^1-function $\eta(t) : (0,T) \to \mathbb{R}$ such that

$$\{x \in (\xi_1(t), \xi_2(t)); u_x(x,t) = 0\} = \{\eta(t)\} \tag{3.16}$$

for each $t \in (0,T)$ and

$$-a_1 + \delta \leq \eta(t) \quad \text{for all } t \in (0,T), \tag{3.17}$$

where $\xi_i(t)$ is defined by (1.11), (1.12). Therefore, we see that

$$u_x(x,t) > 0 \quad \text{for } \xi_1(t) < x < -a_1+\delta, \quad 0 < t < T, \tag{3.18}$$

and it follows from Lemma 3.3 that

$$\{x; x < -a_1+\delta\} \subset S^c, \tag{3.19}$$

where S is the blow-up set of $u(x,t)$.

Here, if we show that

$$\lim_{t\uparrow T} \eta(t) = \eta_0 \tag{3.20}$$

exists, then by Lemmas 3.2 and 3.3 we can obtain the results of Theorem 3.4. Hence, we shall prove (3.20).

Assume that $\lim_{t\uparrow T} \eta(t)$ does not exist. Then, if we set $\eta_- = \liminf_{t\uparrow T} \eta(t)$ and $\eta_+ = \liminf_{t\uparrow T} \eta(t)$,

$$-a_1 + \delta \leq \eta_- < \eta_+ \leq \infty. \tag{3.21}$$

Choose $-a_1+\delta < s_1 < \eta_-$ and $\eta_- < s_2 < \eta_+$ such that

$$\alpha = (s_1+s_2)/2 \in (\eta_-, \eta_+). \tag{3.22}$$

Then, since $\lim_{t\uparrow T} u(\eta(t),t) = \infty$, by Lemma 3.2 we get $\lim_{t\uparrow T} u(x,t) = \infty$ for each $x \in (\eta_-, \eta_+)$. Hence, if T_0 is chosen close enough to T, we obtain

$$u_x(x,T_0) > 0 \quad \text{for } s_1 < x < s_2 \tag{3.23}$$

and

$$u(s_1,t) < u(s_2,t) \quad \text{for } t \in (T_0,T). \tag{3.24}$$

Set $w = u - v$ where $v(x,t) = \sigma_\alpha u = u(2\alpha - x,t)$, and consider $w(x,t)$ in the rectangle region $R = \{s_1 < x < \alpha, T_0 < t < T\}$. Then, we see

$$w(x,T_0) = u(x,T_0) - \sigma_\alpha u(x,T_0) \le 0 \quad \text{in } [s_1,\alpha] \tag{3.25}$$

and

$$w(x,s_1) = u(s_1,t) - u(s_2,t) \le 0 \quad \text{in } t \in [T_0,T). \tag{3.26}$$

By the same method as we used in the proof of (2.16) we obtain

$$w(x,t) \le 0 \quad \text{for } (x,t) \in [s_1,\alpha] \times [T_0,T). \tag{3.27}$$

Since $w(\alpha,t) = 0$, we get

$$\tfrac{1}{2} w_x(a,t) = u_x(\alpha,t) \ge 0 \quad \text{for } t \in [T_0,T). \tag{3.28}$$

This is a contradiction of $\alpha \in (\eta_-, \eta_+)$. Therefore, we obtain (3.20) and $S = \{\eta_0\}$. The proof is complete. □

4. The upper bound estimates and bounded-point blow-up. In this section we show $\eta_0 < \infty$ where η_0 is as in Theorem 3.4. In order to show this, we need the upper bound estimates of the blow-up solution of (0.1), (0.2). We must further assume (A11) on $f(u)$ such that $f(u)$ grows more rapidly than u and $g(u)$, and we choose the suitable initial data $\varphi(x)$ corresponding to (A11).

(A11) There exists a C^2-function $\Phi(v)$ such that

(i) $\Phi, \Phi', \Phi'' > 0$ for $v > 0, \Phi(0) = \Phi'(0) = 0$ and $f(v)/\beta'(v) \ge \Phi(v)$ near $v = 0$;

(ii) $\int_1^\infty d\xi/\Phi(\xi) < \infty$;

(iii) There are constants $C > 0$ and $v_1 > 0$ such that

$$4\Phi''(f'\Phi - \Phi' f) \ge (g'')^2\Phi \quad \text{for } v \ge v_1$$

and

$$\frac{(g'')^2\Phi}{4\Phi''\beta'} + \frac{f\Phi'}{\Phi\beta'} < C \quad \text{for } 0 \le v \le v_1;$$

(iv) $$\int_0^1 \sup_{0 \le v \le H^{-1}(t)} \frac{g'(v)}{\beta'(v)}\, dt < \infty,$$

where $H(\xi) = \int_\xi^\infty \frac{d\eta}{\Phi(\eta)}$.

$$\varphi'' - g(\varphi)' + f(\varphi) \ge \Phi(\varphi) \quad \text{in } \mathcal{D}', \tag{A12}$$

where $\Phi(\eta)$ is as in (A11).

Remark 4.1. (A11) is satisfied by (0.4) if $p > \max\{m, 2q-1, m+q-1\}$ and $2q \geq m+1$. In this case, we can put $\Phi(\xi) \approx \xi^{p/m-\delta}$ for sufficiently small $\delta > 0$ (as $\xi \to \infty$) and $\Phi(\xi) = m\xi^{(p+m-1)/m}$ (as $\xi \to 0$). In general, we can not replace $\Phi(\xi)$ by the function $F(\xi)$ in (A10).

LEMMA 4.2. *Assume* (A1)–(A12). *Let* $u_n(x,t)$ *be a solution of the regularized problem*

$$\begin{aligned} &\partial_t \beta(u) - u_{xx} + g(u)_x = f(u), && (x,t) \in [-n,n] \times (0,T), \\ &u(x,0) = \varphi_n(x), && x \in [-n,n] \times (0,T), \\ &u(\pm n,t) = \Phi(1/n)t + 1/n, && t > 0, \end{aligned} \tag{4.1}$$

with the blow-up time T_n. *Let* $\varphi_n(x)$ *be as in Lemma* 2.2, *and let us add the following condition to it*:

$$\varphi_n'' - \{g(\varphi_n)\}' + f(\varphi_n) \geq \Phi(\varphi_n) \quad \text{in } \mathcal{D}' \tag{4.2}$$

(*the existence of the above* $\varphi_n(x)$ *is guaranteed by assumption* (A12)). *Then, for some* $c_1 > 0$,

$$u_n(x,t) \leq H^{-1}(c_1(T_n' - t)) \quad \text{for } (x,t) \in \mathbb{R} \times [0, T_n'), \tag{4.3}$$

where $H(\xi) = \int_\xi^\infty d\eta/\Phi(\eta)$ *and* $T_n' = \min\{T_n, T\}$.

LEMMA 4.3. *Lemmas* 2.2 *and* 2.4 *hold for large* n *if* (2.3) *is replaced by* (4.1). *Furthermore, it holds that* $u_n(x,t) \geq 1/n + \Phi(1/n)t$ *for* $(x,t) \in [-n,n] \times [0, T_n)$.

Proof. Noting the condition (A11)(i) and using the comparison principle, we obtain $u_n(x,t) \geq 1/n + \Phi(1/n)t$. Proceeding with a proof similar to that of Lemma 2.4, we get the assertion of Lemma 4.3. □

Proof of Lemma 4.2 (see Friedman and Lacey [4]). Set

$$J = u_t - c(t)\Phi(u) \tag{4.4}$$

where $u = u_n$, and

$$c(t) = \frac{\Phi(1/n)}{\Phi(1/n + T\Phi(1/n))} e^{-Ct}$$

where $C > 0$ is as in (A11)(iii). We compute $(\beta' J)_t - J_{xx}$ in the following way:

$$(\beta' J)_t - J_{xx} = B(x,t)J - g' J_x + c(t)A(x,t),$$

where

$$A(x,t) = f'\Phi - \Phi' f - c\beta''\Phi^2 + C\beta'\Phi - g''\Phi u_x + \Phi''(u_x)^2$$

and

$$B(x,t) = -g'' u_x - c\beta''\Phi + f'.$$

Here we used the next relation:

$$u_{xt} = J_x + c\Phi' u_x.$$

We further compute that

$$\begin{aligned} A(x,t) &= \Phi''\left\{(u_x)^2 - \frac{g''}{\Phi''}\Phi u_x\right\} + f'\Phi - \Phi' f - c\beta''\Phi^2 + C\beta'\Phi \\ &= \Phi''\left(u_x - \frac{g''}{2\Phi''}\Phi\right)^2 - \frac{(g'')^2\Phi^2}{4\Phi''} + f'\Phi - \Phi' f - c\beta''\Phi^2 + C\beta'\Phi \\ &\geq \frac{4\Phi''[f'\Phi - \Phi' f - c\beta''\Phi^2 + C\beta'\Phi] - (g'')^2\Phi^2}{4\Phi''}. \end{aligned}$$

Noting $\beta' > 0$ and condition (A11) we get

$$4C\Phi''\Phi\beta' - 4\Phi''\Phi' f - (g'')\Phi^2 \geq 4\beta'\Phi''\Phi\left\{C - \frac{\Phi' f}{\Phi\beta'} - \frac{(g'')^2\Phi}{4\Phi''\beta'}\right\} \geq 0 \quad \text{for } 0 \leq v \leq v_1.$$

Hence, considering condition (A11) again, and noting $\beta'' \leq 0$, we see that

$$A(x,t) \geq 0. \tag{4.5}$$

Thus, we have

$$(\beta' J)_t - J_{xx} \geq B(x,t)J - g' J_x. \tag{4.6}$$

On the other hand,

$$\begin{aligned} J(\pm n,t) &= u_t(\pm n,t) - c(t)\Phi(u_n(\pm n,t)) \\ &= \Phi(1/n) - \frac{\Phi(1/n)}{\Phi(1/n + T\Phi(1/n))} e^{-Ct}\Phi(1/n + \Phi(1/n)t) \geq 0 \end{aligned} \tag{4.7}$$

and

$$\begin{aligned} J(x,0) &= u_{n,t}(x,0) - \Phi(u_n(x,0)) \\ &= \varphi'' - \{g(\varphi_n)\}' + f(\varphi_n) - \Phi(\varphi_n) \geq 0 \quad \text{(by (4.2))}. \end{aligned} \tag{4.8}$$

Applying the maximum principle to J, we obtain

$$J(x,t) \geq 0 \quad \text{in } [-n,n] \times [0, T_n'), \tag{4.9}$$

that is,

$$u_{n,t} \geq c(t)\Phi(u_n).$$

Here we note that

$$\begin{aligned} \frac{\Phi(1/n)}{\Phi(1/n + T\Phi(1/n))} &= \frac{\Phi(1/n)}{\Phi(1/n) + T\Phi(1/n)\int_0^1 \Phi'(1/n + T\Phi(1/n)s)\,ds} \\ &= \frac{1}{1 + T\int_0^1 \Phi'(1/n + T\Phi(1/n)s)\,ds} \geq 1/2 \quad \text{for large } n. \end{aligned}$$

Hence, if we put $c_1 = \frac{1}{2}e^{-CT}$, we get

$$u_{n,t} \geq c_1\Phi(u_n). \tag{4.10}$$

Integrate (4.10) over $[t, T_n')$ for each $x \in [-n, n]$. Then, we have

$$\int_t^{T_n'} \frac{u_{n,t}}{c_1 \Phi(u_n)} dt \geq T_n' - t. \tag{4.11}$$

Setting $H(\xi) = \int_\xi^\infty d\eta/\Phi(\eta)$, we have

$$-\frac{1}{c_1}[H(u_n)]_t^{T_n'} \geq T_n' - t,$$

that is,

$$-\frac{1}{c_1}\{H(u_n(x, T_n')) - H(u_n(x,t))\} \geq T_n' - t.$$

Therefore,

$$H(u_n(x,t)) \geq c_1(T_n' - t) \tag{4.12}$$

Since $H(\xi)$ is a decreasing function in ξ, we obtain

$$u_n(x,t) \leq H^{-1}(c_1(T_n' - t)).$$

The proof is complete. □

THEOREM 4.4. *In Theorem* 3.4, *if we further assume* (A11) *and* (A12), *we get*

$$\eta_0 < \infty \tag{4.13}$$

and

$$\lim_{t \uparrow T} \xi_2(t) < \infty. \tag{4.14}$$

Proof. Let $T' \in (0, T)$ be fixed and set $h(t) = H^{-1}(c_1(T' - t))$. Then by Lemma 4.2, if n is large enough, $T' < T_n'$ and

$$u_n(x,t) \leq H^{-1}(c_1(T_n' - t)) \leq h(t). \tag{4.15}$$

Put

$$v(x,t) = u_n(x + k(t), t) \tag{4.16}$$

where $k(t) = \int_0^t l(h(s))ds$ and $l(\xi) = \sup_{0 \leq v \leq \xi}(g'(v)/\beta'(v))$.

Then $v(x,t)$ satisfies the following equation:

$$\beta'(v)v_t - v_{xx} = \beta' \times \left\{k' - \frac{g'(v)}{\beta'(v)}\right\} v_x + f(v).$$

Since

$$\frac{g'(v(x,t))}{\beta'(v(x,t))} = l(v) \leq l(h(t)) = k'(t),$$

we obtain

$$k'(t) - \frac{g'(v)}{\beta'(v)} \geq 0 \quad \text{for } (x,t) \in [-k(t) - n, -k(t) + n] \times [0, T'). \tag{4.17}$$

On the other hand, noting condition (A11)(iv) we see that

$$
\begin{aligned}
k(t) \le k(T') &= \int_0^{T'} l(H^{-1}(c_1(T'-s)))\,ds \\
&= \frac{1}{c_1}\int_0^{c_1T'} l(H^{-1}(t))\,dt \quad (\text{put } t = c_1(T'-s)) \\
&\le k(T) = \frac{1}{c_1}\int_0^{c_1T} l(H^{-1}(t))\,dt \\
&< \infty \quad \text{for } t \in (0,T').
\end{aligned} \tag{4.18}
$$

Thus, for each $a \ge a_1$ there exists N such that

$$
a \le n - k(T) \le n - k(t) \quad \text{for all } n \ge N \quad \text{and each} \quad t \in [0,T']. \tag{4.19}
$$

Put $\tilde{v}(x,t) = \sigma_a v = v(2a-x,t)$. Then we can consider

$$
w = v(x,t) - \tilde{v}(x,t) \quad \text{in} \bigcup_{0\le t\le T'} [a, n-k(t)] \times \{t\}
$$

since $n - k(T) \le n - k(t)$ for $t \in [0,T']$. As w satisfies the equation

$$
\begin{aligned}
\beta'(v)w_t - w_{xx} + c(x,t)w = &\left\{\beta'(\tilde{v})\left(k' - \frac{g'(\tilde{v})}{\beta'(\tilde{v})}\right) + \beta'(v)\left(k' - \frac{g'(v)}{\beta'(v)}\right)\right\} v_x \\
&- \left\{\beta'(\tilde{v})\left(k' - \frac{g'(\tilde{v})}{\beta'(\tilde{v})}\right)\right\} w_x
\end{aligned} \tag{4.20}
$$

where

$$
c(x,t) = -\frac{f(v) - f(\tilde{v})}{v - \tilde{v}} + \frac{\beta'(v) - \beta'(\tilde{v})}{v - \tilde{v}}\tilde{v}_t,
$$

if we set $h(x,t) = e^{-\gamma t}w$ where γ is chosen later, then h satisfies the following equation:

$$
\begin{aligned}
&\beta'(v)h_t - h_{xx} + \{\gamma\beta'(v) + c\}h \\
&\quad = \left\{\beta'(\tilde{v})\left(k' - \frac{g'(\tilde{v})}{\beta'(\tilde{v})}\right) + \beta'(v)\left(k' - \frac{g'(v)}{\beta'(v)}\right)\right\} e^{-\gamma t}v_x \\
&\qquad - \left\{\beta'(\tilde{v})\left(k' - \frac{g(v)}{\beta'(\tilde{v})}\right)\right\} h_x.
\end{aligned} \tag{4.21}
$$

Since $\beta'(v) > 0$ and $c < \infty$, choosing γ large enough, we get

$$
\gamma\beta'(v) + c > 0. \tag{4.22}
$$

On the other hand, as $u(x,t) \ge 1/n + \Phi(1/n)t$ for $(x,t) \in [-n,n] \times [0,T')$ and $v(n - k(t),t) = u(n,t) = 1/n + \Phi(1/n)t$, we obtain

$$
\begin{aligned}
h(n-k(t),t) &= e^{-\gamma t}\{v(n-k(t),t) - \sigma_a v(n-k(t),t)\} \\
&= e^{-\gamma t}\left\{\frac{1}{n} + \Phi\left(\frac{1}{n}\right)t - \sigma_a v(n-k(t),t)\right\} \le 0
\end{aligned} \tag{4.23}
$$

and

$$h(a,t) = e^{-\gamma t}\{v(a,t) - v(a,t)\} = 0. \tag{4.24}$$

Noting the condition on φ_n in Lemma 2.2, we also obtain

$$\begin{aligned} h(x,0) &= u_n(x + k(0), 0) - \sigma_a u_n(x + k(0), 0) \\ &= \varphi_n(x) - \sigma_a \varphi_n(x) \leq 0 \quad \text{for each } x \in [a,n]. \end{aligned} \tag{4.25}$$

We claim that $h \leq 0$ in $\cup_{0 \leq t \leq T'}[a, n - k(t)] \times \{t\}$. Suppose

$$(\bar{x}, \bar{t}) \in \cup_{0 < t \leq T'}(a, n - k(t)) \times \{t\}$$

is a maximum point and $h(\bar{x}, \bar{t}) > 0$. Then

$$h_t(\bar{x}, \bar{t}) \geq 0, \quad h_{xx}(\bar{x}, \bar{t}) \leq 0, \quad h_x(\bar{x}, \bar{t}) = 0, \tag{4.26}$$

namely,

$$v(\bar{x}, \bar{t}) > \tilde{v}(\bar{x}, \bar{t}), \tag{4.27}$$

$$v_x(\bar{x}, \bar{t}) = \tilde{v}_x(\bar{x}, \bar{t}). \tag{4.28}$$

Assume $\bar{x} \geq \eta_n(\bar{t}) - k(\bar{t})$. Then

$$v_x(\bar{x}, \bar{t}) \leq 0.$$

Noting this, (4.17), and (4.26), we see that

$$\begin{aligned} &\beta'(v)h_t - h_{xx} + \{\gamma\beta'(v) + c\}h \\ &> \left\{\beta'(\tilde{v})\left(k' - \frac{g'(\tilde{v})}{\beta'(\tilde{v})}\right) + \beta'(v)\left(k' - \frac{g'(v)}{\beta'(v)}\right)\right\} e^{-\gamma t} v_x \\ &\quad - \left\{\beta'(\tilde{v})\left(k' - \frac{g(v)}{\beta'(\tilde{v})}\right)\right\} h_x. \end{aligned}$$

This contradicts (4.21).

On the other hand, assume $\bar{x} < \eta_n(\bar{t}) - k(\bar{t})$. Then $v_x(\bar{x}, \bar{t}) > 0$ and $v_x(\bar{x}, \bar{t}) < 0$. These results contradict (4.28). Hence, we obtain $h \leq 0$, that is,

$$w(x,t) \leq 0, \qquad (x,t) \in [a, n - k(t)) \times [0, T'], \tag{4.29}$$

or

$$u_n(x + k(t), t) \leq u_n(2a - x + k(t), t), \qquad (x,t) \in [a, n - k(t)] \times [0, T']. \tag{4.30}$$

Here, if $n \to \infty$, then

$$u(x + k(t), t) \leq u(2a - x + k(t), t) \quad \text{for } (x,t) \in [a, \infty) \times [0, T']. \tag{4.31}$$

Putting $x' = x + k(t), a' = a + k(t)$, and noting $k(t) \leq k(T)$, we obtain for each $a' \in [a_1 + k(T), \infty)$

$$u(x', t) \leq \sigma_{a'} u(x', t) \quad \text{for } (x', t) \in [0, T'].$$

Since this shows that $u(x, t)$ is a decreasing function in $x \in [a_1 + k(T), \infty)$ for $t \in [0, T']$, we get

$$\eta(t) \leq a_1 + k(T).$$

As $T' \in (0, T)$ is chosen arbitrarily, we conclude that

$$\eta(t) \leq a_1 + k(T) \quad \text{for } t \in [0, T). \tag{4.32}$$

Hence, we get

$$\eta_0 = \lim_{t \uparrow T} \eta(t) \leq a_1 + k(T),$$

and noting Theorem 3.4, we obtain

$$S = \{\eta_0\}.$$

Therefore, by virtue of Lemma 1.6, we also obtain (4.14). The proof is complete. □

DYNAMICAL BEHAVIOR OF SOLUTIONS OF A SEMILINEAR HEAT EQUATION WITH NONLOCAL SINGULARITY *

KENG DENG†

Abstract. The heat equation with a nonlocal nonlinearity $u_t = u_{xx} + \varepsilon\|u(\cdot,t)\|^q/(1-u), 0 < x < 1, \varepsilon, q > 0$, subject to $u(0,t) = u(1,t) = 0$ is studied. Stability-instability is analyzed and finite time quenching results are given. Discussions are also extended to more general problems.

Key words. nonlocal parabolic equation, equilibrium state, stability, quenching, global existence

AMS subject classifications. 35K05, 35K20, 35K55, 35K57, 35K60

1. Introduction.

In this paper, the following initial-boundary value problem is considered:

$$\text{(D)}\qquad \begin{aligned} u_t &= u_{xx} + \varepsilon\|u(\cdot,t)\|^q/(1-u), && 0 < x < 1, \quad t > 0,\\ u(0,t) &= u(1,t) = 0, && t > 0,\\ u(x,0) &= u_0(x), && 0 \le x \le 1. \end{aligned}$$

Here $\varepsilon, q > 0$ and $u_0(x)$ is a continuous function with $u_0(0) = u_0(1) = 0$. Moreover, we take

$$\|u(\cdot,t)\| = \int_0^1 |u(x,t)|\,dx$$

and require that $0 \le u_0 < 1$. Then, by the maximum principle, $u(\cdot,t) \ge 0$ for all t in the existence interval.

There are two reasons for considering this problem. One comes from the physical motivation, since the above problem is closely related to a popular model arising in the study of a polarization phenomenon in ionic conductors as follows (in our notation):

$$\text{(K)}\qquad \begin{aligned} u_t &= u_{xx} + \varepsilon/(1-u), && 0 < x < 1, \quad t > 0,\\ u(0,t) &= u(1,t) = 0, && t > 0,\\ u(x,0) &= 0, && 0 \le x \le 1. \end{aligned}$$

In [5], the following were proved for (K):

(a) If $\varepsilon > 8$, there is a finite time T such that $\lim_{t\to T^-} u(\frac{1}{2},t) = 1$;

(b) Whenever (a) holds, $\lim_{t\to T^-} \max_x u_t(x,t) = +\infty$.

This kind of phenomenon is known as quenching, that is, the solution of the equation remains bounded, whereas its derivatives blow up at some moment. It is easily seen that (K) is a special case of (D) (when $q = 0, u_0(x) \equiv 0$). Furthermore, the nonlocal term $\int_0^1 |u(x,t)|\,dx$ can be treated as an average value of $u(x,t)$ on $[0,1]$, which means that we intend to use all the information over the whole interval. Thus, as many other nonlocal mathematical models have been formulated from physical phenomena over

* Received by the editors December 24, 1991; accepted for publication (in revised form) May 12, 1993.

† Department of Mathematics, University of Southwestern Louisiana, Lafayette, Louisiana 70504-1010.

the last few years, a more precise description of the "real world" may be expected. Actually, we shall see that the nonlocal nonlinearity has a remarkable effect on the dynamical behavior of solutions.

The other reason for investigating problem (D) comes from a purely mathematical point of view. Since 1975, when the results for (K) appeared, problem (K) and its various generalizations have been extensively studied (see [6], [7], and the literature cited therein). However, to the best of our knowledge, no one has done any problem of the type described here. Due to the presence of the nonlocal term $\|u(\cdot,t)\|^q$ in the equation, the discussion becomes more complicated, and certain conventional arguments may not apply. Therefore, we want to undertake a study.

The plan of our paper is as follows: in the next section, we present the comparison theorem and local existence of solutions for (D). In §3, we characterize the set of stationary solutions of (D). In §4, we establish stability and quenching results for (D). Finally, we discuss more general problems.

2. Comparison and local existence. For simplicity, let $D_T = (0,1) \times (0,T)$ and $D_T \cup \Gamma_T = [0,1] \times [0,T)$. We begin with the definitions of subsolution and supersolution of (D).

DEFINITION. *A function $u(x,t)$ is called a subsolution of* (D) *on D_T if $u \in C^{2,1}(D_T) \cap C(D_T \cup \Gamma_T)$ satisfies*

$$\text{(C)} \qquad \begin{aligned} u_t &\le u_{xx} + \varepsilon\|u(\cdot,t)\|^q/(1-u), && 0<x<1, \quad 0<t<T, \\ u(x,t) &\le 0, && x=0,1, \quad 0<t<T, \\ u(x,0) &\le u_0(x), && 0 \le x \le 1. \end{aligned}$$

A supersolution is defined by (C) *with reversed inequalities.*

In the sequel, we shall use the comparison principle to conduct our discussion. For this reason, we state the following theorem.

THEOREM 2.1. *Let $u(<1)$ be a subsolution and $v(<1)$ be a supersolution of problem* (D). *Then $u \le v$ on D_T.*

Proof. Suppose $u, v \le \delta < 1$ on D_T. Then $f(s) = 1/(1-s)$ is continuously differentiable for $0 \le s \le \delta$, and the conclusion follows from the relevant theorem in [3].

COROLLARY 2.2. *If $u_0'' + \varepsilon\|u_0\|^q/(1-u_0) \ge 0 (\le 0)$ on $(0,1)$, then $u_t(x,t) \ge 0 (\le 0)$ on D_T.*

Proof. The condition on u_0 implies that u_0 is a subsolution (supersolution) of (D). Thus $u(x,t) \ge u_0(x) (\le u_0(x))$ on D_T. Then let $v(x,t) = u(x,t+h) (0 < h < \frac{T}{2})$. In D_{T-h}, we find that $v(x,0) = u(x,h) \ge u_0(x) (\le u_0(x))$, and $v(x,t)$ is a solution, and thus a supersolution (subsolution), of (D). It follows that $u(x,t+h) \ge u(x,t)$ $(\le u(x,t))$ for $h > 0$ arbitrarily small, and hence $u_t \ge 0 (\le 0)$.

By means of the comparison theorem, we now establish the local existence of solutions of (D).

THEOREM 2.3. *For nontrivial initial datum, there exists a $T_0 < \infty$ such that problem* (D) *has a unique nonnegative solution on D_{T_0}.*

Proof. Clearly $u \equiv 0$ is a subsolution. If there is a supersolution v with $v < 1$ on D_{T_0} for some $T_0 < \infty$, then by the comparison, any solution $u(x,t)$ should be bounded away from one. Recalling the local existence theorem in [3], we then obtain the desired result.

Note that if $v < 1$ then $\|v(\cdot,t)\|^q < 1$ on $0 < t < T_0$ for any $q > 0$. Thus it suffices to find a solution of the ordinary differential equation

$$\text{(O)} \qquad \frac{dv}{dt} = \frac{\varepsilon}{1-v}, \qquad v(0) = \max_{0 \le x \le 1} u_0(x).$$

Problem (O) has a solution of the form $v = 1 - [(1 - v(0))^2 - 2\varepsilon t]^{1/2}$. For sufficiently small t, v remains bounded by one and hence v is an apppropriate supersolution.

3. The stationary solutions. For the stationary solutions of (D), we need to solve

$$\text{(S)} \qquad \begin{aligned} &v'' + \varepsilon \|v\|^q/(1-v) = 0, \qquad 0 < x < 1, \\ &v(0) = v(1) = 0. \end{aligned}$$

If $v(x)$ is a nonnegative classical solution of (S), then by the strong maximum principle, $v(x) > 0$, and consequently $v'' < 0$ on $(0,1)$. Thus v has exactly one maximum at $\xi \in (0,1)$. For convenience, let

$$F(s) = \log \frac{1}{1-s}.$$

Then v also solves

$$\tfrac{1}{2}(v'(x))^2 + \varepsilon \|v\|^q F(v(x)) = \varepsilon \|v\|^q F(\mu), \tag{3.1}$$

where $\mu = v(\xi)$.

Integrating (3.1), we have

$$\int_v^\mu \frac{1}{\sqrt{F(\mu) - F(\eta)}}\, d\eta = \sqrt{2\varepsilon}\|v\|^{q/2}|\xi - x|. \tag{3.2}$$

Since $v(0) = v(1) = 0$, from

$$\int_0^\mu \frac{1}{\sqrt{F(\mu) - F(\eta)}}\, d\eta = \sqrt{2\varepsilon}\|v\|^{q/2}\xi = \sqrt{2\varepsilon}\|v\|^{q/2}(1-\xi), \tag{3.3}$$

it follows that $\xi = \frac{1}{2}$.

Let

$$G(\mu) = \int_0^\mu \frac{1}{F(\mu) - F(\eta)}\, d\eta.$$

Then (3.3) is equivalent to

$$G(\mu) = \sqrt{\varepsilon/2}\|v\|^{q/2}. \tag{3.4}$$

Note that $v(1-x)$ is also a solution of (S). Combining this fact with (3.2) ensures that there is exactly one solution of (S) with $v(\frac{1}{2}) = \mu$. Thus for $0 < x \le \frac{1}{2}$, $v(x)$ is implicitly given by

$$\int_0^{v(x)} \frac{1}{\sqrt{F(\mu) - F(\eta)}}\, d\eta = \sqrt{2\varepsilon}\|v\|^{q/2}x \tag{3.5}$$

and by $v(x) = v(1-x)$ if $\frac{1}{2} < x < 1$, with μ and $\|v\|$ satisfying (3.4). Therefore, we should focus our attention on (3.4). However, for each given ε, in order to count the

number of μ, we need an additional relation between μ and ε that is independent of $\|v\|$. To this end, we let

$$y = \int_0^x (1 - v(s))\, ds, \qquad Y = \int_0^1 (1 - v(s))\, ds = 1 - \|v\|. \tag{3.6}$$

Thus, in lieu of (S), with $h(y) = (1 - v(x(y)))^2$, we find

$$\begin{aligned} &h_{yy} - 2\varepsilon \|v\|^q / h = 0, \qquad 0 < y < Y, \\ &h(0) = h(Y) = 1. \end{aligned} \tag{3.7}$$

Then, using a scale change of variable $z = y/Y$, and setting $w(z) = 1 - h(y)$, we obtain

$$\begin{aligned} &w_{zz} + 2\varepsilon \|v\|^q (1 - \|v\|)^2 / (1 - w) = 0, \qquad 0 < z < 1, \\ &w(0) = w(1) = 0. \end{aligned} \tag{3.8}$$

Note that if $\lambda = \max_{0 \le z \le 1} w(z)$, then $\lambda = 2\mu - \mu^2$ with $\mu = \max_{0 \le x \le 1} v(x)$. By a similar reasoning, we get

$$G(\lambda) = \sqrt{\varepsilon} \|v\|^{q/2} (1 - \|v\|). \tag{3.9}$$

Then the combination of (3.4) and (3.9) yields

$$\|v\| = (\sqrt{2} G(\mu) - G(\lambda)) / (\sqrt{2} G(\mu)). \tag{3.10}$$

Substituting (3.10) into (3.4) and letting

$$K(\mu) = 2 \left(\frac{\sqrt{2} (G(\mu))^{1 + (2/q)}}{\sqrt{2} G(\mu) - G(\lambda)} \right)^q,$$

we then have

$$K(\mu) = \varepsilon. \tag{3.11}$$

On the other hand, for given ε, if μ satisfies (3.11) and $v(x)$ satisfies

$$\int_0^{v(x)} \frac{1}{\sqrt{F(\mu) - F(\eta)}}\, d\eta = 2G(\mu) x,$$

on $0 < x \le \frac{1}{2}$ and $v(x) = v(1 - x)$ on $\frac{1}{2} < x < 1$, then it is easily seen that $v(0) = v(1) = 0, v(\frac{1}{2}) = \mu$, and

$$v'' + 2G^2(\mu)/(1 - v) = 0.$$

Repeating an argument similar to that leading to (3.8), we have

$$2G^2(\mu) = \varepsilon \|v\|^q,$$

which implies that $v(x)$ is a solution of (S). Hence the number of solutions of (3.11) is the same as that of (S).

To help determine the cardinality of the set of solutions of (3.11), we present some lemmas.

LEMMA 3.1. $\sqrt{2}G(\mu) > G(\lambda)$ *for* μ *in* $(0,1)$.

Proof. Since

$$G(\lambda) = \int_0^\lambda \frac{1}{\sqrt{F(\lambda) - F(\tau)}}\, d\tau \quad \text{and} \quad F(\lambda) = \log\frac{1}{1-\lambda} = \log\frac{1}{(1-\mu)^2} = 2F(\mu),$$

by using the change of variable $(1-\eta)^2 = 1 - \tau$, we obtain

$$G(\lambda) = \sqrt{2}\int_0^\mu \frac{1-\eta}{\sqrt{F(\mu) - F(\eta)}}\, d\eta,$$

and so

$$\sqrt{2}G(\mu) - G(\lambda) = \sqrt{2}\int_0^\mu \frac{\eta}{\sqrt{F(\mu) - F(\eta)}}\, d\eta > 0.$$

Since $G(\mu) > 0$ on $(0,1)$, it follows that $K(\mu) > 0$ on $(0,1)$. To investigate the behavior of $K(\mu)$ near $\mu = 0$ and $\mu = 1$, we use a transformation $\theta = \theta(\mu) = [\log(1/(1-\mu))]^{1/2}$. Since $\theta(\mu)$ is strictly increasing on $(0,1)$, we then have that for $\theta \in (0,\infty)$,

$$G(\mu) = 2e^{-\theta^2}\int_0^\theta e^{\sigma^2} d\sigma \tag{3.12}$$

and

$$G(\lambda) = 2e^{-2\theta^2}\int_0^{\sqrt{2}\theta} e^{\sigma^2} d\sigma. \tag{3.13}$$

By this change of variable, we find that

$$K(\mu) = H(\theta) = 2^{3+(q/2)}\left(e^{-\theta^2}\int_0^\theta e^{\sigma^2} d\sigma\right)^{2+q}\left(\sqrt{2}e^{-\theta^2}\int_0^\theta e^{\sigma^2} d\sigma - e^{-2\theta^2}\int_0^{\sqrt{2}\theta} e^{\sigma^2} d\sigma\right)^{-q}.$$

Then from L'Hôpital's rule

$$K(1) = \lim_{\theta\to\infty} H(\theta) = 0 \quad \text{for } q > 0 \tag{3.14}$$

and

$$K(0) = \lim_{\theta\to 0^+} H(\theta) = \begin{cases} 0, & \text{if } 0 < q < 1, \\ 12, & \text{if } q = 1, \\ +\infty & \text{if } q > 1. \end{cases} \tag{3.15}$$

LEMMA 3.2. *There is a* $\mu_0 \in (0,1)$ *such that* $1/\sqrt{F(\mu)} > G(\mu)$ *for* $0 < \mu < \mu_0$ *and* $1/\sqrt{F(\mu)} < G(\mu)$ *for* $\mu_0 < \mu < 1$.

Proof. $G(\mu)$ can be written in the form

$$G(\mu) = \int_0^\mu \frac{f(\eta)}{f(\eta)\sqrt{F(\mu) - F(\eta)}}\, d\eta,$$

where $f(\eta) = F'(\eta) = 1/1 - \eta$.

Upon integration by parts, we obtain

$$G(\mu) = 2\sqrt{F(\mu)} - 2\int_0^\mu \sqrt{F(\mu) - F(\eta)}\, d\eta. \tag{3.16}$$

Thus on $(0,1)$, $G'(\mu)$ exists and equals

$$\begin{aligned} G'(\mu) &= \frac{f(\mu)}{\sqrt{F(\mu)}} - f(\mu)\int_0^\mu \frac{1}{\sqrt{F(\mu) - F(\eta)}}\, d\eta \\ &= f(\mu)\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right). \end{aligned} \tag{3.17}$$

By (3.12), it is easy to check that $G(0) = G(1) = 0$. Since $G(\mu) > 0$ on $(0,1)$, there is at least a μ_0 with $G'(\mu_0) = 0$. If we can show that on $(0,1)$, $G'(\mu)$ has at most one zero, then it follows that $G'(\mu)$ is positive on $(0,\mu_0)$ and negative on $(\mu_0,1)$, and consequently, making use of (3.17) yields the desired result. To this end, we differentiate $G(\mu)$ twice to get

$$G''(\mu) = f'(\mu)\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right) + f(\mu)\left(-\frac{1}{2(F(\mu))^{3/2}} - \frac{1}{\sqrt{F(\mu)}} + G(\mu)\right).$$

At any point μ_0 where $G'(\mu) = 0$, we can see that $G''(\mu_0) = -f(\mu_0)/(2(F(\mu_0))^{3/2}) < 0$, which means $G(\mu)$ can only attain its maximum on $(0,1)$. Thus the proof is complete. □

Remark 3.1. A numerical computation gives $\mu_0 = 0.574$.

In order to analyze the monotonicity of $K(\mu)$, we turn our attention to $K'(\mu)$. By (3.17) and

$$\frac{d}{d\mu}G(\lambda(\mu)) = 2(1-\mu)f(\lambda)\left(\frac{1}{\sqrt{F(\lambda)}} - G(\lambda)\right) = 2f(\mu)\left(\frac{1}{\sqrt{2F(\mu)}} - G(\lambda)\right), \tag{3.18}$$

a straightforward calculation gives

$$\begin{aligned} K'(\mu) &= 2^{1+(q/2)}q(G(\mu))^{1+q}f(\mu) \\ &\quad\times\left\{\left(1+\frac{2}{q}\right)\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right)\left(\sqrt{2}G(\mu) - G(\lambda)\right)\right. \\ &\qquad\left. - G(\mu)\left(2G(\lambda) - \sqrt{2}G(\mu)\right)\right\} \\ &\quad\times(\sqrt{2}G(\mu) - G(\lambda))^{-(1+q)}. \end{aligned} \tag{3.19}$$

Define

$$J(\mu) = \left(1+\frac{2}{q}\right)\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right)(\sqrt{2}G(\mu) - G(\lambda)) - G(\mu)(2G(\lambda) - \sqrt{2}G(\mu)); \tag{3.20}$$

then it turns out that the sign of $K'(\mu)$ is the same as that of $J(\mu)$. However, the sign analysis of J is complicated. We can only obtain some incomplete results; others rely on numerical evidence.

Suppose that there is a $\mu_1 \in (0,1)$ such that $J(\mu_1) = 0$. Then a routine computation shows that at μ_1

$$J'(\mu) = f(\mu)\left\{ -\frac{1}{2}\left(1+\frac{2}{q}\right)(F(\mu))^{-3/2}(\sqrt{2}G(\mu) - G(\lambda)) + \left(\frac{2-q}{q}\right)G(\lambda)\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right)\right\}. \tag{3.21}$$

As a consequence, when $q = 2$, by Lemma 3.1 we see that $J'(\mu_1) < 0$, which implies that $K(\mu)$ should always attain its maximum on $(0,1)$. This is impossible since $\lim_{\mu\to 0^+} K(\mu) = +\infty$. Hence $J(\mu) < 0$ and $K(\mu)$ is decreasing for $0 < \mu < 1$ if $q = 2$.

Then, in view of Lemma 3.2, for $\mu_0 < \mu < 1$ and $q < 2$ or $0 < \mu < \mu_0$ and $q > 2$, we find

$$J(\mu) < 2\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right)(\sqrt{2}G(\mu) - G(\lambda)) - G(\mu)(2G(\lambda) - \sqrt{2}G(\mu)) < 0,$$

which shows that $K(\mu)$ is decreasing on $(\mu_0, 1)$ for $q < 2$ or on $(0, \mu_0)$ if $q > 2$.

We now write $J(\mu)$ in (3.20) as

$$J(\mu) = \frac{2}{q}\left(\frac{1}{\sqrt{F(\mu)}} - G(\mu)\right)\left(\sqrt{2}G(\mu) - G(\lambda)\right) + \frac{1}{\sqrt{F(\mu)}}(\sqrt{2}G(\mu) - G(\lambda) - \sqrt{F(\mu)}G(\mu)G(\lambda)), \tag{3.22}$$

and set

$$J_1(\mu) = \sqrt{2}G(\mu) - G(\lambda) - \sqrt{F(\mu)}G(\mu)G(\lambda). \tag{3.23}$$

LEMMA 3.3. *$J_1(\mu) < 0$ on $(0,1)$.*

Proof. Noting Lemmas 3.1 and 3.2 and the result for the case $q = 2$, we can see that $J_1(\mu) < 0$ on $(0, \mu_0]$. For $\mu_0 < \mu < 1$, we have

(3.24)

$$\begin{aligned} J_1'(\mu) &= f(\mu)\left(G(\lambda) - 2\sqrt{2}G(\mu) - \frac{1}{2\sqrt{F(\mu)}}G(\mu)G(\lambda) + 3\sqrt{F(\mu)}G(\mu)G(\lambda)\right) \\ &= f(\mu)(-2J_1(\mu) + G(\lambda)J_2(\mu)), \end{aligned}$$

where

$$J_2(\mu) = \left(\sqrt{F(\mu)} - \frac{1}{2\sqrt{F(\mu)}}\right)G(\mu) - 1, \tag{3.25}$$

with

$$J_2'(\mu) = f(\mu)\left(-J_2(\mu) + \frac{1}{2\sqrt{F(\mu)}}\left(G(\mu) - \frac{1}{\sqrt{F(\mu)}}\right) + \frac{G(\mu)}{4(F(\mu))^{3/2}}\right). \tag{3.26}$$

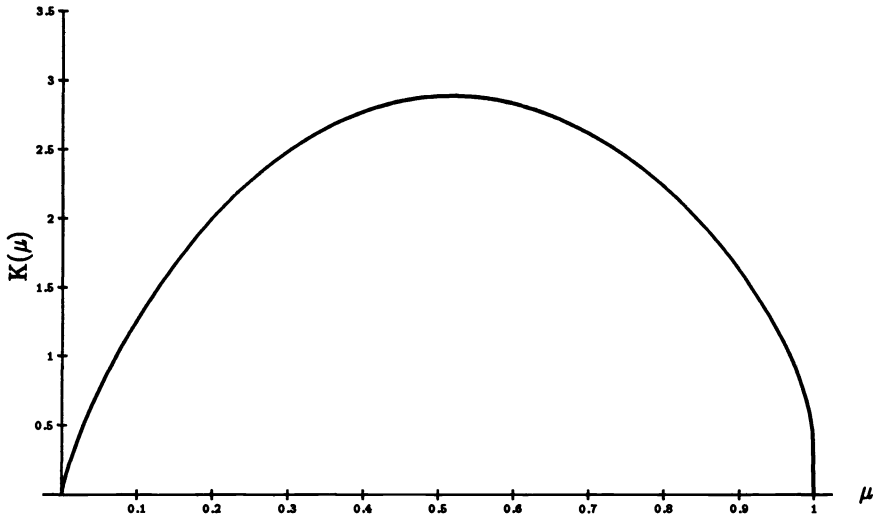

FIG. 1. $K(\mu)$ *for* $q = 0.2$.

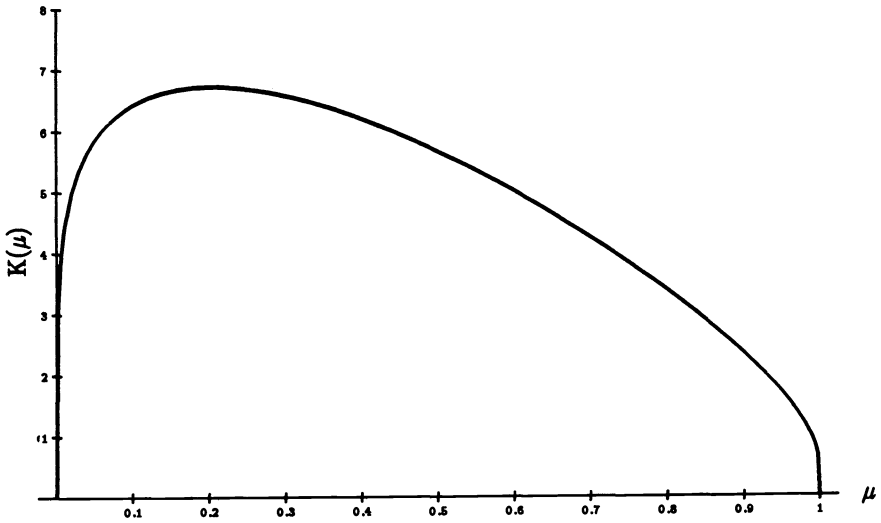

FIG. 2. $K(\mu)$ *for* $q = 0.8$.

If $J_1(\mu) \geq 0$ somewhere in $(\mu_0, 1)$, then there is at least one point $\mu_2(\mu_0 < \mu_2 < 1)$ such that $J_1(\mu_2) = 0$ and $J_1'(\mu_2) \geq 0$. It follows from (3.24) that $J_2(\mu_2) \geq 0$. Then by (3.26) and recalling Lemma 3.2, we can see that $J_2(\mu) > 0$ for all $\mu \in (\mu_2, 1)$, which contradicts the fact that $J_2 < 0$ near $\mu = 1$, since by L'Hôpital's rule $\lim_{\mu \to 1^-} J_2(\mu) = 0$ and $\lim_{\mu \to 1^-} J_2'(\mu) = +\infty$.

By means of (3.22) and all the lemmas, together with the fact that $J(\mu) < 0$ on $(0, \mu_0)$ if $q > 2$, we have the following theorem.

THEOREM 3.4. *If* $q \geq 2$, *there is a unique solution of* (S) *for each given* $\varepsilon > 0$.

Although we cannot provide a rigorous analysis in case $0 < q < 2$, the asymptotic formulas (3.15)–(3.16) and the numerical results of Figs. 1–3, allow us to assert the

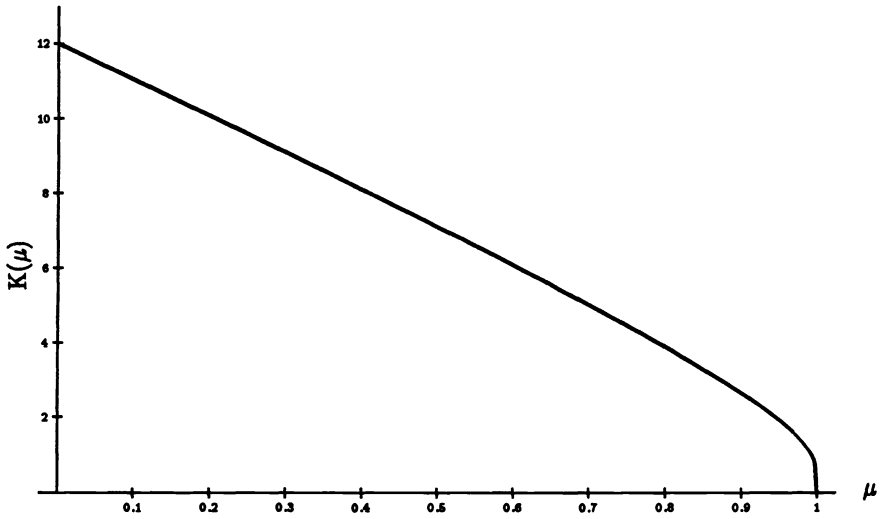

FIG. 3. $K(\mu)$ *for* $q = 1.0$.

following:

(C1) If $0 < q < 1$, there is an $\varepsilon(q)$ such that
  (a) if $\varepsilon > \varepsilon(q)$, there are no positive stationary solutions;
  (b) if $\varepsilon = \varepsilon(q)$, there is a unique solution; and
  (c) if $\varepsilon < \varepsilon(q)$, there are exactly two solutions.

(C2) If $q = 1$, we have the following:
  (a) if $\varepsilon \geq 12$, there are no positive stationary solutions; and
  (b) if $\varepsilon < 12$, there is exactly one solution.

(C3) If $1 < q < 2$, for every $\varepsilon > 0$, there is exactly one solution.

Remark 3.2. If one can verify (C2), then the validity of (C3) follows, since by (3.22) $J(\mu)$ is a decreasing function of q for $0 < \mu < \mu_0$. On the other hand, for $0 < q < 1$, it is easy to check that $\lim_{\mu \to 0+} K'(\mu) = +\infty$; hence (C1) (c) holds at least for small $\varepsilon > 0$.

Remark 3.3. In view of (3.1), (S) has no nonclassical solution $v_s(x)$ in the sense that $v_s(x)$ solves the equation in (S) classically on $(0,1)\backslash\{x = \frac{1}{2}\}$, but $v_s(\frac{1}{2}) = 1$.

4. Stability and quenching. Throughout this section, C1, C2, and C3 will be assumed. In order to get statements about the stability of solutions of (S) or the quenching result for problem (D), we first establish a relationship between solutions of (D) and those of (S).

LEMMA 4.1. *Suppose that* $u(x,t)$ *is monotone in* t *and* $\lim_{t \to \infty} u(x,t) = v(x)(<1)$ *exists. Then* $v(x)$ *is a classical solution of* (S).

Proof. Let

$$G(x,y) = \begin{cases} x(1-y), & 0 \leq x \leq y \leq 1, \\ y(1-x), & 0 \leq y \leq x \leq 1. \end{cases}$$

G is the Green's function for $-(d^2/dy^2)$ with Dirichlet boundary conditions. Since $u(x,t)$ is uniformly bounded and monotone in t, for fixed $x \in [0,1]$,

$$\lim_{t \to \infty} \int_0^1 G(x,y)u(y,t)\,dy = \int_0^1 G(x,y)v(y)\,dy,$$

and then

$$\frac{\partial}{\partial t}\int_0^1 G(x,y)u(y,t_n)\,dy \to 0$$

for some sequence $t_n \to \infty$. On the other hand,

$$\begin{aligned}\frac{\partial}{\partial t}\int_0^1 G(x,y)u(y,t)\,dy &= \int_0^1 G(x,y)u_t(y,t)\,dy \\ &= -u(x,t) + \varepsilon\|u(\cdot,t)\|^q \int_0^1 G(x,y)/(1-u(y,t))\,dy \\ &\to -v(x) + \varepsilon\|v\|^q \int_0^1 G(x,y)/(1-v(y))\,dy\end{aligned}$$

as $t \to \infty$.

Thus

$$v(x) = \varepsilon\|v\|^q \int_0^1 G(x,y)/(1-v(y))\,dy.$$

Moreover, since $v(x) < 1$ on $(0,1)$, $v(x)$ and $v'(x)$ are absolutely continuous, and hence $v(x)$ is a classical solution of (S).

By virtue of the above lemma, we can obtain a complete stability-instability result for stationary solutions of (D). This time, we treat the solution of (S) as a function of x depending on the parameter ε and denote it $v(x,\varepsilon)$.

LEMMA 4.2. *In the case* $0 < q < 1$, *if* $\varepsilon < \varepsilon(q)$, *the two solutions of* (S) *are ordered.*

Proof. Let $\mu_-(\varepsilon) < \mu_+(\varepsilon)$ and denote the corresponding solutions of (S) by $v_-(x,\varepsilon)$ and $v_+(x,\varepsilon)$, respectively. Assuming the assertion is not true, it follows that there is an $\bar{x} \in (0, \frac{1}{2})$ such that $v_-(\bar{x},\varepsilon) > v_+(\bar{x},\varepsilon)$. We now choose a $\delta(\delta < \varepsilon)$ so small that $v_-(x,\delta) \le v_-(x,\varepsilon)$ and $v_-(x,\delta) \le v_+(x,\varepsilon)$. Let $u(x,t,\varepsilon)$ be a solution of (D) with $u_0(x,\varepsilon) = v_-(x,\delta)$. Via the comparison theorem, we then find that

$$u(x,t,\varepsilon) \le v_-(x,\varepsilon) \quad \text{and} \quad u(x,t,\varepsilon) \le v_+(x,\varepsilon).$$

Moreover,

$$\begin{aligned}u_0'' + \varepsilon\|u_0\|^q/(1-u_0) &= v_-''(x,\delta) + \varepsilon\|v_-(\cdot,\delta)\|^q/(1-v_-(x,\delta)) \\ &> v_-''(x,\delta) + \delta\|v_-(\cdot,\delta)\|^q/(1-v_-(x,\delta)) \\ &= 0.\end{aligned}$$

Hence, recalling Corollary 2.2, we have $u_t(x,t,\varepsilon) \ge 0$ in D_T. By Lemma 4.1, $\lim_{t\to\infty} u(x,t,\varepsilon)$ exists and should be equal to one of the two solutions of (S), which leads to a contradiction, since $v_+(\frac{1}{2},\varepsilon) > v_-(\frac{1}{2},\varepsilon)$.

THEOREM 4.3. *Let* $v(x,\varepsilon)(<1)$ *be a positive solution of* (S) *on some* ε *interval* $[a,b]$, *and let* $\mu(\varepsilon) = v(\frac{1}{2},\varepsilon)$. *Then, if* $u'(\varepsilon) > 0$ *on* $[a,b]$, *the solution is stable, whereas it is unstable if* $\mu'(\varepsilon) < 0$.

Proof. For the case $\mu'(\varepsilon) > 0$ we first show that $v(x,\varepsilon_1) < v(x,\varepsilon_2)$ on $(0,1)$ for $a \le \varepsilon_1 < \varepsilon_2 \le b$.

From $\mu'(\varepsilon) > 0$, it follows that $\mu(\varepsilon_1) < \mu(\varepsilon_2)$ if $a \le \varepsilon_1 < \varepsilon_2 \le b$. In view of the conclusions in (C1), (C2), and (C3) in the previous section, we restrict our attention

to the case $0 < q < 1$. It is clear that $\mu'(\varepsilon) > 0$ can only occur in $(0, \mu_0)$, where μ_0 is the critical number in Lemma 3.2, since $K'(\mu) < 0$ in $[\mu_0, 1)$ if $0 < q < 2$. Noting the fact that $G'(\mu) > 0$ in $(0, \mu_0)$, by (3.4) we see that $\varepsilon_1 \|v(\cdot, \varepsilon_1)\|^q < \varepsilon_1 \|v(\cdot, \varepsilon_2)\|^q$. Then from (3.5), we find that for $0 < x \leq \frac{1}{2}$,

$$\int_0^{v(x,\varepsilon_1)} \frac{1}{\sqrt{F(\mu(\varepsilon_1)) - F(\eta)}}\, d\eta < \int_0^{v(x,\varepsilon_2)} \frac{1}{\sqrt{F(\mu(\varepsilon_2)) - F(\eta)}}\, d\eta, \tag{4.1}$$

and consequently

$$\int_{v(x,\varepsilon_1)}^{v(x,\varepsilon_2)} \frac{1}{\sqrt{F(\mu(\varepsilon_2)) - F(\eta)}}\, d\eta > 0.$$

Since $v(x, \varepsilon) = v(1-x, \varepsilon)$ if $\frac{1}{2} < x < 1, v(x, \varepsilon_1) < v(x, \varepsilon_2)$ on $(0, 1)$ for $a \leq \varepsilon_1 < \varepsilon_2 \leq b$.

Let $u(x, t, \varepsilon_1)$ be a solution of (D) with $u_0(x, \varepsilon_1) = v(x, \varepsilon_2)$. Then on $(0, 1)$, we have

$$\begin{aligned} u_0'' + \varepsilon_1 \|u_0\|^q/(1 - u_0) &= v_{xx}(x, \varepsilon_2) + \varepsilon_1 \|v(\cdot, \varepsilon_2)\|^q/(1 - v(x, \varepsilon_2)) \\ &< v_{xx}(x, \varepsilon_2) + \varepsilon_2 \|v(\cdot, \varepsilon_2)\|^q/(1 - v(x, \varepsilon_2)) \\ &= 0. \end{aligned}$$

Hence $u_t \leq 0$. From the comparison principle and monotonicity of u, on $(0, 1)$ we also have

$$v(x, \varepsilon_1) \leq u(x, t, \varepsilon_1) \leq v(x, \varepsilon_2).$$

By Lemma 4.1, $w(x, \varepsilon_1) = \lim_{t \to \infty} u(x, t, \varepsilon_1)$ is a solution of (S) satisfying $v(x, \varepsilon_1) \leq w(x, \varepsilon_1) \leq v(x, \varepsilon_2)$, and in particular, $v(\frac{1}{2}, \varepsilon_1) \leq w(\frac{1}{2}, \varepsilon_1) \leq v(\frac{1}{2}, \varepsilon_2)$. But w is a solution of (S) with ε_1, and so $w(x, \varepsilon_1)$ is either $v(x, \varepsilon_1)$ or else the other solution, $v_+(x, \varepsilon_1)$. From the graph of $K(\mu) = \varepsilon$, it follows that $v_+(\frac{1}{2}, \varepsilon_1) > v(\frac{1}{2}, \varepsilon_2)$, which excludes the possibility that $w(x, \varepsilon_1) = v_+(x, \varepsilon_1)$. We thus show that $v(x, \varepsilon_1)$ is stable from above. With $\varepsilon_1 > \varepsilon_2$, in a similar manner, we can also prove that $v(x, \varepsilon_1)$ is stable from below.

If $\mu'(\varepsilon) < 0$, we know that $v(x, \varepsilon_2) < v(x, \varepsilon_1)$ in a subinterval $[x_0, x_1]$ contained in $(0, 1)$ for $a \leq \varepsilon_1 < \varepsilon_2 \leq b$. Let $u(x, t, \varepsilon_2)$ be a solution of (D) with $u_0(x, \varepsilon_2) = v(x, \varepsilon_1)$. Then on $(0, 1)$, we find that

$$\begin{aligned} u_0'' + \varepsilon_2 \|u_0\|^q/(1 - u_0) &= v_{xx}(x, \varepsilon_1) + \varepsilon_2 \|v(\cdot, \varepsilon_1)\|^q/(1 - v(x, \varepsilon_1)) \\ &> v_{xx}(x, \varepsilon_1) + \varepsilon_1 \|v(\cdot, \varepsilon_1)\|^q/(1 - v(x, \varepsilon_1)) \\ &= 0. \end{aligned}$$

Thus $u_t \geq 0$ on D_T. Consequently, $u(x, t, \varepsilon_2)$ is increasing in t, which indicates that $v(x, \varepsilon_2)$ is unstable. Similarly, it can be shown that with $\varepsilon_1 > \varepsilon_2, v(x, \varepsilon_2)$ is also unstable.

Making use of this theorem combined with the characterization of the stationary solutions in §3, we state the following.

(S1) For $0 < q < 1$, there are two branches of solutions of (S), one stable, the other unstable.

(S2) For $q \geq 1$, the unique solution is unstable.

Next we establish quenching and global existence results for problem (D).

THEOREM 4.4. *Assuming the conjecture at the end of* §3, *we have the following results.*

(I) *Let* $0 < q < 1$.

(a) *For* $\varepsilon < \varepsilon(q)$, *if* $0 < u_0(x) < v_+(x,\varepsilon)$ *on* $(0,1)$, *then* u *exists for all* $t > 0$ *and* $\lim_{t\to\infty} u(x,t) = v_-(x,\varepsilon)$: *if* $u_0 > v_+(x,\varepsilon)$ *on* $(0,1)$, *then* u *quenches in finite time.*

(b) *For* $\varepsilon = \varepsilon(q)$, *if* $0 < u_0 \le v(x,\varepsilon(q))$, *then* u *is global and* $\lim_{t\to\infty} u(x,t) = v(x,\varepsilon(q))$; *if* $u_0 > v(x,\varepsilon(q))$, *then* u *is not global.*

(c) *For* $\varepsilon > \varepsilon(q)$, *if* $u_0(x) > 0$ *on* $(0,1)$, *every solution quenches in finite time.*

(II) *Suppose* $q = 1$.

(a) *For* $\varepsilon < 12$, *if* $0 \le u_0(x) < v(x,\varepsilon)$, *then quenching does not occur and* $\lim_{t\to\infty} u(x,t) = 0$, *while quenching happens in finite time if* $u_0(x) > v(x,\varepsilon)$.

(b) *For* $\varepsilon \ge 12$, *every solution with positive datum on* $(0,1)$ *quenches in finite time.*

(III) *Assume* $q > 1$. *For any* $\varepsilon > 0$, *if* $0 \le u_0(x) < v(x,\varepsilon)$, *then* u *exists globally and* $\lim_{t\to\infty} u(x,t) = 0$, *whereas* u *quenches in finite time if* $u_0(x) > v(x,\varepsilon)$.

Proof. Without causing any confusion, we shall sometimes write the solution of (D) with an initial value u_0 as $u(x,t;u_0)$.

(I) (a) We choose $v_0 = v_-(x,\sigma)$ with $\sigma < \varepsilon$ and $w_0 = v_+(x,\delta)$ with $\delta > \varepsilon$ such that $v_0 \le u_0 \le w_0$ on $(0,1)$. Then, by comparison,

$$u(x,t;v_0) \le u(x,t;u_0) \le u(x,t;w_0).$$

On the other hand, by recalling Corollary 2.2, we can see that $u(x,t;v_0)$ is monotonically increasing while $u(x,t;w_0)$ is monotonically decreasing, since $v_0'' + \varepsilon\|v_0\|^q/(1-v_0) > 0$ and $w_0'' + \varepsilon\|w_0\|^q/(1-w_0) < 0$. Hence, both $\lim_{t\to\infty} u(x,t;v_0)$ and $\lim_{t\to\infty} u(x,t;w_0)$ exist and equal $v_-(x,\varepsilon)$; consequently, so does $\lim_{t\to\infty} u(x,t;u_0)$.

If $u_0(x) > v_+(x,\varepsilon)$, we can find a δ ($\delta < \varepsilon$) so close to ε that $u_0(x) \ge v_+(x,\delta)$. Then set $v_0(x) = v_+(x,\delta)$. We observe that $u_t(x,t;v_0) \ge 0$ on the existence interval wherever u exists. Thus, if u does not quench for all $t > 0$, as $t \to \infty, u(x,t)$ tends to $w(x)$, a stationary solution of (D) with $w(\frac{1}{2}) > v_+(\frac{1}{2},\varepsilon)$. However, in view of Remark 3.3, there are no more stationary solutions of (D) even in the weak sense. Hence u must quench in finite time.

(b) The proof for (b) is similar to that for (a) and hence is omitted.

(c) We choose a δ with $\delta < \varepsilon$ such that $v_0(x) = v_-(x,\delta) \le u_0(x)$. Then we have $u(x,t;u_0) \ge u(x,t;v_0)$. Since $u_t(x,t;v_0) \ge 0, u(x,t;v_0)$ can only exist in finite time, and the conclusion follows.

(II) (a) Since $0 \le u_0(x) < v(x,\varepsilon)$, there is a number $\delta > \varepsilon$ such that $u_0(x) \le v(x,\delta)$ and $\mu(\delta) < \mu(\varepsilon)$. Let $w_0(x) = v(x,\delta)$. Then the comparison theorem yields that $0 \le u(x,t;u_0) \le u(x,t;w_0)$. Because $u(x,t;w_0)$ is monotonically decreasing, as $t \to \infty, u(x,t;w_0)$ approaches a stationary solution of (D) other than $v(x,\varepsilon)$, which must be the null solution.

(b) By the same reason as for (c) of (I), the proof is left out.

(III) We can argue in a similar manner, hence the proof is omitted.

Remark. In [8], for (K) it was proved that there is a critical number ε_0 such that when $\varepsilon < \varepsilon_0 (= \varepsilon_0)$, with certain data, the solution of (K) converges to the smaller (unique) stationary solution, while quenching occurs if $\varepsilon > \varepsilon_0$. The same result holds for solutions of a plasma-type equation $u_t = (u^m)_{xx} + \varepsilon/(1-u)(0 < m < 1)$ [2] and for those of a quasilinear parabolic equation $u_t = u_{xx}/(1+u_x^2) + 1/(1-u)$ [4]. For our problem, when $0 < q < 1$, similar dynamical behavior of solutions can be observed, whereas there are notable differences if $q \ge 1$. This shows that within necessary limits,

the influence of a nonlocal term can be so minimized that results for purely local problems are preserved for nonlocal ones, although analyses are more complicated in general.

5. Further discussion. In this section we describe briefly how the results can be generalized to other cases. First we point out that for problem (D), if the L_1 norm is replaced by the L_p norm ($p > 1$), a similar assertion can still hold. For instance, if $0 < q < 1$, we may conclude that there are two numbers ε_0 and ε_1 ($\varepsilon_0 < \varepsilon_1$) such that when $\varepsilon \le \varepsilon_0$, certain solutions exist globally, while finite time quenching happens if $\varepsilon > \varepsilon_1$. Since by the Hölder inequality, $\|u(\cdot,t)\|_1^q \le \|u(\cdot,t)\|_p^q$, it follows that the solution with the L_p norm is a supersolution of that with the L_1 norm. Hence, if $\varepsilon > \varepsilon_1 = \varepsilon(q)$, every solution must quench. On the other hand, following an idea in [1], we choose $v(x) = 2x(1-x)$ (the reason for such a choice was outlined in the proof of Theorem 4 in [1]) and find that

$$\max_{0\le x\le 1} \frac{1}{1-v} = 2 \quad \text{and} \quad \|v\|_p^q = 2^q \left[\int_0^1 x^p(1-x)^p\right]^{q/p} = 2^q[B(p+1,p+1)]^{q/p}.$$

Let $\varepsilon_0 = 2^{1-q}[B(p+1,p+1)]^{-q/p}$. Then if $\varepsilon \le \varepsilon_0, v(x)$ is a supersolution. Thus $u(x,t)$ is bounded from above by $v(x)$ if $u_0(x) \le v(x)$.

Next we indicate that arguments used for problem (D) can also apply to another kind of problem,

$$\text{(D*)} \qquad \begin{aligned} u_t &= u_{xx} + \varepsilon/(1-\|u(\cdot,t)\|^q u), && 0 < x < 1, \quad t > 0,\\ u(0,t) &= u(1,t) = 0, && t > 0,\\ u(x,0) &= u_0(x), && 0 \le x \le 1. \end{aligned}$$

Because the corresponding stationary solutions of (D^*) satisfy the following boundary value problem,

$$\text{(S*)} \qquad \begin{aligned} &v'' + \varepsilon/(1-\|v\|^q v), && 0 < x < 1,\\ &v(0) = v(1) = 0, \end{aligned}$$

we introduce a transformation $w(x) = \|v\|^q v$. The mapping $v \longmapsto w$ is one-to-one, since if $w_1(x) = w_2(x)$, it follows that $\|w_1\| = \|w_2\|$, which implies that $\|v_1\|^{q+1} = \|v_2\|^{q+1}$, and consequently, $v_1(x) = v_2(x)$. By such a transformation, (S^*) is changed into

$$\text{(S**)} \qquad \begin{aligned} &w'' + \varepsilon\|w\|^{q/(q+1)}/(1-w), && 0 < x < 1,\\ &w(0) = w(1) = 0. \end{aligned}$$

Since (S**) is of the same form as (S), we are able to conduct a discussion similar to our earlier one. However, it is interesting to note that $q/(q+1)$, the power of $\|w\|$, is always less than one. Thus we merely have assertion (C1), and consequently, only Theorem 4.4 (I) is valid. This illustrates that in problem (D), as a multiplier of the parameter ε, the nonlocal term makes a more powerful impact on the prevention of quenching.

Acknowledgment. The author would like to thank the referee for a number of valuable comments and constructive suggestions.

EXISTENCE AND BIFURCATION OF VISCOUS PROFILES FOR ALL INTERMEDIATE MAGNETOHYDRODYNAMIC SHOCK WAVES*

H. FREISTÜHLER† AND P. SZMOLYAN‡

Abstract. A viscous profile for a magnetohydrodynamic shock wave is given by a heteroclinic orbit of a six-dimensional gradient-like system of ordinary differential equations. This system, and thus possibly the existence of a viscous profile, vary with an array δ of four positive dissipation coefficients. It is known that for each choice of δ, all "classical" and "degenerate intermediate" shocks as well as some "nondegenerate intermediate" shocks have viscous profiles, and that, vice versa, each given nondegenerate intermediate shock has no viscous profile for some range of δ. Complementing this picture, it is shown that (i) each nondegenerate intermediate shock does have a (family of) viscous profile(s) for a certain other range of δ, and (ii) such profiles, for all intermediate shocks sharing the same relative flux, are generated in a global heteroclinic bifurcation. Both (i) and (ii) are proved in a regime of δ in which the dissipative effects due to electrical resistivity and longitudinal viscosity dominate those associated with transverse viscosity and heat conduction: The constructive proof is based on a recently formulated method in geometric singular perturbation theory.

Key words. shock waves, magnetohydrodynamics, heteroclinic orbits, singular perturbations

1. Results. Under standard physical assumptions, plane magnetohydrodynamic waves are mathematically governed by the differential equations (e.g., [3]), in space $x \in \mathbf{R}$ and time $t \in \mathbf{R}$,

$$\begin{aligned} \rho_t + (\rho v)_x &= 0, \\ (\rho v)_t + (\rho v^2 + p + \tfrac{1}{2} \mid \mathbf{b} \mid^2)_x &= \lambda v_{xx}, \\ (\rho \mathbf{w})_t + (\rho v \mathbf{w} - \mathbf{b})_x &= \mu \mathbf{w}_{xx}, \\ \mathbf{b}_t + (v\mathbf{b} - \mathbf{w})_x &= \nu \mathbf{b}_{xx}, \\ \mathcal{E}_t + (v(\mathcal{E} + p + \tfrac{1}{2} \mid \mathbf{b} \mid^2) - \mathbf{w} \cdot \mathbf{b})_x &= \lambda (v v_x)_x + \mu (\mathbf{w} \cdot \mathbf{w}_x)_x + \nu (\mathbf{b} \cdot \mathbf{b}_x)_x + \kappa \theta_{xx}. \end{aligned} \tag{1.1}$$

Here $\rho, \theta, p(\rho, \theta) > 0$ denote density, temperature, and pressure of the fluid, $v \in \mathbf{R}$ its longitudinal and $\mathbf{w} \in \mathbf{R}^2$ its transverse velocity, $\mathbf{b} \in \mathbf{R}^2$ the transverse magnetic field, and

$$\mathcal{E} = \rho(\epsilon + \tfrac{1}{2}(v^2 + \mid \mathbf{w} \mid^2)) + \tfrac{1}{2} \mid \mathbf{b} \mid^2$$

the total energy with $\epsilon = \epsilon(\rho, \theta)$ the internal energy per mass. The "longitudinal" fluid viscosity λ and the "transverse" fluid viscosity μ are positive combinations ($\lambda = \zeta + \frac{4}{3}\eta, \mu = \eta$) of the two numbers $(\eta, \zeta \geq 0)$ known as the two viscosity coefficients (cf. [20, §§15, 49, and 78]) of the fluid, ν describes its electrical resistivity, and κ its heat conductivity; the terms involving these coefficients are macroscopic descriptions of dissipative mechanisms. We assume that apart from these mechanisms, the fluid is an ideal gas, i.e., pressure and internal energy are given by

$$p = R\theta\rho \quad \text{and} \quad \epsilon = c_v \theta,$$

where R and c_v, in principle arbitrary positive numbers, are the gas constant and the specific heat at constant volume, respectively. In addition to the thermodynamic quantities p and ϵ already introduced so far, we will also make use of the entropy

$$S = -R \ln \rho + c_v \ln \theta. \tag{1.2}$$

We abbreviate $(\rho, \rho v, \rho \mathbf{w}, \mathbf{b}, \mathcal{E}) \in U \subset (0, \infty) \times \mathbf{R} \times \mathbf{R}^2 \times \mathbf{R}^2 \times (0, \infty)$ as u, and $(\lambda, \mu, \nu, \kappa) \in [0, \infty)^4$ as δ, and write (1.1) briefly in the form

$$u_t + (f(u))_x = (D(u, \delta) u_x)_x. \tag{1.3}$$

In (1.3), all details of (1.1) are subsumed under the two real analytic mappings $f : U \to \mathbf{R}^7$ and $D : U \times [0, \infty)^4 \to \mathbf{R}^{7 \times 7}$.

In the limiting case $\delta = 0$, (1.3) is the (nonstrictly) hyperbolic system of conservation laws describing ideal magnetohydrodynamics. This case admits certain solutions of the form

$$u(x, t) = \begin{cases} u^-, & x < st, \\ u^+, & x > st; \end{cases} \tag{1.4}$$

they are precisely those functions of the form (1.4) which satisfy the Rankine–Hugoniot conditions, i.e.,

$$f(u^-) - su^- = f(u^+) - su^+ = q \tag{1.5}$$

for some constant q. A solution (1.4) of (1.3) with $\delta = 0$ is called a shock if both

$$m(S(u^+) - S(u^-)) > 0 \tag{1.6}$$

and

$$s \text{ is not an eigenvalue of } f'(u^-) \text{ nor of } f'(u^+) \tag{1.7}$$

hold, where in (1.6)

$$m = \rho^-(v^- - s) = \rho^+(v^+ - s) \in \mathbf{R} \tag{1.8}$$

is the relative mass flux associated with the solution (1.4), identical with the first component of the complete relative flux (1.5). Condition (1.6) means that entropy increases in the history of particles crossing the shock, a natural requirement based on the second law of thermodynamics. Condition (1.7) means that the discontinuity is noncharacteristic on either side.

For a given shock (1.4) and a given $\delta \in [0, \infty)^4, |\delta| > 0$, a heteroclinic orbit given by a solution $\phi : \mathbf{R} \to U$ of the system

$$D(\phi(x), \delta)\phi'(x) = f(\phi(x)) - s\phi(x) - q, \quad q \text{ from (1.5)}, \tag{1.9}$$

which connects the fixed points $u^\pm$:

$$\phi(\pm\infty) = u^\pm \tag{1.10}$$

is called a (δ-) profile of the shock. The idea of this notion is that the solution

$$u^\delta(x, t) = \phi(x - st) \tag{1.11}$$

of (1.3) is a regularized counterpart of (1.4) in which the effect of dissipation $D(.,\delta)$ is visibly resolved. The main result of this paper is the following theorem.

THEOREM 1.1. *Every magnetohydrodynamic shock has a δ profile at least for a certain open range of $\delta = (\lambda, \mu, \nu, \kappa) \in \Delta \equiv (0, \infty)^4$.*

Note that there are a number of different types of magnetohydrodynamic shock waves, and that for many q, several shocks of different types coexist with the same relative flux q.

Let us call a shock nondegenerate intermediate if, besides (1.4)–(1.7), it satisfies

$$|\mathbf{b}^+|\mathbf{b}^- = -|\mathbf{b}^-|\mathbf{b}^+ \neq 0, \tag{1.12}$$

i.e., the magnetic fields on either side are strictly antiparallel. All other shocks are classified as slow, fast, or degenerate intermediate. We mostly consider the nondegenerate intermediate shocks, because as we detail below, previously known results imply that all other shocks have δ profiles for all $\delta \in \Delta$. Theorem 1.1 can thus be viewed as a corollary of the following Theorem 1.2. To introduce a concise notation for the situation of interest, we will say that $q \in \mathbf{R}^7$ satisfies condition $\mathcal{I}$ iff a nondegenerate intermediate shock with relative flux q exists. Note also that if condition $\mathcal{I}$ holds for a given q, then all intermediate shocks with relative flux q are nondegenerate.

THEOREM 1.2. *Consider a $q \in \mathbf{R}^7$ which satisfies condition $\mathcal{I}$. Then there exist a number $\omega_0 > 0$ and a smooth function $\gamma : (\omega_0, \infty) \to (0, \infty)$ such that for all $\delta = (\lambda, \mu, \nu, \kappa)$ with*

$$\nu, \lambda > 0, \quad \nu/\lambda > \omega_0, \quad 0 \leq \mu/\lambda, \kappa/\lambda < \gamma(\nu/\lambda) \tag{1.13}$$

all shocks with relative flux q have δ profiles. In particular and more precisely, if $u^-, u^+ \in U, s \in \mathbf{R}$ define an intermediate shock and the number p, defined as the number of positive eigenvalues of $f'(u^-) - sI$ plus the number of negative eigenvalues of $f'(u^+) - sI$ minus eight, is positive, then there exists a p-parameter family of such profiles; if $p = 0$, then a pair of profiles exist.

We also show that the profiles for intermediate shocks are generated in a global heteroclinic bifurcation of system (1.9) with bifurcation parameter δ. A profile is called coplanar if the $\mathbf{b}$ and $\mathbf{w}$ components of ϕ' both remain in a fixed one-dimensional linear subspace of $\mathbf{R}^2$.

THEOREM 1.3. *Consider a $q \in \mathbf{R}^7$ which satisfies condition $\mathcal{I}$. Then there exist (possibly only small) numbers $\gamma_1, \gamma_2 > 0$ and a smooth function $\omega : [0, \gamma_1)^2 \to (0, \infty)$ such that the following holds for all $\delta = (\lambda, \mu, \nu, \kappa)$ with*

$$\nu, \lambda > 0, \quad 0 \leq \mu/\lambda, \kappa/\lambda < \gamma_1, \quad |\nu/\lambda - \omega(0,0)| < \gamma_2. \tag{1.14}$$

If $\nu/\lambda < \omega(\mu/\lambda, \kappa/\lambda)$, then no coplanar δ profiles exist, for any intermediate shock with relative flux q.

For $\nu/\lambda = \omega(\mu/\lambda, \kappa/\lambda)$, of all intermediate shocks with relative flux q only the (unique) one with $p = 0$ has a coplanar δ profile.

If $\nu/\lambda > \omega(\mu/\lambda, \kappa/\lambda)$, then all intermediate shocks with relative flux q (and $p > 0$) have (coplanar) δ profiles.

To interpret these theorems, we recall that slow and fast shocks have been proven in [12], [4], [5], [16] to possess (coplanar) δ profiles for all values of $\delta \in \Delta$ and many values $\delta \in \partial\Delta$. In [4] and [5] this was done by means of the Conley Index theory. For the marginal class of degenerate intermediate shocks the same is known (see [16] and [8]). It seems to be here that the assertion of Theorem 1.1 is established for the first

time for the class of nondegenerate intermediate shocks. Concerning these, [12], [4], and [5] had shown that for any nondegenerate intermediate shock there always is a range in Δ, namely of δ with $\lambda >> \mu, \nu, \kappa$ such that the shock has no δ profile. That nondegenerate intermediate shocks may conversely have $\tilde{\delta}$ profiles for other values $\tilde{\delta}$ ($\in \partial\Delta$), had been recognized long ago; cf. [18], [19, pp. 174–179], and [1]. In recent years Brio and Wu [2], and Wu ([23] and references therein), motivated by questions on the physics of the earth's magnetosphere, presented numerical evidence for stable magnetohydrodynamic traveling waves corresponding to such profiles. Connection matrix theory, a tool closely related to the Conley Index, was used in [21] to prove, nonconstructively, the existence of δ profiles, with *some* $\delta \in \Delta$, for *some* nondegenerate intermediate shocks. In [21], the authors stated also some conjectures about more profiles, which indeed amount to a picture that is roughly similar to our results. In [7] and [8] it was shown that for *all* $\delta \in \Delta$ there exist nondegenerate intermediate shocks which have δ profiles.

Complementing these earlier findings, the investigations whose results we report in this paper have had a double motivation. On one hand, it seems that proofs for the existence of viscous profiles represent a basic first step in any attempt at a more complete theoretical understanding of intermediate magnetohydrodynamic shock waves in the presence of dissipation. Also, we view our results more generally as a contribution to the ongoing debate on admissibility criteria (cf. [14]) in conservation law theory: Theorem 1.1 implies that in the case of magnetohydrodynamics—an example of *nonstrict* hyperbolicity—the simple criterion (1.6) of entropy increase has a satisfactory, consistent dynamical interpretation in the dissipative framework. This, in turn, contrasts especially with results which indicate that the stability of nondegenerate intermediate shock waves undergoes an explosive loss as $\delta \searrow 0$ even along rays $\delta/|\delta| = \text{const}$ (cf. [9], [10], and references therein). On the other hand, the o.d.e. system ((2.1) below) describing magnetohydrodynamic traveling waves is appealing from the dynamical systems point of view. The present paper is based on the idea of applying geometric singular perturbation theory (cf. [6], [22]) to this system.

2. Preliminaries and outline. We now turn to basic details of the problem and our approach. To determine the concrete form of (1.9), we rewrite (1.1), restricting attention to solutions which depend solely on x. The result is

$$\begin{aligned}
\rho v &= m,\\
\lambda \dot{v} &= \rho v^2 + p + \tfrac{1}{2} \mid \mathbf{b} \mid^2 - j,\\
\mu \dot{\mathbf{w}} &= \rho v \mathbf{w} - \mathbf{b} - \tilde{\mathbf{c}},\\
\nu \dot{\mathbf{b}} &= v\mathbf{b} - \mathbf{w} - \mathbf{c},\\
\kappa \dot{\theta} &= v(\mathcal{E} + p + \tfrac{1}{2} \mid \mathbf{b} \mid^2) - \mathbf{w} \cdot \mathbf{b} - \lambda v \dot{v} - \mu \mathbf{w} \cdot \dot{\mathbf{w}} - \nu \mathbf{b} \cdot \dot{\mathbf{b}} - e,
\end{aligned}$$

where dots denote differentiation with respect to x. The parameters m (see (1.8)), $j, e \in \mathbf{R}$, and $\mathbf{c}, \tilde{\mathbf{c}} \in \mathbf{R}^2$ correspond to a relative flux $q = (m, j, \tilde{\mathbf{c}}, \mathbf{c}, e)$. Using isotropy and Galilean invariance, we will from now on assume without loss of generality that

$$m > 0 \quad \text{and} \quad \tilde{\mathbf{c}} = 0.$$

We set $d = 1/m$, $\tau = v/m$ and rescale x by $1/m$; $\mathbf{w}$, $\mathbf{b}$ by m; θ, p, $\mathbf{c}$, j by m^2, and e by m^3 to obtain the following six-dimensional system, which we henceforth will refer to as Σ^6:

$$
\begin{aligned}
&\nu\dot{\mathbf{b}} = -d\mathbf{w} + \tau\mathbf{b} - \mathbf{c},\\
&\lambda\dot{\tau} = \tau + \frac{R\theta}{\tau} + \frac{1}{2} \mid \mathbf{b} \mid^2 - j,\\
&\mu\dot{\mathbf{w}} = \mathbf{w} - d\mathbf{b},\\
&\kappa\dot{\theta} = c_v\theta - \frac{1}{2}(\mid \mathbf{w} \mid^2 - 2d\mathbf{w}\cdot\mathbf{b} + \tau \mid \mathbf{b} \mid^2) - \frac{\tau^2}{2} + j\tau + \mathbf{b}\cdot\mathbf{c} - e.
\end{aligned}
\tag{2.1}
$$

Since in deriving (2.1) we had assumed independence of t, Σ^6 is (1.9) in the case $s = 0$. Again due to Galilean invariance, the restriction $s = 0$ implies no loss of generality. In other words, Σ^6 describes all profiles for magnetohydrodynamic shocks.

Before we outline and then enter the central part of our analysis, we show how previously known results imply the assertion of Theorem 1.1 in the cases which are not covered by Theorem 1.2.

LEMMA 2.1. *Theorem* 1.1 *holds if restricted to shocks whose relative flux* q *violates* $\mathcal{I}$.

To see this, note first the following lemma.

LEMMA 2.2. (i) *All gas-dynamic shocks have* δ *profiles for all values of* $\delta \in \Delta$. (ii) *All slow or fast shocks have* δ *profiles for all values of* $\delta \in \Delta$.

Proof. Statement (i) is a trivial consequence of [13]; compare also similar remarks in [7] and [8]. A gas-dynamic shock is one with $\mathbf{b}^- = \mathbf{b}^+ = 0$. Slow and fast shocks, unless they are gas-dynamic, are characterized by (non-anti- !) parallel magnetic fields, i.e.,

$$
|\mathbf{b}^+|\mathbf{b}^- = |\mathbf{b}^-|\mathbf{b}^+ \neq 0. \tag{2.2}
$$

The existence of profiles for such shocks is known from [4] and [12] and (ii) follows. □

Next observe the following lemma.

LEMMA 2.3. (i) *For any magnetohydrodynamic shock, properties* (1.5) *and* (1.7) *imply that the relative magnetic flux* $\mathbf{c}$ *occurring in the normalized system* Σ^6 *is different from* 0 *unless the shock is gas-dynamic.* (ii) *If* $q \in \mathbf{R}^7$ *is such that* $\mathbf{c} \neq 0$ *and* $\mathcal{I}$ *does not hold, then any shock with relative flux* q *is slow or fast.*

Proof. If $\mathbf{c} = 0$, fixed points of (2.1) with $\mathbf{b} \neq 0$—if there are any—occur grouped in whole circles. According to (1.7), however, the left- and right-hand states u^-, u^+ of a shock are isolated zeros of f. Thus only gas-dynamic shocks are possible if $\mathbf{c} = 0$. On the other hand, if $\mathbf{c} \neq 0$, any states u^-, u^+ satisfying (1.5) have $|\mathbf{b}^-|, |\mathbf{b}^+| > 0$ and fulfil thus either (2.2) or (1.12); violation of $\mathcal{I}$ precludes the latter. □

Remark. (i) Gas-dynamic shocks may be slow or fast or (degenerate!) intermediate.

(ii) Switch-on and switch-off discontinuities, characterized by (1.5), (1.6), and *either* $\mathbf{b}^- = 0$ *or* $\mathbf{b}^+ = 0$, and thus also having magnetic flux $\mathbf{c} = 0$, are no shocks in the sense of this paper: They violate our noncharacteristicity assumption (1.7). However, these discontinuities are already known [16] to have δ profiles for all $\delta \in \Delta$.

Lemmas 2.2 and 2.3 prove Lemma 2.1. Obviously, Lemma 2.1 and Theorem 1.2 together imply Theorem 1.1. Thus, we make the standing assumption that q satisfy $\mathcal{I}$ and prove the conclusions of Theorems 1.2 and 1.3. The whole rest of the paper is devoted to this purpose.

To approach it, we treat Σ^6 as a singularly perturbed problem: In the $\mu, \kappa << \nu, \lambda$ limit, the essential dynamics are captured by the three-dimensional reduced system

Σ^3 in the variables $\mathbf{b}$ and τ that one obtains from Σ^6 by setting $\mu = \kappa = 0$. We use methods from geometric singular perturbation theory [6] to prove the existence of a three-dimensional invariant manifold $\mathcal{C}$ for Σ^6 with the same dynamics as Σ^3. This reduces the whole problem to Σ^3. In our analysis of Σ^3, one key ingredient is the use of a Lyapunov function. While in the analysis of Σ^6 in [12] and [5] a mathematical potential P different from the physical entropy S has been used, it interestingly turns out that for Σ^3, S itself is a Lyapunov function. The other main ingredient in our analysis of Σ^3 consists in a further restriction of attention to the dynamics in the invariant half-plane $\mathbf{Rc} \times (0, \infty)$. The corresponding system Σ^2 in two variables was already discussed in [18]. Our analysis completes the reasoning of [18] and puts it on a mathematically sound basis. Summarizing, we can describe our strategy as finding heteroclinic orbits for Σ^2 and/or for Σ^3, and lifting them to Σ^6.

The geometric singular perturbation approach to the problem of viscous profiles for magnetohydrodynamic shock waves is new. In [5] and [16] slightly related ideas were used to construct isolating neighborhoods in an analysis for the case of limiting values of δ where some of its coefficients vanish. However, the logic in that approach is completely different from ours. The authors of [5] and [16] concluded (for fast and slow shocks) from the existence of δ profiles for all $\delta \in \Delta$ the existence of $\tilde{\delta}$ profiles for marginal dissipation $\tilde{\delta} \in \partial\Delta$. By contrast, we establish (for intermediate shocks) first $\tilde{\delta}$ profiles for certain $\tilde{\delta} \in \partial\Delta$ and subsequently induce δ profiles for a certain range of $\delta \in \Delta$.

Many of the new arguments we present below are not restricted to ideal gases. It would be interesting to investigate the same question for more general equations of state.

In the following §3, we carry out the reduction of Σ^6 to Σ^3. In §4, we analyze the geometry of Σ^3. Combining the results of §§3 and 4, the main results are proved in the final §5.

3. Geometric singular perturbation theory. The dynamical systems approach to singular perturbation problems—in its modern form—goes back to [6], but has only recently become more popular. In [22] a method—based on this invariant manifold approach—is formulated to prove the existence of transversal heteroclinic orbits of singularly perturbed differential equations. In this section we briefly summarize the necessary results from [6] and [22] and then apply them to completely reduce our analysis of the six-dimensional system Σ^6 to that of the three-dimensional system Σ^3. Consider first a general singularly perturbed system of differential equations in the standard form

$$\begin{aligned} \dot{\xi} &= X(\xi, \eta), \\ \varepsilon\dot{\eta} &= Y(\xi, \eta), \end{aligned} \tag{3.1}$$

with $\varepsilon \in (-\varepsilon_0, \varepsilon_0)$, $\varepsilon_0 > 0$ small, and $(\xi, \eta) \in U \subset \mathbf{R}^n \times \mathbf{R}^l$ open. We assume that $X : U \to \mathbf{R}^n$ and $Y : U \to \mathbf{R}^l$ are smooth functions. By setting $\varepsilon = 0$ we obtain the reduced problem

$$\begin{aligned} \dot{\xi} &= X(\xi, \eta), \\ 0 &= Y(\xi, \eta). \end{aligned} \tag{3.2}$$

The basic idea is to obtain orbits of the singularly perturbed problem (3.1), for small values of ε, as smooth perturbations of orbits of the reduced problem (3.2). The following results are contained in [6, Thm. 9.1].

THEOREM 3.1. *In addition to the assumptions made above in this section, assume that*

(a) *the equation* $Y = 0$ *has a manifold* $\mathcal{C}_0$ *of solutions which is the graph of a smooth function* $\hat{\eta} : \hat{U} \subset \mathbf{R}^n \to \mathbf{R}^l$ *and*

(b) *there exist integers* l_s *and* l_u, *with* $l_s + l_u = l$, *such that the partial Jacobian* Y_η *has* l_s *eigenvalues with negative real part, and* l_u *eigenvalues with positive real part, for all points of* $\mathcal{C}_0$.

Then the reduced problem (3.2) *defines a flow on* $\mathcal{C}_0$, *and the following assertions hold in an appropriate neighborhood of* $\mathcal{C}_0 \cap K$, *where* $K \subset U$ *is any compact set satisfying* $K \cap \mathcal{C}_0 \neq \emptyset$.

There exists $\varepsilon_1 > 0$ *such that* $\mathcal{C}_0$ *can be extended to a smooth family of manifolds* $\mathcal{C}_\varepsilon$, $\varepsilon \in (-\varepsilon_1, \varepsilon_1)$. *The manifolds* $\mathcal{C}_\varepsilon$ *are invariant under the flow of the singularly perturbed problem* (3.1), *and the restriction of this flow to* $\mathcal{C}_\varepsilon$ *is a smooth perturbation of the reduced flow on* $\mathcal{C}_0$. *If* $l_s = 0$ [$l_u = 0$], *then* $\mathcal{C}_\varepsilon$ *is moreover positively* [*negatively*] *isolated for the flow* (3.1), *for all* $\varepsilon \in (0, \varepsilon_1)$, *i.e., any orbit whose* ω- [α-] *limit set lies in* $\mathcal{C}_\varepsilon$ *lies itself completely in* $\mathcal{C}_\varepsilon$.

The above theorem is basic for the following proposition.

PROPOSITION 3.2. *Under the assumptions of Theorem* 3.1 *all structurally stable properties of the reduced problem* (3.2) *persist for the restriction of the singularly perturbed problem* (3.1) *to the invariant manifold* $\mathcal{C}_\varepsilon$ *for small* ε. *In particular, (normally) hyperbolic (manifolds of) fixed points of the reduced problem persist identically; their associated stable and unstable manifolds and transversal intersections of these perturb smoothly. Hyperbolicity and transversality extend to the singularly perturbed problem* (3.1) *(without restriction to* $\mathcal{C}_\varepsilon$*) with dimensions of stable and unstable manifolds increased by* l_s *and* l_u, *respectively.*

This proposition summarizes what we use from the second author's paper [22]. For details we refer to [6] and [22], for background material to [15] and [17]. Theorem 1.1 was announced in [22]. Another similar application of geometric singular perturbation theory can be found in [11].

We turn to applying geometric singular perturbation theory to the problem posed in §1. To make system Σ^6 accessible to Theorem 3.1 and Proposition 3.2, we fix $\nu, \lambda, \tilde{\mu}, \tilde{\kappa} > 0$ with $\tilde{\mu} + \tilde{\kappa} = 1$ arbitrarily and consider Σ^6 with $\mu = \varepsilon\tilde{\mu}, \kappa = \varepsilon\tilde{\kappa}$, for small values of $\varepsilon > 0$. From this point of view, Σ^6 is of the form (3.1) with $n = l = 3$ and $\xi = (\mathbf{b}, \tau), \eta = (\mathbf{w}, \theta)$. By setting $\varepsilon = 0$ we obtain the reduced problem Σ^3, which corresponds to (3.2):

$$
\begin{aligned}
\nu\dot{\mathbf{b}} &= -d\mathbf{w} + \tau\mathbf{b} - \mathbf{c}, \\
\lambda\dot{\tau} &= \tau + \frac{R\theta}{\tau} + \frac{1}{2} \mid \mathbf{b} \mid^2 - j, \\
\mathbf{w} &= d\mathbf{b} \equiv \hat{\mathbf{w}}(\mathbf{b}, \tau), \\
\theta &= \frac{1}{c_v}\left(\frac{1}{2}(\tau - d^2)|\mathbf{b}|^2 - \mathbf{b}\cdot\mathbf{c} + \frac{\tau^2}{2} - j\tau + e\right) \equiv \bar{\theta}(\mathbf{b}, \tau).
\end{aligned}
\tag{3.3}
$$

The last two lines describe the domain of definition

$$
\mathcal{C}_0 \subset U^6 \equiv \{(\mathbf{b}, \tau, \mathbf{w}, \theta) \in \mathbf{R}^2 \times (0, \infty) \times \mathbf{R}^2 \times (0, \infty)\}
\tag{3.4}
$$

of Σ^3. With $\hat{\theta} \equiv \bar{\theta}|U^3$, $\mathcal{C}_0$ is the graph of $\hat{\eta} = (\hat{\mathbf{w}}, \hat{\theta})$ over the reduced physical state space

$$
U^3 \equiv \{(\mathbf{b}, \tau) \in \mathbf{R}^3 \ : \ \tau > 0, \ \bar{\theta}(\mathbf{b}, \tau) > 0\};
\tag{3.5}
$$

this is assumption (a) of Theorem 3.1. Assumption (b) is also satisfied, with $l_s = 0$ and $l_u = 3$, since the 3×3 matrix $Y_\eta(\xi, \hat{\eta}(\xi))$, at each $\xi \in U^3$, has the eigenvalues 1, 1, and c_v, which are all positive. We restate [4, Thm. 4.1] as the next lemma.

LEMMA 3.3. *For each choice of* $(\mathbf{c}, d, e, j)$, *there is a compact ball* $K \subset U$ *which contains all fixed points and all heteroclinic orbits of* Σ^6 *with arbitrary* $\delta \in (\Delta \cup \partial\Delta)$.

Applying Theorem 3.1 with this K, for each quadruple $(\nu, \lambda, \tilde{\mu}, \tilde{\kappa})$ as above and each ε with $|\varepsilon| < \varepsilon_1$, $\varepsilon_1 > 0$ appropriate, we obtain an invariant manifold for Σ^6 with ν, λ as given and $\mu = \varepsilon\tilde{\mu}, \kappa = \varepsilon\tilde{\kappa}$. Analogous statements hold for the marginal cases $(\tilde{\mu}, \tilde{\kappa}) = (0, 1)$, $(\tilde{\mu}, \tilde{\kappa}) = (1, 0)$. By iterated application of Theorem 3.1 near these cases, we see that ε_1 can be chosen as $\varepsilon_1 = \gamma(\nu, \lambda) > 0$ independently of $\tilde{\mu}, \tilde{\kappa}$. Observing finally that the phase diagram of Σ^6 depends only on the mutual ratios of the coefficients $\nu, \lambda, \mu, \kappa$, i.e., briefly speaking, on $\delta/|\delta|$, we formulate the implications of Theorem 3.1 and Proposition 3.2 as the next lemma.

LEMMA 3.4. *There is a smooth function* $\tilde{\gamma} : (0, \infty) \to (0, \infty)$ *such that whenever* $\delta = (\lambda, \mu, \nu, \kappa) \in \Delta$ *satisfies* $\mu/\lambda, \kappa/\lambda < \tilde{\gamma}(\nu/\lambda)$, *then* Σ^6 *possesses a three-dimensional invariant manifold* $\mathcal{C}$, *located near* $\mathcal{C}_0$ *and depending smoothly on* $\delta/|\delta|$, *with the following properties:*

(i) *All fixed points and heteroclinic orbits of* Σ^6 *lie in* $\mathcal{C}$.

(ii) *Hyperbolic fixed points of* Σ^3 *are hyperbolic fixed points of* Σ^6 *with dimensions of the corresponding unstable manifolds increased by* 3.

(iii) *The existence of transversal (manifolds of) heteroclinic orbits connecting hyperbolic fixed points of* Σ^3 *implies the existence of transversal (manifolds of) heteroclinic orbits of* Σ^6 *in* $\mathcal{C}$ *connecting the same fixed points.*

By virtue of Lemma 3.4, we can henceforth restrict attention to Σ^3.

4. Geometry of the reduced problem. In this section, we study specific properties of Σ^3 which do not depend on the actual values of $\lambda, \nu > 0$ nor, within the limits of our overall assumption $\mathcal{I}$, on those of the quantities $\mathbf{c}, d, e, j$ associated with the relative flux q. Inserting the last two lines of (3.3) into its first two lines, Σ^3 obtains the form

$$\nu\dot{\mathbf{b}} = (\tau - d^2)\mathbf{b} - \mathbf{c}, \tag{4.1}$$

$$\lambda\dot{\tau} = \frac{1}{2}|\mathbf{b}|^2 + \tau - j + \frac{1}{k\tau}\left(-\frac{\tau^2}{2} - \frac{d^2}{2}|\mathbf{b}|^2 - \mathbf{b}\cdot\mathbf{c} + e\right), \tag{4.2}$$

where $k = 1 + c_v/R$ and λ denotes the original λ divided by $1 + R/c_v$. Mathematically, these equations define a smooth dynamical system $\overline{\Sigma^3}$ on the half-space $\tau > 0$ (of which Σ^3 is the restriction to U^3). Considering this extension in the sequel, we will thus sometimes be dealing with points, orbits, etc., which indeed lie outside the physical range U^3 by assuming nonpositive temperature $\bar{\theta}$. Note, however, that U^3 itself is positively invariant under the flow of $\overline{\Sigma^3}$, as we will prove immediately. First we observe what follows.

LEMMA 4.1. *Systems* Σ^3, $\overline{\Sigma^3}$ *are gradient-like: The entropy*

$$\hat{S}(\mathbf{b}, \tau) \equiv R \ln \tau + c_v \ln \hat{\theta}(\mathbf{b}, \tau), \quad (\mathbf{b}, \tau) \in U^3,$$

and/or the function

$$\overline{S}(\mathbf{b}, \tau) \equiv c_v \tau^{R/c_v} \bar{\theta}(\mathbf{b}, \tau), \quad (\mathbf{b}, \tau) \in \mathbf{R}^2 \times (0, \infty),$$

are strictly increasing along all nonstationary orbits.

Proof. A direct computation shows that

$$(\nu\dot{\mathbf{b}}, \lambda\dot{\tau})^\top = \hat{\theta}(\mathbf{b}, \tau)\nabla\hat{S}(\mathbf{b}, \tau)$$

and/or

$$(\nu\dot{\mathbf{b}}, \lambda\dot{\tau})^\top = \tau^{c_v/R}\nabla\overline{S}(\mathbf{b}, \tau)$$

hold for all $(\mathbf{b}, \tau) \in U^3$ or $(\mathbf{b}, \tau) \in \mathbf{R}^2 \times (0, \infty)$, respectively. □

Remark. $\hat{S}$ is also a reduced version of the mathematical potential P used in [12], [4], [5] and Lemma 4.1 follows thus partially also from (i) the existence of P and (ii) the fact that the reduced problem of a gradient-like singularly perturbed problem is gradient-like with respect to (the restriction of) the same Lyapunov function. Observations (i) and (ii) were made in [12] and [5], respectively.

LEMMA 4.2. *The physical range U^3 is invariant under the forward flow of $\overline{\Sigma^3}$.*

Proof. Consider the forward orbit O^+, with respect to the flow of $\overline{\Sigma^3}$, of a point $u \in \hat{U}$. $\hat{S}$ has a finite value at u and increases along O^+. Suppose that, along O^+, τ approaches zero. Then

$$\theta = \frac{1}{c_v}\left(\frac{1}{2}(\tau - d^2)|\mathbf{b}|^2 - \mathbf{b}\cdot\mathbf{c} + \frac{\tau^2}{2} - j\tau + e\right)$$

must become arbitrarily large, which is impossible. Now suppose that θ approaches zero along O^+. Then τ must become arbitrarily large, which implies that θ becomes large—a contradiction. Thus, τ and θ remain positive and bounded away from zero along O^+. □

Fix $\mathbf{e} \in \mathbf{R}^2$ such that

$$|\mathbf{e}| = 1, \qquad \mathbf{c} = c\mathbf{e} \quad \text{with } c \geq 0, \tag{4.3}$$

and let $E = \mathbf{R}\mathbf{e} \times (0, \infty) \subset \mathbf{R}^3$. The following is obvious.

LEMMA 4.3. *System $\overline{\Sigma^3}$ is invariant under reflection across E. In particular, E is invariant under the flow of $\overline{\Sigma^3}$.*

The properties of $\overline{\Sigma^3}$ to be discussed in the rest of this section are indeed properties of the restriction of $\overline{\Sigma^3}$ to E. Upon introducing the variable $b = \mathbf{b}\cdot\mathbf{e}$, $\overline{\Sigma^2} := \overline{\Sigma^3}|E$ and $\Sigma^2 := \Sigma^3|E$ are governed by the equations

$$\nu\dot{b} = (\tau - d^2)b - c, \tag{4.4}$$

$$\lambda\dot{\tau} = \frac{b^2}{2} + \tau - j + \frac{1}{k\tau}\left(-\frac{\tau^2}{2} - \frac{d^2}{2}b^2 - bc + e\right). \tag{4.5}$$

It is from now on that we make use of our overall assumption $\mathcal{I}$. By part (i) of Lemma 2.3, we have $\mathbf{c} \neq 0$; with (4.3), this amounts to

$$c > 0. \tag{4.6}$$

Note that $\mathbf{c} \neq 0$ implies that all fixed points of $\overline{\Sigma^3}$ must lie in E.

In the next step of our analysis we establish pertinent properties of the nullclines of $\overline{\Sigma^2}$. These are the portions in the half-plane $\tau > 0$ of the hyperbola $H \subset \mathbf{R}^2$ given by

$$h(b, \tau) \equiv (\tau - d^2)b - c = 0, \tag{4.7}$$

and of the solution set $G \subset \mathbf{R}^2$ of the equation

$$g(b,\tau) \equiv b^2(k\tau - d^2) - 2bc + (2k-1)\tau^2 - 2kj\tau + 2e = 0. \tag{4.8}$$

In particular, fixed points of $\overline{\Sigma^2}$ are, of course, given by elements of $H \cap G \cap (\mathbf{R} \times (0,\infty))$. Let H^-, H^+ denote the lower left ($\tau < d^2, b < 0$) and upper right ($\tau > d^2, b > 0$) branch of H, respectively.

LEMMA 4.4. *H and G intersect transversally in precisely four points. With (henceforth assumed) appropriate numbering, these points $u_i = (b_i, \tau_i), i = 0,1,2,3$ satisfy $H^+ \cap G = \{u_0, u_1\}, H^- \cap G = \{u_2, u_3\}$ and, more precisely,*

$$\tau_0 > \tau_1 > d^2 > \tau_2 > \tau_3 > 0,$$
$$b_1 > b_0 > 0 > b_3 > b_2.$$

At least for $i = 1$ and $i = 3$, u_i lies in the physical range $U^2 \equiv \{(b,\tau) \in \mathbf{R}^2 : \tau > 0$ and $\overline{\theta}(b\mathbf{e}, \tau) > 0\}$.

Proof. $H \cap G$ has at most four elements: Multiplying (4.8) by b^2 and substituting $\tau b = d^2 b + c$ from (4.7) yields a fourth-order polynomial in b. By virtue of $\mathcal{I}$ and (1.7), G intersects H^- and H^+ transversally in at least one point each. Since, however, $g \to \infty$ at each of the four infinities of H, $G \cap H^{\pm}$ consist then indeed both of two transversal intersection points. We number the altogether four points such that $b_1 > b_0 > 0 > b_3 > b_2$; this implies $\tau_0 > \tau_1 > d^2 > \tau_2 > \tau_3$.

It remains to show that u_1 and u_3 lie in U^2. Since, due to $\mathcal{I}$, $G \cap H^{\pm} \cap U^2 \neq \emptyset$, it suffices to note that $u_0 \in U^2$ would imply $u_1 \in U^2$, and $u_2 \in U^2$ would imply $u_3 \in U^2$. To see this, reduce $\overline{\Sigma^2}$ still further by setting $\nu = 0$:

$$\begin{aligned} 0 &= h(b,\tau), \\ \lambda\dot{\tau} &= g(b,\tau)/(2k\tau). \end{aligned} \tag{4.9}$$

The flow that these equations define on the portion of H lying in the half-plane $\tau > 0$ corresponds to the flow governed by the single equation

$$\lambda\dot{\tau} = g(c/(\tau - d^2), \tau)/(2k\tau) \tag{4.10}$$

on the two intervals $(0, d^2)$ and (d^2, ∞). In (d^2, ∞), this scalar flow has precisely two fixed points: τ_0 and τ_1. Since the right-hand side of (4.10) is negative for $\tau \in (\tau_1, \tau_0)$, this interval is a heteroclinic orbit from τ_0 to τ_1. Adding a second component $b = c/(\tau - d^2)$ lifts it to a heteroclinic orbit of (4.9). Since by an obvious extension of Lemma 4.2, the physical range $U^2 \cap H$ is positively invariant under the flow of (4.9), we conclude the desired implication $u_0 \in U^2 \Rightarrow u_1 \in U^2$. The argumentation for $u_2 \in U^2 \Rightarrow u_3 \in U^2$ is analogous once one observes additionally that τ_3 must be positive since $\tau_2 > 0 \geq \tau_3$ would again contradict the positive invariance of $U^2 \cap H$ under the flow of (4.9).

In the following we discuss the geometry of the nullclines H and G; cf. [18].

The hyperbola H has a horizontal asymptote at $\tau = d^2$, and the branches H^+ in $b > 0, \tau > d^2$ and H^- in $b < 0, \tau < d^2$. Thus, it remains to discuss G. For given τ the two possible solutions of (4.8) are given by

$$b = \frac{c \pm \sqrt{\pi(\tau)}}{k\tau - d^2}, \qquad \pi(\tau) = c^2 - ((2k-1)\tau^2 - 2kj\tau + 2e)(k\tau - d^2). \tag{4.11}$$

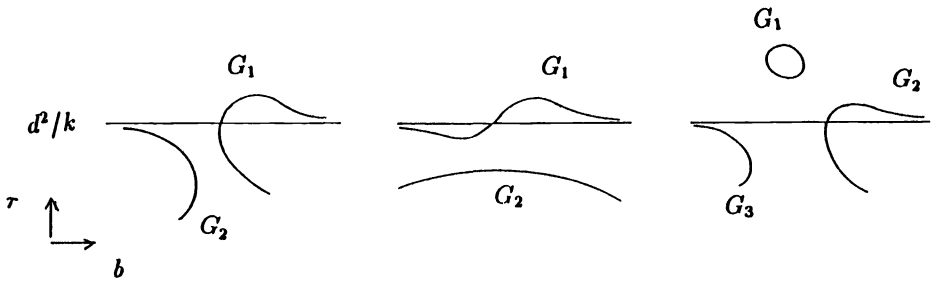

FIG. 1. *Nullclines* $g(b,\tau) = 0$ *in cases* (1), (2), *and* (3).

Real solutions exist for $\pi(\tau) \geq 0$. G has a horizontal asymptote at $\tau = d^2/k$, which G approaches from above as $b \to \infty$ and from below as $b \to -\infty$. Since $k > 1$, the horizontal asymptote of the hyperbola H lies above the horizontal asymptote of G. The geometry of G is determined by the number and the location of zeros τ_i^* of the cubic polynomial π. Since the leading coefficient of π is negative and $\pi(d^2/k) = c^2$ is positive, we have to distinguish three cases:

(1) there exists one zero $\tau_1^* > d^2/k$;
(2) there exist three zeros $\tau_1^* > d^2/k > \tau_2^* > \tau_3^*$;
(3) there exist three zeros $\tau_1^* > \tau_2^* > \tau_3^* > d^2/k$.

In cases (1) and (2), G has two connected components, G_1 and G_2; in case (3), G has three connected components G_1, G_2, and G_3, which are labeled in the order in which they appear as τ decreases (see Fig. 1). Note, that horizontal and vertical lines intersect G at most twice. Furthermore, G has exactly two, zero, and four vertical tangents in cases (1), (2), and (3), respectively. As the parameters c, d, e, and j vary, certain bifurcations are possible. Starting from case (2) the zeros τ_2^* and τ_3^* may coalesce and then disappear; from case (3) the zeros τ_1^* and τ_2^* or the zeros τ_2^* and τ_3^* may coalesce and then disappear; the resulting case is always case (1). Except at these bifurcations, which we do not discuss in the following but which can be treated similarly with unchanged results, G_1 and G_2 are separated by a vertical strip in case (1) and by a horizontal strip in case (2). In case (3), G_1 is separated from G_2 and G_3 by horizontal and vertical strips.

Now we discuss the relative position of H and G for the three cases. We know from Lemma 4.4 that H and G intersect transversally in four fixed points, $u_0, u_1 \in H^+$, $u_2, u_3 \in H^-$.

In case (1) there are two possibilities which give four fixed points.

(a) Both H^+ and H^- intersect G_1;
(b) H^+ intersects G_1, and H^- intersects G_2.

In case (2), remembering that the horizontal asymptote for H lies above the horizontal asymptote for G, we see that H^+ intersects G_1, and H^- intersects G_1 and G_2.

In case (3) there are four possibilities which give four fixed points.

(a) Both H^+ and H^- intersect G_1;
(b) H^+ intersects G_1 and H^- intersects G_3;
(c) both H^+ and H^- intersect G_2;
(d) H^+ intersects G_2 and H^- intersects G_3.

LEMMA 4.5. *The cases* (1.b), (3.b), *and* (3.d) *are not possible, i.e.,* H^- *does not intersect* G_2 *in case* (1), *and* H^- *does not intersect* G_3 *in case* (3).

Proof. We prove the lemma for case (1), the proof for case (3) is similar with G_2

replaced by G_3. G is the solution set of the equation $g(b,\tau)=0$. The critical points of g are the solutions of

$$g_b(b,\tau) = 2b(k\tau - d^2) - 2c = 0, \tag{4.12}$$

$$g_\tau(b,\tau) = kb^2 + 2(2k-1)\tau - 2kj = 0. \tag{4.13}$$

Equation (4.12) describes a hyperbola $\tilde{H}$, which is just H contracted by a factor k in the τ direction. In $b<0$, the parabola P defined by (4.13) intersects $\tilde{H}$ once in the critical point (b_*,τ_*), which is a saddlepoint. The topology of the level curves of g changes at the level value $g(b_*,\tau_*)$, in a way that corresponds to the transition between case (1) and case (2) upon variation of e. This implies that all of G_2 lies in the halfplane $b<b_*$. In particular, G_2 can intersect H^- at most in the quarterplane $Q=\{(b,\tau):\ b<b_*, \tau>\max\{\tau_*,0\}\}$. Since $g_\tau>0$ in Q and $g_b<0$ on $H^-\cap Q$, g is nowhere stationary along $H^-\cap Q$. Since both infinities of G_2 lie on the same side of H^-, this means that G_2 cannot intersect H^- at all. □

The above discussion and Lemma 4.5 imply that the three cases have the following common property.

LEMMA 4.6. *The set $G\cap([b_2,b_1]\times\mathbf{R})$ consists of two smooth graphs $G^\pm$ of functions $g^\pm:[b_2,b_1]\to\mathbf{R}$, distinguished by $g^-(b)<g^+(b), b\in(b_2,b_1)$. u_0 belongs to G^+, u_3 to G^-. u_1 and u_2 each lie on G^+ or G^- or both. (At least) in (b_2,b_1), both g^- and g^+ are smooth, and are stationary in at most one point.*

Finally we characterize the four fixed points.

LEMMA 4.7. (i) *u_0,u_1,u_2,u_3 are hyperbolic fixed points for the flow of $\overline{\Sigma^2}$; u_0 is an unstable node, u_3 is a stable node, u_1 and u_2 are saddles.*

(ii) *At u_1 and u_2 the stable and unstable manifolds are never tangent to vertical or horizontal lines, nor to G or H.*

(iii) *Interpreted, via suspension $(b,\tau)\mapsto(b\mathbf{e},\tau)$, as points in $\mathbf{R}^3$, u_0,u_1,u_2,u_3 are hyperbolic fixed points of $\overline{\Sigma^3}$. As such, the u_i have stable [unstable] manifolds of dimensions i $[3-i]$, $i=0,1,2,3$.*

Proof. For the reduced problem (4.9) u_0 and u_2 are repelling, u_1 and u_3 are attracting. Thus, for sufficiently small ν/λ assertion (i) follows by means of Proposition 3.2. We abbreviate (4.4) and (4.5) as

$$(\dot b,\dot\tau) = (h(b,\tau)/\nu, \tilde g(b,\tau)/\lambda)$$

and compute the derivative

$$A^{\nu,\lambda} = \begin{pmatrix} h_b/\nu & h_\tau/\nu \\ \tilde g_b/\lambda & \tilde g_\tau/\lambda \end{pmatrix}$$

of this vector field at any of the fixed points:

$$A^{\nu,\lambda}(b,\tau) = \begin{pmatrix} 1/\nu & 0 \\ 0 & \frac{1}{\lambda}(1-\frac{1}{k}) \end{pmatrix} \begin{pmatrix} \tau-d^2 & b \\ b & \frac{k}{k-1}(2-\frac{1}{k}+\frac{1}{\tau}(\frac{b^2}{2}-j)) \end{pmatrix}.$$

Taking into account that for symmetric matrices A, B with B positive definite, the number of negative and positive eigenvalues of the product BA does not depend on B, (i) follows for arbitrary $\nu,\lambda>0$. Assertion (ii) follows immediately upon multiplying $A^{\nu,\lambda}(b,\tau)$ by the vectors $(1,0)^\top$, $(0,1)^\top$, $(-h_\tau,h_b)^\top$, and $(-\tilde g_\tau,\tilde g_b)^\top$. To see (iii), we just note that in progressing from $\overline{\Sigma^2}$ to $\overline{\Sigma^3}$, an additional mode is added with eigenspace $E^\perp=\mathbf{e}^\perp\times\{0\}$ and eigenvalue $\tau-d^2$. □

Remarks. (i) Note that in connection with the signal speeds c_f, c_A, c_s of fast magnetoacoustic, Alfvén, and slow magnetoacoustic waves (cf. [3]; $c_f > c_A > c_s > 0$), assertion (iii) of Lemma 4.7 means that the physical states represented by the points u_0, u_1, u_2, u_3 correspond to flow with velocity $v > c_f$, $v \in (c_A, c_f)$, $v \in (c_s, c_A)$, and $v < c_s$, respectively. Correspondingly, the transition (u_0, u_1) is a fast shock, (u_2, u_3) a slow shock, and all (u_i, u_j) with $i \in \{0,1\}, j \in \{2,3\}$ are intermediate shocks.

(ii) The characterization of the fixed points of $\overline{\Sigma^2}$, $\overline{\Sigma^3}$ given in Lemmas 4.4 and 4.7 reflects well-known results [19] on the original full system Σ^6. The geometric statement of Lemma 4.6 puts us in a position to understand the dynamics of Σ^2 (see [18] and [19]) rigorously (see Lemma 5.1) and in all cases (see Fig. 1).

5. Existence and bifurcation of heteroclinic orbits. Gradient-like structure, positive invariance of physical state space, boundedness of the set of points on complete bounded orbits of positive temperature, the dimensions of stable and unstable manifolds, and specific geometric properties pose rather strong restrictions on the flow of Σ^3, which we will now use to prove the theorems stated in §1.

LEMMA 5.1. (i) *With a certain fixed ω, the two-dimensional system $\overline{\Sigma^2}$, depending on $\nu, \lambda > 0$, has heteroclinic orbits of the following types and no others:*

(a) $0 \to 1$, $0 \to 2$, $0 \to 3$, $1 \to 3$, $2 \to 3$ *for $\nu/\lambda > \omega$;*

(b) $0 \to 1$, $1 \to 2$, $2 \to 3$ *for $\nu/\lambda = \omega$;*

(c) $0 \to 1$, $2 \to 3$ *for $\nu/\lambda < \omega$.*

(ii) *At the bifurcation ratio $\nu/\lambda = \omega$, the unstable manifold of $\{u_1\} \times (0,\infty)^2$ and the stable manifold of $\{u_2\} \times (0,\infty)^2$, with respect to the extension of $\overline{\Sigma^2}$ by the equations $\dot{\nu} = 0$, $\dot{\lambda} = 0$, intersect transversally.*

(iii) *All orbits of types $0 \to 1$, $2 \to 3$, $0 \to 2$, $1 \to 3$, $1 \to 2$ are unique, while orbits of type $0 \to 3$ occur in a one-parameter family. In all cases there exist also orbits with α-limit u_0 [ω-limit u_3] which have no ω-limit [α-limit] in the physical range U^2.*

(iv) *The fixed points which lie in the physical range are ordered according to increasing values of the entropy S, i.e., $i < j$ implies $\hat{S}(u_i) < \hat{S}(u_j)$.*

(v) *The fixed points u_1, u_2, and u_3 always lie in the physical range U^2.*

Proof. (i) Consider the rectangle

$$R \equiv [b_2, b_1] \times (0, \bar{\tau}]$$

in the (b, τ) half-plane, with some $\bar{\tau} > \sup\{g^+(b); b_2 \le b \le b_1\}$ (see Fig. 2).

Independently of ν/λ, the flow of $\overline{\Sigma^2}$ leaves R through the boundary portion

$$(\partial R)^+ \equiv (\{b_2\} \times (\tau_2, \bar{\tau}]) \cup ([b_2, b_1] \times \{\bar{\tau}\}) \cup (\{b_1\} \times (\tau_1, \bar{\tau}]),$$

and enters R through

$$(\partial R)^- \equiv (\{b_2\} \times (0, \tau_2)) \cup (\{b_1\} \times (0, \tau_1)).$$

By part (ii) of Lemma 4.7, there are unique orbits Γ_i^u, Γ_i^s which approach the fixed points u_i, $i = 1,2$, from the interior of R, as their α or ω limit, respectively. We investigate possible positions of these orbits.

First, we show that assertions (a) and (c) hold in the extreme cases $\nu/\lambda >> 1$ and $\nu/\lambda << 1$, respectively. These cases can be treated by the geometrical singular perturbation theory from §3. For ν/λ sufficiently large there exists a one-dimensional attracting invariant manifold Γ_3 of $\overline{\Sigma^2}$, close to G^- and containing u_3. For the flow

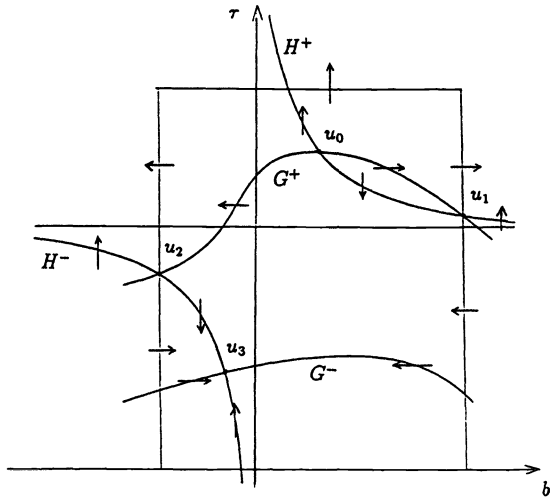

FIG. 2. *Phase portrait of* $\overline{\Sigma^2}$ *in* R.

restricted to Γ_3, u_3 is itself attracting. Let Γ_3^+ be the portion of Γ_3 in $b_3 < b < b_1$. Note that Γ_3^+ must lie in $\tau > 0$, since either the point u_1 or points on its almost vertical unstable manifold lie (arbitrarily) close to Γ_3 (for large enough ν/λ), which implies $\Gamma_3^+ \subset U^2$ by Lemmas 4.2 and 4.4. Hence, the almost vertical strongly unstable manifold of u_0 enters the domain of attraction of Γ_3^+ and an orbit $0 \to 3$ exists, as soon as $\nu/\lambda > \omega^*$ with ω^* sufficiently large—which we henceforth assume. (The idea underlying this argument consists in considering both the reduced and the "fast" problem into which $\overline{\Sigma^2}$ decouples for $\nu/\lambda \to \infty$; cf. [22].) This orbit $0 \to 3$ and parts of H and ∂R bound a region which Γ_1^u intersects but cannot leave. Thus, Γ_1^u has the ω limit u_3. The orbit Γ_1^u, the portion of H^- between u_2 and u_3, and $(\partial R)^+$ bound a region $R' \subset R$ which is negatively invariant. Since Γ_1^s and Γ_2^s point into R', they must both have an α limit u_0. Finally, as u_2 lies in the physical range U^2—this we anticipate from (v)—Γ_2^u is completely contained in $R \setminus (\mathrm{clos}(R'))$ and thus has ω-limit u_3. The four orbits Γ_1^s, Γ_1^u, Γ_2^s, Γ_2^u, being of type $0 \to 1$, $1 \to 3$, $0 \to 2$, $2 \to 3$, respectively, surround a region filled with orbits $0 \to 3$. We have shown that (a) holds if $\omega \geq \omega^*$.

From now on we quit the assumption $\nu/\lambda > \omega^*$ and consider instead cases where $\nu/\lambda < \omega_*$ with a possibly different number $\omega_* > 0$. If ω_* is sufficiently small, the orbits Γ_1^u, Γ_2^s are almost horizontal curves. This shows immediately that no heteroclinic orbit of type $i \to j$ exists, for any $(i,j) \in \{0,1\} \times \{2,3\}$. On the other hand, considering the portions of R above Γ_1^u and below Γ_2^s, respectively, we still see that Γ_1^s and Γ_2^u are heteroclinic orbits of type $0 \to 1$, $2 \to 3$, respectively. We have thus shown that (c) holds if $\omega \leq \omega_*$.

The phase portraits corresponding to cases (a) and (c) are both structurally stable (since they do not contain saddle–saddle connections). They are not equivalent (since, e.g., one of them contains an orbit of type $1 \to 3$, the other does not). Thus for at least a certain value $\omega \in [\omega_*, \omega^*]$, the phase portrait of $\overline{\Sigma^2}$ with $\nu/\lambda = \omega$ *does* contain an orbit Γ which is heteroclinic to saddles. Necessarily, $\Gamma = \Gamma_1^u = \Gamma_2^s$ and (b) holds with this ω. By part (ii) of Lemma 4.7, the intersections of Γ with sufficiently small

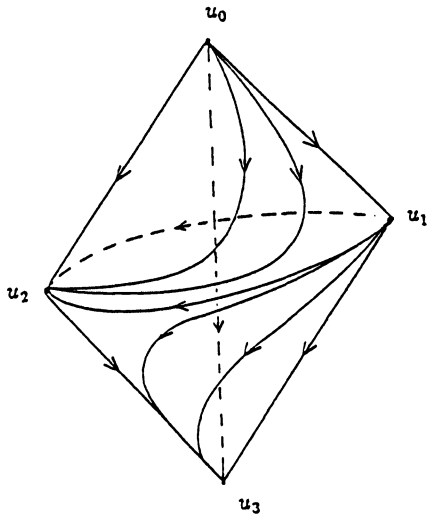

FIG. 3. *Connecting orbits of* Σ^3.

neighborhoods of u_1 and u_2 lie inside the region

$$N \equiv \{(b,\tau) \in R : g(b,\tau) < 0, h(b,\tau) < 0\}.$$

The vertical or horizontal orientation of the vector field along H and G, respectively, together with the piecewise monotonicity property of $g^{\pm}$ mentioned in Lemma 4.6 imply that Γ lies completely in N. At least for ν/λ in a neighborhood of ω, the orbits Γ_1^u, Γ_2^s intersect the $b = 0$ line in unique points $(0,\tau_1^u), (0,\tau_2^s)$ where τ_1^u and τ_2^s are smooth functions of ν/λ. Noting that $\Gamma \subset N$ implies $(\tau_1^u - \tau_2^s)'(\omega) < 0$, we see that the bifurcation takes place locally near ω as described in (a)–(c). Hence ω is unique and (a)–(c) hold globally.

(ii) Immediate from $(\tau_1^u - \tau_2^s)'(\omega) \neq 0$.

(iii) Follows directly from the facts that Γ_1^s connects to u_0, Γ_2^u to u_3, and the behavior of the vector field along H.

(iv) Follows from (i) and Lemma 4.1.

(v) From Lemma 4.4 we know already that $u_1, u_3 \in U^2$. The facts that $u_1 \in U^2$ and that a $1 \to 2$ orbit exists for $\nu/\lambda = \omega$ (case (b)) imply that also $u_2 \in U^2$, by virtue of Lemma 4.2. □

The following lemma characterizes the flow of Σ^3.

LEMMA 5.2. (i) *Assume that* Σ^3 *has four fixed points and that an orbit* $0 \to 3$ *exists in* E. *Then, unique orbits* $0 \to 1$, $2 \to 3$, *a pair of orbits* $1 \to 2$, *and one-parameter families of orbits* $0 \to 2$, $1 \to 3$ *exist for* Σ^3. *The union of these orbits and the fixed points is the boundary of a two-parameter family of orbits* $0 \to 3$. (ii) *Assume that* Σ^3 *has the three fixed points* u_1, u_2, *and* u_3 *and that an orbit* $1 \to 3$ *exists. Then, a unique orbit* $2 \to 3$, *a pair of orbits* $1 \to 2$, *and a one-parameter family of orbits* $1 \to 3$ *exist for* Σ^3.

The situation in the case of assertion (i) is shown in Fig. 3.

Proof. We consider a sufficiently small sphere Ω centered at u_3 and on this sphere a maximal connected reflectionally invariant set $\Omega_0 \neq \emptyset$ of points with α limit u_0.

All orbits passing through points in Ω_0 are heteroclinic orbits $0 \to 3$. We denote the union of these orbits by B.

B is an open, bounded subset of $\mathbf{R}^3$. The invariance of B implies that its boundary ∂B is invariant. Consider now the boundary $\partial\Omega_0$ of Ω_0 relative to Ω. Any point in $\partial\Omega_0$ has u_3 as its ω limit and must have u_1 or u_2 as its α limit . Since certain other points of Ω have no α limit inside the physical domain U^3, $\partial\Omega_0$ contains more than one point. Since the unstable manifold of u_2 lies in the invariant plane E, there is at most one orbit $2 \to 3$; hence, $\partial\Omega_0$ contains in particular a point with α limit u_1, i.e., an element of the unstable manifold W_1^u of u_1. Thus, $\partial\Omega_0$ contains a maximal smooth curve $\Gamma \subset \Omega \cap W_1^u$ of such points. Γ is either a closed curve or has endpoints. If Γ were a closed curve, then all points in B would have α limit u_1, an obvious contradiction. The endpoints of Γ have an α limit u_2 and coincide, lying on the thus existing and necessarily unique orbit $2 \to 3$. The nonempty boundary, with respect to W_1^u, of the set $\partial B \cap W_1^u$ consists of orbits $1 \to 2$; by the reflectional symmetry of Σ^3 (see Lemma 4.3) it is a pair of such orbits.

The remaining assertions of (i) follow by reversing the direction of the flow and the rôles of u_0, u_1, u_2, and u_3. Statement (ii) is proved in the same way. □

Remark. Note that the proof of Lemma 5.2 uses only (parts of) assertions (iii)–(v) of Lemma 5.1—and not the detailed knowledge statements (i) and (ii) provide about bifurcation. The following observation yields a closer connection between the statements of the two lemmas. For $\nu/\lambda = \omega$, the two-dimensional manifold W_1^u of u_1 intersects the two-dimensional stable manifold W_2^s of u_2 in the orbit $1 \to 2$, which lies in the invariant subspace E. Due to the reflectional symmetry of $\overline{\Sigma^3}$ with respect to E, the intersection of W_1^u and W_2^s is nontransversal. If W_1^u and W_2^s are in a sufficiently general position, e.g., if the intersections of W_1^u and W_2^s with the plane $b = 0$, for $\nu/\lambda = \omega$, have contact of some finite order, then a pair of symmetrically located transversal orbits $1 \to 2$ of $\overline{\Sigma^3}$ is generated as ν/λ passes through ω. Since the orbits $0 \to 1$, $2 \to 3$ are trivially transversal, the λ-Lemma [15] then implies the existence of the families of orbits $0 \to 2$, $1 \to 3$, $0 \to 3$ described in Lemma 5.2 for $\nu/\lambda - \omega$ small and positive. However, it seems difficult to verify the generic condition of sufficiently general position analytically.

All orbits established in Lemma 5.2—with the possible exception of orbits $1 \to 2$—are transversal, because of the dimensions of the corresponding stable and unstable manifolds. Since by Lemma 5.1 an orbit $0 \to 3$ (or $1 \to 3$ if u_0 is not physical) exists for $\nu/\lambda > \omega$, Lemma 5.2, Lemma 3.4, Proposition 3.2, and the analogue of Lemma 5.2 for the restriction of Σ^6 to the invariant manifold $\mathcal{C}$ imply the assertion of Theorem 1.2.

To prove Theorem 1.3 we consider systems Σ^4, $\overline{\Sigma^4}$ of four equations

$$\begin{aligned}
\nu\dot{b} &= -dw + \tau b - c,\\
\lambda\dot{\tau} &= \tau + \frac{R\theta}{\tau} + \frac{1}{2} \mid b \mid^2 - j,\\
\mu\dot{w} &= \quad w - db,\\
\kappa\dot{\theta} &= c_v\theta - \frac{1}{2}(\mid w \mid^2 - 2dw \cdot b + \tau \mid b \mid^2) - \frac{\tau^2}{2} + j\tau + bc - e,
\end{aligned}$$

where $(b, \tau, w) \in \mathbf{R} \times (0, \infty) \times \mathbf{R}$ and $\theta > 0$ or $\theta \in \mathbf{R}$, respectively. Representing the restriction of Σ^6 to $E \times E$, Σ^4 governs all coplanar profiles and is related to Σ^2 in precisely the same way as Σ^6 is to Σ^3. Thus, Proposition 3.2, the analogue of Lemma 3.4 for Σ^4, and Lemma 5.1, in particular its part (ii), imply that the bifurcation of

heteroclinic orbits of Σ^4 occurs as described in Theorem 1.3.

Acknowledgment. We would like to acknowledge the hospitality of the Institute for Mathematics and Its Applications, Minneapolis, where we carried out part of these investigations in 1989 and 1990.

TIME-LIKE TRACE REGULARITY OF THE WAVE EQUATION WITH A NONSMOOTH PRINCIPAL PART*

GANG BAO† AND WILLIAM W. SYMES‡

Abstract. A trace regularity result is established for the multidimensional wave equation with nonsmooth variable coefficients in the principal part. It is shown that the time like trace of the solution can be as regular as the solution itself, provided that microlocal restrictions against the tangential oscillations of the coefficients.

Key words. trace regularity, microlocal Sobolev spaces, nonsmooth symbol classes, propagation of singularities, pseudodifferential cutoff

AMS subject classifications. 35L10, 35R25, 35S05

1. Introduction.

A simplified model that governs many physical processes, such as acoustic and seismic wave propagation, is the following wave equation:

$$\left[\frac{1}{c^2(x,t)}\frac{d^2}{dt^2} - \nabla\sigma(x,t)\cdot\nabla\right] u(x,t) = f(x,t),$$

where both coefficients $c(x,t)$ and $\sigma(x,t)$ are functions that may or may not be smooth. In this paper, we continue our study of trace regularity properties for the solution of the multidimensional wave equation with nonsmooth coefficients. The classical trace theorem in Sobolev spaces indicates that there will be a half-derivative loss when a distribution is being restricted to a codimension one hypersurface. On the other hand, the standard method of energy estimates yields that for a strictly hyperbolic partial differential equation with smooth coefficients, the restriction (or trace) map to a codimension one space-like hypersurface, mapping the solution to its trace, is from $H^s(\mathbf{R}^k)$ to $H^s(\mathbf{R}^{k-1})$ locally for any real s. It is our goal in this work to investigate the circumstances under which a time-like trace of the solution is as regular as the solution itself. Obviously, even with smooth coefficients, the answer would be negative without any assumptions, which is essentially due to the ill-posedness nature of time-like hyperbolic Cauchy problems, or the presence of grazing rays. Moreover, the situation will be more complex when nonsmooth coefficients are present, where only limited initial regularity can be propagated.

In many applications, e.g., control and inverse problems, the situation where the coefficients (i.e., the medium) are time independent is of particular interest. Thus we shall throughout assume that the coefficients are time free in the model, i.e., $c(x,t) = c(x)$ and $\sigma(x,t) = \sigma(x)$, although some of the analysis may be extended to the time-dependent case.

The following theorem is the main result of this paper. We show that with additional microlocal smoothness along the tangential directions in the coefficients, the time-like trace can be as regular as the solution itself. Let us denote $d^2(x) = 1/c^2(x)$ and $\Box_d = d^2(x)\partial_t^2 - \Delta$ and $\xi = (\xi', \xi_n)$ is the Fourier variable corresponding to $x = (x', x_n)$. Throughout, the function $c(x)$ is always assumed to be positive as it stands for wave speed in applications.

THEOREM 1.1. *Suppose that $s > 3 + n/2$ and that u solves the problem*

$$[\Box_d - \nabla\sigma(x) \cdot \nabla]u(x,t) = f(x,t)\ , \tag{1.1}$$

$$u(x,t) \in H^l \cap H^{l+1}_{m\ell}(\gamma) \quad \textit{near } \{t = 0\}\ , \tag{1.2}$$

with

$$\gamma = \{(x,t,\xi,\omega), (x,t) \in \Omega, (\xi,\omega) \in \mathbf{R}^{n+1}, |\xi'|^2 = d^2\omega^2 \textit{ and } \xi_n = 0\}\ ,$$

where Ω is a compact subset of $\{(x,t) \in \mathbf{R}^{n+1}, |t|, |x_n| \le \epsilon_0\}$ for small $\epsilon_0 > 0$ and

$$\Gamma = \textit{a conic neighborhood of } \gamma\ .$$

Assume that

(i) $u \in H^{l-1} \cap H^l_{m\ell}(\Gamma)$, $1 \le l \le s$;

(ii) $d(x) \in H^s \cap H^{l+1}_{m\ell}(K)$ *and* $\nabla\sigma(x) \in H^{s-1} \cap H^l_{m\ell}(K)$, $\Pi :\ \Gamma \subset T^*(\mathbf{R}^{n+1}) \to K \subset T^*(\mathbf{R}^n)$ *is the projection map*;

(iii) $f \in H^{l-1} \cap H^l_{m\ell}(\Gamma)$.

Then

$$u\,|_{x_n=0} \in H^l_{\mathrm{loc}}\ ,$$

Trace regularity results are of great importance in diverse fields, such as control theory, boundary and initial boundary value problems of partial differential equations (PDEs), and in particular inverse problems. An interesting example arises from seismic imaging, where one wants to determine the mechanical properties of the earth through analyzing the seismogram measured on the surface of earth, i.e., the solution on a time-like surface. Clearly, modeling this process requires the most precise information about the time-like trace.

In [2], we proved a trace theorem for general linear PDEs with smooth variable coefficients, applying the Hörmander–Nirenberg pseudodifferential cutoff technique and the method of energy estimates. Our theorem indicates that the difficulty mentioned above may be resolved by imposing more smoothness against grazing ray directions. We then studied in [3] the wave equation with nonsmooth coefficients only at lower-order terms. Compared to the general case in [2], a much simpler pseudodifferential cutoff was available, which together with a result on propagation of singularities for strictly hyperbolic $\psi.d.o.$ equations with nonsmooth coefficients at lower order terms enabled us to prove a trace theorem.

The proof of Theorem 1.1 basically follows the framework developed in [3]. However, because of the presence of nonsmooth coefficients in the principal part, additional technical difficulties will necessarily take place. For example, the result on propagation of singularities which is essential in our proof becomes much harder to obtain. When the principal part has smooth or constant coefficients, as in [3], a generalized Rauch's lemma and a commutator lemma allowed us to extend a Beals–Reed theorem (the BRI, Theorem 1 in [7]) on propagation of singularities to a more suitable setting

for linear problems. However, the same idea breaks down when the principal part becomes nonsmooth. To cure the difficulty, a refined approach was introduced by Beals and Reed in [8], where nonsmooth symbol classes and the corresponding calculus were developed. Their approach follows the general outline of Hörmander's proof of the theorem on propagation of singularities for PDEs with smooth coefficients [11], but of course the nonsmoothness of the principal part requires some very delicate commutator estimates. The key step was to establish a sharp Gårding's inequality which allowed them to reduce the microlocal problem to a local one. They then proved a theorem on propagation of singularities for $\psi.d.o$ equations with nonsmooth symbols (the BRII, Theorem 3.2 in [8]). In this paper, we prove an extended version of the Beals–Reed theorem (the BRII). Our theorem assures that under similar hypotheses some lower-order microlocal regularity of the solution, for instance, H^s_{ml}-regularity (for $s \geq 0$), will also propagate along the null bicharacteristics. We also treat the case where coefficients may depend only on some of the variables, while we show that a better result can be expected. We emphasize that this is particularly important since the coefficients in our model are time independent!

We expect that the calculus of nonsmooth symbols developed in [8] and this work will find other applications. Working on PDEs with nonsmooth coefficients, one would often encounter similar commutator estimates.

Recently, studies on trace regularity have received much attention. For solutions of the multidimensional wave equation with constant coefficients, Symes proved in [22], by using the method of geometric optics, that with finitely energy initial data compactly supported away from the boundary, the trace is as regular as the solution in the interior. Similar results were obtained independently by Lasiecka and Triggiani [16] based on an application of the classical Laplace–Fourier transform. They also established (see [17]) a series of sharp global trace regularity results for second order hyperbolic equations with smooth coefficients and Dirichlet or Neumann boundary conditions. More recently, by using a microlocal cutoff technique, Lasiecka and Triggiani in [18] obtained an optimal tangential trace regularity theorem for the wave equation with smooth coefficients in a bounded domain. For a wave equation, Kim [13] proved a trace regularity result by employing a microlocal method, which further allowed him to study the regularity of some boundary controls. Our approach differs from that mentioned above in several aspects: The data in this work need not have compact supports, and the coefficients in the model may be nonsmooth; furthermore, our method relies heavily on various results on propagation of singularities. For more general geometry and functions, Joly studied in [15] some trace regularity results in the case of anisotropic Sobolev spaces in two dimensions where the domain can be any arbitrary open set of $\mathbf{R}^2$.

The outline of the paper is as follows: In the next section, we introduce nonsmooth symbol classes which are more flexible than those defined in [8] in the sense that the coefficients may depend only on part of the variables. We then develop a calculus for this class of nonsmooth symbols which handles a more general class of functions with less regularity than in [8]. We establish a Gårding type inequality. Finally, we present a theorem on propagation of singularities. Section 3 is devoted to the proof of our main theorem. This is done by a combination of microlocal cutoff, the "fattening" lemma, the method of energy estimates, and the theorem on propagation of singularities.

Throughout, the reader is assumed to be familiar with the basic calculus of *pseudodifferential operators* ($\psi.d.o.$) as presented in [24] and [19]. A classical $\psi.d.o.$ P of

order m is denoted as $P \in OPS^m$ with its symbol $p \in S^m$. $ES(P)$ stands for *the essential support* of operator P. H^s is the standard L^2-type Sobolev space and H^s_{loc} means a local Sobolev space. $\langle\xi\rangle$ means $(1+|\xi|^2)^{1/2}$. The Fourier transform of a distribution u is expressed as $\hat{u}$. Usually, the constant from the Fourier transform is assumed to be absorbed by the integral. For simplicity, C serves as a generalized positive constant the precise value of which is not needed. The characteristic function of a set Γ is represented by χ_Γ.

We conclude the introduction by a brief discussion about nonlinear wave equations. The approach of this work may be adopted nicely in the trace regularity study of a class of nonlinear wave equations. In fact, various results on propagation of singularities for semilinear and quasi-linear wave equations have been developed by many people, in particular by Rauch [20], Bony [9], Beals and Reed [7], [8], Beals [4], [5], and Chemin [10]. But compared to the linear case, much higher overall smoothness of both the solution and coefficients would be required. Along this direction, some progress has been made in Bao [1].

2. Propagation of microlocal regularity. We introduce some basic concepts, related material may be found in Beals and Reed [8]. General theoretical aspects as well as applications of nonsmooth microlocal analysis may be found in Rauch [20], Beals [6], and Taylor [25] and references therein.

DEFINITION 2.1. *A distribution u is said to be in $H^s \cap H^r_{m\ell}(x_0,\xi_0)$ if there exist $\phi(x) \in C_0^\infty(\mathbf{R}^n)$ with $\phi(x_0) \neq 0$ and a conic neighborhood $\gamma \subset \mathbf{R}^n\backslash\{0\}$ of ξ_0 such that*

$$\langle\xi\rangle^s(\phi u)^\wedge(\xi) \in L^2(\mathbf{R}^n) \quad \text{and} \quad \langle\xi\rangle^r\chi_\gamma(\xi)(\phi u)^\wedge(\xi) \in L^2(\mathbf{R}^n)\,.$$

Next, we define a nonsmooth symbol class, which follows [8] with one main difference, that is, the present symbol class includes symbols that depend only on part of the variables. An interesting special case deals with PDEs with coefficients depending on part of the variables. For convenience, we denote $x = (x^1, x^2) \in \mathbf{R}^{n_0} \times \mathbf{R}^{n-n_0}$, $1 \leq n_0 \leq n$. The frequency variables corresponding to $x = (x^1, x^2)$ are denoted by $\xi = (\xi^1, \xi^2) \in \mathbf{R}^{n_0} \times \mathbf{R}^{n-n_0}$.

DEFINITION 2.2. *$S^{m;s,r}_{n_0}(K)$ is defined to be the collection of symbols $a(x^1,\xi)$, smooth in ξ, such that*

$$a(x^1,\xi)/\langle\xi\rangle^m \in H^s \cap H^r_{m\ell}(K)$$

as a function of x^1 uniformly in ξ.

In other words, for each $(x^1_0,\xi_0) \in K$, there exist a function $\psi(x^1) \in C_0^\infty(\mathbf{R}^{n_0})$ with $\psi(x^1_0) \neq 0$ and a conic neighborhood γ of ξ_0 such that

$$\langle\zeta\rangle^s\mathcal{F}(\psi a)(\zeta,\xi)/\langle\xi\rangle^m \in L^2(d\zeta)$$

and

$$\langle\zeta\rangle^r\chi_\gamma(\zeta)\mathcal{F}(\psi a)(\zeta,\xi)/\langle\xi\rangle^m \in L^2(d\zeta)$$

with norms independent of ζ.

In particular, when $n = n_0$, the symbol class becomes the one introduced in [8]. In that case, we denote

$$S^{m;s,r}(K) = S^{m;s,r}_n(K)\,.$$

More generally, dealing with operators with lower order terms, we also need the following definition.

DEFINITION 2.3. *For $k \geq 0$ an integer, $S^{m+k;s+k,r+k}_{st,n_0}(K)$ consists of symbols $a(x^1,\xi)$ of the form*

$$a_{m+k}(x^1,\xi) + a_{m+k-1}(x^1,\xi) + \cdots + a_m(x^1,\xi),$$

where $a_m(x^1,\xi) \in S^{m;s,r}(K)$ and for $0 < j \leq k$

$$a_{m+j}(x^1,\xi) = \sum_l a_{j,l}(x^1) P_{m+j,l}(x^1,\xi) \in S^{m;s,r}(K)$$

with $a_{j,l}(x^1) \in H^{s+j} \cap H^{r+j}_{m\ell}(K)$ and $P_{m+j,l}(x^1,\xi) \in S^{m+j}_{1,0}$.

It is easy to observe that

$$S^{m+k;s+k,r+k}_{st,n_0}(K) \subset S^{m+k;s+k,r+k}_{n_0}(K) + \cdots + S^{m;s,r}_{n_0}(K) \subset S^{m+k;s,r}_{n_0}(K)\,.$$

We are now ready to state a linear theorem on propagation of singularities for ψ.d.o. equations with nonsmooth coefficients. Again recall that $x = (x^1,x^2) \in \mathbf{R}^{n_0} \times \mathbf{R}^{n-n_0}$, and $\xi = (\xi^1,\xi^2)$ is the corresponding frequency variable.

THEOREM 2.1. *Let $n_0/2 < s$, $0 \leq l \leq s, q$ and $q < l + s - n_0/2$ $(1 \leq n_0 \leq n)$, and*

$$a(x^1,\xi) \in S^{m+2;s+2,q+2}_{st,n_0}(K)$$

is of real principal type with real principal symbol a_{m+2} which is homogeneous of degree $m+2$ in ξ, and that γ is the null bicharacteristic through the characteristic point (x_0,ξ_0). $K = \Pi\gamma$ with $\Pi : T^*(\mathbf{R}^n) \to T^*(\mathbf{R}^{n_0})$ the projection map. Assume that

(i) $v \in H^{l+m} \cap H^{q+m}_{m\ell}(\gamma)$,
(ii) $v \in H^{l+m} \cap H^{q+m+\epsilon}_{m\ell}(x_0,\xi_0)$ *for some* $0 \leq \epsilon \leq 1$,
(iii) $f \in H^l \cap H^q_{m\ell}(\gamma)$,

and that

$$a(x^1,D_x)v = f.$$

Then

$$v \in H^{q+m+\epsilon}_{m\ell}(\gamma).$$

That is, if the solution v has improved microlocal regularity at a point on a null bicharacteristic, the improved regularity will stay for the rest of the null bicharacteristic.

Remarks on Theorem 2.1. In the case that $l = s$ and $n_0 = n$, we speak of the original Beals–Reed theorem (the BRII). Compared to the BRII, Theorem 2.1 assures that weaker regularity of the solution may also be propagated along null bicharacteristics, and a better regularity result can be achieved when the coefficients depend only on some of the variables.

It seems that the regularity hypotheses on the coefficients and right-hand side cannot be improved much. However, the sharpness questions on this theorem and other theorems on propagation of singularities (the BRI, the BRII, and Theorem 2.1 in [3]) remain open. Needless to say, these questions are extremely important and worthwhile to pursue in the future.

The most precise information about the propagation of singularities may be obtained in the case of one-space dimension, where the wave operator can be factored into products of two simple first-order differential operators. Roughly speaking, the improved microlocal regularity is then propagated along null bicharacteristics with very few restriction on the order of smoothness. The best reference for one-dimensional hyperbolic problems is Rauch and Reed [21].

2.1. About the proof of Theorem 2.1. Theorem 2.1 may be proved by following the general scheme of the proof of the BRII in [8] with some necessary modifications. The main ingredients of their proof are as follows:

- The development of a calculus for the nonsmooth symbol class
- Construction of an appropriate microlocal cutoff b_0 by essentially following Bony's construction in [9].
- Proof of a generalized Gårding's inequality.

The key step was to develop the calculus of the nonsmooth symbol class, which led to a systematic way of handling commutators that involve either nonsmooth functions or nonsmooth symbols ($\psi.d.o.$ with nonsmooth coefficients). It was shown that the nonsmooth symbol class developed by Beals and Reed preserves important continuity properties of smooth $\psi.d.o.$

We point out that when the differential operator of a differential equation has constant coefficients or is with a smooth principal part, the microlocal cutoff may be constructed in a much simpler fashion. In fact, following Hörmander's first proof of the theorem on propagation of singularities in [12] (see also Nirenberg [19]) there exists a $b_0 \in OPS^0$ such that $[P_m, b_0]$ is of order $m-2$ instead of $m-1$, if P_m is the principal part of an mth order partial differential operator with usual assumption on P_m. Having constructed this operator b_0, one may reduce the microlocal regularity problem to a local one by acting b_0 to both sides of the PDE.

For simplicity, we shall skip the formal proof of Theorem 2.1 with the understanding that the proof can be formally done by modifying the proof of the BRII ([8], pp. 174–177). In order to do so, a calculus of general nonsmooth symbols must be developed and also a new Gårding's inequality must be established. Through this process, Theorem 2.2 will play a crucial role since it characterizes the fundamental Sobolev continuous properties of the class of nonsmooth symbols. The rest of this section is devoted to establish the necessary results for completing the proof of Theorem 2.1.

2.2. Sobolev continuity of nonsmooth symbols. We begin with some inequalities that will be used frequently.

PROPOSITION 2.1. *Let*

$$C_g^2 = \sup_{\xi,\eta} \int |g(\zeta,\xi,\eta)|^2 d\zeta$$

and

$$C_K^2 = \sup_{\zeta,\eta} \int |K(\zeta,\xi,\eta)|^2 d\xi \,.$$

For $h \in L^2$, define

$$(Th)(\zeta,\eta) = \int K(\zeta,\xi,\eta) g(\zeta-\xi,\xi,\eta) h(\xi,\eta) d\xi \,.$$

Then

$$||Th|| \le C_g C_K ||h|| \,.$$

Proof. Consider that for any $f(\zeta,\eta) \in L^2$ and $||f|| \le 1$,

$$|(Th,f)| = \left| \int \int f(Th) d\zeta d\eta \right|$$

$$= \left| \int\int\int K(\zeta,\xi,\eta) g(\zeta-\xi,\xi,\eta) f(\zeta,\eta) h(\xi,\eta) d\xi d\zeta d\eta \right| .$$

Interchanging the sequence of integrations and by Cauchy–Schwarz's inequality, we have

$$\begin{aligned} |(Th,f)| &\le \int\int d\xi d\eta |h(\xi,\eta)| \left[\int d\zeta |K(\zeta,\xi,\eta) f(\zeta,\eta)|^2\right]^{1/2} \cdot \left[\int d\zeta |g(\zeta-\xi,\xi,\eta)|^2\right]^{1/2} \\ &\le C_g ||h|| \cdot \left[\int\int\int d\xi d\eta d\zeta |K(\zeta,\xi,\eta) f(\zeta,\eta)|^2\right]^{1/2} \\ &\le C_g C_K \, ||h|| \cdot ||f||, \end{aligned}$$

hence the conclusion follows. □

Similarly, one can prove the following result.

PROPOSITION 2.2. *Denote* $\zeta = (\zeta^1, \zeta^2)$ *and* $\eta = (\eta^1, \eta^2)$, *where* ζ^1, η^1 *and* ξ *are of the same dimension. Let*

$$C_h^2 = \sup_{\zeta} \int d\xi |h(\xi,\zeta)|^2$$

$$C_g^2 = \sup_{\zeta,\xi} \int d\eta |g(\eta,\zeta,\xi)|^2$$

and

$$C_G^2 = \sup_{\eta} \int\int d\xi d\zeta |G(\xi,\eta,\zeta)|^2 .$$

For $v \in L^2$, *define*

$$T(v)(\eta) = \int\int d\xi d\zeta G(\xi,\eta,\zeta) h(\xi,\zeta) g(\eta^1-\zeta^1-\xi, \eta^2-\zeta^2, \zeta, \xi) v(\zeta) .$$

Then

$$||T(v)|| \le C_h C_g C_G ||v|| .$$

Proof. For any $f \in L^2(d\eta)$ with $||f|| \le 1$, consider

$$\begin{aligned} |(T(v),f)| &\le \int d\zeta |v(\zeta)| \int\int d\xi d\eta |h(\xi,\zeta) g(\eta^1-\zeta^1-\xi, \eta^2-\zeta^2, \zeta, \xi)| |G(\xi,\eta,\zeta) f(\eta)| \\ &\le \int d\zeta |v(\zeta)| \left[\int d\xi |h|^2 \int d\eta |g|^2\right]^{1/2} \left[\int\int d\xi d\eta |G|^2 |f|^2\right]^{1/2} \\ &\le C_g C_h \int d\zeta |v(\zeta)| \left[\int\int d\xi d\eta |G|^2 |f|^2\right]^{1/2} \\ &\le C_g C_h C_G ||v|| \, ||f||. \end{aligned}$$ □

PROPOSITION 2.3. *Assume that* K' *is a closed cone which is strictly contained in an open cone* K. *If* $\xi \in K'$, $\eta \in K^C$, *where* K^C *is the complement of* K, *then*

(1) $|\xi - \eta| \ge C_1 |\xi|$, $C_1 > 0$;

(2) *if* $|\xi| \ge C_0 > 0$, *then* $\langle \xi - \eta \rangle \ge C \langle \xi \rangle$.

The following theorem establishes continuity properties of the nonsmooth symbol class. Let $\Pi_1 : (x^1, x^2, \xi^1, \xi^2) \to (x^1, \xi^1, \xi^2)$.

THEOREM 2.2. *Let $n_0/2 < s$, $0 \le l \le s, q$, and $q < l + s - n_0/2$ $(1 \le n_0 \le n)$. Suppose that $a(x^1, \xi) \in S^{m;s,q}_{n_0}(\gamma)$, $0 \le m \le s, l$, $\gamma = \Pi_1\Gamma$. Then*

$$a(x^1, D_x)$$

is a bounded operator from $H^l \cap H^q_{m\ell}(\Gamma)$ to $H^{l-m} \cap H^{q-m}_{m\ell}(\Gamma)$.

Remarks. We list some of the interesting special cases of Theorem 2.2.

- If $n_0 = n$ and $l = s$, then Theorem 2.2 becomes an earlier result of Beals and Reed (Theorem 1.3 in [8]). In addition, the case where $a(x, \xi) = a(x^1, \xi)$ gives rise to Rauch's lemma [20].
- The case $a(x^1, \xi) = a(x)$ is the generalized Rauch's lemma proved in [3] (Lemma 2.3).

Proof. W.l.o.g., we assume that $s < q$, some obvious modification will yield the conclusion for $s \ge q$. For $u \in H^l \cap H^q_{m\ell}(\Gamma)$, we may assume u and $a(x^1, \xi)$ have compact supports in x near x_0, and x^1 near x^1_0, respectively, where $(x_0, \xi_0) \in \Gamma$. Then

$$a(x^1, D_x)u(x) = \int\int e^{ix\cdot\xi} a(x^1, \xi)\hat{u}(\xi)d\xi$$

and

$$\widehat{(au)}(\eta) = \int \hat{a}(\eta^1 - \xi^1, \xi^1, \eta^2)\hat{u}(\xi^1, \eta^2)d\xi^1 \, .$$

Next since $a \in S^{m;s,r}_{n_0}(\gamma)$,

$$\hat{a}(\zeta, \xi) = f(\zeta, \xi)\langle\xi\rangle^m/\langle\zeta\rangle^s$$

where $\sup_\xi \int f^2(\zeta, \xi)d\zeta < \infty$.

Define $v(\xi) = \langle\xi\rangle^l\hat{u}(\xi) \in L^2$. Thus

$$\langle\eta\rangle^{l-m}\widehat{(au)}(\eta) = \int K(\xi^1, \eta)f(\eta^1 - \xi^1, \xi^1, \eta^2)v(\xi^1, \eta^2)d\xi^1$$

with

$$K(\xi^1, \eta) = \langle\eta\rangle^{l-m}/\langle\eta^1 - \xi^1\rangle^s\langle\xi^1, \eta^2\rangle^{l-m} \, .$$

Therefore from Proposition 2.1, it suffices to show that

$$\sup_\eta \int |K(\xi^1, \eta)|^2 d\xi^1 < \infty$$

which follows immediately from Hölder's inequality and the assumption that $s > n_0/2$ and $l \ge m$.

Let θ be a conic neighborhood of ξ_0 such that $u \in H^l \cap H^q_{m\ell}(\theta)$, and $a(x^1, \xi) \in S^{m;s,r}_{n_0}(\sigma)$ where $\sigma = \Pi\theta$ the projection of θ onto the ξ^1-space. Let $\theta' \subset\subset \theta$, be a strictly smaller conic neighborhood of ξ_0 and σ' is the projection of θ'. We must show that

$$\chi_{\theta'}(\eta)\langle\eta\rangle^{q-m}\widehat{(au)}(\eta) \in L^2 \, .$$

Write

$$\hat{a}(\zeta,\xi) = \frac{\chi_\sigma(\zeta) f_1(\zeta,\xi)\langle\xi\rangle^m}{\langle\zeta\rangle^q} + \frac{\chi_{\sigma^C}(\zeta) f_2(\zeta,\xi)\langle\xi\rangle^m}{\langle\zeta\rangle^s}$$
$$\hat{u}(\xi) = \frac{\chi_\theta(\xi) v_1(\xi)}{\langle\xi\rangle^q} + \frac{\chi_{\theta^C}(\xi) v_2(\xi)}{\langle\xi\rangle^l},$$

where $f_i \in L^2(d\zeta)$ uniformly in ξ and $v_i \in L^2$. Then

$$\chi_{\theta'}(\eta)\langle\eta\rangle^{q-m}\hat{u} = \sum_{i,j=1,2} \int K_{ij}(\xi^1,\eta) f_i(\eta^1-\xi^1,\xi^1,\eta^2) v_i(\xi^1,\eta^2) d\xi^1,$$

where

$$K_{11}(\xi^1,\eta) = \frac{\chi_{\theta'}(\eta)\chi_\sigma(\eta^1-\xi^1)\chi_\theta(\xi^1,\eta^2)\langle\xi^1,\eta^2\rangle^m\langle\eta\rangle^{q-m}}{\langle\eta^1-\xi^1\rangle^q\langle\xi^1,\eta^2\rangle^q}$$
$$K_{12}(\xi^1,\eta) = \frac{\chi_{\theta'}(\eta)\chi_\sigma(\eta^1-\xi^1)\chi_{\theta^C}(\xi^1,\eta^2)\langle\xi^1,\eta^2\rangle^m\langle\eta\rangle^{q-m}}{\langle\eta^1-\xi^1\rangle^q\langle\xi^1,\eta^2\rangle^l}$$
$$K_{21}(\xi^1,\eta) = \frac{\chi_{\theta'}(\eta)\chi_{\sigma^C}(\eta^1-\xi^1)\chi_\theta(\xi^1,\eta^2)\langle\xi^1,\eta^2\rangle^m\langle\eta\rangle^{q-m}}{\langle\eta^1-\xi^1\rangle^s\langle\xi^1,\eta^2\rangle^q}$$
$$K_{22}(\xi^1,\eta) = \frac{\chi_{\theta'}(\eta)\chi_{\sigma^C}(\eta^1-\xi^1)\chi_{\theta^C}(\xi^1,\eta^2)\langle\xi^1,\eta^2\rangle^m\langle\eta\rangle^{q-m}}{\langle\eta^1-\xi^1\rangle^s\langle\xi^1,\eta^2\rangle^l}.$$

Once again, by Proposition 2.1, it suffices to show that

$$\sup_\eta \int |K_{ij}(\xi^1,\eta)|^2 d\xi^1 < \infty.$$

We now estimate these kernels separately.

On support K_{11}, $\eta \in \theta'$, $\eta^1-\xi^1 \in \sigma$, $(\xi^1,\eta^2) \in \theta$. Then

$$|K_{11}| \le \frac{\langle\eta\rangle^{q-m}}{\langle\eta^1-\xi^1\rangle^q\langle\xi^1,\eta^2\rangle^{q-m}} \in L^2(d\xi^1).$$

On support K_{12}, $\eta \in \theta'$, $\eta^1-\xi^1 \in \sigma$, and $(\xi^1,\eta^2) \in \theta^C$. Then $\langle\eta^1-\xi^1\rangle \ge C\langle\eta\rangle$, hence

$$|K_{12}| \le \frac{1}{\langle\eta^1-\xi^1\rangle^m\langle\xi^1,\eta^2\rangle^{l-m}} \in L^2(d\xi^1)$$

since $l > n_0/2$.

On support K_{21}, $\eta \in \theta'$, $\eta^1-\xi^1 \in \sigma^C$, and $(\xi^1,\eta^2) \in \theta$, therefore $\langle\xi^1,\eta^2\rangle \ge C\langle\eta\rangle$. It follows that

$$|K_{21}| \le \frac{C}{\langle\eta^1-\xi^1\rangle^s} \in L^2(d\xi^1).$$

On support K_{22}, $\eta \in \theta'$, $\eta^1-\xi^1 \in \sigma^C$, and $(\xi^1,\eta^2) \in \theta^C$, therefore $\langle\xi^1,\eta^2\rangle \ge C\langle\eta\rangle$. It follows that

$$|K_{22}| \le \frac{C}{\langle\eta^1-\xi^1\rangle^{s+l-q}} \in L^2(d\xi^1)$$

because of the assumption $s+l-q > n_0/2$. □

2.3. Calculus of nonsmooth symbol class. With the presence of nonsmooth coefficients, one always needs to study various algebraic properties, such as products of two nonsmooth functions, the action of a nonsmooth symbol ($\psi.d.o.$) to a function, and commutators between smooth (or nonsmooth) $\psi.d.o.$s. To serve the proof of Theorem 2.1, we shall study compositions of an operator that has nonsmooth symbol with a smooth operator from left. The proof of Theorem 2.1 also requires a Gårding's inequality.

DEFINITION 2.4. *For $\Gamma \subset T^*(\mathbf{R}^n)$, $S_{bd}^{m;s,q,l,r}(\Gamma)$ is a collection of symbols that are in $S^{m;s,q}(\Gamma)$ and define bounded maps from*

$$H^l \cap H^r_{m\ell}(\Gamma) \to H^{l-m} \cap H^{r-m}_{m\ell}(\Gamma) .$$

LEMMA 2.1. *Let $n_0/2 < s$, $0 \le l \le s$, $1 \le n_0 \le n$, $s \le s_b$, $n/2 < s_b$, and $q < \min\{s + l - n_0/2, s_b + s - n/2\}$. Let $k \ge 0$ be an integer, and for $|\alpha| \le k$*

$$a(x^1, \xi) \in S^{m;s+k,q+k}_{n_0}(\gamma) , \quad \partial^\alpha_\xi b(x, \xi) \in S^{k-|\alpha|;s_b,q}(\Gamma) , \text{ and } \gamma = \Pi_1\Gamma .$$

Then $b \circ a(x, \xi)$, the symbol of operator $b(x, D)a(x^1, D)$, satisfies

$$\left\{ b \circ a(x, \xi) - \sum_{|\alpha|<k} \frac{1}{\alpha!} \partial^\alpha_\xi b D^\alpha_{x^1} a(x^1, \xi) \right\} \in S^{m;s,q,l,q}_{bd}(\Gamma) .$$

Proof.

$$(b \circ a)(x, D_x)u(x) = \int e^{ix\cdot\xi} b(x, \xi)\widehat{(au)}(\xi) d\xi.$$

It follows from

$$\widehat{(au)}(\xi) = \int \hat{a}(\xi^1 - \zeta^1, \zeta^1, \xi^2)\hat{u}(\zeta^1, \xi^2) d\zeta^1$$

that

$$(b \circ a)(x, D_x)u(x) = \int\int e^{ix\cdot\xi} b(x, \xi)\hat{a}(\xi^1 - \zeta^1, \zeta^1, \xi^2)\hat{u}(\zeta^1, \xi^2) d\zeta^1 d\xi$$

and

$$\widehat{(b \circ au)}(\eta) = \int\int \hat{b}(\eta - \xi, \xi)\hat{a}(\xi^1 - \zeta^1, \zeta^1, \xi^2)\hat{u}(\zeta^1, \xi^2) d\zeta^1 d\xi .$$

Substituting ξ^1 and ζ^2 by $\xi^1 + \zeta^1$ and ξ^2, we have

$$\widehat{(b \circ au)}(\eta) = \int\int \hat{b}(\eta^1 - \xi^1 - \zeta^1, \eta^2 - \zeta^2, \xi^1 + \zeta^1, \zeta^2)\hat{a}(\xi^1, \zeta^1, \zeta^2)\hat{u}(\zeta) d\zeta d\xi^1 .$$

On the other hand,

$$(\partial^\alpha_\xi b D^\alpha_{x_1} a)(x, D_x)u(x) = \int e^{ix\cdot\zeta} (\partial^\alpha_\zeta b D^\alpha_{x_1} a)(x, \zeta)\hat{u}(\zeta) d\zeta$$

and

$$\begin{aligned} \widehat{(\partial^\alpha_\xi b D^\alpha_{x_1} au)}(\eta) &= \int\int e^{ix\cdot(\zeta-\eta)} (\partial^\alpha_\zeta b D^\alpha_{x_1} a)(x, \zeta)\hat{u}(\zeta) d\zeta dx \\ &= \int\int \partial^\alpha_\zeta \hat{b}(\eta^1 - \zeta^1 - \xi^1, \eta^2 - \zeta^2, \zeta)(\xi^1)^\alpha \hat{a}(\xi^1, \zeta)\hat{u}(\zeta) d\zeta d\xi^1 . \end{aligned}$$

Now, defining

$$r(x,D) = b \circ a(x,D) - \sum_{|\alpha|<k} \frac{1}{\alpha!}(\partial_\xi^\alpha b D_{x_1}^\alpha a)(x,D)$$

we then get by Taylor's theorem

(2.1)

$$(\widehat{ru})(\eta) = \sum_{|\alpha|=k} C_\alpha \int\int \left\{ \int_0^1 (1-t)^{k-1} (\partial_\zeta^\alpha \hat{b})(\eta^1 - \zeta^1 - \xi^1, \eta^2 - \zeta^2, \zeta^1 + t\xi^1, \zeta^2) dt \right\} \times (\xi^1)^\alpha \hat{a}(\xi^1, \zeta) \hat{u}(\zeta) d\xi^1 d\zeta$$

for the case $k = 0$, the term in braces should be replaced by $\hat{b}(\eta^1 - \zeta^1 - \xi^1, \eta^2 - \zeta^2, \zeta^1 + t\xi^1, \zeta^2)$.

Therefore

$$(\widehat{ru})(\eta) = \int \hat{r}(\eta - \zeta, \zeta) \hat{u}(\zeta) d\zeta \,,$$

where

$$\hat{r}(\eta,\zeta) = \begin{cases} \displaystyle\int \sum_{|\alpha|=k} C_\alpha \int \left\{ \int_0^1 (1-t)^{k-1} (\partial_\zeta^\alpha \hat{b})(\eta^1 - \xi^1, \eta^2, \zeta^1 + t\xi^1, \zeta^2) dt \right\} \\ \qquad \times (D_{x^1}^\alpha a)\widehat{\ }(\xi^1, \zeta) d\xi^1 \quad \text{if } k \neq 0 \\ \displaystyle\int \hat{b}(\eta^1 - \xi^1, \eta^2, \xi^1 + \zeta^1, \zeta^2) \hat{a}(\xi^1, \zeta) d\xi^1 \quad \text{if } k = 0. \end{cases}$$

Let $K' \subset\subset K$ be a small conic neighborhood of ξ_0, $(x_0, \xi_0) \in \Gamma$, with K sufficiently small so that estimates of Definition 2.2 hold for $\partial_\zeta^\alpha b$ on K and a on $\theta = \Pi K$ (Π the projection map from $\mathbf{R}^n$ to $\mathbf{R}^{n_0}$). In order to show

$$\left\{ b \circ a(x,\xi) - \sum_{|\alpha|<k} \frac{1}{\alpha!} \partial_\xi^\alpha b D_{x^1}^\alpha a(x^1, \xi) \right\} \in S^{m;s,q}(\Gamma)$$

it suffices to prove

$$\langle \eta \rangle^s \frac{\hat{r}(\eta,\zeta)}{\langle \zeta \rangle^m} \in L^2(d\eta) \text{ and } \langle \eta \rangle^q \frac{\chi_{K'}(\eta) \widehat{\ }(r)(\eta,\zeta)}{\langle \zeta \rangle^m} \in L^2(d\eta).$$

This may be proved similarly as in the proof of Theorem 2.2 by treating ζ as a parameter, hence we shall omit it.

We next show that $r(x,D)$ is a bounded operator from $H^l \cap H_{m\ell}^q(\Gamma)$ to $H^{l-m} \cap H_{m\ell}^{q-m}(\Gamma)$.

Let us begin by proving the local part of the conclusion. W.l.o.g., only the case $k \neq 0$ is considered here. For $|\alpha| = k$, let

$$\langle \xi^1 \rangle^\alpha \hat{a}(\xi^1, \zeta) = \frac{h(\xi^1, \zeta) \langle \zeta \rangle^m}{\langle \xi^1 \rangle^s} \text{ and } \hat{u}(\zeta) = v(\zeta)/\langle \zeta \rangle^l,$$

where $h(\xi^1,\zeta) \in L^2(d\xi^1)$ uniformly in ζ and $v \in L^2$. The integral kernel in the expression (2.1) can be written

$$g(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2,\zeta,\xi^1)/\langle\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b},$$

where $g(\eta,\zeta,\xi^1) \in L^2(d\eta)$ uniformly in ζ and ξ^1.

Thus

$$\langle\eta\rangle^{l-m}\widehat{(ru)}(\eta) = \sum_{|\alpha|=k} C_\alpha \int\int K(\xi^1,\eta,\zeta)g(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2,\zeta,\xi^1)h(\xi^1,\zeta)v(\zeta)d\xi^1 d\zeta$$

with

$$K(\xi^1,\eta,\zeta) = \frac{\langle\eta\rangle^{l-m}}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b}\langle\xi^1\rangle^s\langle\zeta\rangle^{l-m}}\,.$$

Because of Proposition 2.2, we only need to show

$$K \in L^2(d\xi^1 d\zeta) \quad \text{uniformly in } \eta\,.$$

We separate it into several pieces:

If $|\eta|/3 \le |\zeta|$, then

$$|K| \le \frac{C}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b}\langle\xi^1\rangle^s};$$

hence $K \in L^2(d\xi^1 d\zeta)$, since $s > n_0/2$ and $s_b > n/2$.

In the region where $|\zeta| < |\eta|/3 \le |(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2)|$, then

$$\begin{aligned}|K| &\le \frac{C}{\langle\xi^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b-l+m}\langle\xi^1\rangle^s\langle\zeta\rangle^{l-m}}\\ &\le \frac{C}{\langle\xi^1\rangle^s\langle\zeta\rangle^{s_b}}.\end{aligned}$$

In the region, $|\zeta| < |\eta|/3$ and $|(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2)| < |\eta|/3$. Since

$$\eta = \zeta + (\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2) + (\xi^1,0)$$

we have

$$|\eta| \le |\zeta| + |(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2)| + |\xi^1|$$

or $|\eta|/3 \le |\xi^1|$. Thus

$$\begin{aligned}|K| &\le \frac{C}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b}\langle\xi^1\rangle^{s-l+m}\langle\zeta\rangle^{l-m}}\\ &\le \frac{C}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2\rangle^{s_b}\langle\zeta\rangle^s},\end{aligned}$$

i.e., $K \in L^2(d\xi^1 d\zeta)$.

We next deal with the microlocal part. Let $\theta' \subset\subset \theta$, then for $|\alpha| = k$, write

$$\langle\xi^1\rangle^\alpha \hat{a}(\xi^1,\zeta) = \frac{\chi_{\theta'}h_1(\xi^1,\zeta)\langle\zeta\rangle^m}{\langle\xi'\rangle^q} + \frac{\chi_{\theta^C}(\xi^1)h_2(\xi^1,\zeta)\langle\zeta\rangle^m}{\langle\xi^1\rangle^s},$$

where $h_i(\xi^1,\zeta) \in L^2(d\xi^1)$ uniformly in ζ. Let

$$\hat{u}(\zeta) = \frac{\chi_{K'}(\zeta)v_1(\zeta)}{\langle\zeta\rangle^q} + \frac{\chi_{K^C}(\zeta)v_2(\zeta)}{\langle\zeta\rangle^l}$$

with v_1 and $v_2 \in L^2$.

The integral kernel of (2.1) can be written as

$$\frac{\chi_{K'}(\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2)g_1(\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2,\zeta,\xi^1)}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2\rangle^r} + \frac{\chi_{K^C}(\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2)g_2(\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2,\zeta,\xi^1)}{\langle\eta^1-\zeta^1-\xi^1,\eta^2-\xi^2\rangle^{s_b}},$$

where $g_i(\eta,\zeta,\xi^1) \in L^2(d\eta)$ uniformly in ξ^1 and ζ.

Therefore, we have the following close form:

$$\begin{aligned}&\chi_{K'}(\eta)\langle\eta\rangle^{q-m}\widehat{(ru)}(\eta)\\ &= \sum_{|\alpha|=k} C_\alpha \int\int\\ &\times \sum_{i,j,h=1,2} G_{i,j,h}(\xi^1,\eta,\zeta)g_i(\eta^1-\zeta^1-\xi^1,\eta^2-\zeta^2,\zeta,\xi^1)h_j(\xi^1,\zeta)v_h(\zeta)d\xi^1 d\zeta.\end{aligned}$$

We only need to show, from Proposition 2.2, that $G_{i,j,h} \in L^2(d\xi^1 d\zeta)$ uniformly in η. The fact that this is indeed so follows from the hypotheses and an analysis of eight different pieces of the kernel. The arguments are similar to the proof of Theorem 2.2 or the proof of the local part. For simplicity, we leave it to the interested reader. □

A simple partition of the unity argument and an application of Leibnitz's rule as in [8] (the proof of Corollary 1.6) give the following result.

COROLLARY 2.1. *Let $n_0/2 < s$, $0 \le l \le s$, $1 \le n_0 \le n$ $s \le s_b$, $n/2 < s$, and $q < \min\{s+l-n_0/2, s_b+s-n/2\}$. Let $k \ge 0$ be an integer, and for $|\alpha| \le k$*

$$a(x^1,\xi) \in S^{m+k;s+k,q+k}_{n_0}(\gamma), \qquad \partial^\alpha_\xi b(x,\xi) \in S^{-|\alpha|;s_b,q}(\Gamma).$$

Then $b \circ a(x,\xi)$, the symbol of operator $b(x,D)a(x^1,D)$, satisfying

$$\left\{ b\circ a(x,\xi) - \sum_{|\alpha|<k} \frac{1}{\alpha!}\partial^\alpha_\xi b D^\alpha_{x^1} a(x^1,\xi) \right\} \in S^{m;s,q,l,q}_{bd}(\Gamma).$$

The proof of Lemma 2.1 may be sharpened in a way similar to the proof of Lemma 1.12 in [8] to yield the following representation.

LEMMA 2.2. *Let $n_0/2 < s$, $0 \le l \le s$, $1 \le n_0 \le n, s$, and $q \le s+l-n_0/2$. Assume also that $k \ge 0$ is an integer and $\mu \ge 0$,*

$$a(x^1,\xi) \in S^{m;s+k,q+k}_{n_0}(\gamma), \qquad \partial^\alpha_\xi b(x,\xi) \in S^{k+\mu}\,.$$

Then there exist symbols $r(x,\xi)$, $\tilde{r}(x,\xi) \in S^{m;s,q,l,q}_{bd}(\Gamma)$ and $p(x,\xi), \tilde{p}(x,\xi) \in S^\mu_{1,0}$, such that

$$\left\{ b\circ a(x,D) - \sum_{|\alpha|<k} \frac{1}{\alpha!}\partial^\alpha_\xi b D^\alpha_x a(x,D) \right\} = r(x,D)p(x,D) + \tilde{p}(x,D)\tilde{r}(x,D)\,.$$

Accordingly, one can also prove a consequence of Lemma 2.2.

COROLLARY 2.2. *The conclusions of Lemma 2.2 hold if the assumptions on a and b are replaced with*

$$a(x^1,\xi) \in S^{m+k;s+k,q+k}_{n_0}(\gamma), \qquad \partial^\alpha_\xi b(x,\xi) \in S^\mu.$$

LEMMA 2.3. *Let $k \geq 1$, $n_0 < s$, $0 \leq l \leq s, q < s + l - n_0/2$, and*

$$a(x^1,\xi) \in S^{k;s+k,q+k}_{n_0}(\gamma).$$

Then the adjoint of a is an operator with symbol

$$a^*(x,\xi) \in S^{k;s+k,r+k}_{n_0}(\gamma)$$

and

$$\{a^*(x,\xi) - \bar{a}(x,\xi)\} \in S^{k-1;s+k-1,q+k-1,l,q}_{bd}(\gamma)\ .$$

The proof follows from the calculus of smooth $\psi.d.o.$ and Theorem 2.2 by observing that

$$a = \sum a_l(x^1)P_l(x^1,\xi)\ , \qquad P_{k,l} \in S^k$$

implies that

$$a^*(x,D) = \sum P^*_l(x,D)\bar{a}_l(x)$$

with $P^*_l(x,\xi) \in S^k$.

Finally, to complete the proof of Theorem 2.1, we need a Gårding type inequality. Let $\Pi : (x^1,x^2,\xi) \to (x^1,\xi)$ be a projection map.

LEMMA 2.4. *Let $n_0/2 < s$, $0 < \epsilon \leq 1$, $x = (x^1,x^2) \in \mathbf{R}^{n_0} \times \mathbf{R}^{n-n_0}$, and*

$$P(x,\xi) = a(x^1,\xi)P_0(x,\xi) + P_1(x,\xi) \geq 0, \tag{2.2}$$

where $a(x^1,\xi) \in S^{\epsilon,s+2\epsilon}_{n_0}(V)$, $P_0(x,\xi) \in S^0(U)$, and $P_1(x,\xi) \in S^\epsilon(U)$ for $V = \Pi U$. Then for all $u \in H^0_{\text{comp}}(U)$

$$Re\langle P(x,D)u,u\rangle \geq -C||u||^2_{H^0(U)}\ .$$

Proof. The proof may be given by following the general outline of the proof of Lemma 3.1 in [8] with some necessary modifications. As in Taylor [24], let $b(D,x,D)$ be the Friedrichs symmetrization of P. Set $R(x,D) = b(D,x,D) - p(x,D)$. If one can show that

$$R(x,D) : H^0_{\text{comp}} \to H^0_{\text{loc}}$$

is a bounded operator, then (2.2) would follow since $\langle b(D,x,D)u,u\rangle \geq 0$.

Let q be a smooth nonnegative even function, supported in $|\xi| \leq 1$ satisfying $\int q^2(\xi)d\xi = 1$, and define

$$F(\xi,\zeta) = \frac{1}{\langle\xi\rangle^{n/4}} q\left(\frac{\zeta-\xi}{\langle\xi\rangle^{1/2}}\right),$$

$$b(\eta,x,\xi) = \int F(\eta,\zeta)P(x,\zeta)F(\xi,\zeta)d\zeta.$$

Then

$$(b(D,x,D)u)\hat{}(\eta) = \int \hat{b}(\eta, \eta-\xi, \xi)\hat{u}(\xi)d\xi\ .$$

Thus

$$(R(x,D)u)\hat{}(\eta) = \int \hat{r}(\eta-\xi,\xi)\hat{u}(\xi)d\xi,$$

where $\hat{R}(\eta,\xi) = \hat{b}(\eta+\xi,\eta,\xi) - \hat{P}(\eta,\xi)$.

If one can show that

$$\langle\eta^1\rangle^s\langle\eta^2\rangle^r|\hat{R}(\eta,\xi)| \le Cg(\eta,\xi) \tag{2.3}$$

with $g \in L^2(d\eta)$ uniformly in ξ for some $r > (n-n_0)/2$, then similar arguments as in the proof of Proposition 2.1 or Proposition 2.2 yield

$$Ru \in H^0.$$

Observe that since $\int F^2(\xi,\zeta)d\zeta = 1$, we have

$$\hat{R} = \int F(\eta+\xi,\zeta)\hat{P}(\eta,\zeta)F(\xi,\zeta)d\zeta - \hat{P}(\eta,\xi) \tag{2.4}$$

$$= \int F(\eta+\xi,\zeta)\{\hat{P}(\eta,\zeta) - \hat{P}(\eta,\xi)\}F(\xi,\zeta)d\zeta$$

$$+ \int \{F(\eta+\xi,\zeta) - F(\xi,\zeta)\}\hat{P}(\eta,\xi)F(\xi,\zeta)d\xi\ . \tag{2.5}$$

On support of $F(\xi,\zeta)$, $|\zeta-\xi| \le \langle\xi\rangle^{1/2}$, hence for large ξ one has $\zeta \approx \xi$. Then (2.4) and the hypotheses on a, P_0, and P_1 imply that

$$|\hat{R}(\eta,\xi)| \le \frac{\langle\xi\rangle^\epsilon}{\langle\eta^1\rangle^{s+2\epsilon}\langle\eta^2\rangle^r} g_0(\eta,\xi)$$

for any r with $g_0(\eta,\xi) \in L^2(d\eta)$ uniformly in ξ.

The estimate (2.3) can then be established by following the proof of Lemma 3.1 in [8]. □

3. Proof of the main theorem. We now prove the main result of this paper, Theorem 1.1, a trace regularity theorem for the linear acoustic wave equation with nonsmooth coefficients in the principal part.

As we mentioned earlier, since the hypersurface $\{x_n = 0\}$ is a time-like surface, the method of energy estimates cannot be applied directly. Following [3], we alter the wave operator $\Box$ by a microlocal cutoff technique so that $\{x_n = 0\}$ will become a space-like surface with respect to the new operator. More precisely, we shall construct a $\psi.d.o.$ equation which is strictly hyperbolic corresponding to the trace $\{x_n = 0\}$. Since the operator in our construction is differential in x_n, the standard method of energy estimates (for example in [14] or [24]) can then be employed to derive the basic estimate. Naturally, there will be a remainder term. We then show that the remainder term can be controlled by the microlocal hypotheses and Theorem 2.1.

Let $\tilde{\Pi}_2 : X \subset T^*(\mathbf{R}^k) \to Y \subset \mathbf{R}^k \times \mathbf{R}^{k_0}$ serve as a map for $k > k_0$,

$$\tilde{\Pi}_2(X) = \{(x,y,\xi) \in Y : (x,y,\xi,\eta) \in X\}\ .$$

Proof of Theorem 1.1. Let γ_0, γ_1 be two conic subsets of the set $\{(x,t,\xi',\omega) \in \mathbf{R}^{n+1} \times \mathbf{R}^n; (x,t) \in \Omega_0,\ (\xi',\omega) \in \mathbf{R}^n, d(x)|\omega| \geq |\xi'|\}$ where Ω_0 is a small compact neighborhood of Ω, and $\gamma_0^{cl} \subset \gamma_1^{int}$. Then, construct an operator $Q \in C^\infty(\mathbf{R}, OPS^0(\mathbf{R}^n))$, $q = q(x,t,\xi',\omega)$, whose symbol satisfies

- $ES(Q) \subset \gamma_1$ and $0 \leq q_0 \leq 1$,
- $q_0 = 1$ on $\gamma_0 \cap \{(x,t,\xi',\omega),\ |(\xi',\omega)| > 1\}$,

where $q_0(\xi',\omega)$ is the principal symbol of Q. Define another operator E as

$$E = Q\Box^d_{x',t} + (I-Q)\Delta^d_{x',t}\ ,$$

where $\Box^d_{x',t} = d^2\partial_t^2 - \partial^2_{x'}$ and $\Delta^d_{x',t} = d^2\partial_t^2 + \partial^2_{x'}$.

Observe that the principal symbol of E

$$e_0 = q_0(d^2\omega^2 - |\xi'|^2) + (1-q_0)(d^2\omega^2 + |\xi'|^2) \geq C(\omega^2 + |\xi'|^2)\ ,$$

for $|(\omega,\xi')| \geq \delta$, with some positive constants C, δ. Hence, E is an elliptic $\psi.d.o.$ of order *two*.

Let $\phi = \phi(x,t) \in C_0^\infty(\mathbf{R}^{n+1})$ with supp $\phi \subseteq \{|x_n| \leq \epsilon_0\}$. We then have a strictly symmetric hyperbolic problem:

$$\begin{aligned}(-\partial^2_{x_n} + E)\phi u &= \Box_d \phi u + (I-Q)(\Delta^d_{x',t} - \Box^d_{x',t})\phi u \\ &= [\Box_d, \phi]u + \phi f + \phi\nabla\sigma\cdot\nabla u + 2(I-Q)\partial^2_{x'}\phi u \\ &= d^2[\partial_t^2, \phi]u - [\Delta, \phi]u + \phi f + \phi\nabla\sigma\cdot\nabla u + 2(I-Q)\partial^2_{x'}\phi u,\end{aligned} \tag{3.1}$$

where $\Box_d = d^2\partial_t^2 - \Delta$.

Thus, we obtain a standard wave equation with x_n playing the role of "time." This together with the fact that ϕ is compactly supported gives us a symmetric hyperbolic Cauchy problem with zero Cauchy data. It follows from a hyperbolic energy estimate in Taylor [24, pp. 73-78] that

(3.2)

$$\begin{aligned}\|(\phi u)\,|_{x_n=0}\,\|_l &\leq C\|\text{ r.h.s. of (3.1)}\|_{l-1} \\ &\leq C[\|\phi_1 u\|_l + \|\phi f\|_{l-1} + \|\phi\nabla\sigma\cdot\nabla u\|_{l-1} + \|(I-Q)\partial^2_{x'}\phi u\|_{l-1,\Omega_1}],\end{aligned}$$

where $\phi_1 \in C_0^\infty$, and $\phi_1 > 0$ on supp(ϕ), and supp$(\phi) \subset\subset \Omega_1$. Let $\tilde\phi \in C_0^\infty(\Omega_1)$ and $\tilde\phi = 1$ on Ω_2, where supp$(\phi) \subset\subset \Omega_2 \subset\subset \Omega_1$. Then the above estimate leads to

$$\|(\phi u)\,|_{x_n=0}\,\|_l \leq C[\|\phi_1 u\|_l + \|\phi f\|_{l-1} + \|\phi\nabla\sigma\cdot\nabla u\|_{l-1} + \|\tilde\phi(I-Q)\partial^2_{x'}\phi u\|_{l-1,\Omega_1}]$$

where we have used $||(1-\tilde\phi)(I-Q)\partial^2_{x'}\phi u||_{l-1,\Omega_1} \leq C||\phi u||_r$ for any real r.

Using the hypotheses, similar to the proposition in Beals and Reed [7], one can show that $u \in H^l_{\text{loc}}$. Hence a generalized Schauder's lemma (Lemma 2.2 in [3]) yields

$$\phi\nabla\sigma\cdot\nabla u \in H^{l-1}\ .$$

Therefore, to complete the proof it suffices to show that

$$(I-Q)\partial^2_{x'}\phi u \in H^{l-1}_{\text{loc}}(\Omega_1)\ ,$$

which requires the use of Lemma 3.1 stated below. In order to apply Lemma 3.1, we choose $B = I - Q \in C^\infty(\mathbf{R}^1, OPS^0(\mathbf{R}^n))$ of order $m = 0$, $A = \Box_d$ of order $m_0 = 2$, and $h = l - 2$ in the statement of Lemma 3.1.

Concerning the assumption (1) of Lemma 3.1, $Ell(A)$ defined as the microlocal elliptic region of $A = \Box_d$ is easy to determine by knowing that the operator $\Box_d$ is elliptic away from the set $\{d^2\omega^2 = |\xi|^2\}$. To verify hypothesis (3), one only needs to look at

$$\Box_d \partial_{x'}^2 \phi u = [\Box_d, \partial_{x'}^2 \phi] u + \partial_{x'}^2 \phi (\nabla\sigma \cdot \nabla u + f) \, .$$

Then $\Box_d \partial_{x'}^2 \phi u \in H^{l-3}$ follows by some simple commutator arguments. Therefore, the only assumption that needs to be checked is

$$u \in H^{l+1}_{m\ell}([T^*(\mathbf{R}^{n+1}) \backslash Ell(\Box_d)] \cap \tilde{\Pi}_2^{-1} ES(I-Q))$$

and this demands Theorem 2.1.

In the statement of Theorem 2.1 choose

$$(m, n_0, n, l, s, q, \epsilon) = (0, n, n+1, l-1, s-2, l, 1)$$

then the microlocal hypotheses verify all the assumptions of Theorem 2.1. Notice that the main assumption, $s > 3 + n/2$, is required by the corresponding hypothesis ("$q < l + s - n_0/2$) in the statement of Theorem 2.1. Let γ_0 and γ_1 approach the set $\{(x,t,\xi,\omega) : \ (x,t) \in \Omega_0 \ , \ \ d|\omega| \geq |\xi'|\}$. The set

$$[T^*(\mathbf{R}^{n+1}) \backslash Ell(\Box)] \cap \tilde{\Pi}_2^{-1} ES(I-Q)$$

is contained in a small (conic) neighborhood of the Hamiltonian flow out of γ. Hence Theorem 2.1 and the microlocal initial hypotheses yield that

$$u \in H^{l+1}_{m\ell}([T^*(\mathbf{R}^{n+1}) \backslash Ell(\Box)] \cap \tilde{\Pi}_2^{-1} ES(I-Q)) \, .$$

We have completed the proof of Theorem 1.1. □

For the sake of completeness, we state a lemma given in [2].

Consider a smooth family of $\psi.d.o.$ $P \in C^\infty(\mathbf{R}^{k-k_0}, OPS^m(\mathbf{R}^{k_0}))$, i.e., for each $y \in \mathbf{R}^{k-k_0}$ with $k_0 < k$, $P(x,y,D_x) \in OPS^m(\mathbf{R}^{k_0})$. It is known, see [2] or [23], that P is not necessarily a $\psi.d.o.$ in $\mathbf{R}^k$. However, as shown in [2], a smooth family of $\psi.d.o.$ behaves like a $\psi.d.o.$

Recall the map, for $k > k_0$,

$$\tilde{\Pi}_2(X) = \{(x,y,\xi) \in Y \subset \mathbf{R}^k \times \mathbf{R}^{k_0} : \ (x,y,\xi,\eta) \in X \subset T^*(\mathbf{R}^k)\} \, .$$

The normal bundle of a foliation $\mathbf{R}^k = \mathbf{R}^{k-k_0} \times \mathbf{R}^{k_0}$ is the set

$$\mathcal{N} = \{(x,y,\xi,\eta) \in \mathbf{R}^{k_0} \times \mathbf{R}^{k-k_0} \times \mathbf{R}^{k_0} \times \mathbf{R}^{k-k_0}, \xi = 0\} \, .$$

LEMMA 3.1 (Fattening lemma). *Let $B(x,y,D_x) \in C^\infty(\mathbf{R}^{k-k_0}, OPS^m(\mathbf{R}^{k_0})$ and $A(x,y,D_x,D_y) \in OPS^{m_0}(\mathbf{R}^k)$, where $1 \leq k_0 \leq k$. Let*

$$\mathcal{N} = \{(x,\xi) \in \mathbf{R}^k \times \mathbf{R}^k, (\xi_1, \cdots, \xi_{k_0}) = 0\}$$

be the normal bundle of $\mathbf{R}^{k_0} \times \mathbf{R}^{k-k_0}$. Also, assume that

(1) *A is microlocal elliptic on a conic set $Ell(A)$, with $\mathcal{N} \subset\subset Ell(A)$;*
(2) *$u \in H^h \cap H^{h+1}_{m\ell}([T^*(\mathbf{R}^k) \backslash Ell(A)] \cap \tilde{\Pi}_2^{-1} ES(B(\cdot,y,\cdot)))$;*
(3) *$A\phi u \in H^{h-m_0+1}_{\text{loc}}(\mathbf{R}^k)$, where $\phi(x) \in C_0^\infty(\mathbf{R}^k)$.*

Then

$$B\phi u \in H^{h-m+1}_{\text{loc}}(\mathbf{R}^k) ,$$

in addition, if B is either a convolutional operator or its symbol has compact support in spatial variables,

$$B\phi u \in H^{h-m+1}(\mathbf{R}^k) .$$

UNIFORM STRICT CONVEXITY OF A COST FUNCTIONAL FOR THREE-DIMENSIONAL INVERSE SCATTERING PROBLEM *

MICHAEL V. KLIBANOV† AND OLGA V. IOUSSOUPOVA‡

Abstract. An inverse problem of determination of the coefficient $a(x)$ in the equation $u_{tt} = \Delta u + a(x)u, x \in \mathbb{R}^3, t \in (0,T)$ is considered with initial conditions $u(x,0) = 0, u_t(x,0) = \delta(x)$, and some additional data that can be treated as *backscattering* information. The goal is to develop a finite-dimensional technique that would be a basis for future computations. We reduce our inverse scattering problem to an equivalent Cauchy problem for a nonlinear hyperbolic integrodifferential equation with the data on the lateral side of a time cylinder. It is assumed that the solution $v(x,t)$ of this equation has the form $v(x,t) = p(x,t) + w(x,t)$, where function $p(x,t)$ is given and function $w(x,t)$ is unknown and has a finite number of nonzero Fourier coefficients. In particular, function $p(x,t)$ can be considered as a first guess. A special cost-functional $J_\lambda(w)$ dependent on a large parameter λ is introduced. The main result of this paper is Theorem 1.1. By this theorem, the functional J_λ is *uniformly strictly convex* on any ball B with the center at the origin with a proper choice of the parameter $\lambda = \lambda(B)$. Therefore, by this theorem, a finite-dimensional perturbation of a true solution of the above-mentioned nonlinear Cauchy problem can be found by convex minimization techniques.

Key words. inverse scattering problem, Carleman estimates, strict convexity, global convergence, imaging, strong scattering

AMS subject classification. 35R30

0. Introduction.

Numerical methods for three-dimensional inverse scattering problems (ISP) currently attract considerable interest. In part, it is due to their significance for imaging of the *complicated internal* structure of inhomogeneous media, such as biological tissues, industrial devices, etc. One of the most attractive advantages of such imaging is in displaying the subtle structures of abnormal inclusions of the media, which is of special importance for diagnosis of some human diseases, noninvasive quality control of industrial devices, etc. Presumably an imaging device should introduce electromagnetic waves into inhomogeneous media. Then this device should measure scattering data all around the media and treat this data computationally. Finally, it should display the image of the internal structure of the media on the basis of computational results. Thus numerical methods for three-dimensional ISPs play a fundamental role in imaging processes. We also refer to such traditional areas of application of three-dimensional ISPs as ocean acoustics and geophysics.

Currently, these methods have been developed mainly in a frequency domain, i.e., for the Helmholtz-like equation $\Delta u + k^2(1 + c(x))u = 0$; cf. Cheney [3], Colton and Monk [4], [5] and Gutman and Klibanov [6]; [3] and [4] contain surveys. However, ISPs with time-dependent data play a substantial role in imaging problems as well. Numerical methods for three-dimensional ISP with time-dependent data have been studied by Baylis, Li, and Morawetz [1] and by Klibanov and Malinsky [13]. ISPs for the equation $u_{tt} = \Delta u + a(x)u, x \in \mathbb{R}^3$ were considered in [1] and [13]. Here

potential $a(x)$ is the unknown function. Note that this equation can be obtained by the Fourier transform from the Schrödinger equation $\Delta V + k^2 V + a(x)V = \delta(x)$ which is commonly used to model many-body systems. A Newton–Kantorovich numerical method was developed in [13] for the weak scattering case, which is in the case when $|a(x)| \ll 1$.

Newton–Kantorovich methods, however, require that a distance between the starting point (i.e., the initial guess) and the solution has to be sufficiently small, which is, of course, not always the case in applications. We note that in practical computations of inverse problems the solutions are usually sought as m-dimensional perturbations of a certain initial guess. Thus it would be very helpful to develop a finite-dimensional technique which would have a *guaranteed* convergence for any fixed dimension m and for any distance between the initial guess and the solution of the ISP. Such a technique would be a basis for future practical computations which would give results sufficient for practical goals. One should expect, however, that the question of convergence of such a method as $m \to \infty$ would be very hard to answer due to *ill-posedness* of the inverse problems; cf. Lavrent'ev et al. [18] and Tikhonov and Arsenin [23] (see also §6).

In this paper we develop such a finite-dimensional technique for an ISP for the above mentioned hyperbolic equation. Our ISP deals with the *backscattering* data. First we get rid of the unknown coefficient $a(x)$ and obtain, in this way, a time-like Cauchy problem (1.21)–(1.23) for a nonlinear hyperbolic integrodifferential equation. This problem is actually equivalent with the original ISP. Let $N \geq 1$ be an arbitrary integer and $m = N^3$. We seek a solution $v(x,t)$ of this nonlinear Cauchy problem in the form $v(x,t) = w(x,t) + p(x,t)$, where function $p(x,t)$ is given, function $w(x,t)$ is unknown, and $w(x,t)$ has m nonzero Fourier coefficients with respect to a certain orthonormal basis. Therefore function $p(x,t)$ can be considered as a first guess for the solution $v(x,t)$. But we do not impose "smallness" conditions on the function $w(x,t)$.

Let function $w_*(x,t)$ be the sought solution and $c_* = c(w_*) \in \mathbb{R}^m$ be the vector of the Fourier coefficients of the function w_*. By Tikhonov's principle one can assume that a solution of an ill-posed problem belongs to an a priori given compact set; see [23]. Thus without loss of generality, we can assume that $c_* \in B_{1/2}$ where

$$B_{1/2} = \{y \in \mathbb{R}^m : |y| < \tfrac{1}{2}\}, \qquad B_1 = \{y \in \mathbb{R}^m : |y| < 1\}.$$

Then we introduce a special weighted minimizing cost functional $J_\lambda = J_\lambda(w)$, where λ is a large positive parameter. The functional J_λ is tightly connected with *Carleman estimates*; cf. Klibanov [12]. Vector $c_* = c(w_*)$ provides a global minimum of J_λ on $\bar{B}_1$, in the case of the absence of a noise in the data (regarding the noise, see Theorem 1.3).

The main result of this paper is Theorem 1.1, which claims that there exists a constant $\tilde{\lambda} = \tilde{\lambda}(B_1)$ such that the functional J_λ is *uniformly strictly convex* on $\bar{B}_1$. The *genuine* meaning of this result is that one can find a finite-dimensional perturbation of the true solution of the nonlinear Cauchy problem (1.21)–(1.23) by convex minimization methods. We note that Theorem 1.1 guarantees a *global* convergence of a number of traditional minimization algorithms to the global minimum w_* of J_λ (on $\bar{B}_1$). In particular, we prove, basically for the sake of completeness, Theorem 1.2 which establishes a convergence rate of the simplest version of the gradient method, in a case when the starting point is the center of B_1 and the data does not contain a noise. We also prove Theorem 1.3, which shows that the gradient method provides a "reasonable" solution even in the presence of a noise in the data. Finally, Theorem

1.1 implies Theorem 1.4, which claims that our "m-dimensional" solution $w(x,t)$ is unique. Of course, Theorem 1.4 cannot be considered as a global uniqueness result (see a discussion of the uniqueness issue below). One can argue, however, that sometimes computations are successfully carried out despite the lack of global uniqueness results. The reason for this is that theorems similar to Theorem 1.4 are sometimes sufficient for practical computations and provide good indications of the validity of global uniqueness results. We consider this paper as a basis for future computations, which will be discussed elsewhere (see also §6).

To our knowledge, Symes was the first one who proved, using an entirely different technique, uniform convexity of a minimizing cost functional for an inverse problem for the equation $u_{tt} = c^2(x_3)\Delta u + \delta(x)f(t)$ with unknown coefficient $c(x_3)$; see, e.g., Theorem 6.1 in [22] and the references cited there. He also raised a question about similar results in a case when the unknown coefficient depends on $n = 3$ variables. As far as we know our result is the first one in this direction.

Let T = constant > 0 and $\mathbb{R}^3_T = R^3 \times (0,T)$. Let a nonnegative function $a \in C^2(\mathbb{R}^3)$ and a function $u(x,t)$ be a solution of the Cauchy problem

$$\begin{aligned} &u_{tt} = \Delta u + a(x)u \quad \text{in } \mathbb{R}^3_T, \\ &u|_{t=0} = 0, \qquad u_t|_{t=0} = \delta(x), \end{aligned} \tag{0.1}$$

where $\delta(x)$ is the delta function. Introduce spherical coordinates

$$x_1 = r\cos\theta\sin\varphi, \quad x_2 = r\sin\theta\sin\varphi, \quad x_3 = r\cos\varphi, \theta \in [0,2\pi), \qquad \varphi \in [0,\pi).$$

Let r_0, R be positive constants such that $r_0 < R < \frac{1}{3}T$. Let $\Omega_{r_0} \subset \mathbb{R}^3$ be a cylinder,

$$\Omega_{r_0} = \left\{ x \in \mathbb{R}^3 \colon \sqrt{x_1^2 + x_2^2} = r\sin\varphi < r_0 \right\}.$$

Let ω be the boundary of Ω_{r_0}.

The principal problem of interest for us is as follows: *Assume that the function $a(x) = 0$ for $x \in \Omega_{r_0}$ and is unknown otherwise. We would like to determine this function for $x \in (\mathbb{R}^3|\Omega_{r_0}) \cap \{/x/ < R\}$ assuming that the following function ψ is given*:

$$u/_\omega = \psi(x,t), \qquad t \in (0,T). \tag{0.2}$$

We note that since function $a(x) = 0$ inside of Ω_{r_0}, then we can uniquely determine function $u(x,t)$ for $(x,t) \in \Omega_{r_0} \times (0,T)$ as a solution of the following boundary value problem:

$$\begin{aligned} &u_{tt} = \Delta u \quad \text{in } \Omega_{r_0} \times (0,T), \\ &u|_{t=0} = 0, \qquad u_t|_{t=0} = \delta(x), \\ &u|_\omega = \psi(x,t). \end{aligned} \tag{0.3}$$

Hence actually the following function $\mu(x,t)$ is given:

$$u = \mu(x,t) \quad \text{for } (x,t) \in \Omega_{r_0} \times (0,T). \tag{0.4}$$

Remarks. (i) In fact, it would be more natural, perhaps, to assume that function $a(x) = 0$ only in the ball $x \in \{|x| < r_0\}$ and function $u(x,t)$ is given only on the

sphere $|x| = r_0$. In this case, however, we would face some specific difficulties related to the fact that the Jacobian

$$\det\left(\frac{\partial(x_1, x_2, x_3)}{\partial(r, \theta, \varphi)}\right) = r^2 \sin\varphi$$

equals zero at $\varphi = 0, \pi$, i.e., on the line $x_1 = x_2 = 0$ (see also the second remark in §3). We would face these difficulties only because we get Carleman estimates in terms of spherical coordinates (not cartesian ones). Consequently, we think that a modification of our Carleman estimates would lead to an elimination of these obstacles. Currently, however, we do not know how to handle this.

(ii) Nevertheless condition (0.2) is not a very restrictive one. For instance, this condition is valid in the case when the function $a(x)$ has a compact support in a neighborhood of a point $\bar{x} = (\bar{x}_1, \bar{x}_2, \bar{x}_3)$ such that $\sqrt{\bar{x}_1^2 + \bar{x}_2^2} > 2r_0$. That is, $a(x) = 0$ for $|x - \bar{x}| > \sigma$, where $0 < \sigma < |\bar{x}| - r_0$. In this case one can assume, for instance, that one measures scattering data on a sphere $|x - \bar{x}| = \sigma$ which certainly can be the case in imaging problems. Then one can get function ψ in (0.2) by solving a boundary value problem similar with (0.3).

(iii) In fact, measurements (0.2) on the surface ω contain backscattering information, which is the only unique "useful" part of the measuring signal. Indeed, waves propagate from the source $x = 0$, which is placed inside of the cylinder Ω_{r_0}, and support of the unknown function $a(x)$ is outside of Ω_{r_0}. If our measurement data did not contain the backscattering signal, we would be unable to get a uniqueness result (see Theorem 1.4 below).

It is widely known that numerical methods for ill-posed problems, and for inverse problems in particular, are closely connected with uniqueness theorems for these problems. It is also well known that global uniqueness results are much more difficult to get in a case where unknown coefficients depend on $n \geq 2$ variables than those for a $n = 1$ case. In particular, uniqueness theorems for the inverse problem (0.1) and (0.2), as well as for closely connected problems of integral geometry, are currently proven only under rather restrictive conditions imposed on $a(x)$; see Lavrent'ev, Romanov, and Shishatskii [18] and Romanov [19]. To our knowledge, the question about the *global* uniqueness theorem for this problem still remains open despite a large number of attempts to answer it. Incidentally, the lack of methods of proofs of global uniqueness results is, perhaps, the second major reason (in addition to ill-posedness) why we cannot yet investigate our functional $J_\lambda(w)$ as $m \to \infty$.

Nevertheless, global uniqueness results were proved for similar multidimensional inverse problems under the assumption that $u(x, 0) \neq 0$ for all "needed" x. These results were proven by the method of Carleman estimates which has been applied to inverse problems beginning from the work of Bukhgeim and Klibanov in 1981 [2], see also the survey in Klibanov [12] and references cited therein. Recently Klibanov et al. started to apply Carleman estimates for proofs of convergence of numerical methods both for ill-posed Cauchy problems and for inverse problems; see [11] and [13]–[15]. The method of the current paper is also based on Carleman estimates. Note that by the classical approach, these estimates are applied to proofs of uniqueness and stability results for ill-posed Cauchy problems; cf. Hörmander [8], Isàkov [9], and Lavrent'ev et al. [18].

The paper is constructed as follows. In §1 we show how to get a time-like Cauchy problem for nonlinear hyperbolic integrodifferential equation, instead of the inverse problem (0.1) and (0.2). In this section, we also introduce the functional J_λ and formulate Theorems 1.1–1.4. In §2 we prove miscellaneous lemmas. In §3 we prove

a special form of the Carleman estimate (Theorem 3.1). Section 4 is devoted to the proof of Theorem 1.1. In §5 we prove Theorems 1.2 and 1.3. Section 6 is devoted to the discussion of the results obtained in this paper.

We close the Introduction with basic notation. In the sequel, all the functions are real valued. Let $T_1 = T - R$. Denote

$$\mathbb{R}^3_{T_1} = \mathbb{R}^3 \times (0, T_1),$$
$$D_{T_1} = \left\{(x,t)\colon r_0 < |x| < R, \sin\varphi > \frac{r_0}{R}, t \in [0,T_1)\right\}.$$

Hence for all $(x,t) \in \bar{D}_{T_1}$,

$$r\sin\varphi \geq \frac{r}{R}\cdot r_0 \geq \frac{r_0^2}{R}$$

and the conic surface

$$\partial_1(D_{T_1}) = \left\{\sin\varphi = \frac{r_0}{R}, r_0 < |x| < R, t \in (0,T_1)\right\} \tag{0.5}$$

is a part of the boundary $\partial(D_{T_1})$ of the domain D_{T_1}. Furthermore $\partial_1(D_{T_1}) \subset \Omega_{r_0}$, because for $(x,t) \in \partial_1(D_{T_1})$

$$\sqrt{x_1^2 + x_2^2} = r\sin\varphi = \frac{r}{R}\, r_0 < r_0.$$

Hence by (0.4) the following functions are given:

$$u|_{\partial_1(D_{T_1})}, \qquad \nabla u|_{\partial_1(D_{T_1})}. \tag{0.6}$$

Consider the part $\partial_2(D_{T_1}$ of the boundary $\partial(D_{T_1})$,

$$\partial_2(D_{T_1}) = \left\{|x| = r_0, \sin\varphi > \frac{r_0}{R}, t \in (0,T_1)\right\}. \tag{0.7}$$

Denote

$$\eta = \partial_1(D_{T_1}) \cup \partial_2(D_{T_1}). \tag{0.8}$$

Hence by (0.4) the following two functions are given:

$$u|_\eta = \psi_1, \qquad \left.\frac{\partial u}{\partial n}\right|_\eta = \psi_2, \tag{0.9}$$

where n is an outward normal vector on η.

Let $H^2(D_{T_1})$ be the Sobolev space and $H_0^2(D_{T_1})$ be a subspace of $H^2(D_{T_1})$ such that for all $f \in H_0^2(D_{T_1})$,

$$f|_\eta = \left.\frac{\partial f}{\partial n}\right|_\eta = 0.$$

More generally, let P be a subdomain of D_{T_1} such that $\partial P \cap \eta = \eta(P) \neq \emptyset$, where ∂P is the boundary of P. Then $H_0^2(P)$ denotes a subspace of $H^2(P)$ such that

$$f|_{\eta(P)} = \left.\frac{\partial f}{\partial n}\right|_{\eta(P)} = 0,$$

for all $f \in H_0^2(P)$. Likewise, we introduce a Sobolev space $H_0^2(r_0, R)$ as a space of functions $f(r)$ having a finite norm

$$\|f\|_{H_0^2(r_0,R)} = \left\{ \int_{r_0}^{R} (|f|^2 + |f'|^2 + |f''|^2) r^2 \, dr \right\}^{1/2}$$

and such that $f(r_0) = f'(r_0) = 0$.

1. Statement of the main results. Solution u of the Cauchy problem (0.1) with $a \in c^2(\mathbb{R}^3)$ has the form

$$u(x,t) = \frac{\delta(t-|x|)}{4\pi|x|} + \hat{u}(x,t), \tag{1.1}$$

where function $\hat{u}(x,t) = 0$ for $t < |x|$, and $\hat{u} \in C^3(t \geq |x|)$. Since $a(x) \geq 0$, using the Kirchgoff formula one can simply derive that

$$\hat{u} \geq 0. \tag{1.2}$$

Consider the function

$$u_1 = \int_0^t u(x,\tau)\, d\tau. \tag{1.3}$$

Then (0.1), (0.8), and (1.1)–(1.3) imply

$$u_{1tt} = \Delta u_1 + a(x) u_1 \quad \text{in } \mathbb{R}^3_T, \tag{1.4}$$

$$u_1(x,t) = 0 \text{ for } t < |x|, \tag{1.5}$$

$$u_1|_{t=|x|} = \frac{1}{4\pi|x|}, \tag{1.6}$$

$$u_1|_\eta = \hat{\psi}_1(x,t), \qquad \left.\frac{\partial u_1}{\partial n}\right|_\eta = \hat{\psi}_2(x,t), \tag{1.7}$$

$$u_1 > 0 \quad \text{for } t \geq |x|, \tag{1.8}$$

$$u_1 \in C^3(t \geq |x|), \tag{1.9}$$

where functions $\hat{\psi}_1, \hat{\psi}_2$ have the form

$$\hat{\psi}_1(x,t) = \int_0^t \psi_1(x,\tau)\, d\tau, \qquad \hat{\psi}_2(x,t) = \int_0^t \psi_2(x,\tau)\, d\tau.$$

Now we want to replace the characteristic conic surface $\{t = |x|\}$ with the plane $\{t = 0\}$. In order to do that we introduce a new function $\tilde{u}(x,t) = u_1(x, t + |x|)$. Hence (1.4)–(1.7) implies

$$\Delta\tilde{u} - 2\tilde{u}_{rt} + \frac{2}{r}\,\tilde{u}_t + a(x)\tilde{u} = 0 \quad \text{in } \mathbb{R}^3_{T_1}, \tag{1.10}$$

$$\tilde{u}|_{t=0} = \frac{1}{4\pi|x|}, \tag{1.11}$$

$$\tilde{u}|_\eta = \hat{\psi}_1(x, t + r), \qquad \left.\frac{\partial\tilde{u}}{\partial n}\right|_\eta = \hat{\psi}_2(x, t + r). \tag{1.12}$$

Likewise, (1.8) and (1.9) lead to

$$\tilde{u} > 0 \text{ in } \mathbb{R}^3_{T_1}, \tag{1.13}$$

$$\tilde{u} \in C^3(\bar{\mathbb{R}}^3_{T_1}). \tag{1.14}$$

Since by (1.13) the function $\tilde{u}$ is positive, we can consider the function $\tilde{v} = \ln\tilde{u}$. Hence $\tilde{u} = e^{\tilde{v}}$. By (1.14), $\tilde{v} \in C^3(\bar{\mathbb{R}}^3_{T_1})$. Besides, (1.10)–(1.12) lead to

$$\Delta\tilde{v} - 2\tilde{v}_{rt} + |\nabla\tilde{v}|^2 - 2\tilde{v}_r\tilde{v}_t + \frac{2}{r}\,\tilde{v}_t + a(x) = 0, \tag{1.15}$$

$$\tilde{v}|_{t=0} = \ln\frac{1}{4\pi r}, \tag{1.16}$$

$$\tilde{v}|_\eta = \ln[\hat{\psi}_1(x, t + r)], \tag{1.17}$$

$$\left.\frac{\partial\tilde{v}}{\partial n}\right|_\eta = \left(\frac{\hat{\psi}_2}{\hat{\psi}_1}\right)(x, t + r). \tag{1.18}$$

Now we can eliminate function $a(x)$ from (1.15) simply by differentiation with respect to t. The price for this is that we will not know initial data for the function.

$$v = \tilde{v}_t. \tag{1.19}$$

Nevertheless by (1.16),

$$\tilde{v}(x,t) = \int_0^t v(x,\tau)\,d\tau + \ln\left(\frac{1}{4\pi r}\right). \tag{1.20}$$

Denote

$$\psi_3 = \frac{\partial}{\partial t}\ln[\hat{\psi}_1(x, t + r)],$$

$$\psi_4 = \frac{\partial}{\partial t}\left[\left(\frac{\hat{\psi}_2}{\hat{\psi}_1}\right)(x, t + r)\right].$$

Thus (1.15)–(1.20) lead to

$$L(v) = 0, \qquad v \in C^2(\bar{\mathbb{R}}^3_{T_1}),$$
$$v|_\eta = \psi_3, \qquad \left.\frac{\partial v}{\partial n}\right|_\eta = \psi_4. \tag{1.21}$$

Here the hyperbolic nonlinear integrodifferential operator L has the form

$$L(v) = L_0 v + 2\nabla v \int_0^t \nabla v(x,\tau)\,d\tau - 2v_t \int_0^t v_r(x,\tau)\,d\tau$$
$$- 2v_r v + \frac{2}{r} v_t + 2\nabla v \nabla g - 2v_t g'(r), \tag{1.22}$$

where

$$L_0 v = \Delta v - 2v_{rt}$$

and

$$g(r) = \ln\left(\frac{1}{4\pi r}\right). \tag{1.23}$$

Now assume that the function $v(x,t)$ is found. Then using (1.20) we find the function $\tilde{v}(x,t)$. Let $\tilde{u} = e^{\tilde{v}}$. Then by (1.10) and (1.11) we obtain

$$a(x) = 4\pi|x|(\Delta\tilde{u} - 2\tilde{u}_{rt})(x,0). \tag{1.24}$$

Therefore we have proven the following lemma.

LEMMA 1.1. *Solving of the inverse problem* (0.1) *and* (0.2) *is equivalent to solving of the time-like Cauchy problem* (1.21)–(1.23).

Below we always assume that function $v(x,t)$ in (1.21)–(1.23) has the form

$$v(x,t) = w(x,t) + p(x,t), \tag{1.25}$$

where function $p(x,t)$ is *given,*

$$p \in H^2(D_{T_1}) \quad \text{and} \quad p|_\eta = \psi_3, \qquad \left.\frac{\partial p}{\partial n}\right|_\eta = \psi_4. \tag{1.26a}$$

Hence $w \in H_0^2(D_{T_1})$. One could consider the function $p(x,t)$ as a first guess for the function $v(x,t)$.

In the sequel, we will assume that the function $w(x,t)$ in (1.25) has a finite number of Fourier coefficients with respect to an orthonormal basis. We describe conditions imposed on this basis below. Let $\varphi_1 = \arcsin(r_0/R), \varphi_2 = \pi - \varphi$ and $L_{2,\varphi}$ be a weighted L_2 space of functions $f(\theta,\varphi), \theta \in (0,2\pi), \varphi \in (\varphi_1,\varphi_2)$ having a finite norm

$$\|f\|_{L_{2,\varphi}} = \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} |f(\theta,\varphi)|^2 \sin\varphi\,d\varphi.$$

Furthermore, let $\tilde{H}_0^2(D_{T_1})$ be a Sobolev space of functions having a finite norm

$$\|f\|_{\tilde{H}_0^2(D_{T_1})} = \left\{ \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_{r_0}^{R} r^2\,dr \right.$$
$$\left. \times \int_0^{T_1} dt[|f|^2 + |f_r|^2 + |f_t|^2 + |f_{rr}|^2 + |f_{tt}|^2] \right\}^{1/2}$$

and such that $f|_{r=r_0} = f_r|_{r=r_0} = 0$.

Choose an orthonormal basis $\{\phi_n(\theta,\varphi)\}_{n=1}^{\infty}$ in $L_{2,\varphi}$ such that the following conditions are fulfilled

$$\phi_n \in c^2([0,2\pi]\times[\varphi_1,\varphi_2]),$$

$$\text{(1.26b)} \qquad \phi_n(0,\varphi) = \phi_n(2\pi,\varphi), \qquad \frac{\partial\phi_n}{\partial\theta}(0,\varphi) = \frac{\partial\phi_n}{\partial\theta}(2\pi,\varphi),$$

$$\phi_n(\theta,\varphi_1) = \frac{\partial\phi_n}{\partial\varphi}(\theta,\varphi_1) = \phi_n(\theta,\varphi_2) = \frac{\partial\phi_n}{\partial\theta}(\theta,\varphi_2) = 0.$$

Only the third set of conditions (1.26b) seems a little bit strange among these because we deal with the L_2 space. For this reason let us briefly describe one *possible* example of an orthonormal basis in $L_{2,\varphi}$, which satisfies (1.26b). Let $\tilde{\phi}_n(\theta,\varphi)$ be an orthonormal basis in $L_2(0,2\pi)\times(\varphi_1,\varphi_2)$ (not $L_{2,\varphi}$!) formed from the trigonometric function

$$\sin(m\theta)\sin\left[\frac{2\pi s(\varphi-\varphi_1)}{(\varphi_2-\varphi_1)}\right], \qquad \sin(m\theta)\cos\left[\frac{2\pi s(\varphi-\varphi_1)}{\varphi_2-\varphi_1}\right],$$

$$\cos(m\theta)\sin\left[\frac{2\pi s(\varphi-\varphi_1)}{\varphi_2-\varphi_1}\right] \quad \text{and} \quad \cos(m\theta)\cos\left[\frac{2\pi s(\varphi-\varphi_1)}{\varphi_2-\varphi_1}\right],$$

where m and s are nonnegative integers. Let $y(\varphi)\in c^2[\varphi_1,\varphi_2]$ be a function such that

$$y(\varphi) > 0 \quad \text{for } \varphi\in(\varphi_1,\varphi_2),$$

$$y(\varphi_1) = y'(\varphi_1) = y(\varphi_2) = y'(\varphi_2) = 0.$$

Consider functions $\{y(\varphi)\tilde{\phi}_n(\theta,\varphi)\}$. They are linearly independent and satisfy conditions (1.26b). Furthermore, this is a complete set of functions in $L_{2,\varphi}$. Therefore, applying the standard orthogonalization process to this set we obtain the desired orthonormal basis $\{\phi_n\}$.

Choose an orthonormal basis $\{Q_n(r)\}_{n=1}^{\infty}$ in $H_0^2(r_0,R)$ such that all functions Q_n are *piecewise analytic* in (r_0,R) and $Q_n\in C^2[r_0,R]$. Finally, let $\{S_n(t)\}_{n=1}^{\infty}$ be an orthonormal basis in $H^2(0,T_1)$ such that all functions $S_n(t)$ are *analytic* in $(0,T_1)$ and $S_n\in C^2[0,T_1]$. Let Σ be a set of products

$$\Sigma = \{\phi_{n_1}(\theta,\varphi)Q_{n_2}(r)S_{n_3}(t)\}_{n_1,n_2,n_3=1}^{\infty}$$

Then $\Sigma\subset(H_0^2(D_{T_1})\cap\tilde{H}_0^2(D_{T_1}))$ and Σ is an orthonormal basis in $\tilde{H}_0^2(D_{T_1})$. Choose an arbitrary positive integer N and denote

$$m = N^3,$$

$$P_N = \left\{ f\in\tilde{H}_0^2(D_{T_1})\colon f(x,t) = \sum_{n_1,n_2,n_3=1}^{N} c_n\phi_{n_1}(\theta,\varphi)Q_{n_2}(r)S_{n_3}(t), n=(n_1,n_2,n_3)\right\}.$$

We note that $P_N\subset(H_0^2(D_{T_1})\cap\tilde{H}_0^2(D_{T_1}))$. If a function is $f\in P_N$, then $c=c(f)\in\mathbb{R}^m$ will denote the vector of the Fourier coefficients of this function.

In the sequel, we assume that in (1.25) $w\in P_N$.

Consider the function

$$f\in H_0^2(D_{T_1})\cap\tilde{H}_0^2(D_{T_1}).$$

Then

$$\|f\|_{\tilde{H}_0^2(D_{T_1})} \leq \|f\|_{H^2(D_{T_1})}.$$

Furthermore, since all norms are equivalent in finite-dimensional spaces, the following lemma is valid.

LEMMA 1.2. *Norms in $H^2(D_{T_1})$ and $\tilde{H}_0^2(D_{T_1})$ are equivalent for $f \in P_N$.*

Now let us discuss the *noise* issue. If the function ψ in (0.2) is given with a noise, then this noise generates a noise in the functions ψ_3, ψ_4, and, consequently, in the function p because of (1.26a). On the other hand, if the function ψ is given without noise, then generally one should not expect noise in the function p. Because of (1.26a), (1.26b), and Lemma 1.1 we will consider the function p as a *given data* for our inverse problem.

DEFINITION. *We will say that the functions $p \in H^2(D_{T_1})$ is an exact data (generated by the function $a(x)$ in (0.1)) if p satisfies* (1.26a) *and there exists a function $w \in P_N$ such that the function $v = w + p$ satisfies* (1.21) *and* (1.22).

Therefore, in the case of exact data one can find the "target" function $a(x)$ by (1.24) exactly. In the case when p is *not* an exact data we will assume that it can be presented in the form

$$p = p_e + p_\delta \tag{1.27}$$

with $p_e, p_\delta \in H^2(D_{T_1})$. Here function p_e is an exact data, function p_δ corresponds to the noise, and

$$\|p_\delta\|_{H^2(D_{T_1})} \leq \delta, \tag{1.28}$$

where a sufficiently small positive constant δ represents the level of noise. By Tikhonov's principle, in the case of noise data, one should find a sequence $\{w_\delta\} \subset P_N$ such that

$$\lim_{\delta \to 0} \|w_\delta - w_*\|_{H^2(D_{T_1})} = 0, \tag{1.29}$$

where w_* is a solution corresponding to the exact data; see [23] (below we will show that the solution w_* is unique; see Theorem 1.4).

Further, by Tikhonov's principle we can assume that function w_* belongs to an a priori given compact set in $\tilde{H}_0^2(D_{T_1})$. Hence for the sake of definiteness and without loss of generality we will assume that

$$\|w_*\|_{\tilde{H}_0^2(D_{T_1})} < \tfrac{1}{2}. \tag{1.30}$$

Thus

$$c_* \in B_{\frac{1}{2}} \tag{1.31}$$

Denote

$$P_N' = \{w \in P_N : \|w\|_{\tilde{H}_0^2(D_{T_1})} < 1\}.$$

Hence (1.30) implies, in particular, that $w_* \in P_N'$.

Since $T > 3R$ and $T_1 = T - R$, then $R/T_1 < \frac{1}{2}$. Choose a constant α,

$$\alpha \in \left(\frac{R}{T_1}, \frac{1}{2}\right), \tag{1.32}$$

and introduce a function β,

$$\beta(x,t) = \beta(r,t) = -(r + \alpha t). \tag{1.33}$$

Likewise, introduce the domain G,

$$G = \left\{(x,t)\colon \beta(r,t) > -R, r > r_0, \sin\varphi > \frac{r_0}{R}, t > 0\right\}. \tag{1.34}$$

Hence

$$\bar{G} \cap \{r = r_0\} = \left\{(x,t)\colon |x| = r_0, 0 \le t \le \frac{R - r_0}{\alpha}, \sin\varphi > \frac{r_0}{R}\right\}.$$

Consequently (1.32) and (1.34) imply $G \subset D_{T_1}$.

Let λ be a positive parameter. Consider a *cost* functional $J_\lambda(w)$,

$$J_\lambda(w) = \int_G [L(w+p)]^2 e^{2\lambda\beta}\, dx\, dt, \qquad w \in P'_N. \tag{1.35}$$

This functional actually depends on an m-dimensional vector $c = c(w) \in B_1$. Therefore in the cases where we wish to emphasize this dependence we will write $F_\lambda(c)$ instead of $J_\lambda(w)$, keeping in mind, of course, that $F_\lambda(c(w)) = J_\lambda(w)$ and that all the statements about $J_\lambda(w)$ can obviously be reformulated for $F_\lambda(c)$. Now (1.21)–(1.23), (1.30), and (1.31) imply that in the case of *exact* data, our inverse problem can be reformulated as follows.

Minimize functional $J_\lambda(w)$ for an appropriate choice of the parameter λ.

Since $J_\lambda(w) \ge 0$ and $J_\lambda(w_*) = 0$, then w_* is a point of global minimum of $J_\lambda(w)$ (in the case of exact data). Let $J'_\lambda(w)(h), h \in P_N$ be the Fréchet derivative of $J_\lambda(w)$ at the point w. The main result of this paper is as follows.

THEOREM 1.1. *There exists a positive constant $\tilde{\lambda} = \tilde{\lambda}(D_{T_1}, P'_N, \alpha)$ such that for all $\lambda \ge \tilde{\lambda}$ functional $J_\lambda(w)$ is uniformly strictly convex on P'_N. That is,*

$$J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \ge \frac{k}{2}\|h\|^2_{H^2(D_{T_1})}$$

for all $w, h \in P'_N$, where a positive constant $k = k(D_{T_1}, P'_N, \alpha, \lambda)$ does not depend on w, h.

Remark. As mentioned above, the main point of Theorem 1.1 is that beginning with a function, which is a finite-dimensional perturbation of a true solution of the nonlinear Cauchy problem (1.21)–(1.23), one can recover the true solution by a convex minimization procedure. We recall that by Lemma 1.1, Cauchy problem (1.21)–(1.23) is equivalent to the original inverse problem (0.1) and (0.2).

Theorem 1.1 guarantees the global convergence on B_1 of a number of well-known minimization algorithms, provided that the starting point of the iterative process would be the center of B_1. For example, consider the simplest version of the gradient method of the minimization of $F_\lambda(c)$. Fix a number $\lambda \ge \tilde{\lambda}$. Let $H_\lambda(a)$ be the Hessian of $F_\lambda(c)$. Clearly, there exists a positive constant $K = K(\lambda, P'_N)$ such that $y^* H_\lambda(c) y \le K|y|^2$ for all vectors $y \in \mathbb{R}^m$ and for all $a \in B_1$. Theorem 1.1, however, implies that in *addition* to that,

$$k|y|^2 \le y^* H_\lambda(c) y \le K|y|^2, \quad y \in \mathbb{R}^m, \quad a \in P'_N. \tag{1.36}$$

Choose a number ξ such that

$$0 < \xi < \frac{2}{K}. \tag{1.37}$$

Define a sequence $\{a_n\}$ by

$$c_0 = 0,$$

$$c_n = c_{n-1} - \xi \nabla [F_\lambda(c_{n-1})], \qquad n \geq 1. \tag{1.38}$$

Consider a number q:

$$q = \max\{|1 - \xi k|, |1 - \xi K|\}. \tag{1.39}$$

Then

$$0 < q < 1. \tag{1.40}$$

THEOREM 1.2. *Assume that we deal with exact data $p(x,t)$ and fix a number $\lambda \geq \tilde{\lambda}$. Let c_* be the solution of the minimization problem* (1.35) *on B_1 and $c_* \in B_{1/2}$. Then we have $c_n \in B_1$ for all n and*

$$|c_n - c_*| \leq |0 - c_*| q^n < \tfrac{1}{2} q^n.$$

Now consider the case of noisy data.

THEOREM 1.3. *Assume that we deal with noisy data $p(x,t)$ given in the form* (1.27) *and* (1.28) *and fix a number $\lambda \geq \tilde{\lambda}$. Let c_* be the solution of the minimization problem* (1.35) *on B_1 with the exact data and $c_* \in B_{1/2}$. Then there exists a sufficiently small number $\hat{\delta} > 0$ such that if $\delta \leq \hat{\delta}$, then*

$$|c_n - c_*| \leq \frac{1}{2} q^n + C_1 \frac{\xi(1 - q^n)}{1 - q} \delta,$$

where positive constants $C_1, \hat{\delta}$ depend only on D_{T_1}, P'_N, α, and λ.

In particular, for every $\delta \in (0, \hat{\delta})$ choose an integer $n_0 = n_0(\delta)$ such that

$$\frac{1}{2} q^{n_0} < \frac{C_1 \xi}{1 - q} \delta$$

and denote $c^\delta = c_{n_0}$. Then

$$|c^\delta - c_*| < \frac{C_1 \xi}{1 - q} \delta,$$

which corresponds to Tikhonov's principle (1.29).

Thus Theorems 1.2 and 1.3 actually claim the global convergence of the gradient method (1.37) and (1.38) on B_1. Similar convergence results of other versions of the gradient method can be obtained as well. Theorem 1.2, or at least its different versions, is well known, of course, as an almost immediate consequence of (1.36); cf. Hestenes [4]. However, we will give a proof of this theorem since we will need it for the proof of Theorem 1.3.

Note that one can consider the following set $P_N(q)$ instead of P'_N:

$$P_N(q) = \{w \in P_N : \|w\|_{\tilde{H}^2(D_{T_1})} < q\},$$

with an arbitrary positive constant q. Definitely Theorems 1.1–1.3 can be reformulated for this case. Hence the following uniqueness result follows immediately from Theorem 1.2.

THEOREM 1.4. *The Cauchy problem* (1.21)–(1.23) *has at most one solution* $v(x,t)$ *of the form* (1.25), *where function* $w \in P_N$ *and the function* p *satisfies* (1.26a). *In particular, inverse problem* (0.1) *and* (0.2) *has at most one solution such that the function* v *satisfies these conditions.*

Now let us *heuristically* discuss possible implications of these results for *practical* computations. One of the advantages of the functional J_λ is that one should calculate four-dimensional integrals over the domain G only once. In (1.35), a finite number of integrals are calculated, using certain combinations of basic functions, $e^{2\lambda\beta}$ and p. Besides, one should not calculate solutions of the forward problem as soon as data $p(x,t)$ is given, which is convenient since computationally the forward problems are usually time consuming.

We note that the weight function $e^{2\lambda\beta}$ decreases rapidly with respect to both r and t. Generally one should probably not expect that by solving the minimization problem, one could get a reasonable approximation for the solution w_* for *all* $(x,t) \in D_{T_1}$. Instead, one should expect to get a good approximation only in a certain neighborhood of the surface η. And this neighborhood is *not* necessarily small.

Thus by virtue of (1.24) one could get a reasonable approximation for the function $a(x)$ in a certain neighborhood of the surface $\eta \cap \{t = 0\} \subset \mathbb{R}^3$, say in the domain $\{x : r_0 < |x| < r_0 + b, \sin\varphi > (r_0/R)\}$, where b is a positive constant. Then by (1.10)–(1.12) one could solve the following linear time-like Cauchy problem:

$$\Delta\tilde{u} - 2\tilde{u}_{rt} + a(x)\tilde{u} = 0, \tag{1.41}$$

in

$$\left\{(x,t) : r_0 < |x| < r_0 + b, \sin\varphi > \frac{r_0}{R}, t \in (0,T_1)\right\}, \tag{1.42}$$

$$\tilde{u}|_{t=0} = \frac{1}{4\pi|x|}, \tag{1.43}$$

$$\tilde{u}|_\eta = \hat{\psi}_1(x,t+r)|_\eta, \qquad \left.\frac{\partial\tilde{u}}{\partial n}\right|_\eta = \hat{\psi}_2(x,t+r)|_\eta. \tag{1.44}$$

Therefore one can get functions

$$\tilde{u}|_{|x|=r_0+b}, \quad \left.\frac{\partial\tilde{u}}{\partial r}\right|_{|x|=r_0+b}, \quad \text{for } \sin\varphi > \frac{r_0}{R}, \quad t \in (0,T_1),$$

in this way. Then one should take $r_1 = r_0 + b$, etc. This procedure is actually very similar to the layer stripping method; cf. Somersalo, Cheney, Isaakson, and Isaakson [20] and Sylvester [21].

Note that in problem (1.41)–(1.44), Cauchy data are given on the part η of the side of the time cylinder (1.41) rather than on the whole lateral surface, which is

$$\eta \cup \left\{ |x| = r_0 + b, \sin\varphi > \frac{r_0}{R}, t \in (0, T_1) \right\}.$$

This indicates that the Cauchy problem (1.41)–(1.44) is perhaps rather unstable; cf. John [10]. On the other hand, one might expect that the initial data (1.43) might provide "more stability" for this problem. Thus the stability question needs to be investigated further in this case. Also, we note that a numerical method for a similar Cauchy problem with the data on the whole lateral surface has been developed in [13] and [14].

On the other hand, since in an imaging process one is expected to measure scattering data *all around* a bounded medium, then it is reasonable to assume that, in addition, function $a(x)$ is given for $|x| > R$ and function $u(x,t)$ is given at the sphere $\{|x| = R\}$ as well. In this case one should replace in (1.26a) the surface η with the surface

$$\eta_1 = \eta \cup \left\{ |x| = R, \sin\varphi > \frac{r_0}{R}, t \in (0, T_1) \right\}.$$

Thus by (1.25) one would have $w|_{\eta_1} = (\partial w/\partial n)|_{\eta_1} = 0$ and functions $Q_n(r)$ satisfying the following additional conditions $Q_n(R) = Q_n'(R) = 0$. Furthermore, domain G should be replaced with

$$\tilde{G} = \left\{ (x,t) \colon r + \alpha t < R', \, r_0 < r < R, \, \sin\varphi > \frac{r_0}{R}, \, t \in (0, T_1) \right\},$$

where R' is a number such that $R' > R$. Thus $G \subset \tilde{G}$.

An obvious modification of the Theorem 1.1 is valid in this case, of course. Furthermore, we feel that this modified ISP is, by its genuine nature, much more stable than the original one, since we "restrict" function w at $\{|x| = R\}$ as well. Certain indications of this were given in Kazemi and Klibanov [11], Klibanov and Malinsky [13], Komornik and Zuazua [16], and Lasiecka and Triggiani [17], where Lipschitz stability estimates were obtained for some hyperbolic Cauchy problems with the data on the lateral side of the time cylinder (see also references in [11], [13], [16], and [17]). Numerical experiments for these Cauchy problems were performed in Klibanov and Rakesh [14], and indeed they demonstrated high stability of these problems. Thus in this case one might expect to have a good approximation for $w_*(x,t)$ for all $(x,t) \in D_{T_1}$ by minimization of J_λ. This line of development will be discussed elsewhere.

2. Auxiliary lemma. The main result of this section is Lemma 2.3, which is based on the special properties of the finite-dimensional space P_N. Since $Q_n(r)$ are piecewise analytic functions then the following lemma is true.

LEMMA 2.1. *There exists a number $R_1 = R_1(N) \in (0, R)$ such that if*

$$\sum_{n=1}^{N} d_n Q_n(r) = 0 \quad \text{for } r \in (0, R_1),$$

with some constants d_n, then

$$\sum_{n=1}^{N} d_n Q_n(r) \equiv 0 \text{ in } (0, R),$$

where functions Q_n were introduced in §2.

LEMMA 2.2. *Let $R_1 = R_1(N)$ be the number defined in the Lemma* 2.1 *and $R_2 \in [R_1, R)$. Let E be the time cylinder such that*

$$E = \left\{(x,t)\colon r_0 < |x| < R_2, \sin\varphi > \frac{r_0}{R}, t \in (t_1,t_2), \text{ where } 0 \le t_1 < t_2 \le T_1\right\}.$$

Then there exists a positive constant $\gamma_1 = \gamma_1(E, D_{T_1}, P_N)$ such that

$$\|f\|_{H^1(E)} \ge \gamma_1 \|f\|_{\tilde{H}_0^2(D_{T_1})}, \qquad f \in P_N.$$

Proof. Since function $f \in P_N$ are analytic in respect to $t \in (0,T)$ then by Lemma 2.1 the following implication is valid:

$$\{f = 0 \text{ in } E\} \to \{f = 0 \text{ in } D_{T_1}\}.$$

Therefore for $f \in P_N$ norms of $H^1(E)$ and $\tilde{H}_0^2(D_{T_1})$ are equivalent since P_N is a finite-dimensional space. □

Finally, Lemmas 1.2 and 2.2 imply that the following lemma is true.

LEMMA 2.3. *Let the number R_2 and the cylinder E be the same as in Lemma* 2.3. *Then there exists a positive constant $\gamma = \gamma(E, D_{T_1}, P_N)$ such that*

$$\|f\|_{H^1(E)} \ge \gamma \|f\|_{H^2(D_{T_1})}, \qquad f \in P_N.$$

3. Special form of a Carleman estimate for P_N. Let us remember by (1.23) and (1.32)–(1.33) we have the following relations:

$$L_0 u = \Delta u - 2u_{rt}, \tag{3.1}$$

$$\beta(r,t) = -(r + \alpha t), \qquad \alpha = \text{ constant } \in \left(\frac{R}{T_1}, \frac{1}{2}\right), \tag{3.2}$$

$$G = \left\{(x,t)\colon \beta(r,t) > -R, r > r_0, \sin\varphi > \frac{r_0}{R}, t > 0\right\}. \tag{3.3}$$

Hence the boundary ∂G of the domain G consists from exactly four pieces, $\omega_1, \omega_2, \omega_3$, and ω_4:

$$\omega_1 = \left\{r = r_0, \sin\varphi > \frac{r_0}{R}, 0 < t < \frac{R - r_0}{\alpha} < T_1\right\}, \tag{3.4}$$

$$\omega_2 = \left\{t = 0, r_0 < r < R, \sin\varphi > \frac{r_0}{R}\right\}, \tag{3.5}$$

$$\omega_3 = \left\{r + \alpha t = R, r > r_0, \sin\varphi > \frac{r_0}{R}, t > 0\right\}, \tag{3.6}$$

$$\omega_4 = \left\{\sin\varphi = \frac{r_0}{R}, \beta(r,t) > -R, r > r_0, t > 0\right\}, \tag{3.7}$$

$$\partial G = \omega_1 \cup \omega_2 \cup \omega_3 \cup \omega_4.$$

In the sequel, C will denote different positive constants dependent only on G, P_N, and $\alpha, C = C(G, P_N, \alpha) > 1$. However, in Lemmas 3.1–3.6, C does not depend on P_N. The main result of this section is the following theorem.

THEOREM 3.1 (special form of a Carleman estimate for P_N). *There exists a sufficiently large constant $\tilde{\lambda} = \tilde{\lambda}(G, P_N, \alpha)$ such that for all $\lambda \geq \tilde{\lambda}$ and for all functions $u \in P_N$ the following Carleman estimate holds:*

$$\int_G (L_0 u)^2 e^{2\lambda\beta}\, dx\, dt \geq C\lambda \int_G (|\nabla u|^2 + u_t^2) e^{2\lambda\beta}\, dx\, dt - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla u|^2 + u_t^2)\, d\sigma.$$

Proof of this theorem consists of proofs of several lemmas (see Lemmas 3.1–3.7 below). Proofs of these lemmas are rather simple, but they require a relatively large number of rather routine calculations, which is "commonplace" in the theory of Carleman estimates (cf. Lavrent'ev et al. [18], Chapter 4). A more elegant proof would probably be the symbol method, as it was done, for instance, by Hörmander [8] and Isàkov [9] for "standard" Carleman estimates, that is, for estimates which are valid for the *whole* Sobolev spaces. But we do not know how to use this method in our *particular* case, because our estimate is valid only for *finite-dimensional* space P_N, and because of a major difficulty in our particular case described below.

Now let us explain why we cannot use the standard Carleman estimate here. First of all, let us remember briefly the Carleman estimate for the operator $Pu = u_{tt} - \Delta u$; cf. Isàkov [9] and Lavrent'ev et al. [18]. Consider domain

$$\Omega = \{|x| < 1, t \in (-b, b)\},$$

where $b =$ constant > 0. Consider a weight function $\beta_1(x,t) = |x|^2 - \sigma t^2$, where $\sigma =$ constant $\in (0,1)$. Choose a constant c such that

$$c \in (0,1) \quad \text{and} \quad \sqrt{\frac{1-c}{\sigma}} < b.$$

Consider domain

$$\Omega_c = \{(x,t)\colon |x| < 1, \beta_1(x,t) > c\}.$$

Then $\Omega_c \subset \Omega$ and the following Carleman estimate is valid:

$$\begin{aligned} \int_{\Omega_c} (Pu)^2 e^{2\lambda\beta_1}\, dx\, dt \geq & D\lambda \int_{\Omega_c} (|_{\Omega_c}(|\nabla u|^2 + u_t^2) e^{2\lambda\beta_1}\, dx\, dt \\ & + D\lambda^3 \int_{\Omega_c} u^2 e^{2\lambda\beta_1}\, dx\, dt, \end{aligned} \tag{3.8}$$

for all $u \in \overset{\circ}{H}{}^2(\Omega_c)$ and for all $\lambda \geq \lambda_0$, where positive constants D, λ_0 depend only on Ω, Ω_c, and σ.

In particular, the last estimate implies, by $b > 1$, uniqueness of a time-like Cauchy problem

$$|u_{tt} - \Delta u| \leq A(|\nabla u| + |u_t| + |u|) \quad \text{in } \Omega,$$

$$u|_{|x|=1} = \left.\frac{\partial u}{\partial r}\right|_{|x|=1} = 0, \tag{3.9}$$

where $A =$ constant > 0; see Hörmander [8], Isàkov [9], and Lavrent'ev et al. [18]. Likewise, using Carleman estimate (3.8) and prescribing nonzero Cauchy data at the surface $\{|x| = 1\}$ one can get Hölder and even Lipshitz stability estimates for this Cauchy problem; cf. Kazemi and Klibanov [11], and Klibanov and Malinsky [13].

Now note that the boundary $\partial\Omega_c$ of the domain of integration in (3.8) consists of *exactly* two parts $\partial_1\Omega_c, \partial_2\Omega_c$, where

$$\partial_1\Omega_c = \{\beta_1(x,t) = c\}, \qquad \partial_2\Omega_c = \{|x| = 1\} \cap \bar{\Omega}, \tag{3.10}$$
$$\partial\Omega = \partial_1\Omega_c \cup \partial_2\Omega_c.$$

Thus $\partial_1\Omega_c$ is the *level surface* of the weight function and $\partial_2\Omega_c$ is the surface, where *Cauchy data* are given.

Property (3.10) *is a genuine feature of the Carleman estimates theory.*

Remark. Sometimes domains of integrations with different properties can be considered. However, as soon as one needs to get a uniqueness or a stability result (on the basis of Carleman estimates) one must inevitably employ domains with the property (3.10).

In the case of Theorem 3.1, however, surface ω_2 is a part of the boundary ∂G; see (3.4)–(3.7). But definitely ω_2 is neither a level surface of the weight function nor a surface where Cauchy data are given (they are given on ω_1 and ω_4, since $u \in P_N \subset H_0^2(D_{T_1})$). All the other surfaces in (3.4)–(3.7) are either level surfaces of the weight function or surfaces, where Cauchy data are given. Nevertheless the surface ω_2 *has* to be a part of the boundary of the domain of integration, because of our need to estimate the integral

$$\int_G e^{2\lambda\beta} \left(\int_0^t u(x,\tau)\, d\tau \right)^2 dx\, dt, \qquad u \in L_2(G)$$

through the integral

$$\int_G u^2 e^{2\lambda\beta}\, dx\, dt,$$

whichever domain G would be (see Lemma 3.8 and (1.22)). Therefore the presence of the surface ω_2 is the major difficulty of our particular case of the Carleman estimate.

Remark. In the sequel, we will always use the fact that in the domain $\{r > r_0, \sin\varphi > r_0/R\}$

$$A_2 \sum_{i=1}^{3} u_{x_i}^2 \le (u_r^2 + u_\theta^2 + u_\varphi^2) \le A_2 \sum_{i=1}^{3} u_{x_i}^2,$$

for all smooth functions u, where positive constants A_1, A_2 depend only on r_0 and r_0/R.

Below we prove Theorem 3.1 by proving Lemmas 3.1–3.7. In these lemmas we first obtain pointwise differential identities using the rule of differentiation of products. Then by integrating these identities over the domain G and employing Gauss' formula, we will get desired L_2 estimates.

Thus in Lemmas 3.1 and 3.2 we estimate from below the integral

$$\int_G 2u_r L_0 u e^{2\lambda\beta}\, dx\, dt.$$

Then in Lemmas 3.3 and 3.4 we estimate from below the integral

$$\int_G -2u_t L_0 u e^{2\lambda\beta}\,dx\,dt.$$

Finally, a combination of two latter estimates and properties of the set P_N will provide the desired Carleman estimate, that is, an estimate from below the integral

$$\int_G (L_0 u)^2 e^{2\lambda\beta}\,dx\,dt, \qquad u \in P_N;$$

see Lemmas 3.5–3.7.

LEMMA 3.1. *For all functions $u \in C^2(\bar{G})$ the following identity is valid:*

(3.11)
$$(2u_r L_0 u) r^2 \sin\varphi e^{2\lambda\beta} = 2\lambda(1-2\alpha)u_r^2 r^2 \sin\varphi e^{2\lambda\beta} - 2\lambda\left(\frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right)\sin\varphi e^{2\lambda\beta} + V_t + \frac{\partial U_1}{\partial r} + \frac{\partial U_2}{\partial\theta} + \frac{\partial U_3}{\partial\varphi},$$

where

(3.12)
$$V = -2u_r^2 r^2 \sin\varphi e^{2\lambda\beta}.$$

The vector functions $U = (U_1, U_2, U_3)$ belongs to C^1 and satisfies the estimate

(3.13)
$$|U| \le C|\nabla u|^2 e^{2\lambda\beta}$$

and

(3.14)
$$U_2(r, 0, \varphi, t) = U_2(r, 2\pi, \varphi, t).$$

Proof. The left-hand side of (3.11) can be rewritten as

$$2u_r\left[u_{rr} + \frac{2}{r}u_r + \frac{1}{r^2\sin^2\varphi}u_{\theta\theta} + \frac{1}{r^2\sin\varphi}\frac{\partial}{\partial\varphi}(\sin\varphi u_\varphi) - 2u_{rt}\right] \times r^2\sin\varphi e^{-2\lambda(r+\alpha t)}.$$

Hence by (3.2)

$$\begin{aligned}
2u_r(L_0u)r^2\sin\varphi e^{2\lambda\beta} &= \frac{\partial}{\partial r}(u_r^2 r^2\sin\varphi e^{2\lambda\beta}) + 2\lambda r^2\sin\varphi u_r^2 e^{2\lambda\beta} \\
&\quad + \frac{\partial}{\partial\theta}\left(2u_r u_\theta\frac{\sin\varphi}{\sin^2\varphi}e^{2\lambda\beta}\right) - 2u_{r\theta}u_\theta\frac{\sin\varphi}{\sin^2\varphi}e^{2\lambda\beta} \\
&\quad + \frac{\partial}{\partial\varphi}(2u_r u_\varphi\sin\varphi e^{2\lambda\beta}) - 2u_{r\varphi}u_\varphi\sin\varphi e^{2\lambda\beta} \\
&\quad + \frac{\partial}{\partial t}(-2u_r^2 r^2\sin\varphi e^{2\lambda\beta}) - 4\lambda\alpha u_r^2 r^2\sin\varphi e^{2\lambda\beta} \\
&= 2\lambda(1-2\alpha)u_r^2 r^2\sin\varphi e^{2\lambda\beta} - 2\lambda\left(\frac{u_\theta^2}{\sin_\varphi^2} + u_\varphi^2\right)\sin\varphi e^{2\lambda\beta} \\
&\quad + V_t + \frac{\partial U_1}{\partial r} + \frac{\partial U_2}{\partial\theta} + \frac{\partial U_3}{\partial\varphi},
\end{aligned}$$

where the function V is as in (3.12), and functions U_1, U_2, U_3 have the forms

$$U_1 = \left(u_r^2 r^2 - \frac{u_\theta^2}{\sin_\varphi^2} - u_\varphi^2\right) \sin\varphi e^{2\lambda\beta}$$

$$U_2 = 2u_r u_\theta \frac{\sin\varphi}{\sin^2\varphi} e^{2\lambda\beta}, \qquad U_3 = 2u_r u_\varphi \sin\varphi e^{2\lambda\beta}. \qquad \square$$

LEMMA 3.2. *For all positive λ and for all functions $u \in H_0^2(G)$ the following estimate is valid*:

$$\begin{aligned} \int_G 2u_r L_0 u e^{2\lambda\beta}\, dx\, dt &\geq 2\lambda \int_G [(1-2\alpha)u_r^2 - Cu_\theta^2 - u_\varphi^2] e^{2\lambda\beta}\, dx\, dt \\ &\quad + \int_{\omega_2} 2u_r^2 e^{2\lambda\beta}\, dx - Ce^{-2\lambda R} \int_{\omega_3} |\nabla u|^2\, d\sigma. \end{aligned} \tag{3.15}$$

Proof. Since $\alpha \in (0, \frac{1}{2})$ then $1 - 2\alpha > 0$. Let $u \in C^2(\bar{G}) \cap H_0^2(G)$ in (3.11). Integrate (3.11) over G using Gauss' formula and (3.12)–(3.14). Noting that $\beta|_{\omega_3} = -R$ and $-(1/\sin^2\varphi) > -(R/r_0)^2$ in G we obtain (3.15) for all functions $u \in C^2(\bar{G}) \cap H_0^2(G)$. But since this set of functions is dense in $H_0^2(G)$, then (3.15) also holds for all $u \in H_0^2(G)$. $\square$

LEMMA 3.3. *For all functions $u \in C^2(\bar{G})$ the following identity is valid*:

$$\begin{aligned} &[-2u_t(L_0 u) r^2 \sin\varphi] e^{2\lambda\beta} \\ &\quad = 4\lambda[u_t^2 + \frac{\alpha}{2} u_r^2 - u_t u_r] r^2 \sin\varphi e^{2\lambda\beta} \\ &\qquad + 2\lambda\alpha \left(\frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right) \sin\varphi e^{2\lambda\beta} - 4u_t^2 r \sin\varphi e^{2\lambda\beta} \\ &\qquad + W_t + \frac{\partial Z_1}{\partial r} + \frac{\partial Z_2}{\partial\theta} + \frac{\partial Z_3}{\partial\varphi}, \end{aligned} \tag{3.16}$$

where

$$W = \left(u_r^2 r^2 + \frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right) \sin\varphi e^{2\lambda\beta}. \tag{3.17}$$

the vector function $Z = (Z_1, Z_2, Z_3)$ belongs to C^1, satisfies the estimate

$$|Z| \leq C(|\nabla u|^2 + u_t^2) e^{2\lambda\beta}, \tag{3.18}$$

and

$$Z_2(r, 0, \varphi, t) = Z_2(r, 2\pi, \varphi, t). \tag{3.19}$$

Proof. The left-hand side of (3.16) can be rewritten as

$$\begin{aligned} &-2u_t(L_0 u) r^2 \sin\varphi e^{2\lambda\beta} \\ &\quad = -2u_t \left[u_{rr} + \frac{2}{r} u_r + \frac{1}{r^2 \sin^2\varphi} u_{\theta\theta} + \frac{1}{r^2 \sin\varphi} \frac{\partial}{\partial\varphi} (\sin\varphi u_\varphi) - 2u_{rt}\right] r^2 \sin\varphi e^{2\lambda\beta}. \end{aligned}$$

Hence

$$
\begin{aligned}
-2u_t(L_0u)r^2\sin\varphi e^{2\lambda\beta} &= \frac{\partial}{\partial r}\left(-2u_tu_rr^2\sin\varphi e^{2\lambda\beta}\right)\\
&+ 2u_{rt}u_rr^2\sin\varphi e^{2\lambda\beta} + 4u_tu_rr\sin\varphi e^{2\lambda\beta}\\
&- 4\lambda u_tu_rr^2\sin\varphi e^{2\lambda\beta} - 4u_tu_rr\sin\varphi e^{2\lambda\beta}\\
&+ \frac{\partial}{\partial\theta}\left(-2u_tu_\theta\frac{\sin\varphi}{\sin^2\varphi}e^{2\lambda\beta}\right) + 2u_{t\theta}u_\theta\frac{\sin\varphi}{\sin^2\varphi}e^{2\lambda\beta}\\
&+ \frac{\partial}{\partial\varphi}\left(-2u_tu_\varphi\sin\varphi e^{2\lambda\beta}\right) + 2u_{t\varphi}u_\varphi\sin\varphi e^{2\lambda\beta}\\
&+ \frac{\partial}{\partial r}\left(2u_t^2r^2\sin\varphi e^{2\lambda\beta}\right) + 4\lambda u_t^2r^2\sin\varphi e^{2\lambda\beta} - 4u_t^2r\sin\varphi e^{2\lambda\beta}\\
&= 4\lambda\left[u_t^2 + \frac{\alpha}{2}u_r^2 - u_tu_r\right]r^2\sin\varphi e^{2\lambda\beta}\\
&+ 2\lambda\alpha\left(\frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right)\sin\varphi e^{2\lambda\beta} - 4u_t^2r\sin\varphi e^{2\lambda\beta}\\
&+ W_t + \frac{\partial Z_1}{\partial r} + \frac{\partial Z_2}{\partial\theta} + \frac{\partial Z_3}{\partial\varphi},
\end{aligned}
$$

where

$$
W = \left(u_r^2r^2 + \frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right)\sin\varphi e^{2\lambda\beta},
$$

and components of the vector function Z have the forms

$$
Z_1 = 2(u_t^2 - u_tu_r)r^2\sin\varphi e^{2\lambda\beta}
$$

$$
Z_2 = -2u_tu_\theta\frac{\sin\varphi}{\sin^2\varphi}e^{2\lambda\beta}, \qquad Z_3 = -2u_tu_\varphi\sin\varphi e^{2\lambda\beta}. \qquad \square
$$

LEMMA 3.4. *For all positive λ and for all functions $u \in H_0^2(G)$, the following inequality holds*:

$$
\begin{aligned}
-\int_G 2u_tL_0ue^{2\lambda\beta}\,dx\,dt &\geq 4\lambda\int_G\left(u_t^2 + \frac{\alpha}{2}u_r^2 - |u_tu_r|\right)e^{2\lambda\beta}\,dx\,dt\\
&+ 2\lambda\alpha\int_G(u_\theta^2 + u_\varphi^2)e^{2\lambda\beta}\,dx\,dt - \frac{4}{r_0}\int_G u_t^2e^{2\lambda\beta}\,dx\,dt\\
&- \int_{\omega_2}\left[u_r^2 + \frac{1}{r^2}\left(\frac{u_\theta^2}{\sin^2\varphi} + u_\varphi^2\right)\right]e^{2\lambda\beta}\,dx\\
&- Ce^{-2\lambda R}\int_{\omega_3}(|\nabla u|^2 + u_t^2)\,d\sigma.
\end{aligned}
\tag{3.20}
$$

Proof. Integrate (3.16) over G, using Gauss' formula and (3.17)–(3.19). Noting that $\beta|_{\omega_3} = -R$ and $(1/\sin^2\varphi) \geq 1$, we obtain (3.20) for all functions $u \in C^2(\bar{G}) \cap H_0^2(G)$. Since the last set of functions is dense in $H_0^2(G)$, then (3.20) is valid for $u \in H_0^2(G)$ as well. $\square$

LEMMA 3.5. *Choose a constant s such that*

$$
0 < s < \frac{1-2\alpha}{1-\alpha}. \tag{3.21}
$$

Then there exists a constant $\lambda_1 = \lambda_1(r_0, \alpha, R) = \lambda_1(G)$ *such that for all* $\lambda > \lambda_1$ *and for all functions* $u \in H_0^2(G)$ *the following inequality is valid*:

$$\begin{aligned}
&\int_G (2u_r - 2su_t) L_0 u e^{2\lambda\beta}\, dx\, dt \\
&\quad \geq C\lambda \int_G (u_r^2 + u_t^2) e^{2\lambda\beta}\, dx\, dt - C\lambda \int_G (u_\theta^2 + u_\varphi^2) e^{2\lambda\beta}\, dx\, dt \\
&\qquad + \int_{\omega_2} [(2-s)u_r^2 - C(u_\theta^2 + u_\varphi^2)] e^{2\lambda\beta} - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla u|^2 + u_t^2)\, d\sigma.
\end{aligned} \tag{3.22}$$

Proof. Multiply inequality (3.20) by s and add to (3.15). Noting that $s < 1$ and $-(1/r^2 \sin^2 \varphi) \geq -C$ in G, we obtain

$$\begin{aligned}
&\int_G (2u_r - 2su_t) L_0 u e^{2\lambda\beta}\, dx\, dt \\
&\quad \geq 2\lambda \int_G \{(1 - 2\alpha + \alpha s)u_r^2 - 2s|u_t||u_r| + 2su_t^2\} e^{2\lambda\beta}\, dx\, dt \\
&\qquad - C\lambda \int_G (u_\theta^2 + u_\varphi^2) e^{2\lambda\beta}\, dx\, dt - \frac{4s}{r_0} \int_G u_t^2 e^{2\lambda\beta}\, dx\, dt \\
&\qquad + \int_{\omega_2} [(2-s)u_r^2 - C(u_\theta^2 + u_\varphi^2)] e^{2\lambda\beta}\, dx - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla u|^2 + u_t^2)\, d\sigma.
\end{aligned} \tag{3.23}$$

Consider the quadratic form

$$f(x_1, x_2) = (1 - 2\alpha + \alpha s)x_1^2 - 2sx_1x_2 + 2sx_2^2.$$

Note that $1 - 2\alpha + 2s > 0$, since $\alpha \in (0, \frac{1}{2})$. Therefore this quadratic form is positive definite for s satisfying (3.21). Hence there exists a positive constant $b = b(\alpha)$ such that

$$f(x_1, x_2) \geq b(x_1^2 + x_2^2),$$

for all x_1, x_2. Let $\lambda_1 = 4s/br_0$. Hence, for $\lambda > \lambda_1$, (3.23) implies

$$\begin{aligned}
&\int_G (2u_r - 2su_t) L_0 u e^{2\lambda\beta}\, dx\, dt \\
&\quad \geq C\lambda \int_G (u_r^2 + u_t^2) e^{2\lambda\beta}\, dx\, dt - C\lambda \int_G (u_\theta^2 + u_\varphi^2) e^{2\lambda\beta}\, dx\, dt \\
&\qquad + \int_{\omega_2} [(2-s)u_r^2 - C(u_\theta^2 + u_\varphi^2)] e^{2\lambda\beta}\, dx - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla u|^2 + u_t^2)\, d\sigma,
\end{aligned}$$

which is exactly (3.22). □

LEMMA 3.6. *There exists a positive constant* $\lambda_2 = \lambda_2(G)$ *such that for all* $\lambda \geq \lambda_2$ *and for all functions* $u \in H_0^2(G)$ *the following inequality is valid*:

$$\begin{aligned}
\int_G (L_0 u)^2 e^{2\lambda\beta}\, dx\, dt \geq\ & C\lambda \int_G (u_r^2 + u_t^2) e^{2\lambda\beta}\, dx\, dt \\
& - C\lambda \int_G (u_\theta^2 + u_\varphi^2) e^{2\lambda\beta}\, dx\, dt \\
& + \frac{1}{2} \int_{\omega_2} [(2-s)u_r^2 - C(u_\theta^2 + u_\varphi^2)] e^{2\lambda\beta}\, dx \\
& - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla u|^2 + u_t^2)\, d\sigma.
\end{aligned} \tag{3.24}$$

Proof. The Cauchy inequality leads to

$$(2u_r - 2su_t)L_0u \le (L_0u)^2 + u_r^2 + (L_0u)^2 + s^2u_t^2$$
$$\le 2(L_0u)^2 + u_r^2 + u_t^2.$$

Hence (3.24) follows immediately from the last inequality and (3.22). □

Until now we have *not* used the assumption $u \in P_N$. As a price for that we have negative signs at u_θ^2, u_φ^2 in (3.24). In order to get rid of this defect we should "supress negative integrals"

$$-C\lambda \int_G (u_\theta^2 + u_\varphi^2)e^{2\lambda\beta}\,dx\,dt, \qquad -\int_{\omega_2} C(u_\theta^2 + u_\varphi^2)e^{2\lambda\varphi}\,dx$$

by "positive integrals"

$$C\lambda \int_G (u_r^2 + u_t^2)e^{2\lambda\beta}\,dx\,dt, \qquad \int_{\omega_2} u_r^2 e^{2\lambda\beta}\,dx.$$

Thus now is the time to use properties of P_N.

LEMMA 3.7. *For all functions $u \in P_N$ the following estimates are valid*:

$$\int_G (u_\theta^2 + u_\varphi^2)e^{2\lambda\beta}\,dx\,dt \le \frac{C}{\lambda}\int_G u_r^2 e^{2\lambda\beta}\,dx\,dt, \tag{3.25}$$

$$\int_{\omega_2} (u_\theta^2 + u_\varphi^2)e^{2\lambda\beta}\,dx \le \frac{C}{\lambda}\int_{\omega_2} u_r^2 e^{2\lambda\beta}. \tag{3.26}$$

Proof. We will only prove the estimate

$$\int_G u_\theta^2 e^{2\lambda\beta}\,dx\,dt \le \frac{C}{\lambda}\int_G u_r^2 e^{2\lambda\beta}\,dx\,dt \tag{3.27}$$

since proofs of (3.25) and (3.26) are completely parallel.

Consider the function $u \in P_N$. Since functions $\{\phi_{n_1}\}$ form an orthonormal basis in L_2, φ, then the function u can be represented in the form

$$u = \sum_{n_1=1}^{N} u_{n_1}(r,t)\phi_{n_1}(\theta,\varphi), \tag{3.28}$$

where

$$u_{n_1}(r,t) = \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} u(r,\theta,\varphi,t)\phi_{n_1}(\theta,\varphi)\sin\varphi\,d\varphi.$$

Hence

$$u_\theta = \sum_{n_1=1}^{N} u_{n_1}(r,t)\,\frac{\partial\phi_{n_1}}{\partial\theta}\,(\theta,\varphi).$$

Hence by the Cauchy inequality,

$$|u_\theta| \le \sqrt{C}\left[\sum_{n_1=1}^{N} u_{n_1}^2(r,t)\right]^{\frac{1}{2}}. \tag{3.29}$$

Denote $q = (R - r_0/\alpha)$. Since the function $\beta = \beta(r,t)$ does not depend on θ, φ then (3.28) and Parceval theorem imply

$$\int_G u^2 e^{2\lambda\beta}\,dx\,dt = \sum_{n_1=1}^{N} \int_0^q dt \int_{r_0}^{R-\alpha t} u_{n_1}^2(r,t) e^{2\lambda\beta} r^2\,dr. \tag{3.30}$$

Similarly (3.29) leads to

$$\int_G u_\theta^2 e^{2\lambda\beta}\,dx\,dt \le C \sum_{n_1=1}^{N} \int_0^q dt \int_{r_0}^{R-\alpha t} u_{n_1}^2(r,t) e^{2\lambda\beta} r^2\,dr.$$

Hence (3.30) and the last estimate imply

$$\int_G u_\theta^2 e^{2\lambda\beta}\,dx\,dt \le C \int_G u^2 e^{2\lambda\beta}\,dx\,dt. \tag{3.31}$$

Now recall that $P_N \subset H_0^2(D_{T_1})$, which means, in particular, that $u|_{r=r_0} = u_r|_{r=r_0} = 0$ for all $u \in P_N$. Hence,

$$u = \int_{r_0}^{r} u_r(y,\theta,\varphi,t)\,dy, \qquad u \in P_N.$$

Hence

$$\begin{aligned}
\int_G u^2 e^{2\lambda\beta}\,dx\,dt &= \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_0^q dt \int_{r_0}^{R-\alpha t} r^2 e^{2\lambda\beta} \left(\int_{r_0}^{r} u_r\,dy\right)^2 dr \\
&\le R^3 \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_0^q dt \int_{r_0}^{R-\alpha t} e^{2\lambda\beta} \int_{r_0}^{r} u_r^2\,dy \\
&= R^3 \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_0^q e^{-2\lambda\alpha t}\,dt \int_{r_0}^{R-\alpha t} u_r^2\,dy \int_y^{R-\alpha t} e^{-2\lambda r}\,dr \\
&= R^3 \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_0^q e^{-2\lambda\alpha t}\,dt \\
&\quad \times \int_{r_0}^{R-\alpha t} u_r^2\,dy \left[\frac{e^{-2\lambda y} - e^{-2\lambda(R-\alpha t)}}{2\lambda}\right] \\
&\le \frac{R^3}{2\lambda r_0^2} \int_0^{2\pi} d\theta \int_{\varphi_1}^{\varphi_2} \sin\varphi\,d\varphi \int_0^q dt \int_{r_0}^{R-\alpha t} u_r^2 e^{2\lambda\beta(y,t)} y^2\,dy \\
&\le \frac{C}{\lambda} \int_G u_r^2 e^{2\lambda\beta}\,dx\,dt.
\end{aligned}$$

Hence we have actually proven that

$$\int_G u^2 e^{2\lambda\beta}\,dx\,dt \le \frac{C}{\lambda} \int_G u_r^2 e^{2\lambda\beta}\,dx\,dt, \qquad u \in H_0^2(G). \tag{3.32}$$

Finally, (3.31) and (3.32) lead to

$$\int_G u_\theta^2 e^{2\lambda\beta}\,dx\,dt \le \frac{C}{\lambda} \int_G u_r^2 e^{2\lambda\beta}\,dx\,dt, \qquad u \in P_N. \qquad \square$$

Proof of Theorem 3.1. This proof follows immediately from Lemmas 3.6 and 3.7. We close this section with one auxiliary result which is quite similar to Lemma 3.7. But the difference is that this result is valid for *all* $u \in L_2(G)$. We omit the proof since a quite similar result is known; see [12].

LEMMA 3.8. *For all functions* $u \in L_2(G)$ *the following inequality is valid*

$$\int_G \left[\int_0^t u(x,t)\,dt\right]^2 e^{2\lambda\beta}\,dx\,dt \le \frac{D}{\lambda}\int_G u^2 e^{2\lambda\beta}\,dx\,dt,$$

where the positive constant D *depends only on the domain* G *and on the constant* α.

4. Proof of Theorem 1.1. Let us remember that the functional $J_\lambda(w)$ has the form

$$J_\lambda(w) = \int_G [L(p+w)]^2 e^{2\lambda\beta}\,dx\,dt, \qquad w \in P_N'. \tag{4.1}$$

Here function $p \in H^2(D_{T_1})$,

$$P_N' = \{w \in P_N : \|w\|_{\tilde{H}_0^2(D_{T_1})} < 1\},$$

and the nonlinear operator L has the form (see (1.22))

$$\begin{aligned} Lv = {} & L_0 v + 2\nabla v \int_0^t \nabla v(x,\tau)\,d\tau - 2v_t \int_0^t v_r(x,\tau)\,d\tau \\ & - 2v_r v + \frac{2}{r}\,v_t + 2\nabla v \nabla g - 2v_t g'(r), \end{aligned} \tag{4.2}$$

with

$$L_0 v = \Delta v - 2v_{rt}, \qquad g(r) = \ln\frac{1}{4\pi r}.$$

The main idea of the proof is that first we prove, by rather simple estimates, that

$$\begin{aligned} & J_\lambda(w+h) - J_\lambda(w) - J_\lambda'(w)(h) \\ & \ge \frac{1}{4}\int_G (L_0 h)^2 e^{2\lambda\beta}\,dx\,dt \\ & \quad - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\,d\tau\right)^2 \right\} e^{2\lambda\beta}\,dx\,dt, \end{aligned}$$

where the positive constant M does not depend on λ, w, and h. Then we note that by Theorem 3.1, (3.32), and Lemma 3.8 the first integral on the right-hand side of the latter estimate, roughly speaking, dominates the second integral. Finally, Lemma 2.4 will provide the desired result.

Proof. First of all, we should calculate

$$J_\lambda(w+h) - J_\lambda(w) \text{ and } J_\lambda'(w)(h)$$

for $w, h \in P_N'$. By (4.1)

$$\begin{aligned} & J_\lambda(w+h) - J_\lambda(w) \\ & = \int_G [L(p+w+h) - L(p+w)][L(p+w+h) + L(p+w)] e^{-2\lambda\beta}\,dx\,dt. \end{aligned} \tag{4.3}$$

By virtue of (4.2),

$$\begin{aligned} L(p+w+h) &= L(p+w) + L_0 h + 2\nabla(p+w)\int_0^t \nabla h(x,\tau)\,d\tau \\ &\quad + 2\nabla h \int_0^t \nabla(p+w)(x,\tau)\,d\tau - 2(p+w)_t \int_0^t h_r(x,\tau)\,d\tau \\ &\quad - 2h_t \int_0^t (p+w)_r(x,\tau)\,d\tau - 2(p+w)h_r \\ &\quad + \frac{2}{r}\,h_t + 2\nabla h\nabla g - 2(p+w)_r h - 2h_t g'(r) \\ &\quad - 2h_r h + 2\nabla h \int_0^t \nabla h(x,\tau)\,d\tau - 2h_t \int_0^t h_r(x,\tau)\,d\tau. \end{aligned}$$

Hence

$$L(p+w+h) - L(p+w) = L_0(h) + L_1(p+w,h) + L_2(h), \tag{4.4}$$

where L_1 is a linear operator with respect to h, and L_2 is a nonlinear operator. Namely,

$$\begin{aligned} L_1(p+w,h) &= 2\nabla(p+w)\int_0^t \nabla h(x,\tau)\,d\tau + 2\nabla h \int_0^t \nabla(p+w)(x,\tau)\,d\tau \\ &\quad - 2(p+w)_t \int_0^t h_r(x,\tau)\,d\tau - 2h_t \int_0^t (p+w)_r(x,\tau)\,d\tau \\ &\quad - 2(p+w)h_r + \frac{2}{r}\,h_t + 2\nabla h\nabla g - 2(p+w)_r h - 2h_t g'(r), \end{aligned} \tag{4.5}$$

and

$$L_2(h) = -2h_r h + 2\nabla h \int_0^t \nabla h(x,\tau)\,d\tau - 2h_t \int_0^t h_r(x,\tau)\,d\tau. \tag{4.6}$$

Although operators L_1, L_2 seem to be rather complicated, they will not give us any "troubles," simply because they do not contain second-order derivatives of h. Thus we will "suppress them by $L_0(h)$" using Theorem 3.1.

By (4.4) we obtain

$$L(p+w+h) + L(p+w) = 2L(p+w) + [L_0(h) + L_1(p+w,h) + L_2(h)].$$

Hence (4.3) leads to

$$\begin{aligned} J_\lambda(w+h) - J_\lambda(h) &= \int_G [L_0(h) + L_1(p+w,h) + L_2(h)] \\ &\quad \times [2L(p+w) + L_0(h) + L_1(p+w,h) + L_2(h)]e^{2\lambda\beta}\,dx\,dt. \end{aligned} \tag{4.7}$$

In order to calculate the Fréchet derivative $J'_\lambda(w)(h)$ we should single out the "linear part," with respect to h, of the right-hand side of (4.7). Hence

$$J'_\lambda(w)(h) = 2\int_G L(p+w)[L_0(h) + L_1(p+w,h)]e^{2\lambda\beta}\,dx\,dt. \tag{4.8}$$

Therefore (4.7) and (4.8) lead to

$$
\begin{aligned}
&J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\
&\quad = \int_G [L_0(h)]^2 e^{2\lambda\beta}\, dx\, dt + \int_G L_0(h)[L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt \\
&\quad + \int_G L_1(p+w,h)[L_0(h) + L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt \\
&\quad + \int_G L_2(h)[2L(p+w) + L_0(h) + L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt.
\end{aligned} \tag{4.9}
$$

Denote

$$
I_1(h,\lambda) = \int_G L_0(h)[L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt, \tag{4.10}
$$

$$
I_2(h,\lambda) = \int_G L_1(p+w,h)[L_0(h) + L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt, \tag{4.11}
$$

and

$$
I_3(h,\lambda) = \int_G L_2(h)[2L(p+w) + L_0(h) + L_1(p+w,h) + L_2(h)] e^{2\lambda\beta}\, dx\, dt. \tag{4.12}
$$

Hence (4.9) can be rewritten as

$$
\begin{aligned}
&J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\
&\quad = \int_G [L_0(h)]^2 e^{2\lambda\beta}\, dx\, dt + I_1(h,\lambda) + I_2(h,\lambda) + I_3(h,\lambda).
\end{aligned} \tag{4.13}
$$

In order to prove the theorem we have to estimate the right-hand side of (4.13) from below. First, we estimate the integrals I_1, I_2, I_3 separately. As in §3, $C > 1$ denotes different positive constants dependent only on G, P'_N, and α. Let M be a positive constant such that

$$
\max\{1, \|w\|_{C^1(\bar{G})}, \|p+w\|_{C^2(\bar{G})}\} \le M, \qquad w \in P'_N. \tag{4.14}
$$

Formally speaking we could replace M with C, but we will not do that in order to make our estimates more clear. We remember that $h \in P'_N$. Hence

$$
\|h\|_{C^1(\bar{G})} \le M. \tag{4.15}
$$

First, we estimate from above the following functions:

$$
[L_1(p+w,h)]^2, \quad [L_2(h)]^2, \quad |L_2(h)|, \quad w, \quad h \in P'_N.
$$

By (4.5) and (4.14),

$$
\begin{aligned}
|L_1(p+w,h)| &\le 2M \int_0^t |\nabla h(x,\tau)|\, d\tau \\
&+ 2M \int_0^t |h_\tau(x,\tau)|\, d\tau + MC|h_t| + MC|\nabla h| + 2M|h|.
\end{aligned} \tag{4.16}
$$

Hence

$$|L_1(p+w,h)|^2 \le CM^2 \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\, d\tau \right)^2 \right\}. \tag{4.17}$$

Furthermore (4.6) and (4.15) imply

$$|L_2(h)| \le 2M \int_0^t |\nabla h(x,\tau)\, d\tau + 2M \int_0^t |h_r(x,\tau)|\, d\tau + 2M|h_r|.$$

Hence

$$|L_2(h)|^2 \le CM^2 \left\{ h_r^2 + \left(\int_0^t |\nabla h(x,\tau)|\, d\tau \right)^2 \right\}. \tag{4.18}$$

On the other hand, (4.6) and the Cauchy inequality imply

$$|L_2(h)| \le C \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t (\nabla h(x,\tau))\, d\tau \right)^2 \right\}. \tag{4.19}$$

Now we are ready to estimate integrals I_1, I_2, and I_3. Using the Cauchy–Schwarz inequality and (4.10) we obtain

$$\begin{aligned} I_1(h,\lambda) &\ge -\frac{1}{4} \int_G |L_0 h|^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad - \int_G [L_1(p+w,h) + L_2(h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &\ge -\frac{1}{4} \int_G (L_0 h)^2 e^{2\lambda\beta}\, dx\, dt - 2 \int_G [L_1(p+w,h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad - 2 \int_G [L_2(h)]^2 e^{2\lambda\beta}\, dx\, dt. \end{aligned}$$

Furthermore, applying (4.17) and (4.18), we get

$$\begin{aligned} I_1(h,\lambda) &\ge -\frac{1}{4} \int_G (L_0 h)^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left[\int_0^t |\nabla h(x,\tau)|\, d\tau \right]^2 \right\} e^{2\lambda\beta}\, dx\, dt. \end{aligned} \tag{4.20}$$

Next, consider the integral I_2. The Cauchy–Schwarz inequality and (4.11) lead to

$$\begin{aligned} I_2(h,\lambda) &\ge -\frac{1}{4} \int_G (L_0 h)^2 e^{2\lambda\beta}\, dx\, dt - \int_G [L_1(p+w,h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad + \int_G [L_1(p+w,h)]^2 e^{2\lambda\beta}\, dx\, dt - \frac{1}{2} \int_G [L_1(p+w,h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad - \frac{1}{2} \int_G [L_2(h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &= -\frac{1}{4} \int_G (L_0 h)^2 e^{2\lambda\beta}\, dx\, dt - \frac{1}{2} \int_G [L_1(p+w,h)]^2 e^{2\lambda\beta}\, dx\, dt \\ &\quad - \frac{1}{2} \int_G [L_2(h)]^2 e^{2\lambda\beta}\, dx\, dt. \end{aligned}$$

Hence applying inequalities (4.17) and (4.18), we obtain

$$
\begin{aligned}
I_2(h,\lambda) \geq & -\frac{1}{4}\int_G (L_0 h)^2 e^{2\lambda\beta}\,dx\,dt \\
& - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\,d\tau \right)^2 \right\} e^{2\lambda\beta}\,dx\,dt.
\end{aligned} \tag{4.21}
$$

Finally, we have to estimate the integral I_3. By (4.12),

$$
\begin{aligned}
I_3(h,\lambda) = & \int_G 2L(p+w)L_2(h)e^{2\lambda\beta}\,dx\,dt + \int_G L_0(h)L_2(h)e^{2\lambda\beta} \\
& + \int_G L_2(h)[L_1(p+w,h) + L_2(h)]e^{2\lambda\beta}\,dx\,dt.
\end{aligned} \tag{4.22}
$$

In order to estimate the first integral in (4.22) we apply (4.14) and (4.19). Thus

$$
\begin{aligned}
& 2\left| \int_G L(p+w)L_2(h)e^{2\lambda\beta}\,dx\,dt \right| \\
& \quad \leq CM \int_G |L_2(h)|e^{2\lambda\beta}\,dx\,dt \\
& \quad \leq CM \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\,d\tau \right)^2 \right\} e^{2\lambda\beta}\,dx\,dt.
\end{aligned} \tag{4.23}
$$

Hence the Cauchy–Schwarz inequality (4.17), (4.18), (4.22), and (4.23) lead to

$$
\begin{aligned}
I_3(H,\lambda) \geq & -\frac{1}{4}\int_G (L_0 h)^2 e^{2\lambda\beta}\,dx\,dt \\
& - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)\,d\tau \right)^2 \right\} e^{2\lambda\beta}\,dx\,dt.
\end{aligned}
$$

Thus estimates (4.20), (4.21), and the last inequality imply

$$
\begin{aligned}
& I_1(h,\lambda) + I_2(h,\lambda) + I_3(h,\lambda) \geq -\frac{3}{4}\int_G (L_0 h)^2 e^{2\lambda\beta}\,dx\,dt \\
& - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\,d\tau \right)^2 \right\} e^{2\lambda\beta}\,dx\,dt.
\end{aligned}
$$

Hence by (4.13) we obtain

$$
\begin{aligned}
& J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \geq \frac{1}{4}\int_G [L_0(h)]^2 e^{2\lambda\beta}\,dx\,dt \\
& - CM^2 \int_G \left\{ |\nabla h|^2 + h_t^2 + h^2 + \left(\int_0^t |\nabla h(x,\tau)|\,d\tau \right)^2 \right\} e^{2\lambda\beta}\,dx\,dt.
\end{aligned}
$$

Furthermore, applying inequality (3.32) and Lemma 3.8 we conclude from the last estimate that

$$
\begin{aligned}
& J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\
& \quad \geq \frac{1}{4}\int_G (L_0 h)^2 e^{2\lambda\beta}\,dx\,dt - CM^2 \int_G (|\nabla h|^2 + h_t^2) e^{2\lambda\beta}\,dx\,dt.
\end{aligned} \tag{4.24}
$$

Now we are ready to apply the Carleman estimate from Theorem 3.1 to the first integral in (4.24). We obtain

$$\begin{aligned} &J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\ &\quad \geq C\lambda \int_G (|\nabla h|^2 + h_t^2) e^{2\lambda\beta}\, dx\, dt - CM^2 \int_G (|\nabla h|^2 + h_t^2) e^{2\lambda\beta}\, dx\, dt \\ &\quad - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla h|^2 + h_t^2)\, d\sigma \end{aligned}$$

for all $w, h \in P'_N$ and for all $\lambda \geq \hat{\lambda}$. Let $\lambda_0 = \max(\hat{\lambda}, 2M^2)$. Then the last inequality leads to

$$\begin{aligned} &J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\ &\quad \geq \frac{1}{2} C\lambda \int_G (|\nabla h|^2 + h_t^2) e^{2\lambda\beta} - Ce^{-2\lambda R} \int_{\omega_3} (|\nabla h|^2 + h_t^2)\, d\sigma, \\ &\qquad w, \quad h \in P'_N, \quad \lambda \geq \lambda_0. \end{aligned} \tag{4.25}$$

Since for $v \in H^2(D_{T_1})$

$$\int_{\omega_3} (|\nabla v|^2 + v_t^2)\, d\sigma \leq C\|v\|_{H^2(D_{T_1})},$$

(4.25) implies

$$\begin{aligned} &J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\ &\quad \geq \frac{1}{2} C\lambda \int_G (|\nabla h|^2 + h_t^2) e^{2\lambda\beta}\, dx\, dt - Ce^{-2\lambda R} \|h\|^2_{H^2(D_{T_1})}, \\ &\qquad w, \quad h \in P'_N, \quad \lambda \geq \lambda_0. \end{aligned} \tag{4.26}$$

Let $R_1 = R_1(N), R_1 \in (0, R)$ be the number defined in Lemma 2.1. Choose an arbitrary number $R_2 \in (R_1, R)$ and denote

$$G(R_2) = \left\{(x,t) : \beta(x,t) > -R_2, |x| > r_0, \sin\varphi > \frac{r_0}{R}, t > 0\right\}.$$

Since $\beta(x,t) = -(r + \alpha t)$ then

$$G(R_2) = \{(x,t) : -(r+\alpha t) > -R_2, |x| > r_0, t > 0\}.$$

Thus $G(R_2) \subset G$ and

$$\exp(2\lambda\beta) > \exp(-2\lambda R_2) > \exp(-2\lambda R) \quad \text{in } G(R_2). \tag{4.27}$$

Let $E = E(R_1, R_2)$ be the time cylinder

$$E = \left\{(x,t) : r_0 < |x| < R_1, \sin\varphi > \frac{r_0}{R}, 0 < t < \frac{R_2 - R_1}{\alpha}\right\}.$$

Hence $E \subset G(R_2)$ and by Lemma 2.3 there exists a positive constant $\gamma = \gamma(E, D_{T_1}, P_N)$ such that

$$\|f\|_{H^1(E)} \geq \gamma \|f\|_{H^2(D_{T_1})}, \qquad f \in P_N. \tag{4.28}$$

Note that since $R_1 = R_1(N)$ depends on P_N only, we can actually choose γ dependent only on D_{T_1} and P_N.

Therefore (4.26)–(4.28) lead to

$$\begin{aligned}
&J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \\
&\geq \frac{1}{2} C\lambda \int_{G(R_2)} (|\nabla h|^2 + h_t^2) e^{2\lambda\beta}\, dx\, dt - Ce^{-2\lambda R} \|h\|^2_{H^2(D_{T_1})} \\
&\geq \frac{1}{2} C\lambda \exp(-2\lambda R_2) \int_{G(R_2)} (|\nabla h|^2 + h_t^2)\, dx\, dt - Ce^{-2\lambda R} \|h\|^2_{H^2(D_{T_1})} \\
&\geq \frac{1}{2} C\lambda \exp(-2\lambda R_2) \int_{E} (|\nabla h|^2 + h_t^2)\, dx\, dt - Ce^{-2\lambda R} \|h\|^2_{H^2(D_{T_1})} \\
&\geq \frac{C\lambda\gamma}{2} \exp(-2\lambda R_2) \|h\|^2_{H^2(D_{T_1})} - Ce^{-2\lambda R} \|h\|^2_{H^2(D_{T_1})} \\
&= \frac{C\lambda\gamma}{2} \exp(-2\lambda R_2) \left[1 - \frac{2}{\lambda\gamma} \exp(-2\lambda(R - R_2))\right] \|h\|^2_{H^2(D_{T_1})}
\end{aligned}$$

for all $w, h \in P'_N$ and for all $\lambda \geq \lambda_0$. Since

$$\lim_{\lambda\to\infty} \left[\frac{2}{\lambda\gamma} \exp(-2\lambda(R - R_2))\right] = 0,$$

then we can choose $\tilde{\lambda} \geq \lambda_0$ such that

$$1 - \frac{2}{\lambda\gamma} \exp[-2\lambda(R - R_2)] > \frac{1}{2} \quad \text{for } \lambda \geq \tilde{\lambda}.$$

Therefore, we finally get the desired estimate

$$J_\lambda(w+h) - J_\lambda(w) - J'_\lambda(w)(h) \geq \frac{k}{2} \|h\|^2_{H^2(D_{T_1})}$$

for all $w, h \in P'_N$ and for all $\lambda \geq \tilde{\lambda}$, where

$$k = \frac{C\lambda\gamma}{2} \exp(-2\lambda R_2). \qquad \square$$

5. Global convergence of the gradient method on B_1. In this section we prove Theorems 1.2 and 1.3. Let us remind the reader that parameter $\lambda \geq \tilde{\lambda}$ is *fixed* in these theorems.

Proof of Theorem 1.2. Let $\{c_n\}$ be the sequence defined in (1.38). By the well-known formula

$$\begin{aligned}
\nabla F_\lambda(c_n) &= \nabla F_\lambda(c_*) + \int_0^1 H_\lambda(c_* + \tau(c_n - c_*))(c_n - c_*)\, d\tau \\
&= A_n(c_n - c_*),
\end{aligned} \tag{5.1}$$

the matrix A_n has the form

$$A_n = \int_0^1 H_\lambda(c_* + \tau(c_n - c_*))\, d\tau.$$

Hence (1.36) implies

$$k|y|^2 \le y^* A_n y \le K|y|^2, \qquad y \in \mathbb{R}^m. \tag{5.2}$$

Since

$$\nabla F_\lambda(c_*) = 0, \tag{5.3}$$

then (5.1) and (1.38) imply

$$\begin{aligned} |c_{n+1} - c_*| &= |c_n - c_* - \xi \nabla F_\lambda(c_n)| \\ &= |(I - \xi A_n)(c_n - c_*)| \le \|I - \xi A_n\| |c_n - c_*|, \end{aligned} \tag{5.4}$$

where I is identity matrix. Since $I - \xi A_n$ is a symmetric matrix, we have

$$\|I - \xi A_n\| = \max\{|1 - \mu_1|, |1 - \mu_m|\},$$

where μ_1 and μ_m are the smallest and the biggest eigenvalues of A_n, respectively. Hence (1.36), (1.39), and (1.40) lead to

$$\|I - \xi A_n\| \le q < 1. \tag{5.5}$$

Thus (5.4) and (5.5) imply

$$|c_{n+1} - c_*| \le q|c_n - c_*|. \tag{5.6}$$

Note that

$$|c_0 - c_*| = |0 - c_*| < \tfrac{1}{2}.$$

Hence by (5.5) and (5.6), $|c_n - c_*| < \frac{1}{2}$ for all n, which implies that $a_n \in B_1$ for all n. Finally, (5.6) leads to

$$|c_n - c_*| \le |0 - c_*| q^n < \tfrac{1}{2} q^n. \qquad \square$$

Proof of Theorem 1.3. In the case of *noisy* data we cannot claim that $\nabla F_\lambda(C_*) = 0$, where c_* is the minimum of J_λ on $\bar{B}_1$ with the *exact* data. However, by (4.8) the gradient $\Delta F_\lambda(c)$ is continuous on $\bar{B}_1$. Hence (1.22), (1.27), and (1.28) imply

$$|\nabla F_\lambda(c_*)| \le c_1 \delta, \tag{5.7}$$

where the positive constant C_1 depends only on D_{T_1}, P'_N, α, and λ. Choose a positive number $\hat{\delta}$ such that

$$\frac{C_1 \xi}{1 - q} \delta < \frac{1}{4} \quad \text{for all } \delta \in (0, \hat{\delta}]. \tag{5.8}$$

By (5.1) and (5.4) we obtain

$$\begin{aligned} |c_{n+1} - c_*| &= |c_n - c_* - \xi \nabla F_\lambda(c_n)| \\ &= |(I - \xi A_n)(c_n - c_*) - \xi \nabla F_\lambda(c_*)| \le \|I - \xi A_n\| |c_n - c_*| + \xi |\nabla F_\lambda(c_*)|. \end{aligned}$$

Hence (5.5) and (5.7) lead to

$$|c_{n+1} - c_*| \leq q|c_n - c_*| + C_1\xi\delta. \tag{5.9}$$

Furthermore, using the mathematical induction method and (5.9), we get

$$\begin{aligned} |c_n - c_*| &\leq |0 - a_*|q^n + C_1\xi\delta(1 + q + q^2 + \cdots + q^n) \\ &< \frac{1}{2}q^n + \frac{C_1\xi(1-q^n)}{1-q}\delta, \end{aligned}$$

as long as $a_n \subset B_1$. But (5.8) and the last inequality imply that $a_n \in B_1$ for all $n > 0$. Therefore

$$|c_n - c_*| < \frac{1}{2}q^n + C_1\frac{\xi(1-q^n)}{1-q}\delta$$

for all n. □

6. Discussion. The main result of this paper is Theorem 1.1, which claims that three-dimensional ISP (0.1), (0.2) with nonoverdetermined data can be reformulated as a locally convex optimization problem. We realize, however, some shortcomings of this result. The major shortcoming consists of imposing restrictive conditions on the wave field itself (function $v(x,t)$) rather than on the unknown coefficient $a(x)$. Generally speaking, we do not even know what these conditions imply for $a(x)$. Also, we cannot regard the "infinite tail" of Fourier series of the function $v(x,t)$ as a small noise because in this case one should assume that Fourier coefficients of $v(x,t)$ decay exponentially as $N \to \infty$ (due to the Carleman estimate). Note that if one would be able to handle the limit as $N \to \infty$, then one would get a global uniqueness result. We remember, however, that the global uniqueness result is a long term open problem for this ISP as well as for many similar three-dimensional problems with nonoverdetermined data. Once again, we wish to point out that Theorem 1.1 represents just a first result in this very difficult direction and this somehow justifies these shortcomings, at least in our opinions.

As to future efforts in this direction, one might try two lines of developments. The first one would consist of computational implementation of this or a similar numerical scheme. The second one would consist of relaxing stringent conditions of Theorem 1.1 by attempting to find a finite number of Fourier coefficients of the function $a(x)$ rather than of the wave field itself. Our preliminary studies show, however, that a more complicated numerical scheme should, perhaps, be considered in that case. Hence a combination of these two approaches rather than a single one should probably be implemented into computer codes.

Acknowledgment. We would like to express our gratitude to S. Gutman, M. Kazemi, R. Malek-Madani, and P. Sacks for fruitful discussions. Our special thanks to K. Kunisch and the Institute of Mathematics of Technical University of Graz, Austria, since the idea of this result occurred when M. Klibanov visited K. Kunisch at this department.

MULTIPLICITY RESULTS FOR TWO CLASSES OF BOUNDARY-VALUE PROBLEMS*

PHILIP KORMAN† AND TIANCHENG OUYANG‡

Abstract. Multiplicity results are provided for two classes of boundary-value problems with cubic nonlinearities, depending on a parameter λ. In particular, it is proved that for sufficiently large λ, there are exactly two solutions, and that all solutions lie on a single smooth solution curve. The last fact allows one to use continuation techniques to compute all solutions.

Key words. multiplicity results, bifurcation of solutions

AMS subject classification. 34B15

1. Introduction.

We consider a Dirichlet problem of the type

$$u'' + \lambda f(x,u) = 0 \quad \text{on } (a,b), \qquad u(a) = u(b) = 0 \tag{1}$$

for two classes of cubic nonlinearities depending on a parameter λ, and we prove existence and multiplicity results. We also study in detail the solution branches as $\lambda \to \infty$. For both types of nonlinearities we show existence of a critical λ_1, such that for $0 < \lambda < \lambda_1$, (1) has no nontrivial solution; it has at least one solution at $\lambda = \lambda_1$; and it has at least two solutions for $\lambda > \lambda_1$, with precisely two solutions for λ sufficiently large (nontrivial solutions that we find are positive by the maximum principle). Moreover, all solutions lie on a single curve of solutions. The last assertion is important for computational purposes, since it allows one to use efficient continuation techniques to compute all solutions of (1).

Exact multiplicity results are usually difficult to establish; see, e.g., Lions [5]. Our main tools are a bifurcation theorem of Crandall and Rabinowitz [2], and a variational argument due to Ambrosetti and Rabinowitz; see [7]. For both problems it is relatively easy to show that there are no solutions for sufficiently small $\lambda > 0$. We then show that for sufficiently large λ the functional corresponding to (1) has at least two critical points: a minimum point (corresponding to the stable maximal solution of (1)), and a saddle point (corresponding to the unstable minimum solution). To show that there are exactly two solutions for sufficiently large λ, we show that all solutions must lie on certain curves in the (λ, u) "plane." We then study the properties of these curves and exclude the possibility of more than two solutions.

The equations that we study have attracted considerable attention. For constant $a(x)$ and $b(x)$, problems (3) and (21) were studied by Smoller and Wasserman [10] (see also [11] and [12]), who obtained exact multiplicity results by a very nontrivial phase plane analysis. The Neumann problem for (3) was studied in detail by Angenent, Mallet-Paret, and Peletier [1] and Rocha [8]; see also Hale [3]. For f independent of x, both Neumann and Dirichlet problems were studied extensively by Schaaf [9].

Our approach appears to be quite general. We intend to consider other equations where exact multiplicity might be three or more for some values of λ. We are also working to extend our results to partial differential equations.

Next we list some background results. Recall that a function $\varphi(x) \in C^2(a,b) \cap C^0[a,b]$ is called a supersolution of (1) if

$$\varphi'' + \lambda f(x,\varphi) \le 0 \quad \text{on } (a,b), \quad \varphi(a) \ge 0, \quad \varphi(b) \ge 0. \tag{2}$$

A subsolution $\psi(x)$ is defined by reversing the inequalities in (2). The following result is standard.

LEMMA 1. *Let $\varphi(x)$ and $\psi(x)$ be, respectively, super- and subsolutions of* (1), *and $\varphi(x) \ge \psi(x)$ on (a,b) with $\varphi(x) \not\equiv \psi(x)$; then $\varphi(x) > \psi(x)$ on (a,b).*

We shall often use this lemma with either $\varphi(x)$ or $\psi(x)$ or both being the solution of (1). The following lemma is a consequence of the first.

LEMMA 2. *Let $u(x)$ be a nontrivial solution of* (1) *with $f(x,0) \equiv 0$. If $u(x) \ge 0$ on (a,b) then $u > 0$ on (a,b).*

We proved the following proposition in [4].

PROPOSITION 1. *Consider the problem* (1) *and assume that $f(x,u) \in C^1([-1,1]\times R_+)$ satisfies*

(i) *$f(-x,u) = f(x,u)$ for all $x \in (-1,1)$ and $u > 0$;*

(ii) *$xf_x(x,u) < 0$ for all $x \in (-1,1)\backslash\{0\}$ and $u > 0$.*

Then any positive solution of (1) *is an even function with $u'(x) < 0$ on $(0, 1]$. Moreover, any two positive solutions of* (1) *do not intersect.*

Remark. Except for the last statement, this proposition is included in the Gidas–Ni–Nirenberg theorem.

Next we state a bifurcation theorem of Crandall and Rabinowitz [2].

THEOREM 1 [2]. *Let X and Y be Banach spaces. Let $(\bar\lambda, \bar x) \in \mathbf{R}\times X$ and let F be a continuously differentiable mapping of an open neighborhood of $(\bar\lambda, \bar x)$ into Y. Let the null-space $N(F_x(\bar\lambda, \bar x)) = \operatorname{span}\{x_0\}$ be one-dimensional and $\operatorname{codim} R(F_x(\bar\lambda, \bar x)) = 1$. Let $F_\lambda(\bar\lambda, \bar x) \notin R(F_x(\bar\lambda, \bar x))$. If Z is a complement of $\operatorname{span}\{x_0\}$ in X, then the solutions of $F(\lambda, x) = F(\bar\lambda, \bar x)$ near $(\bar\lambda, \bar x)$ form a curve $(\lambda(s), x(s)) = (\bar\lambda + \tau(s), \bar x + sx_0 + z(s))$, where $s \to (\tau(s), z(s)) \in \mathbf{R} \times Z$ is a continuously differentiable function near $s = 0$ and $\tau(0) = \tau'(0) = z(0) = z'(0) = 0$.*

Throughout this paper we consider only the classical solutions (which is not a serious restriction in the one-dimensional case). We also assume, without loss of generality, that $(a,b) = (-1,1)$.

2. A class of cubic nonlinearities with double root. On the interval $[-1,1]$ we consider the following boundary-value problem:

$$u'' + \lambda a(x)u^2(1 - b(x)u) = 0, \quad -1 < x < 1, \quad u(-1) = u(1) = 0. \tag{3}$$

We assume throughout this section that $a(x)$ and $b(x)$ are even functions $a(x) \in C^1(-1,1) \cap C^0[-1,1], b(x) \in C^2(-1,1) \cap C^0[-1,1]$, satisfying the following conditions:

$$a(x), b(x) > 0 \quad \text{for } -1 \le x \le 1; \tag{4}$$

$$xb'(x) > 0 \quad \text{and} \quad xa'(x) < 0 \quad \text{for } x \in (-1,1)\backslash\{0\}; \tag{5}$$

$$b''(x)b(x) - 2b'^2(x) > 0 \quad \text{for } -1 < x < 1. \tag{6}$$

For example, $b(x) = x^2 + \alpha$ with $\alpha > 3$ satisfies the above conditions. Notice that condition (6) implies that $1/b(x)$ is a supersolution of (3). To prove our multiplicity result we need the following lemmas. Recall that by maximum principle any solution of (3) is positive on $(-1,1)$.

LEMMA 3. *Every solution of* (3) *is strictly concave, i.e.,* $u'' < 0$ (*or* $1-b(x)u > 0$) *for all* $x \in (-1,1)$.

Proof. Denote $w(x) = b(x)u(x)$. Then one computes

$$w'' + \frac{\lambda a(x)}{b(x)} w^2(1-w) = 2b'u' + b''u. \tag{7}$$

If x_0 is a maximum point of $w(x)$, then

$$0 = w'(x_0) = b'(x_0)u(x_0) + b(x_0)u'(x_0),$$

i.e.,

$$u'(x_0) = -\frac{b'(x_0)}{b(x_0)} u(x_0).$$

Using this in (7), we obtain

$$w''(x_0) + \frac{\lambda a(x_0)}{b(x_0)} w^2(x_0)(1-w(x_0)) = \frac{u(x_0)}{b(x_0)}(b''(x_0)b(x_0) - 2b'^2(x_0)). \tag{8}$$

By our assumptions, the right-hand side of (8) is positive, while $w''(x_0) \le 0$. Hence $w(x_0) < 1$, i.e., $1 - b(x)u(x) > 0$ for all $x \in (-1,1)$, and the proof follows.

LEMMA 4. *Every solution of* (3) *is an even function with* $u'(x) < 0$ *for* $x \in (0,1]$.

Proof. Using Lemma 3 one sees that Proposition 1 applies, giving the conclusions of the lemma.

LEMMA 5. *Let* $u_\lambda(x)$ *be a continuous-in-*λ *branch of solutions of* (3). *Then either* $\lim_{\lambda\to\infty} u_\lambda(x) = 0$ *or* $\lim_{\lambda\to\infty} u_\lambda(x) = 1/b(x)$ *for all* $x \in (-1,1)$.

Proof. Rewrite (3) in the form

$$u_\lambda(x) = \lambda \int_{-1}^{1} G(x,\xi) a(\xi) u_\lambda^2(\xi)(1 - b(\xi)u_\lambda(\xi))\, d\xi, \tag{9}$$

where $G(x,\xi)$ is the corresponding Green's function, which is easily seen to be strictly positive and bounded on $(-1,1)\times(-1,1)$. By Lemma 3, $u_\lambda(x)$ is bounded as $\lambda \to \infty$ (by $1/b(x)$), and the integral on the right in (9) is positive. It follows that for each $\xi \in (-1,1)$ either $\lim_{\lambda\to\infty} u_\lambda(\xi) = 0$ or $\lim_{\lambda\to\infty} u_\lambda(\xi) = 1/b(\xi)$. Finally, since by Lemma 4 $u_\lambda'(\xi) < 0$ for $\xi \in (0,1)$, it follows that only one of the above possibilities holds for all ξ.

If $u(x)$ is a solution of (3), then the corresponding linearized problem will be used in the sequel

$$w'' + \lambda a(x)(2u - 3b(x)u^2)w = 0, \qquad w(-1) = w(1) = 0. \tag{10}$$

LEMMA 6. *If* (11) *has a nontrivial solution, then* $w(x)$ *does not change sign on* $(-1,1)$, *i.e., we can choose it so that* $w(x) > 0$ *on* $(-1,1)$.

Proof. Assume that $w(x)$ changes sign in $(-1,1)$. Assume that $w(x)$ has a zero on $[0,1)$, and the other case is similar. Without loss of generality (taking $-w$ if necessary), we may assume that $w(x) < 0$ on $(x_1,x_2), 0 \le x_1 < x_2 \le 1, w(x_1) = w(x_2) = 0$, and $w(x) > 0$ for $x < x_1$ and close to x_1, and for $x > x_2$ and close to x_2 (unless $x_2 = 1$). Differentiating (3), we obtain

$$(u')'' + \lambda a(x)(2u - 3b(x)u^2)u' = -\lambda a'u^2(1-bu) + \lambda ab'u^3. \tag{11}$$

Multiply (10) by u', (11) by w, and subtract and integrate both sides. Obtain

$$[w'u' - w(u')']|_{x_1}^{x_2} = \lambda \int_{x_1}^{x_2} [a'u^2(1-bu) - ab'u^3]w\,dx. \tag{12}$$

The quantity on the right side in (12) is positive by our assumptions. The one on the left is equal to

$$w'(x_2)u'(x_2) - w'(x_1)u'(x_1),$$

which is negative by Lemma 4. The contradiction proves the lemma.

LEMMA 7. *Let $u(x)$, the solution of* (3), *be such that* $\max_{[-1,1]} b(x)u(x) \leq \frac{1}{2}$. *Then the only solution of* (10) *is* $w \equiv 0$.

Proof. Since $u(x) > 0$ solves (3), it is the principal eigenfunction of

$$z'' + \lambda a(x)(u - b(x)u^2)z = \mu z, \qquad z(-1) = z(1) = 0,$$

corresponding to the principal eigenvalue $\mu = 0$. The principal eigenvalue of

$$w'' + \lambda a(x)(2u - 3b(x)u^2)w = \mu w, \qquad w(-1) = w(1) = 0 \tag{13}$$

must be positive, since $2u - 3bu^2 \geq u - bu^2$ for all $x \in (-1,1)$, with inequality being strict near $x = \pm 1$, by our assumption. If $w(x)$ is a nontrivial solution of (10), it is a nonprincipal eigenfunction of (13) (corresponding to $\mu = 0$), and so it must change sign on $[-1,1]$. But this contradicts the previous lemma.

THEOREM 2. *There exists a critical λ_1, such that for $0 < \lambda < \lambda_1$ the problem* (3) *has no solution; it has at least one solution at $\lambda = \lambda_1$; and it has at least two solutions for $\lambda > \lambda_1$. All solutions lie on a single curve of solutions, which is smooth in λ. For each $\lambda > \lambda_1$ there are finitely many solutions, and different solutions are strictly ordered on $(-1,1)$. Moreover, there exists $\lambda_2 \geq \lambda_1$, so that for $\lambda > \lambda_2$ the problem* (3) *has exactly two solutions denoted by $u^-(x,\lambda) < u^+(x,\lambda)$, with $u^+(x,\lambda)$ strictly monotone increasing in λ, $u^-(0,\lambda)$ strictly monotone decreasing in λ, and $\lim_{\lambda\to\infty} u^+(x,\lambda) = 1/b(x)$, $\lim_{\lambda\to\infty} u^-(x,\lambda) = 0$ for all $x \in (-1,1)$. (Recall that all solutions of* (3) *are positive by maximum principle.)*

Proof. Multiply (3) by u and integrate

$$\int_{-1}^{1} u'^2 dx = \lambda \int_{-1}^{1} a(x)u^2u(1-b(x)u)\,dx. \tag{14}$$

By the Poincaré inequality,

$$\int_{-1}^{1} u'^2 dx \geq \frac{\pi^2}{4} \int_{-1}^{1} u^2 dx.$$

On the other hand,

$$\int_{-1}^{1} a(x)u^2u(1-b(x)u)\,dx \leq \frac{a(0)}{4b(0)} \int_{-1}^{1} u^2\,dx.$$

Thus (3) has no solution for $\lambda < \pi^2 b(0)/a(0)$.

Existence of at least two solutions for sufficiently large λ follows similarly to the proof of a theorem of Ambrosetti and Rabinowitz; see [7, p. 12]. We outline the argument. Solutions of (3) are critical points on $H_0^1(-1,1)$ of the functional

$$J(u) = \int_{-1}^{1} \left(\frac{1}{2}u'^2 - \lambda a(x)\frac{u^3}{3} + \lambda a(x)b(x)\frac{u^4}{4} \right) dx.$$

It is easy to show that $J(u)$ is bounded from below, so that it must have a global minimum. By the Poincaré inequality, $J(u)$ is positive in a small neighborhood of zero in $H_0^1(-1,1)$. If we now can exhibit a function for which $J(u) < 0$, then in addition to a global minimum, where $J(u) < 0$, the functional $J(u)$ will have another critical point, where $J(u) > 0$, in view of the well-known mountain pass theorem; see [7]. It is easy to check that

$$J\left(\frac{1}{b(1)} \cos \frac{\pi}{2}x \right) < 0$$

for sufficiently large λ. (Alternatively, we could consider the evolution equation corresponding to (3) with the initial data

$$u(x,0) = \frac{1}{b(1)} \cos \frac{\pi}{2}x.$$

It is easy to show that $0 < u(x,t) \leq c$ for some $c > 0$, and so by well-known results, $u(x,t)$ would have to converge as $t \to \infty$ to the set of solutions of (3). Since $J(u(x,0)) < 0$ for sufficiently large λ, and $J(u(x,t))$ is nonincreasing in t, it follows that $u(x,t)$ cannot converge to zero. This would provide us with at least one positive solution of (3), which is sufficient for the arguments that follow.)

It is clear that the problem (3) has a maximal solution for λ large. We now study the curve of maximal solutions for decreasing λ. Rewrite (3) as

$$F(\lambda, u) = u'' + \lambda a(x)u^2(1 - b(x)u) = 0, \tag{15}$$

where $F : R \times C_0^2[-1,1] \to C[-1,1]$. Notice that $F_u(\lambda, u)w$ is given by the left-hand side of (10).

Now let $(\lambda_1, u(x))$ be a solution of (15). If the corresponding linearized equation (10) has only a trivial solution $w = 0$, then by the implicit function theorem we can solve (15) for $\lambda < \lambda_1$ and λ close to λ_1, obtaining a continuous-in-λ branch of solutions. We cannot continue this process of decreasing λ indefinitely, since we know that for $\lambda > 0$ sufficiently small, (15) has no solution. Let λ_0 be the infimum of λ for which we can continue the branch to the left. We claim there is a sequence $\{\lambda_n\}$ and $u_{\lambda_0} \in C_0^2(-1,1)$, a solution of (15) at $\lambda = \lambda_0$, so that as $\lambda_n \downarrow \lambda_0, u_{\lambda_n} \to u_{\lambda_0}$. Indeed, using Lemma 3, we conclude that there is a number $M > 0$, such that for any solution of (15),

$$\|u_\lambda\|_{C_0^2[-1,1]} \leq M.$$

It follows that a subsequence of $\{u_{\lambda_n}\}$ converges uniformly on $[-1,1]$. Passing to the limit in the integral version of (15) (see (9)), we establish the claim.

By the definition of λ_0 it follows that $F_u(\lambda_0, u_{\lambda_0})$ is singular, i.e., (10) has a nontrivial solution, which is positive by Lemma 6. By Lemma 6 one sees that $N(F_u(\lambda_0, u_{\lambda_0})) = \text{span}\{w(x)\}$ is one-dimensional, and then $\text{codim}R(F_u(\lambda_0, u_{\lambda_0})) = 1$,

since $F_u(\lambda_0, u_{\lambda_0})$ is a Fredholm operator of index zero. To apply the Crandall–Rabinowitz theorem (Theorem 1) it remains to check that $F_\lambda(\lambda_0, u_{\lambda_0}) \notin R(F_u(\lambda_0, u_{\lambda_0}))$. Assuming the contrary would imply the existence of $v(x) \not\equiv 0$, such that

$$v'' + \lambda_0(2au_0 - 3abu_0^2)v = au_0^2(1 - bu_0), \quad -1 < x < 1, \quad v(-1) = v(1) = 0. \tag{16}$$

Multiplying (16) by w, (10) by v, and integrating and subtracting, we obtain

$$\int_{-1}^{1} a(x)u_0^2(x)(1 - b(x)u_0(x))w(x)\,dx = 0,$$

which is a contradiction in view of Lemmas 3 and 6.

Applying Theorem 1, we conclude that $(\lambda_0, u_{\lambda_0})$ is a bifurcation point, near which the solutions of (3) form a curve $(\lambda_0 + \tau(s), u_{\lambda_0} + sw + z(s))$ with s near $s = 0$, and $\tau(0) = \tau'(0) = 0, z(0) = z'(0) = 0$. It follows that for λ close to λ_0 and $\lambda > \lambda_0$ we have two solutions $u^-(x, \lambda)$ and $u^+(x, \lambda)$ with $u^-(x, \lambda) < u^+(x, \lambda)$ for all $x \in (-1, 1)$, and that $u^+(x, \lambda)$ is strictly increasing in λ while $u^-(x, \lambda)$ is strictly decreasing. We show next that the upper branch $u^+(x, \lambda)$ is increasing in λ for all $\lambda > \lambda_0$. Differentiate (3) in λ:

$$u_\lambda'' + \lambda a(2u - 3bu^2)u_\lambda = -au^2(1 - bu), \qquad u_\lambda(-1) = u_\lambda(1) = 0. \tag{17}$$

We know by the above that $u_\lambda(x, \lambda) > 0$ for λ close to λ_0 and all $x \in (-1, 1)$. Let λ_1 be the first λ where this inequality is violated, i.e., $u_\lambda(x, \lambda_1) \geq 0$ and $u_\lambda(x_0, \lambda_1) = 0$ for some $x_0 \in (-1, 1)$. Applying the strong maximum principle to (17), we conclude that $u_\lambda(x, \lambda_1) > 0$ for all $x \in (-1, 1)$. Thus $u^+(x, \lambda)$ is strictly increasing in λ for all $\lambda > \lambda_0$.

After turning right the curve of solutions will decrease in λ, until a possible turn to the left occurs. If that happens, Theorem 1 applies exactly as above, and monotonicity of the branches follows similarly, so that after the turn the curve of solutions is increasing in λ (i.e., as we follow the curve for decreasing λ, the solution is decreasing). By the same reasoning as used previously, the curve will eventually have to turn to the right and decrease in λ, and so on. Denote by $(\lambda_i, u_i(x))$ the turning points (i.e., $F(\lambda_i, u_i)$ is singular).

We claim that the set of turning points is finite. Indeed, assuming the contrary, we first rule out a finite accumulation point $\bar{\lambda}$, i.e., $\lambda_{i_k} \to \bar{\lambda}$ along a subsequence. As previously, we show that a subsequence of u_{i_k} converges uniformly on $[-1, 1]$ to a solution $\bar{u}(x)$ of (3). Clearly $F_u(\bar{\lambda}, \bar{u})$ is singular (since otherwise the implicit function theorem would imply local uniqueness of the solution near $(\bar{\lambda}, \bar{u}(x))$). But then we have a contradiction with Theorem 1, which tells us that there can be no more than two solutions near $(\bar{\lambda}, \bar{u}(x))$. Next we rule out an infinite sequence of $\lambda_i \to \infty$. Notice that $u_{i+1}(x) < u_i(x)$ for all $i \geq 1$ and all $x \in (-1, 1)$. By Lemma 5, $u_i(x) \to 0$ as $i \to \infty$, but then we get a contradiction with Lemma 7, which tells us that there can be no bifurcations for sufficiently small u.

We now return to the curve of maximal solutions and follow it for increasing λ. If it turns to the left then Theorem 1 applies, and the curve is decreasing in λ after the turn (i.e., $u(x)$ is increasing when λ is decreasing). Since solutions of (3) are bounded, it follows as above that over any finite interval of λ's there is only a finite number of turns, and the final turn is to the right. Since all the while the solution is increasing, it follows by Lemma 5 that it approaches $1/b(x)$ as $\lambda \to \infty$. We show next that

for sufficiently large λ bifurcation is impossible, so that the curve of solutions keeps moving to the right in the (λ, u) "plane." Indeed, let $w(x)$ be a nontrivial solution of the linearized equation (10), normalized so that $\int_{-1}^{1} w^2\,dx = 1$. Multiply (10) by w, integrate by parts, and use the Poincaré inequality, obtaining

$$\int_{-1}^{1} a(x)(2u - 3b(x)u^2)w^2\,dx \geq \frac{\pi^2}{4\lambda}. \tag{18}$$

Since the quantity on the left is negative for u close to $1/b(x)$, we have a contradiction, which shows that (10) can have only trivial solution for λ large. (That $w(x)$ cannot concentrate near $x = +1$ follows similarly to Lemma 6.)

To recapitulate, we have a smooth curve of solutions which after a possible finite number of turns has a decreasing and single-valued-in-λ lower branch tending to zero, and a monotone increasing and single-valued-in-λ upper branch tending to $1/b(x)$. We show next that there is only one such curve. Indeed, assuming two such curves we would have for sufficiently large λ two upper branches, $v = v(x, \lambda)$ and $u = u(x, \lambda)$, both tending to $1/b(x)$. Denoting $w = u - v$, we express

$$w'' + p(x)w = 0 \quad -1 < x < 1, \quad w(-1) = w(1) = 0,$$

where $p(x) = a(x)[u + v - b(x)(u^2 + uv + v^2)]$ is negative for $u(x)$ and $v(x)$ close to $1/b(x)$. This leads to the same contradiction as previously, unless $w \equiv 0$.

Remark 2.1. Consider an interesting class of problems with the nonlinearity resembling the logistic one,

$$u'' + \lambda u^2(b(x) - u) = 0, \qquad u(-1) = u(1) = 0. \tag{19}$$

If $b(x)$ is an even function satisfying $b(x) > 0$ on $[-1, 1], b'(x) < 0$ for $x > 0$, and $b''(x) < 0$ for all $x \in (-1, 1)$, then it is easy to check that Theorem 2 applies.

Remark 2.2. Lemma 7 provides a lower estimate for the maximum value of any solution where bifurcation occurs, $u_m > 1/2b(0)$.

Remark 2.3. If u_m is the maximum value of the solution on the lower branch then

$$\frac{c_1}{\lambda} \leq u_m \leq \frac{c_2}{\lambda}, \quad \lambda > \lambda_2, \quad c_1, c_2 > 0. \tag{20}$$

Indeed, multiplying (3) by u and integrating,

$$\frac{\pi^2}{4}\int_{-1}^{1} u^2\,dx \leq \int_{-1}^{1} u'^2\,dx < \lambda a(0)u_m \int_{-1}^{1} u^2\,dx.$$

On the other hand, since all solutions are concave down, we have $u(x) \geq u_m|x - 1|$. Using this in (9), we easily obtain the second inequality in (20).

Remark 2.4. Based on the numerical evidence we believe that at $\lambda = \lambda_1$ the solution is unique, while for $\lambda > \lambda_1$ there are exactly two solutions.

3. Cubic nonlinearities with distinct roots. In this section we consider the problem

$$u'' + \lambda u(u - a(x))(b - u) = 0, \quad -1 < x < 1, \quad u(-1) = u(1) = 0. \tag{21}$$

Here b is a positive constant, and the function $a(x) \in C^1[-1,1]$ satisfies the following conditions:

$$(22)\quad a(x) \geq a_0 > 0, \quad a'(x) > 0 \quad \text{for } x \in (0,1), \quad a(-x) = a(x) \quad \text{for all } x \in (-1,1);$$

$$(23)\quad a(x) < \frac{1}{2}b \quad \text{for all } x \in (-1,1).$$

From the maximum principle every solution of (21) satisfies $0 < u < b$ in $(-1,1)$. Notice that, unlike (3), solutions of (21) are concave up near $x = \pm 1$.

LEMMA 8. *The solution of* (21) *is an even function. Moreover,* $u_x < 0$ *for* $x > 0$.

Proof. Since $0 < u(x) < b$ for all $x \in (-1,1)$, one easily sees that Proposition 1 applies.

LEMMA 9. *Let* $u(x,\lambda)$ *be a nontrivial solution of* (21) *for* $\lambda > \lambda_0$. *Then there are only three possibilities for* $\lim_{\lambda\to\infty} u(x,\lambda)$: $0, a(x)$, *and* b. *If the solution is increasing in* λ *then* $\lim_{\lambda\to\infty} u(x,\lambda) = b$ *for all* $x \in (-1,1)$.

Proof. The first part follows from the integral representation of the solution as before. From the previous lemma we know that for any $\lambda > \lambda_0, u(0,\lambda) > a(0)$. If the solution is increasing in λ this leaves us with $\lim_{\lambda\to\infty} u(0,\lambda) = b$. Indeed, the solution cannot tend to $a(x)$ over a subinterval, since $u_x < 0$ while $a'(x) > 0$, and it cannot tend to $a(x)$ at a point for the same reason.

As previously, we need to consider the linearization of (21),

$$(24)\quad w'' + \lambda[-3u^2 + 2(a+b)u - ab]w = 0, \quad -1 < x < 1, \quad w(-1) = w(1) = 0.$$

LEMMA 10. *If* (24) *has a nontrivial solution, we can choose it so that* $w(x) > 0$ *in* $(-1,1)$.

Proof. Assume on the contrary that $w(x)$ changes sign on $(-1,1)$. Assume $w(x)$ has a zero on $(-1,0]$ (the proof is similar if it has a root on $(0,1]$). We may then assume that $w(x) < 0$ on (x_1,x_2) with $-1 \leq x_1 < x_2 \leq 0$, and $w(x_1) = w(x_2) = 0, w'(x_1) < 0, w'(x_2) > 0$ (by changing if necessary to $-w$). Differentiate (21):

$$(25)\quad u_x'' + \lambda[-3u^2 + 2(a+b)u - ab]u_x = \lambda a'u(b-u).$$

Multiply (25) by w, (24) by u_x, and integrate and subtract:

$$(26)\quad (u_x'w - u_xw')|_{x_1}^{x_2} = \lambda \int_{x_1}^{x_2} a'(x)u(b-u)w\,dx.$$

The quantity on the right in (26) is positive by our assumptions, while the one on the left is

$$(27)\quad -u'(x_2)w'(x_2) + u'(x_1)w'(x_1) < 0$$

by Lemma 8.

THEOREM 3. *There exists a critical* λ_1, *such that for* $0 < \lambda < \lambda_1$ *the problem* (21) *has no solution; it has at least one solution at* $\lambda = \lambda_1$; *and it has at least two solutions for* $\lambda > \lambda_1$. *All solutions lie on a single smooth curve of solutions. For each* $\lambda > \lambda_1$ *there are finitely many solutions, and different solutions are strictly ordered. Moreover, there exists* $\lambda_2 \geq \lambda_1$ *so that for* $\lambda > \lambda_2$ *the problem* (21) *has exactly two solutions denoted by* $u^-(x,\lambda) < u^+(x,\lambda)$, *and* $\lim_{\lambda\to\infty} u^+(x,\lambda) = b$ *for all* $x \in (-1,1)$. *Solution* $u^-(x,\lambda)$ *develops a spike layer at* $x = 0$ *as* $\lambda \to \infty$.

Proof. The proof is similar to that of Theorem 2, so we shall not repeat all the details but concentrate on the points that are different. As before we show that (21) has no solutions for sufficiently small $\lambda > 0$. To show existence of at least two solutions for sufficiently large λ, we need to consider the functional

$$J(u) = \int_{-1}^{1} \left(\frac{1}{2}u'^2 + \lambda ab\frac{u^2}{2} - \lambda(a+b)\frac{u^3}{3} + \lambda\frac{u^4}{4} \right) dx$$

on $H_0^1(-1,1)$, and produce a function for which $J(u) < 0$. Consider the functional

$$\bar{J}(u) = \int_{-1}^{1} \left(ab\frac{u^2}{2} - (a+b)\frac{u^3}{3} + \frac{u^4}{4} \right) dx.$$

Using the condition (23) one computes $\bar{J}(b) < 0$. The function $u \equiv b$ does not satisfy the boundary conditions; however, it is clear that one can now construct $u_0(x) \in H_0^1(-1,1)$ with $\bar{J}(u_0(x))$ arbitrarily close to $\bar{J}(b)$, i.e., $\bar{J}(u_0) < 0$. Then for sufficiently large λ we have $J(u_0) < 0$, as desired.

To apply Theorem 1 it remains to verify that $F_\lambda(\lambda_0, u_{\lambda_0}) \notin R(F_u(\lambda_0, u_{\lambda_0}))$, where the map F and $(\lambda_0, u_{\lambda_0})$ are defined the same way as in the proof of Theorem 2. Assuming the contrary, we have $\int_{-1}^{1} u''w\,dx = 0$ (u is solution of (21), w of (24)). Notice that $w(x)$ is an even function (for otherwise the linear problem (24) would have another positive solution $w(-x)$, which is impossible). We then conclude that

$$\int_0^1 u''w\,dx = \int_0^1 u'w'\,dx = \int_0^1 uw''\,dx = 0.$$

Next we multiply (24) by xu_x, (25) by xw, and integrate and subtract. Using the above formula,

$$u'(1)w'(1) + \int_0^1 xa'(x)wu(b-u)\,dx = 0,$$

which is a contradiction, since both terms on the left are positive.

Proceeding as in the proof of Theorem 2, we follow the curve of maximal solutions left until a turning point $\lambda = \lambda_0$. Near that point, Theorem 1 implies existence of two solutions with $u^-(x,\lambda) < u^+(x,\lambda)$ for all $x \in (-1,1)$, and that u^- is decreasing in λ while u^+ is increasing in λ (for λ close to λ_0).

By Lemma 9, as $\lambda \to \infty$, any solution $u(x,\lambda)$ of (21) can only approach $0, b$, or $a(x)$. By Lemma 8, $u(x,\lambda)$ cannot approach $a(x)$ over any interval, since u_x and a' have opposite signs over $(-1,1)\backslash\{0\}$. On the other hand, $u(0,\lambda) > a(0)$, since $x = 0$ is the maximum point of $u(u_{xx}(0,\lambda) < 0)$. It follows that there are just two possibilities as $\lambda \to \infty$: either the solution approaches b for all $x \in (-1,1)$, or the solution approaches zero for $x \in (-1,1)\backslash\{0\}$, while $u(0,\lambda) > a(0)$, i.e., a spike-layer shape. (The possibility that $u^-(x,\lambda)$ approaches b on some proper subinterval of $(-1,1)$, and zero on its complement, is easily ruled out by the argument used in the proof of Proposition 1.)

As in Theorem 2 we show the existence of a smooth curve of solutions, which after possibly finitely many turns, has an upper branch $u^+(x,\lambda)$ single-valued in λ, and tending to b as $\lambda \to \infty$ (notice that for u close to b, (24) has only the trivial solution). The lower branch can also have only (possibly) finitely many turns, and it cannot tend to zero at a finite λ (as can be seen by converting (21) into an equivalent

integral equation). It is easy to see that the lower branch cannot approach b as $\lambda \to \infty$ (setting $w = u^+(x,\lambda) - u^-(x,\lambda)$, we obtain an equation similar to (24)). Hence the lower branch has to approach a spike layer shape described above. We next show that as this happens, further bifurcations (turns) are impossible. From (24) we obtain, as previously (normalizing w),

$$\int_{-1}^{1} [-3u^2 + 2(a+b)u - ab]w^2\,dx \geq \frac{\pi^2}{4\lambda}.$$

Since the quantity on the left is negative for u close to the spike layer, it follows that (24) has only the trivial solution.

We now have a smooth curve of solutions, which after a finite number of turns has an upper branch strictly monotone increasing and single-valued in λ and tending to b as $\lambda \to \infty$, and a lower branch single-valued in λ and tending to the spike-layer shape. We next show that there are no other solutions. Indeed, any other solution would have to lie on another curve of solutions, having the same properties. In particular, we would have another upper branch, tending to b, which was already ruled out previously.

Acknowledgment. It is a pleasure to thank Wei-Ming Ni for very useful discussions and encouragement.

BANANAS AND BANANA SPLITS: A PARAMETRIC DEGENERACY IN THE HOPF BIFURCATION FOR MAPS*

BRUCE B. PECKHAM†, CHRISTOS E. FROUZAKIS‡, AND IOANNIS G. KEVREKIDIS§

Abstract. The set of Hopf bifurcations for a two-parameter family of maps is typically a curve in the parameter plane. The side of the curve on which the invariant circle exists is further divided by horn-shaped resonance regions, with each region corresponding to maps that have a periodic orbit of a certain period. With the presence of a parametric degeneracy, the resonance regions sometimes take the form of closed "bananas" instead of open-ended horns. The authors investigate this local codimension-two bifurcation, emphasizing resonance regions as projections to the parameter plane of surfaces in phase × parameter space. The authors present scenarios where the degeneracy occurs "naturally" and illustrate them through an adaptive control application. More global implications of the local study are also discussed.

Key words. Hopf bifurcation, resonance, Arnold horns, parametric degeneracy

AMS subject classifications. 58F14, 58F40

1. Introduction.

When a fixed point for a map of $\mathbf{R}^n, n \geq 2$, has a complex conjugate pair of eigenvalues on the unit circle, we expect it to undergo a Hopf (also called Neimark–Sacker) bifurcation under perturbation. In a typical two-parameter family containing such a point, there is a Hopf bifurcation curve in the parameter plane which separates maps with an attracting fixed point from those with a repelling fixed point. The change in stability of the fixed point across the Hopf curve is accompanied, except possibly near the strong resonances, by the birth of an invariant topological circle from the fixed point. The side of the Hopf curve on which the invariant circle exists, as well as its stability, is determined by the relationship between the parameters, the linear terms, and some nonlinear terms in the family of maps. Again with the exception of parameter values near strong resonances, it is known that all local recurrence is restricted to the fixed point and to the invariant circle, when the latter exists.

On the side of the Hopf curve without the invariant circle, all nearby maps are locally topologically equivalent. On the side with the invariant curve, however, the parameter space must be further subdivided because, restricted to the invariant circle, we expect the rotation number of the maps, a topological invariant, to change with the parameters. From circle map theory we know that the existence of a reduced rational rotation number p/q implies the existence of at least one least-period-q orbit, so we concentrate in this paper on determining the location in phase × parameter space where periodic orbits of certain period exist. Such sets are called *period-q resonance surfaces*, or *p/q resonance surfaces* if we wish to identify the rotation number of the

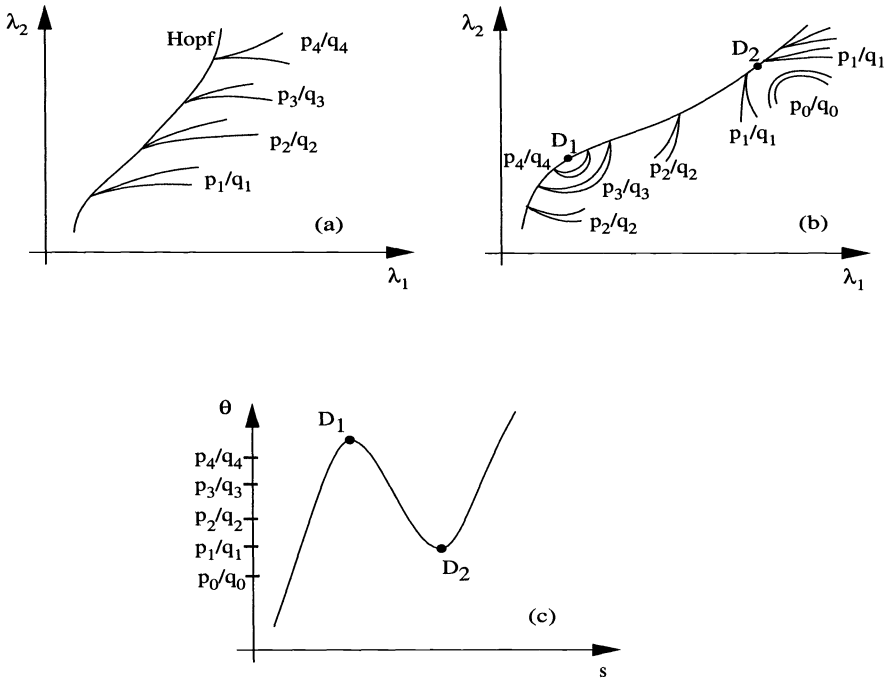

FIG. 1. *Typical Hopf bifurcations*: (a) *Parameter plane without angular degeneracies.* (b) *Parameter plane with two angular degeneracies (at D_1 and D_2).* (c) *Angle θ of fixed-point eigenvalue vs. arc length s along the Hopf curve in* (b).

period-q orbit. Their projections to parameter space are called *period-q resonance regions*, or *p/q resonance regions*, or (*Arnold*) *resonance horns* if we wish to suggest their shape. They are also called phase locking regions or entrainment regions, with both names originating in the context of Poincaré maps of two frequency flows on a torus; in this case, regions of constant frequency ratio for the flow correspond to regions of existence of a certain periodic orbit for the map.

It is known that a period-q resonance region typically opens out from every point on the Hopf curve for which the fixed point has an eigenvalue of $e^{2\pi ip/q}$, *with* p/q any reduced rational with $q \geq 5$, as suggested in Fig. 1a. In order to ensure that a specific resonance region opens in the horn–shaped manner suggested by that figure, several nondegeneracy conditions must be satisfied. Some nondegeneracy conditions pertain only to the phase variables, others include reference to the parameters as well. The failure of any one of the nondegeneracy conditions to hold results in a "degenerate" Hopf bifurcation. Of specific interest to us is the following nondegeneracy condition with respect to the parameters: it is usually assumed that the argument of the eigenvalues of the fixed point varies monotonically along the Hopf curve. When the argument *fails* to vary monotonically we say the Hopf bifurcation has an *angular degeneracy.* In this case, the nearby Arnold resonance regions can appear locally in shapes such as closed "bananas" rather than as the open horns of Fig. 1a. Figure 1b suggests a possible scenario for resonance regions near the Hopf bifurcation curve. The Hopf points with angular degeneracies are at D_1, a "banana" point, and at D_2, a "banana-split" point.

To emphasize the nonmonotonicity at the points with angular degeneracies, we show in Fig. 1c the argument of one of the eigenvalues of the neutral fixed point as a

function of arclength, s, along the Hopf bifurcation curve of Fig. 1b. The argument fails to vary monotonically through points D_1 and D_2.

To be more precise, we make the following definition. Unless otherwise noted, we assume throughout the paper that we are dealing with a k-parameter family of functions $\mathbf{F}_\mu : \mathbf{R}^2 \to \mathbf{R}^2, \mu \in \mathbf{R}^k$, which is C^∞ as a function from $\mathbf{R}^2 \times \mathbf{R}^k \to \mathbf{R}^2$. We will be mostly interested in two-parameter families ($k = 2$).

DEFINITION. Let $\mathbf{F}_\mu$ be a family of smooth maps of the plane with the following properties:

1. A map in the family has a fixed point

$$\mathbf{F}_{\mu_0}(\mathbf{x}_0) = \mathbf{x}_0.$$

2. The fixed point is nonhyperbolic, with complex conjugate eigenvalues on the unit circle. That is, the Jacobian

$$D\mathbf{F}_{\mu_0}(\mathbf{x}_0) \text{ has eigenvalues } e^{\pm 2\pi i \omega_0},$$

where $\omega_0 \in \mathbf{R}$, but $2\omega_0 \notin \mathbf{Z}$ to ensure that the eigenvalues in a neighborhood of the bifurcation point are complex.

Then $(\mathbf{x}_0, \mu_0)$ is a *Hopf bifurcation point* for the family $\mathbf{F}_\mu$.

The implicit function theorem guarantees that there exist unique fixed points near $\mathbf{x}_0$ for maps $\mathbf{F}_\mu$ corresponding to parameter values μ near μ_0. The fixed points can be described by a C^∞ function $\mathbf{x} = \mathbf{x}(\mu)$ satisfying $\mathbf{x}(\mu_0) = \mathbf{x}_0$. The eigenvalues of the nearby fixed point $\mathbf{x}(\mu)$ can be written as $\lambda_\pm = \lambda_\pm(\mu) = \lambda_\pm(\mathbf{x}(\mu)) = e^{\rho(\mu) \pm i(2\pi\omega_0 + \alpha(\mu))}$. This defines both $\rho(\mu)$ and $\alpha(\mu)$ uniquely, once a choice of ω_0 has been fixed, as C^∞ functions which must satisfy $\rho(\mu_0) = 0, \alpha(\mu_0) = 0$.

It is customary to study the Hopf bifurcation by making a change of parameters to (ρ, α) from the original parameters μ. This is possible whenever $\nabla_\mu \rho(\mu_0)$ and $\nabla_\mu \alpha(\mu_0)$ are linearly independent vectors.

DEFINITION. The point $(\mathbf{x}_0, \mu_0)$ is a *Hopf bifurcation point with a parametric degeneracy* if the vectors $\nabla_\mu \rho(\mu_0)$ and $\nabla_\mu \alpha(\mu_0)$ are *not* linearly independent.

DEFINITION. A Hopf bifurcation point satisfies the *eigenvalue crossing condition* if

$$\nabla_\mu \rho(\mu_0) \neq \mathbf{0}.$$

DEFINITION. We say $(\mathbf{x}_0, \mu_0)$ is a *bifurcation point with an angular degeneracy* for the family $\mathbf{F}_\mu$ if it has a parametric degeneracy, but the eigenvalue crossing condition is satisfied.

When the eigenvalue crossing condition is satisfied, as it generically is in two-parameter families, the implicit function theorem guarantees the continuation of a Hopf bifurcation curve through μ_0 in the parameter plane. If we express the Hopf curve with arc length parametrization as $\mu = \mu(s)$ with $\mu(0) = \mu_0$, it follows that $\rho(\mu(s)) = 0$.

If we monitor the argument of the neutral eigenvalue of the fixed point along the Hopf curve, we see that having an angular degeneracy is equivalent to $\frac{d}{ds}\alpha(\mu(s))|_{s=0} = 0$. This is why we call the degeneracy an *angular* degeneracy. An angular degeneracy occurs either when $\nabla_\mu \alpha(\mu_0)$ is nonzero but parallel to $\nabla_\mu \rho(\mu_0)$ or when $\nabla_\mu \alpha(\mu_0) = \mathbf{0}$ (the latter being a nongeneric occurrence in two-parameter families).

We think of the Hopf bifurcation with an angular degeneracy as arising from two possible scenarios in applications. The first is easier to explain and understand:

the "natural" parameters (μ above) in an application are *not* related in a one-to-one fashion to the "universal unfolding" parameters of the modulus and angle of the eigenvalues of the associated fixed point for the corresponding map, or equivalent parameters such as $\rho(\mu)$ and $\alpha(\mu)$ defined above. The lack of injectivity results in singular points for the change of parameters from μ to (ρ, α). Geometrically, we can think of curves of singular points as places we need to "fold" the natural parameter plane in order to place it on top of the corresponding points in the "universal" parameter plane. When the Hopf curve crosses such a fold curve in the natural parameter plane, we have an angular degeneracy. The description of the geometric "folding" of the parameter space is further detailed in §2.4.

The other general scenario where an angular degeneracy arises is along a curve of "secondary" Hopf bifurcations in the two-dimensional parameter space. Although locally the same as an angular degeneracy on a primary Hopf curve, this case cannot be dismissed as merely an "unfortunate" choice of parameters because a "good" parameter choice is usually determined with respect to primary bifurcation phenomena. One codimension-two bifurcation point, a Chenciner or transcritical Hopf point, *requires* the existence of an infinity of angular degeneracies, each on its own secondary Hopf curve inside its own resonance region. It was in studying bifurcations near a Chenciner point, in fact, when we first became interested in the angular degeneracy we describe in this paper [Mc], [Jo]. We discuss this scenario in more detail in §3. We also present in that section a model of a discrete-time adaptive control application that has a Chenciner point on a primary Hopf curve, a secondary Hopf curve connecting two Takens–Bogdanov points on the boundaries of a primary resonance region, an angular degeneracy on the secondary Hopf curve, and banana-shaped secondary resonance regions.

The main areas of emphasis of the paper are determining a model, or normal form, for a Hopf bifurcation with an angular degeneracy, investigating nearby resonance surfaces and their projections to parameter space, relating this bifurcation information for the model to the bifurcation picture for a generic two-parameter family of maps with a Hopf bifurcation with an angular degeneracy, and describing situations in which the angular degeneracy is expected to occur. The main result (Theorem 2.5 and its corollary) is that the resonance regions near a generic Hopf bifurcation point with an angular degeneracy "look" either like those near point D_1 or like those near point D_2 in Fig. 1b. We also discuss more global results about parameter space regions where banana resonance regions are expected to appear.

The paper is organized as follows. In §2, we recall some basic results about Hopf bifurcations, present the (known) Arnold theory for individual resonance horns (with emphasis on the resonance surfaces and using variations on Arnold's proofs), present analogous results for resonance regions near an angular degeneracy, and then consider the implications for the full bifurcation picture near an angular degeneracy. In §3, we describe scenarios in which secondary Hopf bifurcations with angular degeneracies are expected to occur, and present the adaptive control model. We discuss global parameter space bananas in §4, and make final comments in §5.

2. Local resonance regions near a Hopf bifurcation.

2.1. Background. We begin by recalling some standard terminology and results about Hopf bifurcations and normal forms.

DEFINITION. A *p/q resonant Hopf bifurcation point* is a Hopf bifurcation point having eigenvalues $e^{\pm 2\pi i p/q}$ and rotation number p/q around the fixed point for (an appropriate lift of) the linearization of the map at the Hopf point. The fraction p/q

must be in lowest terms. If $q \geq 5$, the bifurcation is said to be *weakly resonant*; if $3 \leq q \leq 4$, it is said to be *strongly resonant*. (Sometimes $q = 1$ and $q = 2$ are called strong resonances as well, although the eigenvalues for those cases are real.)

Note that, for a fixed choice of p/q, the p/q resonant Hopf bifurcation is a codimension-two bifurcation—one parameter is needed to bring the norm of the fixed-point eigenvalue to one, and the other parameter is needed to bring the argument of the fixed-point eigenvalue to the appropriate value of $2\pi p/q$.

THEOREM 2.1 (normal form theorem). *Let $(\mathbf{x}_0, \mu_0)$ be a Hopf bifurcation point for the k-parameter family of functions $\mathbf{F}_\mu : \mathbf{R}^2 \to \mathbf{R}^2$, C^∞ as a function from $\mathbf{R}^2 \times \mathbf{R}^k \to \mathbf{R}^2$. Then there exists a neighborhood of μ_0 in the parameter space for which the original family can be converted by a polynomial change of variables into the form*

$$\mathbf{f}_\mu(\mathbf{z}) = e^{\rho(\mu)+i\phi(\mu)}(\mathbf{z} + A(\mu)\mathbf{z}^2\overline{\mathbf{z}} + \cdots + B(\mu)\overline{\mathbf{z}}^{q-1} + \cdots), \tag{1}$$

by identifying $\mathbf{x} \in \mathbf{R}^2$ with $\mathbf{z} \in \mathbf{C}$, a translation (to bring the unique fixed point at each parameter value to the origin), and a "near identity" polynomial change of variables. $A(\mu) = A_1(\mu) + iA_2(\mu)$ and $B(\mu) = B_1(\mu) + iB_2(\mu)$ are complex valued functions. The omitted terms are all $O(|\mathbf{z}|^{q+1})$, except possibly those of the form $\mathbf{z}^j\overline{\mathbf{z}}^{j-1}, j \geq 3$ which are $O(|\mathbf{z}|^5)$. These "intermediate order" omitted terms are all invariant with respect to rotations; the $\overline{\mathbf{z}}^{q-1}$ term is the lowest-order term in the normal form which is not invariant with respect to all rotations. The dependence of all the functions with respect to μ is C^∞.

Proof. See [Ar], [GH], [Ru], for example. □

THEOREM 2.2 (Hopf bifurcation theorem). *Let $\mathbf{F}_\mu : \mathbf{R}^2 \to \mathbf{R}^2$ be a family of functions for which $\mathbf{F} : (\mu, \mathbf{x}) \to \mathbf{F}_\mu(\mathbf{x})$ is C^∞. Assume the eigenvalue crossing condition holds at $(\mathbf{x}_0, \mu_0)$ and that this point is not strongly resonant. Then*

1. *there is a unique fixed point near $\mathbf{x}_0$ for all maps near μ_0 in the parameter space. A C^∞-smooth Hopf bifurcation curve, defined by the neutral linear stability of the corresponding fixed point, passes through the point $(\mathbf{x}_0, \mu_0)$ in the parameter plane. The fixed point is stable on one side of the Hopf curve and unstable on the other side;*

2. *if in the normal form of equation (1) $A_1(\mu_0)$ is negative (positive), then an attracting (repelling) invariant circle surrounding the fixed point is born from the fixed point as the parameter crosses the Hopf bifurcation curve from the side with the attracting fixed point to the side with the repelling fixed point (from the side with the repelling fixed point to the side with the attracting fixed point). The smoothness of the invariant circles can be guaranteed to be C^r for any $r < \infty$ by suitably restricting the parameter space to a neighborhood of μ_0. Local recurrent points are the fixed point and some points on the invariant circle, when the circle exists.*

Proof. 1. The existence of a unique fixed point follows from the implicit function theorem. The stability follows from the Hartman–Grobman theorem.

2. See Ruelle's textbook [Ru] for a proof of this part of the theorem using the technique of graph transforms. □

When $A_1(\mu_0) < 0$, the Hopf bifurcation is called *supercritical*; when $A_1(\mu_0) > 0$, the bifurcation is called *subcritical*; when $A_1(\mu_0) = 0$, the bifurcation is called *transcritical* or a *Chenciner* point.

2.2. Individual nondegenerate resonance surfaces and regions (à la Arnold). The Hopf bifurcation theorem implies that the bifurcation study would be complete if we knew how to divide the parameter space on the side of the Hopf curve with the invariant circle into topological equivalence classes. Consequently, we

begin by studying surfaces in phase × parameter space corresponding to periodic orbits of a certain period. We first present a nondegenerate two-parameter model for investigating a "resonant" Hopf bifurcation in the neighborhood of a fixed point with eigenvalues $e^{\pm 2\pi ip/q}$. We will locate all local period-q points in a family containing such a resonant Hopf point; they will usually live on the invariant circle guaranteed by the Hopf bifurcation theorem. Although the results in this subsection are not new (cf. [Ar]), we include the subsection for several reasons: to emphasize the surfaces in phase × parameter space instead of just their projection to parameter space, to highlight the differences between the nondegenerate and the degenerate cases, to present some proofs which are slightly different from Arnold's proofs, and to make the paper more self-contained.

Arnold's analysis begins by studying vector fields which are invariant with respect to rotations of $e^{2\pi ip/q}$. He then shows that the qth iterates of maps such as the model families in (2) and (3) below are, up to arbitrarily high order, time-one maps of these equivariant vector fields. In contrast, we have chosen to work directly with maps, and for $q \geq 5$, although many of our arguments are suggested by his analysis, especially for his $q = 4$ case.

Our model family of maps near a p/q resonant Hopf bifurcation point is

$$\mathbf{f}_{(\rho,\alpha)}(\mathbf{z}) = e^{2\pi ip/q} e^{\rho + i\alpha}(\mathbf{z} + A\mathbf{z}^2\bar{\mathbf{z}} + B\bar{\mathbf{z}}^{q-1}), \tag{2}$$

where ρ and α are small real parameters, $\mathbf{z}$ is a complex variable, $\bar{\mathbf{z}}$ is its complex conjugate, p and q are integers, and $A = A_1 + iA_2$ and $B = B_1 + iB_2$ are complex constants with $A_1 \neq 0, B \neq 0$. We consider only the local bifurcation for $\mathbf{z}, \rho, \alpha$ near $\mathbf{0}, 0$, and 0, respectively. Our justification for using this model is in the proof of Corollary 2.4 below, where we show that a generic family near a p/q resonant Hopf point can be changed into the form of equation (2) plus some higher-order terms.

Properties of the (nondegenerate) resonant Hopf model. For the family defined by equation (2), which satisfies the hypotheses of the Hopf bifurcation theorem if $q \geq 5$, the fixed point $z = \mathbf{0}$ has eigenvalue $e^{\rho + i(\alpha + 2\pi p/q)}$. (The corresponding fixed point for the map in $\mathbf{R}^2$, obtained by identifying $\mathbf{R}^2$ with $\mathbf{C}$, has eigenvalues $e^{\rho \pm i(\alpha + 2\pi p/q)}$.) The line $\rho = 0$, where the origin $\mathbf{z} = 0$ changes from attracting ($\rho < 0$) to repelling ($\rho > 0$), is a Hopf bifurcation curve. The argument of the eigenvalue is monotonic along the Hopf curve. In fact, it equals $\alpha + 2\pi p/q$ at $(\rho, \alpha) = (0, \alpha)$. (Contrast this with the degenerate model, where this monotonicity fails to hold, in the next subsection.)

The local p/q resonance region, where period-q orbits exist, for equation (2) with $p/q = 1/5, A = -1 - i, B = 1$, is the horn-shaped region in Fig. 2. All three representative phase portraits are for the 5th iterate of the map. In phase portrait A, the 5th iterates rotate counterclockwise on the (attracting) invariant circle; in C they rotate clockwise; in B they move from saddles (×'s) toward nodes (filled circles).

More formally, we restate the following (known) theorem.

THEOREM 2.3. *Assume the family* $\mathbf{f}_{(\rho,\alpha)}$ *is defined as in* (2) *and* $q \geq 5$. *Then there exists a closed neighborhood* N *of the origin in the phase* × *parameter space with the following properties:*

1. *The set of least-period-*q *(*p/q*) points in* N *is topologically a punctured (closed) disk. The puncture point is the origin—the* p/q *resonant Hopf bifurcation point which is a fixed point. The union of the least-period-*q *points and the fixed point is a closed disk.*

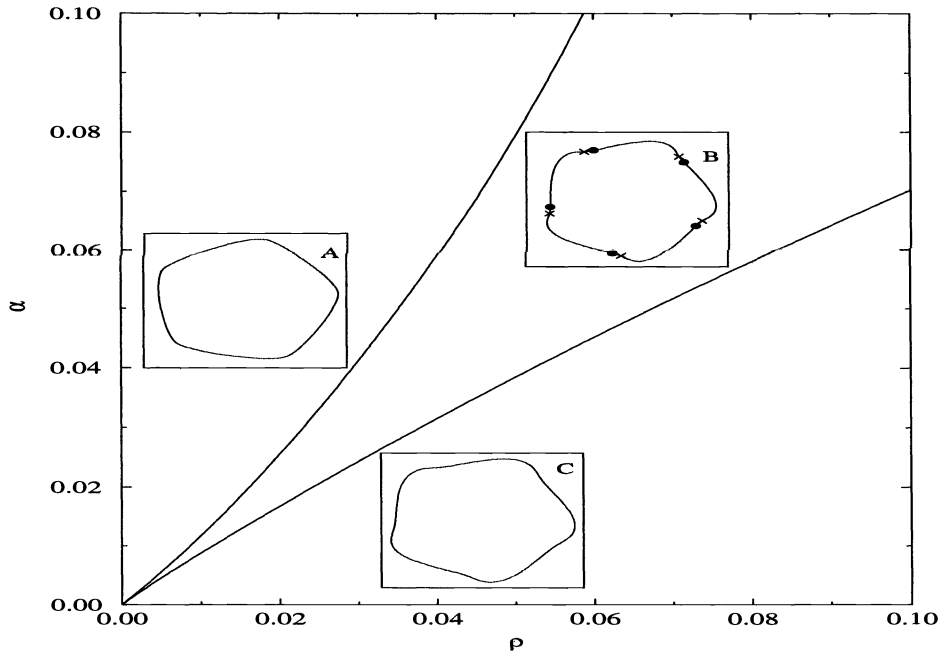

FIG. 2. *The nondegenerate Hopf model. Computations were done using* (2) *with* A=-1-i, B=1, *and* p/q=1/5.

2. *If* $A_1 \neq 0$, *then the projection of the least-period-q* (p/q) *points in* N *to the parameter space is an* (*Arnold*) *resonance horn, emanating from the origin in the parameter space, with both sides tangent to the vector* $(-A_1, -A_2)$. *If, in addition,* $B \neq 0$, *the horns have positive measure, and the order of tangency is* $\frac{q-2}{2}$. *The parameter values near* $(\rho, \alpha) = (0,0)$ *for which the corresponding maps have least-period-q orbit*(*s*) *near* $\mathbf{z} = \mathbf{0}$ *are precisely those inside and on the boundary of the resonance horn, excluding the tip of the horn, to which the* p/q *resonant Hopf point projects.*

3. *In the interior of this horn, there exists a pair of period-q* (p/q) *orbits, one attracting and one repelling when restricted to the invariant circle. The two orbits meet in a single saddle-node orbit on the boundaries of the horn* (*excluding the resonant Hopf point itself*).

Proof. 1. We determine all period-q points by looking at all solutions to $\mathbf{f}^q(\mathbf{z}) - \mathbf{z} = \mathbf{0}$ which are not fixed points. Expanding in terms of the parameters ρ and α and the modulus of $\mathbf{z}$, solving for the parameters, and neglecting higher-order terms leads to the result.

2. Eliminate the phase variables from the expressions obtained for the proof of the above item.

3. Follow arguments similar to those of Arnold [Ar].

Details are in the Appendix. □

COROLLARY 2.4. *Let* $\mathbf{F}_\mu : \mathbf{R}^2 \to \mathbf{R}^2$ *be a family of maps which satisfies the hypotheses of the Hopf bifurcation theorem as stated in* §2.1. *Assume also that* $(\mathbf{x}_0, \mu_0)$ *is a* p/q *weakly resonant Hopf bifurcation point* (*defined also in* §2.1), *without a parametric degeneracy* (*defined in the introduction*). *Then there is a neighborhood of* $(\mathbf{x}_0, \mu_0)$ *in the phase* × *parameter space in which the conclusions of Theorem* 2.3 *will hold,*

where in item 2, A is replaced by $A(\mu_0)$, B is replaced by $B(\mu_0)$, and the vector to which the resonance horn is tangent is the vector that $-A(\mu_0)$ is mapped to by the linearization of the coordinate change from the (ρ, α) parameter space to the original μ parameter space.

Proof. Change variables to bring the original equation into the form of equation (2) plus some higher-order terms. Details are in the Appendix. □

2.3. Resonance surfaces and regions near an angular degeneracy. Our model family of maps having least-period-q points near an angular degeneracy is

$$\mathbf{f}_{(\rho,\tau)}(\mathbf{z}) = e^{2\pi i\omega_0} e^{\rho + i(c_1\rho + c_2\tau^2)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1}), \tag{3}$$

where ρ and τ are real parameters, $\mathbf{z}$ is a complex variable, $\overline{\mathbf{z}}$ is its complex conjugate, q is an integer, ω_0 is a real constant, c_1 and $c_2 \neq 0$ are real constants, and $A = A_1 + iA_2$ and $B = B_1 + iB_2$ are complex constants. As before, we consider only the local bifurcation for $\mathbf{z}, \rho, \tau$ near $\mathbf{0}, 0$, and 0, respectively. The use of this model is justified in Corollary 2.6.

As with the nondegenerate family in (2), this family has a Hopf bifurcation along $\rho = 0$. This family is "degenerate" because the argument of the fixed-point eigenvalue, $2\pi\omega_0 + c_1\rho + c_2\tau^2$, does not vary monotonically along the Hopf curve $\rho = 0$ as τ passes through zero. This causes a change in the appearance of the resonance regions, as we now describe in Theorem 2.5.

THEOREM 2.5 (properties of the degenerate Hopf model). *Assume the family $\mathbf{f}_{(\rho,\tau)}$ is defined as in (3) and $q \geq 5$. Assume A_1, c_2, and $A_2 - c_1A_1$ are all nonzero, and $\omega_0 \neq p/q$ but is sufficiently close to p/q. Then there exists a closed neighborhood N of the origin in the phase $\times$ parameter space with the following properties:*

1. *The set of least-period-q (p/q) points in N and the projection of this set to the parameter space are described by one of four cases. If we define $\alpha_0 := 2\pi(\omega_0 - p/q)$, then the four cases are determined by the signs of the three quantities $A_1, (A_2 - c_1A_1)/(c_2A_1)$, and $(\alpha_0A_1)/(A_2 - c_1A_1)$, as indicated respectively in the following list:*

   a. $(-,-,+)$ *or* $(+,+,-)$: *a twice-punctured sphere which projects to a banana-shaped region with both tips on the Hopf line.*

   b. $(+,-,+)$ *or* $(-,+,-)$: *two disjoint punctured closed disks, each projecting to disjoint resonance horns, each with its tip on the Hopf line (a "banana split").*

   c. $(-,+,+)$ *or* $(+,-,-)$: *a closed cylinder which projects to a "thickened" parabolic region.*

   d $(-,-,-)$ *or* $(+,+,+)$: *the empty set (projecting to the empty set).*

The punctures, present in the first two cases, are p/q resonant Hopf points located at $(\mathbf{z}, (\rho, \tau)) = (\mathbf{0}, (0, \pm\sqrt{-\alpha_0/c_2}))$, and project to corresponding horn tips. If $B \neq 0$, the parameter space horns have positive measure and have order of tangency $\frac{q-2}{2}$ at the tips. In all cases, the "centers" of the horns are pieces of parabolas to lowest order. The parameter values near $(\rho, \tau) = (0, 0)$, for which the corresponding maps have least-period-q (p/q) orbit(s) near $\mathbf{z} = \mathbf{0}$, are precisely those inside and on the boundary of the resonance region(s), excluding the resonant fixed points which project to the horn tips.

2. *On the interior of this region(s), there exists a pair of least-period-q (p/q) orbits, one attracting and one repelling, when restricted to the invariant circle. The two orbits meet in a single saddle-node orbit on the boundaries of the horn (excluding the resonant Hopf point(s) itself).*

Note: The terms in quotations are made more precise in the proof. Parameter space projections of cases (a), (b), and (c) are illustrated in Fig. 3a–3c, respectively.

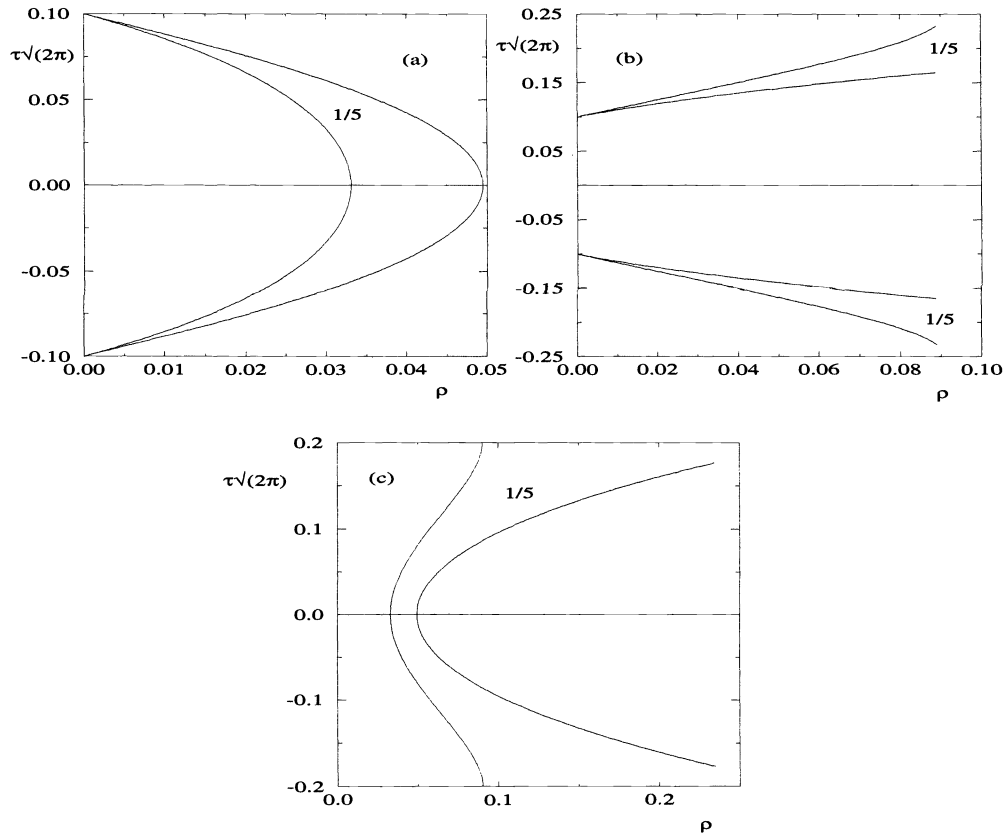

FIG. 3. *Period-5 resonance regions near a Hopf point with an angular degeneracy. Computations were done using equation* (3) *with* $A = -1 - i, B = 1, c_1 = -0.5$, *and* (a) $\omega_0 = 0.21, c_2 = -1$, (b) $\omega_0 = 0.19, c_2 = +1$, (c) $\omega_0 = 0.21, c_2 = +1$.

Proof. 1. The nondegenerate family of equation (2) and the degenerate family of equation (3) differ only in the appearance of their parameters: α has now been replaced by $\alpha_0 + c_1\rho + c_2\tau^2$. The proof is thus obtained by a (noninjective) change of parameters. Details are in the Appendix. See also the end of the next subsection, where with the aid of Fig. 4 we describe geometrically how the degenerate parameter space "unfolds" onto the nondegenerate parameter space.

2. Same as the proof of item 3 in Theorem 2.3. □

For the statement of the following corollary, we recall notation from the introduction: $\mu(s)$ is an arclength parametrization of the Hopf curve which passes through the bifurcation point at $s = 0$, and $e^{\rho(\mu)\pm i(2\pi\omega_o+\alpha(\mu))}$ are the eigenvalues of the corresponding fixed point along the Hopf curve.

COROLLARY 2.6. *Let* $\mathbf{F}_\mu : \mathbf{R}^2 \to \mathbf{R}^2$ *be a family of maps which satisfies the hypotheses of the Hopf bifurcation theorem as stated in* §2.1, *including the eigenvalue crossing condition. Assume that* $(\mathbf{x}_0, \mu_0)$ *is a Hopf bifurcation point with an angular degeneracy* (*defined in the introduction*), *the eigenvalues of* $D\mathbf{F}_{\mu_0}(\mathbf{x}_0)$ *are* $e^{\pm 2\pi i\omega_0}$, *the rotation number around* $\mathbf{x}_0$ *of* (*a lift of*) $D\mathbf{F}_{\mu_0}(\mathbf{x}_0)$ *is* $+\omega_0$, *and* $\omega_0 \neq p/q$ *for* $q \leq 4$ (*not strongly resonant*).

Assume also that and $\nabla_\mu\alpha(\mu_0) \neq \mathbf{0}$. *Thus* $\nabla_\mu\rho(\mu_0)$ *and* $\nabla_\mu\alpha(\mu_0)$ *are nonzero parallel vectors and* $\frac{d}{ds}\alpha(\mu(s))|_{s=0} = 0$. *Assume, however, that* $\frac{d^2}{ds^2}\alpha(\mu(s))|_{s=0} \neq 0$.

Then for any p/q sufficiently close to ω_0, there is a closed neighborhood N of $(\mathbf{x}_0, \mu_0)$ in the phase $\times$ parameter space inside which the set of least-period-q (p/q) points in N is described by one of the four cases (a)–(d) *enumerated in statement* 1 *of Theorem* 2.5. *The four cases are determined in the same way as in Theorem* 2.5, *after we put the original equation in its normal form up to $O(|z|^3)$ terms, change parameters from μ to (ρ, τ), let $A = A(\mu_0)$, and write the eigenvalue argument $\phi(\rho, \tau) = \omega_0 + c_1\rho + c_2\tau^2 + \cdots$, a form justified in the proof.*

Proof. This proof is similar to that of Corollary 2.4. We show that there is a nonsingular change of coordinates which brings our original equation into the same form as our model with an angular degeneracy except for higher-order terms. Details are in the Appendix. □

2.4. Discussion. Although the theorems and their corollaries in the previous subsection stated results for only one p/q resonance surface at a time, there are some relationships between nearby resonance surfaces we wish to point out.

First, for a p/q resonance horn away from an angular degeneracy, we recall from Corollary 2.4 that the angle at which it meets the Hopf curve is determined by the coefficient $A(\mu)$ of the $z^2\overline{z}$ term in the normal form, where μ is the parameter value corresponding to a p/q resonant Hopf point. Since this coefficient varies smoothly along the Hopf curve, the angles at which the various resonance horns meet the Hopf curve will also vary smoothly along the Hopf curve. (No similar statement can be made about the "$B(\mu)$" coefficient of the $\overline{z}^{q-1}$ term; it is not even the coefficient of the same term in the normal form as we move from one resonant Hopf point to another.) This implies that along the Hopf curve for any family, the angle at which a p/q resonance horn meets the Hopf curve varies smoothly as p/q varies. This is even true if the B coefficient in the normal form near a particular p/q resonant Hopf point is zero; the order of tangency of the saddle-node curves for that particular p/q resonance horn, however, would not be of order $\frac{q-2}{2}$.

A similar statement holds for the consistency in the shape of resonance regions near an angular degeneracy. The "parabolas" which define the "centers" of the p/q resonance regions (defined in the proof of Theorem 2.3) vary smoothly in p/q.

We also point out that, even though there are four distinct cases for individual resonance regions, the collection of resonance surfaces and regions near a single Hopf bifurcation with an angular degeneracy has one of the following two forms:

a. Twice-punctured disks which project to "bananas" for all p/q on one side of ω_0; the empty set for all p/q on the other side of ω_0.

b. Pairs of punctured disks which project to "banana splits" for all p/q on one side of ω_0; closed cylinders which project to thickened parabolas for all p/q on the other side of ω_0.

Analytically, this is because the signs of the three quantities A_1, $(A_2 - c_1A_1)/(c_2A_1)$, and $(\alpha_0A_1)/(A_2 - c_1A_1)$ determine the four cases; only the last quantity can change sign as p/q is varied (via $\alpha_0 := 2\pi(\omega_0 - p/q)$).

The first case is illustrated schematically in Fig. 1b near point D_1 and for the model family below in Fig. $4d_1$. The second case is illustrated schematically in Fig. 1b near point D_2 and for the model family below in Fig. $4d_2$. See also Fig. 10, described in the proof of Theorem 2.5 in the Appendix, for a further description of how nearby resonance regions change as varying p/q causes α_0 to change between positive and negative.

Model family. To portray a bifurcation picture with more than one resonance region near an angular degeneracy, we used the following family:

$$\mathbf{f}_{(\rho,\tau)}(\mathbf{z}) = e^{2\pi i\omega_0} e^{\rho+i(c_1\rho+c_2\tau^2)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}}) \tag{4}$$

with $\omega_0 = 0.19, c_1 = -0.5, A = -1 - i, B = 1, C = 1, q = 5$. Figure $4d_1$, using $c_2 = -1$, shows two banana resonance regions; Fig. $4d_2$, using $c_2 = +1$, shows a banana split resonance region and two parabolic resonance regions.

The family of equation (4) is the same as the model degenerate family we began with in equation (3), except for the $\mathbf{z}^3\overline{\mathbf{z}}$ term. We made this alteration because the family of equation (3) is invariant to rotations by $2\pi p/q$. This is fine for computing the p/q resonance region, but not for any other resonance region. For example, if $p/q = 1/5$, and we were computing the $1/6$ resonance region, the invariance with respect to rotations by $2\pi/5$ would imply that period-6 orbits must appear in groups of 5. Thus, a saddle-node birth of a pair of period-6 orbits would result in the birth of 10 period-6 orbits, or 60 period-6 points. The $\mathbf{z}^3\overline{\mathbf{z}}$ term was chosen because it is of high enough order so as not to affect the existence of the invariant circle, and because it is not invariant to any rotations about the origin in phase space. Thus no unwanted symmetries are present.

The geometry of the parameter change, or "Theorem 2.3 to Theorem 2.5 in pictures." Figures $4d_1$ and $4d_2$ can be thought of as having been created via parameter space "surgeries" of a bifurcation diagram for a corresponding nondegenerate family. Specifically, if we start with the bifurcation diagram of Fig. 4a for the nondegenerate family $\mathbf{f}_{(\rho,\alpha)}(\mathbf{z}) = e^{\rho+i\alpha}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}})$, we can change it into either Fig. $4d_1$ or $4d_2$ with the coordinate change $\alpha = 2\pi\omega_0 + c_1\rho + c_2\tau^2$. This coordinate change, replacing α with τ, can be decomposed into the following three coordinate changes, each having a simple geometric interpretation:

a. Shear to make the "singular line" perpendicular to the Hopf curve: $\alpha = \hat{\alpha} + c_1\rho$ (Figs. 4a and 4b).

b. "Unfold a double cover of half of the nondegenerate parameter space": $\hat{\alpha} = 2\pi\omega_0 + c_2|\hat{\tau}|, c_2 = \pm 1$ (from Fig. 4b to $4c_1$ for $c_2 = 1$; from Fig. 4b to $4c_2$ for $c_2 = -1$).

c. Smooth the fold lines: $\hat{\tau} = \tau|\tau|$ (from Fig. $4c_1$ to $4d_1$, or from Fig. $4c_2$ to $4d_2$).

A rescaling would give the same picture as Fig. $4d_1$ for any negative c_2, and the same picture as Fig. $4d_2$ for any positive c_2.

It is now easier to see why the nondegeneracy conditions of Theorem 2.5 are necessary. The value of A_1 must be nonzero so that the resonance horns emerge transverse to the Hopf curve. The expression $A_2 - c_1A_1$ must be nonzero to ensure the resonance horns cross the fold line transversely (the horns emerge with slope $\frac{A_2}{A_1}$ and the slope of the fold line is c_1). If c_2 were zero, the fold might be even more degenerate.

More general degenerate families could also be considered as geometric unfoldings of a double cover of half a nondegenerate parameter space, but only to lowest-order terms. The model families behave better because they have constant coefficients A and B; in a more general family these coefficients would depend on the parameters.

3. Angular degeneracies on secondary Hopf bifurcation curves. So far, the only reason we have given for expecting a Hopf bifurcation with an angular degeneracy is that the relationship between an application's natural parameters and the "universal" parameters, the modulus and argument of a fixed point's eigenvalue,

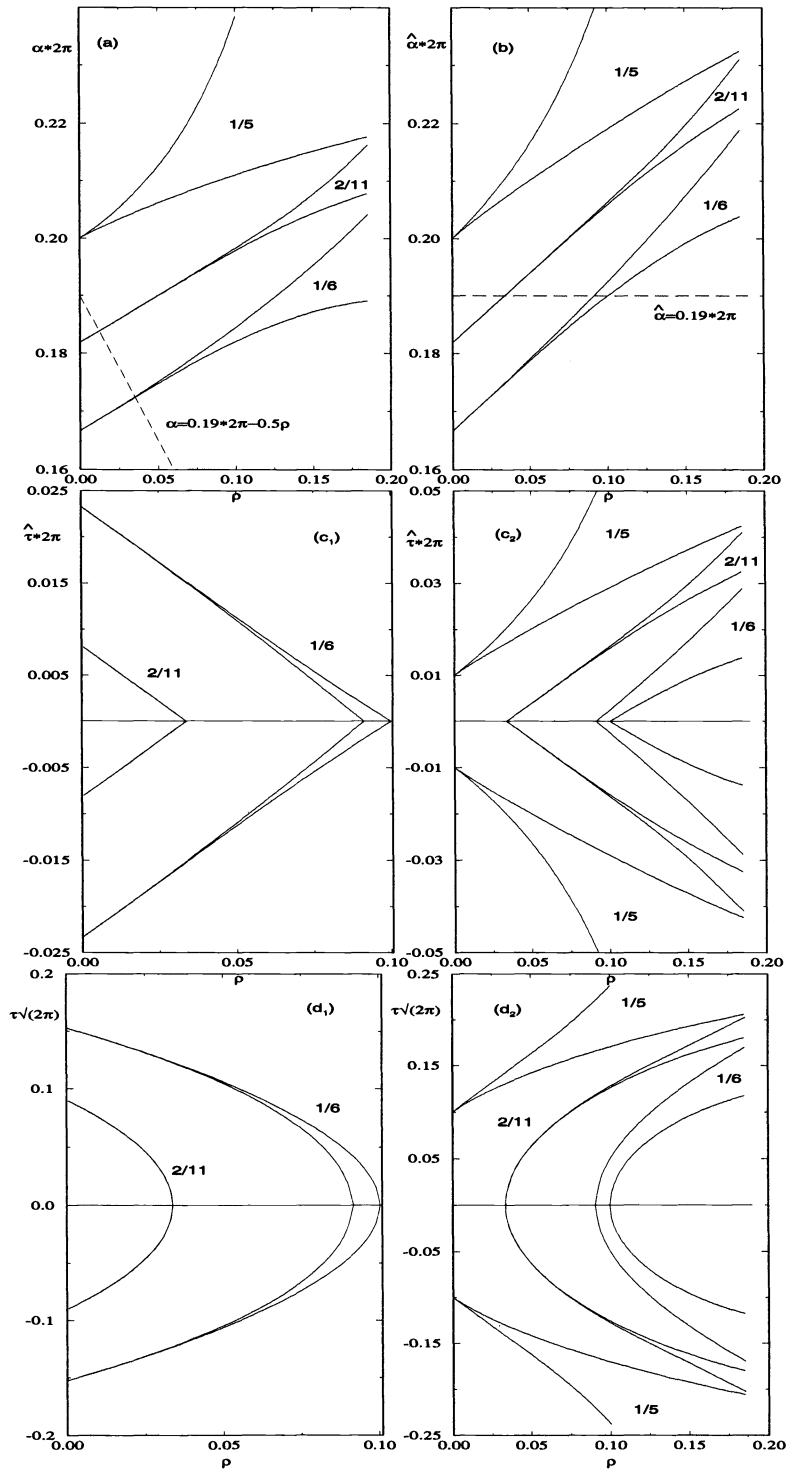

FIG. 4. *Relationship of the nondegenerate parameter space to the degenerate one*: (a) $\mathbf{f}_{(\rho,\alpha)}(\mathbf{z}) = e^{2\pi i\omega_0}e^{\rho+i\alpha}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}})$; (b) $\mathbf{f}_{(\rho,\hat{\alpha})}(\mathbf{z}) = e^{2\pi i\omega_0}e^{\rho+i(\hat{\alpha}+c_1\rho)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}})$; (c) $\mathbf{f}_{(\rho,\hat{\tau})}(\mathbf{z}) = e^{2\pi i\omega_0}e^{\rho+i(2\pi\omega_0+c_1\rho+c_2|\hat{\tau}|)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}})$; (d) $\mathbf{f}_{(\rho,\tau)}(\mathbf{z}) = e^{2\pi i\omega_0}e^{\rho+i(c_1\rho+c_2\tau^2)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1} + C\mathbf{z}^3\overline{\mathbf{z}})$ *In all figures,* $\omega_0 = 0.19, c_1 = -0.5, A = -1 - i, B = 1, C = 1, q = 5$; *in* c_1 *and* d_1, *the constant* $c_2 = -1$; *in* c_2 *and* d_2, *the constant* $c_2 = +1$.

could be nonhomeomorphic. We now describe some scenarios in which the angular degeneracy is expected, or even guaranteed, to occur, even for the "best" choice of parametrizations. They all involve secondary, rather than primary, Hopf bifurcations. These scenarios, in fact, were the original motivation behind our study of a Hopf bifurcation with an angular degeneracy which led to this paper.

3.1. Takens–Bogdanov points and secondary bifurcations. When a fixed point of a family $\mathbf{F}_\mu$ undergoes a (primary) Hopf bifurcation, one result can be the birth of periodic orbits as the Hopf curve in the parameter plane is crossed. Period-q resonance regions (horns), described throughout this paper, where period-q orbits exist, emanate from a point on the primary Hopf curve where the eigenvalues of $D\mathbf{F}_\mu$ at the associated fixed point are located at a qth root of unity.

The sides of a period-q resonance region are period-q saddle-node bifurcation curves, characterized by having an eigenvalue of $D\mathbf{F}_\mu^q$ at one. As a saddle-node curve is traced out in the parameter space, away from the primary Hopf bifurcation, the second eigenvalue may vary. (For $q \geq 5$ and parameter values near the primary Hopf bifurcation, the second eigenvalue determines the local attraction or repulsion normal to the invariant curve.) If the second eigenvalue also becomes equal to one, we generically have a double 1, or "Takens–Bogdanov" point [Bo], [Ta]. One consequence of the analysis of a generic Takens–Bogdanov point is the emergence of a (secondary) Hopf bifurcation curve from the Takens–Bogdanov point, tangent to the saddle-node and extending *into* the primary resonance region. This secondary Hopf bifurcation curve is characterized by the existence of a period-q point where the eigenvalues of $D\mathbf{F}_\mu^q$ are complex conjugate and on the unit circle. A (secondary) period-mq resonance horn, analogous to a primary period-m resonance horn, will emanate from a point on the secondary Hopf curve where $D\mathbf{F}_\mu^q$ at the associated period-q point has an eigenvalue at an mth root of unity.

Only five possibilities exist for the global continuation of a Hopf curve in a two-parameter family: (1) continuation in each direction terminates at a Takens–Bogdanov point; (2) continuation in each direction terminates at a "double (-1) point" [Ar], [Ta]; (3) continuation in one direction terminates at a Takens–Bogdanov point, continuation in the other direction terminates at a double (-1) point; (4) continuation forms a closed curve; or (5) continuation proceeds forever (in an unbounded parameter space). Possibilities (1) and (2) imply the existence of local extrema for the argument of the neutral eigenvalue along the Hopf curve. These local extrema are generically the Hopf bifurcation points with angular degeneracies.

Several possible scenarios, all involving secondary Hopf bifurcations and most involving Takens–Bogdanov points, are suggested in Figs. 5a–e. In Figs. 5a–d, we can assume the eigenvalue argument is zero at one of the Takens–Bogdanov points. Continuity of this eigenvalue along the secondary Hopf bifurcation curve, coupled with the assumed fact that no double (-1) points are encountered along the way, implies that the argument must return to zero at the other Takens–Bogdanov point. Thus the argument (generically nonconstant) must reach a maximum or minimum at least once along the secondary Hopf curve. In Fig. 5e, if by moving all the way around the secondary Hopf curve also returns the secondary rotation number to its value at the starting point, then relative extrema must exist. Thus, these scenarios will lead to Hopf bifurcations with angular degeneracies.

Differences in the figures depend on which side of the horn the second Takens–Bogdanov point appears, on which side of the secondary Hopf bifurcation curve the secondary invariant curves exist, and on which type of angular degeneracy is realized

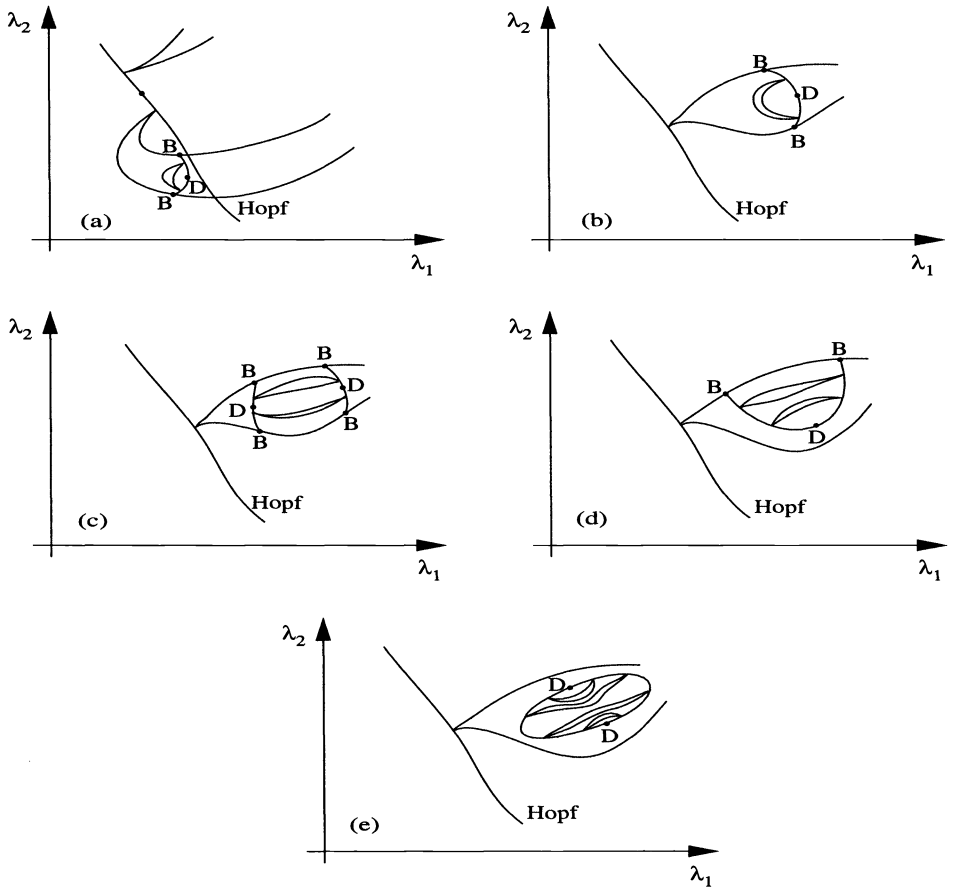

FIG. 5. *Angular degeneracies D due to Bogdanov points B.*

("banana" vs. "banana split"). Although there are no Takens–Bogdanov points in Fig. 5e, it could turn into Fig. 5d by "expanding" the secondary Hopf circle through a variation of an auxiliary parameter, for example, until the "top" angular degeneracy "hit" the saddle-node curves bounding the resonance horn. Other similar scenarios are also possible.

Figure 5a is an illustration of a pair of resonance horns which exist near a "Chenciner" point [Ch]. A Chenciner point is yet another degenerate Hopf bifurcation point: the Hopf bifurcations change between supercritical and subcritical at the Chenciner point. This is illustrated by the switch in the side of the primary Hopf bifurcation curve into which the primary resonance horns grow. As part of his thesis, Johnson [Jo] showed that there *necessarily* exist two Takens–Bogdanov points, one on each side of the primary resonance horn which "turns around," and a secondary Hopf curve which connects them. In this case, there *must* be a Hopf point with an angular degeneracy along that secondary Hopf bifurcation curve. The adaptive control application, which we describe next, has a bifurcation diagram with features similar to Fig. 5a.

3.2. The adaptive control application. Consider the problem of controlling the linear, discrete-time, single-input, single-output (SISO) plant with unknown, con-

stant coefficients (see the 1984 textbook by Goodwin and Sin [GS]):

$$y(t+1) = -\alpha_1 y(t) - \alpha_2 y(t-1) + \beta_0 u(t). \tag{5}$$

In designing the controller, a first-order reference model of (5) is assumed:

$$\hat{y}(t+1) = \hat{\alpha}_1(t) y(t) + \hat{\beta} u(t), \tag{6}$$

where $-\hat{\alpha}_1$ and $\hat{\beta}$ are estimates of the actual system parameters α and β. Thus, two sources of plant/reference-model error are introduced by the reference model: (1) the use of a first-order model (since $\hat{\alpha}_2 = 0, \alpha_2$ becomes a measure of the plant/reference-model *order* mismatch); (2) it is assumed that a good estimate of the gain of the manipulated variable (β_0) is known (thus, $\hat{\beta}$ is a constant). The objective of the controller $u(t)$ is to make the system follow the set point $y^*(t)$; inverting (6), the control law

$$u(t) = \frac{y^*(t+1) - \hat{\alpha}_1(t) y(t)}{\hat{\beta}}$$

is obtained. Choosing $y^*(t+1) = \text{constant} \neq 0$, it is possible to set $y^* = 1$ without loss of generality. The recursive identifier for α_1 is a scalar form of the projection algorithm of [GRC]:

$$\hat{\alpha}_1(t) = \hat{\alpha}_1(t-1) + y(t-1)\frac{y(t)-1}{c + y^2(t-1)}.$$

Defining $x(t+1) = y(t)$, the closed-loop system can be written as

$$\begin{aligned} x(t+1) &= y(t), \\ y(t+1) &= -\alpha_1 y(t) - \alpha_2 x(t) + \frac{\beta_0}{\hat{\beta}}\left(1 - \hat{\alpha}_1(t) y(t)\right), \\ \hat{\alpha}_1(t+1) &= \hat{\alpha}_1(t) + \frac{y(t)}{c + y^2(t)}(y(t+1) - 1), \end{aligned}$$

and after defining $a = -\alpha_1$, $b = -\alpha_2$, $k = \beta_0/\hat{\beta}$, and $z = a - k\hat{\alpha}_1$ the final form of the map G: $R^3 \mapsto R^3$

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} \mapsto \begin{pmatrix} y \\ bx + k + zy \\ z - \frac{ky}{c+y^2}(bx + k + zy - 1) \end{pmatrix}$$

is derived. The system is characterized by three parameters. The small and positive constant c pertains to the estimation algorithm chosen; it is used to prevent division by zero in the estimator. In our calculations it was kept fixed at the representative value of $c = 0.1$. The second parameter, k, is a measure of the error in the assumption of the value of the gain of the manipulated variable ($k = 1$ implies no error), and finally, b is a measure of the plant/reference-model order mismatch ($b = 0$ implies no order error).

Bifurcation analysis reveals a Hopf bifurcation locus for the period-1 fixed point (it corresponds to the set point of the process) in the (k, b) parameter plane

$$b = b_h = -\frac{c+1}{c+2}.$$

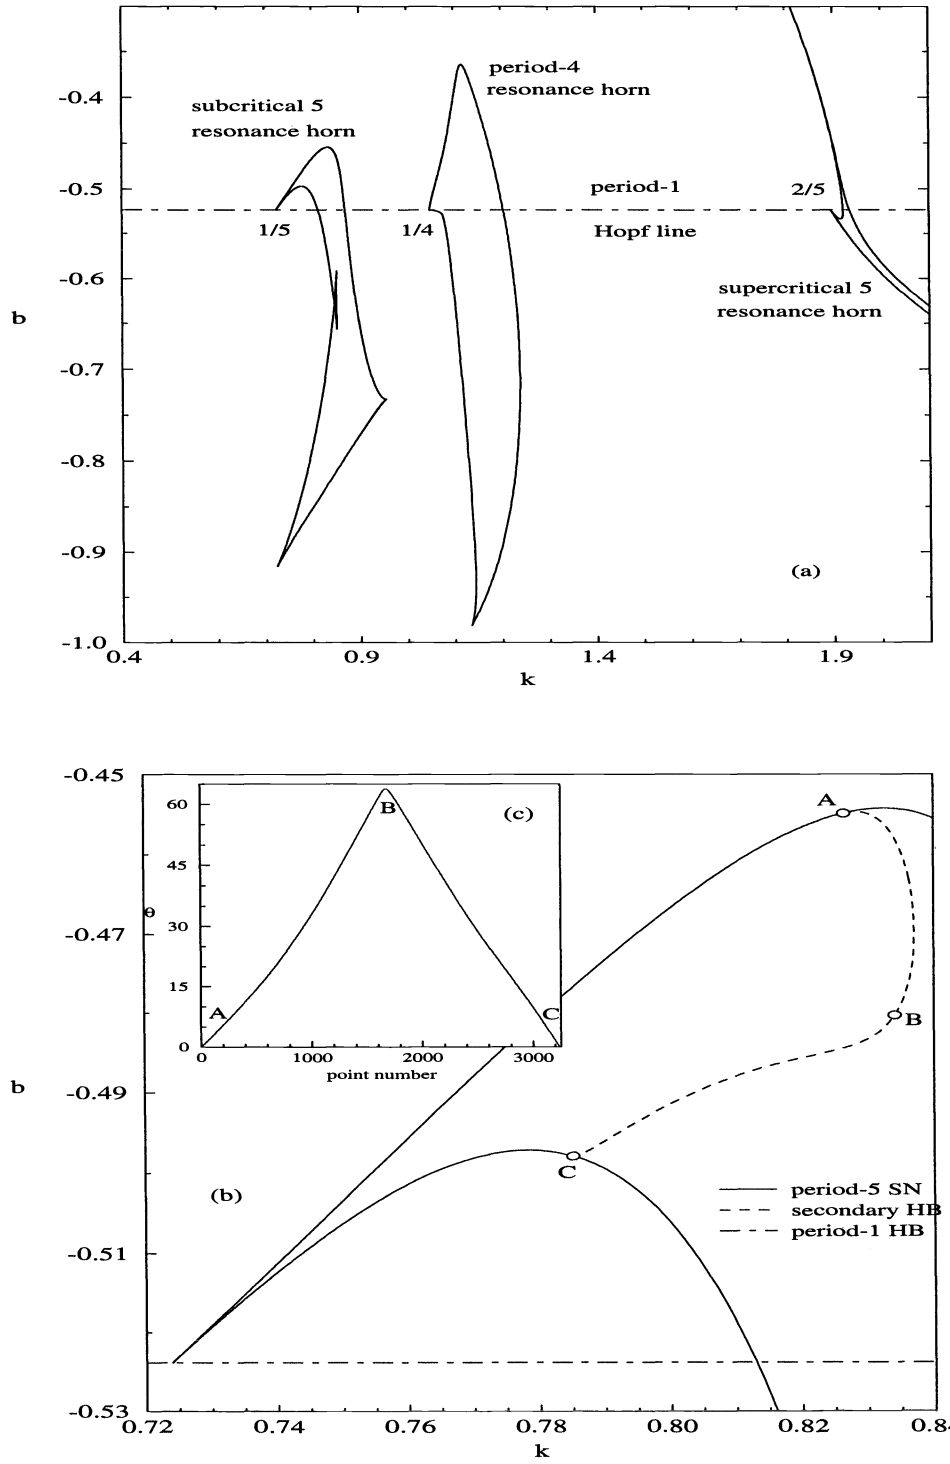

FIG. 6. *Adaptive control system*: (a) *parameter space*, (b) *local bifurcations inside the subcritical period-5 horn*, (c) *angle vs location on secondary Hopf curve.*

Along the Hopf-bifurcation locus, two complex eigenvalues are located on the unit circle (critical eigenvalues) while the third, real eigenvalue is given by

$$\lambda_1 = -b_h = \frac{c+1}{c+2}.$$

Since λ_1 lies well within the unit circle for our choice of $c = 0.1$, the dynamics are strongly contracting in the direction corresponding to λ_1. It is therefore expected that the system will behave in a fashion similar to a map of the plane in the neighborhood of the Hopf bifurcation. It can be easily shown that as k is varied along the Hopf-bifurcation line, the critical eigenvalues start at (-1,-1) at $k = 2.092857$ and then move monotonically over the entire unit circle, approaching (1,1) as $k \to 0$. As described, for example, in Corollary 2.4, primary resonance horns are expected to emanate from this line. This is confirmed in Fig. 6a; the details of the local bifurcations at the tip of the subcritical period-5 horn are shown in Fig. 6b [FAK], [Fr]. The continuation calculations were performed using AUTO86 by Doedel [Do], [DK] (and a real-time graphics interface for it by Dr. M. A. Taylor in our group).

On each side of this period-5 horn we observe a Takens–Bogdanov point (two eigenvalues of $D\mathbf{G}^5$ at one); they are marked A and C in Fig. 6b. As predicted by the theory, we were able to compute the secondary Hopf bifurcation curve inside the period-5 horn connecting the two Takens–Bogdanov points. Along this curve, the two relevant eigenvalues of the corresponding period-5 orbit "start" with zero argument (point A) and after reaching a maximum argument of about 63.8^o on the unit circle (point B—the angular degeneracy) they move back to zero argument at point C (Fig. 6c). Secondary resonance regions originate from this secondary Hopf curve. Figure 7 shows the banana-shaped secondary resonance horns associated with a 6th and 7th root of unity, when the eigenvalues are $\cos(\frac{2\pi}{6}) \pm i \sin(\frac{2\pi}{6})$ and $\cos(\frac{2\pi}{7}) \pm i \sin(\frac{2\pi}{7})$, respectively. The 6th root of unity is crossed twice along the AC curve (at points F and G) where $(k, b) \approx (0.8369, -0.4725)$ and $(0.8274, -0.48418)$, respectively. Similarly, the period-7 resonance horn opens and closes at points D and E on the AC curve, where $(k, b) \approx (0.8366, -0.4645)$ and $(0.8183, -0.48603)$, respectively. We have numerically traced the boundaries of the period-6 and period-7 resonance horns for G^5 in Fig. 7. (Period-6 (respectively, 7) for G^5 means period $5 * 6 = 30$ (respectively, $5 * 7 = 35$) for the original map G.) These secondary resonance horns both "open" and "close" on the secondary (i.e., period-5) Hopf bifurcation curve, suggesting that point B is a banana point rather than a banana split point. We would need to compute higher-order terms in the normal form on the center manifold, however, in order to be sure.

We note that in other examples with an angular degeneracy on a secondary Hopf curve the argument of the eigenvalue at the maximum point (that is, at the angular degeneracy) is only a couple of degrees instead of 63.8^o, as it is here. This is why this example was good for computing bananas: period 5×6 saddle-nodes are much easier to compute than, say, saddle-nodes of period 5×180.

4. Global bananas. All of our results to this point have been local in nature. Banana regions or banana split/parabolic regions have been shown to exist in arbitrarily small neighborhoods of a Hopf bifurcation point with an angular degeneracy. On the other hand, banana resonance regions seem to appear in our numerically computed bifurcation diagrams even relatively far from angular degeneracies. For example, the period-30 and 35 bananas of Fig. 7 seem relatively far from the angular degeneracy — far enough, at least, so that their shapes would not still be called

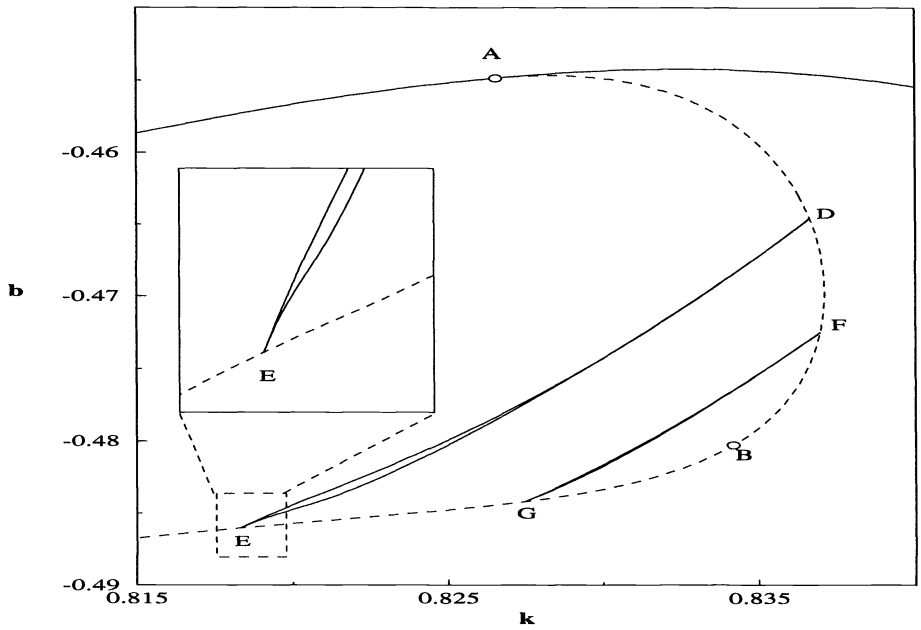

FIG. 7. *Period-30 and period-35 "bananas".*

parabolic. Also, in the schematic bifurcation diagrams of Fig. 5, all the secondary resonance regions are closed bananas, even in the case of Fig. 5c, where the two angular degeneracies are intended to be locally banana split points. It is even possible that the saddle-node curves, which bound the primary resonance regions of Fig. 5, if continued beyond the point where the diagrams stop, could "end" at a second cusp on another (or the same) primary Hopf bifurcation curve. We now give the following global banana result, where the existence of one p/q resonant Hopf point implies the existence of another.

THEOREM 4.1. *Let* $\mathbf{F}$ *be a* C^∞ *function from* $\mathbf{R}^2 \times \mathbf{R}^2 \to \mathbf{R}^2$ *which represents a two-parameter family of diffeomorphisms of the plane. Assume the following:*

1. *There is a Hopf bifurcation curve with a* p/q *resonant point,* $q \geq 3$, *which does not have an angular degeneracy.*

2. *The region of phase* $\times$ *parameter space where a* p/q *orbit exists is compact.*

Then there must exist another p/q *resonant Hopf point somewhere in that compact region of phase* $\times$ *parameter space. Both points are puncture points on the same component of least-period-q points (i.e., the component of the* p/q *resonance surface) in the phase* $\times$ *parameter space. (That is, the existence of one end of a banana implies a second end must also exist.)*

Proof. Theorem 2.3 tells us that the surface of period-q points near the assumed p/q resonant Hopf point is a punctured disk. The idea of the proof is to consider this surface globally in the phase $\times$ parameter space. It can be shown that the closure of the set of least-period-q points in phase $\times$ parameter space forms an orientable topological two-manifold. (In the simplest case, this manifold would be a topological sphere, but it might have some number of handles, as well.) All points on this manifold are least-period-q points under the map $(\mathbf{x}, \mu) \to (\mathbf{F}_\mu(\mathbf{x}), \mu)$, except possibly for isolated fixed points such as the p/q resonant Hopf point projecting to the (first) tip

of the resonance horn (if $q \geq 5$). The proof of the existence of the second fixed point on the resonance surface emanating from the first p/q resonant Hopf point is almost the same as the proof of Theorem 2 of [P2]. That theorem proves the existence of a p/q Hopf point on a p/q surface that emanates not from a first p/q Hopf point, but from "zero forcing amplitude" in a two-parameter family of maps of the plane generated by return maps of a periodically forced planar oscillator. The p/q surface for a forced oscillator "naturally" has an invariant circle as a boundary component; the map restricted to this invariant circle is a rigid rotation by p/q. To convert our situation to that of [P2], we need to replace the first p/q Hopf point with a boundary circle on which the map is a rotation by p/q. But this is easily done by "blowing up" the p/q resonant Hopf point (extending the phase space in polar coordinates to $r = 0$). The proof of the existence of the second p/q Hopf point then follows from [P2]. □

We next present a corollary which describes conditions under which a whole collection of secondary global banana regions will exist.

COROLLARY 4.2. *Let $\mathbf{F}_\mu$ be a generic two-parameter family of diffeomorphisms of $\mathbf{R}^2$. Assume the following:*

1. *There is a p/q resonance surface in the phase $\times$ parameter space resulting from a (primary) p/q resonant Hopf bifurcation.*
2. *The p/q resonance surface includes two Takens–Bogdanov points for the qth iterate of the map; the two Takens–Bogdanov points are connected by a secondary Hopf bifurcation curve (also along the p/q resonance surface).*
3. *Along the secondary Hopf curve the argument of the neutral eigenvalue of $D\mathbf{F}_\mu^q$ has a single local extremum, say $2\pi\omega_0$.*
4. *There is no other secondary Hopf curve on the p/q resonance surface.*
5. *All secondary periodic point surfaces emanating from the secondary Hopf curve are contained in a compact region of phase $\times$ parameter space.*

Then, for every $m/n \in (0, \omega_0)$, the period-qn surface emanating out of the m/n secondary Hopf point must connect to the period-qn resonance surface emanating from the unique m/n Hopf point on the secondary Hopf curve on the other side of the local extremum. (Thus, all resonance regions emanating from the secondary Hopf curve are globally closed bananas.)

Proof. The hypotheses of Theorem 4.1 are satisfied for each $m/n \in (0, \omega_0)$, so a second m/n Hopf point must exist. The assumptions of a single local extremum and no other secondary Hopf curves imply that there is only one "appropriate" point. This point, therefore, is where the other end of the global banana must be. □

Note: It seems that all primary resonance horns near and on one side of a Chenciner point on a Hopf bifurcation curve satisfy the hypotheses of Corollary 4.2. This would give us an infinite collection of primary resonance horns, each having its own infinite collection of global bananas.

5. Conclusions and comments. Although the parametric degeneracy we studied in this paper was specifically along a Hopf bifurcation curve, *any* parametric degeneracy (with respect to parameters in a universal unfolding of a local bifurcation) can be thought of, in its simplest form, as merely a local "folding in half" of the degenerate parameter space, in order to map it to the universal (nondegenerate) parameter space. We could, for example, have included the strongly resonant cases in Theorems 2.3 and 2.5 and their corollaries, even though the projections of the resonance surfaces near the strongly resonant Hopf points to the (nondegenerate) parameter space are not necessarily cusps.

It might be useful to write explicit conditions in terms of the original map to determine (a) an angular degeneracy and (b) the type: banana vs. banana-split (harder, since higher-order terms are required). We found it much easier to verify conditions of the theorem by numerically computing arguments of eigenvalues along the Hopf curve, as we did for the adaptive control application to produce Fig. 6c, than by computing a normal form (especially when needing to use a center manifold).

We point out that the global results (Theorem 4.1 and Corollary 4.2) are very much dependent on the phase space being two-dimensional. The fixed-point theorem from [P2] quoted in the proof of Theorem C applies only in that setting. On the other hand, we expect local results in higher dimensions to be preserved by use of a center manifold. Note that Corollary 4.2 does not exclude the possibility of "nonbanana" resonance regions which do not emanate from the secondary Hopf curve. For example, if the local banana-split horn "partners" connect to form a global banana, we would expect the local parabolic regions to also connect, forming global annuli, projections of tori from the phase $\times$ parameter space. This scenario can be imagined by extending the two p_1/q_1 horns in Fig. 1b until they connect, forming a global banana; the global p_0/q_0 region would then likely be an annulus.

We caution our readers that knowing the complete structure of resonance regions for a family of maps does not necessarily mean we have a complete bifurcation classification, even locally in a neighborhood of a nondegenerate Hopf bifurcation point. We do know that all maps on the side of the Hopf bifurcation curve without the invariant circle, including all those on the curve itself, are locally topologically equivalent. We also know that on the side with the invariant curve, the parameter space must be divided at least into the following equivalence classes: the interiors of each resonance region (circles in resonance), each boundary of each resonance region (circles in resonance with saddle-node orbits), and curves "parallel" to the resonance regions along which the corresponding maps restricted to the invariant circle are conjugate to a rigid rotation with an irrational rotation number. What is missing is a guarantee that all the maps in a given resonance region are equivalent. Corollary 2.4 comes close to giving this guarantee: the existence of a *single* attracting/repelling pair of periodic orbits as stated in part 3 of Corollary 2.4 implies that all maps corresponding to parameter values in the interior of a resonance horn and close enough to the tip *are* topologically equivalent. This may not, however, imply that this uniqueness of equivalence classes within a single resonance region can be extended to hold for *all* resonance regions in a fixed neighborhood (not depending on p/q) of a Hopf bifurcation point. This is why in Corollary 2.6, where we make a claim about the shapes of resonance regions "for all p/q sufficiently close to ω_0," we were unable to claim, as we did in Theorem 2.3, Corollary 2.4, and Theorem 2.5, that there exists a single pair of period-q orbits inside the corresponding p/q resonance region.

Even if a complete local classification could be established, no such claim could ever be made about the global bananas being the complete bifurcation diagram. Check [ACHM], for example, to see a variety of possible further subdivisions of a single resonance region into further equivalence classes. These further subdivisions are possible in part because, away from the Hopf curve, as well as near strong resonances, the invariant circle which is born in the Hopf bifurcation may break. This allows nonuniqueness of rotation numbers, which in turn allows resonance regions to overlap. Near strong resonances, in fact, they *must* overlap, because of global manifold crossings which imply the existence of an infinite number of periodic orbits for fixed parameter values.

There are an additional number of related questions we have not addressed in this paper: (a) No upper bound is given on the number of resonant Hopf points which may exist on a given two-manifold of period-q points; more than two could certainly exist. We conjecture that Lefschetz index theory could be used to show that the fixed points should generically come in pairs, having indices plus and minus one, respectively. "Mutant" bananas, with 4 tips, for example, could easily be constructed by parameter space surgery on a family having a banana with 2 tips! (b) Cusp points (saddle-nodes with a higher-order degeneracy—not to be confused with cusps at resonant Hopf points) may also appear along the saddle-node boundaries of resonance regions. They usually appear in pairs, as well, such as on the left-hand side of the subcritical period-5 resonance horn in Fig. 6a. Work in progress further describes these pairs of cusps [MP]. (c) Finally, finding examples that would exhibit all schematic scenarios pictured in Figs. 5a–5e remains, to our knowledge, an open problem.

6. Appendix: Proofs.

6.1. Proof of Theorem 2.3. As indicated in §2.2, many of the arguments in this section are adaptations of arguments which Arnold [Ar] uses for $q = 4$. We also note that the symmetry of equation (2) implies that $\mathbf{f}^q(\mathbf{z}) = \mathbf{z}$ is equivalent to $\mathbf{f}(\mathbf{z}) = e^{2\pi ip/q}\mathbf{z}$. The latter equation is easier to use for verifying property 1 of Theorem 2.3, but more difficult to generalize to Corollary 2.4, where the symmetry is not present. So we stick to solving $\mathbf{f}^q(\mathbf{z}) = \mathbf{z}$.

Property 1.

We start with the following lemmas.

LEMMA 6.1. *Assume $q \geq 1$ and*

$$\mathbf{f}(\mathbf{z}) = \mu(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + \cdots + B\overline{\mathbf{z}}^{q-1} + \cdots), \tag{7}$$

where the omitted terms are all $O(|\mathbf{z}|^{q+1})$, except those of the form $\mathbf{z}^j\overline{\mathbf{z}}^{j-1}, 3 \leq j \leq \frac{q+1}{2}$, which are $O(|\mathbf{z}|^5)$. Then

$$\mathbf{f}^n(\mathbf{z}) = \mu^n\left(\mathbf{z} + A\left(\sum_{k=0}^{n-1}|\mu|^{2k}\right)\mathbf{z}^2\overline{\mathbf{z}} + \cdots + B\left(\sum_{k=0}^{n-1}|\mu|^{-2k}\overline{\mu}^{kq}\right)\overline{\mathbf{z}}^{q-1}\right) + \cdots, \tag{8}$$

where the omitted terms are all $O(|\mathbf{z}|^{q+1})$, except those of the form $\mathbf{z}^j\overline{\mathbf{z}}^{j-1}, 3 \leq j \leq \frac{q+1}{2}$, which are $O(|\mathbf{z}|^5)$.

Proof. Direct calculation and induction on n. □

LEMMA 6.2. *Assume the $C^k, k \geq 2$ family of C^∞ maps, $\mathbf{f}_{(\rho,\alpha)}$, is defined by*

$$\mathbf{f}_{(\rho,\alpha)}(\mathbf{z}) = e^{2\pi ip/q}e^{\rho+i\alpha}(\mathbf{z} + A(\rho,\alpha)\mathbf{z}^2\overline{\mathbf{z}} + \cdots + B(\rho,\alpha)\overline{\mathbf{z}}^{q-1} + \cdots), \tag{9}$$

where the omitted terms are as in Lemma 6.1. Let $A = A(0,0), B = B(0,0), \mathbf{z} = re^{i\theta}$. Assume $A \neq 0, B \neq 0$, and $q \geq 2$. Then the least-period-q points near $(\rho, \alpha, \mathbf{z}) = (0,0,\mathbf{0})$ are given by the solutions of the equation

$$\rho + i\alpha + Ar^2 + \cdots + Br^{q-2}e^{-qi\theta} + \cdots = 0, r \neq 0, \tag{10}$$

where the θ-independent omitted terms are $O(r^4, \rho^2, \alpha^2, \alpha\rho, \rho r^2, \alpha r^2)$, and all other omitted terms are $O(r^q, \rho r^{q-2}, \alpha r^{q-2})$.

Proof. Period-q points satisfy $\mathbf{f}^q(\mathbf{z}) - \mathbf{z} = \mathbf{0}$. Use Lemma 6.1 to compute $\mathbf{f}^q(\mathbf{z})$, and expand $A(\rho,\alpha), B(\rho,\alpha), \mu^q, \mu^q - 1, \sum_{k=0}^{q-1}|\mu|^{2k}$, and $\sum_{k=0}^{q-1}|\mu|^{-2k}\overline{\mu}^{kq}$, with $\mu =$

$e^{2\pi ip/q}e^{\rho+i\alpha}$ to get power series in ρ and α. Then substitute $\mathbf{z} = re^{i\theta}$ and divide through by $qre^{i\theta}$. (Dividing by r eliminates only the origin, which is a fixed point.) It can be shown (Proposition 3.2 in [CMY] or Theorem 1, part A in [P2]) that solutions to equation (10) can only have a least period of q or 1. Since period-1 points are only at $\mathbf{z} = 0$, then period-q points with $r \neq 0$ must be *least* period-q points. □

Although we cannot solve (10) for the period-q points as a function of the parameters ρ and α, we can solve for the parameters as a function of the phase variables r and θ. By the implicit function theorem on (10), this is apparently

$$\rho + i\alpha = -Ar^2 - \cdots - Br^{q-2}e^{-qi\theta} - \cdots. \tag{11}$$

By choosing r small enough, say less than r_0, we can be sure that Ar^2 dominates all omitted θ-independent terms, and $Br^{q-2}e^{-qi\theta}$ dominates all θ-dependent terms.

For $0 < r \leq r_0, 0 \leq \theta < 2\pi$ equation (11) is an explicit parametrization of the punctured disk which is the least-period-q surface. Adding r=0, corresponding to the resonant Hopf point, fills in the puncture point in the disk. This completes the proof of Property 1.

Property 2. We now use equation (11) to determine the region in parameter space to which this disk projects. Ignoring the omitted higher-order terms, which are the same as for equation (10) in the statement of Lemma 6.2, and, for now, the r^{q-2} term, we get $\rho + i\alpha = -Ar^2 + \cdots$, or equating real and imaginary parts, respectively,

$$\rho = -A_1 r^2; \alpha = -A_2 r^2. \tag{12}$$

Eliminating r gives

$$\alpha = \frac{A_2}{A_1}\rho, \frac{\rho}{-A_1} > 0. \tag{13}$$

That is, to the lowest-order terms in ρ and α, the parameter values for which period-q points exist trace out a ray in the parameter space from the origin in the direction of $(-A_1, -A_2)$ as r increases from 0.

If we now include the θ-dependent term from equation (11), $Br^{q-2}e^{-qi\theta}$, we see that for a fixed value of r, and letting θ vary from 0 to 2π, a circle in the parameter space is swept out (q times), having center at $(\rho, \alpha) = (-A_1 r^2, -A_2 r^2)$ and radius $|B|r^{q-2}$. When $q \geq 5$, sweeping out all such circles for small r covers a horn-shaped region in the parameter space. See Fig. 8 where we have drawn two such circles and the corresponding horn for a resonance region. Since the distance from the origin of these circles varies with r^2 and the width of the horn varies with r^{q-2}, the two sides of the horn are tangent of order $\frac{q-2}{2}$.

This completes the proof of property 2 of Theorem 2.3, but as a heuristic comment, we note that the terms on the right-hand side of equation (11), including those not explicitly written, can be separated into θ–independent and θ–dependent terms. If we considered all θ–independent terms, the analogue of equation (12) would be a semi-infinite curve instead a straight ray. This curve we call the "center of the resonance horn." (This would be well defined if the equation were completely in normal form—all nonresonant terms eliminated. This, however, would bring up the question of convergence of an infinite sequence of coordinate changes. Our wish to avoid this technicality is why these comments are merely heuristic.) The center of the resonance horn is still, of course, tangent to the vector $(-A_1, -A_2)$ at the origin. Now adding the $Br^{q-2}e^{-qi\theta}$ term will cause parameter space circles to be swept out as θ varies with r

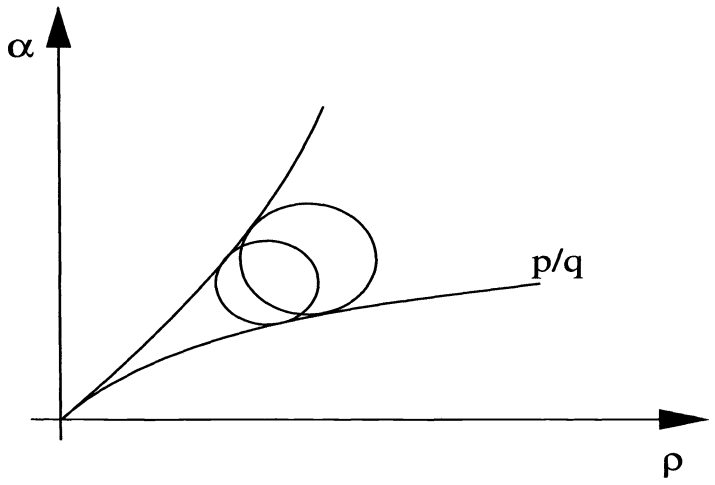

FIG. 8. *"Sweeping out" the resonance horn.*

held fixed. The centers of the circles are on the center of the resonance horn. Finally, including the higher-order θ–dependent terms will cause the circles which are swept out as θ varies to be slightly deformed. The horn sides are still tangent to $(-A_1, -A_2)$ at the origin, and the order of tangency is still $\frac{q-2}{2}$. Thus the only parameter values near $(\rho, \alpha) = (0, 0)$ for which period-q points near $\mathbf{z} = \mathbf{0}$ can exist are inside and on the boundary of the described resonance horn in the parameter space.

Property 3. (As in Arnold [Ar] for q=4.) From the terms that *do* explicitly appear in equation (11), it is apparent that any point in the interior of the horn lies on exactly two distinct circles, each circle corresponding to a different value of r and having its respective center at $(-A_1 r^2, -A_2 r^2)$. See Fig. 8 again. As θ varies from 0 to 2π, each circle is traced out q times (in the negative angular direction). When included, the higher-order terms do not qualitatively affect this result. Thus there are q different phase points which correspond to the same parameter value on the circle. In fact, together these q phase points form one complete period-q orbit. Thus each parameter value on the interior of the horn has two distinct period-q orbits for the associated map. That one is a saddle and the other a node is verifiable using techniques similar to those used by Arnold for $q = 4$ (§35J in [Ar]).

6.2. Proof of Corollary 2.4. The normal form theorem assures us that the original equation can be brought into the form of equation (1). We would like to make a change of parameters from $\boldsymbol{\mu}$ to (ρ, α) where the relationship between them has already been defined by $\frac{2\pi p}{q} + \alpha = \phi$ and equation (1). This is possible if the change of parameters, which we will call $\mathbf{h}$, is nonsingular at $\boldsymbol{\mu}_0$. Equivalently, we must have the vectors $\nabla_\mu \rho(\boldsymbol{\mu}_0)$ and $\nabla_\mu \alpha(\boldsymbol{\mu}_0)$ being independent, which we do because we assumed the absence of a parametric degeneracy (defined in the introduction).

Renaming $\mathbf{f}_\mathbf{u} = \mathbf{f}_{\mathbf{h}^{-1}(\rho,\alpha)}$ to be $\mathbf{f}_{\rho,\alpha}$ brings the equation into the form

$$(14)\quad \mathbf{f}_{(\rho,\alpha)}(\mathbf{z}) = e^{2\pi i p/q} e^{\rho + i\alpha}(\mathbf{z} + A(\mathbf{h}^{-1}(\rho,\alpha))\mathbf{z}^2\bar{\mathbf{z}} + \cdots + B(\mathbf{h}^{-1}(\rho,\alpha))\bar{\mathbf{z}}^{q-1} + \cdots).$$

Now we push through the conclusions and proofs of Theorem 2.3 using the family of equation (14), which is a generalization of our model family of equation (2). The lemmas used to prove Theorem 2.3 were actually proved already in the more general

form of equation (14). Compare equation (14) with equation (9) in Lemma 6.2, in particular. Since the results of Theorem 2.3 hold for equation (14), both results of the corollary now follow directly from the fact that the function $\mathbf{h}^{-1}$ is a nonsingular C^∞ map from the (ρ, α) parameter plane to the μ parameter plane.

6.3. Proof of item 1 of Theorem 2.5. Rewrite equation (3), replacing ω_0 with $p/q + \alpha_0/2\pi$:

$$\mathbf{f}_{(\rho,\tau)}(\mathbf{z}) = e^{2\pi i p/q} e^{\rho + i(\alpha_0 + c_1\rho + c_2\tau^2)}(\mathbf{z} + A\mathbf{z}^2\overline{\mathbf{z}} + B\overline{\mathbf{z}}^{q-1}). \tag{15}$$

This is the same as the equation for the nondegenerate Hopf bifurcation (equation (2)), but with $\alpha_0 + c_1\rho + c_2\tau^2$ replacing α. Since the nondegenerate analysis was valid for α sufficiently small, the same analysis will hold for $\alpha_0 + c_1\rho + c_2\tau^2$ sufficiently small. We treat α_0 as a third parameter which is small if ω_0 is sufficiently close to p/q. Therefore we first consider the five-dimensional phase $\times$ parameter space, and then obtain the theorem by restricting to an "α_0 = small constant" slice.

The least-period-q set, analogous to equation (10), becomes

$$\rho + i(\alpha_0 + c_1\rho + c_2\tau^2) + Ar^2 + \cdots + Br^{q-2}e^{-qi\theta} + \cdots = 0, r \neq 0. \tag{16}$$

Thinking of this complex equation as two scalar equations, we see that the Jacobian with respect to ρ and r^2 at $(r^2, \theta, \rho, \tau, \alpha_0) = (0, \theta, 0, 0, 0)$ is $A_2 - c_1A_1$, which was assumed to be nonzero. So we can solve locally for ρ and r^2 as a function of θ, τ, and α_0. This would seem to indicate the period-q surface is always locally a cylinder: $\theta \in \mathbf{S}^1, \tau \in$ an interval. But the circle swept out as θ varies for a fixed value of r^2 collapses to a point (a fixed point of the map) when $r^2 = 0$ and doesn't exist if $r^2 < 0$. So we must determine the topology of the least-period-q set by determining the values of τ which correspond to $r^2 > 0$ and to $r^2 = 0$. This is what we proceed to do.

By ignoring the θ-dependent terms for now, and eliminating r from equation (16), we obtain an expression analogous to equation (13) for the "center" of our p/q resonance horn to lowest order in the three small parameters ρ, τ, and α_0: $\alpha_0 + c_1\rho + c_2\tau^2 = \frac{A_2}{A_1}\rho, \frac{\rho}{-A_1} > 0$. This is equivalent to

$$\tau^2 = \frac{A_2 - c_1A_1}{c_2A_1}\left(\rho - \alpha_0\frac{A_1}{A_2 - c_1A_1}\right), \frac{\rho}{-A_1} > 0. \tag{17}$$

Treating α_0 as small, nonzero, and fixed, we see that there are actually eight cases, all pieces of parabolas, depending on the signs of $(A_2 - c_1A_1)/(c_2A_1), (\alpha_0A_1)/(A_2 - c_1A_1)$, and A_1. We have sketched the four cases assuming $A_1 < 0$ in Fig. 9. The dashed lines are included in the diagram merely for reference—they are the part of the parabola excluded by $\frac{\rho}{-A_1} > 0$, which corresponds to the side of the Hopf curve without the invariant circle. If A_1 were positive, we would get four similar cases, each a reflection across the τ axis of one of the Fig. 9 cases. (It might be useful to compare Fig. 9a with Figs. 3a, $4d_1$, and the horns near D_1 in Fig. 1b; Fig. 9b with Figs. 3b, $4d_2$, and the horns near D_2 in Fig. 1b; and Fig. 9c with Figs. 3c, $4d_2$, and the horns near D_2 in Fig. 1b.)

We choose an appropriate neighborhood of phase $\times$ (ρ, τ) space by first restricting (ρ, τ, α_0) to a small enough neighborhood of the origin so that the terms explicitly written in equation (16) dominate the (higher-order) unwritten terms. We can choose this neighborhood as a cube with sides at $\rho = \pm\overline{\rho}, \tau = \pm\overline{\tau}, \alpha_0 = \pm\overline{\alpha_0}$ by making small enough choices for $\overline{\rho}, \overline{\tau}$, and $\overline{\alpha_0}$. In cases (a) and (b), we further restrict $\overline{\alpha_0}$,

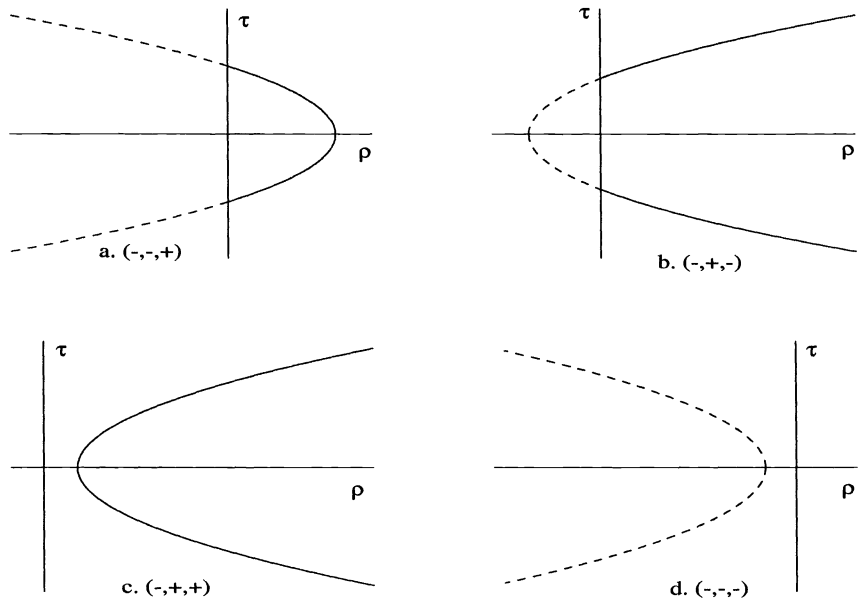

FIG. 9. *"Centers" of resonance regions near a Hopf bifurcation with an angular degeneracy. Labels are for the signs of* $A_1, (A_2 - c_1A_1)/(c_2A_1)$, *and* $(\alpha_0 A_1)/(A_2 - c_1A_1)$, *respectively.*

if necessary, so that $\sqrt{|\overline{\alpha_0}/c_2|} < \overline{\tau}/2$. This ensures that in an "α_0 = constant" slice of our three-dimensional space, the banana "tips" on the τ axis are included in the neighborhood.

From Fig. 9, it is now apparent that the center curve(s) can be parametrized in the four respective cases (a), (b), (c), and (d) by $\tau \in$

(a) (τ_-, τ_+),
(b) $(-\overline{\tau}, \tau_-) \cup (\tau_+, \overline{\tau})$,
(c) $(-\overline{\tau}, \overline{\tau})$,
(d) the empty set,

where from equation (17), $\tau_\pm = \pm\sqrt{|\alpha_0/c_2|}$.

Reintroducing the θ-dependent terms from equation (16) and varying $\theta \in [0, 2\pi)$ gives a parametrization of the least-period-q surface as the product of the appropriate set of the above four for τ with the unit circle. The puncture points corresponding to $r^2 = 0$ in cases (a) and (b) are at $\tau_\pm$. This gives us the twice-punctured sphere for case (a), the two punctured disks for case (b), the cylinder for case (c), and the empty set for case (d). Including the neglected higher-order terms does not change the topology of these sets.

For the projections to the (ρ, τ) parameter space, we fix τ (α_0 is already fixed) and let θ vary from zero to 2π. This traces out a closed curve restricted to τ = constant in the parameter space. Unless the θ-dependent terms all vanish (including all higher-order terms), the closed curve covers a positive length line segment which provides the "thickening" of the respective center lines into regions and establishes the shapes of the respective resonance regions. If the coefficient $B \neq 0$, the length of the line segment varies with r^{q-2} while the distance from the τ axis varies with r^2, establishing the order of tangency at the tips.

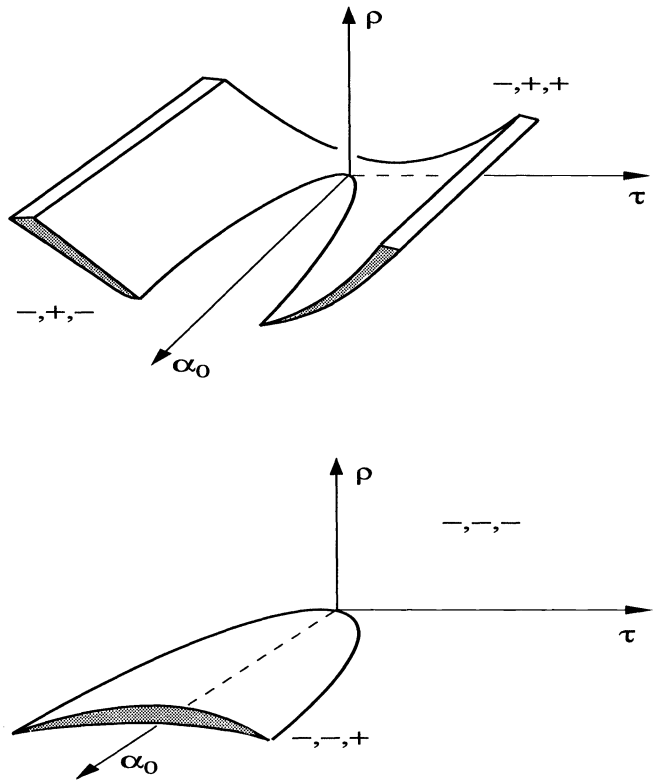

FIG. 10. *Resonance regions in a three parameter space near a Hopf bifurcation with an angular degeneracy. Labels are for the signs of* $A_1, (A_2 - c_1A_1)/(c_2A_1)$, *and* $(\alpha_0 A_1)/(A_2 - c_1A_1)$, *respectively.*

For further illustration we have sketched the resonance regions in the three-parameter space (ρ, τ, α_0) in Fig. 10 for two distinct cases. The sign of A_1 is assumed to be negative in both cases; the sign of $(A_2 - c_1A_1)/(c_2A_1)$ is assumed to be positive in the first case, negative in the second. The sign of the third quantity, $(\alpha_0 A_1)/(A_2 - c_1A_1)$, is determined by the sign of α_0, which is one of the parameters in the figure.

6.4. Proof of Corollary 2.6. Restrict a neighborhood of $(\mathbf{x}_0, \boldsymbol{\mu}_0)$ in phase $\times$ parameter space so that it contains no strongly resonant Hopf points. Choose a p/q with the condition that there is a Hopf point in the restricted neighborhood with eigenvalues $e^{\pm 2\pi i p/q}$. Delete from this neighborhood any of the Hopf points with eigenvalues $e^{\pm 2\pi i r/s}$ with $s < q$. On this deleted, restricted neighborhood, we can change variables to write the equations in the form of equation (1). This defines the functions $\rho(\boldsymbol{\mu}_0)$ and $\phi(\boldsymbol{\mu}_0)$.

We define a change of parameters from $\boldsymbol{\mu}$ to (ρ, τ) where $\rho(\boldsymbol{\mu})$ is defined by equation (1) and $\tau(\boldsymbol{\mu})$ is a linear variable with respect to the $\boldsymbol{\mu}$ parameter space in a direction perpendicular to $\nabla_{\mu}\rho(\boldsymbol{\mu}_0)$. This makes $\nabla_{\mu}\tau(\boldsymbol{\mu}_0)$ and $\nabla_{\mu}\rho(\boldsymbol{\mu}_0)$ independent vectors and ensures that the parameter change is nonsingular, and therefore a local C^{∞} diffeomorphism.

The normal form of equation (1) can now be rewritten, after replacing $\mathbf{h}^{-1}(\rho, \tau)$

with (ρ, τ), as

$$\mathbf{f}_{(\rho,\tau)}(\mathbf{z}) = e^{\rho + i\phi(\rho,\tau)}(\mathbf{z} + A(\rho,\tau)\mathbf{z}^2\bar{\mathbf{z}} + \cdots + B(\rho,\tau)\bar{\mathbf{z}}^{q-1} + \cdots), \tag{18}$$

where the series expansion of ϕ is $\phi(\rho,\tau) = \omega_0 + c_1\rho + c_2\tau^2 +$ higher-order terms in ρ and τ. The constant term ω_0 is determined by the eigenvalues at the bifurcation point $\boldsymbol{\mu}_0$; the τ term is absent because of the angular degeneracy; c_1 is nonzero because we assumed $\nabla_\mu(\alpha(\boldsymbol{\mu}_0)) \neq 0$; c_2 is nonzero because we assumed that $\frac{d^2}{ds^2}\alpha(\boldsymbol{\mu}(s))|_{s=0} \neq 0$. Except for the higher-order terms in $\phi(\rho,\tau)$, this family is the same as our model degenerate family of equation (3). The proof of Theorem 2.5 still works for the family in equation (18) because the higher-order terms in the expansion of ϕ contribute only to terms already considered as higher order in equation (16).

The fact that the change of parameters between (ρ,τ) and $\boldsymbol{\mu}$ is a local diffeomorphism and the fact that no period-q points can exist arbitrarily close to any of Hopf points deleted from our neighborhood completes the proof.

TRACE FORMULAS AND THE BEHAVIOUR OF LARGE EIGENVALUES*

VASSILIS G. PAPANICOLAOU†

Abstract. Let $\mu_1, \mu_2, \ldots, \mu_n, \ldots$ be the Dirichlet spectrum of the operator $-d^2/dx^2 + q$ acting on $L^2(0,b)$. In the special case where $q \equiv 0$, $\mu_n = \pi^2 n^2/b^2$. In the early 1950s Gelfand, Levitan [*Dokl. Akad. Nauk SSSR*, 88 (1953), pp. 593–599], and others discovered the asymptotic formula

$$\mu_n = \frac{\pi^2 n^2}{b^2} + \frac{1}{b}\int_0^b q(x)dx + O(n^{-2})$$

and the trace formula

$$\sum_n \left[\mu_n - \frac{\pi^2 n^2}{b^2}\right] = \frac{q(0)+q(b)}{4}, \qquad \text{provided that } \int_0^b q(x)dx = 0,$$

where $q \in C^2[0,b]$. These are beautiful formulas with many applications, for example in solving inverse problems.

Inspired by the above formulas, this paper obtains some results involving the spectra of two self-adjoint operators L and L_0 (where L can be thought as a perturbation of L_0). The following cases are considered:

(i) $L_0 = -d^2/dx^2$ and $L = L_0 + Q(x)$, with $Q(x)$ being an $r \times r$ real symmetric matrix (thus L_0 and L act on vectors $u = (u_1, \ldots, u_r)$, $u_j \in L^2(0,b)$);

(ii) $L_0 = (-\Delta)^m$ with Dirichlet boundary conditions and $L = L_0 + q$ acting on $L^2(0,b)$ or $L^2(D)$, where $D = (0,b_1) \times (0,b_2)$. The fact that ∂D has corners, thus it is not smooth, plays an essential role.

Some remarks are also made for the case where $L_0 = -\Delta$ with Neumann boundary conditions and $L = -\Delta$ with boundary conditions of the third kind (Robin).

Introduction.

Consider the classical eigenvalue problem

$$Lu(x) = -u''(x) + q(x)u(x) = \mu u(x), \qquad u(0) = u(b) = 0,$$

where q is a smooth function on $[0,b]$. Problems of this type have been studied for the last 150 years. They have very rich mathematical theory and numerous applications. Two of the most famous results concerning the spectrum $\{\mu_n\}_{n=1}^{\infty}$ of the above problem are the *asymptotic formula*

$$\mu_n = \frac{\pi^2 n^2}{b^2} + \frac{1}{b}\int_0^b q(x)dx + O(n^{-2})$$

and the *trace formula*

$$\sum_n \left[\mu_n - \frac{\pi^2 n^2}{b^2}\right] = \frac{q(0)+q(b)}{4} \quad \text{provided that } \int_0^b q(x)dx = 0.$$

These formulas can be thought of as comparisons of the spectrum of L with the set $\{\nu_n = \pi^2 n^2/b^2\}_{n=1}^{\infty}$, namely the spectrum of the "unperturbed" operator $L_0 u = u''$. Their most important application is in solving inverse problems, namely, given some spectral-related data, how do we reconstruct the (now unknown) function q. The asymptotic formula, for example, gives a necessary condition for the existence of a q, while the trace formula, in certain formulations of the inverse problem, actually takes part in the explicit construction of q. In the periodic case, for instance (see [C]), and also in the case where two spectra are known (see [B] for a variant of this case), the solution of the inverse problem is achieved by deriving differential (evolution) equations of the eigenvalues with respect to the interval! Thus, knowledge of the spectrum for one interval yields knowledge of it for all intervals and hence q is constructed via a trace formula.

The main purpose of the present work is to obtain asymptotic and trace formulas for more general operators L_0 and $L = L_0 + q$. The formulas we derive reveal certain interesting quantitative and asymptotic properties of the spectrum of a variety of eigenvalue problems that appear quite often in mathematical physics, engineering, etc. In particular, the formulas presented here can be helpful in solving inverse problems.

Finally, there seems to be a theoretical application of the results of this work, namely, since in some sense $L - L_0 = q$, the trace formulas suggest a concept of trace for multiplication operators $(Tf)(x) = q(x)f(x)$, when q is smooth and satisfy certain zero-average conditions.

1. Preliminaries. Let L_0 and L be the operators on $L^2(0,b)$ defined by

$$L_0 u = -u'' \quad \text{and} \quad Lu = L_0 u + q(x)u(x), \tag{1.1}$$

where $q \in C^2[0,b]$ and $0 < b < \infty$. We assume Dirichlet (i.e., zero) boundary conditions for the functions in the domain of L_0 (and L), in order to have a unique well-defined self-adjoint operator. We call $\mu_1 < \mu_2 < \cdots < \mu_n < \ldots$ the eigenvalues of L and $\phi_1(x), \phi_2(x), \ldots, \phi_n(x), \ldots$, the associated orthonormal eigenfunctions. Similarly, $\nu_1 < \nu_2 < \cdots < \nu_n < \ldots$ and $\psi_1(x), \psi_2(x), \ldots, \psi_n(x), \ldots$, are the corresponding quantities for L_0. In fact, for this particular case we have

$$\nu_n = \frac{\pi^2 n^2}{b^2} \qquad \text{and} \qquad \psi_n(x) = \sqrt{\frac{2}{b}} \sin \frac{\pi n x}{b}. \tag{1.2}$$

In the early 1950s Levitan and others proved that

$$\mu_n = \nu_n + \frac{1}{b}\int_0^b q(x)dx + O(n^{-2}). \tag{1.3}$$

Their proof can be found in [L-G]. A simpler proof was given later by Hochstadt with the help of an ingenious transformation (see [H.H]). These methods have the advantage of giving the full asymptotic behaviour of μ_n, but the big disadvantage is that they work only for these particular operators.

From now on (and without loss of generality) we will assume that the average of q on $[0,b]$ is zero, namely

$$\int_0^b q(x)dx = 0 \tag{1.4}$$

(since the average of q causes only a constant shift of the spectrum).

A simple, general, and convincing (but not rigorous) way of proving (1.3) is by using the ideas of the WKB approximation (from Wentzel, Kramers, and Brillouin—this approach was shown to us by Professor Venakides). We discuss this very interesting method in the next section.

Yet there is a third method of obtaining a result of the type of (1.3). It can be applied to much more general situations, it is rigorous and abstract, but it yields weaker results. It is based on the following lemma.

LEMMA. *Let A be a self-adjoint operator (bounded or unbounded) acting on $L^2(D)$, where D is a domain in R^d. Consider the family of operators*

$$H(s) = A + sq(x), \qquad s \in [0,1]. \tag{1.5}$$

For convenience, let us assume that q is in $C^r(\bar{D})$, where we can take r as big as we wish.

We also assume that, for each s, the operator $H(s)$ has a discrete spectrum

$$\lambda_1(s) < \lambda_2(s) < \cdots < \lambda_n(s) < \ldots.$$

(Notice that, given the fact that $\lambda_n(s)$ is continuous in s, the assumption implies that the eigenvalues of $H(s)$, being simple for all s, never cross each other. It is, therefore, a very strong assumption, especially in higher dimensions.)

Then

$$\frac{d\lambda_n}{ds} = (q\chi_n, \chi_n) \tag{1.6}$$

and

$$\frac{d^2\lambda_n}{ds^2} = -2(q\chi_n, R_n(s)q\chi_n), \tag{1.7}$$

where $(\cdot\,,\cdot)$ is the inner product of $L^2(D)$, $\chi_n(x;s)$ is the eigenfunction of $H(s)$ that corresponds to $\lambda_n(s)$, normalized such that $(\chi_n, \chi_n) = 1$, and $R_n(s) = [I - P_n(s)][H(s) - \lambda_n(s)]|-1$, $P_n(s)$ being the (orthogonal) projection onto χ_n. (The proof can be found in [R-S, §13.16].

Now, the standard Taylor's theorem with remainder gives

$$|\lambda_n(1) - \lambda_n(0) - \lambda_n'(0)| \le \tfrac{1}{2} \sup_{0\le s\le 1} |\lambda_n''(s)|. \tag{1.8}$$

In certain cases (for example, see §4), (1.7) can help us to obtain a good upper bound for the right-hand side of (1.8). For instance, if A is L_0 of (1.1) and q is in $C^1[0,b]$, we get easily that this upper bound is $O(n^{-1})$, which is a weaker version of (1.3), but requires less smoothness for q (notice that the Riemann–Lebesgue lemma is involved). For the details see [R-S, Thm. 13.82.5].

Recently, Friedlander (see [F]) and Feldman, Knorrer, and Trubowitz (see [F-K-T]) obtained some results concerning the distribution of the Floquet eigenvalues of the operator $-\Delta + q$, where q is periodic on $\mathbf{R}^2$. Their findings remind (1.3), but there are exceptional zero-density sets of eigenvalues which do not obey the asymptotics.

Few years after the discovery of (1.3), Gelfand (see [G-L]) observed that, assuming (1.4), i.e., zero average for q, one has the beautiful trace formula

$$\operatorname{tr}(L - L_0) \overset{\text{def}}{=} \sum_n \left[\mu_n - \frac{\pi^2 n^2}{b^2}\right] = \frac{q(0) + q(b)}{4}. \tag{1.9}$$

The following proof of (1.9) appeared in a lecture given by Douady (see [D-H-V]). It utilizes the heat kernel in a neat way and it inspired the derivations of the other trace formulas in the present work. This is why we decided to include it in our introduction.

Let L and L_0 be as in (1.1) and, for $t > 0$, let $k(t,x,y)$ and $p_b(t,x,y)$ be the integral kernels of the (compact) operators e^{-tL} and e^{-tL_0}, respectively. In other words, $k(t,x,y)$ and $p_b(t,x,y)$ are the heat kernels of L and L_0. If we set

$$p_\infty(t,x,y) = \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{|x-y|^2}{4t}\right) - \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{|x+y|^2}{4t}\right) \tag{1.10a}$$

(which, incidentally, is the heat kernel of L_0 acting on $(0,\infty)$, with Dirichlet boundary condition at 0), then it can be easily checked that (see, for example, [J])

$$p_b(t,x,y) = \sum_{k\in Z} p_\infty(t,x,y+2kb), \qquad 0 \le x, \quad y \le b. \tag{1.10b}$$

Thus, as $t \downarrow 0$, we have uniformly in $x, y \in [0,b]$ that

$$p_b(t,x,y) = \frac{1}{\sqrt{4\pi t}}\left[\exp\left(-\frac{|x-y|^2}{4t}\right) - \exp\left(-\frac{|x+y|^2}{4t}\right) - \exp\left(-\frac{|x+y-2b|^2}{4t}\right)\right] + \frac{e^{-c/t}}{\sqrt{t}} O(1),$$

where $c = b^2/4$. In particular,

$$p_b(t,x,x) = \frac{1}{\sqrt{4\pi t}}\left[1 - \exp\left(-\frac{x^2}{t}\right) - \exp\left(-\frac{|x-b|^2}{t}\right)\right] + \frac{e^{-c/t}}{\sqrt{t}} O(1). \tag{1.11}$$

Also, it is not hard to obtain the following perturbation expansion for $k(t,x,y)$

$$k(t,x,y) = \sum_{n=0}^{\infty} k_n(t,x,y), \tag{1.12a}$$

where

$$k_0(t,x,y) = p_b(t,x,y) \tag{1.12b}$$

and, for $n \ge 1$,

$$k_n(t,x,y) = (-1)^n \int_0^t \int_0^b p_b(s,x,z) q(z) k_{n-1}(t-s,z,y)\, dz\, ds. \tag{1.12c}$$

Equation (1.12c) implies

$$|k_n(t,x,y)| \le \frac{1}{n!} \|q\|_\infty^n t^n p_b(t,x,y). \tag{1.13}$$

From (1.13) we get immediately

$$k_n(t,x,y) = O(t^{n-1/2}), \quad \text{as } t \downarrow 0, \text{ uniformly in } x, y. \tag{1.14}$$

Next we write the eigenfunction expansions of $k(t,x,y)$ and $p_b(t,x,y)$

$$k(t,x,y) = \sum_n e^{-\mu_n t}\phi_n(x)\phi_n(y),$$

$$p_b(t,x,y) = \sum_n e^{-\nu_n t}\psi_n(x)\psi_n(y).$$

Thus, by the orthonormality

$$\int_0^b [k(t,x,x) - p_b(t,x,x)]dx = \sum_n [e^{-\mu_n t} - e^{-\nu_n t}] = \mathrm{tr}(e^{-tL} - e^{-tL_0}).$$

We need the short-time asymptotics because, at least formally we have

$$\mathrm{tr}(L - L_0) = \lim_{t\downarrow 0} \frac{1}{t}\mathrm{tr}(e^{-tL} - e^{-tL_0}).$$

Using formulas (1.12) and (1.14) we get easily (as $t \downarrow 0$)

$$\int_0^b k_1(t,x,x)dx = \sum_n [e^{-\mu_n t} - e^{-\nu_n t}] + O(t^{3/2}). \tag{1.15}$$

But by (1.12) and Fubini–Tonelli,

$$\begin{aligned}
\int_0^b k_1(t,x,x)dx &= -\int_0^b \int_0^t \int_0^b p_b(s,x,z)q(z)p_b(t-s,z,x)dzdsdx \\
&= -\int_0^b q(z)\left[\int_0^t \int_0^b p_b(s,x,z)p_b(t-s,z,x)dsdx\right]dz \\
&= -\int_0^b q(z)\left[\int_0^t p_b(t,z,z)ds\right]dz \\
&= -t\int_0^b p_b(t,z,z)q(z)dz
\end{aligned}$$

and thus, because of (1.11)

$$\int_0^b k_1(t,x,x)dx = -\frac{\sqrt{t}}{\sqrt{4\pi}}\int_0^b q(x)dx + \frac{q(0)}{4}t + \frac{q(b)}{4}t + O(t^{3/2}), \tag{1.16}$$

since, if q is in $C^1[0,b]$,

$$\frac{1}{\sqrt{4\pi t}}\int_0^b \exp\left(-\frac{x^2}{t}\right)q(x)dx = \frac{q(0)}{4} + O(\sqrt{t}) \quad \text{as } t \downarrow 0. \tag{1.17}$$

If we assume (1.4), namely

$$\int_0^b q(x)dx = 0,$$

and combine (1.15) and (1.16) we arrive at (1.9) by dividing by t and letting $t \downarrow 0$. We need (1.3) in order to interchange summation and limit, since (1.3) guarantees that $(\mu_n - \nu_n)$ is absolutely summable.

In what follows, we attempt to extend the formulas and ideas presented above.

In §2 we give the vector analog of (1.3) and (1.16). To be more precise, we analyze the case $L_0u = (-d^2/dx^2)u$ and $Lu = L_0u + Q(x)u$, where $Q(x)$ is an $r \times r$ real symmetric matrix and $u = (u_1, \dots, u_r)$ with $u_j \in L^2(0,b)$. We denote this by $u \in L_r^2(0,b)$. This is a Hilbert space and L has a unique self-adjoint extension on $L_r|2(0,b)$ if we prescribe boundary conditions, say, $u(0) = u(b) = 0$. The importance of this problem lies on the idea that, by carefully choosing Q and then letting $r \to \infty$, we might obtain interesting results for the two-dimensional operator $-\Delta + q$.

In §3 we examine the case where $L_0 = -\Delta$ and $L = L_0 + q$ are acting on $L^2(D)$ and where $D = (0,b_1) \times (0,b_2)$. We get two trace formulas, but they cannot reduce to something completely analogous to (1.16) because, to our knowledge, in the two-dimensional case there is no asymptotic formula as strong as (1.3).

In §4 we let $L_0 = (-d^2/dx^2)^m$ and $L = L_0 + q$, acting on $L^2(0,b)$. Here we are able to obtain the complete analogs of (1.3) and (1.16). Formula (4.15) of this section is not new. It exists in the Russian literature (see, for example, [L-S]), but our way of deriving it is different and, in our opinion, simpler.

In §5 we extend the results of §4 to the two-dimensional case. Many of the estimates needed here have been developed in the previous section.

The last section contains some final thoughts. In particular we make some remarks for the case where $L_0 = -\Delta$ with Neumann boundary conditions and $L = -\Delta$ with boundary condition

$$\frac{\partial u}{\partial n}(z) + c(z)u(z) = 0, \qquad z \in \partial D.$$

Here the trace formula involves the boundary function $c(z)$.

2. The vector-valued function case. We define

$$L_r^2(0,b) = \{u = (u_1, \dots, u_r) : u_j \in L^2(0,b),\ 1 \le j \le r\}.$$

This is a Hilbert space with inner product

$$(u,v) = \int_0^b u \cdot v\, dx = \int_0^b (u_1v_1 + \cdots + u_rv_r)dx,$$

where $u = (u_1, \dots, u_r)$ and $v = (v_1, \dots, v_r)$.

For a sufficiently smooth u in $L_r^2(0,b)$ we set

$$L_0u = -\frac{d^2u}{dx^2} + Q_0u \quad \text{and} \quad Lu = L_0u + Q(x)u, \tag{2.1}$$

where Q_0 is an $r \times r$ symmetric matrix with real and constant entries and $Q(x) = [q_{ij}(x)]_{1 \le i,j \le r}$ is also real, symmetric, and such that each q_{ij} is in $C^2[0,b]$ and

$$\int_0^b q_{ij}(x)dx = 0. \tag{2.2}$$

We consider the boundary conditions

$$u(0) = u(b) = 0. \tag{2.3}$$

Then L is a well-defined self-adjoint operator on $L_r^2(0,b)$ and, without loss of generality, Q_0 is a diagonal matrix, namely

$$Q_0 = \operatorname{diag}(a_1, a_2, \dots, a_r), \qquad a_1 \le a_2 \le \cdots \le a_r \tag{2.4}$$

(since Q_0 can be diagonalized by an orthogonal transformation independent of x). The spectrum of L is discrete and has ∞ as its only cluster point (since the variation of parameters method implies that $(L-z)^{-1}$ is compact, etc).

Let us denote by $\mu_1, \mu_2, \ldots, \mu_n, \ldots$ the spectrum of L and by $\nu_1, \nu_2, \ldots, \nu_n, \ldots$ the spectrum of L_0 as usual. Here is the analog of (1.3).

CONJECTURE.

$$\mu_n = \nu_n + O(n^{-2}). \tag{2.5}$$

Proof (adaptation of the WKB method, shown to us by Stephanos Venakides). For convenience we assume (essentialy without loss of generality) that the diagonal entries of Q_0 are distinct. Then, the eigenvalues of L_0 (which decouples to r very simple scalar operators) are

$$\nu_{nk} = a_k + \frac{\pi^2 n^2}{b^2}, \qquad 1 \le k \le r,$$

with corresponding eigenfunctions

$$\psi_{nk}(x) = e_k \sin \frac{\pi n x}{b},$$

where $e_k = (0, \ldots, 0, 1, 0, \ldots, 0)$, i.e., all its entries are zero except for the kth one, which is 1. The assumption that the a_k's are distinct makes the eigenvalues of L_0 simple, at least for all n sufficiently large.

Now we view L as a perturbation of L_0 and thus we make the (unjustified) assumption that for large n, its eigenvalues $\{\mu_{nk}\,;\, 1 \le k \le r,\ n = 1, 2, \ldots\}$ and eigenfunctions $\{\phi_{nk}(x)\,;\, 1 \le k \le r,\ n = 1, 2, \ldots\}$ can be written as expansions in powers of n^{-1}, namely

$$L\phi_{nk} = (\nu_{nk} + c_{-1k}n + c_{0k} + c_{1k}n^{-1} + c_{2k}n^{-2} + \cdots)\phi_{nk} \tag{2.6}$$

and

$$\phi_{nkj}(x) = [A_{0kj}(x) + A_{1kj}(x)n^{-1} + \cdots] \sin[\pi n x/b + \omega_{0kj}(x) + \omega_{1kj}(x)n^{-1} + \cdots],$$

where ϕ_{nkj} is the jth coordinate of ϕ_{nk}. Substituting this in (2.6) and equating coefficients of the same powers of n, we obtain after some algebra that $c_{-1k} = c_{0k} = c_{1k} = 0$, which is (2.5). Formula (2.2) and the boundary conditions play an essential role, as expected. □

We continue with the trace formula. The integral kernel of the semigroup e^{-tL} is given by a formula similar to (1.12), whose probabilistic version (to be a little fancy) is the Feynman–Kac formula

$$k(t, x, y) = E^x \left\{ \exp\left[-tQ_0 - \frac{1}{2}\int_0^{2t} Q(X_s)ds \right] \,\middle|\, X_{2t} = y \right\} p_b(t, x, y), \tag{2.7}$$

where X_s is the Brownian motion process in $(0, b)$ killed at 0 and b and $p_b(t, x, y)$ is its transition density, given by (1.10b). The eigenfunction expansion of this heat kernel is

$$k(t, x, y) = \sum_n e^{-\mu_n t}\phi_n(x) \otimes \phi_n(y),$$

where $\phi_n(x) \otimes \phi_n(y)$ is the $r \times r$ matrix whose ijth entry is $\phi_{ni}(x)\phi_{nj}(y)$, ϕ_{ni} being the ith component of the (normalized) nth eigenfunction ϕ_n of L. A simple step by step adaptation of the proof of (1.9) gives

$$\lim_{t \downarrow 0} \frac{1}{t} \sum_n (e^{-t\mu_n} - e^{-t\nu_n}) = \frac{\mathrm{tr}Q(0) + \mathrm{tr}Q(b)}{4} \tag{2.8}$$

and thus, if (2.5) is true, we can interchange summation and limit and get

$$\mathrm{tr}(L - L_0) = \sum_n (\mu_n - \nu_n) = \frac{\mathrm{tr}Q(0) + \mathrm{tr}Q(b)}{4}. \tag{2.8'}$$

Remark. One good reason for studying operators of the type of L is that, by choosing Q_0 and Q in a suitable way and then letting $r \to \infty$, we might be able to obtain spectral properties of higher-dimensional operators (for example, $-\Delta + q$).

3. The case of a rectangle. Consider the rectangular domain $D = (0, b_1) \times (0, b_2)$ in R^2, where $0 < b_1, b_2 < \infty$. Let L_0 and L be the operators on $L^2(D)$ defined by

$$L_0 u = -\Delta u \quad \text{and} \quad Lu = L_0 u + q(x)u(x), \tag{3.1}$$

where $q \in C^2(\bar{D})$. We assume again Dirichlet (i.e., zero) boundary conditions for the functions in the domain of L_0 (and L), in order to have a unique well-defined self-adjoint operator. We call, as in the introduction, $\mu_1 < \mu_2 \leq \cdots \leq \mu_n \leq \cdots$ the eigenvalues of L and $\phi_1(x), \phi_2(x), \ldots, \phi_n(x), \ldots$ the associated orthonormal eigenfunctions. Similarly, $\nu_1 < \nu_2 \leq \cdots \leq \nu_n \leq \ldots$ and $\psi_1(x), \psi_2(x), \ldots, \psi_n(x), \ldots$ are the corresponding quantities for L_0. Here we have

$$\nu_n = \frac{\pi^2 n_1^2}{b_1^2} + \frac{\pi^2 n_2^2}{b_2^2} \quad \text{and} \quad \psi_n(x) = \frac{2}{\sqrt{b_1 b_2}} \sin \frac{\pi n_1 x_1}{b_1} \sin \frac{\pi n_2 x_2}{b_2}, \tag{3.2a}$$

where n_1 and n_2 are integers depending on n so that we always have $\nu_n \leq \nu_{n+1}$. The asymptotic behaviour of ν_n for large n is (see [C-H], vol. 1, Chap. 6, §4)

$$\nu_n = \frac{4\pi}{b_1 b_2} n + O(\sqrt{n}). \tag{3.2b}$$

The estimate

$$|\mu_n - \nu_n| \leq \|q\|_\infty \tag{3.3}$$

follows easily from the standard minimax argument. Stephanos Venakides asked whether we can say something better than (3.3). We suspect that there must be a better estimate (except for a set of eigenvalues of zero density) when the averages of q along the x_1 and x_2 axes are zero. This is suggested by the formulas (3.12) and (3.16) and by the recent works [F] and [F-K-T] for the case of periodic boundary conditions.

Let us imitate the analysis at the end of §1. The heat kernel $p(t, x, y)$ of L_0 is given by (separation of variables)

$$p(t, x, y) = p_1(t, x_1, y_1)p_2(t, x_2, y_2), \tag{3.4}$$

where, for $j = 1$ or 2, $p_j(t,x,y) = p_{b_j}(t,x,y)$ of (1.17). The heat kernel $k(t,x,y)$ of L is

$$k(t,x,y) = \sum_{n=0}^{\infty} k_n(t,x,y), \tag{3.5a}$$

where

$$k_0(t,x,y) = p(t,x,y) \tag{3.5b}$$

and, for $n \geq 1$,

$$k_n(t,x,y) = -\int_0^t \int_D p(s,x,z)q(z)k_{n-1}(t-s,z,y)dzds. \tag{3.5c}$$

Estimate (1.22) becomes

$$|k_n(t,x,y)| \leq \frac{1}{n!}\|q\|_\infty^n t^n p(t,x,y). \tag{3.6}$$

Thus

$$k_n(t,x,y) = O(t^{n-1}), \quad \text{as } t \downarrow 0, \text{ uniformly in } x,y. \tag{3.7}$$

The eigenfunction expansions give (as in §1)

$$\int_D [k(t,x,x) - p_b(t,x,x)]dx = \sum_n (e^{-\mu_n t} - e^{-\nu_n t}).$$

Because of (3.5) and (3.6) this implies

$$\int_D [k_1(t,x,x) + k_2(t,x,x)]dx = \sum_n (e^{-\mu_n t} - e^{-\nu_n t}) + O(t^2), \quad \text{as } t \downarrow 0. \tag{3.8}$$

Now the same argument used in §1 for the one-dimensional case gives, as $t \downarrow 0$,

$$\int_D k_1(t,x,x)dx = -t\int_D p(t,x,x)q(x)dx,$$

thus, because of (3.4) and (1.17),

(3.9a)

$$\begin{aligned}\int_D k_1(t,x,x)dx &= -t\int_0^{b_2} p_2(t,x_2,x_2)\left[\int_0^{b_1} p_1(t,x_1,x_1)q(x_1,x_2)dx_1\right]dx_2 \\ &= -\frac{b_1 b_2 Q}{4\pi} + \frac{(b_1+b_2)Q}{\sqrt{4\pi}}\sqrt{t} + \frac{b_1[Q_2(0)+Q_2(b_2)] + b_2[Q_1(0)+Q_1(b_1)]}{4\sqrt{4\pi}}\sqrt{t} \\ &\quad - \frac{q(0,0)+q(b_1,0)+q(0,b_2)+q(b_1,b_2)}{16}t + O(t\sqrt{t}),\end{aligned}$$

where

$$\begin{aligned} Q &= \frac{1}{b_1 b_2}\int_D q(x)dx, \quad Q_1(x_1) = \frac{1}{b_2}\int_0^{b_2} q(x_1,x_2)dx_2, \\ Q_2(x_2) &= \frac{1}{b_1}\int_0^{b_1} q(x_1,x_2)dx_1. \end{aligned} \tag{3.10}$$

Also, from (1.12) and (1.13)

$$\int_D k_2(t,x,x)dx = \frac{t}{8\pi}\int_D q(x)^2dx + O(t\sqrt{t}), \qquad \text{as } t \downarrow 0, \tag{3.9b}$$

thus, by substituting in (3.8) we arrive at the following.

THEOREM. *As* $t \downarrow 0$,

$$\begin{aligned}\sum_n (e^{-\mu_n t} - e^{-\nu_n t}) &= -\frac{b_1 b_2 Q}{4\pi} + \frac{(b_1+b_2)Q}{\sqrt{4\pi}}\sqrt{t} + \frac{b_1[Q_2(0)+Q_2(b_2)] + b_2[Q_1(0)+Q_1(b_1)]}{4\sqrt{4\pi}}\sqrt{t} \\ &\quad - \frac{q(0,0)+q(b_1,0)+q(0,b_2)+q(b_1,b_2)}{16}t + \frac{t}{8\pi}\int_D q(x)^2dx + O(t\sqrt{t}),\end{aligned}$$

where the Qs are given by (3.10).

Remark. Suppose that $q(x_1+b_1,x_2) = q(x_1,x_2+b_2) = q(x_1,x_2)$, i.e., q is periodic with period D. Then the theorem implies that q can be recovered from the family of Dirichlet spectra $\{\mu_n(\xi)\}_{n=1}^{\infty}$ of L_ξ, $\xi \in D$, where

$$L_\xi u(x) = -\Delta u(x) + q(x+\xi)u(x).$$

In the one-dimensional case there are "evolution" equations (in ξ) for the $\mu_n(\xi)$'s. Here this does not seem to be the case.

If in (3.10)

$$Q_1(x_1) \equiv Q_2(x_2) \equiv Q = 0 \tag{3.11}$$

(which is not really a strong assumption on q, since $q(x_1,x_2) = \tilde{q}(x_1,x_2) + Q_1(x_1) + Q_2(x_2) - Q$, where $\tilde{q}$ satisfies this assumption or, if we consider the Fourier expansion of q in D, the assumption means that there are no terms in this double series which depend only on x_1 or only on x_2), then the theorem implies

$$\lim_{t\downarrow 0}\frac{1}{t}\sum_n (e^{-\mu_n t} - e^{-\nu_n t}) = -\frac{q(0,0)+q(b_1,0)+q(0,b_2)+q(b_1,b_2)}{16} + \frac{1}{8\pi}\int_D q(x)^2dx, \tag{3.12}$$

but here we cannot pass the limit inside the sum in order to get the complete analog of (1.9), because the asymptotics of $\mu_n - \nu_n$ look messier than in the one-dimensional case, although formula (3.12) suggests (see also [F] and [F-K-T]) that there we can expect better than (3.3).

Before closing this section we want to make a final observation. Assume that (3.11) holds and, for convenience, let the spectrum of L be strictly positive, namely let

$$\mu_1 > 0$$

(otherwise we just need to multiply everything below by e^{-tc}, where c is a constant such that $c + \mu_1 > 0$). Then, if we set

$$\tilde{k}(t,x,y) = k(t,x,y) - p(t,x,y),$$

we have the long-time estimate

$$\tilde{k}(t,x,y) = O(e^{-t(\mu_1 \wedge \nu_1)}), \quad \text{as } t \to \infty, \quad \text{uniformly in } x, y. \tag{3.13}$$

Of course, as we have already seen

$$\sum_n (e^{-\mu_n t} - e^{-\nu_n t}) = \int_D \tilde{k}(t,x,x)dx.$$

Let $\beta > 0$. If we replace t by t^β in the above formula, then divide by t^β and finally integrate with respect to t from 0 to ∞, we get

$$\int_0^\infty \frac{1}{t^\beta}\left[\sum_n (e^{-\mu_n t^\beta} - e^{-\nu_n t^\beta})\right] dt = \int_0^\infty \frac{1}{t^\beta}\left[\int_D \tilde{k}(t^\beta,x,x)dx\right] dt. \tag{3.14}$$

The right-hand side of the above equation is well defined (i.e., converges) for all $\beta > 0$ because of (3.12) and (3.13). To understand a little better the left-hand side, observe that, for $a, b > 0$,

$$\int_0^\infty \frac{e^{-at^\beta} - e^{-bt^\beta}}{t^\beta} dt = \begin{cases} \frac{\Gamma(1/\beta)}{\beta - 1}[b^{1-1/\beta} - a^{1-1/\beta}], & \text{if } \beta \neq 1; \\ \ln b - \ln a, & \text{if } \beta = 1. \end{cases} \tag{3.15}$$

Next we notice that (3.2b) and (3.3) imply (even without (3.11))

$$\sum_n |\mu_n^{-\epsilon} - \nu_n^{-\epsilon}| < \infty \quad \text{for every } \epsilon > 0$$

and therefore, if $0 < \beta < 1$, we can interchange summation and integral in the left-hand side of (3.14) and then use (3.15a) to obtain

$$\begin{aligned} \operatorname{tr}(L^{1-1/\beta} - L_0^{1-1/\beta}) &= \frac{\Gamma(1/\beta)}{\beta - 1} \sum_n [\nu_n^{1-1/\beta} - \mu_n^{1-1/\beta}] \\ &= \int_0^\infty \frac{1}{t^\beta}\left[\int_D \tilde{k}(t^\beta,x,x)dx\right] dt. \end{aligned} \tag{3.16}$$

The question is whether (3.16) is true for any $\beta \geq 1$. The hope that some result of this kind exists comes from the fact that (as we have already pointed out) the right-hand side of (3.16) makes sense for all $\beta > 0$. In fact we can even let $\beta \to \infty$ in the right-hand side of (3.16)

$$\begin{aligned} &\lim_{\beta\to\infty} \int_0^\infty \frac{1}{t^\beta}\left[\int_D \tilde{k}(t^\beta,x,x)dx\right] dt \\ &\quad = \lim_{\beta\to\infty} \int_0^1 \frac{1}{t^\beta}\left[\int_D \tilde{k}(t^\beta,x,x)dx\right] dt + \lim_{\beta\to\infty} \int_1^\infty \frac{1}{t^\beta}\left[\int_D \tilde{k}(t^\beta,x,x)dx\right] dt \\ &\quad = -\frac{q(0,0) + q(b_1,0) + q(0,b_2) + q(b_1,b_2)}{16} + \frac{1}{8\pi}\int_D q(x)^2 dx, \end{aligned}$$

where the first limit is computed by (3.12) and dominated convergence whereas the second limit is 0 by (3.13).

4. Higher-order Schrödinger operators I. We call the operator

$$L = (-\Delta)^m + q \tag{4.1}$$

an *m*th-*order Schrödinger operator.* Such operators appear in many engineering models, for example, in the study of vibrating plates or hydraulic flow, to name a few.

To construct the heat kernel of L (namely the integral kernel of the operator e^{-tL}), we first consider the projection operators E_λ associated to the Laplacian $-\Delta$, acting on $L^2(R^d)$. It is well known (see [S]) that these projections are integral operators. Let $e_d(x, y; \lambda)$ be the integral kernel of E_λ. Since

$$\int_0^\infty e^{-t\lambda} d_\lambda e_d(x, y; \lambda) = \frac{1}{(4\pi t)^{d/2}} \exp\left(-\frac{|x-y|^2}{4t}\right), \tag{4.2}$$

the tables for inverse Laplace transforms give

(4.3)

$$e_d(x, y; \lambda) = \frac{\lambda^{d/4}}{(2\pi|x-y|)^{d/2}} J_{d/2}\big(|x-y|\sqrt{\lambda}\big), \qquad e_d(x, x; \lambda) = \frac{\lambda^{d/2}}{(4\pi)^{d/2}\Gamma[(d/2)+1]},$$

where

$$J_{d/2}(z) = (z/2)^{d/2} \sum_{k=0}^{\infty} \frac{(-z^2/4)^k}{k!\Gamma[k + (d/2) + 1]}$$

is the Bessel function of order $d/2$. Notice that, if d is odd, $J_{d/2}(z)$ is an elementary function. For example,

$$J_{1/2}(z) = \sqrt{\frac{2}{\pi}} \frac{\sin z}{\sqrt{z}}$$

and therefore

$$e_1(x, y; \lambda) = \frac{1}{\pi} \frac{\sin\big(|x-y|\sqrt{\lambda}\big)}{|x-y|}. \tag{4.3′}$$

We also notice that, for any fixed $\lambda > 0$ (and d), $e_d(x, y; \lambda) = f(|x-y|)$, where f is an even entire function of order $1/2$.

In the spirit of the previous sections we set

$$L_0 = (-\Delta)^m. \tag{4.1′}$$

The heat kernel of L_0 in $R|d$ is given by

$$H_d^m(t, x, y) = h_d^m(t, |x-y|) = \int_0^\infty e^{-t\lambda^m} d_\lambda e_d(x, y; \lambda), \tag{4.4}$$

but now $H_d^m(t, x, y) \neq H_1^m(t, x_1, y_1) \dots H_1^m(t, x_d, y_d)$, if $m > 1$. Observe that $h_d^m(t, r)$ is even in r. From the asymptotics of the Bessel functions for a large argument we can conclude that, if $x \neq y$ then $H_d^m(t, x, y) \to 0$ as $t \downarrow 0$, but, if $x = y$, then (4.3) gives

$$\begin{aligned} H_d^m(t, x, x) &= \frac{1}{(4\pi)^{d/2}\Gamma(d/2)} \int_0^\infty e^{-t\lambda^m} \lambda^{(d-2)/2} d\lambda \\ &= \frac{\Gamma(d/2m)}{m(4\pi)^{d/2}\Gamma(d/2)} \frac{1}{t^{(d/2m)}} = C_d^m \frac{1}{t^{(d/2m)}}, \end{aligned} \tag{4.4′}$$

which blows up when $t \downarrow 0$ as expected, since it is the kernel of a semigroup.

Remark. Equations (4.4) and (4.3) imply that

$$H_d^m(t,x,y) = \frac{1}{t^{d/2m}} f_d^m\left(\frac{|x-y|}{t^{1/2m}}\right),$$

where $f_d^m(r)$ is even, entire and, for real r, it is in the Schwartz class, as it follows from Lemma 4.1 below. Therefore,

$$\int_{R^d} |H_d^m(t,x,y)|dy = \int_{R^d} \left| f_d^m\left(\sqrt{y_1^2 + \cdots + y_d^2}\right)\right| dy < \infty.$$

The fact that H_d^m is a heat kernel implies that f_d^m must satisfy the equation

$$(-1)^m \Delta^m f_d^m(r) = \frac{r}{2m}\frac{d}{dr} f_d^m(r) + \frac{d}{2m} f_d^m(r),$$

Δ being the radial Laplacian in R^d, i.e.,

$$\Delta u(r) = u''(r) + \frac{d-1}{r} u'(r).$$

Furthermore, since $f_d^m(r) = H_d^m(1,0,y)$, with $r = |y|$, we obtain from (4.4) (and (4.6)) the integral representation (which is in fact a Hankel transorm)

$$f_d^m(r) = \frac{1}{(2\pi)^{d/2} r^{(d-1)/2}} \int_0^\infty e^{-x^{2m}} x^{(d-1)/2} J_{(d-2)/2}(rx)\sqrt{rx}\,dx, \quad d \geq 2$$

and

$$f_1^m(r) = \frac{1}{\pi}\int_0^\infty e^{-x^{2m}} \cos(rx)dx.$$

Using steepest descents in the integral representation for f_d^m (see [B-O, Chap. 6, §6]) or, better, the method of dominant balance (see [B-O, Chap. 3, §4]—notice that f_d^m is in the Schwartz class) in the differential equation that f_d^m satisfies, we obtain

$$f_d^m(r) \sim K \exp\left(-r^{2m/2m-1} c\beta\right) \cos\left(r^{2m/2m-1} c\alpha\right), \quad \text{as } r \to \infty,$$

where K is a constant and

$$c = \frac{d(2m-1)}{(2m)^{2m/2m-1}}, \quad \alpha = \cos\left(\frac{\pi}{4m-2}\right), \quad \beta = \sin\left(\frac{\pi}{4m-2}\right).$$

Observe that, unless $m = 1$, $f_d^m(r)$ takes both positive and negative values because of the appearance of the cosine. Thus $H_d^m(t,x,y)$ cannot define a probability transition density, but it still defines a (finite) measure on the functions with domain $[0,\infty)$ and range R^d, similar to the Wiener measure (except for the nonnegativity and the almost sure continuity of the paths). For more details, especially for the case $d = 1$, see [H].

To continue we need the asymptotics of $h_d^m(t,r)$ of (4.4), as $r = |x-y| \to \infty$.

LEMMA 4.1. *As* $r \to \infty$

$$\frac{d^l}{dr^l} h_d^m(t,r) = o(r^{-k}), \quad \textit{for any } k > 0,\ l \geq 0 \tag{4.5}$$

(*i.e.*, $h_d^m(t,\cdot)$ *is in the Schwartz class* $\mathcal{S}(R)$).

Proof. We define

$$g_1(\lambda) = e_d(x,y;\lambda), \qquad g_{n+1}(\lambda) = \int_0^\lambda g_n(\xi)d\xi, \quad n \geq 1.$$

Thus, by applying simple integration by parts in (4.2) we obtain

$$\int_0^\infty e^{-t\lambda} g_n(\lambda)d\lambda = \frac{1}{t^n(4\pi t)^{d/2}} \exp\left(-\frac{|x-y|^2}{4t}\right),$$

hence the tables for inverse Laplace transforms imply

$$g_n(\lambda) = \frac{2^{n-1}}{(2\pi)^{d/2}} \frac{\lambda^{\nu/2}}{|x-y|^\nu} J_\nu\big(|x-y|\sqrt{\lambda}\big),$$

where $\nu = n + (d/2) - 1$. Therefore, if we apply integration by parts in the integral of (4.4) n times, we will get

$$h_d^m(t,r) = \frac{C_n}{r^\nu} \int_0^\infty e^{-t\lambda^m} p(\lambda) J_\nu\big(r\sqrt{\lambda}\big)d\lambda,$$

where C_n is a constant that depends only on n, $p(\lambda)$ grows polynomially in λ, and ν is as above. □

Remark. We also have from (4.2) that

$$\frac{de_d}{d\lambda}(x,y;\lambda) = \frac{1}{2(2\pi)^{d/2}} \frac{\lambda^{(d-2)/4}}{|x-y|^{(d-2)/2}} J_{(d-2)/2}\big(|x-y|\sqrt{\lambda}\big), \quad \text{if } d \geq 2 \tag{4.6}$$

and, if $d = 1$,

$$\frac{de_1}{d\lambda}(x,y;\lambda) = \frac{1}{2\pi} \frac{\cos\big(|x-y|\sqrt{\lambda}\big)}{\sqrt{\lambda}}. \tag{4.6′}$$

For the remaining of this section we will restrict ourselves to the case $d = 1$.

The heat kernel of L_0 in $L^2(0,b)$ with ("generalized") Dirichlet boundary conditions (namely, $u(0) = u^{(2)}(0) = \cdots = u^{2(m-1)}(0) = 0$ and $u(b) = u^{(2)}(b) = \cdots = u^{2(m-1)}(b) = 0$), can be constructed from $h_1^m(t,|x-y|)$ by the method of images as in (1.10), thanks to the previous lemma.

$$p_b^m(t,x,y) = \sum_{k\in Z} p_\infty^m(t,x,y+2kb), \qquad 0 \leq x,y \leq b, \tag{4.7a}$$

where from (4.4) and (4.6′) we get

$$\begin{aligned} h_1^m(t,|x-y|) &= \frac{1}{2\pi} \int_0^\infty e^{-t\lambda^m} \frac{\cos\big(|x-y|\sqrt{\lambda}\big)}{\sqrt{\lambda}} d\lambda \\ &= \frac{1}{\pi} \int_0^\infty e^{-ts^{2m}} \cos\big(|x-y|s\big)ds \end{aligned} \tag{4.7b}$$

and

$$p_\infty^m(t,x,y) = h_1^m(t,|x-y|) - h_1^m(t,|x+y|). \tag{4.7c}$$

Then the heat kernel of L in $(0,b)$, with the same boundary conditions is (as in the previous sections)

$$k(t,x,y) = \sum_{n=0}^{\infty} k_n(t,x,y), \tag{4.8a}$$

where

$$k_0(t,x,y) = p_b^m(t,x,y) \tag{4.8b}$$

and, for $n \geq 1$,

$$k_n(t,x,y) = -\int_0^t \int_0^b p_b^m(s,x,z)q(z)k_{n-1}(t-s,z,y)dzds. \tag{4.8c}$$

In fact there is a Feynman–Kac type of expansion for $k(t,x,y)$ (see [H]).

In our regular notation, let $\mu_1, \mu_2, \ldots, \mu_n, \ldots$ be the eigenvalues of L on $(0,b)$ with corresponding (orthonormal) eigenfunctions $\phi_1, \phi_2, \ldots, \phi_n, \ldots$. The corresponding quantities for L_0 are $\nu_1, \nu_2, \ldots, \nu_n, \ldots$ and $\psi_1, \psi_2, \ldots, \psi_n, \ldots$. Of course

$$\nu_n = \left(\frac{\pi n}{b}\right)^{2m} \quad \text{and} \quad \psi_n(x) = \sqrt{\frac{2}{b}} \sin \frac{\pi n x}{b}, \qquad n = 1,2,\ldots \tag{4.9}$$

and

$$|\mu_n - \nu_n| \leq \|q\|_\infty. \tag{4.9'}$$

Then, in the Lemma of §1 we have $H(s) = L_0 + sq$ and so

$$\lambda_n(0) = \nu_n, \quad \lambda_n(1) = \mu_n, \quad \sup_{0 \leq s \leq 1} |\lambda_n''(s)| = O(n^{1-2m}),$$

by (1.7), (4.9), (4.9'), and the definition of $R_n(s)$ given after formula (1.7). Finally, from (1.6) we get

$$\lambda_n'(0) = \frac{2}{b}\int_0^b q(x) \sin^2 \frac{\pi n x}{b} dx = -\frac{1}{b}\int_0^b q(x) \cos \frac{2\pi n x}{b} dx,$$

where we have made our standard assumption, namely

$$\int_0^b q(x)dx = 0. \tag{4.10}$$

Thus, (1.8) and the Riemann–Lebesgue lemma imply

$$\mu_n - \nu_n = O(n^{-k \wedge (2m-1)}), \tag{4.11}$$

where k is such that $q \in C^k[0,b]$. If $m > 1$, (4.11) is quite satisfying, although we believe it can be improved.

Now we want to derive the trace formula for L.

For any $m \geq 2$, (4.8) and (4.7b) easily imply

(4.12)
$$k_0(t,x,y) = O(t^{-1/4}), \quad k_1(t,x,y) = O(t^{3/4}), \quad k_2(t,x,y) = O(t^{7/4}), \quad \text{as } t \downarrow 0,$$

uniformly in x, y. These are very crude estimates but we do not need any better for our analysis. As in §1, we have

$$\operatorname{tr}(e^{-tL} - e^{-tL_0}) = \sum_n (e^{-\mu_n t} - e^{-\nu_n t}) = \int_0^b k_1(t,x,x)dx + O(t^{7/4}).$$

Equation (4.8c) together with Fubini's theorem and the fact that $p_b^m(t,x,y)$ is the kernel of a semigroup give

$$\begin{aligned}\int_0^b k_1(t,x,x)dx &= -\int_0^b \int_0^t \int_0^b p_b^m(s,x,z)q(z)p_b^m(t-s,z,x)dzdsdx \\ &= -t\int_0^b p_b^m(t,z,z)q(z)dz.\end{aligned}$$

Therefore

$$\sum_n (e^{-\mu_n t} - e^{-\nu_n t}) = -t\int_0^b p_b^m(t,z,z)q(z)dz + O(t^{7/4}). \tag{4.13}$$

Now, from (4.7) we have for all $k > 0$, $0 \leq z \leq b$ (as in (1.11))

$$p_b^m(t,z,z) = \frac{C_1^m}{t^{1/2m}} - H_1^m(t,0,2z) - H_1^m(t,0,2b-2z) + o(t^k), \quad \text{as } t \downarrow 0. \tag{4.14}$$

LEMMA 4.2. *For any $f \in C_b(R^d)$ we have*

$$\lim_{t\downarrow 0} \int_{R^d} H_d^m(t,x,y)f(y)dy = f(x)$$

uniformly in x.

Proof. If f is in $L^2(R^d)$, then the statement is true in the L^2 sense, simply because H_d^m is the integral kernel of a semigroup. Furthermore, in the long remark following equation (4.4′) and in Lemma 4.1 right after this remark, we saw some nice estimates for H_d^m. These estimates together with the L^2 convergence immediately imply the statement of the lemma. □

Finally, if we combine (4.13) and (4.14) and then apply Lemma 4.2 and assume (4.10) (namely, that the average of q on $[0,b]$ is zero), we obtain

$$\sum_n (e^{-\mu_n t} - e^{-\nu_n t}) = -t\int_0^b p_b^m(t,z,z)q(z)dz + O(t^{5/4}),$$

for $q \in C^k[0,b]$ $k \geq 2$. Then, because of (4.11) we can divide by t and let $t \downarrow 0$ to conclude

$$\sum_n (\mu_n - \nu_n) = \frac{q(0)+q(b)}{4}, \tag{4.15}$$

by (4.14) and Lemma 4.2.

Remark. Formula (4.15) hints an interesting theoretical implication. It points out that the trace of the difference $[(-d^2/dx^2)^m + q] - (-d^2/dx^2)^m$ is independent of m and, therefore can be thought as the trace of the multiplication operator $(Tu)(x) = q(x)u(x)$. Of course q must be smooth and average-free. The boundary conditions play a role (in case of Neumann or Robin conditions there is a sign change in (4.15)). We believe that there are many things yet to be understood.

5. Higher-order Schrödinger operators II. The diophantine case. In this section we extend the results of §3. To be more precise, we obtain a trace formula and asymptotics of eigenvalues for

$$L = L_0 + q, \quad \text{where } L_0 = (-\Delta)^m$$

acts upon $L^2(D)$, with D being the rectangle $(0, b_1) \times (0, b_2)$ as in §3. It turns out that the asymptotics of the eigenvalues improve as m increases. Intuitively, this means that, as m gets bigger, L becomes a smaller perturbation of L_0.

First, let us decide what are our boundary conditions. The quantity

$$\begin{aligned} p_Q^m(t,x,y) = {} & H_2^m(t,x_1,x_2,y_1,y_2) - H_2^m(t,x_1,x_2,y_1,-y_2) \\ & - H_2^m(t,x_1,x_2,-y_1,y_2) + H_2^m(t,x_1,x_2,-y_1,-y_2), \end{aligned} \tag{5.1a}$$

where $H_2^m(t,x,y) = H_2^m(t,x_1,x_2,y_1,y_2)$ is defined in (4.4), is the heat kernel of L_0 acting upon the first quadrant $Q = \{(x_1,x_2) : x_1, x_2 > 0\}$. The boundary conditions are

$$\frac{\partial^{2j} p_Q^m}{\partial x_1^{2j}}(t,0,x_2,y_1,y_2) = 0 \quad \text{and} \quad \frac{\partial^{2j} p_Q^m}{\partial x_2^{2j}}(t,x_1,0,y_1,y_2) = 0, \qquad j = 0,1\ldots,m-1.$$

This follows from the fact that $e_d(x,y;\lambda)$ and therefore $H_d^m(t,x,y)$ are even and smooth in $|x-y|$, as explained in the beginning of §4. After this simple observation, it is easy to construct the heat kernel $p_D^m(t,x,y)$ of L_0 in $L^2(D)$ with "generalized Dirichlet" boundary conditions, namely vanishing normal derivatives of order $0, 2, \ldots, m-1$ on ∂D, from $H_2^m(t,x,y)$ by using the method of images (separation of variables fails if $m > 1$).

$$p_D^m(t,x,y) = \sum_{k \in Z^2} p_Q^m(t,x,y+2kb), \quad \text{where } b = (b_1,b_2), \tag{5.1b}$$

where the convergence is guaranteed by the long remark after equation (4.4′).

Assuming (3.11), which says that the average of q along each segment parallel to the sides of the rectangle D is 0, we arrive (by the standard heat kernel approach) at a formula very similar to (3.12) thanks to Lemma 4.2, namely

$$\lim_{t \downarrow 0} \frac{1}{t} \sum_n (e^{-t\mu_n} - e^{-t\nu_n}) = -\frac{1}{16}[q(0,0) + q(b_1,0) + q(0,b_2) + q(b_1,b_2)]. \tag{5.2}$$

The most interesting result of this section is that in certain cases we are able to justify the interchange of limit and summation in (5.2). It is a direct consequence of the following proposition.

PROPOSITION. *Let $\omega = b_1^2/b_2^2$ be irrational and such that, for some $\alpha \geq 2$, $c > 0$, the inequality $|\omega - p/q| > cq^{-\alpha}$, where p and q are positive integers, is true for all but finitely many q (in this case ω is called diophantine; in fact, the set of nondiophantine numbers has Lebesgue measure zero). Then there is a constant $A > 0$ such that, for all n sufficiently large, we have $\nu_{n+1} - \nu_n > An^{m-\alpha}$, where ν_n is the nth ("generalized Dirichlet") eigenvalue of $L_0 = (-\Delta)^m$ on $D = (0, b_1) \times (0, b_2)$, namely*

$$\nu_n = \left(\frac{\pi^2 n_1^2}{b_1^2} + \frac{\pi^2 n_2^2}{b_2^2} \right)^m, \qquad n_1, n_2 = 1, 2, 3, \ldots$$

and the labeling is done in the unique way that makes ν_n increasing with n.

Proof. Set

$$\tau_n = \frac{\pi^2 n_1^2}{b_1^2} + \frac{\pi^2 n_2^2}{b_2^2} \quad \text{and} \quad \tau_{n+1} = \frac{\pi^2 k_1^2}{b_1^2} + \frac{\pi^2 k_2^2}{b_2^2}.$$

If n is such that $n_2 = k_2$, then $k_1 = n_1 + 1$ and the theorem is trivially true. Hence, let us assume that $n_2 \neq k_2$ so that

$$\tau_{n+1} - \tau_n = \frac{\pi^2 |n_2^2 - k_2^2|}{b_1^2} \left| \omega - \frac{k_1^2 - n_2^2}{n_2^2 - k_2^2} \right|.$$

Then, our assumption for ω together with (3.2b) imply (since, for fixed q, the equation $n_2^2 - k_2^2 = q$ has finitely many integer solutions)

$$\tau_{n+1} - \tau_n > \frac{\pi^2}{b_1^2} \frac{c}{\max(n_2^2, k_2^2)^{\alpha - 1}} > \frac{C}{n^{\alpha - 1}}, \tag{5.3}$$

where C is a constant. Finally, since

$$\nu_{n+1} - \nu_n = \tau_{n+1}^m - \tau_n^m = (\tau_{n+1} - \tau_n)(\tau_{n+1}^{m-1} + \cdots + \tau_n^{m-1}),$$

the proof is completed by using (5.3) and (3.2b). □

Remark. If ω is algebraic then any $\alpha > 2$ works. This is the famous Thue–Siegel–Roth Theorem. In fact, the set of all reals for which this is not true has measure zero (see [L]).

COROLLARY. *If μ_n is the nth eigenvalue of $L = L_0 + q$, with $q \in C^r(\bar{D})$ satisfying (3.11), and everything else is as in the previous proposition, then there is a constant $c > 0$ such that*

$$|\mu_n - \nu_n| \leq \frac{c}{n^\beta}, \quad \beta = \min(r/2, m - \alpha), \quad \textit{for all } n \textit{ sufficiently large.}$$

Proof. The notation is the same as in the Lemma of §1; namely, we set

$$H(s) = L_0 + sq \quad \text{with spectrum } \{\lambda_n(s)\}_{n=1}^\infty$$

and

$$R_n(s) = [I - P_n(s)][H(s) - \lambda_n(s)I]^{-1},$$

where $P_n(s)$ is the orthogonal projection on the (one-dimensional) eigenspace which corresponds to $\lambda_n(s)$. Thus, because of the previous proposition, if n is large enough then

$$\|R_n(0)\| \leq \frac{c}{n^{m-\alpha}},$$

with c being a constant. The normalized eigenfunction $\psi_n(x)$ of L_0 is given in (3.2a). Then (1.7) implies that

$$|\lambda_n''(0)| \leq \frac{c}{n^{m-\alpha}} \quad \text{for all } n \text{ sufficiently large.}$$

Also, (1.6) and (3.11) imply

$$\begin{aligned}\lambda_n'(0) &= \int_D q(x)\psi_n(x)^2 dx \\ &= \frac{1}{\sqrt{b_1 b_2}} \int_D q(x) \cos\frac{2n_1 x_1}{b_1} \cos\frac{2n_2 x_2}{b_2} dx = O(\max(n_1, n_2)^{-r}) = O(n^{-r/2}),\end{aligned}$$

as $n \to \infty$ and, therefore, the corollary follows from (1.8). □

Using this corollary we can conclude that, if $r > 2$ and $m - \alpha > 1$ (in particular, if $(b_1/b_2)^2$ is an algebraic irrational and $m \geq 4$), we can bring the limit in (5.2) inside the summation and deduce

$$\sum_n (\mu_n - \nu_n) = \frac{1}{16}[q(0,0) + q(b_1,0) + q(0,b_2) + q(b_1,b_2)]. \tag{5.4}$$

The remark at the end of the previous section applies here as well.

6. Final thoughts (epilogue). One of our main tasks in the previous sections was to find short-time asymptotics for the trace

$$\operatorname{tr}\left(e^{-tL} - e^{-tL_0}\right),$$

where L and L_0 were certain self-adjoint differential operators, L being a perturbation of L, namely $L = L_0 + q$. These asymptotics involved the values of q on the boundary of the domain on which these operators were acting. On the other hand, this trace can be written as a sum of the differences of the eigenvalues $\{e^{t\mu_n}\}$ and $\{e^{-t\nu_n}\}$ of e^{-tL} and e^{-tL_0}, respectively. Then we could take the limits as $t \downarrow 0$. In some cases we were able to interchange limit and trace (i.e., summation) and thus arrive to a formula for

$$\sum_n (\mu_n - \nu_n),$$

which, in some sense, is the trace of $L - L_0$. In the other cases the problem remains open, namely, can we (at least in some "weak" sense) interchange these limiting procedures?

The approach we followed can be applied to more general situations. Here is a final example.

Let L_0 be the operator $-\Delta$ acting upon the rectangle $D = (0, b_1) \times (0, b_2)$ with Neumann boundary conditions (i.e., the normal derivative on ∂D is 0) and L be again the Laplacian operator acting upon D, but this time the boundary condition is

$$\frac{\partial u}{\partial n} + \rho u = 0 \quad \text{on } \partial D,$$

where n is the outward unit normal vector on ∂D and ρ is a smooth function on ∂D *with zero average on each segment of the perimeter of* D. The heat kernel of L_0 is

$$\bar{p}_D(t, x, y) = \bar{p}_{b_1}(t, x_1, y_1)\bar{p}_{b_2}(t, x_2, y_2),$$

where

$$\bar{p}_b(t,x,y) = \sum_{k\in Z} \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{|x-y+2kb|^2}{4t}\right) + \frac{1}{\sqrt{4\pi t}} \exp\left(-\frac{|x+y+2kb|^2}{4t}\right)$$

(p_b is the Neuman heat kernel of $-d^2/dx^2$ acting on $(0,b)$). The heat kernel $k(t,x,y)$ of L is given in [P]. Using the same analysis as in the previous cases we arrive at the formula

$$\lim_{t\downarrow 0} \frac{1}{\sqrt{t}} \sum_n (e^{-t\mu_n} - e^{-t\nu_n})$$

$$= \lim_{t\downarrow 0} \sqrt{t} \int_{\partial D} p_D^m(t,z,z)\rho(z)dz = -\frac{1}{4\sqrt{\pi}}[\rho(0,0) + \rho(b_1,0) + \rho(0,b_2) + \rho(b_1,b_2)].$$

Here, of course, there is no chance that we can interchange limit and summation unless $\rho(0,0) + \rho(b_1,0) + \rho(0,b_2) + \rho(b_1,b_2) = 0$.

Acknowledgments. We thank Stephanos Venakides for initiating the whole inquiry and for many helpful discussions. Also we thank Peter Kuchment for asking instructive questions, Walter Craig for showing to us A. Douady's insightful lecture on the trace formula, and finally Christopher Jones for helpful suggestions that made the paper more readable.

NECESSARY AND SUFFICIENT CONDITIONS FOR MEAN CONVERGENCE OF LAGRANGE INTERPOLATION FOR FREUD WEIGHTS *

D. S. LUBINSKY† AND D. M. MATJILA‡

Abstract. Let $W_\beta(x) := \exp(-\frac{1}{2}|x|^\beta), x \in \mathbb{R}, \beta > 1$. Given $f : \mathbb{R} \to \mathbb{R}$, let $L_n[f](x)$ denote the Lagrange interpolation polynomial to f at the zeros of the orthonormal polynomial of degree n for the weight W_β^2. Let $1 < p < \infty, \Delta \in \mathbb{R}, \alpha > 0$, and $\hat{\alpha} := \min\{1, \alpha\}$. Moreover, let

$$\tau = \tau(p) := 1/p - \hat{\alpha} + \begin{cases} 0, & p \le 4, \\ (\beta/6)(1 - 4/p), & p > 4. \end{cases}$$

It is shown that for

$$\lim_{n\to\infty} \| (f(x) - L_n[f](x)) W(x)(1 + |x|)^{-\Delta} \|_{L_p(\mathbb{R})} = 0, \tag{1}$$

to hold for every continuous function $f : \mathbb{R} \to \mathbb{R}$ satisfying

$$\lim_{|x|\to\infty} |f(x)| W(x)(1 + |x|)^\alpha = 0, \tag{2}$$

it is necessary and sufficient that

$$\Delta > \tau \quad \text{if } 1 < p \le 4;$$
$$\Delta > \tau \quad \text{if } p > 4 \quad \text{and} \quad \alpha = 1;$$
$$\Delta \ge \tau \quad \text{if } p > 4 \quad \text{and} \quad \alpha \ne 1.$$

Moreover, it is shown that (1) holds for every $1 < p < \infty$ and every continuous function f satisfying (2) if and only if $\Delta \ge -\hat{\alpha} + \max\{1, \beta/6\}$. These are special cases of results for more general Freud weights.

1. Introduction and results.

The convergence of Lagrange interpolation at zeros of orthogonal polynomials is a classical and widely studied subject. Let us recall the setting. If $d\alpha$ is a finite positive Borel measure on a finite or infinite interval (a, b), with support containing infinitely many points, and with all power moments

$$\int_a^b x^j \, d\alpha(x), j = 0, 1, 2, \ldots,$$

* Received by the editors September 14, 1992; accepted for publication (in revised form) June 9, 1993.

finite, then we may define orthonormal polynomials $p_n(d\alpha, x)$ (or simply $p_n(x)), n = 0, 1, 2, \ldots$, which satisfy

$$\int_a^b p_n(d\alpha, x)p_m(d\alpha, x)\, d\alpha(x) = \delta_{mn}, \qquad m, n = 0, 1, 2, \ldots.$$

We denote the zeros of $p_n(d\alpha, x)$ by

$$a < x_{nn} < x_{n-1,n} < \cdots < x_{2n} < x_{1n} < b.$$

For functions $f : (a, b) \to \mathbb{R}$, we denote the *Lagrange interpolation polynomial* of degree $\leq n - 1$ to f at the zeros of $p_n(d\alpha, x)$ by $L_n[f](x)$, so that

$$L_n[f](x_{jn}) = f(x_{jn}), \qquad 1 \leq j \leq n. \tag{1.1}$$

The classical Erdös–Turan theorem asserts that if (a, b) is a finite interval, then for each measurable function $f : (a, b) \to \mathbb{R}$ for which

$$\int_a^b f^2\, d\alpha < \infty,$$

we have L_2 convergence:

$$\lim_{n\to\infty} \int_a^b (f - L_n[f])^2\, d\alpha = 0.$$

The extension of the Erdös–Turan theorem to infinite intervals, is due primarily to Shohat; see [3, Chap. III]. The more difficult extension of the Erdös–Turan theorem on a finite interval (a, b) to the $L_p, p \neq 2$ case has attracted many authors and inspired research into fundamental properties of orthogonal polynomials. The results obtained are inherently more special, and necessarily require more knowledge of the orthonormal polynomials than in the L_2 case. We cannot hope to survey this topic here; the reader may find results and references in [12], [14], and [15].

In this paper, we concentrate on weights on the whole real line. We shall deal with "Freud weights," that is, weights of the form

$$d\alpha(x) = W^2(x)dx,$$

where $W : \mathbb{R} \to \mathbb{R}$ is even and of sufficiently smooth and regular decay at infinity. (Note that our weight is of the form W^2, *not* W: This simplifies formulation of results.) Here we shall denote $p_n(d\alpha, x)$ by $p_n(W^2, x), n = 0, 1, 2, \ldots$. Our results apply in particular to

$$W(x) = W_\beta(x) := \exp(-\tfrac{1}{2}|x|^\beta), \qquad x \in \mathbb{R}, \quad \beta > 1. \tag{1.2}$$

Many of our methods are taken from a fundamental paper of Nevai [13], which dealt with the Hermite weight, the case $\beta = 2$ in (1.2). Nevai provided fairly close necessary and sufficient conditions for L_p convergence of the Lagrange interpolation polynomials, in terms of the decay of the interpolated function. Nevai's methods pointed the way of subsequent research: One of Nevai's students, Bonan, obtained "sharp" necessary and sufficient conditions for the generalized Hermite weights $|x|^\beta \exp(-x^2)$,

in an unpublished Ph.D. thesis [1]. His decay condition on the interpolated function was, however, a little more restrictive than Nevai's.

Mean convergence of Lagrange interpolation is dependent on suitable estimates for associated orthonormal polynomials, and so it is not surprising that Nevai and Bonan at the time concentrated on the Hermite weight, for which the relevant estimates and Plancherel type asymptotics were available. By assuming bounds on orthonormal polynomials that were known to be true for the weights W_β^2, β a positive even integer, Knopfmacher and Lubinsky treated fairly general Freud weights $W^2 = e^{-2Q}$ [4]. For the L_p norm with $1 < p < 2$, the results there sharpened and generalised those in [1], and functions with integrable singularities at finitely many points were also discussed, which extended L_2 work in [8].

The possibility of treating weights such as $W_\beta^2, \beta > 1$ is provided by work of Levin and Lubinsky [5], where the correct bounds were obtained for orthonormal polynomials over $\mathbb{R}$ for a large class of weights. We also use the L_p norms of orthonormal polynomials, and these were estimated above and below in [7], using the results of [5].

The following is an important special case of our results.

THEOREM 1.1. *Let $\beta > 1, 1 < p < \infty, \Delta \in \mathbb{R}, \alpha > 0$, and*

$$\hat{\alpha} := \min\{1, \alpha\}. \tag{1.3}$$

Let

$$\tau = \tau(p) := \begin{cases} \frac{1}{p} - \hat{\alpha}, & p \le 4, \\ \frac{1}{p} - \hat{\alpha} + \frac{\beta}{6}\left(1 - \frac{4}{p}\right), & p > 4. \end{cases} \tag{1.4}$$

Denote the Lagrange interpolation polynomials at the zeros of $p_n(W_\beta^2, \cdot)$ by $L_n[\cdot], n \ge 1$, where W_β is given by (1.2). *Then for*

$$\lim_{n\to\infty} \|(f(x) - L_n[f](x))W_\beta(x)(1 + |x|)^{-\Delta}\|_{L_p(\mathbb{R})} = 0, \tag{1.5}$$

to hold for every continuous function $f : \mathbb{R} \to \mathbb{R}$ satisfying

$$\lim_{|x|\to\infty} |f(x)|W_\beta(x)(1 + |x|)^\alpha = 0, \tag{1.6}$$

it is necessary and sufficient that

$$\begin{aligned} &\Delta > \tau \quad \text{if} \quad 1 < p \le 4; \\ &\Delta > \tau \quad \text{if} \quad p > 4 \quad \text{and} \quad \alpha = 1; \\ &\Delta \ge \tau \quad \text{if} \quad p > 4 \quad \text{and} \quad \alpha \ne 1. \end{aligned}$$

Remarks. (a) In the work of Bonan [1], the Hermite weight ($\beta = 2$) was treated, and it was assumed that $\alpha = 2$. In this special case, our sufficient condition is identical to Bonan's, and our necessary condition is also identical if we take the $v(x) = W_\beta(x)(1 + |x|)^{-\Delta}$ in Bonan's work.

(b) The sufficient condition also guarantees the convergence (1.5) if f is not necessarily continuous but is bounded and Riemann integrable on each finite interval and satisfies (1.6). However, we shall not prove this, as it is away from the focus of this paper, which is sharp conditions relating α and Δ. The reader may refer to Bonan's thesis [1] or Knopfmacher and Lubinsky [4].

(c) Results such as the previous ones are useful in investigating convergence of product integration rules (cf. [4]).

(d) When we consider convergence simultaneously for all $1 < p < \infty$, the above result simplifies substantially.

COROLLARY 1.2. *Let $\beta > 1, \Delta \in \mathbb{R}, \alpha > 0$, and $\hat{\alpha} := \min\{1, \alpha\}$. For the convergence* (1.5) *to hold for every $1 < p < \infty$ and every continuous function $f : \mathbb{R} \to \mathbb{R}$ satisfying* (1.6), *it is necessary and sufficient that*

$$\Delta \geq -\hat{\alpha} + \max\left\{1, \frac{\beta}{6}\right\}. \tag{1.7}$$

To formulate our result for more general weights, we need the Mhaskar–Rahmanov–Saff number a_u [9], [10]. Let $W := e^{-Q}$, where $Q : \mathbb{R} \to \mathbb{R}$ is even, continuous, and $xQ'(x)$ is positive and increasing in $(0, \infty)$, with limits 0 and ∞ at 0 and ∞, respectively. For $u > 0$, the uth Mhaskar–Rahmanov–Saff number a_u is the positive root of the equation

$$u = \frac{2}{\pi} \int_0^1 a_u t Q'(a_u t)\, dt/\sqrt{1 - t^2}. \tag{1.8}$$

Under the conditions on Q below, which guarantee that $Q(s)$ and $Q'(s)$ increase strictly in $(0, \infty)$, a_u is uniquely defined and increases with u. It grows roughly like $Q^{[-1]}(u)$, where $Q^{[-1]}$ denotes the inverse of Q on $(0, \infty)$. Its significance lies partly in the identity

$$\|PW\|_{L_\infty(\mathbb{R})} = \|PW\|_{L_\infty[-a_n, a_n]}, \tag{1.9}$$

which holds for polynomials P of degree $\leq n$ [10]. For $W = W_\beta$, one sees that for $u > 0$,

$$a_u = Cu^{1/\beta},$$

where C depends only on β.

Theorem 1.1 is a special case of the following theorem.

THEOREM 1.3. *Let $W := e^{-Q}$, where $Q : \mathbb{R} \to \mathbb{R}$ is even and continuous in $\mathbb{R}$, Q'' is continuous in $(0, \infty)$, and $Q' > 0$ in $(0, \infty)$, while for some $A, B > 1$,*

$$A \leq \frac{d}{dx}(xQ'(x))/Q'(x) \leq B, \qquad x \in (0, \infty). \tag{1.10}$$

Let $1 < p < \infty, \Delta \in \mathbb{R}, \alpha > 0$, and $\hat{\alpha}$ be given by (1.3). *Denote the Lagrange interpolation polynomials at the zeros of $p_n(W^2, \cdot)$ by $L_n[\cdot], n \geq 1$. Then for*

$$\lim_{n \to \infty} \|(f(x) - L_n[f](x))W(x)(1 + |x|)^{-\Delta}\|_{L_p(\mathbb{R})} = 0, \tag{1.11}$$

to hold for every continuous function $f : \mathbb{R} \to \mathbb{R}$ satisfying

$$\lim_{|x| \to \infty} |f(x)|W(x)(1 + |x|)^{\alpha} = 0, \tag{1.12}$$

if $p \leq 4$, it is necessary and sufficient that

$$\Delta > -\hat{\alpha} + \frac{1}{p}; \tag{1.13}$$

and if $p > 4$ *and* $\alpha \neq 1$, *it is necessary and sufficient that*

$$a_n^{1/p-(\hat{\alpha}+\Delta)} n^{(1/6)(1-4/p)} = O(1), \quad n \to \infty; \tag{1.14}$$

and if $p > 4$ *and* $\alpha = 1$, *it is necessary and sufficient that*

$$a_n^{1/p-(\hat{\alpha}+\Delta)} n^{(1/6)(1-4/p)} = O\left(\frac{1}{\log n}\right), \quad n \to \infty. \tag{1.15}$$

The paper is organised as follows: In §2, we present some technical lemmas, such as estimates on orthonormal polynomials and their zeros, and we use these to prove three quadrature sum estimates, including a very technical one (Lemma 2.7), which is essentially a bound on part of the Lebesgue function of Lagrange interpolation.

In §3, we prove the results. The proof of the sufficiency part of Theorem 1.3 involves expressing the given function f, for a given n, as a sum of functions, one vanishing outside $[-a_n/4, a_n/4]$ and another vanishing inside $(-a_n/4, a_n/4)$ and approximating f by a suitable polynomial. This is achieved in Lemmas 3.1–3.4. The proof of the necessary conditions involves the uniform boundedness principle applied to carefully chosen spaces, and interpolation of carefully chosen functions.

2. Technical lemmas. We first need more notation. Throughout, $C, C_1, C_2, \ldots$, denote positive constants independent of n, x, and polynomials of degree n. We shall write $C \neq C(\lambda)$ to indicate that C does not depend on a parameter λ. The same symbol does not necessarily represent the same constant in different occurrences. We use $\sim$ in the following sense: If $\{b_n\}_{n=0}^{\infty}$ and $\{c_n\}_{n=0}^{\infty}$ are sequences of nonzero real numbers, we write

$$b_n \sim c_n,$$

if there exist $C_1, C_2 > 0$ independent of n, such that

$$C_1 \leq b_n/c_n \leq C_2, \qquad n \geq 1.$$

Similar notation is used for sequences of functions. We frequently use $f^n(x)$ to denote $(f(x))^n$, even for $n = -1$. $\mathcal{P}_n$ denotes the polynomials of degree at most n.

If $W^2 : \mathbb{R} \to [0, \infty)$ is a weight, its nth *Christoffel function* is

$$\lambda_n(x) := \lambda_n(W^2, x) := \inf_{P \in \mathcal{P}_{n-1}} \int_{-\infty}^{\infty} (PW)^2(t)\, dt / P^2(x). \tag{2.1}$$

It is well known [14] that

$$\lambda_n(x) = 1 \Big/ \sum_{j=0}^{n-1} p_j^2(x).$$

We also define the *Christoffel numbers*

$$\lambda_{jn} := \lambda_n(x_{jn}), \qquad 1 \leq j \leq n.$$

The leading coefficient of $p_n(x)$ is denoted by γ_n, so that

$$p_n(x) = \gamma_n x^n + \cdots.$$

The Lagrange interpolation polynomial $L_n[f]$ admits the representation

$$L_n[f](x) = \sum_{j=1}^{n} f(x_{jn})\ell_{jn}(x),$$

where the *fundamental polynomials* ℓ_{jn} in turn admit the representation [12, p. 6] or [3, p. 23]

$$\ell_{jn}(x) = \lambda_{jn}\frac{\gamma_{n-1}}{\gamma_n}p_{n-1}(x_{jn})\frac{p_n(x)}{x - x_{jn}}. \tag{2.2}$$

Mean convergence of Lagrange interpolation is closely connected to bounds on orthogonal polynomials and related estimates; accordingly we recall some results from [5]. Throughout this section, we assume that W is as in Theorem 1.3.

THEOREM 2.1. (a) *For $n \geq 1$ and $|x| \leq a_n$,*

$$\lambda_n(W^2, x) \sim \frac{a_n}{n}W^2(x)\max\left\{n^{-2/3}, 1 - \frac{|x|}{a_n}\right\}^{-1/2}. \tag{2.3}$$

Moreover, we can replace $\sim$ by $\geq C \times$ for all $x \in \mathbb{R}$.

(b) *For $n \geq 1$,*

$$|x_{1n}/a_n - 1| \leq Cn^{-2/3}, \tag{2.4}$$

and uniformly for $n \geq 3$ and $2 \leq j \leq n-1$,

$$x_{j-1,n} - x_{j+1,n} \sim \frac{a_n}{n}\max\{n^{-2/3}, 1 - |x_{jn}|/a_n\}^{-1/2}. \tag{2.5}$$

(c) *For $n \geq 1$,*

$$\sup_{x\in\mathbb{R}}|p_n(x)|W(x)|1 - |x|/a_n|^{1/4} \sim a_n^{-1/2}, \tag{2.6}$$

and

$$\sup_{x\in\mathbb{R}}|p_n(x)|W(x) \sim n^{1/6}a_n^{-1/2}. \tag{2.7}$$

(d) *Let $0 < p \leq \infty$. There exists $C > 0$ such that for $n \geq 1$ and $P \in P_n$,*

$$\|PW\|_{L_p(\mathbb{R})} \leq C\|PW\|_{L_p[-a_n,a_n]}. \tag{2.8}$$

(e) *For $n \geq 1$,*

$$\gamma_{n-1}/\gamma_n \sim a_n. \tag{2.9}$$

(f) *Uniformly for $n \geq 2$ and $1 \leq j \leq n-1$,*

$$\max\{n^{-2/3}, 1 - |x_{jn}|/a_n\} \sim \max\{n^{-2/3}, 1 - |x_{j+1,n}|/a_n\}.$$

Proof. (a)–(d) are, respectively, Theorem 1.1, Corollaries 1.2 and 1.4, and Theorem 1.8 in [5]. (e) is Theorem 12.3(b) in [5]. (f) is (1.10) in [5, p. 521]. □

We recall from [7] the next theorem.

THEOREM 2.2. (a) *Given* $0 < p < \infty$, *we have for* $n \geq 1$,

$$\|p_n W\|_{L_p(\mathbb{R})} \sim a_n^{1/p-1/2} \times \begin{cases} 1, & p < 4, \\ (\log n)^{1/4}, & p = 4, \\ n^{(1/6)(1-4/p)}, & p > 4. \end{cases} \tag{2.10}$$

(b) *Uniformly for* $n \geq 1, 1 \leq j \leq n$, *and* $x \in \mathbb{R}$,

$$|\ell_{jn}(x)| \sim \frac{a_n^{3/2}}{n} W(x_{jn}) \left(\max \left\{ n^{-2/3}, 1 - \frac{|x_{jn}|}{a_n} \right\} \right)^{-1/4} \left| \frac{p_n(x)}{x - x_{jn}} \right|. \tag{2.11}$$

(c) *Uniformly for* $n \geq 1, 1 \leq j \leq n$, *and* $x \in \mathbb{R}$,

$$|\ell_{jn}(x)| W^{-1}(x_{jn}) W(x) \leq C. \tag{2.12}$$

Proof. (a), (b), and (c) are, respectively, Theorem 1 and Lemma 2.6(a), (b) in [7]. □

LEMMA 2.3. (a) *Given* $0 < a < b$, *we have uniformly for* $n \geq 1$ *and* $x \in [a, b]$,

$$Q(a_n x) \sim a_n x Q'(a_n x) \sim n. \tag{2.13}$$

(b) *If* A, B *are as in* (1.10), *then*

$$u^{1/B} \leq a_u / a_1 \leq u^{1/A}, \qquad u \in [1, \infty). \tag{2.14}$$

(c) *Given* $\lambda > 1$, *we have for* $v \in (0, \infty)$, *and* $u \in [v/\lambda, \lambda v]$,

$$|a_u / a_v - 1| \sim |u/v - 1|. \tag{2.15}$$

Proof. (a) This is Lemma 5.1(c) in [5].
(b) This is Lemma 5.2(b) in [5].
(c) This is Lemma 5.2(c) in [5]. □

There is an old result of Shohat [3, Chap. III] that establishes the equivalence of convergence of Gauss quadratures and L_2 convergence of Lagrange interpolation. So it is not surprising that quadrature sums play a role here. In the remainder of this section, we prove three quadrature sum estimates. The first is a quadrature sum similar to that in Theorem 6 in [4, p. 85]. In the sequel, we set

$$x_{0n} := x_{1n}(1 + n^{-2/3}); \qquad x_{n+1,n} := x_{nn}(1 + n^{-2/3}). \tag{2.16}$$

LEMMA 2.4. *Let* $\nu \in \mathbb{R}$. *Then uniformly for* $n \geq 1$,

$$\sum_{j=1}^{n} \lambda_{jn} W^{-2}(x_{jn})(1 + |x_{jn}|)^{\nu} \sim \begin{cases} 1, & \nu < -1, \\ \log n, & \nu = -1, \\ a_n^{1+\nu}, & \nu > -1. \end{cases} \tag{2.17}$$

Proof. We first show that uniformly for $n \geq 1$ and $1 \leq j \leq n$,

$$1 + |x_{jn}| \sim 1 + |t|, \qquad t \in [x_{j+1,n}, x_{j-1,n}]. \tag{2.18}$$

To this end, note that (2.5) holds even for $j = 1$ and n, with the definition (2.16) of x_{0n} and $x_{n+1,n}$. First, if $|x_{j\pm1,n}| \le a_n/2$, then (2.5) shows that

$$x_{j-1,n} - x_{j+1,n} \sim a_n/n,$$

so that for t in the range (2.18),

$$\left|\frac{1+|t|}{1+|x_{jn}|} - 1\right| \le \frac{|t-x_{jn}|}{1+|x_{jn}|} \le x_{j-1,n} - x_{j+1,n} \le C_1 a_n/n \to 0, \qquad n \to \infty.$$

(See (2.14) and recall that $A > 1$.) On the other hand, if $|x_{j\pm1,n}| > a_n/2$, then (2.5) shows that

$$\begin{aligned}\left|\frac{1+|t|}{1+|x_{jn}|} - 1\right| &\le \frac{|t-x_{jn}|}{1+|x_{jn}|} \\ &\le C_2(x_{j-1,n} - x_{j+1,n})/a_n \le C_3\frac{1}{n}(\max\{n^{-2/3}, 1-|x_{jn}|/a_n\})^{-1/2} \\ &\le C_4 n^{-2/3} \to 0 \quad \text{as } n \to \infty.\end{aligned}$$

So (2.18) holds in all cases. Next, (2.3) and (2.5) imply that

$$\lambda_{jn} W^{-2}(x_{jn}) \sim x_{j-1,n} - x_{j+1,n}$$

for $2 \le j \le n-1$. By (2.16) this holds for $j = 1, n$ also. So for $1 \le j \le n$,

$$\begin{aligned}\lambda_{jn} W^{-2}(x_{jn})(1+|x_{jn}|)^\nu &\sim (x_{j-1,n} - x_{j+1,n})(1+|x_{jn}|)^\nu \\ &\sim \int_{x_{j+1,n}}^{x_{j-1,n}} (1+|t|)^\nu \, dt.\end{aligned}$$

Summing for $j = 1$ to n, and using

$$x_{0n} \sim -x_{n+1,n} \sim a_n,$$

we obtain (2.17). □

In several places, we shall need to replace $(1+t^2)^\nu$ by an equivalent polynomial on a suitable interval. This is achieved in the following lemma.

LEMMA 2.5. *Let $\nu \in \mathbb{R}$. There exists $C > 0$ such that for $\lambda \ge 2$, there exist polynomials $\hat{P}_\lambda$ of degree $\le C\lambda \log \lambda$ such that*

$$\hat{P}_\lambda(t) \sim (1+t^2)^\nu, \tag{2.19}$$

uniformly for $t \in [-\lambda, \lambda]$ and $\lambda \ge 2$.

Proof. Let $f(t) := \log(1+(\lambda t)^2), t \in [-1,1]$. Then

$$|f'(t)| = \frac{2\lambda^2|t|}{1+(\lambda t)^2} \le \lambda, \qquad t \in [-1,1].$$

By Jackson's theorem, there exists a polynomial R_λ of degree at most λ such that

$$\|f - R_\lambda\|_{L_\infty[-1,1]} \le C_1 \|f'\|_{L_\infty[-1,1]}/\lambda \le C_1. \tag{2.20}$$

Here C_1 is an absolute constant. Next, let

$$S_n(u) := \sum_{j=0}^{n} u^j/j!$$

be the $(n+1)$st partial sum of the Maclaurin series of e^u. It is well known and easy to see that

$$S_n(u) \sim e^u, \qquad |u| \le n/9.$$

Next, from (2.20),

$$\|R_\lambda\|_{L_\infty[-1,1]} \le C_1 + \|f\|_{L_\infty[-1,1]} \le C_1 + \log(1+\lambda^2) \le C_2 \log \lambda.$$

Let $[x]$ denote the greatest integer $\le x$. Then, if we set

$$\hat{P}_\lambda(t) := S_{10[|\nu|C_2 \log \lambda]}(\nu R_\lambda(t/\lambda)),$$

we have for $|\nu|C_2 \log \lambda \ge 1$ and $t \in [-\lambda, \lambda]$ that

$$\hat{P}_\lambda(t) \sim \exp(\nu R_\lambda(t/\lambda)) \sim \exp(\nu f(t/\lambda)) = (1+t^2)^\nu.$$

For small λ, we can set $\hat{P}_\lambda := 1$; Finally, $\hat{P}_\lambda$ has degree $\le 10|\nu|C_2 \lambda \log \lambda$. □

We can now prove our main quadrature sum estimate.

LEMMA 2.6. *Fix $\sigma \in (0,1)$ and an integer $L \ge 3$, and let $\nu \in \mathbb{R}$. Then for $P \in \mathcal{P}_{Ln}$, and $n \ge 1$,*

$$\sum_{|x_{jn}| \le \sigma a_n} \lambda_{jn} |P(x_{jn})| W^{-1}(x_{jn})(1+x_{jn}^2)^\nu \le C_1 \int_{-a_{Ln}}^{a_{Ln}} |PW|(t)(1+t^2)^\nu \, dt. \tag{2.21}$$

Here $C_1 \ne C_1(P,n)$.

Proof. Our method follows that of [6]. Now by definition of the Christoffel function, and by Theorem 2.1(a), we have for $P \in \mathcal{P}_n$ and $x \in \mathbb{R}$ that

$$(PW)^2(x) \le C_2 \frac{n}{a_n} \int_{-\infty}^{\infty} (PW)^2(t) \, dt.$$

It follows that

$$\|PW\|_{L_\infty(\mathbb{R})}^2 \le C_2 \frac{n}{a_n} \|PW\|_{L_\infty(\mathbb{R})} \int_{-\infty}^{\infty} |PW|(t) \, dt,$$

and so, using the infinite–finite range inequality Theorem 2.1(d),

$$\|PW\|_{L_\infty(\mathbb{R})} \le C_3 \frac{n}{a_n} \int_{-a_n}^{a_n} |PW|(t) \, dt. \tag{2.22}$$

Next, let

$$v(t) := (1-t^2)^{-1/2}, \qquad t \in (-1,1),$$

be the Chebyshev weight, and let

$$K_n(x,t) := \sum_{j=0}^{n-1} p_j(v,x)p_j(v,t)$$

be the corresponding kernel function. It is well known [12, p. 108] that

$$K_n(x,x) \sim n, \qquad |x| \le 1; \tag{2.23}$$

$$|K_n(x,t)| \le C_4 \min\left\{n, \frac{1}{|x-t|}\right\}, \qquad x,\ t \in [-1,1]. \tag{2.24}$$

Next, let $\hat{P}_{a_{2Ln}}$ be the polynomial of Lemma 2.5 of degree $O(a_{2Ln}\log a_{2Ln}) = o(n)$ by (2.14) (recall $A > 1$). We now fix x s.t. $|x| \le a_{\sigma n}$ and apply (2.22) to the polynomial

$$R(t) := P(t)\hat{P}_{a_{2Ln}}(t)K_n^2\left(\frac{x}{a_{2Ln}}, \frac{t}{a_{2Ln}}\right),$$

where $P \in \mathcal{P}_{Ln}$. Note that R has degree at most $Ln + o(n) + 2n \le 2Ln$, for $n \ge n_1$, say. By (2.22),

$$\left|P(x)\hat{P}_{a_{2Ln}}(x)K_n^2\left(\frac{x}{a_{2Ln}}, \frac{x}{a_{2Ln}}\right)\right| W(x) = |RW|(x)$$
$$\le C_3\frac{2Ln}{a_{2Ln}}\int_{-a_{2Ln}}^{a_{2Ln}} |PW|(t)|\hat{P}_{a_{2Ln}}(t)|K_n^2\left(\frac{x}{a_{2Ln}}, \frac{t}{a_{2Ln}}\right) dt.$$

By Lemma 2.5 and (2.23), we obtain for $|x| \le a_{\sigma n} (< a_{2Ln})$

$$|PW|(x)(1+x^2)^\nu \le C_4\frac{1}{na_n}\int_{-a_{2Ln}}^{a_{2Ln}} |PW|(t)(1+t^2)^\nu K_n^2\left(\frac{x}{a_{2Ln}}, \frac{t}{a_{2Ln}}\right) dt. \tag{2.25}$$

Then by Theorem 2.1(a) and as $\sigma < 1$, we have

$$\begin{aligned}
&\sum_{|x_{jn}|\le\sigma a_n} \lambda_{jn}|P(x_{jn})|W^{-1}(x_{jn})(1+x_{jn}^2)^\nu \\
&\qquad \le C_5\frac{a_n}{n}\sum_{|x_{jn}|\le\sigma a_n} |PW|(x_{jn})(1+x_{jn}^2)^\nu \\
&\qquad \le C_5\int_{-a_{2Ln}}^{a_{2Ln}} |PW|(t)(1+t^2)^\nu T(t)\,dt,
\end{aligned} \tag{2.26}$$

where by (2.25),

$$\begin{aligned}
T(t) &:= n^{-2}\sum_{|x_{jn}|\le\sigma a_n} K_n^2\left(\frac{x_{jn}}{a_{2Ln}}, \frac{t}{a_{2Ln}}\right) \\
&\le C_6 n^{-2}\sum_{|x_{jn}|\le\sigma a_n} \min\left\{n, \frac{a_{2Ln}}{|x_{jn}-t|}\right\}^2,
\end{aligned}$$

by (2.24). Now for $|x_{jn}| \le \sigma a_n$, we have (see Theorem 2.1(b)) uniformly in j and n,

$$x_{j-1,n} - x_{j+1,n} \sim \frac{a_n}{n}.$$

It follows that by reordering the x_{jn} in terms of increasing distance from t, and splitting into sums involving even and odd j, we can bound $T(t)$, uniformly for $t \in \mathbb{R}$, by

$$T(t) \le C_7 n^{-2} \left\{ n^2 + \sum_{j=1}^{n} \left(\frac{a_{2Ln}}{j a_n / n} \right)^2 \right\}$$
$$\le C_8 \left\{ 1 + \sum_{j=1}^{n} j^{-2} \right\} \le C_9.$$

Here we have used $a_{2Ln}/a_n = O(1)$. Substituting into (2.26) yields the lemma. □

Our last quadrature estimate in this section is essentially an estimate for part of the Lebesgue function of Lagrange interpolation.

LEMMA 2.7. *Let $\beta \in (0,2), \nu \in \mathbb{R}$, and*

$$\sum(x) := \sum_{K\ :|x_{kn}| \ge \beta a_n} |\ell_{kn}(x)| W^{-1}(x_{kn})(1+|x_{kn}|)^{-\nu}. \tag{2.27}$$

Then

$$W(x) \sum(x) \le C a_n^{-\nu} \begin{cases} 1, & |x| \le \beta a_n/2, \\ a_n^{1/2} |p_n W|(x) + \log n, & \beta a_n/2 \le |x| \le 2a_n, \\ a_n/|x|, & |x| \ge 2a_n. \end{cases} \tag{2.28}$$

Proof. We first observe that $|x_{kn}| \sim a_n$ uniformly for $|x| \ge \beta a_n$, so it suffices to consider the case $\nu = 0$. Next, with the definition (2.16), we note that (2.5) persists for $j = 1$ and n. So

$$\begin{aligned} &\frac{a_n^{3/2}}{n} \sum_{|x_{kn}| \ge \beta a_n} (\max\{n^{-2/3}, 1 - |x_{kn}|/a_n\})^{-1/4} \\ &\quad \sim a_n^{1/2} \sum_{|x_{kn}| \ge \beta a_n} (x_{k-1,n} - x_{k+1,n})(\max\{n^{-2/3}, 1 - |x_{kn}|/a_n\})^{1/4} \\ &\quad \le a_n^{1/2} \sum_{|x_{kn}| \ge \beta a_n} (x_{k-1,n} - x_{k+1,n}) \\ &\quad \le a_n^{1/2} 2 x_{1n} \le C_1 a_n^{3/2} \end{aligned} \tag{2.29}$$

by (2.4). We now consider three ranges of x, and use (2.12) for x_{jn} close to x, and (2.11) for x_{jn} not close to x.

Case I. $|x| \le \beta a_n/2$. For this range of x, we have

$$|x_{kn} - x| \sim |x_{kn}| \sim a_n.$$

Then (2.11) yields

$$\sum(x) \le C_1 \frac{a_n^{3/2}}{n} \sum_{|x_{kn}| \ge \beta a_n} (\max\{n^{-2/3}, 1 - |x_{kn}|/a_n\})^{-1/4} \frac{|p_n(x)|}{a_n}$$
$$\le C_2 a_n^{1/2} |p_n(x)| \le C_3 W^{-1}(x),$$

(recall $\nu = 0$) by (2.29) and the bound (2.6) for p_n, since $\beta/2 < 1$. Hence (2.28).

Case II. $\beta a_n/2 \le |x| \le 2a_n$. This is the most complicated case, and we need to split

$$\begin{aligned}\sum(x) &= \sum_{\substack{|x_{kn}|\ge\beta a_n\\ |x_{kn}|\le\frac12|x|}} + \sum_{\substack{|x_{kn}|\ge\beta a_n\\ \frac12|x|<|x_{kn}|<2|x|}} + \sum_{\substack{|x_{kn}|\ge\beta a_n\\ |x_{kn}|\ge 2|x|}} \\ &=: \sum\nolimits_1(x) + \sum\nolimits_2(x) + \sum\nolimits_3(x).\end{aligned} \tag{2.30}$$

$\sum_1$: For k in $\sum_1$, we have $|x_{kn} - x| \sim |x| \sim a_n$, and so by (2.11),

$$\begin{aligned}\sum\nolimits_1(x) &\le C_4\frac{a_n^{3/2}}{n}\sum_{|x_{kn}|\ge\beta a_n}(\max\{n^{-2/3}, 1-|x_{kn}|/a_n\})^{-1/4}\frac{|p_n(x)|}{a_n} \\ &\le C_5 a_n^{1/2}|p_n(x)|,\end{aligned} \tag{2.31}$$

by (2.29).

$\sum_2$: Choose $\ell = \ell(x)$ such that $x \in [x_{\ell+1,n}, x_{\ell n}]$ and split

$$\sum\nolimits_2(x) := \sum\nolimits_{21}(x) + \sum\nolimits_{22}(x),$$

where $\sum_{21}$ sums over those k in $\sum_2$ for which $k \in [\ell(x)-3, \ell(x)+3]$ and $\sum_{22}$ contains the rest. Here, if $|x| \ge x_{0n}$ the term $\sum_{21}$ is taken as zero. Now by (2.12), we see that

$$\sum\nolimits_{21}(x) \le C_6 W^{-1}(x).$$

Next, if the sum below is over those k considered in $\sum_{22}$, we can use (2.11) and then (2.5) to deduce that

(2.32)

$$\begin{aligned}\sum\nolimits_{22}(x) &\le C_7\frac{a_n^{3/2}}{n}\sum(\max\{n^{-2/3}, 1-|x_{kn}|a_n\})^{-1/4}\frac{|p_n(x)|}{|x-x_{kn}|} \\ &\le C_8 a_n^{1/2}|p_n(x)|\sum\frac{x_{k-1,n}-x_{k+1,n}}{|x-x_{kn}|}(\max\{n^{-2/3}, 1-|x_{kn}|/a_n\})^{1/4} \\ &\le C_9 a_n^{1/2}|p_n(x)|\int_{[-2a_n,2a_n]\setminus[x_{\ell+3,n},x_{\ell-3,n}]}(\max\{n^{-2/3}, 1-|t|/a_n\})^{1/4}\frac{dt}{|x-t|},\end{aligned}$$

with obvious modifications, both here and below, when $|x| \ge x_{0n}$. In the last step we used Theorem 2.1(f) and

$$|x-t| \sim |x - x_{k\pm1,n}| \sim |x - x_{kn}|, \qquad t \in [x_{k+1,n}, x_{k-1,n}],$$

provided $k \notin [\ell(x)-3, \ell(x)+3]$. This is an easy consequence of (2.5):

$$\begin{aligned}\left|\frac{x-t}{x-x_{kn}}\right| &\le \left|\frac{x-x_{k\pm1,n}}{x-x_{kn}}\right| = \left|1+\frac{x_{kn}-x_{k\pm1,n}}{x-x_{kn}}\right| \\ &\le 1+\left|\frac{x_{kn}-x_{k\pm1,n}}{x_{k\pm2,n}-x_{kn}}\right| \le C_{10}\end{aligned}$$

by (2.5). Similarly we may derive a lower bound. We proceed to estimate the integral in the right-hand side of (2.32). Let us suppose, as we may, that $x \geq 0$ and set $\tau =: x/a_n$. Note that for the current range of $x, \tau \in [\beta/2, 2]$. Then we see that the integral in (2.32) equals

$$I := \int_{[-2,2]\setminus[x_{\ell+3,n}/a_n, x_{\ell-3,n}/a_n]} (\max\{n^{-2/3}, 1-|s|\})^{1/4} \frac{dt}{|\tau - s|}.$$

In view of the spacing (2.5), we have

$$x_{\ell+3,n}/a_n \leq \tau - \delta_n; \qquad x_{\ell-3,n}/a_n \geq \tau + \delta_n,$$

where

$$\delta_n = \delta_n(x) := C\frac{1}{n}\max\{n^{-2/3}, 1-|x|/a_n\}^{-1/2},$$

and C is independent of n, x, and hence ℓ. So

$$I \leq 2\int_{[0,2]\setminus[\tau-\delta_n,\tau+\delta_n]} (\max\{n^{-2/3}, 1-s\})^{1/4} \frac{ds}{|\tau - s|}. \tag{2.33}$$

Suppose first that $|1-\tau| \geq n^{-2/3}$ and set $\sigma := \frac{1-\tau}{|1-\tau|} = \pm 1$. Then the substitution $(1-s) = |1-\tau|u$ gives

$$\begin{aligned} I &\leq 2|1-\tau|^{1/4} \int_{[(-1/|1-\tau|),(1/|1-\tau|)]\setminus[\sigma-(\delta_n/|1-\tau|),\sigma+(\delta_n/|1-\tau|)]} \left(\max\left\{\frac{n^{-2/3}}{|1-\tau|}, u\right\}\right)^{1/4} \\ &\quad \times \frac{du}{|\sigma - u|} \\ &\leq C_{11}|1-\tau|^{1/4}\left[\int_{[\sigma-1/2,\sigma-(\delta_n/|1-\tau|)]} \frac{du}{|\sigma-u|} + \int_{[2,(1/|1-\tau|)]} u^{-3/4}\,du\right] \end{aligned}$$

(with appropriate replacements for the lower limits $\sigma - \frac{1}{2}, 2$ if necessary)

$$\begin{aligned} &\leq C_{12}\left[|1-\tau|^{1/4}\log\left(\frac{|1-\tau|}{\delta_n}\right) + 1\right] \\ &\leq C_{13}\left[|1-|x|/a_n|^{1/4}\log(n|1-|x|/a_n|^{3/2}) + 1\right] \\ &\leq C_{14}[|1-|x|/a_n|^{1/4}\log n + 1]. \end{aligned} \tag{2.34}$$

If $|1-\tau| < n^{-2/3}$, then note that $\delta_n = Cn^{-2/3}$. Set $\kappa := n^{2/3}(1-\tau)$ and note that $|\kappa| < 1$. Here we use the substitution $(1-s) = n^{-2/3}u$ in (2.33) to obtain

$$\begin{aligned} I &\leq 2n^{-1/6}\int_{[-n^{2/3},n^{2/3}]/[\kappa-C,\kappa-C]} \max\{1,u\}^{1/4}\frac{du}{|\kappa-u|} \\ &\leq C_{15}n^{-1/6}\int_2^{n^{2/3}} u^{-3/4}\,du \leq C_{16}. \end{aligned}$$

Of course as C is independent of κ, so is C_{16}. So also in this case, we have the estimate (2.34). Summarizing, we have from (2.32) to (2.34) that

$$\begin{aligned} W(x)\sum\nolimits_2(x) &= W(x)\left[\sum\nolimits_{21}(x) + \sum\nolimits_{22}(x)\right] \\ &\leq C_{17}[1 + a_n^{1/2}|p_nW|(x)\{|1-|x|/a_n|^{1/4}\log n + 1\}] \\ &\leq C_{18}[\log n + a_n^{1/2}|p_nW|(x)]. \end{aligned} \tag{2.35}$$

Here we have used the bound (2.6) for the orthonormal polynomials.

$\sum_3$: For this range of k, we have $|x_{kn} - x| \sim |x_{kn}| \sim a_n$, so

$$\begin{aligned}\sum\nolimits_3(x) &\le C_{18}\frac{a_n^{3/2}}{n}\sum_{|x_{kn}|\ge\beta a_n}(\max\{n^{-2/3}, 1-|x_{kn}|/a_n\})^{-1/4}\frac{|p_n(x)|}{a_n} \\ &\le C_{19}a_n^{1/2}|p_n(x)|\end{aligned} \tag{2.36}$$

by (2.29). Substituting the estimates (2.31), (2.35), and (2.36) into (2.30) yields the result in this case.

Case III. $|x| \ge 2a_n$. For this range of x, we have $|x_{kn} - x| \sim |x|$, (recall that $x_{1n} = a_n[1 + o(1)]$) so

$$\begin{aligned}\sum(x) &\le C_{20}\frac{a_n^{3/2}}{n}\sum_{|x_{kn}|\ge\beta a_n}(\max\{n^{-2/3}, 1-|x_{kn}|/a_n\})^{-1/4}\frac{|p_n(x)|}{|x|} \\ &\le C_{21}\frac{a_n^{3/2}}{|x|}|p_n(x)|,\end{aligned}$$

by (2.29). Finally, (2.6) of Theorem 2.1(c) yields

$$|p_nW|(x) \le C_{22}a_n^{-1/2}, \qquad |x| \ge 2a_n. \qquad \square$$

3. Proof of the theorems. In proving Theorem 1.3, we shall split our function into pieces that vanish inside or outside $[-\beta a_n, \beta a_n]$, some $\beta > 0$. The proof requires several preliminary steps. Many of the ideas have been taken from Nevai's fundamental paper [13], though the fact that a_n may grow slower than $n^{1/2}$ forces a completely different approach in the following lemma, and elsewhere. Throughout, W is as in Theorem 1.3, and throughout $1 < p < \infty, \alpha > 0, \Delta \in \mathbb{R}$, and $\hat{\alpha}$ is given by (1.3).

LEMMA 3.1. *Assume that if* $p \le 4$, (1.13) *holds and if* $p > 4$, (1.14) *holds. Let* $\varepsilon > 0, \beta \in (0,2)$ *and assume that* $\{f_n\}_{n=1}^{\infty}$ *is a sequence of functions from* $\mathbb{R}$ *to* $\mathbb{R}$ *such that*

$$f_n(x) = 0, \qquad |x| < \beta a_n, \tag{3.1}$$

and

$$|f_nW|(x) \le \varepsilon(1+|x|)^{-\alpha}, \qquad x \in \mathbb{R}, \quad n \ge 1. \tag{3.2}$$

Then

$$\limsup_{n\to\infty}\|L_n[f_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \le C\varepsilon. \tag{3.3}$$

Here C *is independent of* ε, n, *and* $\{f_n\}$.

Proof. Now by Lemma 2.7, and (3.1)–(3.2),

$$\begin{aligned}|L_n[f_n](x)W(x)| &= \left|W(x)\sum_{|x_{kn}|\ge\beta a_n}\ell_{kn}(x)f_n(x_{kn})\right| \\ &\le \varepsilon W(x)\sum_{|x_{kn}|\ge\beta a_n}|\ell_{kn}(x)|W^{-1}(x_{kn})(1+|x_{kn}|)^{-\alpha} \\ &\le C_1\varepsilon a_n^{-\alpha}\begin{cases}1, & |x| \le \beta a_n/2, \\ a_n^{1/2}|p_nW|(x) + \log n, & \beta a_n/2 \le |x| \le 2a_n, \\ a_n/|x|, & |x| \ge 2a_n.\end{cases}\end{aligned} \tag{3.4}$$

Then

$$\begin{aligned}\tau_n^{(1)} &:= \|L_n[f_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\le \beta a_n/2)}\\ &\le C_1\varepsilon a_n^{-\alpha}\|(1+|x|)^{-\Delta}\|_{L_p(|x|\le\beta a_n/2)}\\ &\le C_2\varepsilon a_n^{-\alpha}\begin{cases}1, & \Delta p>1,\\ (\log n)^{1/p}, & \Delta p=1,\\ a_n^{1/p-\Delta}, & \Delta p<1.\end{cases}\end{aligned}$$

Here, if $\Delta p \ge 1$, this term is $o(1)$ as $\alpha > 0$ and a_n grows faster than some positive power of n. Suppose now that $\Delta p < 1$. Note that if $p > 4$, then the power of n in (1.14) is positive, so the power of a_n there, namely $1/p - (\hat{\alpha} + \Delta)$, must be negative. Hence (1.13) holds for all $p > 1$. (We shall use this repeatedly.) So if $\Delta p < 1$, (1.13) shows that

$$a_n^{-\alpha+1/p-\Delta} \le a_n^{-\hat{\alpha}+1/p-\Delta} = o(1). \tag{3.5}$$

Hence in all cases

$$\lim_{n\to\infty} \tau_n^{(1)} = 0. \tag{3.6}$$

Next, from (3.4),

$$\begin{aligned}\tau_n^{(2)} &:= \|L_n[f_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\beta a_n/2\le|x|\le 2a_n)}\\ &\le C_2\varepsilon a_n^{-\alpha}\{a_n^{1/2-\Delta}\|p_nW\|_{L_p[\beta a_n/2,2a_n]} + (\log n)a_n^{1/p-\Delta}\}\\ &\le C_3\varepsilon a_n^{-(\alpha+\Delta)+1/p}\begin{cases}1, & p<4\\ (\log n)^{1/4}, & p=4\\ n^{(1/6)(1-p/4)}, & p>4\end{cases} + C_3\varepsilon(\log n)a_n^{-(\alpha+\Delta)+1/p},\end{aligned}$$

by Theorem 2.2(a). Recall that for all $p > 1$, $-(\alpha + \Delta) + 1/p < 0$ (see (3.5)) and a_n is of polynomial growth, so the second term in the last right-hand side is always $o(1)$. By the same token, for $p \le 4$, this entire last right-hand side is $o(1)$. When $p > 4$ and $\alpha > 1$, then $\alpha > \hat{\alpha}$ (see (1.3)) so (1.14) shows that this whole last right-hand side is $o(1)$. When $p > 4$ and $\alpha \le 1$, our assumption (1.14) shows that this last term is $O(\varepsilon)$. So in all cases,

$$\limsup_{n\to\infty} \tau_n^{(2)} \le C_4\varepsilon. \tag{3.7}$$

Finally, from (3.4),

$$\begin{aligned}\tau_n^{(3)} &:= \|L_n[f_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\ge 2a_n)}\\ &\le C_5 a_n^{-\alpha+1}\||x|^{-1}(1+|x|)^{-\Delta}\|_{L_p(|x|\ge 2a_n)}.\end{aligned}$$

Now from (1.13),

$$\Delta > \frac{1}{p} - \hat{\alpha} \ge \frac{1}{p} - 1,$$

so

$$p(\Delta + 1) > 1, \tag{3.8}$$

and hence

$$\tau_n^{(3)} \le C_6 a_n^{-\alpha+1} a_n^{1/p-(1+\Delta)} = o(1),$$

by (3.5). Together with (3.6) and (3.7), this yields the result. □

Note that we needed only the weaker (1.14) and not (1.15) in the above lemma. Having dealt with functions that vanish inside $(-\beta a_n, \beta a_n)$, we turn to functions that vanish outside this interval. First we estimate the L_p norms of such functions outside $[-2\beta a_n, 2\beta a_n]$ and in Lemma 3.4 below, we shall use Hilbert transforms to estimate their L_p norms over $[-2\beta a_n, 2\beta a_n]$.

LEMMA 3.2. *Assume that if* $p \le 4$, (1.13) *holds; if* $p > 4$ *and* $\alpha \ne 1$, (1.14) *holds; and if* $p > 4$ *and* $\alpha = 1$, (1.15) *holds. Let* $\varepsilon > 0, \beta \in (0,1)$ *and assume that* $\{\psi_n\}_{n=1}^{\infty}$ *is a sequence of functions from* $\mathbb{R}$ *to* $\mathbb{R}$ *such that*

$$\psi_n(x) = 0, \qquad |x| \ge \beta a_n, \tag{3.9}$$

and

$$|\psi_n(W)|(x) \le \varepsilon(1+|x|)^{-\alpha}, \qquad x \in \mathbb{R}, \quad n \ge 1. \tag{3.10}$$

Then

$$\limsup_{n\to\infty} \|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\ge 2\beta a_n)} \le C\varepsilon. \tag{3.11}$$

Here C *is independent of* $\varepsilon, n,$ *and* $\{\psi_n\}$.

Proof. First note that for $|x| \ge 2\beta a_n$ and $|x_{kn}| \le \beta a_n, |x_{kn} - x| \sim |x|$. Then, from Theorem 2.2(b), we have for $|x| \ge 2\beta a_n$

$$\begin{aligned}
|L_n[\psi_n](x)| &= \left| \sum_{|x_{kn}|<\beta a_n} \ell_{kn}(x)\psi_n(x_{kn}) \right| \\
&\le \varepsilon \sum_{|x_{kn}|<\beta a_n} |\ell_{kn}(x)| W^{-1}(x_{kn})(1+|x_{kn}|)^{-\alpha} \\
&\le C_1 \varepsilon \frac{a_n^{3/2}}{n} \frac{|p_n(x)|}{|x|} \sum_{|x_{kn}|<\beta a_n} (1+|x_{kn}|)^{-\alpha} \\
&\le C_2 \varepsilon a_n^{1/2} \frac{|p_n(x)|}{|x|} \sum_{|x_{kn}|<\beta a_n} (x_{k-1,n} - x_{k+1,n})(1+|x_{kn}|)^{-\alpha} \qquad \text{(by (2.5))} \\
&\le C_3 \varepsilon a_n^{1/2} \frac{|p_n(x)|}{|x|} \int_{-2\beta a_n}^{2\beta a_n} (1+|t|)^{-\alpha}\, dt;
\end{aligned}$$

recall that $\beta < 1$ and see (2.18). Let

$$(\log n)^* := \begin{cases} \log n, & \alpha = 1, \\ 1, & \text{otherwise.} \end{cases}$$

We see (by examining $\alpha <, =, > 1$) that

$$\int_{-2\beta a_n}^{2\beta a_n} (1+|t|)^{-\alpha}\, dt \le C_4 a_n^{1-\hat{\alpha}} (\log n)^*, \qquad n \ge 2.$$

Then

$$\begin{aligned}
&\|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\geq 2\beta a_n)} \\
&\quad \leq C_5 \varepsilon a_n^{3/2-\hat{\alpha}} (\log n)^* \|p_n(x)W(x)|x|^{-1-\Delta}\|_{L_p(|x|\geq 2\beta a_n)} \\
&\quad \leq C_5 \varepsilon a_n^{1/2-\hat{\alpha}-\Delta} (\log n)^* \|p_n(x)W(x)\|_{L_p(\mathbb{R})} \quad \text{(recall } \Delta+1>0\text{; see (3.8))} \\
&\quad \leq C_6 \varepsilon a_n^{1/p-(\hat{\alpha}+\Delta)} (\log n)^* \times \begin{cases} 1, & p<4, \\ (\log n)^{1/4}, & p=4, \\ n^{(1/6)(1-4/p)}, & p>4, \end{cases}
\end{aligned}$$

by Theorem 2.2(a). Now if $p \leq 4$, we know that (1.13) holds and a_n is of polynomial growth, so the last right-hand side is $o(1)$. If $p > 4$ and $\alpha \neq 1$, our hypothesis (1.14) ensures that we obtain $O(\varepsilon)$; if $p > 4$ and $\alpha = 1$, our hypothesis (1.15) ensures that again we obtain $O(\varepsilon)$. □

Before proceeding to our third lemma on the L_p norms of Lagrange interpolants, we need the Hilbert transform $H[f](x)$, and its boundedness in suitable weighted L_p spaces. Recall that

$$H[f]x := \lim_{\varepsilon \to 0+} \int_{|t-x|\geq \varepsilon} \frac{f(t)}{t-x}\, dt,$$

and if $f \in L_1(\mathbb{R})$, then this limit exists a.e.

LEMMA 3.3. *Let $1 < p < \infty, s < 1 - 1/p; S > -1/p; s \leq S$. Then for measurable $f : \mathbb{R} \to \mathbb{R}$, for which the right-hand side is finite,*

$$\|H[f](x)(1+|x|)^s\|_{L_p(\mathbb{R})} \leq C\|f(x)(1+|x|)^S\|_{L_p(\mathbb{R})}. \tag{3.12}$$

Proof. This is the special case $R = r = 0$ of Lemma 8 in [11, p. 440]. □

LEMMA 3.4. *Assume that (1.13) holds. Let $\varepsilon > 0, \beta \in (0, 1/2)$, and assume that $\{\psi_n\}_{n=1}^{\infty}$ is a sequence of functions from $\mathbb{R}$ to $\mathbb{R}$ such that*

$$\psi_n(x) = 0, \qquad |x| \geq \beta a_n, \tag{3.13}$$

and

$$|\psi_n W|(x) \leq \varepsilon(1+|x|)^{-\alpha}, \qquad x \in \mathbb{R}, \quad n \geq 1. \tag{3.14}$$

Then

$$\limsup_{n\to\infty} \|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\leq 2\beta a_n)} \leq C\varepsilon. \tag{3.15}$$

Here C is independent of ε, n, and $\{\psi_n\}$.

Proof. Define

$$G(x) := W(x)^{-1}(1+|x|)^{-\alpha}, \qquad x \in \mathbb{R}.$$

Furthermore, for $f : \mathbb{R} \to \mathbb{R}$ such that $fW \in L_1(\mathbb{R})$, we let $S_n[f](x)$ denote the nth partial sum of the orthonormal expansion of f in $\{p_j\}_0^{\infty}$ (so that $S_n[f](x)$ is a linear combination of $p_0, p_1, \ldots, p_{n-1}$). We first show that

$$\begin{aligned}
&\|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\leq 2\beta a_n)} \\
&\qquad \leq C_2\varepsilon \sup_{\|h\|_{L_\infty(\mathbb{R})}\leq 1} \|S_n[hG](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\leq 2\beta a_n)}.
\end{aligned} \tag{3.16}$$

Let χ_n denote the characteristic function of $[-2\beta a_n, 2\beta a_n]$, and for $n \geq 1$, let

$$g_n(x) := \operatorname{sign}\{L_n[\psi_n](x)\}|L_n[\psi_n](x)|^{p-1}\chi_n(x)W^{p-2}(x)(1+|x|)^{-\Delta p}.$$

Observe that

$$\begin{aligned}
&\|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|^p_{L_p(|x|\leq 2\beta a_n)}\\
&\quad = \int_{-\infty}^{\infty} L_n[\psi_n](x)g_n(x)W^2(x)\,dx\\
&\quad = \int_{-\infty}^{\infty} L_n[\psi_n](x)S_n[g_n](x)W^2(x)\,dx\\
&\quad \text{(orthogonality of } g - S_n[g] \text{ to } \mathcal{P}_{n-1})\\
&\quad = \sum_{k=1}^{n} \lambda_n\psi_n(x_{kn})S_n[g_n](x_{kn}) \qquad \text{(Gauss quadrature)}\\
&\quad \leq \epsilon \sum_{|x_{kn}|<\beta a_n} \lambda_{kn}|S_n[g_n](x_{kn})|W^{-1}(x_{kn})(1+|x_{kn}|)^{-\alpha} \qquad \text{(by (3.14))}\\
&\quad \leq C_3\varepsilon \int_{-\infty}^{\infty} |S_n[g_n](x)|W(x)(1+|x|)^{-\alpha}\,dx\\
&\quad \text{(by Lemma 2.6 and as } (1+|t|)^{-\alpha} \sim (1+t^2)^{-\alpha/2})\\
&\quad = C_3\varepsilon \int_{-\infty}^{\infty} S_n[g_n](x)h_n(x)G(x)W^2(x)\,dx,
\end{aligned}$$

where we have set $h_n(x) := \operatorname{sign}(S_n[g_n](x))$, and we have used the definition of G. Then orthogonality and Hölder's inequality (with $q = p/(p-1)$) show that this last expression can be continued as

$$\begin{aligned}
&C_3\varepsilon \int_{-\infty}^{\infty} g_n(x)S_n[h_nG](x)W^2(x)\,dx\\
&\quad = C_3\varepsilon \int_{|x|\leq 2\beta a_n} g_n(x)S_n[h_nG](x)W^2(x)\,dx\\
&\quad \leq C_3\varepsilon \|g_n(x)W(x)(1+|x|)^{\Delta}\|_{L_q(|x|\leq 2\beta a_n)}\\
&\quad \times \|S_n[h_nG](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\leq 2\beta a_n)}\\
&\quad = C_3\varepsilon \|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|^{p-1}_{L_p(|x|\leq 2\beta a_n)}\\
&\quad \times \|S_n[h_nG](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x|\leq 2\beta a_n)}.
\end{aligned}$$

In the last right-hand side we have used the definition of g_n. Cancelling the $(p-1)$th power of the norm in the last right-hand side, and in the left-hand side after the definition of g_n gives (3.16). Next, it is a well-known consequence of the Christoffel–Darboux formula that for $f : \mathbb{R} \to \mathbb{R}$, for which $fW \in L_1(\mathbb{R})$,

$$S_n[f](x) = \frac{\gamma_{n-1}}{\gamma_n}\{p_n(x)H[p_{n-1}fW^2](x) - p_{n-1}(x)H[p_nfW^2](x)\},$$

where H denotes the Hilbert transform, as above. Then using Theorem 2.1(c) and (e), we have for $|x| \leq 2\beta a_n$ (recall $2\beta < 1$) and $h \in L_\infty(\mathbb{R})$ that

$$|S_n[hG](x)W(x)| \leq C_4 a_n^{1/2} \sum_{j=n-1}^{n} |H[p_jhGW^2](x)|. \tag{3.17}$$

Choose $\sigma \in (2\beta, 1)$, and let χ_n^* be the characteristic function of $[-\sigma a_n, \sigma a_n], n \geq 1$. Moreover, let $\|h\|_{L_\infty(\mathbb{R})} \leq 1$. In estimating the Hilbert transform for $|x| \leq 2\beta a_n$, we write

$$H[p_j hGW^2] = H[p_j(1-\chi_n^*)hGW^2] + H[p_j \chi_n^* hGW^2].$$

Now for $|x| \leq 2\beta a_n$, and $j = n-1, n$,

$$\begin{aligned}
|H[p_j(1-\chi_n^*)hGW^2](x)| &= \left| \int_{|t| \in [\sigma a_n, \infty)} \frac{p_j(t)(hGW^2)(t)}{x-t}\, dt \right| \\
&\leq C_5 \int_{\sigma a_n}^{\infty} |p_j W|(t) t^{-1-\alpha}\, dt \\
&\leq C_5 \left(\int_{\sigma a_n}^{\infty} p_j^2(t) W^2(t)\, dt \right)^{1/2} \left(\int_{\sigma a_n}^{\infty} t^{-2-2\alpha}\, dt \right)^{1/2} \\
&\leq C_6 a_n^{-1/2-\alpha}.
\end{aligned}$$

This last estimate and (3.17) give for $|x| \leq 2\beta a_n$,

$$|S_n[hG](x)W(x)| \leq C_4 a_n^{1/2} \sum_{j=n-1}^{n} |H[p_j \chi_n^* hGW^2](x)| + C_7 a_n^{-\alpha}. \tag{3.18}$$

Now let us set for some small $\delta > 0$,

$$\hat{\Delta} := \min\{\Delta, 1/p - \delta\}.$$

We now use Lemma 3.3 with $s = S = -\hat{\Delta}$. Note that

$$S = -\hat{\Delta} = \max\{-\Delta, \delta - 1/p\} > -1/p;$$

also, (1.13) (which, the reader may recall, holds for all $p > 1$) gives

$$-\Delta < -1/p + \hat{\alpha} \leq -1/p + 1,$$

so if $\delta < 1$, then

$$s = -\hat{\Delta} = \max\{-\Delta, \delta - 1/p\} < 1 - 1/p.$$

Thus the requirements of Lemma 3.3 are met. Then as $\hat{\Delta} \leq \Delta$, (3.18), and Lemma 3.3 yield

$$\begin{aligned}
&\|S_n[hG](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(|x| \leq 2\beta a_n)} \\
&\quad \leq C_4 a_n^{1/2} \sum_{j=n-1}^{n} \|H[p_j \chi_n^* hGW^2](x)(1+|x|)^{-\hat{\Delta}}\|_{L_p(\mathbb{R})} \\
&\qquad + C_7 a_n^{-\alpha} \|(1+|x|)^{-\Delta}\|_{L_p(|x| \leq 2\beta a_n)} \\
&\quad \leq C_8 a_n^{1/2} \sum_{j=n-1}^{n} \|(p_j \chi_n^* hGW^2)(x)(1+|x|)^{-\hat{\Delta}}\|_{L_p(\mathbb{R})} \\
&\qquad + C_8 a_n^{-\alpha} \begin{cases} 1, & \Delta p > 1, \\ (\log n)^{1/p}, & \Delta p = 1, \\ a_n^{1/p - \Delta}, & \Delta p < 1, \end{cases} \\
&\quad \leq C_8 a_n^{1/2} \sum_{j=n-1}^{n} \|(p_j W)(x)(1+|x|)^{-(\alpha+\hat{\Delta})}\|_{L_p(|x| \leq a_{\sigma n})} + o(1),
\end{aligned} \tag{3.19}$$

since $\alpha > 0$, and a_n is of polynomial growth, while also by (1.13)

$$-\alpha + 1/p - \Delta \le -\hat{\alpha} + 1/p - \Delta < 0. \tag{3.20}$$

Then using the bound (2.6) (recall $\sigma < 1$), we can continue (3.19) as

$$\begin{aligned} &\le C_9 \|(1+|x|)^{-(\alpha+\hat{\Delta})}\|_{L_p(|x|\le a_{\sigma n})} + o(1) \\ &\le C_{10}, \end{aligned}$$

as again (3.20) implies that

$$p(\alpha + \hat{\Delta}) > 1. \tag{3.21}$$

Finally, this bound and (3.16) yield the result. □

Proof of the sufficient conditions of Theorem 1.3. We remark first that the sufficient conditions in Theorem 1.3 imply those in Lemmas 3.1, 3.2, and 3.4. (Recall here that (1.15) implies (1.14).) Let $\varepsilon > 0$. We can find a polynomial P such that

$$|f - P|(x)W(x)(1+|x|)^{\alpha} \le \varepsilon, \qquad x \in \mathbb{R}. \tag{3.22}$$

(Cf. [2, p. 180].) Then for n large enough,

(3.23)

$$\begin{aligned} &\|(f - L_n[f])(x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \\ &\quad \le \|(f-P)(x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} + \|L_n[P-f](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \\ &\quad \le \varepsilon \|(1+|x|)^{-(\alpha+\Delta)}\|_{L_p(\mathbb{R})} + \|L_n[P-f](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})}. \end{aligned}$$

Here $p(\alpha+\Delta) \ge p(\hat{\alpha}+\Delta) > 1$ (see (3.21)), so the first norm in this last right-hand side is finite. Next, let χ_n denote the characteristic function of $[-a_n/4, a_n/4]$ and write

$$P - f = (P-f)\chi_n + (P-f)(1-\chi_n) =: \psi_n + f_n.$$

We can apply Lemma 3.1 to $\{f_n\}_{n=1}^{\infty}$ with $\beta = 1/4$ to deduce that

$$\limsup_{n\to\infty} \|L_n[f_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \le C_1 \varepsilon.$$

Next, in view of (3.22), $\{\psi_n\}_{n=1}^{\infty}$ satisfy (3.9)–(3.10) and (3.13)–(3.14) in Lemma 3.2 and 3.4 with $\beta = 1/4$, so those lemmas yield

$$\limsup_{n\to\infty} \|L_n[\psi_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \le C_2 \varepsilon.$$

So

$$\limsup_{n\to\infty} \|L_n[P-f](x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \le C_3 \varepsilon. \tag{3.24}$$

Combining (3.23) and (3.24), we have

$$\limsup_{n\to\infty} \|(f - L_n[f])(x)W(x)(1+|x|)^{-\Delta}\|_{L_p(\mathbb{R})} \le C_4 \varepsilon.$$

Letting $\varepsilon \to 0+$ yields the result. □

In the converse direction, we need the following lemma.

LEMMA 3.5. *Let $\sigma \in (0,1), \eta \in (0, 1-\sigma), 1 < p < \infty$. Then there exists C such that for $n \geq 1$ and P of degree at most ηn, we have*

$$\|P\|_{L_p[-a_{\sigma n}, a_{\sigma n}]} \leq C a_n^{1/2} \sum_{j=n-1}^{n} \|p_j W P\|_{L_p[-a_n, a_n]}. \tag{3.25}$$

Proof. Choose $\sigma' \in (\sigma, 1-\eta)$. Let $\delta \in (0,1)$ be such that $\delta\sigma' > \sigma$. For m large enough, Theorem 2.1(a) shows that

$$\lambda_m^{-1}(W,x) \sim \frac{m}{a_m} W^{-1}(x), |x| \leq a_{2\delta m}.$$

Moreover, we can replace $\sim$ by $\leq C \times$ for all $x \in \mathbb{R}$. (We have replaced W by $W^{1/2}$ in (2.3) and used also $a_m(W^{1/2}) = a_{2m}(W)$. Of course our a_ℓ above is $a_\ell(W)$.) Applying this with $m := [\sigma' n/2]$ and using

$$2\delta m = 2\delta[\sigma' n/2] > \sigma n,$$

with n large enough, yields

$$\lambda_{[\sigma' n/2]}^{-1}(W,x) W(x) \begin{cases} \sim n/a_n, & |x| \leq a_{\sigma n}, \\ \leq Cn/a_n, & x \in \mathbb{R}. \end{cases} \tag{3.26}$$

Let P be of degree $\leq \eta n$, and

$$R(x) := \frac{a_n}{n} P(x) \lambda_{[\sigma' n/2]}^{-1}(W,x). \tag{3.27}$$

Then R has degree $\leq \eta n + 2[\sigma' n/2] \leq (\eta + \sigma')n < n-1$, for n large enough, by choice of σ'. Next, with the definition for S_n in Lemma 3.4,

$$R(x) = S_n[R](x) = \frac{\gamma_{n-1}}{\gamma_n} \{p_n(x) H[R p_{n-1} W^2](x) - p_{n-1}(x) H[R p_n W^2](x)\},$$

by the Christoffel–Darboux formula. Using our bounds in Theorem 2.1, we obtain for $|x| \leq a_{\sigma n}$,

$$|RW|(x) \leq C_1 a_n^{1/2} \sum_{j=n-1}^{n} |H[R p_j W^2](x)|.$$

Using Riesz's theorem that H is a bounded operator from $L_p(\mathbb{R})$ to $L_p(\mathbb{R})$ (the special case $S = s = 0$ of Lemma 3.3), we obtain

$$\|RW\|_{L_p[-a_{\sigma n}, a_{\sigma n}]} \leq C_2 a_n^{1/2} \sum_{j=n-1}^{n} \|R p_j W^2\|_{L_p[-a_n, a_n]},$$

where we also used the infinite–finite range inequality (2.8) for the weight W^2. Now (3.26) shows that

$$|RW|(x) \begin{cases} \sim |P(x)|, & |x| \leq a_{\sigma n}, \\ \leq C|P(x)|, & x \in \mathbb{R}. \end{cases}$$

Then (3.25) follows. □

Proof of the necessary conditions of Theorem 1.3. Let $\Delta \in \mathbb{R}, \alpha > 0$. We assume the convergence (1.11) for every continuous $f : \mathbb{R} \to \mathbb{R}$ satisfying (1.12). Let $\eta(x) : \mathbb{R} \to (0, \infty)$ be an even continuous function that is decreasing in $[0, \infty)$, with

$$\eta(x) \geq (\log(2 + |x|))^{-1/(2p)}, \qquad x \in [0, \infty), \tag{3.28}$$

but

$$\lim_{x \to \infty} \eta(x) = 0. \tag{3.29}$$

We let X be the space of all continuous functions $f : \mathbb{R} \to \mathbb{R}$ with

$$\|f\|_X := \max_{x \in \mathbb{R}} |f(x)| W(x)(1 + |x|)^{\alpha} \eta(x)^{-1} < \infty.$$

Furthermore, let Y be the space of all measurable functions $f : \mathbb{R} \to \mathbb{R}$ with

$$\|f\|_Y := \|(fW)(x)(1 + |x|)^{-\Delta}\|_{L_p(\mathbb{R})} < \infty.$$

Now each $f \in X$ satisfies (1.12), so our hypothesis ensures that

$$\lim_{n \to \infty} \|f - L_n[f]\|_Y = 0.$$

By the uniform boundedness principle (recall that X is a Banach space), there exists $C_1 > 0$ such that

$$\|f - L_n[f]\|_Y \leq C_1 \|f\|_X \quad \forall n \geq 1, \quad \forall f \in X.$$

In particular, as $L_1[f] = f(0)$ (recall $p_n(W^2, x) = x$) we obtain for every continuous $f : \mathbb{R} \to \mathbb{R}$ with $f(0) = 0$, that

$$\|f\|_Y \leq C_1 \|f\|_X,$$

provided the norm on the right-hand side is finite. Hence, for every $n \geq 1$ and every continuous f with $f(0) = 0$ for which the right-hand side is finite,

$$\|L_n[f](x) W(x)(1 + |x|)^{-\Delta}\|_{L_p(\mathbb{R})} \leq C_2 \|(fW)(x)(1 + |x|)^{\alpha} \eta(x)^{-1}\|_{L_\infty(\mathbb{R})}. \tag{3.30}$$

Now choose $g_n, n \geq 1$, such that g_n is continuous in $\mathbb{R}$, $g_n = 0$ in $[0, \infty) \cup (-\infty, -a_{n/2})$;

$$\|g_n\|_X = \|(g_n W)(x)(1 + |x|)^{\alpha} \eta(x)^{-1}\|_{L_\infty(\mathbb{R})} = 1; \tag{3.31}$$

and for $x_{jn} \in [-a_{n/2}, 0)$,

$$(g_n W)(x_{jn})(1 + |x_{jn}|)^{\alpha} \eta(x_{jn})^{-1} \operatorname{sign}(p_n'(x_{jn})) = 1.$$

Then for $x > 0$, our choice of g_n and then (2.11) yield

$$\begin{aligned}
|L_n[g_n](x)| &= \left| \sum_{x_{jn} \in [-a_{n/2}, 0)} g_n(x_{jn}) \frac{p_n(x)}{p_n'(x_{jn})(x - x_{jn})} \right| \\
&= \sum_{x_{jn} \in [-a_{n/2}, 0)} \left| \frac{p_n(x)}{p_n'(x_{jn})(x - x_{jn})} \right| W^{-1}(x_{jn})(1 + |x_{jn}|)^{-\alpha} \eta(x_{jn}) \\
&= \sum_{x_{jn} \in [-a_{n/2}, 0)} |\ell_{jn}(x)| W^{-1}(x_{jn})(1 + |x_{jn}|)^{-\alpha} \eta(x_{jn}) \\
&\geq C_3 \frac{a_n^{3/2}}{n} \sum_{x_{jn} \in [-a_{n/2}, 0)} \frac{|p_n(x)|}{x + |x_{jn}|} (1 + |x_{jn}|)^{-\alpha} \eta(x_{jn}) \\
&\geq C_4 \eta(a_n) a_n^{1/2} |p_n(x)| \sum_{x_{jn} \in [-a_{n/2}, 0)} \frac{x_{j-1,n} - x_{j+1,n}}{x + |x_{jn}|} (1 + |x_{jn}|)^{-\alpha}
\end{aligned}$$

by (2.5). At least for $x \geq 1$, we have (see (2.18))

$$x + |x_{jn}| \sim x + |t|, \qquad t \in (x_{j+1,n}, x_{j-1,n}),$$

so for $x \geq 1$,

$$\begin{aligned}
|L_n[g_n](x)| &\geq C_5 \eta(a_n) a_n^{1/2} |p_n(x)| \int_0^{a_{n/4}} \frac{(1+t)^{-\alpha}}{x+t}\, dt \\
&\geq C_5 \eta(a_n) a_n^{1/2} |p_n(x)| \int_0^{\min\{a_{n/4}, x\}} \frac{(1+t)^{-\alpha}}{2x}\, dt \\
&\geq C_6 \eta(a_n) a_n^{1/2} \frac{|p_n(x)|}{x} \begin{cases} 1, & \alpha > 1, \\ \log(1 + \min\{a_{n/4}, x\}), & \alpha = 1, \\ (\min\{a_{n/4}, x\})^{1-\alpha}, & \alpha < 1. \end{cases}
\end{aligned}$$

Let us set

$$(\log x)^* := \begin{cases} \log(1+x) & \text{if } \alpha = 1, \\ 1 & \text{otherwise.} \end{cases}$$

By considering $x \in [1, a_{n/4}]$ and $x \in [a_{n/4}, 2a_n]$ separately, we see that we can rewrite the above as

$$|L_n[g_n](x)| \geq C_7 \eta(a_n) a_n^{1/2} |p_n(x)| x^{-\hat{\alpha}} (\log x)^* \tag{3.32}$$

for $x \in [1, 2a_n]$ (recall the definition (1.3) of $\hat{\alpha}$). Then we obtain from (3.28) that for $x \in [1, 2a_n]$,

$$|L_n[g_n](x)| \geq C_8 (\log n)^{-1/(2p)} a_n^{1/2} |p_n(x)| x^{-\hat{\alpha}}.$$

Hence, using (3.30)–(3.31),

$$\begin{aligned}
C_2 &\geq \|L_n[g_n](x) W(x) (1+|x|)^{-\Delta}\|_{L_p[1,2a_n]} \\
&\geq C_9 (\log n)^{-1/(2p)} a_n^{1/2} \|(p_n W)(x)(1+|x|)^{-(\hat{\alpha}+\Delta)}\|_{L_p[1,2a_n]} \\
&\geq C_{10} (\log n)^{-1/(2p)} a_n^{1/2} \|(p_n W)(x)(1+|x|)^{-(\hat{\alpha}+\Delta)}\|_{L_p[0,2a_n]} - C_{11} (\log n)^{-1/(2p)},
\end{aligned}$$

where we have used the bound (2.6) for p_n in [0, 1]. So

$$C_{12} (\log n)^{1/(2p)} \geq a_n^{1/2} \|(p_n W)(x)(1+|x|)^{-(\hat{\alpha}+\Delta)}\|_{L_p[-2a_n, 2a_n]}.$$

Now let $\hat{P}_{2a_n}$ be the polynomial of Lemma 2.5 of degree $O(a_n \log a_n) = o(n)$ such that for $|x| \leq 2a_n$,

$$\hat{P}_{2a_n}(x) \sim (1+x^2)^{-(\hat{\alpha}+\Delta)/2} \sim (1+|x|)^{-(\hat{\alpha}+\Delta)}.$$

Then we obtain from Lemma 3.5, (with $\sigma = 1/2$, and for example $\eta = 1/4$)

$$\begin{aligned}
C_{13} (\log n)^{1/(2p)} &\geq a_n^{1/2} \sum_{j=n-1}^{n} \|(p_j W)(x) \hat{P}_{2a_n}(x)\|_{L_p[-2a_j, 2a_j]} \\
&\geq C_{14} \|\hat{P}_{2a_n}(x)\|_{L_p[-a_{n/2}, a_{n/2}]} \\
&\geq C_{15} \|(1+|x|)^{-(\hat{\alpha}+\Delta)}\|_{L_p[-a_{n/2}, a_{n/2}]} \\
&\geq C_{16} \begin{cases} a_n^{1/p - (\hat{\alpha}+\Delta)}, & \Delta < 1/p - \hat{\alpha}, \\ (\log n)^{1/p}, & \Delta = 1/p - \hat{\alpha}, \\ 1, & \Delta > 1/p - \hat{\alpha}. \end{cases}
\end{aligned}$$

This is not possible for all large enough n, unless $\Delta > 1/p - \hat{\alpha}$. So we have proved (1.13) for all $1 < p < \infty$ and in particular, for $p \le 4$. This establishes the necessary conditions for $p \le 4$. To prove the necessary conditions for $p > 4$, we return to (3.32). First, for small enough $\delta \in (0,1)$, it is an easy consequence of Theorem 2.1(c) and (d), that

$$\|p_n W\|_{L_p[\delta a_n, 2a_n]} \sim \|p_n W\|_{L_p(\mathbb{R})}.$$

Then by (3.30)–(3.32),

$$\begin{aligned} C_2 &\ge \|L_n[g_n](x)W(x)(1+|x|)^{-\Delta}\|_{L_p[\delta a_n, 2a_n]} \\ &\ge C_{17}\eta(a_n)a_n^{1/2}\|p_n W\|_{L_p[\delta a_n, 2a_n]}a_n^{-(\hat{\alpha}+\Delta)}(\log n)^* \\ &\ge C_{18}\eta(a_n)a_n^{1/p-(\hat{\alpha}+\Delta)}(\log n)^* n^{(1/6)(1-4/p)}, \end{aligned}$$

by (2.10) as $p > 4$. Thus

$$\limsup_{n\to\infty} \eta(a_n)a_n^{1/p-(\hat{\alpha}+\Delta)}(\log n)^* n^{(1/6)(1-4/p)} < \infty, \tag{3.33}$$

for every function η satisfying (3.28)–(3.29). If

$$\limsup_{n\to\infty} a_n^{1/p-(\hat{\alpha}+\Delta)}(\log n)^* n^{(1/6)(1-4/p)} = \infty,$$

then it is easy to construct $\eta(x)$ decreasing slowly enough to 0 to contradict (3.33). So

$$\limsup_{n\to\infty} a_n^{1/p-(\hat{\alpha}+\Delta)}(\log n)^* n^{(1/6)(1-4/p)} < \infty,$$

and it follows that (1.14) is necessary if $\alpha \ne 1$ and (1.15) is necessary if $\alpha = 1$.

Proof of Theorem 1.1. For $W = W_\beta, a_n = Cn^{1/\beta}, n \ge 1$, and the necessary and sufficient conditions in Theorem 1.3 are very easily seen to become those in Theorem 1.1.

Proof of Corollary 1.2. Let

$$\tau(p) := \begin{cases} \frac{1}{p} - \hat{\alpha}, & p \le 4, \\ \frac{1}{p} - \hat{\alpha} + \frac{\beta}{6}\left(1 - \frac{4}{p}\right), & p > 4. \end{cases}$$

For the convergence (1.5) to hold for every $1 < p \le \infty$ and every continuous f satisfying (1.6) with a given $\Delta \in \mathbb{R}$ (independent of p), the necessary conditions of Theorem 1.1 imply that

$$\Delta \ge \tau(p), \qquad 1 < p < \infty.$$

Hence

$$\Delta \ge \lim_{p\to 1+} \tau(p) = 1 - \hat{\alpha};$$

$$\Delta \ge \lim_{p\to\infty} \tau(p) = \frac{\beta}{6} - \hat{\alpha}.$$

So it is necessary that (1.7) holds.

Conversely, for the convergence (1.5) to hold for every $1 < p < \infty$ and every continuous f satisfying (1.6), the sufficient conditions of Theorem 1.1 show that it suffices that

$$\Delta > \tau(p), \qquad 1 < p < \infty. \tag{3.34}$$

First, (1.7) shows that

$$\Delta \geq 1 - \hat{\alpha} > 1/p - \hat{\alpha} = \tau(p), \qquad 1 < p \leq 4.$$

So for $1 < p \leq 4$, (3.34) is fulfilled. Next, we can write for $p > 4$,

$$\tau(p) = \frac{\beta}{6} - \hat{\alpha} + \frac{1}{p}\left(1 - \frac{2\beta}{3}\right).$$

If $1 - (2\beta/3) \geq 0$, then for $4 < p < \infty$

$$\tau(p) \leq \tau(4) = \frac{\beta}{6} - \hat{\alpha} + \frac{1}{4}\left(1 - \frac{2\beta}{3}\right) = -\hat{\alpha} + \frac{1}{4} < 1 - \hat{\alpha} \leq \Delta,$$

by (1.7) so again (3.34) is fulfilled. Finally, if $1 - (2\beta/3) < 0$, then for $4 < p < \infty$

$$\tau(p) < \tau(\infty) = \frac{\beta}{6} - \hat{\alpha} \leq \Delta,$$

by (1.7). So we have shown that (1.7) implies (3.34) for all $1 < p < \infty$, and this establishes that (1.7) is sufficient. □

INVERSE PROBLEMS AT THE BOUNDARY FOR AN ELASTIC MEDIUM *

GEN NAKAMURA† AND GUNTHER UHLMANN‡

Abstract. In this paper, it is proven that one can determine the full Taylor series of the elastic tensor of an elastic, isotropic, inhomogeneous medium in all dimensions $n \geq 2$ and for a generic anisotropic elastic tensor in two dimensions by making measurements at the boundary of the medium of the displacement vectors and corresponding stresses. This information is encoded in the so-called Dirichlet-to-Neumann map.

Key words. inverse boundary problems, elasticity tensor, Dirichlet-to-Neumann map

AMS subject classifications. 35R30, 35P05, 35J05

1. Introduction and statement of the results.

Suppose we have a linear, inhomogeneous elastic medium. The inverse problem we address in this paper is whether knowledge of the displacement and the corresponding stress at the boundary of the medium determines its elastic parameters. In [N-U], the authors proved that the answer is in the affirmative in two dimensions in the case that the medium is isotropic and the Lamé parameters are close to constant in an appropiate topology. In this paper, we prove that from the boundary information given one can determine the Taylor series of the Lamé parameters at the boundary in the isotropic case in all dimensions. We also prove a similar result for anisotropic conductivities in two dimensions which satisfy additional conditions. The boundary determination of the elastic parameters in the isotropic case in two dimensions has been proved earlier in [A-N-S]. In a forthcoming article, we prove that one can determine the Lamé parameters in the interior by making the same type of boundary measurements in all dimensions $n \geq 3$ (see [N-UI]). The result proven in this paper is a necessary ingredient in the proof of the identifiability result in the interior.

Now we state more precisely the problem and the main results. Let $n \geq 2$ be an integer and $\Omega \subset \mathbb{R}^n$ be a bounded domain with smooth boundary $\partial\Omega$. Physically, Ω is considered as a linear, inhomogeneous, elastic medium. The deformation of Ω due to the displacement vector $\vec{f} \in C^\infty(\partial\Omega)$ given on $\partial\Omega$ is expressed by the following Dirichlet boundary value problem in terms of the displacement vector $\vec{u} = \vec{u}(x)$:

$$\begin{cases} L_C \vec{u} &= \operatorname{div} \sigma(\vec{u}) = 0 \text{ in } \Omega, \\ \vec{u}\,|_{\partial\Omega} &= \vec{f}, \end{cases} \tag{1.1}$$

where $\sigma(\vec{u})$ is the stress tensor given by the generalized Hooke's law:

$$\sigma\left(\vec{u}\right) = C\varepsilon\left(\vec{u}\right). \tag{1.2}$$

*Received by the editors April 14, 1993; accepted for publication (in revised form) September 28, 1993.

‡Department of Mathematics, University of Washington, Seattle, Washington, 98195. This research was partially supported by National Science Foundation grant DMS 91-00178.

The componentwise expression of (1.2) is

$$\sigma_{ij}(\vec{u}) = \sum_{k,\ell=1}^{n} C_{ijk\ell}\varepsilon_{k\ell}(\vec{u}) \quad (1 \le i, j \le n). \tag{1.3}$$

Here $\varepsilon(\vec{u})$ is the linear strain given by

$$\varepsilon(\vec{u}) := \operatorname{Sym}\nabla \vec{u} = 2^{-1}(\nabla \vec{u} + (\nabla \vec{u})^T), \tag{1.4}$$

where $C = C(x) = \left(C_{ijk\ell}(x)\right)_{1\le i,j,k,\ell\le n} \in C^\infty(\overline{\Omega})$ denotes the elastic tensor and $(\nabla \vec{u})^T$ denotes the transpose of $\nabla \vec{u}$.

We shall assume throughout the paper that the elastic tensor satisfies the following symmetries and strong convexity, which are physically natural conditions:

Symmetries. For any i, j, k, ℓ $(1 \le i, j, k, \ell \le n)$,

$$\text{(i) } C_{ijk\ell} = C_{ij\ell k}, \quad \text{(ii) } C_{ijk\ell} = C_{jik\ell}, \quad \text{(iii) } C_{ijk\ell} = C_{k\ell ij}. \tag{1.5}$$

Strong convexity. There exists $\delta > 0$ such that

$$\operatorname{trace}(\varepsilon(C\varepsilon)) \ge \delta\|\varepsilon\|^2 \tag{1.6}$$

on $\overline{\Omega}$ for any $n \times n$ matrix ε.

It is well known that (1.1) admits a unique solution $\vec{u} \in C^\infty(\overline{\Omega})$ if C satisfies (1.5) and (1.6). We define $\Lambda_C(\vec{f}) \in C^\infty(\partial\Omega)$ by

$$\Lambda_C(\vec{f}) = \sigma(\vec{u})\,\vec{\nu}\,|_{\partial\Omega}, \tag{1.7}$$

where $\vec{u}$ is the solution of (1.1) and $\vec{\nu}$ denotes the unit outer normal field to $\partial\Omega$.

DEFINITION 1.8. *We call the map*

$$\Lambda_C : C^\infty(\partial\Omega) \ni \vec{f} \longmapsto \Lambda_C(\vec{f}) \in C^\infty(\partial\Omega)$$

the Dirichlet-to-Neumann map (D-N).

The problem we consider in this paper is whether we can recover C and all of its derivatives on $\partial\Omega$ from Λ_C. In this paper, we prove that this is the case for isotropic n-dimensional medium and for a "generic" class of anisotropic elastic tensors in two dimensions.

DEFINITION 1.9. *We call the elastic medium Ω or its elastic tensor C isotropic if $C = (C_{ijk\ell})_{1\le i,j,k,\ell\le n}$ is given by*

$$C_{ijk\ell} = \lambda\delta_{ij}\delta_{k\ell} + \mu(\delta_{ik}\delta_{j\ell} + \delta_{i\ell}\delta_{jk})$$

with Lamé moduli λ, $\mu \in C^\infty(\overline{\Omega})$, where δ_{ik} is the Kronecker delta.

THEOREM 1.10. *For any $n \ge 2$, for any isotropic elastic medium Ω there is an inversion formula for identifying C and all of its derivatives on $\partial\Omega$ from Λ_C.*

Remark 1.11.

(i) The inversion formula can be seen in the proof of Theorem 1.10, which is given in §3.

(ii) Akamatsu, Nakamura, and Steinberg [A-N-S] proved Theorem 1.10 for $n = 2$.

We now describe a corresponding result for anisotropic C in two dimensions under some conditions that we formulate below.

Let $(x^1, \dots, x^n)$ denote local coordinates and $(x_1, \dots, x_n)$ denote cartesian coordinates. Set

$$C^{ijk\ell}(x) = \sum_{a,b,c,d=1}^{n} g^{ai}(x)g^{bj}(x)g^{ck}(x)g^{d\ell}(x)C_{abcd}(x)$$

$$\varepsilon^{ij}(x) = \sum_{a,b=1}^{n} g^{ai}(x)g^{bj}(x)\varepsilon_{ab}(x),$$

where

$$g^{ai}(x) = \sum_{r=1}^{n} \frac{\partial x^a}{\partial x_r}(x)\frac{\partial x^i}{\partial x_r}(x).$$

Assume that there exist scalar functions $\lambda_\alpha \in C^\infty(\overline{\Omega})$ $(1 \le \alpha \le 2n)$ satisfying

$$\sum_{\alpha,\beta=1}^{n(n+1)/2} C^{\alpha,\beta}\varepsilon_\alpha\varepsilon_\beta = \sum_{\alpha=1}^{n(n+1)/2} \lambda_\alpha\varepsilon_\alpha\varepsilon^\alpha \tag{1.12}$$

for any covariant symmetric tensor (ε_α) and the associated contravariant symmetric tensor (ε^α). Here $(C^{\alpha,\beta})$, (ε_α), (ε^α) are defined by renumerating the double indices (i, j), (k, ℓ) of $(C^{ijk\ell})$, (ε_{ij}), (ε^{ij}) into single indices α, β.

THEOREM 1.13. *Let $n = 2$ and C satisfy* (1.12) *and the generic condition in Definition* (2.5). *Then there is an inversion formula for identifying C and all of its derivatives on $\partial\Omega$ from Λ_C.*

Remark 1.14. The inversion formula can be seen in the proof of Theorem 1.13 in §3.

The proof of the main results follows from the asymptotic formula for the full symbol of the D-N map proven in §2. We write the full symbol of the D-N map in terms of the surface impedance tensor. In the isotropic case we can easily recover the elastic tensor from the surface impedance tensor (see §3). For the anisotropic case in two dimensions the surface impedance tensor has three components and the elastic tensor has also three components under the assumption (1.12), so that it becomes possible to determine one from the other. This is the main reason to assume a condition like (1.12). The computations in §2 rely on Stroh's formalism which can be seen, for instance, in [C-S] for the three-dimensional case. We include in the appendix an extension of Stroh's formalism to the n-dimensional case.

We also note that the problem considered here is a direct analog of the inverse conductivity problem. Theorem 1.10 is the analog of a corresponding result proven by Kohn and Vogelius [K-V] for the inverse conductivity problem. Another proof of this result using the full symbol of ther D-N map was given in [S-U]. The boundary determination in the anisotropic case was proven in [L-U].

2. Full symbol of the D-N map. In what follows we identify the orthogonal complement $N^*(\partial\Omega)^\perp$ of the conormal bundle $N^*(\partial\Omega)$ of $\partial\Omega$ and the cotangent bundle $T^*(\partial\Omega)$ of $\partial\Omega$ by giving the Euclidean metric to $\mathbb{R}^n$ and its induced metric to $\partial\Omega$. The identification is done via the unitary map

$$N_y^*(\partial\Omega)^\perp \ni \xi \longmapsto \xi|_{T_y^*(\partial\Omega)} \in T_y^*(\partial\Omega)$$

for each $y \in \partial\Omega$. Moreover, we assume that the elasticity tensor C satisfies (1.5) and (1.6).

Let $s(x)$ be a local defining function of $\partial\Omega$ such that $|ds(x)| = 1$ on $\partial\Omega$ and $x = (x^1, \dots, x^{n-1}, x^n) = (y^1, \dots, y^{n-1}, s) = y$ be local coordinates such that $dy^j \perp ds (1 \leq j \leq n-1)$ near a fixed point $y_0 \in \partial\Omega$. We assume that Ω is locally given by $\{s(x) > 0\}$.

DEFINITION 2.1. *For any $(y, \eta) \in T^*(\partial\Omega)$, we define the surface impedance tensor $Z(y, \eta)$ by*

$$\begin{cases} Z(y,\eta) &= -Q^{-1}(y,\eta) - \sqrt{-1}Q^{-1}(y,\eta)S(y,\eta), \\ Q(y,\eta) &= -(2\pi)^{-1}\int_0^{2\pi} \langle w, w\rangle^{-1} d\varphi, \\ S(y,\eta) &= -(2\pi)^{-1}\int_0^{2\pi} \langle w, w\rangle^{-1}\langle w, \zeta\rangle d\varphi. \end{cases} \tag{2.2}$$

where the (j, k) component $\langle \zeta, w\rangle_j^k$ of the mixed tensor $\langle \zeta, w\rangle$ is given by

$$\langle \zeta, w\rangle_j^k = \sum_{i,\ell=1}^{n} \zeta_i C_j^{i\ell k}(y) w_\ell, \quad C_j^{i\ell k}(y) = \sum_{a,b,c=1}^{n} g^{ai}(y) g^{b\ell}(y) g^{ck}(y) C_{ajbc}(y),$$

where

$$\zeta = (\cos\varphi)|\eta|^{-1}\eta + (\sin\varphi) ds(y) = \sum_{i=1}^{n} \zeta_i (dx^i)_y,$$

$$w = -(\sin\varphi)|\eta|^{-1}\eta + (\cos\varphi) ds(y) = \sum_{i=1}^{n} w_i (dx^i)_y.$$

Similarly, we can define the surface impedance tensor $Z(\overline{y}, \overline{\eta})$ for every surface $\Gamma(\overline{y}) : s(x; \overline{y}) := s(x) - s(\overline{y}) = 0$, where $\overline{y}$ is close to $y \in \partial\Omega$ and $(\overline{y}, \overline{\eta}) \in T^*_{\overline{y}}(\Gamma(\overline{y}))$. By the natural identification $T^*_y(\partial\Omega) \cong T^*_{\overline{y}}(\Gamma(\overline{y})) \cong \mathbb{R}^n$, we can fix $\eta \in T^*_y(\partial\Omega) \cong T^*_{\overline{y}}(\Gamma(\overline{y}))$ and let $Z(\overline{y}, \eta)$ depend smoothly on $\overline{y}$ near $\overline{y} = y$. If any variation along the normal direction of $\partial\Omega$ is necessary, we interpret the surface impedance tensor in this manner. For example, in Theorem 2.6 we consider the derivatives of $Z(y, \eta)$ with respect to s.

DEFINITION 2.3. For any $(y, \eta) \in T^*(\partial\Omega)\backslash 0$, we define $K_s(y, \eta) \in C^\infty([0, \varepsilon); \mathrm{Hom}(\Xi, \Xi))$[1] by

$$K_s(y,\eta) = \begin{bmatrix} K_s^{11}(y,\eta), & K_s^{12}(y,\eta) \\ K_s^{21}(y,\eta), & K_s^{22}(y,\eta) \end{bmatrix} \quad (s \in [0, \varepsilon)), \tag{2.4}$$

with

$$\begin{cases} K_s^{11}(y,\eta) &= -\langle ds(x), ds(x)\rangle^{-1}\langle ds(x), \eta\rangle \\ K_s^{12}(y,\eta) &= -|\eta|\langle ds(x), ds(x)\rangle^{-1} \\ K_s^{21}(y,\eta) &= -|\eta|^{-1}\{\langle \eta, ds(x)\rangle\langle ds(x), ds(x)\rangle^{-1}\langle ds(x), \eta\rangle - \langle \eta, \eta\rangle\} \\ K_s^{22}(y,\eta) &= -\langle \eta, ds(x)\rangle\langle ds(x), ds(x)\rangle^{-1} \end{cases}$$

[1]From now on, $C^\infty(U; V)$ (resp., $C^\infty(U, V)$) denotes the set of smooth V-valued functions (resp., sections $U \longrightarrow V$).

and $\Xi = \pi^*(T^*(\partial\Omega)^{\mathbb{C}} \oplus \pi^*(T^*(\partial\Omega))^{\mathbb{C}}$ with π the natural projection $\pi : T^*(\partial\Omega) \longrightarrow \partial\Omega$. Here "$\oplus$," "$\mathbb{C}$," and "Hom" denote the Whitney sum, complexification, and the vector bundle of homomorphisms, respectively. Moreover, $x = (y, s)$ and $\langle ds(x), ds(x)\rangle$, $\langle ds(x), \eta\rangle$ are defined similarly as the above $\langle \zeta, w\rangle$ by using the identification $\eta \in T_y(\partial\Omega) \cong T_x(\Gamma(x))$.

DEFINITION 2.5. *We say that the elasticity tensor C is* generic *at $(y_0, \eta^0) \in T^*(\partial\Omega)\backslash 0$ if all the eigenvalues of $K_s(y, \eta)$ are distinct for each $s \in [0, \varepsilon)$ and (y, η) in a conic neighborhood (y_0, η^0).*

It is well known that the D-N map

$$\Lambda_C : C^\infty(\partial\Omega, T^*(\partial\Omega)^{\mathbb{C}} \oplus T^*(\partial\Omega)^{\mathbb{C}}) \longrightarrow C^\infty(\partial\Omega, T^*(\partial\Omega)^{\mathbb{C}} \oplus T^*(\partial\Omega)^{\mathbb{C}})$$

is a classical pseudodifferential operator of order 1.

In terms of the above local coordinates $(x^1, \ldots, x^{n-1}, x^n) = (y^1, \ldots, y^{n-1}, s)$, we have the following asymptotic representation formula for the full symbol $\tilde{\sigma}(\Lambda_C)$ of Λ_C.

THEOREM 2.6. *Assume that either* (i) *or* (ii) *is satisfied.*

(i) *C is generic at (y_0, η^0).*

(ii) *C is isotropic near y_0.*

Then we have the following formula for $\tilde{\sigma}(\Lambda_C)(y, \eta)$:

$$\tilde{\sigma}(\Lambda_C)(y, \eta) \simeq -|\eta| Z(y, \eta) + \sum_{j=1}^{\infty} |\eta|^{1-j} W_j (D_s^j Z)(y, \eta) \tag{2.7}$$

in a conic neighborhood of (y_0, η^0), where $D_s = -\sqrt{-1}\frac{\partial}{\partial s}$ and each W_j is a linear bijective map on the set of all $n \times n$ matrices which do not depend on the s derivatives of C. The meaning of "$\simeq$" in (2.7) is as follows. For each $k \in \mathbb{N}$,

$$\tilde{\sigma}(\Lambda_C)(y, \eta) + |\eta| Z(y, \eta) - \sum_{j=1}^{k-1} |\eta|^{1-j} W_j (D_s^j Z)(y, \eta) = 0 \mod (\tilde{T}^{k-1}, S^{-k+1})$$

in a conic neighborhood of (y_0, η^0). Here $\mathrm{mod}(\tilde{T}^{k-1}, S^{-k+1})$ means that we are neglecting the terms in S^{-k+1} in a conic neighborhood (y_0, η^0) and the term $\notin S^{-k+1}$ in a conic neighborhood which depend only on the s derivatives of C up to order $k-1$. Moreover, S^{-k+1} is used to denote either the usual class of classical symbols or the associated class of pseudodifferential operators and $\sum_{k=1}^{n-1}$ does not exist for $n = 1$.

Proof. We first give an outline of the computation of $\tilde{\sigma}(\Lambda_C)(y, \eta)$.

Step 1. We write (1.1) locally in the following form using tensorial notation.

$$\begin{cases} M\vec{u} = 0 & \text{in } \Omega, \\ \vec{u}\,|_{\partial\Omega} = \vec{f}, \end{cases} \tag{2.8}$$

where

$$M\cdot := \left(\sum_{i,\ell=1}^{n} \nabla_i \left(C_j^{i\ell k}(x) \nabla_\ell \cdot \right) \quad \substack{j \downarrow 1,\ldots,n \\ k \rightarrow 1,\ldots,n} \right), \tag{2.9}$$

$$B\cdot := \left(\sum_{i,\ell=1}^{n} C_j^{i\ell k}(x) \frac{\partial s}{\partial x^i}(x) \nabla_\ell \cdot \quad \substack{j \downarrow 1,\ldots,n \\ k \rightarrow 1,\ldots,n} \right), \tag{2.10}$$

and ∇_i is the covariant differential with respect to $\frac{\partial}{\partial x^i}$.

Step 2. We transform (2.8) into the following boundary value problem:

$$\begin{cases} D_s U = N_s U & \text{in } s > 0, \\ [I_n, 0_n] U|_{s=0} & = \Lambda \vec{f}, \end{cases} \tag{2.11}$$

where

$$U = \begin{bmatrix} \Lambda \vec{u} \\ \vec{v} \end{bmatrix}, \qquad \tilde{\sigma}(\Lambda)(y,\eta) = |\eta|, \tag{2.12}$$

$$\vec{v} = -\langle ds, ds\rangle D_s \vec{u} - \langle ds, D_y\rangle \vec{u}, \quad \tilde{\sigma}(\langle ds, D_y\rangle) = \langle ds, \eta\rangle, \tag{2.13}$$

$$K_s(y,\eta) = \sigma(N_s)(y,\eta) \text{ (i.e., the principal symbol of } N) \tag{2.14}$$

and $[I_n, 0_n]$ denotes the matrix whose first n rows and columns is the identity matrix and whose last n rows and n columns is the zero matrix.

Step 3. We diagonalize the system. There exists classical pseudodifferential operators $Q_s(y, D_y)$ and $\widetilde{N}_s(y, D_y)$ of order 0 and 1, respectively, depending smoothly on $s \in [0, \varepsilon)$, such that

$$LQ_s - Q_s \widetilde{L} = 0 \mod S^{-\infty}, \tag{2.15}$$

where

$$L = D_s - N_s, \quad \widetilde{L} = D_s - \widetilde{N}_s, \quad \tilde{\sigma}(\tilde{N}_s) = \begin{bmatrix} \tilde{N}_s^+, & 0_n \\ 0_n, & \tilde{N}_s^- \end{bmatrix} \tag{2.16}$$

with $\pm$ (the imaginary part of each eigenvalue of $\sigma(\tilde{N}_s^{\pm})) > 0$, and

$$\tilde{\sigma}(Q_s) \sim \sigma(Q_s) + \sum_{j=1}^{\infty} R_s^{(-j)}(y,\eta), \quad \text{ord } R_s^{(-j)} = -j \tag{2.17}$$

and the order of the s derivatives of C in each $R_s^{(-j)}$ is not greater than j.

Consider the well-posed Cauchy problem:

$$\begin{cases} (D_s - \widetilde{N}_s^+) \vec{w}^+ = 0 & \text{in } s > 0, \\ \vec{w}^+|_{s=0} = \vec{h}. \end{cases} \tag{2.18}$$

We define the map T by

$$T\vec{h} := \vec{w}^+. \tag{2.19}$$

Step 4. We write the D-N map in terms of Q_s. Clearly,

$$U := Q_s \tilde{J} T \vec{h}, \quad \tilde{J} = \begin{bmatrix} I_n \\ 0_n \end{bmatrix}$$

satisfies

$$(D_s - N_s)U = 0 \bmod C^\infty.$$

Moreover, if $\vec{h}$ satisfies

$$R\vec{h} = \Lambda \vec{f}, \qquad R = ([I_n, 0_n]Q_s\tilde{J}T)|_{s=0}, \tag{2.20}$$

then U satisfies the boundary condition of (2.11). Hence the Poisson operator P is given by

$$P = Q_s\tilde{J}TR^{-1}\Lambda \mod S^{-\infty}. \tag{2.21}$$

Therefore, the D-N map Λ_C is given by

$$\Lambda_C = -\sqrt{-1}[0_n, I_n]P|_{s=0} \mod S^{-\infty}. \tag{2.22}$$

Although (2.22) is a global formula for Λ_C, we only have to compute $\tilde{\sigma}(\Lambda_C)$ in a conic neighborhood of (y_0, η^0) (i.e., microlocally at (y_0, η^0)). Hence in the following we assume that all pseudodifferential operators are defined microlocally at (y_0, η^0) and the the notation for pseudodifferential operators and their symbols such as "$\cdot \in S^{-k+1}$," "$\cdot \equiv \cdot \bmod S^{-k}$," "$\cdot \sim \cdot$," "$\cdot \simeq \cdot$," "$\cdot = \cdot$," "$\bmod(\tilde{T}^{k-1}, S^{-k+1})$," etc. are understood to be microlocal at (y_0, η^0).

We now go into detail of the proof of Theorem 2.6. To start with, we explain more precisely the choice of Q_s and $\tilde{N}_s$.

For simplicity we drop the subscript "s" from now on. So for example, we will simply write Q instead of Q_s.

Since L inherits the ellipticity from that of M, there exists a homogeneous elliptic symbol $\tilde{Q}(y, \eta)$ of order 0 such that

$$K(y, \eta)\tilde{Q}(y, \eta) = \tilde{Q}(y, \eta)\sigma(\tilde{N})(y, \eta). \tag{2.23}$$

Hence there exists $D \in S^0$ such that

$$L\tilde{Q} - \tilde{Q}L' \equiv 0 \bmod S^0, \tag{2.24}$$

where

$$L' = D_s - \Lambda - D, \qquad \Lambda = \sigma(\tilde{N})(y, D_y), \tag{2.25}$$

$$\sigma(D) \equiv -\tilde{Q}^{-1}D_s\tilde{Q} \mod (\tilde{T}^0, S^{-1}). \tag{2.26}$$

Next we seek a pseudodifferential operator $\Phi \in S^0$ such that

$$\Phi - I_{2n} \in S^{-1}, \qquad L'\Phi - \Phi\tilde{L} \equiv 0 \bmod S^{-\infty}. \tag{2.27}$$

Hence Q can be chosen as

$$Q = \tilde{Q}\Phi \tag{2.28}$$

and $\tilde{N}$ is constructed in the process of choosing Q.

In order to construct Q and $\widetilde{N}$ we define

$$\Phi^{(-j)} = \begin{bmatrix} 0_n & \Phi_{12}^{(-j)} \\ \Phi_{21}^{(-j)} & 0_n \end{bmatrix} \in S^{-j} \quad (j = 1, 2, \ldots) \tag{2.29}$$

and

$$E^{(-j)} = \begin{bmatrix} E_+^{-(j)} & 0_n \\ 0_n & E_-^{(-j)} \end{bmatrix} \in S^{-j} \quad (j = 0, 1, 2, \ldots) \tag{2.30}$$

inductively as follows. Set

$$J^{(0)} = L' I_{2n} - I_{2n}(D_s - \Lambda) = \begin{bmatrix} J_{11}^{(0)} & J_{12}^{(0)} \\ J_{21}^{(0)} & J_{22}^{(0)} \end{bmatrix}. \tag{2.31}$$

Define $\Phi^{(-1)}$ and $E^{(0)}$ by

$$\begin{cases} \widetilde{N}^+ \Phi_{12}^{(-1)} - \Phi_{12}^{(-1)} \widetilde{N}^- - \sigma(J_{12}^{(0)}) = 0, \\ \widetilde{N} \Phi_{21}^{(-1)} - \Phi_{21}^{(-1)} \widetilde{N}^+ - \sigma(J_{21}^{(0)}) = 0, \end{cases} \tag{2.32}$$

and

$$E^{(0)} = -\begin{bmatrix} \sigma(J_{11}^{(0)}) & 0_n \\ 0_n & \sigma(J_{22}^{(0)}) \end{bmatrix}. \tag{2.33}$$

Having constructed $\Phi^{(-j)} (1 \le j \le k)$, $E^{(-j)} (0 \le j \le k)$, we define $\Phi^{(-k-1)}$, $E^{(-k)}$ by

$$\begin{cases} \widetilde{N}^+ \Phi_{12}^{(-k-1)} - \Phi_{12}^{(-k-1)} \widetilde{N}^- - \sigma(J_{12}^{(-k)}) = 0, \\ \widetilde{N}^- \Phi_{21}^{(-k-1)} - \Phi_{21}^{(-k-1)} \widetilde{N}^+ - \sigma(J_{21}^{(-k)}) = 0, \end{cases} \tag{2.34}$$

$$E^{(-k)} = -\begin{bmatrix} \sigma(J_{11}^{(-k)}) & 0_n \\ 0_n & \sigma(J_{22}^{(-k)}) \end{bmatrix}, \tag{2.35}$$

where

$$\begin{aligned} J^{(-k)} &= \begin{bmatrix} J_{11}^{(-k)} & J_{12}^{(-k)} \\ J_{21}^{(-k)} & J_{22}^{(-k)} \end{bmatrix} \\ &= L'\Big(I + \sum_{j=1}^{k} \Phi^{(-j)}\Big) - \Big(I + \sum_{j=1}^{k} \Phi^{(-j)}\Big)\Big(D_s - \Lambda - \sum_{j=0}^{k-1} E^{(-j)}\Big). \end{aligned} \tag{2.36}$$

Here we note that (2.32) and (2.34) are uniquely solvable for $\Phi_{12}^{(-1)}$, $\Phi_{21}^{(-1)}$, and $\Phi_{12}^{(-k-1)}$, $\Phi_{21}^{(-k-1)}$, because $\widetilde{N}^+$ and $\widetilde{N}^-$ do not have any common eigenvalues.

We prove now the first key lemma.

LEMMA 2.37.

$$\begin{cases} S^0 \ni J^{(0)} \equiv \widetilde{Q}^{-1} D_s \widetilde{T} \mod (\widetilde{T}^0, S^{-1}), \\ S^{-k} \ni J^{(-k)} \equiv D_s \Phi^{(-k)} \mod (\widetilde{T}^k, S^{-k-1}) \quad (k = 1, 2, \ldots), \end{cases} \tag{2.38}$$

and

$$\text{(2.39)}\qquad \begin{cases} \Phi^{(-k-1)}(y,\eta) & \in \widetilde{T}^{k+1}\cdot S^{-k-1}, \\ E^{(-k)}(y,\eta) & \in \widetilde{T}^{k+1}\cdot S^{-k} \end{cases}$$

for any $k = 0,1,2,\ldots$. *Here, for any* $0 \le \ell \in \mathbb{Z}$, $m \in \mathbb{Z}$, $\widetilde{T}^{\ell}\cdot S^{m}$ *denotes the homogeneous classical symbols of order* m *which depend only on the* s *derivatives of* C *up to order* ℓ.

Proof. It is easy to see that

$$\begin{cases} S^0 \ni J^{(0)} \equiv \widetilde{Q}^{-1}D_s\widetilde{Q} \bmod (\widetilde{T}^0,\, S^{(-1)}), \\ \Phi^{(-1)}(y,\eta) \in \widetilde{T}^1\cdot S^{-1},\ E^{(0)}(y,\eta) \in \widetilde{T}^1\cdot S^0. \end{cases}$$

Then

$$\text{(2.40)}\qquad \begin{cases} S^{-k} \ni J^{(-k)} \equiv D_s\Phi^{(-k)} \bmod (\widetilde{T}^k, S^{-k-1}), \\ \Phi^{(-k-1)}(y,\eta) \in \widetilde{T}^{k+1}\cdot S^{-k-1}, \qquad E^{(-k)}(y,\eta) \in \widetilde{T}^{k+1}\cdot S^{-k} \end{cases}$$

for any $k = 1,2,\ldots$ is proved by induction on k.

Since it is easy to prove that (2.40) is already valid for $k = 1$, we only need to prove (2.40) for $k+1$, assuming that it is already valid for k. Observe that

$$\begin{aligned} &J^{(-k-1)} \\ &= L'\Big(I_{2n} + \sum_{j=1}^{k+1}\Phi^{(-j)}\Big) - \Big(I_{2n} + \sum_{j=1}^{k+1}\Phi^{(-j)}\Big)\Big(D_s - \Lambda - \sum_{j=0}^{k}E^{(-j)}\Big) \\ &= \Big\{L'\Big(I_{2n} + \sum_{j=1}^{k}\Phi^{(-j)}\Big) - \Big(I_{2n} + \sum_{j=1}^{k}\Phi^{(-j)}\Big)\Big(D_s - \Lambda - \sum_{j=0}^{k-1}E^{(-j)}\Big)\Big\} + L'\Phi^{(-k-1)} \\ &\quad - \Phi^{(-k-1)}\Big(D_s - \Lambda - \sum_{j=0}^{k}\Phi^{(-j)}\Big) + \Big(I_{2n} + \sum_{j=1}^{k+1}\Phi^{(-j)}\Big)E^{(-k)} \\ &= \Big\{J^{(-k)} - (\Lambda\Phi^{(-k-1)} - \Phi^{(-k-1)}\Lambda)\Big\} + D_s\Phi^{(-k-1)} + \Big\{\Phi^{(-k-1)}\sum_{j=0}^{k}E^{(-j)} \\ &\qquad\qquad + \sum_{j=1}^{k+1}\Phi^{(-j)}E^{(-k)}\Big\}. \end{aligned}$$

Hence

$$S^{-k-1} \ni J^{-k-1} \equiv D_s\Phi^{(-k-1)} \bmod (\widetilde{T}^{k+1},\, S^{-k-2}).$$

The facts that $\Phi^{(-k-2)}(y,\eta) \in \widetilde{T}^{k+2}\cdot S^{-k-2}$ and $E^{(-k-1)}(y,\eta) \in \widetilde{T}^{k+2}\cdot S^{-k-1}$ are clear from (2.34) and (2.35).

Now let $\widetilde{N}_s$ and Φ_s be pseudodifferential operators of order 1 and 0, respectively, depending smoothly on $s \in [0,\varepsilon)$ such that

$$\text{(2.41)}\qquad \widetilde{\sigma}(\widetilde{N}_s) \sim \Lambda + \sum_{j=0}^{\infty}E_s^{(-j)}, \qquad \Phi_s \sim I_{2n} + \sum_{j=1}^{\infty}\Phi_s^{(-j)}.$$

Then, using (2.36) and (2.38), it is easy to see that Q_s and $\widetilde{N}_s$ satisfy (2.15)–(2.17).

Now we arrange our local coordinates $(x^1, \dots, x^{n-1}, x^n)$ so that

$$\eta^0/|\eta^0| = (1, 0, \dots, 0), \qquad ds(y_0) = (0, \dots, 0, 1) \tag{2.42}$$

and $dx^j (1 \le j \le n)$ are orthonormal at y_0 in terms of these special local coordinates. Then, as in [N], $K(y_0, \eta^0)$ is related to $N(0)$, which is defined by (4.45) in the Appendix through the relation

$$K(y_0, \eta^0) = \begin{bmatrix} -I_n, & 0_n \\ 0_n, & I_n \end{bmatrix} N(0) \begin{bmatrix} -I_n & 0_n \\ 0_n & I_n \end{bmatrix} \tag{2.43}$$

in terms of these coordinates. By using (2.43), we normalize the eigenvectors and the generalized eigenvectors $\langle -a_\alpha, \ell_\alpha \rangle$ $(1 \le \alpha \le 2n)$ of $K(y_0, \eta^0)$ in terms of these coordinates using (4.8) in [C-S]. Here a_α, ℓ_α are similar to those in (4.14) of [C-S].

Let $A_\alpha, L_\alpha (1 \le \alpha \le 2n)$ be covariant vectors such that

$$A_\alpha = a_\alpha, \quad L_\alpha = \ell_\alpha \tag{2.44}$$

in terms of the special local coordinates, and define the $n \times n$ matrices A, L by

$$A = [A_1, \dots, A_n], \qquad L = [L_1, \dots, L_n]. \tag{2.45}$$

Then we can define $\widetilde{Q}$ by

$$\widetilde{Q} = \begin{bmatrix} -A, & -\overline{A} \\ L, & \overline{L} \end{bmatrix}, \tag{2.46}$$

where "$-$" denotes complex conjugate.

Let A^α, L^α $(1 \le \alpha \le 2n)$ be the contravariant vectors associated with A_α, L_α $(1 \le \alpha \le 2n)$ and define the $n \times n$ matrices A', L' by

$$A' = [A^1, \dots, A^n], \qquad L' = [L^1, \dots, L^n]. \tag{2.47}$$

If we interpret (4.8) in [C-S] by using the tranformation rule of covariant and contravariant vectors under change of local coordinates, we have

$$\widetilde{Q}^T J \widetilde{Q}' = I, \tag{2.48}$$

where

$$\widetilde{Q}' = \begin{bmatrix} -A' & -\overline{A}' \\ L' & \overline{L}' \end{bmatrix}, \qquad J = \begin{bmatrix} 0_n & I_n \\ I_n & 0_n \end{bmatrix}. \tag{2.49}$$

Hence

$$\widetilde{Q}^{-1} = (\widetilde{Q}')^T J. \tag{2.50}$$

It is convenient now to introduce the following definition.

DEFINITION 2.51.

(i) *For a given matrix* $F = (F_{jk})_{1\le j,k\le n}$, *we denote the unique solution* X *of the equation* $\widetilde{N}^+X - X\widetilde{N}^- = F$ *by* $X = W(F)$.

(ii) *For* $a, b \in \mathbb{Z}$, $a \ge 0$, *we define* $\sum_{\ell=0}^{\infty} \widetilde{T}^{\ell+a}.S^{b-\ell} = \{$*classical symbols* $r_s(y,\eta)$ *which depend smoothly on* $s \in [0,\varepsilon)$ *and admit an asymptotic expansion* $r_s(y,\eta) \sim \sum_{\ell=0}^{\infty} r_s^{b-\ell}(y,\eta)$ *such that* $r_s(y,\eta) \simeq \sum_{\ell=0}^{\infty} r_s^{b-\ell}(y,\eta)\}$.

Here " $\simeq$ *" means that each* $r_s^{b-\ell}(y,\eta)$ *depends only on the* s *derivatives of* C *up to order* $\ell+a$ *and* $r_s - \sum_{\ell=0}^{k-1} r^{b-\ell} \equiv 0 \bmod (\widetilde{T}^{k+a-1}, S^{b-k})$ *for each* $k \in \mathbb{N}$. *In particular,* $\widetilde{T}^{\ell+a} \cdot S^{b-\ell} = \{$*homogeneous classical symbols* $r_s^{b-\ell}(y,\eta)$ *of order* $b-\ell$ *which depend smoothly on* $s \in [0,\varepsilon)$ *and only on the* s *derivatives of* C *up to order* $\ell+a\}$.

The following is also a key lemma.

LEMMA 2.52. *For each* $j = 1, 2, \ldots$, *we have*

$$\Phi_{12}^{(-j)} \equiv -W^j\big((L')^T D_s^j \overline{A} + (A')^T D_s^j \overline{L}\big) \mod \big(\widetilde{T}^{j-1}, S^{-j-1}\big) \tag{2.53}$$

and

$$\overline{\Phi_{21}^{(-j)}} \equiv (-1)^j \Phi_{12}^{(-j)} \mod (\widetilde{T}^{j-1}, S^{-j-1}). \tag{2.54}$$

Proof. Both statements are proved by induction on j at the same time. From (2.38), (2.48), (2.50), we have

$$\begin{cases} J_{12}^{(0)} \equiv -\big((L')^T D_s \overline{A} + (A')^T D_s \overline{L}\big) \mod (\widetilde{T}^0, S^{-1}), \\ J_{21}^{(0)} \equiv -\big((\overline{L}')^T D_s A + (\overline{A}')^T D_s L\big) \mod (\widetilde{T}^0, S^{-1}). \end{cases} \tag{2.55}$$

Since $\overline{\widetilde{N}^+} = \widetilde{N}^-$, $J_{12}^{(0)} \equiv -\bar{J}_{21}^{(0)} \bmod (\widetilde{T}^0, S^{-1})$, (2.32) and (2.55) imply

$$\begin{cases} \Phi_{12}^{(-1)} \equiv -W\big((L')^T D_s \overline{A} + (A')^T D_s \overline{L}\big) \mod (\widetilde{T}^0, S^{-2}), \\ \overline{\Phi_{21}^{(-1)}} \equiv -\Phi_{12}^{(-1)} \mod (\widetilde{T}^0, S^{-2}). \end{cases} \tag{2.56}$$

Now assume that (2.53) and (2.54) are valid for j. From (2.40) and the induction hypothesis, we have

$$J_{12}^{(-j)} \equiv -W^j\big((L')^T D_s^{j+1} \overline{A} + (A')^T D_s^{j+1} \overline{L}\big) \bmod (\widetilde{T}^j, S^{-j-1}). \tag{2.57}$$

Then (2.53) for $j+1$ follows from (2.34) and (2.57).

From (2.34) and $\overline{\widetilde{N}^+} = \widetilde{N}^-$, we deduce

$$\widetilde{N}^+ \overline{\Phi_{21}^{(-j-1)}} - \overline{\Phi_{21}^{(-j-1)}} \widetilde{N}^- - \overline{\sigma(J_{21}^{(-j)})} = 0. \tag{2.58}$$

By using (2.38) and the induction hypothesis, we have

$$\widetilde{N}^+ \overline{\Phi_{21}^{(-j-1)}} - \overline{\Phi_{21}^{(-j-1)}} \widetilde{N}^- - (-1)^{j+1} \sigma(J_{21}^{-j}) \equiv 0 \mod (\widetilde{T}^j, S^{-j-1}). \tag{2.59}$$

Comparing (2.58) with (2.34), we deduce (2.54) for $j+1$.

LEMMA 2.60. *Let*

$$\widetilde{\Phi}_s = \Phi_s - I_{2n}. \tag{2.61}$$

Then we have

(2.62)
$$\begin{cases} \widetilde{\sigma}(R) = -A\left(I_n - A^{-1}[I_n, 0_n]\widetilde{\sigma}(\widetilde{Q}_0\widetilde{\Phi}_0)\begin{bmatrix} I_n \\ 0_n \end{bmatrix}\right) \\ A^{-1}[I_n, 0_n]\widetilde{\sigma}(\widetilde{Q}_0\widetilde{\Phi}_0)\begin{bmatrix} I_n \\ 0_n \end{bmatrix} \simeq \sum_{j=1}^{\infty} A^{-1}[I_n, 0_n]\widetilde{Q}_0\Phi_0^{(-j)}\begin{bmatrix} I_n \\ 0_n \end{bmatrix} \in \sum_{j=0}^{\infty} \tilde{T}^j \cdot S^{-j} \\ \widetilde{\sigma}(-\sqrt{-1}[0_n, I_n]Q_s\widetilde{J}T|_{s=0}) \simeq -\sqrt{-1}L - \sum_{j=1}^{\infty} \sqrt{-1}[0_n, I_n]\widetilde{Q}_0\Phi_0^{(-j)}\begin{bmatrix} I_n \\ 0_n \end{bmatrix} \\ \qquad\qquad \in \sum_{j=0}^{\infty} \tilde{T}^j \cdot S^{-j}. \end{cases}$$

Proof. By the formula for the full symbol of the composition of two pseudodifferential operators, we have

$$\widetilde{\sigma}(\widetilde{Q}_0\widetilde{\Phi}_0) \sim \sum_{k=0}^{\infty}(k!)^{-1}\langle -i\partial_z, \partial_\zeta\rangle^k \left\{\widetilde{Q}_0(y,\zeta)\widetilde{\Phi}_0(z,\eta)\right\}|_{z=y,\ \zeta=\eta}. \tag{2.63}$$

From now on we denote, for convenience, the right-hand side of (2.63) by $\widetilde{Q}_0 \odot \widetilde{\Phi}_0$. By using (2.39) and (2.41) in (2.64), we conclude

$$\begin{aligned} \widetilde{Q}_0 \odot \widetilde{\Phi}_0 &= \sum_{\ell=1}^{\infty} \sum_{j+k=\ell} (k!)^{-1}\langle -i\partial_z, \partial_\zeta\rangle^k \left\{\widetilde{Q}_0(y,\eta)\widetilde{\Phi}_0^{(1j)}(z,\eta)\right\}|_{z=y,\,\zeta=\eta} \\ &\simeq \sum_{\ell=1}^{\infty} \widetilde{Q}_0(y,\eta)\widetilde{\Phi}_0^{(-\ell)}(y,\eta) \in \sum_{\ell=1}^{\infty} \widetilde{T}^\ell \cdot S^{-\ell}. \end{aligned} \tag{2.64}$$

Then (2.62) follows immediately from (2.20) and (2.63).

LEMMA 2.65.

$$\widetilde{\sigma}(R^{-1}) \simeq -A^{-1} - \sum_{j=1}^{\infty} A^{-1}\,[I_n, 0_n]\,\widetilde{Q}_0\Phi_0^{(-j)}\begin{bmatrix} I_n \\ 0_n \end{bmatrix} A^{-1} \in \sum_{j=0}^{\infty} \widetilde{T}^j \cdot S^{-j}. \tag{2.66}$$

Proof. It is easy to prove that $g^{\odot k} \in \sum_{j=0}^{\infty} \widetilde{T}^{j+1} \cdot S^{-j-k}$ for each k $(2 \le k \in \mathbb{N})$ if $g \in \sum_{j=0}^{\infty} \widetilde{T}^{j+1} \cdot S^{-j-1}$. Here $g^{\odot k}$ denotes the kth power of g with respect to the product "$\odot$." Then, by (2.39),

$$\left(A^{-1}[I_n, 0_n]\left(\widetilde{Q}_0 \odot \tilde{\Phi}_0\right)\begin{bmatrix} I_n \\ 0_n \end{bmatrix}\right)^{\odot k} \in \sum_{j=0}^{\infty} \widetilde{T}^{j+1} \cdot S^{-j-k} \tag{2.67}$$

for each $k \in \mathbb{N}$. Hence we get (2.66) from (2.62).

LEMMA 2.68.

$$\widetilde{\sigma}(\Lambda_C) \simeq -Z|\eta| - \sum_{j=1}^{\infty} 2Q^{-1}\bar{A}\Phi_{21}^{(-j)}A^{-1}|\eta|. \tag{2.69}$$

Proof. It is easy to prove that

$$g_1 \odot g_2 \simeq g_1^{(0)} g_2^{(0)} + \sum_{j=1}^{\infty} \left(g_1^{(-j)} g_2^{(0)} + g_1^{(0)} g_2^{(-j)} \right) \in \sum_{j=0}^{\infty} \widetilde{T}^j \cdot S^{-j}$$

for $g_k \simeq \sum_{j=0}^{\infty} g_k^{(-j)} \in \sum_{j=0}^{\infty} \widetilde{T}^j \cdot S^{-j}$ $(k = 1, 2)$. Then from (2.22), (2.62), and (2.66), we conclude

$$\begin{aligned} \widetilde{\sigma}(\Lambda_C) &\simeq \sqrt{-1} L A^{-1} |\eta| \\ &+ \sum_{j=1}^{\infty} \sqrt{-1} \left\{ [0_n, I_n] \widetilde{Q}_0 + L A^{-1} [I_n, 0_n] \widetilde{Q}_0 \right\} \Phi_0^{(-j)} \begin{bmatrix} I_n \\ 0_n \end{bmatrix} A^{-1} |\eta| \\ &= \sqrt{-1} L A^{-1} |\eta| \\ &+ \sum_{j=1}^{\infty} \sqrt{-1} \left[0_n, \bar{L} - L A^{-1} \bar{A} \right] \Phi_0^{(-j)} \begin{bmatrix} I_n \\ 0_n \end{bmatrix} A^{-1} |\eta|. \end{aligned} \tag{2.70}$$

Using the transformation rule for tensors under change of local coordinates, we have from (2.44) and (4.31) in [C-S] (see the Appendix) that

$$Z = -\sqrt{-1}\, L A^{-1} = -Q^{-1} - \sqrt{-1}\, Q^{-1} S. \tag{2.71}$$

Hence, by using (4.32) and (4.33) in [C-S] and the fact that $Z = Z^*$, we conclude

$$\bar{L} - L A^{-1} \bar{A} = 2\sqrt{-1} Q^{-1} \bar{A}. \tag{2.72}$$

By substituting (2.71) into (2.70), we get (2.69).

Now from (2.53), (2.54), and (2.69), we get

$$\widetilde{\sigma}(\Lambda_C) \simeq -Z|\eta| - \sum_{j=1}^{\infty} 2(-1)^{j+1} Q^{-1} \bar{A} \overline{W^j \left((L')^T D_s^j \bar{A} + (A')^T D_s^j \bar{L} \right)} A^{-1} |\eta|. \tag{2.73}$$

By using (2.71), we can replace $(L')^T D_s^j \bar{A} + (A')^T D_s^j \bar{L}$ by $-\sqrt{-1}(A')^T (D_s^j \bar{Z}) \bar{A}$. Thus we obtain

$$\widetilde{\sigma}(\Lambda_C) \simeq -Z|\eta| + \sum_{j=1}^{\infty} 2\sqrt{-1}(-1)^j Q^{-1} \bar{A} \overline{W^j \left((A')^T (D_s^j \bar{Z}) \bar{A} \right)} A^{-1} |\eta|, \tag{2.74}$$

finally proving (2.7).

3. Proofs of the theorems.

(I) *Proof of Theorem* 1.10. Observe that

$$Q = -S_2, \quad S = S_1 \tag{3.1}$$

in terms of the special local coordinates introduced in §2. Then by using (4.52) and (4.53) in the Appendix, we have

$$Z(y_0, \eta^0) = \begin{bmatrix} \frac{2\mu(\lambda+2\mu)}{\lambda+3\mu}, & 0, & \dots & , & 0, & -\sqrt{-1}\frac{2\mu^2}{\lambda+3\mu} \\ & & \mu & & & \\ 0 & & & \ddots & & 0 \\ & & & & \mu & \\ \sqrt{-1}\frac{2\mu^2}{\lambda+3\mu}, & 0, & \dots & , & 0, & \frac{2\mu(\lambda+2\mu)}{\lambda+3\mu} \end{bmatrix} \tag{3.2}$$

in the special local coordinates.

Hence

(3.3)
$$\mu = 2^{-1}\left(Z_{11} + \sqrt{-1}Z_{1n}\right), \quad \lambda = -2^{-1}\sqrt{-1}Z_{1n}^{-1}\left(Z_{11} - 2\sqrt{-1}Z_{1n}\right)\left(Z_{11} + \sqrt{-1}Z_{1n}\right)$$

in these special local coordinates.

Since the choice of these coordinates is stable near y_0 for the fixed η^0, Theorem 1.10 follows directly from Theorem 2.6 and (3.2).

(II) *Proof of Theorem* 1.13.

Let

$$\left(C^{\alpha,\beta}\right) = \begin{bmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & \lambda_3 \end{bmatrix}$$

in terms of the local coordinates introduced in §2. For simplicity we set

$$a = \lambda_1,\ b = \lambda_2,\ \lambda_3 = 2^{-1}d \tag{3.4}$$

and assume the following technical condition:

$$a > 0, \quad b > 0, \quad d > 0, \quad ab - d^2 > 0 \quad \text{near } y_0. \tag{3.5}$$

Using (4.32), (4.33) in page 320 of [C-S], we have, after tedious computations, the following formula for

$$Z = \begin{bmatrix} Z_{11} & Z_{12} \\ Z_{21} & Z_{22} \end{bmatrix} \tag{3.6}$$

in local coordinates:

$$\begin{cases} Z_{11} &= AB(A+B)\sqrt{A^2+B^2}/\{\sqrt{2}D(A^2+AB+B^2)\} \\ Z_{12} &= -\sqrt{-2}AB\sqrt{A^2+B^2}/\{2(A^2+AB+B^2)\} \\ Z_{21} &= \overline{Z}_{12} \\ Z_{22} &= D(A+B)\sqrt{A^2+B^2}/\{\sqrt{2}(A^2+AB+B^2)\} \end{cases} \tag{3.7}$$

where

$$A = \sqrt{ab - \sqrt{a^2b^2 - abd}},\ B = \sqrt{ab + \sqrt{a^2b^2 - abd^2}}, \quad D = \sqrt{bd}. \tag{3.8}$$

We note that a, b, d can be expressed in terms of A, B, D. By simple algebraic manipulations, (3.7) implies the following formula for A, B, D:

$$\begin{cases} A &= \sqrt{-2}\left(4Z_{11}Z_{22} + Z_{12}^2\right)\left(Z_{11}\sqrt{Z_{22}} \pm \sqrt{Z_{11}^2Z_{22} + Z_{11}Z_{12}^2}\right) \\ &\quad / \left\{Z_{12}\sqrt{4Z_{11}^2Z_{12} + 2Z_{11}Z_{12}^2}\right\}, \\ B &= -\sqrt{-2}\left(4Z_{11}Z_{22} + Z_{12}^2\right)\left(Z_{11}\sqrt{Z_{22}}\right) \pm \sqrt{Z_{11}^2Z_{22} + Z_{11}Z_{12}^2}\Big) \\ &\quad / \left\{Z_{12}\sqrt{4Z_{11}^2Z_{12} + 2Z_{11}Z_{12}^2}\right\}, \\ D &= -\sqrt{-2}\left(4Z_{11}Z_{22} + Z_{12}^2\right)\ \sqrt{-Z_{12}^2Z_{22}} / \left\{Z_{12}\sqrt{4Z_{11}^2Z_{12} + 2Z_{11}Z_{12}^2}\right\}. \end{cases} \tag{3.9}$$

Here the double signs $\pm$ and $\mp$ should read according to the convention that the upper signs and lower signs are grouped together.

Next we show how to recover the derivatives of C at the boundary from the derivatives of Z. By recalling the transformation rule of tensors under change of local coordinates and the stability of the choice of the special local coordinates, we only have to consider (Z_{jk}) and its derivatives.

From now on we simply denote by ∂ any kind of differentiation. Then we have

$$\begin{cases} D^3\partial\left(\frac{Z_{11}}{Z_{22}}\right) = D^{-2}B\partial A + D^{-2}A\partial B - 2D^{-3}AB\partial D \\ D^2\partial\left(-2\sqrt{-1}\frac{Z_{11}}{Z_{12}}\right) = D^{-1}\partial\Lambda + D^{-1}\partial B - D^{-2}(A+B)\partial D \\ (A^2+B^2)^{\frac{1}{2}}(A^2+AB+B^2)^2\partial(\sqrt{-2}Z_{12}) \\ \quad = B^2(A^3+A^2B+B^3)\partial A + A^2(A^3+AB^2+B^3)\partial B. \end{cases} \tag{3.10}$$

The determinant of the coefficients of $\partial A, \partial B, \partial D$ in the right-hand side of (3.10) is $-ABD^{-4}(A^3-B^3)(A^2+B^2) \neq 0$. Hence we can recover $\partial A, \partial B, \partial D$ from $Z_{jk}, \partial Z_{jk}$ $(1 \leq j,k \leq 2)$.

Since the coefficients for $\partial^m A, \partial^m B, \partial^m D \quad (m \geq 2)$ in $\partial^m(\frac{Z_{11}}{Z_{22}})$, $\partial^m(-2\sqrt{-1}\frac{Z_{11}}{Z_{12}})$, $\partial^m(\sqrt{-2}Z_{12})$ are the same as that of $\partial A, \partial B, \partial C$ in $\partial(\frac{Z_{11}}{Z_{22}})$, $\partial(-2\sqrt{-1}\frac{Z_{11}}{Z_{12}})$, $\partial(\sqrt{-2}Z_{12})$, we can also recover $\partial^m A, \partial^m B, \partial^m D \quad (m \geq 2)$ from $\partial^\ell Z_{jk} \quad (1 \leq j,k \leq 2, \quad 0 \leq \ell \leq m)$.

Therefore we have proved Theorem 2.6.

Appendix. In this appendix we point out the modifications which are necessary to generalize Chadwick and Smith's [C-S] results to n-dimensional generic, anisotropic media and n-dimensional isotropic media. We shall write the formulas that need to be changed in [C-S] with the same numbers.

The most important formulas from [C-S] that we have used in the previous sections are (4.31)–(4.33) for n-dimensional, generic, anisotropic media and (4.31)–(4.33), (4.52), (4.53) for n-dimensional, isotropic media.

For n-dimensional, generic, hyperelastic, anisotropic media everything which leads to (4.31)–(4.33) in [C-S] remains basically the same except for the definitions of $Q(\varphi)$ and $R(\varphi)$.

Let $e_j = {}^t(0,\dots,0,1,0,\dots,0) \in \mathbb{C}^n (1 \leq j \leq n)$ and set $m = (\sin\varphi)e_1 - (\cos\varphi)e_n = {}^t(m_1,\dots,m_n), n = (\cos\varphi)e_1 + (\sin\varphi)e_n = {}^t(n_1,\dots,n_n)$. Then we define $Q(\varphi)$ and $R(\varphi)$ by

$$Q(\varphi) = \left(Q_{ij}(n); i \underset{j\to 1,\dots,n}{\downarrow} 1,\dots,n\right), \qquad R(\varphi) = \left(R_{ij}(m,n); i \underset{j\to 1,\dots,n}{\downarrow} 1,\dots,n\right)$$

where

$$Q_{ij}(n) = \sum_{p,q=1}^{n} C_{piqj}n_pn_q, \qquad R_{ij}(m,n) = \sum_{p,q=1}^{n} c_{piqj}m_pn_q.$$

For n-dimensional, isotropic media, we first discuss (4.52) and (4.53) in [C-S] and their related formulas, and then we will discuss (4.31)–(4.33) in [C-S].

The formulas leading to (4.52) and (4.53) need some nontrivial modifications. We define

$$N(0) = \begin{bmatrix} N_1(0), & N_2(0) \\ N_3(0), & N_1^T(0) \end{bmatrix}, \tag{4.45}$$

where

$$N_1(0) = -\begin{bmatrix} \overset{\longleftarrow\ n\ \longrightarrow}{\begin{matrix} 0 & & 1 \\ 0 & \ddots & 0 \\ \frac{\lambda}{\lambda+2\mu} & & 0 \end{matrix}} \end{bmatrix} \begin{matrix} \uparrow \\ n \\ \downarrow \end{matrix}$$

$$N_2(0) = -\begin{bmatrix} \overset{\longleftarrow\ n\ \longrightarrow}{\begin{matrix} \frac{1}{\mu} & & 0 & \\ & \ddots & & \\ & & \frac{1}{\mu} & \\ 0 & & & \frac{1}{\lambda+2\mu} \end{matrix}} \end{bmatrix} \begin{matrix} \uparrow \\ n \\ \downarrow \end{matrix}$$

$$N_3(0) = -\begin{bmatrix} \overset{\longleftarrow\ n\ \longrightarrow}{\begin{matrix} \frac{-4\mu(\lambda+\mu)}{\lambda+2\mu} & & & 0 \\ & -\mu & & \\ 0 & & \ddots & \\ & & & -\mu \\ & & & 0 \end{matrix}} \end{bmatrix} \begin{matrix} \uparrow \\ n \\ \downarrow \end{matrix}$$

$$N(0)\xi_\alpha = i\xi_\alpha \quad (1 \le \alpha \le n-1), \quad N(0)\,\xi_n = i\xi_n + \xi_{n-1}, \tag{4.47}$$

$$\begin{aligned} \xi_\alpha &= \frac{1}{2}(1+i)\mu^{-1/2}\,(0,\dots,0,\overset{\alpha+1}{\underset{\longleftarrow\ n\ \longrightarrow}{\breve{i}}},0,\dots,0,\ 0,\dots,0,\overset{n+\alpha+1}{\underset{\longleftarrow\ n\ \longrightarrow}{\breve{-\mu}}},0,\dots,0), \\ \xi_{n-1} &= \gamma\,(\underset{\longleftarrow\ n\ \longrightarrow}{1,0,\dots,0},\ i,\ \underset{\longleftarrow\ n\ \longrightarrow}{2i\mu,0,\dots,0},-2\mu), \\ \xi_n &= \gamma\,(\underset{\longleftarrow\ n\ \longrightarrow}{-ik,0,\dots,0},\ -k,\ \underset{\longleftarrow\ n\ \longrightarrow}{\mu,0,\dots,0},-i\mu)\,. \end{aligned} \tag{4.48}$$

$$\begin{aligned} N^T(0)\eta_\alpha &= -i\eta_\alpha \quad (1 \le \alpha \le n-2, \alpha = n), \\ N^T(0)\eta_{n-1} &= -i\eta_{n-1} + \eta_n, \\ \eta_{\alpha+n} &= \overline{\eta}_\alpha \quad (1 \le \alpha \le n), \end{aligned} \tag{4.50}$$

$$\begin{aligned} &\eta_\alpha = K\overline{\xi_\alpha} \quad (1 \le \alpha \le n-2), \eta_{n-1} = K\overline{\xi_n},\ \eta_n = K\overline{\xi}_{n-1}, \\ &\eta_{\alpha+n} = K\overline{\xi}_{\alpha+n} \quad (1 \le \alpha \le n-2), \eta_{2n-1} = K\overline{\xi}_{2n},\ \eta_{2n} = K\overline{\xi}_{2n-1}, \end{aligned} \tag{4.51}$$

$$S_1 = -\frac{1}{2}\{(1-2\nu)/(1-\nu)\}\ (e_1 \otimes e_n - e_n \otimes e_1)\,, \tag{4.52}$$

$$S_2 = \mu^{-1}\left[\left\{\frac{1}{4}(3-4\nu)/(1-\nu)\right\}(e_1 \otimes e_1 + e_n \otimes e_n) + \sum_{j=2}^{n-2} e_j \otimes e_j\right]. \tag{4.53}$$

Now in order to discuss (4.32) and (4.33), we set

$$\xi_\pi = \langle a_\pi, \ell_\pi \rangle, \qquad \eta_\pi = \langle \bar{\ell}_\pi, \bar{a}_\pi \rangle \quad (1 \leq \pi \leq 2n).$$

We note that $\bar{a}_\pi$ and $\bar{\ell}_\pi$ are not always the complex conjugates of a_π and ℓ_π. Then it is not so difficult to prove (4.32) and (4.33).

Formula (4.31) can be proved in the same way as in [C-S] (see especially p. 324), because the length of the Jordan chain of our $N(0)$ is also 2.

LOCAL INVERTIBILITY OF SOBOLEV FUNCTIONS*

I. FONSECA† AND W. GANGBO†

Abstract. A local inverse function theorem is established for mappings $v \in W^{1,N}(\Omega, \mathbb{R}^N)$, $\Omega \subset \mathbb{R}^N$ open set, such that $\det \nabla v(x) > 0$ almost everywhere in $x \in \Omega$. Regularity of the local inverse v^{-1} is obtained provided that $|\frac{\text{adj}(\nabla v)}{\det \nabla v}|^s \det \nabla v \in L^1(\Omega)$ for some $1 \leq s < +\infty$. The local invertibility property is used to study the weak lower semicontinuity of a functional involving variation of the domain.

Key words. local invertibility, topological degree, weak lower semicontinuity

AMS subject classification. 49

1. Introduction. The aim of this paper is to give a simple proof of local invertibility of continuous functions $v \in W^{1,N}(\Omega, \mathbb{R}^N)$, where $\Omega \subset \mathbb{R}^N$ is an open set and $\det \nabla v(x) > 0$ almost everywhere in $x \in \Omega$ (Theorem 3.1). We show that the local inverse function w is $W^{1,1}$ and under suitable hypotheses we improve regularity of w to $W^{1,s}$ for some $s > 1$. Precisely, it is shown that v is locally invertible almost everywhere in the sense that for almost every $x \in \Omega$, there is an open neighborhood D of x and there is a function $w \in W^{1,1}(v(D), D)$ such that $v(D)$ is an open set,

$$v \circ w(y) = y \text{ a.e. } y \in v(D), \tag{1}$$

$$w \circ v(x) = x \text{ a.e. } x \in D, \tag{2}$$

and

$$\nabla w(y) = (\nabla v)^{-1}(w(y)) \text{ a.e. } y \in v(D), \tag{3}$$

where $(\nabla v)^{-1}(w(y))$ is the inverse matrix of $\nabla v(w(y))$. Moreover, if we assume that $|\frac{\text{adj}(\nabla v)}{\det \nabla v}|^s \det \nabla v \in L^1(\Omega)$ for some $1 \leq s < +\infty$, then, as in [Sv], we prove that $w \in W^{1,s}(v(D), D)$. One can then deduce easily that if $\det \nabla v(x) \geq \gamma > 0$ a.e. $x \in \Omega$, $v \in W^{1,q}(\Omega)^N$, and $q \geq N(N-1)$, then $v : D \to v(D)$ and $w : v(D) \to D$ are homeomorphisms, (1) holds for every $y \in v(D)$, (2) holds for every $x \in D$, $w \in W^{1,N}(v(D), D)$, and v is an open mapping on $\Omega \setminus L$ for a suitable $L \subset \mathbb{R}^N$ which has zero measure (see Corollary 3.3). In particular, we conclude that if $N = 2$, $v \in W^{1,2}(\Omega)^2$, and $\det \nabla v(x) \geq \gamma > 0$ a.e. $x \in \Omega$, then $w \in W^{1,2}(v(D), D)$ and there is a set of measure zero $L \subset \mathbb{R}^N$ such that v is an open mapping on $\Omega \setminus L$ and a weaker version of [IS] is obtained. Recently, we became aware of a result by Heinonen and Koskela [HK], where they show that if a mapping is in $W^{1,q}$ for some $q > N(N-1)$, its jacobian is positive almost everywhere and $N \geq 3$, then the mapping is open and discrete, and so $L = \emptyset$.

Conversely, if $v \in W^{1,q}(\Omega)^N$ for some $q > N$, $\det \nabla v(x) \neq 0$ a.e. $x \in \Omega$ and if for almost every $x_0 \in \Omega$ v is locally almost invertible in a neighborhood of x_0 in the sense of (1)–(3), then there are open sets $\Omega_1, \Omega_2 \subset \mathbb{R}^N$ and a set of measure zero $N \subset \mathbb{R}^N$

such that $\Omega = \Omega_1 \cup \Omega_1 \cup N$, $\det \nabla v(x) > 0$ a.e. $x \in \Omega_1$ and $\det \nabla v(x) < 0$ a.e. $x \in \Omega_2$ (see Corollary 3.2).

Note that a homeomorphism $v \in W^{1,\infty}(\Omega)^N$ does not need to satisfy $\det \nabla v(x) \neq 0$ a.e. $x \in \Omega$. Such an example is provided in [MZ] (see Remark 3.4).

The result in this paper is in the same spirit as the work in [Ba], [CN], [Sv], and [TQ]. As far as we know, the existence and the regularity of the local inverse function w is not an immediate consequence of these earlier results where assumptions are placed either on the trace $v|_{\partial\Omega}$ or on $|v(\Omega)|$. By an elementary lemma (Lemma 3.5) and the invertibility result found in [TQ], one can obtain the existence of the local inverse function w and then deduce its regularity. Due to his relaxed assumption $q > N - 1$ (here we have $q \geq N$), Tang used an elaborated method to obtain the existence of an inverse $w \in W^{1,1}_{\text{loc}}$ under the condition introduced by [CN], $\int_\Omega \det \nabla v(x) dx \leq |v(\Omega)|$.

The proof that we present here concerning the local invertibility of v is independent of the work by [Ba], [CN], [Sv], and [TQ], and the method employed relies on basic properties of the degree theory.

In the sequel of this paper, we fix a bounded, open set $\Omega \subset \mathbb{R}^N$ and consider a function $v \in W^{1,q}(\Omega)^N$. We denote by ∇v the gradient of v, i.e., the $N \times N$ matrix of the partial derivatives of v, and by $\operatorname{adj} \nabla v$ the adjugate[1] of ∇v.

As an application of the local invertibility property, we study the weak lower semicontinuity of functionals E of the form

$$E(u, v) = \int_\Omega W\Big(\nabla u(x)(\nabla v(x))^{-1}\Big) dx,$$

defined on the set

$$B_{p,q} = \{(u, v) \in W^{1,p}(\Omega, \mathbb{R}^N) \times W^{1,q}(\Omega, \mathbb{R}^N) : \det \nabla v(x) = 1 \text{ a.e. } x \in \Omega\}$$

where $1 \leq p < +\infty$, $N \leq q \leq +\infty$, $\frac{1}{p} + \frac{N-1}{q} = \frac{1}{r} \leq 1$. When $N = 3$, $\nabla u(x) \cdot (\nabla v(x))^{-1}$ represents the lattice of a neutral elastoplastic change of state of a perfect cubic crystal, u is the elastic deformation, and v corresponds to the slip or plastic deformation. (For details, see Ericksen [Er], Davini and Parry [DP], Fonseca and Parry [FP], and Dacorogna and Fonseca [DF].) We prove that under some convexity and growth assumptions on the function W, E is weakly lower semicontinuous on $B_{p,q}$. If $r > 1$ and $q \neq +\infty$, we rely on the div-curl lemma (see Tartar [Ta]) to prove that

$$\nabla u_\epsilon \cdot (\nabla v_\epsilon)^{-1} \rightharpoonup \nabla u \cdot (\nabla v)^{-1} \text{weakly in } L^r$$

whenever

$$(u_\epsilon, v_\epsilon) \rightharpoonup (u, v) \text{ weakly in } B_{p,q}.$$

We notice, however, that the growth condition of W and the weak lower semicontinuity of E on $B_{p,q}$ do not always imply the existence of the minimum of E on $B_{p,q}$. Indeed, $\{(\nabla u_\epsilon \cdot (\nabla v_\epsilon)^{-1}\}$ being relatively compact in L^r does not imply that $\{(\nabla u_\epsilon)\}$ or $\{(\nabla v_\epsilon)^{-1}\}$ are relatively compact in, respectively, L^p, $L^{q/(N-1)}$ (see [DF], Proposition 4.1).

[1] We recall that if A is a $N \times N$ matrix and $\det A \neq 0$, then $\operatorname{adj} A$ is the $N \times N$ matrix such that $A \cdot \operatorname{adj} A = I_N \det A$. In general, the entries of $\operatorname{adj} A$ are certain homogeneous polynomials of degree $N - 1$ of the entries of A.

The paper is organized as follows: In the second section we fix notation and recall some definitions and well-known properties related to the Brouwer degree. In the third section we prove the local invertibility property of the mappings $v \in W^{1,q}(\Omega, \mathbb{R}^N), q \geq N$, under the condition $\det \nabla v(x) > 0$ a.e. $x \in \Omega$. In view of our applications, in addition we prove that if $v_\epsilon \rightharpoonup v$ weakly in $W^{1,q}$ $q \geq N$, $\det \nabla v(x) > 0$ a.e. $x \in \Omega$ and $\det \nabla v_\epsilon(x) = 1$ a.e. $x \in \Omega$ then, up to a subsequence, v_ϵ and v are, respectively, locally invertible on open sets $D_\epsilon(x)$ and $D(x)$ for almost every $x \in \Omega$, where $D_\epsilon(x)$ and $D(x)$ are neighborhoods of x such that $v_\epsilon(D_\epsilon(x)) = v(D(x))$ does not depend on ϵ. The last section is devoted to the applications, where we obtain the weak lower semicontinuity for a class of functionals E on $B_{p,q}$.

2. Preliminaries. In the sequel we will use the following notation.
For $x = (x_1, \ldots, x_N) \in \mathbb{R}^N$, $|x|$ stands for $(|x_1|^2 + \cdots + |x_N|^2)^{1/2}$ and $|x|_\infty := \max\{|x_1|, \ldots, |x_N|\}$. If $A \subset \mathbb{R}^N$ $|A|$ denotes the Lebesgue measure of A, A^c denotes its complement, $\operatorname{dist}(x, A)$ is defined by $\inf\{|x - y| : y \in A\}$, and $\rho(x, A)$ is given by $\inf\{|x - y|_\infty : y \in A\}$.

If $\Omega \subset \mathbb{R}^N$ is an open set, $v \in W^{1,1}(\Omega)^N$, then ∇v is the $N \times N$ matrix of the distributional derivatives $\frac{\partial v_i}{\partial x_j}$. If, furthermore, $\nabla v \in L^N$, then $\det \nabla v$ is the determinant of ∇v.

We recall some properties of mappings.

LEMMA 2.1. *Let Ω be a bounded, open set in $\mathbb{R}^N$ and $v \in (W^{1,N}_{\text{loc}}(\Omega))^N$ such that $\det \nabla v(x) > 0$ a.e. $x \in \Omega$. Then v is a continuous mapping on Ω. Futhermore, if K is a compact set and V is an open set such that $K \subset V \subset\subset \Omega$, then there is a constant C_N depending only on N, such that*

$$|v(x) - v(y)| \leq M^{\frac{1}{N}} C_N \theta(|x - y|)$$

for every $x, y \in K$ that verify $|x - y| \leq \delta$, where

$$M = \int_V |\nabla v(x)|^N dx,$$

$$\theta(t) = \left(\frac{2}{\log(\frac{2}{t})}\right)^{\frac{1}{N}},$$

and

$$\delta = \min\left\{2, \frac{1}{2}(\operatorname{dist}(K, \mathbb{R}^N \setminus V))^2\right\}.$$

Proof. This lemma is an immediate consequence of Theorem 3.5, p. 294, and Proposition 3.3, p. 292 in [GR] and Theorem 4.4, p. 339 in [Re] (see also [Man]). It can also be shown that, under the above hypotheses, v is a monotonic mapping (see the definition of monotonic mapping below).

DEFINITION 2.2 ([GR]). *Let Ω be a bounded, connected, open set in $\mathbb{R}^N$ and $v \in W^{1,N}(\Omega)^N$. We say that v* is monotonic at the point $x \in \Omega$ *if there is a number $0 < r(x) \leq d(x, \partial\Omega)$ such that for almost every $r \in (0, r(x))$ the pre-image of the intersection of the set $v(B(x,r))$ with the unbounded connected component of $\mathbb{R}^N \setminus v(\partial B(x,r))$ is of measure 0 in $B(x,r)$. We say that v is a monotonic mapping in Ω if v is monotonic at every point $x \in \Omega$.*

We make some remarks on the Brouwer degree theory. For details we refer the reader to [Ll], [Sc].

Let $\Omega \subset \mathbb{R}^N$ be a bounded, open set and let $v : \bar{\Omega} \to \mathbb{R}^N$ be a continuous function. For every $p \in \mathbb{R}^N \setminus v(\partial\Omega)$ the *Brouwer degree* $d(v, \Omega, p)$ *of* v *with respect to* Ω *at* p is a well-defined integer depending only on the boundary values of v. In particular, if $v \in C^1(\bar{\Omega})^N$ and $p \in \mathbb{R}^N \setminus (v(\partial\Omega) \cup v(Z_v))$, we have

$$d(v, \Omega, p) = \sum_{x \in v^{-1}(p)} \operatorname{sign} \det \nabla v(x),$$

where

$$\operatorname{sign} t = \begin{cases} 1 & \text{if } t > 0, \\ -1 & \text{if } t < 0, \end{cases}$$

and $v(Z_v)$ denotes the image of the set $\{x \in \Omega : \det \nabla v(x) = 0\}$.

We give some additional properties of the degree.

PROPOSITION 2.3 ([GR]). *Let* $\Omega \subset \mathbb{R}^N$ *be an open, bounded set,* $v \in C^0(\bar{\Omega})^N$, *and let* $p \in \mathbb{R}^N \setminus v(\partial\Omega)$. *Let* C_p *be the connected component of* $\mathbb{R}^N \setminus v(\partial\Omega)$ *containing* p. *Then we have the following properties:*

(4) $d(v, \Omega, p) = d(u, \Omega, p)$ *if* $u \in C^0(\bar{\Omega})^N$ *and* $|u - v|_\infty < \operatorname{dist}(p, v(\partial\Omega))$,

(5) $d(v, \Omega, p) \neq 0 \Rightarrow \exists\, x \in \Omega$ *such that* $v(x) = p$,

(6) $d(v, \Omega, p) = d(v, \Omega, q) \ \forall\ q \in C_p$,

(7) $d(v, \Omega, p) = d(\phi, \Omega, p)$ *if* $\phi \in C^0(\bar{\Omega})^N$ *and* $\phi = v$ *on* $\partial\Omega$.

Moreover, the degree is invariant under homotopy, i.e.,

(8) $$d(H(\cdot, t), \Omega, p) = d(H(\cdot, 0), \Omega, p),$$

for every homotopy $H \in C^0(\bar{\Omega} \times [0, 1])^N$ *such that* $p \notin H(\partial\Omega, t)$ *for every* $t \in [0, 1]$. *Finally, if* $K \subset \bar{\Omega}$ *is a compact set and* $p \notin v(K)$ *then* (*excision property*)

(9) $$d(v, \Omega, p) = d(v, \Omega \setminus K, p)$$

and if $\Omega = \cup_{i=1}^{+\infty} \Omega_i$, Ω_i *mutually disjoint open sets then* (*decomposition property*)

(10) $$\sum_i d(v, \Omega_i, p) = d(v, \Omega, p).$$

Proof. We refer the reader to [Ll].

LEMMA 2.4. *Let* $\Omega \subset \mathbb{R}^N$ *be a bounded, connected, open set and* $v \in W^{1,N}(\Omega)^N$ *such that* $\det \nabla v(x) > 0$ a.e. $x \in \Omega$. *Let* $f : \mathbb{R}^N \to \mathbb{R}$ *be a measurable function. Then*

(i) *for every measurable set* $E \subset \Omega$, $x \to f \circ v(x)$, *and* $y \to N(v, E, y)$ *are measurable and*

(11) $$\int_E f \circ v(x) |\det \nabla v(x)| dx = \int_{\mathbb{R}^N} N(v, E, y) f(y) dy,$$

where $N(v, E, y)$ *is the cardinality of the elements of the set* $\{x \in E : v(x) = y\}$.

(ii) *If, in addition,* f *is a continuous, bounded function, then for every open set* $U \subset\subset \Omega$ *such that* $|\partial U| = 0$

(12) $$\int_{\bar{U}} f \circ v(x) \det \nabla v(x) dx = \int_{\mathbb{R}^N \setminus v(\partial U)} d(v, U, y) f(y) dy.$$

(iii) *If $U \subset\subset \Omega$ is an open set such that $|\partial U| = 0$ and $p \in \mathbb{R}^N \setminus v(\partial U)$, then*

$$d(v, U, p) = \int_U f(v(x)) \det \nabla v(x) dx \tag{13}$$

for any f nonnegative, continuous real-valued function that satisfies $\int_{\mathbb{R}^N} f(x)dx = 1$, with compact support in V, where V is the connected component of $\mathbb{R}^N \setminus v(\partial U)$ containing p.

Remark 2.5. A function $v : \Omega \to \mathbb{R}^N$ is said to satisfy the N property (Lusin's property) if

$$|v(E)| = 0$$

whenever $E \subset \Omega$ is a measurable set such that $|E| = 0$, and v is said to satisfy the N^{-1} property if

$$|v^{-1}(A)| = 0$$

whenever $A \subset \mathbb{R}^N$ is a measurable set such that $|A| = 0$.

(a) It is known that if $v \in W^{1,N}(\Omega)^N$, $\det \nabla v(x) > 0$ a.e. $x \in \Omega$, then v satisfies the N and the N^{-1} property. (See [GR], pp. 296–297.)

(b) Also, if $v \in W^{1,q}(\Omega)^N$ with $q > N$, then v satisfies the N-property. (For details we refer the reader to [MM].)

Proof of Lemma 2.4. We refer the reader to [GR], Theorem 1.8, p. 280, Theorem 2.6, p. 288, or also to [Sv] for the proof of (11) and (12) in the case where U is a domain.

First we prove that (12) is still valid even if U is not connected and (13) is a by-product of this fact. To achieve this, we remark that by Vitali's covering theorem there are $\{D_i\}$, a countable family of open balls mutually disjoint, and a set N of measure zero such that $(\cup_i D_i) \cap N = \emptyset$ and

$$(\cup_i D_i) \cup N = U.$$

Setting $B = \cup_i D_i$, we have $\cup_i \partial D_i \subset \partial B$. If $y \in \mathbb{R}^N \setminus (v(\partial B) \cup v(\partial U))$, then by the decomposition formula (10)

$$\sum_i \chi_{v(D_i)} d(v, D_i, y) = \sum_i d(v, D_i, y) = d(v, B, y). \tag{14}$$

Let $K = \bar{U} \setminus B$. As K is a compact set and $K \subset \partial U \cup N$, if $y \notin v(K)$ then, by the excision property of degree (9), we obtain

$$d(v, U, y) = d(v, U \setminus K, y) = d(v, B, y). \tag{15}$$

By using the fact that v has the N property (see Remark 2.5), $D_i \subset\subset \Omega$, $|\partial U| = |N| = |\partial D_i| = 0$, by (12), (14), and (15) we obtain

$$\begin{aligned} \int_U f \circ v(x) \det \nabla v(x) dx &= \int_B f \circ v(x) \det \nabla v(x) dx \\ &= \sum_i \int_{D_i} f \circ v(x) \det \nabla v(x) dx \end{aligned}$$

$$= \sum_i \int_{v(D_i)\setminus v(\partial D_i)} d(v, D_i, y) f(y) dy$$
$$= \int_{v(B)\setminus v(\partial B)} d(v, B, y) f(y) dy$$
$$= \int_{v(U)\setminus v(\partial U)} d(v, U, y) f(y) dy,$$

and so we obtain (12).

If, furthermore, $\int_{\mathbb{R}^N} f(x)dx = 1$ and the compact support of f is included V, using (12) and the fact that $d(v, D, \cdot)$ is a constant on V, we conclude that

$$\int_D f \circ v(x) \det \nabla v(x) dx = d(v, D, p). \qquad \square$$

DEFINITION 2.6. *Let $\Omega \subset \mathbb{R}^N$ be an open set, let $v : \Omega \to \mathbb{R}^N$ be a function and $x_0 \in \Omega$.*

1. *We say that v is* differentiable at x_0 *if there is a number $R_0 > 0$, a function $\epsilon : \mathbb{R} \to \mathbb{R}$, and a $N \times N$ matrix $\nabla v(x_0)$ such that*

$$v(x_0 + h) = v(x_0) + \nabla v(x_0)h + |h|\epsilon(|h|)$$

for every $h \in B(0, R_0)$ and $\lim_{t\to 0} \epsilon(t) = 0$. In this case we call $\det \nabla v(x_0)$ the Jacobian of v at x_0.

2. *We say that v is* approximately differentiable at x_0 *if there is a set $A \subset \mathbb{R}$ and a $N \times N$ matrix $\nabla v(x_0)$ such that $\lim_{r\to 0} \frac{|A\cap[0,r]|}{r} = 1$ and*

$$\liminf_{t\to 0, t\in A} \gamma_{x_0}(t) = 0,$$

where

$$\gamma_{x_0}(t) = \sup\left\{ \left| \frac{v(x_0 + tz) - v(x_0)}{t} - \nabla v(x_0) z \right| \ : \ |z| = 1 \right\}.$$

In this case we call $\det \nabla v(x_0)$ the weak Jacobian of v at x_0.

LEMMA 2.7. *Let Ω be a bounded open set in $\mathbb{R}^N$.*

(i) *If $v \in W^{1,N}(\Omega)^N$ is a monotonic mapping, then v is almost everywhere in Ω differentiable.*

(ii) *If $v \in W^{1,q}(\Omega)^N, q > N$, then v is almost everywhere in Ω differentiable.*

(iii) *If $v \in W^{1,q}(\Omega)^N, q > N-1$, then v is almost everywhere in Ω approximately differentiable.*

Proof. We refer the reader to [GR, Thm. 5.4, p. 175], to [Re], and to [MZ].

3. Local invertibility in $W^{1,q}$. We first state the main result of this section (Theorem 3.1) and some of its corollaries.

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^N$ be a bounded, open set and let $v \in W^{1,N}(\Omega)^N$ be a function such that $\det \nabla v(x) > 0$ a.e. $x \in \Omega$. Then for almost every $x_0 \in \Omega$, v is locally almost invertible in a neighborhood of x_0, in the sense that there exists $r \equiv r(x_0) > 0$, an open set $D \equiv D(x_0) \subset\subset \Omega$, and a function $w : B(y_0, r) \to D$ with $y_0 = v(x_0)$ such that*

$$w \in W^{1,1}(B(y_0, r))^N,$$
$$w \circ v(x) = x \text{ a.e. } x \in D,$$
$$v \circ w(y) = y \text{ a.e. } y \in B(y_0, r),$$
$$\nabla w(y) = (\nabla v)^{-1}(w(y)) \ \text{ a.e. } \ y \in B(y_0, r).$$

If, in addition, $|\frac{\operatorname{adj}(\nabla v)}{\det \nabla v}|^s \det \nabla v \in L^1(\Omega)$ *for some* $1 \leq s < +\infty$ *then* $w \in W^{1,s}(B(y_0, r), D)$.

Before proving Theorem 3.1, we list some of its consequences.

COROLLARY 3.2. *Let* $\Omega \subset \mathbb{R}^N$ *be a bounded, open set,* $q \geq N$, *and* $v \in W^{1,q}(\Omega)^N$ *be a function such that* $\det \nabla v(x) \neq 0$ a.e. $x \in \Omega$.

(a) *Assume that* $\Omega_1, \Omega_2 \subset \mathbb{R}^N$ *are two open sets and* $N \subset \mathbb{R}^N$ *is a set of measure zero such that* $\Omega = \Omega_1 \cup \Omega_1 \cup N$, $\det \nabla v(x) > 0$ *a.e.* $x \in \Omega_1$, *and* $\det \nabla v(x) < 0$ *a.e.* $x \in \Omega_2$. *Then for almost every* $x_0 \in \Omega$ v *is locally almost invertible in a neighborhood of* x_0 *in the sense above.*

(b) *Conversely, if* $q > N$, $v \in W^{1,q}(\Omega)^N$ *and if for almost every* $x_0 \in \Omega$ v *is locally almost invertible in a neighborhood of* x_0, *then there are open sets* $\Omega_1, \Omega_2 \subset \mathbb{R}^N$ *and a null set* $N \subset \mathbb{R}^N$ *such that* $\Omega = \Omega_1 \cup \Omega_2 \cup N$, $\det \nabla v(x) > 0$ *a.e.* $x \in \Omega_1$, *and* $\det \nabla v(x) < 0$ *a.e.* $x \in \Omega_2$.

COROLLARY 3.3. *Let* $q \geq N$, *let* $\Omega \subset \mathbb{R}^N$ *be a bounded, open set and let* $v \in W^{1,q}(\Omega)^N$ *be a function such that* $\det \nabla v(x) = 1$ *a.e.* $x \in \Omega$. *Then the inverse function* w *of Theorem* 3.1 *is such that*

$$w \in W^{1,\frac{q}{N-1}}(v(D))^N.$$

If, in addition, $q \geq N(N-1)$ *then* $w \circ v(x) = x$ *for every* $x \in D$, $v \circ w(y) = y$ *for every* $y \in B(y_0, r)$, v *is a local homeomorphism and* v *is an open mapping on* $\Omega \setminus L$ *for some set* $L \subset \Omega$ *of zero measure. In particular, if* $N = 2$ *then* $N(N-1) = N = 2$ *and* v *is a local homeomorphism at* x_0.

We make some remarks and state some lemmas needed for the proofs of Corollaries 3.2 and 3.3, which will appear at the end of this section.

Remark 3.4.

1. As mentioned in the introduction, it has been proven recently by Heinonen and Koskela [HK, Cor. 1.10] that if a mapping is in $W^{1,q}$ for some $q > N(N-1)$ and if its jacobian is positive and $N \geq 3$, then the mapping is open and discrete and so $L = \emptyset$.

2. Recall that $v \in W^{1,N}(\Omega)^N$ is said to be a *mapping of bounded distortion* (or usually a *quasi-regular mapping*) if $|\nabla v(x)|^N \leq K(\det \nabla v(x))$ for almost every $x \in \Omega$ and for some constant K. It is well known that every mapping of bounded distortion $v \in W^{1,N}(\Omega)^N$ is locally a homeomorphism at almost every point $x_0 \in \Omega$. (See [Re, Thm. 6.6, p. 187].) Moreover, mappings of bounded distortion are open mappings or constant in Ω. (See [Re, Thm. 6.4, p. 184].)

3. Note that even if $v \in C^1(\bar{\Omega})^N$ is such that $\det \nabla v(x) \geq \gamma > 0 \quad \forall x \in \Omega$, we cannot expect a global invertibility of v without any regularity assumptions on the trace of v (see [Ba]).

4. Under the assumptions of Theorem 3.1, we cannot expect v to be locally invertible everywhere (see [Ba]).

5. An example of a mapping $v \in W^{1,\infty}(\Omega)^2$, $(\Omega \subset \mathbb{R}^2)$, is exhibited in [Ba], with $\det \nabla v(x) = 1$ a.e. $x \in \Omega$, for which there is no sequence $v_r \in C^1(\bar{\Omega})^2$ such that $v_r \to v$ uniformly and $J_{v_r}(x) > 0$ a.e. $x \in \Omega$. Therefore, to prove Theorem 3.1, one cannot approximate the function v by a sequence of smooth functions v_r, expecting the functions v_r to be locally invertible.

6. Note that for every bounded, open set $\Omega \subset \mathbb{R}^N$, there exists a measurable set $E \subset \Omega$ of nonzero measure and a homeomorphism $v \in W^{1,\infty}(\Omega)^N$ such that $\det \nabla v(x) = 0$ for every $x \in E$. (See [MZ, Remarks 3.7].)

7. Due to the previous remark, the assumption $\det \nabla v(x) \neq 0$ a.e. $x \in \Omega$ in Corollary 3.2 is essential.

LEMMA 3.5. *Let $\Omega \subset \mathbb{R}^N$ be an open set and let $v \in C^0(\Omega)^N$ and $x_0 \in \Omega$ be such that v is differentiable at x_0. Assume that $\det(\nabla v(x_0)) \neq 0$. Then there is $r_0 > 0$ such that for every $0 < r \leq r_0$ the following assertions hold:*

$$v(x_0 + h) \neq v(x_0) \text{ for every } h \in \bar{B}(0,r) \setminus \{0\}, \tag{16}$$

$$d(v, B(x_0, r), v(x_0)) = \operatorname{sign}(\det \nabla v(x_0)). \tag{17}$$

Proof. We refer the reader to [Re].

Remark 3.6. The relation between differentiability and topological degree was first observed by Reshetnyak [Re].

LEMMA 3.7. *Let $\Omega \subset \mathbb{R}^N$ be an open set and let $v \in W^{1,N}(\Omega)^N$ be such that $\det \nabla v(x) > 0$ a.e. $x \in \Omega$. Then for every $x_0 \in \Omega$ such that v is differentiable at x_0 and $\det \nabla v(x_0) > 0$, there is $R_0 \equiv R_0(x_0)$ such that for every $0 < R < R_0$ the following hold:*

$$N(v, B(x_0, R), y) = 1 \text{ for almost every } y \in C_R, \tag{18}$$

$$d(v, B(x_0, R), y) = 1 \text{ for every } y \in C_R, \tag{19}$$

$$d(v, B, y) = 1 \text{ for every } y \in v(B) \setminus v(\partial B), \tag{20}$$

for every nonempty, open set $B \subset v^{-1}(C_R) \cap B(x_0, R)$ such that $|\partial B| = 0$,

where C_R is the connected component of $\mathbb{R}^N \setminus v(\partial B(x_0, R))$ that contains $y_0 := v(x_0)$ and $N(v, E, y)$ is the cardinality of the set $\{x \in E : \ v(x) = y\}$.

Proof. By Lemmas 2.1 and 2.7, v is continuous and monotonic on Ω and is differentiable at almost every point $x \in \Omega$. Fix $x_0 \in \Omega$ such that v is differentiable at x_0 and $\det \nabla v(x_0) > 0$.

Proof of (19). By Lemma 3.5 there is $R_0 > 0$ such that $B(x_0, R_0) \subset\subset \Omega$ and $d(v, B(x_0, R), y_0) = 1$ for every $0 < R < R_0$ and (19) follows from (6).

Proof of (18). By using the fact that $\det \nabla v(x) > 0$ a.e. $x \in \Omega$, we have that (11), (12), and (19) yield (18).

Proof of (20). Since v satisfies the N property (see Remark 2.5), $|v(\partial B(x_0, R_0))| = 0$ and $|v(\partial B)| = 0$. Since B is a nonempty open set, by (11) we have that $|v(B)| \neq 0$, so $|v(B) \setminus v(\partial B)| \neq 0$. Let $y \in v(B) \setminus v(\partial B)$ and C be the connected component of $\mathbb{R}^N \setminus v(\partial B)$ containing y. As $|v(\partial B(x_0, R_0))| = 0$ and since $d(v, B, \cdot)$ is a constant on C, we may assume without loss of generality that $y \notin v(\partial B(x_0, R_0))$. Let $\rho_\epsilon \in C^\infty(\mathbb{R}^N)$ be such that

$$0 \leq \rho_\epsilon(y), \ \forall y \in \mathbb{R}^N \ \ \forall \epsilon > 0,$$

$$\frac{1}{2} \leq \rho_\epsilon(y) \ \forall y \in B\left(0, \frac{\epsilon}{2}\right), \tag{21}$$

$$\operatorname{supp} \rho_\epsilon \subset B(0, \epsilon) \ \ \forall \epsilon > 0,$$

$$\int_{\mathbb{R}^N} \rho_\epsilon(y) dy = 1 \ \ \forall \epsilon > 0.$$

Since $y \in v(B)$, there is $x \in B$ such that $y = v(x)$. By (6) we have

$$\lim_{\epsilon \to 0} \int_B \rho_\epsilon(v(z) - y) \det \nabla v(z) dz = d(v, B, y) \tag{22}$$

and by using the continuity of v at x, we deduce that for every $\epsilon > 0$ there is $\delta > 0$ such that $|v(z) - y| \leq \frac{\epsilon}{2}$ for every $z \in B(x, \delta)$. By recalling that $\det \nabla v(z) > 0$ a.e. $z \in B(x, \delta)$, by (21) and (22) we obtain

$$d(v, B, y) > 0. \tag{23}$$

Finally, since the degree $d(v, \cdot, y)$ is a nondecreasing function of the set, by using (19) and the fact that $B \subset v^{-1}(C_R) \cap B(x_0, R)$, we obtain

$$d(v, B, y) \leq d(v, B(x_0, R), y) = 1, \tag{24}$$

which, together with (23) and the fact that the degree is an integer number, yields (20). □

LEMMA 3.8. *Let Ω, v, R_0 and x_0 be as in Lemma* 3.7, (18), *and* (19). *Let C_{R_0} be the connected component of $\mathbb{R}^N \setminus v(\partial B(x_0, R_0))$ containing $y_0 := v(x_0)$. Then for every $r > 0$ such that $B(y_0, r) \subset\subset C_{R_0}$, if $O := v^{-1}(B(y_0, r)) \cap B(x_0, R_0) \subset\subset B(x_0, R_0)$ then*

$$v(O) = B(y_0, r), \quad v(\partial O) \subset \partial v(O) = \partial B(y_0, r). \tag{25}$$

Proof. It is clear that $v(O) \subset B(y_0, r)$. Conversely, if $y \in B(y_0, r)$, by (19) $d(v, B(x_0, R_0), y) = 1$ and so by (5) there exists $x \in B(x_0, R_0)$ such that $y = v(x)$, which implies $y \in v(O)$. Let $x \in \partial O$ and let $\{a_n\} \subset O$, $\{b_n\} \subset B(x_0, R_0) \setminus O$ be such that

$$\lim_{n \to +\infty} a_n = \lim_{n \to +\infty} b_n = x.$$

We have $v(a_n) \in v(O) = v(v^{-1}(B(y_0, r))) = B(y_0, r)$ and $v(b_n) \notin v(O) = B(y_0, r)$. By using the continuity of v at x, we have

$$v(x) = \lim_{n \to +\infty} v(a_n) = \lim_{n \to +\infty} v(b_n),$$

which gives $x \in \partial v(O)$. □

LEMMA 3.9. *Let $v \in W^{1,N}(\Omega)^N$, $\det \nabla v(x) > 0$ a.e. $x \in \Omega$ and let $x_0 \in D$ be such that $v(x) \neq v(x_0)$ for every $x \in \bar{B}(x_0, R_0) \setminus \{x_0\}$. Let $0 < R < R_0$ and let C be an open set containing $y_0 = v(x_0)$. Then there is $r > 0$ such that $v^{-1}(B(y_0, r)) \cap B(x_0, R) \subset\subset B(x_0, R)$.*

Proof. Define

$$d(\delta) = \sup\{|x - x_0| : x \in \bar{B}(x_0, R), \ |v(x) - v(x_0)| \leq \delta\}.$$

Since $v(x) \neq v(x_0)$ for every $x \in \bar{B}(x_0, R) \setminus \{x_0\}$ and v is uniformly continuous on $\bar{B}(x_0, R)$, we have

$$\lim_{\delta \to 0} d(\delta) = 0.$$

Take now $r > 0$ such that $d(r) < \frac{R}{2}$. We have

$$v^{-1}(B(y_0, r)) \cap B(x_0, R) \subset B\left(x_0, \frac{R}{2}\right) \subset\subset B(x_0, R). \qquad \square$$

Proof of Theorem 3.1. Let Ω' be the set of points $x_0 \in \Omega$ such that v is differentiable at x_0 and $\det \nabla v(x_0) > 0$. By Lemmas 2.1 and 2.7 we obtain $|\Omega \setminus \Omega'| = 0$. In the sequel, we fix $x_0 \in \Omega'$, set $y_0 = v(x_0)$, and show that v is locally invertible at x_0. By Lemmas 3.5 and 3.7 there is $R_0 > 0$ such that $B(x_0, R_0) \subset\subset \Omega$,

$$N(v, B(x_0, R_0), y) = 1 \text{ a.e. } y \in C_{R_0}, \tag{26}$$

where C_{R_0} is the connected component of $\mathbb{R}^N \setminus v(\partial B(x_0, R_0))$ containing y_0, with $N(v, B(x_0, R_0), y_0) = 1$. By Lemma 3.9 we deduce that there is $r > 0$ such that

$$v^{-1}(B(y_0, r)) \cap B(x_0, R_0) \subset\subset B(x_0, R_0) \tag{27}$$

and

$$B(y_0, r) \subset\subset C_{R_0}. \tag{28}$$

Setting $D = v^{-1}(B(y_0, r)) \cap B(x_0, R_0)$, by (27) and (28) we have $D \subset v^{-1}(C_{R_0}) \cap B(x_0, R_0)$ and by Lemma 3.8

$$v(D) = B(y_0, r), \quad v(\partial D) \subset \partial v(D) = \partial B(y_0, r). \tag{29}$$

By the N^{-1} property of v (see Remark 2.5 and (29)), we have $|\partial D| = 0$, which together with (20) yields

$$d(v, D, y) = 1 \ \ \forall\, y \in v(D) \setminus v(\partial D). \tag{30}$$

By using the definition of D, the fact that $D \subset B(x_0, R_0)$, (26), and (28), we obtain

$$N(v, D, y) = 1 \text{ a.e. } y \in v(D). \tag{31}$$

Let $N := \{y \in v(D) \equiv B(y_0, r) : \ d(v, D, y) \neq 1\}$ and define the candidate for local inverse function, w, by

$$w(y) = x \ \text{ if } \ y \in v(D) \setminus N \ \text{ and } \ v(x) = y, \quad x \in D, \tag{32}$$

$$w(y) = x, \ \text{ if } \ y \in N, \ \ v(x) = y, \tag{33}$$

$x \in D$ being chosen by the axiom of choice.

Claim 1. $w \in L^\infty(B(y_0, r))^N$. We have $w(y) \in D \subset \Omega$ for every $y \in v(D)$ and so w is uniformly bounded in $v(D)$. To prove that w is Borel measurable, fix $\alpha \in \mathbb{R}$ and show that the set

$$A := \{y \in v(D) : \ w_i(y) \geq \alpha\}$$

is measurable. We obtain $A = A_1 \cup A_2$ where

$$A_1 := \{y \in v(D) \setminus N : \ w_i(y) \geq \alpha\},$$

$$A_2 := \{y \in N : \ w_i(y) \geq \alpha\}.$$

Since $|A_2| = 0$, we deduce that A_2 is measurable. By using the fact that the restriction of v to $v^{-1}(v(D) \setminus N)$ is one-to-one, one can see that

$$\begin{aligned} A_1 &= \{v(x) : \ x \in v^{-1}(v(D) \setminus N), \ x_i \geq \alpha\} \\ &= (v(D) \setminus N) \cap \left(\cup_{n=0}^{+\infty} v\{x \in \bar{B}(x_0, R_0) : \alpha + n \leq x_i \leq \alpha + n + 1\} \right). \end{aligned}$$

By using the fact that for every $n \in \mathbb{N}$, $\{x \in \bar{B}(x_0, R_0) : \alpha + n \leq x_i \leq \alpha + n + 1\}$ is a compact set, v is a continuous function, and $v(D) \setminus N$ is measurable, we obtain that A_1 is measurable and we conclude that $w \in L^\infty(B(y_0, r))^N$.

Claim 2.

$$v \circ w(y) = y \text{ for every } y \in v(D) \equiv B(y_0, r), \tag{34}$$

$$w \circ v(x) = x \text{ for every } x \in D \setminus v^{-1}(N). \tag{35}$$

This follows immediately from (32) and (33). One notices that, due to (30) and Remark 2.5, $|v^{-1}(N)| = 0$.

Claim 3. $f \circ w$ is measurable for every $f : D \to \mathbb{R}$ measurable.

We know that every Lebesgue measurable set is a union of a Borel measurable set and a set of measure zero. To show that $f \circ w$ is measurable, by Claim 1 it suffices to show that $w^{-1}(R)$ is measurable for every $R \subset D$ such that $|R| = 0$. Let R be a subset of D such that $|R| = 0$. We have by (34) that

$$w^{-1}(R) \subset v(R),$$

and since $|R| = 0$, by the N property of v, we obtain that $|w^{-1}(R)| = 0$. Thus $w^{-1}(R)$ is measurable.

Let $g : v(D) = B(y_0, r) \to \mathbb{R}$ be defined by

$$g(y) = \frac{|\mathrm{adj} \nabla v(w(y))|}{\det \nabla v(w(y))}.$$

Claim 4. $g \in L^1(v(D))$.

By Claim 3, g is measurable. By Lemma 2.4 and (11), where we set $f = \chi_{v(D)}$ the indicator of the set $v(D)$, and by Claim 2 and (31) we obtain

$$\int_{v(D)} |g(y)| dy = \int_D |g \circ v(x)| \det \nabla v(x) dx = \int_D |\mathrm{adj} \nabla v(x)| dx.$$

Therefore $g \in L^1(v(D))$.

Claim 5. $w \in W^{1,1}(v(D))^N$ and $\nabla w(y) = (\frac{\mathrm{adj} \nabla v(w(y))}{\det \nabla v(w(y))})^T$.

To prove Claim 5, we fix $\phi \in C_0^\infty(v(D))$ and set $K = \mathrm{supp}\phi$. We show that

$$\int_{v(D)} w_\alpha(y) \frac{\partial \phi}{\partial y_j}(y) dy = -\int_{v(D)} \frac{(\mathrm{adj} \nabla v(w(y)))^j_\alpha}{\det \nabla v(w(y))} \phi(y) dy.$$

Set $\delta = \mathrm{dist}(K, \partial v(D)) > 0$. By using the uniform continuity of v on $\bar{D} \subset B(x_0, R_0)$, we choose $\epsilon > 0$ such that

$$|v(x) - v(x')| \leq \frac{\delta}{4} \text{ for every } x, x' \in \bar{D},\ |x - x'| \leq \epsilon. \tag{36}$$

Let $\{v_n\} \subset C^\infty(\bar{D})^N$ be such that

$$v_n \to v \text{ in } C^0(\bar{D})^N \tag{37}$$

and

$$v_n \rightharpoonup v \text{ in } W^{1,N}(D)^N.$$

By (37) we can assume without loss of generality that

$$|v - v_n|_\infty \leq \frac{\delta}{4} \text{ for every } n \in \mathbb{N}. \tag{38}$$

By the fact that $v(\partial D) \subset \partial v(D)$ (see (29)), and by (36) and (38), we have that

$$\operatorname{dist}(x, \partial D) < \epsilon \text{ implies } \phi(v_n(x)) = 0$$

and so

$$\phi \circ v_n \in C_0^\infty(D).$$

In the sequel we denote by A_α^j the component of the j row and the α column of the $N \times N$ matrix A. By (11), (31), (35), and the fact that for every $n \in \mathbb{N}$, $\sum_{\alpha=1}^N \frac{\partial (\operatorname{adj} \nabla v_n)_\alpha^j}{\partial x_\alpha} = 0$ for every $j = 1, \ldots, N$, we have

$$\begin{aligned}
\int_{v(D)} w_\alpha(y) \frac{\partial \phi}{\partial y_j}(y) dy &= \int_D w_\alpha(v(x)) \frac{\partial \phi}{\partial y_j}(v(x)) \det \nabla v(x) dx \\
&= \lim_{n \to +\infty} \int_D x_\alpha \frac{\partial \phi}{\partial y_j}(v_n(x)) \det \nabla v_n(x) dx \\
&= \lim_{n \to +\infty} \int_D x_\alpha \sum_{k=1}^N (\operatorname{adj} \nabla v_n(x))_k^j \frac{\partial}{\partial x_k} \phi(v_n(x)) dx \\
&= - \lim_{n \to +\infty} \int_D (\operatorname{adj} \nabla v_n(x))_\alpha^j \phi(v_n(x)) dx \\
&= - \int_D (\operatorname{adj} \nabla v(x))_\alpha^j \phi(v(x)) dx \\
&= - \int_D \frac{(\operatorname{adj} \nabla v(w \circ v(x)))_\alpha^j}{\det \nabla v(w \circ v(x))} \phi(\circ v(x)) \det \nabla v(x) dx \\
&= - \int_{v(D)} \frac{(\operatorname{adj} \nabla v(w(y)))_\alpha^j}{\det \nabla v(w(y))} \phi(y) dy.
\end{aligned}$$

This equality, together with Claim 4, yields Claim 5.

Claim 6. $\nabla w \in W^{1,s}(v(D))$ if and only if $|g \circ v|^s \det \nabla v \in L^1(v(D))$ for $1 \leq s < +\infty$. Recall that $g(y) = \frac{|\operatorname{adj} \nabla v(w(y))|}{\det \nabla v(w(y))}$ and that $w \in L^\infty(v(D))^N$. Thus $\nabla w \in W^{1,s}(v(D))$ if and only if $\nabla w \in L^s(v(D))$. The result now follows from Claim 5 and (11). □

Remark 3.10. It is possible to show that if $v \in W^{1,q}(\Omega)^N$, $q > N - 1$, $\operatorname{adj} \nabla v \in L^{\frac{N}{N-1}}(\Omega)$, $\det \nabla v(x) > 0$ a.e. in Ω and if v is continuous, then there is local invertibility a.e. in Ω, i.e., for a.e. $x_0 \in \Omega$ there exists $r > 0$ such that $v|_{B(x_0,r)}$ is almost everywhere injective with the inverse $w \in BV_{\text{loc}}(v(B(x_0, r)), \mathbb{R}^N)$ and there exists a set $E \subset v(B(x_0, r))$ such that

$$\begin{aligned}
&E \text{ is an open set of } v(B(x_0, r)), \\
&|v(B(x_0, r) \setminus E| = 0, \\
&w \in W^{1,1}(E, \mathbb{R}^N), \\
&v \circ w(y) = y \text{ a.e. } y \in v(B(x_0, r)), \\
&w \circ v(x) = x \text{ a.e. } x \in B(x_0, r).
\end{aligned}$$

To see this, we recall that by Lemma 2.7 (iii) v is approximatively differentiable a.e. in Ω and by adapting the proof of Lemma 3.5 accordingly, it is possible to show that

$$d(v, B(x_0, r), v(x_0)) = 1$$

for some $r > 0$. Let C_0 be the connected component of $\mathbb{R}^N \setminus v(\partial B(x_0, r))$ which contains $v(x_0)$. Then

$$d(v, B(x_0, r), y) = 1 \tag{39}$$

for every $y \in C_0$, so if we choose $0 < r' < r$ such that

$$B(x_0, r') \subset B(x_0, r) \cap v^{-1}(C_0),$$

then by (39) (and since $\det \nabla v > 0$ a.e.) we have

$$d(v, B(x_0, r'), y) \leq 1$$

for every $y \in \mathbb{R}^N \setminus v(\partial B(x_0, r'))$. It suffices now to use the results in [TQ], (1.3)–(1.5), (2.26), and Theorem 3.7 (i). Note, however, that in [TQ], it is assumed that $\operatorname{adj} \nabla v \in L^r$, $r \geq \frac{q}{q-1}$ and if $N - 1 < q < N$, then $\frac{q}{q-1} > \frac{N}{N-1}$.

As it turns out, [TQ]'s results still hold for $r = \frac{N}{N-1}$ as remarked by [MTY] (see Theorem 5.3 in [MTY]).

Proof of Corollary 3.2.

Proof of (a). We have

$$v \in W^{1,N}(\Omega_1)^N, \quad \det \nabla v(x) > 0 \ \text{ a.e. } x \in \Omega_1$$

and

$$v \in W^{1,N}(\Omega_2)^N, \quad \det \nabla v(x) < 0 \ \text{ a.e. } x \in \Omega_2.$$

It suffices to apply Theorem 3.1 to v and to $R_0 v$ in Ω_2, where R_0 is a constant rotation with $\det R_0 = -1$.

Proof of (b). We now assume that $v \in W^{1,q}(\Omega)^N$, $q > N$, $\det \nabla v(x) \neq 0$ a.e. $x \in \Omega$, and for almost every $x_0 \in \Omega$, v is locally almost injective in a neighborhood of x_0 in the sense that there is an open set $D \equiv D(x_0) \subset\subset \Omega$ and there is a function $w : v(D) \to D$ such that

$$w \circ v(x) = x \ \text{ a.e. } x \in D. \tag{40}$$

By Vitali's covering theorem there is a countable family of nonempty, open, mutually disjoint balls $\{B_i,\ i \in \mathbb{N}\}$ and there is a sequence of functions $w_i : v(\bar{B}_i) \to \Omega$ such that $\bar{B}_i \subset \Omega$ and

$$\begin{aligned} &|\Omega \setminus \cup_{i=1}^{+\infty} B_i| = 0, \\ &w \circ v(x) = x \ \text{ a.e. } x \in B_i. \end{aligned} \tag{41}$$

The task ahead will be to partition B_i into three subsets B_i^1, B_i^2, and N_i such that B_i^1, B_i^2 are two open sets, N_i is a set of measure zero, and

$$\begin{aligned} &\det \nabla v(x) > 0 \ \text{ a.e. } x \in B_i^1, \\ &\det \nabla v(x) < 0 \ \text{ a.e. } x \in B_i^2. \end{aligned}$$

Using the fact that $v \in W^{1,q}(B_i)^N$, $q > N$, by Lemma 2.7 and (41) we deduce that there is a set $A_i \subset \bar{B}_i$ of measure zero such that v is differentiable at every $x \in B_i \setminus A_i$,

$$\begin{aligned} &w \circ v(x) = x \ \text{ for every } \ x \in \bar{B}_i \setminus A_i, \\ &\det \nabla v(x) \neq 0 \ \text{ for every } \ x \in \bar{B}_i \setminus A_i. \end{aligned} \tag{42}$$

Let $\{C^j\}$ be the countable collection of the (open) connected components of $\mathbb{R}^N \setminus v(\partial B_i)$. By Remark 2.5 (a), (b) we have

$$|v^{-1}(v(\partial B_i \cup A_i))| = 0. \tag{43}$$

We have the following claim.

Claim 1. $d(v, B_i, v(x)) = \operatorname{sign} \det \nabla v(x)$ for every $x \in B_i \setminus v^{-1}(v(\partial B_i \cup A_i))$.

Fix $x \in B_i \setminus v^{-1}(v(\partial B_i \cup A_i))$.

Step 1. We prove that $d(v, B(x, r_0), v(x)) = \operatorname{sign} \det \nabla v(x)$ for r_0 small enough. By using the fact that v is differentiable and $\det \nabla v(x) \neq 0$, by Lemma 3.5 we deduce that there is $r_0 > 0$ such that for every $0 < r \leq r_0$ we have

$$d(v, B(x, r), v(x)) = \operatorname{sign} \det \nabla v(x).$$

Step 2. We show that $d(v, B_i, v(x)) = \operatorname{sign} \det \nabla v(x)$. Indeed, by setting $K = \bar{B}_i \setminus B(x, r_0)$, we have that K is a compact set included in $\bar{B}_i$, and by (42) we have $v(x) \notin v(K)$ because $v(x) \notin v(A_i)$. By the excision property of the degree (see Proposition 2.3), we obtain

$$d(v, B_i, v(x)) = d(v, B(x, r_0), v(x)) = \operatorname{sign} \det \nabla v(x).$$

Claim 2. $\operatorname{sign} \det \nabla v(x) = \operatorname{sign} \det \nabla v(x')$ for every $x, x' \in v^{-1}(C^j) \setminus v^{-1}(v(\partial B_i \cup A_i))$. Assume that $x, x' \in v^{-1}(C^j) \setminus v^{-1}(v(\partial B_i \cup A_i))$. Using Claim 1 and the fact that the degree $d(v, B_i, \cdot)$ is constant on each C^j, we obtain that $\operatorname{sign} \det \nabla v(x) = \operatorname{sign} \det \nabla v(x')$.

We now conclude the proof of Corollary 3.2(b). Let $I = \{j \in \mathbb{N} : \det \nabla v(x) > 0 \text{ a.e. } x \in v^{-1}(C^j)\}$ and $J = \{j \in \mathbb{N} : \det \nabla v(x) < 0 \text{ a.e. } x \in v^{-1}(C^j)\}$. Set

$$B_i^1 = \cup_{j \in I} v^{-1}(C^j) \cap B_i,$$

$$B_i^2 = \cup_{j \in J} v^{-1}(C^j) \cap B_i,$$

and

$$N_i = B_i \setminus (B_i^1 \cup B_i^2).$$

Then $B_i = B_i^1 \cup B_i^2 \cup N_i$. Set $\Omega_1 = \cup_i B_i^1$, $\Omega_2 = \cup_i B_i^2$ and $N = \Omega \setminus (\Omega_1 \cup \Omega_2)$, then $|N| = 0$ and Ω_1, Ω_2 have the required properties. □

Proof of Corollary 3.3. To obtain that $w \in W^{1,q/(N-1)}(v(D), D)$ we take $s = \frac{q}{N-1}$ in Theorem 3.1. If $q \geq N(N-1)$, then $w \in W^{1,N}$,

$$\det \nabla w(y) = \frac{1}{\det \nabla v(w(y))} > 0 \ \text{ a.e. } \ y \in v(D)$$

and so, by Lemma 2.1 we deduce that w is continuous. Hence v and w are homeomorphisms and v is an open mapping in Ω' for some $\Omega' \subset \Omega$ open, where $|\Omega \setminus \Omega'| = 0$. □

4. Semicontinuity involving variation of the domain. The variational treatment of crystals with defects leads to the study of functionals of the type

$$E(u,v)=\int_{\Omega} W(\nabla u(x)(\nabla v(x))^{-1})dx,$$

where $\Omega \subset \mathbb{R}^N$ is a reference domain, W is the strain energy density, u is the elastic deformation and v represents the slip (rearrangement) or plastic deformation with $\det(\nabla v(x))=1$ a.e. $x \in \Omega$. The underlying kinematical mode for slightly defective crystals was introduced by Davini [Dav] and later developed by Davini and Parry [DP]. As it turns out, matrices of the form

$$\nabla u(x)(\nabla v(x))^{-1}$$

represent lattice matrices of defect-preserving deformations (neutral deformations) and by taking the viewpoint that equilibria correspond to a variational principle, Fonseca and Parry [FP] studied the structure of some kind of generalized minimizers (the Young measure solutions) for the energy $E(\cdot,\cdot)$. (Related variational problems were also investigated in [DP].)

Using the div-curl lemma, it follows that if $u_n \rightharpoonup u$ in $W^{1,\infty}$ $w*$ and $v_n \rightharpoonup v$ in $W^{1,\infty}$ $w*$, then

$$\nabla u_n(\nabla v_n)^{-1} \rightharpoonup \nabla u(\nabla v)^{-1} \text{ in } L^{\infty} \, w*.$$

Lower semicontinuity and relaxation properties of $E(\cdot,\cdot)$ were addressed only under additional material symmetry assumptions on W. Existence and regularity properties for minimizers of $E(\cdot,\cdot)$ were obtained in [DF]. Following this work, we stress the fact that the direct methods of the calculus of variations fail to apply to this problem, as sequential weak lower semicontinuity of $E(\cdot,\cdot)$ is not sufficient to guarantee the existence of minimizers. Indeed, with $W(F)=|F|^r$, it is shown in [DF] that there are no minimizers in $\{(u,v) \in W^{1,\infty} \times W^{1,\infty} : \ u(x)=x \text{ on } \partial\Omega, \det(\nabla v(x))=1 \text{ a.e.}\}$ if $0<r<N=2$, while for $r>N$ existence is obtained for smooth (u,v) (see Theorem 2.3 in [DF]).

It is clear that if $\{(u_n,v_n)\}$ is a minimizing sequence and if $|\nabla u_n(\nabla v_n)^{-1}|^r$ is bounded in L^1, then

$$\nabla u_n(\nabla v_n)^{-1} \rightharpoonup L \text{ in } L^r, u_n|_{\partial\Omega}=u_0, \det(\nabla v_n)=1 \text{ a.e.}$$

and so if some type of lower semicontinuity prevails, then

$$\int_{\Omega} W(L)dx \leq \liminf \int_{\Omega} W(\nabla u_n(\nabla v_n)^{-1})dx. \tag{44}$$

It would remain to show that L would still have the same structure, precisely

$$L=\nabla u(\nabla v)^{-1},$$

where $u|_{\partial\Omega}=u_0$, $\det(\nabla v)=1$ a.e. Note that (44) is always satisfied if W is a convex function. On the other hand, formally, as $\det(\nabla v)=1$ a.e. and setting $w=u(v^{-1})$, the energy becomes

$$\int_{v(\Omega)} W(\nabla w(y))dy,$$

which is now an energy functional involving variations of the domain. Hence, under this new formulation, quasi convexity seems to be more appropriate than convexity (see [AF], [Ba], [Da], and [Mo]).

Suppose that W is a quasi-convex function, i.e.,

$$W(F) \leq \frac{1}{|Q|} \int_Q W(F + \nabla\phi(x))dx,$$

where $Q = (0,1)^N, \phi \in W_0^{1,\infty}(Q)^N$, and $\nabla u_n(\nabla v_n)^{-1} \rightharpoonup L$ in L^r. Can we say that

$$\int_\Omega W(L) \leq \liminf \int_\Omega W(\nabla u_n(\nabla v_n)^{-1})?$$

As an example, consider

$$W(F) = |F|^2 + |\det(F)|.$$

Although we are unable to answer this question, we prove the following result which is the main theorem of this section.

THEOREM 4.1. *Let $W : M^{N\times N} \to \mathbb{R}$ be a quasi-convex function such that*

$$-C_1(1 + |A|^s) \leq W(A) \leq C_2(1 + |A|^r)$$

for some constants $C_1, C_2 > 0, r > s \geq 1$, $p \geq 1$, $q \geq N$, $\frac{1}{p} + \frac{N-1}{q} = \frac{1}{r}$ ($W \geq 0$ if $r = s = 1$). If $u_n \rightharpoonup u$ in $W^{1,p}(\Omega)^N$, $v_n \rightharpoonup v$ in $W^{1,q}(\Omega)^N$, and $\det(\nabla v_n) = 1$ a.e. in Ω, then

$$\int_\Omega W(\nabla u(\nabla v)^{-1})dx \leq \liminf \int_\Omega W(\nabla u_n(\nabla v_n)^{-1})dx.$$

Before proving Theorem 4.1, we make some remarks.

Remark 4.2.

1. It is clear that if $u \in W^{1,p}$, $v \in W^{1,q}$, and $\det \nabla v = 1$ a.e., then $\nabla u(\nabla v)^{-1} \in L^r$.

2. If $r > 1$, then $s < r$ is a necessary condition as the following counterexample shows. This is an adaptation of an idea of Tartar by Ball and Murat [BM]. Here $r = s = 2 = N, \Omega = (0,1)^2$, $W(F) = \det(F)$, $u_n \rightharpoonup u$ in $H^1(\Omega)$, $v_n(x) = x$ and

$$\int_\Omega \det \nabla u \not\leq \liminf \int_\Omega \det \nabla u_n.$$

3. The growth condition cannot be dropped even if W is polyconvex and non-negative. More precisely, if the relation between p, q, r, and s does not occur, the conclusion of Theorem 4.1 may be false. Indeed, using the example by Malý [Ma] with $q = +\infty, p < N - 1, W(F) = \det F, N = r = s$, we may find $u_n \rightharpoonup u$ in $W^{1,p}$, $u(x) \equiv x$ with $v_n(x) \equiv x$, and

$$\int_\Omega |\det(\nabla u)| > \liminf \int_\Omega |\det(\nabla u_n)|.$$

Moreover, the growth condition prescribed in Theorem 4.1 is the well-known growth condition ensuring weak lower semicontinuity of $E(u, id)$ in $W^{1,p}$ (see [AF] and [Da]).

4. We may ask if these results can be extended to the case $\frac{N^2}{N+1} < q < N$, since, due to Müller's result ([Mu]), if we assume that $\mathrm{Det}\nabla v = 1$ a.e. then $\mathrm{Det}\nabla v = \det \nabla v$ a.e. in Ω.

5. Since lower semicontinuity of the energy is obtained in Theorem 4.1, the question now amounts to showing that one can find a minimizing sequence $\{\nabla u_n(\nabla v_n)^{-1}\}$ where $\{u_n\}$ is bounded in $W^{1,p}$ and $\{v_n\}$ is bounded in $W^{1,q}$. Actually, one only needs to show that there exists a sequence $\{f_n\} \subset W^{1,\infty}(\Omega,\Omega)$ such that $v_n \circ f_n$ is bounded in $W^{1,q}$ and

$$\begin{cases} \det \nabla f_n(x) &= 1 \text{ a.e. } x \in \Omega, \\ f_n(x) &= x \ x \in \partial\Omega. \end{cases}$$

Due to the examples provided in [DF], we know that this may not be possible since the infimum of E may be zero, which may prevent the existence of minimizing sequences bounded in $W^{1,p} \times W^{1,q}$.

As usual in variational problems for which existence of minimizers is not guaranteed (such as variational problems for material that change phase and, here, for slightly defective materials), we focus on the properties of the minimizing sequences rather than study the macroscopic limit of $\nabla u_n(\nabla v_n)^{-1}$.

What follows may help to understand better why boundedness of $\{\nabla u_n(\nabla v_n)^{-1}\}$ may not entail the boundedness of $\{\nabla u_n\}$ and $\{\nabla v_n\}$. Using Theorem 4.1, we show that we may construct a minimizing sequence $\{\nabla u_\epsilon(\nabla v_\epsilon)^{-1}\}$ with $|\nabla u_\epsilon|_p = 0(\frac{1}{\epsilon^\alpha})$, $|\nabla v_\epsilon|_q = 0(\frac{1}{\epsilon^\beta})$, for any $\alpha, \beta > 0$.

Consider the "perturbed" family of variational problems

$$E_\epsilon(u,v) = \int_\Omega W(\nabla u(\nabla v)^{-1})dx + \epsilon^{\alpha p}|\nabla u_\epsilon|_p^p + \epsilon^{\beta q}|\nabla v_\epsilon|_q^q,$$

where $u|_{\partial\Omega} = u_0$, $\det \nabla v = 1$ a.e., $\frac{1}{|\Omega|}\int_\Omega v(x)dx = 0$. Using the direct method of the calculus of variations, Poincaré's inequality, and Theorem 4.1, it follows immediately that there exists $(u_\epsilon, v_\epsilon) \in W^{1,p} \times W^{1,q}$ such that

$$E_\epsilon(u_\epsilon, v_\epsilon) = \inf\{E_\epsilon(u,v) : \ (u,v) \in W^{1,p} \times W^{1,q}, \ \det \nabla v = 1 \text{ a.e.}\}.$$

Then, given an admissible pair (u,v)

$$\begin{aligned} E(u,v) &= \lim_{\epsilon\to 0+} E_\epsilon(u,v) \\ &\geq \limsup_{\epsilon\to 0+} E_\epsilon(u_\epsilon, v_\epsilon) \\ &\geq \limsup_{\epsilon\to 0+} E(u_\epsilon, v_\epsilon), \\ &\geq \inf E. \end{aligned}$$

Doing the same with $\liminf_{\epsilon\to 0+} E(u_\epsilon, v_\epsilon)$ and taking the infimum in (u,v), we conclude that

$$\inf E = \lim_{\epsilon\to 0+} E(u_\epsilon, v_\epsilon)$$

and $|\nabla u_\epsilon|_p = 0(\frac{1}{\epsilon^\alpha})$, $|\nabla v_\epsilon|_q = 0(\frac{1}{\epsilon^\beta})$.

The following two lemmas will be useful to prove Theorem 4.1.

LEMMA 4.3. *Let Ω', Ω be two open sets of $\mathbb{R}^N$ such that $\Omega' \subset\subset \Omega$; let $q \geq N$ and $v, v_n \in W^{1,q}(\Omega)^N$ be such that $\det \nabla v(x) = \det \nabla v_n(x) = 1$ a.e. $x \in \Omega$. Assume*

that $v_n \rightharpoonup v$ *in* $W^{1,q}(\Omega)^N$. *Then there exists a subsequence of* $\{v_n\}$ *(not relabelled) such that for almost every* $x_0 \in \Omega'$, *there exist open sets* $D, D_n \subset \Omega'$ *containing* x_0, *there exist* $n_0 \in \mathbb{N}$, $r_0 \equiv r(x_0) > 0$, $w : B(y_0, r_0) \to D$, $w_n : B(y_0, r_0) \to D_n$ *with* $y_0 = v(x_0)$ *such that for* $n \geq n_0$,

$$
\begin{aligned}
&w_n \circ v_n(x) = x \ \text{ a.e. } x \in \bar{D}_n,\\
&v_n \circ w_n(y) = y \ \text{ for every } y \in \bar{B}(y_0, r_0) \ \text{ and } \ v_n(D_n) = B(y_0, r_0),\\
&w \circ v(x) = x \ \text{ a.e. } x \in \bar{D} \ \text{ and } \ v(x_0) \neq v(x) \ \text{ for } x \in D, x \neq x_0,\\
&v \circ w(y) = y \ \text{ for every } y \in \bar{B}(y_0, r_0) \ \text{ and } \ v(D) = B(y_0, r_0),\\
&w_n, w \in W^{1, \frac{q}{N-1}}.
\end{aligned}
$$

Proof. By using Lemma 2.1 and the Ascoli–Arzela theorem we obtain that, up to a subsequence, v_n converges to v uniformly in $\bar{\Omega}'$. By Lemmas 3.7 and 2.7 for almost every $x_0 \in \Omega'$, there is $R_0 > 0$ such that

$$
\begin{aligned}
&B(x_0, R_0) \subset\subset \Omega',\\
&N(v, B(x_0, R_0), y) = 1 \ \text{ for almost every } \ y \in C_{R_0},\\
&d(v, B(x_0, R_0), y) = 1 \ \text{ for every } \ y \in C_{R_0},\\
&d(v, B, y) = 1 \text{ for every } \ y \in B \setminus v(\partial B),\\
&\text{for every nonempty open set } B \subset v^{-1}(C_{R_0}) \cap B(x_0, R_0) \text{ such that } |v(\partial B)| = 0,
\end{aligned}
$$

where C_{R_0} is the connected component of $\mathbb{R}^N \setminus v(\partial B(x_0, R_0))$ containing $y_0 := v(x_0)$. Since v is differentiable at x_0 and $\det \nabla v(x_0) \neq 0$ we may assume without loss of generality that $N(v, B(x_0, R_0), y_0) = 1$. Fix $0 < \epsilon < d\big(y_0, v(\partial B(x_0, R_0))\big)$ and choose $n_0 \in \mathbb{N}$ such that $|v_n - v|_\infty < \epsilon$. Set

$$
A_\epsilon := \{y \in C_{R_0} : \operatorname{dist}(y, v(\partial B(x_0, R_0))) > \epsilon\}.
$$

It is obvious that A_ϵ is a nonempty open set.

Claim 1. $d(v_n, B(x_0, R_0), y)$ exists and is equal to 1 for every $y \in A_\epsilon$ and every $n \geq n_0$. By Proposition 2.3 (4), together with the fact that $d(v, B(x_0, R_0), y) = 1$ for every $y \in C_{R_0}$, we have

$$
d(v_n, B(x_0, R_0), y) = 1 \tag{45}
$$

for every $y \in A_\epsilon$ and every $n \geq n_0$.

By Lemma 3.9 there is $0 < r_0 < R_0$ such that

$$
B(y_0, r_0) \subset\subset A_\epsilon \ \text{ and } \ v^{-1}(B(y_0, r_0)) \cap B(x_0, R_0) \subset\subset B(x_0, R_0). \tag{46}
$$

Claim 2. We claim that

$$
B(y_0, r_0) \subset\subset C^n_{R_0}, \tag{47}
$$

where $C^n_{R_0}$ is the connected component of $\mathbb{R}^N \setminus v_n(\partial B(x_0, R_0))$ that contains y_0.

We prove first that $A_\epsilon \subset \mathbb{R}^N \setminus v_n(\partial B(x_0, R_0))$. Assume on the contrary that there is $y \in A_\epsilon \cap v_n(\partial B(x_0, R_0))$ and choose $x \in \partial B(x_0, R_0)$ such that $y = v_n(x)$. We would have $|v_n(x) - v(x)| = |y - v(x)| > \epsilon > |v_n - v|_\infty$, which yields a contradiction. Fix $r' > r_0$ such that $\bar{B}(y_0, r') \subset A_\epsilon$. We have that $B(y_0, r')$ is a connected set included in $\mathbb{R}^N \setminus v_n(\partial B(x_0, R_0))$ and containing y_0. We deduce that $B(y_0, r') \subset C^n_{R_0}$ and $B(y_0, r_0) \subset\subset C^n_{R_0}$.

Set $D = v^{-1}(B(y_0, r_0)) \cap B(x_0, R_0) \subset\subset \Omega'$ and $D_n = v_n^{-1}(B(y_0, r_0)) \cap B(x_0, R_0) \subset\subset \Omega'$. By using (45)–(47) and arguments similar to the ones of the proof of Theorem 3.1, together with Corollary 3.3, we deduce that for $n \geq n_0$ there is $w_n : \bar{B}(y_0, r_0) \to \bar{D}_n$, there is $w : \bar{B}(y_0, r_0) \to \bar{D}$ such that

$$
\begin{aligned}
&w_n, w \in W^{1, \frac{q}{N-1}}(B(y_0, r_0))^N,\\
&w_n \circ v_n(x) = x \ \text{ a.e. } x \in \bar{D}_n,\\
&v_n \circ w_n(y) = y \ \text{ a.e. } y \in \bar{B}(y_0, r_0),\\
&w \circ v(x) = x \ \text{ a.e. } x \in \bar{D} \ \text{ and } \ v(x_0) \neq v(x) \ \text{ for } \ x \in \bar{D}, x \neq x_0,\\
&v \circ w(y) = y \ \text{ a.e. } y \in \bar{B}(y_0, r_0).
\end{aligned}
$$

Finally by Lemma 3.8, $v_n(D_n) = v(D) = B(y_0, r_0)$.

Remark 4.4.

1. It follows from the proof above that if the conclusion of Lemma 4.3 holds for $r \equiv r(x_0) > 0$ then it holds also for $0 < r' < r$. Thus, as v is continuous on $\bar{D}$, $v(x) \neq v(x_0)$ for $x \in D$ and $x \neq x_0$, we deduce that

$$\lim_{r \to 0} \max\{|x - x_0| : \ x \in \bar{D}, v(x) \in B(y_0, r_0)\} = 0.$$

2. It is possible to show that $\lim_{n \to +\infty} |D \Delta D_n| = 0$. We divide the proof into two cases.

Claim 1. $\lim_{n \to +\infty} |D \setminus D_n| = 0$.

Let $F_\epsilon = B(y_0, r_0 - \epsilon)$ and $O_\epsilon = v^{-1}(F_\epsilon) \cap D$. We prove first that for each ϵ fixed there exists $n_0 \equiv n_0(\epsilon) \in \mathbb{N}$ such that $n \geq n_0$ implies $O_\epsilon \subset D_n$. Indeed, since $\{v_n\}$ converges to v uniformly, there exists $n_0 \equiv n_0(\epsilon) \in \mathbb{N}$ such that $|v - v_n|_\infty \leq \frac{\epsilon}{2}$ for every $n \geq n_0$. If $x \in O_\epsilon$, we obtain

$$|v_n(x) - y_0| \leq |v(x) - y_0| + |v(x) - v_n(x)| < r_0$$

and so $x \in D_n$. As $\cup_\epsilon O_\epsilon = D$ and the sequence (O_ϵ) is nonincreasing, we have

$$\lim_{\epsilon \to 0} |D \setminus O_\epsilon| = 0$$

which, together with the fact that $|D \setminus D_n| \leq |D \setminus O_\epsilon|$ for $n \geq n_0$, yields Claim 1.

Claim 2. $\lim_{n \to +\infty} |D_n \setminus D| = 0$.

For $\epsilon > 0$, take $n_0 \equiv n_0(\epsilon) \in \mathbb{N}$ such that $|v - v_n|_\infty \leq \frac{\epsilon}{2}$ for every $n \geq n_0$. For $n \geq n_0$, we have

$$\left\{x \in B(x_0, R_0) : r - \frac{\epsilon}{2} \leq |v_n(x) - y_0| < r\right\} \subset \{x \in B(x_0, R_0) : r - \epsilon \leq |v(x) - y_0| < r + \epsilon\}$$

and since v has the N^{-1} property (see Remark 2.5) we obtain

$$|\cap_\epsilon \{x \in B(x_0, R_0) : r - \epsilon \leq |v(x) - y_0| < r + \epsilon\}| = |\{x \in B(x_0, R_0) : |v(x) - y_0| = r\}| = 0.$$

To conclude the proof of Claim 2, it suffices to remark that for $n \geq n_0$ we obtain

$$D_n \setminus D \subset \{x \in B(x_0, R_0) : r - \epsilon \leq |v(x) - y_0| < r + \epsilon\}.$$

LEMMA 4.5. *Let $p \geq 1$, $q \geq N$, $r \geq 1$ be such that $\frac{1}{p} + \frac{N-1}{q} = \frac{1}{r}$. Assume that $\Omega \subset \mathbb{R}^N$ is an open, bounded set, $u_n, u \in W^{1,q}(\Omega)^N$, $u_n \rightharpoonup u$ in $W^{1,p}(\Omega)^N$, $v_n, v \in W^{1,q}\Omega)^N$, $\det \nabla v_n = \det \nabla v = 1$ a.e. in Ω and $v_n \rightharpoonup v$ in $W^{1,q}(\Omega)^N$. Let $x_0 \in \Omega$, and w_n, w be, respectively, the local inverse function of v_n, v, in the open neighborhoods D_n, D of x_0, let $y_0 = v(x_0)$ and $B(y_0, r_0)$ be as in Lemma 4.3 and Remark 4.4. Then the following conditions hold:*

(i) $u_n \circ w_n \in W^{1,r}(B(y_0,r_0))^N$ *and* $\nabla(u_n \circ w_n)(y) = \nabla u_n(w_n(y))(\nabla v_n(w_n(y)))^{-1}$ *a.e.,*

(ii) $u_n \circ w_n \rightharpoonup u \circ w$ *in* $W^{1,r}(B(y_0,r_0))^N$ *if* $r > 1$,

(iii) $u_n \circ w_n \to u \circ w$ *in* $L^1(B(y_0,r_0))^N$ *and* $\{u_n \circ w_n\}$ *is bounded in* $W^{1,1}(B(y_0,r_0))^N$ *if* $r = 1$.

Proof. We recall that by Lemma 4.3 we have

$$w_n, w \in W^{1,\frac{q}{N-1}}(B(y_0,r_0))^N, \quad v(D) = B(y_0,r_0), v_n(D_n) = B(y_0,r_0), \tag{48}$$

$$\nabla w(y) = (\nabla v(w(y)))^{-1}, \nabla w_n(y) = (\nabla v_n(w_n(y)))^{-1} \text{ a.e. } y \in B(y_0,r_0), \tag{49}$$

$$N(v,D,y) = N(v_n,D_n,y) = 1 \text{ a.e. } y \in B(y_0,r_0), \tag{50}$$

$$w \circ v(x) = x \text{ a.e. } x \in D,\ w_n \circ v_n(x) = x \text{ a.e. } x \in D_n. \tag{51}$$

First step. We prove that $u \circ w, u_n \circ w_n \in W^{1,r}(B(y_0,r_0))^N$.

In fact, by the change of variables formula (11), (48)–(51) we have

$$\begin{aligned}\int_{B(y_0,r_0)} |u \circ w(y)|^r dy &= \int_{v(D)} |u \circ w(y)|^r N(v,D,y) dy \\ &= \int_D |u(x)|^r dx < +\infty.\end{aligned}$$

Thus

$$u \circ w,\ u_n \circ w_n \in L^r(B(y_0,r_0))^N.$$

Let $\phi \in C_0^\infty(B(y_0,r_0))$. By (11), (48)–(51), and the fact that each vector row of $\operatorname{adj} \nabla v$ is divergence free, we have

$$\begin{aligned}\int_{B(y_0,r_0)} u_i \circ w(y) \frac{\partial \phi}{\partial y_j} dy &= \int_D u_i(x) \frac{\partial \phi}{\partial y_j} \circ v(x) dx \\ &= -\int_D \sum_{l=1}^N \frac{\partial u_i}{\partial x_l}(x)((\nabla v(x))^{-1})_j^l \phi \circ v(x) dx \\ &= -\int_{B(y_0,r_0)} \sum_{l=1}^N \frac{\partial u_i}{\partial x_l}(w(y))((\nabla v)^{-1} \circ w(y))_j^l \phi(y) dy.\end{aligned}$$

Thus

$$u \circ w \in W^{1,r}(B(y_0,r_0))^N$$

and

$$\nabla u \circ w(y) = \nabla u(w(y))(\nabla v(w(y)))^{-1} \text{ a.e. in } B(y_0,r_0).$$

We have a similar result for $u_n \circ w_n$.

Second step. We conclude that $\{u_n \circ w_n\}$ is bounded in $W^{1,r}(B(y_0,r_0))^N$. Indeed

$$\int_{B(y_0,r_0)} |u_n \circ w_n(y)|^r dy = \int_{D_n} |u_n(x)|^r dx \le \int_\Omega |u_n(x)|^r dx.$$

Since $r \le p$ and $\{u_n\}$ is bounded in $W^{1,p}(\Omega)^N$ we deduce that $\{u_n \circ w_n\}$ is bounded in $L^r(B(y_0,r_0))^N$.

Also

$$\int_{B(y_0,r_0)} |\nabla u_n \circ w_n(y)|^r dy = \int_D |\nabla u_n(x)(\nabla w_n(x))^{-1}|^r dx$$
$$\leq C'\Big[\int_\Omega |\nabla u_n(x)|^p dx\Big]^{\frac{r}{p}}\Big[\int_\Omega |\nabla v_n(x)|^{\frac{q}{N-1}} dx\Big]^{\frac{r(N-1)}{p}} \leq C$$

for some constant C which does not depend on y_0, r, and n. Thus $\{u_n \circ w_n\}$ is bounded in $W^{1,r}(B(y_0,r_0))^N$.

Third step. We prove that, up to a subsequence, $u_n \circ w_n$ converges strongly in $L^1(B(y_0,r_0))$ to $u \circ w$. Let $f \in C(\bar{B}(y_0,r_0))$. By Remark 4.4, $\lim_{n\to+\infty} |D\Delta D_n| = 0$ and so

$$\chi_{D_n}(x) \to \chi_D(x) \text{ a.e. } x \in \Omega.$$

By using the fact that $u_n \rightharpoonup u$ in $W^{1,p}(\Omega)^N$, $v_n \rightharpoonup v$ in $W^{1,q}(\Omega)^N$ and assuming, without loss of generality, that $u_n \to u$ a.e., $v_n \to v$ a.e., we obtain by (11) and the Lebesgue dominated convergence theorem that

$$\lim_{n\to+\infty} \int_{B(y_0,r_0)} u_n \circ w_n(y) f(y) dy = \lim_{n\to+\infty} \int_{D_n} u_n(x) f(v_n(x)) dx$$
$$= \int_D u(x) f(v(x)) dx$$
$$= \int_{B(y_0,r_0)} u \circ w(y) f(y) dy.$$

Therefore $u_n \circ w_n$ converges strongly to $u \circ w$ in measure and by applying the Sobolev imbedding theorem to the bounded sequence $\{u_n \circ w_n\}$ in $W^{1,r}(\Omega)$, we conclude that, up to a subsequence, $u_n \circ w_n$ converges strongly in $L^1(B(y_0,r_0))$ to $u \circ w$.

Fourth step. Using the second and the third step we conclude that $\{\nabla u_n \circ w_n\}$ is bounded in $W^{1,r}(\Omega)^N$,

$$u_n \circ w_n \rightharpoonup u \circ w \text{ in } W^{1,r}(\Omega)^N \text{ if } r > 1,$$

and

$$u_n \circ w_n \to u \circ w \text{ in } L^1(\Omega)^N \text{ if } r = 1. \qquad \square$$

We now give the proof of Theorem 4.1.

Proof of Theorem 4.1. Without loss of generality (and, if necessary, after extracting a subsequence of $\{(u_n, v_n)\}$), we assume that

$$\liminf_{n\to+\infty} \int_\Omega W(\nabla u_n(x)(\nabla v_n(x))^{-1}) dx = \lim_{n\to+\infty} \int_\Omega W(\nabla u_n(x)(\nabla v_n(x))^{-1}) dx < +\infty.$$

Fix $\epsilon > 0$ and let $\Omega_\epsilon \subset\subset \Omega$ be an open set such that $|\Omega \setminus \Omega_\epsilon| < \epsilon$. By Lemma 2.1 and the Ascoli–Arzela theorem, without loss of generality we assume that v_n converges to v uniformly in $\bar{\Omega}_\epsilon$. Set

$$C = \{x \in \Omega_\epsilon : v \text{ is differentiable and almost invertible at } x\},$$

$$A = \{D(x) : x \in C, D(x) \text{ is an open set of } \Omega_\epsilon,\ v(D(x)) \text{ is an open ball}\},$$

and

$$\Omega'_\epsilon = \cup_{D\in A} D.$$

As in the proof of Lemma 3.9, it is easy to see that

$$\inf\{\mathrm{diam} D(x) \ : \ D(x) \in A\} = 0$$

for every $x \in C$. By Lemma 4.3 and Vitali's covering theorem (see [Fe], Theorem 2.8.17, p. 151) there exists $\{x^j \ : \ j \in \mathbb{N}\} \subset \Omega_\epsilon$, $\{D^j \ : \ j \in \mathbb{N}\}$, a family of mutually disjoint, open neighborhoods of, respectively, x_j, and a set of measure zero N such that

$$\Omega_\epsilon = N \cup_{j\in\mathbb{N}} D^j,$$

and $v : D^j \to B(y^j, r^j)$ admits an inverse $w^j \in W^{1,q/(N-1)}(B(y^j, r^j), D^j)$, in the sense of Theorem 3.1, for some $r_j > 0$ and with $y^j = v(x^j)$. Recall that

$$\begin{aligned}
&\nabla(u \circ w^j)(y) = \nabla u(w^j(y))(\nabla v(w^j(y)))^{-1} \ \text{ a.e. } \ y \in B(y^j, r^j),\\
&w^j \circ v(x) = x \ \text{ a.e. } \ x \in D^j,\\
&v \circ w^j(y) = y \ \text{ a.e. } \ y \in B(y^j, r^j),
\end{aligned}$$

and $D^j = v^{-1}(B(y^j, r^j)) \cap B(x^j, R^j)$ for some $R^j > 0$. Fix $k \in \mathbb{N}$. By Lemma 4.5 we obtain, for each $j = 1, \dots, k$ and up to a subsequence, the existence of $w_n^j \in W^{1,q/(N-1)}(B(y^j, r^j))^N$, which is the inverse function of $v_n|_{D_n^j}$ where $D_n^j = v_n^{-1}(B(y^j, r^j)) \cap B(x^j, R^j)$. Recall that $\frac{1}{r} = \frac{1}{p} + \frac{N-1}{q}$ and also

$$\begin{aligned}
&w_n^j \circ v_n(x) = x \ \text{ a.e. } \ x \in D_n^j,\\
&u_n \circ w_n^j \in W^{1,r}(B(y^j, r^j))^N,\\
&\nabla(u_n \circ w_n^j)(y) = \nabla u_n(w_n^j(y))(\nabla v_n(w_n^j(y)))^{-1} \ \text{ a.e.},\\
&u_n \circ w_n^j \rightharpoonup u \circ w^j \ \text{ in } \ W^{1,r}(B(y^j, r^j))^N \ \text{ if } \ r > 1,\\
&u_n \circ w_n^j \to u \circ w^j \ \text{ in } \ L^1(B(y^j, r^j))^N,\\
&\{u_n \circ w_n^j\} \ \text{ is bounded in } \ W^{1,1}(B(y^j, r^j))^N \ \text{ if } \ r = 1,\\
&\lim_{n\to+\infty} |D_n^j \Delta D^j| = 0.
\end{aligned}$$

Fix

$$0 < \eta < \min\{r^j \ : \ j = 1, \dots, k\}.$$

There exists $n(\eta) \in \mathbb{N}$ such that for every $n \geq n(\eta)$ we obtain

$$\max\{|v_n(x) - v(x)| \ : \ x \in \Omega_\epsilon\} < \eta.$$

Since $D^j = v^{-1}(B(y^j, r^j)) \cap B(x^j, R^j)$, we deduce that for every $n \geq n(\eta)$

$$D_n^j(\eta) := D_n^j \cap v_n^{-1}(B(y^j, r^j - \eta)) \subset D^j,$$

and so $D_n^i \cap D_n^j = \emptyset$ if $i \neq j$. Set

$$D^j(\eta) := D^j \cap v^{-1}(B(y^j, r^j - \eta)).$$

We divide the rest of the proof of Theorem 4.1 into two cases.

First case. We assume that $1 = r = \frac{1}{p} + \frac{N-1}{q}$ and that there is a constant C such that $0 \leq W(F) \leq C(1 + |F|)$ for every $F \in M^{N\times N}$. Since $W \geq 0$ and $\{D^j(\eta)\}, \{D_n^j(\eta)\}$ are mutually disjoint for every $n \in \mathbb{N}$, we have by [FM]

$$\begin{aligned}
\int_{\cup_{j=1}^k D^j(\eta)} W(\nabla u(x)(\nabla v)^{-1}(x))dx &= \sum_{j=1}^k \int_{D^j(\eta)} W(\nabla u(x)(\nabla v)^{-1}(x))dx \\
&= \sum_{j=1}^k \int_{B(y^j,r^j-\eta)} W((\nabla u \circ w^j)(y))dy \\
&\leq \sum_{j=1}^k \liminf_{n\to+\infty} \int_{B(y^j,r^j-\eta)} W((\nabla u_n \circ w_n^j)(y))dy \qquad (52) \\
&= \sum_{j=1}^k \liminf_{n\to+\infty} \int_{D_n^j(\eta)} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&\leq \liminf_{n\to+\infty} \sum_{j=1}^k \int_{D^j} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&\leq \liminf_{n\to+\infty} \int_\Omega W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx.
\end{aligned}$$

By letting η go to zero, k go to infinity, and ϵ go to zero, we have

$$E(u,v) \leq \liminf_{n\to+\infty} E(u_n, v_n).$$

Second case. We assume that $1 < r = \frac{1}{p} + \frac{N-1}{q}$ and that there are some constants $C_1, C_2 > 0, 1 \leq s \leq r$ such that $-C_1(1 + |F|^s) \leq W(F) \leq C_2(1 + |F|^r)$ for every $F \in M^{N\times N}$. The proof follows as in the first case, where on step (52) we use the lower semicontinuity results of [Da] instead of [FM]. Since $\{\nabla u_n(x)(\nabla v_n)^{-1}(x)\}$ is weakly relatively compact in Ω, we have

$$\begin{aligned}
\int_{\cup_{j=1}^k D^j(\eta)} W(\nabla u(x)(\nabla v)^{-1}(x))dx &= \sum_{j=1}^k \int_{D^j(\eta)} W(\nabla u(x)(\nabla v)^{-1}(x))dx \\
&= \sum_{j=1}^k \int_{B(y^j,r^j-\eta)} W((\nabla u \circ w^j)(y))dy \\
&\leq \sum_{j=1}^k \liminf_{n\to+\infty} \int_{B(y^j,r^j-\eta)} W((\nabla u_n \circ w_n^j)(y))dy \\
&= \sum_{j=1}^k \liminf_{n\to+\infty} \int_{D_n^j(\eta)} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&= \sum_{j=1}^k \liminf_{n\to+\infty} [\int_{D^j} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&\quad + \int_{D_n^j(\eta)\setminus D^j} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx
\end{aligned}$$

$$
\begin{aligned}
&- \int_{D^j \setminus D_n^j(\eta)} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx] \\
&\leq \sum_{j=1}^{k} \liminf_{n\to+\infty} \int_{D^j} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&\quad + C_1 \int_{D^j \Delta D_n^j} (1 + |\nabla u_n(x)(\nabla v_n)^{-1}(x)|^s)dx \\
&\leq \liminf_{n\to+\infty} \sum_{j=1}^{k} \int_{D^j} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx \\
&\leq \liminf_{n\to+\infty} \int_{\Omega} W(\nabla u_n(x)(\nabla v_n)^{-1}(x))dx.
\end{aligned}
$$

By letting η go to zero, k go to infinity, and ϵ go to zero, we conclude that

$$E(u, v) \leq \liminf_{n\to+\infty} E(u_n, v_n). \qquad \square$$

MATHEMATICAL ASPECTS OF THE COMBUSTION OF A SOLID BY A DISTRIBUTED ISOTHERMAL GAS REACTION *

JESUS ILDEFONSO DIAZ† AND IVAR STAKGOLD‡

Abstract. When a diffusing gas reacts isothermally with an immobile solid phase, the resulting equations form a semilinear system consisting of a parabolic partial differential equation for the gas concentration coupled with an ordinary differential equation for the solid concentration. Existence and uniqueness proofs are given which include the important case of nonlipschitzian reaction rates such as those of fractional-power type. Various qualitative features of the solution are studied: approach to the steady state; monotonicity in time; and dependence on initial conditions, on the porosity, and on the geometry.

The relationship between the original problem and the pseudo-steady-state approximation of zero porosity is investigated. When the solid reaction rate is nonlipschitzian, there is a conversion front separating a fully converted region adjacent to the boundary and a partially converted interior core. Estimates are given for the time to full conversion. If the gas reaction rate is nonlipschitzian the gas may not at first fully penetrate the solid. Estimates are given for the time at which full penetration occurs.

Key words. gas-solid reactions, reaction-diffusion, combustion, pseudo-steady state

1. Introduction and preliminary results.

Many problems of current interest in chemical engineering and metallurgy involve the interactions of diffusing substances with immobile solid phases (see [1] and [16]).

Here we consider the combustion of a porous solid, known as the *pellet*, as it reacts with a gas diffusing through its pores. The reaction, involving only one species of gas and one of solid, is taken to be simple, irreversible, and isothermal. Structural changes during the reaction are neglected. The state variables are the nondimensional concentrations C of the gas and S of the solid. These concentrations are regarded as continuous functions of time t and of a macroscopic position vector x. Unlike the "shrinking core" model, the reaction is not confined to a thin surface, but is distributed throughout the solid at a rate proportional to the product of a function of C and of a function of S. We assume that the medium can be characterized by effective values of diffusivity and porosity that are independent of position, time, and concentrations. These assumptions can be reconciled with models, such as the Sohn–Szekely model (see [29]), based on a grainlike microstructure for the pellet, with the reaction confined to the surface of the grains.

Mass balances for the solid and gas yield the nondimensional equations

$$S_t = -f(S)g(C) \quad \text{in } (0,\infty)\times\Omega, \tag{1.1}$$

$$\varepsilon C_t - \Delta C = \lambda S_t = -\lambda f(S)g(C) \quad \text{in } (0,\infty)\times\Omega. \tag{1.2}$$

We are therefore dealing with a semilinear system consisting of a parabolic partial differential equation coupled with an ordinary differential equation. Since (1.2) was obtained by dividing the corresponding dimensional equation by the diffusivity, both ε and λ are inversely proportional to the diffusivity. In the problems of interest here, the porosity ε falls in the range (0.01, 0.1), and the Thiele modulus λ in the range (1, 100). The nondimensional reaction rate $f(S)g(C)$ is only defined for $S \geq 0$ and $C \geq 0$ and vanishes when either S or C vanishes. By nondimensionalization we have also made $f(1) = g(1) = 1$. In applications, it is important to consider cases where f and g are only Hölder continuous but not differentiable at $0+$. For instance, successive reactions in which the intermediate steps have special properties may yield an overall reaction rate which is a fractional power of the concentration of one or both of the reactants. Another example is the Sohn–Szekely grain model which, when translated to our variables, leads to $f(S) = S^{2/3}$ and $f(S) = S^{1/2}$ for three- and two-dimensional problems, respectively. With this in mind, we make the following assumptions on f and g:

$$\text{(1.3)} \qquad \begin{cases} f \text{ Hölder continuous on } [0,1], f(0) = 0, f(1) = 1; \\ f(S) \text{ positive, monotone increasing for } S > 0; \\ \text{Same conditions on } g \text{ with } C \text{ replacing } S. \end{cases}$$

The special cases $f(S) = S^m, g(C) = C^p$ play a particularly important role in applications. The nonlipschitz cases $m < 1$ and $p < 1$ yield interesting behavior, such as conversion in finite time, dead cores, and moving fronts [10], [13], [28]. The exponents m and p are known as the *orders* of the solid and gas reactions, respectively.

We take Ω to be a smooth, bounded domain in R^N. As initial and boundary conditions associated with (1.1) and (1.2) we choose

$$\text{(1.4)} \qquad \begin{aligned} &(a)\, S(0,x) = S_0(x), \quad (b)\, C(0,x) = C_0(x), \qquad x \in \Omega, \\ &(c)\, C + \alpha C_\nu = 1, \qquad x \in \partial\Omega, \quad t > 0. \end{aligned}$$

In the rest of the paper we shall assume, at least, that

$$(H_0) \qquad \begin{aligned} &S_0 \in L^\infty(\Omega), \quad C_0 \in H^2(\Omega) \cap L^\infty(\Omega) \quad \text{and} \quad 0 \leq S_0(x) \leq 1, \\ &0 \leq C_0(x) \leq 1 \quad \text{for a.e. } x \in \Omega. \end{aligned}$$

By nondimensionalization we can choose $\|S_0\| = 1, \|C_0\| \leq 1$, where $\| \ \|$ stands for the sup norm. In (1.4), ν is the outward normal derivative and $\alpha \geq 0$ is a constant measuring the boundary resistance to mass transfer from the ambient region where the gas concentration is maintained at a uniform value (which has been taken to be unity through nondimensionalization). The special case $\alpha = 0$ leads to a Dirichlet problem.

The problem (1.1)–(1.4) will be referred to as *problem* (P). We seek a solution $(S(t,x), C(t,x))$ with $S \geq 0$ and $C \geq 0$.

Since ε is small, the term εC_t in (1.2) is often neglected in the chemical engineering literature. This changes (1.2) to an elliptic equation for which no initial condition can be imposed. We are thus facing a singular perturbation whose effect cannot be judged a priori. The new problem is known as the *pseudo-steady-state* (p.s.s.) problem, which we denote by $(\hat{\mathrm{P}})$:

$$\hat{S}_t = -f(\hat{S})g(\hat{C}), \tag{1.5}$$

$$-\Delta\hat{C} = \lambda\hat{S}_t = -\lambda f(\hat{S})g(\hat{C}), \tag{1.6}$$

$$\hat{S}(0,x) = \hat{S}_0(x) \geq 0, \qquad \|\hat{S}_0\| = 1, \tag{1.7}$$

$$\hat{C} + \alpha\hat{C}_\nu = 1, \quad x \in \partial\Omega, \quad t > 0. \tag{1.8}$$

The same nondimensionalization used to obtain (P) gives ($\hat{\text{P}}$). No initial condition is imposed on $\hat{C}$ since $u(x) \doteq \hat{C}(x,0)$ is determined as the unique, necessarily nonnegative, solution of the elliptic problem

$$-\Delta u = -\lambda f(\hat{S}_0)g(u), \quad x \in \Omega; \quad u + \alpha u_\nu = 1, \quad x \in \partial\Omega. \tag{1.9}$$

In previous papers [25], [27], it has been shown that the solution of ($\hat{\text{P}}$) provides a reasonable approximation to the solution of (P) when ε is small. Specifically, the following result was obtained for the case $f(S) = S^m$ and $g(C) = C^p$:

$$\int_0^t (\hat{C} - C)\, d\tau \leq \varepsilon\|w\|, \tag{1.10}$$

where $w(x)$ is the solution of the simple Poisson problem

$$-\Delta w = 1, \quad x \in \Omega; \quad w + \alpha w_\nu = 0, \quad x \in \partial\Omega. \tag{1.11}$$

For $\alpha = 0$, this is the so-called *torsion* problem about which a great deal of information is available (see, for instance, Bandle [2] and McNabb and Keady [20]). The uniformity of (1.10) in time is perhaps unexpected because $C(0,x)$ and $\hat{C}(0,x)$ are not within $0(\varepsilon)$ of each other. In §3 of the present paper we shall extend (1.10) to general f and g obeying (1.3).

It is of particular interest to know if the solid is fully converted in finite time. We observe from (1.1) that $S(t,.)$ is monotonically decreasing; if for some point $x = \xi$, we have $S(T,\xi) = 0$, then $S(t,\xi) = 0$ for $t \geq T$. This property does not hold for C since diffusion from neighboring points may raise the gas concentration. If $\alpha = 1, S$ on the boundary obeys the ordinary differential equation $S_t = -f(S)$, which can be explicitly integrated. If the integral

$$\int_0^1 \frac{ds}{f(s)} \doteq I \tag{1.12}$$

is finite (as is the case when $f(S) = S^m$ with $m < 1$) we find that S vanishes on the boundary for $t \geq I$. It then turns out that $S(t,x)$ is identically zero in Ω for all t sufficiently large. The infimum of such times is the time t_1 to full conversion. We shall estimate that time in terms of the corresponding quantity $\hat{t}_1$ for the pseudo-steady-state problem. Section 4 is devoted to this and related questions.

To prove existence of a solution to (P) and ($\hat{\text{P}}$) we first reformulate the problem in §2 by introducing the new variable $X = 1 - S$, which now places the problem in a quasi-monotone framework. A number of authors have used quasi-monotone methods for reaction-diffusion systems (see, for instance, [18] and [22]). Because of the nonlipschitzian character of our nonlinearity and the absence of diffusion in one of the equations, the existence proofs in the literature are not directly applicable to

our problem. Our proof is based on a constructive *nonlinear* iteration scheme which preserves qualitative properties at each step.

We first prove existence by the method just described. Continuous dependence and uniqueness are then proved by an L^1 technique typical of degenerate quasilinear parabolic problems. Some remarks are made about weakening the regularity assumptions through more abstract approaches. The results in this section were already sketched out in our paper [10].

In §3, we consider the asymptotic behavior of the solution as $t \to \infty$ and the relation between (P) and ($\hat{\text{P}}$) when ε is small. We show that $S, \hat{S}$ tend monotonically to zero as $t \to \infty$ and that $C, \hat{C}$ tend to 1. The approach to 1 is monotonic for $\hat{C}$ and will be monotonic for C if C_0 obeys a certain natural condition. The dependence on ε is discussed in a number of theorems. If $(S_\varepsilon, C_\varepsilon)$ is the solution of (P) for $\varepsilon > 0$ and $(\hat{S}, \hat{C})$ the solution of ($\hat{\text{P}}$), we show that, under expected conditions on C_0 and S_0, we have monotonic convergence of S_ε to $\hat{S}$ and of C_ε to $\hat{C}$ as $\varepsilon \to 0$. Other theorems in this section deal with the behavior as $\varepsilon \to 0$ of $\int_\Omega |S - S_\varepsilon|\, dx$ and $\int_0^t (\hat{C} - C_\varepsilon)\, d\tau$. These theorems provide a strong generalization of (1.10).

In §4, we discuss the conversion of the solid and, to a lesser extent, the penetration of the gas. For many practical purposes the quantity of interest is the fraction of solid converted up to time t,

$$\gamma(t) = 1 - \frac{\int_\Omega S(t,x)\, dx}{\int_\Omega S_0(x)\, dx},$$

with a similar definition for $\hat{\gamma}(t)$. Both of these increase monotonically to 1 as $t \to \infty$. Estimates are given for $\gamma(t)$, particularly in the case of full conversion in finite time (I finite in (1.12)) when the quantities of principal interest are the times t_1 and $\hat{t}_1$ to full conversion. Comparison between different types of reaction is also considered.

For certain $g(C)$, for instance if $g(C) = C^p$ with $p < 1$, the gas may not fully penetrate the solid for small t. It is easy to see that this "dead core" must disappear in finite time so that $C, \hat{C}$ are strictly positive for $t \geq T$. We obtain estimates for this dead core as well as for T.

2. Existence, uniqueness, and continuous dependence. In order to use quasi-monotone methods in their simplest form, we begin by replacing $S(t,x)$ by

$$X(t,x) = 1 - S(t,x). \tag{2.1}$$

Since $S(t,\cdot)$ is monotonically decreasing, $X(t,\cdot)$ is monotonically increasing. Note that if $S_0(x) \equiv 1$, as is often the case in applications, then X is the local *fraction of solid* converted by time t.

Problem (P), considered on a finite interval $(0,T)$ then becomes the problem (P′):

$$X_t = F(X)g(C) \quad \text{in } Q_T, \tag{2.2}$$

$$\varepsilon C_t - \Delta C = -\lambda F(X)g(C) = -\lambda X_t \quad \text{in } Q_T, \tag{2.3}$$

$$X(0,x) = 1 - S_0(x), \quad C(0,x) = C_0(x) \quad \text{on } \Omega, \tag{2.4}$$

$$C + \alpha C_\nu = 1 \quad \text{on } \Sigma_T, \tag{2.5}$$

where $Q_T = (0,T)\times\Omega$, $\Sigma_T = (0,T)\times\partial\Omega$, and $F(X) \equiv f(1-X)$ is monotone decreasing in X with $F(0) = 1, F(1) = 0$.

Similar considerations apply to the p.s.s. problem ($\hat{\text{P}}$); see (1.5)–(1.8). Setting $\hat{X} = 1 - \hat{S}$, we obtain problem ($\hat{\text{P}}'$):

$$\hat{X}_t = F(\hat{X})g(\hat{C}) \quad \text{in } Q_T, \tag{2.2a}$$

$$-\Delta \hat{C} = -\lambda F(\hat{X}) g(\hat{C}) = -\lambda \hat{X}_t \quad \text{in } Q_T, \tag{2.3a}$$

$$\hat{X}(0,x) = 1 - \hat{S}_0(x) \quad \text{on } \Omega, \tag{2.4a}$$

$$\hat{C} + \alpha \hat{C}_\nu = 1 \quad \text{on } \Sigma_T. \tag{2.4b}$$

If (2.2), (2.3) is regarded as a system for the vector (X, C), the forcing term $(F(X)g(C), -\lambda F(X)g(C))$ is nondecreasing in the off-diagonal variables, i.e., *quasi-monotone.* The system is then in a form which makes it relatively simple to use the notions of sub- and supersolutions.

DEFINITION 2.1. *Let*

$$\overline{X} \in W^{1,\infty}(0,T : L^\infty(\Omega)) \quad \textit{and} \quad \bar{C} \in H^1(0,T : L^2(\Omega)) \cap L^2(0,T : H^2(\Omega)) \cap L^\infty((0,T) \times \Omega).$$

The pair $(\bar{X}, \bar{C})$ *is said to be a* supersolution *to* (P′) *if*

$$\begin{aligned}
&\bar{X}_t \geq F(\bar{X}) g(\bar{C}) \quad \textit{in } Q_T,\\
&\varepsilon \bar{C}_t - \Delta \bar{C} \geq -\lambda F(\bar{X}) g(\bar{C}) \quad \textit{in } Q_T,\\
&\bar{C} + \alpha \bar{C}_\nu \geq 1 \quad \textit{on } \Sigma_T,\\
&\bar{X}(0,x) \geq X_0(x) \doteq 1 - S_0(x) \quad \textit{in } \Omega,\\
&\bar{C}(0,x) \geq C_0(x) \quad \textit{in } \Omega,
\end{aligned}$$

at almost every point of the corresponding domain. A subsolution $(\underline{X}, \underline{C})$ *satisfies the same conditions with all five inequalities reversed. If* (X, C) *is both a* supersolution *and a subsolution we say that* (X, C) *is a* solution.

We observe that $(0,0)$ is a subsolution and $(1,1)$ is a supersolution.

Next, we introduce the following iteration scheme: given a pair of smooth functions (X^{k-1}, C^{k-1}), $k \geq 2$, we define the pair (X^k, C^k) as the solution of the *uncoupled nonlinear equations*

$$\begin{aligned}
&X^k_t = F(X^k) g(C^{k-1}) \quad \text{in } Q_T,\\
&X^k(0,x) = X_0(x) \quad \text{in } \Omega,\\
&\varepsilon C^k_t - \Delta C^k = -\lambda F(X^{k-1}) g(C^k) \quad \text{in } Q_T,\\
&C^k + \alpha C^k_\nu = 1 \text{ on } \Sigma_T, \quad C^k(0,x) = C_0(x) \quad \text{in } \Omega.
\end{aligned}$$

The existence and uniqueness of the solutions X^k, C^k of these uncoupled problems satisfying

$$X^k \in W^{1,\infty}(0,T : L^\infty(\Omega)) \quad \text{and} \quad C^k \in H^1(0,T : L^2(\Omega)) \cap L^2(0,T : H^2(\Omega)) \cap L^\infty((0,T) \times \Omega)$$

can be found (for instance) in Vrabie [31] (see Theorem 3.10.1).

We are now in a position to prove existence for the equivalent problems (P′) and (P).

THEOREM 2.1. *Assume* (1.3) *and* (H_0). *Let* $X_0 = 1 - S_0$. *Let* $(\underline{X}, \underline{C})$ *be a subsolution and* $(\bar{X}, \bar{C})$ *a supersolution with* $(\underline{X}, \underline{C}) \leq (\bar{X}, \bar{C})$. *Then there exists a solution* (X, C) *of* (P′) *satisfying* $(\underline{X}, \underline{C}) \leq (X, C) \leq (\bar{X}, \bar{C})$.

Proof. Consider the sequences $(\underline{X}^k, \underline{C}^k)$ and $(\bar{X}^k, \bar{C}^k)$ obtained by applying our iteration scheme to $(\underline{X}^1, \underline{C}^1) = (\underline{X}, \underline{C})$ and $(\bar{X}^1, \bar{C}^1) = (\bar{X}, \bar{C})$, respectively. By

repeated application of the comparison principle for the uncoupled equations, we see that the sequence $(\underline{X}^k, \underline{C}^k)$ is monotonically increasing while $(\bar{X}^k, \bar{C}^k)$ is monotonically decreasing. From the hypothesis $(\underline{X}, \underline{C}) \leq (\bar{X}, \bar{C})$ we can also show that $(\underline{X}^k, \underline{C}^k) \leq (\bar{X}^k, \bar{C}^k)$. The monotonically increasing sequence $(\underline{X}^k, \underline{C}^k)$ is bounded above and must therefore converge as stated to $(\underset{\sim}{X}, \underset{\sim}{C})$. To show that $(\underset{\sim}{X}, \underset{\sim}{C})$ is a solution it is enough to use the following a priori estimates:

$$\|\underline{X}_t^k\|_{L^\infty((0,T)\times\Omega)} \leq 1,$$
$$\|\varepsilon \underline{C}_T^k\|_{L^2(0,T:L^2(\Omega))} \leq \|\lambda F(\underline{X}^{k-1}) g(\underline{C}^k)\|_{L^2(0,T:L^2(\Omega))} + \|C_0\|_{H^1(\Omega)}^{1/2} \leq M(T,\Omega)$$

for some constant $M(T,\Omega) > 0$ independent of k (this follows from a well-known result due to Brezis; see Theorem 1.9.3 in Vrabie [31]); and

$$\|\Delta \underline{C}^k\|_{L^2(0,T:L^2(\Omega))} \leq M(T,\Omega) + |\Omega|^{1/2}.$$

Standard arguments show that $(\underset{\sim}{X}, \underset{\sim}{C})$ is a solution with the regularity mentioned in Definition 2.1. Similarly $(\bar{X}^k, \bar{C}^k)$ converges downwards to a solution $(\tilde{X}, \tilde{C})$; clearly $(\tilde{X}, \tilde{C}) \geq (\underset{\sim}{X}, \underset{\sim}{C})$. □

Remark 2.1. Under the additional assumptions

$$C_0 \in C^{2+\delta}(\Omega) \quad \text{and} \quad S_0 \in C^{\delta}(\Omega),$$

it is possible to show that the functions $(\underline{X}, \underline{C}), (\bar{X}, \bar{C})$ obtained in Theorem 2.1 are, in fact, classical solutions. Indeed, we point out first that the (unique) solutions (X^k, C^k) of the uncoupled problems are classical solutions as follows from an existence result due to Pao [21]. In order to show that the limit $(\underset{\sim}{X}, \underset{\sim}{C})$ is a classical solution we can proceed as follows: since $\varepsilon(\underset{\sim}{C}_t - \Delta \underset{\sim}{C}) \in L^\infty((0,T)\times\Omega)$ we deduce by well-known regularity results (see, e.g., references in [15]) that $\underset{\sim}{C} \in C^\mu([0,T]\times\bar{\Omega})$. Thus $g(\underset{\sim}{C})$ is a Hölder continuous function. Using the explicit formula (4.4) for $\underset{\sim}{X}$ we conclude that $\underset{\sim}{X}$, and hence $F(\underset{\sim}{X})$, is a Hölder continuous function. Finally, from the equation, $\varepsilon(\underset{\sim}{C}_t - \Delta \underset{\sim}{C})$ is a Hölder continuous function, which implies that $\underset{\sim}{C} \in C^{1,2}_{t,x}((0,T)\times\bar{\Omega}) \cap C^0([0,T]\times\bar{\Omega})$ and satisfies the equation in the classical sense.

Remark 2.2. The existence of solutions for the coupled system can also be obtained by means of fixed point arguments using the compactness of some suitable "Green operator." This approach is developed in the article by Diaz and Vrabie [11], where the case of f and g discontinuous at the origin is also considered.

The existence proof of Theorem 2.1 constructs two solutions $(\underset{\sim}{X}, \underset{\sim}{C})$ and $(\tilde{X}, \tilde{C})$. The following theorem, using an L^1 technique typical of some degenerate quasilinear parabolic equations, proves continuous dependence and uniqueness for a general class of solutions (including the ones obtained in Theorem 2.1).

THEOREM 2.2. *Let f and g be continuous nondecreasing functions with $f(0) = g(0) = 0$. Let $(S,C), (S^*,C^*)$ be solutions of* (P) *(in the sense of Definition* 2.1*) corresponding to the initial data $(S_0,C_0), (S_0^*,C_0^*)$. Then for any $t \geq 0$ we have that*

$$\begin{aligned}(2.6)\qquad &\varepsilon \int_\Omega |C(t,x) - C^*(t,x)|\,dx + \lambda \int_\Omega |S(t,x) - S^*(t,x)|\,dx \\ &\quad + \frac{1}{\alpha}\int_0^t \int_{\partial\Omega} |C(\tau,\sigma) - C^*(\tau,\sigma)|\,d\tau\,d\sigma \\ &\leq \varepsilon \int_\Omega |C_0(x) - C_0^*(x)|\,dx + \lambda \int_\Omega |S_0(x) - S_0^*(x)|\,dx.\end{aligned}$$

In particular, a solution (S, C) *(in the sense of Definition* 2.1*) is unique.*

Proof. We start by assuming f and g strictly increasing. We have that

$$(S - S^*)_t + (f(S) - f(S^*))g(C^*) = -f(S)(g(C) - g(C^*)), \tag{2.7}$$

$$\varepsilon(C - C^*)_t - \Delta(C - C^*) + \lambda f(S)(g(C) - g(C^*)) = -\lambda(f(S) - f(S^*))g(C^*). \tag{2.8}$$

Now, multiplying (2.7) by sign $(S - S^*)$ and using

$$\int_0^t \int_\Omega h_t(\tau, x)\text{sign}\,(h(\tau, x))\,dx\,d\tau = \int_\Omega |h(t, x)|\,dx - \int_\Omega |h(0, x)|\,dx \tag{2.9}$$

for any $h \in W^{1,1}(0, T : L^1(\Omega))$, we have that

$$\begin{aligned} &\int_\Omega |S(t, x) - S^*(t, x)|\,dx + \int_0^t \int_\Omega g(C^*)|f(S) - f(S^*)|\,dx\,d\tau \\ &\quad \le \int_\Omega |S_0(x) - S_0^*(x)|\,dx + \int_0^t \int_\Omega f(S)|g(C) - g(C^*)|\,dx\,d\tau, \end{aligned} \tag{2.10}$$

where we have used the fact that $f(S) \ge 0$ if $S \ge 0, g(C) \ge 0$ if $C \ge 0, \text{sign}(S - S^*) = \text{sign}(f(S) - f(S^*))$, and $(f(S) - f(S^*))\text{sign}(f(S) - f(S^*)) = |f(S) - f(S^*)|$. Analogously multiplying (2.8) by $\text{sign}(C - C^*)$ and using the fact that

$$-\int_\Omega \Delta(C - C^*)\text{sign}(C - C^*)\,dx \ge \frac{1}{\alpha}\int_{\partial\Omega} |C - C^*|\,d\sigma, \tag{2.11}$$

we conclude (as before) that

$$\begin{aligned} &\varepsilon \int_\Omega |C(t, x) - C^*(t, x)|\,dx + \frac{1}{\alpha}\int_0^t \int_{\partial\Omega} |C - C^*|\,d\sigma \\ &\qquad + \lambda \int_0^t \int_\Omega f(S)|g(C) - g(C^*)|\,dx\,d\tau \\ &\quad \le \varepsilon \int_\Omega |C_0(x) - C_0^*(x)|\,dx + \lambda \int_0^t \int_\Omega |f(S) - f(S^*)|g(C^*)\,dx\,d\tau. \end{aligned} \tag{2.12}$$

Multiplying (2.10) by λ and adding the result to (2.12) we obtain the conclusion (2.6). Inequalities (2.9) and (2.11) are justified as usual in the L^1 theory of evolution equations by regularizing the sign function. Finally, if f and g are not strictly increasing functions we approximate them by strictly increasing functions and pass to the limit. □

Note that in the case of $\alpha = 0$, the boundary term is absent in (2.6).

For the case of the pseudo-steady-state problem we have the following theorem.

THEOREM 2.3. *Let* f *and* g *be continuous nondecreasing functions with* $f(0) = g(0) = 0$. *Then the problem* $(\hat{\text{P}})$ *has a unique solution* $(\hat{S}, \hat{C})$.

Proof. By the same arguments as in Theorem 2.2 we deduce that if $(\hat{S}, \hat{C})$ and $(\hat{S}^*, \hat{C}^*)$ are two solutions then

$$\begin{aligned} &\lambda \int_\Omega |\hat{S}(t, x) - \hat{S}^*(t, x)|\,dx + \frac{1}{\alpha}\int_0^t \int_{\partial\Omega} |\hat{C}(\tau, \sigma) - \hat{C}^*(\tau, \sigma)|\,d\sigma d\tau \\ &\quad \le \lambda \int_\Omega |\hat{S}(0, x) - \hat{S}^*(0, x)|\,dx. \end{aligned}$$

In particular, as $\hat{S}(0,x) = \hat{S}^*(0,x)$ we conclude that $\hat{S} \equiv \hat{S}^*$ and that $\hat{C}$ and $\hat{C}^*$ are solutions of the elliptic problem

$$-\Delta u + B_t(x,u) = 0 \quad \text{in } \Omega,$$
$$\alpha \frac{\partial u}{\partial \nu} + u = 1 \quad \text{on } \partial\Omega,$$

where $B_t(x,r) = f(\hat{S}(t,x))g(r)$ for any $r \in \mathbb{R}, x \in \Omega$, and $t \in (0,T)$ (here t is a parameter). The uniqueness of $u = \hat{S} = \hat{S}^*$ is now a well-known result since B is monotone nondecreasing in r. □

Remark 2.3. Theorem 2.2 improves a previous result due to Pao [22] where the nonlinearities are assumed to be Lipschitz continuous. Some papers where an L^1 technique is used for parabolic systems are [6], [15], and [33].

Remark 2.4. Basing themselves on our earlier paper [10], DiLiddo and Maddalena were able to prove existence for a different type of problem arising in chemical engineering [12].

3. Asymptotic behavior and monotonicity.

3.1. Monotonicity in λ and initial data. Monotone behavior of the solution of (P′) with respect to initial data and with respect to λ are easy to prove. Monotonicity in time and with respect to ε will require a condition on $C_0(x)$.

PROPERTY I. *For fixed λ and ε, the solutions of* (P′) *are ordered according to their initial values: if $(X_0^{(1)}, C_0^{(1)}) \le (X_0^{(2)}, C_0^{(2)})$ then the respective solutions of* (P′) *satisfy*

$$(X^{(1)}(t,x), C^{(1)}(t,x)) \le (X^{(2)}(t,x), C^{(2)}(t,x)) \quad \textit{for all } x,t.$$

The result follows from the observation that $(X^{(2)}(t,x), C^{(2)}(t,x))$ is a supersolution of problem (P′) with initial data $(X_0^{(1)}, C_0^{(1)})$.

PROPERTY II. *For fixed ε and initial data, the solutions of* (P′) *are ordered inversely with λ:*

$$\lambda_1 \ge \lambda_2 \Rightarrow (X^{(1)}(t,x), C^{(1)}(t,x)) \le (X^{(2)}(t,x), C^{(2)}(t,x)).$$

Again, the proof consists of noting that $(X^{(2)}, C^{(2)})$ is a supersolution of (P′) with $\lambda = \lambda_1$.

Monotonicity with respect to t is a bit more subtle. It is obvious from (2.2) that $X(t,\cdot)$ is monotonically increasing. Since $C_0(x) \le 1$ and the steady state is $C_\infty(x) = 1$, we can only hope to show that $C(t,\cdot)$ is monotonically increasing, but, unfortunately, this cannot be true for all $C_0(x)$. Indeed at $t = 0, C_t \ge 0$ only if

$$-\Delta C_0 + \lambda f(S_0(x)) C_0(x) \le 0. \tag{3.1}$$

Rather than (3.1) we prefer to use the condition

$$-\Delta C_0 + \lambda C_0(x) \le 0, \qquad x \in \Omega, \tag{3.2}$$

which clearly implies (3.1). We also need a condition on the boundary values of $C_0(x)$:

$$C_0 + C_{0,\nu} - 1 \le 0, \qquad x \in \partial\Omega. \tag{3.3}$$

We can then conclude with the following property (see Theorem 3.1).

PROPERTY III. *If $C_0(x)$ satisfies* (3.2) *and* (3.3), *then $t \to (X(t,x), C(t,x))$ is monotone increasing for each x.*

We shall also show (see Lemma 3.1) that under the same conditions on $C_0(x)$ we have monotone behavior with respect to ε. As expected on physical grounds, (X, C) increases as ε decreases.

PROPERTY IV. *For fixed λ and initial data, suppose that $\varepsilon_1 > \varepsilon_2 > 0$ and $C_0(x)$ satisfies* (3.2) *and* (3.3); *then the respective solutions of* (P′) *are ordered so that*

$$(X^1(t,x), C^1(t,x)) \le (X^2(t,x), C^2(t,x)) \quad \textit{for all } (t,x).$$

For the pseudo-steady-state problem only the initial value $\hat{X}_0$ is at our disposal since the initial value $\hat{C}_0$ of the gas concentration is determined from $\hat{X}_0(x)$ as the solution of the elliptic problem

$$\begin{aligned} &-\Delta \hat{C}_0(x) + \lambda F(\hat{X}_0) g(\hat{C}_0) = 0, \qquad x \in \Omega, \\ &\hat{C}_0 + \hat{C}_{0,\nu} = 1, \qquad x \in \partial\Omega. \end{aligned} \tag{3.4}$$

The following results are then easily obtained.

PROPERTY I*. *For fixed λ, the solutions of* ($\hat{\text{P}}'$) *are ordered according to the initial values of $\hat{X}$: if $\hat{X}_0^{(1)} \le \hat{X}_0^{(2)}$, then*

$$\hat{C}_0^{(1)} \le \hat{C}_0^{(2)} \quad \textit{and} \quad (\hat{X}^{(1)}(t,x), \hat{C}^{(1)}(t,x)) \le (\hat{X}^{(2)}(t,x), \hat{C}^{(2)}(t,x)) \quad \textit{for all } (t,x).$$

This follows from the maximum principle or by observing that $\hat{C}_0^{(1)}$ is a subsolution to the scalar elliptic problem for $\hat{C}_0^{(2)}$.

PROPERTY II*. *For fixed initial $\hat{X}_0$, the solutions of* ($\hat{\text{P}}'$) *are ordered inversely with λ:*

$$\lambda_1 \ge \lambda_2 \Rightarrow (\hat{X}^{(1)}, \hat{C}^{(1)}) \le (\hat{X}^{(2)}, \hat{C}^{(2)}) \quad \textit{for all } (t,x).$$

Monotonicity with time is now automatic (see Theorem 3.2).

PROPERTY III*. *$t \to (\hat{X}(t,x), \hat{C}(t,x))$ is monotone increasing for all x.*

In this section we also discuss the behavior as $t \to \infty$. At the simplest level we show that $(X, C) \to (1,1)$ and $(\hat{X}, \hat{C}) \to (1,1)$ as expected. We also discuss the asymptotic limit of (P′) as $\varepsilon \to 0$ and show the various ways in which the solution of (P′) tends to the solution of the pseudo-steady-state problem ($\hat{\text{P}}'$). This relationship requires us to take into account the fact that since $C_0(x) \ne \hat{C}_0(x)$, the limit cannot hold for $t = 0$.

THEOREM 3.1. *Let $0 \le X_0(x) \le 1$, and let $0 \le C_0(x) \le 1$, with $C_0(x)$ satisfying* (3.2) *and* (3.3). *Then the solution (X, C) of* (P′) *has the properties*

$$t \to (X(t,x), C(t,x)) \textit{is monotonically increasing for any } x \in \Omega$$

and

$$\lim_{t\to\infty} (X, C) = (1,1) \quad \textit{in } C([0,\infty) \times \bar{\Omega}).$$

Proof. It is easy to see that $(X_0(x), C_0(x))$ is a subsolution of (P′). We conclude from Theorems 2.1 and 2.2 that

$$X_0(x) \le X(t,x) \le 1, \qquad C_0(x) \le C(t,x) \le 1.$$

From these inequalities, we see at once that, for any $h > 0$, $(X(t+h,x), C(t+h,x))$ is a supersolution of (P′) so that $X(t+h,x) \geq X(t,x)$ and $C(t+h,x) \geq C(t,x)$. Hence (X,C) increases monotonically in time. By the monotone convergence theorem there exists $(X_\infty(x), C_\infty(x))$ with $0 \leq X_\infty \leq 1, 0 \leq C_\infty \leq 1$ such that $\lim_{t\to\infty}(X,C) = (X_\infty, C_\infty)$ in $L^p(\Omega)$ for any p with $1 \leq p \leq \infty$. On the other hand, using the definition of weak solutions and the monotonicity of F and g, it is not difficult to show (see the argument in Sattinger [23]) that (X_∞, C_∞) must be the solution of the stationary problem. □

COROLLARY 3.1. *If* $0 \leq X_0(x) \leq 1$ *and* $0 \leq C_0(x) \leq 1$, *then the solution of* (P′) *satisfies* $\lim_{t\to\infty}(X,C) = (1,1)$.

Proof. Since C_0 does not necessarily satisfy (3.2) and (3.3), $C(t,\cdot)$ may not be monotone. Consider, however, the solution $(X\#, C\#)$ of (P′) with initial data $(X_0, 0)$. Then $(X\#, C\#)$ is easily seen to be a subsolution of (P′) with initial data (X_0, C_0) so that

$$0 \leq X\# \leq X \leq 1, \qquad 0 \leq C\# \leq C \leq 1.$$

By Theorem 3.1, $(X\#, C\#)$ tends monotonically to $(1,1)$ as $t \to \infty$, so that (X,C) also tends to $(1,1)$ as $t \to \infty$ (but perhaps not monotonically). □

For the pseudo-steady-state problem $(\hat{\text{P}})$, the monotonicity in time of $\hat{X}$ and $\hat{C}$ is always guaranteed. The straightforward proof is omitted.

THEOREM 3.2. *If* $(\hat{X}, \hat{C})$ *is the solution of* $(\hat{\text{P}}')$, *then*

$$t \to (\hat{X}(t,x), \hat{C}(t,x)) \text{ is monotonically increasing}$$

for any $x \in \Omega$ *and* $\lim_{t\to\infty}(\hat{X}, \hat{C}) = (1,1)$.

3.2. Monotonicity in ε and the relationship between (P) and $(\hat{\text{P}})$. Consider problem (P′) for fixed λ and fixed initial data (X_0, C_0), but with different values of ε. To emphasize the dependence on ε we relabel the problem (P′) as (P'_ε) and its solution as $(X^\varepsilon, C^\varepsilon)$. When is there monotonicity of (P'_ε) with respect to ε? In practice, ε is often small and problem $(\hat{\text{P}}')$ with initial value $\hat{X}_0 = X_0$ (and $\hat{C}_0$ determined from (3.4)) is used to approximate (P'_ε). In what sense, if any, is this a good approximation?

We begin with two simple lemmas.

LEMMA 3.1. *Let* $\varepsilon_1 \geq \varepsilon_2 \geq 0$; *let* $C_0(x)$ *satisfy* (3.2) *and* (3.3); *and let* (X^i, C^i), $i = 1,2$ *be the solutions of* (P'_ε) *corresponding to* $\varepsilon = \varepsilon_i$ *and initial data independent of* i. *Then*

$$(X^1, C^1) \leq (X^2, C^2) \quad \text{for any } (t,x).$$

Proof. Since $X^1_t \geq 0$ and, by Theorem 3.1, $C^1_t \geq 0$, we have $\varepsilon_2 C^1_t - \Delta C^1 + \lambda F(X^1) g(C^1) = (\varepsilon_2 - \varepsilon_1) C^1_t \leq 0$, so that (X^1, C^1) is a lower solution to (P'_ε) with $\varepsilon = \varepsilon_2$. Hence, for all (t,x), we have

$$(X^1(t,x), C^1(t,x)) \leq (X^2(t,x), C^2(t,x)) \leq (1,1). \qquad \square$$

Remark 3.1. If, for instance, (3.2) does not hold at some point x, then we can have $C^1(t,x) > C^2(t,x)$ for small t.

LEMMA 3.2. *If* $(X_0, C_0) \leq (\hat{X}_0, \hat{C}_0)$ *then* $(X(t,x), C(t,x)) \leq (\hat{X}(t,x)\hat{C}(t,x))$.

Proof. We have

$$\varepsilon \hat{C}_t - \Delta \hat{C} + \lambda F(\hat{X}) g(\hat{C}) = \varepsilon \hat{C}_t \geq 0,$$

where the last inequality follows from Theorem 3.2. In view of the assumption on the initial values, $(\hat{X}, \hat{C})$ is a supersolution of (P′) and the result follows. □

Remark 3.2. If $X_0 = \hat{X}_0$ and $C_0 = \hat{C}_0$, we conclude that problem $(\hat{\mathrm{P}}')$ converts solid more quickly than (P'), as expected.

These two lemmas lead to the following theorem, which deals with the limit as $\varepsilon \to 0$ of (P'_ε).

THEOREM 3.3. *If* $(X_0, C_0) \leq (\hat{X}_0, \hat{C}_0)$, *then* $(X^\varepsilon, C^\varepsilon) \leq (\hat{X}, \hat{C})$ *and* $\lim_{\varepsilon \to 0}(X^\varepsilon, C^\varepsilon) = (\hat{X}, \hat{C})$ *in* $C((0,\infty) \times \Omega)$. *Moreover* $\varepsilon \to X^\varepsilon(t,x)$ *is monotone increasing for any* t, x, *and if* $C_0(x)$ *also satisfies* (3.2) *and* (3.3), $\varepsilon \to C^\varepsilon(t,x)$ *is monotone increasing as well.*

Proof. Suppose C_0 satisfies (3.2), (3.3); then, by Lemma 3.1, $(X^\varepsilon, C^\varepsilon)$ is monotone in ε and so converges to $(\tilde{X}, \tilde{C})$ as $\varepsilon \to 0+$, uniformly on $\bar{\Omega}_T$; moreover, $(\tilde{X}, \tilde{C})$ clearly satisfies the pseudo-steady-state problem $(\hat{\mathrm{P}}')$ and therefore $\tilde{X} = \hat{X}, \tilde{C} = \hat{C}$. Now let $(X^\varepsilon_\#, C^\varepsilon_\#)$ be the unique solution of $(\mathrm{P}'_\varepsilon)$ with initial data $(X_0, 0)$; then $(X^\varepsilon_\#, C^\varepsilon_\#)$ is seen to be a subsolution to $(\mathrm{P}'_\varepsilon)$ for the same ε and initial data (X_0, C_0). It then follows from Lemma 3.2 that

$$(X^\varepsilon_\#, C^\varepsilon_\#) \leq (X^\varepsilon, C^\varepsilon) \leq (\hat{X}, \hat{C}).$$

But $(X^\varepsilon_\#, C^\varepsilon_\#)$ satisfies the conditions of Lemma 3.1, so it is monotone increasing in ε and therefore tends to $(\hat{X}, \hat{C})$ as $\varepsilon \to 0+$. Hence, so does $(X^\varepsilon, C^\varepsilon)$. □

In the following theorem we provide other measures of how well $(\hat{\mathrm{P}}')$ approximates $(\mathrm{P}'_\varepsilon)$ for ε small. The initial data for $(\mathrm{P}'_\varepsilon)$ is (X_0, C_0), and for $(\hat{\mathrm{P}}')$ is $(\hat{X}_0 = X_0, \hat{C}_0)$, where $\hat{C}_0$ is determined from (3.4).

THEOREM 3.4. *Let* $X_0 \in C^\delta(\Omega)$ *for some* $\delta \in (0,1)$ *and let* $C_0 \in C^{2+\delta}(\Omega)$ *with* $(0,0) \leq (X_0, C_0) \leq (1,1)$. *Then the estimate* (2.6) *holds replacing* $(S^* = 1 - X^*, C^*)$ *by* $(\hat{S} = 1 - \hat{X}, \hat{C})$. *In particular,*

$$\|X^\varepsilon(t,x) - \hat{X}(t,x)\|_{L^1(\Omega)} \leq M\varepsilon \tag{3.5}$$

for any $t \geq 0$ (*i.e.,* $X^\varepsilon \to \hat{X}$ *in* $C([0,\infty) : L^1(\Omega))$ *as* $\varepsilon \to 0$), *where* $M = \frac{1}{\lambda}\|C_0 - \hat{C}_0\|_{L^1(\Omega)}$. *Moreover, if*

$$\|C_0 - \hat{C}_0\|_{L^1(\Omega)} \leq L\varepsilon^\gamma \quad \text{for some } L > 0 \text{ and } \gamma > 0, \tag{3.6}$$

then

$$\|X^\varepsilon(t,x) - \hat{X}(t,x)\|_{L^1(\Omega)} \leq \varepsilon^{\gamma+1}\frac{L}{\lambda} \tag{3.7}$$

and

$$\|C^\varepsilon(t,x) - \hat{C}(t,x)\|_{L^1(\Omega)} \leq L\varepsilon^\gamma \tag{3.8}$$

for any $t \geq 0$ (*i.e.,* $(X^\varepsilon, C^\varepsilon) \to (\hat{X}, \hat{C})$ *in* $C([0,\infty) : L^1(\Omega))$ *as* $\varepsilon \to 0$).

Proof. By Theorem 3.2 we have $\hat{C}_t \geq 0$ so that $\varepsilon\hat{C}_t - \Delta\hat{C} + \lambda F(\hat{X})g(\hat{C}) \geq 0$ and the proof of Theorem 2.2 gives the inequality

$$\varepsilon \int_\Omega |C^\varepsilon(t,x) - \hat{C}(t,x)|\,dx + \lambda \int_\Omega |X^\varepsilon(t,x) - \hat{X}(t,x)|\,dx + \frac{1}{\alpha}\int_0^t \int_{\partial\Omega} |C^\varepsilon(\tau,\sigma) - \hat{C}(\tau,\sigma)|\,d\tau\,d\sigma \leq \varepsilon \int_\Omega |C_0(x) - \hat{C}_0(x)|\,dx,$$

which leads to the desired results (3.7) and (3.8). □

The next result shows the convergence of $(X^\varepsilon, C^\varepsilon)$ to $(\hat{X}, \hat{C})$ as $\varepsilon \to 0$ in the space $L^1(0,t : C(\bar{\Omega}))$ independently of the initial difference $\|C_0 - \hat{C}_0\|_{L^\infty(\Omega)}$.

THEOREM 3.5. *Let X_0, C_0 be as in Theorem* 3.4 *and let $C_0 \le \hat{C}_0$. Let $w \in C^\infty(\Omega)$ be the (unique) solution of the linear problem* (1.11). *Then, for any $t > 0$ and any $x \in \bar{\Omega}$,*

$$0 \le \int_0^t (\hat{C}(\tau, x) - C^\varepsilon(\tau, x))\, d\tau \le \varepsilon w(x) \tag{3.9}$$

and

$$0 \le \int_\Omega (\hat{X}(t, x) - X^\varepsilon(t, x))\, dx \le \varepsilon \frac{|\Omega|}{\lambda}, \tag{3.10}$$

so that

$$C^\varepsilon \to \hat{C} \quad \text{in } L^1(0,t : C(\bar{\Omega}))$$

and

$$X^\varepsilon \to \hat{X} \quad \text{in } L^\infty(0,t : L^1(\bar{\Omega})).$$

Proof. Integrate the equations for C^ε and $\hat{C}$ with respect to time; use Lemma 3.2 and the comparison principle to obtain (3.9). Inequality (3.10) follows from Green's formula.

4. On the conversion of the solid and the penetration of the gas.[1]

4.1. Solid conversion. The behavior of $f(S)$ near $S = 0$ will determine whether or not the solid is fully converted in finite time.

THEOREM 4.1. *Consider problems* (P) *and* ($\hat{\text{P}}$) *and let*

$$R(S) = \int_S^1 \frac{d\sigma}{f(\sigma)}, \qquad I = R(0+). \tag{4.1}$$

Then if $I < \infty$, the solid is fully converted in finite time; if $I = \infty, S(x,t)$ and $\hat{S}(x,t)$ are positive for all t at every x where the initial solid concentration is positive.

Proof. We carry out the proof for problem (P), the reasoning being similar for ($\hat{\text{P}}$). We write (1.1) with its initial condition (1.4a) as

$$S_t = -\mu(t,x) f(S), \quad t > 0, \qquad S(0,x) = S_0(x), \tag{4.2}$$

and treat each x individually. If $S_0(\xi) = 0$, then $S(t,\xi) \equiv 0$ for all t, so we confine ourselves to points x where $S_0(x) > 0$. In that case, $S(t,x)$ will itself be positive for some initial time interval, and we can divide (4.2) by $f(S)$ to obtain

$$\frac{d}{dt} R(S) = \mu(t,x), \tag{4.3}$$

where $R(S)$ is defined by (4.1). Note that $R(S)$ is positive and decreasing on $0 < S < 1$. Therefore, $R^{-1}(S)$ is positive and decreasing on $[0, I)$. Integrating (4.3) from 0 to t gives

$$R(S) = R(S_0) + \int_0^t \mu(\tau, x)\, d\tau,$$

[1] In this section $\|\cdot\|$ will stand for the usual sup norm on the x variable, $\|u(t,x)\| = \sup_{x \in \Omega} \|u(t,x)\|$.

and therefore

$$S(t,x) = R^{-1}\left[\int_0^t \mu(\tau,x)\,d\tau + R(S_0(x))\right] \tag{4.4}$$

is the solution of (4.2) as long as $S > 0$. If $I = \infty$, the positivity of R^{-1} on $[0,\infty)$ guarantees that $S(t,x) > 0$, so that the second part of the theorem is proved. If I is finite, (4.4) furnishes a positive solution of (4.2) for $t < T(x)$ where $T(x)$ is defined by

$$R(S_0(x)) + \int_0^T \mu(\tau,x)\,d\tau = I.$$

At $t = T(x), S(x,t) = 0$ and remains equal to zero for $t \geq T(x)$. Since $R^{-1}(I) = 0$, it is useful to extend the definition of R^{-1} through the rule $R^{-1}(z) = 0, z \geq I$. With that agreement (4.4) remains valid for all t even if I is finite.

Returning to (1.1) we can then write

$$\begin{aligned} S(t,x) &= R^{-1}\left[\int_0^t g(C(\tau,x))\,d\tau + R(S_0(x))\right] \\ &\leq R^{-1}\left[\int_0^t g(C(\tau,x))\,d\tau\right]. \end{aligned} \tag{4.5}$$

We have proved in §3 that $C(t,x)$ tends to 1 as $t \to \infty$, uniformly for $x \in \bar{\Omega}$, so that $\int_0^t g(C(\tau,x))\,d\tau \geq I$ for all x if t is sufficiently large. Therefore, there exists T such that $S(t,x) \equiv 0, t \geq T$, and we have *full conversion in finite time.* □

COROLLARY 4.1. *If $f(S) = S^m, I$ is finite if and only if $m < 1$. The explicit formulas are*

$$R_m(S) = \begin{cases} \frac{1-S^{1-m}}{1-m}, & m \neq 1, \\ -\ln S, & m = 1, \end{cases}$$

and thus

$$R_m^{-1}(z) = \begin{cases} [1 - z(1-m)]_+^{1/1-m}, & m \neq 1, \\ e^{-z}, & m = 1, \end{cases} \tag{4.6}$$

where $[u]_+$ stands for the greater of u and 0. We can then rewrite (4.5) as

$$S(t,x) = S_0(x) R_m^{-1}\left[S_0^{-1}(x)\int_0^t g(C(\tau,x))\,d\tau\right].$$

Remark 4.1. We could substitute (4.5) into (1.2) to obtain a nonlinear integro-differential equation for C subject to conditions (1.4b) and (1.4c). A related approach due to McNabb [19] is more useful. He introduces

$$\eta(t,x) = \int_0^t [1 - C(\tau,x)]\,d\tau \qquad (1 - C = \eta_t), \tag{4.7}$$

the time-integrated deviation of C from its steady state. A straightforward calculation shows that η satisfies

$$\begin{aligned} &\varepsilon\eta_t - \Delta\eta = \varepsilon(1 - C_0) + \lambda(S_0 - S), \quad x \in \Omega, \quad t > 0; \\ &\eta(x,0) = 0, \quad \eta + \alpha\eta_\nu = 0, \quad x \in \partial\Omega, \quad t > 0. \end{aligned} \tag{4.8}$$

Although S is unknown in (4.8), considerable information can nevertheless be extracted from this formulation. For instance, because S decreases to 0 as $t \to \infty, \eta(t, \cdot)$ is monotonically increasing to the solution $\eta_\infty(x)$ of the steady-state problem

$$-\Delta\eta_\infty = \varepsilon(1 - C_0) + \lambda S_0, \quad \eta_\infty + \alpha\eta_{\infty,\nu} = 0, \quad x \in \partial\Omega. \tag{4.9}$$

Note that

$$\eta_\infty \leq (\varepsilon + \lambda)w(x), \tag{4.10}$$

where $w(x)$ is the solution of (1.11).

For the p.s.s. problem we define

$$\hat{\eta} = \int_0^t (1 - \hat{C})\, d\tau, \tag{4.11}$$

which satisfies

$$-\Delta\hat{\eta} = \lambda(\hat{S}_0 - \hat{S}), \quad \hat{\eta} + \alpha\hat{\eta}_\nu = 0, \quad x \in \partial\Omega, \tag{4.12}$$

and $\hat{\eta}(t, x)$ tends monotonically to the solution of

$$-\Delta\hat{\eta}_\infty = \lambda\hat{S}_0, \quad \hat{\eta}_\infty + \alpha\hat{\eta}_{\infty,\nu} = 0, \quad x \in \partial\Omega. \tag{4.13}$$

We see that

$$\hat{\eta}_\infty \leq \lambda w(x). \tag{4.14}$$

In the *special case where* $g(C) = C$, (4.5) gives

$$S(t, x) = R^{-1}[t - \eta + R(S_0)],$$

which can be substituted into (4.8) to give a scalar partial differential equation for η. These ideas were exploited in [24] and [28] and will be used to some extent in the remainder of the section.

Remark 4.2. If we had considered a problem *without gas diffusion* and with a gas concentration *maintained at the value one,* the solid concentration $S^*(t, x)$ would satisfy the ordinary differential equation

$$S_t^* = -f(S^*), \quad t > 0, \quad S^*(0, x) = S_0^*(x). \tag{4.15}$$

There are many ways of seeing that $S^*(t, x) \leq S(t, x)$, where S is the solution of (P) with the same initial solid concentration (and any $C_0 \leq 1$). For instance, since R^{-1} is monotone decreasing and $g(C) \leq 1$, (4.5) shows that

$$S(t, x) \geq R^{-1}(t + R(S_0(x))),$$

the right-hand side being precisely $S^*(t, x)$, because now $\mu \equiv 1$ in (4.4). Similarly, we can show $S^* \leq \hat{S}$, the solution of ($\hat{\text{P}}$) with the same initial value.

The quantity that is perhaps of greatest physical interest is the overall conversion fraction $\gamma(t)$. The inverse of this function gives the time required to achieve the

conversion of a specified fraction of the solid. We shall compare problems (P), (P′), and (4.15) with the same initial value $S_0(x)$.

The *overall conversion* at time t for problem (P) is given by

$$\gamma(t) = \frac{\int_\Omega (S_0(x) - S(t,x))\,dx}{\int_\Omega S_0(x)\,dx} = 1 - \frac{\int_\Omega S(t,x)\,dx}{\int_\Omega S_0(x)\,dx}, \tag{4.16}$$

for problem ($\hat{\text{P}}$) by

$$\hat{\gamma}(t) = 1 - \frac{\int_\Omega \hat{S}(t,x)\,dx}{\int_\Omega S_0(x)\,dx},$$

and for (4.15) by

$$\gamma^*(t) = 1 - \frac{\int_\Omega S^*(t,x)\,dx}{\int_\Omega S_0(x)\,dx}.$$

We have already proved the following properties:

(a) $0 \le \gamma(t) \le 1, \quad 0 \le \hat{\gamma}(t) \le 1, \quad 0 \le \gamma^*(t) \le 1;$

(b) $\gamma(t) \le \hat{\gamma}(t), \quad \hat{\gamma}(t) = \gamma^*(t)$ (see Remark 4.2);

(c) *If* $C_0(x) \le \hat{C}_0(x), \quad \gamma(t) \le \hat{\gamma}(t)$ (see Lemma 3.2);

(d) $\lim_{t\to\infty} \gamma(t) = \lim_{t\to\infty} \hat{\gamma}(t) = \lim_{t\to\infty} \gamma^*(t) = 1$ (see Corollary 3.1).

If I is finite, Theorem 4.1 tells us that the solid is fully converted in finite time, that is, $\gamma(t) \equiv 1$ for t sufficiently large. We define full conversion times $t_1, \hat{t}_1, t_1^*$ by

$$t_1 = \inf\{t : \gamma(t) = 1\}, \quad \hat{t}_1 = \inf\{t : \hat{\gamma}(t) = 1\}, \quad t_1^* = \inf\{t : \gamma^*(t) = 1\}.$$

We first observe that t_1^* is known explicitly. We seek the smallest value of t for which $S^*(t,x)$, the solution of (4.15), is identically zero on $\bar{\Omega}$. Since $\|S_0\| = 1$, there is at least one point ξ where $S_0(\xi) = 1$. These points will be the slowest to convert. From (4.4) we have $S(t,\xi) = R^{-1}(t)$, which is positive for $t < I$ and vanishes for $t \ge I$. Therefore, $t_1^* = I$.

From (b) and (c) above we see that

$$t_1 \ge I, \quad \hat{t}_1 \ge I \quad \text{and, if} \quad C_0(x) \le \hat{C}_0(x), \quad t_1 \ge \hat{t}_1.$$

We can obviously characterize t_1 by

$$\inf\{t : S(t,x) \equiv 0, x \in \bar{\Omega}\} = \inf\{t : X(t,x) \equiv 1, x \in \bar{\Omega}\}.$$

By (4.5) and the fact that $R^{-1}(I) = 0$, we also have that t_1 is characterized by

$$\min_{x\in\bar{\Omega}} \int_0^{t_1} g(C(\tau,x))\,d\tau + R(S_0(x)) = I$$

and $\hat{t}_1$ by

$$\min_{x\in\bar{\Omega}} \int_0^{\hat{t}_1} g(\hat{C})\,d\tau + R(\hat{S}_0) = I.$$

If $S_0(x) = \hat{S}_0(x) \equiv 1$, then we see that t_1 and $\hat{t}_1$ satisfy

$$\min_{x\in\bar{\Omega}} \int_0^{t_1} g(C)\,d\tau = I, \qquad \min_{x\in\bar{\Omega}} \int_0^{\hat{t}_1} g(\hat{C})\,d\tau = I. \tag{4.17}$$

Next, we provide estimates for $\hat{t}_1$ when $\hat{S}_0(x) \equiv 1$, the case that occurs most frequently in applications (uniform initial solid concentration).

THEOREM 4.2. *Let $\hat{S}_0 \equiv 1$ and let I be finite. Assume there exist $g_1, g_2 \in C^0([0,1]) \cap C^1((0,1))$ such that $g_1', g_2' \geq 0, g_1(1) = g_2(1) = 1$, and*

$$g_1(r) \leq g(r) \leq g_2(r) \quad \forall\, r \in [0,1]. \tag{4.18}$$

Then

$$I + M_2\lambda\|w\| \leq \hat{t}_1 \leq I + M_1\lambda\|w\|, \tag{4.19}$$

where $M_1 = \sup_{[0,1]} g_1'$, $M_2 = \inf_{[0,1]} g_2'$, and w is defined by (3.9).

Proof. By definition, $\hat{\eta}_t = 1 - \hat{C}$ so that $0 \leq 1 - \hat{\eta}_t \leq 1, 0 \leq \hat{\eta}_t \leq 1$. We immediately see that with M_1, M_2 as defined above,

$$1 - g_1(1 - \hat{\eta}_t) \leq M_1\hat{\eta}_t, \qquad 1 - g_2(1 - \hat{\eta}_t) \geq M_2\hat{\eta}_t,$$

and, therefore,

$$1 - M_1\hat{\eta}_t \leq g_1(1 - \hat{\eta}_t) \leq g(1 - \hat{\eta}_t) \leq g_2(1 - \hat{\eta}_t) \leq 1 - M_2\hat{\eta}_t.$$

Integrating from 0 to $\hat{t}_1$, we find

$$t_1 - M_1\hat{\eta}(\hat{t}_1, x) \leq \int_0^{\hat{t}_1} g(1 - \hat{\eta}_t)\, d\tau \leq \hat{t}_1 - M_2\hat{\eta}(\hat{t}_1, x),$$

and, taking the minimum with respect to x and using the characterization (4.17) for $\hat{t}_1$, we obtain

$$\hat{t}_1 - M_1\|\hat{\eta}(\hat{t}_1, x)\| \leq I \leq \hat{t}_1 - M_2\|\hat{\eta}(\hat{t}_1, x)\|. \tag{4.20}$$

When $t \geq \hat{t}_1, \hat{S} = 0$ so that (4.12) gives

$$\hat{\eta} = \hat{\eta}_\infty = \lambda w(x), \qquad \|\hat{\eta}(t_1, x)\| = \lambda\|w\|,$$

which, when substituted into (4.20) gives the result (4.19). □

Remark 4.3. Special cases of interest correspond to $g(C) = C^p, p > 0$. Our estimates then become

(4.21) (a) if $p = 1$, $\hat{t}_1 = I + \lambda\|w\|$ (take $g_1 = g_2 = g$);

(b) if $p < 1$,

(4.22) $I + p\lambda\|w\| \leq \hat{t}_1 \leq I + \lambda\|w\|$ (take $g_1(r) = r, g_2 = g$);

(c) if $p > 1$,

(4.23) $I + \lambda\|w\| \leq \hat{t}_1 \leq I + \lambda p\|w\|$ (take $g_2(r) = r, g_1 = g$).

The result (a) was first given in [28]. From the inequality $0 \leq \int_0^{\hat{t}_1}(1 - \hat{\eta}_t)\, d\tau = \hat{t}_1 - \lambda w(x)$, we also find

$$\hat{t}_1 \geq \lambda\|w\|, \tag{4.24}$$

which improves the lower bound (b) if $\lambda(1-p)\|w\| \geq I$.

Further improvement follows from using Jensen's inequality, which we illustrate in the case $p < 1$, when the inequality becomes

$$\left(\int_0^t v(\tau)\,d\tau\right)^p \geq t^{p-1}\int_0^t v^p(\tau)\,d\tau,$$

where $v(t)$ is any nonnegative continuous function.

Setting $v = 1 - \hat{\eta}_t$, we find

$$\int_0^{\hat{t}_1} (1-\hat{\eta}_t)^p\,d\tau \leq \hat{t}_1^{1-p}(\hat{t}_1 - \lambda w(x))^p \quad \forall x \in \bar{\Omega},$$

and, taking the minimum over x,

$$I \leq \hat{t}_1^{1-p}(\hat{t}_1 - \lambda\|w\|)^p.$$

This inequality implies $\hat{t}_1 \geq T$, where T is the unique positive solution of

$$I = T^{1-p}(T - \lambda\|w\|)^p, \tag{4.25}$$

which can be shown to always provide a better lower bound to $\hat{t}_1$ than (4.22) and (4.24). As an example, if $p = \frac{1}{2}$, (4.25) gives

$$T = \frac{\lambda\|w\| + \sqrt{\lambda^2\|w\|^2 + I^2}}{2},$$

which is larger than the lower bounds (4.22) and (4.24).

We now turn to estimates for t_1 when $S_0(x) \equiv 1$. These are somewhat more difficult as t_1 also depends on both ε and $C_0(x)$. We will not be able, for instance, to find an exact value for t_1 when $p = 1$, as we did for $\hat{t}_1$ (see (4.21)).

THEOREM 4.3. *Let* $S_0(x) \equiv 1, 0 \leq C_0(x) \leq 1$; *then*

$$t_1 \leq I + M_1(\varepsilon + \lambda)\|w\|,$$

and if also $C_0 \leq \hat{C}_0$, *then*

$$t_1 \geq \hat{t}_1 \geq I + M_2\lambda\|w\|,$$

where M_1, M_2 *are as in Theorem* 4.2.

Proof. We proceed as in Theorem 4.2 to reach the equivalent of (4.20):

$$t_1 - M_1\|\eta(t_1,x)\| \leq I \leq t_1 - M_2\|\eta(t_1,x)\|. \tag{4.26}$$

Unfortunately, $\eta(t_1,x)$ is not known explicitly, so we must use estimates for $\|\eta(t_1,x)\|$. From (4.9) we have

$$\eta(t,x) \leq \eta_\infty(x) \leq (\varepsilon+\lambda)w(x),$$

which yields

$$t_1 \leq I + M_1(\varepsilon+\lambda)\|w\|,$$

the upper bound in Theorem 4.3. The lower bound in the theorem follows from previous results (Theorem 4.2 and Lemma 3.2). □

Remark 4.4. Again we can consider the case C^p and find corresponding forms of (4.21)–(4.24). For instance, (4.21) becomes

$$I + \lambda\|w\| \leq t_1 \leq I + (\lambda + \varepsilon)\|w\|,$$

which is quite satisfactory as long as ε is small.

Remark 4.5. Jensen's inequality can be used to improve some of the bounds.

Remark 4.6. We can also be more accurate in our estimate for $\|\eta(t_1, x)\|$, which appears in the proof of Theorem 4.3. For $t \geq t_1, \eta(t, x)$ satisfies (4.8) with $S_0 \equiv 1, S \equiv 0$; that is,

$$-\Delta\eta = \varepsilon(1 - C_0) + \lambda - \varepsilon\eta_t; \quad \eta + \alpha\eta_\nu = 0 \quad \text{on } \partial\Omega.$$

Now $0 \leq \eta_t \leq 1$, so that

$$\lambda - \varepsilon C_0 \leq -\Delta\eta \leq \varepsilon(1 - C_0) + \lambda$$

and, hence,

$$\lambda w(x) - \varepsilon y(x) \leq \eta(t, x)) \leq (\lambda + \varepsilon)w(x) - \varepsilon y(x),$$

where $y(x)$ satisfies

$$-\Delta y = C_0(x), \quad x \in \Omega; \quad y + \alpha y_\nu = 0 \quad \text{on } \partial\Omega.$$

As an illustration of the use of these inequalities, suppose $C_0 \equiv 1$. Then (4.26) yields

$$t_1 - M_1\lambda\|w\| \leq I \leq t_1 - M_2(\lambda - \varepsilon)\|w\|$$

and

$$I + M_2(\lambda - \varepsilon)\|w\| \leq t_1 \leq I + \lambda M_1\|w\|.$$

If, also, $p = 1$, then with $g_1 = g_2 = g$, we find $M_1 = M_2 = 1$ and

$$I + (\lambda - \varepsilon)\|w\| \leq t_1 \leq I + \lambda\|w\| = \hat{t}_1.$$

Thus, unlike the case where $C_0 \leq \hat{C}_0$, we now have $t_1 \leq \hat{t}_1$.

4.2. Penetration of the gas. In problems (P) and ($\hat{\text{P}}$), the gas concentration tends uniformly to its steady state $C = \hat{C} = 1$. The concentration must therefore be strictly positive for t sufficiently large, but is this necessarily true for all $t > 0$? Our experience with scalar problems involving strong absorption suggests otherwise: there may exist a time-dependent "dead core" in which the concentration is zero at time t (see [4] and [9]). Any such dead core must, of course, disappear in finite time. For problems (P) and ($\hat{\text{P}}$) we define

$$D(t) = \{x \in \Omega : C(t, x) = 0\}, \qquad T = \inf\{t : C(t, x) > 0 \text{ for all } x \in \bar{\Omega}\}, \tag{4.27}$$

$$\hat{D}(t) = \{x \in \Omega : \hat{C}(t, x) = 0\}, \qquad \hat{T} = \inf\{t : \hat{C}(t, x) > 0 \text{ for all } x \in \bar{\Omega}\}. \tag{4.28}$$

As in the scalar case, an important role is played by

$$J = \int_{0+}^{1} \frac{d\sigma}{\sqrt{G(\sigma)}}, \quad \text{where } G(\sigma) = \int_0^\sigma g(C)\, dC. \tag{4.29}$$

Note that if $g(C) = C^p$, J is finite for $0 < p < 1$ and infinite if $p \geq 1$.

Our main result is that (a) no dead core exists if $J = \infty$, and (b) a dead core may exist if J is finite. We prove these assertions below and also provide rough estimates for the location of the dead core and for the time at which it disappears.

THEOREM 4.4. *Let $g(C)$ be such that $J = \infty$. Then*

$$\hat{C}(t,x) > 0 \quad \textit{for all } (t,x) \in [0,\infty) \times \bar{\Omega},$$
$$C(t,x) > 0 \quad \textit{for all } (t,x) \in (0,\infty) \times \bar{\Omega}.$$

Proof. By Theorem 3.2, $\hat{C}(t,x)$ increases monotonically in time, so $\hat{C}(t,x) \geq \hat{C}_0(x)$ with $\hat{C}_0$ defined by (1.9). Thus $\hat{C}_0(x)$ satisfies

$$-\Delta \hat{C}_0 + \lambda g(\hat{C}_0) \geq 0$$

and, therefore, by a result of Vázquez [30], $\hat{C}_0(x) > 0$ in $\bar{\Omega}$, and hence $\hat{C}(t,x) > 0$ in $\bar{\Omega}$ for all $t \geq 0$. In the parabolic case, we have

$$0 = \varepsilon C_t - \Delta C + \lambda f(S) g(C) \leq \varepsilon C_t - \Delta C + \lambda g(C),$$

so that $C(t,x)$ is a supersolution of the scalar problem

$$\varepsilon C^*_t - \Delta C^* + \lambda g(C^*) = 0 \quad \text{on } (0,\infty) \times \Omega,$$
$$C^* + \alpha C^*_\nu = 1 \quad \text{on } (0,\infty) \times \partial\Omega,$$
$$C^*(0,x) = C_0(x) \quad \text{on } \Omega.$$

The strict positivity can be obtained by an easy modification of a result of Bertsch, Kersner, and Peletier [5] and, therefore, $C(t,x) > 0$ on $(0,\infty) \times \bar{\Omega}$. □

Next we show that if J is finite, a dead core is possible in the pseudo-steady-state case.

THEOREM 4.5. *Let $J < \infty$; define*

$$d(x,\partial\Omega) = \textit{ distance from } x \textit{ to } \partial\Omega,$$
$$A = \textit{ half-width of thinnest slab enclosing } \Omega,$$
$$r_i = \textit{ radius of largest inscribed ball,}$$
$$m(t) = f(\inf_{x \in \bar{\Omega}} \hat{S}(t,x)), \qquad M(t) = f(\sup_{x \in \bar{\Omega}} \hat{S}(t,x)).$$

Then

$$\hat{D}(t) \supset \left\{ x \in \Omega : d(x,\partial\Omega) \geq \left[\frac{N}{2\lambda m(t)}\right]^{1/2} J \right\}, \tag{4.30}$$

$$\hat{D}(t) \neq \emptyset \quad \textit{when } \left[\frac{N}{2\lambda m(t)}\right]^{1/2} J < r_i, \tag{4.31}$$

$$\hat{D}(t) = \emptyset \quad \textit{when } \lambda < \frac{J^2}{2a^2 M(t)}. \tag{4.32}$$

$$\hat{D}(t) = \emptyset \quad \textit{for all } t \textit{ if } \lambda < J^2/2a^2. \tag{4.33}$$

Proof. Since f is increasing, we have

$$-\Delta \hat{C} + \lambda M(t) g(\hat{C}) \geq 0 = -\Delta \hat{C} + \lambda f(\hat{S}) g(\hat{C}) \geq -\Delta \hat{C} + \lambda m(t) g(\hat{C}),$$

so that $\hat{C}$ is a subsolution of the scalar elliptic problem

$$-\Delta C^{(\alpha)} + \lambda m(t) g(C^{(\alpha)}) = 0, \qquad x \in \Omega,$$
$$C^{(\alpha)} + \alpha C_\nu^{(\alpha)} = 1, \qquad x \in \partial\Omega.$$

Therefore, $\hat{C}(t,x) \le C^{(\alpha)}(t,x)$, which, in turn, is smaller than the solution $C^{(0)}(t,x)$ of the Dirichlet problem. It follows that $\hat{D}(t)$ is contained in the dead core of $C^{(0)}(t,x)$. It is shown in Diaz [7, Prop. 1.11] that the dead core for $C^{(0)}$ satisfies (4.30); see also [8] and [25]. The assertion (4.31) is an immediate consequence of (4.30).

To prove (4.32) we observe that $\hat{C}$ is a supersolution to the scalar problem with $M(t)$ replacing $f(\hat{S})$. Although conditions for nonexistence of a dead core for this latter problem are available [17], [26], we confine ourselves to the case $\alpha = 0$, when the simple bound (4.32) is derived in [3]. Since $M(t)$ is a decreasing function of time with $M(0) = 1$, the bound (4.33) follows. □

Remark 4.7. To apply (4.31), we need an explicit lower bound for $m(t)$. Such a bound is easily obtained if $\inf_{\bar{\Omega}} \hat{S}_0(x) = \delta > 0$. Then, from Remark 4.2, we find $\hat{S}(t,x) \ge R^{-1}(t + R(\delta))$ so that $m(t) \ge f[R^{-1}(t + R(\delta))]$ and $m(0) \ge f(\delta)$. Therefore, a dead core exists at time t if

$$r_i > J\left\{\frac{N}{2\lambda f[R^{-1}(t + R(\delta))]}\right\}^{1/2}. \tag{4.34}$$

In particular, a dead core exists for sufficiently small t if

$$r_i > J\left\{\frac{N}{2\lambda f(\sigma)}\right\}^{1/2}. \tag{4.35}$$

Note that (4.34) also gives a lower bound for $\hat{T}$:

$$\hat{T} \ge R\left\{f^{-1}\left(\frac{J^2 N}{2\lambda r_i^2}\right) - R(\delta)\right\}. \tag{4.36}$$

We now turn to the parabolic problem when $J < \infty$. Estimates are more cumbersome because the dead core may not be monotonic in t. For instance, if $C_0(x) = 1$, a dead core may form after a certain time and later disappear. We can, however, find an upper bound on T, the time beyond which $C(t,x) > 0$ for all $x \in \bar{\Omega}$. We confine ourselves to the Dirichlet problem ($\alpha = 0$).

THEOREM 4.6. *Let $\alpha = 0, J < \infty$, and let a be the half-width of the thinnest strip enclosing Ω. Then*

$$T \le \frac{\varepsilon + \lambda}{2} a^2, \qquad \hat{T} \le \frac{\lambda}{2} a^2. \tag{4.37}$$

Our proof is based on comparison with a half-space, so we begin with the following lemma.

LEMMA 4.1. *Consider problem* (P′) *for the half-space $x > 0$ with $C(t,0) = 1$ for $t > 0$ and initial values $0 \le X(0,x) \le 1, 0 \le C(0,x) \le 1$. Let*

$$\rho(t) = \inf\{x : C(t,x) \equiv 0\}$$

be the penetration distance of the gas, where $\rho(t)$ is understood to be $+\infty$ if $C(x,t) > 0$ for all x. Then

$$\rho^2 \geq \frac{2t}{\varepsilon + \lambda}, \tag{4.38}$$

an estimate which holds even when $\varepsilon = 0$.

Proof of Lemma 4.1. We give the proof for $\varepsilon > 0$, omitting the simpler case $\varepsilon = 0$. Let us first consider the problem with *zero initial values* for C and X. Condition (3.2) being satisfied, $C(t,\cdot)$ and $\rho(t)$ are monotonically increasing. We write (2.3) as

$$\varepsilon C_t - C_{xx} = -\lambda X_t, \quad x > 0, \quad t > 0$$

and, as in [14], integrate in time from 0 to t to obtain

$$\varepsilon C(t,x) + \lambda X(t,x) = \psi_{xx}, \tag{4.39}$$

where

$$\psi(t,x) = \int_0^t C(\tau,x)\,d\tau.$$

We multiply (4.39) by x and integrate from $x = 0$ to $x = \rho(t)$:

$$\int_0^\rho x(\varepsilon C + \lambda X)\,dx = \int_0^\rho x\psi_{xx}\,dx = t - \psi(t,\rho(t)).$$

By the time monotonicity, $C(\tau,\rho(t)) = 0$ for $\tau < t$, so that $\psi(t,\rho(t)) = 0$. Thus we find

$$t = \int_0^\rho x[\varepsilon C + \lambda X]\,dx \leq (\varepsilon + \lambda)\frac{\rho^2}{2},$$

which proves (4.38) for zero initial values. For other initial values the gas concentration $C(t,x)$ will be larger (Property I, §3.1), and (4.38) must remain true. □

Proof of Theorem 4.6. Let (X_Ω, C_Ω) be the solution of the problem (P′) with $\alpha = 0$. We compare this solution with the solution (X_H, C_H) for a supporting half-space H enclosing Ω with initial values $(X_H(0,x), C_H(0,x)) \leq (X_\Omega(0,x), C_\Omega(0,x))$. Then, since $C_H \leq 1$ on $\partial\Omega$, $(X_H(t,x), C_H(t,x))$ is a subsolution to (P′) for Ω, and hence

$$C_\Omega(t,x) \geq C_H(t,x). \tag{4.40}$$

Now let U be the thinnest slab enclosing Ω; applying (4.40) successively to the half-spaces corresponding to the two faces of U, we see that $C_\Omega(t,x) > 0$ when $t > \frac{\varepsilon+\lambda}{2}a^2$, where a is the half-width of the slab. This yields (4.37). The proof is the same for the pseudo-steady-state case. □

Remark 4.8. When full conversion occurs in finite time ($I < \infty$), we have estimated t_1 and $\hat{t}_1$, the times to full conversion. When $t > t_1$ (or $t > \hat{t}_1$ in the p.s.s. case), the equation for the gas concentration is just the ordinary heat equation, which has the well-known property $C > 0$ for the given boundary conditions. Hence t_1 is an upper bound for T.

We end this section by showing that a dead core can occur for the half-space problem when $g(C) = C^p, p < 1$. Consider again the Dirichlet problem, now with

$C(0,x) = S(0,x) = 1$, the initial condition on C being least favorable for generating a dead core. Our problem then becomes

$$\begin{aligned} &\varepsilon C_t - C_{xx} = -\lambda f(S)g(C) = \lambda S_t, \quad x > 0, \quad t > 0; \\ &C(0,x) = S(0,x) = 1, \qquad C(t,0) = 1. \end{aligned} \tag{4.41}$$

Since conversion of the solid is fastest at $x = 0$, we have

$$f(S(t,0)) \leq f(S(t,x)) \leq 1.$$

From the second inequality we find that $C(t,x) \geq z(t)$, where $z(t)$ is the solution of $z_t = -\lambda g(z), z(0) = 1$. Because $z > 0$ for

$$t < K \doteq \int_0^1 \frac{dz}{g(z)},$$

we see that, as expected, $C(t,x)$ is strictly positive for $t < K$. Note that when $g(z) = z^p, K$ is finite if and only if $p < 1$. Next we show that C develops a dead core at later times by constructing a supersolution $D(t,x)$ of (4.41) over a bounded time interval with $D(t,x) = 0$ for x sufficiently large and some range of t. Since $S(t,0)$ satisfies $S_t = -f(S)$ with initial value one, we find that $S(t,0) = R^{-1}(t)$ (see (4.5) and (4.6)). Because $S(t,0)$ decreases monotonically from 1 to 0, we can find, for each δ with $0 < \delta < 1$, a time T_δ such that

$$f(S(t,0)) \geq 1 - \delta, \qquad 0 < t < T_\delta.$$

Therefore, $f(S(t,x)) \geq 1 - \delta$ for $0 < t < T_\delta$ and $C(t,x) \leq D(t,x)$ on $(0,T_\delta)$ where D satisfies the scalar problem

$$\begin{cases} \varepsilon D_t - D_{xx} = -\lambda(1-\delta)g(D), \quad x > 0, \quad t > 0; \\ D(0,x) = 1, \qquad D(t,0) = 1. \end{cases} \tag{4.42}$$

It was shown in [32] that problem (4.42) exhibits a dead core for all $t > \frac{\varepsilon K}{\lambda(1-\delta)}$. Therefore, (4.41) will have a dead core if we can choose the parameters so that

$$\frac{\varepsilon K}{\lambda(1-\delta)} < T_\delta. \tag{4.43}$$

Let us illustrate the calculation for the case $f(S) = S$. Then $S(t,0) = e^{-t}, T_\delta = -\log(1-\delta)$, and (4.43) is satisfied if, for some $\delta, 0 < \delta < 1$, we have

$$\frac{\varepsilon K}{\lambda} < -(1-\delta)\log(1-\delta).$$

The maximum of the right side occurs at $\delta = 1 - \frac{1}{e}$, and the maximal value is 1. Thus (4.41) will have a dead core if $\frac{\varepsilon K}{\lambda} < 1$.

Remark 4.9. A *bounded* domain Ω of sufficiently large size will also have a dead core for a suitable choice of the parameters. Of course, in this case the dead core must disappear in finite time.

POSITIVE SOLUTIONS OF SINGULAR SUBLINEAR DIRICHLET BOUNDARY VALUE PROBLEMS *

YONG ZHANG†

Abstract. This paper mainly studies the existence of positive solutions of Dirichlet boundary value problems for a class of singular sublinear ordinary differential equations. A necessary and sufficient condition for the existence of $C[0,1]$ positive solutions as well as $C^1[0,1]$ positive solutions is given. The uniqueness of the solution is also concerned, and an application to the Dirichlet problem of semilinear elliptic equations is given.

Key words. sublinear equations, singular Dirichlet problems, positive solutions, lower and upper solutions, radial solutions of semilinear elliptic equations, existence and uniqueness

AMS subject classifications. primary 34B15; secondary 35J65

1. Introduction.

In this paper we are concerned about the singular boundary value problem of second order ordinary differential equations

$$\ddot{x} + f(t,x) = 0, \qquad t \in (0,1), \tag{1.1}$$

$$x(0) = x(1) = 0. \tag{1.2}$$

By singularity we mean that the function f in (1.1) is allowed to be unbounded at the end points $t = 0$ and 1. Recently such problems have interested many authors [1]–[8]. For background, we mention the existence problem of radial solutions of nonlinear elliptic equations as follows:

$$\Delta u + f(|x|,u) = 0, \qquad x \in \Omega,$$
$$u(x)|_{\partial\Omega} = 0, \qquad |x|^{n-1}\left.\frac{\partial u}{\partial \vec{n}}\right|_{\partial\Omega} \text{ exists},$$

where Ω is an n-ball of radius ρ centered at $0 \in R^n, 0 < \rho \le +\infty, n \ge 2$, and when $\rho = +\infty$ (i.e., $\Omega = R^n$) we assume $n > 2$; $f(r,u)$ is continuous for $0 \le r < \rho, u \in (-\infty,\infty)$ (or $(0,\infty)$ if we consider positive solutions).

This problem leads one to treat the boundary value problem of ordinary differential equations

$$\frac{1}{p(r)}\frac{d}{dr}\left(p(r)\frac{du}{dr}\right) + f(r,u) = 0, \qquad r \in (0,\rho),$$
$$\dot{u}(0) = 0, \quad u(\rho) = 0 \quad \text{and} \quad p(\rho)\dot{u}(\rho) \text{ exists},$$

where $p(r) = r^{n-1}$. Under the transformation $t = t(r) = (\int_r^\rho (ds/p(s)) + 1)^{-1}, y(t) = tu(r)$, the above problem is reduced to a singular Dirichlet problem of the form (1.1), (1.2), that is,

$$\ddot{y}(t) + (p^2(r(t))/t^3) f(r(t), y/t) = 0, \qquad t \in (0,1),$$
$$y(0) = y(1) = 0, \quad y(t) \in C^1[0,1] \cap C^2(0,1),$$

where $r(t)$ is the inverse of $t(r)$.

To treat the singular problem (1.1), (1.2), we can make use of three general methods, the shooting method, the operator or topological degree method, and the lower and upper solution method. The first has been used successfully in the study of some special singular problems such as negative exponent Emden–Fowler boundary problems (cf. [1]). In fact, this method is available if one assumes that $f(t,x)$ is decreasing in x. But for other cases it often seems useless. The second method, though it has many advantages in treating nonsingular problems, still has some difficulties when treating singular problems. One can find some results concerning this method for singular problems in [2], [3], and their references. Other valuable results connected with the operator iteration technique are obtained in [4] and [5], where singular boundary value problems with more general boundary conditions have been treated under the condition that $f(t,x)$ is decreasing in x (see [6] and [7] for relevant results). The third method was developed originally for nonsingular problems. Since there are many differences between singular and nonsingular problems, using it as a general method to the singular problems is pending more basic investigations. Some attempts have been made by Zhang in [8] to treat the singular problem (1.1), (1.2) with $f(t,x) = p(t)x^{\alpha}$, where $p(t) \in C(0,1)$, $p(t) > 0, 0 < \alpha < 1$, and in [9] to treat singular boundary value problems of other forms. These and the discussion in this paper show that the lower and upper solution technique is really a very promising method for the study of singular boundary value problems.

In this paper we deal mainly with the existence of positive solutions of the singular boundary value problem (1.1), (1.2) under the following sublinear hypothesis.

(E) $f(t,x) \in C((0,1)\times(0,\infty),[0,\infty))$, $f(t,1) \not\equiv 0$ for $t \in (0,1)$, and there exist constants $\lambda, \mu, N, M (-\infty < \lambda \le \mu < 1, 0 < N \le 1 \le M)$, such that, for $t \in (0,1)$ and $x \in (0,\infty)$,

$$c^{\mu} f(t,x) \le f(t,cx) \le c^{\lambda} f(t,x), \quad \text{if } 0 \le c < N; \tag{1.3}$$

$$c^{\lambda} f(t,x) \le f(t,cx) \le c^{\mu} f(t,x), \quad \text{if } c \ge M. \tag{1.4}$$

Typical functions that satisfy the above sublinear hypothesis are those taking the form

$$f(t,x) = \sum_{k=1}^{n} p_k(t) x^{\lambda_k};$$

here $p_k(t) \in C(0,1)$, $p_k(t) > 0$ on $(0,1)$, $\lambda_k < 1, k = 1,2,\dots,n$.

We will call a function $x(t) \in C[0,1] \cap C^2(0,1)$ a $C[0,1]$ (positive) solution of (1.1), (1.2) if it satisfies (1.1) on $(0,1)$ and the boundary condition (1.2) (and $x(t) > 0$ for $t \in (0,1)$). If, in addition, $\dot{x}(0+)$ and $\dot{x}(1-)$ exist, i.e., $x(t) \in C^1[0,1] \cap C^2(0,1)$, we will call it a $C^1[0,1]$ (positive) solution. Here we point out that, under the condition (E), any nontrivial nonnegative solution of (1.1), (1.2) is in fact a positive solution, since it is a concave function.

The main results of this paper are the following two theorems which will be proved in §3.

THEOREM 1. *Suppose* (E) *holds. Then a necessary and sufficient condition for problem* (1.1), (1.2) *to have a* $C[0,1]$ *positive solution is that*

$$\int_0^1 t(1-t) f(t,1)\, dt < \infty. \tag{1.5}$$

THEOREM 2. *Suppose* (E) *holds. Then a necessary and sufficient condition for problem* (1.1), (1.2) *to have a* $C^1[0,1]$ *positive solution is that*

$$\int_0^1 f(t, t(1-t))\,dt < \infty. \tag{1.6}$$

With respect to relevant results, the author would like to point out that a condition similar to (1.6) has been used by Gatica, Oliker, and Waltman in [4] to obtain $C^1[0,1]$ solutions to singular problems with mixed boundary conditions. The assumption that $f(t,x)$ is decreasing in x is a crucial condition there. Within the scope of Dirichlet problems, the sufficiency part of our Theorem 2 extends their Theorem 2.2, but does not include it.

Though the uniqueness seems to be a property typical of sublinear problems, fully studying it is not easy, especially when $f(t,x)$ has no monotone property in x. We will discuss the uniqueness in §4, where we will mainly prove the following uniqueness theorem.

THEOREM 3. *Suppose that*

(U) $f(t,x) \in C((0,1)\times(0,\infty),[0,\infty))$, *and* $f(t,x)/x$ *is strictly decreasing in* x *for all* $t \in (0,1)$.

Then, if problem (1.1), (1.2) *has a* $C^1[0,1]$ *positive solution, it will admit no other positive solutions.*

As an application of the above theorems we will discuss the existence and uniqueness of radial solutions to Dirichlet problems of semilinear elliptic equations in §5.

2. Preliminary lemmas.

LEMMA 1. *For any* $f(t) \in L^1[0,1]$, *there exists* $g(t) \in C[0,1]$ *with* $g(t) > 0$ *for* $t \in (0,1)$ *and* $g(0) = g(1) = 0$, *such that* $f(t)/g(t) \in L^1[0,1]$.

Proof. Suppose $f(t) \in L^1[0,1]$. Without loss of generality we can assume $f(t) > 0$ for $t \in [0,1]$. Let $l = \int_0^1 f(t)\,dt$, $h(t) = \int_0^t f(s)\,ds$, and, for any given $\varepsilon : 0 < \varepsilon < 1$, let

$$g(t) = [h(t)(l - h(t))]^{\varepsilon}, \qquad t \in [0,1].$$

Then $g(t) \in C[0,1]$, $g(t) > 0$ for $t \in (0,1)$, and $g(0) = g(1) = 0$. Also,

$$0 < \int_0^1 (f(t)/g(t))\,dt = \int_0^l [h(l-h)]^{-\varepsilon}\,dh < \infty.$$

This shows $f(t)/g(t) \in L^1[0,1]$ and hence completes the proof. □

LEMMA 2. *For any* $g(t) \in C[0,1]$ *such that* $g(0) = g(1) = 0$ *and* $g(t) \geq 0$ *for* $t \in [0,1]$, *there exists* $q(t) \in C[0,1] \cap C^2(0,1)$ *such that* $q(0) = q(1) = 0, q(t) \geq g(t)$, *and* $q''(t) \leq 0$ *for* $t \in (0,1)$.

The proof of Lemma 2 will be given in the appendix because of the lengthy argument there involved.

Now let us consider the general singular boundary value problems as follows:

$$\ddot{x} + f(t,x) = 0, \qquad t \in (0,1), \tag{2.1}$$

$$x(0) = r_1, \qquad x(1) = r_2, \tag{2.2}$$

where we assume $f(t,x) \in C((0,1)\times I, R), r_1, r_2 \in I, I$ is an interval in R.

A function $\alpha(t)$ is called a lower solution of (2.1) if $\alpha(t) \in C^2(0,1)$ and, for $t \in (0,1), \alpha(t) \in I, \ddot{\alpha}(t) + f(t,\alpha(t)) \geq 0$. Similarly, $\beta(t)$ is called an upper solution of (2.1) if $\beta(t) \in C^2(0,1)$ and, for $t \in (0,1), \beta(t) \in I, \ddot{\beta}(t) + f(t,\beta(t)) \leq 0$.

LEMMA 3. *Assume that there exist lower and upper solutions of* (2.1), *respectively* $\alpha(t)$ *and* $\beta(t)$, *such that* $\alpha(t), \beta(t) \in C[0,1] \cap C^2(0,1), \alpha(t) \leq \beta(t)$ *for* $t \in [0,1], \alpha(0) = \beta(0) = r_1$, *and* $\alpha(1) = \beta(1) = r_2$. *Then problem* (2.1), (2.2) *admits at least one* $C[0,1]$ *solution* $x(t)$ *such that* $\alpha(t) \leq x(t) \leq \beta(t)$ *for* $t \in [0,1]$. *If, in addition, there exists* $F(t) \in L^1[0,1]$ *such that*

$$|f(t,x)| \leq F(t), \qquad t \in (0,1), \quad \alpha(t) \leq x \leq \beta(t), \tag{2.3}$$

then the solution $x(t)$ *is a* $C^1[0,1]$ *solution.*

Proof. Let $\{a_n\}, \{b_n\}$ be sequences satisfying $0 < \cdots < a_{n+1} < a_n < \cdots < a_1 < b_1 < \cdots < b_n < b_{n+1} < \cdots < 1, a_n \to 0$ and $b_n \to 1$ as $n \to \infty$, and let $\{r_1^{(n)}\}, \{r_2^{(n)}\}$ be sequences satisfying $\alpha(a_n) \leq r_1^{(n)} \leq \beta(a_n), \alpha(b_n) \leq r_2^{(n)} \leq \beta(b_n), n = 1, 2, \ldots$. For each n consider the nonsingular problem

$$\ddot{x} + f(t,x) = 0, \tag{2.1}$$

$$x(a_n) = r_1^{(n)}, \qquad x(b_n) = r_2^{(n)}. \tag{2.4}$$

By a well-known corresponding result in nonsingular boundary value problems (see [13, Thm. 1.5.1]), we come to the conclusion that, for each n, the problem (2.1), (2.4) admits a solution $x_n(t) \in C^2[a_n, b_n]$ such that $\alpha(t) \leq x_n(t) \leq \beta(t), t \in [a_n, b_n]$. Since $[a_1, b_1] \subset [a_n, b_n], n = 1, 2, \ldots$, there is, for each $n, t_n \in [a_1, b_1]$ such that $|\dot{x}_n(t_n)| = |(x_n(b_1) - x_n(a_1))/(b_1 - a_1)| \leq (2/(b_1 - a_1)) \max_{t \in [a_1, b_1]}(|\alpha(t)| + |\beta(t)|)$. This allows us to assume (substituting by subsequences if necessary)

$$t_n \to t_0 \in [a_1, b_1], \quad x_n(t_n) \to x_0 \in [\alpha(t_0), \beta(t_0)], \quad x_n(t_n) \to x_0' \in R, \quad \text{as } n \to \infty.$$

From [14, Thm. 3.2, p. 14] there is a solution $x(t)$ of (2.1), with the maximum existence interval (ω^-, ω^+), such that $x(t_0) = x_0, \dot{x}(t_0) = x_0'$, and $x_n(t)$ converges uniformly to $x(t)$ on any compact subinterval of (ω^-, ω^+). Since

$$[a_n, b_n] \subset [a_{n+1}, b_{n+1}], \quad \bigcup_{n=1}^{\infty} [a_n, b_n] = (0,1) \quad \text{and} \quad \alpha(t) \leq x_n(t) \leq \beta(t) \quad \text{for} \quad t \in [a_n, b_n],$$

one can easily see that $\alpha(t) \leq x(t) \leq \beta(t)$ for $t \in (\omega^-, \omega^+)$. This leads additionally to the fact that $(\omega^-, \omega^+) = (0,1)$, from the Extension Theorem. Also, $x(t)$ satisfies (2.2) because $\alpha(t)$ and $\beta(t)$ do. Thus, $x(t)$ is a $C[0,1]$ solution of (2.1), (2.2).

In addition, if (2.3) holds, then $|\ddot{x}(t)| \leq F(t)$, and hence $\ddot{x}(t)$ is absolutely integrable on $[0,1]$. This implies $x(t) \in C^1[0,1]$, so $x(t)$ is a $C^1[0,1]$ solution of the problem (2.1), (2.2). The proof is complete. □

3. Proof of the main existence results. It is easy to check that in the hypothesis (E) the number λ, μ can be assumed, without loss of generality, to satisfy $\lambda < 0 < \mu < 1$. This will be supposed throughout this section for convenience.

Proof of Theorem 1. 1°. Necessity. Assume that $x(t)$ is a $C[0,1]$ positive solution of problem (1.1), (1.2). Then there is a t_0 such that $\dot{x}(t_0) = 0$, and hence

$$-\dot{x}(t) = \int_{t_0}^{t} f(s, x(s))\, ds, \qquad t \in (0,1). \tag{3.1}$$

Let $c > 0$ be a constant such that $cx(t) \le N$ for $t \in [0,1]$ and $1/c \ge M$. From (1.3) and (1.4) we have

$$f(t,x(t)) \ge (1/c)^{\lambda} f(t,cx(t)) \ge c^{\mu-\lambda} x^{\mu}(t) f(t,1), \qquad t \in (0,1). \tag{3.2}$$

(3.1) as well as condition (E) implies that $\dot{x}(t) \ge 0$ (i.e., $x(t)$ increases) for $t \in (0,t_0)$, and $\dot{x}(t) \le 0$ (i.e., $x(t)$ decreases) for $t \in (t_0,1)$. This, combined with (3.2), yields

$$\begin{aligned} \dot{x}(t) = \int_t^{t_0} f(s,x(s))\,ds &\ge c^{\mu-\lambda} \int_t^{t_0} x^{\mu}(s) f(s,1)\,ds \\ &\ge c^{\mu-\lambda} x^{\mu}(t) \int_t^{t_0} f(s,1)\,ds, \qquad t \in (0,t_0), \end{aligned}$$

and

$$-\dot{x}(t) = \int_{t_0}^{t} f(s,x(s))\,ds \ge c^{\mu-\lambda} x^{\mu}(t) \int_{t_0}^{t} f(s,1)\,ds, \qquad t \in (t_0,1).$$

Dividing both sides of each of the above two inequalities by $c^{\mu-\lambda}x^{\mu}(t)$ and then integrating them, respectively, on $[0,t_0]$ and $[t_0,1]$ we have

$$\begin{aligned} 0 < \int_0^{t_0} t f(t,1)\,dt &= \int_0^{t_0} dt \int_t^{t_0} f(s,1)\,ds \le c^{\lambda-\mu} x^{1-\mu}(t_0)/(1-\mu) < \infty, \\ 0 < \int_0^{1} (1-t) f(t,1)\,dt &= \int_{t_0}^{1} dt \int_{t_0}^{t} f(s,1)\,ds \le c^{\lambda-\mu} x^{1-\mu}(t_0)/(1-\mu) < \infty. \end{aligned}$$

These imply that (1.5) holds.

2°. Sufficiency. Suppose (1.5) holds. Then, by Lemmas 1 and 2, there exists $q(t) \in C[0,1] \cap C^2(0,1)$ satisfying $q(t) > 0$ and $q''(t) \le 0$ for $t \in (0,1)$, and $q(0) = q(1) = 0$, such that

$$\int_0^1 t(1-t) q^{\lambda-\mu}(t) f(t,1)\,dt < \infty. \tag{3.3}$$

This, together with (1.3) and (1.4), implies

$$\int_0^1 t(1-t) q^{-\mu}(t) f(t,q(t))\,dt < \infty. \tag{3.4}$$

Let

$$\begin{aligned} \Gamma_1 &= (1-t) \int_0^t s^{1+\mu}(1-s)^{\mu} f(s,1)\,ds + t \int_t^1 s^{\mu}(1-s)^{1+\mu} f(s,1)\,ds, \\ \Gamma_2 &= (1-t) \int_0^t s q^{-\mu}(s) f(s,q(s))\,ds + t \int_t^1 (1-s) q^{-\mu}(s) f(s,q(s))\,ds + q(t). \end{aligned}$$

One can check that $\Gamma_i \in C[0,1] \cap C^2(0,1), \Gamma_i(0) = \Gamma_i(1) = 0, i = 1,2$, and

$$L_1 t(1-t) \le \Gamma_1(t) \le L_1, \quad q(t) \le \Gamma_2(t) \le L_2, \quad t \in [0,1];$$

$$\Gamma_1''(t) = -t^{\mu}(1-t)^{\mu} f(t,1), \quad \Gamma_2''(t) \le -q^{-\mu}(t) f(t,q(t)), \quad t \in (0,1).$$

Here

$$L_1 = \int_0^1 s^{1+\mu}(1-s)^{1+\mu} f(s,1)\,ds,$$

$$L_2 = \int_0^1 s(1-s)q^{-\mu}(s) f(s,q(s))\,ds + q_0, \qquad q_0 = \max_{t\in[0,1]} q(t).$$

Let $\alpha(t) = a\Gamma_1(t), \beta(t) = b\Gamma_2(t), t \in [0,1]$; here a, b are constants satisfying $0 < a \le 1 \le b$, and their sizes will be determined later. Suppose c_1, c_2 are constants such that $c_1 L_1 \le N, 1/c_1 \ge M, c_2 \ge M, 1/c_2 \le N$. From (1.3), (1.4) we then have

$$\begin{aligned} f(t,\alpha(t)) &\ge (1/c_1)^\lambda f(t, c_1\alpha(t)) \ge c_1^{\mu-\lambda}\alpha^\mu(t) f(t,1) \\ &\ge a^\mu L_1^\mu c_1^{\mu-\lambda} t^\mu (1-t)^\mu f(t,1), \qquad t \in (0,1), \\ f(t,\beta(t)) &\le c_2^{\mu-\lambda}(\beta(t)/q(t))^\mu f(t,q(t)) \\ &\le b^\mu L_2^\mu c_2^{\mu-\lambda} q^{-\mu}(t) f(t,q(t)), \qquad t \in (0,1). \end{aligned}$$

Again, according to (1.3), (1.4) we can find a $k_0 > 0$ such that $f(t,q(t)) \ge k_0 q^\mu(t)$ $f(t,1)$, and consequently, from the definitions of $\Gamma_1(t), \Gamma_2(t)$, we have, when $k > k_0^{-1}, \Gamma_1(t) \le k\Gamma_2(t)$ for $t \in [0,1]$.

Now we choose $a = \min\{1, (L_1^\mu c_1^{\mu-\lambda})^{1/(1-\mu)}\}$ and $b = \max\{1, k_0^{-1}, (L_2^\mu c_2^{\mu-\lambda})^{1/(1-\mu)}\}$. Then the above discussions show that, for such choice of a and $b, \alpha(t)$ and $\beta(t)$ are lower and upper solutions of (1.1), respectively, and satisfy $0 < \alpha(t) \le \beta(t)$ for $t \in (0,1)$ and $\alpha(i) = \beta(i) = 0$ for $i = 0, 1$. From the first conclusion of Lemma 3 we deduce that the problem (1.1), (1.2) admits a $C[0,1]$ solution $x(t)$ satisfying $0 < \alpha(t) \le x(t) \le \beta(t)$ for $t \in (0,1)$. This completes the proof. □

Proof of Theorem 2. 1°. Necessity. Assume that $x(t)$ is a $C^1[0,1]$ positive solution of (1.1), (1.2). Then $\dot{x}(0) > 0$ and $\dot{x}(1) < 0$ since (1.2) holds and $\ddot{x}(t) \le 0, x(t) > 0$ for $t \in (0,1)$. This implies that there are constants I_1 and $I_2, 0 < I_1 < I_2$, such that

$$I_1 t(1-t) \le x(t) \le I_2 t(1-t), \qquad t \in [0,1]. \tag{3.5}$$

Let c be a constant satisfying $cI_2 \le N, 1/c \ge M$. Then (1.3), (1.4), and (3.5) lead to

$$\begin{aligned} f(t,x(t)) &\ge (1/c)^\lambda f\left(t, \frac{cx(t)}{t(1-t)} t(1-t)\right) \\ &\ge c^{\mu-\lambda}(x(t)/t(1-t))^\mu f(t, t(1-t)) \\ &\ge c^{\mu-\lambda} I_1^\mu f(t, t(1-t)), \qquad t \in (0,1). \end{aligned}$$

Dividing by $c^{\mu-\lambda} I_1^\mu$ and integrating, we get

$$\begin{aligned} \int_0^1 f(t, t(1-t))\,dt &\le c^{\lambda-\mu} I_1^{-\mu} \int_0^1 f(t,x(t))\,dt \\ &= c^{\lambda-\mu} I_1^{-\mu}(\dot{x}(0) - \dot{x}(1)) < \infty. \end{aligned}$$

Thus (1.6) has been derived.

2°. Sufficiency. Suppose that (1.6) holds. Let

$$\Gamma(t) = (1-t)\int_0^t s f(s, s(1-s))\,ds + t\int_t^1 (1-s) f(s, s(1-s))\,ds.$$

Then $\Gamma(t) \in C[0,1] \cap C^2(0,1)$ and (3.5) holds if $x(t)$ is replaced by $\Gamma(t)$ and $I_1 = \int_0^1 t(1-t)f(t,t(1-t))\,dt, I_2 = \int_0^1 f(t,t(1-t))\,dt$. Let $\alpha(t) = a\Gamma(t), \beta(t) = b\Gamma(t)$; here $a = \min\{1, (\bar{c}^{\lambda-\mu}I_2^{\lambda})^{1/(1-\mu)}\}, b = \max\{1, (\bar{c}^{\mu-\lambda}I_2^{\mu})^{1/(1-\mu)}\}, \bar{c}$ is a constant satisfying $\bar{c}I_1 \geq M, 1/\bar{c} \leq N$. A similar argument to that we have clarified in part 2° of the proof of Theorem 1 yields that, for $t \in (0,1)$,

$$\begin{aligned}
\ddot{a}(t) + f(t,\alpha(t)) &= -af(t,t(1-t)) + f(t,a\Gamma(t)) \\
&\geq -af(t,t(1-t)) + a^{\mu}\bar{c}^{\lambda-\mu}I_2^{\lambda}f(t,t(1-t)) \geq 0, \\
\ddot{\beta}(t) + f(t,\beta(t)) &= -bf(t,t(1-t)) + f(t,b\Gamma(t)) \\
&\leq -bf(t,t(1-t)) + b^{\mu}\bar{c}^{\mu-\lambda}I_2^{\mu}f(t,t(1-t)) \leq 0.
\end{aligned}$$

So $\alpha(t), \beta(t)$ are, respectively, lower and upper solutions of (1.1), satisfying $0 < \alpha(t) \leq \beta(t)$ for $t \in (0,1)$ and $\alpha(i) = \beta(i) = 0, i = 0,1$. Additionally, when $t \in (0,1)$ and $\alpha(t) \leq x \leq \beta(t)$,

$$\begin{aligned}
0 \leq f(t,x) &\leq (a/\bar{c})^{\lambda} f\left(t, \frac{\bar{c}x}{at(1-t)}t(1-t)\right) \\
&\leq (a/\bar{c})^{\lambda}\left(\frac{\bar{c}x}{at(1-t)}\right)^{\mu} f(t,t(1-t)) \\
&\leq (a/\bar{c})^{\lambda-\mu}(bI_2)^{\mu}f(t,t(1-t)) =: F(t).
\end{aligned}$$

From (1.6) we assert $\int_0^1 F(t)\,dt < \infty$. Thus, according to Lemma 3, we have proved that the problem (1.1), (1.2) admits a $C^1[0,1]$ solution $x(t)$ such that $\alpha(t) \leq x(t) \leq \beta(t)$ for $t \in [0,1]$. This completes the proof. □

4. Uniqueness. In this section we make a brief discussion on the uniqueness of the solution of problem (1.1), (1.2). We can assert the uniqueness for two special cases. The first is that $f(t,x)$ is decreasing in x; the second is that $f(t,x)/x$ is decreasing in x. In the former case the uniqueness is easy to obtain through a standard argument. In fact, in this case, for two solutions of (1.1), say $x_1(t), x_2(t)$, with $x_1(t_i) = x_2(t_i), i = 1,2, x_1(t) \leq x_2(t)$ for $t \in (t_1,t_2)$, where $0 \leq t_1 \leq t_2 \leq 1$, it must be true that $\lim_{t\to t_1}\sup(x_2'(t) - x_1'(t)) \geq 0, \lim_{t\to t_2}\inf(x_2'(t) - x_1'(t)) \leq 0$ and $x_2''(t) - x_1''(t) = f(t,x_1(t)) - f(t,x_2(t)) \geq 0$ for $t \in (t_1,t_2)$, which assure one that $x_1(t) \equiv x_2(t)$ for $t \in [t_1,t_2]$, and hence imply that problem (1.1), (1.2) has at most one solution. In the latter case, using the method given by the author in [8, Lemma 2], we can obtain our Theorem 3. Here we give the proof as follows.

Proof of Theorem 3. Suppose conversely that $x_1(t), x_2(t)$ are different positive solutions of (1.1), (1.2), with

$$x_1(t_i) = x_2(t_i), \quad i = 1,2, \quad 0 < x_1(t) < x_2(t) \quad \text{for } t \in (t_1,t_2), \tag{4.1}$$

and at least one of them is a $C^1[0,1]$ solution. Here t_1, t_2 are some points in $[0,1]$ with $t_1 < t_2$. Then it must be true that $x_1(t) \in C^1[t_1,t_2]$, otherwise we would have $x_2(t) \in C^1[t_1,t_2]$ and $x_1'(t_1^+) = +\infty$ (or $x_1(t_2^-) = -\infty$) since $x_1''(t) \leq 0$, which is impossible because of (4.1).

Since $x_2''(t) \leq 0$ on $(t_1,t_2), x_2(t_1^+)(x_2(t_2^-))$ is either existent or $= +\infty(-\infty)$. This, together with (4.1), yields

$$\lim_{t\to t_1}(x_2'(t) - x_1'(t)) \geq 0, \qquad \lim_{t\to t_2}(x_2'(t) - x_1'(t)) \leq 0.$$

Let $y(t) = x_1(t)x_2'(t) - x_2(t)x_1'(t), t \in (t_1, t_2)$. The above discussion shows $y(t_1^+) \geq y(t_2^-)$. On the other hand, for $t \in (t_1, t_2)$,

$$\begin{aligned} y'(t) &= x_1(t)x_1''(t) - x_2(t)x_1''(t) \\ &= x_1(t)x_2(t)(f(t, x_1(t))/x_1(t) - f(t, x_2(t))/x_2(t)) > 0, \end{aligned}$$

which implies $y(t_2^-) > y(t_1^+)$, a contradiction that proves our conclusion. The proof is complete. □

Remark 1. Condition (U) in Theorem 3 is sharp in the sense that, when $f(t, x)$ is linear in x, the solution of (1.1), (1.2), if any, is not unique.

Remark 2. Besides [8], the function $y(t)$ has also been used to obtain a uniqueness result in [6].

Combining Theorems 2 and 3, we immediately get the following corollary.

COROLLARY 1. *Suppose that conditions* (E) *and* (U) *hold. Then problem* (1.1), (1.2) *has a unique positive solution which is a* $C^1[0, 1]$ *solution, provided* (1.6) *is fulfilled.*

5. Application to subcritical elliptic problems. To show the application of our results to elliptic boundary value problems we consider two kinds of problems.

First, we consider the Dirichlet problem of elliptic equations

$$\Delta u + \sum_{k=1}^{m} p_k(|x|)u^{\lambda_k} = 0, \qquad x \in \Omega,$$

(5.1)

$$u(x)|_{\partial\Omega} = 0, \qquad \left.\frac{\partial u}{\partial \vec{n}}\right|_{\partial\Omega} \text{ exists.}$$

Here Ω is an n-ball of radius ρ centered at $0 \in R^n, 0 < \rho < +\infty, n \geq 2, p_k(r) \in C[0, \rho), p_k > 0$ on $[0, \rho), -\infty < \lambda_k < 1, k = 1, 2, \ldots, m$.

As we show at the beginning of §1 (where we should note that some important relations have been omitted, among them $t'(r) = t^2/p(r), p(r)u'(r) = t\dot{y}(t) - y(t)$, and, when $y(t)$ is a $C^1[0, 1]$ solution of the final problem, $\lim_{t\to 0} y(t)/t = \dot{y}(0) > 0$ and $\lim_{r\to 0}(t\dot{y}(t) - y(t))/p(r) = \lim_{r\to 0} t\ddot{y}(t)t'(r)/p'(r) = -\lim_{r\to 0} p(r)f(r, y(t)/t)/p'(r) = 0$), seeking the positive radial solutions of (5.1) is equivalent to seeking the positive solutions of the following boundary value problem of ordinary differential equations:

$$\begin{aligned} &\ddot{y} + F(t, y) = 0, \qquad t \in (0, 1), \\ &y(0) = y(1) = 0, \qquad y(t) \in C^1[0, 1], \end{aligned}$$

where

$$F(t, y) = (r(t))^{2(n-1)} \sum_{k=1}^{m} (p_k(r(t))/t^{3+\lambda_k})y^{\lambda_k}.$$

Since

$$\int_0^1 F(t, t(1-t))\, dt = \int_0^\rho (r^{n-1}/t(r)) \sum_{k=1}^{m} p_k(r)(1 - t(r))^{\lambda_k}\, dr,$$

and

$$t(r) = \begin{cases} \left(\int_r^\rho s^{-(n-1)}\, ds + 1\right)^{-1} \sim r^{n-2}, & \text{as } r \to 0, \text{ if } n > 2 \\ (\ln\rho - \ln r + 1)^{-1}, & \text{if } n = 2, \end{cases}$$

$$(1 - t(r)) = \left(\int_r^\rho s^{-(n-1)}\, ds + 1\right)^{-1} \int_r^\rho s^{-(n-1)}\, ds \sim (\rho - r), \quad \text{as } r \to \rho,$$

the convergence of $\int_0^1 F(t,t(1-t))\,dt$ is equivalent to that of $\int_0^\rho r\sum_{k=1}^m p_k(r)(\rho-r)^{\lambda_k}\,dr$ (when $n>2$) or $\int_0^\rho r(\ln\rho-\ln r+1)\sum_{k=1}^m p_k(r)(\rho-r)^{\lambda_k}\,dr$ (when $n=2$). Hence, according to Theorem 2 and Corollary 1, and taking note of the continuity of $p_k(r)$ at $r=0$, we immediately deduce the following result.

COROLLARY 2. *Problem* (5.1) *possesses a positive radial solution if and only if* $\int_0^\rho p_k(r)(\rho-r)^{\lambda_k}\,dr<\infty$ *for each* $k=1,2,\dots,m$. *Moreover, the solution, if any, is unique.*

Now we consider the second problem

$$\begin{aligned}&\Delta u+f(|x|,u)=0,\quad x\in R^n,\quad n>2,\\ &\lim_{|x|\to\infty}u(x)=0.\end{aligned}\tag{5.2}$$

We give a nonexistence result as follows.

COROLLARY 3. *Suppose that* $f(r,u)=[0,\infty)\times(0,\infty)\to[0,\infty)$ *is continuous and satisfies condition* (E) *by replacing* t *there by* $r\in[0,\infty)$. *Then, if* $\int_0^\infty rf(r,1)\,dr$ *is nonconvergent, problem* (5.2) *admits no positive radial solutions.*

Proof. If (5.2) admits a positive radial solution, then, using the same transformation given at the beginning of §1, we will deduce that there exists at least a $C[0,1]$ positive solution (belonging to $C^1[0,1)$ in fact) of the problem

$$\begin{aligned}&\ddot{y}+(p^2(r(t))/t^3)f(r(t),y/t)=0\qquad t\in(0,1),\\ &y(0)=y(1)=0.\end{aligned}\tag{5.3}$$

But we have, on the other hand, that

$$\begin{aligned}\int_0^1 t(1-t)(p^2(r(t))/t^3)f(r(t),1/t)\,dt&=\int_0^\infty(1-t(r))p(r)f(r,1/t(r))\,dr\\ &\geq c\int_0^\infty(1-t(r))p(r)t(r)^{-\lambda}f(r,1)\,dr=\infty,\end{aligned}$$

since (E) holds and $t(r)\to 1, p(r)(1-t(r))\sim r$, as $r\to\infty$. Here $c>0$ is some constant. According to Theorem 1, the above relation implies that (5.3) cannot have a positive solution. This contradiction assures us that the conclusion of this corollary must be true. The proof is complete.

Remark. We refer to [10] and [11] for further information on Dirichlet problems concerning semilinear elliptic equations in bounded and unbounded domains. About the significance of finding radial solutions we recall the celebrated result in [12], which asserts that a solution of $\Delta u+f(u)=0, u(x)|_{\partial\Omega}=0$, where Ω is an n-ball, is indeed radially symmetric.

6. Appendix. Although the geometric significance of Lemma 2 is very clear, the analytic demonstration is somewhat complicated. The proof is divided into two steps.

Step 1. Let $g(t)\in C[0,1]$ be given such that $g(t)\geq 0$ on $[0,1]$ and $g(0)=g(1)=0$. We prove there exist point sequences (t_n,x_n) and $(\bar{t}_n,\bar{x}_n), n=0,1,2,\dots$, with $t_0=\bar{t}_0=\frac{1}{2}$ and $x_0=\bar{x}_0>0$, such that

1°. $0<\cdots<t_{n+1}<t_n<\cdots<t_1<t_0(=\frac{1}{2}), t_n\to 0$ as $n\to\infty$;

2°. $x_n\to 0$ as $n\to\infty, k_{n+1}>k_n>0$, and $k_n(t-t_n)+x_n\geq g(t)$ for $t\in[t_{n+1},t_n], n=0,1,2,\dots$, here $k_n=(x_{n+1}-x_n)/(t_{n+1}-t_n)$;

3°. $\bar{t}_0(=t_0) < \bar{t}_1 < \cdots < \bar{t}_n < \bar{t}_{n+1} < \cdots < 1, \bar{t}_n \to 1$ as $n \to \infty$;

4°. $\bar{x}_n \to 0$ as $n \to \infty, \bar{k}_{n+1} < \bar{k}_n < 0$ and $\bar{k}_n(t - \bar{t}_n) + \bar{x}_n \geq g(t)$ for $t \in [\bar{t}_n, \bar{t}_{n+1}], n = 0, 1, 2, \ldots$, here $\bar{k}_n = (\bar{x}_{n+1} - \bar{x}_n)/(\bar{t}_{n+1} - \bar{t}_n)$.

The existence of the points $(t_n, x_n), n = 0, 1, 2, \ldots$, for which 1° and 2° hold can be clarified as follows.

In fact, if there is an $I > 0$ such that $It \geq g(t)$ for $t \in [0, 1]$, then there is a $c_0 > 0$ such that, when $c > c_0, p(t) =: c[\frac{1}{4} - (t - \frac{1}{2})^2]^{1/2} \geq It \geq g(t)$ for $t \in [0, \frac{1}{2}]$. Fix $c > c_0$ sufficiently large and let $\{t_n\}$ be a sequence such that 1° holds. Take $x_n = p(t_n), n = 0, 1, 2, \ldots$; then 2° holds automatically since (t_n, x_n) are, successively, on an elliptic curve.

If the number I does not exist, then fix $t_0 = \frac{1}{2}, x_0 \geq 1 + \max g(t)$ at first, and then choose $(t_n, x_n), n = 1, 2, \ldots$, step by step as follows.

Let k_0 be the number such that $I_0(t) =: k_0(t - t_0) + x_0 \geq g(t)$ for $t \in [0, 1]$ and $I_0(\hat{t}) = g(\hat{t})$ for some $\hat{t} \in [0, t_0)$ (such a number is of course uniquely existent). It is easy to see that $k_0 > 0$ and there is a $t_0^* \in (0, t_0)$ such that $I_0(t) > g(t)$ for $t \in [0, t_0^*)$ and $I_0(t_0^*) = g(t_0^*)$.

Take $t_1 = \frac{1}{2}t_0^*, x_1 = I_0(t_1)$. We have $0 < x_1 < x_0$ and $(x_1 - x_0)/(t_1 - t_0) = k_0$. Denote by k_1 the number that satisfies $I_1(t) =: k_1(t - t_1) + x_1 \geq g(t)$ for $t \in [0, 1]$, and $I_1(\hat{t}) = g(\hat{t})$ for some $\hat{t} \in [0, t_1)$. We have, obviously, that $k_1 > k_0$ and there is a $t_1^* \in (0, t_1)$ such that $I_1(t) > g(t)$ for $t \in [0, t_1^*)$ and $I_1(t_1^*) = g(t_1^*)$.

We then take $t_2 = \frac{1}{2}t_1^*, x_2 = I_1(t_2)$. It implies that $0 < x_2 < x_1$ and $(x_2 - x_1)/(t_2 - t_1) = k_1$.

Generally, when $t_n = \frac{1}{2}t_{n-1}^*, x_n = I_{n-1}(t_n)(>0)$ have been taken, we denote by k_n the number that satisfies $I_n(t) =: k_n(t - t_n) + x_n \geq g(t)$ for $t \in [0, 1]$ and $I_n(\hat{t}) = g(\hat{t})$ for some $\hat{t} \in [0, t_n)$. Then it is true that $k_n > k_{n-1} = (x_n - x_{n-1})/(t_n - t_{n-1})$, and there is a $t_n^* \in (0, t_n)$ such that $I_n(t) > g(t)$ for $t \in [0, t_n^*), I_n(t_n^*) = g(t_n^*)$. We then take $t_{n+1} = t_n^*/2$ and $x_{n+1} = I_n(t_{n+1})$. Obviously, $0 < x_{n+1} < x_n$ and $(x_{n+1} - x_n)/(t_{n+1} - t_n) = k_n$.

So we have proved the existence of the sequence $(t_n, x_n), n = 0, 1, 2, \ldots$, which satisfies 1° and 2°. The points $(\bar{t}_n, \bar{x}_n), n = 0, 1, 2, \ldots$, for which 3° and 4° hold can be gotten in a similar way. And one can adjust x_0 or $\bar{x}_0$ so that $x_0 = \bar{x}_0$ holds. We leave the details to the reader.

Step 2. For any given constants a, b, δ_1, and δ_2 such that $\delta_1 > b - a > \delta_2$, let $m(t) = m(a, b, \delta_1, \delta_2, t) \in C^2[0, 1]$ be a function such that the following conditions hold:

$$\begin{aligned} &m(0) = a, \quad m(1) = b, \quad \dot{m}(0) = \delta_1, \quad \dot{m}(1) = \delta_2, \\ &\ddot{m}(0) = \ddot{m}(1) = 0 \quad \text{and} \quad \ddot{m}(t) \leq 0 \quad \text{for } t \in [0, 1]. \end{aligned} \tag{4.1}$$

To devise a way to construct such a function, let us consider the following example. Take an integer n such that $(n + 1)[\delta_1 - (b - a)] - [(b - a) - \delta_2] > 0$; write

$$\varepsilon = [(n + 1)(\delta_1 - (b - a)) - ((b - a) - \delta_2)]/[(b - a) - \delta_2](> 0)$$

and

$$I = \frac{\delta_1 - \delta_2}{n!}(\varepsilon + 1)(\varepsilon + 2)\ldots(\varepsilon + n + 1),$$

and let $m(t) = a + \delta_1 t - I\int_0^t (t - s)s^n(1 - s)^\varepsilon \, ds$. Then one can examine whether the conditions in (4.1) are all valid (to check this, one should notice that, for any integer n and $\varepsilon > 0, \int_0^1 s^n(1 - s)^\varepsilon \, ds = \int_0^1 (1 - s)^n s^\varepsilon \, ds = n!/(\varepsilon + 1)(\varepsilon + 2)\ldots(\varepsilon + n + 1)$).

Write

$$\delta_{1n} = \frac{k_n + k_{n+1}}{2}(t_n - t_{n+1}), \quad \delta_{2n} = \frac{k_n + k_{n-1}}{2}(t_n - t_{n+1}),$$
$$\bar{\delta}_{1n} = \frac{\bar{k}_n + \bar{k}_{n-1}}{2}(\bar{t}_{n+1} - \bar{t}_n) \quad \text{and} \quad \bar{\delta}_{2n} = \frac{\bar{k}_n + \bar{k}_{n+1}}{2}(\bar{t}_{n+1} - \bar{t}_n),$$

and let

$$m_n(t) = m(x_{n+1}, x_n, \delta_{1n}, \delta_{2n}, t), \bar{m}_n(t) = m(\bar{x}_n, \bar{x}_{n+1}, \bar{\delta}_{1n}, \bar{\delta}_{2n}, t),$$
$$t \in [0,1], n = 0, 1, 2, \ldots,$$

where t_n, x_n, k_n and $\bar{t}_n, \bar{x}_n, \bar{k}_n$ are those constants obtained in step 1, $k_{-1} = \bar{k}_0, \bar{k}_{-1} = k_0$. Now we define $q(t)$ as follows:

$$q(t) = \begin{cases} m_n((t - t_{n+1})/(t_n - t_{n+1})), & t \in [t_{n+1}, t_n], \\ m_n((t - \bar{t}_n)/(\bar{t}_{n+1} - \bar{t}_n)), & t \in [\bar{t}_n, \bar{t}_{n+1}], \\ 0 & t = 0, 1. \end{cases}$$

It is easy to check that $q(t) \in C[0,1] \cap C^2(0,1)$ and satisfies $q''(t) \leq 0$ for $t \in (0,1), q(t_n) = x_n, q(\bar{t}_n) = \bar{x}_n, n = 0, 1, 2, \ldots$. Also, $q(t) \geq k_n(t - t_n) + x_n \geq g(t)$ for $t \in [t_{n+1}, t_n]$ and $q(t) \geq \bar{k}_n(t - \bar{t}_n) + \bar{x}_n \geq g(t)$ for $t \in [\bar{t}_n, \bar{t}_{n+1}], n = 0, 1, 2, \ldots$, since $q(t)$ is a concave function. This completes the proof. □

PARAMETER DEPENDENCE OF PROPAGATION SPEED OF TRAVELLING WAVES FOR COMPETITION-DIFFUSION EQUATIONS*

YUKIO KAN-ON†

Abstract. In this paper, travelling wave solutions for certain competition-diffusion equations are considered, and the monotone dependence of their propagation speed on parameters which appear in the equation are established. To do this, the maximum principle and the bifurcation theory for heteroclinic orbits are employed.

Key words. travelling wave solution, competition-diffusion equation, exponential dichotomy

AMS subject classification. 34C37

1. Introduction.

There have been many studies of reaction-diffusion equations of the form

$$\tilde{u}_t = D\,\tilde{u}_{xx} + \tilde{f}(\tilde{u}), \quad x \in \mathbf{R}, \quad t > 0 \tag{1.1}$$

to explain phenomena that appear in various fields, where $\tilde{u} = (\tilde{u}_j)$ and $\tilde{f} = (\tilde{f}_j)$ are n-dimensional vectors and D is a diagonal constant $n \times n$ matrix. One interesting phenomenon is the appearance of travelling wave solutions which are of form $\tilde{U}(\xi)$, $\xi = x - s\,t$, where s is the propagation speed. To understand this phenomenon, we may study the properties of the solutions $(\tilde{U}, s)$, which satisfy the ODE

$$0 = D\,\tilde{U}_{\xi\xi} + s\,\tilde{U}_{\xi} + \tilde{f}(\tilde{U}), \quad \xi \in \mathbf{R}. \tag{1.2}$$

Comparatively speaking, when $n = 1$ we can easily study the existence of solutions of (1.2) by the analysis of motions in the phase plane, because the so-called *comparison principle* holds in the case of $n = 1$. We introduce here the following scalar equation as a typical and suggestive example:

$$u_t = u_{xx} + u\,(1-u)\,(u-\mu), \quad x \in \mathbf{R}, \quad t > 0. \tag{1.3}$$

For each $0 < \mu < 1$, it follows that (1.3) has two locally stable equilibria $u = 0$ and $u = 1$ in the ODE sense, and that

$$\begin{cases} 0 = u_{\xi\xi} + s\,u_{\xi} + u\,(1-u)\,(u-\mu), & \xi \in \mathbf{R}, \\ u(-\infty) = 0, \quad u(+\infty) = 1 \end{cases}$$

has a unique solution for $s = (2\,\mu - 1)/\sqrt{2}$ (for example, see Murray [11, pp. 304–305]). We note that the above propagation speed is monotone with respect to μ.

In general, the comparison principle does not always hold in case of $n \geq 2$. This leads to considerable complexity for studying travelling wave solutions of (1.1). In this paper, we discuss travelling wave solutions of the following competition-diffusion

* Received by the editors February 22, 1993; accepted for publication (in revised form) October 15, 1993.

† Department of Mathematics, Faculty of Education, Ehime University, Matsyama 790, Japan.

equation, where the comparison principle holds in the framework of (1.1) for $n \geq 2$:

$$\text{(1.4)} \qquad \begin{cases} u_t = u_{xx} + f(u,v), \\ v_t = d\,v_{xx} + g(u,v), \quad x \in \mathbf{R}, \quad t > 0, \\ u(0,x) \geq 0, \quad v(0,x) \geq 0, \quad x \in \mathbf{R}, \end{cases}$$

where

$$f(u,v) = u\,(1 - u - c\,v), \quad g(u,v) = v\,(a - b\,u - v),$$

and a, b, c, and d are positive constants which have ecological meanings.

When both u and v are spatially homogeneous, the evolution of (u,v) is governed by

$$u_t = f(u,v), \quad v_t = g(u,v), \quad t > 0.$$

We easily see that the asymptotic behavior of (u,v) with the initial conditions $u(0) > 0$ and $v(0) > 0$ is classified into the following four cases:

(I) If $a \leq \min(b, 1/c)$, then $\lim_{t \to +\infty}(u,v)(t) = (1,0)$.

(II) If $b < a < 1/c$, then

$$\lim_{t \to +\infty}(u,v)(t) = \left(\frac{1 - a\,c}{1 - b\,c}, \frac{a - b}{1 - b\,c}\right).$$

(III) If $1/c < a < b$, then $(0,a)$ and $(1,0)$ are locally stable and almost every solution converges to one of them as $t \to +\infty$.

(IV) If $a \geq \max(b, 1/c)$, then $\lim_{t \to +\infty}(u,v)(t) = (0,a)$.

In consideration of the situation for (1.3) with $0 < \mu < 1$, when (a,b,c) satisfies case (III), we guess that (1.4) has travelling wave solutions which decay exponentially to two locally stable equilibria, $(0,a)$ and $(1,0)$, and that their propagation speed is monotone with respect to the parameters a, b, and c. To justify our expectation, we study solutions of

$$\text{(1.5a)} \qquad \begin{cases} 0 = u_{\xi\xi} + s\,u_\xi + f(u,v), \\ 0 = d\,v_{\xi\xi} + s\,v_\xi + g(u,v), \quad \xi \in \mathbf{R} \end{cases}$$

with the boundary conditions

$$\text{(1.5b)} \qquad (u,v)(-\infty) = (0,a), \quad (u,v)(+\infty) = (1,0),$$

when (a,b,c) satisfies case (III).

There are many interesting studies for travelling wave solutions of (1.1). Vol'pert and Vol'pert [13] established a unique existence theorem of travelling wave solutions for (1.1) with the so-called *cooperative interaction process*, that is,

$$\frac{\partial \widetilde{f}_i}{\partial \widetilde{u}_j} > 0, \quad i,j = 1,2,\ldots,n, \quad i \neq j.$$

We note that (1.1) with the cooperative interaction process is one of the equations such that the comparison principle holds. On the other hand, for generalized competition-diffusion equations including (1.4), Gardner [4] and Conley and Gardner [2] proved the existence of travelling wave solutions by the topological method, so that their propagation speed is determined implicitly. (We also refer to Tang and Fife [12], Hosono and Mimura [6], and Hosono [5].) For the propagation speed of (1.4), Mimura and Fife [10] proved the existence of solutions with $s = 0$, and Ikeda and Mimura [7] showed numerically the monotone dependence on some parameters. Unfortunately,

we have not known rigorous results on the parameter dependence of the propagation speed. Our main purpose in this paper is to establish the monotone dependence of the propagation speed on the parameters a, b, and c.

Let us explain our approach briefly. Let $\boldsymbol{u}(\xi) = (u, v)(\xi)$ be a positive solution of (1.5) for some s. By formally differentiating (1.5a) with respect to $\mu \in \{a, b, c\}$, we obtain

$$\mathcal{L}\,\boldsymbol{u}_\mu(\xi) = -\begin{pmatrix} s_\mu\, u_\xi(\xi) + f_\mu(\boldsymbol{u}(\xi)) \\ s_\mu\, v_\xi(\xi) + g_\mu(\boldsymbol{u}(\xi)) \end{pmatrix}, \quad \xi \in \mathbf{R}, \tag{1.6}$$

where

$$\mathcal{L}(U, V) = \begin{pmatrix} U_{\xi\xi} + s\,U_\xi + f_u(\boldsymbol{u}(\xi))\,U + f_v(\boldsymbol{u}(\xi))\,V \\ d\,V_{\xi\xi} + s\,V_\xi + g_u(\boldsymbol{u}(\xi))\,U + g_v(\boldsymbol{u}(\xi))\,V \end{pmatrix}.$$

It is suggested from Lemma A.2 in Kan-on and Yanagida [8] that $\mathcal{L}^*(u, v) = 0$ has a nontrivial bounded solution $(u^*, v^*)(\xi)$, which satisfies $u^*(\xi)\,v^*(\xi) < 0$ for any $\xi \in \mathbf{R}$, where $\mathcal{L}^*$ is the adjoint operator of $\mathcal{L}$. By taking the inner product between (1.6) and $(u^*, v^*)(\xi)$, we obtain

$$\begin{aligned} 0 = & s_\mu \int_{\mathbf{R}} \{\, u_\xi(\xi)\,u^*(\xi) + v_\xi(\xi)\,v^*(\xi)\,\}\,d\xi \\ & + \int_{\mathbf{R}} \{\, f_\mu(\boldsymbol{u}(\xi))\,u^*(\xi) + g_\mu(\boldsymbol{u}(\xi))\,v^*(\xi)\,\}\,d\xi. \end{aligned}$$

If $\boldsymbol{u}(\xi)$ satisfies $u_\xi(\xi) > 0 > v_\xi(\xi)$ for any $\xi \in \mathbf{R}$, then we have

$$\begin{aligned} \frac{\partial s}{\partial a} &= -\frac{\int_{\mathbf{R}} v(\xi)\,v^*(\xi)\,d\xi}{\int_{\mathbf{R}} \{\, u_\xi(\xi)\,u^*(\xi) + v_\xi(\xi)\,v^*(\xi)\,\}\,d\xi} > 0, \\ \frac{\partial s}{\partial b} &= \frac{\int_{\mathbf{R}} u(\xi)\,v(\xi)\,v^*(\xi)\,d\xi}{\int_{\mathbf{R}} \{\, u_\xi(\xi)\,u^*(\xi) + v_\xi(\xi)\,v^*(\xi)\,\}\,d\xi} < 0, \\ \frac{\partial s}{\partial c} &= \frac{\int_{\mathbf{R}} u(\xi)\,v(\xi)\,u^*(\xi)\,d\xi}{\int_{\mathbf{R}} \{\, u_\xi(\xi)\,u^*(\xi) + v_\xi(\xi)\,v^*(\xi)\,\}\,d\xi} > 0. \end{aligned}$$

These inequalities suggest that the propagation speed is monotone with respect to a, b, and c. In order to justify the above argument, we shall employ the maximum principle and the bifurcation theory for heteroclinic orbits.

2. Statement of result. We shall say that $(u, v)(\xi)$ is (*strictly*) *monotone* if $u(\xi)$ is (strictly) increasing and $v(\xi)$ (strictly) decreasing. We state the following main theorem for any fixed $d > 0$.

THEOREM 2.1. *There exist families* $(u, v)(\xi; a, b, c)$ *and* $s(a, b, c)$ *defined on* $\mathcal{P} = \{\, (a, b, c) \mid 0 < 1/c < a < b \,\}$ *such that*

(i) $(u, v)(\xi; a, b, c)$ *is a strictly monotone solution of* (1.5) *with* $s = s(a, b, c)$ *for each* $(a, b, c) \in \mathcal{P}$,

(ii) $u(.; a, b, c)$, $v(.; a, b, c)$, *and* $s(a, b, c)$ *are a* C^1 *class in* (a, b, c), *and*

(iii) $s(a, b, c)$ *satisfies* $-2 < s(a, b, c) < 2\sqrt{a\,d}$,

$$\frac{\partial}{\partial a} s(a, b, c) > 0, \quad \frac{\partial}{\partial b} s(a, b, c) < 0, \quad \frac{\partial}{\partial c} s(a, b, c) > 0$$

for any $(a, b, c) \in \mathcal{P}$.

Furthermore, if $(\widetilde{u},\widetilde{v})(\xi)$ *is an arbitrary positive solution of* (1.5) *with* $s=\widetilde{s}$ *for* $(a,b,c)\in\mathcal{P}$, *then* $\widetilde{s}=s(a,b,c)$ *holds and there exists* η *such that* $(\widetilde{u},\widetilde{v})(\xi)=(u,v)(\xi+\eta;a,b,c)$ *for any* $\xi\in\mathbf{R}$.

We shall prove the above theorem in the following section.

3. Proofs.

LEMMA 3.1 (Theorem A.2 in Mimura and Fife [10]). *Suppose that* β *satisfies*

$$1<\beta<\min\left\{\frac{d+\sqrt{d^2+4}}{2},\frac{1+\sqrt{1+4d^2}}{2d}\right\}. \tag{3.1}$$

Then there exists $a_0\in(1/\beta,\beta)$ *such that* (1.5) *has a strictly monotone solution for* $(a,b,c,s)=(a_0,\beta,\beta,0)$.

Let $d>0$ be an arbitrary fixed constant. We denote by $\mathcal{E}$ the set of all parameters $(a,b,c)\in\mathcal{P}$ such that (1.5) has a strictly monotone solution for some s. Then we have $\mathcal{E}\neq\emptyset$ by virtue of Lemma 3.1.

Let $\boldsymbol{u}_0(\xi)=(u_0,v_0)(\xi)$ and s_0 be a strictly monotone solution and its propagation speed, respectively, of (1.5) for $(a,b,c)=(a_0,b_0,c_0)\in\mathcal{E}$. By the maximum principle, we have $\boldsymbol{u}_0(\xi)\in(0,1)\times(0,a_0)$ for any $\xi\in\mathbf{R}$. The linearized operators of (1.5a) around $(u,v)=(0,a_0)$ and $(u,v)=(1,0)$ are represented as

$$\mathcal{L}_0^-(u,v;s)=\begin{pmatrix} p_u^-(\frac{d}{d\xi};s)\,u \\ -a_0\,b_0\,u+p_v^-(\frac{d}{d\xi};s)\,v\end{pmatrix}$$

and

$$\mathcal{L}_0^+(u,v;s)=\begin{pmatrix} p_u^+(\frac{d}{d\xi};s)\,u-c_0\,v \\ p_v^+(\frac{d}{d\xi};s)\,v\end{pmatrix},$$

respectively, where

$$p_u^-(\gamma;s)=\gamma^2+s\gamma+1-a_0\,c_0,\quad p_v^-(\gamma;s)=d\gamma^2+s\gamma-a_0,$$
$$p_u^+(\gamma;s)=\gamma^2+s\gamma-1,\quad p_v^+(\gamma;s)=d\gamma^2+s\gamma+a_0-b_0.$$

We note that $1-a_0\,c_0<0$ and $a_0-b_0<0$ hold for any $(a_0,b_0,c_0)\in\mathcal{P}$. With $*=u,\,v$, we denote by $\lambda_*^\pm(s)$ $(\lambda_*^-(s)<0<\lambda_*^+(s))$ and $\sigma_*^\pm(s)$ $(\sigma_*^-(s)<0<\sigma_*^+(s))$ the solutions of the quadratic equations $p_*^-(\gamma;s)=0$ and $p_*^+(\gamma;s)=0$, respectively. And we put

$$\Lambda_1^\pm(s)=\min\{\lambda_u^\pm(s),\lambda_v^\pm(s)\},\quad \Lambda_2^\pm(s)=\max\{\lambda_u^\pm(s),\lambda_v^\pm(s)\},$$
$$\Sigma_1^\pm(s)=\min\{\sigma_u^\pm(s),\sigma_v^\pm(s)\},\quad \Sigma_2^\pm(s)=\max\{\sigma_u^\pm(s),\sigma_v^\pm(s)\}.$$

From $p_u^\pm(-s;s)<0$ and $p_v^\pm(-s/d;s)<0$, we have

$$\begin{aligned}&\Sigma_1^-(s)\le\sigma_u^-(s)<-s<\lambda_u^+(s)\le\Lambda_2^+(s),\\ &\Sigma_1^-(s)\le\sigma_v^-(s)<-s/d<\lambda_v^+(s)\le\Lambda_2^+(s)\end{aligned} \tag{3.2}$$

for any $s\in\mathbf{R}$ and $(a_0,b_0,c_0)\in\mathcal{P}$. With $*=u,\,v$, by differentiating $p_*^-(\lambda_*^+(s);s)=0$ and $p_*^+(\sigma_*^-(s);s)=0$ with respect to s, we obtain

$$\frac{\partial}{\partial s}\lambda_*^+(s)=-\lambda_*^+(s)/\frac{d}{d\gamma}p_*^-(\lambda_*^+(s);s)<0,$$
$$\frac{\partial}{\partial s}\sigma_*^-(s)=-\sigma_*^-(s)/\frac{d}{d\gamma}p_*^+(\sigma_*^-(s);s)<0$$

for any $s\in\mathbf{R}$ and $(a_0,b_0,c_0)\in\mathcal{P}$. Then we see that $\lambda_u^+(s)$, $\lambda_v^+(s)$, $\sigma_u^-(s)$, and $\sigma_v^-(s)$ are strictly decreasing with respect to s for each $(a_0,b_0,c_0)\in\mathcal{P}$. Furthermore, it

follows that

$$\overline{\Phi}_1^{\pm}(\xi;s)=\begin{cases}\left(\dfrac{p_v^-(\lambda_u^{\pm}(s);s)}{a_0\,b_0},1\right)e^{\Lambda_1^{\pm}(s)\,\xi} & \text{if } \lambda_u^{\pm}(s)<\lambda_v^{\pm}(s),\\ -\left(\dfrac{\frac{d}{d\gamma}p_v^-(\lambda_v^{\pm}(s);s)}{a_0\,b_0},\xi\right)e^{\Lambda_1^{\pm}(s)\,\xi} & \text{if } \lambda_u^{\pm}(s)=\lambda_v^{\pm}(s),\\ (0,1)\,e^{\Lambda_1^{\pm}(s)\,\xi} & \text{if } \lambda_u^{\pm}(s)>\lambda_v^{\pm}(s),\end{cases}$$

$$\overline{\Phi}_2^{\pm}(\xi;s)=\begin{cases}(0,1)\,e^{\Lambda_2^{\pm}(s)\,\xi} & \text{if } \lambda_u^{\pm}(s)\le\lambda_v^{\pm}(s),\\ \left(\dfrac{p_v^-(\lambda_u^{\pm}(s);s)}{a_0\,b_0},1\right)e^{\Lambda_2^{\pm}(s)\,\xi} & \text{if } \lambda_u^{\pm}(s)>\lambda_v^{\pm}(s)\end{cases}$$

and

$$\overline{\Psi}_1^{\pm}(\xi;s)=\begin{cases}(1,0)\,e^{\Sigma_1^{\pm}(s)\,\xi} & \text{if } \sigma_u^{\pm}(s)\le\sigma_v^{\pm}(s),\\ \left(1,\dfrac{p_u^+(\sigma_v^{\pm}(s);s)}{c_0}\right)e^{\Sigma_1^{\pm}(s)\,\xi} & \text{if } \sigma_u^{\pm}(s)>\sigma_v^{\pm}(s),\end{cases}$$

$$\overline{\Psi}_2^{\pm}(\xi;s)=\begin{cases}\left(1,\dfrac{p_u^+(\sigma_v^{\pm}(s);s)}{c_0}\right)e^{\Sigma_2^{\pm}(s)\,\xi} & \text{if } \sigma_u^{\pm}(s)<\sigma_v^{\pm}(s),\\ \left(\xi,\dfrac{\frac{d}{d\gamma}p_u^+(\sigma_u^{\pm}(s);s)}{c_0}\right)e^{\Sigma_2^{\pm}(s)\,\xi} & \text{if } \sigma_u^{\pm}(s)=\sigma_v^{\pm}(s),\\ (1,0)\,e^{\Sigma_2^{\pm}(s)\,\xi} & \text{if } \sigma_u^{\pm}(s)>\sigma_v^{\pm}(s)\end{cases}$$

are linearly independent solutions of $\mathcal{L}_0^-(u,v;s)=0$ and $\mathcal{L}_0^+(u,v;s)=0$, respectively. By the above behavior, for any s, we have

$$\overline{\Phi}_2^{\pm}(\xi;s)=o(|\,\overline{\Phi}_1^{\pm}(\xi;s)\,|),\ \overline{\Phi}_1^{+}(\xi;s)=o(|\,\overline{\Phi}_2^{-}(\xi;s)\,|)\quad\text{as } \xi\to-\infty,$$
$$\overline{\Psi}_1^{\pm}(\xi;s)=o(|\,\overline{\Psi}_2^{\pm}(\xi;s)\,|),\ \overline{\Psi}_2^{-}(\xi;s)=o(|\,\overline{\Psi}_1^{+}(\xi;s)\,|)\quad\text{as } \xi\to+\infty.$$

Let us get the asymptotic expansion of $\boldsymbol{u}_0(\xi)$ as $\xi\to\pm\infty$. By $\boldsymbol{u}_0(-\infty)=(0,a_0)$, we see that $\boldsymbol{u}_0(\xi)$ satisfies

$$\begin{aligned}0&=u_{0\xi\xi}(\xi)+s_0\,u_{0\xi}(\xi)+f(\boldsymbol{u}_0(\xi))\\&=p_u^-(\tfrac{d}{d\xi};s_0)\,u_0(\xi)-u_0(\xi)\,\{\,u_0(\xi)+c_0\,(v_0(\xi)-a_0)\,\}\\&=p_u^-(\tfrac{d}{d\xi};s_0)\,u_0(\xi)+o(u_0(\xi)),\end{aligned}\tag{3.3}$$

$$\begin{aligned}0&=d\,v_{0\xi\xi}(\xi)+s_0\,v_{0\xi}(\xi)+g(\boldsymbol{u}_0(\xi))\\&=p_v^-(\tfrac{d}{d\xi};s_0)\,(v_0(\xi)-a_0)-a_0\,b_0u_0(\xi)\\&\qquad+(v_0(\xi)-a_0)\,(a_0-b_0\,u_0(\xi)-v_0(\xi))\\&=p_v^-(\tfrac{d}{d\xi};s_0)\,(v_0(\xi)-a_0)-a_0\,b_0u_0(\xi)+o(v_0(\xi)-a_0)\end{aligned}\tag{3.4}$$

as $\xi\to-\infty$. Since $0<u_0(\xi)<1$ holds for any $\xi\in\mathbf{R}$, it follows from (3.3) that $u_0(\xi)$ satisfies

$$u_0(\xi)=C_u^-\,e^{\lambda_u^+(s_0)\,\xi}\,(1+o(1))$$

as $\xi\to-\infty$, where C_u^- is a positive constant. By substituting the above expansion

into (3.4), we have

$$v_0(\xi) - a_0 = \begin{cases} \dfrac{a_0 b_0 C_u^- e^{\lambda_u^+(s_0)\xi}}{p_v^-(\lambda_u^+(s_0); s_0)}(1+o(1)) & \text{for } \lambda_u^+(s_0) < \lambda_v^+(s_0), \\ \dfrac{a_0 b_0 C_u^- \xi e^{\lambda_u^+(s_0)\xi}}{\frac{d}{d\gamma}p_v^-(\lambda_u^+(s_0); s_0)}(1+o(1)) & \text{for } \lambda_u^+(s_0) = \lambda_v^+(s_0), \\ \dfrac{a_0 b_0 C_u^- e^{\lambda_u^+(s_0)\xi}}{p_v^-(\lambda_u^+(s_0); s_0)}(1+o(1)) & \\ \quad +C_1 e^{\lambda_v^+(s_0)\xi}(1+o(1)) & \text{for } \lambda_u^+(s_0) > \lambda_v^+(s_0) \end{cases}$$

as $\xi \to -\infty$, where C_1 is some constant. Since $0 < v_0(\xi) < a_0$ holds for any $\xi \in \mathbf{R}$, and since $p_v^-(\lambda_u^+(s_0); s_0) > 0$ holds if $\lambda_u^+(s_0) > \lambda_v^+(s_0)$, we see that C_1 must satisfy $C_1 < 0$. By summarizing the above, we get the following asymptotic expansion:

$$\text{(3.5)} \qquad \begin{cases} u_0(\xi) = C_u^- e^{\lambda_u^+(s_0)\xi}(1+o(1)), \\ v_0(\xi) = a_0 - C_v^- |\xi|^{m_+} e^{\Lambda_1^+(s_0)\xi}(1+o(1)) \end{cases}$$

as $\xi \to -\infty$, where

$$m_\pm = \begin{cases} 1 & \text{if } \lambda_u^\pm(s_0) = \lambda_v^\pm(s_0), \\ 0 & \text{otherwise,} \end{cases}$$

and C_v^- is a positive constant which satisfies

$$C_v^- = \begin{cases} -\dfrac{a_0 b_0 C_u^-}{p_v^-(\lambda_u^+(s_0); s_0)} & \text{for } \lambda_u^+(s_0) < \lambda_v^+(s_0), \\ \dfrac{a_0 b_0 C_u^-}{\frac{d}{d\gamma}p_v^-(\lambda_u^+(s_0); s_0)} & \text{for } \lambda_u^+(s_0) = \lambda_v^+(s_0), \\ -C_1 & \text{for } \lambda_u^+(s_0) > \lambda_v^+(s_0), \end{cases}$$

because $p_v^-(\gamma; s)$ satisfies $p_v^-(\lambda_u^+(s); s) < 0$ if $\lambda_u^+(s) < \lambda_v^+(s)$, and $\frac{d}{d\xi}p_v^-(\lambda_u^+(s); s) > 0$ if $\lambda_u^+(s) = \lambda_v^+(s)$. Analogously we obtain

$$\text{(3.6)} \qquad \begin{cases} u_0(\xi) = 1 - C_u^+ |\xi|^{n_-} e^{\Sigma_2^-(s_0)\xi}(1+o(1)), \\ v_0(\xi) = C_v^+ e^{\sigma_v^-(s_0)\xi}(1+o(1)) \end{cases}$$

as $\xi \to +\infty$, where

$$n_\pm = \begin{cases} 1 & \text{if } \sigma_u^\pm(s_0) = \sigma_v^\pm(s_0), \\ 0 & \text{otherwise,} \end{cases}$$

and C_u^+, C_v^+ are some positive constants. Since $\boldsymbol{u}_0(\xi)$ is on both the unstable manifold at $(u, v) = (0, a_0)$ and the stable manifold at $(u, v) = (1, 0)$, we see from (3.5) and (3.6) that $\boldsymbol{u}_0(\xi)$ satisfies

$$\text{(3.7)} \qquad \boldsymbol{u}_0(\xi) = \begin{cases} (0, a_0) - C_v^- \overline{\Phi}_1^+(\xi; s_0) + o(|\overline{\Phi}_1^+(\xi; s_0)|) & \text{as } \xi \to -\infty, \\ (1, 0) - C_u^+ \overline{\Psi}_2^-(\xi; s_0) + o(|\overline{\Psi}_2^-(\xi; s_0)|) & \text{as } \xi \to +\infty. \end{cases}$$

3.1. Linearized operator. We define the linearized operator $\mathcal{L}$ of (1.5a) around $(u,v)=\boldsymbol{u}_0(\xi)$ and its adjoint operator $\mathcal{L}^*$ by

$$\mathcal{L}(u,v)=\begin{pmatrix} u_{\xi\xi}+s_0\,u_\xi+f_u^0(\xi)\,u+f_v^0(\xi)\,v \\ \\ d\,v_{\xi\xi}+s_0\,v_\xi+g_u^0(\xi)\,u+g_v^0(\xi)\,v \end{pmatrix}$$

and

$$\mathcal{L}^*(u,v)=\begin{pmatrix} u_{\xi\xi}-s_0\,u_\xi+f_u^0(\xi)\,u+g_u^0(\xi)\,v \\ \\ d\,v_{\xi\xi}-s_0\,v_\xi+f_v^0(\xi)\,u+g_v^0(\xi)\,v \end{pmatrix},$$

respectively, where $f_u^0(\xi)=f_u(\boldsymbol{u}_0(\xi))$ and the other functions f_v^0, g_u^0, and g_v^0 are also defined in the same manner with f_u^0.

Since $\boldsymbol{u}_0(\xi)$ is a strictly monotone solution of (1.5) with $s=s_0$, it follows that $\boldsymbol{u}_{0\xi}(\xi)$ is a nontrivial bounded solution of $\mathcal{L}(u,v)=0$ and satisfies $u_{0\xi}(\xi)\geq 0\geq v_{0\xi}(\xi)$ for any $\xi\in\mathbf{R}$. We assume that $\boldsymbol{u}_{0\xi}(\xi)$ satisfies $u_{0\xi}(\xi_1)=0$ and/or $v_{0\xi}(\xi_1)=0$ for some $\xi_1\in\mathbf{R}$. By $f_v^0(\xi)<0$ and $g_u^0(\xi)<0$ for any $\xi\in\mathbf{R}$, we have $\boldsymbol{u}_{0\xi}(\xi_1)=0$ and $\boldsymbol{u}_{0\xi\xi}(\xi_1)=0$. By uniqueness, we obtain $\boldsymbol{u}_{0\xi}(\xi)=0$ for any $\xi\in\mathbf{R}$, that is, $\boldsymbol{u}_0(\xi)$ is a constant function. This contradiction implies that $\boldsymbol{u}_0(\xi)$ satisfies $u_{0\xi}(\xi)>0>v_{0\xi}(\xi)$ for any $\xi\in\mathbf{R}$.

LEMMA 3.2. *Suppose that* $\boldsymbol{u}(\xi)=(u,v)(\xi)$ *is a nontrivial solution of* $\mathcal{L}(u,v)=0$, *which satisfies* $|\,\boldsymbol{u}(\xi)\,|=O(e^{\Lambda_2^+(s_0)\,\xi})$ *as* $\xi\to-\infty$ (*respectively,* $|\,\boldsymbol{u}(\xi)\,|=O(e^{\Sigma_1^-(s_0)\,\xi})$ *as* $\xi\to+\infty$) *and* $u(\xi)\,v(\xi)>0$ *for any* ξ *in a neighborhood of* $\xi=-\infty$ (*respectively,* $\xi=+\infty$). *Then* $\boldsymbol{u}(\xi)$ *satisfies* $u(\xi)\,v(\xi)>0$ *for any* $\xi\in\mathbf{R}$ *and* $\limsup_{\xi\to+\infty}|\,v(\xi)\,|>0$ (*respectively,* $\limsup_{\xi\to-\infty}|\,u(\xi)\,|>0$).

Proof. We show only the proof for the former case, because the latter can be proved in a similar manner. Furthermore, without loss of generality, we may assume $u(\xi)>0$ and $v(\xi)>0$ near $\xi=-\infty$.

We assume one of the following two cases: (i) $u(\xi)$ and/or $v(\xi)$ have zeros, and (ii) $\boldsymbol{u}(\xi)$ satisfies $u(\xi)\,v(\xi)>0$ for any $\xi\in\mathbf{R}$ and $\lim_{\xi\to+\infty}v(\xi)=0$. We put

$$\xi_2=\begin{cases}\inf\{\,\xi\,|\,u(\xi)\,v(\xi)\leq 0\,\} & \text{for the case (i),}\\ +\infty & \text{for the case (ii).}\end{cases}$$

Since $f_v^0(\xi)<0$ and $g_u^0(\xi)<0$ hold for any $\xi\in\mathbf{R}$, with the use of (3.2) and the integration by parts we have

$$\begin{aligned}0&=\int_{-\infty}^{\xi_2}\{\,u_{\xi\xi}(\xi)+s_0\,u_\xi(\xi)+f_u^0(\xi)\,u(\xi)+f_v^0(\xi)\,v(\xi)\,\}\,u_{0\xi}(\xi)\,e^{s_0\,\xi}\,d\xi\\ &=u_\xi(\xi_2)\,u_{0\xi}(\xi_2)\,e^{s_0\,\xi_2}\\ &\qquad+\int_{-\infty}^{\xi_2}f_v^0(\xi)\,\{\,v(\xi)\,u_{0\xi}(\xi)-u(\xi)\,v_{0\xi}(\xi)\,\}\,e^{s_0\,\xi}\,d\xi<0\end{aligned}$$

when $u(\xi_2)=0$, and

$$\begin{aligned}0&=\int_{-\infty}^{\xi_2}\{\,d\,v_{\xi\xi}(\xi)+s_0\,v_\xi(\xi)+g_u^0(\xi)\,u(\xi)+g_v^0(\xi)\,v(\xi)\,\}\,v_{0\xi}(\xi)\,e^{(s_0\,\xi)/d}\,d\xi\\ &=d\,v_\xi(\xi_2)\,v_{0\xi}(\xi_2)\,e^{(s_0\,\xi_2)/d}\\ &\qquad+\int_{-\infty}^{\xi_2}g_u^0(\xi)\,\{\,u(\xi)\,v_{0\xi}(\xi)-v(\xi)\,u_{0\xi}(\xi)\,\}\,e^{(s_0\,\xi)/d}\,d\xi>0\end{aligned}$$

when $v(\xi_2) = 0$ and/or $\xi_2 = +\infty$. These contradictions imply that the desired result holds. □

3.2. Fundamental solutions.

LEMMA 3.3 (Theorem 8.1 in Coddington and Levinson [1]). *Let $B(\xi)$ be an arbitrary 2×2 matrix which satisfies $B(\xi) = O(e^{-\gamma|\xi|})$ as $\xi \to -\infty$ (respectively, $\xi \to +\infty$) for some positive constant γ. Then there exists a fundamental set $\{\phi_1^{\pm}(\xi), \phi_2^{\pm}(\xi)\}$ of solutions of*

$$\mathcal{L}_0^-(\boldsymbol{u}; s) + B(\xi)\,\boldsymbol{u} = 0 \quad \big(\textit{respectively, } \mathcal{L}_0^+(\boldsymbol{u}; s) + B(\xi)\,\boldsymbol{u} = 0\big),$$

which satisfy

$$\phi_j^{\pm}(\xi) = \overline{\Phi}_j^{\pm}(\xi; s) + o(|\,\overline{\Phi}_j^{\pm}(\xi; s)\,|) \quad \textit{as } \xi \to -\infty,$$
$$\Big(\textit{respectively, } \phi_j^{\pm}(\xi) = \overline{\Psi}_j^{\pm}(\xi; s) + o(|\,\overline{\Psi}_j^{\pm}(\xi; s)\,|) \quad \textit{as } \xi \to +\infty\Big).$$

By (3.5) and (3.6), we have

$$\begin{pmatrix} f_u^0(\xi) & f_v^0(\xi) \\ g_u^0(\xi) & g_v^0(\xi) \end{pmatrix} = \begin{cases} \begin{pmatrix} 1 - a_0 c_0 & 0 \\ -a_0 b_0 & -a_0 \end{pmatrix} + o(e^{(\Lambda_1^+(s_0)-\delta)\xi}) \\ \qquad\qquad \text{as } \xi \to -\infty, \\ \begin{pmatrix} -1 & -c_0 \\ 0 & a_0 - b_0 \end{pmatrix} + o(e^{(\Sigma_2^-(s_0)+\delta)\xi}) \\ \qquad\qquad \text{as } \xi \to +\infty \end{cases}$$

for any $0 < \delta < \min\{\Lambda_1^+(s_0), -\Sigma_2^-(s_0)\}$. Then it follows from Lemma 3.3 that there exist fundamental sets $\{\Phi_1^{\pm}(\xi), \Phi_2^{\pm}(\xi)\}$ and $\{\Psi_1^{\pm}(\xi), \Psi_2^{\pm}(\xi)\}$ of solutions of $\mathcal{L}(u, v) = 0$ which satisfy

$$\Phi_j^{\pm}(\xi) = \overline{\Phi}_j^{\pm}(\xi; s_0) + o(|\,\overline{\Phi}_j^{\pm}(\xi; s_0)\,|) \quad \text{as } \xi \to -\infty,$$
$$\Psi_j^{\pm}(\xi) = \overline{\Psi}_j^{\pm}(\xi; s_0) + o(|\,\overline{\Psi}_j^{\pm}(\xi; s_0)\,|) \quad \text{as } \xi \to +\infty.$$

We also see that there exists a nonsingular constant 4×4 matrix $M = (M_{ij})$ such that

$$(\Phi_1^-, \Phi_2^-, \Phi_1^+, \Phi_2^+)(\xi) = (\Psi_1^-, \Psi_2^-, \Psi_1^+, \Psi_2^+)(\xi)\,M,$$
$$(\Psi_1^-, \Psi_2^-, \Psi_1^+, \Psi_2^+)(\xi) = (\Phi_1^-, \Phi_2^-, \Phi_1^+, \Phi_2^+)(\xi)\,\widetilde{M}$$

hold for any $\xi \in \mathbf{R}$, where $\widetilde{M} = (\widetilde{M}_{ij})$ is the inverse matrix of M. Furthermore, by the asymptotic behaviors of $\overline{\Phi}_j^{\pm}(\xi; s)$ and $\overline{\Psi}_j^{\pm}(\xi; s)$, we have

$$\Phi_2^{\pm}(\xi) = o(|\,\Phi_1^{\pm}(\xi)\,|),\ \Phi_1^+(\xi) = o(|\,\Phi_2^-(\xi)\,|) \quad \text{as } \xi \to -\infty,$$
$$\Psi_1^{\pm}(\xi) = o(|\,\Psi_2^{\pm}(\xi)\,|),\ \Psi_2^-(\xi) = o(|\,\Psi_1^+(\xi)\,|) \quad \text{as } \xi \to +\infty.$$

By the fact that an arbitrary solution $(u, v)(\xi)$ of $\mathcal{L}(u, v) = 0$ satisfies

$$\begin{aligned} 0 =& u_{\xi\xi}(\xi) + s_0\,u_\xi(\xi) + f_u^0(\xi)\,u(\xi) + f_v^0(\xi)\,v(\xi) \\ =& p_u^-\left(\tfrac{d}{d\xi}; s_0\right) u(\xi) - c_0\,u_0(\xi)\,v(\xi) + o(u(\xi)) \\ =& p_u^-\left(\tfrac{d}{d\xi}; s_0\right) u(\xi) - c_0\,C_u^-\,e^{\lambda_u^+(s_0)\,\xi}\,(1 + o(1))\,v(\xi) + o(u(\xi)) \end{aligned}$$

as $\xi \to -\infty$, we obtain

$$\Phi_2^{\pm}(\xi)\, e^{-\Lambda_2^{\pm}(s_0)\,\xi} = \begin{cases} \left(\dfrac{p_v^-(\lambda_u^{\pm}(s_0); s_0)}{a_0\, b_0},\ 1 \right) (1 + o(1)) \\ \qquad\qquad \text{if } \lambda_u^{\pm}(s_0) > \lambda_v^{\pm}(s_0), \\ \left(\dfrac{c_0\, C_u^-\, e^{\lambda_u^+(s_0)\,\xi}}{p_u^-(\lambda_u^+(s_0) + \lambda_v^{\pm}(s_0); s_0)},\ 1 \right) (1 + o(1)) \\ \qquad\qquad \text{if } \lambda_u^{\pm}(s_0) \le \lambda_v^{\pm}(s_0) \end{cases}$$

as $\xi \to -\infty$. Similarly, we also have

$$\Psi_1^{\pm}(\xi)\, e^{-\Sigma_1^{\pm}(s_0)\,\xi} = \begin{cases} \left(1,\ \dfrac{p_u^+(\sigma_v^{\pm}(s_0); s_0)}{c_0} \right) (1 + o(1)) \\ \qquad\qquad \text{if } \sigma_u^{\pm}(s_0) > \sigma_v^{\pm}(s_0), \\ \left(1,\ \dfrac{b_0\, C_v^+\, e^{\sigma_v^-(s_0)\,\xi}}{p_v^+(\sigma_u^{\pm}(s_0) + \sigma_v^-(s_0); s_0)} \right) (1 + o(1)) \\ \qquad\qquad \text{if } \sigma_u^{\pm}(s_0) \le \sigma_v^{\pm}(s_0) \end{cases}$$

as $\xi \to +\infty$.

We define the order relations $\succeq_s$ and $\succeq_o$ by the following manner:

$$(u_1, v_1) \succeq_s (u_2, v_2) \Longleftrightarrow u_1 \ge u_2 \text{ and } v_1 \ge v_2,$$
$$(u_1, v_1) \succeq_o (u_2, v_2) \Longleftrightarrow u_1 \ge u_2 \text{ and } v_1 \le v_2.$$

And we denote by $\succ_s$ and $\succ_o$ the relations which are defined by replacing $\le$ with $<$. Since

$$\lambda_u^-(s_0) \le \lambda_v^-(s_0) < \lambda_u^+(s_0) + \lambda_v^-(s_0) < \lambda_u^+(s_0)$$

holds when $\lambda_u^-(s_0) \le \lambda_v^-(s_0)$, we have

$$\begin{cases} p_v^-(\lambda_u^-(s_0); s_0) < 0 & \text{if } \lambda_u^-(s_0) > \lambda_v^-(s_0), \\ p_v^-(\lambda_u^+(s_0); s_0) > 0 & \text{if } \lambda_u^+(s_0) > \lambda_v^+(s_0), \\ p_u^-(\lambda_u^+(s_0) + \lambda_v^-(s_0); s_0) < 0 & \text{if } \lambda_u^-(s_0) \le \lambda_v^-(s_0), \\ p_u^-(\lambda_u^+(s_0) + \lambda_v^+(s_0); s_0) > 0 & \text{if } \lambda_u^+(s_0) \le \lambda_v^+(s_0), \end{cases} \tag{3.8}$$

that is, $\Phi_2^-(\xi) \prec_o (0,0)$ and $\Phi_2^+(\xi) \succ_s (0,0)$ as $\xi \to -\infty$. Similarly, by the fact that

$$\sigma_v^-(s_0) < \sigma_u^+(s_0) + \sigma_v^-(s_0) < \sigma_u^+(s_0) \le \sigma_v^+(s_0)$$

holds if $\sigma_u^+(s_0) \le \sigma_v^+(s_0)$, we also get $\Psi_1^-(\xi) \succ_s (0,0)$ and $\Psi_1^+(\xi) \succ_o (0,0)$ as $\xi \to +\infty$. From Lemma 3.2, we obtain

$$\Phi_2^+(\xi) \succ_s (0,0),\ \Psi_1^-(\xi) \succ_s (0,0) \quad \text{for any } \xi \in \mathbf{R},$$
$$\limsup_{\xi \to +\infty} [\Phi_2^+(\xi)]_2 > 0, \quad \limsup_{\xi \to -\infty} [\Psi_1^-(\xi)]_1 > 0,$$

where we denote by $[\boldsymbol{u}]_j$ the jth element of $\boldsymbol{u}$.

We assume $M_{44} = 0$, that is,

$$\Phi_2^+(\xi) = M_{14}\, \Psi_1^-(\xi) + M_{24}\, \Psi_2^-(\xi) + M_{34}\, \Psi_1^+(\xi).$$

If $M_{34} = 0$, then we have $\lim_{\xi\to+\infty} \Phi_2^+(\xi) = 0$. This contradiction implies that $M_{34} \neq 0$ holds. By $\lim_{\xi\to+\infty}[\Psi_1^+(\xi)]_1 = +\infty$, we get

$$M_{34}\,[\Phi_2^+(\xi)]_1 = M_{34}^2\,[\Psi_1^+(\xi)]_1\,(1+o(1)) > 0$$

as $\xi \to +\infty$. Since $\Phi_2^+(\xi) \succ_s (0,0)$ for any $\xi \in \mathbf{R}$, we have $M_{34} > 0$. By $[\Psi_1^+(\xi)]_2 < 0$ as $\xi \to +\infty$, we obtain

$$0 < \limsup_{\xi\to+\infty}[\Phi_2^+(\xi)]_2 = M_{34} \limsup_{\xi\to+\infty}[\Psi_1^+(\xi)]_1 \le 0.$$

This contradiction implies that $M_{44} \neq 0$ holds. Similarly, we also obtain $\widetilde{M}_{11} \neq 0$. Therefore we see that Φ_2^+ and $\Psi_1^-(\xi)$ satisfy

$$\begin{aligned}
\Phi_2^+(\xi) &= M_{44}\,\Psi_2^+(\xi) + o(|\,\Psi_2^+(\xi)\,|) \quad \text{as } \xi \to +\infty,\\
\Psi_1^-(\xi) &= \widetilde{M}_{11}\,\Phi_1^-(\xi) + o(|\,\Phi_1^-(\xi)\,|) \quad \text{as } \xi \to -\infty.
\end{aligned}$$

Since $\boldsymbol{u}_{0\xi}(\xi)$ is a bounded solution of $\mathcal{L}(u,v) = 0$, it follows that $\boldsymbol{u}_{0\xi}(\xi)$ satisfies

$$\boldsymbol{u}_{0\xi}(\xi) = \begin{cases} M_{30}\,\Phi_1^+(\xi) + M_{40}\,\Phi_2^+(\xi) \\ \qquad = M_{30}\,\overline{\Phi}_1^+(\xi;s_0) + o(|\,\overline{\Phi}_1^+(\xi;s_0)\,|) \quad \text{as } \xi \to -\infty, \\ M_{10}\,\Psi_1^-(\xi) + M_{20}\,\Psi_2^-(\xi) \\ \qquad = M_{20}\,\overline{\Psi}_2^-(\xi;s_0) + o(|\,\overline{\Psi}_2^-(\xi;s_0)\,|) \quad \text{as } \xi \to +\infty, \end{cases}$$

where M_{j0} $(j = 1,2,3,4)$ are some constants. By (3.7), we have $M_{20} = -C_u^+\,\Sigma_2^-(s_0) > 0$ and $M_{30} = -C_v^-\,\Lambda_1^+(s_0) < 0$.

We put $\boldsymbol{U}_4(\xi) = \Phi_2^+(\xi)$. Since $\Phi_2^+(\xi) = M_{44}\,\Psi_2^+(\xi) + o(|\,\Psi_2^+(\xi)\,|)$ as $\xi \to +\infty$, we see that the limits

$$\text{(3.9)} \qquad \lim_{\xi\to-\infty} \left|\, \boldsymbol{U}_4(\xi)\, e^{-\Lambda_2^+(s_0)\,\xi} \,\right|, \quad \lim_{\xi\to+\infty} \left|\, \boldsymbol{U}_4(\xi)\, \xi^{-n_+}\, e^{-\Sigma_2^+(s_0)\,\xi} \,\right|$$

exist and are nonzero.

We put

$$\boldsymbol{U}_2(\xi) = \Phi_2^-(\xi) - \frac{M_{42}}{M_{44}}\,\Phi_2^+(\xi), \quad \boldsymbol{U}_3(\xi) = \Phi_1^+(\xi) - \frac{M_{43}}{M_{44}}\,\Phi_2^+(\xi).$$

By $\Phi_1^+(\xi) = o(|\,\Phi_2^-(\xi)\,|)$ and $\Phi_2^+(\xi) = o(|\,\Phi_1^+(\xi)\,|)$ as $\xi \to -\infty$, we have

$$\boldsymbol{U}_2(\xi) = \Phi_2^-(\xi) + o(|\,\Phi_2^-(\xi)\,|), \quad \boldsymbol{U}_3(\xi) = \Phi_1^+(\xi) + o(|\,\Phi_1^+(\xi)\,|)$$

as $\xi \to -\infty$. Since $\boldsymbol{U}_2(\xi)$ and $\boldsymbol{U}_3(\xi)$ are represented as

$$\begin{aligned}
\boldsymbol{U}_2(\xi) &= N_{12}\,\Psi_1^-(\xi) + N_{22}\,\Psi_2^-(\xi) + N_{32}\,\Psi_1^+(\xi),\\
\boldsymbol{U}_3(\xi) &= N_{13}\,\Psi_1^-(\xi) + N_{23}\,\Psi_2^-(\xi) + N_{33}\,\Psi_1^+(\xi)
\end{aligned}$$

where

$$N_{ij} = \frac{M_{ij}\,M_{44} - M_{i4}\,M_{4j}}{M_{44}} \quad (i = 1,2,3;\, j = 2,3),$$

we also have $\boldsymbol{U}_2(\xi) = O(|\,\Psi_1^+(\xi)\,|)$ and $\boldsymbol{U}_3(\xi) = O(|\,\Psi_1^+(\xi)\,|)$ as $\xi \to +\infty$.

By $\Psi_1^+(\xi) = o(|\,\Psi_2^+(\xi)\,|)$ as $\xi \to +\infty$, we have

$$\begin{aligned}\boldsymbol{u}_{0\xi}(\xi) &= M_{30}\,\Phi_1^+(\xi) + M_{40}\,\Phi_2^+(\xi)\\ &= M_{30}\,\boldsymbol{U}_3(\xi) + \frac{M_{30}\,M_{43} + M_{40}\,M_{44}}{M_{44}}\,\Phi_2^+(\xi)\\ &= (M_{30}\,M_{43} + M_{40}\,M_{44})\,\Psi_2^+(\xi) + o(|\,\Psi_2^+(\xi)\,|)\end{aligned}$$

as $\xi \to +\infty$. From $\lim_{\xi\to+\infty} \boldsymbol{u}_{0\xi}(\xi) = 0$, we obtain $M_{30}\,M_{43} + M_{40}\,M_{44} = 0$, that is, $\boldsymbol{U}_3(\xi) = \boldsymbol{u}_{0\xi}(\xi)/M_{30}$. This means that the limits

$$\lim_{\xi\to-\infty}\left|\,\boldsymbol{U}_3(\xi)\,\xi^{-m_+}e^{-\Lambda_1^+(s_0)\,\xi}\,\right|,\quad \lim_{\xi\to+\infty}\left|\,\boldsymbol{U}_3(\xi)\,\xi^{-n_-}e^{-\Sigma_2^-(s_0)\,\xi}\,\right| \tag{3.10}$$

exist and are nonzero.

We assume that $N_{32} = 0$. By the use of $\boldsymbol{u}_{0\xi}(\xi) = M_{10}\,\Psi_1^-(\xi) + M_{20}\,\Psi_2^-(\xi)$ and $\Phi_2^-(\xi) = o(|\,\Phi_1^-(\xi)\,|)$ as $\xi \to -\infty$, we have

$$\begin{aligned}N_{22}\,\boldsymbol{u}_{0\xi}(\xi) - M_{20}\,\boldsymbol{U}_2(\xi) &= -\,M_{20}\,\Phi_2^-(\xi) + o(|\,\Phi_2^-(\xi)\,|) = o(|\,\Phi_1^-(\xi)\,|),\\ N_{22}\,\boldsymbol{u}_{0\xi}(\xi) - M_{20}\,\boldsymbol{U}_2(\xi) &= (M_{10}\,N_{22} - M_{20}\,N_{12})\,\Psi_1^-(\xi)\\ &= (M_{10}\,N_{22} - M_{20}\,N_{12})\,\widetilde{M}_{11}\\ &\quad\times(\Phi_1^-(\xi) + o(|\,\Phi_1^-(\xi)\,|))\end{aligned}$$

as $\xi \to -\infty$. From the above behavior, we have $M_{10}\,N_{22} - M_{20}\,N_{12} = 0$. By the asymptotic behavior of $\Phi_2^-(\xi)$, we obtain

$$0 = M_{20}\,[N_{22}\,\boldsymbol{u}_{0\xi}(\xi) - M_{20}\,\boldsymbol{U}_2(\xi)]_2 = -M_{20}^2\,e^{\Lambda_2^-(s_0)\,\xi}\,(1 + o(1)) < 0$$

as $\xi \to -\infty$. This contradiction implies that $N_{32} \neq 0$ holds. Then we see that the limits

$$\lim_{\xi\to-\infty}\left|\,\boldsymbol{U}_2(\xi)\,e^{-\Lambda_2^-(s_0)\,\xi}\,\right|,\quad \lim_{\xi\to+\infty}\left|\,\boldsymbol{U}_2(\xi)\,e^{-\Sigma_1^+(s_0)\,\xi}\,\right| \tag{3.11}$$

exist and are nonzero.

We put

$$\boldsymbol{U}_1(\xi) = \Phi_1^-(\xi) + \frac{\widetilde{M}_{21}}{\widetilde{M}_{11}}\,\Phi_2^-(\xi) + \frac{\widetilde{M}_{31}}{\widetilde{M}_{11}}\,\Phi_1^+(\xi) + \frac{\widetilde{M}_{41}}{\widetilde{M}_{11}}\,\Phi_2^+(\xi).$$

Then we have $\boldsymbol{U}_1(\xi) = \Psi_1^-(\xi)/\widetilde{M}_{11}$, that is, the limits

$$\lim_{\xi\to-\infty}\left|\,\boldsymbol{U}_1(\xi)\,\xi^{-m_-}\,e^{-\Lambda_1^-(s_0)\,\xi}\,\right|,\quad \lim_{\xi\to+\infty}\left|\,\boldsymbol{U}_1(\xi)\,e^{-\Sigma_1^-(s_0)\,\xi}\,\right| \tag{3.12}$$

exist and are nonzero.

By summarizing the above arguments, we have

$$\begin{aligned}&(\boldsymbol{U}_1, \boldsymbol{U}_2, \boldsymbol{U}_3, \boldsymbol{U}_4)(\xi)\\ &\quad= (\Phi_1^-, \Phi_2^-, \Phi_1^+, \Phi_2^+)(\xi)\\ &\qquad\times\begin{pmatrix} 1 & 0 & 0 & 0\\ \widetilde{M}_{21}/\widetilde{M}_{11} & 1 & 0 & 0\\ \widetilde{M}_{31}/\widetilde{M}_{11} & 0 & 1 & 0\\ \widetilde{M}_{41}/\widetilde{M}_{11} & -M_{42}/M_{44} & -M_{43}/M_{44} & 1\end{pmatrix}.\end{aligned}$$

This formula shows that $\{\,\boldsymbol{U}_j(\xi)\,\}_{j=1}^4$ is a fundamental set of solutions of $\mathcal{L}(u, v) = 0$.

LEMMA 3.4. *There exists a fundamental set* $\{\boldsymbol{U}_j(\xi)\}_{j=1}^4$ *of solutions of* $\mathcal{L}(u,v) = 0$ *such that the limits* (3.9)–(3.12) *exist and are nonzero.*

3.3. Uniqueness. Let $\boldsymbol{u}_1(\xi) = (u_1, v_1)(\xi)$ and s_1 be an arbitrary positive solution and its propagation speed, respectively, of (1.5) for $(a,b,c) = (a_0, b_0, c_0)$. By the maximum principle and the positivity of $\boldsymbol{u}_1(\xi)$, we see that $\boldsymbol{u}_1(\xi)$ satisfies $\boldsymbol{u}_1(\xi) \in (0,1) \times (0, a_0)$ for any $\xi \in \mathbf{R}$ and has the same asymptotic expansion as $\boldsymbol{u}_0(\xi)$ near $\xi = \pm\infty$ with appropriate change of positive constants $C_u^{\pm}$ and $C_v^{\pm}$.

We first assume $s_0 < s_1$. Since (1.5) does not depend on ξ explicitly, we may assume $u_0(0) = 1/2 = u_1(0)$ without loss of generality. Since $\lambda_u^+(s)$, $\lambda_v^+(s)$, $\sigma_u^-(s)$, and $\sigma_v^-(s)$ are strictly decreasing with respect to s, we see that there exists $\xi_3 \geq 0$ such that $\boldsymbol{u}_1(\xi) \succ_o \boldsymbol{u}_0(\xi)$ for any $|\xi| \geq \xi_3$. We put

$$\underline{u}_1 = \min_{\xi\in[-\xi_3,\xi_3]} u_1(\xi)\,(\in (0,1)), \quad \underline{v}_1 = \max_{\xi\in[-\xi_3,\xi_3]} v_1(\xi)\,(\in (0,a_0)).$$

By $\boldsymbol{u}_0(-\infty) = (0, a_0)$, we can take $\xi_4\,(\in (-\infty, \xi_3])$ as satisfying $\boldsymbol{u}_0(\xi_4) \prec_o (\underline{u}_1, \underline{v}_1)$. Since $\boldsymbol{u}_0(\xi)$ is strictly monotone, we have

$$\boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi-\eta) \begin{cases} \succ_o \boldsymbol{u}_0(\xi) - \boldsymbol{u}_0(\xi-\eta) \succeq_o (0,0) & \text{if } |\xi| \geq \xi_3, \\ \succeq_o \boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi-(\xi_3-\xi_4)) & \\ \quad \succeq_o (\underline{u}_1, \underline{v}_1) - \boldsymbol{u}_0(\xi_4) \succ_o (0,0) & \text{if } |\xi| \leq \xi_3 \end{cases}$$

for any $\eta \geq \xi_3 - \xi_4\,(\geq 0)$. We put

$$\eta_1 = \sup\{\eta \mid \boldsymbol{u}_1(\xi) \not\succ_o \boldsymbol{u}_0(\xi-\eta) \text{ for some } \xi\}.$$

By virtue of $u_0(0) = 1/2 = u_1(0)$, we have $0 \leq \eta_1 \leq \xi_3 - \xi_4$ and

$$\boldsymbol{u}_2(\xi)(= (u_2, v_2)(\xi)) = \boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi-\eta_1) \succeq_o (0,0)$$

for any $\xi \in \mathbf{R}$. We assume that both $\eta_1 > 0$ and $\boldsymbol{u}_2(\xi) \succ_o (0,0)$ for any $\xi \in \mathbf{R}$ hold. Since $\boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi-\eta)$ is strictly monotone in η for any ξ, it follows that there exists $\eta_2 \in (0, \eta_1)$ such that $\boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi - (\eta_1 - \eta)) \succ_o (0,0)$ for any $|\xi| \leq \xi_3$ and $0 \leq \eta \leq \eta_2$. We obtain

$$\boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi - (\eta_1 - \eta)) \succ_o \boldsymbol{u}_0(\xi) - \boldsymbol{u}_0(\xi - (\eta_1 - \eta)) \succ_o (0,0)$$

for any $|\xi| \geq \xi_3$ and $0 \leq \eta \leq \eta_2$. This contradicts the definition of η_1. Since $u_2(0) = 0$ holds if $\eta_1 = 0$, we see that $u_2(\xi)$ and/or $v_2(\xi)$ attain local extremum 0 at some $\xi = \xi_5 \in \mathbf{R}$. Then we have

$$\begin{aligned} 0 \leq & u_{2\xi\xi}(\xi_5) \\ = & - s_1\, u_{1\xi}(\xi_5) - f(\boldsymbol{u}_1(\xi_5)) + s_0\, u_{0\xi}(\xi_5 - \eta_1) + f(\boldsymbol{u}_0(\xi_5 - \eta_1)) \\ = & (s_0 - s_1)\, u_{0\xi}(\xi_5 - \eta_1) + c_0\, u_0(\xi_5 - \eta_1)\, v_2(\xi_5) < 0 \end{aligned}$$

when $u_2(\xi_5) = 0$, and

$$0 \geq d\, v_{2\xi\xi}(\xi_5) = (s_0 - s_1)\, v_{0\xi}(\xi_5 - \eta_1) + b_0\, v_0(\xi_5 - \eta_1)\, u_2(\xi_5) > 0$$

when $v_2(\xi_5) = 0$. These contradictions imply that $s_0 \geq s_1$ holds.

Since we can also derive a contradiction in like manner when we assume $s_0 > s_1$, we have $s_0 = s_1$ as a result.

It follows from (3.7) that $\boldsymbol{u}_1(\xi)$ satisfies

$$\boldsymbol{u}_1(\xi) = (0, a_0) - C_2\, \overline{\Phi}_1^+(\xi; s_0) + o(|\,\overline{\Phi}_1^+(\xi; s_0)\,|)$$

as $\xi \to -\infty$, where C_2 is some positive constant. Since $\overline{\Phi}_1^+(\xi+\eta; s_0) = e^{\Lambda_1^+(s_0)\eta}\,\overline{\Phi}_1^+(\xi; s_0)$ $(1+o(1))$ as $\xi \to -\infty$ for any fixed η, we take η_3 as $C_2 = C_v^-\, e^{-\Lambda_1^+(s_0)\eta_3}$, and put

$$\boldsymbol{u}_3(\xi)(=(u_3, v_3)(\xi)) = \boldsymbol{u}_1(\xi) - \boldsymbol{u}_0(\xi - \eta_3).$$

By virtue of the choice of η_3, we have $\boldsymbol{u}_3(\xi) = o(|\,\overline{\Phi}_1^+(\xi; s_0)\,|)$ as $\xi \to -\infty$. And we see that $\boldsymbol{u}_3(\xi)$ satisfies

$$\begin{cases} u_{3\xi\xi} + s_0\, u_{3\xi} + f_u^1(\xi)\, u_3 + f_v^1(\xi)\, v_3 = 0, \\ d\, v_{3\xi\xi} + s_0\, v_{3\xi} + g_u^1(\xi)\, u_3 + g_v^1(\xi)\, v_3 = 0, \quad \xi \in \mathbf{R}, \end{cases} \tag{3.13}$$

where

$$f_u^1(\xi) = \int_0^1 f_u((1-\theta)\,\boldsymbol{u}_0(\xi-\eta_3) + \theta\,\boldsymbol{u}_1(\xi))\,d\theta$$

and the other functions f_v^1, g_u^1, and g_v^1 are also defined in the same manner with f_u^1. By Lemma 3.3 and

$$\begin{pmatrix} f_u^1(\xi) & f_v^1(\xi) \\ g_u^1(\xi) & g_v^1(\xi) \end{pmatrix} = \begin{pmatrix} 1 - a_0\, c_0 & 0 \\ -a_0\, b_0 & -a_0 \end{pmatrix} + o(e^{(\Lambda_1^+(s_0)-\delta)\,\xi})$$

as $\xi \to -\infty$ for any $0 < \delta < \Lambda_1^+(s_0)$, it follows that there exists a fundamental set $\{\,\widehat{\Phi}_1^{\pm}(\xi), \widehat{\Phi}_2^{\pm}(\xi)\,\}$ of solutions of (3.13) such that $\widehat{\Phi}_j^{\pm}(\xi) = \overline{\Phi}_j^{\pm}(\xi; s_0) + o(|\,\overline{\Phi}_j^{\pm}(\xi; s_0)\,|)$ as $\xi \to -\infty$. Since $\boldsymbol{u}_3(\xi)$ is a bounded solution of (3.13) and satisfies $\boldsymbol{u}_3(\xi) = o(|\,\overline{\Phi}_1^+(\xi; s_0)\,|)$ as $\xi \to -\infty$, we have $\boldsymbol{u}_3(\xi) = C_3\,\widehat{\Phi}_2^+(\xi)$ for some constant C_3. By

$$\begin{aligned} f_v^1(\xi) &= -\,c_0 \int_0^1 \{\,(1-\theta)\,u_0(\xi-\eta_3) + \theta\,u_1(\xi)\,\}\,d\theta \\ &= -\,\frac{c_0}{2}\,\{\,u_0(\xi-\eta_3) + u_1(\xi)\,\} = -c_0\,C_4\,e^{\lambda_u^+(s_0)\,\xi}\,(1+o(1)) \end{aligned}$$

as $\xi \to -\infty$, where C_4 is some positive constant, we obtain

$$\widehat{\Phi}_2^+(\xi)\,e^{-\Lambda_2^+(s_0)\,\xi} = \begin{cases} \left(\dfrac{p_v^-(\lambda_u^+(s_0); s_0)}{a_0\, b_0},\, 1\right)(1+o(1)) \\ \qquad\qquad \text{if } \lambda_u^+(s_0) > \lambda_v^+(s_0), \\ \left(\dfrac{c_0\, C_4\, e^{\lambda_u^+(s_0)\,\xi}}{p_u^-(\lambda_u^+(s_0) + \lambda_v^+(s_0); s_0)},\, 1\right)(1+o(1)) \\ \qquad\qquad \text{if } \lambda_u^+(s_0) \le \lambda_v^+(s_0) \end{cases}$$

as $\xi \to -\infty$ in a similar manner with the calculation of the asymptotic expansion of $\Phi_2^+(\xi)$. By virtue of (3.8), we have $\widehat{\Phi}_2^+(\xi) \succ_s (0,0)$ as $\xi \to -\infty$.

We assume $C_3 \neq 0$. Then we obtain $u_3(\xi)\,v_3(\xi) > 0$ near $\xi = -\infty$. We put

$$\xi_6 = \inf\{\,\xi \mid u_3(\xi)\,v_3(\xi) \le 0\,\}$$

if $u_3(\xi)$ and/or $v_3(\xi)$ have a zero, but otherwise $\xi_6 = +\infty$. Using (3.2) and the

integration by parts, we have

$$\begin{aligned}
0 &= \int_{-\infty}^{\xi_6} \{ u_{1\xi\xi}(\xi) + s_0\, u_{1\xi}(\xi) + f(\boldsymbol{u}_1(\xi)) \}\, u_0(\xi-\eta_3)\, e^{s_0\,\xi}\, d\xi \\
&= u_{1\xi}(\xi_6)\, u_0(\xi_6-\eta_3)\, e^{s_0\,\xi_6} - u_1(\xi_6)\, u_{0\xi}(\xi_6-\eta_3)\, e^{s_0\,\xi_6} \\
&\qquad + \int_{-\infty}^{\xi_6} \{ u_0(\xi-\eta_3)\, f(\boldsymbol{u}_1(\xi)) - u_1(\xi)\, f(\boldsymbol{u}_0(\xi-\eta_3)) \}\, e^{s_0\,\xi}\, d\xi \\
&= u_1(\xi_6)\, u_{3\xi}(\xi_6)\, e^{s_0\,\xi_6} \\
&\qquad - \int_{-\infty}^{\xi_6} u_0(\xi-\eta_3)\, u_1(\xi)\, \{ u_3(\xi) + c_0\, v_3(\xi) \}\, e^{s_0\,\xi}\, d\xi \neq 0
\end{aligned}$$

when $u_3(\xi_6) = 0$, and

$$\begin{aligned}
0 &= \int_{-\infty}^{\xi_6} \{ d\, v_{1\xi\xi}(\xi) + s_0\, v_{1\xi}(\xi) + g(\boldsymbol{u}_1(\xi)) \}\, v_0(\xi-\eta_3)\, e^{(s_0\,\xi)/d}\, d\xi \\
&= d\, v_1(\xi_6)\, v_{3\xi}(\xi_6)\, e^{(s_0\,\xi_6)/d} \\
&\qquad - \int_{-\infty}^{\xi_6} v_0(\xi-\eta_3)\, v_1(\xi)\, \{ b_0\, u_3(\xi) + v_3(\xi) \}\, e^{(s_0\,\xi)/d}\, d\xi \neq 0
\end{aligned}$$

when $v_3(\xi_6) = 0$ and/or $\xi_6 = +\infty$. The aforementioned contradictions imply that $\boldsymbol{u}_1(\xi) = \boldsymbol{u}_0(\xi-\eta_3)$ holds for any $\xi \in \mathbf{R}$.

LEMMA 3.5. *Let $\boldsymbol{u}_1(\xi)$ and s_1 be an arbitrary positive solution and its propagation speed, respectively, of* (1.5) *for $(a,b,c) = (a_0,b_0,c_0)$. Then $s_1 = s_0$ holds and there exists η such that $\boldsymbol{u}_1(\xi) = \boldsymbol{u}_0(\xi+\eta)$ for any $\xi \in \mathbf{R}$.*

3.4. Continuation.

LEMMA 3.6. *$\boldsymbol{u}_0(\xi)$ and s_0 satisfy*

$$\| \boldsymbol{u}_0 \|_{C^2(\mathbf{R})} \leq \begin{cases} C_5(b_0,c_0) & \text{for } s_0 = 0, \\ C_5(b_0,c_0)/|\, s_0\,| & \text{for } s_0 \neq 0, \end{cases}$$

and

$$-2 < s_0 < 2\sqrt{a_0\, d},$$

where $C_5(b_0,c_0)$ is a continuous function in (b_0,c_0) which does not depend on a_0.

Proof. We put

$$U(\xi) = \begin{cases} u_0(\xi)\, e^{(s_0\,\xi)/2} & \text{for } s_0 < 0, \\ v_0(\xi)\, e^{(s_0\,\xi)/(2\,d)} & \text{for } s_0 > 0. \end{cases}$$

We see from (3.2), (3.5), and (3.6) that $U(\xi)$ satisfies $\lim_{\xi\to\pm\infty} U(\xi) = 0$ for any $s_0 \neq 0$. Then it follows that there exists $\xi_7 \in \mathbf{R}$ such that $U(\xi)$ attains positive maximum at $\xi = \xi_7$, that is, $U(\xi)$ satisfies

$$0 \geq U_{\xi\xi}(\xi_7) = \left(\frac{s_0^2}{4} - 1 + u_0(\xi_7) + c_0\, v_0(\xi_7) \right) U(\xi_7)$$

when $s_0 < 0$, and

$$0 \geq U_{\xi\xi}(\xi_7) = \left(\frac{s_0^2}{4\,d} - a_0 + b_0\, u_0(\xi_7) + v_0(\xi_7) \right) \frac{U(\xi_7)}{d}$$

when $s_0 > 0$. Thus we have $-2 < s_0 < 2\sqrt{a_0\, d}$.

Since $0 < u_0(\xi) < 1$ and $0 < v_0(\xi) < a_0 < b_0$ hold for any $\xi \in \mathbf{R}$, we have $\| \boldsymbol{u}_0 \|_{C^0(\mathbf{R})} \leq 1 + b_0$ and

$$
\begin{aligned}
&-b_0\, c_0 < -c_0\, v_0(\xi) \leq f(\boldsymbol{u}_0(\xi)) \leq u_0(\xi) < 1, \\
&-b_0 < -b_0\, u_0(\xi) \leq g(\boldsymbol{u}_0(\xi)) \leq a_0\, v_0(\xi) < b_0^2
\end{aligned} \tag{3.14}
$$

for any $\xi \in \mathbf{R}$. We have the following:

(i) For $s_0 = 0$,

$$
\begin{aligned}
0 =& u_{0\xi}(\xi)^2 + 2 \int_{-\infty}^{\xi} f(\boldsymbol{u}_0(\tau))\, u_{0\xi}(\tau)\, d\tau \\
&\geq u_{0\xi}(\xi)^2 - 2\, b_0\, c_0 \int_{-\infty}^{\xi} u_{0\xi}(\tau)\, d\tau \geq u_{0\xi}(\xi)^2 - 2\, b_0\, c_0, \\
0 =& d\, v_{0\xi}(\xi)^2 + 2 \int_{-\infty}^{\xi} g(\boldsymbol{u}_0(\tau))\, v_{0\xi}(\tau)\, d\tau \geq d\, v_{0\xi}(\xi)^2 - 2\, b_0^3.
\end{aligned}
$$

(ii) For $s_0 > 0$,

$$
\begin{aligned}
0 =& u_{0\xi}(\xi) + \int_{-\infty}^{\xi} e^{s_0(\tau-\xi)} f(\boldsymbol{u}_0(\tau))\, d\tau \\
&\geq u_{0\xi}(\xi) - b_0\, c_0 \int_{-\infty}^{\xi} e^{s_0(\tau-\xi)}\, d\tau = u_{0\xi}(\xi) - b_0\, c_0/s_0, \\
0 =& d\, v_{0\xi}(\xi) + \int_{-\infty}^{\xi} e^{\{s_0(\tau-\xi)\}/d} g(\boldsymbol{u}_0(\tau))\, d\tau \leq d\, v_{0\xi}(\xi) + b_0^2\, d/s_0.
\end{aligned}
$$

(iii) For $s_0 < 0$,

$$
\begin{aligned}
0 =& u_{0\xi}(\xi) - \int_{\xi}^{+\infty} e^{s_0(\tau-\xi)} f(\boldsymbol{u}_0(\tau))\, d\tau, \\
&\geq u_{0\xi}(\xi) - \int_{\xi}^{+\infty} e^{s_0(\tau-\xi)}\, d\tau = u_{0\xi}(\xi) + 1/s_0, \\
0 =& d\, v_{0\xi}(\xi) - \int_{\xi}^{+\infty} e^{\{s_0(\tau-\xi)\}/d} g(\boldsymbol{u}_0(\tau))\, d\tau \leq d\, v_{0\xi}(\xi) - b_0\, d/s_0.
\end{aligned}
$$

By the above inequalities and $u_{0\xi}(\xi) > 0 > v_{0\xi}(\xi)$ for any $\xi \in \mathbf{R}$, we see that there exists a continuous function $C_6(b_0, c_0)$ independent of a_0 such that

$$
\| \boldsymbol{u}_{0\xi} \|_{C^0(\mathbf{R})} \leq \begin{cases} C_6(b_0, c_0) & \text{for } s_0 = 0, \\ C_6(b_0, c_0)/|\, s_0\,| & \text{for } s_0 \neq 0. \end{cases}
$$

By the inequalities $|\, s_0\,| < \max\{2, 2\sqrt{b_0\, d}\}$ and

$$
\| \boldsymbol{u}_{0\xi\xi} \|_{C^0(\mathbf{R})} \leq \frac{1}{\min(1, d)} \left\{ |\, s_0\,|\, \| \boldsymbol{u}_{0\xi} \|_{C^0(\mathbf{R})} + \| (f(\boldsymbol{u}_0), g(\boldsymbol{u}_0)) \|_{C^0(\mathbf{R})} \right\},
$$

we have the desired estimate for $\boldsymbol{u}_0(\xi)$. □

We put $(a, b, c, s) = (a_0, b_0, c_0, s_0) + (\widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})$, $\boldsymbol{z} = {}^t(u, u_\xi, v, v_\xi)$ and

$$
\boldsymbol{f}(\boldsymbol{z}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}) = \begin{pmatrix} u_\xi \\ -s\, u_\xi - u\,(1 - u - c\, v) \\ v_\xi \\ -\{\, s\, v_\xi + v\,(a - b\, u - v)\,\}/d \end{pmatrix}.
$$

Since (1.5) does not depend on ξ explicitly, we may assume $u(0) = 1/2$ without loss of generality. Then (1.5) is rewritten as

$$\text{(3.15)}\qquad \begin{cases} \dfrac{d}{d\xi}\boldsymbol{z} = \boldsymbol{f}(\boldsymbol{z}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}), \quad \xi \in \mathbf{R}, \\ \boldsymbol{z}(-\infty) = {}^t(0, 0, a_0 + \widehat{a}, 0), \\ \boldsymbol{z}(+\infty) = {}^t(1, 0, 0, 0), \\ \boldsymbol{z}(0) = \boldsymbol{z}_0(0) + {}^t(0, \alpha_1, \alpha_2, \alpha_3), \end{cases}$$

where $\boldsymbol{z}_0(\xi) = {}^t(u_0, u_{0\xi}, v_0, v_{0\xi})(\xi)$, and $\alpha = (\alpha_1, \alpha_2, \alpha_3)$ will be determined later. Further, by the change of variables

$$\boldsymbol{z} = \begin{cases} \boldsymbol{z}_0(\xi) + {}^t(0, 0, \widehat{a}, 0) + \boldsymbol{y} & \text{for } \xi < 0, \\ \boldsymbol{z}_0(\xi) + \boldsymbol{y} & \text{for } \xi > 0, \end{cases}$$

(3.15) becomes

$$\text{(3.16)}\qquad \begin{cases} \dfrac{d}{d\xi}\boldsymbol{y} = A(\xi)\,\boldsymbol{y} + \boldsymbol{N}(\xi, \boldsymbol{y}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}), \quad \xi \in \mathbf{R} \setminus \{0\}, \\ \boldsymbol{y}(-\infty) = 0 = \boldsymbol{y}(+\infty), \\ \boldsymbol{y}(0-0) = {}^t(0, \alpha_1, \alpha_2 - \widehat{a}, \alpha_3), \\ \boldsymbol{y}(0+0) = {}^t(0, \alpha_1, \alpha_2, \alpha_3), \end{cases}$$

where $A(\xi) = \boldsymbol{f}_{\boldsymbol{z}}(\boldsymbol{z}_0(\xi); 0)$,

$$\boldsymbol{N}(\xi, \boldsymbol{y}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}) = \boldsymbol{f}(\boldsymbol{z}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}) - \boldsymbol{f}(\boldsymbol{z}_0(\xi); 0) - A(\xi)\,\boldsymbol{y}.$$

Let J be an interval and $Y(\xi)$ be a fundamental matrix of $\frac{d}{d\xi}\boldsymbol{y} = A(\xi)\,\boldsymbol{y}$. We shall say that $\frac{d}{d\xi}\boldsymbol{y} = A(\xi)\,\boldsymbol{y}$ has an *exponential dichotomy* on J if there exist a projection P and positive constants C, γ such that, for any ξ, $\eta \in J$, $Y(\xi)$ satisfies

$$\begin{aligned} &|\,Y(\xi)\,P\,Y(\eta)^{-1}\,| \le C\,e^{-\gamma(\xi-\eta)} && \text{if } \xi \ge \eta, \\ &|\,Y(\xi)\,(I-P)\,Y(\eta)^{-1}\,| \le C\,e^{-\gamma(\eta-\xi)} && \text{if } \eta \ge \xi. \end{aligned}$$

We note that this definition does not depend on the choice of the fundamental matrix $Y(\xi)$.

PROPOSITION 3.7 (Coppel [3, p. 11]). *$\frac{d}{d\xi}\boldsymbol{y} = A(\xi)\,\boldsymbol{y}$ has an exponential dichotomy on J if and only if there exist a projection P and positive constants C, γ such that, for any ξ, $\eta \in J$, $Y(\xi)$ satisfies*

$$\begin{aligned} &|\,Y(\xi)\,P\,\boldsymbol{w}\,| \le C\,e^{-\gamma(\xi-\eta)}\,|\,Y(\eta)\,P\,\boldsymbol{w}\,| && \text{if } \xi \ge \eta, \\ &|\,Y(\xi)\,(I-P)\,\boldsymbol{w}\,| \le C\,e^{-\gamma(\eta-\xi)}\,|\,Y(\eta)\,(I-P)\,\boldsymbol{w}\,| && \text{if } \eta \ge \xi, \end{aligned}$$

where $\boldsymbol{w}$ is an arbitrary constant vector.

We define the matrix $X(\xi)$ by

$$X(\xi) = \begin{pmatrix} U_3(\xi) & U_4(\xi) & U_1(\xi) & U_2(\xi) \\ U_{3\xi}(\xi) & U_{4\xi}(\xi) & U_{1\xi}(\xi) & U_{2\xi}(\xi) \\ V_3(\xi) & V_4(\xi) & V_1(\xi) & V_2(\xi) \\ V_{3\xi}(\xi) & V_{4\xi}(\xi) & V_{1\xi}(\xi) & V_{2\xi}(\xi) \end{pmatrix},$$

where $\{\,(U_j, V_j)(\xi)\,\}_{j=1}^4$ is a fundamental set of solutions of $\mathcal{L}(u, v) = 0$ given in Lemma 3.4. In consideration of the proof of Lemma 3.4, we can take $(U_3, V_3)(\xi)$ as

$(U_3, V_3)(\xi) = \boldsymbol{u}_{0\xi}(\xi)$. Clearly we see that $X(\xi)$ is a fundamental matrix of $\frac{d}{d\xi}\boldsymbol{y} = A(\xi)\boldsymbol{y}$. By virtue of (3.9)–(3.12), the following lemma holds.

LEMMA 3.8. *$\frac{d}{d\xi}\boldsymbol{y} = A(\xi)\boldsymbol{y}$ has an exponential dichotomy on $R_- = (-\infty, 0)$ (respectively, $R_+ = (0, +\infty)$) with the projection $P_- = \mathrm{diag}(0,0,1,1)$ (respectively, $P_+ = \mathrm{diag}(1,0,1,0)$).*

Proof. We may take the constant γ in Proposition 3.7 as satisfying $0 < \gamma < \min\{\Lambda_1^+(s_0), -\Sigma_2^-(s_0)\}$. □

Let $\boldsymbol{x}_j^*(\xi)$ and $x_{ij}^*(\xi)$ be jth row vector and (i,j) element, respectively, of $X(\xi)^{-1}$. We calculate $X(\xi)^{-1}$ directly by the use of the asymptotic behaviors (3.9)–(3.12), and then obtain

$$\begin{aligned}
\boldsymbol{x}_2^*(\xi) &= o(e^{-(\Sigma_2^+(s_0)-\delta)\xi}) \quad \text{as } \xi \to +\infty,\\
\boldsymbol{x}_3^*(\xi) &= o(e^{-(\Lambda_1^-(s_0)+\delta)\xi}) \quad \text{as } \xi \to -\infty,\\
\boldsymbol{x}_4^*(\xi) &= \begin{cases} o(e^{-(\Lambda_2^-(s_0)+\delta)\xi}) & \text{as } \xi \to -\infty,\\ o(e^{-(\Sigma_1^+(s_0)-\delta)\xi}) & \text{as } \xi \to +\infty \end{cases}
\end{aligned}$$

for any $0 < \delta < \min\{-\Lambda_2^-(s_0), \Sigma_1^+(s_0)\}$. Then we see that $(u^*, v^*)(\xi) = (x_{42}^*, x_{44}^*/d)(\xi)$ is a bounded nontrivial solution of $\mathcal{L}^*(u,v) = 0$.

LEMMA 3.9 (Lemma A.2 in [8]). *$(u^*, v^*)(\xi)$ satisfies $u^*(\xi)\, v^*(\xi) < 0$ for any $\xi \in \mathbf{R}$.*

LEMMA 3.10 (Lemma 3.2 in Kokubu [9]). *$\boldsymbol{y}(\xi)$ is a bounded solution of*

$$\begin{cases} \dfrac{d}{d\xi}\boldsymbol{y} = A(\xi)\,\boldsymbol{y} + \boldsymbol{N}(\xi, \boldsymbol{y}; \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s}), \quad \xi \in \mathbf{R} \setminus \{0\}, \\ \boldsymbol{y}(-\infty) = 0, \quad \boldsymbol{y}(+\infty) = 0 \end{cases}$$

if and only if $\boldsymbol{y}(\xi)$ satisfies

$$P_- \left\{ X(0)^{-1}\boldsymbol{y}(0-0) - \int_{R_-} X(\xi)^{-1}\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \right\} = 0$$

and

$$(I - P_+) \left\{ X(0)^{-1}\boldsymbol{y}(0+0) + \int_{R_+} X(\xi)^{-1}\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \right\} = 0.$$

From the previous lemma and (3.16), we define the map $E : \mathbf{R}^7 \to \mathbf{R}^4$ by

$$E(\alpha, \widehat{s}, \widehat{a}, \widehat{b}, \widehat{c}) = \begin{pmatrix} \boldsymbol{x}_3^*(0)\,\boldsymbol{y}(0-0) - \displaystyle\int_{R_-} \boldsymbol{x}_3^*(\xi)\,\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \\ \boldsymbol{x}_4^*(0)\,\boldsymbol{y}(0-0) - \displaystyle\int_{R_-} \boldsymbol{x}_4^*(\xi)\,\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \\ \boldsymbol{x}_2^*(0)\,\boldsymbol{y}(0+0) + \displaystyle\int_{R_+} \boldsymbol{x}_2^*(\xi)\,\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \\ \boldsymbol{x}_4^*(0)\,\boldsymbol{y}(0+0) + \displaystyle\int_{R_+} \boldsymbol{x}_4^*(\xi)\,\boldsymbol{N}(\xi, \boldsymbol{y}(\xi); \widehat{a}, \widehat{b}, \widehat{c}, \widehat{s})\, d\xi \end{pmatrix}.$$

We easily obtain $E(0) = 0$. Since $\boldsymbol{x}_j^*(\xi)$ is a solution of $\frac{d}{d\xi}\boldsymbol{x} = -\boldsymbol{x}\,A(\xi)$ for each j, we

have

$$\frac{\partial}{\partial\mu}\left[\boldsymbol{x}_j^*(0)\,\boldsymbol{y}(0-0)-\int_{R_-}\boldsymbol{x}_j^*(\xi)\,\boldsymbol{N}(\xi,\boldsymbol{y}(\xi);\widehat{a},\widehat{b},\widehat{c},\widehat{s})\,d\xi\right]\Bigg|_{(\alpha,\widehat{a},\widehat{b},\widehat{c},\widehat{s})=0}$$
$$=-\delta_{\mu,\widehat{a}}\,\boldsymbol{x}_j^*(0)\,\boldsymbol{e}-\int_{R_-}\boldsymbol{x}_j^*(\xi)\,\{\,\delta_{\mu,\widehat{a}}\,\boldsymbol{f}_{\boldsymbol{z}}(\boldsymbol{z}_0(\xi);0)\,\boldsymbol{e}+\boldsymbol{f}_\mu(\boldsymbol{z}_0(\xi);0)\,\}d\xi$$
$$=-\int_{R_-}\boldsymbol{x}_j^*(\xi)\,\boldsymbol{f}_\mu(\boldsymbol{z}_0(\xi);0)\,d\xi\quad\text{for } j=3,4,$$
$$\frac{\partial}{\partial\mu}\left[\boldsymbol{x}_j^*(0)\,\boldsymbol{y}(0+0)+\int_{R_+}\boldsymbol{x}_j^*(\xi)\,\boldsymbol{N}(\xi,\boldsymbol{y}(\xi);\widehat{a},\widehat{b},\widehat{c},\widehat{s})\,d\xi\right]\Bigg|_{(\alpha,\widehat{a},\widehat{b},\widehat{c},\widehat{s})=0}$$
$$=\int_{R_+}\boldsymbol{x}_j^*(\xi)\,\boldsymbol{f}_\mu(\boldsymbol{z}_0(\xi);0)\,d\xi\quad\text{for } j=2,4$$

with $\mu=\widehat{a},\widehat{b},\widehat{c},\widehat{s}$, where $\boldsymbol{e}={}^t(0,0,1,0)$, and $\delta_{\mu,\widehat{a}}$ satisfies $\delta_{\mu,\widehat{a}}=1$ if $\mu=\widehat{a}$ but otherwise $\delta_{\mu,\widehat{a}}=0$. By the above formulas, we obtain

$$\det\frac{\partial E}{\partial(\alpha,\widehat{s})}(0)$$
$$=\det\begin{pmatrix} x_{32}^*(0) & x_{33}^*(0) & x_{34}^*(0) & -\displaystyle\int_{R_+}\boldsymbol{x}_3^*(\xi)\,\boldsymbol{f}_{\widehat{s}}(\boldsymbol{z}_0(\xi);0)\,d\xi\\ x_{42}^*(0) & x_{43}^*(0) & x_{44}^*(0) & -\displaystyle\int_{R_-}\boldsymbol{x}_4^*(\xi)\,\boldsymbol{f}_{\widehat{s}}(\boldsymbol{z}_0(\xi);0)\,d\xi\\ x_{22}^*(0) & x_{23}^*(0) & x_{24}^*(0) & \displaystyle\int_{R_+}\boldsymbol{x}_2^*(\xi)\,\boldsymbol{f}_{\widehat{s}}(\boldsymbol{z}_0(\xi);0)\,d\xi\\ x_{42}^*(0) & x_{43}^*(0) & x_{44}^*(0) & \displaystyle\int_{R_+}\boldsymbol{x}_4^*(\xi)\,\boldsymbol{f}_{\widehat{s}}(\boldsymbol{z}_0(\xi);0)\,d\xi \end{pmatrix}$$
$$=\frac{u_{0\xi}(0)}{\det X(0)}\int_{\mathbf{R}}\boldsymbol{x}_4^*(\xi)\,\boldsymbol{f}_{\widehat{s}}(\boldsymbol{z}_0(\xi);0)\,d\xi$$
$$=-\frac{u_{0\xi}(0)}{\det X(0)}\int_{\mathbf{R}}\{u_{0\xi}(\xi)\,u^*(\xi)+v_{0\xi}(\xi)\,v^*(\xi)\}\,d\xi.$$

We also get analogously

$$\det\frac{\partial E}{\partial(\alpha,\widehat{a})}(0)=-\frac{u_{0\xi}(0)}{\det X(0)}\int_{\mathbf{R}}v_0(\xi)\,v^*(\xi)\,d\xi,$$
$$\det\frac{\partial E}{\partial(\alpha,\widehat{b})}(0)=\frac{u_{0\xi}(0)}{\det X(0)}\int_{\mathbf{R}}u_0(\xi)\,v_0(\xi)\,v^*(\xi)\,d\xi,$$
$$\det\frac{\partial E}{\partial(\alpha,\widehat{c})}(0)=\frac{u_{0\xi}(0)}{\det X(0)}\int_{\mathbf{R}}u_0(\xi)\,v_0(\xi)\,u^*(\xi)\,d\xi.$$

We have the following lemmas by virtue of the implicit function theorem, the maximum principle, and Lemma 3.9.

LEMMA 3.11. *There exist C^1-class families $\overline{\boldsymbol{u}}(\xi;b,c)$ and $\overline{a}(b,c)$ defined in a neighborhood of $(b,c)=(b_0,c_0)$ such that $\overline{\boldsymbol{u}}(\xi;b,c)$ is a strictly monotone solution of (1.5) with $(s,a)=(s_0,\overline{a}(b,c))$ for each (b,c) and*

$$(\overline{\boldsymbol{u}}(.;b,c),\overline{a}(b,c))\to(\boldsymbol{u}_0(.),a_0)\quad as\quad(b,c)\to(b_0,c_0)$$

holds.

LEMMA 3.12. *There exist C^1-class families $\boldsymbol{u}(\xi;a,b,c)$ and $s(a,b,c)$ defined in a neighborhood of $(a,b,c)=(a_0,b_0,c_0)$ such that $\boldsymbol{u}(\xi;a,b,c)$ is a strictly monotone solution of* (1.5) *with $s=s(a,b,c)$ for each (a,b,c) and*

$$(\boldsymbol{u}(.;a,b,c),s(a,b,c))\to(\boldsymbol{u}_0(.),s_0)\quad as\quad (a,b,c)\to(a_0,b_0,c_0)$$

holds. Furthermore, $s(a,b,c)$ satisfies

$$\frac{\partial}{\partial a}s(a_0,b_0,c_0)=-\frac{\int_{\mathbf{R}}v_0(\xi)\,v^*(\xi)\,d\xi}{\int_{\mathbf{R}}\{u_{0\xi}(\xi)\,u^*(\xi)+v_{0\xi}(\xi)\,v^*(\xi)\}\,d\xi}>0,$$

$$\frac{\partial}{\partial b}s(a_0,b_0,c_0)=\frac{\int_{\mathbf{R}}u_0(\xi)\,v_0(\xi)\,v^*(\xi)\,d\xi}{\int_{\mathbf{R}}\{u_{0\xi}(\xi)\,u^*(\xi)+v_{0\xi}(\xi)\,v^*(\xi)\}\,d\xi}<0,$$

$$\frac{\partial}{\partial c}s(a_0,b_0,c_0)=\frac{\int_{\mathbf{R}}u_0(\xi)\,v_0(\xi)\,u^*(\xi)\,d\xi}{\int_{\mathbf{R}}\{u_{0\xi}(\xi)\,u^*(\xi)+v_{0\xi}(\xi)\,v^*(\xi)\}\,d\xi}>0.$$

3.5. Nonexistence. Let $\boldsymbol{u}(\xi)=(u,v)(\xi)$ be an arbitrary monotone bounded solution of (1.5a). Since $\boldsymbol{u}(\xi)$ is bounded and satisfies $u_\xi(\xi)\geq 0\geq v_\xi(\xi)$ for any $\xi\in\mathbf{R}$, we have $\liminf_{\xi\to\pm\infty}u_\xi(\xi)=0$ and $\limsup_{\xi\to\pm\infty}v_\xi(\xi)=0$. By (1.5a), we have

$$u_\xi(\tau)=u_\xi(\xi)+s\{u(\xi)-u(\tau)\}+\int_\tau^\xi f(\boldsymbol{u}(\eta))\,d\eta. \tag{3.17}$$

for any $\xi,\tau\in\mathbf{R}$. If $f(\boldsymbol{u}(\xi))\geq 0$ near $\xi=-\infty$ (respectively, $\xi=+\infty$), then we see that the limit $\int_{-\infty}^{\xi}f(\boldsymbol{u}(\eta))\,d\eta$ (respectively, $\int_{+\infty}^{\xi}f(\boldsymbol{u}(\eta))\,d\eta$) exists on $\overline{\mathbf{R}}$ for any ξ, because $\int_\tau^\xi f(\boldsymbol{u}(\eta))\,d\eta$ is increasing (respectively, decreasing) in τ for any ξ. By taking the inferior limit of both hands of (3.17) as $\tau\to-\infty$ (respectively, $\tau\to+\infty$), we get

$$\begin{aligned}&0=u_\xi(\xi)+s\{u(\xi)-u(-\infty)\}+\int_{-\infty}^{\xi}f(\boldsymbol{u}(\eta))\,d\eta\\&\left(\text{respectively, }0=u_\xi(\xi)+s\{u(\xi)-u(+\infty)\}-\int_{\xi}^{+\infty}f(\boldsymbol{u}(\eta))\,d\eta\right)\end{aligned} \tag{3.18}$$

for any $\xi\in\mathbf{R}$ if $f(\boldsymbol{u}(\xi))\geq 0$ near $\xi=-\infty$ (respectively, $\xi=+\infty$). We also have, analogously,

$$\begin{aligned}&0=dv_\xi(\xi)+s\{v(\xi)-v(-\infty)\}+\int_{-\infty}^{\xi}g(\boldsymbol{u}(\eta))\,d\eta\\&\left(\text{respectively, }0=dv_\xi(\xi)+s\{v(\xi)-v(+\infty)\}-\int_{\xi}^{+\infty}g(\boldsymbol{u}(\eta))\,d\eta\right)\end{aligned} \tag{3.19}$$

for any $\xi\in\mathbf{R}$ if $g(\boldsymbol{u}(\xi))\leq 0$ near $\xi=-\infty$ (respectively, $\xi=+\infty$).

LEMMA 3.13. *For each $(a,b,c)\in R^3_+$, if $s\geq 0$ (respectively, $s\leq 0$), then an arbitrary, monotone nonnegative solution $(u,v)(\xi)$ of* (1.5a) *with $(u,v)(-\infty)=(0,0)$ (respectively, $(u,v)(+\infty)=(0,0)$) satisfies $u(\xi)=0$ (respectively, $v(\xi)=0$) for any $\xi\in\mathbf{R}$.*

Proof. We only show the proof for the former case, because the latter can be proved in a similar manner.

Let $\boldsymbol{u}(\xi)=(u,v)(\xi)$ be an arbitrary monotone nonnegative solution of (1.5a) with $(u,v)(-\infty)=(0,0)$ for $s\geq 0$. We assume that $u(\xi_8)>0$ holds for some $\xi_8\in\mathbf{R}$. Since

$f(u,v) > 0$ holds on $(0,\delta] \times [0,\delta]$ for some $\delta > 0$, we see from $\boldsymbol{u}(-\infty) = (0,0)$ that there exists $\xi_9 \in \mathbf{R}$ such that $f(\boldsymbol{u}(\xi)) \geq 0\,(\not\equiv 0)$ for any $\xi \leq \xi_9$. By (3.18), we have

$$0 = u_\xi(\xi_9) + s\,u(\xi_9) + \int_{-\infty}^{\xi_9} f(\boldsymbol{u}(\xi))\,d\xi > 0.$$

This contradiction implies that the desired result holds. □

LEMMA 3.14. *Equation* (1.5) *with* $s = 0$ *has no monotone solution for arbitrary* $(a,b,c) \notin \mathcal{P}$.

Proof. We assume that (1.5) with $s = 0$ has a monotone solution $\boldsymbol{u}(\xi) = (u,v)(\xi)$ for some (a,b,c), which satisfies either $a < 1/c$ or $a = 1/c \leq b$.

We first consider the case for $a = 1/c \leq b$. Then we have $(1 - u - c\,v)(\pm\infty) = 0$. We assume that $(1 - u - c\,v)(\xi)$ attains a negative local minimum at $\xi = \xi_{10}$. By $f(\boldsymbol{u}(\xi_{10})) < 0$ and $g(\boldsymbol{u}(\xi_{10})) < 0$, we have

$$0 \leq (1 - u - c\,v)_{\xi\xi}(\xi_{10}) = f(\boldsymbol{u}(\xi_{10})) + \frac{c}{d}\,g(\boldsymbol{u}(\xi_{10})) < 0.$$

This contradiction implies that $f(\boldsymbol{u}(\xi)) \geq 0$ holds for any $\xi \in \mathbf{R}$. Then, by $\liminf_{\xi\to\pm\infty} u_\xi(\xi) = 0$ and $u_{\xi\xi}(\xi) = -f(\boldsymbol{u}(\xi)) \leq 0$ for any $\xi \in \mathbf{R}$, we obtain $u_\xi(\xi) = 0$ for any $\xi \in \mathbf{R}$, that is, $u(\xi)$ is a constant function. This contradicts the boundary conditions at $\xi = \pm\infty$.

Next, we consider the case for $a < 1/c$. Since $(1 - u - c\,v)(\xi) = 1 - a\,c + o(1) > 0$ as $\xi \to -\infty$, we have

$$0 = u_\xi(\xi) + \int_{-\infty}^{\xi} f(\boldsymbol{u}(\xi))\,d\xi > 0$$

as $\xi \to -\infty$ because of (3.18). This is a contradiction.

Thus we see that the desired result holds when (a,b,c) satisfies either $a < 1/c$ or $a = 1/c \leq b$.

In a similar manner, we can also prove the desired result for the case where either $a > b$ or $a = b \geq 1/c$ holds. □

LEMMA 3.15. *For arbitrary* $(a,b,c) \in \mathcal{P}$, *if* $s \geq 0$ (*respectively,* $s \leq 0$), *then* (1.5a) *has no monotone solution which satisfies*

$$(u,v)(-\infty) = \left(\frac{1 - a\,c}{1 - b\,c}, \frac{a - b}{1 - b\,c}\right), \quad (u,v)(+\infty) = (1,0)$$

$$\left(\textit{respectively,} \quad (u,v)(-\infty) = (0,a), \quad (u,v)(+\infty) = \left(\frac{1 - a\,c}{1 - b\,c}, \frac{a - b}{1 - b\,c}\right)\right).$$

Proof. We only show the proof for the former case, because the latter can be proved in a similar manner.

Contrary to the conclusion, suppose that (1.5a) with the above boundary conditions has a monotone solution $\boldsymbol{u}(\xi) = (u,v)(\xi)$ for some $s \geq 0$. By the boundary conditions at $\xi = \pm\infty$, we have

$$(1 - u - c\,v)(\pm\infty) = 0, \quad (a - b\,u - v)(\pm\infty) \leq 0.$$

We consider the case for $d \leq 1$, and assume that $(1 - u - c\,v)(\xi)$ attains a nonpositive local minimum at $\xi = \xi_{11}$. Since $u_\xi(\xi_{11}) + c\,v_\xi(\xi_{11}) = 0$ and $g(\boldsymbol{u}(\xi_{11})) < 0$,

we have

$$\begin{aligned}0 \leq & (1-u-cv)_{\xi\xi}(\xi_{11}) \\ = & s\left(1-\frac{1}{d}\right)u_\xi(\xi_{11}) + f(\boldsymbol{u}(\xi_{11})) + \frac{c}{d}\,g(\boldsymbol{u}(\xi_{11})) < 0.\end{aligned}$$

This contradiction implies that $f(\boldsymbol{u}(\xi)) > 0$ holds for any $\xi \in \mathbf{R}$ when $d \leq 1$. Analogously, we obtain $g(\boldsymbol{u}(\xi)) < 0$ for any $\xi \in \mathbf{R}$ when $d \geq 1$.

By (3.18) and (3.19), we have

$$0 = s\{u(+\infty) - u(-\infty)\} + \int_{\mathbf{R}} f(\boldsymbol{u}(\xi))\,d\xi > 0 \quad \text{for } d \leq 1,$$

$$0 = s\{v(+\infty) - v(-\infty)\} + \int_{\mathbf{R}} g(\boldsymbol{u}(\xi))\,d\xi < 0 \quad \text{for } d \geq 1.$$

These contradictions imply that the desired result holds. □

3.6. Proof of Theorem 2.1.

LEMMA 3.16. *Let* $\boldsymbol{u}(\xi) = (u,v)(\xi)$ *be a monotone, nonnegative, and bounded solution of* (1.5a) *for* $(a,b,c,s) \in R^3_+ \times \mathbf{R}$. *Then* $\boldsymbol{u}(\xi)$ *satisfies* $f(\boldsymbol{u}(\pm\infty)) = 0$ *and* $g(\boldsymbol{u}(\pm\infty)) = 0$.

Proof. We only show the proof for $f(\boldsymbol{u}(+\infty)) = 0$, because $f(\boldsymbol{u}(-\infty)) = 0$ and $g(\boldsymbol{u}(\pm\infty)) = 0$ can be proved in a similar manner.

Because $\boldsymbol{u}(\xi)$ is monotone bounded, we have $u_\xi(\xi) \geq 0$ for any $\xi \in \mathbf{R}$ and $\liminf_{\xi\to+\infty} u_\xi(\xi) = 0$. We assume $|f(\boldsymbol{u}(+\infty))|\,(\equiv 2f_+) > 0$. Then it follows that there exists ξ_{12} such that

$$f(\boldsymbol{u}(\xi))\begin{cases} \geq f_+ & \text{if } f(\boldsymbol{u}(+\infty)) > 0, \\ \leq -f_+ & \text{if } f(\boldsymbol{u}(+\infty)) < 0 \end{cases}$$

for any $\xi \geq \xi_{12}$.

We first consider the case where both $s \geq 0$ and $f(\boldsymbol{u}(+\infty)) > 0$ hold. Then we have

$$u_{\xi\xi}(\xi) = -s\,u_\xi(\xi) - f(\boldsymbol{u}(\xi)) \leq -f(\boldsymbol{u}(\xi)) \leq -f_+$$

for any $\xi \geq \xi_{12}$, that is,

$$u_\xi(\xi) \leq u_\xi(\xi_{12}) - (\xi - \xi_{12})\,f_+ \to -\infty$$

as $\xi \to +\infty$. This is a contradiction.

We next consider the case where both $s \geq 0$ and $f(\boldsymbol{u}(+\infty)) < 0$ hold. Then we have

$$u_{\xi\xi}(\xi) + s\,u_\xi(\xi) = -f(\boldsymbol{u}(\xi)) \geq f_+$$

for any $\xi \geq \xi_{12}$, that is, $u_\xi(\xi)$ satisfies

$$u_\xi(\xi) \geq e^{s(\xi_{12}-\xi)}\,u_\xi(\xi_{12}) + f_+ \int_{\xi_{12}}^{\xi} e^{s(\eta-\xi)}\,d\eta \to \begin{cases} +\infty & \text{if } s = 0, \\ f_+/s & \text{if } s > 0 \end{cases}$$

as $\xi \to +\infty$. This contradicts the fact that $\liminf_{\xi\to+\infty} u_\xi(\xi) = 0$.

We finally consider the case for $s < 0$. By (1.5a), we have

$$u_\xi(\xi) = e^{s(\tau-\xi)}\,u_\xi(\tau) + \int_{\xi}^{\tau} e^{s(\eta-\xi)}\,f(\boldsymbol{u}(\eta))\,d\eta$$

for any $\xi, \tau \in \mathbf{R}$. By taking the inferior limit of both hands as $\tau \to +\infty$, we obtain

$$u_\xi(\xi) = \int_\xi^{+\infty} e^{s(\eta-\xi)} f(\boldsymbol{u}(\eta))\, d\eta \begin{cases} \geq -f_+/s > 0 & \text{if } f(\boldsymbol{u}(+\infty)) > 0, \\ < 0 & \text{if } f(\boldsymbol{u}(+\infty)) < 0 \end{cases}$$

for any $\xi \geq \xi_{12}$. This is a contradiction.

Thus we have $f(\boldsymbol{u}(+\infty)) = 0$. □

Proof of Theorem 2.1. Let $\mathcal{P}_0 = \{\, (b,c) \,|\, 0 < 1/c < b \,\}$, and let β_0 be a constant which satisfies (3.1). We denote by $\mathcal{E}_0(\beta_0)\,(\subset R^2_+)$ the maximal extended and connected region which is given by applying Lemmas 3.1 and 3.11 to $(b,c) = (\beta_0, \beta_0)$ and $s_0 = 0$, and on which the functions $\overline{\boldsymbol{u}}(\xi; b, c, \beta_0) = (\overline{u}, \overline{v})(\xi; b, c, \beta_0)$ and $\overline{a}(b, c, \beta_0)$ given in Lemma 3.11 for $s_0 = 0$ are C^1 class. We see from $(\beta_0, \beta_0) \in \mathcal{E}_0(\beta_0)$ that $\mathcal{E}_0(\beta_0)$ is a nonempty set. By Lemma 3.14, we have $\mathcal{E}_0(\beta_0) \subset \mathcal{P}_0$ and $1/c < \overline{a}(b, c, \beta_0) < b$ for any $(b,c) \in \mathcal{E}_0(\beta_0)$.

We assume $\partial\mathcal{E}_0(\beta_0) \cap \mathcal{P}_0 \neq \emptyset$. Let $(b_0, c_0) \in \partial\mathcal{E}_0(\beta_0) \cap \mathcal{P}_0$, and let $\{\, (b_n, c_n) \,\}_{n=1}^{\infty} (\subset \mathcal{E}_0(\beta_0))$ be an arbitrary sequence which satisfies $(b_n, c_n) \to (b_0, c_0)$ as $n \to \infty$. Since $1/c_n < \overline{a}(b_n, c_n, \beta_0) < b_n$ for any integer n, we may assume $\overline{a}(b_n, c_n, \beta_0) \to \overline{a}_0 \in [1/c_0, b_0]$ as $n \to \infty$. And we may also assume

$$\overline{u}(0; b_n, c_n, \beta_0) = \begin{cases} \dfrac{2 - \{\overline{a}(b_n, c_n) + b_n\}\, c_n}{2\,(1 - b_n\, c_n)} & \text{if } \overline{a}_0 \in (1/c_0, b_0), \\ 1/2 & \text{if } \overline{a}_0 \in \{\, 1/c_0, b_0 \,\} \end{cases} \tag{3.20}$$

without loss of generality. Because (1.5) does not depend on ξ explicitly. It follows from the Ascoli–Arzela theorem and Lemma 3.6 that, for any fixed $\xi_{13} > 0$, there exist $\{\, (b_{n_j}, c_{n_j}) \,\}_{j=1}^{\infty} (\subset \{\, (b_n, c_n) \,\}_{n=1}^{\infty})$ and $\overline{\boldsymbol{u}}_0(\xi)$ such that

$$\lim_{j \to \infty} \| \overline{\boldsymbol{u}}(.; b_{n_j}, c_{n_j}, \beta_0) - \overline{\boldsymbol{u}}_0 \|_{C^2([-\xi_{13}, \xi_{13}])} = 0.$$

Since $\overline{\boldsymbol{u}}(\xi; b_{n_j}, c_{n_j}, \beta_0)$ is strictly monotone and satisfies

$$\overline{\boldsymbol{u}}(\xi; b_{n_j}, c_{n_j}, \beta_0) \in (0,1) \times (0, \overline{a}(b_{n_j}, c_{n_j}, \beta_0)) \quad \text{on } \mathbf{R}$$

for each j, we see that $\overline{\boldsymbol{u}}_0(\xi)$ is a monotone solution of (1.5a) with $s = 0$ for $(a,b,c) = (\overline{a}_0, b_0, c_0)$, which satisfies $\overline{\boldsymbol{u}}_0(\xi) \in [0,1] \times [0, \overline{a}_0]$ for any $\xi \in \mathbf{R}$.

We first consider the case where either $\overline{a}_0 = 1/c_0$ or $\overline{a}_0 = b_0$ holds. Then we see that the equilibrium points of (1.5a) are $(0,0)$, $(0, \overline{a}_0)$, and $(1,0)$. By $\overline{u}_0(0) = 1/2$ and Lemma 3.16, we have $\overline{\boldsymbol{u}}(+\infty) = (1,0)$ and either $\overline{\boldsymbol{u}}(-\infty) = (0,0)$ or $\overline{\boldsymbol{u}}(-\infty) = (0, \overline{a}_0)$. This contradicts the fact of Lemmas 3.13 and 3.14.

Next, we consider the case for $\overline{a}_0 \in (1/c_0, b_0)$, that is, $(\overline{a}_0, b_0, c_0) \in \mathcal{P}$. Then we see that the equilibrium points of (1.5a) are $(0,0)$, $(0, \overline{a}_0)$, $(1,0)$, and

$$\left(\frac{1 - \overline{a}_0\, c_0}{1 - b_0\, c_0}, \frac{\overline{a}_0 - b_0}{1 - b_0\, c_0} \right).$$

By (3.20), we have

$$0 < \frac{1 - \overline{a}_0\, c_0}{1 - b_0\, c_0} < \overline{u}_0(0) = \frac{1}{2} \left\{ \frac{1 - \overline{a}_0\, c_0}{1 - b_0\, c_0} + 1 \right\} < 1.$$

From Lemmas 3.13, 3.15, and 3.16, we obtain $\overline{\boldsymbol{u}}_0(-\infty) = (0, \overline{a}_0)$ and $\overline{\boldsymbol{u}}_0(+\infty) = (1,0)$. Then we have $(b_0, c_0) \in \operatorname{Int} \mathcal{E}_0(\beta_0)$ by virtue of $(\overline{a}_0, b_0, c_0) \in \mathcal{P}$ and Lemma 3.11. This contradicts the definition of (b_0, c_0).

Therefore we obtain $\mathcal{E}_0(\beta_0) = \mathcal{P}_0$. For each $(b,c) \in \mathcal{P}_0$, we define

$$a^*(b,c,\beta_0) = \sup\{\, a \mid [\overline{a}(b,c,\beta_0), a) \times \{\,(b,c)\,\} \subset \mathcal{E}\,\},$$
$$a_*(b,c,\beta_0) = \inf\{\, a \mid (a, \overline{a}(b,c,\beta_0)] \times \{\,(b,c)\,\} \subset \mathcal{E}\,\}.$$

By Lemma 3.12, we have

$$1/c \le a_*(b,c,\beta_0) < \overline{a}(b,c,\beta_0) < a^*(b,c,\beta) \le b$$

for any $(b,c) \in \mathcal{P}_0$. It follows from Lemma 3.5 that the functions $\boldsymbol{u}(.;a,b,c) = (u,v)(.;a,b,c)$ and $s(a,b,c)$ given in Lemma 3.12 can be regarded as C^1-class single-valued functions in $(a,b,c) \in \mathcal{E}$.

We assume $a^*(b_0,c_0,\beta_0) < b_0$ for some $(b_0,c_0) \in \mathcal{P}_0$. Then we have $(a^*(b_0,c_0,\beta_0), b_0, c_0) \in \mathcal{P}$. Let $\{\, a_n \,\}_{n=1}^{\infty} (\subset (\overline{a}(b_0,c_0,\beta_0), a^*(b_0,c_0,\beta_0)))$ be an arbitrary increasing sequence which satisfies $\lim_{n\to\infty} a_n = a^*(b_0,c_0,\beta_0)$. By Lemmas 3.6 and 3.12, we see that $\{\, s(a_n,b_0,c_0)\,\}_{n=1}^{\infty} (\subset (0, 2\sqrt{b_0 d})$ is a increasing sequence, i.e., the limit $\lim_{n\to\infty} s(a_n,b_0,c_0)\,(\equiv s_0 > 0)$ exists. Then we have

$$\| \boldsymbol{u}(.;a_n,b_0,c_0) \|_{C^2(\mathbf{R})} \le \frac{C_5(b_0,c_0)}{s(a_n,b_0,c_0)} \le \frac{C_5(b_0,c_0)}{s(a_1,b_0,c_0)}$$

for any $n \ge 1$ because of Lemma 3.6. By using an argument similar to the one above, it follows that, for any fixed $\xi_{14} > 0$, there exist $\{\, a_{n_j} \,\}_{j=1}^{\infty} (\subset \{\, a_n \,\}_{n=1}^{\infty})$ and $\boldsymbol{u}_0(\xi)$ such that $\boldsymbol{u}_0(\xi)$ is a strictly monotone solution of (1.5) for $(a,b,c,s) = (a^*(b_0,c_0,\beta_0), b_0, c_0, s_0)$ and satisfies

$$\| \boldsymbol{u}(.;a_{n_j},b_0,c_0) - \boldsymbol{u}_0 \|_{C^2([-\xi_{14},\xi_{14}])} \to 0$$

as $j \to \infty$. By Lemma 3.12, we have $(a^*(b_0,c_0,\beta_0), b_0, c_0) \in \operatorname{Int}\mathcal{E}$. This contradicts the definition of $a^*(b,c,\beta_0)$. Thus we obtain $a^*(b,c,\beta_0) = b$ for any $(b,c) \in \mathcal{P}_0$. In a similar manner, we can also show that $a_*(b,c,\beta_0) = 1/c$ holds for any $(b,c) \in \mathcal{P}_0$. Therefore, we have $\mathcal{E} = \mathcal{P}$.

Finally we shall show that $\overline{a}(b,c,\beta_0)$ is independent of β_0. Let $\overline{a}_1$ be an arbitrary constant such that (1.5) with $(a,s) = (\overline{a}_1, 0)$ has a strictly monotone solution for $(b,c) \in \mathcal{P}_0$. We assume that $\overline{a}(b,c,\beta_0) \ne \overline{a}_1$. Since $s(a,b,c)$ is defined on $\mathcal{P}$ and satisfies $s_a(a,b,c) > 0$, we have

$$0 = s(\overline{a}(b,c,\beta_0),b,c) \begin{cases} < s(\overline{a}_1,b,c) = 0 & \text{if } \overline{a}(b,c,\beta_0) < \overline{a}_1, \\ > s(\overline{a}_1,b,c) = 0 & \text{if } \overline{a}(b,c,\beta_0) > \overline{a}_1. \end{cases}$$

This contradiction implies that $\overline{a}(b,c,\beta_0) = \overline{a}_1$ holds. □

THE CHILD–LANGMUIR LAW FOR THE BOLTZMANN EQUATION OF SEMICONDUCTORS*

NAOUFEL BEN ABDALLAH† AND PIERRE DEGOND†

Abstract. We investigate the so-called Child-Langmuir asymptotics of the one-dimensional stationary Boltzmann–Poisson system. The asymptotics apply when the lattice temperature is small and leads to a singular perturbation problem. We derive the limit problem associated with these asymptotics, and prove the existence of the Child-Langmuir current.

Key words. semiconductors, integral equation, Cauchy problem, contraction, nonlinear differential equation, nonlocal nonlinearity

1. Introduction.

The design of many high technology components in solid-state electronics, in vacuum diode technology or in high power hyperfrequency amplification requires an accurate description of charged-particle transport. Among all the possible models, the Vlasov or the Boltzmann equations, coupled with the Poisson or the Maxwell equations for the fields, provide the most accurate description of the physics of charged-particle transport. The numerical simulation of these models is an important tool for the designers.

The modeling of charged particle transport is particularly difficult, due to space-charge or internal boundary layers which very often appear. The description of such layers can usually be done by means of perturbation analyses of the stationary or time-dependent Vlasov–Poisson equations, which provide singular perturbation problems. One especially interesting problem was investigated by Langmuir and Compton [1], who showed that the charge boundary layer sitting at the cathode of a vacuum diode could produce a limitation of the current intensity which flows through the diode.

The mathematical analysis of this problem first started with a study of the boundary-value problem for the stationary Vlasov–Poisson equation in the one-dimensional cartesian case [2]. The perturbation problem and its convergence towards the reduced problem of [1] was analyzed in [3], in the same one-dimensional cartesian geometry. Then a numerical algorithm for the practical computation of the reduced solution was proposed in [4]. The passage to higher dimensions and more complicated models was investigated in [5] and [6], in which the well-posedness of the boundary value problems for the stationary Vlasov–Poisson, Vlasov–Maxwell, and Vlasov–Poisson–Boltzmann equations are proved in any dimension. Then by combining the ideas of [5], [6], and [3], the perturbation problem for the stationary cylindrically or spherically symmetric Vlasov–Poisson equation was investigated in [7].

Let us consider a simplified one-dimensional device which consists of two highly doped N^+ regions on each side of a lowly doped N^- region. Such an $N^+ - N^- - N^+$ device closely resembles a vacuum diode, where the metallic cathode and anode are replaced by the N^+ zones, and the vacuum region by the N^- zone. If the collisions

of the carriers with the crystal lattice defects were negligible, we could use the same system of stationary Vlasov–Poisson equations and the perturbation problem would lead to the same result as in the vacuum diode case. This was remarked by Shur and Eastman in [8]. Strictly speaking, this asymptotic solution is only relevant for either large direct biases or low lattice temperatures.

However, the collisionless approximation is not valid in realistic situations. To investigate the effects of collisions, Shur and Eastman [9] proposed a model, based on a simplified one-dimensional hydrodynamic model and consisting of two equations of momentum and energy balance. In this paper, we show that the perturbation approach of the collisional kinetic model can be carried on. The reduced problem can be explicitly written, and the proof of its well-posedness is given under some restrictions. It reduces to the Langmuir and Compton [1] or Shur and Eastman [8] solution when the collision frequency vanishes. It also exhibits the same features; namely the current intensity cannot exceed a limiting value which depends on the collision frequency.

The outline of this paper is as follows: In the following section we derive the model which follows from formal asymptotics of the Vlasov–Poisson–Boltzmann system of semiconductors. Its solution is entirely determined by means of the electrostatic potential solution of a semilinear elliptic problem:

$$\varphi'' = n_1 + n_2, \quad \varphi(0) = 0, \quad \varphi(1) = 1, \tag{1}$$

where n_1 is an explicit nonlinear function of φ and n_2 is a solution of an integral equation depending on φ. In §3, we show that this integral equation has a unique solution. In the fourth section, we consider the Cauchy problem

$$\varphi'' = n_1 + n_2, \qquad \varphi(0) = 0, \quad \varphi'(0) = \beta, \tag{2}$$

and prove its well-posedness. Finally, in §5, we prove the existence and uniqueness of the Child-Langmuir current for a large range of values of the relaxation time. The Child-Langmuir current is, as usual, defined as the current for which the solution φ of the boundary value problem (1) has a vanishing derivative at $x = 0$.

2. The model. We consider a one-dimensional unipolar semiconductor structure, which consists of two highly doped N^+ regions on each side of a lowly doped N^- region. In such a structure, the N^+ regions behave approximately like metallic contacts and the N^- region can be modeled just like a vacuum diode, by assuming that the injection of carriers at the $N^+ - N^-$ junctions can be described by a given emission profile $G(V)$ on the source side, and can be neglected on the drain side (see [10] for more details). Of course, this model is very crude (see [11] for more realistic models), but it focuses the analysis on the injection process, which is of primary importance for the global behavior of many devices.

We assume that the $N^+ - N^-$ junctions are located at $X = 0$ (for the source side), and $X = L$ (for the drain side), and that the N^- region is represented by the interval $[0, L]$. The electron distribution function $F(X, V)$, the electric potential $\Phi(X)$, and the electron concentration $N(X)$ satisfy the system of stationary Vlasov–Poisson–Boltzmann equations of semiconductors:

$$V\frac{\partial F}{\partial X} + \frac{e}{m}\frac{d\Phi}{dX}\frac{\partial F}{\partial V} = Q(F), \qquad X \in [0, L], \quad V \in \mathbb{R} \tag{3}$$

$$\frac{d^2\Phi}{dX^2} = \frac{e}{\varepsilon_0} N(X), \quad X \in [0, L], \tag{4}$$

$$N(X) = \int_{-\infty}^{+\infty} F(X,V)\,dV, \qquad X \in [0,L]. \tag{5}$$

We denote the collision operator by $Q(F)$, which models the interaction of the electrons with the crystal defects. The reader will find in [12]–[14] a fairly complete description of these interactions. In this paper, we will restrict our analysis to the relaxation time model

$$Q(F) = -\frac{1}{\mathcal{T}}\left(F(X,V) - N(X)M_T(V)\right), \tag{6}$$

where $\mathcal{T} > 0$ is the relaxation time, $M_T(V)$ is the normalized Maxwellian distribution associated with the lattice temperature T

$$M_T(V) = \frac{1}{\sqrt{\frac{2\pi k_B T}{m}}} \exp\left(-\frac{mV^2}{2k_B T}\right), \tag{7}$$

and k_B is the Boltzmann constant. Finally, ε_0 denotes the medium permittivity. In the Poisson equation (4), we neglect the doping density of the N^- region, which is a fairly good assumption (see [15]). However, the analysis can also be performed with a nonvanishing N^- in the collisionless case (see [20]).

The system (3)–(5) is supplemented with the following boundary conditions (see [10] for details):

$$F(0,V) = G(V), \qquad V > 0, \tag{8}$$

$$F(L,V) = 0, \qquad V < 0, \tag{9}$$

$$\Phi(0) = 0, \qquad \Phi(L) = \Phi_L > 0. \tag{10}$$

Indeed, Φ_L is the applied bias, and since the potential is nearly constant in the N^+ regions, it applies entirely at the boundary of the N^- region. Since the N^+ region on the source side is close to a state of thermal equilibrium with the crystal lattice, it is natural to assume that the injection profile is given by

$$G(V) = N^+ M_T(V), \qquad V > 0, \tag{11}$$

where N^+ is the doping density of the N^+ region. On the other side, the injection is negligible, which implies (9). More generally, we shall assume that $G(V)$ is a given function such that

$$\int_0^\infty G(V)dV = \frac{N^+}{2}$$

and such that the thermal emission velocity V_G given by

$$V_G = \left(\int_0^\infty V^2 G(V)\,dV \Big/ \int_0^\infty G(V)\,dV\right)^{\frac{1}{2}} \tag{12}$$

is equal to the thermal velocity associated with the maxwellian (7)

$$V_G = V_{th} = \sqrt{\frac{k_B T}{m}}.$$

Because of this, we assume that the lattice temperatures in the N^+ and N^- region are the same, which is a fairly unrestrictive assumption for physical applications.

The existence of solutions of the system (3)–(5), (8)–(10) is mathematically proven in [5]. Its numerical solution has been achieved by iterative methods in [15] and [16], by particle methods in [17] and [18], and by Monte-Carlo methods (see [12] and the references therein).

In the "Child-Langmuir" regime, the thermal emission energy is small compared with the applied bias, while the injected current remains finite [3]:

$$\frac{mV_G^2}{2} \ll e\Phi_L$$

or

$$V_G \ll V_L, \qquad V_L = \sqrt{\frac{2e\Phi_L}{m}}. \tag{13}$$

Therefore, we introduce a "small" parameter ε by

$$\varepsilon = \frac{V_G}{V_L} \ll 1. \tag{14}$$

We shall use L, V_L, and Φ_L as characteristic length, velocity, and potential scales. We introduce auxiliary units of density $\overline{N}$, current density $\overline{J}$, distribution function $\overline{F}$, and relaxation time $\overline{T}$, according to

$$\overline{N} = \frac{\varepsilon_0 \Phi_L}{eL^2}, \qquad \overline{J} = e\overline{N}V_L, \qquad \overline{F} = \frac{\overline{N}}{V_L}, \qquad \overline{T} = \frac{L}{V_L}, \tag{15}$$

and use the following scaling:

$$\begin{cases} X = Lx, & V = V_L v, & \Phi = \Phi_L \varphi, \\ N = \overline{N} n, & J = -\overline{J} j, & F = \overline{F} f, \\ & \mathcal{T} = \overline{T}\tau. \end{cases} \tag{16}$$

Furthermore, we introduce a dimensionless profile $g(v)$ and express $G(V)$ according to

$$\overline{F}^{-1} G(V) = \frac{1}{\varepsilon^2} g\left(\frac{V}{V_G}\right) = \frac{1}{\varepsilon^2} g\left(\frac{v}{\varepsilon}\right). \tag{17}$$

The expression (17) means that V_G is the characteristic velocity associated with G and is small, while the factor ε^2 insures that the injected current J_G,

$$J_G = \int_0^\infty VG(V)dV,$$

remains independent of ε in the units of $\overline{J}$. We recall that these two facts are the key hypotheses of the Child-Langmuir asymptotics [3]. We also note that a different normalizing condition of the injection profile G can contribute to a finite built-in potential at the $N^+ - N^-$ interfaces (see [19]). Let us introduce

$$g^\varepsilon(v) = \frac{1}{\varepsilon^2} g\left(\frac{v}{\varepsilon}\right) \tag{18}$$

and write the scaled Vlasov–Poisson–Boltzmann equation

$$v\frac{\partial f^\varepsilon}{\partial x} + \frac{1}{2}\frac{d\varphi^\varepsilon}{dx}\frac{\partial f^\varepsilon}{\partial v} = -\frac{1}{\tau}\left(f^\varepsilon - n^\varepsilon \frac{1}{\varepsilon}M_0\left(\frac{v}{\varepsilon}\right)\right), \tag{19}$$

$$\frac{d^2\varphi^\varepsilon}{dx^2} = n^\varepsilon(x), \quad x \in [0,1], \tag{20}$$

$$n^\varepsilon(x) = \int_{-\infty}^{+\infty} f^\varepsilon(x,v)\,dv, \quad x \in [0,1], \tag{21}$$

$$f^\varepsilon(0,v) = g^\varepsilon(v), \quad v > 0, \tag{22}$$

$$f^\varepsilon(1,v) = 0, \quad v < 0, \tag{23}$$

$$\varphi^\varepsilon(0) = 0, \quad \varphi^\varepsilon(1) = 1, \tag{24}$$

where

$$M_0(v) = \frac{1}{\sqrt{2\pi}}\exp\left(-\frac{v^2}{2}\right). \tag{25}$$

Our aim is to solve the reduced problem corresponding to $\varepsilon = 0$. So we pass formally to the limit in the equations and get the following reduced problem:

$$v\frac{\partial f}{\partial x} + \frac{1}{2}\frac{d\varphi}{dx}\frac{\partial f}{\partial v} = -\frac{1}{\tau}(f - n\,\delta(v)), \tag{26}$$

$$\frac{d^2\varphi}{dx^2} = n(x), \quad x \in [0,1], \tag{27}$$

$$n(x) = \int_{-\infty}^{+\infty} f(x,v)\,dv, \quad x \in [0,1]. \tag{28}$$

$$f(1,v) = 0, \quad v < 0, \tag{29}$$

$$\varphi(0) = 0, \quad \varphi(1) = 1, \tag{30}$$

where $\delta(v)$ is the delta function; the formal limit of (22) can be expressed by

$$\text{supp}\,\{f(0,v), v \geq 0\} = \{v = 0\}, \qquad 0 < \int_0^\infty v f(0,v)\,dv < \infty. \tag{31}$$

In the collisionless case ($\tau = \infty$, see [3]) the condition (31) forces the solution to be a positive measure supported by the characteristics issued from the point $(x,v) = (0,0)$. In the present case ($\tau < \infty$), it is natural to think that the solution will exhibit the same features. This means that the particles fly from the cathode to the anode,

following the same characteristics. However some particles will undergo a collision in their way to the anode. The collision operator at the right-hand side of (26) sends the velocity of the colliding particles back to zero. Thus, after the collision, the particle follows another characteristic, namely the one issued from the point $(y, 0)$ where y is the location of the collision. This new characteristic is given by the equation

$$v^2 - \varphi(x) = \text{constant} = -\varphi(y),$$

that is,

$$v = \sqrt{\varphi(x) - \varphi(y)}. \tag{32}$$

The + sign has to be retained because no electron is emitted at the anode, and then the particles flow from the cathode to the anode. Of course, once the particle is on the secondary characteristic (32), it can suffer a second collision which sends it to a third characteristic and so on. Therefore, in addition to a positive measure supported by the principal characteristics (i.e., issued from $(0,0)$), the solution $f(x,v)$ contains a superposition of the contributions of each of the secondary characteristics (32) for $y \in [0.1]$. Therefore we write it as

$$f(x,v) = n_1(x)\,\delta(v - \sqrt{\varphi(x)}) + \int_0^x \overline{n}_2(x,y)\delta(v - \sqrt{\varphi(x) - \varphi(y)})\,dy, \tag{33}$$

where $n_1(x)$ is the density of particles carried by the principal characteristics and $\overline{n}_2(x,y)\,dy$ is the density of particles carried by the bunch of characteristics issued between the point $(y,0)$ and $(y+dy,0)$. Mathematically speaking, the integral on the right-hand side of (33) can be viewed as a change of variables.

We introduce

$$j_1(x) = n_1(x)\sqrt{\varphi(x)}, \tag{34}$$

$$\overline{j}_2(x,y) = \overline{n}_2(x,y)\,\sqrt{\varphi(x) - \varphi(y)}, \tag{35}$$

$$n_2(x) = \int_0^x \overline{n}_2(x,y)\,dy, \tag{36}$$

$$j_2(x) = \int_0^x \overline{j}_2(x,y)\,dy = \int_0^x \overline{n}_2(x,y)\,\sqrt{\varphi(x) - \varphi(y)}\,dy. \tag{37}$$

j_1 is the current flowing along the principal chracteristics, and n_2 and j_2 are the density and current carried by all the secondary characteristics. We have

$$n_1(x) + n_2(x) = n(x), \tag{38}$$

$$j_1(x) + j_2(x) = j = \text{constant}. \tag{39}$$

Inserting the expression (33) into the equation (26), we formally find the following equation:

$$\left(\frac{dj_1}{dx} + \frac{n_1(x)}{\tau}\right)\delta(v - \sqrt{\varphi(x)}\,)$$
$$+ \int_0^x \left(\frac{\partial \overline{j}_2}{\partial x}(x,y) + \frac{\overline{n}_2(x,y)}{\tau}\right)\delta(v - \sqrt{\varphi(x) - \varphi(y)}\,)\,dy$$
$$= \frac{1}{\tau}\,n(x)\,\delta(v) = \int_0^x \frac{n(y)}{\tau}\,\delta(y - x)\delta(v - \sqrt{\varphi(x) - \varphi(y)}\,)\,dy.$$

The terms in factor of $\delta(v - \sqrt{\varphi(x)})$ and of $\delta(v - \sqrt{\varphi(x) - \varphi(y)})$ can be separated, which leads to

$$\frac{dj_1}{dx} + \frac{n_1(x)}{\tau} = 0, \tag{40}$$

$$\frac{\partial \bar{j}_2}{\partial x}(x,y) + \frac{\bar{n}_2(x,y)}{\tau} = 0, \quad 0 < y < x < 1, \tag{41}$$

$$\bar{j}_2(y,y) = \frac{1}{\tau} n(y). \tag{42}$$

Equation (40) means that the current decreases as one moves along the principal characteristics, because of the collisions. The same is true for each one of the secondary characteristics (equation (41)). Finally, equation (42) specifies that the current carried by one of the secondary characteristics at its starting point y is made of the contribution of all the particles which have collided at this point, either from the principal or the secondary characteristics (cf. (38)). Now we must specify the initial condition for equation (40). For this, it is natural to assume that the current carried by the secondary characteristics vanishes for $x = 0$,

$$\lim_{x \to 0} j_2(x) = 0. \tag{43}$$

Indeed, for small values of x the collisions are negligible, the total current is carried by the principal characteristics, then we deduce from (39) that

$$j_1(0) = j. \tag{44}$$

The total current j that flows through the device will be assumed arbitrary for the moment. By keeping in mind the relations (34) and (35), we can see that the solutions of the equations (40)–(42) and (44) can be written explicitly:

$$j_1(x) = j \exp\Big(-\frac{1}{\tau} \int_0^x \frac{dz}{\sqrt{\varphi(z)}} \Big), \tag{45}$$

$$\bar{j}_2(x,y) = \frac{n(y)}{\tau} \exp\Big(-\frac{1}{\tau} \int_y^x \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}} \Big). \tag{46}$$

For a given φ, equation (45) gives a closed expression of j_1 and (thanks to (34)) the density n_1,

$$n_1(x) = \frac{j}{\sqrt{\varphi(x)}} \exp\Big(-\frac{1}{\tau} \int_0^x \frac{dz}{\sqrt{\varphi(z)}} \Big). \tag{47}$$

The situation is different for $\bar{j}_2$, since $\bar{j}_2$ depends on n, which in turn depends on $\bar{j}_2$ via equations (36) and (35). From now on, we let

$$g_\varphi(x,y) = \exp\Big(-\frac{1}{\tau} \int_y^x \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}} \Big). \tag{48}$$

By using (36), (35), and (46), we obtain

$$n_2(x) - \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x)-\varphi(y)}} n_2(y)\,dy = \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x)-\varphi(y)}} n_1(y)\,dy. \tag{49}$$

Since n_1 has been previously determined by (47), equation (49) is an integral equation for n_2. Then we can write the complete system satisfied by the potential

$$\frac{d^2\varphi}{dx^2} = n(x), \tag{50}$$

$$\varphi(0) = 0, \qquad \varphi(1) = 1, \tag{51}$$

$$n(x) = n_1(x) + n_2(x), \tag{52}$$

where n_1 is given by (47) and n_2 is the solution of (49), and where j in (47) is an arbitrary nonnegative constant. The following results are inspired from the existence of the Child-Langmuir current in the collisionless case (the vacuum diode [3]) and are proven in this paper.

THEOREM 2.1. *There exist* $\tau_1 \geq 7/9$ *and* $\tau_2 \leq 4/5$ *such that for evry* $\tau \in]0,\tau_1] \bigcup [\tau_2, \infty[$, *there exists a unique value* $j = j_{CL}(\tau)$ *such that the problem* (50)–(52), (47), (49) *has a unique solution* φ *that satisfies* $d\varphi/dx(0) = 0$. *Moreover,* $j_{CL}(\tau) \sim 4/9$ *when* τ *tends to* ∞, *and* $j_{CL}(\tau) \sim \tau 9/16$ *when* τ *tends to zero.*

This result expressed in the physical variables gives the expression of the Child-Langmuir current

$$J_{CL} = -j_{CL}\left(\frac{\mathcal{T}}{L}\sqrt{\frac{2e\Phi_L}{m}}\right)\varepsilon_0\sqrt{\frac{2e}{m}}\,\frac{\Phi_L^{3/2}}{L^2}.$$

In the collisionless limit ($\tau \to \infty$), we find the Child-Langmuir current of the vacuum diode [3], and in the collision-dominated limit ($\tau \to 0$), we find

$$J_{CL} = -\frac{9}{16}\mathcal{T}\varepsilon_0\left(\frac{2e}{m}\right)\frac{\Phi_L^2}{L^3},$$

or in terms of the mobility $\mu = \frac{e\mathcal{T}}{m}$ and of the external field $E_L = \frac{\Phi_L}{L}$,

$$J_{CL} = -\frac{9}{8}\varepsilon_0\mu\frac{\Phi_L^2}{L^3} = -\frac{9}{8}\varepsilon_0\mu\frac{E_L^2}{L}.$$

It is remarkable that this formula completely differs from the one used for a homogeneous semiconductor,

$$J = e\mu n E_L,$$

where n is the density of free carriers. Here the only available free carriers are those provided by the injection contact and lead to a current which is proportional to the squared external electric field. As far as we know, such a formula has not been found

previously in the physical literature. (See [21] for an overview of the current-voltage characteristics of the basic semiconductor devices.)

In the vacuum diode case, it is proved that the limit current cannot exceed the Child-Langmuir current. In our case, we prove that a limitation of the limit current occurs.

THEOREM 2.2. *There exists a value* $j_{\max}(\tau)$ *such that the system* (50)–(52), (47), (49) *has no solution for* $j > j_{\max}(\tau)$. *This value satisfies the following estimate:*

$$j_{CL}(\tau) \leq j_{\max}(\tau) < \min\left(\frac{4}{9}, \frac{9}{16}\tau\right).$$

It has been proved neither that the problem (50)–(52), (47), (49) has a unique solution for $j < j_{\max}(\tau)$, nor that $j_{\max}(\tau) = j_{CL}(\tau)$, as could be conjectured from the inspection of the vacuum diode case [3] (however, $j_{\max}(\tau) \sim j_{CL}(\tau)$ in the vicinity of zero and infinity). Some pathologies, which occur in the vacuum diode case in higher dimensions [7], should make us careful about conjectures in this direction. Another open problem is the convergence of the solutions of the perturbed problem (19)–(24) to those of (33) and (47)–(52).

3. The reduced problem. To study the limit problem, we use a change of variable and unknowns in order to get rid of the constants j and τ. Thus, we define the constants λ and δ depending on j and τ according to

$$\delta = \frac{1}{\tau^3 j}, \quad \lambda = \tau^4 j^2 \tag{53}$$

and

$$\varphi(x) = \lambda\tilde{\varphi}(\delta x), \qquad n_1(x) = \lambda\mu^2\tilde{n}_1(\delta x), \quad n_2(x) = \lambda\mu^2\tilde{n}_2(\delta x). \tag{54}$$

With this rescaling, the system becomes, omitting the tildes,

$$\frac{d^2\varphi}{dx^2} = n(x), \tag{55}$$

$$n(x) = n_1(x) + n_2(x), \tag{56}$$

$$n_1(x) = \frac{1}{\sqrt{\varphi(x)}}\, g_\varphi(x, 0), \tag{57}$$

$$\begin{aligned} n_2(x) - \int_0^x \frac{g_\varphi(x,y)}{\sqrt{\varphi(x)-\varphi(y)}} n_2(y)\, dy \\ = \int_0^x \frac{g_\varphi(x,y)}{\sqrt{\varphi(x)-\varphi(y)}} n_1(y)\, dy, \end{aligned} \tag{58}$$

$$\varphi(0) = 0, \qquad \varphi(\delta) = \frac{1}{\lambda}, \tag{59}$$

$$g_\varphi(x,y) = \exp\left(-\int_y^x \frac{dz}{\sqrt{\varphi(z)-\varphi(y)}}\right). \tag{60}$$

The first step for the study of the above system consists in solving the integral equation (58) for a given electric potential φ. This will be done in the following subsection, but we first begin with the following definition.

DEFINITION 3.1. *Let $\alpha \in [1,2)$, $\mu > 0$ and $C > 0$ be given. We define $Q(\alpha, \mu, C)$ as the set of convex functions φ on $[0,\mu]$ such that*

$$\varphi(x) > 0, \quad x \in (0,\mu],$$

$$\varphi(0) = 0, \quad \text{and } |\varphi(x) - \varphi(y)| \geq C\,|x-y|^{\alpha}, \quad x, y \in [0,\mu], \tag{61}$$

and we set

$$L^{\infty}_{\alpha}(0,\mu) = L^{\infty}(0,\mu, x^{\alpha-1}dx) = \{\psi,\, x^{\alpha-1}\,\psi(x) \in L^{\infty}(0,\mu)\}.$$

3.1. The integral equation. Here we consider a given convex nonnegative function and we show the existence and uniqueness of a solution of (58).

PROPOSITION 3.2. *Let φ be given in $Q(\alpha,\mu,C)$ for some α in $[1,2)$, μ and C positive. Then the equation (58) has a unique solution n_2 in $L^{\infty}_{\alpha}(0,\mu)$. This solution has the following properties:*

(1) *n_2 is positive for $x \in (0,\mu)$.*

(2) *The norm of n_2 in $L^{\infty}_{\alpha}(0,\mu)$ can be bounded by a constant depending only on C, α, and μ.*

To prove this proposition we define the map

$$\begin{aligned} K_{\varphi} : L^{\infty}_{\alpha}(0,\mu) &\longrightarrow L^{\infty}_{\alpha}(0,\mu), \\ m(x) &\longmapsto K_{\varphi} m, \end{aligned} \tag{62}$$

such that

$$K_{\varphi} m(x) = G(x) + \int_0^x \frac{g_{\varphi}(x,y)}{\sqrt{\varphi(x) - \varphi(y)}} m(y)\, dy, \tag{63}$$

where

$$G(x) = \int_0^x \frac{g_{\varphi}(x,y)}{\sqrt{\varphi(x) - \varphi(y)}} n_1(y)\, dy. \tag{64}$$

We have the following lemma.

LEMMA 3.3. *The map K_{φ} takes $L^{\infty}_{\alpha}(0,\mu)$ into $L^{\infty}_{\alpha}(0,\mu)$. Moreover , for all m_1 and m_2 in $L^{\infty}_{\alpha}(0,\mu)$ and p integer, the following estimate holds on $[0,\mu]$:*

$$x^{\alpha-1}\,|K^p_{\varphi} m_1(x) - K^p_{\varphi} m_2(x)| \leq C_1^p\, x^{p(1-\frac{\alpha}{2})}\, I_1\, I_2 \cdots I_p \|m_1 - m_2\|_{L^{\infty}_{\alpha}(0,\mu)}, \tag{65}$$

where

$$I_k = \int_0^1 \frac{t^{k\,(1-\frac{\alpha}{2}) - \frac{\alpha}{2}}}{(1-t)^{\frac{\alpha}{2}}}\, dt, \tag{66}$$

and the constant $C_1 = \frac{1}{\sqrt{C}}$.

Proof. Since the definition of $Q(\alpha, \mu, C)$ implies that $\varphi(x) \geq C\, x^{\alpha}$, we deduce from (57) that

$$n_1(x) \leq \frac{1}{\sqrt{C}\, x^{\frac{\alpha}{2}}},$$

and then we have

$$n_1 \in L^{\infty}_{\alpha}(0, \mu).$$

Thus, to prove that $K_{\varphi}(L^{\infty}_{\alpha}) \subset L^{\infty}_{\alpha}$, it is sufficient to prove that

$$h(x) = \int_0^x \frac{g_{\varphi}(x, y)}{\sqrt{\varphi(x) - \varphi(y)}} m(y)\, dy \tag{67}$$

is in L^{∞}_{α} for every m in L^{∞}_{α}.

First, we have

$$x^{\alpha-1}|h(x)| \leq x^{\alpha-1} \int_0^x \frac{\|m\|_{L^{\infty}_{\alpha}(0,\mu)}\, dy}{\sqrt{C}\, y^{\alpha-1}\, (x-y)^{\frac{\alpha}{2}}}.$$

The change of variable $y = xt$ in this integral gives

$$x^{\alpha-1}|h(x)| \leq \frac{x^{1-\frac{\alpha}{2}}}{\sqrt{C}}\, I_1 \|m\|_{L^{\infty}_{\alpha}(0,\mu)} \tag{68}$$

and ensures that $h \in L^{\infty}_{\alpha}(0, \mu)$ since $\alpha < 2$.

Now we prove the estimate (65). Let us set $m = m_1 - m_2$ and $h = K_{\varphi} m_1 - K_{\varphi} m_2$. Then m and h satisfy (67) and the application of (68) proves (65) for $p = 1$. To prove the estimate for all p, we proceed by induction. (The details are left to the reader.) □

LEMMA 3.4. *There exist two positive constants C_2 and γ depending only on α, such that for every k,*

$$I_k \leq \frac{C_2}{k^{\gamma}}.$$

Proof. By the Hölder inequality we find

$$\begin{aligned} I_k &= \int_0^1 \frac{t^{k\,(1-\frac{\alpha}{2})\,-\,\frac{\alpha}{2}}}{(1-t)^{\frac{\alpha}{2}}}\, dt \\ &\leq \left(\int_0^1 t^{k\,(1-\frac{\alpha}{2})\,\beta'}\, dt \right)^{\frac{1}{\beta'}} \left(\int_0^1 \frac{dt}{t^{\frac{\alpha\beta}{2}} (1-t)^{\frac{\alpha\beta}{2}}} \right)^{\frac{1}{\beta}}, \end{aligned}$$

where β is chosen such that $\frac{\alpha\beta}{2} < 1$. Thus, there exists a constant K such that

$$I_k \leq \frac{K}{(1 + k\,(1 - \frac{\alpha}{2})\,\beta')^{\frac{1}{\beta'}}} \leq \frac{C_2}{k^{\frac{1}{\beta'}}}. \tag{69}$$

□

End of the proof of Proposition 3.2. Lemma 3.3, together with Lemma 3.4, implies

$$\|K^p_{\varphi} m_1 - K^p_{\varphi} m_2\|_{L^{\infty}_{\alpha}(0,\mu)} \leq \frac{\|m_1 - m_2\|_{L^{\infty}_{\alpha}(0,\mu)}}{(p!)^{\gamma}} \left[\frac{C_2 \mu^{1-\frac{\alpha}{2}}}{\sqrt{C}} \right]^p,$$

which ensures that K_φ^p is a strict contraction for p large enough. Thus, K_φ has a unique fixed point and this fixed point is the limit of all the sequences

$$n_2^k = K_\varphi(n_2^{k-1}). \tag{70}$$

The positivity of n_2 comes from the positiveness of n_1. Indeed, by induction it is easy to prove that the sequence n_2^k, defined by formula (70) and such that $n_2^1 = 0$, is always positive. Finally, it is readily seen that all the estimates established in this section depend on φ by means of α, μ, and C only.

4. The Cauchy problem. In order to prove the existence of a solution of the problem (55)–(60), we proceed as in [3] or [7] and introduce the Cauchy problem

$$\begin{cases} \dfrac{d^2\varphi}{dx^2} = n(x), \\ n(x) = n_1(x) + n_2(x), \\ \varphi(0) = 0, \quad \dfrac{d\varphi}{dx}(0) = \beta \geq 0, \end{cases} \tag{71}$$

where n_1 and n_2 are given by the formulae (57) and (58). We now give the main theorem of this section.

THEOREM 4.1. *For every fixed value $\beta \geq 0$ there exists a unique solution φ of the Cauchy problem* (71) *defined on $\mathbb{R}^+$. Moreover, this solution is equivalent near $x = 0$ to the solution of*

$$\frac{d^2 f}{dx^2} = \frac{1}{\sqrt{f}}, \qquad f(0) = 0, \quad \frac{df}{dx}(0) = \beta.$$

By "equivalent" we mean that the ratio of the two functions goes to one as x goes to zero.

The proof of this theorem is quite long and will be divided in two steps: First we will prove the existence and uniqueness of the solution on a small interval near zero. Then we will prove the existence and uniqueness on any bounded interval of $\mathbb{R}^+$. The first step will itself contain two cases: The case $\beta = 0$ which is more singular than the case $\beta > 0$. (See also [7], part 2 for similarities with the present problem.)

In the following two subsections we show the local existence and uniqueness of solutions; this result is stated in the next proposition.

PROPOSITION 4.2. *For every fixed value $\beta \geq 0$, there exists a positive constant μ such that the Cauchy problem* (71) *has a unique solution φ on $[0, \mu]$. Moreover, this solution is equivalent near $x = 0$ to the solution of*

$$\frac{d^2 f}{dx^2} = \frac{1}{\sqrt{f}}, \qquad f(0) = 0, \quad \frac{df}{dx}(0) = \beta. \tag{72}$$

Remark. Although the Cauchy problem is nonlinear and nonlocal, we can treat it as a differential equation because $n(x)$ only depends on $\varphi(y)$ for $y \leq x$. This is also important for the numerical computation of φ.

Remark. The solution of equation (72) is given implicitly by

$$\int_0^{f(x)} \frac{dg}{\sqrt{\beta^2 + 4\sqrt{g}}} = x, \quad x \in [0. + \infty);$$

in particular, for $\beta = 0$, we have $f(x) = \left(\frac{3x}{2}\right)^{4/3}$.

4.1. Local existence and uniqueness in the case $\beta > 0$. We begin the proof by showing some a priori estimates. For this aim, we first note that the solution of (71) (if it exists) is strictly convex. Then it satisfies

$$\varphi(x) \geq \beta x. \tag{73}$$

Thus $\varphi \in Q(1, \mu, \beta)$ for all $\mu > 0$, and then we have

$$n_1(x) \leq \frac{1}{\sqrt{\beta\, x}}. \tag{74}$$

By Theorem 3.2, $n_2 \in L^\infty(0, \mu)$ for every μ. Again by Theorem 3.2, we have

$$\|n_2\|_{L^\infty(0,\mu)} \leq K,$$

where K is a constant depending only on β and μ since $\varphi \in Q(1, \mu, \beta)$. Without any loss of generality, we take $\mu \leq 1$, and then the constant K can be chosen independently of μ. Combining the above estimates gives

$$0 \leq \frac{d^2\varphi}{dx^2}(x) \leq K + \frac{1}{\sqrt{\beta\, x}}.$$

Now choosing μ small enough, we get

$$0 \leq \frac{d^2\varphi}{dx^2}(x) \leq \frac{C_2}{\sqrt{x}} \qquad \text{on } (0, \mu).$$

By integrating this inequality twice we get

$$\left| \frac{d\varphi}{dx}(x) - \beta \right| \leq 2\, C_2 \sqrt{x}, \tag{75}$$

$$|\varphi(x) - \beta x| \leq \frac{4}{3}\, C_2\, x^{3/2}. \tag{76}$$

Now we can give the following definition.

DEFINITION 4.3. *We define the set $\mathcal{E}(\mu, \beta)$ as the set of nonnegative C^1 convex functions φ defined on $[0, \mu]$ such that*

$$\varphi(0) = 0, \quad \frac{d\varphi}{dx}(0) = \beta \tag{77}$$

and

$$\frac{1}{\sqrt{x}} \left| \frac{d\varphi}{dx}(x) - \beta \right| \in L^\infty(0, \mu). \tag{78}$$

Then, we define on $\mathcal{E}(\mu, \beta)$ the distance

$$d(\varphi_1, \varphi_2) = \sup_{x \in (0,\mu]} \frac{1}{\sqrt{x}} \left| \frac{d\varphi_1}{dx}(x) - \frac{d\varphi_2}{dx}(x) \right|. \tag{79}$$

Finally we define the map

$$\begin{aligned} \mathcal{S} :\ \mathcal{E}(\mu, \beta) &\to \mathcal{E}(\mu, \beta), \\ \varphi &\longmapsto \mathcal{S}(\varphi), \end{aligned} \tag{80}$$

such that

$$\text{(81)}\qquad \begin{cases} \dfrac{d^2\mathcal{S}(\varphi)}{dx^2} = n(\varphi)(x), \\ n(x) = n_1(\varphi)(x) + n_2(\varphi)(x), \\ \mathcal{S}(\varphi)(0) = 0, \qquad \dfrac{d\mathcal{S}(\varphi)}{dx}(0) = \beta \geq 0, \end{cases}$$

where $n_1(\varphi)$ and $n_2(\varphi)$ are defined by the formulae (57) *and* (58).

We begin with the following lemma.

LEMMA 4.4. *The set $\mathcal{E}(\mu,\beta)$ equipped with the distance d is a complete metric space.*

Proof. The proof is immediate and left to the reader. □

PROPOSITION 4.5. *There exist $\mu > 0$ and $k < 1$ (depending on β) such that for every function φ, ψ in $\mathcal{E}(\mu,\beta)$ the following estimates hold on $(0,\mu]$:*

$$\text{(82)}\qquad |n_1(\varphi)(x) - n_1(\psi)(x)| \leq \frac{k}{4\sqrt{x}}\, d(\varphi,\psi),$$

$$\text{(83)}\qquad |n_2(\varphi)(x) - n_2(\psi)(x)| \leq \frac{k}{4\sqrt{x}}\, d(\varphi,\psi).$$

Proof. We begin by proving (82). We have

$$\begin{aligned} n_1(\varphi)(x) - n_1(\psi)(x) = {} & \frac{1}{\sqrt{\varphi(x)}}\,[g_\varphi(x,0) - g_\psi(x,0)] \\ & + g_\psi(x,0)\left[\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right]. \end{aligned} \qquad \text{(84)}$$

The second term of the right-hand side can be estimated as follows:

$$\begin{aligned} g_\psi(x,0)\left|\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right| &\leq \frac{|\varphi(x) - \psi(x)|}{\sqrt{\varphi(x)}\sqrt{\psi(x)}\left(\sqrt{\varphi(x)} + \sqrt{\psi(x)}\right)} \\ &\leq \frac{1}{2\,\beta^{3/2}x^{3/2}} \int_0^x \left|\frac{d\varphi}{dx}(y) - \frac{d\psi}{dx}(y)\right| dy. \end{aligned} \qquad \text{(85)}$$

Using (79), the last estimate turns to

$$\text{(86)}\qquad g_\psi(x,0)\left|\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right| \leq \frac{1}{3\,\beta^{3/2}}\, d(\varphi,\psi).$$

For the first term of (84) we have

$$\begin{aligned} |g_\varphi(x,0) - g_\psi(x,0)| &= \left|\exp\left(-\int_0^x \frac{dz}{\sqrt{\varphi(z)}}\right) - \exp\left(-\int_0^x \frac{dz}{\sqrt{\psi(z)}}\right)\right| \\ &\leq \left|\int_0^x \frac{dz}{\sqrt{\varphi(z)}} - \int_0^x \frac{dz}{\sqrt{\psi(z)}}\right| \\ &\leq \frac{x}{3\beta^{3/2}}\, d(\varphi,\psi). \end{aligned} \qquad \text{(87)}$$

Therefore we have

$$|n_1(\varphi)(x) - n_1(\psi)(x)| \leq C_3(1 + \sqrt{x})\, d(\varphi, \psi), \tag{88}$$

with a constant C_3 depending only on β. Now by choosing μ small enough so that $C_3(1 + \sqrt{x}) \leq \frac{k}{4\sqrt{x}}$ on $(0, \mu]$, we get the estimate (82). □

To prove (83), we proceed in a likewise manner, but the calculations are much more complicated since n_2 is not given explicitly. We consider two sequences, $n_2^p(\varphi)$ and $n_2^p(\psi)$, defined by

$$n_2^p(\varphi) = K_\varphi(n_2^{p-1}(\varphi)), \quad n_2^0(\varphi) = 0, \tag{89}$$

where K_φ is defined by formula (70) and

$$n_2^p(\psi) = K_\psi(n_2^{p-1}(\psi)), \quad n_2^0(\psi) = 0, \tag{90}$$

where K_ψ is defined analogously. Therefore, we have the following lemma.

LEMMA 4.6. *There exists a constant $C > 0$ which only depends on β such that*

$$\left|n_2^1(\varphi)(x) - n_2^1(\psi)(x)\right| \leq C\, d(\varphi, \psi) \qquad \text{on } (0, \mu]. \tag{91}$$

Proof. First, we prove exactly in the same way as in (85) that

$$\begin{aligned} \left| \frac{1}{\sqrt{\varphi(x) - \varphi(y)}} - \frac{1}{\sqrt{\psi(x) - \psi(y)}} \right| &\leq \frac{4\,(x^{3/2} - y^{3/2})}{3\,\beta^{3/2}\,(x-y)^{3/2}}\, d(\varphi, \psi) \\ &\leq \frac{C}{\sqrt{x-y}}\, d(\varphi, \psi). \end{aligned} \tag{92}$$

Besides, we have

$$\begin{aligned} n_2^1(\varphi)(x) - n_2^1(\psi)(x) = &\int_0^x [n_1(\varphi)(y) - n_1(\psi)(y)] \frac{g_\varphi(x,y)}{\sqrt{\varphi(x) - \varphi(y)}}\, dy \\ &+ \int_0^x n_1(\psi)(y)\, g_\varphi(x,y) \left[\frac{1}{\sqrt{\varphi(x) - \varphi(y)}} - \frac{1}{\sqrt{\psi(x) - \psi(y)}} \right] dy \\ &+ \int_0^x \frac{n_1(\psi)(y)}{\sqrt{\psi(x) - \psi(y)}} [g_\varphi(x,y) - g_\psi(x,y)]\, dy. \end{aligned} \tag{93}$$

From estimates (82) and (92), equation (93) can be estimated as follows:

$$\begin{aligned} \left|n_2^1(\varphi)(x) - n_2^1(\psi)(x)\right| \leq &\int_0^x \frac{k\, d(\varphi, \psi)}{4\sqrt{y}\sqrt{\beta(x-y)}}\, dy \\ &+ \int_0^x \frac{1}{\sqrt{\beta y}} \frac{C\, d(\varphi, \psi)}{\sqrt{x-y}}\, dy \\ &+ \int_0^x \frac{1}{\sqrt{\beta y}\sqrt{\beta(x-y)}} \left[\int_y^x \frac{C\, d(\varphi, \psi)}{\sqrt{h-y}}\, dh \right] dy. \end{aligned} \tag{94}$$

A straightforward computation of the right-hand side integrals leads to

$$\left|n_2^1(\varphi)(x) - n_2^1(\psi)(x)\right| \leq C\, d(\varphi, \psi), \qquad x \in (0, \mu]$$

and this ends the proof of Lemma 4.6. □

We proceed by induction and prove the following lemma:

LEMMA 4.7.

$$|n_2^p(\varphi)(x) - n_2^p(\psi)(x)| \le C\, h_p\left(\sqrt{\frac{x}{\beta}}\right) d(\varphi,\psi), \tag{95}$$

where

$$h_p(z) = \sum_{i=0}^{p-1} z^i \left(\prod_{j=1}^{i} I_j\right)$$

and

$$I_j = \int_0^1 \frac{t^{\frac{j-1}{2}}}{\sqrt{1-t}}\, dt.$$

Proof. We write

$$\begin{aligned} n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x) &= n_2^1(\varphi)(x) - n_2^1(\psi)(x) \\ &+ \int_0^x [n_2^p(\varphi)(y) - n_2^p(\psi)(y)] \frac{g_\varphi(x,y)}{\sqrt{\varphi(x)-\varphi(y)}}\, dy \\ &+ \int_0^x n_2^p(\psi)(y)\, g_\varphi(x,y) \left[\frac{1}{\sqrt{\varphi(x)-\varphi(y)}} - \frac{1}{\sqrt{\psi(x)-\psi(y)}}\right] dy \\ &+ \int_0^x \frac{n_2^p(\psi)(y)}{\sqrt{\psi(x)-\psi(y)}} [g_\varphi(x,y) - g_\psi(x,y)]\, dy. \end{aligned} \tag{96}$$

By using Lemma 4.6 and (92), we have

$$\begin{aligned} \left|n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x)\right| &\le C\, d(\varphi,\psi) \\ &+ \int_0^x \frac{|n_2^p(\varphi)(y) - n_2^p(\psi)(y)|}{\sqrt{\beta(x-y)}}\, dy \\ &+ C\|n_2^p(\psi)\|_{L^\infty} \sqrt{x}\, d(\varphi,\psi) \\ &+ C\|n_2^p(\psi)\|_{L^\infty} x\, d(\varphi,\psi). \end{aligned}$$

For μ small, we get from the preceding inequality

$$\left|n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x)\right| \le C_1\, d(\varphi,\psi) + \int_0^x \frac{|n_2^p(\varphi)(y) - n_2^p(\psi)(y)|}{\sqrt{\beta(x-y)}}\, dy \tag{97}$$

and the result follows easily by induction. □

End of the proof of Proposition 4.5. The inequality (95) passes to the limit and gives

$$|n_2(\varphi)(x) - n_2(\psi)(x)| \le C\, h\left(\sqrt{\frac{x}{\beta}}\right) d(\varphi,\psi), \tag{98}$$

where

$$h(z) = \sum_{i=0}^{+\infty} z^i \left(\prod_{j=1}^{i} I_j\right)$$

is an analytic function defined on $\mathbb{R}$. For μ small enough, we get

$$|n_2(\varphi) - n_2(\psi)| \leq \frac{k}{4\sqrt{x}} d(\varphi, \psi) \quad \forall x \in]0, \mu],$$

and this ends the proof. □

End of the proof of Proposition 4.2. By integrating twice the inequalities (82) and (83), we prove the strict contractivity of the map $\mathcal{S}$ for small μ which yields the existence and uniqueness of the solution on a small interval near zero. □

4.2. Local existence and uniqueness in the case $\beta = 0$. The proof will be analogous to the case $\beta > 0$ but the estimate (73) is not useful; thus we begin by proving the following lemma.

LEMMA 4.8. *There exists a positive μ such that for every solution φ of the system* (71) *with $\beta = 0$, the following estimate holds for every $x \in [0, \mu]$:*

$$\varphi(x) \geq \left(\frac{9}{8}\right)^{2/3} x^{4/3}. \tag{99}$$

Proof. Let φ be a solution of (71). Then the function $g_\varphi(x, 0)$ tends to 1 as x tends to zero. Thus, there exists a constant $\mu_0 > 0$ (depending on φ) such that

$$g_\varphi(x, 0) \geq \frac{1}{2} \quad \forall x \in [0, \mu_0]. \tag{100}$$

Since n_2 is positive, the above estimate gives

$$\frac{d^2\varphi}{dx^2} \geq \frac{1}{2\sqrt{\varphi}} \quad \text{on } [0, \mu_0]. \tag{101}$$

By multiplying this inequality by $\frac{d\varphi}{dx}$ and integrating, we get the estimate (99).

Now the only thing left to show is that μ_0 can be chosen independently of φ.

Let $\mu_1 \geq \mu_0$. For $x \in [\mu_0, \mu_1]$ the following estimate holds:

$$\begin{aligned} \log g_\varphi(x, 0) &= -\int_0^{\mu_0} \frac{dh}{\sqrt{\varphi(h)}} - \int_{\mu_0}^{x} \frac{dh}{\sqrt{\varphi(h)}} \\ &\geq -\int_0^{\mu_0} \frac{dh}{(\frac{9}{8})^{1/3} h^{2/3}} - \int_{\mu_0}^{x} \frac{dh}{\sqrt{\varphi(\mu_0)}} \\ &\geq -(\frac{8}{9})^{1/3} \left(2\,\mu_0^{1/3} + \frac{x}{\mu_0^{2/3}}\right). \end{aligned} \tag{102}$$

The estimate (99) will hold on $[0, \mu_1]$ if $g_\varphi(\mu_1, 0) \geq \frac{1}{2}$. Using the above estimate it is sufficient to take

$$\mu_1 = K\mu_0^{2/3} - 2\mu_0, \qquad K = \left(\frac{9}{8}\right)^{1/3} \log 2. \tag{103}$$

In the case $\mu_0 \geq (\frac{K}{3})^3$ then we take $\mu = \mu_0$. Otherwise, μ_1 defined by formula (103) satisfies

$$\mu_0 \leq \mu_1 \leq \left(\frac{K}{3}\right)^3.$$

Thus formula (103) permits us to build a bounded increasing sequence μ_n, with a limit equal to $(\frac{K}{3})^3$. In both cases we can choose $\mu = (\frac{K}{3})^3$, which ends the proof of the lemma. □

As in the case $\beta > 0$, the preceding lemma allows us to exhibit an equivalent of φ in the neighborhood of $x = 0$. Thus we obtain the analogue of formulae (75) and (76).

PROPOSITION 4.9. *There exist two positive constants μ and B such that the following inequalities hold on $[0, \mu]$ for every solution φ of (71) with $\beta = 0$:*

$$\frac{4}{9} D x^{-2/3} \left(1 - \frac{5}{2} B x^{\frac{1}{3}}\right) \leq \frac{d^2\varphi}{dx^2}(x) \leq \frac{4}{9} D x^{-2/3} \left(1 + \frac{5}{2} B x^{\frac{1}{3}}\right), \tag{104}$$

$$\frac{4}{3} D x^{1/3} \left(1 - \frac{5}{4} B x^{\frac{1}{3}}\right) \leq \frac{d\varphi}{dx}(x) \leq \frac{4}{3} D x^{1/3} \left(1 + \frac{5}{4} B x^{\frac{1}{3}}\right), \tag{105}$$

$$D x^{4/3}(1 - B x^{\frac{1}{3}}) \leq \varphi(x) \leq D x^{4/3}(1 + B x^{\frac{1}{3}}), \tag{106}$$

where

$$D = \left(\frac{9}{4}\right)^{2/3}.$$

Proof. Since φ is a convex function with $\varphi(0) = 0$, then for every $h \geq y \geq 0$ we have

$$\varphi(h) - \varphi(y) \geq \frac{h - y}{h} \varphi(h). \tag{107}$$

Thus using estimate (99), we get for $0 \leq y \leq x \leq \mu$

$$\exp\left(-\left(\frac{8}{9}\right)^{1/3} \int_y^x \frac{dh}{h^{1/6}\sqrt{h - y}}\right) \leq g_\varphi(x, y) \leq 1. \tag{108}$$

Now we apply this inequality for $y = 0$, and by using the inequality $\exp(-u) \geq 1 - u$, we get

$$\frac{1 - C x^{1/3}}{\sqrt{\varphi(x)}} \leq n_1(x) \leq \frac{1}{\sqrt{\varphi(x)}}. \tag{109}$$

Since (99) implies that $n_2 \in L^\infty_{4/3}[0, \mu]$, we have

$$n_2(x) \leq \frac{K}{x^{1/3}},$$

and therefore

$$\frac{1 - C x^{1/3}}{\sqrt{\varphi(x)}} \leq \frac{d^2\varphi}{dx^2}(x) \leq \frac{1}{\sqrt{\varphi(x)}} + \frac{K}{x^{1/3}}. \tag{110}$$

By using this estimate, we proceed as in [7] and prove the proposition. We build some sequences μ_n, B_n, C_n such that

$$\varphi(x) \geq C_n x^{4/3} (1 - B_n x^{1/3}) \quad \forall x \in [0, \mu_n]. \tag{111}$$

From the upper bound for $\frac{d^2\varphi}{dx^2}$ given by (110), we deduce

$$\frac{d^2\varphi}{dx^2}(x) \leq \frac{K}{x^{1/3}} + \frac{1}{\sqrt{C_n}\, x^{2/3}\sqrt{1 - B_n\, x^{1/3}}}. \tag{112}$$

Now we introduce a positive real number t such that

$$\frac{1}{\sqrt{1-u}} \leq 1 + u, \qquad \frac{1}{\sqrt{1+u}} \geq 1 - u, \qquad u \in [0, t]. \tag{113}$$

Thus for $x \in [0, \mu_n] \bigcap [0, (\frac{t}{B_n})^3]$, the estimate (112) turns to

$$\frac{d^2\varphi}{dx^2}(x) \leq \left(K + \frac{B_n}{\sqrt{C_n}}\right) x^{-1/3} + \frac{1}{\sqrt{C_n}\, x^{2/3}}. \tag{114}$$

We integrate this inequality twice, and by setting

$$C_n' = \frac{9}{4\sqrt{C_n}}, \quad B_n' = \frac{1}{C_n'}\left(\frac{9}{10}K + \frac{B_n}{\sqrt{C_n}}\right), \tag{115}$$

we get

$$\varphi(x) \leq C_n'\, x^{4/3}\,(1 + B_n'\, x^{1/3}), \qquad x \in [0, \mu_n] \bigcap [0, \left(\frac{t}{B_n}\right)^3]. \tag{116}$$

By using the above estimate and the first inequality of (110), we get

$$\frac{d^2\varphi}{dx^2}(x) \geq \frac{1 - Cx^{1/3}}{x^{2/3}\sqrt{C_n'}\sqrt{1 + B_n'\, x^{1/3}}}.$$

We integrate this inequality twice, using the estimate (113), and obtain

$$\varphi(x) \geq C_{n+1}\, x^{4/3}\,(1 - B_{n+1}\, x^{1/3}), \quad x \in [0, \mu_{n+1}], \tag{117}$$

where

$$\begin{aligned} C_{n+1} &= \frac{9}{4\sqrt{C_n'}}, \quad B_{n+1} = \frac{2}{5}(B_n' + C), \\ \mu_{n+1} &= \min\left[\mu_n, \left(\frac{t}{B_n}\right)^3, \left(\frac{t}{B_n'}\right)^3\right]. \end{aligned} \tag{118}$$

It is obvious to show that the sequences C_n and C_n' converge and that

$$\lim C_n = \lim C_n' = D = \left(\frac{9}{4}\right)^{2/3}. \tag{119}$$

By using (115) and (118), we can express B_{n+1} by means of B_n and show that B_n and B_n' converge, and that their limits are positive. Also, we can choose K and C in such a way that the limit B of B_n is the same as that of B_n'. This yields that μ_n converges to a positive limit μ. Thus the estimates (104)–(106) hold in $[0, \mu]$. □

Now we are able to define a set $\mathcal{E}'(\mu)$, where the solution lies, as shown in the following definition.

DEFINITION 4.10. *We denote by $\mathcal{E}'(\mu)$ the set of C^1 convex positive functions defined on $[0,\mu]$ such that*

$$\varphi(0) = 0, \quad \frac{d\varphi}{dx}(0) = 0, \tag{120}$$

$$\frac{1}{x^{2/3}}\left|\frac{d\varphi}{dx}(x) - \frac{4}{3}D\,x^{1/3}\right| \leq \frac{5}{3}DB \quad \text{on } (0,\mu).$$

On this set, we define the distance

$$d'(\varphi_1,\varphi_2) = \sup_{x\in(0,\mu]} \frac{1}{x^{2/3}}\left|\frac{d\varphi_1}{dx}(x) - \frac{d\varphi_2}{dx}(x)\right| \tag{121}$$

and then we define the map

$$\begin{aligned} \mathcal{S}:\ \mathcal{E}'(\mu) &\to \mathcal{E}'(\mu), \\ \varphi &\longmapsto \mathcal{S}(\varphi), \end{aligned} \tag{122}$$

such that

$$\begin{cases} \dfrac{d^2\mathcal{S}(\varphi)}{dx^2} = n(\varphi)(x), \\ n(x) = n_1(\varphi)(x) + n_2(\varphi)(x), \\ \mathcal{S}(\varphi)(0) = 0, \quad \dfrac{d\mathcal{S}(\varphi)}{dx}(0) = 0, \end{cases} \tag{123}$$

where $n_1(\varphi)$ and $n_2(\varphi)$ are defined by the formulae (57) *and* (58).

We claim that $\mathcal{S}$ maps $\mathcal{E}'(\mu)$ into itself because the constant B defined in the previous proposition is the limit of both sequences B_n and B'_n. Hence, one can do the same computations as in the proof of the previous proposition and prove the claim. Analogously to the previous section, we have the following lemma.

LEMMA 4.11. *The set $\mathcal{E}'(\mu)$ equipped with the distance d' is a complete metric space.*

Then we have the following proposition.

PROPOSITION 4.12. *There exist $\mu > 0$ and $k < 1$ such that for every function φ, ψ in $\mathcal{E}'(\mu)$, the following estimates hold on $(0,\mu]$:*

$$|n_1(\varphi)(x) - n_1(\psi)(x)| \leq \frac{k}{3x^{1/3}}\,d'(\varphi,\psi), \tag{124}$$

$$|n_2(\varphi)(x) - n_2(\psi)(x)| \leq \frac{k}{3x^{1/3}}\,d'(\varphi,\psi). \tag{125}$$

Proof. The proof of this proposition is analogous to that of Proposition 4.5. We begin by proving the following lemma. □

LEMMA 4.13. *There exists a constant $k_1 < 1$ such that for all φ and ψ in $\mathcal{E}'(\mu)$, the following estimate holds for $0 \leq y < x \leq \mu$:*

$$\left|\frac{1}{\sqrt{\varphi(x)-\varphi(y)}} - \frac{1}{\sqrt{\psi(x)-\psi(y)}}\right| \leq \frac{k_1}{3}\,\frac{x^{5/3}-y^{5/3}}{(x^{4/3}-y^{4/3})^{3/2}}\,d'(\varphi,\psi). \tag{126}$$

Proof. Since

$$\left|\frac{1}{\sqrt{\varphi(x)-\varphi(y)}}-\frac{1}{\sqrt{\psi(x)-\psi(y)}}\right| = \frac{\left|\int_y^x (\varphi'(h)-\psi'(h))\,dh\right|}{\sqrt{\varphi(x)-\varphi(y)}\sqrt{\psi(x)-\psi(y)}\left(\sqrt{\psi(x)-\psi(y)}+\sqrt{\varphi(x)-\varphi(y)}\right)},$$

we take μ small enough such that $(1-\frac{5}{4}B\mu^{1/3})^{3/2} \geq \frac{9}{10}$; therefore, (105) gives

$$\sqrt{\varphi(x)-\varphi(y)}\sqrt{\psi(x)-\psi(y)}\left(\sqrt{\psi(x)-\psi(y)}+\sqrt{\varphi(x)-\varphi(y)}\right) \geq 2\frac{9}{10}\left(\frac{4}{3}D\int_y^x h^{\frac{1}{3}}\,dh\right)^{3/2}.$$

Thus

$$\left|\frac{1}{\sqrt{\varphi(x)-\varphi(y)}}-\frac{1}{\sqrt{\psi(x)-\psi(y)}}\right| \leq d'(\varphi,\psi)\frac{\int_y^x h^{2/3}\,dh}{2\frac{9}{10}\left(\frac{4}{3}D\int_y^x h^{\frac{1}{3}}\,dh\right)^{3/2}}.$$

This proves the result with $k_1 = \frac{4}{9}$. □

By going back to the proof of Proposition 4.12, we prove (124):

$$n_1(\varphi)(x)-n_1(\psi)(x) = g_\varphi(x,0)\left[\frac{1}{\sqrt{\varphi(x)}}-\frac{1}{\sqrt{\psi(x)}}\right] + \frac{1}{\sqrt{\psi(x)}}\left[g_\varphi(x,0)-g_\psi(x,0)\right].$$

Therefore

$$|n_1(\varphi)(x)-n_1(\psi)(x)| \leq \frac{k_1}{3}x^{-1/3}\,d'(\varphi,\psi) + \frac{|g_\varphi(x,0)-g_\psi(x,0)|}{D^{3/2}\,x^{2/3}\sqrt{1-Bx^{1/3}}}.$$

In view of (126), the following estimate holds:

$$|g_\varphi(x,0)-g_\psi(x,0)| \leq \int_0^x \left|\frac{1}{\sqrt{\varphi(h)}}-\frac{1}{\sqrt{\psi(h)}}\right| dh \leq \frac{k_1}{2}\,x^{2/3}\,d'(\varphi,\psi).$$

Then

$$|n_1(\varphi)(x)-n_1(\psi)(x)| \leq \frac{k_1}{3}x^{-1/3}\,d'(\varphi,\psi) + Cd'(\varphi,\psi).$$

By taking $k_1 < k < 1$, we can choose μ small enough so that

$$|n_1(\varphi)(x)-n_1(\psi)(x)| \leq \frac{k}{3}x^{-1/3}\,d'(\varphi,\psi).$$

This ends the proof of (124). To prove (125), we proceed in the exact same manner as in the proof of (83). We consider the following sequences:

$$n_2^p(\varphi) = K_\varphi(n_2^{p-1}(\varphi)), \quad n_2^0(\varphi) = 0, \tag{127}$$

and

$$n_2^p(\psi) = K_\psi(n_2^{p-1}(\psi)), \quad n_2^0(\psi) = 0. \tag{128}$$

Therefore, we have the following lemma.

LEMMA 4.14. *There exist constants $C > 0$, $\mu > 0$ such that*

$$\left|n_2^1(\varphi) - n_2^1(\psi)\right| \le C\, d'(\varphi, \psi), \qquad \text{on } (0, \mu]. \tag{129}$$

Proof. We have

$$\begin{aligned} n_2^1(\varphi)(x) - n_2^1(\psi)(x) &= \int_0^x [n_1(\varphi)(y) - n_1(\psi)(y)] \frac{g_\varphi(x,y)}{\sqrt{\varphi(x) - \varphi(y)}}\, dy \\ &\quad + \int_0^x n_1(\psi)(y)\, g_\varphi(x,y) \left[\frac{1}{\sqrt{\varphi(x) - \varphi(y)}} - \frac{1}{\sqrt{\psi(x) - \psi(y)}}\right] dy \\ &\quad + \int_0^x \frac{n_1(\psi)(y)}{\sqrt{\psi(x) - \psi(y)}} [g_\varphi(x,y) - g_\psi(x,y)]\, dy. \end{aligned} \tag{130}$$

From estimates (124) and (126), the right-hand side of equation (130) can be estimated as follows:

$$\begin{aligned} \left|n_2^1(\varphi)(x) - n_2^1(\psi)(x)\right| &\le \int_0^x \frac{k\, d'(\varphi,\psi)}{3y^{1/3}\sqrt{C(x^{4/3} - y^{4/3})}}\, dy \\ &\quad + \int_0^x \frac{1}{\sqrt{Cy^{4/3}}} \frac{k_1}{3} \frac{x^{5/3} - y^{5/3}}{(x^{4/3} - y^{4/3})^{3/2}}\, d'(\varphi,\psi)\, dy \\ &\quad + \int_0^x \frac{1}{\sqrt{Cy^{4/3}}\sqrt{C(x^{4/3} - y^{4/3})}} \\ &\qquad \left[\int_y^x C\, d'(\varphi,\psi) \frac{k_1}{3} \frac{h^{5/3} - y^{5/3}}{(y^{4/3} - y^{4/3})^{3/2}} dh\right] dy. \end{aligned} \tag{131}$$

By the change of the variable $y = xt$, we prove that the first two integrals of the right-hand side are constant. To compute the third integral, we set

$$A = \int_0^x \frac{1}{\sqrt{Cy^{4/3}}\sqrt{C(x^{4/3} - y^{4/3})}} \left[\int_y^x C \frac{k_1}{3} \frac{h^{5/3} - y^{5/3}}{(h^{4/3} - y^{4/3})^{3/2}}\, dh\right] dy.$$

Then, through Fubini's formula, A satisfies

$$A = C \int_0^x \frac{1}{\sqrt{x^{4/3} - h^{4/3}}} \int_0^h \frac{h^{5/3} - y^{5/3}}{\sqrt{y^{4/3}}\,(h^{4/3} - y^{4/3})^{3/2}}\, dy\, dh.$$

By using the change of variable $y = ht$ for fixed h , we obtain

$$A = CI \int_0^x \frac{dh}{\sqrt{x^{4/3} - h^{4/3}}},$$

where

$$I = \int_0^1 \frac{1 - t^{5/3}}{t^{2/3}(1 - t^{4/3})^{3/2}}\, dt < \infty.$$

Again by the change of variable $h = tx$, we obtain

$$A = C\, x^{1/3},$$

and since the third term of (131) is equal to $A\, d'(\varphi, \psi)$, then

$$\left| n_2^1(\varphi)(x) - n_2^1(\psi)(x) \right| \leq C\, d'(\varphi, \psi), \qquad x \in (0, \mu]$$

and this ends the proof of Lemma 4.14. □

We use this lemma and proceed by induction to prove the following lemma.

LEMMA 4.15.

$$|n_2^p(\varphi)(x) - n_2^p(\psi)(x)| \leq C\, h_p((Cx)^{1/3})\, d'(\varphi, \psi), \tag{132}$$

where

$$h_p(z) = \sum_{i=0}^{p-1} z^i \left(\prod_{j=1}^{i} I_j \right)$$

and

$$I_j = \int_0^1 \frac{t^{\frac{j-1}{3}}}{\sqrt{1 - t^{4/3}}}\, dt.$$

Proof. We write

$$\begin{aligned} n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x) &= n_2^1(\varphi)(x) - n_2^1(\psi)(x) \\ &+ \int_0^x [n_2^p(\varphi)(y) - n_2^p(\psi)(y)] \frac{g_\varphi(x, y)}{\sqrt{\varphi(x) - \varphi(y)}}\, dy \\ &+ \int_0^x n_2^p(\psi)(y)\, g_\varphi(x, y) \left[\frac{1}{\sqrt{\varphi(x) - \varphi(y)}} - \frac{1}{\sqrt{\psi(x) - \psi(y)}} \right] dy \\ &+ \int_0^x \frac{n_2^p(\psi)(y)}{\sqrt{\psi(x) - \psi(y)}} [g_\varphi(x, y) - g_\psi(x, y)]\, dy \end{aligned} \tag{133}$$

and by using Lemma 4.14 and inequalities (87) and (126), we deduce that

$$\begin{aligned} \left| n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x) \right| &\leq C\, d'(\varphi, \psi) \\ &+ \int_0^x \frac{|n_2^p(\varphi)(y) - n_2^p(\psi)(y)|}{\sqrt{C(x^{4/3} - y^{4/3})}}\, dy \\ &+ C x^{1/3}\, d'(\varphi, \psi) \\ &+ C x^{2/3}\, d'(\varphi, \psi). \end{aligned}$$

For μ small, we get from the preceding inequality that

$$\left| n_2^{p+1}(\varphi)(x) - n_2^{p+1}(\psi)(x) \right| \leq C_1\, d'(\varphi, \psi) + \int_0^x \frac{|n_2^p(\varphi)(y) - n_2^p(\psi)(y)|}{\sqrt{C(x^{4/3} - y^{4/3})}}\, dy, \tag{134}$$

and the result follows easily by induction. □

End of the proof of Proposition 4.12. The inequality (132) of Lemma 4.15 passes to the limit and gives

$$|n_2(\varphi)(x) - n_2(\psi)(x)| \leq C\, h((Cx)^{1/3})\, d'(\varphi, \psi), \tag{135}$$

where

$$h(z) = \sum_{i=0}^{+\infty} z^i \left(\prod_{j=1}^{i} I_j \right)$$

is an analytic function defined on $\mathbb{R}$. For μ small enough we get

$$|n_2(\varphi)(x) - n_2(\psi)(x)| \leq \frac{k}{3x^{1/3}}, d'(\varphi, \psi) \quad \forall x \in (0, \mu]$$

and this ends the proof. □

End of the proof of Proposition 4.2. Like in the case $\beta > 0$ treated in the previous section we integrate twice the inequalities (124) and (125) and prove the strict contractivity of the map $\mathcal{S}$ for small μ. This gives the existence and the uniqueness of the solution on a small interval near zero. □

4.3. Global existence and uniqueness. In this section, we show the existence and uniqueness of the solution of the system (71) on an interval $[\mu, A]$, where A is an arbitrary constant. By denoting $\widetilde{\varphi}, \widetilde{n}$ as the quantities defined in Proposition 4.2, we can rewrite the system on $[\mu, A]$:

$$\frac{d^2\varphi}{dx^2} = n(x), \qquad x \in [\mu, A], \tag{136}$$

$$n(x) = n_1(x) + n_2(x), \tag{137}$$

$$n_1(x) = \frac{1}{\sqrt{\varphi(x)}}\, g_{\widetilde{\varphi}}(\mu, 0) \exp\left(- \int_{\mu}^{x} \frac{dz}{\sqrt{\varphi(z)}} \right), \tag{138}$$

$$\begin{aligned} n_2(x) &- \int_0^{\mu} \frac{\widetilde{n}(y)}{\sqrt{\varphi(x) - \widetilde{\varphi}(y)}} g_{\widetilde{\varphi}}(\mu, y) \exp\left(- \int_{\mu}^{x} \frac{dz}{\sqrt{\varphi(z) - \widetilde{\varphi}(y)}} \right) dy \\ &- \int_{\mu}^{x} \frac{g_{\varphi}(x, y)}{\sqrt{\varphi(x) - \varphi(y)}} \left[n_1(y) + n_2(y) \right] dy \\ &= 0, \end{aligned} \tag{139}$$

$$\varphi(\mu) = \widetilde{\varphi}(\mu), \qquad \frac{d\varphi}{dx}(\mu) = \frac{d\widetilde{\varphi}}{dx}(\mu), \tag{140}$$

$$g_{\varphi}(x, y) = \exp\left(- \int_{y}^{x} \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}} \right), \tag{141}$$

$$g_{\widetilde{\varphi}}(x,y) = \exp\Big(- \int_y^x \frac{dz}{\sqrt{\widetilde{\varphi}(z) - \widetilde{\varphi}(y)}} \Big). \tag{142}$$

We apply a fixed-point procedure associated with this new formulation. We set

$$\mathcal{F} = \left\{ \varphi \in C^1[\mu, A] \text{ convex such that } \quad \varphi(\mu) = \widetilde{\varphi}(\mu), \quad \frac{d\varphi}{dx}(\mu) = \frac{d\widetilde{\varphi}}{dx}(\mu) \right\}.$$

We define the map

$$n_1(\varphi)(x) = \frac{1}{\sqrt{\varphi(x)}}\, g_{\widetilde{\varphi}}(\mu, 0) \exp\Big(- \int_\mu^x \frac{dz}{\sqrt{\varphi(z)}} \Big)$$

and the map $n_2(\varphi)$ by the integral equation

$$\begin{aligned} n_2(\varphi)(x) &- \int_0^\mu \frac{\widetilde{n}(y)}{\sqrt{\varphi(x) - \widetilde{\varphi}(y)}} g_{\widetilde{\varphi}}(\mu, y) \exp\Big(- \int_\mu^x \frac{dz}{\sqrt{\varphi(z) - \widetilde{\varphi}(y)}} \Big) dy \\ &- \int_\mu^x \frac{g_\varphi(x,y)}{\sqrt{\varphi(x) - \varphi(y)}} \left[n_1(\varphi)(y) + n_2(\varphi)(y) \right] dy. \\ &= 0. \end{aligned} \tag{143}$$

Finally, we define the map $\mathcal{S}$

$$\begin{aligned} \mathcal{S} :\ & \mathcal{F} \to \mathcal{F}, \\ & \varphi \longmapsto \mathcal{S}(\varphi) \end{aligned} \tag{144}$$

such that

$$\begin{cases} \dfrac{d^2 \mathcal{S}(\varphi)}{dx^2} = n(\varphi)(x), \\ n(\varphi)(x) = n_1(\varphi)(x) + n_2(\varphi)(x), \\ \mathcal{S}(\varphi)(\mu) = \widetilde{\varphi}(\mu), \qquad \dfrac{d\mathcal{S}(\varphi)}{dx}(\mu) = \dfrac{d\widetilde{\varphi}}{dx}(\mu) > 0. \end{cases} \tag{145}$$

The proof of existence and uniqueness of the solution is based on the following proposition.

PROPOSITION 4.16. *There exists a constant k such that for every pair of functions φ, ψ in $\mathcal{F}$ and every integer p that satisfies*

$$|\varphi'(x) - \psi'(x)| \le D_1 (x - \mu)^p \qquad \forall x \in [\mu, A],$$

where D_1 is an arbitrary constant, we have

$$|\mathcal{S}(\varphi)'(x) - \mathcal{S}(\psi)'(x)| \le \frac{k D_1}{p+1} (x - \mu)^{p+1} \qquad \forall x \in [\mu, A].$$

The existence and uniqueness of the solution is an immediate consequence of the above proposition.

COROLLARY 4.17. *There exists an integer p such that the map $\mathcal{S}^p$ is a contraction on $\mathcal{F}$. The considered distance on $\mathcal{F}$ is*

$$d(\varphi, \psi) = \sup_{x \in [\mu, A]} |\varphi'(x) - \psi'(x)|.$$

Proof. Apply the preceding proposition with $p = 0$, then

$$|\mathcal{S}(\varphi)'(x) - \mathcal{S}(\psi)'(x)| \leq k\,(x-\mu)\,d(\varphi,\psi) \qquad \forall x \in [\mu, A].$$

An iteration of this inequality using the preceding proposition gives

$$|\mathcal{S}^p(\varphi)'(x) - \mathcal{S}^p(\psi)'(x)| \leq \frac{k^p\,(x-\mu)^p}{p!}\,d(\varphi,\psi) \qquad \forall x \in [\mu, A].$$

This gives

$$d(\mathcal{S}^p(\varphi), \mathcal{S}^p(\psi)) \leq \frac{k^p\,(A-\mu)^p}{p!}\,d(\varphi,\psi),$$

and we only have to choose p large enough. □

The remainder of this paragraph will consist in proving Proposition 4.16. From now on we will consider a pair φ, ψ of functions in $\mathcal{F}$ that satisfy

$$|\varphi'(x) - \psi'(x)| \leq D_1\,(x-\mu)^p \qquad \forall x \in [\mu, A]. \tag{146}$$

LEMMA 4.18. *There exists a constant k_1 independent of φ, ψ, and p such that*

$$|n_1(\varphi)(x) - n_1(\psi)(x)| \leq k_1\,D_1\,(x-\mu)^p.$$

Proof. The difference of the densities associated, respectively, with φ and ψ reads

$$\begin{aligned} n_1(\varphi)(x) - n_1(\psi)(x) &= \frac{g_{\widetilde{\varphi}}(\mu,0)}{\sqrt{\varphi(x)}}\left[\exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\varphi(z)}}\Big) - \exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\psi(z)}}\Big)\right] \\ &\quad + \left(\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right) g_{\widetilde{\varphi}}(\mu,0)\,\exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\psi(z)}}\Big). \end{aligned} \tag{147}$$

The second term of the right-hand side can be bounded by

$$\left|\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right| \leq \frac{|\varphi(x) - \psi(x)|}{\sqrt{\varphi}\,\sqrt{\psi}\,(\sqrt{\varphi} + \sqrt{\psi})}.$$

By the convexity of φ and ψ, we have $\varphi, \psi \geq \widetilde{\varphi}(\mu) > 0$. Then

$$\left|\frac{1}{\sqrt{\varphi(x)}} - \frac{1}{\sqrt{\psi(x)}}\right| \leq \frac{1}{2(\widetilde{\varphi}(\mu))^{3/2}} \int_\mu^x |\varphi'(s) - \psi'(s)|\,ds \leq k_1'\,D_1\,(x-\mu)^p,$$

where the constant k_1' only depends on μ, $\widetilde{\varphi}(\mu)$ and A.

The first term of (147) can be estimated as follows:

$$\begin{aligned} &\frac{g_{\widetilde{\varphi}}(\mu,0)}{\sqrt{\varphi(x)}}\left[\exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\varphi(z)}}\Big) - \exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\psi(z)}}\Big)\right]. \\ &\leq \frac{1}{\sqrt{\widetilde{\varphi}(\mu)}} \int_\mu^x \left|\frac{1}{\sqrt{\varphi(h)}} - \frac{1}{\sqrt{\psi(h)}}\right| dh \\ &\leq k_1''\,D_1\,(x-\mu)^p \end{aligned} \tag{148}$$

This inequality, combined with the preceding one, ends the proof of the lemma. □

We will prove an analogous lemma for the density n_2. Like previous sections, we will build a sequence n_2^k, prove some estimates on n_2^k, and then pass to the limit.

We set

$$n_2^0(\varphi) = 0, \tag{149}$$

and for all k,

$$\begin{aligned} n_2^{k+1}(\varphi)(x) = &\int_0^\mu \frac{\widetilde{n}(y)}{\sqrt{\varphi(x)-\widetilde{\varphi}(y)}} g_{\widetilde{\varphi}}(\mu,y)\, \exp\Big(-\int_\mu^x \frac{dz}{\sqrt{\varphi(z)-\widetilde{\varphi}(y)}}\Big)dy \\ &+\int_\mu^x \frac{g_\varphi(x,y)}{\sqrt{\varphi(x)-\varphi(y)}}\left[n_1(\varphi)(y)+n_2^k(\varphi)(y)\right] dy. \end{aligned} \tag{150}$$

Notice that

$$n_2^{k+1}(\varphi)(x) = n_2^1(\varphi)(x) + \int_\mu^x \frac{g_\varphi(x,y)\, n_2^k(\varphi)(y)}{\sqrt{\varphi(x)-\varphi(y)}}\, dy. \tag{151}$$

We begin with the following lemma.

LEMMA 4.19. *There exists a constant k_2^1 such that for every φ, ψ that satisfies* (146)*, the following estimate holds on* $[\mu, A]$:

$$|n_2^1(\varphi)(x) - n_2^1(\psi)(x)| \le k_2^1\, D_1\, (x-\mu)^p. \tag{152}$$

Proof. We write

$$n_2^1(\varphi)(x) - n_2^1(\psi)(x) = I + II + III + IV + V, \tag{153}$$

where

$$\begin{aligned} I = &\int_0^\mu \widetilde{n}(y) g_{\widetilde{\varphi}}(\mu,y)\, \exp\left(-\int_\mu^x \frac{dz}{\sqrt{\varphi(z)-\widetilde{\varphi}(y)}}\right) \\ &\times \left[\frac{1}{\sqrt{\varphi(x)-\widetilde{\varphi}(y)}} - \frac{1}{\sqrt{\psi(x)-\widetilde{\varphi}(y)}}\right] dy, \end{aligned} \tag{154}$$

$$\begin{aligned} II = &\int_0^\mu \frac{\widetilde{n}(y)\, g_{\widetilde{\varphi}}(\mu,y)}{\sqrt{\psi(x)-\widetilde{\varphi}(y)}} \left[\exp\left(-\int_\mu^x \frac{dz}{\sqrt{\varphi(z)-\widetilde{\varphi}(y)}}\right)\right. \\ &\left. - \exp\left(-\int_\mu^x \frac{dz}{\sqrt{\psi(z)-\widetilde{\varphi}(y)}}\right)\right] dy, \end{aligned} \tag{155}$$

$$III = \int_\mu^x \frac{n_1(\varphi)(y) - n_1(\psi)(y)}{\sqrt{\varphi(x)-\varphi(y)}}\, g_\varphi(x,y)\, dy, \tag{156}$$

$$IV = \int_\mu^x n_1(\psi)(y) g_\psi(x,y) \left[\frac{1}{\sqrt{\varphi(x)-\varphi(y)}} - \frac{1}{\sqrt{\psi(x)-\psi(y)}}\right] dy, \tag{157}$$

$$V = \int_\mu^x \frac{n_1(\psi)(y)}{\sqrt{\psi(x)-\psi(y)}} \left[g_\varphi(x,y) - g_\psi(x,y)\right] dy. \tag{158}$$

Now we estimate the five terms one by one. First, since from the previous section $\widetilde{n}(y)y^{2/3}$ is a bounded function in the neighborhood of zero, then the term I can be estimated as follows:

$$|I| \leq \int_0^{\mu} Ky^{-2/3} \left| \frac{1}{\sqrt{\varphi(x) - \widetilde{\varphi}(y)}} - \frac{1}{\sqrt{\psi(x) - \widetilde{\varphi}(y)}} \right| dy.$$

But since

$$\left| \frac{1}{\sqrt{\varphi(x) - \widetilde{\varphi}(y)}} - \frac{1}{\sqrt{\psi(x) - \widetilde{\varphi}(y)}} \right| = \frac{|\varphi(x) - \psi(x)|}{\sqrt{\varphi(x) - \widetilde{\varphi}(y)}\sqrt{\psi(x) - \widetilde{\varphi}(y)}(\sqrt{\varphi(x) - \widetilde{\varphi}(y)} + \sqrt{\psi(x) - \widetilde{\varphi}(y)})}$$

and

$$\varphi(x) - \widetilde{\varphi}(y) \geq \frac{d\widetilde{\varphi}}{dx}(\mu)(x - \mu) + \frac{d\widetilde{\varphi}}{dx}(y)(\mu - y) \geq C(x - y),$$

then

$$|I| \leq |\varphi(x) - \psi(x)| \int_0^{\mu} \frac{K' \, dy}{y^{2/3} \, (x - y)^{3/2}}.$$

Therefore,

$$|I| \leq C \frac{|\varphi(x) - \psi(x)|}{\sqrt{x - \mu}} \leq C \, D_1 \, (x - \mu)^p. \tag{159}$$

Analogously,

$$\begin{aligned} |II| &\leq \int_0^{\mu} \frac{C}{y^{2/3}\sqrt{x - y}} \int_{\mu}^{x} \left| \frac{1}{\sqrt{\varphi(z) - \widetilde{\varphi}(y)}} - \frac{1}{\sqrt{\psi(z) - \widetilde{\varphi}(y)}} \right| dz \, dy \\ &\leq C \int_0^{\mu} \frac{dy}{y^{2/3}\sqrt{x - y}} \int_{\mu}^{x} \frac{|\varphi(z) - \psi(z)| \, dz}{(z - y)^{3/2}} \\ &\leq C \int_{\mu}^{x} dz \, |\varphi(z) - \psi(z)| \int_0^{\mu} \frac{dy}{y^{2/3}\sqrt{x - y}\,(z - y)^{3/2}}. \end{aligned}$$

Therefore,

$$|II| \leq C \int_{\mu}^{x} \frac{|\varphi(z) - \psi(z)|}{\sqrt{z - \mu}\sqrt{x - \mu}} \, dz \leq C \, D_1 \, (x - \mu)^p. \tag{160}$$

For III, the estimate comes directly from the one on n_1,

$$|III| \leq \int_{\mu}^{x} \frac{C|n_1(\varphi)(y) - n_1(\psi)(y)|}{\sqrt{x - y}} \, dy.$$

We deduce easily that

$$|III| \leq C \, D_1 \, (x - \mu)^p. \tag{161}$$

For IV, we have, since n_1 is bounded in $L^\infty(\mu, A)$,

$$|IV| \leq C \int_\mu^x \left| \frac{1}{\sqrt{\varphi(x)-\varphi(y)}} - \frac{1}{\sqrt{\psi(x)-\psi(y)}} \right| dy.$$

But since

$$\left| \frac{1}{\sqrt{\varphi(x)-\varphi(y)}} - \frac{1}{\sqrt{\psi(x)-\psi(y)}} \right| \leq C \frac{\int_y^x |\varphi'(h)-\psi'(h)|\, dh}{(x-y)^{3/2}},$$

we use Fubini's theorem and obtain

$$|IV| \leq \int_\mu^x dh\, |\varphi'(h)-\psi'(h)| \int_\mu^h \frac{dy}{(x-y)^{3/2}}.$$

This leads to

$$|IV| \leq \int_\mu^x \frac{|\varphi'(h)-\psi'(h)|}{\sqrt{x-y}}\, dh \leq C\, D_1\, (x-\mu)^p. \tag{162}$$

For the last term, we obtain

$$\begin{aligned}
|V| &\leq \int_\mu^x \frac{C}{\sqrt{x-y}} \int_y^x \left| \frac{1}{\sqrt{\varphi(h)-\varphi(y)}} - \frac{1}{\sqrt{\psi(h)-\psi(y)}} \right| dh\, dy \\
&\leq \int_\mu^x \int_y^x \int_y^h \frac{C\, |\varphi'(t)-\psi'(t)|}{(h-y)^{3/2}\sqrt{x-y}}\, dt\, dh\, dy \\
&\leq \int_\mu^x \int_y^x \int_t^x \frac{C\, |\varphi'(t)-\psi'(t)|}{(h-y)^{3/2}\sqrt{x-y}}\, dh\, dt\, dy \\
&\leq \int_\mu^x \int_y^x \frac{C\, |\varphi'(t)-\psi'(t)|}{\sqrt{t-y}\sqrt{x-y}}\, dt\, dy \\
&\leq \int_\mu^x dt\, |\varphi'(t)-\psi'(t)| \int_\mu^t \frac{C}{\sqrt{t-y}\sqrt{x-y}}\, dy \\
&\leq \int_\mu^x C\, |\varphi'(t)-\psi'(t)| \frac{\sqrt{t-\mu}}{\sqrt{x-t}}\, dt.
\end{aligned}$$

Thus, we have

$$|V| \leq C \int_\mu^x \frac{|\varphi'(t)-\psi'(t)|}{\sqrt{x-t}}\, dt \leq C\, D_1\, (x-\mu)^p. \tag{163}$$

The result follows easily from (159)–(163). □

By using the sequences n_2^k, we prove the following proposition.

PROPOSITION 4.20. *There exists a constant k_2 such that for every φ, ψ in $\mathcal{F}$ that satisfies* (146), *the following estimate holds on* $[\mu, A]$:

$$|n_2(\varphi)(x) - n_2(\psi)(x)| \leq k_2\, D\, (x-\mu)^p.$$

Proof. We will prove this estimate for the difference $|n_2^k(\varphi)(x) - n_2^k(\psi)(x)|$ and then pass to the limit. From (151), we deduce that

$$
\begin{aligned}
n_2^{k+1}(\varphi)(x) - n_2^{k+1}(\psi)(x) &= n_2^1(\varphi)(x) - n_2^1(\psi)(x) \\
&+ \int_\mu^x \frac{n_2^k(\varphi)(y) - n_2^k(\psi)(y)}{\sqrt{\varphi(x) - \varphi(y)}}\, g_\varphi(x,y)dy \\
&+ \int_\mu^x n_2^k(\psi)(y)\, g_\varphi(x,y) \left[\frac{1}{\sqrt{\varphi(x) - \varphi(y)}} - \frac{1}{\sqrt{\psi(x) - \psi(y)}}\right] dy \\
&+ \int_\mu^x \frac{n_2^k(\psi)(y)}{\sqrt{\psi(x) - \psi(y)}}\, [g_\varphi(x,y) - g_\psi(x,y)]\, dy.
\end{aligned}
$$

Since n_2^k can be bounded independently of φ and ψ on $[\mu, A]$, then the last two terms of the above equation can be treated exactly as the terms IV and V of the proof of Lemma 4.19. (See (157) and (158).) By using the result of Lemma 4.18, we can write

$$
\begin{aligned}
&\left|n_2^{k+1}(\varphi)(x) - n_2^{k+1}(\psi)(x)\right| \\
&\quad \le C_1 \left[D_1\,(x-\mu)^p + \int_\mu^x \frac{|n_2^k(\varphi)(y) - n_2^k(\psi)(y)|}{\sqrt{x-y}}\, dy\right].
\end{aligned} \tag{164}
$$

An immediate iteration gives

$$
\left|n_2^k(\varphi)(x) - n_2^k(\psi)(x)\right| \le C_1\, D_1\, (x-\mu)^p\, h_{p,k}\,(C_1\sqrt{x-\mu}), \tag{165}
$$

where

$$
h_{p,k}(z) = \sum_{j=0}^{k-1} z^j \left(\prod_{i=1}^{j} I_{2p+i}\right) \tag{166}
$$

with

$$
I_m = \int_0^1 \frac{t^{m/2}}{\sqrt{1-t}}\, dt, \quad m \in \mathbb{N}. \tag{167}
$$

Since $h_{p,k}\,(C_1\sqrt{x-\mu}) \le h_{0.k}\,(C_1\sqrt{A-\mu})$, and since this sequence is convergent as k tends to infinity, we deduce that

$$
|n_2(\varphi)(x) - n_2(\psi)(x)| \le k_2\, D_1\, (x-\mu)^p. \qquad \square
$$

5. The boundary-value problem and the Child–Langmuir current. In the previous sections we have shown that the Cauchy problem (71) introduced in §4 has a unique solution. After performing the inverse scaling of (54), we obtained that the problem

$$
\frac{d^2\varphi}{dx^2} = n(x), \qquad n(x) = n_1(x) + n_2(x), \tag{168}
$$

$$
n_1(x) = \frac{j}{\sqrt{\varphi(x)}}\, g_\varphi(x,0), \tag{169}
$$

$$
\begin{aligned}
n_2(x) &- \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x) - \varphi(y)}} n_2(y)\, dy, \\
&= \int_0^x \frac{g_\varphi(x,y)}{\tau\sqrt{\varphi(x) - \varphi(y)}} n_1(y)\, dy,
\end{aligned} \tag{170}
$$

$$\varphi(0) = 0, \qquad \frac{d\varphi}{dx}(0) = \beta_1, \tag{171}$$

$$g_\varphi(x,y) = \exp\left(-\frac{1}{\tau} \int_y^x \frac{dz}{\sqrt{\varphi(z) - \varphi(y)}} \right) \tag{172}$$

has a unique solution for every $\tau > 0$, $j \geq 0$, and $\beta_1 \geq 0$. This solution can be written as

$$\varphi(x) = \tau^4 j^2 \, \widetilde{\varphi}\left(\frac{x}{\tau^3 j} \right), \tag{173}$$

where $\widetilde{\varphi}$ is the solution of (71) with $\beta = \frac{\beta_1}{\tau j}$. Therefore φ is a solution of the boundary-value problem (55)–(60) if and only if $\varphi(1) = 1$ or, equivalently, if and only if the corresponding $\widetilde{\varphi}$ satisfies

$$\widetilde{\varphi}\left(\frac{1}{\tau^3 j} \right) = \frac{1}{\tau^4 j^2}. \tag{174}$$

This constraint will give the limitation of the current. Let us start with the following proposition.

PROPOSITION 5.1. *Let φ be the solution of the problem* (168)–(172); *then we have*

$$\int_0^x n(y) g_\varphi(x,y)\, dy = \tau j \,(1 - g_\varphi(x,0)) \tag{175}$$

and

$$\begin{aligned} \varphi'^2(x) = \beta_1^2 + \frac{4j}{\tau} x + 4j \sqrt{\varphi(x)}\, g_\varphi(x,0) \\ + \frac{4}{\tau} \int_0^x n(y) g_\varphi(x,y) \sqrt{\varphi(x) - \varphi(y)}\, dy. \end{aligned} \tag{176}$$

Proof. (46) shows that

$$\begin{aligned} \int_0^x n(y) g_\varphi(x,y)\, dy &= \tau \int_0^x \bar{j}_2(x,y) dy \\ &= \tau j_2(x); \end{aligned}$$

then with (45) and (39) we have

$$\int_0^x n(y) g_\varphi(x,y)\, dy = \tau j \,(1 - g_\varphi(x,0)),$$

which shows (175).

(176) can be shown by multiplying the Poisson equation by $\frac{d\varphi}{dx}$ and integrating it between 0 and x. This leads to

$$\begin{aligned} \varphi'^2(x) - \varphi'^2(0) = 2 \int_0^x \frac{j}{\sqrt{\varphi(y)}} g_\varphi(y,0) \varphi'(y)\, dy \\ + 2 \int_0^x \varphi'(y) \int_0^y \frac{n(z) g_\varphi(y,z)}{\tau \sqrt{\varphi(y) - \varphi(z)}} dz\, dy. \end{aligned} \tag{177}$$

The first integral can be computed by an integration by parts

$$\int_0^x \frac{j}{\sqrt{\varphi(y)}}\, g_\varphi(y,0)\varphi'(y)\,dy = 2jg_\varphi(x,0)\sqrt{\varphi(x)} + 2\frac{j}{\tau}\int_0^x g_\varphi(y,0)dy. \tag{178}$$

For the second integral, we use Fubini's theorem

$$\int_0^x \varphi'(y)\int_0^y \frac{n(z)g_\varphi(y,z)}{\tau\sqrt{\varphi(y)-\varphi(z)}}dz\,dy = \int_0^x n(z)\int_z^x \frac{\varphi'(y))g_\varphi(y,z)}{\tau\sqrt{\varphi(y)-\varphi(z)}}dy\,dz.$$

An integration by parts for fixed z gives

$$\int_0^x n(z)\int_z^x \frac{\varphi'(y)g_\varphi(y,z)}{\tau\sqrt{\varphi(y)-\varphi(z)}}dy\,dz = 2\int_0^x n(z)\frac{g_\varphi(x,z)}{\tau}\sqrt{\varphi(x)-\varphi(z)}dz + 2\int_0^x n(z)\int_z^x \frac{g_\varphi(y,z)}{\tau}dy\,dz.$$

By using Fubini's theorem backward for the last integral and applying (175), we obtain

$$\int_0^x \varphi'(y)\int_0^y \frac{n(z)g_\varphi(y,z)}{\tau\sqrt{\varphi(y)-\varphi(z)}}dz\,dy = 2\int_0^x n(z)\frac{g_\varphi(x,z)}{\tau}\sqrt{\varphi(x)-\varphi(z)}dz + 2\frac{j}{\tau}x - 2\frac{j}{\tau}\int_0^x g_\varphi(y,0)dy. \tag{179}$$

We sum this equation and equation (177) to finally obtain (176). □

Remark. (176) can also be derived from the Boltzmann equation (26) by multiplying by v and integrating. This can be viewed as a sort of energy identity.

This proposition allows us to prove Theorem 2.2.

Proof of Theorem 2.2. First, we deduce from (176) that

$$\varphi'^2(x) \geq \frac{4j}{\tau}x. \tag{180}$$

We take the square root of this inequality and integrate it. Hence the condition $\varphi(1) = 1$ leads to

$$j \leq \frac{9}{16}\tau. \tag{181}$$

Besides, by using the expression (170) of n_2, we have

$$n_2(x) = \int_0^x \frac{n(y)}{\tau\sqrt{\varphi(x)-\varphi(y)}}g_\varphi(x,y)\,dy > \frac{1}{\tau\sqrt{\varphi(x)}}\int_0^x n(y)g_\varphi(x,y)dy.$$

Hence, by using (175) we obtain

$$n_2(x) > \frac{j}{\sqrt{\varphi(x)}}(1-g_\varphi(x,0)) = \frac{j}{\sqrt{\varphi(x)}} - n_1(x).$$

Then (168) leads to

$$\frac{d^2\varphi}{dx^2} > \frac{j}{\sqrt{\varphi}}, \tag{182}$$

which by integration gives

$$j < 4/9 \tag{183}$$

and ends the proof. □

As shown in [3] and [7], the case of a vanishing derivative at $x = 0$ is of great interest (Child–Langmuir regime). In this case, we prove that the boundary-value problem (55)–(60), with the additional requirement that $\frac{d\varphi}{dx}(0) = 0$ and with unprescribed j, has a unique solution. We begin with the following lemma.

LEMMA 5.2. *Let $\widetilde{\varphi}$ be the solution of* (71) *with $\beta = 0$. Then $\widetilde{\varphi}$ has the following asymptotic behavior:*

$$\frac{d\widetilde{\varphi}}{dx} \sim 2\sqrt{x}, \quad \widetilde{\varphi} \sim \frac{4}{3}x^{3/2}, \qquad x \to +\infty, \tag{184}$$

$$\frac{d\widetilde{\varphi}}{dx} \sim 4/3\left(\frac{9}{4}\right)^{2/3} x^{1/3}, \quad \widetilde{\varphi} \sim \left(\frac{9}{4}\right)^{2/3} x^{4/3}, \qquad x \to 0. \tag{185}$$

Besides, $\widetilde{\varphi}$ satisfies the following estimates on $\mathbb{R}_*^+$:

$$\widetilde{\varphi}(x) > \frac{4}{3}x^{3/2}, \quad \widetilde{\varphi}(x) > \left(\frac{9}{4}\right)^{2/3} x^{4/3}. \tag{186}$$

Proof. The asymptotic behavior in the vicinity of 0 (185) is already proven in Theorem 4.1. The global estimates (186) are direct consequences of (176). Indeed, Proposition 5.1 applies for $\widetilde{\varphi}$ with $\beta_1 = 0$ and j and τ replaced by 1. Therefore, we deduce from (182) that $\widetilde{\varphi}'' > \frac{1}{\sqrt{\widetilde{\varphi}}}$. The integration of this inequality leads to the second inequality of (186). The first inequality comes from (180) applied with $\tau = j = 1$.

The only thing left to show is (184). First, we deduce from (176) that

$$\begin{aligned} 4x < \frac{d\widetilde{\varphi}}{dx}^2(x) &\le 4x + 4\sqrt{\widetilde{\varphi}(x)}g_{\widetilde{\varphi}}(x,0) + 4\sqrt{\widetilde{\varphi}(x)}\int_0^x \widetilde{n}(y)g_{\widetilde{\varphi}}(x,y)dy \\ &< 4x + 4\sqrt{\widetilde{\varphi}(x)}; \end{aligned} \tag{187}$$

therefore it is sufficient to prove that $\widetilde{\varphi} = o(x^2)$ in the neighborhood of $+\infty$. Let us introduce the function

$$f(x) = \frac{\widetilde{\varphi}(x)}{x^{5/3}}.$$

We prove now that f is decreasing in the neighborhood of $+\infty$ and consequently it is bounded. The derivative of f has the same sign as

$$A(x) = x\,\widetilde{\varphi}'(x) - \frac{5}{3}\widetilde{\varphi}(x) = x\left[\widetilde{\varphi}'(x) - \frac{3}{2}\widetilde{\varphi}(x)\right] - \frac{1}{6}\widetilde{\varphi}(x). \tag{188}$$

We deduce from (187) that $\widetilde{\varphi}'(x) \le 2\sqrt{x} + 2\widetilde{\varphi}^{1/4}(x)$, and by using the first estimate (186), we bound $A(x)$ by

$$\begin{aligned} A(x) &\le 2x\,\widetilde{\varphi}^{1/4}(x) - \frac{1}{6}\widetilde{\varphi}(x) \\ &\le \widetilde{\varphi}^{1/4}(x)\left(2x - \frac{1}{6}\widetilde{\varphi}^{3/4}(x)\right). \end{aligned}$$

Since $\widetilde{\varphi}(x) \geq \frac{4}{3}x^{3/2}$, then A is negative for large x's. This ends the proof of the lemma. □

Proof of Theorem 2.1. We set $X = \frac{1}{\tau^3 j}$. Then j is determined by the equation

$$\widetilde{\varphi}(X) = \tau^2 X^2, \tag{189}$$

where $\widetilde{\varphi}$ is given by (173). From (181) and (183), we deduce the following estimates on X:

$$X > \frac{9}{4\tau^3}, \qquad X > \frac{16}{9\tau^4}. \tag{190}$$

Therefore, we have studied the equation $B(x) := \widetilde{\varphi}(x) - \tau^2 x^2 = 0$ on the interval $(X_{\min}, +\infty)$, where

$$X_{\min} = \sup\left(\frac{9}{4\tau^3}, \frac{16}{9\tau^4}\right).$$

Thanks to the preceding lemma, it is obvious that $\lim_{x\to+\infty} B(x) = -\infty$. Besides, by inserting the inequality $\widetilde{\varphi}(x) \geq \frac{4}{3}x^{3/2}$ into the expression of B, we find

$$B\left(\frac{16}{9\tau^4}\right) \geq 0.$$

This insures the existence of a solution of $B(x) = 0$. To prove the uniqueness, it is sufficient to prove the implication

$$(x > X_{\min},\ B(x) \leq 0) \Rightarrow (B'(x) < 0). \tag{191}$$

Let us prove (191). The condition $B(x) \leq 0$ implies that $\widetilde{\varphi}(x) \leq \tau^2 x^2$. By using this inequality and (187), we obtain

$$B'(x) < 2\sqrt{1+\tau}\,\sqrt{x} - 2\tau^2 x = 2\sqrt{x}\,(\sqrt{1+\tau} - \tau^2\sqrt{x}).$$

The condition $x > \frac{16}{9\tau^4}$ leads to

$$B'(x) < 2\sqrt{x}\left(\sqrt{1+\tau} - \frac{4}{3}\right).$$

The right-hand side of this inequality is negative when $\tau \leq 7/9$, which proves (191). By using the condition $x > \frac{9}{4\tau^3}$ and proceeding in a likewise manner, we prove (191) in the case $\tau \geq 4/5$.

Finally, we prove that the current is equivalent to $\frac{9}{16}\tau$ when τ tends to zero and to $4/9$ when τ tends to infinity. Since $X(\tau) = 1/(\tau^3 j_{CL}(\tau))$ satisfies $\frac{\widetilde{\varphi}(X)}{X^2} = \tau^2$, then we deduce from the behavior of $\frac{\widetilde{\varphi}(x)}{x^2}$ that $\lim_{\tau\to 0} X(\tau) = +\infty$ and $\lim_{\tau\to\infty} X(\tau) = 0$. Thus, by using the asymptotic behavior of $\widetilde{\varphi}$ in the vicinity of zero and infinity, we obtain the result.

6. Conclusion. We derived a limit model for electron transport in a semiconductor via a Child-Langmuir asymptotics of the Boltzmann equation. The results of Theorem 2.1 seem to be true for all the values of τ but would need more technical arguments. In our analysis we neglected the doping density in the $N-$ region. One of the effects of the doping profile is the loss of the convexity of the potential which

in turn would not be necessarily increasing, and the explicit formulas for the density would not be valid. However, in the collisionless case, when the doping density is not too large, the limit potential is increasing (see [19] or [20]). This result could be extended to the case $\tau \neq \infty$. Finally, the convergence problem of the perturbation problem solutions (19)–(24) to the limit problem solution is not solved yet and its proof is in progress.

GLOBAL EXISTENCE OF SOLUTIONS TO REACTION-HYPERBOLIC SYSTEMS IN ONE SPACE DIMENSION*

DANIELLE D. CARR†

Abstract. Global existence theorems to the initial value and initial-boundary value problems are proved for a general class of reaction-hyperbolic systems that arise from the transport of chemically reacting materials. The basic technique of proof is to use the geometrical properties of the equilibrium set of the nonlinear source terms to construct L^p estimates for each p and to pass to the limit to get an a priori L^∞ bound.

Key words. material transport, energy norms, chemical kinetics, hyperbolic equations, initial value problem, initial-boundary value problem

AMS subject classifications. 35A05, 35B45, 35L45, 35L60

1. Introduction.

We refer to a system of partial differential equations as reaction-hyperbolic if it has the form

$$L\vec{u}(x,t) = \vec{f}(x,t,\vec{u}),$$

where $\vec{u}(x,t)$ is an r-dimensional vector whose components represent the concentrations of the chemical species u_i, L is a smooth first-order hyperbolic operator, and the linear or nonlinear functions in $\vec{f}$ represent the chemical reactions taking place among the species u_i [9]. These systems arise naturally in the study of material transport such as the transport of intracellular materials in nerve axons [1], [3], [5]. In this paper we concentrate on a class of reaction-hyperbolic systems in one space dimension that can be cast into the canonical form

$$\begin{aligned}
(\partial_t + \lambda_1\partial_x)u_1(x,t) &= f_1(u_1,u_2),\\
&\vdots \qquad\qquad \vdots\\
(\partial_t + \lambda_i\partial_x)u_i(x,t) &= -f_{i-1}(u_{i-1},u_i) + f_i(u_i,u_{i+1}),\\
&\vdots \qquad\qquad \vdots\\
(\partial_t + \lambda_r\partial_x)u_r(x,t) &= -f_{r-1}(u_{r-1},u_r),\\
\vec{u}(x,0) &= \vec{u}_0(x),
\end{aligned} \tag{1}$$

where the initial data are nonnegative, continuously differentiable functions that vanish at infinity. Without loss of generality, we assume that all the λ_i are constant and not necessarily distinct. In fact, in many applications several of the λ_i are zero [2].

The problem is said to have a global solution if for any $T \in \mathbb{R}^+$ a bounded solution exists for all time $t \in [0,T]$. Since we allow the source terms to be nonlinear, global existence to system (1) is not obvious. Consider the case where $\vec{u} = (u_1(x,t), u_2(x,t))$ for $x \in \mathbb{R}$. For fixed $\lambda_1, \lambda_2 \in \mathbb{R}$, system (1) reduces to

$$\begin{aligned}
(\partial_t + \lambda_1\partial_x)u_1(x,t) &= f(\vec{u}),\\
(\partial_t + \lambda_2\partial_x)u_2(x,t) &= -f(\vec{u}),\\
\vec{u}(x,0) &= \vec{u}_0(x),
\end{aligned} \tag{2}$$

† Courant Institute of Mathematical Sciences, New York University, 251 Mercer Street, New York, New York, 10012 (dcarr@cims.nyu.edu).

which describes the chemical interactions and the active transport of the species u_i at the rate λ_i along the real line. Note that for $f(\vec{u}) \equiv u_1^2$ and positive initial data, the system

$$\begin{aligned}(\partial_t + \lambda_1\partial_x)u_1(x,t) &= u_1^2,\\ (\partial_t + \lambda_2\partial_x)u_2(x,t) &= -u_1^2,\\ \vec{u}(x,0) &= \vec{u}_0(x),\end{aligned}$$

has no global solutions, since the first characteristic equation $\dot{u}_1 = u_1^2$ has no global solution for positive initial values.

We establish conditions on the source terms so that system (2) and ultimately system (1) are globally solvable. We do this by constructing an interesting family of energy norms which depends in an explicit way on the geometry of the equilibrium set of the source terms. These norms allow us to derive L^p estimates for the solution for each p, and taking the limit we obtain an L^∞ estimate. Global existence follows easily.

In §2, we exploit the fundamental properties of chemical kinetics in order to prove that a local solution exists to system (1) and that if the local solution starts positive for all $x \in \mathbb{R}$ then it stays positive for all local time. If the local solution can be majorized by a constant C that depends only on the initial data and on a fixed time step, then the solution exists globally. This is achieved by repeated successive approximations along the time axis, using the fact that the solution remains bounded by C. In §3, we establish conditions on the source terms for the 2×2 system in order to construct an a priori bound for the solution to the initial value problem. This a priori estimate depends not only on the initial data, but also on the geometry of the equilibrium set of the nonlinear source terms f_i. A special case of the 2×2 system extends Illner's results [6]. In §4, we generalize our results to certain classes of $r \times r$ systems, and finally in §5 we indicate how these results are extended to the initial-boundary value problem.

There are lots of important equations without the form (1), for which one can prove global existence using other methods. Some of these techniques are clearly illustrated in the proof of global existence to the fast axonal transport system [5].

2. Local properties. Chemical reactions can be classified on a kinetic basis by reaction order [7]. For $p > 0$, pth-order reactions are those whose rate is proportional to the product of the concentrations of p reactants. Let $\vec{u} = (u_1(x,t), \ldots, u_r(x,t))$ denote the concentrations of all the chemical species u_i used and produced in a chemical system at position x and at time t. The reaction

$$u_1 + u_2 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} u_3$$

is second order since the formation of u_3 depends on the concentrations of two reactants, u_1 and u_2. The resulting rate equations for the concentrations of u_1, u_2, and u_3 are

$$\begin{aligned}\partial_t u_1(x,t) &= -k_1u_1u_2 + k_2u_3,\\ \partial_t u_2(x,t) &= -k_1u_1u_2 + k_2u_3,\\ \partial_t u_3(x,t) &= k_1u_1u_2 - k_2u_3.\end{aligned}$$

Note that $\partial_t(u_1 + u_2 + 2u_3) = 0$, which is just the conservation of mass.

In general, for a closed system the equations that describe the rates of change of the chemical concentrations u_i with respect to time are

$$\begin{aligned} \partial_t u_i(x,t) &= f_i(\vec{u}), \\ \vec{u}(x,0) &= \vec{u}_0(x), \end{aligned} \tag{3}$$

where $i = 1, \ldots, r$ and the linear or nonlinear functions f_i are rate functions which represent the chemical reactions involving the chemical species u_i. Note that if p is the maximum order of the chemical reactions, then each f_i is a kth-order polynomial of $\vec{u}$ for $0 < k \leq p$. In addition, since the loss of a certain species is proportional to its present amount, u_i is a factor in all terms with negative coefficients in the polynomial f_i. Since the chemical system is closed, mass is conserved and the net reaction rate is zero. Consequently, there exists a linear combination of the f_i involving positive constants such that the sum is zero. Finally, if all the concentrations of the chemical species are zero, then the values of the rate functions f_i are zero. These fundamental properties motivate the following structural hypotheses on the source terms f_i.

DEFINITION 2.1. *$\vec{f}$ is a* reaction function *if and only if $\vec{f}$ satisfies the following three properties:*

(i) *For $p \geq 1$, the components of $\vec{f}$ have the following form:*

$$f_i(x,t,\vec{u}) = \sum_{|\alpha^i| \leq p} c_{\alpha^i}(x,t,\vec{u})\vec{u}^{\alpha^i} - u_i \sum_{|\beta^i| \leq (p-1)} d_{\beta^i}(x,t,\vec{u})\vec{u}^{\beta^i}, \tag{4}$$

where for each $i = 1, \ldots, r$ and $j = 1, \ldots, r$, α_j^i and β_j^i are nonnegative constants; the coefficients $c_{\alpha_j^i}(x,t,\vec{u})$ and $d_{\beta_j^i}(x,t,\vec{u})$ are smooth, nonnegative, uniformly bounded functions in x and t.

(ii) *There exist positive constants b_i such that $\sum_{i=1}^r b_i f_i = 0$.*

(iii) $\vec{f}(x,t,\vec{0}) = \vec{0}$.

Let $C_\infty(\mathbb{R})$ denote the set of all real-valued, continuous functions vanishing at infinity on $\mathbb{R}$. $C_\infty([0,\delta) \times \mathbb{R})$ is the set of all real-valued functions w such that for all $\epsilon > 0$ there is a closed interval $I \subset \mathbb{R}$ with $\mid w(x,t) \mid < \epsilon$ for all $t \in [0,\delta)$ and all $x \notin I$. If we write C_∞^1, we mean the set of those functions, which are continuously differentiable in addition to having the above properties.

PROPOSITION 2.2 (local existence and positivity). *Consider the following system:*

$$\begin{aligned} (\partial_t + \lambda_i \partial_x) u_i(x,t) &= f_i(x,t,\vec{u}), \\ \vec{u}(x,0) &= \vec{u}_0(x), \end{aligned} \tag{5}$$

where $\vec{f} \equiv (f_1, \ldots, f_r)$ is a reaction function, and the initial data u_{0i} are uniformly bounded, nonnegative, $C_\infty^1(\mathbb{R})$ with uniformly bounded derivatives. There is a $\delta > 0$ so that system (5) has a unique nonnegative solution in C_∞^1 for $t \in [0,\delta)$.

Proof. The proof is a straightforward generalization of Cabannes' result, using the method of successive approximations [4]. For details, see [5]. □

3. 2 × 2 systems. Even though we know the basic structure of the reaction function $\vec{f}$, global existence to system (1) is still not obvious since we have not addressed its highly nonlinear nature. In order to figure out the right additional hypotheses for the source terms, consider the following simple chemical equation:

$$\mu u_1 \underset{k_2}{\overset{k_1}{\rightleftharpoons}} \eta u_2, \tag{6}$$

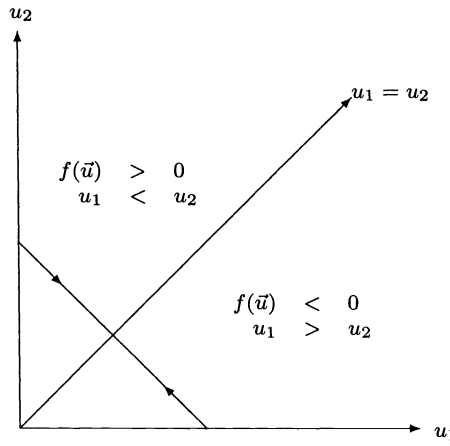

FIG. 1. *Stable equilibria for* $f(\vec{u}) = -k_1 u_1^\eta + k_1 u_2^\eta$.

which leads to the following differential equations for the spatially homogeneous case:

$$\begin{aligned} \partial_t u_1(x,t) &= -k_1 u_1^\mu + k_2 u_2^\eta, \\ \partial_t u_2(x,t) &= k_1 u_1^\mu - k_2 u_2^\eta, \end{aligned} \tag{7}$$

where $k_1, k_2, \eta, \mu > 0$. For $\eta = \mu$ and $k_1 = k_2$, (7) reduces to

$$\begin{aligned} \partial_t u_1(x,t) &= -k_1 u_1^\eta + k_1 u_2^\eta, \\ \partial_t u_2(x,t) &= k_1 u_1^\eta - k_1 u_2^\eta. \end{aligned} \tag{8}$$

Let $f(u_1, u_2) \equiv -k_1 u_1^\eta + k_1 u_2^\eta$ and let $\vec{f}(\vec{u}) \equiv (f(\vec{u}), -f(\vec{u}))$. Note that the chemical system (6) is at steady state when the components of the source term are zero and that this occurs only when the concentrations of the reactants are equal. Define the zero curve for f to be $z(\tau) \equiv \tau$. If the concentration of u_1 is initially less than $z(u_2)$, then f is strictly positive. In this case, the concentration of u_1 increases while the concentration of u_2 decreases until the two are equal. Similarly, if the concentration of u_1 is initially greater than $z(u_2)$, then f is strictly negative, and the chemistry adjusts itself until the two concentrations are equal (see Fig. 1). Thus, the zero line $z(\cdot)$ consists of stable equilibria for system (8). One can easily see that $\max\{\| u_1(x,t) \|_\infty, \| u_2(x,t) \|_\infty\}$ is nonincreasing in time and that the maximum of the initial data is the a priori bound for the solution [6].

For the case when the zero curve no longer coincides with the line $u_1 = u_2$, this bound does not hold. Without loss of generality, let $\frac{k_2}{k_1} = 2$. The zero line $z(u_2) \equiv 2u_2$ still consists of stable equilibria for (7); however, the $\max\{\| u_1(x,t) \|_\infty, \| u_2(x,t) \|_\infty\}$ increases in time in the wedge $u_2 < u_1$ and $u_2 > \frac{1}{2}u_1$ (see Fig. 2). New estimates must be constructed which utilize the highly stable structure of the spatially homogeneous case.

DEFINITION 3.1. *We define a class of source terms* $\vec{f}$ *such that system* (2) *has a curve of stable equilibria for the spatially homogeneous case. We say that* $\vec{f}$ *satisfies the* stability criteria *for the* 2×2 *system if and only if*

(i) $\vec{f}(\vec{u}) \equiv (f(\vec{u}), -f(\vec{u}))$ *is a* C^2 *reaction function of* $\vec{u} \equiv (u_1, u_2)$ *only.*

(ii) *The set of zeros of* f *in the closed first quadrant is given by a continuous, one-to-one function,* $z(\cdot)$, *where* $z(0) \equiv 0$.

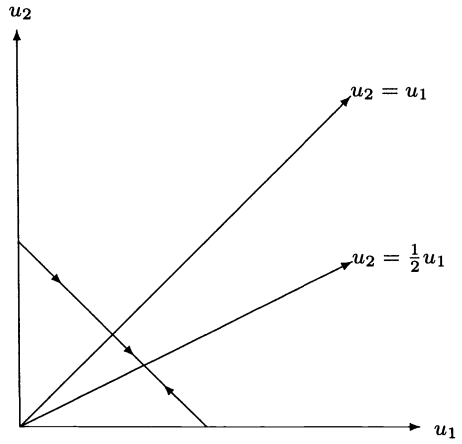

FIG. 2. *Stable equilibria for* $f(\vec{u}) = -k_1 u_1^\eta + k_2 u_2^\eta$, *where* $\frac{k_2}{k_1} = 2$.

(iii) $f(u_1, u_2)(u_1 - z(u_2)) \leq 0$ *for all* $x \in \mathbb{R}$ *and* $t \in [0, \delta)$.

We now prove that if the source term $\vec{f}$ in (2) satisfies the stability criteria, then a global solution exists to (2).

THEOREM 3.2. *Consider the* 2×2 *system:*

$$
\begin{aligned}
(\partial_t + \lambda_1 \partial_x) u_1(x,t) &= f(\vec{u}), \\
(\partial_t + \lambda_2 \partial_x) u_2(x,t) &= -f(\vec{u}), \\
\vec{u}(x,0) &= \vec{u}_0(x),
\end{aligned} \tag{9}
$$

where λ_1 *and* λ_2 *are constants and the initial data* u_{0i} *are uniformly bounded, nonnegative,* $C^1(\mathbb{R}) \cap L^1(\mathbb{R})$ *functions with uniformly bounded derivatives. If the source term* $\vec{f}(\vec{u}) \equiv (f(\vec{u}), -f(\vec{u}))$ *satisfies the stability criteria, then a solution to* (9) *exists for all* $x \in \mathbb{R}$ *and for all* $t \geq 0$.

Proof. To prove Theorem 3.2, we derive an L^∞ a priori estimate for the solution for all time.

By Proposition 2.2, a nonnegative C^1_∞ local solution exists to (9). Pick $T > 0$ and assume that a nonnegative solution exists for all $x \in \mathbb{R}$ and $t \in [0, T]$. For $n > 1$, define the energy norm E_{u_1} as

$$
E_{u_1}(t) \equiv \int_{-\infty}^{\infty} \left[u_1^n(x,t) + \int_0^{u_2(x,t)} n z^{n-1}(\tau) d\tau \right] dx. \tag{10}
$$

All terms in (10) are nonnegative by Proposition 2.2 and the stability criteria. Thus, for all $t \in [0, T]$ we know that

$$
E_{u_1}(t) \geq \int_{-\infty}^{\infty} u_1^n(x,t) dx.
$$

Differentiating E_{u_1} with respect to time and using the differential equations yields the following equalities:

$$
\frac{d}{dt} E_{u_1}(t) = \int_{-\infty}^{\infty} \left[n u_1^{n-1}(x,t) \partial_t u_1(x,t) + n z^{n-1}(u_2) \partial_t u_2(x,t) \right] dx
$$

$$
\begin{aligned}
&= \int_{-\infty}^{\infty} \left[nf(\vec{u})(u_1^{n-1}(x,t) - z^{n-1}(u_2)) \right. \\
&\qquad \left. -\lambda_1 n u_1^{n-1} \partial_x u_1(x,t) - \lambda_2 n z^{n-1}(u_2) \partial_x u_2(x,t) \right] dx \\
&= \int_{-\infty}^{\infty} nf(\vec{u})(u_1^{n-1}(x,t) - z^{n-1}(u_2))dx \\
&\quad - \int_{-\infty}^{\infty} \lambda_1 \partial_x [u_1^n(x,t)]dx - \int_{-\infty}^{\infty} \lambda_2 \partial_x \int_0^{u_2(x,t)} n z^{n-1}(\tau) d\tau dx \\
&= \int_{-\infty}^{\infty} nf(\vec{u})(u_1^{n-1}(x,t) - z^{n-1}(u_2))dx \\
&\quad -\lambda_1 \lim_{x\to\infty} u_1^n(x,t) + \lambda_1 \lim_{x\to-\infty} u_1^n(x,t) \qquad (11) \\
&\quad -\lambda_2 \lim_{x\to\infty} \int_0^{u_2(x,t)} n z^{n-1}(\tau) d\tau + \lambda_2 \lim_{x\to-\infty} \int_0^{u_2(x,t)} n z^{n-1}(\tau) d\tau.
\end{aligned}
$$

All the indicated limits in (11) are zero since the initial data are in $C^1_\infty(\mathbb{R})$. By the stability criteria we know that for all nonnegative u_i, $f(u_1, u_2)(u_1^{n-1} - z^{n-1}(u_2)) \leq 0$. We thus have

$$
\frac{d}{dt} E_{u_1}(t) = \int_{-\infty}^{\infty} nf(\vec{u})(u_1^{n-1}(x,t) - z^{n-1}(u_2))dx \quad \leq \quad 0.
$$

The energy norm E_{u_1} was carefully constructed to be a nonincreasing function of time. Thus, for $0 \leq t \leq T$

$$
E_{u_1}(0) \geq E_{u_1}(t) \geq \int_{-\infty}^{\infty} u_1^n(x,t)dx. \qquad (12)
$$

Estimating $E_{u_1}(0)$ yields the following:

$$
\begin{aligned}
E_{u_1}(0) &= \int_{-\infty}^{\infty} \left[u_{01}^n(x) + \int_0^{u_{02}(x)} n z^{n-1}(\tau) d\tau \right] dx \\
&\leq \int_{-\infty}^{\infty} u_{01}^n(x)dx + n \left(\max_{0\leq s\leq \| u_{02} \|_\infty} z(s) \right)^{n-1} \int_{-\infty}^{\infty} u_{02}(x)dx \\
&\leq \| u_{01} \|_\infty^{n-1} \| u_{01} \|_1 + nz(\| u_{02} \|_\infty)^{n-1} \| u_{02}(x) \|_1 . \qquad (13)
\end{aligned}
$$

Combining (12) and (13) yields the following estimate:

$$
\begin{aligned}
\left\{ \int_{-\infty}^{\infty} u_1^n(x,t)dx \right\}^{\frac{1}{n}} &\leq \{ \| u_{01} \|_\infty^{n-1} \| u_{01} \|_1 \}^{\frac{1}{n}} \qquad (14) \\
&\quad + \{ nz(\| u_{02} \|_\infty)^{n-1} \| u_{02}(x) \|_1 \}^{\frac{1}{n}}.
\end{aligned}
$$

We know that for a given function w if $\overline{\lim}_{p\to\infty} \| w \|_p = s < \infty$, then $\| w \|_\infty \leq s$. Taking the lim sup of both sides of (14), we get the desired L^∞ estimate

$$
\| u_1(x,t) \|_\infty \leq \| u_{01}(x) \|_\infty + z(\| u_{02} \|_\infty) \qquad (15)
$$

for all $t \in [0, T]$.

To find an a priori bound for u_2, we apply a similar argument. Let $m > 1$ and denote the inverse function of $z(\cdot)$ as $\gamma(\cdot)$. Define the energy norm E_{u_2} as

$$E_{u_2}(t) \equiv \int_{-\infty}^{\infty} \left[u_2^m(x,t) + \int_0^{u_1(x,t)} m\gamma^{m-1}(\tau)d\tau \right] dx. \tag{16}$$

Differentiating E_{u_2} with respect to time yields

$$\begin{aligned}
\frac{d}{dt}E_{u_2}(t) &= \int_{-\infty}^{\infty} \left[mu_2^{m-1}(x,t)\partial_t u_2(x,t) + m\gamma^{m-1}(u_1)\partial_t u_1(x,t) \right] dx \\
&= \int_{-\infty}^{\infty} \left[mf(\vec{u})(\gamma^{m-1}(u_1) - u_2^{m-1}(x,t)) \right. \\
&\qquad \left. -\lambda_2 m u_2^{m-1}\partial_x u_2(x,t) - \lambda_1 m\gamma^{m-1}(u_1)\partial_x u_1(x,t) \right] dx \\
&= \int_{-\infty}^{\infty} mf(\vec{u})(\gamma^{m-1}(u_1) - u_2^{m-1}(x,t))dx \\
&\quad -\lambda_2 \lim_{x\to\infty} u_2^m(x,t) + \lambda_2 \lim_{x\to-\infty} u_2^m(x,t) \\
&\quad -\lambda_1 \lim_{x\to\infty} \int_0^{u_1(x,t)} m\gamma^{m-1}(\tau)d\tau \\
&\quad + \lambda_1 \lim_{x\to-\infty} \int_0^{u_1(x,t)} m\gamma^{m-1}(\tau)d\tau \\
&= \int_{-\infty}^{\infty} mf(\vec{u})(\gamma^{m-1}(u_1) - u_2^{m-1}(x,t))dx \quad \leq 0
\end{aligned} \tag{17}$$

by Proposition 2.2 and the stability criteria. Since E_{u_2} is nonincreasing in time, we have by positivity that

$$E_{u_2}(0) \geq E_{u_2}(t) \geq \int_{-\infty}^{\infty} u_2^m(x,t)dx \tag{18}$$

for $0 \leq t \leq T$. Applying the previous argument to estimate $E_{u_2}(0)$, we get our final result for all $t \in [0,T]$:

$$\| u_2(x,t) \|_\infty \leq \| u_{02}(x) \|_\infty + \gamma(\| u_{01} \|_\infty). \tag{19}$$

We have shown that $\max\{\| u_1(x,t) \|_\infty, \| u_2(x,t) \|_\infty\} \leq \mathcal{A}$ for all $t \in [0,T]$, where the a priori bound is defined as

$$\mathcal{A} \equiv \max\{\| u_{01} \|_\infty + z(\| u_{02} \|_\infty), \| u_{02} \|_\infty + \gamma(\| u_{01} \|_\infty)\}. \tag{20}$$

This a priori bound ensures that a solution to (9) exists for all time and space. □

Note that the a priori estimate (20) depends not only on the initial data, but also on the geometry of the zero set of the source terms. As an example, consider the system

$$\begin{aligned}
(\partial_t + \lambda_1\partial_x)u_1(x,t) &= -k_1 u_1^\mu + k_2 u_2^\eta, \\
(\partial_t + \lambda_2\partial_x)u_2(x,t) &= k_1 u_1^\mu - k_2 u_2^\eta, \\
\vec{u}(x,0) &= \vec{u}_0(x),
\end{aligned} \tag{21}$$

where η, μ, k_1, and k_2 are positive constants, λ_1 and λ_2 are arbitrary constants, and for $i = 1,2$ the initial data u_{0i} are nonnegative, uniformly bounded, $C^1(\mathbb{R}) \cap L^1(\mathbb{R})$

functions with uniformly bounded derivatives. The curve of zeros is simply $z(u_2) = (\frac{k_2}{k_1})^{1/\mu} u_2^{\eta/\mu}$, and it is clear that $\vec{f}(\vec{u}) \equiv (-k_1 u_1^\mu + k_2 u_2^\eta, k_1 u_1^\mu - k_2 u_2^\eta)$ satisfies the stability criteria. Thus, by Theorem 3.2 a global solution exists to (21) for any $\eta > 0$ and $\mu > 0$.

Let $\mathcal{K}_1 = (\frac{k_2}{k_1})^{1/\mu}$, $\mathcal{K}_2 = (\frac{k_1}{k_2})^{1/\eta}$, and $\rho = \frac{\eta}{\mu}$. By (20), the a priori bound for the solution to system (21) is

$$\mathcal{A} \equiv \max\{\| u_{01}(x) \|_\infty + \mathcal{K}_1 \| u_{02}(x) \|_\infty^\rho, \mathcal{K}_2 \| u_{01}(x) \|_\infty^{\frac{1}{\rho}} + \| u_{02}(x) \|_\infty\}.$$

Now consider the case when $\mu = \eta$. For $\mathcal{K} = (\frac{k_2}{k_1})^{1/\eta}$, the a priori bound reduces to

$$\mathcal{A} \equiv \max\{\| u_{01}(x) \|_\infty + \mathcal{K} \| u_{02}(x) \|_\infty, \mathcal{K}^{-1} \| u_{01}(x) \|_\infty + \| u_{02}(x) \|_\infty\}.$$

In addition if we set $k_1 = k_2$, the energy norms are simply

$$E_{u_1} = \int_{-\infty}^{\infty} [u_1^n(x,t) + u_2^n(x,t)]\, dx,$$

$$E_{u_2} = \int_{-\infty}^{\infty} [u_2^m(x,t) + u_1^m(x,t)]\, dx,$$

and the a priori bound $\mathcal{A}$ further reduces to

$$\mathcal{A} \equiv \| u_{01}(x) \|_\infty + \| u_{02}(x) \|_\infty .$$

We remark that Illner showed global existence in this case for $\eta = 2$ in [6].

There are various degenerate systems that can be handled by different yet very simple methods. For $k_1, \mu > 0$ the source term in the system

$$\begin{aligned} (\partial_t + \lambda_1 \partial_x) u_1(x,t) &= -k_1 u_1^\mu, \\ (\partial_t + \lambda_2 \partial_x) u_2(x,t) &= k_1 u_1^\mu, \\ u_i(x,0) &= u_{0i}(x), \end{aligned} \tag{22}$$

does not satisfy the stability criteria since the zero curve is not invertible. System (22) can be written as

$$\begin{aligned} (\partial_t + \lambda_1 \partial_x) u_1(x,t) &= f(u_1), \\ (\partial_t + \lambda_2 \partial_x) u_2(x,t) &= -f(u_1), \\ u_i(x,0) &= u_{0i}(x), \end{aligned} \tag{23}$$

where f has the following form:

$$f(u_1) \equiv -u_1 \sum_{|\beta_1^i| \le \mu - 1} d_{\beta_1^i}(x,t,u_1) u_1^{\beta_1^i}$$

(see formula (4)). Since $\vec{f}(u_1) \equiv (f(u_1), -f(u_1))$, we know by Proposition 2.2 that a nonnegative, C_∞^1 local solution exists to (23). For $T > 0$, assume that a nonnegative, C_∞^1 solution exists for $t \in [0,T]$. By positivity, we have that

$$\begin{aligned} u_1(x,t) &= u_{01}(x) + \int_0^t f(u_1(x - \lambda_1(t-s), s))ds \\ &\le \| u_{01}(x) \|_\infty . \end{aligned}$$

Since $f(u_1)$ is a smooth function on a compact set, it has a maximum in terms of the initial datum $u_{01}(x)$. Using positivity, we analyze the integral equation for u_2:

$$\begin{aligned} u_2(x,t) &= u_{02}(x) - \int_0^t f(u_1(x-\lambda_2(t-s),s))ds \\ &\leq \| u_{02}(x) \|_\infty + T \max(-f(\| u_{01}(x) \|_\infty)). \end{aligned}$$

Thus, the a priori bound for the solution to (22) for all $x \in \mathbb{R}$ and $t \in [0,T]$ is

$$\mathcal{A} \equiv \max\{\| u_{01}(x) \|_\infty, \ \| u_{02}(x) \|_\infty + Tk_1 \| u_{01}(x) \|_\infty^\mu\}.$$

4. r × r systems. We now extend the results for the 2×2 system to a certain class of $r \times r$ reaction-hyperbolic systems with the following form:

$$\begin{aligned} (\partial_t + \lambda_1 \partial_x) u_1(x,t) &= f_1(u_1,u_2), \\ &\vdots \qquad\qquad \vdots \\ (\partial_t + \lambda_i \partial_x) u_i(x,t) &= -f_{i-1}(u_{i-1},u_i) + f_i(u_i,u_{i+1}), \\ &\vdots \qquad\qquad \vdots \\ (\partial_t + \lambda_r \partial_x) u_r(x,t) &= -f_{r-1}(u_{r-1},u_r), \\ \vec{u}(x,0) &= \vec{u}_0(x), \end{aligned} \tag{24}$$

where $r > 2$. For $i = 1, \ldots, r$, let F_i be the right-hand side of the ith equation. We extend the definition of stability criteria to $r \times r$ systems.

DEFINITION 4.1. *For the $r \times r$ case, we say that $\vec{F} \equiv (F_1, \ldots, F_r)$ satisfies the stability criteria if and only if*

(i) *$\vec{F}(\vec{u})$ is a C^2 reaction function of $\vec{u}$ only.*

(ii) *For $k = 1, \ldots, r-1$, the set of zeros of f_k in the closed first quadrant is given by a continuous, one-to-one function, $z_k(\cdot)$, where $z_k(0) \equiv 0$.*

(iii) *For $k = 1, \ldots, r-1$, $f_k(u_k, u_{k+1})(u_k - z(u_{k+1})) \leq 0$ for all $x \in \mathbb{R}$ and $t \in [0, \delta)$.*

THEOREM 4.2. *Consider the $r \times r$ system (24), where $r > 2$. If $\vec{F} \equiv (F_1, \ldots, F_r)$ satisfies the stability criteria and the components of the initial data $\vec{u}_0(x)$ are nonnegative, uniformly bounded, $C^1(\mathbb{R}) \cap L^1(\mathbb{R})$ functions, then a global solution exists to system (24).*

Proof. Let $z_k(\cdot)$ denote the zero curve for f_k, and let $\gamma_k(\cdot)$ be its inverse. For $n > 1$, define the following functions:

$$\begin{aligned} \mathcal{Z}_{(\mathrm{m,j})}(\tau) &\equiv z_m \circ z_{m+1} \circ \cdots \circ z_j(\tau), \qquad m \leq j, \\ \Gamma_{(\mathrm{m,j})}(\tau) &\equiv \gamma_m \circ \gamma_{m-1} \circ \cdots \circ \gamma_j(\tau), \qquad m \geq j. \end{aligned} \tag{25}$$

Note that $\mathcal{Z}_{(\mathrm{m,j})}$ and $\Gamma_{(\mathrm{m,j})}$ are compositions of nonnegative, monotonic functions, and are therefore nonnegative and monotonic. Define the following energy norms:

$$E_{u_1}(t) \equiv \int_{-\infty}^{\infty} \left(u_1^n(x,t) + \sum_{k=2}^{r} \int_0^{u_k(x,t)} n \mathcal{Z}_{(1,k-1)}^{n-1}(\tau) d\tau \right) dx,$$

$$\begin{aligned} E_{u_i}(t) \equiv \int_{-\infty}^{\infty} \Bigg(u_i^n(x,t) &+ \sum_{k=1}^{i-1} \int_0^{u_k(x,t)} n \Gamma_{(\mathrm{i-1,k})}^{n-1}(\tau) d\tau \\ &+ \sum_{k=i+1}^{r} \int_0^{u_k(x,t)} n \mathcal{Z}_{(\mathrm{i,k-1})}^{n-1}(\tau) d\tau \Bigg) dx, \end{aligned}$$

$$E_{u_r}(t) \equiv \int_{-\infty}^{\infty} \left(u_r^n(x,t) + \sum_{k=1}^{r-1} \int_0^{u_k(x,t)} n\Gamma^{n-1}_{(\mathrm{r-1,k})}(\tau)d\tau \right) dx.$$

All the terms in the energy norms are nonnegative by Proposition 2.2 and (25). Differentiating $E_{u_i}(t)$ with respect to time yields the following equalities:

$$\begin{aligned}
\frac{d}{dt}E_{u_i}(t) &= \int_{-\infty}^{\infty} \left(nu_i^{n-1}(-f_{i-1} + f_i - \lambda_i \partial_x u_i) + n\Gamma^{n-1}_{(\mathrm{i-1,1})}(u_1)(f_1 - \lambda_1 \partial_x u_1) \right) dx \\
&\quad + \int_{-\infty}^{\infty} \left(\sum_{k=2}^{i-1} n\Gamma^{n-1}_{(\mathrm{i-1,k})}(u_k)(-f_{k-1} + f_k - \lambda_k \partial_x u_k) \right. \\
&\qquad \left. + \sum_{k=i+1}^{r-1} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(u_k)(-f_{k-1} + f_k - \lambda_k \partial_x u_k) \right) dx \\
&\quad + \int_{-\infty}^{\infty} n\mathcal{Z}^{n-1}_{(\mathrm{i,r-1})}(u_r)(-f_{r-1} - \lambda_r \partial_x u_r) dx \\
&= \int_{-\infty}^{\infty} \left(nu_i^{n-1}(-f_{i-1} + f_i) + n\Gamma^{n-1}_{(\mathrm{i-1,1})}(u_1) f_1 \right) dx \\
&\quad + \int_{-\infty}^{\infty} \left(\sum_{k=2}^{i-1} n\Gamma^{n-1}_{(\mathrm{i-1,k})}(u_k)(-f_{k-1} - f_k) \right. \\
&\qquad \left. + \sum_{k=i+1}^{r-1} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(u_k)(-f_{k-1} + f_k) \right) dx \\
&\quad + \int_{-\infty}^{\infty} n\mathcal{Z}^{n-1}_{(\mathrm{i,r-1})}(u_r)(-f_{r-1}) dx \\
&\quad + \int_{-\infty}^{\infty} \left(-\lambda_i n u_i^{n-1} \partial_x u_i - \sum_{k=1}^{i-1} n\Gamma^{n-1}_{(\mathrm{i-1,k})}(u_k)\lambda_k \partial_x u_k \right. \\
&\qquad \left. - \sum_{k=i+1}^{r} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(u_k)\lambda_k \partial_x u_k \right) dx \\
&= \int_{-\infty}^{\infty} \left(nu_i^{n-1}(-f_{i-1} + f_i) + n\Gamma^{n-1}_{(\mathrm{i-1,1})}(u_1) f_1 \right) dx \\
&\quad + \int_{-\infty}^{\infty} \left(\sum_{k=2}^{i-1} n\Gamma^{n-1}_{(\mathrm{i-1,k})}(u_k)(-f_{k-1} - f_k) \right. \\
&\qquad \left. + \sum_{k=i+1}^{r-1} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(u_k)(-f_{k-1} + f_k) \right) dx \qquad (26) \\
&\quad + \int_{-\infty}^{\infty} n\mathcal{Z}^{n-1}_{(\mathrm{i,r-1})}(u_r)(-f_{r-1}) dx \\
&\quad + \int_{-\infty}^{\infty} \left(-\lambda_i \partial_x [u_i^n] - \sum_{k=1}^{i-1} \partial_x \left[\int_0^{u_k(x,t)} n\lambda_k \Gamma^{n-1}_{(\mathrm{i-1,k})}(\tau)d\tau \right] \right. \qquad (27) \\
&\qquad \left. - \sum_{k=i+1}^{r} \partial_x \left[\int_0^{u_k(x,t)} n\lambda_k \mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(\tau)d\tau \right] \right) dx.
\end{aligned}$$

The boundary terms in (27) vanish since the solution is in $C^1_\infty(\mathbb{R}\times[0,T])$. We now expand the sums in (26) to get the following:

$$\begin{aligned}
\frac{d}{dt}E_{u_i} = \int_{-\infty}^{\infty} \Big(& nf_1(u_1,u_2)\left[\Gamma^{n-1}_{(\mathrm{i}-1,1)}(u_1) - \Gamma^{n-1}_{(\mathrm{i}-1,2)}(u_2)\right] \\
& + nf_2(u_2,u_3)\left[\Gamma^{n-1}_{(\mathrm{i}-1,2)}(u_2) - \Gamma^{n-1}_{(\mathrm{i}-1,3)}(u_3)\right] \\
& + \cdots + nf_{i-1}(u_{i-1},u_i)\left[\Gamma^{n-1}_{(\mathrm{i}-1,\mathrm{i}-1)}(u_{i-1}) - u_i^{n-1}\right] \\
& + nf_i(u_i,u_{i+1})\left[u_i^{n-1} - \mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{i})}(u_{i+1})\right] \\
& + nf_{i+1}(u_{i+1},u_{i+2})\left[\mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{i})}(u_{i+1}) - \mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{i}+1)}(u_{i+2})\right] \\
& + \cdots + nf_{r-1}(u_{r-1},u_r)\left[\mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{r}-2)}(u_{r-1}) - \mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{r}-1)}(u_r)\right]\Big)\,dx \\
= \int_{-\infty}^{\infty} \Big(& nf_1(u_1,u_2)\left[\Gamma^{n-1}_{(\mathrm{i}-1,2)}(\gamma_1(u_1)) - \Gamma^{n-1}_{(\mathrm{i}-1,2)}(u_2)\right] \\
& + nf_2(u_2,u_3)\left[\Gamma^{n-1}_{(\mathrm{i}-1,3)}(\gamma_2(u_2)) - \Gamma^{n-1}_{(\mathrm{i}-1,3)}(u_3)\right] \\
& + \cdots + nf_{i-1}(u_{i-1},u_i)\left[\gamma_{i-1}^{n-1}(u_{i-1}) - u_i^{n-1}\right] \\
& + nf_i(u_i,u_{i+1})\left[u_i^{n-1} - z_i^{n-1}(u_{i+1})\right] \\
& + nf_{i+1}(u_{i+1},u_{i+2})\left[\mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{i})}(u_{i+1}) - \mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{i})}(z_{i+1}(u_{i+2}))\right] \\
& + \cdots + nf_{r-1}(u_{r-1},u_r)\left[\mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{r}-2)}(u_{r-1}) - \mathcal{Z}^{n-1}_{(\mathrm{i},\mathrm{r}-2)}(z_{r-1}(u_r))\right]\Big)\,dx. \qquad (28)
\end{aligned}$$

By the stability criteria, $f_i(u_i,u_{i+1}) \geq 0$ for $\gamma_i(u_i) \leq u_{i+1}$ and for $z_i(u_{i+1}) \geq u_i$; we also have that and $f_i(u_i,u_{i+1}) \leq 0$ for $\gamma_i(u_i) \geq u_{i+1}$ and for $z_i(u_{i+1}) \leq u_i$. Since $\Gamma_{(\mathrm{m},\mathrm{j})}$ and $\mathcal{Z}_{(\mathrm{m},\mathrm{j})}$ are nonnegative monotonic functions, we have that each term in the integrand (28) is nonpositive and that

$$\frac{d}{dt}E_{u_i}(t) \leq 0.$$

E_{u_1} and E_{u_r} were carefully constructed to be nonincreasing functions of time as well. Applying the argument in Theorem 3.2 to the energy norms yields the following a priori bounds for the solution:

$$\begin{aligned}
\| u_1 \|_\infty &\leq \| u_{01} \|_\infty + \sum_{k=2}^{r} \mathcal{Z}_{(1,\mathrm{k}-1)}(\| u_{0k} \|_\infty) \\
\| u_i \|_\infty &\leq \| u_{0i} \|_\infty + \sum_{k=1}^{i-1} \Gamma_{(\mathrm{i}-1,\mathrm{k})}(\| u_{0k} \|_\infty) + \sum_{k=i+1}^{r} \mathcal{Z}_{(\mathrm{i},\mathrm{k}-1)}(\| u_{0k} \|_\infty) \qquad (29) \\
\| u_r \|_\infty &\leq \| u_{0r} \|_\infty + \sum_{k=1}^{r-1} \Gamma_{(\mathrm{r}-1,\mathrm{k})}(\| u_{0k} \|_\infty).
\end{aligned}$$

These bounds ensure that a solution to (24) exists for all time and space. □

Note that for $r = 2$, the estimates in (29) reduce to the previous results in (20) by Theorem 3.2:

$$\begin{aligned}
\| u_1 \|_\infty &\leq \| u_{01} \|_\infty + z_1(\| u_{02} \|_\infty), \\
\| u_2 \|_\infty &\leq \| u_{02} \|_\infty + \gamma_1(\| u_{01} \|_\infty).
\end{aligned}$$

5. Initial–boundary value problem. We define the initial-boundary value problem for the $r \times r$ system to be the following:

$$
\begin{aligned}
(\partial_t + \lambda_1 \partial_x) u_1(x,t) &= f_1(u_1, u_2), \\
&\vdots \qquad\qquad \vdots \\
(\partial_t + \lambda_i \partial_x) u_i(x,t) &= -f_{i-1}(u_{i-1}, u_i) + f_i(u_i, u_{i+1}), \\
&\vdots \qquad\qquad \vdots \\
(\partial_t + \lambda_r \partial_x) u_r(x,t) &= -f_{r-1}(u_{r-1}, u_r), \\
\vec{u}(x,0) &= \vec{u}_0(x),
\end{aligned} \tag{30}
$$

where λ_i is arbitrary and $x \in [0, +\infty)$. For those $\lambda_i > 0$, we prescribe the following boundary data:

$$u_i(0,t) = h_i(t). \tag{31}$$

PROPOSITION 5.1 (local existence). *Consider the initial-boundary value problem* (30), (31). *For* $k = 1, \ldots, r-1$, *let each* $f_k : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *be* C^∞, *and let the components of the initial data,* $\vec{u}_0(x)$, *and boundary data,* $\vec{h}(t)$, *be uniformly bounded, continuously differentiable functions with uniformly bounded derivatives. If for those* $\lambda_i > 0$ *the data are compatible at the origin, that is, if*

$$\lim_{s \to 0^+} h_i(s) = \lim_{s \to 0^+} u_{0i}(s)$$

and

$$\lim_{s \to 0^+} h_i'(s) = \lim_{s \to 0^+} [-\lambda_i u_{0i}(s) + F_i(u_i(s,0), u_{i+1}(s,0))],$$

where F_i *is the source term for the* i*th equation in* (30), *then there exists a* $\delta > 0$ *such that the initial-boundary value problem* (30), (31) *has a unique solution for all* $x \geq 0$ *and* $t \in [0, \delta)$. *If in addition the initial data are nonnegative,* $C^1_\infty(\mathbb{R}^+)$ *functions and each* f_k *is a reaction function, then the solution to the initial-boundary value problem is a nonnegative,* $C^1_\infty([0,\delta) \times \mathbb{R}^+)$ *function.*

Proof. See [5] and [8]. □

THEOREM 5.2 (global existence). *Consider the initial-boundary value problem* (30), (31) *and assume the hypotheses defined in Proposition* 5.1. *If* $\vec{F} \equiv (F_1, \ldots, F_r)$ *satisfies the stability criteria, then a solution to* (30), (31) *exists for all* $x \geq 0$ *and for all* $t \geq 0$.

Proof. To prove this theorem, we apply the same argument used in Theorem 4.2, where the energy norms are modified to account for the boundary data at the origin.

For some $T > 0$, assume that a nonnegative solution exists to (30), (31) for all $x \geq 0$ and $t \in [0, T]$.

For those $\lambda_i \leq 0$ where $i = 1, \ldots, r$, we modify the energy norms used in Theorem 4.2 in the following way:

$$
\begin{aligned}
E_{u_i}(t) \equiv \int_0^\infty \Bigg(u_i^n(x,t) + \sum_{k=1}^{i-1} \int_0^{u_k(x,t)} & n\Gamma^{n-1}_{(\mathrm{i-1,k})}(\tau) d\tau \\
& + \sum_{k=i+1}^{r} \int_0^{u_k(x,t)} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(\tau) d\tau \Bigg) dx
\end{aligned}
$$

$$+\sum_{\substack{k=1\\ \lambda_k>0}}^{i-1}\int_t^T\left[\int_0^{h_k(s)} n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau\right]ds$$
$$+\sum_{\substack{k=i+1\\ \lambda_k>0}}^{r}\int_t^T\left[\int_0^{h_k(s)} n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau\right]ds,$$

where $n>1$. Note that for $i=1$, those sums whose limits go from $k=1$ to $k=0$ are set to zero. Similarly, for $i=r$, we set those sums from $k=r+1$ to r to be zero. Differentiating E_{u_i} with respect to time yields

$$\frac{d}{dt}E_{u_i}(t)=\int_0^\infty\left(nu_i^{n-1}(-f_{i-1}+f_i)+n\Gamma^{n-1}_{(i-1,1)}(u_1)f_1\right)dx$$
$$+\int_0^\infty\left(\sum_{k=2}^{i-1}n\Gamma^{n-1}_{(i-1,k)}(u_k)(-f_{k-1}-f_k)\right.$$
$$\left.+\sum_{k=i+1}^{r-1}n\mathcal{Z}^{n-1}_{(i,k-1)}(u_k)(-f_{k-1}+f_k)\right)dx \tag{32}$$
$$+\int_0^\infty\left(n\mathcal{Z}^{n-1}_{(i,r-1)}(u_r)(-f_{r-1})\right)dx$$
$$+\int_0^\infty\left(-\lambda_i\partial_x[u_i^n]-\sum_{k=1}^{i-1}\partial_x\left[\int_0^{u_k(x,t)}n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau\right]\right.$$
$$\left.-\sum_{k=i+1}^{r}\partial_x\left[\int_0^{u_k(x,t)}n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau\right]\right)dx \tag{33}$$
$$-\sum_{\substack{k=1\\ \lambda_k>0}}^{i-1}\int_0^{h_k(t)}n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau-\sum_{\substack{k=i+1\\ \lambda_k>0}}^{r}\int_0^{h_k(t)}n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau.$$

Collecting boundary terms (33), we find as in (27) of Theorem 4.2 that the boundary terms at $+\infty$ vanish since the solution is in C^1_∞. However, the boundary terms at the origin do not vanish and we are left with

$$\lambda_i u_i^n(0,t)+\sum_{\substack{k=1\\ \lambda_k\le 0}}^{i-1}\int_0^{u_k(0,t)}n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau+\sum_{\substack{k=1\\ \lambda_k>0}}^{i-1}\int_0^{u_k(0,t)}n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau$$
$$+\sum_{\substack{k=i+1\\ \lambda_k\le 0}}^{r}\int_0^{u_k(0,t)}n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau+\sum_{\substack{k=i+1\\ \lambda_k>0}}^{r}\int_0^{u_k(0,t)}n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau$$
$$-\sum_{\substack{k=1\\ \lambda_k>0}}^{i-1}\int_0^{h_k(t)}n\lambda_k\Gamma^{n-1}_{(i-1,k)}(\tau)d\tau-\sum_{\substack{k=i+1\\ \lambda_k>0}}^{r}\int_0^{h_k(t)}n\lambda_k\mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau.$$

For all $\lambda_k>0$, the solution $u_k(0,t)$ is the prescribed boundary data $h_k(t)$. So the

boundary terms further reduce to

$$\lambda_i u_i^n(0,t) + \sum_{\substack{k=1\\ \lambda_k \le 0}}^{i-1} \int_0^{u_k(0,t)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau + \sum_{\substack{k=i+1\\ \lambda_k \le 0}}^{r} \int_0^{u_k(0,t)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau. \tag{34}$$

By assumption $\lambda_i \le 0$ and the sums are over those $\lambda_k \le 0$, so the terms in (34) are nonpositive. Thus, the energy norms were modified so that the positive growth factors at the origin vanish and the remaining terms either do not contribute to or decrease the growth of the energy norm as time progresses.

By applying the same manipulations used in Theorem 4.2 to the sums in (32) and combining (34), we can easily show that $E_{u_i}(t)$ is nonincreasing in time. Using the same argument in Theorem 3.2 yields the following a priori bound for solution $u_i(x,t)$, where $\lambda_i \le 0$:

$$\begin{aligned} \| u_i(x,t) \|_\infty \le \| u_{0i} \|_\infty + \sum_{k=1}^{i-1} \Gamma_{(i-1,k)}(\| u_{0k} \|_\infty) + \sum_{k=i+1}^{r} \mathcal{Z}_{(i,k-1)}(\| u_{0k} \|_\infty) \\ + \sum_{\substack{k=1\\ \lambda_k > 0}}^{i-1} \Gamma_{(i-1,k)}(\max_{0\le s\le T} h_k(s)) + \sum_{\substack{k=i+1\\ \lambda_k > 0}}^{r} \mathcal{Z}_{(i,k-1)}(\max_{0\le s\le T} h_k(s)). \end{aligned} \tag{35}$$

For those $\lambda_i > 0$ where $i = 1, \dots, r$, we have the following energy norms:

$$\begin{aligned} E_{u_i}(t) \equiv \int_0^\infty \Bigg(u_i^n(x,t) + \sum_{k=1}^{i-1} \int_0^{u_k(x,t)} n\Gamma^{n-1}_{(\mathrm{i-1,k})}(\tau)d\tau \\ + \sum_{k=i+1}^{r} \int_0^{u_k(x,t)} n\mathcal{Z}^{n-1}_{(\mathrm{i,k-1})}(\tau)d\tau \Bigg) dx \\ + \int_t^T \lambda_i h_i^n(s)ds + \sum_{\substack{k=1\\ \lambda_k > 0}}^{i-1} \int_t^T \left[\int_0^{h_k(s)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau \right] ds \\ + \sum_{\substack{k=i+1\\ \lambda_k > 0}}^{r} \int_t^T \left[\int_0^{h_k(s)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau \right] ds, \end{aligned}$$

where $n > 1$. Again, for $i = 1$ and $i = r$, we set the appropriate sums equal to zero. By differentiating E_{u_i} with respect to time and collecting boundary data, we have

$$\begin{aligned} \lambda_i u_i^n(0,t) + \sum_{\substack{k=1\\ \lambda_k \le 0}}^{i-1} \int_0^{u_k(0,t)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau + \sum_{\substack{k=1\\ \lambda_k > 0}}^{i-1} \int_0^{u_k(0,t)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau \\ + \sum_{\substack{k=i+1\\ \lambda_k \le 0}}^{r} \int_0^{u_k(0,t)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau + \sum_{\substack{k=i+1\\ \lambda_k > 0}}^{r} \int_0^{u_k(0,t)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau \\ - \lambda_i h_i^n(t) - \sum_{\substack{k=1\\ \lambda_k > 0}}^{i-1} \int_0^{h_k(t)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau - \sum_{\substack{k=i+1\\ \lambda_k > 0}}^{r} \int_0^{h_k(t)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau. \end{aligned}$$

Again, all the positive growth factors at the origin vanish, and we are left with

$$\sum_{\substack{k=1\\ \lambda_k \le 0}}^{i-1} \int_0^{u_k(0,t)} n\lambda_k \Gamma^{n-1}_{(i-1,k)}(\tau)d\tau + \sum_{\substack{k=i+1\\ \lambda_k \le 0}}^{r} \int_0^{u_k(0,t)} n\lambda_k \mathcal{Z}^{n-1}_{(i,k-1)}(\tau)d\tau,$$

which consists of nonpositive terms. The a priori bound for solution $u_i(x,t)$, where $\lambda_i > 0$, is

$$\begin{aligned}(36)\quad \| u_i(x,t) \|_\infty \le \| u_{0i} \|_\infty + \max_{0\le s\le T} h_i(s) + \sum_{k=1}^{i-1} \Gamma_{(i-1,k)}(\| u_{0k} \|_\infty) \\ + \sum_{k=i+1}^{r} \mathcal{Z}_{(i,k-1)}(\| u_{0k} \|_\infty) + \sum_{\substack{k=1\\ \lambda_k>0}}^{i-1} \Gamma_{(i-1,k)}(\max_{0\le s\le T} h_k(s)) \\ + \sum_{\substack{k=i+1\\ \lambda_k>0}}^{r} \mathcal{Z}_{(i,k-1)}(\max_{0\le s\le T} h_k(s)).\end{aligned}$$

Global existence of a solution to (30) follows easily. □

Note that the a priori estimates (35), (36) depend on the initial data, boundary data, and on the geometry of the zero set of the source terms. As a simple example, consider the 2×2 system:

$$\begin{aligned}(\partial_t + \lambda_1\partial_x)u_1(x,t) &= f(u_1,u_2)\\ (\partial_t + \lambda_2\partial_x)u_2(x,t) &= -f(u_1,u_2)\\ \vec{u}(x,0) &= \vec{u}_0(x)\\ u_1(0,t) &= h_1(t), \qquad t>0,\end{aligned}$$

where $\lambda_1 > 0$, $\lambda_2 \le 0$, and the initial and boundary data are compatible at the origin as defined in Proposition 5.1. The energy norms as defined in Theorem 5.2 reduce to

$$E_{u_1}(t) \equiv \int_0^\infty \left(u_1^n(x,t) + \int_0^{u_2(x,t)} nz^{n-1}(\tau)d\tau \right) dx + \int_t^T \lambda_1 h_1^n(s)ds,$$

$$E_{u_2}(t) \equiv \int_0^\infty \left(u_2^n(x,t) + \int_0^{u_1(x,t)} n\gamma^{n-1}(\tau)d\tau \right) dx + \int_t^T \int_0^{h_1(s)} n\lambda_1\gamma^{n-1}(\tau)d\tau ds$$

and the a priori bounds given by (35), (36) are

$$\| u_1(x,t) \|_\infty \le \| u_{01}(x) \|_\infty + \max_{0\le s\le T} h_1(s) + z(\| u_{02} \|_\infty),$$

$$\| u_2(x,t) \|_\infty \le \| u_{02}(x) \|_\infty + \gamma(\| u_{01} \|_\infty) + \gamma(\max_{0\le s\le T} h_1(s)).$$

Acknowledgment. The author wishes to thank Michael C. Reed for suggesting this problem, much of which has appeared in the author's dissertation.

GLOBAL ATTRACTORS FOR PARABOLIC PROBLEMS IN FRACTIONAL POWER SPACES*

ALEXANDRE NOLASCO DE CARVALHO† AND JOSÉ GASPAR RUAS-FILHO†

Abstract. This paper deals with global well-posedness and existence of global attractors for systems of weakly coupled semilinear parabolic problems in fractional power spaces which are embedded in L^∞. In these spaces, no growth assumption on the nonlinearity is required for local existence and it can be proven that some sort of dissipation takes place. The tools employed are the theory of invariant regions and the invariance theory. The first provides global existence of solutions whereas the second provides point dissipativeness. Some applications to chemical kinetic problems are considered, as are some problems arising as limiting problems for reaction-diffusion equations in thin domains around a point.

Key words. global attractors, cooperative systems, thin domains, fractional power spaces, reaction-diffusion equations

1. Introduction and statement of the results.

Let Ω be a bounded smooth domain of $\mathbb{R}^n$, $n \leq 3$. In this paper we consider parabolic problems of the form

$$\begin{cases} u_t = d\Delta u - \gamma u + f(u) & \text{in} \quad \Omega, \\ \dfrac{\partial u}{\partial n} = 0 & \text{in} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where d and γ are positive constants.

We are interested in global well-posedness and the existence of global attractors for such problems. To simplify the presentation we assume that u is scalar and the nonlinearity $f : \mathbb{R} \to \mathbb{R}$ is a C^1 function that satisfies

$$\limsup_{|u|\to\infty} \frac{f(u)}{u} \leq -\delta < 0. \tag{1.2}$$

This dissipativeness condition will play a fundamental role in proving that there is an absorbing set for (1.1).

To describe the results we introduce some terminology. Let $X = L^2(\Omega)$ and $A : D(A) \subset X \to X$ be the self-adjoint operator defined by

$$D(A) = \{\phi \in H^2(\Omega) : \tfrac{\partial \phi}{\partial n} = 0 \text{ in } \partial\Omega\},$$

$$A\phi = -d\Delta\phi + \gamma\phi \quad \forall \phi \in D(A).$$

This operator is sectorial, and we can define its fractional powers A^α, $0 \leq \alpha$, and the associated fractional power spaces $X^\alpha = D(A^\alpha)$ endowed with the graph norm. We will be concerned only with $\alpha < 1$.

It is well known that under some growth assumptions on the nonlinearity f, the problem (1.1) has a global attractor in $H^1(\Omega)$. More specifically, if f satisfies

$$|f(u) - f(v)| \leq c(e^{\theta|u|^\eta} + e^{\theta|v|^\eta})|u - v|, \quad \eta < 2 \text{ and } \theta > 0, \text{ if } n = 2,$$

$$|f(u) - f(v)| \leq c(1 + |u|^2 + |v|^2)|u - v| \quad \text{if } n = 3,$$

then the problem (1.1) has a global attractor in $H^1(\Omega)$. (See, for example, Hale [14], Hale and Raugel [15], Carvalho [3], and Carvalho and Oliveira [5].)

These growth assumptions are necessary to obtain local existence of solutions for (1.1) and also play a role in obtaining some energy estimates necessary to guarantee that the solution operator for (1.1) defines a global dynamical system which is bounded dissipative.

It would be interesting to pose the problem (1.1) in a space where no growth assumption on the nonlinearity f was required for local existence and where we were able to prove the existence of a global attractor.

We will consider spaces X^α which are embedded in $L^\infty(\Omega)$. Our aim is to show that in such spaces the problem (1.1) has a global attractor and to obtain some good estimates for the size of the attractor in the uniform norm.

Hale [13] proved the existence of a local attractor for (1.1), which coincides with the embedding of the attractor for $\dot{u} = f(u)$ into the subspace of constant functions of X^α, $\alpha > \frac{3}{4}$, if the diffusion coefficient d is large (see also Hale and Rocha [16], [17] and Hale and Sakamoto [18]). However, the techniques employed by Hale [13] would only apply to global attractors if some a priori bound on the size of the absorbing set could be obtained and only if the diffusion coefficient is large (see Carvalho [3] and Carvalho and Oliveira [5]).

We prove the existence of a global attractor for the problem (1.1) regardless of the size of d. We also give uniform (with respect to d) bounds (in L^∞) on the size of the attractor which will make the results of Carvalho [3] and Carvalho and Oliveira [5] applicable to the case $\alpha \neq \frac{1}{2}$ as in Hale [13], Hale and Rocha [16], [17], and Hale and Sakamoto [18] (see also Fusco [11]).

To carry on this project, we need to obtain that the solution operator associated to (1.1) is globally defined, that orbits of bounded subsets of X^α under the flow defined by (1.1) are bounded subsets of X^α, and that there is a bounded set that attracts points of X^α. Since the solution operator associated to (1.1) is compact, Theorem 3.4.6 in Hale [14] would guarantee the existence of a global attractor.

Recall (see Hale [14], for example) that if $T(t) : X \to X$, $t \geq 0$, is a semigroup of transformations on a Banach space X, then a set $\mathcal{A}$ is an attractor if it is a compact invariant set that attracts a neighborhood $\mathcal{O}$ of itself; that is, $\mathcal{A}$ is compact, $T(t)\mathcal{A} = \mathcal{A}$ for $t \geq 0$, and there is a neighborhood $\mathcal{O}$ of $\mathcal{A}$ such that dist $(T(t)U, \mathcal{A}) \to 0$ as $t \to \infty$. The set $\mathcal{A}$ is a global attractor if it attracts each bounded set of X.

Next, we state our main results. Consider the following system of reaction diffusion equations with dispersion:

$$(1.1)' \qquad \begin{cases} u_t = D\Delta u - \gamma u + \sum_{j=1}^n B_j(x)\frac{\partial u}{\partial x_j} + f(u) & \text{in } \Omega, \\ \\ \dfrac{\partial u}{\partial n} = 0 & \text{in } \partial\Omega, \end{cases}$$

where $u = (u_1, u_2, \ldots, u_N)^\top$, $N \geq 1$, $D = \operatorname{diag}(d_1, \ldots, d_N)$, $d_i > 0$, $1 \leq i \leq N$, and $B_j = \operatorname{diag}(b_j^1, \ldots, b_j^N)$ is continuous in $\bar{\Omega}$, $1 \leq j \leq n$. The nonlinearity $f =$

$(f_1, \dots, f_N)^\top : \mathbb{R}^N \to \mathbb{R}^N$ is assumed to be a C^1 function that satisfies

$$\limsup_{|u_i| \to \infty} \frac{f_i(u)}{u_i} \leq -\delta < 0 \tag{1.3}$$

uniformly with respect to $\hat{u}_i = (u_1, \dots, u_{i-1}, u_{i+1}, \dots, u_N) \in \mathbb{R}^{N-1}$, $1 \leq i \leq N$. In §2, for suitable values of γ, we prove the following result.

THEOREM 1.1. *Under the above hypotheses, the solutions of* (1.1)′ *with initial data in* X^α *are globally defined and orbits of bounded subsets of* X^α *under the flow defined by* (1.1)′ *are also bounded subsets of* X^α.

In §3 we show the existence of a global attractor neglecting the dispersion terms in (1.1)′. Indeed, we prove the following theorem.

THEOREM 1.2. *Suppose that in* (1.1)′, $B_j \equiv 0$, $1 \leq j \leq n$. *Then the solution operator* $\{T(t), t \geq 0\}$ *for* (1.1)′ *is point dissipative and therefore it has a global attractor.*

In §4 we consider the structure of gradient systems that such problems have and prove the next theorem.

THEOREM 1.3. *Let* $\Sigma_i = [-\bar{\xi}_i, \xi_i]$, *where* ξ_i, $\bar{\xi}_i$ *are positive constants,* $1 \leq i \leq N$. *If* $s_i f_i(u_1, \dots, u_{i-1}, s, u_{i+1}, \dots, u_N) < 0$ *whenever* $s_i \notin \Sigma_i$, *then* $\phi(x) \in \Sigma := \Sigma_1 \times \cdots \times \Sigma_N$, $\forall x \in \Omega$, *and* $\forall \phi \in \mathcal{A}$.

Finally, in §5 we consider applications to a class of cooperative systems arising from thin domain problems around a point.

The tools employed are the invariance theory as in Henry [19] and the theory of invariant regions of Chueh, Conley, and Smoller [7].

We believe that the hypothesis (1.2) can be relaxed a little to include the case when the nonlinearity f satisfies $s f(s) - \gamma s^2 < 0$, $|s| \geq \xi$, for some $\xi > 0$. However, we have not been able to prove that, in this case, orbits of bounded subsets of X^α under the flow defined by (1.1) are bounded subsets of X^α.

We remark that other boundary conditions can be considered with little change; hence, we will restrict the presentation to the homogeneous Neumann boundary conditions case. We also remark that if the nonlinearity depends on the spatial variable, the results hold with almost no change in the proofs.

The following result identifies the values of α that we will be considering; its proof can be found in Henry [19, Thm. 1.6.1].

THEOREM 1.4. *Suppose that* $\Omega \subset \mathbb{R}^n$ *is an open bounded set with smooth boundary. Then for* $0 \leq \alpha \leq 1$,

$$X^\alpha \subset W^{1,2}(\Omega) \quad \textit{when} \quad \frac{1}{2} \leq \alpha,$$

$$X^\alpha \subset C^\nu(\Omega) \quad \textit{when} \quad 0 \leq \nu + \frac{n}{2} < 2\alpha.$$

Furthermore, the embedding is compact whenever the inequality is strict.

Therefore, if we assume that $\alpha > \max\{\frac{n}{4}, \frac{1}{2}\}$ for $n = 2, 3$, or $\alpha \geq \frac{1}{2}$ for $n = 1$, we have that

$$X^\alpha \subset H^1(\Omega) \cap L^\infty(\Omega). \tag{1.4}$$

Hereafter we assume that (1.4) holds. The next lemma is the main reason why we are interested in working with such spaces.

LEMMA 1.5. *Let $f : \mathbb{R} \to \mathbb{R}$ be a C^1 function and $f^e : X^\alpha \to X$ be the map defined by*

$$f^e(\phi)(x) = f(\phi(x)).$$

Then, f^e is a well-defined compact map which is Lipschitz continuous in bounded sets of X^α. Furthermore, for any $r > 0$ there exists a constant N_1, depending only on r, such that

$$\|f^e(\phi)\|_{L^\infty(\Omega)} \leq N_1,$$

whenever $\|\phi\|_X^\alpha \leq r$.

The proof of this result is rather trivial and we omit it. This lemma states that the problem (1.1) is locally well posed in X^α even if no growth assumption is made on the nonlinearity f.

2. Proof of Theorem 1.1. In this section we prove that solutions of (1.1)′ with initial data in X^α are globally defined and that orbits of bounded subsets of X^α under the flow defined by (1.1)′ are also bounded subsets of X^α. To prove this result, we will use the following lemma.

LEMMA 2.1. *Let A be a sectorial operator and $f^e : X^\alpha \to X$ be a bounded map which is Lipschitz continuous in bounded subsets of X^α. Then, the problem*

$$\begin{aligned} &\dot{u} + Au = f^e(u), \\ &u(0) = u_0 \in X^\alpha, \end{aligned} \tag{2.1}$$

has a local solution $T(t)u_0$ defined in a maximal interval of existence $[0, t_{\max})$. Furthermore, either $\|T(t)u_0\|_\alpha \to \infty$ when $t \to \infty$ or $t_{\max} = +\infty$.

For a proof of this lemma see Henry [19]. We observe that it is not enough that the nonlinearity f^e be locally Lipschitz continuous. We assume that f is Lipschitz continuous in bounded sets, which is suitable for our applications. Some extra hypothesis is necessary because the phase space is not locally compact.

We know that $A = \operatorname{diag}(A_1, \ldots, A_N)$ defined by

$$D(A_i) = \{\phi \in H^2(\Omega) : \tfrac{\partial \phi}{\partial n} = 0\},$$

$$-A_i\phi = d_i\Delta\phi - \gamma\phi + \textstyle\sum_{j=1}^n b_j^i(x)\frac{\partial \phi}{\partial x_j},$$

generates an analytic semigroup on X^α and that it satisfies the following estimates:

$$\begin{aligned} &\|e^{-At}u_0\|_X^\alpha \leq Me^{-\epsilon t}\|u_0\|_X^\alpha, \quad t \geq 0, \\ &\|e^{-At}u_0\|_X^\alpha \leq Me^{-\epsilon t}t^{-\alpha}\|u_0\|_X, \quad t > 0 \end{aligned} \tag{2.2}$$

for some $\epsilon > 0$, $M \geq 1$.

By writing the problem (1.1)′ in the form (2.1) and using the variation of constants formula, we can view its solution through $u_0 \in X^\alpha$ as

$$T(t)u_0 = e^{-At}u_0 + \int_0^t e^{-A(t-s)}f^e(T(s)u_0)ds,$$

where $(f^e(\phi))(x) = f(\phi(x))$ for all $\phi \in X^\alpha$. If $\|T(t)u_0\|_{L^\infty(\Omega)} \leq N_1$, $t \in [0, t_{\max})$ for some $N_1 > 0$, we have that

$$\|T(t)u_0\|_X^\alpha \leq M\|u_0\|_\alpha e^{-\epsilon t} + MK\int_0^t e^{-\epsilon(t-s)}(t-s)^{-\alpha}ds, \tag{2.3}$$

where $K = \sup_{t\in[0,t_{\max})} \|f^e(T(t)u_0)\|_{L^2(\Omega)}$. Therefore, if we are able to obtain estimates in $L^\infty(\Omega)$ for $T(t)u_0$, $0 \le t < t_{\max}$, a similar estimate can be obtained in X^α and the solutions are globally defined.

To obtain such estimates in $L^\infty(\Omega)$ we introduce the notion of invariant regions as in Smoller [24].

DEFINITION 2.2. *A set $\Sigma \subset \mathbb{R}^N$ is called a positively invariant region for the local solution of (1.1)′ if any solution $T(t)u_0$ that satisfies $u_0(x) \in \Sigma$, $\forall x \in \Omega$ is such that $(T(t)u_0)(x) \in \Sigma$, $\forall x \in \Omega$ and for all t in the maximal interval of existence of the solution.*

Our next result characterizes some of the invariant regions of the problem (1.1)′. Its proof follows Smoller [24] and is presented here for the sake of completeness.

THEOREM 2.3. *Let $\bar\xi_j$, $\xi_j > 0$, $1 \le j \le N$ be such that $u_j f_j(u) < 0$ for all $u \in \mathbb{R}^N$ with $u_j \notin [-\bar\xi_j, \xi_j]$. Then the rectangle $\Sigma = [-\bar\xi_1, \xi_1] \times [-\bar\xi_2, \xi_2] \times \cdots \times [-\bar\xi_N, \xi_N]$ is an invariant region for the local solution of (1.1)′.*

Proof. If there is a solution $v(x,t) = (v^1(x,t), v^2(x,t), \dots, v^N(x,t))$ of (1.1)′ with initial data $v(x,0) = (v^1(x,0), v^2(x,0), \dots, v^N(x,0)) \in \Sigma$ for all $x \in \bar\Omega$, that does not stay in $\Sigma_1 = (-\infty, \xi_1] \times \mathbb{R}^{N-1}$ for all $t \in [0, t_{\max})$, then there is a t_0 and $x_0 \in \Omega$ such that

$$v^1(x,t) < \xi_1, \quad 0 \le t < t_0, \quad x \in \Omega, \quad \text{and} \quad v^1(x_0,t_0) = \xi_1.$$

We observe that x_0 need not to be in Ω. If this is the case, by a change of variables we can assume that $\frac{\partial u}{\partial n} = -\zeta < 0$. Then the maximum happens in Ω and the theorem will follow if we let $\zeta \to 0$.

Therefore, if $v^1(x_0,t) < \xi_1, \forall t \in [0,t_0)$ and $v^1(x_0,t_0) = \xi_1$ implies that $v^1_t(x_0,t_0) < 0$, then Σ_1 is invariant.

Consider the following:

$$v^1_t(x_0,t_0) = d_1 \Delta v^1(x_0,t_0) - \gamma v^1(x_0,t_0) + \sum_{j=1}^{n} B^1_j(x_0) \frac{\partial v^1}{\partial x_j}(x_0,t_0) + f_1(v(x_0,t_0)). \tag{2.4}$$

We claim that $\nabla v^1 = 0$ at (x_0,t_0). In fact, if $\frac{\partial v^1}{\partial x_i} > 0$ at (x_0,t_0) for some $1 \le i \le n$, then $v^1(x_0,t_0) = \xi_1$ and $v^1(x,t_0) > \xi_1$ for some x with $|x - x_0|$ small. This implies that $v^1(x,t) > \xi_1$ for x near x_0 and $t < t_0$ near t. This contradicts the definition of t_0 and $\frac{\partial v^1}{\partial x_i} \le 0$. By using the same reasoning, we obtain that $\frac{\partial v^1}{\partial x_i} < 0$ at (x_0,t_0) for some $1 \le i \le n$ leads to a contradiction and the claim is proved.

Similarly, $v^1_{x_i x_i} \le 0$ for all $1 \le i \le n$. Therefore, $\Delta v^1(x_0,t_0) \le 0$. From expression (2.4), we have that

$$v^1_t(x_0,t_0) \le f_1(v(x_0,t_0)) - \gamma v^1(x_0,t_0).$$

Since $f_1(v(x_0,t_0)) - \gamma v^1(x_0,t_0) < 0$, we conclude that $v^1_t(x_0,t_0) < 0$.

From the reasoning at the beginning of the proof we have that $(-\infty, \xi_1] \times \mathbb{R}^{N-1}$ is an invariant region for the local solution of (1.1)′. In the same way, we obtain that $[-\xi_1, \infty) \times \mathbb{R}^{N-1}$ is also an invariant region. From the fact that the intersection of invariant regions is still invariant, the proof is completed. □

This theorem shows that for any $u_0 \in X^\alpha$ the local solution $T(t)u_0$ of (1.1)′ through u_0 satisfies

$$\|T(t)u_0\|_{L^\infty(\Omega)} \le N_1$$

for some $N_1 > 0$, whenever defined.

It follows from both Lemma 2.1 and expression (2.4) that the problem (1.1)′ defines a global dynamical system in X^α.

Since the semigroup generated by A satisfies (2.2) for some $\epsilon > 0$, our following computations show that orbits of bounded subsets of X^α are bounded subsets of X^α. To do this, we resort once more to the variation of constants formula and to Lemma 2.1.

Let B be a bounded subset of X^α. From the fact that X^α is embedded in $L^\infty(\Omega)$ and from the variation of constant formula, we have that there are constants $K_i > 0$, $1 \leq i \leq 4$ depending only on B such that

$$\begin{aligned}\|T(t)u_0\|_X^\alpha &\leq K_1 + K_2 \int_0^t (t-s)^{-\alpha} e^{-\epsilon(t-s)} \|f(T(s)u_0)\|_{L^\infty(\Omega)} ds \\ &\leq K_1 + K_3 \int_0^t (t-s)^{-\alpha} e^{-\epsilon(t-s)} ds\end{aligned}$$

$\forall t \geq 0$ and $\forall u_0 \in B$. We used that $\|T(t)u_0\|_{L^\infty(\Omega)} \leq K_4$, which follows from the embedding of X^α into $L^\infty(\Omega)$ and from Theorem 2.3. This proves Theorem 1.1.

In what follows, we consider an example of a reaction-diffusion equation with dispersion for which we know that orbits of bounded sets are bounded.

Consider a system of reaction-diffusion equations of chemical kinetics (see, for example, Chueh, Conley, and Smoller [7])

$$\begin{aligned} w_t &= d_1 \Delta w + \textstyle\sum_{i=1}^n \beta_i^1 \frac{\partial w}{\partial x_i} + g(w,v) \qquad \text{in} \quad \Omega, \\ v_t &= d_1 \Delta v + \textstyle\sum_{i=1}^n \beta_i^2 \frac{\partial v}{\partial x_i} + h(w,v) \qquad \text{in} \quad \Omega, \\ \frac{\partial w}{\partial n} &= \frac{\partial v}{\partial n} = 0 \qquad \text{in} \quad \partial\Omega, \end{aligned} \tag{2.5}$$

where $\Omega \subset \mathbb{R}^n$, $n \leq 3$ is as in §1, and $f, g : \mathbb{R}^2 \to \mathbb{R}$ are C^1-functions that satisfy

$$\limsup_{|u|\to\infty} \frac{g(u,v)}{u} = -\infty, \qquad \limsup_{|v|\to\infty} \frac{h(u,v)}{v} = -\infty,$$

where the first limit is uniform with respect to v and the second is uniform with respect to w.

Then the system (2.5) can be rewritten as

$$\begin{aligned} u_t &= D\Delta u - \gamma u + \textstyle\sum_{j=1}^n B_j \frac{\partial u}{\partial x_j} + f(u) \quad \text{in} \quad \Omega, \\ \frac{\partial u}{\partial n} &= 0 \quad \text{in} \quad \partial\Omega, \end{aligned}$$

where

$$u = (w,v)^\top \in \mathbb{R}^2, \quad B_j = \operatorname{diag}(\beta_j^1, \beta_j^2), \quad f(u) = \begin{pmatrix} g(w) + \gamma w \\ h(v) + \gamma v \end{pmatrix} : \mathbb{R}^2 \to \mathbb{R}^2$$

satisfy (1.3) and γ is chosen as follows.

Consider the operator A defined by $A = \operatorname{diag}(A_1, A_2)$,

$$D(A_j) = \{\phi \in H^2(\Omega) : \tfrac{\partial \phi}{\partial n} = 0\},$$

$$A_j \phi = d_j \Delta \phi - \gamma \phi + \textstyle\sum_{i=1}^n \beta_i^j \frac{\partial \phi}{\partial x_i}, \quad j = 1, 2.$$

Let γ be such that the analytic semigroup generated by A decays exponentially to zero as $t \to \infty$. The results in this section imply that the solution operator $S(t)$ for (2.5) is defined globally and orbits of bounded sets under $\{S(t) : t \geq 0\}$ are bounded subsets of X^α.

3. Proof of Theorem 1.2. In this section we use the invariance theory as in Henry [19] to prove that there is a bounded set in X^α which attracts points of X^α. Unfortunately, the techniques employed in this section will not work for systems of reaction-diffusion equations with dispersion due to the fact that we will not be able to find a Lyapunov function for such systems. We state the results of the invariance theory that we will use by starting with the definition of Lyapunov function.

DEFINITION 3.1. *Let $\{S(t),\ t \geq 0\}$ be a dynamical system on X^α. A Lyapunov function is a continuous, real-valued function $V : X^\alpha \to \mathbb{R}$ such that*

$$\dot{V}(\phi) = \limsup_{t \to 0^+} \frac{V(S(t)\phi) - V(\phi)}{t} \leq 0$$

for all $\phi \in X^\alpha$.

The next theorem is a classical result from invariance theory and will be the main tool in the proof of point dissipativeness.

THEOREM 3.2. *Suppose that $u_0 \in X^\alpha$ and $\{S(t)u_0,\ t \geq 0\}$ lies in a compact set in X^α, then $\omega(u_0)$ is nonempty, compact, invariant, connected, and dist$(S(t)u_0, \omega(u_0)) \to 0$ as $t \to +\infty$.*

The following result has a classical and simple proof but we present it to make sure that our Lyapunov function (see later in this section) is suitable.

THEOREM 3.3. *Let V be a Lyapunov function on X^α and define $E = \{\phi \in X^\alpha : \dot{V}(\phi) = 0\}$, $\mathcal{M}$ the maximal invariant subset of E. If $\{S(t)u_0,\ t \geq 0\}$ lies in a compact set in X^α, then $S(t)u_0 \to \mathcal{M}$ as $t \to +\infty$.*

Proof. By hypothesis, $V(S(t)u_0)$ is nonincreasing for $t \geq 0$ and is bounded below (since orbits of points are precompact) so that $\ell = \lim_{t \to \infty} V(S(t)u_0)$ exists. If $y \in \omega(u_0)$, then $V(y) = \ell$, so also $V(S(t)y) = \ell$, $t \geq 0$, and so $\dot{V}(y) = 0$. Thus $\omega(u_0) \subset E$, so $\omega(u_0) \subset \mathcal{M}$ and the result is proved. □

We will apply these results and the results of §2 to obtain the existence of a global attractor for systems of reaction-diffusion equations without dispersion, that is, we consider the problem

$$(1.1)'' \qquad \begin{cases} u_t = D\Delta u - \gamma u + f(u), & \text{in } \Omega, \\ \dfrac{\partial u}{\partial n} = 0, & \text{in } \partial\Omega, \end{cases}$$

where $u = (u_1, u_2, \ldots, u_N)^\top$, $N \geq 1$, $D = \operatorname{diag}(d_1, \ldots, d_N)$, $d_i > 0$, $1 \leq i \leq N$, and $\gamma > 0$. The nonlinearity $f = (f_1, \ldots, f_N)^\top : \mathbb{R}^N \to \mathbb{R}^N$ is assumed to be a C^1 function that satisfies (1.3) and

$$(3.1) \qquad \frac{\partial f_i(u)}{\partial u_j} = \frac{\partial f_j(u)}{\partial u_i} \quad \forall u \in \mathbb{R}^N.$$

To prove that the solution operator for $(1.1)''$ is point dissipative, we must first prove that the orbit of a point $\phi \in X^\alpha$ is a compact subset of X^α. This is a consequence of the following result.

THEOREM 3.4. *In the problem (2.1) assume that the nonlinearity f^e is Lipschitz continuous in bounded subsets of X^α and that A is a sectorial operator with compact*

resolvent. If $T(t)\phi$ is a solution of (1.1)$''$ on $[0,\infty)$ with $\|T(t)\phi\|_\alpha$ bounded as $t \to \infty$, then $\{T(t)\phi,\ t \geq 0\}$ is a compact subset of X^α. Furthermore, if B is a bounded subset of X^α and $T(t)B$ remains in a bounded subset of X^α as $t \to \infty$, then $\{T(t)B,\ t \geq 1\}$ is a compact subset of X^α.

The proof of the above result is very simple and can be easily adapted from Henry [19, Thm. 3.3.6].

Now since all the hypotheses of Theorem 3.4 are satisfied for problem (1.1)$''$, we can conclude that orbits of points under the flow defined by (1.1)$''$ are compact subsets of X^α. From Theorem 3.2 the ω limit set of any point u_0 is a nonempty, compact, invariant set that attracts u_0 under the flow defined by (1.1)$''$.

From Theorem 3.3 we know that the set $\mathcal{M}$ attracts points of X^α. We need to find a Lyapunov function V for which E is a bounded subset of X^α; point dissipativeness will follow.

Let $V : X^\alpha \to \mathbb{R}$ be the function defined by

$$V(\phi) = \frac{1}{2}\int_\Omega \langle D\nabla\phi, \nabla\phi\rangle dx + \frac{\gamma}{2}\int_\Omega |\phi|^2 dx - \int_\Omega F(\phi)dx,$$

where $F : \mathbb{R}^N \to \mathbb{R}$ is such that $\nabla_u F(u) = f(u)$. Then V is continuous and

$$\dot{V}(\phi) \leq 0 \quad \forall \phi \in X^\alpha.$$

Therefore, we must prove that $E = \{\phi \in X^\alpha : \dot{V}(\phi) = 0\}$ is a bounded set in X^α.

The set E is the set of equilibrium points of (1.1)$''$ and therefore any function $\phi \in E$ *must satisfy* $\phi \in X^\alpha$ and

$$\text{(3.2)} \qquad \begin{cases} D\Delta\phi - \gamma\phi + f(\phi) = 0 & \text{in } \Omega, \\ \frac{\partial\phi}{\partial n} = 0 & \text{in } \partial\Omega. \end{cases}$$

To prove that E is a bounded subset of X^α we proceed in the following way. First we prove that there exists a constant $c > 0$ such that $\|\phi\|_{L^\infty(\Omega,\mathbb{R}^N)} \leq c\ \forall \phi \in E$ and then we use (3.2) to prove that $\|D\Delta\phi\|_{L^\infty(\Omega,\mathbb{R}^N)} \leq \max_{|s|\leq c} |-\gamma s + f(s)|$. The result will follow.

LEMMA 3.5. *There exists a constant $\xi > 0$ such that $\|\phi\|_{L^\infty(\Omega,\mathbb{R}^N)} \leq \xi$ for every $\phi \in E$.*

Proof. Let ξ_i be such that $sf(u_1,\ldots,u_{i-1},s,u_{i+1},\ldots,u_N) < 0\ \forall s$ such that $|s| \geq \xi_i$. Then suppose that $\phi := (\phi_1,\ldots,\phi_N) \in E$ and that $\max_{x\in\bar{\Omega}} \phi_k(x) = \phi_k(y) \geq \xi_k$ for some k. Thus, at y

$$\phi_k d_k \Delta\phi_k - \gamma\phi_k^2 + \phi_k f_k(\phi) = 0$$

and $\Delta\phi_k > 0$ since $\xi_k > 0$, but $\Delta\phi_k(y) \leq 0$ (if $y \notin \Omega$ we proceed as in Theorem 2.3). This is a contradiction and $\max_{x\in\bar{\Omega}} \phi_k(x) \leq \xi_k$, $1 \leq k \leq N$. In the same way we obtain that $\min_{x\in\bar{\Omega}} \phi_k(x) \geq -\xi_k$, $1 \leq k \leq N$, and the result is proved. □

COROLLARY 3.6. *The set E is a compact subset of X^α.*

Remark. It is very important, for some applications, to be able to obtain some a priori estimates that do not depend on the size of the diffusion coefficient. See, for example, Carvalho [3] and Carvalho and Oliveira [5]. This is an advantage that this technique (i.e., the use of invariant regions) has over the techniques employed in Hale [14, p. 77], even in the case $\alpha = \frac{1}{2}$. The estimates obtained there for the size of E strongly depend on the size of the diffusion coefficient. It is also important to obtain

good $L^\infty(\Omega)$ bounds on the attractor. Since models are an approximation of a real phenomenon, it is important to know that at least in a neighborhood of the attractor the approximation must be as accurate as we can get; outside this set it does not matter much.

COROLLARY 3.7 (Theorem 1.2). *The solution operator* $\{T(t),\ t \geq 0\}$ *for* (1.1)″ *is point dissipative and therefore has a global attractor.*

The proof of point dissipativeness follows from Theorem 3.3 and Corollary 3.6 and the proof of existence of a global attractor follows from the results in this section, §2, and Theorem 3.4.6 in Hale [14].

4. Proof of Theorem 1.3. In this section we consider the possibility that the problem (1.1) has the structure that the so-called gradient systems have. Such a special class of dynamical systems, for which the flow on the attractor can be better understood, are considered, for example, in Hale [14].

DEFINITION 4.1. *Let* Y *be a Banach space. A strongly continuous* C^r *semigroup* $T(t): Y \to Y$, $t \geq 0$, $r \geq 0$, *is said to be a gradient system if*

1. *Each bounded positive orbit is precompact.*

2. *There exists a Lyapunov function for* $T(t)$; *that is, there is a continuous function* $V: Y \to \mathbb{R}$ *with the property that*

(i) $V(y)$ *is bounded below,*

(ii) $V(u) \to \infty$ *as* $\|y\|_Y \to \infty$,

(iii) $V(T(t)y)$ *is nonincreasing in* t *for each* $y \in Y$,

(iv) *If* y *is such that* $T(t)y$ *is defined for* $t \in \mathbb{R}$ *and* $V(T(t)y) = V(y)$ *for* $t \in \mathbb{R}$, *then* y *is an equilibrium point.*

Observe that the Lyapunov function defined in §3 does not satisfy property 2 (ii). However, we still obtain that the dynamics in the attractor for (1.1) can be described as well as the dynamics of a gradient system.

To obtain these results we consider an auxiliary system, namely

$$\text{(4.1)} \qquad \begin{cases} u_t = D\Delta u - \gamma u + \tilde{f}(u) & \text{in} \quad \Omega, \\ \dfrac{\partial u}{\partial n} = 0 & \text{in} \quad \partial\Omega, \end{cases}$$

where $\tilde{f}$ is obtained from f in the following way. The attractor $\mathcal{A}$ for (1.1) in X^α is a bounded subset of $L^\infty(\Omega, \mathbb{R}^N)$ and therefore we can cut the nonlinearity f in such a way that all the properties of f are preserved. In addition, $\tilde{f}$ is globally Lipschitz continuous and the dynamics in the attractor remain unchanged. That is, the problem (4.1) has a global attractor in X^α which coincides with $\mathcal{A}$.

The problem (4.1) is well posed in $X^{1/2}$ and has an attractor $\tilde{\mathcal{A}}$ in $X^{1/2}$. Therefore we must have $\mathcal{A} \subset \tilde{\mathcal{A}}$. Since $\tilde{\mathcal{A}} \subset X^\alpha$ and we have that it is invariant, it must be contained in $\mathcal{A}$ and they are the same. This reasoning proves the following result.

THEOREM 4.2. *If* $\{T(t), t \geq 0\}$ *is the semigroup defined by* (1.1) *in* X^α, $\mathcal{A}$ *denotes its attractor, and* E *the set of equilibrium points, then* $\mathcal{A} = W^u(E) = \{y \in X^\alpha : T(-t)y$ *is defined for* $t \geq 0$ *and* $T(-t)y \to E$ *as* $t \to \infty\}$. *If, in addition, every element of* E *is hyperbolic, then* E *is a finite set and* $\mathcal{A} = \cup_{x \in E} W^u(x)$.

COROLLARY 4.3 (Theorem 1.3). *Let* $\Sigma_i = [-\bar{\xi}_i, \xi_i]$, *where* $\xi_i, \bar{\xi}_i$ *are positive constants,* $1 \leq i \leq N$. *If* $s_i f_i(u_1, \ldots, u_{i-1}, s, u_{i+1}, \ldots, u_N) < 0$ *whenever* $s_i \notin \Sigma_i$, *then* $\phi(x) \in \Sigma := \Sigma_1 \times \cdots \times \Sigma_N$, $\forall x \in \Omega$ *and* $\forall \phi \in \mathcal{A}$.

Proof. The proof of this result follows in two steps. First we observe that the equilibrium points satisfy that $\phi(x) \in \Sigma$, $\forall x \in \Omega$ (as in Lemma 3.5). The second

part follows from the fact that the α limit set of points in $\mathcal{A}$ are subsets of the set of equilibrium points and that any rectangle containing Σ is invariant. More specifically, let $\epsilon > 0$ and Σ_ϵ be an ϵ neighborhood of Σ. If $\phi \in \Sigma_\epsilon$, then there is a $\tau < 0$ and $e \in E$ such that $\|T(\tau)\phi - e\|_{L^\infty(\Omega,\mathbb{R}^N)} \leq K\|T(\tau)\phi - e\|_X^\alpha < \frac{\epsilon}{2}$, where K is the embedding constant of $X^\alpha \subset L^\infty(\Omega, \mathbb{R}^N)$. This implies that $(T(\tau)\phi)(x) \in \Sigma_\epsilon$, $\forall x \in \bar{\Omega}$. Since Σ_ϵ is invariant we have that $\phi \in \Sigma_\epsilon$.

This proves that for any $\epsilon > 0$ and $\phi \in \mathcal{A}$, $\phi(x) \in \Sigma_\epsilon$ $\forall x \in \bar{\Omega}$. The result follows. □

5. Systems arising from thin domains problems. In this section we consider a class of systems of weakly coupled parabolic partial differential equations of the form

$$\begin{cases} u_t = D\Delta u - \tilde{A}u + f(u) & \text{in } \Omega, \\ \dfrac{\partial u}{\partial n} = 0 & \text{in } \partial\Omega, \end{cases} \tag{5.1}$$

where $u = (u_1, u_2, \ldots, u_N)^\top$, $N \geq 1$, $D = \operatorname{diag}(d_1, \ldots, d_N)$, $d_i > 0$, $1 \leq i \leq N$ and the nonlinearity $f := (f_1(u), \ldots, f_N(u))^\top : \mathbb{R}^N \to \mathbb{R}^N$ is assumed to be a C^1 function that satisfies

$$u_i f_i(u) < 0 \qquad \forall u \in \mathbb{R}^N, \quad u_i \notin [\bar{\xi}, \xi], \quad 1 \leq i \leq N. \tag{5.2}$$

The matrix $\tilde{A}$ is taken as $\tilde{A} = M^{-1}B$ where $M = \operatorname{diag}(L_1, \ldots, L_N)$, with $0 \leq L_i \leq 1$ for $1 \leq i \leq N$ and B is the tridiagonal symmetric matrix

$$B = \begin{bmatrix} m_1 & r_1 & 0 & 0 & 0 & \cdots & 0 & 0 \\ r_1 & m_2 & r_2 & 0 & 0 & \cdots & 0 & 0 \\ 0 & r_2 & m_3 & r_3 & 0 & \cdots & 0 & 0 \\ 0 & 0 & r_3 & m_4 & r_4 & \cdots & 0 & 0 \\ \vdots & \vdots & & \ddots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & & & \cdots & 0 & 0 \\ 0 & 0 & \cdots & 0 & r_{N-3} & m_{N-2} & r_{N-2} & 0 \\ 0 & 0 & \cdots & 0 & 0 & r_{N-2} & m_{N-1} & r_{N-1} \\ 0 & 0 & \cdots & 0 & 0 & 0 & r_{N-1} & m_N \end{bmatrix}, \tag{5.3}$$

where

$$\begin{aligned} m_1 &= \tfrac{a_2}{2l_2} + \tfrac{a_1\rho}{\rho l_1 + a_1(1-\rho)}, \\ m_N &= \tfrac{a_N}{2l_N} + \tfrac{a_{N+1}\sigma}{\sigma l_{N+1} + a_{N+1}(1-\sigma)}, \\ m_k &= \tfrac{a_k}{2l_k} + \tfrac{a_{k+1}}{2l_{k+1}}, \quad k = 2, \ldots, N-1, \\ r_k &= \tfrac{-a_{k+1}}{2l_{k+1}}, \quad k = 1, \ldots, N-1, \end{aligned}$$

and $a_k > 0$, $l_k > 0$ for $1 \leq k \leq N+1$. This problem arises as a limiting problem for reaction-diffusion equations in thin domains around a point. (See Hale and Raugel [15], Carvalho [3], and Carvalho and Oliveira[5] for details.)

To prove that problem (5.1) has a global attractor we have to obtain an invariant region for equation (5.1) as in Theorem 2.3, find a Lyapunov function for it, and show that the set of equilibrium solutions are bounded in the $L^\infty(\Omega)$ norm as in §3.

Assume that f satisfies (3.1). Let $F : \mathbb{R}^N \to \mathbb{R}$ be such that

$$\nabla_u F(u) = f(u)$$

and $V : X^\alpha \to \mathbb{R}$ be the function defined by

$$V(\phi) = \int_\Omega \left(\sum_{i=1}^N \frac{d_i}{2} \|\nabla \phi_i\|^2 + \langle \tilde{A}\phi, \phi \rangle + F(\phi) \right) dx,$$

where $\langle \cdot, \cdot \rangle$ stands for the usual inner product in $\mathbb{R}^n$.

The function V is continuous and

$$\dot{V}(\phi) \leq 0 \quad \forall \phi \in X^\alpha.$$

Thus if $\phi \in E = \{\phi \in X^\alpha : \dot{V}(\phi) = 0\}$ we have that $\phi \in X^\alpha$ and

$$\begin{cases} D\Delta\phi - \tilde{A}\phi + f(\phi) = 0 & \text{in } \Omega, \\ \dfrac{\partial \phi}{\partial n} = 0 & \text{in } \partial\Omega. \end{cases} \tag{5.4}$$

We now prove the $L^\infty(\Omega)$ boundedness of the equilibrium solutions and the existence of the invariant regions for (5.1).

The following result is a consequence of the theory of invariant regions (see Smoller [24, p. 202]) and appears in Carvalho and Oliveira [5] when Ω is an interval.

LEMMA 5.1. *The rectangle* $[\bar{\rho}, \rho]^N$ *is an invariant region for* (5.1) *whenever* $\bar{\rho} \geq \bar{\xi}$ *and* $\rho \geq \xi$.

To prove that E is a bounded subset of X^α we proceed as in §3. First we prove that there exists a constant $c > 0$ such that $\|\phi\|_{L^\infty(\Omega, \mathbb{R}^N)} \leq c \quad \forall \phi \in E$ and then we obtain that

$$\|D\Delta\phi - \tilde{A}\phi\|_{L^\infty(\Omega, \mathbb{R}^N)} \leq \tilde{c} \quad \forall \phi \in E.$$

LEMMA 5.2. *If* E *is the set of equilibrium solutions of* (5.1) *there exists a constant* $\xi > 0$ *such that* $\|\phi\|_{L^\infty(\Omega)} \leq \xi$ *for every* $\phi \in E$.

Proof. Let ξ be such that $s_j f_j(s) < 0 \ \forall s$ such that $|s_j| \geq \xi$. Suppose that $\phi := (\phi_1, \phi_2, \ldots, \phi_N) \in E$ and let $\max_{x \in \bar{\Omega}} \phi_j(x) = \phi_j(y_j)$ (if $y_j \notin \Omega$ we proceed as in Theorem 2.3). We claim that $\phi_j(y_j) \leq \xi$ for all j.

Suppose $\phi_j(y_j) \leq \xi$ for $j = 1, 2, \ldots, k-1$ and $\phi_k(y_k) > \xi$ for some $1 \leq k \leq N$. From the kth equation we obtain

$$0 = \phi_k(y_k) d_k \Delta\phi_k(y_k) - \tfrac{r_k}{L_k} \phi_k(y_k)[\phi_{k+1}(y_k) - \phi_k(y_k)]$$

$$+ \tfrac{r_{k-1}}{L_k} \phi_k(y_k)[\phi_k(y_k) - \phi_{k-1}(y_k)] + \phi_k(y_k) f_k(\phi).$$

At y_k the maximum principle implies (see Protter and Weinberger [23, p. 65])

$$\phi_k(y_k) d_k \Delta\phi_k(y_k) \leq 0$$

and

$$\phi_k(y_k) f_k(\phi(y_k)) < 0.$$

Since $\phi_{k-1}(y_k) \leq \phi_{k-1}(y_{k-1}) \leq \xi$, we also have

$$\frac{r_{k-1}}{L_k}\phi_k(y_k)[\phi_k(y_k) - \phi_{k-1}(y_k)] < \frac{r_{k-1}}{L_k}\phi_k(y_k)[\xi - \phi_{k-1}(y_{k-1})] \leq 0.$$

These inequalities together with (5.5) imply that

$$-\frac{r_k}{L_k}\phi_k(y_k)[\phi_{k+1}(y_k) - \phi_k(y_k)] > 0.$$

It follows that $\phi_{k+1}(y_k) > \phi_k(y_k)$ and

$$\begin{cases} \phi_{k+1}(y_{k+1}) \geq \phi_{k+1}(y_k) > \phi_k(y_k) > \xi, \\ \phi_{k+1}(y_{k+1}) \geq \phi_{k+1}(y_k) > \phi_k(y_k) \geq \phi_k(y_{k+1}). \end{cases}$$

Using the same argument through the $(N-1)$th equation we obtain

$$\begin{aligned} &\phi_N(y_N) > \xi, \\ &\phi_N(y_N) > \phi_{N-1}(y_N), \end{aligned}$$

and the Nth equation gives

$$0 = \phi_N(y_N)d_N\Delta\phi_N(y_N) - \tfrac{m_N - r_{N-1}}{L_N}\phi_N(y_N)[0 - \phi_N(y_N)]$$

$$+\tfrac{r_{N-1}}{L_N}\phi_N(y_N)[\phi_N(y_N) - \phi_{N-1}(y_N)] + \phi_N(y_N)f_N(\phi(y_N)).$$

The same reasoning as before implies that

$$-\frac{m_N - r_{N-1}}{L_N}(\phi_N(y_N))^2 > 0.$$

This contradiction implies $\max_{x\in\bar{\Omega}} \phi_j(x) \leq \xi$ for $1 \leq j \leq N$. In the same way we obtain that $\min_{x\in\bar{\Omega}} \phi_j(x) \geq -\xi$ for $1 \leq j \leq N$ and the result is proved. □

COROLLARY 5.3. *Suppose that* (3.1) *and* (5.2) *hold. Then the set E is a bounded subset of X^α, the solution operator $\{T(t), t \geq 0\}$ for* (5.1) *is point dissipative and has a global attractor $\mathcal{A}$. In addition,*

$$\phi(x) \in [\bar{\xi}, \xi]^N \quad \forall x \in \bar{\Omega}$$

for all $\phi \in \mathcal{A}$ and

$$\mathcal{A} = W^u(E).$$

Furthermore, if each element of E is hyperbolic, E is finite and

$$\mathcal{A} = \cup_{x\in E} W^u(x).$$

If in addition

$$\frac{\partial f_i}{\partial u_j} > 0 \quad \text{for} \quad i \neq j, \tag{5.5}$$

then (5.1) is a cooperative system if Ω is a convex domain (see Kishimoto and Weinberger [20]). For such systems the following result holds.

PROPOSITION 5.4. *Let $\bar{u}$ be a nonconstant equilibrium solution of* (5.1). *Suppose that* (5.5) *holds on the range of $\bar{u}$. Then $\bar{u}$ is unstable.*

COROLLARY 5.5. *If* (5.5) *holds in Σ, then every nonconstant equilibrium solution for* (5.1) *is unstable; that is, if $\bar{u} \in E$ is stable then $\bar{u}$ is constant.*

ON STABILITY OF A DYNAMICAL SYSTEM*

CHARLES S.C. LIN†, BIN YANG†, AND FUDONG CHEN†

Abstract. This note solves an open problem raised by Zeeman in [*Nonlinearity*, 1 (1988), pp. 115–155]. It extends his results about the stability of a dynamical system from C^∞-vector fields to C^m-vector fields, where $1 \leq m \leq \infty$. For any C^m-vector field v, the existence, uniqueness, and global attraction of the steady state of the Fokker–Planck equation in C^{m-1} space is proved. The steady states are used as a tool to classify vector fields. The density of stable C^m-vector fields is also proved.

Key words. dynamical system, stability, semigroup, positive operators, the Fokker–Planck equation, compact manifold

AMS subject classifications. 34C35, 47D05, 58F10

1. Introduction.

Given a vector field v on an oriented n-dimensional Riemannian manifold and $\epsilon > 0$, the time-dependent Fokker–Planck equation is given as follows:

$$\frac{du}{dt} = \epsilon \Delta u - \nabla \cdot (uv), \tag{1}$$

$$u(0) = u_0. \tag{2}$$

Zeeman proved that there is a smooth steady state u of the Fokker–Planck equation for a smooth vector field v on a connected compact Riemannian manifold without boundary cf. [1]. A new definition of stability of a dynamical system is introduced via the steady state. The new definition has a number of advantages over structural stability. Zeeman gave several good examples to compare the two stabilities. One of the advantages of the new definition is that stable vector fields are dense in the C^∞ topology; cf. [1] and [2].

In this paper we deal with C^m-vector fields on an oriented compact Riemannian manifold without boundary, where $1 \leq m < \infty$. The main results are as follows:

(i) For any C^m-vector field v, there is a unique steady state u of the Fokker–Planck equation in C^{m-1} space. Furthermore, all solutions tend to the steady state u.

(ii) The stable C^m-vector fields are dense in the space of C^m-vector field.

2. The steady state of the Fokker–Planck equation.

Let X be an oriented n-dimensional Riemannian manifold, and X connected compact without boundary. In what follows, we shall fix a chart on X. Let $k = (k_1, k_2, \ldots, k_n)$, $|k| = k_1 + k_2 + \cdots + k_n$, where k_i are integers for $i = 1, 2, \ldots, n$. Let C^m be the set of C^m-differentiable functions on X and $C^m(X)$ the space of C^m function with C^m topology defined on a chart by

$$\| u \|_m = \max \sum_{0 \leq |k| \leq m} \left| \frac{\partial^{|k|}}{\partial x^k} u \right|.$$

* Received by the editors October 8, 1992; accepted for publication (in revised form) September 14, 1993.

† Department of Mathematics, Statistics and Computer Science, University of Illinois at Chicago, Chicago, Illinois 60680.

Let

$$U^m = \left\{ u \in C^m; u \geq 0 \text{ and } \int_X u = 1 \right\}$$

and V^m be the space of all C^m-vector fields on X with C^m topology.

DEFINITION 1. *A solution $u^v(t)$ of equation (1) is called a* steady state *if $\frac{d}{dt}u^v(t) = 0$ and $u^v(t) \in U^{m+1}$.*

Given a C^m-vector field v and $\epsilon > 0$, we define the Fokker–Planck linear operator FP_v in $C^{m-1}(X)$ as follows:

$$FP_v u = \epsilon \Delta u - \nabla \cdot (uv), \tag{3}$$

$$D(FP_v) = \{u \in C^{m-1}(X); FP_v u \in C^{m-1}(X)\}. \tag{4}$$

We shall first recall some definitions needed for our results. A *cone* K in a Banach space Y is a closed subset of Y such that for any $\alpha > 0, \alpha K \subseteq K, K \cap (-K) = \{0\}$ and $K + K \subseteq K$.

A *positive operator* P (with respect to cone K) in Y is an operator in Y such that $P(K) \subseteq K$.

A positive operator P is called *strongly positive* if P maps every nonzero point in K onto the interior of K.

The following facts are known; cf. [1] and [3].

(i) There is a semigroup $G(t)$ of bounded linear operator in $C^{m-1}(X)$ with generator FP_v, i.e., the Fokker–Planck equation (1) has a solution $G(t)u_0$ for any $u_0 \in D(FP_v)$.

(ii) $G(t)$ has an expression of the form

$$G(t)u(x) = \int_X g(x, y, t)u(y)\, dy, \tag{5}$$

$$\int_X g(x, y, t)\, dx = 1, \tag{6}$$

where $g(x, y, t)$ is a solution of the Fokker–Planck equation (1) with initial condition $\delta(x - y)$.

(iii) $G(t)$ is a strongly positive operator on $C^{m-1}(X)$ and $G(t)U^{m+1} \subseteq U^{m+1}$ for any $t > 0$.

Therefore, in order to obtain the existence, uniqueness, and global attraction of the steady state of the Fokker–Planck equation, it is enough to prove the following theorem (cf. [1], [2], and [4]).

THEOREM 2.1. *The operator $G(t)$ is compact on $C^{m-1}(X)$ for all $t > 0$.*

To prove Theorem 2.1, we need several lemmas.

LEMMA 2.2. *Let $B = \{f \in C^m(X), \| f \|_m = 1\}$. An operator G is compact on $C^m(X)$ if $\{\frac{\partial^{|k|}}{\partial x^k}(Gf); f \in B\}$ is equicontinuous for all $0 \leq |k| \leq m$ and $\{\partial^{|k|}/\partial x^k(Gf)(x); f \in B\}$ is relatively compact in R for all x in a chart and $0 \leq |k| \leq m$.*

Proof. Applying Ascoli's theorem for each index k, we have a convergent subsequence $(\partial^{|k|}/\partial x^k)(Gf_{k_n}), n = 1, 2, \ldots$. Without loss of generality, by selecting a subsequence of a subsequence if necessary, we may assume there is a subsequence $(\partial^{|k|}/\partial x^k)(Gf_n)$ which is convergent in $C(X)$ for any index k. That implies Gf_n is a Cauchy sequence in $C^m(X)$. Hence, G is a compact operator on $C^m(X)$.

Let $h : R \to R$ be given by $h(r) = e^{-r^2/2}$. It is easy to check that $h^{(l)}(r) = h(r)p_l(r)$, where $p_l(r)$ is a polynomial of degree l. Therefore, Lemma 2.3 is trivial.

LEMMA 2.3. *There is a constant $M > 0$ such that*

$$\max_{r \in R} |h^{(l)}(r)| \leq M$$

and locally

$$|h^{(l)}(r) - h^{(l)}(r')| \leq M|r - r'|$$

for all $0 \leq l \leq m$.

LEMMA 2.4. *For any $v \in V^m$ and $\epsilon > 0$, we have*

$$\left| \frac{\partial^{|k|} g}{\partial x^k}(x, y, t) - \frac{\partial^{|k|} g}{\partial x^k}(x', y, t) \right| \leq M_1(t)|x - x'|, \qquad 0 \leq |k| \leq m \tag{7}$$

for $t > 0$, where $g(x, y, t)$ is a solution of the Fokker–Planck equation arising from v with initial condition $\delta(x - y)$, and $M_1(t)$ is a continuous function.

Proof. Let $X = R^n, v_0 = c - \kappa x$, where c, κ are constants, $c \in R^n, \kappa \in R$. Let $g_0(x, y, t)$ be the solution of the Fokker–Planck equation for v_0 with initial condition the Dirac function $\delta(x - y)$. Then (cf. [1] and [3])

$$g_0(x, y, t) = (2\pi\sigma)^{-n/2} e^{-|x-y-\mu|^2/2\sigma},$$

where $x, y \in R^n$,

$$\sigma = \begin{cases} \frac{\epsilon}{\kappa}(1 - e^{-2\kappa t}) & \text{if } \kappa \neq 0, \\ 2\epsilon t & \text{if } \kappa = 0, \end{cases}$$

and

$$\mu = \begin{cases} c(1 - e^{-\kappa t}) & \text{if } \kappa \neq 0, \\ ct & \text{if } \kappa = 0. \end{cases}$$

By Lemma 2.3, we have

$$\left| \frac{\partial^{|k|} g_0}{\partial x^k}(x, y, t) - \frac{\partial^{|k|} g_0}{\partial x^k}(x', y, t) \right| \leq M(2\pi)^{-n/2} \sigma^{-(n+1)/2} |x - x'|, \qquad 0 \leq |k| \leq m. \tag{8}$$

Since any manifold X can be locally approximated by a Euclidean space and any vector field v on R^n has linear approximation at the origin, we have by arguments similar to [1] that

$$\left| \frac{\partial^{|k|} g}{\partial x^k}(x, y, t) - \frac{\partial^{|k|} g}{\partial x^k}(x', y, t) \right| \leq M_1|x - x'|, \qquad 0 \leq |k| \leq m \tag{9}$$

for the solution $g(x, y, t)$ of the Fokker–Planck equation arising from v with initial condition $\delta(x - y)$, where M_1 depends on t. Obviously, the compactness of X is necessary here.

Proof of Theorem 2.1. Since

$$G(t)f(x) = \int_X g(x, y, t) f(y)\, dy, \tag{10}$$

and $(\partial^{|k|}/\partial x^k)g(x,y,t)$ is continuous for $0 \le |k| \le m-1$, we have

$$\frac{\partial^{|k|}}{\partial x^k} G(t)f(x) = \int_X \frac{\partial^{|k|}}{\partial x^k} g(x,y,t)f(y)\,dy.$$

Thus, by Lemma 2.4 and Lemma 2.2, we see that $G(t)$ is a compact operator on $C^{m-1}(X)$.

COROLLARY 2.5. *$G(t)$ has a unique fixed point u in $C^{m-1}(X)$ with $u \ge 0$ and $\int_X u = 1$. Furthermore, $C^{m-1}(X)$ has a decomposition*

$$C^{m-1}(X) = E + H, \quad E \cap H = \{0\},$$

where

$$E = \operatorname{span}\{u\},$$
$$H = \{h \in C^{m-1}(X);\ G^n(t)h \to 0 \text{ as } n \to \infty\},$$

or

$$H = \left\{h \in C^{m-1}(X);\ \int_X h = 0\right\}.$$

Proof. Since $G(t)$ is a compact and strongly positive operator on $C^{m-1}(X)$, spectral radius r of $G(t)$ is a simple eigenvalue associated with an eigenfunction $u \ge 0$. Furthermore, $C^{m-1}(X)$ can be written as the sum of $G(t)$-invariant subspaces

$$C^{m-1}(X) = E + H, \qquad E = \operatorname{span}\{u\},$$

and $G(t)|_H$ has spectral radius $< r$.

We may assume $\int u = 1$ by scaling u. Hence, $r = 1$ follows from the fact that $\int G(t)u = \int u = 1$, u is a fixed point of $G(t)$ in $C^{m-1}(X)$. Suppose $G(t)$ has another fixed point u_1 in $C^{m-1}(X)$ with $u_1 \ge 0$ and $\int u_1 = 1$, then $u_1 = cu$. $\int u_1 = \int u = 1$ implies $c = 1$.

It is easily seen that

$$H \subset \{h \in C^{m-1}(X);\ G^n(t)h \to 0 \text{ as } n \to \infty\},$$

since the spectral radius of $G(t)|_H$ is less than 1. Conversely suppose $f \in C^{m-1}(X)$ and $G^n(t)f \to 0$ as $n \to \infty$. Since $f = e + h, e \in E, h \in H$ and $G(t)e = e, G^n(t)h \to 0$ as $n \to \infty$, we have $e = 0$ and $f = h \in H$. Consequently,

$$H = \{h \in C^{m-1}(X);\ G^n(t)h \to 0 \text{ as } n \to \infty\}.$$

By (5) and (6), $\int G^n(t)f = \int f$ for any $f \in C^{m-1}(X)$. If $h \in H$ then $G^n(t)h \to 0$ as $n \to \infty$,by the arguments above. Therefore $\int G^n(t)h \to 0$ as $n \to \infty$. It follows that $\int h = 0$.

On the other hand, suppose $f \in C^{m-1}(X)$ and $\int f = 0$. Let $f = e + h, e \in E$ and $h \in H$, then $e = cu$. Since $\int h = 0$ as shown above, $c = \int cu = \int e = \int(f - h) = 0$. Hence, $e = 0$ and $f = h \in H$. This completes the proof of Corollary 2.5.

THEOREM 2.6. *For any vector field $v \in V^m$, the Fokker–Planck equation for v with ϵ-diffusion has a unique steady state $u \in U^{m+1}$, and all solutions tend to the steady state u.*

Proof. Let $\tau > 0$ and u be the unique fixed point of $G(\tau)$ in Corollary 2.5. Since

$$G(\tau)G(t)u = G(t)G(\tau)u = G(t)u,$$

$$G(t)u \geq 0 \text{ and } \int G(t)u = \int u = 1$$

for any $t > 0$, we have $G(t)u = u$ for any $t > 0$ by Corollary 2.5. Hence

$$\frac{d}{dt}(G(t)u) = \frac{d}{dt}(u) = 0,$$

$u \in D(FP_v)$ and u is a steady state of the Fokker–Planck equation in U^{m+1}.

If there is another steady state u_1, then $u_1 \in U^{m+1}$ and

$$\frac{d}{dt}(u_1) = FP_v u_1 = 0.$$

That implies u_1 is an eigenvector of FP_v associated with eigenvalue 0. Hence, u_1 is an eigenvector of $G(t)$ for any $t > 0$ corresponding to the eigenvalue 1 (cf. [5]). In particular,

$$G(\tau)u_1 = u_1.$$

The uniqueness of Corollary 2.5 implies $u = u_1$.

For any solution $G(t)u_0$ in U^{m+1}, $G(t)u_0 - u \in H$ follows from $\int (G(t)u_0 - u) = 0$ and Corollary 2.5. Since $\{G(t)u_0;\ 0 \leq t \leq \tau\}$ is bounded, $\{G(t)u_0 - u;\ 0 \leq t \leq \tau\}$ is bounded also, say, by M.

By the strong positivity of $G(\tau)$, the spectral radius r of $G(\tau)|_H$ is less than one. We can select a ρ such that $r < \rho < 1$. Then, there is an n_0 such that $\| G^n(\tau)|_H) \| \leq \rho^n$ for all $n > n_0$. Given $\epsilon > 0$, there is an n_1 such that $n_1 > n_0$ and $\rho^n M < \epsilon$ for all $n > n_1$. Hence, for any $t > n_1\tau$, $t = n\tau + s$, where $n > n_1$ and $0 < s < \tau$, we have

$$\begin{aligned} \| G(t)u_0 - u \|_{m-1} &= \| G^n(\tau)G(s)u_0 - G^n(\tau)u \|_{m-1} \\ &\leq \rho^n \| G(s)u_0 - u \|_{m-1} \\ &\leq \rho^n M \leq \epsilon. \end{aligned}$$

This completes the proof of Theorem 2.6

3. Density of stable vector fields. In this section we prove that stable vector fields are dense in the space of all C^m-vector fields on a compact connected Riemannian manifold.

DEFINITION 2. *Two C^∞-functions $u, u' : X \to R$ are said to be* equivalent *if there exist diffeomorphisms α, β of X, R, respectively, such that the following diagram commutes.*

$$\begin{array}{ccc} X & \xrightarrow{u} & R \\ \downarrow \alpha & & \downarrow \beta \\ X & \xrightarrow{u'} & R \end{array}$$

Two C^m-functions $u, u' : X \to R$ are said to be C^m-equivalent *if either $u = u'$ or there are neighborhoods of u and u', say, O_u and $O_{u'}$ respectively, in $C^m(X)$ such that every function in $O_u \cap C^\infty$ is equivalent to every function in $O_{u'} \cap C^\infty$.*

A C^m-function f is called C^m-stable *if f has a neighborhood of C^m-equivalents in $C^m(X)$.*

DEFINITION 3. *Two C^m-vector fields v, v' on X are said to be* ϵ-equivalent *in V^m if their corresponding steady states of the Fokker–Planck equation with ϵ-diffusion are C^{m-1}-equivalent in $C^{m-1}(X)$.*

A C^m-vector field v is called ϵ-stable *if it has a neighborhood O in V^m such that every pair of vector fields in O are ϵ-equivalents.*

A C^m-vector field is called stable *if it is ϵ-stable for arbitrarily small $\epsilon > 0$.*

Define a map

$$\pi^\epsilon : V^m \to U^{m+1}$$

by assigning to each $v \in V^m$ the steady state $\pi^\epsilon(v) = u^{v,\epsilon}$ of the Fokker–Planck equation for v with ϵ diffusion. By Corollary 2.5 of §2, the map π^ϵ is well defined. We will use different topologies on the set U^{m+1} in Theorems 3.1 and 3.2.

THEOREM 3.1. *The map $\pi^\epsilon : V^m \to (U^{m+1}, \|\cdot\|_{m-1})$ is differentiable and hence continuous.*

Proof. Recall that

$$C^{m-1}(X) = E + H, \qquad E \cap H = \{0\},$$

where E is the one-dimensional subspace spanned by the steady state, and H is the complementary invariant subspace of $G(t)$. Since $G(t)$ is the semigroup generated by FP_v, H is also an invariant subspace under FP_v. Define

$$\Gamma = FP_v|_H.$$

Γ is an infinitesimal generator of $G(t)|_H$. By the spectral mapping theorem (cf. [5]), 0 is a resolvent point of Γ since 1 is a resolvent point of $G(t)|_H$. Therefore Γ^{-1} is continuous.

Given $v \in V^m$, let $u = \pi^\epsilon(v)$. For any $v' \in V^m, \nabla \cdot (uv') \in C^{m-1}(X)$. Furthermore, $\nabla \cdot (uv') \in H$ because $\int \nabla \cdot (uv') = 0$ follows from integration by parts. Let $u' = \Gamma^{-1}(\nabla \cdot (uv'))$. Then

$$\nabla \cdot (uv') = \Gamma(u') = \epsilon \Delta u' - \nabla \cdot (u'v),$$

$$\begin{aligned} \epsilon \Delta(u + \delta u') &= \epsilon \Delta u + \delta(\epsilon \Delta u') \\ &= \nabla \cdot (uv) + \delta[\nabla \cdot (uv') + \nabla \cdot (u'v)] \\ &= \nabla \cdot [(u + \delta u')(v + \delta v')] + O(\delta^2) \end{aligned}$$

for any $\delta > 0$. It implies

$$\pi^\epsilon(v + \delta v') = u + \delta u' + O(\delta^2).$$

The map $v' \to u' = \Gamma^{-1}(\nabla \cdot (uv'))$ gives the derivative $T_v\pi^\epsilon$. It is continuous because it is the composition of three continuous maps:

$$v' \longmapsto uv' \longmapsto \nabla \cdot (uv') \longmapsto \Gamma^{-1}(\nabla \cdot (uv')),$$

the first being continuous because u is in C^{m+1}, the second being continuous because V^m has C^m topology but H has C^{m-1} topology and the third being continuous by

the continuity of Γ^{-1}. Therefore π^ϵ is differentiable and continuous from V^m to $(U^{m+1}, \|\cdot\|_{m-1})$.

THEOREM 3.2. *The map π^ϵ is open from V^m to $(U^{m+1}, \|\cdot\|_{m+1})$.*

Proof. Let

$$G = \{g \in V^m;\ g = -\nabla f,\ \text{for some } f \in C^{m+1}\},$$

$$W = \{w \in V^m;\ \nabla \cdot w = 0\}.$$

We define the following operators:

$$\pi_1 : G \times W \longrightarrow G, \qquad \pi_1(g, w) = g;$$
$$\tilde{\pi}\colon G \times W \longrightarrow V^m, \qquad \tilde{\pi}\,(g, w) = g + \frac{w}{u}, \quad \text{where } u = \pi^\epsilon(g);$$
$$\tilde{\psi}\colon V^m \longrightarrow G \times W, \qquad \tilde{\psi}\,(v) = (\epsilon \nabla u/u, uv - \epsilon \nabla u), \quad \text{where } u = \pi^\epsilon(v).$$
$$\psi : U^{m+1} \longrightarrow G, \qquad \psi(u) = -\nabla(-\epsilon \ln u);$$
$$\pi^\epsilon|_G : G \longrightarrow U^{m+1}, \qquad \pi^\epsilon|_G(g) = \pi^\epsilon(g) = e^{-f/\epsilon} \quad \text{for some } -\nabla f = g.$$

Then it is easily checked by computation that $\tilde{\pi}$ and $\tilde{\psi}$ are inverse homeomorphisms between $G \times W$ and V^m and $\pi|_G$ and ψ are inverse homeomorphisms between G and $(U^{m+1}, \|\cdot\|_{m+1})$(cf. [1]). Furthermore, we have

$$\pi^\epsilon = (\pi^\epsilon|_G)\pi_1\,\tilde{\psi}\,.$$

Hence π^ϵ is open from V^m to $(U^{m+1}, \|\cdot\|_{m+1})$, because it is the composition of three open maps.

THEOREM 3.3. *For any $\epsilon > 0$, ϵ-stable C^m-vector fields are dense in V^m.*

Proof. Let U_0 be the set of C^{m-1}- stable functions in $(U^{m+1}, \|\cdot\|_{m-1})$. Let V_0 be the inverse image of U_0 under π^ϵ. Then V_0 is the set of ϵ-stable C^m-vector fields because π^ϵ is continuous. In fact, let $v \in V_0$, then $u = \pi^\epsilon v \in U_0$. Since u is C^{m-1}-stable, there is an C^{m-1}-equivalent neighborhood O_u of u in $C^{m-1}(X)$. Therefore, inverse image of O_u under π^ϵ is an ϵ-equivalent neighborhood of v.

Let U_{00} be the set of C^{m+1}-Morse functions with distinct critical values in $(U^{m+1}, \|\cdot\|_{m+1})$. Let V_{00} be the inverse image of U_{00} under π^ϵ. Then U_{00} is dense in U^{m+1} with C^{m+1} topology; cf. [4]. Furthermore, we have $U_{00} \subset U_0$ and $V_{00} \subset V_0$; cf. [6]. For any $v \in V^m$ and its neighborhood O_v, let $u = \pi^\epsilon v$ and $O_u = \pi^\epsilon O_v$. Then O_u is a neighborhood of u in $C^{m+1}(x)$ by Theorem 3.2. Therefore, there is a u_0 in $U_{00} \cap O_u$. We can select v_0 from $V_{00} \cap O_v$ such that $\pi^\epsilon v_0 = u_0$. This implies that ϵ-stable C^m-vector fields are dense in V^m.

THEOREM 3.4. *Stable C^m-vector fields are residual and therefore dense in V^m.*

Proof. It should be noted that ϵ-stable vector fields form an open subset in V^m for any $\epsilon > 0$. Let

$$W = \cap_{n=1}^{\infty} V_{1/n},$$

where $V_{1/n}$ is $(1/n)$-stable set. Then any vector field in W is stable. Now W is residual in V^m because it is a countable intersection of open dense subsets in a Baire space. Therefore the density of stable C^m-vector fields in V^m follows from the density of W in V^m.

MULTIEXISTENCE OF SLOWLY OSCILLATING PERIODIC SOLUTIONS FOR DIFFERENTIAL DELAY EQUATIONS *

YULIN CAO†

Abstract. This paper presents a checkable condition on the function f such that the differential delay equation $\dot{x}(t) = -f(x(t-1))$ has at least n distinct slowly oscillating periodic solutions, where n is any natural number or infinity. As an example, an equation is demonstrated to satisfy the condition proposed for $n = +\infty$, and therefore, it has infinitely many slowly oscillating periodic solutions.

Key words. slowly oscillating periodic solutions, differential delay equations

AMS subject classification. 34K15

1. Introduction.

This paper discusses the differential delay equation

$$\dot{x}(t) = -f(x(t-1)), \tag{1.1}$$

where f is a continuously differentiable function and $f(0) = 0$. For any given number n (n is allowed to be infinity), we will give a checkable condition on the function f such that (1.1) has at least n distinct slowly oscillating periodic solutions. Here, a slowly oscillating periodic solution means that the distances between its zeros are greater than one (i.e., the delay time). Two slowly oscillating periodic solutions are distinct if they are not equal under any time-shift. In §4, an equation is constructed to satisfy the condition proposed for $n = +\infty$, and therefore, it has infinitely many slowly oscillating periodic solutions.

Equation (1.1) is primarily important in the study of slowly oscillating periodic solutions, not only because it is the simplest one among the differential delay equations (or the functional differential equations), but also because some other important differential delay equations can be changed into this form (1.1). For example, the nonlinear equation $\dot{y}(t) = -y(t-1)N(y(t))$ can be changed into (1.1). (See [13, pp. 276–277].) This nonlinear equation has several applications, and the question of multiexistence of slowly oscillating periodic solutions is pertinent here. Cunningham [5] has used it as a population model, Wright [20] has used it in the theory of asymptotic prime number density, and Jones [9] has used it to describe a control system.

Nussbaum [17, Thm. 2.2] has proved that there is only one slowly oscillating periodic solution of the equation

$$\dot{x}(t) = -\alpha h(x(t-1)), \qquad \alpha > \frac{\pi}{2}, \tag{1.2}$$

under the assumptions (i) h is an odd and continuously differentiable function, (ii) $h'(0) = 1$ and $h'(x) > 0$ is monotonically decreasing for $x > 0$, and (iii) $\phi(x) = h(x)x^{-1}$ is strictly monotonically decreasing for $x > 0$. He has demonstrated a special equation which violates the assumption (iii) (he has assumed that $\phi(x)$ is only monotonically decreasing for $x > 0$) and has more than one slowly oscillating periodic solution. Our example in Theorem 4.1 shows that, if the assumption (iii) is violated, there could be

† Department of Mathematics, University of Georgia, Athens, Georgia 30602.

infinitely many slowly oscillating periodic solutions of (1.2). Our main result is based on Kaplan and Yorke's Trajectory Crossing Lemma. (See [11] and [12].) Our basic idea is to construct some solutions whose orbits in the $(x(t), x(t-1))$ plane spiral inward or outward and do not cross each other. If a pair of those orbits forms an annulus-like region, then there is a slowly oscillating periodic solution whose orbit is in this region. Consequently, if we can construct n such disjoint annulus-like regions, then there are n distinct slowly oscillating periodic solutions. This idea is similar to the Poincare–Bendixson Annular Region Theorem for the existence of a limit cycle for planary ordinary differential equations.

2. Definitions and primary results. First, we introduce some definitions and results from [12]. Consider the scalar differential delay equation

$$\dot{x}(t) = -f(x(t-1)), \tag{2.1}$$

where the function $f(x)$ is continuously differentiable and satisfies the following assumption:

$$f(0) = 0, \qquad f'(x) > 0 \quad \text{for all } x \in \mathbb{R}. \tag{H1}$$

Let $C = C([-1,0], \mathbb{R})$ be the Banach space of all continuous functions from $[-1,0]$ to $\mathbb{R}$. Define C_* by the set of all φ in C satisfying

(i) φ has at most one zero in $[-1,0]$, and

(ii) φ must change sign at any zero in $(-1,0)$.

Write $x(t) = x(t; t_0, \varphi)$ to denote the solution of (2.1) satisfying $x(t_0 + \theta) = \varphi(\theta)$ for $\theta \in [-1,0]$. Denote $x_t \in C$, as usual, by $x_t(\theta) = x(t+\theta)$ for $\theta \in [-1,0]$. It is easy to see that $x(t)$ exists for all $t \geq t_0$.

LEMMA 2.1. *Suppose* (H1) *is satisfied. If* $\varphi \in C_*$, *then* $x_t \in C_*$ *for all* $t \geq t_0$, *and the zeros of* x *and* $\dot{x}$ *alternate on* $(t_0, +\infty)$. *If* x *has only finitely many zeros in* $(t_0, +\infty)$, *then* $x(t)$ *monotonically goes to zero eventually, as* $t \to +\infty$.

Proof. The first part is given by [11, Prop. 2.1]. The second part can be deduced from (2.1), because $x(t-1) > 0 (x(t-1) < 0)$ implies that $\dot{x}(t) < 0 (\dot{x}(t) > 0)$.

From Lemma 2.1, one can see that, if $\varphi \in C_*$, then $x(\cdot; t_0, \varphi)$ is a slowly oscillating solution of (2.1), that is, the distance between any pair of successive zeros of x is greater than the delay time (i.e., one). Also from Lemma 2.1, we know that $x(t)$ and $x(t-1)$ cannot equal zero at the same t. The basic idea of [11] is to compare slowly oscillating solutions in the $(x(t), -x(t-1))$ plane. □

DEFINITION 2.1. *Given* $\gamma = (\gamma_1, \gamma_2)$ *and* $S = (s_1, s_2)$ *in* $\mathbb{R}^2$, *we say that* γ *is outside* S *if* $\gamma \neq S$ *and if either of the following is satisfied*:

(i) $\gamma_1 = s_1, |\gamma_2| > |s_2|$, *and* $\gamma_2 s_2 > 0$,

(ii) $s_2 = 0, |\gamma_1| \geq |s_1|$, *and* $\gamma_1 s_1 > 0$.

Let $\gamma(t) = (\gamma_1(t), \gamma_2(t))$ *and* $S(t) = (s_1(t), s_2(t))$ *be two parametrized continuous curves in* $\mathbb{R}^2$ *for* t *in intervals* I_γ *and* I_s, *respectively. We say that* $\gamma | I_\gamma$ *is outside* $S | I_s$ *if there exists a nondecreasing continuous function* T *from* I_γ *onto* I_s *such that* $\gamma(t)$ *is outside* $S(T(t))$ *for all* $t \in I_\gamma$.

Observe that, when the point S in the (u,v) plane is above the u axis, "outside S" means straight above S; when S is below the u axis, "outside S" means straight below S; when S is on the right u axis, "outside S" means on the right side of S; when S is on the left u axis, "outside S" means on the left side of S. Assuming x and y are two solutions of (2.1), whenever we say that $x|I_x$ is outside $y|I_y$, we mean that the curve γ defined by $\gamma(t) = (x(t), -x(t-1))$, for t in the interval I_x, is outside the curve S

defined by $S(t) = (y(t), -y(t-1))$ for t in the interval I_y. When $\sup I_x = +\infty$, we call γ an orbit of x in $\mathbb{R}^2$. From Lemma 2.1 and the discussion that followed, one can see that the orbit of a slowly oscillating solution x of (2.1) rotates in the $(x(t), -x(t-1))$ plane clockwise around the origin. The next lemma is a modification of Kaplan and Yorke's Trajectory Crossing Lemma in [11] and [12].

LEMMA 2.2 (Trajectory Crossing Lemma). *Suppose* (H1) *is satisfied. Let x and y be two solutions of* (2.1). *Assume that $x_{t_0}, y_{T_0} \in C_*$, and assume that for some t_0^* and T_0^* satisfying*

$$t_0^* > t_0 + 1, \qquad T_0^* \geq T_0 + 1,$$

$x|[t_0, t_0^*)$ is outside $y|[T_0, T_0^*)(x|(t_0, t_0^*]$ is outside $y|(T_0, T_0^*])$. If there exists $T_n > T_0^*$ for some $n \geq 1$ such that $y(T_n) = 0$ and y has n zeros on $(T_0, T_n]$, then there exists $t_n > t_0^*$ such that $x(t_n) = 0, x$ has n or $n+1$ zeros on $(t_0, t_n]$, and $x|[t_0, t_n + 1]$ is outside $y|[T_0, T_n + 1](x|(t_0, t_n + 1]$ is outside $y|(T_0, T_n + 1])$.

Moreover, if y has infinitely many zeros in $(T_0, +\infty)$, then x has infinitely many zeros in $(t_0, +\infty)$, and $x|[t_0, +\infty)$ is outside $y|[T_0, +\infty)(x|(t_0, +\infty)$ is outside $y|(T_0, +\infty))$.

Proof. The proof is omitted, because it is similar to the proof of [11, Lemma 3.1]. Here, we just make some comments on the proof. It should be pointed out that the key point in the proof of the Trajectory Crossing Lemma of [11] and [12] is that the orbits of x and y do not cross. The assumption in [11, Lemma 3.1], differing from ours, is that both x and y have infinitely many zeros. But this assumption is not needed in the proof of "noncrossing"; it is needed only in the proof of "outside." Since we assume that y has n zeros in $(T_0, T_n]$, it follows from "noncrossing" and Lemma 2.1 that there exists $t_n > t_0^*$ such that $x(t_n) = 0$ and x has n zeros on $(t_0, t_n]$. If $y(T_0) = 0$, there may be a $\bar{t}_0$ in (t_0, t_0^*) such that $x(\bar{t}_0) = 0$ and $(x(t), -x(t-1))$ is outside $(y(T_0), -y(T_0))$ for all t in $[t_0, \bar{t}_0]$. In this case, x has $n+1$ zeros in some interval $(t_0, t_n]$. By "noncrossing" again, one can see that $x|[t_0, t_n + 1]$, which has the same rotations around the origin as $y|[T_0, T_n + 1]$ does, is outside $y|[T_0, T_n + 1]$. Letting $n \to +\infty$, we know from the first part of the lemma that x has infinitely many zeros. Since the separations of zeros of x and y are greater than one by Lemma 2.1 and Definition 2.1, it follows that $T_n, t_n \to +\infty$ as $n \to +\infty$. Consequently, the second part of the lemma is true.

Note that the assertion in [11, Lemma 3.1] that $x|(t_0, +\infty)$ is outside $y|(T_0, +\infty)$ is not precise: it is not the case that if $x|[t_0, t_0^*)$ is outside $y|[T_0, T_0^*)$, then $x|(t_0, t_0^*)$ is outside $y|(T_0, t_0^*)$. A simple example is given for the case in which $y(t_0 - 1) = 0, x(t_0 - 1) > 0$, and $y(t_0) > x(t_0) > 0$. □

DEFINITION 2.2. *Suppose that x is a solution of* (2.1) *and has infinitely many zeros in $(t_0 - 1, +\infty)$. Assume $x_{t_0} \in C_*$. We say that x spirals outward (inward) in $(t_0, +\infty)$ if there exists some $t_1 > t_0$ such that $x|(t_1, +\infty)$ is outside $x|(t_0, +\infty)(x|(t_0, +\infty)$ is outside $x|(t_1, +\infty))$. We say x spirals toward an orbit γ in $\mathbb{R}^2$ if the point $(x(t), -x(t-1))$ in $\mathbb{R}^2$ approaches the orbit γ as $t \to +\infty$.*

For any slowly oscillating solution $x(t)$ of (2.1), one can see that $x(t_1 - 1) = 0$ for some t_1 implies that x has an extreme value at $t = t_1$. Therefore, by the definition of "outside," if $x|(t_1, +\infty)$ is outside $x|(t_0, +\infty)$ for some $t_1 > t_0$, then the orbit of x must make a complete rotation about the origin when t goes from t_0 to t_1. Let T be the map in Definition 2.1 making $x|(t_1, +\infty)$ outside $x|(t_0, +\infty)$. If $t_n = T^n(t_0)$ is the nth iteration of T at t_0 and $\tilde{T}^n$ is the restriction of T to the interval $(t_n, +\infty)$, then $x|(t_{n+1}, +\infty)$ is outside $x|(t_n, +\infty)$ with the corresponding mapping $\tilde{T}^n$ for $n = 0, 1, \ldots$. Thus, if x spirals outward, then the orbit of x in $\mathbb{R}^2$ rotates outward around

the origin infinitely. The discussion is similar if x spirals inward. Following the discussion above, we have a corollary of Lemma 2.2.

COROLLARY 2.3. *Suppose* (H1) *is satisfied. Let* x *be a solution of* (2.1) *on* $(t_0 - 1, +\infty)$. *Assume* $x_{t_0} \in C_*$ *and assume that there is a* $t_1 > t_0$ *such that* $x|(t_1, t_1 + 1]$ *is outside* $x|(t_0, t_0 + 1]$. *Then* $x|(t_1, +\infty)$ *is outside* $x|(t_0, +\infty)$ *and* x *spirals outward on* $(t_0, +\infty)$.

Proof. If x has n zeros in $(t_0, +\infty)$, following the discussion above, there exists at least one zero of x in the interval $(t_0, t_1]$. Therefore, x has at most $n - 1$ zeros in $(t_1, +\infty)$, contradicting Lemma 2.2. Thus x has infinitely many zeros. The proof is completed by the use of Lemma 2.2.

The following result presents a way to determine the existence of slowly oscillating periodic solutions. The result is implicitly given by [11] and its proof is omitted. □

THEOREM 2.4. *Suppose that* (H1) *is satisfied. Let* x *be a solution of* (2.1) *through* $(t_0, \varphi) \in \mathbb{R} \times C_*$. *If* x *is bounded and spirals outward in* $(t_0, +\infty)$, *then there exists a slowly oscillating periodic solution* $\tilde{x}$ *of* (2.1) *such that* x *spirals outward toward the orbit of* $\tilde{x}$. *If* x *spirals inward in* $(t_0, +\infty)$ *and the orbit of* x *is bounded away from the origin in* $\mathbb{R}^2$, *then there exists a slowly oscillating periodic solution* $\tilde{x}$ *of* (2.1) *such that* x *spirals inward toward the orbit of* $\tilde{x}$ *in* $\mathbb{R}^2$.

3. Multiexistence of slowly oscillating periodic solutions. In this section, we will present a checkable condition on the function f such that (2.1) has at least n distinct slowly oscillating periodic solutions.

THEOREM 3.1. *Suppose that* f *is an odd function and satisfies* (H1). *If there exist* $0 < a_1 < a_2 < \cdots < a_{2n}$ *such that, for* $k = 1, 2, \ldots, n$,

$$\int_0^{f(a_{2k-1})} f(x)\, dx > 2[f(a_{2k-1})]^2 \tag{3.1}$$

and

$$0 < f(a_{2k})/a_{2k} < 1, \tag{3.2}$$

then (2.1) *has at least* n *distinct slowly oscillating periodic solutions. In fact, there exist slowly oscillating solutions* $x^k(\cdot)$ *and slowly oscillating periodic solutions* $\bar{x}^k(\cdot)(k = 1, 2, \ldots, 2n)$ *such that*

(i) $x^{k+1}|(0, +\infty)$ *is outside* $x^k|(0, +\infty)$ *for* $k = 0, 1, 2, \ldots, 2n - 1$.

(ii) x^{2k-1} *spirals outward toward the orbit of* $\bar{x}^{2k-1}$, *and* x^{2k} *spirals inward toward the orbit of* $\bar{x}^{2k}$ *for* $k = 1, 2, \ldots, n$.

(iii) $\bar{x}^{2k-1}$ *and* $\bar{x}^{2k}$ *may be the same up to a time-shift*; $\bar{x}^{2k}$ *and* $\bar{x}^{2j}$ *are distinct for any* $k \neq j$.

If there exists an infinite sequence $\{a_n\}_{n=1}^{\infty}$ *such that* (3.1) *and* (3.2) *are satisfied for each* k, *then* (2.1) *has infinitely many slowly oscillating periodic solutions.*

To prove this theorem, we construct initial values $\varphi_1, \ldots, \varphi_{2n}$ in C_* such that, if $x^k = x(\cdot; \varphi_k)$ is a solution of (2.1) satisfying $x(\theta; \varphi_k) = \varphi_k(\theta)$ for $\theta \in [-1, 0]$, then $x^k(\cdot), k = 1, 2, \ldots, 2n$, satisfy (i) and (ii) of the theorem.

CLAIM A. Suppose that (H1) is satisfied and $\{a_k\}_1^{2n}$ is as in Theorem 3.1. Choose $\delta_{2k-1} > 0$ small enough that

$$\int_0^{f(a_{2k-1})(1-\delta_{2k-1})} f(x)\, dx > 2[f(a_{2k-1})]^2 \tag{3.3}$$

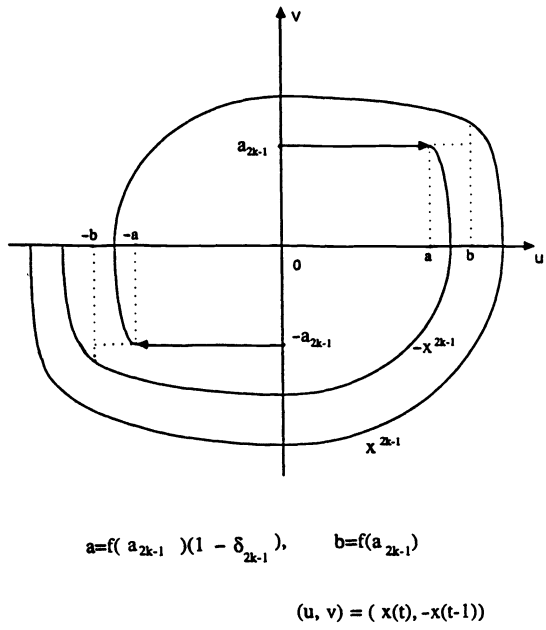

FIG. 1.

and

$$f(a_{2k-1})(1-\delta_{2k-1}) > a_{2k-1}. \tag{3.3)'}$$

If φ_{2k-1} in $C_*(k=1,2,\dots,n)$ is an arbitrary nonincreasing function satisfying

$$\varphi_{2k-1}(\theta)\begin{cases} = a_{2k-1}, & \theta \in [-1,-\delta_{2k-1}], \\ > 0, & \theta \in (-\delta_{2k-1},0), \\ = 0, & \theta = 0, \end{cases} \tag{3.4}$$

then the solution $x^{2k-1} = x(\cdot;\varphi_{2k-1})$ of (2.1) spirals outward in $(0,+\infty)$.

Proof. To prove the claim, we show the existence of the first two positive zeros, t_0 and t_2, of x^{2k-1} and then, prove that $x^{2k-1}|(t_2,t_2+1]$ is outside $x^{2k-1}|(0,1]$.

Note that from the inequality (3.1) and the assumption (H1), one can deduce that $f(a_{2k-1}) > a_{2k-1}$, and thus, there does exist $\delta_{2k-1} \in (0,1)$ such that (3.3) and (3.3)′ are satisfied. Let $x^{2k-1} = x(\cdot;\varphi_{2k-1})$ be the solution of (2.1) satisfying $x^{2k-1}(\theta) = \varphi_{2k-1}(\theta)$ for $\theta \in [-1,0]$. From (2.1), we have

$$x^{2k-1}(t) = -\int_0^t f(\varphi_{2k-1}(\theta-1))\,d\theta \quad \text{for } t \in [0,1].$$

Therefore,

$$x^{2k-1}(t) = -f(a_{2k-1})t \quad \text{for } t \in [0,1-\delta_{2k-1}] \tag{3.5}$$

and

$$-f(a_{2k-1}) < x^{2k-1}(t) < -f(a_{2k-1})(1-\delta_{2k-1}) \quad \text{for } t \in [1-\delta_{2k-1},1]. \tag{3.6}$$

Thus, the orbit of $x^{2k-1}|(0,1]$ in the (u,v) plane (that is, the $(x(t),-x(t-1))$ plane) connects the negative v axis to the negative u axis, and consists of two parts. The first part, $x^{2k-1}|(0,1-\delta_{2k-1}]$, lies in the third quadrant on the line $v=-a_{2k-1}$, while the other part, $x^{2k-1}|[1-\delta_{2k-1},1]$, is bounded by four lines, $v=-a_{2k-1}, v=0, u=-f(a_{2k-1})(1-\delta_{2k-1})$, and $u=-f(a_{2k-1})$. (See Fig. 1.) For t in $[1,2-\delta_{2k-1}]$, from (3.5) we know that

$$
\begin{aligned}
x^{2k-1}(t) &= x^{2k-1}(1) - \int_1^t f(-f(a_{2k-1})(s-1))\,ds \\
&= x^{2k-1}(1) + \int_0^{f(a_{2k-1})(t-1)} \frac{f(x)}{f(a_{2k-1})}\,dx,
\end{aligned} \tag{3.7}
$$

and therefore, for t in $[2-\delta_{2k-1}, 2]$,

$$
\begin{aligned}
x^{2k-1}(t) &\geq x^{2k-1}(2-\delta_{2k-1}) \\
&> -f(a_{2k-1}) + \int_0^{f(a_{2k-1})(1-\delta_{2k-1})} \frac{f(x)}{f(a_{2k-1})}\,dx \\
&> f(a_{2k-1}) > 0,
\end{aligned}
$$

by the first inequality of (3.6) and (3.3). Together with (3.5) and (3.6), the inequality above implies that the first positive zero t_0 of x^{2k-1} does exist and is in $(1, 2-\delta_{2k-1})$.

Now, we want to determine the location of the orbit of $x^{2k-1}|(t_0, t_0+1]$ in the (u, v) plane. Since $x^{2k-1}(t)$ is strictly increasing for $t \in (1, t_0+1)$ by (2.1), the inequality above also implies

$$
x^{2k-1}(t) > f(a_{2k-1}) \quad \text{for } t \in [2-\delta_{2k-1}, t_0+1]. \tag{3.8}
$$

If $t_1 = a_{2k-1}/f(a_{2k-1})$, then t_1 is in $(0, 1-\delta_{2k-1})$ by the choice of δ_{2k-1}. We want to show $t_0 - 1 > t_1$. Using the second inequality of (3.6) and the monotonicity of f we deduce from (3.7) that, for t in $[1, t_1+1] \subset [1, 2-\delta_{2k-1}]$,

$$
\begin{aligned}
x^{2k-1}(t) &\leq x^{2k-1}(1) + \int_0^{f(a_{2k-1})t_1} \frac{f(x)}{f(a_{2k-1})}\,dx \\
&< -f(a_{2k-1})(1-\delta_{2k-1}) + \int_0^{a_{2k-1}} \frac{f(x)}{f(a_{2k-1})}\,dx \\
&< -f(a_{2k-1})(1-\delta_{2k-1}) + a_{2k-1} < 0,
\end{aligned}
$$

by the choice of δ_{2k-1}. Together with (3.5) and (3.6), the inequality above implies $x^{2k-1}(t) < 0$ for all $t \in (0, t_1+1]$ and thus, $t_1 + 1 < t_0$ or $t_0 - 1 > t_1$, where t_0 in $(1, 2-\delta_{2k-1})$ is the first positive zero of x^{2k-1}. Consequently, it follows from (3.5) and the definition of t_1 that

$$
x^{2k-1}(t) < x^{2k-1}(t_1) = -a_{2k-1} \tag{3.8}'
$$

for t in $[t_0-1, 1-\delta_{2k-1}] \subset (t_1, 1-\delta_{2k-1})$. The discussion above shows that the orbit of $x^{2k-1}|(t_0, t_0+1]$ in the (u, v) plane connects the positive v axis to the positive u axis, and consists of two parts. The first part, $x^{2k-1}|(t_0, 2-\delta_{2k-1}]$, lies in the first quadrant above the line $v = a_{2k-1}$ by (3.8)′, while the other part, $x^{2k-1}|[2-\delta_{2k-1}, t_0+1]$, is on the right side of the line $u = f(a_{2k-1})$ by (3.8). (See Fig. 1.)

Since f is an odd function, $\tilde{x}^{2k-1}(t) = -x(t; \varphi_{2k-1}), t \in [-1, +\infty)$, is a solution of (2.1) satisfying $\tilde{x}^{2k-1}(\theta) = -\varphi_{2k-1}(\theta)$ for θ in $[-1, 0]$. From the discussions above one can see that $x^{2k-1}|(t_0, t_0+1]$ is outside $\tilde{x}^{2k-1}|(0, 1]$ and $\tilde{x}|(t_0, t_0+1]$ is outside $x^{2k-1}|(0, 1]$. (See Fig. 1.) The Trajectory Crossing Lemma implies that there exists $t_2 > t_0 + 1$ such that $x^{2k-1}(t_2) = 0$ and $x^{2k-1}|(t_0, t_2+1]$ is outside $\tilde{x}|(0, t_0+1]$.

It is easy to see that the counterpart of $x^{2k-1}|(t_2, t_2+1]$ is $\tilde{x}^{2k-1}|(t_0, t_0+1]$—both orbits connect the negative v axis to the negative u axis—and therefore, the former is outside the latter. Consequently, $x^{2k-1}|(t_2, t_2+1]$ is outside $x^{2k-1}|(0,1]$, since $\tilde{x}^{2k-1}|(t_0, t_0+1]$ is outside the latter, as we mentioned above. The proof is completed by Corollary 2.3. □

CLAIM B. Suppose that (H1) is satisfied and $\{a_k\}_1^{2n}$ is as in Theorem 3.1. Choose $\delta_{2k} > 0$ small enough that

$$f(a_{2k})(1-\delta_{2k}) > \max\{f(a_{2k-1}), f(f(a_{2k}))\}. \tag{3.9}$$

Let $\varphi_{2k} (k = 1, 2, \ldots, n)$ in C_* be an arbitrary nonincreasing function satisfying

$$\varphi_{2k}(\theta) \begin{cases} = a_{2k}, & \theta \in [-1, -\delta_{2k}], \\ > 0, & \theta \in (-\delta_{2k}, 0), \\ = 0, & \theta = 0. \end{cases} \tag{3.10}$$

If $x^{2k} = x(\cdot; \varphi_{2k})$ is the solution of (2.1) and x^{2k-1} is as in Claim A, then $x^{2k}|(0, +\infty)$ is outside $x^{2k-1}|(0, +\infty)$ and x^{2k} spirals inward in $(0, +\infty)$.

Proof. By the assumptions we know that $a_{2k} > a_{2k-1} > 0$ and $a_{2k} > f(a_{2k}) > 0$; thus it follows from the monotonicity of f that there exists $\delta_{2k} > 0$ satisfying (3.9). Suppose $x^{2k} = x(\cdot; \varphi_{2k})$ is the solution of (2.1) satisfying $x^{2k}(\theta) = \varphi_{2k}(\theta)$ for θ in $[-1, 0]$. From (2.1), we have

$$x^{2k} = -\int_0^t f(\varphi_{2k}(\theta - 1))\, d\theta \quad \text{for } t \in [0, 1].$$

Therefore,

$$x^{2k}(t) = -f(a_{2k})t \quad \text{for } t \in [0, 1-\delta_{2k}] \tag{3.11}$$

and

$$-f(a_{2k}) < x^{2k}(t) < -f(a_{2k})(1-\delta_{2k}) \quad \text{for } t \in (1-\delta_{2k}, 1]. \tag{3.12}$$

Thus, the orbit of $x^{2k}|(0,1]$ in the (u, v) plane connects the negative v axis to the negative u axis, and consists of two parts. The first part, $x^{2k}|(0, 1-\delta_{2k}]$, lies in the third quadrant on the line $v = -a_{2k}$, while the other part, $x^{2k}|(1-\delta_{2k}, 1]$, is bounded by the four lines $v = -a_{2k}, v = 0, u = -f(a_{2k})$, and $u = -f(a_{2k})(1-\delta_{2k})$. Since $a_{2k} > a_{2k-1}$ and $f(a_{2k})(1-\delta_{2k}) > f(a_{2k-1})$, from the discussion right after (3.6), we know that the first and the second parts of $x^{2k}|(0,1]$ are below and on the right side of the orbit $x^{2k-1}|(0,1]$, respectively. Thus, $x^{2k}|(0,1]$ is outside $x^{2k-1}|(0,1]$. Therefore, by Claim A and Lemma 2.2, $x^{2k}|(0, +\infty)$ is outside $x^{2k-1}|(0, +\infty)$ and x^{2k} has infinitely many zeros in $(0, +\infty)$.

Let $t = t_0$ be the first positive zero of x^{2k}. One can see that $t_0 > 1$, because x^{2k} is a slowly oscillating solution and $x^{2k}(0) = 0$. Since $x^{2k}(t)$ is increasing in $(1, t_0 + 1)$, we know that

$$-f(a_{2k}) < x^{2k}(t) < 0 \tag{3.13}$$

for $t \in [t_0 - 1, t_0) \subset [0, t_0)$, and

$$\begin{aligned} x^{2k}(t) &= -\int_{t_0}^t f(x^{2k}(s-1))\, ds \\ &< f(f(a_{2k}))(t - t_0) \le f(f(a_{2k})) \quad \text{for } t \in (t_0, t_0 + 1]. \end{aligned} \tag{3.14}$$

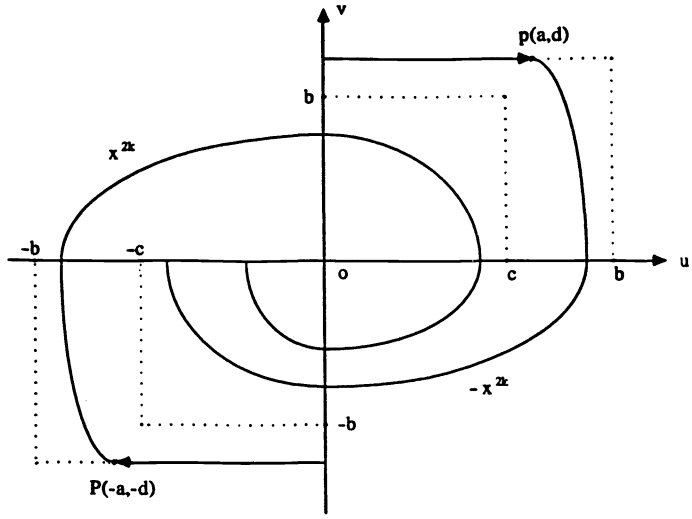

FIG. 2.

Therefore, $x^{2k}|(t_0, t_0+1]$ connects the positive v axis to the positive u axis and is bounded by the four lines $v = f(a_{2k}), v = 0, u = f(f(a_{2k}))$, and $u = 0$.

By the oddness of $f, \tilde{x}^{2k}(t) = -x^{2k}(t)$ is the solution of (2.1) satisfying $\tilde{x}^{2k}(\theta) = -\varphi_{2k}(\theta)$ for θ in $[-1, 0]$. Through the discussion above, we can see that $\tilde{x}^{2k}|(0,1]$ is outside $x^{2k}|(t_0, t_0+1]$ and $x^{2k}|(0,1]$ is outside $\tilde{x}^{2k}|(t_0, t_0+1]$, since $a_{2k} > f(a_{2k})$ and $f(a_{2k})(1-\delta_{2k}) > f(f(a_{2k}))$. (See Fig. 2.) Therefore, by Lemma 2.2, it is easy to see that $\tilde{x}^{2k}|(0, t_0+1]$ is outside $x^{2k}|(t_0, t_2+1]$, where $t = t_2$ is the second zero of x^{2k} for $t > 0$. One can see that the counterpart of $\tilde{x}^{2k}|(t_0, t_0+1]$ is $x^{2k}|(t_2, t_2+1]$—both orbits connect the negative v axis to the negative u axis—and therefore, the former is outside the latter. (See Fig. 2.) Consequently, $x^{2k}|(0,1]$ is outside $x^{2k}|(t_2, t_2+1]$ because $x^{2k}|(0,1]$ is outside $\tilde{x}^{2k}|(t_0, t_0+1]$. By Lemma 2.2, $x^{2k}|(0, +\infty)$ is outside $x^{2k}|(t_2, +\infty)$ since we have shown that x^{2k} has infinitely many zeros in $(0, +\infty)$. This means x^{2k} spirals inward in $(0, +\infty)$ by the definition. Claim B is proven. □

Proof of Theorem 3.1. If in Claim A we choose $\delta_{2k-1} > 0 (k = 2, 3, \ldots, n)$ so small that

$$f(a_{2k-1})(1-\delta_{2k-1}) > f(a_{2k-2})$$

is also satisfied, then similar to the discussions above one can see that $x^{2k-1}|(0,1]$ is outside $x^{2k-2}|(0,1]$ (since both of them connect the negative v axis to the negative u axis); $x^{2k-1}|(0,1]$ is in the exterior of the rectangle bounded by $v = -a_{2k-1}, v = 0, u = 0$, and $u = -f(a_{2k-1})$; and $x^{2k-2}|(0,1]$ is in the interior of that rectangle. Therefore, we have constructed solutions $x^k(\cdot)$ for $k = 1, 2, \ldots, 2n$ satisfying the following.

(i)′ $x^{k+1}|(0, +\infty)$ is outside $x^k|(0, +\infty)$ for $k = 1, 2, \ldots, 2n-1$,

(ii)′ x^{2k-1} spirals outward and x^{2k} spirals inward for $k = 1, 2, \ldots, n$.

The statement that x^{2k-1} spirals outward implies that the orbit of x^{2k-1} is bounded away from the origin of $\mathbb{R}^2$, and the statement that x^{2k} spirals inward implies that x^{2k} is bounded. On the other hand, by the property (i)′ above, the orbit of x^{2k} keeps

x^{2k-1} bounded and the orbit of x^{2k-1} keeps the orbit of x^{2k} bounded away from the origin. Therefore, by Theorem 2.4, there exist slowly oscillating periodic solutions $\bar{x}^{2k}$ and $\bar{x}^{2k-1}$ of (2.1) such that x^{2k-1} spirals outward toward the orbit of $\bar{x}^{2k-1}$ in $\mathbb{R}^2$ and x^{2k} spirals inward toward the orbit of $\bar{x}^{2k}$ in $\mathbb{R}^2$. It is obvious that $\bar{x}^{2k}$ and $\bar{x}^{2j}$ are distinct for any $k \neq j$. The proof is completed. □

4. An example. In this section, an equation is constructed which satisfies the conditions in Theorem 3.1, and which therefore has infinitely many slowly oscillating periodic solutions. Consider the equation

$$\dot{x}(t) = -f(x(t-1)), \tag{4.1}$$

where $f(x) = (b + \frac{3}{4})x + bx \sin[\ln(1 + |x|^{2/(3b)})]$.

PROPOSITION 4.1. *If $b \geq \frac{13}{4}$, then (4.1) has infinitely many slowly oscillating periodic solutions.*

Proof. It is obvious that $f(0) = 0$ and f is an odd function.

$$\begin{aligned} f'(x) &= \left(b + \frac{3}{4}\right) + b \sin[\ln(1 + |x|^{2/(3b)})] \\ &\quad + \frac{\frac{2}{3}|x|^{2/(3b)}}{1 + |x|^{2/(3b)}} \cos[\ln(1 + |x|^{2/(3b)})] \\ &\geq \frac{3}{4} - \frac{\frac{2}{3}|x|^{2/(3b)}}{1 + |x|^{2/(3b)}} > \frac{1}{12} \end{aligned}$$

for all $x \in \mathbb{R}$. Thus, if $x = f^{-1}(y)$ is the inverse of $y = f(x)$ and $\{a_k\}$ is defined by

$$a_{2k} = f^{-1}((e^{(2k-\frac{1}{2})\pi} - 1)^{3b/2}), \qquad a_{2k-1} = f^{-1}((e^{(2k-1)\pi} - 1)^{3b/2}) \tag{4.2}$$

for $k = 1, 2, 3, \ldots$, then $0 < a_1 < a_2 < a_3 < \cdots < a_{2k-1} < a_{2k} < \cdots$, and

$$f(a_{2k}) = \left(b + \frac{3}{4}\right) a_{2k} - (b) a_{2k} < a_{2k}.$$

Consequently,

$$\begin{aligned} \int_0^{f(a_{2k-1})} f(x)\, dx &= \frac{1}{2}\left(b + \frac{3}{4}\right)[f(a_{2k-1})]^2 + \int_0^{f(a_{2k-1})} bx \sin[\ln(1 + |x|^{2/(3b)})] dx \\ &= \frac{1}{2}\left(b + \frac{3}{4}\right)[f(a_{2k-1})]^2 + \int_0^{(2k-1)\pi} \frac{3b^2}{2}(e^s - 1)^{3b-1} e^s \sin s\, ds, \end{aligned}$$

where $s = \ln(1 + |x|^{2/(3b)})$ or $x = (e^s - 1)^{3b/2}$. If $h(s) = (e^s - 1)^{3b-1} e^s$, then $h(s)$ is positive and increasing for $s > 0$. Therefore,

$$\int_{(2j-1)\pi}^{(2j+1)\pi} \frac{3b^2}{2} h(s) \sin s\, ds > 0 \quad \text{for } j \geq 1,$$

and

$$\int_0^{f(a_{2k-1})} f(x)\, dx > \frac{1}{2}\left(b + \frac{3}{4}\right) f^2(a_{2k-1}) \geq 2 f^2(a_{2k-1}).$$

Thus, the function f satisfies the condition in Theorem 3.1 with $\{a_k\}_{k=1}^{\infty}$ defined by (4.2). Consequently, (4.1) has infinitely many slowly oscillating periodic solutions. □

Remark. For the more general function $f(x) = b_1 x + b_2 x \sin[\ln(1 + |x|^{\mu})]$, if $b_1 \geq 4, b_1 > b_2 > b_1 - 1$, and $0 < \mu < (b_1 - b_2)/b_2$, then using the technique of the preceding theorem one can show that this function f satisfies the conditions in Theorem 3.1 with $\{a_k\}_{k=1}^{\infty}$ defined by

$$a_{2k} = f^{-1}((e^{(2k-\frac{1}{2})\pi} - 1)^{1/\mu}), \qquad a_{2k-1} = f^{-1}((e^{(2k-1)\pi} - 1)^{1/\mu}). \tag{4.3}$$

Therefore, the equation (4.1) with this function f has infinitely many slowly oscillating periodic solutions.

ON RECURRENCE RELATIONS FOR SOBOLEV ORTHOGONAL POLYNOMIALS *

W. D. EVANS†, LANCE L. LITTLEJOHN‡, FRANCISCO MARCELLAN§, CLEMENS MARKETT¶, AND ANDRE RONVEAUX‖

Abstract. This paper discusses recurrence relations for sequences of polynomials which are orthogonal with respect to the Sobolev inner product defined on the set of polynomials $\mathcal{P}$ by

$$(p,q)_W = \sum_{k=0}^{N} \int_{\mathbb{R}} p^{(k)}(x)\bar{q}^{(k)}(x)\, d\mu_k(x) \qquad (p,q \in \mathcal{P})$$

for some integer $N \geq 1$, where each $\mu_k, 0 \leq k \leq N$, is a positive Borel measure. It is proven that there exists a real-valued polynomial $h : \mathbb{R} \to \mathbb{R}$ satisfying

$$(*) \qquad (hp,q)_W = (p,hq)_W \qquad (p,q \in \mathcal{P})$$

if and only if each of the measures $\mu_k, 1 \leq k \leq N$, is purely atomic with a finite number of mass points. In addition it is proven that R_j, the set of real roots of $d^j h/dx^j, (1 \leq j \leq N)$, is nonempty and that supp $(\mu_k) \subset \cap_{i=1}^{k} R_i$. It is also shown that if h satisfies the condition $(*)$, then the polynomials orthogonal with respect to the inner product $(\cdot,\cdot)_W$ will satisfy a recurrence relation of order $2m+1$, where $m = \deg(h)$. Furthermore, an algorithm is given to construct a polynomial H of minimal positive degree for which the above properties hold. Several examples will be discussed to illustrate the theory. Lastly it is shown, under certain circumstances, when these orthogonal polynomials will satisfy second-order linear differential equations.

Key words. Sobolev orthogonal polynomials, Borel measures, Dirac point mass measures, recurrence relations, second-order differential equations, structural relations

1. Introduction.

It is well known (i.e., see [3, pp. 21–22]) that every sequence of polynomials $\{\phi_n(x)\}_{n=0}^{\infty}$ orthogonal with respect to an inner product of the form

$$(1.1) \qquad (p,q)_\mu := \int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu(x),$$

where μ is a signed measure on the real line $\mathbb{R}$, satisfies a three-term recurrence relation of the form

$$(1.2) \qquad \begin{aligned} \phi_{n+1}(x) &= (a_n x + b_n)\phi_n(x) - c_n\phi_{n-1}(x) \qquad (n \geq 0), \\ \phi_0(x) &= c_0; \phi_{-1}(x) \equiv 0, \end{aligned}$$

where $\{a_n\}, \{b_n\}, \{c_n\} \subset \mathbb{R}$ and $a_n c_n \neq 0, n = 0, 1, 2, \ldots$. The key step in establishing (1.2) involves dealing with the obvious identity

$$(xp(x), q(x))_\mu = (p(x), xq(x))_\mu \tag{1.3}$$

for all polynomials p, q.

During the last few years, there have been several papers written about polynomials orthogonal with respect to Sobolev inner products. Some of these inner products are of the form

$$(p, q) := \int_I p(x)\bar{q}(x)\, d\mu(x) + \sum_{r=1}^{r_1} M_r p(c_r)\bar{q}(c_r) + \sum_{r=1}^{r_2} N_r p'(d_r)\bar{q}'(d_r), \tag{1.4}$$

where I is some interval on the real line, $M_r \geq 0, N_r \geq 0$, and c_r, d_r are fixed points (not necessarily in I). For example, see the contributions [1], [2], [12], [14], and the references therein. In each of the examples in these papers, the authors exhibit a polynomial $h(x)$ of degree $m \geq 1$ such that

$$(hp, q) = (p, hq)$$

for all polynomials p and q, and from this deduce that the corresponding orthogonal polynomials $\{\phi_n(x)\}$ satisfy a recurrence relation of the form

$$h(x)\phi_n(x) = \sum_{k=n-m}^{n+m} b_{n,k}\phi_k(x).$$

For Sobolev inner products involving derivatives of higher order, see [12].

We remark that all of this work has been influenced and popularized, in one way or another, by the paper of A. M. Krall [10], which has led to attaching mass points to the absolutely continuous measures associated with the classical orthogonal polynomials in order to obtain new orthogonal polynomials satisfying certain fourth-order differential equations.

Note that, in (1.4), if $N_r > 0$ for some $r, 1 \leq r \leq r_2$, it will *not* be the case that

$$(xp(x), q(x)) = (p(x), xq(x))$$

for all polynomials p, q. However, the authors in the above-mentioned papers exhibit polynomials $h : \mathbb{R} \to \mathbb{R}$ of degree $m = m(r_2) \geq 2$ such that

$$(h(x)p(x), q(x)) = (p(x), h(x)q(x))$$

for all polynomials p, q and, from this, deduce that $\{\phi_n(x)\}$ satisfies a $(2m+1)$-term recurrence relation of the form

$$h(x)\phi_n(x) = \sum_{k=n-m}^{n+m} b_{n,k}\phi_k(x) \qquad (n = m, m+1, \ldots).$$

In this paper, we shall be concerned with the weighted Sobolev inner product

$$(p, q)_W := \sum_{k=0}^{N} \int_{\mathbb{R}} p^{(k)}(x)\bar{q}^{(k)}(x)\, d\mu_k(x) \tag{1.5}$$

on the set

$$\mathcal{P} := \left\{ p(x) = \sum_{k=0}^{n} a_k x^k | a_k \in \mathbb{C}, n \in \mathbb{N}_0 \right\}$$

of all polynomials $p : \mathbb{R} \to \mathbb{C}$, where each $\mu_k, k = 0, 1, \ldots, N$, is a positive Borel measure on the Borel subsets $\mathcal{B}(\mathbb{R})$ of the real line $\mathbb{R}$, and $N \geq 1$ is a fixed integer. We shall also assume that the moments $\{c_{n,k}\}_{n=0}^{\infty}$ of $\mu_k, 0 \leq k \leq N$, defined by

$$c_{n,k} := \int_{\mathbb{R}} x^n \, d\mu_k \qquad (n = 0, 1, 2, \ldots; k = 0, 1, \ldots, N),$$

exist and are finite. Notice that the inner product in (1.5) includes every inner product of the form (1.4). We shall also find it necessary in certain situations to let $\mathcal{H}$ denote a Hilbert space generated by the inner product $(\cdot, \cdot)_W$ satisfying the inclusion $\mathcal{P} \subset \mathcal{H}$. It is not assumed that $\mathcal{P}$ is dense in $\mathcal{H}$. We note that an example of $\mathcal{H}$ could be the classical weighted Sobolev space $W_2^N(\mathbb{R}, d\mu_0, \ldots, d\mu_N)$ (see [11]).

Before stating the main theorem of this paper, we note that we shall use the notation δ_{x_0} to denote the Dirac point mass measure defined on the Borel subsets of $\mathbb{R}$ by

$$\delta_{x_0}(B) = \begin{cases} 1 & \text{if } x_0 \in B \\ 0 & \text{if } x_0 \notin B \end{cases} \qquad (B \in \mathcal{B}(\mathbb{R})).$$

Moreover, as is customary, we shall write $d(\delta_{x_0}) = \delta(x - x_0)dx$, where $\delta(x - x_0)$ is the so-called Dirac delta distribution. We list other notation that the reader will frequently encounter in this paper:

$\mathbb{N}_0$ denotes the set of nonnegative natural numbers;
$\mathbb{C}$ denotes the set of complex numbers;
$\bar{z}$ denotes the complex conjugate of the complex number z;
$f^{(k)}(x)$ denotes the kth derivative of the function f with respect to x;
supp (μ) denotes the support of the positive measure μ.

In §3 we shall prove the following theorem.

THEOREM 1.

(i) *Suppose there exists a polynomial $h : \mathbb{R} \to \mathbb{R}$ of degree ≥ 1 satisfying*

$$(hp, q)_W = (p, hq)_W \qquad (p, q \in \mathcal{P}), \tag{1.6}$$

where $(\cdot, \cdot)_W$ is the inner product defined in (1.5). *Then the measures $\mu_k, 1 \leq k \leq N$ are necessarily of the form*

$$\mu_k = \sum_{j=1}^{P(k)} \alpha_{k,j} \delta_{x_{k,j}} \tag{1.7}$$

for some positive integer $P(k)$, where

(a) $\alpha_{k,j} \geq 0, j = 1, \ldots, P(k), k = 1, \ldots, N$;

(b) $\{x_{k,j} | j = 1, \ldots, P(k)\} := R_k \neq \emptyset$ *are the distinct real roots of $h^{(k)}(x), 1 \leq k \leq N$;*

(c) supp $(\mu_k) \subset \cap_{j=1}^{k} R_j \neq \emptyset, k = 1, \ldots, N$.

Moreover, the degree of h is at least $N + 1$ and

(d) *there exists a unique (up to a nonzero, real constant multiple) polynomial $H : \mathbb{R} \to \mathbb{R}$ of minimal degree $m(H)$ $(\geq N + 1)$ satisfying $H(0) = 0$ and*

$$(Hp, q)_W = (p, Hq)_W \qquad (p, q \in \mathcal{P});$$

(e) *the sequence of polynomials* $\{\phi_n(x)\}$ *that are orthogonal with respect to the inner product* $(\cdot,\cdot)_W$ *will satisfy a* $(2m(H)+1)$*-term recurrence relation*

$$H(x)\phi_n(x) = \sum_{k=n-m(H)}^{n+m(H)} b_{n,k}\phi_k(x) \qquad (n \geq m(H)) \tag{1.8}$$

for some real numbers $b_{n,k}$. *Furthermore, the* length (*see Remark* 8 *in* §3, *below*) *of this recurrence relation is at least* $2N+3$.

(ii) *Suppose the measures* $\mu_k, 1 \leq k \leq N$, *in the inner product* (1.5) *are given by*

$$\mu_k = \sum_{j=1}^{Q(k)} \beta_{kj}\delta_{y_{kj}}$$

for some positive integer $Q(k)$ *with* $\operatorname{supp}(\mu_k) = \{y_{k1}, \ldots, y_{k,Q(k)}\}$ (*i.e.,* $\beta_{kj} > 0$ *for* $j = 1, \ldots, Q(k)$). *Then there exists a unique* (*up to a nonzero, real constant multiple*) *polynomial* $H : \mathbb{R} \to \mathbb{R}$ *of minimal degree* $m(H) \geq N+1$ *satisfying the conditions of* (d) *and* (e) *above. Moreover, if* R_k *denotes the set of real roots of* $H^{(k)}(x), 1 \leq k \leq N$, *then* (c) *is valid.* □

Remark 1. The fact that $h^{(k)}(x)$ has at least one real root $(1 \leq k \leq N)$ may seem somewhat surprising upon first glance, but it is a consequence of (1.6) (see Theorem 4 below) and not a condition that is assumed.

Remark 2. Under the conditions of Theorem 1, we see that the measures $\mu_k, 1 \leq k \leq N$, are *purely atomic.* No restriction is placed on the leading measure μ_0; see §5 of this paper for further discussion of this observation.

Remark 3. The Gram–Schmidt orthogonalization process (see [3, pp. 13–14]) may be used to assert the existence of a sequence $\{\phi_n(x)\}$ of *real* polynomials which are orthogonal with respect to the inner product $(\cdot,\cdot)_W$, defined in (1.5). Of course, it may be difficult in practice to explicitly compute each $\phi_n(x)$ by this method. If this is the case and if the recurrence coefficients b_{nk} can be efficiently calculated, then the recurrence relation (1.8) affords an alternative way of computing each $\phi_n(x)$.

The reader should also consult the contribution of Iserles et al. [8] for another approach to effectively finding each $\phi_n(x)$. They consider the inner product (1.5) in the case of $N = 1$ and when the positive Borel measure μ_1 has infinite support. In this case, the polynomials $\{\phi_n(x)\}$ will not necessarily satisfy a recurrence relation of the form (1.8). Consequently, the *computation* of these polynomials will, in general, be quite difficult. However, in [8], the authors give conditions on when these polynomials can be efficiently computed in terms of the orthogonal polynomials associated with the leading measure μ_0.

Throughout this paper we shall speak of *the* orthogonal polynomial sequence $\{\phi_n(x)\}$; of course, each $\phi_n(x)$ is only uniquely determined up to an arbitrary nonzero constant multiple.

Remark 4. As mentioned above, the key step in establishing a three-term recurrence relation for an orthogonal polynomial sequence in a space generated by the inner product (1.1) is in recognizing the identity (1.3). It is interesting to point out that condition (1.3) may be stated in terms of Hermitian operators. Indeed, if $\mathcal{H}$ denotes the Hilbert space generated by $(\cdot,\cdot)_\mu$, then (1.3) is equivalent to the operator $T : \mathcal{P} \to \mathcal{H}$ being Hermitian, where T is defined by

$$T(p(x)) = xp(x), \qquad p \in \mathcal{D}(T) = \mathcal{P}.$$

Moreover, if $\mathcal{P}$ is dense in $\mathcal{H}$, then (1.3) is equivalent to the operator T being symmetric. See Remark 10, below, for further discussion.

At this point, we mention the important work of Duran [4], which we just recently obtained. For each $N \geq 1$, he characterizes those inner products $(\cdot, \cdot)$ on the space $\mathcal{P}$ of polynomials for which the operator $S_N : \mathcal{P} \to \mathcal{P}$ defined by

$$S_N(p(x)) = x^N p(x), \qquad p \in \mathcal{D}(S_N) = \mathcal{P}$$

is Hermitian. From this characterization, he obtains inner products more general than our inner product in (1.5). In §3 of his paper, and by considering an approach different from ours, he does consider the inner product (1.5). Although he shows that the measures $\mu_k, 1 \leq k \leq N$, are discrete in this case, his characterization is not as explicit as our Theorem 1.

Remark 5. In this paper, we shall only consider *real-valued* polynomials h of degree ≥ 1 satisfying (1.6). Further work needs to be done in the case of complex-valued polynomials h satisfying (1.6). The interesting case seems to be when h is real-valued; indeed, this seems to be the only case considered in the literature.

Remark 6. We could have defined our inner product $(\cdot, \cdot)_W$ in (1.5) to be

$$(p, q)_W = \sum_{k=0}^{N} \int_{I_k} p^{(k)}(x) \bar{q}^{(k)}(x)\, d\mu_k. \tag{1.9}$$

where I_k is a real interval $(0 \leq k \leq N)$. A particularly interesting case would arise when $I_k \cap I_j = \emptyset, k, j = 0, \ldots, N$. However, since each μ_k can be extended in an obvious way to a Borel measure on all of $\mathcal{B}(\mathbb{R})$, we see that the inner product (1.9) is a special case of (1.5). We remark, however, that there is at least one *disadvantage* of using (1.5) over (1.9): the inner product in (1.9) can be more descriptive. For example, suppose $\{\phi_n(x)\}$ is an orthogonal polynomial sequence with respect to the inner product

$$(p, q)_I := \int_I p(x)\bar{q}(x)\, d\mu(x),$$

where μ is a positive measure and I is some interval on the real line. The classical theory of orthogonal polynomials dictates that these polynomials will have their roots in the interior of I. This may not be so clear if we write the above inner product as

$$\int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu(x).$$

Remark 7. Before proceeding with the rest of the paper, we point out that if an orthogonal polynomial sequence (OPS) $\{\phi_n(x)\}$ is orthogonal with respect to the inner product

$$(p, q)_W := \sum_{k=0}^{N} \int_{\mathbb{R}} p^{(k)}(x) \bar{q}^{(k)}(x)\, d\mu_k(x)$$

as well as orthogonal with respect to the inner product defined from the leading measure μ_0, i.e.

$$(p, q)_{\mu_0} := \int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu_0(x),$$

then

(i) $\{\phi_n(x)\}$ will satisfy a three-term recurrence relation, and

(ii) $\mu_k, 1 \leq k \leq N$, does not necessarily have the form (1.7), and

(iii) there does not necessarily exist a real-valued polynomial $h(x)$ of degree ≥ 1 such that (1.6) holds.

Indeed, some examples are the classical orthogonal polynomials of Jacobi, Laguerre, and Hermite and, in general, orthogonal polynomials that satisfy higher-order differential equations of the form

$$\sum_{r=1}^{2m} a_r(x)y^{(r)}(x) = \lambda y(x). \tag{1.10}$$

For example, the classical Jacobi polynomials are orthogonal with respect to the inner products

$$(p,q)_J = \int_{-1}^{1} p(x)\bar{q}(x)(1-x)^{\alpha}(1+x)^{\beta}\,dx \qquad (\alpha > -1, \beta > -1),$$

and

$$(p,q)_{J,W} = (p,q)_J + \int_{-1}^{1} p'(x)\bar{q}'(x)(1-x)^{\alpha+1}(1+x)^{\beta+1}\,dx.$$

Similarly, the Laguerre-type polynomials, which satisfy a fourth-order equation of the form (1.10), are orthogonal with respect to the two inner products

$$(p,q)_{\sigma} = \int_{[0,\infty)} p(x)\bar{q}(x)\,d\sigma(x)$$

and

$$(p,q)_{\sigma,W} = (p,q)_{\sigma} + \int_{0}^{\infty} \{x^2e^{-x}p''(x)\bar{q}''(x) + ((2A+2)x+2)e^{-x}p'(x)\bar{q}'(x)\}\,dx,$$

where A is a fixed, positive constant and σ is the Borel measure generated from the monotonic increasing function $\hat{\sigma} : [0,\infty) \to \mathbb{R}$ defined by

$$\hat{\sigma}(x) = \begin{cases} -1/A & \text{if } x = 0, \\ 1 - e^{-x} & \text{if } x > 0. \end{cases}$$

For additional examples and references, see [5] and [6]. Because of this peculiarity, we shall henceforth assume that the polynomials orthogonal with respect to the inner product (1.5) are *not* orthogonal with respect to the leading measure μ_0.

In §2 of this paper, we shall state and prove a measure theoretic result which is essential in the proof of Theorem 1. Section 3 contains a proof of Theorem 1 while §4 considers several examples to illustrate the theory. Lastly, in §5, we discuss refinements of the theorem with applications to semiclassical orthogonal polynomials.

2. A preliminary measure theory result. The following theorem is essential in establishing the proof of Theorem 1.

THEOREM 2. *Suppose σ is a finite, positive Borel measure on the Borel subsets $\mathcal{B}(\mathbb{R})$ of the real line $\mathbb{R}$ with* $\operatorname{supp}(\sigma) \subset J$, *where J is some interval on the real line. In addition, suppose $K : \mathbb{R} \to \mathbb{R}$ is a polynomial of degree $m \geq 1$ such that*

(i) $K(x) \geq 0, x \in J$, *and*

(ii) $\int_J K(x)\,d\sigma(x) = 0$.

Then there exists an integer $P \geq 1$, *points* $x_1, \ldots, x_P \in J$ *satisfying* $K(x_j) = 0, j = 1, \ldots, P$, *and positive constants* $\alpha_1, \ldots, \alpha_P$ *such that*

$$\operatorname{supp}(\sigma) = \{x_1, \ldots, x_P\}$$

and

$$\sigma = \sum_{j=1}^{P} \alpha_j \delta_{x_j}. \tag{2.1}$$

Proof. If $K(x)$ has no roots in J, we can write $J = \cup_{n=1}^{\infty} A_n$, where

$$A_n := \{x \in J | K(x) > 1/n\} \in \mathcal{B}(\mathbb{R}) \qquad (n = 1, 2, 3, \ldots).$$

However, $0 = \int_J K\,d\sigma \geq \int_{A_n} K\,d\sigma \geq (1/n)\sigma(A_n)$ so that $\sigma(A_n) = 0, n = 1, 2, \ldots$, which forces $\sigma(J) = 0$, contradicting the fact that σ is a positive measure with $\operatorname{supp}(\sigma) \subset J$. Consequently, let $\emptyset \neq R := \{y_1, \ldots, y_r\}$ denote the set of distinct roots of $K(x)$ in J. By repeating the above argument, we can show that $\sigma(B) = 0$ whenever $B \in \mathcal{B}(\mathbb{R})$ and $B \cap R = \emptyset$. If $B \in \mathcal{B}(\mathbb{R})$ is arbitrary, we may write $B = (B \setminus R_B) \cup R_B$, where $R_B := R \cap B$. Then $\sigma(B \setminus R_B) = 0$, and thus

$$\sigma(B) = \sigma(R_B) = \sum_{y_j \in R_B} \alpha_j,$$

where $\alpha_j := \sigma(\{y_j\}), j = 1, \ldots, r$. In particular, $\sigma(J) = \sum_{j=1}^{r} \alpha_j$, and since $\sigma(J) > 0$, at least one of the $\alpha_j's$ is positive. Let $S := \{y_j \in R | \alpha_j > 0\}$ so $S = \operatorname{supp}(\sigma)$ and $m \geq r \geq \operatorname{card}(S) := P \geq 1$. For convenience, rewrite $S = \{x_1, \ldots, x_P\}$ where $\sigma(\{x_j\}) = \alpha_j, j = 1, \ldots, P$. Then

$$\sigma(B) = \sum_{x_j \in B} \alpha_j. \tag{2.2}$$

The proof is complete on noting that (2.2) is equivalent to (2.1). □

3. The Proof of Theorem 1. We start with the following basic result.

LEMMA 3. *Suppose there exists a polynomial* $h : \mathbb{R} \to \mathbb{R}$ *of degree* $m \geq 1$ *such that*

$$(hp, q)_W = (p, hq)_W \qquad (p, q \in \mathcal{P}). \tag{3.1}$$

Let $\{\phi_n(x)\}_{n=0}^{\infty}$ *be the orthogonal polynomial sequence generated by* $(\cdot, \cdot)_W$. *Then* $\{\phi_n(x)\}$ *satisfies the* $(2m+1)$*-term recurrence relation*

$$h(x)\phi_n(x) = \sum_{k=n-m}^{n+m} b_{n,k}\phi_k(x) \qquad (n = m, m+1, \ldots), \tag{3.2}$$

where

$$b_{n,k} = \frac{(h\phi_n, \phi_k)_W}{(\phi_k, \phi_k)_W} \qquad (n = m, m+1, \ldots; k = n-m, n-m+1, \ldots, n+m). \tag{3.3}$$

Proof. For $n \geq m$, we can find real constants $b_{n,k}, k = 0, 1, \ldots, n+m$ such that

$$h(x)\phi_n(x) = \sum_{k=0}^{n+m} b_{n,k}\phi_k(x).$$

For $0 \leq r \leq n+m$, the orthogonality of $\{\phi_n(x)\}$ yields

$$(h\phi_n, \phi_r)_W = \sum_{k=0}^{n+m} b_{n,k}(\phi_k, \phi_r)_W = b_{n,r}(\phi_r, \phi_r)_W. \tag{3.4}$$

On the other hand, $(h\phi_n, \phi_r)_W = (\phi_n, h\phi_r)_W = 0$ if $m + r < n$; i.e. $b_{n,r} = 0$ if $r = 0, \ldots, n-m-1$.

This establishes (3.2), and (3.3) follows from (3.4). □

Remark 8. If the polynomials $\{\phi_n(x)\}$ satisfy a recurrence relation of the form (3.2), with $b_{n,n+m} \neq 0, n \geq m$, then we shall say that $\{\phi_n(x)\}$ satisfies a recurrence relation of *length* $2m+1$. We remark that, in general, it can be quite difficult to compute the recurrence coefficients $b_{n,k}$ given in (3.3). See §5 for a further discussion of this. □

THEOREM 4. *Consider the inner product* $(\cdot,\cdot)_W$, *defined in* (1.5), *where the measures* $\mu_k, k = 0, 1, \ldots, N$, *are positive Borel measures on the Borel subsets of the real line. If there exists a polynomial* $h : \mathbb{R} \to \mathbb{R}$ *of degree* $m \geq 1$ *such that* (3.1) *holds for all* $p, q \in \mathcal{P}$, *then*

$$d\mu_k(x) = \sum_{j=1}^{P(k)} \alpha_{k,j}\delta(x - x_{k,j})\,dx \qquad (k = 1, \ldots, N), \tag{3.5}$$

for some positive integer $P(k)$, *where* $\alpha_{k,j} \geq 0, k = 1, \ldots, N; j = 1, \ldots, P(k)$,

$$R_k = \{x_{k,j}\}_{j=1}^{P(k)} \text{ are the distinct real roots of } h^{(k)}(x), \tag{3.6}$$

and

$$\operatorname{supp}(\mu_k) \subset \bigcap_{j=1}^{k} R_j \neq \emptyset \qquad (k = 1, 2, \ldots, N). \tag{3.7}$$

Proof. Suppose $(hp, q)_W = (p, hq)_W$ for all polynomials $p, q \in \mathcal{P}$. That is,

$$\sum_{k=1}^{N}\sum_{j=0}^{k-1} \binom{k}{j} \int_{\mathbb{R}} h^{(k-j)}[p^{(j)}\bar{q}^{(k)} - p^{(k)}\bar{q}^{(j)}]\,d\mu_k = 0 \qquad (p, q \in \mathcal{P}). \tag{3.8}$$

Substituting $p(x) = 1$ and $q(x) = h(x)$ into (3.8) yields

$$\int_{\mathbb{R}} (h'(x))^2\,d\mu_1 + \int_{\mathbb{R}} (h''(x))^2\,d\mu_2 + \cdots + \int_{\mathbb{R}} (h^{(N)}(x))^2\,d\mu_N = 0.$$

Since $\mu_1, \ldots, \mu_N$ are all positive measures, we must have

$$\int_{\mathbb{R}} (h^{(k)}(x))^2\,d\mu_k = 0 \qquad (k = 1, \ldots, N). \tag{3.9}$$

By Theorem 2, we see that for each $k, 1 \leq k \leq N$, there exists an integer $P(k) \geq 1$, distinct real numbers $x_{k,1}, \ldots, x_{k,P(k)}$ and nonnegative constants $\alpha_{k,1}, \ldots, \alpha_{k,P(k)}$ such that

(i) $\operatorname{supp}(\mu_k) \subset \{x_{k,1}, \ldots, x_{k,P(k)}\}$;

(ii) $h^{(k)}(x_{k,j}) = 0, j = 1, \ldots, P(k)$; i.e., $\{x_{k,j}\}_{j=1}^{P(k)}$ are the distinct real roots of $h^{(k)}(x)$;

(iii) $d\mu_k(x) = \sum_{j=1}^{P(k)} \alpha_{k,j}\delta(x - x_{k,j})\,dx, k = 1, \ldots, N$.

This establishes (3.5) and (3.6) of the theorem.

We now prove, by induction, that

$$\int_{\mathbb{R}} (h^{(k-i)}(x))^2\,d\mu_k = 0 \qquad (i = 0, \ldots, k-1; k = i+1, \ldots, N). \tag{3.10}$$

As a consequence of this induction, we will see that

$$\operatorname{supp}(\mu_k) \subset \bigcap_{i=1}^{k} R_1 \qquad (k = 1, \ldots, N). \tag{3.11}$$

Notice that we have established (3.10) in the case of $i = 0$ (see (3.9)). Suppose, then, that for some $r, 0 \leq r < N$, we have

$$\int_{\mathbb{R}} (h^{(k-i)}(x))^2\,d\mu_k = 0 \qquad (i = 0, \ldots, r; k = i+1, \ldots, N). \tag{3.12}$$

We must show that

$$\int_{\mathbb{R}} (h^{(k-r-1)}(x))^2\,d\mu_k = 0 \qquad (k = r+2, \ldots, N). \tag{3.13}$$

For each $k \in \{1, \ldots, N\}$ and $i \in \{0, \ldots, k-1\}$, we may write

$$h^{(k-i)}(x) = Q_{k-i}(x)(x - x_{k-i,1})^{r_{k-i,1}}(x - x_{k-i,2})^{r_{k-i,2}} \cdots (x - x_{k-i,P(k-i)})^{r_{k-i,P(k-i)}}, \tag{3.14}$$

where $Q_{k-i}(x)$ has no real roots and $r_{k-i,j}, j = 1, \ldots, P(k-i)$, are positive integers. From (3.5), we see that (3.12) implies that

$$\sum_{j=1}^{P(k)} \alpha_{kj} Q_{k-i}^2(x_{kj})(x_{kj} - x_{k-i,1})^{2r_{k-i,1}} \cdots (x_{kj} - x_{k-i,P(k-i)})^{2r_{k-i,P(k-i)}} = 0 \tag{3.15}$$
$$(i = 0, \ldots, r; k = i+1, \ldots, N).$$

Since $Q_{k-i}(x_{k,j}) \neq 0$, either $\alpha_{k,j} = 0$ or $x_{k,j}$ is a root of $h^{(k-i)}(x), i = 0, \ldots, r; k = i+1, \ldots, N, j = 1, \ldots, P(k)$. In other words,

$$\operatorname{supp}(\mu_k) \subset R_{k-i} \qquad (i = 0, 1, \ldots, r; k = i+1, \ldots, N),$$

from which it follows that

$$\operatorname{supp}(\mu_k) \subset \bigcap_{i=1}^{k} R_i \qquad (k = 1, \ldots, r+1) \tag{3.16}$$

and

$$\text{supp}\,(\mu_k) \subset \bigcap_{i=k-r}^{k} R_i \qquad (k = r+2, \ldots, N). \tag{3.17}$$

Moreover, (3.5) and (3.12) also imply that

$$\int_{\mathbb{R}} p(x) h^{(k-i)}(x)\, d\mu_k = 0 \qquad (p \in \mathcal{P}; i = 0, \ldots, r; k = i+1, \ldots, N),$$

and consequently (3.8) simplifies to

$$\sum_{k=r+2}^{N} \sum_{j=r+1}^{k-1} \binom{k}{j} \int_{\mathbb{R}} h^{(k-j)} [p^{(j)} \bar{q}^{(k)} - p^{(k)} \bar{q}^{(j)}]\, d\mu_k = 0 \qquad (p, q \in \mathcal{P}). \tag{3.18}$$

Substitute $p(x) = x^{r+1}/(r+1)!$ and $q(x) = x^{n+r+2}/(n+1)_{r+2}$ into (3.18), where $(a)_n$ is the Pochhammer symbol, to get

$$\begin{aligned} &\binom{r+2}{r+1} \int_{\mathbb{R}} h'(x) x^n\, d\mu_{r+2} + \binom{r+3}{r+1} \int_{\mathbb{R}} h''(x) n x^{n-1}\, d\mu_{r+3} + \cdots \\ &\quad + \binom{N}{r+1} \int_{\mathbb{R}} h^{(N-r-1)}(x) n(n-1) \cdots (n-N+r+3) x^{n-N+r+2}\, d\mu_N = 0. \end{aligned}$$

If we write $h'(x) = \sum_{n=0}^{m-1} \beta_n x^n$ and substitute into the above equation, we immediately obtain

$$\int_{\mathbb{R}} (h'(x))^2\, d\mu_{r+2} = \int_{\mathbb{R}} (h''(x))^2\, d\mu_{r+3} = \cdots = \int_{\mathbb{R}} (h^{(N-r-1)}(x))^2\, d\mu_N = 0,$$

thereby establishing (3.13).

Furthermore, using the representations (3.14) and (3.5), we see that (3.13) yields

$$\begin{aligned} &\sum_{j=1}^{P(k)} \alpha_{kj} Q_{k-r-1}^2(x_{kj}) (x_{kj} - x_{k-r-1,1})^{2r_{k-r-1,1}} \\ &\qquad \cdots (x_{kj} - x_{k-r-1,P(k-r-1)})^{2r_{k-r-1,P(k-r-1)}} = 0 \\ &\qquad (k = r+2, \ldots, N), \end{aligned} \tag{3.19}$$

from which it follows that

$$\text{supp}\,(\mu_k) \subset R_{k-r-1} \qquad (k = r+2, \ldots, N).$$

In particular,

$$\text{supp}\,(\mu_{r+2}) \subset R_1. \tag{3.20}$$

Combining (3.17) and (3.20), we find that

$$\text{supp}\,(\mu_{r+2}) \subset \bigcap_{i=1}^{r+2} R_i.$$

This completes the induction and establishes (3.7) of the theorem. The proof of the theorem is now complete. □

COROLLARY 5. *Under the assumptions of Theorem 4, the degree m of $h(x)$ must be at least $N+1$.*

Proof. Suppose, to the contrary, that $1 \leq m \leq N$ so that $h^{(m)}(x) \equiv c \neq 0$, for some constant c. From (3.9), however, we find that

$$\int_{\mathbb{R}} (h^{(m)}(x))^2 \, d\mu_m = c^2 \int_{\mathbb{R}} d\mu_m = 0,$$

contradicting the fact that μ_m is a positive measure. □

Remark 9. See Remark 11, below, for precise conditions for when there exists a polynomial $h : \mathbb{R} \to \mathbb{R}$ of degree *exactly* $N+1$ satisfying $(hp, q)_W = (p, hq)_W, p, q \in P$. By Lemma 3, it now follows that the sequence of polynomials that are orthogonal with respect to the inner product $(\cdot, \cdot)_W$ will satisfy a recurrence relation of length *at least* $2N+3$.

Remark 10. Stating Theorem 4 slightly differently, it is interesting to note that if the operator $T : \mathcal{P} \to \mathcal{H}$, defined by

$$T(p(x)) = h(x)p(x), \qquad p \in \mathcal{D}(T) = \mathcal{P},$$

is Hermitian, then the measures $\mu_k, 1 \leq k \leq N$, defined in the inner product $(\cdot, \cdot)_W$ necessarily satisfy conditions (3.5) and (3.7). As we shall see below, in Theorem 6, the converse statement is also true.

Summarizing the results of this section so far, we know if there exists a real-valued polynomial h of degree $m \geq 1$ such that (3.1) holds, then the corresponding orthogonal polynomials generated by $(\cdot, \cdot)_W$ satisfy a $(2m+1)$-term recurrence relation; that is, *the degree m of $h(x)$ determines the length of the recurrence relation.* Of course, if h does satisfy (3.1), it will not be unique. Indeed,

$$(hPp, q)_W = (p, hPq)_W \qquad (p, q \in \mathcal{P}),$$

where $P : \mathbb{R} \to \mathbb{R}$ is an arbitrary polynomial. It is natural, then, to ask: what is a polynomial $H : \mathbb{R} \to \mathbb{R}$ of *minimal* degree for which (3.1) holds? From Lemma 3, this minimal polynomial will be *optimal* in the sense that it will yield the recurrence relation of *minimal length* for the associated orthogonal polynomials.

To answer this question, write

$$\mu_k = \sum_{j=1}^{Q(k)} \beta_{kj} \delta_{y_{k,j}} \qquad (k = 1, \ldots, N), \tag{3.21}$$

where we shall now assume that $\beta_{kj} > 0$; i.e.,

$$\operatorname{supp}(\mu_k) = \{y_{k,1}, \ldots, y_{k,Q(k)}\} \qquad (k = 1, \ldots, N), \tag{3.22}$$

and $\operatorname{card}(\operatorname{supp}(\mu_k)) := Q(k) \leq P(k)$.

We now define sets $B_k \subset \operatorname{supp}(\mu_k)$ with $\alpha(k) := \operatorname{card}(B_k) \leq Q(k)$ and polynomials $h_k, 1 \leq k \leq N$ as follows:

(i) Let $B_N = \operatorname{supp}(\mu_N)$ and $h_N(x) = \prod_{y_{N,j} \in B_N} (x - y_{N,j})^N$;

(ii) For $1 \le k \le N-1$, let

$$B_k = \operatorname{supp}(\mu_k) \setminus \bigcup_{j=k+1}^{N} \operatorname{supp}(\mu_j)$$

and define

$$h_k(x) = \begin{cases} 1 & \text{if } B_k = \emptyset, \\ \prod_{y_{kj} \in B_k} (x - y_{kj})^k & \text{if } B_k \neq \emptyset. \end{cases}$$

Notice that the degree of $h_k(x)$ is given by

$$\deg(h_k) = \begin{cases} 0 & \text{if } B_k = \emptyset, \\ k\alpha(k) & \text{if } B_k \neq \emptyset. \end{cases}$$

Finally, let $H(x)$ be the polynomial of degree

$$m(H) := 1 + \sum_{k=1}^{N} \deg(h_k), \tag{3.23}$$

defined by

$$H(x) = \int_0^x \prod_{k=1}^{N} h_k(t)\, dt. \tag{3.24}$$

THEOREM 6. *The polynomial $H : \mathbb{R} \to \mathbb{R}$ defined in* (3.24) *is the unique polynomial (up to a nonzero real constant multiple) of minimal degree satisfying $H(0) = 0$ and* (3.1)*, with the positive measures $\mu_k, 1 \le k \le N$, satisfying conditions* (3.21) *and* (3.22)*. Moreover, if R_k denotes the set of real roots of $H^{(k)}(x)$, then*

$$\operatorname{supp}(\mu_k) \subset \bigcap_{j=1}^{k} R_j \qquad (1 \le k \le N). \tag{3.25}$$

Proof. As in (3.8), we see that

$$(Hp, q)_W - (p, Hq)_W = \sum_{k=1}^{N} \sum_{j=0}^{k-1} \binom{k}{j} \int_{\mathbb{R}} H^{(k-j)} [p^{(j)} \bar{q}^{(k)} - p^{(k)} \bar{q}^{(j)}]\, d\mu_k \qquad (p, q \in \mathcal{P}) \tag{3.26}$$

We show that expression (3.26) is zero for all $p, q \in \mathcal{P}$.

From (3.21) and (3.24), we may write

$$H'(x) = (x - y_{N,1})^N \cdots (x - y_{N,\alpha(N)})^N Q_1(x),$$

where $Q_1(x) = h_1(x) \cdots h_{N-1}(x)$. Hence, for $1 \le r \le N$,

$$\frac{dH^r(x)}{dx^r} = (x - y_{N,1})^{N-r+1} \cdots (x - y_{N,\alpha(N)})^{N-r+1} Q_r(x)$$

for some polynomial $Q_r(x)$. Since the exponents $N - r + 1 \geq 1$ for $1 \leq r \leq N$, it follows from (3.21) that

$$\sum_{j=0}^{N-1} \binom{N}{j} \int_{\mathbb{R}} H^{(N-j)}[p^{(j)}\bar{q}^{(N)} - p^{(N)}\bar{q}^{(j)}]\, d\mu_N = 0 \qquad (p, q \in \mathcal{P}).$$

Now write

$$H'(x) = (x - y_{N,1})^N \cdots (x - y_{N,\alpha(N)})^N \prod (x - y_{N-1,j})^{N-1} P_1(x), \qquad y_{N-1,j} \in B_{N-1}$$

for some $P_1 \in \mathcal{P}$. Then, for $1 \leq r \leq N - 1$, we see that

(3.27)
$$\frac{dH^r(x)}{dx^r} = P_r(x)(x - y_{N,1})^{N-r+1} \cdots (x - y_{N,\alpha(N)})^{N-r+1} \prod (x - y_{N-1,j})^{N-r}, \qquad y_{N-1,j} \in B_{N-1}$$

for some polynomial $P_r(x)$.

Since $\operatorname{supp}(\mu_{N-1}) \subset B_N \cup B_{N-1}$, it follows from (3.27) that

$$\sum_{j=0}^{N-2} \binom{N-1}{j} \int_{\mathbb{R}} H^{(N-j-1)}[p^{(j)}\bar{q}^{(N-1)} - p^{(N-1)}\bar{q}^{(j)}]\, d\mu_{N-1} = 0 \qquad (p, q \in \mathcal{P}).$$

Likewise, and in a similar fashion, we can show that each of the terms on the right-hand side of (3.26) is zero. Hence $H(x)$, as given in (3.24), does satisfy (3.1).

Suppose $g : \mathbb{R} \to \mathbb{R}$ is a polynomial satisfying (3.1), and $g(0) = 0$. From (3.6) and (3.7) of Theorem 4, we see that $g'(x)$ is given by

$$g'(x) = P(x) \prod_{k=1}^{Q(1)} (x - y_{1k}) \prod_{k=1}^{Q(2)} (x - y_{2k})^2 \cdots \prod_{k=1}^{Q(n)} (x - y_{Nk})^N,$$

where $P(x)$ is some polynomial.

From the definition of $H(x)$, it is clear that

(3.28) $$H'(x) \text{ divides } g'(x),$$

i.e., $\deg(g) \geq \deg(H)$. If $\deg(H') = \deg(g')$, then (3.28) yields $KH'(x) = g'(x)$ for some constant $K \neq 0$. Hence $C + KH(x) = g(x)$, for some constant C. Since $H(0) = g(0) = 0$, we must have $C = 0$, and hence

$$g(x) = KH(x).$$

Lastly, we establish the inclusion of (3.25) by induction on $r = N, N - 1, \ldots, 1$.

Let $x_0 \in \operatorname{supp}(\mu_N) = \{y_{N,1}, \ldots, y_{N,Q(N)}\}$. Since

$$H'(x) = (x - y_{N,1})^N \cdots (x - y_{N,Q(N)})^N h_1(x) \cdots h_{N-1}(x),$$

we see that

$$H'(x_0) = H''(x_0) = \cdots = H^{(N)}(x_0) = 0;$$

i.e., $x_0 \in \cap_{j=1}^{N} R_j$.

Suppose then that

$$\operatorname{supp}(\mu_k) \subset \bigcap_{j=1}^{k} R_j \qquad (k = N, N-1, \ldots, r+1).$$

We must show

$$\operatorname{supp}(\mu_r) \subset \bigcap_{j=1}^{r} R_j.$$

By the construction of H, we see that $B_k \subset \cap_{j=1}^{k} R_j$, and hence from our induction hypothesis, we have

$$\begin{aligned}
\operatorname{supp}(\mu_r) &= B_r \cup (\operatorname{supp}(\mu_r) \setminus B_r) \\
&= B_r \cup \left(\operatorname{supp}(\mu_r) \cap \bigcup_{j=r+1}^{N} \operatorname{supp}(\mu_j) \right) \\
&\subset \bigcap_{j=1}^{r} R_j \cup \left(\bigcup_{j=r+1}^{N} \operatorname{supp}(\mu_j) \right) \\
&\subset \bigcap_{j=1}^{r} R_j \cup \bigcap_{j=1}^{r+1} R_j \cup \bigcap_{j=1}^{r+2} R_j \cup \cdots \cup \bigcap_{j=1}^{N} R_j \\
&\subset \bigcap_{j=1}^{r} R_j.
\end{aligned}$$

This completes the induction and finishes the proof of the theorem. □

Remark 11. It is clear that the degree of the polynomial H defined in (3.24) is minimized when $\operatorname{card}(B_k), 1 \le k \le N$, is minimized, and this occurs precisely when $\operatorname{supp}(\mu_k)$ is a singleton set; i.e., $\operatorname{supp}(\mu_k) = \{a\}, 1 \le k \le N$, for some real number a. In this case we see that $H(x)$ is necessarily a nonzero, real constant multiple of $(x-a)^{N+1}$.

By combining the proofs of Lemma 3, Theorem 4, Corollary 5, and Theorem 6, we arrive at a proof of Theorem 1.

4. Examples. In all of the examples below, the measure μ_0 is an arbitrary, positive Borel measure. For other papers concerning recurrence relations for orthogonal polynomials, we refer the reader to [2, Thm. 3.1].

1. It is possible that the polynomial $h(x)$ satisfying (1.6) has only complex roots. For example, if the inner product is given by

$$(p,q)_W = \int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu_0(x) + \int_{\mathbb{R}} p'(x)\bar{q}'(x)\delta(x)\, dx,$$

then $(hp,q)_W = (p,hq)_W, p,q \in \mathcal{P}$, where $h(x) = x^2 + 1$. For this example, we note that the minimal polynomial $H(x)$, defined in (3.25), is given by $H(x) = x^2$.

2. From Theorem 1, it follows that there does not exist an inner product $(\cdot,\cdot)_W$ given by (1.5) with $N \ge 1$ such that (3.1) is satisfied for

$$h(x) = x^3 + 3x + 3.$$

Indeed, since $h'(x) = 3x^2 + 3$, we see that $R_1 = \emptyset$, contradicting (c) of Theorem 1. In fact, from (3.9), we find that

$$\int_{\mathbb{R}} (3x^2 + 3)^2 \, d\mu_1(x) = 0,$$

which, of course, implies that $\mu_1 \equiv 0$. It is interesting to note that even if we relax our requirements in Theorem 1 and allow the measure μ_1 to be the zero measure, there are still no inner products of the form (1.5) *with* $N \geq 1$ and *with at least one of the measures* $\mu_k, 1 \leq k \leq N$, *nontrivial* for which (3.1) holds with $h(x) = x^3 + 3x + 3$. To see this, observe that since $\deg(h) = 3$, an argument similar to that given in Theorem 1 implies that *necessarily* $N = 1$ or $N = 2$. Since we ruled out the case $N = 1$ above, the only other possibility is that the inner product has the form

$$(p, q)_W = \int_{\mathbb{R}} p(x)\bar{q}(x) \, d\mu_0 + \int_{\mathbb{R}} p''(x)\bar{q}''(x) \, d\mu_2.$$

Assuming then that $(hp, q)_W = (p, hq)_W$ for all polynomials $p, q \in \mathcal{P}$, we find that

$$\int_{\mathbb{R}} (2h'(p'\bar{q}'' - p''\bar{q}') + h''(p\bar{q}'' - p''\bar{q})) \, d\mu_2 = 0 \qquad (p, q \in \mathcal{P}). \tag{4.1}$$

Substituting

$$p(x) = 1 \quad \text{and} \quad q(x) = \frac{x^{n+2}}{(n+1)(n+2)}$$

into this equation yields

$$\int_{\mathbb{R}} h''(x)x^n \, d\mu_2 = 0 \qquad (n \in \mathbb{N}_0),$$

and, hence, it follows that

$$\int_{\mathbb{R}} (h''(x))^2 \, d\mu_2 = \int_{\mathbb{R}} 36x^2 \, d\mu_2 = 0.$$

Of course, since μ_2 is assumed to be nontrivial, we must have

$$d\mu_2(x) = c\delta(x) \, dx$$

for some real constant $c \neq 0$. However, if we substitute $p(x) = x$ and $q(x) = x^2$ into (4.1) we find that $12c = 0$ and thus arrive at a contradiction. We leave it to the reader to formulate and prove the analogue of Theorem 1 when the measures $\mu_k, 1 \leq k \leq N$, are assumed to be nonnegative with at least one of these measures necessarily being positive.

3. Suppose that the Sobolev inner product is given by

$$(p, q)_W = \int_{\mathbb{R}} p(x)\bar{q}(x) \, d\mu_0(x) + \int_{\mathbb{R}} p'(x)\bar{q}'(x)\delta(x) \, dx + \int_{\mathbb{R}} p''(x)\bar{q}''(x)(\delta(x) + \delta(x-1)) \, dx.$$

We now construct the minimal polynomial $H : \mathbb{R} \to \mathbb{R}$ described in Theorem 6. We find that $B_2 = \{0, 1\}$, $B_1 = \emptyset$, $h_2(x) = x^2(x-1)^2$, and $h_1(x) = 1$. Hence the polynomial $H(x)$ is any nonzero, real multiple of

$$12x^5 - 30x^4 + 20x^3 = 60 \int_0^x h_1(t)h_2(t)\, dt.$$

Notice that, in the notation of Theorem 6, $R_1 = \{0, 1\}$, $R_2 = \{0, \frac{1}{2}, 1\}$ and

$$\{0\} = \operatorname{supp}(\mu_1) \subset R_1, \qquad \{0, 1\} = \operatorname{supp}(\mu_2) \subset R_1 \cap R_2.$$

4. Suppose that $(hp, q)_W = (p, hq)_W$, $(p, q \in \mathcal{P}$, where

$$(p, q)_W = \int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu_0(x) + \int_{\mathbb{R}} p'(x)\bar{q}'(x)\, d\mu_1(x) + \int_{\mathbb{R}} p''(x)\bar{q}''(x)\, d\mu_2(x)$$

and $h(x) = x^5 - 10x^3 + 20x^2 - 15x - 158$. Now $h'(x) = 5(x-1)^3(x+3)$ and $h''(x) = 20(x-1)^2(x+2)$ so that

$$R_1 = \{-3, 1\} \quad \text{and} \quad R_2 = \{-2, 1\}.$$

By Theorem 1, we see that

$$\operatorname{supp}(\mu_1) \subset R_1 \quad \text{and} \quad \operatorname{supp}(\mu_2) \subset R_1 \cap R_2 = \{1\}.$$

Hence, there exists a constant $k > 0$, and nonnegative constants c_1 and c_2 with $c_1^2 + c_2^2 \neq 0$ such that

$$d\mu_2(x) = k\delta(x-1)\, dx, \qquad d\mu_1(x) = (c_1\delta(x-1) + c_2\delta(x+3))\, dx.$$

Since the degree of $h(x)$ is 5, Lemma 3 says that the sequence of polynomials that are orthogonal with respect to $(\cdot, \cdot)_W$ will satisfy an eleven-term recurrence relation. Actually, the algorithm outlined in Theorem 6 indicates that the polynomials will satisfy either a nine-term or a seven-term recurrence relation. Indeed, if $-3 \in \operatorname{supp}(\mu_1)$, then the algorithm outlined in Theorem 6 dictates that

$$h_2(x) = (x-1)^2, \qquad h_1(x) = (x+3),$$

and hence that the minimal polynomial $H(x)$ is any nonzero, real multiple of

$$\int_0^x (t-1)^2(t+3)\, dt.$$

For example, $H(x) = 3x^4 + 4x^3 - 30x^2 + 36x$ will suffice. Consequently, the associated orthogonal polynomials will satisfy a nine-term recurrence relation. On the other hand, if $-3 \notin \operatorname{supp}(\mu_1)$, then $\operatorname{supp}(\mu_1) = \operatorname{supp}(\mu_2) = \{1\}$, and a calculation reveals that $H(x)$ can be taken to be $(x-1)^3$; in this case the polynomials will satisfy a seven-term recurrence relation.

5. Suppose $N = 3$ and

$$\begin{aligned} d\mu_1(x) &= (c_1\delta(x) + c_2\delta(x-1) + c_3\delta(x-2) + c_4\delta(x-3) + c_5\delta(x-4))\, dx, \\ d\mu_2(x) &= (c_6\delta(x) + c_7\delta(x-1) + c_8\delta(x-2))\, dx, \\ d\mu_3(x) &= (c_9\delta(x) + c_{10}\delta(x-1))\, dx, \end{aligned}$$

where $c_i > 0, i = 1, 2, \ldots, 10$. Proceeding as in the previous example, we find that

$$h_3(x) = x^3(x-1)^3,$$
$$h_2(x) = (x-2)^2,$$
$$h_1(x) = (x-3)(x-4),$$

and hence the polynomial $H(x)$ of minimal degree satisfying (3.1) and $H(0) = 0$ is any multiple of

$$1260x^{11} - 1940x^{10} + 123200x^9 - 419265x^8 + 829620x^7 - 960960x^6 + 609840x^5 - 166320x^4.$$

The corresponding orthogonal polynomials will satisfy a 23-term recurrence relation. We emphasize that this length is minimal!

5. Further modifications and applications of Theorem 1. In this section, we shall suppose that the sequence $\{\phi_n(x)\}_{n=0}^{\infty}$ is a monic orthogonal polynomial sequence (MOPS) with respect to the inner product in (1.5). We shall also find it convenient to decompose the inner product (1.5),

$$(p, q)_W = \sum_{k=0}^{N} (p^{(k)}, q^{(k)})_{\mu_k},$$

where the inner products $(\cdot, \cdot)_{\mu_k}$ are defined by

$$(p, q)_{\mu_k} = \int_{\mathbb{R}} p(x)\bar{q}(x)\, d\mu_k \qquad (k = 0, 1, \ldots, N).$$

Let $\{q_n(x)\}_{n=0}^{\infty}$ be the sequence of monic polynomials that is orthogonal with respect to the leading inner product $(\cdot, \cdot)_{\mu_0}$. Writing

$$\phi_n(x) = q_n(x) + \sum_{j=0}^{n-1} \sigma_{n,j} q_j(x), \tag{5.1}$$

we find, in the usual way, the Fourier coefficients $\sigma_{n,j}, 0 \le j \le n-1$:

$$\sigma_{n,j} = \frac{(\phi_n, q_j)_{\mu_0}}{(q_j, q_j)_{\mu_0}} = \frac{-\sum_{k=1}^{N} (\phi_n^{(k)}, q_j^{(k)})_{\mu_k}}{(q_j, q_j)_{\mu_0}} = -\sum_{k=1}^{N} \left(\sum_{s=1}^{Q(k)} \frac{\beta_{k,s} \phi_n^{(k)}(y_{k,s}) q_j^{(k)}(y_{k,s})}{(q_j, q_j)_{\mu_0}} \right).$$

Then (5.1) becomes

$$\phi_n(x) = q_n(x) - \sum_{k=1}^{N} \left(\sum_{s=1}^{Q(k)} \beta_{k,s} \phi_n^{(k)}(y_{k,s}) K_{n-1}^{(0,k)}(x, y_{k,s}) \right), \tag{5.2}$$

where

$$K_{n-1}^{(j,k)}(x, y) = \sum_{l=0}^{n-1} \frac{q_l^{(j)}(x) q_l^{(k)}(y)}{(q_l, q_l)_{\mu_0}}.$$

From the Christoffel–Darboux formula (see [3, p. 23]),

$$K_{n-1}^{(0,0)}(x,y) = \frac{1}{(q_{n-1},q_{n-1})_{\mu_0}} \frac{q_n(x)q_{n-1}(y) - q_{n-1}(x)q_n(y)}{x-y},$$

and taking derivatives with respect to y at the point $y_{k,s}$, we obtain

$$\begin{aligned} K_{n-1}^{(0,k)}(x,y_{k,s}) = \frac{1}{(q_{n-1},q_{n-1})_{\mu_0}} & \left(q_n(x) \sum_{j=0}^{k} \binom{k}{j} \frac{q_{n-1}^{(j)}(y_{k,s})(k-j)!}{(x-y_{k,s})^{k-j+1}} \right. \\ & \left. - q_{n-1}(x) \sum_{j=0}^{k} \binom{k}{j} \frac{q_n^{(j)}(y_{k,s})(k-j)!}{(x-y_{k,s})^{k-j+1}} \right) \\ = \frac{k!(x-y_{k,s})^{-k-1}}{(q_{n-1},q_{n-1})_{\mu_0}} & (q_n(x)T_k(x;y_{k,s};n-1) - q_{n-1}(x)T_k(x;y_{k,s};n)), \end{aligned} \tag{5.3}$$

where $T_k(x;y_{k,s};n)$ denotes the Taylor polynomial of degree k at $y_{k,s}$ for the polynomial $q_n(x)$.

If we denote

$$\tilde{q}_n^{(s)} = \begin{pmatrix} q_n^{(s)}(y_{s,1}) \\ \vdots \\ q_n^{(s)}(y_{s,Q(s)}) \end{pmatrix}, \quad \tilde{K}_{n-1}^{(0,s)} = \begin{pmatrix} K_{n-1}^{(0,s)}(x,y_{s,1}) \\ \vdots \\ K_{n-1}^{(0,s)}(x,y_{s,Q(s)}) \end{pmatrix}, \quad D = \operatorname{diag}(\Lambda_1,\Lambda_2,\ldots,\Lambda_N),$$

where $\Lambda_j = \operatorname{diag}(\beta_{j,1}^{-1},\beta_{j,2}^{-1},\ldots,\beta_{j,Q(j)}^{-1})$, $j=1,2,\ldots,N$, and $\mathcal{R}_{n-1}$ is the block matrix whose diagonal elements are $K_{n-1}^{(i,i)}(y_{i,r},y_{i,s}))_{r,s=1}^{Q(i)}$ while the (l,m) block element is

$$(K_{n-1}^{(l,m)}(y_{l,r},y_{m,s}))_{\substack{r=1,\ldots,Q(l),\\ s=1,\ldots,Q(m)}},$$

then following the same techniques used in [1] and [12], the following result can be deduced.

PROPOSITION 7. *For each* $n \in \mathbb{N}_0$,

(a) *the matrix* $(D+\mathcal{R}_n)$ *is nonsingular*;

(b)
$$\frac{(\phi_n,\phi_n)_W}{(q_n,q_n)_{\mu_0}} = \frac{\det(D+\mathcal{R}_n)}{\det(D+\mathcal{R}_{n-1})};$$

(c)
$$\phi_n(x) = \frac{\begin{vmatrix} q_n(x) & \vdots & (\tilde{K}_{n-1}^{(0,1)})^T \cdots (\tilde{K}_{n-1}^{(0,N)})^T \\ \tilde{q}_n^{(1)} & \vdots & \\ \vdots & \vdots & D+\mathcal{R}_{n-1} \\ \tilde{q}_n^{(N)} & \vdots & \end{vmatrix}}{\det(D+\mathcal{R}_{n-1})},$$

where $(\tilde{K}_{n-1}^{(0,j)})^T$ *denotes the transpose of the vector* $\tilde{K}_{n-1}^{(0,j)}$.

Using (5.3), the following result is an immediate consequence of the above proposition; see also [1, eq. (2.12)] and [12, eq. (2.11)].

COROLLARY 8. *There exists a polynomial $g(x)$ such that*

$$g(x)\phi_n(x) = A_{N,n}(x)q_n(x) + B_{N,n}(x)q_{n-1}(x). \tag{5.4}$$

Indeed,

$$g(x) = \prod_{k=1}^{N} g_k(x), \quad \textit{where}$$

$$g_k(x) = \begin{cases} 1 & \textit{if } B_k = \emptyset, \\ \displaystyle\prod_{y_{kj}\in B_k} (x - y_{kj})^{k+1} & \textit{if } B_k \neq \emptyset, \end{cases}$$

and $A_{N,n}, B_{N,n}$ are polynomials depending on n and, with degrees, respectively, $\deg(g)$ *and* $\deg(g) - 1$.

We remark that, in general, $\deg(g) \geq \deg(h)$. From (5.4), we can explicitly find the parameters $b_{n,k}$ which appear in the recurrence relation (3.2) with some suitable normalization. For example, if $\{\phi_n\}$ is a sequence of monic orthogonal polynomials, multiplication by $g(x)$ in (3.2) yields

$$h(x)g(x)\phi_n(x) = \sum_{k=n-m}^{n+m} b_{n,k}g(x)\phi_k(x) \tag{5.5}$$

and

$$h(x)\left[\sum_{j=n-p}^{n+p} c_{n,j}q_j(x)\right] = \sum_{k=n-m}^{n+m} b_{n,k}\left[\sum_{l=k-p}^{k+p} c_{k,l}q_l(x)\right],$$

where the coefficients $\{c_{n,j}\}$ are the Fourier coefficients of $g(x)\phi_n(x)$ with respect to the orthogonal system $\{q_n\}$. But, from the three-term recurrence relation which is satisfied by the MOPS $\{q_n\}$ and by iteration, we have

$$h(x)q_j(x) = \sum_{l=j-m}^{j+m} d_{j,l}q_l(x),$$

and finally

$$\sum_{j=n-p}^{n+p}\sum_{l=j-m}^{j+m} c_{n,j}d_{j,l}q_l(x) = \sum_{k=n-m}^{n+m}\sum_{l=k-p}^{k+p} b_{n,k}c_{k,l}q_l(x).$$

For fixed n, notice that $2m + 1$ parameters $b_{n,k}$ appear in (5.5). We adopt the convention that

$$\begin{aligned} b_{n,k} &= 0 \quad \text{if } |n-k| > m, \\ c_{k,l} &= 0 \quad \text{if } |k-l| > p, \\ d_{j,l} &= 0 \quad \text{if } |j-l| > m. \end{aligned}$$

Then

$$\sum_{j=n-p-m}^{n+p+m} c_{n,j}d_{j,l} = \sum_{k=n-m-p}^{n+p+m} b_{n,k}c_{k,l} \tag{5.6}$$

for $n-m-p \leq l \leq n+m+p$.

In particular, because of $b_{n,n+m}=1$, we can give the matrix representation

$$C_{2m,p}^{(n)} \begin{pmatrix} b_{n,n+m-1} \\ \vdots \\ b_{n,n-m} \end{pmatrix} = D_{2p,m}^{(n)} \begin{pmatrix} c_{n,n+p} \\ \vdots \\ c_{n,n-p} \end{pmatrix} \tag{5.7}$$

where

$$C_{2m,p}^{(n)} = \begin{pmatrix} c_{n+m-1,n+m-1-p} \cdots & c_{n-m,n+m-1-p} \\ \vdots & \vdots \\ c_{n+m-1,n-m-p} & c_{n-m,n-m-p} \end{pmatrix},$$

$$D_{2p,m}^{(n)} = \begin{pmatrix} d_{n+p,n+m-1-p} \cdots & d_{n-p,n+m-1-p} \\ \vdots & \vdots \\ d_{n+p,n-m-p} & d_{n-p,n-m-p} \end{pmatrix}.$$

However, since $c_{ij}=0$ for $|i-j|>p$ and $c_{i,i-p}>0, i=n+m-1,\ldots,n-m$, we have that $C_{2m,p}^{(n)}$ is a nonsingular upper triangular matrix. As a consequence, we can obtain an explicit representation of the parameters $\{b_{n,k}\}$ of the recurrence relation for which the sequence $\{\phi_n\}$ satisfies in terms of the known parameters $\{c_{i,j}\}$ and $\{d_{i,j}\}$

$$\begin{pmatrix} b_{n,n+m-1} \\ \vdots \\ b_{n,n-m} \end{pmatrix} = (C_{2m,p}^{(n)})^{-1} D_{2p,m}^{(n)} \begin{pmatrix} c_{n,n+p} \\ \vdots \\ c_{n,n-p} \end{pmatrix}.$$

An interesting application of the work in this section is related to the situation when some differential properties of the MOPS $\{q_n\}$ are known. If μ_0 is a semiclassical measure, i.e., if the linear functional u defined on $\mathcal{P}$ by

$$\langle u, p \rangle = \int_{\mathbb{R}} p(x)\, d\mu_0$$

satisfies a distributional equation

$$D(A(x)u) = B(x)u,$$

where A and B are polynomials with $\deg(B) \geq 1$, and D is the derivative operator, it is known (see [13]) that

$$A(x)q_n'(x) = \sum_{j=n-t-1}^{n+r-1} \gamma_{n,j} q_j(x), \tag{5.8}$$

where $\deg(A) := r, \deg(B) := k$, and $t := \max\{r-2, k-1\}$. This last expression, called a structural relation, leads to a second-order linear differential equation

$$A(x,n)q_n''(x) + B(x,n)q_n'(x) + C(x,n)q_n(x) = 0, \tag{5.9}$$

which the MOPS $\{q_n\}$ satisfies. We remark that (5.8) is a weaker condition than (5.9) but, if $\{q_n\}$ satisfies a three-term recurrence relation, then (5.8) is equivalent to (5.9)

(see [7]). However, as the following result shows, there exist nonstandard sequences of MOPS which do not satisfy a three-term recurrence relation such that (5.9) holds.

PROPOSITION 9. *If* $\{q_n\}$ *is a semiclassical* MOPS, *then* $\{\phi_n\}$ *satisfies*

$$\tilde{A}(x,n)\phi_n''(x) + \tilde{B}(x,n)\phi_n'(x) + \tilde{C}(x,n)\phi_n(x) = 0,$$

where $\tilde{A}, \tilde{B}$, *and* $\tilde{C}$ *are polynomials of degrees independent of* n.

Proof. From (5.4), we find

$$(g(x)\phi_n(x))' = A'_{N,n}(x)q_n(x) + B'_{N,n}(x)q_{n-1}(x) + A_{N,n}(x)q_n'(x) + B_{N,n}(x)q_{n-1}'(x).$$

Multiplying by $A(x)$ in the above expression, taking into account the structural relation (5.8) and the three-term recurrence relation for the MOPS $\{q_n(x)\}$, we obtain

$$\begin{aligned} A(x)(g(x)\phi_n(x))' &= S(x,n)q_n(x) + R(x,n)q_{n-1}(x) \\ &= \tilde{S}(x,n)q_n(x) + \tilde{R}(x,n)q_n'(x), \end{aligned} \tag{5.10}$$

where S and R are polynomials and $\tilde{S}$ and $\tilde{R}$ are rational functions.

From (5.4) and (5.10), we obtain

$$\begin{aligned} q_n(x) &= \frac{\begin{vmatrix} g(x)\phi_n(x) & B_{N,n}(x) \\ A(x)(g(x)\phi_n(x))' & R(x,n) \end{vmatrix}}{\begin{vmatrix} A_{N,n}(x) & B_{N,n}(x) \\ S(x,n) & R(x,n) \end{vmatrix}} \\ &= C(x,n)\phi_n(x) + D(x,n)\phi_n'(x), \end{aligned} \tag{5.11}$$

$$\begin{aligned} q_{n-1}(x) &= \frac{\begin{vmatrix} A_{N,n}(x) & g(x)\phi_n(x) \\ S(x,n) & A(x)(g(x)\phi_n(x))' \end{vmatrix}}{\begin{vmatrix} A_{N,n}(x) & B_{N,n}(x) \\ S(x,n) & R(x,n) \end{vmatrix}} \\ &= E(x,n)\phi_n(x) + F(x,n)\phi_n'(x), \end{aligned} \tag{5.12}$$

where C, D, E, and F are rational functions. Using (5.8) and the recurrence relation for $\{q_n\}$, the result follows from (5.11) and (5.12).

Remark 12. The reader will notice that the above proposition includes a constructive approach to constructing the second-order linear differential equation satisfied by the MOPS $\{\phi_n\}$.

ON TWO-DIMENSIONAL DEFINITE ORTHOGONAL SYSTEMS AND A LOWER BOUND FOR THE NUMBER OF NODES OF ASSOCIATED CUBATURE FORMULAE*

H. BERENS†, H. J. SCHMID†, AND Y. XU‡

Abstract. In a comprehensive investigation in the 1960s Krall and Sheffer [*Ann. Mat. Pura Appl.*, 76 (1967), pp. 325–376] characterized all bivariate orthogonal polynomial systems which are generated by a second-order differential equation. Actually, they prove that these nine systems are weakly orthogonal and (positive) definite except possibly for two systems. Their paper is completed by showing that these systems are also definite and by determining all parameters for which the classical positive definite systems remain definite. The authors further derive an explicit form of the three-term recursion formulae for all systems. In addition, it is shown that for the associated cubature problem Möller's lower bound applies.

1. Introduction.

Let us denote by $\mathbf{P} = \mathbf{R}[x, y]$ the ring of polynomials of two variables with real coefficients, and let $\mathbf{P}_k$, $k = 0, 1, \ldots$, be the linear subspace of $\mathbf{P}$ spanned by

$$1, x, y, \ldots, x^k, \quad x^{k-1}y, \ldots, xy^{k-1}, \quad y^k.$$

Following Krall and Sheffer [5], a monomial basis

$$\{P_j^k\}_{j=0,\ k\in\mathbf{N}}^k, \quad \text{where} \quad P_j^k = x^{k-j}y^j + \text{lower-order terms},$$

is said to be a *weak orthogonal system*, if there exist coefficient matrices

$$C_k = (c_{ij}^k)_{i,j=0,1,\ldots,k}, \qquad \bar{C}_k = (\bar{c}_{ij}^k)_{i=1,2,\ldots,k+1,j=0,1,\ldots,k} \in \mathbf{R}^{k+1\times k+1}$$

and

$$D_k = (d_{i,j}^k)_{i=0,1,\ldots,k,j=0,1,\ldots,k-1}, \qquad \bar{D}_k = (\bar{d}_{ij}^k)_{i=1,2,\ldots,k+1,j=0,1,\ldots,k-1} \in \mathbf{R}^{k+1\times k},$$

such that

$$(1) \quad xP_k = L_{k+1}P_{k+1} + C_kP_k + D_kP_{k-1}, \qquad yP_k = F_{k+1}P_{k+1} + \bar{C}_kP_k + \bar{D}_kP_{k-1},$$

where $P_k = (P_0^k, P_1^k, \ldots, P_k^k)^t$, $k = 0, 1, \ldots$ The matrices L_{k+1} and F_{k+1} are defined as the shift matrices $[E_k\ 0]$ and $[0\ E_k]$, where E_k is the identity in $\mathbf{R}^{k+1\times k+1}$ and $P_{-1} = 0$.

The system is said to be *orthogonal* with respect to the linear functional $\mathcal{I} : \mathbf{P} \to \mathbf{R}$ if, for each $k \in \mathbf{N}_0$, $\mathcal{I}(P_kP_l^t) = 0$, $0 \le l < k$, and if rank $\mathcal{I}(P_kP_k^t) = k + 1$. Here, $P_kP_l^t$ is the tensor product of the vectors P_k and P_l and $\mathcal{I}(P_kP_l^t)$ is the matrix, the coefficients of which are determined by the functional acting on the polynomial coefficients of the tensor product. The matrix $\mathcal{I}(P_kP_k^t)$, $k \in \mathbf{N}_0$, is known as the kth *moment matrix* and is denoted by M_k. Instead of saying $\{P_k\}_{k\in\mathbf{N}_0}$ is an orthogonal

system, we also say the system is *definite*; in case the matrices M_k, $k \in \mathbf{N}_0$, are positive definite, we speak of a *positive definite system.*

It is almost obvious that a definite system $\{P_k\}_{k\in\mathbf{N}_0}$ is a weak orthogonal system, i.e., it satisfies the recurrence relations (1). It follows from [11, Thm. 2] that, conversely, *a weak orthogonal system is an orthogonal system with respect to* $\mathcal{I}$, *defined by*

$$\mathcal{I}(P_0^0) = 1 \text{ and } \mathcal{I}(P_j^k) = 0, \qquad 0 \le j \le k,\ k = 1, 2, \ldots,$$

exactly when

$$\text{rank } S_k = k + 1, \quad \text{where } S_k = [D_k\ \bar{D}_k] \in \mathbf{R}^{k+1\times 2k}.$$

Let $\{P_k\}_{k=0}^{\infty}$ be a definite orthogonal system with respect to $\mathcal{I}$. By multiplying (1) by P_{k-1}^t, P_k^t, and P_{k+1}^t, respectively, and applying $\mathcal{I}$, we obtain

$$\text{(2)} \qquad \begin{cases} C_k M_k = \mathcal{I}(xP_kP_k^t), & D_kM_{k-1} = \mathcal{I}(xP_kP_{k-1}^t) = M_kL_k^t, \\ \bar{C}_k M_k = \mathcal{I}(yP_kP_k^t), & \bar{D}_kM_{k-1} = \mathcal{I}(yP_kP_{k-1}^t) = M_kF_k^t. \end{cases}$$

Using these identities, we can compute the moment matrices by induction. Indeed, let $G_k = \text{diag } [2, E_{k-2}]$ and $\bar{G}_k = \text{diag } [E_{k-2}, 2]$; then

$$2\,E_k = L_k^t G_k L_k + F_k^t \bar{G}_k F_k,$$

and consequently,

$$\text{(3)} \qquad 2\,M_k = M_kL_k^tG_kL_k + M_kF_k^t\bar{G}_kF_k = D_kM_{k-1}G_kL_k + \bar{D}_kM_{k-1}\bar{G}_kF_k.$$

Setting $M_0 = 1$, the last equation allows us to compute M_k from M_{k-1}, $k \in \mathbf{N}$.

Again, let $\{P_k\}_{k=0}^{\infty}$ be a definite orthogonal system with respect to $\mathcal{I}$. A cubature formula of degree m for $\mathcal{I}$ is a linear combination of point evaluations

$$K : \mathbf{P} \to \mathbf{R} : p \mapsto K(p) = \sum_{i=0}^{N} \kappa_i\ p(x_i, y_i), \quad \kappa_i \neq 0,\ (x_i, y_i) \in \mathbf{R}^2$$

such that $K(p) = \mathcal{I}(p)$ for all $p \in \mathbf{P}_m$, and at least one $p_0 \in \mathbf{P}_{m+1}$ satisfies $K(p_0) \neq \mathcal{I}(p_0)$. Of special interest are formulae with a minimal number N of nodes. Such formulae are said to be *interpolatory*; i.e., the nodes have the interpolation property. A lower bound for N is

$$N \ge \dim \mathbf{P}_{[m/2]+1} = ([m/2] + 1)([m/2] + 2)/2.$$

The proof is usually given for positive definite systems; the proof in Stroud's book [9, Thm. 3.15-1], however, depends only on the regularity of the moment matrices.

In 1976, Möller [6] improved the bound for strictly positive linear functionals, which nevertheless remains true in the definite case since only orthogonality is involved.

If N is the number of nodes in a cubature formula of degree $m = 2k - 1$ for $\mathcal{I}$, then

$$N \ge \dim \mathbf{P}_{k-1} + \text{rank } M_{k-1}^{\star}/2,$$

where the coefficients of $M^\star_{k-1}$ *are given by*

$$m^\star_{ij} = \mathcal{I}(P^k_{i-1}P^k_j - P^k_i P^k_{j-1}), \qquad i,j = 1,2,\ldots,k.$$

Since $M^\star_{k-1}$ is skew-symmetric, its rank is even. The computation of the coefficients of $M^\star_{k-1}$ and of its rank is difficult in general, and particularly difficult if the integral is not a tensor product of one-dimensional integrals. In the *centrally symmetric case*, where $\mathcal{I}(x^{k-i}y^i) = 0$, $i = 0,1,\ldots,k$, for all odd $k \in \mathbf{N}$, Möller proved

$$\text{rank } M^\star_{k-1} = \begin{cases} k, & \text{if } k \text{ is even,} \\ k-1, & \text{if } k \text{ is odd,} \end{cases} \tag{4}$$

without making use of the explicit form of the matrix.

For the Lebesgue integral over the triangle $\{(x,y) \in \mathbf{R}^2 : 0 \le x,y,1-x-y\}$ Möller [6] computed the rank of $M^\star_{k-1}$ up to $k = 6$ and verified the rank condition (4) for this case. Rasputin [7] then proved it for all $k \in \mathbf{N}$. In a separate paper [2], Berens and Schmid further extended the result to all classical Jacobi weight functions. In their approach, the matrix $M^\star_{k-1}$ was rewritten as

$$\begin{aligned} M^\star_{k-1} &= L_k M_k F_k^t - F_k M_k L_k^t \\ &= L_k \bar{D}_k M_{k-1} - F_k D_k M_{k-1} = (L_k \bar{D}_k - F_k D_k) M_{k-1} \end{aligned}$$

by again applying the identities (2). Introducing

$$M^{\star\star}_{k-1} = L_k \bar{D}_k - F_k D_k,$$

we clearly have

$$\text{rank } M^\star_{k-1} = \text{rank } M^{\star\star}_{k-1}.$$

In the present paper we study a class of definite bivariate orthogonal polynomial systems which are generated by the following second-order differential equation:

$$\mathcal{L}\omega = -\lambda_k \omega, \qquad \lambda_k \in \mathbf{R},\ k \in \mathbf{N}, \tag{5}$$

where

$$\begin{aligned} \mathcal{L}\omega = {} & (ax^2 + d_1 x + e_1 y + f_1)\omega_{xx} + (2axy + d_2 x + e_2 y + f_2)\omega_{xy} \\ & + (ay^2 + d_3 x + e_3 y + f_3)\omega_{yy} + (gx + h_1)\omega_x + (gy + h_2)\omega_y \end{aligned}$$

for some real constants $a \neq 0, g, d_i, e_i, f_i, h_i$, and for

$$\lambda_k = -k((k-1)a + g), \qquad g + ka \neq 0, \quad k = 0,1,\ldots.$$

In their paper, Krall and Sheffer [5] determine all weak orthogonal systems which are generated from (5). Furthermore, they prove that these *nine* systems are indeed either positive definite or definite, except possibly for the systems generated by [5, eqs. (5.22) and (5.53)]. We complete their paper by showing that these systems are also definite, and by determining all parameters for which the classical positive definite systems remain definite. In addition, we shall derive an explicit form of the recursion formula (1) for all these systems, and we will show

$$\text{rank } M^{\star\star}_{k-1} = \begin{cases} k, & \text{if } k \text{ is even,} \\ k-1, & \text{if } k \text{ is odd.} \end{cases} \tag{6}$$

This shows that the lower bound Möller derived for centrally symmetric integrals holds true for all classes considered here. Concerning the existence of cubature formulae of degree $2k-1$ attaining the lower bound, characterizations are known if $\mathcal{I}$ is positive definite and for special functionals even methods are known to construct such formulae; see [8]. In the definite case, however, this is all open. For the existence of cubature formulae of degree $2k-2$, which is not the subject of this paper, we refer to [8] and [11].

Krall and Sheffer were aware of the associated moment problem, i.e., assigning a measure to the functional $\mathcal{I}$ defined by a definite system, in particular a positive measure in case the system is positive definite (Favard's theorem). In the multidimensional case this is quite involved; see Fuglede [3] and the recent results of Xu [10].

2. General approach. We study the nine differential equations separately. To do so, we first determine the coefficients $a_{i\nu}^k$ and $b_{i\nu}^k$ of

$$P_i^k = t_i^k + \sum_{\nu=0}^{k-1} a_{i\nu}^k t_\nu^{k-1} + \sum_{\nu=0}^{k-2} b_{i\nu}^k t_\nu^{k-2} + l.o.t., \qquad t_i^k = x^{k-i}y^i,\ i = 0,1,\dots,k.$$

By applying $\mathcal{L}$ to P_i^k and comparing the coefficients in

$$-\lambda_k \left(t_i^k + \sum_{\nu=0}^{k-1} a_{i\nu}^k t_\nu^{k-1} + \sum_{\nu=0}^{k-2} b_{i\nu}^k t_\nu^{k-2} \right) = \mathcal{L}(t_i^k) + \sum_{\nu=0}^{k-1} a_{i\nu}^k \mathcal{L}(t_\nu^{k-1}) + \sum_{\nu=0}^{k-2} b_{i\nu}^k \mathcal{L}(t_\nu^{k-2}) + l.o.t.,$$

we can compute $a_{i\nu}^k$ and $b_{i\nu}^k$, respectively. Elements $a_{i,j}^k$ and $b_{i,j}^k$, which are not defined explicitly, are equal to zero. In all cases the orthogonal polynomials are of the form

$$P_i^k = t_i^k + \sum_{\nu=-1}^{1} a_{i,i+\nu}^k t_{i+\nu}^{k-1} + \sum_{\nu=-2}^{2} b_{i,i+\nu}^k t_{i+\nu}^{k-2} + l.o.t.,$$

which leads to the recursion formulae

$$(7)\quad \begin{cases} P_i^{k+1} = xP_i^k - \sum_{\nu=-1}^{1} c_{i,i+\nu} P_{i+\nu}^k, - \sum_{\nu=-2}^{2} d_{i,i+\nu} P_{i+\nu}^{k-1}, & i = 0,1,\dots,k, \\ P_i^{k+1} = yP_{i-1}^k - \sum_{\nu=-1}^{1} \bar{c}_{i,i+\nu} P_{i+\nu}^k - \sum_{\nu=-2}^{2} \bar{d}_{i,i+\nu} P_{i+\nu}^{k-1}, & i = 1,2,\dots,k+1. \end{cases}$$

To simplify the notation, we omitted and henceforth will omit the superindex k in $c_{i,j}$ and $d_{i,j}$, respectively. Again, by comparing the coefficients in

$$P_i^{k+1} - xP_i^k = \sum_{\nu=-1}^{1} (a_{i,i+\nu}^{k+1} - a_{i,i+\nu}^k) t_{i+\nu}^k + \sum_{\nu=-2}^{2} (b_{i,i+\nu}^{k+1} - b_{i,i+\nu}^k) t_{i+\nu}^{k-1} + l.o.t.$$

$$= -\sum_{\nu=-1}^{1} c_{i,i+\nu} P_{i+\nu}^k + \sum_{\nu=-1}^{1} c_{i,i+\nu} \sum_{\rho=-1}^{1} a_{i+\nu,i+\nu+\rho}^k P_{i+\nu+\rho}^{k-1} + \sum_{\nu=-2}^{2} (b_{i,i+\nu}^{k+1} - b_{i,i+\nu}^k) P_{i+\nu}^{k-1},$$

we obtain

$$\begin{cases} c_{i,i+\nu} = a_{i,i+\nu}^k - a_{i,i+\nu}^{k+1}, & \nu = -1,0,1, \\ d_{i,i+\nu} = b_{i,i+\nu}^k - b_{i,i+\nu}^{k+1} - \sum_{\rho=-1}^{1} c_{i,i+\rho} a_{i+\rho,i+\nu}^k, & \nu = -2,-1,0,1,2. \end{cases}$$

Analogously, we find

$$\begin{cases} \bar{c}_{i,i+\nu} = a^k_{i-1,i+\nu-1} - a^{k+1}_{i,i+\nu}, & \nu = -1, 0, 1, \\ \bar{d}_{i,i+\nu} = b^k_{i-1,i+\nu-1} - b^{k+1}_{i,i+\nu} - \sum_{\rho=-1}^{1} \bar{c}_{i,i+\rho} a^k_{i+\rho,i+\nu}, & \nu = -2, -1, 0, 1, 2. \end{cases}$$

Hence, we can compute the (possibly) nonvanishing elements of the real $k+1 \times k$ matrices

$$D_k = \begin{bmatrix} d_{0,0} & d_{0,1} & d_{0,2} & & & \\ d_{1,0} & d_{1,1} & d_{1,2} & \ddots & & \\ d_{2,0} & d_{2,1} & d_{2,2} & \ddots & \ddots & \\ & \ddots & \ddots & \ddots & d_{k-3,k-2} & d_{k-3,k-1} \\ & & \ddots & \ddots & d_{k-2,k-2} & d_{k-2,k-1} \\ & & & \ddots & d_{k-1,k-2} & d_{k-1,k-1} \\ & & & & d_{k,k-2} & d_{k,k-1} \end{bmatrix}$$

and

$$\bar{D}_k = \begin{bmatrix} \bar{d}_{1,0} & \bar{d}_{1,1} & \bar{d}_{1,2} & \bar{d}_{1,3} & & & \\ \bar{d}_{2,0} & \ddots & \ddots & \ddots & \ddots & & \\ & \ddots & \ddots & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & \ddots & \ddots & \bar{d}_{k-3,k-1} \\ & & & \ddots & \ddots & \ddots & \bar{d}_{k-2,k-1} \\ & & & & \ddots & \ddots & \bar{d}_{k-1,k-1} \\ & & & & & \ddots & \bar{d}_{k,k-1} \\ & & & & & & \bar{d}_{k+1,k-1} \end{bmatrix}.$$

As stated above, a definite system will be obtained if and only if

$$\operatorname{rank} S_k = \operatorname{rank} [D_k \ \bar{D}_k] = k + 1.$$

In order to prove (6), we have to determine the elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{ij} = \bar{d}_{i,j-1} - d_{i,j-1}, \qquad i, j = 1, 2, \ldots, k.$$

All rank conditions can be attacked directly if the matrices D_k, $\bar{D}_k$ in the recursion formula are explicitly known. To be on the safe side we checked the results by using a Maple program for all nine systems and transferred the results directly into the text. The input is a function defining $a^k_{i,j}$ and $b^k_{i,j}$ for the system in question.

3. Explicit recursion formulae and the rank conditions. In this section we present the nine differential equations, numbered as in [5], the corresponding image polynomials of the monomials under $\mathcal{L}$, the highest coefficients of the corresponding orthogonal polynomials of degree k, and the coefficients of the recursion formulae. Finally, in all cases the conditions on the free parameters are discussed in order to satisfy the rank condition for S_k as well as $M^{\star\star}_{k-1}$. Since we are only interested in

determining the rank of S_k and of $M^{\star\star}_{k-1}$, respectively, we will delete common factors in the rows and columns without changing the notation.

Equation (3.10). Differential equation:

$$\omega_{xx} + \omega_{yy} - x\omega_x - y\omega_y = -k\omega.$$

Monomials:

$$\mathcal{L}(t_i^k) = -kt_i^k + (k-i)(k-i-1)t_i^{k-2} + i(i-1)t_{i-2}^{k-2}.$$

Nonvanishing coefficients $a^k_{i,j}$ and $b^k_{i,j}$:

$$b^k_{i,i-2} = -i(i-1)/2,\ b^k_{i,i} = -(k-i)(k-i-1)/2.$$

Nonvanishing coefficients in the recursion:

$$d_{i,i} = k-i, \qquad \bar{d}_{i,i-2} = i-1.$$

Nonvanishing elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{i,i-1} = i-1, \quad i = 2,3,\dots,k, \quad m^{\star\star}_{i,i+1} = -(k-i), \quad i = 1,2,\dots,k-1.$$

The differential equation defines the product *Hermite* polynomial system (the tensor product of the Hermite polynomials); it is definite, even positive definite, and the rank condition (6) holds.

Equation (3.12). Differential equation:

$$x\omega_{xx} + y\omega_{yy} + (1+\alpha-x)\omega_x + (1+\beta-y)\omega_y = -k\omega.$$

Monomials:

$$\mathcal{L}(t_i^k) = -kt_i^k + (k-i)(k-i-\alpha)t_i^{k-1} + i(i+\beta)t_{i-1}^{k-1}.$$

Nonvanishing coefficients $a^k_{i,j}$ and $b^k_{i,j}$:

$$\begin{aligned}
a^k_{i,i-1} &= -i(i+\beta),\\
a^k_{i,i} &= -(k-i)(k-i+\alpha),\\
b^k_{i,i-2} &= -i(i-1)(i+\beta)(i+\beta-1)/2,\\
b^k_{i,i-1} &= i(i+\beta)(k-i)(k-i+\alpha),\\
b^k_{i,i} &= -(k-i)(k-i-1)(k-i-\alpha)(k-i-\alpha-1)/2.
\end{aligned}$$

Nonvanishing coefficients in the recursion:

$$c_{i,i} = 2k+1-2i+\alpha,\ \bar{c}_{i,i-1} = 2i-1+\beta,\ d_{i,i} = (k-i)(k-i+\alpha),\ \bar{d}_{i,i-2} = (i-1)(i-1+\beta).$$

The matrix S_k:

$$\begin{bmatrix}
k(k+\alpha) & & & 0 & & \\
& (k-1)(k+\alpha+1) & & \beta+1 & & \\
& & \ddots & & 2(\beta+2) & \\
& & & \alpha+1 & & \ddots \\
& & & 0 & & k(k+\beta)
\end{bmatrix};$$

it has rank $k+1$ exactly when $-\alpha, -\beta \notin \mathbf{N}$.

Nonvanishing elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{i,i-1} = (i-1)(i-1+\beta),\ i = 2,3,\ldots,k,\ m^{\star\star}_{i,i+1} = -(k-i)(k-i+\alpha),\ i = 1,2,\ldots,k-1.$$

The differential equation defines the product *Laguerre* polynomial system (the tensor product of the Laguerre polynomials); it is definite if and only if $-\alpha, -\beta \notin \mathbf{N}$, in which case the rank condition (6) also holds. For $\alpha, \beta > -1$ the system is even positive definite.

Equation (3.13). Differential equation:

$$\omega_{xx} + y\omega_{yy} - x\omega_x + (1+\alpha-y)\omega_y = -k\omega.$$

Monomials:

$$\mathcal{L}(t^k_i) = -kt^k_i + i(i+\alpha)t^{k-1}_{i-1} + (k-i)(k-i-1)t^{k-2}_i.$$

Nonvanishing coefficients $a^k_{i,j}$ and $b^k_{i,j}$:

$$a^k_{i,i-1} = -i(i+\alpha),\ b^k_{i,i-2} = (i+\alpha)(i+\alpha-1)i(i-1)/2,\ b^k_{i,i} = -(k-i)(k-i-1)/2.$$

Nonvanishing coefficients in the recursion:

$$\bar{c}^k_{i,i-1} = 2i+\alpha-1, \quad d_{i,i} = k-i, \quad \bar{d}_{i,i-2} = (i-1)(i-1+\alpha).$$

The matrix S_k:

$$\begin{bmatrix} k & & & & 0 & & & & \\ & k-1 & & & \alpha+1 & & & & \\ & & \ddots & & & 2(\alpha+2) & & & \\ & & & \ddots & & & \ddots & & \\ & & & & 1 & & & \ddots & \\ & & & & 0 & & & & k(k+\alpha) \end{bmatrix};$$

rank $S_k = k+1$ exactly when $-\alpha \notin \mathbf{N}$. The classical systems satisfy $\alpha > -1$.

Nonvanishing elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{i,i-1} = (i-1)(i-1+\alpha), \quad i = 2,3,\ldots,k, \quad m^{\star\star}_{i,i+1} = -(k-i),\ i = 1,2,\ldots,k-1.$$

The differential equation defines the product *Hermite–Laguerre* polynomial system (the tensor product of Hermite polynomials and Laguerre polynomials); it is definite if and only if $-\alpha \notin \mathbf{N}$, and in this case the rank condition (6) also holds.

Equation (5.14). Differential equation:

$$(x^2-1)\omega_{xx} + 2xy\omega_{xy} + (y^2-1)\omega_{yy} + gx\omega_x + gy\omega_y = k(k+g-1)\omega,\ -g \notin \mathbf{N}_0.$$

Monomials:

$$\mathcal{L}(t^k_i) = k(k+g-1)t^k_i - (k-i)(k-i-1)t^{k-2}_i - i(i-1)t^{k-2}_{i-2}.$$

Nonvanishing coefficients $a^k_{i,j}$ and $b^k_{i,j}$:

$$b\ b^k_{i,i-2} = -i(i-1), \qquad b\ b^k_{i,i} = -(k-i)(k-i-1),$$

where $b = 2(2k + g - 3)$.

Nonvanishing coefficients in the recursion:

$$d\ d_{i,i-2} = i(i-1), \qquad d\ d_{i,i} = (k-i)(k+g+i-2),$$
$$d\ \bar{d}_{i,i-2} = (i-1)(2k+g-i-1), \quad d\ \bar{d}_{i,i} = (k-i+1)(k-i),$$

where $d = (2k + g - 3)(2k - 1 + g)$. Since $d_{i,i-2} \neq 0$ and

$$\det \begin{bmatrix} d_{00} & 0 & \bar{d}_{11} \\ 0 & \bar{d}_{20} & 0 \\ d_{20} & 0 & \bar{d}_{31} \end{bmatrix} \neq 0,$$

we obtain rank $S_k = k + 1$.

Nonvanishing elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{i,i-1} = \frac{i-1}{2k+g-3}, \quad i = 2, 3, \ldots, k, \quad m^{\star\star}_{i,i+1} = -\frac{k-i}{2k+g-3}, \quad i = 1, 2, \ldots, k-1.$$

The differential equation defines the *circle-polynomial* system (cf. Chap. VI in [1]); it is definite, even positive definite, and the rank condition (6) holds.

Equation (5.19). Differential equation:

$$3y\omega_{xx} + 2\omega_{xy} - x\omega_x - y\omega_y = -k\omega.$$

Monomials:

$$\mathcal{L}(t^k_i) = -kt^k_i + 3(k-i)(k-i-1)t^{k-1}_{i+1} + 2(k-i)it^{k-2}_{i-1}.$$

Nonvanishing coefficients $a^k_{i,j}$ and $b^k_{i,j}$:

$$a^k_{i,i+1} = -3(k-i)(k-i-1),$$
$$b^k_{i,i-1} = -i(k-i), \qquad b^k_{i,i+2} = 9(k-i-2)(k-i-3)(k-i)(k-i-1)/2.$$

Nonvanishing coefficients in the recursion:

$$c_{i,i+1} = 6(k-i), \quad d_{i,i-1} = i, \quad \bar{d}_{i,i-1} = k+1-i.$$

The rank of S_k is easily determined to be equal to $k + 1$.

As shown in [5], and easily verified by the induction formula (3), the moment matrix M_k, $k \in \mathbf{N}_0$, has cross-diagonal nonvanishing elements:

$$m^{(k)}_{i,k-i} = i!(k-i)!, \qquad 0 \leq i \leq k.$$

Nonvanishing elements of $M^{\star\star}_{k-1}$:

$$m^{\star\star}_{i,i} = k - 2i + 1, \qquad i = 1, 2, \ldots, k.$$

The system is definite, not positive definite, and the rank condition (6) holds.

Equation (5.22). Differential equation:

$$(x^2+y+1)\omega_{xx}+(2xy+2x)\omega_{xy}+(y^2+2y+1)\omega_{yy}+gx\omega_x+gy\omega_y = -k(k-1+g)\omega, \ -g \notin \mathbf{N}_0.$$

Monomials:

$$\mathcal{L}(t_i^k) = k(k+g-1)t_i^k + (k-i)(k-i-1)t_{i+1}^{k-1} + 2i(k-1)t_{i-1}^{k-1} + (k-i)(k-i-1)t_i^{k-2} + i(i-1)t_{i-2}^{k-2}.$$

Nonvanishing coefficients $a_{i,j}^k$ and $b_{i,j}^k$:

$$a_{i,i-1}^k = \frac{2i(k-1)}{2k+g-2},$$
$$a_{i,i+1}^k = \frac{(k-i)(k-i-1)}{2k+g-2},$$
$$b_{i,i-2}^k = \frac{i(i-1)(g+2(k-1)(2k-3))}{2(2k+g-2)(2k+g-3)},$$
$$b_{i,i}^k = \frac{(k-i)(k-i-1)(g+2(i+1)(2k-3))}{2(2k+g-2)(2k+g-3)},$$
$$b_{i,i+1}^k = \frac{(k-i)(k-i-1)(k-i-2)(k-i-3)}{2(2k+g-2)(2k+g-3)}.$$

Nonvanishing coefficients in the recursion:

$$c\, c_{i,i-1} = -2ig,$$
$$c\, c_{i,i+1} = -2(k-i)(k+g-1+i),$$
$$c\, \bar{c}_{i,i-1} = -2ig - 4k^2 - 2gk + 4k + 2g,$$
$$c\, \bar{c}_{i,i+1} = 2(k-i+1)(k-i),$$
$$d\, d_{i,i-2} = ig^2(i-1),$$
$$d\, d_{i,i} = g(k-i)(-g^2+5g+2ig-4gk+2ik-5-3i+9k-4k^2+2i^2),$$
$$d\, d_{i,i+2} = (2g+3k-3+i)(-k+i+2)(-k+i+1)(-k+i),$$
$$d\, \bar{d}_{i,i-2} = g^2(-g-2k+1+i)(i-1),$$
$$d\, \bar{d}_{i,i} = g(2k+g-2i-2)(k-i+1)(k-i),$$
$$d\, \bar{d}_{i,i+2} = (k-i-2)(k-i+1)(k-i-1)(k-i),$$

where $c = (2k+g-2)(2k+g)$ and $d = (2k-1+g)(2k+g-3)(2k+g-2)^2$. The entries $d_{i,i-2}$, $i = 2, 3, \ldots, k$, do not vanish. To determine rank S_k it sufficies to determine the rank of the submatrix

$$A = \begin{bmatrix} d_{0,0} & 0 & \bar{d}_{1,1} \\ 0 & \bar{d}_{2,0} & 0 \\ d_{2,0} & 0 & \bar{d}_{3,1} \end{bmatrix}.$$

Here, $\det A = -4kg^5(2k+g-2)(2k+g-3)^2(2k+g-4)$. We obtain a definite orthogonal system if $g \notin \mathbf{N}_0$; this was left open in [5].

It follows from the representation of D_k and $\bar{D}_k$ and formula (3) that the coefficient $m_{k,k}^{(k)}$ of the moment matrix M_k is given by

$$m_{k,k}^{(k)} = \bar{d}_{k+1,k-1}^{(k)}\, m_{k-1,k-1}^{(k-1)}, \qquad k \in \mathbf{N},$$

where

$$\bar{d}_{k+1,k-1}^{(k)} = \frac{-kg^2(g+k-2)}{(g+2k-3)(g+2k-2)^2(g+2k-1)}.$$

Since $M_0 = 1$, $m_{k,k}^{(k)} \neq 0$ for a given admissible g and for all $k \in \mathbf{N}_0$. Assume the system to be positive definite; then $m_{k,k}^{(k)} > 0$ for all $k \in \mathbf{N}_0$. An inductive argument implies that $g < -(2k-1)$ for all $k \in \mathbf{N}$, which is obviously impossible.

Nonvanishing elements of $M_{k-1}^{\star\star}$:

$$
\begin{aligned}
m\, m_{i,i-1}^{\star\star} &= -g^2(i-1), \qquad i = 2,3,\ldots,k,\\
m\, m_{i,i+1}^{\star\star} &= -g(-g+3+3i-3k)(k-i), \qquad i = 1,2,\ldots,k-2,\\
m\, m_{i,i+3}^{\star\star} &= 2(k-i-2)(k-i-1)(k-i), \qquad i = 1,2,\ldots,k-4,
\end{aligned}
$$

where $m = (2k+g-3)(2k+g-2)^2$.

Hence, the system is definite and not positive definite for $g \notin \mathbf{N}_0$, and equation (6) holds.

Equation (5.52). Differential equation:

$$
\begin{aligned}
&(x^2-x)\omega_{xx} + 2xy\omega_{xy} + (y^2-y)\omega_{yy}\\
&+((\alpha+1)x - \beta - 1)\omega_x + ((\alpha+1)y - \gamma - 1)\omega_y = k(k+\alpha)\omega, \quad -\alpha \notin \mathbf{N}_0.
\end{aligned}
$$

Monomials:

$$
\mathcal{L}(t_i^k) = k(k+\alpha)t_i^k - (k-i)(k-i+\beta)t_i^{k-1} - i(i+\gamma)t_{i-1}^{k-1}.
$$

Nonvanishing coefficients $a_{i,j}^k$ and $b_{i,j}^k$:

$$
\begin{aligned}
a_{i,i}^k &= \frac{-(k-i)(k-i+\beta)}{2k+\alpha-1},\\
a_{i,i-1}^k &= \frac{-i(i+\gamma)}{2k+\alpha-1},\\
b_{i,i-2}^k &= \frac{i(i-1)(i+\gamma)(i+\gamma-1)}{2(2k+\alpha-1)(2k+\alpha-2)},\\
b_{i,i-1}^k &= \frac{i(i+\gamma)(k-i)(k-i+\beta)}{(2k+\alpha-1)(2k+\alpha-2)},\\
b_{i,i}^k &= \frac{(k-i-1)(k-i)(k-i+\beta-1)(k-i+\beta)}{2(2k+\alpha-1)(2k+\alpha-2)}.
\end{aligned}
$$

Nonvanishing coefficients in the recursion:

$$
\begin{aligned}
c\, c_{i,i-1} &= -2i(i+\gamma),\\
c\, c_{i,i} &= -1+2i+\alpha-\beta+2\alpha k-2i^2-2i\alpha+2k^2+2i\beta+\beta\alpha,\\
c\, \bar{c}_{i,i-1} &= -2i^2+4ik+2i+2i\alpha-2i\gamma-2k-1-\alpha+2\gamma k+\gamma+\gamma\alpha,\\
c\, \bar{c}_{i,i} &= -2(-k-1+i)(-k-1+i-\beta),\\
d\, d_{i,i-2} &= i(i-1)(i+\gamma)(i-1+\gamma),\\
d\, d_{i,i-1} &= i(-\alpha-2\alpha k+2i\alpha-\beta\alpha+2\beta+2-4i-2i\beta+2k-2k^2+2i^2)(i+\gamma)\\
&= i(i+\gamma)[2(k-i+1)(k-i+\beta+1)-(2k-2i+\beta+1)(2k+\alpha)],\\
d\, d_{i,i} &= (\alpha+k+i-1)(i+\alpha-1+k-\beta)(k-i+\beta)(k-i),\\
d\, \bar{d}_{i,i-2} &= (-\alpha-2k+i)(i-2k-\alpha+\gamma)(i-1)(i-1+\gamma),\\
d\, \bar{d}_{i,i-1} &= [-2i\alpha+\alpha-\gamma\alpha-2\gamma k+2i^2-4ik+2k+2i\gamma](k+1-i)(k+1-i+\beta)\\
&= (k-i+1)(k-i+\beta+1)[2i(i+\gamma)-(2i+\gamma-1)(2k+\alpha)],\\
d\, \bar{d}_{i,i} &= (k+1-i+\beta)(k+1-i)(k-i+\beta)(k-i),
\end{aligned}
$$

where $c = (2k+\alpha-1)(2k+\alpha+1)$ and $d = (2k+\alpha)(2k+\alpha-1)^2(2k+\alpha-2)$.

If $k = 1$ the rank condition is satisfied if and only if

$$\det S_1 = \alpha(\alpha+1)(\beta+1)(\gamma+1)(\alpha-\beta-\gamma-1) \neq 0.$$

Furthermore, in this case rank $M_0^{\star\star} = 0$. Henceforth we shall assume that $k \geq 2$.

In order to obtain rank $S_k = k+1$, the first and last row of S_k must be different from zero. Since $k+\beta$ and $k+\gamma$ are a common factor of the two rows, respectively, we get in addition to $-\alpha \notin \mathbf{N}_0$,

$$-\beta \notin \mathbf{N} \text{ and } -\gamma \notin \mathbf{N}.$$

Thus, $d_{i,i-2}$ and $\bar{d}_{i,i}$ are nonvanishing elements in S_k. The rank condition is satisfied if the determinants of the matrices

$$A = \begin{bmatrix} d_{00} & \bar{d}_{10} & \bar{d}_{11} \\ d_{10} & \bar{d}_{20} & \bar{d}_{21} \\ d_{20} & 0 & \bar{d}_{31} \end{bmatrix} \quad \text{or} \quad B = \begin{bmatrix} d_{k-2,k-2} & 0 & \bar{d}_{k-1,k-1} \\ d_{k-1,k-2} & d_{k-1,k-1} & \bar{d}_{k,k-1} \\ d_{k,k-2} & d_{k,k-1} & \bar{d}_{k+1,k-1} \end{bmatrix}$$

do not vanish. We find

$$\det A = a\ k(k+\beta)(\gamma+1)(\gamma+2)(k+\alpha-\gamma-2)(k+\alpha-\beta-\gamma-2),$$
$$\det B = a\ k(k+\gamma)(\beta+1)(\beta+2)(k+\alpha-\beta-2)(k+\alpha-\beta-\gamma-2),$$

where $a = 2(2k+\alpha-3)(2k+\alpha-2)^2(2k+\alpha-1)$.

Let us first consider the case $\alpha = \beta+\gamma-k+2$. Inserting α into the formulae of $d_{i,j}$ and $\bar{d}_{i,j}$ and deleting the common factor d, we get for D_k,[1] after deleting the common factor $i+\gamma$ in the $(i-1)$st column,

$$\begin{aligned} d_{i+1,i-1} &= i(i+1)(i+\gamma+1), \\ d_{i,i-1} &= i(2(k-i)(k-i+\beta) - (2(k-i)+\beta+1)(k+\beta+\gamma)), \\ d_{i-1,i-1} &= (\beta+\gamma+i)(k-i+\beta+1)(k-i+1), \\ d_{k-1,k-1} &= (\beta+k+\gamma)(\beta+1),\ d_{k,k-1} = -k(\beta+k+\gamma)(\beta+1), \end{aligned}$$

and similarly for $\bar{D}_k$, after deleting the common factor $k-i+\beta$ in the ith column,

$$\begin{aligned} \bar{d}_{i+2,i} &= (k-i+\beta+\gamma)(i+1)(i+\gamma+1), \\ \bar{d}_{i+1,i} &= (k-i)(2i(i+\gamma+1) - (2i+\gamma+1)(k+\beta+\gamma)), \\ \bar{d}_{i,i} &= (k-i+\beta+1)(k-i+1)(k-i), \\ \bar{d}_{1,0} &= -k(k+\beta+\gamma),\ \bar{d}_{2,0} = (k+\beta+\gamma). \end{aligned}$$

Next we add the first $k-1$ columns of D_k to the last $k-1$ columns of $\bar{D}_k$ and obtain for $i = 1, 2, \ldots, k-1$,

$$\begin{aligned} \bar{d}_{i+2,i} &= (i+1)(i+\gamma+1), \\ \bar{d}_{i+1,i} &= -(2i(k-i) + (k-i)(\gamma+1) + i(\beta+1)), \\ \bar{d}_{i,i} &= (k-i+1)(k-i+\beta+1), \\ \bar{d}_{1,0} &= -k, \qquad \bar{d}_{2,0} = 1, \end{aligned}$$

[1] Recall that we do not change the notation when we delete common factors in rows and columns of the matrices under consideration.

where the common factor $k+\beta+\gamma \neq 0$ has been deleted from all elements. Now we subtract the ith column of $\bar{D}_k$ multiplied by i from the $(i-1)$st column of D_k and get

$$\begin{aligned} d_{i+1,i-1} &= 0, \\ d_{i,i-1} &= -i(k-i+\beta+1), \\ d_{i-1,i-1} &= (k-i+1)(k-i+\beta+1), \\ d_{k,k-1} &= -k, \qquad d_{k-1,k-1} = 1; \end{aligned}$$

here, the common factor $(\beta+\gamma+1) \neq 0$ has been deleted. Finally, we subtract for $i = 1, 2, \ldots, k-1$, the $(i-1)$st column of D_k from the ith column of $\bar{D}_k$, which leads to

$$\bar{d}_{i+2,i} = i+1, \quad \bar{d}_{i+1,i} = -(k-i), \quad \bar{d}_{i,i} = 0, \quad \bar{d}_{1,0} = -k, \quad \bar{d}_{2,0} = 1.$$

Thus $\bar{D}_k = D_k$ and rank $S_k = k$. Hence the parameters α, β, γ must in addition satisfy the condition $\beta+\gamma-\alpha \notin \mathbf{N}_0$ in order to get a definite system.

There remains to consider the case when $\beta = \gamma = \alpha + k - 2$. Then

$$\begin{aligned} d_{i+1,i-1} &= i(i+1)(k+i+\alpha-1)(k+i+\alpha-2), \\ d_{i,i-1} &= i(k+i+\alpha-2)(2(k-i+1)(2k-i+\alpha-1) \\ &\qquad -(2k+\alpha)(3k-2i+\alpha-1)), \\ d_{i-1,i-1} &= i(k+i+\alpha-2)(2k-i+\alpha-1)(k-i+1), \end{aligned}$$

where $i(k+i+\alpha-2)$ is a common factor in the $(i-1)$st column of D_k. Similarly,

$$\begin{aligned} \bar{d}_{i+2,i} &= (i+1)(k-i)(k+i+\alpha-1)(2k-i+\alpha-2), \\ \bar{d}_{i+1,i} &= (k-i)(2k-i+\alpha-2)(2(i+1)(k+i+\alpha-1) - (k+2i+\alpha-1)(2k+\alpha)), \\ \bar{d}_{i,i} &= (k-i)(k-i+1)(2k-i+\alpha-2)(2k-i+\alpha-1), \end{aligned}$$

here $(k-i)(2k-i+\alpha-2)$ is a common factor in the ith column of $\bar{D}_k$. Thus, for $i = 1, 2, \ldots, k$,

$$\bar{d}_{i+2,i} - d_{i+1,i-1} = 0, \quad \bar{d}_{i+1,i} - d_{i,i-1} = 0, \quad \bar{d}_{i,i} - d_{i-1,i-1} = 0.$$

By subtracting the first $k-2$ columns in D_k from the last $k-2$ columns of $\bar{D}_k$, we find that the rank of S_k is equivalent to the rank of the following tridiagonal matrix:

$$\begin{bmatrix} a_0 & c_0 & & \\ b_1 & a_1 & \ddots & \\ & \ddots & \ddots & c_{k-1} \\ & & b_k & a_k \end{bmatrix},$$

where

$$\begin{aligned} a_0 &= \bar{d}_{10}, \quad a_i = d_{i,i-1}, \quad i = 1, 2, \ldots, k, \\ b_1 &= \bar{d}_{2,0}, \quad b_i = d_{i,i-2}, \quad i = 2, 3, \ldots, k, \\ c_i &= d_{i,i}, \qquad i = 0, 1, \ldots, k-1. \end{aligned}$$

Since

$$
\begin{aligned}
a_i &= 2(k-i+1)(2k-i+\alpha-1) - (2k+\alpha)(3k-2i+\alpha-1), \qquad i = 0,1,\dots,k,\\
c_i &= (k-i)(2k-i+\alpha-2),\ i = 0,1,\dots,k-1,\\
b_i &= i(k+i+\alpha-2), \qquad i = 1,2,\dots,k,
\end{aligned}
$$

it is not hard to factor the matrix as follows:

$$
\begin{bmatrix}
a_0 & c_0 & & \\
b_1 & a_1 & \ddots & \\
 & \ddots & \ddots & c_{k-1}\\
 & & b_k & a_k
\end{bmatrix}
=
\begin{bmatrix}
\alpha_0 & & & \\
b_1 & \alpha_1 & & \\
 & \ddots & \ddots & \\
 & & b_k & \alpha_k
\end{bmatrix}
\begin{bmatrix}
1 & \gamma_0 & & \\
 & 1 & \ddots & \\
 & & \ddots & \gamma_{k-1}\\
 & & & 1
\end{bmatrix},
$$

where

$$
\begin{aligned}
\alpha_i &= -(2k+\alpha-i-2)(k+\alpha+i-1), \qquad i = 0,1,\dots,k,\\
\gamma_i &= -(k-i)/(k+\alpha+i-1), \qquad i = 0,1,\dots,k-1.
\end{aligned}
$$

Hence, no further restrictions on the parameters α, β, and γ are necessary.

The differential equation defines the *Jacobi polynomial* system on the simplex (cf. Chap. VI in [1]); it is definite if and only if $-\alpha, -\alpha+\beta+\gamma \notin \mathbf{N}_0$ and $-\beta, -\gamma \notin \mathbf{N}$; it is even positive definite for $\alpha > \beta+\gamma+1, \beta > -1, \gamma > -1$.

Nonvanishing elements of M^{**}_{k-1}:

$$
\begin{aligned}
m\, m^{**}_{i,i-1} &= (2k-2i+\alpha-\gamma)(i-1)(i-1+\gamma), \qquad i = 2,3,\dots,k\\
m\, m^{**}_{i,i} &= i(i+\gamma)(2k-2i+\beta+1) - (k-i+1)(k-i+\beta+1)(2i+\gamma-1),\\
&\qquad i = 1,2,\dots,k,\\
m\, m^{**}_{i,i+1} &= -(\alpha-2+2i-\beta)(k-i+\beta)(k-i), \qquad i = 1,2,\dots,k-1,
\end{aligned}
$$

where $m = (2k+\alpha-1)^2(2k+\alpha-2)$. To determine the rank of M^{**}_{k-1}, let us introduce the notation

$$
M^{**} = -\begin{bmatrix}
a_1 & c_1 & & \\
b_2 & a_2 & \ddots & \\
 & \ddots & \ddots & c_{k-1}\\
 & & b_k & a_k
\end{bmatrix},
$$

where

$$
\begin{aligned}
b_i &= -(2k-2i+\alpha-\gamma)(i-1)(i-1+\gamma), \qquad i = 2,3,\dots,k\\
a_i &= (k-i+1)(k-i+\beta+1)(2i+\gamma-1) - i(i+\gamma)(2k-2i+\beta+1),\\
&\qquad i = 1,2,\dots,k,\\
c_i &= (\alpha-2+2i-\beta)(k-i+\beta)(k-i), \qquad i = 1,2,\dots,k-1.
\end{aligned}
$$

Since there is at most one element in the subdiagonal which might vanish, the rank of M^{**} is greater than or equal to $k-2$. Since the rank of M^{**}_{k-1} is even this means rank $M^{**} \geq k-1$ if k is odd.

Denoting the principal minors of M^{**} by A_i, $i = 0, 1, \ldots, k$, we can compute $\det M^{**} = A_k$ recursively via

$$A_0 = 1, \quad A_1 = a_1, \quad A_i = a_i A_{i-1} - b_i c_{i-1} A_{i-2}, \; i = 2, 3, \ldots, k.$$

By introducing the expressions

$$\begin{aligned} S_i &= (k-i)(\gamma+i)(k+\beta-i), \\ T_i &= (2k-2i+\alpha-\gamma-2)(2i+\alpha-\beta-2), \qquad i = 1, 2, \ldots, \end{aligned}$$

we obtain

$$a_i = iS_i - (i-1)S_{i-1} \text{ and } b_i c_{i-1} = -(i-1)S_{i-1}T_{i-1};$$

the recursion for the subdeterminants can then be rewritten as

$$A_0 = 1, \quad A_1 = S_1, \quad A_i = [iS_i - (i-1)S_{i-1}]A_{i-1} + (i-1)S_{i-1}T_{i-1}A_{i-2}, \; i = 2, 3, \ldots, k.$$

In what follows we need the following main identity connecting the S_is and T_is:

$$\begin{aligned} &(m+1)\left[(i-2m+1)S_{i+1} - (i-2m)S_i - S_{2(i-m)+1}\right] \\ &= \frac{(i-2m+1)(i-2m)}{2}\left[T_{i+1} - T_{i-m}\right], \end{aligned}$$

where $m = 0, 1, 2 \ldots$; the identity is easily verified.

By induction we prove that

$$A_i = U_{2i-1} + \sum_{\nu=1}^{[i/2]} \lambda_\nu^i U_{2(i-\nu)-1} T_i T_{i-1} \ldots T_{i-\nu+1}, \qquad i = 1, 2, \ldots, k,$$

where

$$U_{2m-1} = S_1 S_3 \ldots S_{2m-1}, \quad m = 1, 2, \ldots, \quad \text{and } \lambda_\nu^i = \frac{i!}{(i-2\nu)!\nu!2^\nu}.$$

For $i = 1$ we have $a_1 = S_1 = U_1$. By assuming the formula to be true for A_{i-1} and A_i, we obtain for $[(i+1)S_{i+1} - iS_i]A_i + iS_i T_i A_{i-1}$ the expression

$$\begin{aligned} &((i+1)S_{i+1} - iS_i)\left[U_{2i-1} + \sum_{\nu=1}^{[i/2]} \lambda_\nu^i U_{2(i-\nu)-1} T_i T_{i-1} \ldots T_{i-\nu+1}\right] \\ &\qquad + iS_i T_i \left[U_{2i-3} + \sum_{\nu=1}^{[(i-1)/2]} \lambda_\nu^{i-1} U_{2(i-\nu)-3} T_{i-1} T_{i-2} \ldots T_{i-\nu}\right]. \end{aligned}$$

We apply the main identity for $m = 0$ to $[(i+1)S_{i+1} - iS_i]U_{2i-1}$ and get

$$\begin{aligned} &U_{2i+1} + \frac{i(i+1)}{2} U_{2i-1} T_{i+1} - \frac{i(i+1)}{2} U_{2i-3} S_{2i-1} T_i \\ &+ (i+1)S_{i+1} \sum_{\nu=1}^{[i/2]} \lambda_\nu^i U_{2(i-\nu)-1} T_i T_{i-1} \ldots T_{i-\nu+1} + iS_i T_i U_{2i-3} \end{aligned}$$

$$
\begin{aligned}
&+iS_iT_i\sum_{\nu=1}^{[(i-1)/2]}\lambda_\nu^{i-1}U_{2(i-\nu)-3}T_{i-1}T_{i-2}\dots T_{i-\nu}\\
&-iS_iT_i\sum_{\nu=1}^{[i/2]}\lambda_\nu^{i}U_{2(i-\nu)-1}T_{i-1}T_{i-2}\dots T_{i-\nu+1}\\
&=U_{2i+1}+\frac{i(i+1)}{2}U_{2i-1}T_{i+1}\\
&+U_{2i-3}T_i\left[(i+1)\lambda_1^iS_{i+1}-i(\lambda_1^i-1)S_i-\frac{i(i+1)}{2}S_{2i-1}\right]\\
&+(i+1)S_{i+1}\sum_{\nu=2}^{[i/2]}\lambda_\nu^iU_{2(i-\nu)-1}T_iT_{i-1}\dots T_{i-\nu+1}\\
&-iS_iT_i\sum_{\nu=2}^{[i/2]}\lambda_\nu^iU_{2(i-\nu)-1}T_{i-1}T_{i-2}\dots T_{i-\nu+1}\\
&+iS_iT_i\sum_{\nu=2}^{[(i-1)/2]+1}\lambda_{\nu-1}^{i-1}U_{2(i-\nu)-1}T_{i-1}T_{i-2}\dots T_{i-\nu+1}\\
&=U_{2i+1}+\frac{i(i+1)}{2}U_{2i-1}T_{i+1}\\
&+U_{2i-3}T_i\left[(i+1)\lambda_1^iS_{i+1}-i(\lambda_1^i-1)S_i-\frac{i(i+1)}{2}S_{2i-1}\right]\\
&+\sum_{\nu=2}^{[i/2]}U_{2(i-\nu)-1}T_iT_{i-1}\dots T_{i-\nu+1}\left[(i+1)\lambda_\nu^iS_{i+1}-i(\lambda_\nu^i-\lambda_{\nu-1}^{i-1})S_i\right]+R.
\end{aligned}
$$

For i even we have $R=0$, while for i odd, say, $i=2\nu+1$ we obtain

$$R=(2\nu+1)\lambda_\nu^{2\nu}U_{2\nu+1}T_{2\nu+1}\dots T_{\nu+1}.$$

Next we apply the main identity for $m=\nu$ and, by recalling that

$$\lambda_\nu^{i+1}=\frac{(i+1)!}{(i+1-2\nu)!\nu!2^\nu},$$

we obtain

$$
\begin{aligned}
&(i+1)\lambda_\nu^iS_{i+1}-i(\lambda_\nu^i-\lambda_{\nu-1}^{i-1})S_i=\frac{(i+1)!}{(i-2\nu+1)!\nu!2^\nu}\left[(i-2\nu+1)S_{i+1}-(i-2\nu)S_i\right]\\
&=\lambda_\nu^{i+1}\left[S_{2(i-\nu)+1}+\frac{(i-2\nu+1)(i-2\nu)}{2(\nu+1)}(T_{i+1}-T_{i-\nu})\right].
\end{aligned}
$$

Note that the second summand vanishes for i even, say, $i=2\nu$. By setting the undefined term $\lambda_{\nu+1}^{i+1}$ to be equal to 0 for i even and $i=2\nu$, we can rewrite the last equation as

$$(i+1)\lambda_\nu^iS_{i+1}-i(\lambda_\nu^i-\lambda_{\nu-1}^{i-1})S_i=\lambda_\nu^{i+1}S_{2(i-\nu)+1}+\lambda_{\nu+1}^{i+1}(T_{i+1}-T_{i-\nu}).$$

The main identity for $m=1$ can be written as

$$(i-1)S_{i+1}-(i-2)S_i-S_{2i-1}=\frac{(i-1)(i-2)}{4}(T_{i+1}-T_{i-1}),$$

which gives

$$\begin{aligned}&(i+1)\lambda_1^i S_{i+1} - i(\lambda_1^i - 1)S_i - \frac{i(i+1)}{2}S_{2i-1}\\ &= \frac{i(i+1)}{2}[(i-1)S_{i+1} - (i-2)S_i - S_{2i-1}]\\ &= \lambda_2^{i+1}[T_{i+1} - T_{i-1}].\end{aligned}$$

Thus we can simplify the last expression obtained for $[(i+1)S_{i+1} - iS_i]\,A_i + iS_i\,T_iA_{i-1}$ to

$$\begin{aligned}&U_{2i+1} + \lambda_1^{i+1}U_{2i-1}\,T_{i+1} + \lambda_2^{i+1}U_{2i-3}\,T_{i+1}T_i - \lambda_2^{i+1}U_{2i-3}\,T_iT_{i-1}\\ &+ \sum_{\nu=2}^{[i/2]} \lambda_\nu^{i+1}S_{2(i-\nu)+1}U_{2(i-\nu)-1}\,T_iT_{i-1}\ldots T_{i-\nu+1} + \sum_{\nu=2}^{[i/2]} \lambda_{\nu+1}^{i+1}U_{2(i-\nu)-1}\,T_{i+1}T_i\ldots T_{i-\nu+1}\\ &- \sum_{\nu=2}^{[i/2]} \lambda_{\nu+1}^{i+1}U_{2(i-\nu)-1}\,T_iT_{i-1}\ldots T_{i-\nu} + R,\end{aligned}$$

which can be rewritten as

$$\begin{aligned}&U_{2i+1} + \sum_{\nu=0}^{[i/2]} \lambda_{\nu+1}^{i+1}U_{2(i-\nu)-1}\,T_{i+1}T_i\ldots T_{i-\nu+1}\\ &+ \sum_{\nu=2}^{[i/2]} \lambda_\nu^{i+1}U_{2(i-\nu)+1}\,T_iT_{i-1}\ldots T_{i-\nu+1} - \sum_{\nu=1}^{[i/2]} \lambda_{\nu+1}^{i+1}U_{2(i-\nu)-1}\,T_iT_{i-1}\ldots T_{i-\nu} + R;\end{aligned}$$

the last two sums reduce to $-R$, which finally gives

$$U_{2i+1} + \sum_{\nu=1}^{[i/2]+1} \lambda_\nu^{i+1}U_{2(i+1-\nu)-1}\,T_{i+1}T_i\ldots T_{i+1-\nu+1}.$$

Taking into account that for i even, say, $i = 2\nu$ $\lambda_{\nu+1}^{2\nu+1} = 0$ and that for i odd $[i/2] + 1 = [(i+1)/2]$, the last formula completes the induction.

Thus we obtain

$$A_k = S_1S_3\ldots S_{2(k-[k/2])-1} \sum_{\nu=0}^{[k/2]} \lambda_\nu^k S_{2(k-[k/2])+1}S_{k+3}\ldots S_{2(k-\nu)-1}T_kT_{k-1}\ldots T_{k-\nu+1}.$$

Since $S_{2(k-[k/2])-1} = S_k = 0$ for odd k, we get in this case rank $M_{k-1}^{\star\star} = k-1$. To finish the discussion let us assume k to be even. Then $S_1S_3\ldots S_{k-1} \neq 0$. By introducing the shifted factorials (Pochhammer symbols)

$$(a)_0 = 1,\ (a)_n = a(a+1)\ldots(a+n-1), \qquad a \in \mathbf{R},$$

and regarding the identities

$$\begin{aligned}&(a-\nu)_\nu = (-1)^\nu(1-a)_\nu, \qquad (a)_{i-\nu} = (-1)^\nu\frac{(a)_i}{(1-a-i)_\nu},\\ &2^{k/2}\left(\frac{a+1}{2}\right)_{k/2} = (a+1)(a+3)\ldots(a+k-1),\end{aligned}$$

we can fully factorize A_k. Indeed,

$$S_{k+1}S_{k+3}\dots S_{2(k-\nu)-1} = 2^{3(k/2-\nu)}(1/2)_{k/2-\nu}\left(\frac{\gamma+k+1}{2}\right)_{k/2-\nu}\left(\frac{-\beta+1}{2}\right)_{k/2-\nu}$$
$$= 2^{3(k/2-\nu)}(-1)^{\nu}\frac{(1/2)_{k/2}\left(\frac{\gamma+k+1}{2}\right)_{k/2}\left(\frac{-\beta+1}{2}\right)_{k/2}}{\left(\frac{1-k}{2}\right)_{\nu}\left(\frac{-\gamma-2k+1}{2}\right)_{\nu}\left(\frac{\beta-k+1}{2}\right)_{\nu}},$$

similarly

$$T_kT_{k-1}\dots T_{k-\nu+1} = 2^{2\nu}\left(\frac{\alpha-\gamma-2}{2}\right)_{\nu}\left(\frac{\alpha-\beta+2k-2\nu}{2}\right)_{\nu}$$
$$= 2^{2\nu}(-1)^{\nu}\left(\frac{\alpha-\gamma-2}{2}\right)_{\nu}\left(\frac{\beta-\alpha-2k+2}{2}\right)_{\nu},$$

and finally

$$\lambda_{\nu}^{k} = \frac{2^{\nu}}{\nu!}\left(-\frac{k}{2}\right)_{\nu}\left(\frac{1-k}{2}\right)_{\nu}.$$

Thus

$$A_k = S_1S_3\dots S_{k-1}2^{3k/2}\left(\frac{1}{2}\right)_{k/2}\left(\frac{\gamma+k+1}{2}\right)_{k/2}\left(\frac{-\beta+1}{2}\right)_{k/2}\Sigma,$$

where

$$\Sigma = \sum_{\nu=0}^{k/2}\frac{\left(-\frac{k}{2}\right)_{\nu}\left(\frac{\alpha-\gamma-2}{2}\right)_{\nu}\left(\frac{\beta-\alpha-2k+2}{2}\right)_{\nu}}{\nu!\left(\frac{-\gamma-2k+1}{2}\right)_{\nu}\left(\frac{\beta-k+1}{2}\right)_{\nu}}.$$

Since the numerator of Σ vanishes for $\nu > k/2$, we can represent Σ as a generalized hypergeometric series, evaluated at 1; i.e.,

$$\Sigma = {}_3F_2\left(\frac{\alpha-\gamma-2}{2}, \frac{\beta-\alpha-2k+2}{2}, -k/2; \frac{-\gamma-2k+1}{2}, \frac{\beta-k+1}{2}; 1\right). \tag{8}$$

Since the ${}_3F_2$ sum is balanced, we can apply the Pfaff–Saalschütz-formula (see, e.g., [4]) and obtain

$$\Sigma = \frac{\left(\frac{-2k-\alpha+3}{2}\right)_{k/2}\left(\frac{\alpha-\beta-\gamma-1}{2}\right)_{k/2}}{\left(\frac{-\gamma-2k+1}{2}\right)_{k/2}\left(\frac{-\beta+1}{2}\right)_{k/2}} = \frac{\left(\frac{k+\alpha-1}{2}\right)_{k/2}\left(\frac{\alpha-\beta-\gamma-1}{2}\right)_{k/2}}{\left(\frac{\gamma+k+1}{2}\right)_{k/2}\left(\frac{-\beta+1}{2}\right)_{k/2}}.$$

Thus

$$A_k = S_1S_3\dots S_{k-1}2^{3k/2}\left(\frac{1}{2}\right)_{k/2}\left(\frac{k+\alpha-1}{2}\right)_{k/2}\left(\frac{\alpha-\beta-\gamma-1}{2}\right)_{k/2}$$
$$= 2^{3k}\left(\frac{1}{2}\right)_{k/2}^{2}\left(\frac{\gamma+1}{2}\right)_{k/2}\left(\frac{\beta+1}{2}\right)_{k/2}\left(\frac{k+\alpha-1}{2}\right)_{k/2}\left(\frac{\alpha-\beta-\gamma-1}{2}\right)_{k/2}.$$

Hence for the admissible parameters α, β, and γ we get rank $M_{k-1}^{\star\star} = k$ for even k. To summarize, if the system is definite (i.e., $-\alpha, -\alpha+\beta+\gamma \notin \mathbf{N}_0$ and $-\beta, -\gamma \notin \mathbf{N}$), then the rank condition (6) holds. For the positive definite system the proof of the rank condition can be significantly simplified, as done in [2].

Equation (5.53). Differential equation:

$$x^2\omega_{xx} + 2xy\omega_{xy} + (y^2 - y)\omega_{yy} + g(x-1)\omega_x + g(y-\alpha)\omega_y = k(k+g-1)\omega, \ -g \notin \mathbf{N}_0.$$

Monomials:

$$\mathcal{L}(t_i^k) = k(k+g-1)t_i^k - i(i+\alpha g-1)t_{i-1}^{k-1} - g(k-i)t_i^{k-1}.$$

Nonvanishing coefficients $a_{i,j}^k$ and $b_{i,j}^k$:

$$a_{i,i-1}^k = \frac{-i(i-1+\alpha g)}{2k+g-2}, \qquad a_{i,i}^k = \frac{-g(k-i)}{2k+g-2},$$
$$b_{i,i-2}^k = \frac{i(i-1)(i-1+\alpha g)(i-2+\alpha g)}{2(2k+g-2)(2k+g-3)},$$
$$b_{i,i-1}^k = \frac{g(k-i)i(i-1+\alpha g)}{(2k+g-2)(2k+g-3)},$$
$$b_{i,i}^k = \frac{g^2(k-i)(k-i-1)}{2(2k+g-2)(2k+g-3)}.$$

Nonvanishing coefficients in the recursion:

$$c\ c_{i,i-1} = -2i(i-1+\alpha g),$$
$$c\ c_{i,i} = g(g-2+2i),$$
$$c\ \bar{c}_{i,i-1} = 4ik + 2ig - 4k - 2g + 2\alpha gk + \alpha g^2 - 2i^2 + 2i - 2i\alpha g,$$
$$c\ \bar{c}_{i,i} = 2g(-k-1+i),$$
$$d\ d_{i,i-2} = i(i-1)(i-1+\alpha g)(i-2+\alpha g),$$
$$d\ d_{i,i-1} = -ig(g-3+2i)(i-1+\alpha g),$$
$$d\ d_{i,i} = g^2(g-2+i+k)(-k+i),$$
$$d\ \bar{d}_{i,i-2} = (-g+1+i-2k)(i+\alpha g-g-2k)(i-1)(i-2+\alpha g),$$
$$d\ \bar{d}_{i,i-1} = g(k+1-i)(-\alpha g^2 - 2\alpha gk + 2i\alpha g + \alpha g + 2g - 2ig - 2 + 4k - 4ik + 2i^2),$$
$$d\ \bar{d}_{i,i} = g^2(-k-1+i)(-k+i),$$

where $c = (2k+g-2)(2k+g)$ and $d = (2k-1+g)(2k+g-2)^2(2k+g-3)$. To obtain the full rank of S_k, the last row of S_k must be different from zero, i.e., the following elements must not vanish:

$$d_{k,k-2} = k(k-1)(k+\alpha g-1)(k+\alpha g-2),$$
$$d_{k,k-1} = -kg(2k+g-3)(k+\alpha g-1),$$
$$\bar{d}_{k+1,k-1} = (k+g-2)(k+g-\alpha g-1)k(k+\alpha g-1).$$

Hence $-\alpha g \neq 0, 1, 2, \ldots$. Since $\bar{d}_{i,i} \neq 0$, $i = 1, 2, \ldots, k-1$, we consider the submatrix

$$S_k^\star = \begin{bmatrix} \bar{d}_{k-1,k-1} & 0 & d_{k-2,k-2} \\ \bar{d}_{k,k-1} & d_{k-1,k-1} & d_{k-1,k-2} \\ \bar{d}_{k+1,k-1} & d_{k,k-1} & d_{k,k-2} \end{bmatrix},$$

the determinant of which is

$$\det S_k^\star = 2g^4 k(2k+g-2)(2k+g-4)(2k+g-3)^2(k+\alpha g-1).$$

For $-g, -\alpha g \neq 0, 1, 2, \ldots$, a definite system will be obtained independent of α; this was left open by [5].

It follows from the representation of D_k and $\bar{D}_k$ and formula (3) that the coefficient $m_{0,0}^{(k)}$ of the moment matrix M_k is given by

$$m_{0,0}^{(k)} = d_{0,0}^{(k)}\, m_{0,0}^{(k-1)}, \qquad k \in \mathbf{N},$$

where

$$d_{0,0}^{(k)} = \frac{-kg^2(g+k-2)}{(g+2k-3)(g+2k-2)^2(g+2k-1)}.$$

Since $M_0 = 1$, $m_{0,0}^{(k)} \neq 0$ for a given admissible g and for all $k \in \mathbf{N}_0$. Assume that the system is positive definite; then $m_{0,0}^{(k)} > 0$ for all $k \in \mathbf{N}_0$. An inductive argument implies that $g < -(2k-1)$ for all $k \in \mathbf{N}$, which is obviously impossible.

Nonvanishing elements of $M_{k-1}^{\star\star}$:

$$\begin{aligned} m\, m_{i,i-1}^{\star\star} &= -(i-1)(i-2+\alpha g)(2i-3+\alpha g), \qquad i = 2, 3, \ldots, k \\ m\, m_{i,i}^{\star\star} &= g(-2ik+2k-\alpha gk+3i^2-5i+2i\alpha g+2-\alpha g), \\ &\qquad i = 1, 2, \ldots, k, \\ m\, m_{i,i+1}^{\star\star} &= g^2(k-i), \qquad i = 1, 2, \ldots, k-1, \end{aligned}$$

where $m = (2k+g-2)(2k+g-3)$. No element in the superdiagonal vanishes, hence the matrix condition is satisfied. The system is definite and not positive definite if and only if $-g, -\alpha g \notin \mathbf{N}_0$; in this case also the rank condition (6) holds.

Equation (5.55). Differential equation:

$$(x+\alpha)\omega_{xx} + (2y+2)\omega_{xy} + x\omega_x + y\omega_y = k\omega.$$

Monomials:

$$\mathcal{L}(t_i^k) = kt_i^k + (k-i)(k+i-1)t_i^{k-1} + \alpha(k-i)(k-i-1)t_i^{k-2} + 2(k-i)it_{i-1}^{k-2}.$$

Nonvanishing coefficients $a_{i,j}^k$ and $b_{i,j}^k$:

$$a_{i,i}^k = (k-i)(k+i-1),\ b_{i,i-1}^k = (k-i)i,\ b_{i,i}^k = (k-i)(k-i-1)(\alpha+(k+i-1)(k+i-2))/2.$$

Nonvanishing coefficients in the recursion:

$$\begin{aligned} c_{i,i}^k &= -2k, \qquad \bar{c}_{i,i}^k = -(2k-2i+2), \\ d_{i,i-1} &= -i, \qquad d_{i,i} = (k-i)(k+i-1-\alpha), \\ \bar{d}_{i,i-1} &= -(k-i+1), \qquad \bar{d}_{i,i} = (k-i)(k-i+1). \end{aligned}$$

Thus we obtain

$$\begin{bmatrix} k(k-\alpha-1) & & & & & -k & k(k-1) & & & \\ -1 & \ddots & & & & & -(k-1) & \ddots & & \\ & -2 & \ddots & & & & & \ddots & \ddots & \\ & & \ddots & \ddots & & & & & \ddots & 2 \\ & & & \ddots & (2k-\alpha-2) & & & & & -1 \\ & & & & -k & & & & & 0 \end{bmatrix},$$

which is of rank $k+1$ for all α.

In [5] it is shown, and it can be easily verified by the induction formula (3), that the moment matrix M_k, $k \in \mathbf{N}_0$, has vanishing elements $m_{i,j}^{(k)}$ for $k < i+j$ and that the cross-diagonal elements are given by

$$m_{i,k-i}^{(k)} = (-1)^k i!(k-i)!, \qquad 0 \le i \le k.$$

Nonvanishing elements of $M_{k-1}^{\star\star}$:

$$m_{i,i}^{\star\star} = -k + 2i - 1, \; m_{i,i+1}^{\star\star} = -(k-i)(2i-2-\alpha).$$

Hence, the system is definite, not positive definite, for all α; the rank condition (6) is also satisfied.

Acknowledgment. The authors are indebted to Dr. C. Markett for acquainting us with the generalized hypergeometric function ${}_3F_2$ and for pointing out the representation (8) of the sum Σ, which led to the final factorization of A_k. We also thank the referee for his kind and thorough review.

CONVEX APPROXIMATION BY RATIONAL FUNCTIONS*

BO GAO†, DONALD J. NEWMAN†, AND V. A. POPOV‡

This paper is dedicated to Dick Askey and Frank Olver on the occasion of their birthdays.

Abstract. In this paper, the convex approximation to $|x|$ and to convex functions with continuous derivatives are investigated. In the first case, the approximation order $c_1 e^{-c_2\sqrt{n}}$ is achieved by using H^∞ quadrature. In the second case, the estimate $| f(x) - R_n(x) | \leq C\frac{1}{n^{2-\epsilon}}$ is proved, where ϵ is any positive real number.

Key words. convex approximation, rational functions

AMS subject classifications. 41A20, 41A25, 41A29

1. Introduction. The main result of this paper brings a convex approximation by rational functions to a function $f(x) \in \text{Conv}\,[a,\ b]\bigcap C^1[a,\ b]$. The idea for this work comes from a proof to Newman's conjecture (see [3]). Because of its nonlinearity, rational approximation is inherently more difficult than polynomial approximation. The restriction of "form fitting" makes convex rational approximation an even more difficult problem, and very few results are known.

Let R_n denote the set of all rational functions. We first construct a convex approximation to $|x|$ on $[-1, 1]$, and then we extend this result to the whole real line. Since $f(x)$ can be approximated by a polygon, we obtain

$$R_n^*(f) \leq C\,\frac{\|f'\|_{C[a,\,b]}}{n^{2-\epsilon}},$$

where $R_n^*(f)$ is defined by

$$R_n^*(f) = \inf_{\substack{r(x)\in R_n \\ r(x) \text{ is convex}}} \|f(x) - r(x)\|_{C[a,\,b]}.$$

2. Convex approximation to $|x|$ on $[-1, 1]$. The function $|x|$ plays a very important role in approximation theory. As a consequence, rational approximation to $|x|$ has been intensely studied in [2], [4], and [5]. Since the original construction of Newman [2] is in fact a comonotone approximation to $|x|$, it is natural to hope that the same or a modified construction can give a convex approximation to $|x|$. However, this is not the case, because any function that interpolates $|x|$ cannot be convex.

The existence of a convex approximation to $|x|$ comes from the fact that the function $x\arctan(Nx)$ can also give a good approximation to $|x|$ for large N. Although $\arctan(Nx)$ is not a rational function, its integral representation and the theory for super quadrature make it possible to construct a rational function which gives a convex approximation to $|x|$.

From the work of Andersson and Bojanov [1], we have the following theorem.

* Received by the editors June 19, 1992; accepted for publication (in revised form) October 19, 1993. This paper was originally submitted for the special issue dedicated to Frank Olver and Richard Askey (*SIAM J. Math. Anal.*, March 1994, Vol. 25, No. 2).

† Department of Mathematics, Temple University, Philadelphia, PA 19122.

‡ Department of Mathematics, Temple University, Philadelphia, PA 19122, until his death in 1991.

THEOREM A. *For $i = 1, 2, \ldots, n$, there exist $t_i \in [-1, 1]$ and $A_i \geq 0$ such that*

$$\sup_{\|f\|_{H^\infty(D)} \leq 1} \left| \int_{-1}^{1} f(t)dt - \sum_{i=1}^{n} A_i f(t_i) \right| \leq C n e^{-\pi n} \leq C' e^{-3\sqrt{n}},$$

where D is the unit disk and $H^\infty(D)$ is the space of all functions which are analytic and bounded in D.

Obviously this result can be reformulated by conformal mapping in the following way.

THEOREM A′. *There exist $t_i \in (0, 1)$ and $A_i \geq 0$, $i = 1, 2, \ldots, n$, such that*

$$\sup_{\|f\|_{H^\infty(\Omega)} \leq M} \left| \int_{0}^{1} f(t)dt - \sum_{i=1}^{n} A_i f(t_i) \right| \leq C M e^{-3\sqrt{n}},$$

where C is an absolute constant and $\Omega = \{z : |z - \frac{1}{2}| \leq \frac{1}{2}\}$.

Now consider the function $g_N(x) = (2/\pi)\, x \arctan(Nx)$. From elementary calculus it is easy to prove the next lemma.

LEMMA 1. *For $x \geq 0$ and $N > 0$, we have*

$$0 \leq x - g_N(x) = \frac{2x}{\pi} \int_{Nx}^{\infty} \frac{dt}{1 + t^2} \leq \frac{2}{\pi N}, \tag{1}$$

$$g_N(x) = \frac{2}{\pi} \int_{0}^{1} \frac{Nx^2}{1 + N^2 x^2 t^2}\, dt, \tag{2}$$

$$g_N'(x) = \frac{2}{\pi} \left(\arctan(Nx) + \frac{Nx}{1 + N^2 x^2} \right) = \frac{2}{\pi} \int_{0}^{1} \frac{2Nx}{(1 + N^2 x^2 t^2)^2}\, dt, \tag{3}$$

and

$$g_N''(x) = \frac{2}{\pi} \frac{2N}{(1 + N^2 x^2)^2} = \frac{2}{\pi} \int_{0}^{1} \frac{2N(1 - 3t^2 N^2 x^2)}{(1 + t^2 N^2 x^2)^3}\, dt \geq \frac{C_0}{N^3}. \tag{4}$$

Before using the quadrature formula to obtain our theorem, we need the following lemma.

LEMMA 2. *For $a \geq 0$ and $\Omega = \{z : |z - \frac{1}{2}| \leq \frac{1}{2}\}$ we have*

$$\left| \frac{1}{1 + z^2 a^2} \right| \leq 2 \max\{2, a\}.$$

Proof. Let $z = x + iy$. For $|z - \frac{1}{2}| = \frac{1}{2}$, we have

$$y^2 = x - x^2,$$

$$1 + z^2 a^2 = 1 + (2x^2 - x)a^2 + 2ixya^2,$$

and

$$\max_{z \in \Omega} \left| \frac{1}{1 + z^2 a^2} \right| = \frac{1}{\min_{z \in \Omega} |1 + z^2 a^2|},$$

but

$$\min_{z\in\Omega}|1+z^2a^2| = \min_{y^2=x-x^2}|1+(2x^2-x)a^2+2ixya^2|$$
$$\geq \frac{1}{2}\min_{y^2=x-x^2}|1+(2x^2-x)a^2+2x|y|a^2|$$
$$\geq \begin{cases} \frac{1}{4} & \text{if } 0\leq x\leq \frac{1}{2a^2} \quad (\text{since } 1-xa^2+2x^2a^2\geq \frac{1}{2}),\\ \frac{1}{2a} & \text{if } \frac{1}{2a^2}\leq x\leq \frac{1}{2} \quad (\text{since } |y|\geq \sqrt{\frac{1}{2a^2}}\sqrt{1-x}\geq \frac{1}{a}),\\ \frac{1}{2} & \text{if } \frac{1}{2}\leq x\leq 1 \quad (\text{since } 1-xa^2+2x^2a^2\geq 1). \end{cases}$$

From the last inequality, Lemma 2 follows.

Using Lemmas 1 and 2 and Theorem A′ we can prove the following theorem.

THEOREM 1. *There exist a constant C and a rational function $r(x)$ of degree n such that for $x\in[-1,1]$*

$$\text{(a)} \qquad ||x|-r(x)|\leq C\,e^{-\frac{\sqrt{n}}{3}}$$

and

$$\text{(b)} \qquad r''(x)\geq 0.$$

Proof. By applying Lemma 1 and Theorem A′ to (2)–(4), we obtain

$$\left\|\frac{Nx^2}{1+z^2N^2x^2}\right\|_{H^\infty(\Omega)} \leq 2\,N\,x^2\,\max(2,\,Nx)\leq C_1\,N^2,$$

$$\left\|\frac{2Nx}{(1+z^2N^2x^2)^2}\right\|_{H^\infty(\Omega)} \leq 2\,N\,x\,(2\,\max(2,\,Nx))^2\leq C_2\,N^3,$$

and

$$\left\|\frac{2N(1-3z^2N^2x^2)}{(1+z^2N^2x^2)^3}\right\|_{H^\infty(\Omega)} \leq (2N+6\,N^3\,x^2)\,(2\,\max(2,\,Nx))^3\leq C_3\,N^6.$$

These inequalities imply that

$$\text{(5)} \qquad \left|g_N(x)-\frac{2}{\pi}\sum_{i=1}^{n}A_i\,\frac{Nx^2}{1+t_i^2x^2N^2}\right|\leq C_4\,N^2\,e^{-3\sqrt{n}},$$

$$\left|g_N'(x)-\frac{2}{\pi}\sum_{i=1}^{n}A_i\,\frac{2Nx}{(1+t_i^2x^2N^2)^2}\right|\leq C_5\,N^3\,e^{-3\sqrt{n}},$$

and

$$\text{(6)} \qquad \left|g_N''(x)-\frac{2}{\pi}\sum_{i=1}^{n}A_i\,\frac{2N(1-3t_i^2N^2x^2)}{(1+t_i^2N^2x^2)^3}\right|\leq C_6\,N^6\,e^{-3\sqrt{n}},$$

respectively. Let

$$r(x)=\frac{2}{\pi}\sum_{i=1}^{n}A_i\,\frac{Nx^2}{1+t_i^2x^2N^2}.$$

By (5) and (1), we have

$$||x| - r(x)| \le ||x| - g_N(x)| + |g_N(x) - r(x)| \le \frac{2}{\pi N} + C_4 N^2 e^{-3\sqrt{n}}. \tag{7}$$

Pick

$$N = \frac{1}{2}\left(\frac{C_0}{C_6}\right)^{\frac{1}{9}} e^{\frac{\sqrt{n}}{3}}$$

in (7), so that for $x \ge 0$ we have

$$||x| - r(x)| \le \frac{1}{\pi}\left(\frac{C_6}{C_0}\right)^{\frac{1}{9}} e^{-\frac{\sqrt{n}}{3}} + \frac{C_4}{4}\left(\frac{C_0}{C_6}\right)^{\frac{2}{9}} e^{-\frac{7}{3}\sqrt{n}} \le C\, e^{-\frac{\sqrt{n}}{3}}.$$

From

$$\frac{C_6}{C_0} N^9 e^{-3\sqrt{n}} = \left(\frac{1}{2}\right)^9 < 1,$$

we find that

$$C_6 N^6 e^{-3\sqrt{n}} < \frac{C_0}{N^3}.$$

Then by (4) and (6) we see that for $x \ge 0$, $r''(x) > 0$. Since $r(x)$ and $r''(x)$ are even functions, and since we have shown the necessary results for $x \ge 0$, Theorem 1 is proven for $x \in [-1, 1]$.

3. Convex approximation to $f(x) \in \mathbf{Conv}\,[a, b] \bigcap C^1[a, b]$. Now, we consider the convex approximation to $f(x) \in \mathrm{Conv}\,[a, b] \bigcap C^1[a, b]$, the space of all convex functions with continuous derivative. This space was the first function space on which the rational approximation was shown to be better than the polynomial approximation. The main result we have obtained is the following theorem.

THEOREM 2. *For every $\epsilon > 0$, n large and $f(x) \in \mathrm{Conv}\,[a, b] \bigcap C^1[a, b]$, there exists a rational function $r(x)$ of degree n which is convex on the interval $[a, b]$ such that*

$$\|f(x) - r(x)\|_{C[a, b]} \le C \frac{\|f'\|_{C[a, b]}}{n^{2-\epsilon}},$$

where C is an absolute constant.

Before we give the proof of Theorem 2, we need the definition of the ski-slope function and some preliminary results.

DEFINITION 1. *The "ski-slope" function $k(x)$ on $x \in [0, \infty]$ is defined by*

$$k(x) = \begin{cases} 1 - x, & 0 \le x < 1, \\ 0, & x \ge 1. \end{cases}$$

We first prove that any convex polygonal function $g(x)$ on $[0, 1]$ can be written as a linear combination of $k(x)$.

LEMMA 3. *Given the interval $[0, 1]$ and a partition of the interval $0 = x_0 < x_1 < \cdots < x_N = 1$, let $g(x)$ be any convex polygonal function on $[0, 1]$ with vertices*

$x_0, \ldots, x_N$ such that $g(x)$ is a nonincreasing function and $g(1) = 0$. Then there exists a linear combination of $k(x)$, defined by

$$K(x) = \sum_{i=0}^{N-1} a_i\, k\left(\frac{x}{x_{i+1}}\right),$$

with

$$a_{N-1} = \frac{g(x_{N-1})}{1 - x_{N-1}}$$

and

$$a_i = \frac{g(x_i) - \displaystyle\sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right)}{1 - \dfrac{x_i}{x_{i+1}}}, \qquad i = N-2,\ \ldots,\ 1,\ 0$$

such that

$$K(x) = g(x) \quad \text{for } x \in [0, 1] \tag{8}$$

and

$$0 \le a_i \le 2\|g'\|_{L^\infty[0,1]}. \tag{9}$$

Proof. By the definition of $k(x)$, for $i = 0,\ 1,\ \ldots,\ N$, we have

$$k\left(\frac{x}{x_{i+1}}\right) = \begin{cases} 1 - \dfrac{x}{x_{i+1}}, & 0 \le x < x_{i+1}, \\ 0, & x \ge x_{i+1}. \end{cases}$$

Therefore, for $x \in [x_i,\ x_{i+1}]$, $i = 0,\ 1,\ \ldots,\ N-1$, we have

$$K(x) = \sum_{j=i}^{N-1} a_j\, k\left(\frac{x}{x_{j+1}}\right) \tag{10}$$

and

$$\begin{aligned} K(x_i) &= a_i\, k\left(\frac{x_i}{x_{i+1}}\right) + \sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right) \\ &= \frac{g(x_i) - \displaystyle\sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right)}{1 - \dfrac{x_i}{x_{i+1}}}\, k\left(\frac{x_i}{x_{i+1}}\right) + \sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right) \\ &= g(x_i) - \sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right) + \sum_{j=i+1}^{N-1} a_j\, k\left(\frac{x_i}{x_{j+1}}\right) = g(x_i). \end{aligned}$$

Obviously, $K(x_N) = K(1) = 0 = g(x_N)$. Thus we have proved that (8) holds for $x = x_i$, $i = 0,\ 1,\ \ldots,\ N$. Since $K(x)$ is also a polygonal function with the same

vertices as $g(x)$, we have $K(x) = g(x)$ for $x \in [0, 1]$. Now if we assume that c_i is the slope of $g(x)$ on the interval $[x_i, x_{i+1}]$, then $c_i - c_{i+1} \leq 0$ for $i = 0, \ldots, N-1$, and by (10), we have

$$\sum_{j=i}^{N-1} a_j \, k\left(\frac{x}{x_{j+1}}\right) = g(x) = c_i(x - x_i) + g(x_i) \quad x \in [x_i, x_{i+1}].$$

Since the left-hand side is just a straight line for $[0, x_{i+1}]$, then in fact we have

$$\sum_{j=i}^{N-1} a_j \, k\left(\frac{x}{x_{j+1}}\right) = c_i(x - x_i) + g(x_i) \quad x \in [0, x_{i+1}].$$

Therefore, we obtain for $i = 0, \ldots, N-2$,

$$\begin{aligned} a_i &= \frac{g(x_i) - \sum_{j=i+1}^{N-1} a_j \, k\left(\frac{x_i}{x_{j+1}}\right)}{1 - \frac{x_i}{x_{i+1}}} \\ &= \frac{g(x_i) - (c_{i+1}(x_i - x_{i+1}) + g(x_{i+1}))}{1 - \frac{x_i}{x_{i+1}}} \\ &= x_{i+1}\,(c_{i+1} - c_i) \geq 0. \end{aligned}$$

Finally, since $0 \leq x_{i+1} \leq 1$, for $i = 0, \ldots, N-2$, we have

$$0 \leq a_i \leq 2 \max |c_i| \leq 2\|g'\|_{L^\infty[0,1]}.$$

In addition, these inequalities hold for a_{N-1} by its definition and the mean value theorem. □

LEMMA 4. *For $f(x) \in \mathrm{Conv}[a, b] \cap C^1[a, b]$, there exists a partition of $[a, b]$, $a = x_0 < x_1 < \cdots < x_N = b$ such that the polygonal function $g(x)$, which has the x_i's as its vertices and interpolates $f(x)$ at the x_i's, satisfies*

$$\|f(x) - g(x)\|_{C[a,b]} \leq 2(b-a)\frac{\|f'\|_{C[a,b]}}{N^2}. \tag{11}$$

Proof. Without loss of generality, we can assume that $[a, b] = [0, 1]$. Let

$$F(x) = \frac{f(x) - f'(0)x}{|f'(1) - f'(0)|}.$$

Then we have that $F(x) \in \mathrm{Conv}[0,1] \cap C^1[0,1], F'(0) = 0, F'(x) \geq 0$, and $F'(1) = \|F'(x)\|_{C[0,1]} = 1$. Since $x + F'(x)$ is an increasing function on $[0, 1]$, the x_i's which satisfy $x_i + F'(x_i) = (2i/N)$ for $i = 0, 1, \ldots, N$ form a partition of [0,1]. Now let $g_1(x)$ be the polygonal function with the x_i's as its vertices, and let $g_1(x)$ interpolate $F(x)$ at the x_i's. For $x \in [x_{i-1}, x_i]$ we have

$$\begin{aligned} |F(x) - g_1(x)| &\leq (x_i - x_{i-1})\,[F'(x_i) - F'(x_{i-1})] \\ &\leq \frac{1}{4}\,[x_i - x_{i-1} + F'(x_i) - F'(x_{i-1})]^2 \\ &= \frac{1}{4}\left(\frac{2}{N}\right)^2 = \frac{1}{N^2}. \end{aligned}$$

Now let $g(x) = |f'(1)-f'(0)|\, g_1(x)+f'(0)x$ to have (11) hold for $[a, b] = [0, 1]$. Finally, for a general closed interval $[a, b]$, (11) holds by a linear transformation. □

COROLLARY 1. *If $N \geq 2$, $f(x) \in \mathrm{Conv}[0,1] \cap C^1[0,1]$, $f'(x) \leq 0$ and $f(1) = 0$, then there exists a partition of $[0,1]$, $0 = x_0 < x_1 < \cdots < x_N = 1$, and a function $K(x)$ as defined in Lemma 3 such that*

$$x_1 = \frac{1}{N^2} \tag{12}$$

and

$$\|f(x) - K(x)\|_{C[0,1]} \leq 6\frac{\|f'(x)\|_{C[0,1]}}{N^2}\,. \tag{13}$$

Proof. The partition of [0,1] is obtained by setting $x_1 = \frac{1}{N^2}$ and applying Lemma 4 to $f(x)$ on the interval $[x_1, 1]$ with N replaced by $N-1$. Let $g(x)$ be the resulting polygonal function with $g(0) = f(0)$. We then have

$$|f(x) - g(x)| \leq [x_1 - 0][f'(x_1) - f'(0)] \leq 2\frac{\|f'(x)\|_{C[0,1]}}{N^2} \quad \text{for } x \in [0, x_1]$$

and

$$|f(x) - g(x)| \leq 2\left(1 - \frac{1}{N^2}\right)\frac{\|f'(x)\|_{C[0,1]}}{(N-1)^2} \leq 6\frac{\|f'(x)\|_{C[0,1]}}{N^2} \quad \text{for } x \in [x_1, 1].$$

Corollary 1 then follows from Lemma 3. □

Now we extend the results of §2 into the whole real line.

LEMMA 5. *Let ν be a positive integer and let $\mu = e^{\sqrt{\nu}/3}$. Define the rational function*

$$r(x) = \frac{2}{\pi}\sum_{i=1}^{\nu} A_i \frac{\mu x^2}{1 + t_i^2 x^2 \mu^2},$$

where the A_i's and the t_i's are constants determined by Theorem 1. Then for $x \in [-1, 1]$,

$$\||x| - r(x)\| \leq \frac{C}{\mu}, \tag{14}$$

$$r'(x) = \frac{2}{\pi}\left(\arctan(\mu x) + \frac{\mu x}{1 + x^2\mu^2}\right) + O\left(\frac{1}{\mu^3}\right), \tag{15}$$

and

$$r''(x) = \frac{2}{\pi}\left(\frac{\mu}{(1 + x^2\mu^2)^2}\right) + O\left(\frac{1}{\mu^3}\right). \tag{16}$$

In addition, for $|x| \geq 1$ we have

$$|r(x)| \leq C\, x^2, \tag{17}$$

$$|r'(x)| \leq 2C\, |x|, \tag{18}$$

and

$$|r''(x)| \le 8C, \tag{19}$$

where C is a constant.

Proof. (14)–(16) are direct results of Theorem 1, and by the definition of $r(x)$, for $x \ge 1$, we have

$$|r'(x)| = \frac{2}{\pi}\sum_{i=1}^{\nu} A_i \frac{2\mu x}{(1+t_i^2\mu^2x^2)^2} \le \frac{2r(x)}{x}$$

and

$$|r''(x)| = \left|\frac{2}{\pi}\sum_{i=1}^{\nu} A_i \frac{2\mu(1-3t_i^2\mu^2x^2)}{(1+t_i^2\mu^2x^2)^3}\right| \le \frac{r'(x)}{x} + 3\frac{r'(x)}{x} = 4\frac{r'(x)}{x}.$$

Solving these two differential inequalities with the initial condition $r(1) = 1+O(e^{-\sqrt{\nu}/3})$, we find that (17)–(19) hold for $x \ge 1$. These results also hold for $x \le -1$ by the symmetric property of $r(x)$. □

From Lemma 5 we have the next theorem.

THEOREM 3. *Let ν be a positive integer and set $\mu = e^{\sqrt{\nu}/3}$. Define $r(x)$ to be the function in Lemma 5 and let $T(x) = \frac{1}{2}(|x-1| - 2|x| + |x+1|)$. Also define*

$$S(x) = \frac{3}{2}\left[r\left(\frac{x-1}{3}\right) - 2r\left(\frac{x}{3}\right) + r\left(\frac{x+1}{3}\right)\right], \tag{20}$$

$$\eta(x) = \left(1 + \left(\frac{x^2}{2}\right)^{\nu}\right)^{-1}, \tag{21}$$

$$\eta_1(x) = \mu^{\frac{3}{2}} \frac{x^2}{(\mu^2+x^2)^2}, \tag{22}$$

and

$$t(x) = S(x)\,\eta(x) + \eta_1(x).$$

For large ν we then have

$$3r\left(\frac{x}{3}\right) = |x| + O\left(\frac{1}{\mu}\right) \quad \text{for } x \in [-3,3], \tag{23}$$

$$|T(x) - S(x)| \le O\left(\frac{1}{\mu}\right) \quad \text{for } x \in [-2,2], \tag{24}$$

$$|T(x) - t(x)| \le \frac{C_1}{\mu} \quad \text{for } x \in (-\sqrt{\mu},\ \sqrt{\mu}), \tag{25}$$

$$t''(x) \ge 0 \quad \text{for } x \in \left[\tfrac{1}{2},\ \sqrt{\mu}\right], \tag{26}$$

and

$$\text{the degree of } t(x) \le 10\nu\,, \tag{27}$$

where C_1 is an absolute constant.

Proof. (23) is evident from Theorem 1. (24) and (27) can be seen easily after some simple calculations. To prove (25), we first obtain

$$\eta(x) = \begin{cases} 1 + O\left(\frac{1}{2^\nu}\right), & 0 \le |x| \le 1, \\ 1 + O(1), & 1 \le |x| \le 2, \\ O\left(\frac{1}{2^{\frac{\nu}{2}}}\right)\left(\frac{1}{(1+x^2)^2}\right), & |x| \ge 2, \end{cases} \tag{28}$$

and

$$|\eta_1(x)| \le O\left(\frac{1}{\mu^{\frac{3}{2}}}\right) \quad \text{for } x \in [-\sqrt{\mu}, \sqrt{\mu}], \tag{29}$$

from (21) and (22), respectively. Now by (23) and (24), for $0 \le |x| \le 1$,

$$\begin{aligned} |T(x) - t(x)| &\le |T(x) - S(x)\eta(x)| + \frac{1}{\mu^{\frac{3}{2}}} \\ &\le |T(x) - S(x)| + |S(x)| O\left(\frac{1}{2^\nu}\right) + \frac{1}{\mu^{\frac{3}{2}}} \\ &\le O\left(\frac{1}{\mu}\right) + O\left(\frac{1}{2^\nu}\right) + \left(\frac{1}{\mu^{\frac{3}{2}}}\right) = O\left(\frac{1}{\mu}\right). \end{aligned} \tag{30}$$

Note that for $|x| \ge 1$, $T(x) = 0$. Because of this fact and by (28), (29), and (24), for $1 \le |x| \le 2$, we have

$$\begin{aligned} |T(x) - t(x)| &\le |T(x) - S(x)\eta(x)| + \frac{1}{\mu^{\frac{3}{2}}} \\ &\le |T(x) - S(x)||\eta(x)| + \frac{1}{\mu^{\frac{3}{2}}} \\ &\le O\left(\frac{1}{\mu}\right) + \frac{1}{\mu^{\frac{3}{2}}} = O\left(\frac{1}{\mu}\right). \end{aligned} \tag{31}$$

For $2 \le |x| \le \sqrt{\mu}$, by (17), (28), and (29) together with $T(x) = 0$, we find

$$\begin{aligned} |T(x) - t(x)| &\le |S(x)\eta(x)| + \frac{1}{\mu^{\frac{3}{2}}} \\ &\le O\left(\frac{1}{2^\nu}\frac{x^2}{(1+x^2)^2}\right) + \frac{1}{\mu^{\frac{3}{2}}} \le O\left(\frac{1}{\mu}\right). \end{aligned} \tag{32}$$

Then, (25) follows directly from (30)–(32).

For (26), and from (21) and (22), we first compute

$$\eta'(x) = \frac{-\nu x\left(\frac{x^2}{2}\right)^{\nu-1}}{\left(1 + \left(\frac{x^2}{2}\right)^\nu\right)^2}, \tag{33}$$

$$\eta''(x) = \frac{\nu(2\nu+1)\left(\frac{x^2}{2}\right)^{\nu-1}\left(\left(\frac{x^2}{2}\right)^{\nu} - \frac{2\nu-1}{2\nu+1}\right)}{\left(1+\left(\frac{x^2}{2}\right)^{\nu}\right)^3}, \tag{34}$$

and for $x \in [-\sqrt{\mu}, \sqrt{\mu}]$,

$$\eta_1''(x) = \frac{\mu^{\frac{3}{2}}(3x^4 - 8x^2\mu^2 + \mu^4)}{(\mu^2+x^2)^4} \geq \frac{1}{\mu^{\frac{5}{2}}}. \tag{35}$$

Furthermore, let $x_0 = \sqrt{2}\left(\frac{2\nu-1}{2\nu+1}\right)^{1/(2\nu)}$ be the solution of $\eta''(x) = 0$. Then by (33) and (34), there exists $\delta \in (0, \frac{1}{3}]$ such that

$$\max(|\eta(x)|,\ |\eta'(x)|,\ |\eta''(x)|) \leq \frac{C_2\nu^2}{(1+\delta)^{\nu}(1+x^2)}, \quad x \in [x_0+\delta, \sqrt{\mu}], \tag{36}$$

$$\max(|\eta'(x)|,\ |\eta''(x)|) \leq \frac{C_2\nu^2}{(1+\delta)^{\nu}}, \quad x \in \left[\frac{1}{2}, x_0-\delta\right], \tag{37}$$

and

$$\max(|\eta'(x)|,\ |\eta''(x)|) \leq C_3\nu^2, \quad x \in [x_0-\delta,\ x_0+\delta]. \tag{38}$$

Now from (17)–(19), (35), and (36), together with

$$t''(x) = \eta_1''(x) + S''(x)\eta(x) + 2S'(x)\eta'(x) + S(x)\eta''(x) \tag{39}$$

and

$$\lim_{\nu\to\infty} \frac{\mu^k}{(1+\delta)^{\nu}} = 0 \qquad \text{for } k > 0\,, \tag{40}$$

we obtain

$$t''(x) \geq \frac{1}{\mu^{\frac{5}{2}}} - (64 + 16x + 8x^2)\frac{C\,C_2\,\nu^2}{(1+\delta)^{\nu}(1+x)^2} \geq 0$$

for $x_0 + \delta \leq x \leq \sqrt{\mu}$ and ν large.

For $x \in [\frac{1}{2},\ x_0+\delta]$, by the definition of $S(x)$ and (16), we have

$$\begin{aligned} S''(x) &= \frac{3}{2}\left[r''\left(\frac{x-1}{3}\right) - 2r''\left(\frac{x}{3}\right) + r''\left(\frac{x+1}{3}\right)\right], \\ &= \frac{3}{\pi}\left(\frac{\mu}{(1+(\frac{x-1}{3})^2\mu^2)^2} - 2\frac{\mu}{(1+(\frac{x}{3})^2\mu^2)^2} + \frac{\mu}{(1+(\frac{x+1}{3})^2\mu^2)^2}\right) + O\left(\frac{1}{\mu^3}\right) \\ &\geq -\frac{C_4}{\mu^3}, \qquad x \in \left[\frac{1}{2},\ x_0+\delta\right]. \end{aligned} \tag{41}$$

For $x \in [\frac{1}{2},\ x_0-\delta]$, from (14), (15), and the definition of $S(x)$, it is easy to obtain $|S(x)| \leq 12$ and $|S'(x)| \leq 6\max_{-1\leq x\leq 1}|r'(x)| \leq 12$; combining those facts, $0 \leq \eta(x) \leq 1$, (37), (39) and (41), we find that

$$t''(x) \geq \frac{1}{\mu^{\frac{5}{2}}} - \frac{C_4}{\mu^3}\eta(x) - \frac{12C_2\,\nu^2}{(1+\delta)^{\nu}} - \frac{12\,C_2\,\nu^2}{(1+\delta)^{\nu}} \geq 0, \quad x \in \left[\frac{1}{2},\ x_0-\delta\right]$$

holds for ν large.

Finally, for $x \in (x_0 - \delta, x_0 + \delta)$, from the definition of $S(x)$ and mean value theorem, we have

$$S(x) = \frac{3}{2} \cdot \frac{2}{9} r''(\xi_1), \quad \xi_1 \in \left(\frac{x_0 - \delta - 1}{3}, \frac{x_0 + \delta + 1}{3} \right).$$

By the fact that $\frac{x_0 - \delta - 1}{3} > 0$, $\frac{x_0 + \delta + 1}{3} < 1$, and (16), we obtain

$$|S(x)| \leq \frac{C_5}{\mu^3}, \qquad x \in [x_0 - \delta, x_0 + \delta]. \tag{42}$$

Similarly, if we replace $r'(x)$ in $S'(x)$ by (15) and from that

$$\left(\frac{2}{\pi} \left(\arctan(\mu x) + \frac{\mu x}{1 + x^2 \mu^2} \right) \right)'' = \frac{2}{\pi} \frac{-4x\mu^3}{(1 + x^2\mu^2)^3},$$

we have

$$S'(x) = \frac{2}{3\pi} \frac{-4\xi_2 \mu^3}{(1 + \xi_2^2 \mu^2)^3} + O\left(\frac{1}{\mu^3} \right), \quad \xi_2 \in \left(\frac{x_0 - \delta - 1}{3}, \frac{x_0 + \delta + 1}{3} \right)$$

and

$$|S'(x)| \leq \frac{C_6}{\mu^3}, \qquad x \in [x_0 - \delta, x_0 + \delta]. \tag{43}$$

From (41)–(43), (35), (38), and (39), we have that

$$t''(x) \geq \frac{1}{\mu^{\frac{5}{2}}} - \frac{C_4}{\mu^3} \eta(x) - \frac{C_5}{\mu^3} C_3 \nu^2 - \frac{C_6}{\mu^3} C_3 \nu^2 \geq 0, \qquad x \in [x_0 - \delta,\ x_0 + \delta]$$

holds for ν large. Therefore, we have shown that $t''(x) \geq 0$ for $x \in [\frac{1}{2}, \sqrt{\mu}]$. □

By Theorem 3 and the fact that $k(x) = 2T(\frac{x+1}{2})$ for $x \geq 0$, we have the following corollary.

COROLLARY 2. *For $x \in [0, \sqrt{\mu}]$, let*

$$\tilde{t}(x) = 2\, t\left(\frac{x+1}{2} \right) = 2 \left[S\left(\frac{x+1}{2} \right) \eta\left(\frac{x+1}{2} \right) + \eta_1\left(\frac{x+1}{2} \right) \right].$$

Then we have

$$\|k(x) - \tilde{t}(x)\| \leq \frac{C}{\mu} \tag{44}$$

and

$$\tilde{t}''(x) \geq 0\,. \tag{45}$$

We are now ready to demonstrate the proof of Theorem 2.

Proof. Without loss of generality, we set $[a, b] = [0, 1]$ and for $f(x) \in \text{Conv}\,[0, 1] \bigcap C^1[0, 1]$, we assume that $f'(x) \leq 0$, $\|f'\|_{C[0,1]} = 1$, and $f(1) = 0$. By Corollary 1, there exist x_i and $a_i, i = 0, 1, \ldots, N-1$ such that

$$\|f(x) - \sum_{i=0}^{N-1} a_i k\left(\frac{x}{x_{i+1}} \right) \|_{C[0,1]} \leq \frac{6}{N^2}.$$

If we set

$$R(x) = \sum_{i=0}^{N-1} a_i \tilde{t}\left(\frac{x}{x_{i+1}}\right)$$

by (12), we have $(x/x_i) \leq N^2$ for $x \in [0, 1]$. If $N^2 \leq \sqrt{\mu}$, from (44), (45), and $a_i \geq 0$, we obtain

$$R''(x) \geq 0 \qquad \text{for } x \in [0, 1],$$

and

$$\begin{aligned} |f(x) - R(x)| &\leq \left| f(x) - \sum_{i=0}^{N-1} a_i\, k\left(\frac{x}{x_{i+1}}\right)\right| \\ &\quad + \left|\sum_{i=0}^{N-1} a_i\, k\left(\frac{x}{x_{i+1}}\right) - \sum_{i=0}^{N-1} a_i\, \tilde{t}\left(\frac{x}{x_{i+1}}\right)\right| \\ &\leq \frac{6}{N^2} + N\frac{C}{\mu}\,. \end{aligned} \tag{46}$$

Now given $\epsilon > 0$, let $N = n^{1-\epsilon}$ and $\nu = n^{\epsilon}$. For large n we have $N^2 \leq \sqrt{\mu}$ and $N^3 \ll \mu$. By (46), and because the degree of $R(x)$ is $10n$, we finally get Theorem 2.

SPLINE WAVELETS OF SMALL SUPPORT*

DEBAO CHEN†

Abstract. Every mth order cardinal spline wavelet is a linear combination of the functions $\{N_{m+l}^{(l)}(2x-j), j \in \mathbf{Z}\}$. Here the function N_m is the mth order cardinal B-spline. This paper proves that the single function $N_{m+l}^{(l)}(2x)$, or $N_{m+l}^{(l)}(2x-1)$ is a wavelet when m and l satisfy some mild conditions. As l decreases, so does the support of the wavelet. When l increases,the smoothness of the dual wavelet improves. Each wavelet is constructed by spline multiresolution analysis. The dual multiresolution analyses are given.

1. Introduction.

The simplest example of an orthonormal spline wavelet basis is the Haar basis. The orthonormal spline wavelet bases of higher-order spline wavelets were given by Battle [2] and Lemarié [20] by using different methods. Cohen, Daubechies, and Feauveau constructed biorthogonal wavelet bases of compactly supported wavelets [11], [13]. The most important advantage of Cohen, Daubechies, and Feauveau's construction is that both wavelet and dual wavelet are compactly supported, and are still symmetric or antisymmetric. In particular, they constructed compactly supported spline wavelets with compactly supported dual wavelets. As they pointed out, their theory also can be used to construct noncompactly supported wavelets. Their contributions have been very significant. Chui and Wang [8], [9] introduced the following mth order compactly supported cardinal spline wavelet:

$$\psi_m(x) = \frac{1}{2^{m-1}} \sum_{j=0}^{2m-2} (-1)^j N_{2m}(j+1) N_{2m}^{(m)}(2x-j).$$

Here the cardinal B-splines N_m are defined recursively by the equations

$$N_1(x) = \chi_{[0,1)}(x),$$

$$N_m(x) = (N_{m-1} * N_1)(x) = \int_0^1 N_{m-1}(x-t)\,dt, \qquad m = 2, 3, \ldots .$$

This cardinal spline wavelet has been studied by several other authors as well. (See, for example, Auscher [1], Micchelli [24], and Unser and Aldroubi [27].) The advantage of the cardinal spline wavelet is that the wavelet spaces are kept orthogonal and the wavelets are still symmetric or antisymmetric. The dual wavelet is still an mth-order spline function. In a previous paper [3], we extended Chui and Wang's work and proved that the functions

$$\psi_{m,l;c}(x) = \frac{1}{2^{l-1}} \sum_{j=-1}^{m+l-1} (-1)^j N_{m+l}(j+1+c) N_{m+l}^{(l)}(2x-j), \qquad -1 < c < 1$$

* Received by the editors March 10, 1993; accepted for publication (in revised form) October 14, 1993.

† Department of Mathematics, Oklahoma State University, Stillwater, Oklahoma 74078.

are also mth-order compactly supported spline wavelets; here $m+l$ is even and $l \geq 1$ (if $l = 1$, we assume $-2/3 \leq c \leq 2/3$). When $c = 0$, the wavelet $\psi_{m,l;0} = \psi_{m,l}$ is symmetric or antisymmetric. The dual wavelet $\widetilde{\psi}_{m,l;0} = \widetilde{\psi}_{m,l}$ is an lth-order spline function.

In fact, every mth-order cardinal spline wavelet can be written as

$$\psi_{a,m,l}(x) = \frac{1}{2^{l-1}} \sum_j a_j N_{m+l}^{(l)}(2x - j),$$

where $a = \{a_j\}$ is a real sequence that is either finite or infinite.

We ask the following question: Is the single function $N_{m+l}^{(l)}(2x - j)$ a wavelet? In this paper we prove that it is a wavelet when m and l satisfy some mild conditions. Some proofs in this paper are borrowed from Cohen, Daubechies, and Feauveau [10], [11], [13] and Chui and Wang [7], [8], [9].

Using the derivative of certain functions to construct wavelets is a typical method in the construction of wavelet frames and dyadic wavelet transforms [16], [22]. In this paper, we show that this method is also a source of wavelet bases.

First we define the term "wavelet." For a given function f, we will use throughout this paper the notation

$$f_{j,k}(x) = 2^{j/2} f(2^j x - k), \qquad j, k \in \mathbf{Z}.$$

DEFINITION 1. *An element ψ of $L^2(\mathbf{R})$ is called a "wavelet" if*

(1) *$\{\psi_{j,k}\}_{j,k\in\mathbf{Z}}$ is a Riesz basis for $L^2(\mathbf{R})$, and*

(2) *its dual basis is of the form $\{\widetilde{\psi}_{j,k}\}_{j,k\in\mathbf{Z}}$ for some function $\widetilde{\psi}$ in $L^2(\mathbf{R})$.*

We also call $\widetilde{\psi}$ the dual wavelet of ψ. Sometimes we call ψ and $\widetilde{\psi}$ dual wavelets.

Following Mallat [21] and Meyer [23] we define the multiresolution analysis.

DEFINITION 2. *A multiresolution analysis (MRA) of $L^2(\mathbf{R})$ is a sequence $\{V_j\}_{j\in\mathbf{Z}}$ of closed subspaces of $L^2(\mathbf{R})$ such that the following hold:*

(1) *$V_j \subset V_{j+1}$ for all $j \in \mathbf{Z}$;*

(2) *$\cup_{j=-\infty}^{\infty} V_j$ is dense in $L^2(\mathbf{R})$ and $\cap_{j=-\infty}^{\infty} V_j = \{0\}$;*

(3) *$f(x) \in V_j \iff f(2x) \in V_{j+1}$ for all $j \in \mathbf{Z}$;*

(4) *$f(x) \in V_0 \iff f(x-k) \in V_0$ for all $k \in \mathbf{Z}$;*

(5) *there exists a function $\phi \in V_0$ such that $\{\phi(x-k) : k \in \mathbf{Z}\}$ is a Riesz basis of V_0.*

It is well known [4], [17], [21], [23] that the B-spline N_m can serve as the scaling function ϕ in Definition 2 and generates the mth-order spline MRA $\{V_j^m\}_{j\in\mathbf{Z}}$.

Throughout this paper we use the following convention for the Fourier transform:

$$\widehat{f}(\omega) = \int_{-\infty}^{\infty} f(t) e^{-\omega t i}\, dt. \tag{1.1}$$

The Fourier transform of the scaling function N_m is

$$\widehat{N}_m(\omega) = \left(\frac{1 - e^{-\omega i}}{i\omega}\right)^m. \tag{1.2}$$

Hence, we have

$$\widehat{N}_m(\omega) = P_m(e^{-\frac{\omega}{2}i}) \widehat{N}_m\left(\frac{\omega}{2}\right) = \prod_{k=1}^{\infty} P_m(e^{-2^{-k}\omega i}), \tag{1.3}$$

where

$$P_m(z) = \left(\frac{1+z}{2}\right)^m.$$

2. Preliminaries. Let m_0, $\widetilde{m}_0$, m_1, and $\widetilde{m}_1$ be 2π-periodic functions that satisfy

$$m_0(0) = \widetilde{m}_0(0) = 1, \qquad m_0(\pi) = \widetilde{m}_0(\pi) = 0, \tag{2.1}$$

$$\Delta(\omega) = m_0(\omega)m_1(\omega+\pi) - m_1(\omega)m_0(\omega+\pi) \neq 0, \tag{2.2}$$

and

$$\widetilde{m}_0(\omega) = \overline{m_1(\omega+\pi)}/\overline{\Delta(\omega)}, \qquad \widetilde{m}_1(\omega) = -\overline{m_0(\omega+\pi)}/\overline{\Delta(\omega)}. \tag{2.3}$$

These assumptions lead to

$$m_0(\omega)\overline{\widetilde{m}_0(\omega)} + m_1(\omega)\overline{\widetilde{m}_1(\omega)} = 1, \tag{2.4}$$

$$m_0(\omega)\overline{\widetilde{m}_0(\omega+\pi)} + m_1(\omega)\overline{\widetilde{m}_1(\omega+\pi)} = 0, \tag{2.5}$$

$$m_0(\omega)\overline{\widetilde{m}_0(\omega)} + m_0(\omega+\pi)\overline{\widetilde{m}_0(\omega+\pi)} = 1. \tag{2.6}$$

Also, we suppose that the Fourier coefficients of m_0 and $\widetilde{m}_0$ have exponential decay, or at least belong to l^1. We define, first in the sense of tempered distributions, the scaling functions and wavelets by

$$\begin{aligned}
\widehat{\phi}(\omega) &= \prod_{k=1}^{\infty} m_0(2^{-k}\omega), \\
\widehat{\psi}(\omega) &= m_1\left(\frac{\omega}{2}\right)\widehat{\phi}\left(\frac{\omega}{2}\right), \\
\widehat{\widetilde{\phi}}(\omega) &= \prod_{k=1}^{\infty} \widetilde{m}_0(2^{-k}\omega), \\
\widehat{\widetilde{\psi}}(\omega) &= \widetilde{m}_1\left(\frac{\omega}{2}\right)\widehat{\widetilde{\phi}}\left(\frac{\omega}{2}\right).
\end{aligned}$$

Since we have assumed that m_0 and $\widetilde{m}_0$ vanish at $\omega = \pi$, we can express these filters in a factored form

$$\begin{aligned}
m_0(\omega) &= \left(\frac{1+e^{-i\omega}}{2}\right)^L p(\omega), \\
\widetilde{m}_0(\omega) &= \left(\frac{1+e^{-i\omega}}{2}\right)^{\widetilde{L}} \widetilde{p}(\omega).
\end{aligned}$$

The following theorem was proved in [11] and [13]. The authors of [11] and [13] mainly consider the case in which there are finitely many terms in the Fourier series of m_0, $\widetilde{m}_0$, m_1, and $\widetilde{m}_1$. But as the authors pointed out, the following theorem is still true if there are infinitely many terms, having sufficiently decay.

THEOREM 1. *Suppose that* $[-\pi,\pi] = D_1 \cup D_2 \cup \cdots \cup D_j = \widetilde{D}_1 \cup \widetilde{D}_2 \cup \cdots \cup \widetilde{D}_k$,

and that there exist $q > 0$, $\widetilde{q} > 0$ *so that*

$$\begin{aligned} |p(\omega)| &\le q, \quad \omega \in D_1, & |\widetilde{p}(\omega)| &\le \widetilde{q}, \quad \omega \in \widetilde{D}_1, \\ |p(\omega)p(2\omega)| &\le q^2, \quad \omega \in D_2, & |\widetilde{p}(\omega)\widetilde{p}(2\omega)| &\le \widetilde{q}^2, \quad \omega \in \widetilde{D}_2, \\ &\vdots \qquad \vdots & &\vdots \qquad \vdots \\ |p(\omega)p(2\omega)\cdots p(2^{j-1}\omega)| &\le q^j, \quad \omega \in D_j, & |\widetilde{p}(\omega)\widetilde{p}(2\omega)\cdots\widetilde{p}(2^{k-1}\omega)| &\le \widetilde{q}^k, \quad \omega \in \widetilde{D}_k. \end{aligned}$$

Then

$$|\widehat{\phi}(\omega)| \le C(1+|\omega|)^{-L+K}, \qquad |\widehat{\widetilde{\phi}}(\omega)| \le C(1+|\omega|)^{-\widetilde{L}+\widetilde{K}}$$

with $K = \log_2 q$ *and* $\widetilde{K} = \log_2 \widetilde{q}$. *If* $L - K > 1/2$ *and* $\widetilde{L} - \widetilde{K} > 1/2$, *then the functions* $\widehat{\phi}$, $\widehat{\widetilde{\phi}}$, $\widehat{\psi}$, *and* $\widehat{\widetilde{\psi}}$ *are square integrable so that we can define the functions* ϕ, $\widetilde{\phi}$, ψ, *and* $\widetilde{\psi}$ *via inverse Fourier transforms. Furthermore we have the following items:*

1. *The functions* ϕ *and* $\widetilde{\phi}$ *are dual scaling functions, and they generate dual MRAs.*

2. *The functions* ψ *and* $\widetilde{\psi}$ *are dual wavelets in the sense of Definition* 1.

3. *If* $L - K > 1$, $\widetilde{L} - \widetilde{K} > 1$, *and* K *and* $\widetilde{K}$ *are not integers, then* ϕ, $\psi \in C^{L-K-1}$, *and* $\widetilde{\phi}$, $\widetilde{\psi} \in C^{\widetilde{L}-\widetilde{K}-1}$.

Let us consider any l^1 sequences $\{p_k\}$, $\{q_k\}$ and their associated Laurent series

$$P(z) = \frac{1}{2}\sum_{k=-\infty}^{\infty} p_k z^k, \qquad Q(z) = \frac{1}{2}\sum_{k=-\infty}^{\infty} q_k z^k,$$

which satisfy $P(1) = 1$, $P(-1) = Q(1) = 0$. Following Chui [4] we consider the determinant

$$\Delta_{P,Q}(z) = \begin{vmatrix} P(z) & Q(z) \\ P(-z) & Q(-z) \end{vmatrix}.$$

If $\Delta_{P,Q}(z) \neq 0$ on $|z| = 1$, we define

$$\begin{aligned} G(z) &= \frac{Q(-z)}{\Delta_{P,Q}(z)} = \frac{1}{2}\sum_{n=-\infty}^{\infty} g_n z^n, \\ H(z) &= \frac{-P(-z)}{\Delta_{P,Q}(z)} = \frac{1}{2}\sum_{n=-\infty}^{\infty} h_n z^n. \end{aligned} \tag{2.7}$$

If we let

$$m_0(\omega) = P(e^{-\omega i}), \quad \widetilde{m}_0(\omega) = \overline{G(e^{-\omega i})}, \quad m_1(\omega) = Q(e^{-\omega i}), \quad \widetilde{m}_1(\omega) = \overline{H(e^{-\omega i})}$$

then the conditions (2.1)–(2.3) are satisfied.

3. Main results. In this section, we construct a special kind of biorthogonal wavelet basis. Our wavelets are the B-spline's derivatives of certain orders which are dilated and, in some cases, translated. One advantage of our wavelets is that the wavelets are quite simple and have relatively small supports. We define

$$\xi_{m,l}(x) = \begin{cases} 2^{1-l}N_{m+l}^{(l)}(2x) & \text{if } m+l \text{ is odd, or } (m+l)/2 \text{ is odd,} \\ 2^{1-l}N_{m+l}^{(l)}(2x-1) & \text{if } (m+l)/2 \text{ is even.} \end{cases} \tag{3.1}$$

LEMMA 1. *Let* $z = e^{-\frac{1}{2}\omega i}$. *Then*

$$\widehat{\xi}_{m,l}(\omega) = Q_{m,l}(z)\widehat{N}_m\left(\frac{\omega}{2}\right),$$

where

$$Q_{m,l}(z) = \begin{cases} 2^{-l}(1-z)^l & \text{if } m+l \text{ is odd or } (m+l)/2 \text{ is odd,} \\ 2^{-l}z(1-z)^l & \text{if } (m+l)/2 \text{ is even.} \end{cases} \tag{3.2}$$

Proof. We prove only the first case. For the second case, the proof is similar. Recall that

$$N_{m+l}^{(l)}(x) = \sum_{k=0}^{l}(-1)^k\binom{l}{k}N_m(x-k).$$

When $m+l$ is odd or $(m+l)/2$ is odd, we have

$$\xi_{m,l}(x) = 2^{1-l}\sum_{k=0}^{l}(-1)^k\binom{l}{k}N_m(2x-k).$$

Hence,

$$\widehat{\xi}_{m,l}(\omega) = 2^{-l}\sum_{k=0}^{l}(-1)^k\binom{l}{k}z^k\widehat{N}_m\left(\frac{\omega}{2}\right) = 2^{-l}(1-z)^l\widehat{N}_m\left(\frac{\omega}{2}\right). \qquad \square$$

When $m+l$ is odd or $(m+l)/2$ is odd, we have

$$\Delta_{P_m,Q_{m,l}}(z) = \begin{vmatrix} 2^{-m}(1+z)^m & 2^{-l}(1-z)^l \\ 2^{-m}(1-z)^m & 2^{-l}(1+z)^l \end{vmatrix} = 2^{-(m+l)}\big((1+z)^{m+l} - (1-z)^{m+l}\big).$$

When $(m+l)/2$ is even, we have

$$\Delta_{P_m,Q_{m,l}}(z) = \begin{vmatrix} 2^{-m}(1+z)^m & 2^{-l}z(1-z)^l \\ 2^{-m}(1-z)^m & -2^{-l}z(1+z)^l \end{vmatrix} = -2^{-(m+l)}z\big((1+z)^{m+l} + (1-z)^{m+l}\big).$$

Let $z = e^{-\omega i}$. When $m+l$ is even, whether $(m+l)/2$ is even or odd, we have

$$|\Delta_{P_m,Q_{m,l}}(z)| = \cos^{m+l}\frac{\omega}{2} + \sin^{m+l}\frac{\omega}{2} \neq 0.$$

When $m+l$ is odd, we have

$$\begin{aligned}\Delta_{P_m,Q_{m,l}}(z) &= \left(\frac{1+e^{-\omega i}}{2}\right)^{m+l} - \left(\frac{1-e^{-\omega i}}{2}\right)^{m+l} \\ &= e^{-(m+l)\omega i/2}\left(\cos^{m+l}\frac{\omega}{2} - (-1)^{(m+l-1)/2}i\sin^{m+l}\frac{\omega}{2}\right).\end{aligned}$$

Hence

$$|\Delta_{P_m,Q_{m,l}}(z)| = \left(\cos^{2(m+l)}\frac{\omega}{2} + \sin^{2(m+l)}\frac{\omega}{2}\right)^{1/2} \neq 0.$$

Therefore, we can define the following functions on the unit circle.

$$
\begin{aligned}
G_{m,l}(z) &= \frac{Q_{m,l}(-z)}{\Delta_{P_m,Q_{m,l}}(z)} = \begin{cases} \dfrac{2^m(1+z)^l}{(1+z)^{m+l}-(1-z)^{m+l}}, \\ \quad \text{when } m+l \text{ is odd, or } (m+l)/2 \text{ is odd}, \\ \dfrac{2^m(1+z)^l}{(1+z)^{m+l}+(1-z)^{m+l}}, \\ \quad \text{when } (m+l)/2 \text{ is even}, \end{cases} \\
H_{m,l}(z) &= \frac{-P_m(-z)}{\Delta_{P_m,Q_{m,l}}(z)} = \begin{cases} \dfrac{-2^l(1-z)^m}{(1+z)^{m+l}-(1-z)^{m+l}}, \\ \quad \text{when } m+l \text{ is odd, or } (m+l)/2 \text{ is odd}, \\ \dfrac{2^l z^{-1}(1-z)^m}{(1+z)^{m+l}+(1-z)^{m+l}}, \\ \quad \text{when } (m+l)/2 \text{ is even}. \end{cases}
\end{aligned} \tag{3.3}
$$

We define the following functions.

$$
\widehat{\widetilde{N}}_{m,l}(\omega) = \prod_{k=1}^{\infty} \overline{G_{m,l}(e^{-2^{-k}\omega i})}, \tag{3.4}
$$

$$
\widehat{\widetilde{\xi}}_{m,l}(\omega) = \overline{H_{m,l}(e^{-\frac{\omega i}{2}})}\widehat{\widetilde{N}}_{m,l}\left(\frac{\omega}{2}\right). \tag{3.5}
$$

By (3.3), we know that

$$
\overline{G_{m,l}(e^{-\omega i})} = \left(\frac{1+e^{-\omega i}}{2}\right)^l \widetilde{p}_{m,l}(\omega),
$$

where

$$
\widetilde{p}_{m,l}(\omega) = \begin{cases} \dfrac{2^{m+l}e^{-m\omega i}}{(1+e^{-\omega i})^{m+l}-(1-e^{-\omega i})^{m+l}}, & \text{when } (m+l)/2 \text{ is odd}, \\ \dfrac{2^{m+l}e^{-m\omega i}}{(1+e^{-\omega i})^{m+l}+(1-e^{-\omega i})^{m+l}}, & \text{when } m+l \text{ is odd, or } (m+l)/2 \text{ is even}. \end{cases} \tag{3.6}
$$

By (1.3) we know that the function $\widehat{N}_m$ satisfies the conditions in Theorem 1 with $q = 1$. We need to prove that the function $\widehat{\widetilde{N}}_{m,l}$ satisfies the conditions in Theorem 1 so that we can obtain the dual scaling function $\widetilde{N}_{m,l}$ and dual wavelet $\widetilde{\xi}_{m,l}$ via inverse Fourier transforms. We see that

$$
|\widetilde{p}_{m,l}(\omega)| = \begin{cases} \dfrac{1}{\sin^{m+l}(\omega/2)+\cos^{m+l}(\omega/2)}, & \text{when } m+l \text{ is even}, \\ \dfrac{1}{\left(\sin^{2(m+l)}(\omega/2)+\cos^{2(m+l)}(\omega/2)\right)^{1/2}}, & \text{when } m+l \text{ is odd}. \end{cases} \tag{3.7}
$$

THEOREM 2. *Let $\widetilde{p}_{m,l}$ be defined as in* (3.6). *If* $2 \le m+l \le 6$ *or* $m+l = 8, 10$,

then we have

$$|\widetilde{p}_{m,l}(\omega)| \le \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right|, \qquad 0 \le |\omega| \le \frac{\pi}{3}, \quad \frac{2\pi}{3} \le |\omega| \le \pi,$$

$$|\widetilde{p}_{m,l}(\omega)\widetilde{p}_{m,l}(2\omega)| \le \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right|^2, \qquad \frac{\pi}{3} \le |\omega| \le \frac{2\pi}{3}.$$

If $m+l = 7, 9$, *or* $m+l \ge 11$, *then we have* $[-\frac{2\pi}{3}, -\frac{\pi}{3}] \cup [\frac{\pi}{3}, \frac{2\pi}{3}] = D_1 \cup D_2$ *such that*

$$|\widetilde{p}_{m,l}(\omega)| \le \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right|, \qquad 0 \le |\omega| \le \frac{\pi}{3}, \quad \frac{2\pi}{3} \le |\omega| \le \pi,$$

$$|\widetilde{p}_{m,l}(\omega)\widetilde{p}_{m,l}(2\omega)| \le \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right|^2, \qquad \omega \in D_1,$$

$$|\widetilde{p}_{m,l}(\omega)\widetilde{p}_{m,l}(2\omega)\widetilde{p}_{m,l}(4\omega)| \le \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right|^3, \qquad \omega \in D_2.$$

We postpone the proof of Theorem 2 to the next section. It is easy to see that

$$\left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right| = \begin{cases} \dfrac{2^{m+l}}{1+3^{(m+l)/2}} & \text{if } m+l \text{ is even,} \\ \dfrac{2^{m+l}}{\sqrt{1+3^{m+l}}} & \text{if } m+l \text{ is odd.} \end{cases} \tag{3.8}$$

Let

$$\alpha_{m,l} = l - \log_2 \left|\widetilde{p}_{m,l}\left(\frac{2\pi}{3}\right)\right| = \begin{cases} \log_2(1+3^{(m+l)/2}) - m & \text{if } m+l \text{ is even,} \\ \frac{1}{2}\log_2(1+3^{m+l}) - m & \text{if } m+l \text{ is odd.} \end{cases}$$

By Theorem 1 and Theorem 2 we have the next theorem.

THEOREM 3. *If* $\alpha_{m,l} > 1/2$, *then the functions* N_m *and* $\widetilde{N}_{m,l}$ *are dual scaling functions which generate the dual MRAs* $\{V_j^m\}$ *and* $\{\widetilde{V}_j^{m,l}\}$, *respectively. The functions* $\xi_{m,l}$ *and* $\widetilde{\xi}_{m,l}$ *are dual wavelets in the sense of Definition* 1. *In addition, if* $\alpha_{m,l} > 1$, *then the dual scaling function* $\widetilde{N}_{m,l}$ *and the dual wavelet* $\widetilde{\xi}_{m,l}$ *are in* $C^{\alpha_{m,l}-1}$.

Theorem 3 is mainly based on Theorem 1 and Theorem 2. It has been pointed out in [11] and [13] that the conditions in Theorem 1 are not strictly necessary to ensure that $\widehat{\phi}$ is in $L^2(\mathbf{R})$. But we can prove a weaker inverse theorem on the square integrability of the function $\widehat{\phi}$.

THEOREM 4. *Let*

$$m_0(\omega) = \left(\frac{1+e^{-i\omega}}{2}\right)^L p(\omega), \qquad \widehat{\phi}(\omega) = \prod_{k=1}^{\infty} m_0(2^{-k}\omega).$$

Suppose that p *is continuous and*

$$|p(\omega)| = f\left(\sin^2\frac{\omega}{2}\right), \quad |p(\omega)| \ge 1, \quad \left|p\left(\frac{2\pi}{3}\right)\right| = 2^M, \quad M > L.$$

Then the function $\widehat{\phi}$ *is not in* $L^2(\mathbf{R})$.

Proof. Since p is continuous, we can choose ϵ between 0 and $M-L$ such that for some $\delta > 0$,

$$|p(\omega)| > 2^{L+\epsilon}, \qquad \omega \in \left[\frac{2\pi}{3} - \delta, \frac{2\pi}{3} + \delta\right].$$

For any nonnegative integer j we have

$$\begin{aligned}\sin\left(\frac{2\pi}{3}\cdot 2^j+\omega\right) &= \sin\left(\frac{2\pi}{3}\cdot 2^j\right)\cos\omega+\cos\left(\frac{2\pi}{3}\cdot 2^j\right)\sin\omega\\ &= (-1)^j\sin\frac{2\pi}{3}\cos\omega+\cos\frac{2\pi}{3}\sin\omega\\ &= (-1)^j\sin\left(\frac{2\pi}{3}+(-1)^j\omega\right).\end{aligned}$$

Hence,

$$|p(\omega)|>2^{L+\epsilon},\qquad \omega\in\left[\frac{2\pi}{3}\cdot 2^j-\delta,\frac{2\pi}{3}\cdot 2^j+\delta\right].$$

If $\omega\in[\frac{2\pi}{3}\cdot 2^n-\delta,\frac{2\pi}{3}\cdot 2^n+\delta]$, then $2^{-k}\omega\in[\frac{2\pi}{3}\cdot 2^{n-k}-2^{-k}\delta,\frac{2\pi}{3}\cdot 2^{n-k}+2^{-k}\delta]$, $k=1,2,\dots,n$. Consequently, we have

$$\begin{aligned}\int_{\frac{2\pi}{3}\cdot 2^n-\delta}^{\frac{2\pi}{3}\cdot 2^n+\delta}|\widehat{\phi}(\omega)|^2\,d\omega &= \int_{\frac{2\pi}{3}\cdot 2^n-\delta}^{\frac{2\pi}{3}\cdot 2^n+\delta}\left|\frac{\sin(\omega/2)}{\omega/2}\right|^{2L}\prod_{k=1}^{\infty}|p(2^{-k}\omega)|^2\,d\omega\\ &\geq \int_{\frac{2\pi}{3}\cdot 2^n-\delta}^{\frac{2\pi}{3}\cdot 2^n+\delta}\left|\frac{\sin(\omega/2)}{\omega/2}\right|^{2L}\prod_{k=1}^{n}|p(2^{-k}\omega)|^2\,d\omega\\ &\geq C_1\int_{\frac{2\pi}{3}\cdot 2^n-\delta}^{\frac{2\pi}{3}\cdot 2^n+\delta}\left(\frac{1}{\frac{2\pi}{3}\cdot 2^n+\delta}\right)^{2L}(2^{L+\epsilon})^{2n}\,d\omega\\ &= 2C_1\delta\left(\frac{2^n}{\frac{2\pi}{3}\cdot 2^n+\delta}\right)^{2L}\cdot 2^{2n\epsilon}>C_2,\end{aligned}$$

where C_1 and C_2 are positive constants that do not depend on n. The last inequality is true for sufficiently large n. Hence,

$$\int_{-\infty}^{\infty}|\widehat{\phi}(\omega)|^2\,d\omega\geq\sum_{n=1}^{\infty}\int_{\frac{2\pi}{3}\cdot 2^n-\delta}^{\frac{2\pi}{3}\cdot 2^n+\delta}|\widehat{\phi}(\omega)|^2\,d\omega=+\infty.$$

Since the function $\widehat{\widetilde{N}}_{m,l}$ satisfies all the conditions in Theorem 4 and $|\widetilde{p}_{m,l}(\frac{2\pi}{3})|=2^{l-\alpha_{m,l}}$, we derive the following theorem.

THEOREM 5. *If $\alpha_{m,l}<0$, then the functions $\widehat{\widetilde{N}}_{m,l}$ and $\widehat{\widetilde{\xi}}_{m,l}$ are not in $L^2(\mathbf{R})$. Consequently, the function $\xi_{m,l}$ is not a wavelet when $\alpha_{m,l}<0$.*

There is still a gap: "$0\leq\alpha_{m,l}\leq 1/2$." However, this gap is not too large. It is easy to see that for any fixed m, there is at most one integer l such that $\alpha_{m,l}$ is in this gap. When $1\leq m\leq 20$, one can verify that only the following twelve $\alpha_{m,l}$'s are in the interval $[0,1/2]$.

$$\begin{array}{llll}\alpha_{2,1}=0.403677, & \alpha_{3,1}=0.321928, & \alpha_{6,2}=0.357552, & \alpha_{7,2}=0.132368,\\ \alpha_{10,3}=0.302257, & \alpha_{11,3}=0.095397, & \alpha_{13,4}=0.472181, & \alpha_{14,4}=0.264736,\\ \alpha_{15,4}=0.0571438, & \alpha_{17,5}=0.434596, & \alpha_{18,5}=0.227069, & \alpha_{19,5}=0.0195527.\end{array}$$

We have seen that the length of the support of the wavelet $\xi_{m,l}$ is $(m+l)/2$. When $l<m$, the length of the support of the wavelet $\xi_{m,l}$ is even less than the length of the support of the scaling function N_m. The smoothness of the dual wavelet $\widetilde{\xi}_{m,l}$ is $\alpha_{m,l}-1$. The smaller l is, the smaller the support of the wavelet $\xi_{m,l}$. The larger l is, the better the smoothness of the dual wavelet $\widetilde{\xi}_{m,l}$. For applications, if one wants

the small support of the wavelet, one can choose small l. If one wants the better smoothness of the dual wavelet, one can choose large l.

Although the dual scaling functions and dual wavelets are noncompactly supported, the algorithms should be still manageable since the dual filters are fractions of trigonometric polynomials and can be implemented in a fast recursive way.

We compare the wavelet $\xi_{m,l}$ with the wavelet $\psi_{m,l}$. In [3] we proved that the function

$$\psi_{m,l}(x) = \frac{1}{2^{l-1}} \sum_{j=0}^{m+l-2} (-1)^j N_{m+l}(j+1) N_{m+l}^{(l)}(2x-j)$$

is also an mth-order spline wavelet. The support of the wavelet $\psi_{m,l}$ is $[0, m+l-1]$. The dual wavelet $\widetilde{\psi}_{m,l}$ is an lth-order spline function. If $l_1 = m + 2l_2 - 2$, then the functions ξ_{m,l_1} and ψ_{m,l_2} have the same length of the support. The smoothness of the wavelet ξ_{m,l_1} is

$$\begin{aligned}\alpha_{m,l_1} - 1 &= \log_2(1 + 3^{(m+m+2l_2-2)/2}) - m - 1 = \log_2(1 + 3^{(m+l_2-1)}) - m - 1 \\ &> (m + l_2 - 1)\log_2 3 - m - 1 = l_2 \log_2 3 + (m-1)(\log_2 3 - 1) - 2,\end{aligned}$$

which is much better than the smoothness of the wavelet ψ_{m,l_2}, except when $m = l_1 = l_2 = 1$. In this aspect, the wavelets $\xi_{m,l}$ are better than the wavelets $\psi_{m,l}$. But the dual wavelets $\widetilde{\xi}_{m,l}$ are no longer spline functions except when $m = l = 1$. In this aspect, the wavelets $\psi_{m,l}$ are better than the wavelets $\xi_{m,l}$.

At the end of this section we mention an interesting fact. Obviously, for any integer j, the function $\psi(\cdot - j)$ is a wavelet if the function ψ is a wavelet. In general, the function $\psi(\cdot - 1/2)$ is not a wavelet. For example, when $m+l$ is even and $\alpha_{m,l} > 1/2$, the function $\xi_{m,l}$ is a wavelet but the function $\xi_{m,l}(\cdot - 1/2)$ is not a wavelet. But when $m + l$ is odd and $\alpha_{m,l} > 1/2$, both $\xi_{m,l}$ and $\zeta_{m,l}(x) = \xi_{m,l}(x - 1/2)$ are wavelets. In fact, we have

$$\widehat{\zeta}_{m,l}(\omega) = Q_{m,l}^*(e^{-\omega i/2})\widehat{N}_m\left(\frac{\omega}{2}\right) = 2^{-l}e^{-\omega i/2}(1 - e^{-\omega i/2})^l \widehat{N}_m\left(\frac{\omega}{2}\right)$$

and

$$|\Delta_{P_m, Q_{m,l}^*}(z)| = |\Delta_{P_m, Q_{m,l}}(z)| \neq 0, \qquad |z| = 1.$$

Hence, we can prove that $\zeta_{m,l}(x) = \xi_{m,l}(x - 1/2)$ is a wavelet when $\alpha_{m,l} > 1/2$.

When $m + l$ is even, the center of the wavelet $\xi_{m,l}$ is an integer or half-integer. When $m + l$ is odd, the center of the wavelet $\xi_{m,l}$ is the fourth integer $(m + l)/4$.

4. The proof of Theorem 2. We have seen that Theorem 2 is essential in our constructions. In this section we shall prove Theorem 2. Recall that

$$|\widetilde{p}_{m,l}(\omega)| = \begin{cases} \dfrac{1}{\sin^{m+l}(\omega/2) + \cos^{m+l}(\omega/2)}, & \text{when } m+l \text{ is even,} \\ \dfrac{1}{\left(\sin^{2(m+l)}(\omega/2) + \cos^{2(m+l)}(\omega/2)\right)^{1/2}}, & \text{when } m+l \text{ is odd.} \end{cases} \tag{4.1}$$

Let

$$\sin^2(\omega/2) = x, \quad f(x) = 4x(1-x), \quad f_2(x) = f(f(x)),$$

$$W_p(x) = \frac{1}{x^p + (1-x)^p}, \quad F_p(x) = \frac{1}{W_p(x)} = x^p + (1-x)^p.$$

If $m+l$ is even, by setting $p=(m+l)/2$ we have

$$|\widetilde{p}_{m,l}(\omega)| = W_p(x), \quad |\widetilde{p}_{m,l}(2\omega)| = W_p(f(x)), \quad |\widetilde{p}_{m,l}(4\omega)| = W_p(f_2(x)).$$

If $m+l$ is odd, by setting $p=m+l$ we have

$$|\widetilde{p}_{m,l}(\omega)| = \sqrt{W_p(x)}, \quad |\widetilde{p}_{m,l}(2\omega)| = \sqrt{W_p(f(x))}, \quad |\widetilde{p}_{m,l}(4\omega)| = \sqrt{W_p(f_2(x))}.$$

It is easy to see that Theorem 2 is equivalent to the following theorems.

THEOREM 6. *Let $1 \le p \le 5$. We have*

$$F_p(x) \ge F_p\left(\frac{3}{4}\right), \quad \textit{when} \quad 0 \le x \le \frac{1}{4}, \quad \frac{3}{4} \le x \le 1, \tag{4.2}$$

$$F_p(x)F_p(f(x)) \ge F_p^2\left(\frac{3}{4}\right), \quad \textit{when} \quad \frac{1}{4} \le x \le \frac{3}{4}. \tag{4.3}$$

THEOREM 7. *Let $p \ge 6$. We have*

$$F_p(x) \ge F_p\left(\frac{3}{4}\right), \quad \textit{when} \quad 0 \le x \le \frac{1}{4}, \quad \frac{3}{4} \le x \le 1, \tag{4.4}$$

$$F_p(x)F_p(f(x)) \ge F_p^2\left(\frac{3}{4}\right), \quad \textit{when} \quad \frac{1}{4} \le x \le 0.41, \quad 0.59 \le x \le \frac{3}{4}, \tag{4.5}$$

$$F_p(x)F_p(f(x))F_p(f_2(x)) \ge F_p^3\left(\frac{3}{4}\right), \quad \textit{when} \quad 0.41 \le x \le 0.59. \tag{4.6}$$

Since $F_p(x) = F_p(1-x)$ and $f(x) = f(1-x)$, we only need to prove the above theorems for $0.5 \le x \le 1$. First we prove Theorem 6.

Proof of Theorem 6. Since the function F_p is increasing on $[1/2, 1]$, the inequality (4.2) is obvious.

Let

$$A_p(x) = F_p(x)F_p(f(x)) = (x^p + (1-x)^p)(f^p(x) + (1-f(x))^p).$$

The derivative of the function A_p is

$$\begin{aligned} A_p'(x) =& p(x^{p-1} - (1-x)^{p-1})(f^p(x) + (1-f(x))^p) \\ & - 4p(x^p + (1-x)^p)(f^{p-1}(x) - (1-f(x))^{p-1})(2x-1). \end{aligned} \tag{4.7}$$

When $p=1$, the function F_1 is the constant 1, and the inequality (4.3) is obvious. When $p=2,3$, we have

$$\begin{aligned} A_2'(x) &= 2(2x-1)(6(1-f(x))^2 - 1), \\ A_3'(x) &= 3(2x-1)^3(6x-1)(6x-5). \end{aligned}$$

When $1/2 \le x \le 3/4$, we see that $3/4 \le f(x) \le 1$. One can verify that the functions A_2' and A_3' are negative on $(1/2, 3/4]$. Hence, the functions A_2 and A_3 are decreasing on $[1/2, 3/4]$, which proves inequality (4.3) for $p=2,3$.

Since the functions $(x^{p-1} - (1-x)^{p-1})/(2x-1)$ and $x^p + (1-x)^p$ can be expressed as polynomials in $f(x)$, the function $A_p'(x)/(2x-1)$ can be expressed as a polynomial

in $f(x)$ also. By a simple calculation we have

$$\begin{aligned} A_4'(x) &= -(2x-1)(6f^5(x) - 50f^4(x) + 108f^3(x) - 126f^2(x) + 81f(x) - 20) \\ &= -(2x-1)B_4(f(x)) \\ A_5'(x) &= -\frac{5}{4}(2x-1)(30f^5(x) - 150f^4(x) + 264f^3(x) + 231f^2(x) + 106f(x) - 20) \\ &= -\frac{5}{4}(2x-1)B_5(f(x)). \end{aligned}$$

The zeros of the polynomials B_4 and B_5 are

$$0.537296, \quad 0.542624 \pm 0.927367i, \quad 0.92954, \quad 5.78125$$

and

$$0.52765, \quad 0.528725 \pm 0.525581i, \quad 0.906141, \quad 2.50876.$$

Looking at these zeros, we see that the polynomial B_p, $p = 4, 5$ has only one zero in $[3/4, 1]$. Because the function f is decreasing on $[1/2, 1]$ and $f(1/2) = 1$, and $f(3/4) = 3/4$, the function A_p', $p = 4, 5$ has only one zero x_p in $(1/2, 3/4]$. Since

$$\begin{aligned} A_p'(3/4) &= -p((3/4)^{p-1} - (1/4)^{p-1})((3/4)^p + (1/4)^p) < 0, \\ \lim_{x \to 1/2} \frac{A_p'(x)}{2x-1} &= p(p-1)(1/2)^{p-2} - p(1/2)^{p-3} > 0, \end{aligned}$$

the function A_p, $p = 4, 5$ is increasing on $[1/2, x_p]$ and decreasing on $[x_p, 3/4]$. So when $p = 4, 5$ and $1/2 \le x \le 3/4$, we have

$$\begin{aligned} A_p(x) &\ge \min[A_p(1/2), A_p(3/4)] \\ &= \min[(1/2)^{p-1}, ((3/4)^p + (1/4)^p)^2] = ((3/4)^p + (1/4)^p)^2 = F_p^2(3/4) \end{aligned}$$

which proves inequality (4.3) for $p = 4, 5$. □

When $p \ge 6$, one can verify that $A_p(1/2) < A_p(3/4)$. That is why we need to consider the function $F_p(x)F_p(f(x))F_p(f_2(x))$ when $p \ge 6$. Before we prove Theorem 7, we establish the following lemma.

LEMMA 2. *The function $A_p(x) = F_p(x)F_p(f(x))$ is decreasing on $[0.7, 3/4]$.*

Proof. In the proof of Theorem 6, we have already seen that this conclusion is true for $p = 1, 2, 3$. In the following we shall prove that this conclusion is true for $p \ge 4$. In fact, in Theorem 7, we only need this lemma for $p \ge 6$. Recall that

$$\begin{aligned} (1/p)A_p'(x) = &(x^{p-1} - (1-x)^{p-1})(f^p(x) + (1-f(x))^p) \\ &- 4(x^p + (1-x)^p)(f^{p-1}(x) - (1-f(x))^{p-1})(2x-1). \end{aligned}$$

When $0.7 \le x \le 3/4$, we have $2x - 1 \ge 0.4$. Since the functions $x^p + (1-x)^p$ and $f^{p-1}(x) - (1-f(x))^{p-1}$ are positive on $[1/2, 3/4]$, we have

(4.8)

$$\begin{aligned} &(1/p)A_p'(x) \\ &\le (x^{p-1} - (1-x)^{p-1})(f^p(x) + (1-f(x))^p) - 1.6(x^p + (1-x)^p)(f^{p-1}(x) - (1-f(x))^{p-1}). \end{aligned}$$

When $0.7 \le x \le 3/4$, we have $3/4 \le f(x) \le f(0.7) = 0.84$. Hence,

$$\begin{aligned} & f^p(x) + (1-f(x))^p - (f^{p-1}(x) - (1-f(x))^{p-1}) \\ & = f^{p-1}(f(x)-1) + (1-f(x))^p + (1-f(x))^{p-1} \\ & \le -0.16 f^{p-1}(x) + (1/4)^p + (1/4)^{p-1} \\ & \le -0.16(3/4)^{p-1} + (5/4)(1/4)^{p-1} \\ & = (-0.16 \cdot 3^{p-1} + 5/4)(1/4)^{p-1} < 0. \end{aligned} \tag{4.9}$$

The last inequality is true for $p \ge 3$. Also we have

$$x^{p-1} - (1-x)^{p-1} - 1.6(x^p + (1-x)^p) < x^{p-1} - 1.6x^p = x^{p-1}(1-1.6x) < -0.12x^{p-1} < 0. \tag{4.10}$$

Combining the inequalities (4.8)–(4.10), we see that $A_p'(x) < 0$ when $0.7 \le x \le 3/4$. Hence, the function A_p is decreasing on $0.7 \le x \le 3/4$. □

Proof of Theorem 7. Since the function F_p is increasing on $[1/2, 1]$, the inequality (4.4) is obvious.

By Lemma 2, the function $F_p(x)F_p(f(x))$ is decreasing on $[0.7, 3/4]$. This proves the inequality (4.5) for $0.7 \le x \le 3/4$.

For $0.59 \le x \le 0.7$ we use a different strategy. When $p \ge 6$, we have

$$(3.001)^p = 3^p + p \cdot 3^{p-1} \cdot 0.001 + \cdots > 3^p + 6 \cdot 3^5 \cdot 0.001 > 3^p + 1. \tag{4.11}$$

Then we have

$$F_p^2(3/4) = ((3/4)^p + (1/4)^p)^2 < \left(\frac{3.001}{4}\right)^{2p} = \left(\frac{9.006001}{16}\right)^p < 0.5629^p. \tag{4.12}$$

It is easy to see that the function F_p is increasing on $[1/2, 1]$ and the function $F_p(f(x))$ is decreasing on $[1/2, (2+\sqrt{2})/4]$. When $x \in [a, b] \subset [1/2, (2+\sqrt{2})/4]$ we have

$$F_p(x)F_p(f(x)) \ge F_p(a)F_p(f(b)) = (a^p + (1-a)^p)(f^p(b) + (1-f(b))^p) > (af(b))^p. \tag{4.13}$$

By using the above fact, we can prove that the inequality (4.5) is true for $0.59 \le x \le 0.7$. In fact, when $0.59 \le x \le 0.6$ we have

$$F_p(x)F_p(f(x)) > (0.59 \cdot f(0.6))^p = (0.59 \cdot 0.96)^p = 0.5664^p > 0.5629^p > F_p^2(3/4).$$

When $0.6 \le x \le 0.62$ we have

$$F_p(x)F_p(f(x)) > (0.6 \cdot f(0.62))^p = (0.6 \cdot 0.9424)^p = 0.56544^p > 0.5629^p > F_p^2(3/4).$$

When $0.62 \le x \le 0.65$ we have

$$F_p(x)F_p(f(x)) > (0.62 \cdot f(0.65))^p = (0.62 \cdot 0.91)^p = 0.5642^p > 0.5629^p > F_p^2(3/4).$$

When $0.65 \le x \le 0.68$ we have

$$F_p(x)F_p(f(x)) > (0.65 \cdot f(0.68))^p = (0.65 \cdot 0.8704)^p = 0.56576^p > 0.5629^p > F_p^2(3/4).$$

When $0.68 \le x \le 0.7$ we have

$$F_p(x)F_p(f(x)) > (0.68 \cdot f(0.7))^p = (0.68 \cdot 0.84)^p = 0.5712^p > 0.5629^p > F_p^2(3/4).$$

In the rest of the proof, we need to prove the inequality (4.6). First, by inequality (4.11), we have

$$F_p^3(3/4) = \left(\frac{3^p+1}{4^p}\right)^3 < \left(\frac{3.001}{4}\right)^{3p} < 0.4223^p.$$

Note these facts: The function F_p is increasing on $[1/2, 1]$. The function $F_p(f(x))$ is decreasing on $[1/2, (2+\sqrt{2})/4]$. The function $F_p(f_2(x))$ is decreasing on $[1/2, (2+\sqrt{2-\sqrt{2}})/4]$. When $1/2 \le x \le 0.59$, we have

$$\begin{aligned} F_p(x)F_p(f(x))F_p(f_2(x)) &\ge F_p(1/2)F_p(f(0.59))F_p(f_2(0.59)) \\ &> (1/2)^p \cdot f^p(0.59) \cdot (1 - f_2(0.59))^p \\ &= (0.5 \cdot 0.9676 \cdot 0.87459904)^p = (0.423131015552)^p \\ &> 0.4223^p > F_p^3(3/4). \end{aligned}$$

Finally, we must mention that all the above numbers are accurate. We did not perform any rounding. □

5. Final remarks. In [3] and in this paper we proved that the functions $\psi_{m,l;c}$, $L^{(l)}_{m+l;c}(2x-1)$, and $\xi_{m,l}$ are mth-order spline wavelets. In fact, every mth-order cardinal spline wavelet can be written as

$$\psi_a(x) = \frac{1}{2^{l-1}} \sum_j a_j N^{(l)}_{m+l}(2x-j), \qquad \sum_j a_j \neq 0,$$

where $a = \{a_j\}$ is a real sequence, whether finite or infinite. The function ψ_a is also dependent on m and l, but we omit the subscripts m and l. The problem is how to choose these a_j's to ensure that the function ψ_a is a wavelet. First, we need to choose $a = \{a_j\}$ to be in l^1. The Fourier transform of ψ_a is

$$\widehat{\psi}_a(\omega) = Q_a(e^{-\omega i/2})\widehat{N}_m\left(\frac{\omega}{2}\right),$$

where

$$Q_a(z) = \left(\frac{1-z}{2}\right)^l \sum_j a_j z^j.$$

Second, we must choose $\{a_j\}$ such that the determinant

$$\Delta_{P_m,Q_a}(z) = \begin{vmatrix} P_m(z) & Q_a(z) \\ P_m(-z) & Q_a(-z) \end{vmatrix}$$

is not equal to zero on the unit circle. Then we can define

$$G_a(z) = \frac{Q_a(-z)}{\Delta_{P_m,Q_a}(z)}, \qquad H_a(z) = \frac{-P_m(-z)}{\Delta_{P_m,Q_a}(z)},$$

$$\widehat{\widehat{N}}_a(\omega) = \prod_{k=1}^{\infty} \overline{G_a(e^{-2^{-k}\omega i})}, \qquad \widehat{\widehat{\psi}}_a(\omega) = \overline{H_a(e^{-\frac{\omega i}{2}})}\widehat{\widehat{N}}_a\left(\frac{\omega}{2}\right).$$

Third, we need to prove that the function $\overline{G_a}$ satisfies the hypotheses of Cohen, Daubechies, and Feauveau's theorems so that we can obtain the dual scaling function and dual wavelet via inverse Fourier transforms. To construct the wavelets $\xi_{m,l}$ and

$\psi_{m,l;c}$, we used different strategies to prove that the corresponding functions $\overline{G_a}$'s satisfy the hypotheses of Cohen, Daubechies, and Feauveau's theorems. If the sequence $\{a_j\}$ is symmetric, then the wavelet and dual wavelet are symmetric (if l is even) or antisymmetric (if l is odd). If the sequence $\{a_j\}$ is finite and if the determinant $\Delta_{P_m,Q_a}(z)$ is a monomial, then both wavelet and dual wavelet are compactly supported. The authors of [13] consider mainly the case in which $m + l$ is even. We also can construct compactly supported wavelets when $m + l$ is odd. At least, it is interesting from a theoretical viewpoint. If

$$\widehat{\widetilde{N}}_a(\omega) = \prod_{k=1}^{\infty} \overline{G_a(e^{-2^{-k}\omega i})} = A_a(e^{-\omega i})\widehat{N}_l(\omega),$$

where A_a is a Laurent series, then the dual wavelet is an lth-order spline function [3]. In this case both wavelet and dual wavelet are spline functions, and we can obtain biorthogonal spline wavelet basis. Furthermore, if $m = l$, then the wavelet spaces W_j^m are kept orthogonal and the wavelet basis is nonorthogonal only inside a given scale.

Finally, we mention that our method also can be used to construct nonspline wavelets.

Appendix. In illustration of our techniques, we present some graphs of the scaling functions, the wavelets, the dual scaling functions, and the dual wavelets for $m = 1$ (Fig. 1), $m = 2$ (Fig. 2), and $m = 3$ (Fig. 3).

Acknowledgments. I am deeply grateful to Ward Cheney, my supervisor, for his encouragement, patience, and assistance throughout my years in Austin, and for his guidance in my research and writing of this paper. From the very begining of my research for my Ph.D. dissertation, he has strongly encouraged and advised me to study wavelet theory. I wish to express special thanks to John Gilbert for his many suggestions and help in my work. I appreciate the opportunity as a teaching assistant for his class on wavelets, which helped me in both teaching and research. I am also indebted to Ingrid Daubechies,Charles Chui,and Jian-Zhong Wang for their advice, help, and suggestions. In particular, I wish to acknowledge the generosity of Jian-Zhong Wang for sharing with me his ideas and knowledge about wavelet theory. Finally, I thank Albert Cohen and the referees for their comments and suggestions that improved the presentation of this paper.

NONLINEAR STABILITY OF STRONG DETONATIONS FOR A VISCOUS COMBUSTION MODEL *

TAI-PING LIU† AND LONG-AN YING‡

Abstract. Strong detonations for a viscous combustion model are studied. These waves are of ZND (Zeldovich–von Neumann–Doring) type. It is shown that these waves are nonlinearly stable. The analysis consists of an energy method for the fluid variable and a pointwise estimate for the reactant. Strong detonations are compressive, which allows for a priori determination of their time-asymptotic location by the conservation law for the perturbation.

Key words. detonation waves, nonlinear stability

AMS subject classifications. 35K55, 76N10

1. Introduction.

Consider the viscous combustion model:

$$(u+qz)_t + f(u)_x = \beta u_{xx}, \tag{1.1}_1$$

$$z_t = -K\phi(u)z \tag{1.1}_2$$

[1], [3]. Here u represents the lumped fluid variables and z is the concentration of the reactant. The viscosity β, the heat release q, and the reaction rate K are positive constants. Motivated by the study of shock waves for gas dynamics, we require the flux $f(u)$ to satisfy

$$f'(u) > 0, \qquad f''(u) > 0 \tag{1.2}$$

so that (1.1) models detonations instead of deflagrations. The concentration z lies between 0 and 1, with $z = 1$ the unburnt state and $z = 0$ the completely burnt state. The reaction rate function $\phi(u)$ is smooth and satisfies

$$\phi(u) = \begin{cases} 1 & \text{for } u > 0, \\ 0 & \text{for } u < 0, \end{cases}$$
$$\phi'(u) > 0 \quad \text{for } 0 < u < 1, \tag{1.3}$$

so that $u = 0$ is the ignition temperature.

Well-posedness of the initial-value problem for (1.1) has been established [4], [5]. Our purpose is to study the nonlinear stability of strong detonation waves. There are two types of combustion waves for (1.1) and (1.2), and they are strong and weak detonation waves. Both are travelling waves:

$$(u, qz)(x,t) = (s,y)(x-\sigma t) \equiv (s, q\zeta)(x-\sigma t),$$
$$s(-\infty) = u_l, \qquad s(+\infty) = u_r,$$
$$\zeta(-\infty) = 0, \qquad \zeta(+\infty) = 1. \tag{1.4}$$

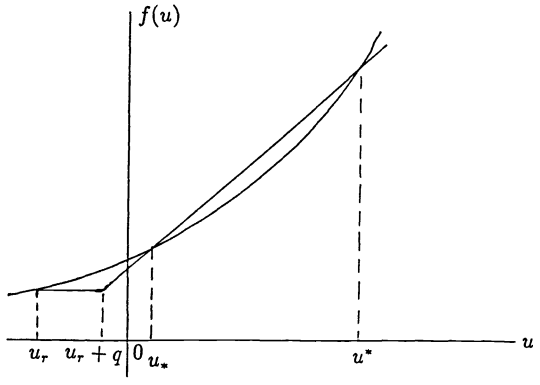

FIG. 1. *Chapman–Jouget diagram for detonations.*

By putting (1.4) into (1.1), we obtain ordinary differential equations for (s, y). The first equation in (1.1) is a conservation law and can be integrated to yield the jump condition

$$\sigma = \frac{f(u_r) - f(u_l)}{u_r + q - u_l}. \tag{1.5}$$

In general there are two values, u_* and u^*, for the left state u_l for each given right state u_r and wave speed σ; see Fig. 1.

The main difference between the weak detonation (u_*, u_r) and the strong detonation (u^*, u_r) is that the former is undercompressive and the latter is not:

$$\sigma > f'(u_*),$$

$$f'(u^*) > \sigma > f'(u_r). \tag{1.6}$$

The strong compressibility property (1.6) allows us to determine a priori the time-asymptotic location of a strong detonation when perturbed. This is done using the conservation laws

$$\int_{-\infty}^{\infty} (u + qz - (s + y))(x, t)\, dx = \int_{-\infty}^{\infty} (u + qz - (s + y))(x, 0)\, dx, \qquad t \geq 0. \tag{1.7}$$

The reason this can be done is that no characteristic leaves the detonation and therefore a perturbation does not give rise to diffusion waves. A diffusion wave would carry finite mass and make a contribution to the conservation law (1.7), in addition to that of the translation of the detonation [2]. A weak detonation, on the other hand, is undercompressive and a perturbation would give rise to a diffusion wave. As a consequence, the time-asymptotic wave location cannot be determined a priori. Different analysis is needed for its stability. We leave this to the future.

2. Preliminaries. Travelling waves (1.1) and (1.4) satisfy

$$s' = \beta^{-1}(-\sigma(s + y) + f(s) + c) \equiv g(s, y), \tag{2.1}_1$$

$$y' = -\frac{K}{\sigma}\phi(s)y, \tag{2.1}_2$$

$$(s, y)(-\infty) = (u_l, 0), \qquad (s, y)(\infty) = (u_r, q).$$

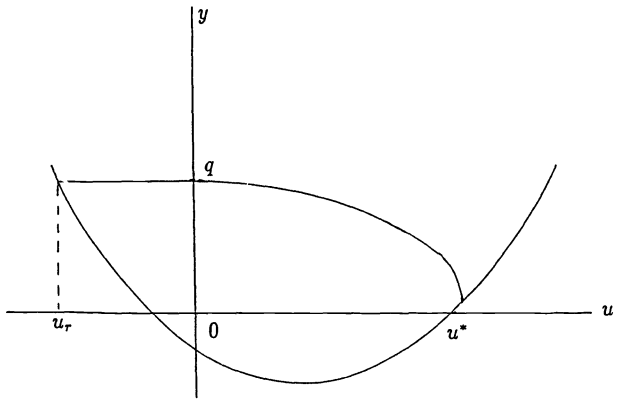

FIG. 2. *Phase diagram for strong detonations.*

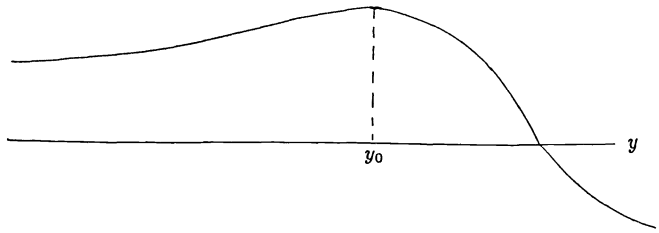

FIG. 3. *Fluid variable profile for strong detonation.*

We are interested in strong detonations, such as $u_l = u^*$. From the compressibility property (1.6), $(u^*, 0)$ is an unstable node for (2.1) and there is a unique connecting orbit provided that σ is not small [3], [4]. The trajectory is not monotone around $(u^*, 0)$ (see Fig. 2):

$$\begin{aligned} &f'(s)_x > 0 \quad \text{for } \eta < \eta_0, \\ &f'(s)_x < 0 \quad \text{for } \eta > \eta_0 \end{aligned} \tag{2.2}$$

for some constant η_0. For small heat release q, the effect of y in the $(2.1)_1$ is small and therefore s is almost monotone:

$$\begin{aligned} &0 < \int_{-\infty}^{\eta_0} f'(s)_\eta \, d\eta = \delta_1 << 1, \\ &f'(s, \eta) - \sigma > C \quad \text{for } -\infty < \eta < \eta_0 \end{aligned} \tag{2.3}$$

for some positive constant C; see Fig. 3.

3. Time-asymptotic analysis. Consider a perturbation of the strong detonation $(u^*, 0; u_r, 1)$:

$$(u, qz)(x, 0) = (s, y)(x) + (\bar{u}, \bar{y})(x, 0) \equiv (u_0, qz_0)(x). \tag{3.1}$$

From the compressibility property (1.6) there is no characteristic leaving the detonation and carrying diffusion waves. Thus the perturbation can cause, time-asymptotically, only the translation of the detonation. Suppose the amount of translation is x_0:

$$(u, qz)(x, t) \to (s, y)(x + x_0 - \sigma t) \quad \text{as } t \to \infty. \tag{3.2}$$

From (1.7), letting $t \to \infty$, we obtain

$$\int_{-\infty}^{\infty} \{(s+y)(x+x_0-\sigma t)-(s+y)(x-\sigma t)\}\,dx = \int_{-\infty}^{\infty} (\bar{u}+\bar{y})(x,0)\,dx.$$

Denote by $\psi(x_0)$ the left-hand side of the above identity; we have $\psi(0)=0$ and

$$\psi'(x_0) = \int_{-\infty}^{\infty} (s+y)'(x+x_0-\sigma t)\,dx = (s+y)|_{-\infty}^{\infty} = u_r + q - u^*.$$

It follows that

$$\psi(x_0) = x_0(u_r+q-u^*),$$
$$x_0 = (u_r+q-u^*)^{-1}\int_{-\infty}^{\infty} (\bar{u}+\bar{y})(x,0)\,dx.$$

This determines the time-asymptotic location of the detonation. We may translate (s,y) so that we can assume, without loss of generality, $x_0=0$, or equivalently,

$$\int_{-\infty}^{\infty} (\bar{u}+\bar{y})(x,t)\,dx = \int_{-\infty}^{\infty} (\bar{u}+\bar{y})(x,0) = 0, \qquad t \geq 0. \tag{3.3}$$

This is used by considering the antiderivative $v(x,t)$:

$$(u+qz)(x,t) = (s+y)(x-\sigma t) + v_x(x,t),$$
$$v(x,t) \equiv \int_{-\infty}^{x} (\bar{u}+\bar{y})(\xi,t)\,d\xi, \qquad v(\pm\infty,t)=0. \tag{3.4}$$

By integrating the difference of (1.1) and (2.1), we have

$$v_t + f(s+v_x+q(\zeta-z)) - f(s) = v_{xx} + q(\zeta-z)_x,$$
$$v(x,0) = \int_{-\infty}^{x} (\bar{u}+\bar{y})(\eta,0)\,d\eta, \tag{3.5}$$

(3.6)

$$(z-\zeta)(x,t) = z_0(x)\exp\left(-K\int_0^t \phi(u(x,\tau))\,d\tau\right) - \zeta(x)\exp\left(-K\int_0^t \phi(s(x,\tau))\,d\tau\right).$$

(3.5) can also be written as

$$v_t + f'(s)v_x = v_{xx} + q(\zeta-z)_x - f'(s)q(\zeta-z) + O(1)(v_x^2 + q^2(\zeta-z)^2). \tag{3.7}$$

4. Stability analysis. We start with the standard energy estimate by integrating (3.7) times v :

$$\frac{1}{2}\int_{-\infty}^{\infty} v^2(x,T)\,dx + \int_0^T\int_{-\infty}^{\infty}\left(v_x^2 - \frac{1}{2}f'(s)_x v^2\right)dx\,dt$$
$$= \frac{1}{2}\int_{-\infty}^{\infty} v^2(x,0)\,dx + \int_0^T\int_{-\infty}^{\infty}[-v_x q(\zeta-z) - vf'(s)q(\zeta-z)$$
$$+ O(1)v(v_x^2 + q^2(\zeta-z)^2)]\,dx\,dt.$$

With this and (2.2), we have from Cauchy–Schwarz that

$$\begin{aligned}\int_{-\infty}^{\infty} v^2(x,T)\,dx + \int_0^T\int_{-\infty}^{\infty} v_x^2\,dx\,dt + \int_0^T\int_{\sigma t+\eta_0}^{\infty} |f'(s)_x|v^2\,dx\,dt \\ \le \int_{-\infty}^{\infty} v^2(x,0)\,dx + \int_{-\infty}^{\infty} O(1)[q^2(\zeta-z)^2 + vq(\zeta-z)]\,dx\,dt \\ + \int_0^T\int_{-\infty}^{\sigma t+\eta_0} |f'(s)_x|v^2\,dx\,dt.\end{aligned} \tag{4.1}$$

Here we have made the following a priori assumption:

$$\sup_{-\infty<x<\infty,0\le t\le T} |v(x,t)| = \delta_2 << 1. \tag{4.2}$$

The second and third terms on the right-hand side of (4.1) are estimated, respectively, by using (3.6), (1.3) and (3.5), (1.6). We start with the latter by first rewriting (3.5) as

$$v_t + (f'(s)-\sigma)v_\eta = v_{\eta\eta} + q(\zeta-z)_\eta - f'(s)q(\zeta-z) + O(1)(v_\eta^2 + q^2(\zeta-z)^2),$$
$$\eta \equiv x - \sigma t,$$

and so

$$v_\eta = (f'(s)-\sigma)^{-1}[-v_t + v_{\eta\eta} + q(\zeta-z)_\eta - f'(s)\dot{q}(\zeta-z) + O(1)(v_\eta^2 + q^2(\zeta-z)^2)].$$

Integrating this times v over $(-\infty,\eta), \eta < \eta_0$, we have from (2.3) that

$$\begin{aligned}\frac{1}{2}v^2(\eta,t) &= \int_{-\infty}^{\eta} (f'(s)-\sigma)^{-1}[-vv_t + vv_{\eta\eta} + qv(\zeta-z)_\eta \\ &\qquad - vf'(s)q(\zeta-z) + O(1)v(v_\eta^2 + q^2(\zeta-z)^2)]d\eta \\ &= (f'(s)-\sigma)^{-1}(vv_\eta + qv(\zeta-z))(\eta,t) \\ &\quad + \int_{-\infty}^{\eta} (f'(s)-\sigma)^{-1}[-vv_t - v_\eta^2 - qv_\eta(\zeta-z) - vf'(s)q(\zeta-z) \\ &\quad + O(1)v(v_\eta^2 + q^2(\zeta-z)^2)]\,d\eta \\ &\quad + \int_{-\infty}^{\eta} (f'(s)-\sigma)^{-2}f'(s)_\eta[-vv_\eta - qv(\zeta-z)]\,d\eta,\end{aligned} \tag{4.3}$$

$$\begin{aligned}\int_0^T\int_{-\infty}^{\eta_0} f'(s)_\eta \frac{v^2}{2}\,d\eta\,dt \le \int_0^T\int_{-\infty}^{\eta_0} O(1)f'(s)_\eta(vv_\eta + qv(\zeta-z))\,d\eta\,dt \\ + O(1)\delta_1\int_0^T\int_{-\infty}^{\eta_0}[q^2(\zeta-z)^2 + O(1)vq(\zeta-z) \\ + (f'(s)_\eta v)^2]\,d\eta\,dt.\end{aligned}$$

This and (4.1) yield, for $\delta_1 + \delta_2$ small,

$$\begin{aligned}\int_{-\infty}^{\infty} v^2(x,T) + \int_0^T\int_{-\infty}^{\infty} v_x^2\,dx\,dt + \int_0^T\int_{-\infty}^{\infty} |f'(s)_x|v^2\,dx\,dt \\ \le \int_{-\infty}^{\infty} v^2(x,0)\,dx + \int_0^T\int_{-\infty}^{\infty}[O(1)q^2(\zeta-z)^2 + O(1)vq(\zeta-z)]\,dx\,dt.\end{aligned} \tag{4.4}$$

We now turn to the estimates for $\zeta - z$ using (3.6). From the hypotheses (4.2) and (1.3), there exists a positive constant D and $\eta_1, \eta_2, \eta_2 > \eta_1 > \eta_0$ such that

$$\phi(u) = 0 \quad \text{for } x - \sigma t > \eta_2, \tag{4.5}$$

$$\phi(u) > D \quad \text{for } x - \sigma t < \eta_1, \tag{4.6}$$

$$f'(s)_x < -D \quad \text{for } \eta_2 > x - \sigma t > \eta_1, \tag{4.7}$$

$$f'(s) - \sigma > D \quad \text{for } x - \sigma t < \eta_1; \tag{4.8}$$

cf. Fig. 3. Thus we have from (3.6) and (4.5) that

$$\begin{aligned} &(z-\zeta)(x,t) = z_0(x) - \zeta(x) \quad \text{for } x - \sigma t > \eta_2, \\ &\int_0^T \int_{\sigma t + \eta_2}^{\infty} [O(1)q^2(\zeta - z)^2 + O(1)vq(\zeta - z)]\, dx\, dt \\ &\qquad = O(1)q(q + \delta_2) \int_{\eta_2}^{\infty} |z_0(x) - \zeta(x)||x|\, dx. \end{aligned} \tag{4.9}$$

The region $\eta_1 < x - \sigma t < \eta_2$ has a finite width in both x and t directions and therefore we have from (3.6) and (3.4) that

$$\begin{aligned} (z - \zeta(x)) &= (z_0(x) - \zeta(x)) \exp\left(-K \int_{(x-\eta_2)/\sigma}^{t} \phi(u(x,\tau))\, d\tau\right) \\ &\quad + \zeta(x) \left[\exp\left(-K \int_{(x-\eta_2)/\sigma}^{t} \phi(s(x,\tau))\, d\tau\right) - \exp\left(-K \int_{(x-\eta_2)/\sigma}^{t} \phi(u(x,\tau))\, d\tau\right)\right] \\ &= O(1)(z_0(x) - \zeta(x)) + O(1) \int_{(x-\eta_2)/\sigma}^{t} (\phi(s(x,\tau)) - \phi(u(x,\tau)))\, d\tau \\ &= O(1)(z_0(x) - \zeta(x)) + \int_{(x-\eta_2)/\sigma}^{t} O(1)(q(z-\zeta) + v_x)(x,\tau)\, d\tau \\ &= O(1)(z_0(x) - \zeta(x)) + \left[O(1) \int_{(x-\eta_2)/\sigma}^{t} (q(z-\zeta) + v_x)^2(x,\tau)\, d\tau\right]^{1/2}, \end{aligned}$$

where we have used the Cauchy–Schwarz inequality. This and (4.7) yield

$$\begin{aligned} &\int_0^T \int_{\eta_1 + \sigma t}^{\eta_2 + \sigma t} [q^2(\zeta - z)^2 + |vq(\zeta - z)|]\, dx\, dt \\ &\quad = \int_0^T \int_{\eta_1 + \sigma t}^{\eta_2 + \sigma t} O(1)[q(\zeta - z)^2 + qv^2]\, dx\, dt \\ &\quad = \int_0^T \int_{\eta_1 + \sigma t}^{\eta^2 + \sigma t} O(1)q[(z_0(x) - \zeta(x))^2 + \int_{(x-\eta_2)/\sigma}^{t} (q(z-\zeta) + v_x)^2(x,\tau)\, d\tau]\, dx\, dt \\ &\qquad + \int_0^T \int_{\eta_1 + \sigma t}^{\eta_2 + \sigma t} O(1)q|f'(s)_x|v^2\, dx\, dt \\ &\quad = \int_{\eta_1}^{\infty} O(1)q|z_0(x) - \zeta(x)|^2\, dx \\ &\qquad + \int_0^T \int_{\eta_1 + \sigma t}^{\eta_2 + \sigma t} O(1)[q^2(z-\zeta)^2 + qv_x^2 + q|f'(s)_x|v^2]\, dx\, dt. \end{aligned}$$

Hence we have, for q small,

$$\begin{aligned}
&\int_0^T \int_{\eta_1+\sigma t}^{\eta_2+\sigma t} [O(1)q^2(\zeta - z)^2 + |vq(\zeta - z)|]\, dx\, dt \\
&= \int_{\eta_1}^{\infty} O(1)q|z_0(x) - \zeta(x)|^2\, dx \\
&\quad + \int_0^T \int_{\eta_1+\sigma t}^{\eta_2+\sigma t} O(1)q(v_x^2 + |f'(s)_x|v^2)\, dx\, dt.
\end{aligned} \tag{4.10}$$

We finally turn to the same integral as (4.9) and (4.10) but for the region $x - \sigma t < \eta_1$ by using (4.6) and (3.6)

$$\begin{aligned}
(z-\zeta)(x,t) &= O(1)\left[|z_0(x) - \zeta(x)| + \int_0^t |\phi(s(x,\tau)) - \phi(u(x,\tau))|\, d\tau\right] \\
&\quad \times \exp\left(-K\int_0^t \phi(s(x,\tau))\, d\tau\right) \\
&= O(1)[|z_0(x) - \zeta(x)| \\
&\qquad + \int_{t_1(x)}^t |\phi(s(x,\tau)) - \phi(u(x,\tau))| d\tau] \exp(-KDt_2(x)), \\
t_1(x) &\equiv \max((x-\eta_2)/\sigma, 0), t_2(x) \equiv \max((x-\eta_1)/\sigma, 0).
\end{aligned} \tag{4.11}$$

In particular, we have for some $C > 0$,

$$(z-\zeta)(x,t) = O(1)(z_0(x) + \zeta(x))\exp(-Ct) \quad \text{for } x < 0.$$

Thus

$$\int_0^T \int_{-\infty}^0 [q^2(z-\zeta)^2 + |vq(\zeta - z)|]\, dx\, dt = O(1)q(q+\delta_2)\int_{-\infty}^0 (z_0(x) + \zeta(x))\, dx. \tag{4.12}$$

Again from (4.11), for $x > 0$ and $\eta = x - \sigma t < \eta_1$,

$$(z-\zeta)(x,t) = O(1)\left[|z_0(x) - \zeta(x)| + \int_{t_1(x)}^t |\phi(s(x,\tau)) - \phi(u(x,\tau))| d\tau\right] \exp(-C|\eta - \eta_1|),$$

whence

$$\begin{aligned}
&\int_{|\eta_1|/\sigma}^T \int_0^{\eta_1+\sigma t} [q^2(z-\zeta)^2 + |vq(\zeta - z)|]\, dx\, dt \\
&\le q\int_0^T \int_0^{\sigma t} O(1)|z_0(x) - \zeta(x)|^2 e^{-Ct}\, dx\, dt \\
&\quad + q\int_{|\eta_1|/\sigma}^T \int_0^{\eta_1+\sigma t} O(1)\left[\int_{t_1(x)}^t |s(x,\tau) - u(x,\tau)|\, d\tau\right]^2 \\
&\quad \times e^{-C|x-\sigma t|}\, dx\, dt + q\int_{|\eta_1|/\sigma}^T \int_0^{\eta_1+\sigma t} O(1)v^2 \times e^{-C|x-\sigma t|}\, dx\, dt \equiv \mathrm{I} + \mathrm{II} + \mathrm{III}.
\end{aligned}$$

Clearly,

$$\mathrm{I} = O(1)q\int_0^\infty |z_0(x)-\zeta(x)|^2\,dx$$

and, by a change of order of integrations,

$$\mathrm{III} \le O(1)q\int_0^T\int_{-\infty}^{\eta_1} O(1)v^2(\eta,t)e^{-C|\eta|}\,d\eta\,dt, \qquad \eta \equiv x-\sigma t.$$

Thus we may apply the same procedure in deriving (4.4) from (4.3) to obtain

$$\begin{aligned}\mathrm{III} &= O(1)q\int_0^T\int_{-\infty}^{\eta_1}[q^2(\zeta-z)^2+O(1)vq(\zeta-z)+f'(s)_\eta v^2]\,dx\,dt\\ &= O(1)q\int_0^T\int_{-\infty}^{\eta_1+\sigma t}[q^2(\zeta-z)^2+O(1)|vq(\zeta-z)|+|f'(s)_\eta v^2|]\,dx\,dt.\end{aligned}$$

From (3.4) and Cauchy–Schwarz we see that

$$\begin{aligned}\mathrm{II} &\le q\int_0^T\int_0^{\sigma t} O(1)\left[\int_{(x-\eta_2)/\sigma}^t (|q(z-\zeta)|+|v_x|)(x,\tau)\,d\tau\right]^2 e^{-C|x-\sigma t|}\,dx\,dt\\ &= q\int_0^T\int_0^{\sigma t} O(1)\left[\int_{(x-\eta_2)/\sigma}^t (q^2(z-\zeta)^2+v_x^2)(x,\tau)\,d\tau\right]|x-\sigma t|e^{-C|x-\sigma t|}\,dx\,dt\\ &= O(1)q\int_0^{\sigma t}\int_{x/\sigma}^T\left[\int_{(x-\eta_2)/\sigma}^t (q^2(z-\zeta)^2+v_x^2)(x,\tau)\,d\tau\right]e^{-C|x-\sigma t|/2}\,dx\,dt\\ &= O(1)q\int_0^{\sigma t}\int_{(x-\eta_2)/\sigma}^T (q^2(z-\zeta)^2+v_x^2)\,dx\,dt.\end{aligned}$$

We conclude from these estimates for I–III and (4.9)–(4.12) that, for q small,

$$\begin{aligned}&\int_0^T\int_{-\infty}^\infty [O(1)q^2(\zeta-z)^2+O(1)qv(\zeta-z)]\,dx\,dt\\ &\quad= O(1)q\int_0^\infty x|z_0(x)-\zeta(x)|\,dx+O(1)q\int_{-\infty}^0 (z_0(x)+\zeta(x))\,dx\\ &\qquad+O(1)q\int_0^T\int_{-\infty}^\infty (|f'(s)_x|v^2+v_x^2)\,dx\,dt.\end{aligned}\tag{4.13}$$

Finally, we have from (4.4) and (4.13), for $q+\delta_1+\delta_2$ sufficiently small, the following main energy estimate:

$$\begin{aligned}&\int_{-\infty}^\infty v^2(x,T)+\int_0^T\int_{-\infty}^\infty (v_x^2+|f'(s)_x|v^2)\,dx\,dt\\ &\quad\le \int_{-\infty}^\infty v^2(x,0)\,dx+O(1)q\int_0^\infty x|z_0(x)-\zeta(x)|\,dx\\ &\qquad+O(1)q\int_{-\infty}^0 (z_0(x)+\zeta(x))\,dx.\end{aligned}\tag{4.14}$$

We now state our stability result.

THEOREM. *Suppose that q is small,*

$$\int_{-\infty}^{x} (u_0(x) - s(x))\,dx \quad \text{and} \quad \int_{-\infty}^{x} (z_0(x) - \zeta(x))\,dx$$

are sufficiently small in the space $H^3(-\infty, +\infty)$, and that as $x \to \pm\infty$,

$$u_0(x) - s(x) = O(|x|^{-3/2-\epsilon}), \qquad u_0'(x) - s'(x) = O(|x|^{-1/2-\epsilon}),$$
$$u_0''(x) - s''(x) = O(|x|^{-1/2-\epsilon}) \qquad \frac{d^k}{dx^k}(z_0(x) - \zeta(x)) = O(|x|^{-2-\epsilon}),$$

$k = 0, \ldots, 3$, for some $\epsilon > 0$. Then $u(\cdot, t) - s(\cdot - \sigma t)$ and $z(\cdot, t) - \zeta(\cdot - \sigma t)$ decay to zero in the $L^\infty(x)$ as $t \to +\infty$.

Proof. From our hypotheses, the energy estimate (4.14) becomes

$$\int_{-\infty}^{\infty} v^2(x, T) + \int_0^T \int_{-\infty}^{\infty} (v_x^2 + |f'(s)_x| v^2)\,dx\,dt = O(1)\delta,$$

for a small constant δ. By similar arguments we may use the differentiations of (3.4) and (3.5) to obtain energy estimates for higher derivatives of v :

$$\int_{-\infty}^{\infty} w^2(x, T)\,dx + \int_0^T \int_{-\infty}^{\infty} \left(\frac{\partial w}{\partial x}\right)^2 dx\,dt = O(1)\delta,$$
$$\int_{-\infty}^{\infty} w_1^2(x, 0)\,dx + \int_0^T \int_{-\infty}^{\infty} \left(\frac{\partial w_1}{\partial x}\right)^2 dx\,dt = O(1)\delta,$$
$$w \equiv v_x = u + qz - (s + q\zeta), \qquad w_1 \equiv w_x.$$

In turn these estimates imply that the assumption (3.5) holds by the Sobolev inequality. In fact, the same arguments also yield the equicontinuity of the L^2 norms of w and w_1. Since their double integrals are bounded, it follows that

$$\int_{-\infty}^{\infty} w^2(x, T)\,dx \to 0 \quad \text{as } T \to \infty.$$

To finish the proof, it remains to show that one of the quantities, $(u - s)(x, t)$ and $(z - \zeta)(x, t)$, goes to zero as $t \to \infty$.

From (3.6)

$$\begin{aligned}(u - s)(x, t) &= w(x, t) - q(z - \zeta)(x, t)\\ &= w(x, t) - q(z_0(x) - \zeta(x)) \exp\left(-K \int_0^t \phi(u(x, \tau))\,d\tau\right)\\ &\quad - q\zeta(x)\left[\exp\left(-K \int_0^t \phi(u(x, \tau))\,d\tau\right) - \exp\left(-K \int_0^t \phi(s(x, \tau))\,d\tau\right)\right]\\ &= w(x, t) + O(1)q(z_0(x) - \zeta(x)) + Kq\zeta(x) \int_0^t O(1)(u - s)(x, \tau)\,d\tau.\end{aligned}$$

Take a constant $E, \sigma > E > 0$. We have for $x > Et$,

$$O(1)q(z_0(x) - \zeta(x)) = O(t^{-2-\epsilon}) \to 0.$$

Thus it follows from Gronwall's inequality that $(u-s)(x,t) \to 0$ as $t \to 0$. For $x < Et$, we have from (3.6) and (4.6) that

$$\begin{aligned}(z-\zeta)(x,t) &= O(1)(z_0+\zeta)(x)\exp\left(-KD\left(t-\frac{x-\eta_1}{\sigma}\right)\right)\\ &= O(1)\exp(-t[1-D/\sigma]+\eta_1/\sigma) \to 0 \quad \text{as } t \to 0.\end{aligned}$$

This completes the proof of the theorem.

APPROXIMATION PRÈS DU TEMPS D'EXPLOSION DES SOLUTIONS D'ÉQUATIONS D'ONDE QUASI-LINÉAIRES EN DIMENSION DEUX*

SERGE ALINHAC†

Abstract. For a general quasi-linear wave equation in two space dimensions and Cauchy data of size ϵ, we construct an approximate solution using the method of nonlinear geometric optics.

Away from the blow up time, we obtain arbitrary accuracy near the light cone.

Near the blow up time, we make explicit the behavior of the solution and of the error terms.

Key words. équation d'onde quasi-linéaire, solution approchée, optique géométrique non linéaire

AMS subject classification. 35L40

Introduction. Dans ce travail, nous étudions les solutions d'équations d'onde quasi-linéaires en dimension deux d'espace, pour des données de Cauchy C_0^∞ de taille ε.

De nombreux mathématiciens ont contribué à cette étude, parmi lesquels on peut citer Klainerman, John, et Hörmander (on trouvera dans [6] une bibliographie détaillée).

Il a été notamment établi que le temps de vie T_ε de la solution est de l'ordre de A_0^2/ε^2, et que la solution u est approximée, pour tout $A < A_0$ et $t \leq A^2/\varepsilon^2$, par une fonction u_a de la forme

$$u_a = \frac{\varepsilon}{r^{1/2}} R(r-t, \omega, \tau), \quad \text{où } x = r(\cos\omega, \sin\omega), \qquad \tau = \varepsilon\sqrt{t},$$

R étant solution d'une équation de type Burger.

Ces procédés d'approximations, qualifiés "d'optique géométrique non linéaire" sont classiques (voir, par exemple, Di Perna et Majda [3], Majda [8], [9], Hörmander [5], ou encore [1]).

Le présent article a pour but de décrire une construction beaucoup plus précise, en insistant sur le comportement de la solution u_a et de l'erreur près du bord du cône de lumière, c'est-à-dire dans une zone de la forme $-\text{cte} \leq r - t \leq M$ (les données de Cauchy étant supportées dans $|x| \leq M$).

De plus, on ne se limitera pas à $t \leq A^2/\varepsilon^2$ $(A < A_0)$: on établira les comportements de la solution et de l'erreur pour

$$t \leq \frac{A_0^2}{\varepsilon^2} + 2\frac{A_0 A_1}{\varepsilon} - o\Big(\frac{1}{\varepsilon}\Big),$$

c'est-à-dire au voisinage du temps d'explosion de $\nabla^2 u_a$.

La motivation de cette étude est le désir de préciser les estimations connues de T_ε et de comprendre la nature du comportement explosif de u lorsque $t \underset{<}{\to} T_\varepsilon$. Un premier pas dans cette direction a été fait dans [2].

†Université de Paris-Sud, Département de Mathématiques, 91405 Orsay Cedex, France.

Cet article étant par nécessité assez technique, nous avons adopté le plan suivant.

• Au §1 sont introduites les notations et le problème précis.

• Au §2, nous résumons la construction et les estimations d'erreurs zone par zone, après quelques commentaires destinés à aider le lecteur à saisir les enjeux.

• Le §3 est consacré à une première période de temps où les interactions non linéaires sont faibles.

• Au §4, on explicite la transition assez délicate de cette première période au temps $t \leq A^2/\varepsilon^2$ $(A < A_0)$, en résumant les résultats obtenus au §5.

• Enfin, le §6 est consacré à l'étude pour $t \geq A^2/\varepsilon^2$ et jusqu'à une distance $o\left(\frac{1}{\varepsilon}\right)$ du temps d'explosion.

1. Notations et position du problème.

• Dans R^3, on note (x_0, x_1, x_2) les variables, en utilisant souvent la notation commode $x_0 = t$, $x = (x_1, x_2)$.

Les coordonnées polaires en (x_1, x_2) seront alors notées (r, ω), avec $r = (x_1^2 + x_2^2)^{1/2}$, $x_1 = r\cos\omega$, $x_2 = r\sin\omega$, $\omega_1 = \cos\omega$, $\omega_2 = \sin\omega$, $\partial_\omega = x_1\partial_2 - x_2\partial_1$.

Pour une fonction $f(x,t)$, on notera par abus

$$|f|_0 = \left(\int |f(x,t)|^2\, dx\right)^{1/2} \quad \text{et} \quad \|f\|_0 = \sup_x |f(x,t)|\,,$$

les normes L^2 et L^∞ de f à t fixé.

• On considère l'équation des ondes quasi-linéaire à coefficients réels

$$\partial_t^2 u - \Delta_x u + g_{ij}^k\, \partial_k u\, \partial_{ij}^2 u = 0, \tag{1.1}$$

où la sommation est étendue aux indices $0 \leq i, j, k \leq 2$, $\partial_k = \partial/\partial x_k$, $g_{ij}^k = g_{ji}^k$, $g_{00}^k = 0$, $\Delta_x = \partial_1^2 + \partial_2^2$ et $\Box = \partial_t^2 - \Delta_x$.

Avec $\omega_0 = -1$, on définit comme dans [5]

$$g(\omega) = g_{ij}^k\, \omega_i \omega_j \omega_k. \tag{1.2}$$

On suppose données des fonctions $u^0(x,\varepsilon)$, $u^1(x,\varepsilon)$, réelles de classe C^∞ dans $\mathrm{R}^n \times [0, \varepsilon_0[$, supportées dans $|x| \leq M$, pour lesquelles on a

$$u^0(x,\varepsilon) = \varepsilon u_1^0(x) + \varepsilon^2 u_2^0(x) + \cdots,\ u^1(x,\varepsilon) = \varepsilon u_1^1(x) + \varepsilon^2 u_2^1(x) + \cdots.$$

On considère, pour $\varepsilon > 0$, le problème de Cauchy

$$\Box u + g_{ij}^k\, \partial_k u\, \partial_{ij}^2 u = 0, \quad u(x,0) = u^0(x,\varepsilon), \quad \partial_t u(x,0) = u^1(x,\varepsilon). \tag{1.3}$$

On se propose de construire une solution approchée u_a du problème (1.3), en portant une attention particulière aux comportements de la solution u_a et de l'erreur $J_a = \Box u_a + g_{ij}^k\, \partial_k u_a\, \partial_{ij}^2 u_a$ près du temps d'explosion.

2. Résultats obtenus: Description de la solution approchée et estimations des erreurs.

2.1. Quelques généralités.

2.1.1. Dans la description de la solution approchée u_a de (1.3) qui sera construite en détail aux §§3–6, nous distinguons systématiquement deux zones d'espace temps et trois périodes de temps.

• La zone dite "extérieure" est située au bord du cône de lumière, et est définie par $-C_0 \leq r - t \leq M$, pour une constante C_0 assez grande (en fait, $C_0 \gg |\sigma_0|$, voir plus bas).

• La zone dite "intérieure," définie par $r - t \leq -C_0 + 3$. Les trois périodes de temps sont définies comme suit.

• La "période I" est $0 \leq t \leq 2\varepsilon^{-\lambda}$, où $\lambda < 2$ est à choisir (on prendra en fait $\lambda = \frac{14}{9}$).

• La "période II" est $\varepsilon^{-\lambda} \leq t \leq A^2/\varepsilon^2$, où A est un nombre positif fixé arbitrairement, avec toutefois $A < A_0$ (voir plus bas).

• La "période III" commence à $t = A^2/\varepsilon^2$, et s'achève avec l'explosion de la solution.

La solution approchée u_a sera en fait construite séparément dans chaque domaine, les fonctions correspondantes étant notées $u_a^{I,i}$ (i pour "intérieur"), $u_a^{I,e}$ (e pour "extérieur"), $u_a^{II,i}$, etc.

La solution u_a sera obtenue enfin par recollement des morceaux à l'aide de troncatures.

• Pour $\theta \in C^\infty(\mathrm{R})$ vérifiant $\theta(s) = 1$ pour $s \leq 1$ et $\theta(s) = 0$ pour $s \geq 2$, on pose

$$u_a^I = (1-\theta)(r-t+C_0-1)u_a^{I,e} + \theta(r-t+C_0-1)u_a^{I,i} \ ,$$

et de même pour les périodes II et III.

• Pour les périodes I et II, on pose

$$u_a = \theta(te^\lambda)u_a^I + (1-\theta(te^\lambda))u_a^{II} \ .$$

• Dans un souci de simplification, le passage de la période II à la période III se fait par simple recollement de u_a^{II} et u_a^{III} sur $t = A^2/\varepsilon^2$.

2.1.2. La constante C_0 choisie en §2.1.1 est assez grande pour assurer le fait suivant : la solution approchée u_a construite n'explose pas en zone intérieure, même en période III.

C'est en zone extérieure que se produit (en période III) l'explosion de la solution approchée u_a.

Du fait qu'on espère voir la vraie solution u se comporter comme u_a, on s'intéresse donc tout spécialement à la zone extérieure.

La preuve que u manifeste effectivement un "comportement explosif" près des points où u_a explose est délicate, et nécessite que u_a soit une très bonne approximation de u (cette preuve est fournie en [2]). C'est ce point qui explique la différence de traitement du présent travail entre les deux zones.

La transition "vers l'intérieur" s'opérera donc essentiellement en négligeant dans u_a^e des termes devenus inutiles pour u_a^i.

En revanche, l'absence de lacune pour les solutions libres de l'équation des ondes en dimension deux, et les interactions non linéaires, obligent à considérer le comportement de u_a^i pour de grandes valeurs de $t - r$. Or l'on sait [5] qu'une solution u à données C_0^∞ de $\Box u = 0$ s'écrit

$$u = \frac{1}{r^{1/2}} F\Big(r-t, \omega, \frac{1}{r}\Big),$$

où $F(\sigma,\omega,z)$ vérifie des inégalités "de type symbole"

$$\left|\partial_\omega^\alpha \partial_z^\beta \partial_\sigma^\gamma F(\sigma,\omega,z)\right| \leq C_{\alpha\beta\gamma}(1+|\sigma|)^{-\frac{1}{2}+|\beta|-|\gamma|}.$$

Si l'on développe F par la formule de Taylor en $z=0$, on obtient

$$u \sim \frac{1}{r^{1/2}}\Big\{F_0(r-t,\omega)+\frac{1}{r}F_1(r-t,\omega)+\cdots+\frac{1}{r^k}F_k(r-t,\omega)+\cdots\Big\},$$

où $F_k(\sigma,\omega)$ est un symbole en σ d'ordre $-\frac{1}{2}+k$ (et de type $(1,0)$).

Ce développement ne nous apprend donc rien sur le comportement de u dans toute zone $\varepsilon \leq \dfrac{r}{t} \leq 1-\varepsilon$ $(\varepsilon>0)$, tandis qu'il est arbitrairement précis en zone extérieure.

On voit ainsi que les termes négligés de u_a^e seraient devenus dans u_a^i, de toutes façons, non significatifs.

2.1.3. Les formes successives de u_a à travers les trois périodes se laissent comprendre de la façon suivante.

En période I, on calcule tout simplement u_a par un développement en série de ε

$$u_a = \varepsilon u_1 + \varepsilon^2 u_2 + \cdots$$

• Les interactions quadratiques "de première génération" (c'est-à-dire celles de

$$u_1 \sim \frac{S_0(r-t,\omega,\frac{1}{r})}{r^{1/2}}$$

avec lui-même) font apparaître des termes en

$$\varepsilon^2\sqrt{t}\,\frac{1}{r^{1/2}}S_1\Big(r-t,\omega,\frac{1}{r}\Big), \quad \text{puis } \varepsilon^3 t\,\frac{1}{r^{1/2}}S_2\Big(r-t,\omega,\frac{1}{r}\Big), \text{etc.}$$

les S_i étant certains symboles en σ. Cela conduit à introduire le temps lent $\tau=\varepsilon\sqrt{t}$, de façon à écrire la somme

$$\frac{\varepsilon}{r^{1/2}}(S_0+\tau S_1+\tau^2 S_2+\ldots)$$

sous la forme

$$\frac{\varepsilon}{r^{1/2}}S\Big(r-t,\omega,\frac{1}{r},\tau\Big).$$

• Les interactions de "deuxième génération" (c'est-à-dire celles de u_1 avec u_2) font apparaître, outre des termes comme ci-dessus, des termes de la forme

$$\frac{\varepsilon^3\log t}{r^{1/2}}S_3\Big(r-t,\omega,\frac{1}{r}\Big), \quad \text{puis } \frac{\varepsilon^5(\log t)^2}{r^{1/2}}S_3\Big(r-t,\omega,\frac{1}{r}\Big), \textit{etc.}$$

Cela conduit à introduire un deuxième temps lent $\zeta=\varepsilon^2\log t$, tous les termes se sommant en

$$\frac{\varepsilon}{r^{1/2}}F\Big(r-t,\omega,\frac{1}{r},\tau,\zeta\Big).$$

En période II, on cherchera donc la solution sous la forme modulée

$$u_a \sim \frac{\varepsilon}{r^{1/2}} F\Big(r-t, \omega, \frac{1}{r}, \tau, \zeta\Big),$$

l'équation aux dérivées partielles satisfaite par F traduisant les effets des interactions quadratiques.

En première approximation, (et notamment, en zone intérieure), cette équation n'est autre que l'équation de Burger en les variables $\sigma = r - t$ (espace) et τ (temps). C'est un fait classique (cf., par exemple, [5]).

Si l'on recherche une précision supérieure, on doit faire appel en deuxième période à un modèle plus complexe, l'apparition des termes en $(\log t)^k$ décrits plus haut correspondant à des valeurs entières d'indices pour certaines équations à points singuliers-réguliers (cf. [10]).

La transition entre les périodes I et II consistera à imposer à F comme conditions initiales sur $\tau = \zeta = 0$ les valeurs obtenues en période I.

En période III, le temps lent ζ et la variable $z = \dfrac{1}{r}$ deviennent redondants, car

$$z = \frac{\varepsilon^2}{\tau^2}\Big(1 + \frac{\sigma\varepsilon^2}{\tau^2}\Big)^{-1}, \qquad \zeta = 2\varepsilon^2 \log \frac{\tau}{\varepsilon}.$$

On va donc simplifier, pour $\tau \geq A$, la forme de u_a en $u \sim \dfrac{\varepsilon}{r^{1/2}} F_\varepsilon(r-t, \omega, \tau)$ (cette nouvelle fonction F_ε dépendant alors de ε). Le raccord entre les zones II et III consistera à imposer

$$F_\varepsilon(\sigma, \omega, A) = F\Big(\sigma, \omega, \frac{\varepsilon^2}{A^2}\Big(1 + \frac{\sigma\varepsilon^2}{A^2}\Big)^{-1}, A, 2\varepsilon^2 \log \frac{A}{\varepsilon}\Big).$$

Bien entendu, dans l'étude de $u_a^{III,e}$, on porte une attention particulière à l'explosion des dérivées d'ordre supérieur ou égal à deux. Ce sont ces résultats qui servent de point de départ, dans [2], à l'étude du comportement explosif de la vraie solution u.

2.1.4. L'erreur liée à l'approximation de u par u_a sera évaluée en calculant le comportement de $J_a = \Box u_a + g_{ij}^k \partial_k u_a \partial_{ij}^2 u_a$, et en obtenant des estimations de $\dot{u} = u - u_a$ en périodes I et II.

2.2. Description en période I. On définit les fonctions $u_j(x,t)$ $(j \geq 1)$ par

$$\Box u_1 = 0, \quad u_1(x,0) = u_1^0(x), \quad \partial_t u_1(x,0) = u_1^1(x), \tag{2.2.1}$$

$$\Box u_j + Q_j = 0, \qquad u_j(x,0) = u_j^0(x), \partial_t u_j(x,0) = u_j^1(x) \quad \text{pour } j \geq 2, \tag{2.2.2}$$

où $Q_p = \displaystyle\sum_{\ell+\ell'=p} g_{ij}^k \partial_k u_\ell \partial_{ij}^2 u_{\ell'}$.

Il est bien connu (cf. [4], [5]) que

$$u_1 \sim \frac{R(r-t,\omega)}{r^{1/2}} \quad (r \to +\infty, r - t \geq -C), \tag{2.2.3}$$

pour

$$R(\sigma,\omega)=\frac{1}{2\sqrt{2\pi}}\int_{s\geq\sigma}\frac{1}{\sqrt{s-\sigma}}\Big\{\tilde{R}(s,\omega,u_1^1)-\partial_s\tilde{R}(s,\omega,u_1^0)\Big\}\,ds, \tag{2.2.4}$$

$\tilde{R}(s,\omega,v)$ désignant la transformée de Radon

$$\tilde{R}(s,\omega,v)=\int_{x\omega=s}v(x)\,dx \quad \text{de } v.$$

Par ailleurs, on établit au lemme 3.2.1 que

$$u_2-\frac{g(\omega)}{2}(\partial_\sigma R)^2\sim\frac{L(r-t,\omega)}{r^{1/2}}\quad (r\to+\infty,\ r-t\geq -C)\ , \tag{2.2.5}$$

pour une certaine fonction C^∞ $L(\sigma,\omega)$.

2.2.1. En zone extérieure, la proposition 3.1.1 fournit une approximation arbitraire de u_k : pour tous $N,N'\in\mathbb{N}$, il existe des fonctions C^∞ L_k^ℓ et $R_k^{\ell,\ell'}$ telles que

$$u_k=\frac{1}{r^{1/2}}\Bigg\{\sum_{0\leq 2\ell\leq k-1}(\log t)^\ell L_k^\ell\Big(r-t,\omega,\frac{1}{r}\Big)+\sum_{\substack{\ell\geq 1\\ \ell+2\ell'\leq k-1}}t^{\ell/2}(\log t)^{\ell'}R_k^{\ell,\ell'}\Big(r-t,\omega,\frac{1}{r}\Big)\Bigg\}+r_k,$$

avec $r_k=O(r^{-N})$ et $\Box L_k^\ell/r^{1/2}=O(r^{-N'})$.

On considérera dans la suite N et N' comme fixés, très grands, selon les besoins. Les dépendances de L_k^ℓ et $R_k^{\ell,\ell'}$ ne sont jamais explicitées.

On prendra, pour q grand, à choisir,

$$u_a^{I,e}=\sum_{\ell=1}^{q}\varepsilon^\ell u_\ell, \tag{2.2.6}$$

d'où il résulte par construction $J_a=O(\varepsilon^{q+1}t^{(q-3)/2})$.

2.2.2. En zone intérieure, nous n'utilisons les termes u_k que pour $k\leq 7$. Nous prenons d'abord $u_1^i=u_1$, $u_2^i=u_2$; pour u_3^i et u_4^i, nous ne gardons que les deux termes principaux de $u_{3,a}$ et $u_{4,a}$; enfin, pour u_5^i, u_6^i et u_7^i, nous ne gardons que les termes principaux de $u_{5,a}$, $u_{6,a}$ et $u_{7,a}$ (tous ces termes sont explicités en §3.2).

Nous posons donc

$$u_a^{I,i}=\sum_{\ell=1}^{7}\varepsilon^\ell u_\ell^i\ . \tag{2.2.7}$$

2.2.3. Après recollement, on obtient pour J_a les estimations

$$\big|\partial_{x,t,\omega}^\alpha J_a\big|_0\leq C_\alpha\Big\{\frac{\varepsilon^3}{1+t}+\varepsilon^5(1+t)^{1/2}+\varepsilon^8(1+t)^{5/2}\Big\}\,|\log t|^{q-1}\,, \tag{2.2.8}$$

avec de plus à l'extérieur

$$\|\partial^{\alpha}_{x,t,\omega} J_a\|_0 \leq C_\alpha \ \varepsilon^{q+1} \ t^{(q-3)/2}. \tag{2.2.9}$$

2.2.4. Les deux fonctions R et L jouent dans la suite un rôle essentiel. Introduisons dès maintenant quelques commentaires et hypothèses qui s'y rapportent.

• Nous faisons sur R et g l'hypothèse de non dégénérescence suivante :

(ND) Il existe un point (σ_0, ω_0) et un nombre $\kappa \geq 2$ tels que

(i) $-g(\omega_0)\,\partial^2_\sigma R(\sigma_0, \omega_0) < 0$,

(ii) $\forall A$, $\exists C > 0$ avec, pour $|\sigma - \sigma_0| + |\omega - \omega_0| \leq A$,

$$-g(\omega)\,\partial^2_\sigma R(\sigma, \omega) \geq -g(\omega_0)\,\partial^2_\sigma R(\sigma_0, \omega_0) + C(|\sigma - \sigma_0| + |\omega - \omega_0|)^\kappa.$$

Remarquons que cela implique que (σ_0, ω_0) est un point (unique) de minimum absolu de $-g(\omega)\,\partial^2_\sigma R(\sigma, \omega)$.

Dans le cas spécial où l'équation considérée serait de la forme $\partial_t^2 u - c^2(u_t)\,\Delta u = 0$ et les données initiales invariantes par rotation, cette hypothèse devrait être remplacée par

(ND)′ Il existe un point σ_0 et un nombre $\kappa \geq 2$ tels que

(i) $-g\,\partial^2_\sigma R(\sigma_0) < 0$,

(ii) $\forall A$, $\exists C > 0$ avec, pour $|\sigma - \sigma_0| \leq A$,

$$-g\,\partial^2_\sigma R(\sigma) \geq -g\,\partial^2_\sigma R(\sigma_0) + C\,|\sigma - \sigma_0|^\kappa \ .$$

• Définissons la fonction $S(\sigma, \omega, \tau)$ par

$$\partial_\tau S - \frac{g}{2}(\partial_\sigma S)^2 = 0, \quad S(\sigma, \omega, 0) = R(\sigma, \omega) + \varepsilon L(\sigma, \omega) \ . \tag{2.2.10}$$

La fonction $\varepsilon/r^{1/2}\, S(r - t, \omega, \tau)$ apparaîtra ultérieurement comme une assez bonne approximation de u.

Comme c'est la dérivée S' de S qui satisfait une équation de Burger, on retrouve bien ici le fait que ce sont les dérivées secondes $\nabla^2 u$ qui "doivent" exploser.

• Posons

$$A_0 = \frac{1}{g(\omega_0)\,\partial^2_\sigma R(\sigma_0, \omega_0)}, \quad A_1 = -A_0^2\, g(\omega_0)\,\partial^2_\sigma L(\sigma_0, \omega_0), \quad \text{et} \quad \tau_* = \tau_*(\varepsilon) = A_0 + \varepsilon A_1.$$

Compte tenu de l'hypothèse (ND) et des propriétés bien connues de l'équation de Burger, on note que A_0 est le temps de vie de S pour $\varepsilon = 0$, tandis que $\tau_*(\varepsilon)$ approxime à $0(\varepsilon^2)$ près le temps de vie de S dans le cas général.

2.3. Description en période *II*.

2.3.1. En zone extérieure, et compte tenu de la proposition 3.1.1, nous remarquons que, formellement,

$$u_a^{I,e} \sim \frac{\varepsilon}{r^{1/2}} F(r - t, \omega, \frac{1}{r}, \tau, \zeta).$$

La proposition 4.1.1 permet de construire, dans un intervalle $0 \leq \tau \leq \tau_1$ (où $\tau_1 = A_0 + o(1)$), une fonction $F(\sigma, \omega, z, \tau, \zeta)$ qui se raccorde bien à $u_a^{I,e}$. Nous posons donc

$$u_a^{II,e} = \frac{\varepsilon}{r^{1/2}} F\Big(r - t, \omega, \frac{1}{r}, \tau, \zeta\Big). \tag{2.3.1}$$

2.3.2. En zone intérieure, nous choisissons

$$u_a^{II,i} = \varepsilon u_1 + \varepsilon^2 \Big(u_2 - \frac{g}{2}\chi\Big(\frac{t}{r}\Big)^{1/2} (\partial_\sigma R)^2\Big) + \chi \frac{\varepsilon}{r^{1/2}} \Big[S(r-t, \omega, \tau) - S(r-t, \omega, 0)\Big] , \tag{2.3.2}$$

où u_1, u_2, R et S sont définis au §2.2, tandis que χ dénote (par abus) une troncature

$$\chi\Big(\frac{r}{1+t}\Big), \quad \text{avec } \chi \in C^\infty(R), \quad \chi(s) = 0 \quad \text{pour } s \leq \frac{1}{2}, \quad \chi(s) = 1 \quad \text{pour } s \geq \frac{2}{3}.$$

On choisit l'expression (2.3.2) pour des raisons techniques : le lemme 4.2.1 indique en fait l'équivalence

$$u_a^{II,i} \sim \chi \frac{\varepsilon}{r^{1/2}} S(r - t, \omega, \tau). \tag{2.3.3}$$

2.3.3. Après recollement spatial et temporel, on obtient pour J_a en période II

$$\big|\partial^\alpha_{x,t,\omega} J_a\big|_0 \leq C_\alpha \frac{\varepsilon}{t^2} \log t \tag{2.3.4}$$

avec de plus à l'extérieur

$$\big\|\partial^\alpha_{x,t,\omega} J_a\big\|_0 \leq C_\alpha \ \varepsilon^{q+1-\lambda\left(\frac{q-3}{2}\right)} . \tag{2.3.5}$$

2.4. Bilan des erreurs en périodes I et II. Les estimations indiquées ci-dessus permettent d'établir sans difficulté le théorème suivant.

THÉORÈME 2.4.1. *Pour tout A, $0 < A < A_0$, il existe $\varepsilon_A > 0$ tel que, pour tout $0 < \varepsilon \leq \varepsilon_A$ et $t \leq \dfrac{A^2}{\varepsilon^2}$, on ait*

(i) $\big|\partial^\alpha_{x,t,\omega}(u - u_a)\big|_0 \leq C_\alpha \ \varepsilon^{23/9} \, |\log \varepsilon|$.

(ii) *Pour tout p, il existe q tel que l'on ait de plus, à l'extérieur,*

$$\big\|\partial^\alpha_{x,t,\omega}(u - u_a)\big\|_0 \leq C_\alpha \ \varepsilon^p.$$

Rappelons que q apparaît en (2.2.6). On choisit dorénavant q en sorte que ii) ait lieu pour $p = 8$.

2.5. Description en période III. Dans toute la suite on posera $z = \frac{1}{r}$, $\tau = \varepsilon\sqrt{t}$, $\zeta = \varepsilon^2 \log t$. Pour une fonction $S(\sigma, \omega, z, \tau, \zeta)$ régulière, on notera $S' = \partial_\sigma S$, $S'' = \partial_\sigma^2 S$, etc., et $\dot{S} = \partial_\tau S$, $\ddot{S} = \partial_\tau^2 S$, etc.

2.5.1. L'hypothèse (ND) sur le minimum de $-g\partial_\sigma^2 R$ assure que la solution $u_a^{II,i}$ définie par (2.3.2) n'explose pas en période III. Nous prenons donc

$$u_a^{III,i} = u_a^{II,i} . \tag{2.5.1}$$

2.5.2. Notons, pour la fonction F de (2.3.1),

$$F_A(\sigma,\omega) = F\Big(\sigma,\omega,\frac{\varepsilon^2}{A^2}\Big(1+\frac{\sigma\varepsilon^2}{A^2}\Big)^{-1}, A, 2\varepsilon^2\log\frac{A}{\varepsilon}\Big), \tag{2.5.2}$$

et définissons (par abus) une nouvelle fonction $F(\sigma,\omega,\tau)$ par

$$\partial_\tau F - \frac{g}{2}(\partial_\sigma F)^2 = 0, \qquad F(\sigma,\omega,A) = F_A(\sigma,\omega). \tag{2.5.3}$$

D'autre part, en notant

$$E(F) = -\frac{1}{\tau^3}\Big(\frac{1}{4}+\partial_\omega^2\Big)F - \frac{\sigma g}{2\tau^2}F'F'' - \frac{\partial_\tau F}{4\tau^2} + \frac{\partial_\tau^2 F}{4\tau} + g^k_{ij}(\omega_k F' A_{ij} F' + \omega_i\omega_j F'' A_k F)$$

l'expression introduite au lemme 6.1.1 (dans laquelle les A_k, A_{ij} sont des opérateurs d'ordre 1 en ∂_ω, ∂_τ), définissons une fonction $G(\sigma,\omega,\tau)$ par

$$\partial_\tau G - g(\partial_\sigma F)\partial_\sigma G = \int_M^\sigma E(F)\,ds, \qquad G(\sigma,\omega,A) = 0. \tag{2.5.4}$$

Nous choisissons alors

$$u_a^{III,e} = \frac{\varepsilon}{r^{1/2}}(F+\varepsilon^2 G)(r-t,\omega,\tau). \tag{2.5.5}$$

2.5.3. Le raccord entre les périodes II et III se traduit par l'estimation

$$\big\|\partial_{x,\omega}^\alpha(\partial_t^+)^k(u-u_a)\big\|_0 \le C_{\alpha,k}\varepsilon^8 \text{ pour } \tau = A, \tag{2.5.6}$$

où ∂_t^+ désigne la dérivée à droite en $t = \dfrac{A^2}{\varepsilon^2}$.

2.5.4. Après recollement, on obtient pour J_a les estimations

$$\text{A l'intérieur, } \big|\partial_{x,t,\omega}^\alpha J_a\big|_0 \le C_\alpha\varepsilon^5\,|\log\varepsilon|\,, \tag{2.5.7}$$

$$\left\{\begin{array}{ll} & \text{A l'extérieur, sous l'hypothèse (ND)} \\ & \text{(ou (ND)'), pour un } \nu_1 > 0, \\ \text{(i)} & |J_a|_0 \le C\dfrac{\varepsilon^7}{(\tilde\tau-\tau)^{3-\nu_1}}, \\ \text{(ii)} & |\nabla J_a|_0 + |\partial_\omega J_a|_0 \le C\dfrac{\varepsilon^7}{(\tilde\tau-\tau)^{9/2-\nu_1}}, \\ \text{(iii)} & |\nabla^2 J_a|_0 + |\partial_\omega\nabla J_a|_0 + |\partial_\omega^2 J_a|_0 \le C\dfrac{\varepsilon^7}{(\tilde\tau-\tau)^{6-\nu_1}}. \end{array}\right. \tag{2.5.8}$$

On a posé ici $\tilde\tau = \tilde\tau(\varepsilon) = \tau_*(\varepsilon) - C\varepsilon^{\kappa/\kappa-1} - C\varepsilon^2\,|\log\varepsilon|$, pour un C assez grand (cf. lemme 6.4.1).

2.5.5. La solution approchée u_a possède en outre les propriétés suivantes:

$$\text{A l'intérieur } \big\|\partial_{x,t,\omega}^\alpha u_a\big\|_0 \le C_\alpha\varepsilon^2\ . \tag{2.5.9}$$

$$
(2.5.10)\qquad \left\{\begin{array}{ll} & \text{A l'extérieur,}\\ \text{(i)} & |u_a| + |\nabla_{x,t,\omega} u_a| \le C\varepsilon^2\\ \text{(ii)} & \text{Pour } k \ge 2,\\ & \displaystyle\sum_{|\alpha|\le k} \left|\partial^\alpha_{x,t,\omega} u_a\right| \le C_\alpha \frac{\varepsilon^2}{(\tilde\tau-\tau)^{\frac{3k}{2}-\frac12}}\\ \text{(iii)} & \displaystyle\left\|\partial^2_{ij} u_a(x,t) - \frac{\varepsilon}{r^{1/2}}\omega_i\omega_j F''(r-t,\omega,\tau)\right\|_0 \le C\frac{\varepsilon^4}{(\tilde\tau-\tau)^{5/2}}\ . \end{array}\right.
$$

3. La solution en période I. On écrit formellement $u = \varepsilon u_1 + \varepsilon^2 u_2 + \cdots$, et l'on choisit les u_j en sorte que

(i) $\Box u_1 = 0$, $u_1|_{t=0} = u_1^0$, $\partial_t u_1|_{t=0} = u_1^1$, puis, pour $j \ge 2$,

(ii) $\Box u_j + Q_j = 0$, $u_j|_{t=0} = u_j^0$, $\partial_t u_j|_{t=0} = u_j^1$, où $Q_p = \sum_{\ell+\ell'=p} g^k_{ij}\,\partial_k u_\ell\,\partial^2_{ij} u_{\ell'}$.

Pour alléger, on écrira souvent $g\partial u\partial^2 v$ au lieu de $\sum_{i,j,k} g^k_{ij}\,\partial_k u\,\partial^2_{ij} v$.

Nous allons maintenant choisir des approximations des u_j à l'extérieur et à l'intérieur.

3.1. Les approximations à l'extérieur. Elle reposent sur le lemme suivant.

LEMME 3.1.1. *Soit S une fonction C^∞ de ses arguments.*

(a) *Pour tous $\mu \in \mathbb{R}$ et $k \in \mathbb{N}$, on a l'identité*

$$
\begin{aligned}
(3.1.1)\quad & \frac{1}{t^\mu(\log t)^k}\Box\frac{t^\mu(\log t)^k}{r^{1/2}} S\Big(r-t,\omega,\frac1r,\tau,\zeta\Big)\\
&= \frac{-2S'}{t\sqrt r}\Big(\mu+\frac{k}{\log t}\Big) + \frac{QS}{r^{5/2}} + \frac{1}{t^2\sqrt r}\Big(\mu(\mu-1) + \frac{(2\mu-1)k}{\log t} + \frac{k(k-1)}{(\log t)^2}\Big) S\\
&\quad + \frac{\varepsilon}{\sqrt{rt}}\left[-\Big(\dot S' + \frac z4 \dot S\Big) + \frac{\dot S}{t}\Big(\mu+\frac{k}{\log t}\Big)\right]\\
&\quad + \frac{\varepsilon^2}{t\sqrt r}\left[\frac{\ddot S}{4} - 2\partial_\zeta S' - z\partial_\zeta S + \frac2t\partial_\zeta S\Big(\mu+\frac{k}{\log t}\Big)\right] + \frac{\varepsilon^3}{t^{3/2}\sqrt r}\partial_\zeta \dot S + \frac{\varepsilon^4}{t^2\sqrt r}\partial^2_\zeta S,
\end{aligned}
$$

où $QS = -\Big(\frac14 + \partial^2_\omega\Big) S + 2\partial_z S' - 2z\partial_z S' - z^2\partial^2_z S$.

(b) *Pour toute $S(r-t,\omega)$, tous $\mu \in \mathbb{R}$ et $k \in \mathbb{N}$ et tous $N \in \mathbb{N}$, $N' \in \mathbb{N}$, il existe des fonctions $\Sigma_\ell\Big(r-t,\omega,\frac1r\Big)$ $(0 \le \ell \le k)$ et $L_\ell\Big(r-t,\omega,\frac1r\Big)$ $(0 \le \ell \le k+1)$ telles que*

$$
\Box\frac{1}{r^{1/2}}\left\{\sum_{\ell\le k} t^{\mu+\frac32}(\log t)^\ell\Sigma_\ell + \sum_{\ell\le k+1}(\log t)^\ell L_\ell\right\} = t^\mu(\log t)^k S + O(z^N).
$$

De plus, $\Box\dfrac{L_\ell}{r^{1/2}} = O(z^{N'})$, et Σ_0 ne contient pas de terme en $\Big(\dfrac1r\Big)^{\mu+3/2}$.

Preuve. (a) Remarquons tout d'abord qu'à l'extérieur, on peut écrire $t = r-\sigma = r(1-\sigma z)$ et $r = t\big(1+\frac{\sigma}{t}\big)$, ce qui permet d'échanger asymptotiquement toute puissance de r et toute puissance de t. On a

$$
\begin{aligned}
\Box t^\mu(\log t)^k u = t^\mu(\log t)^k\Big\{&\Box u + \frac2t\Big(\mu+\frac{k}{\log t}\Big)\partial_t u\\
&+\frac{1}{t^2}\Big(\mu(\mu-1) + \frac{(2\mu-1)k}{\log t} + \frac{k(k-1)}{(\log t)^2}\Big) u\Big\}\ .
\end{aligned}
$$

D'autre part,

$$\Box \frac{S}{r^{1/2}} = \frac{1}{r^{1/2}} \Big\{ \partial_t^2 - \partial_r^2 - \frac{1}{r^2} A \Big\} S,$$

où $A = \frac{1}{4} + \partial_\omega^2$; comme

$$(\partial_t + \partial_r) S = -\frac{1}{r^2} \partial_z S + \frac{\varepsilon}{2\sqrt{t}} \dot{S} + \frac{\varepsilon^2}{t} \partial_\zeta S,$$

$$\begin{aligned}(\partial_t^2 - \partial_r^2) S = &- \frac{2}{r^3} \partial_z S - \frac{1}{r^2} \Big\{ -2 \partial_z S' + \frac{1}{r^2} \partial_z^2 S + \frac{\varepsilon}{2\sqrt{t}} \partial_z \dot{S} + \frac{\varepsilon^2}{t} \partial_{z\zeta}^2 S \Big\} \\ &- \frac{\varepsilon}{4t^{3/2}} \dot{S} + \frac{\varepsilon}{2\sqrt{t}} \Big\{ -2\dot{S}' + \frac{1}{r^2} \partial_z \dot{S} + \frac{\varepsilon}{2\sqrt{t}} \ddot{S} + \frac{\varepsilon^2}{t} \partial_\zeta \dot{S} \Big\} - \frac{\varepsilon^2}{t^2} \partial_\zeta S \\ &+ \frac{\varepsilon^2}{t^2} \Big\{ -2 \partial_\zeta S' + \frac{1}{r^2} \partial_{z\zeta}^2 S + \frac{\varepsilon}{2\sqrt{t}} \partial_\zeta \dot{S} + \frac{\varepsilon^2}{t} \partial_\zeta^2 S \Big\},\end{aligned}$$

et on trouve

$$\begin{aligned}\Box \frac{S}{r^{1/2}} = \frac{1}{r^{5/2}} QS + \frac{\varepsilon}{\sqrt{rt}} \Big(-\dot{S}' - \frac{z}{4} \dot{S} \Big) + \frac{\varepsilon^2}{t\sqrt{r}} \Big(\frac{\ddot{S}}{4} - 2 \partial_\zeta S' - z \partial_\zeta S \Big) \\ + \frac{\varepsilon^3}{t^{3/2}\sqrt{r}} \partial_\zeta \dot{S} + \frac{\varepsilon^4}{t^2 \sqrt{r}} \partial_\zeta^2 S \ .\end{aligned}$$

(b) A l'aide de la formule (3.1.1) (appliquée à des fonctions indépendantes de τ, ζ), on obtient, si $\mu \neq -\frac{3}{2}$,

$$\Box \frac{t^{\mu+\frac{3}{2}}}{r^{1/2}} \left\{ \sum_{0 \leq \ell \leq k} (\log t)^\ell \Sigma_\ell (r-t, \omega) \right\} = t^\mu (\log t)^k S + \sum_{\substack{\ell \geq 0 \\ 0 \leq \ell' \leq k}} t^{\mu-1-\ell} (\log t)^{\ell'} S_{\ell,\ell'} (r-t, \omega),$$

avec

$$\Sigma_k(\sigma, \omega) = \frac{-1}{2(\mu + \frac{3}{2})} \int_M^\sigma S(s, \omega)\, ds, \text{etc.}$$

Si $\mu = -\frac{3}{2}$, on obtient

$$\Box \frac{(\log t)^{k+1} L(r-t, \omega, \frac{1}{r})}{r^{1/2}} = t^\mu (\log t)^k S + \sum_{\substack{\ell \geq 0 \\ \ell' \leq k}} t^{\mu-1-\ell} (\log t)^{\ell'} S_{\ell,\ell'} (r-t, \omega) + O(z^N),$$

en choisissant

$$L(\sigma, \omega, 0) = \frac{-1}{2(k+1)} \int_M^\sigma S(s, \omega)\, ds,$$

et L solution, à un ordre convenable en z, de $QL = 0$.

En répétant cette procédure, on obtient, si $\mu + \frac{3}{2} \notin \mathbb{N}$,

$$\Box \frac{1}{r^{1/2}} \Big(\sum_{\substack{\ell' \leq k \\ 0 \leq \ell \leq N}} t^{\mu+\frac{3}{2}-\ell} (\log t)^{\ell'} \Sigma_{\ell,\ell'} (r-t, \omega) \Big) = t^\mu (\log t)^k S + O(z^{N+1-\mu}).$$

Si $\mu+\frac{3}{2}=q\in\mathbb{N}$, on trouve

$$\Box\frac{1}{r^{1/2}}\Big\{\sum_{\substack{\ell'\le k\\ 0\le\ell\le N}} t^{\mu+\frac{3}{2}-\ell}(\log t)^{\ell'}\Sigma_{\ell,\ell'}(r-t,\omega) + \sum_{1\le\ell'\le k+1}(\log t)^{\ell'}L_{\ell'}\Big(r-t,\omega,\frac{1}{r}\Big)\Big\} = t^{\mu}(\log t)^k S + O(z^{N+1-\mu}).$$

De plus, $\Sigma_{q,0}=0$. Dans tous les cas, on réécrit le premier terme de la solution obtenue sous la forme

$$\sum_{\ell\le k}\frac{t^{\mu+\frac{3}{2}}}{r^{1/2}}(\log t)^{\ell}\Sigma_{\ell}\Big(r-t,\omega,\frac{1}{r}\Big)\ ,$$

Σ_0 vérifiant la condition du lemme. □

Nous sommes alors en mesure de prouver la proposition suivante.

PROPOSITION 3.1.1. *Pour tous $N,N'\in\mathbb{N}$, le terme u_k peut s'écrire*

$$u_k=\frac{1}{r^{1/2}}\Big\{\sum_{\substack{\ell\ge 0\\ 2\ell\le k-1}}(\log t)^{\ell}L_k^{\ell}\Big(r-t,\omega,\frac{1}{r}\Big) + \sum_{\substack{\ell\ge 1\\ \ell+2\ell'\le k-1}} t^{\ell/2}(\log t)^{\ell'}R_k^{\ell,\ell'}\Big(r-t,\omega,\frac{1}{r}\Big)\Big\}+r_k,$$

où

$$r_k=O(z^N),\quad \textit{et}\quad \Box\frac{L_k^{\ell}}{r^{1/2}}=O(z^{N'}).$$

De plus, si $\ell=2p$ $(p\ge 1)$, $R_k^{\ell,0}$ ne contient pas de terme en $\big(\frac{1}{r_k}\big)^p$.

Enfin, si l'on pose $U_k=\sum_{\ell=1}\varepsilon^{\ell}u_{\ell}$, on a

$$\mathcal{F}_k\equiv\Box U_k+g\,\partial U_k\,\partial^2U_k=\frac{\varepsilon^2}{r}\sum_{\substack{h\ge k-1\\ m+2p\le h}}\varepsilon^{h-m-2p}\tau^m\zeta^pF_{m,p}(\sigma,\omega,z),$$

avec la majoration $\mathcal{F}_k=O\big(\varepsilon^{k+1}t^{(k-3)/2}\big)$.

Preuve. (a) Pour $k=1$, on a $u_1=\frac{1}{r^{1/2}}R_0^{0,0}\big(r-t,\omega,\frac{1}{r}\big)$ (voir [5]). Procédons alors par récurrence, en supposant correcte la forme de u_j pour $j\le k-1$. Comme toute dérivée (en x ou t) de u_j a encore la même forme (en oubliant cette fois que $\frac{L_k^{\ell}}{r^{1/2}}$ est dans le noyau de $\Box$), on obtient

$$Q_k=\sum\frac{1}{r}t^{\ell/2}(\log t)^{\ell'}t^{q/2}(\log t)^{q'}R_j^{\ell,\ell'}R_{j'}^{q,q'},$$

où la somme $\sum$ est étendue à tous les indices ℓ,ℓ',q,q',j,j' tels que $\ell\ge 0$, $q\ge 0$, $\ell+2\ell'\le j-1$, $q+2q'\le j'-1$, $j+j'=k$.

En développant les fonctions R, on trouve formellement

$$Q_k=\sum_{p\ge 0,\,m\ge 0}t^{(m-2\ell)/2}(\log t)^pS_{m,p}(r-t,\omega),\quad \ell\ge 1,\quad m+2p\le k-2.$$

Le lemme 3.1.1 permet alors de "résoudre" $\Box v_k + Q_k = 0$ sous la forme

$$v_k = \frac{1}{r^{1/2}} \Big\{ \sum_{\substack{m+2p \le k-1 \\ m \ge 1}} t^{m/2} (\log t)^p \Sigma_{m,p}\Big(r-t, \omega, \frac{1}{r}\Big) + \sum_{\substack{2p \le k-1 \\ p \ge 1}} (\log t)^p L_p \Big\}.$$

En effet, les termes en $t^{-3/2}(\log t)^p$ dans Q_k ne peuvent apparaître que pour $m \ge 1$, donc pour $2p \le k-3$; le terme correspondant dans v_k est alors en $(\log t)^{p+1}$, où $2(p+1) \le k-1$. D'autre part, pour $m-2\ell \neq -3$, le terme de v_k correspondant au terme $t^{(m-2\ell)/2}(\log t)^p$ de Q_k est en $t^{(m+3-2\ell)/2}(\log t)^p$; on écrit $t^{(m+3-2\ell)/2} = t^{(m+1)/2} \frac{1}{t^{\ell-1}}$, et $(m+1)+2p \le k-1$ comme annoncé.

(b) Au point (a), on a obtenu v_k telle que $\Box v_k + Q_k$ soit de l'ordre d'une puissance de z arbitraire. On a donc $\Box(u_k - v_k)$ de décroissance arbitraire à l'extérieur: par vitesse finie de propagation $u_k - v_k$ coïncide à l'extérieur avec la solution w de $\Box w = f$, où f est de décroissance arbitraire. Par une adaptation immédiate de [1], on obtient que w diffère d'une solution libre par une fonction de décroissance arbitraire: $u_k - v_k = (L_k^0(r-t, \omega, \frac{1}{r}))/r^{1/2} + r_k$. La forme de u_k est donc celle annoncée.

(c) Comme $\Box U_k + g\partial U_k \partial^2 U_k = \sum_{k+1 \le \ell+\ell' \le 2k} \varepsilon^{\ell+\ell'} g\partial u_\ell \partial^2 u_{\ell'}$, et $|\partial^\alpha u_\ell| \le C \dfrac{t^{(\ell-1)/2}}{r^{1/2}}$, on a $\Box U_k + g\partial U_k \partial^2 U_k = O\Big(\varepsilon^{k+1} t^{\frac{k-3}{2}}\Big)$.

On peut aussi écrire

$$\varepsilon^k u_k = \frac{\varepsilon}{r^{1/2}} \sum \varepsilon^{k-1-\ell-2\ell'} \tau^\ell \zeta^{\ell'} R_k^{\ell,\ell'}(\sigma, \omega, z) \ ,$$

et

$$\mathcal{F}_k = \frac{\varepsilon^2}{r} \sum_{\substack{m \ge 0 \\ p \ge 0 \\ h \ge k-1 \\ m+2p \le h}} \varepsilon^{h-m-2p} \tau^m \zeta^p F_{m,p}(\sigma, \omega, z). \qquad \square$$

3.2. Les approximations à l'intérieur. Ici, on modifie le point de vue du §3.1, qui ne peut donner de résultats qu'à l'extérieur (voir §2.1) ; nous nous contentons de choisir pour les termes u_k^i des approximations assez grossières des u_k, en portant une attention spéciale au comportement symbolique en σ et à l'approximation des solutions d'équations d'ondes non homogènes.

Les développements de cette section sont très proches de la partie correspondante de [1], dans le cas irrotationnel $\omega \equiv 0$.

Le fait de travailler avec des données *générales* (c'est-à-dire non nécessairement invariantes par rotation) n'apporte aucune modification non triviale ; en particulier, le paragraphe 7 de [1] consacré au comportement des solutions de l'équation des ondes non homogène s'étend sans difficulté au cas général, avec estimation des dérivées ∂_ω^α (outre les dérivées en $\partial_{x,t}^\alpha$). Néanmoins, il est nécessaire ici d'augmenter la précision de la solution approchée, ce qui entraîne quelques complications techniques.

Nous nous contentons ici d'insister sur les aspects nouveaux de la construction, renvoyant le lecteur à [1] pour les généralités. Nous noterons génériquement S_m une fonction $S(r-t, \omega)$ qui se comporte comme un symbole d'ordre m en la première variable $\sigma = r - t$.

3.2.1 On choisit pour u_1^i la solution de $\Box u_1 = 0$, avec des données $u_1|_{t=0} = u_1^0$, $\partial_t u_1|_{t=0} = u_1^1$, c'est-à-dire $u_1^i \equiv u_1$.

Le comportement $u_1 \sim (R(r-t, \omega))/r^{1/2}$ est établi dans [4], [5].

3.2.2 On choisit pour u_2^i la solution de $\Box u_2 + g_{ij}^k \partial_k u_1 \partial_{ij}^2 u_1 = 0$, avec des données $u_2|_{t=0} = u_2^0$, $\partial_t u_2|_{t=0} = u_2^1$, c'est-à-dire $u_2^i \equiv u_2$.

Comme en [1], on introduit une troncature $\chi = \chi\Big(r/(1+t)\Big)$, où $\chi \in C^\infty(\mathbb{R})$, $\chi(s) = 0$ pour $s \leq \frac{1}{2}$, $\chi(s) = 1$ pour $s \geq \frac{2}{3}$.

Le lemme suivant précise le comportement asymptotique de u_2.

LEMME 3.2.1. *On a $u_2 = \overline{u}_2 + z$, avec $\overline{u}_2 = (1-\theta(t))\frac{g}{2}\sqrt{t/r}\,\chi R'^2$, (rappelons que $\theta \in C^\infty(\mathbb{R})$ vaut 1 près de $t=0$) et z vérifiant les propriétés:*

Il existe une fonction $L(\sigma,\omega)$ de classe C^∞, supportée dans $\sigma \leq M$, avec $\left|\partial_\omega^k L\right| \leq C_k(1+|\sigma|)^{1/2}$, et pour $\ell \geq 1$,

$$\int \left|\partial_\omega^k \partial_\sigma^\ell L\right|^2 (\sigma,\omega)\,d\sigma \leq C_{k,\ell}, \qquad \left|\partial_\omega^k \partial_\sigma^\ell L\right| \leq C_{k,\ell}\ ,$$

telle que

(i) *Pour $r \leq Ct$, $(C<1)$, $|\alpha| \geq 1$,*

$$\left|\partial_{x,t}^\alpha \partial_\omega^\beta z\right| \leq \frac{C}{(1+t)^{1+\frac{3}{4}\inf(|\alpha|,4)}}.$$

(ii) *Pour $r \geq Ct$, $(C<1)$, $|\alpha| \geq 1$,*

$$\left|\partial_{x,t}^\alpha \partial_\omega^\beta \Big(z - \frac{L(r-t,\omega)}{r^{1/2}}\Big)\right| \leq C_{\alpha,\beta}\Big\{\frac{S_{-1/2} + h_t(r-t,\omega)}{1+t} + \frac{S_{1/2}}{(1+t)^{3/2}}\Big\},$$

où $\int |h_t(\sigma,\omega)|^2\,d\sigma \leq 1$.

Preuve. (a) Il faut d'abord établir une forme précise du terme quadratique

$$Q_2 = g_{ij}^k \partial_k u_1 \partial_{ij}^2 u_1\ .$$

D'après [5], on sait que $u_1 = \frac{1}{r^{1/2}} F\Big(r-t,\omega,\frac{1}{r}\Big)$, où

$$\left|\partial_\omega^\alpha \partial_z^\beta \partial_\sigma^\gamma F(\sigma,\omega,z)\right| \leq C(1+|\sigma|)^{-\frac{1}{2}+|\beta|-|\gamma|}\ ,$$

et par ailleurs, $\left|\partial_{x,t}^\alpha u_1\right| \leq C_\alpha/(1+t)^{1+|\alpha|}$ pour $r \leq Ct$, $(C<1)$.

- Pour $r \leq Ct$, $(C<1)$, on a donc $Q_2 = O\Big(1/(1+t)^5\Big)$.
- Pour $r \geq Ct$, on peut écrire

$$u_1 = \frac{S_{-1/2}}{r^{1/2}} + \frac{S_{1/2}}{r^{3/2}} + \cdots + \frac{S_{\frac{k}{2}-1}}{r^{k/2}} + \cdots$$

$$\nabla u_1 = \frac{S_{-3/2}}{r^{1/2}} + \frac{S_{-1/2}}{r^{3/2}} + \cdots + \frac{S_{\frac{k}{2}-2}}{r^{k/2}} + \cdots, \qquad \nabla^2 u_1 = \frac{S_{-5/2}}{r^{1/2}} + \cdots + \frac{S_{\frac{k}{2}-3}}{r^{k/2}} + \cdots$$

On obtient donc

$$Q_2 = \frac{S_{-4}}{r} + \frac{S_{-3}}{r^2} + \frac{S_{-2}}{r^3} + \frac{S_{-1}}{r^4} + \frac{S_0}{r^5} + \cdots,$$

le premier terme valant en fait $g(\omega)\dfrac{R'R''}{r}$.

(b) On va maintenant relever les termes de Q_2. Remarquons que si

$$L \in S_m, \Box\chi\frac{L}{r^{1/2}} = \chi\frac{S_m}{r^{5/2}} + O\Big(\frac{1}{t^{5/2-m}}\Big),$$

donc

$$\Box\Big(\chi\frac{L}{r^{1/2}}t^\mu\Big) = t^{\mu-2}\chi\frac{S_m}{r^{1/2}} - 2\mu\chi\frac{L't^{\mu-1}}{r^{1/2}} + O\Big(\frac{1}{t^{\frac{5}{2}-m-\mu}}\Big).$$

Comme

$$t^\alpha = r^\alpha + \sum_{k\geq 1}\frac{S_{+k}}{r^{k-\alpha}},$$

on a finalement

$$\text{(3.2.1)}\quad \Box\Big(\chi\frac{L}{r^{1/2}}t^\mu\Big) = -2\mu\chi\frac{L'}{r^{3/2-\mu}} + \chi\Big(\frac{S_m}{r^{5/2-\mu}} + \frac{S_{m+1}}{r^{3/2-\mu}} + \cdots\Big) + O\Big(\frac{1}{t^{5/2-m-\mu}}\Big).$$

On en déduit, en commençant avec

$$\mu = \frac{1}{2},\quad m = -3,\quad \Box\overline{u}_2 + Q_2 = \frac{S_{-3}}{r^2} + \frac{S_{-2}}{r^3} + \cdots + O\Big(\frac{1}{t^5}\Big);$$

en relevant les termes successifs, il vient

$$\Box\Big(\overline{u}_2 + \chi\Big(\frac{S_{-2}}{r} + \frac{S_{-1}}{r^2} + \frac{S_0}{r^3}\Big)\Big) + Q_2 = O\Big(\frac{1}{t^5}\Big)\ .$$

(c) La solution de $\Box v = O\Big(\dfrac{1}{t^5}\Big)$ peut être étudiée à l'aide du paragraphe 7 de [1]: on a dans ce cas

$$\Big|O\Big(\frac{1}{t^5}\Big)\Big|_0 \leq \frac{C}{t^4},$$

donc $\lambda = 3$. Les estimations du lemme, qui sont trivialement vraies avec $L \equiv 0$ pour la partie explicite

$$\frac{S_{-2}}{r} + \frac{S_{-1}}{r^2} + \frac{S_0}{r^3}$$

de z, résultent alors du lemme 7 de [1], points b et c. □

3.2.3. Nous posons

$$\overline{u}_3 = (1-\theta(t))\chi\frac{t}{\sqrt{r}}\frac{g^2}{6}(R'^3)', \qquad \bar{\bar{u}}_3 = (1-\theta(t))\chi g\sqrt{\frac{t}{r}}R'L',$$

et nous choisissons $u_3^i = \overline{u}_3 + \bar{\bar{u}}_3$.

Les raisons de ce choix résultent d'une analyse du terme d'interaction cubique $Q_3 = g_{ij}^k\,\partial_k u_1\,\partial_{ij}^2 u_2 + g_{ij}^k\,\partial_k u_2\,\partial_{ij}^2 u_1$, qui est résumée dans le lemme suivant.

LEMME 3.2.2. *On a*

$$Q_3 = \chi\frac{g^2}{3}(R'^3)''\frac{\sqrt{t}}{r} + \chi\frac{g}{r}(R'L')' + W_1$$

et $\Box u_3 + Q_3 = W_2$, *avec*

$$\left|\partial^\alpha_{x,t,\omega} W_1\right|_0 + \left|\partial^\alpha_{x,t,\omega} W_2\right|_0 \leq \frac{C_\alpha}{1+t} \ .$$

Preuve. (a) On a

$$\begin{aligned} Q_3 = {} & g^k_{ij}\,\partial_k\Big(\chi\frac{R}{r^{1/2}}\Big)\partial^2_{ij}\Big(\overline{u}_2 + \chi\frac{L}{r^{1/2}}\Big) + g^k_{ij}\,\partial_k\Big(\overline{u}_2 + \chi\frac{L}{r^{1/2}}\Big)\partial^2_{ij}\Big(\chi\frac{R}{r^{1/2}}\Big) \\ & + g^k_{ij}\,\partial_k\Big(u_1 - \chi\frac{R}{r^{1/2}}\Big)\partial^2_{ij}u_2 + g^k_{ij}\,\partial_k u_2\,\partial^2_{ij}\Big(u_1 - \chi\frac{R}{r^{1/2}}\Big) \\ & + g^k_{ij}\,\partial_k\Big(\chi\frac{R}{r^{1/2}}\Big)\partial^2_{ij}\Big(z - \chi\frac{L}{r^{1/2}}\Big) + g^k_{ij}\,\partial_k\Big(z - \chi\frac{L}{r^{1/2}}\Big)\partial^2_{ij}\Big(\chi\frac{R}{r^{1/2}}\Big) \\ \equiv {} & Q^0_3 + Q^1_3 + Q^2_3. \end{aligned}$$

• Comme

$$|\partial^\alpha_{\overline{u}_2}|_0 \leq C(1+t)^{1/2}, \left|\partial^\alpha\Big(u_1 - \chi\frac{R}{r^{1/2}}\Big)\right| \leq \frac{C}{(1+t)^{3/2}}$$

si $|\alpha| \geq 1$, on a facilement

$$|\partial^\alpha Q^1_3|_0 \leq \frac{C}{1+t}.$$

• L'estimation de Q^2_3 est plus délicate, et fait appel au lemme 3.2 1: on obtient

$$|\partial^\alpha Q^2_3|_0 \leq \frac{C}{1+t}.$$

(b) Dans Q^0_3, les termes obtenus en faisant porter les dérivées uniquement sur la variable $r-t$ des symboles valent

$$\chi^2\frac{g^2}{3}(R'^3)''\frac{\sqrt{t}}{r} + \chi^2\frac{g}{r}(R'L')'.$$

Les différences avec les termes annoncés sont de la forme

$$(\chi - \chi^2)\frac{1}{t^{1/2}}S_{-13/2} + (\chi - \chi^2)\frac{1}{t}S_{-3/2} = O\Big(\frac{1}{t^{5/2}}\Big),$$

leurs normes L^2 sont bornées par $C/(1+t)^{3/2}$.

Tous les autres termes faisant intervenir R et $\overline{u}_2$ sont de la forme $\dfrac{S_m}{t^{3/2}}$, avec $m \leq -\dfrac{7}{2}$ ou sont majorés par $\dfrac{1}{t^5}$; tous les autres termes faisant intervenir R et L sont majorés par $\dfrac{S_{-3/2}}{t^2}$, ou sont $O\Big(\frac{1}{t^{9/2}}\Big)$. Tous ces termes sont bornés en norme L^2 par $\dfrac{C}{1+t}$. □

3.2.4. L'analyse des termes d'interactions $Q_\ell = \sum_{\ell'+\ell''=\ell} g^k_{ij}\,\partial_k u_{\ell'}\,\partial^2_{ij}u_{\ell''}$ devient vite fastidieuse pour $\ell \geq 4$. Il importe donc de systématiser un peu la construction.

• La forme de la solution en zone II ($t \geq \varepsilon^{-\lambda}$) et l'exigence $\|\nabla\dot{u}\|_0 = o(\varepsilon^{7/2})$ rendent nécessaire de choisir $\lambda > \dfrac{3}{2}$. Les termes de Q_ℓ qui sont négligeables sont ceux dont l'intégrale de la norme L^2 jusqu'au temps $\varepsilon^{-\lambda}$ est $o(\varepsilon^{5/2-\ell})$.

• D'autre part, en supposant le terme principal de u_ℓ de la forme $\overline{u}_\ell = \chi a_\ell^1(r-t,\omega)t^{\frac{1}{2}(\ell-2)}$, on trouve que le terme principal de Q_ℓ vaut $\chi t^{\frac{1}{2}(\ell-4)} g \sum (a_{\ell'}^1)'(a_{\ell''}^1)''$. On en déduit par récurrence que $\overline{u}_\ell$ a bien la forme voulue (grâce à la formule (3.2.1)).

• Des deux points précédents on déduit que Q_ℓ lui-même est négligeable si $t^{1/2(\ell-4)+1/2+1}|_{t=\varepsilon^{-\lambda}} = o(\varepsilon^{5/2-\ell})$, i.e. $-\lambda/2(\ell-1) > \frac{5}{2} - \ell$, soit $\ell > 7$ pour λ proche de $\frac{3}{2}$.

• De même, les termes non principaux de Q_ℓ, qui sont de la forme $S_m \times t^{1/2(\ell-4)-1/2}$, sont négligeables si $-\frac{\lambda}{2}(\ell-2) > \frac{5}{2} - \ell$, soit $\ell > 4$ pour λ proche de $\frac{3}{2}$.

Nous devons donc encore analyser en détail Q_4, exactement comme nous l'avons fait pour Q_3 au lemme 3.1. (c).

En notant $\overline{u}_4 = \chi \frac{g^3}{6} \frac{t^{3/2}}{r^{1/2}} (3R'^2 R''^2 + R'^3 R''')$, $\bar{\bar{u}}_4 = \chi \frac{g^2}{2} \frac{t}{r^{1/2}} (2R' R'' L' + R'^2 L'')$, on choisit $u_4^i = \overline{u}_4 + \bar{\bar{u}}_4$.

LEMME 3.2.3. *On a*

$$\Box u_4 + Q_4 = W_3 \ , \ \textit{avec} \ \left|\partial_{x,t,\omega}^\alpha W_3\right|_0 \leq \frac{C_\alpha}{(1+t)^{1/2}} \ .$$

Preuve. (a) On a

$$\begin{aligned}
Q_4 &= g_{ij}^k \partial_k u_2 \partial_{ij}^2 u_2 + g_{ij}^k \partial_k u_1 \partial_{ij}^2 u_3 + g_{ij}^k \partial_k u_3 \partial_{ij}^2 u_1 \\
&= \Big[g_{ij}^k \partial_k \overline{u}_2 \partial_{ij}^2 \overline{u}_2 + g_{ij}^k \partial_k \overline{u}_2 \partial_{ij}^2 \Big(\chi \frac{L}{r^{1/2}}\Big) \\
&+ g_{ij}^k \partial_k u_2 \partial_{ij}^2 \Big(z - \chi \frac{L}{r^{1/2}}\Big) + g_{ij}^k \partial_k \Big(\chi \frac{L}{r^{1/2}}\Big) \partial_{ij}^2 \overline{u}_2 + g_{ij}^k \partial_k \Big(z - \chi \frac{L}{r^{1/2}}\Big) \partial_{ij}^2 \overline{u}_2 \\
&+ g_{ij}^k \partial_k \Big(\chi \frac{L}{r^{1/2}}\Big) \partial_{ij}^2 \Big(\chi \frac{L}{r^{1/2}}\Big) + g_{ij}^k \partial_k \Big(z - \chi \frac{L}{r^{1/2}}\Big) \partial_{ij}^2 \Big(\chi \frac{L}{r^{1/2}}\Big) \Big] \\
&+ \Big[g_{ij}^k \partial_k \Big(\chi \frac{R}{r^{1/2}}\Big) \Big(\partial_{ij}^2 \overline{u}_3 + \partial_{ij}^2 \bar{\bar{u}}_3\Big) + g_{ij}^k \partial_k (\overline{u}_3 + \bar{\bar{u}}_3) \partial_{ij}^2 \Big(\chi \frac{R}{r^{1/2}}\Big) \\
&+ g_{ij}^k \partial_k \Big(u_1 - \chi \frac{R}{r^{1/2}}\Big) \partial_{ij}^2 u_3 + g_{ij}^k \partial_k u_3 \partial_{ij}^2 \Big(u_1 - \chi \frac{R}{r^{1/2}}\Big) \Big] = Q_4^0 + Q_4^1 \ .
\end{aligned}$$

Comme

$$\left|\partial^\alpha \Big(\partial_k \overline{u}_2 \partial_{ij}^2 \overline{u}_2 - \frac{g^2}{4} \frac{t}{r} \chi^2 \omega_k \omega_i \omega_j (R'^2)'(R'^2)''\Big)\right|_0 \leq \frac{C}{(1+t)^{1/2}} \ ,$$

$$\left|\partial^\alpha \Big(\partial_k \overline{u}_2 \partial_{ij}^2 \Big(\chi \frac{L}{r^{1/2}}\Big) - \chi^2 \frac{g}{2} \frac{\sqrt{t}}{r} \omega_k \omega_i \omega_j (R'^2)' L''\Big)\right|_0 \leq \frac{C}{1+t} \ ,$$

et que les autres types de termes Q_4^0 ont leur norme L^2 bornée par $\frac{C}{(1+t)^{1/2}}$, il vient

$$\left|\partial^\alpha \Big[Q_4^0 - \chi \Big\{ \frac{g^3}{2} (R'^2 R''^2)' + \frac{g^2}{r^{1/2}} (R' R'' L')' \Big\}\Big]\right|_0 \leq \frac{C}{(1+t)^{1/2}} \ .$$

De même

$$\left|\partial^\alpha \Big(\partial_k \Big(\chi \frac{R}{r^{1/2}}\Big) \partial_{ij}^2 \overline{u}_3 - \chi^2 \frac{g^2}{6} R' (R'^3)''' \omega_k \omega_i \omega_j\Big)\right|_0 \leq \frac{C}{(1+t)^{1/2}} \ ,$$

$$\left|\partial^\alpha\left(\partial_k\left(\chi\frac{R}{r^{1/2}}\right)\partial_{ij}^2\bar{\bar{u}}_3-\chi^2\frac{g}{r^{1/2}}R'(R'L')''\omega_k\omega_i\omega_j\right)\right|_0\leq\frac{C}{1+t}\ ,$$

et tous les autres termes de Q_4^1 ont leur norme L^2 bornée par $\dfrac{C}{(1+t)^{1/2}}$, d'où

$$\left|\partial^\alpha\left[Q_4^1-\chi\left\{\frac{g^3}{6}(R'(R'^3)'')'+\frac{g^2}{r^{1/2}}(R'(R'L')')'\right\}\right]\right|_0\leq\frac{C}{(1+t)^{1/2}}\ .$$

(b) Par application de (3.2.1), on voit que les termes non principaux de $\Box u_4$ satisfont l'estimation du lemme 3.2.3. □

3.2.5. Les termes $\bar{u}_5$, $\bar{u}_6$ et $\bar{u}_7$ sont de la forme indiquée en §3.2.4, et

$$|\partial^\alpha(\Box\bar{u}_\ell+Q_\ell)|_0\leq C(1+t)^{\frac{1}{2}(\ell-4)}\ .$$

Nous pouvons résumer toute la construction du paragraphe 3.2 dans la proposition suivante.

PROPOSITION 3.2.1. *Posons* $u_a=u_a^I=\varepsilon u_1^i+\varepsilon^2u_2^i+\cdots+\varepsilon^7u_7^i$, *où les* u_j^i *ont été construits aux* §§3.2.1–3.2.5. *Alors, pour* $t\leq\dfrac{\text{cte}}{\varepsilon^2}$,

$$\left|\partial_{x,t,\omega}^\alpha J_a\right|_0\leq C_\alpha\left\{\frac{\varepsilon^3}{1+t}+\varepsilon^5(1+t)^{1/2}+\varepsilon^8(1+t)^{5/2}\right\}.$$

3.3. Recollement et estimation de l'erreur. On pose finalement, avec $k\geq 7$ à choisir,

$$u_a^I=(1-\theta(r-t+C_0-1))u_a^e+\theta(r-t+C_0-1)u_a^i,$$

où $u_a^i=\varepsilon u_1^i+\ldots+\varepsilon^7u_7^i$, et $u_a^e=U_k$.

On a alors l'estimation suivante de l'erreur $J_a=J_a^I=\Box u_a^I+g\partial u_a^I\partial^2u_a^I$.

PROPOSITION 3.3.1. *Pour tout* k *et* $t\leq\dfrac{\text{cte}}{\varepsilon^2}$, *on peut choisir* N *et* N' *en sorte que*

$$\left|\partial_{x,t,\omega}^\alpha J_a\right|_0\leq C_\alpha\left\{\frac{\varepsilon^3}{1+t}+\varepsilon^5(1+t)^{1/2}+\varepsilon^8(1+t)^{5/2}\right\}|\log t|^{k-1},$$

et de plus, pour $r-t\geq -C_0+1$,

$$\left\|\partial_{x,t,\omega}^\alpha J_a\right\|_0\leq C_\alpha\varepsilon^{k+1}t^{\frac{k-3}{2}}.$$

Preuve. L'estimation est celle de la proposition 3.1.1 à l'extérieur, celle de la proposition 3.2.1 à l'intérieur.

Remarquons que pour $3\leq j\leq 7$, la différence $u_j-u_j^i$ est formée de termes contenant une puissance non nulle de z ou de $(\log t)$, ou de termes indépendants de z et $(\log t)$ de la forme $S(r-t,\omega)/r^{1/2}t^{\ell/2}$, avec $0\leq\ell\leq j-3$. Donc

$$u^e-u^i=\sum_{3\leq j\leq 7}\frac{\varepsilon^j}{r^{1/2}}\left\{\sum_{\substack{\ell\geq 1\\ \ell\leq 2j-1}}(\log t)^\ell L_j^\ell+\sum_{\substack{\ell\geq 1\\ \ell'\geq 1\\ \ell+2\ell'\leq j-1}}t^{\ell/2}(\log t)^{\ell'}R_k^{\ell,\ell'}+\sum_{\ell\leq j-3}t^{\ell/2}R_k^{\ell,0}\right\}$$
$$+\sum_{8\leq j\leq k}\varepsilon^iu_j.$$

On en déduit

$$\|\partial^\alpha(u^e-u^i)\|_0 \le C\,|\log t|^{k-1}\left\{\frac{\varepsilon^3}{(1+t)^{1/2}}+\varepsilon^8 t^3\right\},$$

et

$$\|\partial^\alpha(\partial_t+\partial_r)(u^e-u^i)\|_0 \le C\,|\log t|^{k-1}\left\{\frac{\varepsilon^3}{(1+t)^{3/2}}+\varepsilon^8 t^2\right\}.$$

On écrit alors, avec $\delta = u^i - u^e$,

$$\Box(\theta u^i+(1-\theta)u^e) = \theta\Box u^i+(1-\theta)\Box u^e+[\Box,\theta]\delta\ ,$$

$$\begin{aligned} g\partial(\theta u^i+(1-\theta)u^e)\partial^2(\theta u^i+(1-\theta)u^e) &= g\partial(u^e+\theta\delta)\partial^2(u^e+\theta\delta)\\ &= g\,\partial u^e\partial^2 u^e+\theta\{g\,\partial u^e\partial^2\delta+g\,\partial\delta\partial^2 u^e\}+\theta^2 g\,\partial\delta\partial^2\delta+g[\partial,\theta]\delta\partial^2(\theta\delta)\\ &\quad+g\,\partial\delta[\partial^2,\theta]\delta+g\,\partial u^e[\partial^2,\theta]\delta+g[\partial,\theta]\delta\partial^2 u^e\\ &= (1-\theta)g\,\partial u^e\partial^2 u^e+\theta g\,\partial u^i\partial^2 u^i+\theta(\theta-1)g\,\partial\delta\partial^2\delta+\text{crochets}, \end{aligned}$$

en sorte que

$$J_a = \theta J_a^i+(1-\theta)J_a^e+\text{crochets}.$$

Comme $[\Box,\theta] = -2\theta'(\partial_t+\partial_r)-\dfrac{\theta'}{r}$, on a

$$\|[\Box,\theta]\delta\|_0 \le C\,|\log t|^{k-1}\left\{\frac{\varepsilon^3}{(1+t)^{3/2}}+\varepsilon^8 t^2\right\};$$

d'autre part, les termes quadratiques contenant des crochets sont bornés par $\dfrac{C\varepsilon}{r^{1/2}}\,\|\partial^\alpha\delta\|_0$ qui est encore inférieur, d'où l'estimation. □

4. La solution en période *II*. Soit dorénavant fixé A, $0<A<A_0$. Il s'agit maintenant de prolonger, pour $0\le\tau\le A$, la solution construite en période I.

4.1. La construction à l'extérieur. Remarquons que

$$u_a^e = U_k = \frac{\varepsilon}{r^{1/2}}\left\{\sum\varepsilon^{k-1-2\ell}\zeta^\ell L_k^\ell+\sum\varepsilon^{k-1-\ell-2\ell'}\tau^{\ell/2}\zeta^{\ell'}R_k^{\ell,\ell'}\right\}+\cdots$$

avec les propriétés supplémentaires indiquées à la proposition 3.1.

Cela conduit à chercher une solution approchée de l'équation sous la forme $u = \dfrac{\varepsilon}{r^{1/2}}F(\sigma,\omega,z,\tau,\zeta)$, avec $\sigma = r-t$, $z=\dfrac{1}{r}$, $\tau=\varepsilon\sqrt{t}$, $\zeta=\varepsilon^2\log t$, F dépendant elle même de ε (nous ne l'indiquons jamais) ; F devra en outre s'écrire $F = F_0+\tau G$, $F_0(\sigma,\omega,z,\zeta) = F(\sigma,\omega,z,0,\zeta)$ vérifiant, identiquement en ζ, l'équation

$$Q F_0 \equiv \left[-\left(\frac14+\partial_\omega^2\right)+2(1-z)\partial_{z\sigma}^2-z^2\partial_z^2\right]F_0 = 0 \quad \text{(cf. (3.1.1))}.$$

4.1.1 Les variables étant surabondantes, nous indiquons dans le lemme suivant le choix opéré.

LEMME 4.1.1. *Pour toute fonction F régulière, en posant*

$$u = \frac{\varepsilon}{r^{1/2}}F\Big(r-t,\omega,\frac1r,\varepsilon\sqrt{t},\varepsilon^2\log t\Big),$$

on a

$$\partial_i u = \frac{\varepsilon}{r^{1/2}}(\omega_i F' + z A_i F),\ \partial_{ij}^2 u = \frac{\varepsilon}{r^{1/2}}(\omega_i\omega_j F'' + z A_{ij} F)\ ,$$

où A_i *et* A_{ij} *sont des opérateurs différentiels en* $(\sigma, \omega, z, \tau, \zeta)$. *De plus,*

$$\Box u + g\partial_u \partial^2 u = \frac{\varepsilon}{r^{5/2}} Q F_0 + \frac{\varepsilon^2}{\sqrt{rt}}\Big\{ z(1-\sigma z) Q G - \Big(\dot F' + \frac{z}{4}\dot F\Big)$$
$$+\frac{\tau z}{1-\sigma z}\Big(\frac{\ddot F}{4} - 2\partial_\zeta F' - z\partial_\zeta F\Big) + \frac{\tau^2 z^2}{(1-\sigma z)^2}\partial_\zeta \dot F + \frac{\tau^3 z^3}{(1-\sigma z)^3}\partial_\zeta^2 F$$
$$+(1-\sigma z)^{1/2} g_{ij}^k (\omega_k F' + z A_k F)(\omega_i\omega_j F'' + z A_{ij} F)\Big\}.$$

Preuve. C'est (3.1.1) pour $\mu = k = 0$, où l'on utilise $t = r(1 - \sigma z)$. □

Nous définirons dorénavant, pour simplifier, l'opérateur H et la forme quadratique q par l'identité

$$\Box u + g\partial u \partial^2 u = \frac{\varepsilon}{r^{5/2}} Q F_0 + \frac{\varepsilon^2}{\sqrt{rt}}\Big\{ HF + q(F,F)\Big\}.$$

Bien entendu, il nous suffira de résoudre l'équation d'onde à des approximations arbitraires $O(z^N) + O(\zeta^{N'})$.

Les résultats de cette étude formelle en z et ζ sont résumées dans la proposition suivante.

PROPOSITION 4.1.1. (i) (*Existence*). *Pour tous* N, N', *et toutes fonctions* $\varphi_\ell(\sigma,\omega)$ $(\ell \le N-2)$, *on peut trouver une fonction* $F = F_0 + \tau G$ *définie pour* $\tau \in [0, \tau_1]$ *telle que* $QF_0 = O(z^N)$, $HF + q(F,F) = O(z^N) + O(\zeta^{N'})$, *avec*

$$\partial_\tau^{2\ell}\partial_z^\ell F(\sigma,\omega,0,0,0) = \varphi_\ell(\sigma,\omega) \quad \textit{pour } 0 \le \ell \le N-2.$$

(ii) (*Unicité*). *Si une fonction* $F = F_0 + \tau G$ *vérifie* $QF_0 = O(z^N)$, $HF + q(F,F) = O(z^N) + O(\zeta^{N'})$ *et* $\partial_\tau^{2\ell}\partial_z^\ell F(\sigma,\omega,0,0,0) = \varphi_\ell(\sigma,\omega)$ *pour* $0 \le \ell \le N-2$, *elle est déterminée à* $O(z^{N-1}) + O(\zeta^{N'})$ *près.*

Preuve. (a) Notons d'abord que $F_0|_{z=0}$ détermine tout le jet en z d'une solution de $QF_0 = 0$, car toutes les fonctions considérées sont bien entendu supportées pour $\sigma \le M$. Inversement, on peut trouver une solution F_0 de $QF_0 = O(z^N)$ pour laquelle $F_0|_{z=0}$ est donnée.

(b) Posons $G = \sum_{k\ge 0} G_k z^k$, $F_0 = \sum_{k\ge 0} f_k z^k$, et ordonnons l'équation $HF + q(F,F) = 0$ selon les puissances de z.

• Pour $z = 0$, on trouve

$$(4.1)_0 \qquad -\tau\dot G_0' - G_0' + g(f_0' + \tau G_0')(f_0'' + \tau G_0'') = 0.$$

• D'autre part, le terme en z^{k-1} dans QG vaut

$$-\Big(\frac14 + \partial_\omega^2\Big) G_{k-1} + 2kG_k' - 2(k-1)G_{k-1}' - (k-1)(k-2)G_{k-1}.$$

Remarquons que dans les opérateurs zA_iF, $zA_{ij}F$, les termes qui contiennent des dérivées en z sont de la forme $z^k\partial_z$, $k \ge 2$, ou $z^4\partial_z^2$; le terme en z^ℓ dans zA_jF

ou $zA_{ij}F$ ne fait donc intervenir que les coefficients f_j, G_j pour $j \leq \ell - 1$. Le terme en z^k dans $q(F,F)$, que nous noterons $q_k(F,F)$, vaut alors

$$
\begin{aligned}
&g\Big\{(f_0' + \tau G_0')(f_k'' + \tau G_k'') + \ldots + (f_k' + \tau G_k')(f_0'' + \tau G_0'')\Big\} \\
&\quad -\frac{\sigma}{2} g\Big\{(f_0' + \tau G_0')(f_{k-1}'' + \tau G_{k-1}'') + \ldots + (f_{k-1}' + \tau G_{k-1}')(f_0'' + \tau G_0'')\Big\} \\
&\quad + g_{ij}^p \omega_i \omega_j \Big\{(f_0'' + \tau G_0'')\,\tilde{A}_p(f_{k-1} + \tau G_{k-1}) + \ldots + (f_{k-1}'' + \tau G_{k-1}'')\,\tilde{A}_p(f_0 + \tau G_0)\Big\} \\
&\quad + g_{ij}^p \omega_p \Big\{(f_0' + \tau G_0')\,\tilde{A}_{ij}(f_{k-1} + \tau G_{k-1}) + \ldots + (f_{k-1}' + \tau G_{k-1}')\,\tilde{A}_{ij}(f_0 + \tau G_0)\Big\} \\
&\quad + \text{termes en } G_j \ \ (j \leq k-2)\ ,
\end{aligned}
$$

où $\tilde{A}_p$ et $\tilde{A}_{ij}$ désignent les parties "de poids zéro" de A_p et A_{ij} (qui ne contiennent pas de dérivées en ζ).

L'annulation du terme en z^k conduit à l'équation

$$
\begin{aligned}
(4.1)_k \quad &-\tau \dot{G}_k' + (2k-1) G_k' + \Big\{ -\Big(\frac{1}{4} + (k-1)(k-2) + \partial_\omega^2\Big) G_{k-1} - 2(k-1) G_{k-1}' \\
&\quad -\frac{1}{4}(\tau \dot{G}_{k-1} + G_{k-1}) + \frac{\tau}{4}(\tau \ddot{G}_{k-1} + 2\dot{G}_{k-1}) - 2\tau^2 \partial_\zeta G_{k-1}' \Big\} \\
&\quad + q_k(F,F) = \text{termes en } F_0\ ,\quad G_j\ \ (j \leq k-2)\ .
\end{aligned}
$$

(c) L'équation $(4.1)_0$ détermine G_0 en fonction de f_0 : en particulier, $G_0 = \frac{g}{2}(f_0')^2 + \frac{g^2}{2}\tau (f_0')^2 f_0'' + \tau^2 \ldots$.

Ecrivons $(4.1)_1$:

$$
-\tau \dot{G}_1' + G_1' - \Big(\frac{1}{2} + \partial_\omega^2\Big) G_0 - 2\tau^2 \partial_\zeta G_0' - 2\tau \partial_\zeta f_0' + q_1(F,F) = 0.
$$

Avec $f_1' = +\frac{1}{2}\Big(\frac{1}{4} + \partial_\omega^2\Big) f_0$, posons $G_1 = \sum_{\ell \geq 0} G_1^\ell \tau^\ell$; pour $\tau = 0$, on obtient de $(4.1)_1$

$$
G_1^{0\prime} - \Big(\frac{1}{2} + \partial_\omega^2\Big) G_0 + \text{termes en } f_0 = 0;
$$

l'annulation du terme en τ dans $(4.1)_1$ fournit

$$
-2\partial_\zeta f_0' + g\Big\{G_0' f_1'' + f_0' G_1^{0\prime\prime} + f_1' G_0'' + f_0'' G_1^{0\prime} - \frac{\sigma}{2}(f_0' G_0'' + f_0'' G_0')\Big\} + \text{termes en } f_0 = 0.
$$

Si l'on exprime G_1^0 dans la deuxième équation à l'aide de la première, on obtient une équation en f_0 de la forme $\partial_\zeta f_0' +$ (termes en f_0 sans dérivées en ζ) $= 0$. Comme $f_0|_{\zeta=0} = \varphi_0$, on en déduit f_0 à $O(\zeta^{N'})$ près.

Avec ce choix de f_0, on résoud $(4.1)_0$ sur un certain intervalle $[0, \tau_1]$, et tous les autres f_k sont déterminés (à la même approximation), ainsi que G_1^0 ; si l'on note $G_1 = G_1^0 + \tau^2 \tilde{G}_1$, l'équation $(4.1)_1$ se réduit, après division par τ^2, à

$$
-\tau \dot{\tilde{G}}_1' - \tilde{G}_1' + g(f_0' + \tau G_0')\tau \tilde{G}_1'' + g(f_0'' + \tau G_0'')\tau \tilde{G}_1' = \text{termes connus}.
$$

Cette équation linéaire possède une (unique) solution sur le même intervalle $[0, \tau_1]$.

On a ainsi résolu $(4.1)_1$, G_1 n'étant déterminé qu'à un élément près du noyau.

(d) Abordons maintenant la résolution de $(4.1)_k$, $k \geq 2$. A ce stade, F_0 est connue, ainsi que les G_j, $j \leq k-2$. Le noyau de l'équation $(4.1)_{k-1}$ est formé des fonctions v vérifiant

$$-\tau \dot{v} + (2k-3)v + \tau g(f_0' + \tau G_0')v' = 0.$$

Ces fonctions sont de la forme

$$v = h\tau^{2k-3} + \tau^{2k-2}\tilde{h},$$

où h est arbitraire, $\tilde{h}$ étant déterminé par h. Plus précisément,

$$v = h\tau^{2k-3} + g f_0' h' \tau^{2k-2} + \frac{1}{2}\Big(g^2(f_0')^2 h'' + (g^2 f_0' f_0'' + g G_0')h'\Big)\tau^{2k-1} + \tau^{2k}\ldots.$$

L'équation $(4.1)_k$ détermine les coefficients G_k^ℓ de $G_k = \sum_{\ell \geq 0} G_k^\ell \tau^\ell$ pour $\ell \leq 2k-4$; les coefficients G_k^{2k-3} et G_k^{2k-2} sont alors connus en fonction de h. L'annulation du terme en τ^{2k-1} conduit à une équation en h de la forme

$$-2\partial_\zeta h' + (\text{termes en } h \text{ sans dérivées en } \zeta) = \text{termes connus}.$$

Comme pour f_0, la connaissance de $h|_{\zeta=0} = \varphi_{k-1}$ détermine h à $O(\zeta^{N'})$ près. On peut alors trouver sur $[0, \tau_1]$ une solution de $(4.1)_k$ sous la forme $G_k = \sum_{0 \leq \ell \leq 2k-2} G_k^\ell \tau^\ell + \tau^{2k}\tilde{G}_k$, $\tilde{G}_k$ satisfaisant une équation linéaire à point singulier régulier et à indices négatifs. □

4.1.2. Choix de u_a^e. Compte tenu de la structure de la solution $U_k = \sum_{\ell \leq k} \varepsilon^\ell u_\ell$ construite à la proposition 3.1, on a

$$\Big(\frac{r^{1/2}}{\varepsilon} U_k\Big)(\sigma, \omega, 0, 0, 0) = \sum_{\ell \leq k} \varepsilon^\ell L_\ell^0(\sigma, \omega, 0) = \varphi_0(\sigma, \omega), \tag{4.1.1}$$

$$(\partial_\tau^{2\ell}\partial_z^\ell)\Big(\frac{r^{1/2}}{\varepsilon} U_k\Big)(\sigma, \omega, 0, 0, 0) = 0.$$

Nous choisissons donc pour u_a^e la fonction $\frac{\varepsilon}{r^{1/2}} F$, où F est donnée par la proposition 4.1, correspondant aux fonctions $\varphi_0, \varphi_1 = 0, \ldots, \varphi_\ell = 0$, φ_0 définie ci-dessus. Comme $(4.1)_0$ signifie que $v = f_0 + \tau G_0$ est solution de $\partial_\tau v = \frac{g}{2}(\partial_\sigma v)^2$, avec $v(\sigma, \omega, 0, \zeta) = f_0(\sigma, \omega, \zeta) = R(\sigma, \omega) + O(\varepsilon) + O(\zeta)$, le temps de vie de G_0 vaut $A_0 + O(\varepsilon)$.

La solution construite $u_a^{II,e}$ existe donc et est régulière pour $0 \leq \tau \leq A$, pour ε assez petit.

4.1.3. Recollement. Dans la période de transition $\varepsilon^{-\lambda} \leq t \leq 2\varepsilon^{-\lambda}$, la solution U_k fournit une autre solution approchée (à $\varepsilon^{k+1-\lambda(\frac{k-3}{2})}$ près) de $\Box u + g\partial u \partial^2 u = 0$ de la forme $\frac{\varepsilon}{r^{1/2}} F$: la partie "unicité" de la proposition 4.1 garantit que les deux solutions diffèrent arbitrairement peu pour N, N' et k assez grands (pour $\lambda < 2$ fixé).

4.2. La construction a l'intérieur. Comme en §4.1, nous nous limitons à $0 \leq \tau \leq A$. Ici, on simplifie résolument la construction à l'extérieur, mais, comme en §3.2, on doit apporter un soin particulier à l'étude du comportement en σ, et au recollement entre les deux périodes.

4.2.1 Les symboles $R(\sigma,\omega)$ et $L(\sigma,\omega)$ ont été définis au 3.2. Définissons $S = S_\varepsilon(\sigma,\omega,\tau)$ comme la solution de

$$\partial_\tau S - \frac{g}{2}(\partial_\sigma S)^2 = 0, \qquad S(\sigma,\omega,0) = R(\sigma,\omega) + \varepsilon L(\sigma,\omega). \tag{4.2.1}$$

Par analogie avec le traitement de [1], nous posons

$$u = u_a^i = \varepsilon u_1^i + \varepsilon^2 z + \chi \frac{\varepsilon}{r^{1/2}} K(r-t,\omega,\tau), \tag{4.2.2}$$

où

$$K(\sigma,\omega,\tau) = S(\sigma,\omega,\tau) - S(\sigma,\omega,0),$$

u_1^i et z ayant été définis au paragraphe 3.2 a et b.

L'approximation obtenue par le choix (4.2.2) est précisée au lemme suivant.

LEMME 4.2.1. *On a* $\left|\partial^\alpha_{x,t,\omega} J_a\right|_0 \le C_\alpha \dfrac{\varepsilon}{t^2}$.

Preuve. (a) Calculons $\Box u$: d'après le lemme 3.2.1 et sa preuve, $\Box z = W$ satisfait à $|\partial^\alpha W|_0 \le C_\alpha/(1+t)^{3/2}$. Donc

$$\Box u = \varepsilon^2 W - \frac{\varepsilon^2 \chi}{\sqrt{rt}} \partial_\tau K' + H_1,$$

où

$$H_1 = \frac{\varepsilon}{r^{1/2}}\left\{(\chi_{tt} - \chi'')K - 2K'(\chi_t + \chi') + \frac{\varepsilon}{\sqrt{t}}\partial_\tau K\left(\chi_t - \frac{\chi}{4t}\right) + \chi\frac{\varepsilon^2}{4t}\partial_\tau^2 K - \frac{\chi}{r^2}\left(\frac{1}{4} + \partial_\omega^2\right)K\right\}.$$

Par ailleurs, on peut écrire u sous la forme

$$\begin{aligned} u &= \chi\frac{\varepsilon S(r-t,\omega,\tau)}{r^{1/2}} + \varepsilon\left(u_1 - \chi\frac{R(r-t,\omega)}{r^{1/2}}\right) + \varepsilon^2\left(z - \chi\frac{L(r-t,\omega)}{r^{1/2}}\right) \\ &= \chi\frac{\varepsilon}{r^{1/2}} S(r-t,\omega,\tau) + \varepsilon r_1, \end{aligned}$$

les estimations de r_1 résultant du lemme 3.2.b. On a donc

$$g_{ij}^k \partial_k u \partial_{ij}^2 u = \varepsilon^2 g \frac{\chi^2}{r} S' S'' + \varepsilon^2 H_2,$$

avec

$$\begin{aligned} H_2 = &\left\{g_{ij}^k \partial_k\left(\frac{\chi S}{r^{1/2}}\right)\partial_{ij}^2\left(\chi\frac{S}{r^{1/2}}\right) - g\frac{\chi^2}{r} S' S''\right\} \\ &+\left\{g_{ij}^k \partial_k\left(\chi\frac{S}{r^{1/2}}\right)\partial_{ij}^2 r_1 + g_{ij}^k \partial_k r_1 \partial_{ij}^2\left(\chi\frac{S}{r^{1/2}}\right) + g_{ij}^k \partial_k r_1 \partial_{ij}^2 r_1\right\} = H_2^1 + H_2^2. \end{aligned}$$

Finalement

$$J_a = \varepsilon^2 W + H_1 + \varepsilon^2 H_2 + \chi\frac{\varepsilon^2}{r\sqrt{t}}\partial_\tau S' \frac{t-r}{\sqrt{t+\sqrt{r}}} + \frac{\chi(\chi-1)}{r}\varepsilon^2 g S' S''.$$

(b) On voit facilement, comme dans [1], que S est borné en σ, tandis que S' est essentiellement en $\frac{1}{\sigma}$ ($|\sigma| \to +\infty$). On en déduit que $K = \frac{g}{2}\int_0^\tau R'^2(\sigma,\omega,s)\,ds$ se comporte en $\frac{1}{\sigma^2}$. D'autre part, à l'intérieur, la fonction S ne présente aucune singularité pour $\tau \leq A$, à cause de (ND). On a alors

$$|\partial^\alpha H_1|_0 \leq \frac{C\varepsilon}{(1+t)^2} \quad \text{et} \quad |\partial^\alpha H_2^1|_0 \leq \frac{C}{(1+t)^{3/2}}.$$

Un terme typique de H_2^2 est

$$\partial_{ij}^2\Big(\chi\frac{S}{r^{1/2}}\Big)\Big\{\partial_k\Big(u_1 - \chi\frac{R}{r^{1/2}}\Big) + \varepsilon\partial_k\Big(z - \chi\frac{L}{r^{1/2}}\Big)\Big\} :$$

le premier produit est majoré par $\dfrac{S_{-3}}{t^2}$, le second par $\varepsilon\dfrac{S_{-5/2}}{t^{3/2}}$; ce terme est donc majoré en norme L^2 par

$$\frac{C}{(1+t)^{3/2}} + \frac{C\varepsilon}{1+t} \leq \frac{C}{(1+t)^{3/2}};$$

quant au terme $\partial_k r_1\,\partial_{ij}^2 r_1$, il est majoré par

$$\frac{S_{-2}}{t^3} + \varepsilon\frac{S_{-1}}{t^{5/2}} + \varepsilon^2\frac{S_{-1}}{t^2}.$$

Au total, $|\partial^\alpha H_2^2|_0 \leq C/(1+t)^{3/2}$. Les autres termes de J_a sont négligeables, et l'on trouve

$$|\partial^\alpha J_a|_0 \leq \frac{C\varepsilon^2}{(1+t)^{3/2}} + \frac{C\varepsilon}{(1+t)^2} \leq C\frac{\varepsilon}{(1+t)^2}. \qquad \square$$

4.2.2. Le recollement. Les solutions u_a^i construites en périodes I et II aux §§3.2 et 4.2.1. se recollent très bien en période de transition $\varepsilon^{-\lambda} \leq t \leq 2\varepsilon^{-\lambda}$. En effet, on peut écrire

$$\begin{aligned} u^I = \varepsilon u_1 + \chi\frac{g}{2r^{1/2}}\varepsilon\tau R'^2 + \varepsilon^2 z + \frac{\chi g^2}{6r^{1/2}}\varepsilon\tau^2(R'^3)' + \frac{\chi g}{r^{1/2}}\varepsilon^2\tau R'L' \\ + \chi\frac{g^3}{6r^{1/2}}\varepsilon\tau^3(3R'^2R''^2 + R'^3R''') + \chi\frac{g^2}{2r^{1/2}}\varepsilon^2\tau^2(2R'R''L' + R'^2L'') \\ + \varepsilon^5\overline{u}_5 + \varepsilon^6\overline{u}_6 + \varepsilon^7\overline{u}_7, \end{aligned}$$

et

$$\begin{aligned} u^{II} - u^I = \chi\frac{\varepsilon}{r^{1/2}}\Big\{S(r-t,\omega,\tau) - R - \frac{g}{2}\tau R'^2 - \frac{g^2}{6}\tau^2(R'^3)' \\ - \frac{g^3}{6}\tau^3(3R'^2R''^2 + R'^3R''') - a_5^1\tau^4 - a_6^1\tau^5 - a_7^1\tau^6\Big\} \\ - \chi\frac{\varepsilon^2}{r^{1/2}}\Big\{L + g\tau R'L' + \frac{g^2}{2}\tau^2(2R'R''L' + R'^2L'')\Big\}. \end{aligned}$$

Il faut d'abord éclaircir la structure des termes principaux $\overline{u}_\ell = \chi a_\ell^1(r-t,\omega t^{\frac{1}{2}(\ell-2)})$ de u_ℓ, en affinant l'analyse amorcée au §3.2.4. ($a_1^1(\sigma,\omega) = R(\sigma,\omega)$).

LEMME 4.2.2. *L'expression* $\sum_{\ell\geq 1}\tau^{\ell-1}a^1_\ell(\sigma,\omega)$ *est le développement de Taylor en* τ *de la solution* $R(\sigma,\omega,\tau)$ *de l'équation*

$$\partial_\tau R=\frac{g}{2}(\partial_\sigma R)^2,\qquad R(\sigma,\omega,0)=R(\sigma,\omega). \tag{4.2.3}$$

Preuve. (a) Le terme principal de $Q_\ell=\sum_{\ell'+\ell''=\ell}g^k_{ij}\,\partial_k u_{\ell'}\,\partial^2_{ij}u_{\ell''}$ vaut

$$\chi t^{\frac{1}{2}(\ell-4)}g\sum(a^1_{\ell'})'(a^1_{\ell''})''=\chi g t^{\frac{1}{2}(\ell-4)}\Big\{\sum_{\ell'<\ell'',\,\ell'+\ell''=\ell}(a^1_{\ell'})'(a^1_{\ell''})'+\frac{1}{2}[(a^1_{\ell/2})']^2\Big\}',$$

d'où, pour $\ell\geq 2$ d'après (3.2.1),

$$a^1_\ell=\frac{1g}{\ell-1}\Big\{\quad\Big\}.$$

(b) Pour une donnée arbitraire $A_1(\sigma,\omega)$, soit $A(\sigma,\omega,\tau)$ la solution de $\partial_\tau A=\frac{g}{2}(A')^2$, $A(\sigma,\omega,0)=A_1(\sigma,\omega)$. Elle s'écrit formellement

$$A=A_1+\tau A_2+\tau^2A_3+\cdots+\tau^kA_{k+1}+\cdots,$$

en sorte que l'équation

$$A_2+2\tau A_3+\cdots+k\tau^{k-1}A_{k+1}+\cdots=\frac{g}{2}\Big\{A'_1+\tau A'_2+\cdots+\tau^kA'_{k+1}+\cdots\Big\}^2$$

conduit aux relations

$$A_2=\frac{g}{2}(A'_1)^2,\ldots,(k-1)A_k=\frac{g}{2}\Big\{2\sum_{\substack{\ell'+\ell''=k\\ \ell'\leq\ell''}}A'_{\ell'}A'_{\ell''}+(A'_{k/2})^2\Big\}.$$

Comme $a^1_1=R(\sigma,\omega)$, le lemme est prouvé. □

De la même façon, en notant $\bar{\bar{u}}_\ell=\chi a^2_\ell(r-t,\omega)t^{\frac{1}{2}(\ell-3)}$ le terme "sous principal" de u_ℓ ($a^2_1=0$, $a^2_2=L$), on obtient le lemme suivant.

LEMME 4.2.3. *L'expression* $\sum_{\ell\geq 2}\tau^{\ell-2}a^2_\ell(\sigma,\omega)$ *est le développement de Taylor en* τ *de la solution* $L(\sigma,\omega,\tau)$ *de l'équation*

$$\partial_\tau L=g(\partial_\sigma R)(\partial_\sigma L),\qquad L(\sigma,\omega,0)=L(\sigma,\omega), \tag{4.2.4}$$

la fonction $R(\sigma,\omega,\tau)$ *étant définie par* (4.2.3).

Preuve. (a) Le terme "sous principal" de Q_ℓ est le terme principal dans l'expression

$$\sum_{\ell'+\ell''=\ell}\Big\{g^k_{ij}\,\partial_k\bar{u}_\ell,\,\partial^2_{ij}\bar{\bar{u}}_{\ell''}+g^k_{ij}\,\partial_k\bar{\bar{u}}_{\ell'}\,\partial^2_{ij}\bar{u}_{\ell''}\Big\},$$

soit

$$\chi t^{\frac{1}{2}(\ell-5)}g\sum_{\ell'+\ell''=\ell}\Big\{(a^1_{\ell'})'(a^2_{\ell''})''+(a^2_{\ell'})'(a^1_{\ell''})''\Big\}.$$

Donc, pour $\ell\geq 2$, grâce à (3.2.1),

$$a^2_\ell=\frac{g}{\ell-2}\Big\{\sum_{\substack{\ell'<\ell''\\ \ell'+\ell''=\ell}}(a^1_{\ell'})'(a^2_{\ell''})'+(a^1_{\ell''})'(a^2_{\ell'})'+(a^1_{\ell/2})'(a^2_{\ell/2})'\Big\}.$$

(b) Pour une donnée arbitraire $B_2(\sigma,\omega)$, soit $B(\sigma,\omega,\tau)$ la solution de

$$\partial_\tau B = g A' B', \qquad B(\sigma,\omega,0) = B_2,$$

où $A = A_1 + \tau A_2 + \cdots$.

Elle s'écrit $B = B_2 + \tau B_3 + \cdots + \tau^k B_{k+2} + \cdots$, en sorte que l'équation

$$B_3 + \cdots + k\tau^{k-1} B_{k+2} + \cdots = g(A_1' + \cdots + \tau^k A_{k+1}' + \cdots)(B_2' + \cdots + \tau^j B_{j+2}' + \cdots)$$

conduit aux relations

$$(\ell - 2) B_\ell = g \sum_{\ell'+\ell''=\ell} A_{\ell'}' B_{\ell''}'. \qquad \square$$

Compte tenu des lemmes 4.2.2 et 4.2.3, on peut donc écrire

$$\begin{aligned} u^{II} - u^I = \chi \frac{\varepsilon}{r^{1/2}} \Big\{ S(r-t,\omega,\tau) - R(r-t,\omega,\tau) - \varepsilon L(r-t,\omega,\tau) \Big\} \\ + \chi \frac{\varepsilon}{r^{1/2}} \Big\{ R(r-t,\omega,\tau) - \sum_{1\le\ell\le 7} \tau^{\ell-1} a_\ell^1(r-t,\omega) \Big\} \\ + \chi \frac{\varepsilon}{r^{1/2}} \Big\{ L(r-t,\omega,\tau) - \sum_{2\le\ell\le 4} \tau^{\ell-2} a_\ell^2(r-t,\omega) \Big\} . \end{aligned}$$

Le premier terme est étudié au lemme suivant.

LEMME 4.2.4. *La solution $S(\sigma,\omega,\tau)$ de (4.2.1) s'écrit*

$$S(\sigma,\omega,\tau) = R(\sigma,\omega,\tau) + \varepsilon L(\sigma,\omega,\tau) + \varepsilon^2 \tilde{S}(\sigma,\omega,\tau),$$

où R et L sont définis respectivement par (4.2.3) et (4.2.4), et où $\tilde{S}$ est intégrable en σ.

Preuve. En remplaçant dans l'équation de S, on trouve

$$\begin{aligned} \partial_\tau R + \varepsilon \partial_\tau L + \varepsilon^2 \partial_\tau \tilde{S} = \frac{g}{2} (\partial_\sigma R + \varepsilon \partial_\sigma L + \varepsilon^2 \partial_\sigma \tilde{S})^2 = \frac{g}{2} (\partial_\sigma R)^2 + \varepsilon g (\partial_\sigma R)(\partial_\sigma L) \\ + \varepsilon^2 g \Big(\partial_\sigma R \partial_\sigma \tilde{S} + \frac{1}{2} (\partial_\sigma L)^2 \Big) + \varepsilon^3 g \partial_\sigma L \partial_\sigma \tilde{S} + \frac{g}{2} \varepsilon^4 (\partial_\sigma \tilde{S})^2, \end{aligned}$$

soit

$$\partial_\tau \tilde{S} = g(\partial_\sigma R + \varepsilon \partial_\sigma L) \partial_\sigma \tilde{S} + \varepsilon^2 \frac{g}{2} (\partial_\sigma \tilde{S})^2 + \frac{g}{2} (\partial_\sigma L)^2, \qquad \tilde{S}(\sigma,\omega,0) = 0.$$

On voit facilement (comme dans [1, Lem. 5.1.1]) que $R(\sigma,\omega,\tau)$ se comporte comme un symbole d'ordre $-\frac{1}{2}$ en σ, tandis que $\partial_\sigma L$ est dans $L^2(\mathbb{R}_\sigma)$. On en déduit que $\tilde{S}$ est intégrable en σ. $\square$

On obtient finalement les estimations suivantes:

$$\begin{aligned} \big| \partial_{x,t,\omega}^\alpha (u^{II} - u^I) \big|_0 &\le C\varepsilon^3 + C\varepsilon^8 (1+t)^{7/2} + C\varepsilon^5 (1+t)^{3/2} \\ &\le C\varepsilon^8 (1+t)^{7/2} \end{aligned} \tag{4.2.5}$$

(car $t \sim \varepsilon^{-\lambda}$, $\lambda > \frac{3}{2}$),

$$\big\| \partial_{x,t,\omega}^\alpha (u^{II} - u^I) \big\|_0 \le C\varepsilon^8 (1+t)^3. \tag{4.2.6}$$

4.2.3. Estimation de J_a en zone de transition et choix de λ. On pose, pour $\varepsilon^{-\lambda} \le t \le 2\varepsilon^{-\lambda}$,

$$u = u_a = \theta(t\varepsilon^{+\lambda})u^I + (1-\theta(t\varepsilon^{+\lambda}))u^{II}.$$

LEMME 4.2.5. *En zone de transition, on a, si* $\frac{3}{2} < \lambda \le \frac{14}{9}$,

$$|\partial^\alpha_{x,t,\omega} J_a|_0 \le \frac{C_\alpha \varepsilon}{t^2}.$$

Preuve. On écrit

$$\begin{aligned} J_a = \theta\Box u^I + (1-\theta)\Box u^{II} + 2\varepsilon^{+\lambda}\theta'(u^I - u^{II}) + \varepsilon^{+2\lambda}\theta''(u^I - u^{II}) \\ + g^k_{ij}\theta^2 \partial_k u^I \partial^2_{ij} u^I + g^k_{ij}(1-\theta)^2 \partial_k u^{II} \partial^2_{ij} u^{II} \\ + \theta(1-\theta) g^k_{ij}(\partial_k u^I \partial^2_{ij} u^{II} + \partial_k u^{II} \partial^2_{ij} u^I) + r \ , \end{aligned}$$

où r regroupe les termes contenant au moins une dérivée de θ, d'où

$$|\partial^\alpha r|_0 \le C \frac{\varepsilon^{2+\lambda}}{(1+t)^{1/2}}.$$

Donc

$$\begin{aligned} J_a = \theta J^I_a + (1-\theta) J^{II}_a + r + (2\varepsilon^{+\lambda}\theta' + \varepsilon^{+2\lambda}\theta'')(u^I - u^{II}) \\ + \theta(\theta-1)\Big\{ g^k_{ij}\partial_k u^I \partial^2_{ij} u^I + g^k_{ij}\partial_k u^{II}\partial^2_{ij} u^{II} \\ - g^k_{ij}(\partial_k u^I \partial^2_{ij} u^{II} + \partial_k u^{II}\partial^2_{ij} u^I)\Big\} \end{aligned}$$

et le dernier terme vaut $\theta(\theta-1) g^k_{ij}\partial_k(u^I - u^{II})\partial^2_{ij}(u^I - u^{II})$. Finalement,

$$\begin{aligned} |\partial^\alpha J_a|_0 \le C\Big\{ \frac{\varepsilon^3}{1+t} + \varepsilon^5(1+t)^{1/2} + \varepsilon^8(1+t)^{5/2} + \frac{\varepsilon}{(1+t)^2} + \frac{\varepsilon^{2+\lambda}}{(1+t)^{1/2}} \\ + \varepsilon^{+\lambda+8}(1+t)^{7/2} + \varepsilon^{16}(1+t)^{6,5}\Big\} \le C\frac{\varepsilon}{(1+t)^2} \end{aligned}$$

pour $\frac{3}{2} \le \lambda \le \frac{14}{9}$. □

On fixe dorénavant $\lambda = \frac{14}{9}$.

4.3. Le recollement intérieur/extérieur. On procède exactement comme au §3.3.

• On a

$$u^e_a = \frac{\varepsilon}{r^{1/2}} F\Big(r-t, \omega, \frac{1}{r}, \tau, \zeta\Big),$$

et avec les notations de la proposition 4.1.1, $F = f_0 + \tau G_0 + O(z)$. D'après $(4.1)_0$, la fonction $v = f_0 + \tau G_0$ est solution de

$$\dot v = \frac{g}{2}(\partial_\sigma v)^2, \qquad v(\sigma,\omega,0,\zeta) = f_0(\sigma,\omega,\zeta), \tag{4.3.1}$$

et la fonction f_0 satisfait, par construction et grâce à (4.1.1),

$$f_0 = \varphi_0 + O(\zeta) = R(\sigma,\omega) + \varepsilon L(\sigma,\omega) + \sum_{2\le\ell\le k} \varepsilon^\ell L^0_\ell(\sigma,\omega,0) + O(\zeta). \tag{4.3.2}$$

On a donc

$$\|\partial^\alpha (S-v)\|_0 \leq C_\alpha \varepsilon^2 (\log t)\ . \tag{4.3.3}$$

• Par ailleurs, dans la zone de recollement,

$$u_1 - \frac{R}{r^{1/2}} \quad \text{et} \quad z - \frac{L}{r^{1/2}}$$

se comportent comme les premiers termes négligés qui sont de la forme

$$\frac{S_{1/2}(r-t,\omega)}{r^{3/2}} \quad \text{et} \quad \frac{S_{-2}(r-t,\omega)}{r},$$

respectivement. Donc

$$\left\| (\partial_t + \partial_r)\left[\varepsilon\Big(u_1 - \frac{R}{r^{1/2}}\Big) + \varepsilon^2\Big(z - \frac{L}{r^{1/2}}\Big)\right]\right\|_0 \leq C\frac{\varepsilon}{t^{5/2}}.$$

La preuve est alors identique à celle de la proposition 3.3.1 et conduit au résultat suivant.

PROPOSITION 4.3.1. *Pour $u_a = u_a^{II} = \theta u_a^i + (1-\theta)u_a^e$ on a*

$$\left|\partial^\alpha_{x,t,\omega} J_a\right|_0 \leq C_\alpha \frac{\varepsilon \log t}{t^2}.$$

5. Conclusions pour les périodes I et II. On a fixé A, $0 < A < A_0$ et l'on a construit aux paragraphes 3 et 4 une solution approchée u_a (pour $t \leq \dfrac{A^2}{\varepsilon^2}$) de l'équation $\Box u + g\,\partial u\,\partial^2 u = 0$ sous la forme

$$u_a = \theta(t\varepsilon^\lambda)\Big\{\theta(r-t+C_0-1)u_a^{I,i} + (1-\theta(r-t+C_0-1))u_a^{I,e}\Big\}$$
$$+(1-\theta)(t\varepsilon^\lambda)\Big\{\theta(r-t+C_0-1)u_a^{II,i} + (1-\theta(r-t+C_0-1))u_a^{II,e}\Big\}\Big(\lambda = \frac{14}{9}\Big),$$

pour laquelle on a prouvé l'estimation

$$\int_0^{\frac{A^2}{\varepsilon^2}} \left|\partial^\alpha_{x,t,\omega} J_a\right|_0 ds \leq C_\alpha \varepsilon^{23/9}\,|\log\varepsilon| \tag{5.1}$$

(c'est une conséquence immédiate des propositions 3.3, 4.3 et du lemme 4.2.5).

En fait, pour tout $p \in \mathbb{N}$, on peut choisir q en sorte que u_a vérifie, à l'extérieur,

$$\left\|\partial^\alpha_{x,t,\omega} J_a\right\|_0 \leq C_\alpha \varepsilon^p. \tag{5.2}$$

Un argument standard d'inégalités d'énergie (cf. [5], [1]), utilisant l'hypothèse d'induction sur le temps

$$\left\|\partial^2_{x,t,\omega}(u-u_a)\right\|_0 \leq \frac{\varepsilon}{(1+t)^{1/2}},$$

permet alors de conclure que, pour $0 < A < A_0$ et ε petit, on a, pour $t \leq \dfrac{A^2}{\varepsilon^2}$,

$$\left|\partial^\alpha_{x,t,\omega} \nabla(u-u_a)\right|_0 \leq C_\alpha \varepsilon^{23/9}\,|\log\varepsilon|\,. \tag{5.3}$$

Le même argument, utilisé cette fois dans un domaine $t \geq C_0$, $t - C_0 \leq r \leq 2\dfrac{A^2}{\varepsilon^2} + M - t$, où seule (5.2) intervient, montre qu'en fait, pour tout p, on peut trouver q tel que

$$\text{(5.4)} \qquad \text{A l'extérieur,} \quad \left\| \partial^{\alpha}_{x,t,\omega} \nabla (u - u_a) \right\|_0 \leq C_{\alpha}\, \varepsilon^p.$$

6. La solution en période *III*. Nous n'avons pour l'instant étudié u_a et u que pour $\tau \leq A$, $0 < A < A_0$.

Nous abordons maintenant l'étude du moment où τ s'approche de la valeur critique $\tau_*(\varepsilon)$, où les dérivées secondes de u_a deviennent infinies quelque part à l'extérieur (cf. §2).

A l'intérieur, nous conserverons la solution approchée $u_a^{II,i}$ construite au paragraphe 4.2, puisqu'elle n'explose pas.

6.1. Nous allons d'abord simplifier la structure de $u_a^{II,e}$ en remarquant que, pour

$$\tau \geq A > 0, \qquad z = \frac{\varepsilon^2}{\tau^2}\left(1 + \frac{\sigma \varepsilon^2}{\tau^2}\right)^{-1}.$$

Le lemme suivant est une variante du lemme 4.1.

LEMME 6.1.1. *Pour toute fonction F, en posant $u = \dfrac{\varepsilon}{r^{1/2}} F(r - t, \omega, \tau)$, on a*

$$\text{(6.1.1)} \qquad \Box u + g\, \partial u\, \partial^2 u$$
$$= \frac{\varepsilon^2}{\sqrt{rt}} \Bigg\{ - \dot{F}' + g F' F'' + \varepsilon^2 \Bigg[- \frac{1}{\tau^3}\left(\frac{1}{4} + \partial_{\omega}^2\right) F - \frac{\sigma g}{2\tau^2} F' F'' - \frac{\dot{F}}{4\tau^2} + \frac{\ddot{F}}{4\tau}$$
$$+ g^k_{ij}\left(\omega_k F' A_{ij} F' + \omega_i \omega_j F'' A_k F\right)\Bigg] + \varepsilon^4 R(F) \Bigg\},$$

où les A_k, A_{ij} sont des opérateurs différentiels en ∂_{ω}, ∂_{τ} d'ordre 1 à coefficients réguliers en $(\omega, \tau, \varepsilon^2\sigma)$, et R est une expression quadratique de dérivées de F précisée en (6.2.1).

Preuve. (a) D'après (3.1.1), on a

$$\Box u = \frac{-\varepsilon}{r^{5/2}}\left(\frac{1}{4} + \partial_{\omega}^2\right) F - \frac{\varepsilon^2}{\sqrt{rt}}\left(\dot{F}' + \frac{\dot{F}}{4r}\right) + \frac{\varepsilon^3}{\sqrt{r}\, t}\, \frac{\ddot{F}}{4}.$$

(b) On a, pour $i \geq 1$,

$$\tilde{\partial}_i F = r^{1/2}\, \partial_i \frac{F}{r^{1/2}} = \omega_i F' + \frac{\varepsilon^2}{\tau^2}\left(\frac{t}{r}\right)\left(- \frac{\omega_i}{2} F + \omega_i \perp \partial_{\omega} F\right)$$

et

$$\tilde{\partial}_0 F = \partial_0 F = -F' + \frac{\varepsilon^2}{2\tau} \dot{F},$$

donc $\tilde{\partial}_i = \omega_i \partial_{\sigma} + \varepsilon^2 A_i$, où A_i est un opérateur du premier ordre en $\partial_{\omega}, \partial_{\tau}$, à coefficients réguliers en $(\omega, \tau, \varepsilon^2\sigma)$, car $\dfrac{t}{r} = \left(1 + \varepsilon^2 \dfrac{\sigma}{\tau^2}\right)^{-1}$.

De façon générale, pour $|\alpha| = k$,

$$\tilde{\partial}^{\alpha} = \omega^{\alpha}\, \partial_{\sigma}^k + \varepsilon^2 A^1_{\alpha}\, \partial_{\sigma}^{k-1} + \varepsilon^4 A^2_{\alpha}\, \partial_{\sigma}^{k-2} + \cdots + \varepsilon^{2k} A^k_{\alpha},$$

où A^k_α est un opérateur d'ordre k en $(\partial_\omega, \partial_\tau)$, à coefficients réguliers en $(\omega, \tau, \varepsilon^2\sigma)$.

On notera en particulier $\tilde\partial^2_{ij} F = \omega_i\omega_j F'' + \varepsilon^2 A_{ij} F' + \varepsilon^4 B_{ij} F$, en sorte que les termes quadratiques $g\partial u\partial^2 u$ s'écrivent

$$\frac{1}{\varepsilon^2} g\partial u\partial^2 u = g^k_{ij}\frac{1}{r}\tilde\partial_k F\tilde\partial^2_{ij} F = \frac{1}{r}\Big\{ g F' F'' + \varepsilon^2 g^k_{ij}(A_k F\omega_i\omega_j F'' + \omega_k F' A_{ij} F') + \varepsilon^4 g^k_{ij}(A_k F A_{ij} F' + \omega_k F' B_{ij} F) + \varepsilon^6 g^k_{ij} A_k F B_{ij} F\Big\}.$$

On obtient ainsi le résultat, avec

$$R(F) = \Big(\frac{t}{r}\Big)^{1/2}\Big\{ g^k_{ij}(A_k F A_{ij} F' + \omega_k F' B_{ij} F) + \varepsilon^2 g^k_{ij} A_k F B_{ij} F\Big\} + * g^k_{ij}(\omega_k F' A_{ij} F' + \omega_i\omega_j F'' A_k F) + \sum_{|\alpha|\le 2} * \partial^\alpha_{\sigma,\omega,\tau} F, \tag{6.1.2}$$

$*$ désignant des coefficients réguliers en (σ, ω, τ). □

Dorénavant, nous noterons $E(F)$ le terme $-\frac{1}{\tau^3}\big(\frac{1}{4} + \partial^2_\omega\big) F + \cdots$ entre crochets au lemme 6.1.1.

Désignons par $F_A(\sigma, \omega)$ la valeur prise en $\tau = A$ par $\dfrac{r^{1/2}}{\varepsilon} u^e_a$, construite au §4.1.

Notons alors F la solution de

$$\partial_\tau F = \frac{g}{2}(\partial_\sigma F)^2, \qquad F(\sigma, \omega, A) = F_A(\sigma, \omega), \tag{6.1.3}$$

et G la solution de

$$\partial_\tau G - g\partial_\sigma F\partial_\sigma G = \int_M^\sigma E(F)\, ds, \qquad G(\sigma, \omega, A) = 0. \tag{6.1.4}$$

Enfin, posons

$$u_a = u^{III,e}_a = \frac{\varepsilon}{r^{1/2}}\Big(F(r-t, \omega, \tau) + \varepsilon^2 G(r-t, \omega, \tau)\Big).$$

6.2. Estimation de l'erreur sur $\tau = A$. Le raccord (brutal) entre les périodes *II* et *III* est justifié par le lemme suivant.

LEMME 6.2.1. *La fonction S étant définie par* (4.2.1), *on a*

(i) $F_A(\sigma, \omega) = S(\sigma, \omega, A) + O(\varepsilon^2 \log \varepsilon)$,

(ii) *Pour $\tau = A$, $\big\|\partial^\alpha_{x,\omega}(\partial^+_t)^k(u - u_a)\big\|_0 \le C_{\alpha,k}\varepsilon^8$, où ∂^+_t désigne la dérivée à droite en $t = \dfrac{A^2}{\varepsilon^2}$.*

Preuve. (a) L'estimation (i) est prouvée au §4.3.

(b) Notons $u^I_a = \dfrac{\varepsilon}{r^{1/2}} F_\pm(r - t, \omega, \tau)$ les solutions approchées en périodes *II* et *III* (pour $t \le A^2/\varepsilon^2$ et $t \ge A^2/\varepsilon^2$, respectivement), exprimées en variables (σ, ω, τ) au voisinage de $\tau = A$.

On a, pour

$$\tau = A, \qquad \partial^+_t(u - u_a) = \partial_t u - \frac{\varepsilon}{r^{1/2}}\Big(-F'_+ + \frac{\varepsilon}{2\sqrt{t}}\dot F_+\Big),$$

$$\partial_t^-(u-u_a) = \partial_t u - \frac{\varepsilon}{r^{1/2}}\Big(-F'_- + \frac{\varepsilon}{2\sqrt{t}}\dot{F}_-\Big),$$

en sorte que

$$\partial_t^+(u-u_a) - \partial_t^-(u-u_a) = \frac{\varepsilon}{r^{1/2}}\Big((F_+ - F_-)' - \frac{\varepsilon}{2\sqrt{t}}\overbrace{(F_+ - F_-)}^{\bullet}\Big) = -\frac{\varepsilon^2}{2\sqrt{rt}}\overbrace{(F_+ - F_-)}^{\bullet},$$

à cause des choix (6.1.3), (6.1.4) ($F_+ = F + \varepsilon^2 G$).

Or, si une fonction régulière F satisfait une équation du type

$$-\dot{F}' + gF'F'' + \varepsilon^2[\text{dérivées de } F] + \cdots = r,$$

la donnée $F|_{\tau=A}$ détermine $\dot{F}|_{\tau=A}$ à une erreur près de l'ordre de r.

Pour F_-, r est arbitrairement petit, tandis que $r = O(\varepsilon^4)$ pour F_+ ; donc

$$\overbrace{(F_+ - F_-)}^{\bullet} = O(\varepsilon^4).$$

Comme d'autre part on sait par (5.4) que $\big\|\partial_{x,\omega}^{\alpha}(\partial_t^-)^k(u-u_a)\big\|_0 \le C_\alpha \varepsilon^p$, on obtient (ii). □

6.3. Estimations des dérivées de F, G et u_a. La fonction $v = -gF'$ est solution de l'équation de Burger.

6.3.1. Solutions de l'équation de Burger.

LEMME 6.3.1. *Soit $v = v(\sigma,\omega,\tau)$ la solution de l'équation de Burger*

$$\partial_\tau v + v\partial_\sigma v = 0, \qquad v(\sigma,\omega,0) = w(\sigma,\omega), \tag{6.3.1}$$

où $w \in C^\infty$ est supposée telle que $\inf_{\sigma,\omega} \partial_\sigma w = \dfrac{-1}{\tau_*} < 0$. Pour $0 \le \tau < \tau_*$, on peut définir $X = X(\sigma,\omega,\tau)$ et $D = D(X,\omega,\tau)$ par

$$X + \tau w(X,\omega) = \sigma, \qquad D(X,\omega,\tau) = 1 + \tau(\partial_\sigma w)(X,\omega). \tag{6.3.2}$$

Alors toute dérivée $\partial_\sigma^i \partial_\omega^j \partial_\tau^\ell v$ $(i+j+\ell = k)$ est de la forme

$$\partial_\sigma^i \partial_\omega^j \partial_\tau^\ell v(\sigma,\omega,\tau) = \sum_{\substack{0 \le 2p \le k-1+q \\ q \le k-1}} a_{pq}(X,\omega,\tau)\frac{(\partial_\sigma^2 w)^q}{D^{k+p}}(X,\omega,\tau), \tag{6.3.3}$$

pour certains coefficients a_{pq} réguliers.

En particulier,

$$\Big|\partial_\sigma^i \partial_\omega^j \partial_\tau^\ell v(\sigma,\omega,\tau)\Big| \le \frac{C}{D^{3k/2-1/2}}\ . \tag{6.3.4}$$

Preuve. (a) Il est bien connu que $v(\sigma,\omega,\tau) = w(X,\omega)$, d'où $\partial_\sigma v = (\partial_\sigma w)\partial_\sigma X$, $\partial_\omega v = (\partial_\sigma w)\partial_\omega X + \partial_\omega w$, $\partial_\tau v = (\partial_\sigma w)\partial_\tau X$, avec

$$\partial_\sigma X = \frac{1}{D}, \quad \partial_\omega X = -\tau\frac{\partial_\omega w}{D}, \quad \partial_\tau X = -\frac{w}{D},$$

ce qui prouve (6.3.3) pour $k = 1$.

(b) La dérivation (en σ par exemple) d'un terme $a_{pq}(\partial_\sigma^2 w)^q / D^{k+p}$ produit une somme de la forme

$$\partial_X a_{pq} \frac{(\ )^q}{D^{k+p+1}} + \frac{a_p}{D^{k+p}} q(\ )^{q-1} \frac{(\partial_\sigma^3 w)}{D} - (k+p) a_{pq} \frac{(\ )^q}{D^{k+p+1}} \tau(\partial_\sigma^2 w) \frac{1}{D},$$

d'où (6.3.3) par récurrence.

(c) Comme $D \geq 0$, on a $|\nabla_{X,\omega} D| \leq \text{cte } D^{1/2}$, soit $\tau(|\partial_\sigma^2 w| + |\partial_\omega \partial_\sigma w|) \leq \text{cte } D^{1/2}$. Comme $D \geq \text{cte} > 0$ pour $\tau \geq 0$ petit, on en déduit $|\partial_\sigma^2 w| + |\partial_\omega \partial_\sigma w| \leq \text{cte } D^{1/2}$.

La majoration (6.3.4) découle alors immédiatement de (6.3.3). □

6.3.2. L'équation de Burger inhomogène.

LEMME 6.3.2. *Soit $h(\sigma, \omega, \tau)$ la solution de l'équation*

$$\partial_\tau h + v \partial_\sigma h + h \partial_\sigma v = \psi(X, \omega, \tau), \qquad h(\sigma, \omega, 0) = 0 \ , \tag{6.3.5}$$

où v et X sont définis au lemme 6.3.1, et ψ est donnée.

Alors, pour $\tau < \tau_*$, toute dérivée $\partial_\sigma^i \partial_\omega^j \partial_\tau^\ell h$ $(i + j + \ell = k)$ est de la forme

$$\partial_\sigma^i \partial_\omega^j \partial_\tau^\ell h = \sum_{\substack{\ell'' \leq k \\ \ell' \leq 2(k-\ell'') \\ q \geq 2\ell' - 3(k-\ell'')}} *(X, \omega, \tau) \frac{(\partial_\sigma^2 w)^q}{D^{1+\ell'+\ell''}} \partial_{X,\omega,\tau}^{\ell''} C, \tag{6.3.6}$$

où $C(X, \omega, \tau) = \int_0^\tau (D\psi)(X, \omega, s)\, ds$.

En particulier,

$$\left| \partial_\sigma^i \partial_\omega^j \partial_\tau^\ell h \right| \leq C \sum_{\ell'' \leq k} \frac{1}{D^{1+\frac{3k-\ell''}{2}}} \left| \partial_{X,\omega,\tau}^{\ell''} C \right|. \tag{6.3.7}$$

Preuve. (a) On utilise les variables (X, ω, τ) et on cherche h sous la forme $h(\sigma, \omega, \tau) = H(X, \omega, \tau)$. L'équation (6.3.5) devient alors $\partial_\tau H + \dfrac{\partial_\sigma w}{D} H = \psi$, qu'on peut écrire, en posant $H = \dfrac{C}{D}$, $\partial_\tau C = D\psi$, soit $C = \int_0^T D\psi\, ds$.

(b) On a alors

$$\begin{aligned}
\partial_\sigma h &= \frac{1}{D} \partial_X C \frac{1}{D} - \frac{C\tau}{D^3} \partial_\sigma^2 w \ , \\
\partial_\omega h &= \frac{1}{D} (\partial_X C \partial_\omega X + \partial_\omega C) - \frac{C}{D^2} (\partial_X D \partial_\omega X + \partial_\omega D) \ , \\
\partial_\tau h &= \frac{1}{D} (\partial_X C \partial_\tau X + \partial_\tau C) - \frac{C}{D^2} (\partial_X D \partial_\tau X + \partial_\tau D),
\end{aligned}$$

ce qui prouve (6.3.6) pour $k = 1$.

(c) La dérivation (en σ par exemple) d'un terme de (6.3.6) produit une somme de la forme

$$* \frac{(\ )^q \partial^{\ell''} C}{D^{2+\ell'+\ell''}} + *q \frac{(\ )^{q-1}}{D^{2+\ell'+\ell''}} \partial^{\ell''} C + * \frac{(\ )^{q+1}}{D^{3+\ell'+\ell''}} \partial^{\ell''} C + * \frac{(\ )^q}{D^{2+\ell'+\ell''}} \partial^{\ell''+1} C \ .$$

Ces termes sont du type voulu, car $q - 1 \geq 2(\ell' + 1) - 3(k + 1 - \ell'')$, $q + 1 \geq 2(\ell' + 2) - 3(k + 1 - \ell'')$ etc.

(d) Puisque $\ell' - \frac{q}{2} \le \frac{3}{2}(k-\ell'')$, $1+\ell'+\ell''-\frac{q}{2} \le 1+\frac{3k}{2}-\frac{\ell''}{2}$, d'où (6.3.7). □

6.3.3. Estimations de F et G. Nous allons maintenant utiliser ces lemmes pour préciser les comportements de F et G définies par (6.1.3) et (6.1.4); on a alors $v = -gF'$, $h = -gG'$, $w = -gF'_A$. On notera $\tilde{X}$ et $\tilde{D}$ les fonctions définies par (6.3.2) et $\tau_*(A,\varepsilon)$ le temps de vie pour ce w là, et on posera, pour $\tau < \tau_*(A,\varepsilon)$

$$
\begin{aligned}
(6.3.8) \qquad & X(\sigma,\omega,\tau) = \tilde{X}(\sigma,\omega,\tau-A),\\
& D(x,\omega,\tau) = 1+(\tau-A)(\partial_\sigma w)(x,\omega).
\end{aligned}
$$

LEMME 6.3.3. *Pour $\tau < A+\tau_*(A,\varepsilon)$, on a les inégalités*

(i) $|F| + |\nabla_{\sigma,\omega,\tau} F| \le C$,

(ii) $|\partial^\alpha_{\sigma,\omega,\tau} F| \le C_\alpha / D(X,\omega,\tau)^{(3k/2)-2}$ *pour* $|\alpha| = k \ge 2$,

(iii) $|G| \le C$, $|\partial^\alpha_{\sigma,\omega,\tau} G| \le C_\alpha / D(X,\omega,\tau)^{3k/2-1/2}$ *pour* $|\alpha| = k \ge 1$.

Preuve. (a) Si $i \ge 1$, $\partial^i_\sigma \partial^j_\omega F = \partial^j_\omega \partial^{i-1}_\sigma \left(\frac{-v}{g}\right)$ et l'on applique (6.3.4). Si $\ell \ge 1$,

$$
\partial_\tau F = \frac{v^2}{2g}, \quad \text{et} \quad (\partial^i_\sigma \partial^j_\omega \partial^{\ell-1}_\tau)\Big(\frac{v^2}{2g}\Big) = \sum_{k'+k''\le k-1} * \partial^{k'} v \, \partial^{k''} v
$$

est majoré, grâce à (6.3.4), par $\dfrac{C}{D^{(3(k'+k''))/2-1}} \le \dfrac{C}{D^{3k/2-2}}$.

(b) Comme

$$
F(\sigma,\omega,\tau) = -\frac{1}{g}\int_M^\sigma v(s,\omega,\tau)\,ds,
$$

on obtient par le changement de variable $x = X(s,\omega,\tau)$, $dx = \dfrac{ds}{D}$,

$$
F(\sigma,\omega,\tau) = -\frac{1}{g}\int_M^{X(\sigma,\omega,\tau)} w(x,\omega)\,D(x,\omega,\tau)\,dx.
$$

Donc

$$
\begin{aligned}
&\partial_\omega(gF(\sigma,\omega,\tau))\\
&\qquad = -(Dw)(X,\omega,\tau)\,\partial_\omega X - \int_M^X \partial_\omega(wD)\,dx = \tau(w\,\partial_\omega w)(X,\omega,\tau) - \int_M^X \ldots dx,
\end{aligned}
$$

et

$$
\partial^2_\omega(gF) = \tau\,\partial_\omega(w\,\partial_\omega w) - \tau^2\,\partial_X(w\,\partial_\omega w)\frac{\partial_\omega w}{D} + \tau\,\partial_\omega(wD)\frac{\partial_\omega w}{D} - \int_M^X \partial^2_\omega(wD)\,dx.
$$

A partir de là, le même raisonnement que pour les fonctions v et h implique (i) et (ii).

(c) En posant, dans (6.1.4), $h = -gG'$, on obtient (6.3.5) avec $\psi(X,\omega,\tau) = -gE(F)$. Rappelons que

$$
E(F) = -\frac{1}{\tau^3}\Big(\frac{1}{4}+\partial^2_\omega\Big)F - \frac{\sigma}{2\tau^2 g} v v' + *v^2 + *v^2 v' + *v\nabla v + *v'\nabla F,
$$

en sorte que $D\psi$ est une fonction régulière de (X,ω,τ), ainsi que C. On déduit donc de (6.3.7) $\left|\partial_\sigma^i\,\partial_\omega^j\,\partial_\tau^\ell h\right| \le \dfrac{C}{D^{1+3k/2}}$.

On a alors, si $i \ge 1$, $\partial_\sigma^i\,\partial_\omega^j G = \partial_\omega^j\,\partial_\sigma^{i-1}\Big(-\dfrac{h}{g}\Big)$; si $\ell \ge 1$,

$$\partial_\tau G = \frac{1}{g}\,v\,h - \frac{1}{g}\int_M^X (D\psi)(x,\omega,\tau)\,dx,$$

d'où

$$\left|\partial_\sigma^i\,\partial_\omega^j\,\partial_\tau^{\ell-1}\,\partial_\tau G\right| \le \sum_{k'+k''\le k-1} \left|\partial^{k'} v\right|\left|\partial^{k''} h\right| + \frac{C}{D^{(3(k-1)/2)-1/2}} \le \frac{C}{D^{3k/2-1}}.$$

Enfin,

$$G(\sigma,\omega,\tau) = -\frac{1}{g}\int_M^\sigma \frac{C}{D}(X,\omega,\tau)\,ds = -\frac{1}{g}\int_M^X C(x,\omega,\tau)\,dx,$$

d'où

$$\partial_\omega(gG) = +\tau\,\partial_\omega w\,\frac{C}{D} - \int_M^X \partial_\omega C\,dx,$$

et (iii). □

6.3.4. Estimations de u_a. Il résulte de ce lemme que, dans la fonction $F+\varepsilon^2 G$, les dérivées de F dominent toujours celles de G pourvu que $\dfrac{\varepsilon^2}{D^{\frac{3}{2}}} \le$ cte. Par ailleurs

$$\partial_i(F(r-t,\omega,\tau)) = F'\omega_i + \partial_\omega F\,O(\varepsilon^2), \qquad \partial_t(F(r-t,\omega,\tau)) = -F' + \frac{\varepsilon}{2\sqrt{t}}\dot{F};$$

pour évaluer les dérivées de u_a, il suffit donc de considérer F et de négliger ω et τ. Cela conduit au lemme suivant.

LEMME 6.3.4. (Dérivées de u_a) *Pour $\tau < A + \tau_*(A,\varepsilon)$, on a les estimations*

(i) $|u_a| + |\nabla_{x,t,\omega} u_a| \le C\varepsilon^2$.

(ii) *Pour $|\alpha| = k \ge 2$,*

$$\left|\partial^\alpha_{x,t,\omega} u_a\right| \le C_\alpha \frac{\varepsilon^2}{D(X,\omega,\tau)^{3k/2-1/2}}.$$

6.3.5. Estimations des dérivées de J_a.

LEMME 6.3.5. *On a, pour $\tau < A + \tau_*(A,\varepsilon)$,*

(i) $|J_a| \le C\dfrac{\varepsilon^8}{D^{\frac{7}{2}}}$,

(ii) $|\nabla_x J_a| + |\partial_\omega J_a| \le C\dfrac{\varepsilon^8}{D^5}$,

(iii) $|\nabla_x^2 J_a| + |\partial_\omega \nabla_x J_a| + |\partial_\omega^2 J_a| \le C\dfrac{\varepsilon^8}{D^{13/2}}$, *où $D = D(X,\omega,\tau)$.*

Preuve. D'après (6.1.3) et les choix de F et G, on a

$$\begin{aligned} J_a = \frac{\varepsilon^6}{\sqrt{rt}}\Big\{ &+ gG'G'' - \frac{1}{\tau^3}\Big(\frac{1}{4}+\partial_\omega^2\Big)G - \frac{\sigma g}{2\tau^2}(F'G''+F''G') - \frac{\dot{G}}{4\tau^2} + \frac{\ddot{G}}{4\tau} \\ &+ g_{ij}^k\Big(\omega_k F' A_{ij} G' + \omega_k G' A_{ij} F' + \omega_i\omega_j F'' A_k G + \omega_i\omega_j G'' A_k F\Big) \\ &+ Q(F+\varepsilon^2 G, F+\varepsilon^2 G) + \varepsilon^2\Big(-\frac{\sigma g}{2\tau^2} G'G'' + g_{ij}^k(\omega_k G' A_{ij} G' + \omega_i\omega_j G'' A_k G)\Big)\Big\}. \end{aligned}$$

Le terme $R(F)$ est contrôlé par les dérivées secondes de F, tandis que le terme le plus singulier entre les accolades est $gG'G''$. On obtient alors les estimations du lemme sans difficulté à partir du lemme (6.3.3). □

6.4. Non dégénérescence et estimations L^2 des erreurs. Sous l'hypothèse (ND) (ou (ND)'), nous précisons maintenant le temps de vie $\tau_*(A,\varepsilon)$ de (6.1.3), ainsi qu'une minoration du dénominateur D des estimations des lemmes (6.3.4)–(6.3.6).

LEMME 6.4.1. *Sous l'hypothèse* (ND), *il existe C tel que, en posant*

$$\tilde\tau = \tilde\tau(\varepsilon) = \tau_*(\varepsilon) - C\varepsilon^{\frac{\kappa}{\kappa-1}} - C\varepsilon^2\,|\log\varepsilon|\,,$$

on ait

(i) $\tau_*(A,\varepsilon) \geq \tilde\tau - A$,

(ii) $\mathrm{cte}\,/(\tilde\tau-\tau) \leq \sup_{\sigma,\omega}\,|gF''(\sigma,\omega,\tau)| \leq \mathrm{cte} + 1/\tilde\tau - \tau$,

(iii) *Il existe une fonction $\sigma_0(\varepsilon)$ et une constante $C_1 > 0$ telles que*

$$D(x,\omega,\tau) \geq \mathrm{cte}\left(\tilde\tau - \tau + C_1(|\omega-\omega_0| + |x-\sigma_0(\varepsilon)|)^\kappa\right).$$

Dans le cas invariant par rotation, et sous l'hypothèse (ND)', (i) et (ii) restent vraies tandis que (iii) est remplacée par

(iii)' $D(x,\tau) \geq \mathrm{cte}\left(\tilde\tau - \tau + C_1\,|x-\sigma_0(\varepsilon)|^\kappa\right)$.

Preuve. (a) D'après l'hypothèse (ND), nous avons

$$-gR''(\sigma,\omega) \geq -gR''(\sigma_0,\omega_0) + C\,d^\kappa\ ,$$

où $d = |\sigma-\sigma_0| + |\omega-\omega_0|$. Cela implique

$$\begin{aligned}&-g(R''+\varepsilon L'')(\sigma,\omega)\\ &\geq -g\Big(R''(\sigma_0,\omega_0)+\varepsilon L''(\sigma_0,\omega_0)\Big) - C'\varepsilon(|\sigma-\sigma_0|+|\omega-\omega_0|) + C\,d^\kappa,\end{aligned}$$

d'où

$$-g(R''+\varepsilon L'')(\sigma,\omega) \geq -g(\quad)(\sigma_0,\omega_0) - C''\varepsilon^{\frac{\kappa}{\kappa-1}} + \frac{C}{2}\,d^\kappa.$$

Les propriétés élémentaires de l'équation de Burger montrent alors que

$$\begin{aligned}-gS''(\sigma,\omega,A) &= \left(A + \frac{1}{-g(R''+\varepsilon L'')(\phi(\sigma,\omega))}\right)^{-1}\\ &\geq \left(A + \frac{1}{-g(\ )(\sigma_0,\omega_0) - C''\varepsilon^{\frac{\kappa}{\kappa-1}} + \frac{C}{2}\,|\phi(\sigma,\omega)-(\sigma_0,\omega_0)|}\right)^{-1},\end{aligned}$$

où $\phi^{-1}(\sigma,\omega)$ correspond au déplacement sur les caractéristiques de l'équation de Burger, à ω fixé, entre $\tau=0$ et $\tau=A$, et $\phi^{-1}(\sigma_0,\omega_0) = (\sigma_0(\varepsilon),\omega_0)$. Comme ϕ est un difféomorphisme et $A < A_0$, $|\phi(\sigma,\omega)-(\sigma_0,\omega_0)| \geq \mathrm{cte}\,\tilde d$, où $\tilde d = |\omega-\omega_0| + |\sigma-\sigma_0(\varepsilon)|$ (ϕ, comme σ_0 dépendent de ε, mais les constantes des estimations n'en dépendent pas).

D'où, pour un $C_1 > 0$,

$$-gS''(\sigma,\omega,A) \geq \left(A + \frac{1}{-g(\ )(\sigma_0,\omega_0)}\right)^{-1} - C\varepsilon^{\frac{\kappa}{\kappa-1}} + C_1\,\tilde d^\kappa\ .$$

Comme

$$\frac{1}{g(\ )(\sigma_0,\omega_0)} = A_0 + \varepsilon A_1 + O(\varepsilon^2),$$

le lemme (6.2.1(i)) implique

$$-gF''_A(\sigma,\omega) \geq \frac{-1}{-A + A_0 + \varepsilon A_1} - C\varepsilon^{\frac{\kappa}{\kappa-1}} - C\varepsilon^2 |\log\varepsilon| + C_1\tilde{d}^\kappa, \tag{6.4.1}$$

avec de plus $-gF''_A(\sigma_0(\varepsilon),\omega_0) = \frac{1}{A-\tau_*} + O(\varepsilon^2 |\log\varepsilon|)$.

De (6.4.1), on déduit que

$$\tau_*(A,\varepsilon) = \inf \frac{1}{gF''_A} \geq \tilde{\tau} - A \ .$$

Comme

$$\sup_{\sigma,\omega} |gF''| \leq \text{cte} + \frac{1}{\tau_*(A,\varepsilon) - (\tau - A)}$$

est vraie pour toute solution d'une équation de Burger, on obtient (ii).

On a enfin

$$D(x,\omega,\tau) = 1 - (\tau - A)gF''_A(x,\omega) \geq \text{cte}\left(\tau_* - \tau - C\varepsilon^{\frac{\kappa}{\kappa-1}} - C\varepsilon^2 |\log\varepsilon| + C_1\tilde{d}^\kappa\right) \ ,$$

d'où (iii). □

Il s'ensuit en particulier que les lemmes 6.3.3–6.3.5 sont vrais pour $\tau < \tilde{\tau}$.

La minoration (iii) de D nous permet d'obtenir des estimations en moyenne meilleures qu'elles ne seraient si on avait $C_1 = 0$.

LEMME 6.4.2. *Il existe $\nu_1 > 0$ tel que, pour $A \leq \tau < \tilde{\tau}$, dans la zone extérieure, on ait*

(i) $|J_a|_0 \leq C\varepsilon^7/(\tilde{\tau} - \tau)^{3-\nu_1}$;

(ii) $|\nabla J_a|_0 + |\partial_\omega J_a|_0 \leq C\varepsilon^7/(\tilde{\tau} - \tau)^{\frac{9}{2}-\nu_1}$;

(iii) $|\nabla^2 J_a|_0 + |\partial_\omega \nabla J_a|_0 + |\partial^2_\omega J_a|_0 \leq C\varepsilon^7/(\tilde{\tau} - \tau)^{6-\nu_1}$.

Preuve. (a) Supposons qu'une fonction $f(\sigma,\omega,\tau) \geq 0$ satisfasse $f(\sigma,\omega,\tau) \leq 1/D(X,\omega,\tau)^\lambda$. On a alors

$$\begin{aligned}\int f^2(\sigma,\omega,\tau)\,d\sigma\,d\omega &\leq \int d\omega \int \frac{d\sigma}{D(X,\omega,\tau)^{2\lambda}} = \int d\omega \int \frac{dx}{D(x,\omega,\tau)^{2\lambda-1}} \\ &\leq \text{cte} \int d\omega \int \frac{dx}{(\tilde{\tau} - \tau + C_1 |x - \sigma_0(\varepsilon)|^\kappa)^{2\lambda-1}}.\end{aligned}$$

En coupant l'intégrale en x en $|x - \sigma_0(\varepsilon)|^\kappa \geq \tilde{\tau} - \tau$ et $\leq \tilde{\tau} - \tau$, il vient

$$\left(\int f^2(\sigma,\omega,\tau)\,d\sigma\,d\omega\right)^{1/2} \leq \frac{\text{cte}}{(\tilde{\tau} - \tau)^{\lambda - \frac{1}{2} - \frac{1}{2\kappa}}}.$$

(b) L'application de la remarque précédente avec $f = |J_a|$ etc., pour les valeurs $\lambda = \frac{7}{2}, 5$ et $\frac{13}{2}$ conduit au résultat, avec $\nu_1 = \frac{1}{2\kappa}$. □

INSTABILITY OF STATIONARY BUBBLES *

ANNE DE BOUARD†

Abstract. The paper is concerned with the study, by means of a linearized operator, of the instability of stationary solutions of a nonlinear Schrödinger equation with nonvanishing "boundary conditions." We prove that this operator possesses a real positive eigenvalue, and that when they exist, the stationary "bubbles" are always orbitally unstable.

Key words. nonlinear Schrödinger equations, solitary waves, stability

AMS subject classifications. 35B35, 35Q51, 35Q55

1. Introduction. In this work, we study the instability theory of stationary solutions of a nonlinear Schrödinger equation

$$i\frac{\partial \varphi}{\partial t} + \Delta\varphi + F(|\varphi|^2)\varphi = 0 \quad \text{in } \mathbb{R}^n \tag{1}$$

under general assumptions on F. The solutions considered here, unlike the classical standing waves of equation (1), satisfy the particular "boundary condition"

$$\varphi(x,t) \to \sqrt{\rho_0} \quad \text{when } |x| \to +\infty, \tag{2}$$

where ρ_0 is a real positive constant and $F(\rho_0) = 0$. They are the stationary case of a new class of solitary wave solution of equation (1). For example, in the context of a Boson gas with two-body attractive and three-body repulsive interactions, described by the "$\psi^3 - \psi^5$" nonlinear Schrödinger equation

$$i\frac{\partial \psi}{\partial t} + \Delta\psi - \alpha_1\psi + \alpha_3|\psi|^2\psi - \alpha_5|\psi|^4\psi = 0, \tag{3}$$

where $\psi(x,t) \in \mathbb{C}, x \in \mathbb{R}^n, t \in \mathbb{R}_+, n = 1, 2$, or 3, and $\alpha_3, \alpha_5 > 0$, these stationary solutions can be interpreted as "rarefaction bubbles." They represent the nucleation of a stable phase, which is given by the stationary solution $\psi = 0$, into a metastable phase, given by the solution $\psi = \sqrt{\rho_0}$, where 0 and ρ_0 are two minima of the potential V corresponding to equation (3)

$$V(|\psi|^2) = \alpha_1|\psi|^2 - \frac{1}{2}\alpha_3|\psi|^4 + \frac{1}{3}\alpha_5|\psi|^6$$

if $V(0) < V(\rho_0)$ (see [2]).

In space dimension one, some localised solutions traveling with a velocity v, having the form $\psi(x,t) = \varphi(x - vt)$ and corresponding to nonstationary "bubbles" have also been found (see [1]). The "boundary condition" is then

$$\lim_{x \to \pm\infty} \psi(x,t) - \sqrt{\rho_0}e^{\mp i\mu},$$

* Received by the editors September 14, 1992; accepted for publication (in revised form) August 26, 1993.

where μ is a real number depending on the velocity v, with $\mu = 0$ when $v = 0$.

These solutions seem also to have interpretations in other fields of physics where equation (3) occurs (see [2]).

Here, we will be concerned with the general equation (1). Our aim in the paper is to give criteria for the existence of stationary solutions having the same behaviour as those described for equation (3), and to show that for any F satisfying those assumptions and for any space dimension n, such solutions are always unstable. This means that if φ is such a solution, then one can find initial data arbitrarily close to φ such that the corresponding solution of equation (1) quits any given neighborhood of φ in a finite time t_0.

In [2] (see also [4]), Barashenkov et al. considered the linearized evolution equation around such a stationary solution and studied the operators L_1 and L_2 (see §3 for a definition of these operators) to conclude to the existence of a time exponentially growing solution for this equation. We will use a more refined analysis of this linearized operator to show our result (see Theorem 4.1), and in particular, we prove that it possesses a real positive eigenvalue.

The nonlinear Schrödinger equation possesses some other localised solutions which have been extensively studied during the last few years: the stationary states. These solutions are written in the form

$$\varphi(x,t) = e^{i\omega t}u_\omega(x)$$

(see for example [8], [11], [13], [18], [19]). Some stability and instability results for such solutions of equation (1) with a pure power nonlinearity, i.e., when $F(|\varphi|^2)\varphi = \lambda|\varphi|^{p-1}\varphi$, $1 < p < \frac{n+2}{n-2}$, $\lambda > 0$, were proved in [5], [8].

A general theory about stability of solitary waves in Hamiltonian systems was introduced by Grillakis, Shatah, and Strauss [13]. This allows one to obtain stability and instability conditions for some stationary states of equation (1) for more general nonlinearities.

This theory does not seem to apply to the solutions we consider here because these solutions do not belong to $L^2(\mathbb{R}^n)$, and because of the "bad" spectral structure of the Hamiltonian operator.

Let us also mention two papers from Grillakis [11], [12] concerning the study of the linearized operator around a stationary state and the analysis of the instability mechanism.

This work is organized as follows. In §2, we define what we call the "stationary bubbles" and give some existence results for such solutions. Section 3 is devoted to the study of the spectrum of the linearized operator and to the proof of the fact that this operator possesses a real positive eigenvalue with maximal real part. In the last section, we use the result of §3 to show the instability of the stationary bubbles (see Theorem 4.1). The appendix contains the proof of a few technical results used in §§3 and 4.

The notations are as follows. Given equation (1) where φ is a complex valued function of $x \in \mathbb{R}^n$ and $t \in \mathbb{R}$, and where $\Delta\varphi = \sum_{j=1}^n (\partial^2\varphi/\partial x_j^2)$, we assume that F is defined and continuously differentiable in $\mathbb{R}_+$, except in the last section, where F is assumed to be more regular. We also assume that there is a real positive constant ρ_0 such that $F(\rho_0) = 0$ and we set $r_0 = \sqrt{\rho_0}$. For any positive integer m, $H^m(\mathbb{R}^n)$ will denote the Sobolev space of real-valued functions defined on $\mathbb{R}^n$ whose partial derivatives up to order m are in $L^2(\mathbb{R}^n)$. $\mathbb{H}^m(\mathbb{R}^n)$ will denote the space of complex valued functions whose real and imaginary parts are both in $H^m(\mathbb{R}^n)$ and will sometimes be

identified with $H^m(\mathbb{R}^n) \times H^m(\mathbb{R}^n)$. If A is a linear operator on a Banach space, then we will represent its spectrum by $\sigma(A)$, and its resolvent set by $\rho(A) = \mathbb{C}\backslash\sigma(A)$.

2. Existence of the stationary bubbles. In this section, we give some existence results of radially symmetric stationary solutions of equation (1) having the behaviour (2) as $|x|$ goes to infinity. More precisely, according to the definition from Barashenkov et al. [2], a stationary bubble is defined as a real-valued function φ of $x \in \mathbb{R}^n$, satisfying

(i) $\varphi(x) = \varphi(r)$ (i.e., φ is radially symmetric),
(ii) $\Delta\varphi + F(\varphi^2)\varphi = 0$ in $\mathbb{R}^n$,
(iii) $0 < \varphi(r) < r_0$ $\forall r \in [0, \infty)$, $\lim_{r\to+\infty} \varphi(r) = r_0$, and
(iv) $\varphi_r(0) = 0$, $\varphi_r(r) > 0$ $\forall r \in (0, +\infty)$.

Because of condition (iii), we will look for solutions φ such that $u = r_0 - \varphi$ belongs to $H^1(\mathbb{R}^n)$. Hence if φ satisfies (ii), then u is a solution of

$$\Delta u - F((r_0 - u)^2)(r_0 - u) = 0 \quad \text{in } \mathbb{R}^n,\ u \in H^1(\mathbb{R}^n). \tag{4}$$

We set

$$V(s) = -\int_{\rho_0}^{s} F(\tau)\, d\tau. \tag{5}$$

Then we may write the energy associated with equation (1) in terms of $u = r_0 - \varphi$:

$$E(u) = \frac{1}{2}\int_{\mathbb{R}^n} |\nabla u|^2\, dx + \frac{1}{2}\int_{\mathbb{R}^n} V(|r_0 - u|^2)\, dx. \tag{6}$$

We begin with the case $n \geq 2$, since the existence results are not exactly the same as in the case $n = 1$.

2.1. The case $n \geq 2$. In this section we assume that

$$F'(\rho_0) < 0, \tag{7}$$

$$\exists \rho_1 \quad \text{such that } 0 \leq \rho_1 < \rho_0 \quad \text{and} \quad V(\rho_1) < 0, \tag{8}$$

where V is defined by (5).

Then the following result holds.

THEOREM 2.1. *Suppose that F satisfies assumptions* (7) *and* (8); *then there exists a real-valued function $\varphi \in C^2(\mathbb{R}^n)$, which is a stationary bubble, i.e., which satisfies conditions* (i)–(iv). *Moreover, under assumptions* (7) *and* (8), *any stationary bubble φ is twice continuously differentiable in $\mathbb{R}^n$ and satisfies the following property*:

(v) $\exists C > 0$, $\exists \delta > 0$ *such that* $\forall \alpha \in \mathbb{N}^n$ *with* $|\alpha| \leq 2$, $|\partial_x^\alpha(\varphi(x) - r_0)| \leq Ce^{-\delta|x|}, \forall x \in \mathbb{R}^n$.

Proof. This theorem is proved by applying Theorem 1 of Berestycki and Lions [7] if $n \geq 3$ or Berestycki, Gallouët, and Kavian [6] if $n = 2$ to equation (4), or more precisely, to the equation:

$$-\Delta u = g(u), \quad u \in H^1(\mathbb{R}^n), \quad u \neq 0, \tag{9}$$

where g is defined by

$$g(s) = \begin{cases} -F((r_0 - s)^2)(r_0 - s) & \text{if } 0 \leq s \leq r_0, \\ 0 & \text{if } s \geq r_0, \\ -g(-s) & \text{if } s \leq 0. \end{cases}$$

Then there is a positive, radially symmetric, decreasing solution u of (9), and since u is positive, and $u < r_0$ by the maximum principle, u is a solution of (4). Hence, $\varphi = r_0 - u$ is a stationary bubble. Lemmas 1 and 2 in §4 of Berestycki and Lions [7] then show that any function φ satisfying (i)–(iv) is twice continuously differentiable and satisfies (v). □

Remark 2.1. Conditions (7) and (8) will be fulfilled if we assume that V has a minimum at ρ_0 with $V''(\rho_0) > 0$ and at least one more minimum at ρ_1, with $0 < \rho_1 < \rho_0$ and $V(\rho_1) < V(\rho_0)$. It was suggested in [2] that such potentials V should lead to the existence of stationary bubbles.

Remark 2.2. Any solution $u \in H^1(\mathbb{R}^n)$ of the problem $-\Delta u = g(u)$ satisfies the Pohozaev identity (see [7])

$$\frac{n-2}{2} \int_{\mathbb{R}^n} |\nabla u|^2 \, dx = n \int_{\mathbb{R}^n} G(u) \, dx, \tag{10}$$

where G is defined by $G(\xi) = \int_0^\xi g(s) \, ds$. This identity enables one to show that assumption (8) is necessary for the existence of a stationary bubble: if $V(\rho) \geq 0$ for $0 \leq \rho \leq \rho_0$, then such a solution cannot exist.

2.2. The case $n = 1$. This case is of course much simpler, and in fact, we have in this case necessary and sufficient conditions for the existence of a stationary bubble. Also, the solution is unique as soon as it exists. The following result holds.

THEOREM 2.2. *A necessary and sufficient condition of the existence of a stationary bubble φ for equation* (1) *is that*

$$\eta_0 = \sup\{\eta, 0 < \eta < \rho_0, V(\eta) = 0\} \text{ exists}, \qquad 0 < \eta_0 < \rho_0 \quad \text{and} \quad F(\eta_0) < 0. \tag{11}$$

When (11) *is satisfied, such a solution is unique. Moreover if $F'(\rho_0) < 0$, then φ satisfies* (v) (*i.e., $\partial^\alpha(\varphi - r_0)$ is exponentially decreasing for all $|\alpha| \leq 2$*).

Proof. This theorem can be proved by applying Theorem 5 of Berestycki and Lions [7] to the problem

$$-u'' = -F((r_0 - u)^2)(r_0 - u) = g(u). \tag{12}$$

If we set $G(\xi) = \int_0^\xi g(s) \, ds$, then one has $G(2r_0) = 0$ and we can easily show that condition (11) is equivalent to

$$\xi_0 = \inf\{\xi > 0, G(\xi) = 0\} \text{ exists},$$
$$\xi_0 > 0 \quad \text{and} \quad g(\xi_0) > 0,$$

which is the necessary and sufficient condition of Theorem 5 of [7]. □

Remark 2.3. Consider the "$\psi^3 - \psi^5$" nonlinear Schrödinger equation (3). This equation can be rewritten in the following form by a rescaling and a change of function (see [1]), at least in a restricted domain of the parameters α_i:

$$i\frac{\partial \varphi}{\partial t} + \Delta\varphi + (|\varphi|^2 - \rho_0)(2A + \rho_0 - 3|\varphi|^2)\varphi = 0.$$

Here we have $V(\rho) = (\rho - \rho_0)^2(\rho - A)$, and condition (11) is satisfied if and only if $0 < A < \rho_0$. The stationary bubble is then given by

$$\varphi(x) = \frac{\sqrt{\rho_0}\cosh(\kappa x)}{\left(\frac{\rho_0}{A} + \sinh^2(\kappa x)\right)^{1/2}},$$

where

$$\kappa = \sqrt{\rho_0(\rho_0 - A)}.$$

3. The linearized operator. This section is devoted to the study of the linearization of equation (1) around a stationary bubble and to the proof of the linearized instability.

In what follows, φ is a (real-valued) stationary bubble satisfying properties (i)–(v) of §2, and F is supposed to satisfy $F'(\rho_0) < 0$.

Since F is in $\mathcal{C}^1(\mathbb{R}^+)$, the function $h : z \mapsto F(|z|^2)z$ is in $\mathcal{C}^1(\mathbb{R}^2)$, i.e., h' is defined by

$$h'(z)w = \lim_{\epsilon \to 0} \frac{1}{\epsilon}[h(z + \epsilon w) - h(z)]$$

for any $z, w \in \mathbb{C}$. Then if $\varphi + u$ is a solution of (1) with $u(x,t) \in \mathbb{C}, u$ satisfies

$$i\frac{\partial u}{\partial t} + \Delta u + h(\varphi + u) - h(\varphi) = 0$$

and we may write the linearized equation for u as

$$i\frac{\partial u}{\partial t} + \Delta u + h'(\varphi)u = 0$$

or

$$i\frac{\partial u}{\partial t} + \Delta u + F(\varphi^2)u + 2\varphi F'(\varphi^2)\mathcal{R}e(\varphi u) = 0.$$

Hence we set

$$\mathcal{U}(x,t) = \begin{pmatrix} u_1(x,t) \\ u_2(x,t) \end{pmatrix} = (\mathcal{R}e\ u(x,t), \mathcal{I}m\ u(x,t))^t \in \mathbb{R}^2,$$

where $\mathcal{R}e\ u$ is the real part of u and $\mathcal{I}m\ u$ is its imaginary part. We then obtain

$$\frac{\partial \mathcal{U}}{\partial t} = A\mathcal{U} \tag{13}$$

with

$$A = \begin{pmatrix} 0 & L_1 \\ -L_2 & 0 \end{pmatrix}, \qquad \begin{cases} L_1 v = -\Delta v + q_1 v, \\ L_2 v = -\Delta v + (q_1 + q_2)v, \end{cases}$$

and

$$\begin{cases} q_1(x) = q_1(r) = -F(\varphi^2(r)), & r = |x|, \\ q_2(x) = q_2(r) = -2\varphi^2(r)F'(\varphi^2(r)), & r = |x|. \end{cases}$$

We then consider the space $\mathbb{L}^2_r(\mathbb{R}^n)$ of $\mathbb{R}^2$-valued radially symmetric functions of $L^2(\mathbb{R}^n) \times L^2(\mathbb{R}^n)$; A is seen as an unbounded operator on $\mathbb{L}^2_r(\mathbb{R}^n)$. Then, since q_1 and q_2 are in $L^2(\mathbb{R}^n) + L^\infty(\mathbb{R}^n)$, L_1 and L_2 are self-adjoint operators with $D(L_1) = D(L_2) = H^2_r(\mathbb{R}^n) = H^2(\mathbb{R}^n) \cap L^2_r(\mathbb{R}^n)$ (see [17]) and A is closed with maximal domain

$$D(A) = \mathbb{H}^2_r(\mathbb{R}^n) = \mathbb{H}^2(\mathbb{R}^n) \cap \mathbb{L}^2_r(\mathbb{R}^n).$$

Because the aim of this section is to study the spectrum of A, we have to complexify this space. Accordingly, we consider

$$\tilde{\mathbb{L}}^2_r(\mathbb{R}^n) = \mathbb{L}^2_r(\mathbb{R}^n) + i\mathbb{L}^2_r(\mathbb{R}^n),$$

which is identified here with the space of $\mathbb{C}^2$-valued, radially symmetric, square integrable functions. Similarly,

$$\tilde{\mathbb{H}}^2_r(\mathbb{R}^n) = \mathbb{H}^2_r(\mathbb{R}^n) + i\mathbb{H}^2_r(\mathbb{R}^n)$$

with a similar identification. $\tilde{\mathbb{L}}^2_r(\mathbb{R}^n)$ is endowed with its natural inner product

$$((\mathcal{U}, \mathcal{V})) = \mathcal{R}e[\langle u_1, v_1\rangle + \langle u_2, v_2\rangle],$$

where

$$\mathcal{U} = (u_1, u_2)^t, \qquad \mathcal{V} = (v_1, v_2)^t \in \tilde{\mathbb{L}}^2_r(\mathbb{R}^n)$$

and

$$\langle u, v\rangle = \int_{\mathbb{R}^n} u\bar{v}\, dx \quad \text{for } u, v \in \mathbb{L}^2_r(\mathbb{R}^n).$$

We also set

$$\langle\langle \mathcal{U}, \mathcal{V}\rangle\rangle = \langle u_1, v_1\rangle + \langle u_2, v_2\rangle \in \mathbb{C}.$$

We are first interested in locating the "essential spectrum" of the linear unbounded operator A; by this we mean the set of all the values of the spectrum which are not discrete eigenvalues of finite multiplicity (see [17, Vol. IV] for a precise definition). This question is studied in the following lemma.

LEMMA 3.1. *$\sigma_e(A) \subset i\mathbb{R}$ where $\sigma_e(A)$ is the essential spectrum of A.*

Proof. We have

$$\lim_{|x|\to+\infty} q_1(x) = 0 \quad \text{and} \quad \lim_{|x|\to+\infty} q_2(x) = -2\rho_0 F'(\rho_0) = c_0 > 0,$$

and q_1, q_2 converge exponentially to their limit. Thus, A is a relatively compact perturbation of

$$A_0 = \begin{pmatrix} 0 & -\Delta \\ \Delta - c_0 & 0 \end{pmatrix}.$$

Let us first show that $\sigma_e(A_0) \subset i\mathbb{R}$. For any complex number λ,

$$(A_0 + \lambda)(A_0 - \lambda) = A_0^2 - \lambda^2 = \begin{pmatrix} \Delta(-\Delta + c_0) - \lambda^2 & 0 \\ 0 & \Delta(-\Delta + c_0) - \lambda^2 \end{pmatrix} \tag{14}$$

and the spectrum of the differential operator with constant coefficients $\Delta(-\Delta + c_0)$ is imbedded in the set of values of its symbol

$$p(\xi) = -|\xi|^2(|\xi|^2 + c_0).$$

Hence $\sigma(\Delta(-\Delta + c_0)) \subset]-\infty, 0]$ and if $\lambda \notin i\mathbb{R}$ then $\lambda^2 \notin \mathbb{R}^-$ and $A_0^2 - \lambda^2$ is invertible, showing that the nullspace of $A_0 - \lambda$ is $\{0\}$.

Moreover, since if $\lambda^2 \notin]-\infty, 0]$, there is an $\alpha > 0$, depending on λ, such that

$$\frac{\|\xi|^2(|\xi|^2 + c_0) + \lambda^2|}{(1 + |\xi|^2)^2} \geq \alpha > 0 \quad \forall \xi \in \mathbb{R}^n,$$

we have for $v \in H^2(\mathbb{R}^n)$

$$|\langle(-\Delta(-\Delta + c_0) + \lambda^2)v, v\rangle| \geq \alpha\|v\|^2_{H^2}.$$

Hence for $\mathcal{U} \in \tilde{\mathbb{H}}^2_r(\mathbb{R}^n)$

$$|\langle\langle (A_0^2 - \lambda^2)\mathcal{U}, \mathcal{U}\rangle\rangle| \geq \alpha \|\mathcal{U}\|^2_{\tilde{\mathbb{H}}^2_r}.$$

This together with (14) and the fact that $A_0^2 - \lambda^2$ is invertible shows that the range of $A_0 - \lambda$ is $\tilde{\mathbb{L}}^2_r(\mathbb{R}^n)$ and that $\lambda \notin \sigma(A_0)$.

Now, even if Weyl's theorem does not exactly apply here because A is not self-adjoint, an adaptation of the proof of this theorem, using for instance Lemma 3, §XIII-4 of [17] (see Lemma A.1 of the appendix for the statement) shows that the essential spectra of A and A_0 are the same. Indeed, it is not difficult to prove that assumption (ii) of Lemma A.1 is satisfied. The proof of Lemma 3.1 is then complete. □

Remark 3.1. If A has an eigenvalue with positive real part, then it is necessarily an isolated point of the spectrum, by the preceding result. Note that the discrete eigenvalues of A are symmetric with respect to the imaginary axis: if $\mathcal{U} = (u_1, u_2)^t$ is an eigenfunction of A corresponding to an eigenvalue λ, then $(\bar{u}_1, \bar{u}_2)^t$ and $(u_1, -u_2)^t$ are eigenfunctions of A corresponding respectively to $\bar{\lambda}$ and $-\lambda$. We shall show now that A does have an eigenvalue with positive real part.

We begin with the proof of a few properties concerning the self-adjoint operators L_1 and L_2.

LEMMA 3.2. *L_1 is a positive operator, i.e., $(L_1 u, u) > 0$ for any $u \in H^1_r(\mathbb{R}^n)$ with $u \neq 0$.*

Proof. Since $L_1 = -\Delta + q_1(r)$ with $\lim_{r\to+\infty} q_1(r) = 0$, we have $\sigma_e(L_1) = [0, +\infty[$. Now, $L_1\varphi = 0$ and $0 < \varphi(0) \leq \varphi(r) < r_0$ for all $r \geq 0$, thus $q_1(r) = \frac{\Delta\varphi}{\varphi}$ and for $u \in H^1_r(\mathbb{R}^n)$

$$\begin{aligned}\langle L_1 u, u\rangle &= \int_{\mathbb{R}^n} |\nabla u|^2\, dx + \int_{\mathbb{R}^n} \frac{\Delta\varphi}{\varphi}|u|^2\, dx \\ &= \sigma_n \int_0^{+\infty} |u_r|^2 r^{n-1}\, dr + \sigma_n \int_0^{+\infty} (r^{n-1}\varphi_r)_r \frac{|u|^2}{\varphi}\, dr,\end{aligned}$$

σ_n being the measure of the unit sphere in $\mathbb{R}^n$. Hence, integrating by parts, we obtain

$$\begin{aligned}\langle L_1 u, u\rangle &= \sigma_n \int_0^{+\infty} |u_r|^2 r^{n-1}\, dr - 2\sigma_n \int_0^{+\infty} \frac{\varphi_r}{\varphi} \mathcal{R}e(u_r \bar{u}) r^{n-1}\, dr \\ &\quad + \sigma_n \int_0^{+\infty} \frac{\varphi_r^2}{\varphi^2}|u|^2 r^{n-1}\, dr \\ &= \sigma_n \int_0^{+\infty} \varphi^2 \left[\frac{|u_r|^2}{\varphi^2} - \frac{2\varphi_r}{\varphi^3}\mathcal{R}e(u_r\bar{u}) + \frac{|u|^2\varphi_r^2}{\varphi^4}\right] r^{n-1}\, dr \\ &= \sigma_n \int_0^{+\infty} \varphi^2 \left|\frac{u_r}{\varphi} - \frac{u\varphi_r}{\varphi^2}\right|^2 r^{n-1}\, dr \\ &= \sigma_n \int_0^{+\infty} \varphi^2 \left|\left(\frac{u}{\varphi}\right)_r\right|^2 r^{n-1}\, dr\end{aligned}$$

and this leads to

$$\langle L_1 u, u\rangle = \int_{\mathbb{R}^n} \varphi^2 \left|\left(\frac{u}{\varphi}\right)_r\right|^2 dx = \left\|\varphi\left(\frac{u}{\varphi}\right)_r\right\|^2_{L^2(\mathbb{R})^n},$$

which proves the lemma. □

LEMMA 3.3. *$\sigma_e(L_2) = [c_0, +\infty[$; L_2 has at least one negative eigenvalue, and only one if $n = 1$.*

Proof. Since $L_2 = -\Delta + q_1(r) + q_2(r)$ and $\lim_{n\to+\infty} q_2(r) = c_0$, we have $\sigma_e(L_2) = [c_0, +\infty[$.

Assume first that $n \geq 2$; then we have

$$L_1\varphi = 0 = -\varphi_{rr} - \frac{n-1}{r}\varphi_r + q_1(r)\varphi.$$

Differentiating this equation with respect to r, we obtain

$$-\varphi_{rrr} - \frac{n-1}{r}\varphi_{rr} + (q_1(r) + q_2(r))\varphi_r + \frac{n-1}{r^2}\varphi_r = 0.$$

This gives

$$L_2\varphi_r = -\frac{n-1}{r^2}\varphi_r.$$

Since $\varphi \in C^2(\mathbb{R}^n)$ and φ_r is exponentially decreasing when $r \to +\infty$, we have $\varphi_r \in H^1(\mathbb{R}^n)$ and $\varphi_r/r \in L^2(\mathbb{R}^n)$. Moreover $\langle L_2\varphi_r, \varphi_r\rangle < 0$, hence by the min–max theorem, L_2 has at least one negative eigenvalue.

Now if $n = 1$, we have $L_2\dot{\varphi}_r = 0$ and φ_r is a generator of the kernel of L_2 in $L^2(\mathbb{R}^n)$, because any solution of the differential equation $L_2u = 0$ on $[0, +\infty[$, independent of φ_r satisfies $u(x) \sim u_0e^{c_0x}$ where $u_0 \in \mathbb{C}$ and thus is not in $L^2(\mathbb{R}^n)$. Since φ vanishes only for $r = 0$, we deduce by the Sturm–Liouville theory that L_2 has a unique negative eigenvalue, corresponding to an always-positive eigenfunction. □

Remark 3.2. $0 \in \sigma_e(L_1)$, L_1 is self-adjoint, and 0 is not an eigenvalue for L_1, consequently, the range of L_1 is dense in $L^2(\mathbb{R}^n)$ and we can define L_1^{-1} as an unbounded operator with dense domain in $L^2(\mathbb{R}^n)$, as was noted in [2]. Assume now that $\mathcal{U} = (u_1, u_2)^t$ is an eigenfunction for A corresponding to a real eigenvalue λ, i.e.,

$$\begin{cases} L_1u_2 = \lambda u_1, \\ -L_2u_1 = \lambda u_2. \end{cases}$$

Then $u_1 \in D(L_1^{-1}), u_2 = \lambda L_1^{-1}u_1$, and $(L_2 + \lambda^2 L_1^{-1})u_1 = 0$, which tells us that u_1 is in the nullspace of $L_2 + \lambda^2 L_1^{-1}$. Conversely, if we prove that there is a positive γ such that $L_2 + \gamma L_1^{-1}$ has a nontrivial nullspace $N(L_2 + \gamma L_1^{-1})$ and $D(L_2 + \gamma L_1^{-1}) = D(L_2) \cap D(L_1^{-1})$, then taking $u_1 \in N(L_2 + \gamma L_1^{-1})$ and $u_2 = \sqrt{\gamma} L_1^{-1}u_1$, we obtain an eigenfunction $(u_1, u_2)^t$ of A for the positive eigenvalue $\sqrt{\gamma}$.

Thus we have to study the operator $L_2 + \lambda^2 L_1^{-1}$ for $\lambda \in \mathbb{R}^*$.

LEMMA 3.4. *For any $\lambda \in \mathbb{R}^*$, the operator $L_2 + \lambda^2 L_1^{-1}$ satisfies the following properties:*

(i) *$L_2 + \lambda^2 L_1^{-1}$ is self-adjoint on its maximal domain, which is $D(L_2) \cap D(L_1^{-1})$.*

(ii) *$\sigma_e(L_2 + \lambda^2 L_1^{-1}) \subset [c_0, +\infty[$.*

Proof. (i) Since $L_2 + \lambda^2 L_1^{-1} = L_1 + \lambda^2 L_1^{-1} + q_2$ and $u \mapsto q_2u$ is a bounded self-adjoint operator on $L^2_r(\mathbb{R}^n)$, it suffices to prove that $D(L_1 + \lambda^2 L_1^{-1}) = D(L_1) \cap D(L_1^{-1})$, and that $L_1 + \lambda^2 L_1^{-1}$ is self-adjoint on $D(L_1) \cap D(L_1^{-1})$. The result is then obtained by applying the Kato–Rellich theorem (see [17, Vol. IV]).

Now, since L_1 is self-adjoint, positive, and since 0 is not an eigenvalue of L_1, the spectral theorem gives

$$L_1 + \lambda^2 L_1^{-1} = \int_{-\infty}^{+\infty} \left(\mu + \frac{\lambda^2}{\mu}\right) dP_\mu.$$

Thus $L_1 + \lambda^2 L_1^{-1}$ is self-adjoint on

$$D(L_1 + \lambda^2 L_1^{-1}) = \left\{ u \in L^2(\mathbb{R}^n), \int_{-\infty}^{+\infty} \left(\mu + \frac{\lambda^2}{\mu}\right)^2 d(P_\mu u, u) < +\infty \right\}.$$

But if $u \in D(L_1 + \lambda^2 L_1^{-1})$ then

$$\int_{-\infty}^{+\infty} \mu^2 \, d(P_\mu u, u) < +\infty$$

and

$$\int_{-\infty}^{+\infty} \frac{1}{\mu^2} \, d(P_\mu u, u) < +\infty.$$

Hence $u \in D(L_1) \cap D(L_1^{-1})$. This proves (i).

To prove (ii) let us first show that

$$\sigma_e(L_2 + \lambda^2 L_1^{-1}) = \sigma_e(-\Delta + c_0 + \lambda^2 L_1^{-1}).$$

Using Weyl's theorem, we only have to prove that $u \mapsto (q_1 + q_2 - c_0)u$ is relatively compact with respect to $-\Delta + c_0 + \lambda^2 L_1^{-1}$. Consider $D(-\Delta + c_0 + \lambda^2 L_1^{-1}) = H_r^2(\mathbb{R}^n) \cap D(L_1^{-1})$, endowed with the graph norm

$$|||u|||^2 = \|(-\Delta + \lambda^2 L_1^{-1})u\|_{L^2}^2 + \|u\|_{L^2}^2.$$

Then we have

$$\begin{aligned} |||u|||^2 &= \|\Delta u\|_{L^2}^2 + \lambda^4 \|L_1^{-1} u\|_{L^2}^2 + 2\lambda^2 \mathcal{R}e\langle -\Delta u, L_1^{-1} u\rangle + \|u\|_{L^2}^2 \\ &= \|\Delta u\|_{L^2}^2 + \lambda^4 \|L_1^{-1} u\|_{L^2}^2 + 2\lambda^2 \mathcal{R}e\langle L_1 u, L_1^{-1} u\rangle - 2\lambda^2 \mathcal{R}e\langle q_1 u, L_1^{-1} u\rangle + \|u\|_{L^2}^2 \\ &\geq \|\Delta u\|_{L^2}^2 + \lambda^4 \|L_1^{-1} u\|_{L^2}^2 + 2\lambda^2 \|u\|_{L^2}^2 + \|u\|_{L^2}^2 - \lambda^4 \|L_1^{-1} u\|_{L^2}^2 - \alpha^2 \|u\|_{L^2}^2 \end{aligned}$$

with $\alpha = \sup_{r \geq 0} q_1(r)$. Hence if $u \in D(L_1^{-1}) \cap H_r^2$,

$$\|\Delta u\|_{L^2}^2 + (2\lambda^2 + 1)\|u\|_{L^2}^2 \leq |||u|||^2 + \alpha^2 \|u\|_{L^2}^2$$

and $D(-\Delta + c_0 + \lambda^2 L_1^{-1})$ is continuously imbedded in $H_r^2(\mathbb{R}^n)$. Now, since $u \mapsto (q_1 + q_2 - c_0)u$ is compact from $H_r^2(\mathbb{R}^n)$ into $L_r^2(\mathbb{R}^n)$, we obtain by Weyl's essential spectrum theorem that

$$\sigma_e(L_2 + \lambda^2 L_1^{-1}) = \sigma_e(-\Delta + c_0 + \lambda^2 L_1^{-1}).$$

On the other hand, we have

$$\inf_{\substack{u \in D(-\Delta + c_0 + \lambda^2 L_1^{-1}) \\ \|u\|_{L^2} = 1}} \langle (-\Delta + c_0 + \lambda^2 L_1^{-1})u, u\rangle \geq c_0,$$

and hence

$$\sigma_e(L_2 + \lambda^2 L_1^{-1}) \subset \sigma_e(-\Delta + c_0 + \lambda^2 L_1^{-1}) \subset [c_0, +\infty[,$$

which proves (ii). □

Now we are able to prove the following theorem about the existence of a real eigenvalue for A.

THEOREM 3.1. *The operator*

$$A = \begin{pmatrix} 0 & L_1 \\ -L_2 & 0 \end{pmatrix}$$

defined on $\tilde{\mathbb{L}}^2_r(\mathbb{R}^n)$ *has a real positive eigenvalue with maximal real part, given by*

$$\lambda_{max} = \left[- \inf_{u \in H^1_r(\mathbb{R}^n) \cap D(L_1^{-1})} \frac{\langle L_2 u, u \rangle}{\langle L_1^{-1} u, u \rangle} \right]^{1/2}.$$

Proof. According to Lemma 3.4, L_2 has a negative eigenvalue. On the other hand, $D(L_1^{-1}) = R(L_1)$ is dense in $L^2_r(\mathbb{R}^n)$. In fact it can be proved that $D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)$ is dense in $H^1_r(\mathbb{R}^n)$ (see [9] for the details). Hence, there is a $u_0 \in D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)$ such that $\langle u_0, L_2 u_0 \rangle < 0$. Since L_1^{-1} is positive, we deduce that

$$-\infty \leq \inf_{\substack{u \neq 0 \\ u \in D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)}} \frac{\langle u, L_2 u \rangle}{\langle u, L_1^{-1} u \rangle} < 0.$$

Let us show that this expression is finite. If $u \in H^1_r(\mathbb{R}^n) \cap D(L_1^{-1})$, then with $L_1^{1/2}$ and $L_1^{-1/2}$ as defined by the spectral theorem, we have

$$\begin{aligned} \langle L_2 u, u \rangle &= \langle L_1 u, u \rangle + \langle q_2 u, u \rangle \\ &\geq \langle L_1 u, u \rangle - \beta \|u\|^2_{L_2(\mathbb{R}^n)}, \qquad \beta = \sup_{r \geq 0} q_2(r) \\ &\geq \langle L_1 u, u \rangle - \beta \langle L_1^{1/2} u, L_1^{-1/2} u \rangle \\ &\geq \langle L_1 u, u \rangle - \beta \langle L_1 u, u \rangle^{1/2} \langle L_1^{-1} u, u \rangle^{1/2} \\ &\geq -\frac{\beta^2}{4} \langle L_1^{-1} u, u \rangle, \end{aligned}$$

where we have used Young's inequality in the last estimate. Hence,

$$\inf_{\substack{u \neq 0 \\ u \in D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)}} \frac{\langle u, L_2 u \rangle}{\langle u, L_1^{-1} u \rangle} \geq -\frac{\beta^2}{4} > -\infty.$$

Now, let $u_n \in D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)$, with $\|u_n\|^2_{L^2} = 1$ and

$$\lim_{n \to +\infty} \frac{\langle u_n, L_2 u_n \rangle}{\langle u_n, L_1^{-1} u_n \rangle} = \inf_{\substack{u \neq 0 \\ u \in D(L_1^{-1}) \cap H^1_r(\mathbb{R}^n)}} \frac{\langle u, L_2 u \rangle}{\langle u, L_1^{-1} u \rangle} = -\gamma.$$

Then $\langle u_n, L_1^{-1} u_n \rangle$ is bounded, since if it was not, $\langle u_n, L_2 u_n \rangle$ would not be bounded either. But $\langle u_n, L_2 u_n \rangle$ is negative for large n and

$$\langle u_n, L_2 u_n \rangle = \langle u_n, L_1 u_n \rangle + \langle u_n, q_2 u_n \rangle \geq -\beta \|u_n\|^2_{L_2} = -\beta,$$

hence $\langle u_n, L_2 u_n \rangle$ is bounded.

This proves that

$$\lim_{n\to+\infty}\langle L_2u_n+\gamma L_1^{-1}u_n,u_n\rangle=0.$$

Now, for all u in $H_r^1\cap D(L_1^{-1})$, $\langle(L_2+\gamma L_1^{-1})u,u\rangle\geq 0$ and 0 is exactly the infimum of the spectrum of $L_2+\gamma L_1^{-1}$. Moreover, since from Lemma 3.4, $\sigma_e(L_2+\gamma L_1^{-1})\subset[c_0,+\infty[$, 0 is necessarily an eigenvalue for $L_2+\gamma L_1^{-1}$, i.e., $N(L_2+\gamma L_1^{-1})\neq 0$ and using the argument in Remark 3.2, this implies that $\sqrt{\gamma}$ is an eigenvalue for A.

If $\lambda^2>\gamma$ and $u\in H_r^2\cap D(L_1^{-1}), u\neq 0$, then

$$\begin{aligned}\langle(L_2+\lambda^2L_1^{-1})u,u\rangle&\geq\langle(L_2+\gamma L_1^{-1})u,u\rangle+(\lambda^2-\gamma)\langle L_1^{-1}u,u\rangle\\&\geq(\lambda^2-\gamma)\langle L_1^{-1}u,u\rangle>0.\end{aligned}$$

Hence we have $N(L_2+\lambda^2L_1^{-1})=0,\forall\lambda>\sqrt{\gamma}$, and $\sqrt{\gamma}$ is a maximal eigenvalue for A. □

Remark 3.3. If z is a (not necessarily real) eigenvalue for A, and if $(u_1,u_2)^t$ is a corresponding eigenvector, then

$$z^2=-\frac{\langle L_2u_1,u_1\rangle}{\langle L_1^{-1}u_1,u_1\rangle}$$

and hence $z^2\in\mathbb{R}$. This shows that $\sqrt{\gamma}$ is of maximal real part among all the eigenvalues of A.

Remark 3.4. For the case of the usual stationary states, which are solutions of equation (1.1) having the form $\varphi(x,t)=e^{i\omega t}u_\omega(x)$ with u_ω satisfying the equation

$$\Delta u_\omega-\omega u_\omega+F(|u_\omega|^2)u_\omega=0,\qquad u_\omega\in H^1(\mathbb{R}^n),$$

linearizing around one of those real-valued solutions leads to the linearized operator

$$A_\omega=\begin{pmatrix}0&L_1^\omega\\-L_2^\omega&0\end{pmatrix}$$

with

$$\begin{cases}L_1^\omega=-\Delta-F(u_\omega^2)+\omega,\\L_2^\omega=-\Delta-F(u_\omega^2)-2u_\omega^2F'(u_\omega^2)+\omega.\end{cases}$$

Although A_ω has a form similar to our operator A, the main difference is that 0 is an eigenvalue for L_1^ω since $u_\omega\in L^2(\mathbb{R}^n)$. If we define P as the orthogonal projection on $[N(L_1^\omega)]^\perp$, the existence of real eigenvalues for A_ω can be proved by studying the kernel of $PL_2^\omega P+\lambda^2(L_1^\omega)^{-1}$ defined on $[N(L_1^\omega)]^\perp$. Now, in our proof of Theorem 3.1, the fact that L_2 has at least one negative eigenvalue was essential. But here, even if L_2^ω always has a negative eigenvalue, it may happen that $PL_2^\omega P$ is a positive operator and hence that $N(PL_2^\omega P+\lambda^2(L_1^\omega)^{-1})=\{0\}$ for all $\lambda\in\mathbb{R}$. This shows that in the case of stationary states, unlike the case of stationary bubbles, a more refined study of the operator $PL_2^\omega P+\lambda^2(L_1^\omega)^{-1}$ has to be done to draw conclusions about the stability or instability of the solutions (see the works of Grillakis [11] and [12] for some results in this direction).

4. Instability of the stationary bubbles. In this section, we prove the main result of the paper (Theorem 4.1), which is the instability of the stationary bubbles, using the results of the preceding section concerning the linearized operator. But to

prove such a result, some regularity has to be assumed for F, and we will also need some regularity about the bubbles we consider.

We assume in what follows that (7) and (8) are satisfied, and thus by Theorems 2.1 and 2.2, any stationary bubble satisfies property (v) of §2.

The following proposition shows that the stationary bubbles are regular when F is.

PROPOSITION 4.1. *Assume that F is in $\mathcal{C}^m(\mathbb{R}^+)$ with m a positive integer. Let φ be a stationary bubble; then $r_0 - \varphi \in H^{m+2}(\mathbb{R}^n)$.*

Proof. We set $u = r_0 - \varphi$. Since φ satisfy properties (i)–(v) of §2, we have $u \in H^2(\mathbb{R}^n) \cap L^\infty(\mathbb{R}^n)$, and u satisfies

$$-\Delta u = g(u)$$

with $g(s) = -F((r_0 - s)^2)(r_0 - s)$, i.e., $g \in \mathcal{C}^m(\mathbb{R}^2)$ and $g(0) = 0$. The result then follows from Moser's composition inequality ([15, I-2]).

In what follows we assume that $F \in \mathcal{C}^{m+2}(\mathbb{R}^n)$, with m an integer larger than $\frac{n}{2}$. We consider the space of functions $u \in \mathbb{H}^m(\mathbb{R}^n)$ defined in §1, this space is identified with $H^m(\mathbb{R}^n) \times H^m(\mathbb{R}^n)$.

We give a very classical result concerning the existence of solutions φ for the evolution equation (1), such that $r_0 - \varphi \in H^m(\mathbb{R}^n)$. □

PROPOSITION 4.2. *Let $u_0 \in \mathbb{H}^m(\mathbb{R}^m)$. Then there exist $T_+, T_- \in]0, +\infty]$ depending only on $\|u_0\|_{\mathbb{H}^m}$ such that the equation*

$$i\frac{\partial u}{\partial t} + \Delta u - F(|r_0 - u|^2)(r_0 - u) = 0 \tag{15}$$

has a unique solution $u \in \mathcal{C}^0(]T_-, T_+[, \mathbb{H}^m(\mathbb{R}^n)) \cap \mathcal{C}^1(]T_-, T_+[, \mathbb{H}^{m-2}(\mathbb{R}^n))$ satisfying $u(0) = u_0$.

Proof. The proof is obvious since $i\Delta$ generates a unitary group in $\mathbb{H}^m(\mathbb{R}^n)$ and $v \mapsto F(|r_0 - v|^2)(r_0 - v)$ is locally Lipschitz on $\mathbb{H}^m(\mathbb{R}^n)$ for $m > \frac{n}{2}$ (see for example the proof of Proposition A.1). □

The following theorem is the main result of the paper.

THEOREM 4.1. *Let φ be a stationary bubble (satisfying properties* (i)–(v) *of* §2). *Then φ is unstable in the following sense. $\exists \varepsilon > 0, \forall \delta > 0, \exists u_0 \in \mathbb{H}^m(\mathbb{R}^n)$ satisfying $\|u_0\|_{\mathbb{H}^m} < \delta$ and such that if $u(t) \in \mathbb{H}^m(\mathbb{R}^n)$ and $v(t) = u(t) + \varphi$ is the solution of equation* (1) *with $v(0) = u_0 + \varphi$, then $\exists t_0 > 0$ such that $\|u(t_0)\|_{\mathbb{H}^m} > \varepsilon$.*

Proof. Let φ be a stationary bubble; if $v = \varphi + u$ is a solution of equation (1), then u is a solution of

$$i\frac{\partial u}{\partial t} + \Delta u + h'(\varphi)u + [h(\varphi + u) - h(\varphi) - h'(\varphi)u] = 0,$$

where $h(z) = F(|z|^2)z$. From Proposition A.1, we get

$$\|h(\varphi + u) - h(\varphi) - h'(\varphi)u\|_{\mathbb{H}^m} = O(\|u\|^2_{\mathbb{H}^m}) \quad \text{as } \|u\|_{\mathbb{H}^m} \to 0.$$

Hence u satisfies an equation of the form

$$\frac{\partial \mathcal{U}}{\partial t} = A\mathcal{U} + f(\mathcal{U}), \tag{16}$$
$$\mathcal{U} = (u_1, u_2)^t = (\mathcal{R}e\ u, \mathcal{I}m\ u)^t,$$

where A is the operator defined in §3 and

$$\|f(\mathcal{U})\|_{\mathbb{H}^m} = O(\|\mathcal{U}\|^2_{\mathbb{H}^m}) \quad \text{as } \|\mathcal{U}\|^2_{\mathbb{H}^m} \to 0.$$

It follows from Proposition 4.1 that $r_0 - \varphi \in H^m(\mathbb{R}^n)$. Therefore, $q_1 = F(\varphi^2)$ and $q_2 - c_0 = 2\varphi^2 F'(\varphi^2) - c_0$ are in $H^m(\mathbb{R}^n)$, and for any $\mathcal{U} = (u_1, u_2)^t \in \mathbb{H}^m$, the following holds:

$$\begin{aligned}((A\mathcal{U},\mathcal{U})) &= (L_1 u_2, u_1)_m - (L_2 u_1, u_2)_m \\ &= (q_1 u_2, u_1)_m - ((q_1 + q_2)u_1, u_2)_m \\ &\le (2\|q_1\|_{H^m} + \|q_2\|_{L^\infty} + \|q_2 - c_0\|_{H^m})\|\mathcal{U}\|^2_{\mathbb{H}^m},\end{aligned}$$

where we still denote by $((\cdot,\cdot))$ the inner product of the real Hilbert space $\mathbb{H}^m(\mathbb{R}^n)$, and by $(\cdot,\cdot)_m$ the inner product of $H^m(\mathbb{R}^n)$.

This shows that A generates a $\mathcal{C}^0$ semigroup $S(t)$ in $\mathbb{H}^m(\mathbb{R}^n)$ satisfying

$$\|S(t)\|_{\mathcal{L}(\mathbb{H}^m)} \le Me^{\omega t}, \tag{17}$$

where $e^{\omega t}$ is the spectral radius of $S(t)$ and

$$\omega = \inf_{t>0}\left\{\frac{\ln\|S(t)\|}{t}\right\} \ge \sqrt{\lambda_{\max}} > 0.$$

Then Proposition A.2 applies with $X = \mathbb{H}^m(\mathbb{R}^n)$ and the instability of the fixed point 0 in equation (16) follows, which means that there is a positive ε such that for any positive δ, one can find $\mathcal{U}_0 \in \mathbb{H}^m(\mathbb{R}^n)$ with $\|\mathcal{U}_0\|_{\mathbb{H}^m} < \delta$ such that if $\mathcal{U}(t)$ is the solution of equation (16) with $\mathcal{U}(0) = \mathcal{U}_0$, then there is a positive t_0 for which $\|\mathcal{U}(t_0)\|_{\mathbb{H}^m} > \varepsilon$. This proves Theorem 4.1. □

Remark 4.1. Although the linearized operator A possesses an eigenfunction $u_0 \in H^m(\mathbb{R}^n)$ corresponding to its maximal eigenvalue $\lambda_{\max} > 0$, it remains unclear whether this eigenfunction provides a nonlinearly unstable solution $u(t)$. The difficulty lies in the fact that the real number ω in estimate (17) may be greater than $\lambda_{\max}$. The existence of a positive eigenvalue $\lambda_{\max}$ only allows us to say that ω is positive.

Remark 4.2. When a family of traveling waves $\varphi_v(x - vt)$ is considered, with $v \mapsto \varphi_v$ continuous with values in X, then one has to study the stability modulo translations, because if $|v_1 - v_2|$ is small then $|\varphi_{v_1} - \varphi_{v_2}|_X$ is also small, but one cannot expect $\sup_{t\in\mathbb{R}} |\varphi_{v_1}(\cdot - v_1 t) - \varphi_{v_2}(\cdot - v_2 t)|_X$ to be small since the two traveling waves are propagating with different velocities. In the case of the bubbles, in dimension $n = 1$, the family of traveling waves is not continuous with values in $H^1(\mathbb{R}^n)$ and one has moreover if $v_1 \ne v_2, \lim_{|x|\to\infty} \varphi_{v_1}(x) \ne \lim_{|x|\to\infty} \varphi_{v_2}(x)$, so that $\varphi_{v_1} - \varphi_{v_2}$ is not in $H^1(\mathbb{R}^n)$. In addition, a paper from Barashenkov and Panova [3] tends to show by numerical computations that the (one-dimensional) cubic-quintic traveling bubbles, which seem to be unstable for low velocities and to become stable after some critical velocity v_c, present a real stability for $v > v_c$ and not only a stability modulo translations. Therefore it is not obvious whether this form of instability has to be considered here. However, the remark after Theorem 2 in [14] allows us to say that the stationary bubbles are indeed unstable modulo translations, since if φ is a stationary bubble, then the family $\{\varphi(\cdot - \alpha) - \varphi, \alpha \in \mathbb{R}^n\}$ is a C^1 family with values in $H^1(\mathbb{R}^n)$.

Appendix. The first lemma, which is a well-known adaptation of Weyl's essential spectrum theorem to the case of closed unbounded operators, follows for instance from Lemmas 2 and 3, §XIII-4 in [17].

LEMMA A.1. *Let A and B be closed unbounded operators with dense domain on a Banach space. We assume that*

(i) *$\sigma(A)$ has an empty interior set in $\mathbb{C}$,*

(ii) *each connected component of $\mathbb{C}\backslash\sigma(A)$ contains a point in $\rho(B)$, and*

(iii) *there is a λ_0 in $\rho(B)\cap\rho(A)$ such that $(A-\lambda_0)^{-1}-(B-\lambda_0)^{-1}$ is a compact operator.*

Then $\sigma_e(A) = \sigma_e(B)$.

Proof. Using Lemma 2, §XIII-4 in [17], one can connect $\sigma_e(A)$ and $\sigma_e((A-\lambda_0)^{-1})$; then [17, Lem. 3, §XIII-4] applies to $(A-\lambda_0)^{-1}$ and $(B-\lambda_0)^{-1}$, which are bounded operators. □

Now, we prove a proposition which allows us to linearize equation (1) in $\mathbb{H}^m(\mathbb{R}^n)$ if $m > \frac{n}{2}$ and which is used in the proof of Theorem 4.1.

PROPOSITION A.1. *Let m be an integer greater than $\frac{n}{2}$, and let $g : \mathbb{R}^2 \to \mathbb{R}^2$ be a function of class C^{m+2} on $\mathbb{R}^2$. Then for any $v \in \mathbb{H}^m(\mathbb{R}^n) = H^m(\mathbb{R}^n) \times H^m(\mathbb{R}^n)$ there are positive constants a and b, depending only on $\|v\|_{\mathbb{H}^m}$ such that, for any $u \in \mathbb{H}^m(\mathbb{R}^n)$ with $\|u\|_{\mathbb{H}^m} \le a$,*

$$\|g(u+v) - g(v) - g'(v)u\|_{\mathbb{H}^m} \le b\|u\|^2_{\mathbb{H}^m}.$$

Proof. Let $u = (u_1, u_2)^t, v = (v_1, v_2)^t \in \mathbb{H}^m(\mathbb{R}^n)$. Then

$$\begin{aligned} g(u+v) - g(v) - g'(v)u &= \int_0^1 (1-t)g''(v+tu)(u,u)\,dt \\ &= \sum_{i,j=1}^{2} u_i u_j \int_0^1 (1-t)\frac{\partial^2 g}{\partial y_i \partial y_j}(v+tu)\,dt. \end{aligned}$$

Hence

$$\begin{aligned} &\|g(v+u) - g(v) - g'(v)u\|_{\mathbb{H}^m} \\ &\quad \le \|u\|^2_{\mathbb{H}^m}\left(C + C'\int_0^1 (1-t)\left\|\frac{\partial^2 g}{\partial y_i \partial y_j}(v+tu) - \frac{\partial^2 g}{\partial y_i \partial y_j}(0)\right\|_{\mathbb{H}^m} dt\right). \end{aligned}$$

Since $\partial_{y_i}\partial_{y_j} g_k \in C^m(\mathbb{R}^2)$ for $i, j, k \in \{1, 2\}$, it follows that

$$\left\|\frac{\partial^2 g}{\partial y_i \partial y_j}(v) - \frac{\partial^2 g}{\partial y_i \partial y_j}(0)\right\|_{\mathbb{H}^m} \le C(\|v\|_{L^\infty})(1 + \|v\|_{\mathbb{H}^m}),$$

as in the proof of Proposition 4.1.

The last term is bounded with $\|v\|_{\mathbb{H}^m}$ and this proves Proposition A.1. □

The following proposition, which makes the connection between linearized and nonlinear instability, follows from a theorem due to Henry, Perez, and Wreszinski [14]; we recall it here for the sake of completeness, but in a slightly weaker form, which is in fact sufficient in our case.

PROPOSITION A.2. *Let X be a Banach space, A a linear unbounded operator on X, and consider the equation*

$$\frac{\partial \mathcal{U}}{\partial t} = A\mathcal{U} + f(\mathcal{U}), \tag{18}$$

where $f : \mathbb{R}^+ \to \mathbb{R}$ satisfies

$$\|f(\mathcal{U})\|_X = O(\|\mathcal{U}\|^2_X) \quad \text{as } \|\mathcal{U}\|_X \to 0.$$

Assume that A generates a $\mathcal{C}^0$ semigroup $S(t)$ on X satisfying $\|S(t)\|_{\mathcal{L}(X)} \leq Me^{\omega t}$ with

$$\omega = \inf_{t>0} \left\{ \frac{\|S(t)\|_{\mathcal{L}(X)}}{t} \right\} > 0.$$

Then 0 is an unstable fixed point of equation (18), i.e., $\exists \varepsilon > 0, \forall \delta > 0, \exists \mathcal{U}_0 \in X$ with $\|\mathcal{U}_0\|_X < \delta$ and $\exists t_0 > 0$ such that $\|\mathcal{U}(t_0)\|_X > \varepsilon$ where $\mathcal{U}(t)$ is the solution of (18) with $\mathcal{U}(0) = \mathcal{U}_0$.

Proof. We denote by $T(t)$ the nonlinear semigroup associated with equation (18), i.e., $T(t)\mathcal{U}_0 = \mathcal{U}(t)$ where $\mathcal{U}(t)$ is the solution of (18) with $\mathcal{U}(0) = \mathcal{U}_0$. Also, we denote by $\|\cdot\|$ the norm on the Banach space X.

Since $f(\mathcal{U}) = O(\|\mathcal{U}\|^2)$ as $\|\mathcal{U}\| \to 0$ there are constants $a_1 > 0$ and $c > 0$ such that

$$\|\mathcal{U}\| < a_1 \Rightarrow \|f(\mathcal{U})\| \leq c\|\mathcal{U}\|^2.$$

Assume that 0 is a stable fixed point of $T(t)$, i.e., $\forall \varepsilon > 0, \exists \alpha > 0, \|\mathcal{U}_0\| < \alpha \Rightarrow \|T(t)\mathcal{U}_0\| < \varepsilon$ for all positive t. First, let us take $\varepsilon = a_1$; then $\exists a_0 > 0$ such that $\|\mathcal{U}_0\| < a_0 \Rightarrow \|\mathcal{U}(t)\| < a_1, \forall t \geq 0$, where $\mathcal{U}(t) = T(t)\mathcal{U}_0$.

But we have

$$T(t)\mathcal{U}_0 = S(t)\mathcal{U}_0 + \int_0^t S(t-r) f(\mathcal{U}(r))\, dr. \tag{19}$$

Thus, we have for $t \in [0, t_0]$ and $\|\mathcal{U}_0\| < a_0$

$$\begin{aligned} \|\mathcal{U}(t)\| &\leq Me^{\omega t}\|\mathcal{U}_0\| + \int_0^t \|S(t-r)\|_{\mathcal{L}(X)} \|f(\mathcal{U}(r))\|\, dr \\ &\leq Me^{\omega t}\|\mathcal{U}_0\| + a_1 MC \int_0^t e^{\omega(t-r)} \|\mathcal{U}(r)\|\, dr, \end{aligned}$$

and using the Gronwall lemma,

$$\|\mathcal{U}(t)\| \leq e^{\omega t_0}(M + e^{a_1 MCt_0})\|\mathcal{U}_0\| \tag{20}$$

as soon as $t \in [0, t_0]$ and $\|\mathcal{U}_0\| < a_0$.

Then using equation (19) again, we obtain for $t_0 > 0$ and $\|\mathcal{U}_0\| < a_0$

$$\begin{aligned} \|T(t)\mathcal{U}_0 - S(t)\mathcal{U}_0\| &\leq \int_0^{t_0} \|S(t_0 - r)\| \|f(\mathcal{U}(r))\|\, dr \\ &\leq MC \int_0^{t_0} e^{\omega(t_0 - r)} \|\mathcal{U}(r)\|\, dr, \end{aligned}$$

and with (20),

$$\|T(t_0)\mathcal{U}_0 - S(t_0)\mathcal{U}_0\| \leq b(t_0)\|\mathcal{U}_0\|^2 \ \forall t_0 > 0 \quad \text{and} \quad \|\mathcal{U}_0\| < a_0.$$

From now on, we take a positive t_0 and assume, by changing b if necessary, that

$$b = b(t_0) \geq \frac{e^{\omega t_0} - 1}{8a_0 M^2}. \tag{21}$$

Then let

$$\varepsilon < \inf\left\{a_1, \frac{e^{\omega t_0}-1}{32M^3b}\right\}$$

and let $\alpha > 0$ be such that $\|\mathcal{U}_0\| < \alpha \Rightarrow \|\mathcal{U}(t)\| \leq \varepsilon$, for all positive t. Take $\lambda \in \sigma(S(t_0))$ with $|\lambda| = e^{\omega t_0}$. Note that $e^{\omega t_0}$ is the spectral radius of $S(t_0)$, i.e., $\lambda = e^{i\theta}e^{\omega t_0}$, with $\theta \in \mathbb{R}$.

Let N be an integer large enough so that

$$e^{\omega N t_0} \leq \frac{e^{\omega t_0 - 1}}{16M^3b\alpha} \tag{22}$$

and

$$|e^{iN\theta} - 1| \leq \frac{1}{12}. \tag{23}$$

Then, since $\lambda \in \sigma(S(t_0))$, we can find ξ and $\eta \in X$ such that $\|\xi\|^2 + \|\eta\|^2 \geq 1$ and $\|S(t_0)(\xi + i\eta) - \lambda(\xi + i\eta)\|_{X+iX}$ is arbitrarily small. To be more precise, we choose ξ and η in X such that $\|\eta\| \leq \|\xi\| = 1$ and satisfying

$$\|S(Nt_0)(\xi + i\eta) - \lambda^N(\xi + i\eta)\|_{X+iX} \leq \frac{1}{12}e^{\omega N t_0}.$$

Then we have

$$\|S(Nt_0)\xi - \mathcal{R}e(\lambda^N(\xi + i\eta))\| = \|S(Nt_0)\xi - e^{\omega N t_0}(\cos(N\theta)\xi - \sin(N\theta)\eta)\| \leq \frac{e^{\omega N t_0}}{12}.$$

Since it follows from (23) that

$$|\cos N\theta| \geq 1 - \frac{1}{12}$$

and

$$|\sin N\theta| \leq \frac{1}{12},$$

we obtain

$$\|S(Nt_0)\xi\| \geq \frac{3}{4}e^{\omega N t_0}.$$

Now, let

$$\delta = \frac{e^{\omega t_0} - 1}{16M^3be^{\omega N t_0}}.$$

It follows from (22) that $\delta \leq \alpha$, and thus if we take $\mathcal{U}_0 = \delta\xi$, we must have $\|T(t)\mathcal{U}_0\| \leq \varepsilon$ for all positive t. We will show that this is not satisfied, and more precisely that $\|\mathcal{U}(Nt_0)\| = \|T(Nt_0)\mathcal{U}_0\| \geq \varepsilon$.

For $0 \leq n \leq N$, we have

$$\begin{aligned}\mathcal{U}(nt_0) = T(nt_0)\mathcal{U}_0 &= S(nt_0)\mathcal{U}_0 + \sum_{k=0}^{n-1} S((n-1-k)t_0)[\mathcal{U}((k+1)t_0) - S(t_0)\mathcal{U}(kt_0)] \\ &= S(nt_0)\mathcal{U}_0 + \sum_{k=0}^{n-1} S((n-1-k)t_0)[T(t_0)\mathcal{U}(kt_0) - S(t_0)\mathcal{U}(kt_0)].\end{aligned}$$

Then, it is easy to show by induction, using (21) and (20), that

$$\|\mathcal{U}(nt_0) - S(nt_0)\mathcal{U}_0\| \leq \frac{\delta}{4} e^{\omega n t_0}, \quad 0 \leq n \leq N.$$

We deduce that

$$\|\mathcal{U}(Nt_0)\| \geq \|S(Nt_0)\mathcal{U}_0\| - \frac{\delta}{4} e^{\omega N t_0} \geq \frac{\delta}{2} e^{\omega N t_0} > \frac{e^{\omega t_0} - 1}{32 M^3 b} \geq \varepsilon,$$

and this proves the result. □

Acknowledgments. I am indebted to J. C. Saut who brought the subject to my attention, and J. Ginibre, who considerably simplified some of the proofs.

HEARING POINT MASSES IN A STRING*

ROBERT CARLSON†

Abstract. The spectral and inverse spectral theory for certain singular Sturm–Liouville problems is developed. These boundary value problems arise when considering the wave equation corresponding to a string with finitely many embedded point masses. These singular eigenvalue equations, their solutions, and the associated Hilbert space operators are constructed as limits of regular problems. The eigenfunctions of the singular problem are shown to be solutions of a regular eigenvalue problem with interior point conditions.

Expressions describing the distribution of large eigenvalues are developed. Algorithms are given for extracting information about the singularities from eigenvalues corresponding to one or two sets of boundary conditions. In the generic case a single spectrum determines the (unordered) set of lengths of the intervals separating the singularities.

Key words. Sturm–Liouville problem, inverse eigenvalue problem, inverse spectral theory

AMS subject classification. 34A55

1. Introduction.

The one-dimensional linear wave equation for the transverse vibrations of a string in the absence of exterior forces with constant tension 1 is [3]

$$\frac{\partial^2 u}{\partial t^2} = \frac{1}{\rho(x)} \frac{\partial^2 u}{\partial x^2},$$

subject to appropriate boundary conditions. "Hearing" the string density $\rho(x)$ is the problem of recovering ρ from the eigenvalues of the linear operator, which sends function f in its domain to f''/ρ. We are interested in direct and inverse spectral problems suggested by the physical model where the string density includes two contributions: a fixed, possibly inhomogeneous background density, and a finite family of masses with fixed "locations" and densities increasing to infinity. For technical convenience we use the reduction to Liouville normal form [5, p. 296] to remove the influence of the background density from the leading coefficient.

The main purpose of this work is to understand the effect of point masses on the sequence of eigenvalues of the string, and to extract information about the locations of the point masses from a single Sturm–Liouville problem. To make sense of point masses, we begin with ordinary differential operators of the form

$$L_\epsilon f = \frac{-1}{\rho_\epsilon(x)}[f''(x) + q(x)f(x)],$$

with ρ_ϵ integrable and real-valued, and q continuous and real-valued. The functions in the domain of the operator are assumed to satisfy the self-adjoint boundary conditions

$$af(0) - bf'(0) = 0, \tag{1.a}$$

$$cf(1) - df'(1) = 0,$$

*Received by the editors February 16, 1993; accepted for publication (in revised form) November 16, 1993.

where a, b, c, d are real. The limiting behavior is considered when the coefficients $\rho_\epsilon(x)$, $\epsilon > 0$, converge in the sense of distributions to

$$\rho_0(x) = 1 + \sum_{j=0}^{J-1} m_j \delta(x - x_j), \quad 0 < x_0 < \cdots < x_{J-1} < 1, \quad m_j > 0.$$

Under suitable hypotheses, the eigenvalues $\lambda_{\epsilon,k}$ converge to $\lambda_{0,k}$. The asymptotic behavior of $\lambda_{0,k}$ is described, and we give an algorithm for the recovery of the lengths $l_j = x_j - x_{j-1}$ from the tail $\{\lambda_{0,k}\}_{k>N}$ of a single eigenvalue sequence. This algorithm has a natural approximation when only a finite set of eigenvalues is known; it also provides an approach for approximating l_j when the masses have large but finite density.

The analysis of inverse spectral problems for second-order differential equations has led to a substantial body of literature. Early work on these problems was done by Borg [6], followed shortly thereafter by extensive work in the Soviet Union [14]–[18]. In particular, Krein [16] considered string equations with measures as coefficients; an extensive development of the spectral theory for such operators is in [15]. Inverse spectral problems are usually considered in the Liouville normal form

$$-y'' + q(x)y = \lambda y.$$

Unless $q(x)$ is even or otherwise constrained, one needs the spectra from two sets of boundary conditions, or one spectrum and a sequence of norming constants, to uniquely determine $q(x)$. Such inversion problems were solved for string equations with measures as coefficients by Krein [16].

More recently, new geometric ideas were developed for these problems by McKean and Trubowitz and their coworkers (see [21] and the references therein). Much of the recent work stressing irregular leading coefficients is motivated by geophysical models for oscillations of the earth. Hald [12] poses problems with an interior jump condition. Andersson [2] and Coleman and McLaughlin [11] consider problems of the form

$$(p^2 y')' + \lambda p^2 y = 0$$

with coefficients too irregular for the classic reduction to Liouville normal form. These and related results are surveyed in [19] and [8].

The investigation begins in §2, where convergence results show that the eigenvalue equation has meaningful solutions in the infinite density limit. In particular, Lemma 2.3 shows that the limiting solutions of the eigenvalue equation can be characterized as solutions of the "background" equation (no point masses) with interior point conditions at the point mass locations. These interior point conditions explicitly involve the mass at that point and the eigenvalue parameter.

Section 3 is devoted to an operator theoretic interpretation of the infinite density limit. For technical convenience we assume that 0 is not an eigenvalue of the "background" problem. We show that the limiting solutions of the eigenvalue equation from §2, which also satisfy the above boundary conditions, are the eigenfunctions of a self-adjoint Hilbert space operator with compact inverse. It is interesting that the Hilbert space on which the operator acts is not $L^2[0,1]$ but can be viewed as a finite-dimensional extension of this space [10].

Section 4 addresses the direct and inverse spectral theory for the limit operator. There is a fairly simple description of the eigenvalue asymptotics (Theorem 4.1), although they are more complex than in the usual case with regular coefficients. Turning

to the inverse spectral problem, we show that the eigenvalues are the zeros of an entire function $f(\lambda)$ of order $1/2$, which can thus be recovered, up to a constant factor, from the eigenvalues. An analysis of this entire function shows that in the case of Dirichlet boundary conditions, and generically for other separated boundary conditions, the unordered set of lengths $\{l_j = x_j - x_{j-1}\}$ is (constructively) determined by the tail $\{\lambda_k\}_{k=N}^{\infty}$ of an eigenvalue sequence from one set of boundary conditions. In the case of embedded point masses in an otherwise homogeneous string ($q(x) = 0$), additional results refine what was previously known about eigenvalue inversion for a string.

For the reader's convenience we mention some notational conventions. When convenient, $x(j)$ is written for x_j. Also, ∂_x is used for $\partial/\partial x$. A piecewise continuous function has limits $f(x_j^+) = \lim_{x \downarrow x_j} f(x)$ and $f(x_j^-) = \lim_{x \uparrow x_j} f(x)$.

2. Limiting solutions of the eigenvalue equation. Consider first the behavior, as $\epsilon \to 0$, $\epsilon > 0$, of the solutions of the initial value problem

$$L_\epsilon y_\epsilon = \lambda y_\epsilon, \quad y_\epsilon(0,\lambda) = b, \quad y_\epsilon'(0,\lambda) = a, \tag{2.a}$$

with

$$L_\epsilon y = \frac{-1}{\rho_\epsilon(x)}[\partial_x^2 y(x) + q(x)y(x)].$$

Write

$$\rho_\epsilon(x) = 1 + B_\epsilon(x) = 1 + \sum_j m_j b_{\epsilon,j}(x),$$

and assume that the functions $b_{\epsilon,j}(x) \geq 0$ are supported in the intervals $[x_j - \epsilon, x_j + \epsilon]$ and satisfy

$$\int_0^1 b_{\epsilon,j}(x)dx = 1.$$

The first lemma provides bounds for $|y_\epsilon(x,\lambda)|$ and $|y_\epsilon'(x,\lambda)|$ independent of ϵ. Let $M = \sum m_j$.

LEMMA 2.1. *If $y_\epsilon(x,\lambda)$ is the solution of* (2.a) *then, independent of ϵ, there is a function $K(a,b,\|q\|_\infty)$ such that*

$$|y_\epsilon(x,\lambda)| \leq K \ \exp(|Im\sqrt{\lambda}|x) \exp\left(\left|\sqrt{\lambda}\int_0^x B_\epsilon(t)dt\right|\right)$$

$$\leq K \ \exp(|Im\sqrt{\lambda}|x) \exp(|\sqrt{\lambda}M|)$$

and

$$|y_\epsilon'(x,\lambda)| \leq K[1 + |\sqrt{\lambda}|] \exp(|Im\sqrt{\lambda}|x) \exp(|\sqrt{\lambda}M|).$$

Proof. First introduce the solutions $C(x,t,\lambda)$, $S(x,t,\lambda)$ of the equation

$$-y''(x) + q(x)y = \lambda y(x),$$

which satisfy

$$C(t,t,\lambda) = 1, \quad C'(t,t,\lambda) = 0,$$

$$S(t,t,\lambda) = 0, \quad S'(t,t,\lambda) = 1.$$

We will write $C(x,\lambda)$ for $C(x,0,\lambda)$ and $S(x,\lambda)$ for $S(x,0,\lambda)$. The eigenvalue equation can be rewritten

$$-y_\epsilon'' + qy_\epsilon - \lambda y_\epsilon = B_\epsilon \lambda y_\epsilon.$$

This leads by variation of parameters to the equivalent integral equation

$$y_\epsilon(x,\lambda) = bC(x,\lambda) + aS(x,\lambda) - \lambda \int_0^x S(x,t,\lambda) B_\epsilon(t) y_\epsilon(t,\lambda)\, dt. \tag{2.b}$$

The function $S(x,t,\lambda)$ in turn can be represented as the unique solution of

$$S(x,t,\lambda) = \frac{\sin(\sqrt{\lambda}[x-t])}{\sqrt{\lambda}} - \int_t^x \frac{\sin(\sqrt{\lambda}[x-u])}{\sqrt{\lambda}} q(u) S(u,t,\lambda)\, du. \tag{2.c}$$

Defining the iterates

$$S_0(x,t,\lambda) = \frac{\sin(\sqrt{\lambda}[x-t])}{\sqrt{\lambda}},$$

$$S_{n+1}(x,t,\lambda) = \frac{\sin(\sqrt{\lambda}[x-t])}{\sqrt{\lambda}} + \int_t^x \frac{\sin(\sqrt{\lambda}[x-u])}{\sqrt{\lambda}} q(u) S_n(u,t,\lambda)\, du,$$

we find that

$$|S_0(x,t,\lambda)| \le \exp(|Im(\sqrt{\lambda}\,)||x-t|)$$

and, if $K_1 = \|q\|_\infty$,

$$|S_{n+1}(x,t,\lambda) - S_n(x,t,\lambda)| \le K_1 \int_t^x \exp(|Im(\sqrt{\lambda})||x-u|)|S_n(u,t,\lambda) - S_{n-1}(u,t,\lambda)|\, du.$$

By induction these inequalities yield the estimates

$$|S_{n+1}(x,t,\lambda) - S_n(x,t,\lambda)| \le \exp(|Im(\sqrt{\lambda})||x-t|)[K_1|x-t|]^n/n!,$$

and since $0 \le x,t \le 1$ there is a constant K_2 such that

$$|S(x,t,\lambda)| \le \exp(|Im(\sqrt{\lambda})||x-t|)\exp(K_1|x-t|]) \le K_2 \exp(|Im(\sqrt{\lambda})||x-t|).$$

Differentiation of (2.c) gives

$$\partial_t S(x,t,\lambda) = -\cos(\sqrt{\lambda}[x-t]) + \int_t^x \frac{\sin(\sqrt{\lambda}[x-u])}{\sqrt{\lambda}} q(u) \partial_t S(u,t,\lambda)\, du,$$

so that an argument like the previous one yields, with a new constant,

$$|\partial_t S(x,t,\lambda)| \le K_2 \exp(|Im(\sqrt{\lambda})||x-t|).$$

The estimates for $y_\epsilon(x,\lambda)$ and $y'_\epsilon(x,\lambda)$ are similarly obtained by using Picard iteration. Suppressing the ϵ for notational convenience, define

$$\phi_0(x,\lambda) = bC(x,\lambda) + aS(x,\lambda),$$

and for $n \ge 1$,

$$\phi_n(x,\lambda) = \phi_0(x,\lambda) - \lambda \int_0^x S(x,t,\lambda) B_\epsilon(t) \phi_{n-1}(t,\lambda)\, dt.$$

It is simple to see that there is a function $K_3(a,b)$ such that

$$|\phi_1 - \phi_0|(x,\lambda) \le K_3|\lambda| \exp(|Im\sqrt{\lambda}|x) \int_0^x B_\epsilon(t)dt$$

and then, by induction [20, p. 331],

$$|\phi_n - \phi_{n-1}|(x,\lambda) \le K_3|\lambda|^n \exp(|Im\sqrt{\lambda}|x) \left[\int_0^x B_\epsilon(t)dt\right]^n /n!.$$

Summing, we get the estimate for $|y_\epsilon(x,\lambda)|$. Differentiation of (2.b) and a parallel argument produces the estimates for $|y'_\epsilon(x,\lambda)|$. □

LEMMA 2.2. *As $\epsilon \to 0$, the functions $y_\epsilon(x,\lambda)$ converge uniformly on compact subsets of $[0,1] \times C$ to a continuous function $y_0(x,\lambda)$.*

Proof. Let $\eta \le \epsilon$. Using (2.b), we find

$$|y_\epsilon - y_\eta| \le \left|\lambda \int_0^x S(x,t,\lambda)B_\epsilon(t)[y_\epsilon(t,\lambda) - y_\eta(t,\lambda)]\ dt\right|$$

$$+ \left|\lambda \int_0^x S(x,t,\lambda)[B_\epsilon(t) - B_\eta(t)]y_\eta(t,\lambda)\ dt\right|.$$

The last integral is estimated first. Since

$$y_\eta(t,\lambda) = y_\eta(x_j - \epsilon,\lambda) + \int_{x_j-\epsilon}^t \partial_u y_\eta(u,\lambda)du,$$

we can write

$$\left|\lambda \int_0^x S(x,t,\lambda)[B_\epsilon(t) - B_\eta(t)]y_\eta(t,\lambda)\ dt\right|$$
$$\le |\lambda| \sum_j m_j \left|\int_{x_j-\epsilon}^x S(x,t,\lambda)[b_{\epsilon,j}(t) - b_{\eta,j}(t)]y_\eta(x_j - \epsilon,\lambda)\ dt\right|$$
$$+ |\lambda| \sum_j m_j \left|\int_{x_j-\epsilon}^x S(x,t,\lambda)[b_{\epsilon,j}(t) - b_{\eta,j}(t)] \int_{x_j-\epsilon}^t \partial_u y_\eta(u,\lambda)\ du\ dt\right|.$$

On compact subsets of $[0,1] \times [0,1] \times C$, the second sum directly above goes to 0 as $\epsilon \to 0$ because of the uniform bounds on $|\partial_u y_\eta(u,\lambda)|$ derived in Lemma 2.1, and because the support of $b_{\epsilon,j}$ and $b_{\eta,j}$ are in $[x_j - \epsilon, x_j + \epsilon]$. The first sum goes to 0 because of the continuity of $S(x,t,\lambda)$ and the uniform bounds on $|y_\eta(t,\lambda)|$.

Thus for any $\xi > 0$ and any compact subset of $[0,1] \times [0,1] \times C$ we can find ϵ such that

$$\left|\lambda \int_0^x S(x,t,\lambda)[B_\epsilon(t) - B_\eta(t)]y_\eta(t,\lambda)\ dt\right| < \xi.$$

For such ϵ, ξ, we have

$$|y_\epsilon - y_\eta| \le \xi + K_2|\lambda| \int_0^x \exp(|\sqrt{\lambda}|)|B_\epsilon(t)|y_\epsilon(t,\lambda) - y_\eta(t,\lambda)|\ dt.$$

By Gronwall's inequality [13, p. 24],

$$|y_\epsilon - y_\eta| \le \xi \exp\Big(|K_2\lambda| \int_0^x \exp(|\sqrt{\lambda}|)|B_\epsilon(t)|\, dt\Big)$$

and so we have convergence to a continuous limit uniformly in compact subsets of $[0,1] \times C$. □

LEMMA 2.3. *The functions $y_0(x,\lambda)$ satisfy the differential equation*

$$-y_0'' + q(x)y_0 = \lambda y_0, \quad x \ne x_j \tag{2.d}$$

and interior point conditions

$$-\lambda m_j y_0(x_j,\lambda) = y_0'(x_j^+,\lambda) - y_0'(x_j^-,\lambda).$$

Moreover, $y_\epsilon'(x,\lambda)$ converges uniformly to $y_0'(x,\lambda)$ on compact subsets of $\{[0,1] \setminus \{x_j\}\} \times C$.

Proof. To see that the equations and interior point conditions are satisfied by the limiting solutions $y_0(x,\lambda)$, first observe that the functions $y_\epsilon(x,\lambda)$ satisfy the equation

$$-y_\epsilon'' + q(x)y_\epsilon = \lambda y_\epsilon, \quad |x - x_j| > \epsilon,$$

so that the uniform limit satisfies the differential equation away from x_j. Differentiation of (2.b) gives

$$y_\epsilon'(x,\lambda) = bC'(x,\lambda) + aS'(x,\lambda) - \lambda \int_0^x \partial_x S(x,t,\lambda) B_\epsilon(t) y_\epsilon(t,\lambda)\, dt.$$

Thus $y_0'(x_j^-,\lambda)$ and $y_0'(x_j^+,\lambda)$ exist and satisfy

$$y_0'(x_j^-,\lambda) = bC'(x_j,\lambda) + aS'(x_j,\lambda) - \lambda \sum_{i<j} m_i \partial_x S(x_j,x_i,\lambda) y_\epsilon(x_i,\lambda),$$

$$y_0'(x_j^+,\lambda) = bC'(x_j,\lambda) + aS'(x_j,\lambda) - \lambda \sum_{i\le j} m_i \partial_x S(x_j,x_i,\lambda) y_\epsilon(x_i,\lambda).$$

Subtracting gives the desired interior point conditions. □

Suppose that $y_1(x,\lambda,\epsilon)$, $y_2(x,\lambda,\epsilon)$ are solutions of (2.a) for $\epsilon > 0$, satisfying the initial conditions

$$y_1(0,\lambda,\epsilon) = 1, \quad y_2(1,\lambda,\epsilon) = 0,$$
$$y_1'(0,\lambda,\epsilon) = 0, \quad y_2'(1,\lambda,\epsilon) = 1.$$

Then the variation of parameters formula gives us solutions of the inhomogeneous equation

$$[L_\epsilon - \lambda]f = g, \quad f(0) = 0 = f'(0)$$

in the form

$$f(x,\lambda,\epsilon) = \int_0^x G_\epsilon(x,t,\lambda) g(t)\, dt$$

with

$$G_\epsilon(x,t,\lambda) = -y_1(x,\lambda,\epsilon)y_2(t,\lambda,\epsilon) + y_1(t,\lambda,\epsilon)y_2(x,\lambda,\epsilon).$$

As a consequence of Lemma 2.2 we have the next lemma.

LEMMA 2.4. *As $\epsilon \to 0$, the kernels $G_\epsilon(x,t,\lambda)$ converge uniformly on compact subsets of $[0,1]\times[0,1]\times C$ to a continuous function $G_0(x,t,\lambda)$ with $G_0(x,x,\lambda)=0$.*

3. The limit operator. As is well known, there are self-adjoint Hilbert space operators associated to the operators L_ϵ with boundary conditions (1.a). It will be convenient to have a Hilbert space operator interpretation of

$$L_0 = \lim_{\epsilon\to 0} L_\epsilon.$$

This is most conveniently done when there is no nontrivial solution of

$$-y'' + q(x)y = 0$$

that satisfies the boundary conditions (1.a). In this situation we will establish a convergence result for the inverses of the operators L_ϵ.

For continuous functions $g(x)$, consider the boundary value problems

$$\frac{-1}{\rho_\epsilon}[\partial_x^2 f_\epsilon + q(x)f_\epsilon] = g, \tag{3.a}$$

$$af(0) - bf'(0) = 0,$$

$$cf(1) - df'(1) = 0.$$

When 0 is not an eigenvalue, the self-adjoint operator $-\partial_x^2 + q(x)$ with these boundary conditions has an inverse which is an integral operator K with continuous kernel $K(x,t)$ [9, p. 192]. Rewriting the differential equation as

$$-\partial_x^2 f_\epsilon + q(x)f_\epsilon = g + B_\epsilon g$$

and applying K results in the equation

$$f_\epsilon(x) = \int_0^1 K(x,t)g(t)dt + \int_0^1 K(x,t)B_\epsilon g.$$

Since $K(x,t)$ and $g(x)$ are continuous, this equation will have a limiting form, and we have

LEMMA 3.1. *For each $g \in C[0,1]$, $\lim_{\epsilon\to 0} f_\epsilon(x)$ exists, and the operator $R : C[0,1] \to C[0,1]$ given by*

$$Rg = \lim_{\epsilon\to 0} f_\epsilon(x) = \int_0^1 K(x,t)g(t)dt + \sum_j m_j K(x,x_j)g(x_j) \tag{3.b}$$

is continuous and linear.

R will not extend continuously to $L^2[0,1]$, so we consider a new inner product on $C[0,1]$ given by

$$\langle f,g\rangle = \int_0^1 f(x)\bar{g}(x)dx + \sum_j m_j f(x_j)\bar{g}(x_j).$$

Define $\mathcal{H}$ to be the completion of $C[0,1]$ with respect to this inner product, i.e., $\mathcal{H} = L^2([0,1],\mu)$, where μ is the Lebesgue measure plus $\sum_j m_j\delta(x-x_j)$.

THEOREM 3.2. *R extends to a compact, self-adjoint operator on $\mathcal{H}$ with trivial null space. Every function f in the range of R is continuously differentiable except at $\{x_j\}$, where $f'(x_j^+)$ and $f'(x_j^-)$ exist.*

Proof. It suffices to test R on the continuous functions in $\mathcal{H}$. If g is continuous with $\|g\|_{\mathcal{H}} \leq 1$ then $\|g\|_2 \leq 1$ and the closure of

$$\left\{ \int_0^1 K(x,t)g(t)dt \mid \|g\|_{\mathcal{H}} \leq 1 \right\}$$

is compact in $C[0,1]$ and consists of functions whose derivative is (absolutely) continuous on [0,1]. Since the functionals given by evaluation at x_j are continuous on $C[0,1]$, the set also has compact closure in $\mathcal{H}$. The remaining term $\sum_j m_j K(x,x_j)g(x_j)$ is a continuous finite rank operator, so the R extends to a compact operator on $\mathcal{H}$. The structure of the second term in (3.b) [9, p. 192] gives the jump discontinuities of f at x_j.

To prove that R is self-adjoint, we simply compute

$$\begin{aligned}
\langle Rg, h\rangle &= \int_0^1 \Big(\int_0^1 K(x,t)g(t)dt + \sum_j m_j K(x,x_j)g(x_j) \Big) \bar{h}(x)dx \\
&\quad + \sum_k m_k \Big(\int_0^1 K(x_k,t)g(t)dt + \sum_j m_j K(x_k,x_j)g(x_j) \Big) \bar{h}(x_k) \\
&= \int_0^1 \int_0^1 K(x,t)g(t)dt\ \bar{h}(x)dx + \int_0^1 \sum_j m_j K(x,x_j)g(x_j)\bar{h}(x)dx \\
&\quad + \sum_k m_k \int_0^1 K(x_k,t)g(t)dt\ \bar{h}(x_k) + \sum_k m_k \sum_j m_j K(x_k,x_j)g(x_j)\bar{h}(x_k) \\
&= \langle g, Rh\rangle.
\end{aligned}$$

We can finish the argument by showing that when K has a trivial null space, so does R. Suppose that $Rg = 0$ for some $g \in \mathcal{H}$. Then we would have a sequence $\{g_n\}$ of continuous functions converging in $\mathcal{H}$ so that $Rg_n \to 0$ in $\mathcal{H}$. The sequence $\{g_n\}$ has a limit $h \in L^2[0,1]$, which must satisfy

$$\int_0^1 K(x,t)h(t)\ dt = \sum a_j K(x,x_j).$$

Since the left-hand side is continuously differentiable, all $a_j = 0$, and then $h = 0$. As a consequence, $g_n \to 0$ in H. □

Let L_0 be the densely defined inverse of R. From (3.b) we see that if $f \in E$ where $E = \{f$ has two continuous derivatives, the boundary conditions (1.a) are satisfied, and f and f'' vanish at all $x_j\}$, then $L_0 f = -\partial_x^2 f + q(x)f$. Further, a sequence of continuous functions g_n, which peak to a value of one at x_j and vanish for $|x - x_j| > 1/n$, will converge in $\mathcal{H}$ to a vector $v = 1_{x(j)}$ with $Rv = m_j K(x,x_j)$, so that $F = \text{span}\ \{K(x,x_j)\}$ is in the domain of L_0. Further, L_0 acting on $E + F$ has dense range in $\mathcal{H}$.

THEOREM 3.3. *The eigenfunctions ψ_k of $L_0 = R^{-1}$ are the functions satisfying the differential equations*

$$-\psi_k''(x) + q(x)\psi_k(x) = \lambda_k \psi_k(x), \quad x \neq x_j$$

and the boundary and interior point conditions

$$a\psi_k(0) - b\psi_k'(0) = 0, \quad c\psi_k(1) - d\psi_k'(1) = 0,$$

$$-\lambda_k m_j \psi_k(x_j) = \psi_k'(x_j^+) - \psi_k'(x_j^-).$$

Proof. Since 0 is not an eigenvalue of R, all eigenfunctions ψ_k of R, with eigenvalues $\mu_k = 1/\lambda_k$, are in the range of R and must be continuous. Using (3.b), we consider

$$\int_0^1 K(x,t)\psi_k(t)dt + \sum_j m_j K(x,x_j)\psi_k(x_j) = \mu_k\psi_k(x).$$

If we compute the difference of the derivatives from above and below x_j we find [9, p. 192]

$$-m_j\psi_k(x_j) = \mu_k[\psi_k'(x_j^+) - \psi_k'(x_j^-)].$$

Of course, for $x \neq x_j$ these functions satisfy $\mu_k[-\psi_k'' + q\psi_k] = \psi_k$.

Conversely, suppose ψ_k satisfies the equation and boundary and interior point conditions. Then the function $h = \psi_k - \lambda_k \sum_j m_j K(x,x_j)\psi_k(x_j)$ satisfies the differential equation

$$-h''(x) + q(x)h(x) = \lambda_k\psi_k, \quad x \neq x_j,$$

the boundary conditions, and has a continuous derivative on [0,1]. Thus h satisfies the equation for all $x \in [0,1]$ and we have

$$\psi_k - \lambda_k \sum_j m_j K(x,x_j)\psi_k(x_j) = \lambda_k \int_0^1 K(x,t)\psi_k(t)\,dt,$$

which is what we wanted to show. □

To establish the convergence of the eigenvalues of L_ϵ to those of L_0, we first provide a lemma using the technique of [21, p. 30]. Suppose y_0 is as described in Lemma 2.3, satisfying the initial conditions

$$y(0) = b, \quad y'(0) = a. \tag{3.c}$$

LEMMA 3.4. *If λ is an eigenvalue for L_0, then*

$$\partial_\lambda[cy_0(1) - dy_0'(1)] \neq 0.$$

Proof. For $x \neq x_j$, differentiate the equation

$$-y_0'' + q(x)y_0 = \lambda y_0 \tag{3.d}$$

with respect to λ to get

$$-[\partial_\lambda y_0]'' + q(x)\partial_\lambda y_0 = y_0 + \lambda\partial_\lambda y_0. \tag{3.e}$$

Multiply (3.c) by $\partial_\lambda y_0$, equation (3.d) by y_0, and subtract to get

$$-[(\partial_\lambda y_0)'y_0 - (\partial_\lambda y_0)y_0']' = y_0^2.$$

Integration yields

$$
\begin{aligned}
&-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_0^-)\\
&-\sum_{j=1}^{J-1}\Big([(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_j^-)-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_{j-1}^+)\Big)\\
&-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](1)+[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_{J-1}^+)=\int_0^1 y_0^2
\end{aligned}
$$

or

$$
\begin{aligned}
&-\sum_{j=0}^{J-1}\Big([(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_j^-)-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_j^+)\Big)\\
&-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](1)=\int_0^1 y_0^2.
\end{aligned}
$$

Differentiation of the interior point conditions

$$-\lambda m_j y_0(x_j)=y_0'(x_j^+)-y_0'(x_j^-)$$

gives

$$-m_j y_0(x_j)-\lambda m_j\partial_\lambda y_0(x_j)=\partial_\lambda y_0'(x_j^+)-\partial_\lambda y_0'(x_j^-).$$

Placing this into the above, we find

$$
\begin{aligned}
&\sum_{j=0}^{J-1}\Big([(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_j^-)-[(\partial_\lambda y_0)'y_0-(\partial_\lambda y_0)y_0'](x_j^+)\Big)\\
&=\sum_{j=0}^{J-1}\Big([(\partial_\lambda y_0)'(x_j^-)-(\partial_\lambda y_0)'(x_j^+)]y_0(x_j)-\partial_\lambda y_0(x_j)[y_0'(x_j^-)-y_0'(x_j^+)]\Big)\\
&=\sum_{j=0}^{J-1}\Big([m_j y_0(x_j)+\lambda m_j\partial_\lambda y_0(x_j)]y_0(x_j)-\partial_\lambda y_0(x_j)[\lambda m_j y_0(x_j)]\Big)\\
&=\sum_{j=0}^{J-1}\Big(m_j y_0^2(x_j)\Big).
\end{aligned}
$$

Thus we have

$$[(\partial_\lambda y_0)'y_0-\partial_\lambda y_0 y_0'](1)=\int_0^1 y_0^2+\sum_{j=0}^{J-1}\Big(m_j y_0^2(x_j)\Big).$$

At an eigenvalue λ_n we must have $cy_0(1,\lambda_n)-d_0y'(1,\lambda_n)=0$. At least one of c,d is not zero. Suppose it is c. Then we find

$$[(d\partial_\lambda y_0)'(1,\lambda_n)-c\partial_\lambda y_0(1,\lambda_n)]y_0'(1,\lambda_n)=c\left[\int_0^1 y_0^2+\sum_{j=0}^{J-1}\Big(m_j y_0^2(x_j,\lambda_n)\Big)\right]$$

and so

$$\partial_\lambda[cy_0(1,\lambda_n)-dy_0'(1,\lambda_n)]\neq 0.$$

The argument is the same if $d \neq 0$.

Finally, let $\psi_{\epsilon,k}$ denote the eigenfunction of L_ϵ corresponding to the kth eigenvalue $\lambda_{\epsilon,k}$ and satisfying the initial conditions

$$\psi_{\epsilon,k}(0) = b, \quad \psi'_{\epsilon,k}(0) = a.$$

THEOREM 3.5. *For all* $k = 1, 2, \ldots,$

$$\lambda_k = \lim_{\epsilon \to 0} \lambda_{\epsilon,k}$$

and

$$\psi_k(x, \lambda_k) = \lim_{\epsilon \to 0} \psi_{\epsilon,k}(x, \lambda_{\epsilon,k})$$

uniformly for $x \in [0, 1]$.

Proof. We begin the proof with some bounds on the eigenvalues of L_ϵ. The operator L_ϵ is self-adjoint with respect to the inner product $\langle f, g \rangle_\epsilon = \int_0^1 f(x)\bar{g}(x)\rho_\epsilon(x)\, dx$. If $\phi(x)$ is one of its eigenfunctions with eigenvalue $\lambda_{\epsilon,n}$, then

$$\lambda_{\epsilon,n} = \frac{\langle L_\epsilon \phi, \phi \rangle_\epsilon}{\langle \phi, \phi \rangle_\epsilon} = \frac{\int_0^1 [-\phi''(x) + q(x)\phi(x)]\bar{\phi}(x)\, dx}{\int_0^1 \rho_\epsilon(x)\phi(x)\bar{\phi}(x)\, dx}.$$

If the eigenvalues of $-\partial_x^2 + q(x)$ with the boundary conditions (1.a) are nonnegative, then so is the right-hand side. Otherwise let ζ_1 be the smallest eigenvalue of $-\partial_x^2 + q(x)$ with the boundary conditions (1.a). Since $\rho_\epsilon(x) \geq 1$, if $\lambda_{\epsilon,n} < 0$ we have

$$\lambda_{\epsilon,n} \geq \frac{\int_0^1 [-\phi''(x) + q(x)\phi]\bar{\phi}(x)\, dx}{\int_0^1 \phi(x)\bar{\phi}(x)\, dx} \geq \zeta_1.$$

Thus there is an a priori lower bound for the eigenvalues of all L_ϵ, $\epsilon > 0$.

Now suppose that λ_1 is the smallest eigenvalue of L_0. By virtue of the description of the eigenfunctions given in Theorem 3.3, the dimension of the eigenspace is one. Since $\partial_\lambda [c y_0(1, \lambda_0) - d y_0'(1, \lambda_0)] \neq 0$, the function $c y_0(1, \lambda_0) - d y_0'(1, \lambda_0)$ has values of opposite sign in any neighborhood of λ_0. By virtue of the convergence results in Lemmas 2.2 and 2.3, for small ϵ the operator L_ϵ has an eigenvalue $\lambda_{\epsilon,i}$, the ith largest independent of ϵ by continuity of the eigenvalues, with $\lim_{\epsilon \to 0} \lambda_{\epsilon,i} = \lambda_1$. Let ζ be the minimum of 0 and the smallest eigenvalue of $-\partial_x^2 + q(x)$. If $i \neq 1$, then the inequalities $\lambda_{\epsilon,i} > \lambda_{\epsilon,1} > \zeta$ imply the convergence of a subsequence of $\lambda_{\epsilon,1}$ to an eigenvalue of L_0 which is smaller than λ_1, an impossibility. Thus $i = 1$. The rest of the eigenvalues are handled in similar fashion. □

4. Eigenvalue asymptotics and inverse problems. In this section, using the characterization of the eigenfunctions of L_0 in Theorem 3.3, the behavior of the eigenvalues λ_k of L_0 is described as $\lambda_k \to \infty$. Procedures are given for recovering the point masses and their positions from one or two spectra.

Given a basis for the solutions of the eigenvalue equation (2.d) on the intervals between the points x_j, we can find transition matrices which describe the change of representation as each x_j is crossed. For notational simplicity define $\omega = \sqrt{\lambda}$, $l_j = x_j - x_{j-1}$, $x_{-1} = 0$, and $x_J = 1$. The eigenfunctions are first represented in the bases

$$C(x, x_{j-1}, \lambda), \quad S(x, x_{j-1}, \lambda), \quad x_{j-1} < x < x_j.$$

Writing the coefficients of a solution y of the eigenvalue equation with respect the these bases as a column vector and using the interior point conditions

$$y(x_j^+,\lambda) = y(x_j^-,\lambda), \quad y'(x_j^+,\lambda) = y'(x_j^-,\lambda) - \omega^2 m_j y(x_j),$$

it is routine to compute that the transition matrix at x_j has the form

$$T_j = \begin{pmatrix} C(x_j,x_{j-1},\lambda) & S(x_j,x_{j-1},\lambda) \\ C'(x_j,x_{j-1},\lambda) & S'(x_j,x_{j-1},\lambda) \end{pmatrix} - \lambda m_j \begin{pmatrix} 0 & 0 \\ C(x_j,x_{j-1},\lambda) & S(x_j,x_{j-1},\lambda) \end{pmatrix}.$$

Of course, the transition across all of the points x_j is then represented by $T = T_{J-1}\dots T_0$.

In looking for eigenvalues we can assume that $y(0,\lambda) = b$, $y'(0,\lambda) = a$, and then the condition that the boundary conditions at both ends are satisfied is

$$(c \quad -d) \begin{pmatrix} C(x_J,x_{J-1},\lambda) & S(x_J,x_{J-1},\lambda) \\ C'(x_J,x_{J-1},\lambda) & S'(x_J,x_{J-1},\lambda) \end{pmatrix} T(\lambda) \begin{pmatrix} b \\ a \end{pmatrix} = 0.$$

It is well known [21, p. 13] that the following estimates are valid for all $x \in [0,1]$, $\lambda \in C$, and for all coefficients q satisfying a uniform bound:

$$|C(x,x_j,\lambda) - \cos(\omega[x-x_j])| \le \frac{K}{|\omega|}\exp(|Im(\omega)|), \tag{4.a}$$

$$|S(x,x_j,\lambda) - \sin(\omega[x-x_j])/\omega| \le \frac{K}{|\lambda|}\exp(|Im(\omega)|),$$

$$|C'(x,x_j,\lambda) + \omega\sin(\omega[x-x_j])| \le K\ \exp(|Im(\omega)|),$$

$$|S'(x,x_j,\lambda) - \cos(\omega[x-x_j])| \le \frac{K}{|\omega|}\exp(|Im(\omega)|).$$

Based on these estimates, we see that if

$$G(\omega) = \begin{pmatrix} 1 & 0 \\ 0 & \omega \end{pmatrix},$$

then

$$T_j = G(\omega)\left[\begin{pmatrix} \cos(\omega l_j) & \sin(\omega l_j) \\ -\sin(\omega l_j) & \cos(\omega l_j) \end{pmatrix} + O\left(\frac{1}{\omega}\exp(|Im(\omega)|)\right)\right]G^{-1}(\omega),$$

$$-m_j\omega G(\omega)\left[\begin{pmatrix} 0 & 0 \\ \cos(\omega l_j) & \sin(\omega l_j) \end{pmatrix} + O\left(\frac{1}{\omega}\exp(|Im(\omega)|)\right)\right]G^{-1}(\omega).$$

Thus T has the form

$$T = G(\omega)\left[\begin{pmatrix} 0 & 0 \\ B_1 & B_2 \end{pmatrix} m_0\dots m_{J-1}(-\omega)^J + O(\omega^{J-1}\exp(J|Im(\omega)|))\right]G^{-1}(\omega) \tag{4.b}$$

with

$$B_1(\omega) = \cos(\omega l_0)\sin(\omega l_1)\dots\sin(\omega l_{J-1}),$$

$$B_2(\omega) = \sin(\omega l_0)\dots\sin(\omega l_{J-1}).$$

Let $Q_T = G^{-1}TG$.

The location of the eigenvalues of L_0 is approximately given by the zero set of an elementary entire function.

THEOREM 4.1. *There is a sequence* $\{\alpha_N | N = 0, 1, 2, \ldots\}$ *satisfying* $N^2 \leq \alpha_N < [N+1]^2$ *such that for* N *sufficiently large, the number of eigenvalues* λ_k *of* L_0 *with* $\lambda_k < \alpha_N$ *agrees with the number of roots* $r < \alpha_N$ *of the entire function* $h(\lambda)$, *where*

$$h(\lambda) = \lambda^J \cos(\omega l_0) \frac{\sin(\omega l_1)}{\omega} \cdots \frac{\sin(\omega l_{J-1})}{\omega} \cos(\omega l_J) \quad \text{if} \quad bd \neq 0,$$

$$h(\lambda) = \lambda^J \frac{\sin(\omega l_0)}{\omega} \cdots \frac{\sin(\omega l_{J-1})}{\omega} \cos(\omega l_J) \quad \text{if} \quad b = 0,\ d \neq 0,$$

$$h(\lambda) = \lambda^J \cos(\omega l_0) \frac{\sin(\omega l_1)}{\omega} \cdots \frac{\sin(\omega l_J)}{\omega} \quad \text{if} \quad d = 0,\ b \neq 0,$$

$$h(\lambda) = \lambda^J \frac{\sin(\omega l_0)}{\omega} \cdots \frac{\sin(\omega l_J)}{\omega} \quad \text{if} \quad b = 0,\ d = 0.$$

Moreover, if r_k *is the root of* $h(\lambda)$ *closest to* λ_k, *then*

$$|\sqrt{\lambda_k} - \sqrt{r_k}| = O(\lambda_k^{-1/(2J+2)}).$$

Proof. Details will be provided for the cases $bd \neq 0$. The other cases are similar.

The proof is similar to the discussion in [21, p. 27]. We begin with the observation that if

$$|z - n\pi| > \beta > 0, \quad n = 0, 1, 2, \ldots,$$

then there is a constant c_β such that

$$\exp(|Im(z)|) < c_\beta |\sin(z)|,$$

and similarly, if

$$|z - [n\pi + \pi/2]| > \beta > 0, \quad n = 0, 1, 2, \ldots,$$

then

$$\exp(|Im(z)|) < c_\beta |\cos(z)|.$$

Based on the explicit form of $h(\lambda)$ one sees easily that α_N can be chosen so that there is a $\beta > 0$ with $|\alpha_N - r| > \beta$ whenever $h(r) = 0$.

The condition that there is an eigenvalue at $\lambda = \omega^2$ is the equation

$$cy(1,\lambda) - dy'(1,\lambda) = (\, c \quad -d\,) G \begin{pmatrix} \cos(\omega l_J) & \sin(\omega l_J) \\ -\sin(\omega l_J) & \cos(\omega l_J) \end{pmatrix} Q_T G^{-1} \begin{pmatrix} b \\ a \end{pmatrix} = 0.$$

Using (4.b) we see that in case $db \neq 0$ this equation has the form

$$\text{(4.c)} \quad cy(1,\lambda) - dy'(1,\lambda) = -db\cos(\omega l_J) B_1(\omega) \omega^{J+1} + O(\omega^J \exp([J+1]|Im(\omega)|)) = 0.$$

On the contour $|\lambda| = \alpha_N$ there is a constant K so that

$$|cy(1,\lambda) - dy'(1,\lambda) + dbh(\lambda)| < \left| \frac{K}{\omega} h(\lambda) \right|.$$

For N sufficiently large, Rouche's theorem yields the first part of the theorem.

For more precise information about eigenvalue location, let Z_j denote the set of roots of $\sin(\omega l_j)$ or $\cos(\omega l_j)$, depending on which trigonometric function appears in $h(\lambda)$. Then

$$|\sin(\omega l_j)| \geq \frac{2}{\pi}\operatorname{dist}(\omega, Z_j),$$

and similarly for cosine, so that

$$h(\lambda) \geq K_1 \omega^{J+1} \prod_{j=0}^{J} \operatorname{dist}(\omega, Z_j).$$

Again, by making use of (4.c), we have, for large ω,

$$|cy(1,\lambda) - dy'(1,\lambda) + dbh(\lambda)| < |K\omega^J|.$$

Thus at any eigenvalue λ_k we must have

$$\prod_{j=0}^{J} \operatorname{dist}(\sqrt{\lambda_k}, Z_j) \leq \frac{K_2}{\sqrt{\lambda_k}}.$$

Letting $Z = \cup_{j=0}^{J} Z_j$ implies

$$\operatorname{dist}(\sqrt{\lambda_k}, Z) \leq K_2 \lambda_k{}^{-1/(2j+2)}. \qquad \square$$

Among the set $\mathcal{L}$ of $(J+1)$-*tuples* l_j such that $0 < l_0 < \cdots < l_J$ and $\sum_j l_j = 1$, it will be convenient to distinguish a certain subset. If the vectors $B_i = (\beta_{i,0}, \ldots, \beta_{i,J})$, $i = 1, 2$ are distinct and where $\beta_{i,j} = \pm 1$, then the subset of $\mathcal{L}$ satisfying an equation of the form

$$\sum_j \beta_{1,j} l_j = \sum_j \beta_{2,j} l_j$$

is a hypersurface, and the set $U \subset \mathcal{L}$ consisting of those $(J+1)-$ *tuples* that satisfy no equation of this form is an open dense set.

THEOREM 4.2. *If $b = d = 0$, or if $b^2 + d^2 \neq 0$ and the size ordered lengths l_j, $j = 0, \ldots, J$ are an element of U, then the lengths l_j are determined by the eigenvalues $\{\lambda_k : k > K\}$ of L_0.*

Proof. Again, we emphasize the case $bd \neq 0$, leaving the minor modification needed for the other cases to the reader. To begin, we assume that all eigenvalues λ_k of L_0 are known. From (4.c) (and its analog for the other boundary conditions), we see that the entire function $cy(1,\lambda) - dy'(1,\lambda)$, whose zeros are precisely the eigenvalues of L_0, has order $1/2$. Thus [1, p. 207]

$$cy(1,\lambda) - dy'(1,\lambda) = K_1 \prod (1 - \lambda/\lambda_k),$$

where K_1 is a nonzero constant (recall that zero is not an eigenvalue).

From the function $f(\lambda) = \prod(1 - \lambda/\lambda_k)$, we can recover $h(\lambda)$ up to a constant multiple. Rewriting $h(\lambda)$ with exponentials, we find that

$$h(\lambda) = -\left[\frac{\omega}{2i}\right]^{J+1} \sum_B \alpha_B \exp\left(i\omega \sum_j \beta_{j,B} l_j\right), \tag{4.d}$$

where the index set B consists of vectors $(\beta_0, \dots, \beta_J)$ with $\beta_j = \pm 1$, and $\alpha_B = \pm 1$.

For real ν, consider the integrals

$$\text{(4.e)} \qquad \lim_{X\to\infty} X^{-1} \int_1^X \exp(-i\nu\omega)\omega^{-\mu} f(\lambda)\, d\omega.$$

From (4.c) and (4.d) these limits will all be zero for $\mu > J+1$, and there will be a finite set of ν with nonzero limits for $\mu = J+1$ corresponding to the coefficients of $dbh(\lambda)$ in the representation (4.d). Thus the eigenvalues of L_0 determine J and they determine $h(\lambda)$ up to a constant multiple.

The assumption that the size ordered set of lengths is in U means that the terms $\nu_B = \sum_j \beta_{j,B} l_j$ appearing in (4.d) are all distinct. Consequently, the set of these ν_B will be exactly those ν for which a nonzero limit appears in (4.e).

The lengths l_j can be found as follows. The largest value is $\nu_B = \sum_j l_j$. The next largest is $\sum_j l_j - 2l_0$. Thus l_0 can be found. Proceeding inductively, after finding $l_0 < \cdots < l_K$ and discarding those values of ν_B of the form $\sum_j l_j - 2\sum_{k=0}^{K} \pm l_k$, the next largest is $\sum_j l_j - 2l_{k+1}$.

Note that the same procedure is applicable if the eigenvalues $\lambda_1, \dots, \lambda_K$ are unknown: Let $\mu_1, \dots, \mu_K$ be real and nonzero, and consider the function

$$g(\lambda) = \prod_{k=1}^{K}(1 - \lambda/\mu_k) \prod_{k>K}(1 - \lambda/\lambda_k) = \frac{\prod_{k=1}^{K}(1-\lambda/\mu_k)}{\prod_{k=1}^{K}(1-\lambda/\lambda_k)} f(\lambda).$$

For all values $\mu \geq J+1$, the integrals

$$\lim_{X\to\infty} X^{-1} \int_1^X \exp(-i\nu\omega)\omega^{-\mu} g(\lambda)\, d\omega, \quad \nu \text{ real}$$

will yield the same values, up to a nonzero constant factor, since

$$\frac{\prod_{k=1}^{K}(1-\lambda/\mu_k)}{\prod_{k=1}^{K}(1-\lambda/\lambda_k)} \to \prod_{k=1}^{K} \lambda_k/\mu_k$$

as $\lambda \to \infty$.

In case $b = 0 = d$, so that $h(\lambda)$ is a product of sines, the lengths can be recovered, without any restrictions, by using the location of the zeros of $h(\lambda)$. The location of the first positive zero gives the value of the largest l_j, and the multiplicity of the zero gives the number of intervals of that length. By successively examining the larger zeros of $h(\lambda)$ we can get all the lengths l_j. □

Without restrictions on the lengths l_j, some ambiguity can arise in the cases other than $b = 0 = d$. In particular, if $2l_1 + 2l_2 = 1$, the lengths $(2l_1, l_2, l_2)$ and $(l_1, l_1, 2l_2)$ will not be distinguished in case we have the boundary conditions $b = 0, d \neq 0$, which can be seen by observing that

$$\sin(2l_1\omega)\sin(l_2\omega)\cos(l_2\omega) = 2\sin(2l_1\omega)\sin(2l_2\omega) = \sin(l_1\omega)\sin(2l_2\omega)\cos(l_1\omega).$$

Since the proof of Theorem 4.2 only depended on the leading asymptotics of the function $cy(1,\lambda) - dy'(1,\lambda)$, the information about the lengths l_j and thus the points x_j was obtained without necessarily knowing $q(x)$. The remaining results address the case of point masses embedded in an otherwise homogeneous string, so that we can

assume $q(x) = 0$. It is convenient to express solutions of the eigenvalue equation in the basis $\cos(\omega x)$, $\sin(\omega x)/\omega$ on each interval (x_j, x_{j+1}). A straightforward computation shows that the transition matrix at x_j has the form

$$\mathcal{T}_j = G(\omega)\left[I + \frac{m_j\omega}{2}A_j(\omega)\right]G^{-1}(\omega),$$

where

$$A_j(\omega) = \begin{pmatrix} \sin(2\omega x_j) & 1-\cos(2\omega x_j) \\ -1-\cos(2\omega x_j) & -\sin(2\omega x_j) \end{pmatrix}.$$

Let $\mathcal{T} = \mathcal{T}_{J-1}\dots\mathcal{T}_0$ and let

$$Q_{\mathcal{T}}(\omega) = G^{-1}(\omega)\mathcal{T}(\omega)G(\omega) = \begin{pmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{pmatrix}.$$

Expanding the product for $\mathcal{T}$ gives

$$Q_{\mathcal{T}}(\omega) = I + \sum_j \frac{m_j\omega}{2}\begin{pmatrix} \sin(2\omega x_j) & 1-\cos(2\omega x_j) \\ -1-\cos(2\omega x_j) & -\sin(2\omega x_j) \end{pmatrix} + \cdots.$$

Now the condition that λ is an eigenvalue can be written as

(4.f)

$$\begin{aligned} f(\lambda) &= (c \quad -d)\,G(\omega)\begin{pmatrix} \cos(\omega) & \sin(\omega) \\ -\sin(\omega & \cos(\omega) \end{pmatrix}G^{-1}(\omega)G(\omega)Q_{\mathcal{T}}G^{-1}(\omega)\begin{pmatrix} b \\ a \end{pmatrix} \\ &= \frac{ac}{\omega}[\cos(\omega)Q_{12} + \sin(\omega)Q_{22}] + bc[\cos(\omega)Q_{11} + \sin(\omega)Q_{21}] \\ &\quad + ad[\sin(\omega)Q_{12} - \cos(\omega)Q_{22}] + bd\omega[\sin(\omega)Q_{11} - \cos(\omega)Q_{21}] = 0. \end{aligned}$$

Since $q(x) = 0$ is known and $\mathcal{T}(0) = I$, (4.f) gives

$$f(0) = (c \quad -d)\begin{pmatrix} \cos(\omega) & \sin(\omega)/\omega \\ -\omega\sin(\omega) & \cos(\omega) \end{pmatrix}\begin{pmatrix} b \\ a \end{pmatrix}.$$

Also,

$$f(\lambda) = K_1\prod(1-\lambda/\lambda_k),$$

so that $K_1 = f(0)$, and knowing the eigenvalues of L_0 determines $f(\lambda)$.

If we expand the product for $Q_{\mathcal{T}}$, gathering the terms with like powers of ω, we see that $f(\lambda)$ can be written as a polynomial in ω with coefficients which are generalized trigonometric polynomials with the form $\sum_k[\alpha_k\cos(f_k\omega) + \beta_k\sin(f_k\omega)]$. Analogous with the proof of Theorem 4.2, the frequencies and coefficients can be extracted from the sequence of eigenvalues by considering

$$\lim_{X\to\infty} X^{-1}\int_1^X \cos(\nu\omega)\omega^{-\mu}f(\lambda)\,d\omega, \quad \lim_{X\to\infty} X^{-1}\int_1^X \sin(\nu\omega)\omega^{-\mu}f(\lambda)\,d\omega.$$

Consider in particular the terms of lowest degree in ω with a nonconstant coefficient. These are

$$\frac{ac}{2}\sum_{j=0}^{J-1} m_j[\cos(\omega) - \cos(\omega[1-2x_j])], \quad ac \neq 0, \tag{4.g}$$

$$\frac{1}{2}\sum_{j=0}^{J-1} m_j[(ad-bc)\sin(\omega)-(bc+ad)\sin(\omega[1-2x_j])], \quad ac=0, \quad a^2+c^2\neq 0,$$

$$\frac{bd}{2}\sum_{j=0}^{J-1} m_j[\cos(\omega)+\cos(\omega[1-2x_j])], \quad a=c=0.$$

Since the distinct frequencies and the coefficients of the terms with distinct frequencies are determined from the eigenvalues, expressions (4.g) yield the following theorem.

THEOREM 4.3. *Suppose $q(x)=0$ and $ac\neq 0$ or $a=c=0$. Then the eigenvalues of L_0 determine the points x_j up to reflection about $x=1/2$, and they determine the sum of the masses at x_j and $1-x_j$. If $ac=0$ but not both a and c are zero, then the eigenvalues of L_0 determine the points x_j up to reflection about $x=1/2$ if the masses at x_j and $1-x_j$ are not equal. In this case the difference of the masses at x_j and $1-x_j$ is determined.*

Of course, by imposing additional constraints such as symmetry of the mass locations or restriction of the masses to $(0,1/2)$, this result will give conditions for the unique determination of the positions and masses from a single spectrum.

Next, while still restricting to $q(x)=0$, we consider the case when two spectra are given with different boundary conditions (that is, not differing only by scalings), with respective constants a_1,b_1,c_1,d_1 and a_2,b_2,c_2,d_2. We first consider the case when $a_1c_1a_2c_2\neq 0$. By a simple scaling we can assume $a_1=a_2$, $c_1=c_2$. Now notice that if, after this scaling, $b_1c_1+a_1d_1\neq b_2c_2+a_2d_2$, or equivalently $b_1/a_1+d_1/c_1\neq b_2/a_2+d_2/c_2$, then if we form the difference $f_1(\lambda)-f_2(\lambda)$ and use (4.f) with the expansion of Q_T in powers of ω, we can find $\sum_{j=0}^{J-1} m_j(bc+ad)\sin(\omega[1-2x_j])$. By knowing $m_{x(j)}+m_{1-x(j)}$ and $m_{x(j)}-m_{1-x(j)}$, we can find the masses at each x_j. Other cases are argued similarly. In summary, we have the following theorem.

THEOREM 4.4. *Suppose $q(x)=0$ and the eigenvalues of the operator L_0 are known for two linearly independent sets of boundary conditions. Then the masses m_j and locations x_j are determined if*

$$a_1c_1a_2c_2\neq 0, \quad b_1/a_1+d_1/c_1\neq b_2/a_2+d_2/c_2$$

or

$$a_1c_1=0, \quad b_1c_1+a_1d_1\neq 0, \quad a_2c_2\neq 0.$$

EIGENVALUES OF THE FAR FIELD OPERATOR AND INVERSE SCATTERING THEORY*

DAVID COLTON† AND RAINER KRESS‡

Abstract. An eigenvalue-free region is determined for the far field operator corresponding to the scattering of time harmonic acoustic or electromagnetic waves by an inhomogeneous medium. In addition, a simple proof is given showing that for a nonabsorbing medium the far field operator is normal. These results are then used to derive a new method for solving the inverse scattering problem for acoustic and electromagnetic waves.

Key words. inverse scattering, far field operator

AMS subject classifications. 35P25, 35R30

1. Introduction.

The unitarity of the scattering matrix for nonabsorbing media is a basic result in scattering theory [1], [5]. For absorbing media, the scattering matrix is no longer a unitary operator and little is known about its spectrum. Closely related to the scattering matrix is the far field operator, which plays a central role in the dual space method for solving the inverse scattering problem [3]. Indeed, for nonabsorbing media, we will show in this paper that the unitarity of the scattering matrix follows from the proof of the normality of the far field operator. Since the far field operator is compact, zero is always an element of the spectrum, and of particular concern in the dual space method is the question of whether or not zero is an eigenvalue. In particular, if zero is an eigenvalue the dual space method does not work and this has led to various modifications of the far field operator to avoid this problem (c.f. [2], [4]).

In this paper, we shall consider an approach other than changing the far field operator for modifying the dual space method. In particular, instead of modifying the far field operator F, we shall consider $\lambda I - F$ where λ is not in the spectrum of F. Then, instead of considering modified far field operators, the corresponding dual space method makes use of the adjoint of the Herglotz operator discussed in §§5.5 and 7.4 of [3]. In this sense the present approach can be viewed as an extension of the method of Kirsch and Kress for solving the inverse obstacle problem (c.f. [3]) to the case of an inhomogeneous medium. We mention in passing that although in this paper we are only concerned with the scattering of acoustic and electromagnetic waves by an inhomogeneous medium, our ideas are also easily extendable to the case of obstacle scattering.

To accomplish the above program, we begin by establishing a relationship between the far field operator and Herglotz wave functions. As a consequence of this analysis, we obtain a region in the complex plane that is free of eigenvalues of the far field operator and, in the case of nonabsorbing media, a simple proof of the normality of the far field operator. We then combine these results with a denseness argument to derive a new method for solving the inverse scattering problem for acoustic and electromagnetic waves in an inhomogeneous medium. In our view, this new method

combines the attributes of both simplicity and flexibility and we hope to examine in the near future whether or not numerical experiments confirm this view.

2. The far field operator for acoustic waves in an inhomogeneous medium. We consider the scattering of a time harmonic acoustic plane wave by an inhomogeneous medium of compact support with complex valued refractive index $n \in C^1(\mathbb{R}^3), \operatorname{Im} n \geq 0$. Then, if $k > 0$ is the wave number, ω the frequency, and the incident field is given by

$$U^i(x,t) = \exp[i(kx \cdot d - \omega t)], \tag{2.1}$$

where $x \in \mathbb{R}^3$ and $d \in \mathbb{R}^3, |d| = 1$ is the direction of propagation, under appropriate assumptions [3] the amplitude u of the total field $U(x,t) = u(x)e^{-i\omega t}$ satisfies

$$\Delta u + k^2 n(x) u = 0 \quad \text{in } \mathbb{R}^3, \tag{2.2}$$

$$u(x) = e^{ikx\cdot d} + u^s(x), \quad x \in \mathbb{R}^3, \tag{2.3}$$

$$\lim_{r\to\infty} r\left(\frac{\partial u^s}{\partial r} - iku^s\right) = 0, \tag{2.4}$$

where $r = |x|$. From (2.2)–(2.4) it is easy to deduce [3] that $u^s(x) = u^s(x;d)$ has the asymptotic behavior

$$u^s(x;d) = \frac{\exp(ik|x|)}{|x|} u_\infty(\hat{x};d) + O\left(\frac{1}{|x|^2}\right) \tag{2.5}$$

as $|x| \to \infty$, where $\hat{x} = x/|x|$ and u_∞ is the *far field pattern* of the scattered field u^s.

Now let B denote an open ball (or some other domain with connected boundary) containing the support of $m := 1 - n$ and let ν be the exterior unit normal to ∂B. If Ω denotes the unit sphere in $\mathbb{R}^3$, then any solution of the Helmholtz equation

$$\Delta u + k^2 u = 0 \tag{2.6}$$

of the form

$$v(x) = \int_\Omega e^{ikx\cdot d} g(d)\, ds(d), \tag{2.7}$$

where $g \in L^2(\Omega)$ is called a *Herglotz wave function* with kernel g [3]. Solutions of (2.6) satisfying (2.4) are said to be radiating. Such solutions have the asymptotic behavior (2.5) [3].

LEMMA 2.1. *Let $v^s, w^s \in C^1(\mathbb{R}^3 \setminus B)$ be radiating solutions to the Helmholtz equation with far field patterns v_∞ and w_∞, respectively. Then*

$$\int_{\partial B} \left(v^s \frac{\partial \overline{w^s}}{\partial \nu} - \overline{w^s} \frac{\partial v^s}{\partial \nu}\right) ds = -2ik \int_\Omega v_\infty \overline{w_\infty}\, ds.$$

Proof. By Green's theorem, the value of the integral on the left-hand side remains the same if we replace ∂B by a sufficiently large sphere of radius R centered at the origin. The lemma now follows from

$$v^s(x) \frac{\partial \overline{w^s(x)}}{\partial |x|} - \overline{w^s(x)} \frac{\partial v^s(x)}{\partial |x|} = \frac{-2ik}{|x|^2} v_\infty(\hat{x}) \overline{w_\infty(\hat{x})} + O\left(\frac{1}{|x|^3}\right) \tag{2.8}$$

and letting R tend to infinity.

LEMMA 2.2. *Let $v^s \in C^1(\mathbb{R}^3\setminus B)$ be a radiating solution of the Helmholtz equation with far field pattern v_∞ and let w_h^i be a Herglotz wave function with kernel h. Then*

$$\int_{\partial B}\left(v^s\frac{\partial\overline{w_h^i}}{\partial\nu}-\overline{w_h^i}\frac{\partial v^s}{\partial\nu}\right)ds=4\pi\int_\Omega v_\infty\bar{h}\,ds\ .$$

Proof. From [3, p. 20], we have the integral representation

$$v_\infty(\hat{x})=\frac{1}{4\pi}\int_{\partial B}\left\{v^s(y)\frac{\partial}{\partial\nu}e^{-ik\hat{x}\cdot y}-\frac{\partial v^s}{\partial\nu}(y)e^{-ik\hat{x}\cdot y}\right\}ds(y)\ ,\quad \hat{x}\in\Omega\ . \tag{2.9}$$

Hence, since

$$w_h^i(x)=\int_\Omega e^{ik\,x\cdot d}\,h(d)\,ds(d)\ , \tag{2.10}$$

we have

$$\begin{aligned}&\int_{\partial B}\left(v^s(x)\,\frac{\partial\overline{w_h^i}}{\partial\nu}\,(x)-\overline{w_h^i(x)}\,\frac{\partial v^s}{\partial\nu}\,(x)\right)ds_{(x)} \\ &=\int_\Omega\overline{h(d)}\int_{\partial B}\left(v^s(x)\,\frac{\partial}{\partial\nu(x)}e^{-ik\,x\cdot d}-e^{-ik\,x\cdot d}\,\frac{\partial v^s(x)}{\partial\nu}\right)ds(x)\,ds(d) \\ &=4\pi\int_\Omega\overline{h(d)}v_\infty(d)\,ds(d).\end{aligned} \tag{2.11}$$

We now define the *far field operator* $F: L^2(\Omega)\to L^2(\Omega)$ corresponding to the far field pattern u_∞ by

$$(Fg)(\hat{x}):=\int_\Omega u_\infty(\hat{x};d)g(d)\,ds(d) \tag{2.12}$$

and note that F is a compact operator on $L^2(\Omega)$. The connection between the far field operator and Herglotz wave functions is given by the following theorem.

THEOREM 2.3. *Let v_g^i and v_h^i be Herglotz wave functions with kernels $g,h\in L^2(\Omega)$, respectively and let v_g, v_h be the solutions of* (2.2)–(2.4) *with $e^{ikx\cdot d}$ replaced by v_g^i and v_h^i, respectively. Then*

$$ik^2\int\int_B \operatorname{Im} n\,v_g\overline{v_h}\,dx=2\pi(Fg,h)-2\pi(g,Fh)-ik(Fg,Fh),$$

where $(\cdot,\cdot)$ denotes the inner product on $L^2(\Omega)$.

Proof. Let v_g^s, v_h^s denote the scattered fields corresponding to v_g and v_h, respectively and let $v_{g,\infty}, v_{h,\infty}$ be the corresponding far field patterns. Then, using Green's theorem, Lemma 2.1, and Lemma 2.2, we have

$$\begin{aligned}2ik^2\int\int_B \operatorname{Im} n\,v_g\overline{v_h}\,dx&=\int_{\partial B}\left(v_g\,\frac{\partial\overline{v_h}}{\partial\nu}-\overline{v_h}\,\frac{\partial v_g}{\partial\nu}\right)ds \\ &=\int_{\partial B}\left(v_g^s\,\frac{\partial\overline{v_h^s}}{\partial\nu}-\overline{v_h^s}\,\frac{\partial v_g^s}{\partial\nu}\right)ds+\int_{\partial B}\left(v_g^s\,\frac{\partial\overline{v_h^i}}{\partial\nu}-\overline{v_h^i}\,\frac{\partial v_g^s}{\partial\nu}\right)ds\end{aligned} \tag{2.13}$$

$$+\int_{\partial B}\left(v_g^i\frac{\partial\overline{v_h^s}}{\partial\nu}-\overline{v_h^s}\frac{\partial v_g^i}{\partial\nu}\right)ds$$
$$=-2ik\int_\Omega v_{g,\infty}\overline{v_{h,\infty}}\,ds+4\pi\int_\Omega v_{g,\infty}\bar{h}\,ds-4\pi\int_\Omega g\overline{v_{h,\infty}}\,ds$$
$$=-2ik(Fg,Fh)+4\pi(Fg,h)-4\pi(g,Fh)\,,$$

noting that Fg is the far field pattern corresponding to the incident field v_g^i.

COROLLARY 2.4. *Assume that* $\operatorname{Im} n\geq 0$. *Then, except for possibly zero,* F *has no real eigenvalues.*

Proof. Let $Fg=\lambda g$ with $\lambda\in\mathbb{R}$ and $\lambda\neq 0$. Then, choosing $h=g$ in Theorem 2.3, we have

$$ik^2\int\int_B \operatorname{Im} n\,|v_g|^2dx=4\pi i\operatorname{Im}(Fg,g)-ik(Fg,Fg)$$
$$=4\pi i\operatorname{Im}\lambda\|g\|^2-ik\|Fg\|^2. \tag{2.14}$$

Since $\operatorname{Im}\lambda=0$ we now have that $Fg=0$ and hence, since $\lambda\neq 0, g=0$.

COROLLARY 2.5. *Assume that* $\operatorname{Im} n=0$. *Then* F *is normal and hence has a countable number of eigenvalues.*

Proof. From Theorem 2.3 we have that

$$ik(Fg,Fh)=2\pi\{(Fg,h)-(g,Fh)\} \tag{2.15}$$

and hence

$$(g,ikF^*Fh)=2\pi\{(g,Fh)-(g,F^*h)\} \tag{2.16}$$

for all $g,h\in L^2(\Omega)$. We can now conclude that

$$ikF^*F=2\pi\{F-F^*\}. \tag{2.17}$$

By reciprocity [3, p. 53], we have

$$(F^*g)(\hat{x})=\int_\Omega\overline{u_\infty(d;\hat{x})}g(d)\,ds(d)=\int_\Omega\overline{u_\infty(-\hat{x};-d)}g(d)\,ds(d), \tag{2.18}$$

and hence if we define $R:L^2(\Omega)\to L^2(\Omega)$ by $(Rg)(d):=g(-d)$ we have that

$$F^*g=\overline{RFR\bar{g}}. \tag{2.19}$$

From this, observing that $(Rg,Rh)=(g,h)=(\bar{h},\bar{g})$ for all $g,h\in L^2(\Omega)$, we find that

$$(F^*g,F^*h)=(RFR\bar{h},RFR\bar{g})=(FR\bar{h},FR\bar{g}) \tag{2.20}$$

and hence, from (2.15),

$$ik(F^*g,F^*h)=2\pi\{(FR\bar{h},R\bar{g})-(R\bar{h},FR\bar{g})\}=2\pi\{(g,F^*h)-(F^*g,h)\}. \tag{2.21}$$

If we now proceed as in the derivation of (2.17), we find that

$$ikFF^*=2\pi\{F-F^*\} \tag{2.22}$$

and the proof is finished.

We note that (c.f. [1], [5]) the far field operator F is related to the scattering matrix S by

$$S = I + \frac{ik}{2\pi} F. \tag{2.23}$$

From (2.17) and (2.22) we now see that $SS^* = S^*S = I$, i.e., our analysis provides a rather simple proof of the well-known fact that the scattering matrix is a unitary operator.

3. The inverse scattering problem for acoustic waves in an inhomogeneous medium. The analysis of the preceding section suggests a new method for solving the inverse scattering problem for acoustic waves in an inhomogeneous medium. To see this, let Γ be a smooth surface contained in the interior of the support of m such that k^2 is not a Dirichlet eigenvalue for $-\Delta$ in the interior of Γ. For $\varphi \in L^2(\Gamma)$, define the single-layer potential

$$u_\varphi(x) := \int_\Gamma \Phi(x,y)\varphi(y)\, ds(y), \quad x \in \mathbb{R}^3 \setminus \Gamma, \tag{3.1}$$

where

$$\Phi(x,y) := \frac{1}{4\pi} \frac{e^{ik|x-y|}}{|x-y|}, \quad x \neq y, \tag{3.2}$$

and note that the far field pattern of u_φ is given by

$$u_{\varphi,\infty}(\hat{x}) = \frac{1}{4\pi} \int_\Gamma e^{-ik\,\hat{x}\cdot y} \varphi(y)\, ds(y). \tag{3.3}$$

Finally, for $\lambda \neq 0$ define $g \in L^2(\Omega)$ by

$$\lambda g(\hat{x}) := u_{\varphi,\infty}(\hat{x}) \tag{3.4}$$

and the Herglotz wave function v_g by

$$v_g(x) := \int_\Omega e^{ik\,x\cdot d} g(d)\, ds(d). \tag{3.5}$$

Now let u_∞ be the far field pattern corresponding to (2.2)–(2.4) and let $\sigma(F)$ denote the spectrum of the far field operator F corresponding to u_∞. For $\lambda \notin \sigma(F)$, let $g_\ell \in L^2(\Omega)$ be the unique solution of

$$Fg - \lambda g = \frac{1}{ki^{\ell+1}} Y_\ell \tag{3.6}$$

where Y_ℓ is a spherical harmonic order of $\ell, \ell = 0, 1, 2, \ldots$. Then, since the scattered field is uniquely determined by its far field pattern [3, p. 32], we have from (3.6) and unique continuation that if there exists a unique solution φ_ℓ of the integral equation $\lambda g_\ell = u_{\varphi,\infty}$ (c.f. [3, p. 128]) then

$$\int_\Omega u(x;d) g_\ell(d)\, ds(d) - v_{g_\ell}(x) - u_{\varphi_\ell}(x) = h_\ell^{(1)}(k|x|) Y_\ell(\hat{x}) \tag{3.7}$$

for $x \in \mathbb{R}^3 \setminus B$, where $h_\ell^{(1)}$ denotes the spherical Hankel function of the first kind of order $\ell, -L \leq \ell \leq L$. To solve the inverse scattering problem of determining n

from u_∞, one now tries to construct n from the overdetermined system (3.6), (3.7). If this system is formulated as an optimization problem as in [3, pp. 266–268], then the minimum value of the cost functional will be zero provided the following theorem is true, where

$$Y := \{w \in C^2(\bar{B}) : \Delta w + k^2 n w = 0 \text{ in } B\},$$

$$W := \left\{ \left(w - v_g - u_\varphi, \frac{\partial}{\partial \nu}(w - v_g - u_\varphi) \right) : \varphi \in L^2(\Gamma)\ ,\ \lambda g = u_{\varphi,\infty}\ ,\ w \in Y \right\},$$

and B is as defined in the previous section.

THEOREM 3.1. *Suppose $\lambda \notin \sigma(F)$. Then W is dense in $L^2(\partial B) \times L^2(\partial B)$.*

Proof. We first note that if j_0 is the spherical Bessel function of order zero then, since [3, p. 31]

$$\int_\Omega e^{ik\, d\cdot(x-y)} ds(d) = 4\pi j_0(k|x-y|), \tag{3.8}$$

we have that

$$v_g(x) = \frac{1}{\lambda} \int_\Gamma j_0(k|x-y|)\varphi(y)\, ds(y)\ . \tag{3.9}$$

Now suppose $a, b \in L^2(\Omega)$ satisfy

$$\int_{\partial B} \left\{ (w - v_g - u_\varphi)\bar{a} + \frac{\partial}{\partial \nu}(w - v_g - u_\varphi)\bar{b} \right\} ds = 0 \tag{3.10}$$

for all $w \in Y$ and $\varphi \in L^2(\Gamma)$. Then, setting $w = 0$ and defining

$$v(x) := \int_{\partial B} \left\{ \Psi(x,y)\overline{a(y)} + \frac{\partial}{\partial \nu(y)} \Psi(x,y)\overline{b(y)} \right\} ds(y)\ ,\quad x \in \mathbb{R}^3 \setminus \partial B, \tag{3.11}$$

where

$$\Psi(x,y) := \frac{1}{\lambda}\, j_0(k|x-y|) + \Phi(x,y), \tag{3.12}$$

we have from (3.10) that

$$\int_\Gamma \varphi v\, ds = 0 \tag{3.13}$$

for all $\varphi \in L^2(\Gamma)$. Hence $v = 0$ on Γ and, since k^2 is not a Dirichlet eigenvalue for $-\Delta$ in the interior of Γ, we have that $v = 0$ in the interior of Γ. By unique continuation, $v = 0$ in B and hence the L^2–jump relations for single- and double-layer potentials [3, p. 44] imply that

$$v_+ = \bar{b}, \quad \frac{\partial v}{\partial \nu}|_+ = -\bar{a} \quad \text{on } \partial B, \tag{3.14}$$

where $+$ denotes the limit taken from the exterior of B. Setting $\varphi = 0$ in (3.10) now implies that

$$\int_{\partial B} \left(\frac{\partial v}{\partial \nu}|_+\, w - v_+ \frac{\partial w}{\partial \nu} \right) ds = 0 \tag{3.15}$$

for all $w \in Y$.

We now define

$$v^s(x) := \int_{\partial B} \left\{ \Phi(x,y)\overline{a(y)} + \frac{\partial}{\partial \nu(y)} \Phi(x,y)\overline{b(y)} \right\} ds(y) \tag{3.16}$$

for $x \in \mathbb{R}^3 \setminus \bar{B}$ and

$$v^0(x) := \frac{1}{\lambda} \int_{\partial B} \left\{ j_0(k|x-y|)\overline{a(y)} + \frac{\partial}{\partial \nu(y)} j_0(k|x-y|)\overline{b(y)} \right\} ds(y) \tag{3.17}$$

for $x \in \mathbb{R}^3$ and note that from (3.8), v^0 is a Herglotz wave function

$$v^0(x) = \int_\Omega e^{ik\,x\cdot d}\, \tilde{g}(d)\, ds(d) \tag{3.18}$$

with kernel $\tilde{g} \in L^2(\Omega)$ defined by

$$\tilde{g}(d) := \frac{1}{4\pi\lambda} \int_{\partial B} \left\{ e^{-ik\,y\cdot d}\, \overline{a(y)} + \frac{\partial}{\partial \nu(y)} e^{-ik\,y\cdot d}\, \overline{b(y)} \right\} ds(y). \tag{3.19}$$

From (3.16) and (3.19) we now see that v^s has the far field pattern $v_\infty = \lambda \tilde{g}$.

In (3.15) we now set

$$w(x) = u^s(x; -\hat{z}) + e^{-ik\,x\cdot\hat{z}}, \tag{3.20}$$

where $\hat{z} \in \Omega$, and use Green's theorem to deduce that

$$\begin{aligned} &\int_{\partial B} \left(\frac{\partial v^s}{\partial \nu}(x)\, e^{-ik\,x\cdot\hat{z}} - v^s(x)\, \frac{\partial}{\partial \nu} e^{-ik\,x\cdot\hat{z}} \right) ds(x) \\ &+ \int_{\partial B} \left(\frac{\partial v^0}{\partial \nu}(x) u^s(x; -\hat{z}) - v^0(x)\, \frac{\partial u^s}{\partial \nu}(x; -\hat{z}) \right) ds(x) = 0. \end{aligned} \tag{3.21}$$

Substituting (3.18) into (3.21) and interchanging orders of integration, we now have from (2.9) and reciprocity that

$$\begin{aligned} v_\infty(\hat{z}) &= \int_\Omega \tilde{u}_\infty(-d; -\hat{z})\tilde{g}(d)\, ds(d) \\ &= \int_\Omega \tilde{u}_\infty(\hat{z}; d)\tilde{g}(d)\, ds(d), \end{aligned} \tag{3.22}$$

i.e.,

$$F\tilde{g} = v_\infty = \lambda \tilde{g}. \tag{3.23}$$

Since $\lambda \notin \sigma(F)$ we have that $\tilde{g} = 0$. This implies $v_\infty = 0$ and hence $v^s = 0$ in $\mathbb{R}^3 \setminus \bar{B}$ and $v^0 = 0$ in $\mathbb{R}^3$. Hence, $v = 0$ in $\mathbb{R}^3 \setminus \bar{B}$ and from (3.14) we now have that $a = b = 0$. The theorem is now proved.

4. The far field operator for electromagnetic waves in an inhomogeneous medium. We now consider the scattering of a time harmonic electromagnetic plane wave by an inhomogeneous medium of compact support. In particular, factoring out the time harmonic term $e^{-i\omega t}$ and letting $n \in C^1(\mathbb{R}^3)$, $\operatorname{Im} n \geq 0$, denote the

refractive index, we have that the (normalized) electric field E and magnetic field H satisfy [3, p. 239] the Maxwell equations

$$\operatorname{curl} E - ikH = 0, \quad \operatorname{curl} H + iknE = 0 \quad \text{in } \mathbb{R}^3, \tag{4.1}$$

where $k > 0$ is the wave number and $E = E^i + E^s, H = H^i + H^s$ with (E^i, H^i) being the incident electromagnetic field and (E^s, H^s) the scattered electromagnetic field. More specifically, (E^s, H^s) satisfies the Silver–Müller radiation condition

$$\lim_{r\to\infty} (H^s \times x - rE^s) = 0 \tag{4.2}$$

and we will assume that the incident field (E^i, H^i) is given by

$$\begin{aligned} E^i(x) &= E^i(x; d, p) = \frac{i}{k} \operatorname{curl}\operatorname{curl} p\, e^{ik\,x\cdot d} = ik\,(d \times p) \times d\, e^{ik\,x\cdot d}, \\ H^i(x) &= H^i(x; d, p) = \operatorname{curl} p\, e^{ik\,x\cdot d} = ik\, d \times p\, e^{ik\,x\cdot d}, \end{aligned} \tag{4.3}$$

where d is the direction, $d \in \mathbb{R}^3, |d| = 1$, and p is the polarization, $p \in \mathbb{R}^3$, of the incident plane wave.

From (4.1) and (4.2) it is easy to deduce [3] that the scattered electric field $E^s(x) = E^s(x; d, p)$ has the asymptotic behavior

$$E^s(x; d, p) = \frac{\exp(ik|x|)}{|x|} \left\{ E_\infty(\hat{x}; d, p) + 0\left(\frac{1}{|x|^2}\right) \right\} \tag{4.4}$$

as $|x| \to \infty$, where E_∞ is the *electric far field pattern*. We again let $m := 1 - n$, assume that m has compact support, and let B denote an open ball (or some other domain with connected boundary) containing the support of m with ν the exterior unit normal to ∂B. A solution to the Maxwell equations

$$\operatorname{curl} E - ikH = 0, \quad \operatorname{curl} H + ikE = 0 \tag{4.5}$$

of the form

$$\begin{aligned} E(x) &= \int_\Omega E^i(x; d, g(d))\, ds(d), \\ H(x) &= \int_\Omega H^i(x; d, g(d))\, ds(d), \end{aligned} \tag{4.6}$$

where $g \in T^2(\Omega) := \{g : \Omega \to \mathbb{C}^3 : g \in L^2(\Omega), g \cdot \nu = 0\}$ with ν being the exterior unit normal to the unit sphere Ω, is called an *electromagnetic Herglotz pair* with kernel g [3]. Solutions of (4.5) satisfying (4.2) are said to be radiating. Such solutions are easily seen to have the asymptotic behavior (4.4) [3].

LEMMA 4.1. *Let $E_1^s, H_1^s \in C^1(\mathbb{R}^3 \setminus \bar{B})$ and $E_2^s, H_2^s \in C^1(\mathbb{R}^3 \setminus \bar{B})$ be radiating solutions of the Maxwell equations with electric far field patterns $E_{1,\infty}, E_{2,\infty}$, respectively. Then*

$$\int_{\partial B} (\nu \times E_1^s \cdot \operatorname{curl} \overline{E_2^s} - \nu \times \overline{E_2^s} \cdot \operatorname{curl} E_1^s)\, ds = -2ik \int_\Omega E_{1,\infty} \cdot \overline{E_{2,\infty}}\, ds \ .$$

Proof. By the vector Green's theorem, the value of the integral on the left-hand side remains the same if we replace ∂B by a sufficiently large sphere of radius R centered at the origin. The lemma now follows from

$$\begin{aligned} &\nu(x) \times E_1^s(x) \cdot \operatorname{curl} \overline{E_2^s(x)} - \nu(x) \times \overline{E_2^s(x)} \cdot \operatorname{curl} E_1^s(x) \\ &= \frac{-2ik}{|x|^2} E_{1,\infty}(\hat{x}) \overline{E_{2,\infty}(\hat{x})} + O\left(\frac{1}{|x|^3}\right) \end{aligned} \tag{4.7}$$

and letting R tend to infinity.

LEMMA 4.2. *Let $E^s, H^s \in C^1(\mathbb{R}^3 \setminus B)$ be a radiating solution to the Maxwell equations with electric far field pattern E_∞ and let E_h^i, H_h^i be an electromagnetic Herglotz pair with kernel h. Then*

$$\int_{\partial B} (\nu \times E^s \cdot \operatorname{curl} \overline{E_h^i} - \nu \times \overline{E_h^i} \cdot \operatorname{curl} E^s)\, ds = -4\pi i k \int_\Omega E_\infty \cdot \overline{h}\, ds.$$

Proof. From [3, p. 157], we have the integral representation

$$E_\infty(\hat{x}) = \frac{ik}{4\pi} \hat{x} \times \int_{\partial B} \{\nu(y) \times E(y) + (\nu(y) \times H(y)) \times \hat{x}\} e^{-ik\hat{x}\cdot y}\, ds(y). \tag{4.8}$$

Furthermore, since

$$E_h^i(x) = \int_\Omega E^i(x; d, h(d))\, ds(d)\,, \tag{4.9}$$

we have

$$\begin{aligned} &\int_{\partial B} \nu(x) \times E^s(x) \cdot \operatorname{curl} \overline{E_h^i(x)}\, ds(x) \\ &= -k^2 \int_{\partial B} \nu(x) \times E^s(x) \cdot \int_\Omega d \times \overline{h(d)}\, e^{-ik\,x\cdot d} ds(d)\, ds(x) \\ &= k^2 \int_\Omega \overline{h(d)} \cdot \left(d \times \int_{\partial B} \nu(x) \times E^s(x)\, e^{-ik\,x\cdot d} ds(x) \right) ds(d) \end{aligned} \tag{4.10}$$

and

$$\begin{aligned} &-\int_{\partial B} \nu(x) \times \overline{E_h^i(x)} \cdot \operatorname{curl} E^s(x)\, ds(x) = ik \int_{\partial B} \overline{E_h^i(x)} \cdot \nu(x) \times H^s(x)\, ds(x) \\ &= k^2 \int_{\partial B} \left(\int_\Omega (d \times \overline{h(d)}) \times d\, e^{-ik\,x\cdot d}\, ds(d) \right) \cdot (\nu(x) \times H^s(x))\, ds(x) \\ &= k^2 \int_\Omega \overline{h(d)} \cdot \left(d \times \int_{\partial B} (\nu(x) \times H^s(x)) \times d\, e^{-ik\,x\cdot d} ds(x) \right) ds(d). \end{aligned} \tag{4.11}$$

Equations (4.8), (4.10), and (4.11) now imply the lemma.

We now define the *electric far field operator* $F : T^2(\Omega) \to T^2(\Omega)$ corresponding to the electric far field pattern E_∞ by

$$(Fg)(\hat{x}) := \int_\Omega E_\infty(\hat{x}; d, g(d))\, ds(d) \tag{4.12}$$

and note that F is a compact operator on $T^2(\Omega)$. The connection between the electric far field operator and electromagnetic Herglotz pairs is given by the following theorem.

THEOREM 4.3. *Let E_g^i, H_g^i and E_h^i, H_h^i be electromagnetic Herglotz pairs with kernels $g, h \in T^2(\Omega)$, respectively and let E_g and E_h be the solutions of* (4.1)–(4.3) *with E^i, H^i replaced by E_g^i, H_g^i and E_h^i, H_h^i, respectively. Then*

$$k \int\int_B \operatorname{Im} n\, E_g \cdot \overline{E_h}\, dx = -2\pi(Fg, h) - 2\pi(g, Fh) - (Fg, Fh)$$

where $(\cdot\,,\cdot)$ denotes the inner product on $T^2(\Omega)$.

Proof. Let E_g^s, E_h^s denote the scattered electric fields corresponding to E_g, H_g and E_h, H_h, respectively and let $E_{g,\infty}, E_{h,\infty}$ be the corresponding electric far field patterns. Then, using the vector Green's theorem, Lemma 4.1, and Lemma 4.2 we have

$$
\begin{aligned}
(4.13)\quad 2ik^2 \int\int_B \operatorname{Im} n\, E_g \cdot \overline{E_h}\, dx &= \int_{\partial B} \left(\nu \times E_g \cdot \operatorname{curl} \overline{E_h} - \nu \times \overline{E_h} \cdot \operatorname{curl} E_g\right) ds \\
&= \int_{\partial B} \left(\nu \times E_g^s \cdot \operatorname{curl} \overline{E_h^s} - \nu \times \overline{E_h^s} \cdot \operatorname{curl} E_g^s\right) ds \\
&+ \int_{\partial B} \left(\nu \times E_g^s \cdot \operatorname{curl} \overline{E_h^i} - \nu \times \overline{E_h^i} \cdot \operatorname{curl} E_g^s\right) ds \\
&+ \int_{\partial B} \left(\nu \times E_g^i \cdot \operatorname{curl} \overline{E_h^s} - \nu \times \overline{E_h^s} \cdot \operatorname{curl} E_g^i\right) ds \\
&= -2ik \int_\Omega E_{g,\infty} \cdot \overline{E_{h,\infty}}\, ds - 4\pi ik \int_\Omega E_{g,\infty} \cdot \overline{h}\, ds - 4\pi ik \int_\Omega g \cdot \overline{E_{h,\infty}}\, ds \\
&= -2ik(Fg, Fh) - 4\pi ik(Fg, h) - 4\pi ik(g, Fh)\,,
\end{aligned}
$$

noting that Fg is the electric far field pattern corresponding to the incident electric field E_g^i.

We note that the different factors ik^2 and k occurring in Theorems 2.3 and 4.3 are due solely to our normalization of the Herglotz wave functions and electromagnetic Herglotz pairs and have no mathematical or physical significance.

COROLLARY 4.4. *Assume that* $\operatorname{Im} n \geq 0$. *Then, except for possibly zero, F has no purely imaginary eigenvalues.*

Proof. Suppose $Fg = \lambda g$ with $\operatorname{Re} \lambda = 0, \lambda \neq 0$. Then, choosing $h = g$ in Theorem 4.3, we have

$$
\begin{aligned}
(4.14)\quad k \int\int_B \operatorname{Im} n\, |E_g|^2 dx &= -4\pi \operatorname{Re}(Fg, g) - (Fg, Fg) \\
&= -4\pi \operatorname{Re} \lambda \|g\|^2 - \|Fg\|^2.
\end{aligned}
$$

Since $\operatorname{Re} \lambda = 0$ we now have that $Fg = 0$ and hence, since $\lambda \neq 0, g = 0$.

COROLLARY 4.5. *Assume that* $\operatorname{Im} n = 0$. *Then F is normal and hence has a countable number of eigenvalues.*

Proof. From Theorem 4.3 we have that

$$
(4.15)\quad (Fg, Fh) = -2\pi\{(Fg, h) + (g, Fh)\}
$$

and hence

$$
(4.16)\quad (g, F^*Fh) = -2\pi\{(g, Fh) + (g, F^*h)\}
$$

for all $g, h \in T^2(\Omega)$. We can now conclude that

$$
(4.17)\quad F^*F = -2\pi\{F + F^*\}.
$$

We now note that by reciprocity [3, p. 179] we have

$$
\begin{aligned}
(4.18)\quad (Fh, g) &= \int_\Omega \int_\Omega E_\infty(d; \hat{x}, h(\hat{x})) \cdot \overline{g(d)}\, ds(\hat{x})\, ds(d) \\
&= \int_\Omega \int_\Omega h(\hat{x}) \cdot E_\infty(-\hat{x}; -d, \overline{g(d)})\, ds(d)\, ds(\hat{x})
\end{aligned}
$$

for all $g, h \in T^2(\Omega)$ and hence

$$(F^*g)(\hat{x}) = \int_\Omega \overline{E_\infty(-\hat{x}; -d, \overline{g(d)})}\, ds(d) \quad . \tag{4.19}$$

If we now define $R : T^2(\Omega) \to T^2(\Omega)$ by $(Rg)(d) := g(-d)$ we have that

$$F^*g = \overline{RFR\bar{g}}. \tag{4.20}$$

Now proceeding as in the proof of Corollary 2.5 we find that

$$FF^* = -2\pi\{F + F^*\} \tag{4.21}$$

and the proof is finished.

5. The inverse scattering problem for electromagnetic waves in an inhomogeneous medium. As in the scalar case, the analysis of the preceding section suggests a new method for solving the inverse scattering problem for electromagnetic waves in an inhomogeneous medium. In particular, let Γ be a smooth surface contained in the interior of the support of m such that k is not a Maxwell eigenvalue [3, p. 168] for the interior of Γ. For $\varphi \in T^2(\Gamma)$, define the vector potential

$$(A_\varphi)(x) := \int_\Gamma \Phi(x, y)\varphi(y)\, ds(y), \quad x \in \mathbb{R}^3 \setminus \Gamma, \tag{5.1}$$

and corresponding electromagnetic field

$$\tilde{E}_\varphi := \operatorname{curl} A_\varphi, \quad \tilde{H}_\varphi := \frac{1}{ik} \operatorname{curl} \tilde{E}_\varphi \tag{5.2}$$

and note that the electric far field pattern $\tilde{E}_{\varphi,\infty}$ of $\tilde{E}_\varphi$ is given by

$$\tilde{E}_{\varphi,\infty}(\hat{x}) = \frac{ik}{4\pi}\, \hat{x} \times \int_\Gamma e^{-ik\hat{x}\cdot y}\varphi(y)\, ds(y). \tag{5.3}$$

Finally, for $\lambda \neq 0$ define $g \in T^2(\Omega)$ by

$$\lambda g(\hat{x}) = \tilde{E}_{\varphi,\infty}(\hat{x}) \tag{5.4}$$

and the electromagnetic Herglotz pair E_g, H_g by

$$E_g(x) = \int_\Omega E^i(x; d, g(d))\, ds(d), \quad H_g(x) = \int_\Omega H^i(x; d, g(d))\, ds(d). \tag{5.5}$$

Now let E_∞ be the electric far field pattern corresponding to (4.1)–(4.3) and F the far field operator corresponding to E_∞. For $\lambda \notin \sigma(F)$, let $g_\ell^{(i)} \in T^2(\Omega)$ be the unique solution of

$$Fg - \lambda g = E_{\infty,\ell}^{(i)}, \tag{5.6}$$

where $\ell = 0, 1, 2, \ldots$, $i = 1, 2$, and

$$\begin{aligned} E_{\infty,\ell}^{(1)} &:= \frac{1}{i^\ell} \operatorname{Grad} Y_\ell, \\ E_{\infty,\ell}^{(2)} &:= -\frac{1}{ki^{\ell+1}} \nu \times \operatorname{Grad} Y_\ell, \end{aligned} \tag{5.7}$$

with Grad denoting the surface gradient. Then, since the scattered electric field is uniquely determined by its far field pattern [3, p. 157], we have from (5.6) and unique continuation that if there exists a unique solution $\varphi_\ell^{(i)}$ to the integral equation $\lambda g_\ell^{(i)} = E_{\varphi,\infty}$ (c.f. [3, p. 197]) then

$$\int_\Omega E(x;d,g_\ell^{(i)}(d))\,ds(d) - Eg_\ell^{(i)}(x) - \tilde{E}_{\varphi_\ell^{(i)}}(x) = E_\ell^{(i)}(x) \tag{5.8}$$

for $x \in \mathbb{R}^3 \setminus B$, where

$$\begin{aligned} E_\ell^{(1)}(x) &:= \operatorname{curl}\operatorname{curl}\{x h_\ell^{(1)}(k|x|)Y_\ell(\hat{x})\}, \\ E_\ell^{(2)}(x) &:= \operatorname{curl}\{x h_\ell^{(1)}(k|x|)Y_\ell(\hat{x})\}\,. \end{aligned} \tag{5.9}$$

As in the scalar case, one now tries to solve the inverse scattering problem of determining n from E_∞ by trying to construct n from the overdetermined system (5.6)–(5.9). If this problem is formulated as an optimization problem, then, as in the scalar case, it is easily seen that the minimum value of the cost functional will be zero provided the following theorem is true, where

$$\begin{aligned} Y := \{&(\mathcal{E},\mathcal{H}) \in C^1(\bar{B}) \times C^1(\bar{B}) : \operatorname{curl}\mathcal{E} - ik\mathcal{H} = 0, \\ &\operatorname{curl}\mathcal{H} + ikn(x)\mathcal{E} = 0 \text{ in } B\}, \\ W := \{&\nu \times (\mathcal{E} - E_g - \tilde{E}_\varphi),\ \nu \times \operatorname{curl}(\mathcal{E} - E_g - \tilde{E}_\varphi) : \\ &\varphi \in T^2(\Gamma),\ \lambda g = \tilde{E}_{\varphi,\infty}\,, (\mathcal{E},\mathcal{H}) \in Y\}, \end{aligned}$$

and B is as defined in the previous sections.

THEOREM 5.1. *Suppose $ik\lambda \notin \sigma(F)$. Then W is dense in $T^2(\partial B) \times T^2(\partial B)$.*

Proof. We first note that from (3.8) we have

$$\begin{aligned} E_g(x) &= ik \int_\Omega e^{ik\,x\cdot d}\, g(d)\,ds(d) \\ &= \frac{1}{4\pi\lambda} \operatorname{curl} \int_\Omega \int_\Gamma \varphi(y) e^{ik\,d\cdot(x-y)}\,ds(y)\,ds(d) \\ &= \frac{1}{\lambda} \operatorname{curl} \int_\Gamma \varphi(y) j_0(k|x-y|)\,ds(y). \end{aligned} \tag{5.10}$$

Now suppose that $a, b \in T^2(\partial B)$ satisfy

$$\int_{\partial B} \{(\mathcal{E} - E_g - \tilde{E}_\varphi)\cdot \bar{a} + \operatorname{curl}(\mathcal{E} - E_g - \tilde{E}_\varphi)\cdot \bar{b}\} ds = 0 \tag{5.11}$$

for all $(\mathcal{E},\mathcal{H}) \in Y$ and $\varphi \in T^2(\Gamma)$. Define

$$A(x) := \frac{1}{k^2} \operatorname{curl}\operatorname{curl} \int_{\partial B} \Psi(x,y)\overline{a(y)}\,ds(y) + \operatorname{curl} \int_{\partial B} \Psi(x,y)\overline{b(y)}\,ds(y) \tag{5.12}$$

for $x \in \mathbb{R}^3 \setminus \partial B$, where Ψ is given by (3.12). Then $E := \operatorname{curl} A$ is given by

$$E(x) = \operatorname{curl} \int_{\partial B} \Psi(x,y)\overline{a(y)}\,ds(y) + \operatorname{curl}\operatorname{curl} \int_{\partial B} \Psi(x,y)\overline{b(y)}\,ds(y) \tag{5.13}$$

for $x \in \mathbb{R}^3 \setminus \partial B$ and hence $\operatorname{curl} E = k^2 A$ for $x \in \mathbb{R}^3 \setminus \partial B$. Setting $\mathcal{E} = 0$ in (5.11) and using the vector identities

$$\begin{aligned} &\operatorname{curl}_y\{\Psi(x,y)\varphi(x)\} \cdot \overline{a(y)} = \varphi(x) \cdot \operatorname{curl}_x\{\Psi(x,y)\overline{a(y)}\}, \\ &\operatorname{curl}_y \operatorname{curl}_y\{\Psi(x,y)\varphi(x)\} \cdot \overline{b(y)} = \varphi(x) \cdot \operatorname{curl}_x \operatorname{curl}_x\{\Psi(x,y)\overline{b(y)}\} \end{aligned} \tag{5.14}$$

now shows that

$$\int_\Gamma \varphi \cdot E \, ds = 0 \tag{5.15}$$

for all $\varphi \in T^2(\Omega)$. Hence $\nu \times E = 0$ on Γ and since k is not a Maxwell eigenvalue for the interior of Γ we have that $E = 0$ in the interior of Γ. By unique continuation, $E = 0$ in B and hence $A = 0$ in B also. The L^2–jump relations for vector potentials [3, p. 165] now imply that

$$\nu \times \operatorname{curl} A_+ = \bar{a}, \quad \nu \times A_+ = \bar{b} \quad \text{on } \partial B \tag{5.16}$$

where $+$ again denotes the limit taken from the exterior of B. Setting $\varphi = 0$ in (5.11) now implies that

$$\int_{\partial B} \{\nu \times \mathcal{E} \cdot \operatorname{curl} A_+ - \nu \times A_+ \cdot \operatorname{curl} \mathcal{E}\} \, ds = 0 \tag{5.17}$$

for all $(\mathcal{E}, \mathcal{H}) \in Y$.

We now define

$$A^s(x) := \frac{1}{k^2} \operatorname{curl}\operatorname{curl} \int_{\partial B} \Phi(x,y)\overline{a(y)} \, ds(y) + \operatorname{curl} \int_{\partial B} \Phi(x,y)\overline{b(y)} \, ds(y) \tag{5.18}$$

for $x \in \mathbb{R}^3 \setminus \bar{B}$ and

$$\begin{aligned} A^0(x) := &\frac{1}{\lambda k^2} \operatorname{curl}\operatorname{curl} \int_{\partial B} j_0(k|x-y|)\overline{a(y)} \, ds(y) \\ &+ \frac{1}{\lambda} \operatorname{curl} \int_{\partial B} j_0(k|x-y|)\overline{b(y)} \, ds(y) \end{aligned} \tag{5.19}$$

for $x \in \mathbb{R}^3$ and note that from (3.8) we have

$$A^0(x) = \int_\Omega e^{ik\,x\cdot d} \, \tilde{g}(d) \, ds(d), \tag{5.20}$$

where

$$\tilde{g}(d) := \frac{1}{4\pi\lambda} \int_{\partial B} e^{-ik\,y\cdot d} \{(d \times \overline{a(y)}) \times d + ik\, d \times \overline{b(y)}\} \, ds(y). \tag{5.21}$$

In particular, from (5.10) and (5.21) we see that the far field pattern A_∞ of A^s is given by $A_\infty = \lambda \tilde{g}$.

In (5.17) we now set

$$\begin{aligned} \mathcal{E}(x) &= E^i(x; -\hat{z}, p) + E^s(x; -\hat{z}, p), \\ \mathcal{H}(x) &= H^i(x; -\hat{z}, p) + H^s(x; -\hat{z}, p), \end{aligned} \tag{5.22}$$

where $\hat{z} \in \Omega, p \in \mathbb{R}^3$, and use the vector Green's theorem to deduce that

$$\begin{aligned}(5.23)\qquad &\int_{\partial B} \{\nu(x) \times E^i(x;-\hat{z},p) \cdot \operatorname{curl} A^s(x) \\ &\qquad -\nu(x) \times A^s(x) \cdot \operatorname{curl} E^i(x;-\hat{z},p)\}\, ds(x) \\ &+ \int_{\partial B} \{\nu(x) \times E^s(x;-\hat{z},p) \cdot \operatorname{curl} A^0(x) \\ &\qquad -\nu(x) \times A^0(x) \cdot \operatorname{curl} E^s(x;-\hat{z},p)\}\, ds(x) = 0.\end{aligned}$$

Setting $ikB^s := \operatorname{curl} A^s$ and using (4.8) we now see that the first integral in (5.23) is given by

$$\begin{aligned}(5.24)\qquad &\int_{\partial B} \{\nu(x) \times E^i(x;-\hat{z},p) \cdot \operatorname{curl} A^s(x) \\ &\qquad -\nu(x) \times A^s(x) \cdot \operatorname{curl} E^i(x;-\hat{z},p)\}\, ds(x) \\ &= -ik \int_{\partial B} \{E^i(x;-\hat{z},p) \cdot \nu(x) \times B^s(x) \\ &\qquad +H^i(x;-\hat{z},p) \cdot \nu(x) \times A^s(x)\}\, ds(x) \\ &= k^2\, p \cdot \left(\hat{z} \times \int_{\partial B} \{\nu(x) \times A^s(x) + (\nu(x) \times B^s(x)) \times \hat{z}\} e^{-ik\,x\cdot\hat{z}}\, ds(x) \right) \\ &= -4\pi i k\, p \cdot A_\infty(\hat{z}).\end{aligned}$$

Inserting (5.20) into the second integral in (5.23) and interchanging orders of integration, we now have from (4.8) and reciprocity that

$$\begin{aligned}(5.25)\qquad &\int_{\partial B} \{\nu(x) \times E^s(x;-\hat{z},p) \cdot \operatorname{curl} A^0(x) - \\ &\qquad -\nu(x) \times A^0(x) \cdot \operatorname{curl} E^s(x;-\hat{z},p)\}\, ds \\ &= ik \int_\Omega \tilde{g}(d) \cdot \left(d \times \int_{\partial B} \{-\nu(x) \times E^s(x) + \right. \\ &\qquad \left. + [\nu(x) \times H^s(x)] \times d\} e^{ik\,x\cdot d}\, ds(x) \right) ds(d) \\ &= 4\pi\, p \cdot \int_\Omega E_\infty(\hat{z}; d, \tilde{g}(d))\, ds(d) \\ &= 4\pi p \cdot (F\tilde{g})(\hat{z}) \ .\end{aligned}$$

From (5.23)–(5.25) we now have that

$$(5.26)\qquad F\tilde{g} = ik\, A_\infty = ik\, \lambda \tilde{g}.$$

Since $ik\,\lambda \notin \sigma(F)$, we have that $\tilde{g} = 0$. This implies $A_\infty = 0$ and hence $A^s = 0$ in $\mathbb{R}^3 \setminus \bar{B}$ and $A^0 = 0$ in $\mathbb{R}^3$. Hence, $A = 0$ in $\mathbb{R}^3 \setminus \bar{B}$ and from (5.16) we now have that $a = b = 0$. The theorem is now proved.

THE INVERSE EIGENVALUE PROBLEM WITH FINITE DATA FOR PARTIAL DIFFERENTIAL EQUATIONS*

DAVID C. BARNES† AND ROGER KNOBEL‡

Abstract. This work is concerned with the inverse eigenvalue problem for the partial differential equation $\nabla^2 u + (\lambda - q(x,y))u = 0$. We study the problem of reconstructing the coefficient function $q(x,y)$ (or at least a numerical approximation to it) using only a finite amount of spectral data, say, $\lambda_n(q)$ for $n = 1, 2, \ldots, N$. One of the essential tasks considered here is that of determining how much information about the unknown function can be contained in such a fixed and finite amount of spectral data. A numerical method, based on a constrained least squares procedure, is devised for extracting such information, and several examples are given. A proof of convergence for the numerical method is provided. We show that the main difficulty with the finite inverse problem is that the eigenvalues are continuous in some very weak topologies. This work is a higher-dimensional version of the problem considered by Barnes [*SIAM J. Math Anal.*, 22 (1991), pp. 732–753] for ordinary differential equations.

Key words. inverse eigenvalue problem, continuous dependence

AMS subject classification. 35B25

1. Formulation of the finite inverse problem.

1.1. Introduction. Assume that $\mathcal{D}$ is a bounded piecewise smooth domain in the x, y plane, let $\vec{\nu}$ be a unit normal vector on $\partial\mathcal{D}$, and consider the eigenvalue problem

$$\nabla^2 u + (\lambda - q(x,y))u = 0, \quad \text{with} \quad \sigma_1 u + \sigma_2 \frac{\partial u}{\partial \vec{\nu}} = 0 \quad \text{on} \quad \partial\mathcal{D}. \tag{1}$$

Here, σ_1 and σ_2 are given functions, but both cannot vanish at the same time. Denote the eigenvalues of (1) by $\lambda_n(q)$ and let $q^*(x,y)$ represent the unknown coefficient function. Suppose that a finite amount of spectral data $\boldsymbol{\Lambda} = (\Lambda_1, \Lambda_2, \ldots, \Lambda_N)$ is given so that $\lambda_n(q^*) = \Lambda_n$ for $n = 1, 2, \ldots, N$. We want to construct the best possible approximation to $q^*(x,y)$ using the given data. A problem similar to this has been considered by Seidman [13]; however, he assumed that the domain $\mathcal{D}$ was the unit ball in N-dimensional space and that the coefficient functions were all radially symmetric. Such symmetry reduces the higher-dimensional problem to the one-dimensional case. Our work does not make such assumptions. For some additional results concerning this problem, see [3]–[5], [10], and [12].

Clearly, such a finite inverse problem cannot be solved uniquely. Therefore, we understand that a solution to such a problem is simply a sequence of functions $q_N(x,y)$ which has the correct spectral behavior—that is, a sequence satisfying the following interpolation condition: For each N, there is an ϵ_N such that

$$|\lambda_i(q_N) - \lambda_i(q^*)| < \epsilon_N \quad \text{for } i = 1, 2, \ldots, N \quad \text{and} \quad \epsilon_N \to 0 \quad \text{as } N \to \infty. \tag{2}$$

Next, we must provide a proper mathematical foundation for understanding the results. In particular, it is critical that the sequence $q_N(x,y)$ should converge to $q^*(x,y)$

in some suitable topology as $N \to \infty$. If so, it is necessary to understand something about the topology used and how accurate the approximation is. Also, for a given fixed value of N, we need to have some idea of how many different functions (in addition to q^*) might satisfy the spectral conditions $\boldsymbol{\lambda}(q) = \boldsymbol{\Lambda}$.

Theorem 2.4 and Corollaries 2.3 and 2.7 provide some partial answers to these questions. They show that, assuming a uniqueness condition, as $N \to \infty$, the approximating sequence $q_N(x, y)$ converges to $q^*(x, y)$ in a certain norm (we call it the 1Max norm) and that the eigenvalues are continuous in the topology generated by it. The continuity theorem indicates what kind of variation in the solution of such an inverse problem is still possible, even assuming that the uniqueness condition is satisfied and that all of the requirements of a finite amount of spectral data have been met. This analysis provides a proper mathematical foundation for the finite inverse problem.

A useful tool is the following variational characterization of eigenvalues using the Rayleigh quotient [6], [14]. Let $\mathcal{L}(\cdot)$ be a self-adjoint operator defined on a dense subspace $\mathbf{D}$ of a separable Hilbert space. Suppose that the lower part of the spectrum of $\mathcal{L}(\cdot)$ consists of isolated eigenvalues $\lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \cdots$, each with finite multiplicity. Let u_i denote the eigenfunction corresponding to λ_i and let $\mathcal{U}_n$ be the subspace spanned by the first n eigenfunctions $u_1, u_2, \ldots, u_n$. Let $\mathcal{V}_n$ be any other n-dimensional subspace of $\mathbf{D}$. Let $\mathcal{R}(u)$ denote the Rayleigh quotient for $\mathcal{L}(\cdot)$. It is defined by

$$\mathcal{R}(u) = \frac{(\mathcal{L}(u), u)}{(u, u)}.$$

It follows that

$$\lambda_n \leq \max_{u \in \mathcal{V}_n} \mathcal{R}(u) \quad \text{and that} \quad \lambda_n = \max_{u \in \mathcal{U}_n} \mathcal{R}(u). \tag{3}$$

2. The topology of the finite inverse eigenvalue problem.

2.1. Continuity properties of the eigenvalues. In a bounded two-dimensional domain $\mathcal{D}$, let $\mathcal{C}(\mathcal{D}, H)$ be the class of measurable functions $q(x, y)$ with domain $\mathcal{D}$ satisfying $|q| \leq H$. It is convenient to assume that all functions in $\mathcal{C}(\mathcal{D}, H)$ vanish outside of $\mathcal{D}$. A major part of the theory of the finite inverse problem hinges on a topological analysis of the continuity properties of the eigenvalues $\lambda_n(q)$, which are simply real-valued functions defined on $\mathcal{C}(\mathcal{D}, H)$. To understand why, consider a classical theorem which says that the eigenvalues are continuous functions of q in the L_∞ norm. It is clearly not possible to construct any kind of reasonable approximation to the partial derivatives of $q(x, y)$ using only a finite amount of spectral data. But this continuity theorem does provide a little insight into the information content of the spectral data.

On the other hand, it follows easily from Corollary 2.3 that the eigenvalues are still continuous in the much weaker L_2 norm. Therefore, we cannot even construct a uniform approximation to $q^*(x, y)$. With each new and weaker topology in which the eigenvalues are continuous, we understand more about the information content of the spectral data because we know more about what kind of information that the data does *not* contain. This leads us to consider the problem of characterizing, in an understandable way, the weakest topology in which the first N eigenvalues are continuous.[1] It is this topology which provides an accurate measure of the information

[1] A basis for the open sets in this topology may be taken as the collection of subsets of $\mathcal{C}(\mathcal{D}, H)$ which are inverse images of an open interval under the mapping $\lambda_n : q \to \Re$ for $n = 1, 2, \ldots, N$.

content of the spectral data. Because the topology depends on N, it seems to be very difficult to characterize it exactly, but we will provide some approximations to it.

We will be especially concerned with the following three different topologies defined on $\mathcal{C}(\mathcal{D}, H)$: the topology of weak convergence of a sequence,[2] denoted by $q_n(x,y) \rightsquigarrow q(x,y)$, and the topologies defined by a pair of norms $\|\cdot\|_{1\text{Max}}$ and $\|\cdot\|_{\nabla^2}$. First, we will define the norms.

Given a function $q(x,y) \in \mathcal{C}(\mathcal{D}, H)$ and coefficients σ_1, σ_2 defined on $\partial\mathcal{D}$, let $\overrightarrow{\nu}$ be a unit normal vector and let $f(x,y)$ be the solution of the problem

$$\nabla^2 f = q(x,y) \quad \text{with} \quad 2\sigma_1 f + \sigma_2 \frac{\partial f}{\partial \overrightarrow{\nu}} = 0 \quad \text{on} \quad \partial\mathcal{D}. \tag{4}$$

Since an extra factor of 2 is included in the boundary condition of (4), the integral formula

$$\iint_{\mathcal{D}} q(s,t) u_n^2 \, ds\, dt = \iint_{\mathcal{D}} \left[\nabla^2 f(x,y)\right] u_n^2 \, ds\, dt = \iint_{\mathcal{D}} f(x,y) \left[\nabla^2 u_n^2\right] \, ds\, dt$$

will hold. It is easy to check that the following relation defines a norm $\|\cdot\|_{\nabla^2}$ on $\mathcal{C}(\mathcal{D}, H)$. For $q(x,y) \in \mathcal{C}(\mathcal{D}, H)$, let

$$\|q\|_{\nabla^2} = \max_{(x,y)\in\mathcal{D}} |f(x,y)|$$

with f defined by (4). Using Green's function $\mathcal{G}(x,y,s,t)$ for (4), it follows that

$$f(x,y) = \iint_{\mathcal{D}} \mathcal{G}(x,y,s,t) q(s,t) \, ds\, dt, \tag{5}$$

so that the ∇^2 norm also may be expressed as

$$\|q\|_{\nabla^2} = \max_{x,y\in\mathcal{D}} |f(x,y)| = \max_{x,y\in\mathcal{D}} \left| \iint_{\mathcal{D}} \mathcal{G}(x,y,s,t) q(s,t) \, ds\, dt \right|.$$

We will also be concerned with the 1Max norm defined by

$$\|q\|_{1Max} = \max_{x,y\in\mathcal{D}} \left| \int_0^x \int_0^y q(s,t) \, ds\, dt \right|.$$

We are assuming, for convenience, that the domain $\mathcal{D}$ is contained in the positive quadrant and that $q(x,y)$ vanishes outside $\mathcal{D}$. In analogy with the ∇^2 norm, the 1Max norm could also be defined as the maximum value of the function $f(x,y)$, the unique solution of the characteristic initial value problem $f_{xy} = q(x,y)$ with boundary conditions $f(0,y) = f(x,0) = 0$.

Now that these three topologies have been introduced, we will show that, in fact, all of them are equivalent in the class $\mathcal{C}(\mathcal{D}, H)$. Therefore, compactness of $\mathcal{C}(\mathcal{D}, H)$ in the weak topology gives compactness in both norm topologies. One reason to consider two different but equivalent norms is that it is difficult to compute $\|\cdot\|_{\nabla^2}$ since the Poisson equation (4) must be solved while it requires only a quadrature to compute

[2] Weak convergence means that $\int\int_{\mathcal{D}} f(x,y) q_n(x,y) \, dx\, dy \to \int\int_{\mathcal{D}} f(x,y) q(x,y) \, dx\, dy$ for every function $f(x,y)$ having $\int\int_{\mathcal{D}} f^2(x,y) \, dx\, dy < \infty$. The weak topology is useful because it makes $\mathcal{C}(\mathcal{D}, H)$ compact [6].

$\|\cdot\|_{1\text{Max}}$. However, it turns out that, at least for the study of inverse problems, it is analytically more convenient to use $\|\cdot\|_{\nabla^2}$. Furthermore, we will show later that, if $H\to\infty$, then the three topologies are not equivalent.

THEOREM 2.1. *If $q(x,y)$, $q_n(x,y) \in \mathcal{C}(\mathcal{D},H)$, then as $n\to\infty$, the following are all equivalent:*

(1) $q_n(x,y) \rightsquigarrow q(x,y)$,
(2) $\|q_n - q\|_{\nabla^2}\to 0$,
(3) $\|q_n - q\|_{1\text{Max}}\to 0$.

Proof. We will prove the logical implications (1) $\Leftrightarrow$ (2) and (1) $\Leftrightarrow$ (3). First, supposing that (1) holds, use Green's function to define $Q_n(x,y)$ by

$$Q_n(x,y) = \iint_{\mathcal{D}} \mathcal{G}(x,y,s,t)q_n(s,t)\,ds\,dt.$$

Let $\Delta q_n = q_n - q$ and $\Delta Q_n = Q_n - Q$. Then the weak convergence implies, for each fixed point (x,y), that

$$\Delta Q_n(x,y) = \iint_{\mathcal{D}} \mathcal{G}(x,y,s,t)\Delta q_n(s,t)\,ds\,dt\to 0.$$

However, $\Delta Q_n(x,y)$ is uniformly bounded and equicontinuous, implying that there is a uniformly convergent subsequence. Since the limit must be unique, every such subsequence must converge to the same function. Thus, the overall convergence is uniform. Using Green's function characterization of the ∇^2 norm (5) shows that $\|q_n - q\|_{\nabla^2}\to 0$.

Now suppose (2). Let $h(x,y) \in \mathcal{C}(\mathcal{D},H)$ be any function smooth enough so that, for some choice of $r(x,y) \in L_2[\mathcal{D}]$, it can be represented in the form

$$h(x,y) = \iint_{\mathcal{D}} \mathcal{G}(x,y,s,t)r(s,t)\,dt\,ds.$$

Consider

$$\begin{aligned}(h,\Delta q_n) &= \iint_{\mathcal{D}} h(x,y)\Delta q_n(x,y)\,dx\,dy \\ &= \iint_{\mathcal{D}} r(s,t)\left(\iint_{\mathcal{D}} \mathcal{G}(x,y,s,t)\Delta q_n(x,y)\,dx\,dy\right) ds\,dt \\ &= \iint_{\mathcal{D}} r(s,t)\Delta Q_n(s,t)\,ds\,dt = (r,\Delta Q_n).\end{aligned}$$

Since $\Delta Q_n(s,t)$ converges uniformly to zero, it follows that $(h,q_n)\to 0$, which implies weak convergence for smooth functions $h(x,y)$. Since such smooth functions are dense in $\mathcal{C}(\mathcal{D},H)$, condition (1) follows.

Now suppose (1). Given $(x,y) \in \mathcal{D}$, let $h(s,t) = 1$ for $s \le x$ and $t \le y$; otherwise, let $h(s,t) = 0$. Weak convergence implies the following pointwise convergence (in (x,y)):

$$(h,\Delta q_n) = \iint_{\mathcal{D}} h(s,t)\Delta q_n(s,t)\,ds\,dt = \int_{-\infty}^{x}\int_{-\infty}^{y} \Delta q_n(s,t)\,dt\,ds\to 0.$$

However, the sequence of functions $\int_{-\infty}^{x}\int_{-\infty}^{y} q_n(s,t)\,ds\,dt$ is uniformly bounded and equicontinuous so that it will converge uniformly. Thus, $\|\Delta q_n\|_{1\text{Max}}\to 0$.

Now suppose (3). It follows that, if $\mathcal{X}(s,t)$ is the characteristic function of any rectangle contained in $\mathcal{D}$, then $\iint_{\mathcal{D}} \mathcal{X}(s,t)\Delta q_n(s,t)\,ds\,dt \to 0$. Taking linear combinations of such characteristic functions shows that the same result holds for any step function defined on a rectangular grid. Since such functions are dense, it follows that $q_n(x,y) \rightsquigarrow q(x,y)$. □

Incidentally, this theorem shows that the topology generated by the ∇^2 norm is really independent of the terms σ_1 and σ_2 used in the boundary conditions of (4).

We will now show that the eigenvalues of (1) are continuous on $\mathcal{C}(\mathcal{D},H)$ with respect to these three topologies. Of course, since all three are actually identical, we will need only one proof.

THEOREM 2.2. *Let $\lambda_n(q)$ denote the nth eigenvalue of* (1) *corresponding to $q(x,y)$, and let $q_1, q_2 \in \mathcal{C}(\mathcal{D},H)$. Let μ_n denote the nth eigenvalue of* (1) *corresponding to the constant function $q(x,y) = H$ so that $\mu_n = \lambda_n(H)$. Then for all $n = 1,2,\ldots,N$,*

$$|\lambda_n(q_1) - \lambda_n(q_2)| \le 4N(H + |\mu_N|)\|q_1 - q_2\|_{\nabla^2}. \tag{6}$$

Proof. Let u be any function of the general form

$$u = \sum_{i=1}^{N} \alpha_i u_i \quad \text{where} \quad \sum_{i=1}^{N} \alpha_i^2 = 1 \quad \text{and} \quad \iint_{\mathcal{D}} u_i^2\,dA = 1,$$

where u_i are eigenfunctions corresponding to some coefficient function $p \in \mathcal{C}(\mathcal{D},H)$. We will show that any such function u satisfies the inequality

$$\left|\iint_{\mathcal{D}} u^2(q_1 - q_2)\,dA\right| \le 4N(H + |\mu_N|)\|q_1 - q_2\|_{\nabla^2}. \tag{7}$$

By assuming for a moment that this is true, we see that

$$\iint_{\mathcal{D}} u^2 q_1\,dA \le \iint_{\mathcal{D}} u^2 q_2\,dA + 4N(H + |\mu_N|)\|q_1 - q_2\|_{\nabla^2}.$$

The Rayleigh quotient for this problem is given by

$$\mathcal{R}(u,q) = \frac{\iint_{\mathcal{D}} u_x^2 + u_y^2 + q(x,y)u^2\,dA + \int_{\partial\mathcal{D}} u\partial u/\partial\vec{\nu}\,ds}{\iint_{\mathcal{D}} u^2\,dA}.$$

Equation (7) shows that $\mathcal{R}(u,q_1) \le \mathcal{R}(u,q_2) + 4N(H + |\mu_N|)\|\Delta q\|_{\nabla^2}$. Now take the maximum over all functions u in the space spanned by the first N eigenfunctions corresponding to the function q_2. It follows from the Min/Max principle (3) that $\lambda_n(q_1) \le \lambda_n(q_2) + 4N(H+|\mu_N|)\|\Delta q\|_{\nabla^2}$. Reversing the roles of q_1 and q_2 and repeating this argument gives the other half of (6) and proves the theorem. Now we need only to prove (7).

Let $u = \sum_{i=1}^{N} \alpha_i u_i$ with $\sum_{i=1}^{N} \alpha_i^2 = 1$ and suppose that f solves (4). Then

$$\begin{aligned}\iint_{\mathcal{D}} u^2\Delta q\,dA = \iint_{\mathcal{D}} u^2\nabla^2 f\,dA &= \iint_{\mathcal{D}} f\nabla^2 u^2\,dA \\ &= \sum_{i,j=0}^{N} \alpha_i\alpha_j \iint_{\mathcal{D}} f\nabla^2(u_i u_j)\,dA.\end{aligned} \tag{8}$$

Now u_i, u_j are eigenfunctions corresponding to some other function $p \in \mathcal{C}(\mathcal{D}, H)$ so that $\nabla^2 u_i = (p - \lambda_i(p))u_i$. Thus,

$$|\nabla^2(u_i u_j)| \leq |u_j u_i(p - \lambda_i(p))| + 2|\nabla u_i||\nabla u_j| + |u_i u_j(p - \lambda_j(p))|.$$

This inequality shows that the expression $|\iint_{\mathcal{D}} f \nabla^2 u_i u_j \, dA|$ is bounded above by the following term:

$$\|\Delta q\|_{\nabla^2} \iint_{\mathcal{D}} |u_j u_i(p - \lambda_i(p))| + 2|\nabla u_i||\nabla u_j| + |u_i u_j(p - \lambda_j(p))| \, dA. \tag{9}$$

Using the elementary inequality $|u_j u_i(p - \lambda_i(p))| \leq |u_i u_j(H + \mu_N)$ followed by the normalizing condition and Cauchy's inequality shows that the integral of the first and last terms in (9) are bounded by $H + \mu_N$. Combining the relation $\int\int |\nabla u_i|^2 = \lambda_i - \int\int q u_i^2 \, dA$ with a second application of Cauchy's inequality shows that the middle term of (9) is bounded by $(H + |\lambda_i|)^{1/2}(H + |\lambda_j|)^{1/2}$. Now, replace $|\lambda_i(p)|$ and $|\lambda_j(p)|$ with the larger value μ_N, add all three terms together, and substitute into (8). Finally, use Cauchy's inequality again and the normalizing condition to obtain (7). □

COROLLARY 2.3. *The eigenvalues $\lambda_n(q)$ are continuous on $\mathcal{C}(\mathcal{D}, H)$ with respect to weak convergence as well as with respect to the* 1Max *and the* ∇^2 *norms.*

Since the L_p norm is stronger than either the 1Max *or the* ∇^2 *norm, it also follows that the eigenvalues are continuous in the L_p norm for any $p \geq 1$.*

The second part of the corollary follows from the inequality

$$\|q\|_{1Max} = \max_{x,y \in \mathcal{D}} \left| \int_0^x \int_0^y q(s,t) \, ds \, dt \right| \leq \int_0^\infty \int_0^\infty |q(s,t)| \, ds \, dt \leq \|q\|_p.$$

The assumption that the functions q are uniformly bounded is crucial to the success of Theorems 2.2 and 2.4. All three topologies become very different if we let $H \to \infty$. For example, let $\mathcal{D}$ be the unit square, use Dirichlet boundary conditions, and take a perturbation in $q(x,y)$ of the form $\Delta q_{i,j}(x,y) = H \sin(i\pi x + j\pi y)$ where i, j are integers. A short calculation shows that $\|\Delta q_{i,j}\|_{1\text{Max}} = 3H/(ij\pi^2)$. Solving for f in the equation $\nabla^2 f = \Delta q_{i,j}$ gives

$$f(x,y) = \frac{-H}{(i^2 + j^2)\pi^2} \sin(i\pi x + j\pi y) \quad \text{so that} \quad \|\Delta q_{i,j}\|_{\nabla^2} = \frac{H}{(i^2 + j^2)\pi^2}.$$

Now, take $i = 1$ and $H = j$ to find that $\|\Delta q_{1,j}\|_{1\text{Max}} = 3$, while $\|\Delta q_{1,j}\|_{\nabla^2} \to 0$ as $j \to \infty$. In the L_2 norm, however, $\|q_{1,j}\|_{L^2} \to \infty$. Since the L_2 norms of any weakly convergent sequence must be uniformly bounded, $\Delta q_{i,j}(x,y)$ does not converge weakly. It is also easy to construct examples where $\|\Delta q_{i,j}\|_{1\text{Max}} \to 0$ without converging weakly.

Thus, the eigenvalues are continuous in some very weak topologies, and this is the root of the difficulty with the finite inverse eigenvalue problem. To illustrate further, suppose we are trying to find a numerical solution of such a problem for (1). Suppose that the unknown function is $q^*(x,y)$ and let $f^*(x,y)$ be the corresponding solution of (4). Then any other solution $f(x,y)$ of (4) that is a good uniform approximation to $f^*(x,y)$ will provide an equally valid solution to the finite inverse eigenvalue problem. This means that, at most, the only information contained in a finite amount of spectral data is a uniform approximation to $f^*(x,y)$. Therefore, reconstructing a pointwise approximation to $q^*(x,y)$ requires one to apply the operator $\nabla^2(\cdot)$ to the uniform approximation f, resulting in a very ill conditioned operation. Unfortunately, the fact is that a finite amount of spectral data simply cannot yield any better information about the function $q^*(x,y)$.

2.2. Some convergence theorems. Although the spectral data may not contain all of the information we want it to have, we will now show that, under a uniqueness condition, any sequence of interpolating functions (2) will converge to $q*$ in the weak topology as $N\to\infty$. The fundamental tool is the compactness of the class $\mathcal{C}(\mathcal{D}, H)$.

THEOREM 2.4. *Let Λ_n denote some spectral data for the problem* (1). *Suppose that the data is sufficient to insure that the infinite inverse eigenvalue problem always has a unique solution. That is, there is a unique function $q^* \in \mathcal{C}(\mathcal{D}, H)$ for which $\lambda_n(q^*) = \Lambda_n$ for all n. Let q_N be any sequence of functions which interpolates to the data $\lambda_n(q^*)$ as in* (2). *Then as $N\to\infty$,*

$$q_N \rightsquigarrow q^* \quad \text{and} \quad \|q_N - q^*\|_{1\text{Max}}\to 0 \quad \text{and} \quad \|q_N - q^*\|_{1\text{Max}}\to 0.$$

Proof. The proof follows the lines of the one given in [4]. Let q_N be the sequence of interpolation functions. Since $\mathcal{C}(\mathcal{D}, H)$ is compact, we may select a weakly convergent subsequence $q_{N_j} \rightsquigarrow \bar{q} \in \mathcal{C}(\mathcal{D}, H)$ as $j\to\infty$. The interpolation condition (2) shows that $\lambda_n(q^*) = \lambda_n(\bar{q})$ for all n so that $q^* = \bar{q}$. Thus, for any convergent subsequence, $q_{N_j} \rightsquigarrow q^*$ as $j\to\infty$ so that $q_N \rightsquigarrow q^*$ as $N\to\infty$. □

Of course, the difficulty with this theorem is that currently very little is known about the uniqueness of the inverse eigenvalue problem for partial differential equations, although progress has been made in the corresponding problem for ordinary differential equations [11]. In one of the few known uniqueness results dealing with the inverse problem for (1), Nachman, Sylvester, and Uhlmann [12] gave the following condition under which the infinite inverse problem will have unique solutions.

THEOREM 2.5 (Nachman et al.). *Consider* (1) *with Dirichlet boundary conditions. Suppose that $q_1(x, y)$ and $q_2(x, y)$ are two functions for which $\lambda_n(q_1) = \lambda_n(q_2)$ for all n and also that on the boundary of $\mathcal{D}$, the corresponding eigenfunctions, called $u_n^{[1]}$ and $u_n^{[2]}$, have equal normal derivatives*

$$\frac{\partial u_n^{[1]}}{\partial \nu} = \frac{\partial u_n^{[2]}}{\partial \nu}, \tag{10}$$

then $q_1 = q_2$.

Combining Theorems 2.4 and 2.5 yields the following theorem.

THEOREM 2.6. *Suppose that q^* and q_N are functions in $\mathcal{C}(\mathcal{D}, H)$ that satisfy $\lambda_n(q^*) = \lambda_N(q_N)$ for $n = 1, 2, \ldots, N$ and suppose that all of their corresponding eigenfunctions satisfy the normal derivative condition* (10). *Then as $N\to\infty$,*

$$q_N \rightsquigarrow q^* \quad \text{and} \quad \|q_N - q^*\|_{1\text{Max}}\to 0 \quad \text{and} \quad \|q_N - q^*\|_{1\text{Max}}\to 0. \tag{11}$$

Since $\mathcal{C}(\mathcal{D}, H)$ is compact, we can find a function, $\widehat{q} \in \mathcal{C}(\mathcal{D}, H)$, and a weakly convergent subsequence, $q_{N_i}\to\widehat{q}$, as $i\to\infty$. However, Theorem 2.1 shows that $\lambda_n(\widehat{q}) = \lambda_n(q^*)$ for all n. Theorem 2.6 implies that $q^* = \widehat{q}$. Since every convergent subsequence of q_N converges to the same q^*, it follows that q_N must converge to q^* as $N\to\infty$.

It is easy to see that an analogous theorem will continue to hold under any kind of condition on the spectral data or on the class $\mathcal{C}(\mathcal{D}, H)$ that gives uniqueness of the infinite inverse eigenvalue problem.

Still, it seems likely that many other inverse problems for (1) will not have unique solutions when the class of functions $\mathcal{C}(\mathcal{D}, H)$ is unrestricted. It seems more reasonable to expect a uniqueness result if the class $\mathcal{C}(\mathcal{D}, H)$ is constrained in some way—say, by requiring the functions $q(x, y)$ to be convex or to have some kind of symmetry.

Frequently, in applied inverse problems, a great deal is known about the qualitative behavior of the unknown function. An elementary example of such a constraint is used in the numerical calculation given in §5 below.

As another use of the idea of a subclass of $\mathcal{C}(\mathcal{D}, H)$, consider the case in which it is known that the function q^* satisfies a uniform Lipschitz condition

$$|q^*(x,y) - q^*(s,t)| \leq L(|x-y| + |s-t|). \tag{12}$$

Thus, we may also constrain the interpolating functions q_N to satisfy (12) and still be assured of obtaining a solution of the inverse problem. Then weak convergence implies uniform convergence so that q_N converges uniformly to q. Even if the uniqueness condition is not satisfied, then compactness still assures us of the existence of a uniformly convergent subsequence. If the Lipschitz condition is assumed to hold only on some subset of the domain $\mathcal{D}$, then we may select the interpolating sequence q_N to satisfy the Lipschitz condition there; thus we are assured of uniform convergence on the subset and, at least, of weak convergence elsewhere. We will show below how such constraints on the interpolating sequence q_N may be numerically implemented.

2.3. The isospectral equivalence classes $\mathcal{C}_N(\mathcal{D}, H)$ of $\mathcal{C}(\mathcal{D}, H)$. Since uniqueness is not readily available, we will consider the behavior of the set of isospectral equivalence classes on $\mathcal{C}(\mathcal{D}, H)$. We assume that only a finite amount of data is given. Thus, two functions q_1, q_2 are equivalent if $\lambda_n(q_1) = \lambda_n(q_2)$ for $n = 1, 2, 3, \ldots, N$. Call this set of equivalence classes $\mathcal{C}_N(\mathcal{D}, H)$, which inherits a natural topology from $\mathcal{C}(\mathcal{D}, H)$. Reinterpreting Theorem 2.4 in the light of these equivalence classes provides the following result.

COROLLARY 2.7. *The infinite inverse eigenvalue problem has a unique solution if and only if the diameter (as measured in the* 1Max *norm) of each equivalence class $\mathcal{C}_N(\mathcal{D}, H)$ tends to zero as $N \to \infty$.*

Let R^N be Euclidean N-dimensional space and define a mapping

$$\Phi : \mathcal{C}(\mathcal{D}, H) \to R^N \quad \text{by} \quad \Phi(q) = \boldsymbol{\lambda}(q),$$

using the brief notation $\boldsymbol{\lambda}(q) = (\lambda_1(q), \lambda_2(q), \ldots, \lambda_N(q))$. Let $\mathcal{S}(\mathcal{D}, H) \subset R^N$ be the range of Φ. Define a topology on $\mathcal{S}(\mathcal{D}, H)$ by using the component-wise convergence criteria $\boldsymbol{\lambda}(q_j) \to \boldsymbol{\lambda}(q^*)$ if and only if, for each $n = 1, 2, \ldots, N$, $\lambda_n(q_j) \to \lambda_n(q^*)$ as $j \to \infty$. Now topologize $\mathcal{C}(\mathcal{D}, H)$, using the weakest topology in which the first N eigenvalues are continuous. This simply means that $q_j \to q^*$ as $j \to \infty$ if and only if $\lambda_n(q_j) \to \lambda_n(q^*)$ for each $n = 1, 2, \ldots, N$. Now Φ induces a natural mapping of the equivalence classes $\mathcal{C}_N(\mathcal{D}, H)$ onto $\mathcal{S}(\mathcal{D}, H) \subset R^N$, and the map will be both continuous and one-to-one. Thus, $\mathcal{C}_N(\mathcal{D}, H)$ is homeomorphic to a subset of ordinary N-dimensional Euclidean space. This determines the weakest topology on $\mathcal{C}_N(\mathcal{D}, H)$, in which the eigenvalues are continuous. Unfortunately, knowing the topology on $\mathcal{C}_N(\mathcal{D}, H)$ still does not easily translate into usable conditions on the coefficient functions q themselves which, of course, belong to $\mathcal{C}(\mathcal{D}, H)$ and not to $\mathcal{C}_N(\mathcal{D}, H)$.

3. Higher-order equations in many dimensions. Similar methods can be applied to more general eigenvalue problems. We will use the standard notation and terminology for general partial differential operators as given, for example, by Friedman [7].

Let Ω be a bounded set in p-dimensional space, let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p)$ be a multi-index, and let $D^\alpha = D_1^{\alpha_1} D_2^{\alpha_2} \cdots D_p^{\alpha_p}$ where $D_j = \partial / \partial x_j$. Let $\|u\|_m^\Omega$ be the Sobolev norm of order m for functions u defined on Ω. Let $\mathcal{L}$ be the differential

operator defined by $\mathcal{L} = \sum_{|\alpha| \leq 2m} a_\alpha(\boldsymbol{x}) D^\alpha$ where $\boldsymbol{x} \in \Omega$. Details of the conditions on Ω and $\mathcal{L}$, under which eigenvalue problems for such operators are well posed, have been studied extensively [7] and will not be repeated here. We will simply assume that the operator is such that the variational principle (3) is valid and that the following standard a priori inequality will hold for all u in an appropriate Sobolev space [1], [7]:

$$\|u\|_{2m}^{\Omega} \leq C \left(\|\mathcal{L}(u)\|_0^{\Omega} + \|u\|_0^{\Omega} \right).$$

The constant C is independent of u. This inequality takes the place of those used in §2.2.

As an example of what can be done with these methods, we will study the eigenvalue problem

$$\mathcal{L}(u) + (\lambda - q(\boldsymbol{x}))u = 0 \quad \text{with} \quad \frac{\partial^j u}{\partial \mu^j} = 0 \quad \text{on} \quad \partial\Omega \quad \text{for} \quad j = 0, 1, 2 \ldots m-1. \tag{13}$$

Here, μ is the outward normal to the boundary. To define the appropriate norm of a function $q(\boldsymbol{x})$, let f be the unique solution of the Dirichlet problem

$$\mathcal{L}(f) = q(\boldsymbol{x}) \quad \text{with} \quad \frac{\partial^j f}{\partial \mu^j} = 0 \quad \text{on} \quad \partial\Omega \quad \text{for} \quad j = 0, 1, 2 \ldots m-1.$$

Now define the norm $\|q\|_{\mathcal{L}}$ by

$$\|q\|_{\mathcal{L}} = \max_{\boldsymbol{x} \in \Omega} |f(\boldsymbol{x})|.$$

The following theorem gives the continuity of the eigenvalues of (13).

THEOREM 3.1. *Let $\lambda_n(q)$ denote the nth eigenvalue of the problem* (13). *There is a constant $C_n(H, \mathcal{D})$ which depends only on H, n, and $\mathcal{D}$, for which*

$$|\lambda_n(q_1) - \lambda_n(q_2)| \leq C_n(H, \mathcal{D}) \|q_1 - q_2\|_{\mathcal{L}}.$$

Proof. Proceeding as before, we see that u^2 satisfies the boundary conditions (13), so that

$$\int_\Omega \Delta q u^2 \, dV = \int_\Omega \mathcal{L}(f) u^2 \, dV = \int_\Omega f \mathcal{L}(u^2) \, dV \leq \|f\|_\infty \int_\Omega |\mathcal{L}(u^2)| \, dV.$$

Suppose that the eigenfunction is normalized so that $\|u\|_0^{\Omega} = 1$. Now for any $u \in \mathcal{U}(q)$, the expression $\mathcal{L}(u^2)$ can be written as a linear combination of terms like $D^{\alpha_i} u_k D^{\alpha_j} u_l$. The Schwartz inequality shows that $\int_\Omega |\mathcal{L}(u^2)| \, dV$ is bounded by a sum of terms like $C \|u_k\|_i^{\Omega} \|u_l\|_j^{\Omega}$, where C is a constant. The rest of the proof is much like that for the two-dimensional case. □

It is now clear that all of the two-dimensional theorems have generalizations to these higher-dimensional, higher-order problems. It is also interesting to observe that the higher-order problems are more poorly conditioned than the lower-order ones. To justify this observation, consider the problem of attempting to obtain pointwise data about q from the spectral data $\boldsymbol{\Lambda}$. Theorem 2.6 shows that the only information about q that is contained in a finite amount of data is a uniform approximation to the solution f of $\mathcal{L}(f) = q(\boldsymbol{x})$. So reconstructing q requires that the differential operator $\mathcal{L}(\cdot)$ be applied to the uniform approximation to f, resulting in a very ill conditioned operation. Such a manipulation becomes more ill conditioned as the order of the operator increases.

4. Application to optimization problems. These continuity properties also have applications to certain variational methods for isoperimetric inequalities. One application is to the existence theory for "eigenvalue gap" problems like those considered in [2]. These problems ask for the extremals of quantities such as $\lambda_2(q) - \lambda_1(q)$ or $\lambda_2(q)/\lambda_1(q)$. Given our continuity theorems, it is easy to show the existence of extremals for such problems on $\mathcal{C}(\mathcal{D}, H)$ since the differences and ratios of eigenvalues are continuous functions on a compact set.

5. Numerical examples.

5.1. Introduction. In this section we present three examples illustrating the numerical solution of the finite data problem in two dimensions. Our approach here is a least squares method that generalizes the algorithm described in [4] for the inverse Sturm–Liouville problem. The first example uses Dirichlet eigenvalues to construct an approximation of a function $q(x, y)$ defined on a rectangle and containing certain symmetry properties. In the second example, the symmetry assumptions are dropped, and an approximation to a general $q(x, y)$ is accomplished, using eigenvalues from four sets of boundary conditions. Finally, our third example exhibits the approximation of a characteristic function $q(x, y)$.

In each of the examples, the given spectral data $\boldsymbol{\Lambda}$ consists of N eigenvalues of (1). Using the data $\boldsymbol{\Lambda}$, functions $q_{N,M} \in \mathcal{C}(\mathcal{D}, H)$ of the form

$$q_{N,M}(x, y) = \sum_{k=1}^{M} \beta_k h_k(x, y) \tag{14}$$

are constructed to approximate $q(x, y)$. In general, the number of basis functions M is assumed to be at least as large as the number of given eigenvalues N. In [4], for example, M was taken to be $N \leq M \leq 2N$, and here we generally use $M = N$. For $q_{N,M}(x, y)$ of the form (14), the resulting spectral data $\boldsymbol{\lambda}(q_{N,M})$ depends on the parameters $\boldsymbol{\beta} = (\beta_1, \ldots, \beta_M)^t$, and we denote it by $\boldsymbol{\lambda}(\boldsymbol{\beta})$. Our approximation $q_{N,M}(x, y)$ is then found by solving for the $\boldsymbol{\beta}$ that minimizes the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2$.

Although any well-behaved basis could be used, our choice for $\{h_k(x, y)\}_{k=1}^{M}$ will be piecewise constant functions: subdividing $\mathcal{D}$ into disjoint subsets $\cup_{k=1}^{M} D_k$, we define the function $h_k(x, y)$ to be 1 on D_k and 0 otherwise. The condition $q_{N,M} \in \mathcal{C}(\mathcal{D}, H)$ is easily implemented by requiring $|\beta_k| \leq H$ for each k. As discussed earlier, other kinds of useful and interesting constraints may be imposed on the coefficients $\boldsymbol{\beta}$. An efficient way to implement such ideas numerically has been given by Hanson and Haskel [8]. The program can solve constrained least squares problems for matrices. Specifically, it solves the following problem:

$$\begin{aligned} &\text{Minimize} \quad \|\boldsymbol{C} - \Gamma\boldsymbol{\beta}\|_2 \quad \text{subject to constraints} \\ &E\boldsymbol{\beta} = \boldsymbol{F} \quad \text{and} \quad G\boldsymbol{\beta} \geq \boldsymbol{K}. \end{aligned} \tag{15}$$

Letting $\mathcal{B}(H)$ denote the set

$$\mathcal{B}(H) = \{\boldsymbol{\beta} \in \boldsymbol{R}^M \mid |\beta_k| \leq H\},$$

we will consider the nonlinear constrained least squares problem

$$\min_{\boldsymbol{\beta} \in \mathcal{B}(H)} \|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2 = \|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta}^*)\|_2. \tag{16}$$

To minimize the norm $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(\boldsymbol{\beta})\|_2$, we approximate the nonlinear problem (16) with a sequence of linear least squares problems. Beginning with an initial guess $\boldsymbol{\beta}_0$, $\boldsymbol{\lambda}(\boldsymbol{\beta})$ in (17) is replaced by its linearization $L_0(\boldsymbol{\beta}) = \boldsymbol{\lambda}(\boldsymbol{\beta}_0) + \Gamma_0(\boldsymbol{\beta} - \boldsymbol{\beta}_0)$ about $\boldsymbol{\beta}_0$. Finding $\boldsymbol{\beta}_1 \in \mathcal{B}(H)$, which minimizes $\|\boldsymbol{\Lambda} - L_0(\boldsymbol{\beta})\|_2$ over the set $\mathcal{B}(H)$, constructs our new approximation. One may then repeat this procedure to produce a sequence of successive approximations by computing the linearization $L_i(\boldsymbol{\beta})$ of $\boldsymbol{\lambda}(\boldsymbol{\beta})$ at $\boldsymbol{\beta}_i$ and by finding a solution $\boldsymbol{\beta}_{i+1} \in \mathcal{B}(H)$ of

$$\min_{\boldsymbol{\beta} \in \mathcal{B}(H)} \|\boldsymbol{\Lambda} - L_i(\boldsymbol{\beta})\|_2 = \|\boldsymbol{\Lambda} - L_i(\boldsymbol{\beta}_{i+1})\|_2. \tag{17}$$

At this point, the least squares method of [8] may be used to implement any additional constraints on $\boldsymbol{\beta}_i$.

Much of the computational cost of the method lies in the construction of $L_i(\boldsymbol{\beta})$. To compute the linearization of the spectral data $\boldsymbol{\lambda}(\boldsymbol{\beta}) = (\lambda_1(\boldsymbol{\beta}), \ldots, \lambda_N(\boldsymbol{\beta}))^t$ at $\boldsymbol{\beta} = \boldsymbol{\beta}_i$, one must compute eigenvalues and eigenfunctions of (1). In our numerical examples, we use the Rayleigh–Ritz method to estimate the eigenvalues $\boldsymbol{\lambda}(\boldsymbol{\beta})$. To compute the linear component Γ of the linearization, note that if $\lambda_k(\boldsymbol{\beta}_i)$ is a simple eigenvalue with L^2-normalized eigenfunction $\phi_k(x, y)$, then a formal calculation [9] of the derivative of $\lambda_k(\boldsymbol{\beta})$ at $\boldsymbol{\beta} = \boldsymbol{\beta}_i$ yields

$$\frac{\partial \lambda_k}{\partial \beta_j}(\boldsymbol{\beta}_i) = \iint_{\mathcal{D}} h_j(x, y) \phi_k^2(x, y) \, \mathrm{d}A = \iint_{\mathcal{D}_j} \phi_k^2(x, y) \, \mathrm{d}A.$$

The linearization $L_i(\boldsymbol{\beta}) = \boldsymbol{\lambda}(\boldsymbol{\beta}_i) + \Gamma_i(\boldsymbol{\beta} - \boldsymbol{\beta}_i)$ is then computed by forming the $N \times M$ matrix Γ_i given by

$$[\Gamma_i]_{jk} = \iint_{\mathcal{D}_j} \phi_k^2(x, y) \, \mathrm{d}A.$$

In our numerical calculations, we chose not to update Γ_i at each step, but rather to take Γ_0 as an approximation to Γ_i and to replace (17) with the minimization problem

$$\min_{\boldsymbol{\beta} \in \mathcal{B}(H)} \|\boldsymbol{\Lambda} - \tilde{L}_i(\boldsymbol{\beta})\|_2 = \|\boldsymbol{\Lambda} - \tilde{L}_i(\boldsymbol{\beta}_{i+1})\|_2, \tag{18}$$

where $\tilde{L}_i(\boldsymbol{\beta}) = \boldsymbol{\lambda}(\boldsymbol{\beta}) + \Gamma_0(\boldsymbol{\beta} - \boldsymbol{\beta}_i)$.

5.2. Recovery of a symmetric potential on a rectangle. Our first example is a generalization of the inverse Sturm–Liouville problem with symmetric potential. Here we consider a rectangular domain $\mathcal{D} = [0, \pi/a] \times [0, \pi]$ with functions $q(x, y)$ defined on $\mathcal{D}$ that are symmetric with respect to the two midlines of the rectangle, i.e.,

$$q(\pi/a - x, y) = q(x, y) = q(x, \pi - y).$$

Our spectral data $\boldsymbol{\Lambda}$ are the first N eigenvalues of (1) with the Dirichlet condition $u = 0$ on $\partial\mathcal{D}$. Such an inverse problem was previously considered in [10], where an algorithm based on the Rayleigh–Ritz method was used to construct approximations to a truncated Fourier series expansion of $q(x, y)$.

A piecewise constant approximation to $q(x, y)$ is constructed by dividing $\mathcal{D}$ into a uniform grid of $4M$ subrectangles. D_k will denote a subset of $\mathcal{D}$ consisting of four of these smaller rectangles symmetrically chosen around the midlines $x = \pi/2a$ and

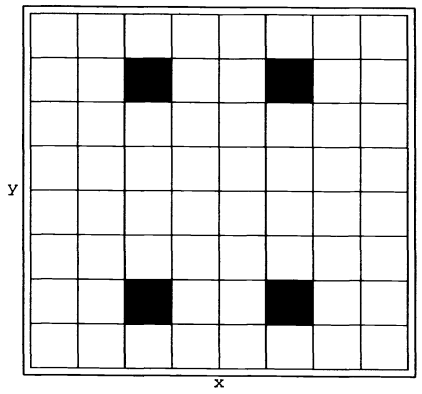

FIG. 1.

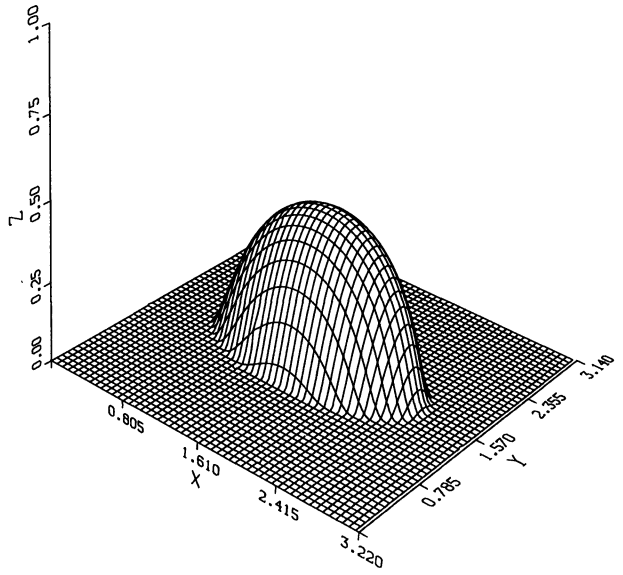

FIG. 2.

$y = \pi/2$ of $\mathcal{D}$ (see Fig. 1). Each of the resulting M step functions $h_k(x, y)$ is then symmetric with respect to the midlines of $\mathcal{D}$.

The rectangle here will be $\mathcal{D} = [0, \pi/\sqrt{0.95}] \times [0, \pi]$. The choice of $a = \sqrt{0.95}$ guarantees that the lowest 50 eigenvalues of $\beta = 0$ are simple, allowing the linearization formula to be used at $\beta_0 = 0$. The function for which we will construct an approximation is as follows:

$$q(x,y) = \begin{cases} \exp(-\frac{1}{d(x,y)}) & \text{if } d(x,y) = (\frac{3\pi}{8})^2 - (x - \frac{\pi}{2\sqrt{0.95}})^2 - 4(y - \frac{\pi}{2}) > 0 \\ 0 & \text{otherwise.} \end{cases}$$

The graph of this function is shown in Fig. 2. Starting with $\beta_0 = 0$ as an initial guess of a solution to the nonlinear problem (17), up to five iterations of the linear least squares problem (18) were solved over the set $\mathcal{B}(1)$ for $N = 9, 16$, and 25. The subrectangles of $\mathcal{D}$ were formed by dividing $\mathcal{D}$ into a uniform grid of $2\sqrt{N} \times 2\sqrt{N}$

TABLE 1

$N = M$	Grid	$\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q_{N,M})\|_2$	$\|q - q_{N,M}\|_{1Max}$
9	6x6	0.0029	0.180
16	8x8	0.0011	0.050
25	10x10	0.0060	0.023

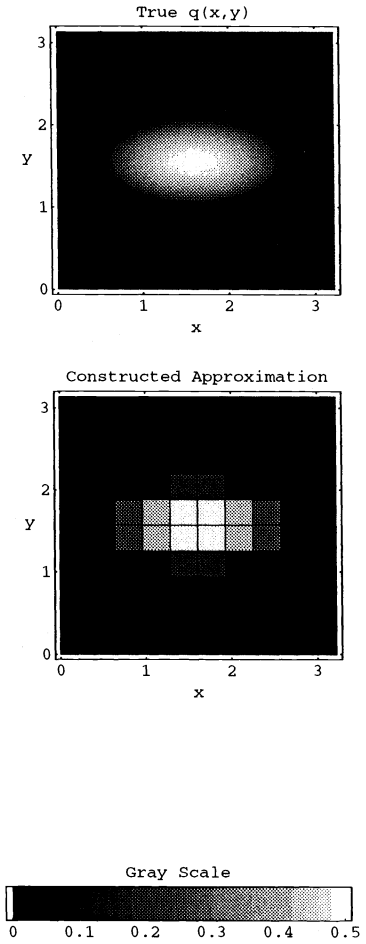

FIG. 3.

for a total of $4M$ rectangles. For each N, the final computed $\boldsymbol{\beta}_i \in \boldsymbol{R}^N$ was used to construct $q_{N,M}$ given by (14). Estimates of the resulting errors $\|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q_{N,M})\|_2$ and $\|q - q_{N,M}\|_{1Max}$ are shown in Table 1.

Fig. 3 displays a density plot representation of the actual $q(x, y)$ along with a density plot of the piecewise constant approximation constructed on a 10×10 grid using $N = 25$ eigenvalues.

5.3. Recovery of a general potential on a rectangle. Our next example illustrates a generalization of the two-spectra inverse problem for the Sturm–Liouville equation. We will continue to consider $q(x, y)$ defined on a rectangular domain $\mathcal{D}$;

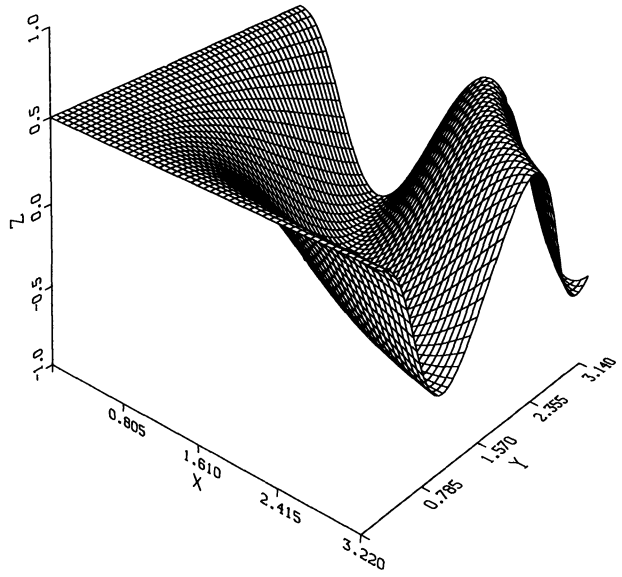

FIG. 4.

however, here $q(x, y)$ is no longer assumed to be symmetric with respect to the midlines of the rectangle. The spectral data $\boldsymbol{\Lambda}$ used to construct an approximation to $q(x, y)$ will consist of eigenvalues from four different sets of boundary conditions. In particular, we use $\boldsymbol{\Lambda} = \cup_{i=1}^{4} \boldsymbol{\Lambda}_i$, where $\boldsymbol{\Lambda}_i$ are eigenvalues resulting from the following boundary conditions:

$$\begin{aligned}
\boldsymbol{\Lambda}_1 &: \quad u(x,0) = u(y,0) = u(x,\pi) = u(\pi/a, y) = 0, \\
\boldsymbol{\Lambda}_2 &: \quad u(x,0) = u(y,0) = u(x,\pi) = u_x(\pi/a, y) = 0, \\
\boldsymbol{\Lambda}_3 &: \quad u(x,0) = u(y,0) = u_y(x,\pi) = u(\pi/a, y) = 0, \\
\boldsymbol{\Lambda}_4 &: \quad u(x,0) = u(y,0) = u_y(x,\pi) = u_x(\pi/a, y) = 0.
\end{aligned}$$

A piecewise constant approximation to $q(x, y)$ is constructed by dividing $\mathcal{D}$ into a uniform grid of M subrectangles D_k. As before, the M basis functions $h_k(x, y)$ are taken to be 1 on D_k and 0 otherwise.

On the rectangle $\mathcal{D} = [0, \pi/\sqrt{0.95}] \times [0, \pi]$, we constructed an approximation to the function

$$q(x, y) = 0.5 \cos(xy).$$

The graph of $q(x, y)$ is shown in Fig. 4. The constructed approximation used $N = 100$ eigenvalues (25 eigenvalues from each boundary condition) and $M = 100$ basis functions (a 10×10 grid of $\mathcal{D}$). Beginning with an initial guess of $\boldsymbol{\beta}_0 = 0$, seven iterations of the linear least squares problem (18) were solved to find $\boldsymbol{\beta}_7 \in \boldsymbol{R}^{100}$. The resulting piecewise constant function $q_{100,100}(x, y)$ was estimated to satisfy

$$\|q - q_{100,100}\|_{1\text{Max}} = 0.033 \quad \|\boldsymbol{\Lambda} - \boldsymbol{\lambda}(q_{100,100})\|_2 = 0.0052.$$

Density plots of $q(x, y)$ and $q_{100,100}(x, y)$ are shown in Fig. 5.

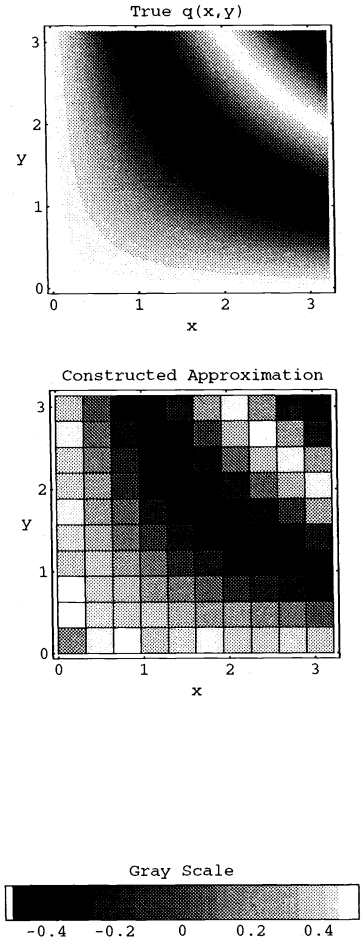

FIG. 5.

5.4. Recovery of a characteristic function. Our final example is a special case of the preceding problems, namely, the reconstruction of a function of the form

$$q(x,y) = \begin{cases} 1 & \text{if } (x,y) \in S, \\ 0 & \text{otherwise,} \end{cases}$$

where S is a subset of $\mathcal{D}$. The algorithm proceeds as in §5.3; however, once $\boldsymbol{\beta}$ has been computed, we then take

$$S_{N,M} = \bigcup_{\beta_k \geq 0.5} D_k$$

as an approximation to S.

Returning to the rectangle $\mathcal{D} = [0, \pi/\sqrt{0.95}] \times [0, \pi]$, we exhibit an approximation to the characteristic function for the region S shown in Fig. 6. This set is comprised of two parts, namely, the lower half of a disk with radius 0.5 centered at the center of $\mathcal{D}$, and a square with side length 0.2 centered at $(3\pi/4\sqrt{0.95}, 3\pi/4)$.

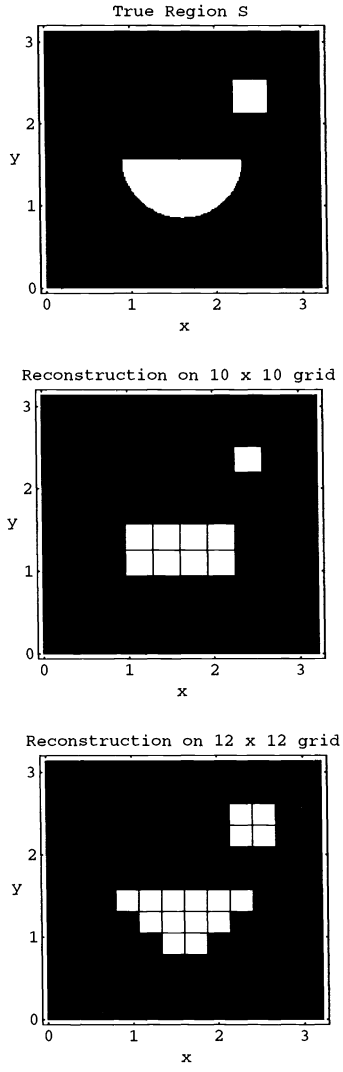

FIG. 6.

Using 100 eigenvalues (25 from each boundary condition), two approximations to S were constructed, one on a 10×10 mesh and a second on a 12×12 mesh. The resulting approximations $S_{100,100}$ and $S_{100,144}$ are shown in Fig. 6.

FREE BOUNDARY PROBLEMS FOR POTENTIAL AND STOKES FLOWS VIA NONSMOOTH ANALYSIS*

SRDJAN STOJANOVIC† AND THOMAS SVOBODNY‡

Abstract. A new approach to some free boundary problems of the type of jets and cavities for potential flows is introduced. Both potential *and* Stokes flows are considered. The variable domain problems are relaxed so that they become nonsmooth optimization problems on fixed domains for somewhat singular state equations. State equations are considered, and multivalued generalized gradients of the variational functionals are studied. The method is constructive.

Key words. free boundary, Stokes problem, nonsmooth analysis

AMS subject classification. 35Q

1. Introduction. Consider the following now-classical variational problem introduced and solved by Alt and Caffarelli [2], and studied extensively by Alt, Caffarelli, and Friedman. (See [3] and [8] and references given there.) (See also [14] for numerical considerations; for the simplicity of presentation we discuss the very particular geometry: $\Omega = (-a, a) \times (0, 2)$.)

Find $w \in H^1(\Omega)$ satisfying the boundary conditions

$$w = 0 \text{ in } \{(x,0); -a < x < a\},\ w = 2 \text{ in } \{(x,2); -a < x < a\} \tag{1.1.1}$$

such that the variational functional

$$\mathbf{J}(w) = \int_\Omega \left[|\nabla w|^2 + g^2 \mathbf{I}_{\{w>0\}}\right] \tag{1.1.2}$$

is minimized. Here $\mathbf{I}_D$ is a characteristic function of the set D, i.e.,

$$\mathbf{I}_D(x) = \begin{cases} 1 & \text{if } x \in D, \\ 0 & \text{if } x \notin D, \end{cases} \tag{1.1.3}$$

and $g \geq 0$ is a given function.

It is well known (see [2]) that, under certain conditions, a minimizer w satisfies

$$\begin{gathered} \Delta w = 0 \text{ in } \Omega \cap \{w > 0\}, \\ |\nabla w| = g,\ w = 0 \text{ in } \Omega \cap \partial\{w > 0\}, \\ w = 0 \text{ in } \{(x,0); -a < x < a\},\ w = 2 \text{ in } \{(x,2); -a < x < a\}, \\ w_x = 0 \text{ in } \{(\pm a, y); 0 < y < 2\}. \end{gathered} \tag{1.1.4}$$

REMARK 1.1.1. *Moreover, if $g_y \leq 0$ then, using monotone rearrangemets (see [11]) one can easily show that that there exists a minimizer w such that $w_y \geq 0$. That implies that there exists a function $u = u(x)$ such that $\Omega \cap \partial\{w > 0\} = \{(x, u(x)); -a < x < a\}$. Furthermore, if $g \in C^{k,\alpha}(\Omega)$ then, by the theorem of Alt and Caffarelli, $u \in C^{k+1,\alpha}$.*

The applications of this problem are mainly in potential fluid mechanics, i.e., in free boundary problems of the type of jets and cavities for potential flows. (See [8] and the references given there.)

Unfortunately, the above variational approach failed, in the case of Stokes and Navier–Stokes equation. The reason is that there is no known analog of the functional (1.1.2).

In this paper we introduce a new approach to this problem. The approach is discussed in the case of potential flow (§2), and in the case of the Stokes flow (§3). Results of the §2 were announced by Stojanovic in [15]. See [4] for a related method.

2. Potential flow.

2.1. Statement of the problem. To further motivate our approach, we observe that the "Euler equation" for the minimizer of the functional (1.1.2) is

$$\begin{aligned} \Delta w &= \xi_{\Omega\cap\partial\{w>0\}} \text{ in } \mathcal{D}'(\Omega), \\ w = 0 \text{ in } \{(x,0); -a < x < a\},\ & w = 2 \text{ in } \{(x,2); -a < x < a\}, \\ w_x &= 0 \text{ in } \{(\pm a, y); 0 < y < 2\}, \end{aligned} \tag{2.1.1}$$

where for any regular surface Γ, the measure ξ_Γ is defined by

$$\xi_\Gamma(\varphi) = \int_\Gamma g\varphi d\sigma. \tag{2.1.2}$$

Of course, (2.1.1) is a very difficult equation since the measure on the right-hand side depends on a solution. On the other hand, if the right-hand side does not depend on a solution, i.e., if the equation is merely

$$\begin{aligned} \Delta w &= \xi_\Gamma \text{ in } \mathcal{D}'(\Omega), \\ w = 0 \text{ in } \{(x,0); -a < x < a\},\ & w = 2 \text{ in } \{(x,2); -a < x < a\}, \\ w_x &= 0 \text{ in } \{(\pm a, y); 0 < y < 2\}, \end{aligned} \tag{2.1.3}$$

for some given (fixed) regular surface Γ, then (2.1.3) is a fairly simple equation. So the idea is to study (2.1.3) and then to look for Γ such that if w is the corresponding solution of (2.1.3), then

$$\Gamma = \Omega \cap \partial\{w > 0\}. \tag{2.1.4}$$

So, consider the set of admissible shapes (see Remark 1.1.1)

$$U = \left\{u \in H_0^3(-1,1); 0 \le u(x) \le 1, -1 < x < 1\right\}. \tag{2.1.5}$$

Denote

$$\Gamma_u = \{(x, u(x)); -1 < x < 1\}, \tag{2.1.6}$$

and extend $u \in U$ as zero outside of $(-1,1)$. Define the domain

$$\Omega_u = \{(x,y);\ |x| < a,\ u(x) < y < 2\}. \tag{2.1.7}$$

Let $w = w^u$, be the solution of

$$\begin{aligned} \Delta w &= 0 \text{ in } \Omega_u, \\ w = 0 \text{ in } \{(x,0); -a < x < -1 \text{ or } 1 < x < a\},\ & w = 0 \text{ in } \Gamma_u, \\ w = 2 \text{ in } \{(x,2); -a < x < a\},\ & w_x = 0 \text{ in } \{(\pm a, y); 0 < y < 1\}. \end{aligned} \tag{2.1.8}$$

We could also take $a = \infty$ in (2.1.8), i.e., consider a flow in an infinite channel. Then the last condition in (2.1.8) is substituted by the requirement that w is bounded.

In the context of potential fluid mechanics, w is a stream function. If a stream function w is known then, of course, the velocity vector field $\mathbf{v}$ can be computed easily as $\mathbf{v} = \langle w_y, -w_x \rangle$.

The problem we propose is the following.

For given $g = g(x, y)$ such that (we will not always have to assume this much)

$$g \in C^{1,1}(\Omega), \tag{2.1.9}$$

$$g = 0 \text{ in } \Omega \cap \{|x| > 1\}, \tag{2.1.10}$$

find (if possible) $u \in U$ such that, if w^u is the corresponding solution of (2.1.8), then also

$$|\mathbf{v}| = |\nabla w^u| = g \text{ in } \Gamma_u. \tag{2.1.11}$$

We note that by the Bernoulli's law

$$P + \frac{1}{2}|\nabla w^u|^2 = \text{const} \tag{2.1.12}$$

throughout the fluid (here P denotes the pressure). Hence, we see that requesting specific velocity profile on the immersed obstacle is equivalent to requesting the specific pressure (and hence, force) profile. In §3 we shall study the exactly analogous problem for the Stokes equation. So the method introduced here, although not as satisfactory as the variational method of Alt and Caffarelli [2], is applicable to more important equations.

2.2. A relaxation of the problem. Suppose that there exists an $u \in U$ such that corresponding w^u solves (2.1.8) and (2.1.11). We shall say then that u is an *exact shape*. Now, extend w^u from Ω_u to Ω as z^u:

$$z^u = \begin{cases} w^u & \text{on } \Omega_u, \\ 0 & \text{on } \Omega \backslash \Omega_u. \end{cases} \tag{2.2.1}$$

Lemma 2.2.1 follows.

LEMMA 2.2.1. *If $u \in U$ is an exact shape, then $z^u \in H^1(\Omega)$, and it is a solution of the following elliptic boundary value problem (with singular right-hand side):*

$$\begin{gathered} \Delta z^u = \xi_u \text{ in } \Omega, \\ z^u = 0 \text{ in } \{(x,0); -a < x < a\},\ z^u = 2 \text{ in } \{(x,2); -a < x < a\}, \\ (z^u)_x = 0 \text{ in } \{(\pm a, y); 0 < y < 1\}, \end{gathered} \tag{2.2.2}$$

where $\xi_u \in H^{-1}(\Omega)$ is a measure given by

$$\xi_u(\varphi) = \int_{\Gamma_u} g\varphi d\sigma. \tag{2.2.3}$$

Proof. The proof is obvious, since by elliptic estimates w^u is regular in Ω_u, $z^u \in C^{0,1}(\bar{\Omega})$ (regarding regularity near corners, see the beginning of the proof of the Theorem 2.3.1), and in particular $z^u \in H^1(\Omega)$.

By the trace theorem,

$$|\xi_u(\varphi)| \le \|g\|_{L^2(\Gamma_u)}\|\varphi\|_{L^2(\Gamma_u)} \le c_u\|g\|_{H^1(\Omega)}\|\varphi\|_{H^1(\Omega)}. \tag{2.2.4}$$

So, in particular, $\xi_u \in H^{-1}(\Omega)$. Also, since $g \ge 0$, ξ_u is a measure.

Now, more explicitly, (2.2.2) can be written as the following: Find $z \in H^1(\Omega)$ such that

$$z^u = 0 \text{ in } \{(x,0); -a < x < a\},\ z^u = 2 \text{ in } \{(x,2); -a < x < a\} \tag{2.2.5}$$

and

$$-\int_\Omega \nabla z^u \cdot \nabla\varphi = \int_{\Gamma_u} g\varphi d\sigma \tag{2.2.6}$$

for all $\varphi \in H^1(\Omega)$ such that

$$\varphi = 0 \text{ in } \{(x,0); -a < x < a\} \cup \{(x,2); -a < x < a\}. \tag{2.2.7}$$

To check (2.2.6), we note that by the maximum principle, a solution of (2.1.8) is positive. Hence (2.1.11) and the boundary condition in (2.1.8) imply that

$$\frac{\partial w^u}{\partial \nu_u} = -g \text{ in } \Gamma_u, \tag{2.2.8}$$

where ν_u is the exterior unit normal to $\partial\Omega_u$. Hence,

$$\begin{aligned} -\int_\Omega \nabla z^u \cdot \nabla\varphi &= -\int_{\Omega_u} \nabla w^u \cdot \nabla\varphi \\ &= \int_{\Omega_u} (\Delta w^u)\varphi - \int_{\partial\Omega_u} \frac{\partial w^u}{\partial \nu_u}\varphi d\sigma = \int_{\Gamma_u} g\varphi d\sigma, \end{aligned} \tag{2.2.9}$$

which completes the proof of the lemma.

LEMMA 2.2.2. *Let z^u be a solution of* (2.2.5)–(2.2.7). *If it happens that $z^u|_{\Gamma_u} = 0$, then $z^u|_{\Omega_u}$ is a solution of* (2.1.8)–(2.1.11), *i.e., u is an exact shape.*

Proof. In the next section we shall prove that z^u is regular enough so that calculations performed here are legitimate. More precisely, by (2.3.6) below, it suffices to assume that $\varphi \in C_0^1(\Omega)$. We have

$$\begin{aligned} \int_{\Gamma_u} g\varphi d\sigma = &-\int_{\Omega_u} \nabla z^u \cdot \nabla\varphi - \int_{\Omega\setminus\Omega_u} \nabla z^u \cdot \nabla\varphi = \int_{\Omega_u} (\Delta z^u)\varphi \\ &+ \int_{\Omega\setminus\Omega_u} (\Delta z^u)\varphi - \int_{\partial\Omega_u} \frac{\partial z^u}{\partial \nu}\varphi d\sigma - \int_{\partial(\Omega\setminus\Omega_u)} \frac{\partial z^u}{\partial \nu}\varphi d\sigma. \end{aligned} \tag{2.2.10}$$

Let ν be exterior to Ω_u, and let

$$z^{u,\text{int}} \stackrel{\text{def}}{=} z^u|_{\Omega\setminus\Omega_u},\ z^{u,\text{ext}} \stackrel{\text{def}}{=} z^u|_{\Omega_u}. \tag{2.2.11}$$

Then (2.2.10) implies that

$$\int_{\Gamma_u} g\varphi d\sigma = \int_{\Gamma_u} \left(\frac{\partial z^{u,\text{int}}}{\partial \nu} - \frac{\partial z^{u,\text{ext}}}{\partial \nu}\right)\varphi d\sigma,\ \forall \varphi \in C_0^1(\Omega). \tag{2.2.12}$$

So,

$$g = \frac{\partial z^{u,\text{int}}}{\partial \nu} - \frac{\partial z^{u,\text{ext}}}{\partial \nu} \text{ on } \Gamma_u. \tag{2.2.13}$$

We observe that (2.2.13) always holds for the solution of (2.2.2).

Now, if $z^u|_{\Gamma_u} = 0$, then $z^u|_{\Omega \setminus \Omega_u} = 0$, so that $(\partial z^{u,\text{int}})/\partial \nu = 0$, and then $g = -(\partial z^{u,\text{ext}})/\partial \nu$ on Γ_u, i.e.,

$$g = |\nabla (z^u|_{\Omega_u})| \text{ on } \Gamma_u, \tag{2.2.14}$$

i.e., (2.1.11) holds.

Lemma 2.2.2 motivates the following.

DEFINITION 2.2.1. *$u^* \in U$ is said to solve the* relaxed free boundary problem *if the corresponding z^u defined by* (2.2.2) *is such that*

$$\Phi(u) = \frac{1}{2} \int_{\Gamma_u} (z^u)^2 d\sigma \tag{2.2.15}$$

is minimized, i.e., $u^* \in U$ is such that

$$\Phi(u^*) = \min_{u \in U} \Phi(u). \tag{2.2.16}$$

Of course, an exact shape is a minimizer, i.e., a solution of (2.2.16). On the other hand, a solution of (2.2.16) is an exact shape, provided an exact shape exists.

We do not consider whether an exact shape exists. Rather, we shall study the relaxed problem introduced in Definition 2.2.1.

2.3. The state equation. It will be convenient to state the regularity theorem for the general boundary value. So let ψ be a given function on Ω such that $z^u = \psi$ on $\partial_0 \Omega \subset \partial \Omega$. We assume that the boundary and ψ are sufficiently regular (see [16] for details; also, we shall give some details in the case of the boundary and boundary values in our case). For any $z \in H^1(\Omega)$, we define $\|z\|_{L^\infty(\partial\Omega)}$ as

$$\|z\|_{L^\infty(\partial\Omega)} \overset{\text{def}}{=} \inf \{m \geq 0; -m \leq z \leq m \text{ on } \partial\Omega \text{ in } H^1(\Omega)\}, \tag{2.3.1}$$

where inequalities in $H^1(\Omega)$ are defined in, e.g., [16]. Also, we define

$$W^{2,q}_{\{y>0\}-loc}(\Omega) \overset{\text{def}}{=} \cap_{\epsilon>0} W^{2,q}(\Omega \cap \{y > \epsilon\}). \tag{2.3.2}$$

We have the next theorem.

THEOREM 2.3.1. *For any $u \in U$ the state equation* (2.2.2) *has a unique weak solution. Let q be such that $2 \leq q < \infty$. If $g \in W^{1,q}(\Omega)$, then*

$$z^u \in W^{1,q}(\Omega) \cap C^\infty(\bar{\Omega} \setminus \Gamma_u), \tag{2.3.3}$$

and the a priori estimate

$$\|z^u\|_{W^{1,q}(\Omega)} \leq c\left(1 + \|u\|_{C^{0,1}(-1,1)}\right)\left(\|g\|_{W^{1,q}(\Omega)} + \|\psi\|_{W^{1,q}(\Omega)}\right). \tag{2.3.4}$$

holds. If in addition $q > 2$, then

$$\|z^u\|_{L^\infty(\Omega)} \leq c\left(1 + \|u\|_{C^{0,1}(-1,1)}\right)\left(\|g\|_{W^{1,q}(\Omega)} + \|\psi\|_{L^\infty(\partial\Omega)}\right). \tag{2.3.5}$$

Moreover, if $g \in W^{2,q}(\Omega)$, *and* (2.1.10) *holds, then* (*see* (2.2.11))

$$z^{u,\mathrm{ext}} \in W^{2,q}(\Omega_u),\ z^{u,\mathrm{int}} \in W^{2,q}_{\{y>0\}-\mathrm{loc}}(\Omega \setminus \bar{\Omega}_u) \tag{2.3.6}$$

and the a priori estimates

$$\|z^{u,\mathrm{ext}}\|_{W^{2,q}(\Omega_u)} \le c\left(\|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right) \tag{2.3.7}$$

and

$$\begin{aligned} &\|z^{u,\mathrm{int}}\|_{W^{2,q}((\Omega\setminus\Omega_u)\cap\{y>\epsilon\})} \\ &\le c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right) \end{aligned} \tag{2.3.8}$$

hold.

Proof. Since $\xi_u \in H^{-1}(\Omega)$ existence and uniqueness of a weak solution z^u of (2.2.2) is trivial. Also, since z^u is harmonic in $\Omega\setminus\Gamma_u$, it follows that $z^u \in C^\infty(\bar{\Omega}\setminus\Gamma_u)$. Few words are needed here because of the presence of corners in Ω. To prove regularity of z^u in the neighborhood of corners, say, in the neighborhood of $(-a,0)$, one can extend z^u in $\{x<-a, 0<y<2\}$ as $\widetilde{z^u}$ by the formula

$$\widetilde{z^u}(x,y) \overset{\mathrm{def}}{=} \begin{cases} z^u(-2a-x,y) & \text{if } x<-a, \\ z^u(x,y) & \text{if } x \ge -a. \end{cases} \tag{2.3.9}$$

Then since $\widetilde{z^u}$ is continuous on $\{x=-a\}$ and $\widetilde{z^u}_x = 0$ on $\{x=-a\}$, it is elementary to show that $\widetilde{z^u}$ is harmonic across $\{x=-a\}$. Indeed, let $B_\rho(A) = B_1 \cup (B_\rho(A)\cap\{x=-a\}) \cup B_2 \subset \{0<y<2\}$ be a ball centered at $A \in \{x=-a\}$ with radius ρ. Here, $B_1 = B_\rho(A)\cap\{x>-a\}$ and $B_2 = B_\rho(A)\cap\{x<-a\}$. Then,

$$\begin{aligned} \int_{B_\rho(A)} \widetilde{z^u}\Delta\varphi &= \int_{B_1} \widetilde{z^u}\Delta\varphi + \int_{B_2} \widetilde{z^u}\Delta\varphi \\ &= \int_{\{x=-a\}\cap B_\rho(A)} \left[-\varphi_x \widetilde{z^u} + \varphi \widetilde{z^u}_x + \varphi_x \widetilde{z^u} - \varphi \widetilde{z^u}_x\right] dy = 0 \end{aligned} \tag{2.3.10}$$

for all $\varphi \in C_0^\infty(B_\rho(A))$, so that $\widetilde{z^u}$ is harmonic across $\{x=-a\}$ as claimed. Henceforth $\widetilde{z^u}$ is as regular in the neighborhood of $(-a,0)$ as the (extended) boundary data is. In our case the boundary data is $\psi = 0$, so that (2.3.3) follows.

Set $\varphi = \psi - z^u$ in (2.2.6). It easily follows that

$$\begin{aligned} \int_\Omega |\nabla z^u|^2 &= \int_{\Gamma_u} g(\psi - z^u)d\sigma - \int_\Omega \nabla z^u \cdot \nabla\psi \\ &\le \left(\int_{\Gamma_u} g^2 d\sigma\right)^{\frac{1}{2}} \left[\left(\int_{\Gamma_u} \psi^2 d\sigma\right)^{\frac{1}{2}} + \left(\int_{\Gamma_u} (z^u)^2 d\sigma\right)^{\frac{1}{2}}\right] \\ &\qquad + \left|\int_\Omega \nabla z^u \cdot \nabla\psi\right|. \end{aligned} \tag{2.3.11}$$

Now since $z^u = (z^u - \psi) + \psi$, using Poincaré inequality, we have

$$\begin{aligned} \|z^u\|_{H^1(\Omega)} &\le c\left(\|\nabla(z^u-\psi)\|_{L^2(\Omega)} + \|\psi\|_{H^1(\Omega)}\right) \\ &\le c\left(\|\nabla z^u\|_{L^2(\Omega)} + \|\psi\|_{H^1(\Omega)}\right). \end{aligned} \tag{2.3.12}$$

Combining (2.3.11) and (2.3.12), we get

$$\|z^u\|^2_{H^1(\Omega)} \le c\left(1+\|u\|_{C^{0,1}(-1,1)}\right)\left[\|g\|_{H^1(\Omega)}\left(\|\psi\|_{H^1(\Omega)}+\|z^u\|_{H^1(\Omega)}\right)\right]$$
$$+c\|z^u\|_{H^1(\Omega)}\|\psi\|_{H^1(\Omega)}+c\|\psi\|^2_{H^1(\Omega)}. \tag{2.3.13}$$

In (2.3.13) the inequality follows from the proof of the trace theorem (see, e.g., [12] or [7]). Indeed, one can see ([7], p. 132) that for $1 \le q < \infty$, one has

$$\|z^u\|^q_{L^q(\Gamma_u)} \le c\left(1+\|u\|^2_{C^{0,1}(-1,1)}\right)^{\frac{1}{2}}\|z^u\|^q_{W^{1,q}(\Omega)}, \tag{2.3.14}$$

which implies

$$\|z^u\|_{L^q(\Gamma_u)} \le c\left(1+\|u\|_{C^{0,1}(-1,1)}\right)^{\frac{1}{q}}\|z^u\|_{W^{1,q}(\Omega)}. \tag{2.3.15}$$

From (2.3.13) we easily conclude that (2.3.4) holds for $q=2$.

Proceeding, we assume $\frac{1}{q}+\frac{1}{q'}=1$ and

$$\begin{aligned}|\xi_u(\varphi)| &\le \|g\|_{L^q(\Gamma_u)}\|\varphi\|_{L^{q'}(\Gamma_u)}\\ &\le c\left(1+\|u\|_{C^{0,1}(-1,1)}\right)^{\frac{1}{q}}\|g\|_{W^{1,q}(\Omega)}\left(1+\|u\|_{C^{0,1}(-1,1)}\right)^{\frac{1}{q'}}\|\varphi\|_{W^{1,q'}(\Omega)}\\ &= c\left(1+\|u\|_{C^{0,1}(-1,1)}\right)\|g\|_{W^{1,q}(\Omega)}\|\varphi\|_{W^{1,q'}(\Omega)}. \end{aligned}\tag{2.3.16}$$

So, $\xi_u \in (W^{1,q'}(\Omega))^*$ (here X^* represents the dual space of the space X) and

$$\|\xi_u\|_{(W^{1,q'}(\Omega))^*} \le c\left(1+\|u\|_{C^{0,1}(-1,1)}\right)\|g\|_{W^{1,q}(\Omega)}. \tag{2.3.17}$$

We know (see, e.g., [1]) that ξ has a representation $\xi(\varphi)=\int_\Omega [f_0\varphi+f_1\varphi_x+f_2\varphi_y]$, for some $f_i \in L^q(\Omega), i=0,1,2$, and

$$\|\xi_u\|_{(W^{1,q'}(\Omega))^*} = \sum_{i=0}^{2}\|f_i\|_{L^q(\Omega)}. \tag{2.3.18}$$

Now from elliptic regularity (see [16], p. 179), we have

$$\|z^u\|_{W^{1,q}(\Omega)} \le c\left(\sum_{i=0}^{2}\|f_i\|_{L^q(\Omega)}+\|\psi\|_{W^{1,q}(\Omega)}+\|z^u\|_{H^1(\Omega)}\right). \tag{2.3.19}$$

From (2.3.17)–(2.3.19) and since (2.3.4) is already proved in the case $q=2$, we conclude that (2.3.4) holds.

To prove (2.3.5), we recall (see, e.g., [16], p. 103) that if $q>2$ and if $z^u \le 0$ on $\partial_0\Omega$ in the sense of $H^1(\Omega)$, then

$$\operatorname*{ess\,sup}_{\Omega} z^u \le c\left(\sum_{i=0}^{2}\|f_i\|_{L^q(\Omega)}+\|z^u\|_{L^2(\Omega)}\right). \tag{2.3.20}$$

Hence,

$$\begin{aligned}&\operatorname*{ess\,sup}_{\Omega}\left(z^u-\|z^u\|_{L^\infty(\partial\Omega)}\right)\\ &\le c\left(\sum_{i=0}^{2}\|f_i\|_{L^q(\Omega)}+\|z^u\|_{L^2(\Omega)}+\|z^u\|_{L^\infty(\partial\Omega)}\right),\end{aligned}\tag{2.3.21}$$

and similarly for $-z^u + \|z^u\|_{L^\infty(\partial\Omega)}$. This easily implies (2.3.5).

Now, we shall consider further regularity of $z^u|_{\Omega_u}$ and $z^u|_{\Omega\setminus\Omega_u}$. Since the singular set is on Γ_u, we expect higher regularity in the tangential direction. To prove that this is the case we flatten the Γ_u first, since then it is easier to differentiate.

Define v, $\tilde{g}$, and $\tilde{\varphi}$ by $v(x,y) = z^u(x, y+u(x))$, $\tilde{g}(x,y) = g(x, y+u(x))\sqrt{1+u'^2(x)}$, $\tilde{\varphi}(x,y) = \varphi(x, y+u(x))$ and operator L by $Lv = \Delta v + v_{yy}(u_x)^2 - 2v_{xy}u_x - v_y u_{xx}$. Of course, L is uniformly elliptic, since the matrix

$$[l_{ij}] = \begin{bmatrix} 1 & -u_x \\ -u_x & 1+u_x^2 \end{bmatrix} \tag{2.3.22}$$

is positive definite. Indeed, $l_{ij}\xi_i\xi_j = (\xi_1 - u_x\xi_2)^2 + \xi_2^2$. So, if c is such that $|u_x| \le c$, then if $|\xi_2| < \frac{1}{2c}|\xi_1|$ then $(\xi_1 - u_x\xi_2)^2 > \frac{1}{4}\xi_1^2$. On the other hand, if $|\xi_2| \ge \frac{1}{2c}|\xi_1|$ then $\xi_2^2 \ge \frac{1}{4c^2}\xi_1^2$. So, it is easy to see that if we take $\alpha = \min\left(\frac{1}{4}, \frac{1}{8c^2}\right)$ then $l_{ij}\xi_i\xi_j \ge \alpha|\xi|^2$.

Also let Ξ_u be the map with the image Ω given by the formula

$$\Xi_u(x,y) = (x, y+u(x)). \tag{2.3.23}$$

Then, $\Delta z^u \circ \Xi_u = Lv$, and since $|\det D\Xi_u| = 1$ (here $D\Xi_u$ is the gradient matrix of the map Ξ_u so that $|\det D\Xi_u|$ is the Jacobian)

$$(Lv)(\tilde{\varphi}) = (\Delta z^u)(\varphi). \tag{2.3.24}$$

Hence

$$\begin{aligned} (Lv)(\tilde{\varphi}) &= \int_{\Gamma_u} g\varphi d\sigma = \int g(x,u(x))\varphi(x,u(x))\sqrt{1+u'^2(x)}dx \\ &= \int_{\{y=0\}} \tilde{g}\tilde{\varphi}dx \stackrel{\text{def}}{=} \tilde{\xi}(\tilde{\varphi}). \end{aligned} \tag{2.3.25}$$

So

$$Lv = \tilde{\xi} \tag{2.3.26}$$

in the sense of distributions. Since the singular set is now on $\{y=0\}$, we expect higher regularity in x direction. To prove that, we want to differentiate (or more precisely, difference) equation (2.3.26) with respect to x. Somewhat more precisely, define the standard difference operator (in the x direction) δ_h^1 as

$$\left(\delta_h^1 u\right)(x) = \frac{1}{h}\left(u(x+h,y) - u(x,y)\right), \; h \neq 0. \tag{2.3.27}$$

Then from (2.3.26) we get

$$(Lv)\left(\delta_{-h}^1\tilde{\varphi}\right) = \tilde{\xi}\left(\delta_{-h}^1\tilde{\varphi}\right). \tag{2.3.28}$$

We shall discuss in some details only the right-hand side. We have

$$\begin{aligned} \tilde{\xi}\left(\delta_{-h}^1\tilde{\varphi}\right) &= \int_{\{y=0\}} \tilde{g}\delta_{-h}^1\tilde{\varphi}dx \\ &= -\int_{\{y=0\}} \left(\delta_h^1\tilde{g}\right)\tilde{\varphi}dx \longrightarrow -\int_{\{y=0\}} \tilde{g}_x\tilde{\varphi}dx, \end{aligned} \tag{2.3.29}$$

as $h \to 0$. We conclude that $(Lv)_x(\tilde{\varphi}) = \tilde{\xi}_x(\tilde{\varphi})$, and hence

$$L_1 v_x = \tilde{\xi}_x - v_{yy} 2u_x u_{xx} + v_y u_{xxx}, \tag{2.3.30}$$

where $L_1 w = \Delta w + (u_x)^2 w_{yy} - 2u_x w_{xy} - 3u_{xx} w_y$, and where $\tilde{\xi}_x(\tilde{\varphi}) \stackrel{\text{def}}{=} \int_{\{y=0\}} \tilde{g}_x \tilde{\varphi} dx$. We observe that the differencing performed above is legitimate, since

$$\tilde{\xi}_x - v_{yy} 2u_x u_{xx} + v_y u_{xxx} \in \left(W^{1,q'}\right)^*. \tag{2.3.31}$$

Indeed, $g \in W^{2,q}(\Omega)$; also, observe that $u_{xxx} \in L^2$ and that $L^2 \hookrightarrow \left(W^{1,q'}\right)^*$. Also, since L_1 has the same principal part as L, L_1 is uniformly elliptic as well.

Now we can conclude from (2.3.30)–(2.3.31) that $v_x \in W^{1,q}$. This implies, by the trace theorem, that $v_x|_{\{y=0\}} \in W^{1-\frac{1}{q},q}$, so that

$$v|_{\{y=0\}} \in W^{2-\frac{1}{q},q}. \tag{2.3.32}$$

We observe that because of (2.1.5) and (2.1.10), the preceding analysis is true also in the $\{y > 0\}$ neighborhood of (the preimage of) $(\pm 1, 0)$, so that (2.3.32) holds up to the initial and terminal points of (the preimage of) Γ_u. Elliptic regularity then yields $v|_{\{y \geq 0\}} \in W^{2,q}$.

Unfortunately, we cannot claim the same global result for $v|_{\{y \leq 0\}}$ because of the nonsmoothness of $\partial(\Omega \setminus \Omega_u)$, i.e., we have to localize in $\{y < 0\}$. This concludes the proof of (2.3.6). Now, regarding estimates (2.3.7) and (2.3.8), we have

$$\begin{aligned} \|z^{u,\text{ext}}\|_{W^{2,q}(\Omega_u)} &\leq c\left(\|u\|_{H^3(-1,1)}\right) \|v|_{\{y \geq 0\}}\|_{W^{2,q}\left(\Xi_u^{-1}(\Omega_u)\right)} \\ &\leq c\left(\|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right), \end{aligned} \tag{2.3.33}$$

and similarly (after localization in $\{y < 0\}$) for $z^{u,\text{int}}$, which completes the proof of the theorem.

COROLLARY 2.3.1. *If $g \in W^{2,q}(\Omega)$ for some $q > 2$, and if* (2.1.10) *holds, then $z^u \in C^{0,1}_{\{y>0\}-\text{loc}}(\bar{\Omega})$ and the following a priori estimate holds:*

$$\|z^u\|_{C^{0,1}(\bar{\Omega} \cap \{y \geq \epsilon\})} \leq c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right), \tag{2.3.34}$$

for any $\epsilon > 0$.

Proof. From (2.3.7) and (2.3.8) and by the imbedding theorem (see, e.g., [9]), we have

$$\begin{aligned} &\|z^{u,\text{ext}}\|_{C^1(\bar{\Omega}_u)} + \|z^{u,\text{int}}\|_{C^1(\overline{\Omega \setminus \Omega_u} \cap \{y \geq 0\})} \\ &\quad \leq c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right). \end{aligned} \tag{2.3.35}$$

This implies (2.3.34).

COROLLARY 2.3.2. *If $g \in W^{2,q}(\Omega)$ for some $q > 2$, and if* (2.1.10) *holds, then*

$$z_y^{u,\text{int}} \in C^{0,1-\frac{2}{q}}\left(\overline{\Gamma_u}\right), \tag{2.3.36}$$

and the following a priori estimate

$$\|z_y^{u,\text{int}}\|_{C^{0,1-\frac{2}{q}}\left(\overline{\Gamma_u}\right)} \leq c\left(\|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right) \tag{2.3.37}$$

holds.

The interest in this corollary is due to the lack of $(\Omega \setminus \Omega_u)$-global regularity of z^u.

Proof. Let τ and ν be unit tangent and unit normal to Γ_u. More precisely, set $\tau = 1/(\sqrt{1+u'^2})\,\langle 1, u'\rangle$, and $\nu = 1/(\sqrt{1+u'^2})\,\langle u', -1\rangle$. It is elementary to compute that then $z_y^{u,\text{int}} = u'/(\sqrt{1+u'^2}) z_\tau^{u,\text{int}} - 1/(\sqrt{1+u'^2}) z_\nu^{u,\text{int}}$. Since, by Theorem 2.3.1, $z_\tau^{u,\text{int}} = z_\tau^{u,\text{ext}}$ and (also, by Lemma 2.2.2) $z_\nu^{u,\text{int}} = g + z_\nu^{u,\text{ext}}$ on Γ_u, we have

$$z_y^{u,\text{int}}\big|_{\Gamma_u} = \left(\frac{u'}{\sqrt{1+u'^2}} z_\tau^{u,\text{ext}} - \frac{1}{\sqrt{1+u'^2}} \left[g + z_\nu^{u,\text{ext}} \right] \right) \Big|_{\Gamma_u} . \tag{2.3.38}$$

The corollary follows due to the Ω_u-*global* regularity of $z^{u,\text{ext}}$, and by the imbedding theorem. Indeed,

$$\begin{aligned} \|z_y^{u,\text{int}}\|_{C^{0,1-\frac{2}{q}}(\overline{\Gamma_u})} &= \left\| \frac{u'}{\sqrt{1+u'^2}} z_\tau^{u,\text{ext}} - \frac{1}{\sqrt{1+u'^2}} \left[g + z_\nu^{u,\text{ext}} \right] \right\|_{C^{0,1-\frac{2}{q}}(\overline{\Gamma_u})} \\ &\le c\|u\|_{H^3(-1,1)} \left[\|z^{u,\text{ext}}\|_{C^{1,1-\frac{2}{q}}(\overline{\Gamma_u})} + \|g\|_{C^{0,1-\frac{2}{q}}(\overline{\Gamma_u})} \right] \\ &\le c\|u\|_{H^3(-1,1)} \left[\|z^{u,\text{ext}}\|_{W^{2,q}(\Omega_u)} + \|g\|_{W^{1,q}(\Omega_u)} \right] \\ &\le c\left(\|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)} \right). \end{aligned} \tag{2.3.39}$$

We finish this section with the consideration of existence of a minimizer. Now, in order to claim existence of a minimizer, i.e., existence of a solution of the relaxed problem, one needs compactness. One way of introducing compactness would be to bound the set of admissible shapes to

$$U_b = \{u \in U; \|u\|_{H^3(-1,1)} \le b\}, \tag{2.3.40}$$

where b is some prescribed (large) positive constant.

PROPOSITION 2.3.1. *Let $g \in W^{1,q}(\Omega)$, for some $q > 2$. Then, there exists an $u^* \in U_b$ such that*

$$\Phi(u^*) = \min_{u \in U_b} \Phi(u). \tag{2.3.41}$$

Proof. Let $(u_n)_{n=1,2,\ldots} \subset U_b$ be a minimizing sequence. By Theorem 2.3.1 we know that

$$\|z^{u_n}\|_{H^1(\Omega)} + \|z^{u_n}\|_{C^{1-\frac{2}{q}}(\bar{\Omega})} \le c. \tag{2.3.42}$$

By taking subsequences, if necessary, we can assume without loss of generality that there exist $u^* \in U_b$ and $z^* \in H^1(\Omega)$ such that

$$u^n \to u^* \text{ in } H^2(-1,1), \tag{2.3.43}$$

$$z^{u_n} \rightharpoonup z^* \text{ weakly in } H^1(\Omega),\ z^{u_n} \to z^* \text{ in } C^0(\bar{\Omega}). \tag{2.3.44}$$

Recall that

$$-\int_\Omega \nabla z^{u_n} \cdot \nabla \varphi = \int_{\Gamma_{u_n}} g\varphi d\sigma \tag{2.3.45}$$

for all $\varphi \in H^1(\Omega)$ such that $\varphi|_{\{y=0\}} = \varphi|_{\{y=2\}} = 0$. If, in addition, $\varphi \in C^1(\bar{\Omega})$ then it is easy to see that

$$\lim_{n\to\infty} \int_{\Gamma_{u_n}} g\varphi d\sigma = \int_{\Gamma_{u^*}} g\varphi d\sigma. \tag{2.3.46}$$

Hence, for such φ we can pass $n \to \infty$ in (2.3.45) to conclude

$$-\int_{\Omega} \nabla z^* \cdot \nabla \varphi = \int_{\Gamma_{u^*}} g\varphi d\sigma \tag{2.3.47}$$

for any $\varphi \in C^1(\bar{\Omega})$ such that $\varphi|_{\{y=0\}} = \varphi|_{\{y=2\}} = 0$. But then, by the density, (2.3.47) holds for all $\varphi \in H^1(\Omega)$ such that $\varphi|_{\{y=0\}} = \varphi|_{\{y=2\}} = 0$. We conclude, by uniqueness, that $z^* = z^{u^*}$. Now since $\Phi(u_n) = \frac{1}{2}\int_{\Gamma_{u_n}} (z^{u_n})^2 d\sigma$, (2.3.43) and (2.3.44) imply that $\lim_{n\to\infty} \Phi(u_n) = \Phi(u^*)$, which completes the proof of the proposition.

2.4. Differentiability properties of the variational functional Φ. Since our problem is to minimize functional Φ, we want to derive information about the *multivalued* generalized gradient of Φ (see also Remark 2.4.1).

To make our results more precise, we shall introduce several definitions.

Let Φ be a real-valued function on the subset U of the Banach space X.

DEFINITION 2.4.1. *Φ is said to be* directionally differentiable *at $u \in U$ if the limit*

$$\lim_{\lambda \downarrow 0} \frac{\Phi(u+\lambda v) - \Phi(u)}{\lambda} \tag{2.4.1}$$

exists for any $v \in X$ such that $u + \lambda v \in U$, for small enough $\lambda > 0$. If that is the case, then the limit in (2.4.1) *is called* directional derivative *and it is denoted by $\Phi'(u; v)$.*

DEFINITION 2.4.2. *Φ is said to be* subdifferentiable *at u, if there exists an $f \in X^*$ such that*

$$\Phi'(u; v) \geq f(v) \tag{2.4.2}$$

for every $v \in X$ such that $u + \lambda v \in U$, for small enough $\lambda > 0$. Set of all such f's is called subdifferential, *and it is denoted by $\partial_* \Phi(u)$.*

DEFINITION 2.4.3. *Φ is said to be* superdifferentiable *at u, if there exists an $f \in X^*$ such that*

$$\Phi'(u; v) \leq f(v) \tag{2.4.3}$$

for every $v \in X$ such that $u + \lambda v \in U$, for small enough $\lambda > 0$. Set of all such f's is called superdifferential, *and it is denoted by $\partial^* \Phi(u)$.* If Φ is both sub- and superdifferentiable at $u \in \text{int}(U)$, and moreover $\partial_* \Phi(u) \cap \partial^* \Phi(u) \neq \emptyset$, then $\partial_* \Phi(u) \cap \partial^* \Phi(u)$ is a singleton and Φ is Gâteaux differentiable.

We go back now to our problem. Of course, $X = H_0^3(-1, 1)$, U is defined in (2.1.5).

Proceeding, define the adjoint variable p^u, as a solution of the (adjoint) equation

$$\begin{aligned} \Delta p^u &= \eta_u \text{ in } \Omega, \\ p^u &= 0 \text{ in } \{(x,0); -a < x < a\} \cup \{(x,2); -a < x < a\}, \\ p_x^u &= 0 \text{ in } \{(\pm a, y); 0 < y < 2\}, \end{aligned} \tag{2.4.4}$$

where $\eta_u \in H^{-1}(\Omega)$ is a (signed) measure given by

$$\eta_u(\varphi) = \int_{\Gamma_u} z^u \varphi d\sigma. \tag{2.4.5}$$

Obviously, (2.4.4) is the same type of equation as (2.2.2).

In this section, as before, $z^{u,\text{ext}} = z^u|_{\Omega_u}$ and $z^{u,\text{int}} = z^u|_{\Omega\setminus\Omega_u}$; also, later we shall use the notation $p^{u,\text{ext}} = p^u|_{\Omega_u}$ and $p^{u,\text{int}} = p^u|_{\Omega\setminus\Omega_u}$. That is essential in this calculation, since z^u and p^u are *not* differentiable *across* the Γ_u.

LEMMA 2.4.1. *Let $g \in W^{2,q}(\Omega)$, for some $q \geq 2$. Then*

$$p^{u,\text{ext}} \in W^{2,q}(\Omega_u),\ p^{u,\text{int}} \in W^{2,q}_{\{y>0\}-loc}(\Omega\setminus\bar{\Omega}_u) \tag{2.4.6}$$

and the a priori estimates

$$\|p^{u,\text{ext}}\|_{W^{2,q}(\Omega_u)} \leq c\left(\|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right), \tag{2.4.7}$$

and

$$\begin{aligned}&\|p^{u,\text{int}}\|_{W^{2,q}((\Omega\setminus\Omega_u)\cap\{y\geq\epsilon\})}\\ &\quad\leq c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right)\end{aligned} \tag{2.4.8}$$

hold.

Proof. Comparing (2.2.2) and (2.4.4) we see that the only difference is in right-hand sides. Namely, in (2.4.5), $z^u \notin W^{2,q}(\Omega)$. Nevertheless, for example, $z^{u,\text{ext}} \in W^{2,q}(\Omega_u)$, and since η_u depends on z^u only through the trace on Γ_u, and since z^u and $z^{u,\text{ext}}$ have same traces on Γ_u we easily conclude the proof of the lemma.

We shall use the usual notation: $v^+ \stackrel{\text{def}}{=} v\mathbf{I}_{\{v>0\}}$, and $v^- \stackrel{\text{def}}{=} -v\mathbf{I}_{\{v<0\}}$. So, $v = v^+ - v^-$.

Now we are ready to state the following.

THEOREM 2.4.1. *Let $g \in W^{2,q}(\Omega)$, for some $q > 2$. Then Φ is directionally differentiable at any $u \in U$ such that $u(x) > 0$ for $-1 < x < 1$, and*

$$\begin{aligned}&\Phi'(u;v)\\ &= \int_{-1}^{1}\left(z^u(z_y^{u,\text{ext}}v^+ - z_y^{u,\text{int}}v^-)\sqrt{1+u'^2} + \frac{1}{2}(z^u)^2\frac{u'v'}{\sqrt{1+u'^2}}\right)dx\\ &\quad + \int_{\Gamma_u}\left((gp^{u,\text{ext}})_y v^+ - (gp^{u,\text{int}})_y v^-\right)d\sigma + \int_{-1}^{1} gp^u\frac{u'v'}{\sqrt{1+u'^2}}dx.\end{aligned} \tag{2.4.9}$$

Moreover, if

$$z^u z_y^{u,\text{int}} + (gp^{u,\text{int}})_y \leq z^u z_y^{u,\text{ext}} + (gp^{u,\text{ext}})_y \ \ a.e.\ in\ (-1,1), \tag{2.4.10}$$

then Φ is subdifferentiable at u and

$$\begin{aligned}&\partial_*\Phi(u)\\ &= \left[\left(z^u z_y^{u,\text{int}} + (gp^{u,\text{int}})_y\right)\sqrt{1+u'^2}, \left(z^u z_y^{u,\text{ext}} + (gp^{u,\text{ext}})_y\right)\sqrt{1+u'^2}\right]\\ &\quad - \left(\frac{u'}{\sqrt{1+u'^2}}\left(\frac{1}{2}(z^u)^2 + gp^u\right)\right)'\\ &\stackrel{\text{def}}{=} [l\partial_*\Phi(u), r\partial_*\Phi(u)] \subset L^\infty(-1,1).\end{aligned} \tag{2.4.11}$$

On the other hand, if

$$z^u z_y^{u,\text{int}} + (gp^{u,\text{int}})_y \geq z^u z_y^{u,\text{ext}} + (gp^{u,\text{ext}})_y \ \ a.e.\ in\ (-1,1), \tag{2.4.12}$$

then Φ is superdifferentiable at u and

$$\begin{aligned}\partial^*\Phi(u) &= \left[\left(z^u z_y^{u,\mathrm{ext}} + (gp^{u,\mathrm{ext}})_y\right)\sqrt{1+u'^2}, \left(z^u z_y^{u,\mathrm{int}} + (gp^{u,\mathrm{int}})_y\right)\sqrt{1+u'^2}\right] \\ &\quad - \left(\frac{u'}{\sqrt{1+u'^2}}\left(\frac{1}{2}(z^u)^2 + gp^u\right)\right)' \\ &\stackrel{\mathrm{def}}{=} [l\partial^*\Phi(u), r\partial^*\Phi(u)] \subset L^\infty(-1,1). \end{aligned} \tag{2.4.13}$$

Proof. We attempt to differentiate Φ. To this end, for given $u \in U$ and a suitable direction $v \in H_0^3(-1,1)$ (suitable in a sense that $u + \lambda v \in U$ for small enough $\lambda > 0$) we try to compute the (one-sided) directional derivative $\Phi'(u;v)$. Using the regularity result (Theorem 2.3.1, and Corollary 2.3.2), we compute

$$\begin{aligned}\Phi'(u;v) &= \lim_{\lambda \downarrow 0} \frac{\Phi(u+\lambda v) - \Phi(u)}{\lambda} \\ &= \lim_{\lambda\downarrow 0} \frac{1}{2\lambda}\left(\int_{\Gamma_{u+\lambda v}} (z^{u+\lambda v})^2 d\sigma - \int_{\Gamma_u} (z^u)^2 d\sigma\right) \\ &= \int_{-1}^{1}\left(z^u(z_y^{u,\mathrm{ext}} v^+ - z_y^{u,\mathrm{int}} v^-)\sqrt{1+u'^2} + \frac{1}{2}(z^u)^2 \frac{u'v'}{\sqrt{1+u'^2}}\right) dx \\ &\quad + \lim_{\lambda\downarrow 0} \frac{1}{2\lambda}\int_{\Gamma_u}\left((z^{u+\lambda v})^2 - (z^u)^2\right) d\sigma, \end{aligned} \tag{2.4.14}$$

Before proceeding with the proof, we shall need the following lemma (more precisely, its corollary).

LEMMA 2.4.2. *Under previous assumptions on u, and v, and for any $\alpha < 1$ the following estimate holds*:

$$\|z^{u+\lambda v} - z^u\|_{C^0(\bar{\Omega})} \le c\lambda^\alpha. \tag{2.4.15}$$

Proof. We need to compare $z^{u+\lambda v}$ and z^u. This is difficult to do in the original domain Ω since the (singular) right-hand sides of the equations that they satisfy act on disjoint sets, so that there is no obvious cancellation. So, the idea of the proof is to map the original domain into different domains in such a way that the cancellation takes place.

As before, let Ξ_u be the map with the image Ω given by the formula $\Xi_u(x,y) = (x, y + u(x))$. Then $\Xi_u^{-1}(x,y) = (x, y - u(x))$, and (set $A = (x,y)$) $\mathrm{dist}(\Xi_{u+\lambda v}^{-1}(A) - \Xi_u^{-1}(A)) \le c\lambda$. Now consider $\tilde{z}^{u+\lambda v}$ and $\tilde{z}^u$ defined as

$$\tilde{z}^{u+\lambda v} = z^{u+\lambda v} \circ \Xi_{u+\lambda v},\ \tilde{z}^u = z^u \circ \Xi_u, \tag{2.4.16}$$

and operators L_u and $L_{u+\lambda v}$ defined by

$$L_u w = \Delta w + w_{yy}(u_x)^2 - 2w_{xy}u_x - w_y u_{xx}, \tag{2.4.17}$$

$$\begin{aligned} L_{u+\lambda v} w &= \Delta w + w_{yy}(u_x + \lambda v_x)^2 - 2w_{xy}(u_x + \lambda v_x) - w_y(u_{xx} + \lambda v_x) \\ &= L_u w + \lambda\left[w_{yy}(2u_x v_x + \lambda v_x^2) - 2w_{xy}v_x - w_y v_{xx}\right]. \end{aligned} \tag{2.4.18}$$

Then $\tilde{z}^{u+\lambda v} - \tilde{z}^u$ satisfies the equation

$$L_u\left(\tilde{z}^{u+\lambda v} - \tilde{z}^u\right) = \gamma - \lambda\left[\tilde{z}_{yy}^{u+\lambda v}(2u_x v_x + \lambda v_x^2) - 2\tilde{z}_{xy}^{u+\lambda v} v_x - \tilde{z}_y^{u+\lambda v} v_{xx}\right] \tag{2.4.19}$$

in $\Xi_{u+\lambda v}^{-1}(\Omega) \cap \Xi_u^{-1}(\Omega)$, where

$$\gamma(\varphi) \stackrel{\text{def}}{=} \int_{\{y=0\}} (G_1 - G_2)\,\varphi dx \tag{2.4.20}$$

and where

$$\begin{aligned} G_1(x,y) &\stackrel{\text{def}}{=} g(x, y + u(x) + \lambda v(x))\sqrt{1 + (u'(x) + \lambda v'(x))^2}, \\ G_2(x,y) &\stackrel{\text{def}}{=} g(x, y + u(x))\sqrt{1 + (u'(x))^2}. \end{aligned} \tag{2.4.21}$$

Observe that

$$\|G_1 - G_2\|_{W^{1,q}\left(\Xi_{u+\lambda v}^{-1}(\Omega) \cap \Xi_u^{-1}(\Omega)\right)} \leq c\lambda. \tag{2.4.22}$$

Now since

$$\operatorname{dist}\left(\partial\left(\Xi_{u+\lambda v}^{-1}(\Omega)\right), \partial\left(\Xi_u^{-1}(\Omega)\right)\right) \leq c\lambda \tag{2.4.23}$$

and because of the Hölder continuity of $z^{u+\lambda v}$ and z^u, we conclude that

$$\|\tilde{z}^{u+\lambda v} - \tilde{z}^u\|_{C^0\left(\partial\left(\Xi_{u+\lambda v}^{-1}(\Omega) \cap \Xi_u^{-1}(\Omega)\right)\right)} \leq c\lambda^\alpha. \tag{2.4.24}$$

Then (2.4.19), (2.4.22), and (2.4.24) imply that

$$\|\tilde{z}^{u+\lambda v} - \tilde{z}^u\|_{C^0\left(\overline{\Xi_{u+\lambda v}^{-1}(\Omega) \cap \Xi_u^{-1}(\Omega)}\right)} \leq c\lambda^\alpha. \tag{2.4.25}$$

Then we have (set $A = (x, y)$)

$$\begin{aligned} &\left|z^{u+\lambda v}(A) - z^u(A)\right| \\ &\quad = \left|\tilde{z}^{u+\lambda v}\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{z}^u\left(\Xi_u^{-1}(A)\right)\right| \\ &\quad \leq \left|\tilde{z}^{u+\lambda v}\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{z}^u\left(\Xi_{u+\lambda v}^{-1}(A)\right)\right| \\ &\qquad + \left|\tilde{z}^u\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{z}^u\left(\Xi_u^{-1}(A)\right)\right| \\ &\quad \leq c\lambda^\alpha + c\lambda^\alpha = c\lambda^\alpha. \end{aligned} \tag{2.4.26}$$

In (2.4.26), we also used the Hölder continuity of $\tilde{z}^u$. This completes the proof of the lemma.

COROLLARY 2.4.1.

$$\lim_{\lambda \downarrow 0} \frac{1}{\lambda} \int_{\Gamma_u} \left(z^{u+\lambda v} - z^u\right)^2 d\sigma = 0. \tag{2.4.27}$$

Proof. Take $\alpha > \frac{1}{2}$ in the lemma. Then

$$\frac{\left\|z^{u+\lambda v} - z^u\right\|_{C^0(\bar{\Omega})}^2}{\lambda} \leq c\lambda^\beta, \ \beta = 2\alpha - 1 > 0. \tag{2.4.28}$$

Now we can proceed with the proof of the theorem. We compute the last term in (2.4.14).

$$\begin{aligned}
&\lim_{\lambda\downarrow 0}\frac{1}{2\lambda}\int_{\Gamma_u}\left((z^{u+\lambda v})^2-(z^u)^2\right)d\sigma\\
&=\lim_{\lambda\downarrow 0}\frac{1}{\lambda}\int_{\Gamma_u}(z^{u+\lambda v}-z^u)z^u d\sigma+\lim_{\lambda\downarrow 0}\frac{1}{2\lambda}\int_{\Gamma_u}\left(z^{u+\lambda v}-z^u\right)^2 d\sigma\\
&=\lim_{\lambda\downarrow 0}\frac{1}{\lambda}\int_{\Gamma_u}(z^{u+\lambda v}-z^u)z^u d\sigma=-\lim_{\lambda\downarrow 0}\frac{1}{\lambda}\int_{\Omega}\nabla p^u\cdot\nabla(z^{u+\lambda v}-z^u)\\
&=\lim_{\lambda\downarrow 0}\frac{1}{\lambda}\left(\int_{\Gamma_{u+\lambda v}}gp^u d\sigma-\int_{\Gamma_u}gp^u d\sigma\right)\\
&=\int_{\Gamma_u}\left((gp^{u,\mathrm{ext}})_y v^+-(gp^{u,\mathrm{int}})_y v^-\right)d\sigma+\int_{-1}^{1}gp^u\frac{u'v'}{\sqrt{1+u'^2}}dx. \qquad (2.4.29)
\end{aligned}$$

Now from (2.4.14) and (2.4.29) we conclude that Φ is directionally differentiable, and that (2.4.9) holds. Furthermore, if (2.4.10) holds, then

$$\begin{aligned}
&\Phi'(u;v)\\
&=\int_{-1}^{1}\left(z^u(z_y^{u,\mathrm{ext}}v^+-z_y^{u,\mathrm{int}}v^-)\sqrt{1+u'^2}+\frac{1}{2}(z^u)^2\frac{u'v'}{\sqrt{1+u'^2}}\right)dx\\
&\quad+\int_{\Gamma_u}\left((gp^{u,\mathrm{ext}})_y v^+-(gp^{u,\mathrm{int}})_y v^-\right)d\sigma+\int_{-1}^{1}gp^u\frac{u'v'}{\sqrt{1+u'^2}}dx\\
&\geq\int_{-1}^{1}\left(\tau-\left(\frac{u'}{\sqrt{1+u'^2}}\left(\frac{1}{2}(z^u)^2+gp^u\right)\right)'\right)v dx \qquad (2.4.30)
\end{aligned}$$

for all

$$\begin{aligned}
\tau\in\Big[&\left(z^u z_y^{u,\mathrm{int}}+(gp^{u,\mathrm{int}})_y\right)\sqrt{1+u'^2},\\
&\left(z^u z_y^{u,\mathrm{ext}}+(gp^{u,\mathrm{ext}})_y\right)\sqrt{1+u'^2}\Big]. \qquad (2.4.31)
\end{aligned}$$

This proves that Φ is subdifferentiable at u and that (2.4.11) holds. Similarly, one can consider superdifferentiability of Φ. So the theorem follows.

REMARK 2.4.1. *The previous suggests the numerical algorithm* (the steepest descent method) *for minimization of* Φ, *i.e., for the numerical solution of the relaxed free boundary problem:*

Choose $u_0\in U$. *If* $u_n\in U$ *is already known, then* u_{n+1} *is determined as follows:*

- *compute* z^{u_n} *as a solution of* (2.2.2);
- *compute* p^{u_n} *as a solution of* (2.4.4);
- *if* (2.4.10) *holds, compute an* u_{n+1} *such that*

$$u_{n+1}\in\left(u_n-\rho_n A^{-1}\left(\partial_*\Phi(u_n)\right)\right)\cap U,\ \rho_n>0, \qquad (2.4.32)$$

and if (2.4.12) *holds, compute an* u_{n+1} *such that*

$$u_{n+1}\in\left(u_n-\rho_n A^{-1}\left(\partial^*\Phi(u_n)\right)\right)\cap U,\ \rho_n>0. \qquad (2.4.33)$$

Here, A is the isomorphism between $H_0^3(-1,1)$ and its dual. More precisely, $\bar{u} = A^{-1}(l)$ means that $\bar{u}$ solves the following boundary value problem:

$$-\frac{d^6\bar{u}}{dx^6} = l \text{ in } (-1,1),$$

$$\bar{u}(-1) = \bar{u}'(-1) = \bar{u}''(-1) = \bar{u}(1) = \bar{u}'(1) = \bar{u}''(1) = 0. \tag{2.4.34}$$

If neither (2.4.10) *nor* (2.4.12) *holds, i.e., if Φ is neither convex nor concave at the point u_n, then it is more delicate to determine the steep(est) descent direction.*

3. Stokes flow.

3.1. Statement of the problem. The purpose of this section is to extend the previous results to the case of Stokes flow.

We consider a motionless body $\mathcal{B}$ in a viscous incompressible fluid moving in a bounded region Λ containing $\mathcal{B}$. The boundary of the region Λ will be denoted as $\partial\Lambda$. Fluid is moving at the velocity $\mathbf{h}$ at $\partial\Lambda$, and $\mathbf{h}$ is such that $\int_{\partial\Lambda} \mathbf{h}\cdot\mathbf{n}d\sigma = 0$, where $\mathbf{n}$ is the unit (exterior) normal to $\partial\Lambda$.

The boundary of the body $\partial\mathcal{B}$ consists of two disjoint and connected parts Σ and Γ, $\partial\mathcal{B} = \Sigma\cup\Gamma$. We shall suppose that Γ can be described as

$$\Gamma = \Gamma_u = \{(x_1, u(x_1)); -1 < x_1 < 1\} \tag{3.1.1}$$

for some function $u \in U$, where

$$U = \left\{u \in H_0^3(-1,1); 0 \le u(x_1) \le 1, -1 < x_1 < 1\right\}. \tag{3.1.2}$$

So, if we want to emphasize the dependence on $u \in U$ we shall write also $\mathcal{B} = \mathcal{B}_u$.

Denote by Ω_u the actual flow region $\Omega_u \overset{\text{def}}{=} \Lambda \setminus \bar{\mathcal{B}}_u$. Also, we assume that Σ is such that $\partial\mathcal{B}$ is sufficiently regular. Finally, denote,

$$\Omega = \{(x_1,x_2);\ -1 < x_1 < 1,\ 0 < x_2 < u(x_1)\}\cup\Omega_u\cup\Gamma_u, \tag{3.1.3}$$

so that $\Omega\setminus\bar{\Omega}_u = \{(x_1,x_2);\ -1 < x_1 < 1,\ 0 < x_2 < u(x_1)\}$.

Now, the velocity vector field of the fluid $\mathbf{w} = \mathbf{w}^u$, and the pressure p, are the solution of the Stokes system

$$\begin{gathered} -\nu\Delta\mathbf{w} + \nabla p = \mathbf{0} \text{ in } \Omega_u,\ \nabla\cdot\mathbf{w} = 0 \text{ in } \Omega_u, \\ \mathbf{w} = 0 \text{ in } \Gamma_u\cup\Sigma,\ \mathbf{w} = \mathbf{h} \text{ in } \partial\Lambda \end{gathered} \tag{3.1.4}$$

We observe that the pressure p in (3.1.4) is determined only uniquely up to the additive constant.

The problem we propose is the following:

For given $\mathbf{g} = \mathbf{g}(x_1,x_2)$ such that (we will not always have to assume this much)

$$\mathbf{g} \in C^{1,1}(\Omega)^2, \tag{3.1.5}$$

$$\mathbf{g} = \mathbf{0} \text{ in } \Omega\cap\{|x_1| > 1\}, \tag{3.1.6}$$

find (if possible) $u \in U$ such that if $\mathbf{w}^u$ is the corresponding solution of (3.1.4), then also

$$-pn_j + \nu\left(\frac{\partial w_j}{\partial x_i} + \frac{\partial w_i}{\partial x_j}\right)n_i = g_j \text{ in } \Gamma_u,\ j = 1,2, \tag{3.1.7}$$

where $\mathbf{n} = (n_i)_{i=1,2}$ is the unit normal exterior to Ω_u. We observe now that if (3.1.7) is to be satisfied in addition to (3.1.4) (and if (3.1.7) and (3.1.4) have a solution) then pressure p is determined *uniquely*. Also, we note that condition (3.1.7) means that fluid motion exhibits force distribution $\mathbf{g}$ on the boundary Γ_u. So, the problem we propose is to find a shape of the immersed body so that the prescribed force field is generated at the boundary.

We can simplify this problem right away. Let, as usual, $V = V(\Omega) \stackrel{\text{def}}{=} \{\mathbf{u} \in H_0^1(\Omega)^2;\ \nabla \cdot \mathbf{u} = 0\}$. We have the following lemma.

LEMMA 3.1.1. *If* $\mathbf{w} \in V \cap H^2(\Omega)^2$, *and* $\partial\Omega \in C^{0,1}$, *then*

$$\frac{\partial w_i}{\partial x_j} n_i = 0 \text{ on } \partial\Omega. \tag{3.1.8}$$

Proof. Let $\varphi \in C^\infty(R^2)^2$ be an arbitrary function. We have

$$0 = \int_\Omega \frac{\partial w_i}{\partial x_i} \frac{\partial \varphi_j}{\partial x_j} = \int_\Omega \frac{\partial w_i}{\partial x_j} \frac{\partial \varphi_j}{\partial x_i} = \int_{\partial\Omega} \frac{\partial w_i}{\partial x_j} n_i \varphi_j. \tag{3.1.9}$$

So the lemma follows.

Lemma 3.1.1 implies that requesting (3.1.7) (in addition to (3.1.4)) is equivalent to requesting

$$-pn_j + \nu \frac{\partial w_j}{\partial x_i} n_i = g_j \text{ in } \Gamma_u,\ j = 1, 2. \tag{3.1.10}$$

Note that (3.1.10) is closely related to the equvalence of problems (3.2.2) and (3.2.3) (and hence, (3.2.4)).

3.2. Relaxation of the problem. Suppose that there exist a u, and a pair $(\mathbf{w}^u, p^u)$, a solution of (3.1.4), such that also (3.1.7) holds. So, we suppose existence for the free boundary problem (3.1.4) and (3.1.7). To refer to such an assumption we shall say that u is supposed to be an *exact shape*. Extend $\mathbf{w}^u$ from Ω_u to Ω as $\mathbf{z}^u$:

$$\mathbf{z}^u = \begin{cases} 0 & \text{on } \Omega \setminus \bar{\Omega}_u, \\ \mathbf{w}^u & \text{on } \Omega_u. \end{cases} \tag{3.2.1}$$

Lemma 3.2.1 follows.

LEMMA 3.2.1. *If* u *is an exact shape, then* $\mathbf{z}^u \in H^1(\Omega)^2$, *and it solves the Stokes system* (*with singular right-hand side*)

$$\frac{\nu}{2} \int_\Omega D(\mathbf{z}^u) : D(\varphi) = \xi_u(\varphi),\ \ \forall \varphi \in V, \tag{3.2.2}$$

i.e.,

$$\nu \int_\Omega \nabla \mathbf{z}^u : \nabla \varphi = \xi_u(\varphi),\ \ \forall \varphi \in V, \tag{3.2.3}$$

i.e.,

$$\begin{aligned} -\nu \Delta \mathbf{z}^u + \nabla p &= \xi_u,\ \ \textit{in } \mathcal{D}'(\Omega)^2, \\ \nabla \cdot \mathbf{z}^u &= 0,\ \ \textit{a.e. in } \Omega, \end{aligned} \tag{3.2.4}$$

where $\xi_u \in H^{-1}(\Omega)^2$ *is a signed vector measure given by*

$$\xi_u(\varphi) = \int_{\Gamma_u} \mathbf{g} \cdot \varphi d\sigma. \tag{3.2.5}$$

Here, $D(\mathbf{z}^u) : D(\varphi^u) = (\frac{\partial z_j}{\partial x_i} + \frac{\partial z_i}{\partial x_j})(\frac{\partial \varphi_j}{\partial x_i} + \frac{\partial \varphi_i}{\partial x_j})$, and throughout the paper the summation convention is assumed.

Proof of the Lemma. The proof is similar to the proof of Lemma 2.2.1; see also the proof of Lemma 3.2.2.

LEMMA 3.2.2. *Let* $u \in U$ *be given. Then, if* $\mathbf{z}^u$ *is a solution of* (3.2.2) *and if it happens that* $\mathbf{z}^u|_{\Gamma_u} = 0$, *then there exists pressure* p^u *such that* $(\mathbf{z}^u|_{\Omega_u}, p^u|_{\Omega_u})$ *is a solution of* (3.2.2) *and* (3.1.7), *i.e.,* u *is an exact shape.*

Proof. Observe that any test function $\varphi \in V$ must satisfy $0 = \int_{\Omega\setminus\bar{\Omega_u}} \nabla \cdot \varphi = \int_{\partial(\Omega\setminus\bar{\Omega_u})} \varphi \cdot \mathbf{n} d\sigma = \int_{\Gamma_u} \varphi \cdot \mathbf{n} d\sigma$. From (3.2.2) we see (here we assume the regularity of $\mathbf{z}^u|_{\Omega\setminus\bar{\Omega_u}}$ and $\mathbf{z}^u|_{\Omega_u}$, to be proved in the next section),

$$\begin{aligned}\int_{\Gamma_u} \mathbf{g} \cdot \varphi d\sigma &= \frac{\nu}{2}\left(\int_{\Omega\setminus\bar{\Omega_u}} D(\mathbf{z}^u) : D(\varphi) + \int_{\Omega_u} D(\mathbf{z}^u) : D(\varphi)\right) \\ &= \int_{\Omega\setminus\bar{\Omega_u}} (-\nu\Delta\mathbf{z}^u)\cdot\varphi + \int_{\Omega_u} (-\nu\Delta\mathbf{z}^u)\cdot\varphi \\ &\quad + \int_{\partial(\Omega\setminus\bar{\Omega_u})} \nu D(\mathbf{z}^u)\mathbf{n}\cdot\varphi d\sigma + \int_{\partial\Omega_u} \nu D(\mathbf{z}^u)\mathbf{n}\cdot\varphi d\sigma. \end{aligned} \tag{3.2.6}$$

To fix ideas, let $\mathbf{n}$ be the unit normal exterior to Ω_u. Then (3.2.6) is equal to

$$\begin{aligned}&\int_{\Omega\setminus\bar{\Omega_u}} (-\nu\Delta\mathbf{z}^u)\cdot\varphi + \int_{\Omega_u} (-\nu\Delta\mathbf{z}^u)\cdot\varphi \\ &+ \int_{\Gamma_u} \nu\left(D(\mathbf{z}^u)^{\text{ext}} - D(\mathbf{z}^u)^{\text{int}}\right)\mathbf{n}\cdot\varphi d\sigma \end{aligned} \tag{3.2.7}$$

where $f^{\text{int}} \overset{\text{def}}{=} f|_{\Omega\setminus\bar{\Omega_u}}$ and $f^{\text{ext}} \overset{\text{def}}{=} f|_{\Omega_u}$.

We conclude that there exists $p^u \in L^2(\Omega)$ such that

$$-\nu\Delta\mathbf{z}^u + \nabla p^u = \mathbf{0} \text{ in } \Omega\setminus\bar{\Omega}_u, \tag{3.2.8}$$

$$-\nu\Delta\mathbf{z}^u + \nabla p^u = \mathbf{0} \text{ in } \Omega_u. \tag{3.2.9}$$

For such p we have

$$\begin{aligned}\int_{\Gamma_u} \mathbf{g}\cdot\varphi d\sigma &= \int_{\Omega\setminus\bar{\Omega_u}} (-\nabla p^u)\cdot\varphi + \int_{\Omega_u} (-\nabla p^u)\cdot\varphi \\ &\quad + \int_{\Gamma_u} \nu\left(D(\mathbf{z}^u)^{\text{ext}} - D(\mathbf{z}^u)^{\text{int}}\right)\mathbf{n}\cdot\varphi d\sigma \\ &= \int_\Omega p^u \nabla\cdot\varphi - \int_{\partial(\Omega\setminus\bar{\Omega_u})} p^u\varphi\cdot\mathbf{n}d\sigma - \int_{\partial\Omega_u} p^u\varphi\cdot\mathbf{n}d\sigma \\ &\quad + \int_{\Gamma_u} \nu\left(D(\mathbf{z}^u)^{\text{ext}} - D(\mathbf{z}^u)^{\text{int}}\right)\mathbf{n}\cdot\varphi d\sigma. \end{aligned} \tag{3.2.10}$$

Let $[f]_{\text{int}}^{\text{ext}} \overset{\text{def}}{=} f^{\text{ext}}|_{\Gamma_u} - f^{\text{int}}|_{\Gamma_u}$ be the jump accross Γ_u. Then (3.2.10) implies that

$$\int_{\Gamma_u} g_j \varphi_j d\sigma = \int_{\Gamma_u} \left[-p^u n_j + \nu \left(\frac{\partial z_j^u}{\partial x_i} + \frac{\partial z_i^u}{\partial x_j} \right) n_i \right]_{\text{int}}^{\text{ext}} \varphi_j d\sigma \tag{3.2.11}$$

for all φ such that $\int_{\Gamma_u} \varphi_j n_j = 0$. This implies

$$\left[-p^u n_j + \nu \left(\frac{\partial z_j^u}{\partial x_i} + \frac{\partial z_i^u}{\partial x_j} \right) n_i \right]_{\text{int}}^{\text{ext}} - g_j = (\text{const}) n_j, \ j = 1, 2. \tag{3.2.12}$$

We note that (3.2.12) holds for any p^u such that (3.2.8) and (3.2.9) hold.

Now suppose that $\mathbf{z}^u|_{\Gamma_u} = 0$. Then $\mathbf{z}^u|_{\Omega \setminus \bar{\Omega}_u} = 0$, and without loss of generality we can choose $p^u|_{\Omega \setminus \bar{\Omega}_u} = 0$. Then (3.2.12) implies

$$\left(-p^u n_j + \nu \left(\frac{\partial z_j^u}{\partial x_i} + \frac{\partial z_i^u}{\partial x_j} \right) n_i \right)^{\text{ext}} \Bigg|_{\Gamma_u} - g_j = (\text{const}) n_j, \ j = 1, 2, \tag{3.2.13}$$

for any p^u satisfying (3.2.9). So, there exists p^u such that (3.2.9) holds and such that

$$\left(-p^u n_j + \nu \left(\frac{\partial z_j^u}{\partial x_i} + \frac{\partial z_i^u}{\partial x_j} \right) n_i \right)^{\text{ext}} \Bigg|_{\Gamma_u} - g_j = 0, \ j = 1, 2, \tag{3.2.14}$$

which is nothing but (3.1.7).

Lemma 3.2.2 motivates the following definition.

DEFINITION 3.2.1. *$u^* \in U$ is said to solve the* relaxed free boundary problem *if the corresponding $\mathbf{z}^u$ defined by* (3.2.2), *is such that if*

$$\Phi(u) = \frac{1}{2} \int_{\Gamma_u} |\mathbf{z}^u|^2 d\sigma \tag{3.2.15}$$

then

$$\Phi(u^*) = \min_{u \in U} \Phi(u). \tag{3.2.16}$$

3.3. The state equation. Let s be the segment

$$s = \{-1 \leq x \leq 1, y = 0\}, \tag{3.3.1}$$

and let

$$S_\epsilon = \{(x, y); \text{dist}((x, y), s) \leq \epsilon\}. \tag{3.3.2}$$

Define

$$W^{2,q}_{s-\text{loc}}(\Omega) \overset{\text{def}}{=} \cap_{\epsilon > 0} W^{2,q}(\Omega \setminus S_\epsilon). \tag{3.3.3}$$

Now we have the next theorem.

THEOREM 3.3.1. *Let q be such that $1 < q < \infty$, and $\partial\Omega \in C^2$. Let $u \in U$. Then the state equation* (3.2.2) *has a unique weak solution $\mathbf{z}^u$, and*

$$\mathbf{z}^u \in V \cap C^\infty(\Omega \setminus \Gamma_u)^2. \tag{3.3.4}$$

More importantly, the following regularity results hold:
(a) L^p-estimate: *If* $\mathbf{g} \in W^{1,q}(\Omega)^2$, *then*

$$\begin{aligned} &\|\mathbf{z}^u\|_{W^{1,q}(\Omega)^2} + \|p^u\|_{L^q(\Omega)/R} \le c\left(1 + \|u\|_{C^{0,1}(-1,1)}\right) \\ &\cdot \left(\|\mathbf{g}\|_{W^{1,q}(\Omega)^2} + \|\mathbf{h}\|_{W^{1-\frac{1}{q},q}(\partial\Omega)^2}\right). \end{aligned} \tag{3.3.5}$$

(b) maximum modulus estimate: *If, moreover,* $q > 2$, *then*

$$\begin{aligned} &\|\mathbf{z}^u\|_{L^\infty(\Omega)^2} \le c\left(1 + \|u\|_{C^{0,1}(-1,1)}\right) \\ &\left(\|\mathbf{g}\|_{W^{1,q}(\Omega)^2} + \|\mathbf{h}\|_{L^\infty(\partial\Omega)^2}\right). \end{aligned} \tag{3.3.6}$$

(c) *If* $\mathbf{g} \in W^{2,q}(\Omega)^2$, *and* (3.1.6) *holds, then*

$$\mathbf{z}^{u,\mathrm{ext}} \in W^{2,q}(\Omega_u)^2,\ \mathbf{z}^{u,\mathrm{int}} \in W^{2,q}_{s-\mathrm{loc}}(\Omega \setminus \bar{\Omega}_u)^2 \tag{3.3.7}$$

and the a priori estimates

$$\begin{aligned} &\|\mathbf{z}^{u,\mathrm{ext}}\|_{W^{2,q}(\Omega_u)^2} + \|p^{u,\mathrm{ext}}\|_{W^{1,q}(\Omega)/R} \\ &\le c\left(\|u\|_{H^3(-1,1)}, \|\mathbf{g}\|_{W^{2,q}(\Omega)^2}, \|\mathbf{h}\|_{W^{2-\frac{1}{q},q}(\partial\Omega)^2}\right), \end{aligned} \tag{3.3.8}$$

and

$$\begin{aligned} &\|\mathbf{z}^{u,\mathrm{int}}\|_{W^{2,q}((\Omega\setminus\Omega_u)\cap\{y>\epsilon\})^2} + \|p^{u,\mathrm{int}}\|_{W^{1,q}((\Omega\setminus\Omega_u)\cap\{y>\epsilon\})/R} \\ &\le c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|\mathbf{g}\|_{W^{2,q}(\Omega)^2}, \|\mathbf{h}\|_{W^{2-\frac{1}{q},q}(\partial\Omega)^2}\right) \end{aligned} \tag{3.3.9}$$

hold.

Proof. The interior regularity $\mathbf{z}^u \in C^\infty(\Omega \setminus \Gamma_u)^2$ follows easily (see, e.g., [6]). The proof of (3.3.5) is similar to the proof of (2.3.4). One has to use (see [5]) the following L^q-estimate for the Stokes problem:

$$\begin{aligned} &\|\mathbf{z}^u\|_{W^{1,q}(\Omega)^2} + \|p^u\|_{L^q(\Omega)/R} \\ &\le c\left\{\|F\|_{W^{-1,q}(\Omega)^2} + \|\mathbf{h}\|_{W^{1-\frac{1}{q},q}(\partial\Omega)^2}\right\}, \end{aligned} \tag{3.3.10}$$

where F is the right-hand side; in our case $F(\varphi) = \int_{\Gamma_u} \mathbf{g} \cdot \varphi d\sigma$.

We prove now (3.3.6). We use the following important result (see [13]) for biharmonic functions:

If $\Delta^2\varphi = 0$ in Ω, then

$$\|\nabla\varphi\|_{L^\infty(\Omega)^2} \le c\|\nabla\varphi\|_{L^\infty(\partial\Omega)^2}. \tag{3.3.11}$$

Let $\mathbf{w}$ solve the homogeneous Stokes problem

$$-\nu\Delta\mathbf{w} + \nabla p = 0 \text{ in } \Omega, \tag{3.3.12}$$

$$\nabla \cdot \mathbf{w} = 0 \text{ in } \Omega, \tag{3.3.13}$$

$$\mathbf{w} = \mathbf{h} \text{ on } \partial\Omega, \tag{3.3.14}$$

where $\mathbf{h}$ is such that $\int_{\partial\Omega} \mathbf{h} \cdot \mathbf{n} d\sigma = 0$. It is well known (see, e.g., [10]) that (3.3.13) and (3.3.14) imply the existence of φ such that $\mathbf{w} = \mathbf{curl}\varphi$. Here $\mathbf{curl}\varphi = \langle \frac{\partial\varphi}{\partial y}, -\frac{\partial\varphi}{\partial x} \rangle$.

Also let $\mathrm{curl}\mathbf{v} = \frac{\partial v_2}{\partial x} - \frac{\partial v_1}{\partial y}$. Now, since curl $\mathbf{curl}\varphi = -\Delta\varphi$, and since $\mathrm{curl}\nabla p = 0$, we conclude from (3.3.12) that $\Delta^2\varphi = 0$, and hence (3.3.11) follows. But then we have

$$\begin{aligned} &\| \mathbf{w}\|_{L^\infty(\Omega)^2} = \|\mathbf{curl}\varphi\|_{L^\infty(\Omega)^2} = \|\nabla\varphi\|_{L^\infty(\Omega)^2} \\ &\leq c\|\nabla\varphi\|_{L^\infty(\partial\Omega)^2} = c\|\mathbf{curl}\varphi\|_{L^\infty(\partial\Omega)^2} = c\|\mathbf{h}\|_{L^\infty(\partial\Omega)^2}. \end{aligned} \tag{3.3.15}$$

Now, (3.3.6) follows by linearity from (3.3.5) and (3.3.15) and by the imbedding theorem.

As in §2, define $\tilde{\mathbf{z}}$, $\tilde{p}$, $\tilde{\mathbf{g}}$ and $\tilde{\varphi}$ by $\tilde{\mathbf{z}}(x,y) \stackrel{\text{def}}{=} \mathbf{z}^u(x, y+u(x)), \tilde{p}(x,y) \stackrel{\text{def}}{=} p^u(x, y+u(x)), \tilde{\mathbf{g}}(x,y) \stackrel{\text{def}}{=} \mathbf{g}(x, y+u(x))\sqrt{1+u'^2(x)}, \tilde{\varphi}(x,y) \stackrel{\text{def}}{=} \varphi(x, y+u(x))$. Define operator L by $Lv = \Delta v + v_{yy}(u_x)^2 - 2v_{xy}u_x - v_y u_{xx}$, and $\tilde{\nabla}$ by $\tilde{\nabla}\tilde{p} = \langle \tilde{p}_x - \tilde{p}_y u_x, \tilde{p}_y\rangle$. Then, as before, L is uniformly elliptic.

Let, also, Ξ_u be the map with the image Ω given by the formula $\Xi_u(x,y) = (x, y+u(x))$. Then, $(-\nu\Delta\mathbf{z}^u + \nabla p^u) \circ \Xi_u = -\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p}$, and since $|\det D\Xi_u| = 1$ (here $D\Xi_u$ is the gradient matrix of the map Ξ_u so that $|\det D\Xi_u|$ is the Jacobian)

$$\left(-\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p}\right)(\tilde{\varphi}) = (-\nu\Delta\mathbf{z}^u + \nabla p^u)(\varphi). \tag{3.3.16}$$

Hence

$$\begin{aligned} \left(-\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p}\right)(\tilde{\varphi}) &= \int_{\Gamma_u} \mathbf{g}\cdot\varphi d\sigma \\ &= \int \mathbf{g}(x,u(x))\cdot\varphi(x,u(x))\sqrt{1+u'^2(x)}dx \\ &= \int_{\{y=0\}} \tilde{\mathbf{g}}\cdot\tilde{\varphi}dx \stackrel{\text{def}}{=} \tilde{\xi}(\tilde{\varphi}). \end{aligned} \tag{3.3.17}$$

So,

$$-\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p} = \tilde{\xi} \tag{3.3.18}$$

in the sense of distributions. Then from (3.3.18) we get

$$\left(-\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p}\right)\left(\delta^1_{-h}\tilde{\varphi}\right) = \tilde{\xi}\left(\delta^1_{-h}\tilde{\varphi}\right). \tag{3.3.19}$$

We have

$$\begin{aligned} \tilde{\xi}\left(\delta^1_{-h}\tilde{\varphi}\right) &= \int_{\{y=0\}} \tilde{\mathbf{g}}\cdot\delta^1_{-h}\tilde{\varphi}dx = -\int_{\{y=0\}} \left(\delta^1_h\tilde{\mathbf{g}}\right)\cdot\tilde{\varphi}dx \\ &\longrightarrow -\int_{\{y=0\}} \tilde{\mathbf{g}}_x\cdot\tilde{\varphi}dx \stackrel{\text{def}}{=} -\tilde{\xi}_x(\tilde{\varphi}), \end{aligned} \tag{3.3.20}$$

as $h \to 0$. We conclude that $(-\nu L\tilde{\mathbf{z}} + \tilde{\nabla}\tilde{p})_x(\tilde{\varphi}) = \tilde{\xi}_x(\tilde{\varphi})$, and hence

$$\begin{aligned} &-\nu L_1\tilde{\mathbf{z}}_x + \tilde{\nabla}\tilde{p}_x \\ &= \tilde{\xi}_x + \nu\left(\tilde{\mathbf{z}}_{yy}2u_xu_{xx} - \tilde{\mathbf{z}}_y u_{xxx}\right) + \left\langle \tilde{p}_y u_{xx}, 0\right\rangle, \end{aligned} \tag{3.3.21}$$

where $L_1 w = \Delta w + (u_x)^2 w_{yy} - 2u_x w_{xy} - 3u_{xx}w_y$. The rest of the proof is similar to the proof of (2.3.8).

Again, in order to claim existence of a minimizer, i.e., existence of a solution of the relaxed problem, one needs some kind of compactness. So let

$$U_b = \{u \in U; \|u\|_{H^3(-1,1)} \leq b\}, \tag{3.3.22}$$

where b is some prescribed positive constant.

PROPOSITION 3.3.1. *Let $\mathbf{g} \in W^{1,q}(\Omega)^2$, for some $q > 2$. Then, there exists an $u^* \in U_b$ such that*

$$\Phi(u^*) = \min_{u \in U_b} \Phi(u). \tag{3.3.23}$$

Proof. The proof is similar to the proof of Proposition 2.3.1.

3.4. Differentiability properties of the variational functional Φ. Our goal is to derive information about the *multivalued* generalized gradient of Φ.

Define the adjoint variable ζ^u, as a solution of the (adjoint) equation

$$\begin{aligned} -\nu\Delta\zeta^u + \nabla q = \eta_u \ \text{ in } \ \mathcal{D}'(\Omega)^2, \ \nabla\cdot\zeta^u = 0 \ \text{ a.e. in } \ \Omega, \\ \zeta^u = 0 \ \text{ on } \ \partial\Omega, \end{aligned} \tag{3.4.1}$$

where $\eta_u \in H^{-1}(\Omega)$ is a vector (signed) measure given by

$$\eta_u(\varphi) = \int_{\Gamma_u} \mathbf{z}^u \cdot \varphi d\sigma. \tag{3.4.2}$$

Obviously, (3.4.1) is the same type of equation as (3.2.2).

In this section, as before, $\mathbf{z}^{u,\text{ext}} = \mathbf{z}^u|_{\Omega_u}$ and $\mathbf{z}^{u,\text{int}} = \mathbf{z}^u|_{\Omega\setminus\Omega_u}$; also, below we shall use the notation $\zeta^{u,\text{ext}} = \zeta^u|_{\Omega_u}$ and $\zeta^{u,\text{int}} = \zeta^u|_{\Omega\setminus\Omega_u}$.

LEMMA 3.4.1. *Let $\mathbf{g} \in W^{2,q}(\Omega)^2$, for some $q > 1$. Then*

$$\zeta^{u,\text{ext}} \in W^{2,q}(\Omega_u)^2, \ \zeta^{u,\text{int}} \in W^{2,q}_{s-\text{loc}}(\Omega\setminus\bar{\Omega}_u)^2. \tag{3.4.3}$$

and the a priori estimates

$$\|\zeta^{u,\text{ext}}\|_{W^{2,q}(\Omega_u)^2} \leq c\left(\|u\|_{H^3(-1,1)}, \|\mathbf{g}\|_{W^{2,q}(\Omega)^2}, \|\mathbf{h}\|_{W^{2-\frac{1}{q},q}(\Omega)^2}\right), \tag{3.4.4}$$

and

$$\begin{aligned} &\|\ \zeta^{u,\text{int}}\|_{W^{2,q}(\Omega\setminus S_\epsilon)} \\ &\leq c\left(\epsilon, \|u\|_{H^3(-1,1)}, \|g\|_{W^{2,q}(\Omega)}, \|\psi\|_{W^{2,q}(\Omega)}\right) \end{aligned} \tag{3.4.5}$$

hold.

Proof. The proof is the same as the proof of Lemma 2.4.1.

We have the next theorem.

THEOREM 3.4.1. *Assume* (3.1.5) *and* (3.1.6). *Then Φ is directionally differentiable at any $u \in U$ such that $u(x) > 0$ for $-1 < x < 1$, and*

$$\begin{aligned} &\Phi'(u;v) \\ &= \int_{-1}^{1} \left(\mathbf{z}^u \cdot (\mathbf{z}^{u,\text{ext}}_y v^+ - \mathbf{z}^{u,\text{int}}_y v^-)\sqrt{1+u'^2} + \frac{1}{2}|\mathbf{z}^u|^2 \frac{u'v'}{\sqrt{1+u'^2}}\right) dx \\ &\quad + \int_{\Gamma_u} \left((\mathbf{g}\cdot\zeta^{u,\text{ext}})_y v^+ - (\mathbf{g}\cdot\zeta^{u,\text{int}})_y v^-\right) d\sigma \\ &\quad + \int_{-1}^{1} \mathbf{g}\cdot\zeta^u \frac{u'v'}{\sqrt{1+u'^2}} dx. \end{aligned} \tag{3.4.6}$$

Moreover, if

$$\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{int}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y \le \mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{ext}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y \quad a.e.\ in\ (-1,1), \tag{3.4.7}$$

then Φ *is subdifferentiable at* u *and*

$$\begin{aligned}
&\partial_* \Phi(u) \\
&= \left[\left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{int}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y\right) \sqrt{1+u'^2}, \left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{ext}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y\right) \sqrt{1+u'^2} \right] \\
&\quad - \left(\frac{u'}{\sqrt{1+u'^2}} \left(\frac{1}{2} |\mathbf{z}^u|^2 + \mathbf{g} \cdot \zeta^u \right) \right)'
\end{aligned}$$

$$\stackrel{\mathrm{def}}{=} [l\partial_*\Phi(u), r\partial_*\Phi(u)] \subset L^\infty(-1,1). \tag{3.4.8}$$

On the other hand, if

$$\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{int}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y \ge \mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{ext}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y \quad a.e.\ in\ (-1,1), \tag{3.4.9}$$

then Φ *is superdifferentiable at* u *and*

$$\begin{aligned}
&\partial^* \Phi(u) \\
&= \left[\left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{ext}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y\right) \sqrt{1+u'^2}, \left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{int}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y\right) \sqrt{1+u'^2} \right] \\
&\quad - \left(\frac{u'}{\sqrt{1+u'^2}} \left(\frac{1}{2} |\mathbf{z}^u|^2 + \mathbf{g} \cdot \zeta^u \right) \right)'
\end{aligned}$$

$$\stackrel{\mathrm{def}}{=} [l\partial^*\Phi(u), r\partial^*\Phi(u)] \subset L^\infty(-1,1). \tag{3.4.10}$$

Proof. As before, we compute

$$\begin{aligned}
\Phi'(u;v) &= \lim_{\lambda \downarrow 0} \frac{\Phi(u+\lambda v) - \Phi(u)}{\lambda} \\
&= \lim_{\lambda \downarrow 0} \frac{1}{2\lambda} \left(\int_{\Gamma_{u+\lambda v}} |\mathbf{z}^{u+\lambda v}|^2 d\sigma - \int_{\Gamma_u} |\mathbf{z}^u|^2 d\sigma \right) \\
&= \int_{-1}^{1} \left(\mathbf{z}^u \cdot (\mathbf{z}_y^{u,\mathrm{ext}} v^+ - z_y^{u,\mathrm{int}} v^-) \sqrt{1+u'^2} + \frac{1}{2} |\mathbf{z}^u|^2 \frac{u'v'}{\sqrt{1+u'^2}} \right) dx \\
&\quad + \lim_{\lambda \downarrow 0} \frac{1}{2\lambda} \int_{\Gamma_u} \left(|\mathbf{z}^{u+\lambda v}|^2 - |\mathbf{z}^u|^2 \right) d\sigma.
\end{aligned} \tag{3.4.11}$$

LEMMA 3.4.2. *Under previous assumptions on* u *and* v, *and for any* $\alpha < 1$, *the following estimate holds*

$$\|\mathbf{z}^{u+\lambda v} - \mathbf{z}^u\|_{C^0(\bar{\Omega})^2} \le c\lambda^\alpha. \tag{3.4.12}$$

Proof. Let, as before, Ξ_u be the map with the image Ω given by the formula $\Xi_u(x,y) = (x, y + u(x))$. Then $\Xi_u^{-1}(x,y) = (x, y - u(x))$, and (set $A = (x,y)$) $\operatorname{dist}\left(\Xi_{u+\lambda v}^{-1}(A) - \Xi_u^{-1}(A)\right) \le c\lambda$. Now consider $\tilde{\mathbf{z}}^{u+\lambda v}, \tilde{\mathbf{z}}^u, \tilde{p}^{u+\lambda v}, \tilde{p}^u$ defined as $\tilde{\mathbf{z}}^{u+\lambda v} = \mathbf{z}^{u+\lambda v} \circ \Xi_{u+\lambda v}, \tilde{\mathbf{z}}^u = \mathbf{z}^u \circ \Xi_u, \tilde{p}^{u+\lambda v} = p^{u+\lambda v} \circ \Xi_{u+\lambda v}, \tilde{p}^u = p^u \circ \Xi_u$, and operators L_u

and $L_{u+\lambda v}$ defined by

$$\begin{aligned} L_u w &= \Delta w + w_{yy}(u_x)^2 - 2w_{xy}u_x - w_y u_{xx}, \\ L_{u+\lambda v} w &= \Delta w + w_{yy}(u_x+\lambda v_x)^2 - 2w_{xy}(u_x+\lambda v_x) - w_y(u_{xx}+\lambda v_x) \\ &= L_u w + \lambda\left[w_{yy}(2u_x v_x + \lambda v_x^2) - 2w_{xy}v_x - w_y v_{xx}\right], \end{aligned} \tag{3.4.13}$$

and

$$\begin{aligned} \tilde{\nabla}_u w &= \langle w_x - w_y u_x, w_y\rangle, \\ \tilde{\nabla}_{u+\lambda v} w &= \langle w_x - w_y(u+\lambda v)_x, w_y\rangle = \tilde{\nabla}_u w - \langle \lambda v_x, 0\rangle. \end{aligned} \tag{3.4.14}$$

Then $\tilde{\mathbf{z}}^{u+\lambda v} - \tilde{\mathbf{z}}^u$ and corresponding $\tilde{p}^{u+\lambda v} - \tilde{p}^u$ satisfy the equation

$$\begin{aligned} -\nu L_u\left(\tilde{\mathbf{z}}^{u+\lambda v} - \tilde{\mathbf{z}}^u\right) + \tilde{\nabla}_u\left(\tilde{p}^{u+\lambda v} - \tilde{p}^u\right) \\ = \gamma + \langle \lambda v_x, 0\rangle \\ +\nu\lambda\left[\tilde{\mathbf{z}}_{yy}^{u+\lambda v}(2u_x v_x + \lambda v_x^2) - 2\tilde{\mathbf{z}}_{xy}^{u+\lambda v} v_x - \tilde{\mathbf{z}}_y^{u+\lambda v} v_{xx}\right] \end{aligned} \tag{3.4.15}$$

in $\Xi_{u+\lambda v}^{-1}(\Omega) \cap \Xi_u^{-1}(\Omega)$, where

$$\gamma(\varphi) \stackrel{\text{def}}{=} \int_{\{y=0\}} (\mathbf{G}_1 - \mathbf{G}_2)\,\varphi dx \tag{3.4.16}$$

and where

$$\mathbf{G}_1(x,y) \stackrel{\text{def}}{=} \mathbf{g}(x, y+u(x)+\lambda v(x))\sqrt{1+(u'(x)+\lambda v'(x))^2}, \tag{3.4.17}$$

$$\mathbf{G}_2(x,y) \stackrel{\text{def}}{=} \mathbf{g}(x, y+u(x))\sqrt{1+(u'(x))^2}. \tag{3.4.18}$$

Observe that

$$\|\mathbf{G}_1 - \mathbf{G}_2\|_{W^{1,q}\left(\Xi_{u+\lambda v}^{-1}(\Omega)\cap\Xi_u^{-1}(\Omega)\right)^2} \le c\lambda. \tag{3.4.19}$$

Now since $\operatorname{dist}\left(\partial\left(\Xi_{u+\lambda v}^{-1}(\Omega)\right), \partial\left(\Xi_u^{-1}(\Omega)\right)\right) \le c\lambda$ and because of the Hölder continuity of $\mathbf{z}^{u+\lambda v}$ and $\mathbf{z}^u$, we conclude that

$$\|\tilde{\mathbf{z}}^{u+\lambda v} - \tilde{\mathbf{z}}^u\|_{C^0\left(\partial\left(\Xi_{u+\lambda v}^{-1}(\Omega)\cap\Xi_u^{-1}(\Omega)\right)\right)^2} \le c\lambda^\alpha. \tag{3.4.20}$$

Then (3.3.6), (3.4.19), and (3.4.20) imply that

$$\|\tilde{\mathbf{z}}^{u+\lambda v} - \tilde{\mathbf{z}}^u\|_{C^0\left(\overline{\Xi_{u+\lambda v}^{-1}(\Omega)\cap\Xi_u^{-1}(\Omega)}\right)^2} \le c\lambda^\alpha. \tag{3.4.21}$$

Then we have (set $A = (x,y)$)

$$\begin{aligned} &\left|\mathbf{z}^{u+\lambda v}(A) - \mathbf{z}^u(A)\right| \\ &\quad = \left|\tilde{\mathbf{z}}^{u+\lambda v}\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{\mathbf{z}}^u\left(\Xi_u^{-1}(A)\right)\right| \\ &\quad \le \left|\tilde{\mathbf{z}}^{u+\lambda v}\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{\mathbf{z}}^u\left(\Xi_{u+\lambda v}^{-1}(A)\right)\right| \\ &\qquad + \left|\tilde{\mathbf{z}}^u\left(\Xi_{u+\lambda v}^{-1}(A)\right) - \tilde{\mathbf{z}}^u\left(\Xi_u^{-1}(A)\right)\right| \\ &\qquad\qquad c\lambda^\alpha + c\lambda^\alpha = c\lambda^\alpha. \end{aligned} \tag{3.4.22}$$

In (3.4.22) we also used the Hölder continuity of $\tilde{\mathbf{z}}^u$. This completes the proof of the lemma.

COROLLARY 3.4.1.

$$\lim_{\lambda \downarrow 0} \frac{1}{\lambda} \int_{\Gamma_u} \left| \mathbf{z}^{u+\lambda v} - \mathbf{z}^u \right|^2 d\sigma = 0. \tag{3.4.23}$$

Now, we can proceed with the proof of the theorem. We compute the last term in (3.4.11).

$$\begin{aligned}
&\lim_{\lambda \downarrow 0} \frac{1}{2\lambda} \int_{\Gamma_u} \left(|\mathbf{z}^{u+\lambda v}|^2 - |\mathbf{z}^u|^2 \right) d\sigma \\
&= \lim_{\lambda \downarrow 0} \frac{1}{\lambda} \int_{\Gamma_u} (\mathbf{z}^{u+\lambda v} - \mathbf{z}^u) \cdot \mathbf{z}^u d\sigma + \lim_{\lambda \downarrow 0} \frac{1}{2\lambda} \int_{\Gamma_u} \left| \mathbf{z}^{u+\lambda v} - \mathbf{z}^u \right|^2 d\sigma \\
&= \lim_{\lambda \downarrow 0} \frac{1}{\lambda} \int_{\Gamma_u} (\mathbf{z}^{u+\lambda v} - \mathbf{z}^u) \cdot \mathbf{z}^u d\sigma = \lim_{\lambda \downarrow 0} \frac{\nu}{\lambda} \int_{\Omega} \nabla \zeta^u : \nabla (\mathbf{z}^{u+\lambda v} - \mathbf{z}^u) \\
&= \lim_{\lambda \downarrow 0} \frac{1}{\lambda} \left(\int_{\Gamma_{u+\lambda v}} \mathbf{g} \cdot \zeta^u d\sigma - \int_{\Gamma_u} \mathbf{g} \cdot \zeta^u d\sigma \right) \\
&= \int_{\Gamma_u} \left((\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y v^+ - (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y v^- \right) d\sigma \\
&\quad + \int_{-1}^{1} \mathbf{g} \cdot \zeta^u \frac{u'v'}{\sqrt{1+u'^2}} dx.
\end{aligned} \tag{3.4.24}$$

Now from (3.4.11) and (3.4.24) we conclude that Φ is directionally differentiable, and that (3.4.6) holds. Furthermore, if (3.4.7) holds, then

$$\begin{aligned}
&\Phi'(u;v) \\
&\quad = \int_{-1}^{1} \left(\mathbf{z}^u \cdot (\mathbf{z}_y^{u,\mathrm{ext}} v^+ - \mathbf{z}_y^{u,\mathrm{int}} v^-) \sqrt{1+u'^2} + \frac{1}{2} |\mathbf{z}^u|^2 \frac{u'v'}{\sqrt{1+u'^2}} \right) dx \\
&\qquad + \int_{\Gamma_u} \left((\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y v^+ - (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y v^- \right) d\sigma + \int_{-1}^{1} \mathbf{g} \cdot \zeta^u \frac{u'v'}{\sqrt{1+u'^2}} dx \\
&\quad \geq \int_{-1}^{1} \left(\tau - \left(\frac{u'}{\sqrt{1+u'^2}} \left(\frac{1}{2} |\mathbf{z}^u|^2 + \mathbf{g} \cdot \zeta^u \right) \right)' \right) v dx
\end{aligned} \tag{3.4.25}$$

for all

$$\begin{aligned}
\tau \in \Big[&\left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{int}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{int}})_y \right) \sqrt{1+u'^2}, \\
&\left(\mathbf{z}^u \cdot \mathbf{z}_y^{u,\mathrm{ext}} + (\mathbf{g} \cdot \zeta^{u,\mathrm{ext}})_y \right) \sqrt{1+u'^2} \Big].
\end{aligned} \tag{3.4.26}$$

This proves that Φ is subdifferentiable at u and that (3.4.8) holds. Similarly, one can consider superdifferentiability of Φ. So the theorem follows.

Acknowledgment. We thank Eduardo Casas for useful discussions.

ANALYSIS OF A ONE-DIMENSIONAL MODEL FOR COMPRESSIBLE MISCIBLE DISPLACEMENT IN POROUS MEDIA*

YOUCEF AMIRAT† AND MOHAND MOUSSAOUI‡

Abstract. We consider a one-dimensional model problem for the motion of compressible miscible fluids in porous media, without molecular diffusion or dispersion, governed by a nonlinear hyperbolic-parabolic system. We assume the viscosity to be constant. We establish an existence result for nonsmooth data for the concentration. In the case of Dirichlet boundary conditions for the pressure, assuming the data to be smooth, we prove the existence and uniqueness of a smooth solution.

Key words. nonlinear equations, hyperbolic-parabolic system, porous media

AMS subject classifications. 35B40, 76S05, 76T05

1. Introduction.

We are concerned with the single-phase miscible displacement of one compressible fluid by another in a porous medium, under the assumptions that the fluids are miscible in all proportions and that there is no volume change due to the mixing of components (in the sense of Scheidegger [10]). The composition of the mixture is given by the mass concentration. We neglect the molecular diffusion and dispersion and omit the gravitational terms. We only consider the one-dimensional case which can be viewed as modelling experiments in a core sample. The equations corresponding to the description given are as follows (see Chavent and Jaffré [4], Douglas and Roberts [5]):

$$a(x,u)\,\partial_t p + \partial_x q = 0, \tag{1.1}$$

$$\phi(x)\,\partial_t u + q\,\partial_x u + b(x,u)\,\partial_t p = 0, \tag{1.2}$$

$$q = -\frac{k(x)}{\mu(u)}\partial_x p \tag{1.3}$$

for $x \in \Omega$, $t > 0$. Here $\Omega =]0,1[$ represents the core sample, $q(x,t)$ is the single-phase Darcy velocity, $k(x)$ the absolute permeability, $\phi(x)$ the porosity, $\mu(u)$ the viscosity of the mixture, $p(x,t)$ the pressure, $u(x,t)$ the concentration, and

$$a(x,u) = \phi(x)\,(u\,(z_1 - z_2) + z_2), \tag{1.4}$$

$$b(x,u) = \phi(x)\,(z_1 - z_2)\,u\,(1-u), \tag{1.5}$$

where z_i, $i = 1,2$, is the constant compressibility factor for the ith component. In addition to (1.1)–(1.5), we consider the initial and boundary conditions (of mixed type for the pressure):

$$p(0,t) = p_1 \quad \text{(constant)}, \quad q(1,t) = q_1(t), \quad p(x,0) = p_0(x), \tag{1.6}$$

$$u(0,t) = u_1(t), \quad u(x,0) = u_0(x), \tag{1.7}$$

for $x \in \Omega$, $t > 0$. The aim of the present paper is to discuss the existence of a solution (p, u) under reasonable conditions on the data p_1, q_1, p_0, u_0 and u_1. In this study, we assume the viscosity μ to be constant, and for case of exposition, we consider a model problem by taking $\phi \equiv 1$, $\frac{k}{\mu} \equiv 1$, $z_1 = 2$, $z_2 = 1$. The case where μ depends of u is more complicated; we intend to address it in a forthcoming publication.

The paper is organized as follows. Section 2 introduces the notations and hypotheses of the model problem. In §3, we state the existence theorem and describe the method employed. Roughly speaking, our results are as follows. If the data q_1 and p_0 are sufficiently smooth and u_0 and u_1 are functions of finite total variation, then there exists a solution (p, u) where p is a smooth function and u is of finite total variation. This is obtained by the use of Schauder's fixed point theorem. Section 4 is devoted to the proof of the existence theorem. In the final section, we discuss the system (1.1)–(1.5) provided with initial and boundary conditions, of Dirichlet type for the pressure. Assuming the data to be smooth, we then prove that this problem admits a unique smooth solution (p, u).

Note that (1.1)–(1.5) have been considered in Amirat, Hamdache, and Ziani [2], [3] for the related homogenization problems in two cases. For incompressible fluids, since $z_1 = z_2 = 0$, then $a(x, u) = b(x, u) = 0$; for two fluids with the same compressibility factor z, $b(x, u) = 0$ and $a(x, u) = \phi(x)\, z$.

2. The model problem. Let T be a strictly positive real number. We set $\Omega =]0, 1[$ and $Q = \Omega \times]0, T[$. Let a and b denote the functions defined as

$$a(s) = \begin{cases} 1 & \text{if} \quad s \le 0, \\ 1 + s & \text{if} \quad 0 \le s \le 1, \\ 2 & \text{otherwise;} \end{cases} \qquad b(s) = \begin{cases} s(1 - s) & \text{if} \quad 0 \le s \le 1, \\ 0 & \text{otherwise.} \end{cases} \tag{2.1}$$

We seek two functions u and p defined on Q, solutions of the nonlinear parabolic-hyperbolic system

$$a(u)\, \partial_t p - \partial_x^2 p = 0, \tag{2.2}$$

$$\partial_t u - (\partial_x p)\, \partial_x u + b(u)\, \partial_t p = 0, \tag{2.3}$$

satisfying the boundary and initial conditions

$$p(0, t) = p_1 \quad \text{(constant)}, \quad -\partial_x p(1, t) = q_1(t), \quad t \in]0, T[, \tag{2.4}$$

$$p(x, 0) = p_0(x), \quad x \in \Omega, \tag{2.5}$$

$$u(0, t) = u_1(t), \quad t \in]0, T[, \tag{2.6}$$

$$u(x, 0) = u_0(x), \quad x \in \Omega. \tag{2.7}$$

Observe that we may suppose $p_1 = 0$ by considering $(p - p_1)$ instead of p. We shall do this in the sequel. The following assumptions are made about the boundary and initial conditions:

$$\begin{aligned} &\text{There exists a function} \quad \overline{p} \in L^2(0, T; H^2(\Omega)) \cap H^1(0, T; L^2(\Omega)) \cap L^\infty(0, T; H^1(\Omega)) \\ &\text{such that} \quad \overline{p}(0, t) = 0, \quad -\partial_x \overline{p}(1, t) = q_1(t), \quad t \in]0, T[, \\ &\qquad\qquad \overline{p}(x, 0) = p_0(x), \quad x \in \Omega. \end{aligned} \tag{2.8}$$

$$\begin{aligned} &\text{There is a constant} \quad M > 0 \quad \text{such that} \\ &0 \le -p_0'(x),\ q_1(t) \le M, \quad x \in \Omega,\ t \in]0, T[, \end{aligned} \tag{2.9}$$

$$0 \le u_0(x),\ u_1(t) \le 1, \quad x \in \Omega,\ t \in]0,T[, \tag{2.10}$$

$$u_0 \in BV(\Omega), \quad u_1 \in BV(0,T). \tag{2.11}$$

We make the following comments about these assumptions.

(i) Conditions (2.8) and (2.9) are fulfilled if, for instance,

$$p_0 \in W^{1,\infty}(\Omega), \quad p_0(0) = 0, \quad -p_0' \ge 0, \quad q_1 \in H^{1/2}(]0,T[) \cap C^0([0,T]), \quad q_1 \ge 0.$$

(ii) The optimal assumption which could replace (2.4) would be

$$p(0,t) = p_1(t), \quad -\partial_x p(1,t) = q_1(t), \quad t \in]0,T[, \tag{2.4}'$$

with $p_1 \in H^{3/4}(]0,T[)$ so that for any fixed u in $L^1(Q)$, $0 \le u \le 1$, there exists a solution p of problem (2.2), (2.4)', (2.5) such that $q = -\partial_x p$ satisfies

$$q(x,t) \ge 0 \quad \text{for almost every} \quad (x,t) \in Q.$$

(iii) Since u stands for a concentration, it is quite natural to impose (2.10). Condition (2.11) seems to be a minimal smoothness condition to solve the transport equation (2.3) in a reasonable sense.

(iv) Equation (2.3), subject to the boundary and initial conditions (2.6), (2.7), is a well-posed problem whenever $-\partial_x p(x,t) \ge 0$ almost everywhere in Q. That is what motivates Hypothesis (2.9) on the one hand and the boundary condition (2.4) on the other for p on $x = 0$.

3. The existence result and the method.

DEFINITION 3.1. *A pair (p,u) is said to be a weak solution of problem* (2.2)–(2.7) *if the following assertions hold true*:

(i) $p \in L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega))$, $q \in L^\infty(Q)$,

(ii) $u \in L^\infty(Q)$, $0 \le u \le 1$,

(iii) *p is solution of* (2.2), (2.4), *and* (2.5),

(iv) *u is a weak solution of* (2.3), (2.6), *and* (2.7), *that is, for any φ in $C_0^1([0,1[J\times[0,T[)$,*

$$\int_Q [u(\partial_t\varphi + \partial_x(q\,\varphi)) - b(u)\,\partial_t p\,\varphi]\,dx\,dt = -\int_0^1 u_0(x)\,\varphi(x,0)\,dx - \int_0^T u_1(t)\,q(0,t)\,\varphi(0,t)\,dt.$$

Above $C_0^1([0,1[J \times [0,T[)$ is the space of C^1-differentiable functions having compact support on $[0,1[J \times [0,T[$.

The main result is the following theorem.

THEOREM 3.2. *Under hypotheses* (2.8)–(2.11), *problem* (2.2)–(2.7) *admits a weak solution (p,u) in the sense of Definition* 3.1. *Moreover,*

(i) $\partial_x u \in L^\infty(0,T;M(\Omega))$,

(ii) $\partial_t u \in L^2(0,T;M(\Omega))$, *where $M(\Omega)$ denotes the space of Radon measures on Ω.*

This will be obtained by the use of Schauder's fixed point theorem. Let us introduce the closed convex set in $L^1(Q)$ defined as

$$\mathcal{C} = \{u \in L^1(Q), \quad 0 \leq u \leq 1 \quad \text{a.e. in} \quad Q\}.$$

The idea is then to start from u in $\mathcal{C}$. The pressure equation (2.2) with conditions (2.4) and (2.5) admits a unique solution p. Next, we consider a solution w of the concentration equation

$$\partial_t w + q\,\partial_x w + b(w)\,\partial_t p = 0,$$

where $q = -\partial_x p$, subject to the boundary and initial conditions (2.6) and (2.7). We then set $\mathcal{T}(u) = w$. So we define a mapping $\mathcal{T}$ from $L^1(Q)$ into itself and the problem (2.2)–(2.7) reduces to show the existence of a fixed point of $\mathcal{T}$. The main difficulties are to show that $\mathcal{T}$ is continuous and that $\mathcal{T}(\mathcal{C})$ is relatively compact in $\mathcal{C}$. In fact, we obtain a solution (p,u) of problem (2.2)–(2.7) by the use of a sequence of perturbations $(\mathcal{T}_\eta)_{\eta>0}$ of the mapping $\mathcal{T}$. The concentration equation is replaced by

$$\begin{cases} \partial_t w_\eta + q_\eta\,\partial_x w_\eta + b(w_\eta)\,\partial_t p_\eta = 0, \\ w_\eta(x,0) = u_0^\eta(x), \quad w_\eta(0,t) = u_1^\eta(t), \end{cases}$$

where $q_\eta, p_\eta, u_0^\eta, u_1^\eta$ are suitable regularizations of q, p, u_0 and u_1, respectively. We then set $\mathcal{T}_\eta(u) = w_\eta$. We establish that for any $\eta > 0$, $\mathcal{T}_\eta$ has a fixed point denoted u_η. Finally, a weak solution (p,u) of (2.2)–(2.7) will be obtained as the limit of a subsequence of $(p_\eta, u_\eta)_{\eta>0}$.

Remark 3.3. There is no regularizing effect for the concentration. Indeed, taking $u_0 \equiv 1$, $u_1 \equiv 0$, and q a strictly positive constant, then (p,u) defined by

$$p(x,t) = q\,x, \qquad u(x,t) = \begin{cases} 1 & \text{if} \quad x - q\,t > 0, \\ 0 & \text{if} \quad x - q\,t < 0, \end{cases}$$

is a solution of the corresponding problem (2.2)–(2.7).

4. Proof of Theorem 3.2. The proof is divided into several steps. First, one has the following proposition.

PROPOSITION 4.1. *Let $a = a(x,t)$ be given in $L^\infty(Q)$, such that $1 \leq a(x,t) \leq 2$ for almost every $(x,t) \in Q$. Assume that conditions* (2.8) *and* (2.9) *are fulfilled. Then, there exists a unique function $p \in L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega))$ solution of*

$$\begin{cases} a(x,t)\,\partial_t p - \partial_x^2 p = 0, \quad (x,t) \in Q, \\ p(0,t) = 0, \quad -\partial_x p(1,t) = q_1(t), \quad t \in]0,T[, \\ p(x,0) = p_0(x), \quad xJ \in \Omega. \end{cases} \tag{4.1}$$

Furthermore, one has the estimates

$$||p||_{L^2(0,T;H^2(\Omega))} + ||\partial_t p||_{L^2(Q)} \leq C, \tag{4.2}$$

where C is a constant depending only on the function $\overline{p}$ in (2.8), *and*

$$0 \leq -\partial_x p(x,t) \leq M \quad \textit{for almost every} \quad (x,t) \in Q, \tag{4.3}$$

where M is the constant in (2.9).

Proof. For a given smooth function a (for instance in $C^0(\overline{Q})$), the existence in

$L^2(0,T;H^2(\Omega))\cap H^1(0,T;L^2(\Omega))$ of a solution of (4.1) is well known; see, for example, Ladyzhenskaya, Solonnikov, and Ural'tseva [8]. Therefore, it suffices to derive estimate (4.2) to obtain at the same time the existence of a solution of (4.1) with a in $L^\infty(Q)$. To do so, we put $\tilde{p} = p - \bar{p}$. One easily verifies that

$$a(x,t)\,\partial_t\tilde{p} - \partial_x^2\tilde{p} = f, \quad (x,t) \in Q, \tag{4.4}$$

$$\begin{aligned} &\tilde{p}(0,t) = 0, \quad \partial_x\tilde{p}(1,t) = 0, \quad t \in]0,T[, \\ &\tilde{p}(x,0) = 0, \quad x \in \Omega. \end{aligned} \tag{4.5}$$

Here $f = -(a\,\partial_t\bar{p} - \partial_x^2\bar{p})$. Multiplying (4.4) by $\partial_t\tilde{p}$ and integrating over $Q_t = \Omega\times]0,t[$ with $0 < t < T$, one obtains

$$\begin{aligned} \int_0^t\int_0^1 a(x,s)\,|\partial_t\tilde{p}|^2\,dx\,ds + \frac{1}{2}\int_0^1 |\partial_x\tilde{p}(x,t)|^2\,dx &= \int_0^t\int_0^1 f(x,t)\,\partial_t\tilde{p}\,dx\,ds \\ &\le \frac{1}{2}\int_0^t\int_0^1 |f(x,t)|^2\,dx\,ds + \frac{1}{2}\int_0^t\int_0^1 |\partial_t\tilde{p}|^2\,dx\,ds. \end{aligned}$$

Since $a(x,t) \ge 1$, one deduces

$$||\partial_t\tilde{p}||^2_{L^2(Q)} + ||\partial_x\tilde{p}||^2_{L^\infty(0,T;L^2(\Omega))} \le 2\,C\,||\bar{p}||^2_W,$$

where $W = L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega)) \cap L^\infty(0,T;H^1(\Omega))$. Hence (4.2) and the existence of a solution of (4.1) follow. The uniqueness is obvious. To prove (4.3), we note that $q = -\partial_x p$ is formally a solution of

$$\begin{cases} \partial_t q - \partial_x\left(\dfrac{1}{a(x,t)}\partial_x q\right) = 0, \quad (x,t) \in Q, \\ \partial_x q(0,t) = 0, \quad q(1,t) = q_1(t), \quad t \in]0,T[, \\ q(x,0) = -p_0'(x), \quad x \in \Omega. \end{cases} \tag{4.6}$$

Since $q \in L^2(0,T;H^1(\Omega))$ and $\partial_t q \in L^2(0,T;H^{-1}(\Omega))$, then $q \in C^0([0,T];H^{-1}(\Omega))$. Therefore the initial condition in (4.6) for q is meaningful. A reflexion procedure with respect to $x = 0$ allows the transformation of (4.6) to a mixed Cauchy–Dirichlet problem over $]-1,1[\times]0,T[$. Then the maximum principle gives (4.3). This completes the proof.

Now let us define the mappings $\mathcal{T}_\eta$ and the approximate fixed points u_η. With any fixed u in $\mathcal{C}$, we associate the solution p of

$$\begin{cases} a(u)\,\partial_t p - \partial_x^2 p = 0, \quad (x,t) \in Q, \\ p(0,t) = 0, \quad -\partial_x p(1,t) = q_1(t), \quad t \in]0,T[, \\ p(x,0) = p_0(x), \quad x \in \Omega. \end{cases} \tag{4.7}$$

Setting $q = -\partial_x p$, p and q then satisfy estimates (4.2) and (4.3). Let us introduce a regularization q_η of q, such that, for any $\eta > 0$, small enough,

(i) $\eta \le q_\eta(x,t) \le M + \eta$, for every $(x,t) \in Q$,

(ii) q_η converges, as η tends to 0, to q strongly in $L^2(Q)$ and weakly in $L^2(0,T;H^1(\Omega))$,

(iii) $|\partial_x(q_\eta)| \le \frac{C}{\eta}$, where C is a constant independent on η.

Such a regularization exists and may be constructed as follows. First one extends q by even symetrization with respect to $x = 0, x = 1, t = 0, t = T$ into a function q_2

defined on $\tilde{Q} =]-1, 2[J\times]-T, 2T[$. Then we choose a cutoff function θ in $\mathcal{D}(\tilde{Q})$ such that $\theta \equiv 1$ on Q and $0 \leq \theta \leq 1$. Then we set

$$\tilde{q} = \begin{cases} \theta q_2 & \text{in} \quad \tilde{Q}, \\ 0 & \text{outside.} \end{cases}$$

One easily verifies that $0 \leq \tilde{q} \leq M$ and $\tilde{q}$ is bounded in $L^2(I\!R_t, H^1(I\!R))$. Next we consider a regularizing kernel ρ with support in the unit ball satisfying $\rho \in \mathcal{D}(I\!R^2)$, $\rho \geq 0$ and $\int_{I\!R^2} \rho(x,t)\,dx\,dt = 1$. Then we set $\rho_\eta(x,t) = \frac{1}{\eta^2}\,\rho(\frac{x}{\eta}, \frac{t}{\eta})$. It is easily seen that the function

$$q_\eta(x,t) = \eta + \int_{I\!R^2} \rho_\eta(x-\xi, t-\tau)\,\tilde{q}(\xi,\tau)\,d\xi\,d\tau \quad \text{for} \quad (x,t) \in Q$$

satisfies (i), (ii), and (iii).

By using similar techniques of regularisation, we define a $C^2(\overline{Q})$ function p_η converging to p in $W = L^2(0,T; H^2(\Omega)) \cap H^1(0,T; L^2(\Omega)) \cap L^\infty(0,T; H^1(\Omega))$, satisfying the following properties:

(i) $p_\eta(0,t) = 0, \quad 0 < t < T,$

(ii) $||p_\eta||_W \leq K\,||p||_W$, K independent of η,

(iii) $||\partial_x p_\eta||_{L^\infty(Q)} \leq M'$ with M' independent of η,

(iv) $||p_\eta||_{C^2(\overline{Q})} \leq K(\eta)\,||p||_W$.

In the sequel M is set in place of $\max(M, M')$.

The regularisation of the data u_0 and u_1 is done through the following lemma.

LEMMA 4.2. *Let $v_0 \in BV(\Omega)$ and $v_1 \in BV(0,T)$ with $0 \leq v_0 \leq 1$, $0 \leq v_1 \leq 1$. Then for any η, $0 < \eta < \frac{1}{2}$, there exist two sequences $(v_0^\eta) \subset C^1(\overline{\Omega})$, $(v_1^\eta) \subset C^1([0,T])$ satisfying*

(i) $v_0^\eta(0) = v_1^\eta(0)$,

(ii) $(v_0^\eta)'(0) = (v_1^\eta)'(0) = 0$,

(iii) $0 \leq v_0^\eta \leq 1, \quad 0 \leq v_1^\eta \leq 1$,

(iv) $||v_0^\eta||_{W^{1,1}(\Omega)} + ||v_1^\eta||_{W^{1,1}(]0,T[)} \leq C\,(||v_0||_{BV(\Omega)} + ||v_1||_{BV(0,T)})$, *where C is a constant independent of η,*

(v) (v_0^η, v_1^η) *converges to (v_0, v_1) in $L^1(\Omega) \times L^1(0,T)$ as η tends to zero.*

Proof. The proof is a consequence of the following.

Let f in $BV(\Omega)$, the latter equipped with the norm $||f||_{BV(\Omega)} = ||f||_{L^\infty(\Omega)} + TV(f)$ (or, equivalently, $||f||_{BV(\Omega)} = ||f||_{L^1(\Omega)} + TV(f)$). Then there exists a sequence (g_η) in $C^1(\overline{\Omega})$ and a constant C independent of η such that

(a) $g_\eta(0) = g_\eta'(0) = 0$,

(b) $||g_\eta||_{W^{1,1}(\Omega)} \leq C||f||_{BV(\Omega)}$,

(c) (g_η) converges to f in $L^1(\Omega)$ as η tends to zero; $0 \leq g_\eta \leq 1$ if $0 \leq f \leq 1$.

First we introduce the sequence (f_η) defined by

$$f_\eta(x) = \begin{cases} f(x) & \text{if} \quad 2\eta \leq x < 1, \\ 0 & \text{if} \quad 0 < x < 2J\eta. \end{cases}$$

Then it is clear that

(1) $||f_\eta||_{L^\infty(\Omega)} \leq ||f||_{L^\infty(\Omega)}, \quad 0 \leq f_\eta \leq 1$ if $0 \leq f \leq 1$,

(2) $TV(f_\eta) \leq C\,||f||_{BV(\Omega)}$, with a constant C independent of η,

(3) $f_\eta \to f$ in $L^p(\Omega)$, for any $p, 1 \leq p < \infty$.

Next we consider the sequence $(\tilde{g}_\eta)$ defined on $\mathbb{R}$ by the convolution

$$\tilde{g}_\eta(x) = \frac{1}{\eta}\int_{-\infty}^{+\infty} \rho\left(\frac{x-y}{\eta}\right) \tilde{f}_\eta(y)\, dy,$$

where $\tilde{f}_\eta$ denotes the extension of f_η by zero outside Ω and ρ is a nonnegative regularizing kernel, $\rho \in \mathcal{D}(]-1,1[)$, $\int_{-\infty}^{+\infty} \rho(y)\, dy = 1$. Then one easily verifies that the sequence (g_η) obtained by restricting each $\tilde{g}_\eta$ to Ω satisfies (a), (b), and (c). Now we define w_η as the solution of

$$\begin{cases} \partial_t w_\eta + q_\eta\, \partial_x w_\eta + b(w_\eta)\, \partial_t p_\eta = 0, & (x,t) \in Q, \\ w_\eta(0,t) = u_1^\eta(t), \quad w_\eta(x,0) = u_0^\eta(x), & t \in]0,T[,\ x \in \Omega, \end{cases} \tag{4.8}$$

and set $\mathcal{T}_\eta(u) = w_\eta$.

PROPOSITION 4.3. *For any $\eta > 0$, the mapping $\mathcal{T}_\eta$ is well defined and has a fixed point in $\mathcal{C}$.*

The proof relies on a priori estimates. We shall note those which are independent of the parameter η.

LEMMA 4.4. *For any u in $\mathcal{C}$, $\mathcal{T}_\eta(u) = w_\eta$ is well defined and satisfies the following estimates*:

$$0 \le w_\eta(x,t) \le 1, \qquad \text{for every} \quad (x,t) \in Q, \tag{4.9}$$

$$||w_\eta||_{L^\infty(0,T;W^{1,1}(\Omega))} + ||\partial_t(w_\eta)||_{L^2(0,T;L^1(\Omega))} \le C_1, \tag{4.10}$$

$$||w_\eta||_{L^\infty(0,T;H^1(\Omega))} + ||\partial_t(w_\eta)||_{L^2(Q)} \le C_2(\eta), \tag{4.11}$$

where C_1 and $C_2(\eta)$ are constants which depend on the data, C_1 independent of η.

Remark 4.5. In Lemma 4.4, the compatibility conditions necessary for the existence of a smooth solution w_η are

$$\begin{aligned} &u_0^\eta \in C^1(\overline{\Omega}), \quad u_1^\eta \in C^1([0,T]), \\ &u_0^\eta(0) = u_1^\eta(0), \quad (u_1^\eta)'(0) + q_\eta(0,0)\,(u_0^\eta)'(0) = 0. \end{aligned} \tag{4.12}$$

Clearly, from Lemma 4.2, these conditions hold. Also notice that, from properties (i) and (iii) of p_η, we have

$$-M \le p_\eta(x,t) \le M. \tag{4.13}$$

Proof of Lemma 4.4. Let $u \in \mathcal{C}$. From Proposition 4.1, problem (4.7) has a unique solution p. We consider now the problem (4.8) where, for convenience we drop the subscript η except for q_η, which will be denoted $\overline{q}$ throughout the sequel; that is,

$$\partial_t w + \overline{q}\, \partial_x w + \partial_t p\, b(w) = 0, \quad (x,t) \in Q, \tag{4.14}$$

$$w(0,t) = u_1(t), \quad t \in]0,T[, \quad w(x,0) = u_0(x), J \quad x \in \Omega. \tag{4.15}$$

Equation (4.14) may be reduced (at least formally) to a linear equation by introducing an antiderivative of $\frac{1}{b(s)}$, namely $G(s) = \ln \frac{s}{(1-s)}$ defined on $]0,1[$. However, the boundary value problem is well posed only if u_0 and u_1 do not assume the values 0 or 1. We introduce a perturbation of (4.14), namely,

$$\partial_t w^\varepsilon + \overline{q}\, \partial_x w^\varepsilon + (b(w^\varepsilon) + \varepsilon(1+\varepsilon))\partial_t p = 0, \tag{4.16}$$

where $\varepsilon > 0$. Setting

$$G^\varepsilon(s) = \frac{1}{1+2\varepsilon} \ln\left(\frac{\varepsilon + s}{\varepsilon + 1 - s}\right), \quad s \in [0,1],$$

it is readily verified that $G^\varepsilon(w^\varepsilon)$ is solution of

$$\partial_t(G^\varepsilon(w^\varepsilon)) + \overline{q}\,\partial_x(G^\varepsilon(w^\varepsilon)) + \partial_t p = 0.$$

Following an idea used by Kazhikhov and Shelukin [6] and Serre [11], we introduce the auxiliary function

$$h^\varepsilon = G^\varepsilon(w^\varepsilon) + p.$$

Thus, h^ε is a solution of

$$\text{(4.17)} \qquad \begin{cases} \partial_t h^\varepsilon + \overline{q}\,\partial_x h^\varepsilon = -q\,\overline{q}, \quad (x,t) \in Q, \\ h^\varepsilon(0,t) \equiv h_1^\varepsilon(t) = \dfrac{1}{1+2\varepsilon} \ln\left(\dfrac{\varepsilon + u_1(t)}{\varepsilon + 1 - u_1(t)}\right), \quad t \in]0,T[, \\ h^\varepsilon(x,0) \equiv h_0^\varepsilon(x) = \dfrac{1}{1+2\varepsilon} \ln\left(\dfrac{\varepsilon + u_0(x)}{\varepsilon + 1 - u_0(x)}\right) + p_0(x), \quad x \in \Omega. \end{cases}$$

According to (4.12) and (4.13), we have

$$h_0^\varepsilon \in C^1(\overline{\Omega}), \quad h_1^\varepsilon \in C^1([0,T]),$$
$$h_0^\varepsilon(0) = h_1^\varepsilon(0), \quad h_1^{\varepsilon\prime}(0) + \overline{q}(0,0)\,h_0^{\varepsilon\prime}(0) = -q(0,0)\,\overline{q}(0,0).$$

Furthermore, q and $\overline{q}$ belong to $C^1(\overline{Q})$ and $\overline{q}$ is positive. Then, problem (4.17) has a unique solution in $C^1(\overline{Q})$. Therefore, the function

$$w^\varepsilon = \frac{(1+\varepsilon)\,e^{(1+2\varepsilon)(h^\varepsilon - p)} - \varepsilon}{1 + e^{(1+2\varepsilon)(h^\varepsilon - p)}}$$

is a solution of (4.16). It remains to prove that $(w^\varepsilon)_{\varepsilon>0}$ converges, as ε tends to 0, to a solution of (4.14) and (4.15). To this end, we introduce the function

$$v^\varepsilon = \frac{e^{(1+2\varepsilon)h^\varepsilon}}{1 + e^{(1+2\varepsilon)h^\varepsilon}}.$$

A straightforward calculation shows that v^ε is a solution of

$$\begin{cases} \partial_t v_\varepsilon + \overline{q}\,\partial_x v_\varepsilon = -(1+2\varepsilon)\,v^\varepsilon(1-v^\varepsilon)\,q\,\overline{q}, \quad (x,t) \in Q, \\ v^\varepsilon(0,t) = \dfrac{\varepsilon + u_1(t)}{1+2\varepsilon}, \quad t \in]0,T[, \\ v_\varepsilon(x,0) = \dfrac{(\varepsilon + u_0(x))\,e^{(1+2\varepsilon)\,p_0(x)}}{(1+\varepsilon - u_0(x)) + (\varepsilon + u_0(x))\,e^{(1+2\varepsilon)\,p_0(x)}}, \quad x \in \Omega. \end{cases}$$

Then, one easily verifies that, as ε tends to 0, $(v^\varepsilon)_{\varepsilon>0}$ converges in $H^1(Q)$ weak and in $L^2(Q)$ strong to a v solution of

$$\text{(4.18)} \qquad \partial_t v + \overline{q}\,\partial_x v = -v(1-v)\,q\,\overline{q}, \quad (x,t) \in Q,$$
$$v(0,t) = u_1(t), \quad t \in]0,T[,$$

$$\text{(4.19)} \qquad v(x,0) = \frac{u_0(x)\,e^{p_0(x)}}{(1-u_0(x)) + u_0(x)\,e^{p_0(x)}}, \quad x \in \Omega,$$

satisfying, in addition, $0 \le v(x,t) \le 1$ for $(x,t) \in Q$. According to (4.12) and (4.13), v belongs to $C^1(\overline{Q})$. On the other hand, w^ε may be written in the form

$$w^\varepsilon = \frac{(1+\varepsilon)\, e^{-(1+2\varepsilon)\, p}\, v^\varepsilon - \varepsilon(1-v^\varepsilon)}{(1-v^\varepsilon) + v^\varepsilon\, e^{-(1+2\varepsilon)p}}.$$

It follows that, as ε tends to 0, $(w^\varepsilon)_{\varepsilon>0}$ converges in $H^1(Q)$ weak to w given by

$$w = \frac{e^{-p}\, v}{(1-v) + v\, e^{-p}}. \tag{4.20}$$

It is easily verified that w is a solution of problem (4.14) and (4.15) and satisfies (4.9). Let us now prove estimates (4.10) and (4.11). They will be a consequence of the following lemma.

LEMMA 4.6. *Let v be the solution of Problem* (4.18) *and* (4.19). *Then*

$$||v||_{L^\infty(0,T;W^{1,1}(\Omega))} + ||v||_{W^{1,\infty}(0,T;L^1(\Omega))} \le C_3, \tag{4.21}$$

$$||v||_{L^\infty(0,T;H^1(\Omega))} + ||v||_{W^{1,\infty}(0,T;L^2(\Omega))} \le C_4(\eta), \tag{4.22}$$

where C_3 and $C_4(\eta)$ are constants, C_3 independent of η.

Indeed, admitting this lemma for a moment, from the inequalities $-M \le p \le 0$ it follows that

$$1 \le (1-v) + v\, e^{-p} \le e^M.$$

Then, using the relation

$$w = \frac{e^{-p}\, v}{(1-v) + v\, e^{-p}}$$

together with (4.2) and (4.3), the estimates (4.10) and (4.11) follow immediately.

Proof of Lemma 4.6. From (4.18) and (4.19) it follows that

$$\begin{aligned} |\overline{q}(0,t)\, \partial_x v(0,t)| &= |-u_1(t)(1-u_1(t))\, q(0,t)\, \overline{q}(0,t) - \partial_t u_1(t)| \\ &\le \frac{1}{4} M(M+\eta) + |\partial_t u_1(t)| \le \frac{1}{2} M^2 + |\partial_t u_1(t)| \qquad \text{for} \quad \eta \le M \end{aligned}$$

for almost every $t \in]0,T[$, and thus

$$\int_0^T |\overline{q}(0,t)\, \partial_x v(0,t)|\, dt \le \frac{1}{2} M^2\, T + \int_0^T |\partial_t u_1(t)|\, dt. \tag{4.23}$$

Now we differentiate (4.18) with respect to x. We get

$$\partial_t(\partial_x v) + \partial_x(\overline{q}\, \partial_x v) = -v(1-v)\, (q\, \partial_x \overline{q} + \overline{q}\, \partial_x q) + q\, \overline{q}\, (2v-1)\, \partial_x v. \tag{4.24}$$

Multiplying (4.24) by $\operatorname{sign}(\partial_x v)$ and integrating in x yields

$$\begin{aligned} \frac{d}{dt} \int_0^1 |\partial_x v|\, dx &+ \int_0^1 \partial_x(\overline{q}\, |\partial_x v|)\, dx \\ &= \int_0^1 v(v-1)\, (q\, \partial_x \overline{q} + \overline{q}\, \partial_x q) \operatorname{sign}(\partial_x v)\, dx + \int_0^1 q\, \overline{q}\, (2v-1)\, |\partial_x v|\, dx. \end{aligned}$$

Hence, by integration in time from 0 to t, $0 < t < T$, we obtain

$$\int_0^1 |\partial_x v(x,t)|\,dx + \int_0^t \overline{q}(1,s)\,|\partial_x v(1,s)|\,ds \le \int_0^1 |\partial_x v(x,0)|\,dx + \int_0^t \overline{q}(0,s)\,|\partial_x v(0,s)|\,ds + \frac{M}{2}\int_0^t\int_0^1 (|\partial_x q| + |\partial_x \overline{q}|)\,dx\,ds + 2\,M^2 \int_0^t\int_0^1 |\partial_x v|\,dx\,ds.$$

Using (4.23), Proposition 4.1 and the definition of $\overline{q}$, we obtain

$$\int_0^1 |\partial_x v(x,t)|\,dx \le K_1 + 2\,M^2 \int_0^t\int_0^1 |\partial_x v|\,dx\,ds$$

for any $t > 0$, $t \le T$, where K_1 is a constant independent of η. Thus, in view of Gronwall's lemma, $\partial_x v$ is bounded in $L^\infty(0,T;L^1(\Omega))$ by a constant depending on the data but which does not depend on η. That $\partial_t v$ is bounded in the same way follows readily from (4.18). Hence (4.21) follows. To prove (4.22), we multiply (4.24) by $\partial_x v$. We get

$$\frac{1}{2}\frac{d}{dt}|\partial_x v|^2 + \partial_x(\overline{q}\,\partial_x v)\,\partial_x v = \partial_x(v(v-1)q\,\overline{q})\,\partial_x v. \tag{4.25}$$

Then, by integration over $Q_t =]0,1[\times]0,t[$, with $0 < t \le T$, we obtain

$$\frac{1}{2}\int_0^1 |\partial_x v(x,t)|^2\,dx + \frac{1}{2}\int_0^t \overline{q}(1,s)|\partial_x v(1,s)|^2\,ds = \frac{1}{2}\int_0^1 |\partial_x v(x,0)|^2\,dx + \frac{1}{2}\int_0^t \overline{q}(0,s)|\partial_x v(0,s)|^2\,ds - \frac{1}{2}\int_0^t\int_0^1 \partial_x\overline{q}(x,s)|\partial_x v(x,s)|^2\,dx\,ds + \int_0^t\int_0^1 (\partial_x(v(v-1)q\overline{q})\,\partial_x v)(x,s)\,dx\,ds.$$

The first term on the right side is majorised in terms of $H^1(\Omega)$ norm of the data p_0 and u_0. For the second, we again use (4.18). We have

$$\begin{aligned}\overline{q}(0,s)\,|\partial_x v(0,s)|^2 &= -u_1(s)(1-u_1(s))\,q(0,s)\,\overline{q}(0,s)\,\partial_x v(0,s) - \partial_t u_1(s)\,\partial_x v(0,s)\\ &\le \frac{1}{4}\,M\sqrt{M+\eta}\,\sqrt{\overline{q}(0,s)}\,|\partial_x v(0,s)| + |\partial_t u_1(s)|\,\frac{1}{\sqrt{\eta}}\cdot\sqrt{\eta}|\partial_x v(0,s)|\\ &\le \frac{M^3}{8} + \frac{1}{4}\,\overline{q}(0,s)\,|\partial_x v(0,s)|^2 + \frac{1}{\eta}\,|\partial_t u_1(s)|^2 + \frac{\eta}{4}\,|\partial_x v(0,s)|^2\\ &\le \frac{M^3}{8} + \frac{1}{2}\,q(0,s)\,|\partial_x v(0,s)|^2 + \frac{1}{\eta}\,|\partial_t u_1(s)|^2 \quad \text{since} \quad \overline{q}(0,s) \ge \eta.\end{aligned}$$

Hence

$$\frac{1}{2}\int_0^t \overline{q}(0,s)\,|\partial_x v(0,s)|^2\,ds \le \frac{M^3}{8}\,t + \frac{1}{\eta}\int_0^t |\partial_t u_1(s)|^2\,ds.$$

For the third term, according to the property (iii) of $\overline{q}$, one has

$$\int_0^t\int_0^1 (\partial_x\overline{q}\,|\partial_x v|^2)(x,s)\,dx\,ds \le \frac{C}{\eta}\int_0^t\int_0^1 |J\partial_x v(x,s)|^2\,dx\,ds.$$

For the last term, one has

$$I = \int_0^t \int_0^1 (2v - 1)\, q\, \bar{q} |\partial_x v|^2 \, dx\, ds + \int_0^t \int_0^1 v(v-1)(q\, \partial_x \bar{q} + \bar{q}\, \partial_x q)\, \partial_x v \, dx\, ds,$$

where

$$I = \int_0^t \int_0^1 \partial_x (v(v-1) q\, \bar{q})\, \partial_x v \, dx\, ds.$$

Hence,

$$I \leq (2M^2 + 1) \int_0^t \int_0^1 |\partial_x v|^2 \, dx\, ds + \frac{M^2}{4} \int_0^t \int_0^1 (|\partial_x \bar{q}|^2 + |\partial_x q|^2)\, dx\, ds.$$

Finally,

$$\frac{1}{2} \int_0^1 |\partial_x v|^2(x,t)\, dx + \frac{1}{2} \int_0^1 \bar{q}(1,s)\, |\partial_x v(1,s)|^2 \, ds \leq K_2 + \frac{K_3}{\eta} + \left(K_4 + \frac{C}{\eta}\right) \int_0^t \int_0^1 |\partial_x v|^2 \, dx\, ds,$$

where K_2, K_3, and K_4 are constants independent of η. Consequently, $\partial_x v$ is bounded in $L^\infty(0,T; L^2(\Omega))$ by a constant which depends on the data, but also on the parameter η. Thanks to (4.18), the same holds true for $\partial_t v$. Lemma 4.6 is proved.

Clearly, by (4.9), $\mathcal{T}_\eta(\mathcal{C})$ is contained in $\mathcal{C}$ and, according to Lemmas 4.2 and 4.4, $\mathcal{T}_\eta(\mathcal{C})$ is relatively compact in $\mathcal{C}$ since by (4.11) it is contained in a bounded set of $H^1(Q)$. To prove the statement of Proposition 4.3, it thus remains to show the following lemma.

LEMMA 4.7. *For any $\eta > 0$, the mapping $\mathcal{T}_\eta$ from $\mathcal{C}$ into itself is continuous for the $L^1(Q)$ norm.*

Proof. Let (u^n) be an arbitrary sequence which converges, as n tends to ∞, to a function u in $L^1(Q)$. In fact, (u^n) converges, as n tends to ∞, to u in $L^r(Q)$, for any r, $1 \leq r < \infty$. The associated sequence (p^n) with (u^n) is bounded in the space $L^2(0,T; H^2(\Omega)) \cap H^1(0,T; L^2(\Omega))$. Then there is a subsequence, still denoted by (p^n), which is weakly convergent. It is easily seen that the limit p of (p^n) is a solution of

$$\begin{cases} a(u)\partial_t p - \partial_x^2 p = 0, & (x,t) \in Q, \\ p(0,t) = 0, \quad -\partial_x p(1,t) = q_1(t), & t \in]0,T[, \\ p(x,0) = p_0(x), & x \in \Omega. \end{cases}$$

Since this problem has a unique solution, the whole sequence (p^n) converges to p. In addition, the sequence $q^n = -\partial_x p^n$ converges, as n tends to ∞, to $q = -\partial_x p$, strongly in $L^2(Q)$. Indeed,

$$(q^n) \quad \text{is bounded in} \quad L^2(0,T; H^1(\Omega)),$$
$$(\partial_t q^n) \quad \text{is bounded in} \quad L^2(0,T; H^{-1}(\Omega)).$$

Consequently, by Aubin's theorem (see Lions [9]), $\{q^n\}$ is compactly imbedded in $L^2(Q)$. Therefore, (q^n) and $(\bar{q}^n)$ converge, respectively, as n tends to ∞, to q and $\bar{q}$ in $L^r(Q)$, for any r, $1 \leq r < \infty$. Let us now consider w and w^n the respective solutions

of problems (4.14) and (4.15) with respective coefficients $\overline{q}$ and $\overline{q}^n$. We also introduce the auxiliary functions v and v^n by the definition

$$v = \frac{e^p\, w}{(1-w) + w\, e^p}, \quad v^n = \frac{e^{p^n}\, w^n}{(1-w^n) + w^n\, e^{p^n}}.$$

Clearly, (v^n) is bounded in $H^1(Q)$ and v is in $H^1(Q)$ and they are solutions of the corresponding equations (4.18), with respective coefficients $(q, \overline{q})$ and $(q^n, \overline{q}^n)$, with the same boundary and initial conditions (4.19). Then, the difference $z^n = v - v^n$ satisfies

$$\begin{aligned}\partial_t z^n + \overline{q}^n\, \partial_x z^n =& (\overline{q}^n - \overline{q})\, \partial_x v + \overline{q}^n\, q^n\, (v + v^n - 1)\, z^n \\ &+ v(v-1)\, (q\,\overline{q} - q^n\, \overline{q}^n).\end{aligned}$$

Multiplying by $\operatorname{sign}(z^n)$ and integrating in x it follows

$$\begin{aligned}\frac{d}{dt}\int_0^1 |z^n|\, dx + \overline{q}^n(1,t)\, |z^n(1,t)| &\le \int_0^1 \partial_x(\overline{q}^n)\, |z^n|\, dx + \int_0^1 |\overline{q}^n - \overline{q}|\, |\partial_x v|\, dx \\ &+ M(M+\eta)\int_0^1 |z^n|\, dx + \frac{1}{4}\int_0^1 |q\,\overline{q} - q^n\,\overline{q}^n|\, dx \\ &\le \left(2\,M^2 + \frac{C}{\eta}\right)\int_0^1 |z^n|\, dx + \int_0^1 |\overline{q}^n - \overline{q}|\, |\partial_x v|\, dx \\ &+ \frac{M}{4}\int_0^1 |\overline{q} - \overline{q}^n|\, dx + \frac{M+\eta}{4}\int_0^1 |q - q^n|\, dx.\end{aligned}$$

Integrating in time, we obtain

$$\begin{aligned}\int_0^1 |z^n(x,t)|\, dx \le \left(2\,M^2 + \frac{C}{\eta}\right)\int_0^t\int_0^1 |z^n(x,s)|\, dx\, ds + \frac{C}{\sqrt{\eta}}\left(\int_0^t\int_0^1 |\overline{q}^n - \overline{q}|^2\, dx\, ds\right)^{1/2} \\ + \frac{M}{2}\int_0^t\int_0^1 (|\overline{q} - \overline{q}^n| + |q - q^n|)\, dx\, ds.\end{aligned}$$

For any $\varepsilon > 0$, we can find an integer N such that $n > N$ implies

$$\int_0^1 |Jz^n(x,t)J|\, dx \le K_5(\eta)\int_0^t\int_0^1 |Jz^n(x,s)J|\, dx\, ds + K_6(\eta)\,\varepsilon,$$

where $K_5(\eta)$ and $K_6(\eta)$ are constants. So, putting $y^n(t) = \int_0^1 |z^n(x,t)|\, dx$ we obtain, with Gronwall's lemma,

$$|y^n(t)| \le C(\eta)\,\varepsilon.$$

This means that v^n converges, as n tends to ∞, to v in $L^\infty(0,T; L^1(\Omega))$. Using the fact that (p^n) is uniformly bounded and weakly convergent to p, together with the relations linking w and v, one readily deduces that (w^n) converges, as n tends to ∞, to w in $L^r(Q)$, for any r, $1 \le r < \infty$. Lemma 4.7 is proved. Hence Proposition 4.3 follows.

We are now in a position to prove Theorem 3.2.

Proof of Theorem 3.2. Take a real sequence (η_n) which tends to 0 as n tends to ∞. For any n, there is a pair (p^n, u^n) solution of

$$a(u^n)\, \partial_t p^n - \partial_x^2 p^n = 0, \quad (x,t) \in Q, \tag{4.26}$$

$$\partial_t u^n + \overline{q}^n\, \partial_x u^n + \partial_t p^n\, b(u^n) = 0, \quad (x,t) \in Q, \tag{4.27}$$

satisfying the boundary and initial conditions (2.4)–(2.7), after a regularization in order to verify (4.12) and (4.13). Since (u^n) is bounded in the space $L^\infty(0,T;W^{1,1}(\Omega))\cap H^1(0,T;L^1(\Omega))$ (see Remark 4.5), there is a subsequence, still denoted (u^n) which converges to a function u in $L^1(Q)$ and therefore also in $L^r(Q)$ for any r, $1 \le r < \infty$. The sequence (p^n) is bounded in $L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega))$. Then there is a subsequence, still denoted (p^n), which converges, as n tends to ∞, weakly in $L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega))$ to a function p. By a compacity argument, $q^n = -\partial_x p^n$ converges, as n tends to ∞, to $q = -\partial_x p$ in $L^2(Q)$ for any r, $1 \le r < \infty$. Therefore, $\overline{q}^n$ converges, as n tends to ∞, to q in $L^r(Q)$ for any r, $1 \le r < \infty$, and also in $L^2(0,T;H^1(\Omega))$ weak. Trivially, $a(u^n)$ (resp., $b(u^n)$) converges, as n tends to ∞, to $a(u)$ (resp., $b(u)$) in $L^r(Q)$, for any r, $1 \le r < \infty$. Then, we can pass to the limit in (4.26). We obtain

$$\begin{cases} a(u)\partial_t p - \partial_x^2 p = 0, & (x,t) \in Q, \\ p(0,t) = 0, \quad q(1,t) = q_1(t), & t \in]0,T[, \\ p(x,0) = p_0(x), & x \in \Omega. \end{cases}$$

On the other hand, for any n and any φ in $C_0^1([0,1[J \times [0,T[)$,

$$\int_0^T \int_0^1 (u^n\, \partial_t \varphi + u^n\, \partial_x(\overline{q}^n\, \varphi) - b(u^n)\, \partial_t p^n\, \varphi)\, dx\, dt$$
$$= -\int_0^1 u_0(x)\, \varphi(x,0)\, dx - \int_0^T u_1(t)\, \overline{q}^n\, \varphi(0,t)\, dt,$$

and passing to the limit in each term is meaningful. Note in particular that the convergence of $\overline{q}^n$ to q in $L^2(0,T;H^1(\Omega))$ weak implies that of $\overline{q}^n(0,t)$ to $q(0,t)$ in $L^2(0,T)$ weak. The proof of Theorem 3.2 is now complete.

For uniqueness, we have only the following result.

THEOREM 4.8. *Let us assume that the data are smooth and satisfy the necessary compatibility conditions. Then,* (2.2)–(2.7) *has at most one solution* (p,u) *such that* u *belongs to* $C^\alpha(\overline{Q})$ *with* $\alpha > 0$.

Proof. Note first that if (p,u) is a solution of problem (2.2)–(2.7) with u in $C^\alpha(\overline{Q})$, $\alpha > 0$, then it is well known that p belongs to $C^{2+\alpha,1+\alpha/2}(\overline{Q})$ whenever the data are smooth and satisfy the necessary compatibility conditions. Now let (p,u) and $(\tilde{p},\tilde{u})$ be two solutions, with u and $\tilde{u}$ in $C^\alpha(\overline{Q})$, $\alpha > 0$. Setting $q = -\partial_x p$, $\tilde{q} = -\partial_x \tilde{p}$ and using equations of p and $\tilde{p}$, one can find a constant C such that

$$||\partial_t p - \partial_t \tilde{p}||^2_{L^2(Q)} + ||q - \tilde{q}||^2_{L^2(Q)} \le C\, ||u - \tilde{u}||^2_{L^2(Q)}.$$

Using equations satisfied by u and $\tilde{u}$ and the previous estimate, we show also that there is another constant C' such that

$$\int_0^1 |u(x,t) - \tilde{u}(x,t)|^2\, dx \le C' \int_0^t \int_0^1 |u(x,s) - \tilde{u}(x,s)|^2\, dx\, ds$$

for any t, $0 < t < T$. Hence $u = \tilde{u}$ by virtue of Gronwall's lemma, which proves the theorem.

5. A case of existence and uniqueness of a smooth solution. In this section we are concerned with system (2.2)–(2.3), which is provided with the boundary

and initial conditions

$$p(0,t) = p_1, \quad p(1,t) = p_2, \quad t \in]0,T[, \tag{5.1}$$

$$p(x,0) = p_0(x), \quad x \in \Omega, \tag{5.2}$$

$$u(0,t) = u_1(t), \quad t \in]0,T[\tag{5.3}$$

$$u(x,0) = u_0(x), \quad x \in \Omega, \tag{5.4}$$

where p_1 and p_2 are constants. Comparing this problem to (2.2)–(2.7), we note that we have only replaced (2.4) by (5.1). Assume conditions (2.10)–(2.11) are fulfilled and in addition,

$$p_0 \in C^{2,\overline{\alpha}}(\overline{\Omega}), \quad p_0(0) = p_1, \quad p_1(0) = p_2, \quad p_0''(0) = p_0''(1) = 0, \quad -p_0'' \geq 0, \tag{5.5}$$

$$\text{there exists} \quad m > 0 \quad \text{such that} \quad m \leq -p_0', \tag{5.6}$$

$$\begin{aligned} &u_0 \in C^{1,\overline{\alpha}}(\overline{\Omega}), \quad u_1 \in C^{1,\overline{\alpha}/2}([0,T]), \quad \text{with} \\ &u_0(0) = u_1(0), \quad u_1'(0) - p_0'(0)\, u_0'(0) = 0, \end{aligned} \tag{5.7}$$

$\overline{\alpha} > 0$ to be chosen later. We then state the next theorem.

THEOREM 5.1.

(i) *There is a constant β, $0 < \beta \leq \overline{\alpha}$, such that problem* (2.2)–(2.3), (5.1)–(5.7) *is uniquely solvable in the space $C^{2+\beta,1+\beta/2}(\overline{Q}) \times C^{\beta}(\overline{Q})$.*

(ii) *If, in addition, $0 < u_0(x) < 1$, $0 < u_1(t) < 1$, then u lies in $C^{1+\beta/2}(\overline{Q})$.*

The proof requires several steps. The essential point is the following result of Alkhutov and Mamedov [1] , see also Krylov [7]. Consider the boundary value problem

$$\begin{cases} \partial_t V - K(x,t)\, \partial_x^2 V = f, & (x,t) \in Q, \\ V(0,t) = V(1,t) = 0, & t \in]0,T[, \\ V(x,0) = 0, & x \in \Omega. \end{cases} \tag{5.8}$$

Previously, f is in $L^p(Q)$ and K is a given function in $L^\infty(Q)$ such that there is a constant $\alpha > 0$, with

$$\frac{1}{\alpha} \leq K(x,t) \leq \alpha \qquad \text{for almost every} \quad (x,t) \in Q.$$

Then (see Alkhutov and Mamedov [1], p. 480) we have the following lemma.

LEMMA 5.2. *Under the aforementioned hypotheses, there is σ_0, $0 < \sigma_0 < 1$, such that if $p \in [2-\sigma_0, 2+\sigma_0]$, then problem* (5.8) *is uniquely solvable in $W_p^{2,1}(Q)$ for each $f \in L^p(Q)$ where $W_p^{2,1}(Q) = \{v \in L^p(Q);\ v_t, v_x, v_{xx} \in L^p(Q)\}$.*

The first step consists in proving the next proposition.

PROPOSITION 5.3. *Problem* (2.2), (2.3), *and* (5.1)–(5.4) *admits a solution (p,u) in the space $L^2(0,T;H^2(\Omega)) \cap H^1(0,T;L^2(\Omega)) \times H^1(Q)$.*

Proof. It suffices to prove the estimate (4.22) with a constant $C_4(\eta)$ which is in fact independent of the parameter η. To do so, first note, by means of the maximum principle and the new boundary condition (5.1), that

$$m \leq q(x,t) \leq M \quad \text{for almost every} \quad (x,t) \in Q.$$

Next, using again the maximum principle, we can show that

$$\partial_x q(x,t) \geq 0 \qquad \text{for almost every} \quad (x,t) \in Q.$$

Then, from (4.25), after integration over $Q_t = \Omega\times]0,t[$, $0 < t < T$ it follows that

$$\frac{1}{2}\int_0^1 |\partial_x v(x,t)|^2\,dx + \frac{1}{2}\int_0^t \overline{q}(1,s)|\partial_x v(1,s)|^2\,ds + \frac{1}{2}\int_0^t\int_0^1 (\partial_x \overline{q}\,|\partial_x v(x,s)|^2)\,dx\,ds$$
$$= \frac{1}{2}\int_0^1 |\partial_x v(x,0)|^2\,dx + \frac{1}{2}\int_0^t \overline{q}(0,s)|\partial_x v(0,s)|^2\,ds + \int_0^t\int_0^1 \partial_x(v(v-1)q\,\overline{q})\,\partial_x v\,dx\,ds.$$

Since the three terms on the left side are positive, we have a similar estimate to (4.22) with a constant independent of η whenever

$$\int_0^t \overline{q}(0,s)\,|\partial_x v(0,s)J|^2\,ds \le C,$$

where C is a constant independent of η. This can be performed as in Lemma 4.6 with m playing the role of η. Note that we have assumed, as is permissible, that $\overline{q}$ and $\partial_x\overline{q}$ verify

$$\overline{q}(x,t) \ge m, \quad \partial_x\overline{q}(x,t) \ge 0 \quad \text{for almost every} \quad (x,t) \in Q.$$

We now use Lemma 5.2 to show the existence of a smoother solution.

PROPOSITION 5.4. *Let $r = 2 + \sigma_0$, with σ_0 given in Lemma 5.2. Then system (2.2)-(2.3) subject to conditions (5.1)–(5.7) admits a solution (p,u) such that*

(i) $p \in W_r^{2,1}(Q)$,

(ii) $\partial_x u \in L^\infty(0,T;L^r(\Omega))$,

(iii) $\partial_t u \in L^r(0,T;L^r(\Omega))$.

Proof. We use the result of Alkhutov and Mamedov [1], for u given in $\mathcal{C}$, and the solution p of problem (2.2), (5.1), and (5.2) satisfies the estimate

$$||p||_{W_r^{2,1}(Q)} \le C,$$

where C is a constant which depends only on the boundary and initial conditions on p. The exponent r depends only on the values of $a(u)$ and not on those of u. In fact, we must show (ii) and (iii). To do so, we proceed as in §4 by introducing the function v solution of

$$\partial_t v + q\,\partial_x v = v(v-1)\,q\,\overline{q}, \quad (x,t) \in Q, \tag{5.9}$$

$$\begin{aligned} &v(0,t) = u_1(t), \quad t \in]0,T[, \\ &v(x,0) = u_0(x)\,e^{p_0(x)}\,[\,(1-u_0(x)) + u_0(x)\,e^{p_0(x)}\,]^{-1}, \quad x \in \Omega. \end{aligned} \tag{5.10}$$

We must estimate $\partial_x v$ and $\partial_t v$ in $L^\infty(0,T;L^r(\Omega))$. This may be obtained as in the previous section by differentiating (5.9) with respect to x and multiplying by $|\partial_x v|^{r-2}\,\partial_x v$. This allows us to bound $\partial_x v$ and $\partial_t v$ in $L^\infty(0,T;L^r(\Omega))$ and therefore $\partial_x u$ and $\partial_t u$ in $L^\infty(0,T;L^r(\Omega))$ and $L^r(0,T;L^r(\Omega))$ according to the relation

$$u = \frac{e^{-p}\,v}{(1-v) + v\,e^{-p}}.$$

Proposition 5.4 is proved.

Proof of Theorem 5.1. We put $\beta = 1 - \frac{2}{r}$ and assume $\beta \le \overline{\alpha}$. In view of Sobolev's imbedding theorem, since u belongs to $W^{1,r}(Q)$, u is in $C^\beta(\overline{Q})$. Therefore, we see that

by using the pressure equation, if follows, according to Theorem 12.2 in Ladyzhenskaya, Solonnikov and Ural'tseva [8], that p belongs to $C^{2+\beta,1+\beta/2}(\overline{Q})$. Next, if we assume that $0 < u_0 < 1$, $0 < u_1 < 1$, we can introduce the function h (as in Lemma 4.4 with $\varepsilon = 0$) solution of the problem

$$\begin{cases} \partial_t h + q\,\partial_x h = -q^2, & (x,t) \in Q, \\ h(x,0) = \ln\left(\dfrac{u_0(x)}{1-u_0(x)}\right) + p_0(x), & x \in \Omega, \\ h(0,t) = \ln\left(\dfrac{u_1(t)}{1-u_1(t)}\right), & t \in]0,T[. \end{cases}$$

By the method of characteristics one can easily prove, since q and $\partial_x q$ are in $C^{\beta/2}(\overline{Q})$, that h is in $C^{1+\beta/2}(\overline{Q})$. The second part of Theorem 5.1 follows from the relation

$$u = \frac{e^{h-p}}{1+e^{h-p}}.$$

This completes the proof.

ON ASYMPTOTIC SELF-SIMILAR BEHAVIOUR FOR A QUASILINEAR HEAT EQUATION: SINGLE POINT BLOW-UP *

VICTOR A. GALAKTIONOV†

Abstract. The author studies the asymptotic behaviour near a finite blow-up time $t = T$ of solutions to the degenerate quasilinear parabolic equation

$$u_t = (u^\sigma u_x)_x + u^\beta \quad \text{in } \mathbb{R} \times (0, T),$$

where $\sigma > 0$ and $\beta > \sigma + 1$ are fixed constants. These values of parameters σ, β correspond to single point blow-up. The initial function is assumed to be bounded, symmetric, nonincreasing in $|x|$, and compactly supported. It is proved that the rescaled function $f(\xi, t) = (T-t)^{1/(\beta-1)} u(\xi(T-t)^m, t), m = [\beta - (\sigma+1)]/2(\beta-1) > 0$, behaves as $t \to T$ like a nontrivial self-similar profile $\theta(\xi) > 0$ in $\mathbb{R}, \theta(\xi) \to 0$ as $\xi \to \infty$.

Key words. quasilinear heat equation, single point blow-up, asymptotic behaviour, nonconstant self-similar solution

AMS subject classifications. 34E10, 35B40, 35K55, 35K65

1. Introduction and main result.

We consider the Cauchy problem for the one-dimensional quasilinear degenerate parabolic equation:

$$u_t = (u^\sigma u_x)_x + u^\beta \quad \text{for } x \in \mathbb{R}, t > 0, \tag{1.1}$$

$$u(x, 0) = u_0(x) \geq 0 \quad \text{in } \mathbb{R}; \qquad u_0 \not\equiv 0, \quad \sup u_0 < \infty, \tag{1.2}$$

where $\sigma > 0$ and $\beta > 1$ are fixed constants. This problem is a mathematical model of combustion in a medium where both heat conduction coefficient $k(u) = u^\sigma$ and heat source $Q(u) = u^\beta$ depend upon the temperature $u = u(x, t) \geq 0$. Local in time existence of a weak solution, uniqueness and comparison results for (1.1) and (1.2) are well known; see [4]–[6], [25], [27]–[30], and the references therein. The solution $u = u(x, t)$ is a nonnegative continuous compactly supported function, which is the classical one at any point where $u > 0$. If $1 < \beta < \sigma + 3$, then for a given arbitrary initial function $u_0 \not\equiv 0$, the solution blows up in a finite time $T > 0$ so that

$$\sup_{x \in \mathbb{R}} u(x, t) \to \infty \quad \text{as } t \to T. \tag{1.3}$$

T is then called a finite blow-up time. If $\beta \geq \sigma + 3$, then (1.3) holds for any initial function u_0 large enough (cf. [15] and [30, p. 208]). We assume that the solution $u(x, t)$ of (1.1) and (1.2) blows up as $t \to T$, where T depends on the initial function and exponents σ, β. We also assume that

$$\begin{gathered} u_0 = u_0(|x|), u_0 \text{ does not increase,} \\ u_0 \text{ is a compactly supported function,} \\ \sup |(u_0^\sigma)_x| < \infty. \end{gathered} \tag{1.4}$$

Then by uniqueness and by the maximum principle we have that $u = u(|x|,t) \geq 0$ in $\mathbb{R} \times (0,T)$, $u(|x|,t)$ does not increase in $|x|$ for any fixed $t \in (0,T)$, and

$$\operatorname{supp} u(x,t) \equiv \{x \in \mathbb{R} | u(x,t) > 0\} = (-h(t), h(t)), \tag{1.5}$$

where $h(t) > 0$ for $t \in [0,T)$ is a continuous nondecreasing function. See a full list of references in [25] concerning properties of interfaces corresponding to weak solutions of degenerate nonlinear heat equations of the type (1.1).

For $\beta \geq \sigma+1$, heat interfaces of a general compactly supported solution have been proved to be localized [11] (see also [30, p. 235]). Namely, there exists the constant $\xi_* = \xi_*(\sigma,\beta) > 0$ such that under above hypotheses on any $t \in [0,T)$

$$h(t) \leq h(0) + \xi_* T^m, \qquad m = \frac{\beta - (\sigma+1)}{2(\beta-1)} \geq 0. \tag{1.6}$$

For $\beta = \sigma + 1$ $(m = 0)$ we have $\xi_*(\sigma, \sigma+1) = L_s/2 \equiv \pi(\sigma+1)^{1/2}/\sigma$, and (1.6) yields the best possible upper estimate [13] (see also [14]): $h(t) \leq h(0) + L_s/2$ in $(0,T)$. If $1 < \beta < \sigma + 1$ $(m < 0)$, then the solution is not localized, $u(|x|,t) \to \infty$ as $t \to T$ for any $x \in \mathbb{R}$ [15], [10] (see also [30, p. 383]), and there holds

$$h(t) = \xi_0 (T-t)^m (1 + o(1)) \to \infty \quad \text{as } t \to T \tag{1.7}$$

(cf. [30, p. 248]), where $\xi_0 = \xi_0(\sigma,\beta) > 0$. Above estimates of interfaces of blowing up solutions have been proved by the method of intersection comparison of $u(x,t)$ with explicit blowing up self-similar solutions of (1.1), which will be discussed later.

This paper is devoted to the analysis of the asymptotic behaviour of the solution near a finite blow-up time for the case $\beta > \sigma + 1$ which corresponds to *single point blow-up*; see [18] and [30, Chap. IV]. We prove that under above hypotheses on the initial function, the solution has a space-time structure of nonconstant self-similar solution near a finite blow-up time. The asymptotic stability of the unique nontrivial symmetric self-similar solution $u_*(x,t) = (T-t)^{-1/\sigma}\theta(x)$ of (1.1) with $\beta = \sigma + 1$ (regional blow-up) has been proved in [12]; see also [30, p. 243].

1.1. Self-similar solution for $\beta > \sigma + 1$. Equation (1.1) admits a blowing up self-similar solution of the form

$$u_*(x,t) = (T-t)^{-1/(\beta-1)}\theta(\xi), \qquad \xi = |x|/(T-t)^m, \tag{1.8}$$

where the function $\theta \geq 0$ satisfies the following nonlinear ordinary differential equation derived by substituting (1.8) into (1.1):

$$A(\theta) \equiv (\theta^\sigma \theta')' - m\theta'\xi - \frac{1}{\beta-1}\theta + \theta^\beta = 0 \quad \text{for } \xi > 0, \tag{1.9}$$

and the symmetry boundary condition

$$\theta'(0) = 0 \ (\theta(0) > 0). \tag{1.10}$$

Problem (1.9), (1.10) with $\beta > \sigma + 1$ admits a positive strictly decreasing solution [1] (see also [30, p. 190] for N-dimensional analysis of a similar equation) having the following behaviour at infinity:

$$\theta(\xi) = C_* \xi^{-2/(\beta-(\sigma+1))}(1 + o(1)) \to 0 \quad \text{as } \xi \to \infty, \tag{1.11}$$

where the constant $C_* > 0$ depends on exponents σ and β. Notice that any solution $\theta(\xi) \geq 0$ in $\mathbb{R}_+$ satisfies (1.11) with some constant $C_* > 0$. Hence, (1.8) is the classical blowing up solution defined in $\mathbb{R} \times [0, T)$. Any solution of (1.9) that satisfies (1.10) and (1.11) is uniformly bounded:

$$\sup_{\xi \in \mathbb{R}} \theta(\xi) < \left(\frac{\beta + \sigma + 1}{(\beta - 1)(\sigma + 2)} \right)^{1/(\beta-1)}$$

(cf. [1] and [30, p. 187]). It follows from (1.8) and (1.11) that for $x \neq 0$

$$u_*(x,t) \to C_* |x|^{-2/(\beta-(\sigma+1))} \quad \text{as } t \to T. \tag{1.12}$$

Moreover, solution (1.8) satisfies $u_t > 0$ in $\mathbb{R} \times [0, T)$ [30, p. 190], and hence

$$u_*(x,t) < C_* |x|^{-2/(\beta-(\sigma+1))} \quad \text{in } (\mathbb{R} \backslash \{0\}) \times [0, T). \tag{1.13}$$

Therefore, $u_*(x,t)$ blows up at the single point $x = 0$. Uniqueness of self-similar solution (1.8) with monotone for $\xi > 0$ function θ remains an open problem. Notice that in general problem (1.9) and (1.10) has at least $M = -[-1/2m] - 1$ ($[p]$ denotes the entire part of p) different positive solutions $\theta_1, \theta_2, \ldots, \theta_M$, where $\theta_k(\xi)$ has exactly k maxima and minima for $\xi \geq 0$; see [1] and [30, p. 188]. The problem of the structure of stable manifolds corresponding to such nonmonotone solutions θ_k is open now.

1.2. The main result. We prove that the asymptotic behaviour as $t \to T$ of the solution $u(x,t), \beta > \sigma + 1$, is described by a blowing up self-similar solution (1.8) having the same blow-up time T. By using a standard technique, we now state the above problem as follows. Let us introduce the new rescaled function:

$$f(\xi, \tau) = (T - t)^{1/(\beta-1)} u(\xi (T - t)^m, t), \tag{1.14}$$

where $\tau = -\log(T - t)$: $[0, T) \to [\tau_0, \infty), \tau_0 = -\log T$, is the new time. Then $f(\xi, \tau)$ satisfies the quasilinear parabolic equation

$$f_\tau = A(f) \quad \text{in } \mathbb{R} \times (\tau_0, \infty), \tag{1.15}$$

$$f(\xi, \tau_0) = f_0(\xi) \equiv T^{1/(\beta-1)} u_0(\xi T^m) \quad \text{in } \mathbb{R}, \tag{1.16}$$

where A is the stationary operator given in (1.9) and f_0 is a nonnegative symmetric compactly supported initial function. Denote by

$$\begin{aligned} \omega(f_0) = \{ & g = g(|\xi|) \geq 0, \quad g \in \mathbb{C}(\mathbb{R}) \mid \exists \tau_j \to \infty \text{ such that} \\ & f(\cdot, \tau_j) \to g(\cdot) \quad \text{as } \tau_j \to \infty \text{ uniformly on compacts in } \mathbb{R} \} \end{aligned} \tag{1.17}$$

the ω-limit set of the solution to the problem (1.15) and (1.16). Therefore the problem of the asymptotic behaviour of $u(x,t)$ near a finite blow-up time $t = T$ is reduced to the problem of stabilization as $\tau \to \infty$ to stationary solutions of equation (1.15).

We now state the main result of the paper.

THEOREM 1.1. *Let $\beta > \sigma + 1$. Assume that* (1.4) *holds. Then*

$$\omega(f_0) \subseteq \{ \theta = \theta(|\xi|) > 0 \mid \theta(\cdot) \textit{ satisfies } (1.9)\text{–}(1.11) \}. \tag{1.18}$$

If problem (1.9)–(1.11) admits a unique, strictly monotone solution $\theta > 0$ (we expect that this is true in one-dimensional case), then (1.18) implies that

$$f(\xi,\tau) \to \theta(\xi) \quad \text{as} \quad \tau \to \infty$$

uniformly on compacts in ξ. Notice also that since $\omega(f_0) \neq \varnothing$ by definition, (1.18) by itself yields the existence of at least one nonnegative weak solution to the stationary problem (1.9) and (1.10).

The main difficulties in the proof of Theorem 1.1 are as follows. The first one is to prove that the constant profile $\theta \equiv (\beta-1)^{-1/(\beta-1)}$ satisfying (1.9) does not appear in the ω-limit. On the other hand, the second difficulty is the fact that degenerate equation (1.15) and (1.9) is not of divergence form, and any explicit Lyapunov function with good properties cannot be constructed. We also need some additional sharp upper and lower estimates of the solution near $t = T$. See §§2–5.

Finally, we note that in the semilinear equation (1.1) with $\sigma = 0$ the corresponding ω-limit set consists of the unique constant profile $\theta \equiv (\beta-1)^{-1/(\beta-1)}$. This has been proved in [19] (see also [20]) by deriving certain upper and lower bounds of solutions and using the construction of an explicit Lyapunov function for the rescaled equation (1.15) and nonexistence result for equation (1.9), $\sigma = 0$, which was proved in [2]. General results on nonexistence of nontrivial self-similar solutions for the N-dimensional equation $u_t = \Delta u + u^\beta$ with $1 < \beta \le (N+2)/(N-2)_+$ and the corresponding formal Lyapunov analysis have been done in [22]. Necessary bounds of a wide class of solutions were proved in [23]. It is interesting that a similar Lyapunov function yields important results about ω-limits for the heat equation with the critical absorption exponent $u_t = \Delta u - u^{1+2/N}$; see [16] and also [30, pp. 121–125]. In this case the choice of a unique, stable nonconstant asymptotic profile is made by using a so-called energy equation for the norm of the solution in the corresponding weighted L^1-space [16], [30, p. 125]. For the quasilinear equation $u_t = \operatorname{div}(u^\sigma \nabla u) - u^{\sigma+1+2/N}$ with $\sigma > 0$, a similar result has been proved in [21] without using a Lyapunov function for the corresponding rescaled equation.

2. First estimates. We begin with simple lower and upper estimates of the solution.

PROPOSITION 2.1 ([30, Chap. IV]). *Assume that* (1.4) *holds. Then*

$$f(0,\tau) > (\beta-1)^{-1/(\beta-1)} = \theta_0 > 0 \quad \textit{for } \tau > \tau_0, \tag{2.1}$$

and there exists a constant $\mu_* > 0$ *such that*

$$f(\xi,\tau) \le \mu_* \quad \textit{in } \mathbb{R} \times (\tau_0,\infty). \tag{2.2}$$

Estimate (2.1) implies that $\omega(f_0)$ does not contain the function $g \equiv 0$. It follows from (2.2) that $\omega(f_0)$ consists of uniformly bounded functions. Notice that $f(\xi,\tau)$ is a compactly supported function for $\tau > \tau_0$ and (1.6) and (1.14) yield

$$\operatorname{supp} f(\xi,\tau) = \{|\xi| < p(\tau)\}, \tag{2.3}$$

where

$$p(\tau) = O(\exp(\tau m)) \to \infty \quad \text{as } \tau \to \infty. \tag{2.4}$$

By using (2.2) and Bernstein-type estimates in the form [3] (cf. general results in [5] and [6]), we obtain the following estimate.

PROPOSITION 2.2. *Under hypotheses* (1.4) *there exists a constant* $\mu_1 > 0$ *such that*

$$|(f^{\sigma+1})_\xi| \le \mu_1 \quad \text{in } \mathbb{R} \times (\tau_0, \infty). \tag{2.5}$$

This implies that the ω-limit set, $\omega(f_0)$, is well defined by (1.17).

The stationary equation

$$A(\theta) = 0 \quad \text{in } \mathbb{R} \tag{2.6}$$

admits the unique nontrivial constant solution $\theta \equiv \theta_0$ in $\mathbb{R}$. The following result implies that $\{g \equiv \theta_0\} \cap \omega(f_0) = \varnothing$.

LEMMA 2.3. *Assume that* (1.4) *holds. Then there exist constants* $C_0 > 0$ *and* $\gamma_0 > \theta_0$ *such that as* $\tau \to \infty$

$$f(\xi, \tau) \le C_0 |\xi|^{-2/(\beta-(\sigma+1))} \quad \text{for } |\xi| > 0, \tag{2.7}$$

$$f(0, \tau) \ge \gamma_0. \tag{2.8}$$

Proof. It was proved in [18] by using the beautiful idea from [8] that under hypotheses (1.4) and the following additional assumption on the initial function

$$u_0^\sigma u_0' + \lambda_0 x u_0^\beta \le 0 \quad \text{in } \mathbb{R}_+, \tag{2.9}$$

where $\lambda_0 \in (0, \lambda_*]$, $\lambda_* = \sigma/(\sigma+2\beta) < 1$, is an arbitrary constant, there holds $J(x,t) = u^\sigma u_x + \lambda_0 x u^\beta \le 0$ in $\mathbb{R}_+ \times (0,T)$. Consider now arbitrary initial data satisfying (1.4). Fix $t_0 \in (0,T)$ and $\delta > 0$ small enough. Since $\beta > \sigma + 1$, we have that $u^{\sigma-\beta} u_x < 0$ is not integrable in x on $(h(t) - \delta, h(t))$. Therefore, for any $t \in [t_0, T)$ there exists $\xi_\delta(t) \in (h(t)-\delta, h(t))$ such that $J(\xi_\delta(t), t) < 0$. Since by the strong maximum principle [7] $(u^{\sigma+1})_{xx}(0, t_0) < 0$, we then conclude that $J(x, t_0) \le 0$ in $(0, \xi_\delta(t_0))$ provided that $\lambda_0 > 0$ is small. Hence it follows from [18] that $J \le 0$ in $(0, h(t) - \delta) \times (t_0, T)$. Since $\delta > 0$ is small, integrating this inequality over $(0, x)$ yields (2.7) with

$$C_0 = \left[\frac{\beta - (\sigma+1)}{2} \lambda_0 \right]^{-1/(\beta-(\sigma+1))}$$

Since $J(0,t) \equiv 0$ we have that $J_x(0,t) \equiv (u^\sigma u_x)_x + \lambda_0 u^\beta \le 0$. This implies that $u_t \le (1 - \lambda_0) u^\beta$ for $x = 0$, and integrating over (t, T) leads to (2.8) with $\gamma_0 = (1 - \lambda_0)^{-1/(\beta-1)} \theta_0$. □

From (2.7) and (2.8) we conclude that if $g \in \omega(f_0)$, then

$$g(0) > \theta_0 \quad \text{and} \quad g(\xi) \to 0 \quad \text{as } |\xi| \to \infty. \tag{2.10}$$

The proof of Theorem 1.1 is based on the construction of a suitable Lyapunov function corresponding to (1.15).

3. Lyapunov function. Set

$$v(\xi, \tau) = f^{\sigma+1}(\xi, \tau). \tag{3.1}$$

Then $v(\xi,\tau) \geq 0$ solves the equation

$$v_\tau = a(v)v_{\xi\xi} + b(\xi, v, v_\xi) \quad \text{in } \mathbb{R} \times (\tau_0, \infty), \tag{3.2}$$

$$v(\xi, 0) = v_0(\xi) \equiv f_0^{\sigma+1}(\xi) \quad \text{in } \mathbb{R}, \tag{3.3}$$

where the coefficients

$$a(v) = |v|^{\sigma/(\sigma+1)}, \tag{3.4}$$

$$b(\xi, v, w) = -m\xi w - \frac{\sigma+1}{\beta-1}v + (\sigma+1)|v|^{(\beta-1)/(\sigma+1)}v, \tag{3.5}$$

are now defined for arbitrary values $v \in \mathbb{R}$. We shall use a general approach to the construction of the Lyapunov function which is due to [31].

For fixed $\xi_0 \geq 0, v_0, w_0$, denote by $\varphi(\xi_0, \xi, v_0, w_0)$ the solution to the ordinary differential equation

$$a(\varphi)\varphi''_{\xi\xi} + b(\xi, \varphi, \varphi'_\xi) = 0 \tag{3.6}$$

either for $\xi \in [0, \xi_0]$ or for $\xi \in [\xi_0, \infty)$, with boundary conditions

$$\varphi|_{\xi=\xi_0} = v_0, \qquad \varphi'_\xi|_{\xi=\xi_0} = w_0. \tag{3.7}$$

Equation (3.6) is a degenerate one. Therefore, formally we have no automatically good properties (e.g., existence, uniqueness, continuous dependence upon parameters, etc.) of the solution that we need for the construction of a Lyapunov function. According to [31], the existence of a Lyapunov function will depend on the aforementioned properties of solutions φ.

3.1. Good and bad properties of functions φ. We begin with some simple preliminary good properties of solutions to (3.6) and (3.7). We shall denote by $\varphi'(\xi_0, \xi, v_0, w_0)$ the derivative $\varphi'_\xi(\xi_0, \xi, v_0, w_0)$.

PROPOSITION 3.1 (see [1] and [30, Chap. IV]). *For any fixed $\xi_0 \geq 0, v_0, w_0$, there exists a weak solution $\varphi(\xi_0, \xi, v_0, w_0)$ of (3.6) and (3.7), a $\mathbb{C}^1$-function for $\xi \in [0, \infty)$, which is bounded with its derivative $\varphi'(\xi_0, \xi, v_0, w_0)$ on any compact in ξ, and $\varphi \in \mathbb{C}^\infty$ at any point where $\varphi \neq 0$.*

Thus, any local in ξ weak solution of (3.6) can be extended for the half-space $[0, \infty)$. Notice that by well-known Bernstein estimates, if $|\varphi| \leq c_1$ on a compact $K = [\xi_1, \xi_2]$ then $|\varphi'|_{\xi_1}^{\xi_2}| \leq c_2$ on K, where the constant c_2 depends on c_1, K, σ, and β. By dividing (3.6) over $a(\varphi)$ and integrating over (ξ_1, ξ_2), we have that $|\varphi'|_{\xi_1}^{\xi_2}|$ is small provided that $|\varphi|$ is small on K; see also [1] and estimates in [17].

The following result is the straightforward consequence of the structure of degenerate equation (3.6) (cf. a similar result in [17, p. 169] for a different degenerate equation).

PROPOSITION 3.2. *Fix some $\xi_0 \geq 0, v_0, w_0$ and an arbitrary compact $K \subset \bar{\mathbb{R}}_+ = [0, \infty)$, such that $\xi_0 \in K$. Assume that the solution $\varphi(\xi_0, \xi, v_0, w_0)$ of (3.6) and (3.7) satisfies*

$$\varphi^2 + (\varphi')^2 \neq 0 \quad \text{for any } \xi \in K. \tag{3.8}$$

Then the functions $\varphi(\xi_0, \xi, v_0, w_0)$ and $\varphi'(\xi_0, \xi, v_0, w_0)$ are continuous on K with respect to small perturbations of the parameters ξ_0, v_0, w_0.

Since (3.6) is degenerate, the continuous dependence on parameters and the uniqueness of the solution to (3.6), (3.7) on K may not exist if $v_0^2 + w_0^2 = 0$, or, in general, if (3.8) is not valid. But it is important that in any case we have the uniqueness to the left of $\xi = \xi_0 > 0$.

PROPOSITION 3.3. *For any given* $\xi_0 > 0$ *and* $v_0 = w_0 = 0$ *there exists the following unique solution to* (3.6) *and* (3.7) *for* $\xi < \xi_0$:

$$\varphi(\xi_0, \xi, 0, 0) \equiv 0 \quad \text{for } \xi \in [0, \xi_0]. \tag{3.9}$$

This is easily proved by a local analysis of (3.6) in a small left neighbourhood of the point $\xi = \xi_0$; see [1], [9], and [24].

We now state some bad properties of "nonuniqueness to the right" to solutions of the degenerate nonlinear equation (3.6).

PROPOSITION 3.4. *For any fixed* $\xi_0 > 0$ *and* $v_0 = w_0 = 0$, *problem* (3.6)–(3.7) *for* $\xi > \xi_0$ *has the unique solution* $\varphi_*(\xi_0, \xi, 0, 0) > 0$ *in a small right neighbourhood of the point* $\xi = \xi_0$.

The proof is based on using the Banach contraction principle applied to the integral equation being equivalent to (3.6) and (3.7) with $v_0 = w_0 = 0$ in a small right neighbourhood of $\xi = \xi_0$. See a similar analysis in [24] and [9] of equations with a degeneracy of the type as given in (3.6). The uniqueness result in Proposition 3.3 is the direct consequence of the structure of the integral equation previously mentioned. A local analysis of the integral equation yields the following behaviour of the solution φ_* for $\xi > \xi_0$:

$$\varphi_*(\xi_0, \xi, 0, 0) = (m\sigma\xi_0(\xi - \xi_0))^{(\sigma+1)/\sigma}(1 + o(1)) \quad \text{as } \xi \to \xi_0 + 0. \tag{3.10a}$$

In the case $\xi_0 = 0$ from the previous integral equation we have the estimate of a solution which could be nonunique,

$$\varphi_*(0, \xi, 0, 0) \le (\text{const } \xi^2)^{(\sigma+1)/\sigma} \quad \text{as } \xi \to +0. \tag{3.10b}$$

By Proposition 3.3, we have that $\varphi_*(\xi_0, \xi, 0, 0) \equiv 0$ for any $\xi \in [0, \xi_0]$.

Thus, for any given $\xi_0 > 0$ problem (3.6) and (3.7) with $v_0 = w_0 = 0$ has the following one-dimensional family of different solutions:

$$\varphi(\xi_0, \xi, 0, 0) = 0 \quad \text{for } 0 \le \xi \le \xi_*, \tag{3.11}$$

$$\varphi(\xi_0, \xi, 0, 0) = \pm\varphi_*(\xi_*, \xi, 0, 0) \quad \text{for } \xi > \xi_*, \tag{3.12}$$

where $\xi_* \ge \xi_0$ is an arbitrary constant. We now sum up bad properties which we will need later.

PROPOSITION 3.5. *There exists a maximal set* $B_* \subset \mathbb{R}^3_+ = \{\xi_0 > 0, v_0 \in \mathbb{R}, w_0 \in \mathbb{R}\}$ *of parameters* (ξ_0, v_0, w_0) *such that for any point* $S \equiv (\xi_0, v_0, w_0) \in B_*$ *the solution* $\varphi(\xi_0, \xi, v_0, w_0)$ *satisfies*

$$\exists \xi_* \in [0, \xi_0] \text{ such that (cf. (3.8))}$$
$$(\varphi(\xi_0, \xi_*, v_0, w_0))^2 + (\varphi'(\xi_0, \xi_*, v_0, w_0))^2 = 0, \tag{3.13}$$

and hence by Proposition 3.3

$$\varphi(\xi_0, \xi, v_0, w_0) \equiv 0 \quad \text{for } \xi \in [0, \xi_*]. \tag{3.14}$$

Notice that, by Proposition 3.2, if $S \notin B_*$ then (3.8) holds on any compact K, and hence there exist uniqueness and continuous dependence of the solution $\varphi(\xi_0, \xi, v_0, w_0)$ on K.

The set B_* that was given also has some good properties.

PROPOSITION 3.6. *Fix arbitrary $(\xi_0, v_0, w_0) \in B_*$. Then, uniformly on $[0, \xi_0]$, the functions $\varphi(\xi_0, \xi, v_0, w_0)$ and φ' are continuous with respect to a small perturbation of parameters ξ_0, v_0, w_0 and in particular*

$$\varphi(\xi_0, \xi, v, w) \to 0 \quad \text{as } v \to v_0, w \to w_0 \tag{3.15}$$

uniformly on $[0, \xi_*]$, where $\xi_* \in [0, \xi_0]$ is given by (3.13).

Proof. First of all, by Proposition 3.2 there exists a continuous dependence of the solution φ and the derivative φ' on any compact subset $K_\varepsilon = [\xi_* + \varepsilon, \xi_0]$ (we now suppose that $0 < \xi_* < \xi_0$), where $\varepsilon > 0$ is an arbitrarily small constant. Suppose on the contrary that there is no continuous dependence of $\varphi(\xi_0, \xi, v_0, w_0)$ on $[0, \xi_*]$. Without loss of generality we may assume that there exist suitable sequences $\{\xi_{0k}\} \to \xi_0, \{v_{0k}\} \to v_0, \{w_{0k}\} \to w_0$ such that the functional sequence $\{\varphi(\xi_{0k}, \xi, v_{0k}, w_{0k})\}$ does not converge to $\varphi(\xi_0, \xi, v_0, w_0) \equiv 0$ as $k \to \infty$ uniformly on $[0, \xi_*]$. Then by standard compactness argument for ordinary differential equations (see Proposition 3.1 and comments given after it), we conclude that there exists a subsequence $\{k'\}$ such that

$$\varphi(\xi_{0k'}, \xi, v_{0k'}, w_{0k'}) \to \bar{\varphi}(\xi) \quad \text{as } k' \to \infty$$

uniformly on $[0, \xi_0]$, where $\bar{\varphi} \in \mathbb{C}^1$ is a weak solution to (3.6) on $[0, \xi_0]$ and $\bar{\varphi} \not\equiv 0$ on $[0, \xi_*]$ by assumption. Since $\bar{\varphi}(\xi) \equiv \varphi(\xi_0, \xi, v_0, w_0)$ on $[\xi_*, \xi_0]$, we have that $\bar{\varphi}(\xi_*) = \bar{\varphi}'(\xi_*) = 0$. Therefore the assertion $\bar{\varphi} \not\equiv 0$ on $[0, \xi_*]$ contradicts Proposition 3.3. Thus, $\bar{\varphi} \equiv 0$ on $[0, \xi_*]$ and that $\varphi' \to 0$ as $k \to \infty$ follows from the gradient estimate stated after Proposition 3.1. This completes the proof. □

3.2. Formal construction of Lyapunov function. Assume now for a moment that (3.2) is a uniformly parabolic equation with smooth bounded coefficients, and suppose that there is no problem with integrabilities at $\xi = \infty$ of given functions on solutions $v(\xi, \tau)$. Then, according to a general approach [31], there exists a formal Lyapunov function of the form

$$L[v](\tau) = \int_{\mathbb{R}} \Phi(\xi, v(\tau), v_\xi(\tau))\, d\xi, \tag{3.16}$$

which is nonincreasing on evolution trajectories corresponding to different solutions $v(\xi, \tau)$:

$$\frac{d}{d\tau} L[v](\tau) = -\int_{\mathbb{R}} \rho(\xi, v, v_\xi)(v_\tau)^2\, d\xi \le 0 \quad \text{for } \tau > \tau_0. \tag{3.17}$$

The functions $\rho(\xi, v, w) \ge 0$ and $\Phi(\xi, v, w)$ are determined as follows.

By using the structure of (3.2) that has a general form, we deduce that (3.17) holds if functions ρ and Φ, assumed to be smooth enough, satisfy the following system of linear partial differential equations:

$$\rho b = -\Phi_v + \Phi_{\xi w} + w\Phi_{vw}, \qquad \rho a = \Phi_{ww}, \tag{3.18}$$

where the coefficients $a(v)$ and $b(\xi, v, w)$ are given in (3.4) and (3.5). Indeed, by formal calculations

$$\frac{d}{d\tau} \int \Phi = \int (\Phi_v v_\tau + \Phi_w v_{\tau\xi}).$$

Integrating by parts in the last term yields

$$\int \Phi_w v_{\tau\xi} = -\int \frac{\partial}{\partial\xi}(\Phi_w)v_\tau = -\int (\Phi_{\xi w} + \Phi_{vw}v_\xi + \Phi_{ww}v_{\xi\xi})v_\tau.$$

Finally, since $v_{\xi\xi} \equiv (v_\tau - b)/a$, we obtain that

$$\frac{d}{d\tau}\int \Phi = \int \left\{ \left[\Phi_v - \Phi_{\xi w} - \Phi_{vw}v_\xi + \frac{b}{a}\Phi_{ww} \right] v_\tau - \frac{1}{a}\Phi_{ww}(v_\tau)^2 \right\}.$$

Hence, (3.17) is valid provided that (3.18) holds. From (3.18) we obtain the linear first-order equation for the function ρ,

$$b\rho_w - aw\rho_v - a\rho_\xi = \rho(wa'_v + a'_\xi - b'_w), \tag{3.19}$$

which can be easily solved by the characteristic's method.

Denote

$$F(\xi, v_0, w_0) = \left. \frac{wa'_v + a'_\xi - b'_w}{a} \right|_{\substack{v=\varphi(0,\xi,v_0,w_0) \\ w=\varphi'(0,\xi,v_0,w_0)}}. \tag{3.20}$$

Then we have

$$\rho(\xi, v, w) = G(v_0, w_0) \exp\left\{ -\int_0^\xi F(\zeta, v_0, w_0)\, d\zeta \right\}\Bigg|_{\substack{v_0=\varphi(\xi,0,v,w) \\ w_0=\varphi'(\xi,0,v,w)}}, \tag{3.21}$$

where G is an arbitrary smooth function to be determined later, and as above $\varphi'(\xi, 0, v, w) = \varphi'_\eta(\xi, \eta, v, w)$ with $\eta = 0$, and

$$\Phi(\xi, v, w) = a\int_0^w (w - \eta)\rho(\xi, v, \eta)\, d\eta + z(\xi, v), \tag{3.22}$$

$$z(\xi, v) = -\int_0^v b(\xi, \mu, 0)\rho(\xi, \mu, 0)\, d\mu. \tag{3.23}$$

It is easily calculated that for coefficients given in (3.4) and (3.5) there holds

$$F(\xi, v_0, w_0) = \frac{\sigma}{\sigma+1}\frac{\varphi'}{\varphi} + m\xi|\varphi|^{-\sigma/(\sigma+1)} \equiv \frac{\sigma}{\sigma+1}(\log|\varphi|)' + m\xi|\varphi|^{-\sigma/(\sigma+1)}, \tag{3.24}$$

where $\varphi = \varphi(0, \xi, v_0, w_0)$. Hence, setting $G(v_0, w_0) = |v_0|^{-\sigma/(\sigma+1)}$, we deduce that

$$\rho(\xi, v, w) = |v|^{-\sigma/(\sigma+1)} \times \exp\left\{ -m\int_0^\xi \zeta|\varphi(0, \zeta, \varphi(\xi, 0, v, w), \varphi'(\xi, 0, v, w))|^{-\sigma/(\sigma+1)}\, d\zeta \right\}. \tag{3.25}$$

It follows from (3.22) and (3.23) that

$$\begin{aligned} \Phi(\xi, v, w) = {} & |v|^{\sigma/(\sigma+1)} \int_0^w (w - \eta)\rho(\xi, v, \eta)\, d\eta \\ & - \int_0^v \rho(\xi, \mu, 0)\left[-\frac{\sigma+1}{\beta-1}\mu + (\sigma+1)|\mu|^{(\beta-1)/(\sigma+1)}\mu \right] d\mu. \end{aligned} \tag{3.26}$$

Notice that formally the Lyapunov function (3.16) satisfies the identity

$$L[v](S) - L[v](\tau_0) = -\int_{\tau_0}^{S} d\tau \int_{\mathbb{R}} \rho(\xi, v, v_\xi)(v_\tau)^2 \, d\xi \le 0 \tag{3.27}$$

for any fixed $S > \tau_0$.

It follows from (3.25), (3.26), and Propositions 3.2 and 3.6 that the functions $\rho(\xi, v, w)$ and $\Phi(\xi, v, w)$ are bounded and continuous for $v > 0$. We set $\rho(0, v, w) = \Phi(0, v, w) = \rho(\xi, 0, 0) = \Phi(\xi, 0, 0) \equiv 0$.

PROPOSITION 3.7. *For any* $\xi \ge 0, v > 0, w \le 0$

$$\rho(\xi, v, w) \le v^{-\sigma/(\sigma+1)}, \tag{3.28}$$

(3.29)

$$\Phi(\xi, v, w) \le \frac{w^2}{2} + (\sigma+1)^2 \left[\frac{1}{(\beta-1)(\sigma+2)} v^{(\sigma+2)/(\sigma+1)} + \frac{1}{\beta+\sigma+1} v^{(\beta+\sigma+1)/(\sigma+1)} \right].$$

In general, these properties are not enough to prove (3.27) for a weak solution of the degenerate equation. We begin with the proof of a weakened form of (3.27) by using some regularizing approach.

4. Regularized problem. It is well known (see [3], [5], [25], [27]–[30], and the references therein) that a weak solution of a nonlinear parabolic equation with a degenerate diffusion operator of nonstationary filtration type can be constructed as the limit of a sequence of classical solutions to a regularized problem. For the Cauchy problem (1.15)–(1.16), this regularized problem can be stated as follows. Fix $\varepsilon > 0$ small enough, and consider the initial-boundary value problem in $B_\varepsilon \times \mathbb{R}_+$, $B_\varepsilon = \{|\xi| < 1/\varepsilon\}$, for quasilinear uniformly parabolic equation (3.2) with the function $a(v)$ replaced by

$$a_\varepsilon(v) = (\varepsilon^2 + v^2)^{\sigma/(2(\sigma+1))}, \tag{4.1}$$

and the boundary and initial data

$$v(\xi, 0) = v_0(\xi) \quad \text{in } B_\varepsilon, \tag{4.2}$$

$$v = 0 \quad \text{for } \xi = \pm 1/\varepsilon, \tau > \tau_0. \tag{4.3}$$

For any small $\varepsilon > 0$ problem (3.2), (4.1)–(4.3) has a unique local in time classical solution $v_\varepsilon = v_\varepsilon(|\xi|, \tau)$, which is strictly monotone in $|\xi|$; see e.g., [7] and [25]. By well-known results (see [5] and [25]) we may conclude that

$$v_\varepsilon(\xi, \tau) \to v(\xi, \tau) \quad \text{as } \varepsilon \to 0 \tag{4.4}$$

uniformly on any compact subset of $\mathbb{R} \times (\tau_0, \infty)$. By general regularity results [5], we also have that

$$(v_\varepsilon)_\xi \to v_\xi \quad \text{as } \varepsilon \to 0 \tag{4.5}$$

in $L^2_{\text{loc}}(\mathbb{R} \times (\tau_0, \infty))$ and uniformly on compact subsets, and, in particular,

$$(v_\varepsilon^\alpha)_\tau \to (v^\alpha)_\tau, \quad \alpha = (\sigma+2)/2(\sigma+1) \quad \text{as } \varepsilon \to 0 \tag{4.6}$$

in $L^2_{\mathrm{loc}}(\mathbb{R}\times(\tau_0,\infty))$. Notice that by this construction at any point of nondegeneracy (ξ,τ), where $v(\xi,\tau)>0$ is the classical solution, we have that as $\varepsilon\to 0$ the function v_ε converges to v with first derivatives. By Bernstein estimates we also have that on any given compact subset of $\mathbb{R}\times(\tau_0,\infty)$ as $\varepsilon\to 0$

$$|v_\varepsilon(\xi,\tau)|\le C_1,\qquad |(v_\varepsilon(\xi,\tau))_\xi|\le C_2.$$

(We shall denote by $C_i>0$ different constants which are independent of $\varepsilon>0$.)

4.1. Lyapunov function for the regularized problem. Since the regularized equation is uniformly parabolic, by the method given in §3 we can construct the classical Lyapunov function. It can be easily calculated by (3.21)–(3.23) with $a(v)$ replaced by the function (4.1). Then instead of (3.25) and (3.26), we obtain the functions

(4.7)
$$\rho_\varepsilon(\xi,v,w)=(\varepsilon^2+v^2)^{-\sigma/(2(\sigma+1))}\times\exp\left\{-m\int_0^\xi\zeta[\varepsilon^2+\varphi_\varepsilon^2(0,\zeta,\varphi_\varepsilon(\xi,0,v,w),\varphi'_\varepsilon(\xi,0,v,w))]^{-\sigma/(2(\sigma+1))}d\zeta\right\},$$

(4.8)
$$\Phi_\varepsilon(\xi,v,w)=(\varepsilon^2+v^2)^{\sigma/(2(\sigma+1))}\int_0^w(w-\eta)\rho_\varepsilon(\xi,v,\eta)\,d\eta - \int_0^v\rho_\varepsilon(\xi,\mu,0)\left[-\frac{\sigma+1}{\beta-1}\mu+(\sigma+1)|\mu|^{(\beta-1)/(\sigma+1)}\mu\right]d\mu.$$

As above, the function $\varphi_\varepsilon(\xi_0,\xi,v_0,w_0)$ is the unique classical solution of the nondegenerate ordinary differential equation

$$a_\varepsilon(\varphi)\varphi_{\xi\xi}+b(\xi,\varphi,\varphi_\varepsilon)=0, \tag{4.9}$$

$$\varphi|_{\xi=\xi_0}=v_0,\qquad \varphi_\xi|_{\xi=\xi_0}=w_0. \tag{4.10}$$

The following upper estimates of $\rho_\varepsilon,\Phi_\varepsilon$ and the lower one of Φ_ε are direct consequences of (4.7) and (4.8).

PROPOSITION 4.1. *For any* $\xi\ge 0, v\ge 0, w\le 0$

$$\rho_\varepsilon(\xi,v,w)\le(\varepsilon^2+v^2)^{-\sigma/(2(\sigma+1))}, \tag{4.11}$$

$$\Phi_\varepsilon(\xi,v,w)\le\frac{w^2}{2}+P_\varepsilon(v), \tag{4.12}$$

where

$$P_\varepsilon(v)=\int_0^v(\varepsilon^2+\mu^2)^{-\sigma/(2(\sigma+1))}\left[\frac{\sigma+1}{\beta-1}\mu+(\sigma+1)\mu^{(\beta+\sigma)/(\sigma+1)}\right]d\mu, \tag{4.13}$$

and

$$\Phi_\varepsilon(\xi,v,w)\ge -R(v), \tag{4.14}$$

where

$$R(v)=\frac{(\sigma+1)^2}{\beta+\sigma+1}v^{(\beta+\sigma+1)/(\sigma+1)}\quad \text{if } v>v_*=\theta_0^{\sigma+1},\qquad R(v)=0\quad \text{if } v\le v_*.$$

We now prove the main estimate following from calculations given above.

LEMMA 4.2. *For any $S > \tau_0$ and $\varepsilon > 0$ small enough, there holds*

$$\int_{\tau_0}^{S} d\tau \int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)(\partial_\tau v_\varepsilon)^2 \, d\xi < C_3, \tag{4.15}$$

where C_3 does not depend on S.

Proof. Denote

$$L_\varepsilon[v](\tau) = \int_{B_\varepsilon} \Phi_\varepsilon(\xi, v, v_\xi) \, d\xi. \tag{4.16}$$

Then by construction,

$$\frac{d}{d\tau} L_\varepsilon[v_\varepsilon](\tau) = -\int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)(\partial_\tau v_\varepsilon)^2 \, d\xi \le 0 \quad \text{for } \tau > \tau_0. \tag{4.17}$$

Integrating over (τ_0, S), $S > \tau_0$, yields

$$L_\varepsilon[v_\varepsilon](S) - L_\varepsilon[v_\varepsilon](\tau_0) = -\int_{\tau_0}^{S} d\tau \int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)(\partial_\tau v_\varepsilon)^2 \, d\xi. \tag{4.18}$$

It follows from (4.18), (1.4), and Proposition 4.1 that

$$\int_{\tau_0}^{S} d\tau \int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)[(v_\varepsilon)_\tau]^2 \, d\xi + L_\varepsilon[v_\varepsilon](S) = L_\varepsilon[v_0] \le C_4. \tag{4.19}$$

Then, using estimate (4.14) in (4.19) yields

$$\int_{\tau_0}^{S} d\tau \int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)(\partial_\tau v_\varepsilon)^2 d\xi \le C_4 + \int_{B_\varepsilon} R(v_\varepsilon(\xi, S)) \, d\xi. \tag{4.20}$$

By (4.4) and (2.2) we have that for large S, provided that $\varepsilon > 0$ is small enough,

$$R(v_\varepsilon(\xi, S)) \le 2\frac{(\sigma+1)^2}{\beta+\sigma+1}\mu_*^{\beta+\sigma+1} \quad \text{for } \xi \in \mathbb{R}. \tag{4.21}$$

Therefore, since by Lemma 2.3 and (4.4) on any compact subset $K \subset \mathbb{R}$,

$$v_\varepsilon(\xi, S) \le 2C_0^{\sigma+1}|\xi|^{-2(\sigma+1)/(\beta-(\sigma+1))} \quad \text{on } K,$$

we conclude that $R(v_\varepsilon(\xi, S)) \equiv 0$ outside some uniformly bounded neighbourhood of the origin $\xi = 0$. Finally, we have

$$\int_{B_\varepsilon} R(v_\varepsilon(\xi, S)) \, d\xi \le C_5. \tag{4.22}$$

Using this estimate in (4.20) implies that

$$\int_{\tau_0}^{S} d\tau \int_{B_\varepsilon} \rho_\varepsilon(\xi, v_\varepsilon, (v_\varepsilon)_\xi)(\partial_\tau v_\varepsilon)^2 \, d\xi \le C_4 + C_5 = C_6, \tag{4.23}$$

where the right-hand side is independent of S. This completes the proof. □

4.2. Passage to the limit $\varepsilon \to 0$. We first need to prove the following estimate.

LEMMA 4.3. *For any fixed $S > \tau_1 = \tau_0 + 1$ and $L > 0$ small enough,*

$$\int_{\tau_1}^{S} d\tau \int_0^L \rho(\xi, v, v_\xi)(v_\tau)^2 \, d\xi \le C_7, \tag{4.24}$$

where the constant C_7 does not depend on S.

We begin with some properties of the solution $\varphi_\varepsilon(\xi_0, \xi, v_0, w_0)$ to the problem (4.9)–(4.10).

PROPOSITION 4.4. *For arbitrary fixed $\xi_0 > 0, v_0 \in \mathbb{R}, w_0 \in \mathbb{R}$ uniformly on $[0, \xi_0]$*

$$\varphi_\varepsilon \to \varphi, \ \varphi'_\varepsilon \to \varphi \quad \text{as } \varepsilon \to 0. \tag{4.25}$$

Proof. The limit (4.25) is the straightforward consequence of the continuous dependence of the solution φ_ε and derivative φ'_ε on the parameter ε provided the limiting solution φ with $\varepsilon = 0$ is such that $\varphi^2 + (\varphi')^2 \neq 0$ on $[0, \xi_0]$ (cf. the similar Proposition 3.2). If φ does not satisfy the aforementioned condition and there exists $\xi_* \in [0, \xi_0]$ such that $\varphi^2 + (\varphi')^2 = 0$ for $\xi = \xi_*$ (hence $\varphi \equiv 0$ in $[0, \xi_*]$), then by using the idea from the proof of Proposition 3.6 (based on the uniqueness result given in Proposition 3.3) we conclude that $\varphi_\varepsilon \to 0 \equiv \varphi, \varphi'_\varepsilon \to 0 \equiv \varphi'$ as $\varepsilon \to 0$ on $[0, \xi_*]$. Here we use a natural gradient bound, see Proposition 3.1 and remarks given after it. Hence, (4.25) holds again, which completes the proof. □

We now introduce the "good" set

$$G_* = \mathbb{R}^3_+ \setminus B_*, \tag{4.26}$$

where the "bad" set B_* is given in Proposition 3.5. It follows from the definition that G_* can be defined also as follows:

$$G_* = \{(\xi_0, v_0, w_0) \in \mathbb{R}^3_+ | \varphi(\xi_0, \xi, v_0, w_0) \text{ satisfies (3.8) on } K = [0, \xi_0]\}. \tag{4.27}$$

Then by continuous dependence of φ' on parameters $(\xi_0, v_0, w_0) \in G_*$ (see Proposition 3.2) we deduce that G_* is open. It follows from (4.27), (3.25), and (3.26) that by standard regularity results

$$\rho \text{ and } \Phi \text{ are smooth enough on } G_* \tag{4.28}$$

and hence, by construction, these functions satisfy (3.18) and (3.19) on G_* in the classical sense. By Propositions 3.7, 4.1, 4.4, and (4.27), we obtain the following.

PROPOSITION 4.5. *As $\varepsilon \to 0$,*

$$(\varepsilon^2 + v^2)^{\sigma/(2(\sigma+1))} \rho_\varepsilon(\xi, v, w) \to v^{\sigma/(\sigma+1)} \rho(\xi, v, w) \quad \text{on } G_*. \tag{4.29}$$

Proof of Lemma 4.3. Fix $L > 0$ small enough and $S > \tau_1$. It follows from (4.4), (4.5), and Propositions 2.1 and 2.2 that for any $(\xi, \tau) \in [0, L] \times [\tau_1, S]$,

$$(\xi, v_\varepsilon, (v_\varepsilon)_\xi) \in [0, L] \times \left[\frac{1}{2}\theta_0^{\sigma+1}, 2\mu_*^{\sigma+1}\right] \times [-2\mu_1, 0] \equiv \mathcal{M}_L.$$

One can see from (3.6) and (3.7) that

$$\mathcal{M}_L \subset G_* \cap \left\{ v \geq \frac{1}{2}\theta_0^{\sigma+1} > 0 \right\}, \tag{4.30}$$

provided that $L > 0$ is small enough. Estimate (4.24) is now a straightforward consequence of (4.15), Proposition 4.5 and (4.4)–(4.6). □

A regularity of the functions ρ and Φ and convergence of the type (4.29) on the bad set B_* are unknown. We have shown only that both functions are continuous on $\mathbb{R}^3_+$; see §3.

5. Proof of Theorem 1.1. Let us rewrite the weighted estimate (4.24) for small $L > 0$:

$$\int_{\tau_1}^{S} d\tau \int_0^L (v^{\sigma/(\sigma+1)}\rho(\xi, v, v_\xi))(\partial_\tau v^\alpha)^2 \, d\xi \leq C_8, \tag{5.1}$$

where $\alpha = (\sigma+2)/2(\sigma+1)$. The function $v^{\sigma/(\sigma+1)}\rho$ in (5.1) given by (3.25) is nonnegative. Unfortunately, it is not strictly positive for $v > 0$. One can see that the following result is valid.

PROPOSITION 5.1. *There holds*

$$\rho(\xi, v, w) = 0 \quad \text{on } B_*, \qquad \rho > 0 \quad \text{on } G_*. \tag{5.2}$$

Proof. If $(\xi, v, w) \in B_*$, then by the definition of B_* there exists $\zeta_0 \in [0, \xi)$ such that $|\varphi(\xi, \zeta, v, w)| \sim (\zeta - \zeta_0)_+^{(\sigma+1)/\sigma}$ as $\zeta \to \zeta_0 > 0$ and $|\varphi(\xi, \zeta, v, w)| \lesssim \zeta^{2(\sigma+1)/\sigma}$ as $\zeta \to 0$; see (3.10)–(3.12). It follows that the integral in the right-hand side of (3.25) diverges, and hence $\rho = 0$. If $(\xi, v, w) \in G_*$, then $\varphi^2 + \varphi'^2 \neq 0$ on $[0, \xi]$ by Proposition 3.5 and (4.27), hence $\rho > 0$. □

By the definition of B_* and Proposition 3.3, we also have the following good property.

PROPOSITION 5.2. *Let $g(\xi) \geq 0$ on a compact $[0, \xi_1]$ be a nonnegative nonincreasing solution of* (1.9) *and* (1.10) *with $g(0) > 0$. Then setting $\bar{g} = g^{\sigma+1}$ we have*

$$B_* \cap \{(\xi, \bar{g}(\xi), \bar{g}'(\xi)) \mid \xi \in (0, \xi_1]\} = \varnothing. \tag{5.3}$$

Since the good set G_* is open, we have the following.

LEMMA 5.3. *Let $g(\xi)$ be as in Proposition* 5.2. *For any point $S_0 = (\xi_0, \bar{g}(\xi_0), \bar{g}'(\xi_0)), \xi_0 \in (0, \xi_1]$, there exists a neighbourhood $Q(S_0) \subset \mathbb{R}_+ \times \mathbb{R}_+ \times \mathbb{R}_-$ such that*

$$B_* \cap Q(S_0) = \varnothing. \tag{5.4}$$

We now begin with some local version of Theorem 1.1.

LEMMA 5.4. *There exists $\bar{\xi}_1 > 0$ such that*

$$\begin{aligned} \omega(f_0) \subseteq \mathcal{W}(\bar{\xi}_1) \equiv \{ & g \geq 0 \mid g \text{ satisfies } (1.9) \text{ and } (1.10), \\ & g^{\sigma+1} \leq N_* = \mu_*^{\sigma+1} \text{ in } [0, \bar{\xi}_1], \ g^{\sigma+1}(0) \geq n_0 = \theta_0^{\sigma+1}\}. \end{aligned} \tag{5.5}$$

Proof. By using Propositions 2.1 and 2.2, we conclude that for any $\xi_1 > 0$ small enough, the estimates

$$n_0/2 \leq v(\xi, \tau) \leq N_*, \qquad -\mu_1 \leq v_\xi(\xi, \tau) \leq 0 \tag{5.6}$$

hold for $\xi \in [0,\xi_1], \tau > \tau_0$. We derive a lower estimate of $\rho(\xi, v, w)$ in the domain

$$\{0 \le \xi \le \xi_1, n_0/2 \le v \le N_*, -\mu_1 \le w \le 0\} \subset \bar{\mathbb{R}}_+ \times \bar{\mathbb{R}}_+ \times \bar{\mathbb{R}}_-, \tag{5.7}$$

given by estimates (5.6). It follows from the analysis of problem (3.6)–(3.7) considered for $\xi \in [0,\xi_1]$, ξ_1 is small enough, with arbitrary $\xi_0 \in [0,\xi_1]$ and boundary values $v = v_0, w = w_0$ satisfying (cf. (5.6)) $n_0/2 \le v \le N_*, -\mu_1 \le w \le 0$, that for any $\xi \in (0,\xi_1], \zeta \in (0,\xi)$, there holds

$$\varphi(\xi, \zeta, v, w) \ge n_0/4. \tag{5.8}$$

Then we deduce from (3.25) that in the domain given by (5.7),

$$\rho(\xi, v, w) \ge v^{-\sigma/(\sigma+1)} \exp\left\{-\frac{m}{2}\left(\frac{n_0}{4}\right)^{-\sigma/(\sigma+1)} \xi_1^2\right\} \equiv C_9 v^{-\sigma/(\sigma+1)}. \tag{5.9}$$

(Notice that a similar result follows from (4.30), (5.2) since the bounded set $\mathcal{M}_L$ with $L = \xi_1$ is closed and ρ is continuous on $\mathcal{M}_L$.) Using (5.1) with $L = \xi_1$ implies that

$$\int_{\tau_1}^{S} d\tau \int_0^{\xi_1} (\partial_\tau v^\alpha)^2 \, d\xi \le C_{10}, \tag{5.10}$$

where by Lemma 4.3 and (5.9) the right-hand side does not depend on S.

Take now an arbitrary $g \in \omega(f_0)$ so that there exists $\tau_j \to \infty$ such that $v(\xi, \tau_j) \to g(\xi)$ as $j \to \infty$ uniformly on $[0, 2\xi_1]$. Let us rewrite (3.2) with coefficients (3.4) and (3.5) in the form

$$\partial_\tau v^\gamma = \gamma v_{\xi\xi} - m\xi(v^\gamma)_\xi - \frac{1}{\beta - 1} v^\gamma + (v^\gamma)^\beta, \tag{5.11}$$

in $\mathbb{R} \times (\tau_0, \infty)$, where $\gamma = (\sigma + 1)^{-1}$. By Propositions 2.1 and 2.2 and by general regularity results [5], [6] we conclude that

$$v(\xi, \tau_j + s) \to h(\xi, s) \quad \text{as } j \to \infty \tag{5.12}$$

in $L^\infty_{\mathrm{loc}}(\mathbb{R}_+ : C(\mathbb{R}))$, where $h(\xi, s)$ is the unique nonnegative weak solution of the Cauchy problem for the same equation

$$\partial_s h^\gamma = \gamma h_{\xi\xi} - m\xi(h^\gamma)_\xi - \frac{1}{\beta - 1} h^\gamma + (h^\gamma)^\beta, \tag{5.13}$$

which satisfies $h(\xi, 0) = g(\xi)$ in $\mathbb{R}$.

By using a standard technique (cf. [26] and [4]), we have from (5.10) that $h \equiv g$ is a stationary solution to (5.13) on $[0, \bar{\xi}_1]$ with arbitrary $\bar{\xi}_1 < \xi_1$. Indeed, using (5.10) yields for $s \in [0, 1]$

$$\begin{aligned}
&\|v^\alpha(\cdot, \tau_j + s) - v^\alpha(\cdot, \tau_j)\|^2_{L^2((0,\bar{\xi}_1))} \\
&\quad \equiv \int_0^{\bar{\xi}_1} |v^\alpha(\xi, \tau_j + s) - v^\alpha(\xi, \tau_j)|^2 \, d\xi \\
&\quad \le \int_0^{\bar{\xi}_1} d\xi \int_{\tau_j}^{\tau_j + s} |\partial_\tau v^\alpha(\xi, \tau)|^2 \, d\tau \\
&\quad \le \int_0^{\bar{\xi}_1} d\xi \int_{\tau_j}^{\infty} |\partial_\tau v^\alpha(\xi, \tau)|^2 \, d\tau \to 0
\end{aligned}$$

as $j \to \infty$. Hence,

$$
\begin{aligned}
&\|v^\alpha(\cdot,\tau_j+s)-v^\alpha(\cdot,\tau_j)\|^2_{L^2((0,\bar\xi_1)\times(0,1))}\\
&\equiv \int_0^1 \|v^\alpha(\cdot,\tau_j+s)-v^\alpha(\cdot,\tau_j)\|^2_{L^2((0,\bar\xi_1))}\,ds\\
&\le \int_0^{\bar\xi_1} d\xi \int_{\tau_j}^\infty |\partial_\tau v^\alpha(\xi,\tau)|^2\,d\tau \to 0 \quad \text{as } j\to\infty.
\end{aligned}
\tag{5.14}
$$

Therefore, we have that $v^\alpha(\xi,\tau_j+s)\to g^\alpha(\xi)$ as $j\to\infty$ in $L^2((0,\bar\xi_1)\times(0,1))$. Hence, the function $h(\xi,s)$ in (5.12) does not depend on s (see the detailed analysis in [26]), hence the result. □

Proof of Theorem 1.1. We now make a continuation in (5.5) with respect to $\bar\xi_1$. Assume for a contradiction that

$$
X_* = \sup\{\bar\xi_1 > 0 \mid (5.5) \text{ is valid}\} < \infty. \tag{5.15}
$$

Then by continuity we have (cf. (5.5))

$$
\omega(f_0) \subseteq \mathcal{W}(X_*). \tag{5.16}
$$

Then it can be easily seen that any $g\in\omega(f_0)$ is a nonnegative monotone decreasing function on $[0,X_*]$. We now prove that the function

$$
\inf_{\xi\in[0,X_*]} \rho(\xi,v(\xi,\tau),v_\xi(\xi,\tau)) \equiv \rho_*(\tau;X_*) \tag{5.17}
$$

satisfies

$$
\liminf_{\tau\to\infty} \rho_*(\tau;X_*) = C_{11} > 0. \tag{5.18}
$$

Indeed, suppose for a contradiction that (5.18) is false, and hence there exist sequences $\{\xi_k\}\subset[0,X_*]$ and $\{\tau_k\}\to\infty$ such that

$$
\rho(\xi_k,v(\xi_k,\tau_k),v_\xi(\xi_k,\tau_k))\to 0 \quad \text{as } k\to\infty. \tag{5.19}
$$

We can assume that $v(\cdot,\tau_k)\to\bar g(\cdot)\in\mathcal{W}(X_*)$ as $k\to\infty$ uniformly on $[0,X_*]$. Let $\{\xi_k\}\to\xi_0\in[0,X_*]$. Then by compactness we deduce that $v(\xi_k,\tau_k)\to\bar g(\xi_0)$, $v_\xi(\xi_k,\tau_k)\to\bar g'(\xi_0)$ and hence by continuity of the functions ρ and $\bar g(\xi)$ we have that

$$
\rho(\xi_k,v(\xi_k,\tau_k),v_\xi(\xi_k,\tau_k))\to\rho(\xi_0,\bar g(\xi_0),\bar g'(\xi_0))=0. \tag{5.20}
$$

Hence, by Proposition 5.1, $(\xi_0,\bar g(\xi_0),\bar g'(\xi_0))\in B_*$ contradicting (5.3). Thus, (5.18) is valid.

We now prove that there exists a constant $C_{12}>0$ such that

$$
v(\xi,\tau)\ge C_{12} \quad \text{on } [0,X_*] \text{ for large } \tau. \tag{5.21}
$$

If we assume for a contradiction that for some sequence $\{\tau_k\}\to\infty$

$$
\inf_{\xi\in[0,X_*]} v(\xi,\tau_k) \equiv v(X_*,\tau_k)\to 0 \quad \text{as } k\to\infty, \tag{5.22}
$$

then, by compactness, there exists $\bar{g} \in \mathcal{W}(X_*)$ such that $v(\cdot, \tau_k) \to \bar{g}(\cdot)$ uniformly on $[0, X_*]$. By continuity of the heat flux [25] corresponding to the weak solution $v(\xi, \tau)$, it then follows from (5.22) that $v_\xi(X_*, \tau_k) \to 0$. Then by passing to the limit $\tau_k \to \infty$ we arrive at the equalities $\bar{g}(X_*) = \bar{g}'(X_*) = 0$, which contradict the nonexistence of such a solution to the problem (1.9) and (1.10); see Proposition 3.3.

By Proposition 2.2, estimate (5.21) implies that for a small enough fixed $\delta > 0$,

$$v(\xi, \tau) \geq C_{13} \quad \text{in } [0, X_* + \delta] \quad \text{for large } \tau. \tag{5.23}$$

Therefore, since the equation for $v(\xi, \tau)$ is uniformly parabolic on $[0, X_* + \delta]$ for large τ, we conclude that

$$|v_{\xi\xi}(\xi, \tau)| \leq C_{14} \quad \text{in } [0, X_* + \delta] \text{ for large } \tau. \tag{5.24}$$

In particular, this implies that for small fixed $\delta > 0$ any point $(\xi, v(\xi, \tau), v_\xi(\xi, \tau)), \xi \in [X_*, X_* + \delta]$, is contained in a small neighbourhood of the point $(X_*, v(X_*, \tau), v_\xi(X_*, \tau))$ for $\tau > \tau_0$ large enough.

We now prove that there exists small $\delta_0 > 0$ such that (cf. (5.18))

$$\liminf_{\tau \to \infty} \rho_*(\tau; X_* + \delta_0) = C_{15} > 0. \tag{5.25}$$

If it is false, then there exist a decreasing sequence $\{\delta_k > 0\} \to 0$ and $\{\xi_k\} \subset (X_*, X_* + \delta_k)$ (see (5.18)), $\{\tau_k\} \to \infty$, such that (5.19) is valid. As previously seen, we have that $v(\cdot, \tau_k) \to \bar{z}(\cdot) = z^{\sigma+1}, z \in \omega(f_0)$ and by (5.16) there exists $\bar{g} \in \mathcal{W}(X_*)$ such that

$$\bar{z} \equiv \bar{g} \quad \text{on } [0, X_*], \tag{5.26}$$

and by estimates (5.23) and (5.24)

$$\bar{z} \text{ and } \bar{z}' \text{ are continuous at the point } \xi = X_*. \tag{5.27}$$

Since $\{\xi_k\} \to X_* + 0$, by passing to the limit $k \to \infty$ we deduce that by continuity

$$\rho(\xi_k, v(\xi_k, \tau_k), v_\xi(\xi_k, \tau_k)) \to \rho(X_*, \bar{z}(X_*), \bar{z}'(X_*)) = 0,$$

which by (5.26), (5.27) again contradicts Proposition 5.2.

Thus, (5.25) holds for some $\delta_0 > 0$. Hence, $(\xi, v, v_\xi) \in G_*$ for any $\xi \in (0, X_* + \delta_0)$ and τ large enough. It then follows from Proposition 4.5 and (5.1) with $L = X_* + \delta_0$ that (5.10) is valid with $\xi_1 = X_* + \delta$, τ_1 replaced by $\tau_* \gg 1$, and arbitrary $S > \tau_*$. Using the method of the proof of Lemma 5.4 we conclude that $\omega(f_0) \subseteq \mathcal{W}(X_* + \delta_0/2)$, which contradicts the definition of X_* given in (5.15). Hence, $X_* = \infty$, which is equivalent to (1.18), and this completes the proof of Theorem 1.1. □

Acknowledgments. The author thanks Professor R. V. Kohn for helpful discussions at the beginning of this work and is grateful to the Courant Institute of Mathematical Sciences for their hospitality during his visit in May, 1990, when this work was started. This research was completed whilst the author was a visitor at the University of Bristol School of Mathematics. The author is grateful to the Royal Society for their financial support under a Guest Research Fellowship and also for the support of the London Mathematical Society. He also thanks the staff of the School

of Mathematics at the University of Bristol for their hospitality and especially Mrs. R. Rees for typing this paper.

Finally, the author thanks the referee for useful suggestions and remarks.

TWO-PHASE STEFAN PROBLEM WITH SUPERCOOLING*

IVAN G. GÖTZ† AND BORIS ZALTZMAN‡

Abstract. Both one-dimensional two-phase Stefan problems with the thermodynamic equilibrium condition $\theta(R(t),t)=0$ and with the kinetic rule $\theta(R(t),t)=-\varepsilon\dot{R}(t)$ at the moving boundary $x=R(t)$ are considered. We study the properties of the regular solutions of the problem with equilibrium condition. They are obtained as a limit of solutions of the problem with the kinetic law as $\varepsilon\to 0$. The peculiarity of our problem is the partial supercooling of the liquid phase ($\theta<0$) at the initial state. First, we show that the simply connected supercooled liquid phase disappears in a finite time, and after this the solution becomes the classical one. Second, under appropriate structural assumptions on the initial data, we prove the smoothness of the free boundary $x=R(t)$ everywhere except at a point $t=\bar{t}$. At this point the function R may have a jump $R(\bar{t}+0)-R(\bar{t}-0)>0$ exactly equal to the interval in which $\theta(x,\bar{t}-0)\le -L$. Here L is the dimensionless latent heat.

Key words. kinetic undercooling, supercooled, Stefan problem, blowup

AMS subject classifications. 35K05, 35R35, 80A22

1. Introduction.

The problems considered are based on the usual Stefan model for liquid-solid phase transitions. Let the curve $x=R(t)$ be defined as the interface that separates the liquid phase $\{x>R(t)\}$ from the solid one $\{x<R(t)\}$. We may write the following dimensionless form of the Stefan problem on the space interval (0,1):

$$\theta_t=\theta_{xx} \quad \text{in} \quad Q_T^-\cup Q_T^+, \tag{1.1}$$

where $Q_T^{\pm}=\{(x,t):\pm(x-R(t))>0,\ 0<t<T,\ 0<x<1\}$, subject to the initial and boundary conditions

$$\theta(x,0)=\theta_0(x),\quad 0\le x\le 1, \tag{1.2}$$

$$\theta(i,t)=\theta^i(t),\quad 0\le t\le T,\ i=0,1, \tag{1.3}$$

and the Stefan condition on the interface

$$L\dot{R}(t)=\theta_x(R(t)-0,t)-\theta_x(R(t)+0,t), \tag{1.4}$$

$$R(0)=R_0,\quad 0<R_0<1. \tag{1.5}$$

Here θ is the dimensionless temperature scaled so that the equilibrium phase change temperature is zero, and $L=l/c$, where the constant heat capacity c is assumed to be the same in each phase, and where l is the dimension latent heat.

Assuming the phase equilibrium condition at the phase change interface

$$\theta(R(t),t)=0,\quad 0<t<T, \tag{1.6}$$

we complete the formulation of the problem. If no superheating and supercooling appears, i.e.,

$$\theta(x,t)(x-R(t)) \geq 0 \quad \text{in } Q_T := \{(x,t) : 0 < t < T,\ 0 < x < 1\}, \tag{1.7}$$

then the problem (1.1)–(1.6) has a global classical solution under appropriate smoothness conditions on the initial-boundary data. If the inequality (1.7) does not hold for $t = 0$, or $x = 0, 1$ then a finite time blowup of a solution may appear. (See Sherman [1], Fasano and Primicerio [2], Fasano, Primicerio, Howison, and Ockendon [3] and the references therein.) That means that no global classical solution exists. Therefore we shall mainly use the weak formulation of the problem (1.1)–(1.6).

Problem (A^0). *To find functions* R, θ *which satisfy the boundary conditions* (1.3), *the weak form of the equilibrium condition* (1.6)

$$\theta(x,t) \to 0 \quad \text{as} \quad x \to R(t) \quad \text{for a.e. } t \in (0,T), \tag{1.8}$$

and the following integral identity:

$$-\iint_{Q_T} U(x,t)\psi_t(x,t)dxdt + \iint_{Q_T} \theta_x(x,t)\psi_x(x,t)dxdt = \int_0^1 U_0(x)\psi(x,0)dx, \tag{1.9}$$

for every $\psi \in W_2^{1,1}(Q_T)$, $\psi(i,t) = 0$, $i = 0, 1$, $t \geq 0$, $\psi(x,T) = 0$, $0 < x < 1$; *with*

$$U(x,t) = \theta(x,t) + L \cdot H(x - R(t)), \quad \text{in } Q_T,$$
$$U_0(x) = \theta_0(x) + L \cdot H(x - R_0), \quad 0 < x < 1,$$

where H *is the Heaviside function*

$$H(s) = \begin{cases} 1, & s > 0, \\ 0, & s < 0. \end{cases}$$

Another natural way to complete the problem (1.1)–(1.5) is to introduce the kinetic law of the supercooling and superheating on the melting boundary:

$$\theta^\varepsilon(R^\varepsilon(t),t) = -\varepsilon \dot{R}^\varepsilon(t), \quad 0 < t < T, \tag{1.6$^\varepsilon$}$$

with some positive relaxation parameter ε. (See Visintin [4], Xie [5], Charach, Zaltzman, and Götz [6].)

Problem (A^ε). *To find functions* R^ε, θ^ε *satisfying* (1.1)–(1.5) *and* (1.6)$^\varepsilon$.

Visintin has proved the existence of the weak solution for the problem (A^ε) but with Neumann boundary conditions. He also obtained the solution of the problem (A^0) by letting ε tend to zero. We shall proceed in a similar way.

DEFINITION. *The functions* θ, R *are a regular solution of the problem* (A^0) *if there exists a sequence* $\varepsilon_n \to 0$ *as* $n \to \infty$, *such that the following convergence conditions hold for the solutions* θ^{ε_n}, R^{ε_n} *of the problems* (A^{ε_n}):

$$\begin{aligned} &\theta^{\varepsilon_n} \to \theta \quad \text{weakly in } L_2(0,T;H^1(0,1)), \quad \text{strongly in } L_2(Q_T), \\ &R^{\varepsilon_n} \to R \quad \text{weakly star in } BV(0,T). \end{aligned} \tag{1.10}$$

In §2 we present some preliminary results concerning the existence of solutions and the maximum principle. In the third section we obtain the smoothness (piecewise

with respect to time) of a regular solution of the problem (A^0). Section 4 is devoted to the verification of the inequality (1.7) for a regular solution after some time t_*, although it does not hold at the initial state $t = 0$. That means the disappearance of a supercooled liquid in a finite time t_*. In the fifth section we study the fine structure of a regular solution of the problem (A^0). We show that there exists at most one blowup time $t = \bar{t}$ provided that the initial temperature $\theta_0(x)$ has only one interval in the liquid phase where $\theta_0(x) < -L$. Before the instant $\bar{t}$ and after it a regular solution is smooth. At the point $t = \bar{t}$ the free boundary $R(t)$ may have a jump $R(\bar{t}+0) - R(\bar{t}-0) > 0$ which is exactly equal to the interval where $\theta(x, \bar{t}-0) \le -L$.

2. Preliminary results.

THEOREM 1. *Let the functions* θ_0, θ^i, $i = 0, 1$ *satisfy the smoothness assumptions*

$$\theta^i \in C^1(\mathbf{R}) \cap L_\infty(\mathbf{R}), \quad \theta_0 \in C^1[0, R_0] \cap C^1[R_0, 1] \cap C[0, 1], \tag{2.1}$$

the consistency conditions

$$\theta^i(0) = \theta_0(i), \quad i = 0, 1, \tag{2.2}$$

and suppose that

$$\text{the functions } \theta^0, \ \theta^1 \text{ do not change sign for } t > 0. \tag{2.3}$$

Then the following three statements hold:

1. *There exists a unique solution of the problem* (A^ε) *for every* $\varepsilon > 0$, *for some* $T_\varepsilon > 0$:

$$\begin{aligned} &R^\varepsilon \in C^1(0, T_\varepsilon), \ \theta^\varepsilon \in C(\overline{Q}_{T_\varepsilon}) \cap C^{2,1}(Q^{\pm}_{T_\varepsilon}), \\ &\theta^\varepsilon_x \in C(\overline{Q}^{\pm}_{T_\varepsilon} \setminus \{x = 0, 1\}), \end{aligned} \tag{2.4}$$

$$\text{either } T_\varepsilon = +\infty \text{ or } \min\{1 - R^\varepsilon(T_\varepsilon), R^\varepsilon(T_\varepsilon)\} = 0. \tag{2.5}$$

2. *The following estimates hold independently of* ε:

$$\iint_{Q_T} (\theta^\varepsilon_x)^2 dx dt + \varepsilon \int_0^T |\dot{R}^\varepsilon(t)|^2 dt \le C(T), \tag{2.6}$$

$$\int_0^T |\dot{R}^\varepsilon(t)| dt \le C(T), \tag{2.7}$$

for every bounded $T < T_\varepsilon$.

3. *There exists a regular solution of the problem* (A^0),

$$\theta \in L_2(0, T; H^1(0, 1)) \cap L_\infty(Q_T), \ R \in BV(0, T), \tag{2.8}$$

where $T = \liminf_{\varepsilon_n \to 0} T_{\varepsilon_n}$ *for the corresponding sequence* $\{\varepsilon_n\}$.

The first statement of Theorem 1 is proved in [5]. One can obtain the estimates (2.6) and (2.7) by multiplying the differential equations of the problem (A^ε) by the test functions $\psi_1(x, t) := \theta^\varepsilon(x, t) - f(x, t)$, and $\psi_2(x, t) := \operatorname{sign}\theta^\varepsilon(x, t) - g(x, t)$, respectively,

and then integrating by parts in each subdomain $Q_T^{\pm}$. Here $f(x,t) := \theta^0(t) + (\theta^1(t) - \theta^0(t))x$ and $g(x,t) := sign\theta^0(t) + (sign\theta^1(t) - sign\theta^0(t))x$. Similar estimates were obtained by Visintin in [4], where it also has been proved that the estimates (2.6) and (2.7) imply the convergence conditions (1.10), and consequently the existence of a regular solution of the problem (A^0) with the property (2.8).

LEMMA 1 (maximum principle). *Under the assumptions of Theorem* 1 *the function* θ^ε *may have only positive local minima and only negative local maxima inside of the domain* Q_T. *In particular,*

$$\max\{\sup_{\overline{Q}_T}|\theta^\varepsilon|, \sup_{\overline{Q}_T}|\theta|\} \le \max\{\sup_{(0,1)}|\theta_0|, \sup_{t\in(0,T),i=0,1}|\theta^i(t)|\} =: \theta_M. \tag{2.9}$$

The function θ^ε may have local extrema inside the domain Q_T only on the curve $x = R^\varepsilon(t)$. Therefore the statement of Lemma 1 follows immediately from the Stefan condition (1.4) and from the kinetic law $(1.6)^\varepsilon$ with positive constants L, ε.

LEMMA 2. *Suppose that the strict inequalities*

$$\theta^0(t) < -\gamma, \ \theta^1(t) > \gamma \quad \textit{for } t \ge 0, \quad \textit{for some } \ \gamma > 0, \tag{2.10}$$

hold under the assumptions of Theorem 1. *Then there exist global solutions of the problems* (A^0), (A^ε), *i.e.,* $T = T_\varepsilon = +\infty$. *Moreover,*

$$\eta \le R^\varepsilon(t), R(t) \le 1 - \eta \quad \textit{for } t \ge 0, \quad \textit{for some } \eta > 0. \tag{2.11}$$

Proof. Let us take the linear barrier function

$$u(x) := -\gamma + Ax, \quad x \in (0,1). \tag{2.12}$$

The constant A is chosen so that the function $v := u - \theta^\varepsilon$ is positive for $t = 0$, $x \in (0,1)$ and $t \ge 0$, $x = 0, 1$. Namely,

$$A > \max\{\max_{x\in[0,1]}|\theta_0'(x)|, \sup_{t\ge 0}|\theta^1(t)| + \gamma\}. \tag{2.13}$$

Moreover, we must fulfill the inequality $u(R_0) > 0$, i.e.,

$$A > \frac{\gamma}{R_0}. \tag{2.14}$$

The function v solves the homogeneous heat conduction equation in the subdomains $Q_T^{\pm}$, hence it may have local extrema inside the domain Q_T only for $x = R^\varepsilon(t)$. We suppose that there exists $t_0 > 0$ such that

$$v(x,t) > 0, \ x \in [0,1], \ t \in [0,t_0), \tag{2.15}$$

$$v(R^\varepsilon(t_0), t_0) = 0. \tag{2.16}$$

Then

$$\begin{aligned} u(R^\varepsilon(t_0)) &= \theta^\varepsilon(R^\varepsilon(t_0), t_0) = -\varepsilon\dot{R}^\varepsilon(t_0) \\ &= \frac{\varepsilon}{L}(v_x(R^\varepsilon(t_0) - 0, t_0) - v_x(R^\varepsilon(t_0) + 0, t_0)) < 0. \end{aligned} \tag{2.17}$$

From (2.15) we find the inequality

$$\frac{d}{dt}u(R^\varepsilon(t)) = A\dot{R}^\varepsilon(t) = -\frac{A}{\varepsilon}\theta^\varepsilon(R^\varepsilon(t),t) \geq -\frac{A}{\varepsilon}u(R^\varepsilon(t)) \tag{2.18}$$

for $t \in [0,t_0]$. Because of (2.14), we have $u(R_0) > 0$, and so the differential inequality (2.18) implies that $u(R^\varepsilon(t)) > 0$ must hold for every $t \in [0,t_0]$, which is the same as

$$R^\varepsilon(t) > \eta = \gamma/A, \quad t \geq 0.$$

We complete the proof of Lemma 2 by proving the second part of the inequality (2.11) in a similar way and by using the convergence conditions (1.10). □

3. Smoothness (piecewise with respect to time) of a regular solution of the problem (A^0). Since a regular solution of the problem (A^0) is the limit of the solutions for the problems (A^ε), it is sufficient to prove estimates for the solutions of the problems (A^ε) which are local in time and uniform with respect to $\varepsilon > 0$. The idea of the following statement is similar to that of [7].

LEMMA 3. *In addition to the assumptions of Lemma 2 let us suppose that the following estimates,*

$$\varepsilon_n|\dot{R}^{\varepsilon_n}(\tau)|^2 \leq C, \quad \int_0^1 (\theta_x^{\varepsilon_n}(x,\tau))^2dx \leq C, \tag{3.1}$$

hold for some $\tau \geq 0$ and for every $n \in \mathbf{N}$. Then there exist positive constants ν, C_1 depending on C but independent of ε_n such that

$$\|\dot{R}^{\varepsilon_n}\|_{L_3(\tau,\tau+\nu)} \leq C_1, \tag{3.2}$$

$$\int_\tau^{\tau+\nu}\int_0^1 (\theta_t^{\varepsilon_n})^2dxdt + \max_{t\in[\tau,\tau+\nu]}\int_0^1 (\theta_x^{\varepsilon_n}(x,t))^2dx \leq C_1. \tag{3.3}$$

Proof. Let us define the function $\phi(x,t) = \theta^0(t) + x(\theta^1(t) - \theta^0(t))$. We multiply equation (1.1) by the function $(\theta_t^{\varepsilon_n} - \phi_t)$ and integrate it over the intervals $\Omega^-(t) := (0, R^{\varepsilon_n}(t))$ and $\Omega^+(t) := (R^{\varepsilon_n}(t), 1)$. Summing the results of the integration, we obtain

$$\begin{aligned}\int_0^1 (\theta_t^{\varepsilon_n}(x,t))^2dx + \frac{1}{2}\frac{d}{dt}\left(\int_0^1 (\theta_x^{\varepsilon_n}(x,t))^2dx + \varepsilon_n L(\dot{R}^{\varepsilon_n}(t))^2\right) \\ = -[\theta_x^{\varepsilon_n}]_{R^{\varepsilon_n}(t)+0}^{R^{\varepsilon_n}(t)-0}[(\theta_x^{\varepsilon_n})^2]_{R^{\varepsilon_n}(t)+0}^{R^{\varepsilon_n}(t)-0} + \int_0^1 \theta_t^{\varepsilon_n}\phi_t dx + \phi_{tx}(t)(\theta^1(t) - \theta^0(t)).\end{aligned} \tag{3.4}$$

The third term on the right-hand side is bounded, and the second one, I_2, can be estimated in a standard way:

$$|I_2| \leq \delta\int_0^1 (\theta_t^{\varepsilon_n}(x,t))^2dx + C(\delta) \quad \text{for} \quad \delta > 0. \tag{3.5}$$

Defining $z(t) = \int_0^1 (\theta_x^{\varepsilon_n}(x,t))^2dx$, we can estimate the first term on the right-hand side of the identity (3.4) with the help of the following inequalities:

$$|\theta_x^{\varepsilon_n}(R^{\varepsilon_n}(t) - 0, t)|^3 \leq \int_{x'}^{R^{\varepsilon_n}(t)} |(\theta_x^{\varepsilon_n}(x,t))_x^3|dx + |\theta_x^{\varepsilon_n}(x',t)|^3 \tag{3.6}$$

$$\leq 3\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_{xx}(x,t)||\theta^{\varepsilon_n}_x(x,t)|^2dx + |\theta^{\varepsilon_n}_x(x',t)|^3$$

$$\leq 3\delta\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_{xx}(x,t)|^2dx + \frac{3}{\delta}\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_x(x,t)|^4dx + |\theta^{\varepsilon_n}_x(x',t)|^3$$

$$\leq 3\delta\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_{xx}(x,t)|^2dx$$

$$+\frac{3}{\delta}\left(\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_{xx}(x,t)|^2dx\right)^{1/2}\left(\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_x(x,t)|^2dx\right)^{3/2} + |\theta^{\varepsilon_n}_x(x',t)|^3$$

$$\leq 6\delta\int_{\Omega^-(t)} |\theta^{\varepsilon_n}_{xx}(x,t)|^2dx + \frac{3}{\delta^3}z^3(t) + |\theta^{\varepsilon_n}_x(x',t)|^3,$$

$$|\theta^{\varepsilon_n}_x(R^{\varepsilon_n}(t)+0,t)|^3 \leq 6\delta\int_{\Omega^+(t)} |\theta^{\varepsilon_n}_{xx}(x,t)|^2dx + \frac{3}{\delta^3}z^3(t) + |\theta^{\varepsilon_n}_x(x'',t)|^3, \tag{3.7}$$

where $x' \in (0, R^{\varepsilon_n}(t))$ and $x'' \in (R^{\varepsilon_n}(t), 1)$ are chosen so that

$$|\theta^{\varepsilon_n}_x(x',t)|^2 \leq \int_{\Omega^-(t)} (\theta^{\varepsilon_n}_x(x,t))^2dx/R^{\varepsilon_n}(t) \leq z(t)/\eta, \tag{3.8}$$

$$|\theta^{\varepsilon_n}_x(x'',t)|^2 \leq \int_{\Omega^+(t)} (\theta^{\varepsilon_n}_x(x,t))^2dx/(1-R^{\varepsilon_n}(t)) \leq z(t)/\eta, \tag{3.9}$$

and where the constant $\eta > 0$ is defined as in Lemma 2. Applying the estimates (3.5)–(3.9) to the identity (3.4) for sufficiently small $\delta > 0$ we get

$$\int_0^1 (\theta^{\varepsilon_n}_t(x,t))^2dx + \frac{d}{dt}\left(\int_0^1 (\theta^{\varepsilon_n}_x(x,t))^2dx + \varepsilon_n L(\dot{R}^{\varepsilon_n}(t))^2\right)$$
$$\leq C_3(1 + z^{3/2}(t) + z^3(t)). \tag{3.10}$$

The standard method applied to this differential inequality with the help of the assumptions (3.1) gives us the local estimate

$$\max_{t\in[\tau,\tau+\nu]} z(t) \leq C_4, \tag{3.11}$$

with the constants ν, C_4 independent of ε_n. Furthermore, integrating the inequality (3.10) over the interval $(\tau, \tau+\nu)$, we obtain the estimate (3.3). The estimate (3.2) follows from (3.3), (3.6), and (3.7) coupled with the Stefan condition (1.4). That completes the proof of Lemma 3. □

THEOREM 2. *Under the assumptions of Lemma* 2 *there exists a finite or countable number of intervals* (t_i, t^i), $i \in I$ *such that*

$$|(0,T) \setminus \cup_{i\in I}(t_i,t^i)| = 0 \quad \textit{for all } T > 0, \tag{3.12}$$

$$\sup_{t\in(t_i+\delta,t^i-\delta)} |\dot{R}(t)| + \sup_{x\in(0,1),t\in(t_i+\delta,t^i-\delta)} |\theta_x(x,t)| \leq C^i(\delta), \quad \textit{for all } \delta > 0,\ i \in I, \tag{3.13}$$

where $R(t)$, $\theta(x,t)$ *is a regular solution of the problem* (A^0).

Proof. At first we will show that due to the estimate (2.6) for almost every $\tau \geq 0$ one can choose a subsequence $\varepsilon_n \to 0$ fulfilling the conditions (3.1) of Lemma 3. If a

contrary statement is valid then there exists a set $\mathfrak{T} \in (0,T)$ with nonzero measure such that

$$\int_0^1 |\theta^{\varepsilon_n}(x,\tau)|^2 dx + \varepsilon_n |\dot{R}^{\varepsilon_n}(\tau)|^2 \to +\infty \quad \text{as} \quad n \to \infty$$

for every $\tau \in \mathfrak{T}$ and for every subsequence $\varepsilon_n \to 0$. However, in this case we have

$$\int_0^T \left(\int_0^1 |\theta_x^{\varepsilon_n}(x,\tau)|^2 dx + \varepsilon_n |\dot{R}^{\varepsilon_n}(\tau)|^2 \right) d\tau$$
$$\geq \int_{\tau \in \mathfrak{T}} \int_0^1 |\theta_x^{\varepsilon_n}(x,\tau)|^2 dx + \varepsilon_n |\dot{R}^{\varepsilon_n}(\tau)|^2) d\tau \to +\infty \quad \text{as} \quad n \to \infty,$$

which contradicts (2.6).

By finding the value $\nu(\tau)$ from Lemma 3 for every admissible τ we determine the set $V := \cup_{\tau \geq 0}(\tau, \tau + \nu(\tau))$. One can represent this open set as a unity of either a finite or countable number of nonintersecting intervals $V = \cup_{i \in I}(t_i, t^i)$, which satisfy the property (3.12). Moreover, due to the estimates (3.2) and (3.3), we obtain similar estimates for a regular solution of the problem (A^0):

$$\|\dot{R}\|_{L_3(t_i+\delta, t^i-\delta)} \leq C_i(\delta), \tag{3.14}$$

$$\int_{t_i+\delta}^{t^i-\delta} \int_0^1 \theta_t^2 dx dt + \sup_{t \in (t_i+\delta, t^i-\delta)} \int_0^1 (\theta_x(x,t))^2 dx \leq C_i(\delta) \tag{3.15}$$

for every $\delta > 0$, $i \in I$. From the embedding theorems we have

$$W_3^1(t_i + \delta, t^i - \delta) \subset H^{2/3}[t_i + \delta, t^i - \delta],$$

where $H^{2/3}$ is the space of Hölder-continuous functions with exponent $2/3$. Hence

$$R \in H^{2/3}[t_i + \delta, t^i - \delta] \text{ for all } \delta > 0, \ i \in I. \tag{3.16}$$

The estimate (3.15) implies

$$\|\theta_{xx}(\cdot,t)\|_{L_2((0,R(t))\cup(R(t),1))} = \|\theta_t(\cdot,t)\|_{L_2(0,1)} \leq \text{const}$$

for almost every $t \in (t_i, t^i)$ and therefore from the embedding $W_2^2 \subset H^{1+1/2}$ we obtain

$$\theta(\cdot,t) \in H^{1+1/2}[0,R(t)] \cap H^{1+1/2}[R(t),1] \tag{3.17}$$

for a.e. $t \in (t_i, t^i)$, $i \in I$. We can now apply the results of [8] about solutions of the heat conduction equation with the initial data from $H^{1+\alpha}$ in noncylindrical domains of the class $H^{\frac{1+\alpha}{2}}$. They state

$$\theta \in H^{1+\alpha, \frac{1+\alpha}{2}}(\overline{Q}_{t,\delta}^{\pm}) \quad \text{a.e. } t \in (t_i, t^i), \ \delta > 0, \tag{3.18}$$

where $Q_{t,\delta}^{\pm} := \{(x,\tau) : (x,\tau) \in Q_{t^i-\delta}^{\pm}, \ \tau > t\}$. In our case (see (3.16) and (3.17)), we can choose $\alpha = 1/3$. Then (3.18) and the Stefan condition imply the desired estimate (3.13). That completes the proof of Theorem 2. □

4. Finite time disappearance of the supercooled liquid. Henceforth, in addition to the conditions on the boundary data (2.1), we assume structural restrictions on the initial data, namely, the following:

$$\begin{aligned} &\text{There exists } s_0 \in [R_0, 1) \text{ such that} \\ &\theta_0(x)(x - s_0) > 0,\ x \in [0,1],\ x \neq s_0, R_0. \end{aligned} \tag{4.1}$$

This condition prescribes the phase state of the material in different subintervals of (0,1):

$$\begin{aligned} (0, R_0) &: H(x - R_0) = 0,\ \theta_0(x) < 0 \ - \text{ nonsuperheated solid}, \\ (R_0, s_0) &: H(x - R_0) = 1,\ \theta_0(x) < 0 \ - \text{ supercooled liquid}, \\ (s_0, 1) &: H(x - R_0) = 1,\ \theta_0(x) > 0 \ - \text{ nonsupercooled liquid}. \end{aligned}$$

The properties (2.10) and (2.11) imply that the point $x = 0$ for $t \geq 0$ is always in the nonsuperheated solid phase ($H(0 - R(t)) = 0,\ \theta(0,t) < 0$) and the point $x = 1$ for $t \geq 0$ is always in the nonsupercooled liquid phase ($H(1 - R(t)) = 1,\ \theta(1,t) > 0$). Therefore the supercooled liquid phase lies between the normal solid and liquid phases. The main result of the present section can be formulated briefly as follows: The supercooled liquid phase disappears in a finite time, after that a regular solution of the problem (A^0) coincides with the unique solution of the classical Stefan problem. More precisely, see the next theorem.

THEOREM 3. *Let us assume the fulfillment of* (4.1) *in addition to the conditions of Lemma* 2. *Then there exists* $t_* < t'$ *such that the following inequality,*

$$\theta(x,t)(x - R(t)) \geq 0, \tag{4.2}$$

holds for a.e. $x \in (0,1),\ t \geq t_*$. *Here* $t' := (\frac{7}{2}U_M + 2)/\gamma$ (*see proof of Lemma* 5) *and* $U_M = \theta_M + L$, θ_M *is the maximum absolute value of the temperature* (*see* (2.9)).

Proof of Theorem 3. We consider the functions

$$\begin{aligned} \phi^\varepsilon(x,t) &= \max\{-\theta^\varepsilon(x,t)(x - R^\varepsilon(t)), 0\}, \\ \phi(x,t) &= \max\{-\theta(x,t)(x - R(t)), 0\}. \end{aligned}$$

The statement of Theorem 3 is equivalent to the identity

$$\phi(x,t) \equiv 0,\ x \in (0,1),\ t \geq t_*. \tag{4.3}$$

We use two auxiliary results, which we shall prove later.

LEMMA 4. *Under the conditions of Theorem* 3 *the inequality*

$$\int_0^1 \phi^\varepsilon(x,t_2)dx \leq \int_0^1 \phi^\varepsilon(x,t_1)dx + C\varepsilon \tag{4.4}$$

holds for every $t_1,\ t_2$ *such that* $0 \leq t_1 < t_2 \leq T$.

LEMMA 5. *Under the conditions of Theorem* 3 *there exists* $\varepsilon_0 > 0$ *such that for every* $\varepsilon \in (0, \varepsilon_0)$ *we can choose* $t^\varepsilon \in (0, t')$ *such that*

$$\int_0^1 \phi^\varepsilon(x,t^\varepsilon)dx \leq C\varepsilon, \tag{4.5}$$

where the constant C *is independent of* ε.

Let us continue the proof of Theorem 3. Due to the convergence conditions (1.10) we can state

$$\phi^{\varepsilon_n}(x,t) \to \phi(x,t) \text{ as } \varepsilon_n \to 0 \text{ a.e. in } Q_T. \tag{4.6}$$

Therefore the inequality (4.4) gives us

$$\int_0^1 \phi(x,t_2)dx \le \int_0^1 \phi(x,t_1)dx \tag{4.7}$$

for a.e. $t_1, t_2 \in (0,T)$, $t_2 > t_1$. Moreover, using (4.4) and (4.5), we obtain

$$\begin{aligned} 0 \le \int_0^1 \phi(x,t)dx &= \lim_{\varepsilon_n \to 0} \int_0^1 \phi^{\varepsilon_n}(x,t)dx \\ &\le \lim_{\varepsilon_n \to 0} \left(\int_0^1 \phi^{\varepsilon_n}(x,t^{\varepsilon_n})dx + C\varepsilon_n \right) \le \lim_{\varepsilon_n \to 0} (2C\varepsilon_n) = 0 \end{aligned} \tag{4.8}$$

for a.e. $t \in (t^0, T)$, where $t^0 := \limsup_{\varepsilon_n \to 0} t^{\varepsilon_n}$ and the values t^{ε_n} are given in Lemma 5.

Let us denote

$$t_* := \sup \left\{ t : t \in (0,T),\ \operatorname{ess\,inf}_{0<\tau<t} \int_0^1 \phi(x,\tau)dx > 0 \right\}. \tag{4.9}$$

By (4.8) we have $t_* \le t^0 \le t'$. On the other hand, the convergence (4.6) allows us to choose the sequence $\tau^{\varepsilon_n} \to t_*$ as $n \to \infty$ such that

$$\int_0^1 \phi^{\varepsilon_n}(x,\tau^{\varepsilon_n})dx \to 0 \quad \text{as} \quad n \to \infty.$$

Therefore, letting $n \to \infty$ in the inequality (4.4) with $t_1 = \tau^{\varepsilon_n}$ we finally obtain

$$\int_0^1 \phi(x,t)dx \equiv \phi(y,t) \equiv 0 \quad \text{a.e. } y \in (0,1),\ t \in (t_*, T),$$

which completes the proof of Theorem 3. □

Before starting to prove Lemmas 4 and 5 we study the structure of sets where the functions θ and θ^ε are positive or negative.

LEMMA 6. *Under the assumptions of Theorem* 3 *there exist integrable functions* s^ε, *with* s *satisfying the inequalities*

$$0 \le s(t) \le 1, \quad 0 \le s^\varepsilon(t) \le 1, \quad \text{a.e. } t \in (0,T)$$

such that

$$\theta^\varepsilon(x,t)(x - s^\varepsilon(t)) \ge 0 \quad \text{a.e. in } Q_T, \tag{4.10}$$

$$\theta(x,t)(x - s(t)) \ge 0 \quad \text{a.e. in } Q_T. \tag{4.11}$$

Proof of Lemma 6. Due to the convergence (1.10) it is sufficient to find the functions s^ε for $\varepsilon > 0$. With the help of Sard's theorem (see [10]) one can state that

for almost every $\alpha \in \mathbf{R}$ the level set $\Gamma_{\pm}^{\alpha}$ is a finite sum of smooth curves. Here $\Gamma_{\pm}^{\alpha} = \Gamma^{\alpha} \cap Q_T^{\pm}$, $\Gamma^{\alpha} := \{(x,t) : (x,t) \in Q_T,\ \theta^{\varepsilon}(x,t) = \alpha\}$.

Let us now take an admissible $\alpha > 0$, and an arbitrary point $(\tilde{x}, \tilde{t}) \in \Gamma^{\alpha}$. Now we are going to prove that

$$\theta^{\varepsilon}(x, \tilde{t}) \geq 0 \quad \text{for every } x \in (\tilde{x}, 1). \tag{4.12}$$

In order to do this, we shall construct the continuous function S^{α} such that

$$\theta^{\varepsilon}(S^{\alpha}(t), t) \geq \alpha \ \text{ for } t \in (0, \tilde{t}),\ S^{\alpha}(0) \in (s_0, 1),\ S^{\alpha}(\tilde{t}) = \tilde{x}.$$

Then the inequality $\theta^{\varepsilon} \geq 0$ will hold on the parabolic boundary of the domain $Q^{\alpha} := \{(x,t) :\ t \in (0, \tilde{t}),\ x \in (S^{\alpha}(t), 1)\}$. Using the maximum principle (Lemma 1), we then obtain $\theta^{\varepsilon}(x,t) \geq 0$ for each $(x,t) \in Q^{\alpha}$, which implies the inequality (4.12).

Now we construct the function $S^{\alpha}(t)$. There are two alternatives:

(i) There exists a connected piece $\Gamma \subset (\Gamma_{+}^{\alpha} \cap Q_{\tilde{t}}^{+})$ or $\Gamma \subset (\Gamma_{-}^{\alpha} \cap Q_{\tilde{t}}^{-})$, such that $(\tilde{x}, \tilde{t}) \in \Gamma$.

(ii) There exists a neighborhood V of the point $(\tilde{x}, \tilde{t})$ such that $\theta^{\varepsilon}(x,t) \geq \alpha$ (or $\theta^{\varepsilon}(x,t) \leq \alpha$) for $(x,t) \in V \cap Q_{\tilde{t}}$.

At first we consider the case (i). Using the regularity of the level sets of the solutions for the heat conduction equation (see [8, pp. 178–181]), we find $\hat{t} \in [0, \tilde{t})$ and $S^{\alpha} \in C[\hat{t}, \tilde{t}]$ such that

(1) $\theta^{\varepsilon}(S^{\alpha}(t), t) = \alpha$ for $t \in (\hat{t}, \tilde{t})$, $S^{\alpha}(\tilde{t}) = \tilde{x}$,

(2) $(S^{\alpha}(t), t) \in \Gamma$ for each $t \in (\hat{t}, \tilde{t})$,

(3) $\hat{t} = 0$ or $S^{\alpha}(\hat{t}) = R^{\varepsilon}(\hat{t})$.

If $\hat{t} \neq 0$ then we can afterwards consider the same alternatives (i) or (ii) at the new point $(R^{\varepsilon}(\hat{t}), \hat{t})$.

Now we consider the alternative (ii). Since the solution of the homogeneous heat conduction equation might have minima or maxima only on the boundary of the domain, $\tilde{x} = R^{\varepsilon}(\tilde{t})$ holds. However, using Lemma 1 we obtain

$$\theta^{\varepsilon}(x,t) \geq \alpha \quad \text{on the set } \{x = R^{\varepsilon}(t)\} \cap V \cap Q_{\tilde{t}}.$$

Defining $\hat{t} := \max\{0, \sup\{t :\ \theta^{\varepsilon}(R^{\varepsilon}(t), t) < \alpha,\ t < \tilde{t}\}\}$ and $S^{\alpha}(t) := R^{\varepsilon}(t)$ for $t \in (\hat{t}, \tilde{t})$ we deduce that either $\hat{t} = 0$ or alternative (i) holds at the point $(R^{\varepsilon}(\hat{t}), \hat{t})$, because of choice of $\hat{t}$.

Since the number of the connected pieces of curves Γ_{-}^{α}, Γ_{+}^{α} is finite we complete the construction of the function $S^{\alpha}(t)$ on the interval $(0, \tilde{t})$ by repeating this procedure a finite number of times and consequently prove the validity of the inequality (4.12).

In a similar manner, we can prove that for almost every $\alpha < 0$ and arbitrary $(\tilde{x}, \tilde{t})$ such that $\theta^{\varepsilon}(\tilde{x}, \tilde{t}) = \alpha$ the inequality

$$\theta^{\varepsilon}(x, \tilde{t}) \leq 0 \tag{4.13}$$

holds for each $x \in (0, \tilde{x})$. The validity of the inequalities (4.12) and (4.13) is enough for the existence of the function s^{ε} and, consequently, for the function s. We have completed the proof of Lemma 6. □

Proof of Lemma 4. Let consider the set

$$D_{t_1}^{t_2} := \{(x,t) : t \in (t_1, t_2),\ x \in co(R^{\varepsilon}(t), s^{\varepsilon}(t))\} \ \text{ for } 0 < t_1 < t_2 < T,$$
$$\text{where } co(x_1, x_2) = (\min\{x_1, x_2\}, \max\{x_1, x_2\}) \ \text{ for every } x_1, x_2 \in \mathbf{R}.$$

Due to (4.10) we have $\operatorname{supp}\{\phi\} \subset D_0^T$,

$$\theta^\varepsilon(x,t)(x - R^\varepsilon(t)) \equiv 0 \quad \text{for} \quad (x,t) \in D_0^T \setminus \operatorname{supp}\{\phi\}.$$

Hence

$$\begin{aligned} &\int_0^1 \phi^\varepsilon(x,t_2)dx - \int_0^1 \phi^\varepsilon(x,t_1)dx = \int_0^1 \int_{t_1}^{t_2} \phi_t^\varepsilon(x,t)dxdt \\ &= \iint_{D_{t_1}^{t_2}} \theta_t^\varepsilon(x,t)(R^\varepsilon(t) - x)dxdt + \iint_{D_{t_1}^{t_2}} \theta^\varepsilon(x,t)\dot{R}^\varepsilon(t)dxdt. \end{aligned} \tag{4.14}$$

Moreover, the inequalities (4.10) imply $\theta^\varepsilon(s^\varepsilon(t),t) = 0$, $\theta_x^\varepsilon(s^\varepsilon(t),t) \geq 0$ for $t \in (0,T)$, and so

(4.15)

$$\begin{aligned} &\iint_{D_{t_1}^{t_2}} \theta_{xx}^\varepsilon(x,t)(R^\varepsilon(t) - x)dxdt = \int_{t_1}^{t_2} dt \int_{co(R^\varepsilon(t),s^\varepsilon(t))} \theta_{xx}^\varepsilon(x,t)(R^\varepsilon(t) - x)dx \\ &= \int_{t_1}^{t_2} dt \int_{co(R^\varepsilon(t),s^\varepsilon(t))} \theta_x^\varepsilon(x,t)dx - \int_{t_1}^{t_2} \theta_x^\varepsilon(s^\varepsilon(t),t)|R^\varepsilon(t) - s^\varepsilon(t)|dt \\ &\leq \int_{t_1}^{t_2} \theta^\varepsilon(R^\varepsilon(t),t)\operatorname{sign}(R^\varepsilon(t) - s^\varepsilon(t))dt = \int_{t_1}^{t_2} |\theta^\varepsilon(R^\varepsilon(t),t)|dt. \end{aligned}$$

Summing up (4.14), (4.15), and taking into account that $\theta^\varepsilon(x,t)\dot{R}^\varepsilon(t) \leq 0$ in D_0^T, we obtain

$$\int_0^1 \phi^\varepsilon(x,t_2)dx \leq \int_0^1 \phi^\varepsilon(x,t_1)dx + \int_{t_1}^{t_2} |\theta^\varepsilon(R^\varepsilon(t),t)|dt.$$

Estimating the second integral in the right-hand side of this inequality by using the kinetic condition $(1.6)^\varepsilon$ and the estimate (2.7), we end with

$$\int_{t_1}^{t_2} |\theta^\varepsilon(R^\varepsilon(t),t)dt| = \varepsilon \int_{t_1}^{t_2} |\dot{R}^\varepsilon(t)|dt \leq \varepsilon C,$$

and complete the proof of Lemma 4. □

Proof of Lemma 5. Due to the uniform boundedness of the functions ϕ^ε, it is sufficient to estimate the value $|s^\varepsilon(t) - R^\varepsilon(t)|$. If $s_0 = R_0$ then the inequality (4.5) holds for $t^\varepsilon := 0$ and every $\varepsilon > 0$. Otherwise, if $s_0 > R_0$ then the value

$$t^\varepsilon := \sup\{t : \ s^\varepsilon(t) - R^\varepsilon(t) \geq \varepsilon, \ t \in (0,T)\}$$

is positive for $\varepsilon < s_0 - R_0$. Let us consider the function $r(t) = R^\varepsilon(t) + \varepsilon$ on the interval $(0,t^\varepsilon)$. By the definition of t^ε we have $r(t) \leq s^\varepsilon(t)$ for $t \in (0,t^\varepsilon)$, and

$$\theta^\varepsilon(x,t) \leq 0 \ \text{ in } D := \{(x,t) : \ 0 < x < r(t), \ 0 < t < t^\varepsilon\}. \tag{4.16}$$

We define the test function as follows:

$$\psi(x,t) = \begin{cases} (r(t) - x)/\varepsilon & \text{for } R^\varepsilon(t) < x < r(t), \ t \in (0,t^\varepsilon), \\ x/R^\varepsilon(t) & \text{for } 0 < x < R^\varepsilon(t), \ t \in (0,t^\varepsilon). \end{cases}$$

Testing (1.1) by the function ψ in the domain D we obtain the identity

$$\begin{aligned}(4.17)\quad &\int_0^{r(t)} U^\varepsilon(x,t)\psi(x,t)dx|_{t=0}^{t=t^\varepsilon} - \iint_D U^\varepsilon\psi_t dxdt \\ &= -\iint_D \psi_x\theta_x^\varepsilon dxdt = -\int_0^{t^\varepsilon} \frac{R^\varepsilon(t)+\varepsilon}{R^\varepsilon(t)\varepsilon}\theta^\varepsilon(R^\varepsilon(t),t)dt + \frac{1}{\varepsilon}\int_0^{t^\varepsilon}\theta^\varepsilon(r(t),t)dt \\ &\quad + \int_0^{t^\varepsilon}\frac{\theta^0(t)}{R^\varepsilon(t)}dt,\end{aligned}$$

where $U^\varepsilon(x,t) = \theta^\varepsilon(x,t) + LH(x - R^\varepsilon(t))$ in Q_T. The first integral on the left-hand side of the identity can be estimated by the maximum of the function $|U^\varepsilon(x,t)|$:

$$(4.18)\qquad |I_1| \le 2U_M.$$

Let us estimate the second integral on the left-hand side of the identity (4.17):

(4.19)

$$\begin{aligned}|I_2| \le U_M\iint_D |\psi_t|dxdt = U_M\Bigg(&\int_0^{t^\varepsilon}\int_0^{R^\varepsilon(t)}\left|\frac{x\dot{R}^\varepsilon(t)}{(R^\varepsilon(t))^2}\right|dxdt \\ &+\int_0^{t^\varepsilon}\int_{R^\varepsilon(t)}^{r(t)}\frac{|\dot{R}^\varepsilon(t)|}{\varepsilon}dxdt\Bigg) \le \frac{3}{2}U_M\int_0^{t^\varepsilon}|\dot{R}^\varepsilon(t)|dt \le \frac{3}{2}U_M.\end{aligned}$$

The first integral on the right-hand side of (4.17) can be estimated as follows:

$$(4.20)\qquad |J_1| = \left|\int_0^{t^\varepsilon}\frac{R^\varepsilon(t)+\varepsilon}{R^\varepsilon(t)}\dot{R}^\varepsilon(t)dt\right| \le \left(1+\frac{\varepsilon}{R_0}\right).$$

Because of (4.16) the second integral on the right-hand side of (4.17) is nonpositive, and therefore (4.17)–(4.20) imply

$$\frac{7}{2}U_M + 1 + \frac{\varepsilon}{R_0} \ge -\int_0^{t^\varepsilon}\theta^0(t)/R^\varepsilon(t)dt \ge \int_0^{t^\varepsilon}|\theta^0(t)|dt > \gamma t^\varepsilon.$$

Using the definition of t' and choosing $\varepsilon_0 < R_0$, we obtain $t^\varepsilon < t'$ and $|s^\varepsilon(t^\varepsilon) - R^\varepsilon(t^\varepsilon)| \le \varepsilon$, completing the proof of Lemma 5. □

COROLLARY 1. *If $s_0 = R_0$ then $t_* = 0$.*

This follows immediately from the proof of Lemma 5.

COROLLARY 2. *The function R is nondecreasing on the interval $(0, t_*)$.*

Let us consider the values t^ε, defined in Lemma 5. Obviously, $\liminf_{\varepsilon\to 0} t^\varepsilon \ge t_*$. On the other hand $s^\varepsilon(t) \ge R^\varepsilon(t) + \varepsilon$ for $t \in (0, t^\varepsilon)$, and hence

$$\dot{R}^\varepsilon(t) = -\theta^\varepsilon(R^\varepsilon(t),t)/\varepsilon \ge 0 \quad \text{for } t \in (0, t^\varepsilon).$$

Therefore the function R is monotone nondecreasing on the interval $(0, t_*)$ as the limit of the nondecreasing functions R^ε.

COROLLARY 3.

$$(4.21)\qquad \inf_{0<\tau<t}\left(\liminf_{\tau'\to\tau} s(\tau') - \limsup_{\tau'\to\tau} R(\tau')\right) > 0$$

for every $t \in (0, t_*)$.

Assume the contrary is valid, namely, that there exists $t \in (0, t_*)$ such that

$$\liminf_{\tau \to t} s(\tau) \le \limsup_{\tau \to t} R(\tau). \tag{4.22}$$

The function θ is continuous outside any neighborhood of the free boundary $x = R(t)$ since it is the solution of the heat conduction equation in the domain Q_T^+. Therefore (4.22) implies $\theta(x,t) \ge 0$ for $x > \limsup_{\tau \to t} R(\tau) = R(t+0)$ and so

$$\lim_{\tau \to t+0} \int_0^1 \phi(x,\tau)dx = 0.$$

Then from the inequality (4.7) we immediately conclude that

$$\int_0^1 \phi(x,\tau)dx \equiv 0 \quad \text{for} \quad \tau \in (t, t_*)$$

and obtain the desired contradiction with the definition of t_* (4.9).

5. Fine structure of a regular solution. Now we start to study the behavior of a regular solution up to the time t_*, i.e., in the presence of the supercooled liquid phase. We assume the simplified structure of the initial data as follows:

$$\begin{aligned} &\text{There exist } r_0^+,\ r_0^- \in (R_0, 1), \quad \text{such that} \\ &\theta_0(x) < -L, \quad x \in (r_0^-, r_0^+), \\ &\theta_0(x) > -L, \quad x \in [R_0, r_0^-) \cup (r_0^+, 1]. \end{aligned} \tag{5.1}$$

As we know from [2], the only reason for the blowup of the solution for the one-phase Stefan problem is the presence of the set $\{\theta \le -L\}$. For the sake of simplicity we consider the case when there is only one simply connected component of this critical set.

THEOREM 4. *Let us suppose, in addition to the assumptions of Theorem* 3, *that the structure of the initial data satisfies* (5.1). *Then for a regular solution of the problem* (A^0) *there exists at most one point* $\bar{t} \in [0, t_*]$ *such that*

$$\sup_{t \in (\delta, \bar{t}-\delta) \cup (\bar{t}+\delta, T)} |\dot{R}(t)| \le C(\delta) \quad \textit{for every } \delta > 0. \tag{5.2}$$

Moreover,

$$R(\bar{t}+0) \ge R(\bar{t}-0), \tag{5.3}$$

$$\theta(x, \bar{t}-0) \le -L \textit{ for } x \in (R(\bar{t}-0), R(\bar{t}+0)), \tag{5.4}$$

$$\theta(x, \bar{t}+0) = \theta(x, \bar{t}-0) > -L \textit{ for } x \in (R(\bar{t}+0), 1]. \tag{5.5}$$

Proof. At first we study the structure of the critical set

$$M := \{(x,t) :\ \theta(x,t) < -L,\ R(t) < x < 1,\ 0 < t < t_*\}.$$

We show that, in spite of the nonsmoothness of the boundary $x = R(t)$, the structure of the set $M \cap \{t = \tau\}$ is similar to the structure of the set $M \cap \{t = 0\}$ for every $\tau > 0$.

LEMMA 7. *Under the condition of Theorem* 4 *there exist functions* r^+, r^- *defined on* $(0,t_r)$, *such that*

$$R(t) \le r^-(t) < r^+(t) < 1, \text{ for } t \in (0,t_r), \tag{5.6}$$

$$(x,t) \in M \text{ iff } 0 < t < t_r,\ r^-(t) < x < r^+(t). \tag{5.7}$$

Moreover the set M *is connected.*

Proof of Lemma 7. Using Corollaries 2 and 3, we can choose a function $l \in C^2(0,t_*)$ such that

$$R(t) < l(t) \le s(t),\ t \in (0,t_*),\ l(0) \in (r_0^+, s_0), \tag{5.8}$$

$$-L < \theta(l(t),t) \le 0,\ t \in (0,t_*), \tag{5.9}$$

$$\sup_{0<\tau<t}(l(\tau) - R(\tau)) > \frac{1}{2}\sup_{0<\tau<t}(s(\tau) - R(\tau)),\ t \in (0,t_*). \tag{5.10}$$

Now we study the properties of the function θ as the solution of the heat conduction equation in the domain $\Omega_\tau := \{(x,t) : 0 < t < \tau,\ R(t) < x < l(t)\}$ with the following boundary condition on the nonsmooth boundary $x = R(t)$:

$$\theta(x,t) \to 0 \text{ as } x \to R(t) + 0, \text{ a.e. } t \in (0,t_*). \tag{5.11}$$

Because of Corollary 2 we know only that the function R is nondecreasing on the interval $(0,t_*)$. Let us approximate the function R by nondecreasing functions $R^\delta \in C^2(0,t_*)$ for $\delta \in (0,\delta_0)$ such that

$$R(t) < R^{\delta'}(t) \le R^\delta(t) < 1,\ t \in (0,t_*),\ \delta', \delta \in (0,\delta_0),\ \delta' < \delta; \tag{5.12}$$

$$R^\delta(t) \to R(t),\ \delta \to 0, \text{ a.e. } t \in (0,t_*). \tag{5.13}$$

For every $\delta \in (0,\delta_0)$ we solve the problem

$$\begin{cases} \theta_t^\delta - \theta_{xx}^\delta = 0, \text{ in } \Omega_\tau^\delta := \{(x,t) : t \in (0,\tau), R^\delta(t) < x < l(t)\}, \\ \theta^\delta(R^\delta(t),t) = 0,\ 0 < t < \tau, \\ \theta^\delta(l(t),t) = \theta(l(t),t),\ 0 < t < \tau, \\ \theta^\delta(x,0) = \theta_0^\delta(x),\ R^\delta(o) < x < 1, \end{cases} \tag{5.14}$$

where τ and δ_0 are chosen so that $R^{\delta_0}(t) < l(t)$ for $t \in (0,\tau)$. The function $\theta_0^\delta \in C^2(R^\delta(0), l(0))$ satisfies the conditions

$$\theta_0^\delta(R^\delta(0)) = 0,\ \theta_0^\delta(l(0)) = \theta_0(l(0)), \tag{5.15}$$

$$\theta_0(x) \le \theta_0^{\delta'}(x) \le \theta_0^\delta(x) \le 0 \text{ for } x \in (R^\delta(0), l(0)),\ \delta' < \delta, \tag{5.16}$$

$$\theta_0^\delta(x) \to \theta_0(x) \text{ as } \delta \to 0,\ x \in (R(0), l(0)), \tag{5.17}$$

$$\text{the function } \theta_0^\delta(x) \text{ has the structure (5.1).} \tag{5.18}$$

Conditions (5.15) and (5.16) imply the existence of the solutions θ^δ of problems (5.14) which are continuous in $\overline{\Omega}_\tau^\delta$ and smooth in Ω_τ^δ and which satisfy

$$\theta(x,t) \le \theta^{\delta'}(x,t) \le \theta^\delta(x,t) \le 0 \text{ in } \Omega_\tau^\delta \tag{5.19}$$

for every $\delta', \delta \in (0,\delta_0)$, $\delta' < \delta$.

For arbitrary $t = t_0$, $t_0 \in (0, \tau)$ we consider the level sets

$$G^a := \{(x,t) : \theta^\delta(x,t) = a,\ (x,t) \in \Omega^\delta_{t_0}\},\ a < -L$$

starting with $t = t_0$. Since the function θ^δ is continuous in $\overline{\Omega}^\delta_{t_0}$ and greater than $-L$ on the side boundaries, the simply connected pieces of G^a can be represented for a.e. $a < -L$ by graphs of the functions $g^a \in W_1^1(0, t_0)$ (see, for example, [9, pp. 178–181]), i.e.,

$$G^a = \{(x,t) : x = g^a(t),\ t \in (0, t_0)\}.$$

We consider the domain $D = \{(x,t) : g^a(t) < x < g^{a'}(t),\ t \in (0, t_0)\}$ for every admissible pair $a, a' < -L$ such that $g^a(t) < g^{a'}(t)$ on $(0, t_0)$. Since $\theta^\delta < -L$ on the parabolic boundary of the domain D (because of (5.18)), this inequality holds also inside D, in particular,

$$\theta^\delta(x, t_0) < -L \text{ for } g^a(t_0) < x < g^{a'}(t_0).$$

Since this inequality is valid for a.e. $a, a' < -L$, we conclude that the set $M \cap \{x = t_0\}$ is the interval

$$\{(x, t_0) : \theta^\delta(x, t_0) < -L\} = (r^-_\delta(t_0), r^+_\delta(t_0)).$$

Doing the same thing for every $t_0 \in (0, \tau)$ we define the functions $r^\pm_\delta$ on the whole interval $(0, \tau)$.

Let us take the function $\theta^0(x,t)$—the pointwise limit of the functions $\theta^\delta(x,t)$ as $\delta \to 0$. It exists as a consequence of inequality (5.19). The functions θ^0 and θ solve the same problem in the domain Ω_τ. Moreover, due to (5.19), the values $r^+_\delta(t)$ do not decrease as $\delta \to 0$ and the values $r^-_\delta(t)$ do not increase as $\delta \to 0$, $t \in (0, \tau)$. Defining the functions $r^\pm$ as the pointwise limits of the functions $r^\pm_\delta$, respectively, we obtain

$$\theta^0(x,t) < -L \iff t \in (0, t_*),\ x \in (r^-(t), r^+(t)). \tag{5.20}$$

The set $M^0 := \{(x,t) : \theta^0(x,t) < -L,\ t \in (0, t_*),\ x \in (R(t), 1)\}$ is connected, because $M^0 = \cup_\delta M^\delta$ and the sets $M^\delta := \{(x,t) : \theta^\delta(x,t) < -L,\ t \in (0, t_*),\ x \in (R^\delta(t), 1)\}$ are connected.

Now we need only to prove that the functions θ and θ^0 coincide. The function $v := \theta^0 - \theta$ solves the following homogeneous problem:

$$\begin{cases} v_t - v_{xx} = 0 \ \text{ in } \Omega_\tau, \\ v(x,0) = 0,\ R(0) \le x \le l(0), \\ v(l(t), t) = 0,\ 0 < t < \tau, \\ v(x,t) \to 0 \ \text{ as } x \to R(t) + 0,\ 0 < t < \tau. \end{cases} \tag{5.21}$$

LEMMA 8. *The function $v(x,t) \equiv 0$ is the unique bounded solution of the problem* (5.21).

Proof of Lemma 8. For every positive δ,

$$\delta < \delta_0 := \inf_{0<t<\tau}(l(t) - R(t)),$$

we define the function

$$r^\delta(t) = R(t) + \delta, \quad t \in (0, \tau)$$

and the domain

$$D^\delta = \{(x,t) : t \in (0,\tau),\ x \in (r^\delta(t), l(t))\}.$$

The distance from every point $(x_0,t_0) \in \overline{D}^\delta$ to the left part of the parabolic boundary of the domain

$$\{(x,t) :\ 0 < t \le t_0,\ R(t_0-0) < x < l(t_0)\}$$

is no less than δ. Since the function v satisfies the heat conduction equation in this domain, the local estimates of the solutions for parabolic differential equations imply $v \in W_2^{2,1}(D^\delta)$ for every $\delta \in (0,\delta_0)$. Multiplying the differential equation of the problem (5.21) by the function v, we obtain the following after integrating by parts in the domain D^δ:

$$\frac{1}{2}\int_{R(0)+\delta}^{R(\tau)+\delta} v^2(g(x),x)dx + \iint_{D^\delta} v_x^2 dxdx + \int_0^\tau v v_x|_{x=r^\delta(t)} dt = 0,$$

where $g(x) := \sup\{t : (x,t) \in D^\delta\}$. Then, integrating this identity with respect to $\delta \in (0,\delta_0)$ and applying the last condition in (5.21), we get

$$\begin{aligned}
0 &\ge \int_0^{\delta_0} \left(\iint_{D^\delta} v_x^2 dxdt + \frac{1}{2}\int_0^\tau (v^2(t,R(t)+\delta))_x dt \right) d\delta \\
&= \int_0^{\delta_0} \left(\iint_{D^\delta} v_x^2 dxdt + \frac{1}{2}\int_0^\tau \frac{d}{d\delta}(v^2(t,R(t)+\delta))dt \right) d\delta \\
&= \int_0^{\delta_0} \iint_{D^\delta} v_x^2 dxdtd\delta + \frac{1}{2}\int_0^\tau v^2(t,R(t)+\delta)dt - \frac{1}{2}\lim_{\xi\to 0}\int_0^\tau v^2(t,R(t)+\xi)dt \\
&= \int_0^{\delta_0} \iint_{D^\delta} v_x^2 dxdxd\delta + \frac{1}{2}\int_0^\tau v^2(R(t)+\delta,t)dt.
\end{aligned}$$

This inequality immediately yields $v \equiv 0$ in Ω_τ for every $\tau \in (0,t_*)$ and completes the proof of Lemma 8. □

Therefore, $\theta^0 \equiv \theta$ in Ω_{t_*}. Together with (5.20), this identity also concludes the proof of Lemma 7. □

Let us continue the proof of Theorem 4. As we know from Theorem 2, a regular solution of the problem (A^0) is piecewise smooth with respect to t. Now we going to study the following question: On what does the size of every smoothness interval depend?

LEMMA 9. *Let us assume—under the conditions of Theorem 4—that for some $t', t'' \in (0,t_*)$, $t' < t''$ the following statements hold:*

$$|\theta_x(x,t')| < \text{const},\ x \in [0,1], \tag{5.22}$$

$$|\dot{R}(t)| < C(\delta),\ t \in [t', t''-\delta) \ \textit{for every } \delta > 0, \tag{5.23}$$

$$\limsup_{t\to t''-0} \dot{R}(t) = +\infty. \tag{5.24}$$

Then

$$\liminf_{t\to t''-0} r^-(t) = R(t''-0). \tag{5.25}$$

Proof of Lemma 9. Suppose that (5.25) does not hold. Note that the function θ is continuous inside of the domain $\{(x,t) : 0 < x < 1,\ t' < t < t''\}$. Therefore $r^-(t) > R(t)$ for every $t \in [t', t'')$. Then the converse of (5.25) implies that

$$r^-(t) - R(t) > \alpha > 0 \text{ for } t \in [t', t''']. \tag{5.26}$$

Because $\theta(R(t),t) = 0$, $\theta(r^-(t),t) = -L$, and $\theta(x,t') \geq -L$ for $x \in (R(t'), r^-(t'))$, we have $\theta(x,t) > -L$ for $t \in (t', t''']$, $R(t) < x < r^-(t)$. Therefore we can choose the positive value δ and the function $q \in C(t', t'')$ such that

$$q(t) - R(t) > \alpha/2, \quad t \in (t', t''), \tag{5.27}$$

$$\theta(q(t),t) > -L + \delta, \quad t \in (t', t''), \tag{5.28}$$

$$\theta(x,t') > -L + \delta, \quad x \in (R(t'), q(t')). \tag{5.29}$$

Making the transformation

$$\tau := t, \quad y := x - R(t)$$

and setting $S(\tau) := q(\tau) - R(\tau)$, we obtain that θ, R solve the following problem:

$$\theta_\tau - \dot{R}\theta_y - \theta_{yy} = 0 \text{ in } Q' \setminus \{y = 0\},$$
$$\theta_y(+0,\tau) - \theta_y(-0,\tau) = -L\dot{R},\ \theta(0,\tau) = 0, \quad \tau \in (t', t''),$$

where $Q' := \{(y,\tau) :\ \tau \in (t', t''), -R(\tau) < y < S(\tau)\}$.

We construct the following barrier function in the domain Q':

$$w(y) = \begin{cases} Ay, & y < 0, \\ (A - L\beta)(1 - e^{-\beta y})/\beta, & y > 0. \end{cases}$$

One can choose positive constants A, β so that the function $v = \theta - w$ is nonnegative on the parabolic boundary of the domain Q':

$$A = \max\{\max_{0 \leq x \leq 1} |\theta_x(x,t')|, \max_{t' \leq t \leq t''} |\theta^0(t)|\},$$

$$\frac{A - L\beta}{\beta}(1 - e^{-\beta y_1}) < \delta - L, \tag{5.30}$$

where

$$y_1 = \min\left\{\alpha/2, \frac{L - \delta}{\max_{0 \leq x \leq 1} |\theta_x(x,t')|}\right\}$$

and the constant α is taken from the inequality (5.27). We can choose β to satisfy (5.30), since the left-hand side of this inequality tends to $-L$ as $\beta \to +\infty$. Thus the function v satisfies the following problem:

$$v_\tau - \dot{R}v_y - v_{yy} = F(y,\tau) \text{ in } Q' \setminus \{y = 0\},$$
$$v(0,\tau) = 0,$$
$$v(y,\tau) \geq 0 \text{ on the parabolic boundary of the domain } Q',$$

where

$$F(y,\tau) = \begin{cases} -(\beta - \dot{R})w_y = (v_y(-0,\tau) - v_y(+0,\tau))w_y/L \text{ for } 0 < y < S(\tau), \\ \dot{R}(\tau)w_y \text{ for } -R(\tau) < y < 0. \end{cases}$$

Since $yw_y(y) \le 0$ and $\dot{R}(\tau) \ge 0$, the function $F(y,\tau)$ is nonnegative up to the time when $v(y,\tau) \ge 0$. However, under this condition the function v cannot have a negative minimum inside of the domain Q', i.e., $v(y,\tau) \ge 0$ in Q'. Hence

$$0 \le (v_y(+0,\tau) - v_y(-0,\tau))/L = \beta - \dot{R}(\tau), \quad \text{and}$$
$$\dot{R}(\tau) \le \beta, \ \tau \in (t', t'').$$

This contradicts the condition (5.24), and we have proved Lemma 9. □

Let us continue the proof of Theorem 4 by applying Theorem 2. One can suppose that (t_i, t^i) are maximal intervals from (3.13), i.e., for every $i \in I$

$$\text{either} \quad \limsup_{t \to t^i - 0} \dot{R}(t) = +\infty \quad \text{or } t^i = +\infty, \tag{5.31}$$

and one of the following three statements is valid:

(i) $t_i = 0$,

(ii) $t_i = t^k$ for some $k \in I$,

(iii) $t_i = \lim_{\{l\} \subset I} t^l$.

Let us take $i \in I$ such that $t_i > 0$. Assume that

$$\text{there exists } x_0 \in (R(t_i + 0), 1), \quad \text{such that } \theta(x_0, t_i) \le -L. \tag{5.32}$$

Then by the maximum principle there are sequences converging to $x_n \to x_0$, $\tau_n \to t_i - 0$ as $n \to \infty$ such that $\theta(x_n, \tau_n) < -L$. According to Lemma 7, we therefore have $r^+(\tau_n) > x_n$. The limit process as $n \to \infty$ gives us

$$\limsup_{t \to t_i - 0} r^+(t) \ge x_0 > R(t_i + 0). \tag{5.33}$$

Moreover, the assertion of Lemma 9 states

$$\liminf_{t \to t^k - 0} r^-(t) = R(t^k - 0) \quad \text{for every } k \in I, \ t^k < \infty.$$

Therefore the alternatives (ii) and (iii) imply

$$\liminf_{t \to t_i - 0} r^-(t) = R(t_i - 0) \le R(t_i + 0). \tag{5.34}$$

Since the function θ is continuous outside every neighborhood of the boundary $x = R(t)$, the conditions (5.33) and (5.34) and the simple connectedness of the set M immediately yield the inequality

$$\theta(x, t_i) \le -L, \ x \in (R(t_i + 0), x_0). \tag{5.35}$$

Let us choose $t' \in (t_i, t^i)$ such that $R(t') < x_0$ and

$$\theta(R(t'), t) < 0, \quad t \in (t_i, t^i). \tag{5.36}$$

Now we prove that the conditions (3.13), (5.35), (5.36) imply a contradiction, which means that the assumption (5.32) is not admissible. Using the estimate (3.13) we test the heat conduction equation for the function θ by $(x - R(t'))$ over the domain

$$\{(x,t) : t_i + \delta < t < t',\ R(t) < x < R(t')\},$$

$$(5.37)\quad -\int_{R(t_i+\delta)}^{R(t')} \theta(x, t_i+\delta)(x - R(t'))dx + \int_{t_i+\delta}^{t'} \theta_x(R(t)+0,t)(R(t) - R(t'))dt + \int_{t_i+\delta}^{t'} \theta(R(t'),t)dt = 0.$$

Due to the condition (5.36) the third integral is strictly negative. The second integral I_2^δ can be estimated with the help of the Stefan condition

$$\theta_x(R(t)+0,t) = \theta_x(R(t)-0,t) - L\dot{R}(t) \geq -L\dot{R}(t),$$

and hence

$$(5.38)\qquad I_2^\delta \leq \int_{t_i+\delta}^{t'} L\dot{R}(t)(R(t') - R(t))dt = \frac{L}{2}(R(t') - R(t_i+\delta))^2.$$

One can estimate the first integral I_1^δ in the identity (5.37) by using the inequality (5.35),

$$(5.39)\qquad \lim_{\delta\to 0} I_1^\delta = -\int_{R(t_i)}^{R(t')} \theta(x,t_i)(x - R(t'))dx \leq -\frac{L}{2}(R(t') - R(t_i))^2.$$

Therefore, letting $\delta \to 0$ in the identity (5.37), we obtain the contradiction

$$0 = \frac{L}{2}(R(t') - R(t_i))^2 - \frac{L}{2}(R(t') - R(t_i))^2 > 0.$$

So the converse of condition (5.32) is valid:

$$(5.40)\qquad \theta(x,t_i) > -L,\quad x \in (R(t_i+0), 1).$$

Since the set M is simply connected, (5.40) implies $M \cap \{t \geq t_i\} = \emptyset$. Then the statement of Lemma 9 yields $t^i = \infty$. Thus there exists at most one interval (t_i, t^i), $i \in I$ such that $t_i > 0$. If we denote $\bar{t} := t_i > 0$, then because of the properties (3.13) and (5.40), we obtain the validity of the inequalities (5.2) and (5.5) from the statement of Theorem 4.

In order to complete the proof of Theorem 4, we need only to prove the inequality (5.4). Note that, by the definition of the weak solution for the problem (A^0), the function U (see the formulation of the weak solution of the problem (A^0)) solves the heat conduction equation

$$U_t - U_{xx} = 0$$

in the domain

$$\{(x,t) : 0 < t < t_*,\ x \in (R(\bar{t}-0), R(\bar{t}+0))\}.$$

Here we have used the monotonicity of the function R on the interval $(0, t_*)$. Therefore

$$\lim_{t\to\bar{t}-0} U(x,t) = \lim_{t\to\bar{t}+0} U(x,t), \quad x \in (R(\bar{t}-0), R(\bar{t}+0)),$$

and

$$\theta(x,\bar{t}-0) + L = \theta(x,\bar{t}+0), \ x \in (R(\bar{t}-0), R(\bar{t}+0)). \tag{5.41}$$

From $\theta(x,t) \le 0$ for $x \in (0, R(t))$, $t \ge 0$, we deduce $\theta(x,\bar{t}+0) \le 0$, which together with (5.41) implies the inequality (5.4). The proof of Theorem 4 is now complete. □

COROLLARY 4. *If we replace the condition* (2.10) *by*

$$\theta^0(t) \le 0, \quad -L \le \theta^1(t) \le 0 \quad t \ge 0, \quad \theta_0(x) \le 0, \quad x \in (0,1), \tag{5.42}$$

then under the condition (5.1) *the statement of Theorem* 4 *also is valid.*

But the lifetime of the solution might be finite in this case, since the moving boundary can touch the fixed one, $x = 1$. This setup of the problem is simpler, because of $\theta^\varepsilon \le 0$, $\theta \le 0$ in Q_T and the functions R^ε, R are nondecreasing over the whole interval $(0,T)$. The conditions (5.42) also describe the one-phase initial-boundary data:

$$\theta^0(t) = 0, \ -L \le \theta^1(t) \le 0, \ t \ge 0;$$
$$\theta_0(x) = 0, \ x \in [0, R_0]; \ \theta_0(x) \le 0, \ x \in [R_0, 1].$$

It is obvious to see that after the jump of the free boundary, the solution becomes two-phase.

COROLLARY 5. *The results of Theorem* 4 *can be proved also for the problem* (A^0) *with Neuman boundary conditions*

$$\theta_x(i,t) = f^i(t), \quad 0 < t < T, \ i = 0,1,$$

where in addition to the conditions of Theorem 4 *we need the inequalities*

$$f^i(t) \ge 0, \quad 0 < t < T, \ i = 0,1.$$

The last condition makes sure that the temperature is nonpositive in the solid phase, and a new critical set $\{\theta < -L\}$ does not appear at the right boundary of the interval $x = 1$. However, similar to Corollary 4, we are able to study our solution only until the moving boundary touches the fixed one.

COROLLARY 6. *One can make the condition* (5.1) *less restrictive by introducing a finite number* N *of connected pieces of the set* $\{x : \theta_0(x) < -L\}$. *Then there exist at most* N *values* $t_i \in [0,T]$, $i = 1,\dots,M$, $M \le N$ *such that*

$$\sup_{t\in(t_i+\delta, t_{i+1}-\delta)} |\dot{R}(t)| \le C_i(\delta) \quad \textit{for every } \delta > 0, \ i = 0,\dots,M,$$
$$R(t_i+0) \ge R(t_i-0), \ i = 1,\dots,M-1,$$
$$\theta(x, t_i-0) \le -L, \ x \in (R(t_i-0), R(t_i+0)), \ i = 1,\dots,M,$$

where $t_0 = 0$, $t_{M+1} = T$.

6. Conclusion. We have studied the qualitative properties of the regular solutions of the problem (A^0). As follows from Theorem 4, the size of the jump of the free boundary is uniquely determined by the values of the temperature. Namely, the free boundary jumps exactly over the interval where $\theta \leq -L$. Please note that the arbitrary weak solution of the problem (A^0) does not have the previous property: The size of the jump can be anything. This fact implies, in particular, the nonuniqueness of the weak solution of the problem (A^0) (see, for example, [7]). Therefore the remaining open question is the uniqueness of a regular solution of the problem (A^0). It seems to be that the main difficulty of this task is to prove the uniqueness of a regular solution after the jump of the free boundary, i.e., with the following initial data at $t = \bar{t}$:

$$\begin{aligned}
&\theta(x, \bar{t}+0) = \vartheta(x), \ x \in (0,1), \\
&\vartheta \in C([0, R(\bar{t}+0)]), \ \vartheta(x) \leq 0, \ 0 \leq x \leq R(\bar{t}+0), \\
&\vartheta \in C([R(\bar{t}+0), 1]), \ \vartheta(x) \geq -L, \ R(\bar{t}+0) \leq x \leq 1, \\
&\lim_{x \to R(\bar{t}+0)+0} \vartheta(x) = -L, \lim_{x \to R(\bar{t}+0)-0} \theta(x) = 0.
\end{aligned}$$

The one-phase Stefan problem of this type was investigated by Fasano and Primicerio [2]. By using the maximum principle they proved the uniqueness of the solution. Unfortunately this method does not work for the two-phase problem.

NEW UNIQUENESS THEOREMS FOR THE ONE-DIMENSIONAL DRIFT-DIFFUSION SEMICONDUCTOR DEVICE EQUATIONS*

FATIHA ALABAU†

Abstract. We consider the one-dimensional drift-diffusion semiconductor device equations, under the assumption of zero generation-recombination. The uniqueness theorems that are given in the literature for this system do not hold for large values of the applied bias. The purpose of this paper is to introduce new techniques, which allow us to prove uniqueness theorems, in the case of symmetric p-n and p-i-n junctions, which are valid for arbitrary values of the applied bias. These techniques are essentially based on new monotonicity principles. As a direct consequence of these principles, we prove that the voltage-current characteristic of a symmetric p-n or p-i-n junction is strictly increasing.

1. Introduction.

In this paper we consider the uniqueness and the qualitative behavior of solutions of a system of differential equations that arises in the physics of semiconductor devices. This system, derived by Van Roosbroeck [16], forms a one-dimensional parameter-dependent system.

Under scaled form (see [11], [1]), the equations we consider are

$$\varepsilon\psi'' = n - p - N, \tag{1.1}$$

$$n' = n\psi' + J_n, \tag{1.2}$$

$$p' = -p\psi' - J_p, \tag{1.3}$$

in $\Omega =]-1, 1[$. This system is assumed to satisfy the boundary conditions

$$\psi(-1) = \psi_{-1}, \qquad \psi(1) = \psi_1, \tag{1.4}$$

$$n(-1) = n_{-1}, \qquad n(1) = n_1, \tag{1.5}$$

$$p(-1) = p_{-1}, \qquad p(1) = p_1, \tag{1.6}$$

where $\psi_{\pm 1}$, $n_{\pm 1}$, $p_{\pm 1}$ are given by

$$\psi_x = \log\left(\frac{N(x) + \sqrt{N^2(x) + 4\delta^4}}{2\delta^2}\right) - U(x), \qquad x = \pm 1, \tag{1.7}$$

$$n_x = \frac{N(x) + \sqrt{N^2(x) + 4\delta^4}}{2}, \qquad x = \pm 1, \tag{1.8}$$

$$p_x = \frac{-N(x) + \sqrt{N^2(x) + 4\delta^4}}{2}, \qquad x = \pm 1. \tag{1.9}$$

System (1.1)–(1.6) models the transport of electrons and holes in a semiconductor device under the effect of a parameter V, which acts on the device only through the boundary condition (1.4). Our model assumes that the mobilities are constant and that there are no generation-recombination effects. This last assumption (which is not physically realistic under strong forward bias) implies that the unknown electron and hole current densities are constant. We use this property throughout this paper, so that our results do not apply (at least directly) to the case of nonzero generation-recombination. The purpose of this paper is to derive qualitative new results on this simplified model, rather than to consider a more complex one. We shall discuss in §4 how these results can be extended to more complex models, in particular to the case of small generation-recombination terms. The unknowns are the functions ψ, n, p and the numbers J_n, J_p, which represent, respectively, the electrostatic potential, the electron and hole densities, and the electron and hole current densities. The given function N is called the doping profile. The number ε is a small positive constant, $-U(-1)$ and $-U(1)$ are the voltages applied at the endpoints of $\overline{\Omega}$, and δ is a positive number.

The parameter of interest in our study is

$$V = U(1) - U(-1); \tag{1.10}$$

this is called the applied bias and it will be allowed to take values in all $\mathbb{R}$, whereas ε and δ are kept fixed.

To express clearly that (1.1)–(1.6) is solved for a given V, we will refer to this system, when necessary, by the notation (1.1)–$(1.6)_V$.

Many results that concern the existence of solutions of the steady-state semiconductor device equations, (under a more general form than (1.1)–(1.6)), have been proved (see, e.g.,[13], [11], [8], [19]). In particular, for all strictly positive numbers ε and δ, for all V in $\mathbb{R}$, and for all piecewise-smooth functions N, (1.1)–$(1.6)_V$ admits at least one solution

$$(\psi, n, p, J_n, J_p) \in (H^1(\Omega))^3 \times \mathbb{R}^2. \tag{1.11}$$

Moreover, every solution (ψ, n, p, J_n, J_p) that satisfies (1.11) satisfies $n > 0$ and $p > 0$ on $\overline{\Omega}$.

The situation is wide open (see, e.g., [12], [18], [7]) as far as uniqueness or multiplicity of the solutions of the steady-state semiconductor device equations is concerned, even in the one-dimensional case. Moreover, the voltage-current curve (or characteristic) of the device that expresses the unknown current

$$I = J_n + J_p, \tag{1.12}$$

in terms of the applied bias, and that describes the electrical behavior of the semiconductor device, is of primary interest for the device engineers.

The purpose of our paper is to introduce new tools for considering the problem of uniqueness of solutions of (1.1)–$(1.6)_V$ for arbitrary values of V, and for studying the behavior of the voltage-current characteristic.

We first remark that, for physical reasons, the solution is not, in general, unique (see [12], [17], and [20] for numerical examples of multiplicity). Actually, the physical

performances of certain devices, like, for instance, thyristors, are explicitly based on the existence of multiple steady-state solutions. However, in multidimensional cases, uniqueness of solutions holds for sufficiently small $|V|$, uniformly with respect to the doping profile N (see [13], [11], and the references therein, [9], and see also the recent paper [14], which treats the case of weak solutions). Hence, it is important to distinguish between the case of small $|V|$ (that is close to equilibrium) for which uniqueness holds uniformly with respect to the doping profile N, and the case of nonsmall $|V|$, for which it is known, but not proved, that uniqueness does not hold uniformly with respect to the doping profile (see [18]). Therefore, uniqueness results for arbitrary V can be obtained only under additional assumptions on the doping profile N.

The methods used for proving uniqueness for small $|V|$, in the above-mentioned papers, and in [6] are essentially based on a perturbation argument for small $|V|$ (or small λ as in [6]), either based on a monotonicity property of the second member of the equation (1.1) with respect to ψ (when n and p are defined as functions of ψ through the continuity equations (1.2),(1.3) and the boundary conditions (1.5),(1.6)), or on a contraction property (as in [9]). This means that, for small $|V|$, the nonlinear system formed by the semiconductor equations is *weakly* coupled (see [12]). This is *no longer true* for arbitrary V. Therefore, one has to find other techniques, not only to get uniqueness results for arbitrary V, but also to find under which hypotheses on the doping profile N such uniqueness results hold.

One of the goals of this paper is to introduce new arguments for proving such uniqueness results. To formulate our results, we first recall here some basic definitions concerning semiconductor devices. The semiconductor is said to be *symmetric* when N is odd. A region where N is > 0 (resp., < 0) is called an *n-region* (resp., *p-region*). A region where $N = 0$ is called an *i-region*. The number of sign alterations of the doping profile N characterizes the type of the semiconductor. For a *pn-junction*, N has only one alteration of sign in the device. For a p-i-n junction, N has only one alteration of sign, but it is equal to zero in the i-region. The junction is said to be abrupt (resp., smooth) when N is discontinuous (resp., continuous) at the point where it changes its sign.

The purpose of this paper is threefold. First, we identify general a priori conditions on the solutions of (1.1)–(1.6) (see (2.2) and (2.3)), which are sufficient for proving global uniqueness theorems. This is done by introducing and proving some new monotonicity principles. More precisely, under the above-mentioned conditions on the solutions of (1.1)–(1.6), and when N is odd and satisfies additional hypotheses depending on the polarisation (i.e., on the sign of V) of the device, we show that the electric field $-\psi'$ satisfies a local and a global monotonicity property with respect to the current I. Whenever these monotonicity properties hold, we prove that (1.1)–(1.6) has a unique solution. We also give (in Remark 2.7), a physical interpretation of the above-mentioned conditions.

Second, we prove that these conditions are satisfied under additional assumptions on the doping profile N and for arbitrary large values of $|V|$. This allows us to prove that (1.1)–$(1.6)_V$ has a unique solution for all $V \leq 0$ (i.e., in the reverse-biased case) when N satisfies one of the following two hypotheses.

(i) N is odd and is in $\mathcal{C}^1(\overline{\Omega})$, $0 \leq N'$ on $\overline{\Omega}$ (which is an example of smooth pn or p-i-n junction);

(ii) N is odd, $N = 1$ on $[0, 1]$ (which is an example of abrupt pn-junction), and for all $V \geq V_0 = V_0(\delta, \varepsilon) > 0$ (i.e., in the forward-biased case) when (ii) holds.

The doping profiles N satisfying (i) or (ii) have at most one alteration of sign. Therefore our results partially answer the conjecture formulated by Mock [12] and by Rubinstein [17], which predicts that, when N has at most two alterations of sign in the device, then (1.1)–$(1.6)_V$ has a unique solution for all V.

Third, it is well known that numerical simulations and physical experiments predict that the voltage-current curve of a pn-junction is a strictly increasing function of V. We establish that this property is a direct consequence of the new monotonicity principles introduced in this paper and prove it for the devices described above. This is, to our knowledge, the first proof of a result which was known from numerical simulations, but was not demonstrated rigorously.

Furthermore, our results have obvious direct applications to current-driven models (see [10]), for which the current is assumed to be given, whereas the bias is an unknown.

The results of the present paper generalize our previous papers [4], [5] in the following sense. In [4], we consider two different types of devices, namely, bipolar membranes and unipolar (or single carrier) devices. In this last case only one type of charges (for instance, electrons) is transported through the device. Hence in the unipolar case, the system (1.1)–$(1.6)_V$ reduces to a system of two equations (derived from (1.1)–$(1.6)_V$, by setting one of the concentrations n or p equal to zero). For this case we prove global uniqueness of solutions for *arbitrary* V and for *arbitrary* doping profiles N. For the bipolar membrane case, one has to consider the full system (1.1)–(1.3). Of course, as is explained above, uniqueness of solutions of this full system for arbitrary V does not hold for arbitrary doping profiles N. In [4], we obtain uniqueness results in the case of bipolar membranes, for arbitrary large $|V|$, under the strong assumption of a *zero* doping profile N. The technique used in [4] is based on a decoupling method, which is valid whenever the doping profile N is piecewise constant. However, to obtain uniqueness results, we apply a maximum principle that for technical reasons is directly applicable only for a *zero* doping profile N. This argument is no longer applicable directly for a *nonzero* doping profile N. In [5], we obtained a first result for an example of *nonzero* odd doping profile (namely, $N(x) = sign(x)$). In [5] we use the decoupling method introduced in [4]. However, because of the technical difficulties generated by the presence of a *nonzero* doping profile, we need to apply a maximum principle on the first derivative of a function satisfying a true third-order differential equation (see Remark 2.6 in the present paper). As a consequence, we only prove in [5] a local uniqueness theorem for the solutions of the symmetrized version of system (1.1)–$(1.6)_V$ (which is the system derived from (1.1)-$(1.6)_V$ by only considering the symmetric solutions) when $V \leq 0$. In the present paper, we introduce a new decoupling method, which is valid even if the doping profile is not piecewise constant, but only in the case of symmetric (see Definition 1.2 in this paper) solutions. As a consequence of this new decoupling, we prove more general results, and in particular that (1.1)–$(1.6)_V$ has a unique solution (which is, of course, necessarily symmetric) under the above given assumptions on N and V. We also prove the monotonicity of the voltage-current curve in the cases given above.

Note here that the present results do not apply to the bipolar membrane case, which is under consideration in [4]. In this last case there is no symmetry assumption because of the boundary conditions for the bipolar membranes, which are slightly different from the boundary conditions for semiconductors.

Note also that the local monotonicity property mentioned in this paper has indeed been introduced in an informal way in [5].

The paper is organized as follows. Section 2 is devoted to the reverse biased case. In §2.1 we derive, for general symmetric devices, sufficient a priori conditions on the solutions for proving uniqueness and monotonicity of the current. In §2.2 we give applications of these results to symmetric smooth and abrupt pn-junctions. In §3 we study the forward-biased case. In §3.1 we give a priori sufficient conditions on the solutions for proving uniqueness of solutions and monotonicity of the current in the case of abrupt pn-junctions. In §3.2 we prove that these a priori conditions are satisfied for strong forward biases.

Throughout this paper solutions of (1.1)–(1.6)$_V$ will always be assumed to satisfy (1.11).

We assume from now on that the semiconductor device is symmetric (see [4] and [3] for nonsymmetric devices). This assumption gives the following important remarks.

Remark 1.1. Let (ψ, n, p, J_n, J_p) be a solution of (1.1)–(1.6). We define the corresponding symmetrized vector $(\psi^s, n^s, p^s, J_n^s, J_p^s)$ in $(H^1(\Omega))^3 \times \mathbb{R}^2$ by

$$\psi^s(x) = -\psi(-x),\ n^s(x) = p(-x),\ p^s(x) = n(-x) \quad \forall x \text{ in } \overline{\Omega}, \tag{1.13}$$

and

$$J_n^s = J_p,\ J_p^s = J_n. \tag{1.14}$$

Then it is easy to check that $(\psi^s, n^s, p^s, J_n^s, J_p^s)$ is also a solution of (1.1)–(1.6).

DEFINITION 1.2. *A solution of* (1.1)–(1.6) *is said to be* symmetric *if it coincides with its symmetrized vector.*

Remark 1.3. We deduce from Remark 1.1 that if (1.1)–(1.6) has a nonsymmetric solution then it has multiple solutions.

2. Reverse-biased symmetric semiconductor devices. A symmetric semiconductor is said to be *reverse-biased* when $N(1)V < 0$. It is at *equilibrium* when $V = 0$. To fix the sign of V in the reverse-biased case, we assume, without loss of generality, within this section that

$$0 < N(1). \tag{2.1}$$

We set $\Omega_+ = (0, 1)$.

2.1. Sufficient conditions for proving uniqueness of solutions and monotonicity of the current.

THEOREM 2.1. *Assume that* $N|_{\overline{\Omega}_+} \in C^1(\overline{\Omega}_+)$ *and let* $V \leq 0$ *be such that the following two hypotheses are verified.*

(i) *All solutions* (ψ, n, p, J_n, J_p) *of* (1.1)–(1.6)$_V$ *are such that*

$$I\psi'(x) \leq 0 \quad \forall x \in \overline{\Omega}_+, \tag{2.2}$$

where I *is given by* (1.12).

(ii) *There exists a symmetric solution* (ψ, n, p, J_n, J_p) *of* (1.1)–(1.6)$_V$ *that is such that*

$$0 \leq (n - p)(x) \quad \forall x \in \overline{\Omega}_+. \tag{2.3}$$

Then (1.1)-(1.6)$_V$ *has a unique solution satisfying* (1.11).

The proof is divided in two steps. We first prove that under hypothesis (i) of Theorem 2.1 all solutions of (1.1)–(1.6)$_V$ are symmetric. We then prove uniqueness in the class of symmetric solutions. These two results are independent, so that we give them separately. Let us first give the result of symmetry.

THEOREM 2.2. *Assume that* $N|_{\overline{\Omega}_+} \in \mathcal{C}^1(\Omega_+)$ *and let* $V \leq 0$ *be such that there exists a solution* $(\bar{\psi}, \bar{n}, \bar{p}, \bar{J}_n, \bar{J}_p)$ *of* (1.1)-(1.6)$_V$ *satisfying* (2.2). *Then this solution is symmetric.*

Proof. We set

$$I = \bar{J}_n + \bar{J}_p, \ J = \bar{J}_n - \bar{J}_p,$$

$$\psi(x) = \bar{\psi}(x), \ n(x) = \bar{n}(x), \ p(x) = \bar{p}(x) \quad \forall x \in \overline{\Omega}_+,$$

and

$$\phi(x) = -\bar{\psi}(-x), \ \tilde{n}(x) = \bar{p}(-x), \ \tilde{p}(x) = \bar{n}(-x) \quad \forall x \in \overline{\Omega}_+.$$

Then $(\psi, n, p, \bar{J}_n, \bar{J}_p)$ and $(\phi, \tilde{n}, \tilde{p}, \bar{J}_p, \bar{J}_n)$ are both solutions of (1.1)–(1.3) on Ω_+.

Because of Remark 1.1, we can assume without loss of generality that

$$J \leq 0. \tag{2.4}$$

Let us first assume that $V < 0$. Since (2.1) holds, we have

$$I < 0. \tag{2.5}$$

From (1.1)–(1.3), we obtain

$$4(np - \tilde{n}\tilde{p})' = -2I\varepsilon(\psi - \phi)'' + 2J(n + p + \tilde{n} + \tilde{p}) \quad \text{on } \Omega_+.$$

From (2.4) and since $(\bar{\psi}, \bar{n}, \bar{p})$ is in $\mathcal{C}^1(\overline{\Omega}) \times (\mathcal{C}(\overline{\Omega}))^2$, we deduce that

$$4(np - \tilde{n}\tilde{p}) \leq -2I\varepsilon(\psi - \phi)' \quad \text{on } \Omega_+. \tag{2.6}$$

Since $(\psi, n, p, \bar{J}_n, \bar{J}_p)$ and $(\phi, \tilde{n}, \tilde{p}, \bar{J}_p, \bar{J}_n)$ are solutions of (1.1)–(1.3), we obtain

$$\varepsilon(\psi - \phi)^{(3)} = (n + p)\psi' - (\tilde{n} + \tilde{p})\phi'.$$

We now replace in this last equation $n + p$ by $\left((n - p)^2 + 4np\right)^{1/2}$, do the same thing for $\tilde{n} + \tilde{p}$, and use (2.2) and (2.5), (2.6) to obtain

$$\varepsilon(\psi - \phi)^{(3)} \leq (\psi - \phi)''a_1 + (\psi - \phi)'a_0 \quad \text{on } \Omega_+, \tag{2.7}$$

where a_1 is a smooth function on $\overline{\Omega}_+$ and where a_0 is given by

$$a_0 = \tilde{n} + \tilde{p} - \frac{2I\varepsilon\psi'}{n + p + \tilde{n} + \tilde{p}}.$$

From (2.2), it follows that

$$a_0 > 0 \text{ on } \overline{\Omega}_+.$$

Since (2.6) holds, we have

$$0 \leq (\psi - \phi)'(1).$$

However, we also have $(\psi - \phi)'(0) = 0$, so that the maximum principle (see [15]) applied to (2.7) implies

$$0 \leq (\psi - \phi)' \quad \text{on } \Omega_+. \tag{2.8}$$

Since

$$((n - \tilde{n}) \exp(-\psi))' = \tilde{n} \exp(-\psi)(\psi - \phi)' + J \exp(-\psi),$$

we obtain

$$(n - \tilde{n})(x) \leq -J \exp(\psi(x)) \int_x^1 \exp(-\psi(t))dt \quad \forall x \text{ in } \Omega_+.$$

From (2.2) and (2.4)-(2.5), we deduce that

$$(n - \tilde{n})(x) \leq -J(1 - x) \quad \forall x \in \Omega_+.$$

By following a similar argument for $(p - \tilde{p})$, we obtain

$$(\psi - \phi)'' \leq 0 \text{ in } \Omega_+.$$

This together with (2.8) implies that $\psi = \phi$ on $\overline{\Omega}_+$. The equations $n = \tilde{n}$, $p = \tilde{p}$, and $J = 0$ follow at once. This proves the theorem when $V < 0$. If $V = 0$, we remark that inequality (2.7) becomes an equality, so that the same conclusion holds.

This concludes the proof.

We now prove uniqueness in the class of symmetric solutions under weaker hypotheses than those of Theorem 2.1.

THEOREM 2.3. *Assume that* $N|_{\overline{\Omega}_+} \in C^1(\overline{\Omega}_+)$ *and let* $V \leq 0$ *be such that there exists a symmetric solution* (ψ, n, p, J_n, J_p) *of* (1.1)–(1.6)$_V$ *satisfying* (2.2) *and* (2.3). *Then, the problem* (1.1)–(1.6)$_V$ *has a unique symmetric solution satisfying* (1.11).

Proof. Assume first that $V < 0$ and let $(\phi, \tilde{n}, \tilde{p}, \tilde{J}_n, \tilde{J}_p)$ be another symmetric solution of (1.1)-(1.6)$_V$.

We set

$$I = J_n + J_p \ , \ \tilde{I} = \tilde{J}_n + \tilde{J}_p$$

and

$$J = J_n - J_p \ , \ \tilde{J} = \tilde{J}_n - \tilde{J}_p.$$

As in the proof of Theorem 2.2, we replace $n + p$ by $\left((n - p)^2 + 4np\right)^{1/2}$, so that, finally, we obtain

$$\begin{aligned} \varepsilon(\psi - \phi)^{(3)} = (\psi - \phi)'' b_1 + \frac{4\psi'}{n + p + \tilde{n} + \tilde{p}}(np - \tilde{n}\tilde{p}) \\ + (\tilde{n} + \tilde{p})(\psi - \phi)' + I - \tilde{I} \text{ on } \Omega_+, \end{aligned} \tag{2.9}$$

where b_1 is a smooth function on $\overline{\Omega}_+$.

Since $J = \tilde{J} = 0$, we have

$$4(np - \tilde{n}\tilde{p})' = -2I(n-p) + 2\tilde{I}(\tilde{n} - \tilde{p}) \quad \text{on } \Omega_+. \tag{2.10}$$

Let M be a primitive of N and x_0 be an arbitrary point of $\overline{\Omega}_+$. Integration of (2.10) yields

$$\begin{aligned} 4(np - \tilde{n}\tilde{p})(x) = &-2(I - \tilde{I})\,(\varepsilon\psi'(x) + M(x) - (\varepsilon\psi'(x_0) + M(x_0))) \\ &-2\tilde{I}\varepsilon(\psi - \phi)'(x) + 2\tilde{I}\varepsilon(\psi - \phi)'(x_0) \\ &+4(np - \tilde{n}\tilde{p})(x_0) \quad \forall x \in \overline{\Omega}_+. \end{aligned} \tag{2.11}$$

We use this last equality in (2.9) to obtain

$$\begin{aligned} \varepsilon(\psi - \phi)^{(3)}(x) = &(\psi - \phi)''(x)b_1(x) + (\psi - \phi)'(x)b_0(x) \\ &+(I - \tilde{I})(1 - \frac{2\psi'(x)}{(n + p + \tilde{n} + \tilde{p})(x)}\,(\varepsilon\psi'(x) + M(x) \\ &- (\varepsilon\psi'(x_0) + M(x_0)))) \\ &+\frac{\psi'(x)}{(n + p + \tilde{n} + \tilde{p})(x)}\left(2\tilde{I}\varepsilon(\psi - \phi)'(x_0) + 4(np - \tilde{n}\tilde{p})(x_0)\right) \quad \forall x \in \overline{\Omega}_+, \end{aligned} \tag{2.12}$$

where b_0 is given by

$$b_0 = \tilde{n} + \tilde{p} - \frac{2\tilde{I}\varepsilon\psi'}{n + p + \tilde{n} + \tilde{p}}\,.$$

Using (2.2) and the fact that I and $\tilde{I}$ have the same sign, we obtain

$$0 < b_0 \text{ on } \overline{\Omega}_+.$$

Note that we can assume, without loss of generality, that

$$I - \tilde{I} \leq 0. \tag{2.13}$$

We claim that the following inequalities:

$$0 \leq (\psi - \phi)'(0) \quad \text{and} \quad 0 \leq (\psi - \phi)'(1) \tag{2.14}$$

hold. To prove this, we proceed as in [5, Lem. 3.3]. Assume to the contrary that we have

$$0 > (\psi - \phi)'(0) \quad \text{or} \quad 0 > (\psi - \phi)'(1).$$

We set $E = \{x \in [0,1], (\psi - \phi)'(x) = 0\}$.

Let us first assume that $(\psi - \phi)'(1) < 0$ holds and let $y^\star$ be the largest element of E. Hence, we have

$$(\psi - \phi)' \leq 0 \quad \text{on } [y^\star, 1] \quad \text{and} \quad (\psi - \phi)'(y^\star) = 0.$$

From (2.13) and

$$((n - \tilde{n})\exp(-\psi))' = \tilde{n}\exp(-\psi)(\psi - \phi)' + ((I - \tilde{I})/2)\exp(-\psi)\,, \tag{2.15}$$

we deduce that

$$0 \leq n - \tilde{n} \quad \text{on } [y^\star, 1].$$

In a similar way, we obtain

$$0 \leq -(p - \tilde{p}) \quad \text{on } [y^\star, 1].$$

Now, however, (1.1) implies

$$\varepsilon(\psi - \phi)'' = (n - \tilde{n}) - (p - \tilde{p}). \tag{2.16}$$

Hence, we obtain

$$0 \leq (\psi - \phi)'' \quad \text{on } [y^\star, 1].$$

This contradicts the inequality $(\psi - \phi)'(1) < 0$. Therefore, we can now assume that we have

$$(\psi - \phi)'(0) < 0 \quad \text{and} \quad 0 \leq (\psi - \phi)'(1). \tag{2.17}$$

Let $x^\star$ be the smallest element of E. Hence, we have

$$(\psi - \phi)' \leq 0 \quad \text{on } [0, x^\star] \quad \text{and} \quad (\psi - \phi)'(x^\star) = 0.$$

From (2.15) and since $\psi(0) = 0$, we deduce that

$$(n - \tilde{n})(x) \leq (n - \tilde{n})(0)\exp(\psi(x)) \quad \forall x \in [0, x^\star].$$

In a similar way, we obtain

$$-(p - \tilde{p})(x) \leq -(p - \tilde{p})(0)\exp(-\psi(x)) \quad \forall x \in [0, x^\star].$$

From (2.16) and since

$$(n - p)(0) = (\tilde{n} - \tilde{p})(0) = 0 \tag{2.18}$$

holds, we obtain

$$\varepsilon(\psi - \phi)''(x) \leq 2(n - \tilde{n})(0)\sinh(\psi(x)) \quad \forall x \in [0, x^\star]. \tag{2.19}$$

We now set $x = 0$ and $x_0 = 1$ in (2.11) and use (2.18) to derive

$$\begin{aligned} 4(n - \tilde{n})(0)(n + \tilde{n})(0) = {} & 2(I - \tilde{I})\left(\varepsilon\psi'(1) + M(1) - (\varepsilon\psi'(0) + M(0))\right) \\ & -2\tilde{I}\varepsilon(\psi - \phi)'(0) + 2\tilde{I}\varepsilon(\psi - \phi)'(1). \end{aligned} \tag{2.20}$$

From property (2.3) we deduce that the function $\varepsilon\psi' + M$ is increasing on $\overline{\Omega}_+$. Since (2.5) (with I replaced by $\tilde{I}$), (2.13), and (2.17) hold we deduce that

$$(n - \tilde{n})(0) \leq 0. \tag{2.21}$$

Now from (2.5), (2.2) and $\psi(0) = 0$ we deduce that

$$0 \leq \sinh(\psi(x)) \quad \forall x \in [0, 1].$$

Using this last inequality and (2.21) in (2.19), we obtain

$$(\psi - \phi)'' \leq 0 \text{ on } [0, x^*],$$

which contradicts (2.17).

Hence we proved inequality (2.14).

The function $\varepsilon\psi' + M$ is increasing on $\overline{\Omega}_+$. Thus, from the inequalities $b_0 > 0$, (2.2), (2.5), (2.13)–(2.14), and from the maximum principle applied to (2.12), we conclude that

$$0 \leq (\psi - \phi)' \text{ on } \overline{\Omega}_+. \tag{2.22}$$

This proves the theorem when $V < 0$. Moreover, if $V = 0$, then

$$I = \tilde{I}, \qquad np = \tilde{n}\tilde{p} = n_1 p_1 \quad \text{on} \quad \Omega,$$

so that we get to the same conclusion. Hence theorem 2.3 is proved.

Observe that Theorem 2.1 follows from Theorems 2.2 and 2.3.

Remark 2.4. We have proved and applied in the proof of Theorem 2.3 two new monotonicity principles that are satisfied by the symmetric solutions of (1.1)–$(1.6)_V$ in the reverse-biased case. Let ψ and ϕ be the electrostatic potentials, I and $\tilde{I}$ be the two respective currents corresponding to two symmetric solutions. Then the first monotonicity principle expresses a local monotonicity property of the electric field with respect to the current in the following sense.

If (2.2), (2.3) hold, then

$$I \leq \tilde{I} \implies 0 \leq (\psi - \phi)'(0) \quad \text{and} \quad 0 \leq (\psi - \phi)'(1).$$

The second monotonicity principle expresses a global monotonicity property of the electric field with respect to the current in the following sense.

If (2.2), (2.3) hold, then

$$I \leq \tilde{I} \quad \text{and} \quad 0 \leq (\psi - \phi)'(0), \qquad 0 \leq (\psi - \phi)'(1) \implies 0 \leq (\psi - \phi)' \quad \text{on } \overline{\Omega}_+.$$

Remark 2.5. It is important to remark that the proof of the global monotonicity property mentioned in Remark 2.4 relies on a new decoupling method (compared to the one introduced in [4] and [3]), which uses the properties of the symmetric solutions of (1.1)–(1.6) and allows us to prove that $(\psi - \phi)'$ satisfies a second-order differential equation, namely (2.12), which is decoupled from the equations satisfied by $n - \tilde{n}$ and $p - \tilde{p}$.

Remark 2.6. When the doping profile is not necessarily odd but is piecewise-constant, we have introduced in [3] a general decoupling method. One main difficulty in this case is to justify a maximum principle on the derivative of the solution of a third-order differential equation, for which the zero-order coefficient is not vanishing. Our new decoupling method allows us to avoid this difficulty in the case of symmetric devices.

Remark 2.7. The a priori properties (2.2) and (2.3) have a precise physical meaning. The inequality (2.2) means that the current I and the electric field $-\psi'$ flow in the same direction. The inequality (2.3) means that the electron density is larger than the hole density. We will see in §2.2 that this property is always satisfied when N has only one alteration of sign. Moreover, we can remark that we have already used (2.2) in [5] to justify a generalized maximum principle (see [15]), which

allowed us to prove that the symmetric solutions of (1.1)–(1.6) are locally unique (see also [3] for the forward-biased case). The new decoupling technique introduced here and (2.3) are fundamental for the proof of global uniqueness.

We now study the monotonicity of the voltage-current curve.

THEOREM 2.8. *Assume that* $N|_{\overline{\Omega}_+} \in C^1(\overline{\Omega}_+)$ *and let* V *and* $\tilde{V}$ *be such that* $V < \tilde{V} \leq 0$. *Assume moreover that there exists a symmetric solution* (ψ, n, p, J_n, J_p) *(resp.,* $(\phi, \tilde{n}, \tilde{p}, \tilde{J}_n, \tilde{J}_p)$*) of* (1.1)–$(1.6)_V$ *(resp.,* (1.1)–$(1.6)_{\tilde{V}}$*) satisfying* (2.2) *and* (2.3).

Then the following property holds:

$$I < \tilde{I}, \tag{2.23}$$

where $I = J_n + J_p$ *and* $\tilde{I} = \tilde{J}_n + \tilde{J}_p$.

Proof. From the hypotheses and Theorem 2.3, we know that (1.1)–$(1.6)_V$ (resp., (1.1)–$(1.6)_{\tilde{V}}$) has a unique symmetric solution. We claim that (2.23) holds. To the contrary, assume that

$$0 \leq I - \tilde{I}. \tag{2.24}$$

As in the proof of Theorem 2.3, we show that if $(\psi - \phi)'(0) \leq 0$ and $(\psi - \phi)'(1) \leq 0$ hold, then we have $(\psi - \phi)' \leq 0$ on $\overline{\Omega}_+$, which contradicts the hypothesis $V < \tilde{V}$. Hence we have either $0 < (\psi - \phi)'(0)$ or $0 < (\psi - \phi)'(1)$.

Let us first assume that $0 < (\psi - \phi)'(1)$. Then, we claim that $(\psi - \phi)'$ changes sign on $\overline{\Omega}_+$. Assume to the contrary that $(\psi - \phi)'$ keeps a constant sign on $\overline{\Omega}_+$. We deduce then from (2.24) that

$$0 < (\psi - \phi)' \quad \text{on } \overline{\Omega}_+.$$

From this, we get

$$2(I - \tilde{I}) \cosh \psi < ((n - \tilde{n}) \exp(-\psi) - (p - \tilde{p}) \exp(\psi))' \quad \text{on } \overline{\Omega}_+,$$

which contradicts (2.24).

Therefore $(\psi - \phi)'$ changes sign on $\overline{\Omega}_+$. We now proceed as in the proof of Theorem 2.3. Let $y^\star$ be the largest element of

$$X = \{x \in \overline{\Omega}_+, (\psi - \phi)'(x) = 0\}.$$

We use the inequalities $0 \leq (\psi - \phi)'$ on $[y^\star, 1]$ and (2.24) in (2.15) to deduce that

$$(n - \tilde{n}) \leq 0 \quad \text{on } [y^\star, 1].$$

In a similar way, we obtain

$$-(p - \tilde{p}) \leq 0 \quad \text{on } [y^\star, 1].$$

Thus we have $(\psi - \phi)'' \leq 0$ on $[y^\star, 1]$, which contradicts $0 < (\psi - \phi)'(1)$. Hence, we proved that we have

$$(\psi - \phi)'(1) \leq 0.$$

Assume now that $0 < (\psi - \phi)'(0)$, and let $x^\star$ be the smallest element of X. Since we have $0 \leq (\psi - \phi)'$ on $[0, x^\star]$, we deduce that

$$2(n - \tilde{n})(0) \sinh \psi(x) \leq \varepsilon(\psi - \phi)''(x) \quad \forall x \in [0, x^\star].$$

Now setting $x = 0$ and $x_0 = 1$ in (2.11), we obtain

$$0 \leq (n - \tilde{n})(0).$$

From (2.2) and (2.5), we obtain $0 \leq \psi$ on $\overline{\Omega}_+$. So that finally, we obtain

$$0 \leq (\psi - \phi)'' \quad \text{on } [0, x^\star],$$

which contradicts the inequality $0 < (\psi - \phi)'(0)$. Hence (2.24) is impossible, and this concludes the proof.

2.2. Applications to reverse-biased symmetric pn-junctions. We gave in the previous subsection sufficient a priori conditions, in the reverse-biased case, to be satisfied by the solutions of (1.1)–(1.6) in order to prove uniqueness and monotonicity of the current. We now give applications of these results.

THEOREM 2.9. *Assume that* $N|_{\overline{\Omega}} \in \mathcal{C}^1(\overline{\Omega})$ *and that*

$$0 \leq N' \quad \text{on } \overline{\Omega}_+.$$

Then for every $V \leq 0$, *(1.1)-(1.6)*$_V$ *has a unique solution. Moreover, the function*

$$V \in]-\infty, 0] \mapsto I \in \mathbb{R}$$

is continuous and strictly increasing.

Proof. Assume that $V \leq 0$ and let (ψ, n, p, J_n, J_p) be a solution of (1.1)–(1.6)$_V$. Since N is in $\mathcal{C}^1(\overline{\Omega})$, we obtain

$$\varepsilon\psi^{(3)} = (n + p)\psi' + I - N' \quad \text{on } \overline{\Omega}. \tag{2.25}$$

Moreover, we also have

$$\psi''(-1) = 0, \qquad \psi''(1) = 0. \tag{2.26}$$

Since $N(1)V \leq 0$, we obtain $I \leq 0$. The maximum principle applied to (2.25) subject to the Neumann boundary conditions (2.26) implies

$$0 \leq \psi' \quad \text{on } \overline{\Omega}_+.$$

Hence (2.2) is satisfied for every $V \leq 0$ and for every solution of (1.1)–(1.6)$_V$. We deduce from Theorem 2.2 that for every $V \leq 0$, all the solutions of (1.1)–(1.6)$_V$ are symmetric. Hence, we have

$$\varepsilon(n - p)'' = (n - p)(\varepsilon\psi'^2 + n + p) - N(n + p) \quad \text{on } \overline{\Omega}_+, \tag{2.27}$$

and

$$(n - p)(0) = 0, \qquad (n - p)(1) = N(1) \geq 0.$$

Since $0 \leq N$ on $\overline{\Omega}_+$, an easy application of the maximum principle to (2.27) proves that $n - p$ satisfies (2.3).

Theorems 2.3 and 2.8 prove that (1.1)–(1.6)$_V$ has a unique solution for every $V \leq 0$ and that the current is a strictly increasing function of V on $(-\infty, 0]$. We deduce the continuity of the voltage-current curve from this uniqueness result and from [11, Thm. 3.5.2].

Remark 2.10. In the case of abrupt symmetric pn-junction, N is discontinuous at 0, so that ψ'' is also discontinuous at 0. Hence (2.25) does not hold in all Ω and information is lost at the junction $x = 0$. This is the reason why it is not possible, in this case, to proceed as in Theorem 2.9 for proving (2.2). However, using a result of [6] on the qualitative properties of the solutions of (1.1)–(1.6) in the reverse-biased case, we can prove the following theorem.

THEOREM 2.11. *Assume that* $N|_{\overline{\Omega}_+} = 1$. *Then for every* $V \leq 0$, (1.1)–$(1.6)_V$ *has a unique solution. Moreover, the function*

$$V \in]-\infty, 0] \mapsto I \in \mathbb{R}$$

is continuous and strictly increasing.

Proof. Since $N(1)V \leq 0$, we have $I \leq 0$. This together with [6, Prop. 10] prove (2.2). Moreover, as in the proof of Theorem 2.9, (2.3) holds for every symmetric solution. This concludes the proof.

Remark 2.12. Mock [13] and Rubinstein [17] made the conjecture that (1.1)–$(1.6)_V$ can have multiple solutions for certain values of V (indeed in the forward-biased case) only when N has at least three alterations of sign in the device. As a "corollary" of this conjecture, uniqueness should hold for pn-junctions. Theorems 2.9 and 2.11 partially answer this conjecture. Moreover the fact that N has only one alteration of sign in the above-mentioned theorems is essential for proving inequality (2.3).

Remark 2.13. In addition to Remark 2.7, we can note that inequality (2.3) expresses, in the case of pn-junctions, the following physical property: in an n-type region of the device (that is, in a region where $N > 0$) the electron density is larger than the hole density.

3. Forward-biased symmetric abrupt pn-junctions. A symmetric semiconductor is said to be *forward-biased* when $0 < N(1)V$.

It is well known that the semiconductor behaves very differently in reverse and forward-biased cases. We will see now that this last case generates several difficulties. First, it is easy to check that property (2.2) does not hold for all $V > 0$. On the other hand, we will see in this section that even when (2.2) holds, the proofs of theorems similar to Theorems 2.3, 2.8, and 2.11 require important changes, due to the fact that the electric field has an opposite direction compared to the one it has in the reverse-biased case.

3.1. Sufficient conditions for proving uniqueness of the solutions and monotonicity of the current.

THEOREM 3.1. *Assume that*

$$N|_{\overline{\Omega}_+} = 1, \tag{3.1}$$

and let $V > 0$ *be such that hypothesis* (i) *of Theorem* 2.1 *holds. Then* (1.1)–$(1.6)_V$ *has a unique solution.*

We first prove, as in the reverse-biased case, the following result of symmetry, whose proof (similar to that of Theorem 2.2) is left to the reader.

THEOREM 3.2. *Assume that* $N|_{\overline{\Omega}_+} \in \mathcal{C}^1(\overline{\Omega}_+)$ *and let* $V > 0$ *be such that there exists a solution* $(\bar{\psi}, \bar{n}, \bar{p}, \bar{J}_n, \bar{J}_p)$ *of* (1.1)–$(1.6)_V$ *satisfying* (2.2). *Then this solution is symmetric.*

We now prove uniqueness in the class of symmetric solutions under a stronger assumption on N.

THEOREM 3.3. *Assume that* (3.1) *holds and let* $V > 0$ *be such that every symmetric solution of* (1.1)–(1.6)$_V$ *satisfies* (2.2). *Then* (1.1)–(1.6)$_V$ *has a unique symmetric solution.*

Proof. Let (ψ, n, p, J_n, J_p) and $(\phi, \tilde{n}, \tilde{p}, \tilde{J}_n, \tilde{J}_p)$ be two symmetric solutions of (1.1)-(1.6)$_V$. We set

$$I = J_n + J_p, \qquad \tilde{I} = \tilde{J}_n + \tilde{J}_p.$$

We can assume without loss of generality that (2.13) holds. As for the reverse-biased case in Theorem 2.3, this implies that

$$0 \le (\psi - \phi)'(0) \quad \text{and} \quad 0 \le (\psi - \phi)'(1). \tag{3.2}$$

We claim that

$$0 \le (\psi - \phi)' \quad \text{on } \overline{\Omega}_+.$$

Assume to the contrary that $(\psi - \phi)'$ has a strictly negative minimum at y_0 in Ω_+. Equation (2.12) is still satisfied, but $M(x)$ is now equal to x for all x in $\overline{\Omega}_+$ (since (3.1) holds). Moreover, from (2.2) we deduce that $b_0 > 0$. We now choose $x_0 = y_0$ in (2.12). We deduce from the maximum principle applied to (2.12) that

$$2\tilde{I}\varepsilon(\psi - \phi)'(y_0) + 4(np - \tilde{n}\tilde{p})(y_0) < 0. \tag{3.3}$$

On the other hand, there exists two unknown constants α and $\tilde{\alpha}$ such that

$$n + p = \varepsilon\frac{\psi'^2}{2} + \psi + \alpha \quad \text{and} \quad \tilde{n} + \tilde{p} = \varepsilon\frac{\phi'^2}{2} + \phi + \tilde{\alpha} \quad \text{on } \overline{\Omega}_+.$$

Hence we have, since hypothesis (i) of theorem 2.1, $0 < I$ and (3.2) hold,

$$0 \le \alpha - \tilde{\alpha} = -(\varepsilon/2)(\psi - \phi)'(1)(\psi + \phi)'(1). \tag{3.4}$$

Since (3.1) holds, any symmetric solution of (1.1)–(1.6)$_V$ satisfies (2.3). So we can replace $n - p$ by $\left((n+p)^2 - 4np\right)^{1/2}$. We do the same thing for $\tilde{n} - \tilde{p}$; this leads to

$$\begin{aligned} &\varepsilon(n - p + \tilde{n} - \tilde{p})(\psi - \phi)''(x) \\ &= (\psi - \phi)'(x)c_1(x) + (n + p + \tilde{n} + \tilde{p})(x)\left((\psi - \phi)(x) + \alpha - \tilde{\alpha}\right) \\ &\quad + 2(I - \tilde{I})\left(\varepsilon\psi'(x) + x - (\varepsilon\psi'(y_0) + y_0)\right) \\ &\quad - \left(2\tilde{I}\varepsilon(\psi - \phi)'(y_0) + 4(np - \tilde{n}\tilde{p})(y_0)\right) \quad \text{on } \overline{\Omega}_+, \end{aligned} \tag{3.5}$$

where c_1 is a smooth function on $\overline{\Omega}_+$.

Now assume first that

$$0 < (\psi - \phi)'(0).$$

Then $(\psi - \phi)$ attains a strictly positive maximum at a point $x^\star \in (0, y_0)$. However, we obtain a contradiction by applying the maximum principle to (3.5) and using (2.3) and (3.3)–(3.4). Hence we proved that

$$(\psi - \phi)'(0) = 0,$$

which implies

$$0 \leq (n - \tilde{n})(0).$$

We now choose $x_0 = 0$ in (2.12) and apply the maximum principle once again to this equation. This leads to

$$0 \leq (\psi - \phi)' \quad \text{on } \overline{\Omega}_+,$$

which contradicts the assumption that $(\psi - \phi)'$ has a strictly negative minimum on Ω_+. This proves that

$$0 \leq (\psi - \phi)' \text{ on } \overline{\Omega}_+,$$

and concludes the proof.

Remark 3.4. In the forward-biased case, the current I is positive. Hence if (2.2) holds, the electric field is positive on $\overline{\Omega}_+$ (whereas it is negative in the reverse-biased case). This explains why we cannot conclude directly in the proof of Theorem 3.3 that $0 \leq (\psi - \phi)'$ on $\overline{\Omega}_+$ (as we did in the proof of Theorem 2.3), and why we have to use in addition a maximum principle argument on $\psi - \phi$. This is also the reason why Theorem 3.3 requires N to satisfy (3.1).

We now study the monotonicity of the current.

THEOREM 3.5. *Assume that* (3.1) *holds and let* V *and* $\tilde{V}$ *be such that* $0 < V < \tilde{V}$. *Assume moreover that every symmetric solution* (ψ, n, p, J_n, J_p) *resp.,* $(\phi, \tilde{n}, \tilde{p}, \tilde{J}_n, \tilde{J}_p)$) *of* (1.1)–$(1.6)_V$ *(resp.,* (1.1)–$(1.6)_{\tilde{V}}$*) satisfies* (2.2). *Then the following property holds:*

$$I < \tilde{I}, \tag{3.6}$$

where

$$I = J_n + J_p \ , \ \tilde{I} = \tilde{J}_n + \tilde{J}_p.$$

Proof. We deduce from the hypotheses and from Theorem 3.3 that (1.1)–$(1.6)_V$ (resp., (1.1)–$(1.6)_{\tilde{V}}$) has a unique symmetric solution.

As in the proof of Theorem 2.8, we claim that (3.6) holds. To the contrary, assume that

$$0 \leq I - \tilde{I}. \tag{3.7}$$

We first prove that if we have

$$(\psi - \phi)'(0) \leq 0 \text{ and } (\psi - \phi)'(1) \leq 0, \tag{3.8}$$

then $(\psi - \phi)' \leq 0$ on $\overline{\Omega}_+$.

Hence assume that (3.8) holds; then if $(\psi - \phi)'$ attains a stictly positive maximum at $y_0 \in \Omega_+$, we deduce, as in the proof of Theorem 3.3, that

$$0 < 2\tilde{I}\varepsilon(\psi - \phi)'(y_0) + 4(np - \tilde{n}\tilde{p})(y_0).$$

By using a maximum principle on $\psi - \phi$ on $(0, y_0)$, we prove as in the proof of Theorem 3.3 that we have a contradiction. Thus we get

$$(\psi - \phi)' \leq 0 \text{ on } \overline{\Omega}_+,$$

which contradicts $V < \tilde{V}$.

Hence we have either $0 < (\psi - \phi)'(0)$ or $0 < (\psi - \phi)'(1)$. We conclude as in the Proof of theorem 2.8 that this case also leads to a contradiction.

Therefore (3.7) is satisfied, and this completes the proof.

3.2. Application to strongly forward-biased symmetric abrupt pn- junctions. We prove in this subsection that the hypotheses of Theorem 3.1 are satisfied for strongly forward-biased pn-junctions.

THEOREM 3.6. *Assume that* (3.1) *holds. Then there exists* $V_0 = V_0(\delta, \varepsilon) > 0$ *such that for all* $V \geq V_0$, (1.1)-$(1.6)_V$ *has a unique solution.*

Moreover, the function

$$V \in [V_0, +\infty) \mapsto I \in \mathbb{R}$$

is continuous and strictly increasing.

From Theorems 3.2, 3.3, and 3.5, it is sufficient to find for which values of V every solution of (1.1)–$(1.6)_V$ satisfies (2.2). As has already been mentioned at the beginning of this section, this property does not hold for all $V > 0$.

However, we will see that this property holds asymptotically; that is, for sufficiently large V. Since the proof is very technical, it is divided into some lemmas.

LEMMA 3.7. *For all* V *satisfying*

$$V \geq \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right) + \frac{\varepsilon}{(n_1+p_1)^2}, \tag{3.9}$$

every solution (ψ, n, p, J_n, J_p) *of* (1.1)–$(1.6)_V$ *satisfies*

$$\psi'(-1) < 0 \quad \text{and} \quad \psi'(1) < 0. \tag{3.10}$$

Proof. First, it is easy to check that $V > 0$ implies $I > 0$. Assume from now on that

$$V > \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right), \tag{3.11}$$

and let us introduce as in [6] the functions

$$m(x) = min(n(x), p(x) - 1), \qquad M(x) = max(n(x), p(x) - 1) \quad \forall x \in [-1, 0],$$

$$\bar{m}(x) = min(n(x) - 1, p(x)), \qquad \bar{M}(x) = max(n(x) - 1, p(x)) \quad \forall x \in [0, 1].$$

One can easily check that [6, §3, Prop. 2] still holds, so that m (resp., $\bar{m}$) has no minima in $(-1, 0)$ (resp., $(0, 1)$) and M (resp., $\bar{M}$) has no maxima in $(-1, 0)$ (resp., $(0, 1)$).

Several cases are now possible:

(i) $0 \leq \psi'(-1)$ and $0 \leq \psi'(1)$,
(ii) $0 > \psi'(-1)$ and $0 \leq \psi'(1)$,
(iii) $0 \leq \psi'(-1)$ and $0 > \psi'(1)$,
(iv) $0 > \psi'(-1)$ and $0 > \psi'(1)$.

Let us first assume that

$$0 \leq \psi'(-1). \tag{3.12}$$

From $I > 0$ and (3.12) we deduce that $m = p - 1$ and $M = n$ in a right neighborhood of -1. Therefore m is decreasing and M is increasing on $(-1, 0)$.

We claim that ψ'' does not vanish on $(-1,0]$. Thus, assume that ψ'' vanishes on $(-1,0]$ and let x_0 be the smallest element of the set

$$\{x \in (-1,0], \psi''(x) = 0\}.$$

Then there exists $x^\star \in (-1, x_0)$ such that $n'(x^\star) = p'(x^\star) = 0$. This implies that $n' < 0$ in a left neighborhood of $x^\star$ ($x^\star$ being excepted), but this contradicts the fact that M is increasing on $(-1,0)$.

Therefore, if (3.12) holds, then

$$0 < \psi''(x) \quad \forall x \in (-1,0]. \tag{3.13}$$

In the same way, we prove that

$$0 \leq \psi'(1), \tag{3.14}$$

implies

$$\psi''(x) < 0 \quad \forall x \in [0,1). \tag{3.15}$$

Hence if case (i) holds, we obtain $\psi(-1) < \psi(1)$, which contradicts (3.11). Thus, case (i) is impossible.

Let us now examine case (ii). We set

$$J = J_n - J_p. \tag{3.16}$$

From (1.2), (1.3), we obtain

$$2(np)' = -I(n-p) + J(n+p). \tag{3.17}$$

We claim that $J > 0$. Thus, assume that $J \leq 0$.

Then, we have $2(np)' \leq -I(n-p)$. Integration of this inequality from -1 to 0 and from 0 to 1 leads to $\psi'(1) < \psi'(-1)$, which contradicts assumption (ii).

Hence $J > 0$ holds. Let now x_0 be the largest element of the set

$$\{x \in (-1,0), \psi'(x) = 0\},$$

which is not empty since (3.15) holds. The maximum principle applied, on the interval $[-1, x_0]$, to the equation

$$\varepsilon\psi^{(3)} = (n+p)\psi' + I, \tag{3.18}$$

subject to Dirichlet boundary conditions at -1 and x_0, leads to

$$\psi' < 0 \quad \text{on } [-1, x_0). \tag{3.19}$$

Hence, ψ has a minimum at $x = x_0$. We now apply the maximum principle, on the interval $[-1, x_0]$, to the equation

$$\varepsilon\psi^{(4)} = (n + p + \varepsilon\psi'^2)\psi'' - \psi'^2 + J\psi',$$

subject to Dirichlet boundary conditions at -1 and x_0.

This yields $0 < \psi''$ on $(-1, x_0)$. Clearly, from (3.18) and from the definition of x_0, we obtain

$$0 \leq \psi''(x_0) < \psi''(x) \leq \psi''(0^-) \quad \text{on } (x_0, 0],$$

and

$$I \leq (n-p)' \quad \text{on } [0,1].$$

Integration of this last inequality from 0 to 1 leads to $\varepsilon\psi''(0^-) \leq 2 - I$, so that we have

$$0 < I < 2. \tag{3.20}$$

From $\psi''(-1) = 0$ and $0 \leq \psi''$ on $[-1, x_0]$, we deduce that $0 < (n-p)'(-1)$.

This, together with the right-hand side of (3.20), implies

$$-\frac{2}{n_1 + p_1} < \psi'(-1) < 0. \tag{3.21}$$

On the other hand, integration of the equation $(n+p)' = (n-p)\psi' + J$ on the intervals $[-1,0]$ and $[0,1]$, and elimination of the unknown constants, gives

$$2\psi(0) = 2J + \frac{\varepsilon}{2}(\psi'(1) + \psi'(-1))(\psi'(1) - \psi'(-1)). \tag{3.22}$$

Using (3.20), (3.21) and $J > 0$ in this last equation, we obtain

$$-\frac{\varepsilon}{(n_1 + p_1)^2} \leq \psi(0).$$

Since (3.11) and $0 < \psi'$ on $[0,1)$ hold, we obtain

$$V < \log\left(\frac{1 + \sqrt{1 + 4\delta^4}}{2\delta^2}\right) + \frac{\varepsilon}{(n_1 + p_1)^2}.$$

Hence, if (3.9) holds, then case (ii) is impossible.

Since case (iii) can be treated in a similar way, the proof of Lemma 3.7 is complete.

Assume now that (3.9) is satisfied, so that (3.10) holds. Then we have either

$$\psi'(0) \leq 0 \quad \text{or} \quad \psi'(0) > 0.$$

If $\psi'(0) \leq 0$, we conclude, from the maximum principle, that $\psi' \leq 0$ on $[-1,1]$, and (2.2) follows at once.

Therefore, the only case left is when (3.10) and $0 < \psi'(0)$ are satisfied. Let us examine this final case.

LEMMA 3.8. *Assume that V satisfies* (3.9) *and let (ψ, n, p, J_n, J_p) be a solution of* (1.1)–(1.6)$_V$, *which is such that* $0 < \psi'(0)$ *and*

$$0 \leq J, \tag{3.23}$$

where J is given by (3.16).

Then the following properties are satisfied:

$$0 \leq \psi'' \quad \text{on } [-1,0], \tag{3.24}$$

$$0 \geq \psi'' \quad \text{on } [0,1]. \tag{3.25}$$

Moreover, there exists a constant

$$V^\star = V^\star(\delta,\varepsilon) > \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right) + \frac{\varepsilon}{(n_1+p_1)^2},$$

such that for all $V \geq V^\star$, *we have*

$$0 < n'(1). \tag{3.26}$$

Proof. From (3.23), we deduce (3.24) as in the proof of lemma 3.7. Now, since

$$(n+p)'(-1) = -\psi'(-1) + J,$$

we have $0 < (n+p)'(-1)$. From this and the inequality $0 < (n-p)'(-1)$, we deduce that $0 < n'(-1)$, which, together with (3.24), implies

$$0 < n' \quad \text{on } [-1,0]. \tag{3.27}$$

On the other hand, (3.17) and (3.23) imply $\psi'(-1) \leq \psi'(1)$, which in turn yields $0 < (n-p)'(1)$. This proves that $\bar{m} = n - 1$ and $\bar{M} = p$ in a left neighborhood of 1. One of the following two cases can now occur:

$$0 \leq p'(1) \tag{3.28}$$

or

$$0 > p'(1). \tag{3.29}$$

Assume first that (3.28) holds. Thus, (3.26) is satisfied. Since $\bar{m}$ has no minima in $(0,1)$, $\bar{m}$ is increasing on $(0,1)$.

Now let y_0 be the smallest element of $\{x \in (0,1), \psi'(x) = 0\}$ and assume that the set $Y = \{x \in (y_0,1), \psi''(x) = 0\}$ is not empty. We call y_1 the largest element of Y. Then, ψ'' has a strictly negative minimum on $(y_1,1)$.

Moreover, we have

$$0 < \psi'(1) + J \leq \psi'(x) + J \leq \psi'(y_1) + J \quad \forall x \in [y_1,1].$$

From the maximum principle applied on the interval $[y_1,1]$ to the equation

$$\varepsilon\psi^{(4)} = (n+p+\varepsilon\psi'^2)\psi'' + \psi'(\psi'+J), \tag{3.30}$$

subject to homogeneous Dirichlet boundary conditions, we obtain a contradiction. Hence we have $Y = \emptyset$, and therefore (3.25) is satisfied.

Assume now that (3.29) holds. Since we have $\bar{M}'(1) = p'(1) < 0$ and since $\bar{M}$ has no maxima on $(0,1)$, $\bar{M}$ is decreasing on $[0,1]$.

We claim that the set $Z = \{x \in (y_0,1], \psi''(x) > 0\}$ is empty. Thus assume that this set is not empty and let y_2 be the first point of $(y_0,1]$, starting from $x = 1$, where ψ'' vanishes by changing its sign.

Since $\bar{M} = p$ on $[y_2,1]$, we have $p'(y_2) \leq 0$. Moreover $\bar{M} = n - 1$ on a left neighborhood of y_2, so that we have $n'(y_2) \leq 0$. From this, we deduce

$$\psi'(y_2) + J = (n+p)'(y_2) \leq 0.$$

On the other hand we deduce from the definition of y_0 that $\psi''(y_0) \leq 0$.

Now let y_3 be the first point, starting from $x = y_2$, where ψ'' vanishes by changing its sign. Then ψ'' has a strictly positive maximum on (y_3, y_2). This contradicts the maximum principle, applied on the interval $[y_3, y_2]$, to (3.30).

Hence $Z = \emptyset$, so that (3.25) holds. We deduce from (3.24) and (3.25) that

$$\psi'(1) + \psi'(-1) \leq 2\psi(1),$$

which together with the inequality $\psi'(-1) \leq \psi'(1)$ implies

$$\psi'(-1) < \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right) - V. \tag{3.31}$$

This, together with the inequality $0 < (n-p)'(-1)$, gives

$$\left(V - \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right)\right)(n_1+p_1) < I. \tag{3.32}$$

In addition, since $0 \leq J$ holds, we obtain

$$\left(V - \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right)\right)(n_1+p_1) < 2J_n. \tag{3.33}$$

Since (3.27) holds, we have $n_{-1} \leq n(0)$. Moreover, since (3.29) and (3.25) hold, we have

$$p' < 0 \quad \text{on } [0,1].$$

Therefore, we obtain

$$p_1^2 \leq n(0)p(0). \tag{3.34}$$

But, since $J \geq 0$ holds, we obtain

$$-I(\varepsilon\psi'' + 1) \leq 2(np)' \quad \text{on } [0,1].$$

Integrating this last equation from 0 to 1, and using (3.34) leads to

$$0 < \varepsilon\psi'(0) \leq 2p_1 I^{-1} + \varepsilon\psi'(1) + 1.$$

We use now (3.32) to obtain

$$-2p_1\left(\left(V - \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right)\right)(n_1+p_1)\varepsilon\right)^{-1} - \frac{1}{\varepsilon} < \psi'(1) < 0. \tag{3.35}$$

We now set $x = 1$ in (1.2) and use (3.33) and (3.35) to deduce that there exists a constant

$$V^\star = V^\star(\delta,\varepsilon) > \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right) + \frac{\varepsilon}{(n_1+p_1)^2},$$

such that for all $V \geq V^\star$, (3.26) holds.

This concludes the proof of Lemma 3.8.

Proof of Theorem 3.6. Let V be such that $V \geq V^\star$ and let (ψ, n, p, J_n, J_p) be a solution of (1.1)–(1.6)$_V$, which is such that $0 < \psi'(0)$.

We assume without loss of generality that (3.23) holds. From (3.25)–(3.27) we obtain

$$n_{-1} \leq n \leq n_1. \tag{3.36}$$

If $0 < p'(1)$ holds, we deduce from (3.25) and from the property that $\bar{M}$ has no maxima in $(0,1)$, that

$$\min(p(0), p(1)) \leq p \leq \max(p(0), p(1)) \quad \text{on } [0,1],$$

from which we obtain

$$n_1 - 2 \leq p \leq n_1 + 1 \quad \text{on } [0,1]. \tag{3.37}$$

In the same way we obtain

$$n_1 - 2 \leq p \leq n_1 + 1 \quad \text{on } [-1,0]. \tag{3.38}$$

If now we have $p'(1) \leq 0$, we prove in the same way that (3.37) and (3.38) hold.

From these inequalities we deduce that

$$|\psi''| \leq \frac{3}{\varepsilon} \quad \text{on } [-1,1].$$

Double integration of this last inequality from -1 to 1 gives

$$V < \frac{3}{2\varepsilon} + \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right).$$

Therefore, if $V \geq V_0$, where

$$V_0 = \max\left(V^\star, \frac{3}{2\varepsilon} + \log\left(\frac{1+\sqrt{1+4\delta^4}}{2\delta^2}\right)\right),$$

then we necessarily have $\psi'(0) \leq 0$.

This proves that for all $V \geq V_0$, every solution of (1.1)–(1.6)$_V$ satisfies (2.2). We now apply Theorems 3.1 and 3.5 to deduce uniqueness and monotonicity of the voltage-current curve on $[V_0, +\infty)$. The continuity of this curve is a direct consequence of this uniqueness result and from [11, Thm. 3.5.2].

Remark 3.9. For all $V \geq V_0$ we proved that the problem (1.1)–(1.6)$_V$ has a unique solution (ψ, n, p, J_n, J_p). Since this solution is symmetric, it is easy to check that it satisfies $(n+p)'(1) \leq 0$. Hence we deduce easily that $p'(1) < 0$ holds for all $V \geq V_0$.

Remark 3.10. From Mock's uniqueness theorem for small $|V|$, we deduce that there exists a constant V_1 in $(0, V_0)$ such that (1.1)–(1.6)$_V$ has a unique solution for all V in $[0, V_1] \cup [V_0, +\infty)$.

4. Conclusion and discussion. We have analyzed in this paper the one-dimensional drift-diffusion model. The uniqueness theorems that are given in the literature for more complex models, as well as for the simplified one under consideration in this paper, hold only for small values of the applied bias. The purpose of the present paper is to show that uniqueness theorems that are valid for arbitrary values of the applied bias can be obtained. Such results are obtained by proving and using new qualitative properties, indeed monotonicity properties, of the drift-diffusion equations. This allows to obtain uniqueness theorems for arbitrary values of the applied bias for the case of symmetric p-n and p-i-n junctions.

We have considered the drift-diffusion model under the assumption of a zero generation-recombination term R, constant mobilities and ideal ohmic contacts. We shall discuss now how our results can be extended to more complex models. The main restriction is due to the assumption that R vanishes. When R does not vanish and depends on the unknowns n and p, as is the case for instance for Shockley–Read–Hall or Auger recombination terms, the electron and hole current densities J_n and J_p are no longer constant, since they satisfy in this case

$$J_n' = R, \qquad J_p' = -R\,.$$

Therefore, if R is not identically zero, $J = J_n - J_p$ is no longer constant, so that the symmetry Theorems 2.2 and 3.2 and the uniqueness Theorems 2.3 and 3.3 do not apply. However, the techniques introduced in this paper for obtaining global uniqueness theorems in the case where $R = 0$, lead (with minor changes) to local uniqueness theorems under the same hypotheses. This, together with the implicit function theorem, give local uniqueness theorems for the case of small generation-recombination terms of the form τR, where τ is a sufficiently small strictly positive parameter. Of course the restriction on τ depends on the applied bias V, which limits the practical use of these results. It would be interesting to have an estimate on the restriction on τ in terms of V. The extension of these results to the case of nonsmall generation-recombination terms is not trivial and requires probably other techniques. Moreover, for technical reasons, our results do not hold for the case of space-dependent mobilities.

As mentioned at the beginning of this section, we have considered the case where the device has ideal ohmic contacts. This means that the boundary data for n and p satisfy the following electro-neutrality condition

$$n_x - p_x - N(x) = 0, \qquad x = \pm 1\,, \tag{4.1}$$

and the following thermal equilibrium condition

$$n_{-1}p_{-1} = n_1 p_1. \tag{4.2}$$

We consider in this paper the case of symmetric boundary data. This means that $\psi_{\pm 1}, n_{\pm 1}, p_{\pm 1}$ satisfy

$$\psi_{-1} = -\psi_1, \quad n_{-1} = p_1, \quad p_{-1} = n_1. \tag{4.3}$$

Therefore, in the case of symmetric boundary data, (4.2) necessarily holds. It is easy to check that the general uniqueness Theorems 2.1 and 3.1 (but also Theorems 2.2, 2.3, 3.1, and 3.2) are still valid for arbitrary boundary data, this even if (4.1) does not hold. These general theorems lead to uniqueness theorems for symmetric p-n and

p-i-n junctions, provided that the solutions of the drift-diffusion model satisfy the a priori conditions (2.2) and (2.3). One can show that these conditions are still satisfied for reverse (resp., forward) biased p-n junctions provided that n_1 and p_1 satisfy

$$N(1) \leq \quad (\text{resp., } \geq)\ n_1 - p_1, \qquad 0 \leq n_1 - p_1. \tag{4.4}$$

so that the uniqueness theorems for reverse (resp., forward) p-n junctions are still valid when (4.1) is replaced by (4.4). Therefore, the uniqueness theorems presented here are valid for more general boundary conditions. We conjecture that they are also still valid for sufficiently large $|V|$, even if (4.4) does not hold. Extension of these results to the case of more general devices (nonsymmetric, multiple junctions, etc.), should also be analyzed.

LOCAL REGULARITY OF THE ONE-DIMENSIONAL MOTION OF A VISCOELASTIC MEDIUM*

JONG UHN KIM†

Abstract. We establish the local regularity of solutions to the Cauchy problem which arises in linear viscoelasticity. Our method involves MacCamy's trick and Hörmander's result on the propagation of singularity.

Key words. local regularity, viscoelastic medium, microlocal regularity, singular support, bicharacteristic strip

AMS subject classifications. 35B65, 35L99, 45K05, 73F99

Introduction. In this paper we shall investigate the local regularity of solutions to the Cauchy problem associated with the one-dimensional motion of a linear viscoelastic medium. The model equation is given by

$$u_{tt} = a_0(x,t)u_{xx} + a_1(x,t)u_x + a_2(x,t)u_t + a_3(x,t)u + \int_0^t \{b_0(x,t,s)u_{xx}(x,s) + b_1(x,t,s)u_x(x,s)\}\,ds \tag{0-1}$$

for $(x,t) \in R \times [0,\infty)$, where $u(x,t)$ denotes the displacement.

The initial conditions are

$$u(x,0) = u_0(x), \qquad u_t(x,0) = u_1(x), \quad \text{in } R. \tag{0-2}$$

Throughout this paper, we assume that

$$a_j(x,t) \in C^\infty(R \times [0,\infty)) \quad \text{for} \quad j = 0,\dots,3, \tag{0-3}$$

$$\text{all the derivatives of } a_j\text{'s are bounded in } R \times [0,\infty), \tag{0-4}$$

$$a_0(x,t) \geq c > 0 \quad \text{for all} \quad (x,t) \in R \times [0,\infty) \quad \text{for some constant} \quad c, \tag{0-5}$$

$$b_j(x,t,s) \in C^\infty(R \times [0,\infty) \times [0,\infty)) \quad \text{for} \quad j = 0,1, \tag{0-6}$$

$$\text{all the derivatives of } b_j\text{'s are bounded in } R \times [0,\infty) \times [0,\infty). \tag{0-7}$$

There are many mathematical works on dynamic viscoelasticity. Most of them are listed as references in [4] and [11]. In particular, singularity of solution was investigated in [1], [3], [5], [8], [9], and [10] among others. The memory term makes the equation nonlocal and the qualitative behavior of solution depends on the regularity of the memory kernel. A smooth memory kernel can cause the emergence of stationary singularities, which is impossible for hyperbolic equations without memory. On the other hand, a singular kernel can have a regularizing effect on solutions. The precise statements of these phenomena can be found in [8] and [11]. The present work is the outgrowth of an effort to extend some of the results in [8] to an equation with

variable coefficients. We focus on the smooth memory kernel. The main result is given in Theorem 2.1 below. Our method is different from the previous works. Our argument consists of (i) MacCamy's trick, (ii) Hörmander's result on the propagation of singularity, and (iii) classical argument of the energy method.

MacCamy's trick is to introduce a new unknown function so that the integral term of the equivalent equation involves lower-order derivatives. In order to obtain C^∞ regularity, we repeat differentiation in x and t, respectively, and boost the regularity step by step. This is a typical procedure in the classical energy method. In each step, we use the result of Hörmander [6] on the propagation of singularity to obtain microlocal regularity along each bicharacteristic strip.

In §1, we present some preliminaries and notation. We state our main results in §2 and the proofs are given in §§3 and 4.
